
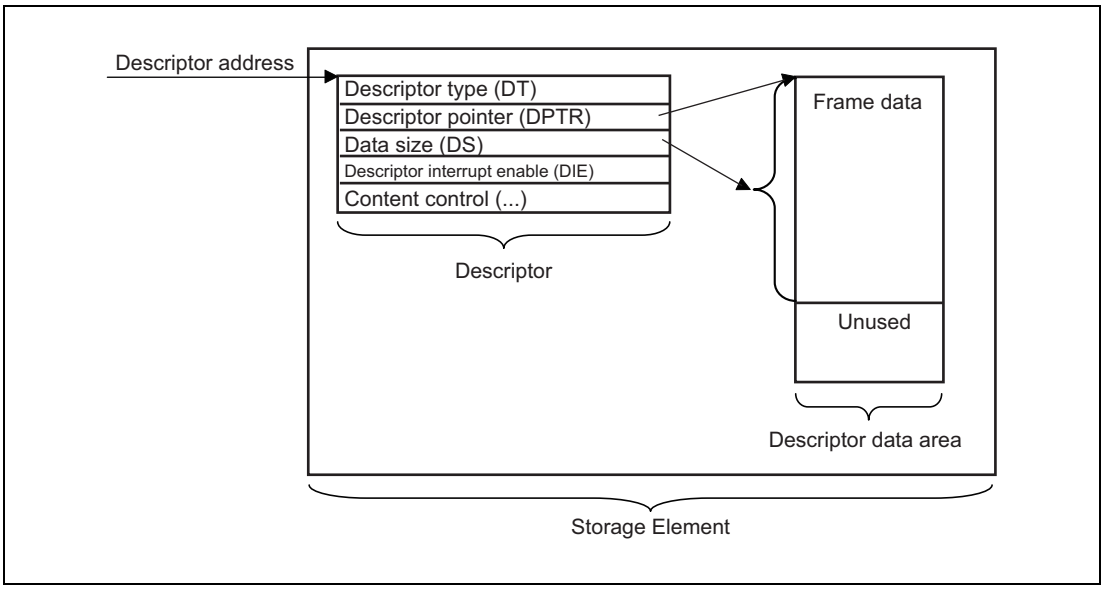

Figure 25.15 Example of URAM Memory Map

The descriptor must be aligned with a 32-bit boundary in the URAM.

Descriptors are generally configured of 64 bits, but are configured of 160 bits when reception and storage of gPTP timestamps is enabled.

The frame data must also be aligned with a 32-bit boundary in the URAM.

The amount of data in the frame is defined by the data size bits (DESCR.DS). In reception, these bits indicate the upper limit on the size of frames to be received. If the data size is not aligned with a 32-bit boundary, the residual bytes in the data area are set as unused bytes.

CAUTION

AVB-DMAC will store the data area pointed by descriptor for specified data size, even if there is no enough space.

25.4.3.2 Using Descriptor Chains in Queues

Transmission and reception descriptors in the URAM are grouped into queues. Each queue handles frames so that they are transmitted in order of priority and received separately. A queue is capable of controlling one or more frames. Accordingly, multiple descriptors can be assigned to one queue. A combination of multiple descriptors is referred to as a descriptor chain.

For a descriptor chain, the three general descriptor types listed below are defined. For details on these descriptor types, see **Section 25.4.3.6, Descriptor Type**.

- Descriptors that define frame data
- Descriptors that control the descriptor chain itself (e.g. LINK, EOS).
- Descriptors that arbitrate access by hardware or software

Figure 25.16 shows the two basic topologies for descriptor chains. In the simplified examples in the figure, all descriptors allocated to the chain are stored in the array.

- For a linear descriptor chain, the last descriptor in the array is a control descriptor indicating the end of the descriptors (e.g. EEMPTY).
- For a cyclic descriptor chain, the last descriptor in the array is a control descriptor that returns to the first descriptor in the array (e.g. LINK).

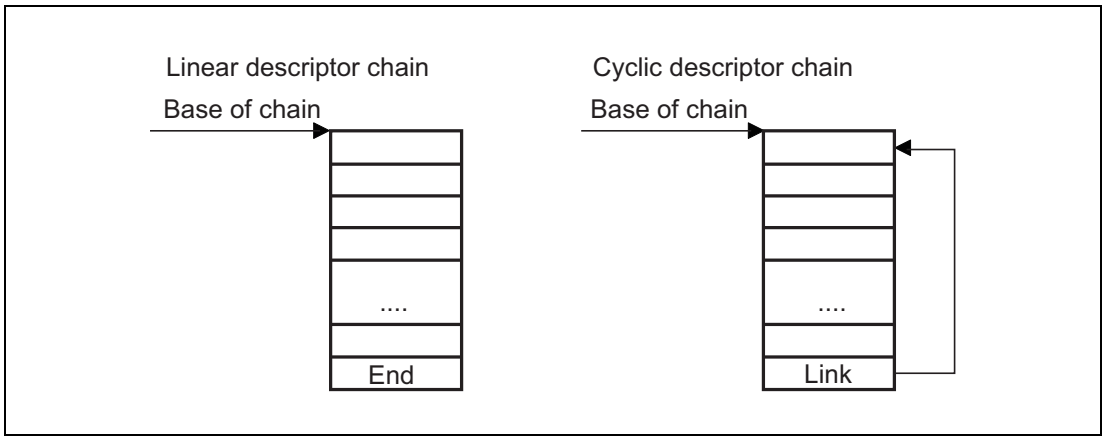

Figure 25.16 Outline of the Basic Descriptor Chains

The relationship between queues and descriptor chains is defined by the base addresses of chains. A queue is connected to one descriptor chain over one round of processing. There is also a method of switching to a different chain while in operation mode.

There are no restrictions on the number of link descriptors and their locations within the chain. The last descriptor of a designed chain determines the topology.

Which chain structure is to be used or which topology is suitable depends on the application. A description of how to design descriptor chains to suit various applications is given in **Section 25.4.4.2**. Procedure for Setting Reception Descriptors, and **Section 25.4.5.2, Setting Up Transmission Descriptors**.

25.4.3.3 Descriptor Base Address Table

Concerning the base address table to be written in the URAM, set the address of the top descriptor of respective queues.

Entries 0 to 3 are used to access transmission queues 0 to 3. Subsequent entries are used to access reception queues. Entry 4 thus corresponds to reception queue 0.

The configuration of entries in the base address table is the same as the configuration of link descriptors. We recommend using the descriptor type (DESCR.DT) LINKFIX. The link descriptor does not need to be updated because it does not change even after descriptor processing, so it does not require updating. The first descriptor of a chain performs hardware and software synchronization. If the application requires hardware and software synchronization for the base addresses, use the descriptor type (DESCR.DT) LINK.

The CPU is only capable of using LINKFIX and LINK as descriptor types (DESCR.DT) of descriptors in the base address table.

Set the location of the base address table in the URAM in the descriptor base address table register (ETNBnDBAT).

Figure 25.17 shows an example of a base address table for controlling four transmission and three reception queues. The boxes to the right of the table represent descriptor chains of a topology.

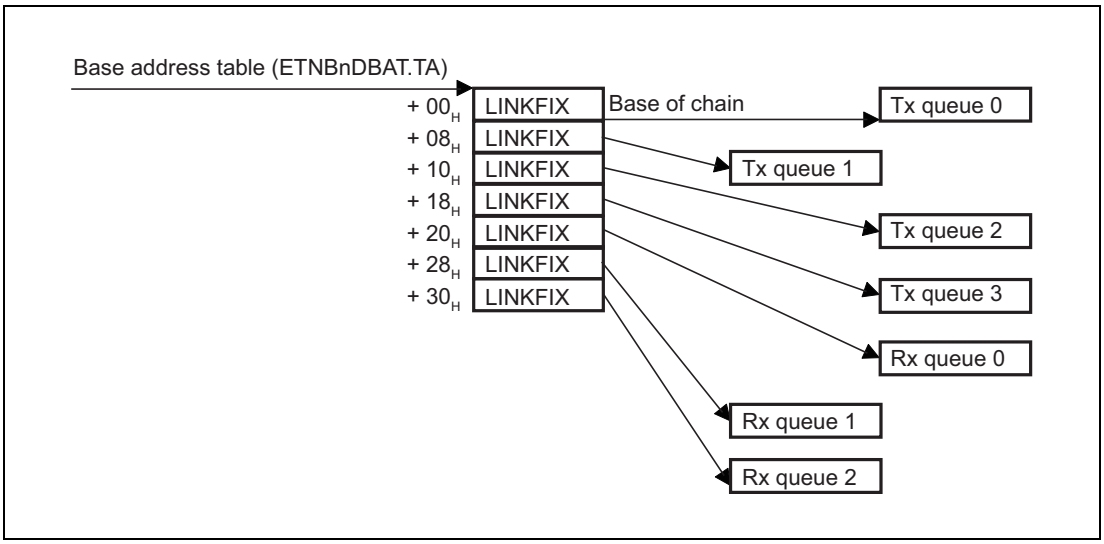

Figure 25.17 Example of a Base Address Table for Reception and Transmission Queues

CAUTION

The size of the descriptors in the base address table is always eight bytes even if the queue itself includes extended descriptors.

25.4.3.4 Descriptor Chain Processing

When a descriptor is currently being processed or the queue for a descriptor is active, the current descriptor is a descriptor to be processed. The current descriptor address for use by a queue q can be checked in the current descriptor address register q (ETNBnCDARq).

The current descriptor is stored in a register or descriptor as described below.

- In the descriptor base address table registers for all q queues (ETNBnDBAT) (ETNBnDBAT.TA + 8 × q) when the operating mode shifts to operation mode.
- In the descriptor base address table register (ETNBnDBAT) (ETNBnDBAT.TA + 8 × q) when a base address load request is issued for a queue q by setting the corresponding bit (ETNBnDLR.LBAq) in the descriptor base address load request register.
- It is set to DESCR.DPTR when a link descriptor (LINK, LINKFIX) is processed.

After a descriptor has been processed, the current descriptor for the same queue is incremented by the size of the descriptors being handled by the queue (8 bytes for normal descriptors and 20 bytes for extended descriptors). The AVB-DMAC updates the descriptor type and informs the CPU that the descriptor has been processed.

25.4.3.5 Descriptor Interrupts

A descriptor is able to issue a descriptor interrupt on completion of its processing. The setting of the descriptor interrupt enable bits (DESCR.DIE) in each descriptor selects disabling or generation of the descriptor interrupt.

The descriptor interrupt is a common resource that is shared between reception and transmission queues. Software control of the descriptor interrupt provides a flexible method of application-specific flag processing.

Figure 25.18 illustrates the way in which the AVB-DMAC generates descriptor interrupts (or sets bits in the descriptor interrupt status register (ETNBnDIS.DPFi)). Processing of a descriptor with the value i in the descriptor interrupt enable bits (DESCR.DIE) leads to the corresponding bit in the descriptor interrupt status register (ETNBnDIS.DPFi) being set.

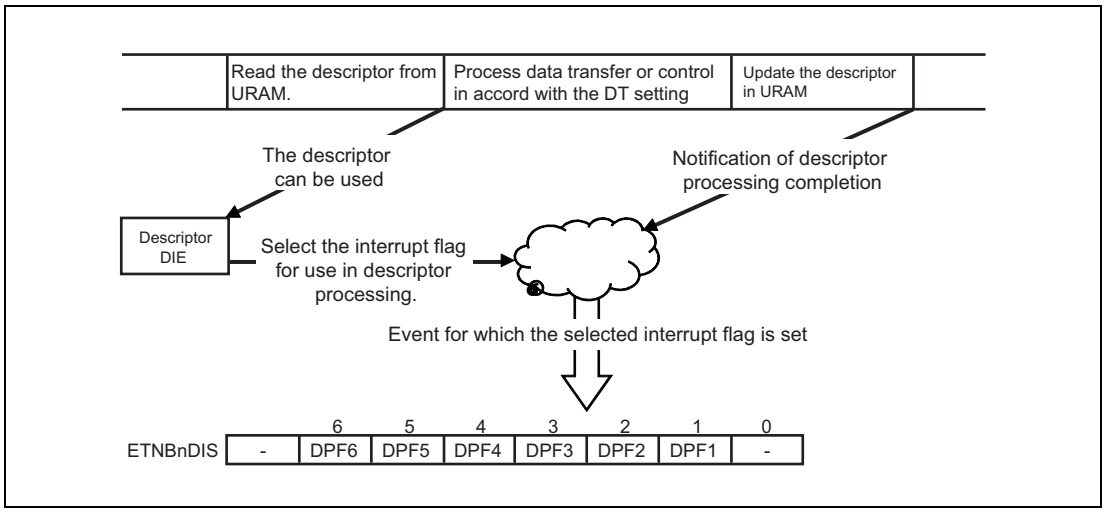

Figure 25.18 Method of Descriptor Interrupt Generation

25.4.3.6 Descriptor Type

The descriptor types (indicated by the DESCR.DT bits) supported by the AVB-DMAC fall into the following three categories.

- Definitions of frame data
- Control of descriptor chains
- Hardware and software arbitration

Table 25.111 is a summary of the descriptor types available for the AVB-DMAC. Entries under "Name" are the names of the descriptor types and the values under "DT" are the corresponding values to be set in the descriptor type field (DESCR.DT). A given descriptor may be handled differently according to whether it is in a transmission or reception queue, so the transmission and reception columns list the scopes of control and processing of the descriptor types.

The abbreviations defined below are used in the transmission and reception columns.

Definition of SW:

- The descriptor is processed by software.
- Software has access to and may modify the descriptor and descriptor data area.
- The descriptor cannot be changed by hardware (AVB-DMAC).

Definition of HW:

- The descriptor is processed by hardware (AVB-DMAC).
- Software must modify neither the descriptor nor the descriptor data area.
- Hardware (AVB-DMAC) processes the descriptor and subsequently changes the descriptor type.

Invalid:

This descriptor type is not used in transfer in the given direction (transmission or reception).

Do not write the value to the descriptor type (DESCR.DT) field.

Hardware does not process the descriptor type. The current descriptor address (ETNBnCDARq.CDA) is not changed even when the queue is of a descriptor type of this setting.

Table 25.111 Summary of Descriptor Types

Name	DT	Description	Reception	Transmission
Frame data				
FSTART	5	Frame Start The descriptor points to valid data for a frame. The frame starts with the given data and continues with that indicated by the next descriptor.	SW	HW
FMID	4	Frame Middle The descriptor points to valid data for a frame. The frame started with a previous descriptor and continues to the data indicated by the next descriptor.	SW	HW
FEND	6	Frame End The descriptor points to valid data for a frame. The frame continues from the previous descriptor and ends with the data indicated by in this descriptor.	SW	HW
FSINGLE	7	Frame Single The descriptor points to valid data for a complete frame.	SW	HW
Chain control				
LINK	8	Link Defines the next descriptor in the chain.	HW	HW
LINKFIX	9	Fixed Link Defines the next descriptor in the chain, but not changed by AVB-DMAC after processing.	SW	SW
EOS	10	End Of Set Control element to split descriptor chain. Chain stops and waits for user interaction.	HW	HW
HW/SW arbitration				
FEMPTY	12	Frame Empty A descriptor related to frame data but not containing valid data for a frame	HW	SW
FEMPTY_IS	13	Frame Empty Incremental Start A descriptor related to frame data but not containing valid data for a frame DESCR.DPTR sets the base address of an “incremental data area” in the URAM.	HW	Invalid
FEMPTY_IC	14	Frame Empty Incremental Continue A descriptor related to frame data but not containing valid data for a frame Data indicated by the pointer are for storage in an incremental data area in the URAM.	HW	Invalid
FEMPTY_ND	15	Frame Empty No Data Storage A descriptor related to frame data but not containing valid data for a frame The descriptor is processed in the same way as FEMPTY but data are not stored in the URAM.	HW	Invalid
LEMPTY	2	Link Empty A link descriptor for processing by the AVB-DMAC	SW	SW
EEMPTY	3	EOS Empty An EOS descriptor for processing by the AVB-DMAC	SW	SW
DT0	0	Reserved	Invalid	Invalid
DT1	1	Reserved	Invalid	Invalid
DT11	11	Reserved	Invalid	Invalid

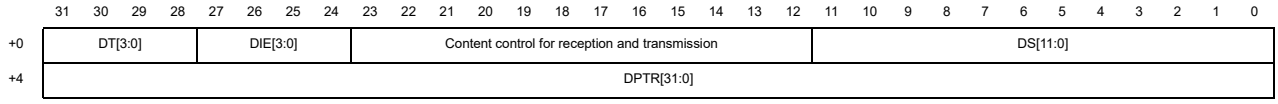
(1) Layout of General Descriptors in the URAM

The AVB-DMAC updates processed descriptors in the URAM. The field to be changed in a descriptor being updated depends upon whether the direction is transmission or reception and the queue mode. Other fields will not be changed. There are no restrictions on the values set in unused descriptor fields (indicated by "—" in the figure).

(2) Frame Data Descriptors

The allocation of bits in the frame data descriptors (FSTART, FMID, FEND, and FSINGLE) is shown below.

- Normal descriptor (usable in both reception and transmission)



- Extended descriptor (usable only in reception)

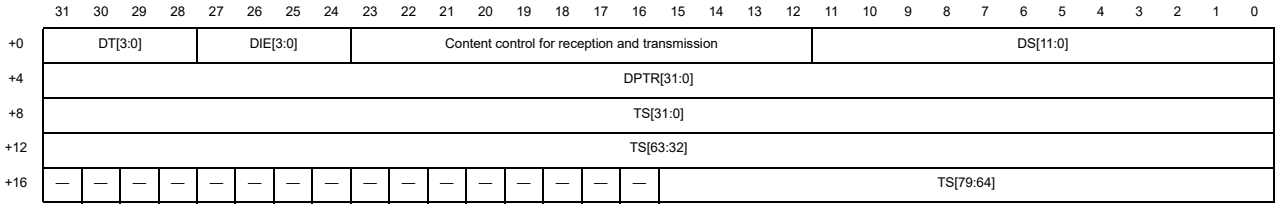


Table 25.112 Contents of Frame Data Descriptors (DESCR)

Bit Name	Function
DT[3:0]	Descriptor Type 5: FSTART 4: FMID 6: FEND 7: FSINGLE For details, see **Section 25.4.4.2, Setting Up Reception Descriptors**, and **Section 25.4.5.2, Setting Up Transmission Descriptors**.
DIE[3:0]	Descriptor Interrupt Enable 0000_B: Descriptor interrupt is disabled. 0001_B to 1111_B: The corresponding descriptor interrupt is generated (ETNBnDIS.DPFi).
—	Content Control For details, see **Section 25.4.4.2, Setting Up Reception Descriptors**, and **Section 25.4.5.2, Setting Up Transmission Descriptors**.
DS[11:0]	Data Size Size of the data area/frame data for the descriptor (in bytes)
DPTR[31:0]	Descriptor Pointer Pointer to the data area for the descriptor
TS[79:0]	Timestamp Timestamp of the received frame (only available in extended descriptors)

CAUTION

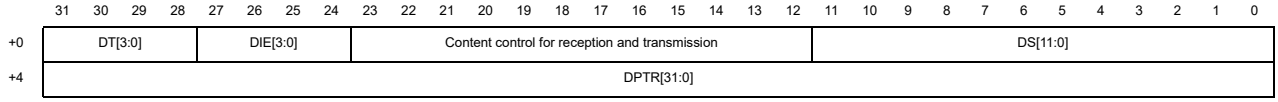
The upper reserved bits of TS[79:0] are set to 0000_H after the time stamp is stored.

(3) Hardware/Software Arbitration Descriptors (Only for Reception)

The allocation of bits in the descriptors for hardware/software arbitration (FEMPTY, FEMPTY_IS, FEMPTY_IC, and FEMPTY_ND) is shown below.

The allocation of bits in the arbitration descriptors for use in reception is the same as in frame data descriptors.

- Normal descriptor



- Extended descriptor (usable only in reception)

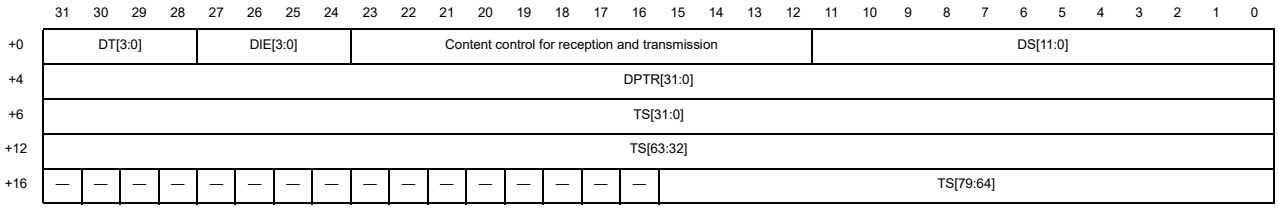


Table 25.113 Contents of Hardware/Software Arbitration Descriptors (DESCR)

Bit Name	Function
DT[3:0]	Descriptor Type 12: FEMPTY 13: FEMPTY_IS 14: FEMPTY_IC 15: FEMPTY_ND For details, see **Table 25.111, Summary of Descriptor Types**.
DIE[3:0]	Descriptor Interrupt Enable 0000_B: Descriptor interrupt is disabled. 0001_B to 1111_B: The corresponding descriptor interrupt is generated (ETNBnDIS.DPFi).
—	Content Control For details, see **Section 25.4.4.2, Setting Up Reception Descriptors**, and **Section 25.4.5.2, Setting Up Transmission Descriptors**.
DS[11:0]	Data Size Size of the data area/frame data for the descriptor (in bytes)
DPTR[31:0]	Descriptor Pointer Pointer to the data area for the descriptor
TS[79:0]	Timestamp Timestamp of the received frame (only available in extended descriptors)

CAUTION

When the descriptor is an extended descriptor, it has a 12-byte unused area.

In an FEMPTY descriptor, the descriptor type (DT), descriptor interrupt enable (DIE), data size (DS), and descriptor pointer (DPTR) fields are used.

In an FEMPTY_IS descriptor, the descriptor type (DT), descriptor interrupt enable (DIE), and descriptor pointer (DPTR) fields are used.

In an FEMPTY_IC descriptor, the descriptor type (DT) and descriptor interrupt enable (DIE) are used.

In an FEMPTY_ND descriptor, the descriptor type (DT), descriptor interrupt enable (DIE), and data size (DS) are used.

(4) Link Descriptors

The allocation of bits in the link descriptors (LINK and LINKFIX) is shown below.

- Normal descriptor

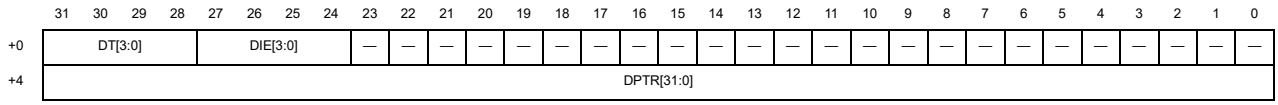

Table 25.114 Contents of Link Descriptors (DESCR)

Bit Name	Function
DT[3:0]	Descriptor Type 8: LINK 9: LINKFIX For details, see **Table 25.111, Summary of Descriptor Types**.
DIE[3:0]	Descriptor Interrupt Enable 0000_B: Descriptor interrupt is disabled. 0001_B to 1111_B: The corresponding descriptor interrupt is generated (ETNBnDIS.DPFi).
—	Content Control For details, see **Section 25.4.4.2, Setting Up Reception Descriptors**, and **Section 25.4.5.2, Setting Up Transmission Descriptors**.
DPTR[31:0]	Descriptor Pointer Pointer to the data area for the descriptor.

CAUTION

When the descriptor is an extended descriptor, it has a 12-byte unused area.

(5) Other Descriptors

The allocation of bits in the other descriptors (EOS, FEMPTY (only for transmission), LEMPTY, and EEMPTY) is shown below.

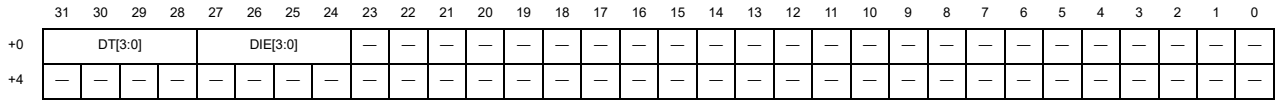

Table 25.115 Contents of Other Descriptors (DESCR)

Bit Name	Function
DT[3:0]	Descriptor Type 10: EOS 12: FEMPTY (only for transmission) 2: LEMPTY 3: EEMPTY For details, see **Table 25.111, Summary of Descriptor Types**.
DIE[3:0]	Descriptor Interrupt Enable 0000_B: Descriptor interrupt is disabled. 0001_B to 1111_B: The corresponding descriptor interrupt is generated (ETNBnDIS.DPFi).

CAUTION

When the descriptor is an extended descriptor, it has a 12-byte unused area.

(6) How to Use Frame Data Descriptors

The descriptor data area size field (DESCR.DS) can specify up to 2048 bytes of Ethernet frame data per data area. Settings higher than 2048 (bytes) cannot be made.

In general, Ethernet frames are not of uniform length. The AVB-DMAC is capable of dividing frame data into multiple descriptors in order to minimize the memory capacity for frame data. This function allows processing of frames that are longer than the limit for descriptor data areas. Frames divided based on a frame data structure can also be supported.

To handle both frames divided up into multiple data areas and descriptors for complete single frames, four types (DESCR.DT) FSTART, FEND, FMID, and FSINGLE are defined.

Figure 25.19 shows the mapping of frame data by frame data descriptors. The descriptor data areas are allocated to the URAM. For frames that require division into four or more data areas, additional FMID descriptors can be added as required.

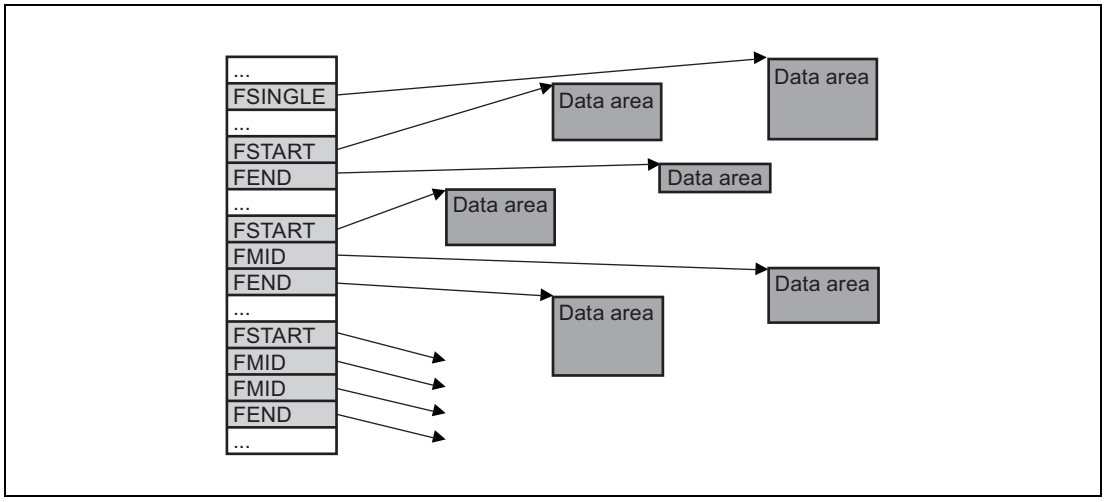

Figure 25.19 Mapping of Frame Data

For reception, set the descriptor data areas to the maximum size (i.e. give DESCR.DS its maximum value). The AVB-DMAC will store received frame data in the given area. If a received frame has more data than the maximum size, the AVB-DMAC will divide the data up.

For transmission, set the frame data size to the actual data size. The AVB-DMAC modifies the descriptor type (DESCR.DT) to FEMPTY after processing the relevant descriptor. The data size (DESCR.DS) and descriptor pointer (DESCR.PTR) fields retain their settings.

A descriptor data area including unused space produces an empty space between frame data. In reception, an “incremental data area” can be used to prevent empty spaces. For incremental data areas, see **Section 25.4.4.3(2), Incremental Data Areas**.

As well as reducing the memory capacity taken up by the descriptor area in the URAM, division into frames can be used to identify different sections of data (e.g. for separating a header and data).

(7) How to Use Chain Control Descriptors

(a) Link Descriptors

The link descriptors can be used to set up cyclic descriptor chains (for details, see **Section 25.4.3.2, Using Descriptor Chains in Queues**)

After a LINK descriptor is processed, its descriptor type (DESCR.DT) is changed to LEMPTY. The descriptor pointer (DESCR.PTR) retains its setting.

After processing of a LINKFIX descriptor, the descriptor type (DESCR.DT) is not updated. Software can change the descriptor type (DESCR.DT), descriptor interrupt enable (DESCR.DIE), and descriptor pointer (DESCR.DPTR). Take care, however, to check the current descriptor address register q (ETNBnCDARq.CDA) before changing the descriptor pointer (DESCR.DPTR).

(b) EOS Descriptor

Use the EOS descriptor to divide a descriptor chain into various segments. The queue can continue even after an EOS descriptor.

In transmission, the transmit start request bit in the transmit configuration control register (ETNBnTCCR.TSRQq) is cleared.

In reception, when the frame currently received is one divided for storage (e.g., received data whose frames are the FMID type or FEND type for storage), the data is not fully stored and the receive queue full interrupt (ETNBnRIS2.QFFr) is generated.

(8) How to Use Hardware and Software Arbitration Descriptors

In hardware processing of descriptors, the empty descriptor types (FEMPTY, LEMPTY, and EEMPTY) are used to distinguish various descriptors. For software, they can be used to initiate checking for empty spaces, etc.

(a) FEMPTY, FEMPTY_IS, FEMPTY_IC, and FEMPTY_ND

These descriptor types (DESCR.DT) are used for descriptors that do not contain effective data. Of these, only FEMPTY is used in transmission.

(b) LEMPTY

This descriptor type (DESCR.DT) is assigned to LINK descriptors after they have been processed.

The descriptor pointer (DESCR.DPTR) of an LEMPTY descriptor still points to the linked descriptor.

(c) EEMPTY

This descriptor type (DESCR.DT) is assigned to EOS descriptors after they have been processed.

The descriptor pointer (DESCR.DPTR) of an EEMPTY descriptor is not used.

(9) Synchronization between Descriptor Access by Hardware and Software

In primary HW/SW synchronization, the descriptor type (DESCR.DT) allocated to the URAM is usable. This makes it possible to minimize access by the AVB-DMAC to the SFR via the CPU, leading to higher performance.

Basic concepts of synchronization:

- Descriptor sets are allocated so that it is exclusively used by hardware or software, depending on the direction of transmission (see **Table 25.111, Summary of Descriptor Types**).
- Software must not change a descriptor assigned to hardware processing (the hardware does not change descriptors assigned to software processing).

In the case of software processing, the software must process the information in the descriptor and the corresponding frame data before changing the descriptor type. If a descriptor type assigned to hardware is set in DESCR.DT, the software should not change any part of the descriptor or of the corresponding frame data.

25.4.3.7 Tips for Optimizing Performance in Handling Descriptors

The following items are recommended as ways to ensure the optimal use of data structures in the URAM.

They are not requirements, but using a different approach may increase the load on the system bus within the LSI chip.

- Register descriptors with 64-bit alignment (this does not apply to extended descriptors).
- While in operation mode, use LINKFIX instead of LINK whenever a descriptor need not be changed. Hardware modifies the descriptor type (DESCR.DT) fields of LINK descriptors.
- Make an access to frame data in units of 128-byte blocks maximum.
- Design the descriptor chains in ways that minimize parallelism of processing.
  This helps in dividing the chains into segments allocated to different cache pages, and in arranging the different segments exclusively for access by software or hardware.
- Minimize the number of divided frames. This can reduce the overhead of descriptor handling.

25.4.4 Control in Reception

The point of the AVB-DMAC is to transfer data between the E-MAC and URAM without intervention by the CPU.

Create descriptors that define the amounts of frame data to be stored and the locations. After the E-MAC receives a frame, it stores the received frame data and the conditions of reception as the MAC state. If the descriptor is extended, the timestamp is also stored. For a description of how to set up descriptors for use in reception, see **Section 25.4.4.2, Setting Up Reception Descriptors**.

The AVB-DMAC filters received frames to separate them into various classifications (separation filtering). More specifically, this is done to separate received frames into the various reception queues and to set the priorities of different classes of received frames. For more on separation filtering, see **Section 25.4.4.1(1), Separation Filtering**.

Figure 25.20 shows the reception data bus and the selection of queues for use in reception.

Each frame received from the E-MAC is stored in the reception FIFO; in parallel with this, the frame is analyzed to identify its type and the target queue number. After the E-MAC completes reception, the target queue number is generated and stored in the reception FIFO. Appending of a reception flag depends on the storage of one frame among the reception queues in the URAM, and the unread frame counter (UFC) is also associated with frame storage.

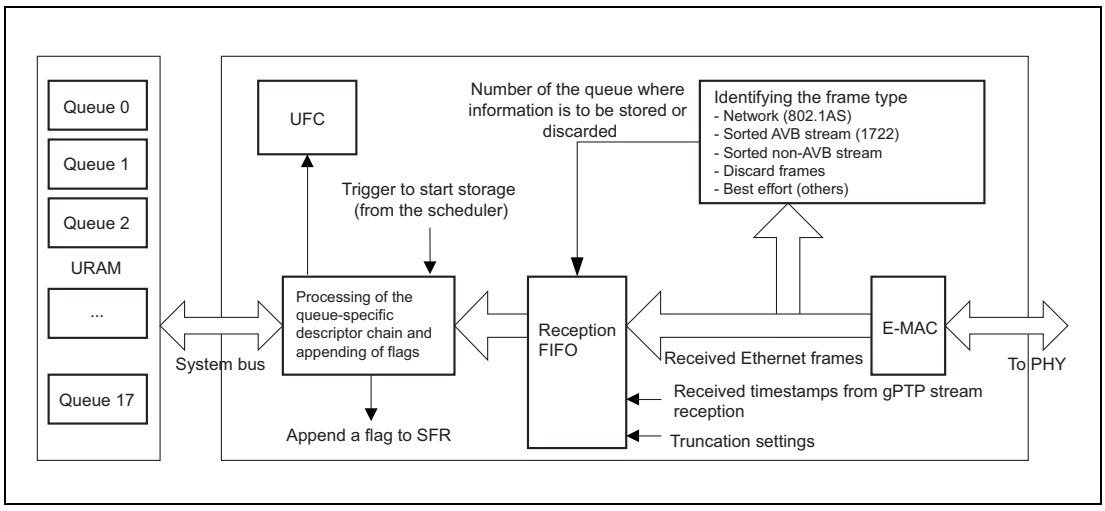

Figure 25.20 Mechanism of General Reception Queue Selection

25.4.4.1 Reception Queues

The AVB-DMAC applies its separation filtering mechanism to select the reception queue for storing a received frame. The AVB-DMAC stores all received frames in the URAM.

There are two conditions for the AVB-DMAC to discard a received frame.

- Detection of an error during reception by the E-MAC
  - Whether error frames are discarded or stored in reception queue 0 (best effort) depends on the setting of the error frame enable bit in the receive configuration register (ETNBnRCR.EFFS). If error frames are to be stored (ETNBnRCR.EFFS = 1), they are always stored in queue 0 (best effort). In this case, characteristics specific to the queue (e.g. truncation) will vary. If the storage of timestamps for reception queue 0 (best effort) is enabled (the timestamp enable bit in the receive configuration register ETNBnRCR.ETS0 = 1), timestamps are stored even for error frames.
  - The separation filter is unable to determine where the frame data should be stored.
- Receive frame failure in the separation filter
  - Whether discarding error frames or storing in reception queue 0 (best effort) depends on the stream filtering select bit (ETNBnRCR.ESF) in the receive configuration register.

The flowchart in **Figure 25.21** shows how the AVB-DMAC selects the reception queue in accord with the frame type, including judgment by the separation filter. Selection of the queue starts when the E-MAC completes frame reception. The result is storage of the frame in the proper queue or the frame being discarded.

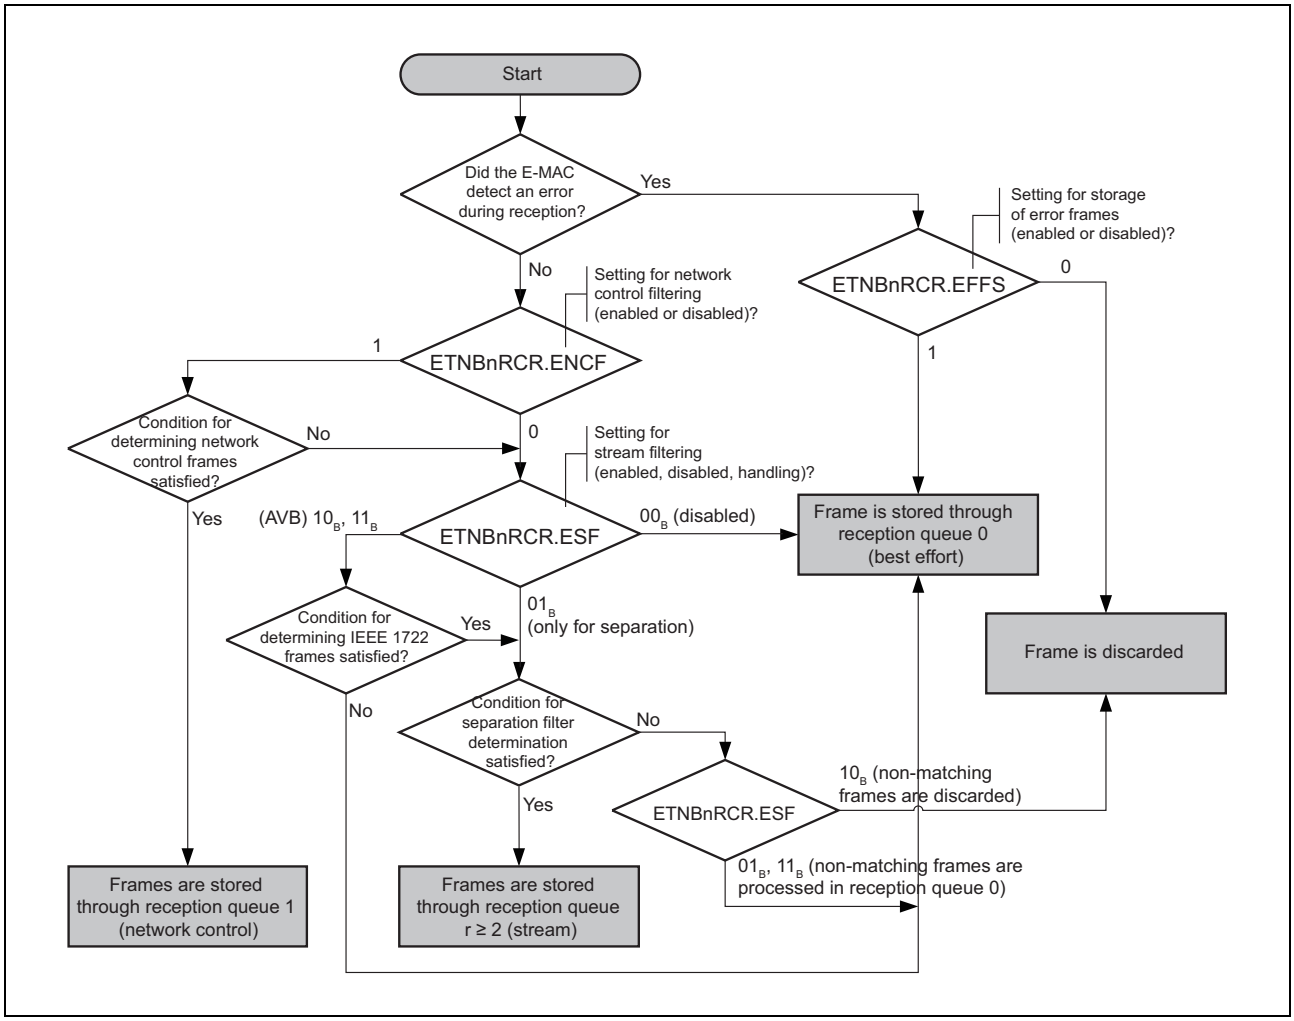

Figure 25.21 Mechanism of Reception Queue Selection

Notes on the meanings of entries in the flowchart

- "Condition for determining network control frames"
  The Ethernet destination address (DA) is 01:80:C2:00:00:0E.
  The Ethernet type (ET) is 88:F7.
- "Condition for determining IEEE 1722 frames"
  The Ethernet destination address (DA) is within the range from 91:E0:F0:00:00:00 to 91:E0:F0:00:FE:FF.
  The VLAN tagged TPID (tag protocol identifier) field (VL) is 81:00.
  The Ethernet type (ET) is 22:F0.
- "Condition for separation filter determination"
  See **Section 25.4.4.1(1), Separation Filtering**.

Figure 25.22 shows the allocation of bits related to the network and stream types in Ethernet frames. The preambles of Ethernet frames are not taken into account.

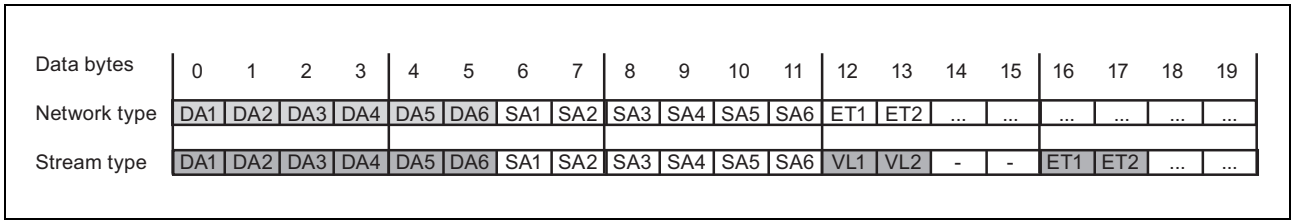

Figure 25.22 Data Bytes of Ethernet Frames Used in Classification

(1) Separation Filtering

Separation filtering involves the checking of up to 64 bits (eight successive bytes) in received Ethernet frames. The setting for the first byte (i.e. the setting of the separation filter offset configuration register (ETNBnSFO.FBP)), selects the part of frames to be used in separation filtering. There is also a common filter mask (separation filter mask configuration register i(ETNBnSFMi.CFM)), which limits the separation filter processing to a bit mask that can be set to the lower number of bytes or can be set appropriately.

Examples

To use one byte in separation, set separation filter mask configuration register 0 (ETNBnSFM0.CFM) to 0000 $00FF_H$ and separation filter mask configuration register 1 (ETNBnSFM1.CFM) to 0000 0000_H.

To use seven bytes in separation, set separation filter mask configuration register 0 (ETNBnSFM0.CFM) to FFFF $FFFF_H$ and separation filter mask configuration register 1 (ETNBnSFM1.CFM) to 00FF $FFFF_H$.

CAUTION

If bits at some positions are set to 0 in the separation mask, in order to match with the pattern, the bits at the corresponding positions of the pattern must also be set to 0. Only those bits in which the separation filter pattern configuration register i (ETNBnSFPi.FPs) setting is equal to the separation filter mask configuration register i (ETNBnSFMi.CFM) are sorted by matching with received data.

Figure 25.23 shows separation filtering. The selected data from a received frame (Rx_Frame[63:0]) are masked by the common filter mask. As a result, the selected frame data can be obtained. This value is compared with all filter patterns. The separation filter circuit in the AVB-DMAC selects the filter pattern that matches the queue having the lowest index s or selects a flag to indicate that there is no matching separation pattern.

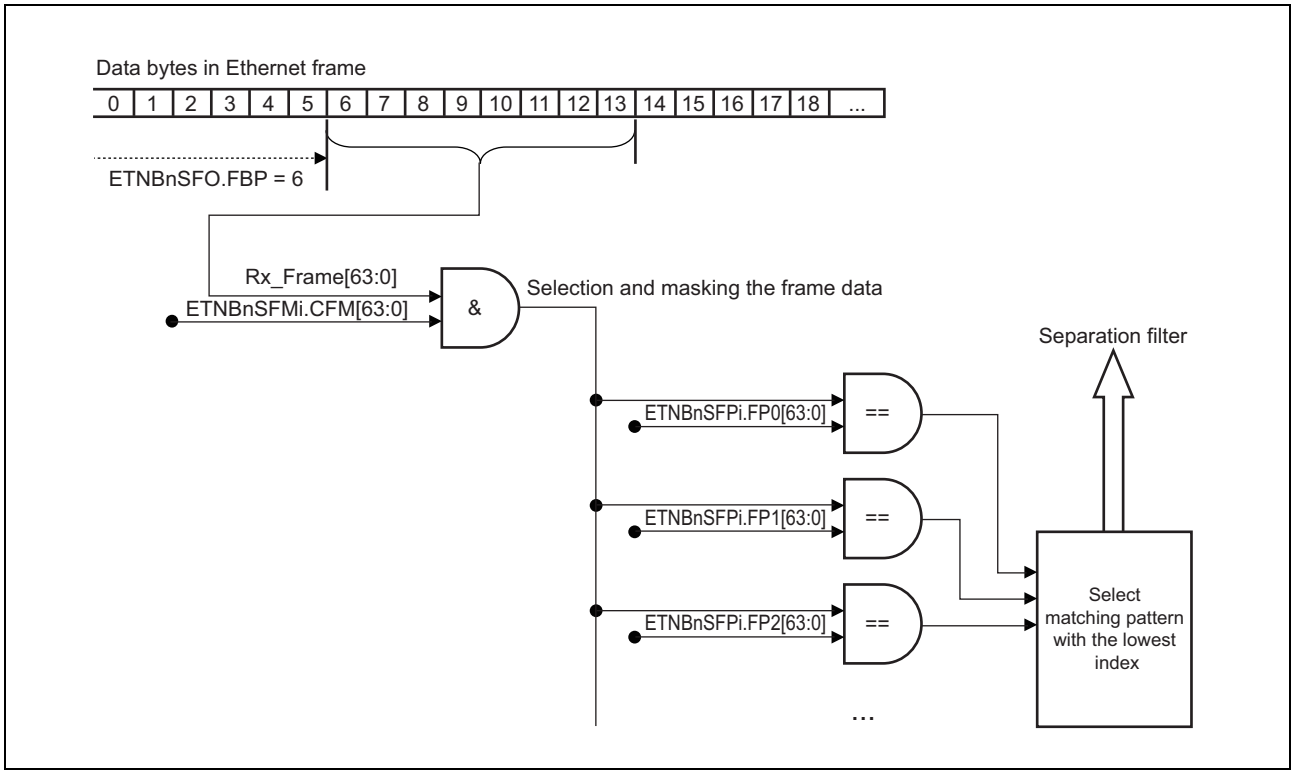

Figure 25.23 Separation Filtering

(2) Stream separation

The AVB-DMAC applies separation filtering to sort frames received in streams. An AVB network has a concept of “Talker” and “Listener”. A Talker is an end station that generates one or more streams. A Listener is an end station that has the role of being a sink for at least one stream. The various A/V streams are identified by 8-byte stream IDs.

The number of end stations within an AVB network and their roles differ with the application.

The stream ID is a general pattern of the AVB network for identifying one stream. **Figure 25.24** shows the bit allocation of bits in IEEE1722 Ethernet frames and stream ID fields.

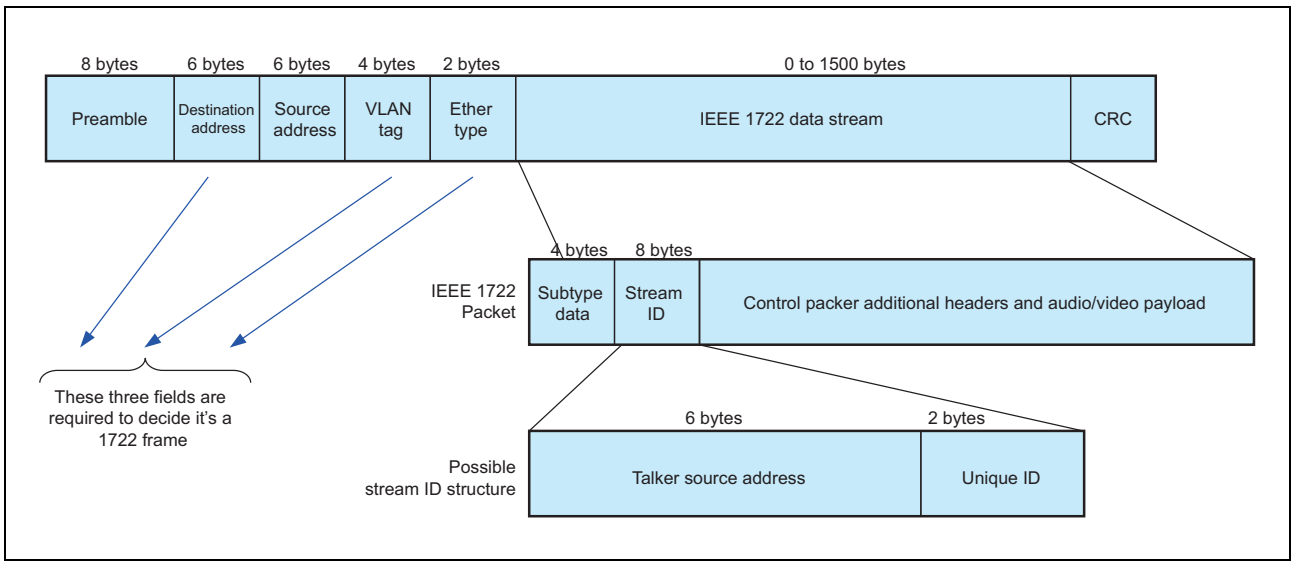

Figure 25.24 IEEE 1722 Frame Layout and Stream ID

The IEEE 1722 standard stipulates that the stream ID field starts from the 23rd byte (not counting the preamble). Accordingly, set the separation filter offset (ETNBnSFO.FBP) to 22 in operations on IEEE 1722 streams. Set the separation filter mask (ETNBnSFMi) and separation filter pattern (ETNBnSFPi) in accord with the specification of the product in which the chip is being used.

Example: In the example of a stream ID shown in **Figure 25.24**, the current application divides the field into the talker source address and the unique stream ID. The unique ID is used to differentiate between multiple streams from the same talker. Based on this, there are two settings for separation filter masking:

- To divide various streams into individual queues, set ETNBnSFM0.CFM to FFFF $FFFF_H$ and ETNBnSFM1.CFM to FFFF $FFFF_H$.
- To divide streams from respective talkers into individual queues, set ETNBnSFM0.CFM to FFFF $FFFF_H$ and ETNBnSFM1.CFM to 0000 $FFFF_H$. This excludes the unique ID from the filter condition.

(3) Reconfiguration of separation filter during operation mode

In configuration mode the initial separation filter configuration is defined. To prevent inconsistent filter results during operation mode, direct parameter change is not possible; instead update mechanism by ETNBnSFVi.LV and ETNBnSFL.LC should be used.

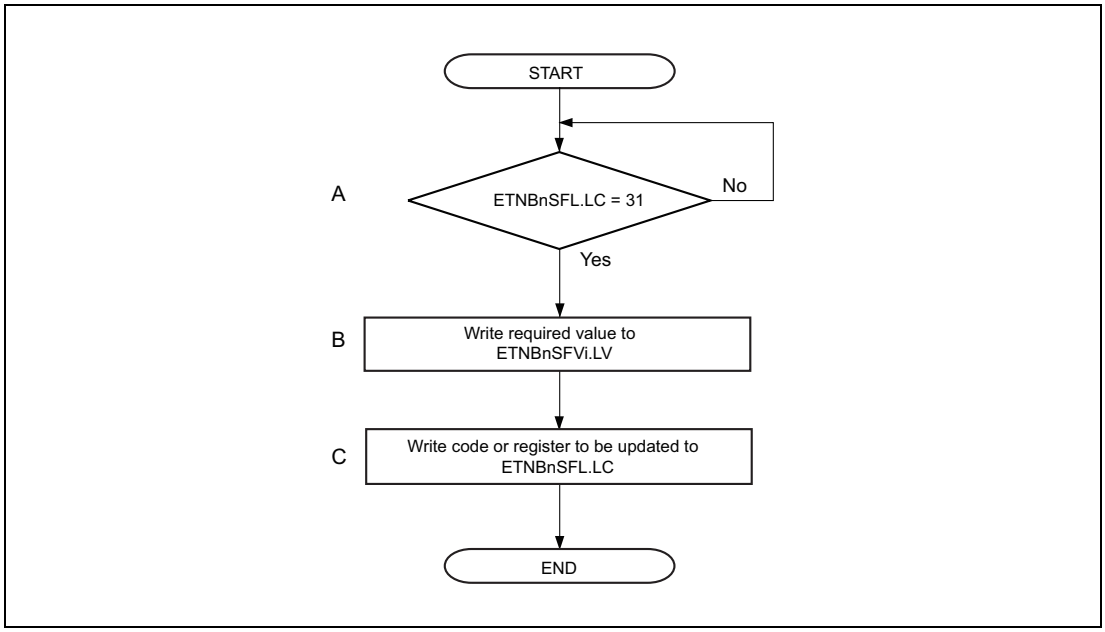

Figure 25.25 SW flow to update separation filter during operation mode

When reconfigure separation filter, AVB-DMAC guarantees consistent classification for one received frame. If reconfiguration requires a sequence of parameter changes, CPU has to order reconfiguration based on application demand.

AVB-DMAC updates filter configurations when no frame reception is handled. In worse case the update is delayed by one frame reception. Exact duration depends on PHY speed and frame size. By reading ETNBnSFL.LC CPU can observe when a previous update has been processed.

Note that frame classification happens during frame reception and storage into internal Rx-FIFO. There may be frames with old classification pending in Rx-FIFO or under storage to URAM when filter reconfiguration is accepted.

25.4.4.2 Setting Up Reception Descriptors

For reception, the descriptor mechanism is essentially as described in **Section 25.4.3, Descriptors**.

This section describes memory operations that are especially required in handling reception queues.

(1) Reception Descriptor Types

The type of a descriptor is defined by the descriptor type (DESCR.DT) field.

Table 25.116 shows the descriptor types used in reception.

Table 25.116 Descriptor Types in Reception

Descriptor Type (DESCR.DT)	Operation	Write-back
Frame Start (FSTART)	No data is stored in receive queues. The ETNBnRIS2.QFFr bit indicates that queue r is full and the received frame is not stored. This descriptor is used again for processing of the next reception, if any.	Not changed
Frame Middle (FMID)	Same as FSTART	Not changed
Frame End (FEND)	Same as FSTART	Not changed
Frame Single (FSINGLE)	Same as FSTART	Not changed
Link (LINK)	Processing proceeds to the descriptor specified by DESCR.DPTR.	LEMPTY
Fixed Link (LINKFIX)	Same as LINK	Not changed
End Of Set (EOS)	A stop point defined by software has been reached. A frame of this type within a divided frame (writing of FMID or FEND) stops the frame being stored and the frame is lost. ETNBnRIS2.QFFr indicates that the frame has been lost. If this happens at the start of a frame (writing of FSTART or FSINGLE), storing of frames starts from the next descriptor. In either case, processing shifts to the next descriptor in the chain.	EEMPTY
Frame Empty (FEMPTY)	The descriptor can be used to store received data. Up to DESCR.DS bytes are stored in the descriptor data area. For details, see **Section 25.4.4.3(1), Storing Frame Data in the Descriptor Data Area**.	FSTART, FMID, FEND, or FSINGLE
Frame Empty Incremental Start (FEMPTY_IS)	The descriptor can be used to store received data. All data for the frame are stored in the descriptor's data area. DESCR.DPTR indicates the base address of the incremental data area. For details, see **Section 25.4.4.3(2), Incremental Data Areas**.	FEND or FSINGLE
Frame Empty Incremental Continue (FEMPTY_IC)	The descriptor can be used to store received data. The remaining bytes of frame data are stored in the descriptor's data area. DESCR.DPTR is undefined, but is written back at the start position within the incremental data area after processing. For details, see **Section 25.4.4.3(2), Incremental Data Areas**.	FEND or FSINGLE
Frame Empty No Data storage (FEMPTY_ND)	The descriptor can be used to store received data. Up to DESCR.DS bytes are captured from the reception FIFO but not stored. After processing, DESCR.DS is written back as 0. For details, see **Section 25.4.4.3(c), No Data are Stored**	FSTART, FMID, FEND or FSINGLE
Link Empty (LEMPTY)	Same as FSTART	Not changed
EOS Empty (EEMPTY)	Same as FSTART	Not changed

(2) Configuration of Reception Frame Data Descriptors

Figure 25.26 shows the configuration of descriptors for use with reception queues. The reception-specific fields are the same whether the descriptor is normal or extended. The reception-specific fields (DESCR.MSC, DESCR.PS, DESCR.EI, and DESCR.TR) are described in **Table 25.117**.

For the other fields and the descriptor types, see **Section 25.4.3.6, Descriptor Type**.

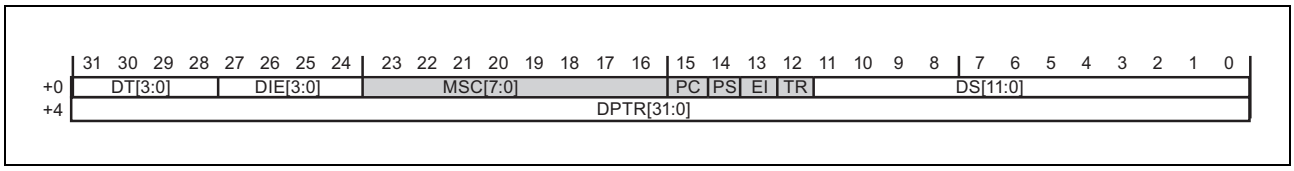

Figure 25.26 Configuration of Descriptor for a Received Frame

Table 25.117 Configuration of a Received Descriptor

Bit Name	Function
MSC	MAC Status Code These bits indicate errors in reception detected by the E-MAC. In the case of a divided frame, these bits are set to the same value within all descriptors for the frame data. Details of the bits are as follows. MSC[7]: Received frame has a multicast address. MSC[6]: Fixed to 0 MSC[5]: Fixed to 0 MSC[4]: Received frame has residual bits. MSC[3]: Received frame is too long*1 MSC[2]: Received frame is too short MSC[1]: Error in frame reception*2 MSC[0]: Received frame has a CRC error.
PC	Payload CRC Status This bit informs about result of payload CRC check. AVB-DMAC does not make any confirmation if a frame contains a payload CRC. CPU need to analyze frame content before evaluate this bit. 0: Payload CRC is not matching 1: Payload CRC is correct
PS	Padding Selection This bit specify whether frame data are to be padded when stored in this descriptor. Insertion of padding data is in accord with the settings in the ETNBnRPC register. 0: Padding is not to be inserted. 1: Padding data may be inserted. This depends on the ETNBnRPC settings.
EI	Error Indication This bit indicates the detection of an error in frame data while a frame was being stored. The bit is set to 1 for a descriptor in which an error has been detected. If the descriptor is for a divided frame, storage of the frame is aborted. 0: No error 1: Error is detected
TR	Truncation Indication This bit will be set if received data is more than 4092 bytes, and received data will be truncate to 4092 bytes. These bits are set to the same value within all frame data descriptors for a divided frame. 0: Data have not been truncated. 1: Data have been truncated.

Note 1. "Received frame is too long" is set when MAC receive the frame that length is more than ETNBnRFLR configuration value.

Note 2. "Error in frame reception" is set when MAC detect AVB_RX_DV=1 and AVB_RX_ER=1 while reception.

CAUTION

The ETNBnRCR.EFFS bit specifies whether or not frames with errors detected by the E-MAC are to be stored in the URAM. When the storing of error frames is disabled, error codes are not written to DESCR.MSC.

25.4.4.3 Reception Processing

After initialization, the AVB-DMAC becomes able to select a proper reception queue and store it in the descriptor data area in the URAM. Received data is stored into the URAM as long as the descriptor data area capacity suffices.

Received frames are classified and stored in the reception FIFO in accord with the algorithm described in **Section 25.4.4.1(1), Separation Filtering**. The frames are sorted, truncated, or discarded by the separation filter on reception by the MAC before stored in the reception FIFO. The following data are stored in the reception FIFO.

- MAC status of received frames
- Length of received frames
- Timestamp of received frames
- Target reception queue
- Received frame data

If the reception FIFO contains even one frame, the scheduler executes storing in the reception queue (see **Section 25.4.2.2, Scheduling Reception and Transmission**).

If there is even one empty data descriptor in a queue for which reception has started, the storage of frame data starts. Received frames for a queue that is already full (there is no empty frame descriptor or the UFC stop level has been reached) are discarded from the reception FIFO. This ensures that one queue being full does not prevent the storage of data in the other queues.

(1) Storing Frame Data in the Descriptor Data Area

Frame data for storage are assumed to be in either of the two patterns described below.

- The data for an entire frame will fit in the descriptor data area.
  - In this case, the descriptor type (DESCR.DT) is FSINGLE.
- Frame data to be stored in the descriptor data area arrive in divided form.
  - In this case, FSTART is written to the descriptor type (DESCR.DT) bits of the first of the frame data to arrive and FMID and FEND are written to the type bits of descriptors for subsequent data.

The descriptor type is updated by the AVB-DMAC in the last step of descriptor processing, so software can always access the descriptor assigned to DESCR.DT.

When normal synchronization mode is used, the CPU can write FEMPTYxxx directly to the descriptor type field after processing the stored element. Do not change the descriptor or any part of the descriptor data area after FEMPTYxxx is written to DESCR.DT.

(a) Storing Frame Data for a Whole Single Frame

For a frame with an FSINGLE descriptor, all data for the frame are held at the position defined by DESCR.DPTR. DESCR.DS indicates the length of the received frame.

If DESCR.DS is bigger than the actual size of a received frame, the FEMPTY or FEMPTY_ND descriptor is stored in place of the FSINGLE descriptor after processing.

Also, the FEMPTY_IS and FEMPTY_IC descriptors, which always hold the full frame data for the reception FIFO, are stored in place of the FSINGLE descriptor after processing.

(b) Storing Frame Data as Divided Frames

Divided frames are handled in the same way as a single frame. A frame stored with divided descriptors must be recombined before use. DESCR.EI and DESCR.TS are only valid in the last descriptor of the sequence for a divided frame.

CAUTION

If the data area size setting in DESCR.DS is not a multiple of four, the number of bytes set in DESCR.DS is fetched from the reception FIFO and the remaining bytes are used as the next storage area.

After a received frame is divided into different descriptors, handle each storage element separately, and allocate the descriptor type, intending software, after processing.

Accordingly, an error frame (FEMPTYxxx instead of FMID or FEND) may exist while a descriptor chain is being processed. In such a case, the CPU must postpone processing of the error frame to the next trigger point.

(c) No Data are Stored

The application specification may lead to some types of received frames being unimportant (for example, when the application only requires stream data from the Ethernet frames). Storing frames in divided form makes separating out the unnecessary parts of Ethernet frames possible.

If part of a divided frame is not required, use the FEMPTY_ND descriptor for that part so that it is not stored in the URAM. Not storing the data negates the need for bandwidth on the data bus, improving the overall performance.

When an FEMPTY_ND descriptor is processed, DESCR.DS is set to 0. This brings the frame data section of the descriptor into agreement with the FEMPTY type. DESCR.DS = 0 is for the unique identification of the descriptor after writing.

(2) Incremental Data Areas

Secure space in the URAM for storing received data. Even when data are placed in the URAM area such that all descriptor data areas of a chain are contiguous, a received frame being shorter than the descriptor data area will lead to an empty space. **Figure 25.27** shows an example of settings and the memory map.

Certain applications require that data areas be contiguous (e.g. when received data are to be processed other than by hardware as A/V codec modules). When the length of received frames differs (e.g. when payloads vary between having one or two A/V packages), the use of a static pointer in the descriptor produces empty spaces in the data area. This may necessitate direct additional processing to remove the empty spaces.

Accordingly, and to reduce the CPU load imposed by copying data, the AVB-DMAC supports an "incremental data area" function.

When incremental data areas are in use, all descriptors use a common data area for storage. One descriptor (FEMPTY_IS) defines the base address of the incremental data area and the next descriptor (FEMPTY_IC) in the descriptor chain to store receive data. **Figure 25.28** shows an example of settings and the memory map.

Use of an incremental data area does not reduce the memory space in the individual descriptor data areas.

The hardware and software synchronization strategy and performance are also not changed.

It is also possible to divide a frame up among various descriptors in a way that reflects its structure (e.g. one descriptor for the Ethernet header and one for the data payload).

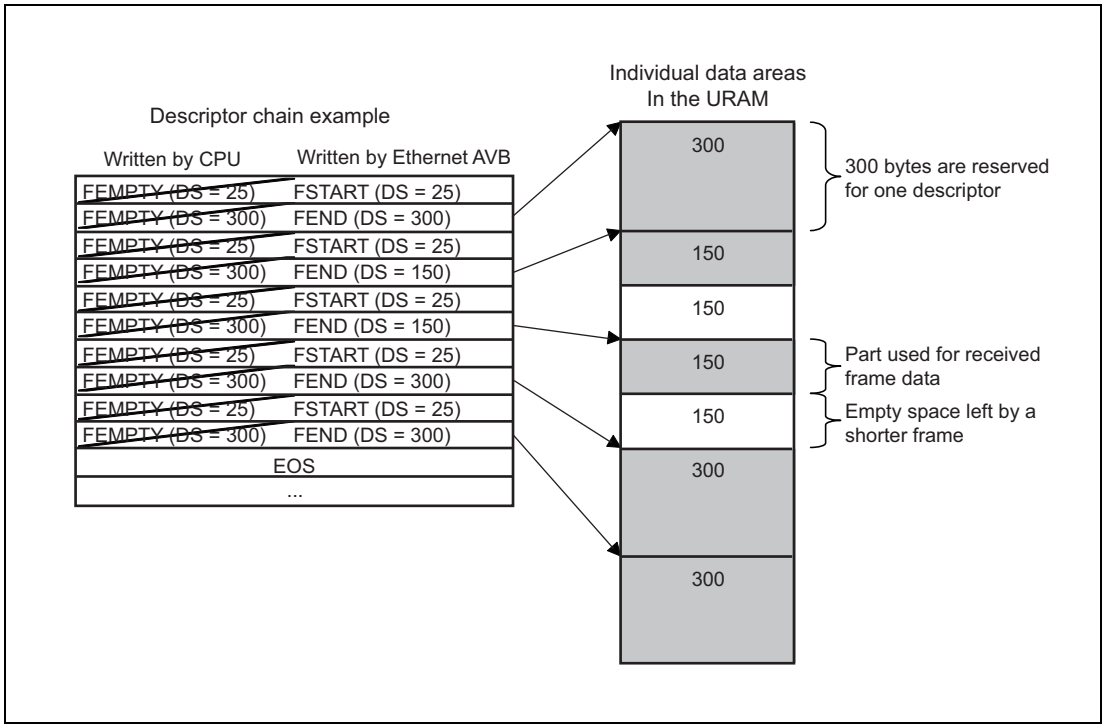

Figure 25.27 A Reception Queue Using Individual Descriptor Data Areas

Figure 25.27 and **Figure 25.28** show how control of the data storage areas by a descriptor chain varies according to whether individual or incremental data areas are in use. The chains are configured for storing received frames consisting of a 25-byte header ((which is treated as one descriptor outside of the range of this example) and a 150- or 300-byte payload (whether one or two 150-byte payload packages are transmitted with one Ethernet frame depends on the data source).

In **Figure 25.27**, the EOS descriptor is added as an example of a re-synchronization point. If the frame source transmits a frame containing more than 325 bytes, the frame will be divided among three descriptors, meaning that synchronization of the header and data sequences is lost. Despite this, however, the frame is not divided across the EOS descriptor, so even if the synchronization is off before EOS, AVB-DMAC handles the next descriptor chain as normal. The EOS is not required because the incremental descriptor always stores all data being processed while an incremental data area is in use.

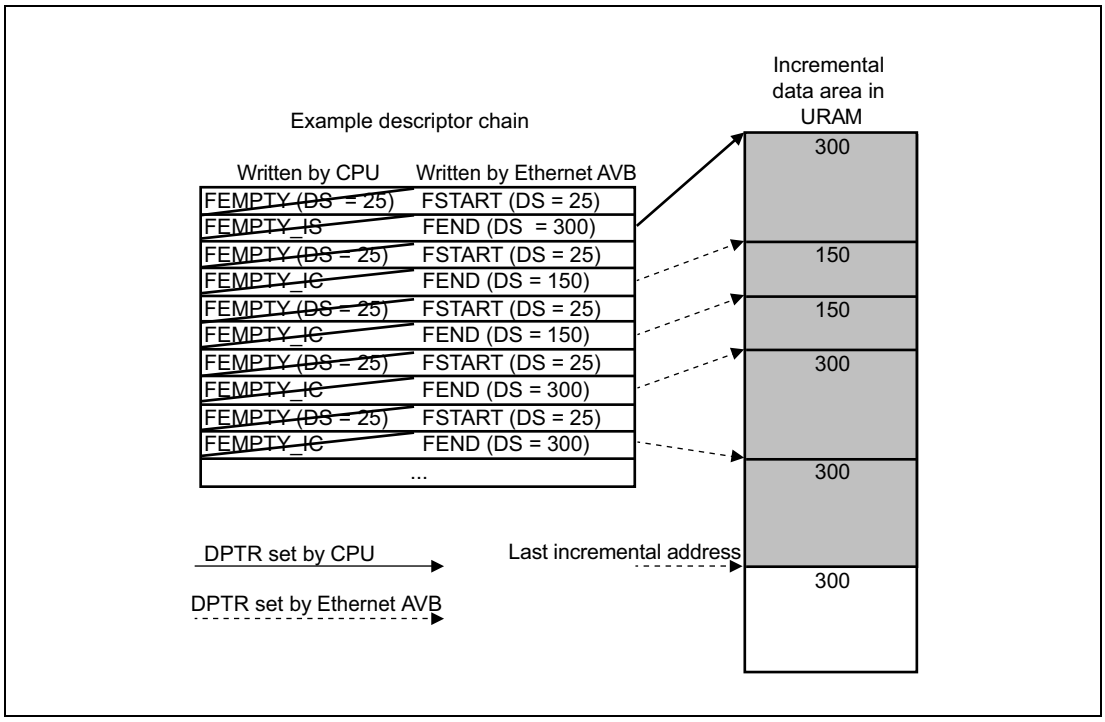

Figure 25.28 Reception Queue Using a Common Incremental Data Area

As **Figure 25.28** shows, when data are stored in an incremental data area, the descriptor pointers in the FEMPTY_IC descriptors (DESCR.DPTR) are updated. Accordingly, the resulting FEND or FSINGLE descriptor is in the same format as after writing to an FEMPTY descriptor.

Software captures received data from an incremental data area that has no empty storage areas between frame data. All empty spaces are allocated to the end of the incremental data areas. If RQCi.PIAr is 0, incremental data areas are limited to multiples of four bytes. When the amount of data for storage in an incremental data area is not a multiple of four bytes, from one to three bytes of empty space will be produced. DESCR.DS can be read to check for such empty spaces.
If RQCi.PIAr is 1, there is no limitation about frame start position inside incremental data areas. No empty space is produced between frames.

It is not possible to directly control the amount of received data to be stored from the incremental descriptor (FEMPTY_IS, FEMPTY_IC) because other descriptors (FEMPTY and FEMPTY_ND) are also applicable with DESCR.DS. All received data in the chain are always stored in an incremental descriptor.

(a) Setting Up an Incremental Data Area

A descriptor chain in the incremental data area having N descriptors (one FEMPTY_IS and N-1 FEMPTY_IC) means that a storage area for the maximum of N times the capacity must be prepared.

As **Figure 25.28** shows, DESCR.DPTR of an FEMPTY_IS descriptor indicates the base address of the incremental data area. The DPTR in FEMPTY_IC descriptor indicates the address of next store data.

(b) Processing an Incremental Data Area Based on Descriptors

Since data processing by the CPU is the same regardless of how the AVB-DMAC stores the data, data stored in an incremental data area do not require any special handling.

(c) Padding

Use padding for received frame data that are not aligned correctly in the specified memory structure. Padding can be set individually for each descriptor. Accordingly, in the reception of divided frames, padding can be restricted to only those frames that require it (e.g. A/V payload data.)

Padding can also be used to optimize system performance in an incremental data area (e.g. to prevent inefficient access by aligning received data with 32-byte boundaries in the incremental data area), as well as to fulfill application-specific requirements for specified memory structures (e.g. formats required by other modules that will be processing the received data).

Padding can only be used in an incremental data area.

The value $0000\ 0000_H$ is always used in padding.

Padding is the addition of the number of words (from one to seven 32-bit words) set in the stored padding counter in the receive padding configuration register (ETNBnRPC.PCNT). This padding is repeatedly inserted in accord with the value in the stored data counter (ETNBnRPC.DCN) (from one to 255 32-bit words). When the stored data counter (ETNBnRPC.DCNT) reaches 0, however, padding is not repeated.

The first word of padding is always inserted at the position specified by DESCR.DPTR. When divided frames are in use, a padding word can be inserted at any byte position, and padding is handled on a 32-bit basis (e.g. an incremental data area where the first descriptor is for a 42-byte header data and the second descriptor holds padded payload data).

The next figure shows a general example of how padding is inserted and an example of setting up padding. A indicates frame data A received from the E-MAC, while B indicates frame data already stored in the descriptor data area (32-bit word units).

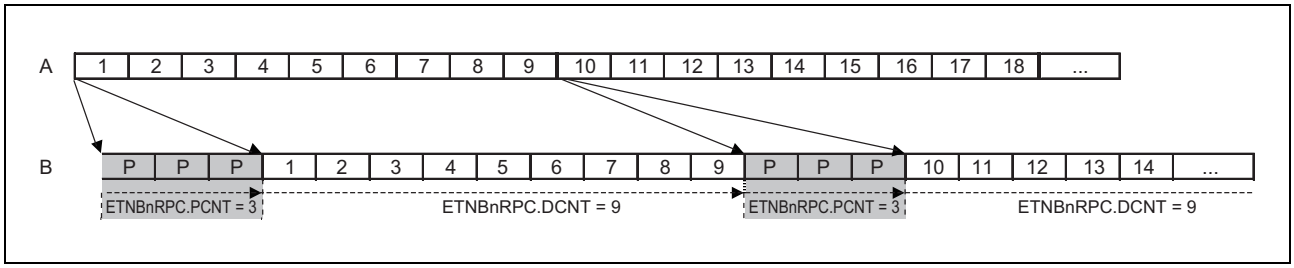

Figure 25.29 Example of a Padding Setting

Both padding and received frame data are counted in the descriptor size (DESCR.DS).

(3) Mode with Write-Back

Constructing a descriptor chain requires software (see **Figure 25.30**).

In the example in the figure, the variable SWdescr (software descriptor pointer) is a structure to identify a descriptor being processed. When Operation mode is entered and when the load base address function (ETNBnDLR.LBAq) is used, SWdescr should be initialized (start condition of flow).

The frame_processing() function processes the stored data. The function can use SWdescr.DT to check whether processing of a frame is completed. How frame data are processed differs with the application, so create functions that handle processing in accord with the specification.

The processing section is common to all modes of reception. The number of frames processed in response to each trigger can be restricted. When multiple frames have to be processed in a batch, waiting for individual trigger boxes must be skipped for these frames.

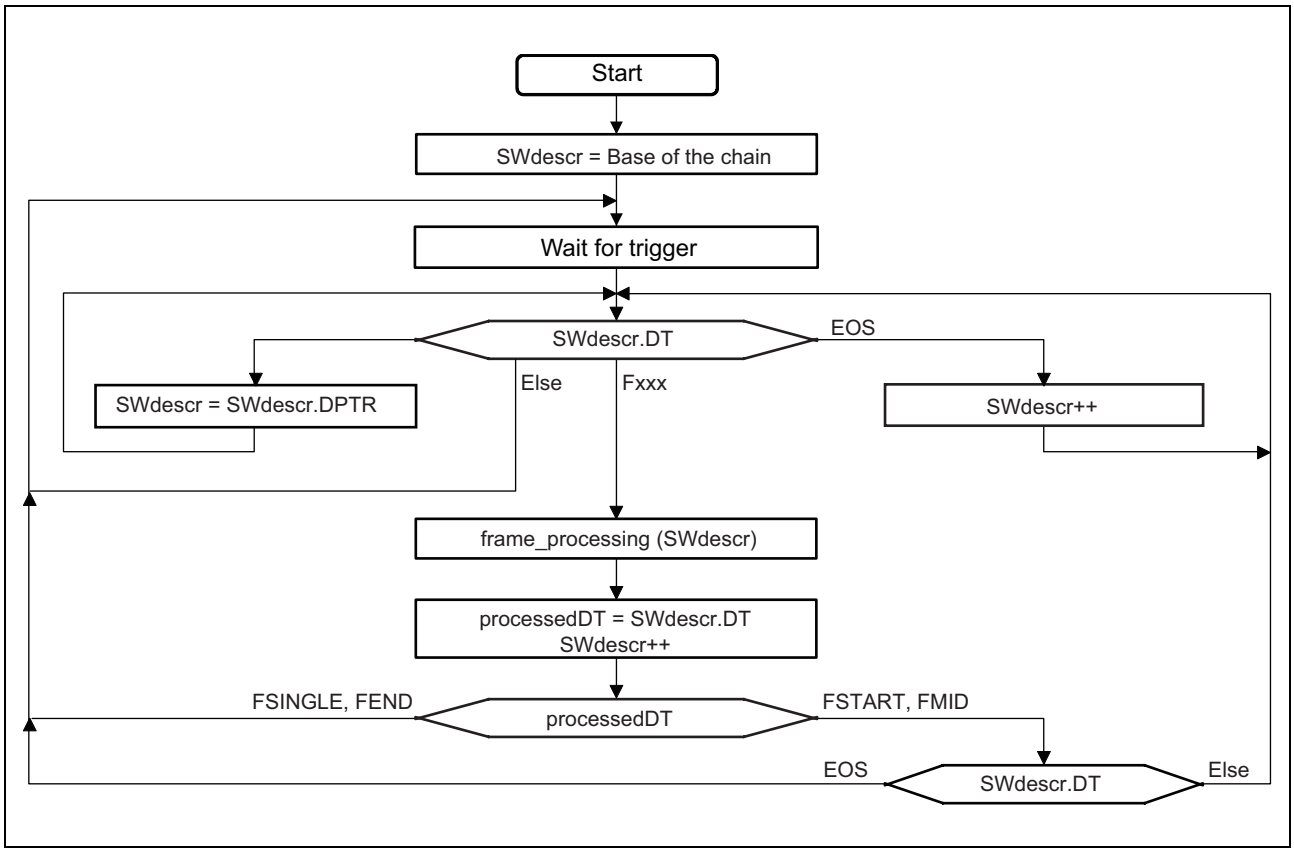

Figure 25.30 Flow of Reception Descriptor Processing (with Write-Back)

(4) Support for Reception Timestamps

Capturing reception timestamps is essential for IEEE 802.1AS time synchronization. Other types of received frames may also require that a reception timestamp be appended; this depends on the application. The AVB-DMAC supports reception timestamps based on the gPTP timer by storing timestamps that have been captured when the frame delimiter (SDF) for a received frame starts in the last frame data descriptor (FEND or FSINGLE). For the gPTP timer, see **Section 25.4.7.1, gPTP Timer**.

When timestamps are to be stored, use extended descriptors for the entire reception queue. Furthermore, timestamps are always stored for reception queue 1 (Network Control). Timestamps for reception queue 0 (best effort) and reception queue r ($r \geq 2$; for stream data) can be selected by the timestamp enable bits in the receive configuration register (ETNBnRCR.ETS0 or ETNBnRCR.ETS2).

25.4.4.4 Unread Frame Counters

Each reception queue has an unread frame counter (ETNBnUFCVi). Use the unread frame counter configuration bits in the receive queue configuration register (ETNBnRQCi.UFCCr) to select from among the four stop levels for each unread frame counter. The 0 setting disables the stop functions. For how to set this up, see **Figure 25.31**.

Operations of the AVB-DMAC (hardware) and CPU (software) drive an unread frame counter (UFC) in the following ways.

- The hardware indicates that it has added a new frame to the descriptor chain for the queue (this increments the counter).
- Software indicates how many frames from the descriptor chain it has processed by writing to the corresponding bits of the unread frame counter decrement register for the queue (this decrements the register by the number written).

The unread frame counter is based on the number of frames stored in the URAM and is only incremented by one even when a received frame is divided into different descriptors. Failure in storing a descriptor chain requires care because this may unread frame counter may fail in synchronization as described in **Section 25.4.4.4(1), Unread Frame (UFC) Synchronization Failure**.

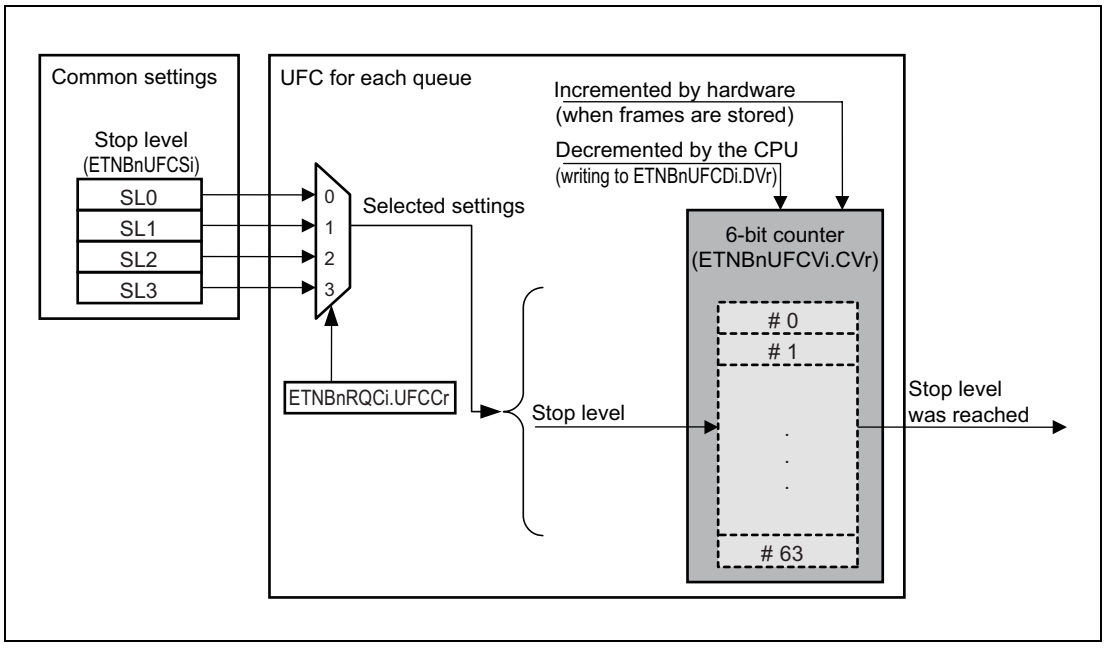

Figure 25.31 Overview of an Unread Frame Counter

Unless synchronization of hardware and software is not established, the current unread frame counter value (ETNBnUFCVi.CVr) indicates the number of unread frames in the queue.

The indicator that the stop level has been reached prevents the storage of further received frames in the descriptor chain. Selecting 0 as the stop level disables this function. Otherwise, further received frames for the queue are discarded once its unread frame counter reaches the stop level. When the unread frame counter stop function activates, the receive queue full interrupt flag in the receive interrupt status register 2 (ETNBnRIS2.QFFr) is set.

Set the unread frame counter stop level configuration register (ETNBnUFCS) for each reception queue that will use the unread frame counter function while the current operating mode is configuration mode.

(1) Unread Frame (UFC) Synchronization Failure

The unread frame counters do not recognize failure to store a frame in the URAM. In other words, the AVB-DMAC increments the counter for a queue each time it captures a frame for that queue from the reception FIFO whether or not it succeeds in storing the frame normally in the descriptor chain.

In general, synchronization of hardware and software fails under the following conditions.

- An unread frame counter reaching its maximum value
  When the value of a counter in an unread frame counter register i (ETNBnUFCVi) (i = 0 to 4) reaches 63, synchronization can fail.
  The CPU can only judge that a failure in synchronization has not occurred when the stop level is set to 63.
- A queue not having enough space for a descriptor or the associated data
  In this case, the corresponding receive queue full interrupt flag (ETNBnRIS2.QFFr) in receive interrupt status register 2 is set.
  If an unread frame counter reaches its stop level write-back mode(ETNBnRQCi.RSM[1:0]=00_B), the receive queue full interrupt flag (ETNBnRIS2.QFFr) in the receive interrupt status register 2 is set. Software must respond to this.
- A problem occurring during access to memory

The unread frame counter may set flags to frames over the number of frames actually usable for a descriptor chain, and consequently, it causes synchronization to fail. To retrieve the correct starting point for operations, use the descriptor base address load request (ETNBnDLR.LBAq) for the given queue.

25.4.4.5 Payload CRC support

AVB-DMAC supports checking a CRC which is located at the end of Ethernet frame data directly before Ethernet Frame Check sequence. Number ETNBnPCRC.CAS defines the first data byte of an Ethernet frame which is part of the payload CRC in range of 0 to 255. Refer to **Figure 25.3** about byte numbering inside an Ethernet frame.
The payload CRC should always be located before Frame Check Sequence. Note that the payload CRC cannot be evaluated if the received frame has padded data after payload CRC to achieve a minimum frame length of 64 bytes (including Frame Check Sequence). The CRC is checked at the point where the received frame data is taken from Rx-FIFO and assembled for writing via system bus to URAM.
The Payload CRC protects complete data path from source node creating the Ethernet frame up to the point the Ethernet frame is written to URAM.
Each frame received is checked for a potential payload CRC. It is up to CPU to analyze frame content to identify if a frame contains CRC (e.g. by frame type or VLAN ID). Only for frames CPU knows that there is a CRC inside, the result of HW CRC check in DESCR.PC should be evaluated.
The CPU should not use padding function for queues where frames containing payload CRC are stored into.

(1) Example of checking CRC used by Autosar

In Autosar End To End Extension, there is a payload format defined containing a payload CRC.
Figure 25.32 illustrates a frame if IEEE 802.3 basic frame format is used to transfer an Autosar E2E frame. In this case ETNBnPCRC.CAS should be set to 13 to check a CRC over all parts of Autosar E2E frame. In case of using additional frame headers (e.g. for 802.1Q VLAN tagged frames) the start position differs.

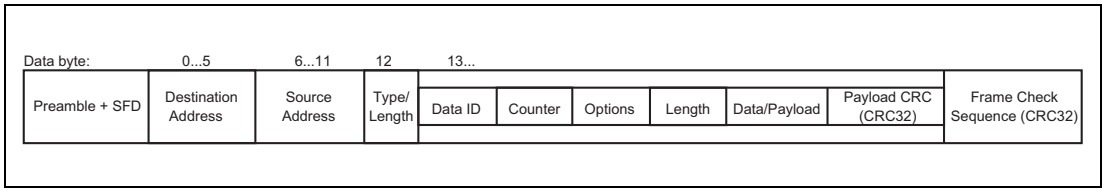

Figure 25.32 Frame format used by Autosar E2E

(2) Algorithm of payload CRC check

AVB-DMAC provides payload CRC check based on 32-bit polynomial F4AC_FB13$_H$ with initial value of FFFF FFFF$_H$ and a check value of 6FB3_2240$_H$.

These reference frames a used for functional confirmation, where the last listed byte is last byte of 60 byte frame.

[52 random data] 00 00 00 00 40 22 b3 6f
[53 random data] F2 01 83 25 1a 72 4f
[52 random data] 0F AA 00 55 f8 2d 66 20
[52 random data] 00 FF 55 11 6e 99 d7 9b
[47 random data] 33 22 55 AA BB CC DD EE FF 3d 34 5a a6
[53 random data] 92 6B 55 78 8a 68 ee
[52 random data] FF FF FF FF ff ff ff ff

(3) Mechanism to check Payload CRC logic

The Payload CRC logic can be checked by using loop back mode during initialization time. By this method CPU has full control over the frame to be checked.
Because payload CRC is stored as normal frame data in URAM, during operation time CPU can confirm DESCR.PC flagging by re-calculating CRC in SW.

25.4.5 Transmission Control

Areas in the URAM for storing transmission descriptors must also be secured (for descriptors, see **Section 25.4.3, Descriptors**).

The AVB-DMAC fetches data from the URAM in accord with the procedure the descriptor describes. Descriptors are retaining information about tags of transmit frames, too. The tag information is used to maintain the relationships between state information and timestamps for the software and the AVB-DMAC. After completion of transmission of frames, information about the statuses and timestamps of transmitted frames are accessible.

25.4.5.1 Transmission Modes

The AVB-DMAC has two modes of transmission.

- AVB transmission mode
  Selection of the transmit configuration register transmission queue priority (ETNBnTGC.TQP[1:0] bits set to 01_B or 11_B).
- Non-AVB transmission mode
  Selection of the transmit configuration register transmission queue priority (ETNBnTGC.TQP[1:0] bits set to 00_B).

(1) AVB Transmission Mode

AVB transmission supports the control of traffic through the output port to implement various traffic classes.

(a) Support for Traffic Classes and Associated Priority

When transmission is in AVB transmission mode, streams of traffic are transmitted in accord with the part of the AVB specification called Forwarding and Queuing for Time Sensitive Streams (FQTSS; for details on this, see the IEEE 802.1Q standard).

In the AVB specification, at least one queue for a reserving stream under the Stream Reservation Protocol (SR stream) and at least one queue for a non-SR stream are present, and high-priority queues are reserved for SRP traffic.

The AVB-DMAC supports four traffic classes: SR Class A, SR Class B, Network Control (NC) traffic (gPTP frames), and best effort (BE) traffic. Allocating a specific queue to Network Control (NC) frames ensures the control of synchronization.

The AVB-DMAC realizes compliance with the AVB standards by handling queues with the following architecture (in terms of traffic classes).

- Four transmission queues (Q3, Q2, Q1, and Q0) are available.
- Q3 and Q2 are for SR streams (one each for Class A and Class B).
- Q1 is for low-bandwidth Network Control (NC) traffic (gPTP frames)
- Q0 is for other types of traffic (MSRPDU*1, MVRPDU*2, best effort (BE), etc.)

Note 1. MSRPDU: Multiple Stream Registration Protocol Data Unit
Note 2. MVRPDU: Multiple VLAN Registration Protocol Data Unit

Fetching from queues proceeds in order of priority of the above traffic types. Three systems of priority are available through the setting of the transmit queue priority bits in the transmit configuration register (ETNBnTGC.TQP[1:0]). In the default priority scheme, which is called AVB mode 1 (selected by ETNBnTGC.TQP[1:0] = 01_B), operation of the AVB-DMAC is fully in accord with the AVB specification. AVB mode 2 (transmit queue priority bits (ETNBnTGC.TQP[1:0] = 11_B) is an alternative priority scheme and varies from the AVB specification. Using this scheme thus requires more care. The other setting (ETNBnTGC.TQP[1:0]=00_B) is for non-AVB-mode transmission.

Table 25.118 Default and Alternative Priority Orders in AVB Transmission Mode

Priority Schemes (AVB Mode)	Priority Order of Queues
AVB mode 1 (Default)	Q3 (SR Class A) > Q2 (SR Class B) > Q1 (NC) > Q0 (BE)
AVB mode 2 (Alternative)	Q1 (NC) > Q3 (SR Class A) > Q2 (SR Class B) > Q0 (BE)

(b) Transmission Selecting Algorithm and CBS

The algorithm the AVB-DMAC applies to select frames for transmission is in accord with the specifications under section 8.6.8, Transmission selection, of the IEEE 802.1Q standard. For AVB mode, the CBS (credit-based shaping) algorithm is applied to the Class A and Class B SR queues (Q3 and Q2). Use of the CBS enables correct handling of the priorities of transmission from the SR queues. For the CBS algorithm, see **Section 25.4.6, CBS (Credit-Based Shaping)**.

When all the following conditions are determined as True, an SR queue (Q3 or Q2) is selected and transmitted at the specified time.

- The queue contains at least one frame ready for transmission.
- The queue has available credit.
- Unless an SR queue satisfies the above conditions, a higher priority queue is not present (not ready for transmission).

A non-SR queue (Q1 or Q0) is selected if the conditions below both hold.

- The queue contains at least one frame ready for transmission.
- As well as the above condition, a higher priority queue is not present (not ready for transmission).

Figure 25.33 and **Figure 25.34** are flowcharts of selection for transmission in AVB mode 1 (default) and AVB mode 2 (alternative).

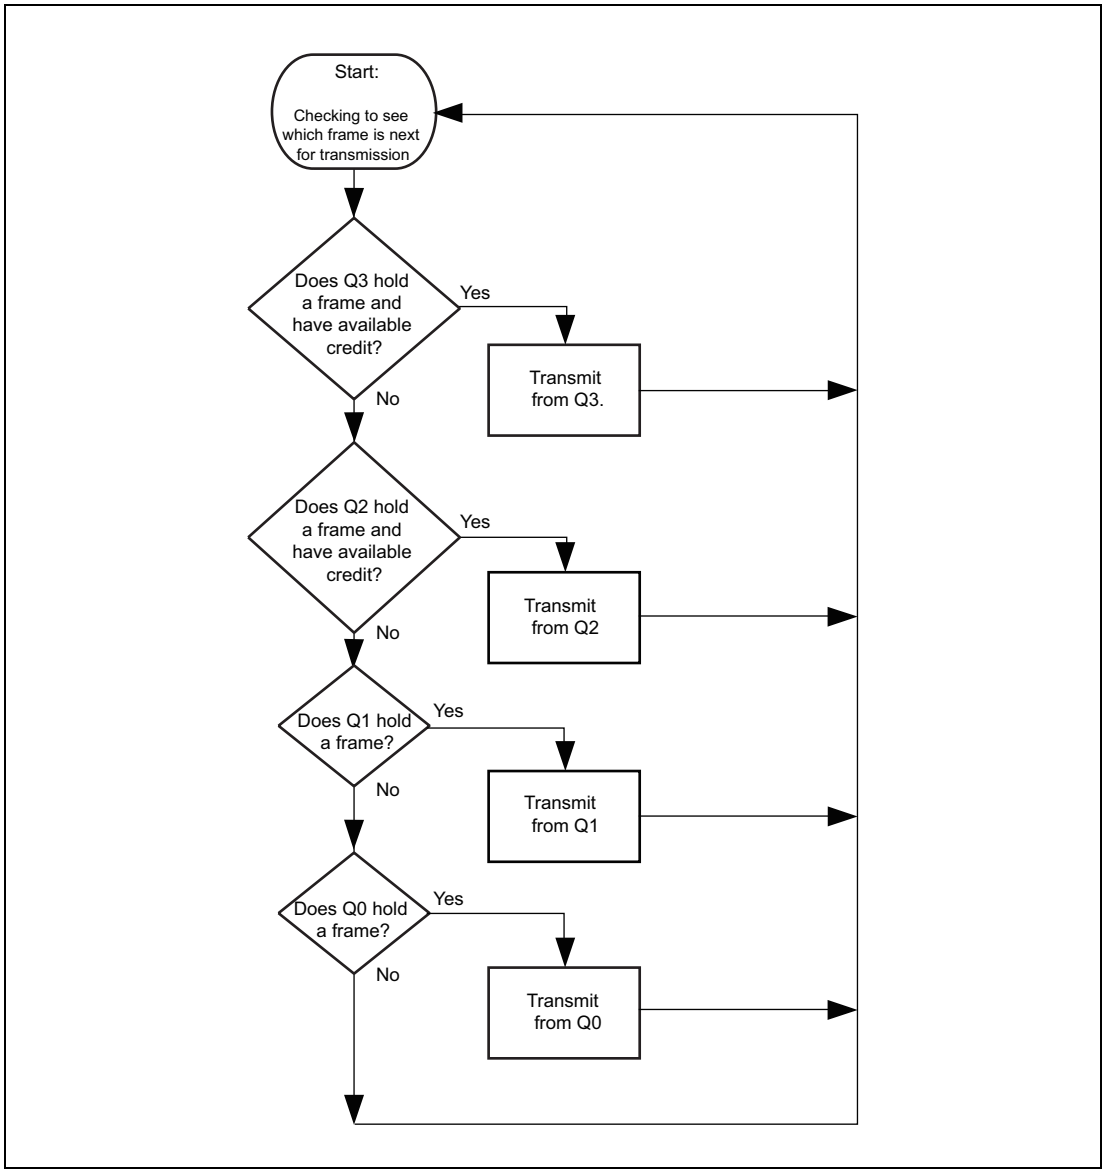

Figure 25.33 Flow of Selection for Transmission in AVB Mode 1 (Default)

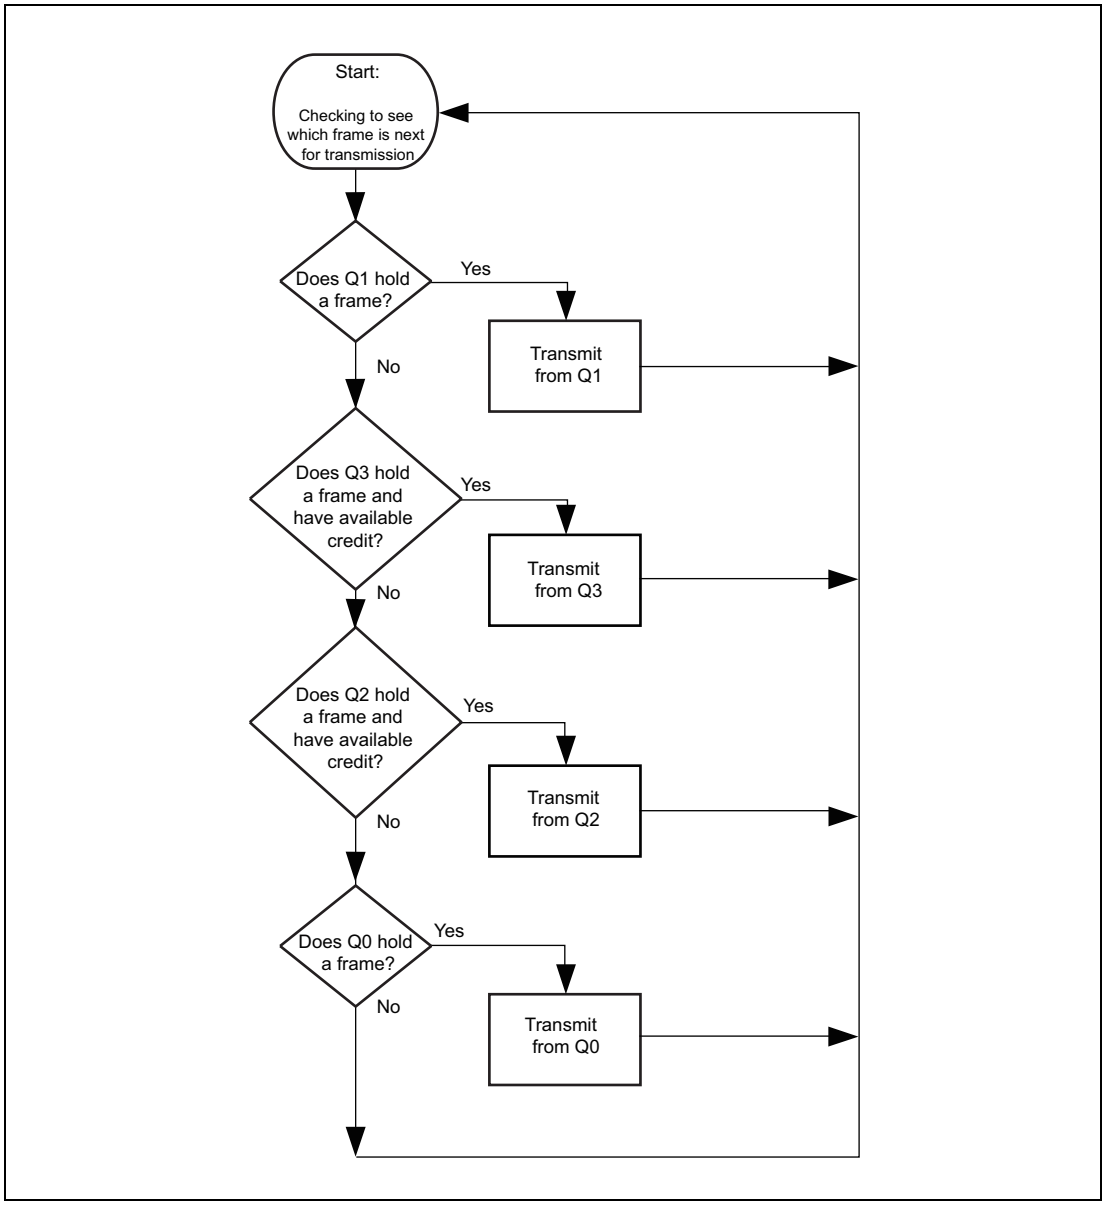

Figure 25.34 Flow of Selection for Transmission in AVB Mode 2 (Alternative)

(2) Non-AVB Transmission Mode

In non-AVB transmission mode, an absolute priority scheme is used. The SR Class is not supported and the CBS algorithm is not used.

In non-AVB transmission mode (when the transmit queue priority bits in the transmit configuration register (ETNBnTGC.TQP[1:0]) are 00_B), data is fetched for transmission in a strict order of priority (Q3 > Q2 > Q1 > Q0).

Figure 25.35 shows the flow of selection in non-AVB transmission mode.

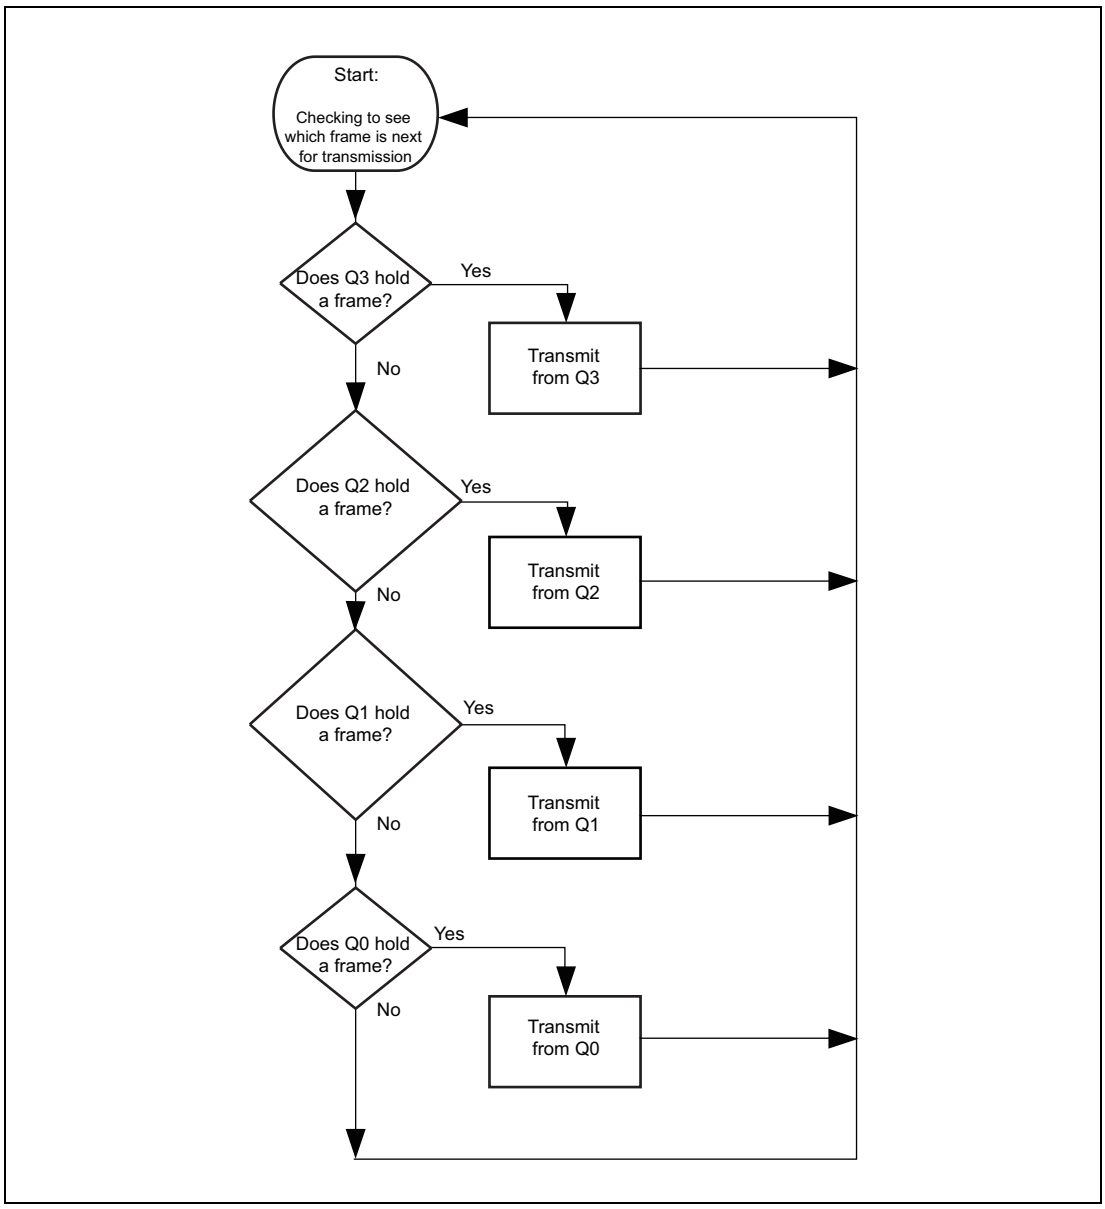

Figure 25.35 Flow of Selection for Transmission in Non-AVB Mode

(3) Setting the Size of the Transmission FIFO

The transmission FIFO is made up of 122 clusters. Each cluster can hold up to 128 bytes.

The size of the part of the transmission FIFO for use by each of the four transmission queues can be set by the corresponding transmit queue configuration t bits in the transmit control register (ETNBnTGC.TBDt). The maximum number of clusters required can be determined from the maximum length of frames for transmission from the queue t.

General Usage Examples:

Q0: Frames containing up to 1500 bytes → 1500/128 = 11.7 → 12 clusters

Q1: Frames containing up to 1024 bytes → 1024/128 = 8.0 → 8 clusters

Q3: Frames containing up to 1996 bytes → 1996/128 = 15.6 → 16 clusters

Q4: Frames containing up to 1996 bytes → 1996/128 = 15.6 → 16 clusters

When the depth of all transmission queues is 2, the following number of clusters is required.

2 × (12 + 8 + 16 + 16) + 16 = 2 × 52 + 16 = 120

25.4.5.2 Setting Up Transmission Descriptors

(1) Transmission Descriptor Type

The type of a descriptor is defined by the descriptor type (DESCR.DT) field.

Table 25.119 shows the descriptor types used in transmission.

Table 25.119 Descriptor Types in Transmission

Descriptor Type (DESCR.DT)	Operation	Write-back
Frame Start (FSTART)	The AVB-DMAC fetches the first of the data for the divided frame and proceeds to processing of the next descriptor.	FEMPTY
Frame Middle (FMID)	The AVB-DMAC fetches the second or subsequent data for the divided frame and proceeds to processing of the next descriptor.	FEMPTY
Frame End (FEND)	The AVB-DMAC fetches the last of the data for the divided frame. When the frame of data that has been fetched to the transmission FIFO is ready for transmission by the E-MAC, the AVB-DMAC proceeds to processing of the next descriptor.	FEMPTY
Frame Single (FSINGLE)	The AVB-DMAC fetches the frame of data. When the frame of data that has been fetched to the transmission FIFO is ready for transmission by the E-MAC, the AVB-DMAC proceeds to processing of the next descriptor.	FEMPTY
Link (LINK)	Processing proceeds to the descriptor specified by DESCR.DPTR.	LEMPTY
Fixed Link (LINKFIX)	Same as LINK	Not changed
End Of Set (EOS)	This is a transmission stop point defined by software This leads to clearing of the transmit start request bit (ETNBnTCCR.TSRQt), which stops transmission. When the ETNBnTCCR.TSRQt is again set to 1 (a new transmission start request is issued), processing proceeds to the next descriptor.	EEMPTY
Frame Empty (FEMPTY)	No frame data are ready for transmission This leads to clearing of the transmit start request bit (ETNBnTCCR.TSRQt), which stops transmission. When the ETNBnTCCR.TSRQt is again set to 1 (a new transmission start request is issued), processing starts at this descriptor.	Not changed
Link Empty (LEMPTY)	Same as FEMPTY	Not changed
EOS Empty (EEMPTY)	Same as FEMPTY	Not changed

(2) Configuration of Transmission Frame Data Descriptors

Figure 25.36 shows the configuration of descriptors for use with transmission queues. The transmission-specific fields (DESCR.TSR, and DESCR.TAG) are described in **Table 25.120**.

For the other fields and the descriptor types, see **Section 25.4.3.6, Descriptor Type**.

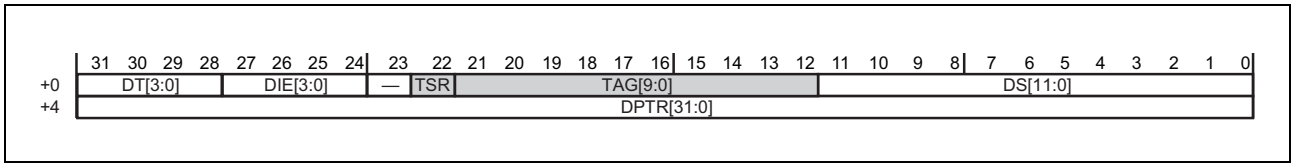

Figure 25.36 Configuration of Descriptor for a Transmitted Frame

Table 25.120 Configuration of a Transmission Descriptor

Bit Name	Function
TSR	Timestamp Store Request This bit specifies whether the transmission timestamp is to be stored within the EthernetAVB module. 0: The timestamp FIFO within the EthernetAVB module does not retain a transmission timestamp. 1: The timestamp FIFO within the EthernetAVB module retains a transmission timestamp. Only control this bit while the current DESCR.DT is FEND or FSINGLE.
TAG	Frame Tag This TAG field is used to associate each frame data with a timestamp. Frame TAG is not required but is recommended. Only control this bit while the current DESCR.DT is FEND or FSINGLE.

For the timestamp FIFO function, see **Section 25.4.5.4, Timestamping in Transmission**.

25.4.5.3 Transmission

(1) Transmitting Frames

Setting the transmit start request bit in the transmit configuration control register (ETNBnTCCR.TSRQt) starts the transfer of frames to the corresponding transmission queue.

The descriptor to the current descriptor address of the queue (ETNBnCDARq.CDA) is read first.

If this descriptor is a descriptor for frame transmission (FSINGLE, etc.), the AVB-DMAC fetches the frame data from the data area indicated by the descriptor, writes FEMPTY back to the descriptor type (DESCR.DT) bits, then proceeds to processing of the next descriptor.

If the descriptor is not for transmission, processing is as dictated by the given descriptor (for these descriptors, see the descriptions in **Section 25.4.3, Descriptors**).

If a base address load request is issued for a descriptor chain while it is being processed (by setting 1 in the LBAq bit for transmission queue that is currently being processed in the descriptor base address load request register, ETNBnDLR), processing proceeds to the new descriptor chain. Changing the chain does not interrupt frame fetching, but note that frames that have not been fetched from the old chain remain where they are.

Figure 25.37 shows descriptor processing during transmission.

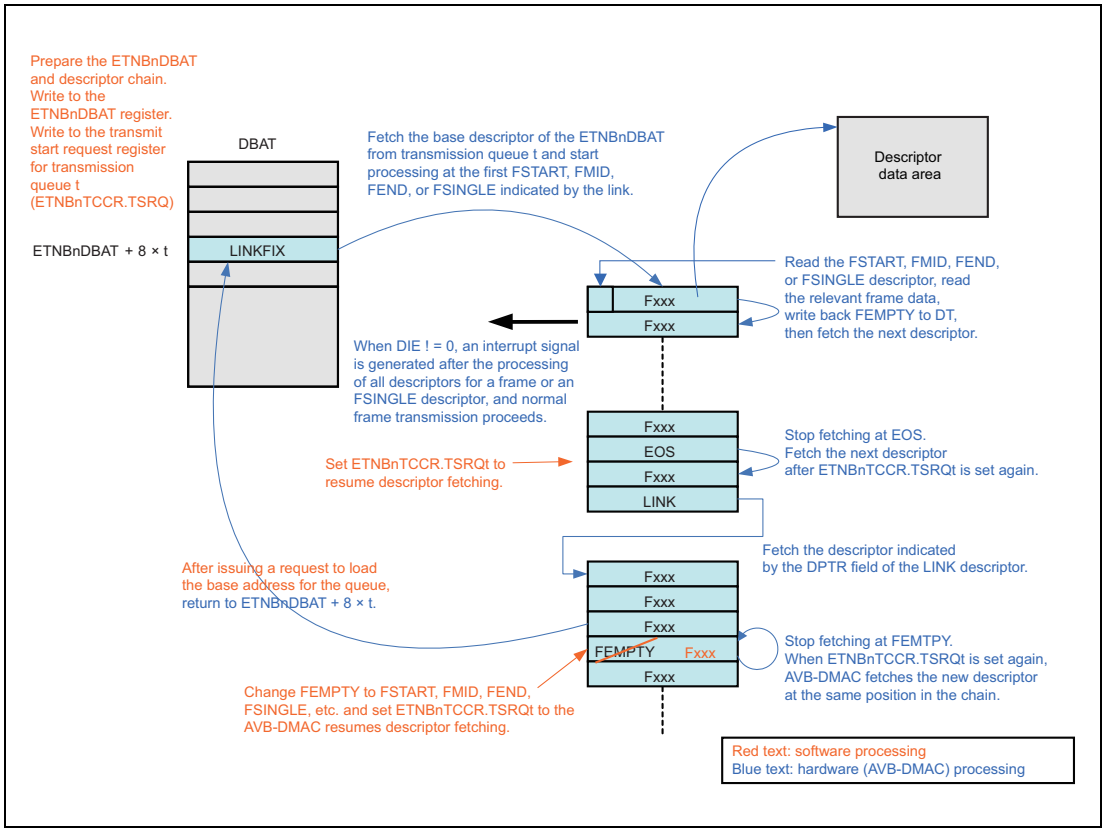

Figure 25.37 Descriptor Processing During Transmission

(2) Examples of Descriptor Usage

(a) Immediate Frame Transmission

Immediate frame transmission is a pattern in which fetching by the AVB-DMAC starts whenever software adds data to a queue. FEMPTY descriptors are used as HW/SW synchronization stop points.

Create descriptor chains that have FEMTPY descriptors at the stop points.

Figure 25.38 shows the flow for software implementing this pattern.

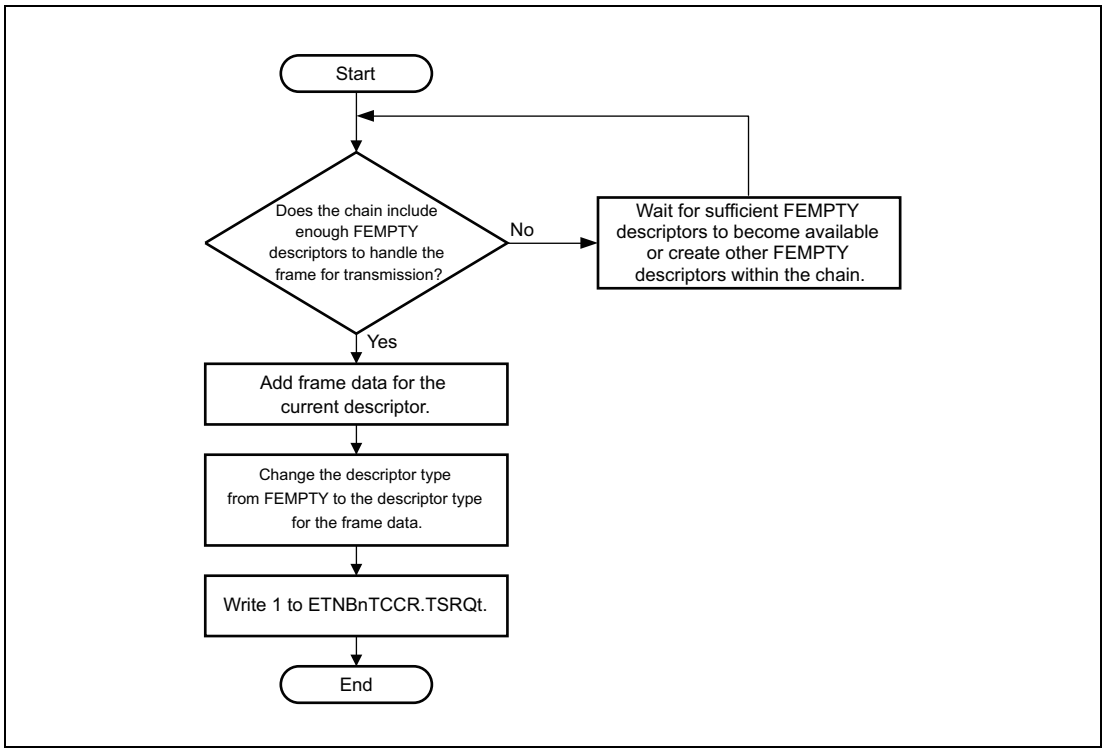

Figure 25.38 Software Flow for Immediate Frame Transmission

Figure 25.39 shows software and AVB-DMAC operations for immediate frame transmission.

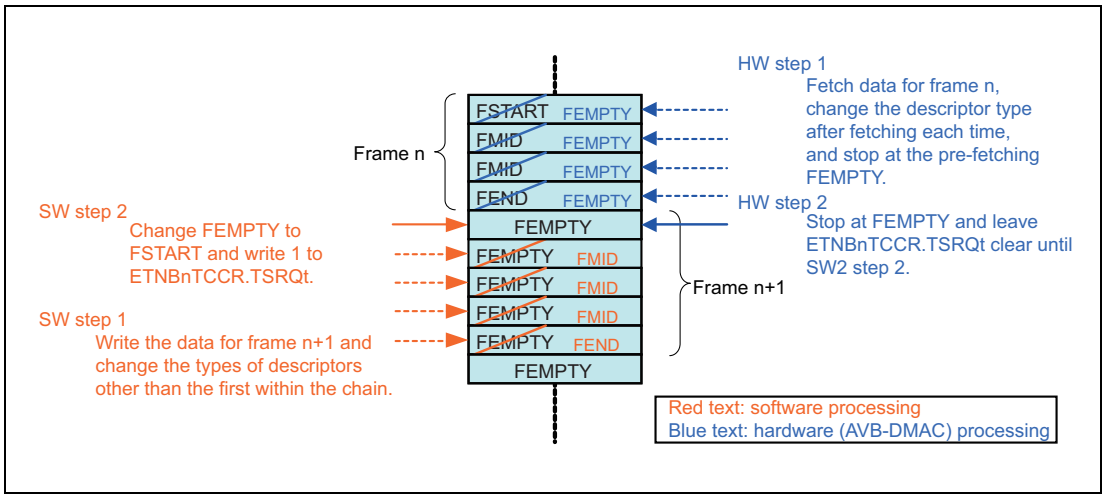

Figure 25.39 Software and AVB-DMAC Operations for Immediate Frame Transmission

(b) Frame Set Transmission with Changing of the Active Descriptor Chain

This pattern is used when data are transmitted with a delay for software control to secure bandwidth or for other reasons, rather than immediately transmitted. EOS descriptors are used for the stop points.

Start by creating a descriptor chain that has a FEMPTY descriptor at its stop point.

Figure 25.40 shows the software flow in this pattern.

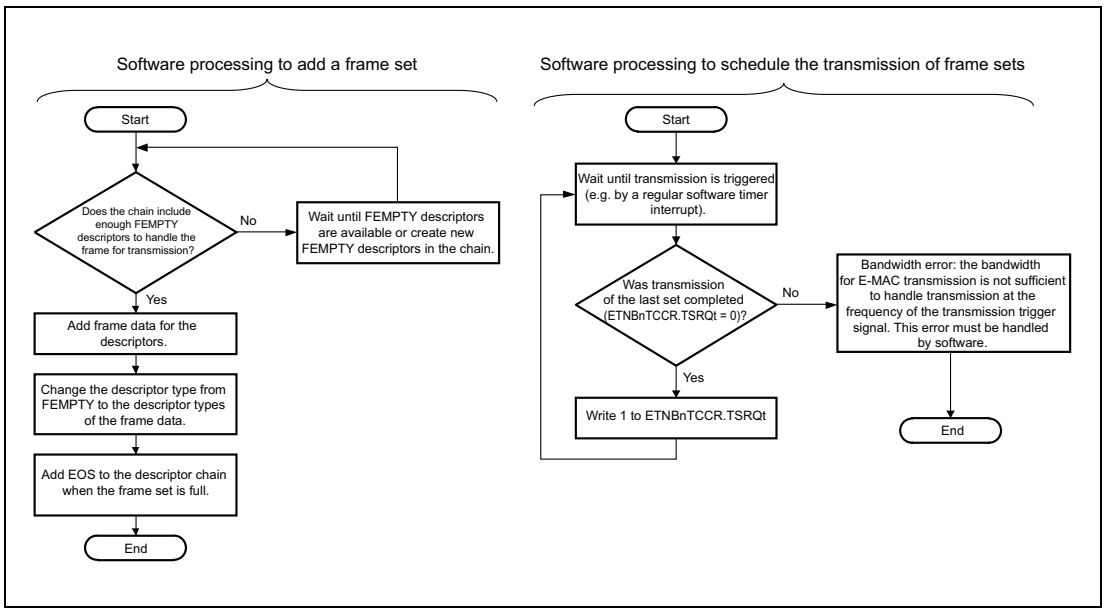

Figure 25.40 Software Flow for Frame Set Transmission with Changing of the Active Descriptor Chain

Figure 25.41 shows software and AVB-DMAC operations for frame set transmission.

(c) Frame Set Transmission Using a Shadow Descriptor Chain

This pattern is used when data are transmitted with a delay for software control to secure bandwidth or for other reasons, rather than immediately transmitted. Two or more descriptor chains are used. The chains are classified into the active chain and shadow chains. EOS descriptors are used for the stop points.

Create descriptor chains that have FEMTPY descriptors at the stop points.

Figure 25.42 shows the flow for software implementing this pattern.

25.4.5.4 Timestamping in Transmission

Transmission timestamps are important in satisfying the requirements for time synchronization of the IEEE 802.1AS standard. This information can also be useful to other applications and in testing. The AVB-DMAC supports the storage of timestamps for transmitted frames. The timestamp values are based on the gPTP timer and are captured at the same time as sending of the Start of Frame Delimiter (SFD) for transmitted frames.

When the timestamp storage request field (DESCR.TSR) is set to 1, selecting storage of a timestamp, the tag number defined in the tag field (DESCR.TAG) of the last descriptor in a set (FEND) or of an FSINGLE descriptor for the frame being transmitted is stored with the timestamp. To make identification and association easy, the values of timestamp are stored together with tag numbers. The timestamp FIFO is accessible at any time.

Figure 25.44 shows the mechanism supporting transmission timestamping.

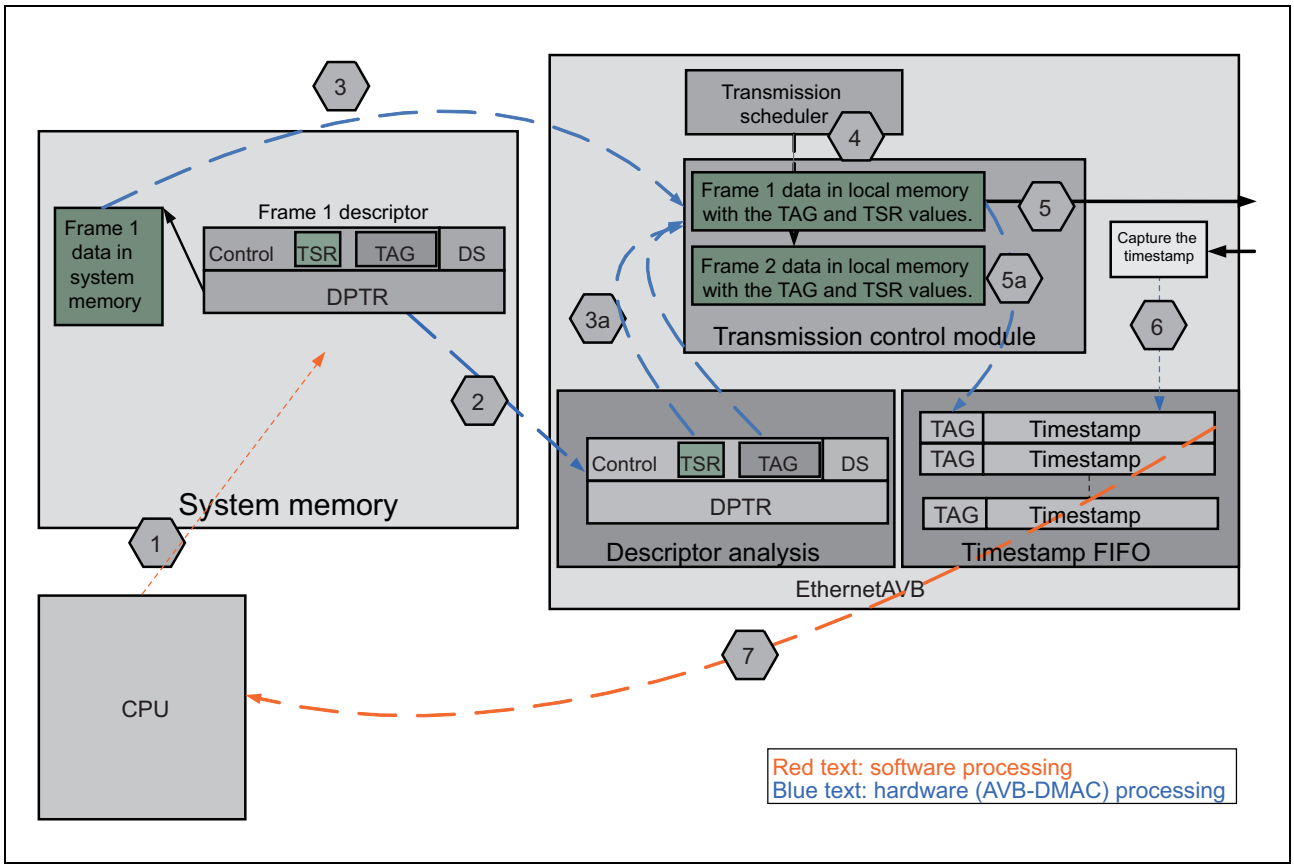

Figure 25.44 Mechanism to Support Transmission Timestamps

The method of using this function is described below:

1. Secure space in the URAM for the frame requiring timestamping.
   Write the tag number of the frame to the frame tag field (DESCR.TAG) and set the timestamp storage request field (DESCR.TSR) to 1.
2. The AVB-DMAC fetches and analyzes the descriptor. The timestamp storage request field (DESCR.TSR) is 1, so it recognizes that transmitting this frame also requires storage of the timestamp.
3. The AVB-DMAC fetches the data for frame 1 and temporarily stores the frame in internal memory for scheduling.

   3a: The frame tag field (DESCR.TAG) and timestamp storage request field (DESCR.TSR) are stored with the fetched data.)
4. Under the control of priority settings according to credit-based shaping (CBS) or another scheme, the transmission scheduler determines the time to transmit frame 1.
5. Transmission of frame 1 starts.

   5a: The information relating to frame 1 is stored in the timestamp FIFO.
6. The gPTP timestamp is captured at the start of sending the frame delimiter (SFD) for transmission and stored with the tag in the timestamp FIFO. On completion of the transmission, an interrupt is generated. For this to happen, the descriptor interrupt control register (ETNBnDIC) must be set beforehand.
7. The entry can now be read from the timestamp FIFO.

Use the timestamp FIFO for the time synchronization of frames with IEEE 802.1AS compliance.

Timestamping can also be used with other frames, but take care not to allow the timestamp FIFO to overflow. When the FIFO is full, further timestamps supplied to it are lost.

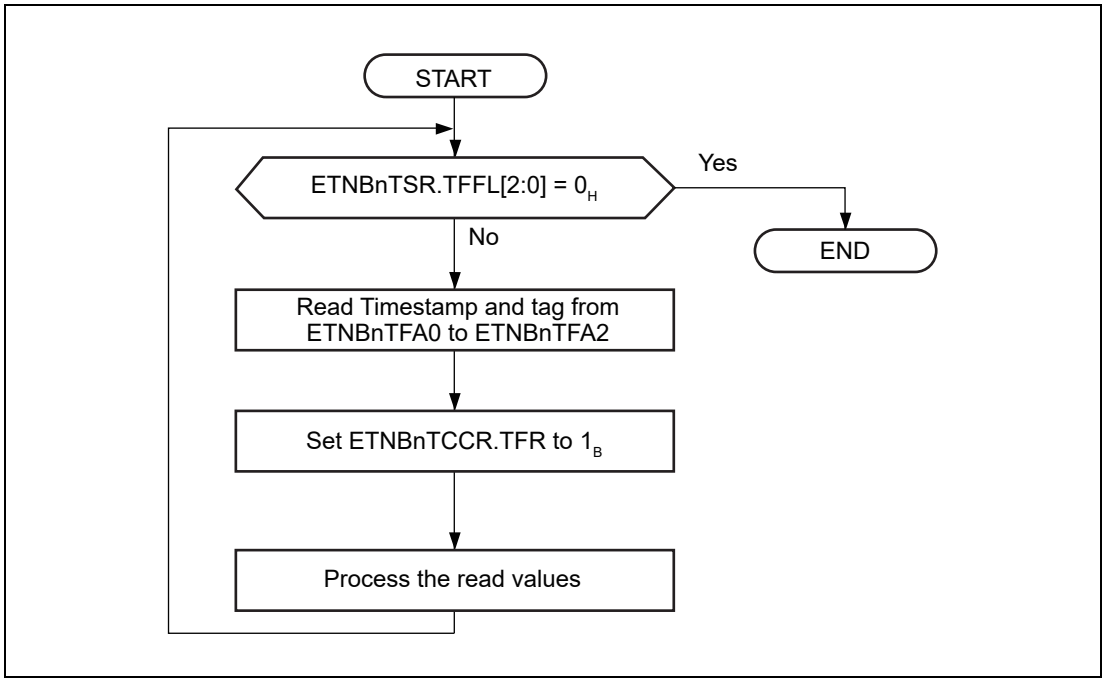

Figure 25.45 Flow of Transmission Timestamping

(1) Ending Transmission

Figure 25.46 shows the procedure for ending transmission.

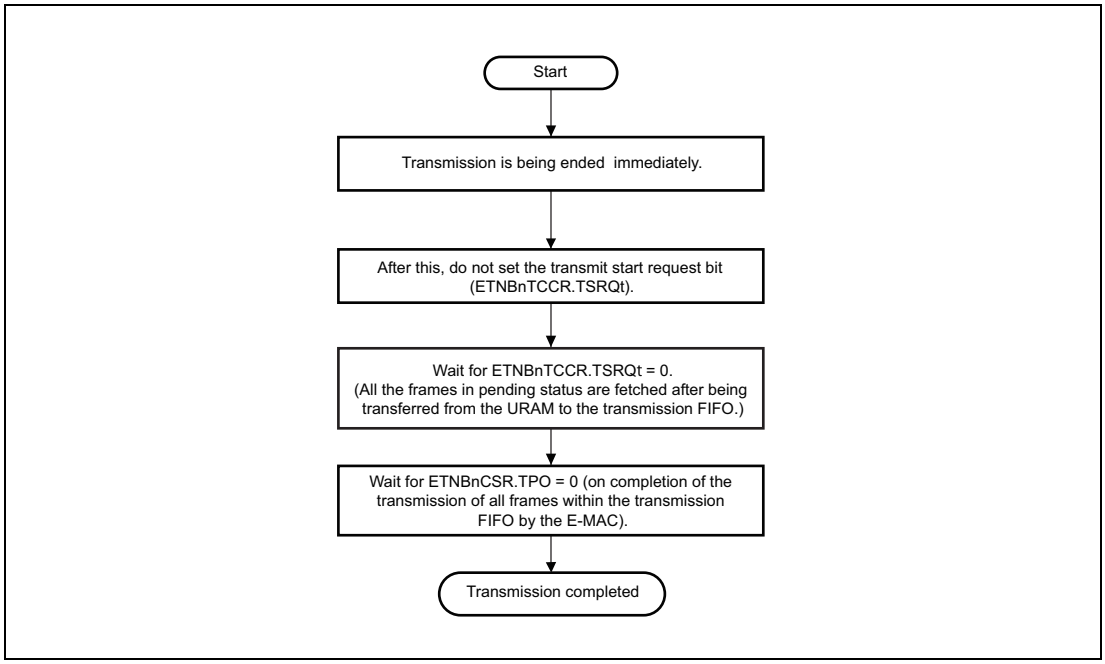

Figure 25.46 Procedures for Ending Transmission

25.4.6 CBS (Credit-Based Shaping)

In AVB transmission mode (i.e. when the transmit queue priority field in the transmit configuration register (ETNBnTGC.TQP) is 01_B or 11_B), transmission queues Q3 and Q2 are respectively assigned to Class A and Class B stream traffic and the CBS (Credit Based Shaping) algorithm is used to select the transmission queues in order to satisfy the Forwarding and Queuing for Time Sensitive Streams (FQTSS) specification (see section 8.6.8 or section 34 in IEEE 802.1Q).

The CBS algorithm is based on the concept of transmission credit for each queue. Credit can be thought of as the degree to which a queue has the “right” to transmit at a given time. Actually, in AVB transmission mode as specified in IEEE 802.1Q, queues that are subject to the CBS algorithm are able to transmit when the following conditions are met.

- At least one frame is stored in the queue.
- The credit for the queue is 0 or a positive value.

The credit for a transmission queue is incremented while one or more frames from the queue are present in the transmission FIFO but transmission of these frames is not proceeding. This state is indicated by the transmission process status bit for queue t in the AVB-DMAC status register (ETNBnCSR.TPOt) being clear (0). The credit is decremented while transmission of a frame from the queue is in progress. This mechanism is used to control transmission so that the transmission of frames from the queues for each of the traffic classes does not exceed the specified maximum bandwidth.

IEEE 802.1Q defines the following parameters for queues under the control of the CBS algorithm.

portTransmitRate: Maximum transmission data rate of an external port. The E-MAC determines this parameter.

bandwidthFraction: Maximum fraction of portTransmitRate that can be used for a queue.

idleSlope: Rate of change of credit for a queue when transmission of frames from the queue is not proceeding so the credit value (in bits per second) is increasing. idleSlope is also equal to the maximum fraction of the total bandwidth (portTransmitRate) that is available to the given queue under a specified condition (frames from the queue can be placed in a continuous stream. See Annex L of IEEE 802.Q.
idleSlope = bandwidthFraction × portTransmitRate

sendSlope: Rate of change of credit for a queue while transmission of a frame from the queue is in progress so the credit value is decreasing. (in bits per second).
The value of sendSlope is defined as follows:
sendSlope = idleSlope - portTransmitRate

Furthermore, the values below are used to define individual traffic classes (or queues for the classes) under control of the algorithm. See Annex L of IEEE 802.Q.

maxFrameSize: Maximum size of frames (in bits) of the corresponding traffic class that can be transmitted from a port

maxInterferenceSize: Maximum burst size (in bits) by which delays for the corresponding traffic class can be allowed

hiCredit: Maximum credit value (positive number). Can be calculated by using the following equation: hiCredit = maxInterferenceSize × (idleSlope / portTransmitRate)

loCredit: Minimum credit value (negative number). Can be calculated by using the following equation: loCredit = maxFrameSize × (sendSlope / portTransmitRate)

Figure 25.47 shows how the CBS algorithm works and the meaning of the above parameters.

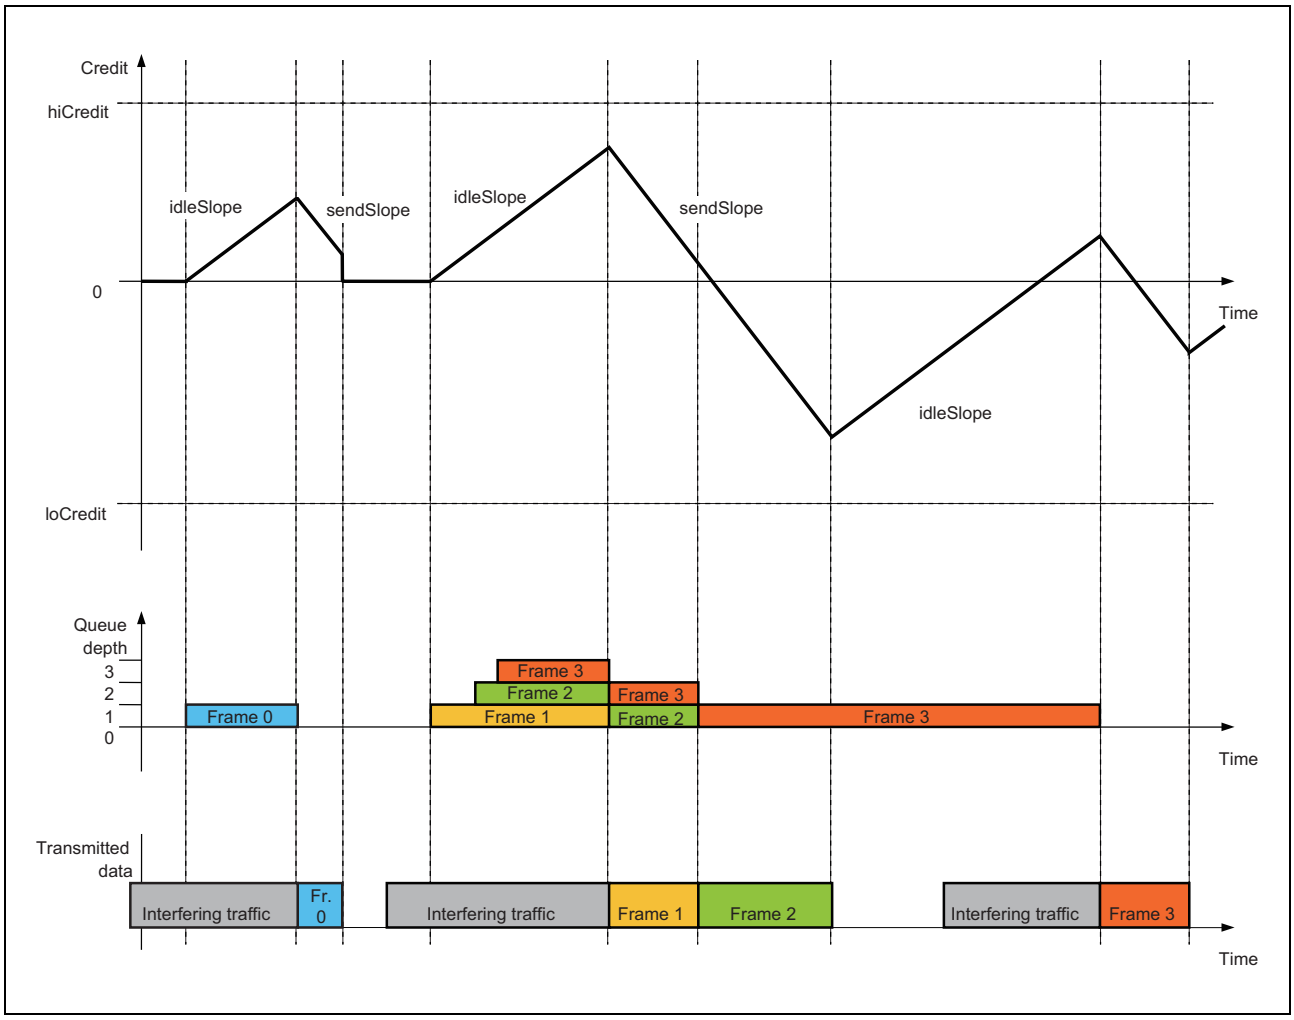

Figure 25.47 CBS (Credit-Based Shaping) Operation

Figure 25.48 shows the implementation of CBS in the AVB-DMAC.

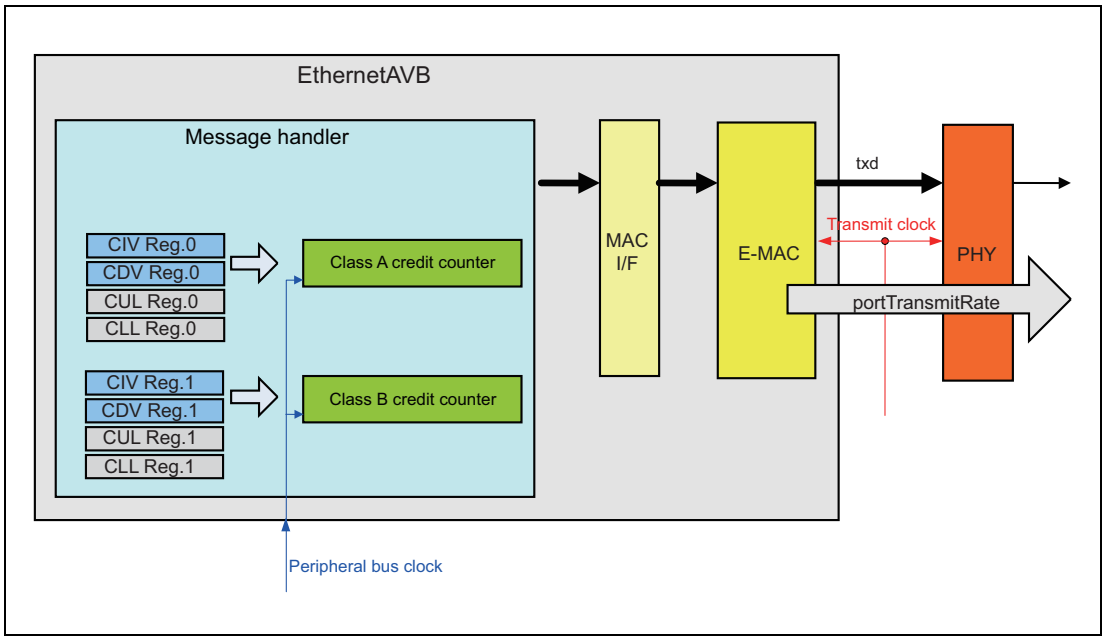

Figure 25.48 CBS (Credit-Based Shaping) Operation in the AVB-DMAC

The above implementation is based on “credit counters” for the respective traffic classes (SR Class A and Class B). The following parameters apply for these classes.

CBS increment value (CIV): Signed positive number
The credit is incremented by this amount every peripheral bus clock cycle while a frame from the queue is pending but transmission has not started (idleSlope).

CBS decrement value (CDV): Signed negative number
The credit is decremented by this amount every peripheral bus clock cycle while transmission of a frame from the queue is proceeding (sendSlope).

The CBS increment value (CIV) and CBS decrement value (CDV) are defined as follows.

CIV = idleSlope × Mfactor

CDV = sendSlope × Mfactor

Mfactor is a multiplier factor to ensure accuracy for CIV and CDV. CIV and CDV are calculated by using the following equations.

CIV = (portTransmitRate/CHI_freq) × bwFraction × Mfactor

CDV = (portTransmitRate/CHI_freq) × (bwFraction - 1) × Mfactor

CHI_freq is the frequency of the peripheral bus clock. The credit counters are driven by the peripheral bus clock, so calculating the slope parameters for CBS requires (1/CHI_freq).

Use software to prepare Mfactor for the CBS parameters. All queues for the same Class must have the same CBS parameters. Mfactor for a specified Class c can be changed during operation, unless transmission is pending for that Class (i.e. the transmit process status bit in the AVB-DMAC status register (ETNBnCSR.TPOt) = 0). At that time, the credit counter values for Class A and Class B are 0.

Note that the credit value will not match a new incrementation or decrementation parameter if Mfactor is changed while the credit counter value is non-zero. Mfactor is not present in the AVB-DMAC registers.

Set the CIV and CDV parameters in the CBS increment value registers c (ETNBnCIVRc) and the CBS decrement value registers c (ETNBnCDVRc). These are treated as dynamic settings since they should be updated when streams are registered or erased in accord with IEEE 802.1Qat.

The AVB-DMAC also has CBS upper limit registers c (ETNBnCULc) (the upper limit registers for Classes A and B) and CBS lower limit registers c (ETNBnCLLc) (the lower limit registers for Classes A and B). Set Mfactor to match the credit value and set the upper limit (hiCredit) and the lower limit (loCredit) for each class as defined above.

CUL = hiCredit × Mfactor = maxInterferenceSize × bwFraction × Mfactor

CLL = loCredit × Mfactor = maxFrameSize × (bwFraction - 1) × Mfactor

Example:

Assume that portTransmitRate = 100 Mbps, CHI_freq = 100 MHz and bwFraction = 3%.
Then idleSlope and sendSlope represented as one bit vs. cycles of the peripheral bus clock are as follows.

idleSlope = (portTransmitRate/CHI_freq) × bwFraction = 100/100 (Mbps/MHz) × 3% = 0.030 of a bit per high-speed peripheral bus clock cycle

sendSlope = idleSlope - (portTransmitRate/CHI_freq) = -0.97 bits per peripheral bus clock cycle

Let Mfactor be 100, then CIV and CDV parameters are determined as follows.

CIV = idleSlope × Mfactor = 3.0

CDV = sendSlope × Mfactor = -97

25.4.6.1 Restrictions on CIV, CDV and Mfactor

The maximum value (the minimum value for negative numbers) up to which the credit counter will not overflow determines the maximum values of CIV and CDV that can be set in the CBS registers. This maximum credit value is equivalent to the worst case of the hiCredit value, and the maximum values for Class A and Class B are calculated as follows.

<Conditions>

- Class A maximum value (hiCredit_max_classA)
  classA bwFraction ≅ 100%
  Maintaining the proper relations in the transmission priority order requires waiting for a period equivalent to the maximum frame size.
  hiCredit_max_classA ≅ maxInterferenceSize for Class A = Interference due to one max. sized frame = header + max. size payload + CRC (2000 bytes) + preamble (8 bytes) + IFG (12 bytes) + processing_delay (≅ 80 bytes) ≅ 2100 bytes
- Class B maximum value (hiCredit_max_classB)
  classB bwFraction ≅ 100%
  Maintaining the proper relations in the transmission priority order requires waiting for a period equivalent to the maximum size of frames in the Class A transmission queue and other transmission queues.
  hiCredit_max_classB ≅ maxInterferenceSize for Class B = Interference due to two max-size frames = 2× hiCredit_max_classA ≅ 4200 bytes

hiCredit_max_classA = 16800

hiCredit_max_classB = 33600

The maximum values that can be selected with Mfactor for the 32-bit signed counter without overflow are:

Mfactor_max_classA = 2^{31}-1 / hiCredit_max_classA ≅ 127826 and
Mfactor_max_classB = 2^{31}-1 / hiCredit_max_classB ≅ 63913.

A high degree of accuracy can be achieved even with a low bandwidth. In Class B, bandwidthFraction = 0.05% and the bandwidth error < 0.1%.

The maximum value of CIV is calculated from the following equation.

CIV = idleSlope x Mfactor = (portTransmitRate / CHI_freq) × bandwidthFraction × Mfactor

When Mfactor is the maximum value and bandwidthFraction is the maximum value (up to 100%):

CIV_max_classA = (portTransmitRate / CHI_freq) × Mfactor_max_classA and
CIV_max_classB = (portTransmitRate / CHI_freq) × Mfactor_max_classB.

Table 25.121 shows examples of values for portTransmitRate and peripheral clock frequency. Note that the values in the table are the limits of CIV up to which the 32-bit credit counter will not overflow. The CIV parameters are implemented as 16 bits + a sign bit, so a further limit of CIV ≤ 65535 applies to both Class A and Class B.

Table 25.121 Example of Maximum Values for Class A and Class B CIV Parameters

portTransmitRate	clk_chi[MHz]	CIV_max_classA	CIV_max_classB
100 Mbps	25	511304	255652
100 Mbps	100	127826	63913

25.4.6.2 Credit Incrementation during Inter-Frame Gaps (IFGs)

The inter-frame gap (IFG) after a frame is transmitted is not treated as part of frame transmission by the CSB credit counter. During an IFG, the credit is incremented for all SR queues that have pending frames or negative credit. **Figure 25.49** illustrates credit operations during IFGs.

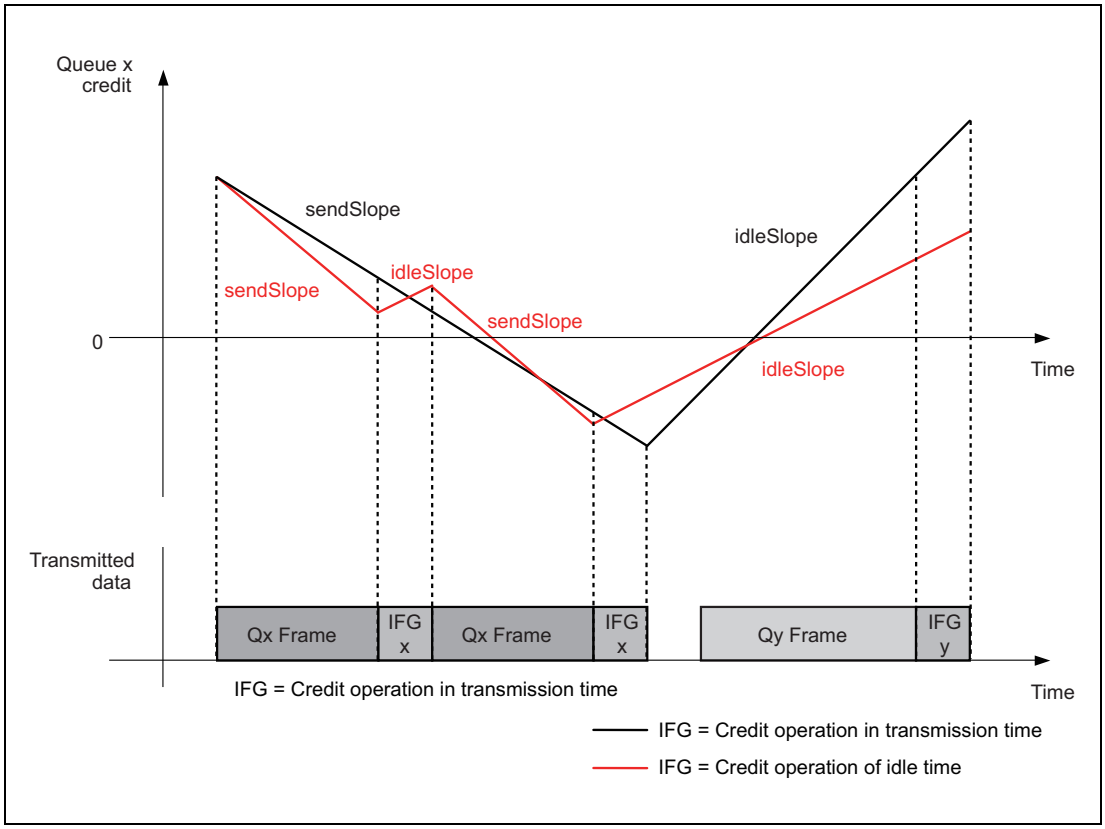

Figure 25.49 Credit Operations during IFGs

Accordingly, the IFG need not be included in calculation of the bandwidth requirements for the specified SR Class when deciding the idleSlope, sendSlope, and CIV and CDV parameters. However, IFG must also be included in the calculation in order to confirm that the total bandwidth allocated to all SR Classes does not exceed 100% of portTransmitRate. This is described in section 35.2.2.8.4 of IEEE 802.1Q.

25.4.6.3 Example

The case of a Class A 48-kHz stereo audio stream among Ethernet frames is described as an example.

After every Class A measurement interval (125 us), 80 octets consisting of two sets of six 32-bit samples plus a 32-octet header are stored as audio data within a frame. The IEEE 802.3 also imposes a 42-octet media-specific framing overhead (an 8-octet preamble, 14-octet IEEE 802.3 header, 4-octet IEEE 802.1Q priority/VID Tag, 4-octet CRC, and 12-octet IFG) are also added. Accordingly, the total frame size is 80 + 42 = 122, and one such frame is transmitted after every class measurement interval.

This represents a total bandwidth of about 7.8 Mbits per second (122 octets × 8 bits per octet × 8000 frames per second) for this class. If the E-MAC is assumed to run at 100 Mbps (portTransmitRate), this is equivalent to the allocation of about 7.8% of the total bandwidth to each Class A queue. If other traffic classes are to share the total transmission bandwidth, checking that this 7.8% allocation does not lead to the total allocation of bandwidth being greater than 100% of portTransmitRate is required.

To obtain the CIV and CDV parameters for a given class, the IFG must not be taken into account in calculation of the frame size must not include the IFG. For this case, therefore, we obtain an 80-bit payload + 30-bit overhead = 110-octet measurement interval for the class ≤ the total bandwidth for the class = 7.04 Mbps = 7.04% of portTransmitRate.

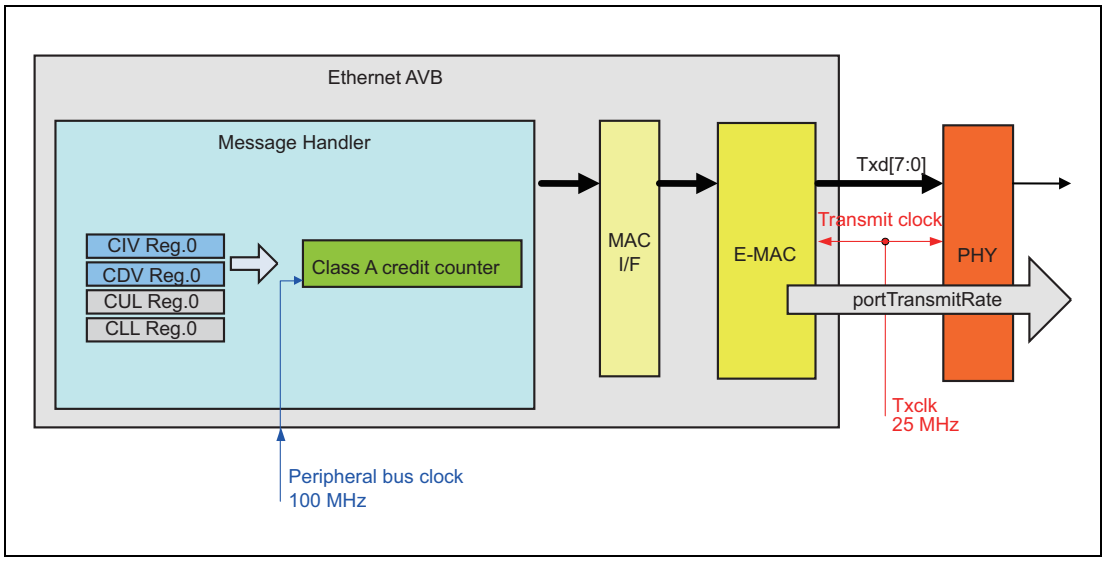

Figure 25.50 Example of CBS Settings

Given that:

- the E-MAC runs at 100 Mbps, so portTransmitRate = 100 Mbps and
- Peripheral bus clock (operating clock for the credit counter) frequency = 100 MHz,

securing a bandwidth of 7.04 Mbits/sec for Class A requires configuring the CBS parameters as follows.

- bandwidthFraction = 7.04%
- idleSlope = (portTransmitRate/CHI_freq) × bandwidthFraction = 0.0704 bits per high-speed peripheral bus clock cycle
- sendSlope = idleSlope – (portTransmitRate/CHI_freq) = –0.9296 bits per high-speed peripheral bus clock cycle

When Mfactor = 100, the parameters are as follows.

- CIV = idleSlope × Mfactor = 7.04 bits per high-speed peripheral bus clock cycle
- CDV = sendSlope × Mfactor = -92.96 bits per high-speed peripheral bus clock cycle

These are the final values for setting in the ETNBnCIVR1 and ETNBnCDVR1 registers.

25.4.7 IEEE802.1: gPTP

25.4.7.1 gPTP Timer

An 84-bit timer is provided to support the gPTP function. **Figure 25.51** shows the definitions of bits for the timer and in related registers. gPTP timer will start after ETNBnCCC.CSEL configure and transit to operation mode.

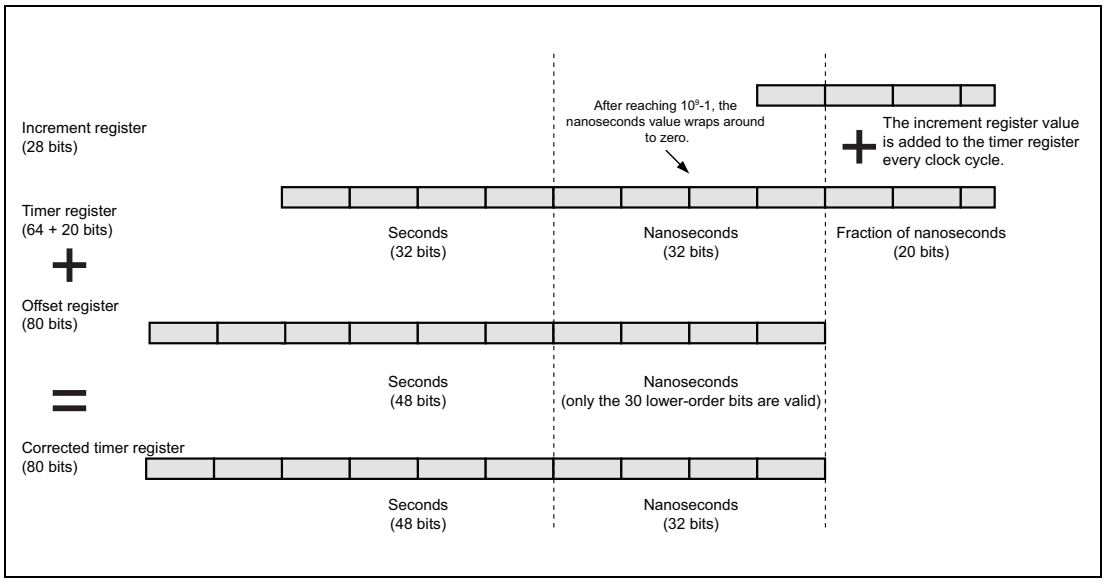

Figure 25.51 Definitions of gPTP Timer Bits and Related Bits

The higher-order 32 bits indicate seconds. For the next 32 bits, counting by one corresponds to the passage of 1 ns. The lower-order 20 bits are a fractional value (less than 1 ns). Software can only read the higher-order 32 bits, indicating seconds, and the subsequent 32-bits, indicating nanoseconds. The lower-order 20 bits, representing less than 1 ns, are not readable. They are only used within the AVB-DMAC to maintain accuracy in time measurement.

The timer can be reset by setting the timer control request bits in the gPTP configuration control register (ETNBnGCCR.TCR[1:0]) to 01_B. These bits are set to 00_B on completion of normal resetting of the timer.

After the timer starts, the value in the gPTP timer increment register (ETNBnGTI.TIV) is added to the value of the gPTP timer every clock cycle.

After setting a value in the gPTP timer increment register (ETNBnGTI.TIV), set the timer increment value setting request bit in the gPTP configuration control register (ETNBnGCCR.LTI). If this bit is not set to 1, new values that are written will not be reflected in the register. This bit returns to 0 after the setting is completed.

An offset to the gPTP timer is also available. If this is required, set the value in the gPTP timer offset register (ETNBnGTOi.TOV). After setting a value in this register, set the timer offset value setting request bit in the gPTP configuration control register (ETNBnGCCR.LTO). If this bit is not set to 1, new values that are written will not be reflected in the register. This bit returns to 0 after the setting is completed. When adding an offset, take care that it does not exceed 80 bits.

The value of the gPTP timer can be read from the gPTP timer capture register (ETNBnGCTi.CTV). Set the timer capture source select bits in the gPTP configuration control register (ETNBnTCCR.TCSS) to select the timer value for capture as the value of the gPTP timer, the corrected value of the gPTP timer (value with the offset added), or the AVTP presentation time. Setting the timer control request bits in

the gPTP configuration control register (ETNBnGCCR.TCR[1:0]) to 11_B initiates the capture. Once normal capture of the timer is complete, the value of the timer control request bits in the gPTP configuration control register (ETNBnGCCR.TCR[1:0]) returns to 00_B.

The timer for gPTP operates as a free-running timer but can be synchronized with the Grandmaster clock.

25.4.7.2 Free-Running Operation

The IEEE 802.1 AS standard for timing and synchronization does not prescribe the physical adjustment of local clocks to the Grandmaster clock. To avoid negative effects from the correction procedure, we recommend the use of a free-running timer.

As a free-running timer, the timer counts the local time in seconds or nanoseconds. The gPTP timer increment register (ETNBnGTI.TIV) is set to 1 ns (the setting value = 0010 0000_H) and the gPTP timer offset register (ETNBnGTOi.TOV) is set to 0. The ratio information captured at the time of the gPTP delay measurement and synchronization procedures is used to correct the frequency ratio to that of the Grandmaster clock. The Grandmaster clock can be calculated from the local clock by using the information collected during the gPTP measurement and synchronization procedures.

25.4.7.3 Synchronization with the Grandmaster Clock

In situations requiring physical synchronization of the local clock with the Grandmaster clock, the fractional nanoseconds value (the 20 lower-order bits of the gPTP timer) is used to make the adjustment. Specifically, the increment value is finely adjusted to correct for deviations of the clock frequency from that of the Grandmaster clock.

Use the timer offset value (in the gPTP timer offset registers, ETNBnGTOi.TOV) to correct for offsets from the theoretical value (at start-up, etc.). The sum of the timer value and the offset register is the “corrected timer” value.

Note that only the nanoseconds portion of the gPTP timer offset registers (ETNBnGTOi.TOV[31:0]) is valid.

The following equation gives a method of calculating the increment (ETNBnGTI.TIV) from the frequency of the gPTP clock and its deviation from that of the Grandmaster clock. Variable d is the deviation (d = 10^{-6} for 1 ppm).

$$ETNBnGTI.TIV = round\left(\frac{2^{20}GHz}{f_{GPTP}} \times (1+d)\right)$$

After adjusting for the current deviation of clock frequency, re-set the gPTP timer increment register (ETNBnGTI.TIV).

After calculating the new offset value, re-set the gPTP timer offset register (ETNBnGTOi.TOV).

25.4.7.4 Continuous AVTP capture

By setting ETNBnGCCR.TCR to 10_B continuous AVTP timer value capture is activated. In this mode CPU has always access to current AVTP value by reading ETNBnGCTi.CTV[31:0].

The following flow should be used to enter continuous AVTP capture mode.

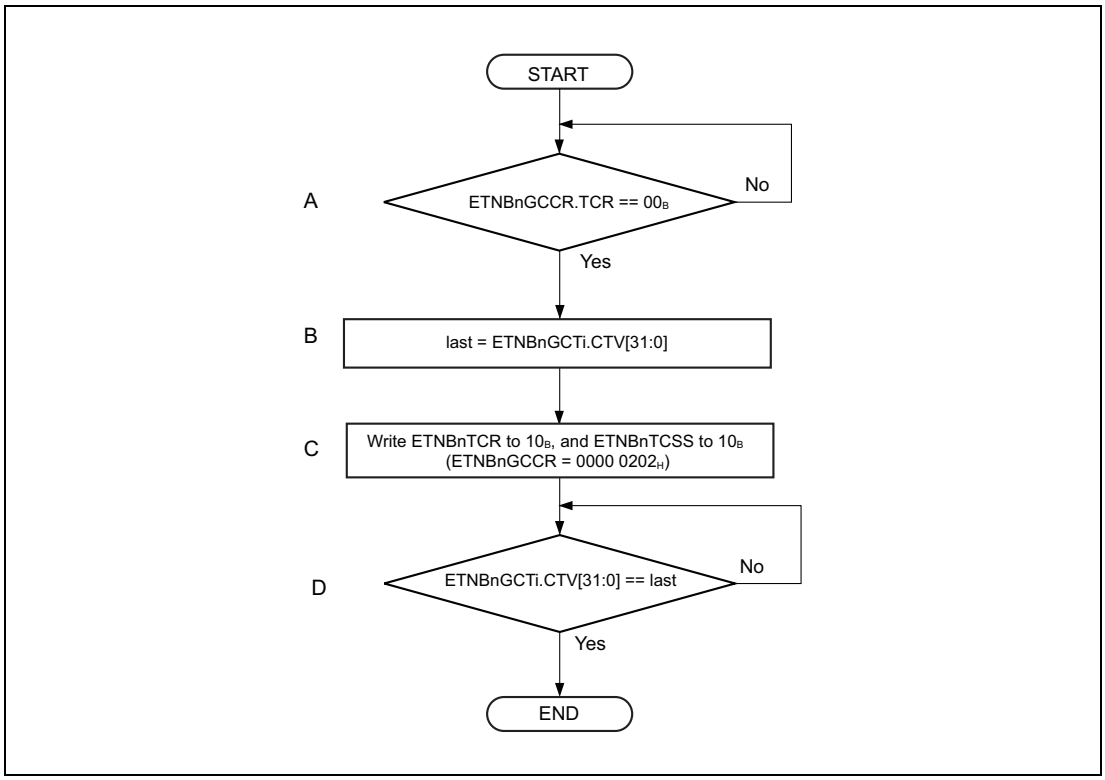

Figure 25.52 SW flow entering continuous AVTP capture mode

The following flow should be used to leave continuous AVTP capture mode.

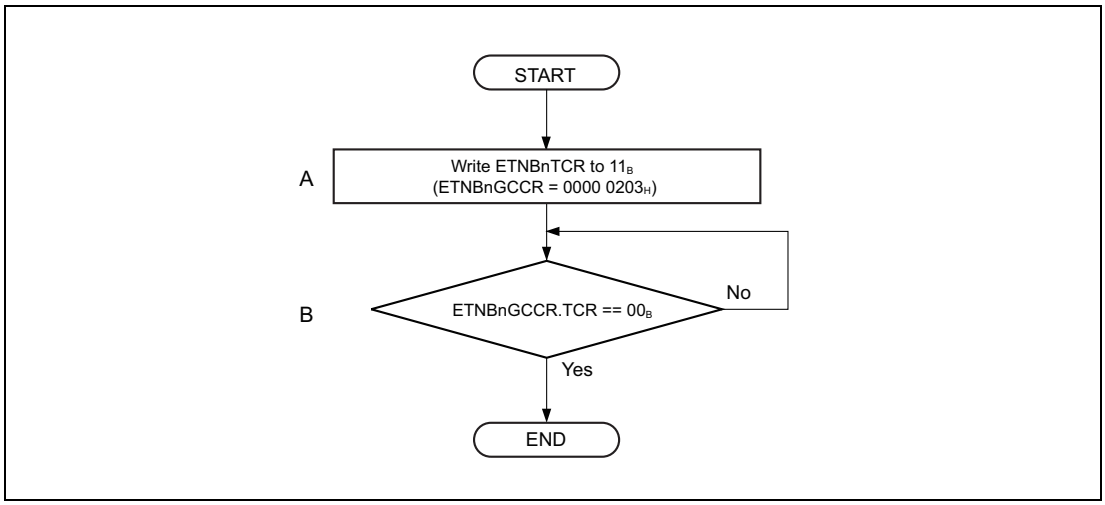

Figure 25.53 SW flow leaving continuous AVTP capture mode

25.4.7.5 Support Provided by the gPTP Timer in Transmission and Reception

The timer value described above is used in the timestamp values captured when start frame delimiters are detected in reception and generated in transmission.

Captured timestamp values for received frames are stored in the corresponding descriptors. Those for transmitted frames are stored with tag information in the timestamp FIFO. The timestamp values are thus correlated with both transmitted and received frames.

Note that the use of corrected timer values can introduce an error due to the offset correction in the gPTP synchronization procedure.

Errors due to the SDF notification and the asynchronous interface between the timer modules must also be taken into account.

25.4.8 Support for IEEE 1722

For IEEE 1722, the following two functions are supported.

- Output and capture of values in the IEEE 1722 AVTP (Audio/Video Transport Protocol) presentation time format
- Comparison of IEEE 1722 AVTP presentation timestamps

The 32-bit AVTP timestamp field of IEEE 1722 frames holds the AVTP presentation time when the AVTP timestamp enable bit in the frame is 1. The AVTP timestamp field is generated from the gPTP timer and is given as seconds (gPTP_seconds) and nanoseconds (gPTP_nanoseconds) according to the following equation.

AVTP timestamp = (gPTP_seconds × 10^9 + gPTP_nanoseconds) modulo 2^{32}

The AVTP presentation time can be read from the gPTP timer capture register (ETNBnGCTi.CTV). Set the timer capture source select bits in the gPTP configuration control register (ETNBnGCCR.TCCS) to select the timer value for capture as the AVTP presentation time. Setting the timer control request bits in the gPTP configuration control register (ETNBnGCCR.TCR[1:0]) to 11_B initiates the capture. The value is obtained by adding the maximum transit time defined in the gPTP maximum transit time register (ETNBnGMTT.MTTV) to the corrected timer value. The AVTP presentation time wraps around approximately every four seconds.

CAUTION

The AVTP presentation time captured in ETNBnGCTi.CTV is only valid when the corrected timer value is in synchronization with the Grandmaster clock. That is, the timer increment and timer offset values for the corrected timer value must be adjusted during the synchronization procedure so that the corrected gPTP clock is physically adjusted to match the time kept by the Grandmaster clock.

25.4.8.1 AVTP compare

AVB-DMAC provides 8 independent AVTP compare units. Each unit is able to handle single shot comparison as well as periodic comparison. ETNBnGSR.PCMi informs about the current mode of unit i. To 4 units the single shot compare value can provided via AVTP-FIFO to relax timing requirements to application SW.

When the AVTP Presentation Time value has reached or exceeded the configured comparison value a pulse of one clk_chi (peripheral bus clock) clock cycle is applied to the interrupt flag ETNBnGIS.PTMFi is set to 1.
The configured max transit time value is not taken in count when comparing.
SW should ensure that configured comparison value is well in future to take into account SW inaccuracy.
SW should ensure that comparison value is not too far in future (more than 2 seconds) with respect to current AVTP timer value to guarantee comparison functionality.

When writing to ETNBnGCCR, SW can use a 32-bit access if ETNBnGCCR.TCSS is written to 11_B and all other bits not required for comparison value programming are written to 0.

(1) Single shot compare

An AVTP compare unit used in single shot mode generates exactly one match after CPU programs the comparison value. The following flow should be used to program absolute comparison values in single shot mode.

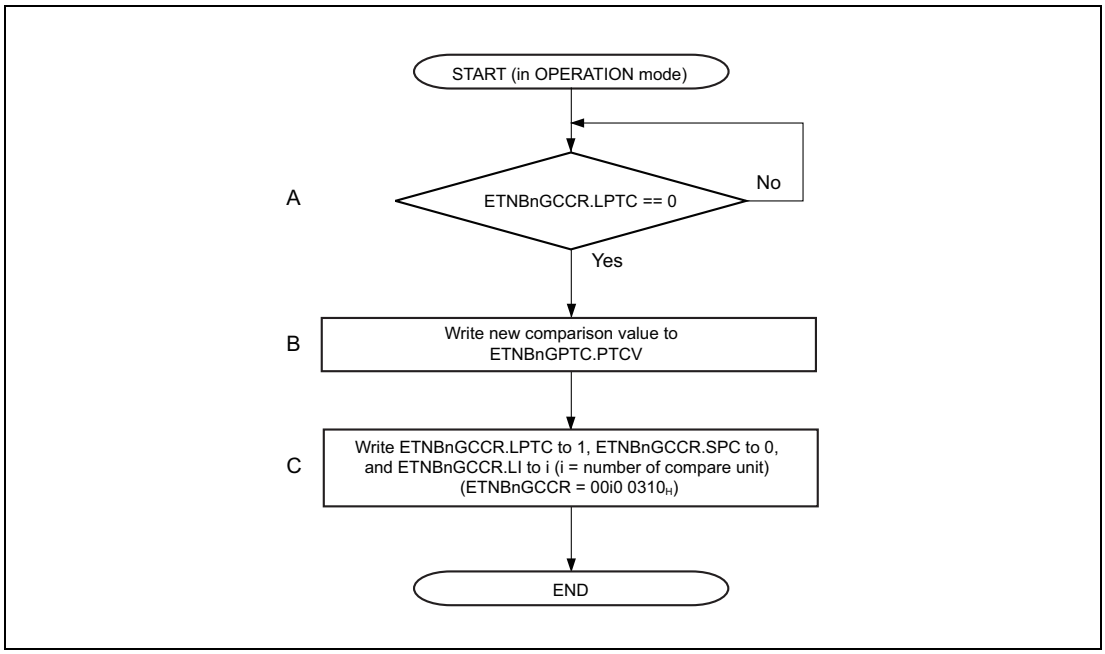

Figure 25.54 SW flow to program a single shot compare value

(2) Periodic compare

An AVTP compare unit used in periodic compare mode generates matches of configured period until CPU disables periodic mode. Optionally, it is possible to define the initial phase before repetition starts.

The following flow should be used to start periodic compare mode or to change period value.

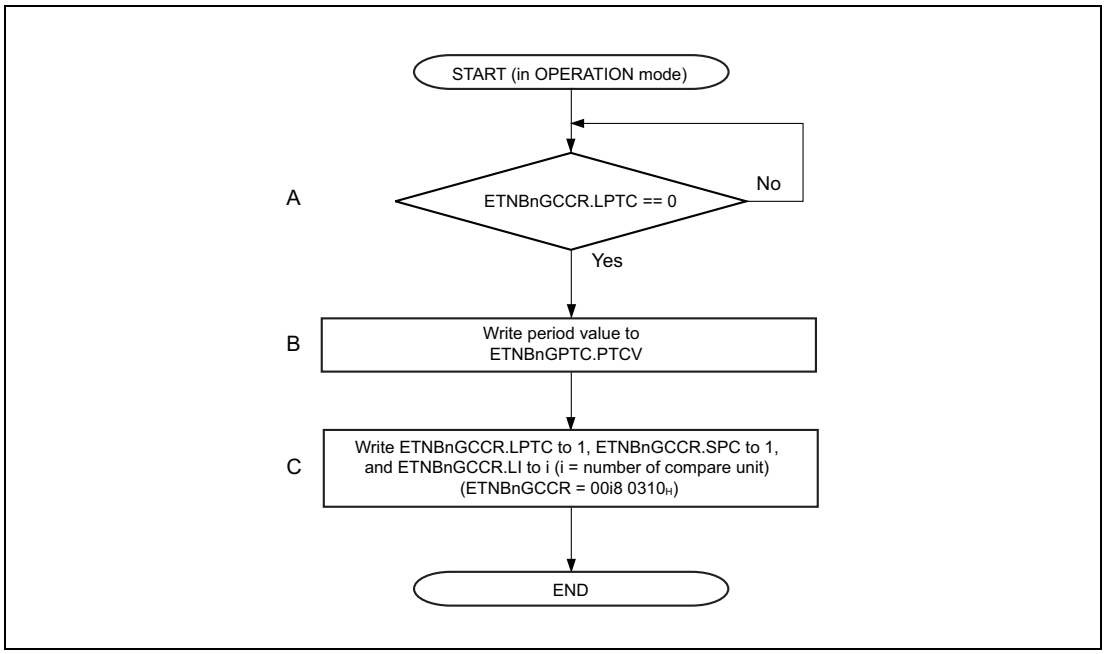

Figure 25.55 SW flow to program period value (without phase relation)

Some application may require phase relation between periodical match events generated by different units. In this case the next flow can be used to enter periodic compare mode with phase relation. A compare unit will only start a period when there is no pending comparison. If the absolute starting point of all units (box B in flow) is well in future the period of all units start at the same time (e.g. 48 kHz on unit 1 and 96 kHz on unit 2).

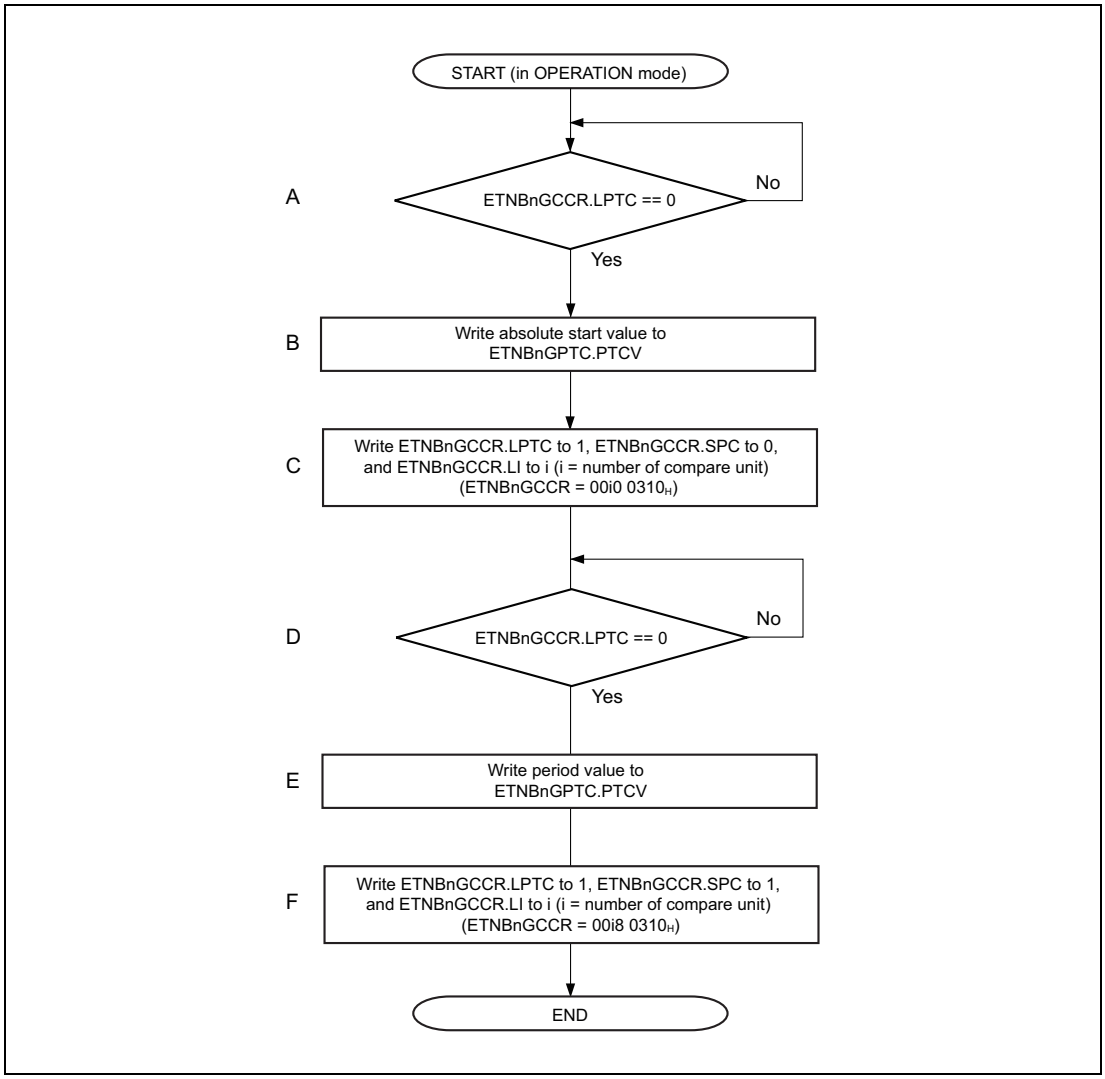

Figure 25.56 SW flow to program period value (with phase relation)

The periodic mode is left by entering single-shot mode. Do not write new comparison value in ETNBnGPTC.PTCV for changing mode as shown in flow below, this value will not be used as new comparison value.

The following flow should be used to leave periodic compare mode.

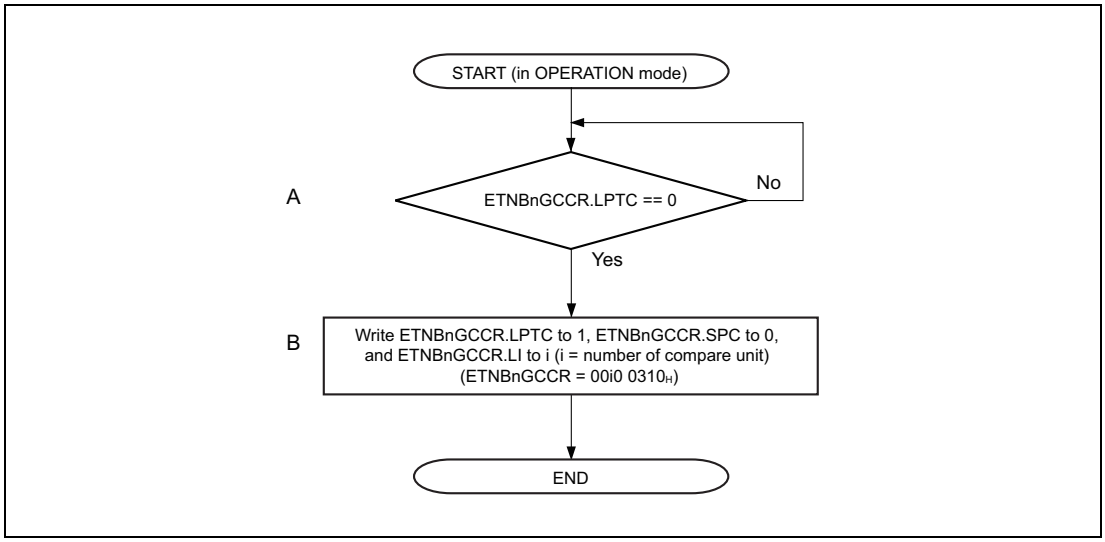

Figure 25.57 SW flow to end period mode

The last periodical comparison happens after Point B in SW flow. AVB-DMAC leaves periodic mode after last periodical comparison happens. This is flagged by ETNBnGSR.PCMi. Comparison unit can only be reused after ETNBnGCR.PCMi is 0.

(3) FIFO based single-shot compare

Some comparison units provides the possibility to use timestamps from a FIFO. To use this possibility CPU writes AVTP timestamp to ETNBnGPTFi instead of ETNBnGPTC. By writing to ETNBnGPTFi the value is added to FIFO, no load is required but CPU needs to check if AVTP-FIFO is able to accept new values.

FIFO usage may reduce CPU load because CPU can program a bunch of timestamps at same time. When there is no comparison ongoing in AVTP compare unit, the next value from AVTP-FIFO is loaded and comparison starts. If the FIFO is empty no value is loaded and no further match event is generated.
When moving from single-shot comparison to FIFO based single-shot comparison, the 1st FIFO value is immediately loaded independent of an ongoing comparison.
By reading ETNBnGSR.AFFLi CPU can observe number of pending timestamps.

The following flow should be used to add timestamps to the AVTP-FIFO of compare unit. If FIFO depth is insufficient, FIFO size should be extended in SW (box E).

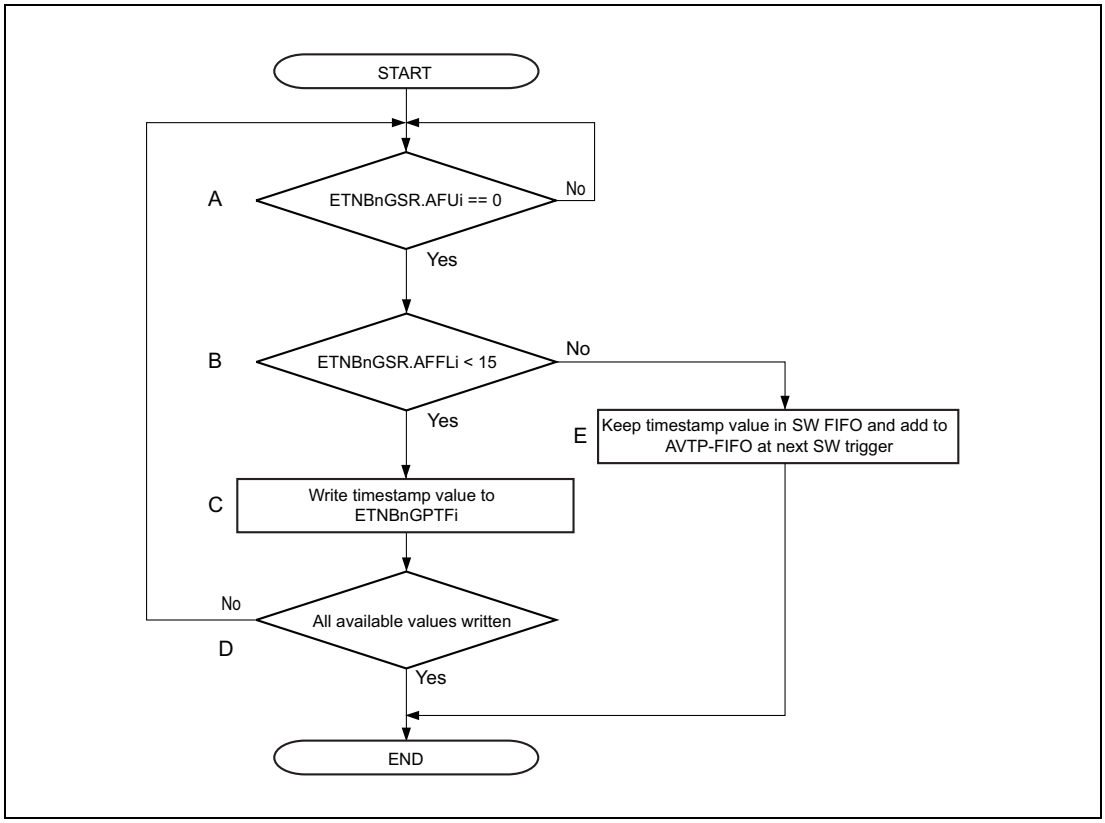

Figure 25.58 SW flow to add timestamp to AVTP-FIFO

It is recommended to combine box A and B into one access to limit accesses to ETNBnGSR register.

25.4.9 gPTP Timer Functionality in Configuration Mode

When ETNBnCCC.GAC is 1, it is possible to use some gPTP functions in configuration mode. Because the frame handling mechanisms are not available in configuration mode, usage of gPTP support is restricted. Only basic timer functions of gPTP support can be used:

- gPTP timer is running based on selected clock source (ETNBnCCC.CSEL).
- Offset and increment value can be configured and adjusted.
- Capture function (timer, corrected timer, AVTP)
- SW compare function

When AVTP FIFO functionality is used in configuration mode, there is no error flagging by ETNBnESR.ET = 1011_B available.

25.4.10 Flow Control

The E-MAC supports flow control for full-duplex operation in compliance with the IEEE 802.3 standards. This flow control is applicable to both reception and transmission. In regard to the transmission of PAUSE frames, flow control operates in the following ways.

(1) PAUSE Frame Transmission

PAUSE frames can also be transmitted in response to software operations. Writing a timer value to the manual PAUSE frame register (ETNBnMPR) starts the transmission of a PAUSE frame. This only causes the transmission of one PAUSE frame.

(2) PAUSE Frame Reception

After reception of a PAUSE frame, transmission of the next frame does not proceed until the time indicated by the Timer value elapses. However, transmission of a frame currently being transmitted continues. PAUSE frames are only received while the operation mode for flow control in reception in the E-MAC mode register (ETNBnECMR.RXF) is set to “1”. The number of received PAUSE frames is counted.

(3) PAUSE Frames with the Timer Value 0

The setting of the 0-time PAUSE frame enable bit (ETNBnECMR.ZPF) enables or disables the reception and transmission of PAUSE frames with the TIME parameter value 0.

- When control of PAUSE frames with the TIME parameter value 0 is enabled
  A PAUSE frame with the TIME parameter value 0 is transmitted when the capacity of the reception FIFO is less than the value of the Receive FIFO Warning Level bits (ETNBnRCR.RFCL[12:0]) while the time indicated by the TIME parameter value has not elapsed.
  Reception of a PAUSE frame with the TIME parameter value 0 leads to release from the transmission standby state.
- When control of PAUSE frames with the TIME parameter value 0 is disabled
  PAUSE frames with the TIME parameter value 0 are not transmitted. Received PAUSE frames with the TIME parameter value 0 are discarded.

25.4.11 Interrupts

The EthernetAVB module has three EI level interrupts from the AVB-DMAC and one EI level interrupt from the E-MAC.

Table 25.122 lists interrupts.

Table 25.122 EthernetAVB Interrupts

Interrupt Source Name
Transmit/receive data management interrupt
Error management interrupt
Other management (FIFO caution level, etc.) interrupt
E-MAC interrupt

The AVB-DMAC related interrupts include descriptor interrupts (15 sources), error interrupts (11 sources), reception interrupts (56 sources), transmission interrupts (8 sources), and gPTP interrupts (8 source). From the CPU's perspective, each appears as three of the above four interrupt sources.

The states of an AVB-DMAC-related interrupt sources can be checked in the following registers.

- Descriptor interrupt status register (ETNBnDIS)
- Error interrupt status register (ETNBnEIS)
- Receive interrupt status register (ETNBnRIS0 to 2)
- Transmit interrupt status register (ETNBnTIS)
- gPTP interrupt status register (ETNBnGIS)

The interrupts are controlled by the corresponding interrupt enable bits. However, the status flags operate independently of the settings of the enable bits.

The states of grouped interrupts can only be checked by reading the interrupt summary status register (ETNBnISS) and the queue full error interrupt status bit in the error interrupt status register (ETNBnEIS.QFS). This reduces the load on the CPU.

25.4.11.1 Transmit/Receive Data Management Interrupt

The management interrupt for transmission and reception is conveyed when the following interrupt sources are generated:

- Receive frame interrupt in the receive interrupt status register 0 (ETNBnRIS0.FRFr)
- Receive warning interrupt in the receive interrupt status register 1 (ETNBnRIS1.RWFr)
- Frame transmitted interrupt in the transmit interrupt status register (ETNBnTIS.FTFt)
- Descriptor interrupt in the descriptor interrupt status register (ETNBnDIS.DPFi)

The general error interrupt state can be checked by reading the descriptor interrupt summary bits in the interrupt summary status register (ETNBnISS.DPMi), the frame received interrupt summary bit (ETNBnISS.FRM), the receive warning interrupt summary bit (ETNBnISS.RWM) and the frame transmitted interrupt summary bit (ETNBnISS.FTM).

25.4.11.2 Error Management Interrupt

The error management interrupt is conveyed when interrupt conditions corresponding to the following sources are satisfied.

- Tx-Buffer full interrupt when delaying fetching of transmit frame (ETNBnEIS.TBFF)
- Interrupt for MAC Status FIFO overwrite (ETNBnEIS.MFFF)
- Timestamp FIFO full error interrupt in the error interrupt status register (ETNBnEIS.TFFF)
- CBS limitation interrupts in the error interrupt status register (ETNBnEIS.CULF1, ETNBnEIS.CULF0, ETNBnEIS.CLLF1, ETNBnEIS.CLLF0)
- Separation Error in the error interrupt status register (ETNBnEIS.SEF)
- Queue Error in the error interrupt status register (ETNBnEIS.QEF)
- MAC Transmission Error in the error interrupt status register (ETNBnEIS.MTEF)
- MAC Reception Error in the error interrupt status register (ETNBnEIS.MREF)
- Receive FIFO full interrupt in the receive interrupt status register 2 (ETNBnRIS2.RFFF)
- Receive queue full interrupt in the receive interrupt status register 2 (ETNBnRIS2.QFFr)

The general error interrupt state can be checked by reading the error interrupt summary bit in the interrupt summary status register (ETNBnISS.EM).

25.4.11.3 Other Management (FIFO Warning, etc.) Interrupts

The other management (FIFO warning, etc.) interrupt is conveyed when interrupt conditions corresponding to the following sources are satisfied.

(1) Reception related interrupt

Receive FIFO warning interrupt in the receive interrupt status register 1 (ETNBnRIS1.RFWF)

(2) Transmission related interrupts

MAC status FIFO warning interrupt in the transmit interrupt status register (ETNBnTIS.MFWF)

MAC status FIFO update interrupt in the transmit interrupt status register (ETNBnTIS.MFUF)

Timestamp FIFO warning interrupt in the transmit interrupt status register (ETNBnTIS.TFWF)

Timestamp FIFO update interrupt in the transmit interrupt status register (ETNBnTIS.TFUF)

(3) gPTP related interrupts

AVTP presentation target match interrupt in the gPTP interrupt status register (ETNBnGIS.PTMFi)

The general error interrupt state can be checked by reading the receive FIFO warning error interrupt status bit in the interrupt summary status register (ETNBnISS.RFWM), the MAC status FIFO warning interrupt status bit (ETNBnISS.MFWM), the MAC status FIFO updated interrupt status bit (ETNBnISS.MFUM), the timestamp FIFO warning interrupt status bit (ETNBnISS.TFWM), the timestamp FIFO update interrupt status bit (ETNBnISS.TFUM), and the combined gPTP interrupt status bit (ETNBnISS.CGIM).

25.4.11.4 E-MAC Interrupt

The E-MAC interrupt is conveyed when the E-MAC interrupt source is generated.

The general error interrupt state can be checked by reading the E-MAC interrupt summary bit in the interrupt summary status register (ETNBnISS.MM).

25.4.12 Flows of Operations

25.4.12.1 Flow of E-MAC Initialization

Figure 25.59 shows the flow of E-MAC initialization (for AVB mode and full-duplex operation).

25.4.13 Connection to PHY-LSI

25.4.13.1 Accessing MII Registers

MII registers in the PHY-LSI are accessed via ETNBnPIR in this LSI. ETNBnPIR is used as a serial interface conforming to the MII frame format specified in IEEE802.3u.

25.4.13.2 MII Management Frame Format

Figure 25.73 shows the format of an MII management frame. To access an MII register, a management frame is implemented by the program in accordance with the procedures shown in **25.4.13.3 MII Register Access Procedure**.

Access Type	MII Management Frame							
Item	PRE	ST	OP	PHYAD	REGAD	TA	DATA	IDLE
Number of bits	32	2	2	5	5	2	16	
Read	1..1	01	10	00001	RRRRR	Z0	D..D	
Write	1..1	01	01	00001	RRRRR	10	D..D	X

[Legend]

PRE: 32 consecutive 1s
ST: Write of 01_B indicating start of frame
OP: Write of code indicating access type
PHYAD: Write of 00001_B if the PHY-LSI address is 1 (sequential write starting with the MSB).
This bit changes depending on the PHY-LSI register address.
REGAD: Write of 0001_B if the register address is 1 (sequential write starting with the MSB).
This bit changes depending on the PHY-LSI register address.
TA: Time for switching data transmission source on MII interface
(a) Write: 10_B written
(b) Read: Bus release (notation: Z0) performed
DATA: 16-bit data. Sequential write or read from MSB
(a) Write: 16-bit data write
(b) Read: 16-bit data read
IDLE: Wait time until next MII management format input
(a) Write: Independent bus release (notation: X) performed
(d) Read: Bus already released in TA: control unnecessary

Figure 25.73 MII Management Frame Format

25.4.13.3 MII Register Access Procedure

The program accesses MII registers via ETNBnPIR. Access is implemented by a combination of 1-bit-unit data write, 1-bit-unit data read, bus release, and independent bus release. **Figure 25.74** to **Figure 25.77** show the MII register access timing. The timing will differ depending on the PHY-LSI type.

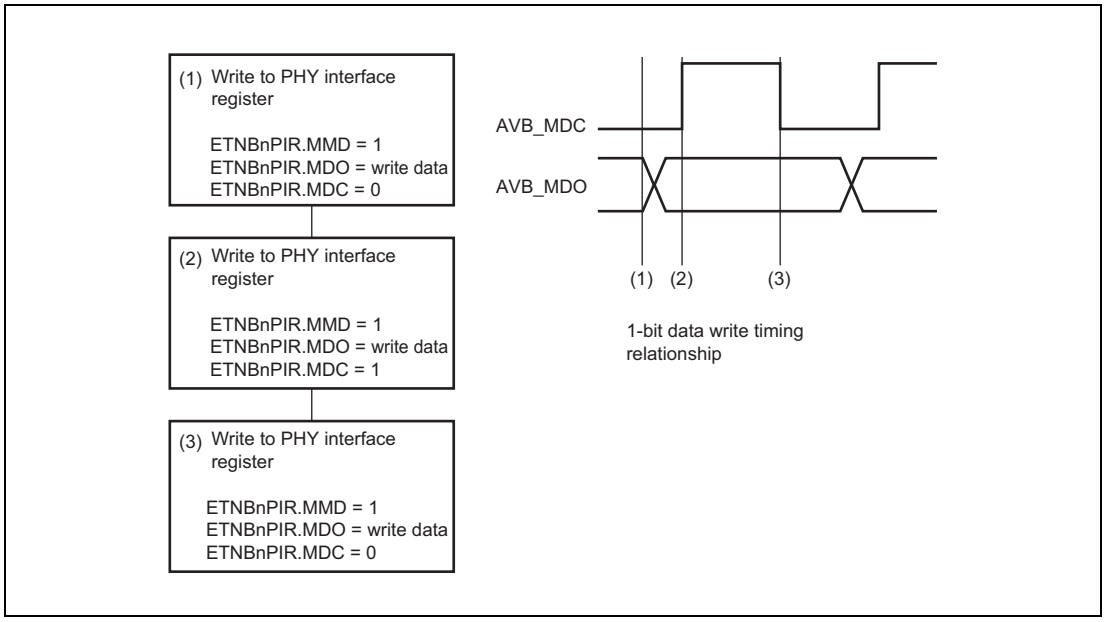

Figure 25.74 1-Bit Data Write Flowchart

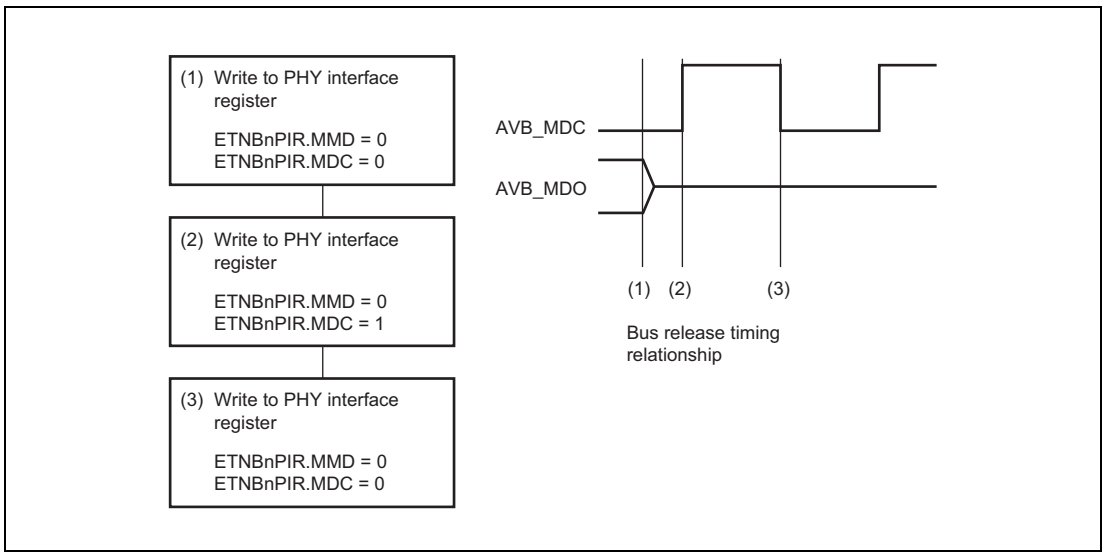

Figure 25.75 Bus Release Flowchart (TA in Read in Figure 25.73)

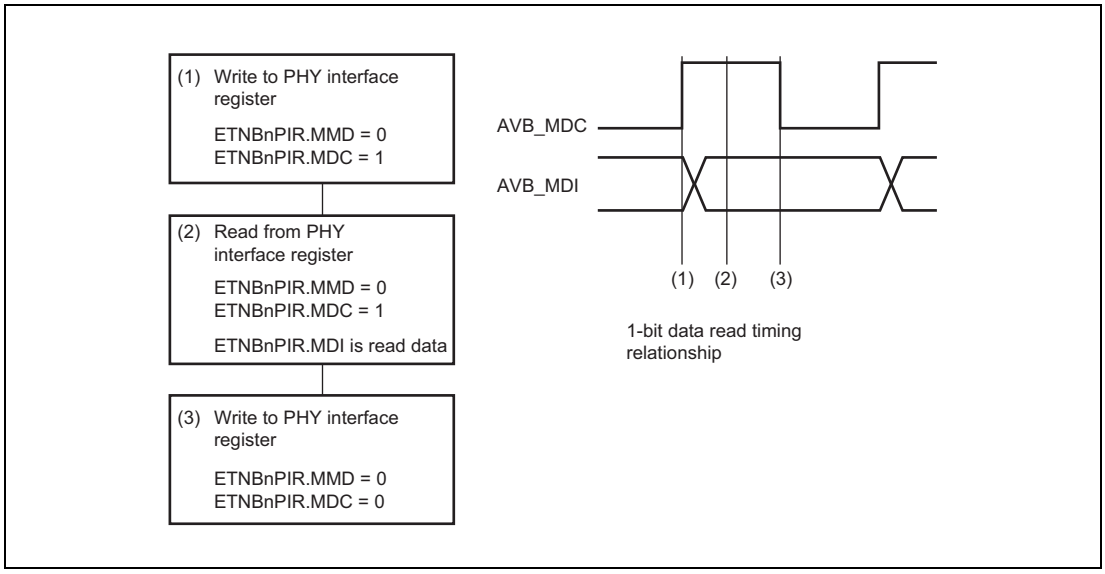

Figure 25.76 1-Bit Data Read Flowchart

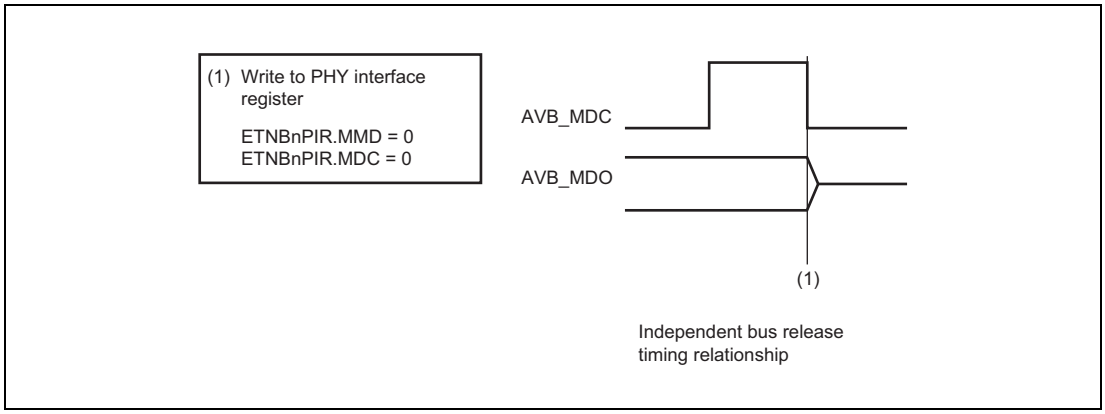

Figure 25.77 Independent Bus Release Flowchart (IDLE in Write in Figure 25.73)

25.4.14 SGMII interface

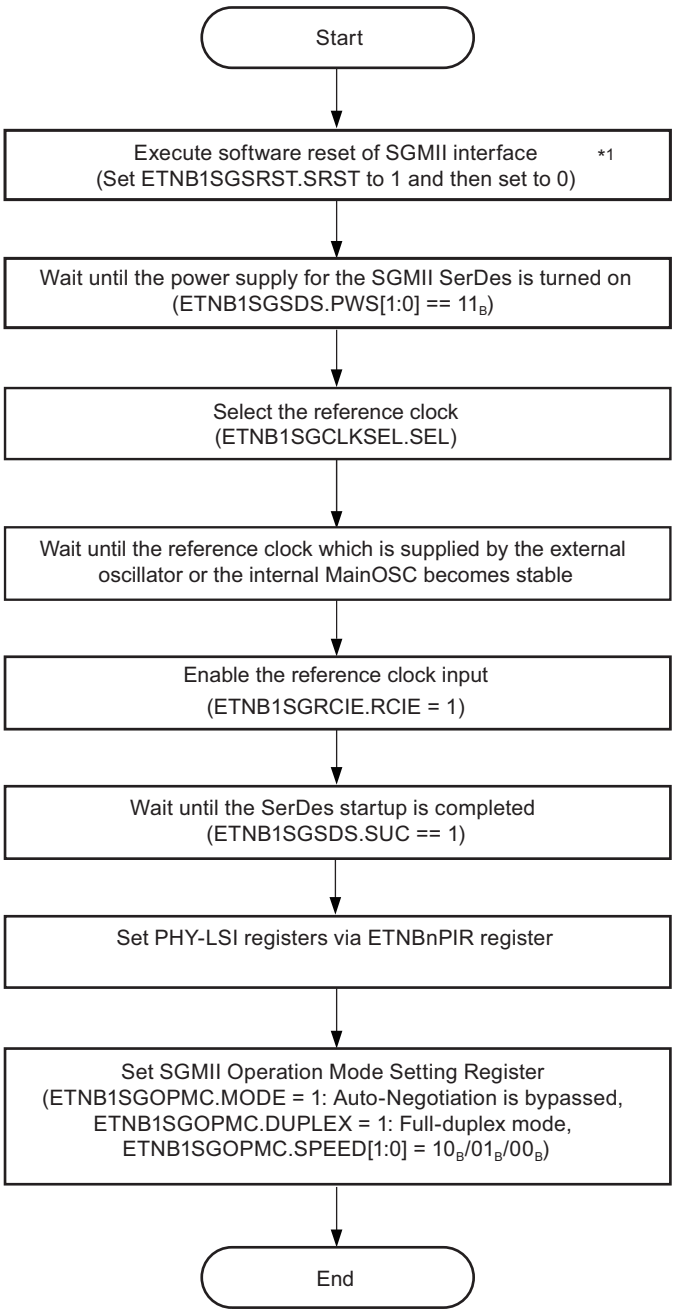
25.4.14.1 SGMII SerDes Power Control

The Power supply for the SGMII SerDes is controlled as follows.

- After power-on reset, the power supply for the SGMII SerDes is off.
- When the ETNB is in Module standby mode, the power supply for the SGMII SerDes is kept off. When the Module standby of the ETNB is cancelled, the power supply for the SGMII SerDes is turned on. When the ETNB transits to Module standby mode again, the power supply for the SGMII SerDes is turned off again.
- When the reset (which sources are shown in **Section 25.1.5, Reset Sources**) for the ETNB is activated, the power supply for the SGMII SerDes is turned off. At this time. the MSR_ETNB register (Module Standby Register for ETNB) is also reset, so the ETNB transits to Module standby mode, and the power supply for SGMII SerDes is kept off until the Module standby mode is cancelled.
- When the chip transits to STOP mode (refer to **Section 15, Standby Controller (STBC)**), the power supply for the SGMII SerDes is turned off. When the STOP mode is cancelled, the power supply for the SGMII SerDes is turned on.

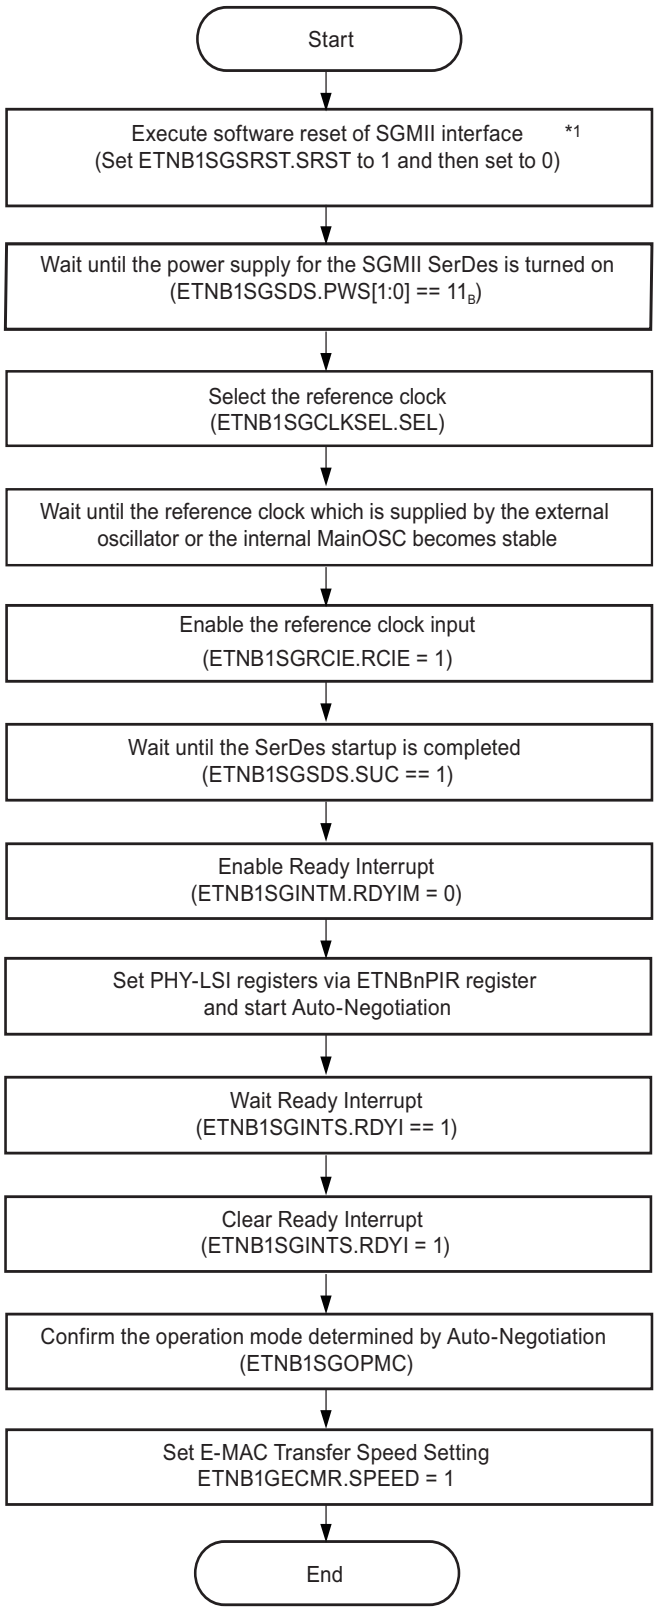
25.4.14.2 SGMII System Startup

After cancelling Module standby mode of the ETNB or STOP mode, before operating AVB-DMAC and E-MAC, the CPU must follow the sequence of steps shown in **Figure 25.78** or **Figure 25.79**. The **Figure 25.78** shows the flow in the case when Auto-Negotiation with PHY-LSI is bypassed (ETNB1SGOPMC.MODE = 1). The **Figure 25.79** shows the flow in the case when Auto-Negotiation with PHY-LSI is not bypassed (ETNB1SGOPMC.MODE = 0).



Note 1. Need to input Configuration pattern or IDLE Ordered Set pattern more than 4µs.
The note doesn't apply for RH850/U2A-EVA.

Figure 25.78 SGMII System Startup (Auto-Negotiation with PHY-LSI is bypassed)



Note 1. Need to input Configuration pattern or IDLE Ordered Set pattern more than 4µs.
The note doesn't apply for RH850/U2A-EVA.

Figure 25.79 SGMII System Startup (Auto-Negotiation with PHY-LSI is not bypassed)

25.4.15 Usage Notes

25.4.15.1 Checksum Calculation of Ethernet Frames

This LSI is capable of calculating the checksum data of the received frames. Only the data fields of the Ethernet frames are subject to checksum calculation. Specifically, a data field follows the length/type field and is followed by the CRC field. **Figure 25.80** shows schematics indicating which parts of the Ethernet frames are calculated. Calculation involves 16-bit addition only; it does not involve bit inversion. Note that when the checksum data is valid, the CRC data (4 bytes) is not transferred as a receive frame, and the checksum data (sum data) is added automatically. **Figure 25.81** shows schematics of Ethernet frames to which the checksum data has been added.

CAUTION

Also for the frames with VLANtag inserted, the 15th byte from the top and the following bytes before the CRC field are subject to calculation.

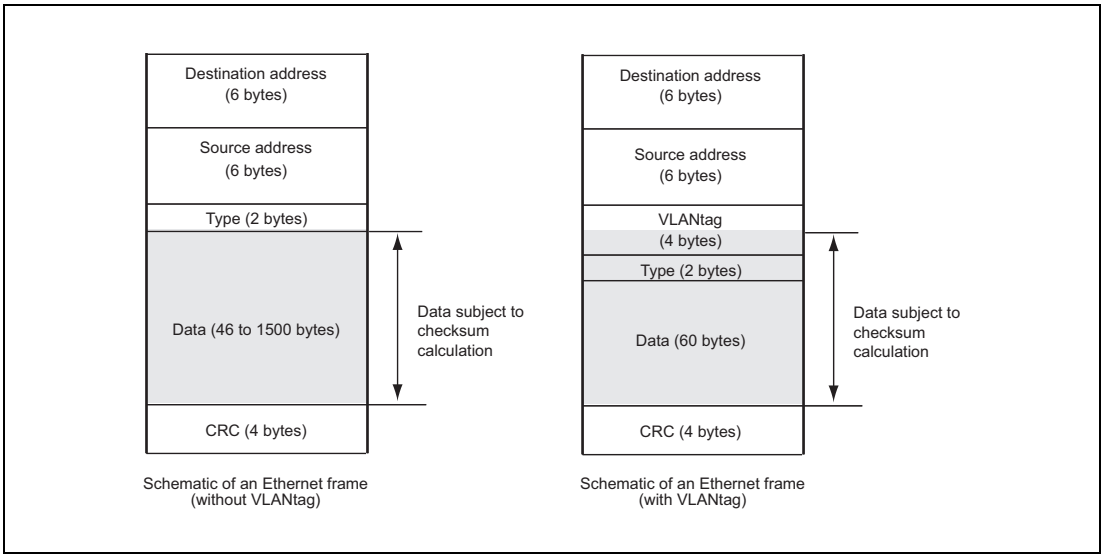


Figure 25.80 Data Subject to Checksum Calculation

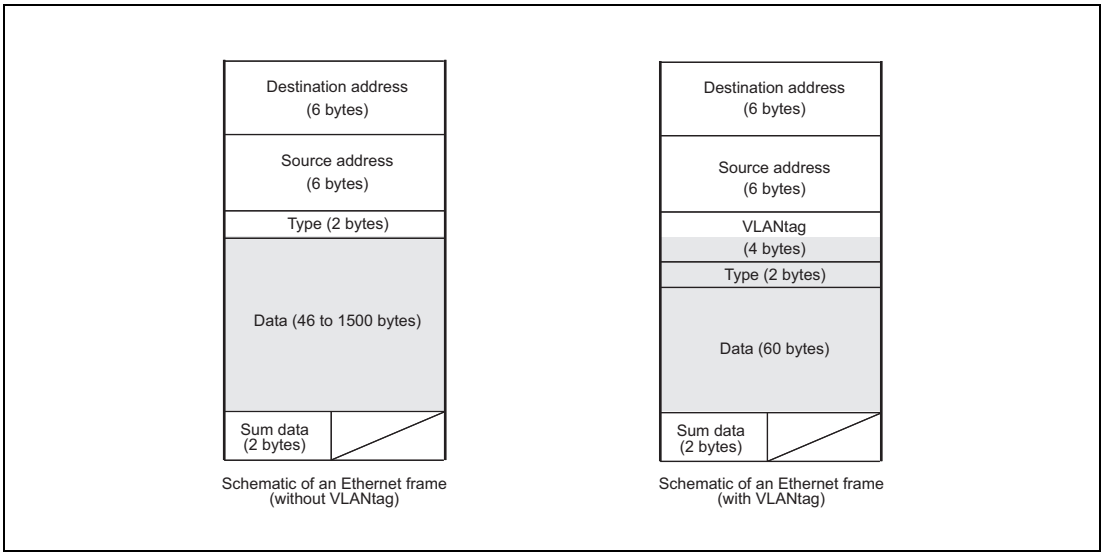

Figure 25.81 Data after Checksum Data Addition

25.4.15.2 Rx-FIFO read error may not be flagged when using FEMPTY_ND descriptor

After reading the last byte targeted to the FEMPTY_ND descriptor, there can be up to 3 bytes read from Rx-FIFO targeted to the next descriptor of the same frame. Rx-FIFO read errors of not stored data due to FEMPTY_ND are neither flagged in DESCR.EI nor by ETNBnEIS.QEF as per target specification.

When external ECC logic flags detect Rx-FIFO read error related to last byte targeted to FEMPTY_ND descriptor, data in the next descriptor may be corrupted without notification.

The issue is limited to implementations where Rx-FIFO error information is provided to Ethernet AVB and also to applications using FEMPTY_ND descriptor.

The issue only occurs when the first byte saved in the descriptor following FEMPTY_ND is not a multiple of 4 bytes inside the received frame.

Use a FEMPTY descriptor to store unwanted data if consistent error flagging is required.

25.4.15.3 When trying to release non-existing timestamp FIFO entry, new FIFO update flag may be lost

When SW releases an entry of timestamp FIFO by writing ETNBnTCCR.TFR while this FIFO is empty (ETNBnTSR.TFFL is set to 0), flagging of next FIFO update may be inconsistent. The next timestamp is correctly stored in FIFO and the fill level is incremented to 1 but ETNBnTIS.TFUF is not set to 1.

The issue is limited to applications releasing FIFO entries without checking if there are entries available.

Do not release not existing FIFO entries .

25.4.15.4 gPTP compare may fail for range of compare values

When the comparison value (ETNBnGPTC.PTCV) is in the range of [x-1 to x+1] (x is the configured increment value in ETNBnGTI.TIV), it may happen that a comparison match is not detected when Timer wraps around.

The issue is limited to applications using the AVTP comparison function.

Do not configure comparison values inside the critical range.

25.4.15.5 UFC stop level triggers ETNBnRIS2.QFFr even no received frame is lost

When a received frame is dropped due to non-availability of empty descriptor, ETNBnRIS2.QFFr is correctly set to 1.

Additionally, when ETNBnUFCVi.CVr reached the configured stop level (ETNBnUFCS.SLj), the queue full flag (ETNBnRIS2.QFFr) is set to 1 even before any further received frame is dropped.

The issue is limited to applications using unread frame counter with stop level function.

Such application gets information about lost received frames which in fact might not have lost.

25.4.15.6 ETNBnRIS0.FRFr may be lost when data processing stops close to or below the configured warning level.

When SW decrements UFC counter value (CV) to WL-1, resulting CV can still be WL due to recent new storage completion, ETNBnRIS0.FRFr is set to 0.

Any further reception will set ETNBnRIS0.FRFr as normal.

The issue is limited to applications using a single frame interrupt triggered by ETNBnRIS0.FRFr and not be able to process each interrupt in time.

The missing interrupt due to this effect is automatically recovered by the next frame reception as usual.

25.4.15.7 Receive Frame Interrupt and Descriptor Interrupt may be issued before Completion of Writing Data

When receive frame interrupt is issued, the software should check that the descriptor type is updated correctly before processing the frame data.

The descriptor type is shown in the descriptor field DESCR.DT (the address of the current descriptor is shown by the register ETNBnCDARq). If DESCR.DT is not yet updated by the DMA hardware (e.g. from FEMPTY to FEND), then the write of data to the memory is not completed. In that case the software should repeat checking the descriptor type until an update has happened.

Alternatively the software can use the Unread Frame Counter (UFC) value to compare with its processed descriptors to confirm there is no missing descriptor from the last received interrupt.

Section 26 Single Edge Nibble Transmission (RSENT)

This section contains a generic description of the Renesas Single Edge Nibble Transmission (RSENT). The first part in this section describes the RH850/U2A-EVA specific properties, such as the number of units, register base addresses, etc.
The remainder of the section describes the functions and registers of the RSENT.

26.1 Features of RSENT for RH850/U2A-EVA

26.1.1 Number of Units and Channels

This microcontroller has the following number of RSENT units.

Each RSENT unit has a single channel interface. “Number of channels” therefore has the same meaning as “number of units” in this section.

Table 26.1 Number of Units

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of Units	8 (n = 0 to 7)	8 (n = 0 to 7)	8 (n = 0 to 7)	8 (n = 0 to 7)	8 (n = 0 to 7)	8 (n = 0 to 7)	8 (n = 0 to 7)	8 (n = 0 to 7)	8 (n = 0 to 7)	6 (n = 0 to 5)
Name	RSENTn									

Table 26.2 Index

Index	Description
n	Throughout this section, the individual RSENT units are identified by the index “n” (n = 0 to 7); for example, RSENTnTSPC indicates the RSENTn time stamp register.

26.1.2 Register Base Addresses

RSENTn register addresses are represented by an offset from the base address <RSENTn_base>.

The following table shows the base address <RSENTn_base> of each RSENTn channels.

Table 26.3 Register Base Addresses

Base Address Name	Base Address	Bus Group
<RSENT0_base>	FFD3 3600$_H$	P-Bus Group 3
<RSENT1_base>	FFD3 3700$_H$	P-Bus Group 3
<RSENT2_base>	FFD3 3800$_H$	P-Bus Group 3
<RSENT3_base>	FFD3 3900$_H$	P-Bus Group 3
<RSENT4_base>	FFD3 3A00$_H$	P-Bus Group 3
<RSENT5_base>	FFD3 3B00$_H$	P-Bus Group 3
<RSENT6_base>	FFD3 3C00$_H$	P-Bus Group 3
<RSENT7_base>	FFD3 3D00$_H$	P-Bus Group 3

26.1.3 Clock Supply

The RSENTn clock supply is shown in the following table.

Table 26.4 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name	Description
RSENTn	RSENT Communication Clock	CLK_HSB	Communication clock
	Register Access Clock	CLK_HSB	Bus clock

Note: Communication clock and register access clock must be in the range of 33.3 MHz to 80 MHz.

26.1.4 Interrupt, DMA/DTS Requests and Error Notifications

RSENTn interrupt and DMA/DTS requests are listed in the following table.

Table 26.5 Interrupt and DMA/DTS Requests

Unit Interrupt Name	Description	Interrupt Number	DMA Trigger number	DTS Trigger number
RSENT0				
INTRSENT0SI	RSENT status interrupt	512	—	—
INTRSENT0RI	RSENT receive interrupt	513	group0-21	group3-42
RSENT1				
INTRSENT1SI	RSENT status interrupt	514	—	—
INTRSENT1RI	RSENT receive interrupt	515	group0-22	group3-43
RSENT2				
INTRSENT2SI	RSENT status interrupt	516	—	—
INTRSENT2RI	RSENT receive interrupt	517	group0-23	group3-44
RSENT3				
INTRSENT3SI	RSENT status interrupt	518	—	—
INTRSENT3RI	RSENT receive interrupt	519	group0-24	group3-45
RSENT4				
INTRSENT4SI	RSENT status interrupt	520	—	—
INTRSENT4RI	RSENT receive interrupt	521	group0-25	group3-46
RSENT5				
INTRSENT5SI	RSENT status interrupt	522	—	—
INTRSENT5RI	RSENT receive interrupt	523	group0-26	group3-47
RSENT6				
INTRSENT6SI	RSENT status interrupt	524	—	—
INTRSENT6RI	RSENT receive interrupt	525	group0-27	group3-48
RSENT7				
INTRSENT7SI	RSENT status interrupt	526	—	—
INTRSENT7RI	RSENT receive interrupt	527	group0-28	group3-49

This module has no error notifications.

26.1.5 Reset Sources

RSENTn reset sources are listed in the following table. RSENTn is initialized by these sources.

Table 26.6 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
RSENTn	All registers	√	√	√	√	√	√	—

Note: For more details of reset explanation, refer to **Section 9, Reset Controller**.

26.1.6 External Input/Output Signals

External input/output signals of RSENT are listed below.

Table 26.7 External Input/Output Signals

Unit Signal Name	I/O	Description	Alternative Port Pin Signal Name
RSENT0			
rsent_rx	I	RSENT Data Input	RSENT0RX
rsent_spc	O	RSENT SPC Extension Output	RSENT0SPCO
RSENT1			
rsent_rx	I	RSENT Data Input	RSENT1RX
rsent_spc	O	RSENT SPC Extension Output	RSENT1SPCO
RSENT2			
rsent_rx	I	RSENT Data Input	RSENT2RX
rsent_spc	O	RSENT SPC Extension Output	RSENT2SPCO
RSENT3			
rsent_rx	I	RSENT Data Input	RSENT3RX
rsent_spc	O	RSENT SPC Extension Output	RSENT3SPCO
RSENT4			
rsent_rx	I	RSENT Data Input	RSENT4RX
rsent_spc	O	RSENT SPC Extension Output	RSENT4SPCO
RSENT5			
rsent_rx	I	RSENT Data Input	RSENT5RX
rsent_spc	O	RSENT SPC Extension Output	RSENT5SPCO
RSENT6			
rsent_rx	I	RSENT Data Input	RSENT6RX
rsent_spc	O	RSENT SPC Extension Output	RSENT6SPCO
RSENT7			
rsent_rx	I	RSENT Data Input	RSENT7RX
rsent_spc	O	RSENT SPC Extension Output	RSENT7SPCO

26.1.7 Combinations of Pins and Ports

Combinations of RSENT pins and ports are listed in the following table.

Table 26.8 Combinations of Pins and Ports

Function	Pin Name	Port Name
RSENT0	RSENT0RX	P3_4/P6_14*1/P10_7/P20_2
	RSENT0SPCO	P2_4/P6_14*1
RSENT1	RSENT1RX	P3_5/P10_8/P17_4*1/P20_3
	RSENT1SPCO	P17_4*1/P20_9/P20_13
RSENT2	RSENT2RX	P4_13*1/P10_13*1/P20_12*1
	RSENT2SPCO	P4_13*1/P10_13*1/P20_4/P20_12*1
RSENT3	RSENT3RX	P4_12*1/P10_14*1/P20_13
	RSENT3SPCO	P4_12*1/P10_14*1/P20_0
RSENT4	RSENT4RX	P3_2*1/P6_13*1/P17_0
	RSENT4SPCO	P3_2*1/P4_6/P6_13*1/P20_1
RSENT5	RSENT5RX	P3_3*1/P17_1
	RSENT5SPCO	P3_3*1/P4_7
RSENT6	RSENT6RX	P21_1*1/P24_4*1
	RSENT6SPCO	P21_1*1/P24_4*1/P24_6
RSENT7	RSENT7RX	P21_0*1/P24_5*1
	RSENT7SPCO	P21_0*1/P24_5*1/P24_7

Note 1. These ports are share pins. For more details, refer to **Section 26.4.4.1, Multiplexing of the RSENTnRX and RSENTnSPCO Pin Functions**.

26.2 Overview

26.2.1 Functional Overview

The RSENT interface supports the following standard specification (SAE J2716 version APR2016) functions:

- Triple speed expansion Tick Time: Clock cycle (1 µs to 90 µs)
- Variable data transmission rate
  - Up to 74.9 kbps (based on 8 nibble data at 3 µs clock rate)
  - Up to 224.7 kbps (based on 8 nibble data at 1 µs clock rate)
- Unidirectional communication: Between the sensor and MCU
- Bidirectional communication: Between the sensor and MCU (supported in SPC mode)
- Single edge data transmission: Coded by the temporal distance of two serially-detected falling edges on a data line
- Transmission frame with up to 8 data nibbles + status and communication nibbles.
- Data transmission protected with CRC is available.
  - CRC data can be read with the RSENTnSRXD.SCRC bits and RSENTnFRXD.FCRC bits.
- Calibration phrase in each data frame (RSENTnCPL.CPLV bits)
- 1-wire interface (sent_rx and sent_spc share a single terminal.)
- Multiple sensors can connect to the RSENT channel that has the standard expansion function. Received data from sensors is detected by software or sDMA.
- The timestamp function: Master or slave can be selected for the RSENT module (RSENTnTSPC.TMS bit).
  Each RSENT macro consists of one RSENT channel.
  Each timestamp counter of macros can run independently, or in order to synchronize the timestamp across multiple channels, one instance can be set as master and reset the configured consecutive timestamp counters.
  Depending on the total number of instances, more than one master-slave (s) pairs can be configured.
- RSENT has two interrupt request (status interrupt and receive interrupt)
- RSENT has one sDMA/DTS request (receive interrupt)
- The RSENT circuit consists of the following functions:
  - Data receive part
  - Clock recovery
  - Register group

26.2.2 Block Diagram

The following figure shows a block diagram of the RSENT module.

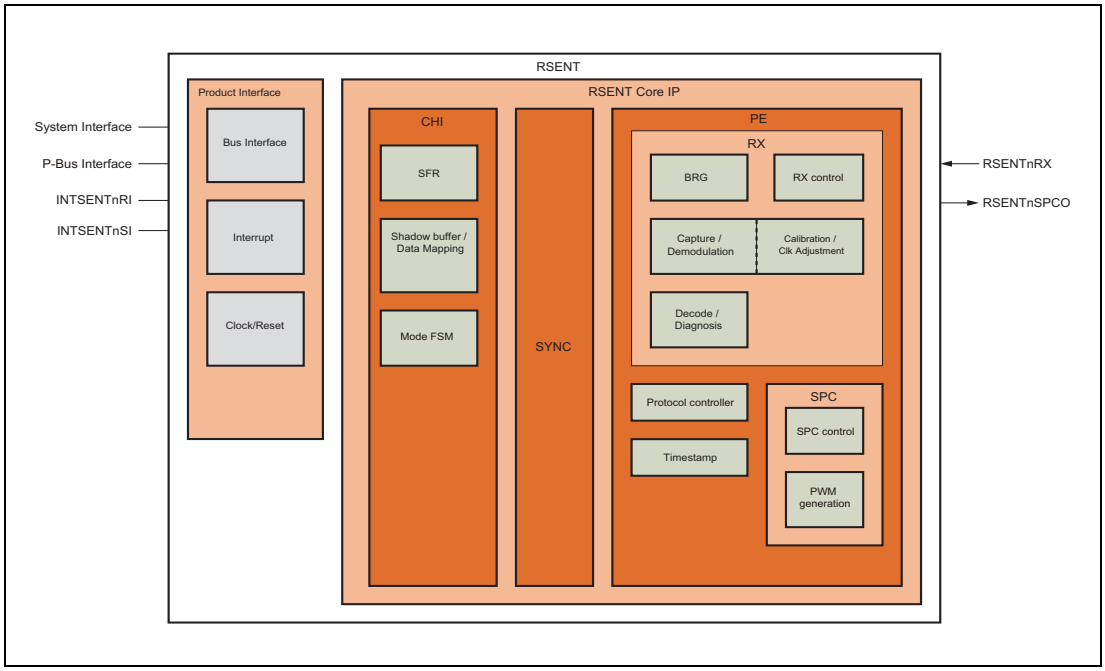

Figure 26.1 Block Diagram of RSENT

26.3 Registers

26.3.1 List of Registers

RSENTn registers are listed in the following table.

For details about <RSENTn_base>, see **Section 26.1.2, Register Base Addresses**.

Table 26.9 List of Registers

Module Name	Register Name	Abbreviation	Address	Access Protection	
				PBG	Other
RSENTn	RSENT Timestamp Register	RSENTnTSPC	<RSENTn_base> + 0000_H	1*1	—
	RSENT Timestamp Counter	RSENTnTSC	<RSENTn_base> + 0004_H	1*1	—
	RSENT Communication Configuration Register	RSENTnCC	<RSENTn_base> + 0010_H	1*1	—
	RSENT Baud Rate Prescaler Register	RSENTnBRP	<RSENTn_base> + 0014_H	1*1	—

26.3.2 RSENTnTSPC — RSENT Timestamp Register

Access: This register can be read or written in 32-bit units.

Address: <RSENTn_base> + 0000_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TMS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	TTM[6:0]							—	TTPV[6:0]

Table 26.10 RSENTnTSPC Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	TMS	Timestamp Mode Selection 0: Master mode 1: Slave mode
15	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
14 to 8	TTM[6:0]	Timestamp Tick Multiplier 0000000_B: 1 0000001_B: 2 0000010_B: 3 : 1111111_B: 128
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	TTPV[6:0]	Timestamp Tick Prescaler Value 0000000_B: 1 0000001_B: 2 0000010_B: 3 : 1111111_B: 128

RSENTnTSPC.TMS (Timestamp Mode Selection)

This bit defines the timestamp counter synchronization mode.

For information about the timestamp clock settings, see **Section 26.4.2.1, Timestamp**.

When this bit is set to 0, the timestamp counter operates in master mode.

When writing $0000\ 0000_H$ to RSENTnTSC, the timestamp counter is cleared. In addition all RSENT timestamp counters operating as slave of RSENT are also cleared. For master-slave interconnection, see **Section 26.4.2.1(2), Timestamp Counter Operation**.

When this bit is set to 1, the timestamp counter operates in slave mode.

The timestamp counter is only cleared when writing $0000\ 0000_H$ to the timestamp counter of RSENT module that operates in master mode.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

The RSENT module operating in slave mode should have the same timestamp counter prescaler settings as the RSENT module that operates in master mode.

The CPU should not set this bit to 1 for RSENT module that operates in master mode.

RSENTnTSPC.TTM (Timestamp Tick Multiplier)

These bits define the multiplication value of the 1-µs time tick used for the timestamp counter.

For timestamp clock configuration, see **Section 26.4.2.1, Timestamp**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnTSPC.TTPV (Timestamp Tick Prescaler Value)

These bits define the prescaler value to generate a 1-µs clock tick.

For timestamp clock configuration, see **Section 26.4.2.1, Timestamp**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

The CPU should configure this value in such a way that, based on the supplied communication clock, a 1-µs clock tick is generated.

26.3.3 RSENTnTSC — RSENT Timestamp Counter Register

Access: This register can be read or written in 32-bit units.

Address: <RSENTn_base> + 0004_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TS[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TS[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 26.11 RSENTnTSC Register Contents

Bit Position	Bit Name	Function
31 to 0	TS[31:0]	Timestamp counter value

RSENTnTSC.TS (Timestamp)

These bits indicate the current timestamp counter value.

The CPU can only write to these bits values other than $0000\ 0000_H$ if RSENT is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

When the timestamp counter is configured to operate in slave mode (RSENTnTSPC.TMS = 1), writing to this register has no effect when the RSENT module is in either of the OPERATION IDLE or OPERATION ACTIVE modes (the RSENTnMST.OMS bits are either 011_B or 101_B).

The timestamp counter is incremented on every timestamp counter tick (as configured in the RSENTnTSPC.TTPV and RSENTnTSPC.TTM bits) when the RSENT module is in either of the OPERATION IDLE or OPERATION ACTIVE modes (the RSENTnMST.OMS bits are either 011_B or 101_B).

When the timestamp counter is configured to operate in master mode (RSENTnTSPC.TMS = 0), the CPU writes $0000\ 0000_H$ to these bits and RSENTnTSC.TS is set to $0000\ 0000_H$.

When the slave mode setting is made for the timestamp counter of channel n (RSENTnTSPC.TMS = 1), writing to the timestamp counter of the channel that is the master for channel n leads to the RSENTnTSC.TS bits being set to $0000\ 0000_H$.

For timestamp mode selection, see **Section 26.4.2.1, Timestamp**.

26.3.4 RSENTnCC — RSENT Communication Configuration Register

Access: This register can be read or written in 32-bit units.

Address: <RSENTn_base> + 0010_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 26.12 RSENTnCC Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
12	SOPC	SPC Output Polarity Control 0: SPC pulse active high 1: SPC pulse active low
11	FCM	Frame Check Method 0: Check against next calibration pulse 1: Check against previous calibration pulse
10	SCCD	Slow Channel CRC Check 0: Slow channel CRC check enabled 1: Slow channel CRC check disabled
9	FCCD	Fast Channel CRC Check 0: Fast channel CRC check enabled 1: Fast channel CRC check disabled
8	DCF	Data nibble CRC Format 0: SAE J2716 2010/2016 format 1: pre SAE J2716 2010 format
7, 6	SMF[1:0]	Serial Message Format 00_B: No serial message extraction 01_B: Short serial message format 10_B: Enhanced serial message format 11_B: Setting prohibited
5	PPTC	Pause Pulse Type Configuration 0: Pause pulse for variable message length 1: Pause pulse for fixed message length
4	PPC	Pause Pulse Configuration 0: Pause pulse absent 1: Pause pulse present
3 to 1	NDN[2:0]	Number of Data Nibbles 000_B: 1 data nibble 001_B: 2 data nibbles 010_B: 3 data nibbles 011_B: 4 data nibbles 100_B: 5 data nibbles 101_B: 6 data nibbles 110_B: 7 data nibbles 111_B: 8 data nibbles

Table 26.12 RSENTnCC Register Contents (2/2)

Bit Position	Bit Name	Function
0	SPCE	SPC Mode Enable 0: SPC mode disabled 1: SPC mode enabled

RSENTnCC.SOPC (SPC Output Polarity Control)

When this bit is set to 0, the SPC pulse is sent as an active high signal. The default output value is low level.

When this bit is set to 1, the SPC pulse is sent as an active low signal. The default output value is high level.

For SPC operation, see also **Section 26.4.4, SPC Function**.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

NOTE

Any change to this bit from the default value becomes effective on the output value when entering the OPERATION_ACTIVE mode (RSENTnMST.OMS is 101_B). When entering RESET mode (RSENTnMST.OMS is 000_B), the output level is set to the default value (low level).

RSENTnCC.FCM (Frame Check Method)

When this bit is set to 0, the current calibration pulse is compared to the next received calibration pulse.

The buffer update mechanism is operating according to the preferred option as described in SAE J2716 2016.

When this bit is set to 1, the current calibration pulse is compared to the previously received calibration pulse.

The buffer update mechanism is operating according to the second option as described in SAE J2716 2016 which should be only used if extra latency to process the second calibration pulse can not be tolerated.

For buffer update timings, see also **Section 26.4.3.2(3), Fast Channel Message Reception**.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnCC.SCCD (Slow Channel CRC Check Disable)

When this bit is set to 1, the CRC check for the slow channel is disabled. In this case, messages are stored in the slow channel message reception buffer with the received CRC.

When this bit is set to 1, the RSENTnCS.SCS bit is not set.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnCC.FCCD (Fast Channel CRC Check Disable)

When this bit is set to 1, the CRC check for the fast channel is disabled. In this case, messages are stored in the fast channel message reception buffer with the received CRC.

When this bit is set to 1, the RSENTnCS.FCS bit is not set.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnCC.DCF (Data Nibble CRC Format)

This bit selects between the SAE J2716 2016 data nibble CRC format and the legacy format.

When this bit is set to 0 the recommended CRC implementation according to SAE J2716 2016 *Section 5.4.2.2* is selected.

When this bit is set to 1 the legacy CRC implementation according to SAE J2716 2008 (refer to SAE J2716 2016 *Section 5.4.2.1*) is selected.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (RSENTnMST.OMS = 001_B)

RSENTnCC.SMF (Serial Message Format)

These bits define the serial message format expected to be received for automatic extraction.

When these bits are set to 00_B, no serial message is extracted and the status and communications nibbles are stored in the RSENTnSRXD register.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

The CPU shall set these bits to 00_B when RSENTnCC.SPCE is set to 1 and more than one sensor is connected to the RSENT module.

RSENTnCC.PPTC (Pause Pulse Type Configuration)

This bit defines the pause pulse type.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

The CPU should not set this bit to 1 when the RSENTnCC.PPC bit is set to 0.

RSENTnCC.PPC (Pause Pulse Configuration)

This bit defines the presence or absence of the pause pulse.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnCC.NDN (Number of Data Nibbles)

These bits define the number of data nibbles included in an RSENT message.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnCC.SPCE (SPC Mode Enable)

This bit enables the SPC mode.

For details about SPC mode operation, see also **Section 26.4.4, SPC Function**.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

26.3.5 RSENTnBRP — RSENT Baud Rate Prescaler Register

Access: This register can be read or written in 32-bit units.

Address: <RSENTn_base> + 0014_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	TTF[3:0]				—	TTI[6:0]

Table 26.13 RSENTnBRP Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
27 to 24	TTF[3:0]	Time Tick Decimal Fraction 0000_B: 0.0 µs 0001_B: 0.1 µs 0010_B: 0.2 µs : 1000_B: 0.8 µs 1001_B: 0.9 µs Other than above: Setting prohibited
23	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
22 to 16	TTI[6:0]	Time Tick Integer 0000000_B: 1 µs 0000001_B: 2 µs 0000010_B: 3 µs : 1011000_B: 89 µs 1011001_B: 90 µs Other than above: Setting prohibited
15	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
14 to 8	SCDV[6:0]	Sample Clock Division Value 0000000_B: 1 0000001_B: 2 0000010_B: 3 : 1111110_B: 127 1111111_B: 128
7 to 5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 26.13 RSENTnBRP Register Contents (2/2)

Bit Position	Bit Name	Function
4 to 0	SCMV[4:0]	Sample Clock Multiplication Value 00000_B: 1 00001_B: 2 00010_B: 3 : 11110_B: 31 11111_B: 32

RSENTnBRP.TTF (Time Tick Decimal Fraction)

These bits define the decimal part of the tick length in 0.1-µs granularity.

For tick length configuration, see **Section 26.4.2.2(2), RX and SPC Tick Settings**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnBRP.TTI (Time Tick Integer)

These bits define the integer part of the tick length.

For tick length configuration, see **Section 26.4.2.2(2), RX and SPC Tick Settings**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnBRP.SCDV (Sample Clock Division Value)

These bits define the division value for the sample clock generation logic.

For RSENTnBRP settings, see **Section 26.4.2.2(1), RX BRP Setting**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnBRP.SCMV (Sample Clock Multiplication Value)

These bits define the multiplication value for the sample clock generation logic.

For RSENTnBRP settings, see **Section 26.4.2.2(1), RX BRP Setting**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

26.3.6 RSENTnIDE — RSENT Interrupt/DMA Enable Register

Access: This register can be read or written in 32-bit units.

Address: <RSENTn_base> + 0018_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

2	FMIE	Fast Channel Message Lost Interrupt Enable 0: Interrupt disabled 1: Interrupt enabled
1	FCIE	Fast Channel CRC Error Interrupt Enable 0: Interrupt disabled 1: Interrupt enabled
0	FRIE	Fast Channel Receive Interrupt Enable 0: Interrupt disabled 1: Interrupt enabled

RSENTnIDE.SEIE (Slow Channel Encoding Error Interrupt Enable)

This bit enables the generation of the slow channel encoding error interrupt.

The CPU can not write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.SMIE (Slow Channel Message Lost Interrupt Enable)

This bit enables the generation of the slow channel message lost interrupt.

The CPU can not write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.SCIE (Slow Channel CRC Error Interrupt Enable)

This bit enables the generation of the slow channel CRC error interrupt.

The CPU can not write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.NRIE (No Response Error Interrupt Enable)

This bit enables the generation of the no response error interrupt.

The CPU can not write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

The CPU should not set this bit when the SPC mode is disabled (RSENTnCC.SPCE set to 0).

RSENTnIDE.CVIE (Calibration Pulse Length Variation Error Interrupt Enable)

This bit enables the generation of the calibration pulse length variation error interrupt.

The CPU can not write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.CLIE (Calibration Pulse Length Error Interrupt Enable)

This bit enables the generation of the calibration pulse length error interrupt.

The CPU can not write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.FNIE (Fast Channel Nibble Count Error Interrupt Enable)

This bit enables the generation of the fast channel nibble count error interrupt.

The CPU can not write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.FEIE (Fast Channel Nibble Encoding Error Interrupt Enable)

This bit enables the generation of the fast channel nibble encoding error interrupt.

The CPU can not write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.FMIE (Fast Channel Message Lost Interrupt Enable)

This bit enables the generation of the fast channel message lost interrupt.

The CPU can not write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.FCIE (Fast Channel CRC Error Interrupt Enable)

This bit enables the generation of the fast channel CRC error interrupt.

The CPU can not write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.FRIE (Fast Channel Receive Interrupt Enable)

This bit enables the generation of the fast channel receive interrupt.

The fast channel receive interrupt can be also used to notify a DMA request.

The CPU can not write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

26.3.7 RSENTnMDC — RSENT Mode Control Register

Access: This register can be read or written in 32-bit units.

Address: <RSENTn_base> + $001C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 26.15 RSENTnMDC Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2 to 0	OMC[2:0]	Operation Mode Control 000_B: RESET 001_B: CONFIGURATION 011_B: OPERATION IDLE 101_B: OPERATION ACTIVE Other than above: Setting prohibited

RSENTnMDC.OMC (Operation Mode Control)

These bits are used to control the operation mode of the RSENT module.

- 000_B: RESET

  In RESET mode, the mode can only be changed to CONFIGURATION mode.

- 001_B: CONFIGURATION

  In CONFIGURATION mode, the mode can only be changed to RESET mode or OPERATION ACTIVE mode.

- 011_B: OPERATION IDLE

  In OPERATION IDLE mode, the mode can be changed to OPERATION ACTIVE mode, CONFIGURATION mode, or RESET mode.

- 101_B: OPERATION ACTIVE

  In OPERATION ACTIVE mode, the mode can be changed to OPERATION IDLE mode, CONFIGURATION mode, or RESET mode. However, it is recommended to process to the OPERATION IDLE mode first.

  For the recommended methods to change between operation modes, see **Section 26.4.3.1, Changing Operation Modes**.

- Other than above: Setting prohibited

  The CPU should not write any other value than listed above into this register.
  The CPU should follow the mode change flows as shown in **Section 26.4.3.1, Changing Operation Modes**.

26.3.8 RSENTnSPCT — RSENT SPC Transmission Register

Access: This register can be read or written in 32-bit units.

Address: <RSENTn_base> + 0020_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	TLL[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 26.16 RSENTnSPCT Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	TLL[6:0]	Length of the Trigger Low Phase in Ticks 0000000_B: 1 tick 0000001_B: 2 ticks 0000010_B: 3 ticks : 1111110_B: 127 ticks 1111111_B: 128 ticks

RSENTnSPCT.TLL (Trigger Low Length)

These bits define the length of the SPC trigger pulse.

When the CPU writes to these bits, an SPC trigger pulse with the configured length is sent starting from the next SPC trigger tick. In case RSENTnCS.NRS is set by the RSENT module following a write to these bits, no SPC trigger pulse is sent.

For details about SPC communication, see **Section 26.4.4, SPC Function**.

The CPU can only write to these bits if the RSENT module is in the OPERATION ACTIVE mode (the RSENTnMST.OMS bits are 101_B) and SPC communication is enabled (RSENTnCC.SPCE is 1_B).

It is important to note that two consecutive write access might not cause a no response error as the previous request might not have started yet.

After writing to this register, the CPU should wait for at least one SPC trigger tick before writing again to this register.

26.3.9 RSENTnMST — RSENT Mode Status Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RSENTn_base> + 0024_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	OMS[2:0]		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 26.17 RSENTnMST Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is returned.
2 to 0	OMS[2:0]	Operation Mode 000_B: RESET 001_B: CONFIGURATION 011_B: OPERATION IDLE 101_B: OPERATION ACTIVE Other than above: Reserved

RSENTnMST.OMS (Operation Mode Status)

These bits indicate the current operation mode.

These bits are read only.

These bits are updated after a mode change request is made in the RSENTnMDC.OMC register.

- 000_B: RESET mode

  When in RESET mode, all registers are set to their reset values and write access to all registers except the RSENTnMDC register is disabled.
  When in RESET mode, RSENT communication is disabled.

- 001_B: CONFIGURATION mode

  When in CONFIGURATION mode, write access to the timestamp registers (RSENTnTSPC and RSENTnTSC register), configuration registers (RSENTnCC and RSENTnBRP register), RSENTnIDE register, and mode control register (RSENTnMDC.OMC) is enabled.
  When in CONFIGURATION mode, RSENT communication is disabled.
  When entering CONFIGURATION mode, all status registers and receive buffer registers are set to their reset values.

- 011_B: OPERATION IDLE mode

  In OPERATION IDLE mode, no reception or SPC trigger transmission is possible.
  When entering OPERATION IDLE mode, frames in the receive buffer can be analyzed as in OPERATION ACTIVE mode, but no new frames are received.

- 101_B: OPERATION ACTIVE mode

  In OPERATION ACTIVE mode, reception and SPC trigger transmission are possible.

- Other than above: Reserved

26.3.10 RSENTnCS — RSENT Communication Status Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RSENTn_base> + 0028_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 26.18 RSENTnCS Register Contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is returned.
10	SES	Slow channel Encoding Error Status 0: Not detected 1: Detected
9	SMS	Slow Channel Message Lost Status 0: Not detected 1: Detected
8	SCS	Slow Channel CRC Error Status 0: Not detected 1: Detected
7	NRS	No Response Error Status 0: Not detected 1: Detected
6	CVS	Calibration Pulse Length Variation Error Status 0: Not detected 1: Detected
5	CLS	Calibration Pulse Length Error Status 0: Not detected 1: Detected
4	FNS	Fast Channel Nibble Count Error Status 0: Not detected 1: Detected
3	FES	Fast Channel Nibble Encoding Error Status 0: Not detected 1: Detected
2	FMS	Fast Channel Message Lost Status 0: Not detected 1: Detected
1	FCS	Fast Channel CRC Error Status 0: Not detected 1: Detected
0	FRS	Fast Channel Receive Status 0: Not detected 1: Detected

RSENTnCS.SES (Slow Channel Encoding Error Status)

This bit represents the slow channel encoding error status.

This bit is read only.

In the short serial message format (RSENTnCC.SMF = 01_B), this bit is set when the sequence on serial start bit (bit #3) is different from "1000 0000 0000 0000_B" (a single 1 and 15 0s).

In the enhanced serial message format (RSENTnCC.SMF = 10_B), this bit is set when following the reception of a start sequence ("0111 1110_B") on the serial data bit 3, bit 13 or bit 18 are not received as "0".

When this bit is set in the short serial message format the received communication and status nibble is used to assemble a serial message.

When this bit is set in the enhanced serial message format the RSENT module checks the presence of a new start sequence at the same time and uses the received communication and status nibble to assemble a serial message.

This bit is cleared when writing 1'b1 to RSENTnCSC.SEC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.SMS (Slow Channel Message Lost Status)

This bit represents the slow channel message lost status.

This bit is read only.

This bit is set when there is an attempt to update the slow channel message reception buffer, but the previous message has not been read yet.

This bit is cleared when writing 1 to RSENTnCSC.SMC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.SCS (Slow Channel CRC Error Status)

This bit represents the slow channel CRC error status.

This bit is read only.

This bit is set when a CRC error is detected on the slow channel and the slow channel CRC detection is enabled (RSENTnCC.SCCD is set to 0).

This bit is cleared when writing 1 to RSENTnCSC.SCC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.NRS (No Response Error Status)

This bit represents the no response error status.

This bit is read only.

This bit is set when

- The CPU writes to the RSENTnSPCT.TLL bits and

- SPC mode enabled (RSENTnCC.SPCE set to 1) and
- No complete response was received from the sensor for the previous SPC trigger.

This bit is set after 4 Register Access Clocks + 5 RSENT Communication Clocks (Maximum time) from the CPU writes to the RSENTnSPCT.TLL.

This bit is cleared when writing 1 to RSENTnCSC.NRC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.CVS (Calibration Pulse Length Variation Error Status)

This bit represents the calibration pulse length variation error status.

This bit is read only.

When RSENTnCC.PPTC is 0, then this bit is set when two successive calibration pulses differ by more than 1.5625%.

When RSENTnCC.PPTC is 1, this bit is never set. In this mode (pause pulse with fixed message length), the CPU needs to check the variation of the ratio of calibration pulse to message length by reading the RSENTnCPL and RSENTnML registers.

This bit is cleared when writing 1 to RSENTnCSC.CVC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.CLS (Calibration Pulse Length Error Status)

This bit represents the calibration pulse length error status.

This bit is read only.

This bit is set when the measured calibration pulse length is less than 42 clock ticks or more than 70 clock ticks (deviation of 25 % from nominal length).

This bit is cleared when writing 1 to RSENTnCSC.CLC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.FNS (Fast Channel Nibble Count Error Status)

This bit represents the fast channel nibble count error status.

This bit is read only.

This bit is set when there is an unexpected number of falling edges between two calibration pulses.

This bit is cleared when writing 1 to RSENTnCSC.FNC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.FES (Fast Channel Nibble Encoding Error Status)

This bit represents the fast channel nibble encoding error status.

This bit is read only.

This bit is set when on the fast channel a measured nibble period is less than 12 clock ticks or more than 27 clock ticks.

This bit is cleared when writing 1 to RSENTnCSC.FEC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.FMS (Fast Channel Message Lost Status)

This bit represents the fast channel message lost status.

This bit is read only.

This bit is set when the fast channel message reception buffer is updated, but the previous messages in the foreground and background buffer have not been read yet.

This bit is cleared when writing 1 to RSENTnCSC.FMC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.FCS (Fast Channel CRC Error Status)

This bit represents the fast channel CRC error status.

This bit is read only.

This bit is set when a CRC error is detected on the fast channel and the fast channel CRC detection is enabled (RSENTnCC.FCCD is set to 0).

This bit is cleared when writing 1 to RSENTnCSC.FCC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.FRS (Fast Channel Receive Status)

This bit represents the fast channel receive status.

This bit is read only.

This bit is set when the fast channel message reception buffer was updated.

This bit is cleared when the CPU reads the RSENTnFRXD or RSENTnEFRD1 register.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

26.3.11 RSENTnCSC — RSENT Communication Status Clear Register

Access: This register can be read or written in 32-bit units.

Address: <RSENTn_base> + $002C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

2	FMC	Fast Channel Message Lost Clear 0: — 1: Clear
1	FCC	Fast Channel CRC Error Clear 0: — 1: Clear
0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

RSENTnCSC.SEC (Slow Channel Encoding Error Clear)

Writing 1 sets RSENTnCS.SES to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.SMC (Slow Channel Message Lost Clear)

Writing 1 sets RSENTnCS.SMS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.SCC (Slow Channel CRC Error Clear)

Writing 1 sets RSENTnCS.SCS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.NRC (No Response Error Clear)

Writing 1 sets RSENTnCS.NRS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.CVC (Calibration Pulse Length Variation Error Clear)

Writing 1 sets RSENTnCS.CVS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.CLC (Calibration Pulse Length Error Clear)

Writing 1 sets RSENTnCS.CLS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.FNC (Fast Channel Nibble Count Error Clear)

Writing 1 sets RSENTnCS.FNS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.FEC (Fast Channel Nibble Encoding Error Clear)

Writing 1 sets RSENTnCS.FES to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.FMC (Fast Channel Message Lost Clear)

Writing 1 sets RSENTnCS.FMS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.FCC (Fast Channel CRC Error Clear)

Writing 1 sets RSENTnCS.FCS to 0.

Writing 0 has no effect.

This bit is always read as 0.

26.3.12 RSENTnSRTS — RSENT Slow Channel Receive Timestamp Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RSENTn_base> + 0030_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	STS[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 26.20 RSENTnSRTS Register Contents

Bit Position	Bit Name	Function
31 to 0	STS[31:0]	Slow Channel Receive Timestamp

RSENTnSRTS.STS (Slow Channel Receive Timestamp)

These bits are read only.

These bits are updated when the slow channel message reception buffer is updated with the timestamp counter value of the last frame provided to the slow channel message.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

26.3.13 RSENTnSRXD — RSENT Slow Channel Receive Data Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RSENTn_base> + 0034_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SND	—	SCRC[5:0]						—	—	—	SMGC	IDD[19:16]

Table 26.21 RSENTnSRXD Register Contents

Bit Position	Bit Name	Function
31	SND	Slow Channel New Data 0: Slow channel frame data is not updated since last read. 1: Slow channel frame data is updated since last read.
30	Reserved	When read, the value after reset is returned.
29 to 24	SCRC[5:0]	Slow Channel CRC Data
23 to 21	Reserved	When read, the value after reset is returned.
20	SMGC	Slow Channel Configuration Bit Data
19 to 0	IDD[19:0]	Slow Channel Data / ID Information

RSENTnSRXD.SND (Slow Channel New Data)

This bit indicates that the slow channel message reception buffer is holding data that has not been read.

This bit is read only.

This bit is set when the slow channel message reception buffer is updated.

This bit is cleared automatically whenever it is read.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

RSENTnSRXD.SCRC (Slow Channel CRC)

These bits are representing the slow channel CRC data.

These bits are read only.

These bits are updated when the slow channel message reception buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

RSENTnSRXD.SMGC (Slow Channel Configuration Bit)

This bit represents the slow channel configuration bit.

This bit is read only.

This bit is updated when the slow channel message reception buffer is updated.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

RSENTnSRXD.IDD (ID/ Data)

These bits are representing the slow channel data and ID information.

The alignment within this register depends on the message format. For details, see **Section 26.4.3.2(5), Slow Channel Message Reception**.

These bits are read only.

These bits are updated when the slow channel message reception buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

26.3.14 RSENTnCPL — RSENT Calibration Pulse Length Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RSENTn_base> + 0038_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CPLV [16]
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CPLV[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 26.22 RSENTnCPL Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned.
16 to 0	CPLV[16:0]	Calibration Pulse Length Value of Received Message

RSENTnCPL.CPLV (Calibration Pulse Length Value)

These bits are used by the CPU to calculate the ratio of two consecutive calibration pulses or the calibration pulse to message length in pause pulse with fixed message length mode for message diagnostics.

These bits are read only.

In modes other than pause pulse with fixed message length (RSENTnCC.PPTC = 1) or SPC mode (RSENTnCC.SPCE = 1), these bits are invalid and should not be used.

These bits are updated with the measured calibration pulse length in sample clock ticks when the fast channel receive message buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

26.3.15 RSENTnML — RSENT Message Length Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RSENTn_base> + $003C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Table 26.23 RSENTnML Register Contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is returned.
20 to 0	MLV[20:0]	Message Length Value of Received Message

RSENTnML.MLV (Message Length Value)

These bits are used by the CPU to calculate the ratio of the calibration pulse to message length in pause pulse with fixed message length mode for message diagnostics.

These bits are read only.

In modes other than pause pulse with fixed message length, these bits are invalid and should not be used.

These bits are updated with the measured message length in sample clock ticks when the fast channel receive message buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

26.3.16 RSENTnFRTS — RSENT Fast Channel Receive Timestamp Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RSENTn_base> + 0040_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FTS[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 26.24 RSENTnFRTS Register Contents

Bit Position	Bit Name	Function
31 to 0	FTS[31:0]	Fast Channel Receive Timestamp

RSENTnFRTS.FTS (Fast Channel Receive Timestamp)

These bits are read only.

These bits are updated when the fast channel message reception buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

26.3.17 RSENTnFRXD — RSENT Fast Channel Receive Data Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RSENTn_base> + 0044_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SNDM	FND	FCCN[1:0]		FCRC[3:0]				ND[23:16]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 26.25 RSENTnFRXD Register Contents

Bit Position	Bit Name	Function
31	SNDM	Slow Channel New Data Mirror 0: Slow channel frame data is not updated since last read. 1: Slow channel frame data is updated since last read.
30	FND	Fast Channel New Data 0: Fast channel frame data is not updated since last read. 1: Fast channel frame data is updated since last read.
29, 28	FCCN[1:0]	Fast Channel Status and Communications Nibble[1:0]
27 to 24	FCRC[3:0]	Fast Channel CRC Data
23 to 0	ND[23:0]	Fast Channel Nibble Data

RSENTnFRXD.SNDM (Slow Channel New Data Mirror)

This bit indicates that the slow channel message reception buffer is holding data that has not been read.

This bit is read only.

This bit is set when the slow channel message reception buffer is updated.

This bit is cleared automatically whenever the slow channel new data bit (RSENTnSRXD.SND) is read.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

RSENTnFRXD.FND (Fast Channel New Data)

This bit indicates that the fast channel message reception buffer is holding data that has not been read.

This bit is read only.

This bit is set when the fast channel message reception buffer is updated.

This bit is cleared automatically whenever it is read RSENTnFRXD or RSENTnEFRD1.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

RSENTnFRXD.FCCN (Fast Channel Communication Nibble)

These bits are representing the fast channel communication nibble bits [1:0].

These bits are read only.

These bits are updated when the fast channel message reception buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

RSENTnFRXD.FCRC (Fast Channel CRC)

These bits are representing the fast channel CRC data.

These bits are read only.

These bits are updated when the fast channel message reception buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

RSENTnFRXD.ND (Fast Channel Nibble Data)

These bits are representing the fast channel nibble data.

The alignment of the nibble data depends on nibble data count (RSENTnCC.NDN). For details, see **Section 26.4.3.2(3), Fast Channel Message Reception**.

These bits are read only.

These bits are updated when the fast channel message reception buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

26.3.18 RSENTnCPLM — RSENT Calibration Pulse Length Mirror Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RSENTn_base> + 0050_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CPLVM [16]

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 26.26 RSENTnCPLM Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned.
16 to 0	CPLVM[16:0]	Calibration pulse length value (Mirror) of received message

Calibration Pulse Length Value Mirror (RSENTnCPLM.CPLVM)

These bits are mirror bits of RSENTnCPL.CPLV.
These bits are read only.
In modes other than pause pulse with fixed message length (RSENTnCC.PPTC = 1) or SPC mode (RSENTnCC.SPCE = 1), these bits are invalid and should not be used.
These bits are updated with the measured calibration pulse length in sample clock ticks when the fast channel receive message buffer is updated.
These bits are cleared when RSENTnMST.OMS is changed to 001_B (CONFIGURATION).

26.3.19 RSENTnMLM — RSENT Message Length Mirror Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RSENTn_base> + 0054_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	MLVM[20:16]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MLVM[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 26.27 RSENTnMLM Register Contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is returned.
20 to 0	MLVM[20:0]	Message length value (Mirror) of received message

Message Length Value Mirror (RSENTnMLM.MLVM)

These bits are mirror bits of RSENTnML.MLV.
These bits are read only.
These bits are updated when the fast channel receive message buffer is updated.

26.3.20 RSENTnFRTSM — RSENT Fast Channel Receive Timestamp Mirror Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RSENTn_base> + 0058_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FTSM[31:16]

Table 26.28 RSENTnFRTSM Register Contents

Bit Position	Bit Name	Function
31 to 0	FTSM[31:0]	Fast channel receive Timestamp (Mirror)

Fast Channel Timestamp Mirror (RSENTnFRTSM.FTSM)

These bits are mirror bits of RSENTnFRTS.FTS.
These bits are read only.
These bits are updated when the fast channel receive message buffer is updated.
These bits are cleared when RSENTnMST.OMS is changed to 001_B (CONFIGURATION).

26.3.21 RSENTnEFRD0 — RSENT Expanded Fast Channel Receive Data Register 0

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RSENTn_base> + $005C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 26.29 RSENTnEFRD0 Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned.
7	SNDM	Slow channel New Data (Mirror) 0: Slow channel frame data not updated since last read. 1: Slow channel frame data updated since last read.
6	FND	Fast channel New Data 0: Fast channel frame data not updated since last read. 1: Fast channel frame data updated since last read.
5, 4	FCCN[1:0]	Fast Channel Communication Nibble bits [1:0]
3 to 0	FCRC[3:0]	Fast channel CRC data

Slow Channel New Data Mirror (RSENTnEFRD0.SNDM)

This bit indicates that the slow channel message buffer is holding data that has not been read.
This bit is read only.
This bit is set when the slow channel receive message buffer is updated.
This bit is cleared automatically whenever the slow channel new data bit (RSENTnSRXD.SND) is read.
This bit is cleared when RSENTnMST.OMS is changed to 001_B (CONFIGURATION).

Fast Channel New Data (RSENTnEFRD0.FND)

This bit indicates that the fast channel message buffer is holding data that has not been read.
This bit is read only.
This bit is set when the fast channel receive message buffer is updated.
This bit is cleared automatically whenever it is read RSENTnFRXD or RSENTnEFRD1.
This bit is cleared when RSENTnMST.OMS is changed to 001_B (CONFIGURATION).

Fast Channel Communication Nibble (RSENTnEFRD0.FCCN)

These bits represent the fast channel communication nibble bits [1:0].
These bits are read only.
These bits are updated when the fast channel receive message buffer is updated.
These bits are cleared when RSENTnMST.OMS is changed to 001_B (CONFIGURATION).

Fast Channel CRC (RSENTnEFRD0.FCRC)

These bits represent the fast channel CRC data.
These bits are read only.
These bits are updated when the fast channel receive message buffer is updated.
These bits are cleared when RSENTnMST.OMS is changed to 001_B (CONFIGURATION).

26.3.22 RSENTnEFRD1 — RSENT Expanded Fast Channel Receive Data Register 1

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RSENTn_base> + 0060_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ND[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 26.30 RSENTnEFRD1 Register Contents

Bit Position	Bit Name	Function
31 to 0	ND[31:0]	Nibble Data Fast channel nibble data

Nibble Data (RSENTnEFRD1.ND)

These bits represent the fast channel nibble data.

The alignment of the nibble data depends on nibble count. For details, refer to **Section 26.4.3.2(3), Fast Channel Message Reception**.

These bits are read only.

These bits are updated when the fast channel receive message buffer is updated.

These bits are cleared when RSENTnMST.OMS is changed to 001_B (CONFIGURATION).

26.3.23 RSENTTSSEL — RSENT Timestamp Mode Selection Register

Access: This register can be read or written in 32-bit units.

Address: $FFD33E00_H$

Value after reset: $0000\ 0000_H$. This register is initialized by any reset source except module reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 26.31 RSENTTSSEL Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 28	MSSEL7[3:0]	RSENT7 Master Selection. This selection is valid only when RSENT7 is in slave mode (when the RSENT7TSPC.TMS bit = 1_B) 0000_B: No timestamp master. 0001_B: RSENT0 is the master of RSENT7. 0010_B: RSENT1 is the master of RSENT7. 0011_B: RSENT2 is the master of RSENT7. 0100_B: RSENT3 is the master of RSENT7. 0101_B: RSENT4 is the master of RSENT7. 0110_B: RSENT5 is the master of RSENT7. 0111_B: RSENT6 is the master of RSENT7. 1000_B: No timestamp master. Other than above: Setting prohibited
27 to 24	MSSEL6[3:0]	RSENT6 Master Selection. This selection is valid only when RSENT6 is in slave mode (when the RSENT6TSPC.TMS bit = 1_B) 0000_B: No timestamp master. 0001_B: RSENT0 is the master of RSENT6. 0010_B: RSENT1 is the master of RSENT6. 0011_B: RSENT2 is the master of RSENT6. 0100_B: RSENT3 is the master of RSENT6. 0101_B: RSENT4 is the master of RSENT6. 0110_B: RSENT5 is the master of RSENT6. 0111_B: No timestamp master. 1000_B: RSENT7 is the master of RSENT6. Other than above: Setting prohibited
23 to 20	MSSEL5[3:0]	RSENT5 Master Selection. This selection is valid only when RSENT5 is in slave mode (when the RSENT5TSPC.TMS bit = 1_B) 0000_B: No timestamp master. 0001_B: RSENT0 is the master of RSENT5. 0010_B: RSENT1 is the master of RSENT5. 0011_B: RSENT2 is the master of RSENT5. 0100_B: RSENT3 is the master of RSENT5. 0101_B: RSENT4 is the master of RSENT5. 0110_B: No timestamp master. 0111_B: RSENT6 is the master of RSENT5. 1000_B: RSENT7 is the master of RSENT5. Other than above: Setting prohibited

Table 26.31 RSENTTSSEL Register Contents (2/2)

Bit Position	Bit Name	Function
19 to 16	MSSEL4[3:0]	RSENT4 Master Selection. This selection is valid only when RSENT4 is in slave mode (when the RSENT4TSPC.TMS bit = 1_B) 0000_B: No timestamp master. 0001_B: RSENT0 is the master of RSENT4. 0010_B: RSENT1 is the master of RSENT4. 0011_B: RSENT2 is the master of RSENT4. 0100_B: RSENT3 is the master of RSENT4. 0101_B: No timestamp master. 0110_B: RSENT5 is the master of RSENT4. 0111_B: RSENT6 is the master of RSENT4. 1000_B: RSENT7 is the master of RSENT4. Other than above: Setting prohibited
15 to 12	MSSEL3[3:0]	RSENT3 Master Selection. This selection is valid only when RSENT3 is in slave mode (when the RSENT3TSPC.TMS bit = 1_B) 0000_B: No timestamp master. 0001_B: RSENT0 is the master of RSENT3. 0010_B: RSENT1 is the master of RSENT3. 0011_B: RSENT2 is the master of RSENT3. 0100_B: No timestamp master. 0101_B: RSENT4 is the master of RSENT3. 0110_B: RSENT5 is the master of RSENT3. 0111_B: RSENT6 is the master of RSENT3. 1000_B: RSENT7 is the master of RSENT3. Other than above: Setting prohibited
11 to 8	MSSEL2[3:0]	RSENT2 Master Selection. This selection is valid only when RSENT2 is in slave mode (when the RSENT2TSPC.TMS bit = 1_B) 0000_B: No timestamp master. 0001_B: RSENT0 is the master of RSENT2. 0010_B: RSENT1 is the master of RSENT2. 0011_B: No timestamp master. 0100_B: RSENT3 is the master of RSENT2. 0101_B: RSENT4 is the master of RSENT2. 0110_B: RSENT5 is the master of RSENT2. 0111_B: RSENT6 is the master of RSENT2. 1000_B: RSENT7 is the master of RSENT2. Other than above: Setting prohibited
7 to 4	MSSEL1[3:0]	RSENT1 Master Selection. This selection is valid only when RSENT1 is in slave mode (when the RSENT1TSPC.TMS bit = 1_B) 0000_B: No timestamp master. 0001_B: RSENT0 is the master of RSENT1. 0010_B: No timestamp master. 0011_B: RSENT2 is the master of RSENT1. 0100_B: RSENT3 is the master of RSENT1. 0101_B: RSENT4 is the master of RSENT1. 0110_B: RSENT5 is the master of RSENT1. 0111_B: RSENT6 is the master of RSENT1. 1000_B: RSENT7 is the master of RSENT1. Other than above: Setting prohibited
3 to 0	MSSEL0[3:0]	RSENT0 Master Selection. This selection is valid only when RSENT0 is in slave mode (when the RSENT0TSPC.TMS bit = 1_B) 0000_B: No timestamp master. 0001_B: No timestamp master. 0010_B: RSENT1 is the master of RSENT0. 0011_B: RSENT2 is the master of RSENT0. 0100_B: RSENT3 is the master of RSENT0. 0101_B: RSENT4 is the master of RSENT0. 0110_B: RSENT5 is the master of RSENT0. 0111_B: RSENT6 is the master of RSENT0. 1000_B: RSENT7 is the master of RSENT0. Other than above: Setting prohibited

26.4 Operation

26.4.1 Modes of Operation

The RSENT module can be in one of the following modes:

- RESET mode
- CONFIGURATION mode
- OPERATION IDLE mode
- OPERATION ACTIVE mode

CPU should follow the mode change flow as shown in **Section 26.4.3.1, Changing Operation Modes**.

Figure 26.2 shows the possible transitions between the channel modes:

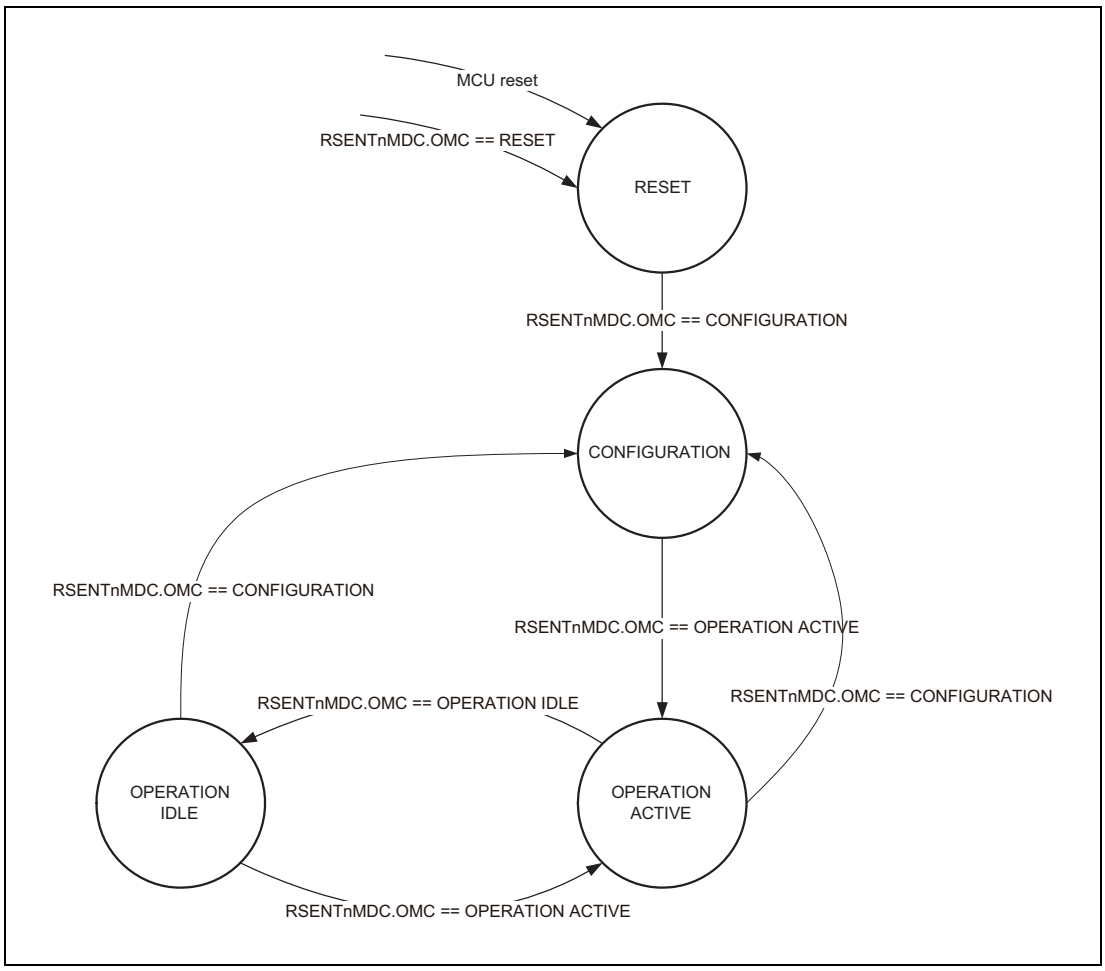

Figure 26.2 Transition between Operation Modes

The current operation mode status can be seen in the RSENTnMST.OMS bits.

26.4.1.1 RESET Mode

This mode is the initial mode that the RSENT module automatically enters after the hardware reset (MCU reset) is cleared. Its purpose is to provide a clean reset of the registers in the RSENT module.

The RESET mode is also entered after the RSENTnMDC.OMC bits have been set to 000_B. In this state, all, configuration, control (except RSENTnMDC.OMC bits and bits in the RSENTTSSEL register), and status registers are set to their reset value. Any on-going transmission or reception process is stopped immediately and the interface pins of the RSENT module are set to their default values.

Read access to all registers is possible in this state. Write access is limited to the RSENTnMDC register and RSENTTSSEL registers.

26.4.1.2 CONFIGURATION Mode

The CONFIGURATION mode is entered after the RSENTnMDC.OMC bits have been set to 001_B.

The interface pins of the RSENT are set to their default values.

Regarding the output polarity setting of RSENTnSPCO pin and the timing that becomes effective, refer to the explanation of “RSENTnCC.SOPC (SPC Output Polarity Control)” in **Section 26.3.4, RSENTnCC — RSENT Communication Configuration Register**.

However, the transition from OPERATION_ACTIVE mode to CONFIGURATION mode is allowed only when the SPC mode is enabled and the communication is not ongoing.

In this state, all status registers (RSENTnCS) and the receive buffer registers (RSENTnSRTS, RSENTnSRXD, RSENTnCPL, RSENTnML, RSENTnFRTS, RSENTnFRXD, RSENTnCPLM, RSENTnMLM, RSENTnFRTSM, RSENTnEFRD0, and RSENTnEFRD1) are set to their default values.

Read access to all registers is possible in this state.

Write access is limited to both timestamp registers (RSENTnTSPC and RSENTnTSC) and configuration registers (RSENTnCC, RSENTnBRP, RSENTnIDE, and RSENTnMDC).

26.4.1.3 OPERATION IDLE Mode

This mode is entered after the RSENTnMDC.OMC bits have been set to 011_B.

In OPERATION IDLE mode, no reception and transmission are done.

When entering OPERATION IDLE mode, frames in the receive buffer can be analyzed as in OPERATION ACTIVE mode, but no new frames are received.

Read access to all registers is possible in this state.

Write access is granted only to RSENTnTSC, RSENTnIDE, RSENTnMDC, and RSENTnCSC.

26.4.1.4 OPERATION ACTIVE Mode

This mode is entered after the RSENTnMDC.OMC bits have been set to 101_B.

In OPERATION ACTIVE mode, transmission and reception can take place.

Frame reception and status flagging starts after a valid calibration pulse (including the falling edge at the beginning) was detected.

Read access to all registers is possible in this state.

Write access is granted only to RSENTnTSC, RSENTnIDE, RSENTnMDC, RSENTnSPCT, and RSENTnCSC.

26.4.1.5 Register Behavior in Operation Modes

Table 26.32 shows the register behavior when the RSENT module transitions to the indicated operation modes. The table also gives an overview about the access restriction in each operation mode.

Table 26.32 Register Behavior in Operation Modes

		MCU Reset	RESET		CONFIGURATION		OPERATION IDLE		OPERATION ACTIVE	
Register Name	**Symbol**	**Change**	**Change**	**R/W**	**Change**	**R/W**	**Change**	**R/W**	**Change**	**R/W**
RSENT Timestamp Register	RSENTnTSPC	0000 0000$_H$	0000 0000$_H$	R	Unchanged	R/W	Unchanged	R	Unchanged	R
RSENT Timestamp Counter	RSENTnTSC	0000 0000$_H$	0000 0000$_H$	R	Unchanged	R/W	Unchanged	R/W *1	Unchanged	R/W *1
RSENT Communication Configuration Register	RSENTnCC	0000 0000$_H$	0000 0000$_H$	R	Unchanged	R/W	Unchanged	R	Unchanged	R
RSENT Baud Rate Prescaler Register	RSENTnBRP	0000 0000$_H$	0000 0000$_H$	R	Unchanged	R/W	Unchanged	R	Unchanged	R
RSENT Interrupt/DMA Enable Register	RSENTnIDE	0000 0000$_H$	0000 0000$_H$	R	Unchanged	R/W	Unchanged	R/W	Unchanged	R/W
RSENT Mode Control Register	RSENTnMDC	0000 0000$_H$	0000 0000$_H$	R/W	Unchanged	R/W	Unchanged	R/W	Unchanged	R/W
RSENT SPC Transmission Register	RSENTnSPCT	0000 0000$_H$	0000 0000$_H$	R	Unchanged	R	Unchanged	R	Unchanged	R/W
RSENT Mode Status Register	RSENTnMST	0000 0000$_H$	0000 0000$_H$	R	0000 0001$_H$	R	0000 0003$_H$	R	0000 0005$_H$	R
RSENT Communication Status Register	RSENTnCS	0000 0000$_H$	0000 0000$_H$	R	0000 0000$_H$	R	Unchanged	R	Unchanged	R
RSENT Communication Status Clear Register	RSENTnCSC	0000 0000$_H$	0000 0000$_H$	R	Unchanged	R/W	Unchanged	R/W	Unchanged	R/W
RSENT Slow Channel Receive Timestamp Register	RSENTnSRTS	0000 0000$_H$	0000 0000$_H$	R	0000 0000$_H$	R	Unchanged	R	Unchanged	R
RSENT Slow Channel Receive Data Register	RSENTnSRXD	0000 0000$_H$	0000 0000$_H$	R	0000 0000$_H$	R	Unchanged	R	Unchanged	R
RSENT Calibration Pulse Length Register	RSENTnCPL	0000 0000$_H$	0000 0000$_H$	R	0000 0000$_H$	R	Unchanged	R	Unchanged	R
RSENT Message Length Register	RSENTnML	0000 0000$_H$	0000 0000$_H$	R	0000 0000$_H$	R	Unchanged	R	Unchanged	R

RSENT Expanded Fast Channel Receive Data Register 0	RSENTnEFRD0	0000 0000$_H$	0000 0000$_H$	R	0000 0000$_H$	R	Unchanged	R	Unchanged	R
RSENT Expanded Fast Channel Receive Data Register 1	RSENTnEFRD1	0000 0000$_H$	0000 0000$_H$	R	0000 0000$_H$	R	Unchanged	R	Unchanged	R

Note 1. Means write restriction exists.

26.4.1.6 Mode Status Change Timing

This section shows the change timing of the RSENTnMST.OMS register i.e. the timing properties of the arrows in **Figure 26.2**. **Table 26.33** shows the change timing with respect to Falling Edge Detection, Register Access Clock, RSENT Communication Clock and sample clock.

Table 26.33 Mode Status Change Timing

Transition	Condition	Transition Time
RESET to CONFIGURATION		5 Register Access Clocks + 3 RSENT Communication Clocks
CONFIGURATION to OPERATION ACTIVE		5 Register Access Clocks + 6 RSENT Communication Clocks
OPERATION ACTIVE to OPERATION IDLE		Falling edge of next frame sync nibble + 5 sample clocks + 4 RSENT Communication Clocks + 4 Register Access Clocks
	In case frame reception has not started so far (falling edge of calibration pulse of 1st frame not detected)	5 Register Access Clocks + 1 sample clock + 7 RSENT Communication Clocks
OPERATION IDLE to CONFIGURATION		4 Register Access Clocks + 4 RSENT Communication Clocks
OPERATION ACTIVE to CONFIGURATION		4 Register Access Clocks + 7 RSENT Communication Clocks + 1 sample clock (+ 1 Register Access Clock - safety margin for user)
OPERATION IDLE to OPERATION ACTIVE		5 Register Access Clocks + 6 RSENT Communication Clocks

26.4.2 Clock Configuration

26.4.2.1 Timestamp

(1) Timestamp Clock Configuration

RSENT incorporates the timestamp counter.

The minimum required resolution of the timestamp is 1 µs. Depending on the supplied RSENT communication Clock frequency, the user should configure the RSENTnTSPC.TTPV bits to set the output of prescaler TPV to 1 µs clock tick. The input frequency is divided by the configured timestamp prescaler value RSENTnTSPC.TTPV.

Depending on the configured tick lengths, the resolution can be decreased by configuring the RSENTnTSPC.TTM bits. The already divided input frequency is divided further by the value of the RSENTnTSPC.TTM bits.

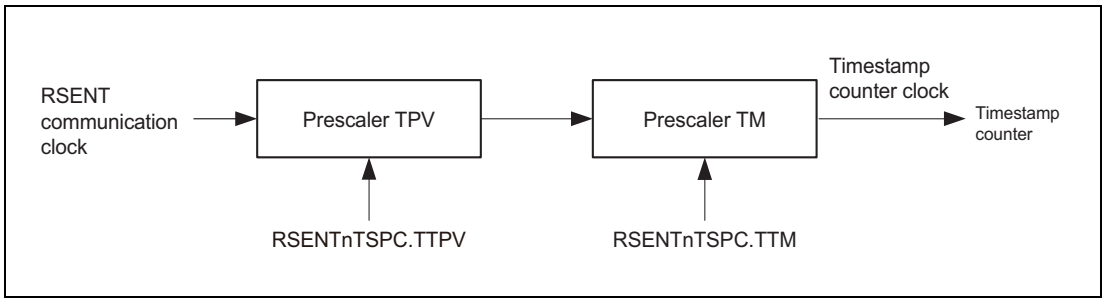

Figure 26.3 Timestamp Counter Clock Generation

(2) Timestamp Counter Operation

The timestamp counter value can be initialized to any value by writing to the RSENTnTSC.TS bits only when the RSENT module is in CONFIGURATION mode.

When timestamp counters are configured to operate in master mode (RSENTnTSPC.TMS = 0), the CPU can reset the timestamp counter by writing $0000\ 0000_H$ to the RSENTnTSC.TS bits when the RSENT module is in OPERATION IDLE or OPERATION ACTIVE mode.

When timestamp counters are configured to operate in slave mode (RSENTnTSPC.TMS = 1), the timestamp counter is cleared when the CPU writes $0000\ 0000_H$ to the RSENTnTSC.TS bits of the channel set in the master when the RSENT module is in OPERATION IDLE or OPERATION ACTIVE mode. The RSENT module operating in slave mode should have the same timestamp counter prescaler settings as master RSENT module. When timestamp counter synchronization occurs, the internal timestamp counter prescalers are also synchronized.

The current timestamp counter value can be read from the RSENTnTSC.TS bits.

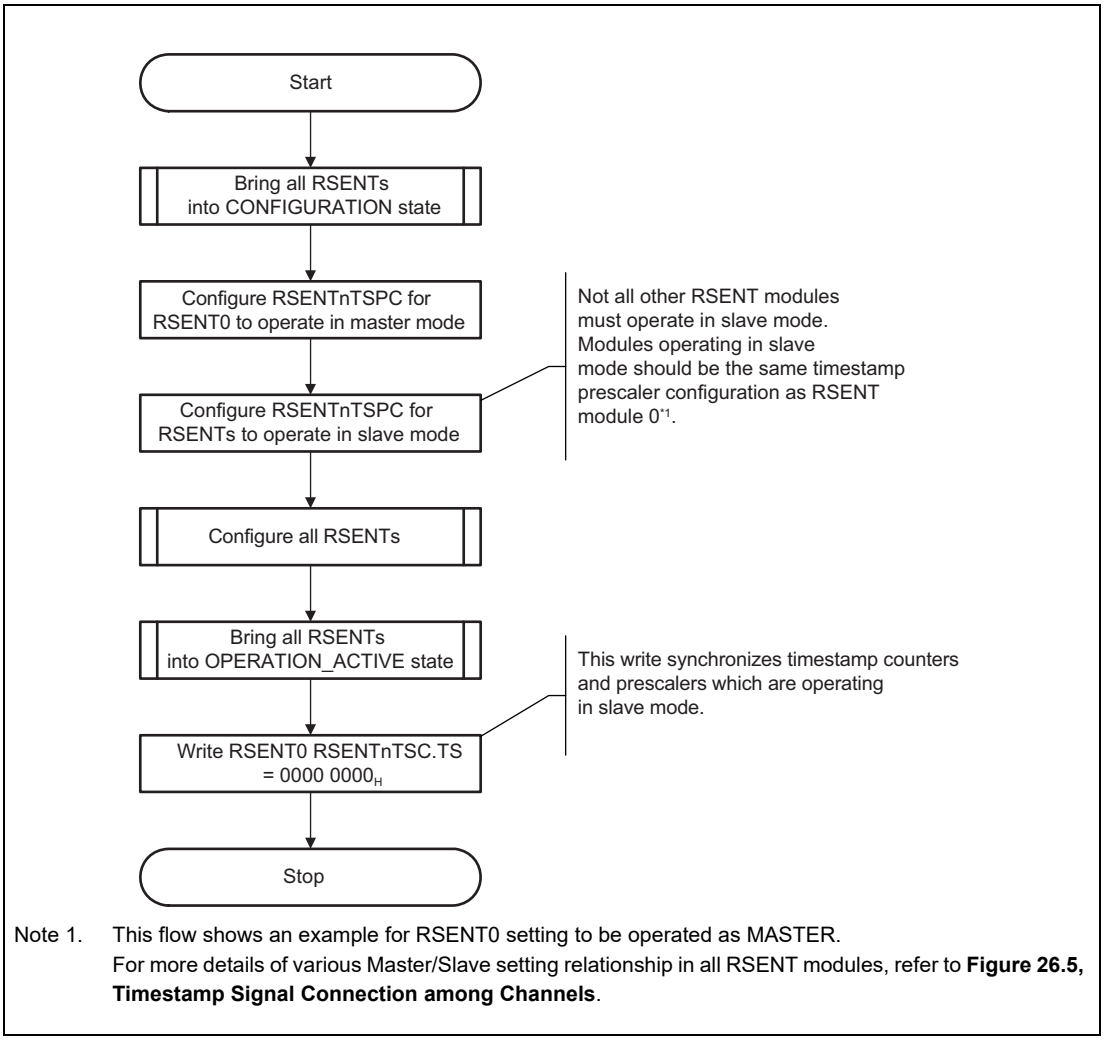
When the RSENT module is in OPERATION ACTIVE mode, each received message is stored with its related timestamp. Timestamp values are taken for fast channel and slow channel data.

The timestamp value is captured when the calibration pulse is detected.

The timestamp value for the fast channel is stored in the RSENTnFRTS.FTS bits or RSENTnFRTSM.FTSM bits register field when the fast channel receive message buffer is updated.

The timestamp value for the slow channel is stored in the RSENTnSRTS.STS bits. The timestamp value for the slow channel is identical to the timestamp value of the last fast channel message contributing to the slow channel message.

In case timestamp counter synchronization is required, the following flow should be used.



Note 1. This flow shows an example for RSENT0 setting to be operated as MASTER.
For more details of various Master/Slave setting relationship in all RSENT modules, refer to **Figure 26.5, Timestamp Signal Connection among Channels**.

Figure 26.4 Timestamp Counter Synchronization

Further synchronization can be done as long as master RSENT module is in either OPERATION ACTIVE or OPERATION IDLE state.

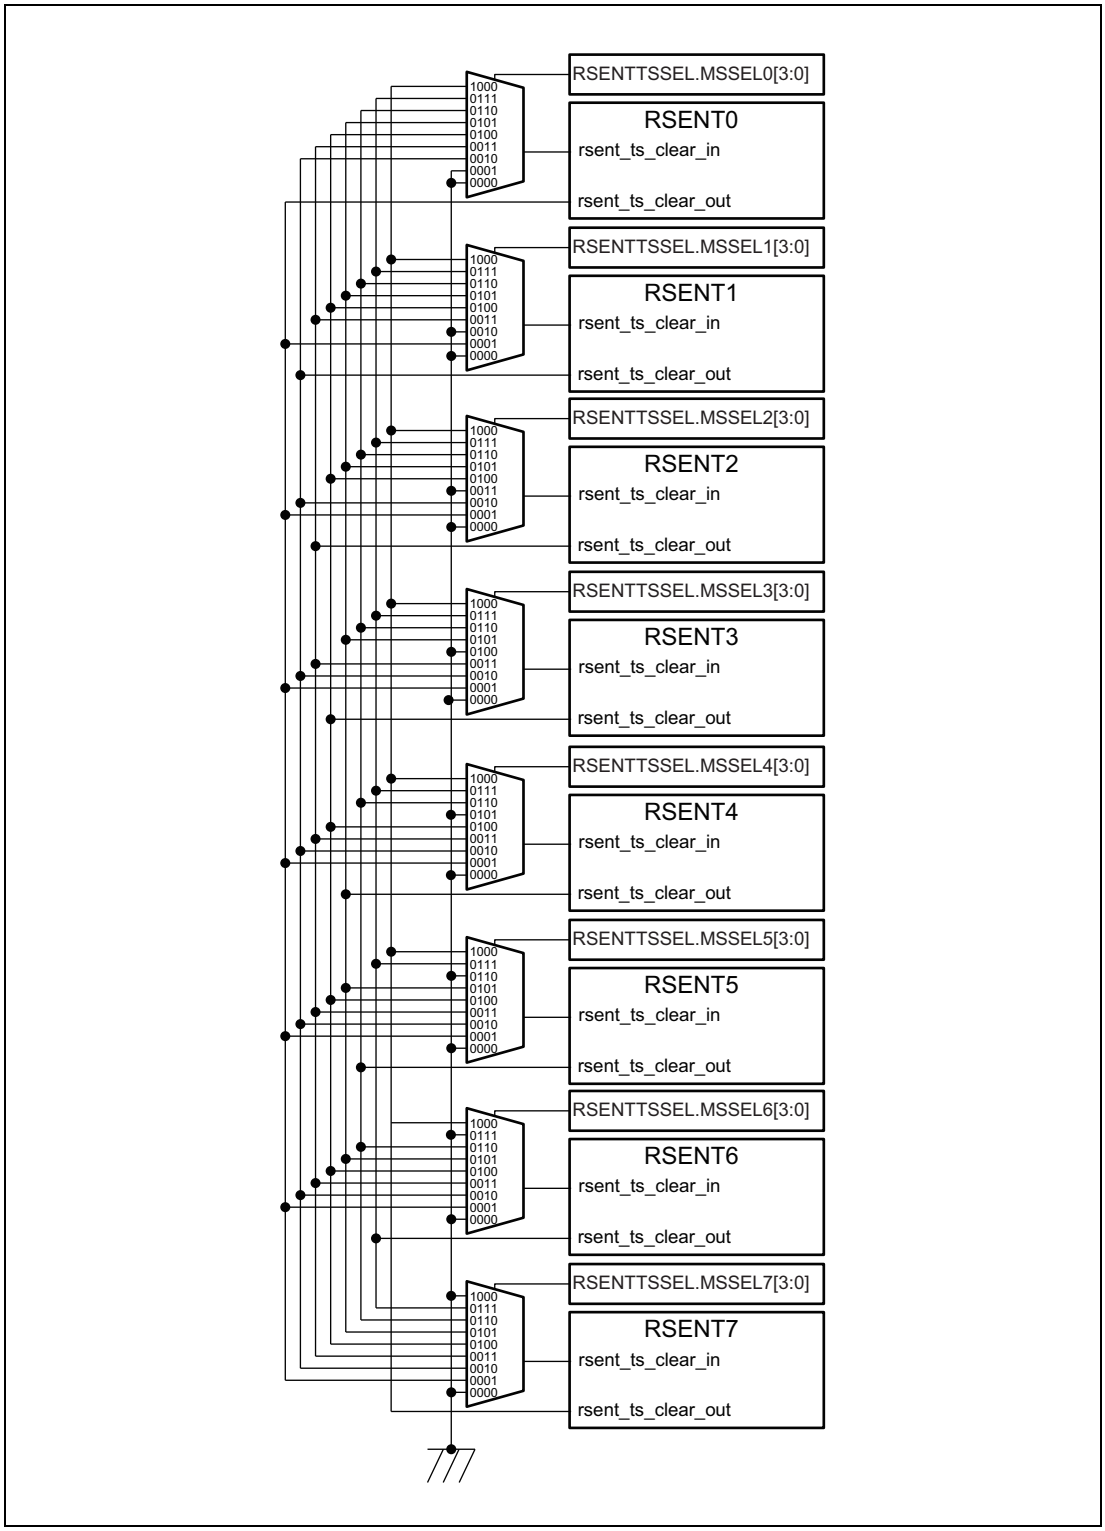


Figure 26.5 Timestamp Signal Connection among Channels

Timestamp clear input (sent_ts_clear_in) is used to clear the timestamp counter value. This signal shall be connected to the sent_ts_clear_out pin of the RSENT units which are dedicated as timestamp masters.

Timestamp clear output (sent_ts_clear_out) is set for one clock cycle when the timestamp counter is configured to operate in the master mode (RSENTnTSPC.TMS = 0) and the CPU clears the timestamp counter.

In master mode, the clearing timing is output to the output signal sent_ts_clear_out. In slave mode, the input signal sent_ts_clear_in from the master can be used to clear the timestamp.

When the timestamp counter is configured to operate in master mode (RSENTnTSPC.TMS = 0), sent_ts_clear_in has no effect on the timestamp counter register. This signal shall be connected to 1'b0 for the RSENT unit which is configured as master.

When the timestamp counter is configured to operate in slave mode (RSENTnTSPC.TMS = 1), the dedicated timestamp masters can be chosen by various setting of RSENTTSSEL register, while multi-masters or master/slave(s) relation is decided by the setting of RSENTnTSPC.TMS of each unit beforehand.

Setting examples:

[Example 1] RSENT2 operate as master and RSENT0, RSENT1, RSENT3, RSENT4, RSENT5, RSENT7 operate as slaves.

- RSENT0TSPC.TMS = 1_B
- RSENT1TSPC.TMS = 1_B
- RSENT2TSPC.TMS = 0_B
- RSENT3TSPC.TMS = 1_B
- RSENT4TSPC.TMS = 1_B
- RSENT5TSPC.TMS = 1_B
- RSENT6TSPC.TMS = Don't care
- RSENT7TSPC.TMS = 1_B
- RSENTTSSEL.MSSEL0[3:0] = 0011_B
- RSENTTSSEL.MSSEL1[3:0] = 0011_B
- RSENTTSSEL.MSSEL2[3:0] = 0011_B
- RSENTTSSEL.MSSEL3[3:0] = 0011_B
- RSENTTSSEL.MSSEL4[3:0] = 0011_B
- RSENTTSSEL.MSSEL5[3:0] = 0011_B
- RSENTTSSEL.MSSEL6[3:0] = 0000_B
- RSENTTSSEL.MSSEL7[3:0] = 0011_B

[Example 2] RSENT0, RSENT1, RSENT2, RSENT3, RSENT4, RSENT5, RSENT6, RSENT7 operate in master mode without slaves (RSENT1 is the timestamp master).

- RSENT0TSPC.TMS = 0_B
- RSENT1TSPC.TMS = 0_B
- RSENT2TSPC.TMS = 0_B
- RSENT3TSPC.TMS = 0_B
- RSENT4TSPC.TMS = 0_B
- RSENT5TSPC.TMS = 0_B
- RSENT6TSPC.TMS = 0_B

- RSENT7TSPC.TMS = 0_B
- RSENTTSSEL.MSSEL0[3:0] = 0001_B
- RSENTTSSEL.MSSEL1[3:0] = 0010_B
- RSENTTSSEL.MSSEL2[3:0] = 0011_B
- RSENTTSSEL.MSSEL3[3:0] = 0100_B
- RSENTTSSEL.MSSEL4[3:0] = 0101_B
- RSENTTSSEL.MSSEL5[3:0] = 0110_B
- RSENTTSSEL.MSSEL6[3:0] = 0111_B
- RSENTTSSEL.MSSEL7[3:0] = 1000_B

26.4.2.2 Communication Clock Configuration

(1) RX BRP Setting

"RSENT communication clock frequency ($f_{COMMUNICATION}$)" is multiplied by the configured lowest term fraction set by RSENTnBRP.SCDV and RSENTnBRP.SCMV to generate the sample clock.

The RSENTnBRP.SCDV and RSENTnBRP.SCMV values should be selected in such a way that a sample clock frequency (f_{SAMPLE}) of 16 MHz is generated according to the following formula.

$$f_{SAMPLE} = 16\ MHz = f_{COMMUNICATION} \times \frac{Sample\ Clock\ Multiplication\ Value\ (RSENTnBRP.SCMV+1)}{Sample\ Clock\ Division\ Value\ (RSENTnBRP.SCDV+1)}$$

Where Sample Clock Multiplication Value = 1 (RSENTnBRP.SCMV = 5'd0),
Sample Clock Division Value = 5 (RSENTnBRP.SCDV = 7'd4),
$f_{COMMUNICATION} = 80\ MHz$
$f_{SAMPLE} = 80 \times 1/5 = 16\ MHz$

(2) RX and SPC Tick Settings

The used tick length in RX and SPC function can be configured with the RSENTnBRP.TTI and RSENTnBRP.TTF bits. Tick lengths from 1.0 µs to 90.0 µs with a resolution of 0.1 µs can be configured.

The RSENTnBRP.TTI holds the integer part of the tick length and the RSENTnBRP.TTF bits hold the fractional part of the tick length. The tick length is then calculated by:

$$T_{TICK} = T_{RSENTnBRP.TTI} + T_{RSENTnBRP.TTF}$$

Where RSENTnBRP.TTI = 0, RSENTnBRP.TTF = 3

$$T_{TICK} = 1 + 0.3 = 1.3\ \mu s$$

26.4.3 RSENT Operation

When starting transfer through RSENTn in this product series, be sure to make the pin settings corresponding to the RSENTn interface, then follow the flow for the individual settings described in this section.

For details of the pin settings, see **Section 2, Pin Functions**.

26.4.3.1 Changing Operation Modes

Once initialization has been completed in CONFIGURATION mode, operation can be enabled by entering OPERATION ACTIVE mode. This is done by setting the RSENTnMDC.OMC bits to OPERATION ACTIVE and waiting for the RSENTnMST.OMS to transition to OPERATION ACTIVE.

Once in OPERATION ACTIVE mode the RSENT module begins to receive messages or SPC communication can be started depending on the configuration.

Figure 26.6 shows the communication enabled flow assuming that the RSENT module is in RESET mode:

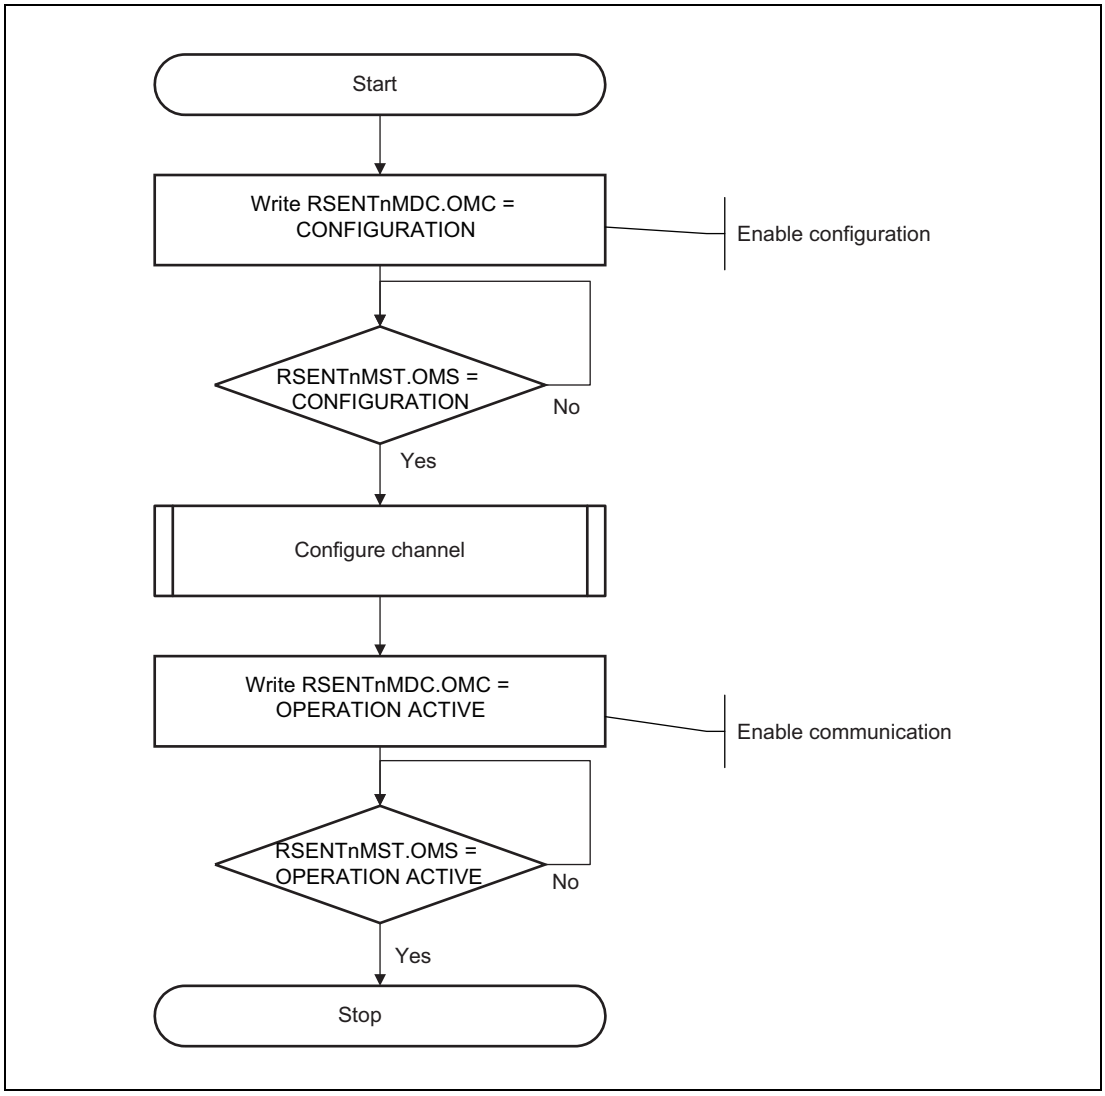

Figure 26.6 Communication Enable Flow

To leave OPERATION ACTIVE mode, communication should be disabled first by entering OPERATION IDLE mode. This is done by setting the RSENTnMDC.OMC bits to OPERATION IDLE and waiting for the RSENTnMST.OMS bits to transition to OPERATION IDLE.

However, when the SPC is enabled (RSENTnCC.SPCE = 1) and the SPC trigger transmission has not been requested after the previous SPC communication has been completed (e.g. successful reception for the previous SPC trigger transmission), the RSENT module can directly enter the CONFIGURATION mode.

The transition between OPERATION ACTIVE and OPERATION IDLE depends on the setting of the RSENTnCC.SPCE bit.

(1) RSENTnCC.SPCE = 0

In case a reception is currently ongoing, the mode change from OPERATION ACTIVE to OPERATION IDLE takes place when the falling edge at the end of the next status communication nibble is detected or an error was flagged.

In case no reception is ongoing, the mode change from OPERATION ACTIVE to OPERATION IDLE takes place immediately.

(2) RSENTnCC.SPCE = 1

In case a reception is ongoing, the mode change from OPERATION ACTIVE to OPERATION IDLE takes place when the falling edge of the end pulse is received.

In case a no response error is flagged, the mode change from OPERATION ACTIVE to OPERATION IDLE takes place at the same time as the error flagging.

The mode change from OPERATION ACTIVE to OPERATION IDLE takes place when the sequence of making a SPC trigger and receiving the response has been completed. This means when a response was already received, the transition takes place immediately. When the response is still pending, the mode change from OPERATION ACTIVE to OPERATION IDLE takes place when the falling edge of the end pulse is received.

CONFIGURATION mode can be entered by writing CONFIGURATION to the RSENTnMDC.OMC bits and waiting for the RSENTnMST.OMS to transition to CONFIGURATION.

Once CONFIGURATION mode is entered, the remaining status and message information stored in the RSENT module is lost since status and message information is cleared in CONFIGURATION mode.

Figure 26.7 shows the communication disable flow assuming that the RSENT module is in OPERATION ACTIVE mode.

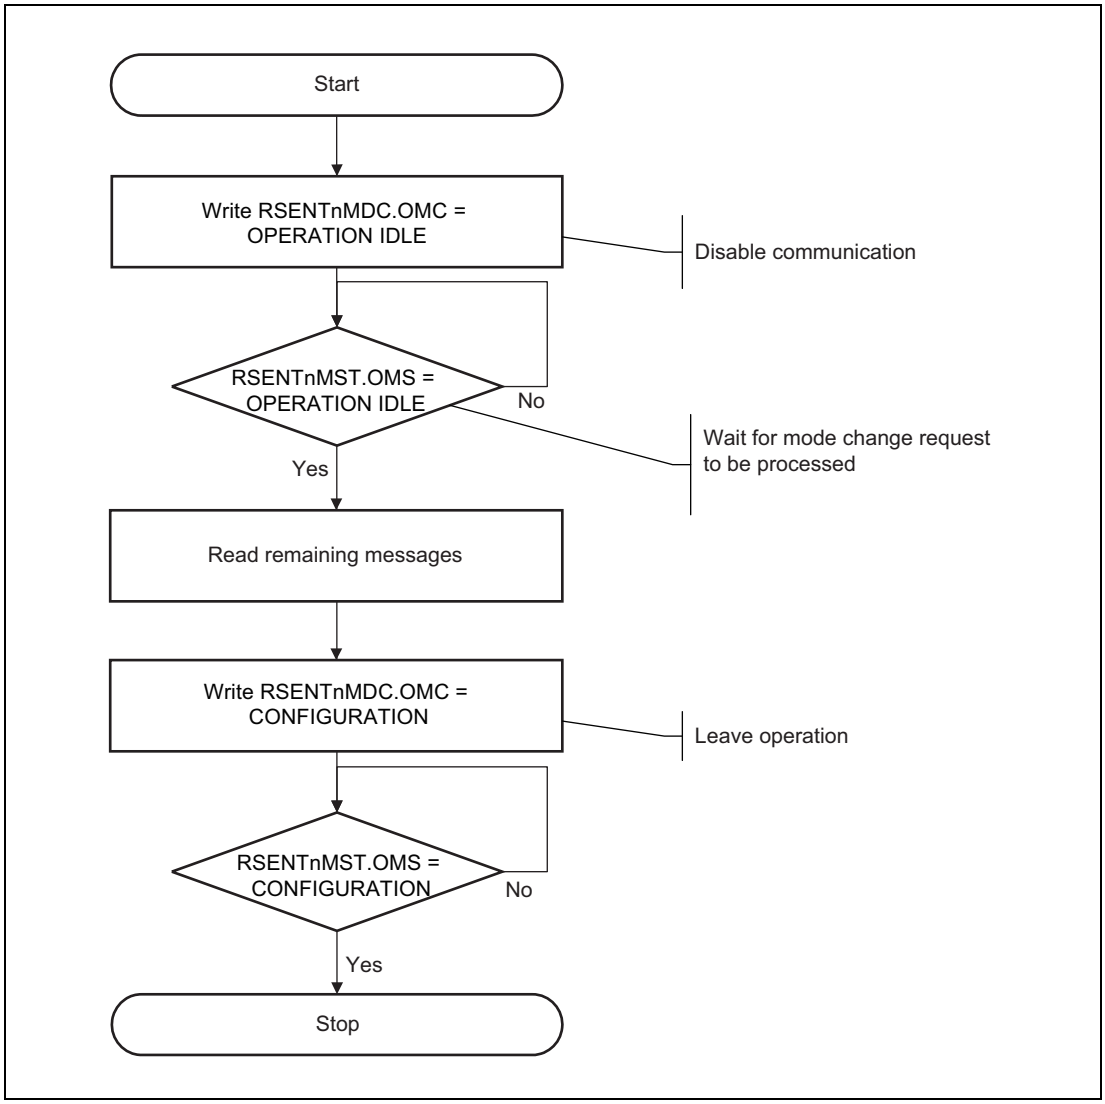

Figure 26.7 Communication Disable Flow

26.4.3.2 Message Reception

RSENT message reception is composed of the calibration pulse reception followed by the data nibble pulse reception.

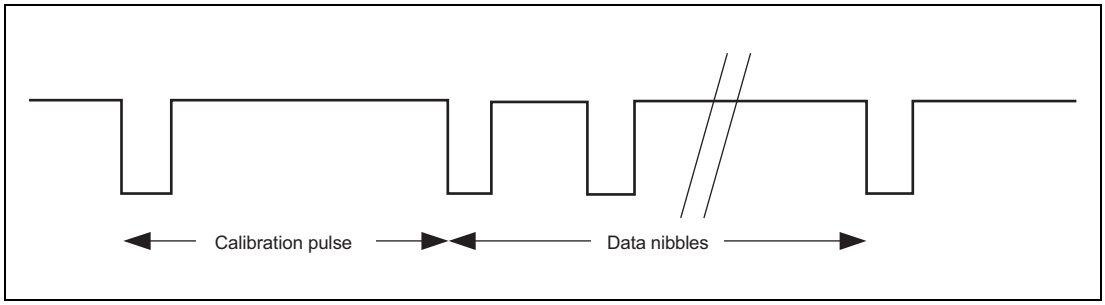

Figure 26.8 RSENT Received Message Structure

(1) Calibration Pulse Reception

Within the calibration pulse reception phase the internally generated clock tick is adjusted to the transmit clock speed.

In addition, the calibration pulse is used to end the previous message and perform message diagnostics. The RSENT module supports automatic calibration pulse length diagnostics in variable message length modes (RSENTnCC.PPTC = 0). In case the calibration pulse ratio check fails, the calibration pulse length variation error flag (RSENTnCS.CVS) is set to 1.

(2) Data Nibble Reception

The receive function of the RSENT module is a straightforward capture and compare function. The RSENT module receives sensor information encoded by the temporal distance of two consecutive falling edges on the data line. The temporal distance (the Number of Clock Ticks) is captured and compared against a set of values to determine the actual nibble value. The data encoding is illustrated in **Table 26.34, Data Nibble Encoding** below.

Table 26.34 Data Nibble Encoding

Nibble Period (Number of Clock Ticks)	Nibble Value (Binary)
12	0000_B
13	0001_B
14	0010_B
15	0011_B
16	0100_B
17	0101_B
18	0110_B
19	0111_B
20	1000_B
21	1001_B
22	1010_B
23	1011_B
24	1100_B
25	1101_B
26	1110_B
27	1111_B

The received data nibbles are composed into an RSENT message which is then stored in the fast channel message reception buffer.

Any other received nibble period during the reception of data nibbles will cause a fast channel nibble encoding error.

(3) Fast Channel Message Reception

Messages received on the fast message channel are stored in a receive buffer.

A fast channel message reception buffer is composed of the calibration pulse length register (RSENTnCPL), the message length register (RSENTnML), the fast channel receive timestamp register (RSENTnFRTS), and the fast channel receive data register (RSENTnFRXD).

All registers are placed on successive addresses that allows transferring the register content into memory using sDMA.

The RSENT module is equipped with a double receive buffer structure that allows the storage of two complete RSENT messages including the related timestamp and message length information. Message decoding and assembling are done in a separate register stage.

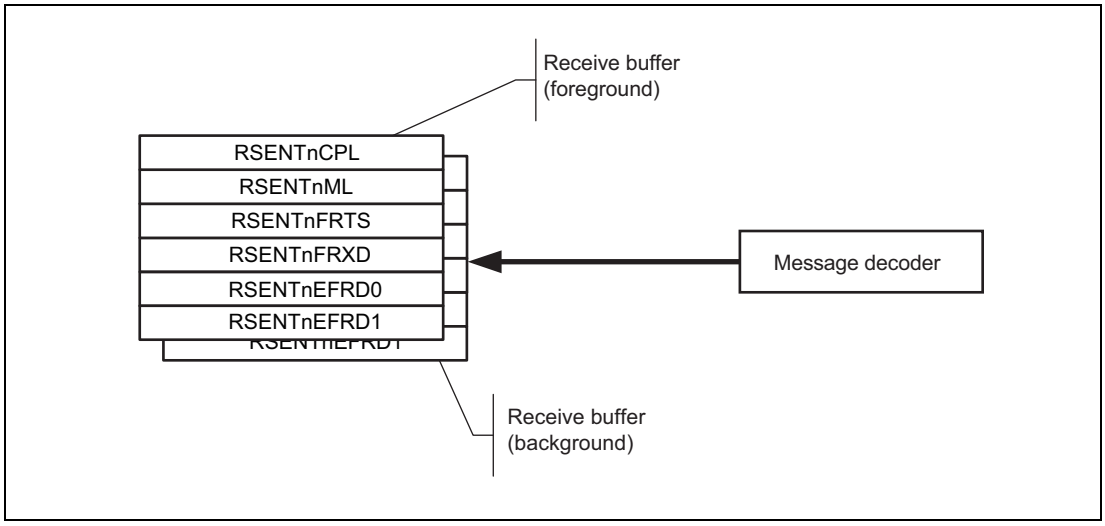

Figure 26.9 Fast Channel Message Reception Buffer

The first received message is placed into the message buffer that can be accessed by the CPU. This buffer (except the RSENTnFRXD.SNDM and RSENTnEFRD0.SNDM bits) is not updated any more until the RSENTnFRXD.FND bit or RSENTnEFRD1 register was read.

When a new message is placed into a receive buffer, the RSENTnFRXD.FND bit and RSENTnEFRD0.FND bits are set. At the same time, the RSENTnCS.FRS bit is set and, if enabled, a receive interrupt request is generated.

When the foreground receive buffer is holding an unprocessed message (the RSENTnFRXD.FND and RSENTnEFRD0.FND bits are 1), any further incoming message is placed in the background buffer. The background buffer is updated with any further incoming messages. In case an unprocessed background message buffer message is overwritten, the RSENTnCS.FMS bit is set to 1.

When the CPU reads the RSENTnFRXD.FND bit or RSENTnEFRD1 register and there is valid data in the background buffer, the data previously located in the background buffer becomes available in the receive buffer and is accessible by the CPU. If enabled, a new interrupt request for fast channel data is generated and RSENTnCS.FRS is set.

When the RSENTnEFRD0.FND and RSENTnFRXD.FND/RSENTnCS.FRS bit is not set, the data in the receive buffer is not defined and the CPU should not access the receive buffer.

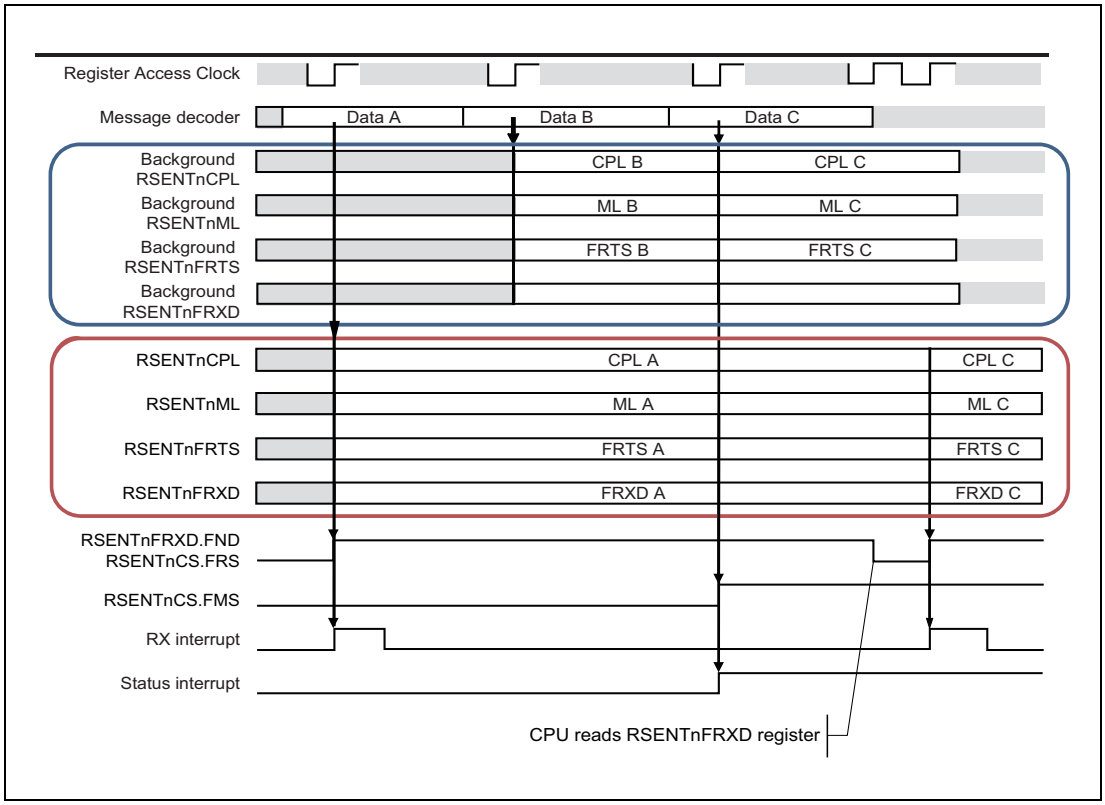

Figure 26.10 Fast Channel Message Reception Buffer Update Timing

The update timing of the receive buffer depends on the applied configuration as depicted in **Figure 26.11** to **Figure 26.14**.

The RSENTnFRTS register is updated with the current timestamp counter register value when the calibration pulse is detected.

The data alignment in the RSENTnFRXD register depends on the nibble data count (RSENTnCC.NDN).

Table 26.35 Data Nibble Alignment in RSENTnFRXD Register

RSENTnFRXD RSENTnCC.NDN	23:20	19:16	15:12	11:8	7:4	3:0
000_B	Undefined	Undefined	Undefined	Undefined	Undefined	Nibble 1
001_B	Undefined	Undefined	Undefined	Undefined	Nibble 1	Nibble 2
010_B	Undefined	Undefined	Undefined	Nibble 1	Nibble 2	Nibble 3

(a) SAE operation with variable message length and preferred check method (RSENTnCC.SPCE = 0, RSENTnCC.PPTC = 0, RSENTnCC.FCM = 0)

In this operation mode, the RSENT module automatically performs the check for successive calibration pulse variation according to the preferred option in the J2716 2016 specification. In this mode, message diagnostics is done after the calibration pulse was received following a message.

If this check is passed, the message reception buffer is updated.

If this check is not passed, the message reception buffer is not updated and RSENTnCS.CVS is set to 1.

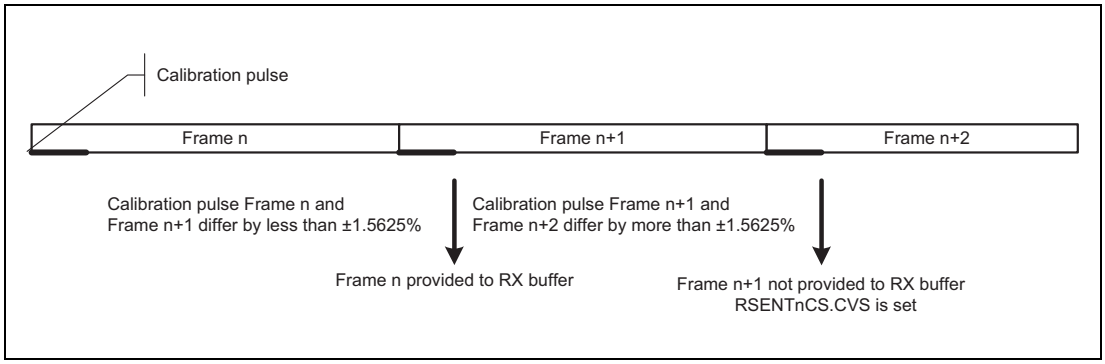

Figure 26.11 Buffer Update in Variable Message Length Mode and Preferred Check Method

(b) SAE operation with variable message length and optional check method (RSENTnCC.SPCE = 0, RSENTnCC.PPTC = 0, RSENTnCC.FCM = 1)

In this operation mode, the RSENT module automatically performs the check for successive calibration pulse variation according to the optional frame check method as described in the J2716 2016 specification. In this mode, the calibration pulse of the current frame is compared to the calibration pulse of the last valid preceding frame.

If this check is passed, the message reception buffer is updated.

If this check is not passed, the message reception buffer is not updated and RSENTnCS.CVS is set to 1.

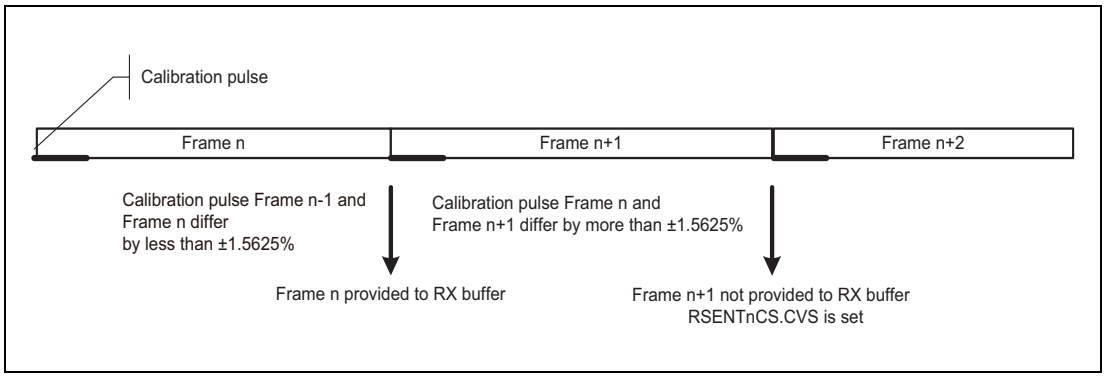

Figure 26.12 Buffer Update in Variable Message Length Mode and Optional Check Method

(c) SAE operation with fixed message length (RSENTnCC.SPCE = 0, RSENTnCC.PPTC = 1)

In this mode, the RSENT module does not perform the check for calibration pulse and message length ratio according to the preferred option in the J2716 2016 specification. In this mode, the RSENT module provides the calibration pulse length in the RSENTnCPL register and the message length information in the RSENTnML register. The numbers provided are based on samples.

The message buffer is updated at the beginning of the following calibration pulse irrespective of the values in the RSENTnCPL and RSENTnML registers. The CPU needs to calculate the ratio and either accept or discard the message.

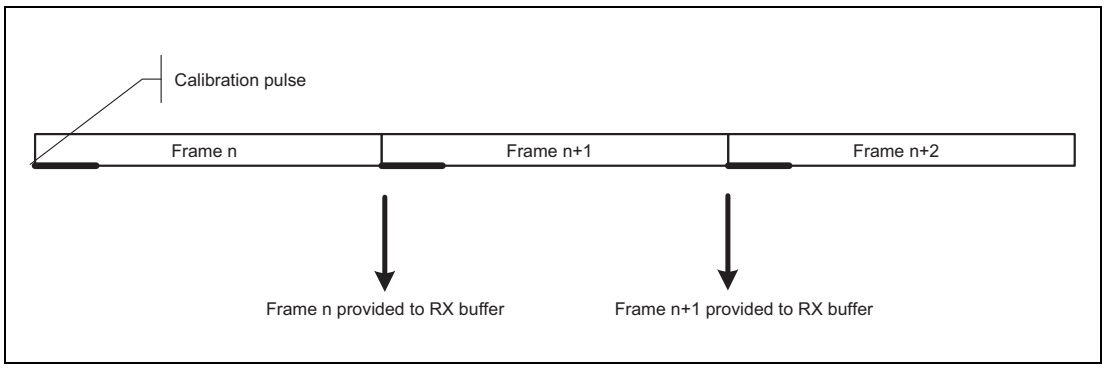

Figure 26.13 Buffer Update in Fixed Message Length Mode

The RSENTnCS.CVS (calibration pulse width variation error status) bit is never set in this mode.

(d) SPC operation (RSENTnCC.SPCE = 1)

In this operation mode, sensor data transmission is done following a SPC master trigger pulse. Within SAE SENT communication, the calibration pulse or pause pulse is terminating the previous message. In SPC communication, the sensor is only sending data following a SPC trigger request. An end pulse sent by the sensor is terminating the message. The message buffer is updated at the beginning of the end pulse.

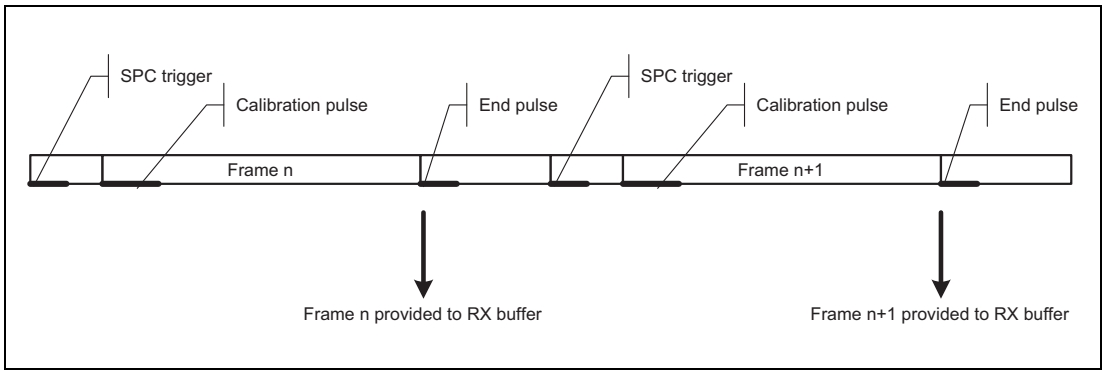

Figure 26.14 Buffer Update in SPC Mode

The RSENTnCS.CVS (calibration pulse width variation error status) bit is never set in this mode.

The RSENT module provides the calibration pulse length in the RSENTnCPL register and the message length information in the RSENTnML register. The numbers provided are based on samples. The CPU needs to calculate the ratio of calibration pulses and/or message length and either accept or discard the message.

In case of variable message length mode, the RSENT module cannot perform this check because the receive timing of the next calibration pulse depends on the next SPC trigger timing.

(4) Fast Channel Reception Flow

In **Figure 26.15**, the recommended reception flow for the fast channel message reception buffer is shown.

When using a polling or event driven method, the CPU should only read the setting of the RSENTnCS.FRS bit to check the availability of new fast channel data.

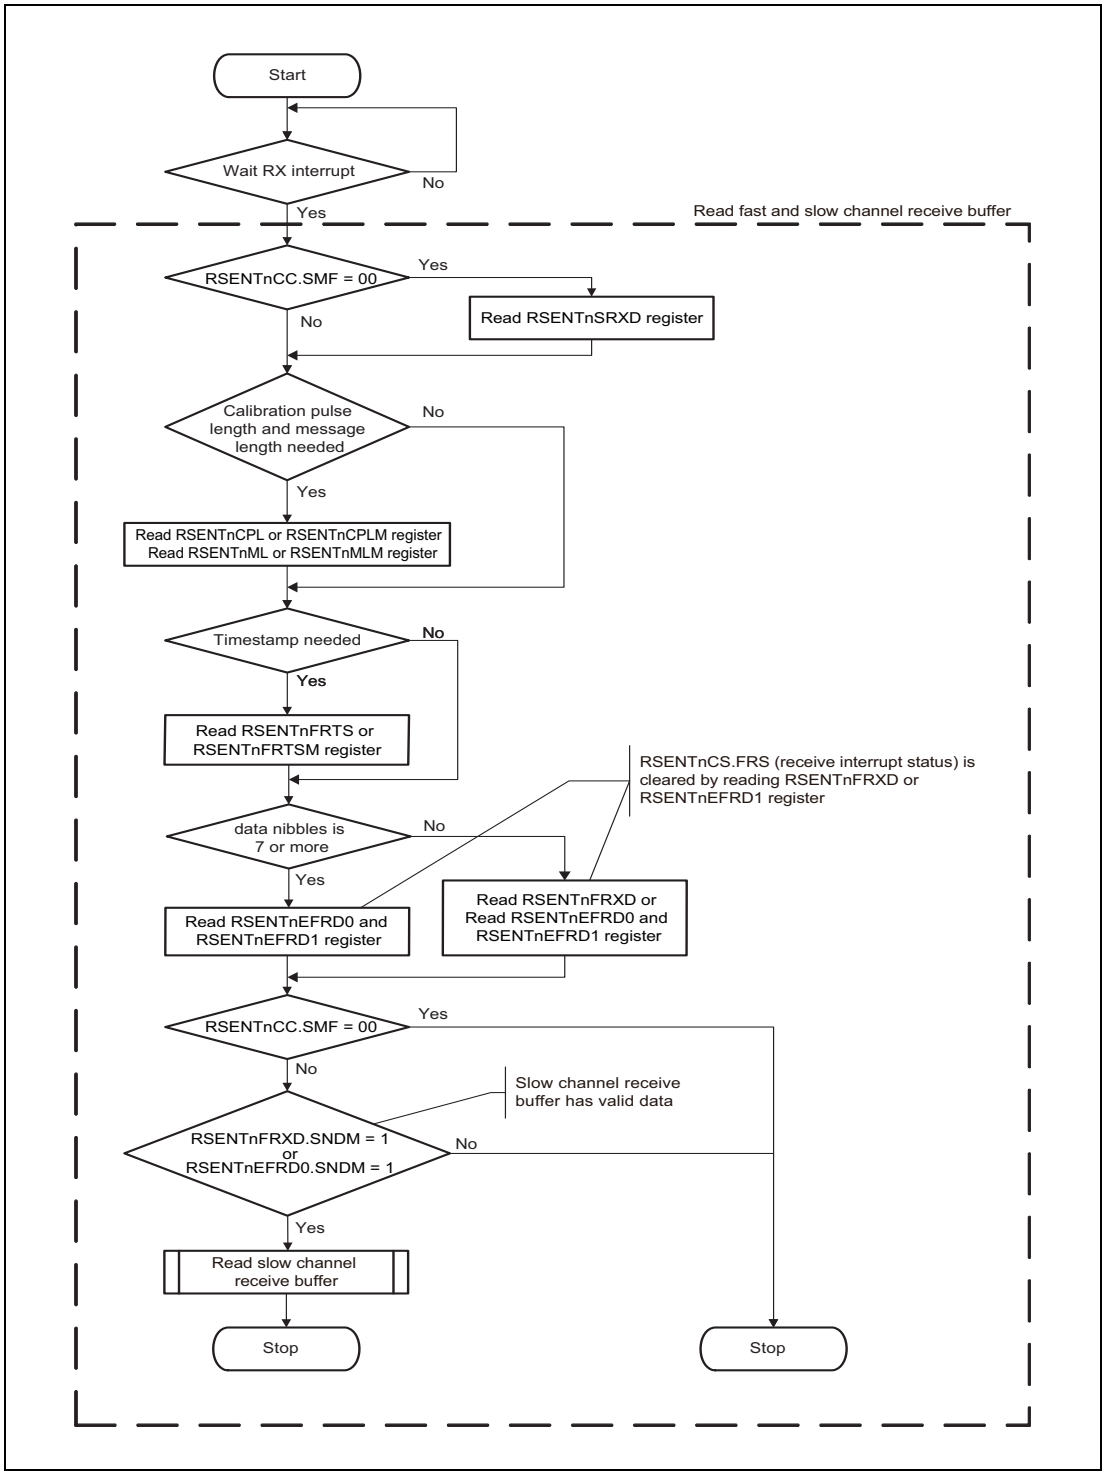

Figure 26.15 Fast Channel Reception Flow

In any case, the CPU should keep the order in reading the receive buffer registers as shown in the flow. The RSENTnFRXD or RSENTnEFRD0 register should be the last register to be accessed.

The handling of the slow channel receive buffer is described in **Section 26.4.3.2(6), Slow Channel Reception Flow**.

In case of SAE communication with pause pulse and fixed message length, the flow must be extended by checking of the ratio of the calibration pulse to message length. This variation check must be performed by the CPU. In case the variation check fails, the CPU must discard the received message.

(5) Slow Channel Message Reception

The RSENT module supports extraction of the slow message out of the fast channel messages by using the bits 3 and 2 out of the status and communications nibble. In order to enable the slow channel extraction, the CPU should set the RSENTnCC.SMF bits to the expected serial message format.

When no serial message extraction is selected (RSENTnCC.SMF = 00_B), the RSENTnSRXD register becomes part of the fast channel message reception buffer structure (including background buffer) and RSENTnSRTS register should be ignored. The communications and status nibble is placed in the RSENTnSRXD.IDD bits. Furthermore no slow channel new data and slow channel message lost flags are generated.

In order to receive the slow channel serial message, all fast channel serial messages contributing to a slow channel serial message must be received successfully and the received slow channel serial message must comply with the selected serial message format.

A message lost on the fast channel does not impact the reception on the slow channel.

A slow channel message reception buffer is composed of the slow channel receive timestamp register (RSENTnSRTS) and the slow channel receive data register (RSENTnSRXD).

In opposite to the fast channel message reception buffer, the slow channel message reception buffer does not support a double receive buffer structure; only a single receive buffer structure is available.

Message decoding and assembling is done in a separate register stage.

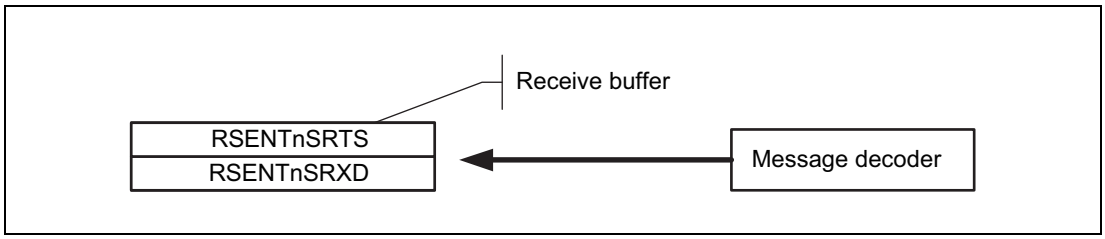

Figure 26.16 Slow Channel Message Reception Buffer

The slow channel message reception buffer is updated at the same time as the fast channel message reception buffer that holds the last status and communication nibble required for the slow channel message. The RSENTnSRXD.SND bit is set to 1 at the same time.

Further updates to the buffer are not carried out until after the RSENTnSRXD.SND bit has been read.

When the receive buffer is holding an unprocessed message (RSENTnSRXD.SND is 1), any further incoming message is lost (the slow channel message reception buffer is not updated) and RSENTnCS.SMS is set to 1.

When the CPU reads the RSENTnSRXD register, RSENTnSRXD.SND is automatically cleared.

The RSENTnSRTS register is updated with the current timestamp counter register value of the last frame contributing to the slow channel message.

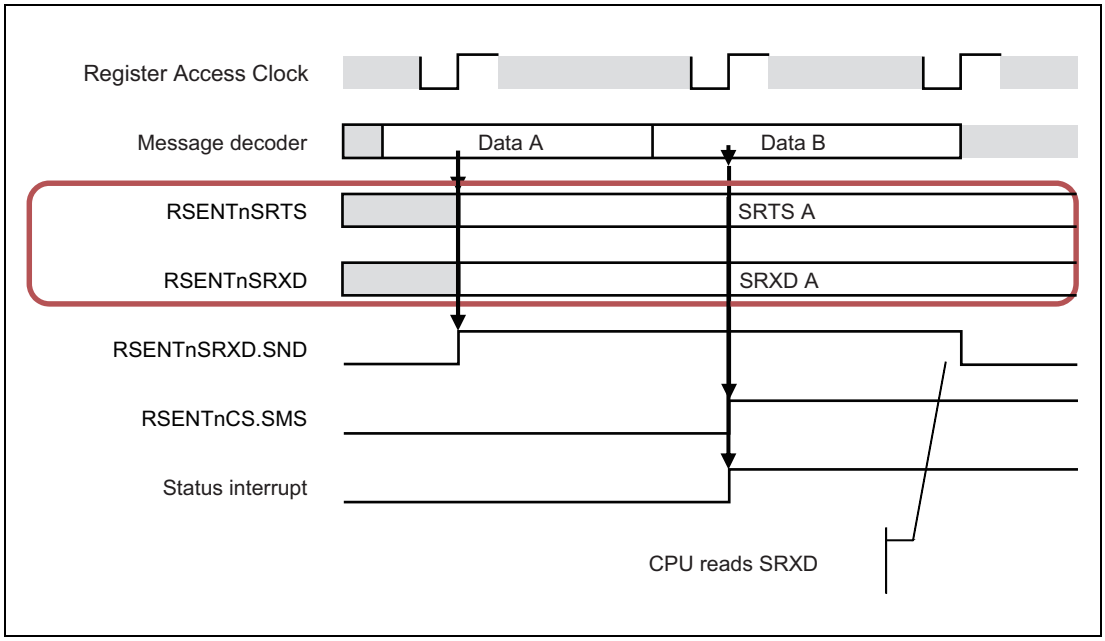

Figure 26.17 Slow Channel Message Reception Buffer Update Timing

The data alignment in the RSENTnSRXD register depends on the slow channel message format (RSENTnCC.SMF) and the received configuration bit.

Table 26.37 Data Alignment in RSENTnSRXD Register

RSENTnCC.SMF	RSENTnSRXD.SMGC	RSENTnSRXD.IDD [19:16]	RSENTnSRXD.IDD [15:12]	RSENTnSRXD.IDD [11:8]	RSENTnSRXD.IDD [7:4]	RSENTnSRXD.IDD [3:0]
00_B	Undefined	Undefined	Undefined	Undefined	Undefined	Status and communication nibble
01_B	Undefined	Undefined	Undefined	Message ID[3:0]	DATA[7:4]	DATA[3:0]
10_B	0	Message ID[7:4]	Message ID[3:0]	DATA[11:8]	DATA[7:4]	DATA[3:0]
10_B	1	Message ID[3:0]	DATA[15:12]	DATA[11:8]	DATA[7:4]	DATA[3:0]

(6) Slow Channel Reception Flow

In **Figure 26.18**, the recommended reception flow for the slow channel message reception buffer is shown. When the slow channel receive data is required, this process should be executed as part of the fast channel reception flow.

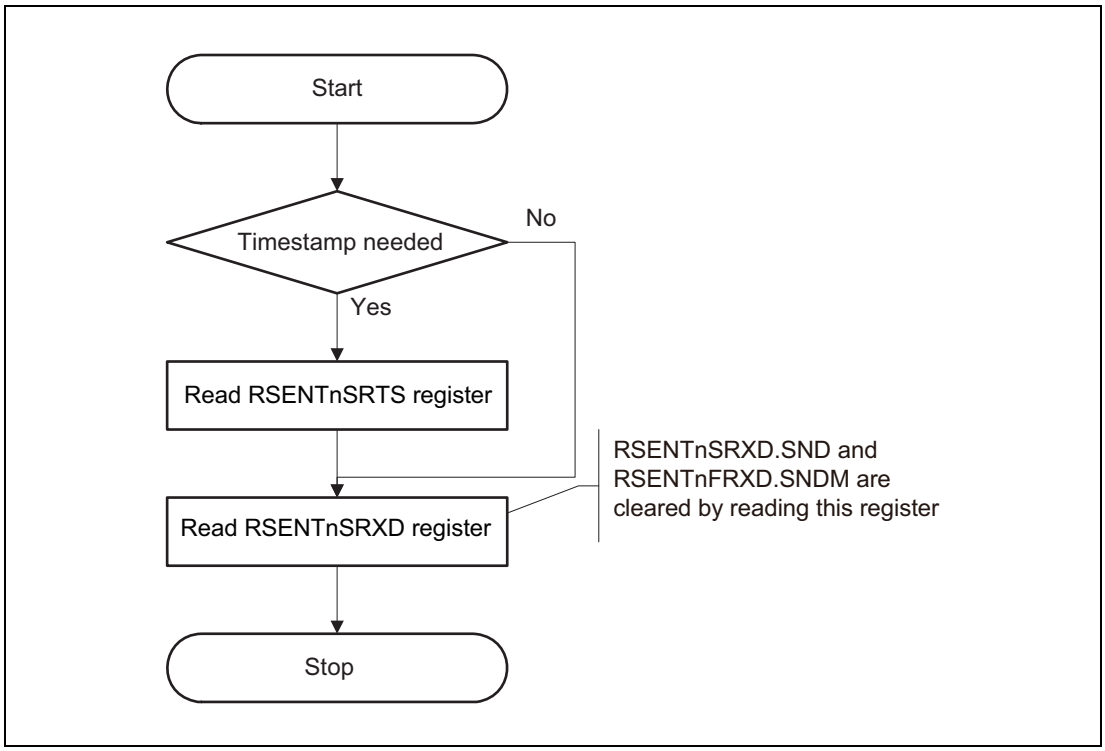

Figure 26.18 Slow Channel Reception Flow

In any case, the CPU should keep the order in reading the slow channel message reception buffer registers as shown in the flow. The RSENTnSRXD.SND bit should be accessed as last.

(7) DMA Flow

In case of DMA usage, the start address for the DMA usage and the number of transfers define which part of the receive buffer will be transferred. The RSENTnFRXD or RSENTnEFRD1 register should be the last register to be accessed using a 32-bit access method.

In case of SAE communication with pause pulse and fixed message length, the flow must be extended by checking of the ratio of the calibration pulse to message length. This variation check must be performed by the CPU. In case the variation check fails, the CPU must discard the received message.

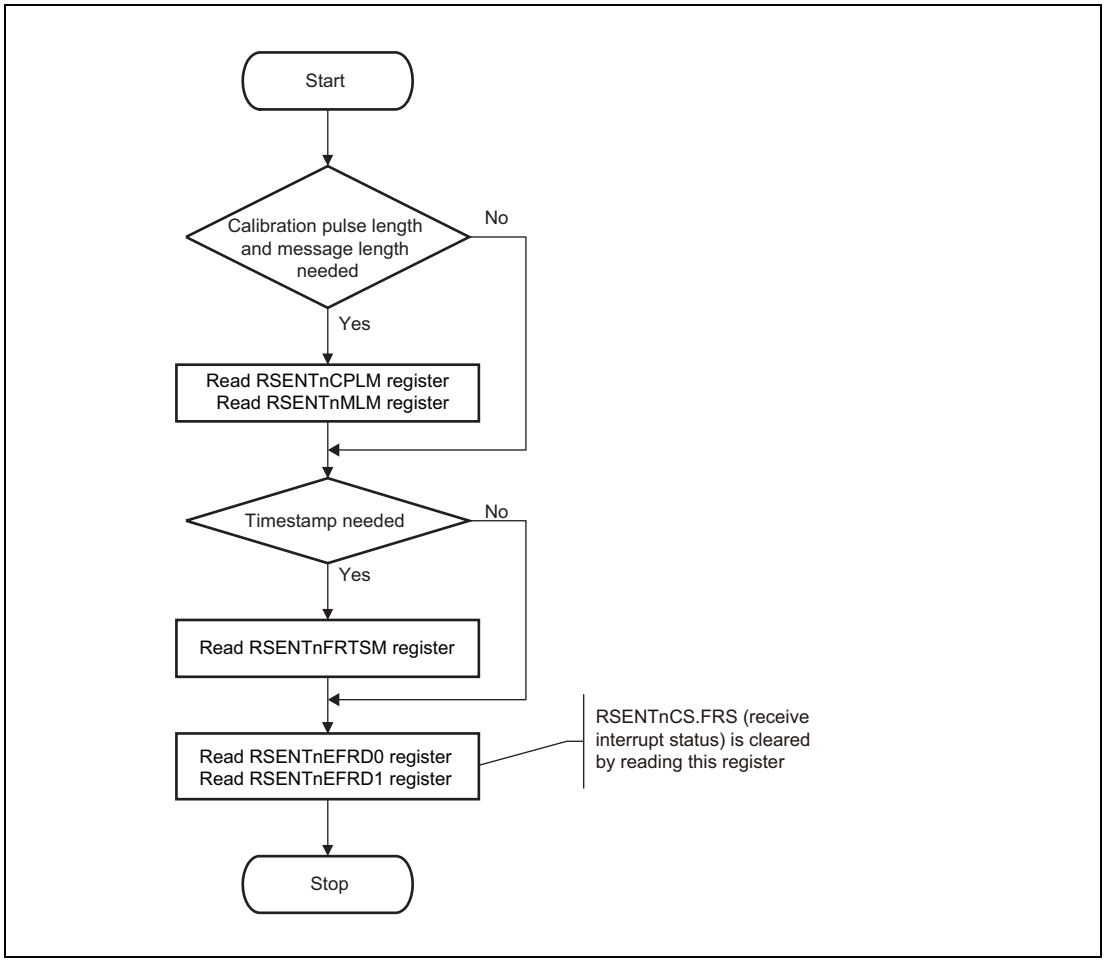

Figure 26.19 DMA Reception Flow

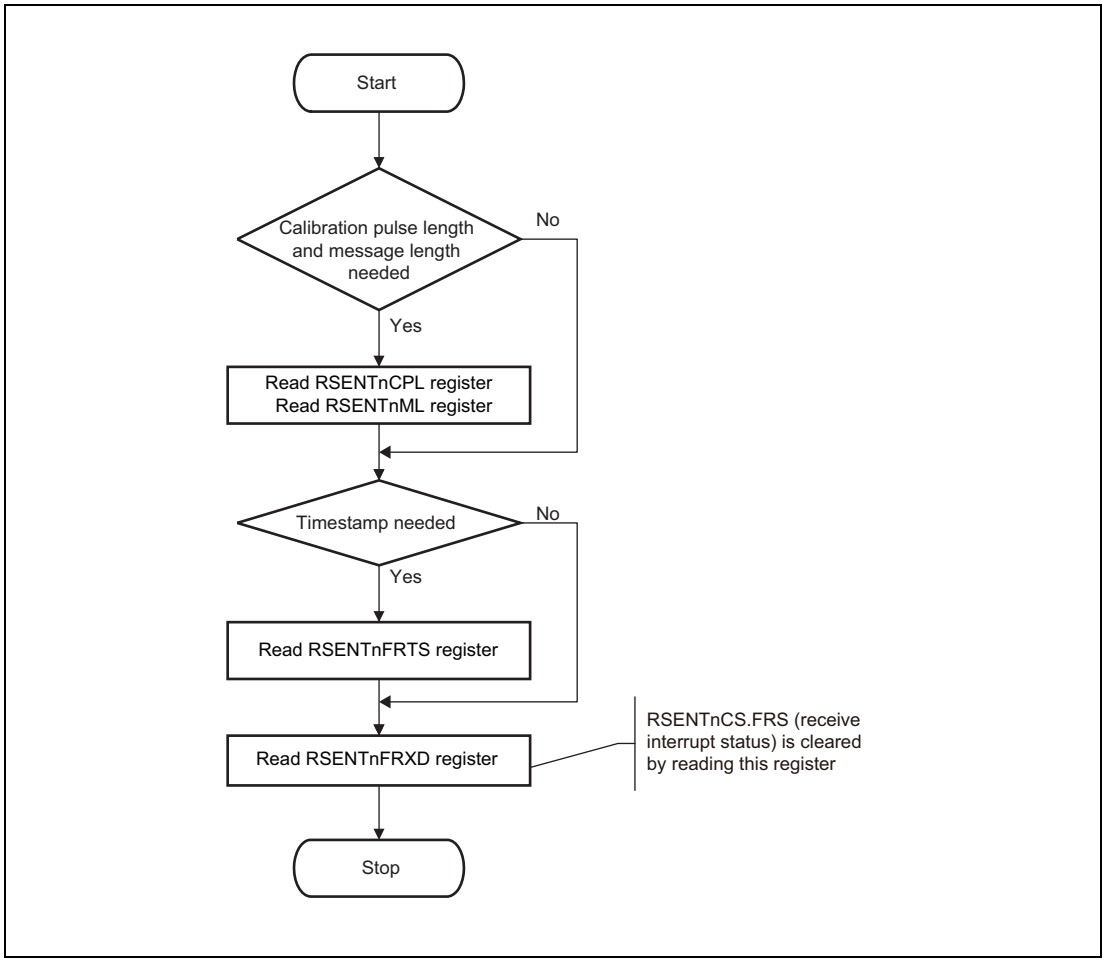

Figure 26.20 DMA Reception Flow (Data Nibble are 6 or Less)

In the software processing, when the transferred data set, the CPU should check the status of the transferred RSENTnFRXD.SNDM bit. If this bit is set to 1, then the user needs to read the slow channel message reception buffer if needed.

(8) Error Flagging

Message lost errors (RSENTnCS.SMS or RSENTnCS.FMS) are flagged when a new message's diagnostics pass before the previous message is read.

The SPC communication error (shown in RSENTnCS.NRS) is flagged when the CPU writes to RSENTnSPTC.TLL before or during response reception.

The update timings for fast channel reception errors (RSENTnCS.CVS, RSENTnCS.CLS, RSENTnCS.FNS, RSENTnCS.FES, and RSENTnCS.FCS) and slow channel reception errors (RSENTnCS.SCS and RSENTnCS.SES) depends on the configuration of RSENTnCC.SPCE, RSENTnCC.FCM, RSENTnCC.PPC, and RSENTnCC.PPTC.

Table 26.38, Error flag set timing when RSENTnCC.SPCE = 0 and **Table 26.39, Error flag set timing when RSENTnCC.SPCE = 1** list the timings with which the error flags corresponding to each setting are updated.

In case a nibble encoding error or calibration pulse length error is detected, message reception is terminated immediately. No further error flagging for this message is done. Message decoding starts again after a calibration pulse without calibration length error (RSENTnCS.CLS) is detected.

Table 26.38 Error flag set timing when RSENTnCC.SPCE = 0

RSENTnCC.SPCE	0							
RSENTnCC.FCM	0				1			
RSENTnCC.PPC	0		1		0		1	
RSENTnCC.PPTC	0	1	0	1	0	1	0	1
RSENTnCS.FCS	EC	×	EC	IM	IM	×	IM	IM
RSENTnCS.FES	EC	×	EC	IM	IM	×	IM	IM
RSENTnCS.FNS	EC	×	EC	—	—	×	—	—
RSENTnCS.SCS	IM	×	IM	IM	IM	×	IM	IM
RSENTnCS.SES	IM	×	IM	IM	IM	×	IM	IM
RSENTnCS.CLS	IM	×	IM	IM	IM	×	IM	IM
RSENTnCS.CVS	EC	×	EC	—	EC	×	EC	—

Note: EC: End of calibration pulse
IM: Immediately when detected
—: Not set
×: Invalid configuration

NOTE

When RSENTnCC.PPC and RSENTnCC.PPTC are 1_B, the mode is pause pulse with fixed message length.

When this mode, this diagnostic can be used as the receiver does not need to wait for the next calibration pulse to diagnose the current receive frame, so RSENTnCS.FNS and RSENTnCS.CVS are not set.

Table 26.39 Error flag set timing when RSENTnCC.SPCE = 1

RSENTnCC.SPCE	1							
RSENTnCC.FCM	0				1			
RSENTnCC.PPC	0		1		0		1	
RSENTnCC.PPTC	0	1	0	1	0	1	0	1
RSENTnCS.FCS	IM	×	IM	IM	IM	×	IM	IM
RSENTnCS.FES	IM	×	IM	IM	IM	×	IM	IM
RSENTnCS.FNS	—	×	—	—	—	×	—	—
RSENTnCS.SCS	IM	×	IM	IM	IM	×	IM	IM
RSENTnCS.SES	IM	×	IM	IM	IM	×	IM	IM
RSENTnCS.CLS	IM	×	IM	IM	IM	×	IM	IM
RSENTnCS.CVS	—	×	—	—	—	×	—	—

Note: IM: Immediately when detected
—: Not set
×: Invalid configuration

NOTE

In case the sensor stops communication, no buffer update or status update for last message takes place. The SW should take care of this by timeout checks.
SPC mode is a communication of only one frame that is start the SPC trigger to the starting point.
The Error flags are immediately set when they are detected. So RSENTnCS.FNE and RSENTnCS.CVS are not set.

When a transition to OPERATION IDLE is configured in RSENTnMDC.OMC and an error for the calibration or the fast channel reception is detected in the message in which the mode transition was requested, the error is not flagged and the message is aborted.

In case of a fast channel encoding error or a calibration pulse length error the OPERATION IDLE mode is entered immediately.

In case of a fast channel nibble count error, fast channel CRC error, or fast channel calibration pulse variation error the OPERATION IDLE state is entered at the end of the next status and communications nibble.

RSENTnCS.FNS is only set after a valid calibration pulse was detected and all following nibbles have a valid length (≥ 12 ticks and ≤ 27 ticks) or no nibble was received between two valid calibration pulses.

RSENTnCS.FES is only set if the nibble with an encoding error occurred in the communication and status nibble, CRC nibble or in one of the expected data nibbles.

If SPC is enabled (RSENTnCC.SPCE = 1), RSENTnCS.CLS is set if a calibration pulse was expected but the pulse length does not meet the calibration pulse range. If SPC is disabled (RSENTnCC.SPCE = 0), RSENTnCS.CLS is set only after a valid calibration pulse has been received and a calibration pulse was expected but the pulse length does not meet the calibration pulse range.

During re-synchronization additional error flags might be set which is not affecting the reception of the following frame.

26.4.4 SPC Function

The RSENT module supports an extension of the SAE J2716 specification known as SPC, whereby the RSENT module can pull down the RX line to initiate RSENT message transmission.

The user can configure the polarity of the sent_spc port.

The text below describes the behavior of the sent_spc port with the default settings of RSENTnCC.SOPC. When the value of RSENTnCC.SOPC after a reset is changed, the sent_spc port operates with inverted polarity.

The user can enable or disable the SPC extension by setting the RSENTnCC.SPCE bit. When the RSENTnCC.SPCE bit is set to 0, SPC is disabled. The sent_spc port is driven low by the RSENT module, allowing normal RSENT reception to take place. When the RSENTnCC.SPCE bit is set to 1, SPC is enabled and the sent_spc port can be driven high by the RSENT module to request a frame transmission by the sensor.

The transmission function of the RSENT module is a straightforward PWM function. The purpose of this function is to communicate in direction to the sensor by the output sent_spc. With the sent_spc output, the RSENT module can pull down the signal line by an external transistor.

The signal line will be held low for a configured length of tick time specified in the RSENTnSPCT.TLL bits.

The Tick time is configured with the RSENTnBRP.TTI bits and the RSENTnBRP.TTF bits which are equal to the transmission tick time. For details, see **Section 26.4.2.2(2), RX and SPC Tick Settings**.

Figure 26.21 and **Figure 26.22** show an example of the SPC circuit connection.

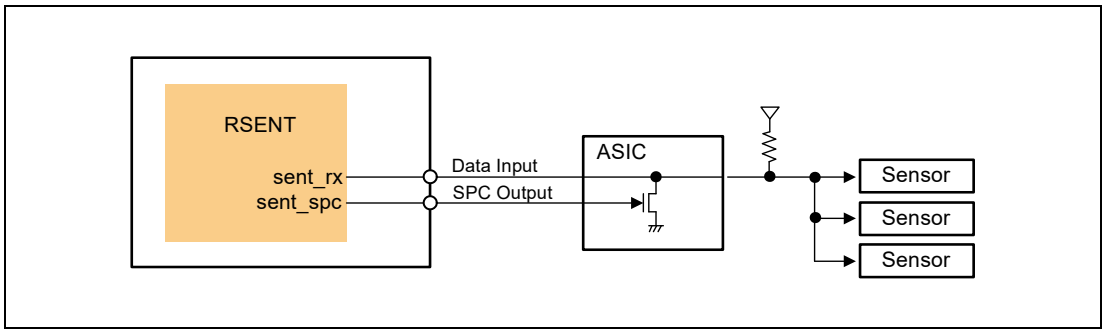

Figure 26.21 Example of the Circuit for two-wire interface

In a single sensor system, this function can be used to trigger data transmission from the sensor. Further data can be sent to the sensor by varying the trigger pulse length. In a multi sensor system, this function can be used to address a dedicated sensor and request a data transmission.

Once RSENT SPC initialization is complete, transmission can be triggered by writing the trigger pulse width to the RSENTnSPCT.TLL register. When a transmission is triggered, the trigger pulse with the configured length is sent. Then a frame reception is expected. After frame reception was done, a new trigger pulse can be sent.

Writing to RSENTnSPCT.TLL requests a SPC trigger transmission. After writing to RSENTnSPCT.TLL, the CPU should read RSENTnCS.NRS to check whether the previous request was completed or not.

In case RSENTnCS.NRS is set, no SPC trigger is sent and any potentially ongoing reception at this time is aborted. The CPU should clear RSENTnCS.NRS by writing 1'b1 to RSENTnCSC.NRC. The CPU can write again to RSENTnSPCT.TLL to request a SPC trigger transmission.

In case RSENTnCS.NRS is not set, the CPU should set a reception timeout counter in software. If a reception occurs before the timeout counter elapses, the user should process the received slow and fast channel data as shown in the fast channel reception flow (**Figure 26.15, Fast Channel Reception Flow**) and slow channel reception flow (**Figure 26.18, Slow Channel Reception Flow**).

When the timeout counter elapses without any successful reception, the addressed sensor seems not to send any valid response. The CPU should analyze the RSENTnCS register to analyze the reason for no successful reception. A new request can be made considering that when RSENTnCS.NRS gets set no SPC trigger is sent.

According to the SPC protocol, a frame is received when the falling edge of the end pulse has been detected. It is the user responsibility to not make a SPC trigger request during the end pulse as this might not be recognized by the sensor.

Purpose of the timeout function is to define a timeout window for response reception in software.

Figure 26.22, Transmission Flow shows a transmission flow with a timeout function implemented in software. The timeout function is optional and can be omitted if not needed.

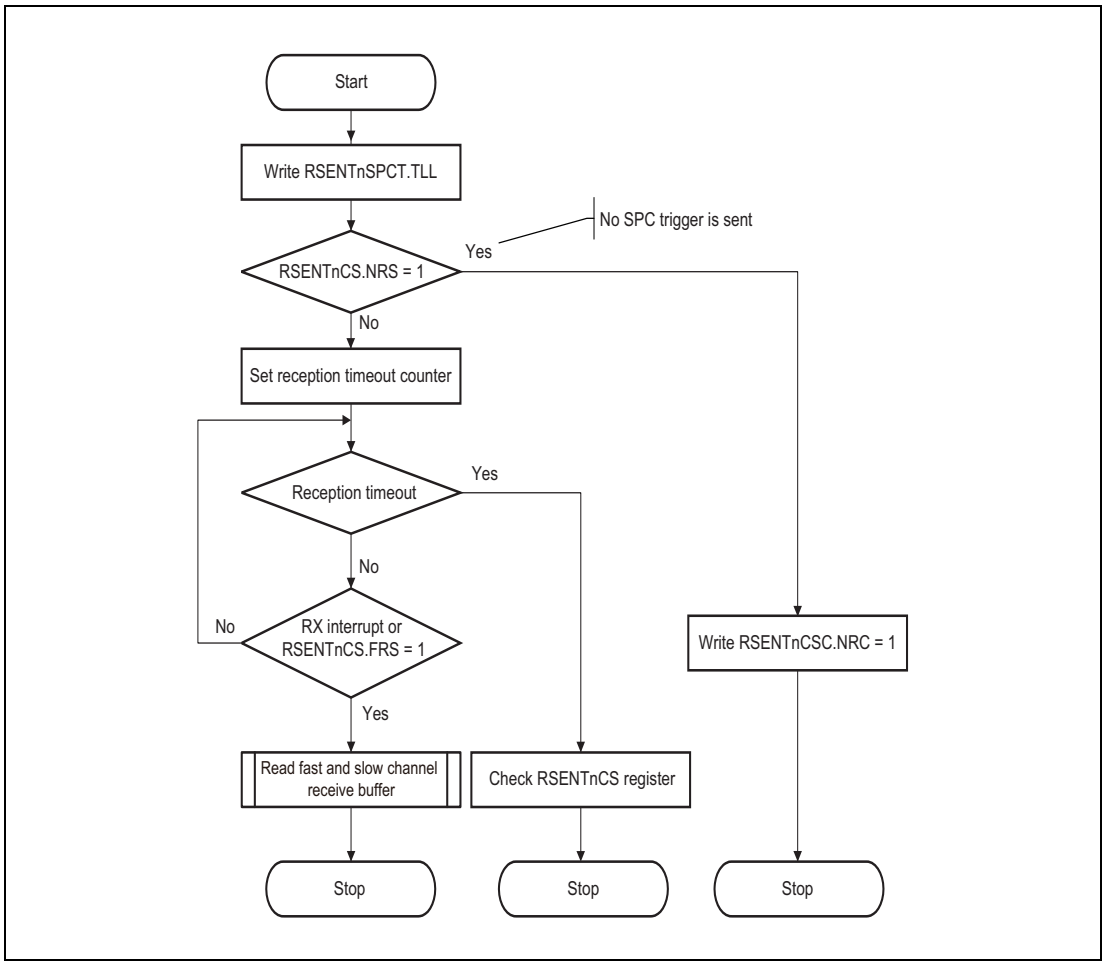

Figure 26.22 Transmission Flow

26.4.4.1 Multiplexing of the RSENTnRX and RSENTnSPCO Pin Functions

The RSENTnRX input pin and RSENTnSPCO output pin functions are assigned to the same multiplexed pin. Two functions can be used on the pin, when it is set for an N-ch open-drain configuration.

Figure 26.23 is a block diagram of multiplexing of the RSENTnRX and RSENTnSPCO pin functions.

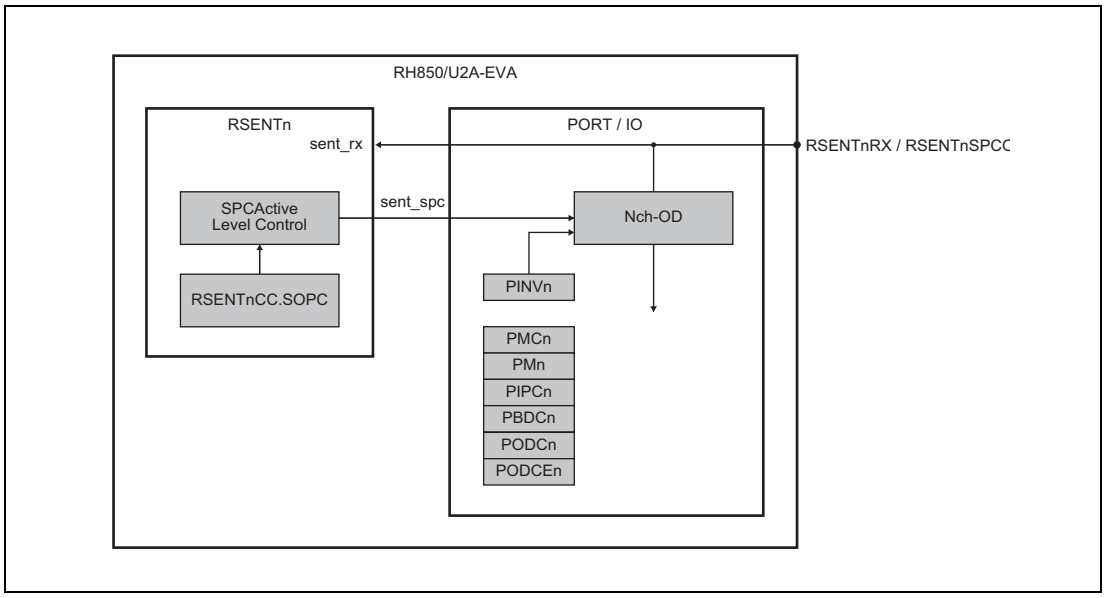

Figure 26.23 Multiplexing of the RSENTnRX and RSENTnSPCO Pin Functions

Connect the sent_spc signal, which is an RSENT output signal, to an N-ch open drain I/O buffer. The RSENT is able to control the polarity of sent_spc output and the polarity of the pin output by setting the RSENTnCC.SOPC bit and the PINVn register of the I/O buffer, respectively. These registers must be set in an appropriate combination.

Table 26.40 lists the register settings when the RSENTnRX and RSENTnSPCO pin functions share the same pin.

Table 26.40 Setting for Multiplexing of the RSENTnRX and RSENTnSPCO Pin Functions

Register Name		Setting	Description
PMCn	Port mode control register	1	Alternative mode
PMn	Port mode register	0	Output mode (output enabled)
PIPCn	Port IP control register	0	I/O mode is controlled by PMn.PMn_m (software or hardware I/O control)
PBDCn	Port bi-direction control register	1	Bi-direction mode is enabled
PODCn	Port open-drain control register	1	N-ch open drain (PODCn_m = 1 or PODCEn_m = 0)
PODCEn	Port open-drain expansion register	0	N-ch open drain (PODCn_m = 1 or PODCEn_m = 0)
PINVn	Port output level inversion register	0	The pin output level is not inverted (active low when RSENTnCC.SOPC = 1)
		1	The pin output level is inverted (active high when RSENTnCC.SOPC = 0)
PFCn	Port function control register	—	Specify an alternative function of the pins. For details, see **Table 2.8, Alternative mode selection table**.
PFCEn	Port function control expansion register		
PFCAEn	Port function control addition expansion register		

26.4.5 Interrupts and Checks

The RSENT module provides two interrupt lines.

The successful fast channel receive interrupt notifies the CPU that the fast channel message reception buffer was updated and is holding a set of valid received data. Also, the reception status bit is set (RSENTnCS.FRS).

The status interrupt notifies the CPU that at least one of the error flags or message lost flags in the RSENTnCS register is set.

Whether a status flag in the RSENTnCS register is contributing to the generation of an interrupt event or not can be set individually.

The execution of the CRC checks can be disabled for the slow channel and fast channel individually. In case a check is disabled, the CRC of the received message is not checked and the related error flag is never set.

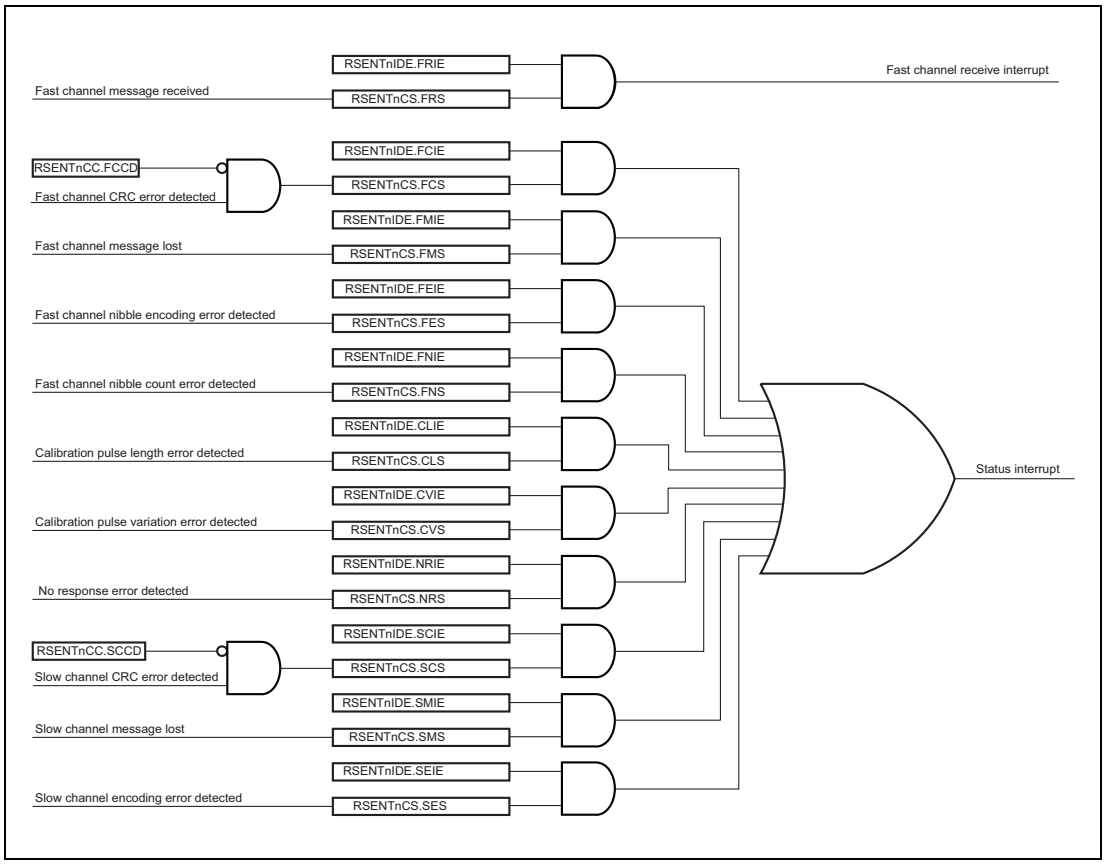

Figure 26.24 Interrupt Structure

Table 26.41, Status Flag Influence to Receive Buffer Behavior gives an overview about the relationship between set status flags and the buffer update.

Table 26.41 Status Flag Influence to Receive Buffer Behavior

RSENTnCS	Fast Channel Message Reception Buffer	Slow Channel Message Reception Buffer
FRS	Updated	Updated if all status and communications nibbles of slow channel messages are received and RSENTnCS.SES=0 and RSENTnCS.SCS=0
FCS	Not updated	Receive process aborted. Search for new start condition
FMS	Background buffer overwritten	Not impacted
FES	Not updated	Receive process aborted. Search for new start condition
FNS	Not updated	Receive process aborted. Search for new start condition
CLS	Not updated	Receive process aborted. Search for new start condition
CVS	Not updated	Receive process aborted. Search for new start condition
NRS	Not updated	Receive process aborted. Search for new start condition
SCS	Not impacted	Not updated
SMS	Not impacted	Message lost
SES	Not impacted	Receive process aborted (Refer to **Section 26.3.10, RSENTnCS — RSENT Communication Status Register** - RSENTnCS.SES (Slow Channel Encoding Error Status))

Section 27 Peripheral Sensor Interface 5 (PSI5)

The Peripheral Sensor Interface 5 (PSI5) is a function of interface the PSI5 (PSI5 v2.0) standard for sensor. PSI5 is implemented 4 channels.

27.1 Features PSI5 for RH850/U2A-EVA

27.1.1 Number of Channels

This microcontroller has the following number of PSI5 channels.

Table 27.1 Number of Channels

Product	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of channels	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	3 (n = 0, 2, 3)
Name	PSI5n									

Table 27.2 Index

Index	Description
n	Throughout this section, the individual channels of the PSI5 are identified by the index “n” (n = 0 to 3).

27.1.2 Register Base Addresses

PSI5n base addresses are listed in the following table. PSI5n register addresses are given as offsets from the base address in general.

Table 27.3 Register Base Addresses

Base address Name	Base Address	Bus Group
<PSI50_base>	FFD5 2000_H	P-Bus Group 3
<PSI51_base>	FFD5 2400_H	P-Bus Group 3
<PSI52_base>	FFD5 2800_H	P-Bus Group 3
<PSI53_base>	FFD5 $2C00_H$	P-Bus Group 3
<PSI5_SELB_base>	FFD5 3000_H	P-Bus Group 3

27.1.3 Clock Supply

Clock supply by and to PSI5n is listed in the following table.

Table 27.4 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name	Description
PSI5n	PCLK	CLK_HSB	Bus clock
	psi5_com_clk		Communication clock
PSI5_SELB	PCLK		Bus clock

For details of clock supply, see **Section 13, Clock Controller**.

27.1.4 Interrupt Requests and Error Notifications

The PSI5 can generate the interrupt requests shown in the following table.

Table 27.5 Interrupt and DMA/DTS Requests

Unit Interrupt Name	Description	Interrupt	DMA Trigger	DTS Trigger
PSI50				
INTPSI50SI*1	PSI50 status interrupt	600	—	—
INTPSI50RI	PSI50 receive interrupt	601	Group0-146	Group3-16
INTPSI50TI	PSI50 transfer interrupt	602	—	—
PSI51				
INTPSI51SI*1	PSI51 status interrupt	603	—	—
INTPSI51RI	PSI51 receive interrupt	604	Group0-147	Group3-17
INTPSI51TI	PSI51 transfer interrupt	605	—	—
PSI52				
INTPSI52SI*1	PSI52 status interrupt	606	—	—
INTPSI52RI	PSI52 receive interrupt	607	Group0-148	Group3-18
INTPSI52TI	PSI52 transfer interrupt	608	—	—
PSI53				
INTPSI53SI*1	PSI53 status interrupt	609	—	—
INTPSI53RI	PSI53 receive interrupt	610	Group0-149	Group3-19
INTPSI53TI	PSI53 transfer interrupt	611	—	—

Note 1. A set of multiple interrupts. See **Section 27.4.1, Interrupt**.

This module has no error notifications.

27.1.5 Reset Sources

PSI5n reset sources are shown below. PSI5n is initialized by the following reset sources.

Table 27.6 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
PSI5n	All registers	√	√	√	√	√	√	—

27.1.6 External Input/Output Signals

The external input/output signals of the PSI5 are listed in the following table.

Table 27.7 External Input/Output Signals

Unit Signal Name	I/O	Description	Alternative Port Pin Signal Name
PSI50			
psi5_rx_data	I	PSI50 data input	PSI50RX
psi5_tx_data	O	PSI50 data output	PSI50TX
PSI51			
psi5_rx_data	I	PSI51 data input	PSI51RX
psi5_tx_data	O	PSI51 data output	PSI51TX
PSI52			
psi5_rx_data	I	PSI52 data input	PSI52RX
psi5_tx_data	O	PSI52 data output	PSI52TX
PSI53			
psi5_rx_data	I	PSI53 data input	PSI53RX
psi5_tx_data	O	PSI53 data output	PSI53TX

27.2 Overview

27.2.1 Functional Overview

Among the main functions defined under the PSI5 standard (PSI5 v2.0), this IP supports the following:

- Communication Mode
  - PSI5-A: Asynchronous mode
  - PSI5-P: Synchronous parallel bus mode
  - PSI5-U: Synchronous parallel universal bus mode
  - PSI5-D: Synchronous daisy chain bus mode
  - PSI5-V: Variable time triggered synchronous operation mode
- Sensor to ECU Communication
  - Data can be received up to eight slots.
  - Bit rates: Low speed (125 kbps); High speed (189 kbps)
  - Automatic detection of start bits
  - Manchester to binary code conversion
  - Receivable bit length: 10 to 28 bits
  - Serial message frames can be received up to eight slots.
  - Automatic calculation of check bits for both data and serial message frames
  - Stores CRC and parity bits received with the data.
- ECU to Sensor Communication
  - Tooth Gap Mode
  - Pulse Width Mode
  - Automatic detection of start conditions
  - Frame formats 1 to 4 can be used
  - Automatic appending of synchronization bits
  - Automatic appending of CRCs
- PAS compatibility mode
  - 250 kbps
  - MSB First reception
  - Parity check
- Appending of a timestamp to receive data and serial message frames
  - Master and slave function for synchronization of timestamp

Table 27.8 List of Operation Modes

Operation Mode		Normal Mode	PAS Compatibility Mode
Bit rate		125 kbps / 189 kbps	250 kbps
Data word length		10 to 28 bits	8 to 24 bits
Data direction		LSB first	MSB first
Data transmission parameter			
	Value of bit time (TYP.)	8 µs / 5.3 µs	4 µs
	Value of gap time (MIN.)	8.4 µs / 5.6 µs	2 µs
Communication Mode		PSI5-A, PSI5-P, PSI5-U, PSI5-D, PSI5-V	PSI5-A only

27.2.2 Block Configuration

Figure 27.1 is a block diagram of PSI5n.

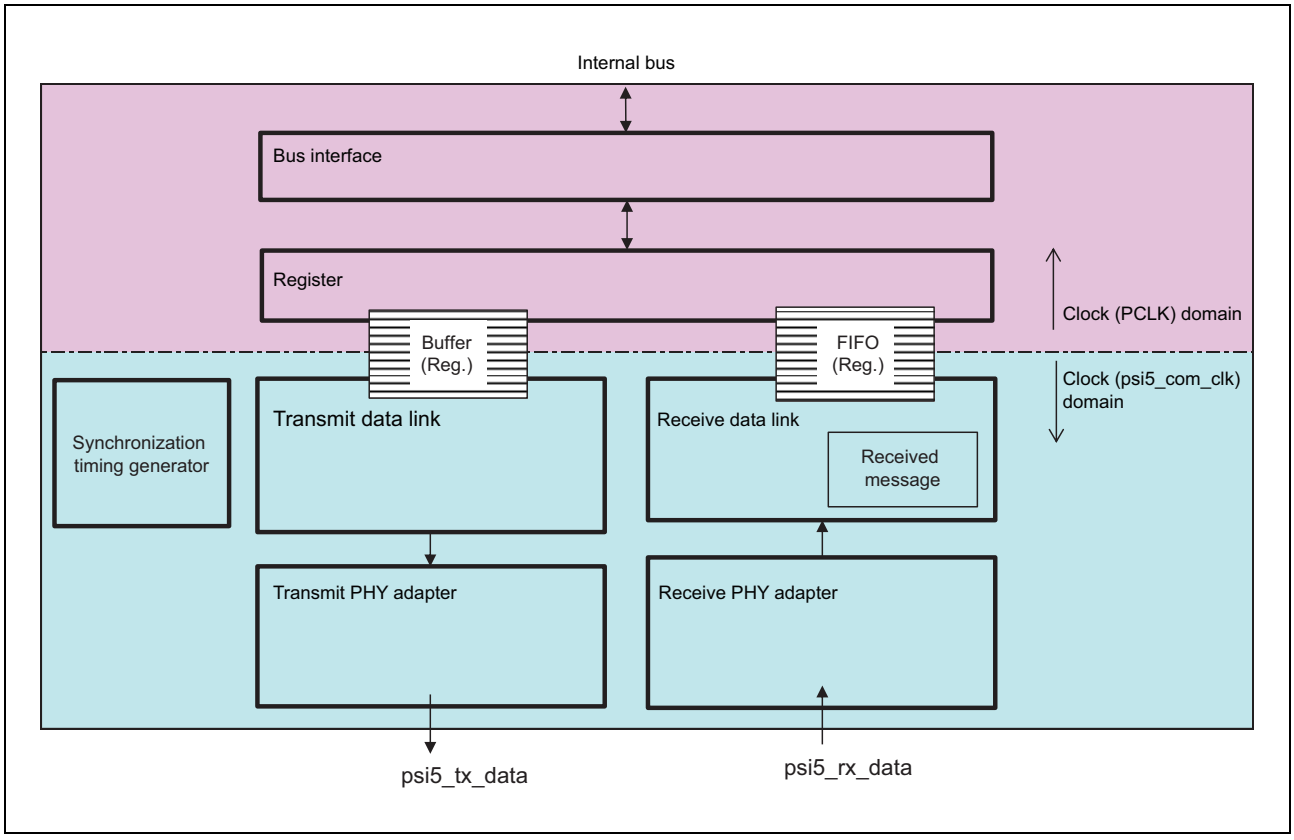

Figure 27.1 Block Diagram of PSI5

27.3 Registers

27.3.1 List of Registers

The PSI5n is controlled and operated by the registers listed in the table below.

For PSI5n base address <PSI5n_base>, see **Section 27.1.2, Register Base Addresses**.

Table 27.9 List of Registers (1/2)

Register Name	Symbol	Address	Access Protection	
			PBG	Other
PSI5 channel control register	PSI5nCHCTRL	<PSI5n_base> + 0000_H	*1	—
PSI5 IP timer control register	PSI5nIPTIMERCTRL	<PSI5n_base> + 0010_H	*1	—
PSI5 IP timer counter	PSI5nIPTIMER	<PSI5n_base> + 0014_H	*1	—
PSI5 operating mode/communication mode register	PSI5nOPMCOMM	<PSI5n_base> + 0020_H	*1	—
PSI5 operating-mode bit rate register	PSI5nOPMBITRATE	<PSI5n_base> + 0024_H	*1	—
PSI5 operating-mode cycle time register	PSI5nOPMCYCT	<PSI5n_base> + 0028_H	*1	—
PSI5 interrupt status register	PSI5nPSI5INT	<PSI5n_base> + 0030_H	*1	—
PSI5 receive data emulation register	PSI5nEMRXDATA	<PSI5n_base> + 0040_H	*1	—
PSI5 receive data status emulation register	PSI5nEMRXDST	<PSI5n_base> + 0044_H	*1	—
PSI5 receive data IP timer emulation register	PSI5nEMRXDTIM	<PSI5n_base> + 0048_H	*1	—
PSI5 receive data FIFO emulation register	PSI5nEMRXDFIFO	<PSI5n_base> + $004C_H$	*1	—
PSI5 receive-message receive message emulation register	PSI5nEMRXMRXMSG	<PSI5n_base> + 0050_H	*1	—
PSI5 receive-message channel receive status emulation register	PSI5nEMRXMRXST	<PSI5n_base> + 0054_H	*1	—
PSI5 receive-message channel receive timestamp emulation register	PSI5nEMRXMRXTIM	<PSI5n_base> + 0058_H	*1	—
PSI5 receive-message channel FIFO emulation register	PSI5nEMRXMFIFO	<PSI5n_base> + $005C_H$	*1	—
PSI5 transmission setting register	PSI5nTXSETTING	<PSI5n_base> + 0080_H	*1	—
PSI5 synchronization control register	PSI5nSYNCCTRL	<PSI5n_base> + 0084_H	*1	—
PSI5 transmission status register	PSI5nTXST	<PSI5n_base> + 0088_H	*1	—
PSI5 transmission status clear register	PSI5nTXSTCLR	<PSI5n_base> + $008C_H$	*1	—
PSI5 transmission status interrupt enable register	PSI5nTXSTINTEN	<PSI5n_base> + 0090_H	*1	—
PSI5 transmit data control register	PSI5nTXDCTRL	<PSI5n_base> + 0094_H	*1	—
PSI5 transmit data register	PSI5nTXDATA	<PSI5n_base> + 0098_H	*1	—
PSI5 receive sampling setting register	PSI5nRXSPLSET	<PSI5n_base> + 0100_H	*1	—
PSI5 receive slot 1 setting register	PSI5nRXS1SET	<PSI5n_base> + 0108_H	*1	—
PSI5 receive slot 2 setting register	PSI5nRXS2SET	<PSI5n_base> + $010C_H$	*1	—
PSI5 receive slot 3 setting register	PSI5nRXS3SET	<PSI5n_base> + 0110_H	*1	—
PSI5 receive slot 4 setting register	PSI5nRXS4SET	<PSI5n_base> + 0114_H	*1	—
PSI5 receive slot 5 setting register	PSI5nRXS5SET	<PSI5n_base> + 0118_H	*1	—
PSI5 receive slot 6 setting register	PSI5nRXS6SET	<PSI5n_base> + $011C_H$	*1	—
PSI5 receive slot 7 setting register	PSI5nRXS7SET	<PSI5n_base> + 0120_H	*1	—
PSI5 receive slot 8 setting register	PSI5nRXS8SET	<PSI5n_base> + 0124_H	*1	—
PSI5 receive data register	PSI5nRXDATA	<PSI5n_base> + 0128_H	*1	—
PSI5 receive data status register	PSI5nRXDST	<PSI5n_base> + $012C_H$	*1	—
PSI5 receive data IP timer register	PSI5nRXDTIM	<PSI5n_base> + 0130_H	*1	—
PSI5 receive data FIFO register	PSI5nRXDFIFO	<PSI5n_base> + 0134_H	*1	—

Table 27.9 List of Registers (2/2)

Register Name	Symbol	Address	Access Protection	
			PBG	Other
PSI5 receive module status register	PSI5nRXMODST	<PSI5n_base> + 0138_H	*1	—
PSI5 receive module status clear register	PSI5nRXMODSTCLR	<PSI5n_base> + $013C_H$	*1	—
PSI5 receive module status interrupt enable register	PSI5nRXMODSTINTEN	<PSI5n_base> + 0140_H	*1	—
PSI5 receive message channel setting register	PSI5nRXMSET	<PSI5n_base> + 0180_H	*1	—
PSI5 receive-message receive message register	PSI5nRXMRXMSG	<PSI5n_base> + 0184_H	*1	—
PSI5 receive-message channel receive status register	PSI5nRXMRXST	<PSI5n_base> + 0188_H	*1	—
PSI5 receive-message channel receive timestamp register	PSI5nRXMRXTIM	<PSI5n_base> + $018C_H$	*1	—
PSI5 receive-message channel FIFO register	PSI5nRXMFIFO	<PSI5n_base> + 0190_H	*1	—

n = 1: PBG30#3
n = 2: PBG30#4
n = 3: PBG30#5

27.3.2 PSI5nCHCTRL — PSI5 Channel Control Register

This register controls the channel operation.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + 0000_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CHEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 27.10 PSI5nCHCTRL Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	CHEN	Channel Enable 0: Channel disabled 1: Channel enabled In synchronous mode, the PSI5 starts to send a synchronization pulse after enabling the channel. In asynchronous mode, the PSI5 sets psi5_tx_data according to PSI5nTXSETTING.DEFTXVAL. When the channel is enabled, writing to the following registers is disabled: PSI5nOPMCOMM, PSI5nOPMBITRATE, PSI5nOPMCYCT, PSI5nTXSETTING, PSI5nRXSPLSET, PSI5nRXSmSET, and PSI5nRXMSET After writing to this bit, check that the setting is reflected by reading the bit by software.

CAUTION

The following registers must be set only when channel operation is enabled (PSI5nCHCTRL.CHEN = 1).

- PSI5nRXMODSTINTEN.RXDEXISTINTEN = 1
- PSI5nTXSTINTEN.TXDEMPTYINTEN = 1
- PSI5nTXDATA.TXDATA

27.3.3 PSI5nIPTIMERCTRL — PSI5 IP Timer Control Register

This register controls the IP timer.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + 0010_H

Value after reset: $0001\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MSTSLV
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TSCLR	—	—	—	—	—	—	—	IPTIMEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Table 27.11 PSI5nIPTIMERCTRL Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	MSTSLV	Specifies timer master/slave mode. 0: Slave mode is selected 1: Master mode is selected • In slave mode: The IP timer counts up according to the count-up timing signal (psi5_ts_tick_in) input through the master channel. The value of the PSI5nIPTIME register is cleared when the TSCLR bit is set or in response to the input of the clearing timing signal (psi5_ts_clr_in) through the master channel. • In master mode: IPTIMER counts up in response to the clock generated by the internal baud rate generator. PSI5 outputs the count-up timing signal (psi5_ts_tick_out). Setting the TSCLR bit to 1 clears the values in PSI5nIPTIMER (the clearing timing signal (psi5_ts_clr_out) is output).
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	TSCLR	IP Timer Clear Trigger 0: The IP timer (PSI5nIPTIME register) is not cleared. 1: The IP timer (PSI5nIPTIME register) is cleared. The TSCLR bit setting is valid when the MSTSLV bit is set to 1. Read value is always 0.
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	IPTIMEN	IP Timer Enable 0: IP timer is disabled. 1: IP timer is enabled. In slave mode, set the IPTIMEN bit after enabling the IP timer of the master channel.

27.3.4 PSI5nIPTIMER — PSI5 IP Timer Counter

This is a counter for the IP timer.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + 0014_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	COUNTVAL[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	COUNTVAL[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 27.12 PSI5nIPTIMER Register Contents

Bit Position	Bit Name	Function
31 to 0	COUNTVAL	In master mode, this timer counts up in response to the internal baud rate clock. In slave mode, this timer counts up by a tick pulse of the psi5_ts_tick_in signal. This value is used by the PSI5nRXDTIM register. This counter wrap around to 0 after reaching $FFFFFFFF_H$. When writing to this register, it needs several cycles until the write value is reflected because the write value should be transmitted to the synchronizer.

27.3.5 PSI5nOPMCOMM — PSI5 Operating Mode/Communication Mode Register

This register sets the communication mode.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + 0020_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	COMMODE		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 27.13 PSI5nOPMCOMM Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2 to 0	COMMODE	Specify communication mode. 000_B: Asynchronous mode 001_B: Synchronous Parallel Bus Mode 010_B: Synchronous Universal Bus Mode 011_B: Synchronous Daisy Chain Bus Mode 100_B: Variable Time Triggered Synchronous Operation Mode Other than above: Setting prohibited

27.3.6 PSI5nOPMBITRATE — PSI5 Operating-Mode Bit Rate Register

This register sets a bit rate.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + 0024_H

Value after reset: $0000\ 029F_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BITRATECNT															
Value after reset	0	0	0	0	0	0	1	0	1	0	0	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 27.14 PSI5nOPMBITRATE Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	BITRATECNT	Specify the 1-bit clock count considering communication clock tolerance. • For transfer at 80 MHz (12.5 ns) and 125 kbps (clock tolerance: 5%: 8.4 µs) psi5_com_clk is used as the counter clock. Counting cycle = 8.4 µs/12.5 ns = 672 = $2A0_H$ Setting value: $2A0\text{-}001_H = 29F_H$ This value is used to secure the bit length while no edge is detected in bit judgment.

27.3.7 PSI5nOPMCYCT — PSI5 Operating-Mode Cycle Time Register

This register sets a count value.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + 0028_H

Value after reset: $0000\ 9C3F_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	TTTTCNT			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TTTTCNT															
Value after reset	1	0	0	1	1	1	0	0	0	0	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 27.15 PSI5nOPMCYCT Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
19 to 0	TTTTCNT	Specify the count value. Specify the count value for the SYNC signal's period. Use psi5_com_clk as the count clock. The default value is 500 μs when counting at 80 MHz (T = 12.5 ns). Count cycle: 500 μs / 12.5 ns = 40000 = $9C40_H$ Setting value: $9C40_H$-001_H = $9C3F_H$

27.3.8 PSI5nPSI5INT — PSI5 Interrupt Status Register

This register indicates the status of an interrupt that occurred in the PSI5.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + 0030_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	INT_SYNCED	INT_SYNCST	INT_TXDEMPTY
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	INT_RXDSCNFERR	INT_RXDERR	INT_RXDFOVF	INT_RXDEXIST	INT_RXMERR	INT_RXMFOVF	INT_RXMEXIST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.16 PSI5nPSI5INT Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset is returned.
18	INT_SYNCED	INT_SYNCED interrupt generation 0: Was not generated 1: Generated
17	INT_SYNCST	INT_SYNCST interrupt generation 0: Was not generated 1: Generated
16	INT_TXDEMPTY	INT_TXDEMPTY interrupt generation 0: Was not generated 1: Generated
15 to 7	Reserved	When read, the value after reset is returned.
6	INT_RXDSCNFERR	INT_RXDSCNFERR interrupt generation 0: Was not generated 1: Generated
5	INT_RXDERR	INT_RXDERR interrupt generation 0: Was not generated 1: Generated
4	INT_RXDFOVF	INT_RXDFOVF interrupt generation 0: Was not generated 1: Generated
3	INT_RXDEXIST	INT_RXDEXIST interrupt generation 0: Was not generated 1: Generated
2	INT_RXMERR	INT_RXMERR interrupt generation 0: Was not generated 1: Generated
1	INT_RXMFOVF	INT_RXMFOVF interrupt generation 0: Was not generated 1: Generated
0	INT_RXMEXIST	INT_RXMEXIST interrupt generation 0: Was not generated 1: Generated

NOTE

For details about interrupts in the PSI5, see **Section 27.4, Operation**.

27.3.9 PSI5nEMRXDATA — PSI5 Receive Data Emulation Register

This is a mirror register of the receive data register (PSI5nRXDATA).

For details on PSI5nRXDATA, see **Section 27.3.26, PSI5nRXDATA — PSI5 Receive Data Register**.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + 0040_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	RXDATA															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.17 PSI5nEMRXDATA Register Contents

Bit Position	Bit Name	Function
31 to 0	RXDATA	Mirror data of PSI5nRXDATA. Data is not updated even if it is read.

27.3.10 PSI5nEMRXDST — PSI5 Receive Data Status Emulation Register

This is a mirror register of the receive data status register (PSI5nRXDST).

For details on PSI5nRXDST, see **Section 27.3.27, PSI5nRXDST — PSI5 Receive Data Status Register**.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + 0044_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 27.18 PSI5nEMRXDST Register Contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is returned.
10 to 8	RXCHKD	These bits act as mirrors of the PSI5nRXDST.RXCHKD bits. Data is not updated even if it is read.
7 to 4	RXSLOTNUM	These bits act as mirrors of the PSI5nRXDST.RXSLOTNUM bits. Data is not updated even if it is read.
3 to 1	Reserved	When read, the value after reset is returned.
0	RXSTATUS	This bit acts as a mirror of the PSI5nRXDST.RXSTATUS bit. Data is not updated even if it is read.

27.3.11 PSI5nEMRXDTIM — PSI5 Receive Data IP Timer Emulation Register

This is a mirror register of the receive data IP timer register (PSI5nRXDTIM).

For details on PSI5nRXDTIM, see **Section 27.3.28, PSI5nRXDTIM — PSI5 Receive Data IP Timer Register**.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + 0048_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 0	RXDTIM	Mirror data of the PSI5nRXDTIM register. Data is not updated even if it is read.

27.3.12 PSI5nEMRXDFIFO — PSI5 Receive Data FIFO Emulation Register

This is a mirror register of the receive data FIFO register (PSI5nRXDFIFO).

For details on PSI5nRXDFIFO, see **Section 27.3.29, PSI5nRXDFIFO — PSI5 Receive Data FIFO Register**.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + $004C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 27.20 PSI5nEMRXDFIFO Register Contents

Bit Position	Bit Name	Function
31 to 0	RXDST	Mirror data of the PSI5nRXDFIFO register. Data is not updated even if it is read.

27.3.13 PSI5nEMRXMRXMSG — PSI5 Receive-Message Receive Message Emulation Register

This is a mirror register of the receive-message receive message register (PSI5nRXMRXMSG).

For details on PSI5nRXMRXMSG, see **Section 27.3.34, PSI5nRXMRXMSG — PSI5 Receive-Message Receive Message Register**.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + 0050_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CONFIGBIT	—	—	—	—	—	—	—	SERIALID

Table 27.21 PSI5nEMRXMRXMSG Register Contents

Bit Position	Bit Name	Function
31	CONFIGBIT	This bit acts as a mirror of the PSI5nRXMRXMSG.CONFIGBIT bit. Data is not updated even if it is read.
30 to 24	Reserved	When read, the value after reset is returned.
23 to 16	SERIALID	These bits act as mirrors of the PSI5nRXMRXMSG.SERIALID bits. Data is not updated even if it is read.
15 to 0	DATAFIELD	These bits act as mirrors of the PSI5nRXMRXMSG.DATAFIELD bits. Data is not updated even if it is read.

27.3.14 PSI5nEMRXMRXST — PSI5 Receive-Message Channel Receive Status Emulation Register

This is a mirror register of the receive-message channel receive status register (PSI5nRXMRXST).

For details on PSI5nRXMRXST, see **Section 27.3.35, PSI5nRXMRXST — PSI5 Receive-message Channel Receive Status Register**.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + 0054_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	RXSYNC

Table 27.22 PSI5nEMRXMRXST Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset is returned.
18 to 16	RXSYNC	These bits act as mirrors of the PSI5nRXMRXST.RXSYNC bits. Data is not updated even if it is read.
15, 14	Reserved	When read, the value after reset is returned.
13 to 8	RXCRC	These bits act as mirrors of the PSI5nRXMRXST.RXCRC bits. Data is not updated even if it is read.
7 to 4	SLOTNUM	These bits act as mirrors of the PSI5nRXMRXST.SLOTNUM bits. Data is not updated even if it is read.
3 to 1	Reserved	When read, the value after reset is returned.
0	RXSTATUS	This bit acts as a mirror of the PSI5nRXMRXST.RXSTATUS bit. Data is not updated even if it is read.

27.3.15 PSI5nEMRXMRXTIM — PSI5 Receive-Message Channel Receive Timestamp Emulation Register

This is a mirror register of the receive-message channel receive timestamp register (PSI5nRXMRXTIM).

For details on PSI5nRXMRXTIM, see **Section 27.3.36, PSI5nRXMRXTIM — PSI5 Receive-message Channel Receive Timestamp Register**.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + 0058_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RXMTIM

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.23 PSI5nEMRXMRXTIM Register Contents

Bit Position	Bit Name	Function
31 to 0	RXMTIM	Mirror data of the PSI5nRXMRXTIM register. Data is not updated even if it is read.

27.3.16 PSI5nEMRXMFIFO — PSI5 Receive-Message Channel FIFO Emulation Register

This is a mirror register of the receive-message channel FIFO register (PSI5nRXMFIFO).

For details on PSI5nRXMFIFO, see **Section 27.3.37, PSI5nRXMFIFO — PSI5 Receive-message Channel FIFO Register**.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + $005C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 27.24 PSI5nEMRXMFIFO Register Contents

Bit Position	Bit Name	Function
31 to 0	RXMFIFO	Mirror data of the PSI5nRXMFIFO register. Data is not updated even if it is read.

27.3.17 PSI5nTXSETTING — PSI5 Transmission Setting Register

This register specifies transmission settings.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + 0080_H

Value after reset: $1067\ 47F7_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	LONGCNT															
Value after reset	0	0	0	1	0	0	0	0	0	1	1	0	0	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PHY MODE	DEF TXVAL	SHORTCNT													
Value after reset	0	1	0	0	0	1	1	1	1	1	1	1	0	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 27.25 PSI5nTXSETTING Register Contents

Bit Position	Bit Name	Function
31 to 16	LONGCNT	Set the allowable upper limit of “long” synchronization pulse width when synchronous signal is output in the Pulse Width method. The upper limit when psi5_com_clk is at 80 MHz is 52.5 µs. Counting cycle: 52.5 µs / 12.5 ns = 4200 = 1068_H Setting value: 1068_H- 0001_H = 1067_H
15	PHYMODE	Specifies synchronous pulse PHY layer mode. 0: Tooth Gap method is selected. 1: Pulse Width method is selected. When the Pulse Width method is selected, the pulse width should comply with the value within the pulse width specified by the SHORTCNT bits in the Tooth Gap method.
14	DEFTXVAL	Specifies the initial value of synchronization pulse when data is not transmitted. 0: (0) is transmitted. 1: (1) is transmitted.
13 to 0	SHORTCNT	Set the allowable upper limit of “short” synchronization pulse width when synchronous signal is output in the Pulse Width or Tooth Gap method. The upper limit when psi5_com_clk is at 80 MHz is 25.5 µs. Counting cycle: 25.5 µs / 12.5 ns = 2040 = $07F8_H$ Setting value: $07F8_H$- 0001_H = $07F7_H$

CAUTION

- The PSI5nTXSETTING.SHORTCNT bit must be set to 1 or higher.
- The setting value below should be used.
  PSI5nOPMCYCT.TTTTCNT > PSI5nTXSETTING.LONGCNT > PSI5nTXSETTING.SHORTCNT

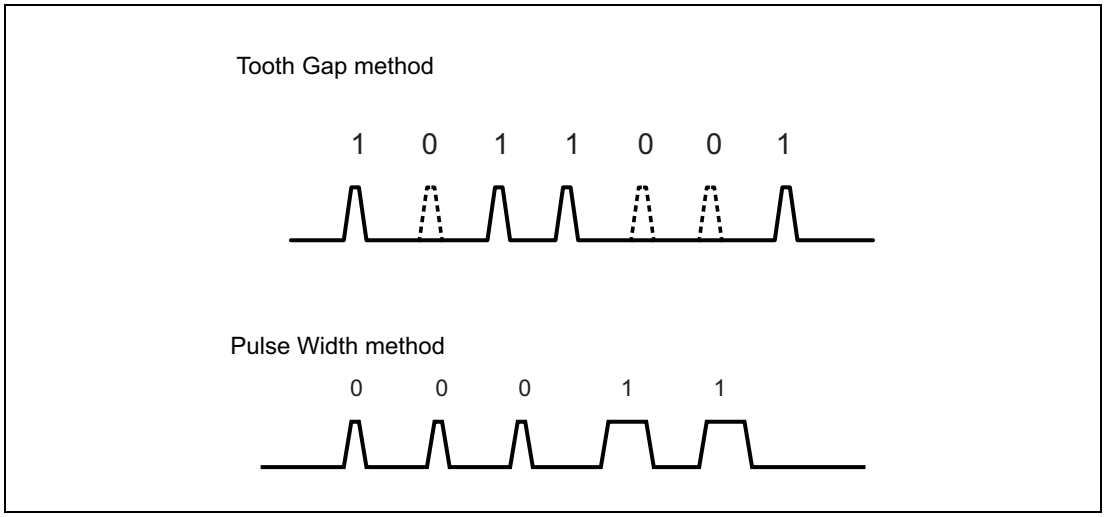

Figure 27.2 Pulse Width Method and Tooth Gap Method

27.3.18 PSI5nSYNCCTRL — PSI5 Synchronization Control Register

This register controls the start trigger in variable time triggered synchronous operation mode.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + 0084_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	VALTIMSYNC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 27.26 PSI5nSYNCCTRL Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	VALTIMSYNC	Synchronization signal send trigger in variable time triggered synchronous operation mode 0: Not effective. 1: The synchronization pulse is issued. This bit is always 0 when it is read. Do not write 1 to the VALTIMSYNC bit in any modes other than variable time triggered synchronous operation mode.

27.3.19 PSI5nTXST — PSI5 Transmission Status Register

This register indicates the transmission status.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + 0088_H

Value after reset: $0000\ 0001_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	SYNCED	SYNCST	—	—	—	—	—	—	—	TXDEMPTY
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.27 PSI5nTXST Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is returned.
9	SYNCED	Indicates synchronization signal transmit complete. 0: Synchronization signal transmit is not started or is incomplete. 1: Synchronization signal transmit is complete. When the SYNCED bit is set, the INT_SYNCED interrupt is asserted. The SYNCED bit is set even when 0 is sent in the Tooth Gap method.
8	SYNCST	Indicates start of synchronization signal transmit 0: Synchronization signal is not sent. 1: Synchronization signal is started to send. When the SYNCST bit is set, the INT_SYNCST interrupt is asserted. The SYNCST bit is set even when 0 is sent in the Tooth Gap method.
7 to 1	Reserved	When read, the value after reset is returned.
0	TXDEMPTY	Indicates Tx data buffer empty status. 0: Transmit data buffer is not empty 1: Transmit data buffer is empty When the TXDEMPTY bit is set, the INT_TXDEMPTY interrupt is asserted.

27.3.20 PSI5nTXSTCLR — PSI5 Transmission Status Clear Register

This register clears the setting in the PSI5nTXST register.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + $008C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	SYNCEDCLR	SYNCSTCLR	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Table 27.28 PSI5nTXSTCLR Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	SYNCEDCLR	Clears the value of the PSI5nTXST.SYNCED bit. 0: No operation is done. The read value is always 0. 1: Clears the value of the PSI5nTXST.SYNCED bit
8	SYNCSTCLR	Clears the value of the PSI5nTXST.SYNCST bit. 0: No operation is done. The read value is always 0. 1: Clears the value of the PSI5nTXST.SYNCST bit.
7 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

27.3.21 PSI5nTXSTINTEN — PSI5 Transmission Status Interrupt Enable Register

This register controls transmission status interrupts.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + 0090_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.29 TXSINTEN Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	SYNCED INTEN	Controls the INT_SYNCED interrupt. 0: Interrupt disabled (Masked) 1: Interrupt enabled
8	SYNCSTINTEN	Controls the INT_SYNCST interrupt. 0: Interrupt disabled (Masked) 1: Interrupt enabled
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	TXDEMPTYINTEN	Controls the INT_TXDEMPTY interrupt. 0: Interrupt disabled (Masked) 1: Interrupt enabled

27.3.22 PSI5nTXDCTRL — PSI5 Transmit Data Control Register

This register controls transmit data.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + 0094_H

Value after reset: $0000\ 0001_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 27.30 PSI5nTXDCTRL Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2 to 0	FRMFORMAT	Specify the Tx frame format. 001_B: Frame 1 (Short) 010_B: Frame 2 (Long: 4-bit data or 8-bit data) 011_B: Frame3 (XLong) 100_B: Frame4 (XXLong) Other than above: Setting prohibited

27.3.23 PSI5nTXDATA — PSI5 Transmit Data Register

This register stores transmit data.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + 0098_H

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TXDATA															
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 27.31 PSI5nTXDATA Register Contents

Bit Position	Bit Name	Function
31 to 0	TXDATA	Tx Data Write Tx data without the Start field, Synchronization bit, and CRC field (Tx data is written in LSB first). Data arrangement differs depending on the transmit frame format specified in the PSI5nTXDCTRL.FRMFORMAT bit. (See **Table 27.32**.) The data is sent after these bits are written. Read value is always 0.

Table 27.32 PSI5nTXDATA.TXDATA Data Arrangement in Transmit Frame Format

TXDATA Bit Position	Transmit Frame Format (PSI5nTXDCTRL.FRMFORMAT)									
	Frame1 “Short”		Frame2 “Long” (4-Bit Data Nibbles)		Frame2 “Long” (8-Bit Data Word)		Frame3 “XLong”		Frame4 “XXLong”

27.3.24 PSI5nRXSPLSET — PSI5 Receive Sampling Setting Register

This register controls the sampling timing for received data.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + 0100_H

Value after reset: $0000\ 0027_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	SMPLPROD							
Value after reset	0	0	0	0	0	0	0	0	0	0	1	0	0	1	1	1
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 27.33 PSI5nRXSPLSET Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7 to 0	SMPLPROD	Specify the value of the sampling interval counter for received data. This counter is counted up based on the psi5_com_clk signal. Specify a 16 times sampling for 1-bit length. psi5_com_clk: 80 MHz (T = 12.5 ns), Bit rate: L (125 kHz, T = 8 µs), Count cycle: 500 ns / 12.5 ns = 40 = 28_H Setting value: 28_H- 01_H = 27_H. Example settings when psi5_com_clk = 80 MHz

Baud Rate	Setting Value
125 kHz	27_H
189 kHz	19_H
250 kHz	13_H

27.3.25 PSI5nRXSmSET — PSI5 Receive Slot m Setting Register (m = 1 to 8)

These registers set the receive slots.

Access: This register can be read or written in 32-bit units.

Address: PSI5nRXS1SET: <PSI5n_base> + 0108_H, PSI5nRXS2SET: <PSI5n_base> + $010C_H$,
PSI5nRXS3SET: <PSI5n_base> + 0110_H, PSI5nRXS4SET: <PSI5n_base> + 0114_H,
PSI5nRXS5SET: <PSI5n_base> + 0118_H, PSI5nRXS6SET: <PSI5n_base> + $011C_H$,
PSI5nRXS7SET: <PSI5n_base> + 0120_H, PSI5nRXS8SET: <PSI5n_base> + 0124_H

Value after reset: $00A0\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SLTEN	—	—	—	—	PAS CMP	ERR DET	LENGTH					OFFSETCNT			
Value after reset	0	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0
R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OFFSETCNT															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 27.34 PSI5nRXSmSET Register Contents

Bit Position	Bit Name	Function
31	SLTEN	Slot Enable 0: Slot m is disabled. 1: Slot m is enabled.
30 to 27	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
26	PASCMP	Specifies PAS compatibility mode. 0: PSI5 mode is selected. (LSB first) 1: PAS compatibility mode is selected. (MSB first)
25	ERRDET	Specifies the error detection scheme. 0: 1-bit parity 1: 3-bit CRC
24 to 20	LENGTH	Specify the data length
19 to 0	OFFSETCNT	Specify the count value of the offset timer. When the count value reaches the specified value, the PSI5 starts to receive the data in Slot m. The value counted by psi5_com_clk is used. • Rx module starts to find start bits (S1, S2) after expiration of the offset counter. A margin should be included taking clock uncertainty, sampling rate, and inter-slot period into consideration. For example, Start time: 44 µs psi5_com_clk: 80 MHz (T = 12.5 ns) Offset value: 44 us / 12.5 ns = 3520 = $0DC0_H$ OFFSETCNT: $0DC0_H$- 0001_H = $0DBF_H$

CAUTION

In asynchronous mode (PSI5nOPMCOMM.COMMODE = 000_B), only PSI5nRXS1SET is available.

The ERRDET must always be set to 0 in PAS compatibility mode (PASCMP = 1).

27.3.26 PSI5nRXDATA — PSI5 Receive Data Register

This register is the receive data register.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + 0128_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.35 PSI5nRXDATA Register Contents

Bit Position	Bit Name	Function
31 to 0	RXDATA	Received Data These bits hold received data that does not include a start bit and CRC/parity bits (received data is stored in LSB first). These bits are effective only when PSI5nRXMODST.RXDEXIST = 1.

27.3.27 PSI5nRXDST — PSI5 Receive Data Status Register

This register indicates the status of received data.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + $012C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	RXCHKD			RXSLOTNUM				—	—	—	RXSTATUS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.36 PSI5nRXDST Register Contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is returned.
10 to 8	RXCHKD	Raw Data of CRC or Parity In parity mode, setting is as below: RXCHKD[2:1]: 00_B RXCHKD[0]: Parity value These bits are effective only when PSI5nRXMODST.RXDEXIST bit = 1
7 to 4	RXSLOTNUM	Indicate the slot number of received PSI5nRXDATA.RXDATA. The slot number of the first received data is 1 (the slot number is from 1 to 8). These bits are effective only when PSI5nRXMODST.RXDEXIST = 1.
3 to 1	Reserved	When read, the value after reset is returned.
0	RXSTATUS	Indicates the status of Rx data. 0: No error. 1: CRC, parity, or syntax error occurred. Syntax error includes the following three types: – An illegal start bit – Data shorter than PSI5nRXSmSET.LENGTH (A long data error cannot be detected.) – Manchester code error

27.3.28 PSI5nRXDTIM — PSI5 Receive Data IP Timer Register

This register indicates the IPTIMER value in received data.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + 0130_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RXDTIM															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RXDTIM															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.37 PSI5nRXDTIM Register Contents

Bit Position	Bit Name	Function
31 to 0	RXDTIM	Specify the PSI5nIPTIMER value when the last data (CRC or Parity) is received. These bit fields are effective only when the PSI5nRXMODST.RXDEXIST bit is set to 1.

27.3.29 PSI5nRXDFIFO — PSI5 Receive Data FIFO Register

This register is the receive data FIFO register.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + 0134_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RXDST															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	RXDST															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.38 PSI5nRXDFIFO Register Contents

Bit Position	Bit Name	Function
31 to 0	RXDST	These bits are used for DMA. These bits can be read after data is received (when PSI5nRXMODST.RXDEXIST= 1 and the INT_RXDEXIST interrupt is asserted). This register acts as FIFO whose content includes PSI5nRXDATA, PSI5nRXDST, and PSI5nRXDTIM. Read the receive data three times each. Data is read in the following order: PSI5nRXDATA, PSI5nRXDST, and then PSI5nRXDTIM. Exclusive access is required between PSI5nRXDFIFO and “PSI5nRXDATA, PSI5nRXDST, or PSI5nRXDTIM”.

27.3.30 PSI5nRXMODST — PSI5 Receive Module Status Register

This register is the status register for the receive module.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + 0138_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	RXDSCNFERR	—	—	—	—	—	—	—	RXDERR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	RXDFOVF	—	—	—	—	—	—	—	RXDEXIST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.39 PSI5nRXMODST Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is returned.
24	RXDSCNFERR	Indicates collision errors of synchronization pulse and reception of sensor data. 0: No error has occurred. 1: An error has occurred. When this bit is set, the INT_RXDSCNFERR interrupt is asserted.
23 to 17	Reserved	When read, the value after reset is returned.
16	RXDERR	Indicates the status of receive data. 0: No error. 1: CRC, parity, or syntax error occurred. This bit is set by PSI5nRXDST.RXSTATUS bit. When this bit is set, the INT_RXDERR interrupt is asserted.
15 to 9	Reserved	When read, the value after reset is returned.
8	RXDFOVF	Receive Data FIFO Overflow Flag 0: No overflow. 1: Overflow occurred. When this bit is set, the INT_RXDFOVF interrupt is asserted.
7 to 1	Reserved	When read, the value after reset is returned.
0	RXDEXIST	Indicates whether or not Rx data exists. 0: No Rx data exists. 1: Rx data exists. When the PSI5nRXDATA, PSI5nRXDST, and PSI5nRXDTIM registers are read, this bit is cleared. When this bit is set, the INT_RXDEXIST interrupt is asserted.

27.3.31 PSI5nRXMODSTCLR — PSI5 Receive Module Status Clear Register

This register is the status clear register for the receive module.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + $013C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	RXDSCNFERRCLR	—	—	—	—	—	—	—	RXDERRCLR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	RXDFOVFCLR	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R

Table 27.40 PSI5nRXMODSTCLR Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
24	RXDSCNFERRCLR	Clears the PSI5nRXMODST.RXDSCNFERR bit. 0: No operation is done. 1: The RXDSCNFERR bit is cleared. Read value is always 0.
23 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	RXDERRCLR	Clears the PSI5nRXMODST.RXDERR bit. 0: No operation is done. 1: The RXDERR bit is cleared. Read value is always 0.
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	RXDFOVFCLR	Clears the PSI5nRXMODST.RXDFOVF bit. 0: No operation is done. 1: The RXDFOVF bit is cleared. Read value is always 0.
7 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

27.3.32 PSI5nRXMODSTINTEN — PSI5 Receive Module Status Interrupt Enable Register

This register is the status interrupt enable register for the receive module.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + 0140_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	RXDSCNFERRINTEN	—	—	—	—	—	—	—	RXDERRINTEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

	—	—	—	—	—	—	—	RXDFOVFINTEN	—	—	—	—	—	—	—	RXDEXISTINTEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Table 27.41 PSI5nRXMODSTINTEN Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
24	RXDSCNFERRINTEN	INT_RXDSCNFERR Interrupt Enable 0: Interrupt disabled (Masked) 1: Interrupt enabled
23 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	RXDERRINTEN	INT_RXDERR Interrupt Enable 0: Interrupt disabled (Masked) 1: Interrupt enabled
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	RXDFOVFINTEN	INT_RXDFOVF Interrupt Enable 0: Interrupt disabled (Masked) 1: Interrupt enabled
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	RXDEXISTINTEN	INT_RXDEXIST Interrupt Enable 0: Interrupt disabled (Masked) 1: Interrupt enabled

27.3.33 PSI5nRXMSET — PSI5 Receive Message Channel Setting Register

This register sets the channels for the receive module.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + 0180_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 27.42 PSI5nRXMSET Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7	RXM8EN	Controls the messaging channel for slot 8. 0: Messaging channel is disabled. 1: Messaging channel is enabled.
6	RXM7EN	Controls the messaging channel for slot 7. 0: Messaging channel is disabled. 1: Messaging channel is enabled.
5	RXM6EN	Controls the messaging channel for slot 6. 0: Messaging channel is disabled. 1: Messaging channel is enabled.
4	RXM5EN	Controls the messaging channel for slot 5. 0: Messaging channel is disabled. 1: Messaging channel is enabled.
3	RXM4EN	Controls the messaging channel for slot 4. 0: Messaging channel is disabled. 1: Messaging channel is enabled.
2	RXM3EN	Controls the messaging channel for slot 3. 0: Messaging channel is disabled. 1: Messaging channel is enabled.
1	RXM2EN	Controls the messaging channel for slot 2. 0: Messaging channel is disabled. 1: Messaging channel is enabled.
0	RXM1EN	Controls the messaging channel for slot 1. 0: Messaging channel is disabled. 1: Messaging channel is enabled.

27.3.34 PSI5nRXMRXMSG — PSI5 Receive-Message Receive Message Register

This register is the receive message register.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + 0184_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CONFIGBIT	—	—	—	—	—	—	—	SERIALID							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.43 PSI5nRXMRXMSG Register Contents

Bit Position	Bit Name	Function
31	CONFIGBIT	Configuration Bit in the Received Serial Data Frame See **Figure 27.3**.
30 to 24	Reserved	When read, the value after reset is returned.
23 to 16	SERIALID	Serial ID in the Received Serial Data Frame See **Figure 27.3**.
15 to 0	DATAFIELD	Data Field in the Received Serial Data Frame See **Figure 27.3**.

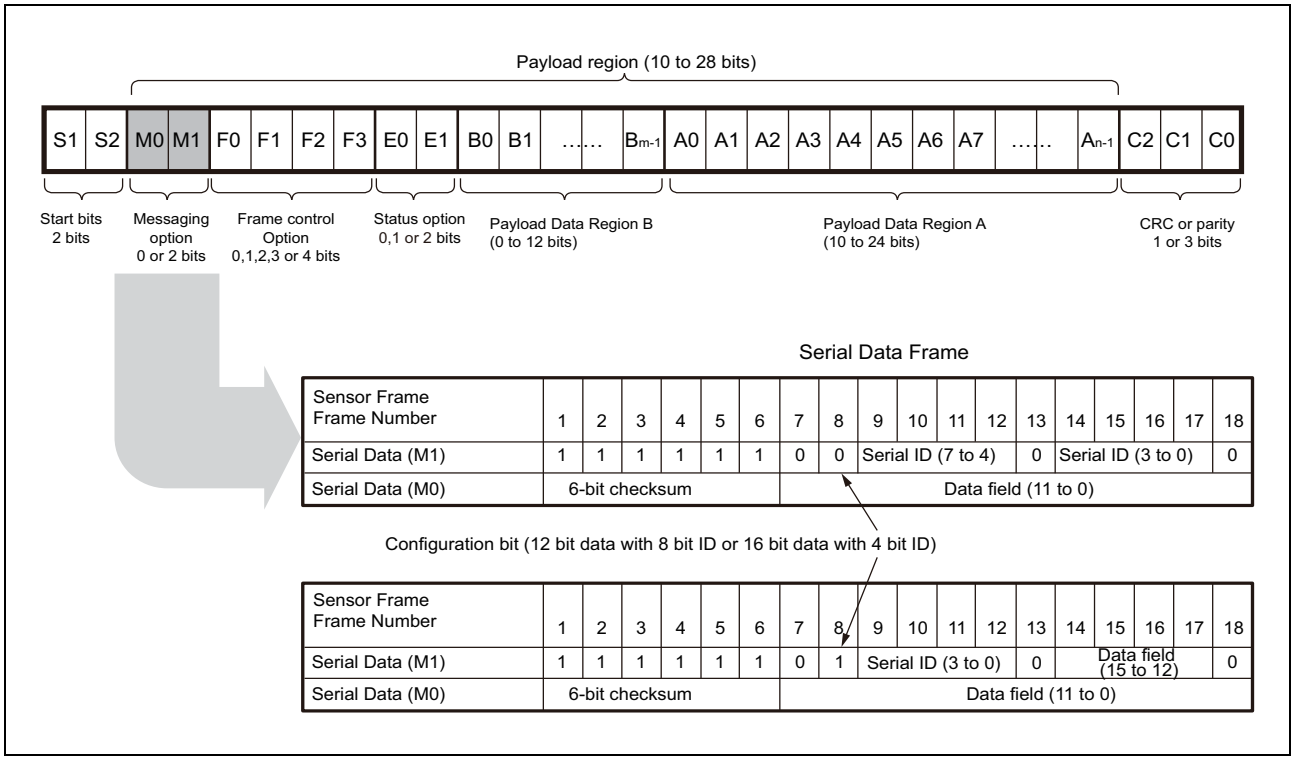

Figure 27.3 Serial Data Frame Configured by the Two Messaging Bits of the Sensor Data Frame (Messaging Channel)

27.3.35 PSI5nRXMRXST — PSI5 Receive-message Channel Receive Status Register

This register is the receive status register for the receive-message channel.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + 0188_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	RXSYNC		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	RXCRC						SLOTNUM				—	—	—	RXSTATUS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.44 PSI5nRXMRXST Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset is returned.
18 to 16	RXSYNC	Received Synchronization Bit Raw Data (the frame numbers 7, 13, and 18 of the sensor frame) For the sensor frame, see **Figure 27.3**.
15, 14	Reserved	When read, the value after reset is returned.
13 to 8	RXCRC	Received CRC Raw Data
7 to 4	SLOTNUM	Received Serial Data Frame's Slot Number
3 to 1	Reserved	When read, the value after reset is returned.
0	RXSTATUS	Indicates the error state of Rx data. 0: No error. 1: CRC or Syntax error occurred. A syntax error also occurs when the receive synchronization bit has received a value other than 0 while RXSYNC = 000_B.

27.3.36 PSI5nRXMRXTIM — PSI5 Receive-message Channel Receive Timestamp Register

This register indicates the value of the receive-message channel receive timestamp.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + $018C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RXMTIM															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RXMTIM															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.45 PSI5nRXMRXTIM Register Contents

Bit Position	Bit Name	Function
31 to 0	RXMTIM	Indicate the PSI5nIPTIMER value when the last data (frame number 18 of the sensor frame) is received. For the sensor frame, see **Figure 27.3**. These bits are effective only when PSI5nRXMMST.RXMEXIST = 1.

27.3.37 PSI5nRXMFIFO — PSI5 Receive-message Channel FIFO Register

This register indicates the receive-message channel FIFO information.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + 0190_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RXMFIFO															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RXMFIFO

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.46 PSI5nRXMFIFO Register Contents

Bit Position	Bit Name	Function
31 to 0	RXMFIFO	These bits can be read after data is received (when PSI5nRXMMST.RXMEXIST= 1: INT_RXMEXIST interrupt is asserted). This register acts as FIFO whose content includes PSI5nRXMRXMSG, PSI5nRXMRXST, and PSI5nRXMRXTIM. Read the received data three times each. Data is read in the following order: PSI5nRXMRXMSG, PSI5nRXMRXST, and then PSI5nRXMRXTIM. Exclusive access is required between PSI5nRXMFIFO and “PSI5nRXMRXMSG, PSI5nRXMRXST, or PSI5nRXMRXTIM”.

27.3.38 PSI5nRXMMST — PSI5 Receive-message Channel Module Status Register

This register is the status register for the receive-message channel module.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <PSI5n_base> + 0194_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RXM ERR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.47 PSI5nRXMMST Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned.
16	RXMERR	Rx Message Error 0: No error. 1: Error occurred. When this bit is set, the INT_RXMERR interrupt is asserted.
15 to 9	Reserved	When read, the value after reset is returned.
8	RXMFOVF	Rx Message FIFO Overflow Flag 0: No overflow. 1: Overflow occurred. When this bit is set, the INT_RXMFOVF interrupt is asserted.
7 to 1	Reserved	When read, the value after reset is returned.
0	RXMEXIST	Indicates whether Rx Serial Data Frame exists. 0: No Rx serial data exists. 1: Rx serial data exists. When the PSI5nRXMRXMSG, PSI5nRXMRXST, and PSI5nRXMRXTIM registers are read, this bit is cleared. When this bit is set, the INT_RXMEXIST interrupt is asserted.

27.3.39 PSI5nRXMMSTCLR — PSI5 Receive-message Channel Module Status Clear Register

This register is used to clear the receive-message channel module status register.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + 0198_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RXMERRCLR

Table 27.48 PSI5nRXMMSTCLR Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	RXMERRCLR	Clears the status of the PSI5nRXMMST.RXMERR bit. 0: No operation is done. 1: The RXMERR bit is cleared. Read value is always 0.
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	RXMFOVFCLR	Clears the status of the PSI5nRXMMST.RXMFOVF bit. 0: No operation is done. 1: The RXMFOVF bit is cleared. Read value is always 0.
7 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

27.3.40 PSI5nRXMMSTINTEN — PSI5 Receive-message Channel Module Status Interrupt Enable Register

This register controls interrupts from the receive-message channel module.

Access: This register can be read or written in 32-bit units.

Address: <PSI5n_base> + $019C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RXM ERR INTEN

0	RXMEXIST INTEN	INT_RXMEXIST Interrupt Enable 0: Interrupt disabled (Masked) 1: Interrupt enabled

27.3.41 PSI5TSSEL — PSI5 Timestamp Function Mode Selection Register

This register specifies the timestamp setting.

This register can be controlled when the PSI5 is stopped (PSI5nCHCTRL.CHEN = 0).

Access: This register can be read or written in 32-bit units.

Address: <PSI5_SELB_base> + 0000_H

Value after reset: $0000\ 0000_H$ This register is initialized by any reset source except module reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 27.50 PSI5TSSEL Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 15	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
14 to 12	PSI5MSSEL3 [2:0]	PSI53 Timestamp Master Selection. This selection is valid only when PSI53 is in slave mode (PSI53IPTIMERCTRL.MSTSLV bit = 0_B) 000_B: No timestamp master. 001_B: PSI50 is the timestamp master of PSI53 (Supplies the count clock from PSI50 to PSI53). 010_B: PSI51 is the timestamp master of PSI53 (Supplies the count clock from PSI51 to PSI53). 011_B: PSI52 is the timestamp master of PSI53 (Supplies the count clock from PSI52 to PSI53). 100_B: No timestamp master. Other than above: Setting prohibited.
11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10 to 8	PSI5MSSEL2 [2:0]	PSI52 Timestamp Master Selection. This selection is valid only when PSI52 is in slave mode (PSI52IPTIMERCTRL.MSTSLV bit = 0_B) 000_B: No timestamp master. 001_B: PSI50 is the timestamp master of PSI52 (Supplies the count clock from PSI50 to PSI52). 010_B: PSI51 is the timestamp master of PSI52 (Supplies the count clock from PSI51 to PSI52). 011_B: No timestamp master. 100_B: PSI53 is the timestamp master of PSI52 (Supplies the count clock from PSI53 to PSI52). Other than above: Setting prohibited.
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 27.50 PSI5TSSEL Register Contents (2/2)

Bit Position	Bit Name	Function
6 to 4	PSI5MSSEL1 [2:0]	PSI51 Timestamp Master Selection. This selection is valid only when PSI51 is in slave mode (PSI51IPTIMERCTRL.MSTSLV bit = 0_B) 000_B: No timestamp master. 001_B: PSI50 is the timestamp master of PSI51 (Supplies the count clock from PSI50 to PSI51). 010_B: No timestamp master. 011_B: PSI52 is the timestamp master of PSI51 (Supplies the count clock from PSI52 to PSI51). 100_B: PSI53 is the timestamp master of PSI51 (Supplies the count clock from PSI53 to PSI51). Other than above: Setting prohibited.
3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2 to 0	PSI5MSSEL0 [2:0]	PSI50 Timestamp Master Selection. This selection is valid only when PSI50 is in slave mode (PSI50IPTIMERCTRL.MSTSLV bit = 0_B) 000_B: No timestamp master. 001_B: No timestamp master. 010_B: PSI51 is the timestamp master of PSI50 (Supplies the count clock from PSI51 to PSI50). 011_B: PSI52 is the timestamp master of PSI50 (Supplies the count clock from PSI52 to PSI50). 100_B: PSI53 is the timestamp master of PSI50 (Supplies the count clock from PSI53 to PSI50). Other than above: Setting prohibited.

27.4 Operation

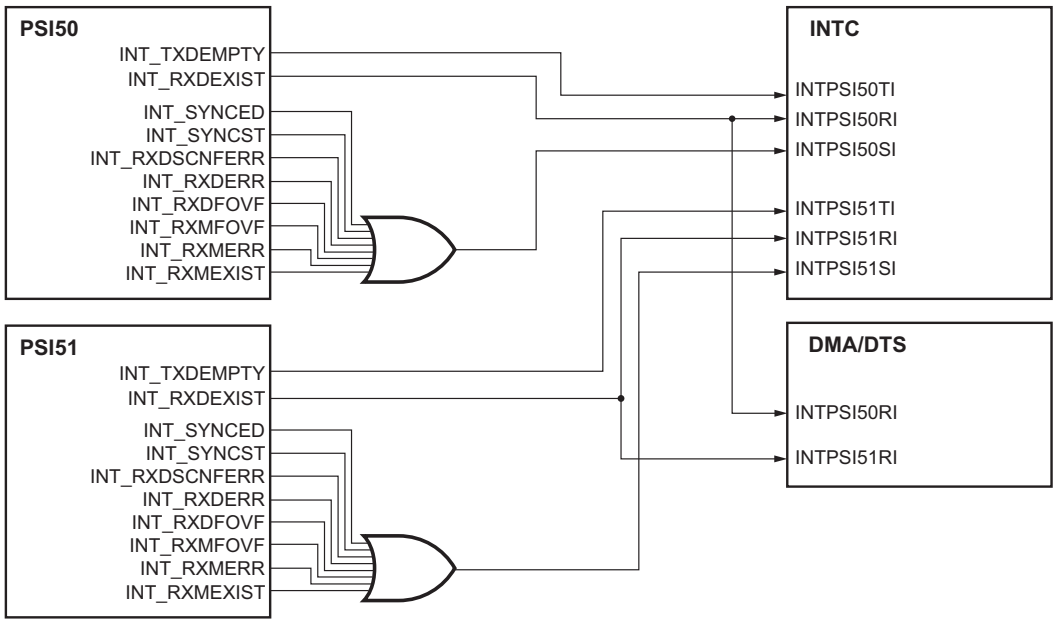
27.4.1 Interrupt

The PSI5 has 10 interrupt signals.

Table 27.51 PSI5 Interrupt Signals and Corresponding Registers

Interrupt Signal	Function	Source Register Bit	Interrupt Enable Register Bit
INT_SYNCED	Synchronization end interrupt	PSI5nTXST. SYNCED	PSI5nTXSTINTEN. SYNCEDINTEN
INT_SYNCST	Synchronization start interrupt	PSI5nTXST. SYNCST	PSI5nTXSTINTEN. SYNCSTINTEN
INT_TXDEMPTY	Transmit data empty interrupt	PSI5nTXST. TXDEMPTY	PSI5nTXSTINTEN. TXDEMPTYINTEN
INT_RXDSCNFERR	Synchronization pulse and receive data conflict error interrupt	PSI5nRXMODST. RXDSCNFERR	PSI5nRXMODSTINTEN. RXDSCNFINTEN
INT_RXDERR	Receive data error interrupt	PSI5nRXMODST. RXDERR	PSI5nRXMODSTINTEN. RXDERRINTEN
INT_RXDFOVF	Receive data FIFO overflow interrupt	PSI5nRXMODST. RXDFOVF	PSI5nRXMODSTINTEN. RXDFOVFINTEN
INT_RXDEXIST	Receive data exist interrupt	PSI5nRXMODST. RXDEXIST	PSI5nRXMODSTINTEN. RXDEXISTINTEN
INT_RXMFOVF	Receive message FIFO overflow interrupt	PSI5nRXMMST. RXMFOVF	PSI5nRXMMSTINTEN. RXMFOVFINTEN
INT_RXMERR	Receive message error interrupt	PSI5nRXMMST. RXMERR	PSI5nRXMMSTINTEN. RXMERRINTEN
INT_RXMEXIST	Receive message exist interrupt	PSI5nRXMMST. RXMEXIST	PSI5nRXMMSTINTEN. RXMEXISTINTEN

The following figure shows the relationship between the PSI5 interrupt signals, and RH850/U2A-EVA's interrupt controller INTC and DMA.



Note 1. Description of PSI52 and PSI53 are omitted (same configuration as PSI50 and PSI51).

Figure 27.4 PSI5 Interrupt Signals

27.4.2 Setting Operation Mode

Before the PSI5n starts operating, initial settings including the sensor connection status and operation mode must be configured. The following describes necessary initial settings.

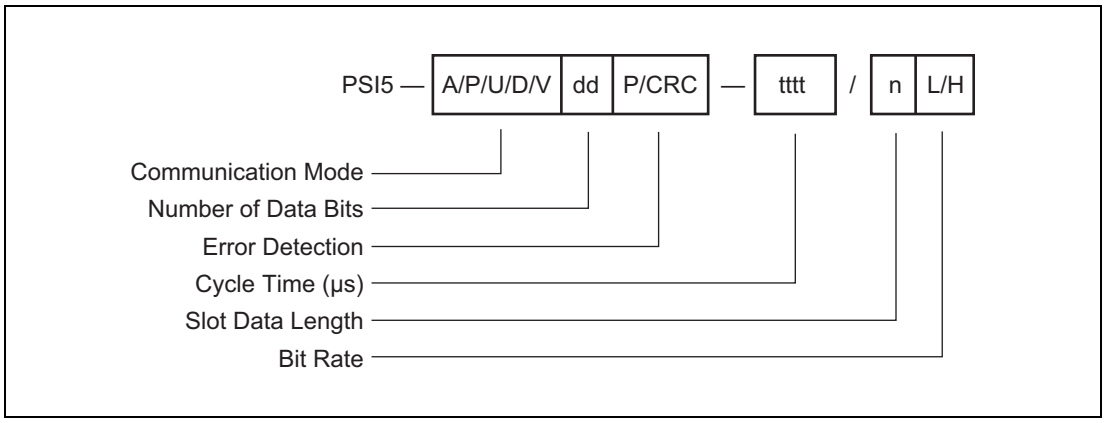


Figure 27.5 Setting PSI5 Operation Mode

Table 27.52 Setting Operation Mode

Item		Description
Communication Modes	A	Asynchronous Mode
	P	Synchronous Parallel Bus Mode
	U	Synchronous Universal Bus Mode
	D	Synchronous Daisy Chain Bus Mode
	V	Variable Time Triggered Synchronous Operation Mode
Number of data bits	dd	Data length of each slot specified in the PSI5nRXSmSET.LENGTH bit (10 to 28 bits)
Error Detection	P	One Parity Bit
	CRC	Three Bits CRC
Cycle time	tttt	Cycle Time (Minimum cycle time allowed in variable time triggered synchronous operation mode) (µs)
Slot count/cycle (n)	n	Select the slot to be used in the PSI5nRXMSET.
Bit Rate	L	125 kbps
	H	189 kbps

27.4.2.1 Setting for Transmit/Receive Mode

Set PSI5nOPMCOMM, PSI5nOPMBITRATE, and PSI5nOPMCYCT to the value corresponding to the specification of the PS15 sensor and its connection status.

27.4.2.2 Setting for Data Reception

The RH850/U2A-EVA receives data on psi5_com_clk.

A 16-times sampling is used for bit detection.

The bit length depends on the setting of PSI5nRXSPLSET.SMPLPROD[7:0].

- PSI5nRXSPLSET.SMPLPROD[7:0]: Set the sampling interval.

Set the value counted by psi5_com_clk. The RH850/U2A-EVA uses a 16-times sampling.

27.4.2.3 Initial Setting for Asynchronous Mode

In asynchronous mode, only PSI5nRXS1SET is available. Writing 1 to SLTEN in PSI5nRXS2SET to PSI5nRXS8SET is prohibited (so disable them).

In asynchronous mode, set the SLTEN, PASCMP, ERRDET, and LENGTH fields in PSI5nRXS1SET. The OFFSETCNT field is not available.

27.4.2.4 Initial Setting for Synchronous Mode

In synchronous mode, specify all fields of PSI5nRXS1SET to PSI5nRXS8SET appropriately.

The recommended setting values for PSI5nRXS1SET.OFFSETCNT and PSI5nRXS2SET to PSI5nRXS8SET.OFFSETCNT can be obtained as the results of the formula in **Figure 27.6** and **Figure 27.7**. In these figures, tcom_clk indicates the time for one psi5_com_clk cycle. Other variables are the variables specified by the PSI5 standard.

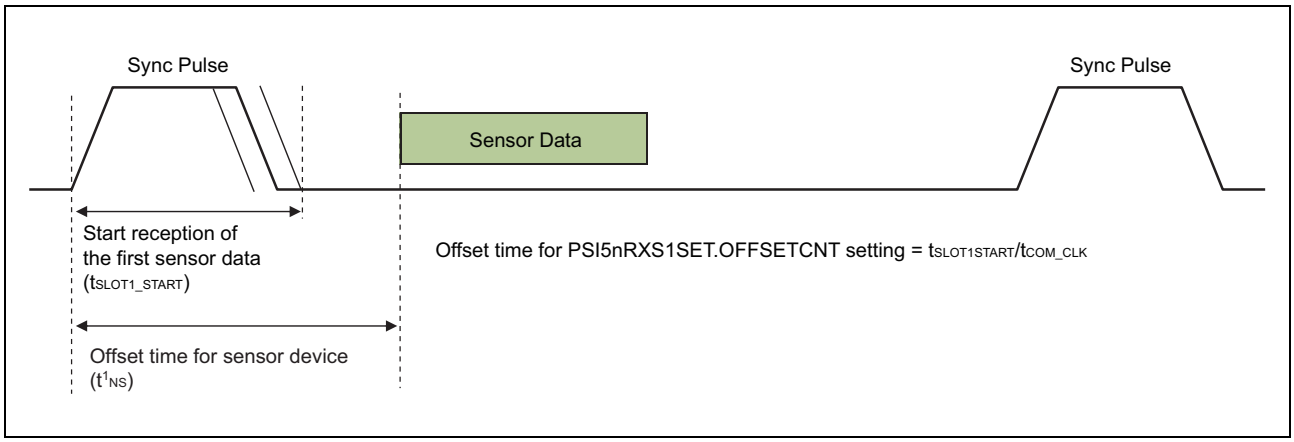

Figure 27.6 Recommended Setting of PSI5nRXS1SET.OFFSETCNT

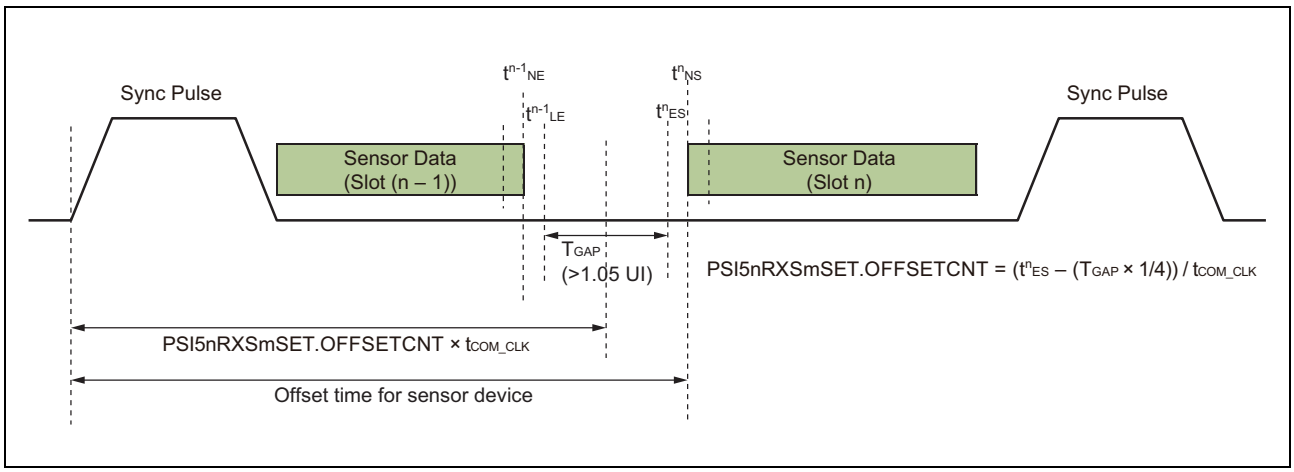

Figure 27.7 Recommended Setting of PSI5nRXSmSET.OFFSETCNT (m = 2 to 8)

27.4.2.5 Setting for Serial Message Reception

To receive a serial message, write 1 to PSI5nRXMSET. RXMmEN (m = 1 to 8) in the corresponding slot.

27.4.2.6 Initial Setting in Asynchronous Mode

In asynchronous mode, registers for transmission are disables except PSI5nTXSETTING.DEFTXVAL fields. Use the value after reset.

The PSI5 outputs the value set in PSI5nTXSETTING. DEFTXVAL after the start of operation (although the standard does not define output data in asynchronous mode). The value after reset is 1.

27.4.2.7 Initial Setting in Synchronous Mode

Set the value in PSI5nTXSETTING.

PSI5nTXSETTING.DEFTXVAL sets a synchronization pulse value for the period during which data is not transmitted. In Tooth GAP mode, set PSI5nTXSETTING.DEFTXVAL to 1. In pulse width mode, the value is not specified in the standard. Set the value specified by a system designer.

In variable time triggered synchronous operation mode, the user must specify the timing for synchronization pulse output.

When issuing a synchronization pulse, write 1 to the PSI5nSYNCCTRL.VALTIMSYNC bits.

Set the data format to be transmitted to the sensor in PSI5nTXDCTRL.FRMFORMAT.

27.4.2.8 Setting for Timestamping

A timestamp is appended to the received data so that the order of the received data and messages can be identified.

Timestamping is available in two modes: master mode for generation of the timing for counting up within the PSI5, and slave mode for counting with an input signal from the master. In master mode, the count-up timing is output to the output signal psi5_ts_tick_out. In slave mode, the input signal psi5_ts_tick_in is used for counting up.

To use a timestamp, set PSI5nIPTIMERCTRL.IPTIMEN to 1. Specify master or slave in PSI5nIPTIMERCTRL.MSTSLV.

In master mode, the count-up timing is complete when the internal baud rate counter is complete. The value to complete the baud rate counter is the setting of PSI5nOPMBITRATE.BITRATECNT.

The timestamp can be cleared by writing 1 to PSI5nIPTIMERCTRL.TSCLR irrespective of master or slave. In master mode, the clearing timing is output to the output signal psi5_ts_clr_out. In slave mode, the input signal psi5_ts_clr_in from the master can be used to clear the timestamp.

(1) Setting of Master/Slave Mode in Timestamp Mode

For PSI5, the dedicated timestamp slaves for a master can be chosen by various setting of PSI5TSSEL register, while multi-masters or master/slave(s) relation is decided by the setting of PSI5nIPTIMERCTRL.MSTSLV of each PSI5 unit beforehand.

Setting examples:

PSI52 operates as master and PSI50, PSI53 operate as slaves

PSI50IPTIMERCTRL.MSTSLV = 0_B

PSI51IPTIMERCTRL.MSTSLV = Don’t care

PSI52IPTIMERCTRL.MSTSLV = 1_B

PSI53IPTIMERCTRL.MSTSLV = 0_B

PSI5TSSEL.PSI5MSSEL0[2:0] = 011_B

PSI5TSSEL.PSI5MSSEL1[2:0] = 000_B (Initial value)

PSI5TSSEL.PSI5MSSEL2[2:0] = 011_B

PSI5TSSEL.PSI5MSSEL3[2:0] = 011_B

PSI50, PSI51, PSI52 and PSI53 operate in master mode without slaves

PSI50IPTIMERCTRL.MSTSLV = 1_B

PSI51IPTIMERCTRL.MSTSLV = 1_B

PSI52IPTIMERCTRL.MSTSLV = 1_B

PSI53IPTIMERCTRL.MSTSLV = 1_B

PSI5TSSEL.PSI5MSSEL0[2:0] = 001_B

PSI5TSSEL.PSI5MSSEL1[2:0] = 010_B

PSI5TSSEL.PSI5MSSEL2[2:0] = 011_B

PSI5TSSEL.PSI5MSSEL3[2:0] = 100_B

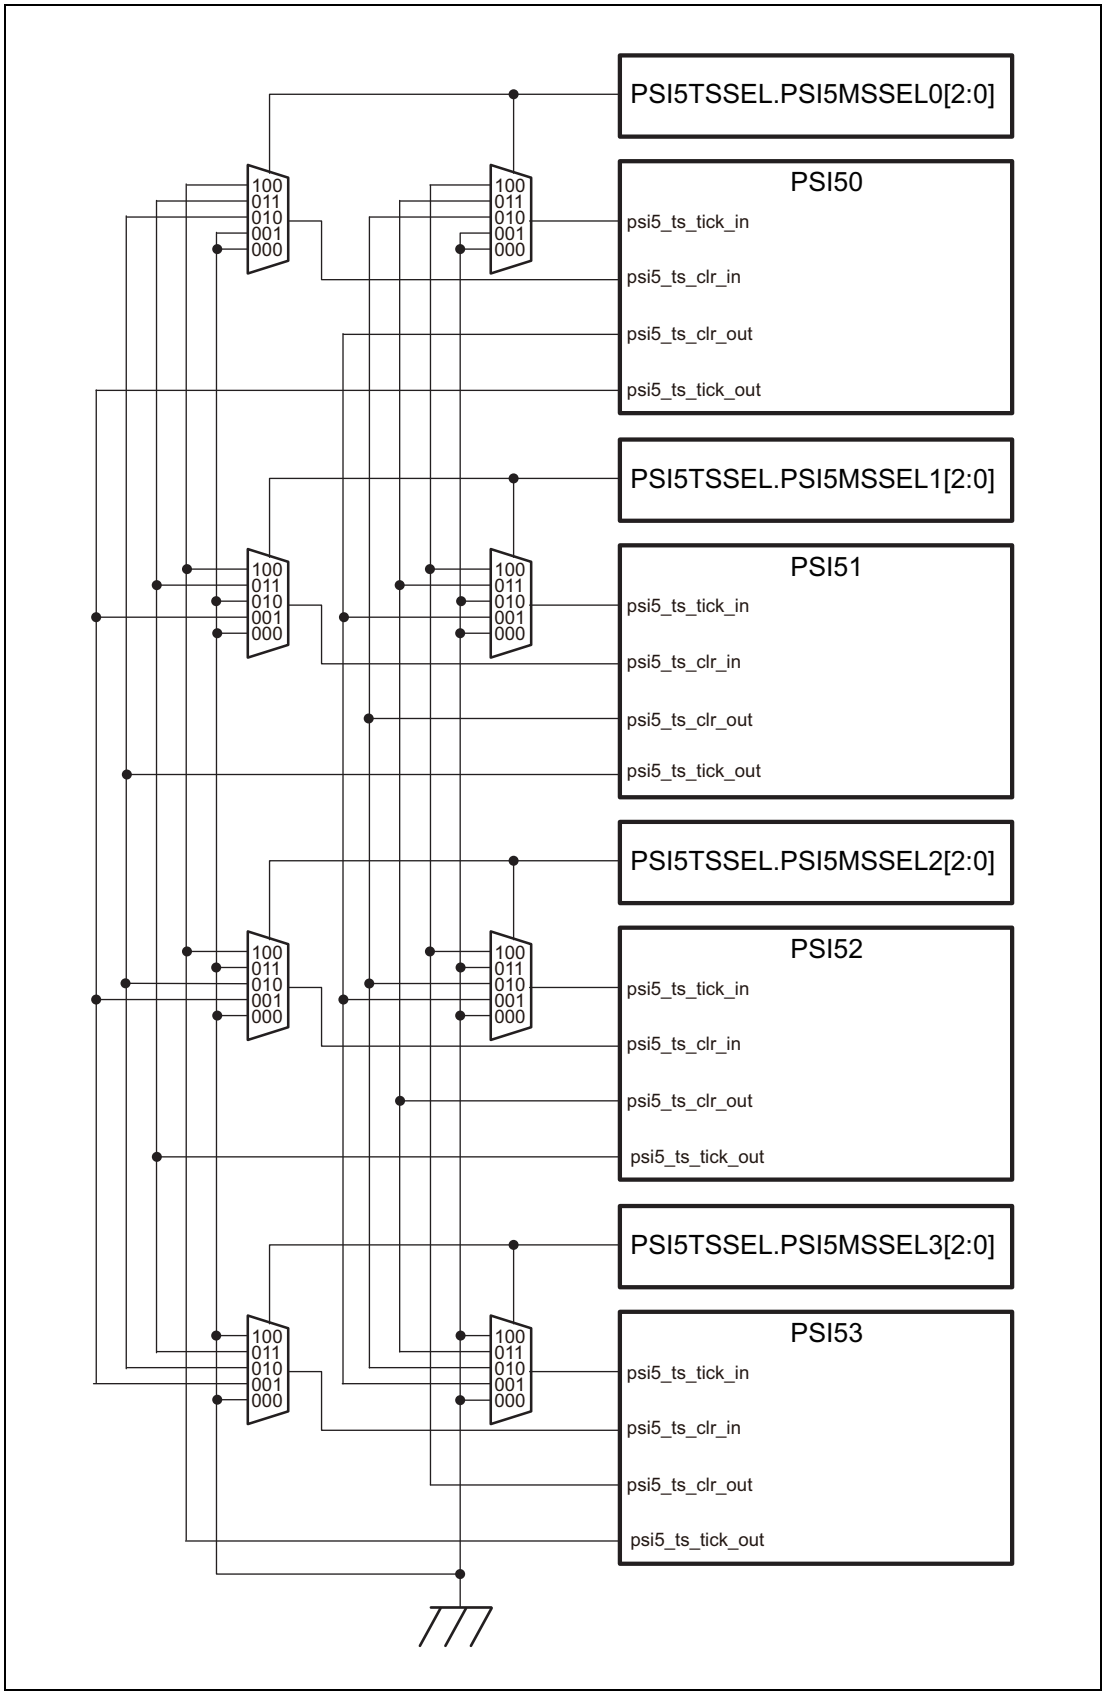

Figure 27.8 Relationship Between PSI50, PSI51, PSI52 and PSI53

27.4.3 Operation Flow

27.4.3.1 Starting Operation

Figure 27.10 shows the flow from initialization to the start of operation. When resetting the sensor or releasing it from reset, issue instructions to the PHY as these operations are performed by the PHY.

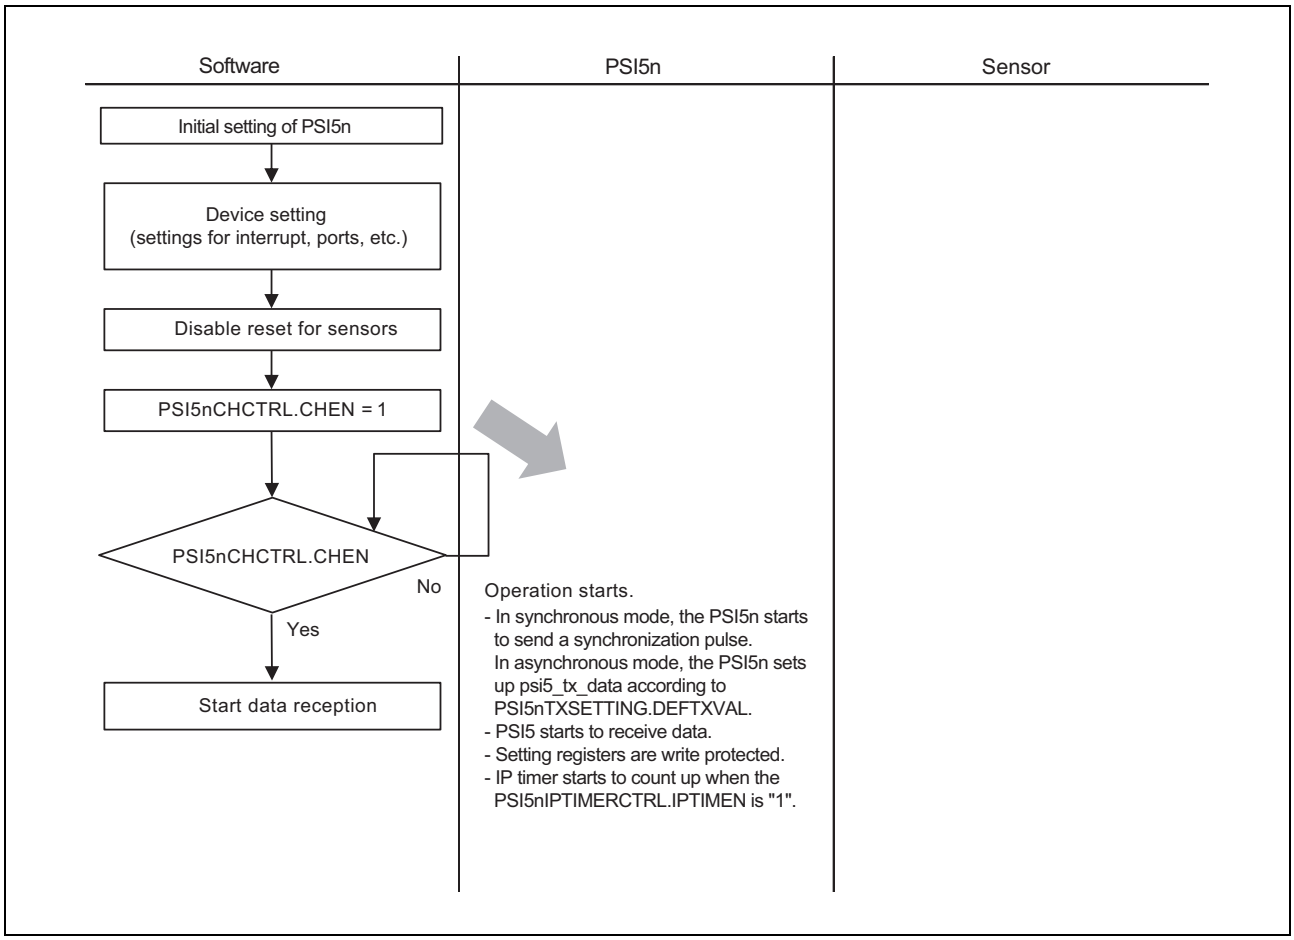

Figure 27.10 Flow of Starting Operation

27.4.3.2 Flow of Data Reception

Figure 27.11 shows the flow of data reception. The interrupt enable (PSI5nRXMODSTINTEN.RXDEXISTINTEN = 1) in the flowchart is not required when polling is used for detection of reception, or when it is always enabled (this applies to enabling of other interrupts in the subsequent sections).

The received data without the start bit and CRC/parity bits can be read out from PSI5nRXDATA.RXDATA.

Regarding the FIFO buffer shown in **Figure 27.11**, when data are received, that state is retained, and even if the register is empty, the received data are set from the FIFO buffer to the register. In cases of overflow because of delays in the reading out of data, new data are written to the buffer.

When reading data from the FIFO buffer, check that the value of PSI5nRXMDST.RXDEXIST is 0. Since PSI5nRXMDST.RXDEXIST being 1 indicates that data which have not been read out remain in the FIFO buffer, repeat the processing for reading.

The PSI5nRXDST. RXSTATUS is set to 1 in response to a start-bit error, Manchester code error, CRC error, or parity error during data reception. Specifically, in cases where multiple errors are detected during the reception of a single frame, the FIFO buffer for received data is updated every time an error occurs.

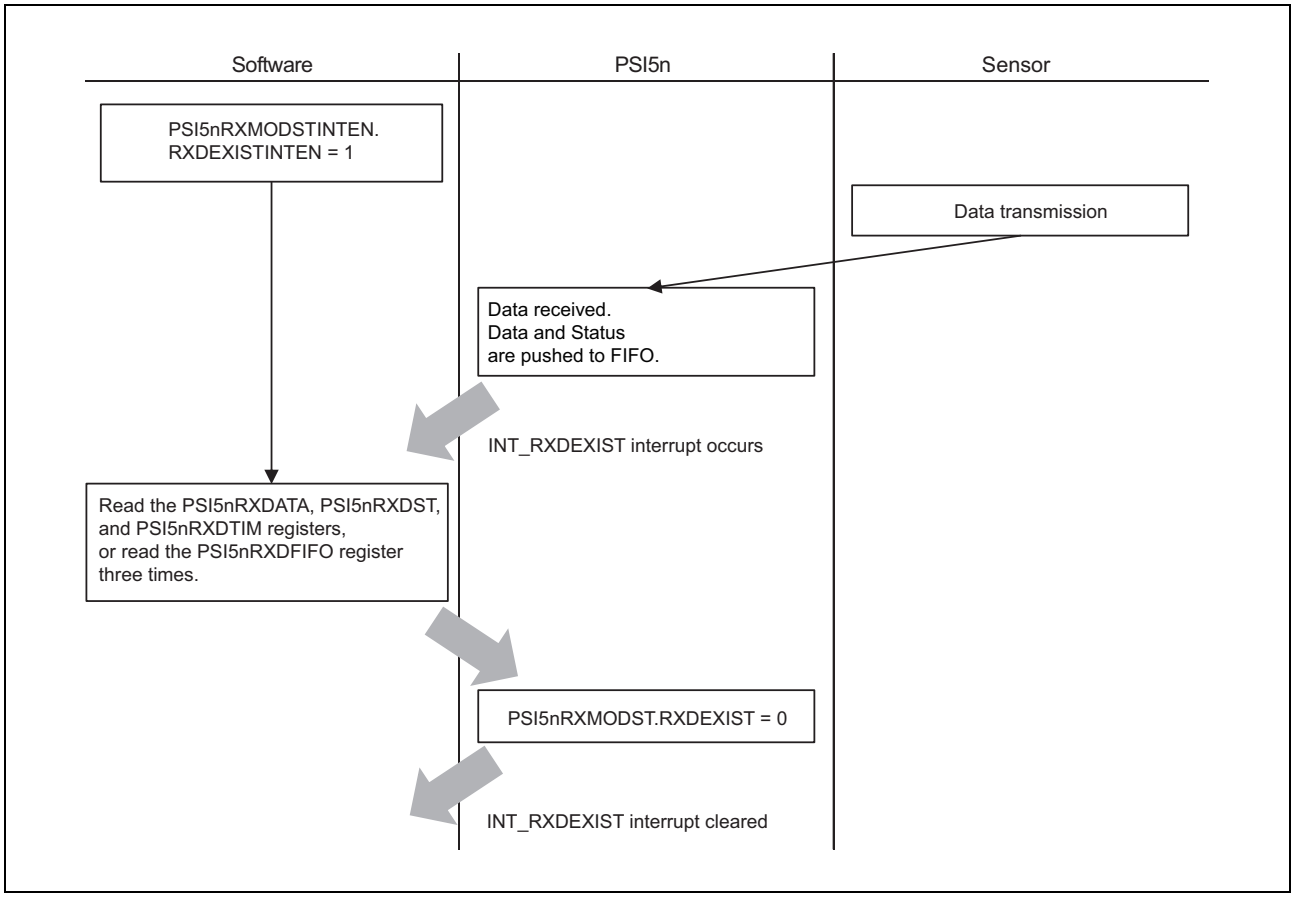

Figure 27.11 Data Reception Flow

27.4.3.3 Flow of Data Transmission

Figure 27.12 shows the flow of data transmission.

Transmit data arrangement to be written to the PSI5nTXDATA.TXDATA differs depending on the transmit frame format specified in the PSI5nTXDCTRL.FRMFORMAT bit (See **Table 27.32**). The data must not include a start bit, synchronization bit, or CRC (these are automatically appended).

Once PSI5nTXDCTRL.FRMFORMAT has been set, it does not need to be set again after that.

The PSI5 module does not have a FIFO buffer for transmission, so processing for transmission is sequential. When you intend to write to the transmission buffer, read the state of the buffer empty flag to check if it currently indicates the buffer empty state (PSI5nTXST.TXDEMPTY = 1). If the transmission buffer holds data to be transmitted at the time of writing (PSI5nTXST.TXDEMPTY = 0), transmitted data become undefined when data are written to the transmission buffer.

PSI5nTXST.TXDEMPTY becomes 1 to indicate the completion of transmission when reading of the last bit of the data from the transmission buffer starts.

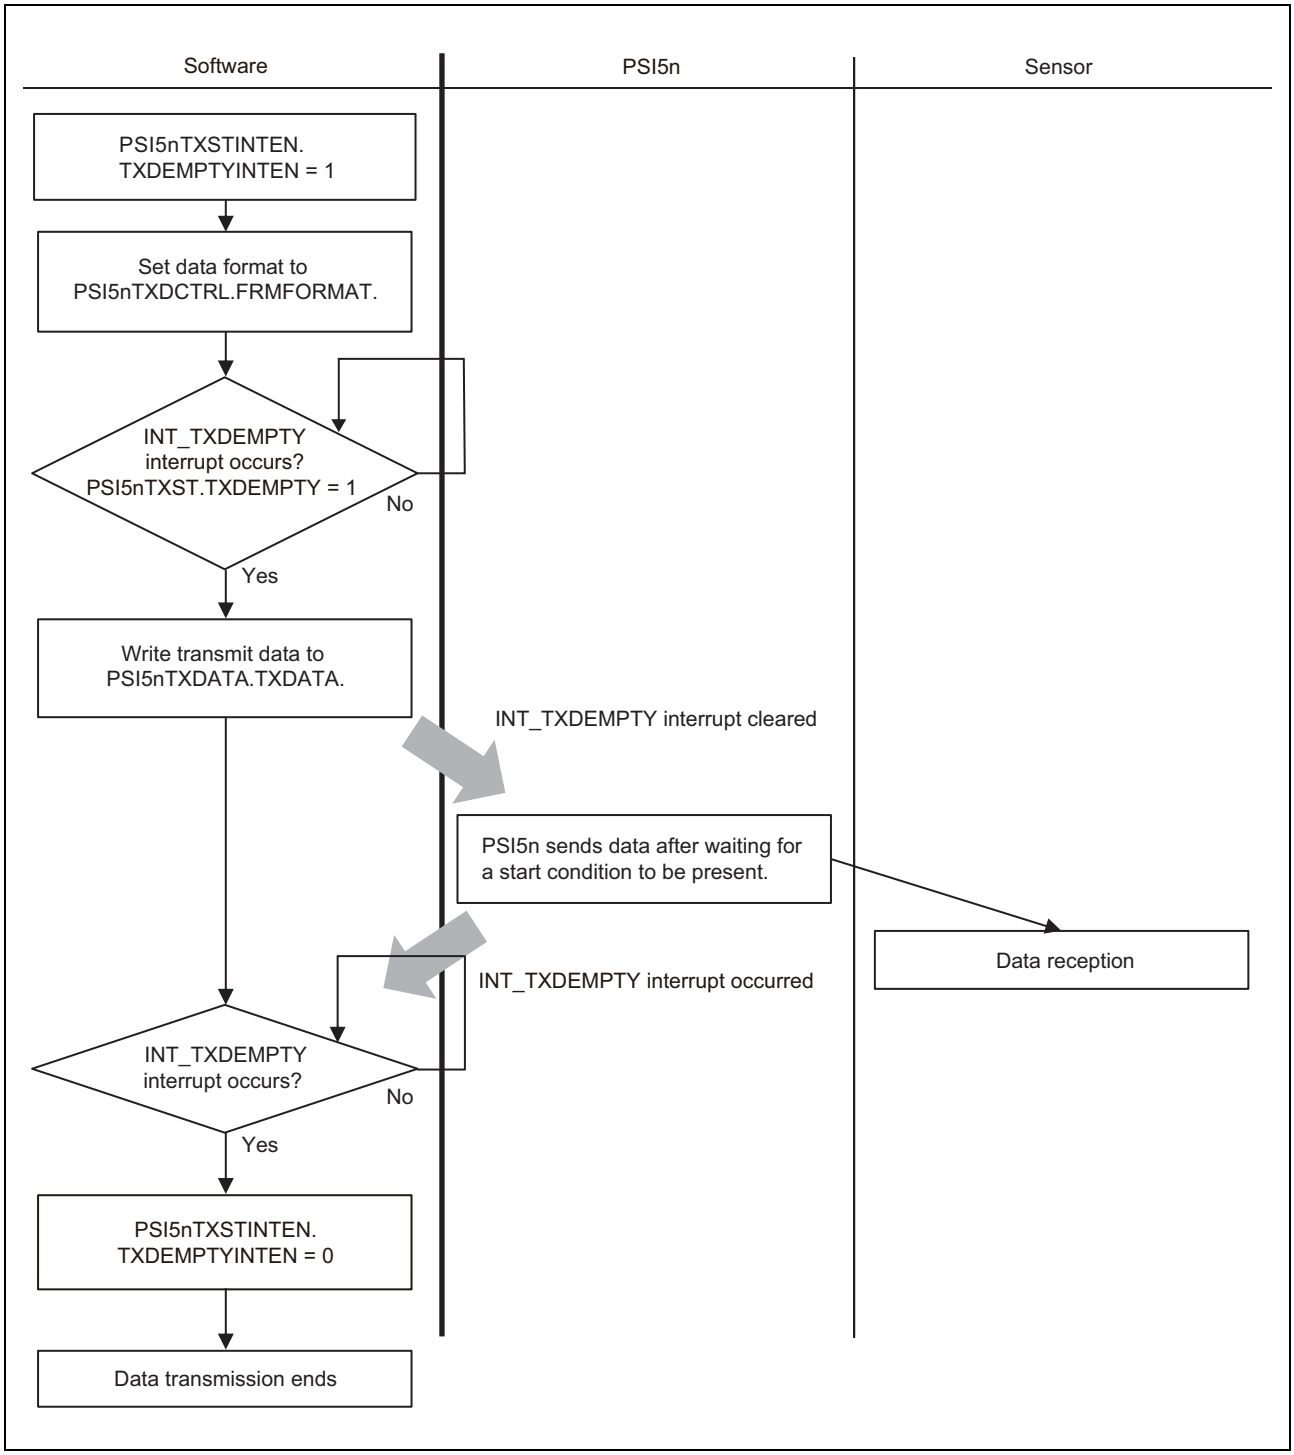

Figure 27.12 Data Transmission Flow

27.4.3.4 Serial Message Reception Flow

Figure 27.13 shows the flow of serial message reception.

The received serial message can be read out from PSI5nRXMRXMSG.

In **Figure 27.13**, the FIFO buffer holds the serial message and its state and the received data are set from the FIFO buffer to the register if the register is empty. In cases of overflow because of delays in the reading out of data, new data are written to the buffer.

When reading data from the FIFO buffer, check that the value of PSI5nRXMMST.RXMEXIST is 0. Since PSI5nRXMMST.RXMEXIST being 1 indicates that data which have not been read out remain in the FIFO buffer, repeat the processing for reading.

If either a CRC error or a receive data error occurs after the detection of the start bit in the message (after reception of M1 (Frame No.) = 111111_B), PSI5nRXMRXST.RXSTATUS is set to 1. In this case, handling of the received message is system-dependent. When an receive data error occurs, the message up to that data is stored in order from the least-significant bit of PSI5nRXMRXMSG.

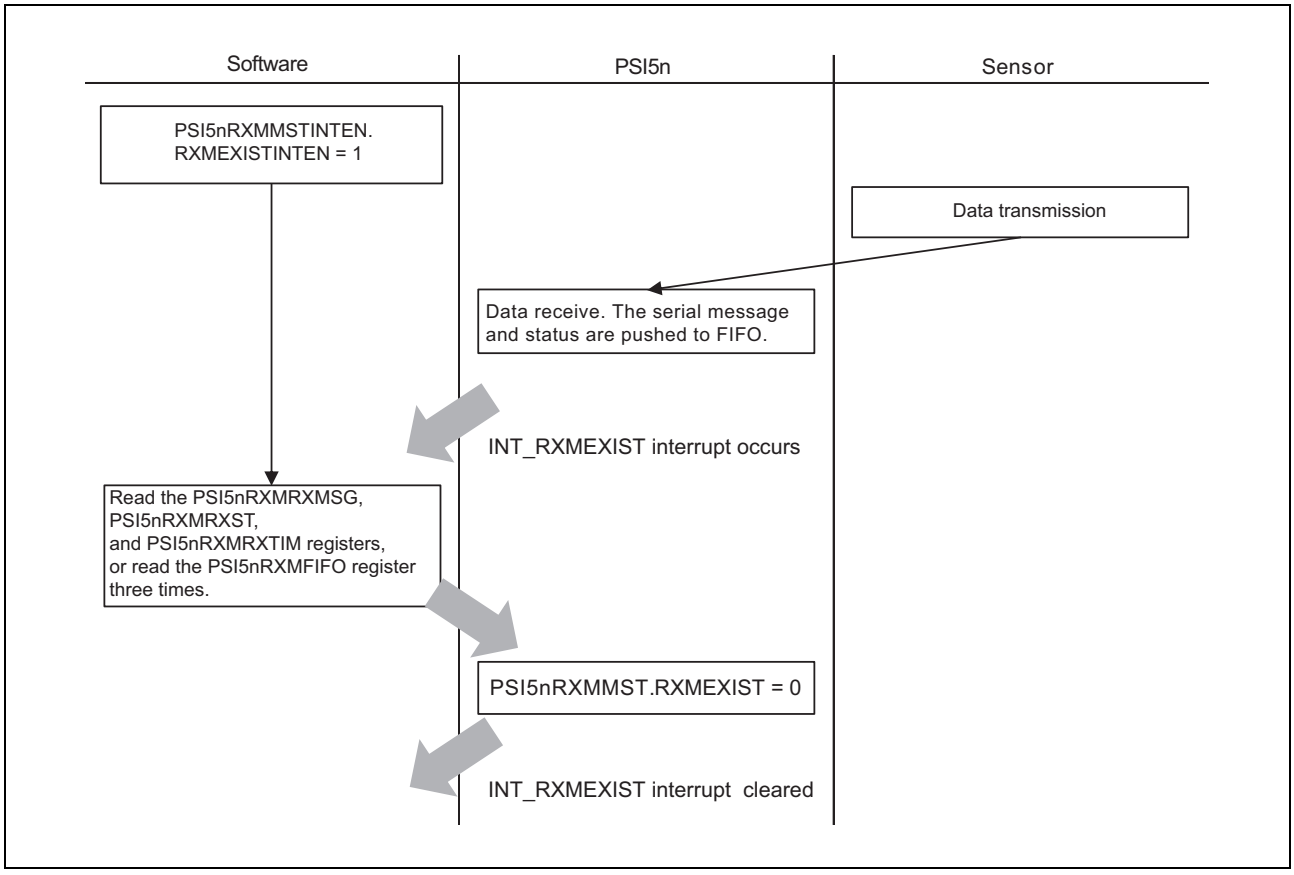

Figure 27.13 Serial Message Reception Flow

27.4.3.5 Parity and CRC Errors in Received Data

Error flags (PSI5nRXMODST.RXDERR and PSI5nRXMMST.RXMERR) are set in response to the detection of parity or CRC errors in received data. Reception operations proceed whether or not errors are detected.

Each of the error flags has a corresponding clearing bit (PSI5nRXMODSTCLR.RXDERRCLR and PSI5nRXMMSTCLR.RXMERRCLR).

27.4.3.5.1 Operation after Error Detection in Asynchronous Mode and PAS Compatibility Mode

When external noise and so on lead to errors in the Manchester code during the reception of data while the PSI5 is in the asynchronous mode or PAS compatibility mode, reception of the data being received is assumed to be complete, the parity or CRC error flag is set, and the data are stored in the reception FIFO buffer. Even when a Manchester code error occurs, the next data reception starts immediately. Due to this specification, even if a Manchester code error occurs for one bit because of external noise during data reception, the following data bit is assumed to be the start bit, and reception starts. In this situation, multiple Manchester code errors may occur and multiple reception complete interrupts can be generated. In such cases, the maximum number of errors corresponds to the number of bits in the unit of data.

Accordingly, this raises the possibility of producing an overflow. If an overflow occurs even though the data retrieval assumed during system designing is performed, the transfer may be malfunctioning due to factors such as noise.

In synchronous mode, data reception is halted at slot n + 1 in response to an error in the Manchester code while reception in slot n is in progress. For this reason, even if further errors occur or data is resent while in slot n, they are ignored.

27.4.4 PAS Compatibility Mode

The RH850/U2A-EVA has a PAS compatibility mode. The PAS compatibility mode supported by the RH850/U2A-EVA is as shown in **Table 27.53**.

Table 27.53 Supported PAS Compatibility Mode

Operation Mode		PAS Compatibility Mode
Bit rate		250 kbps
Data word length		8 to 24 bits
Data direction		MSB first
Data transmission parameter		
	Value of bit time (TYP.)	4 µs
	Value of gap time (MIN.)	2 µs
Communication Mode		PSI5-A only

In PAS compatibility mode, set 1 in PSI5nRXS1SET.PASCMP. At that time, set 0 (parity) in PSI5nRXS1SET.ERRDET.

27.4.5 Baud Rate

The communication clock is generated, by dividing 1 cycle of psi5_com_clk by 1 to 2^{16}.

1 bit cycle waveform = (value set in PSI5nOPMBITRATE.BITRATECNT) / psi5_com_clk

Baud rate = 1/1 bit cycle waveform

The following shows an example baud rate setting.

Table 27.54 Example Baud Rate Setting

Baud Rate [kbps]	psi5_com_clk		Value Set in PSI5nOPMBITRATE.BITRATECNT	Bit Time [µs]
	Frequency [MHz]	Cycle [ns]		
125	80	12.5	$29F_H$	8.4
189	80	12.5	$1BC_H$	5.57
250	80	12.5	$14F_H$	4.2

Section 28 Peripheral Sensor Interface 5 S (PSI5S)

This section contains a generic description of peripheral sensor interface 5 S (PSI5S).

The first part of this section describes the specific properties of this product, such as the number of channels and register base addresses.

The remainder of this section describes the functions and registers of PSI5S.

28.1 Features of PSI5S for RH850/U2A-EVA

28.1.1 Units and Channels

This product contains a PSI5S with the number of channels shown below.

Table 28.1 Number of Units

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of Units	2 (j = 0 to 1)	2 (j = 0 to 1)	2 (j = 0 to 1)	2 (j = 0 to 1)	2 (j = 0 to 1)	2 (j = 0 to 1)	2 (j = 0 to 1)	1 (j = 1)	1 (j = 1)	1 (j = 1)
Name	PSI5Sj									

Table 28.2 Index

Index	Description
j	The individual units are identified by the index “j” (j = 0 to 1)
n	The individual channels are identified by the index “n” (n = 0 to 7)
m	The individual packet frames in a channel are identified by the index “m” (m = 0 to 6)
r	The individual bit setting in register description by the index “r” (r = 0 to 31)

28.1.2 Register Base Addresses

The base address <PSI5Sj_base> of PSI5S is shown listed in **Table 28.3**.

Table 28.3 Register Base Addresses <PSI5Sj_base>

Base Address Name	Base Address	Bus Group
<PSI5S0_base>	FFD5 0000_H	P-Bus Group 3
<PSI5S1_base>	FFD5 1000_H	P-Bus Group 3

28.1.3 Clock Supply

The clocks supply to PSI5S are listed in the following table.

Table 28.4 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name	Description
PSI5S	PCLK	CLK_HSB	Bus clock
	psis_clk	CLK_HSB	UART communication clock
	psis_mult_clk	CLK_UHSB	UART communication multiply clock

For details of clock supply, see **Section 13, Clock Controller**.

28.1.4 Interrupt Requests and Error Notifications

The PSI5S interrupt requests are listed in the following table.

Table 28.5 Interrupt Requests

Interrupt Symbol Name	Unit Interrupt Signal	Description	Interrupt Number
PSI5S0			
INTPSI5S0INTCH0	int_psis_ch0	Communication interrupt for CH0	584
INTPSI5S0INTCH1	int_psis_ch1	Communication interrupt for CH1	585
INTPSI5S0INTCH2	int_psis_ch2	Communication interrupt for CH2	586
INTPSI5S0INTCH3	int_psis_ch3	Communication interrupt for CH3	587
INTPSI5S0INTCH4	int_psis_ch4	Communication interrupt for CH4	588
INTPSI5S0INTCH5	int_psis_ch5	Communication interrupt for CH5	589
INTPSI5S0INTCH6	int_psis_ch6	Communication interrupt for CH6	590
INTPSI5S0INTCH7	int_psis_ch7	Communication interrupt for CH7	591
PSI5S1			
INTPSI5S1INTCH0	int_psis_ch0	Communication interrupt for CH0	592
INTPSI5S1INTCH1	int_psis_ch1	Communication interrupt for CH1	593
INTPSI5S1INTCH2	int_psis_ch2	Communication interrupt for CH2	594
INTPSI5S1INTCH3	int_psis_ch3	Communication interrupt for CH3	595
INTPSI5S1INTCH4	int_psis_ch4	Communication interrupt for CH4	596
INTPSI5S1INTCH5	int_psis_ch5	Communication interrupt for CH5	597
INTPSI5S1INTCH6	int_psis_ch6	Communication interrupt for CH6	598
INTPSI5S1INTCH7	int_psis_ch7	Communication interrupt for CH7	599

This module has no error notifications.

The PSI5S DMA requests are listed in the following table.

Table 28.6 DMA/DTS Requests

Interrupt Symbol Name	Unit Signal	Description	sDMA Trigger Number	DTS Trigger Number
PSI5S0				
INTPSI5S0RXDMACH0	dma_psis_ch0_rx	PSI5S0 DMA request (CH0 RX)	Group1-61	Group1-15
INTPSI5S0RXDMACH1	dma_psis_ch1_rx	PSI5S0 DMA request (CH1 RX)	Group1-62	Group1-16
INTPSI5S0RXDMACH2	dma_psis_ch2_rx	PSI5S0 DMA request (CH2 RX)	Group1-63	Group1-17
INTPSI5S0RXDMACH3	dma_psis_ch3_rx	PSI5S0 DMA request (CH3 RX)	Group1-64	Group1-18
INTPSI5S0RXDMACH4	dma_psis_ch4_rx	PSI5S0 DMA request (CH4 RX)	Group1-65	Group1-19

28.1.5 Reset Sources

Table 28.7 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
PSI5S	All registers	√	√	√	√	√	√	—

For details of reset source, see **Section 9, Reset Controller**.

28.1.6 External Input/Output Signals

PSI5S has the input/output pins listed in **Table 28.8**.

Table 28.8 Pin Configuration

Unit Signal Name	Description	Alternative Port Pin Signal
PSI5S0		
psis_rx_data	UART Rx data	PSI5S0RX
psis_tx_data	UART Tx data	PSI5S0TX
psis_tx_sclk	UART clock	PSI5S0CLK
PSI5S1		
psis_rx_data	UART Rx data	PSI5S1RX
psis_tx_data	UART Tx data	PSI5S1TX
psis_tx_sclk	UART clock	PSI5S1CLK

28.2 Outline of Functions

28.2.1 Functional Overview

PSI5S performs UART communication with an external transceiver (PSI5 transceiver).

PSI5S implements a peripheral sensor interface compliant with PSI5 Version 2.2 via the external transceiver.

This document describes the general specifications of PSI5S.

The following table lists the features of PSI5S.

Table 28.9 Features

Item	Specification
UART communication	Sampling clock output*1: 6.67 MHz to 26.67 MHz Baud rate*2: 1.333 Mbps to 5.333 Mbps Frame format (total of 10 or 11 bits) • Start bit: 1 bit • Data: 8 bits • Parity: None, even parity, 0 parity, or odd parity (can be specified separately for reception and transmission) • Stop bit: 1 bit
Sensor-to-ECU communication	• Possible reception of eight channels of frame data • Possible reception of 8-bit to 28-bit payload • Automatic calculation of CRC and parity values from payload • Possible storage of the CRC and parity bits attached to the data in received frames • Monitoring of the number of packets in received frames • Timestamp function for received messages. • Monitoring of the received frames by WDT.
ECU-to-sensor communication	• Automatic calculation of the CRC value to be added to frame data • Output format selectable from frame 1 to frame 4
Other interface	Interrupt output • Eight channels (Ch0 to Ch7) DMA request output • Eight channels (Ch0 to Ch7) for reception and seven channels (Ch1 to Ch7) for transmission

Note 1. For details about the clock specifications, see **Section 28.5.1, Common Setting Procedure**.

Note 2. For details about the baud rate of UART communication, see **Section 28.5.1, Common Setting Procedure**.

28.2.1.1 Terms

Table 28.10 Abbreviations

HW	Hardware
SW	Software
PSI5	Peripheral Sensor Interface 5
UART	Universal Asynchronous Receiver Transmitter
Mbps	Megabits per second
SFR	Special Function Register
ECU	Electronic Control Unit
Ch	Channel
Frm	Frame
Sync	Synchronous
Async	Asynchronous
Rx	Receive
Tx	Transmit
WDT	Watch Dog Timer
MB	MailBox
INT	Interrupt
DDSR	Downstream Data Shift Register
GTM	Generic Timer Module

A “packet” means a UART frame.

A “packet frame” means a group of three to six packets (UART frames) that are received from a transceiver.

A “PSI5 frame” means data that is reconstructed from a packet frame after removing start, stop, and parity bits from the packet frame.

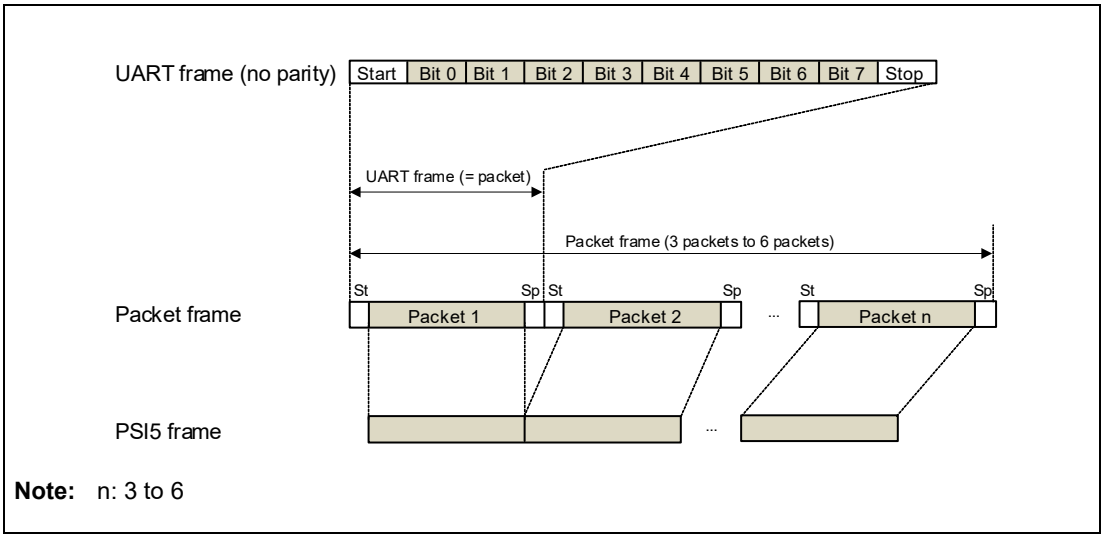

Figure 28.1 Definitions of Packet and Frames (without Parity)

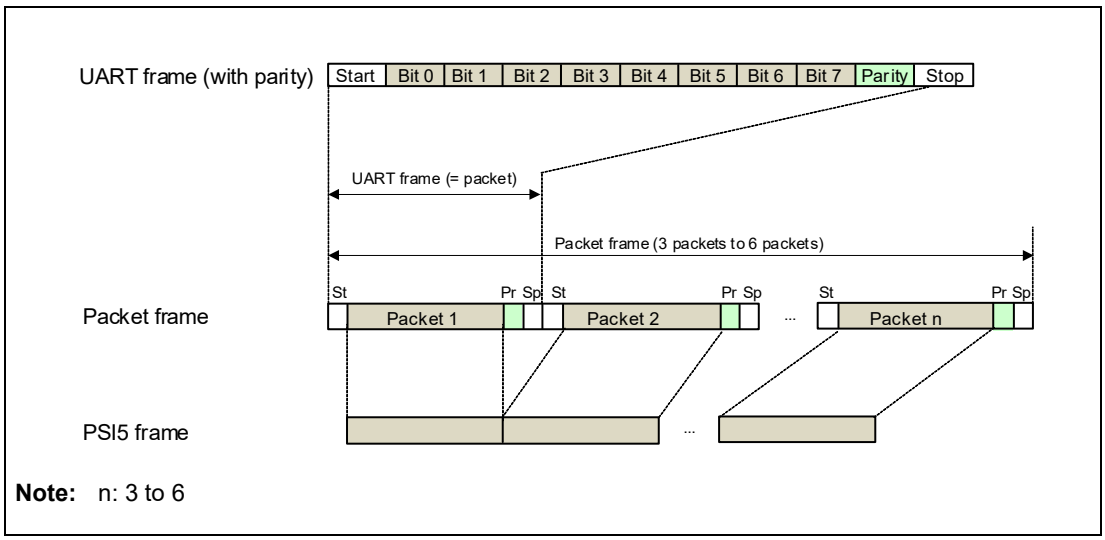

Figure 28.2 Definitions of Packet and Frames (with Parity)

The PSI5 frame format is as follows.

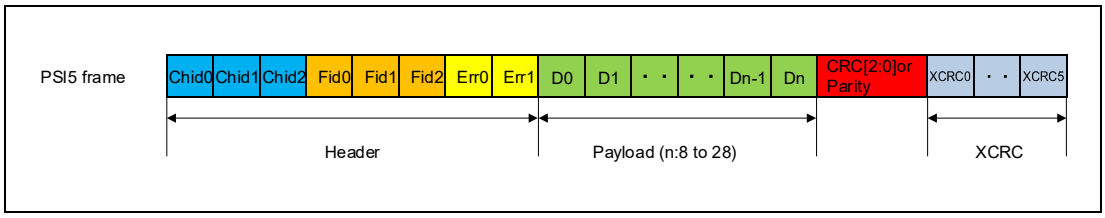

Figure 28.3 PSI5 Frame Format

28.2.2 Block Diagram

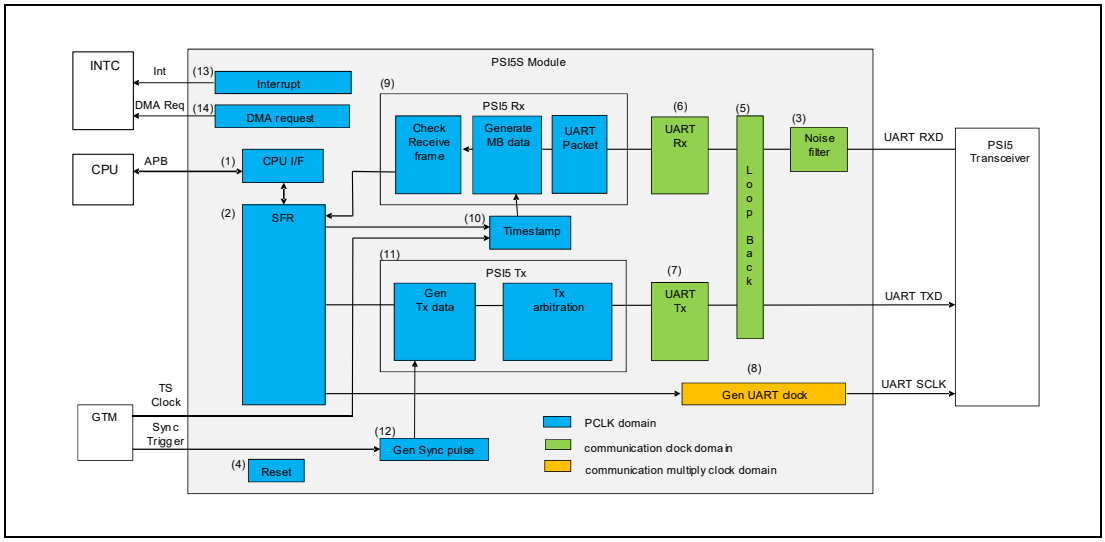

Figure 28.4 PSI5S Block Diagram

The following table lists the functions of PSI5S.

Table 28.11 PSI5S Function List

No	Name	Function
(1)	CPU interface	P-Bus interface (write/read access)
(2)	SFR	Special function registers (detect some kinds of errors)
(3)	Noise filter	Removes signals of less than 37.5 ns.
(4)	Reset	Generates an asynchronous reset via input reset signal or software setting.
(5)	Loopback	UART loopback setting
(6)	UART Rx	UART receiver
(7)	UART Tx	UART transmitter
(8)	Gen UART clock	Generates the UART communication clock.
(9)	PSI5 Rx	Restores PSI5 frame data from UART reception data. Checks for errors in reception data. PSI5 frame data is watched by WDT.
(10)	Timestamp	Generates a timestamp via the GTM or according to internal timing. When a header or synchronization pulse is received, the timestamp value is captured.
(11)	PSI5 Tx	Generates ECU-to-sensor data. When a sync pulse is input to the transceiver as command data, UART transmission is performed.
(12)	Gen Sync pulse	Generates a sync pulse when the input sync trigger is detected by the GTM.
(13)	Interrupt	Generates an interrupt signal when an interrupt factor occurs.
(14)	DMA request	Generates a DMA request signal when a sDMAC/DTS request factor occurs.

28.3 Registers

28.3.1 List of Registers

The PSI5S registers are listed in the following table.

For details on <PSI5Sj_base >, see **Section 28.1.2, Register Base Addresses**.

Table 28.12 List of Registers (1/8)

Module Name	Register Name	Symbol	Address	Access Protection	
				PBG	Other
PSI5S	PSI5S/UART Operation Enable register	PSI5SjPUOEB	<PSI5Sj_base> + 0000_H	*1	—
	PSI5S/UART Operation Mode register	PSI5SjPUOMD	<PSI5Sj_base> + 0004_H	*1	—
	PSI5S/UART Operation Status register	PSI5SjPUOS	<PSI5Sj_base> + 0008_H	*1	—
	PSI5S/UART Noise Filter Set register	PSI5SjPUNFST	<PSI5Sj_base> + $000C_H$	*1	—
	PSI5S/UART Software Reset register	PSI5SjPUSWR	<PSI5Sj_base> + 0010_H	*1	—
	PSI5S Receive Mailbox Data Clear register	PSI5SjPRMBC	<PSI5Sj_base> + 0014_H	*1	—
	PSI5S/UART Communication Loop Back register	PSI5SjPUCLB	<PSI5Sj_base> + 0020_H	*1	—
	PSI5S/UART Rx/Tx Parity Set register	PSI5SjPUPTS	<PSI5Sj_base> + 0024_H	*1	—
	PSI5S/UART Baud Rate Clock Enable register	PSI5SjPUBCE	<PSI5Sj_base> + 0028_H	*1	—
	PSI5S/UART Baud Rate Parameter register	PSI5SjPUBPR	<PSI5Sj_base> + $002C_H$	*1	—
	PSI5S Timestamp Prescaler register	PSI5SjPTPS	<PSI5Sj_base> + 0030_H	*1	—
	PSI5S Timestamp Counter A Select register	PSI5SjPTCAS	<PSI5Sj_base> + 0034_H	*1	—
	PSI5S Timestamp Counter B Select register	PSI5SjPTCBS	<PSI5Sj_base> + 0038_H	*1	—
	PSI5S Timestamp Counter A Enable register	PSI5SjPTCAE	<PSI5Sj_base> + 0040_H	*1	—
	PSI5S Timestamp Counter A Clear register	PSI5SjPTCAC	<PSI5Sj_base> + 0044_H	*1	—
	PSI5S Timestamp Counter B Enable register	PSI5SjPTCBE	<PSI5Sj_base> + 0048_H	*1	—
	PSI5S Timestamp Counter B Clear register	PSI5SjPTCBC	<PSI5Sj_base> + $004C_H$	*1	—
	PSI5S All Timestamp Counter Enable register	PSI5SjPATCE	<PSI5Sj_base> + 0050_H	*1	—
	PSI5S All Timestamp Counter Clear register	PSI5SjPATCC	<PSI5Sj_base> + 0054_H	*1	—
	UART Communication Rx Interrupt Enable	PSI5SjUCRIE	<PSI5Sj_base> + 0058_H	*1	—
	UART Communication Tx Interrupt Enable	PSI5SjUCTIE	<PSI5Sj_base> + $005C_H$	*1	—
	UART Communication DMA Request Enable register	PSI5SjUCDRE	<PSI5Sj_base> + 0060_H	*1	—
	UART Communication Rx Data register	PSI5SjUCRD	<PSI5Sj_base> + 0070_H	*1	—
	UART Communication Rx Status register	PSI5SjUCRS	<PSI5Sj_base> + 0074_H	*1	—
	UART Communication Rx Status Clear register	PSI5SjUCRSC	<PSI5Sj_base> + 0078_H	*1	—
	PSI5S Tx Frame Start register	PSI5SjPTFST	<PSI5Sj_base> + 0080_H	*1	—
	PSI5S Tx Frame Number register	PSI5SjPTFNM	<PSI5Sj_base> + 0084_H	*1	—
	PSI5S Tx Frame Data1 register	PSI5SjPTFD1	<PSI5Sj_base> + 0088_H	*1	—
	PSI5S Tx Frame Data2 register	PSI5SjPTFD2	<PSI5Sj_base> + $008C_H$	*1	—
	PSI5S Tx Frame Status register	PSI5SjPTFS	<PSI5Sj_base> + 0090_H	*1	—
	PSI5S Tx FIFO Status register	PSI5SjPTFIS	<PSI5Sj_base> + 0094_H	*1	—
	UART Communication Tx Data register	PSI5SjUCTD	<PSI5Sj_base> + $00A0_H$	*1	—
	UART Communication Tx Monitoring register	PSI5SjUCTM	<PSI5Sj_base> + $00A4_H$	*1	—
	UART Communication Tx Status register	PSI5SjUCTS	<PSI5Sj_base> + $00A8_H$	*1	—
	UART Communication Tx Status Clear register	PSI5SjUCTSC	<PSI5Sj_base> + $00AC_H$	*1	—

Table 28.12 List of Registers (2/8)

Module Name	Register Name	Symbol	Address	Access Protection	
				PBG	Other

28.3.2 Common Register/Config

28.3.2.1 PSI5SjPUOEB — PSI5S/UART Operation Enable Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0000_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 28.13 PSI5SjPUOEB Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	OPEN	Operation enable 0: Disable 1: Enable The value 1 can be written to this bit when PSI5SjPUOS.ACSTS is 0 (= configuration mode). The value 0 can be written to this bit at any time. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.2.2 PSI5SjPUOMD — PSI5S/UART Operation Mode Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0004_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 28.14 PSI5SjPUOMD Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	OPMD	Operation mode select 0: UART mode 1: PSI5S mode This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). This bit is cleared when by writing 1 to PSI5SjPUSWR.SWRST.

28.3.2.3 PSI5SjPUOS — PSI5S/UART Operation Status Register

Access: This register is a read-only register that can be read in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0008_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	MSTS	ACSTS	SWSTS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.15 PSI5SjPUOS Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is returned.
2	MSTS	Mode status 0: UART mode (PSI5SjPUOEB.OPEN = 1, PSI5SjPUOMD.OPMD = 0) 1: PSI5S mode (PSI5SjPUOEB.OPEN = 1, PSI5SjPUOMD.OPMD = 1) This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
1	ACSTS	Active status 0: Not Active (Configuration mode: PSI5SjPUOEB.OPEN = 0) 1: Active (UART mode or PSI5S mode: PSI5SjPUOEB.OPEN = 1) This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
0	SWSTS	Software (SW) reset status 0: SW reset not asserted 1: SW reset asserted Writing 1 to PSI5SjPUSWR.SWRST sets this bit to 1. This bit is read as 1 during SW reset execution. After SW reset execution, the bit is cleared to 0.

28.3.2.4 PSI5SjPUNFST — PSI5S/UART Noise Filter Set Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + $000C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	NFSET
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 28.16 PSI5SjPUNFST Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	NFSET	Noise filter setting 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.2.5 PSI5SjPUSWR — PSI5/UART Software Reset Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0010_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SWRST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 28.17 PSI5SjPUSWR Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	SWRST	Software (SW) reset 0: Ignored 1: Start software reset for PSI5S This bit is always read as 0.

28.3.2.6 PSI5SjPRMBC — PSI5S Receive MailBox Data Clear Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0014_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MBCLR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 28.18 PSI5SjPRMBC Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	MBCLR	MailBox clear All MailBox data clear 0: Ignored 1: All MailBox data cleared to 0 This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode).

28.3.2.7 PSI5SjPUCLB — PSI5S/UART Communication Loop Back Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0020_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	TMKV[6:0]							LBEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28.19 PSI5SjPUCLB Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7 to 1	TMKV	Test Mode Key Values Test mode key values for loopback test function These bits are always read as 0.
0	LBEN	3rd write value of loopback test sequence enable 0: Disable 1: Enable Test function set sequence is described in **Section 28.5.11.1, Loopback Test Setting Procedure** This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.2.8 PSI5SjPUPTS — PSI5S/UART Rx/Tx Parity Set Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0024_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 28.20 PSI5SjPUPTS Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9 to 8	UTPRTY[1:0]	UART Tx Parity 0: Parity disable 1: Even parity 2: 0 parity (Parity is always 0) 3: Odd parity When the CPU sets parity to disable (= 00B), a packet (UART frame) is composed of 1 start bit, 8 data bits and 1 stop bit (10 bits in total). Otherwise, a packet (UART frame) is composed of 1 start bit, 8 data bits, 1 parity bit and 1 stop bit (11 bits in total). These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1 to 0	URPRTY[1:0]	UART Rx parity 0: Parity disable 1: Even parity 2: Parity don’t care 3: Odd parity When the CPU sets parity to disable (= 00B), a packet (UART frame) is composed of 1 start bit, 8 data bits and 1 stop bit (10 bits in total). Otherwise, a packet (UART frame) is composed of 1 start bit, 8 data bits, 1 parity bit and 1 stop bit (11 bits in total). These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.2.9 PSI5SjPUBCE — PSI5S/UART Baud Rate Clock Enable Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0028_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 28.22 PSI5SjPUBPR Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
19 to 16	RXOSMP[3:0]	RX Over sample number 0 to 3: Setting prohibited 4: 5 samples … *x*: *x*+1 samples … 15: 16 samples These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
15 to 8	SCKDIV[7:0]	Clock divide value of UART SCLK (psis_tx_sclk) 0 = 1/1 1 = 1/2 … *x* = 1/(*x*+1) … 255 = 1/256 Writing to these bits are prohibited when PSI5SjPUBCE.SCKEN is 1. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	SCKPRS[6:0]	Prescaler of UART SCLK (psis_tx_sclk) 0 = 1/1 1 = 1/2 … *x* = 1/(*x*+1) … 127 = 1/128 Writing to these bits are prohibited when PSI5SjPUBCE.SCKEN is 1. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.2.11 PSI5SjPTPS — PSI5S Timestamp Prescaler Register

Access: This register can be read or written in 32-bit units.

Address: <PSI5Sj_base> + 0030_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	TSPRSU[9:0]									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	TSPRSL[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28.23 PSI5SjPTPS Register Contents

Bit Position	Bit Name	Function
31 to 26	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
25 to 16	TSPRSU[9:0]	Timestamp prescaler (upper) These bits define the load data of the timestamp prescaler counter (upper 10 bits). These bits configure a max 1 ms enable pulse from a 1 µs enable pulse The timestamp prescaler counter (upper) loads this setting and starts counting down until it reaches 1. Loading and counting down count are continuously repeated. When the timestamp prescaler counter (upper) becomes 1, the timestamp tick is output. If the CPU sets 0 to these bits, this pulse is not output. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
15 to 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	TSPRSL[6:0]	Timestamp prescaler (lower) These bits define the load data of the timestamp prescaler counter (lower 7 bits). The timestamp prescaler counter (lower) loads this setting and starts counting down until it reaches 1. Loading and counting down count are continuously repeated. These bits configure a 1 µs clock from PCLK. When the timestamp prescaler counter (lower) becomes 1, a 1 µs enable pulse is output. When the CPU sets 0 to these bits, the 1 µs enable pulse is not output. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.2.12 PSI5SjPTCAS — PSI5S Timestamp Counter A Select Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0034_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28.24 PSI5SjPTCAS Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	TSCACLS	Timestamp counter A clear select 0: Signal generated by PSI5S is selected 1: GTM output is selected This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	TSCAEBS	Timestamp counter A enable select 0: Signal generated by PSI5S is selected (= PSI5SjPTCAE.TSCAEB = 1 or PSI5SjPATCE.ATSCEB = 1). 1: GTM output is selected This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	TSCACKS	Timestamp counter A clock select 0: Signal generated by PSI5S is selected 1: GTM output is selected This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.2.13 PSI5SjPTCBS — PSI5S Timestamp Counter B Select Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0038_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Table 28.25 PSI5SjPTCBS Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	TSCBCLS	Timestamp counter B clear select 0: Signal generated by PSI5S is selected 1: GTM output is selected This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	TSCBEBS	Timestamp counter B enable select 0: Signal generated by PSI5S is selected 1: GTM output is selected This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	TSCBCKS	Timestamp counter B clock select 0: Signal generated by PSI5S is selected 1: GTM output is selected This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.2.14 PSI5SjPTCAE — PSI5S Timestamp Counter A Enable Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0040_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 28.32 PSI5SjUCRIE Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	IERFIN	Interrupt enable of UART Rx finish flag 0: Disable 1: Enable This bit controls interrupt by PSI5SjUCRS.UTRFIN. This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 0 (= UART mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
2	IEROE	Interrupt enable of UART Rx overrun error flag 0: Disable 1: Enable This bit controls interrupt by PSI5SjUCRS.UTROE. This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 0 (= UART mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
1	IERFE	Interrupt enable of UART Rx framing error flag 0: Disable 1: Enable This bit controls interrupt by PSI5SjUCRS.UTRFE. This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 0 (= UART mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
0	IERPE	Interrupt enable of UART Rx parity error flag 0: Disable 1: Enable This bit controls interrupt by PSI5SjUCRS.UTRPE. This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 0 (= UART mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.2.21 PSI5SjUCTIE — UART Communication Tx Interrupt Enable

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + $005C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 28.33 PSI5SjUCTIE Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	IETFIN	Interrupt enable of UART Tx finish flag 0: Disable 1: Enable This bit controls interrupt by PSI5SjUCRS.UTTFIN. This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 0 (= UART mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
0	IETOWE	Interrupt enable of UART Tx overwrite error flag 0: Disable 1: Enable This bit controls interrupt by PSI5SjUCRS.UTTFOWE. This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 0 (= UART mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.2.22 PSI5SjUCDRE — UART Communication DMA Request Enable Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0060_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 28.34 PSI5SjUCDRE Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	DRQEUTFN	DMA request enable at UART Tx finish 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 0 (= UART mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
0	DRQEURFN	DMA request enable at UART Rx finish 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 0 (= UART mode). This bit is cleared when writing 1 to PSI5SjPUSWR.SWRST.

28.3.3 Common Register/Rx

28.3.3.1 PSI5SjUCRD — UART Communication Rx Data Register

Access: This register is a read-only register that can be read in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0070_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	UTRDT[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.35 PSI5SjUCRD Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned.
7 to 0	UTRDT[7:0]	UART read data When the stop bit of the Rx UART frame is detected in UART mode, PSI5SjUCRD.UTRDT is stored. If the next UART frame finishes before the CPU has read this address, PSI5SjUCRS.UTROE is set to 1 and this register is overwritten with new data. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.3.2 PSI5SjUCRS — UART Communication Rx Status Register

Access: This register is a read-only register that can be read in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0074_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	UTRFIN	UTROE	UTRFE	UTRPE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.36 PSI5SjUCRS Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is returned.
3	UTRFIN	UART Rx finish flag 0: A frame is not received successfully 1: A frame is received successfully When the stop bit of the UART frame is detected in UART mode without any error occurring, this bit is set to 1 and an interrupt (int_psis_ch0) and DMA request (dma_psis_ch7_rx) occur. This bit is cleared by writing 1 to PSI5SjUCRSC.UTRFINCL. When PSI5SjUCRS.UTRFIN is set and 1 is written to PSI5SjUCRSC.UTRFINCL in the same clock cycle, PSI5SjUCRS.UTRFIN remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
2	UTROE	UART Rx overrun error flag 0: No error 1: An overrun error detected If the stop bit of the next UART frame is detected in UART mode before the CPU has read PSI5SjUCRD.UTRDT, this bit is set to 1 and an interrupt (int_psis_ch0) occurs. This bit is cleared by writing 1 to PSI5SjUCRSC.UTROECL. When PSI5SjUCRS.UTROE is set and 1 is written to PSI5SjUCRSC.UTROECL in the same clock cycle, PSI5SjUCRS.UTROE remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
1	UTRFE	UART Rx framing error flag 0: No error 1: A framing error detected If the stop bit of the UART frame bit is detected in UART mode when the bit detection value is 0, this bit is set to 1 and an interrupt (int_psis_ch0) occurs. If an Rx overrun error occurs during stop bit detection, this bit remains 0. This bit is cleared by writing 1 to PSI5SjUCRSC.UTRFECL. When PSI5SjUCRS.UTRFE is set and 1 is written to PSI5SjUCRSC.UTRFECL in the same clock cycle, PSI5SjUCRS.UTRFE remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).

Table 28.36 PSI5SjUCRS Register Contents (2/2)

Bit Position	Bit Name	Function
0	UTRPE	UART Rx parity error 0: No error 1: A parity error detected If the stop bit of the UART frame is detected in UART mode when a parity error has been detected, this bit is set to 1 and an interrupt (int_psis_ch0) occurs. If a framing error or Rx overrun error occurs during stop bit detection, this bit remains 0. This bit is cleared by writing 1 to PSI5SjUCRSC.UTRPECL. When PSI5SjUCRS.UTRPE is set and 1 is written to PSI5SjUCRSC.UTRPECL in the same clock cycle, PSI5SjUCRS.UTRPE remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).

28.3.3.3 PSI5SjUCRSC — UART Communication Rx Status Clear Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0078_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	UTRFINCL	UTROECL	UTRFECL	UTRPECL
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 28.37 PSI5SjUCRSC Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	UTRFINCL	UART Rx finish flag clear 0: Ignored 1: UART Rx finish flag (PSI5SjUCRS.UTRFIN) clear This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 0 (= UART mode).
2	UTROECL	UART Rx overrun error clear 0: Ignored 1: Overrun error (PSI5SjUCRS.UTROE) clear This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 0 (= UART mode).
1	UTRFECL	UART Rx framing error clear 0: Ignored 1: Framing error (PSI5SjUCRS.UTRFE) clear This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 0 (= UART mode).
0	UTRPECL	UART Rx parity error clear 0: Ignored 1: Parity error (PSI5SjUCRS.UTRPE) clear This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 0 (= UART mode).

28.3.4 Common Register/Tx

28.3.4.1 PSI5SjPTFST — PSI5S Tx Frame Start Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0080_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 28.38 PSI5SjPTFST Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	TXST	Tx start PSI5S command data transmission start 0: Ignored 1: Transmission start When the CPU writes 1 to this bit, 1-8 command data (PSI5SjPTFD1.TDT1 to PSI5SjPTFD2.TDT8) transmission starts. This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).

28.3.4.2 PSI5SjPTFNM — PSI5S Tx Frame Number Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0084_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	TXNUM[2:0]		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 28.39 PSI5SjPTFNM Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2 to 0	TXNUM[2:0]	Tx command data number 000_B: 1 packet (UART frame) send (PSI5SjPTFD1.TDT1) 001_B: 2 packet (UART frame) send (PSI5SjPTFD1.TDT1 to PSI5SjPTFD1.TDT2) 010_B: 3 packet (UART frame) send (PSI5SjPTFD1.TDT1 to PSI5SjPTFD1.TDT3) 011_B: 4 packet (UART frame) send (PSI5SjPTFD1.TDT1 to PSI5SjPTFD1.TDT4) 100_B: 5 packet (UART frame) send (PSI5SjPTFD1.TDT1 to PSI5SjPTFD2.TDT5) 101_B: 6 packet (UART frame) send (PSI5SjPTFD1.TDT1 to PSI5SjPTFD2.TDT6) 110_B: 7 packet (UART frame) send (PSI5SjPTFD1.TDT1 to PSI5SjPTFD2.TDT7) 111_B: 8 packet (UART frame) send (PSI5SjPTFD1.TDT1 to PSI5SjPTFD2.TDT8) These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.4.3 PSI5SjPTFD1 — PSI5S Tx Frame Data1 Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0088_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TDT4[7:0]								TDT3[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TDT2[7:0]								TDT1[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28.40 PSI5SjPTFD1 Register Contents

Bit Position	Bit Name	Function
31 to 24	TDT4[7:0]	These bits define the transmission data of the 4th packet (UART frame). When PSI5SjPTFNM.TXNUM is less than 3, this setting is ignored. These bits cannot be written when PSI5SjPTFS.TXSTS is 1. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
23 to 16	TDT3[7:0]	These bits define the transmission data of the 3rd packet (UART frame). When PSI5SjPTFNM.TXNUM is less than 2, this setting is ignored. These bits cannot be written when PSI5SjPTFS.TXSTS is 1. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
15 to 8	TDT2[7:0]	These bits define the transmission data of the 2nd packet (UART frame). When PSI5SjPTFNM.TXNUM is less than 1, this setting is ignored. These bits cannot be written when PSI5SjPTFS.TXSTS is 1. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
7 to 0	TDT1[7:0]	These bits define the transmission data of the 1st packet (UART frame). These bits cannot be written when PSI5SjPTFS.TXSTS is 1. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.4.4 PSI5SjPTFD2 — PSI5S Tx Frame Data2 Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + $008C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TDT8[7:0]								TDT7[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TDT6[7:0]								TDT5[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28.41 PSI5SjPTFD2 Register Contents

Bit Position	Bit Name	Function
31 to 24	TDT8[7:0]	These bits define the transmission data of the 8th packet. When PSI5SjPTFNM.TXNUM is less than 7, these setting are ignored. These bits cannot be written when PSI5SjPTFS.TXSTS is 1. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
23 to 16	TDT7[7:0]	These bits define the transmission data of the 7th packet. When PSI5SjPTFNM.TXNUM is less than 6, these setting are ignored. These bits cannot be written when PSI5SjPTFS.TXSTS is 1. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
15 to 8	TDT6[7:0]	These bits define the transmission data of the 6th packet. When PSI5SjPTFNM.TXNUM is less than 5, these setting are ignored. These bits cannot be written when PSI5SjPTFS.TXSTS is 1. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
7 to 0	TDT5[7:0]	These bits define the transmission data of the 5th packet. When PSI5SjPTFNM.TXNUM is less than 4, these setting are ignored. These bits cannot be written when PSI5SjPTFS.TXSTS is 1. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.4.5 PSI5SjPTFS — PSI5S Tx Frame Status Register

Access: This register is a read-only register that can be read in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0090_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXSTS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.42 PSI5SjPTFS Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned.
0	TXSTS	Tx status 0: Transmission not busy 1: Transmission busy When the CPU sets 1 to PSI5SjPTFST.TXST, this bit is set to 1. When all transmission data (PSI5SjPTFD1, PSI5SjPTFD2) has been sent to the Tx shifter, this bit is reset to 0. When this bit is 1, PSI5SjPTFD1 and PSI5SjPTFD2 cannot be written. This bit is read only. The write value is ignored. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).

28.3.4.6 PSI5SjPTFIS — PSI5S Tx FIFO Status Register

Access: This register is a read-only register that can be read in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0094_H

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXFFFL	TXFFEP
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.43 PSI5SjPTFIS Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is returned.
1	TXFFFL	Tx FIFO full 0: Not full 1: Full This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
0	TXFFEP	Tx FIFO empty 0: Not empty 1: Empty This bit is set to 1 by writing 1 to PSI5SjPUSWR.SWRST. This bit is set to 1 when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).

28.3.4.7 PSI5SjUCTD — UART Communication Tx Data Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + $00A0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.44 PSI5SjUCTD Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7 to 0	UTTDT[7:0]	UART transmission data These bits cannot be written when PSI5SjUCTM.UTTBBF is 1. When the CPU writes PSI5SjUCTD.UTTDT while PSI5SjUCTM.UTTBBF is 1, PSI5SjUCTS.UTTOWE is set to 1. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 0 (= UART mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.4.8 PSI5SjUCTM — UART Communication Tx Monitoring Register

Access: This register is a read-only register that can be read in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + $00A4_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	UTTF	UTTBBF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.45 PSI5SjUCTM Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is returned.
1	UTTF	UART transmission flag 0: Not transmitting 1: Transmitting When stop bit output ends without any subsequent write data, this bit is reset to 0. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
0	UTTBBF	UART Tx shifter busy flag 0: Permitted to write to PSI5SjUCTD.UTTDT 1: Prohibited to write to PSI5SjUCTD.UTTDT This bit shows status of Tx shifter busy in UART mode. When CPU writes PSI5SjUCTD.UTTDT, this bit is set to 1. When PSI5SjUCTD.UTTDT data is stored in the Tx shifter, this bit is reset to 0. When this bit is 1, PSI5SjUCTD.UTTDT cannot be written. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).

28.3.4.9 PSI5SjUCTS — UART Communication Tx Status Register

Access: This register is a read-only register that can be read in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + $00A8_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 28.46 PSI5SjUCTS Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is returned.
1	UTTFIN	UART transmission finish 0: Transmission not finished 1: A UART frame transmission has finished When PSI5SjUCTD.UTTDT data is sent to the Tx shifter, this bit is set to 1 and an interrupt (int_psis_ch1) and DMA request (dma_psis_ch7_tx) occur. This bit is cleared by writing 1 to PSI5SjUCTSC.UTTFINCL. When PSI5SjUCTS.UTTFIN is set and 1 is written to PSI5SjUCTSC.UTTFINCL in the same clock cycle, PSI5SjUCTS.UTTFIN remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
0	UTTOWE	UART transmission overwrite error 0: No error 1: Overwrite error When the CPU writes 1 to PSI5SjUCTD.UTTDT in PSI5SjUCTM.UTTBBF, this bit sets to 1 and an interrupt (int_psis_ch1) occurs. This bit is cleared by writing 1 to PSI5SjUCTSC.UTTOWECL. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).

28.3.4.10 PSI5SjUCTSC — UART Communication Tx Status Clear Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + $00AC_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 28.47 PSI5SjUCTSC Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	UTTFINCL	UART Tx finish flag clear 0: Ignored 1: UART Tx finish flag (PSI5SjUCTS.UTTFIN) clear This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 0 (= UART mode).
0	UTTOWECL	UART Tx overwrite error clear 0: Ignored 1: Overwrite error (PSI5SjUCTS.UTTOWE) clear This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 0 (= UART mode).

28.3.5 Ch0 Register/Config

28.3.5.1 PSI5SjPRCF10 — PSI5S Receive Config1 ch0 Register

Access: This register can be read or written in 32-bit units.

Address: <PSI5Sj_base> + 0100_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28.48 PSI5SjPRCF10 Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
27 to 24	PFRMIDLE[3:0]	Packet frame idle Minimum packet frame gap (all channels) 0: The next packet frame is detected after 1 gap. 1: The next packet frame is detected after 2 gaps. ... n: The next packet frame is detected after n+1 gaps. ... 15: The next packet frame is detected after 16 gaps. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
23 to 21	F6PKT[2:0]	Frame 6 packet number (Ch0) 000_B: Frame 6 data is ignored 011_B: Packet number is set to 3 100_B: Packet number is set to 4 101_B: Packet number is set to 5 110_B: Packet number is set to 6 Other than above: Setting prohibited “Frame 6” is a packet frame whose FID is 101_B. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
20 to 18	F5PKT[2:0]	Frame 5 packet number (Ch0) 000_B: Frame 5 data is ignored 011_B: Packet number is set to 3 100_B: Packet number is set to 4 101_B: Packet number is set to 5 110_B: Packet number is set to 6 Other than above: Setting prohibited “Frame 5” is a packet frame whose FID is 100_B. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

Table 28.48 PSI5SjPRCF10 Register Contents (2/3)

Bit Position	Bit Name	Function
17 to 15	F4PKT[2:0]	Frame 4 packet number (Ch0) 000_B: Frame 4 data is ignored 011_B: Packet number is set to 3 100_B: Packet number is set to 4 101_B: Packet number is set to 5 110_B: Packet number is set to 6 Other than above: Setting prohibited “Frame 4” is a packet frame whose FID is 011_B. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
14 to 12	F3PKT[2:0]	Frame 3 packet number (Ch0) 000_B: Frame 3 data is ignored 011_B: Packet number is set to 3 100_B: Packet number is set to 4 101_B: Packet number is set to 5 110_B: Packet number is set to 6 Other than above: Setting prohibited “Frame 3” is a packet frame whose FID is 010_B. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
11 to 9	F2PKT[2:0]	Frame 2 packet number (Ch0) 000_B: Frame 2 data is ignored 011_B: Packet number is set to 3 100_B: Packet number is set to 4 101_B: Packet number is set to 5 110_B: Packet number is set to 6 Other than above: Setting prohibited “Frame 2” is a packet frame whose FID is 001_B. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared when writing 1 to PSI5SjPUSWR.SWRST.
8 to 6	F1PKT[2:0]	Frame 1 packet number (Ch0) 000_B: Frame 1 data is ignored 011_B: Packet number is set to 3 100_B: Packet number is set to 4 101_B: Packet number is set to 5 110_B: Packet number is set to 6 Other than above: Setting prohibited “Frame 1” is a packet frame whose FID is 000_B. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared when writing 1 to PSI5SjPUSWR.SWRST.
5 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.*1, *2
3	TSCS	Timestamp counter select (Ch0) 0: Select timestamp counter B 1: Select timestamp counter A This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
2	TSEN	Timestamp capture enable (Ch0) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
1	RFCPS	Rx frame checksum CRC/parity select (Ch0) 0: Parity select 1: CRC select This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.

Table 28.48 PSI5SjPRCF10 Register Contents (3/3)

Bit Position	Bit Name	Function
0	CHEN	Channel enable (Ch0) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.

Note 1. bit[5]: Channel 0 does not have SYSEL, because channel 0 does not have synchronous mode.

Note 2. bit[4]: Channel 0 does not have TSCTS (Timestamp capture trigger select), because channel 0 is always the header receive timing is selected.

28.3.5.2 PSI5SjPRCF20 — PSI5S Receive Config2 ch0 Register

Access: This register can be read or written in 32-bit units.

Address: <PSI5Sj_base> + 0104_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28.49 PSI5SjPRCF20 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29 to 25	F6PAYLD[4:0]	The payload bit length of packet frame 6 (Ch0) 8: Sets 8 … *x*: Sets *x* … 28: Sets 28 Other than above: Setting prohibited If the initial value (0) is set to these bits, it is handled as 8. These bits are used to determine the CRC/parity calculation scope. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
24 to 20	F5PAYLD[4:0]	The payload bit length of packet frame 5 (Ch0) 8: Sets 8 … *x*: Sets *x* … 28: Sets 28 Other than above: Setting prohibited If the initial value (0) is set to these bits, it is handled as 8. These bits are used to determine the CRC/parity calculation scope. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
19 to 15	F4PAYLD[4:0]	The payload bit length of packet frame 4 (Ch0) 8: Sets 8 … *x*: Sets *x* … 28: Sets 28 Other than above: Setting prohibited If the initial value (0) is set to these bits, it is handled as 8. These bits are used to determine the CRC/parity calculation scope. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

Table 28.49 PSI5SjPRCF20 Register Contents (2/2)

Bit Position	Bit Name	Function
14 to 10	F3PAYLD[4:0]	The payload bit length packet frame 3 (Ch0) 8: Sets 8 … *x*: Sets *x* … 28: Sets 28 Other than above: Setting prohibited If the initial value (0) is set to these bits, it is handled as 8. These bits are used to determine the CRC/parity calculation scope. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
9 to 5	F2PAYLD[4:0]	The payload bit length of packet frame 2 (Ch0) 8: Sets 8 … *x*: Sets *x* … 28: Sets 28 Other than above: Setting prohibited If the initial value (0) is set to these bits, it is handled as 8. These bits are used to determine the CRC/parity calculation scope. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
4 to 0	F1PAYLD[4:0]	The payload bit length of packet frame 1 (Ch0) 8: Sets 8 … *x*: Sets *x* … 28: Sets 28 Other than above: Setting prohibited If the initial value (0) is set to these bits, it is handled as 8. These bits are used to determine the CRC/parity calculation scope. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.5.3 PSI5SjPWDE0 — PSI5S WDT Enable ch0 Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0108_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28.53 PSI5SjPCIE0 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 15	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
14	IEBCTFN	Interrupt enable of command Tx finish (Ch0) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
13 to 12	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
11	IEBRFN	Interrupt enable of Rx packet frame finish flag (Ch0) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
10	IEBRFEX	Interrupt enable of Rx frame excess error (Ch0) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
9	IEBRFLK	Interrupt enable of Rx frame lack error (Ch0) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
8	IEBROV	Interrupt enable of Rx overrun error (Ch0) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.

Table 28.53 PSI5SjPCIE0 Register Contents (2/2)

Bit Position	Bit Name	Function
7	IEBRWDT	Interrupt enable Rx WDT error (Ch0) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	IEBUTFR	Interrupt enable of Rx UART framing error (Ch0) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
4	IEBUTPT	Interrupt enable of Rx UART parity error (Ch0) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
3	IEBTRST	Interrupt enable of Rx transceiver status error (Ch0) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
2	IEBPT	Interrupt enable of Rx payload data parity error (Ch0) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
1	IEBCRC	Interrupt enable of Rx payload data CRC error (Ch0) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
0	IEBXCRC	Interrupt enable of packet frame XCRC error (Ch0) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.5.7 PSI5SjPDRE0 — PSI5S DMA transfer Request Enable ch0 Register

Access: This register can be read or written in 32-bit units.

Address: <PSI5Sj_base> + $011C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DRQEWDT	DRQERFN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 28.54 PSI5SjPDRE0 Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	DRQEWDT	Enable of DMA request by the WDT error (Ch0) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
0	DRQERFN	Enable of DMA request by the channel data Rx finish (Ch0) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.6 Ch0 Register/Rx

28.3.6.1 PSI5SjPRES0 — PSI5S Receive Error Status ch0 Register

Access: This register is a read-only register that can be read in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0130_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—*1	—*1	—*1	—*1	RERRF2	RERRF1
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.55 PSI5SjPRES0 Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is returned.
1	RERRF2	Rx error at packet frame 2 (Ch0) 0: No error 1: An error has occurred This bit is set to 1 when any of “Rx overrun error”, “Rx WDT error”, “UART framing error”, “UART parity error”, “transceiver status error”, “payload data parity error”, “payload data CRC error” or “packet frame XCRC error” in packet frame2 of Ch0 has occurred. This bit is cleared when writing 1 to PSI5SjPRESC0.RERRCLF2. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
0	RERRF1	Rx error at packet frame 1 (Ch0) 0: No error 1: An error has occurred This bit is set to 1 when any of “Rx overrun error”, “transceiver status error”, “payload data parity error”, or “payload data CRC error” in packet frame1 of Ch0 has occurred. This bit is cleared when writing 1 to PSI5SjPRESC0.RERRCLF1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).

Note 1. Ch0 only has frame 1 and frame2. (Other channels have frame 1 to frame 6.)

28.3.6.2 PSI5SjPRESC0 — PSI5S Receive Error Status Clear ch0 Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0134_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—*1	—*1	—*1	—*1	RERRCLF2	RERRCLF1
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 28.56 PSI5SjPRESC0 Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	RERRCLF2	Rx error clear for packet frame 2 (Ch0) 0: Ignored 1: Clears PSI5SjPRES0.RERRF2 This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
0	RERRCLF1	Rx error clear for packet frame 1(Ch0) 0: Ignored 1: Clears PSI5SjPRES0.RERRF1 This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).

Note 1. Ch0 only has packet frame 1 and packet frame2. (Other channels have frame1 to frame 6.)

28.3.6.3 PSI5SjPTCDT0 — PSI5S Timestamp Capture Data ch0 Register

Access: This register is a read-only register that can be read in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + 0138_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	TSCD[23:16]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSCD[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.57 PSI5SjPTCDT0 Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned.
23 to 0	TSCD[23:0]	Timestamp capture data (Ch0) These bits are cleared by writing 1 to PSI5SjPTCDC0.TSCCLR. These bits are cleared by writing 0 to PSI5SjPRCF10.TSEN. These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

28.3.6.4 PSI5SjPTCDC0 — PSI5S Timestamp Capture Data Clear ch0 Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: <PSI5Sj_base> + $013C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSCCLR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 28.58 PSI5SjPTCDC0 Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	TSCCLR	Timestamp capture clear(Ch0) 0: Ignored 1: Clears timestamp capture This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).

28.3.7 Ch0 Register/Interrupt

28.3.7.1 PSI5SjPCIS0 — PSI5S CPU Interrupt Status ch0 Register

Access: This register is a read-only register that can be read in 32-bit or 16-bit units.

Address: <PSI5Sj_base> + 0150_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	ISTCTFN	—	—	ISTRFN	ISTRFEX	ISTRFLK	ISTROV	ISTRWDT	—	ISTUTFR	ISTUTPT	ISTTRST	ISTPT	ISTCRC	ISTXCRC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.59 PSI5SjPCIS0 Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 15	Reserved	When read, the value after reset is returned.
14	ISTCTFN	Interrupt status of command Tx finish 0: PSI5S command transmission has not finished 1: PSI5S command transmission has finished When the last command sent to the Tx shifter, a PSI5S frame is stored in a MB and the frame has no errors, this bit is set to 1 and an interrupt (int_psis_ch0) occurs. This bit is cleared by writing 1 to PSI5SjPCISC0.ISTCCTFN. When PSI5SjPCIS0.ISTCTFN is set and 1 is written to PSI5SjPCISC0.ISTCCTFN in the same clock cycle, PSI5SjPCIS0.ISTCTFN remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
13 to 12	Reserved	When read, the value after reset is returned.
11	ISTRFN	Interrupt status of Rx finish (Ch0) 0: PSI5S frame is not received successfully 1: PSI5S frame is received successfully When a PSI5S frame is stored in a MB and the PSI5S frame has no errors, this bit is set to 1 and an interrupt (int_psis_ch0) and DMA request (dma_psis_ch0_rx) occur. This bit is cleared by writing 1 to PSI5SjPCISC0.ISTCRFN. When PSI5SjPCIS0.ISTRFN is set and 1 is written to PSI5SjPCISC0.ISTCRFN in the same clock cycle, PSI5SjPCIS0.ISTRFN remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).

Table 28.59 PSI5SjPCIS0 Register Contents (2/3)

Bit Position	Bit Name	Function
10	ISTRFEX	Interrupt status Rx frame excess error (Ch0) 0: No error 1: Error detected When a packet over PSI5SjPRCF10.FmPKT(m = 1 to 6) is received, this bit is set to 1 and an interrupt (int_psis_ch0) occurs. This bit is cleared by writing 1 to PSI5SjPCISC0.ISTCRFEX. When PSI5SjPCIS0.ISTRFEX is set and 1 is written to PSI5SjPCISC0.ISCTRFEX in the same clock cycle, PSI5SjPCIS0.ISTRFEX remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
9	ISTRFLK	Interrupt status of Rx frame lack error (Ch0) 0: No error 1: Error detected When a packet frame gap is detected while the packet is under PSI5SjPRCF10.FmPKT (m=1 to 6), this bit is set to 1 and an interrupt (int_psis_ch0) occurs. This bit is cleared by writing 1 to PSI5SjPCISC0.ISTCRFLK. When PSI5SjPCIS0.ISTRFLK is set and 1 is written to PSI5SjPCISC0.ISTCRFLK in the same clock cycle, PSI5SjPCIS0.ISTRFLK remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
8	ISTROV	Interrupt status of Rx overrun error (Ch0) 0: No error 1: Error detected When an attempt is made to store the next PSI5S frame in a MB before the CPU has read that MB or set PSI5SjPRMBC.MBCLR, this bit is set to 1 and an interrupt (int_psis_ch0) occurs. This bit is cleared by writing 1 to PSI5SjPCISC0.ISTCROV. When PSI5SjPCIS0.ISTROV is set and 1 is written to PSI5SjPCISC0.ISTCROV in the same clock cycle, PSI5SjPCIS0.ISTROV remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
7	ISTRWDT	Interrupt status of Rx WDT error (Ch0) 0: No error 1: Error detected When a WDT error occurs in PSI5S mode, this bit is set to 1 and an interrupt (int_psis_ch0) and DMA request (dma_psis_ch0_rx) occur. This bit is cleared by writing 1 to PSI5SjPCISC0.ISTCRWDT. When PSI5SjPCIS0.ISTRWDT is set and 1 is written to PSI5SjPCISC0.ISTCRWDT in the same clock cycle, PSI5SjPCIS0.ISTRWDT remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
6	Reserved	When read, the value after reset is returned.
5	ISTUTFR	Interrupt status of Rx UART framing error (Ch0) 0: No error 1: Error detected If the stop bit of the UART frame is detected in PSI5S mode when the bit detection value is 0, this bit is set to 1 and an interrupt (int_psis_ch0) occurs. This bit is cleared by writing 1 to PSI5SjPCISC0.ISTCUTFR. When PSI5SjPCIS0.ISTUTFR is set and 1 is written to PSI5SjPCISC0.ISTCUTFR in the same clock cycle, PSI5SjPCIS0.ISTUTFR remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).

Table 28.59 PSI5SjPCIS0 Register Contents (3/3)

Bit Position	Bit Name	Function
4	ISTUTPT	Interrupt status of Rx UART parity error (Ch0) 0: No error 1: Error detected If the stop bit of the UART frame is detected in PSI5S mode when a UART parity error has occurred, this bit is set to 1 and an interrupt (int_psis_ch0) occurs. This bit is cleared by writing 1 to PSI5SjPCISC0.ISTCUTPT. When PSI5SjPCIS0.ISTUTPT is set and 1 is written to PSI5SjPCISC0.ISTCUTPT in the same clock cycle, PSI5SjPCIS0.ISTUTPT remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
3	ISTTRST	Interrupt status of Rx transceiver status error (Ch0) 0: No error 1: Error detected When a PSI5S frame is stored in a MB and a transceiver status error occurs, this bit is set to 1 and an interrupt (int_psis_ch0) occurs. This bit is cleared by writing 1 to PSI5SjPCISC0.ISTCTRST. When PSI5SjPCIS0.ISTTRST is set and 1 is written to PSI5SjPCISC0.ISTCTRST in the same clock cycle, PSI5SjPCIS0.ISTTRST remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
2	ISTPT	Interrupt status of payload data parity error (Ch0) 0: No error 1: Error detected When a PSI5S frame is stored in a MB and a payload data parity error occurs, this bit is set to 1 and an interrupt (int_psis_ch0) occurs. This bit is cleared by writing 1 to PSI5SjPCISC0.ISTCPT. When PSI5SjPCIS0.ISTPT is set and 1 is written to PSI5SjPCISC0.ISTCPT in the same clock cycle, PSI5SjPCIS0.ISTPT remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
1	ISTCRC	Interrupt status of payload data CRC error (Ch0) 0: No error 1: Error detected When a PSI5S frame is stored in a MB and a payload data CRC error occurs, this bit is set to 1 and an interrupt (int_psis_ch0) occurs. This bit is cleared by writing 1 to PSI5SjPCISC0.ISTCCRC. When PSI5SjPCIS0.ISTCRC is set and 1 is written to PSI5SjPCISC0.ISTCCRC in the same clock cycle, PSI5SjPCIS0.ISTCRC remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
0	ISTXCRC	Interrupt status of packet frame XCRC error (Ch0) 0: No error 1: Error detected When a PSI5S frame is stored in a MB and an XCRC error occurs, this bit is set to 1 and an interrupt (int_psis_ch0) occurs. This bit is cleared by writing 1 to PSI5SjPCISC0.ISTCXCRC. When PSI5SjPCIS0.ISTXCRC is set and 1 is written to PSI5SjPCISC0.ISTCXCRC in the same clock cycle, PSI5SjPCIS0.ISTXCRC remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).

28.3.7.2 PSI5SjPCISC0 — PSI5S CPU Interrupt Status Clear ch0 Register

Access: This register can be read or written in 32-bit or 16-bit units.

Address: <PSI5Sj_base> + 0154_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 28.60 PSI5SjPCISC0 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 15	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
14	ISTCCTFN	Interrupt status of command Tx finish (Ch0) 0: Ignored 1: Clears PSI5SjPCIS0.ISTCTFN This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
13 to 12	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
11	ISTCRFN	Interrupt status of Rx finish (Ch0) 0: Ignored 1: Clears PSI5SjPCIS0.ISTRFN This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
10	ISTCRFEX	Interrupt status of Rx frame excess error (Ch0) 0: Ignored 1: Clears PSI5SjPCIS0.ISTRFEX This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
9	ISTCRFLK	Interrupt status of Rx frame lack error (Ch0) 0: Ignored 1: Clears PSI5SjPCIS0.ISTRFLK This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
8	ISTCROV	Interrupt status of Rx overrun error (Ch0) 0: Ignored 1: Clears PSI5SjPCIS0.ISTROV This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).

Table 28.60 PSI5SjPCISC0 Register Contents (2/2)

Bit Position	Bit Name	Function
7	ISTCRWDT	Interrupt status of Rx WDT error (Ch0) 0: Ignored 1: Clears PSI5SjPCIS0.ISTRWDT This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	ISTCUTFR	Interrupt status of Rx UART framing error (Ch0) 0: Ignored 1: Clears PSI5SjPCIS0.ISTUTFR This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
4	ISTCUTPT	Interrupt status of Rx UART parity error (Ch0) 0: Ignored 1: Clears PSI5SjPCIS0.ISTUTPT This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
3	ISTCTRST	Interrupt status of Rx transceiver status error (Ch0) 0: Ignored 1: Clears PSI5SjPCIS0.ISTTRST This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
2	ISTCPT	Interrupt status of payload data parity error (Ch0) 0: Ignored 1: Clears PSI5SjPCIS0.ISTPT This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
1	ISTCCRC	Interrupt status of payload data CRC error (Ch0) 0: Ignored 1: Clears PSI5SjPCIS0.ISTCRC This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
0	ISTCXCRC	Interrupt status of packet frame XCRC error (Ch0) 0: Ignored 1: Clears PSI5SjPCIS0.ISTXCRC This bit is always read as 0. This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).

28.3.8 Ch *n* Register/Config (*n*: 1 to 7)

28.3.8.1 PSI5SjPRCF1n — PSI5S Receive Config1 chn Register (n: 1 to 7)

Access: This register can be read or written in 32-bit units.

Address: PSI5SjPRCF11: <PSI5Sj_base> + 0180_H

Table 28.61 PSI5SjPRCF1n Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 21	F6PKT[2:0]	Frame 6 packet number (Ch *n*) 000_B: Frame 6 data is ignored 011_B: Packet number is set to 3 100_B: Packet number is set to 4 101_B: Packet number is set to 5 110_B: Packet number is set to 6 Other than above: Setting prohibited The packet number means the number of UART frames number per packet frame. “Frame 6” is the packet frame whose FID is 101_B. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
20 to 18	F5PKT[2:0]	Frame 5 packet number (Ch *n*) 000_B: Frame 5 data is ignored 011_B: Packet number is set to 3 100_B: Packet number is set to 4 101_B: Packet number is set to 5 110_B: Packet number is set to 6 Other than above: Setting prohibited The packet number means the number of UART frames number per packet frame. “Frame 5” is the packet frame whose FID is 100_B. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

Table 28.61 PSI5SjPRCF1n Register Contents (2/3)

Bit Position	Bit Name	Function
17 to 15	F4PKT[2:0]	Frame 4 packet number (Ch *n*) 000_B: Frame 4 data is ignored 011_B: Packet number is set to 3 100_B: Packet number is set to 4 101_B: Packet number is set to 5 110_B: Packet number is set to 6 Other than above: Setting prohibited The packet number means the number of UART frames number per packet frame. "Frame 4" is the packet frame whose FID is 011_B. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
14 to 12	F3PKT[2:0]	Frame 3 packet number (Ch *n*) 000_B: Frame 3 data is ignored 011_B: Packet number is set to 3 100_B: Packet number is set to 4 101_B: Packet number is set to 5 110_B: Packet number is set to 6 Other than above: Setting prohibited The packet number means the number of UART frames number per packet frame. "Frame 3" is the packet frame whose FID is 010_B. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
11 to 9	F2PKT[2:0]	Frame 2 packet number (Ch *n*) 000_B: Frame 2 data is ignored 011_B: Packet number is set to 3 100_B: Packet number is set to 4 101_B: Packet number is set to 5 110_B: Packet number is set to 6 Other than above: Setting prohibited The packet number means the number of UART frames number per packet frame. "Frame 2" is the packet frame whose FID is 001_B. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
8 to 6	F1PKT[2:0]	Frame 1 packet number (Ch *n*) 000_B: Frame 1 data is ignored 011_B: Packet number is set to 3 100_B: Packet number is set to 4 101_B: Packet number is set to 5 110_B: Packet number is set to 6 Other than above: Setting prohibited The packet number means the number of UART frames number per packet frame. "Frame 1" is the packet frame whose FID is 000_B. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
5	SYSEL	Asynchronous mode/synchronous mode select 0: Synchronous mode 1: Asynchronous mode This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
4	TSCTS	Timestamp capture trigger select (Ch *n*) 0: Transmission synchronous pulse timing selected 1: Header receive timing selected (CH *n*) This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.

Table 28.61 PSI5SjPRCF1n Register Contents (3/3)

Bit Position	Bit Name	Function
3	TSCS	Timestamp counter select (Ch *n*) 0: Timestamp counter B selected 1: Timestamp counter A selected This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
2	TSEN	Timestamp capture enable (Ch *n*) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
1	RFCPS	Rx frame checksum CRC/parity select (Ch n) 0: Parity selected 1: CRC selected This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
0	CHEN	Channel enable (Ch *n*) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.

Table 28.62 PSI5SjPRCF2n Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29 to 25	F6PAYLD[4:0]	The payload bit length of packet frame 6 (Ch *n*) (Refer to **Figure 28.3** about payload) 0 to 7 : Setting prohibited 8 : Sets 8 … x : Sets x … 28 : Sets 28 29 to 31 : Setting prohibited If the initial value (0) is set to these bits, it is handled as 8. These bits are used to determine the CRC/parity calculation scope (*n*:1 to 7). These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
24 to 20	F5PAYLD[4:0]	The payload bit length of packet frame 5 (Ch *n*) (Refer to **Figure 28.3** about payload) 0 to 7 : Setting prohibited 8 : Sets 8 … x : Sets x … 28 : Sets 28 29 to 31 : Setting prohibited If the initial value (0) is set to these bits, it is handled as 8. These bits are used to determine about the CRC/parity calculation scope (*n*:1 to 7). These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

Table 28.62 PSI5SjPRCF2n Register Contents (2/2)

Bit Position	Bit Name	Function
19 to 15	F4PAYLD[4:0]	The payload bit length of packet frame 4 (Ch *n*) (Refer to **Figure 28.3** about payload) 0 to 7 : Setting prohibited 8 : Sets 8 … x : Sets x … 28 : Sets 28 29 to 31 : Setting prohibited If the initial value (0) is set to these bits, it is handled as 8. These bits are used to determine the CRC/parity calculation scope.(*n*:1 to 7) These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
14 to 10	F3PAYLD[4:0]	The payload bit length of packet frame 3 (Ch *n*) (Refer to **Figure 28.3** about payload) 0 to 7 : Setting prohibited 8 : Sets 8 … x : Sets x … 28 : Sets 28 29 to 31 : Setting prohibited If the initial value (0) is set to these bits, it is handled as 8. These bits are used to determine the CRC/parity calculation scope. (*n*:1 to 7) These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
9 to 5	F2PAYLD[4:0]	The payload bit length of packet frame 2 (Ch *n*) (Refer to **Figure 28.3** about payload) 0 to 7 : Setting prohibited 8 : Sets 8 … x : Sets x … 28 : Sets 28 29 to 31 : Setting prohibited If the initial value (0) is set to these bits, it is handled as 8. These bits are used to determine the CRC/parity calculation scope.(*n*:1 to 7) These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
4 to 0	F1PAYLD[4:0]	The payload bit length of packet frame 1 (Ch *n*) (Refer to **Figure 28.3** about payload) 0 to 7 : Setting prohibited 8 : Sets 8 … x : Sets x … 28 : Sets 28 29 to 31 : Setting prohibited If the initial value (0) is set to these bits, it is handled as 8. These bits are used to determine the CRC/parity calculation scope.(*n*:1 to 7) These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

Table 28.67 PSI5SjPCIEn Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 14	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
13	IEBDDSFN	Interrupt enable of DDSR finish flag (Ch *n*) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
12	IEBDDSOW	Interrupt enable of DDSR overwrite (Ch *n*) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
11	IEBRFN	Interrupt enable of Rx frame finish flag (Ch *n*) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
10	IEBRFEX	Interrupt enable of Rx frame excess error (Ch *n*) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
9	IEBRFLK	Interrupt enable of Rx frame lack error (Ch *n*) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.

Table 28.67 PSI5SjPCIEn Register Contents (2/2)

Bit Position	Bit Name	Function
8	IEBROV	Interrupt enable of Rx overrun error (Ch *n*) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
7	IEBRWDT	Interrupt enable of Rx frame WDT error (Ch *n*) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
6 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	IEBTRST	Interrupt enable of Rx transceiver status error (Ch *n*) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
2	IEBPT	Interrupt enable of parity error (Ch *n*) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
1	IEBCRC	Interrupt enable of CRC error (Ch *n*) 0: Disable 1: Enable This bit can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Note: n: 1 to 7

28.3.8.8 PSI5SjPDREn — PSI5S DMA Transfer Request Enable chn Register

Access: This register can be read or written in 32-bit units.

Address: PSI5SjPDRE1: <PSI5Sj_base> + $019C_H$
PSI5SjPDRE2: <PSI5Sj_base> + $021C_H$
PSI5SjPDRE3: <PSI5Sj_base> + $029C_H$
PSI5SjPDRE4: <PSI5Sj_base> + $031C_H$
PSI5SjPDRE5: <PSI5Sj_base> + $039C_H$
PSI5SjPDRE6: <PSI5Sj_base> + $041C_H$
PSI5SjPDRE7: <PSI5Sj_base> + $049C_H$

Value after reset: $0000\ 0000_H$

Table 28.72 PSI5SjPRESn Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 6	Reserved	When read, the value after reset is returned.
5	RERRF6	Rx error at packet frame 6 (Ch *n*) 0: No error 1: An error has occurred This bit is set to 1 when any of “Rx overrun error”, “transceiver status error”, “payload data parity error”, or “payload data CRC error” in packet frame6 of Ch *n* has occurred. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
4	RERRF5	Rx error at packet frame 5 (Ch *n*) 0: No error 1: An error has occurred This bit is set to 1 when any of “Rx overrun error”, “transceiver status error”, “payload data parity error”, or “payload data CRC error” in packet frame5 of Ch *n* has occurred. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
3	RERRF4	Rx error at packet frame 4 (Ch *n*) 0: No error 1: An error has occurred This bit is set to 1 when any of “Rx overrun error”, “transceiver status error”, “payload data parity error”, or “payload data CRC error” in packet frame4 of Ch *n* has occurred. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).

Table 28.72 PSI5SjPRESn Register Contents (2/2)

Bit Position	Bit Name	Function
2	RERRF3	Rx error at packet frame 3 (Ch *n*) 0: No error 1: An error has occurred This bit is set to 1 when any of “Rx overrun error”, “transceiver status error”, “payload data parity error”, or “payload data CRC error” in packet frame3 of Ch *n* has occurred. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
1	RERRF2	Rx error at packet frame 2 (Ch *n*) 0: No error 1: An error has occurred This bit is set to 1 when any of “Rx overrun error”, “transceiver status error”, “payload data parity error”, or “payload data CRC error” in packet frame2 of Ch *n* has occurred. This bit is cleared by when writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
0	RERRF1	Rx error at packet frame 1 (Ch *n*) 0: No error 1: An error has occurred This bit is set to 1 when any of “Rx overrun error”, “transceiver status error”, “payload data parity error”, or “payload data CRC error” in packet frame1 of Ch *n* has occurred. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).

Note: n: 1 to 7

28.3.9.2 PSI5SjPRESCn — PSI5S Receive Error Status Clear chn Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: PSI5SjPRESC1: <PSI5Sj_base> + $01B4_H$
PSI5SjPRESC2: <PSI5Sj_base> + 0234_H

Table 28.77 PSI5SjPDDDn Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 4	DDSRDT[19:0]	DDSR transmission data (Ch *n*) These bits cannot be written when PSI5SjPDDSn.DDSRSTS is 1. When PSI5SjPDDTPn.DDSRTYPE is 0, DDSR transmission data uses the 3 LSBs. PSI5SjPDDDn.DDSRDT [19:3] should be set to all 1's. When PSI5SjPDDTPn.DDSRTYPE is 1, DDSR transmission data uses the 13 LSBs. PSI5SjPDDDn.DDSRDT [19:13] should be set to all 1's. When PSI5SjPDDTPn.DDSRTYPE is 2, DDSR transmission data uses the 19 LSBs. PSI5SjPDDDn.DDSRDT [19] should be set to all 1's. When PSI5SjPDDTPn.DDSRTYPE is 3, DDSR transmission data uses 20 bits. These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
3 to 0	DDSRADR[3:0]	DDSR transmission address (Ch *n*) These bits cannot be written when PSI5SjPDDSn.DDSRSTS is 1.(n: 1 to 7) These bits can be written when PSI5SjPUOS.ACSTS is 0 (= configuration mode) or when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode). These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

Note: n: 1 to 7

28.3.10.3 PSI5SjPDDSn — PSI5S DDSR Status Chn Register

Access: This register can be read-only in 32-bit, 16-bit or 8-bit units.

Address: PSI5SjPDDS1: <PSI5Sj_base> + $01C8_H$
PSI5SjPDDS2: <PSI5Sj_base> + 0248_H
PSI5SjPDDS3: <PSI5Sj_base> + $02C8_H$
PSI5SjPDDS4: <PSI5Sj_base> + 0348_H
PSI5SjPDDS5: <PSI5Sj_base> + $03C8_H$
PSI5SjPDDS6: <PSI5Sj_base> + 0448_H
PSI5SjPDDS7: <PSI5Sj_base> + $04C8_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 28.78 PSI5SjPDDSn Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned.
0	DDSRSTS	DDSR status 0: DDSR transmission is not in progress 1: DDSR transmission is in progress In PSI5S mode, writing to PSI5SjPDDDn sets this bit to 1. When the last data of PSI5SjPDDDn is written to the Tx shifter, this bit becomes 0. PSI5SjPDDDn is cannot written when PSI5SjPDDSn.DDSRSTS is 1. This bit is cleared by writing 1 to PSI5SjPDDSPn.DDSRSTP. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).

Note: n: 1 to 7

28.3.10.4 PSI5SjPDDSPn — PSI5S DDSR Stop chn Register

Access: This register can be read or written in 32-bit, 16-bit or 8-bit units.

Address: PSI5SjPDDSP1: <PSI5Sj_base> + $01CC_H$
PSI5SjPDDSP2: <PSI5Sj_base> + $024C_H$
PSI5SjPDDSP3: <PSI5Sj_base> + $02CC_H$
PSI5SjPDDSP4: <PSI5Sj_base> + $034C_H$
PSI5SjPDDSP5: <PSI5Sj_base> + $03CC_H$
PSI5SjPDDSP6: <PSI5Sj_base> + $044C_H$
PSI5SjPDDSP7: <PSI5Sj_base> + $04CC_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 28.80 PSI5SjPCISn Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 14	Reserved	When read, the value after reset is returned.
13	ISTDDSFN	CPU interrupt status of DDSR finish (Ch *n*) 0: DDSR transmission has not finished 1: DDSR transmission has finished When PSI5SjPDDDn data is written to the Tx shifter, this bit is set to 1 and an interrupt (int_psis_chn) and DMA request (dma_psis_chn_tx) occur. (n = 1 to 7) This bit is cleared by writing 1 to PSI5SjPCISCn.ISTCDDSFN. When PSI5SjPCISn.ISTDDSFN is set and 1 is written to PSI5SjPCISCn.ISTCDDSFN in the same clock cycle, PSI5SjPCISn.ISTDDSFN remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
12	ISTDDSOW	CPU interrupt status of DDSR overwrite error (Ch *n*) 0: No error 1: Error detected When the CPU writes 1 to PSI5SjPDDD*n* in PSI5SjPDDS*n*.DDSRSTS, this bit is set to 1 and an interrupt (int_psis_ch*n*) occurs.(*n*: 1 to 7) This bit is cleared by writing 1 to PSI5SjPCISC*n*.ISTCDDSOW. When PSI5SjPCIS*n*.ISTDDSOW is set and 1 is written to PSI5SjPCISC*n*.ISTCDDSOW in the same clock cycle, PSI5SjPCIS*n*.ISTDDSOW remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).

Table 28.80 PSI5SjPCISn Register Contents (2/3)

Bit Position	Bit Name	Function
11	ISTRFN	Interrupt status of Rx finish (Ch *n*) 0: PSI5S frame is not received successfully 1: PSI5S frame is received successfully When a PSI5S frame is stored in a MB and the PSI5S frame has no errors (no mailbox overrun error), this bit is set to 1 and an interrupt (int_psis_chn) and DMA request (dma_psis_chn_rx) occur. (n: 1 to 7) This bit is cleared by writing 1 to PSI5SjPCISCn.ISTCRFN. When PSI5SjPCISn.ISTRFN is set and 1 is written to PSI5SjPCISCn.ISTCRFN in the same clock cycle, PSI5SjPCISn.ISTRFN remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
10	ISTRFEX	Interrupt status of Rx frame excess error (Ch0) 0: No error 1: Error detected When a packet over PSI5SjPRCF1n.FmPKT (m = 1 to 6) is received, this bit is set to 1 and an interrupt (int_psis_chn) occurs. This bit is cleared by writing 1 to PSI5SjPCISCn.ISTCRFEX. When PSI5SjPCISn.ISTRFEX is set and 1 is written to PSI5SjPCISCn.ISTCRFEX in the same clock cycle, PSI5SjPCISn.ISTRFEX remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
9	ISTRFLK	Interrupt status of Rx frame lack error (Ch0) 0: No error 1: Error detected When a packet frame gap is detected while the packet is under PSI5SjPRCF1n.FmPKT (m = 1 to 6), this bit is set to 1 and an interrupt (int_psis_chn) occurs. (n: 1 to 7) This bit is cleared by writing 1 to PSI5SjPCISCn.ISTCRFLK. When PSI5SjPCISn.ISTRFLK is set and 1 is written to PSI5SjPCISCn.ISTCRFLK in the same clock cycle, PSI5SjPCISn.ISTRFLK remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
8	ISTROV	Interrupt status of Rx overrun error (Ch *n*) 0: No error 1: Error detected When an attempt is made to store the next PSI5S frame in a MB before the CPU has read that MB, this bit is set to 1 and an interrupt (int_psis_ch*n*) occurs. (n: 1 to 7) This bit is cleared by writing 1 to PSI5SjPCISCn.ISTCROV. When PSI5SjPCISn.ISTROV is set and 1 is written to PSI5SjPCISCn.ISTCROV in the same clock cycle, PSI5SjPCISn.ISTROV remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
7	ISTRWDT	Interrupt status of Rx WDT error (Ch *n*) 0: No error 1: Error detected When an WDT error occurs in PSI5S mode, this bit is set to 1 and an interrupt (int_psis_chn) and DMA request (dma_psis_chn_rx) occur. (n: 1 to 7) This bit is cleared by writing 1 to PSI5SjPCISCn.ISTCRWDT. When PSI5SjPCISn.ISTRWDT is set and 1 is written to PSI5SjPCISCn.ISTCRWDT in the same clock cycle, PSI5SjPCISn.ISTRWDT remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
6 to 4	Reserved	When read, the value after reset is returned.

Table 28.80 PSI5SjPCISn Register Contents (3/3)

Bit Position	Bit Name	Function
3	ISTTRST	Interrupt status of Rx transceiver status error (Ch *n*) 0: No error 1: Error detected When a PSI5S frame is stored in a MB and a transceiver status error occurs, this bit is set to 1 and an interrupt (int_psis_chn) occurs. (n: 1 to 7) This bit is cleared by writing 1 to PSI5SjPCISCn.ISTCTRST. When PSI5SjPCISn.ISTTRST is set and 1 is written to PSI5SjPCISCn.ISTCTRST in the same clock cycle, PSI5SjPCISn.ISTTRST remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
2	ISTPT	Interrupt status of payload data parity error (Ch *n*) 0: No error 1: Error detected When a PSI5S frame is stored in a MB and a payload data parity error occurs, this bit is set to 1 and an interrupt (int_psis_chn) occurs. (n: 1 to 7) This bit is cleared by writing 1 to PSI5SjPCISCn.ISTCPT. When PSI5SjPCISn.ISTPT is set and 1 is written to PSI5SjPCISCn.ISTCPT in the same clock cycle, PSI5SjPCISn.ISTPT remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
1	ISTCRC	Interrupt status of payload data CRC error (Ch *n*) 0: No error 1: Error detected When a PSI5S frame is stored in a MB and a payload data CRC error occurs, this bit is set to 1 and an interrupt (int_psis_chn) occurs. (n: 1 to 7) This bit is cleared by writing 1 to PSI5SjPCISCn.ISTCCRC. When PSI5SjPCISn.ISTCRC is set and 1 is written to PSI5SjPCISCn.ISTCCRC in the same clock cycle, PSI5SjPCISn.ISTCRC remains 1. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. This bit is cleared when PSI5SjPUOS.ACSTS is changed to 0 (= configuration mode).
0	Reserved	When read, the value after reset is returned*1.

Note: n: 1 to 7

Note 1. b[5][4][0]: These bits are not reserved in Ch0. If these errors (UART framing error, UART parity error, XCRC Error) occur, the error is stored in channel 0, frame 2".

28.3.11.2 PSI5SjPCISCn — PSI5S CPU Interrupt Status Clear chn Register

Access: This register can be read or written in 32-bit or 16-bit units.

Address: PSI5SjPCISC1: <PSI5Sj_base> + $01D4_H$
PSI5SjPCISC2: <PSI5Sj_base> + 0254_H
PSI5SjPCISC3: <PSI5Sj_base> + $02D4_H$

Table 28.81 PSI5SjPCISCn Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 14	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
13	ISTCDDSFN	Interrupt status clear DDSR Tx finish (Ch*n*) 0: Ignored 1: Clear PSI5SjPCIS*n*.ISTDDSFN This bit defines about clearance of CPU interrupt status of DDSR finish (Ch *n*) in PSI5S mode (PSI5SjPCIS*n*.ISTDDSFN). When this bit is written to 1, PSI5SjPCIS0.ISTDDSFN is cleared to 0. This bit is always read as 0. (n: 1 to 7) This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
12	ISTCDDSOW	Interrupt status clear DDSr overwrite error Clear at CPU interrupt status of DDSR overwrite error (Ch*n*) 0: Ignored 1: Clear PSI5SjPCIS*n*.ISTDDSOW This bit defines about clearance of CPU interrupt status of DDSR overwrite (Ch *n*) in PSI5S mode (PSI5SjPCIS*n*.ISTDDSOW). When this bit is written to 1, PSI5SjPCIS0.ISTDDSOW is cleared to 0. This bit is always read as 0. (n: 1 to 7) This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
11	ISTCRFN	Interrupt status clear Rx finish Clear at CPU interrupt status of Rx finish (Ch*n*) 0: Ignored 1: Clear PSI5SjPCIS*n*.ISTRFN This bit defines about clearance of CPU interrupt status of Rx finish (Ch *n*) in PSI5S mode (PSI5SjPCIS*n*.ISTRFN). When this bit is written to 1, PSI5SjPCISn.ISTRFN is cleared to 0. This bit is always read as 0. (n: 1 to 7) This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).

Table 28.81 PSI5SjPCISCn Register Contents (2/3)

Bit Position	Bit Name	Function
10	ISTCRFEX	Interrupt status clear Rx frame excess error Clear at CPU interrupt status of Rx frame excess error (Ch*n*) 0: Ignored 1: Clear PSI5SjPCIS*n*.ISTRFEX This bit defines about clearance of CPU interrupt status of Rx frame (=packet) (Ch *n*) excess error in PSI5S mode (PSI5SjPCIS*n*.ISTRFEX). When this bit is written to 1, PSI5SjPCIS*n*.ISTRFEX is cleared to 0. This bit is always read as 0. (n: 1 to 7) This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
9	ISTCRFLK	Interrupt status clear Rx frame lack error Clear at CPU interrupt status of Rx frame lack error (Ch*n*) 0: Ignored 1: Clear PSI5SjPCIS*n*.ISTRFLK This bit defines about clearance of CPU interrupt status of Rx frame (packet) (Ch *n*) lack error (Ch*n*) in PSI5S mode (PSI5SjPCIS*n*.ISTRFLK). When this bit is written to 1, PSI5SjPCISn.ISTRFLK is cleared to 0. This bit is always read as 0. (n: 1 to 7) This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
8	ISTCROV	Interrupt status clear Rx overrun error Clears at CPU interrupt status of Rx overrun error (Ch*n*) 0: Ignored 1: Clear PSI5SjPCIS*n*.ISTROV This bit defines about clearance of CPU interrupt status of overrun error (Ch *n*) in PSI5S mode (PSI5SjPCIS*n*.ISTROV). When this bit is written to 1, PSI5SjPCISn.ISTROV is cleared to 0. This bit is always read as 0. (n: 1 to 7) This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
7	ISTCRWDT	Interrupt status clear Rx WDT error Clear at CPU interrupt status of Rx WDT error (Ch*n*) 0: Ignored 1: Clear PSI5SjPCIS*n*.ISTRWDT This bit defines about clearance of CPU interrupt status of WDT error (Ch*n*) in PSI5S mode (PSI5SjPCIS*n*.ISTRWDT). When this bit is written to 1, PSI5SjPCISn.ISTRWDT is cleared to 0. This bit is always read as 0. (n: 1 to 7) This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
6 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	ISTCTRST	Interrupt status clear transceiver status error Clear at CPU interrupt status of Rx transceiver status error (Ch*n*) 0: Ignored 1: Clear PSI5SjPCIS*n*.ISTTRST This bit defines about clearance of CPU interrupt status of transceiver status error (Ch *n*) in PSI5S mode (PSI5SjPCIS*n*.ISTTRST). When this bit is written to 1, PSI5SjPCISn.ISTTRST is cleared to 0. This bit is always read as 0. (n: 1 to 7) This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).

Table 28.81 PSI5SjPCISCn Register Contents (3/3)

Bit Position	Bit Name	Function
2	ISTCPT	Interrupt status clear parity error Clear at CPU interrupt status of payload data parity error (Ch*n*) 0: Ignored 1: Clear PSI5SjPCIS*n*.ISTPT This bit defines about clearance of CPU interrupt status of payload data parity error (Ch *n*) in PSI5S mode (PSI5SjPCIS*n*.ISTPT). When this bit is written to 1, PSI5SjPCISn.ISTPT is cleared to 0. This bit is always read as 0. (n: 1 to 7) This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
1	ISTCCRC	Interrupt status clear CRC error Clear at CPU interrupt status of payload data CRC error (Ch*n*) 0: Ignored 1: Clear PSI5SjPCIS*n*.ISTCRC This bit defines about clearance of CPU interrupt status of payload data CRC error (Ch *n*) in PSI5S mode (PSI5SjPCIS*n*.ISTCRC). When this bit is written to 1, PSI5SjPCISn.ISTCRC is cleared to 0. This bit is always read as 0. (n: 1 to 7) This bit can be written when PSI5SjPUOS.ACSTS is 1 and PSI5SjPUOS.MSTS is 1 (= PSI5S mode).
0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Note: n: 1 to 7

28.3.12 Ch 0 Frm m MB Data (m: 1, 2)

28.3.12.1 PSI5SjPMB0mS — PSI5S Receive MailBox ch0 Frmm Status Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: PSI5SjPMB01S: <PSI5Sj_base> + 0500_H
PSI5SjPMB02S: <PSI5Sj_base> + $050C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DCI[3:0]				—	—	—	CHID[2:0]			FID[2:0]			MBORERR	WDTERR	—

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.82 PSI5SjPMB0mS Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 28	DCI[3:0]	DCI value (Ch0, Frm *m*) The DCI value is generated by a 4-bit counter, and every time the PSI5 frame data is restored, it is incremented by 1. These bits are read only. The write value is ignored. (m: 1, 2) These bits are cleared by writing 1 to PSI5SjPRMBC.MBCLR. These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
27 to 25	Reserved	When read, the value after reset is returned.
24 to 22	CHID[2:0]	Rx channel ID (Ch0, Frm *m*) These bits are cleared by writing 1 to PSI5SjPRMBC.MBCLR. These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
21 to 19	FID[2:0]	Rx frame ID (Ch0, Frm *m*) These bits are cleared by writing 1 to PSI5SjPRMBC.MBCLR. These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
18	MBORERR	MailBox overrun error (Ch0, Frm *m*) 0: No error 1: Error detected This bit is cleared by writing 1 to PSI5SjPRMBC.MBCLR. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
17	WDTERR	Rx frame WDT error (Ch0, Frm *m*) 0: No error 1: Error detected This bit is cleared by writing 1 to PSI5SjPRMBC.MBCLR. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
16	Reserved	When read, the value after reset is returned.
15	UTFRERR	UART framing error (Ch0, Frm2)*1 0: No error 1: Error detected This bit is cleared by writing 1 to PSI5SjPRMBC.MBCLR. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. When this error occurs, data is stored in channel 0, frame 2. So, this error exists only in channel 0, frame 2. *1 This bit is only in 50CH (Frm2)

Table 28.82 PSI5SjPMB0mS Register Contents (2/2)

Bit Position	Bit Name	Function
14	UTPTERR	UART parity error (Ch0, Frm2) *1 0: No error 1: Error detected This bit is cleared by writing 1 to PSI5SjPRMBC.MBCLR. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. When this error occurs, data is stored in channel 0, frame 2. So, this error exists only in channel 0, frame 2. *1 This bit is only in $50C_H$ (Frm2)
13	HEADERR	Header error (Ch0, Frm *m*) 0: No error 1: Error detected This bit is cleared by writing 1 to PSI5SjPRMBC.MBCLR. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
12 to 11	HEADST[1:0]	Header status These bits are cleared by writing 1 to PSI5SjPRMBC.MBCLR. These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
10	CRCERR	Rx CRC/Parity error (Ch0, Frm *m*) 0: No error 1: Error detected When PSI5SjPRCF10.RFCPS is 1, this bit shows a CRC error. When PSI5SjPRCF10.RFCPS is 0, this bit shows a parity error. This bit is cleared by writing 1 to PSI5SjPRMBC.MBCLR. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
9 to 7	CRC[2:0]	Rx frame CRC/Parity (Ch0, Frm *m*)*2 When PSI5SjPRCF10.RFCPS is 1, these bits show the CRC (3 bits). When PSI5SjPRCF10.RFCPS is 0, bit [9] shows the parity, and bits [8:7] are reserved. These bits are cleared by writing 1 to PSI5SjPRMBC.MBCLR. These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
6	XCRCERR	Rx XCRC error (Ch0, Frm2) *1 0: No error 1: Error detected This bit is cleared by writing 1 to PSI5SjPRMBC.MBCLR. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST. When this error occurs, data is stored in channel 0, frame 2. So, this error exists only in channel 0, frame 2. *1 This bit is only in 50CH (Frm2)
5 to 0	XCRC[5:0]	Rx frame XCRC (Ch0, Frm *m*) These bits are cleared by writing 1 to PSI5SjPRMBC.MBCLR. These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

Note: m: 1, 2
Frm, frame: packet frame

Note 1. Bits [17], [15], [14] and [6] are used only in $50C_H$ (Frm2)

Note 2. When PSI5SjPRCF10.RFCPS is 1, bits [9:7] are the CRC, and when PSI5SjPRCF10.RFCPS is 0, bit [9] is the parity, bits [8:7] are reserved.

28.3.12.2 PSI5SjPMB0mD — PSI5S Receive MailBox ch0 Frmm Data Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: PSI5SjPMB01D: <PSI5Sj_base> + 0504_H
PSI5SjPMB02D: <PSI5Sj_base> + 0510_H

Table 28.85 PSI5SjPMBnmS Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 28	DCI[3:0]	DCI value (Ch*n*, Frm *m*) The DCI value is generated by a 4-bit counter, and every time the PSI5 frame data is restored, the count is incremented by 1. These bits are cleared by writing 1 to PSI5SjPRMBC.MBCLR. These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
27 to 25	Reserved	When read, the value after reset is returned.
24 to 22	CHID[2:0]	Rx channel ID (Ch*n*, Frm *m*) These bits are cleared by writing 1 to PSI5SjPRMBC.MBCLR. These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
21 to 19	FID[2:0]	Rx frame ID (Ch*n*, Frm *m*) These bits are cleared by writing 1 to PSI5SjPRMBC.MBCLR. These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
18	MBORERR	Mailbox overrun error (Ch*n*, Frm *m*) 0: No error 1: Error detected This bit is cleared by writing 1 to PSI5SjPRMBC.MBCLR. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
17 to 14	Reserved	When read, the value after reset is returned.
13	HEADERR	Header error (Ch*n*, Frm *m*) 0: No error 1: Error detected This bit is cleared by writing 1 to PSI5SjPRMBC.MBCLR. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.
12 to 11	HEADST[1:0]	Header status (Ch*n*, Frm *m*) These bits are cleared by writing 1 to PSI5SjPRMBC.MBCLR. These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
10	CRCERR	Rx CRC/Parity error (Ch*n*, Frm *m*) 0: No error 1: Error detected When PSI5SjPRCF1*m*.RFCPS is 1, this bit shows a CRC error. And when PSI5SjPRCF1*m*.RFCPS is 0, this bit shows a parity error. This bit is cleared by writing 1 to PSI5SjPRMBC.MBCLR. This bit is cleared by writing 1 to PSI5SjPUSWR.SWRST.

Table 28.85 PSI5SjPMBnmS Register Contents (2/2)

Bit Position	Bit Name	Function
9 to 7	CRC[2:0]	Rx frame CRC/Parity (Ch*n*, Frm *m*) *1 These bits show the Rx frame CRC/Parity. (Ch*n*, Frm *m*) When PSI5SjPRCF1*m*.RFCPS is 1, these bits show the CRC (3 bits). When PSI5SjPRCF1*m*.RFCPS is 0, bit [9] shows the parity, and bits [8:7] are reserved. These bits are cleared by writing 1 to PSI5SjPRMBC.MBCLR. These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.
6	Reserved	When read, the value after reset is returned.
5 to 0	XCRC[5:0]	Rx frame XCRC (Ch*n*, Frm *m*) These bits are cleared by writing 1 to PSI5SjPRMBC.MBCLR. These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

Note: n: 1 to 7
m: 1 to 6
Frm, frame: packet frame
Bits [15],[14] and [6]: These bits are not reserved in channel 0. When these errors (UART framing error, UART parity error, XCRC Error) occur, the error is stored in channel 0, frame 2.

Note 1. When PSI5SjPRCF1n.RFCPS is 1 bits [9:7] are the CRC, and when PSI5SjPRCF1n.RFCPS is 0 bit [9] is the parity, and bits [8:7] are reserved.

28.3.13.2 PSI5SjPMBnmD — PSI5S Receive MailBox ch0 Frmm Data Register

Access: This register is a read-only register that can be read in 32-bit units.

23 to 0	TMST[23:0]	Timestamp data (Ch*n*, Frm *m*) These bits are cleared by writing 1 to PSI5SjPRMBC.MBCLR. These bits are cleared by writing 1 to PSI5SjPUSWR.SWRST.

Note: n: 1 to 7
m: 1 to 6
Frm, frame: packet frame

28.4 Operation Modes

PSI5S has three operation modes: Configuration, PSI5S, and UART modes.

The operation mode state machine controls the transition of PSI5S between these operation modes.

Figure 28.5 shows the state transitions controlled by the operation mode state machine.

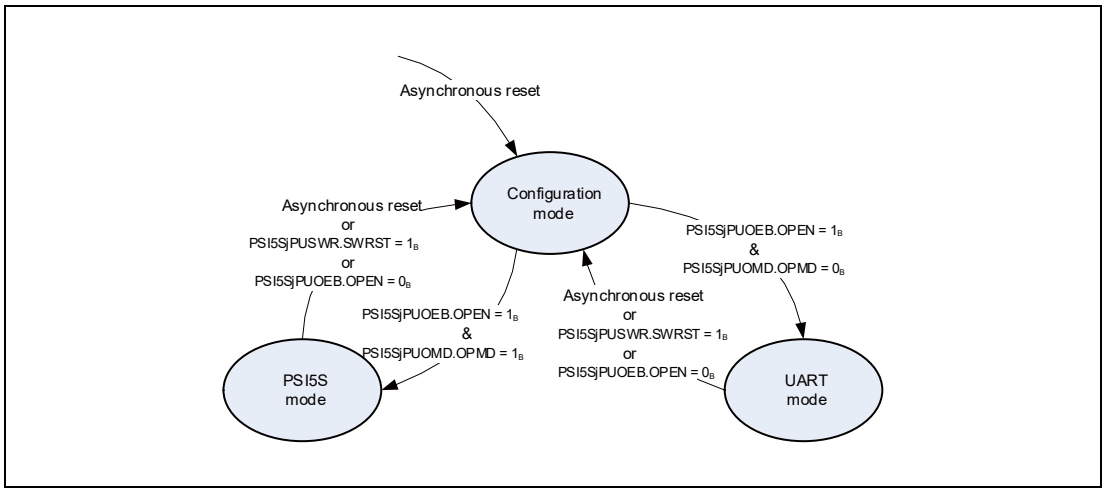

Figure 28.5 State Transitions by Operation Mode State Machine

Table 28.88 below describes the individual states:

Table 28.88 Operation Modes (States)

No	Operation Mode	Explanation
1	Configuration mode	Configuration operation mode • Setting SFR of PSI5S.
2	PSI5S mode	PSI5S operation mode • Communication of a PSI-5 frame is performed.
3	UART mode	UART operation mode • Communication of UART packet frame.

When the PSI5S is not transmitting after 16 PCLK cycles of setting of returning to the configuration mode from PSI5S mode or UART mode, the PSI5S returns to the configuration mode.

When the PSI5S is transmitting after 16 PCLK cycles of setting of returning to the configuration mode, the PSI5S returns to the configuration mode in the following timing:

In UART mode: The PSI5S ends transmission operation of the 2 UART frames at the maximum.

In PSI5S mode: The PSI5S ends transmission operation of the 9 UART frames at the maximum.

NOTE

Even during reception, the PSI5S stops reception operation and returns to the reception standby state.

Interrupt and DMA request when the PSI5S return to the configuration mode is following:

Interrupt: PSI5S does not generate interrupts after 14 or more PCLK cycles of returning to the configuration mode. Note that, because interrupt status flags are cleared when the PSI5S module returns to the configuration mode, interrupt status cannot be read if the PSI5S module returns to the configuration mode after it has issued an interrupt.

DMA request: PSI5S module does not issue DMA requests after 14 or more PCLK cycles of returning to the configuration mode.

28.5 Setting Procedures

Figure 28.6 shows the setting procedure to use PSI5S in PSI5S mode.

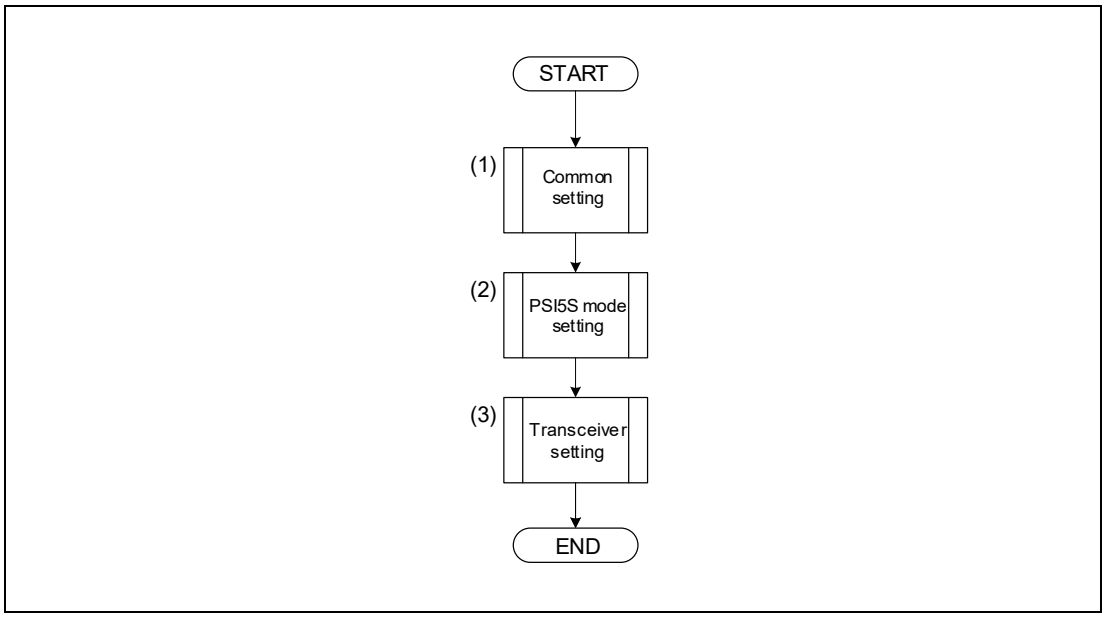

Figure 28.6 PSI5S mode Setting Procedure

(1) Specify the common settings. For details, see **Section 28.5.1, Common Setting Procedure**.

(2) Set up PSI5S mode. For details, see **Section 28.5.2, PSI5S mode Setting Procedure**.

(3) Set up the transceiver. For details, see **Section 28.5.4, Procedure for Transmitting Transceiver Commands**.

Figure 28.7 shows the setting procedure to use the PSI5S in UART mode.

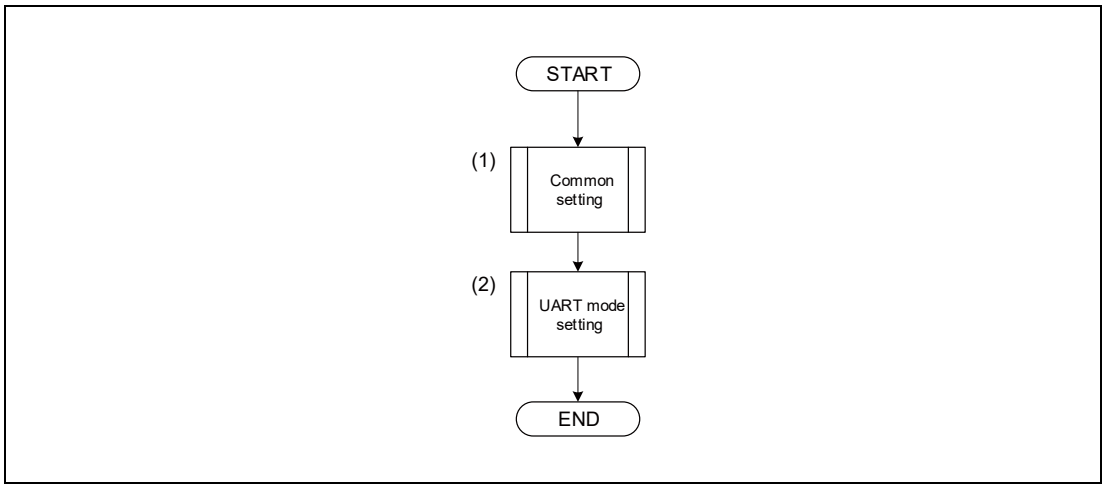

Figure 28.7 UART Mode Setting Procedure

(1) Specify the common settings. For details, see **Section 28.5.1, Common Setting Procedure**.

(2) Set up the UART mode. For details, see **Section 28.5.3, UART Mode Setting Procedure**.

28.5.1 Common Setting Procedure

This section describes the common setting procedure to use the PSI5S in PSI5S or UART mode.

Perform the procedure shown in **Figure 28.8** below when the PSI5S is in configuration mode.

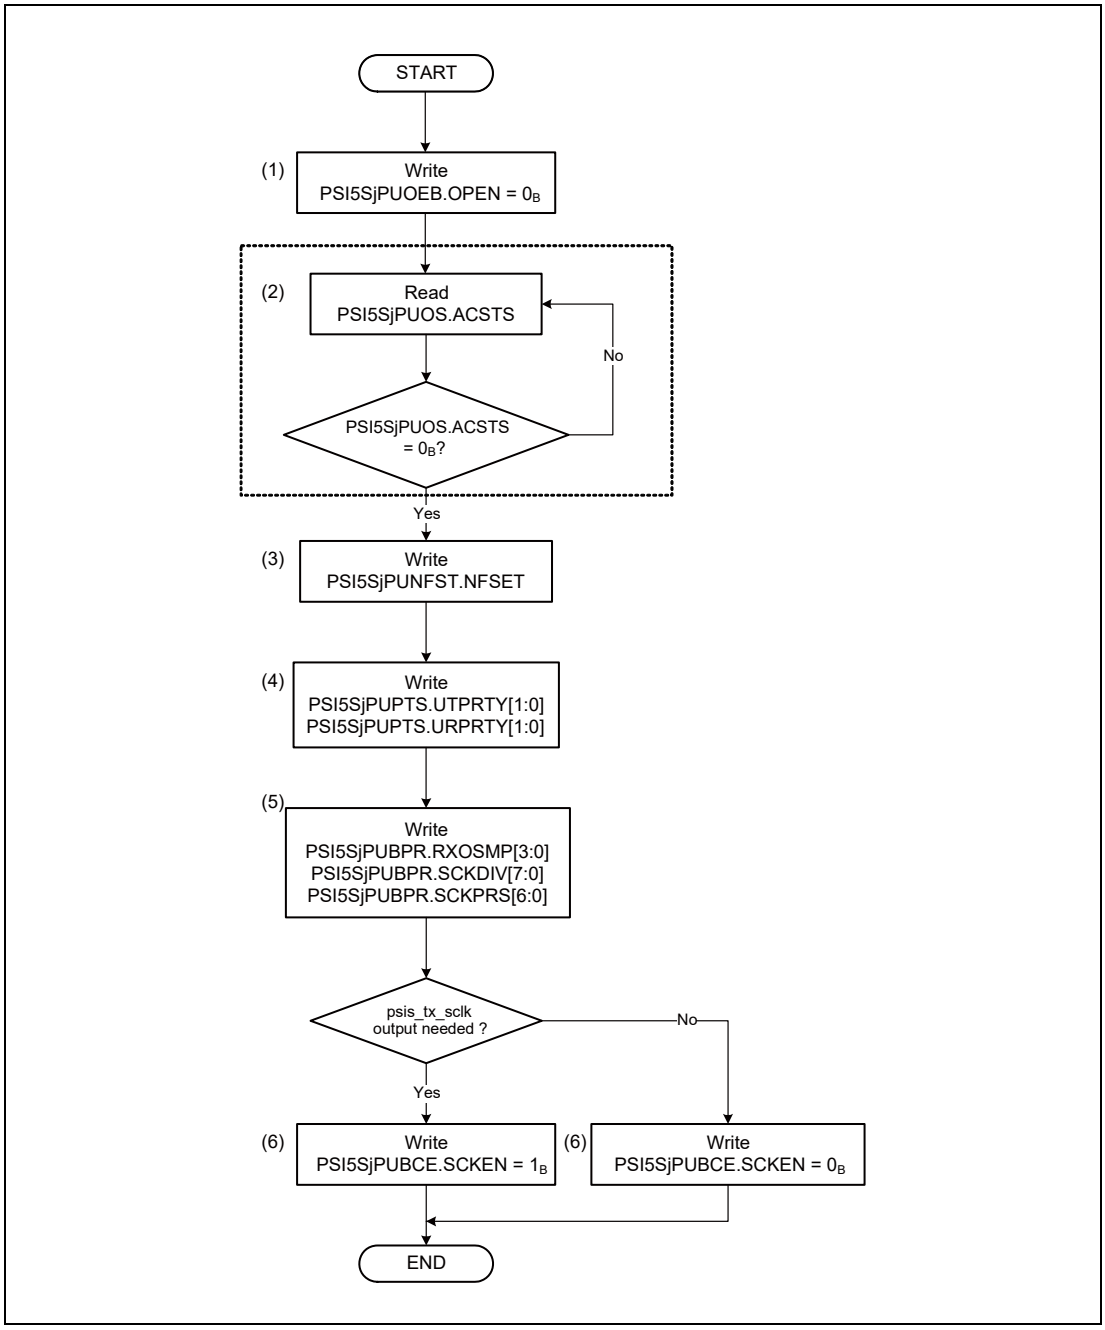

Figure 28.8 Common Setting Procedure

(1) PSI5SjPUOEB: PSI5S/UART Operation Enable register
Change the operation mode to configuration mode.

(2) PSI5SjPUOS: PSI5S /UART Operation Status register
Wait until PSI5S transitions to the configuration mode.

(3) PSI5SjPUNFST: PSI5S/UART Noise Filter Set register
Specify whether to use a noise filter for the signal input to the psis_rx_data pin, which is a UART Rx pin.

(4) PSI5SjPUPTS: PSI5S/UART rx/tx Parity Set register
Specify the parity bit settings for both UART reception and UART transmission.

(5) PSI5SjPUBPR: PSI5S/UART Baud rate Parameter register
Specify the baud rate for UART communication. The baud rate is determined by the oversample number, clock division ratio, and division ratio of the prescaler.
The clock division ratio and the division ratio of the prescaler are also used to set the frequency of the sampling clock (psis_tx_sclk).

Calculate the baud rate of UART communication using the following formula:

Baud rate = [psis_clk frequency] * (1/prescaler division ratio) * (1/clock division ratio) * (1/oversample number)

Example: Prescaler division ratio = 1 (PCKPRS setting = 0)

Clock division ratio = 3 (SCKDIV setting = 2)

Oversample number = 5 (RXOSMP setting = 4)

The calculation result is as follows:

Baud rate = 80MHz * (1/1) * (1/3) * (1/5) = 5.33 Mbps

Calculate the frequency of the sampling clock using the following formula:

psis_tx_sclk = [psis_mult_clk frequency] * (1/2) * (1/prescaler division ratio) * (1/clock division ratio)

Example: Prescaler division ratio = 1 (PCKPRS setting = 0)

Clock division ratio = 3 (SCKDIV setting = 2)

The calculation result is as follows:

psis_tx_sclk = 160MHz * (1/2) * (1/1) * (1/3) = 26.67 MHz

If the output of the psis_tx_sclk signal is required, specify the following setting:

(6) PSI5SjPUBCE: PSI5S/UART Baud rate Clock Enable register
Specify whether to enable the output of psis_tx_sclk clock.

28.5.2 PSI5S mode Setting Procedure

This section describes the setting procedure to use PSI5S in PSI5S mode.

Perform the procedure shown in **Figure 28.9** below after performing the procedure described in **Section 28.5.1, Common Setting Procedure**.

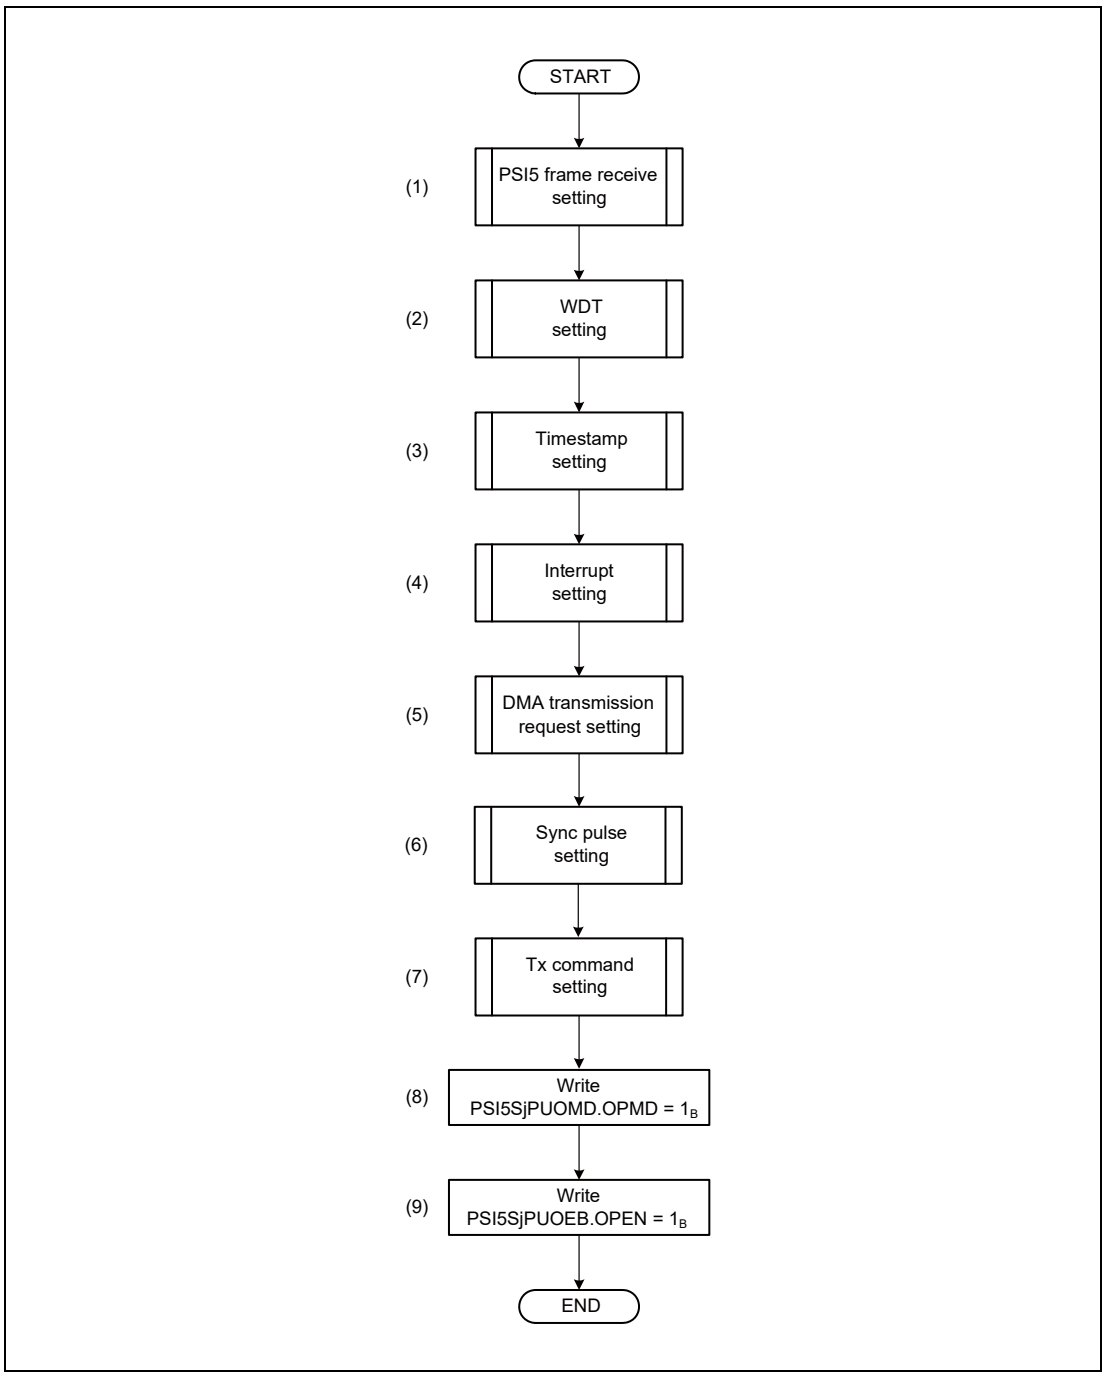

Figure 28.9 PSI5S mode Setting Procedure

(1) Set up PSI5 frame reception. For details, see **Section 28.5.2.1, PSI5 Frame Reception Setting**.

(2) Set up the WDT. For details, see **Section 28.5.2.2, WDT Setting**.

(3) Set up timestamps. For details, see **Section 28.5.2.3, Timestamp Setting**.

(4) Set up interrupts. For details, see **Section 28.5.2.4, Interrupt Setting**.

(5) Set up DMA transfer requests. For details, see **Section 28.5.2.5, DMA Transfer Request Setting**.

(6) Setup synchronization pulse. For details, see **Section 28.5.2.6, Synchronization Pulse Setting Procedure**.

(7) Set up Tx command. For details, see **Section 28.5.2.7, Tx Command Setting Procedure**.

(8) PSI5SjPUOMD: PSI5S/UART Operation Mode register
Set the operation mode to PSI5S mode.

(9) PSI5SjPUOEB: PSI5S/UART Operation Enable register
Start the operation of PSI5S.

28.5.2.1 PSI5 Frame Reception Setting

This section describes how to set up PSI5 frame reception.

Perform the procedure shown in **Figure 28.10** below for channel 0 and the required channels among channels 1 to 7.

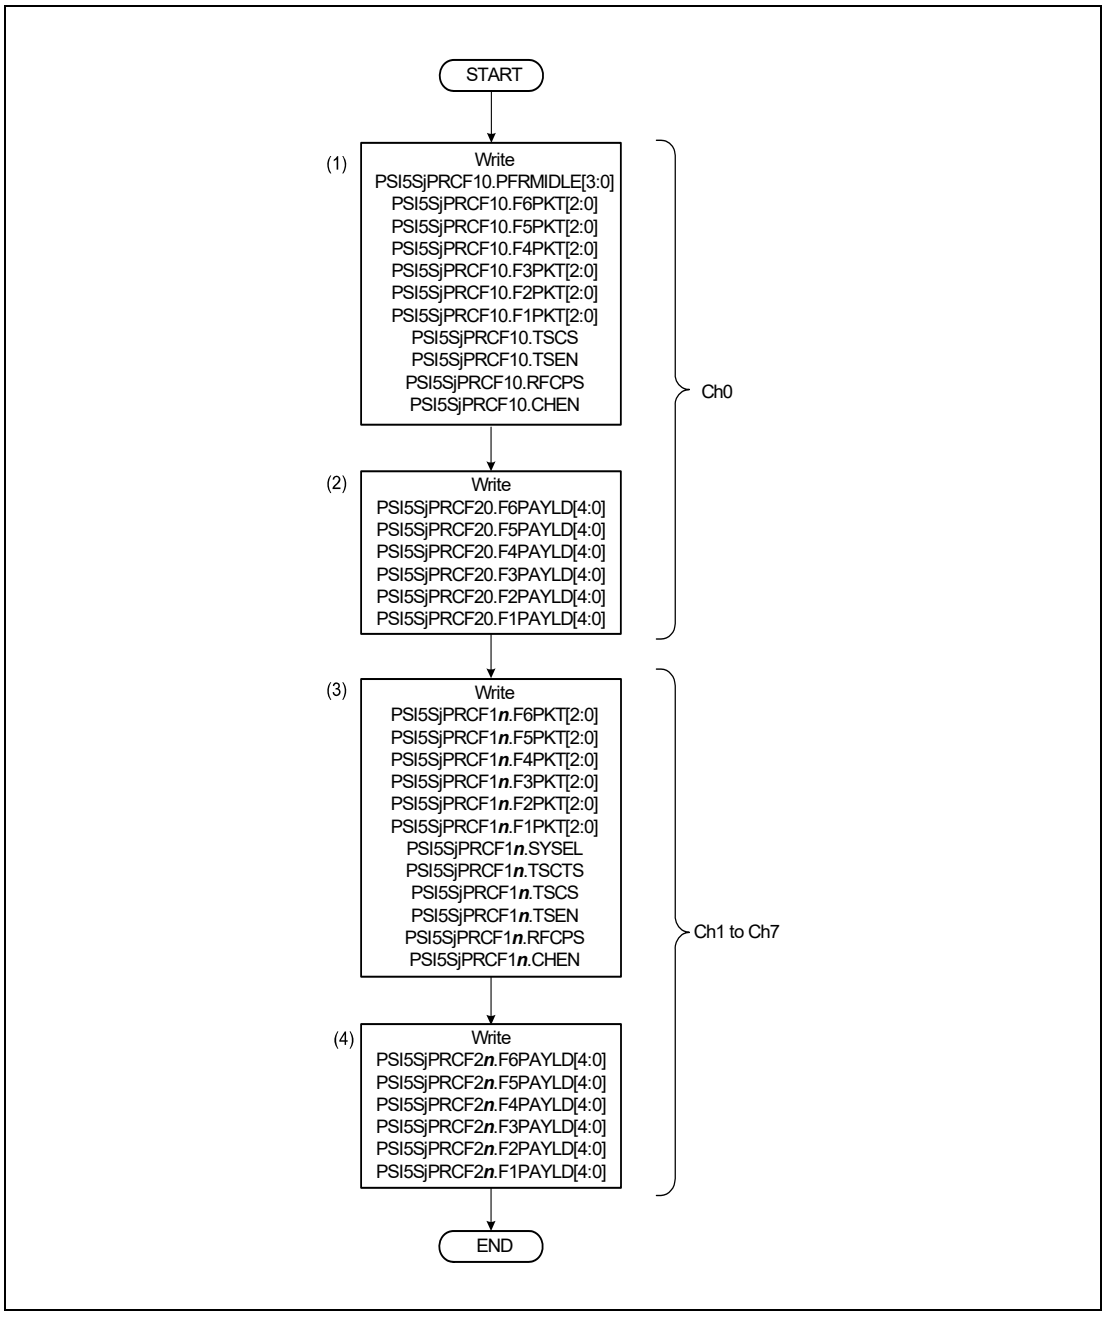

Figure 28.10 PSI5 Frame Reception Setting Procedure

(1) PSI5SjPRCF10: PSI5S Receive Config1 ch0 register
Specify the desired settings in the PSI5 frame reception configuration 1 register for channel 0.

(2) PSI5SjPRCF20: PSI5S Receive Config2 ch0 register
Specify the desired settings in the PSI5 frame reception configuration 2 register for channel 0.

(3) PSI5SjPRCF1*n*: PSI5S Receive Config1 ch***n*** register (*n* = 1 to 7)
Specify the desired settings in the PSI5 frame reception configuration 1 register for channel *n*.

(4) PSI5SjPRCF2*n*: PSI5S Receive Config2 ch***n*** register (*n* = 1 to 7)
Specify the desired settings in the PSI5 frame reception configuration 2 register for channel *n*.

The value of the PSI5SjPRCF1*n*.F*m*PKT[2:0] bits is determined by the relationship between the values of the PSI5SjPRCF1*n*.RFCPS and PSI5SjPRCF2*n*.F*m*PAYLD[4:0] bits as shown in **Table 28.89**. Note that if a value other than those shown in the table is set to the PSI5SjPRCF1*n*.F*m*PKT[2:0] bits, the operation of PSI5S will be unpredictable. (*n* = 1 to 7, *m* = 1 to 6)

Table 28.89 List of PSI5SjPRCF1*n*.F*m*PKT[2:0] Settings

	PSI5SjPRCF1*n*.F*m*PKT[2:0]	
PSI5SjPRCF2*n*.F*m*PAYLD[4:0]	PSI5SjPRCF1*n*. RFCPS = 0 (Checksum of Rx frame is parity)	PSI5SjPRCF1*n*. RFCPS = 1 (Checksum of Rx frame is CRC)
8	3_H	4_H
9	3_H	4_H
10	4_H	4_H
11	4_H	4_H
12	4_H	4_H
13	4_H	4_H
14	4_H	4_H
15	4_H	4_H
16	4_H	5_H
17	4_H	5_H
18	5_H	5_H
19	5_H	5_H
20	5_H	5_H
21	5_H	5_H
22	5_H	5_H
23	5_H	5_H
24	5_H	6_H
25	5_H	6_H
26	6_H	6_H
27	6_H	6_H
28	6_H	6_H

Note: n = 1 to 7, m = 1 to 6

(1) PSI5 Frame Reception Setting (no payload checksum in reception frame)

IF there is no Payload Checksum in a reply frame from a transceiver (excluding the Payload bit number of 10, 18 and 24 bits), the Rx Frame checksum CRC/Parity Select bit (PSI5SjPRCF1***n***.RFCPS) is set as Parity (= 0) and the payload parity error is ignored. PSI5S recognizes the staffing bit as a parity bit.

For the procedure of the frame reception from a transceiver, see **Section 28.5.6.3, Response Frame from Transceiver Reception**.

28.5.2.2 WDT Setting

This section describes how to set up the WDT.

Perform the procedure shown in **Figure 28.11** below for the channels that require the WDT.

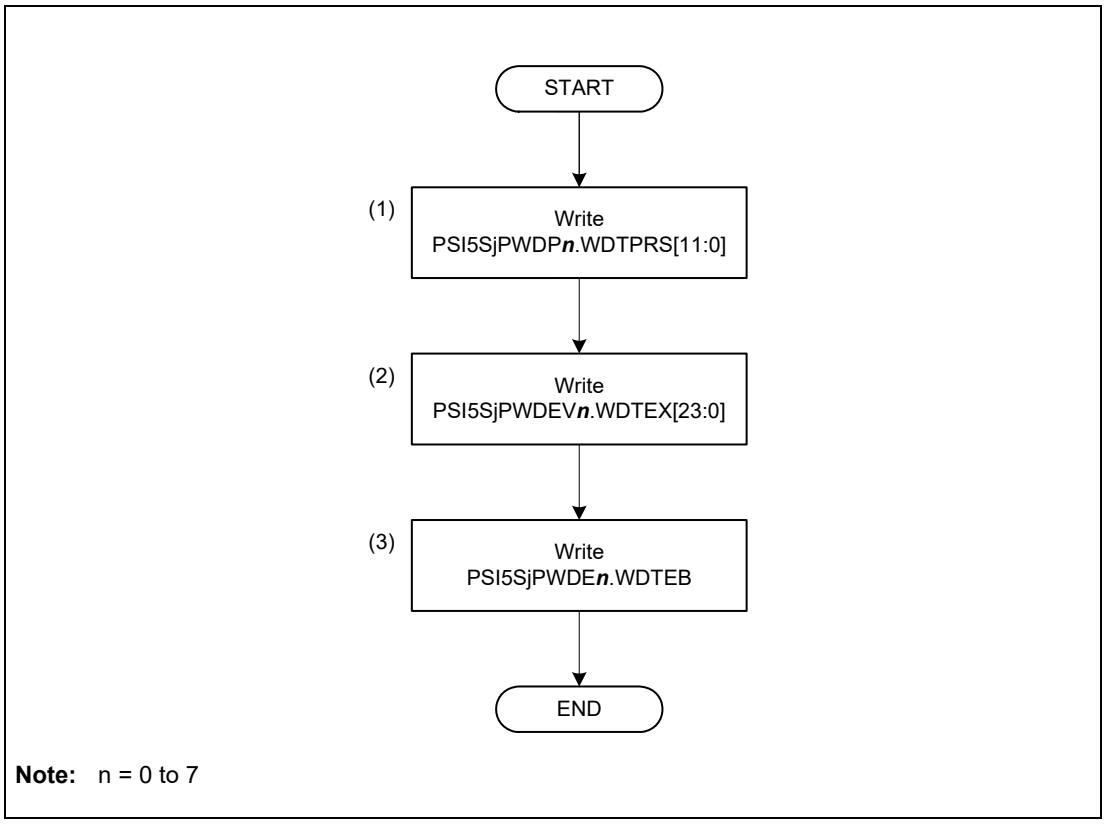

Figure 28.11 WDT Setting Procedure

(1) PSI5SjPWDP*n*: PSI5S WDT Prescaler ch***n*** register
Specify the WDT prescaler settings for channel *n*. (*n*: 0 to 7)

(2) PSI5SjPWDEV*n*: PSI5S WDT Expiration Value ch***n*** register
Specify the expiration value of the WDT for channel *n*. (*n*: 0 to 7)

(3) PSI5SjPWDE*n*: PSI5S WDT Enable ch***n*** register
Enable the WDT for channel *n*. (*n*: 0 to 7)
The WDT can be enabled when PSI5S is in either the PSI5S_active or configuration state.

28.5.2.3 Timestamp Setting

This section describes how to set up timestamp counters A and B.

Perform the procedure shown in **Figure 28.12** below for the timestamps to be used. **Figure 28.12** shows the setting procedure to control timestamp counters A and B separately.

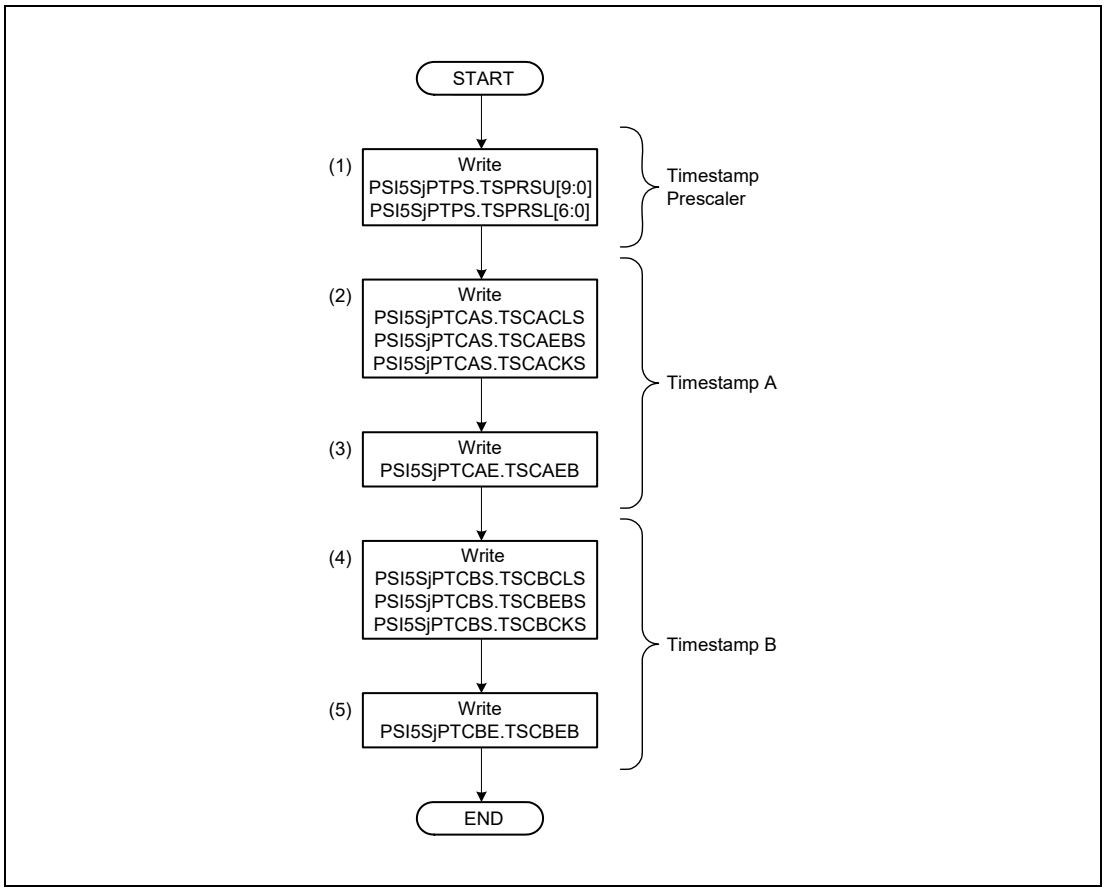

Figure 28.12 Timestamp Setting Procedure (for Separate Control)

(1) PSI5SjPTPS: PSI5S Timestamp Prescaler register
Specify the settings of the timestamp prescaler.

(2) PSI5SjPTCAS: PSI5S Timestamp Counter A Select register
Select the clear signal, enable signal, and clock signal for timestamp counter A.

(3) PSI5SjPTCAE: PSI5S Timestamp Counter A Enable register
Enable the operation of timestamp counter A. By this setting, timestamp counter A starts.

(4) PSI5SjPTCBS: PSI5S Timestamp Counter B Select register
Select the clear signal, enable signal, and clock signal for timestamp counter B.

(5) PSI5SjPTCBE: PSI5S Timestamp Counter B Enable register
Enable the operation of timestamp counter B.

Figure 28.13 below shows a different setting procedure than the above to control timestamp counters A and B together.

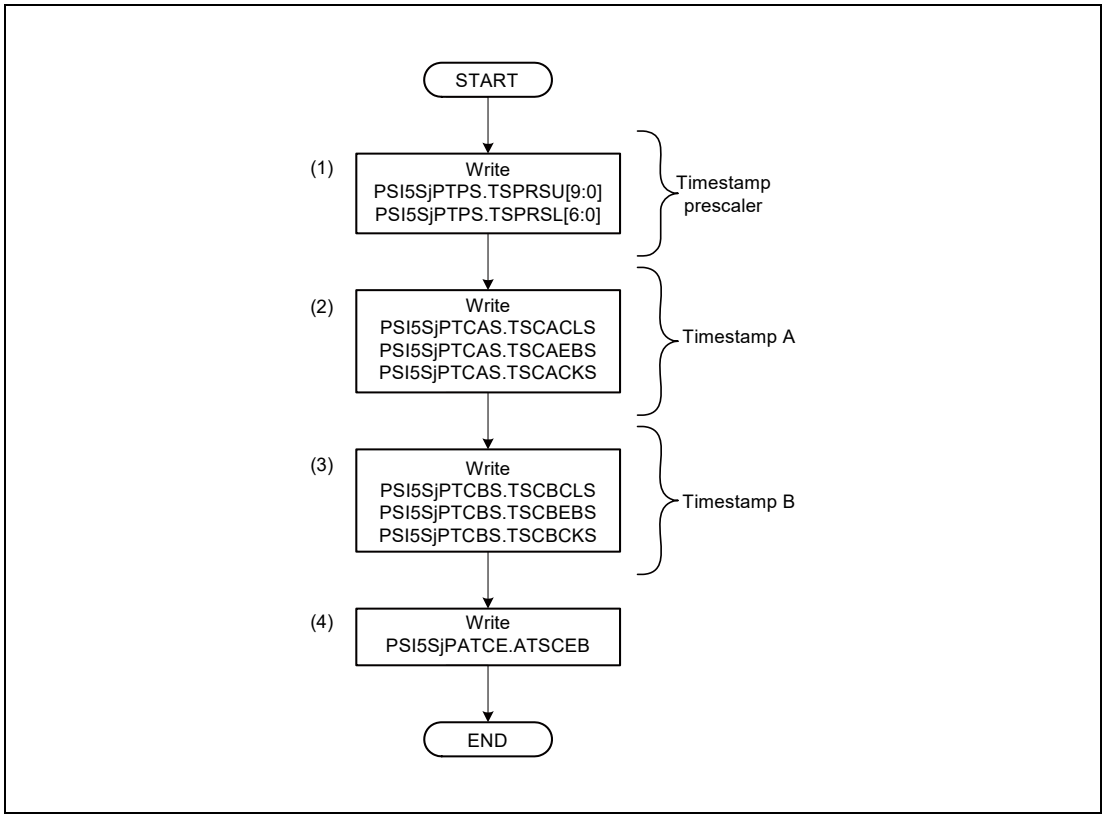

Figure 28.13 Timestamp Setting Procedure (for Batch Control)

(1) PSI5SjPTPS: PSI5S Timestamp Prescaler register
Specify the settings of the timestamp prescaler.

(2) PSI5SjPTCAS: PSI5S Timestamp Counter A Select register
Select the clear signal, enable signal, and clock signal for timestamp counter A.

(3) PSI5SjPTCBS: PSI5S Timestamp Counter B Select register
Select the clear signal, enable signal, and clock signal for timestamp counter B.

(4) PSI5SjPATCE: PSI5S All Timestamp Counter Enable register
Enable the operation of timestamp counters A and B together. By this setting, timestamp counters A and B start.

Note that clear instructions can also be issued for timestamp counters A and B separately or in a batched manner.

28.5.2.4 Interrupt Setting

This section describes how to set up interrupts.

Perform the procedure shown in **Figure 28.14** below for the required channels among channels 0 to 7.

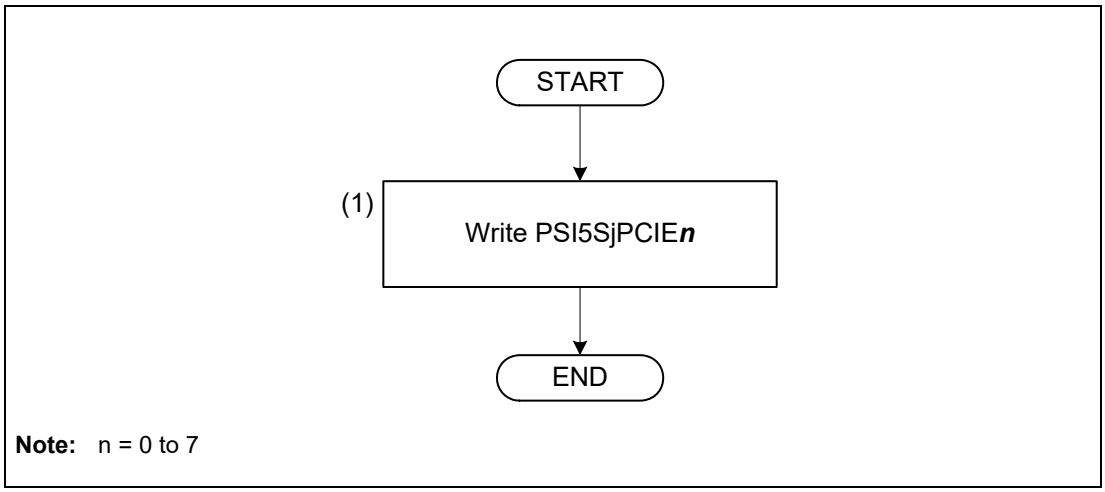

Figure 28.14 Interrupt Setting Procedure

(1) PSI5SjPCIE*n*: PSI5S CPU Interrupt Enable ch*n* register (*n*: 0 to 7)
Specify the settings of the interrupt enable bits according to the interrupt factors.

Table 28.90 below lists the enable bits in the interrupt enable register.

Table 28.90 Interrupt Enable Register Bits

Register Symbol	Bit Symbol	Factor
PSI5SjPCIE0	IEBXCRC	XCRC error
PSI5SjPCIE(0 to 7)	IEBCRC	CRC error
PSI5SjPCIE(0 to 7)	IEBPT	Parity error
PSI5SjPCIE(0 to 7)	IEBTRST	Transceiver status error
PSI5SjPCIE0	IEBUTPT	UART Rx parity error
PSI5SjPCIE0	IEBUTFR	UART Rx framing error
PSI5SjPCIE(0 to 7)	IEBRWDT	WDT error
PSI5SjPCIE(0 to 7)	IEBROV	PSI5 frame reception overrun error
PSI5SjPCIE(0 to 7)	IEBRFLK	PSI5 frame lack error
PSI5SjPCIE(0 to 7)	IEBRFEX	PSI5 frame excess error
PSI5SjPCIE(0 to 7)	IEBRFN	PSI5 frame reception finish
PSI5SjPCIE(1 to 7)	IEBDDSOW	DDSR overwrite error
PSI5SjPCIE(1 to 7)	IEBDDSFN	DDSR transmit finish
PSI5SjPCIE0	IEBCTFN	Command data transmit finish

28.5.2.5 DMA Transfer Request Setting

This section describes how to set up DMA transfer requests.

Perform the procedure shown in **Figure 28.15** below for the required channels among channels 0 to 7.

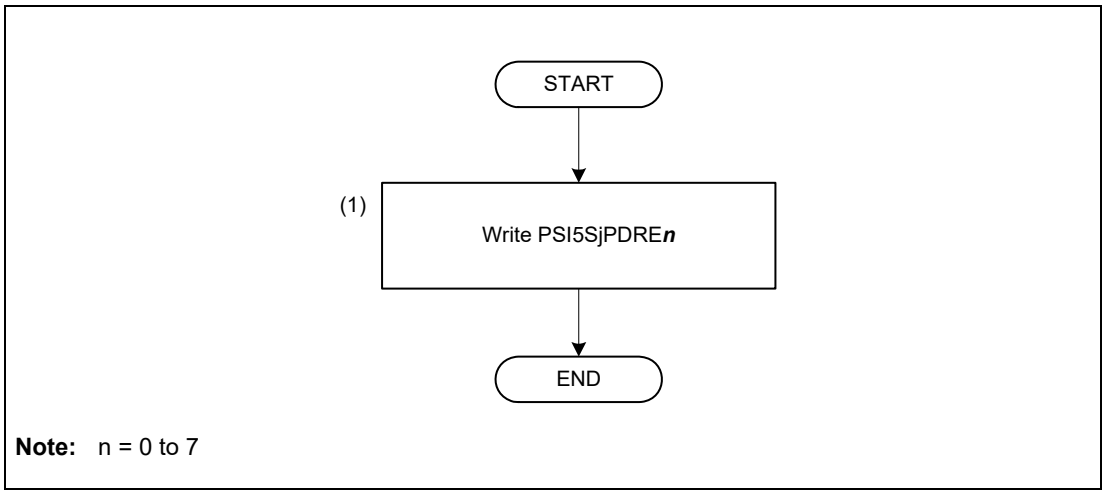

Figure 28.15 DMA Transfer Request Enable Setting Procedure

When you enable the output of DMA transfer requests, check the contents of the following status register:

(1) PSI5SjPDRE*n*: PSI5S DMA transfer Request Enable ch*n* register (*n*: 0 to 7)
Enable the output of DMA transfer requests.

Table 28.91 below lists the enable bits in the transfer request enable register.

Table 28.91 DMA Transfer Request Enable Register Bits

Register Symbol	Bit Symbol	Factor
PSI5SjPDRE(0 to 7)	DRQERFN	PSI5 last frame reception finish
PSI5SjPDRE(0 to 7)	DRQEWDT	WDT error
PSI5SjPDRE(1 to 7)	DRQETFN	DDSR transmit finish

28.5.2.6 Synchronization Pulse Setting Procedure

This section describes how to set up a synchronization pulse.

Perform the procedure shown in **Figure 28.16** below for the channels that require a synchronization pulse.

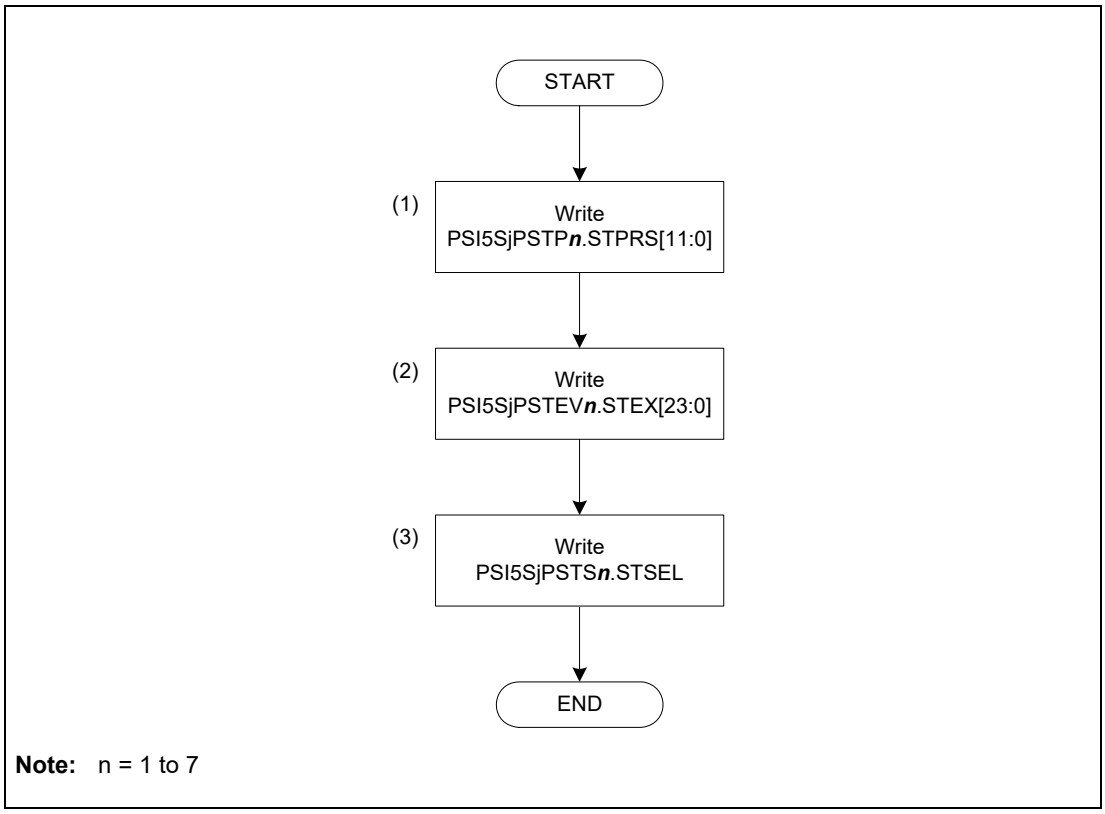

Figure 28.16 Synchronization Pulse Setting Procedure

(1) PSI5SjPSTP***n***: PSI5S Sync Trigger Prescaler ch***n*** register.
Specify settings of the sync trigger prescaler for channel n. (***n***: 1 to 7)

(2) PSI5SjPSTEV***n***: PSI5S Sync Trigger Expiration Value ch***n*** register.
Specify settings of the sync trigger expiration value for channel n. (***n***: 1 to 7)

(3) PSI5SjPSTS***n***: PSI5S Sync Trigger Select ch***n*** register.
Specify settings of the selection of synchronous trigger for channel n. (***n***: 1 to 7)

28.5.2.7 Tx Command Setting Procedure

This section describes how to set up the Tx command data for ECU-to-sensor communication.

Perform the procedure shown in **Figure 28.17** below for the Tx command of each channels that requires a synchronization pulse.

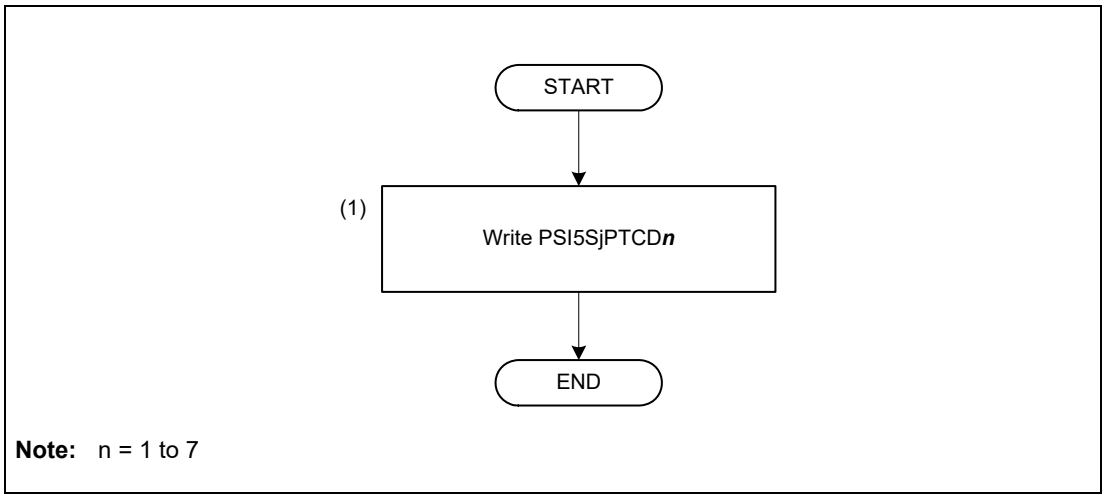

Figure 28.17 Tx Command Setting Procedure

(1) PSI5SjPTCD***n***: PSI5S Tx command Data ch***n*** register.
Specify the settings of the Tx command for channel ***n***. (***n***: 1 to 7)

28.5.3 UART Mode Setting Procedure

PSI5S has a UART mode in which PSI5S can operate as a UART with limited functions.

For details on the UART specifications, see **Table 28.9, Features**.

Perform the procedure shown in **Figure 28.18** below after performing the procedure described in **Section 28.5.1, Common Setting Procedure**.

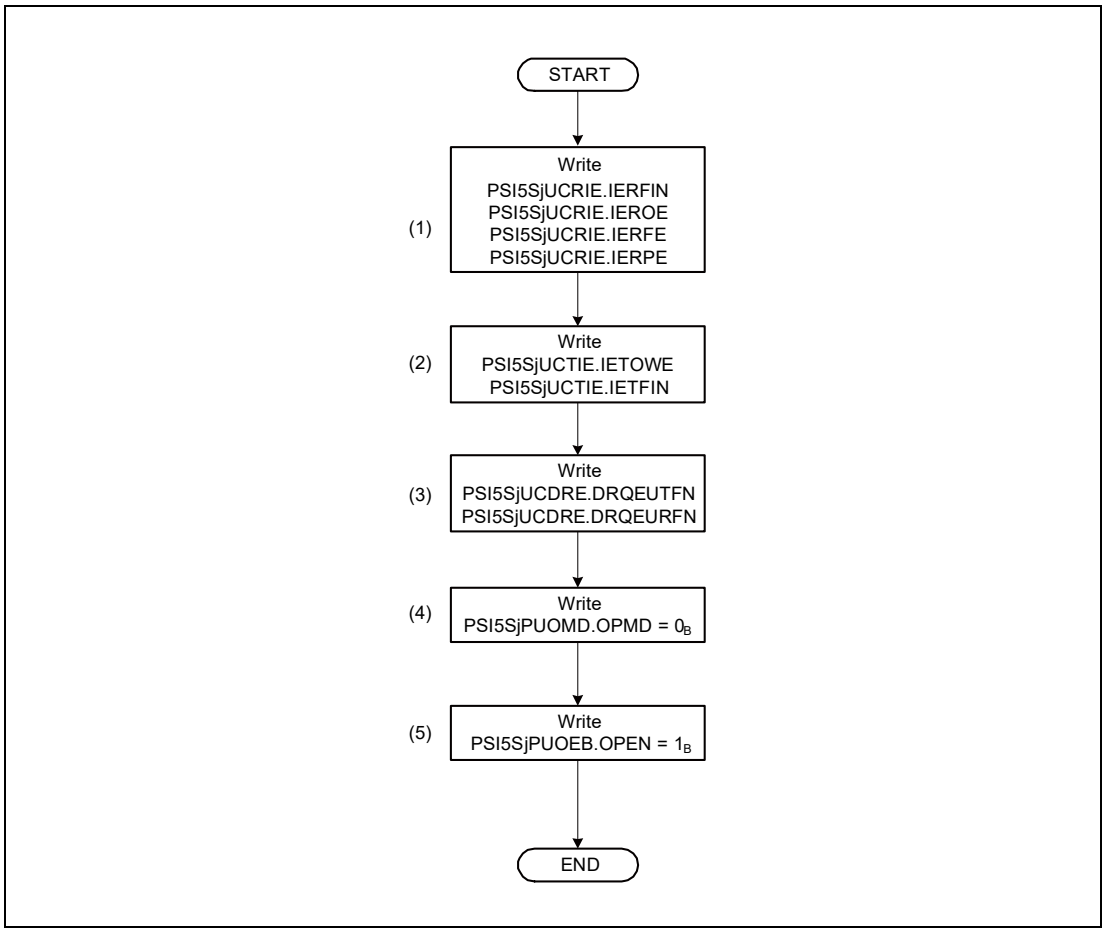

Figure 28.18 UART Mode Setting Procedure

(1) PSI5SjUCRIE: UART Communication Rx Interrupt Enable register
Specify settings of the interrupts at the end of UART frame reception, at the occurrence of a UART overrun error, at the occurrence of a UART framing error and at the occurrence of a UART parity error.

(2) PSI5SjUCTIE: UART Communication Tx Interrupt Enable register
Specify settings of the interrupts at the end of UART frame transmission and at the occurrence of a UART overwrite error.

(3) PSI5SjUCDRE: UART Communication DMA Request Enable register
Specify settings of the DMA transfer requests at the end of UART reception and at the end of UART transmission.

(4) PSI5SjPUOMD: PSI5S/UART Operation Mode register
Set the operation mode to UART mode.

(5) PSI5SjPUOEB: PSI5S/UART Operation Enable register
Start the operation of PSI5S.

28.5.4 Procedure for Transmitting Transceiver Commands

This section describes how to transmit commands for an externally connected PSI5 transceiver.

Perform this setting procedure after performing the procedure described in **Section 28.5.2, PSI5S mode Setting Procedure**.

PSI5 frame reception setting of Ch0 is required, because the response frame from the transceiver is stored in Ch0 MB.

(See **Section 28.5.2.1, PSI5 Frame Reception Setting**)

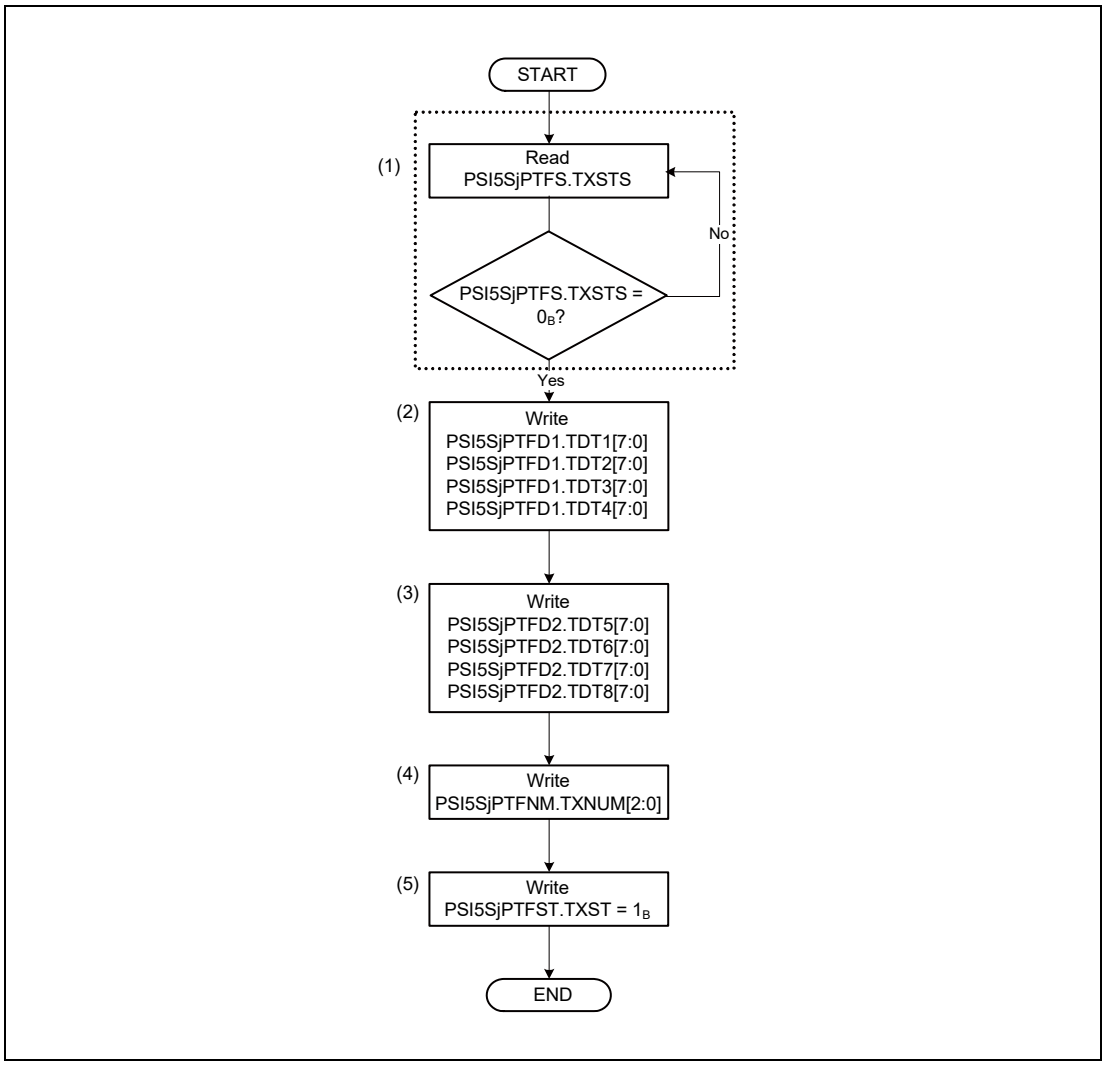

Figure 28.19 Transceiver Setting Procedure

(1) PSI5SjPTFS: PSI5S Tx Frame Status register
Read the TXSTS bit to check that the UART is not busy with transmission (TXSTS = 0). If the UART is busy (TXSTS = 1), wait until it is not busy.

(2) PSI5SjPTFD1: PSI5S Tx Frame Data1 register
Sequentially set the 1st to 4th bytes of the data to be transmitted continuously in this register. If the continuously transmitted data is less than 4 bytes, set only the data to be transmitted.

(3) PSI5SjPTFD2: PSI5S Tx Frame Data2 register
Sequentially set the 5th to 8th bytes of the data to be transmitted continuously in this register. If the continuously transmitted data is less than 9 bytes, set only the data to be transmitted.

(4) PSI5SjPTFNM: PSI5S Tx Frame Number register
Set the number of bytes to be transmitted continuously in this register.

(5) PSI5SjPTFST: PSI5S Tx Frame Start register
Start continuous transmission.

As an example, **Table 28.92** below describes the settings of PSI5SjPTFD1, PSI5SjPTFD2, and PSI5SjPTFNM registers to set up the external transceiver that uses the command format shown below in **Figure 28.20**.

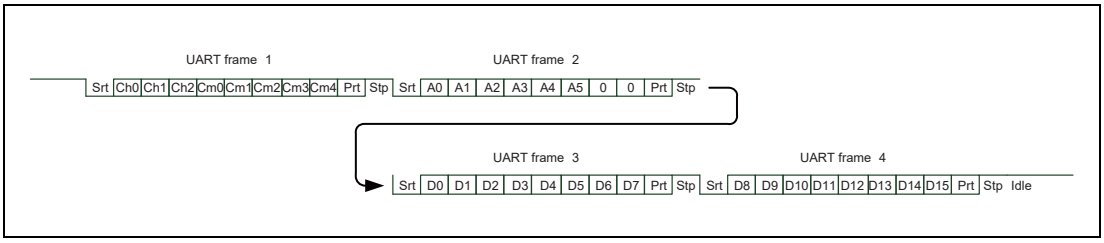

Figure 28.20 Example of Command Format

Table 28.92 List of Register Settings

Register Symbol	Bit Symbol	Value
PSI5SjPTFD1	TDT1[7:0]	{Cm[4:0], Ch[2:0]}
PSI5SjPTFD1	TDT2[7:0]	{0b00, A[5:0]}
PSI5SjPTFD1	TDT3[7:0]	D[7:0]
PSI5SjPTFD1	TDT4[7:0]	D[15:8]
PSI5SjPTFD2	TDT5[7:0]	N/A
PSI5SjPTFD2	TDT6[7:0]	N/A
PSI5SjPTFD2	TDT7[7:0]	N/A
PSI5SjPTFD2	TDT8[7:0]	N/A
PSI5SjPTFNM	TXNUM[2:0]	3_H

28.5.5 DDSR Transmission Procedure

This section describes how to perform DDSR transmission.

Perform the procedure shown in **Figure 28.21** below for channels 1 to 7.

This procedure must be performed when the operation mode is PSI5S mode.

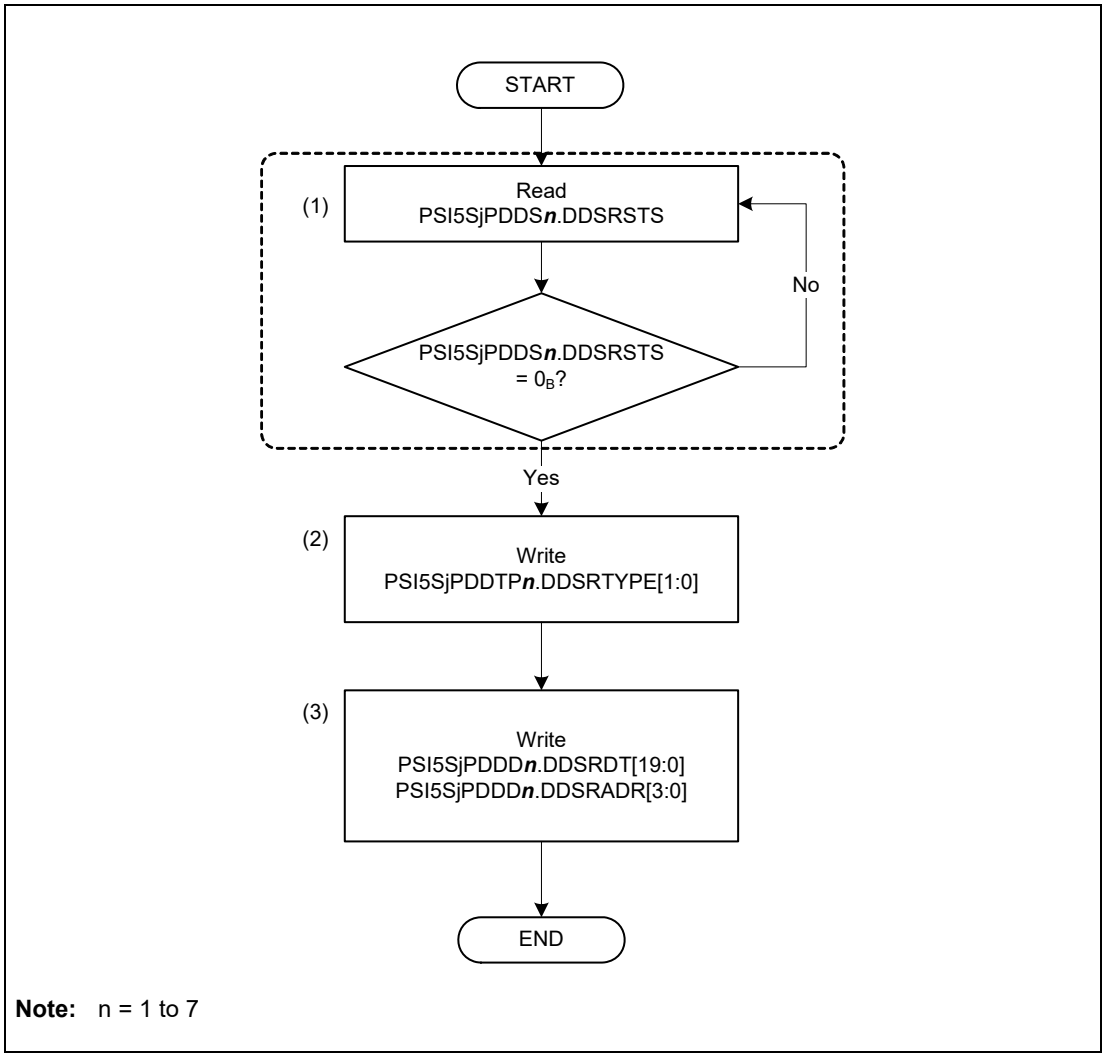

Figure 28.21 DDSR Transmission Procedure

(1) PSI5SjPDDS*n*. DDSRSTS: PSI5S DDSR Status Ch*n* register (*n*: 1 to 7)
Check the DDSR transmission status. When the DDSRSTS bit is 1, wait until the value changes to 0.
Note that if DDSR transmit data is written to the PSI5SjPDDD*n* register when the DDSRSTS bit is 1, an overwrite error occurs. For details, see **Section 28.6.2.9, Abnormal Transmission (Transmission Error)**.

(2) PSI5SjPDDTP*n*: PSI5S DDSR Type Ch*n* register (*n*: 1 to 7)
Specify the type of ECU-to-sensor data.

(3) PSI5SjPDDD*n*: PSI5S DDSR Data Ch*n* register (*n*: 1 to 7)
Set DDSR transmit data in this register.

Figure 28.22 shows the procedure of DDSR overwrite error processing.

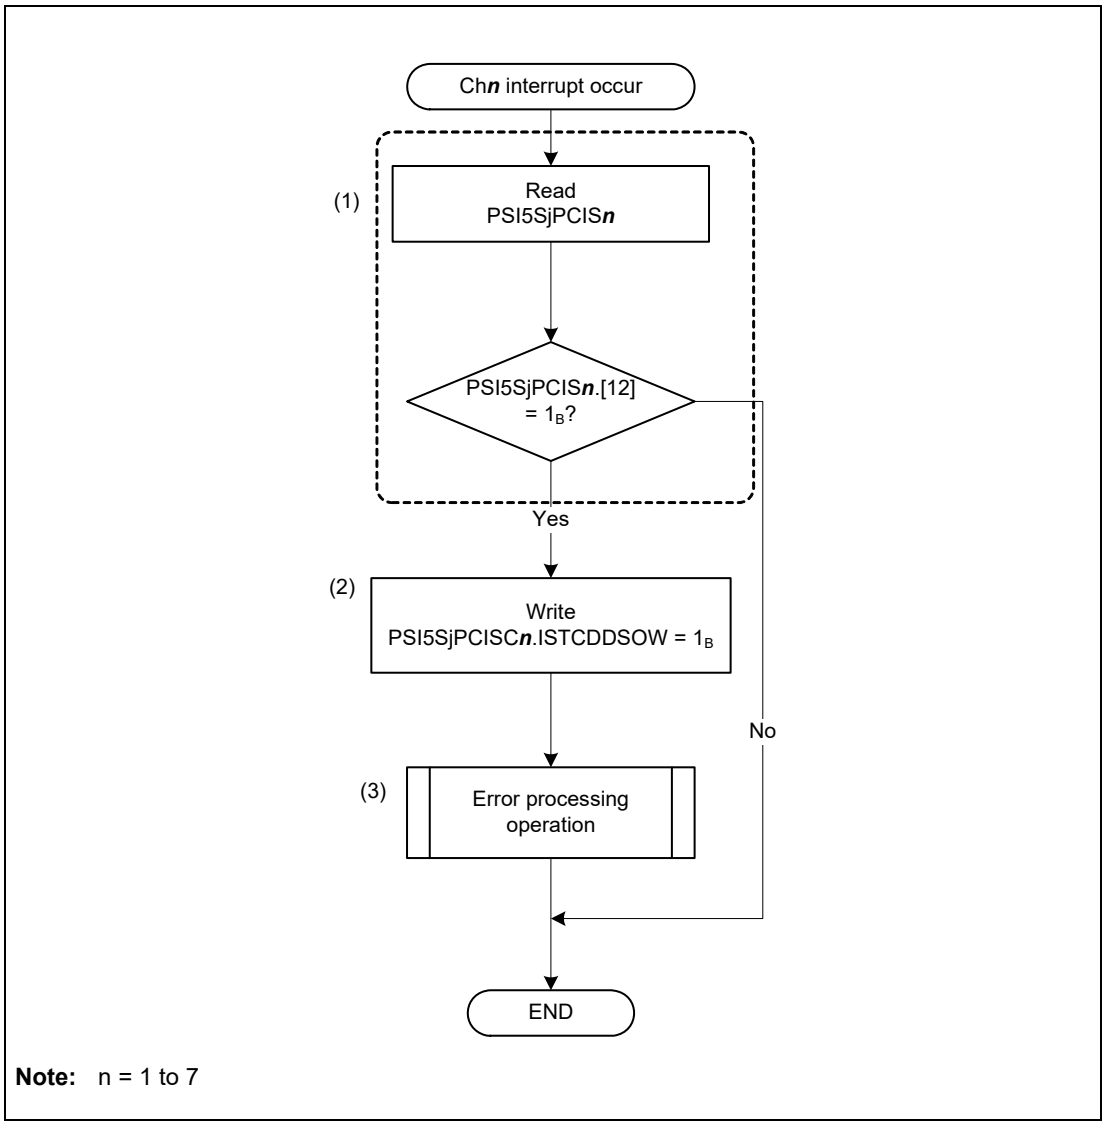

Figure 28.22 DDSR Overwrite Error Processing Procedure

(1) PSI5SjPCIS***n***: PSI5S CPU Interrupt Status ch***n*** register. (***n***: 1 to 7)
Read PSI5SjPCIS***n*** to check whether the DDSR overwrite error is set (PSI5SjPCIS***n***[12] = 1). If the DDSR overwrite error is not set (PSI5SjPCIS***n***[12] = 0), finish the processing.

(2) PSI5SjPCISC***n***: PSI5S CPU Interrupt Status chn Clear register. (***n***: 1 to 7)
Clear the DDSR overwrite error.

(3) Perform the processing to be done when a DDSR overwrite error occurs.

28.5.6 PSI5 Frame Reception Procedures

28.5.6.1 Normal Reception

This section describes the procedure of PSI-5 frame reception.

PSI5S can receive PSI5 frames only in PSI5S mode.

Figure 28.23 shows the operations to normally receive PSI5 frames.

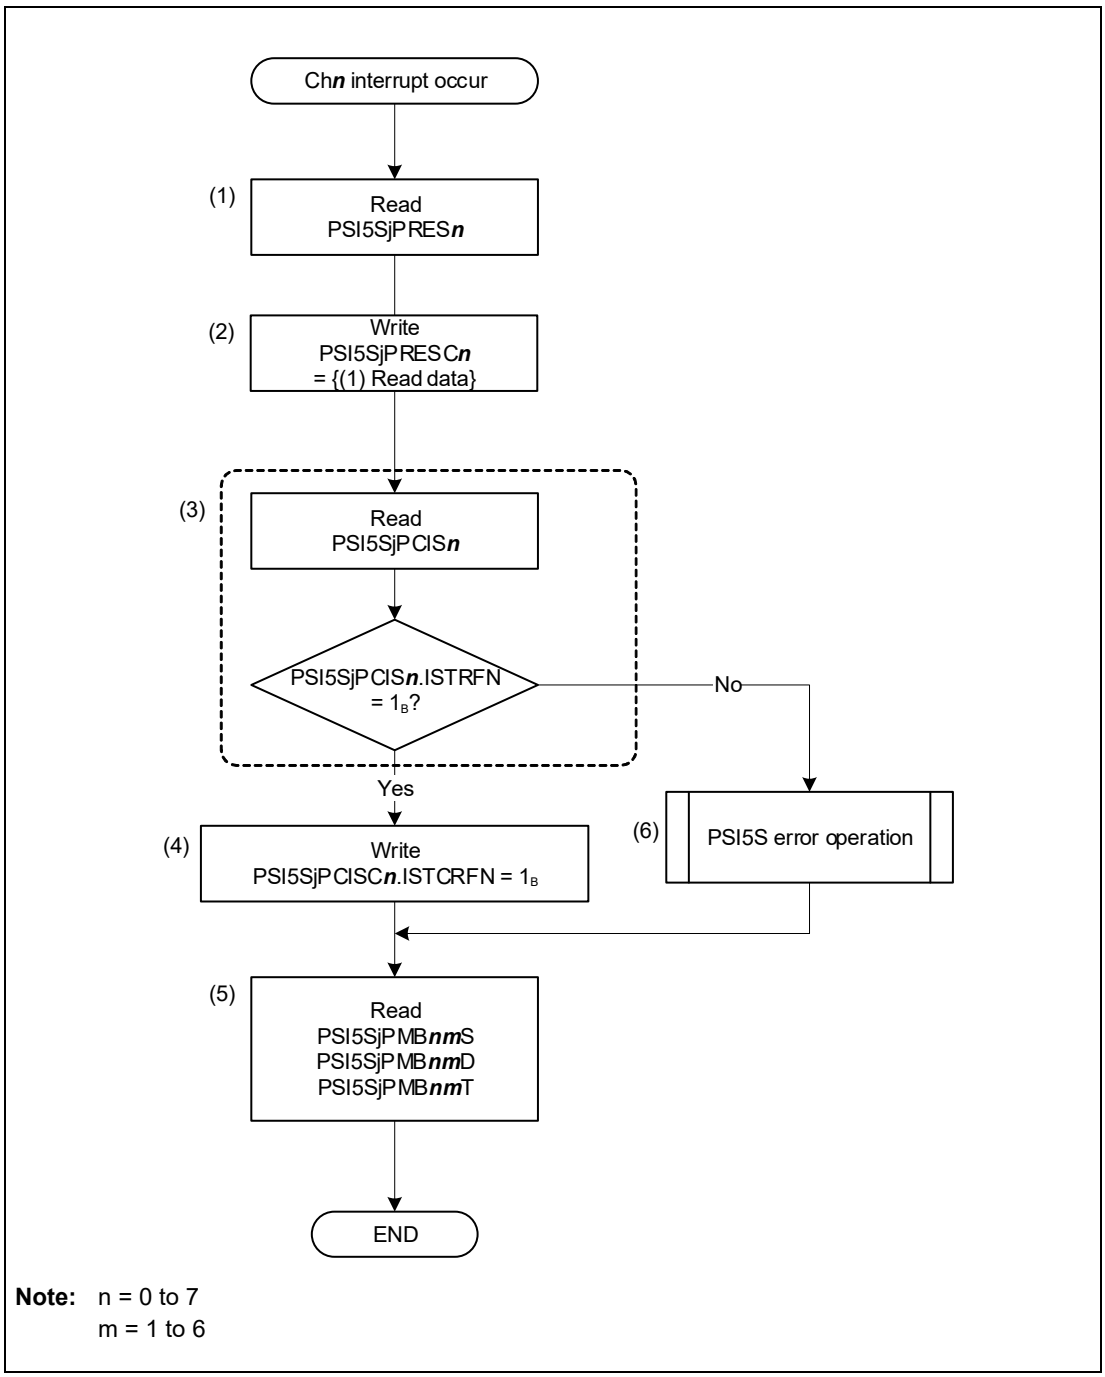

Figure 28.23 Procedure of Normal Reception of PSI5 Frames

(1) PSI5SjPRES*n*: PSI5S Receive Error Status ch*n* register (*n*: 0 to 7)
Check the frame that caused the interrupt. (This step is optional.)

(2) PSI5SjPRESC*n*: PSI5S Receive Error Status Clear ch*n* register (*n*: 0 to 7)
Clear the flag indicating the status of the frame that caused the interrupt. (This operation is optional.)

(3) PSI5SjPCIS*n*: PSI5S CPU Interrupt Status ch*n* register (*n*: 0 to 7)
Read the PSI5S interrupt status register to check that the ISTRFN bit is set.

(4) PSI5SjPCISC*n*: PSI5S CPU Interrupt Status ch*n* register (*n*: 0 to 7)
Clear the flag indicating the end of frame reception.

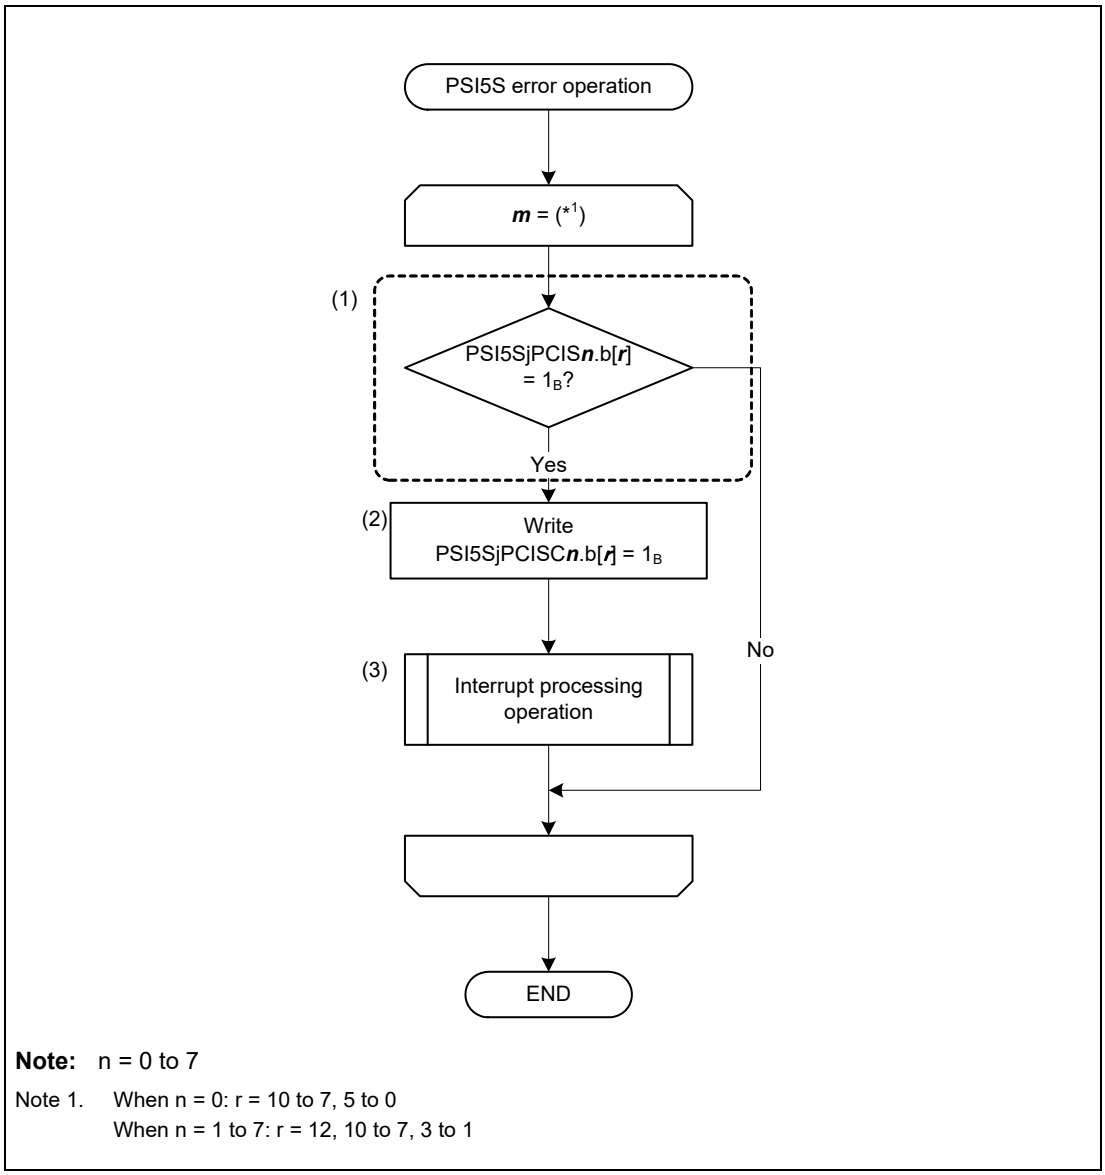
(5) PSI5SjPMB*nm*S: PSI5S receive MailBox ch*n* frm*m* Status register (*n*: 0 to 7, *m*: 1 to 6)
PSI5SjPMB*nm*D: PSI5S receive MailBox ch*n* frm*m* Data register (*n*: 0 to 7, *m*: 1 to 6)
PSI5SjPMB*nm*T: PSI5S receive MailBox ch*n* frm*m* Timestamp register (*n*: 0 to 7, *m*: 1 to 6)
Read the PSI5 frame status, data, and timestamp stored in the mailbox.

(6) If the ISTRFN bit is not set, perform error processing.

28.5.6.2 Abnormal Reception

This section describes how to process an error during PSI5 frame reception.

For the processes from the occurrence of an interrupt to the reading of the interrupt status, see processes (1) and (2) in **Figure 28.24**.



Note: n = 0 to 7

Note 1. When n = 0: r = 10 to 7, 5 to 0
When n = 1 to 7: r = 12, 10 to 7, 3 to 1

Figure 28.24 Procedure of Error Processing in PSI5 Frame Reception

(1) Check the cause of the error indicated in the PSI5S interrupt status register.

(2) PSI5SjPCISC*n*: PSI5S CPU Interrupt Status ch*n* register (*n*: 0 to 7)
If an error-cause flag is set, clear the flag.

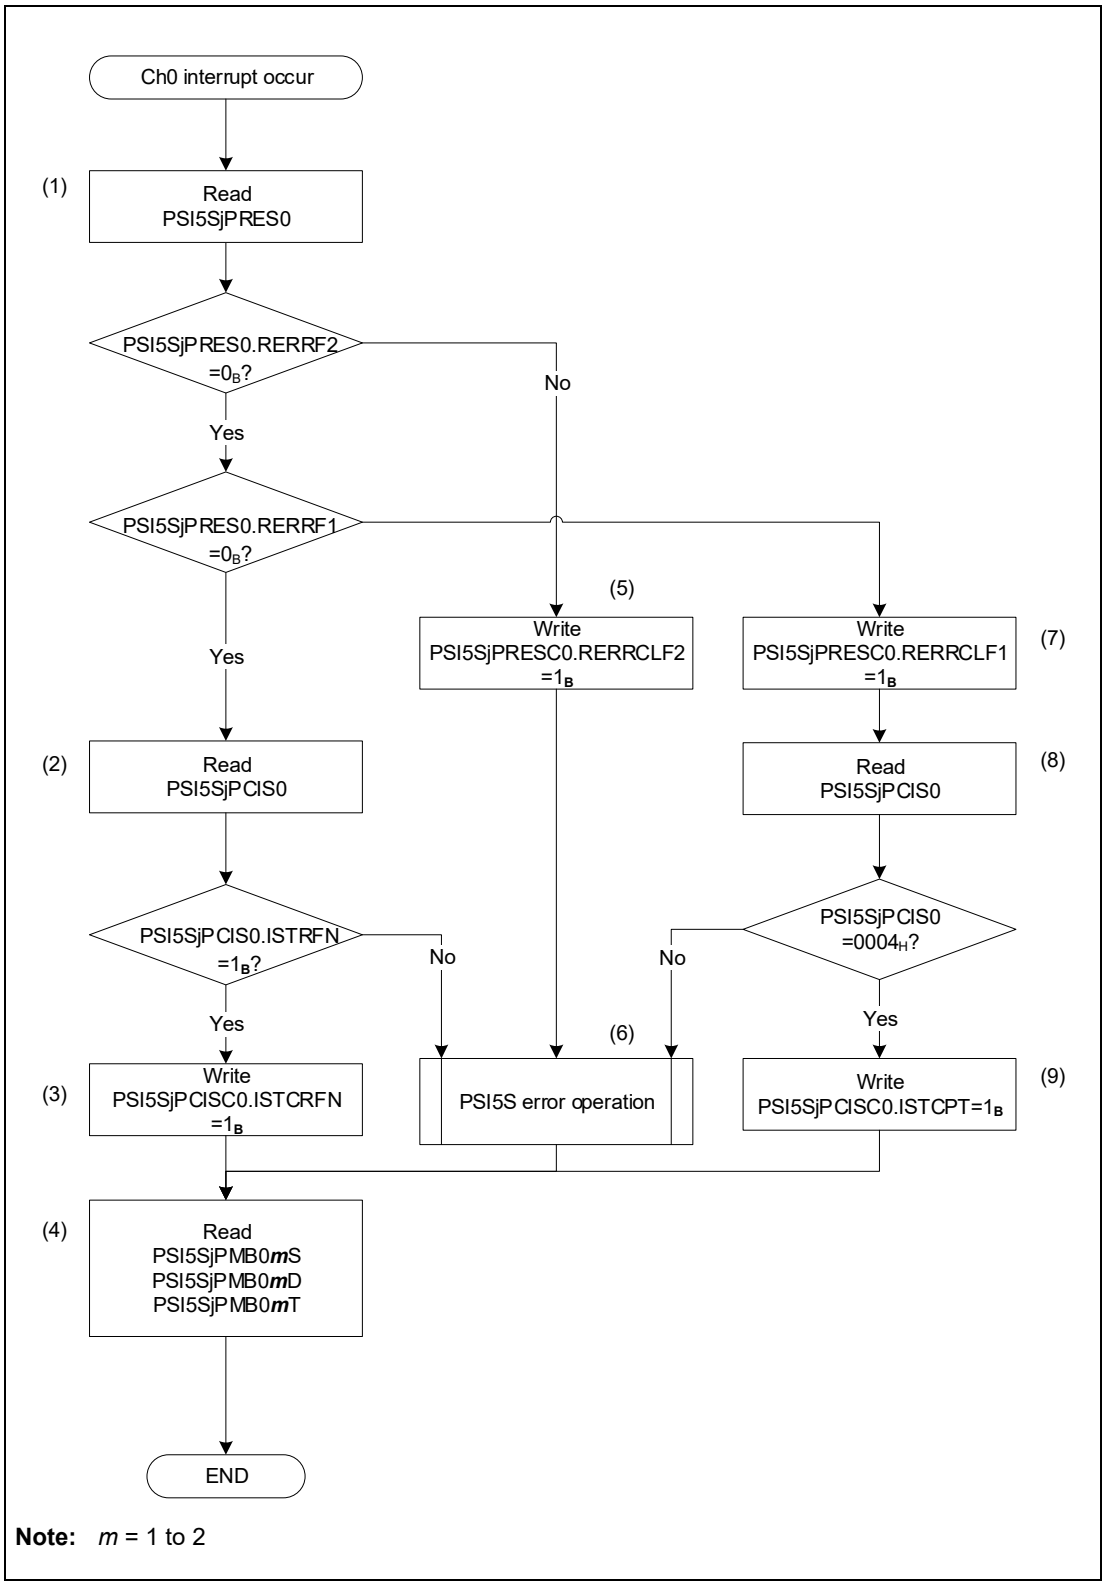
(3) Perform the error processing that corresponds to the indicated cause of the error.

Figure 28.74 shows the occurrence timing of errors other than WDT errors during PSI5 frame reception.

For the occurrence timing of WDT errors, see **Section 28.6.2.8, Abnormal Reception (WDT Error)**.

28.5.6.3 Response Frame from Transceiver Reception

This section describes the procedure of the response frame from the transceiver reception.



Note: *m* = 1 to 2

Figure 28.25 Procedure of Response Frame from Transceiver Reception

(1) PSI5SjPRES0: PSI5S Receive Error Status ch0 register.
Check the error frame that caused the interrupt.

(2) PSI5SjPCIS0: PSI5S CPU Interrupt Status ch0 register.
Read the PSI5S interrupt status register to check that the ISTRFN bit is set.

(3) PSI5SjPCISC0: PSI5S CPU Interrupt Status ch0 register.
Clear the flag indicating the end of frame reception.

(4) PSI5SjPMB0***m***S: PSI5S receive MailBox ch0 frm***m*** Status register (***m***: 1 to 2)
PSI5SjPMB0***m***D: PSI5S receive MailBox ch0 frm***m*** Data register (***m***: 1 to 2)
PSI5SjPMB0***m***T: PSI5S receive MailBox ch0 frm***m*** Timestamp register (***m***: 1 to 2)
Read the PSI5 frame status, data, and timestamp stored in the mailbox.

(5) PSI5SjPRESC0: PSI5S Receive Error Status Clear ch0 register.
Clear the flag indicating the error of frame 2.

(6) When the following cases, perform error processing.
- The flag indicating the end of reception is not set.
- The error frame occurs in frame 2 of ch0.
- The error frame occurs in frame 1 of ch0, and it has been set to other than a payload data parity error.

(7) PSI5SjPRESC0: PSI5S Receive Error Status Clear ch0 register.
Clear the flag indicating the error of frame 1.

(8) PSI5SjPCIS0: PSI5S CPU Interrupt Status ch0 register.
Read the PSI5S CPU Interrupt Status ch0 register to check that none of the flags except the ISTPT bit have been set.

(9) PSI5SjPCISC0: PSI5S CPU Interrupt Status ch0 register.
Clear the flag indicating the payload data parity error.

For the setting of frame reception from a transceiver, see **Section 28.5.2.1(1), PSI5 Frame Reception Setting (no payload checksum in reception frame)**.

28.5.7 Initialization and Operation Stop Procedures

28.5.7.1 Initialization by Software Reset

This section describes how to initialize PSI5S by a software reset.

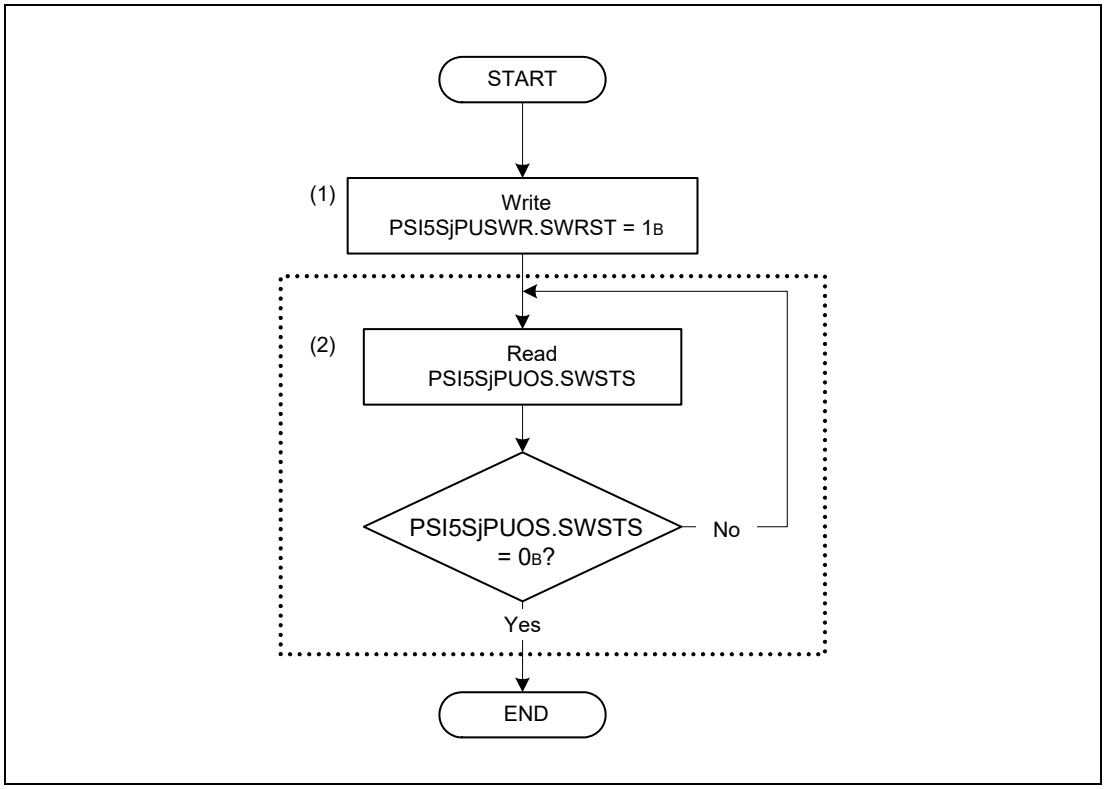


Figure 28.26 Initialization by Software Reset Procedure

(1) PSI5SjPUSWR: PSI5S/UART Software Reset register
Issue a software reset.

(2) PSI5SjPUOS: PSI5S/UART Operation Status register
Wait until the SW reset bit changes to 0.

28.5.7.2 DDSR Transmission Stop

This section describes how to stop DDSR transmission.

The transmission stop operation can be performed for individual channels.

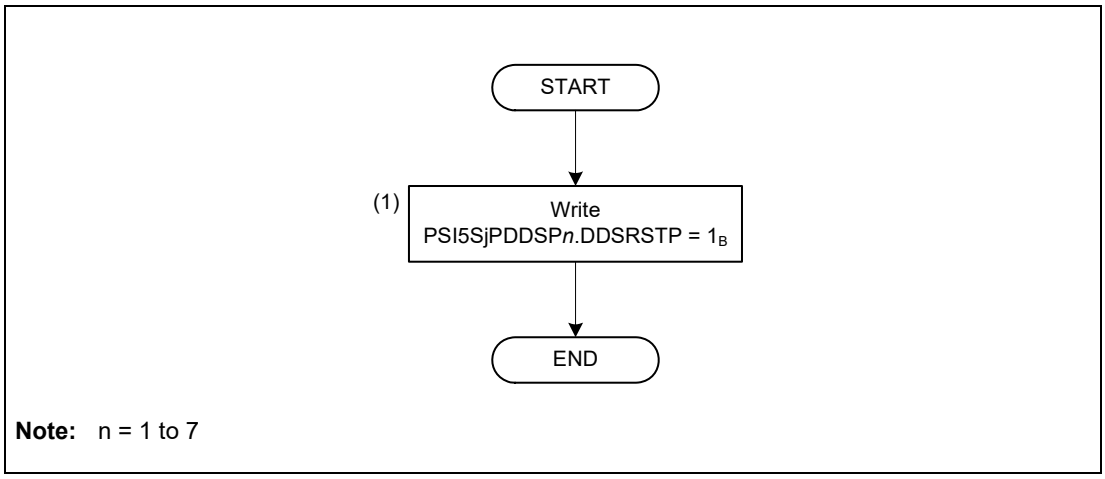

Figure 28.27 DDSR Transmission Stop Operation Procedure

(1) PSI5SjPDDSP*n*: PSI5S DDSR Stop ch*n* register (*n*: 1 to 7)
Stop data transmission from DDSR.

28.5.7.3 MailBox Initialization

This section describes the operation to initialize mailboxes (MBs).

This operation initializes the MBs for all channels together.

This operation must be performed when PSI5S is in configuration mode.

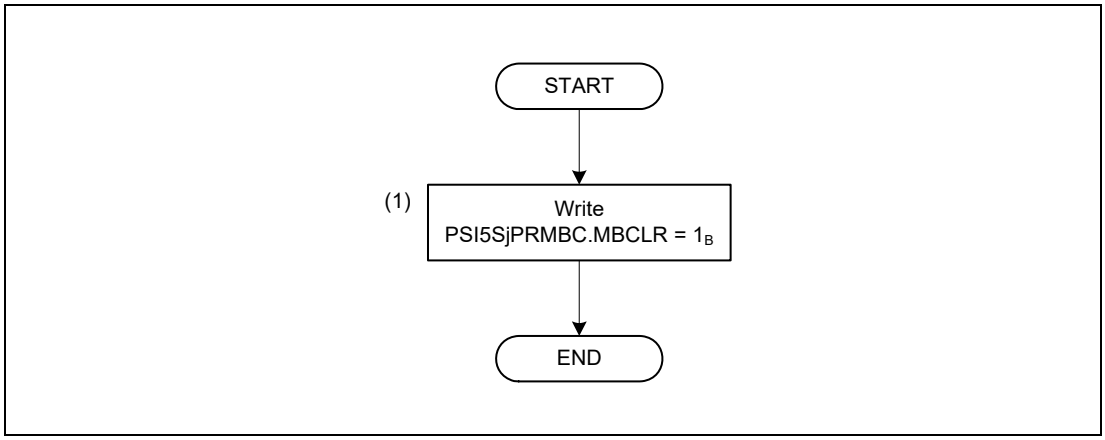

Figure 28.28 MailBox Initialization Procedure

(1) PSI5SjPRMBC: PSI5S Receive MailBox Data Clear register
Write 1 to the MBCLR bit to clear the mailboxes.

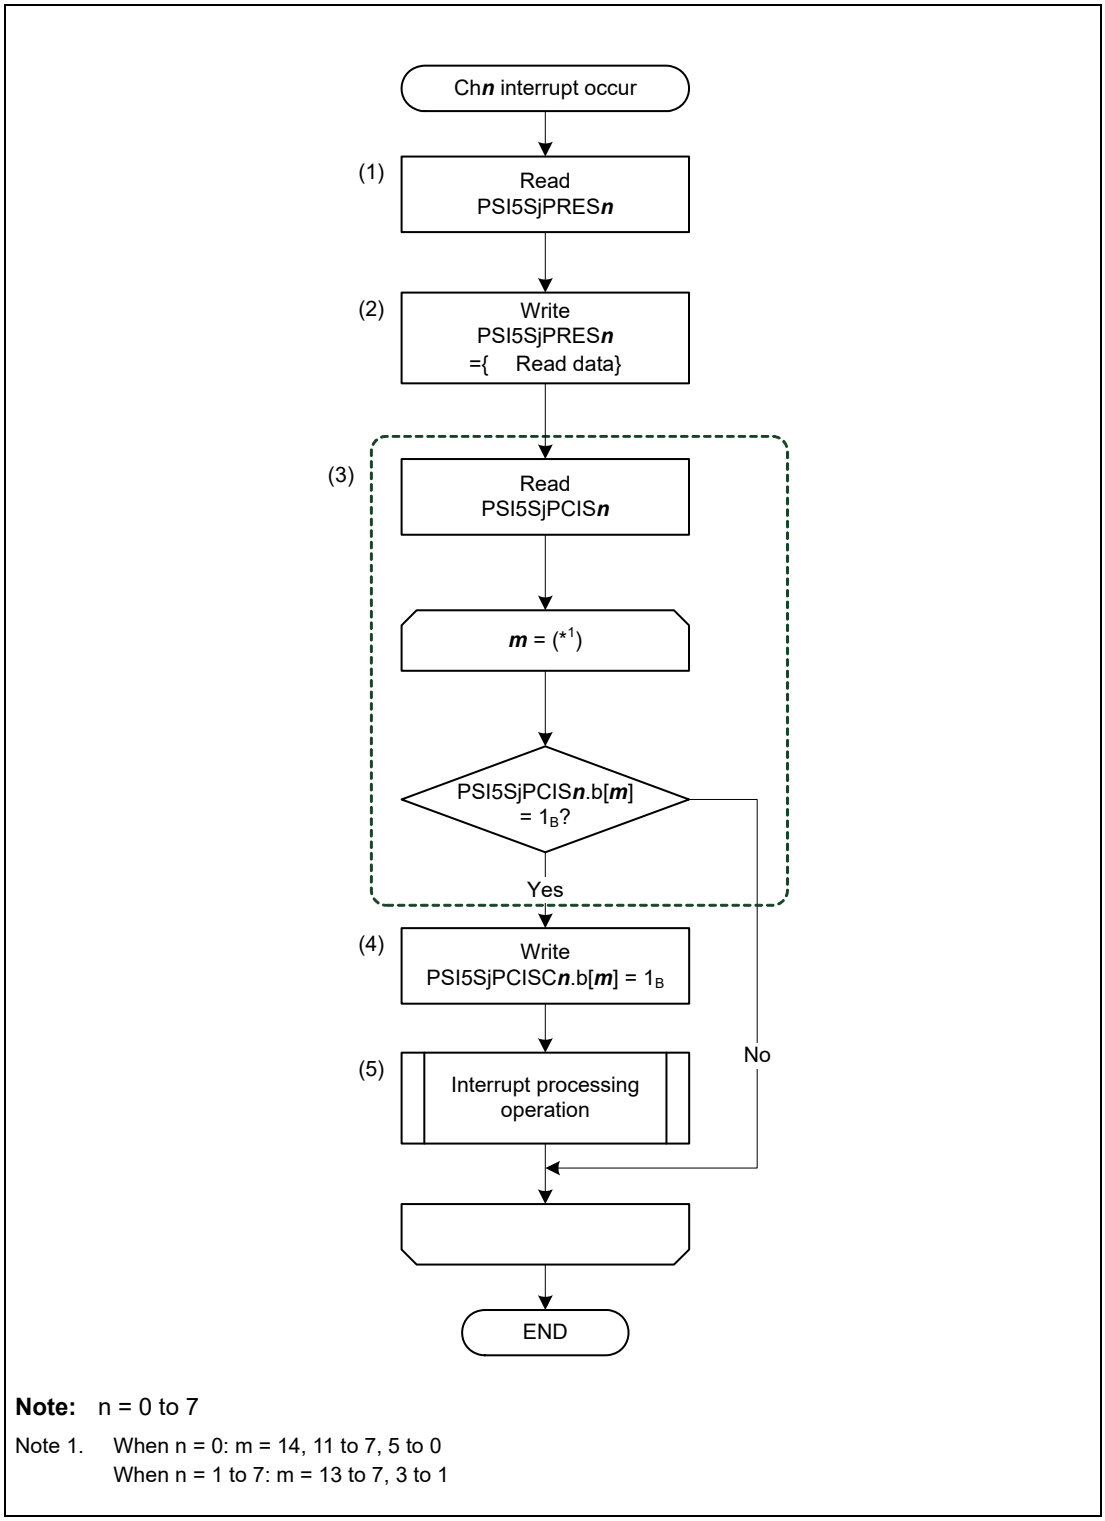
28.5.8 Interrupt Processing Procedures

28.5.8.1 Interrupt Processing in PSI5S mode

This section describes how to process interrupts in PSI5S mode.

Interrupts occur on individual channels.

This interrupt processing operation can be used for channels 0 to 7.



Note: n = 0 to 7

Note 1. When n = 0: m = 14, 11 to 7, 5 to 0
When n = 1 to 7: m = 13 to 7, 3 to 1

Figure 28.29 Interrupt Processing Procedure

(1) PSI5SjPRES*n*: PSI5S Receive Error Status ch*n* register (*n*: 0 to 7)
Check the frame that caused the reception error. (This step is optional.)

(2) PSI5SjPRESC*n*: PSI5S Receive Error Status Clear chn register (*n*: 0 to 7)
Clear the flag indicating the status of the frame that caused the reception error. (This step is optional.)

(3) PSI5SjPCIS*n*: PSI5S CPU Interrupt Status ch*n* register (*n*: 0 to 7)
Read the interrupt status register, and check all interrupt factors.

(4) PSI5SjPCISC*n*: PSI5S CPU Interrupt Status ch*n* register (*n*: 0 to 7)
Clear the bit corresponding to the relevant interrupt factor.

(5) Perform the interrupt process that corresponds to the interrupt factor.

Note that processes (3) and (4) must be performed for each interrupt factor bit.

28.5.8.2 Interrupt Processing in UART Mode

This section describes how to process interrupts in UART mode.

Interrupts can occur during both UART reception and UART transmission.

For the processing of interrupts during UART reception, see **Section 28.5.10.1, UART Reception**.

For the processing of interrupts during UART transmission, see **Section 28.5.10.2, UART Transmission**.

28.5.9 DMA Request Processing Procedures

28.5.9.1 DMA Request (Reception) Processing in PSI5S mode

This section describes how to process DMA requests (reception) in PSI5S mode.

DMA requests (reception) can occur on individual channels.

This request processing operation can be used for channels 0 to 7.

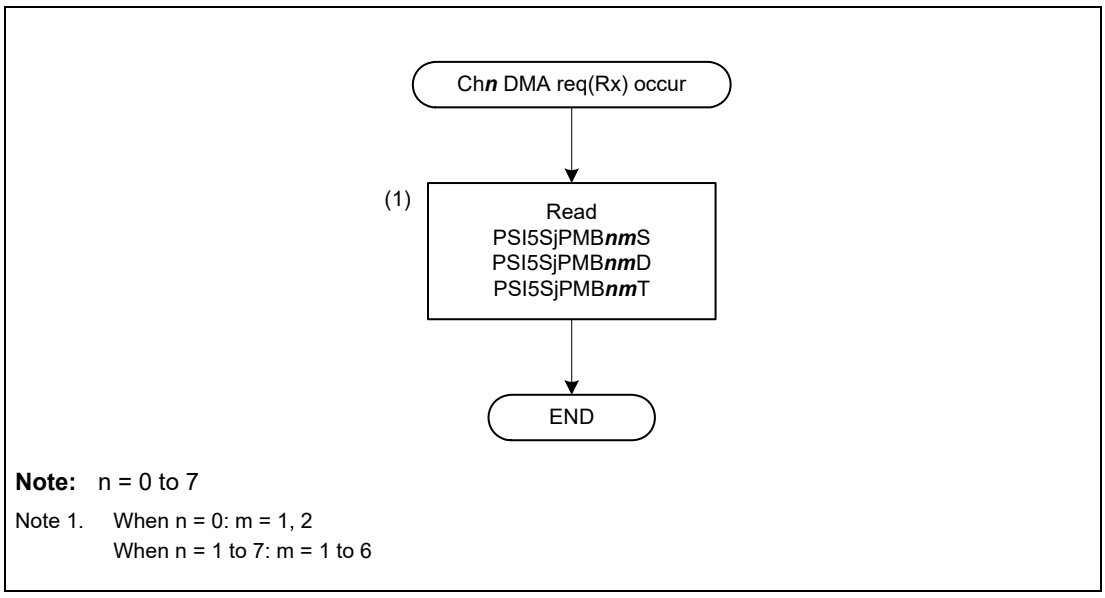


Figure 28.30 Procedure of DMA Request (Reception) Processing in PSI5S mode

(1) PSI5SjPMB*nm*S: PSI5S Receive MailBox ch0 Frm1 Status register (when $n = 0$, $m = 1$ to 2; when $n = 1$ to 7, $m = 1$ to 6)
PSI5SjPMB*nm*D: PSI5S Receive MailBox ch0 Frm1 Data register (when $n = 0$, $m = 1$ to 2; when $n = 1$ to 7, $m = 1$ to 6)
PSI5SjPMB*nm*T: PSI5S Receive MailBox ch0 Frm1 Timestamp register (when $n = 0$, $m = 1$ to 2; when $n = 1$ to 7, $m = 1$ to 6)
Check the mailbox data corresponding to the relevant frame.

NOTE

In asynchronous mode of Ch1 to Ch0, the data storage position is switched from frm1 to frm2, ..., frm6, and frm1, in this order, each time a PSI5 frame is received. Therefore, when received data is to be read by DMA, storage addresses must be managed by software. (Data storage position of Ch0 is always frm1.)

28.5.9.2 DMA Request (Transmission) Processing in PSI5S mode

This section describes how to process DMA requests (transmission) in PSI5S mode.

DMA requests (transmission) can occur on individual channels.

This request processing operation can be used for channels 0 to 7.

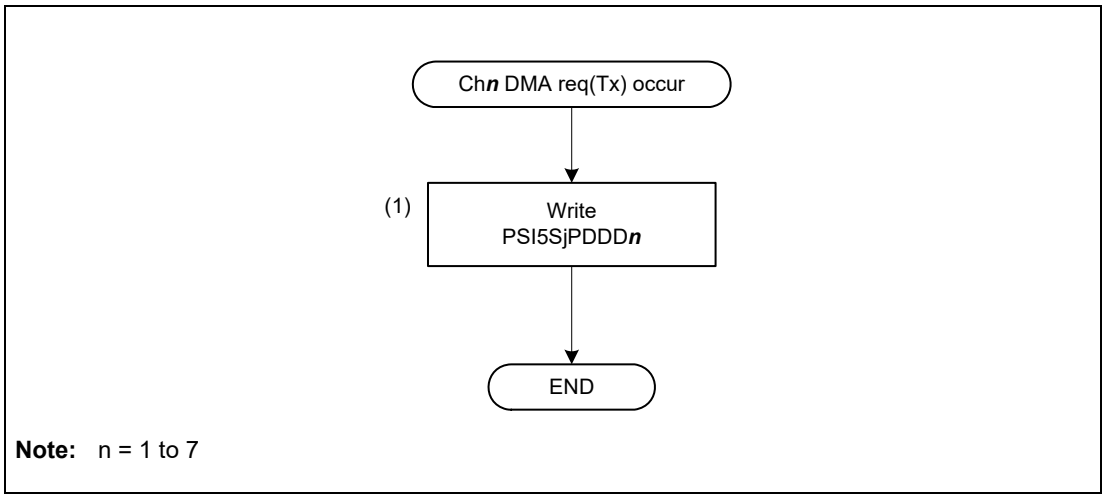

Figure 28.31 Procedure of DMA Request (Transmission) Processing in PSI5S mode

(1) PSI5SjPDDD*n*: PSI5S DDSR Data Ch*n* register (***n***: 1 to 7)
Set transmit data in DDSR.

28.5.9.3 DMA Request (Reception) Processing in UART Mode

This section describes how to process DMA requests (reception) in UART mode.

DMA requests (reception) occur on channel 7.

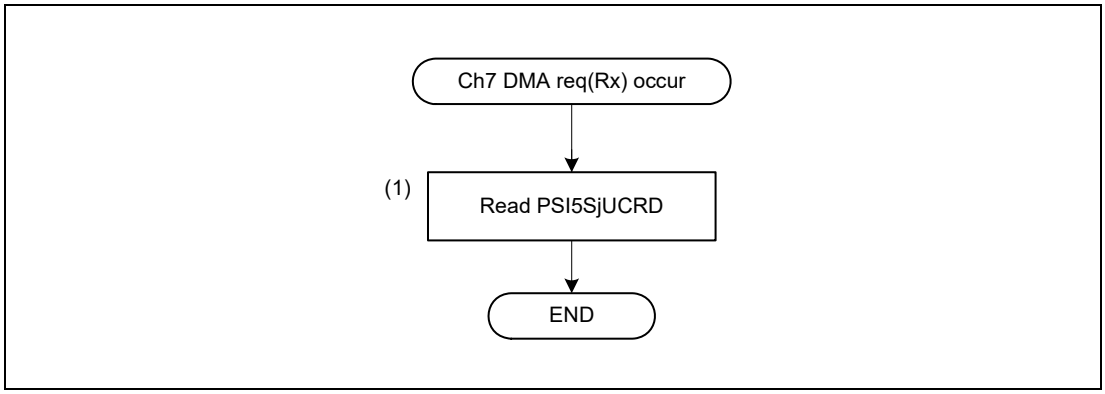

Figure 28.32 Procedure of DMA Request (Reception) Processing in UART Mode

(1) PSI5SjUCRD: UART Communication Rx Data register
Read receive data from this register.

28.5.9.4 DMA Request (Transmission) Processing in UART Mode

This section describes how to process DMA requests (transmission) in UART mode.

DMA requests (transmission) occur on channel 7.

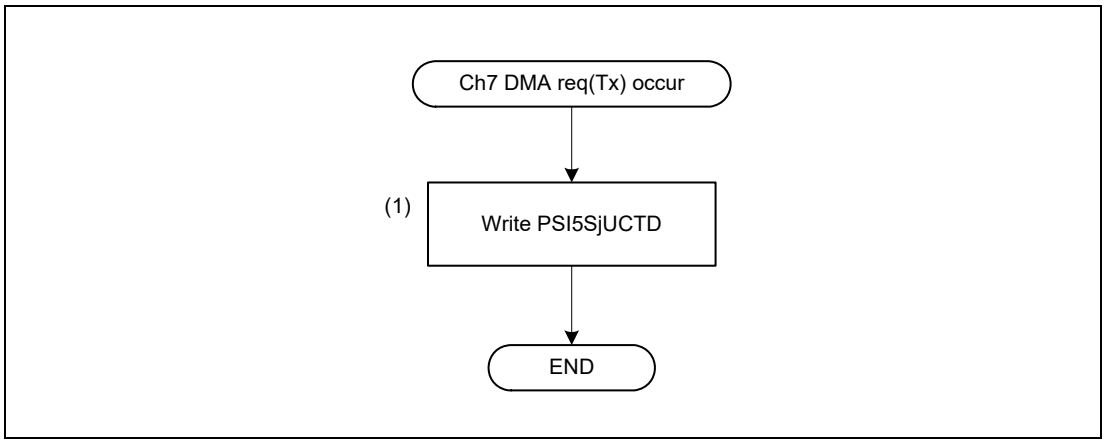

Figure 28.33 Procedure of DMA Request (Transmission) Processing in UART Mode

(1) PSI5SjUCTD: UART Communication Tx Data register
Write transmit data to this register.

28.5.10 UART Mode Communication Procedures

This section describes UART communication procedures.

UART communication can be performed only in UART mode.

28.5.10.1 UART Reception

Figure 28.34 below shows the processing procedure of normal UART reception.

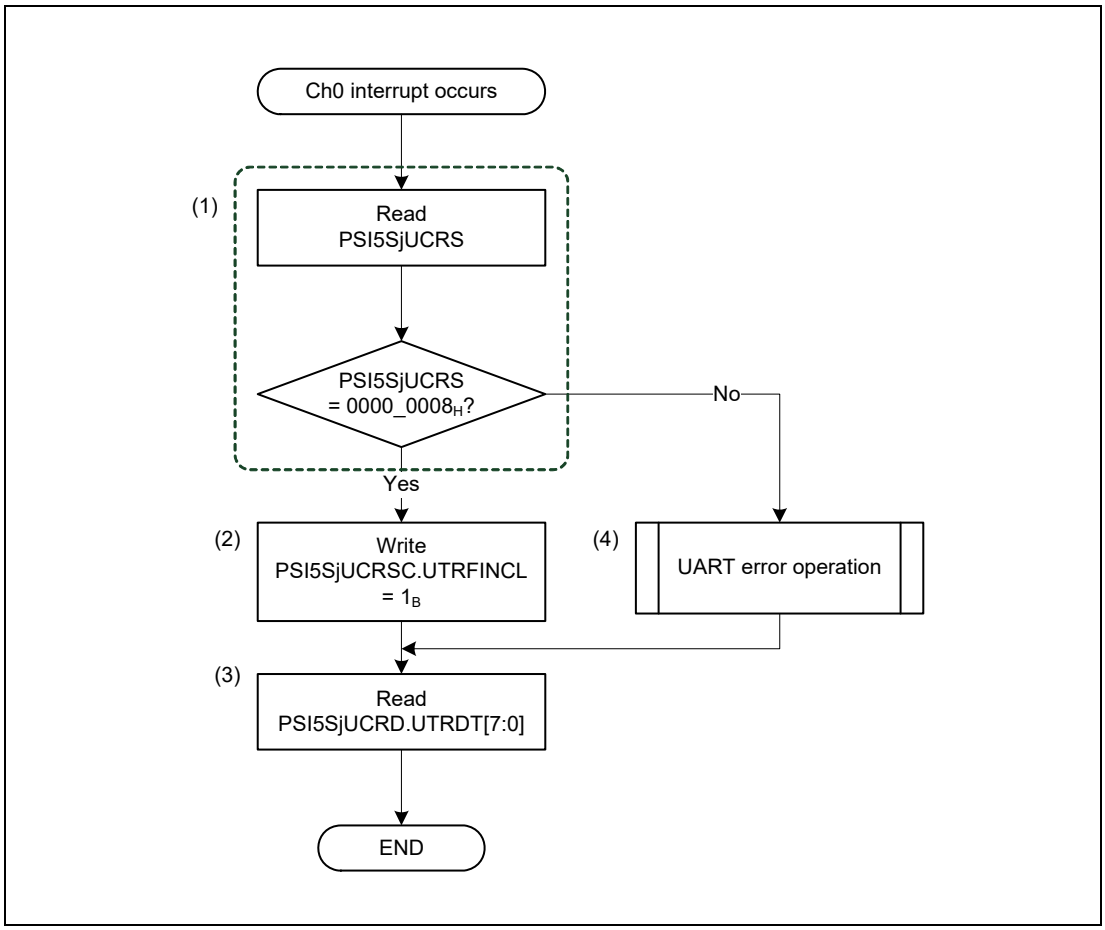

Figure 28.34 UART Reception Procedure

(1) PSI5SjUCRS: UART Communication Rx Status register
Read the UART reception status register, and check that the flag indicating the end of reception is set.

(2) PSI5SjUCRSC: UART Communication Rx Status Clear register
If the flag indicating the end of reception is set, clear it.

(3) PSI5SjUCRD: UART Communication Rx Data register
Read receive data from this register.

Note: If this step is skipped, a reception overrun error occurs at the time of receiving the next data.

(4) If the flag indicating the end of reception is not set, perform error processing.

Figure 28.35 shows the processing to be performed when a reception overrun error, receive framing error, or receive parity error occurs.

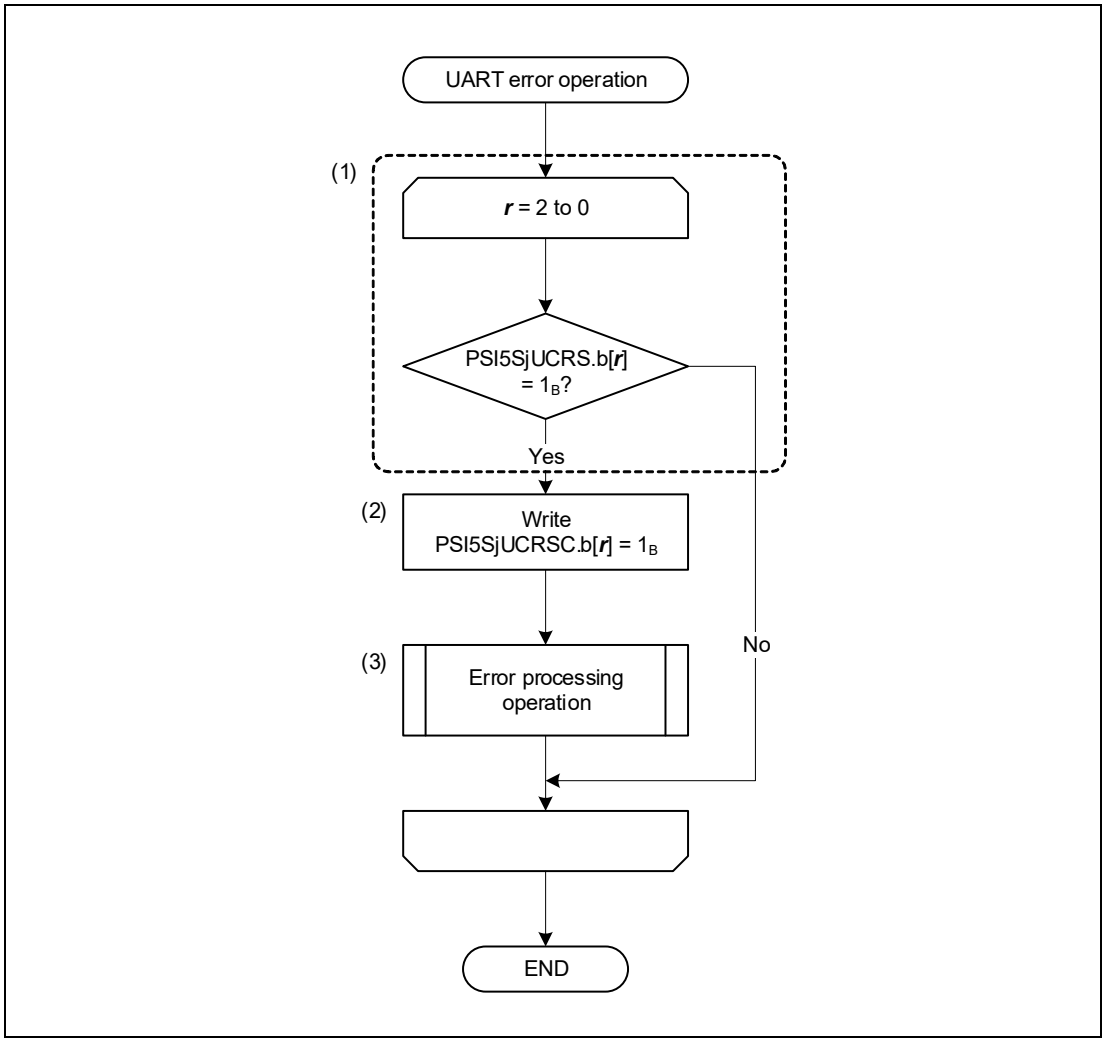

Figure 28.35 UART Reception Error Processing Procedure

(1) Check the states of error factor bits in the UART reception status register.

(2) PSI5SjUCRSC: UART Communication Rx Status Clear register
If an error-cause flag is set, clear the flag.

(3) Perform the processing corresponding to the indicated error cause.

28.5.10.2 UART Transmission

The procedure of UART transmission uses the UART transmission busy flag or the transmission end interrupt.

Figure 28.36 shows the UART transmission procedure using the UART transmission busy flag.

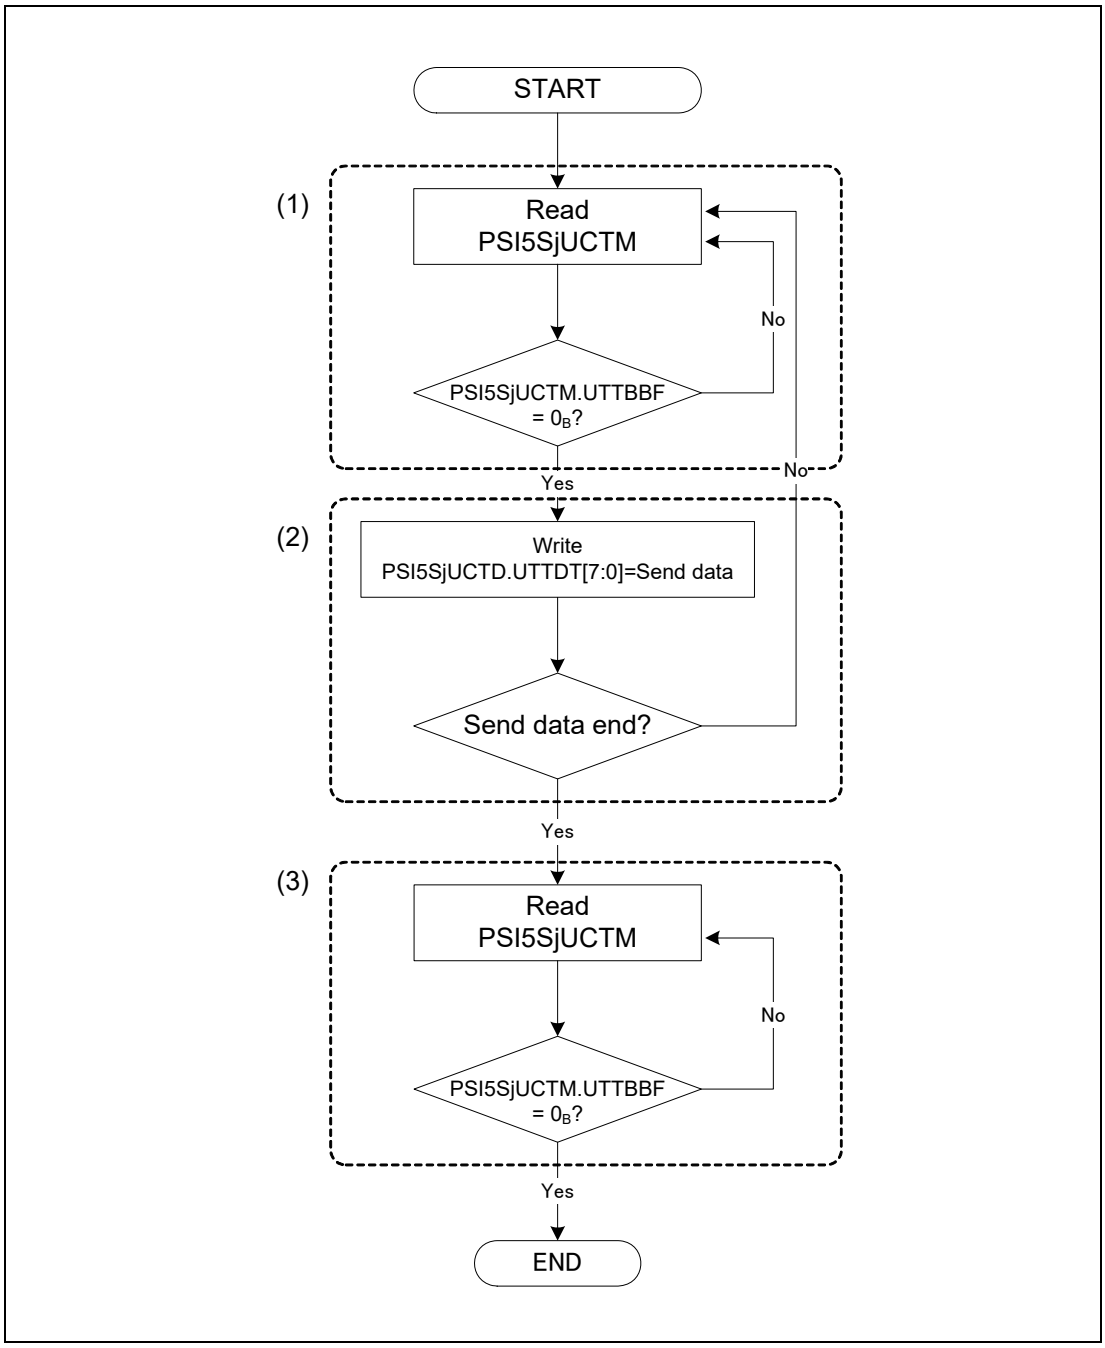

Figure 28.36 UART Transmission Procedure (Using UART Transmission Busy Flag)

(1) PSI5SjUCTM: UART Communication Tx Monitoring register
Read the UART communication Tx monitoring register to check that the UART Tx buffer is not busy.

(2) PSI5SjUCTD: UART Communication Tx Data register
Write transmit data to this register.

(3) PSI5SjUCTM: UART Communication Tx Monitoring register
Read the UART communication Tx monitoring register to check that the UART Tx buffer is not busy.

Figure 28.37 below shows the UART transmission procedure using the transmission end interrupt.

Because no transmission end interrupt of the previous transmission is generated for the first transmission operation, the UART transmission busy flag must be used for the first transmission operation and the transmission end interrupt thereafter.

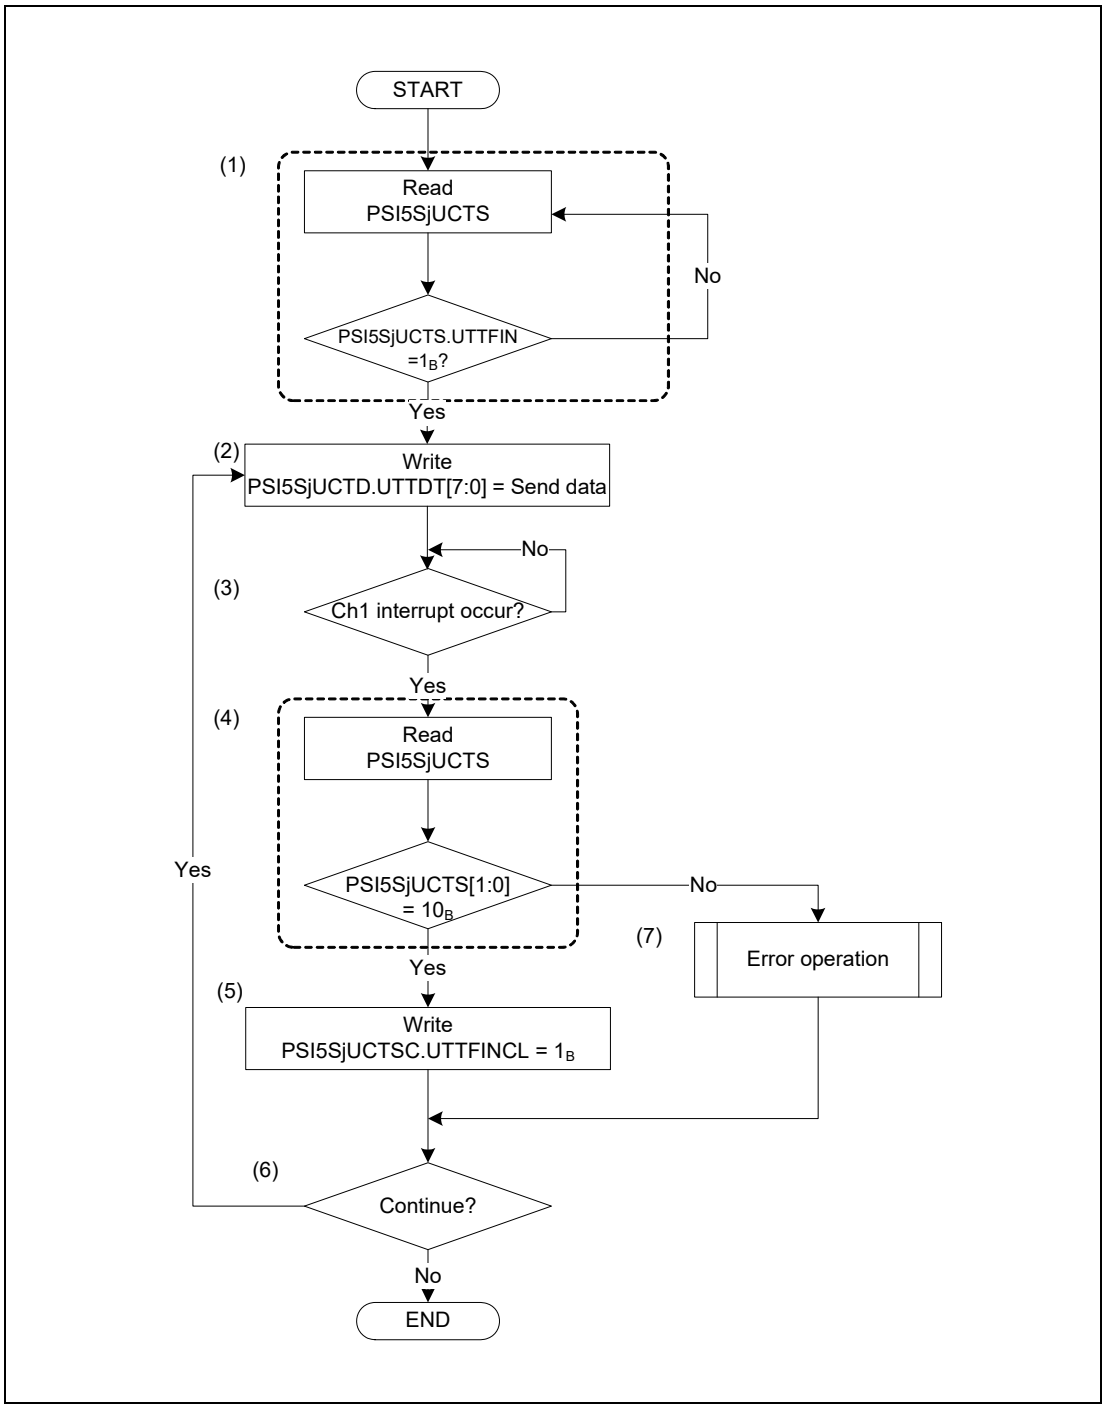

Figure 28.37 UART Transmission Procedure (Using Transmission End Interrupt)

(1) PSI5SjUCTS: UART Communication Tx Status register
Read the UART communication status register to check that the UART is ready for transmission.

(2) PSI5SjUCTD: UART Communication Tx Data register
Write transmit data to this register.

(3) Wait until a channel 1 interrupt occurs. When it occurs, proceed to step (4).

(4) PSI5SjUCTS: UART Communication Tx Status register
Read the UART communication status register to check that the transmission end flag is set and the overwrite error flag is not set.

(5) PSI5SjUCTSC: Uart Communication Tx Status Clear register
Clear the flag indicating the end of transmission.

(6) To continue the processing, proceed to step (2). If not, finish the processing.

(7) Perform the corresponding error processing, see **Figure 28.38**.

Figure 28.38 below shows the procedure of the processing to be performed when a transmission overwrite error occurs.

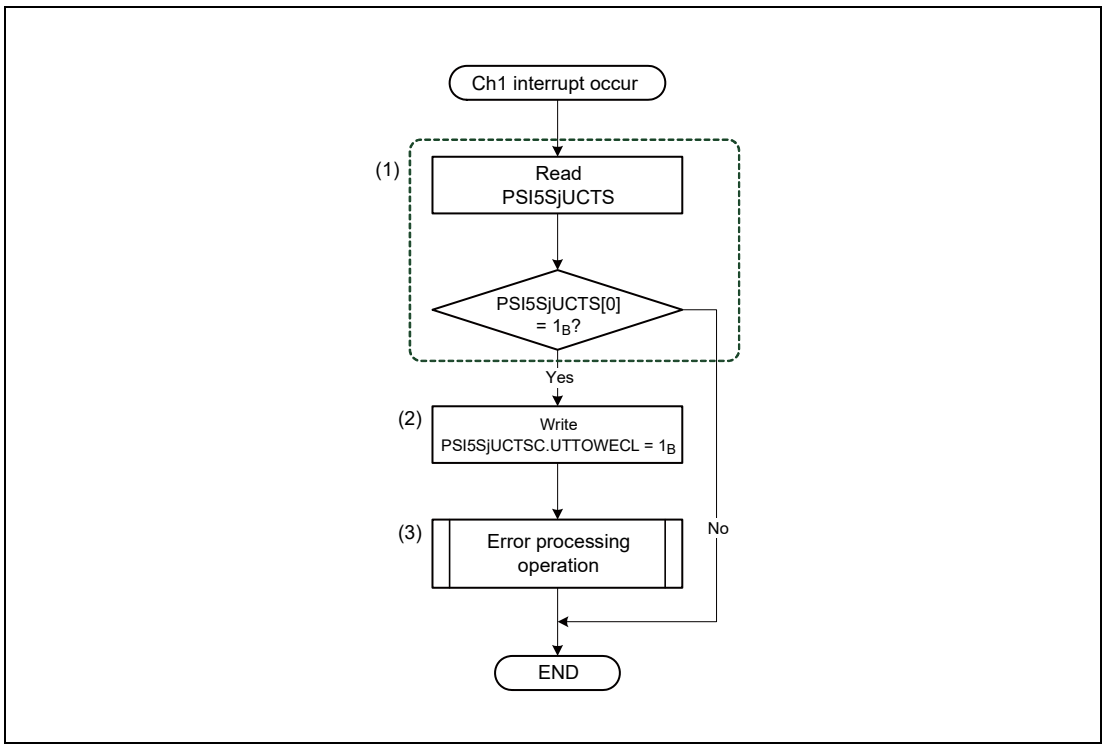

Figure 28.38 UART Transmission Error Processing Procedure

(1) PSI5SjUCTS: UART Communication Tx Status register
Read the UART communication status register to check that the transmission overwrite error flag is set.
If the flag is not set, finish the processing.

(2) PSI5SjUCTSC: UART Communication Tx Status Clear register
Clear the transmission overwrite error flag.

(3) Perform the processing to be done when a transmission overwrite error occurs.

28.5.11 Loopback Test

28.5.11.1 Loopback Test Setting Procedure

This setting procedure must be performed after the common setting procedure (**Section 28.5.1, Common Setting Procedure**).

Figure 28.39 below shows the Loopback test setting procedure.

PSI5S enters the test mode only when the values below are written to the register in the order shown in the figure three times.

If a different value is written midway, the whole procedure becomes invalid. In such a case, perform three new writes from the beginning.

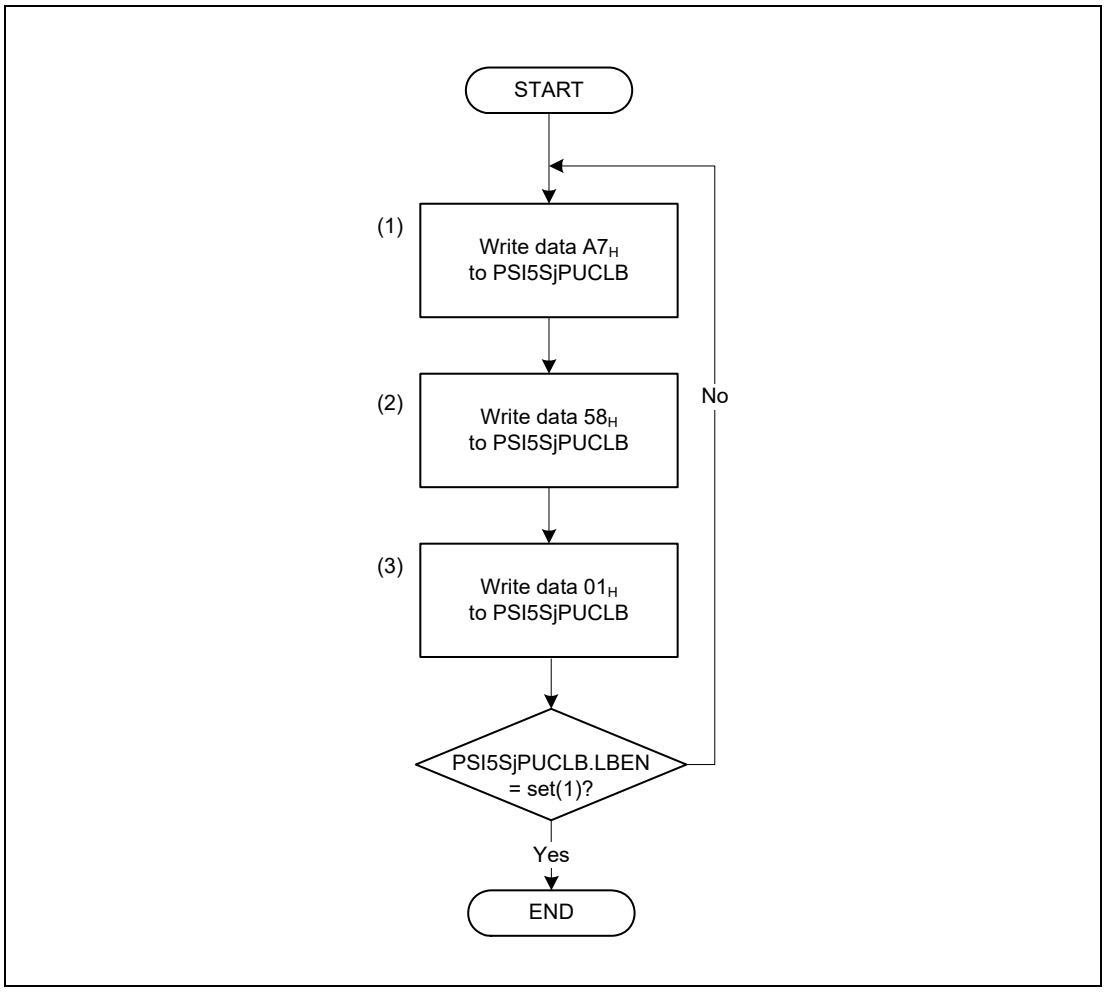

Figure 28.39 Loopback Test Setting Procedure

Then PSI5S mode setting (**Section 28.5.2, PSI5S mode Setting Procedure**) is performed.

The loopback test is performed under the following conditions:

- Communication mode is asynchronous mode.
- Sync commands are not transmitted (sync pulses are not generated).

28.5.11.2 Loopback Test Procedure

This section describes the procedure to perform a loopback test.

As an example, **Figure 28.40** below shows the procedure of the loopback test in which a PSI5 frame (five packets) on pseudo channel *n* (*n*: 1 to 7) are turned back to the reception block and the reception of the frame is checked by using a special function register (SFR).

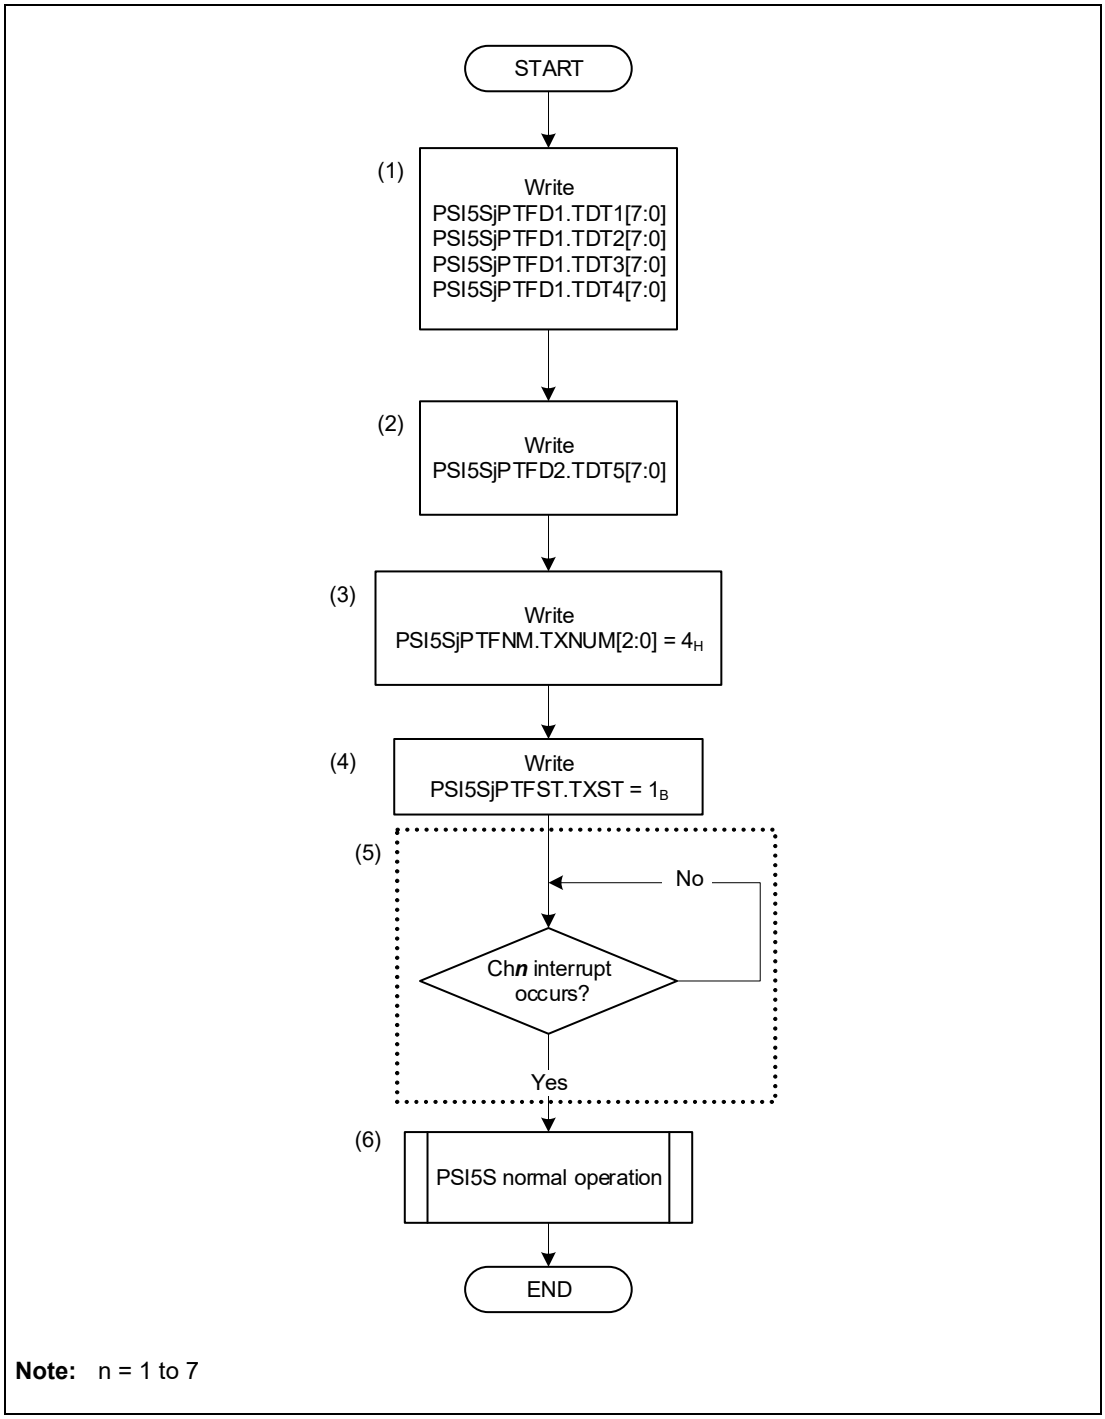

Figure 28.40 Loopback Test Procedure

(1) PSI5SjPTFD1: PSI5S Tx Frame Data1 register
In this register, set the first to fourth bytes of the data (PSI5 frame on pseudo channel *n* [*n*: 1 to 7]) to be transmitted continuously.

(2) PSI5SjPTFD2: PSI5S Tx Frame Data2 register
In this register, set the fifth byte of the data (PSI5 frame on pseudo channel *n* [*n*: 1 to 7]) to be transmitted continuously.

(3) PSI5SjPTFNM: PSI5S Tx Frame Number register
Specify 5-packet transmission (4_H) in this register.

(4) PSI5SjPTFST: PSI5S Tx Frame Start register
Write 1 to this register to start transmission.

(5) Wait until an interrupt outputs on channel *n* (*n*: 1 to 7).

(6) Subsequent processes follow the PSI5 frame reception procedure described in **Section 28.5.6, PSI5 Frame Reception Procedures**.

28.5.12 Configuration Mode Entering Procedure

Figure 28.41 below shows the configuration mode entering procedure.

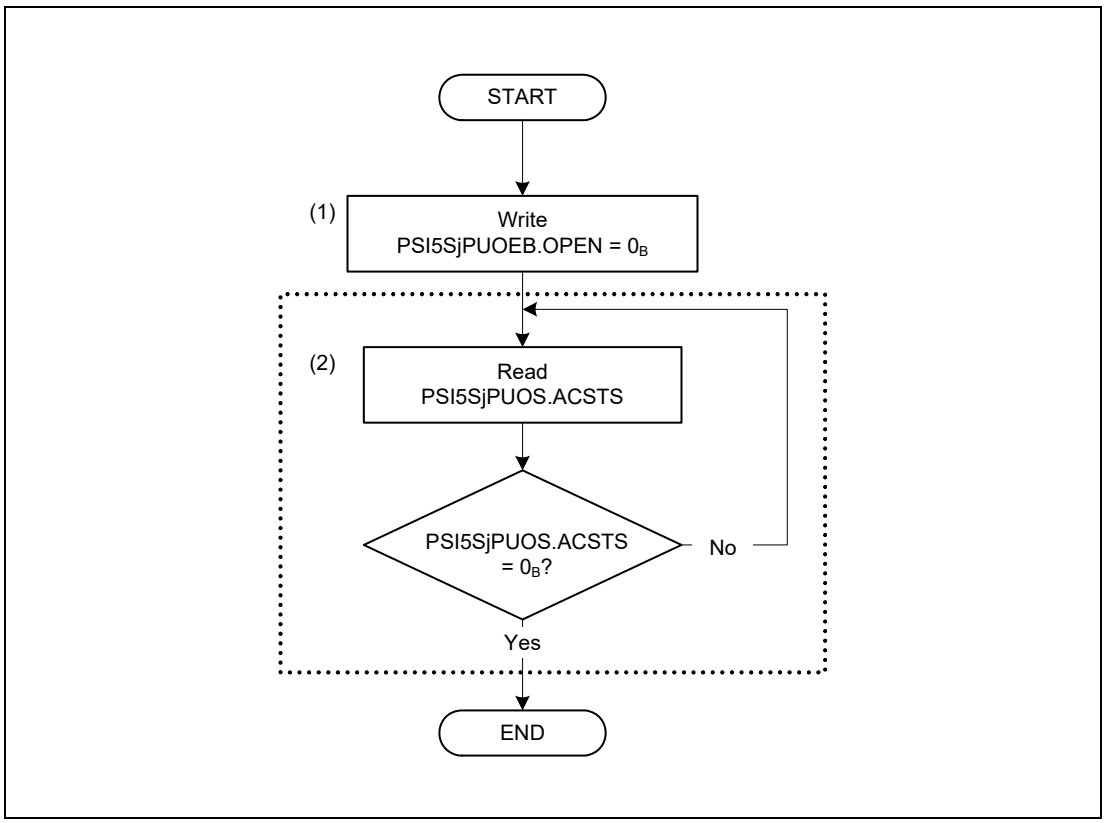

Figure 28.41 Configuration Mode Entering Procedure

(1) PSI5SjPUOEB: PSI5S/UART Operation Enable register
Stop the operation of PSI5S module.

(2) PSI5SjPUOS: PSI5S/UART Operation Status register
Wait until the Active Status bit change to 0.

The timing of return to the configuration mode, see **Section 28.4, Operation Modes**.

28.6 Operations

This chapter describes the functional configuration of PSI5S and PSI5S operations in individual operation modes.

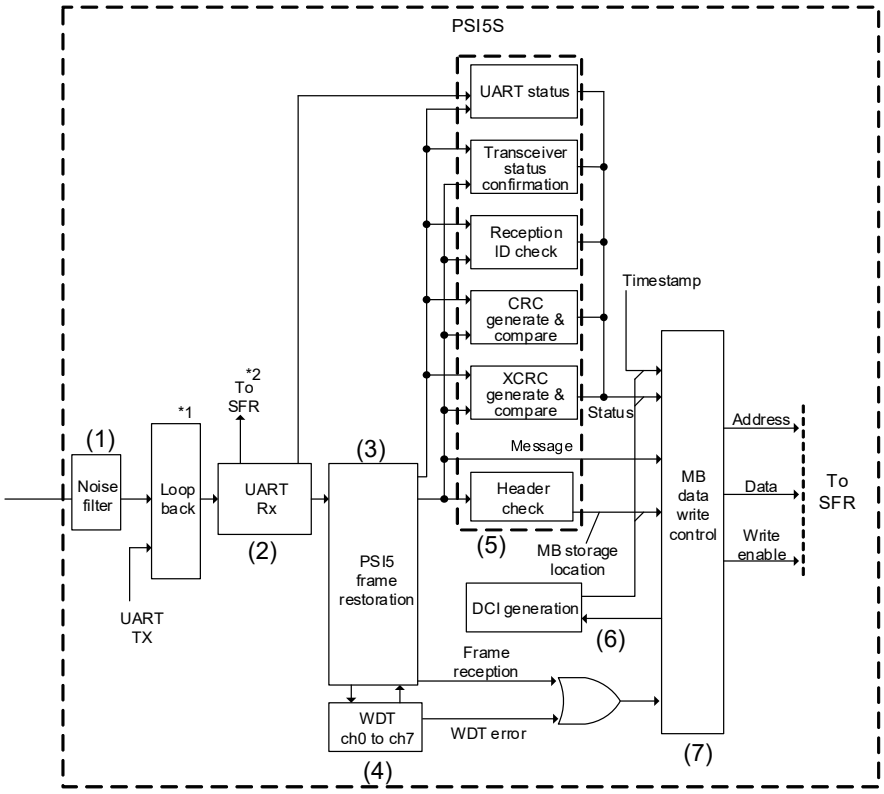
28.6.1 Functional Configuration

The sections that follow describe the functions of PSI5S.

28.6.1.1 PSI5S Reception Function

PSI5S receives sensor-to-ECU data, and stores the status (if a reception error is detected), received data, and timestamp in SFR.

Figure 28.42 below shows the block diagram for PSI5S reception.



(1) Take the majority of received signals to remove the noise.
(2) Perform UART reception, and output 1-byte data and reception error.
(3) Receive UART frames. If the idle time longer than the specified value has elapsed, the next frame is regarded as a header. After the header reception, check the number of frames by ChID and FrmID. If the specified number of frames has been received, it is restored as PSI5 frames.
(4) Monitor whether PSI5 frames of each channel receive a specified number of packets within the time. WDT errors are generated if the time expires without receiving.
(5) Generate the followings from the restored PSI5 frame data.
· After generating XCRC/CRC, the error determination status value, UART status flag, and status value from the header
· Message data
· MB storage location address from ChID and FrmID in the reception header
(6) Generate the 4-bit DCI value and update it after MB data for 3 addresses is written. MB data is configured by combining the DCI value with status/message/timestamp data.
(7) When the WDT error or frame is received, it is stored to the MB storage location in the order of status, message, and timestamp.

Note 1. When loopback is set, UART transmit data is wrapped.
Note 2. When data is received in UART mode, the received data and status are output to SFR.

Figure 28.42 Block Diagram for PSI5S Reception

For the timing of reception, see **Figure 28.74**.

The following figure shows the flow of data reception.

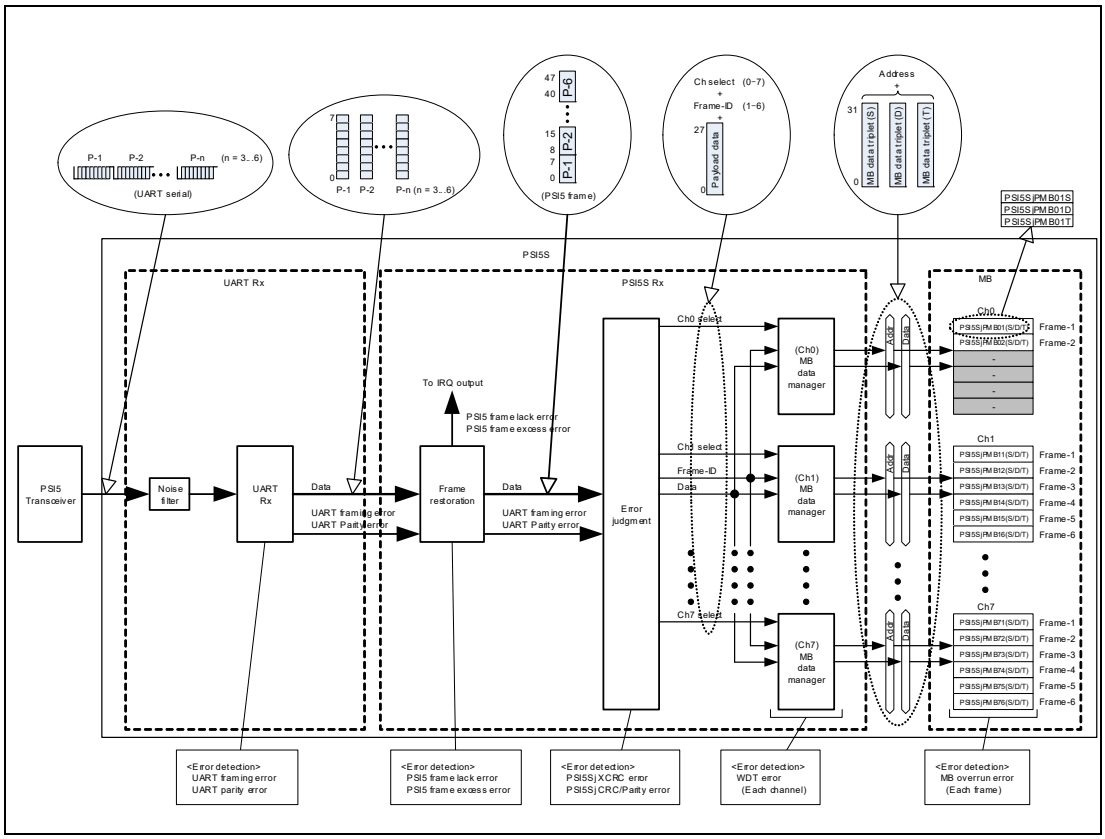


Figure 28.43 PSI5S Reception Data Flow

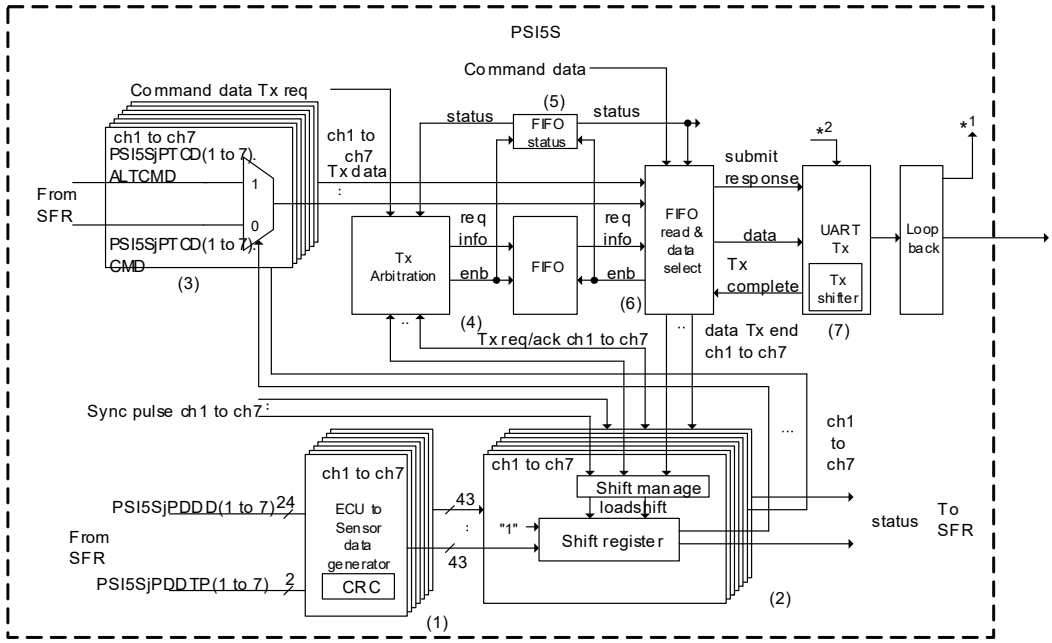
28.6.1.2 PSI5S Transmission Function

PSI5S generates ECU-to-sensor data, and transmits a Sync command when it is triggered by a synchronization pulse on individual channels.

PSI5S also has a function to transmit the data set by the CPU via SFR.

The following figure shows the block diagram for PSI5S transmission.



(1) After transmission data is updated, calculate the 6-bit or 3-bit CRC value according to the PSI5 type.
After the calculation, generate ECU to sensor data by the start bit, data, and CRC value.
(The length of data differs according to the PSI5 type.)
(2) After ECU to sensor data is generated, load the data to the shift register.
Output data in 1-bit unit by sync pulse with starting from the start bit.
Shift register is shifted by data Tx end, and continue to output after the load of status flag to the shift of last data.
(3) Select PSI5SjPTCD.ALTCMD or CMD by the value output in (2) above. After the selection, generate 1-byte data by combining it with ChID.
(4) To carry out arbitration in response to a request from the CPU or Sync pulse. Request information sequentially to the transmission FIFO.
(5) Generate status (full/empty) by write/read pointer to the FIFO.
(6) If request information of 1 or more is in the FIFO, read it.
Output the transmission start and select data signal to UART transmission unit.
(7) Generate the UART frame data by the transmission start signal, and perform UART transmission.
When the stop bit is transmitted, output the transmission complete signal.

Note 1. When loopback is set, UART transmission data is wrapped and not output externally.

Note 2. When data is updated by CPU write in UART mode, perform UART transmission.

Figure 28.44 Block Diagram for PSI5S Transmission

For the timing of the transmission, see **Figure 28.68**.

Transmit requests between command data (**Section 28.6.2.3, Normal Transmission (Command Data)**) and ECU-to-sensor data (**Section 28.6.2.4, Normal Transmission (ECU-to-Sensor Data)**) are arbitrated, and then UART starts transmission.

Figure 28.45 below shows the block configuration related to the transmit request arbitration function.

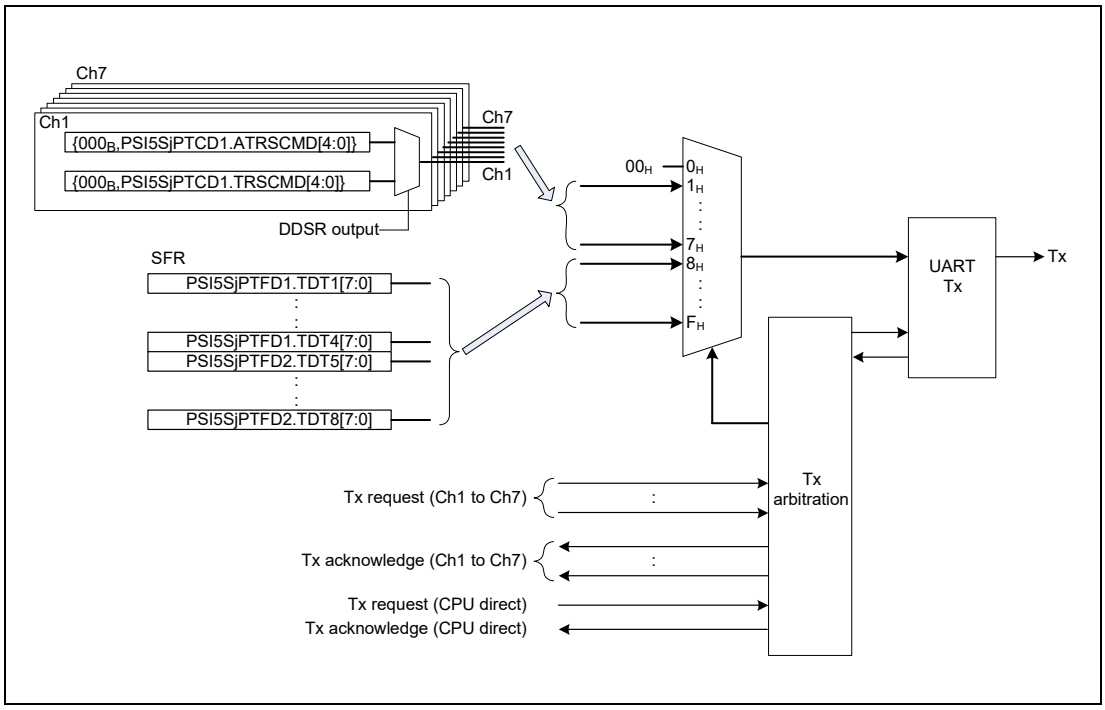


Figure 28.45 Block Diagram for Transmit Request Arbitration

28.6.1.3 Timestamp Generation Function

Based on the timing of clock input from the GTM or the timing of a divided clock (1 to 1023 µs in 1-µs steps) generated from PCLK, a timestamp counter runs to measure time. PSI5S has two timestamp counters for timestamps A and B, and the timestamp counters can be enabled and cleared together or separately.

In synchronous mode of Ch1 to Ch7, the timestamp value is captured at the timing of PSI5 frame header reception or the synchronization pulse. In asynchronous mode of Ch1 to Ch7, the timestamp value is captured in the timing of PSI5 frame header reception. In asynchronous mode of Ch0, the timestamp value is captured in the timing of PSI5 frame header reception. (Ch0 is always asynchronous mode.) The timestamp value of Ch0 is also captured at the timing of a WDT error occurs in any of the channels.

Timestamp capture values are available for channels 0 to 7. When PSI5 frame reception ends, one of the timestamp capture values is selected according to the channel ID in the header, and used as a timestamp value. If the received frame is an invalid frame, the timestamp capture value for channel 0 is selected. Determination of invalid frames follows the specifications listed in **Table 28.94** and **Table 28.96**. If a WDT error occurs, the timestamp capture value of Ch0 is used as the timestamp value.

Note that timestamp capture values are all zeros when the timestamp capture enable bit (PSI5SjPRCF1n.TSEN) is 0 (disable). Also, the timestamp capture values can be cleared by the clear bit (PSI5SjPTCDCn).

Figure 28.46 below shows the block diagram for the timestamp generation function.

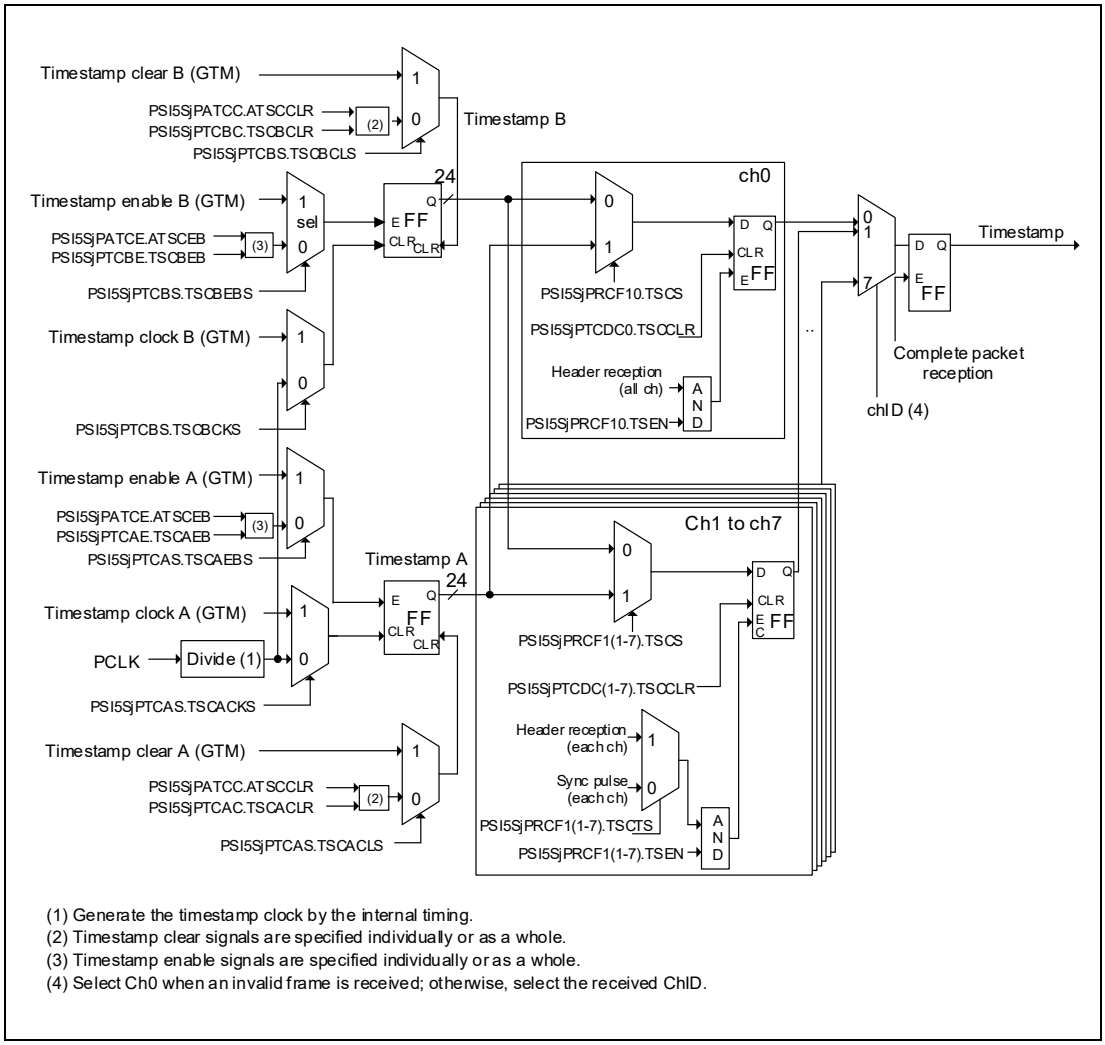

Figure 28.46 Block Diagram for Timestamp Generation

Figure 28.47 below shows an operation in which a timestamp capture value is fetched when the header of a PSI5 frame is received, and a timestamp value is generated when PSI5 frame reception ends.

The same operation can be performed in both synchronous and asynchronous modes.

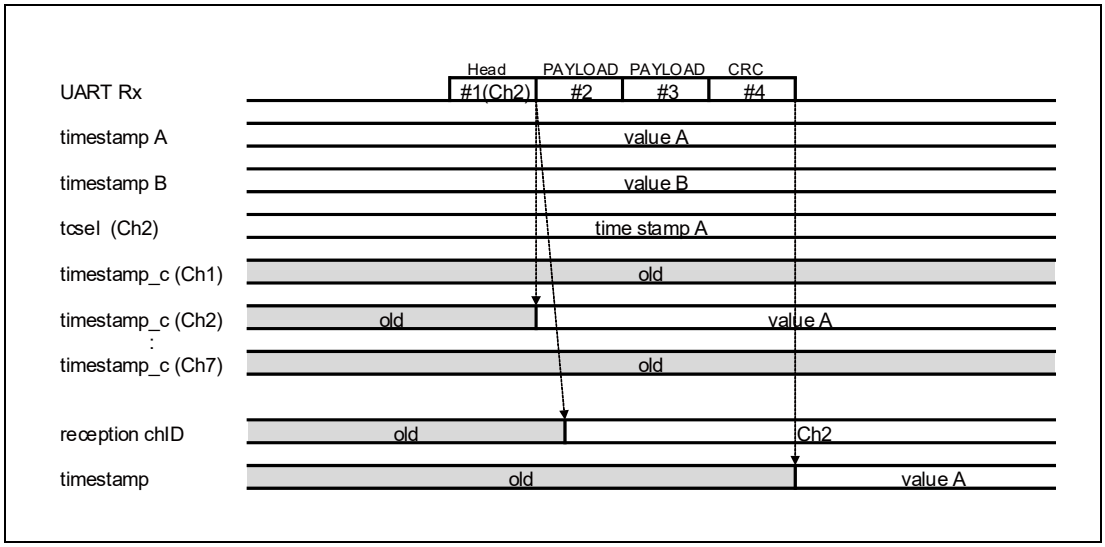

Figure 28.47 Timestamp Generation Operation (Timestamp Capture Triggered by Header Reception)

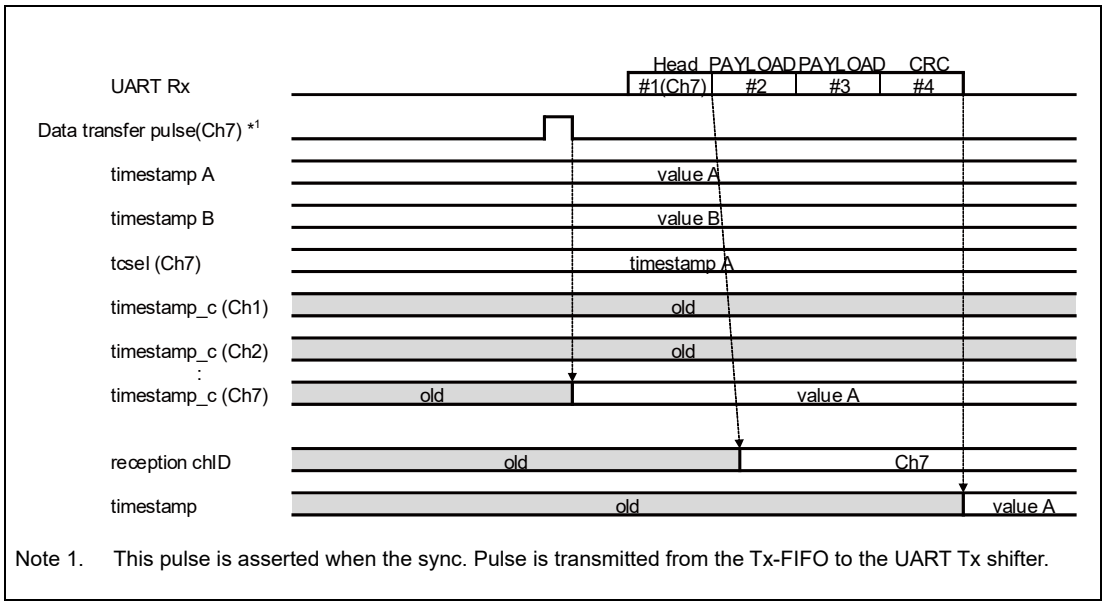
Figure 28.48 below shows an operation in which a timestamp capture value is fetched when a synchronization pulse outputs, and a timestamp value is generated when PSI5 frame reception ends.

This operation can be performed only in synchronous mode.



Note 1. This pulse is asserted when the sync. Pulse is transmitted from the Tx-FIFO to the UART Tx shifter.

Figure 28.48 Timestamp Generation Operation (Timestamp Capturing Triggered by Synchronization Command Transmission)

Figure 28.49 below shows an operation in which a timestamp capture value is fetched when a WDT error occurs, and a timestamp value is generated immediately.

The same operation can be performed in both synchronous and asynchronous modes.

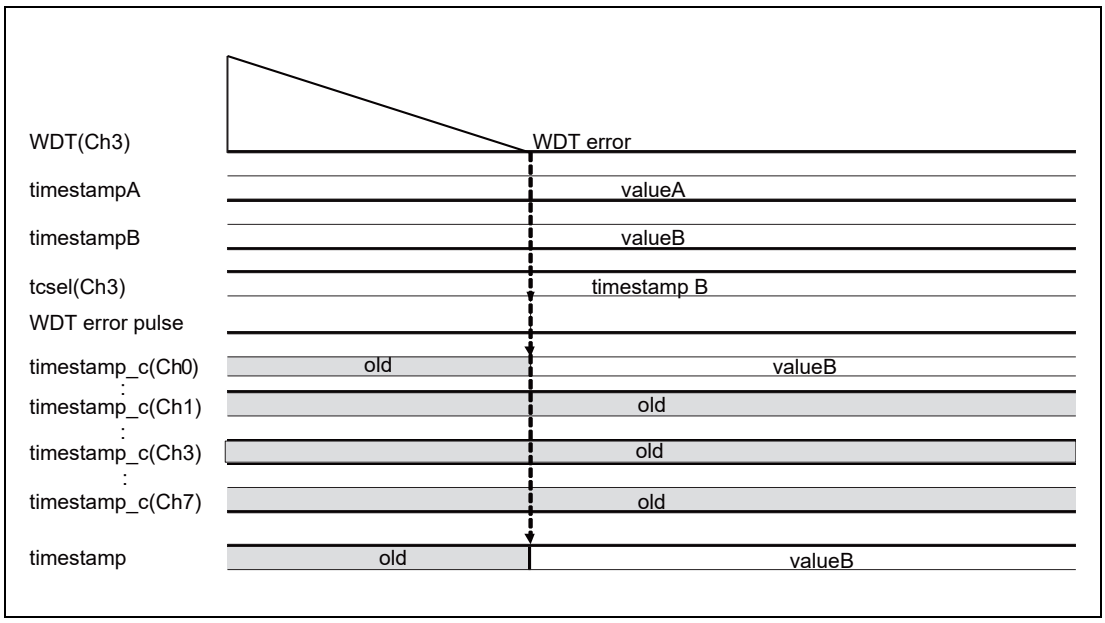


Figure 28.49 Timestamp Generation Operation (Capturing Triggered by WDT Error)

28.6.1.4 Synchronization Pulse Generation Function

The timing of the synchronization pulse for channels 0 to 7 is selected from the rising edge of the synchronization trigger signal for each channel input from the GTM or the timing of a divided clock (1 to 1024 µs in 1-µs step) generated from PCLK.

The divided clock timing generation function operates when the function is selected in SFR and its operation is enabled (PUOEB.OPEN = 0x1). With other settings, counters stop with a counter value of 0.

Interval of the synchronization pulse for each channel should be longer than time of the number of packets to be received. Otherwise, operation of the PSI5S module will be unpredictable.

The following figure shows a block diagram for the synchronization pulse generation circuit:

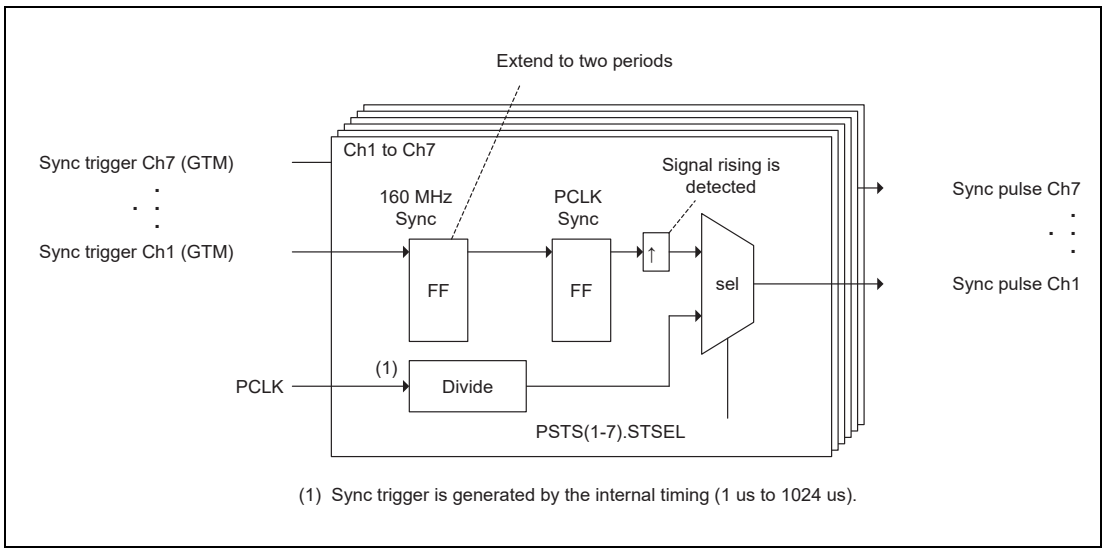

Figure 28.50 Block Diagram for Synchronization Pulse Generation

Figure 28.51 below shows an outline of the operation in which synchronization pulses are generated.

Synchronization pulses are generated by synchronizing the Sync trigger signal from the GTM with PCLK.

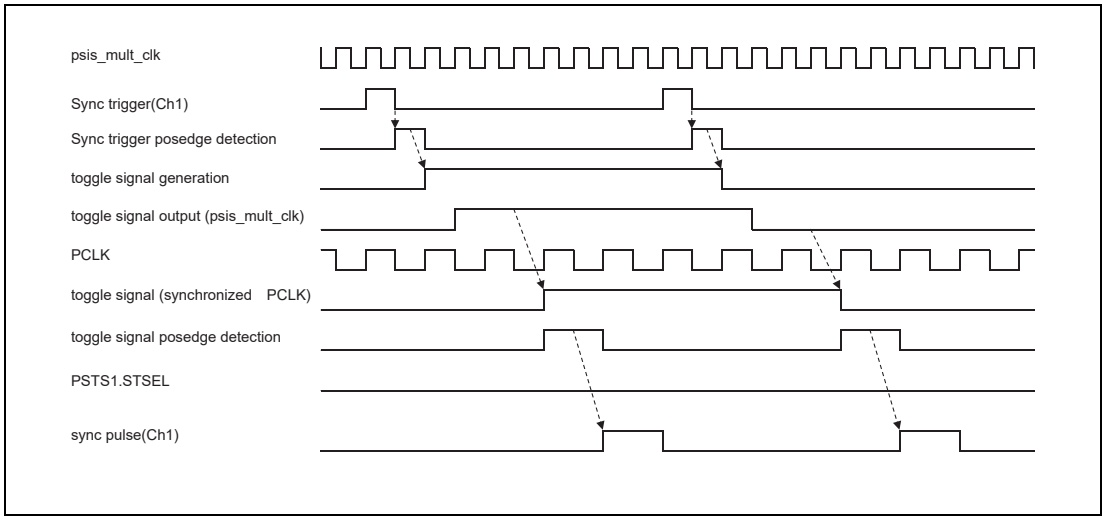

Figure 28.51 Synchronization Pulse Generation Operation (Input from the GTM)

The synchronization pulses (sync pulse signals) are also generated by a frequency divider.

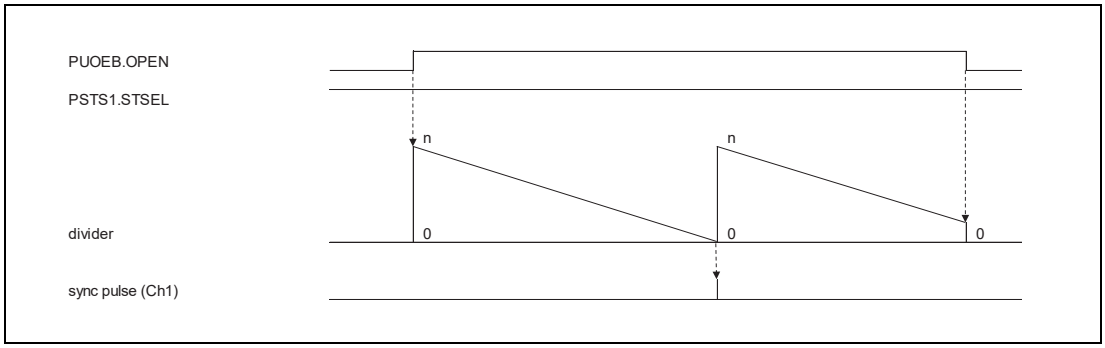

Figure 28.52 Synchronization Pulse Generation Operation (Internal Timing)

28.6.2 Operations in PSI5S mode

PSI5S performs UART reception of four to six frames when the operation mode is set to PSI5S mode (PSI5SjPUOMD.OPMD = 1_H) and the module operation is enabled (PSI5SjPUOEB.OPEN = 1_H).

PSI5S restores PSI5 frame data with corresponding functions shown in **Figure 28.42**.

After restoring the data, PSI5S checks for reception errors, and then stores data (such as the status value generated from the received frame data, payload value of the received frame data, and the timestamp value generated as described in **Section 28.6.1.3, Timestamp Generation Function**) as mailbox data in SFR.

The following figure shows the flow of reception.

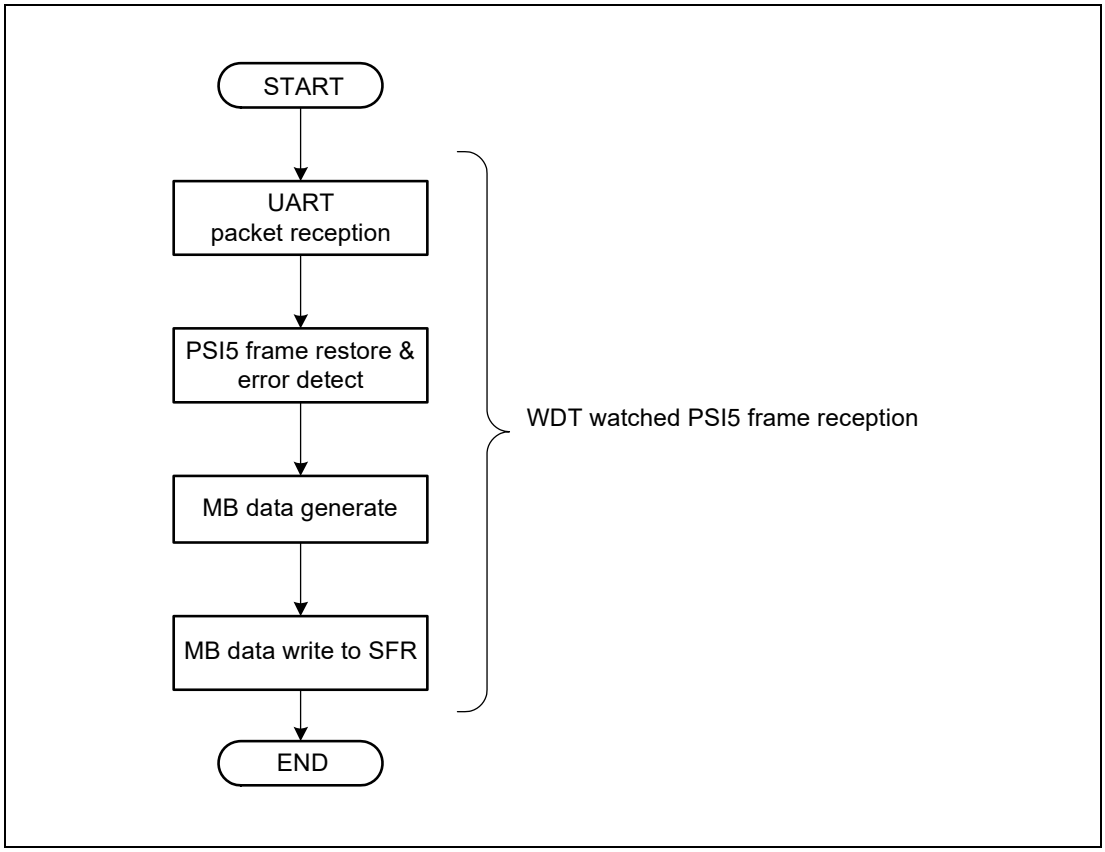

Figure 28.53 Flow of Reception

28.6.2.1 Normal Reception (in Synchronous Mode)

PSI5S performs reception according to the flow shown in **Figure 28.53**.

In synchronous mode, PSI5S starts reception with the synchronization pulse for each channel used as the trigger, and receives a specified number of PSI5 frames.

A WDT installed for each channel is used to monitor reception to determine whether the specified number of PSI5 frames are received within a specified time.

(1) Receiving UART Frames

PSI5S receives UART frames, and restores PSI5 frame data.

For the UART specifications, see **Section 28.2.1, Functional Overview**.

UART receive data is filtered by a noise filter (filtering of three prescaler cycles of data signal based on a majority decision) according to the settings.

Sampling enable generate counter and Sampling counter is reset and UART reception starts when the start bit is detected at a sampling point that starting from the falling edge detection after noise filtering.

NOTE

A sampling point is different in oversample number (odd or even).

Figure 28.54 and **Figure 28.55** below show examples of UART reception.

The following example assumes that the oversample number is set to 5_H.

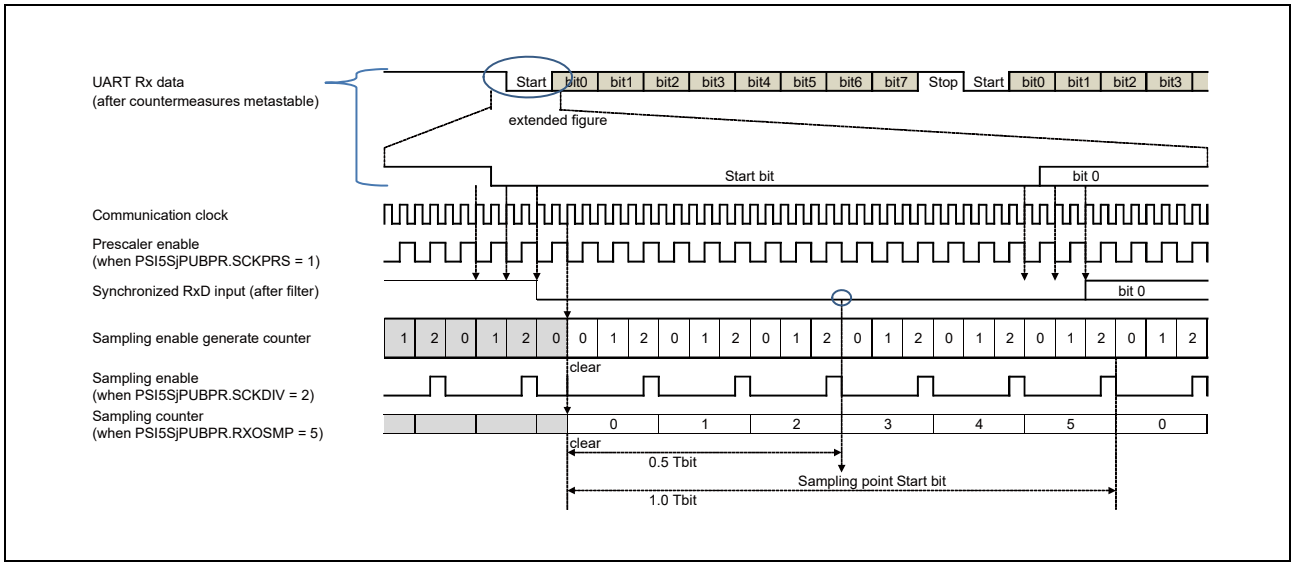

Figure 28.54 UART Frame Reception Start (PSI5SjUBPR.RXOSMP = 5 [ODD])

The following example assumes that the oversample number is set to 4_H.

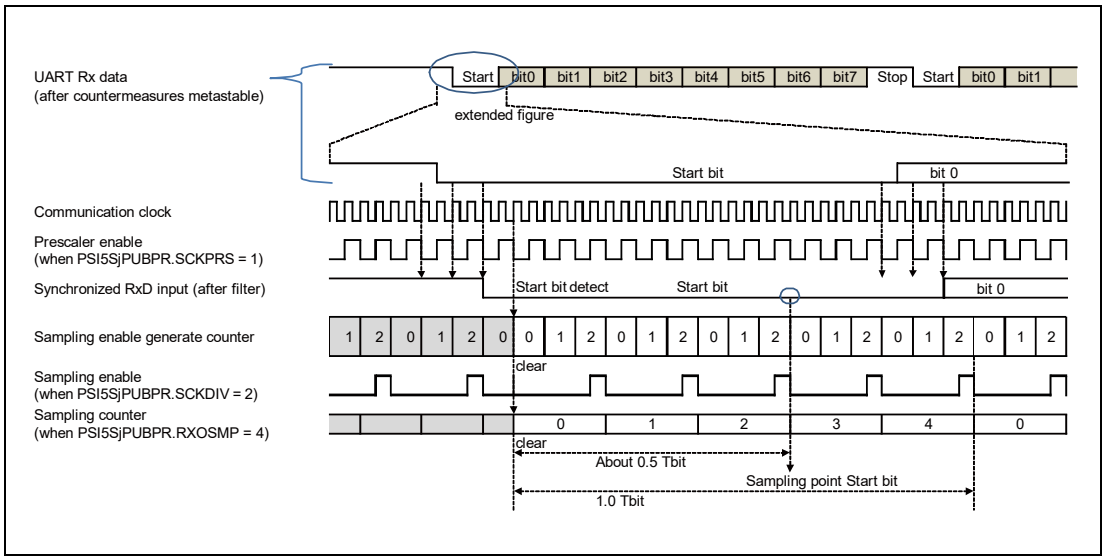

Figure 28.55 UART Frame Reception Start (PSI5SjUBPR.RXOSMP = 4 [EVEN])

Figure 28.56 below shows an example of an operation in which UART frames are received continuously.

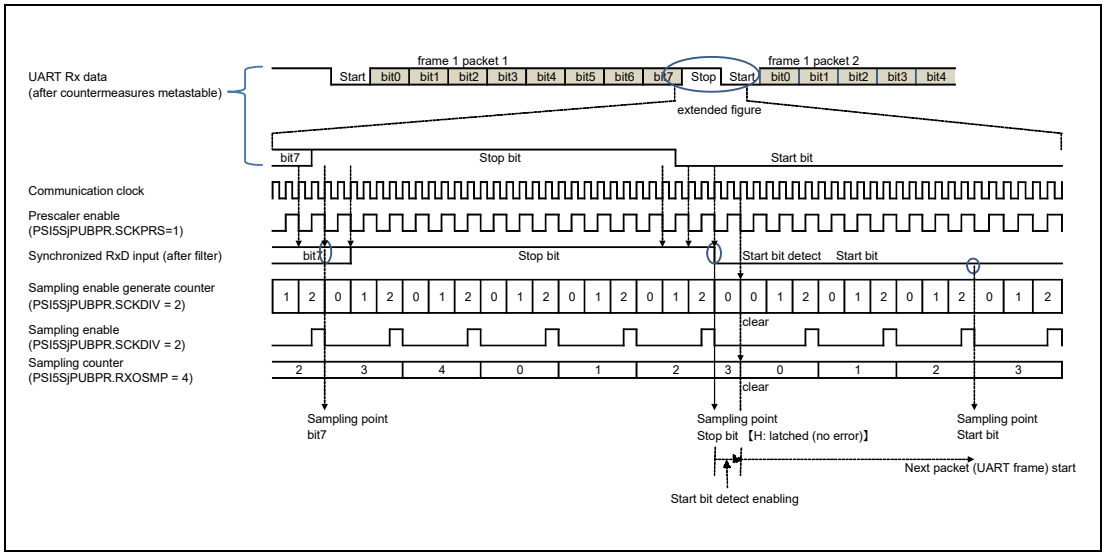

Figure 28.56 UART Frame Reception End (Frame Continue) (PSI5SjPRCF10.PFRMIDLE = 0)

Figure 28.57 below shows an example of an operation in which the last packet frame is received.

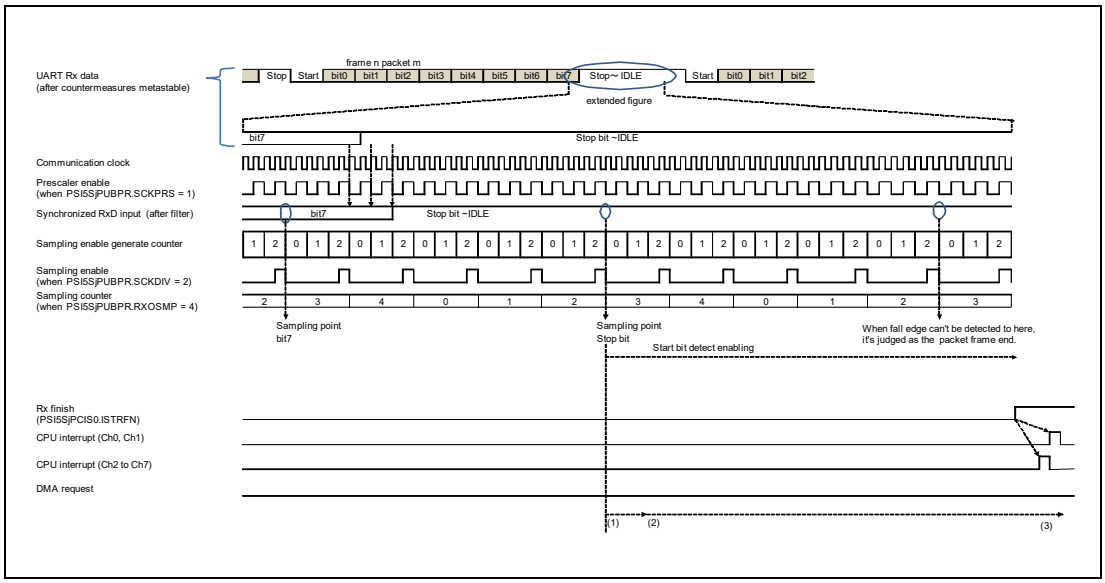

Figure 28.57 UART Frame Reception End (Packet Frame End) (PSI5SjPRCF10.PFRMIDLE = 0)

(1) The stop bit of the last packet is detected.

(2) The asynchronous transfer processing based on PCLK and the communication clock, causes a delay of several clock cycles.

(3) After 50-60 cycles of PCLK (for restoring PSI5 frame data, determining errors and storing mailbox data), the flag indicating the end of reception is set (PSI5SjPCIS0.ISTRFN = 1) and an interrupt is output.

Figure 28.58 below shows an example of an operation in which the end of packet frame is detected.

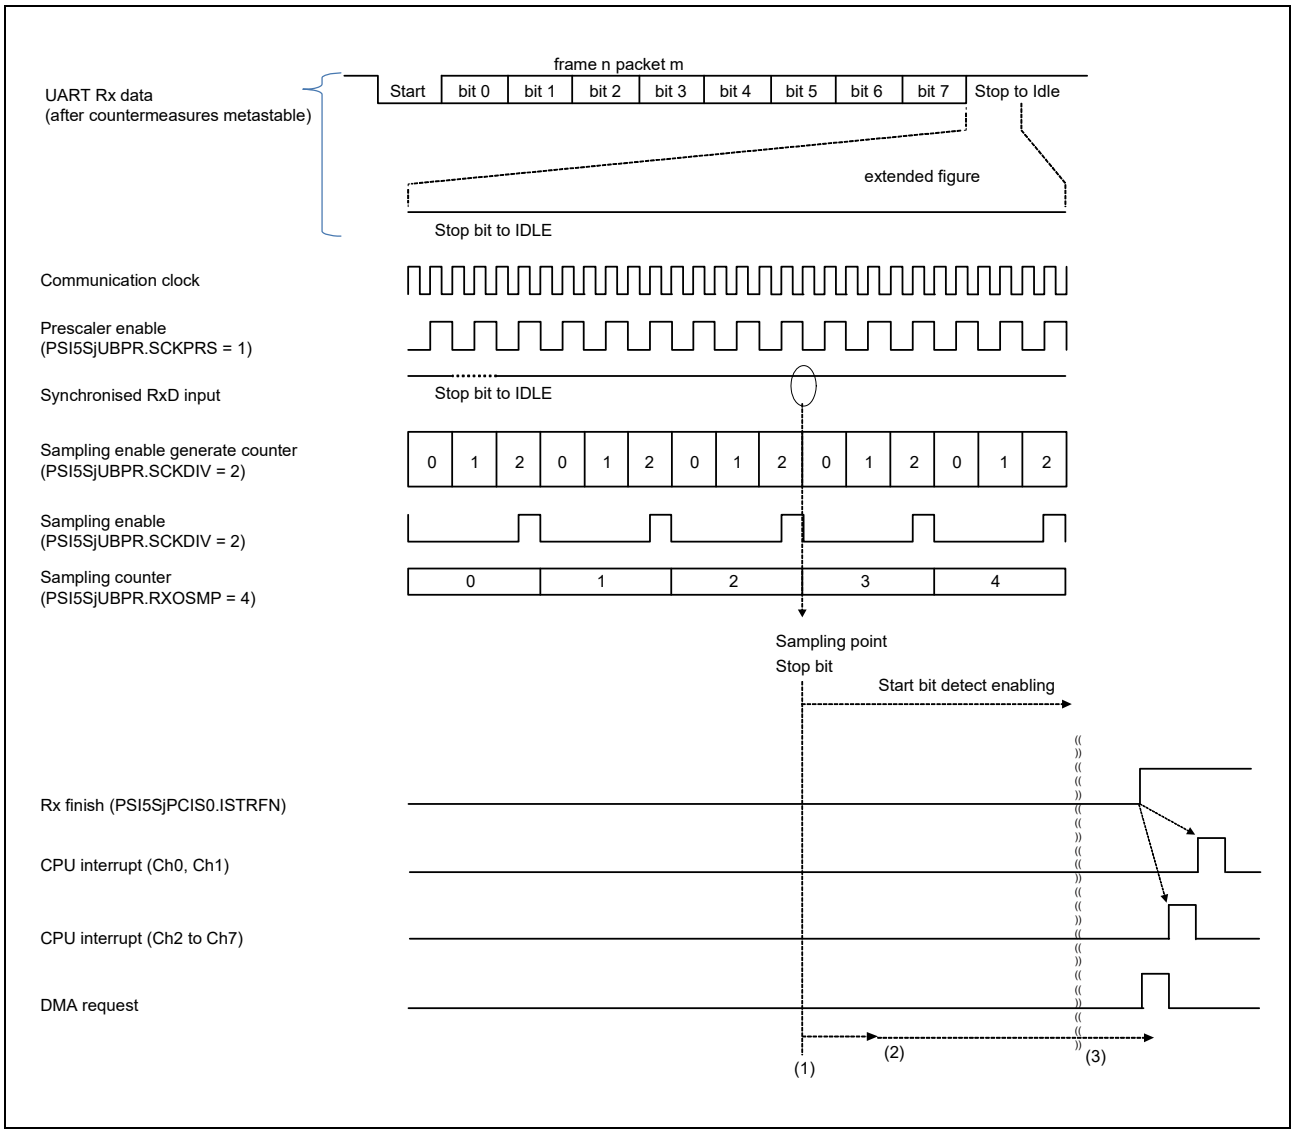

Figure 28.58 UART Frame Reception (Channel End) (PSI5SjPRCF10.PFRMIDLE = 0)

(1) When the stop bit of the last packet is detected, the flag indicating the end of reception is set (PSI5SjPCIS0.ISTRFN = 1).
The asynchronous transfer processing based on PCLK and the communication clock causes a delay of several clock cycles.

(2) After 50-60 cycle of PCLK (for Restoring PSI5 frame data, determining errors and storing mailbox data), the flag indicating the end of reception is set (PSI5SjPCIS0.ISTRFN = 1) and an interrupt outputs.
When reception of all packet frames in a channel ends, an interrupt and a DMA request are output.

PSI5 frame data consists of a header, payload, and XCRC bits (**Figure 28.3**).

UART frames are input successively, and the maximum interval to the next packet frame is specified in the PSI5SjPRCF10. PFRMIDLE[3:0] bits.

If the actual interval between frames exceeds the specified value, the UART frame that is received next is treated as a header.

After the header of a frame is received, the number of received packets in the frame (PSI5SjPRCF1(0-7).F(1-6)PKT) is referenced according to the channel ID and frame ID in the header. The number of packets to be received is determined from the number of already received packets. When FrmID is not 0_H in ch0, the number of packets to be received is 6_H (maximum value). When FrmID is an illegal value (6_H or 7_H) in ch1 to ch7, the number of packets to be received is 6_H (maximum value).

If excess or deficiency of the number of packets to be received is detected, reception error occurs. For details, see **Section 28.6.2.7, Abnormal Reception (Reception Error)**.

If too few packets are received, the received packets are not stored.

If a WDT error occurs, the received packets at the time of the WDT error occurrence are stored.

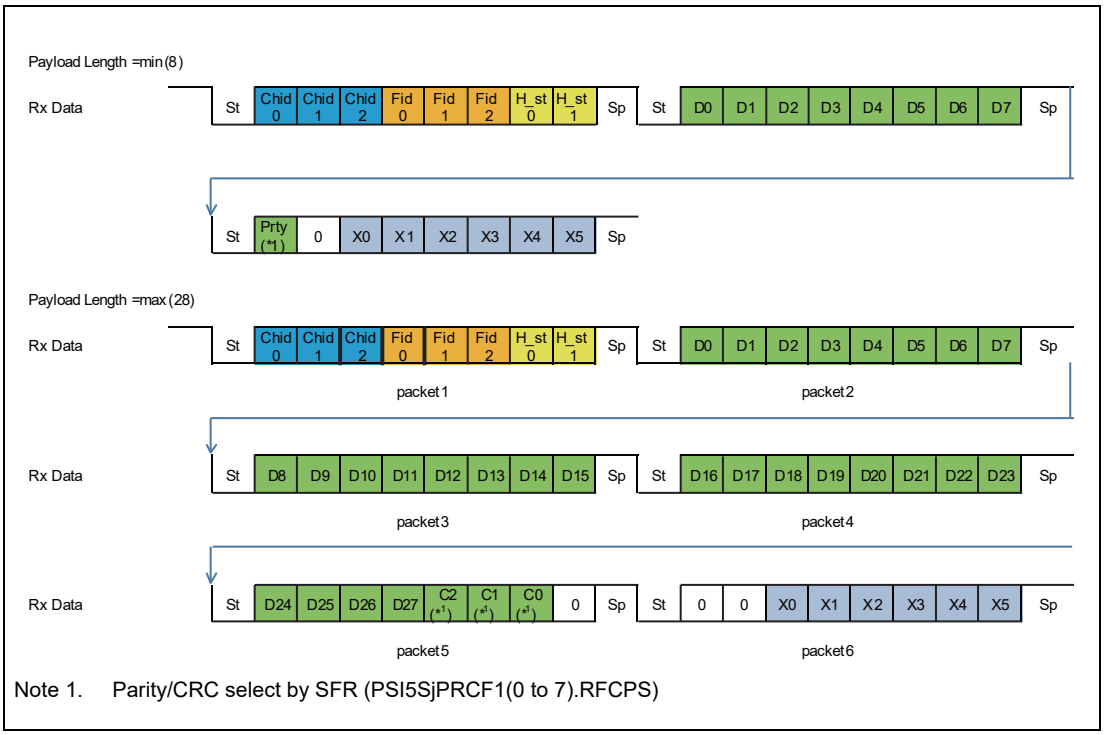
If too many packets are received, the received packets over the specified number are not stored.

Table 28.93 below shows the correspondence between the settings of PSI5SjPRCF1(0-7).F(1-6)PKT and the number of packets to be received.

Table 28.93 PSI5 Frame Reception Packet Number

Value of PSI5SjPRCF1(0 to 7).F(1 to 6)PKT	Specification
0_H	Mask the corresponding frame. (Receive data is not stored in SFR)
1_H, 2_H	Setting prohibited
3_H to 6_H	Packet number is PSI5SjPRCF1(0-7).F(1-6)PKT value (3_H to 6_H)
7_H	Setting prohibited

The following figure shows the data format of a PSI5 frame when the payload bit length is min/max.



Note 1. Parity/CRC select by SFR (PSI5SjPRCF1(0 to 7).RFCPS)

Figure 28.59 PSI5 Frame Data Format (Payload = 8 Bits (min.) to 28 Bits (max.))

(2) Restoring PSI5 Frame Data and Determining Errors

After receiving all the packets to be received, PSI5S finishes packet frame reception and restores the PSI5 frame data.

For how to determine errors when restoring the PSI5 frame data, see **Section 28.6.2.7, Abnormal Reception (Reception Error)**.

(3) Generating MailBox Storage Data

After determining errors in PSI5 frame data, PSI5S generates three types of mailbox storage data (triplet).

The three types of mailbox storage data contain the status, data, and timestamp, respectively, and have the same value of data consistency indicator (DCI) in the upper four bits.

The DCI value installed for each channel is generated by a 4-bit up-counter. The up-counter value is incremented each time PSI5 data is restored. PSI5S is initialized by an asynchronous reset or software reset.

The following figure shows the timing of generating the DCI value.

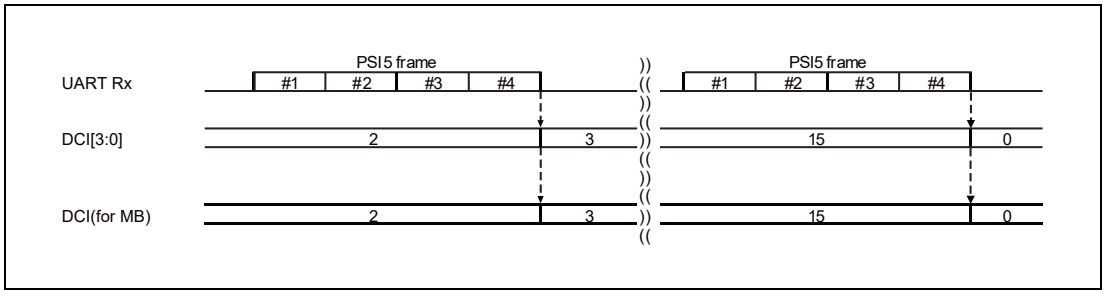


Figure 28.60 DCI Generation Timing

Figure 28.61 below shows the bit format of the mailbox data (triplet).

For details, see **Section 28.3.12, Ch 0 Frm m MB Data (m: 1, 2)** or **Section 28.3.13, Ch n Frm m MB Data (n: 1 to 7) (m: 1 to 6)**.

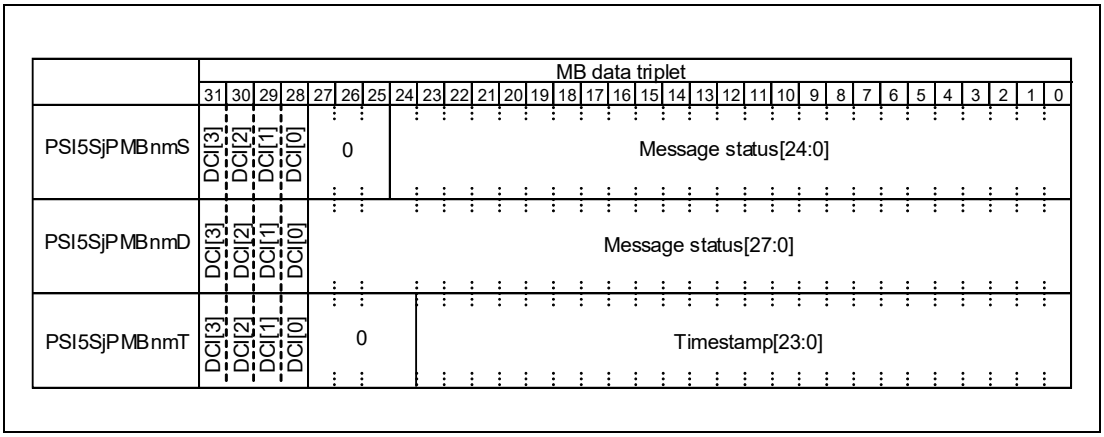

Figure 28.61 MB Data Triplet

(4) Writing MailBox Data to SFR

After generating mailbox storage data, PSI5S obtains the storage destination of the mailbox data in SFR by using the channel ID and frame ID in the header.

The conditions for deciding the storage destination are as follows.

Channel 0 is a virtual channel. If an XCRC error or UART reception error occurs, the received frame is determined to be an invalid frame, and the mailbox data is stored in frames on channel 0. The mailbox data is also stored in frames on channel 0 when the frame ID is invalid or a WDT error occurs.

Table 28.94 PSI5 Frame MB Target Generate (Sync)

XCRC error, UART parity error, UART framing error	FrmID	MB target
No	0≤FrmID≤5	Ch: Receive ChID Frm: Receive FrmID
	6, 7	Ch: 0
Yes	Not related	Frm: 2

The storage data and the storage destination when a WDT error occurs in synchronous mode are as shown in **Table 28.99**.

Table 28.95 below lists the 1st addresses of the frames to write mailbox data that is generated from the received channel ID and frame ID.

Table 28.95 MB write 1st Address Generate (by Frame ID)

Frm ID	Frame	Write 1st address							
		Ch0	Ch1	Ch2	Ch3	Ch4	Ch5	Ch6	Ch7
0	Frame1	500_H	548_H	590_H	$5D8_H$	620_H	668_H	$6B0_H$	$6F8_H$
1	Frame2	$50C_H$	554_H	$59C_H$	$5E4_H$	$62C_H$	674_H	$6BC_H$	704_H
2	Frame3	$50C_H$	560_H	$5A8_H$	$5F0_H$	638_H	680_H	$6C8_H$	710_H
3	Frame4	$50C_H$	$56C_H$	$5B4_H$	$5FC_H$	644_H	$68C_H$	$6D4_H$	$71C_H$
4	Frame5	$50C_H$	578_H	$5C0_H$	608_H	650_H	698_H	$6E0_H$	728_H
5	Frame6	$50C_H$	584_H	$5CC_H$	614_H	$65C_H$	$6A4_H$	$6EC_H$	734_H
6	Error frame	$50C_H$							
7	Error frame	$50C_H$							

The mailbox data storage addresses must be in the range from 500_H to $73C_H$ shown in the address map (**Table 28.12**).

When mailbox data is stored in frame 3 on channel 1, the 1st address of the storage destination is 560_H.

After deciding the storage destination, PSI5S stores the status in the area beginning with the 1st address, data in the area beginning with the address “1st address + 4,” and timestamp in the area beginning with the address “1st address + 8.”

(5) Monitoring PSI5 Frame Reception with the WDT

With the WDT installed for each channel, PSI5S monitors reception of the specified number of PSI5 frames to be received.

When the synchronization pulse is transmitted to the Tx shifter register after synchronization pulse input from GTM, the WDT counter fetches a specified expiration value and starts counting. When the specified number of frames are received or the WDT counter value becomes 0, the WDT counter stops, and waits for the rising edge of the next synchronization pulse. At the rising edge of the next synchronization pulse, the WDT counter fetches a specified expiration value, and starts counting. If the WDT counter value becomes 0, a WDT error is assumed. For details, see **Section 28.6.2.8, Abnormal Reception (WDT Error)**.

The WDT expiration value (PSI5SjPWDEVn.WDTEX) should be shorter than the interval time of synchronization pulse.

NOTE

Frame reception time < WDT expiration time < {(the interval time of synchronization pulse) - (maximum arbitration delay time)}
(maximum arbitration delay time) = bit time * 154 + 50 * (PCLK period)

The following figure shows the WDT operation (without WDT error).

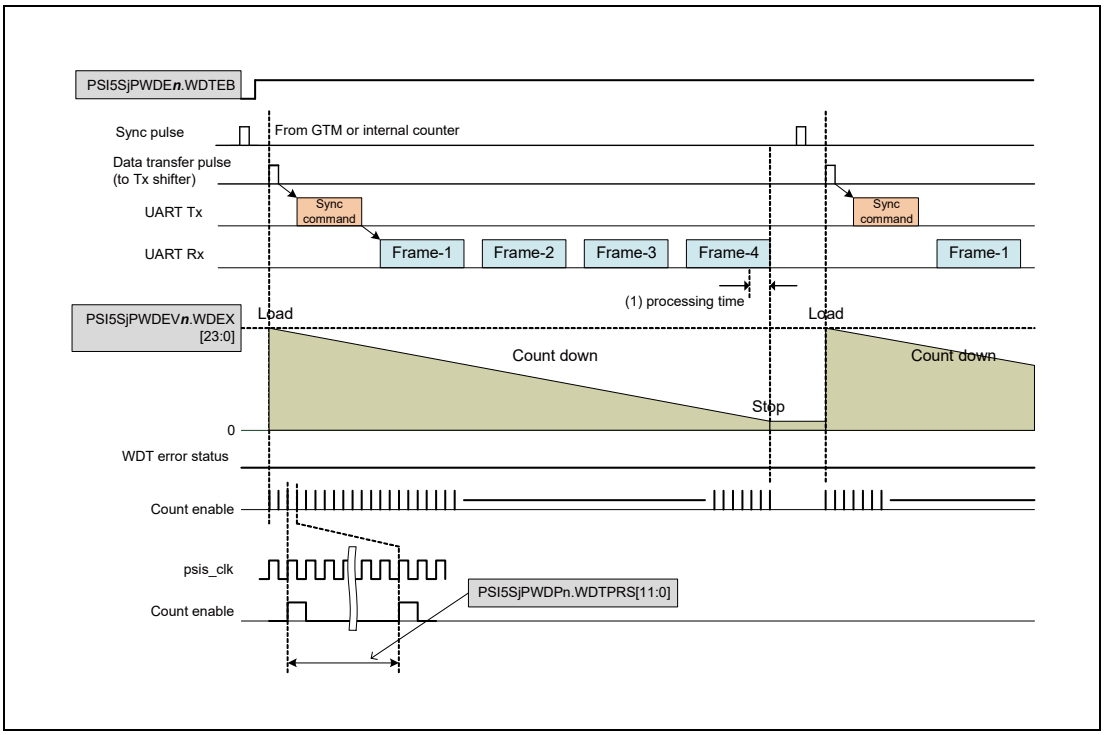

Figure 28.62 WDT Operation Timing (Sync Mode) (without WDT Error)

NOTE

The WDT counter stops in 50 cycles after a stop bit of the last frame is received. A WDT error occurs in a case that the WDT counter expires within the 50 clock cycles even if the stop bit of the last frame is received.

The number of packets to be received on each channel is obtained as follows:

- When the value set in PSI5SjPRCF1(0-7).F(1-6)PKT is not 0_H, the frame is monitored.
- When the value set in PSI5SjPRCF1(0-7).F(1-6)PKT is 0_H, the frame is not monitored.

28.6.2.2 Normal Reception (in Asynchronous Mode)

Unlike synchronous communication, asynchronous communication does not transfer PSI5 frames in synchronization with synchronizing pulses. In asynchronous mode, PSI5S receives PSI5 frames from the transceiver according to the packets transmitted from the sensor.

(1) Receiving UART frames

This operation is the same as that described in **Section 28.6.2.1(1), Receiving UART Frames**.

(2) Restoring PSI5 Frame data and determining Errors

This operation is the same as that described in **Section 28.6.2.1(2), Restoring PSI5 Frame Data and Determining Errors**.

(3) Generating MailBox storage data

This operation is the same as that described in **Section 28.6.2.1(3), Generating MailBox Storage Data**.

(4) Writing MailBox data to SFR

This operation is different from that described in **Section 28.6.2.1(4), Writing MailBox Data to SFR** in the following points.

After generating mailbox storage data, PSI5S obtains the storage destination of the mailbox data by using the channel ID in the header and the frame ID counter*1 installed for each channel.

In asynchronous mode, the frame ID is fixed to 0. Therefore, the frame ID is replaced with the frame ID counter in order to always store the data of the six latest frames.

Note 1. The frame ID counter is a hexadecimal counter that operates only in asynchronous mode and is incremented each time mailbox data is stored in SFR.

The following figure shows an outline of the counter operation.

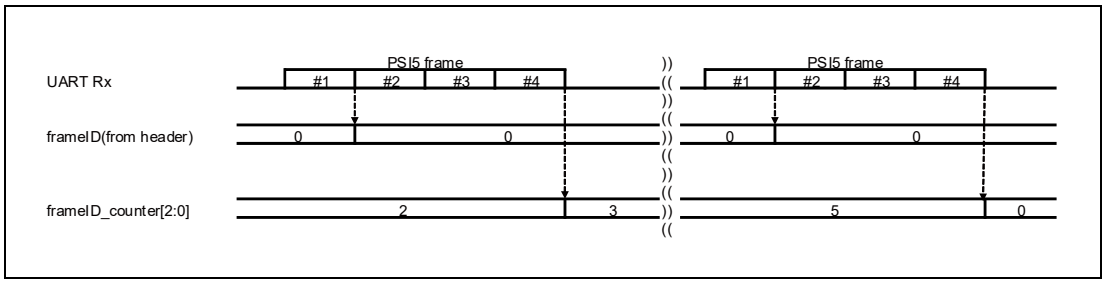

Figure 28.63 Frame ID Counter (Asynchronous Mode Only)

Table 28.96 below shows the conditions for obtaining the storage destination.

Table 28.96 PSI5 Frame MB Target Generate (Async)

XCRC error, UART parity error, UART framing error	FrmID	MB target
No	= 0_H	Ch: Receive ChID Frm: Frame ID counter data (Active Asynchronous mode)
	≠ 0_H	Ch: 0 Frm: 2
Yes	Not related	

The storage data and the storage destination when a WDT error occurs in asynchronous mode are as shown in **Table 28.100**.

(5) Monitoring PSI5 Frame Reception with the WDT

With the WDT installed for each channel, PSI5S checks that PSI5 frames are received frame by frame.

When the WDT enable bit (PSI5SjPWDE(0-7).WDTEB) is set to 1 in PSI5S mode, the WDT counter fetches a specified expiration value and starts counting. Each time a frame is received or the WDT counter value becomes 0, the WDT counter fetches the specified expiration value again and starts counting.

If the WDT counter value becomes 0, occurrence of a WDT error is assumed. For details, see **Section 28.6.2.8, Abnormal Reception (WDT Error)**.

The following figure shows the WDT operation (without a WDT error).

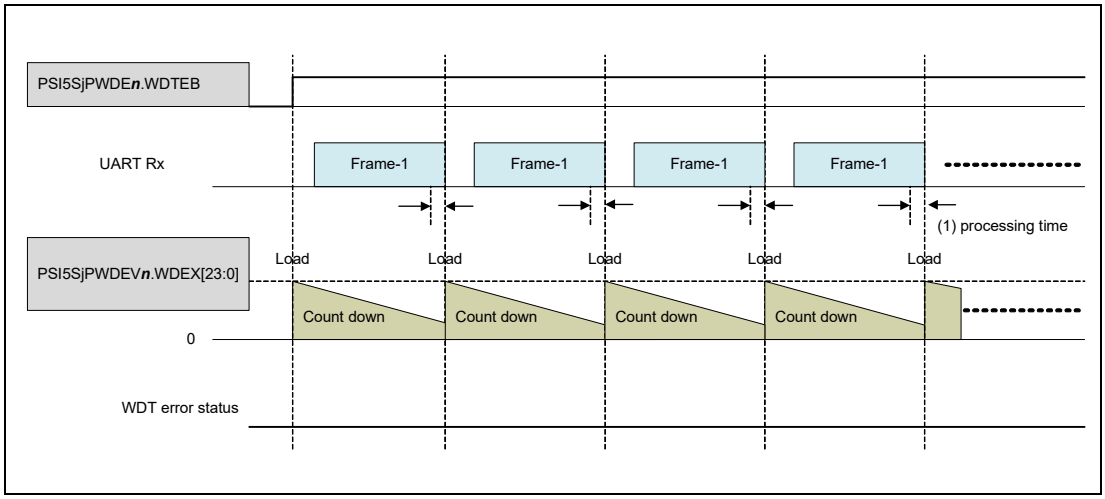

Figure 28.64 WDT Operation Timing (Asynchronous Mode) (without WDT Error)

NOTE

The WDT counter restart in 50 cycles after a stop bit of the frame is received. A WDT error occurs in a case that the WDT counter expires within the 50 clock cycles even if the stop bit of the frame is received.

28.6.2.3 Normal Transmission (Command Data)

After transmitting data (PSI5SjPTFD1 and PSI5SjPTFD2) and the number of transmit packets (PSI5SjPTFNM.TXNUM) is set, PSI5S transmits UART frames according to the specified number of transmit packets when the transmission start bit (PSI5SjPTFST.TXST) is set. No idle time is set between UART frames. To maintain continuous transmission, packet frames are transmitted without idle time between them.

For the UART specifications, see **Section 28.2.1, Functional Overview**.

For 8-byte communication, data is transmitted in order of PSI5SjPTFD1.TDT1[7:0], PSI5SjPTFD1.TDT2[7:0], ..., and PSI5SjPTFD2.TDT8[7:0].

The following figure shows the operation of command data transmission.

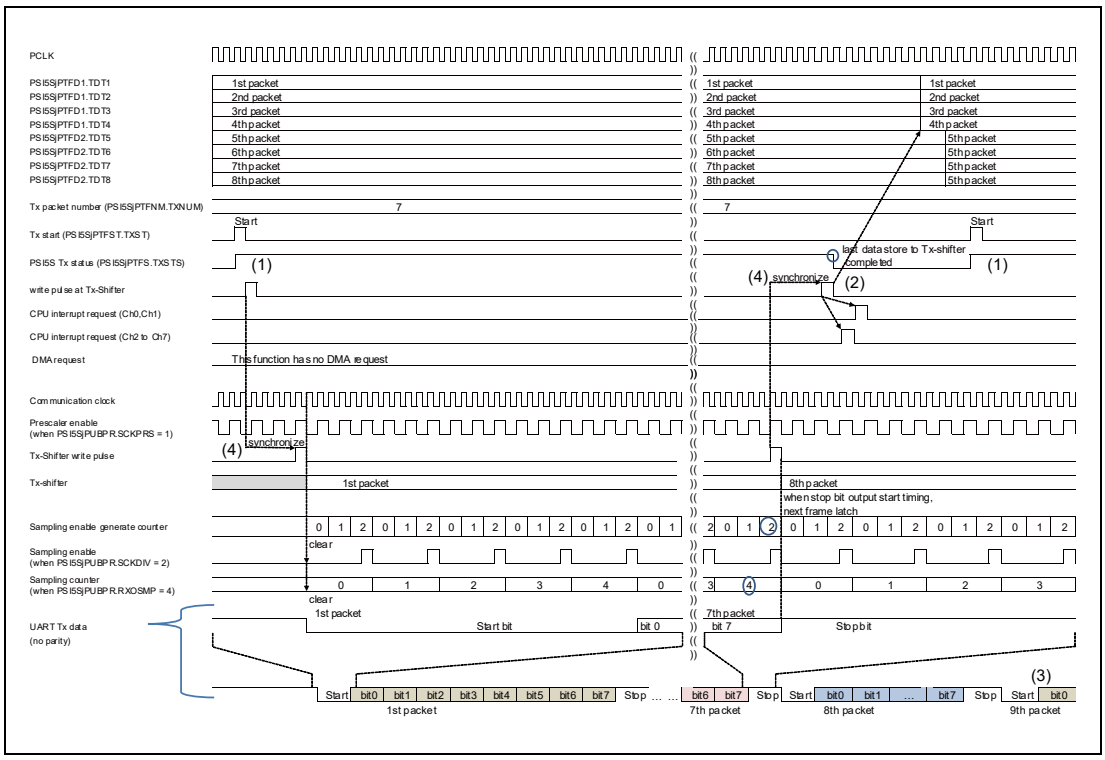

Figure 28.65 Command Data Transmission (8-byte)

(1) The PSI5SjPTFS.TXSTS bit is 1 when TXST is 1.

(2) In the timing of stop bit output, next packet data is set in the transmit data shift register (Tx shifter). The PSI5SjPTFS.TXSTS bit is cleared to 0 to enable writing of the next data by the CPU.

(3) If the CPU writes transmit data continuously, packets are transmitted without idle time.

(4) The asynchronous transfer processing based on PCLK and the communication clock causes a delay of several clock cycles.

28.6.2.4 Normal Transmission (ECU-to-Sensor Data)

In PSI5S mode, PSI5S transmits a Sync command in synchronization with the synchronization pulse generated by the GTM or an internal counter. Because the initial value of ECU-to-sensor data is set to all 1's, the output value of the Sync command is 1 (command data (PSI5SjPTCD*n* (*n*: 1-7).ATRSCMD[4:0] and PSI5SjPTCD*n* (*n*: 1-7).ACHID[2:0])) unless the transmit data is updated.

After the frame type (frame 1 to frame 4) of ECU-to-sensor data and the ECU-to-sensor data (maximum data size: 20 bits, address: 4 bits) to be transmitted are set, PSI5S generates frame data by adding CRC bits at the end of ECU-to-sensor data. Note that all unused bits for ECU-to-sensor data must be 1.

The generating polynomial for CRC is "g(x) = x6 + x4 +x3 + 1" (initial value: 010101_B) when the number of CRC bits is 6, or "g(x) = x3 + x + 1 (initial value: 111_B)" when the number of CRC bits is 3. The range of CRC calculation is zero extension of the number of CRC bit in the MSB of ECU-to-sensor data (maximum of 24 bits). Data bits are transmitted LSB first.

Because the channels set to asynchronous mode do not use synchronization pulses, ECU-to-sensor transmission is not performed on those channels.

Table 28.97 below shows the frame types available for ECU-to-sensor data.

Table 28.97 ECU-to-Sensor Frame Types

Value of PSI5SjDDSRTYPE[1:0]	Specification	Start Bit	CRC	CRC Calculation Scope
0	Frame 1 (Short) Frame length = 15 ECU to Sensor data = data[2:0], address[2:0]	010_B	3 bits x3+x+1	000_B,data[2:0], address[2:0] (9 bits)
1	Frame 2 (Long) Frame length=29 ECU to Sensor data = data[12:0], address [2:0]	010_B	3 bits x3+x+1	000_B, data[12:0], address [2:0] (19 bits)
2	Frame 3 (XLong) Frame length = 37 ECU to Sensor data = data[18:0], address[2:0]	010_B	3 bits x3+x+1	000_B, data[18:0], address [2:0] (25 bits)
3	Frame 4 (XXLong) Frame length = 43 ECU to Sensor data = data[19:0], address[3:0]	011111110_B	6 bits x6+x4+x3+1	000000_B, data[19:0], address[3:0] (30 bits)

The following figure shows the format of frame data.

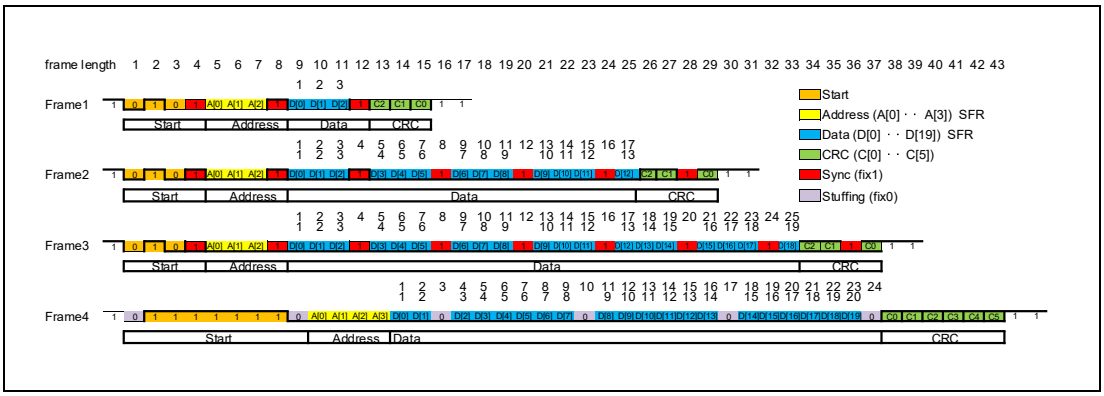

Figure 28.66 ECU-to-Sensor Data Format

After ECU-to-sensor data is generated, the data shifts bit by bit beginning with the start bit at the rising edge of a synchronization pulse for each channel.

Based on the value output by shifting, the command data in SFR is selected (from "PSI5SjPTCD*n* (n: 1 to 7). ATRSCMD[4:0] and one bit of PSI5SjPTCD*n* (n: 1 to 7). ACHID[2:0]" and "PSI5SjPTCD*n* (n: 1 to 7). TRSCMD[4:0] and one bit of PSI5SjPTCD*n*(n: 1 to 7). CHID[2:0]").

When the value output by shifting is 0, the command data in SFR is "PSI5SjPTCD***n*** (n: 1 to 7).TRSCMD[4:0] and one bit of PSI5SjPTCD***n*** (n: 1 to 7).CHID[2:0]".

When the value output by shifting is 1, the command data in SFR is "PSI5SjPTCD***n***(n: 1 to 7).ATRSCMD[4:0] and one bit of PSI5SjPTCD***n***(n: 1 to 7).ACHID[2:0]".

A UART frame is generated from the selected data, and output.

The following figure shows the format of the UART frame to be output.

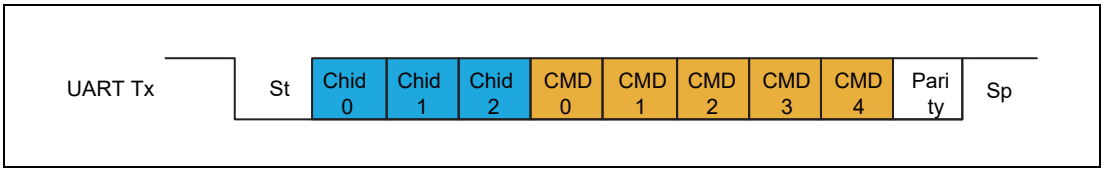

Figure 28.67 ECU-to-Sensor Data Format (UART Frame)

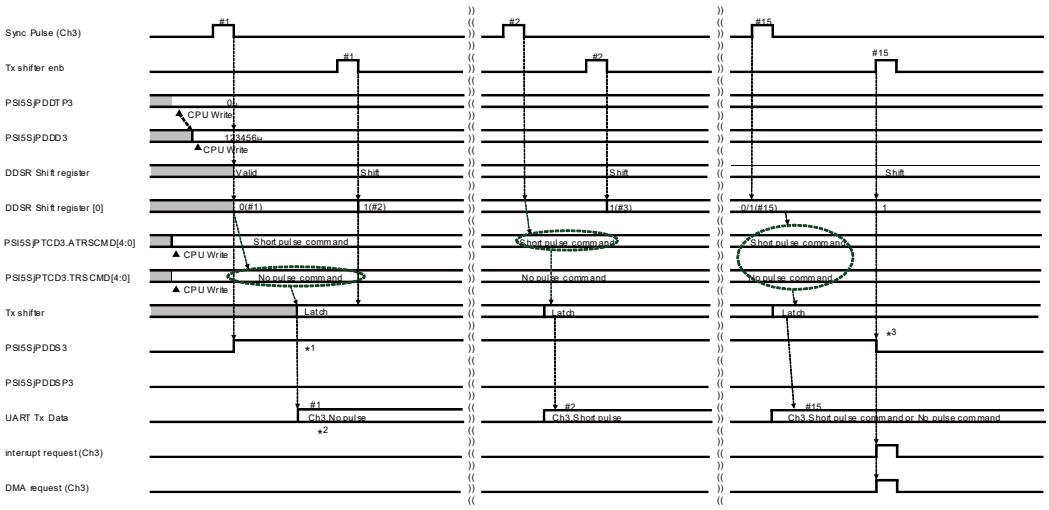
The following figure shows the operation of ECU-to-sensor data transmission.

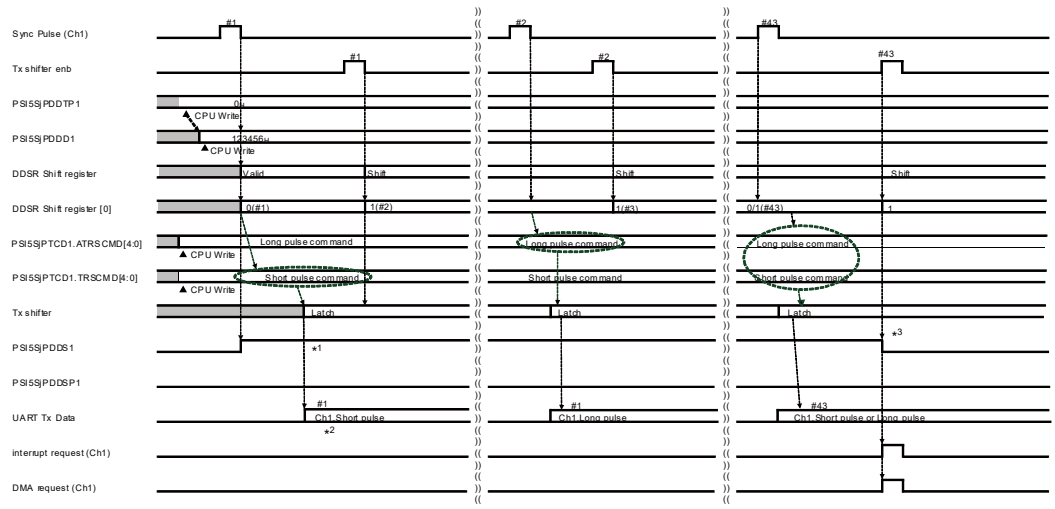


Note 1. When DDSR data is changed, DDSR transmission status is asserted.

Note 2. When the sync pulse (Ch3) is asserted, UART Tx data is transmitted.
Command data is selected by the shift register output value (0: TRSCMD, 1: ATRSCMD).

Note 3. When the last data is transmitted, the DDSR transmission status is deasserted.

Figure 28.68 ECU-to-Sensor Data Transmission (Frame 1)



Note 1. When DDSR data is changed, the DDSR transmission status is asserted.

Note 2. When the sync pulse (Ch1) is asserted, UART Tx data is transmitted.
Command data is selected by the shift register output value (0: TRSCMD, 1: ATRSCMD).

Note 3. When the last data is transmitted, the DDSR transmission status is deasserted.

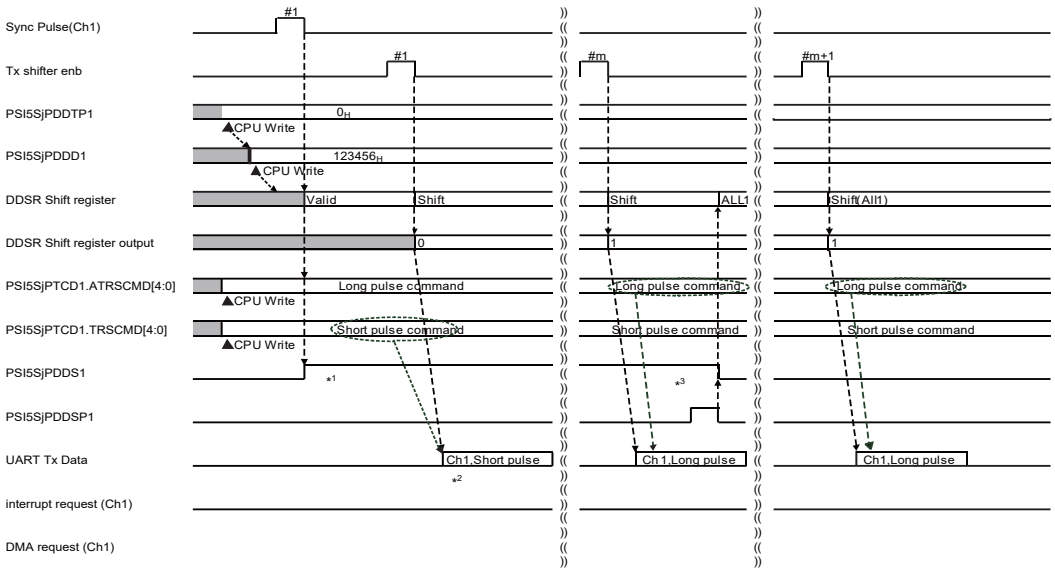
Figure 28.69 ECU-to-Sensor Data Transmit (Frame 4)

28.6.2.5 Normal Transmission (ECU-to-Sensor Data Transmission Stopped)

If transmission is stopped (PSI5SjPDDSP(1-7).DDSRSTP = 1) during ECU-to-sensor data transmission, PSI5S performs the following operations:

- Initializing the DDSR shift register (set all 1)
- De-asserting the DDSR transmission status signal

The following figure shows the operation that is performed when ECU-to-sensor data transmission is stopped.



Note 1. When DDSR data is changed, the DDSR transmission status is asserted.

Note 2. When the sync pulse (Ch1) is asserted, UART Tx data is transmitted.
Command data is selected by the shift register output value (0: TRSCMD, 1: ATRSCMD).

Note 3. When the DDSR stop comes during data transmission, Tx data is initialized (ALL1).

Figure 28.70 ECU-to-Sensor Data Transmission Stop

28.6.2.6 Normal Transmission (Transmit Request Arbitration)

Transmit requests are arbitrated by using the function shown in **Figure 28.45** and output by UART transmission.

The priority of arbitration is: Ch1 (high priority) > Ch2 > Ch3 > Ch4 > Ch5 > Ch6 > Ch7 > Command data (low priority)

The following figure shows an operation in which requests are input after the lower priority requests are input.

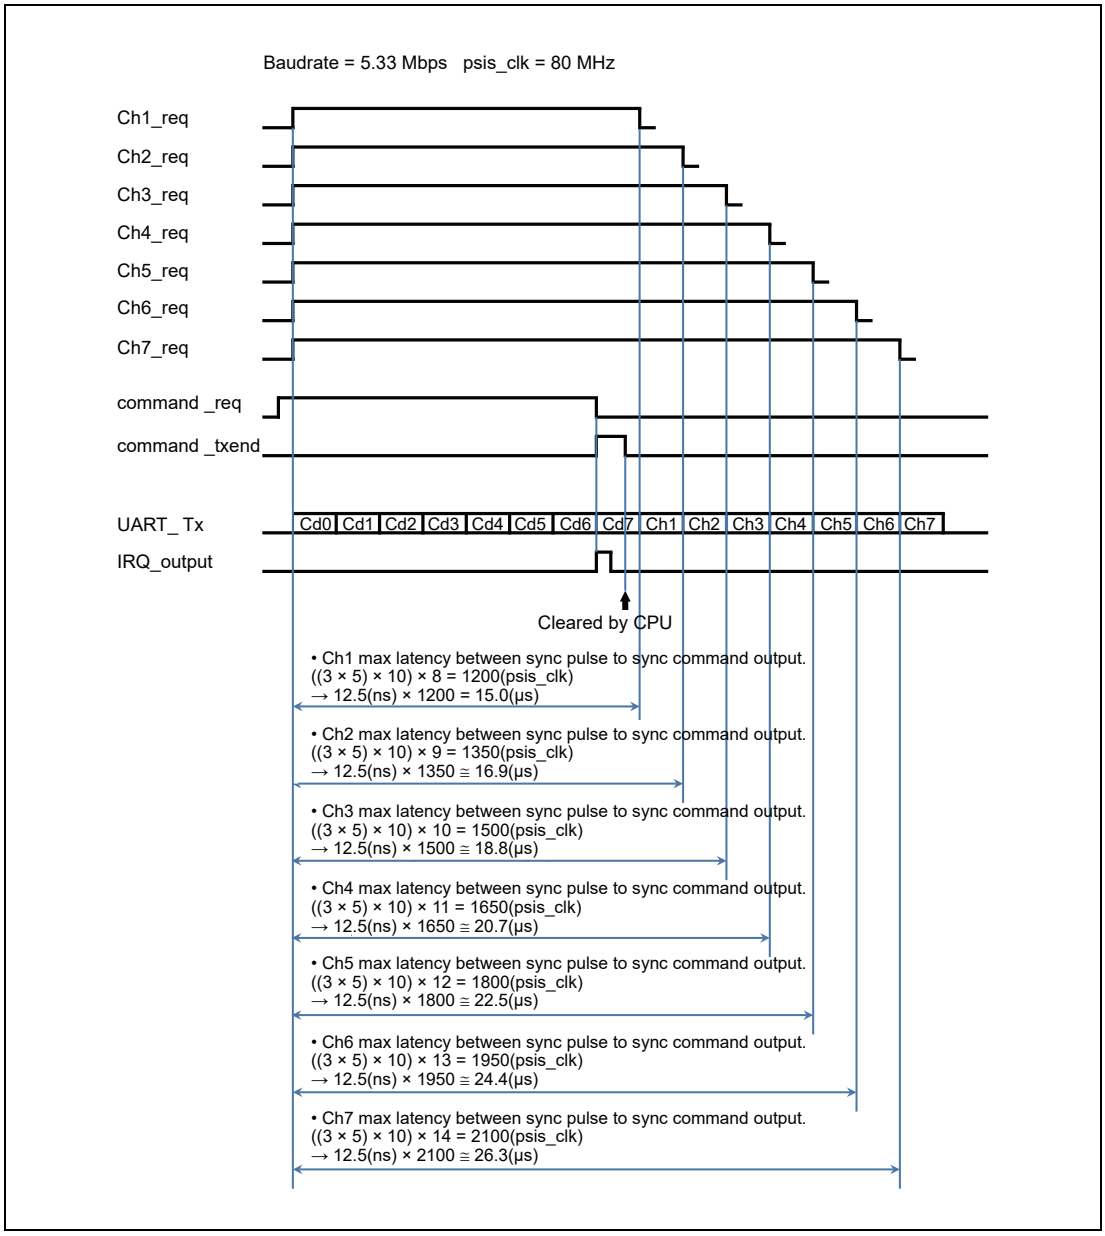


Figure 28.71 Arbitration Tx Request (max latency)

The following figure shows an operation in which all requests are input simultaneously.

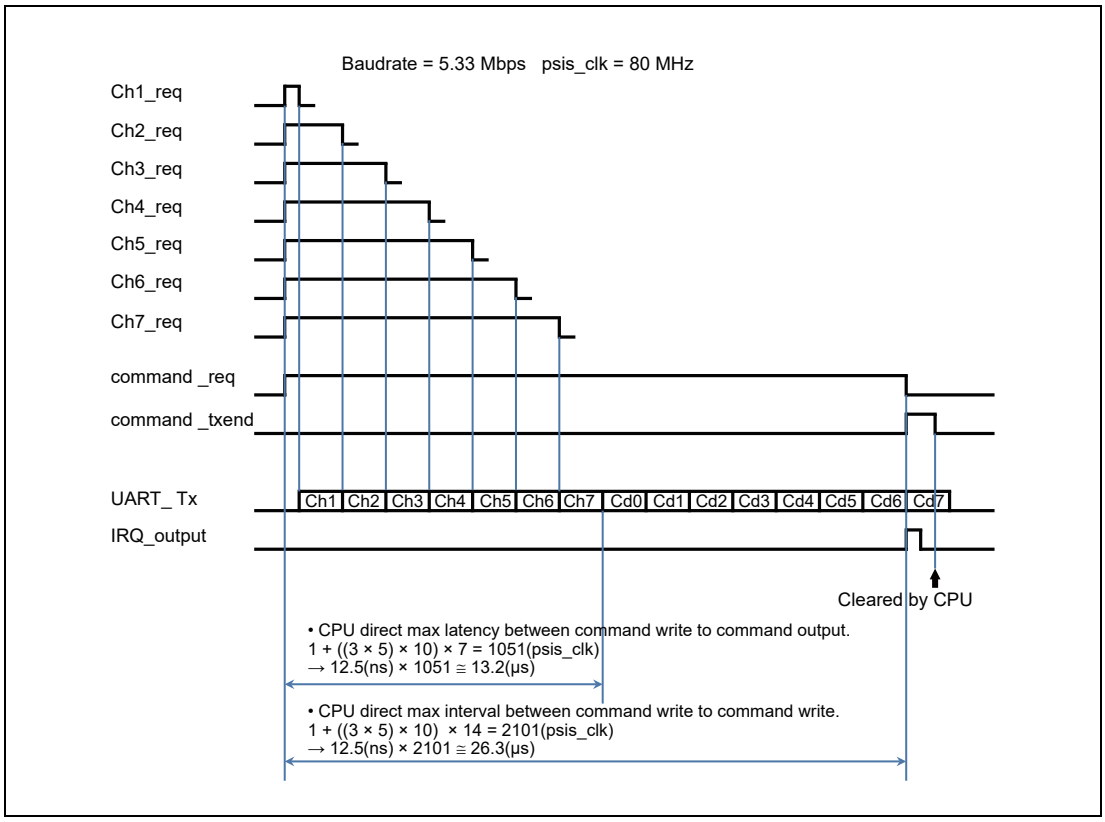

Figure 28.72 Arbitration Tx Request (All Requests Share the Same Timing)

Tx request in FIFO is cleared when the operation enable register (PSI5SjPUOEB.OPEN) is set to 0.

28.6.2.7 Abnormal Reception (Reception Error)

After restoring a PSI5 frame, PSI5S determines whether reception errors have occurred. Then, PSI5S checks for XCRC errors, CRC errors, transceiver status errors, and mailbox overrun.

If mailbox overrun has occurred, the data in the mailbox will be unpredictable.

Other errors are checked for at different timings. The timing for determining other errors is as follows:

UART-related errors (parity and framing errors) are checked for when a UART frame is received.

A WDT error is determined to have occurred when the WDT counter value becomes 0. For details, see **Section 28.6.2.8, Abnormal Reception (WDT Error)**.

An error status is cleared by writing 1 to the corresponding bit in the reception status clear register. The error status is also cleared when the operation mode is switched to configuration mode.

Table 28.98 below lists PSI5 frame reception errors.

Table 28.98 PSI5 Frame Reception Errors

Error	Detect Timing	Detection Condition
XCRC	PSI5 frame received	The agreement of XCRC (6-bit) value which was calculated from received data and the reception XCRC (6-bit) value is confirmed.
CRC	PSI5 frame received & RFCPS=1	The agreement of CRC (3-bit) value which was calculated from received data and the reception CRC (3-bit) value is confirmed.
Parity	PSI5 frame received & RFCPS=0	The agreement of even parity value which was calculated from received data and the reception parity value is confirmed.
Transceiver status	PSI5 frame received & error in header$\neq 0_H$	When the error status value of the received header data is other than 0.
UART parity	UART frame received	The received parity value does not match.
UART framing	UART frame received	The received stop bit value is 0.
WDT	WDT counter value reaches 0	Same as timing of detection
MB overrun	PSI5 frame received	The previous data has not been read.
PSI5 frame lack	IDLE time is passed*1	The number of received packets is less than the number of packets to be received.
PSI5 frame excess	UART frame received*2	The number of received packets exceeds the number of packets to be received.

Note 1. When a PSI5 frame lack error is occurred, the new PSI5 frame data is not stored.
Then if a WDT error occurs, the received packets at the time of the WDT error occurrence is stored.

Note 2. When a PSI5 frame excess error is occurred, the extra data of the new PSI5 frame is not stored.

When the number of received packets exceeds the number of packets to be received, a PSI5 frame excess error, XCRC error and CRC error occur. In this case, a PSI5 frame excess error is detected for the received Ch, and the received data is stored as Ch 0 Frm 2 MB data.

The generating polynomial for XCRC is "$g(x)$ = x6 + x4 +x3 + 1." The initial value of the XCRC bits is 010101_B.

The generating polynomial for CRC is "$g(x)$ = x3 + x + 1." The initial value of the XCRC bits is 111_B.

The following figure shows the ranges of calculation for the XCRC and CRC values for a PSI5S frame that uses CRC and has a payload of 13 bits.

The calculation target of XCRC is PSI5 frame data excluding XCRC, and 0 extension of 6bits to MSB.
The calculation target of CRC is the payload data, and 0 extension of 3bits to MSB.

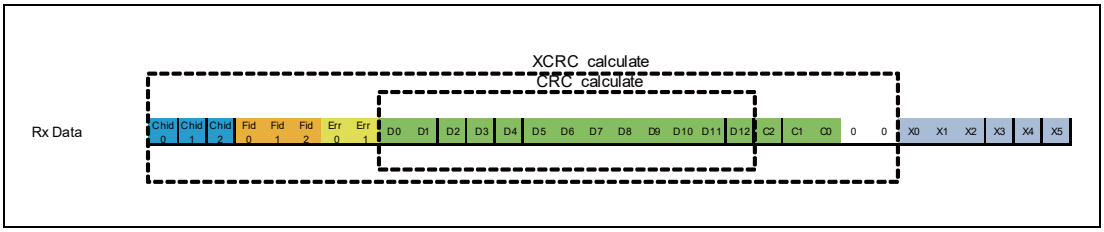

Figure 28.73 Calculate Area of XCRC, CRC

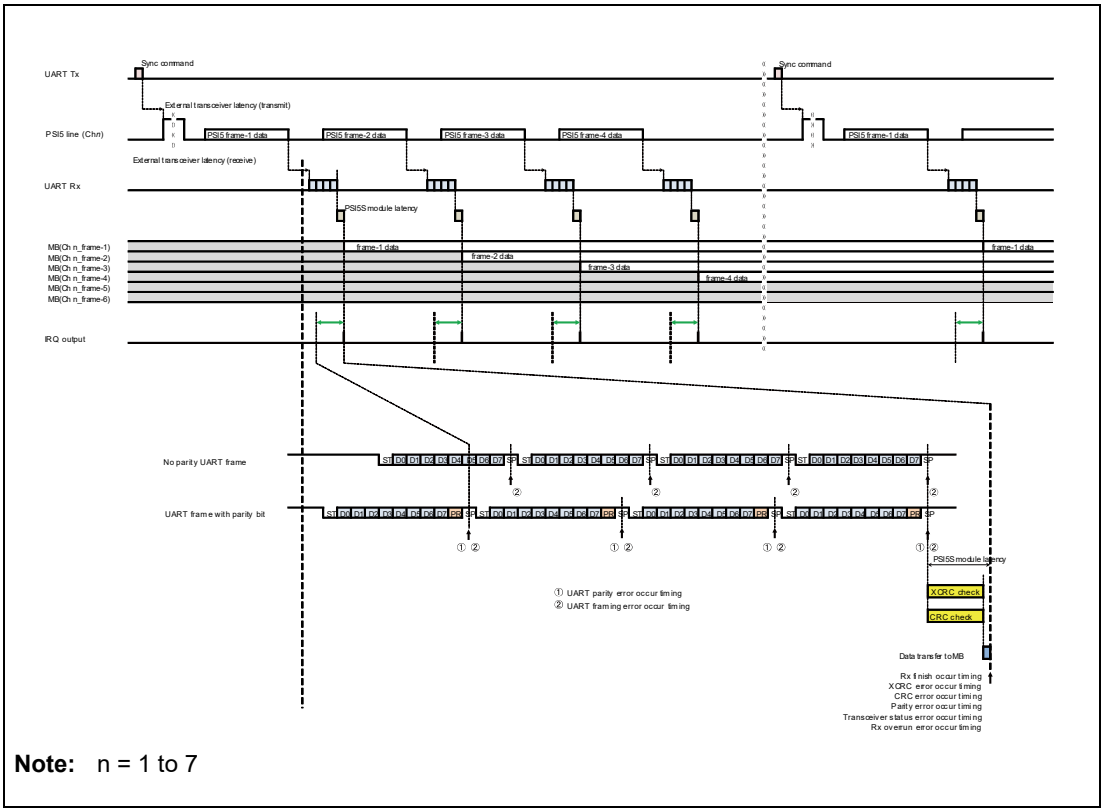
The following figure shows the detection timing of reception errors.



Note: n = 1 to 7

Figure 28.74 Sensor-to-ECU Data Is Received (Reception Error Is Detected)

The following figure shows the operation for error detection when too many or too few UART frames are received.

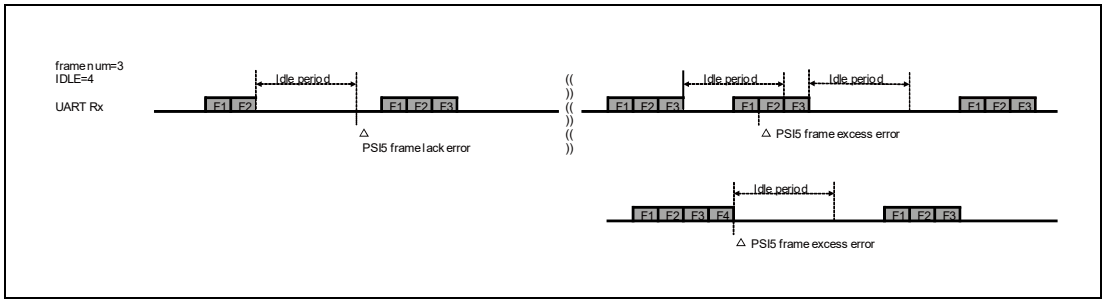


Figure 28.75 UART Frame Error Is Detected (Frame Lack or Frame Excess)

When the PSI5S transitions to the PSI5S mode during a PSI5 frame reception, any error of “UART framing error”, “UART parity error”, “payload data parity error”, “Frame lack error” and “packet frame XCRC error” possibly occurs. Because the PSI5S doesn't detect a bus idle condition when the PSI5S transitions to the PSI5S mode.

28.6.2.8 Abnormal Reception (WDT Error)

The synchronous and asynchronous modes differ from each other in WDT error determination, as follows.

(1) Synchronous Mode

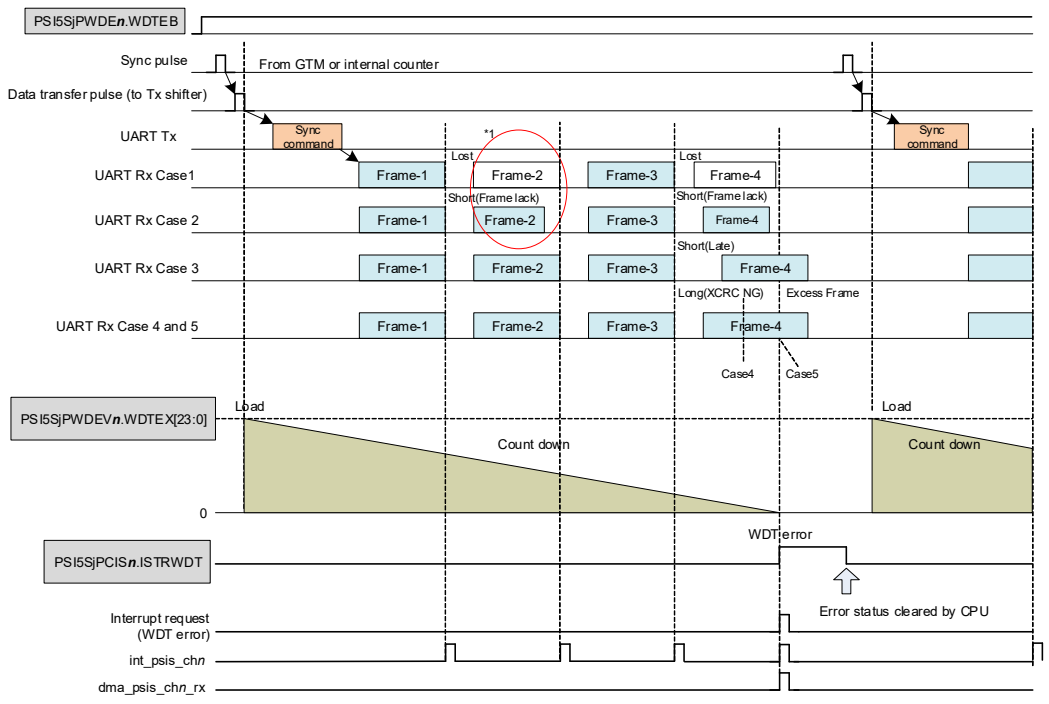
When the synchronization pulse is transmitted to the Tx shifter after synchronization pulse input, the WDT value is reset to the expiration value, and, at the same time, the WDT starts the next operation. If the WDT counter reaches 0 before receiving all the packets to be received, a WDT error is assumed.

Note that the WDT starts operation again after the rising edge of the next synchronization pulse for each channel is detected.

If a WDT error occurs, an interrupt status (PSI5SjPCISn.ISTRWDT) occurs. The interrupt status is cleared by writing 1 to the corresponding bit (PSI5SjPCISCn.ISTCRWDT) in the interrupt status clear register.

The data received until the transmission of the synchronization pulse to the Tx shifter after a WDT error is detected is not stored.

The following figure shows the operation that is performed when a WDT error occurs in synchronous mode.



Note: n = 0 to 7

Note 1. Missing or incomplete packet frames are not stored the data and the error flags.

Figure 28.76 WDT Operation Timing (Sync Mode) — WDT Error

Below shows the MailBox triplet when a WDT error occurs in synchronous mode.

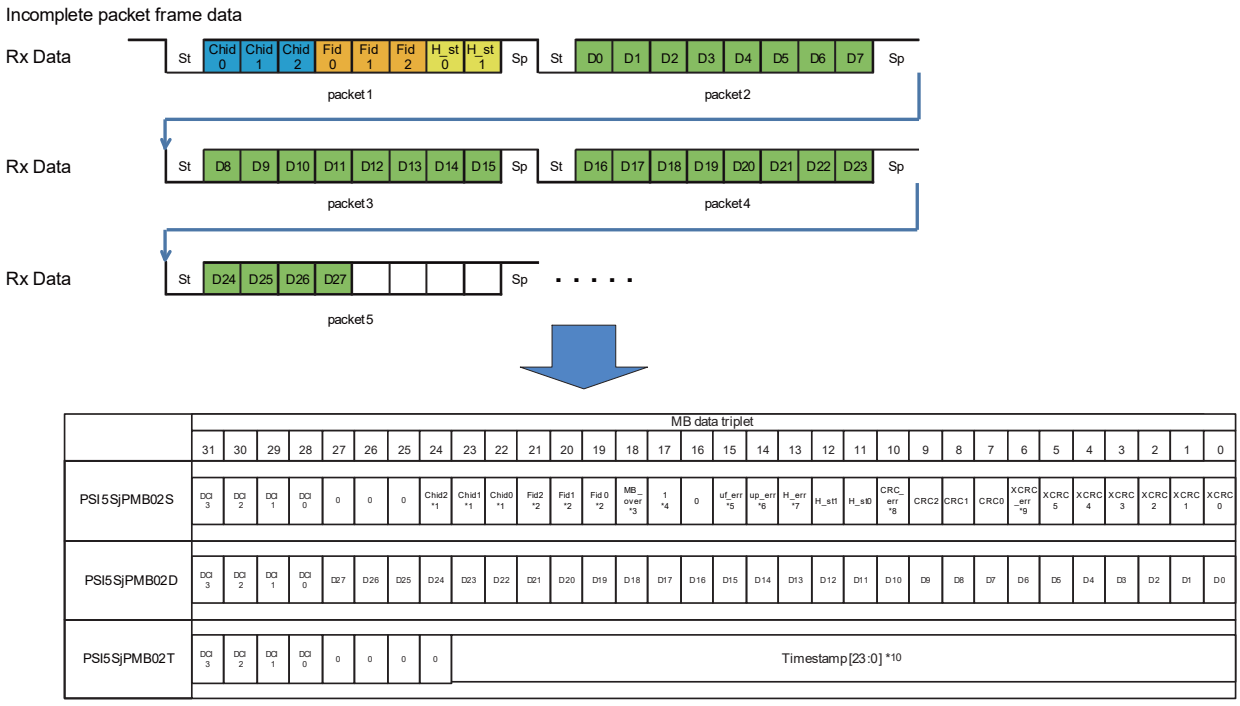
Table 28.99 MB Data Triplet - WDT Error (Synchronous Mode)

Case of UART Rx	Case1	Case2	Case3	Case4	Case5
Store location	ch0/frm2	ch0/frm2	ch0/frm2	ch0/frm2	ch0/frm2
DCI	Ch0	Ch0	Ch0	Ch0	Ch0
CHID	Channel where WDT error detected	Channel where WDT error detected	Channel where WDT error detected	CHID in the header of the reception frame	Channel where WDT error detected
FID	Packet Frame Counter of channel where WDT error detected	Packet Frame Counter of channel where WDT error detected	Packet Frame Counter of channel where WDT error detected	FrmID in the header of reception frame	Packet Frame Counter of channel where WDT error detected
MBORERR	MailBox overrun error	MailBox overrun error	MailBox overrun error	MailBox overrun error	MailBox overrun error
WDTERR	1	1	1	0	1
UTFRERR	0	UART framing error	UART framing error	UART framing error	UART framing error
UTPTERR	0	UART parity error	UART parity error	UART parity error	UART parity error
HEADERR	0	Header error	Header error	Header error	Header error
HEADST	0	HEADST in the header of the reception frame	HEADST in the header of the reception frame	HEADST in the header of the reception frame	HEADST in the header of the reception frame
CRCERR	0	0	0	CRC error	CRC error
CRC	000_B	000_B	000_B	CRC of reception frame data	CRC of reception frame data
XCRCERR	0	0	0	1	1
XCRC	00_0000_B	00_0000_B	00_0000_B	XCRC of reception frame data	XCRC of reception frame data
Payload data	000_0000_H	Incomplete frame data *1, *2	Incomplete frame data *1, *2	Payload data of received frame data	Incomplete frame data *1, *2
Time stamp	At WDT error detection (Ch0)	At WDT error detection (Ch0)	At WDT error detection (Ch0)	At header reception (Ch0)	At WDT error detection (Ch0)

Note 1. Not received (missing or incomplete) packet bits are “0”.

Note 2. Incomplete data is stored in packets 2 to 4 and the lower 4 bits of packet 5.

The following figure shows incomplete data format and store location.



(*1) The channel ID of the WDT error occurrence channel (0-7).
(*2) When the WDT error occurrence channel is set Async mode (PSI5SjPRCF1n.SYSEL = 1), Fid[2:0] is stored.
When the WDT error occurrence channel is set Sync mode (PSI5SjPRCF1n.SYSEL = 0), packet frame counter value is stored.
(*3) When MB overrun error occur, this bit is set.
(*4) WDT error status is set.
(*5) When 6packet frame data has UART framing error, this bit is set.
(*6) When 6packet frame data has UART parity error, this bit is set.
(*7) If H_st[1:0] ≠ 0b00, this bit is set.
(*8) When 6packet frame data has CRC error, this bit is set.
(*9) When 6packet frame data has XCRC error, this bit is set.
(*10) The capture value of timestamp (Ch0) at WDT error occurrence.

Figure 28.77 PSI5 frame data format and MB data triplet at WDT error

The following figure shows the operation of the packet frame counter.

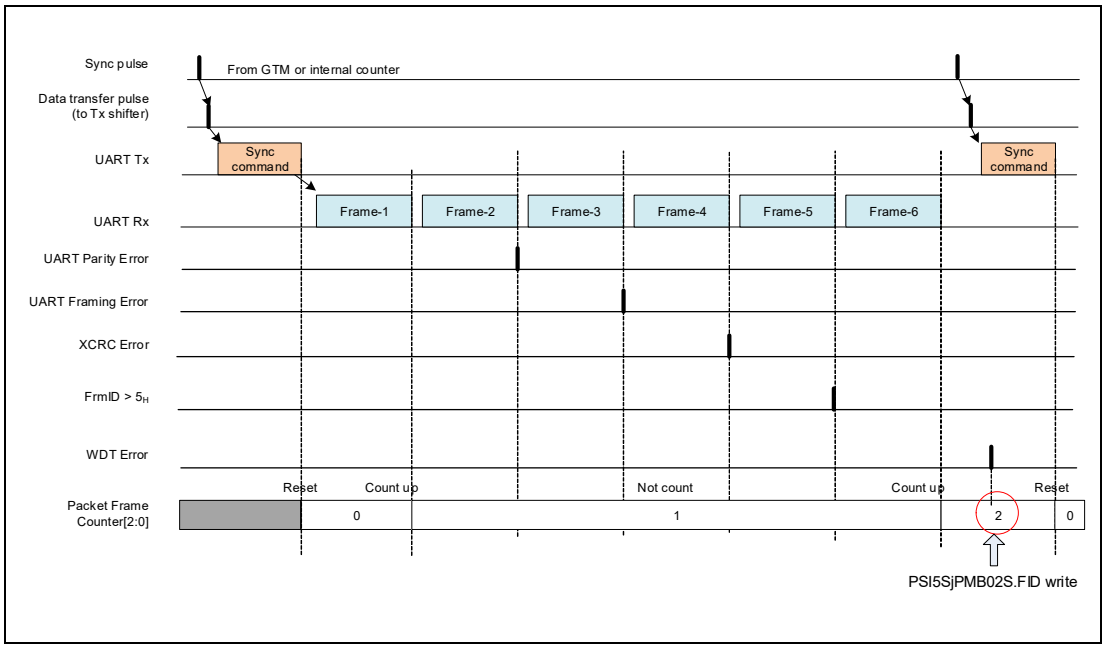


Figure 28.78 Packet Frame Counter

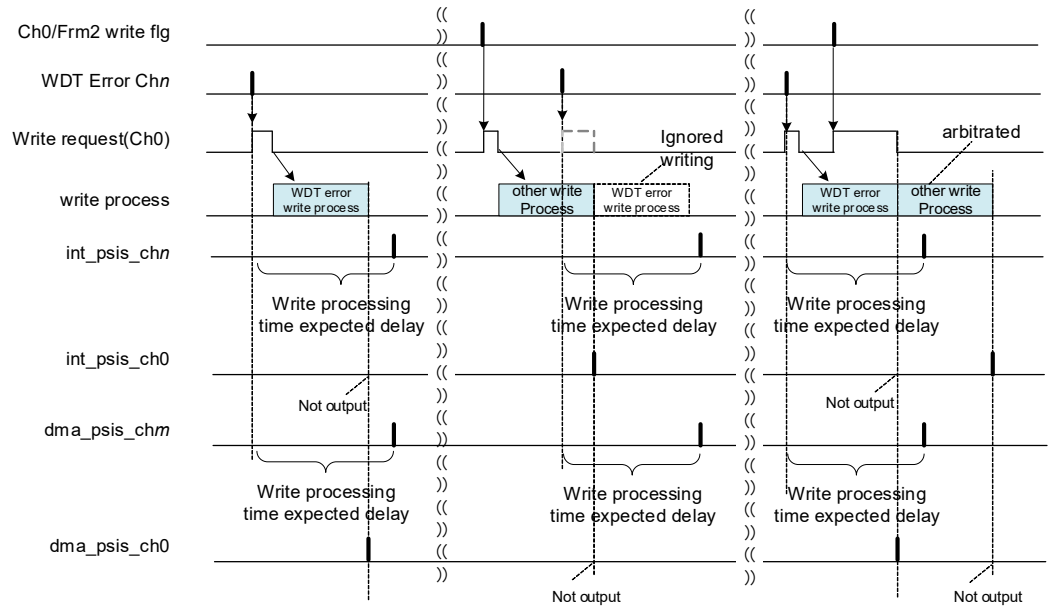
The following figure shows the arbitration of the write request to Ch0 and the operation of the interrupt and DMA request.



Note: n = 0 to 7, m = 1 to 7

Figure 28.79 Write Request Arbitrated and Interrupt/DMA Output (Synchronous Mode)

The interrupt / DMA request by WDT error outputs from detection Ch after writing the MailBox of Ch0.

When a write request by WDT error during the write processing to Ch0/frm2, interrupt/DMA request outputs and the MB data triplet is discarded.

When a write request by another error (not WDT error) during the write processing to Ch0/frm2, the interrupt/DMA request outputs and the MB data triplet write after the write processing to Ch0/frm2.

(2) Asynchronous Mode

When reception of a frame ends, the WDT value is reset to the expiration value, and, at the same time, the WDT starts the next operation. If the WDT counter reaches 0 before reception of the next frame ends, occurrence of a WDT error is assumed.

In such a case, the WDT value is reset to the initial value, and the WDT starts operation again.

The conditions for starting the first operation of the WDT are as follows.

When the WDT enable bit is set to 1, an expiration value is set in the WDT counter. When the operation mode is subsequently switched to PSI5S mode, the WDT starts operation. If the WDT enable bit is 0 (disable), the WDT does not start operation.

If a WDT error occurs, an interrupt status (PSI5SjPCISn.ISTRWDT) occurs. The interrupt status is cleared by writing 1 to the corresponding bit (PSI5SjPCISCn.ISTCRWDT) in the interrupt status clear register.

The following figure shows the operation that is performed when a WDT error occurs in asynchronous mode.

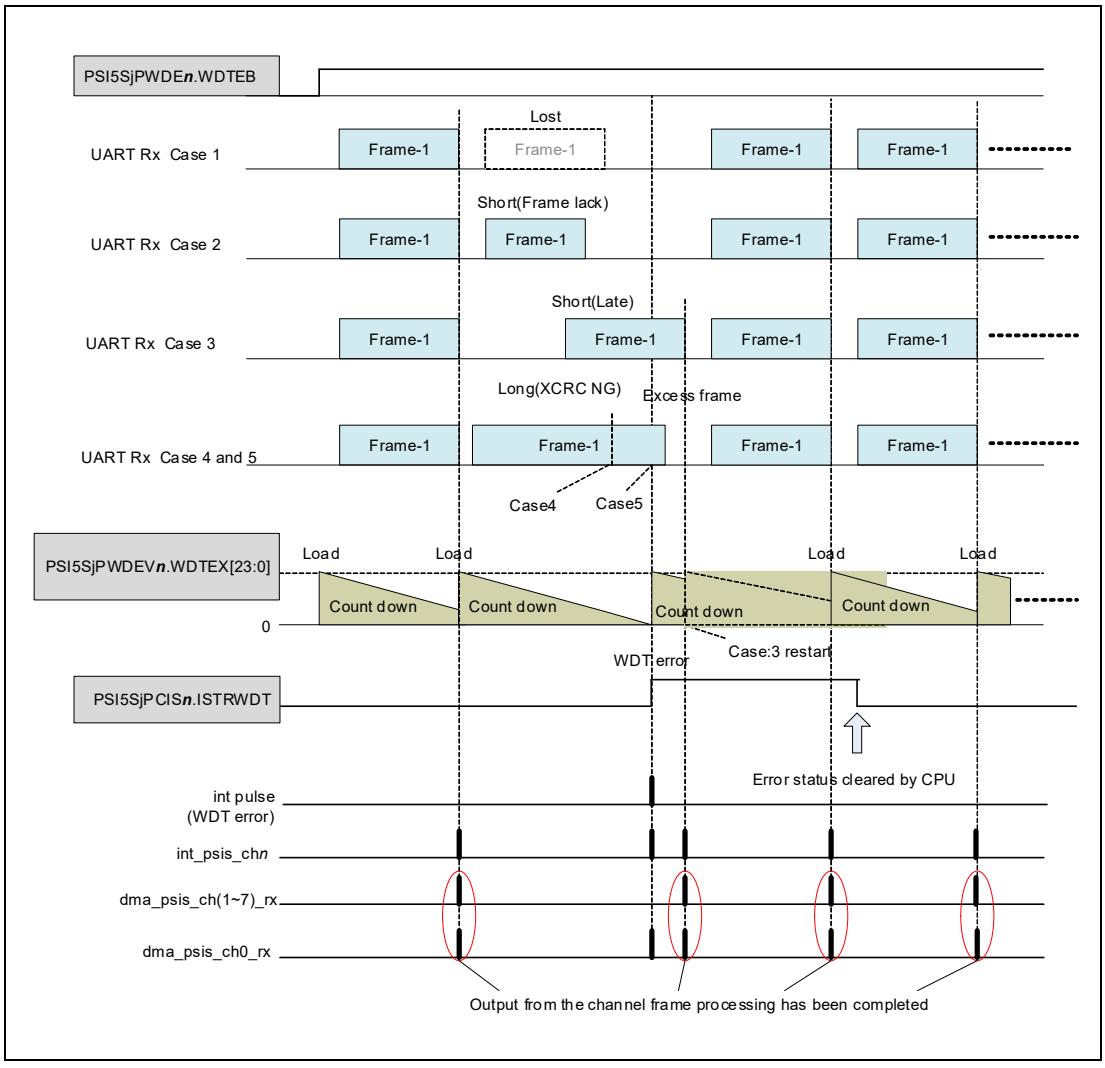


Figure 28.80 WDT Operation Timing (Asynchronous Mode) (WDT Error)

Below shows the MailBox triplet when a WDT error occurs in asynchronous mode.

Table 28.100 MB Data Triplet - WDT Error (Asynchronous Mode)

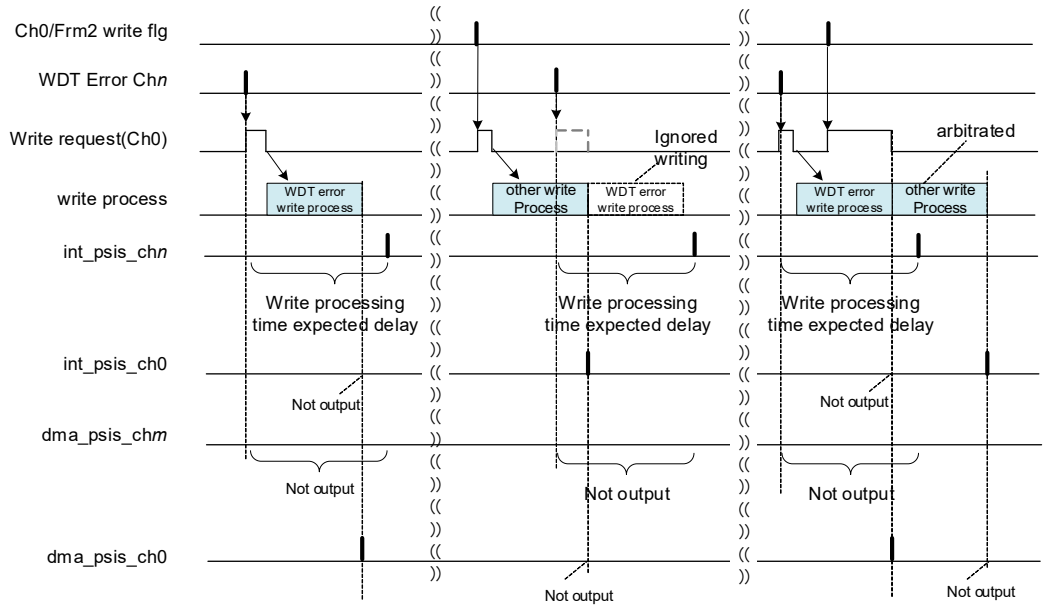
Case of UART Rx	Case1	Case2	Case3	Case4	Case5
Store location	ch0/frm2	ch0/frm2	ch0/frm2	ch0/frm2	ch0/frm2
DCI	Ch0	Ch0	Ch0	Ch0	Ch0
CHID	Channel where WDT error detected	Channel where WDT error detected	Channel where WDT error detected	CHID in the header of the reception frame	Channel where WDT error detected
FID	000_B	FmID in the header of reception frame	FmID in the header of reception frame	FmID in the header of reception frame	FmID in the header of reception frame
MBORERR	MailBox overrun error	MailBox overrun error	MailBox overrun error	MailBox overrun error	MailBox overrun error
WDTERR	1	1	1	0	1
UTFRERR	0	UART framing error	UART framing error	UART framing error	UART framing error
UTPTERR	0	UART parity error	UART parity error	UART parity error	UART parity error
HEADERR	0	Header error	Header error	Header error	Header error
HEADST	0	HEADST in the header of reception frame	HEADST in the header of reception frame	HEADST in the header of reception frame	HEADST in the header of reception frame
CRCERR	0	0	0	CRC error	CRC error
CRC	000_B	000_B	000_B	CRC of reception frame data	CRC of reception frame data
XCRCERR	0	0	0	1	1
XCRC	00_0000_B	00_0000_B	00_0000_B	XCRC of reception frame data	XCRC of reception frame data
Payload data	000_0000_H	Incomplete frame data *1, *2, *3	Incomplete frame data *1, *2, *3	Payload data of received frame data	Incomplete frame data *1, *2, *3
Time stamp	At WDT error detection (Ch0)	At WDT error detection (Ch0)	At WDT error detection (Ch0)	At header reception (Ch0)	At WDT error detection (Ch0)

Note 1. Not received (missing or incomplete) packet bits are “0”.

Note 2. Incomplete data is stored in packets 2 to 4 and the lower 4 bits of packet 5.

Note 3. The incomplete data format is the same as synchronous mode.

The following figure shows the arbitration of the write request to Ch0 and the operation of the interrupt and DMA request.



Note: n = 0 to 7, m = 1 to 7

Figure 28.81 Write Request Arbitrated and Interrupt/DMA Output (Asynchronous Mode)

The interrupt request by WDT error outputs from detection Ch after writing the MailBox of Ch0.

The DMA request by WDT error outputs from Ch0 after writing the MailBox of Ch0.

When a write request by WDT error during the write processing to Ch0/frm2, interrupt request outputs and the MB data triplet is discarded.

When a write request by another error (not WDT error) during the write processing to Ch0/frm2, the interrupt request outputs and the MB data triplet write after the write processing to Ch0/frm2.

NOTE

When UART Parity error or UART Framing error or XCRC error is occurred, the received data is stored in Frame2 of Ch0. In that case, there is possible to detect the WDT error of reception Ch, because the reception is not stored in expected Ch.

28.6.2.9 Abnormal Transmission (Transmission Error)

If ECU-to-sensor data is set for a channel while ECU-to-sensor data is being transmitted*1 in the same channel, an ECU-to-sensor data overwrite error is determined to have occurred.

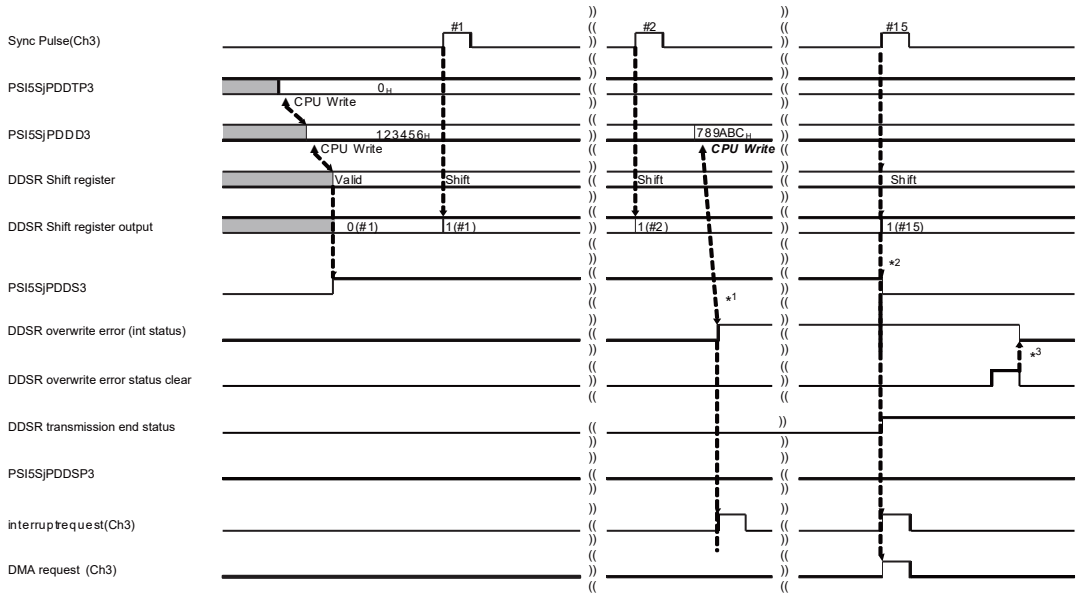
Note 1. Period from setting the value of transmission command to storing the last data in the Tx shifter.

If an overwrite error is determined, the data written afterward is not transmitted.

Data that is already being transmitted is not affected by the overwrite error.

If an overwrite error occurs, an interrupt status signal (PSI5SjPCIS1.ISTDDSOW) is asserted. The interrupt status signal is cleared by writing 1 to the corresponding bit (PSI5SjPCISC1.ISTCDDSOW) in the interrupt status clear register.

The following figure shows the operation that is performed when an ECU-to-sensor data overwrite error occurs.



Note 1. When the DDSR data is changed while DDSR status = 1, the DDSR overwrite error status is asserted.
Note 2. When all data has been outputs, the status is cleared
Note 3. 1 is written to the DDSR overwrite error clear status bit and the DDSR overwrite error status is cleared.

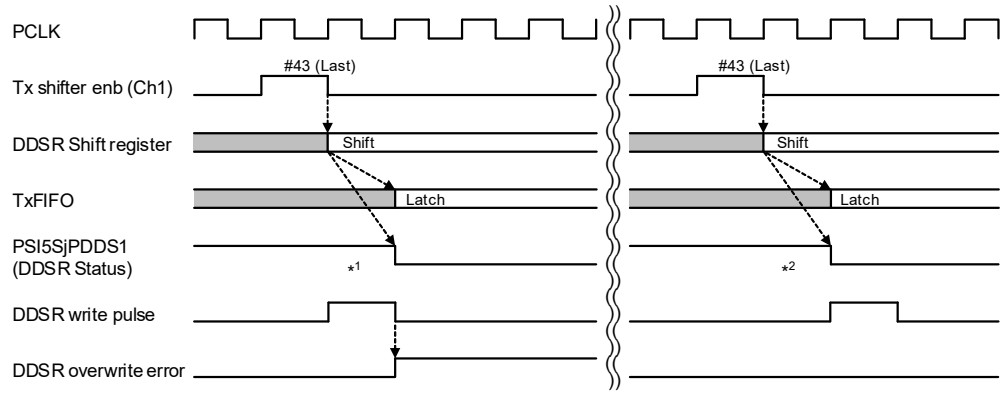
Figure 28.82 ECU-to-Sensor Data Transmission (Overwrite Error)

The following describes the operation that is performed when updating the ECU-to-sensor data conflicts with the start of the last data transmission triggered by a synchronization pulse.

When updating the ECU-to-sensor data occurs after 1 PCLK cycle from the start of the last data transmission triggered by a synchronization pulse, occurrence of an overwrite error is assumed.

When updating the ECU-to-sensor data occurs after 2 PCLK cycles from the start of the last data transmission triggered by a synchronization pulse, occurrence of an overwrite error is not assumed.

In configuration mode, even if updating the ECU-to-sensor data occurs, PSI5S does not start the transmission and PSI5S does not detect an overwrite error.



Note 1. If DDSR data is updated before or during the same PCLK cycle that the DDSR status is cleared, the DDSR overwrite error status is asserted.

Note 2. If DDSR data is updated 1 PCLK cycle or more after the DDSR status is cleared, the DDSR overwrite error status is not asserted.

Figure 28.83 ECU-to-Sensor Data Transmit (Overwrite Error Operation is Conflicted)

28.6.2.10 Interrupt Output

PSI5S can output eight interrupt signals.

Interrupts can be output only when interrupt output is enabled. If an interrupt factor occurs when interrupt output is disabled, no interrupt is output, but the interrupt status is indicated.

Table 28.101 below lists the factors of interrupts that are output in PSI5S mode.

Table 28.101 Interrupt Output Timings

Output Signal	Interrupt Output Timing
int_psis_ch0 to 7	When MB data is received and stored to SFR.
int_psis_ch0 to 7	When WDT operates, the specified time elapses, and the value matches the compare value.
int_psis_ch0 to 7	When a UART frame is received after the start of the idle period.
int_psis_ch0 to 7	When a UART frame is received and the next UART frame is received before the start of the idle period.
int_psis_ch0	When the last command data is stored in the Tx shifter.
int_psis_ch1 to 7	When the last DDSR data is stored in the Tx shifter.
int_psis_ch1 to 7	When DDSR data is written while another DDSR data is being transmitted.

The following describes the interrupt statuses and how to clear them.

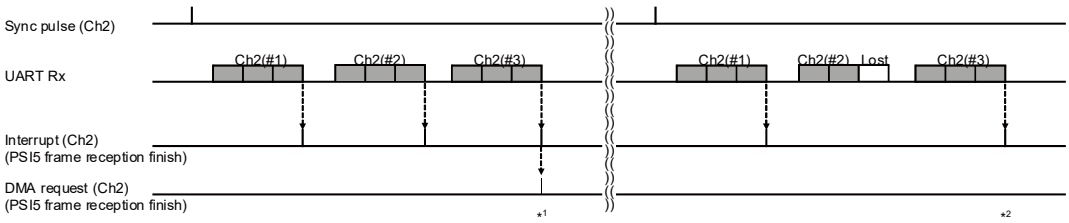
To clear an interrupt status, write 1 to the bit corresponding to the interrupt status in the interrupt status clear register.

Table 28.102 Interrupt Statuses

Equipped Ch	Interrupt Status
Ch0	XCRC error
Ch0 to Ch7	CRC error
Ch0 to Ch7	Parity error
Ch0 to Ch7	Transceiver status error
Ch0	UART Rx parity error
Ch0	UART Rx framing error
Ch0 to Ch7	WDT error
Ch0 to Ch7	PSI5 frame reception overrun error
Ch0 to Ch7	PSI5 frame lack error
Ch0 to Ch7	PSI5 frame excess error
Ch0 to Ch7	PSI5 frame reception finish
Ch1 to Ch7	DDSR overwrite error
Ch1 to Ch7	DDSR transmit finish
Ch0	Command data transmit finish

The following describes the operation in which an interrupt status occurs and is cleared.

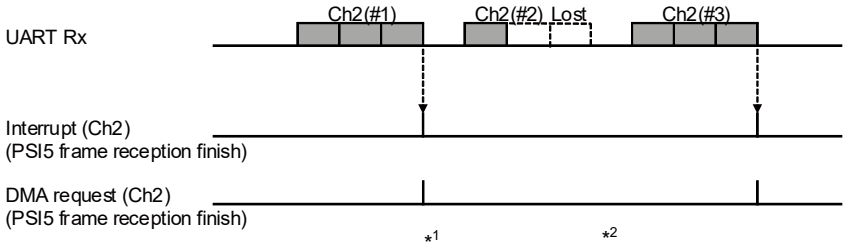
The following figure shows interrupt output and DMA request output operations in synchronous mode.



Note 1. When the last frame is received at each Ch, a DMA request is asserted.
Note 2. When the last frame is received at each Ch but there is a frame lost, a DMA request is not asserted.

Figure 28.84 Interrupt and DMA Request Timing (Synchronous Mode)

The following figure shows interrupt output and DMA request output operations in asynchronous mode.



Note 1. When a frame is received at each Ch, an interrupt and DMA request are asserted.
Note 2. When a frame is received at each Ch but there is a frame lost, an interrupt and DMA request are not asserted.

Figure 28.85 Interrupt and DMA Request Timing (Asynchronous Mode)

If the occurrence of an error status and the clearing of an interrupt status occur at the same time, the occurrence of the error has priority over the occurrence of the interrupt status.

The following figure shows the operation that is performed under conditions for setting and clearing interrupts.

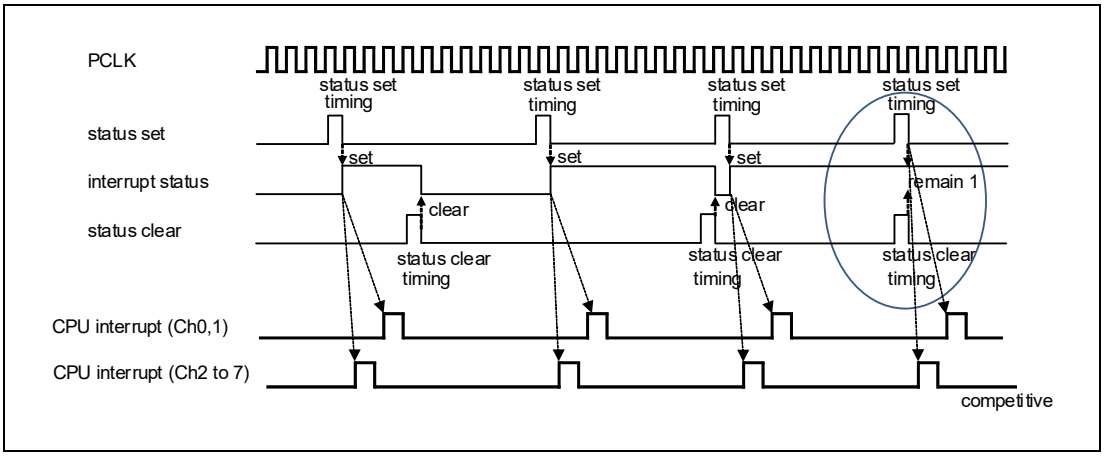


Figure 28.86 Interrupt Operation (Competitive)

If an interrupt setting condition is met while an interrupt status bit is set, an interrupt is output.

The following figure shows the operation described above.

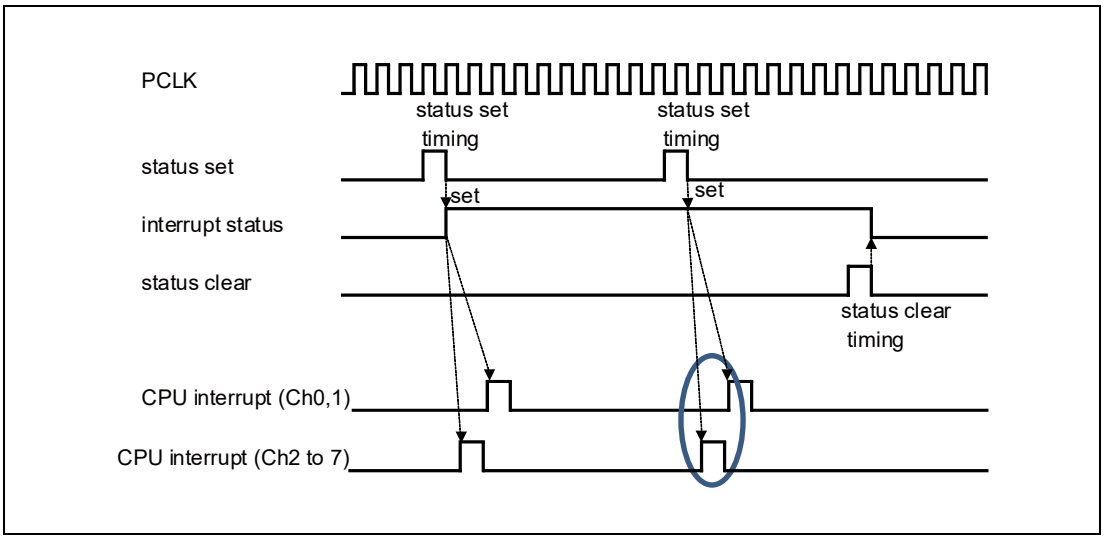

Figure 28.87 Interrupt Operation (Error Setting Occurs When Interrupt Status Is Set)

NOTE

A interrupt may be outputted in a period of maximum 14 PCLK even after PUOS.ACSTS becomes 0.

Then the interrupt should be ignored.

28.6.2.11 DMA Request Output

PSI5S can output 15 DMA requests (eight receive requests and seven transmit requests).

DMA requests are output only when DMA request output is enabled. DMA requests are not output when DMA request output is disabled.

Table 28.103 below lists the factors of DMA requests that are output in PSI5S mode.

Table 28.103 Timings of DMA Transfer Request Output

Operation Mode	Equipped Channel	Rx/Tx	DMA Request Output Factor
PSI5S mode	Ch0 to Ch7	Rx	<Sync> When last the PSI5 frame is stored in SFR. <Async> When a PSI5 frame is stored in SFR.
	Ch0 to Ch7	Rx	When a WDT error occurs.
	Ch1 to Ch7	Tx	When the last DDSR data is stored in the Tx shifter

Figure 28.76, **Figure 28.80**, **Figure 28.84**, and **Figure 28.85** show the DMA request output operations for reception.

Figure 28.68 and **Figure 28.69** show the DMA request output operations for transmission.

28.6.2.12 Transition to Configuration Mode

The operation of PSI5S to return to the configuration mode is described in **Section 28.4, Operation Modes**.

Figure 28.88 below describes the transition to the configuration mode during reception and transmission.

When CPU writes PSI5SjPUOEB.OPEN to 0 during reception, PSI5S waits for 16 PCLK cycles and then transitions to configuration mode if the PSI5S is not sending a frame.

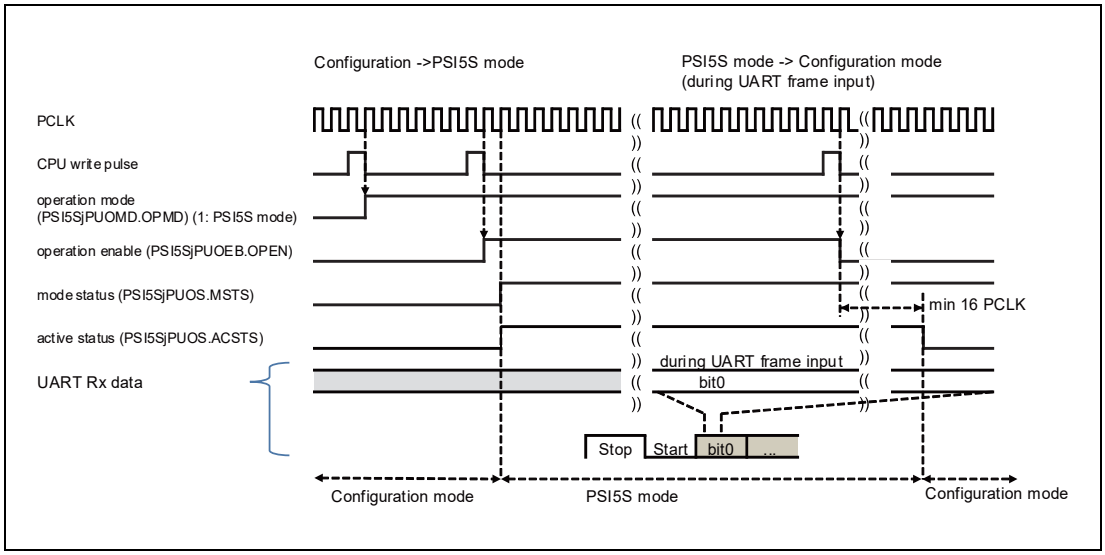

Figure 28.88 Move from PSI5S mode to Configuration Mode (Rx)

When CPU writes PSI5SjPUOEB.OPEN to 0 during transmission, PSI5S waits for 16 PCLK cycles and then transitions to configuration mode if the PSI5S isn't sending a frame. If PSI5S sends a frame, it transitions to configuration mode after it completes to send the frame.

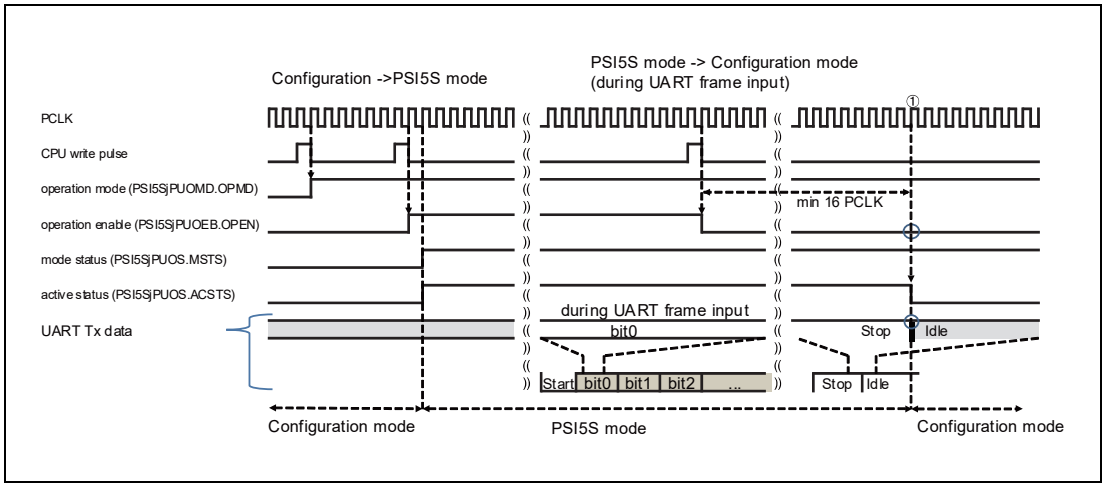

Figure 28.89 Move from PSI5S mode to Configuration Mode (Tx)

NOTE

In a case that the command to transceiver has been accepted in UART transmission module in PSI5S when CPU writes PSI5SjPUOEB.OPEN to 0, PSI5S wait for completion of the UART transmission. The maximum period of the mode transition time is a period of 9 UART frames.

28.6.3 Operations in UART Mode

When the operation mode is UART mode (PSI5SjPUOMD.OPMD = 0) and the operation is enabled (PSI5SjPUOEB.OPEN = 1), PSI5S can perform 1-byte UART communication with external devices.

Baud rate settings (prescaler division ratio, clock division ratio, and oversample number) are described in **Section 28.5.1, Common Setting Procedure**.

For the UART specifications, see **Section 28.2.1, Functional Overview**.

28.6.3.1 Normal Reception

PSI5S receives UART frames. Each time PSI5S receives one UART frame, PSI5S performs serial-to-parallel (S/P) conversion and determines whether there are any reception errors.

If no reception errors are found, PSI5S determines that the reception is normal, and then updates the receive data register (PSI5SjUCRD) and normal reception end status (PSI5SjUCRS.UTRFIN).

Figure 28.90 shows an example of UART reception.

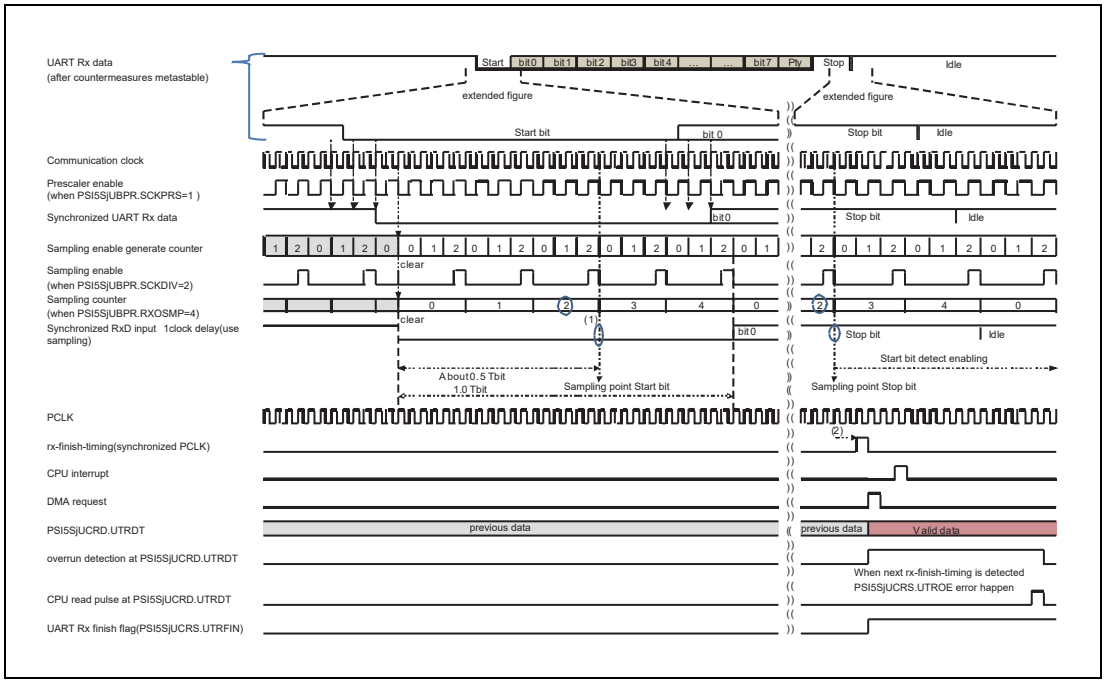

Figure 28.90 UART Rx (No Error)

(1) When the sampling counter value is “PSI5SjPUBPR.RXOSMP/2,” PSI5S samples receive data. (Example: When PSI5SjPUBPR.RXOSMP = 4, PSI5S fetches receive data when the sampling counter value is 2.)

(2) The asynchronous transfer processing based on PCLK and the communication clock causes a delay of several clock cycles.

28.6.3.2 Normal Transmission

When the transmit data register (PSI5SjUCID) is updated, PSI5S transmits UART frames.

When transmission ends, PSI5S updates the transmission status (PSI5SjUCTS, PSI5SjUCTM).

Figure 28.91 shows an example of UART transmission.

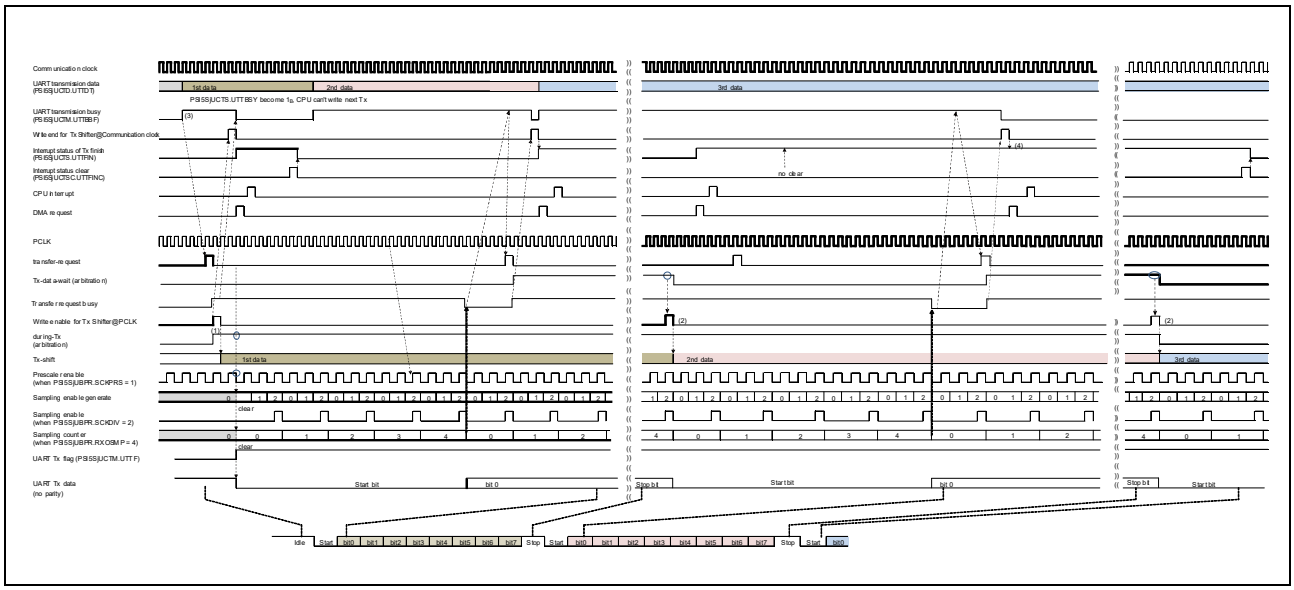

Figure 28.91 UART Tx (No Error)

(1) When the value of transfer-request is 1 and the during-Tx signal is high level, the signal to enable writing to the transmit data shift register (Tx Shifter) is output.

(2) When the Tx-data-wait signal is high at the end of stop bit, the write enable signal to the Tx shifter is generated.

(3) Even if the Tx Shifter register is not being used, PSI5S is busy until asynchronous transfer ends.

(4) Even when the PSI5SjUCTS.UTTFIN signal is high level, interrupts and DMA requests are generated.

Items (1) and (2) above describe the conditions for storing data in the Tx shifter.

28.6.3.3 Abnormal Reception (Reception Error)

After UART reception ends, parity, framing, and overrun errors are detected if they exist.

If an overrun error occurs, the data which is read from the mailbox is unpredictable.

If an error occurs, an interrupt status (see **Table 28.104**) occurs. The interrupt status signal is cleared by writing 1 to the corresponding bit (see **Table 28.104**) in the interrupt status clear register.

Table 28.104 below describes reception errors that can occur during operations in UART mode.

Table 28.104 UART Communication Rx Errors

Error	Status	Status Clear	Detection Condition
Parity error	PSI5SjUCRS.UTRPE	PSI5SjUCRSC.UTRPECL	When UART stop bit is received, the received parity value does not match.
Framing error	PSI5SjUCRS.UTRFE	PSI5SjUCRSC.UTRFECL	When UART stop bit is received, the received stop bit value is 0.
Overrun error	PSI5SjUCRS.UTROE	PSI5SjUCRSC.UTROECL	When UART stop bit is received, a new data is received before the previous data is read.*1

Note 1. When the PSI5S module returns to UART mode after a transition to configuration mode, an overrun error is not detected even if a new data is received in a condition that a previous received data has not been read.

PSI5S controls the Rx-finish timing and various errors when the stop bit is sampled (midway between stop bits).

Figure 28.92 and **Figure 28.93** below show examples of operation in which an Rx overrun, framing, and parity error occur when reception ends.

If both parity and framing errors occur, occurrence of a framing error is assumed.

When no errors occur, the Rx-finish status signal is set to high level.

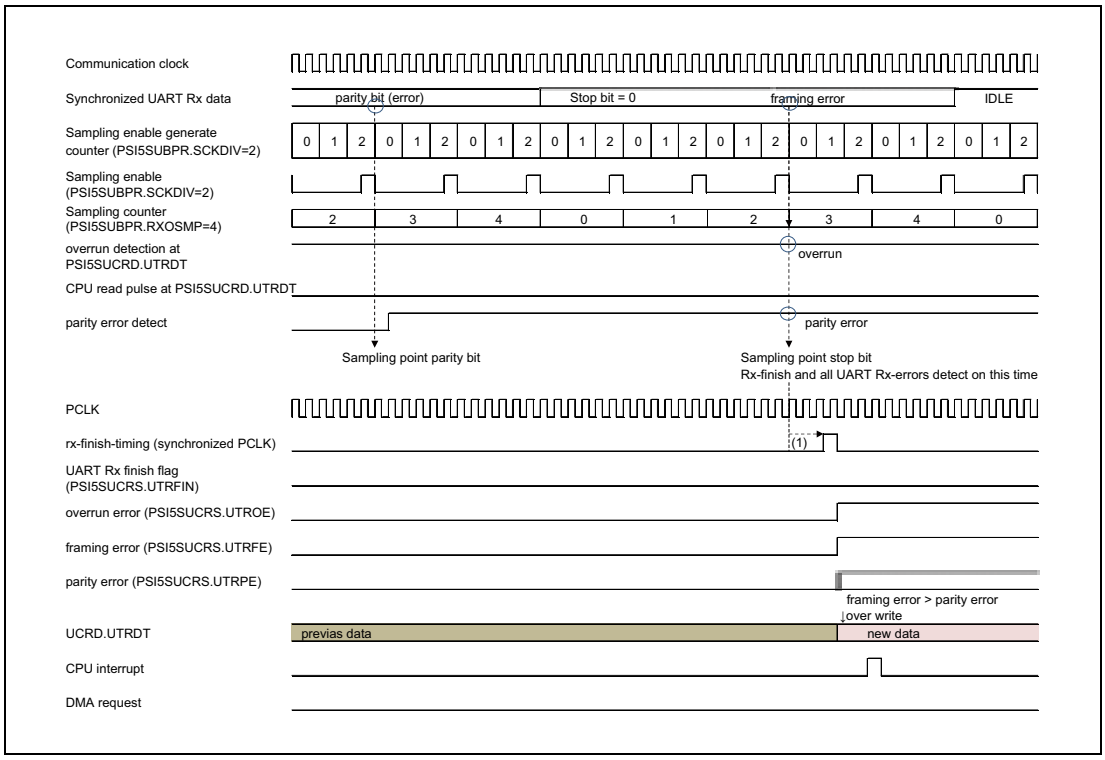

Figure 28.92 UART Rx (Received Error)

(1) The asynchronous transfer processing based on PCLK and the communication clock causes a delay of several clock cycles.

Figure 28.93 below describes an operation in which an overrun error is detected, as well as an example of an operation in which overrun error detection conflicts with receive data reading and an overrun error is not detected.

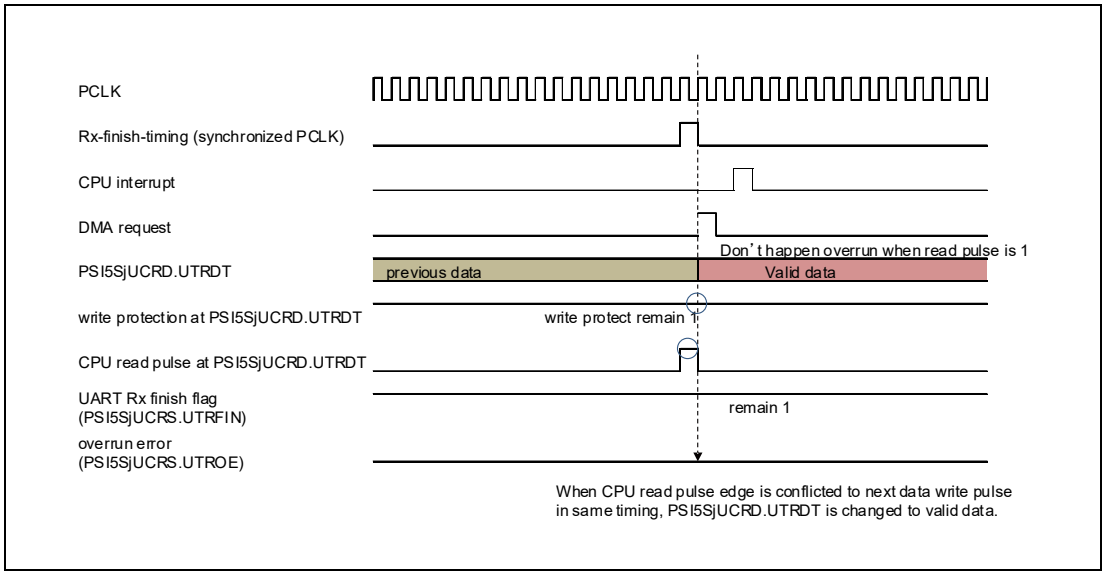

Figure 28.93 UART Rx (Overrun Error Is Not Detected)

The following figure shows an example of operation in which overrun error detection conflicts with receive data reading and an overrun error is detected.

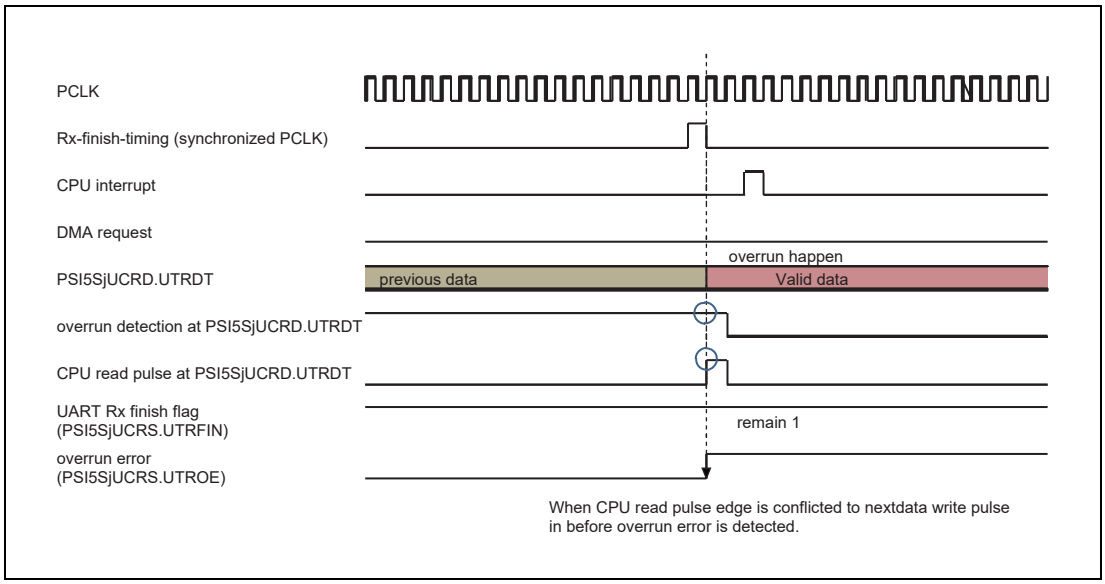

Figure 28.94 UART Rx (Overrun Error Is Detected)

28.6.3.4 Abnormal Transmission (Transmission Error)

This section describes the transmission errors that can occur in UART mode.

A transmission error is detected if new transmit data is set while PSI5S is busy with UART transmission.

When occurrence of an overwrite error is determined, the data written subsequently is not transmitted.

Already set data is not affected by the overwrite error, and the data is transmitted.

The interrupt status is caused by the occurrence of an overwrite error. The interrupt status can be cleared by writing 1 to the interrupt status clear register.

Table 28.105 UART Communication Tx Error

Error	Status	Status Clear	Detection Condition
Overwrite error	PSI5SjUCTS.UTTOWE	PSI5SjUCTSC.UTTOWECL	CPU writes (PSI5SjUCTD.UTTDT[7:0]), while PSI5SjUCTS.UTTBBF is asserted.

The following figure shows an example of operation in which transmission errors occur.

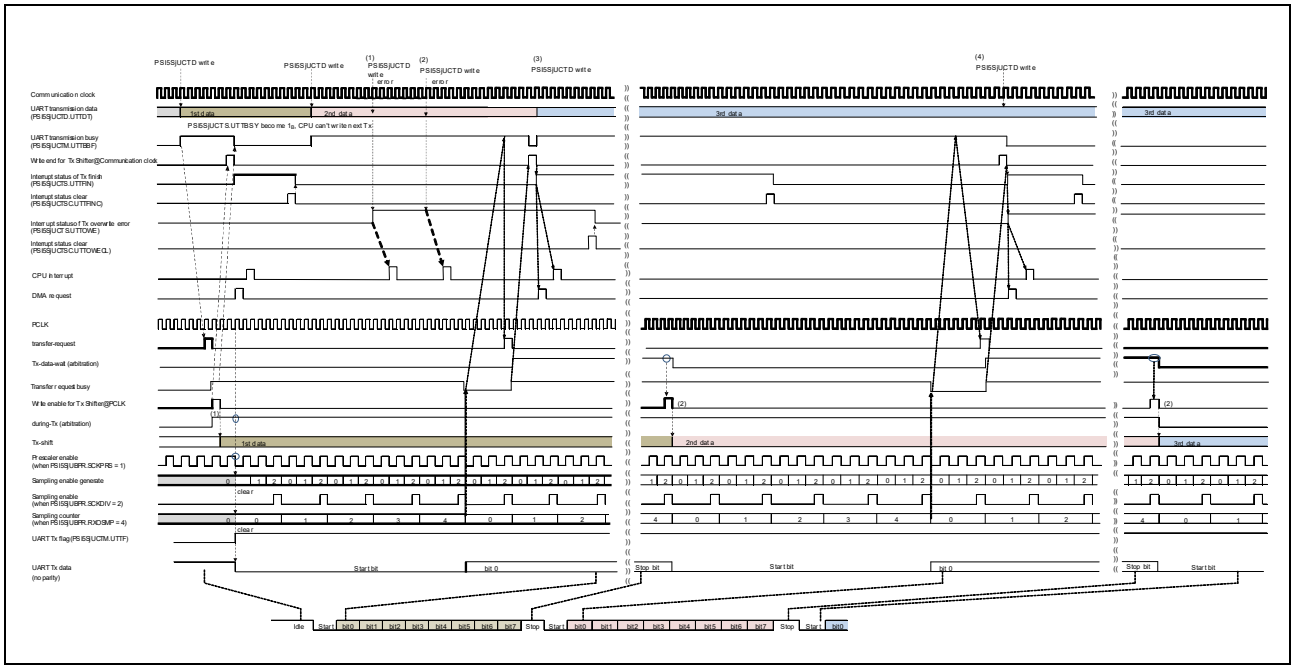

Figure 28.95 UART Tx (Overwrite Error)

(1) If data is written to the PSI5SjUCTD register with the PSI5SjUCTM.UTTBBF signal set to high level, the PSI5SjUCTM.UTTOWE signal is set to high level (indicating an overwrite error), and an interrupt is output.

(2) If data is written again to the PSI5SjUCTD register while the PSI5SjUCTS.UTTOWE signal is high level (indicating an overwrite error), an interrupt is outputs again.

(3) Even in the overwrite error status (PSI5SjUCTS.UTTOWE = high level), the PSI5SjUCTS.UTTFIN signal is set to high level and interrupts and DMA requests are output.

(4) This timing is a boundary for the occurrence of an overwrite error (PSI5SjUCTS.UTTOWE = high level). The overwrite error occurs together with transmission end (PSI5SjUCTS.UTTFIN = 1). In this case, both status signals are set to high level, and interrupts and DMA requests are output.

In configuration mode, even if data is written to the PSI5SjUCTD register, the PSI5S does not start the transmission and the PSI5S does not detect overwrite error.

28.6.3.5 Interrupt Output

PSI5S can output eight interrupt signals.

In UART mode, interrupts are output to channels 0 and 1.

Interrupts can be output only when interrupt output is enabled. If an interrupt factor occurs when interrupt output is disabled, no interrupt is output, but the interrupt status is indicated.

Table 28.106 below lists the factors of interrupts that are output in UART mode.

Table 28.106 Interrupt Output Timings

Output Signal	Interrupt Output Timing
int_psis_ch0	When UART data is received
int_psis_ch1	When UART data is stored in the Tx shifter.
int_psis_ch1	When UART data is written before the Tx shifter data is read.

Table 28.107 below describes the interrupt statuses and clearing of interrupt statuses.

To clear an interrupt status, write 1 to the bit corresponding to the interrupt status in the interrupt status clear register.

Table 28.107 Interrupt Status

Equipped Ch	Interrupt Status
Ch0	UART Rx parity error
Ch0	UART Rx framing error
Ch0	UART Rx overrun error
Ch0	UART Rx finish
Ch1	UART Tx overwrite error
Ch1	UART Tx finish

Figure 28.92, **Figure 28.93**, **Figure 28.94** and **Figure 28.95** show interrupt output operations.

28.6.3.6 DMA Request Output

PSI5S can output 15 DMA requests (eight receive requests and seven transmit requests).

In UART mode, DMA requests are output to channel 7 for reception and transmission.

If a request output factor occurs, one PCLK cycle of pulse signal outputs.

DMA requests are output only when DMA request output is enabled. DMA requests are not output when DMA request output is disabled.

Table 28.108 below lists the factors of DMA requests that are output in UART mode.

Table 28.108 Timings of DMA Transfer Request Output

Operation Mode	Equipped Ch	Rx/Tx	DMA Request Output Factor
UART mode	Ch7	Rx	When UART data is received (no error)
	Ch7	Tx	When UART data is stored in the Tx shifter

Figure 28.90 and **Figure 28.91** show the DMA request output operations.

28.6.3.7 Transition to Configuration Mode

The operation of PSI5S to return to the configuration mode is described in **Section 28.4, Operation Modes**.

Figure 28.96 below describes the transition to the configuration mode during reception and transmission.

When CPU writes PSI5SjPUOEB.OPEN to 0 during reception, PSI5S waits for 16 PCLK cycles and then transitions to configuration mode if the PSI5S isn't sending a frame.

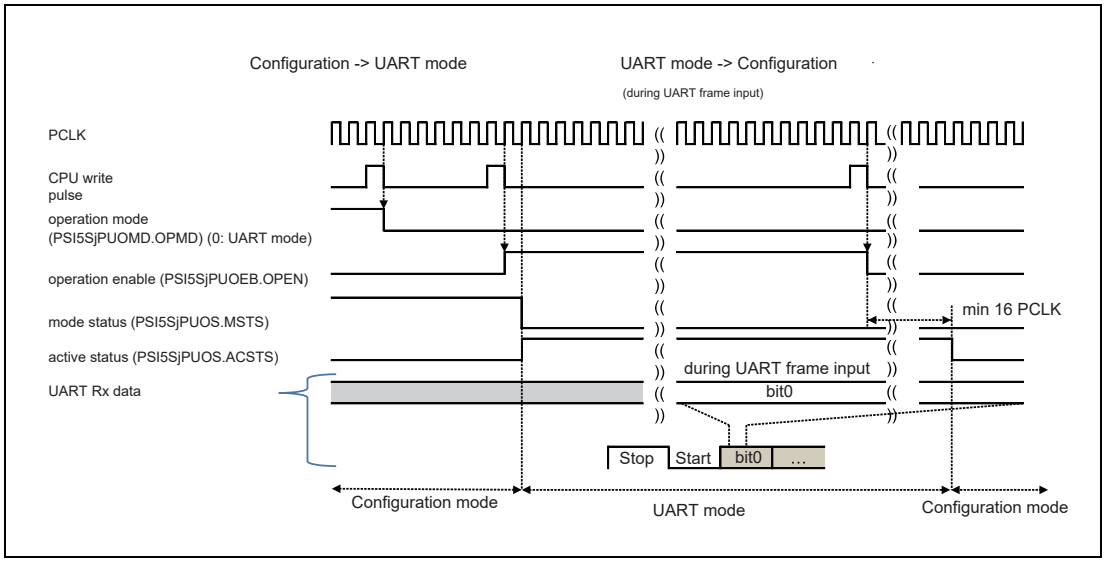

Figure 28.96 Move from UART Mode to Configuration Mode (Rx)

When CPU writes PSI5SjPUOEB.OPEN to 0 during transmission, PSI5S waits for 16 PCLK cycles and then transitions to configuration mode if the PSI5S isn't sending a frame. If PSI5S is sending a frame, it will transition to configuration mode after it completes to send the frame.

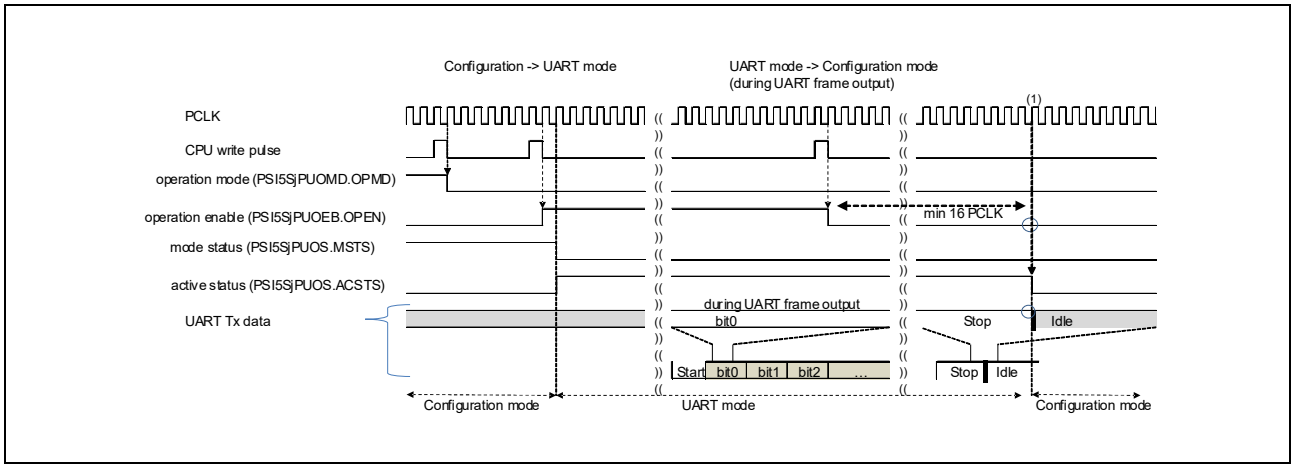

Figure 28.97 Move from UART Mode to Configuration Mode (Tx)

NOTE

In a case that the command to transceiver has been accepted in UART transmission module in PSI5S when CPU writes PSI5SjPUOEB.OPEN to 0, PSI5S wait for completion of the UART transmission. The maximum period of the mode transition time is a period of 2 UART frames.

28.6.4 Clearing Status Signals

Each status signal can be cleared by writing 1 to the corresponding bit in the status clear register. Note, however, that the following statuses are cleared automatically when their clearing conditions are met:

PSI5SjPUOS.SWSTS: Cleared when the software reset period has passed (**Figure 28.26**)

PSI5SjPUOS.ACSTS: Cleared when PSI5S returns to the configuration mode

PSI5SjPTFS.TXSTS: Cleared when the last byte of data is stored in the Tx shifter (**Figure 28.65**)

PSI5SjUCTM.UTTF: Cleared when stop bits are transferred in UART mode.

PSI5SjUCTM.UTTBBF: Cleared when transmit data is loaded into the transmit buffer in UART mode (**Figure 28.91**)

PSI5SjPDDS(1-7).DDSRSTS: Cleared when the last ECU-to-sensor data is stored in the Tx shifter in PSI5S mode (**Figure 28.68**) or when a DDSR transmission stop request is generated (**Figure 28.70**)

If setting and clearing conditions are both met at the same time, setting conditions have priority over clearing conditions.

28.7 Note

28.7.1 Notes

When the UART receive data pin is “Low” level at the transition to UART mode, the PSI5S may detect a UART parity error or a UART framing error.

28.7.2 Restrictions

- Baud rate tolerance must be within 1.5%.
- The minimum interval is 60 PCLK cycles from transition to configuration mode until set operation to enable (PSI5SjPUOEB.OPEN = 1).

Section 29 Renesas High-Speed Serial I/F (RHSIF)

This section contains a generic description of the Renesas high-speed Serial I/F (RHSIF). The first part in this section describes all this product specific properties, such as the number of units and register base addresses. The remainder of this section describes the functions and registers of the RHSIF.

29.1 Features RHSIF for RH850/U2A-EVA

29.1.1 Number of Units and Channels

This microcontroller has the following number of Renesas high-speed Serial I/F (RHSIF) units.

Table 29.1 Number of Units

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of Units	1 (n = 0)	1 (n = 0)	1 (n = 0)	1 (n = 0)	1 (n = 0)	1 (n = 0)	—	—	—	—
Name	RHSIFn									

Note: Regarding the unit index “n” in this section, the individual RHSIF units are identified by the index “n”.

29.1.2 Register Base Addresses

RHSIFn base addresses are listed in the following table. RHSIFn register addresses are given as offsets from the base address in general.

Table 29.2 Register Base Addresses

Base Address Name	Base Address	Bus Group
<RHSIF0_L1_base>	FF00 0000_H	P-Bus Group 9
<RHSIF0_L2_base>	1000 0000_H	H-Bus Group 0

29.1.3 Clock Supply

Clock supply by and to RHSIFn is listed in the following table.

Table 29.3 Clock Supply

Unit Name	Clock for the Unit	Supply Clock Name
RHSIFn (L2)	H-Bus clock (Register access/Operation clock)	CLK_HBUS
RHSIFn (L1)	PCLK (Register access/Operation clock)	CLK_HBUS
	CLK_MOSC Communication clock (Internal)	CLK_MOSC
	CLK_LSB Communication clock (Internal)	CLK_LSB
	RHSIF0_REFCLK Communication clock (External)	HSIF0_REFCLK

29.1.4 Interrupt Requests and Error Notifications

RHSIFn interrupt requests are listed in the following table.

Table 29.4 Interrupt and DMA/DTS Requests

Interrupt Symbol Name	Unit Interrupt Signal	Description	Interrupt Number	DMA Trigger Number	DTS Trigger Number
RHSIF0					
INTRHSIF0TXCMP	RHSIFnTXCMP (n = 0)	Transmit complete interrupt	612	—	—
INTRHSIF0TXEX	RHSIFnTXERR (n = 0)	Transmit exception interrupt	613	—	—
INTRHSIF0RXCMP	RHSIFnRXCMP (n = 0)	Receive complete interrupt	614	—	—
INTRHSIF0RXEX	RHSIFnRXERR (n = 0)	Receive exception interrupt	615	—	—
INTRHSIF0ICLCR	RHSIFnRXICLC (n = 0)	ICLC receive interrupt	616	—	—
INTRHSIF0INTCH0	int_hsif_ch0	Channel 0 interrupt	617	Group1-120	Group2-40
INTRHSIF0INTCH1	int_hsif_ch1	Channel 1 interrupt	618	Group1-121	Group2-41
INTRHSIF0INTCH2	int_hsif_ch2	Channel 2 interrupt	619	Group1-122	Group2-42
INTRHSIF0INTCH3	int_hsif_ch3	Channel 3 interrupt	620	Group1-123	Group2-43
INTRHSIF0STR	int_hsif_str	Stream interrupt	621	—	—
INTRHSIF0ERR	int_hsif_err / int_hsif_sec	Error interrupt / Security interrupt	622	—	—

This module has no error notifications.

29.1.5 Reset Sources

RHSIFn reset sources are shown below. RHSIFn is initialized by the following reset sources.

Table 29.5 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
RHSIFn	All registers	√	√	√	√	√	√	—

29.1.6 External Input/Output Signals

External input/output signals of RHSIF units are listed below.

Table 29.6 External Input/Output Signals

Unit Signal Name	Description	Alternative Port Pin Signal
RHSIF0		
RHSIF0_REFCLK	RHSIF0 Reference clock input/output	HSIF0_REFCLK
RHSIF0_RXDN	RHSIF0 receive data differential input	HSIF0_RXDN
RHSIF0_RXDP	RHSIF0 receive data differential input	HSIF0_RXDP
RHSIF0_TXDN	RHSIF0 transmission data differential output	HSIF0_TXDN
RHSIF0_TXDP	RHSIF0 transmission data differential output	HSIF0_TXDP

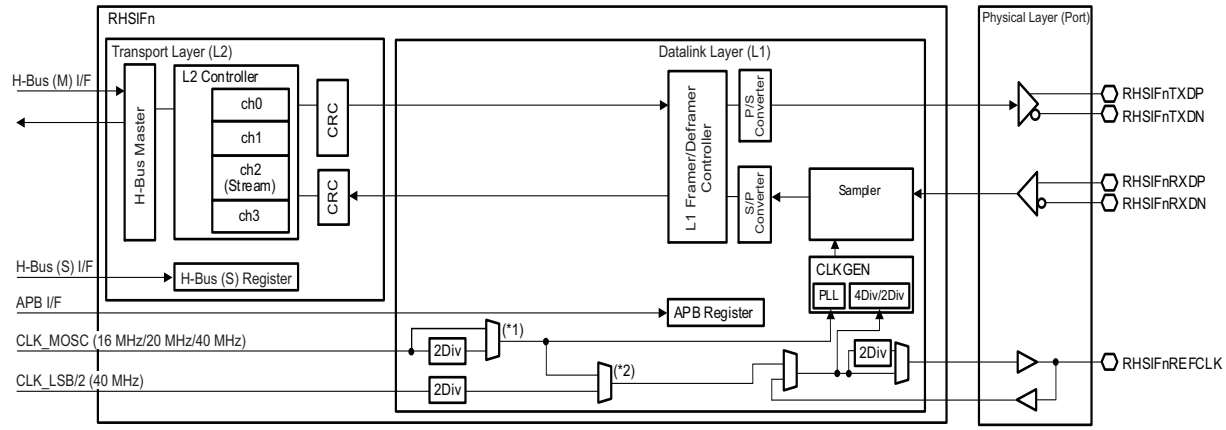
29.2 Overview

29.2.1 Functional Overview

- Four channels, including one channel with data streaming capability
- Bus master interface used by target node to access shared memory
- H-Bus bus master supporting “Write/Read” command
  - Writing a single 8/16/32 bit data value into the register of a target device
  - Reading a single data from 8/16/32 bit register of a target device
  - Support of 32-bit address range
- Built-in DMA controller supporting “Stream write” command
  - 128 or 256-bit data transfer on streaming channel
  - Up to two outstanding requests of “Stream write” are supported by the initiator
- Transfers protected by CRC16
- Programmable time outs for detection of blocked answer transfers
- Automatic frame transfer ID generation for detection of dropped frames
- Fixed priority channel selection
- Remote trigger of event/interrupt in the target device by the initiator
- Access protection from an external master
  - Can configure four access windows
  - Can configure of access rule (Prohibited, R, W, RW) at each window
- Security function
  - Authentication at the time of initial communication
  - ID authentication
  - Challenge and response authentication
- Point-to-point high speed serial communication between two devices
- Full duplex communication
- Supports dual mode (register configurable Master/Slave).
- Supports asynchronous data transfer at data rates up to a maximum of 320 M Baud
- Transmits and receives data, CTS, ICLC and unsolicited frames
- Supports automatic ping response generation in slave mode
- Supports detection of unsupported channel number and unsupported payload sizes
- The interface is based on IEEE 1596.3-1996 reduced range link LVDS IOs
- Built-in self test functions

29.2.2 Block Diagram

The following figure shows a top level block diagram of the RHSIF module.



Note 1. When CLK_MOSC frequency is 16 MHz / 20 MHz, it selects CLK_MOSC.
When CLK_MOSC frequency is 40 MHz, it selects CLK_MOSC divided into 2: CLK_MOSC/2

Note 2. When CLK_MOSC frequency is 20 MHz / 40 MHz, it selects clock outputted from **Note 1.**: CLK_MOSC or CLK_MOSC/2.
When CLK_MOSC frequency is 16 MHz, it selects CLK_LSB divided into 2: CLK_LSB/2

Figure 29.1 Module Block Diagram

CAUTION

When CLK_MOSC frequency is 24MHz, RHSIF can NOT operate normally.

29.2.3 Communication Protocol

29.2.3.1 Protocol Definitions

Table 29.7 Protocol Definitions

Item	Definition	Comment
Master	The module that supplies the clock and controls Link initialization on the Slave interface.	L1
Slave	The module that receives the clock.	L1
Initiator	The module that sends an L2 frame with either the Write, Read, Stream, Event, or ID command	L2
Target	The module that sends an L2 frame with either the Read Answer, ACK, or NACK command	L2
TxLink	Point-to-point connection executing transfer from Master to Slave.	L1
RxLink	Point-to-point connection executing transfer from Slave to Master.	L1

29.2.3.2 Connection

The **Figure 29.2** shows the connection between master and slave of RHSIF.

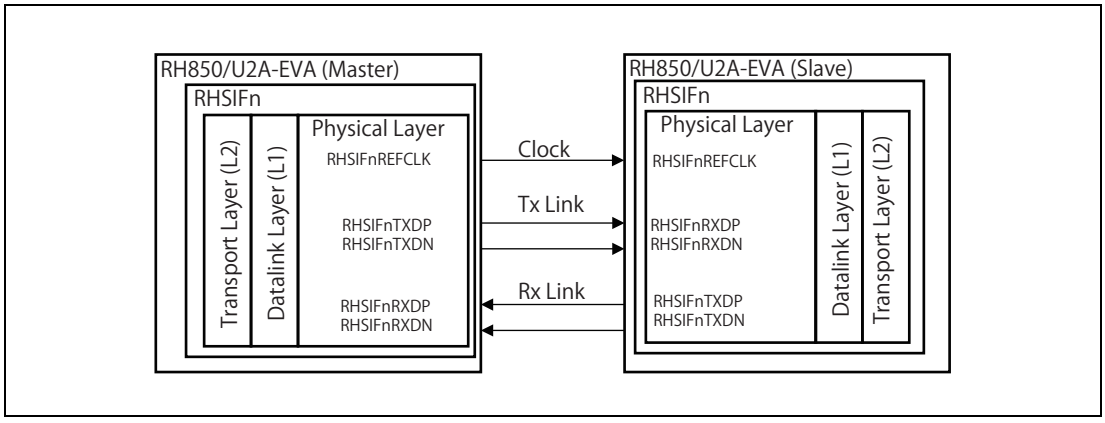


Figure 29.2 Connection between Master and Slave of RHSIF

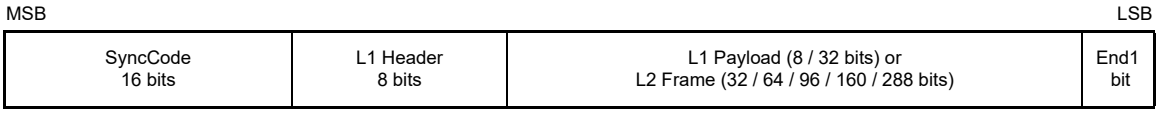
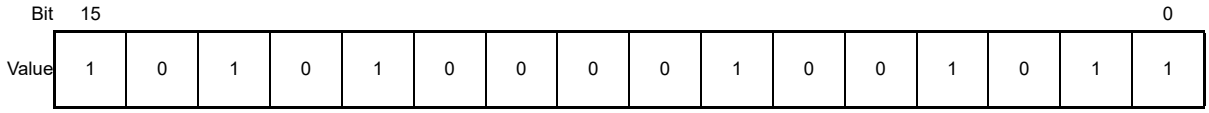
29.2.3.3 L1 Frame

The L1 Frame Format is shown below.



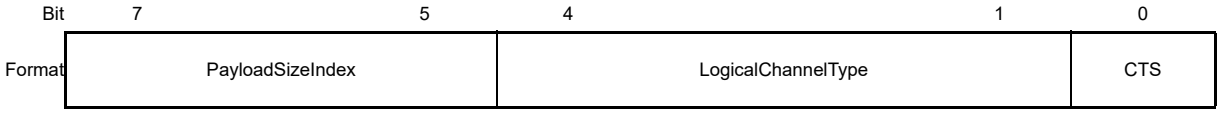
(1) SyncCode

The value in this field is assigned to SyncCode, and the value is fixed in $A84B_H$



(2) L1 Header Format

The value in this field is assigned to L1 Header.



(a) List of Payload Size Index

The **Table 29.8**. shows the details of the payload size index values.

Table 29.8 List of Payload Size Index

Payload Size Index	Payload Size	Total Frame Size*1	Comment
000	8	32	Interface Control
001	32	56	—
010	64	88	—
011	96	120	—
100	128	152	Not used
101	256	280	Not used
110	160	184	—
111	288	312	—

Note 1. “Endbit” is excluded from Total Frame Size.

(b) List of Logical Channel Types

The **Table 29.9** shows the details of Logical Channel Type values.

Table 29.9 List of Logical Channel Types

Logical Channel Type	Logical Channel Type Master	Logical Channel Type Slave
0000	Interface Control	Interface Control PING answer (32 bit value)
0001	Reserved for future use	
0010	Reserved for future use	
0011	CTS frame for flow control	
0100	Data Channel A	
0101	Data Channel B	
0110	Data Channel C	
0111	Data Channel D	
1000-1111	Reserved for future use	

(c) List of CTS

The **Table 29.10** shows the details of CTS values.

Table 29.10 List of CTS

CTS	Function
0	BackPressure
1	Ready

(3) L1 Payload

The value in this field is assigned to L1 Payload as ICLC Command.

(a) List of ICLC Commands

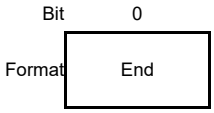
The **Table 29.11** shows the details of ICLC command values.

Table 29.11 List of ICLC Commands

Value (hex)	Function
00_H	PING (Sends by master interface. Slave sends back a fixed 32-bit payload result ($ABCDEF01_H$))
02_H	Slave interface PLL start (in preparation for high speed mode)
04_H	Slave interface PLL stop (after fallback from high speed mode)
08_H	Selects the Slow Speed mode for transfers from the Master interface to the Slave interface
10_H	Selects the Fast Speed mode for transfers from the Master interface to the Slave interface
20_H	Selects the Slow Speed mode for transfers from the Slave interface to the Master interface
80_H	Selects the Fast Speed mode for transfers from the slave interface to the master interface
31_H	Enables the Slave interface transmitter
32_H	Disables the Slave interface transmitter
34_H	Turn on test mode (Send 101010 .. on RX line continuously using actual configured RX line data rate; cancelled by issuing “test mode off” command.)
38_H	Turns off the test mode (Cancels the clock test mode and payload loopback)
FF_H	Turns on the payload loopback (Incoming frames at Slave interface are looped back until cancelled by a Frame containing “test mode off”.)

(4) Endbit

The value in this field is assigned to Endbit.



(a) List of Endbit

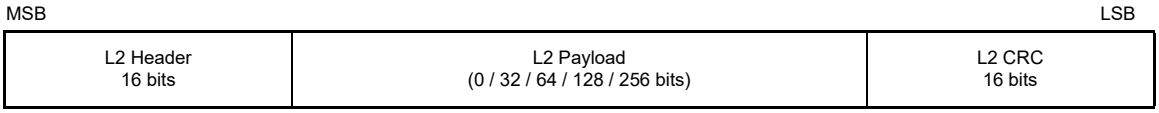
The **Table 29.12** shows the details of the Endbit values.

Table 29.12 List of Endbit

Endbit	Function
0	Normal
1	Sleep

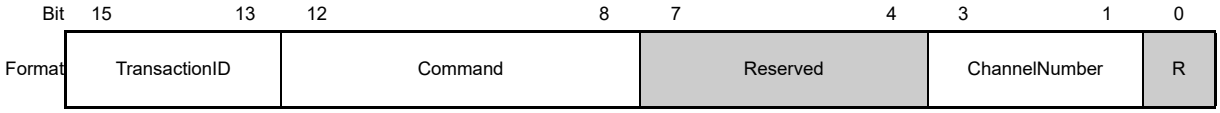
29.2.3.4 L2 Frame

The L2 Frame Format is shown below.



(1) L2 Header Format

The value in this field is assigned to L2 Header.



(a) Transaction ID

The value in this field is assigned to the outgoing frame. Afterwards, it is automatically increased and the new value is assigned to the next outgoing frame. It wraps around.

(b) List of L2 Commands

The **Table 29.13** shows the details of the L2 Command values.

Table 29.13 List of L2 Commands

Header Bit Number					Command
12	11	10	9	8	
0	0	0	0	0	Reads 8 bits
0	0	0	0	1	Reads 16 bits
0	0	0	1	0	Reads 32 bits
0	0	0	1	1	Reserved
0	0	1	0	0	Writes 8 bits
0	0	1	0	1	Writes 16 bits
0	0	1	1	0	Writes 32 bits
0	0	1	1	1	Reserved
0	1	0	0	0	ACK
0	1	0	0	1	NACK (ACK Error)
0	1	0	1	0	Read Answer
0	1	0	1	1	Reserved
0	1	1	0	0	Event Command (Trigger)
0	1	1	0	1	Reserved
0	1	1	1	0	Reserved
0	1	1	1	1	Reserved
1	0	0	0	0	Reserved
1	0	0	0	1	Reserved
1	0	0	1	0	ID Read (Read JTAG ID)*1
1	0	0	1	1	Reserved
1	0	1	0	0	Reserved
1	0	1	0	1	Reserved
1	0	1	1	0	Reserved
1	0	1	1	1	Stream
1	1	0	0	0	Reserved
1	1	0	0	1	Reserved
1	1	0	1	0	Reserved
1	1	0	1	1	Reserved
1	1	1	0	0	Reserved
1	1	1	0	1	Reserved
1	1	1	1	0	Reserved
1	1	1	1	1	Reserved

Note 1. Refer to **Section 53, Boundary Scan**, **Table 53.5** for details.

(c) List of Channel Number

The **Table 29.14** shows the details of the Channel Number values.

Table 29.14 List of Channel Number

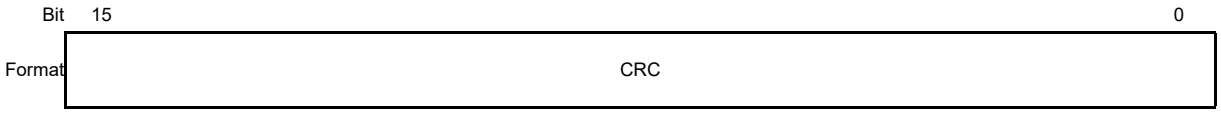
HSSL Channel Name	Channel Number Coding in Header (s)			Comment
	HSSL Header (Binary)		Data Link Layer Header (Binary)	
	Code Table I	Code Table II		
0 (channel A)	000	100	0100	In use
1 (channel B)	001	101	0101	In use
2 (channel C)	010	110	0110	In use
3 (channel D)	011	111	0111	In use
4 (channel E)	100	000	1000	Reserved
5 (channel F)	101	001	1001	Reserved
6 (channel G)	110	010	1010	Reserved
7 (channel H)	111	011	1011	Reserved

(2) L2 Payload

The value in this field is assigned to actual data.

(3) L2 CRC

The value in this field is assigned to CRC.



The last field of the L2 frame contains the CRC field. To setup the CRC value, this protocol uses the following algorithm:

- CRC-16-CCITT polynomial x16 + x12 + x5 + 1

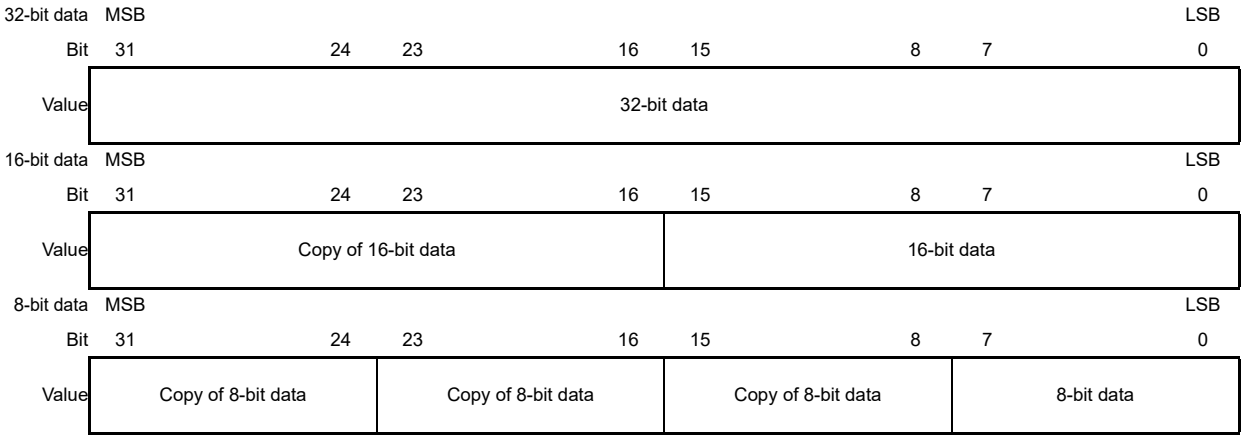
with the following standard properties:

- seed: $FFFF_H$
- calculation direction: Most significant bit first (most significant bit to least significant bit in the header, and then the most significant bit to least significant bit in the payload)
- CRC result direction: Most significant bit first

29.2.3.5 Data Format

(1) Non Stream data format

Data is mapped into a 32-bit wide frame for 8 to 16 bits with no specific data frames defined. The following pictures show the mapping of 8/16/32 bit data into the 32 bit wide data frame.

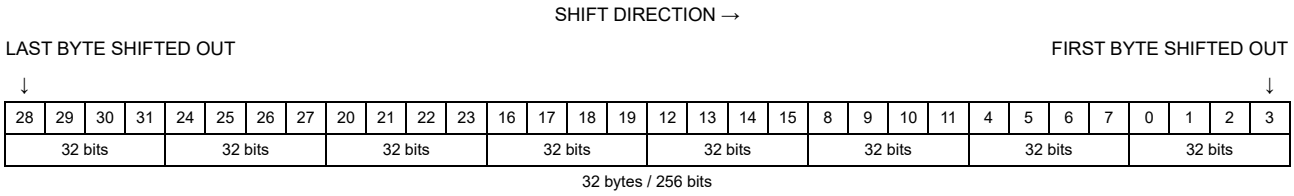


(2) Stream data format

(a) 256-bit Data Stream Format

Data is transmitted in a stream frame as a sequence of 8 times a 32-bit value. The initiator and target modules must be able to accept the data sequence in this format.

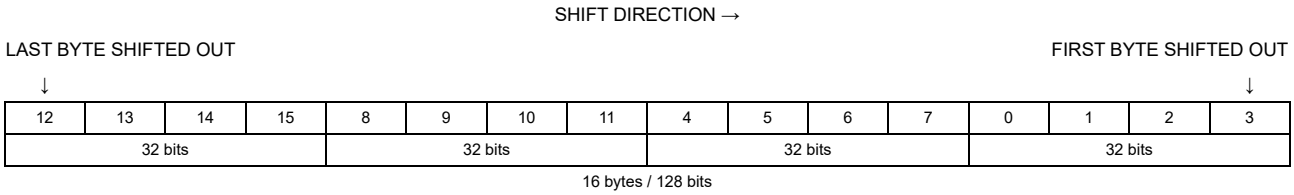
The bytes are sent with the most significant bit sent first.



(b) 128-bit Data Stream Format

Data is transmitted in a stream frame as a sequence of 4 times a 32-bit value. The initiator and target modules must be able to accept the data sequence in this format.

The bytes are sent with the most significant bit sent first.



29.2.3.6 All Sending and Receiving Frames

The **Figure 29.3** shows the all sending and receiving frames.

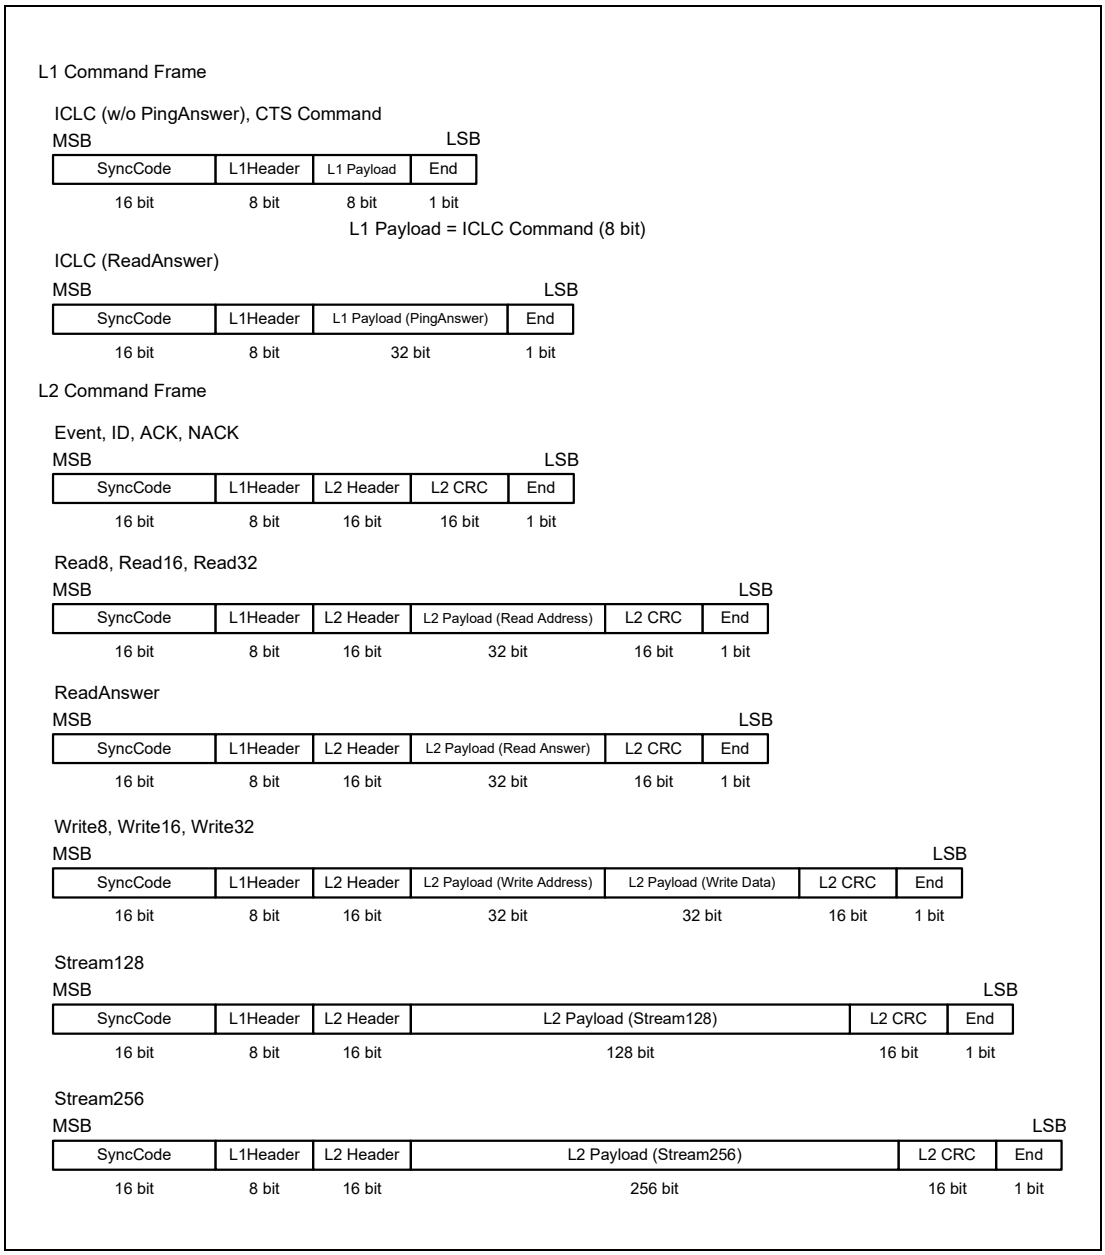


Figure 29.3 All Sending and Receiving Frames

29.2.3.7 Number of Transfer Bits in each Frame

Table 29.15 Number of Transfer Bits in each Frame List

#	Layer	L1			L2			L1	Total Bit	Command	Direction
		Sync	Header	Payload	Header	Payload	CRC	END			
1	L1	16	8	8	—			1	33	ICLC (w/o PingAnswer)	Master → Slave
2										CTS*1	
3				32					57	ICLC PingAnswer	Slave → Master
4	L2	16	8	—	16	—	16	1	57	ID, Event	Initiator → Target
5										ACK, NACK	Target → Initiator
6						32			89	Read8, Read16, Read32	Initiator → Target
7										ReadAnswer	Target → Initiator
8						64			121	Write8, Write16, Write32	Initiator → Target
9						128			185	Stream128	Initiator → Target
10						256			313	Stream256	Initiator → Target

Note 1. payload size is fixed to 8-bit data when transmitting and can be any size when receiving.

29.2.3.8 List of Command and Response

Table 29.16 List of Command and Response

#	Layer	Command Issue	Response	
			Normal	Abnormal
1	L1	Ping	PingAnswer	NoResponse
2	L2	ID	ReadAnswer	NACK
3		Event	ACK	NoResponse
4		Read8, Read16, Read32	ReadAnswer	NACK
5		Write8, Write16, Write32	ACK	NACK
6		Stream128, Stream256	ACK	NACK

29.2.3.9 Command Pipelining

The protocol does not allow pipelining of commands. The initiator shall not send any new command before the target has returned an answer (ACK, NACK, Read Answer). If the target receives a command before it is able to answer the previous command, it shall ignore the command.

There is one exception to this rule. Stream Commands can be pipelined. This feature is only available for Stream Commands. The initiator is allowed to send the next command before it has received an answer from the target linked per Transaction ID to the command sent before. The pipeline depth is limited to a sequence of two commands in the current protocol.

In summary, the initiator is allowed to send a Stream Command, which can be immediately followed by a second Stream Command. After the second command, the initiator has to stop and wait for an answer from the target.

The target shall be capable of receiving pipelined Stream Commands up to a pipeline depth of two Stream Commands.

29.3 Operation

29.3.1 Operation Flow

The RHSIF can perform data transmission/reception after the initial setting is configured according to the setup flow shown in **Figure 29.4** below.

For details about the initial setting for L2 and L1, refer to **Section 29.4, Transport Layer (L2)** and **Section 29.5, Datalink Layer (L1)**, respectively.

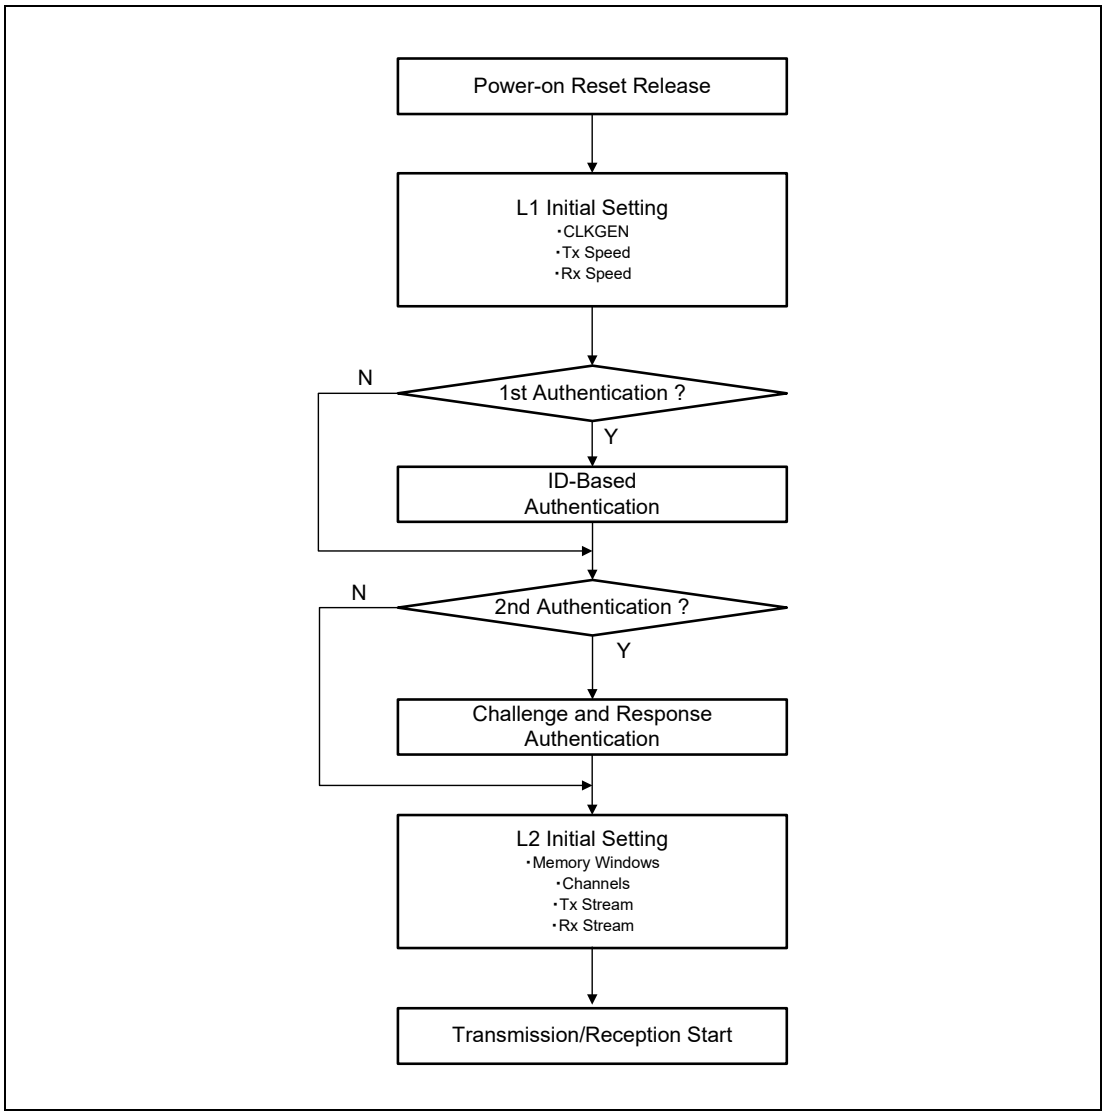

Figure 29.4 Operation Flow

29.4 Transport Layer (L2)

29.4.1 Overview

29.4.1.1 Functional Overview

The Renesas High-speed Serial Interface Transport Layer IP (hereinafter referred to as “L2”) is compliant with following specifications.

L2 supports following features / functions.

- Supports 4 channels
  - Supports stream transfer on channel 2
  - Channel arbitration: Fixed (Higher) Ch.0 → Ch.1 → Ch.2 → Ch.3 (lower)
- Generates header
  - Manages transaction-ID
  - Supports both channel number code table I and II
- Generates and validates CRC-16
- Supports both initiator node and target node
- Initiator node function
  - Generates and transmit following request Commands
    - Read Command (8 bits, 16 bits, 32 bits)
    - Write Command (8 bits, 16 bits, 32 bits)
    - Event Command
    - ID Command
    - Stream Command (256 bits, 128 bits)
  - Number of outstanding requests: Non-Stream = 1 / channel, Stream = 2 (channel 2 only)
  - Detects reply timeout
    - The timeout value is programmable by register setting
  - Implements the DMA controller for stream transmission
- Target node function
  - Number of acceptable requests: Non-Stream = 1 / channel, Stream = 2 (channel 2 only)
  - Translates HSSL Commands to H-Bus master requests
    - Refer to **Section 44, Functional Safety** about the H-Bus SPID setting.
  - Supports the access protect function from an external master
    - Supports 4 areas, independent of channel
      - Can configure access rule (prohibited, read only, write only, read/write)
      - Can configure memory access window
    - Supports special authentication based on the security policy of this product
      - 256-bit ID authentication
      - “Challenge and response” authentication

– Generates and transmits the following reply Commands as target node
  - ACK/NACK Command
  - Read Answer Command
– Implements the DMA controller for stream reception
– Generates interrupt by receiving Event Command

29.4.1.2 Block Diagram

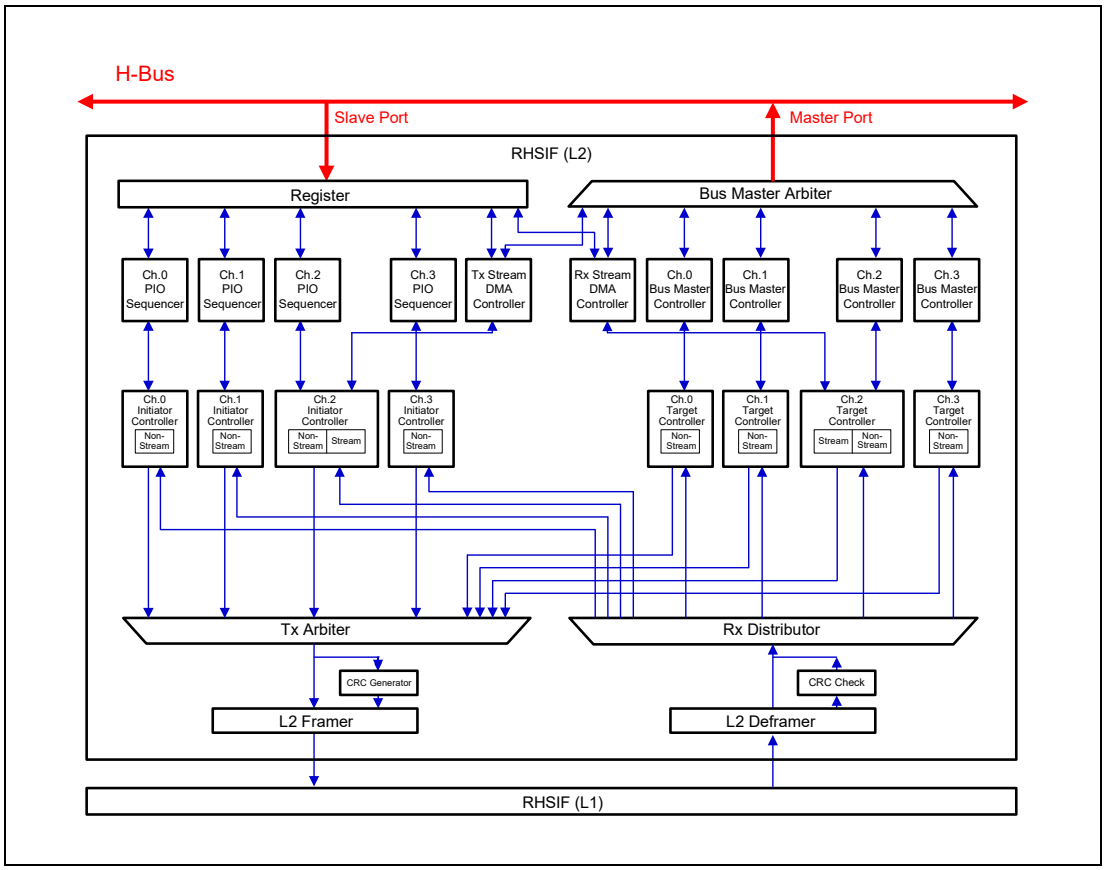

Figure 29.5 Block Diagram of L2

29.4.2 Registers

This section describes the L2 registers in detail.

In case of a concurrent update of the same register bit, L2 module write (hardware write) has higher priority than CPU write (software write).

29.4.2.1 List of Registers

The register map of an L2 module is shown in **Table 29.17**.

The L2 module remains in reset while RESET.

The values shown in **Table 29.17** in the registers description under “Values after Reset” are related to this reset state.

For further information about the L2 operation modes, refer to **Section 29.4.3, Operation**.

The specific base address of a module for an L2 module needs to be added to each of the specified offset addresses.

Table 29.17 List of Registers (1/3)

Module Name	Register Name	Symbol	Address	Access	Access Protection	
					HBG	Other
RHSIFn	Module mode register	RHSIFnMMD	<RHSIFn_L2_base> + 000_H	32, 16, 8	HBG91	-
	Module control register	RHSIFnMCT	<RHSIFn_L2_base> + 008_H	32, 16, 8	HBG91	(*1)
	Module status register	RHSIFnMST	<RHSIFn_L2_base> + 010_H	32, 16, 8	HBG91	-
	Module interrupt status register	RHSIFnMIST	<RHSIFn_L2_base> + 018_H	32, 16, 8	HBG91	-
	Module reply timeout time register	RHSIFnMRT	<RHSIFn_L2_base> + 020_H	32, 16, 8	HBG91	-
	Module memory window A start address register	RHSIFnMWAA	<RHSIFn_L2_base> + 040_H	32, 16, 8	HBG91	(*1)
	Module memory window A size register	RHSIFnMWAS	<RHSIFn_L2_base> + 048_H	32, 16, 8	HBG91	(*1)

	Channel 2 mode register	RHSIFnCMD2	<RHSIFn_L2_base> + 500_H	32, 16, 8	HBG91	-
	Channel 2 control register	RHSIFnCCT2	<RHSIFn_L2_base> + 508_H	32, 16, 8	HBG91	-
	Channel 2 status register	RHSIFnCST2	<RHSIFn_L2_base> + 510_H	32, 16, 8	HBG91	-
	Channel 2 status clear register	RHSIFnCSC2	<RHSIFn_L2_base> + 518_H	32, 16, 8	HBG91	-
	Channel 2 interrupt enable register	RHSIFnCIE2	<RHSIFn_L2_base> + 520_H	32, 16, 8	HBG91	-
	Channel 2 read/write address register	RHSIFnCAR2	<RHSIFn_L2_base> + 528_H	32, 16, 8	HBG91	-
	Channel 2 write data register	RHSIFnCWD2	<RHSIFn_L2_base> + 530_H	32, 16, 8	HBG91	-
	Channel 2 read data register	RHSIFnCRD2	<RHSIFn_L2_base> + 538_H	32, 16, 8	HBG91	-
	Channel 3 mode register	RHSIFnCMD3	<RHSIFn_L2_base> + 580_H	32, 16, 8	HBG91	-
	Channel 3 control register	RHSIFnCCT3	<RHSIFn_L2_base> + 588_H	32, 16, 8	HBG91	-
	Channel 3 status register	RHSIFnCST3	<RHSIFn_L2_base> + 590_H	32, 16, 8	HBG91	-
	Channel 3 status clear register	RHSIFnCSC3	<RHSIFn_L2_base> + 598_H	32, 16, 8	HBG91	-
	Channel 3 interrupt enable register	RHSIFnCIE3	<RHSIFn_L2_base> + $5A0_H$	32, 16, 8	HBG91	-
	Channel 3 read/write address register	RHSIFnCAR3	<RHSIFn_L2_base> + $5A8_H$	32, 16, 8	HBG91	-
	Channel 3 write data register	RHSIFnCWD3	<RHSIFn_L2_base> + $5B0_H$	32, 16, 8	HBG91	-
	Channel 3 read data register	RHSIFnCRD3	<RHSIFn_L2_base> + $5B8_H$	32, 16, 8	HBG91	-

Note: Addresses other than those listed above are reserved. Do not access reserved addresses.

Note 1. Data cannot be written to these bits from the IP's master port. When the RHSIF's master port writes to these bits, these bits have the read-only (R) attribute. These bits can be read from all master devices. Initial value depends on specified setting. For details, refer to each section.

Note 2. Data can be read from or written to these bits only via the master port of RHSIF. When another master device such as a CPU, accesses these bits, these bits have the read-only (R) attribute.

Note 3. Data can be read from or written to these bits only from ICUMHA. When another master device such as a CPU accesses these bits, these bits have the read-only (R) attribute.

The access size mentioned in **Table 29.17** is required for write accesses. In addition all registers are readable by 8, 16 and 32 bit access.

The user should not access the registers marked as reserved in **Table 29.17**.

The user should not write bits to a value specified as "invalid" in the description of the registers.

29.4.2.2 Legend

This section explains the module state dependent abbreviations used for the L2 registers description.

Conditions:

- R/W: Bit is readable and writable
- R: Read-only bit; the user cannot write to this bit
- W: Write-only bit; Read value is always “0”

Indexes used for register and register Bit Names

The prefix of the "HSIFn" bit name is omitted.

M: The character “(M)” means “0”, “1”, “2”, “3”, “4”, “5”, “6” or “7”.

N: The character “(N)” means “0”, “1”, “2”, or “3”.

X: The character “(X)” means “A”, “B”, “C”, or “D”.

Reserved bits:

- Always read as 0
- Writing to these bits has no effect (hardware protection)

29.4.2.3 Detailed Register Descriptions

Detailed specifications of each register are described below.

(1) RHSIFnMMD — Module Mode Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + 000_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CHCT
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 29.18 RHSIFnMMD Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	CHCT	This bit specifies the type of the channel number code table to used for L2. Note that this bit can only be changed at the time of initial setting. You cannot change this setting dynamically during system operation. 0: Table II (Ch.0 = 100_B, Ch.1 = 101_B, Ch.2 = 110_B, Ch.3 = 111_B) 1: Table I (Ch.0 = 000_B, Ch.1 = 001_B, Ch.2 = 010_B, Ch.3 = 011_B)

(2) RHSIFnMCT — Module Control Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + 008_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	WDWE	WDRE	—	—	WCWE	WCRE	—	—	WBWE	WBRE	—	—	WAWE	WARE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	*1	*1	R	R	*1	*1	R	R	*1	*1	R	R	*1	*1

Note 1. Data cannot be written to these bits from RHSIF's master port. When RHSIF's master port writes to these bits, these bits have the read-only (R) attribute. These bits can be read from all master devices.

Table 29.19 RHSIFnMCT Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 14	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
13	WDWE	This bit specifies whether to enable the write operation for memory window D. 0: Disables writing. 1: Enables writing. You can change this bit only when the initiator node function and target node function of all channels are disabled (RHSIFnCMD(N).INME(N)=0, TNME(N)=0).
12	WDRE	This bit specifies whether to enable the read operation for memory window D. 0: Disables reading. 1: Enables reading. You can change this bit only when the initiator node function and target node function of all channels are disabled (RHSIFnCMD(N).INME(N)=0, TNME(N)=0).
11, 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	WCWE	This bit specifies whether to enable the write operation for memory window C. 0: Disables writing. 1: Enables writing. You can change this bit only when the initiator node function and target node function of all channels are disabled (RHSIFnCMD(N).INME(N)=0, TNME(N)=0).
8	WCRE	This bit specifies whether to enable the read operation for memory window C. 0: Disables reading. 1: Enables reading. You can change this bit only when the initiator node function and target node function of all channels are disabled (RHSIFnCMD(N).INME(N)=0, TNME(N)=0).
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	WBWE	This bit specifies whether to enable the write operation for memory window B. 0: Disables writing. 1: Enables writing. You can change this bit only when the initiator node function and target node function of all channels are disabled (RHSIFnCMD(N).INME(N)=0, TNME(N)=0).

Table 29.19 RHSIFnMCT Register Contents (2/2)

Bit Position	Bit Name	Function
4	WBRE	This bit specifies whether to enable the read operation for memory window B. 0: Disables reading. 1: Enables reading. You can change this bit only when the initiator node function and target node function of all channels are disabled (RHSIFnCMD(N).INME(N)=0, TNME(N)=0).
3, 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	WAWE	This bit specifies whether to enable the write operation for memory window A. 0: Disables writing. 1: Enables writing. You can change this bit only when the initiator node function and target node function of all channels are disabled (RHSIFnCMD(N).INME(N)=0, TNME(N)=0).
0	WARE	This bit specifies whether to enable the read operation for memory window A. 0: Disables reading. 1: Enables reading. You can change this bit only when the initiator node function and target node function of all channels are disabled (RHSIFnCMD(N).INME(N)=0, TNME(N)=0).

(3) RHSIFnMST — Module Status Register

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + 010_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	AUTS1	AUTS0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.20 RHSIFnMST Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is returned.
1	AUTS1	This bit indicates the status of the second authentication of the link partner. 0: Second authentication not completed. 1: Second authentication completed.
0	AUTS0	This bit indicates the status of the first authentication of the link partner. 0: First authentication not completed. 1: First authentication completed.

(4) RHSIFnMIST — Module Interrupt Status Register

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + 018_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DBGS	—	—	AESS	—	—	SRES	STES	CERS3	CERS2	CERS1	CERS0	—	SRCS1	SRCS0	STCS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.21 RHSIFnMIST Register Contents (1/2)

Bit Position	Bit Name	Function
31	DBGS	When set to 1, this bit indicates that there is a debug interrupt factor.
30 to 29	Reserved	When read, the value after reset is returned.
28	AESS	When set to 1, this bit indicates that there is an error interrupt factor concerning authentication or window mis-hit.
27, 26	Reserved	When read, the value after reset is returned.
25	SRES	When set to 1, this bit indicates that there is an error interrupt factor concerning stream reception.
24	STES	When set to 1, this bit indicates that there is an error interrupt factor concerning stream transmission.
23	CERS3	When set to 1, this bit indicates that there is an error interrupt factor concerning channel 3.
22	CERS2	When set to 1, this bit indicates that there is an error interrupt factor concerning channel 2.
21	CERS1	When set to 1, this bit indicates that there is an error interrupt factor concerning channel 1.
20	CERS0	When set to 1, this bit indicates that there is an error interrupt factor concerning channel 0.
19	Reserved	When read, the value after reset is returned.
18	SRCS1	When set to 1, this bit indicates that there is a factor for completing stream interrupt reception (of not less than the specified size).
17	SRCS0	When set to 1, this bit indicates that there is a factor for completing stream interrupt reception (of not less than the data size of one frame).
16	STCS	When set to 1, this bit indicates that there is a factor for completing stream interrupt transmission.
15	Reserved	When read, the value after reset is returned.
14	TERS3	When set to 1, this bit indicates that there is a factor for receiving an Event Command as a channel 3 interrupt.
13	AKRS3	When set to 1, this bit indicates that there is a factor for receiving an ACK Command as a channel 3 interrupt.
12	RARS3	When set to 1, this bit indicates that there is a factor for receiving a Read Answer Command as a channel 3 interrupt.
11	Reserved	When read, the value after reset is returned.

Table 29.21 RHSIFnMIST Register Contents (2/2)

Bit Position	Bit Name	Function
10	TERS2	When set to 1, this bit indicates that there is a factor for receiving an Event Command as a channel 2 interrupt.
9	AKRS2	When set to 1, this bit indicates that there is a factor for receiving an ACK Command as a channel 2 interrupt.
8	RARS2	When set to 1, this bit indicates that there is a factor for receiving a Read Answer Command as a channel 2 interrupt.
7	Reserved	When read, the value after reset is returned.
6	TERS1	When set to 1, this bit indicates that there is a factor for receiving an Event Command as a channel 1 interrupt.
5	AKRS1	When set to 1, this bit indicates that there is a factor for receiving an ACK Command as a channel 1 interrupt.
4	RARS1	When set to 1, this bit indicates that there is a factor for receiving a Read Answer Command as a channel 1 interrupt.
3	Reserved	When read, the value after reset is returned.
2	TERS0	When set to 1, this bit indicates that there is a factor for receiving an Event Command as a channel 0 interrupt.
1	AKRS0	When set to 1, this bit indicates that there is a factor for receiving an ACK Command as a channel 0 interrupt.
0	RARS0	When set to 1, this bit indicates that there is a factor for receiving a Read Answer Command as a channel 0 interrupt.

(5) RHSIFnMRT — Module Reply Timeout Time Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + 020_H

Value after reset: 0000 $F3FF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RSCL[3:0]				—	—	RCNT[9:0]									
Value after reset	1	1	1	1	0	0	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29.22 RHSIFnMRT Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 12	RSCL[3:0]	These bits specify the reference clock for the reply timer. Note that these bits can be changed only at the time of initial setting. You cannot change the setting dynamically during system operation. 0000: Communication clock (cclk) 0001: Communication clock (cclk) divided by 2 0010: Communication clock (cclk) divided by 4 0011: Communication clock (cclk) divided by 8 0100: Communication clock (cclk) divided by 16 0101: Communication clock (cclk) divided by 32 0110: Communication clock (cclk) divided by 64 0111: Communication clock (cclk) divided by 128 1000: Communication clock (cclk) divided by 256 1001: Communication clock (cclk) divided by 512 1010: Communication clock (cclk) divided by 1024 1011: Communication clock (cclk) divided by 2048 1100: Communication clock (cclk) divided by 4096 1101: Communication clock (cclk) divided by 8192 1110: Communication clock (cclk) divided by 16384 1111: Communication clock (cclk) divided by 32768
11, 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9 to 0	RCNT[9:0]	These bits specify the limit count for the reply timer. If the pulse count of the clock specified by the RSCL bits reaches the value specified in these bits, a reply timeout is determined. When 0 is specified in these bits, the reply timeout does not occur. If, however, no reply Command is detected with 0 specified in these bits, the initiator on the channel is disabled. Therefore, specifying 0 in these bits is prohibited if the system does not have a measure to recover from the status in which the initiator is disabled. Note that these bits can be changed only at the time of initial setting. You cannot change the setting dynamically during system operation.

(6) RHSIFnMW (A, B, C, D) A — Module Memory Window (A, B, C, D) Start Address Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: RHSIFnMWAA:<RHSIFn_L2_base> + 040_H
RHSIFnMWAB:<RHSIFn_L2_base> + 050_H
RHSIFnMWAC:<RHSIFn_L2_base> + 060_H
RHSIFnMWAD:<RHSIFn_L2_base> + 070_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MW(X)A[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MW(X)A[15:2]														—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	R	R

Note 1. This bit is readable/writable (RW) or read-only (R). For details, see the description of the bit.

Table 29.23 RHSIFnMW (A, B, C, D) A Register Contents

Bit Position	Bit Name	Function
31 to 2	MW(X)A	These bits specify the start address of the window that is allowed to be accessed when RHSIF generates a H-Bus read or write request as bus master. Write 0 to all the bits lower than those corresponding to the valid size value set in RHSIFnMW(X)S. Example: When the valid size is 4 kilobytes, set the MW(X)A[11:2] bits to $0000\_0000\_00_B$. The MW(X)A[6:2] bits must always be 0. When RHSIFnMCT.W(X)RE = 1 or RHSIFnMCT.W(X)WE = 1, the value of these bits (MW(X)A) must not be changed. For details, see **Section 29.4.3.1(1), Setting Memory Windows**. Data cannot be written to these bits from RHSIF's master port. When RHSIF's master port writes to these bits, these bits have the read-only (R) attribute. These bits can be read from all master devices.
1, 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

(7) RHSIFnMW (A, B, C, D) S — Module Memory Window (A, B, C, D) Size Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: RHSIFnMWAS: <RHSIFn_L2_base> + 048_H
RHSIFnMWBS:<RHSIFn_L2_base> + 058_H
RHSIFnMWCS:<RHSIFn_L2_base> + 068_H
RHSIFnMWDS:<RHSIFn_L2_base> + 078_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MW(X)S[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MW(X)S[15:2]														—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	R	R

Note 1. This bit is readable / writable (R/W) or read-only (R). For details, see the description of the bit.

Table 29.24 RHSIFnMW (A, B, C, D) S Register Contents

Bit Position	Bit Name	Function
31 to 2	MW(X)S	These bits specify the size of the window that is allowed to be accessed when RHSIF generates a H-Bus read or write request as bus master. Write 1 to all the bits lower than those corresponding to the valid size value, and write 0 to all the bits higher than those corresponding to the valid size value. Examples of settings are as follows: 0000_0000_0000_0000_0000_0000_0111_11b: 128 bytes 0000_0000_0000_0000_0000_0000_1111_11b: 256 bytes 0000_0000_0000_0000_0000_0001_1111_11b: 512 bytes … 0011_1111_1111_1111_1111_1111_1111_11b: 1 GB 0111_1111_1111_1111_1111_1111_1111_11b: 2 GB 1111_1111_1111_1111_1111_1111_1111_11b: 4 GB The MW(X)S[6:2] bits must always be 1. When RHSIFnMCT.W(X)RE = 1 or RHSIFnMCT.W(X)WE = 1, the value of these bits (MW(X)S) must not be changed. For details, see **Section 29.4.3.1(1), Setting Memory Windows**. Data cannot be written to these bits from RHSIF's master port. When RHSIF's master port writes to these bits, these bits have read-only (R) attribute. These bits can be read from all master devices.
1 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

(8) RHSIFnSTMD — Stream Tx Mode Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + 200_H

Value after reset: $0000\ 1110_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	STNK	—	—	—	STPS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	1	0	0	0	1	0	0	0	1	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.25 RHSIFnSTMD Register Contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
20	STNK	This bit specifies the operation that is necessary when L2, operating as an initiator node, receives a NACK Command from a link partner in response to a Stream Command the initiator node transmitted. 0: Stops the DMAC. (Same as the operation that is necessary when an error occurs) 1: Continues the DMAC operation. (Same as the operation to be done when an ACK Command is received) Note that this bit can be changed only at the time of initial setting. You cannot change the setting dynamically during system operation.
19 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	STPS	This bit specifies the data payload size of the frame when L2, operating as an initiator node, transmits a Stream Command. **Note:** Transmission / reception in 128 bits is only available for communication between the devices with the same STPS values. 0: 256 bits 1: 128 bits Note that this bit can be changed only at the time of initial setting. You cannot change the setting dynamically during system operation.
15 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

(9) RHSIFnSTCT — Stream Tx Control Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + 208_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STDE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 29.26 RHSIFnSTCT Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	STDE	This bit specifies whether to enable the DMAC. Write 1 to this bit to start the DMAC when L2, operating as an initiator node, transmits a Stream Command. 0: Disables the DMAC. 1: Enables the DMAC. This bit is automatically cleared when the transfer ends (normally or abnormally). For details about abnormal cases, see **Section 29.4.3.4, Stream Command Transmission by Initiator Node**. During the transfer (while this bit is 1), 0 must not be written to this bit.

NOTE

Note that when using a bit-manipulation instruction for writing to this register, the read-modify-write operation may inadvertently set the STDE bit to 1.

(10) RHSIFnSTST — Stream Tx Status Register

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + 210_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	STE4	—	—	STE3	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	STE2	STE1	—	STE0	—	STC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.27 RHSIFnSTST Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned.
23	STE4	This bit is set to 1 when a memory window mis-hit occurs and the DMAC stops abnormally (because of the error) after RHSIF, operating as an initiator, has started the DMAC for Stream Command transmission.
22 to 21	Reserved	When read, the value after reset is returned.
20	STE3	This bit is set to 1 when a transfer error occurs in the H-Bus and the DMAC stops abnormally (because of the error) after L2, operating as an initiator, has started the DMAC for Stream Command transmission.
19 to 6	Reserved	When read, the value after reset is returned.
5	STE2	This bit is set to 1 when a reply Command (ACK, NACK, or Read Answer) causing a transaction ID error is detected and the DMAC stops abnormally (because of the error) after L2, operating as an initiator, has started the DMAC for Stream Command transmission.
4	STE1	This bit is set to 1 when the DMAC stops abnormally because it does not receive any response within the time set in the RHSIFnMRT bits after L2, operating as an initiator, has started the DMAC for Stream Command transmission.
3	Reserved	When read, the value after reset is returned.
2	STE0	This bit is set to 1 when an NACK Command is received and the DMAC stops abnormally after L2, operating as an initiator, has started the DMAC for Stream Command transmission. This bit is not set when RHSIFnSTMD.STNK = 1.
1	Reserved	When read, the value after reset is returned.
0	STC	This bit is set to 1 when the transfer of all data ends normally after L2, operating as an initiator, has started the DMAC for Stream Command transmission.

(11) RHSIFnSTSC — Stream Tx Status Clear Register

Access: This register is a write-only register that can be write in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + 218_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	STEC4	—	—	STEC3	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	W	R	R	W	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	STEC2	STEC1	—	STEC0	—	STCC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	W	W	R	W	R	W

Table 29.28 RHSIFnSTSC Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When writing, write the value after reset.
23	STEC4	Writing 1 to this bit clears the RHSIFnSTST.STE4 bit. Writing 0 to this bit is ignored.
22 to 21	Reserved	When writing, write the value after reset.
20	STEC3	Writing 1 to this bit clears the RHSIFnSTST.STE3 bit. Writing 0 to this bit is ignored.
19 to 6	Reserved	When writing, write the value after reset.
5	STEC2	Writing 1 to this bit clears the RHSIFnSTST.STE2 bit. Writing 0 to this bit is ignored.
4	STEC1	Writing 1 to this bit clears the RHSIFnSTST.STE1 bit. Writing 0 to this bit is ignored.
3	Reserved	When writing, write the value after reset.
2	STEC0	Writing 1 to this bit clears the RHSIFnSTST.STE0 bit. Writing 0 to this bit is ignored.
1	Reserved	When writing, write the value after reset.
0	STCC	Writing 1 to this bit clears the RHSIFnSTST.STC bit. Writing 0 to this bit is ignored.

(12) RHSIFnSTIE — Stream Tx Interrupt Enable Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + 220_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	STEE4	—	—	STEE3	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R	R	R/W	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	STEE2	STEE1	—	STEE0	—	STCE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R/W	R	R/W

Table 29.29 RHSIFnSTIE Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23	STEE4	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnSTST.STE4 bit. 0: Does not assert int_hsif_err when the RHSIFnSTST.STE4 bit is 1. 1: Asserts int_hsif_err when the RHSIFnSTST.STE4 bit is 1.
22 to 21	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
20	STEE3	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnSTST.STE3 bit. 0: Does not assert int_hsif_err when the RHSIFnSTST.STE3 bit is 1. 1: Asserts int_hsif_err when the RHSIFnSTST.STE3 bit is 1.
19 to 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	STEE2	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnSTST.STE2 bit. 0: Does not assert int_hsif_err when the RHSIFnSTST.STE2 bit is 1. 1: Asserts int_hsif_err when the RHSIFnSTST.STE2 bit is 1.
4	STEE1	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnSTST.STE1 bit. 0: Does not assert int_hsif_err when the RHSIFnSTST.STE1 bit is 1. 1: Asserts int_hsif_err when the RHSIFnSTST.STE1 bit is 1.
3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	STEE0	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnSTST.STE0 bit. 0: Does not assert int_hsif_err when the RHSIFnSTST.STE0 bit is 1. 1: Asserts int_hsif_err when the RHSIFnSTST.STE0 bit is 1.
1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	STCE	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnSTST.STC bit. 0: Does not assert int_hsif_str when the RHSIFnSTST.STC bit is 1. 1: Asserts int_hsif_str when the RHSIFnSTST.STC bit is 1.

(13) RHSIFnSTSA — Stream Tx Source Address Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + 228_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	STSA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	STSA[15:4]												—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Table 29.30 RHSIFnSTSA Register Contents

Bit Position	Bit Name	Function
31 to 4	STSA	These bits specify the start address of the area storing the data to be transferred when L2, operating as an initiator node, starts the DMAC for Stream Command transmission. When the data payload of the Stream Command to be transmitted is 256 bits (when RHSIFnSTMD.STPS = 0), the STSA[4] bit must always be 0. When RHSIFnSTCT.STDE = 1, the value of these bits (STSA) must not be changed. The settings for RHSIFnSTSA and RHSIFnSTBC which causes wrap around of address is not allowed.
3 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

(14) RHSIFnSTBC — Stream Tx Byte Count Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + 230_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	STBC[24:16]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 29.31 RHSIFnSTBC Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
24 to 4	STBC	These bits specify the total number of bytes of the data to be transferred when L2, operating as an initiator node, starts the DMAC for Stream Command transmission. When the data payload of the Stream Command to be transmitted is 256 bits (when RHSIFnSTMD.STPS = 0), the STBC[4] bit must always be 0. When 0 is set in these bits, 2^{25} bytes (32 MBytes) are transferred. The value read from these bits indicates the number of remaining bytes of the data. When RHSIFnSTCT.STDE = 1, the value of these bits (STBC) must not be changed. The setting of RHSIFnSTSA and RHSIFnSTBC that causes wrap around of address is not allowed.
3 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

CAUTION

Write to unused Channel Register should not be executed.

NOTE

Note that when using a bit-manipulation instruction for writing to this register, the read-modify-write operation may inadvertently set the STBC bits to 1.

(15) RHSIFnSRMD — Stream Rx Mode Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + 280_H

Value after reset: $0000\ 0010_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	SRMC	—	—	—	SRPS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R/W

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.32 RHSIFnSRMD Register Contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
20	SRMC	This bit specifies the operation to be done if an error occurs when L2, operating as a target node, receives a Stream Command. 0: Automatically clears the RHSIFnSRCT.SRDE bit automatically when an error occurs. 1: Does not automatically clear the RHSIFnSRCT.SRDE bit automatically when an error occurs. For the conditions of errors, see the description of the RHSIFnSRCT.SRDE bit. Note that this bit can be changed only at the time of initial setting. You cannot change the setting dynamically during system operation.
19 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	SRPS	This bit specifies the frame data payload size that is expected when L2, operating as a target node, receives a Stream Command. 0: 256 bits 1: 128 bits Note that this bit can be changed only at the time of initial setting. You cannot change the setting dynamically during system operation.
15 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

(16) RHSIFnSRCT — Stream Rx Control Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + 288_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SRDE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 29.33 RHSIFnSRCT Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	SRDE	This bit specifies whether to enable the DMAC. Write 1 to this bit to start the DMAC when L2, operating as a target node, receives a Stream Command. 0: Disables the DMAC (ignores the Stream Command that is received without any response). 1: Enables the DMAC (automatically transfers the Stream Command that is received to a storage area). When RHSIFnCMD2.TNME2 = 0, you must not set this bit to 1. When RHSIFnSRMD.SRMC = 0, this bit is cleared to 0 automatically when one of the following events occur: • An error occurs when Stream Command data is transferred to the H-Bus. • When a Stream Command is received, Stream Command data is discarded because the data storage area is full. • An error is detected in a stream Command that is received. • In channel 2, a Command causing a CRC error is detected. • H-Bus Write request's address does not hit any memory window.

NOTE

Note that when using a bit-manipulation instruction for writing to this register, the read-modify-write operation may inadvertently set the SRDE bit to 1.

(17) RHSIFnSRST — Stream Rx Status Register

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + 290_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SRA	—	—	—	—	—	—	—	SRE2	—	SRE1	SRE0	—	—	—	—

	SRTA	—	—	—	—	—	—	—	—	—	—	—	—	—	SRC1	SRC0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.34 RHSIFnSRST Register Contents

Bit Position	Bit Name	Function
31	SRA	This bit is set to 1 if RHSIFnSRCT.SRDE is cleared automatically because L2, operating as a target node, detects errors related to the Stream Command that is received. For the conditions of errors, see the description of the RHSIFnSRCT.SRDE bit.
30 to 24	Reserved	When read, the value after reset is returned.
23	SRE2	This bit is set to 1 if a memory window mis-hit occurs when RHSIF, operating as a target node, transfers Stream Command data that is received to the H-Bus.
22	Reserved	When read, the value after reset is returned.
21	SRE1	This bit is set to 1 if Stream Command data is discarded because the data storage area is full when L2, operating as a target node, receives a Stream Command.
20	SRE0	This bit is set to 1 if an error occurs when L2, operating as a target node, transfers Stream Command data that is received to the H-Bus.
19 to 16	Reserved	When read, the value after reset is returned.
15	SRTA	This bit indicates the processing status of the received Stream Command when L2 is operating as a target node. 0: No Command is being processed. 1: Command(s) is being processed.
14 to 2	Reserved	When read, the value after reset is returned.
1	SRC1	This bit is set to 1 when the size of unprocessed data (in the received Stream Command when L2 is operating as a target node) is not less than the value set in RHSIFnSRBC.
0	SRC0	This bit is set to 1 when the size of unprocessed data (in the received Stream Command when L2 is operating as a target node) is not 0.

(18) RHSIFnSRSC — Stream Rx Status Clear Register

Access: This register is a write-only register that can be write in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + 298_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 29.35 RHSIFnSRSC Register Contents

Bit Position	Bit Name	Function
31	SRAC	Writing 1 to this bit clears the RHSIFnSRST.SRA bit. Writing 0 to this bit is ignored.
30 to 24	Reserved	When writing, write the value after reset.
23	SREC2	Writing 1 to this bit clears the RHSIFnSRST.SRE2 bit. Writing 0 to this bit is ignored.
22	Reserved	When writing, write the value after reset.
21	SREC1	Writing 1 to this bit clears the RHSIFnSRST.SRE1 bit. Writing 0 to this bit is ignored.
20	SREC0	Writing 1 to this bit clears the RHSIFnSRST.SRE0 bit. Writing 0 to this bit is ignored.
19 to 0	Reserved	When writing, write the value after reset.

(19) RHSIFnSRIE — Stream Rx Interrupt Enable Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + $2A0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 29.36 RHSIFnSRIE Register Contents

Bit Position	Bit Name	Function
31	SRAE	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnSRST.SRA bit. 0: Does not assert int_hsif_err when the RHSIFnSRST.SRA bit is 1. 1: Asserts int_hsif_err when the RHSIFnSRST.SRA bit is 1.
30 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23	SREE2	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnSRST.SRE2 bit. 0: Does not assert int_hsif_err when the RHSIFnSRST.SRE2 bit is 1. 1: Asserts int_hsif_err when the RHSIFnSRST.SRE2 bit is 1.
22	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
21	SREE1	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnSRST.SRE1 bit. 0: Does not assert int_hsif_err when the RHSIFnSRST.SRE1 bit is 1. 1: Asserts int_hsif_err when the RHSIFnSRST.SRE1 bit is 1.
20	SREE0	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnSRST.SRE0 bit. 0: Does not assert int_hsif_err when the RHSIFnSRST.SRE0 bit is 1. 1: Asserts int_hsif_err when the RHSIFnSRST.SRE0 bit is 1.
19 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	SRCE1	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnSRST.SRC1 bit. 0: Does not assert int_hsif_str when the RHSIFnSRST.SRC1 bit is 1. 1: Asserts int_hsif_str when the RHSIFnSRST.SRC1 bit is 1.
0	SRCE0	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnSRST.SRC0 bit. 0: Does not assert int_hsif_str when the RHSIFnSRST.SRC0 bit is 1. 1: Asserts int_hsif_str when the RHSIFnSRST.SRC0 bit is 1.

(20) RHSIFnSRDA — Stream Rx Destination Area Start Address Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + $2A8_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SRDA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Table 29.37 RHSIFnSRDA Register Contents

Bit Position	Bit Name	Function
31 to 4	SRDA	These bits specify the start address of the area to store data when L2, operating as a target node, receives a Stream Command. Write 0 to all the bits lower than those corresponding to the valid size value set in RHSIFnSRDS. Example: When the valid size is 4 kilobytes, set the SRDA[11:4] bits to $0000\_0000\_00_B$. When the data payload of the Stream Command to be received is 256 bits (when RHSIFnSRMD.SRPS = 0), the SRDA[4] bit must always be 0. When RHSIFnSRCT.SRDE = 1, the value of these bits (SRDA) must not be changed.
3 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

(21) RHSIFnSRDS — Stream Rx Destination Area Size Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + $2B0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	SRDS[24:16]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SRDS[15:4]												—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Table 29.38 RHSIFnSRDS Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
24 to 4	SRDS	These bits specify the valid size of the area to store data when L2, operating as a target node, receives a Stream Command. Write 1 to all the bits lower than those corresponding to the valid size value, and write 0 to all the bits higher than those corresponding to the valid size value. Examples of settings are as follows: $0\_0000\_0000\_0000\_0000\_0000_B$: 16 bytes $0\_0000\_0000\_0000\_0000\_0001_B$: 32 bytes ... $0\_1111\_1111\_1111\_1111\_1111_B$: 16 Mbytes $1\_1111\_1111\_1111\_1111\_1111_B$: 32 Mbytes When the data payload of the Stream Command to be received is 256 bits (when RHSIFnSRMD.SRPS = 0), the valid size must not be set to 16 bytes. When RHSIFnSRCT.SRDE = 1, the value of these bits (SRDS) must not be changed.
3 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

(22) RHSIFnSRBC — Stream Rx Byte Count Register

Access: This register can be read or written in 32-bit units.

Address: <RHSIFn_L2_base> + $2B8_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	SRBC[24:16]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Table 29.39 RHSIFnSRBC Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
24 to 4	SRBC	These bits specify the number of bytes that triggers a notification when L2, operating as a target node, receives a Stream Command. When the size of unprocessed data reaches or exceeds the value specified in these bits, the RHSIFnSRST.SRC1 bit is set to 1. If the data payload of the Stream Command to be received is 256 bits (when RHSIFnSRMD.SRPS = 0), the SRBC[4] bit must always be 0. If 0 is set in these bits, a notification is triggered when the size of unprocessed data reaches 2^{25} bytes (32 Mbytes). When RHSIFnSRCT.SRDE = 1, the value of these bits (SRBC) must not be changed.
3 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

(23) RHSIFnSRWP — Stream Rx Write Pointer Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RHSIFn_L2_base> + $2C0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	SRWP[24:16]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SRWP[15:4]												—	—	—	SRWT
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.40 RHSIFnSRWP Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is returned.
24 to 4	SRWP	These bits indicate the value of the write pointer (offset value from start address) to the area to store received data when L2, operating as a target node, receives a Stream Command. The number of valid bits of the pointer corresponds to the value set in RHSIFnSRDS. All the bits higher than valid bits show 0. These bits are initialized when the RHSIFnSRCT.SRDE bit changes from 0 to 1. For details, see **Section 29.4.3.5, Stream Command Reception by Target Node**.
3 to 1	Reserved	When read, the value after reset is returned.
0	SRWT	This bit is a toggle bit for the SRWP bits. This bit is toggled each time the SRWP bits wrap around. This bit is initialized when the RHSIFnSRCT.SRDE bit changes from 0 to 1.

(24) RHSIFnSRRP — Stream Rx Read Pointer Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + $2C8_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	SRRP[24:16]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SRRP[15:4]												—	—	—	SRRT
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W

Table 29.41 RHSIFnSRRP Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
24 to 4	SRRP	These bits indicate the value of the read pointer (offset value from start address) to the area to store received data when L2, operating as a target node, receives a Stream Command. The number of valid bits of the pointer corresponds to the value set in RHSIFnSRDS. All the bits higher than valid bits must be 0. These bits are initialized when the RHSIFnSRCT.SRDE bit changes from 0 to 1. For details, see **Section 29.4.3.5, Stream Command Reception by Target Node**.
3 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	SRRT	This bit is a toggle bit for the SRRP bits. This bit is toggled each time the SRRP bits wrap around. This bit is initialized when the RHSIFnSRCT.SRDE bit changes from 0 to 1.

NOTE

Note that when using a bit-manipulation instruction for writing to this register, the read-modify-write operation may inadvertently set the SRRP bits or the SRRT bit to 1.

(25) RHSIFnAID (0, 1, 2, 3, 4, 5, 6, 7) — Authentication ID Register (0, 1, 2, 3, 4, 5, 6, 7)

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: RHSIFnAID0: <RHSIFn_L2_base> + 300_H
RHSIFnAID1: <RHSIFn_L2_base> + 308_H
RHSIFnAID2: <RHSIFn_L2_base> + 310_H
RHSIFnAID3: <RHSIFn_L2_base> + 318_H
RHSIFnAID4: <RHSIFn_L2_base> + 320_H
RHSIFnAID5: <RHSIFn_L2_base> + 328_H
RHSIFnAID6: <RHSIFn_L2_base> + 330_H
RHSIFnAID7: <RHSIFn_L2_base> + 338_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note 1. This bit is readable/writable (R/W) or read-only (R). For details, see the description of the bit.

Table 29.42 RHSIFnAID (0, 1, 2, 3, 4, 5, 6, 7) Register Contents

Bit Position	Bit Name	Function
31 to 0	AID(M)	These bits store the ID data for the first authentication (ID-based authentication). HSIFnAID0.AID0[31:0]: ID[31:0] HSIFnAID1.AID1[31:0]: ID[63:32] HSIFnAID2.AID2[31:0]: ID[95:64] HSIFnAID3.AID3[31:0]: ID[127:96] HSIFnAID4.AID4[31:0]: ID[159:128] HSIFnAID5.AID5[31:0]: ID[191:160] HSIFnAID6.AID6[31:0]: ID[223:192] HSIFnAID7.AID7[31:0]: ID[255:224] Data can be read from or written to these bits only via the master port of L2. When another master device such as a CPU accesses these bits, these bits have the read-only (R) attribute.

(26) RHSIFnAAD (0, 1, 2, 3) — Authentication Answer Data Register (0, 1, 2, 3)

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: RHSIFnAAD0: <RHSIFn_L2_base> + 340_H
RHSIFnAAD1: <RHSIFn_L2_base> + 348_H
RHSIFnAAD2: <RHSIFn_L2_base> + 350_H
RHSIFnAAD3: <RHSIFn_L2_base> + 358_H

Value after reset: $0000\ 0000_H$

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.45 RHSIFnAEST Register Contents

Bit Position	Bit Name	Function
31 to 30	Reserved	When read, the value after reset is returned.
29	WES1	This bit is set to 1 when RHSIF, as a target node, tries to issue H-Bus Write for Stream Command that does not hit any memory window.
28	WES0	This bit is set to 1 when RHSIF, as an initiator node, tries to issue H-Bus Read for Stream Command that does not hit any memory window.
27,25,23,21	WEW(N)	This bit is set to 1 when RHSIF, as a target node, receives Write Command on Channel (N) whose targeted address does not hit any memory window.
26,24,22,20	WER(N)	This bit is set to 1 when RHSIF, as a target node, receives Read Command on Channel (N) whose targeted address does not hit any memory window.
19 to 17	Reserved	When read, the value after reset is returned.
16	AES	This bit is set to 1 when RHSIF, as a target node, receives Stream Command on Channel (N) before authentication is completed.
15,11,7,3	AEW(N)	This bit is set to 1 when RHSIF, as a target node, receives Write Command on Channel (N) before authentication is completed.
14,10,6,2	AER(N)	This bit is set to 1 when RHSIF, as a target node, receives Read Command on Channel (N) before authentication is completed.
13,9,5,1,	AEI(N)	This bit is set to 1 when RHSIF, as a target node, receives ID Command on Channel (N) before authentication is completed.
12,8,4,0	AEE(N)	This bit is set to 1 when RHSIF, as a target node, receives Event Command on Channel (N) before authentication is completed.

(29) RHSIFnAESC — Authentication Error Status Clear Register

Access: This register is a write-only register that can be write in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + $3E8_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 29.46 RHSIFnAESC Register Contents

Bit Position	Bit Name	Function
31 to 30	Reserved	When writing, write the value after reset.
29	WESC1	Writing 1 to this bit clears the RHSIFnAEST.WES1 bit. Writing 0 to this bit is ignored.
28	WESC0	Writing 1 to this bit clears the RHSIFnAEST.WES0 bit. Writing 0 to this bit is ignored.
27,25,23,21	WEWC(N)	Writing 1 to this bit clears the RHSIFnAEST.WEW(N) bit. Writing 0 to this bit is ignored.
26,24,22,20	WERC(N)	Writing 1 to this bit clears the RHSIFnAEST.WER(N) bit. Writing 0 to this bit is ignored.
19 to 17	Reserved	When writing, write the value after reset.
16	AESC	Writing 1 to this bit clears the RHSIFnAEST.AES bit. Writing 0 to this bit is ignored.
15,11,7,3	AEWC(N)	Writing 1 to this bit clears the RHSIFnAEST.AEW(N) bit. Writing 0 to this bit is ignored.
14,10,6,2	AERC(N)	Writing 1 to this bit clears the RHSIFnAEST.AER(N) bit. Writing 0 to this bit is ignored.
13,9,5,1,	AEIC(N)	Writing 1 to this bit clears the RHSIFnAEST.AEI(N) bit. Writing 0 to this bit is ignored.
12,8,4,0	AEEC(N)	Writing 1 to this bit clears the RHSIFnAEST.AEE(N) bit. Writing 0 to this bit is ignored.

(30) RHSIFnAEIE — Authentication Error Interrupt Enable Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + $3F0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 29.47 RHSIFnAEIE Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29	WESE1	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnAEST.WES1 bit. 0: Does not assert int_hsif_sec when the RHSIFnAEST.WES1 bit is 1. 1: Asserts int_hsif_sec when the RHSIFnAEST.WES1 bit is 1.
28	WESE0	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnAEST.WES0 bit. 0: Does not assert int_hsif_sec when the RHSIFnAEST.WES0 bit is 1. 1: Asserts int_hsif_sec when the RHSIFnAEST.WES0 bit is 1.
27,25,23,21	WEWE(N)	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnAEST.WEW(N) bit. 0: Does not assert int_hsif_sec when the RHSIFnAEST.WEW(N) bit is 1. 1: Asserts int_hsif_sec when the RHSIFnAEST.WEW(N) bit is 1.
26,24,22,20	WERE(N)	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnAEST.WER(N) bit. 0: Does not assert int_hsif_sec when the RHSIFnAEST.WER(N) bit is 1. 1: Asserts int_hsif_sec when the RHSIFnAEST.WER(N) bit is 1.
19 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	AESE	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnAEST.AES bit. 0: Does not assert int_hsif_sec when the RHSIFnAEST.AES bit is 1. 1: Asserts int_hsif_sec when the RHSIFnAEST.AES bit is 1.
15,11,7,3	AEWE(N)	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnAEST.AEW(N) bit. 0: Does not assert int_hsif_sec when the RHSIFnAEST.AEW(N) bit is 1. 1: Asserts int_hsif_sec when the RHSIFnAEST.AEW(N) bit is 1.
14,10,6,2	AERE(N)	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnAEST.AER(N) bit. 0: Does not assert int_hsif_sec when the RHSIFnAEST.AER(N) bit is 1. 1: Asserts int_hsif_sec when the RHSIFnAEST.AER(N) bit is 1.
13,9,5,1,	AEIE(N)	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnAEST.AEI(N) bit. 0: Does not assert int_hsif_sec when the RHSIFnAEST.AEI(N) bit is 1. 1: Asserts int_hsif_sec when the RHSIFnAEST.AEI(N) bit is 1.

Table 29.47 RHSIFnAEIE Register Contents (2/2)

Bit Position	Bit Name	Function
12,8,4,0	AEEE(N)	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnAEST.AEE(N) bit. 0: Does not assert int_hsif_sec when the RHSIFnAEST.AEE(N) bit is 1. 1: Asserts int_hsif_sec when the RHSIFnAEST.AEE(N) bit is 1.

(31) RHSIFnCMD (0, 1, 2, 3) — Channel (0, 1, 2, 3) Mode Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <RHSIFn_L2_base> + 400_H
<RHSIFn_L2_base> + 480_H
<RHSIFn_L2_base> + 500_H
<RHSIFn_L2_base> + 580_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TNME (N)
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	INME (N)
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 29.48 RHSIFnCMD (0, 1, 2, 3) Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	TNME(N)	This bit specifies whether to enable the target node function. 0: Disables reception of Read, Write, Event, ID, and Stream Commands (ignores these Commands without any response). 1: Enables reception of Read, Write, Event, ID, and Stream Commands. Even when this bit is 1, whether Read, Write, and Stream Commands can be received depends on other individual settings. For details, see **Section 29.4.3.3, Non-Stream Command Reception by Target Node** and **Section 29.4.3.5, Stream Command Reception by Target Node**.
15 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	INME(N)	This bit specifies whether to enable the initiator node function. 0: Disables transmission of Read, Write, Event, ID, and Stream Commands. 1: Enables transmission of Read, Write, Event, ID, and Stream Commands. This bit must not be cleared to 0 while L2 is transmitting data or waiting for a response by using the initiator node function.

(32) RHSIFnCCT (0, 1, 2, 3) — Channel (0, 1, 2, 3) Control Register

Access: This register is a write-only register that can be write in 32-bit units.

Address: RHSIFnCCT0: <RHSIFn_L2_base> + 408_H
RHSIFnCCT1: <RHSIFn_L2_base> + 488_H
RHSIFnCCT2: <RHSIFn_L2_base> + 508_H
RHSIFnCCT3: <RHSIFn_L2_base> + 588_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CTYW (N)	—	—	CTY(N)[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	W	R	R	W	W	W	W	W

Table 29.49 RHSIFnCCT (0, 1, 2, 3) Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When writing, write the value after reset.
7	CTYW(N)	"1" must be written to this bit at the same time as writing data to the CTY(N) bits when L2, operating as an initiator node, transmits a request Command other than a Stream Command. When this bit is 0, the data written to the CTY(N) bits is ignored.
6, 5	Reserved	When writing, write the value after reset.
4 to 0	CTY(N)	A Command type must be set in these bits when L2, operating as an initiator node, transmits a request Command other than a Stream Command. When L2 transmits a Command, 1 must be written to the CTYW(N) bit at the same time as writing data to these bits. 00000: Read Command (8 bits) 00001: Read Command (16 bits) 00010: Read Command (32 bits) 00100: Write Command (8 bits) 00101: Write Command (16 bits) 00110: Write Command (32 bits) 01100: Event Command 10010: ID Command Only the above Command types can be set.

(33) RHSIFnCST (0, 1, 2, 3) — Channel (0, 1, 2, 3) Status Register

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: RHSIFnCST0: <RHSIFn_L2_base> + 410_H
RHSIFnCST1: <RHSIFn_L2_base> + 490_H
RHSIFnCST2: <RHSIFn_L2_base> + 510_H
RHSIFnCST3: <RHSIFn_L2_base> + 590_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CRE(N)	—	—	—	—	—	—	—	—	—	—	BRE(N)	—	—	—	TER(N)

	RDY(N)	—	—	—	—	—	—	—	AOE(N)	—	IDE(N)	TOE(N)	—	AKE(N)	AKR(N)	RAR(N)
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.50 RHSIFnCST (0, 1, 2, 3) Register Contents (1/2)

Bit Position	Bit Name	Function
31	CRE(N)	This bit is set to 1 when a Command causing a CRC error is detected in the channel corresponding to the bit number. For details, see **Section 29.4.3.6, CRC Error Handling**.
30 to 21	Reserved	When read, the value after reset is returned.
20	BRE(N)	This bit is set to 1 when an error has occurred during data transfer in the H-Bus by a Read or Write Command received by L2 operating as a target node.
19 to 17	Reserved	When read, the value after reset is returned.
16	TER(N)	This bit is set to 1 when L2, operating as a target mode, receives an Event Command. Note that L2 ignores an event if another Event Command is received when this bit is already set to 1.
15	RDY(N)	This bit indicates whether L2, operating as an initiator node, can transmit request Commands other than Stream Commands. 0: Request Commands cannot be transmitted (the initiator node function is disabled or L2 is waiting for a reply Command). 1: Request Commands can be transmitted. Transmission of request Commands (writing 1 to the RHSIFnCCT(N).CTYW(N) bit) must be done only when this bit is 1.
14 to 8	Reserved	When read, the value after reset is returned.
7	AOE(N)	This bit is set to 1 when an error that cannot be classified as the one indicated by the AKE or IDE bit is detected after L2, operating as an initiator node, has transmitted a Read, Write, Event, or ID Command. In particular, the following event corresponds to this error: • A Read Command transmitted by RHSIF has met the "Any Other" condition in *the Table 18 of the HSSL / SIPI Interprocessor Bus Protocol Specification*.
6	Reserved	When read, the value after reset is returned.
5	IDE(N)	This bit is set to 1 when a reply Command (ACK, NACK, or Read Answer) causing a transaction ID error is detected after L2, operating as an initiator node, has transmitted a Read, Write, Event or ID Command.
4	TOE(N)	This bit is set to 1 when L2 cannot receive a response within the time set in RHSIFnMRT after L2, operating as an initiator node, has transmitted a Read, Write, Event, or ID Command.
3	Reserved	When read, the value after reset is returned.

Table 29.50 RHSIFnCST (0, 1, 2, 3) Register Contents (2/2)

Bit Position	Bit Name	Function
2	AKE(N)	This bit is set to 1 when L2 receives an NACK Command after L2, operating as an initiator node, has transmitted a Read, Write, Event, or ID Command.
1	AKR(N)	This bit is set to 1 when L2 receives an ACK Command after L2, operating as an initiator node, has transmitted a Write or Event Command.
0	RAR(N)	This bit is set to 1 when L2 receives a Read Answer Command after L2, operating as an initiator node, has transmitted a Read or ID Command.

(34) RHSIFnCSC (0, 1, 2, 3) — Channel (0, 1, 2, 3) Status Clear Register

Access: This register is a write-only register that can be write in 8-, 16-, or 32-bit units.

Address: RHSIFnCSC0: <RHSIFn_L2_base> + 418_H
RHSIFnCSC1: <RHSIFn_L2_base> + 498_H
RHSIFnCSC2: <RHSIFn_L2_base> + 518_H
RHSIFnCSC3: <RHSIFn_L2_base> + 598_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 29.52 RHSIFnCIE (0, 1, 2, 3) Register Contents (1/2)

Bit Position	Bit Name	Function
31	CREE(N)	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnCST(N).CRE(N) bit. 0: Does not assert int_hsif_err when the RHSIFnCST(N).CRE(N) bit is 1. 1: Asserts int_hsif_err when the RHSIFnCST(N).CRE(N) bit is 1.
31 to 21	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
20	BREE(N)	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnCST(N).BRE(N) bit. 0: Does not assert int_hsif_err when the RHSIFnCST(N).BRE(N) bit is 1. 1: Asserts int_hsif_err when the RHSIFnCST(N).BRE(N) bit is 1.
19 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	TERE(N)	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnCST(N).TER(N) bit. 0: Does not assert int_hsif_ch(N) when the RHSIFnCST(N).TER(N) bit is 1. 1: Asserts int_hsif_ch(N) when the RHSIFnCST(N).TER(N) bit is 1.
15 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7	AOEE(N)	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnCST(N).AOE(N) bit. 0: Does not assert int_hsif_err when the RHSIFnCST(N).AOE(N) bit is 1. 1: Asserts int_hsif_err when the RHSIFnCST(N).AOE(N) bit is 1.
6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	IDEE(N)	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnCST(N).IDE(N) bit. 0: Does not assert int_hsif_err when the RHSIFnCST(N).IDE(N) bit is 1. 1: Asserts int_hsif_err when the RHSIFnCST(N).IDE(N) bit is 1.
4	TOEE(N)	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnCST(N).TOE(N) bit. 0: Does not assert int_hsif_err when the RHSIFnCST(N).TOE(N) bit is 1. 1: Asserts int_hsif_err when the RHSIFnCST(N).TOE(N) bit is 1.
3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 29.52 RHSIFnCIE (0, 1, 2, 3) Register Contents (2/2)

Bit Position	Bit Name	Function
2	AKEE(N)	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnCST(N).AKE(N) bit. 0: Does not assert int_hsif_err when the RHSIFnCST(N).AKE(N) bit is 1. 1: Asserts int_hsif_err when the RHSIFnCST(N).AKE(N) bit is 1.
1	AKRE(N)	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnCST(N).AKR(N) bit. 0: Does not assert int_hsif_ch(N) when the RHSIFnCST(N).AKR(N) bit is 1. 1: Asserts int_hsif_ch(N) when the RHSIFnCST(N).AKR(N) bit is 1.
0	RARE(N)	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnCST(N).RAR(N) bit. 0: Does not assert int_hsif_ch(N) when the RHSIFnCST(N).RAR(N) bit is 1. 1: Asserts int_hsif_ch(N) when the RHSIFnCST(N).RAR(N) bit is 1.

(36) RHSIFnCAR (0, 1, 2, 3) — Channel (0, 1, 2, 3) Write/Read Address Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: RHSIFnCAR0: <RHSIFn_L2_base> + 428_H
RHSIFnCAR1: <RHSIFn_L2_base> + $4A8_H$
RHSIFnCAR2: <RHSIFn_L2_base> + 528_H
RHSIFnCAR3: <RHSIFn_L2_base> + $5A8_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 29.54 RHSIFnCWD (0, 1, 2, 3) Register Contents

Bit Position	Bit Name	Function
31 to 0	CWD(N)	These bits are used to set the data to be transmitted when L2, operating as an initiator node, transmits a Write Command. When the request size is 8 bits, set the data in the CDW(N)[7:0] bits. When the request size is 16 bits, set the data in the CDW(N)[15:0] bits. When the request size is 32 bits, set the data in the CDW(N)[31:0] bits.

(38) RHSIFnCRD (0, 1, 2, 3) — Channel (0, 1, 2, 3) Read Data Register

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: RHSIFnCRD0:<RHSIFn_L2_base> + 438_H
RHSIFnCRD1:<RHSIFn_L2_base> + $4B8_H$
RHSIFnCRD2:<RHSIFn_L2_base> + 538_H
RHSIFnCRD3:<RHSIFn_L2_base> + $5B8_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 29.55 RHSIFnCRD (0, 1, 2, 3) Register Contents

Bit Position	Bit Name	Function
31 to 0	CRD(N)	These bits contain the data that is received from a target node after L2, operating as an initiator node, has transmitted a Read or ID Command to the target node. When the request size is 8 bits, reference the CRD(N)[7:0] bits. When the request size is 16 bits, reference the CRD(N)[15:0] bits. When the request size is 32 bits, reference the CRD(N)[31:0] bits. These bits are valid only when RHSIFnCST(N).RAR(N) = 1.

29.4.3 Operation

29.4.3.1 Initial Settings

The procedure for the initial settings of L2 is as follows:

(1) Set the memory windows

(2) Set the channels

(3) Set the link partner authentication (only for systems that use the target node function and require authentication) *1

(4) Set the transmission stream (only for systems that transmit Stream Commands by using the initiator node function)

(5) Set the reception stream (only for systems that receive Stream Commands by using the target node function)

Note 1. To complete link partner authentication, you need to at least specify the settings below before step.(3).
At step.(1): Open memory window for the IP's register space.
for first authentication: RHSIFnAID0-7
for second authentication: RHSIFnARD0-3
At step.(2): Enable target node function on at least one channel.

The following sections describe how to specify settings with individual procedural steps:

(1) Setting Memory Windows

Figure 29.6 shows the flow to set memory windows in L2.

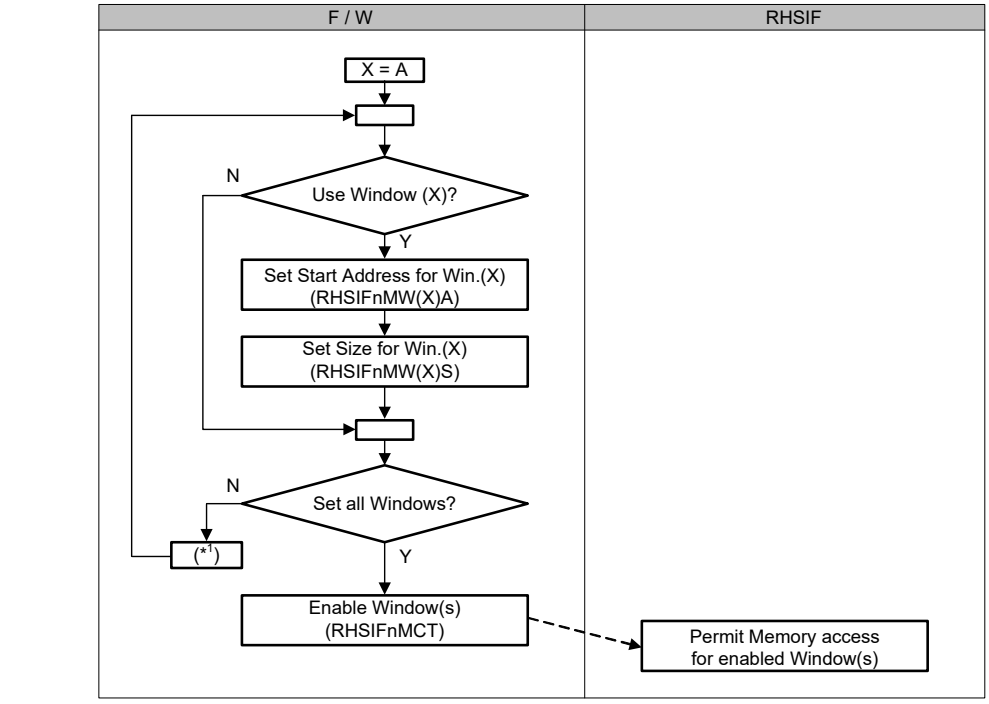
When the target node function of L2 is enabled, link partners can access (read and write) information in the product with L2 installed. If, however, unspecified link partners are permitted to access L2 without restriction, security problems can occur. Therefore, L2 has a function to enable you to specify the space (called a “window”) that is permitted to be accessed.

You can set up to four windows independently of channels. For each window, specify a start address and a size to prevent window areas from overlapping. You can also set read and write permissions separately for individual windows.

This window setting is valid for H-Bus requests which are issued by RHSIF as master. For details, refer to **Section 29.4.3.3, Non-Stream Command Reception by Target Node**, **Section 29.4.3.4, Stream Command Transmission by Initiator Node** and **Section 29.4.3.5, Stream Command Reception by Target Node**.

If you set windows at a time other than during the initial settings after a reset, you must disable the initiator node function on all channels (clear the RHSIFnCMD(N).INME(N) bit to 0), and the target node function on all channels (clear the RHSIFnCMD(N).TNME(N) bit to 0) before setting windows.

In normal mode, RHSIFnMCT, RHSIFnMW(X)A, and RHSIFnMW(X)S cannot be written to RHSIF’s master port. Reading data from these registers is possible from all master modules.



Note 1. Current Value = “A” → Change to “B”, ..., Current Value = “C” → Change to “D”

Figure 29.6 Setting Memory Windows

Figure 29.7 shows an example of setting memory windows.

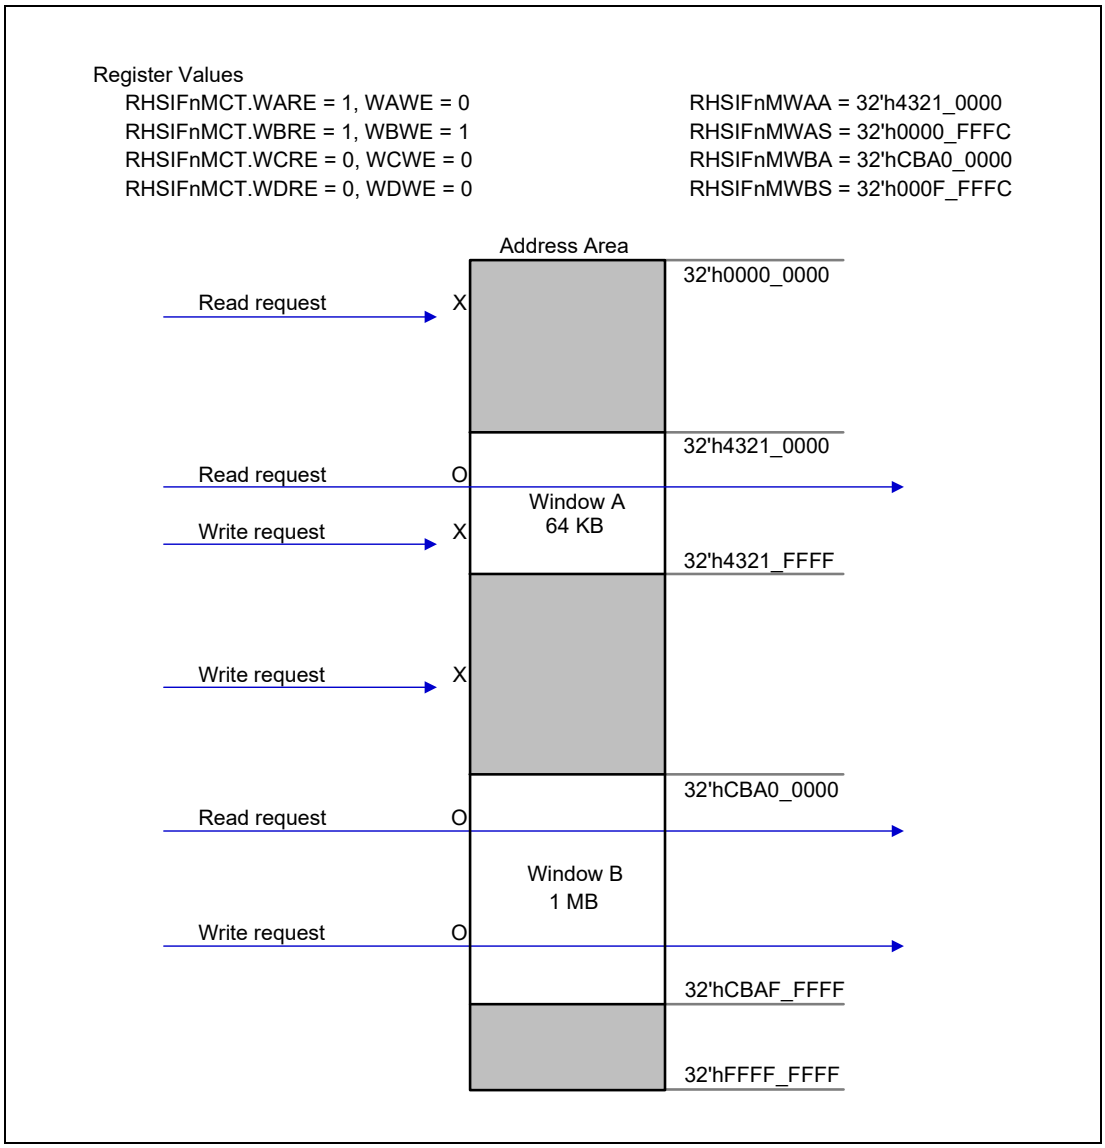


Figure 29.7 Example of Setting Memory Windows

(2) Setting Channels

Figure 29.8 shows the flow of setting channels for L2. Enable the functions to be used for individual channels.

When the RHSIFnCMD(N).INME(N) bit is set to 1 for a channel, L2 is enabled to transmit non-Stream Commands (Read, Write, Event, and ID Commands) through the channel. For details, see **Section 29.4.3.2, Non-Stream Command Transmission by Initiator Node**.

Also, specify a reply timeout time according to the system. The reply timer starts when L2 (Layer 2) finishes to transmit last symbol of a request Command. The reply timer stops when one of the following events occurs;

- L2 detects an expected reply Command.
- For Read Command, L2 detects reply Command with error (except CRC error).
- Reply timeout occurs

The reply timeout time that is specified applies to all channels.

When the RHSIFnCMD(N).TNME(N) bit is set to 1 for a channel, L2 is enabled to receive non-Stream Commands (Read, Write, Event, and ID Commands) through the channel. For details, see **Section 29.4.3.3, Non-Stream Command Reception by Target Node**.

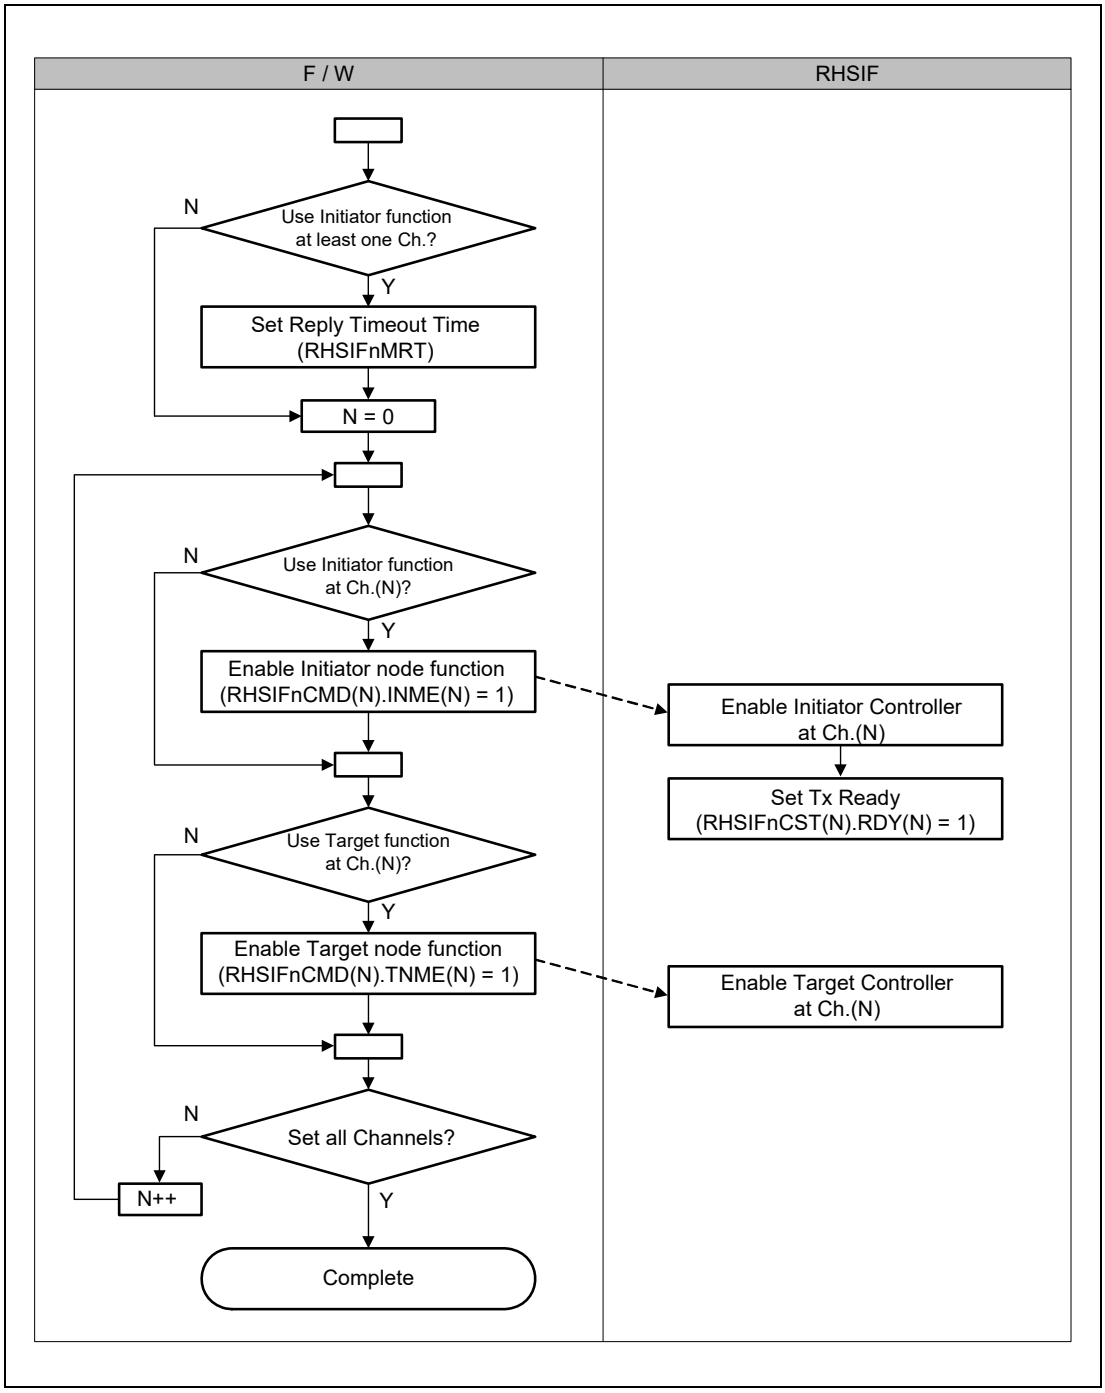

Figure 29.8 Setting Channels

(3) Setting Link Partner Authentication

When the target node function of L2 is enabled, link partners can access (read and write) information in the product with L2 installed. If, however, unspecified link partners are permitted to access L2, security problems can occur. Therefore, L2 has a function to authenticate link partners.

Link partner authentication is performed by using the following two steps:

1. Authentication based on a 256-bit key ID*1
2. Challenge-and-response authentication*2

You can enable or disable each type of authentication by using FLASH option byte. When link partner authentication is disabled, link partners can access the internal space of the product with L2 installed without performing the authentication procedure described in this section. Specify settings of the relevant FLASH option byte for RHSIF according to the security level required of the product with L2 installed.

Note 1. First Authentication (ID-based Authentication) needs setting.
Product shipping setting is invalid.
For the values of the FLASH option byte, refer to **Section 47, Basic Hardware Protection (BHP)**.

Note 2. Second Authentication (Challenge and Response Authentication) needs setting.
Product shipping setting is invalid.
For the values of the FLASH option byte for security, Refer to the *RH850/U2A-EVA Group Security User's Manual: Hardware*.

(a) First Authentication (ID-Based)

Figure 29.9 shows a concept of the first authentication (ID-based authentication), and the procedure for the authentication is described below.

(1) The link partner issues a Write Command (32 bits) for the address corresponding to the RHSIFnAID0 register in L2. Write data is the [31:0] bits of key ID (256 bits).

(2) Upon receiving the Write Command, the target controller of L2 checks the address in the Command.

A) When the address matches any of RHSIFnAID0 to RHSIFnAID7, the target controller determines the Write Command to be valid, and then issues a master write request to the H-Bus.

B) When the address does not match any of RHSIFnAID0 to RHSIFnAID7, the target controller ignores the Write Command without returning any reply Command.

(3) Upon receiving the H-Bus write request, the register unit of L2 checks the master ID in the request.

A) When the master ID matches the ID of L2, L2 determines the request to be valid, and then writes data to RHSIFnAID0.

B) When the master ID does not match, L2 does not execute the Write Command to RHSIFnAID0, and then returns an OKAY response.

(4) In the manner similar to steps (1) to (3), data is set in the RHSIFnAID1 to RHSIFnAID7 registers.

(5) When data is set in RHSIFnAID7, L2 compares the data (32 bits x 8 = 256 bits) in RHSIFnAID0 to RHSIFnAID7 with the data of FLASH option byte.

Refer to **Section 47, Basic Hardware Protection (BHP)** and **Table 47.24, RHSIFIDn Contents** for details.

A) If the data matches each other, L2 determines that the link partner passes the authentication. When only the first authentication is required, L2 determines whether the Read or Write Command from the link partner is valid according to the window setting described in **Section 29.4.3.1(1), Setting Memory Windows**

When the second authentication is also required, the procedure described in **Section 29.4.3.1(2), Setting Channels** is performed.

B) If the data does not match, L2 determines that the link partner fails the authentication. In such a case, the authentication procedure must be repeated beginning from step (1). If the link partner fails the authentication three consecutive times, L2 determines that the link partner is unauthorized, and will not let the link partner pass the authentication until a reset signal is asserted.

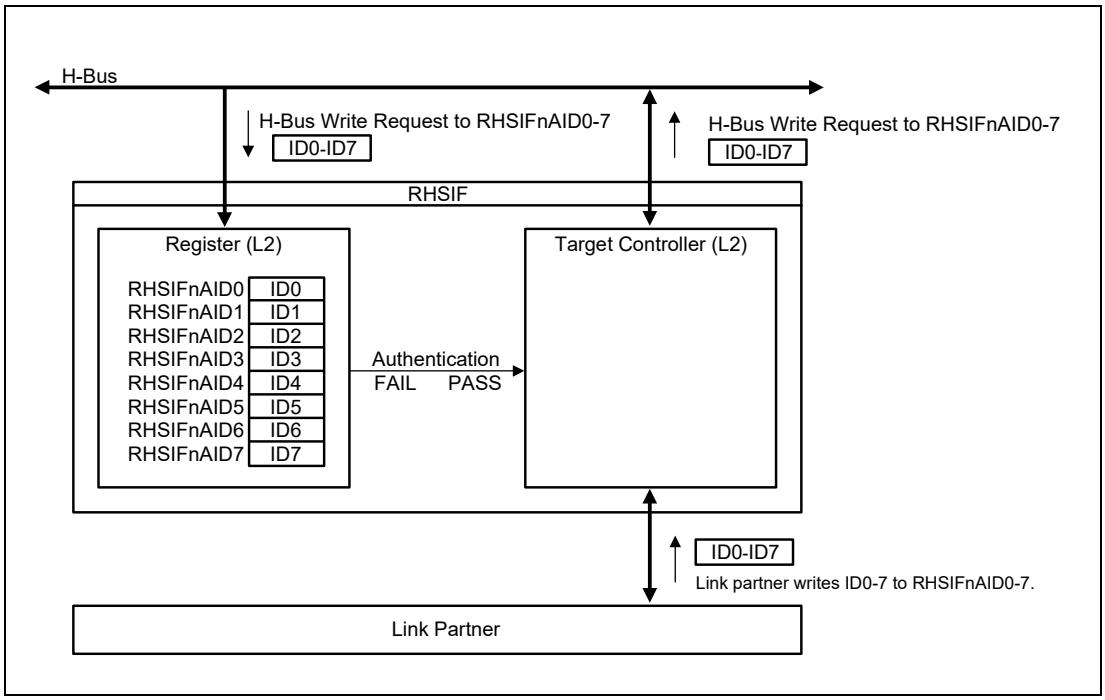

Figure 29.9 Concept of ID-Based Authentication

(b) Second Authentification (Challenge and Response)

Figure 29.10 and **Figure 29.11** show a concept of the second authentication (challenge-and-response authentication), and the procedure for the authentication is described below. Note that this manual describes only how to set the data to be used for challenge and response. For the procedure of challenge and response, see the manual for the product in which L2 is installed.

Step 1 Preparation of the challenge data (Figure 29.10)

(1) Prepare the challenge data, and send it to the Link Partner. The way to generate the challenge data is selectable.
In the example in this figure, challenge data is generated by ICUMHA and send it via RHSIF to the Link Partner.

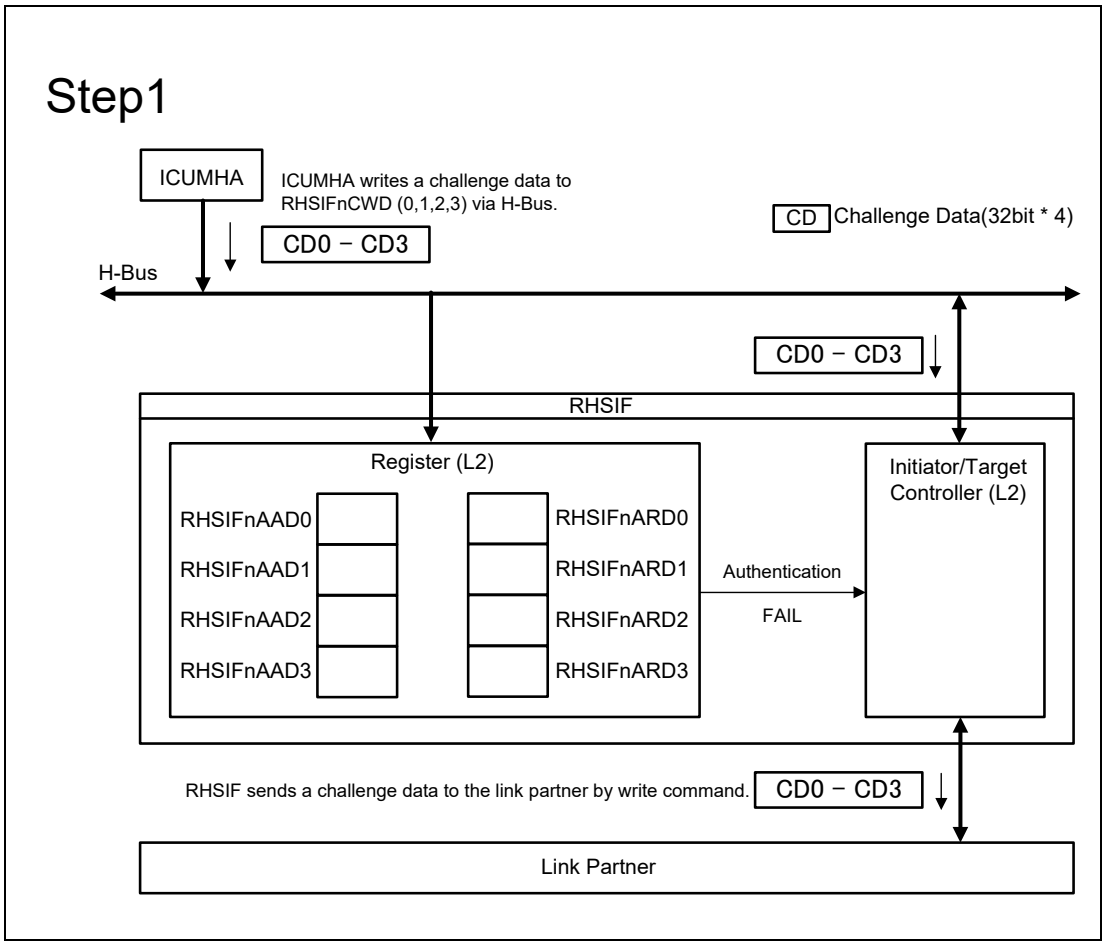

Figure 29.10 Concept of Challenge and Response Authentication (Preparation of the challenge data)

Step 2 Calculate the response data and compare it (Figure 29.11)

(1) The security module (ICUMHA) connected to the H-Bus calculates Answer (Response) data from Challenge data, and then sets the [31:0] bits of the Response data in the RHSIFnAAD0 register in L2.

(2) Upon receiving the H-Bus write request, the register unit of L2 checks the master ID in the request.

A) When the master ID matches the one in the ICUMHA, L2 determines the request to be valid, and then writes data to RHSIFnAAD0.

B) When the master ID does not match, L2 does not execute the Write Command to RHSIFnAAD0, and then returns an OKAY response.

(3) In the manner similar to steps (1) and (2), data is set in the RHSIFnAAD1 to RHSIFnAAD3 registers.

(4) The link partner issues a Write Command (32 bits) for the address corresponding to the RHSIFnARD0 register in L2. Write data is the [31:0] bits of Response data.

(5) Upon receiving the Write Command, the target controller of L2 checks the address in the Command.

A) When the address matches any of RHSIFnARD0 to RHSIFnARD3, the target controller determines the Write Command to be valid, and then issues a master write request to the H-Bus.

B) When the address does not match any of RHSIFnARD0 to RHSIFnARD3, the target controller ignores the Write Command without returning any reply Command.

(6) Upon receiving the H-Bus write request, the register unit of L2 checks the master ID in the request.

A) When the master ID matches the ID of L2, L2 determines the request to be valid, and then writes data to RHSIFnARD0.

B) When the master ID does not match, L2 does not execute the Write Command to RHSIFnARD0, and then returns an OKAY response.

(7) In the manner similar to steps (4) to (6), data is set in the RHSIFnARD1 to RHSIFnARD3 registers.

(8) When data is set in RHSIFnARD3, L2 compares the data (32 bits x 4 = 128 bits) in RHSIFnARD0 to RHSIFnARD3 with the data (32 bits x 4 = 128 bits) preset in RHSIFnAAD0 to RHSIFnAAD3.

A) If the data matches each other, L2 determines that the link partner passes the authentication. After that, L2 determines whether the read or Write Command from the link partner is valid according to the window setting described in **Section 29.4.3.1(1), Setting Memory Windows**.

B) If the data does not match, L2 determines that the link partner fails the authentication. In such a case, the authentication procedure must be repeated beginning from step (1). If the link partner fails the authentication three consecutive times, L2 determines that the link partner is unauthorized, and will not let the link partner pass the authentication until a reset signal is asserted.

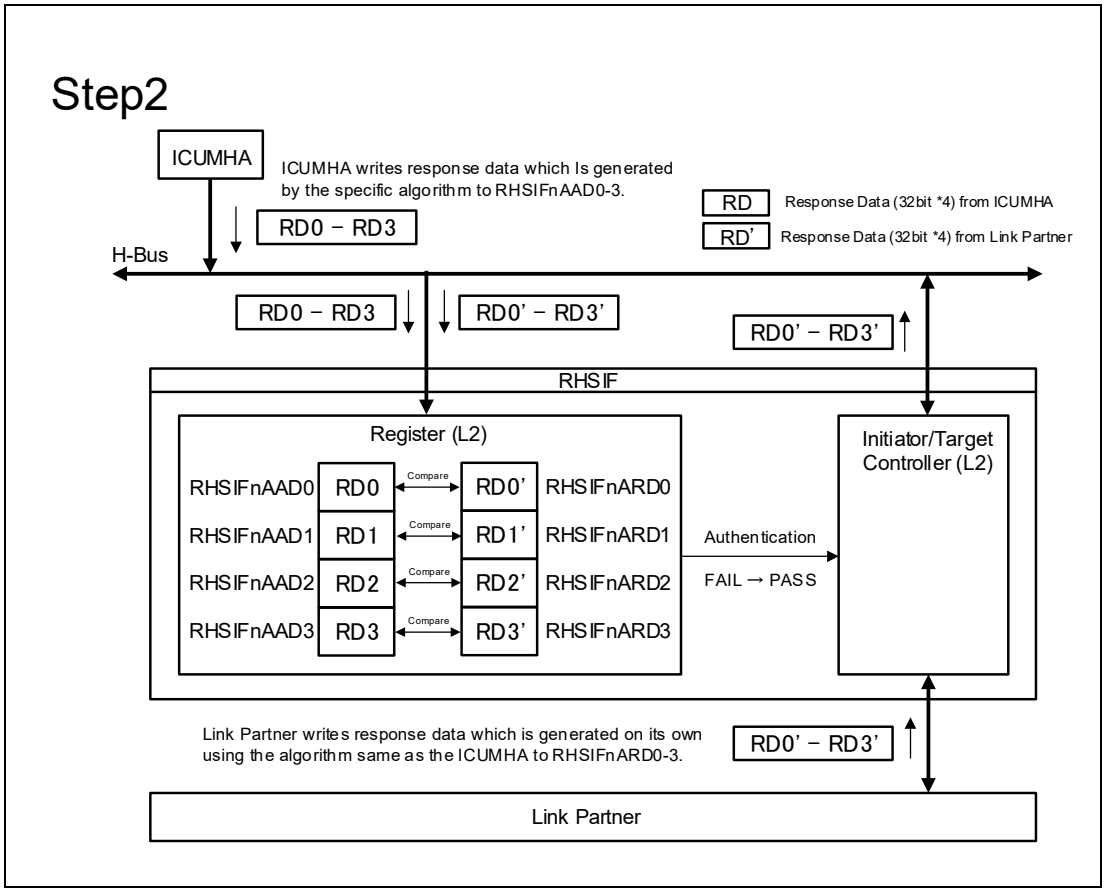

Figure 29.11 Concept of Challenge and Response Authentication (Calculates and Compares Response Data)

(4) Setting Tx Stream for Initiator Node

Figure 29.12 shows the flow of the initial settings of Stream Command transmission by L2.

RHSIF's protocol defines the data payload size of a Stream Command as 256 bits. You, however, can also set the data payload size to 128 bits for L2. Note that the data payload size can be changed only at the time of the initial settings. You cannot change this setting dynamically during system operation. Specify an appropriate value in the relevant parameter during the initial settings according to the system.

There are two modes for receiving NACK Command.

- RHSIFnSTMD.STNK = 0: L2 regards reception of the NACK Command as occurrence of an error.
- RHSIFnSTMD.STNK = 1: L2 regards reception of the NACK Command as reception of an ACK Command.

Select an appropriate mode according to the application program.

For details about the flow of Stream Command transmission, see **Section 29.4.3.4, Stream Command Transmission by Initiator Node**.

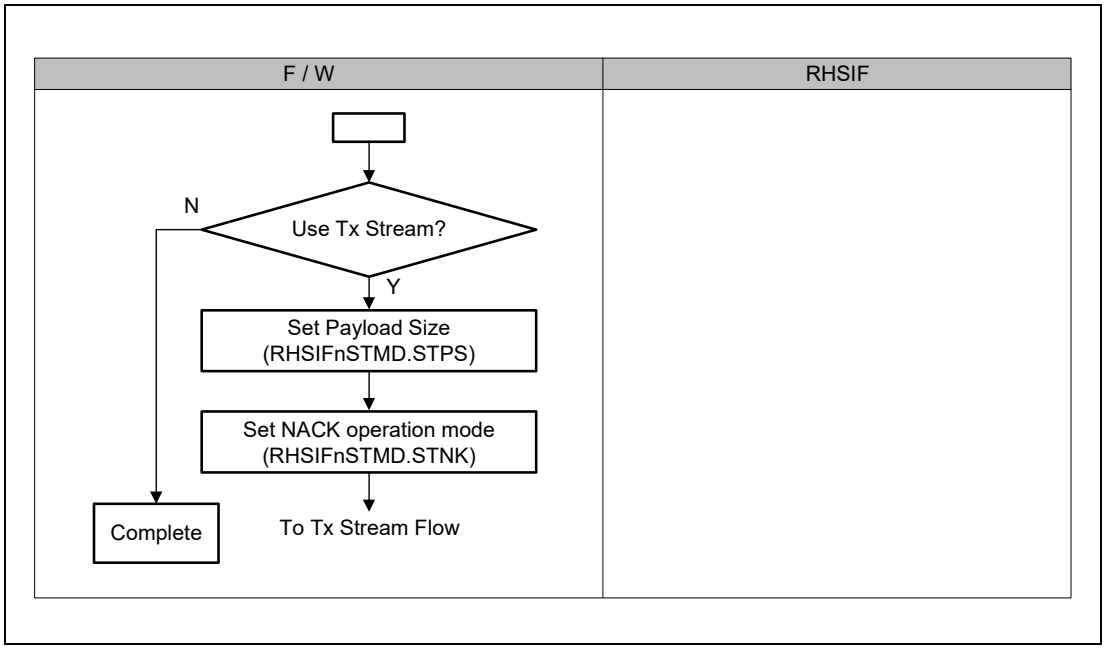

Figure 29.12 Initial Setting of Tx Stream

(5) Setting Rx Stream for Target Node

Figure 29.13 shows the flow of the initial settings of Stream Command reception by L2.

RHSIF defines the data payload size of a Stream Command as 256 bits. You, however, can also set the data payload size to 128 bits for L2. Note that the data payload size can be changed only at the time of the initial settings. You cannot change this setting dynamically during system operation. Specify an appropriate value in the relevant parameter during the initial settings according to the system.

How to handle an error occurring in a command that is received or during data transfer depends on the application program. L2 allows you to select the operation that is necessary when an error occurs in the following two modes:

- RHSIFnSRMD.SRMC = 0: The RHSIFnSRCT.SRDE bit is cleared automatically when an error occurs.
  Select this mode when you want to stop data storage immediately after the error occurs.
  Note that, because L2 can receive two Stream Commands concurrently, if an H-Bus error occurs, L2 might store the data up to the data causing the error.
- RHSIFnSRMD.SRMC = 1: The RHSIFnSRCT.SRDE bit is not cleared automatically when an error occurs.
  Select this mode when you want to let the firmware determine the processing that is necessary if an error occurs.
  To stop data storage after the processing is determined, clear the RHSIFnSRCT.SRDE bit by the firmware.

Select an appropriate mode according to the application program.

For details about the flow of Stream Command reception, see **Section 29.4.3.5, Stream Command Reception by Target Node**.

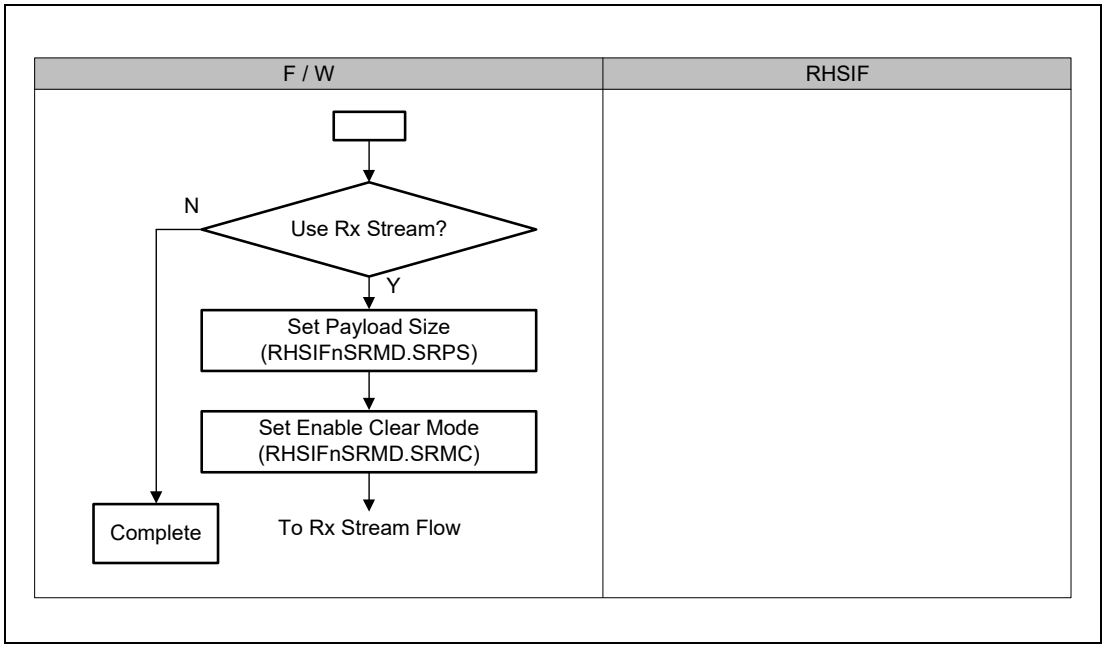

Figure 29.13 Initial Setting of Rx Stream

29.4.3.2 Non-Stream Command Transmission by Initiator Node

Figure 29.14 to **Figure 29.17** show the flows for transmitting non-stream requests (Read, Write, Event, and ID Commands) by using the initiator node function of L2.

Transmission of non-stream requests is performed under control of the firmware. A request is transmitted by accessing a register, and an interrupt is used as the trigger for checking response.

The following describes the transmission operation, using Read Command transmission (**Figure 29.14**) for example.

When a Command transmission request is found, whether transmission is enabled must be checked first. Transmission is enabled when the RHSIFnCST(N).RDY(N) bit is 1. Then, a target address must be set in the RHSIFnCAR(N) register, and a trigger for transmission must be issued by using the RHSIFnCCT(N) register. When the trigger is issued, L2 generates and transmits the Command.

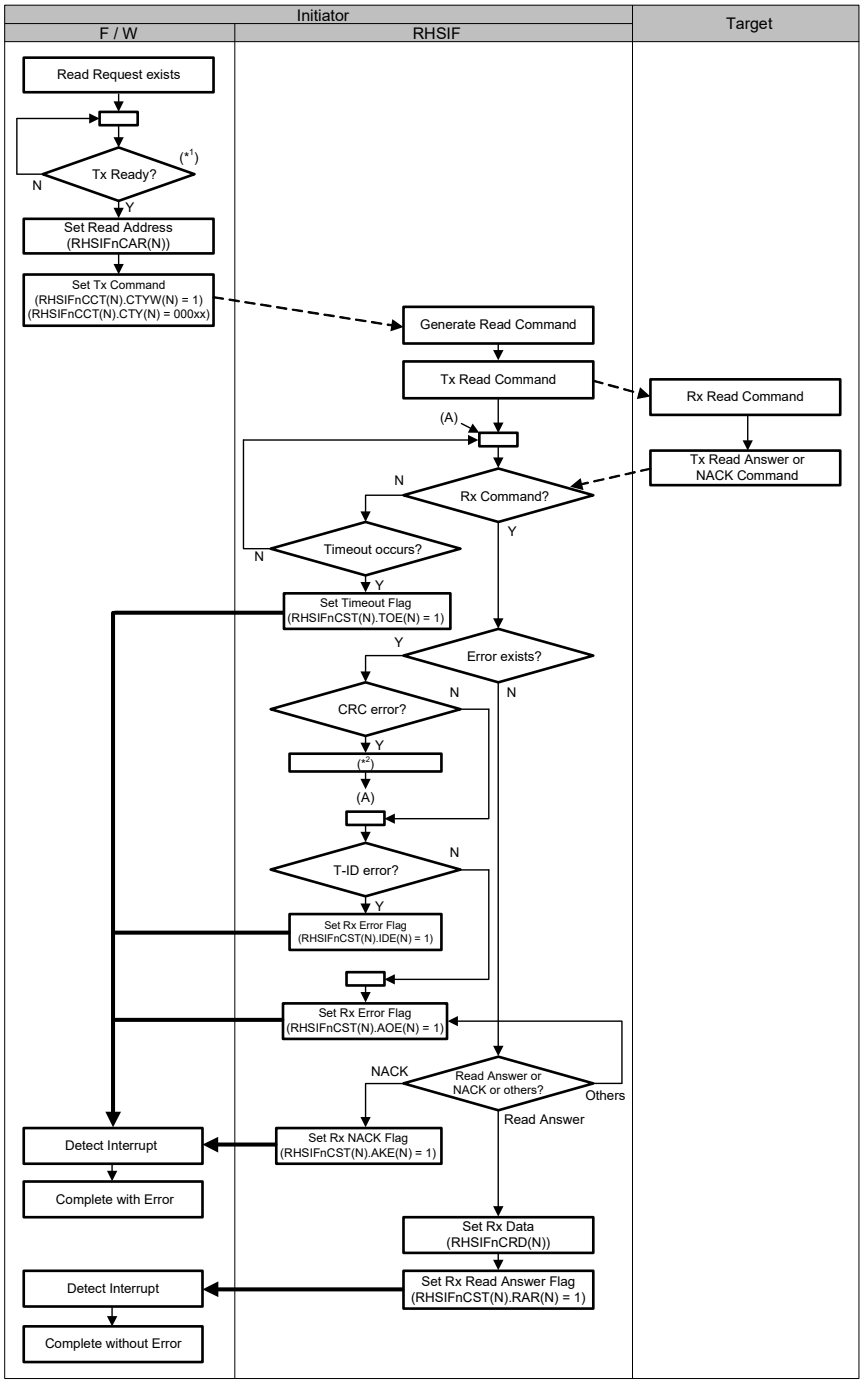
After transmitting the Command, L2 waits for a reply Command from the link partner. L2 subsequently performs one of the following four operations depending on the response of the link partner and whether a frame error occurs:

(1) When the link partner returns a Read Answer Command (normal case)
L2 sets the RHSIFnCST(N).RAR(N) bit, and (when interrupt is enabled) generates an int_hsif_ch(N) interrupt.
Checking of read data in the RHSIFnCRD(N) register and other necessary processing must be performed.

(2) When the link partner returns an NACK Command
L2 sets the RHSIFnCST(N).AKE(N) bit, and (when interrupt is enabled) generates an int_hsif_err interrupt.
Retransmission of the Command and other necessary processing must be performed.

(3) When the reply Command from the link partner involves an error
L2 sets the RHSIFnCST(N).IDE(N) or RHSIFnCST(N).AOE(N) bit according to the type of the error, and (when interrupt is enabled) generates an int_hsif_err interrupt.
Retransmission of the Command and other necessary processing must be performed.
In case reply Command has CRC error, L2 performs special action. For details, see **Section 29.4.3.6, CRC Error Handling**.

(4) When the link partner does not respond (reply timeout occurs)
If the reply Command from the link partner cannot be detected within the time set in the RHSIFnMRT register after Command transmission, L2 sets the RHSIFnCST(N).TOE(N) bit, and (when interrupt is enabled) generates an int_hsif_err interrupt.
Retransmission of the Command and other necessary processing must be performed.



Note 1. RHSIFnCST(N).RDY(N) = 1

Note 2. In case Rx Command has CRC error, RHSIF performs special action. For details, see **Section 29.4.3.6, CRC Error Handling**.

Figure 29.14 Tx Read Command Operation

Note 2. In case Rx Command has CRC error, RHSIF performs special action. For details, see **Section 29.4.3.6, CRC Error Handling**.

Figure 29.17 Tx ID Command Operation

29.4.3.3 Non-Stream Command Reception by Target Node

Figure 29.18 to **Figure 29.21** show the flows for receiving non-stream requests (Read, Write, Event, and ID Commands) by using the target node function of L2.

Because the hardware of L2 automatically processes Commands that are received, the firmware of L2 does not need to perform any processing.

The following describes the reception operation, using the Read Command reception (**Figure 29.18**) for example.

Upon receiving a Command, L2 first checks whether an error has occurred. When an error is detected, L2 discards the command that is received without returning any reply Command. In the case the command that is received has a CRC error, L2 performs special action. For details, see **Section 29.4.3.6, CRC Error Handling**.

When no error is detected, L2 checks the following items to determine whether read access is enabled:

(1) Whether the target node function has been enabled for the relevant channel

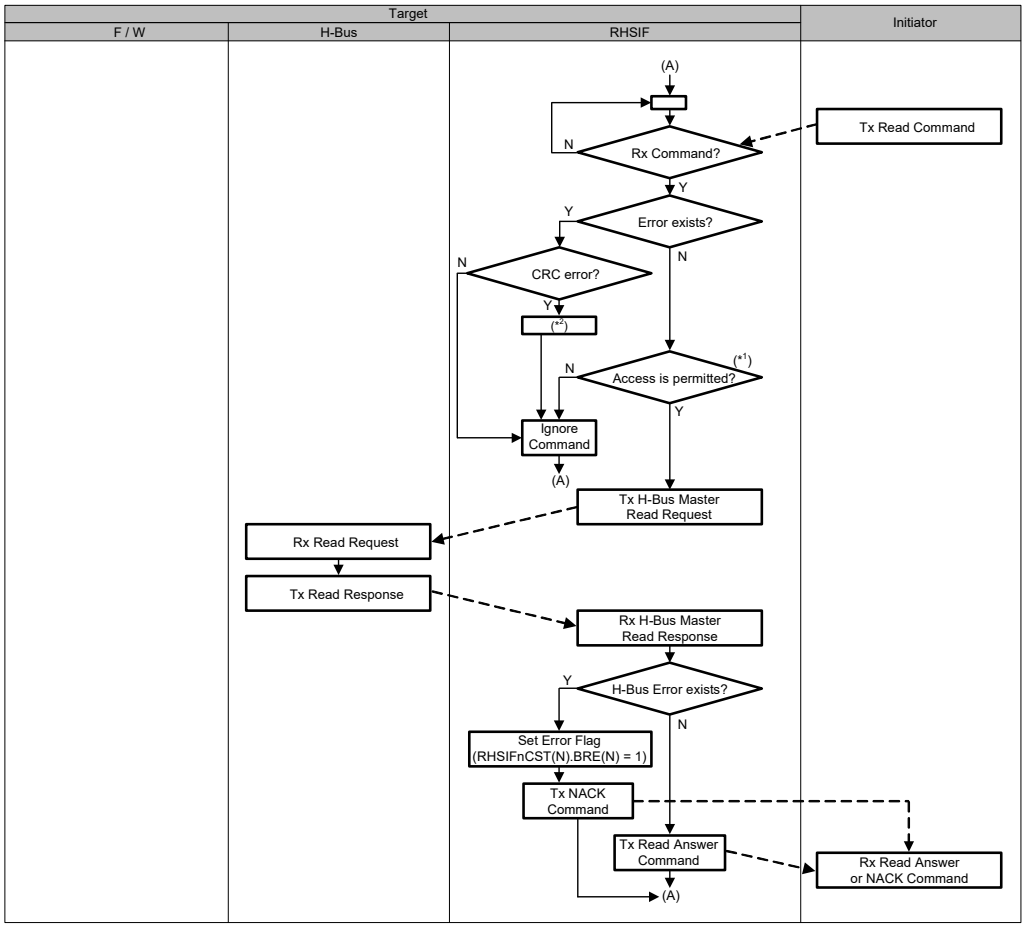
(2) Whether authentication has been performed (when authentication is required)

(3) Whether the target address corresponds to a valid memory window

(4) Whether reading of the window described in (3) above is permitted

If the result of any of the above checks is negative, L2 discards the command that is received without returning any reply Command.

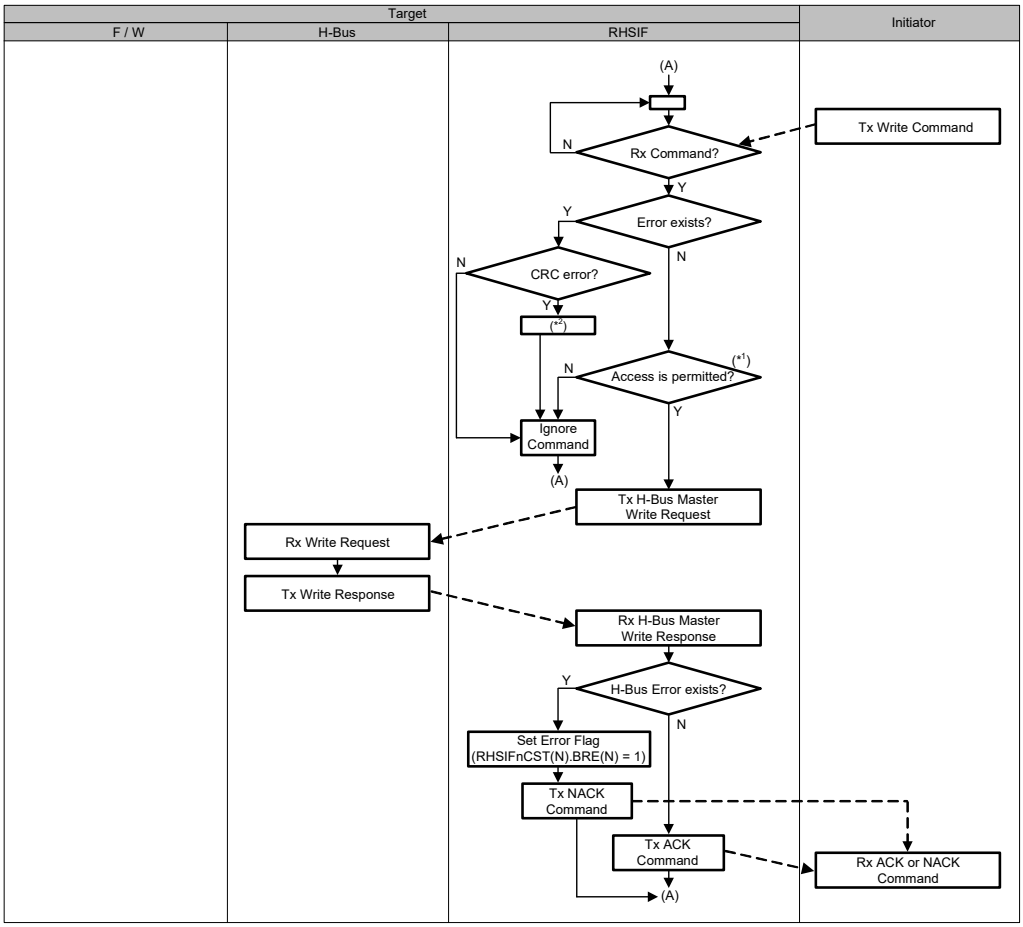
If the results of all of the above checks are positive, L2 issues a Master Read request to the H-Bus. After receiving a response from the H-Bus, L2 transmits a Read Answer Command (when no H-Bus response error is detected) or an NACK Command (when an H-Bus response error is detected) to the link partner.



Note 1. All of following conditions are satisfied:
1. RHSIFnCMD(N).TNME(N) = 1
2. Authentication(s) is PASSed. (As required)
3. Address is inside of any Memory Windows which are defined by RHSIFnMW(X)A and RHSIFnMW(X)S
4. Read is allowed for a Memory Window whose address is hit (RHSIFnMCT.W(X)RE = 1)

Note 2. In case Rx Command has CRC error, L2 performs special action. For details, see **Section 29.4.3.6, CRC Error Handling**.

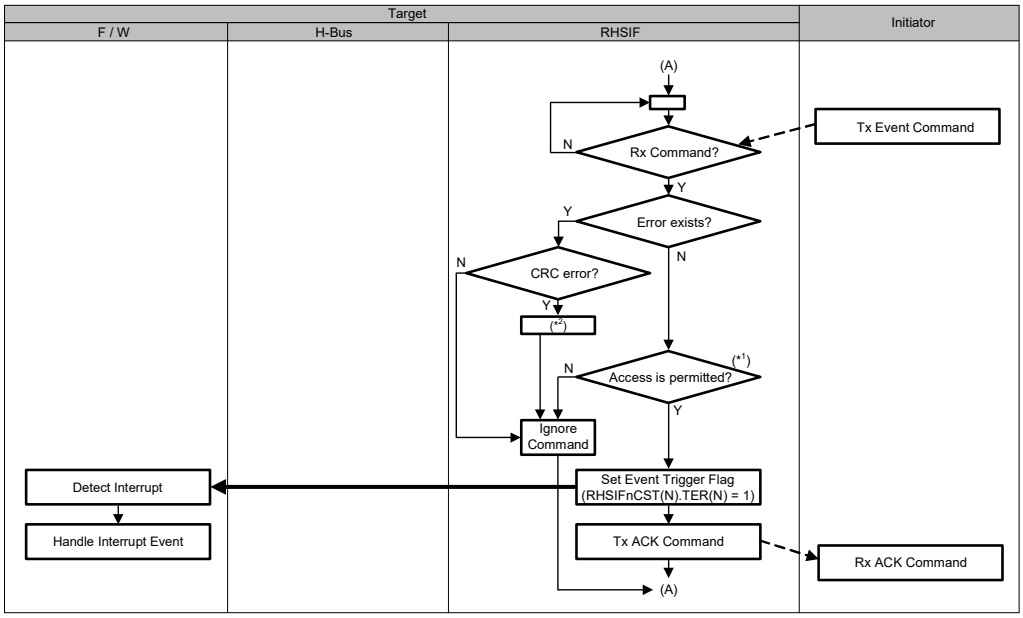
Figure 29.18 Rx Read Command Operation



Note 1. All of following conditions are satisfied:
1. RHSIFnCMD(N).TNME(N) = 1
2. Authentication(s) is PASSed. (As required)
3. Address is inside of any Memory Windows which are defined by RHSIFnMW(X)A and RHSIFnMW(X)S
4. Write is allowed for a Memory Window whose address is hit (RHSIFnMCT.W(X)WE = 1)

Note 2. In case Rx Command has CRC error, L2 performs special action. For details, see **Section 29.4.3.6, CRC Error Handling**.

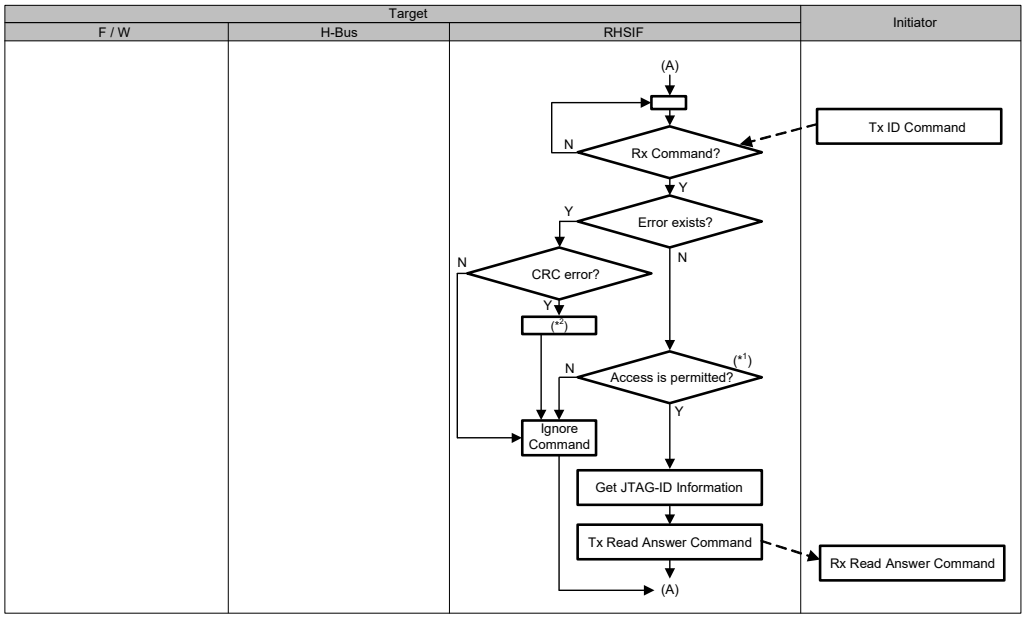
Figure 29.19 Rx Write Command Operation



Note 1. The following conditions are satisfied:
1. RHSIFnCMD(N).TNME(N) = 1
2. Authentication(s) is PASSed. (As required)

Note 2. In case Rx Command has CRC error, L2 performs special action. For details, see **Section 29.4.3.6, CRC Error Handling**.

Figure 29.20 Rx Event Command Operation



Note 1. The following conditions are satisfied:
1. RHSIFnCMD(N).TNME(N) = 1
2. Authentication(s) is PASSed. (As required)

Note 2. In case Rx Command has CRC error, L2 performs special action. For details, see **Section 29.4.3.6, CRC Error Handling**.

Figure 29.21 Rx ID Command Operation

29.4.3.4 Stream Command Transmission by Initiator Node

Figure 29.22 and **Figure 29.23** show the flow for transmitting Stream Commands by using the initiator node function and internal DMAC of L2.

After preparing stream data, the firmware must set the start address of the area containing the data and the number of bytes to be transferred, and then enable the DMAC.

L2 internally has a 512-bit data buffer, and obtains data by issuing a Master Read request to the H-Bus with the maximum size is 256-bit. For L2, the maximum number of outstanding requests to the H-Bus is set to 2.

If source address does not hit any window or read operation is not allowed for a memory window whose address is hit RHSIF does not issue H-Bus read request. When RHSIF collects all the responses to transmitted H-Bus requests and transmitted request commands, it sets the RHSIFnSTST.STE4 bit, and then stops the DMAC.

If an error is detected in the response from the H-Bus, L2 collects all the responses to transmitted H-Bus requests and transmitted request commands, it sets the RHSIFnSTST.STE3 bit, and then stops the DMAC.

If no error is detected in the response from the H-Bus, L2 generates and transmits a Stream Command in units of the size specified by the RHSIFnSTMD.STPS bit. RHSIF allows up to two Stream Commands to be transmitted to a link partner before the link partner responds. Compliant with this specification, L2 can transmit a maximum of two outstanding requests to a link partner.

The Stream Command data to be transmitted is realigned in L2 so that the data alignment meets the specification. For the data alignment, see **Figure 29.24**.

After normally transmitting all data (specified number of bytes to be transferred), L2 sets the RHSIFnSTST.STC bit, and (when interrupt is enabled) generates an int_hsif_str interrupt.

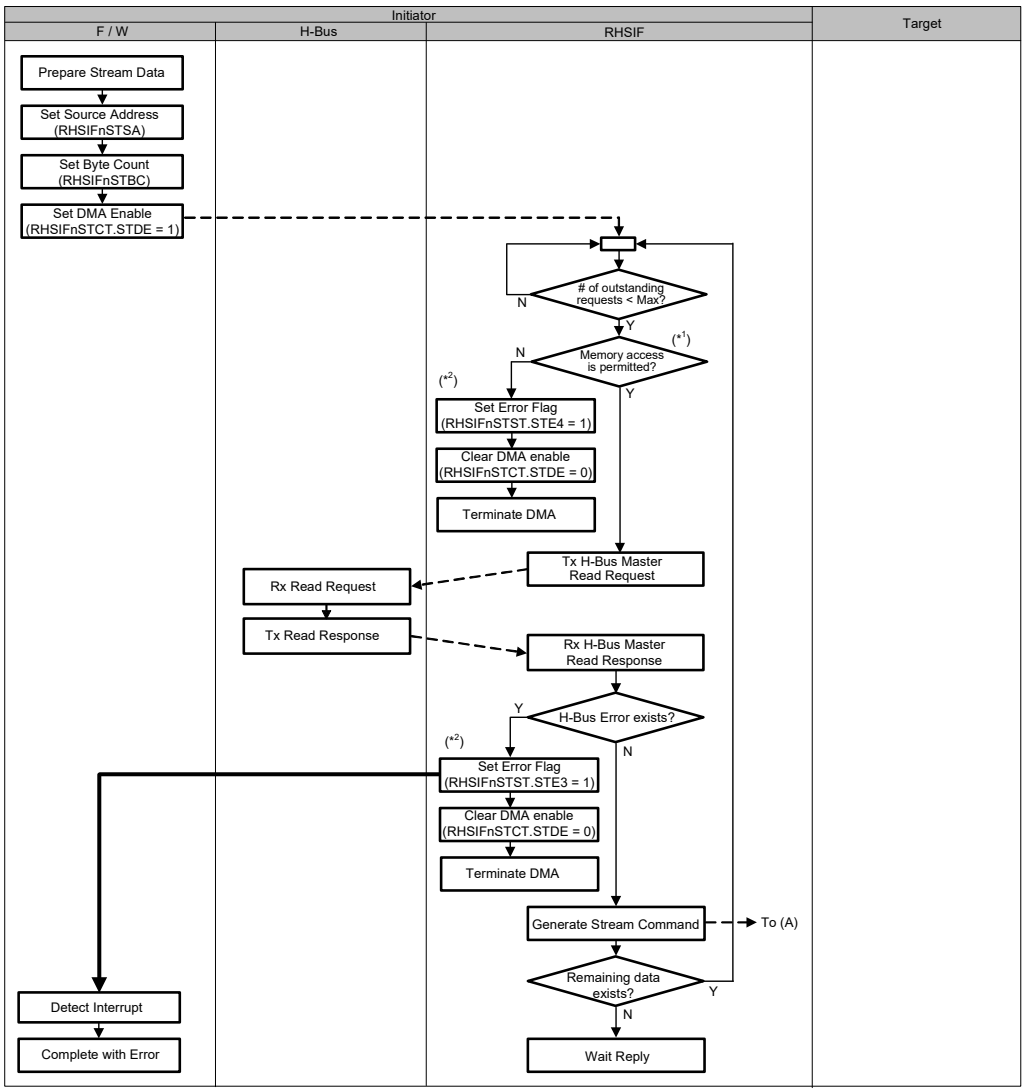
If an error (including timeout) is caused by a reply command during transmission, L2 collects all the responses to transmitted H-Bus requests and transmitted request commands, it sets the RHSIFnSTST.STE1 or RHSIFnSTST.STE2 bit, and then stops the DMAC.

Note that the operation L2 performs when it receives an NACK Command depends on the value of the RHSIFnSTMD.STNK bit. When the RHSIFnSTMD.STNK bit is 0, L2 regards reception of the NACK Command as occurrence of an error, it sets the RHSIFnSTST.STE0 bit, and then stops the DMA transfer. When the RHSIFnSTMD.STNK bit is 1, L2 regards reception of the NACK Command as reception of an ACK Command, and continues the DMA transfer. Specify an appropriate value in the RHSIFnSTMD.STNK bit according to the usage of the data to be transferred.

If more than one error (receives NACK, detects T-ID error, or reply timeout) occur during a DMA operation, only first error is set to RHSIFnSTST.STE0, STE1, or STE2.

In case reply Command has CRC error, L2 performs special action. For details, see **Section 29.4.3.6, CRC Error Handling**.

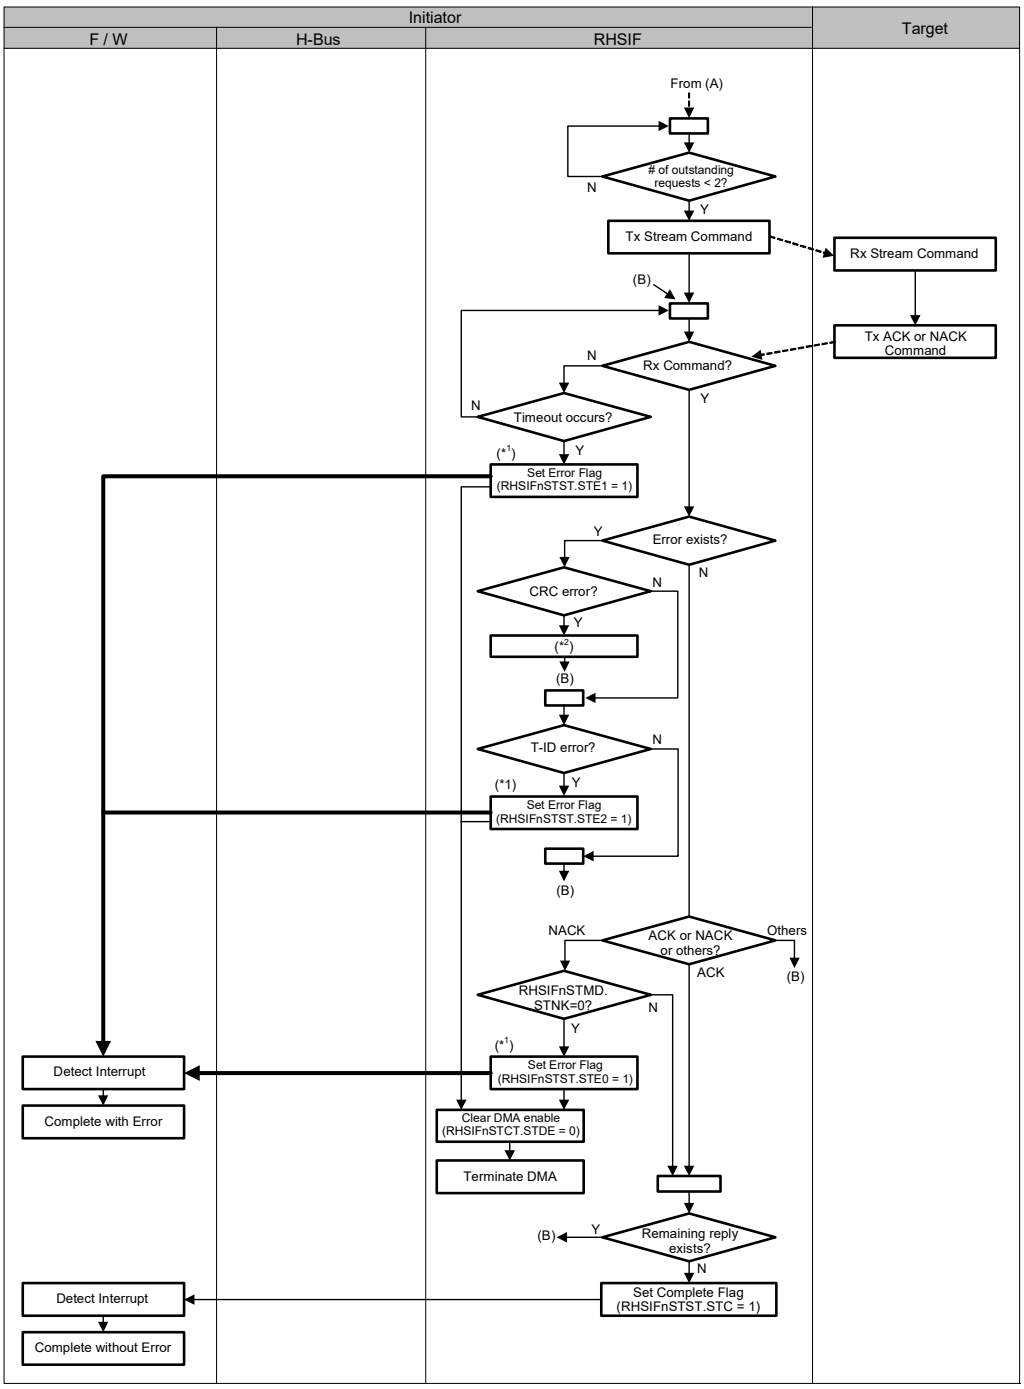
Note that Stream Commands must not be issued together with a non-Stream Command (Read, Write, Event, or ID Command). The firmware must be controlled so that non-Stream Commands are not transmitted while a Stream Command is being transmitted.



Note 1. All of following conditions are satisfied:
1. Source address is inside of any memory window which are defined by RHSIFnMW(X)A and RHSIFnMW(X)S
2. Read is allowed for a memory window whose address is hit (RHSIFnMCT.W(X)WE=1)

Note 2. This bit is set after all responses/replies are received for all H-Bus requests/request commands that are already transmitted.

Figure 29.22 Tx Stream Command Operation (1)



Note 1. This bit is set after all responses/replies are received for all H-Bus requests/request commands that are already transmitted.

Note 2. In case Rx Command has CRC error, L2 performs special action. For details, see **Section 29.4.3.6, CRC Error Handling**.

Figure 29.23 Tx Stream Command Operation (2)

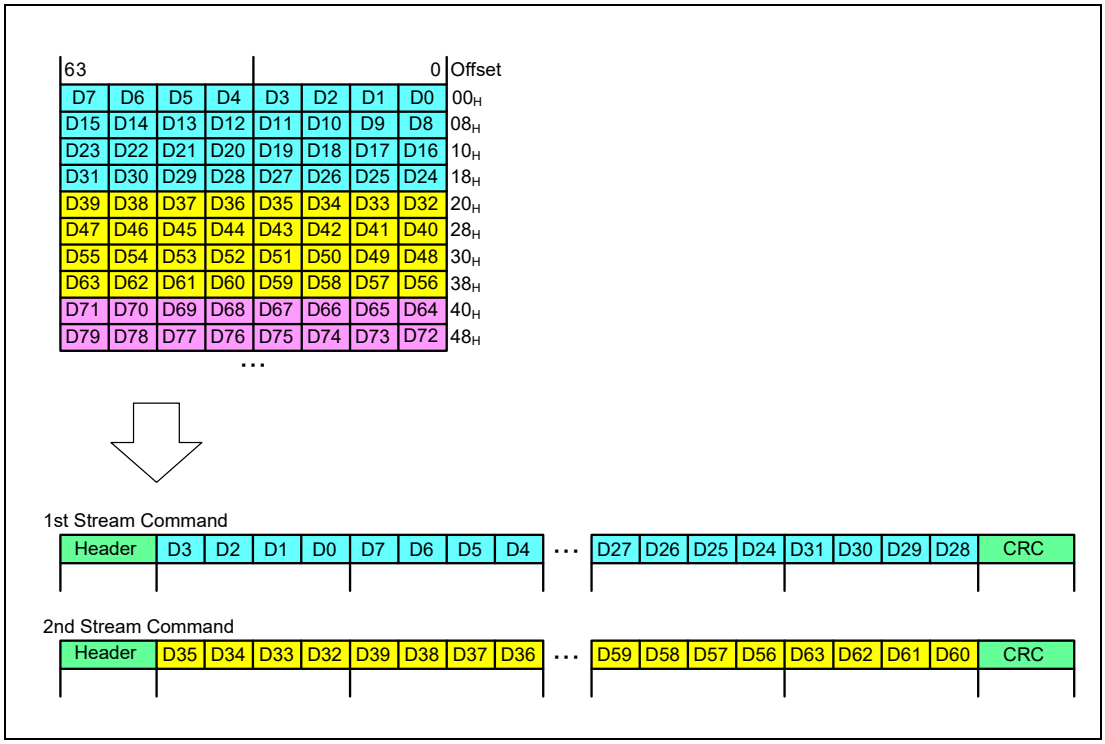


Figure 29.24 Tx Stream Data Alignment

29.4.3.5 Stream Command Reception by Target Node

Figure 29.25 and **Figure 29.26** show the flow for receiving Stream Commands by using the target node function and internal DMAC of L2.

First, the type of interrupt must be selected. L2 provides the following two status types:

(1) Status indicating that the size of unprocessed data is not 0 (RHSIFnSRST.SRC0)

(2) Status indicating that the size of unprocessed data is at least the specified size (RHSIFnSRST.SRC1)

An appropriate type must be selected according to the system.

Upon receiving a Stream Command, L2 first checks whether an error has occurred. When an error is detected, L2 discards the received Command without returning any reply Command. In the case the command that is received has CRC error, L2 performs special action. For details, see **Section 29.4.3.6, CRC Error Handling**.

When the RHSIFnSRMD.SRMC bit is 0, L2 automatically clears the RHSIFnSRCT.SRDE bit to 0 and sets the RHSIFnSRST.SRA to prevent extra data from being stored subsequently.

When no error is detected, L2 checks the following items to determine whether stream transfer is enabled:

(1) Whether the target node function has been enabled for channel 2

(2) Whether authentication has been performed (when authentication is required)

(3) Whether DMA for stream reception has been enabled

If the result of any of the above checks is negative, L2 discards the command that is received without returning any reply Command.

If destination address does not hit any window or write operation is not allowed for a memory window whose address is hit, RHSIF discards the command that is received without returning any reply Command, and sets the RHSIFnSRST.STE2 bit to 1. When the RHSIFnSRMD.SRMC bit is 0, RHSIF automatically clears the RHSIFnSRCT.SRDE bit to 0 and sets the RHSIFnSRST.SRA to prevent extra data from being stored subsequently.

If the results of all the above checks are positive, L2 checks the size of the free space in the stream storage buffer. If the buffer does not have enough free space to store the data that is received, L2 discards the command that is received, returns a NACK Command, and sets the RHSIFnSRST.SRE1 bit to 1. When the RHSIFnSRMD.SRMC bit is 0, L2 automatically clears the RHSIFnSRCT.SRDE bit to 0 and sets the RHSIFnSRST.SRA to prevent extra data from being stored subsequently.

If the buffer has enough free space to store received data, L2 issues a Master Write request to the H-Bus. RHSIF allows up to two Stream Commands to be transmitted to a link partner before the link partner responds. Compliant with this specification, L2 can receive up to two Stream Commands concurrently. The maximum number of outstanding requests to the H-Bus is 2.

The data alignment of the Stream Commands that are received complies with the specifications. Therefore, the Stream Command data to be transmitted is realigned in L2 before transmission to the H-Bus. For the data alignment, see **Figure 29.24**.

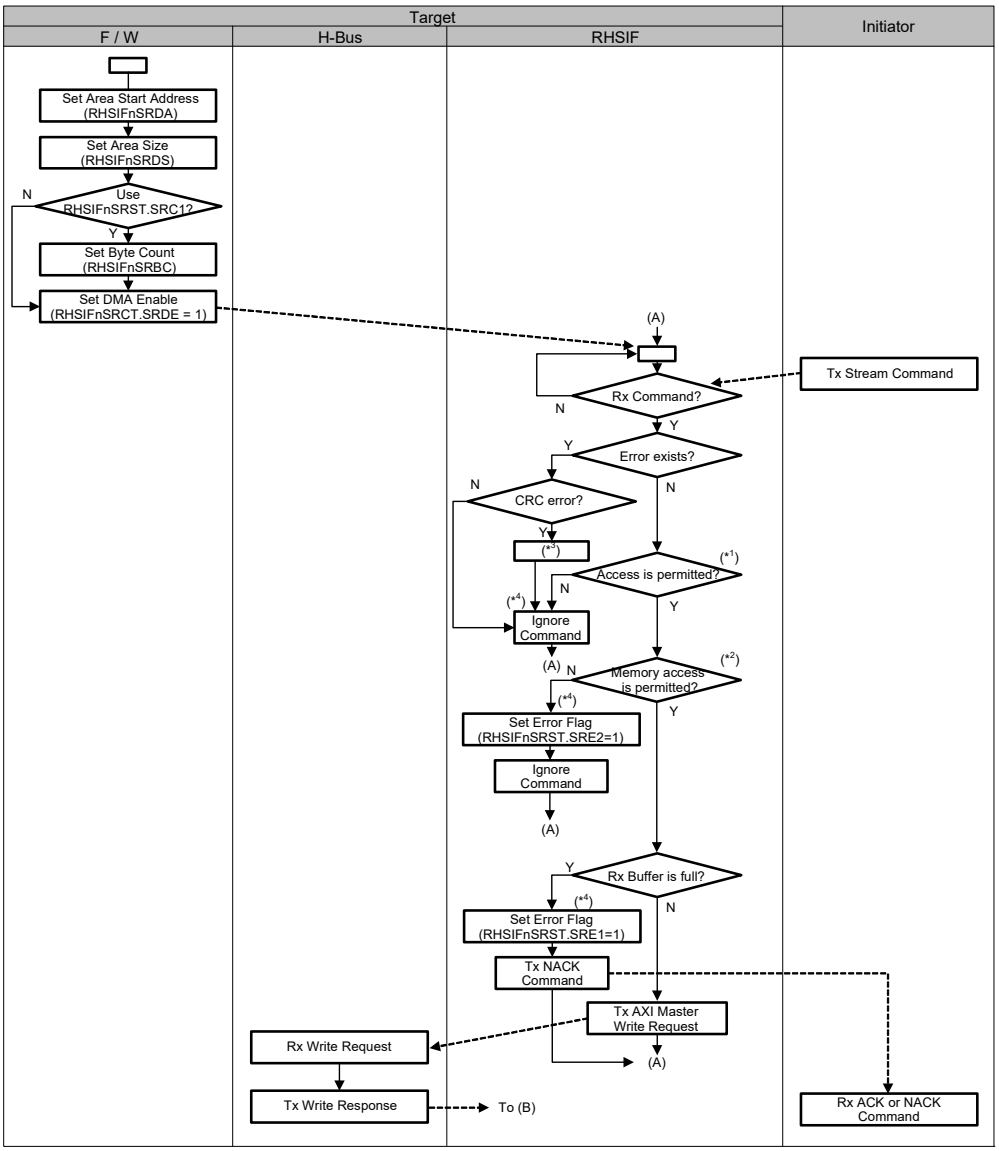
After receiving a response from the H-Bus, L2 subsequently performs one of the following operations depending on whether an error occurs in the response from the H-Bus:

(1) When no H-Bus response error is detected
L2 updates the write pointer (RHSIFnSRWP) for the data payload size of the command that is received, and returns an ACK Command to the link partner.

(2) When an H-Bus response error is detected
L2 updates the write pointer (RHSIFnSRWP) for the data payload size of the command that is received, returns a NACK Command to the link partner, and sets the RHSIFnSRST.SRE0 bit to 0. When the RHSIFnSRMD.SRMC bit is 0, L2 automatically clears the RHSIFnSRCT.SRDE bit to 0 and sets the RHSIFnSRST.SRA to prevent extra data from being stored subsequently.

If the values of write pointer and read pointer differ from each other, an int_hsif_str interrupt is generated (when the RHSIFnSRIE.SRCE0 bit is 1). Also, if the size of unprocessed data reaches or exceeds the size specified in the RHSIFnSRBC register, an int_hsif_str interrupt is generated (when the RHSIFnSRIE.SRCE1 bit is 1).

The firmware must check the data size with the write pointer as needed, and process the data in the data storage area. After data processing ends, the firmware must update the read pointer for the size of processed data. Updating of the read pointer must always be performed in units of the size specified by the RHSIFnSRMD.SRPS bit. **Figure 29.27** shows an example of updating the pointer.



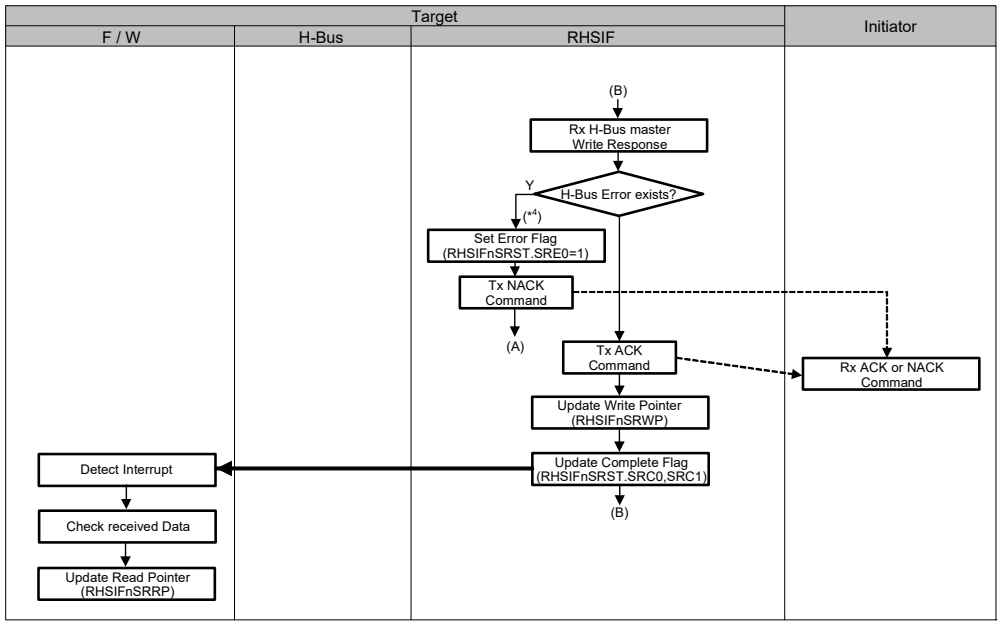
Note 1. The following conditions are satisfied:
1. RHSIFnCMD(N).TNME(N) = 1
2. Authentication(s) is PASSed. (As required)
3. DMA is enabled (RHSIFnSRCT.SRDE = 1)

Note 2. All of following conditions are satisfied:
1. Destination address is inside of any memory window which are defined by RHSIFnMW(X)A and RHSIFnMW(X)S
2. Write is allowed for a memory window whose address is hit (RHSIFnMCT.W(X)WE=1)

Note 3. In case Rx Command has CRC error, L2 performs special action. For details, see **Section 29.4.3.6, CRC Error Handling**.

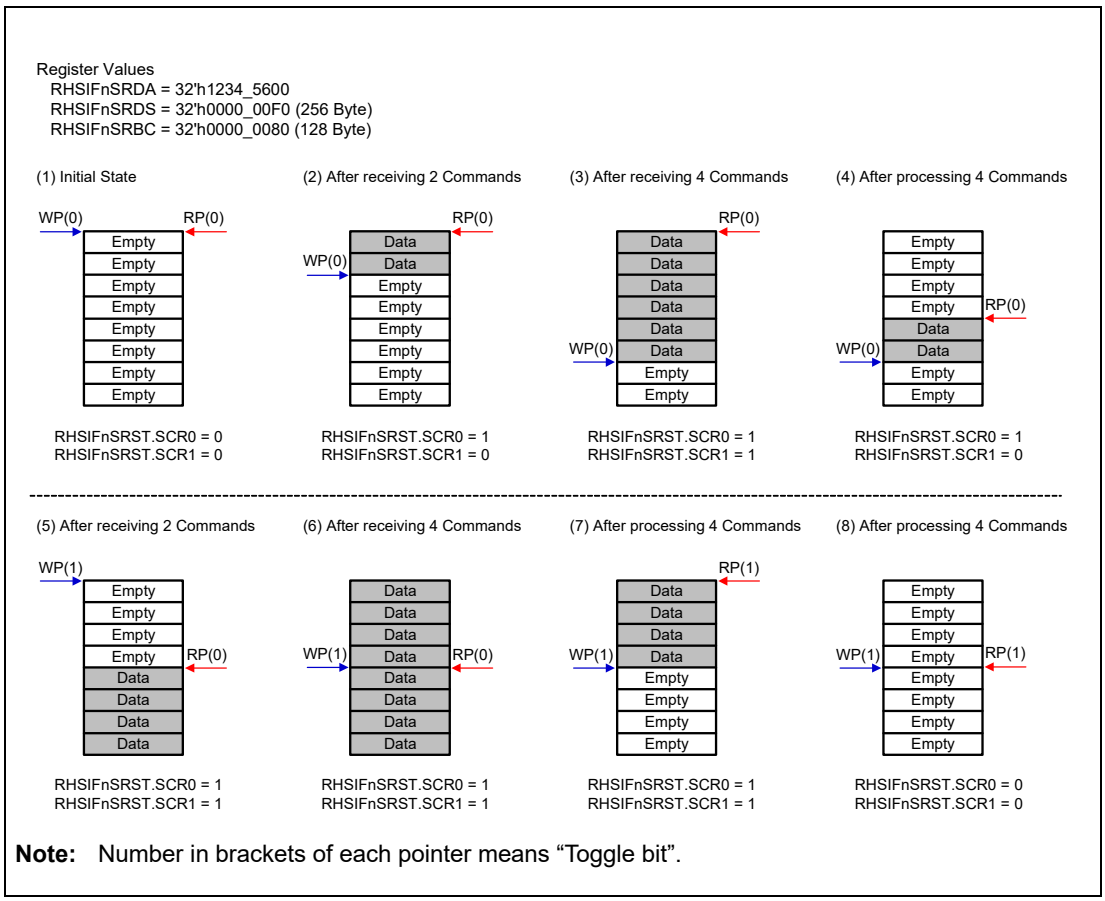
Note 4. If DMA is enabled (RHSIFnSRCT.SRDE = 1), clear DMA Enable (RHSIFnSRCT.SRDE) and set DMA abort (RHSIFnSRST.SRA) if RHSIFnSRMD.SRMC = 0.

Figure 29.25 Rx Stream Command Operation(1)



Note 4. If DMA is enabled (RHSIFnSRCT.SRDE = 1), clear DMA Enable (RHSIFnSRCT.SRDE) and set DMA abort (RHSIFnSRST.SRA) if RHSIFnSRMD.SRMC = 0.

Figure 29.26 Rx Stream Command Operation(2)



Note: Number in brackets of each pointer means “Toggle bit”.

Figure 29.27 Rx Stream Pointer Operation Example

If an error occurs during Stream Command reception when the RHSIFnSRMD.SRMC bit is 0, L2 automatically clears the RHSIFnSRCT.SRDE bit and stops receiving any more Commands. (For detailed conditions, see the description of the RHSIFnSRCT.SRDE bit.)

If reception of Stream Commands is to be resumed in this status, the following procedure must be followed:

(1) Detect interrupt by the RHSIFnSRST.SRA bit. (If RHSIFnSRIE.SRAE bit is 1.)

(2) Check that the RHSIFnSRCT.SRDE bit is 0.

(3) Wait until L2 can check that the RHSIFnSRST.SRTA bit is 0.

(4) Reset the RHSIFnSRCT.SRDE bit to 1.

This procedure also applies when the firmware has cleared the RHSIFnSRCT.SRDE bit to 0 because of the system. (In this case, RHSIFnSRST.SRA is not set.)

29.4.3.6 CRC Error Handling

If a CRC error is detected in a command that is received, the header information also cannot be trusted, and, therefore, the command that is received cannot be determined to be a request or a reply. For this reason, the operation of L2 differs from those other errors.

Upon receiving a Command involving a CRC error, L2 performs the following operations:

- Sets the RHSIFnCST(N).CRE(N) bit
- Discards the command that is received
- Clears the RHSIFnSRCT.SRDE bit when the error has occurred in channel 2 and the RHSIFnSRMD.SRMC bit is 0

Based on the above operations, necessary processing must be executed when a CRC error is detected.

29.4.4 Interrupt Specification

29.4.4.1 Interrupt Signals and Corresponding Interrupt Sources

Table 29.56 shows a list of interrupt signals, interrupt status register fields, interrupt source register fields and interrupt enable register fields. The interrupt signal is output as long as the corresponding interrupt enable bit is set to 1 and the corresponding status / flag bit is set to 1.

All interrupt signals are synchronized to ACLK, level signal, and active high.

Table 29.56 Interrupt Signal List (1/2)

Signal	Status	Source	Enable	Description
int_hsif_ch0	RHSIFnMIST.RARS0	RHSIFnCST0.RAR0	RHSIFnCIE0.RARE0	Read Answer received at Ch.0
	RHSIFnMIST.AKRS0	RHSIFnCST0.AKR0	RHSIFnCIE0.AKRE0	ACK received at Ch.0
	RHSIFnMIST.TERS0	RHSIFnCST0.TER0	RHSIFnCIE0.TERE0	Event received at Ch.0
int_hsif_ch1	RHSIFnMIST.RARS1	RHSIFnCST1.RAR1	RHSIFnCIE1.RARE1	Read Answer received at Ch.1
	RHSIFnMIST.AKRS1	RHSIFnCST1.AKR1	RHSIFnCIE1.AKRE1	ACK received at Ch.1
	RHSIFnMIST.TERS1	RHSIFnCST1.TER1	RHSIFnCIE1.TERE1	Event received at Ch.1
int_hsif_ch2	RHSIFnMIST.RARS2	RHSIFnCST2.RAR2	RHSIFnCIE2.RARE2	Read Answer received at Ch.2
	RHSIFnMIST.AKRS2	RHSIFnCST2.AKR2	RHSIFnCIE2.AKRE2	ACK received at Ch.2
	RHSIFnMIST.TERS2	RHSIFnCST2.TER2	RHSIFnCIE2.TERE2	Event received at Ch.2
int_hsif_ch3	RHSIFnMIST.RARS3	RHSIFnCST3.RAR3	RHSIFnCIE3.RARE3	Read Answer received at Ch.3
	RHSIFnMIST.AKRS3	RHSIFnCST3.AKR3	RHSIFnCIE3.AKRE3	ACK received at Ch.3
	RHSIFnMIST.TERS3	RHSIFnCST3.TER3	RHSIFnCIE3.TERE3	Event received at Ch.3
int_hsif_str	RHSIFnMIST.STCS	RHSIFnSTST.STC	RHSIFnSTIE.STCE	Tx stream completed
	RHSIFnMIST.SRCS0	RHSIFnSRST.SRC0	RHSIFnSRIE.SRCE0	Rx stream completed (more than 1 Stream Command data size)
	RHSIFnMIST.SRCS1	RHSIFnSRST.SRC1	RHSIFnSRIE.SRCE1	Rx stream completed (more than RHSIFnSRBC)
int_hsif_err	RHSIFnMIST.CERS(N)	RHSIFnCST0.AKE(N)	RHSIFnCIE0.AKEE(N)	NACK received at Ch.(N)
		RHSIFnCST0.TOE(N)	RHSIFnCIE0.TOEE(N)	Reply timeout detected at Ch.(N)
		RHSIFnCST0.IDE(N)	RHSIFnCIE0.IDEE(N)	Transaction-ID error detected at Ch.(N)
		RHSIFnCST0.AOE(N)	RHSIFnCIE0.AOEE(N)	Any other error detected at Ch.(N)
		RHSIFnCST0.BRE(N)	RHSIFnCIE0.BREE(N)	Bus error detected at Ch.(N)
		RHSIFnCST0.CRE(N)	RHSIFnCIE0.CREE(N)	CRC error detected at Ch.(N)
	RHSIFnMIST.STES	RHSIFnSTST.STE0	RHSIFnSTIE.STEE0	NACK received at Tx stream Ch.
		RHSIFnSTST.STE1	RHSIFnSTIE.STEE1	Reply timeout detected at Tx stream Ch
		RHSIFnSTST.STE2	RHSIFnSTIE.STEE2	Transaction-ID error detected at Tx stream Ch.
		RHSIFnSTST.STE3	RHSIFnSTIE.STEE3	Bus error detected at Tx stream Ch.
		RHSIFnSTST.STE4	RHSIFnSTIE.STEE4	Window mis-hit detected at Tx stream Ch.
	RHSIFnMIST.SRES	RHSIFnSRST.SRE0	RHSIFnSRIE.SREE0	Bus error detected at Rx stream Ch.
		RHSIFnSRST.SRE1	RHSIFnSRIE.SREE1	Buffer overflow detected at Rx stream Ch.
		RHSIFnSRST.SRE2	RHSIFnSRIE.SREE2	Window mis-hit detected at Rx stream Ch.
		RHSIFnSRST.SRA	RHSIFnSRIE.SRAE	Rx stream aborted by error.

Table 29.56 Interrupt Signal List (2/2)

Signal	Status	Source	Enable	Description
int_hsif_sec	RHSIFnMIST.AESS	RHSIFnAEST.AEE(N)	RHSIFnAEIE.AEEE(N)	Event received at Ch.(N) before authentication is completed.
		RHSIFnAEST.AEI(N)	RHSIFnAEIE.AEIE(N)	ID received at Ch.(N) before authentication is completed.
		RHSIFnAEST.AER(N)	RHSIFnAEIE.AERE(N)	Read received at Ch.(N) before authentication is completed.
		RHSIFnAEST.AEW(N)	RHSIFnAEIE.AEWE(N)	Write received at Ch.(N) before authentication is completed.
		RHSIFnAEST.AES	RHSIFnAEIE.AESE	Stream received at Ch.2 before authentication is completed.
		RHSIFnAEST.WER(N)	RHSIFnAEIE.WERE(N)	Received Read at Ch.(N) does not hit any memory window.
		RHSIFnAEST.WEW(N)	RHSIFnAEIE.WEWE(N)	Received Write at Ch.(N) does not hit any memory window.
		RHSIFnAEST.WES0	RHSIFnAEIE.WESE0	H-Bus Read for Stream does not hit any window.
		RHSIFnAEST.WES1	RHSIFnAEIE.WESE1	H-Bus Write for Stream does not hit any window.

Figure 29.28 shows the logic for interrupt generation. The corresponding bit in the source register / field is ANDed with the corresponding enable bit in the interrupt enable register / field. Moreover, respective factors are ORed to an interrupt signal.

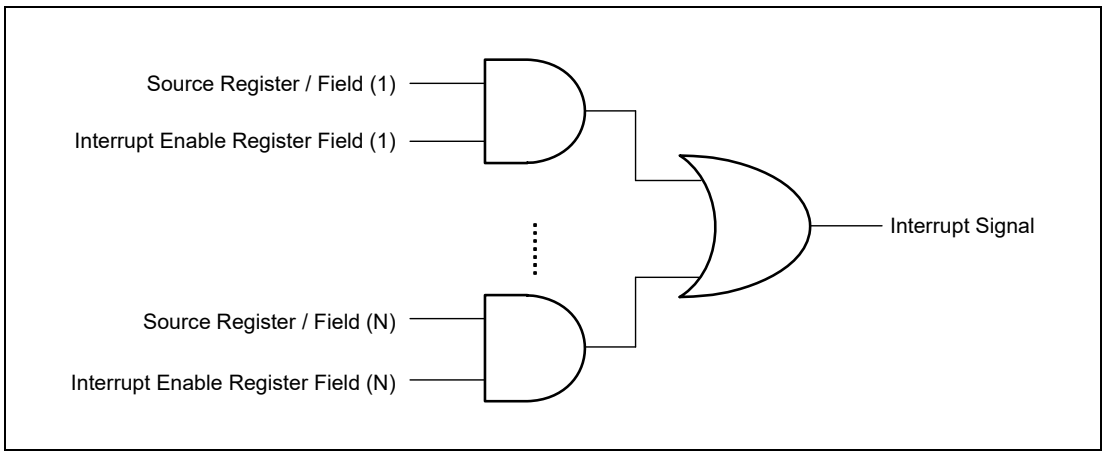


Figure 29.28 Interrupt Signal Generation Logic

29.4.4.2 Interrupt Signal Status Register

L2 has a register to monitor the interrupt factor state. This register (RHSIFnMIST) indicates the current state of the interrupt factors. Whether an interrupt is active can be checked by a single register read.

29.5 Datalink Layer (L1)

29.5.1 Overview

Regarding the basic functions and specifications, refer to the protocol specifications.

29.5.1.1 Functional Overview

The Renesas High-speed Serial Interface Datalink Layer IP (henceforth, called “L1”) is compliant with following specifications.

(1) L1

- Addition of L1 header information to the L2 frame for data transmission
- Removal of the L1 header from the receive data and transmission to L2
- Generation and transmission of Interface Control Logical Channel (hereafter, ICLC) commands
- Reception and execution of ICLC commands
- Generation of interrupt sources for transmission completion, transmission error, reception completion, reception error, and ICLC command reception
- Generation and transmission of CTS commands
- Frame arbitration: Fixed (Higher) PingAnswer → CTS Command → ICLC Command → L2 Frame (lower)
- Execution of flow control
- Execution of Loopback test mode
- Execution of toggle pattern test mode

(2) Physical Interface

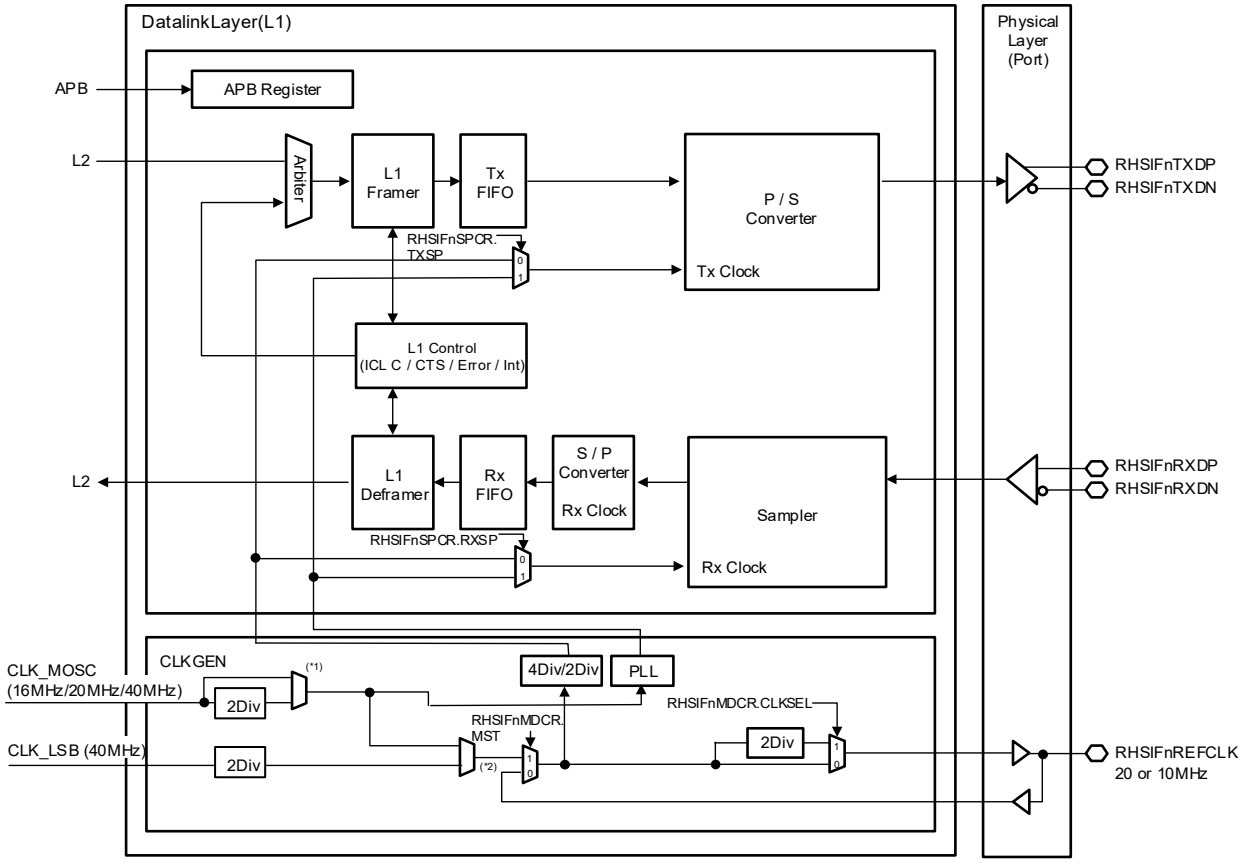
This layer consists of LVDS differential interface (input and output) and the reference clock. Regarding the basic functions and specifications, refer to the protocol specification.

Table 29.57 Physical Interface

External Port	Specification Item	Specification
Clock (RHSIFnREFCLK)	Electrical Characteristics	TTL / CMOS
	Frequency	20 MHz,10 MHz
Data (RHSIFnTXDP, RHSIFnTXDN, RHSIFnRXDP, RHSIFnRXDN)	Electrical Characteristics	LVDS (based on IEEE1596.3-1996 reducedrangelink)
	BaudRate (FastMode) Using PLL	320 M Baud, 160 M Baud, 80 M Baud selectable
	BaudRate (SlowMode) Using REFCLK	5 M Baud

29.5.1.2 Block Diagram

(1) L1



Note 1. When CLK_MOSC frequency is 16MHz / 20MHz, it selects CLK_MOSC.
When CLK_MOSC frequency is 40MHz, it selects CLK_MOSC divided into 2: CLK_MOSC/2

Note 2. When CLK_MOSC frequency is 20MHz / 40MHz, it selects clock outputted from **Note 1.**: CLK_MOSC or CLK_MOSC/2.
When CLK_MOSC frequency is 16MHz, it selects CLK_LSB divided into 2: CLK_LSB/2

Figure 29.29 Block Diagram of L1 and Physical Interface

CAUTION

When CLK_MOSC frequency is 24MHz, RHSIF can NOT operate normally.

29.5.2 Registers

This section describes the L1 registers in detail.

In case of a concurrent update of the same register bit, L1 module write (hardware write) has higher priority than CPU write (software write).

29.5.2.1 List of Registers

The register map of an L1 module is shown in **Table 29.58**.

The L1 module remains in reset while RESET.

The values shown in **Table 29.58** in the L1 registers description under “Values after Reset” are related to this reset state.

For further information about the L1 operation modes, refer to **Section 29.5.3, Operation**.

The module specific base address of an L1 module needs to be added to each of the specified offset addresses.

Table 29.58 Registers Address Map

Module Name	Register Name	Symbol	Address	Access	Access Protection	
					PBG	Other
RHSIFn	Mode Control Register	RHSIFnMDCR	<RHSIFn_L1_base> + 000_H	32	PBG90#2	—
	Sleep Mode Control Register	RHSIFnSMCR	<RHSIFn_L1_base> + 004_H	32	PBG90#2	—
	PLL Control Register	RHSIFnPCR	<RHSIFn_L1_base> + 008_H	32	PBG90#2	—
	Speed Control Register	RHSIFnSPCR	<RHSIFn_L1_base> + $00C_H$	32	PBG90#2	—
	Test Mode Control Register	RHSIFnTMDCR	<RHSIFn_L1_base> + 010_H	32	PBG90#2	—

29.5.2.2 Legend

This section explains the module state dependent abbreviations used for the L1 registers description.

Conditions:

- R/W: Bit is readable and writable
- R: Read-only bit; the user cannot write to this bit
- W: Write-only bit; Read value is always “0”

Reserved bits:

- Always read as 0
- Writing to these bits has no effect (hardware protection)

29.5.2.3 Detailed Register Description

Detailed specifications of each register are described below.

(1) RHSIFnMDCR — Mode Control Register

Access: This register can be read or written in 32-bit units.

Address: <RHSIFn_L1_base> + 000_H

Value after reset: $0001\ 0100_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CTSEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CTSV	—	—	—	—	—	—	CLKSEL	MST
Value after reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R/W	R/W

Table 29.59 RHSIFnMDCR Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	CTSEN	This bit specifies whether to enable the flow control. 0: Disable automatic flow control. 1: Enable automatic flow control. Set this bit to “1” to enable flow control and stop next frame transfer. See **Section 29.5.3.5, CTS Commands**.
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	CTSV	This bit specifies CTS Value of L1 header for all frames. 0: Frame unreceivable. 1: Frame receivable.
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	CLKSEL	This bit specifies REFCLK frequency. 0: 20MHz. 1: 10MHz.
0	MST	This bit specifies whether Master or Slave. 0: Slave. 1: Master.

(2) RHSIFnSMCR — Sleep Mode Control Register

Access: This register can be read or written in 32-bit units.

Address: <RHSIFn_L1_base> + 004_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SLP
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 29.60 RHSIFnSMCR Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	SLP	Specify whether to set the sleep mode during data transmission or in the next transmission frame. 0: L1 End bit = 0 (Normal mode for the link partner) 1: L1 End bit = 1 (Transitioning to sleep mode for the link partner)

(3) RHSIFnPCR — PLL Control Register

Access: This register can be read or written in 32-bit units.

Address: <RHSIFn_L1_base> + 008_H

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PLLSTBY
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 29.61 RHSIFnPCR Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	PLLSTBY	This bit specifies whether PLL Standby or PLL Active. This bit is updated only when writing directly. It is not updated when ICLC (Slave interface PLL start, Slave interface PLL stop) command reception. 0: PLL Active. 1: PLL Standby.

(4) RHSIFnSPCR — Speed Control Register

Access: This register can be read or written in 32-bit units.

Address: <RHSIFn_L1_base> + $00C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	FMBR[1:0]		—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TXSP	—	—	—	—	—	—	—	RXSP
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Table 29.62 RHSIFnSPCR Register Contents

Bit Position	Bit Name	Function
31 to 26	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
25 to 24	FMBR1	These bits specify Fast Speed Mode Baud Rate. 00: 80MBaud 01: 160MBaud 10: 320MBaud 11: Setting prohibited
23 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	TXSP*1	This bit specifies whether Slow Speed Mode or Fast Speed Mode for data transmission. This bit is updated only when writing directly. It is not updated when ICLC (Select Slow Speed mode for transfers from the Slave interface to the Master interface, Select Fast Speed mode for transfers from the Slave interface to the Master interface) command reception. 0: Slow Speed Mode. 1: Fast Speed Mode.
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	RXSP*1	This bit specifies whether Slow Speed Mode or Fast Speed Mode for data reception. This bit is updated only when writing directly. It is not updated when ICLC (Select Slow Speed mode for transfers from the Master interface to the Slave interface, Select Fast Speed mode or transfers from the Master interface to the Slave interface) command reception. 0: Slow Speed Mode. 1: Fast Speed Mode.

Note 1. In case of setting '1' to RHSIFnSPCR.TXSP or RHSIFnSPCR.RXSP, set '0' to RHSIFnPCR.PLLSTBY for activating PLL.

(5) RHSIFnTMDCR — Test Mode Control Register

Access: This register can be read or written in 32-bit units.

Address: <RHSIFn_L1_base> + 010_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	CKTM	CKTMSEL	—	—	—	—	—	—	TXLPBK	RXLPBK
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Table 29.63 RHSIFnTMDCR Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	CKTM*1	This bit is specified for selecting clock test mode. This bit is updated when ICLC command is for "Turn on testmode" or "Turn off test mode" as well as writing to this bit directly. 0: Disable. 1: Clock test mode.
8	CKTMSEL	Clock Selection of Clock test mode 0: RX Baud Rate/2 Clock 1: TX Baud Rate/2 Clock
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	TXLPBK*1*3	This bit is specified for selecting TX-RX loopback test mode. 0: Disable. 1: TX-RX loopback testmode.
0	RXLPBK*1*2	This bit is specified for selecting RX-TX loopback test mode. This bit is updated when ICLC command is for "Turn on payload loopback" or "Turn off test mode" as well as writing to this bit directly. 0: Disable. 1: RX-TX loopback test mode.

Note 1. Setting 2 bits or more to 1 at the same time is prohibited.

Note 2. In Rx-Tx loopback testmode, received ICLC Turn off command is output by looping back.

Note 3. In case of setting '1' to RHSIFnTMDCR.TXLPBK, set the same value to RHSIFnSPCR.TXSP and RHSIFnSPCR.RXSP. Unless the same Baud Rate is set to both transmitter/receiver, the communication will not be done normally.

(6) RHSIFnL1SR — L1 Status Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RHSIFn_L1_base> + 018_H

Value after reset: $0001\ 0101_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RCTS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TFFUL	TFEMP	—	—	—	—	—	—	RFFUL	RFEMP
Value after reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.64 RHSIFnL1SR Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned.
16	RCTS	This bit indicates the CTS value that is received. 0: Link partner is not receivable 1: Link partner is receivable
15 to 10	Reserved	When read, the value after reset is returned.
9	TFFUL	This bit indicates TX FIFO full status. 0: Not full. 1: Full.
8	TFEMP	This bit indicates TX FIFO empty status. 0: Not empty. 1: Empty.
7 to 2	Reserved	When read, the value after reset is returned.
1	RFFUL	This bit indicates RX FIFO full status. 0: Not full. 1: Full.
0	RFEMP	This bit indicates RX FIFO empty status. 0: Not empty. 1: Empty.

(7) RHSIFnLTXFRMRL1 — Last Tx Frame L1 Result Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RHSIFn_L1_base> + 030_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TL1E
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TL1P[7:0]								TL1H[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.65 RHSIFnLTXFRMRL1 Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned.
16	TL1E	This bit indicates last Tx Endbit.
15 to 8	TL1P[7:0]	These bits indicate Last Tx L1 Payload.
7 to 0	TL1H[7:0]	These bits indicate Last Tx L1 Header.

(8) RHSIFnLRXFRMRL1 — Last Rx Frame L1 Result Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RHSIFn_L1_base> + 034_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RL1E
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	T2L1H[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.67 RHSIFnLTXFRMRL2 Register Contents

Bit Position	Bit Name	Function
31 to 16	T2L2H[15:0]	These bits indicate Last Tx L2 Header of L2 frame.
15 to 8	Reserved	When read, the value after reset is returned.
7 to 0	T2L1H[7:0]	These bits indicate Last Tx L1 Header of L2 frame.

(10) RHSIFnLRXFRMRL2 — Last Rx Frame L2 Result Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RHSIFn_L1_base> + $03C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	R2L2H[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	R2L1H[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.68 RHSIFnLRXFRMRL2 Register Contents

Bit Position	Bit Name	Function
31 to 16	R2L2H[15:0]	These bits indicate Last Rx L2 Header of L2 frame.
15 to 8	Reserved	When read, the value after reset is returned.
7 to 0	R2L1H[7:0]	These bits indicate Last Rx L1 Header of L2 frame.

(11) RHSIFnTXRXCR — TX/RX Control Register

Access: This register can be read or written in 32-bit units.

Address: <RHSIFn_L1_base> + 050_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 29.69 RHSIFnTXRXCR Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	TXEN	This bit specifies whether to enable transmission. This bit is updated when the ICLC command is for "Enable Slave interface transmitter" or "Disable Slave interface transmitter" as well as writing to this bit directly. 0: Disable. 1: Enable.
15 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	RXEN	This bit specifies whether to enable reception. 0: Disable. 1: Enable.

(12) RHSIFnICCR — ICLC Command Control Register

Access: This register can be read or written in 32-bit units.

Address: <RHSIFn_L1_base> + 060_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 29.70 RHSIFnICCR Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	ITRG	ICLC Command Tx Trigger. This bit is cleared automatically after ICLC command transmission is completed. 0: Disable. 1: Trigger.
15 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7 to 0	PLD[7:0]*1	ICLC Command (Payload)

Note 1. Do not specify any commands except the commands described in **Table 29.11**.

(13) RHSIFnCCR — CTS Frame Control Register

Access: This register can be read or written in 32-bit units.

Address: <RHSIFn_L1_base> + 070_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CTRG
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CTS	PLD[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29.71 RHSIFnCCR Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	CTRG	CTS Frame Tx Trigger. This bit is cleared automatically after CTS Frame transmission is completed. 0: Disable. 1: Trigger.
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	CTS	CTS Value
7 to 0	PLD[7:0]	CTS Frame (Payload)

(14) RHSIFnTXCMPST — Tx Complete Status Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RHSIFn_L1_base> + 080_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TCL2
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	TCCT	—	—	—	—	—	—	—	TCIC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.72 RHSIFnTXCMPST Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned.
16	TCL2	This bit indicates the status of L2 frame transmission. 0: L2 frame transmission not completed. 1: L2 frame transmission completed.
15 to 9	Reserved	When read, the value after reset is returned.
8	TCCT	This bit indicates the status of L1 CTS frame transmission. 0: L1 CTS frame transmission not completed. 1: L1 CTS frame transmission completed.
7 to 1	Reserved	When read, the value after reset is returned.
0	TCIC	This bit indicates the status of L1 ICLC command transmission. 0: L1 ICLC command transmission not completed. 1: L1 ICLC command transmission completed.

(15) RHSIFnTXCMPSC — Tx Complete Status Clear Register

Access: This register is a write-only register that can be write in 32-bit units.

Address: <RHSIFn_L1_base> + 084_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TCCL2
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TCCCT	—	—	—	—	—	—	—	TCCIC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W	R	R	R	R	R	R	R	W

Table 29.73 RHSIFnTXCMPSC Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When writing, write the value after reset.
16	TCCL2	Writing 1 to this bit clears the RHSIFnTXCMPST.TCL2 bit. Writing 0 to this bit is ignored.
15 to 9	Reserved	When writing, write the value after reset.
8	TCCCT	Writing 1 to this bit clears the RHSIFnTXCMPST.TCCT bit. Writing 0 to this bit is ignored.
7 to 1	Reserved	When writing, write the value after reset.
0	TCCIC	Writing 1 to this bit clears the RHSIFnTXCMPST.TCIC bit. Writing 0 to this bit is ignored.

(16) RHSIFnTXCMPIE — Tx Complete Interrupt Enable Register

Access: This register can be read or written in 32-bit units.

Address: <RHSIFn_L1_base> + 088_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TCEL2
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TCECT	—	—	—	—	—	—	—	TCEIC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Table 29.74 RHSIFnTXCMPIE Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	TCEL2	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnTXCMPST. TCL2 bit.
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	TCECT	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnTXCMPST.TCCT bit.
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	TCEIC	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnTXCMPST.TCIC bit.

(17) RHSIFnTXERRST — Tx Error Status Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RHSIFn_L1_base> + 090_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TERSZ	—	—	—	—	—	—	—	—	—	—	TERSZI5	TERSZI4	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TERCTF	TERCTE	TERCTD	TERCTC	TERCTB	TERCTA	TERCT9	TERCT8	—	—	—	—	—	TERCT2	TERCT1	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.75 RHSIFnTXERRST Register Contents (1/2)

Bit Position	Bit Name	Function
31	TERSZ	This bit indicates the status of payload size error of transmission. 0: Payload size error has not occurred. 1: Payload size error occurred.
30 to 21	Reserved	When read, the value after reset is returned.
20	TERSZI5	This bit indicates that the payload size of transmission is 3'b101. 0: Payload size index is not 3'b101. 1: Payload size index is 3'b101.
19	TERSZI4	This bit indicates that the payload size of transmission is 3'b100. 0: Payload size index is not 3'b100. 1: Payload size index is 3'b100.
18 to 16	Reserved	When read, the value after reset is returned.
15	TERCTF	This bit indicates that the logical channel type of transmission is 4'b1111. 0: Logical channel type of transmission is not 4'b1111. 1: Logical channel type of transmission is 4'b1111.
14	TERCTE	This bit indicates that the logical channel type of transmission is 4'b1110. 0: Logical channel type of transmission is not 4'b1110. 1: Logical channel type of transmission is 4'b1110.
13	TERCTD	This bit indicates that the logical channel type of transmission is 4'b1101. 0: Logical channel type of transmission is not 4'b1101. 1: Logical channel type of transmission is 4'b1101.
12	TERCTC	This bit indicates that the logical channel type of transmission is 4'b1100. 0: Logical channel type of transmission is not 4'b1100. 1: Logical channel type of transmission is 4'b1100.
11	TERCTB	This bit indicates that the logical channel type of transmission is 4'b1011. 0: Logical channel type of transmission is not 4'b1011. 1: Logical channel type of transmission is 4'b1011.
10	TERCTA	This bit indicates that the logical channel type of transmission is 4'b1010. 0: Logical channel type of transmission is not 4'b1010. 1: Logical channel type of transmission is 4'b1010.
9	TERCT9	This bit indicates that the logical channel type of transmission is 4'b1001. 0: Logical channel type of transmission is not 4'b1001. 1: Logical channel type of transmission is 4'b1001.
8	TERCT8	This bit indicates that the logical channel type of transmission is 4'b1000. 0: Logical channel type of transmission is not 4'b1000. 1: Logical channel type of transmission is 4'b1000.

Table 29.75 RHSIFnTXERRST Register Contents (2/2)

Bit Position	Bit Name	Function
7 to 3	Reserved	When read, the value after reset is returned.
2	TERCT2	This bit indicates that the logical channel type of transmission is 4'b0010. 0: Logical channel type of transmission is not 4'b0010. 1: Logical channel type of transmission is 4'b0010.
1	TERCT1	This bit indicates that the logical channel type of transmission is 4'b0001. 0: Logical channel type of transmission is not 4'b0001. 1: Logical channel type of transmission is 4'b0001.
0	Reserved	When read, the value after reset is returned.

(18) RHSIFnTXERRSC — Tx Error Status Clear Register

Access: This register is a write-only register that can be write in 32-bit units.

Address: <RHSIFn_L1_base> + 094_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TERCSZ	—	—	—	—	—	—	—	—	—	—	TERCSZI5	TERCSZI4	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	R	R	R	R	R	R	R	R	R	R	W	W	R	R	R

	TERCCTF	TERCCTE	TERCCTD	TERCCTC	TERCCTB	TERCCTA	TERCCT9	TERCCT8	—	—	—	—	—	TERCCT2	TERCCT1	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	R	R	R	R	R	W	W	R

Table 29.76 RHSIFnTXERRSC Register Contents

Bit Position	Bit Name	Function
31	TERCSZ	Writing 1 to this bit clears the RHSIFnTXERRST.TERSZ bit. Writing 0 to this bit is ignored.
30 to 21	Reserved	When writing, write the value after reset.
20	TERCSZI5	Writing 1 to this bit clears the RHSIFnTXERRST.TERSZI5 bit. Writing 0 to this bit is ignored.
19	TERCSZI4	Writing 1 to this bit clears the RHSIFnTXERRST.TERSZI4 bit. Writing 0 to this bit is ignored.
18 to 16	Reserved	When writing, write the value after reset.
15	TERCCTF	Writing 1 to this bit clears the RHSIFnTXERRST.TERCTF bit. Writing 0 to this bit is ignored.
14	TERCCTE	Writing 1 to this bit clears the RHSIFnTXERRST.TERCTE bit. Writing 0 to this bit is ignored.
13	TERCCTD	Writing 1 to this bit clears the RHSIFnTXERRST.TERCTD bit. Writing 0 to this bit is ignored.
12	TERCCTC	Writing 1 to this bit clears the RHSIFnTXERRST.TERCTC bit. Writing 0 to this bit is ignored.
11	TERCCTB	Writing 1 to this bit clears the RHSIFnTXERRST.TERCTB bit. Writing 0 to this bit is ignored.
10	TERCCTA	Writing 1 to this bit clears the RHSIFnTXERRST.TERCTA bit. Writing 0 to this bit is ignored.
9	TERCCT9	Writing 1 to this bit clears the RHSIFnTXERRST.TERCT9 bit. Writing 0 to this bit is ignored.
8	TERCCT8	Writing 1 to this bit clears the RHSIFnTXERRST.TERCT8 bit. Writing 0 to this bit is ignored.
7 to 3	Reserved	When writing, write the value after reset.
2	TERCCT2	Writing 1 to this bit clears the RHSIFnTXERRST.TERCT2 bit. Writing 0 to this bit is ignored.
1	TERCCT1	Writing 1 to this bit clears the RHSIFnTXERRST.TERCT1 bit. Writing 0 to this bit is ignored.
0	Reserved	When writing, write the value after reset.

(19) RHSIFnTXERRIE — Tx Error Interrupt Enable Register

Access: This register can be read or written in 32-bit units.

Address: <RHSIFn_L1_base> + 098_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TERESZ	—	—	—	—	—	—	—	—	—	—	TERESZI5	TERESZI4	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TERECTF	TERECTE	TERECTD	TERECTC	TERECTB	TERECTA	TERECT9	TERECT8	—	—	—	—	—	TERECT2	TERECT1	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R

Table 29.77 RHSIFnTXERRIE Register Contents (1/2)

Bit Position	Bit Name	Function
31	TERESZ	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnTXERRST.TERSZ bit. 0: Does not assert RHSIFnTXERR when the RHSIFnTXERRST.TERSZ bit is 1. 1: Assert RHSIFnTXERR when the RHSIFnTXERRST.TERSZ bit is 1.
30 to 21	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
20	TERESZI5	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnTXERRST.TERSZI5 bit. 0: Does not assert RHSIFnTXERR when the RHSIFnTXERRST.TERSZI5 bit is 1. 1: Assert RHSIFnTXERR when the RHSIFnTXERRST.TERSZI5 bit is 1.
19	TERESZI4	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnTXERRST.TERSZI4 bit. 0: Does not assert RHSIFnTXERR when the RHSIFnTXERRST.TERSZI4 bit is 1. 1: Assert RHSIFnTXERR when the RHSIFnTXERRST.TERSZI4 bit is 1.
18 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15	TERECTF	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnTXERRST.TERCTF bit. 0: Does not assert RHSIFnTXERR when the RHSIFnTXERRST.TERCTF bit is 1. 1: Assert RHSIFnTXERR when the RHSIFnTXERRST.TERCTF bit is 1.
14	TERECTE	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnTXERRST.TERCTE bit. 0: Does not assert RHSIFnTXERR when the RHSIFnTXERRST.TERCTE bit is 1. 1: Assert RHSIFnTXERR when the RHSIFnTXERRST.TERCTE bit is 1.
13	TERECTD	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnTXERRST.TERCTD bit. 0: Does not assert RHSIFnTXERR when the RHSIFnTXERRST.TERCTD bit is 1. 1: Assert RHSIFnTXERR when the RHSIFnTXERRST.TERCTD bit is 1.
12	TERECTC	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnTXERRST.TERCTC bit. 0: Does not assert RHSIFnTXERR when the RHSIFnTXERRST.TERCTC bit is 1. 1: Assert RHSIFnTXERR when the RHSIFnTXERRST.TERCTC bit is 1.
11	TERECTB	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnTXERRST.TERCTB bit. 0: Does not assert RHSIFnTXERR when the RHSIFnTXERRST.TERCTB bit is 1. 1: Assert RHSIFnTXERR when the RHSIFnTXERRST.TERCTB bit is 1.

Table 29.77 RHSIFnTXERRIE Register Contents (2/2)

Bit Position	Bit Name	Function
10	TERECTA	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnTXERRST.TERCTA bit. 0: Does not assert RHSIFnTXERR when the RHSIFnTXERRST.TERCTA bit is 1. 1: Assert RHSIFnTXERR when the RHSIFnTXERRST.TERCTA bit is 1.
9	TERECT9	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnTXERRST.TERCT9 bit. 0: Does not assert RHSIFnTXERR when the RHSIFnTXERRST.TERCT9 bit is 1. 1: Assert RHSIFnTXERR when the RHSIFnTXERRST.TERCT9 bit is 1.
8	TERECT8	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnTXERRST.TERCT8 bit. 0: Does not assert RHSIFnTXERR when the RHSIFnTXERRST.TERCT8 bit is 1. 1: Assert RHSIFnTXERR when the RHSIFnTXERRST.TERCT8 bit is 1.
7 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	TERECT2	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnTXERRST.TERCT2 bit. 0: Does not assert RHSIFnTXERR when the RHSIFnTXERRST.TERCT2 bit is 1. 1: Assert RHSIFnTXERR when the RHSIFnTXERRST.TERCT2 bit is 1.
1	TERECT1	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnTXERRST.TERCT1 bit. 0: Does not assert RHSIFnTXERR when the RHSIFnTXERRST.TERCT1 bit is 1. 1: Assert RHSIFnTXERR when the RHSIFnTXERRST.TERCT1 bit is 1.
0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

(20) RHSIFnRXCMPST — Rx Complete Status Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RHSIFn_L1_base> + $0A0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RCL2

Table 29.80 RHSIFnRXCMPIE Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	RCEL2	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXCMPST.RCL2 bit. 0: Does not assert RHSIFnRXERR when the RHSIFnRXCMPST.RCL2 bit is 1. 1: Assert RHSIFnRXERR when the RHSIFnRXCMPST.RCL2 bit is 1.
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	RCECT	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXCMPST.RCCT bit. 0: Does not assert RHSIFnRXERR when the RHSIFnRXCMPST.RCCT bit is 1. 1: Assert RHSIFnRXERR when the RHSIFnRXCMPST.RCCT bit is 1.
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	RCEIC	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXCMPST.RCIC bit. 0: Does not assert RHSIFnRXERR when the RHSIFnRXCMPST.RCIC bit is 1. 1: Assert RHSIFnRXERR when the RHSIFnRXCMPST.RCIC bit is 1.

(23) RHSIFnRXERRST — Rx Error Status Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RHSIFn_L1_base> + $0B0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RERSZ	—	—	—	—	—	—	—	—	—	—	RERSZI5	RERSZI4	—	—	—

Table 29.81 RHSIFnRXERRST Register Contents (1/2)

Bit Position	Bit Name	Function
31	RERSZ	This bit indicates that the status of payload size error of reception. 0: Payload size error not occurred. 1: Payload size error occurred.
30 to 21	Reserved	When read, the value after reset is returned.
20	RERSZI5	This bit indicates that the payload size of reception is 101_B. 0: Payload size index is not 101_B. 1: Payload size index is 101_B.
19	RERSZI4	This bit indicates that the payload size of reception is 100_B. 0: Payload size index is not 100_B. 1: Payload size index is 100_B.
18 to 16	Reserved	When read, the value after reset is returned.
15	RERCTF	This bit indicates that the logical channel type of reception is 1111_B. 0: Logical channel type of reception is not 1111_B. 1: Logical channel type of reception is 1111_B.
14	RERCTE	This bit indicates that the logical channel type of reception is 1110_B. 0: Logical channel type of reception is not 1110_B. 1: Logical channel type of reception is 1110_B.
13	RERCTD	This bit indicates that the logical channel type of reception is 1101_B. 0: Logical channel type of reception is not 1101_B. 1: Logical channel type of reception is 1101_B.
12	RERCTC	This bit indicates that the logical channel type of reception is 1100_B. 0: Logical channel type of reception is not 1100_B. 1: Logical channel type of reception is 1100_B.
11	RERCTB	This bit indicates that the logical channel type of reception is 1011_B. 0: Logical channel type of reception is not 1011_B. 1: Logical channel type of reception is 1011_B.
10	RERCTA	This bit indicates that the logical channel type of reception is 1010_B. 0: Logical channel type of reception is not 1010_B. 1: Logical channel type of reception is 1010_B.
9	RERCT9	This bit indicates that the logical channel type of reception is 1001_B. 0: Logical channel type of reception is not 1001_B. 1: Logical channel type of reception is 1001_B.
8	RERCT8	This bit indicates that the logical channel type of reception is 1000_B. 0: Logical channel type of reception is not 1000_B. 1: Logical channel type of reception is 1000_B.

Table 29.81 RHSIFnRXERRST Register Contents (2/2)

Bit Position	Bit Name	Function
7 to 3	Reserved	When read, the value after reset is returned.
2	RERCT2	This bit indicates that the logical channel type of reception is 0010_B. 0: Logical channel type of reception is not 0010_B. 1: Logical channel type of reception is 0010_B.
1	RERCT1	This bit indicates that the logical channel type of reception is 0001_B. 0: Logical channel type of reception is not 0001_B. 1: Logical channel type of reception is 0001_B.
0	RERIPV	This bit indicates whether or not the command undefined in **Table 29.11** is received. 0: Command defined in the table is received. 1: Command undefined in the table is received.

(24) RHSIFnRXERRSC — Rx Error Status Clear Register

Access: This register is a write-only register that can be write in 32-bit units.

Address: <RHSIFn_L1_base> + $0B4_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RERCSZ	—	—	—	—	—	—	—	—	—	—	RERCSZI5	RERCSZI4	—	—	—

	RERCCTF	RERCCTE	RERCCTD	RERCCTC	RERCCTB	RERCCTA	RERCCT9	RERCCT8	—	—	—	—	—	RERCCT2	RERCCT1	RERCIPV
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	R	R	R	R	R	W	W	W

Table 29.82 RHSIFnRXERRSC Register Contents

Bit Position	Bit Name	Function
31	RERCSZ	Writing 1 to this bit clears the RHSIFnRXERRST.RERSZ bit. Writing 0 to this bit is ignored.
30 to 21	Reserved	When writing, write the value after reset.
20	RERCSZI5	Writing 1 to this bit clears the RHSIFnRXERRST.RERSZI5 bit. Writing 0 to this bit is ignored.
19	RERCSZI4	Writing 1 to this bit clears the RHSIFnRXERRST.RERSZI4 bit. Writing 0 to this bit is ignored.
18 to 16	Reserved	When writing, write the value after reset.
15	RERCCTF	Writing 1 to this bit clears the RHSIFnRXERRST.RERCTF bit. Writing 0 to this bit is ignored.
14	RERCCTE	Writing 1 to this bit clears the RHSIFnRXERRST.RERCTE bit. Writing 0 to this bit is ignored.
13	RERCCTD	Writing 1 to this bit clears the RHSIFnRXERRST.RERCTD bit. Writing 0 to this bit is ignored.
12	RERCCTC	Writing 1 to this bit clears the RHSIFnRXERRST.RERCTC bit. Writing 0 to this bit is ignored.
11	RERCCTB	Writing 1 to this bit clears the RHSIFnRXERRST.RERCTB bit. Writing 0 to this bit is ignored.
10	RERCCTA	Writing 1 to this bit clears the RHSIFnRXERRST.RERCTA bit. Writing 0 to this bit is ignored.
9	RERCCT9	Writing 1 to this bit clears the RHSIFnRXERRST.RERCT9 bit. Writing 0 to this bit is ignored.
8	RERCCT8	Writing 1 to this bit clears the RHSIFnRXERRST.RERCT8 bit. Writing 0 to this bit is ignored.
7 to 3	Reserved	When writing, write the value after reset.
2	RERCCT2	Writing 1 to this bit clears the RHSIFnRXERRST.RERCT2 bit. Writing 0 to this bit is ignored.
1	RERCCT1	Writing 1 to this bit clears the RHSIFnRXERRST.RERCT1 bit. Writing 0 to this bit is ignored.
0	RERCIPV	Writing 1 to this bit clears the RHSIFnRXERRST.RERIPV bit. Writing 0 to this bit is ignored.

(25) RHSIFnRXERRIE — Rx Error Interrupt Enable Register

Access: This register can be read or written in 32-bit units.

Address: <RHSIFn_L1_base> + $0B8_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 29.83 RHSIFnRXERRIE Register Contents (1/2)

Bit Position	Bit Name	Function
31	RERESZ	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXERRST.RERSZ bit. 0: Does not assert RHSIFnRXERR when the RHSIFnRXERRST.RERSZ bit is 1. 1: Assert RHSIFnRXERR when the RHSIFnRXERRST.RERSZ bit is 1.
30 to 21	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
20	RERESZI5	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXERRST.RERSZI5 bit. 0: Does not assert RHSIFnRXERR when the RHSIFnRXERRST.RERSZI5 bit is 1. 1: Assert RHSIFnRXERR when the RHSIFnRXERRST.RERSZI5 bit is 1.
19	RERESZI4	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXERRST.RERSZI4 bit. 0: Does not assert RHSIFnRXERR when the RHSIFnRXERRST.RERSZI4 bit is 1. 1: Assert RHSIFnRXERR when the RHSIFnRXERRST.RERSZI4 bit is 1.
18 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15	RERECTF	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXERRST.RERCTF bit. 0: Does not assert RHSIFnRXERR when the RHSIFnRXERRST.RERCTF bit is 1. 1: Assert RHSIFnRXERR when the RHSIFnRXERRST.RERCTF bit is 1.
14	RERECTE	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXERRST.RERCTE bit. 0: Does not assert RHSIFnRXERR when the RHSIFnRXERRST.RERCTE bit is 1. 1: Assert RHSIFnRXERR when the RHSIFnRXERRST.RERCTE bit is 1.
13	RERECTD	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXERRST.RERCTD bit. 0: Does not assert RHSIFnRXERR when the RHSIFnRXERRST.RERCTD bit is 1. 1: Assert RHSIFnRXERR when the RHSIFnRXERRST.RERCTD bit is 1.

Table 29.83 RHSIFnRXERRIE Register Contents (2/2)

Bit Position	Bit Name	Function
12	RERECTC	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXERRST.RERCTC bit. 0: Does not assert RHSIFnRXERR when the RHSIFnRXERRST.RERCTC bit is 1. 1: Assert RHSIFnRXERR when the RHSIFnRXERRST.RERCTC bit is 1.
11	RERECTB	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXERRST.RERCTB bit. 0: Does not assert RHSIFnRXERR when the RHSIFnRXERRST.RERCTB bit is 1. 1: Assert RHSIFnRXERR when the RHSIFnRXERRST.RERCTB bit is 1.
10	RERECTA	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXERRST.RERCTA bit. 0: Does not assert RHSIFnRXERR when the RHSIFnRXERRST.RERCTA bit is 1. 1: Assert RHSIFnRXERR when the RHSIFnRXERRST.RERCTA bit is 1.
9	RERECT9	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXERRST.RERCT9 bit. 0: Does not assert RHSIFnRXERR when the RHSIFnRXERRST.RERCT9 bit is 1. 1: Assert RHSIFnRXERR when the RHSIFnRXERRST.RERCT9 bit is 1.
8	RERECT8	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXERRST.RERCT8 bit. 0: Does not assert RHSIFnRXERR when the RHSIFnRXERRST.RERCT8 bit is 1. 1: Assert RHSIFnRXERR when the RHSIFnRXERRST.RERCT8 bit is 1.
7 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	RERECT2	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXERRST.RERCT2 bit. 0: Does not assert RHSIFnRXERR when the RHSIFnRXERRST.RERCT2 bit is 1. 1: Assert RHSIFnRXERR when the RHSIFnRXERRST.RERCT2 bit is 1.
1	RERECT1	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXERRST.RERCT1 bit. 0: Does not assert RHSIFnRXERR when the RHSIFnRXERRST.RERCT1 bit is 1. 1: Assert RHSIFnRXERR when the RHSIFnRXERRST.RERCT1 bit is 1.
0	REREIPV	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXERRST.RERIPV bit. 0: Does not assert RHSIFnRXERR when the RHSIFnRXERRST.RERIPV bit is 1. 1: Assert RHSIFnRXERR when the RHSIFnRXERRST.RERIPV bit is 1.

(26) RHSIFnRXICST — Rx ICLC Command Status Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RHSIFn_L1_base> + $0C0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RIPA

Table 29.84 RHSIFnRXICST Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned.
16	RIPA	This bit indicates the status of ICLC ping answer. 0: Ping answer not received. 1: Ping answer received.
15 to 12	Reserved	When read, the value after reset is returned.
11	RITOL	This bit indicates the status of ICLC turn on payload loopback. 0: Turn on payload loopback not received. 1: Turn on payload loopback received.
10	RITOF	This bit indicates the status of ICLC turn off payload loopback. 0: Turn off payload loopback not received. 1: Turn off payload loopback received.
9	RITON	This bit indicates the status of ICLC turn on test mode. 0: Turn on test mode not received. 1: Turn on test mode received.
8	RIDT	This bit indicates the status of ICLC disable Tx port. 0: Disable Tx port not received. 1: Disable Tx port received.
7	RIET	This bit indicates the status of ICLC enable Tx port. 0: Enable Tx port not received. 1: Enable Tx port received.
6	RIFT	This bit indicates the status of ICLC select FastMode Tx port. 0: Select FastMode Tx port not received. 1: Select FastMode Tx port received.
5	RIST	This bit indicates the status of ICLC select SlowMode Tx port. 0: Select SlowMode Tx port not received. 1: Select SlowMode Tx port received.
4	RIFR	This bit indicates the status of ICLC select FastMode Rx port. 0: Select FastMode Rx port not received. 1: Select FastMode Rx port received.
3	RISR	This bit indicates the status of ICLC select SlowMode Rx port. 0: Select SlowMode Rx port not received. 1: Select SlowMode Rx port received.
2	RIPSTP	This bit indicates the status of ICLC PLL Stop. 0: PLL Stop not received. 1: PLL Stop received.

Table 29.84 RHSIFnRXICST Register Contents (2/2)

Bit Position	Bit Name	Function
1	RIPSRT	This bit indicates the status of ICLC PLL Start. 0: PLL Start not received. 1: PLL Start received.
0	RIPG	This bit indicates the status of ICLC Ping. 0: Ping not received. 1: Ping received.

(27) RHSIFnRXICSC — Rx ICLC Command Status Clear Register

Access: This register is a write-only register that can be write in 32-bit units.

Address: <RHSIFn_L1_base> + $0C4_H$

Value after reset: $0000\ 0000_H$

Table 29.86 RHSIFnRXICIE Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	RIEPA	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXICST.RIPA bit. 0: Does not assert RHSIFnRXICLC when the RHSIFnRXICST.RIPA bit is 1. 1: Assert RHSIFnRXICLC when the RHSIFnRXICST.RIPA bit is 1.
15 to 12	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
11	RIETOL	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXICST.RITOL bit. 0: Does not assert RHSIFnRXICLC when the RHSIFnRXICST.RITOL bit is 1. 1: Assert RHSIFnRXICLC when the RHSIFnRXICST.RITOL bit is 1.
10	RIETOF	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXICST.RITOF bit. 0: Does not assert RHSIFnRXICLC when the RHSIFnRXICST.RITOF bit is 1. 1: Assert RHSIFnRXICLC when the RHSIFnRXICST.RITOF bit is 1.
9	RIETON	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXICST.RITON bit. 0: Does not assert RHSIFnRXICLC when the RHSIFnRXICST.RITON bit is 1. 1: Assert RHSIFnRXICLC when the RHSIFnRXICST.RITON bit is 1.
8	RIEDT	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXICST.RIDT bit. 0: Does not assert RHSIFnRXICLC when the RHSIFnRXICST.RIDT bit is 1. 1: Assert RHSIFnRXICLC when the RHSIFnRXICST.RIDT bit is 1.
7	RIEET	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXICST.RIET bit. 0: Does not assert RHSIFnRXICLC when the RHSIFnRXICST.RIET bit is 1. 1: Assert RHSIFnRXICLC when the RHSIFnRXICST.RIET bit is 1.
6	RIEFT	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXICST.RIFT bit. 0: Does not assert RHSIFnRXICLC when the RHSIFnRXICST.RIFT bit is 1. 1: Assert RHSIFnRXICLC when the RHSIFnRXICST.RIRF bit is 1.
5	RIEST	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXICST.RIST bit. 0: Does not assert RHSIFnRXICLC when the RHSIFnRXICST.RIST bit is 1. 1: Assert RHSIFnRXICLC when the RHSIFnRXICST.RIST bit is 1.

Table 29.86 RHSIFnRXICIE Register Contents (2/2)

Bit Position	Bit Name	Function
4	RIEFR	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXICST.RIFR bit. 0: Does not assert RHSIFnRXICLC when the RHSIFnRXICST.RIFR bit is 1. 1: Assert RHSIFnRXICLC when the RHSIFnRXICST.RIFR bit is 1.
3	RIESR	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXICST.RISR bit. 0: Does not assert RHSIFnRXICLC when the RHSIFnRXICST.RISR bit is 1. 1: Assert RHSIFnRXICLC when the RHSIFnRXICST.RISR bit is 1.
2	RIEPSTP	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXICST.RIPSTP bit. 0: Does not assert RHSIFnRXICLC when the RHSIFnRXICST.RIPSTP bit is 1. 1: Assert RHSIFnRXICLC when the RHSIFnRXICST.RIPSTP bit is 1.
1	RIEPSRT	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXICST.RIPSRT bit. 0: Does not assert RHSIFnRXICLC when the RHSIFnRXICST.RIPSRT bit is 1. 1: Assert RHSIFnRXICLC when the RHSIFnRXICST.RIPSRT bit is 1.
0	RIEPG	This bit specifies whether to enable the interrupt that is triggered by the RHSIFnRXICST.RIPG bit. 0: Does not assert RHSIFnRXICLC when the RHSIFnRXICST.RIPG bit is 1. 1: Assert RHSIFnRXICLC when the RHSIFnRXICST.RIPG bit is 1.

29.5.3 Operation

29.5.3.1 Initial Settings

(1) Clocks generated by CLKGEN and transfer mode

The CLKGEN generates the clock for data transmission / reception. **Table 29.87** below shows the correspondence between the clocks to be generated and the transfer mode. The switching between master mode and slave mode, the transfer mode, and the baud rate for fast transfer mode are specified by setting the registers.

During operation in slave mode, the transfer mode can be switched between fast and slow by the ICLC command transmitted from the master.

Table 29.87 Clocks Generated by CLKGEN

Data Transfer Modes	Operation Modes	Clock Sources	Sampling Clock Frequency	Baud Rate
Fast Speed mode	Master / slave	Internal PLL	320, 160, 80 MHz	320, 160, 80 M Baud
Slow Speed mode	Master	System clock	20 MHz	5 M Baud
	Slave	External clock	10, 20 MHz	

(2) L1 settings

(1) Master / slave setting
Specify the master or slave operation by setting the RHSIFnMDCR.MST register. When the master operation is specified, also specify the frequency of the clock to be output to the communication device by setting the RHSIFnMDCR.CLKSEL.

(2) Flow control setting
Specify the automatic flow control setting by setting the RHSIFnMDCR.CTSEN register.

(3) RxD enable setting
Enable or disable RxD reception by setting the RHSIFnTXRXCR.RXEN register.

(4) TxD enable setting
Enable or disable TxD transmission by setting the RHSIFnTXRXCR.TXEN.

(5) Interrupt enable setting
Enable or disable interrupts by setting the RHSIFn*IE registers for L2 and L1, respectively.

(6) Transmission / reception speed setting for fast transfer mode
Specify the transmission / reception speed (baud rate) by setting the RHSIFnSPCR.FMBR register.

(7) Transfer mode setting for transmission / reception
Specify the transfer speed mode for transmission and reception by setting the RHSIFnSPCR.TXSP and RHSIFnSPCR.RXSP registers, respectively.

(8) Procedure for releasing CLKGEN standby
After power-on reset release, the PLL in the CLKGEN is in the standby (OFF) state. It is necessary to release the PLL from the standby state (ON) to perform data transmission / reception in fast transfer mode. When switching from PLL OFF to PLL ON, be sure to release the standby state of the PLL by using the procedures of steps (a) to (e) described below.
If data transmission/reception is performed in fast transfer mode without following the procedure, the baud rate is unstable and normal operation may not be achieved.

(a) Insert waits by software so that the external reference clock (RHSIF0_REFCLK) becomes stable 1 µs before the PLL is released from the standby state (indicated by step (d) below). During master operation, however, no wait is required because the internal clock is used as the reference clock for PLL at this time.

(b) Set the following registers as required.
RHSIFnMDCR.MST
RHSIFnMDCR.CLKSEL
RHSIFnSPCR.FMBR
RHSIFnSPCR.TXSP
RHSIFnSPCR.RXSP
Be sure to update these registers when the PLL is in the standby state.

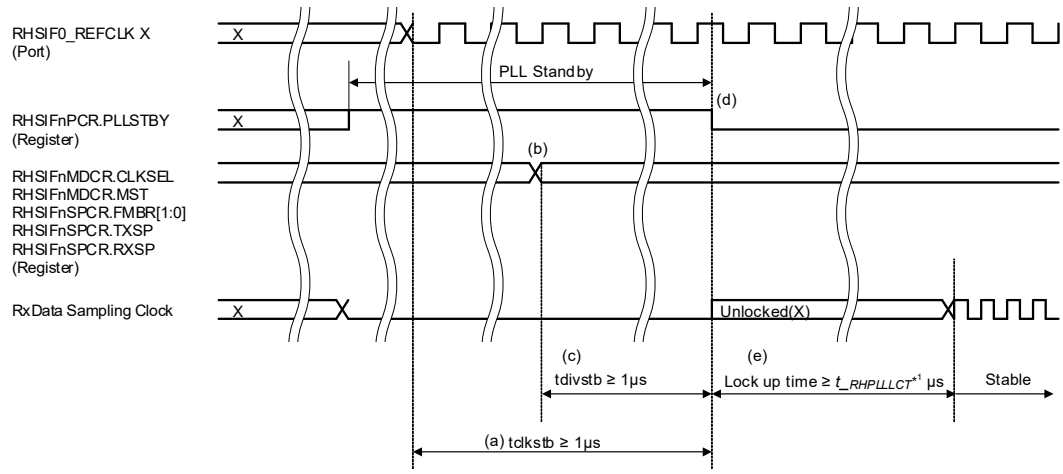
(c) Insert waits for at least 1 µs by software.

(d) Clear the RHSIFnPCR.PLLSTBY bit to “0”. The PLL released from the standby starts running.

(e) Insert waits for at least tRHPLLLCT µs by software until the PLL locks up. For details of PLL locked time, refer to **Section 55, Electrical Characteristics**.

Note: When switching from PLL ON to PLL OFF, set the RHSIFnPCR.PLLSTBY bit to “1” first to set the PLL in standby state, and then change the registers described in step (b) above. If setting values of these registers are changed while the PLL is running, the PLL may not operate normally.

Figure 29.30 below shows a timing chart for the procedure of steps (a) to (e) above.



Note 1. For details of PLL locked time, refer to **Section 55, Electrical Characteristics**.

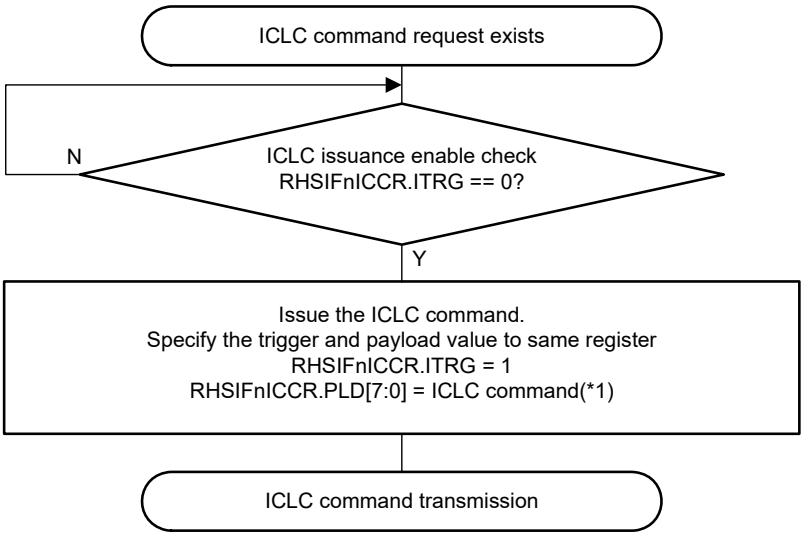
Figure 29.30 Timing Chart for Releasing CLKGEN from Reset State

29.5.3.2 ICLC Command Control Method

(1) Basic operation: ICLC command issuance

An ICLC command can be issued from the master to a slave. An ICLC command request is transmitted by firmware. Transmit a request by accessing the register and check the response by using an interrupt as trigger.

Figure 29.31 below shows the procedure flow for issuing an ICLC command.



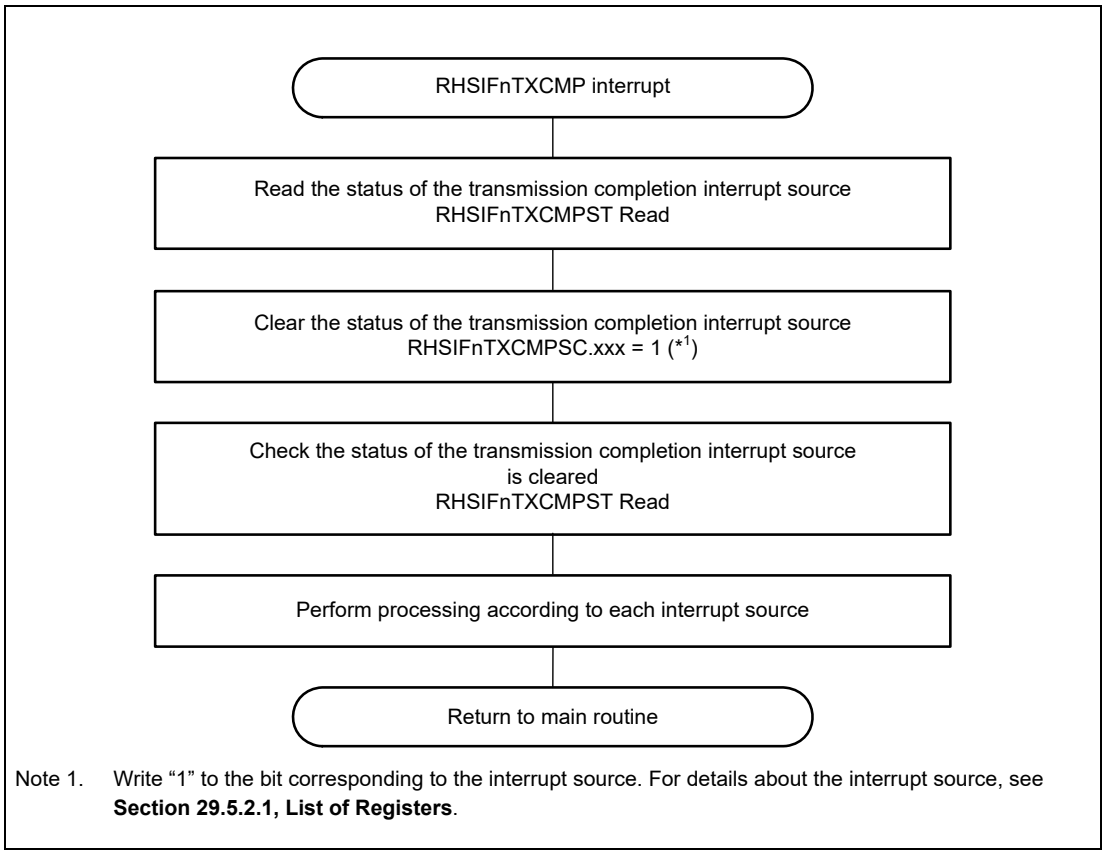
Note 1. See **Table 29.11** for details about the payload values for the ICLC command.

Figure 29.31 Procedure Flow for Issuing ICLC Command

For details about the ICLC commands supported by this product, see **Table 29.11 List of ICLC Commands**.

(2) Basic Operation of Interrupt

Figure 29.32 below shows the procedure flow for processing an interrupt, using transmission completion interrupt as example.



Note 1. Write “1” to the bit corresponding to the interrupt source. For details about the interrupt source, see **Section 29.5.2.1, List of Registers**.

Figure 29.32 Procedure Flow for Processing Transmission Completion Interrupt

The processing is similar to the other interrupts. See **Table 29.88** below for the status registers, status clear registers and interrupt enable registers for the other interrupts.

Table 29.88 List of Interrupt Related Registers

Interrupt	Status Register	Status Clear Register	Interrupt Enable Register
RHSIFnTXCMP	RHSIFnTXCMPST	RHSIFnTXCMPSC	RHSIFnTXCMPIE
RHSIFnTXERR	RHSIFnTXERRST	RHSIFnTXERRSC	RHSIFnTXERRIE
RHSIFnRXCMP	RHSIFnRXCMPST	RHSIFnRXCMPSC	RHSIFnRXCMPIE
RHSIFnRXERR	RHSIFnRXERRST	RHSIFnRXERRSC	RHSIFnRXERRIE
RHSIFnRXICLC	RHSIFnRXICST	RHSIFnRXICSC	RHSIFnRXICIE

(3) Basic operation: Execution of ICLC “PING” command

Figure 29.33 below shows a flow for transmitting an ICLC “PING” command and receiving an ICLC “PING Answer”. The ICLC “PING Answer” can automatically be transmitted without firmware.

After completion of transmission, the device waits for a response from the link partner. The following five cases can be considered according to the responding state of the link partner and whether there is a frame error.

(a) When the device operates as the master and the link partner sends back an ICLC “PING Answer” (normal case)
When the device completes transmission of a PING command, a transmission completion interrupt is generated.
Wait until the device receives the ICLC “PING Answer”.
When the device receives the “PING Answer”, a reception completion interrupt and an ICLC reception interrupt are generated.

(b) Transmission errors when the device operates as the master
If an error occurs after the device transmits an ICLC “PING” command, a transmission error interrupt is generated.

(c) Reception errors when the device operates as the master
If an error occurs after the device receives the ICLC “PING Answer”, a reception error interrupt is generated.

(d) Reception errors when the device operates as a slave
If an error occurs after the device receives the ICLC “PING” command, a reception error interrupt is generated.

(e) Transmission errors when the device operates as a slave
If an error occurs after the device transmits an ICLC “PING Answer”, a transmission error interrupt is generated.

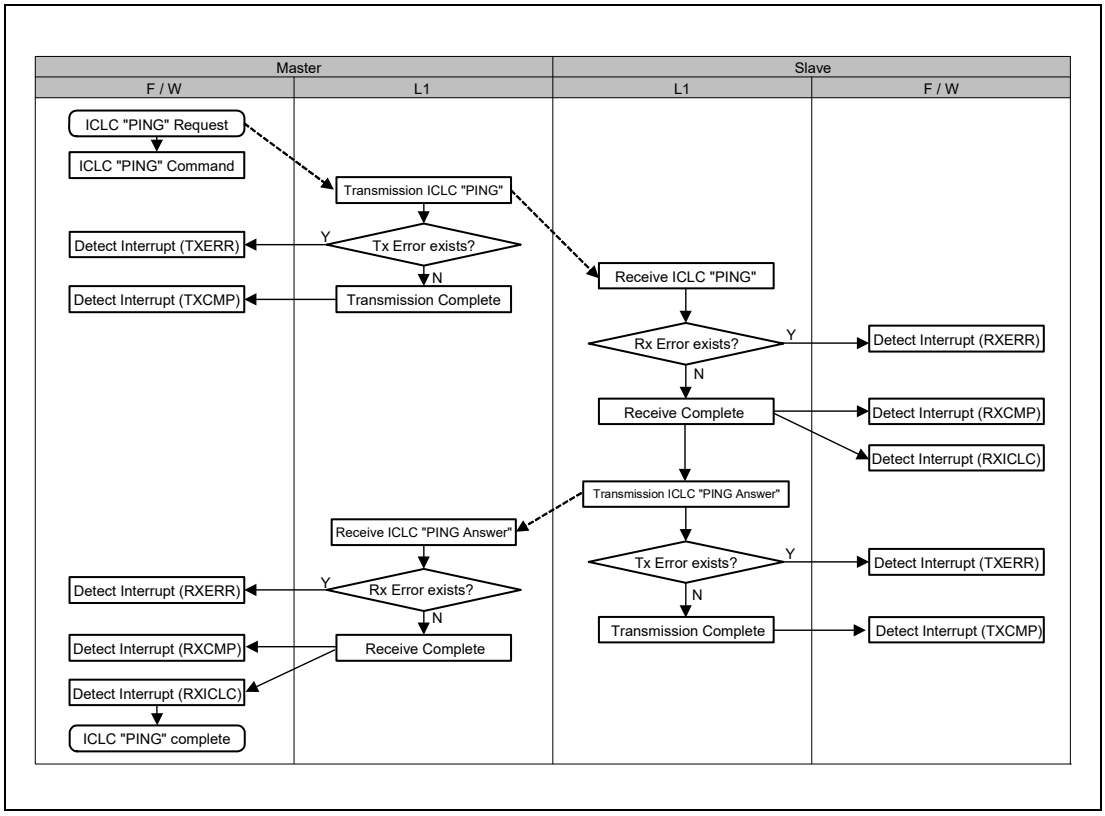


Figure 29.33 Flow for ICLC “PING” Command Execution

For the ICLC commands other than “PING”, the processing is the same except the slave does not send back an ICLC “PING Answer”.

29.5.3.3 Changing Communication Speed Using ICLC Commands

(1) Changing from slow transfer mode to fast transfer mode

Figure 29.34 to **Figure 29.40** show the procedure for changing the communication speed (transfer mode) from slow transfer mode to fast transfer mode.

For fast transfer mode, the transfer rate (baud rate) can be selected from 320, 160 and 80 M Baud. Be sure to specify the transfer rate in advance, by setting the RHSIFnSPCR register.

Also, be sure to enable transmission for the master.

(a) Enable transmission for the RX link slave.
Transmit the ICLC “Enable Slave interface transmitter” command.

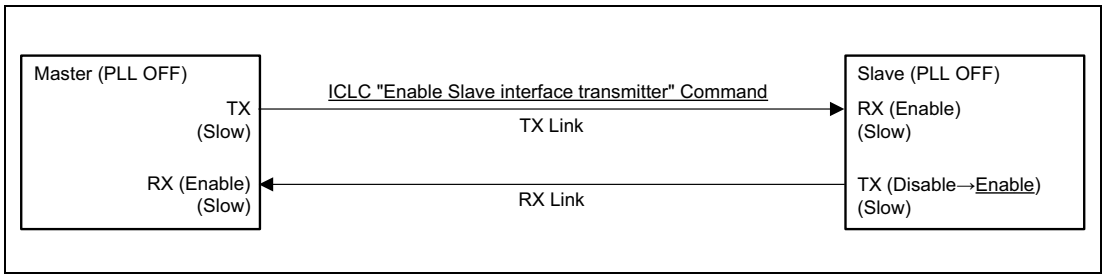

Figure 29.34 Enabling Transmission for RX Link Slave

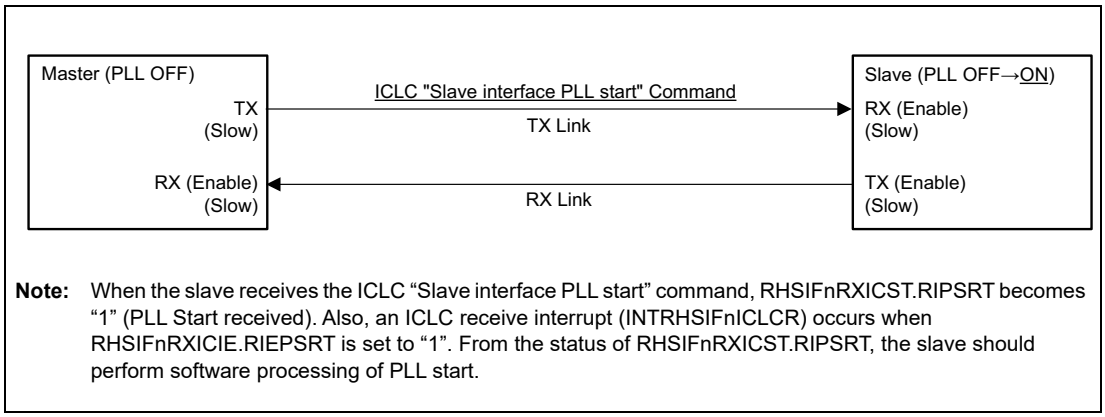
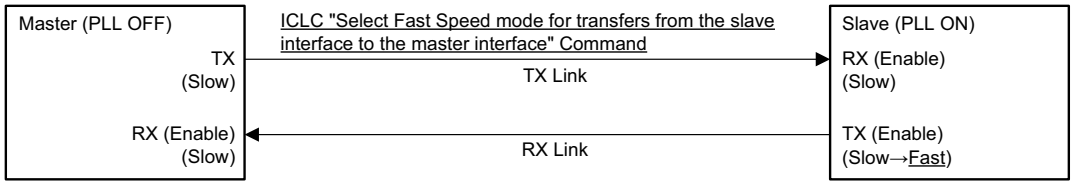
(b) Start operation of the PLL in slave
Transmit the ICLC “Slave interface PLL start” command. Refer to **(8), Procedure for releasing CLKGEN standby** in **Section 29.5.3.1(2), L1 settings** for details.



Note: When the slave receives the ICLC “Slave interface PLL start” command, RHSIFnRXICST.RIPSRT becomes “1” (PLL Start received). Also, an ICLC receive interrupt (INTRHSIFnICLCR) occurs when RHSIFnRXICIE.RIEPSRT is set to “1”. From the status of RHSIFnRXICST.RIPSRT, the slave should perform software processing of PLL start.

Figure 29.35 Starting Operation of PLL in Slave

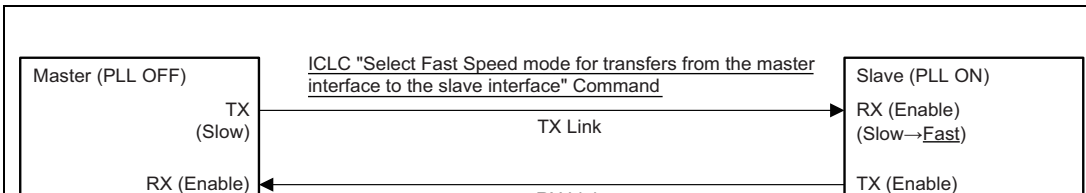
(c) Set the transmission speed mode for Rx link slave to fast mode
Transmit the ICLC “Select Fast Speed mode for transfers from the slave interface to the master interface” command.



Note: When the slave receives the ICLC “Select Fast Speed mode for transfers from the Slave interface to the Master interface” command, RHSIFnRXICST.RIFT becomes "1" (Select FastMode Tx port received). Also, an ICLC receive interrupt (INTRHSIFnICLCR) occurs when RHSIFnRXICIE.RIEFT is set to "1". From the status of RHSIFnRXICST.RIFT, the slave should perform software processing of fast speed mode for data transmission.

Figure 29.36 Setting Transmission Speed Mode for Slave to Fast

(d) Set the reception speed mode for Tx link slave to fast mode
Transmit the ICLC “Select Fast Speed mode for transfers from the Master interface to the Slave interface” command.



Note: When the slave receives the ICLC “Select Fast Speed mode for transfers from the Master interface to the Slave interface” command, RHSIFnRXICST.RIFR becomes “1” (Select FastMode Rx port received). Also, an ICLC receive interrupt (INTRHSIFnICLCR) occurs when RHSIFnRXICIE.RIEFR is set to “1”. From the status of RHSIFnRXICST.RIFR, the slave should perform software processing of fast speed mode for data reception.

Figure 29.37 Setting Reception Speed for Slave to Fast

(e) Start operation of the PLL in master
Release the PLL from the standby state and start operation of the PLL by setting the APB registers. Refer to **(8), Procedure for releasing CLKGEN standby**, in **Section 29.5.3.1(2), L1 settings** for details.

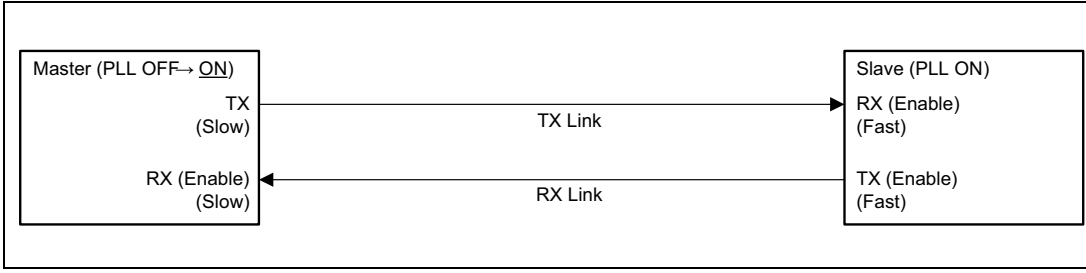


Figure 29.38 Starting Operation of PLL in Master

(f) Set the reception speed mode for Rx link and the transmission speed mode for Tx link of master to fast mode
Set the Rx and Tx speed modes to fast mode by setting RHSIFnSPCR.TXSP to “1” and RHSIFnSPCR.RXSP to “1”.

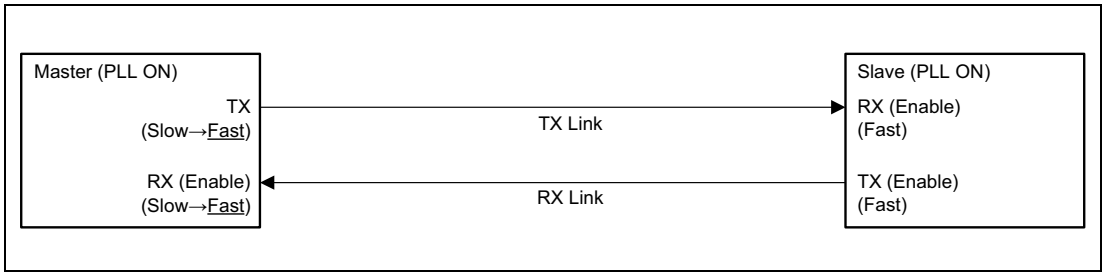

Figure 29.39 Setting Rx and Tx Speed Modes for Master to Fast

(g) Check the link establishment
Transmit the ICLC “PING” command and make sure that a “PING ANSWER” is sent back.

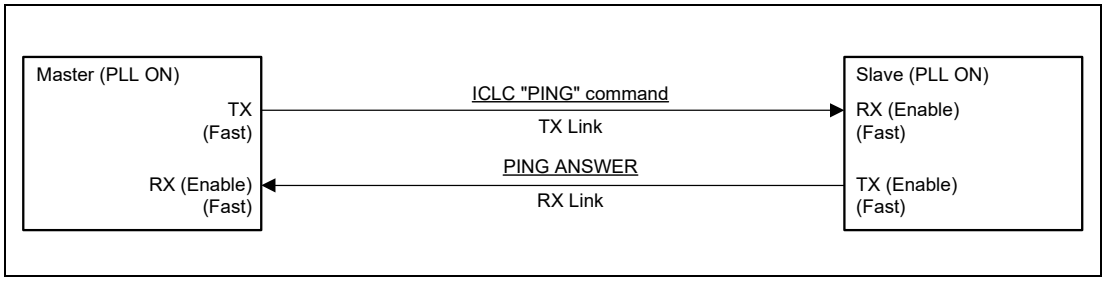

Figure 29.40 Checking Link Establishment

(2) Changing from fast transfer mode to slow transfer mode

Figure 29.41 to **Figure 29.47** show the procedure for changing the communication speed (transfer mode) from fast transfer mode to slow transfer mode.

Be sure to enable transmission for the master in advance

(a) Enable transmission for the RX link slave
Transmit the ICLC “Enable Slave interface transmitter” from the master to slave.

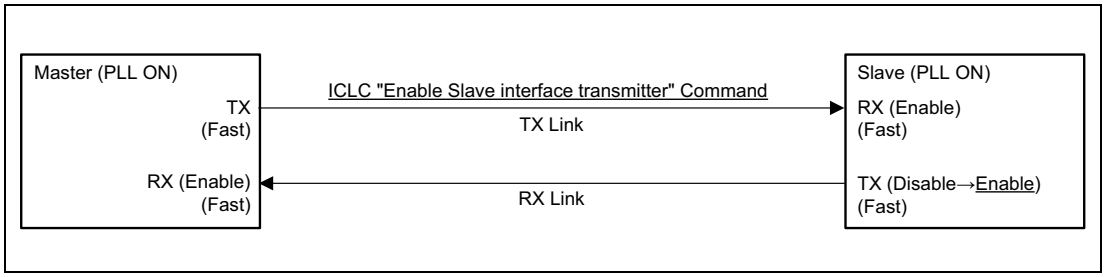

Figure 29.41 Enabling Transmission for RX Link Slave

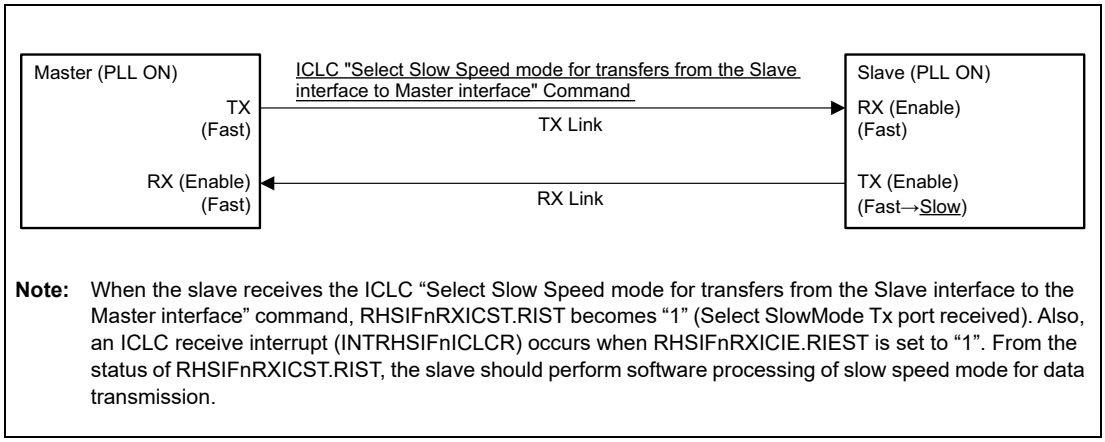
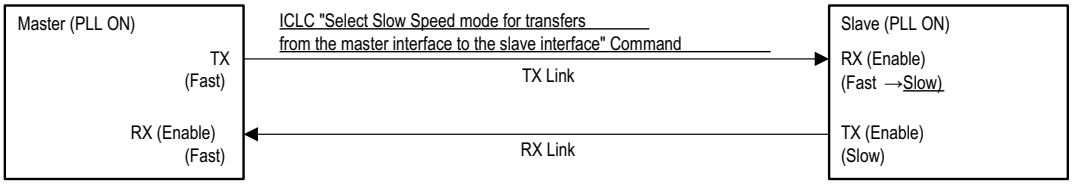
(b) Set the transmission speed mode for slave to slow mode
Transmit the ICLC “Select Slow Speed mode for transfers from the Slave interface to Master interface” command from the master to slave.



Note: When the slave receives the ICLC “Select Slow Speed mode for transfers from the Slave interface to the Master interface” command, RHSIFnRXICST.RIST becomes “1” (Select SlowMode Tx port received). Also, an ICLC receive interrupt (INTRHSIFnICLCR) occurs when RHSIFnRXICIE.RIEST is set to “1”. From the status of RHSIFnRXICST.RIST, the slave should perform software processing of slow speed mode for data transmission.

Figure 29.42 Setting Transmission Speed Mode for Slave to Slow

(c) Set the reception speed mode for slave to slow mode
Transmit the ICLC “Select Slow Speed mode for transfers from the Master interface to the Slave interface” command from the master to slave.



Note: When the slave receives the ICLC “Select Slow Speed mode for transfers from the Master interface to the Slave interface” command, RHSIFnRXICST.RISR becomes "1" (Select SlowMode Rx port received). Also, an ICLC receive interrupt (INTRHSIFnICLCR) occurs when RHSIFnRXICIE.RIESR is set to “1”. From the status of RHSIFnRXICST.RISR, the slave should perform software processing of slow speed mode for data reception.

Figure 29.43 Setting Reception Speed for Slave to Slow

(d) Set the reception and transmission speed modes for master to slow mode
Set the Rx and Tx speed modes to slow by setting RHSIFnSPCR.RXSP to “0” and RHSIFnSPCR.TXSP to “0”.

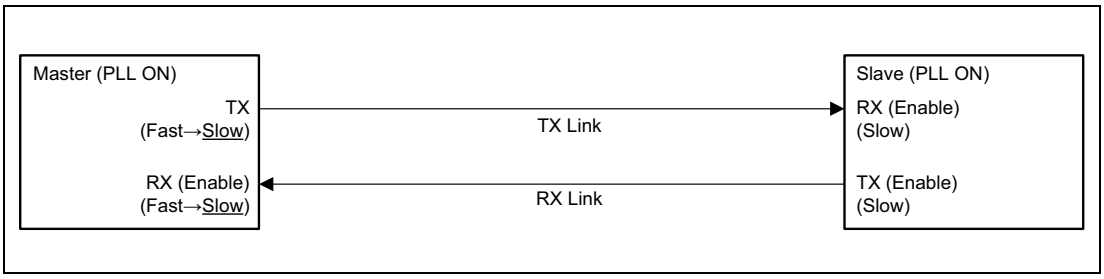


Figure 29.44 Setting Rx and Tx Speed Modes for Master to Slow

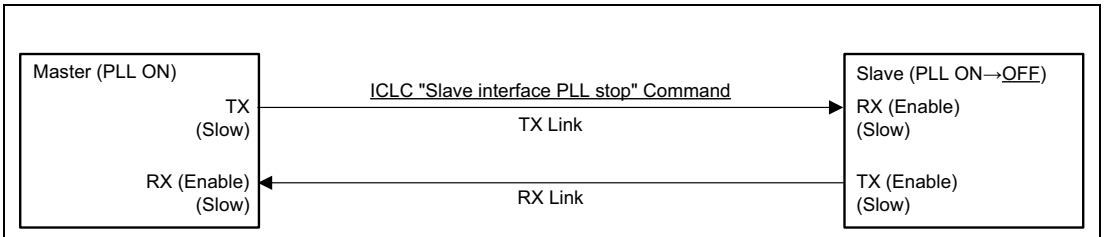
(e) Stop the operation of the PLL in slave
Transmit the ICLC “Slave interface PLL stop” command.



Note: When the slave receives the ICLC “Slave interface PLL stop” command, RHSIFnRXICST.RIPSTP becomes "1" (PLL Stop received). Also, an ICLC receive interrupt (INTRHSIFnICLCR) occurs when RHSIFnRXICIE.RIEPSTP is set to “1”. From the status of RHSIFnRXICST.RIPSTP, the slave should perform software processing of PLL stop.

Figure 29.45 Stopping Operation of PLL in Slave

(f) Stop the operation of the PLL in master
Set RHSIFnPCR.PLLSTBY to “1” to stop the PLL operation in master.

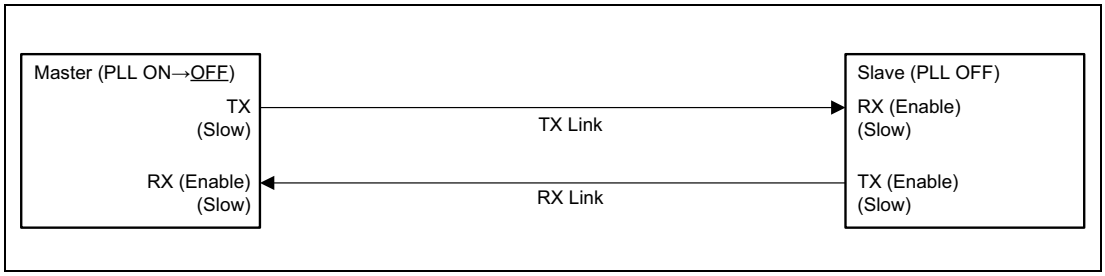


Figure 29.46 Stopping PLL Operation in Master

(g) Check the link establishment
Transmit the ICLC “PING” command from the master to slave, and make sure that a “PING ANSWER” is sent back.

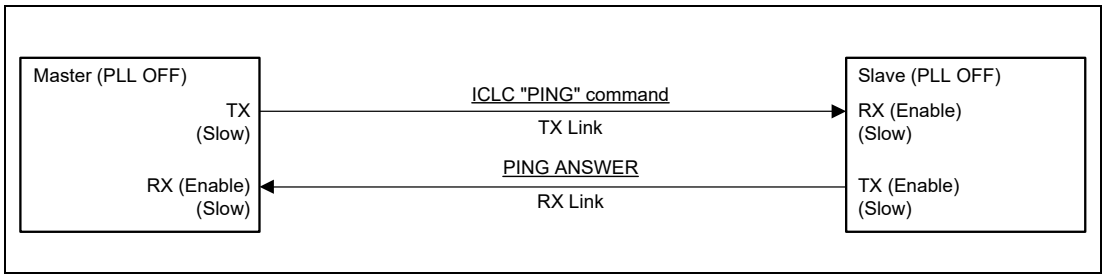

Figure 29.47 Checking Link Establishment

29.5.3.4 Transiting Slave State Using ICLC Commands

When the device is operating as a slave, the state transits according to the ICLC command that is received as follows.

(1) Transmission enabled / disabled state

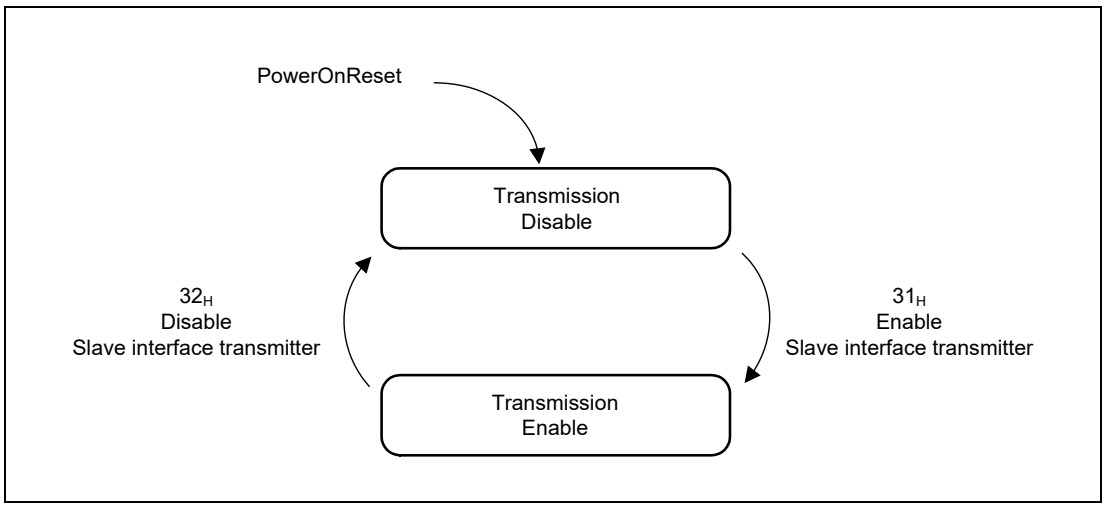

Figure 29.48 Transition between Transmission Enabled and Disabled States

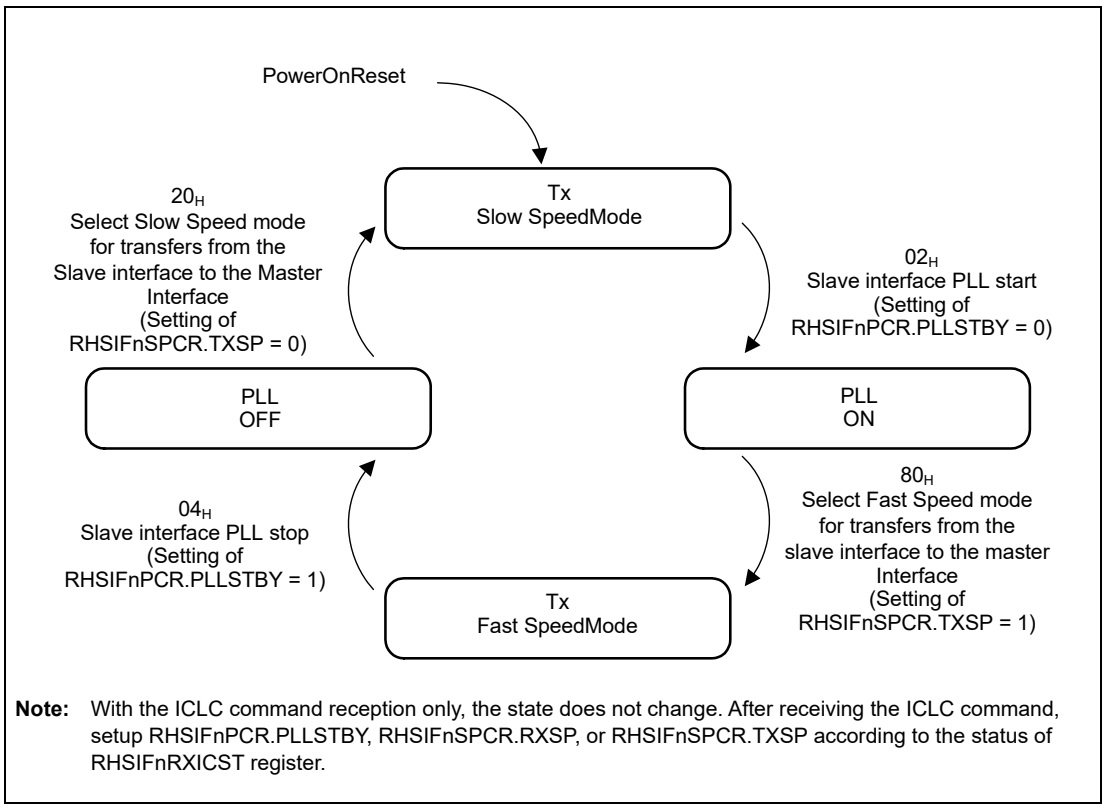
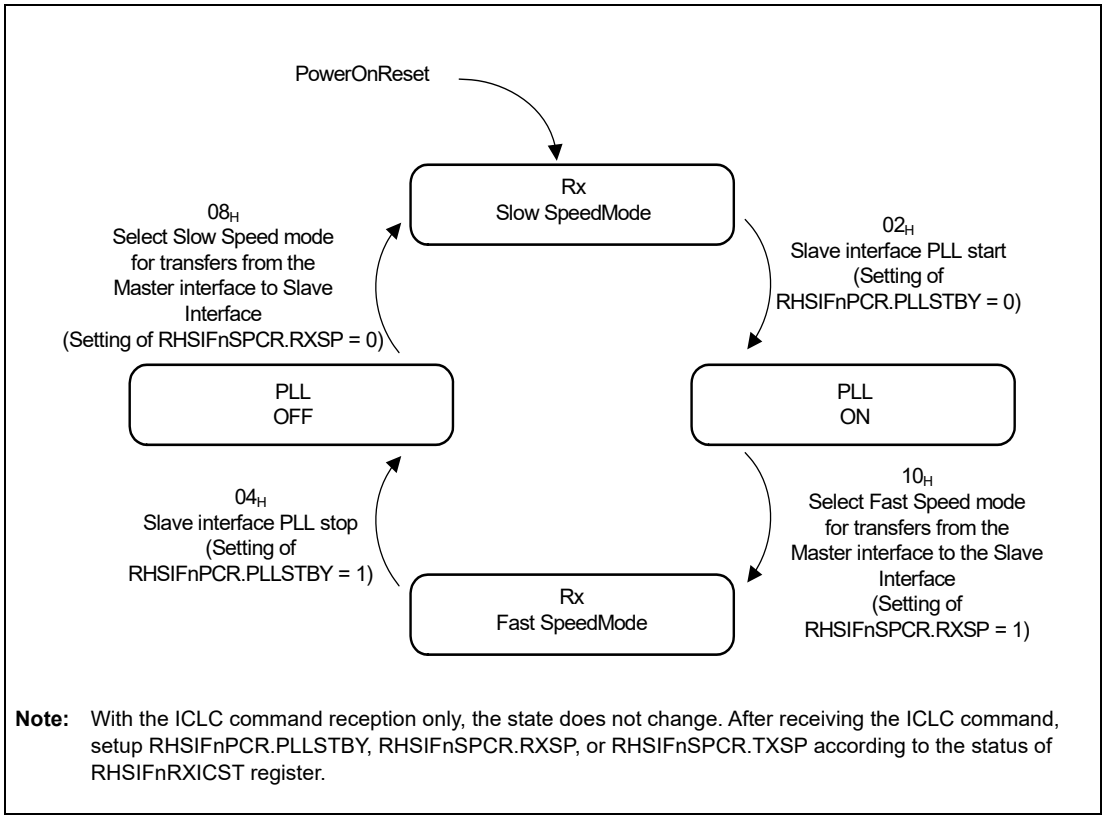
(2) Tx Speed Mode Slow / Fast



Note: With the ICLC command reception only, the state does not change. After receiving the ICLC command, setup RHSIFnPCR.PLLSTBY, RHSIFnSPCR.RXSP, or RHSIFnSPCR.TXSP according to the status of RHSIFnRXICST register.

Figure 29.49 Transition between Tx Speed Modes Slow and Fast

(3) Rx Speed Mode Slow / Fast



Note: With the ICLC command reception only, the state does not change. After receiving the ICLC command, setup RHSIFnPCR.PLLSTBY, RHSIFnSPCR.RXSP, or RHSIFnSPCR.TXSP according to the status of RHSIFnRXICST register.

Figure 29.50 Transition between the Slow and Fast RX Speed Modes

(4) Test Mode

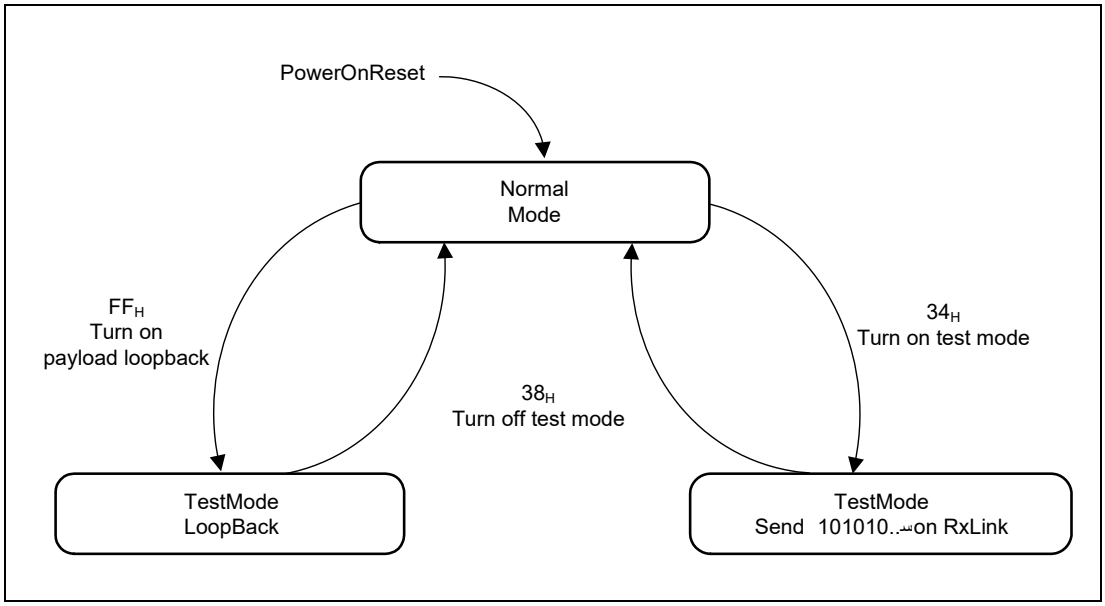


Figure 29.51 Transition between Test Modes

29.5.3.5 CTS Commands

(1) For Flow Control by CTS

The automatic flow control is enabled after PowerOnReset.

The automatic flow control is disabled by the RHSIFnMDCR.CTSEN=0.

(a) When the Automatic Flow Control is Enabled

(i) Link partner is not ready

Link partner: Transmits a frame with a CTS value =0.

This Product: Receives a frame and reflects the CTS value to RHSIFnL1SR.RCTS

This Product: Suppresses the next frame transmission

Link partner: Transmits a frame with a CTS value = 1 after becoming receivable

This Product: Receives a frame and reflects the CTS value to RHSIFnL1SR.RCTS

This Product: Resumes the transmission of the next frame.

(ii) This product is not ready

This Product: When RxDFIFO is full, transmits a CTS command frame of CTS value = 0.

This Product: When RxDFIFO is not full, transmits a CTS command frame with a CTS value = 1

CAUTION

Do not write '0' to RHSIFnMDCR.CTSV while Automatic Flow Control is enabled.

(b) When the Automatic Flow Control is Disabled

By using the following register, it is possible to control the flow manually.

(i) reception status of Link partner

RHSIFnL1SR.RCTS

(ii) reception status of This Product

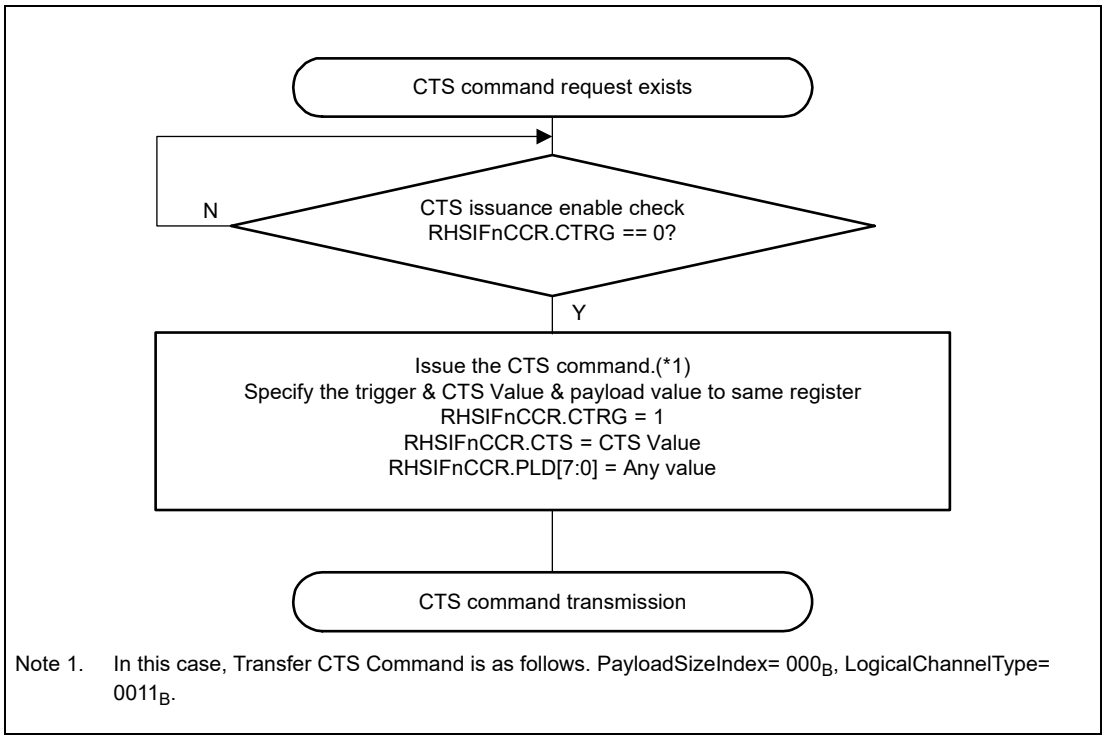
RHSIFnL1SR.RFFUL

RHSIFnMDCR.CTSV

(2) Basic Operation: CTS Command Issuance

A CTS command request is transmitted by firmware. Transmit a request by accessing the register.

Figure 29.52 below shows the procedure flow for issuing a CTS command.



Note 1. In this case, Transfer CTS Command is as follows. PayloadSizeIndex= 000_B, LogicalChannelType= 0011_B.

Figure 29.52 Procedure Flow for Issuing CTS Command

29.5.3.6 Sleep Mode

(1) Transitioning to Sleep Mode for the Link Partner

If an L2 frame, ICLC command, or CTS command is transmitted after RHSIFnSMCR.SLP is set to “1”, the L1 END bit continues to transmit “1”. This makes the Link Partner to transit to sleep mode.

(2) Recovering from Sleep Mode

Enter either of the following signals to the reception data pin to recover the device from sleep mode.

- In fast transfer mode: Zero-level signal of 8-bit rate or more
- In slow transfer mode: Zero-level signal of 1-bit rate or more

This makes the device to restore from sleep mode.

29.5.4 Interrupt Specification

29.5.4.1 Interrupt Source List

The tables below list the error interrupt sources detected in L1.

Table 29.89 Transmission Completion Interrupt

No	Register		Description
	Register Name	Bit Name	
1	RHSIFnTXCMP	TCL2	Transmission frame L2 completion interrupt
2		TCCT	Transmission frame CTS completion interrupt
3		TCIC	Transmission frame ICLC completion interrupt

Table 29.90 Transmission Error Interrupts

No	Register		Description
	Register Name	Bit Name	
1	RHSIFnTXERRST	TERSZ	This bit indicates the status of payload size error of transmission.
2		TERSZI5	Transmission frame L1 header payload code error (undefined code 5_H detected)
3		TERSZI4	Transmission frame L1 header payload code error (undefined code 4_H detected)
4		TERCTF	Transmission frame L1 header channel type code error (undefined code F_H detected)
5		TERCTE	Transmission frame L1 header channel type code error (undefined code E_H detected)
6		TERCTD	Transmission frame L1 header channel type code error (undefined code D_H detected)
7		TERCTC	Transmission frame L1 header channel type code error (undefined code C_H detected)
8		TERCTB	Transmission frame L1 header channel type code error (undefined code B_H detected)
9		TERCTA	Transmission frame L1 header channel type code error (undefined code A_H detected)
10		TERCT9	Transmission frame L1 header channel type code error (undefined code 9_H detected)
11		TERCT8	Transmission frame L1 header channel type code error (undefined code 8_H detected)
12		TERCT2	Transmission frame L1 header channel type code error (undefined code 2_H detected)
13		TERCT1	Transmission frame L1 header channel type code error (undefined code 1_H detected)

Table 29.91 Reception Completion Interrupt

No	Register		Description
	Register Name	Bit Name	
1	RHSIFnRXCMPST	RCL2	Reception frame L2 completion interrupt
2		RCCT	Reception frame CTS completion interrupt
3		RCIC	Reception frame ICLC completion interrupt

Table 29.92 Reception Error Interrupts

No	Register		Description
	Register Name	Bit Name	
1	RHSIFnRXERRST	RERSZ	This bit indicates the status of payload size error of reception.
2		RERSZI5	Reception frame L1 header payload code error (undefined code 5_H detected)
3		RERSZI4	Reception frame L1 header payload code error (undefined code 4_H detected)
4		RERCTF	Reception frame L1 header channel type code error (undefined code F_H detected)
5		RERCTE	Reception frame L1 header channel type code error (undefined code E_H detected)
6		RERCTD	Reception frame L1 header channel type code error (undefined code D_H detected)
7		RERCTC	Reception frame L1 header channel type code error (undefined code C_H detected)
8		RERCTB	Reception frame L1 header channel type code error (undefined code B_H detected)
9		RERCTA	Reception frame L1 header channel type code error (undefined code A_H detected)
10		RERCT9	Reception frame L1 header channel type code error (undefined code 9_H detected)
11		RERCT8	Reception frame L1 header channel type code error (undefined code 8_H detected)
12		RERCT2	Reception frame L1 header channel type code error (undefined code 2_H detected)
13		RERCT1	Reception frame L1 header channel type code error (undefined code 1_H detected)
14		RERIPV	Reception ICLC command undefined error.

Table 29.93 ICLC Reception Completion Interrupt

No	Register		Description
	Register Name	Bit Name	
1	RHSIFnRXICST	RIPA	Reception of PING answer frame
2		RITOL	Reception of turn on payload loopback frame
3		RITOF	Reception of turn off test mode frame
4		RITON	Reception of turn on test mode frame
5		RIDT	Reception of Disable slave interface transmitter frame
6		RIET	Reception of Enable slave interface transmitter frame
7		RIFT	Reception of Select Fast Speed mode for transfers from the Slave interface to the Master interface frame
8		RIST	Reception of Select Slow Speed mode for transfers from the Slave interface to the Master interface frame
9		RIFR	Reception of Select Fast Speed mode for transfers from the Master interface to the Slave interface frame
10		RISR	Reception of Select Slow Speed mode for transfers from the Master interface to the Slave interface frame
11		RIPSTP	Reception of Slave interface PLL stop
12		RIPSRT	Reception of Slave interface PLL start
13		RIPG	Reception of PING frame

29.5.4.2 Error detect conditions

The tables below list the error detect conditions.

Table 29.94 The combination of Transmission Payload size index and Transmission Logical channel type

			Logical Channel Type						
			ICLC(*2)	CTS(*2)	L2Frame				
			0000_B	0011_B	0100_B	0101_B	0110_B	0111_B	others(*3)
Payload_Size_Index	8bit	000_B	TCIC	TCCT	TERSZ	TERSZ	TERSZ	TERSZ	TERSZ
	32bit	001_B	TCIC	-(*1)	TCL2	TCL2	TCL2	TCL2	TERSZ
	64bit	010_B	-(*1)	-(*1)	TCL2	TCL2	TCL2	TCL2	TERSZ
	96bit	011_B	-(*1)	-(*1)	TCL2	TCL2	TCL2	TCL2	TERSZ
	Not used	100_B	-(*1)	-(*1)	TERSZI4	TERSZI4	TERSZI4	TERSZI4	TERSZ TERSZI4(*4)
		101_B	-(*1)	-(*1)	TERSZI5	TERSZI5	TERSZI5	TERSZI5	TERSZ TERSZI5(*4)
	160bit	110_B	-(*1)	-(*1)	TCL2	TCL2	TCL2	TCL2	TERSZ
	288bit	111_B	-(*1)	-(*1)	TCL2	TCL2	TCL2	TCL2	TERSZ

Note 1. These conditions will not occur.

Note 2. In L1 Frame, error bits are generated only when Logical Channel Type is 0000_B(ICLC) or 0011_B(CTS).

Note 3. In L2 Frame, the generated error bit is always TERSZ when the Logical Channel Type is other than b01xx.

Note 4. Either TERSZI4 or TERSZI5 is simultaneously generated with TERSZ according to the Payload Size Index value.

Table 29.95 The combination of Reception Payload size index and Reception Logical channel type (1 of 2)

			Logical_Channel_Type							
			ICLC	Reserved		CTS	L2Frame			
			0000_B	0001_B	0010_B	0011_B	0100_B	0101_B	0110_B	0111_B
Payload_Size_Index	8bit	000_B	RCIC	RERCT1	RERCT2	RCCT	RERSZ	RERSZ	RERSZ	RERSZ
	32bit	001_B	RCIC RERSZ	RERCT1	RERCT2	RCCT	RCL2	RCL2	RCL2	RCL2

	96bit	011_B	RERCT8	RERCT9	RERCTA	RERCTB	RERCTC	RERCTD	RERCTE	RERCTF
	Not used	100_B	RERCT8 RERSZI4(*1)	RERCT9 RERSZI4(*1)	RERCTA RERSZI4(*1)	RERCTB RERSZI4(*1)	RERCTC RERSZI4(*1)	RERCTD RERSZI4(*1)	RERCTE RERSZI4(*1)	RERCTF RERSZI4(*1)
		101_B	RERCT8 RERSZI5(*1)	RERCT9 RERSZI5(*1)	RERCTA RERSZI5(*1)	RERCTB RERSZI5(*1)	RERCTC RERSZI5(*1)	RERCTD RERSZI5(*1)	RERCTE RERSZI5(*1)	RERCTF RERSZI5(*1)
	160bit	110_B	RERCT8	RERCT9	RERCTA	RERCTB	RERCTC	RERCTD	RERCTE	RERCTF
	288bit	111_B	RERCT8	RERCT9	RERCTA	RERCTB	RERCTC	RERCTD	RERCTE	RERCTF

Note 1. Either RERSZI4 or RERSZI5 is simultaneously generated with RERCT8~RERCTF according to the Payload Size Index value.

29.5.4.3 Operation Upon Error Occurrence

The operations upon error occurrence in L1 consist only of the following.

- Assertion of error interrupt
- Indication of error interrupt status by register

29.5.5 Debug

Table 29.97 List of Debug Function

Purpose	Item	Content		APB Register
Debug	ICLC(34_H)	Turn on test mode (Send 101010.. Txline data rate)		RHSIFnTMDCR.CKTMSEL
	Loopback	TxD->RxD		RHSIFnTMDCR.TXLPBK

29.5.6 Usage Note

29.5.6.1 About Fast Mode of Slave

A fast mode of Slave (It's sampled using a reference clock.) recommends following correspondence because there is a possibility that BER (the bit error rate) deteriorates by influence of a jitter.

- Use Slave's fast mode only when sending / receiving various ICLC commands (during communication establishment).
- After confirming the establishment of communication by the PING command of ICLC when communicating by a fast mode, begin to change to Master (sampling by MOSC) and communicate from tRHPLLLCT µs later (PLL locked time of a clock change). For details of PLL locked time, refer to **Section 55, Electrical Characteristics**.

Section 30 Clock Extension Peripheral Interface (CXPI)

This section contains a generic description of the clock extension peripheral interface (CXPI).

The first part in this section describes the RH850/U2A-EVA specific properties, such as the number of units, register base addresses, etc.

The remainder of the section describes the functions and registers of the CXPI.

30.1 Features of CXPI for RH850/U2A-EVA

30.1.1 Number of Units and Channels

This microcontroller has the following number of CXPI units.

Each CXPI unit has a single channel interface. “Number of channels” therefore has the same meaning as “number of units” in this section.

Table 30.1 Number of Units

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of Units	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	—	—	—	—
Name	CXP1n									

Table 30.2 Index

Index	Description
n	Throughout this section, the individual CXPI function A units are identified by the index “n” (n = 0 to 3); for example, CXP1nMODE indicates the CXP1n mode selection register.

30.1.2 Register Base Addresses

CXP1n base addresses are listed in the following table.

CXP1n register addresses are given as offsets from the base addresses.

Table 30.3 Register Base Addresses

Base Address Name	Base Address	Bus Group
<CXP10_base>	FFD4 0000_H	P-Bus Group 3
<CXP11_base>	FFD4 1000_H	P-Bus Group 3
<CXP12_base>	FFD4 2000_H	P-Bus Group 3
<CXP13_base>	FFD4 3000_H	P-Bus Group 3

30.1.3 Clock Supply

The CXP1n clock supply is shown in the following table.

Table 30.4 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name	Description
CXP1n	CXPI Communication clock (PCLK)	CLK_HSB	Timer count clock
	Register access clock	CLK_HSB	Bus clock

30.1.4 Interrupt Request and Error Notifications

CXP1n interrupt requests are listed in the following table.

Table 30.5 Interrupt Request

Unit Interrupt Signal	Description	Interrupt Number	DMA Trigger Number
CXP10			
INTCXP10TI	CXPI transfer interrupt	673	—
INTCXP10RI	CXPI receive interrupt	674	—
INTCXP10SI	CXPI status interrupt	675	—
CXP11			
INTCXP11TI	CXPI transfer interrupt	676	—
INTCXP11RI	CXPI receive interrupt	677	—
INTCXP11SI	CXPI status interrupt	678	—
CXP12			
INTCXP12TI	CXPI transfer interrupt	679	—
INTCXP12RI	CXPI receive interrupt	680	—
INTCXP12SI	CXPI status interrupt	681	—
CXP13			
INTCXP13TI	CXPI transfer interrupt	682	—
INTCXP13RI	CXPI receive interrupt	683	—
INTCXP13SI	CXPI status interrupt	684	—

This module has no error notifications.

30.1.5 Reset Sources

CXP1n reset sources are listed in the following table. CXP1n is initialized by these reset sources.

Table 30.6 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
CXP1n	All registers	√	√	√	√	√	√	—

30.1.6 External Input/Output Signals

External input/output signals of CXP1n are listed below.

Table 30.7 External Input/Output Signals

Unit Signal Name	Description	Alternative Port Pin Signal
CXP10		
pt_cxpi_rxd	CXPI receive data Input	CXP10RX
cxpi_pt_txd	CXPI transmit data Output	CXP10TX
CXP11		
pt_cxpi_rxd	CXPI receive data Input	CXP11RX
cxpi_pt_txd	CXPI transmit data Output	CXP11TX
CXP12		
pt_cxpi_rxd	CXPI receive data Input	CXP12RX
cxpi_pt_txd	CXPI transmit data Output	CXP12TX
CXP13		
pt_cxpi_rxd	CXPI receive data Input	CXP13RX
cxpi_pt_txd	CXPI transmit data Output	CXP13TX

30.1.7 Combinations of Pins and Ports

Combinations of CXPI pins and ports are listed in the following table.

Table 30.8 Combinations of Pins and Ports

Function	Pin name	Port name
CXP10	CXP10RX	P2_9/P4_9/P10_5/P10_8/P20_2/P20_14
	CXP10TX	P2_10/P4_8/P10_0/P10_4/P10_6/P10_9
CXP11	CXP11RX	P2_4/P4_4
	CXP11TX	P2_5/P4_5
CXP12	CXP12RX	P2_1/P3_2/P21_4
	CXP12TX	P2_0/P3_3/P21_5
CXP13	CXP13RX	P2_11/P4_15
	CXP13TX	P2_12/P4_14

30.2 Overview

The Clock Extension Peripheral Interface (CXPI) supports the following standard specification (JASO D015) functions:

- Baud rate can be chosen
  - 9.6 kbps/10.4 kbps/19.2 kbps/20.0 kbps
- Operation mode
  - Master mode/Slave mode
- Access method
  - Event trigger method/Polling method
- PWM encoding/decoding function is used to output and sample the PWM waveform

30.2.1 Block Diagram

The figures below are block diagrams of the CXPI.

- When CXP1nMODE.CXP1nMD = 0_B (in CXPI-PWM mode) (The IP (MCU) handles encoding and decoding.)

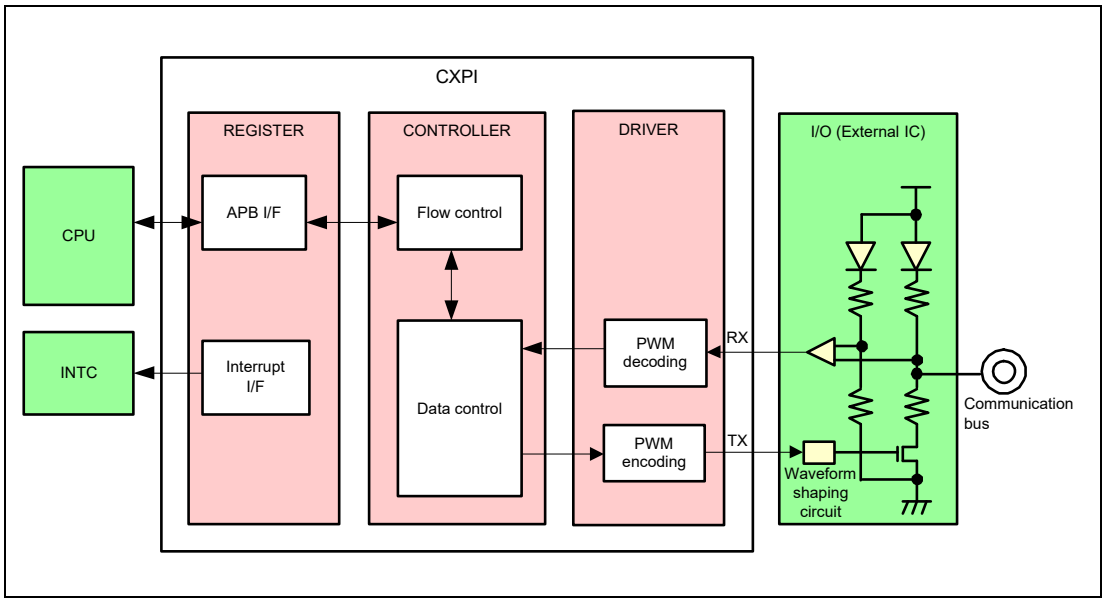

Figure 30.1 Block Diagram (in CXPI-PWM Mode)

- When CXP1nMODE.CXP1nMD = 1_B (in CXPI-NRZ mode) (The external IC handles encoding and decoding.)

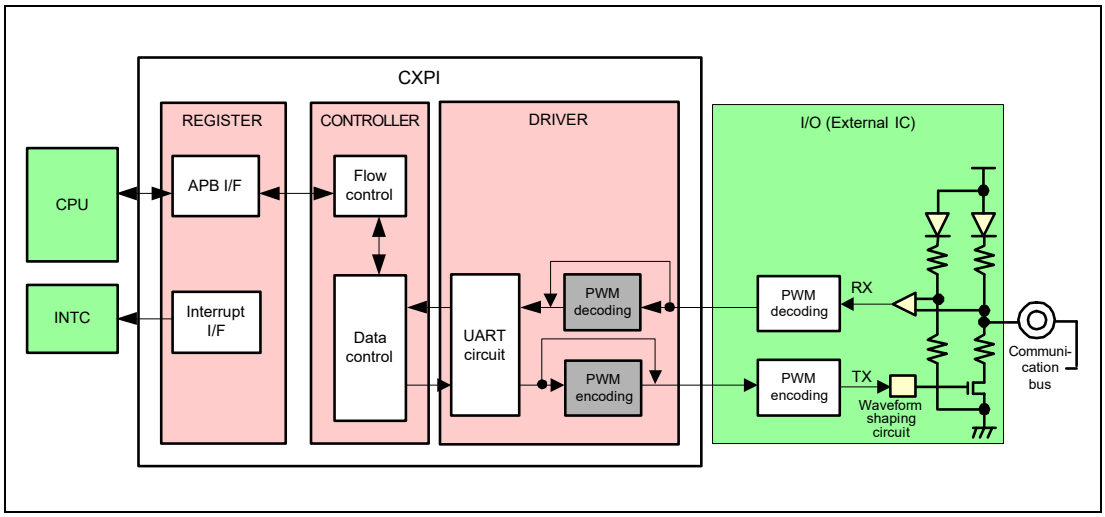

Figure 30.2 Block Diagram (in CXPI-NRZ Mode)

30.3 List of Registers

30.3.1 List of CXP1n Control Registers

The table below lists the CXP1n control registers.

Table 30.9 List of Registers (1/2)

Module Name	Register Name	Symbol	Address	Access Size	Access Protection	
					PBG	Other
CXP1n	CXPI Operating Mode Select Register	CXP1nMODE	<CXP1n_base> + 000_H	8, 16, 32	*1	—
	CXPI Baud Rate Setting Register	CXP1nBRT	<CXP1n_base> + 004_H	8, 16, 32	*1	—
	CXPI Logical Value 1 Setting Register	CXP1nV1LW	<CXP1n_base> + 008_H	8, 16, 32	*1	—
	CXPI Logical Value 0 Setting Register	CXP1nV0LW	<CXP1n_base> + $00C_H$	8, 16, 32	*1	—
	CXPI Sampling Setting Register	CXP1nSAMP	<CXP1n_base> + 010_H	8, 16, 32	*1	—

	CXPI Automatic Response Data Register 06	CXP1nARDATA06	<CXP1n_base> + 414_H	8, 16, 32	*1	—

Note 1. n = 0: PBG31#1
n = 1: PBG31#2
n = 2: PBG31#3
n = 3: PBG31#4

30.4 Function Details

30.4.1 Register Descriptions

30.4.1.1 CXP1nMODE —CXPI Operating Mode Select Register

This register sets the operation of the CXPI controller.

Write access to this register is only enabled in bus sleep mode*2. It is disabled in other modes.

Note 2. CXP1nFLW1.CXP1nCXMD = 01_B

Access: CXP1nMODE register can be read or written in 32-bit units.
CXP1nMODEL register can be read or written 16-bit units.
CXP1nMODELL, CXP1nMODELH registers can be read or written 8-bit units.

Address: CXP1nMODE: <CXP1n_base> + 000_H
CXP1nMODEL: <CXP1n_base> + 000_H
CXP1nMODELL: <CXP1n_base> + 000_H,
CXP1nMODELH: <CXP1n_base> + 001_H

Value after reset: 0000 0200_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 30.10 CXP1nMODE Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10	CXP1nARESEN	Automatic response enable 0: Disables automatic response 1: Enables automatic response
9	CXP1nREPOP	Retransmission setting 0: Retransmission is not judged (unlimited number of retransmissions) 1: Retransmission is judged (the number of retransmissions is set by the CXP1nREP register)
8	CXP1nACC	CXPI access method setting 0: Event trigger method 1: Polling method
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	CXP1nMS	Node setting 0: Slave node 1: Master node
2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	CXP1nMD	Transfer mode setting 0: CXPI-PWM mode 1: CXPI-NRZ mode

Table 30.10 CXP1nMODE Register Contents (2/2)

Bit Position	Bit Name	Function
0	CXP1nEN	Operation enable 0: Disables operation (forced reset issued) 1: Enables operation

CXP1nARESEN Bit

This bit enables/disables automatic response.
For details, see **Section 30.5.4.4(1), PID Reception to Response Transmission**.

When automatic response is enabled (1_B), the PID received from another node is compared with the automatic response PID set in the CXP1nARPID register.
If they match, a frame of the response field is transmitted automatically.

NOTE

This function is defined as automatic response.

CXP1nREPOP Bit

This bit specifies whether or not retransmission is determined.
For details, see **Section 30.5.7.3, Retransmission Processing**.

[What is retransmission processing?]
This function retransmits a frame if the received data differs from the transmitted data due to a loss in arbitration, error, etc.
The node which sent the PID retransmits the same PID. Retransmission must be done after IFS has been detected.

- When CXP1nREPOP = 1_B:
  The number of retransmissions is the value set in the CXP1nREP register.
  For details, see **Section 30.4.1.10, CXP1nREP — CXPI Retransmission Setting Register**.
- When CXP1nREPOP = 0_B:
  The number of retransmissions is unlimited.
  Note that setting CXP1nREPOP to 0_B initializes the CXP1nFLG2 register, disabling writing to the register.

CXP1nACC Bit

This bit specifies the access method of the CXPI.
For details, see **Section 30.5.2, CXPI Operation Overview**.

- When CXP1nACC = 0_B:
  The CXPI operates in the event trigger method.
  Each node can transmit frames freely upon detecting an idle state.
- When CXP1nACC = 1_B:
  The CXPI operates in the polling method.
  The slave node transmits a response for the request from the master node.
  It can transmit any frame when receiving the PTYPE field that represents an event request from the master node.

The master node operates in the same way as in the event trigger method.

CXP1nMS Bit

This bit specifies whether the node is the master node or a slave node.

- When CXP1nMS = 0_B:
  The node operates as a slave node.
  A slave node operates in synchronization with the CXPI clock signal from the master node.
- When CXP1nMS = 1_B:
  The node operates as the master node.
  The master node transmits CXPI clock signals to the communication bus.

CXP1nMD Bit

This bit specifies the transfer mode of the CXPI.
For details, see **Section 30.5.5.5, PWM Encoding/Decoding**.

- When CXP1nMD = 0_B:
  The CXPI operates in CXPI-PWM mode.
  In CXPI-PWM mode, the CXPI uses PWM encoding/decoding by the IP to transmit and receive on a PWM basis.
- When CXP1nMD = 1_B:
  The CXPI operates in CXPI-NRZ mode.
  In CXPI-NRZ mode, the CXPI handles transfer to the transceiver in the UART format.
  The transceiver encodes/decodes the UART protocol into PWM and outputs the resulting data as CXPI communications (PWM encoding/decoding by the IP is turned off).

CXP1nEN Bit

This bit enables/disables the CXPI operation.

- When CXP1nEN = 1_B (enabling operation):
  Various settings and operations are enabled.
  Note that the mode sequencer[*1] transitions from initializing mode to bus sleep mode.
- When CXP1nEN = 0_B (disabling operation):
  Various settings and operations are disabled.
  Note that the mode sequencer[*1] transitions to initializing mode.

Setting CXP1nEN to 0_B issues a forced reset.
A forced reset initializes all registers except for this register. In the slave node, the CXP1nFLG1.CXP1nFAIL bit and the CXP1nERR.CXP1nERRCNT bit are not initialized.

In the master node, the CXP1nFLG1.CXP1nFAIL bit and the CXP1nERR.ERRCNT bit are also initialized.

Note 1. For details, see **Section 30.5.8.7, Software Reset**.

If the application found a physical bus error, a forced reset is issued to initialize the IP if sleep mode is enabled.
For details about the mode sequencer, see **Section 30.4.1.17, CXP1nFLW1 — CXP1 Flow Register 1**.

30.4.1.2 CXP1nBRT — CXPI Baud Rate Setting Register

This register sets the CXPI nominal bit (Tbit) frequency of the CXPI bus.

Write access to this register is only enabled in bus sleep mode[*1]. It is disabled in other modes.

Note 1. CXP1nFLW1.CXP1nCXMD = 01_B

Access: CXP1nBRT register can be read or written in 32-bit units.
CXP1nBRTL register can be read or written 16-bit units.
CXP1nBRTLL, CXP1nBRTLH registers can be read or written 8-bit units.

Address: CXP1nBRT: <CXP1n_base> + 004_H
CXP1nBRTL: <CXP1n_base> + 004_H

Table 30.11 CXP1nBRT Register Contents

Bit Position	Bit Name	Function
31 to 15	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
14 to 4	CXP1nBRP	CXPI nominal bit time setting (1 Tbit width) The CXPI nominal bit (Tbit) frequency is calculated by using the following equation: • CXPI nominal bit (Tbit) frequency = operating reference frequency (divclk) / CXP1nBRP
3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2 to 0	CXP1nPRS	CXPI basic division ratio setting The operating reference frequency is calculated by using the following equation: • Operating reference frequency (divclk) = input frequency (PCLK) / (CXP1nPRS + 1)

CXP1nBRP Bits

These bits set the division ratio of the operating reference frequency (divclk).
The divided clock of the operating reference frequency (divclk) is defined as the CXPI nominal bit (Tbit) frequency.
This clock is used to generate the communication baud rate and wakeup pulses.

CXP1nPRS Bits

These bits set the division ratio of PCLK to generate the operating reference frequency (divclk).
The operating reference frequency (divclk) is used to generate the communication waveform and sampling timing.

The conditions for setting and clearing of the CXP1nBRT register are as follows:

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

Recommended Communication Baud Rate Settings

The table below lists the recommended communication baud rate settings.

Table 30.12 List of Communication Baud Rate Settings

Macro Operating Frequency (PCLK)	Target Communication Baud Rate	CXP1nPRS	CXP1nBRP	Generated Communication Baud Rate
40 MHz	20 kbps	000_B	$7D0_H$	20 kbps
	19.2 kbps	001_B	412_H	19.19 kbps

		011_B	412_H	9.60 kbps

Relationship between Clocks and Functions

This IP operates based on the following three clocks:

- Bus clock (PCLK)
- Operating reference frequency (divclk)
- CXPI nominal bit (Tbit) frequency

The figure below shows the relationship between the clocks and functions (registers).

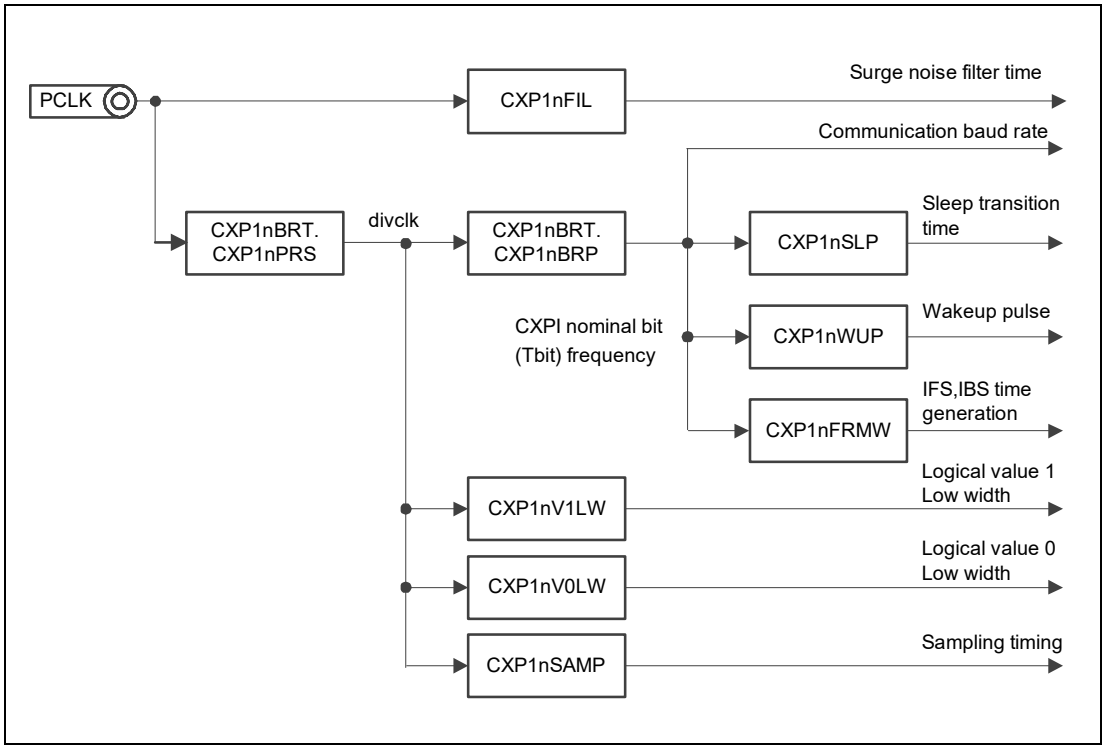

Figure 30.3 Relationship between Clocks and Functions (CXPI-PWM)

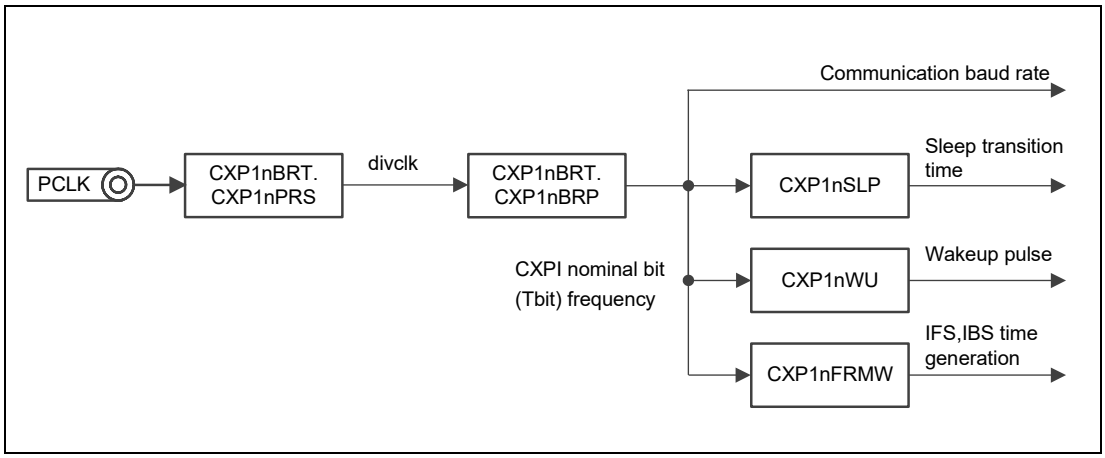

Figure 30.4 Relationship between Clocks and Functions (CXPI-NRZ)

30.4.1.3 CXP1nV1LW — CXPI Logical Value 1 Setting Register

This register sets the low width (startup timing) of logical value 1 in CXPI-PWM mode.

Write access to this register is only enabled in bus sleep mode[*1]. It is disabled in other modes.

Note 1. CXP1nFLW1.CXP1nCXMD = 01_B

Writing to this register is prohibited in CXPI-NRZ mode.

Access: CXP1nV1LW register can be read or written in 32-bit units.
CXP1nV1LWL register can be read or written 16-bit units.
CXP1nV1LWLL, CXP1nV1LWLH registers can be read or written 8-bit units.

Address: CXP1nV1LW: <CXP1n_base> + 008_H
CXP1nV1LWL: <CXP1n_base> + 008_H
CXP1nV1LWLL: <CXP1n_base> + 008_H,
CXP1nV1LWLH: <CXP1n_base> + 009_H

Value after reset: 0000 0001_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 30.13 CXP1nV1LW Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9 to 0	CXP1nV1LCNT	Logical value 1 low width setting These bits set the low width of logical value 1 in CXPI-PWM mode. The low width of logical value 1 is set by using the following equation: • Low width of logical value 1 = 1 / operating reference frequency (divclk) × CXP1nV1LCNT Range of allowable settings: 001_H to $3FF_H$

CXP1nV1LCNT Bits

These bits set the low width of logical value 1 in CXPI-PWM mode.
The logical value 1 waveform of the CXPI communication bus is generated by this setting.

The table below lists the range of allowable settings.

Table 30.14 Allowable Settings of CXP1nV1LCNT

Macro Operating Frequency (PCLK)	Communication Baud Rate (CXPI Nominal Bit (Tbit) Frequency)	CXP1nPRS	CXP1nBRP	CXP1nV1LCNT*3	
				MIN*1	MAX*2
40 MHz	20 kbps	0000_B	$7D0_H$	$0DC_H$	$30C_H$
	19.2 kbps	0001_B	412_H	073_H	196_H
	10.4 kbps	0001_B	783_H	$0D4_H$	$2ED_H$
		0010_B	502_H	$08E_H$	$1F3_H$
	9.6 kbps	0010_B	$56D_H$	099_H	$21D_H$
		0011_B	412_H	073_H	196_H

Note 1. The setting range of MIN is determined by the following specified value:
Ttx_1_lo_dom: 0.11 × CXPI nominal bit (Tbit) time

Note 2. The setting range of MAX is determined by the following specified value:
Ttx_1_lo_rec: 0.39 × CXPI nominal bit (Tbit) time + 0.6 × τ
τ (time constant of the entire system): 1 µs to 5 µs (excluded from the calculation of the range of allowable settings)

Note 3. In the master node, the startup timing in synchronization with the internally-generated baud rate counter

The conditions for setting and clearing of the CXP1nV1LW register are as follows:

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

Access

The table below lists the conditions for access to these bits and operations when accessed.

Table 30.15 CXP1nV1LCNT Bit Access Conditions

Access Conditions				Writing	Reading (Read Value)
CXP1nMODE			CXP1nFLW1. CXP1nCXMD		
CXP1nEN	CXP1nMD	CXP1nMS			
0_B	x_B	x_B	xx_B	Not possible	Initial value
1_B	0_B (CXPI-PWM)	0_B (Slave)	xx_B	Disabled	Setting value
		1_B (Master)	01_B (Bus Sleep)	Enabled	Setting value
			Other than above	Disabled	Setting value
	1_B (in CXPI-NRZ mode)	X_B	XX_B	Prohibited	Initial value

Note: "Writing not possible" means that writing is ignored.
"Writing disabled" is a limitation to specifications. Not guarded by hardware.

30.4.1.4 CXP1nV0LW — CXPI Logical Value 0 Setting Register

This register sets the low width (timing) of logical value 0 in CXPI-PWM mode.

Write access to this register is only enabled in bus sleep mode[*1]. It is disabled in other modes.

Note 1. CXP1nFLW1.CXP1nCXMD = 01_B

Writing to this register is prohibited in CXPI-NRZ mode.

Access: CXP1nV0LW register can be read or written in 32-bit units.
CXP1nV0LWL register can be read or written 16-bit units.
CXP1nV0LWLL, CXP1nV0LWLH registers can be read or written 8-bit units.

Address: CXP1nV0LW: <CXP1n_base> + $00C_H$
CXP1nV0LWL: <CXP1n_base> + $00C_H$
CXP1nV0LWLL: <CXP1n_base> + $00C_H$,
CXP1nV0LWLH: <CXP1n_base> + $00D_H$

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	CXP1nV0LCNT										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.16 CXP1nV0LW Register Contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10 to 0	CXP1nV0LCNT	Logical value 0 low width setting These bits set the low width of logical value 0 in CXPI-PWM mode. • When CXP1nMODE.CXP1nMD = 0_B (CXPI-PWM mode) The low width of logical value 0 is set by using the following equation: • Low width of logical value 0 = 1 / operating reference frequency (divclk) × CXP1nV0LCNT Range of allowable settings: 001_H to $7FF_H$ **NOTE:** Writing to these bits is prohibited in CXPI-NRZ mode.

CXP1nV0LCNT Bits

These bits set the low width of logical value 0 in CXPI-PWM mode.
The logical value 0 waveform of the CXPI communication bus is generated by this setting.

The table below lists the range of allowable settings.

Table 30.17 Allowable Settings of CXP1nV0LCNT

Macro Operating Frequency (PCLK)	Communication Baud Rate (CXPI Nominal Bit (Tbit) Frequency)	CXP1nPRS	CXP1nBRP	CXP1nV0LCNT*3	
				MIN*1	MAX*2
40 MHz	20 kbps	000_B	$7D0_H$	CXP1nV1LCNT + 078_H	758_H
	19.2 kbps	001_B	412_H	CXP1nV1LCNT + $03F_H$	$3D3_H$
	10.4 kbps	001_B	783_H	CXP1nV1LCNT + 074_H	$70F_H$
		010_B	502_H	CXP1nV1LCNT + $04D_H$	$4B5_H$
	9.6 kbps	010_B	$56D_H$	CXP1nV1LCNT + 054_H	519_H
		011_B	412_H	CXP1nV1LCNT + $03F_H$	$3D3_H$

Note 1. The setting range of MIN is determined by the following specified value:
Ttx_0_lo_dom: Ttx_1_lo_dom + 0.06 × CXPI nominal bit (Tbit) time
Ttx_0_lo_rec: Ttx_1_lo_rec + 0.06 × CXPI nominal bit (Tbit) time
Note that the MAX values are assumed for Ttx_1_lo_*** and the time constant for the entire system is not reflected in the specified value.

Note 2. MAX is calculated based on:
Range of allowable settings: CXPI nominal bit (Tbit) time – 0.06 × CXPI nominal bit (Tbit) time
Time when the condition that the receiving node is at a high level should be detected: 0.06 × CXPI nominal bit (Tbit) time

Note 3. In the master node, the startup timing in synchronization with the internally-generated baud rate counter.
In the slave node, the startup timing in synchronization with the sampling counter starting upon detection of the falling edge of the bus.
Make settings so that the condition CXP1nV1LCNT < CXP1nV0LCNT is satisfied.

The conditions for setting and clearing of the CXP1nV0LW register are as follows:

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

Access

The table below lists the conditions for access to these bits and operations when accessed.

Table 30.18 CXP1nV0LCNT Access Conditions

Access Conditions			Writing	Reading (Read Value)
CXP1nMODE		CXP1nFLW1. CXP1nCXMD		
CXP1nEN	CXP1nMD			
0_B	x_B	xx_B	Not possible	Initial value
1_B	0_B (CXPI-PWM)	01_B (Bus Sleep)	Enabled	Initial value
	1_B (in CXPI-NRZ mode)	XX_B	Prohibited	Initial value

Note: "Writing not possible" means that writing is ignored.
"Writing disabled" is a limitation to specifications. Not guarded by hardware.

30.4.1.5 CXP1nSAMP — CXPI Sampling Setting Register

This register sets the sampling timing in CXPI-PWM mode.

Write access to this register is only enabled in bus sleep mode[*1]. It is disabled in other modes.

Note 1. CXP1nFLW1.CXP1nCXMD = 01_B

Access: CXP1nSAMP register can be read or written in 32-bit units.
CXP1nSAMPL register can be read or written 16-bit units.
CXP1nSAMPLL, CXP1nSAMPLH registers can be read or written 8-bit units.

Address: CXP1nSAMP: <CXP1n_base> + 010_H
CXP1nSAMPL: <CXP1n_base> + 010_H
CXP1nSAMPLL: <CXP1n_base> + 010_H,
CXP1nSAMPLH: <CXP1n_base> + 011_H

Value after reset: 0000 0001_H

Table 30.19 CXP1nSAMP Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15	CXP1nSTYPE.	Sampling timing method setting This bit sets the sampling timing method in CXPI-PWM mode. 0: Offset sampling 1: Absolute position sampling **NOTE:** Writing to this bit is prohibited in CXPI-NRZ mode.
14 to 11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10 to 0	CXP1nSMP	Sampling timing setting These bits set the sampling timing in CXPI-PWM mode. Range of allowable settings: 001_H to $7FF_H$ **NOTE:** Writing to these bits is prohibited in CXPI-NRZ mode.

CXP1nSTYPE and CXP1nSMP Bits

This register sets the sampling method and sampling timing.

- When CXP1nMODE.CXP1nMD = 0_B (in CXPI-PWM mode)
  - When CXP1nSTYPE = 0 (offset sampling)
    Offset sampling starts from the rising edge of RX (logical value 1).[*1]
    Data is counted from the starting point at divclk and sampled at the timing specified by the CXP1nSMP bit.

Note 1. The starting point is always updated when receiving logical value 1.

– When CXP1nSTYPE = 1 (absolute position sampling)
In absolute position sampling, data is counted starting from the rising edge of RX at divclk and sampled at the timing specified by the CXP1nSMP bit.

- When CXP1nMODE.CXP1nMD = 1_B (in CXPI-NRZ mode)
Writing to this register is prohibited (limitation to specifications).

The table below lists the range of allowable settings.

Table 30.20 Allowable Settings of CXP1nSMP

CXP1nSTYPE	CXP1nSMP	
	MIN.	MAX.
0_B Offset sampling	001_H	(CXP1nV0LCNT - CXP1nV1LCNT) – 1
1_B Absolute position sampling	CXP1nV1LCNT + 1	CXP1nV0LCNT – 1

The conditions for setting and clearing of the CXP1nSAMP register are as follows:

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

Access (Common to the CXP1nSTYPE and CXP1nSMP Bits)

The table below lists the conditions for access to these bits and operations when accessed.

Table 30.21 CXP1nSMP Access Conditions

Access Conditions			Writing	Reading (Read Value)
CXP1nMODE		CXP1nFLW1. CXP1nCXMD		
CXP1nEN	CXP1nMD			
0_B	x_B	xx_B	Disabled	Initial value
1_B	0_B (CXPI-PWM)	01_B (Bus Sleep)	Enabled	Initial value
	1_B (in CXPI-NRZ mode)	XX_B	Prohibited	Initial value

30.4.1.6 CXP1nFIL — CXPI Input Filter Setting Register

This register sets the surge noise filter time.

Write access to this register is only enabled in bus sleep mode[*1]. It is disabled in other modes.

Note 1. CXP1nFLW1.CXP1nCXMD = 01_B

Writing to this register is prohibited in CXPI-NRZ mode.

Access: CXP1nFIL register can be read or written in 32-bit units.
CXP1nFILL register can be read or written 16-bit units.
CXP1nFILLL, CXP1nFILLH registers can be read or written 8-bit units.

Address: CXP1nFIL: <CXP1n_base> + 014_H
CXP1nFILL: <CXP1n_base> + 014_H
CXP1nFILLL: <CXP1n_base> + 014_H,
CXP1nFILLH: <CXP1n_base> + 015_H

Value after reset: 0000 0000_H

Table 30.22 CXP1nFIL Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8 to 0	CXP1nSURGE	Surge noise filter time setting Eliminate the surge not exceeding the filter time (up to 12.775 µs when PCLK = 40 MHz) in CXPI-PWM mode. 000_H: Surge filter OFF 001_H to $1FF_H$: Specifies a surge noise filter time. Setting range: 001_H to $1FF_H$ Surge noise filter time = CXP1nSURGE × PCLK **NOTE:** Writing to these bits is prohibited in CXPI-NRZ mode.

CXP1nSURGE Bits

These bits eliminate the surge not exceeding the filter time (up to 12.775 µs when PCLK = 40 MHz) in CXPI-PWM mode.

(1) Noise filter time isn't supposed to exceed PWM low width and high width.

(2) In the slave node, PWM low width becomes big by noise filter time.

The conditions for setting and clearing of the CXP1nFIL register are as follows:

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

Access

The table below lists the conditions for access to these bits and operations when accessed.

Table 30.23 CXP1nSURGE Access Conditions

Access Conditions			Writing	Reading (Read Value)
CXP1nMODE		CXP1nFLW1. CXP1nCXMD		
CXP1nEN	CXP1nMD			
0_B	x_B	xx_B	Not possible	Initial value
1_B	0_B (CXPI-PWM)	01_B (Bus Sleep)	Enabled	Setting value
		Other than above	Disabled	Setting value
	1_B (CXPI-NRZ)	xx_B	Disabled	Setting value

Note: "Writing disabled" is a limitation to specifications. Not guarded by hardware.
"Writing not possible" means that writing is ignored.

30.4.1.7 CXP1nWU — CXPI Wakeup Pulse Setting Register

This register sets the timing of the transmission wakeup pulse.

Write access to this register is only enabled in bus sleep mode[*1]. It is disabled in other modes.

Note 1. CXP1nFLW1.CXP1nCXMD = 01_B

Access: CXP1nWU register can be read or written in 32-bit units.
CXP1nWUL register can be read or written 16-bit units.
CXP1nWULL, CXP1nWULH registers can be read or written 8-bit units.

Address: CXP1nWU: <CXP1n_base> + 018_H
CXP1nWUL: <CXP1n_base> + 018_H
CXP1nWULL: <CXP1n_base> + 018_H,
CXP1nWULH: <CXP1n_base> + 019_H

Value after reset: 0000 0101_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Value after reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.24 CXP1nWU Register Contents

Bit Position	Bit Name	Function
31 to 12	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
11 to 8	CXP1nWTXDOM	Wakeup pulse transmission dominant setting The dominant level time of the wakeup pulse from a slave node is set by using the following equation: Wakeup pulse dominant level time = CXPI nominal bit (Tbit) time × CXP1nWTXDOM **NOTE:** Writing to these bits is prohibited for the master node because it cannot transmit a wakeup pulse.
7 to 0	CXP1nWTXREC	Wakeup pulse transmission recessive setting The recessive level time of the wakeup pulse from a slave node is set by using the following equation: Wakeup pulse recessive level interval = CXPI nominal bit (Tbit) time × CXP1nWTXREC **NOTE:** Writing to these bits is prohibited for the master node because it cannot transmit a wakeup pulse.

CXP1nWTXDOM and CXP1nWTXREC Bits

These bits set the dominant width and recessive width of the wakeup pulse.
For details, see **Section 30.5.4.10, Wakeup Pulse Transmission Operation**.

The range of settings is as follows depending on the specified values for wakeup pulse transmission.

Specified dominant width: Ttx_wakeup (min: 250 µs/max: 2500 µs)
Specified recessive width: Ttx_wakeup_space (min: 5 ms/max: 10 ms)

Table 30.25 Allowable Settings of CXP1nWU

CXPI Nominal Bit (Tbit) Frequency	Allowable Settings of CXP1nWTXDOM	Wakeup Pulse Dominant Width by Setting Value	Allowable Settings of CXP1nWTXREC	Wakeup Pulse Recessive Width by Setting Value
20 kbps	5_H to F_H	250 µs to 750 µs	64_H to $C8_H$	5 ms to 10 ms
19.2 kbps	5_H to F_H	260 µs to 781 µs	60_H to $C0_H$	5 ms to 10 ms
10.4 kbps	3_H to F_H	288 µs to 1442 µs	34_H to 68_H	5 ms to 10 ms
9.6 kbps	3_H to F_H	313 µs to 1563 µs	30_H to 60_H	5 ms to 10 ms

The conditions for setting and clearing of the CXP1nWU register are as follows:

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

Access

The table below lists the conditions for access to these bits and operations when accessed.

Table 30.26 CXP1nWU Access Conditions

Access Conditions			Writing	Reading (Read Value)
CXP1nMODE		CXP1nFLW1. CXP1nCXMD		
CXP1nEN	CXP1nMS			
0_B	x_B	xx_B	Not possible	Initial value
1_B	0_B (slave node)	01_B	Enabled	Setting value
		Other than above	Disabled	Setting value
	1_B (master node)	xx_B	Disabled	Setting value

Note: "Writing disabled" is a limitation to specifications. Not guarded by hardware.
"Writing not possible" means that writing is ignored.

30.4.1.8 CXP1nFRMW — CXP1 Inter-Frame Setting Register

This register sets the CXPI inter-frame timing.

Write access to this register is only enabled in bus sleep mode[*1]. It is disabled in other modes.

Note 1. CXP1nFLW1.CXP1nCXMD = 01_B

Access: CXP1nFRMW register can be read or written in 32-bit units.
CXP1nFRMWL register can be read or written 16-bit units.
CXP1nFRMWLL, CXP1nFRMWLH registers can be read or written 8-bit units.

Address: CXP1nFRMW: <CXP1n_base> + $01C_H$
CXP1nFRMWL: <CXP1n_base> + $01C_H$
CXP1nFRMWLL: <CXP1n_base> + $01C_H$,
CXP1nFRMWLH: <CXP1n_base> + $01D_H$

Value after reset: 0000 1422_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 30.27 CXP1nFRMW Register Contents

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
12 to 8	CXP1nIFS	IFS time setting Set the CXPI nominal bit (Tbit) time for the invalid period between transmission and reception. Setting range: 11_H to $1E_H$ (setting of any other value is prohibited) IFS time: (Value of CXP1nIFS + 1) × nominal bit (Tbit) time
7 to 4	CXP1nIBS2	Inter-transmission frame timing 2 setting Set the CXPI nominal bit (Tbit) time for the interval between response frames. CXPI-PWM mode setting range: 1_H to 9_H (setting of any other value is prohibited) CXPI-NRZ mode setting range: 1_H to 8_H (setting of any other value is prohibited) IBS time: Value of CXP1nIBS2 × nominal bit (Tbit) time
3 to 0	CXP1nIBS1	Inter-transmission frame timing 1 setting Set the CXPI nominal bit (Tbit) time for the interval between the PID frame and response frame transmission. CXPI-PWM mode setting range: 1_H to 9_H (setting of any other value is prohibited) CXPI-NRZ mode setting range: 1_H to 8_H (setting of any other value is prohibited) IBS time: Value of CXP1nIBS1 × nominal bit (Tbit) time

CXP1nIFS Bits

These bits set the invalid period between transmission and reception.

- CXP1nMODE.CXP1nMS = $0/1_B$ (common to the master node and the slave node)
  Sets the CXPI nominal bit (Tbit) time for the invalid period between transmission and reception.
  - Transmission and reception
    The IFS time is counted at the CXPI nominal bit (Tbit) time after CRC frame transmission and reception is completed, and it continues until the counter value matches the setting value of the CXP1nIFS bit + 1.
    The CXPI operation state transitions to the idle state after the IFS period has passed, enabling communications.

CXP1nIBS2 Bits

These bits set the CXPI nominal bit (Tbit) time for the IBS time between response frames.

- CXP1nMODE.CXP1nMS = $0/1_B$ (common to the master node and the slave node)
  - Transmission
    The IBS time is counted at the CXPI nominal bit (Tbit) time after detecting the stop bit of the UART frame, and the next transmission is started upon detection of a match with the setting of the CXP1nIBS2 bit.
  - Reception
    This function does not operate.

NOTE

A data length error occurs if the IBS lasts for 10 Tbits or longer.

CXP1nIBS1 Bits

These bits set the CXPI nominal bit (Tbit) time for the interval between the PID frame and response frame transmission.

- CXP1nMODE.CXP1nMS = $0/1_B$ (common to the master node and the slave node)
  Sets the CXPI nominal bit (Tbit) time for the interval between the PID frame and response frame transmission.
  - Transmission
    The IBS time is counted at the CXPI nominal bit (Tbit) time after detecting the stop bit of the UART frame, and the next transmission is started upon detection of a match with the setting of the CXP1nIBS1 bit.
  - Reception
    This function does not operate.

NOTE

A data length error occurs if the IBS lasts for 10 Tbits or longer.

The conditions for setting and clearing of the CXP1nFRMW register are as follows:

[HW setting condition]

- None

[HW clearing condition]

– CXP1nMODE.CXP1nEN = 0_B (forced reset)

Not allowed setting of 0_H.

30.4.1.9 CXP1nSLP — CXPI Sleep Setting Register

This register sets the time for transition to sleep mode.

Write access to this register is only enabled in bus sleep mode and slave node[*1]. It is disabled in other modes.

Note 1. CXP1nFLW1.CXP1nCXMD = 01_B & CXP1nMODE.CXP1nMS = 0_B

Access: CXP1nSLP register can be read or written in 32-bit units.
CXP1nSLPL register can be read or written 16-bit units.
CXP1nSLPLL, CXP1nSLPLH registers can be read or written 8-bit units.

Address: CXP1nSLP: <CXP1n_base> + 020_H
CXP1nSLPL: <CXP1n_base> + 020_H
CXP1nSLPLL: <CXP1n_base> + 020_H,
CXP1nSLPLH: <CXP1n_base> + 021_H

Value after reset: 0000 0001_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 30.28 CXP1nSLP Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9 to 0	CXP1nSLPWAIT	Sleep transition time setting Sleep transition time = CXP1nSLPWAIT × CXPI nominal bit (Tbit) time

CXP1nSLPWAIT Bits

These bits set the sleep transition time from the reception of the sleep frame.
For details, see **Section 30.5.4.9, Sleep Frame Reception Operation**.

- When CXP1nMODE.CXP1nMS = 0 (slave node)
  Counting starts after the sleep frame has been transmitted and proceeds at the CXPI nominal bit (Tbit) time. A sleep transition completion interrupt is generated when the counter value matches the setting value of the CXP1nSLPWAIT bit.

  Sleep transition time = CXP1nSLPWAIT × CXPI nominal bit (Tbit) time

The range of settings of these bits is as follows depending on the specified values of the sleep transition time.

Table 30.29 Allowable Settings of CXP1nSLPWAIT (in Slave Mode)

CXPI Nominal Bit (Tbit) Frequency	Allowable Settings of CXP1nSLPWAIT	Sleep Transition Completion Time by Setting Value
20 kbps	$1F4_H$ to $3E8_H$	25 ms to 50 ms
19.2 kbps	$1E0_H$ to $3C0_H$	25 ms to 50 ms
10.4 kbps	104_H to 208_H	25 ms to 50 ms
9.6 kbps	$0F0_H$ to $1E0_H$	25 ms to 50 ms

The conditions for setting and clearing of the CXP1nSLP register are as follows:

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.10 CXP1nREP — CXPI Retransmission Setting Register

This register sets the CXPI retransmission.

This register is only valid while CXP1nMODE.CXP1nREPOP = 1.

Access: CXP1nREP register can be read or written in 32-bit units.
CXP1nREPL register can be read or written 16-bit units.
CXP1nREPLL register can be read or written 8-bit units.

Address: CXP1nREP: <CXP1n_base> + 024_H
CXP1nREPL: <CXP1n_base> + 024_H
CXP1nREPLL: <CXP1n_base> + 024_H

Value after reset: 0000 $00FA_H$

Table 30.30 CXP1nREP Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7, 6	CXP1nAIREP	Loss-of-arbitration retransmission count setting 2 (CXP1nSND.CXP1nREPSEL = 10_B) Set the number of retransmissions when arbitration is lost. 00_B: No retransmission 01_B: One round of retransmission 10_B: Two rounds of retransmission 11_B: Unlimited
5, 4	CXP1nARREP	Loss-of-arbitration retransmission count setting 1 (CXP1nSND.CXP1nREPSEL = 01_B) Set the number of retransmissions when arbitration is lost. 00_B: No retransmission 01_B: One round of retransmission 10_B: Two rounds of retransmission 11_B: Unlimited
3, 2	CXP1nEIREP	Error retransmission count setting 2 (CXP1nSND.CXP1nREPSEL = 10_B) Set the number of retransmissions when an error is detected. 00_B: No retransmission 01_B: One round of retransmission 10_B: Two rounds of retransmission 11_B: Unlimited
1, 0	CXP1nERREP	Error retransmission count setting 1 (CXP1nSND.CXP1nREPSEL = 01_B) Set the number of retransmissions when an error is detected. 00_B: No retransmission 01_B: One round of retransmission 10_B: Two rounds of retransmission 11_B: Unlimited

CXP1nAIREP Bits

The setting value of these bits is reflected in the CXP1nFLG2.CXP1nAREP bit.
For details, see **Section 30.4.1.16, CXP1nFLG2 — CXPI Flag Register 2**.

CXP1nARREP Bits

The setting value of these bits is reflected in the CXP1nFLG2.CXP1nAREP bit.
For details, see **Section 30.4.1.16, CXP1nFLG2 — CXPI Flag Register 2**.

CXP1nEIREP Bits

The setting value of these bits is reflected in the CXP1nFLG2.CXP1nEREP bit.
For details, see **Section 30.4.1.16, CXP1nFLG2 — CXPI Flag Register 2**.

CXP1nEREP Bits

The setting value of these bits is reflected in the CXP1nFLG2.CXP1nEREP bit.
For details, see **Section 30.4.1.16, CXP1nFLG2 — CXPI Flag Register 2**.

The conditions for setting and clearing of the CXP1nREP register are as follows:

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.11 CXP1nWUP — CXPI Wakeup Control Register

This register sets the CXPI wakeup request.

Access: CXP1nWUP register can be read or written in 32-bit units.
CXP1nWUPL register can be read or written 16-bit units.
CXP1nWUPLL, CXP1nWUPLH registers can be read or written 8-bit units.

Address: CXP1nWUP: <CXP1n_base> + 028_H
CXP1nWUPL: <CXP1n_base> + 028_H
CXP1nWUPLL: <CXP1n_base> + 028_H,
CXP1nWUPLH: <CXP1n_base> + 029_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CXP1n STCLR	—	—	—	—	—	—	—	—	—	CXP1n WUP REQ	—	—	—	CXP1n CLK Off	CXP1n CLK On
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R/W	R/W

Table 30.31 CXP1nWUP Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15	CXP1nSTCLR	CXPI state clear request flag 0: — (Writing 0 is ignored) 1: CXPI state clear (simple reset) The read value is 0.
14 to 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	CXP1nWUPREQ	Wakeup pulse transmission request flag This bit issues a wakeup pulse transmission request in a slave node. 0: — (Writing 0 is ignored) 1: Wakeup pulse transmission The read value is 0.
4 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	CXP1nCLKOFF	CXPI clock stop request flag This bit issues a CXPI clock stop request or notification of non-detection of the CXPI clock. • In CXPI-PWM mode 0: — (Writing 0 is ignored) 1: CXPI clock output stop The read value is 0. • In CXPI-NRZ mode 0: — (Writing 0 is ignored) 1: Notification of non-detection of the CXPI clock requested The read value is 0.

Table 30.31 CXP1nWUP Register Contents (2/2)

Bit Position	Bit Name	Function
0	CXP1nCLKON	CXPI clock output request flag This bit issues a CXPI clock output or CXPI clock detection notification. • CXPI-PWM mode 0: — (Writing 0 is ignored) 1: CXPI clock output The read value is 0. • CXPI-NRZ mode 0: — (Writing 0 is ignored) 1: CXPI clock detection notification request The read value is 0.

CXP1nSTCLR Bit

Writing 1 to this bit issues a simple reset.
CXPI state clear (write 1 to CXP1nWUP.CXP1nSTCLR) is prohibited in offset sampling PWM mode (CXP1nSTYPE = 0_B and CXP1nMD = 1_B).
For details, see **Section 30.5.8.7, Software Reset**.

If the application found a physical bus error, a simple reset is issued to restore the communication when CXP1nSFRI.CXP1nSSLP = 0_B (sleep prohibited).

A simple reset initializes the following:

- CXPI transmission control register (CXP1nSND)
- CXPI flag register 2 (CXP1nFLG2)
- CXPI flow register 1 (CXP1nFLW1) (CXP1nFLW1.CXP1nCXMD is excluded)
- CXPI flow register 2 (CXP1nFLW2)

Access

The table below lists the conditions for access to this bit and operations when accessed.

Table 30.32 CXP1nSTCLR Bit Access Conditions

Access Conditions			
CXP1nMODE		CXP1nSFRI. CXP1nSSLP	Writing of 1
CXP1nEN	CXP1nMS		
0_B	x_B	x_B	Not possible
1_B	0_B	x_B	Disabled
	1_B	0_B	Enabled
		1_B	Disabled

Note: "Writing not possible" means that writing is ignored.
"Writing disabled" is a limitation to specifications. (Not guarded by hardware.)
The read value is always 0.

CXP1nWUPREQ Bit

This bit issues a wakeup pulse transmission request in a slave node.
When 1 is written to this bit, the CXPI transmits a wakeup pulse and enters send wakeup mode.
For details, see **Section 30.5.4.10, Wakeup Pulse Transmission Operation**.

Access

The table below lists the conditions for access to this bit and operations when accessed.

Table 30.33 CXP1nWUPREQ Bit Access Conditions

Access Condition			
CXP1nMODE		CXP1nFLG1. CXP1nCLKDET	Writing of 1
CXP1nEN	CXP1nMS		
0_B	x_B	x_B	Not possible
1_B	0_B Slave	0_B CXPI clock not detected	Enabled
		1_B CXPI clock detected	Not possible
	1_B Master	x_B	Disable

CXP1nCLKOFF bit

Writing 1 to this bit stops the CXPI clock (CXPI-PWM mode), or issues a notification of non-detection of the CXPI clock (CXPI-NRZ mode).

1. CXP1nMODE.CXP1nMD = 0_B (CXPI-PWM mode)

- CXP1nMODE.CXP1nMS = 1_B (master node)
  Writing 1 to this bit stops the CXPI clock output.
  The CXPI enters bus sleep mode after detecting that the CXPI clock has been stopped (CXP1nFLG1.CXP1nCLKDET = 0_B).
  - CXPI clock stop timing
    When the transmission pin level is low: The CXPI clock is stopped after a low level has been output.
    When the transmission pin level is high: The CXPI clock is stopped immediately.
- CXP1nMODE.CXP1nMS = 0_B (slave node)
  Writing to this bit is prohibited (limitation to specifications).

2. CXP1nMODE.CXP1nMD =1_B (CXPI-NRZ mode)

- CXP1nMODE.CXP1nMS = 1_B (master node) / When CXP1nMODE.CXP1nMS = 0_B (slave node)
  Writing 1 to this bit transitions the CXPI to bus sleep mode.

Access

The table below lists the conditions for access to this bit and operations when accessed.

Table 30.34 CXP1nCLKOFF Bit Access Conditions (1/2)

Access Conditions					
CXP1nMODE			CXP1nFLW1.		
CXP1nEN	CXP1nMD	CXP1nMS	CXP1nCXMD	CXP1nCXST	Writing of 1
0_B	x_B	x_B	xx_B	xxx_B	Not possible

Table 30.34 CXP1nCLKOFF Bit Access Conditions (2/2)

Access Conditions					
CXP1nMODE			CXP1nFLW1.		
CXP1nEN	CXP1nMD	CXP1nMS	CXP1nCXMD	CXP1nCXST	Writing of 1
1_B	0_B (CXPI-PWM)	0_B Slave	xx_B	xxx_B	Disabled
		1_B Master	11_B Normal	010_B Transmission/ reception stopped (IDLE)	Enabled
				Other than above	Disabled
			Other than above	xxx_B	Disabled
	1_B (CXPI-NRZ)	$0_B/1_B$ Slave/Master	11_B Normal	010_B Transmission/ reception stopped (IDLE)	Enabled
				Other than above	Disabled
			Other than above	xxx_B	Disabled

Note: "Writing not possible" means that writing is ignored.
"Writing disabled" is a limitation to specifications. Not guarded by hardware.
The read value is 0.

CXP1nCLKON Bit

Writing 1 to this bit in bus sleep mode outputs the CXPI clock (CXPI-PWM mode), or issues a notification of detection of the CXPI clock (CXPI-NRZ mode).

1. CXP1nMODE.CXP1nMD = 0_B (CXPI-PWM mode)

- When CXP1nMODE.CXP1nMS = 1_B (master node)
  Writing 1 to this bit outputs the CXPI clock.
  The CXPI enters normal mode after detecting the CXPI clock.
- When CXP1nMODE.CXP1nMS = 0_B (slave node)
  Writing to this bit is disabled.

2. CXP1nMODE.CXP1nMD = 1_B (CXPI-NRZ mode)

- When CXP1nMODE.CXP1nMS = 1_B (master node) or CXP1nMODE.CXP1nMS = 0_B (slave node)
  Writing 1 to this bit leads to transition to normal mode.

NOTE

Setting of the CXP1nCLKON and CXP1nCLKOFF bits should be mutually exclusive.
If 1_B is set in both bits at the same time, writing to these bits is ignored and the output request is not issued.

Access

The table below lists the conditions for access to this bit and operations when accessed.

Table 30.35 CXP1nCLKON Bit Access Conditions

Access Conditions					
CXP1nMODE			CXP1nFLW1. CXP1nCXMD	CXP1nCLKOFF. Write Value	Writing of 1
CXP1nEN	CXP1nMD	CXP1nMS			
0_B	x_B	x_B	xx_B	x_B	Not possible
1_B	0_B (CXPI-PWM)	0_B Slave	xx_B	x_B	Disabled
		1_B Master	01_B Bus Sleep	0_B	Enabled
				1_B	Not possible
			Other than above	x_B	Not possible
1_B	1_B (CXPI-NRZ)	$0_B/1_B$ Slave/Master	11_B Normal	0_B	Enabled
				1_B	Not possible
			Other than above	x_B	Disabled

Note: "Writing not possible" means that writing is ignored.
"Writing disabled" is a limitation to specifications. Not guarded by hardware.
The read value is always 0.

30.4.1.12 CXP1nSND — CXPI Transmission Control Register

This register sets the CXPI transmission request.

Access: CXP1nSND register can be read or written in 32-bit units.
CXP1nSNDL register can be read or written 16-bit units.
CXP1nSNDLL register can be read or written 8-bit units.

Address: CXP1nSND: <CXP1n_base> + $02C_H$
CXP1nSNDL: <CXP1n_base> + $02C_H$
CXP1nSNDLL: <CXP1n_base> + $02C_H$

Value after reset: $0000\ 0000_H$

Table 30.36 CXP1nSND Register Contents

Bit Position	Bit Name	Function
31 to 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5, 4	CXP1nREPSEL	Retransmission setting flag Specify the setting for retransmission when PID transmission or frame transmission is requested. 00_B: No retransmission 01_B: Setting 1 10_B: Setting 2 11_B: Setting prohibited
3	CXP1nSPTREQ	PTYPE transmission request flag Requests transmission of PTYPE in polling mode. 0: No PTYPE transmission request (transmission canceled) 1: PTYPE transmission requested
2	CXP1nSRSREQ	Response transmission request flag 0: — (Writing 0 is ignored) 1: Response transmission requested The read value is 0.
1	CXP1nSFRREQ	Frame transmission request flag Requests frame transmission. 0: No frame transmission request (transmission canceled) 1: Frame transmission requested
0	CXP1nSIDREQ	PID transmission request Requests PID transmission. 0: No PID transmission request (transmission canceled) 1: PID transmission requested

CXP1nREPSEL Bit

These bits specify the setting for retransmission when PID transmission or frame transmission is requested.
These bits are only valid while the CXP1nMODE.CXP1nREPOP bit is set to 1_B.

[HW setting condition]

- None

[HW clearing conditions]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)
- A fatal error occurred.
- CXP1nWUP.CXP1nSTCLR = 1_B

CXP1nSPTREQ Bit

Requests transmission of PTYPE in polling mode.

Writing 1 to this bit triggers the CXPI to transmit PTYPE when the following condition is satisfied. (This bit is cleared at the start of transmission.)

1. CXP1nMODE.CXP1nACC = 1_B (polling mode)

- CXP1nMODE.CXP1nMS = 1_B (master node)
  The PTYPE transmission can be canceled by writing 0 to this bit when the condition is not satisfied.

  After PTYPE has been transmitted, the CXPI enters the state of waiting for setting response judgment/response data (CXP1nFLW1.CXP1nCXST = 100_B).

[HW setting condition]

- None

[HW clearing conditions]

- PTYPE transmission is started.
- CXP1nMODE.CXP1nEN = 0_B (forced reset)
- A fatal error occurred.
- CXP1nWUP.CXP1nSTCLR = 1_B (simple reset)

The table below lists the data transmitted in PTYPE transmission.

Table 30.37 Configuration of PTYPE

Parity Bit	Frame TYPE
1 bit (odd parity bit) Fixed to 1_B	7 bits (fixed to 00_H)

2. Mode other than above

Writing to this bit is disabled. Writing to this bit is ignored.

Access

The table below lists the conditions for access to this bit and operations when accessed.

Table 30.38 CXP1nSPTREQ Access Conditions

Access Conditions			Writing	Reading (Read Value)
CXP1nMODE				
CXP1nEN	CXP1nACC	CXP1nMS		
0_B	x_B	x_B	Not possible	Initial value
1_B	0_B Event trigger	x_B	Not possible	Initial value
	1_B Polling	1_B Master	Enabled*1	State
		0_B Slave	Not possible	Initial value

Note 1. For control, see **Section 30.6.2.4, Restriction of Transmission Request**.

CXP1nSRSREQ bit

This bit initiates data transmission of the response field when the received PID is judged to be a response.

When 1_B is written to this bit while CXP1nFLW1.CXST = 100_B (state of waiting for setting response judgment/response data), the CXPI transmits data in the response field.

Data transmission is not performed if 1 is written to this bit while CXP1nFLW1.CXST is not 100_B.

Table 30.39 Data for Response of a Normal Frame

Frame Information CXP1nSFRI	Frame Information (Extension DLC) CXP1nSFRI	Data CXP1nSDATAm	CRC CXP1nSCRC
1 byte	—	0 to 12 bytes	1 byte

Table 30.40 Data for Response of a Long Frame

Frame Information CXP1nSFRI	Frame Information (Extension DLC) CXP1nSFRI	Data CXP1nSDATAm*1	CRC CXP1nSCRC
1 byte	1 byte	0 to 255 bytes (Extension DLC)	2 bytes

Note 1. Transfer proceeds while updating the data for transmission in units of 8 bytes by using the transmission data setting request interrupt.

CXP1nSFRREQ Bit

When 1 is written to this bit, the CXPI performs data transmission*2 when the following conditions are satisfied.

Note 2. For details, see **Section 30.5.7.1, Transmission**.

1. CXP1nMODE.CXP1nACC = 0_B (event trigger method)

- When CXP1nMODE.CXP1nMS = 1_B (master node) or CXP1nMODE.CXP1nMS = 0_B (slave node)
  - CXP1nFLW1.CXP1nCXST = 010_B (transmission/reception stopped (IDLE))

2. CXP1nMODE.CXP1nACC = 1_B (polling method)

- When CXP1nMODE.CXP1nMS = 1_B (master node)

– CXP1nFLW1.CXP1nCXST = 010_B (transmission/reception stopped (IDLE))

- When CXP1nMODE.CXP1nMS = 0_B (slave node)
  – CXP1nFLW1.CXP1nSPIDEN = 1_B (slave transmit allowed) and CXP1nFLW1.CXP1nCXST = 010_B (transmission/reception stopped (IDLE))

Data for Transmission

Table 30.41 Frame Structure of a Normal Frame

PID Field CXP1nSPID	Frame Information CXP1nSFRI	Data CXP1nSDATAm	CRC CXP1nSCRC
1 byte	1 byte	0 to 12 bytes	1 byte

Table 30.42 Frame Structure of a Long Frame

PID Field CXP1nSPID	Frame Information CXP1nSFRI	Frame Information (Extension DLC) CXP1nSFRI	Data CXP1nSDATAm*1	CRC CXP1nSCRC
1 byte	1 byte	1 byte	0 to 255 bytes	2 bytes

Note 1. Transfer proceeds while updating the data for transmission in units of 8 bytes by using the transmission data setting request interrupt.

Transmission is canceled by writing 0 to this bit.
The conditions for cancellation are as follows:

- When CXP1nMODE.CXP1nREPOP = 0_B (no automatic retransmission judgment)
  Transmission can be canceled before transmission starts.
  Retransmission can be canceled during transmission.
- When CXP1nMODE.CXP1nREPOP = 1_B (automatic retransmission judged)
  Transmission can be canceled before transmission starts.

[HW setting condition]

- None

[HW clearing conditions]

- A fatal error occurred.
- Transmission started (CXP1nMODE.CXP1nREPOP = 1 (automatic retransmission judged))
- Normal transmission has completed (CXP1nMODE.CXP1nREPOP = 0 (no automatic retransmission judgment))
- CXP1nWUP.CXP1nSTCLR = 1_B
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

Access

The table below lists the conditions for access to this bit and operations when accessed.

Table 30.43 CXP1nSFRREQ Bit Access Conditions

Access Conditions				Writing	Reading (Read Value)
		CXP1nSND			
CXP1nMODE.CXP1nEN	CXP1nFLG1.CXP1nFAIL	CXP1nSPTREQ Write Value	CXP1nSIDREQ Write Value		
0_B	x_B	x_B	x_B	Not possible	Initial value
1_B	0_B	0_B	0_B	Enabled*1	State
			1_B	Not possible	Initial value
		1_B	x_B	Not possible	Initial value
	1_B	x_B	x_B	Not possible	Initial value

Note 1. For control, see **Section 30.6.2.4, Restriction of Transmission Request**.

CXP1nSIDREQ Bit

When 1 is written to this bit, the CXPI performs data transmission when the following conditions are satisfied.

1. CXP1nMODE.CXP1nACC = 0_B (event trigger method)

- When CXP1nMODE.CXP1nMS = 1_B (master node) or CXP1nMODE.CXP1nMS = 0_B (slave node)
  - CXP1nFLW1.CXP1nCXST = 010_B (transmission/reception stopped (IDLE))

2. CXP1nMODE.CXP1nACC = 1_B (polling method)

- CXP1nMODE.CXP1nMS = 1_B (master node)
  - CXP1nFLW1.CXP1nCXST = 010_B (transmission/reception stopped (IDLE))
- CXP1nMODE.CXP1nMS = 0_B (slave node)
  - CXP1nFLW1.CXP1nSPIDEN = 1_B (slave transmit allowed) and CXP1nFLW1.CXP1nCXST = 010_B (transmission/reception stopped (IDLE))

Data for transmission

Table 30.44 PID Field

PID Field CXP1nSPID
1 byte

Transmission is canceled by writing 0 to this bit.
The conditions for cancellation are as follows:

- When CXP1nMODE.CXP1nREPOP = 0_B (no automatic retransmission judgment)
  - Transmission can be canceled before transmission starts.
  - Retransmission can be canceled during transmission.
- When CXP1nMODE.CXP1nREPOP = 1_B (automatic retransmission judged)
  - Transmission can be canceled before transmission starts.

[HW setting condition]

- None

[HW clearing conditions]

- A fatal error occurred.
- Transmission started (CXP1nMODE.CXP1nREPOP = 1_B (automatic retransmission judged))
- Normal transmission has completed (CXP1nMODE.CXP1nREPOP = 0_B (no automatic retransmission judgment))
- CXP1nWUP.CXP1nSTCLR = 1_B
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

Access

The table below lists the conditions for access to this bit and operations when accessed.

Table 30.45 CXP1nSIDREQ Bit Access Conditions

Access Conditions			Writing	Reading (Read Value)
		CXP1nSND		
CXP1nMODE.CXP1nEN	CXP1nFLG1.CXP1nFAIL	CXP1nSPTREQ. Write Value		
0_B	x_B	x_B	Not possible	Initial value
1_B	0_B	0_B	Enabled*1	State
		1_B	Not possible	Initial value
	1_B	x_B	Not possible	Initial value

Note 1. For control, see **Section 30.6.2.4, Restriction of Transmission Request**.

30.4.1.13 CXP1nIMSK — CXPI Interrupt Mask Register

This register sets masking of the CXPI interrupt. It masks the interrupt request to the CPU.

Interrupt sources are reflected in the CXP1nINT register even if interrupts are masked in this register.

Access: CXP1nIMSK register can be read or written in 32-bit units.
CXP1nIMSKL register can be read or written 16-bit units.
CXP1nIMSKLL, CXP1nIMSKLH registers can be read or written 8-bit units.

Address: CXP1nIMSK: <CXP1n_base> + 030_H
CXP1nIMSKL: <CXP1n_base> + 030_H
CXP1nIMSKLL: <CXP1n_base> + 030_H,
CXP1nIMSKLH: <CXP1n_base> + 031_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 30.46 CXP1nIMSK Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15	CXP1nERRMSK	Error detection interrupt mask setting 0: Enables interrupts 1: Disables interrupts
14	CXP1nSLPMSK	Sleep transition completion interrupt mask setting 0: Enables interrupts 1: Disables interrupts
13	CXP1nREXMSK	PTYPE transmission completion interrupt mask setting 0: Enables interrupts 1: Disables interrupts
12	CXP1nRFQMSK	Received data save request interrupt mask setting 0: Enables interrupts 1: Disables interrupts
11	CXP1nRPTMSK	PTYPE reception completion interrupt mask setting 0: Enables interrupts 1: Disables interrupts
10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	CXP1nRFRMSK	Frame reception completion interrupt mask setting 0: Enables interrupts 1: Disables interrupts
8	CXP1nRIDMSK	PID reception completion interrupt mask setting 0: Enables interrupts 1: Disables interrupts
7 to 5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 30.46 CXP1nIMSK Register Contents (2/2)

Bit Position	Bit Name	Function
4	CXP1nSFQMSK	Transmission data setting request interrupt mask setting 0: Enables interrupts 1: Disables interrupts
3	CXP1nSPTMSK	PTYPE transmission completion interrupt mask setting 0: Enables interrupts 1: Disables interrupts
2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	CXP1nSFRMSK	Frame transmission completion interrupt mask setting 0: Enables interrupts 1: Disables interrupts
0	CXP1nSIDMSK	PID transmission completion interrupt mask setting 0: Enables interrupts 1: Disables interrupts

For details on the CXP1nIMSK register, see **Section 30.5.9, Interrupts**.

The conditions for setting and clearing of the CXP1nIMSK register are as follows:

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.14 CXP1nINT — CXPI Interrupt Source Register

This is a status register that indicates interrupt sources.

Access: CXP1nINT register can be read or written in 32-bit units.
CXP1nINTL register can be read or written 16-bit units.
CXP1nINTLL, CXP1nINTLH registers can be read or written 8-bit units.

Address: CXP1nINT: <CXP1n_base> + 034_H
CXP1nINTL: <CXP1n_base> + 034_H
CXP1nINTLL: <CXP1n_base> + 034_H,
CXP1nINTLH: <CXP1n_base> + 035_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 30.47 CXP1nINT Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15	CXP1nERRINT	Error detection interrupt source flag Indicates that an error detection interrupt request was generated. 0: No interrupt source 1: Interrupt source generated
14	CXP1nSLPINT	Sleep transition completion interrupt source flag Indicates that a sleep transition completion interrupt request was generated. 0: No interrupt source 1: Interrupt source generated
13	CXP1nREXINT	PTYPE valid period completion interrupt source flag Indicates that a PTYPE valid period completion interrupt request was generated. 0: No interrupt source 1: Interrupt source generated
12	CXP1nRFQINT	Received data save request interrupt source flag Indicates that a received data save request interrupt request was generated. 0: No interrupt source 1: Interrupt source generated
11	CXP1nRPTINT	PTYPE reception completion interrupt source flag Indicates that a PTYPE reception completion interrupt request was generated. 0: No interrupt source 1: Interrupt source generated
10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	CXP1nRFRINT	Frame reception completion interrupt source flag Indicates that a frame reception completion interrupt request was generated. 0: No interrupt source 1: Interrupt source generated

Table 30.47 CXP1nINT Register Contents (2/2)

Bit Position	Bit Name	Function
8	CXP1nRIDINT	PID reception completion interrupt source flag Indicates that a PID reception completion interrupt request was generated. 0: No interrupt source 1: Interrupt source generated
7 to 5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4	CXP1nSFQINT	Transmission data setting request interrupt source flag Indicates that a transmission data setting request interrupt request was generated. 0: No interrupt source 1: Interrupt source generated
3	CXP1nSPTINT	PTYPE transmission completion interrupt source flag Indicates that a PTYPE transmission completion interrupt request was generated. 0: No interrupt source 1: Interrupt source generated
2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	CXP1nSFRINT	Frame transmission completion interrupt source flag Indicates that a frame transmission completion interrupt request was generated. 0: No interrupt source 1: Interrupt source generated
0	CXP1nSIDINT	PID transmission completion interrupt source flag Indicates that a PID transmission completion interrupt request was generated. 0: No interrupt source 1: Interrupt source is generated

CXP1nERRINT Bit

This bit indicates whether or not an error interrupt is generated.
For details, see **Section 30.5.9.3(1), Error Detection**.

[HW setting conditions]

An error occurred (One of CXP1nERR[7:0] is 1).
A fatal error occurred (CXP1nFTERR = 1_B).
A state error occurred (CXP1nSTERR = 1_B).

[HW clearing conditions]

The error register was cleared (CXP1nERR[7:0] = 00_H).
CXP1nMODE.CXP1nEN = 0_B (forced reset)

The CXP1nSLPINT Bit

This bit indicates whether or not a sleep transition completion interrupt is generated. Process flow should be such that it is cleared by software when interrupt occurs.
For details, see **Section 30.5.9.3(2), Sleep Transition Completion**.

- When CXP1nMODE.CXP1nMS = 0_B (slave node)

[HW setting condition]

- The sleep transition time[*1] has passed after a sleep frame has been received.

Note 1. Sleep transition time = CXP1nSLPWAIT × CXPI nominal bit (Tbit) time

[HW clearing conditions]

- The CXPI makes the transition from bus sleep mode to normal mode (Other than Send Wakeup mode to Normal mode)
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nREXINT Bit

This bit indicates that the PTYPE valid period has passed.
For details, see **Section 30.5.9.2(5), PTYPE Valid Period Completion**.

1. When CXP1nMODE.CXP1nACC = 0_B (event trigger mode)
   This interrupt is not generated.
2. When CXP1nMODE.CXP1nACC = 1_B (polling mode)

- When CXP1nMODE.CXP1nMS = 1_B (master node)

[HW setting condition]

- PID reception has been accepted in response to PTYPE transmission.

[HW clearing conditions]

- PTYPE transmission is completed.
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

- When CXP1nMODE.CXP1nMS = 0_B (slave node)

[HW setting condition]

- PID transmission/reception has been accepted in response to PTYPE reception.

[HW clearing conditions]

- PTYPE reception is completed.
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nRFQINT Bit

This bit indicates whether or not a received data save request interrupt is generated.
For details, see **Section 30.5.9.2(3), Received Data Save Request**.

- When CXP1nMODE.CXP1nMS = 1_B (master node) or CXP1nMODE.CXP1nMS = 0_B (slave node)

[HW setting condition]

- Eight bytes of data have been received in a long frame.

[HW clearing conditions]

- The CXPI started to transmit PID, or received PID.
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nRPTINT Bit

This bit indicates whether or not a PTYPE reception completion interrupt is generated.
For details, see **Section 30.5.9.2(1), PTYPE Reception Completion**.

1. When CXP1nMODE.CXP1nACC = 0_B (event trigger mode)
   This interrupt is not generated.
2. When CXP1nMODE.CXP1nACC = 1_B (polling mode)

- When CXP1nMODE.CXP1nMS = 1_B (master node)
  This interrupt is not generated.
- When CXP1nMODE.CXP1nMS = 0_B (slave node)

[HW setting condition]

- PTYPE reception is completed.

[HW clearing conditions]

- The CXPI started to receive the PID.
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nRFRINT Bit

This bit indicates whether or not a frame reception completion interrupt is generated.
For details, see **Section 30.5.9.2(4), Frame Reception Completion**.

- When CXP1nMODE.CXP1nMS = 1_B (master node) or CXP1nMODE.CXP1nMS = 0_B (slave node)

[HW setting condition]

- A frame has been received.

[HW clearing conditions]

- The CXPI started to transmit PID, or received PID.
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nRIDINT Bit

This bit indicates whether or not a PID reception completion interrupt is generated.
For details, see **Section 30.5.9.2(2), PID Reception Completion**.

- When CXP1nMODE.CXP1nMS = 1_B (master node) or CXP1nMODE.CXP1nMS = 0_B (slave node)

[HW setting condition]

- PID has been received.

[HW clearing conditions]

- The CXPI started to receive the ID.
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nSFQINT Bit

This bit indicates whether or not a transmission data setting request interrupt is generated.
For details, see **Section 30.5.9.1(3), Transmission Data Setting Request**.

- When CXP1nMODE.CXP1nMS = 1_B (master node) or CXP1nMODE.CXP1nMS = 0_B (slave node)

[HW setting condition]

- Eight bytes of data have been transmitted in a long frame.

[HW clearing conditions]

- The CXPI started to transmit PID, or received PID.
  CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nSPTINT Bit

This bit indicates whether or not a PTYPE transmission completion interrupt is generated.
For details, see **Section 30.5.9.1(1), PTYPE Transmission Completion**.

1. When CXP1nMODE.CXP1nACC = 1_B (polling mode)

- When CXP1nMODE.CXP1nMS = 1_B (master node)

[HW setting condition]

- PTYPE transmission is completed.

[HW clearing conditions]

- PTYPE transmission is started.
  CXP1nMODE.CXP1nEN = 0_B (forced reset)

- When CXP1nMODE.CXP1nMS = 0_B (slave node)
  This interrupt is not generated.

2. When CXP1nMODE.CXP1nACC = 0_B (event trigger mode)
   This interrupt is not generated.

CXP1nSFRINT Bit

This bit indicates whether or not a frame transmission completion interrupt is generated.
For details, see **Section 30.5.9.1(4), Frame Transmission Completion**.

- When CXP1nMODE.CXP1nMS = 1_B (master node) or CXP1nMODE.CXP1nMS = 0_B (slave node)

[HW setting conditions]

- Frame transmission is completed.

[HW clearing condition]

- The CXPI started to transmit PID
- PID received PID (CXP1nINT.CXP1nRIDINT=1_B & CXP1nFLW1.CXP1nCXST=110_B).
  However, exclude cases where received PID does not match tag.
  However, excluding the case of automatic response target.
- CXP1nMODE.CXP1nEN = 0_B (forced reset).

CXP1nSIDINT Bit

This bit indicates whether or not a PID transmission completion interrupt is generated.
For details, see **Section 30.5.9.1(2), PID Transmission Completion**.

- When CXP1nMODE.CXP1nMS = 1_B (master node) or CXP1nMODE.CXP1nMS = 0_B (slave node)

[HW setting condition]

- CXP1nFLW1.CXP1nCXST = 101_B (PID transmission) and reception is completed.
- The transmitted data and received data match in PID transmission loopback.

NOTE

This bit is not set if a bit error or framing error occurs. The PID includes a sleep frame.

[HW clearing conditions]

- PID transmission is started.
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.15 CXP1nFLG1 — CXPI Flag Register 1

This register is a status register that indicates the state of the CXPI.

Access: CXP1nFLG1 register can be read or written in 32-bit units.
CXP1nFLG1L register can be read or written 16-bit units.
CXP1nFLG1LL register can be read or written 8-bit units.

Address: CXP1nFLG1: <CXP1n_base> + 038_H
CXP1nFLG1L: <CXP1n_base> + 038_H
CXP1nFLG1LL: <CXP1n_base> + 038_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 30.48 CXP1nFLG1 Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7	CXP1nFAIL	Failure management flag 0: Normal state 1: Transmission prohibited
6	CXP1nFTERR	Fatal error status 0: No error 1: An error occurred
5	CXP1nSTERR	State error status 0: No error 1: An error occurred
4, 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	CXP1nRFTFID	Frame TYPE/frame ID reception flag 0: Not received 1: Received
1	CXP1nCLKDET	CXPI clock detection status 0: CXPI clock not detected 1: CXPI clock detected
0	CXP1nEXREQ	External request flag 0: Internal request transfer 1: External request transfer Only 0 can be written to this bit. Writing 1 to this bit is ignored.

CXP1nFAIL Bit

Writing 0 to this bit clears the CXP1nERR.CXP1nERRCNT bit at the same time.

Writing 1 to this bit prohibits writing to CXP1nSND.CXP1nSIDREQ (PID transmission request) and CXP1nSND.CXP1nSFRREQ (frame transmission request) and CXP1nSND.CXP1nSPTREQ (PTYPE transmission request) and CXP1nSND.CXP1nSRSREQ (response request) to prohibit transmission requests.
For details, see **Section 30.5.7.6, Failure Management Function**.

- When CXP1nMODE.CXP1nMS = 1_B (master node)

[HW setting condition]

- An error[*1] is detected when CXP1nERR.CXP1nERRCNT > $F7_H$.

[HW clearing conditions]

- CXPI clock is detected (CXP1nFLG1.CXP1nCLKDET is set) when CXP1nFLW1.CXP1nCXMD = 01 (Bus Sleep mode)
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

- When CXP1nMODE.CXP1nMS = 0_B (slave node)

[HW setting condition]

- An error[*1] is detected when CXP1nERR.CXP1nERRCNT > $F7_H$.

[HW clearing conditions]

- 1 is written to CXP1nWUP.CXP1nWUPREQ (Wakeup pulse transmission request flag)
- The CXPI clock is detected when CXP1nFLW1.CXP1nCXMD = 01_B (bus sleep).

Note 1. The following errors apply:
CXP1nERR.CXP1nBITERR (bit error)
CXP1nDLNERR (data length error)
CXP1nFRMERR (framing error)

CXP1nFTERR Bit

This bit indicates whether or not a fatal error occurred.
A fatal error is caused by a mechanical breakdown.
For details, see **Section 30.5.7.4(10), Fatal Error (Not Defined in CXPI Specifications)**.

[HW setting condition]

- A mechanical breakdown occurred.

[HW clearing conditions]

- Transmission is started. (PID or Frame or Sleep or PTYPE) (including retransmission).
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nSTERR Bit

This bit indicates whether or not a state error occurred.
For details, see **Section 30.5.7.4(9), State Error (Not Defined in CXPI Specifications)**.

1. When CXP1nMODE.CXP1nACC = 0_B (event trigger mode)

- PTYPE is detected.

2. When CXP1nMODE.CXP1nMS = 1_B (master node)

- PTYPE is detected.

3. When CXP1nMODE.CXP1nACC = 1_B (polling mode) and CXP1nMODE.CXP1nMS = 0_B (slave node)

- When the IP in a slave node starts PID transmission because it receives a PTYPE field in polling mode, it receives the PTYPE field again and loses an arbitration.

[HW clearing conditions]

- Transmission is started. (PID or Frame or Sleep or PTYPE) (including retransmission)
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nRFTFID Bit

This bit is a status bit indicating whether or not the frame TYPE/frame ID has been received.
The frame TYPE/frame ID is judged to have been received even if a parity error occurs.
For details, see **Section 30.5.8.8, Status**.

[HW setting condition]

- Frame TYPE or frame ID is received (Send loop-back is included)

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nCLKDET Bit

This bit indicates whether or not the clock has been detected.

1. When CXP1nMODE.CXP1nMD = 0_B (CXPI-PWM mode)

- When CXP1nMODE.CXP1nMS = 1_B (master node) or CXP1nMODE.CXP1nMS = 0_B (slave node)

[HW setting condition]

- The CXPI clock was detected.
  After detecting a wakeup pulse, the CXPI detects the CXPI clock when detecting the rising edge four or five times on the receive pin.
  However, it initializes the falling edge counter if the CXPI nominal bit (Tbit) frequency is slower than the frequency set by CXP1nBRT.

[HW clearing conditions]

- The CXPI clock was not detected.
  If the CXPI nominal bit (Tbit) frequency is slower than the frequency set by CXP1nBRT, the CXPI clock is determined not to have been detected.
- CXP1nMODE.CXP1nEN = 0_B (forced reset)
- Bus sleep mode transition is completed (transition by a sleep frame).

2. When CXP1nMODE.CXP1nMD = 1_B (CXPI-NRZ mode)

- When CXP1nMODE.CXP1nMS = 1_B (master node) or CXP1nMODE.CXP1nMS = 0_B (slave node)

[HW setting condition]

- CXP1nWUP.CXP1nCLKON = 1_B is written.

[HW clearing conditions]

- CXP1nWUP.CXP1nCLKOFF = 1_B is written.
- Bus sleep mode transition is completed (transition by a sleep frame).
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nEXREQ Bit

This bit indicates an external request or internal request.

- When CXP1nMODE.CXP1nMS = 1_B (master node) or CXP1nMODE.CXP1nMS = 0_B (slave node)

[HW setting condition]

- An externally requested transfer is completed. (termination by error is included)

[HW clearing conditions]

- An internally requested transmission is started. (PID or Frame or Sleep or PTYPE) (including retransmission)
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.16 CXP1nFLG2 — CXPI Flag Register 2

This register is a status register that indicates the status of the CXPI.

Access: CXP1nFLG2 register can be read or written in 32-bit units.
CXP1nFLG2L register can be read or written 16-bit units.
CXP1nFLG2LL register can be read or written 8-bit units.

Address: CXP1nFLG2: <CXP1n_base> + $03C_H$
CXP1nFLG2L: <CXP1n_base> + $03C_H$
CXP1nFLG2LL: <CXP1n_base> + $03C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	CXP1n SRSV	CXP1n RRSV	CXP1n AREP		CXP1n EREP	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.49 CXP1nFLG2 Register Contents

Bit Position	Bit Name	Function
31 to 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	CXP1nSRSV	Frame retransmission reservation flag*1 Indicates whether or not frame retransmission is reserved. 0: No retransmission reservation (retransmission canceled) 1: Retransmission is reserved
4	CXP1nRRSV	PID retransmission reservation flag*1 Indicates whether or not PID retransmission is reserved. 0: No retransmission reservation (retransmission canceled) 1: Retransmission is reserved
3, 2	CXP1nAREP	Loss-of-arbitration retransmission remaining count flag*2 Indicate the number of remaining retransmissions when arbitration is lost. 00_B: No retransmission remaining (retransmission canceled) 01_B: One round of retransmission remaining 10_B: Two rounds of retransmission remaining 11_B: Unlimited number of retransmissions remaining
1, 0	CXP1nEREP	Error retransmission remaining count flag*2 Indicate the number of remaining retransmissions when an error is detected. 00_B: No retransmission remaining (retransmission canceled) 01_B: One round of retransmission remaining 10_B: Two rounds retransmission remaining 11_B: Unlimited number of retransmissions remaining

Note 1. Not allowed changing from 0_B to 1_B.

Note 2. Not allowed changing from "No retransmission remaining" to "Retransmission remaining".

To cancel retransmission, clear all CXP1nFLG2 bits.

CXP1nSRSV Bit

This bit indicates whether or not frame retransmission is reserved.
For details, see **Section 30.5.7.3, Retransmission Processing**.

- CXP1nMODE.CXP1nREPOP = 0_B (no automatic retransmission judgment)
  - This bit is fixed to 0.
- CXP1nMODE.CXP1nREPOP = 1_B (automatic retransmission judged)

[HW setting conditions]

- When an error is detected when CXP1nEREP ≠ 00_B (the number of retransmissions when detecting an error is other than 0) and a frame transmission request is set
- When an error is detected when CXP1nAREP ≠ 00_B (the number of retransmissions when arbitration is lost is other than 0) and a frame transmission request is set

[HW clearing conditions]

- A fatal error occurred.
- CXP1nWUP.CXP1nSTCLR = 1_B is written (simple reset).
- Transmission is started. (PID or Frame or Sleep or PTYPE) (including retransmission)
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

Access

The table below lists the conditions for access to this bit and operations when accessed.

Table 30.50 CXP1nSRSV Bit Access Conditions

Access Conditions			
CXP1nMODE.			
CXP1nEN	CXP1nREPOP	Writing	Reading (Read Value)
0_B	x_B	Not possible	Initial value
1_B	0_B	Not possible	Initial value
1_B	1_B	Enabled	Setting value

The CXP1nRRSV bit

This bit indicates whether or not PID retransmission is reserved.
For details, see **Section 30.5.7.3, Retransmission Processing**.

- CXP1nMODE.CXP1nREPOP = 0_B (no automatic retransmission judgment)
  - This bit is fixed to 0.
- CXP1nMODE.CXP1nREPOP = 1_B (automatic retransmission judged)

[HW setting conditions]

- When an error is detected when CXP1nEREP ≠ 00_B (the number of retransmissions when detecting an error is other than 0) and a PID transmission request is set
- When an error is detected when CXP1nEREP ≠ 00_B (the number of retransmissions when arbitration is lost other than 0) and a PID transmission request is set

[HW clearing conditions]

- A fatal error occurred.
- CXP1nWUP.CXP1nSTCLR = 1_B is written (simple reset).
- Transmission is started. (PID or Frame or Sleep or PTYPE) (including retransmission)
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

Access

The table below lists the conditions for access to this bit and operations when accessed.

Table 30.51 CXP1nRRSV Bit Access Conditions

Access Conditions		Writing	Reading (Read Value)
CXP1nMODE.			
CXP1nEN	CXP1nREPOP		
0_B	x_B	Not possible	Initial value
1_B	0_B	Not possible	Initial value
1_B	1_B	Enabled	Setting value

The CXP1nAREP Bit

This bit indicates the number of remaining retransmissions when arbitration is lost*1.
For details, see **Section 30.5.7.3, Retransmission Processing**.

Note 1. CXP1nFLG2.CXP1nAREP is used when detecting CXPI-NRZ mode and PID start bit error.

- CXP1nMODE.CXP1nREPOP = 0_B (no automatic retransmission judgment)
  - This bit is fixed to 0.
- CXP1nMODE.CXP1nREPOP = 1_B (automatic retransmission judged)

[HW setting conditions]

- The number of retransmissions is decremented when a loss in arbitration is detected.
- The number of retransmissions is decremented when detecting CXPI-NRZ mode and PID start bit error.
- When transmission is started (CXP1nSND.CXP1nREPSEL = 10_B (setting 2)), CXP1nREP.CXP1nAIREP is set.
- Transmission is started (CXP1nSND.CXP1nREPSEL = 01_B (setting 1)). CXP1nREP.CXP1nARREP is set.

[HW clearing conditions]

- A fatal error occurred.
- CXP1nWUP.CXP1nSTCLR = 1_B is written (simple reset).
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

Access

The table below lists the conditions for access to this bit and operations when accessed.

Table 30.52 CXP1nAREP Bit Access Conditions

Access Conditions		Writing	Reading (Read Value)
CXP1nMODE.			
CXP1nEN	CXP1nREPOP		
0_B	X_B	Not possible	Initial value
1_B	0_B	Not possible	Initial value
1_B	1_B	Enabled	Setting value

The CXP1nEREP Bit

These bits indicate the number of remaining retransmissions when an error is detected.
For details, see **Section 30.5.7.3, Retransmission Processing**.

- CXP1nMODE.CXP1nREPOP = 0_B (no automatic retransmission judgment)
  - This bit is fixed to 0.
- CXP1nMODE.CXP1nREPOP = 1_B (automatic retransmission judged)

[HW setting conditions]

- The number of retransmissions is decremented when detecting an error.
- When transmission is started (CXP1nSND.CXP1nREPSEL = 10_B (setting 2)), CXP1nREP.CXP1nEIREP is set.
- When transmission is started (CXP1nSND.CXP1nREPSEL = 01_B (setting 1)), CXP1nREP.CXP1nERREP is set.

[HW clearing conditions]

- A fatal error occurred.
- CXP1nWUP.CXP1nSTCLR = 1_B is written (simple reset).
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

Access

The table below lists the conditions for access to these bits and operations when accessed.

Table 30.53 CXP1nEREP Bit Access Conditions

Access Conditions		Writing	Reading (Read Value)
CXP1nMODE.			
CXP1nEN	CXP1nREPOP		
0_B	X_B	Not possible	Initial value
1_B	0_B	Not possible	Initial value
1_B	1_B	Enabled	Setting value

30.4.1.17 CXP1nFLW1 — CXP1 Flow Register 1

This is a status register that indicates the CXP1 operating state.

Access: CXP1nFLW1 register is a read-only register that can be read in 32-bit units.
CXP1nFLW1L register is a read-only register that can be read in 16-bit units.
CXP1nFLW1LL, CXP1nFLW1LH registers are read-only registers that can be read in 8-bit units.

Address: CXP1nFLW1: <CXP1n_base> + 040_H
CXP1nFLW1L: <CXP1n_base> + 040_H
CXP1nFLW1LL: <CXP1n_base> + 040_H,
CXP1nFLW1LH: <CXP1n_base> + 041_H

Value after reset: 0000 0020_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	CXP1nCXMD		CXP1nCXST			—	CXP1n SLP SEQ	CXP1n RXIDLE	CXP1n ESEQ	CXP1n SPIDEN	CXP1n SRES SEQ	CXP1n SSEQ	CXP1n RSEQ
Value after reset	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 30.54 CXP1nFLW1 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset is returned.
12, 11	CXP1nCXMD	CXPI operating mode status Indicate the CXPI operating mode. 00_B: Initializing 01_B: Bus Sleep 10_B: Send Wakeup 11_B: Normal
10 to 8	CXP1nCXST	CXPI operating state Indicate the CXPI operating state. 000_B: Waiting for IFS to elapse 001_B: Waiting for IFS to elapse after transfer is suspended due to an error 010_B: Transmission/reception stopped (IDLE) 011_B: Transmitting PTYPE NOTE: Only when CXP1nMODE.CXP1nACC = 1_B (polling mode) and CXP1nMODE.CXP1nMS = 1_B 100_B: Waiting for response judgment/response data to be set 101_B: PID transmission 110_B: Response (frame information/extension DLC/data/CRC) transmission/reception 111_B: Waiting for the end of the frame (IBS elapsing)
7	Reserved	When read, the value after reset is returned.
6	CXP1nSLPSEQ	Sleep frame status This bit indicates the state of reception to a sleep frame. 0: No sleep reception 1: Sleep reception in progress
5	CXP1nRXIDLE	CXPI bus idle status 0: Not idle 1: Idle
4	CXP1nESEQ	Received PID (External factor) status 0: No received PID (No external factor) 1: Received PID (Externally requested transfer in progress)

Table 30.54 CXP1nFLW1 Register Contents (2/2)

Bit Position	Bit Name	Function
3	CXP1nSPIDEN	Slave node transmission enable status 0: Not allowed slave node transmission 1: Allowed slave node transmission
2	CXP1nSRESSEQ	Non-automatic response transmission status 0: No transmission factor 1: Transmission in progress (transmitting node)
1	CXP1nSSEQ	Transmission factor status 0: No transmission factor 1: Transmission in progress (transmitting node)
0.	CXP1nRSEQ	Reception factor status 0: No reception factor 1: Reception in progress (receiving node)

CXP1nCXMD Bits

These bits indicate the CXPI operating mode.
For details, see **Section 30.5.8.8, Status**.

[HW setting condition]

- State transition (mode sequencer)

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nCXST Bits

These bits indicate the CXPI operating status.

The read data of these bits is only valid while CXP1nCXMD = 11_B (normal mode).
Fixed to 000_B when CXP1nCXMD is not 11_B (other than normal mode).
For details, see **Section 30.5.8.8, Status**.

[HW setting conditions]

- State transition (flow sequencer)

  These bits change to 001_B (waiting for IFS to elapse after transfer is suspended due to an error) if one of the following condition is satisfied.

- A fatal error is detected.
- A transfer error is detected.
- CXP1nWUP.CXP1nSTCLR = 1_B is written (simple reset).

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nSLPSEQ Bit

This bit indicates the state of reception to a sleep frame.

The read data of this bit is only valid while CXP1nCXMD = 11_B (normal mode).
Fixed to 0 when CXP1nCXMD is not 11_B (other than normal mode).

- When CXP1nMODE.CXP1nMS = 0_B (slave node)

[HW setting condition]

- PID = $1F_H$ is received.

[HW clearing conditions]

- The sleep transition time[*1] has passed after a sleep frame has been received.

Note 1. Sleep transition time = CXP1nSLPWAIT × CXPI nominal bit (Tbit) time

- Received DLC is not 8_H.
- Received 1st byte DATA is not 00_H.
- CXP1nWUP.CXP1nSTCLR = 1_B is written.
- A fatal error is detected.
- A transfer error is detected.
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nRXIDLE Bit

This bit indicates the CXPI bus idle or not idle.

[HW setting condition]

- After detected stop bit by CXPI bus.
- A fatal error is detected.
- CXP1nWUP.CXP1nSTCLR = 1B is written.
- CXP1nMODE.CXP1nEN = 0B (forced reset)

[HW clearing conditions]

- Detected start bit by CXPI bus.

CXP1nESEQ Bit

This bit indicates the received PID (External factor) status.
The read data of this bit is only valid while CXP1nCXMD = 11_B (normal mode).
Fixed to 0 when CXP1nCXMD is not 11_B (other than normal mode).

[HW setting condition]

- An external PID is detected when CXP1nCXST = 010_B (transmission/reception stopped (IDLE))/000_B (waiting for IFS to elapse)/101_B (PID transmission).

[HW clearing conditions]

- An external PID is detected and the IBS time has passed.
- An external PID is detected and disagree with CXP1nRPIDF.
- An external PID is detected and CXP1nFLG1.CXP1nFAIL = 1_B.
- Response Frame transmission/reception is completed
- A fatal error is detected.
- A transfer error is detected.
- CXP1nWUP.CXP1nSTCLR = 1_B is written.
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nSPIDEN Bit

This bit indicates slave node transmission enable status.

The read data of this bit is only valid while CXP1nCXMD = 11_B (normal mode).
Fixed to 0 when CXP1nCXMD is not 11_B (other than normal mode).

1. CXP1nMODE.CXP1nACC = 0_B (event trigger mode)
   This bit is fixed to 0.
2. CXP1nMODE.CXP1nACC = 1_B (polling mode)

- When CXP1nMODE.CXP1nMS = 1_B (master node)

[HW setting condition]

- PTYPE is detected when CXP1nCXST = 011_B (transmitting PTYPE).

[HW clearing conditions]

- The IBS time has passed.
- An external PID is detected.
- The external PID acceptance time ends (9 Tbits or more passed while CXP1nCXST = 100_B (waiting for response judgment/response data setting))
- A fatal error is detected.
- A transfer error is detected.
- CXP1nWUP.CXP1nSTCLR = 1_B is written.
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

- When CXP1nMODE.CXP1nMS = 0_B (slave node)

[HW setting condition]

- PTYPE is detected while CXP1nCXST = 000_B (waiting for IFS to elapse)/010_B (transmission/reception stopped (IDLE)).

[HW clearing conditions]

- The IBS time has passed.
- An external PID is detected.
- PID transmission or frame transmission is performed.
- The external PID acceptance time ends (9 Tbits or more passed while CXP1nCXST = 100_B (waiting for response judgment/response data setting)).
- A fatal error is detected.
- A transfer error is detected.
- CXP1nWUP.CXP1nSTCLR = 1_B is written.
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nSRESSEQ Bit

This bit indicates manual response transmission status.
This bit is only valid while CXP1nCXMD = 11_B (normal mode).
Fixed to 0 when CXP1nCXMD is not 11_B (other than normal mode).

[HW setting condition]

- Transfer is started.

[HW clearing conditions]

- Transfer ends.
- A fatal error is detected.
- A transfer error is detected.
- CXP1nWUP.CXP1nSTCLR = 1_B is written (simple reset).
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nSSEQ Bit

This bit indicates transmission factor status.
The read data of this bit is only valid while CXP1nCXMD = 11_B (normal mode).
Fixed to 0 when CXP1nCXMD is not 11_B (other than normal mode).

[HW setting conditions]

- A frame is transmitted.
- A frame is retransmitted.
- An external PID is detected and response (start bit) is transmitted.

[HW clearing conditions]

- Response transmission is completed.
- A fatal error is detected.
- Loss-of-Arbitration.
- A transfer error is detected.
- CXP1nWUP.CXP1nSTCLR = 1_B is written (simple reset).
- CXP1nMODE.CXP1nEN = 0_B (forced reset).

CXP1nRSEQ Bit

This bit indicates reception factor status
The read data of this bit is only valid while CXP1nCXMD = 11_B (normal mode).
Fixed to 0 when CXP1nCXMD is not 11_B (other than normal mode).

[HW setting conditions]

- The PID is transmitted.
- The PID is retransmitted.
- An external PID is detected and response (start bit) is received.

[HW clearing conditions]

- A response has been received.
- A fatal error is detected.
- Loss-of-Arbitration
- A transfer error is detected.
- CXP1nWUP.CXP1nSTCLR = 1_B is written (simple reset).
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.18 CXP1nFLW2 — CXPI Flow Register 2

This is a status register that indicates the CXPI transfer frame.

Access: CXP1nFLW2 register is a read-only register that can be read in 32-bit units.
CXP1nFLW2L register is a read-only register that can be read in 16-bit units.
CXP1nFLW2LL, CXP1nFLW2LH registers are read-only registers that can be read in 8-bit units.

Address: CXP1nFLW2: <CXP1n_base> + 044_H
CXP1nFLW2L: <CXP1n_base> + 044_H
CXP1nFLW2LL: <CXP1n_base> + 044_H,
CXP1nFLW2LH: <CXP1n_base> + 045_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	CXP1n FRMPHS		CXP1n DATANO							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 30.55 CXP1nFLW2 Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is returned.
9, 8	CXP1nFRMPHS	Response frame phase status 00: Frame information or extension DLC 01: Data 10: CRC 11: Undefined CXP1nFLW1.CXP1nRSEQ = 1 (receiving node): Response frame phase status being received. CXP1nFLW1.CXP1nSSEQ=1 (transmitting node): Response frame phase status of next Transmission data.
7 to 0	CXP1nDATANO	Transmit/receive data number status For data frames: CXP1nFLW1.CXP1nRSEQ = 1 (receiving node): Data number being received CXP1nFLW1.CXP1nSSEQ =1 (transmitting node): Data number of next Transmission data. When transfer is completed normally: Quantity of transfer data When transfer ends in an error: Suspended data number

CXP1nFRMPHS Bits

[HW setting condition]

- When receiving data (Including loop-back reception on transmitting node)

[HW clearing conditions]

- A fatal error occurred.
- CXP1nWUP.CXP1nSTCLR = 1_B is written (simple reset).
- Transfer is started.
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nDATANO Bits

This is status that indicates the number of data.

[HW setting condition]

- When receiving data (Including loop-back reception on transmitting node).

[HW clearing conditions]

- A fatal error occurred.
- CXP1nWUP.CXP1nSTCLR = 1_B is written (simple reset).
- Transfer is started.
- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.19 CXP1nERR — CXPI Error Register

This is a status register that indicates the CXPI operating state.

Access: CXP1nERR register can be read or written in 32-bit units.
CXP1nERRL register can be read or written 16-bit units.
CXP1nERRLL, CXP1nERRLH registers can be read or written 8-bit units.

Address: CXP1nERR: <CXP1n_base> + $04C_H$
CXP1nERRL: <CXP1n_base> + $04C_H$
CXP1nERRLL: <CXP1n_base> + $04C_H$,
CXP1nERRLH: <CXP1n_base> + $04D_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CXP1nERRCNT								CXP1n FRM ERR	CXP1n ORN ERR	—	CXP1n DLN ERR	—	CXP1n PTY ERR	CXP1n CRC ERR	CXP1n BIT ERR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R	R/W	R/W	R/W

Table 30.56 CXP1nERR Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 8	CXP1nERRCNT	Error counter The error counter indicates the update condition and the result of addition or subtraction. When detecting an error with the error counter value greater than 248, CXP1nFLG1.CXP1nFAIL is set to 1, and PID transmission and frame transmission is stopped.
7	CXP1nFRMERR	Framing error flag An error is detected if the stop bit of the UART frame received by the receiving node is 0. 0: Error not detected 1: Error detected
6	CXP1nORNERR	Overrun error flag An error is detected if the long frame received data is overwritten. 0: Error not detected 1: Error detected
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4	CXP1nDLNERR	Data length error flag The receiving node compares the DLC of the frame information with the data length of the received frame. A data length error is detected if they do not match. 0: Error not detected 1: Error detected
3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 30.56 CXP1nERR Register Contents (2/2)

Bit Position	Bit Name	Function
2	CXP1nPTYERR	Parity error flag The receiving node calculates the number of logical 1s in the received PID field and PTYPE field. It detects a parity error if the number is an even number. The received PID and PTYPE are invalid when detecting an error. 0: Error not detected 1: Error detected
1	CXP1nCRCERR	CRC error flag The receiving node compares the result of automatic CRC calculation and the received CRC value. It detects a CRC error if they do not match. 0: Error not detected 1: Error detected
0	CXP1nBITERR	Bit error flag The value of the transmitted bit and the value of the received bit are compared. A bit error is detected if they do not match. Transmission processing is suspended if a bit error occurs. 0: Error not detected 1: Error detected

CXP1nERRCNT Bits

These bits indicate the error counter value.
For details, see **Section 30.5.7.6, Failure Management Function**.

[HW setting conditions]

- Error counter + 8 when the transmitted PTYPE field has an error
- Error counter + 8 when the transmitted PID field has an error (including the received PID has a framing error after arbitration lost)
- Error counter + 8 when the transmitted response field has an error (excluding the underrun (with data length error) on long frame)
- Error counter – 1 when the transmitted PTYPE field has no error
- Error counter – 1 when the transmitted PID field has no error
- Error counter – 1 when the transmitted response field has no error

NOTE

The upper limit of the error counter is 255.
The lower limit of the error counter is 0.
The following errors apply:

- CXP1nBITERR (bit error)
- CXP1nDLNERR (data length error)
- CXP1nFRMERR (framing error)

[HW clearing conditions]

- Cleared by setting CXP1nMODE.CXP1nEN = 0_B (forced reset) only when CXP1nMODE.CXP1nMS = 1_B (master node)
- Only when CXP1nMODE.CXP1nMS = 0_B (slave node)
- When CXP1nFLG1.CXP1nCLKDET = 0_B and CXP1nWUP.CXP1nWUPREQ = 1_B are written
- When CXP1nFLG1.CXP1nCLKDET = 1_B while CXP1nFLW1.CXP1nCXMD = 01_B (bus sleep mode)
- When CXP1nFLG1.CXP1nFAIL = 0_B is written

CXP1nFRMERR Bit

This bit indicates whether or not a framing error occurred.
For details, see **Section 30.5.7.4(8), Framing Error**.

[HW setting condition]

- The stop bit of the received UART frame is 0.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nORNERR Bit

This bit indicates whether or not an overrun error occurred.
For details, see **Section 30.5.7.4(7), Overrun Error**.

- Long frame (received DLC = F_H)

[HW setting condition]

- A frame reception completion interrupt is generated while CXP1nRFQINT = 1_B (received data save request interrupt source flag).

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

- Normal frame (received DLC ≠ F_H)
  This interrupt is not generated.

CXP1nDLNERR Bit

This bit indicates whether or not a data length error occurred.
For details, see **Section 30.5.7.4(5), Data Length Error**.

[HW setting condition]

- Data length error occurred.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nPTYERR Bit

This bit indicates whether or not a parity error occurred.
For details, see **Section 30.5.7.4(3), Parity Error**.

[HW setting condition]

- A parity error is detected.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nCRCERR Bit

This bit indicates whether or not a CRC error occurred.
For details, see **Section 30.5.7.4(2), CRC Error**.

[HW setting condition]

- A CRC error is detected.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nBITERR Bit

This bit indicates whether or not a bit error occurred.
For details, see **Section 30.5.7.4(1), Bit Error**.

[HW setting conditions]

- Bit error occurred.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.20 CXP1nRPID — CXPI Received PID Register

This register indicates the received PID.

Access: CXP1nRPID register is a read-only register that can be read in 32-bit units.
CXP1nRPIDL register is a read-only register that can be read in 16-bit units.
CXP1nRPIDLL register is a read-only register that can be read in 8-bit units.

Address: CXP1nRPID: <CXP1n_base> + 060_H
CXP1nRPIDL: <CXP1n_base> + 060_H
CXP1nRPIDLL: <CXP1n_base> + 060_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CXP1n RPRT	CXP1nRFID						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 30.57 CXP1nRPID Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned.
7	CXP1nRPRT	Parity status Indicates the received parity bit.
6 to 0	CXP1nRFID	Received frame ID status Indicate the received frame ID.

CXP1nRPRT Bit

This bit indicates the parity of the received frame ID or transmitted frame ID.

[HW setting condition]

- The PID is received or transmitted.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nRFID Bits

These bits indicate the received frame ID or transmitted frame ID.
For details, see **Section 30.5.6.1, PID**.

[HW setting condition]

- The PID is received or transmitted.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.21 CXP1nSPID — CXPI Transmission PID Register

This register sets the PID for transmission.

Access: CXP1nSPID register can be read or written in 32-bit units.
CXP1nSPIDL register can be read or written 16-bit units.
CXP1nSPIDLL register can be read or written 8-bit units.

Address: CXP1nSPID: <CXP1n_base> + 070_H
CXP1nSPIDL: <CXP1n_base> + 070_H
CXP1nSPIDLL: <CXP1n_base> + 070_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CXP1nSPRT	CXP1nSFID						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.58 CXP1nSPID Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7	CXP1nSPRT	Parity setting Sets the parity bit of the frame ID.
6 to 0	CXP1nSFID	Transmission frame ID setting Set the frame ID for transmission. Range of allowable settings: 01_H to $7F_H$

CXP1nSPRT Bit

This bit sets the parity bit of the frame ID.

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nSFID Bits

These bits set the frame ID.

There are several reserved frame IDs for which the usage is specified.
The table below lists the reserved frame IDs.

Reserved Frame ID	Name	Usage
00_H	Event transmission enable (PTYPE)	Used when CXP1nMODE.CXP1nACC = 1_B
$2F_H$	Inspection request (for ECU supplier)	Inspection
$6F_H$	Inspection response (for ECU supplier)	Inspection
$1F_H$	For a request frame	Sleep frame or diagnostic request
$5F_H$	For a response frame	Diagnostic response
$3F_H$	Reserved for future extension	—
$7F_H$	Reserved for future extension	—

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.22 CXP1nRPIDF1m — CXPI Received Frame ID Setting Register 1m (m = 01 to 12)

This register sets the frame ID for reception.

Access: CXP1nRPIDF1m register can be read or written in 32-bit units.
CXP1nRPIDF1mL register can be read or written 16-bit units.
CXP1nRPIDF1mLL register can be read or written 8-bit units.

Address: CXP1nRPIDF1m: <CXP1n_base> + $080_H + 4_H \times (m - 1)$
CXP1nRPIDF1mL: <CXP1n_base> + $080_H + 4_H \times (m - 1)$
CXP1nRPIDF1mLL: <CXP1n_base> + $080_H + 4_H \times (m - 1)$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	CXP1nFID						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.59 CXP1nRPIDF1m Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	CXP1nFID	Frame ID setting Set the frame ID for reception. 00_H: The setting of this register is invalid (The frame ID corresponding to the data of own node is not specified) 01_H to $7F_H$: The frame ID corresponding to the data of own node can be specified

CXP1nFID Bits

These bits set the frame ID for reception of the response field and for manual response.

There are several reserved frame IDs for which the usage is specified.
The table below lists the reserved frame IDs.

Reserved Frame ID	Name	Usage
00_H	Event transmission enable (PTYPE)	Used when CXP1nMODE.CXP1nACC = 1_B
$2F_H$	Inspection request (for ECU supplier)	Inspection
$6F_H$	Inspection response (for ECU supplier)	Inspection
$1F_H$	For a request frame	Sleep frame or diagnostic request
$5F_H$	For a response frame	Diagnostic response
$3F_H$	Reserved for future extension	—
$7F_H$	Reserved for future extension	—

The following frames are received irrespective of the settings of this register.

Frame ID	Name	Usage
00_H	Event transmission enable	Used for the polling method
$1F_H$	For a request frame	Sleep frame or diagnostic request
$5F_H$*1	For a response frame	Diagnostic response

Note 1. Only for master node setting

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.23 CXP1nRPIDF2m —CXPI Received Frame ID Setting Register 2m (m = 01 to 04)

This register sets the frame ID for reception. A frame can be received with a partial match of bits of the frame ID by using mask bits.

Access: CXP1nRPIDF2m register can be read or written in 32-bit units.
CXP1nRPIDF2mL register can be read or written 16-bit units.
CXP1nRPIDF2mLL, CXP1nRPIDF2mLH registers can be read or written 8-bit units.

Address: CXP1nRPIDF2m: <CXP1n_base> + $0B0_H$ + 4_H × (m − 1)
CXP1nRPIDF2mL: <CXP1n_base> + $0B0_H$ + 4_H × (m − 1)
CXP1nRPIDF2mLL: <CXP1n_base> + $0B0_H$ + 4_H × (m − 1),
CXP1nRPIDF2mLH: <CXP1n_base> + $0B0_H$ + 4_H × (m − 1) + 1_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	CXP1nFIDMSK							—	CXP1nFID						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.60 CXP1nRPIDF2m Register Contents

Bit Position	Bit Name	Function
31 to 15	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
14 to 8	CXP1nFIDMSK	Received frame ID mask setting Mask the frame ID of the set bits. Range of allowable settings: 00_H to $7F_H$
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	CXP1nFID	Frame ID setting Set the frame ID for reception. 00_H: The setting of this register is invalid (The frame ID corresponding to the data of own node is not specified) 01_H to $7F_H$: The frame ID corresponding to the data of own node can be specified

CXP1nFIDMSK Bits

These bits mask the frame ID value for the bits being set to 1.

- Setting example: CXP1nFID = 35_H, CXP1nFIDMSK = 03_H
  Received FID = 33_H → Discard
  Received FID = 34_H → Receive
  Received FID = 36_H → Receive
  Received FID = 37_H → Receive

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nFID Bits

These bits set the frame ID for reception of the response field and for manual response.
For details, see **Section 30.5.6.1, PID**.

There are several reserved frame IDs for which the usage is specified.
The table below lists the reserved frame IDs.

Reserved Frame ID	Name	Usage
00_H	Event transmission enable (PTYPE)	Used when CXP1nMODE.CXP1nACC = 1_B
$2F_H$	Inspection request (for ECU supplier)	Inspection
$6F_H$	Inspection response (for ECU supplier)	Inspection
$1F_H$	For a request frame	Sleep frame or diagnostic request
$5F_H$	For a response frame	Diagnostic response
$3F_H$	Reserved for future extension	—
$7F_H$	Reserved for future extension	—

The following frames are received irrespective of the settings of this register.

Fame ID	Name	Usage
00_H	Event transmission enable	Used for the polling method
$1F_H$	For a request frame	Sleep frame or diagnostic request
$5F_H$*1	For a response frame	Diagnostic response

Note 1. Only for master node setting

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.24 CXP1nARPID —CXPI Automatic Response PID Setting Register

This register sets the PID for automatic response.

Access: CXP1nARPID register can be read or written in 32-bit units.
CXP1nARPIDL register can be read or written 16-bit units.
CXP1nARPIDLL register can be read or written 8-bit units.

Address: CXP1nARPID: <CXP1n_base> + $0C0_H$
CXP1nARPIDL: <CXP1n_base> + $0C0_H$
CXP1nARPIDLL: <CXP1n_base> + $0C0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	CXP1nARFID						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.61 CXP1nARPID Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	CXP1nARFID	Automatic response frame ID setting Set the frame ID for automatic response. 00_H: The setting of this register is invalid (The frame ID corresponding to the data of own node is not specified) 01_H to $7F_H$: The frame ID corresponding to the data of own node can be specified.

CXP1nARFID Bits

These bits set the frame ID for automatic response.
For details, see **Section 30.5.6.1, PID**.

There are several reserved frame IDs for which the usage is specified.
The table below lists the reserved frame IDs.

Reserved Frame ID	Name	Usage
00_H	Event transmission enable (PTYPE)	Used when CXP1nMODE.CXP1nACC = 1_B
$2F_H$	Inspection request (for ECU supplier)	Inspection
$6F_H$	Inspection response (for ECU supplier)	Inspection
$1F_H$	For a request frame	Sleep frame or diagnostic request
$5F_H$	For a response frame	Diagnostic response
$3F_H$	Reserved for future extension	—
$7F_H$	Reserved for future extension	—

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.25 CXP1nRFRI —CXPI Received Frame Information Register

This register stores the received frame information.

Access: CXP1nRFRI register is a read-only register that can be read in 32-bit units.
CXP1nRFRIL register is a read-only register that can be read in 16-bit units.
CXP1nRFRILL, CXP1nRFRILH registers are read-only registers that can be read in 8-bit units.

Address: <CXP1nRFRI: <CXP1n_base> + 120_H
CXP1nRFRIL: <CXP1n_base> + 120_H
CXP1nRFRILL: <CXP1n_base> + 120_H,
CXP1nRFRILH: <CXP1n_base> + 121_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CXP1nRDLC2								CXP1nRDLC1				CXP1nRWUP	CXP1nRSLP	CXP1nRCT	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 30.62 CXP1nRFRI Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned.
15 to 8	CXP1nRDLC2	Extended frame data length status Indicate the received extension DLC. Setting range: 00_H to FF_H
7 to 4	CXP1nRDLC1	Data length status Indicate the length of the received data. 0_H to C_H: Data length D_H to E_H: None F_H: Long frame
3	CXP1nRWUP	Wakeup indicator status Indicates the received wakeup indicator. 0: No wakeup by the own node as a trigger 1: Wakeup by the own node as a trigger
2	CXP1nRSLP	Sleep indicator status Indicates the received sleep indicator. 0: Disables sleep mode 1: Enables sleep mode
1, 0	CXP1nRCT	Counter status Indicate the received counter value.

CXP1nRDLC2 Bits

Indicate the extension DLC value received in a long frame.

[HW setting condition]

- Frame information (extension DLC) is received.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nRDLC1 Bits

These bits indicate the received DLC value.

[HW setting condition]

- Frame information is received.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nRWUP Bit

This bit indicates the received wakeup indicator value.

[HW setting condition]

- Frame information is received.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nRSLP Bit

This bit indicates the received sleep indicator value.

[HW setting condition]

- Frame information is received.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nRCT Bits

These bits indicate the received counter value.

[HW setting condition]

- Frame information is received.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.26 CXP1nSFRI — CXPI Transmission Frame Information Register

This register sets the transmission frame information.

Access: CXP1nSFRI register can be read or written in 32-bit units.
CXP1nSFRIL register can be read or written 16-bit units.
CXP1nSFRILL, CXP1nSFRILH registers can be read or written 8-bit units.

Address: CXP1nSFRI: <CXP1n_base> + 130_H
CXP1nSFRIL: <CXP1n_base> + 130_H
CXP1nSFRILL: <CXP1n_base> + 130_H,
CXP1nSFRILH: <CXP1n_base> + 131_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CXP1nSDLC2								CXP1nSDLC1				CXP1n SWUP	CXP1n SSLP	CXP1nSCT	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.63 CXP1nSFRI Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 8	CXP1nSDLC2	Extended frame data length setting Set the extension DLC in a long frame. Setting range: 00_H to FF_H
7 to 4	CXP1nSDLC1	Data length setting 0_H to C_H: Data length D_H to E_H: Setting prohibited F_H: Long frame
3	CXP1nSWUP	Wakeup indicator setting 0: No wakeup by the own node as a trigger 1: Wakeup by the own node as a trigger
2	CXP1nSSLP	Sleep indicator setting 0: Disables sleep mode 1: Enables sleep mode
1, 0	CXP1nSCT	Counter setting Indicate the continuity of frames. Set these bits considering the continuity of frames by the application. Range of allowable settings: 0_H to 3_H

The conditions for setting and clearing of the CXP1nSFRI register are as follows:

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.27 CXP1nARFRI — CXPI Automatic Response Frame Information Register

This register sets the automatic response frame information.

Access: CXP1nARFRI register can be read or written in 32-bit units.
CXP1nARFRIL register can be read or written 16-bit units.
CXP1nARFRILL register can be read or written 8-bit units.

Address: CXP1nARFRI: <CXP1n_base> + 140_H
CXP1nARFRIL: <CXP1n_base> + 140_H
CXP1nARFRILL: <CXP1n_base> + 140_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CXP1nASDLC				CXP1nASWUP	CXP1nASSLP	CXP1nASCT	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.64 CXP1nARFRI Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7 to 4	CXP1nASDLC	Data length setting Set the data length of frames for automatic response. Range of allowable settings: 00_H to $0C_H$ (0 byte to 12 bytes) Other than above: Setting prohibited
3	CXP1nASWUP	Wakeup indicator setting Sets the wakeup indicator of frames for automatic response. 0: No wakeup by the own node as a trigger 1: Wakeup by the own node as a trigger
2	CXP1nASSLP	Sleep indicator setting Sets the sleep indicator of frames for automatic response. 0: Disables sleep mode 1: Enables sleep mode
1, 0	CXP1nASCT	Counter setting Set the counter of frames for automatic response. Used to indicate the continuity of frames. Set these bits considering the continuity of frames by the application. Range of allowable settings: 00_H to 03_H

The conditions for setting and clearing of the CXP1nARFRI register are as follows:

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.28 CXP1nRCRC — CXPI Received CRC Register

This register indicates the CRC of the received frame.

Access: CXP1nRCRC register is a read-only register that can be read in 32-bit units.
CXP1nRCRCL register is a read-only register that can be read in 16-bit units.
CXP1nRCRCLL, CXP1nRCRCLH registers are read-only registers that can be read in 8-bit units.

Address: CXP1nRCRC: <CXP1n_base> + $1A0_H$
CXP1nRCRCL: <CXP1n_base> + $1A0_H$
CXP1nRCRCLL: <CXP1n_base> + $1A0_H$,
CXP1nRCRCLH: <CXP1n_base> + $1A1_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CXP1nRCRC2								CXP1nRCRC1							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 30.65 CXP1nRCRC Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned.
15 to 8	CXP1nRCRC2	Upper CRC status These bits indicate the upper CRC of the extended received frame.
7 to 0	CXP1nRCRC1	Lower CRC status These bits indicate the lower CRC of the extended received frame.

CXP1nRCRC2 Bits

These bits indicate the CRC value (upper byte) received in a long frame.
Data in these bits is invalid while CXP1nRFRI.CXP1nRDLC1 = 00_H to $0C_H$ (normal frame).

NOTE

The upper byte is indicated when data is received in an extended frame.

[HW setting condition]

- A frame is received.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nRCRC1 Bit

These bits indicate the received CRC value.

NOTE

The lower byte is indicated when data is received in an extended frame.

[HW setting condition]

- A frame is received.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.29 CXP1nSCRC — CXPI Transmission CRC Register

This register indicates CRC of the frame for transmission. It stores the CRC value generated by the controller.

Access: CXP1nSCRC register is a read-only register that can be read in 32-bit units.
CXP1nSCRCL register is a read-only register that can be read in 16-bit units.
CXP1nSCRCLL, CXP1nSCRCLH registers are read-only registers that can be read in 8-bit units.

Address: CXP1nSCRC: <CXP1n_base> + $1B0_H$
CXP1nSCRCL: <CXP1n_base> + $1B0_H$
CXP1nSCRCLL: <CXP1n_base> + $1B0_H$,
CXP1nSCRCLH: <CXP1n_base> + $1B1_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CXP1nSCRC2								CXP1nSCRC1							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 30.66 CXP1nSCRC Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned.
15 to 8	CXP1nSCRC2	Upper CRC status Indicate the upper CRC of the extended transmission frame.
7 to 0	CXP1nSCRC1	Lower CRC status Indicate the lower CRC of the extended transmission frame.

CXP1nSCRC2 Bits

These bits indicate the CRC value for transmission in a long frame.
Data in these bits is invalid while CXP1nSFRI.CXP1nSDLC1 = 00_H to $0C_H$ (normal frame).

NOTE

The upper byte is indicated when data is transmitted in an extended frame.

[HW setting condition]

- A frame is transmitted.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

CXP1nSCRC1 Bits

These bits indicate the CRC value for transmission.

NOTE

The lower byte is indicated when data is transmitted in an extended frame.

[HW setting condition]

- A frame is transmitted.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.30 CXP1nARCRC — CXPI Automatic Response CRC Register

This register indicates the CRC value of the automatic response frame. It stores the CRC value generated by the controller.

Access: CXP1nARCRC register is a read-only register that can be read in 32-bit units.
CXP1nARCRCL register is a read-only register that can be read in 16-bit units.
CXP1nARCRCLL register is a read-only register that can be read in 8-bit units.

Address: CXP1nARCRC: <CXP1n_base> + $1C0_H$
CXP1nARCRCL: <CXP1n_base> + $1C0_H$
CXP1nARCRCLL: <CXP1n_base> + $1C0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CXP1nASCRC							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 30.67 CXP1nARCRC Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned.
7 to 0	CXP1nASCRC	CRC status This register indicates the CRC value of the automatic response frame.

CXP1nASCRC Bits

These bits indicate the CRC value for transmission in an automatic response.

[HW setting condition]

- A frame is transmitted.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.31 CXP1nRDATAm — CXPI Received Data Register m (m = 01 to 08)

This register indicates the received data.

Access: CXP1nRDATAm register is a read-only register that can be read in 32-bit units.
CXP1nRDATAmL register is a read-only register that can be read in 16-bit units.
CXP1nRDATAmLL, CXP1nRDATAmLH registers are read-only registers that can be read in 8-bit units.

Address: CXP1nRDATAm: <CXP1n_base> + 200_H+ 4_H × (m - 1)
CXP1nRDATAmL: <CXP1n_base> + 200_H + 4_H × (m - 1)
CXP1nRDATAmLL: <CXP1n_base> + 200_H + 4_H × (m - 1),
CXP1nRDATAmLH: <CXP1n_base> + 200_H + 4_H × (m - 1) + 1_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CXP1nRDAT															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 30.68 CXP1nRDATAm Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned.
15 to 0	CXP1nRDAT	Received data status Indicate the received data.

CXP1nRDAT Bits

These bits indicate the received data.

[HW setting condition]

- A frame is received.

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.32 CXP1nSDATAm — CXPI Transmission Data Register m (m = 01 to 08)

This register sets the data for transmission.

Access: CXP1nSDATAm register can be read or written in 32-bit units.
CXP1nSDATAmL register can be read or written 16-bit units.
CXP1nSDATAmLL, CXP1nSDATAmLH registers can be read or written 8-bit units.

Address: CXP1nSDATAm: <CXP1n_base> + 300_H + 4_H × (m - 1)
CXP1nSDATAmL: <CXP1n_base> + 300_H + 4_H × (m - 1)
CXP1nSDATAmLL: <CXP1n_base> + 300_H + 4_H × (m - 1),
CXP1nSDATAmLH: <CXP1n_base> + 300_H + 4_H × (m - 1) + 1_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CXP1nSDAT															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.69 CXP1nSDATAm Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	CXP1nSDAT	Transmission data setting Set the data for transmission. Setting range: 0000_H to $FFFF_H$

CXP1nSDAT Bits

These bits indicate the data for transmission.

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.4.1.33 CXP1nARDATAm — CXPI Automatic Response Data Register m (m = 01 to 06)

This register sets the transmission data.

Access: CXP1nARDATAm register can be read or written in 32-bit units.
CXP1nARDATAmL register can be read or written 16-bit units.
CXP1nARDATAmLL, CXP1nARDATAmLH registers can be read or written 8-bit units.
Note that writing is only possible while the CXP1nMODE.CXP1nEN is 1.
While CXP1nMODE.CXP1nEN = 0, the initial value is read.

Address: CXP1nARDATAm: <CXP1n_base> + 400_H + 4_H × (m - 1)
CXP1nARDATAmL: <CXP1n_base> + 400_H + 4_H × (m - 1)
CXP1nARDATAmLL: <CXP1n_base> + 400_H + 4_H × (m - 1),
CXP1nARDATAmLH: <CXP1n_base> + 400_H + 4_H × (m - 1) + 1_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CXP1nARDAT															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.70 CXP1nARDATAm Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	CXP1nARDAT	Automatic response data setting Set the automatic response data. Setting range: 0000_H to $FFFF_H$

CXP1nARDAT Bits

These bits indicate the data for transmission in an automatic response.

[HW setting condition]

- None

[HW clearing condition]

- CXP1nMODE.CXP1nEN = 0_B (forced reset)

30.5 Operation

30.5.1 CXPI System Configuration

The transfer mode for this IP can be selectable from CXPI-PWM mode and CXPI-NRZ mode.

Since different functions are assigned to the IP and the CXPI transceiver depending on the transfer mode, the external connections for the LSI are also different.

In addition, since some functions are not supported by the IP, they must be supported externally.

The following describes the system configuration in each transfer mode.

(1) CXPI-PWM mode (CXP1nMODE.CXP1nMD = 0_B)

Figure 30.5, System Configuration in CXPI-PWM Mode shows the CXPI system configuration when CXPI-PWM mode is selected.

NOTE

It has the same system configuration in the master node and the slave node.

Since this IP performs PWM encoding/decoding in CXPI-PWM mode, it communicates with the CXPI transceiver in the PWM waveform.

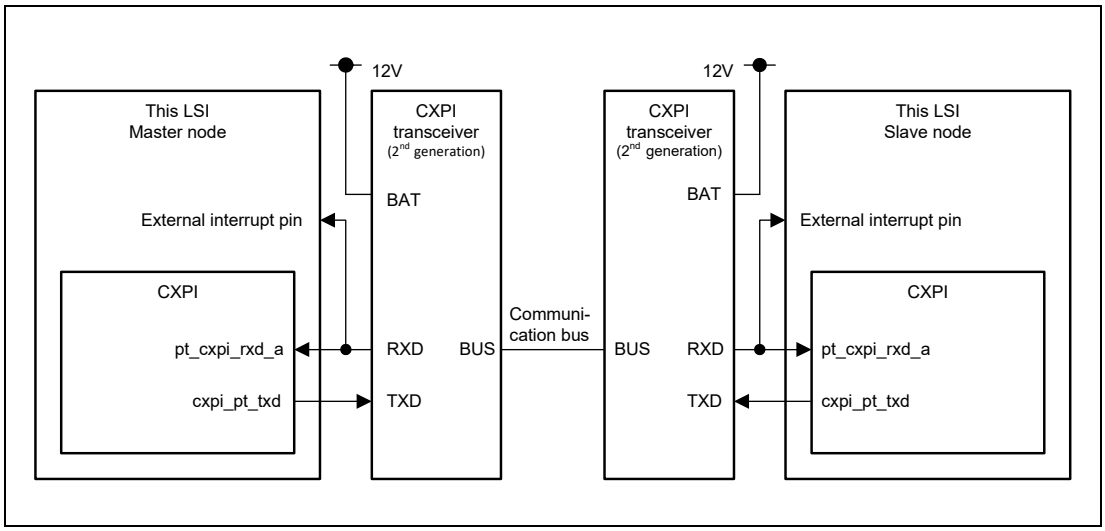

Figure 30.5 System Configuration in CXPI-PWM Mode

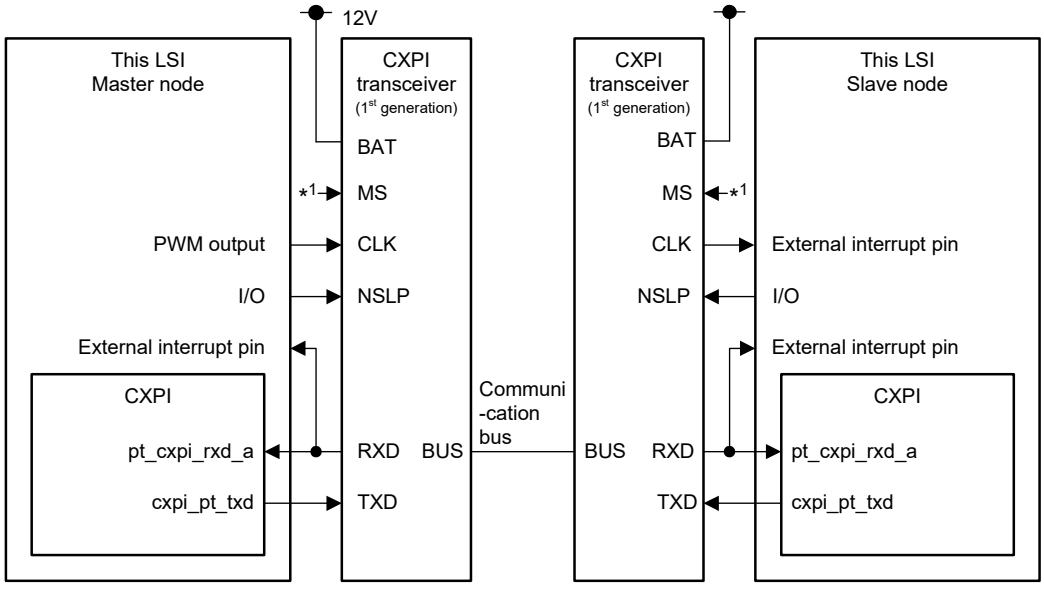
[Pins to be provided by the LSI:]

- External interrupt pin (connected to RXD)
  This IP does not have the wakeup pulse detection function.
  The CXPI transceiver detects wakeup pulses.
  The CXPI transceiver outputs a detection signal to the LSI after detecting a wakeup pulse.
  This LSI detects a detection signal at the external interrupt pin and returns from LSI standby mode.
- Transmit pin (cxpi_pt_txd) (connected to TXD)
  This is the CXPI transmit pin.
- Receive pin (pt_cxpi_rxd_a) (connected to RXD)
  This is the CXPI receive pin.

(2) CXPI-NRZ mode (CXP1nMODE.CXP1nMD = 1_B)

Figure 30.6 shows the CXPI system configuration when CXPI-NRZ mode is selected for this IP.

In CXPI-NRZ mode, the CXPI transceiver performs PWM encoding/decoding.
The communication interface with the CXPI transceiver is UART.
For this reason, the following CXPI transceiver pins must be controlled.



Note 1. The specifications for the MS pin differs from one CXPI transceiver manufacturer to another. Handle the pin based on the manufacturer's specifications.

Figure 30.6 System Configuration in CXPI-NRZ Mode

[Pins to be provided by the LSI]

Common to the master node and slave nodes

- External interrupt pin (connected to RXD)
  This IP does not have the wakeup pulse detection function.
  The CXPI transceiver detects wakeup pulses.
  The CXPI transceiver outputs a detection signal to the LSI after detecting a wakeup pulse.
  This LSI detects a detection signal at the external interrupt pin and returns from LSI standby mode.
- I/O (connected to NSLP)
  This is the pin to reduce the current consumption of the CXPI transceiver. (Only the wakeup pulse receive circuit operates.)
  Setting NSLP = 0 reduces the current consumption.
  Setting NSLP = 1 changes the CXPI transceiver to operating mode.
- — (connected to the MS pin)
  This pin is used to select from the master node and the slave node.
  Since the specifications for the MS pin differ from one manufacturer to another, handle the pin based on the specifications.
- Transmit pin (cxpi_pt_txd) (connected to TXD)
  This is the CXPI transmit pin. The transceivers communicate with each other in UART mode.
- Receive pin (pt_cxpi_rxd_a) (connected to RXD)
  This is the CXPI receive pin. The transceivers communicate with each other in UART mode.

Master node

- Duty 50 clock (PWM output) (connected to CLK)
  The LSI outputs bit rate clock cycles so that the CXPI transceiver can perform PWM encoding/decoding. Timer resources are needed this. Be based upon the specification of the transceiver about the output waveform.

Slave node

- External interrupt pin (connected to CLK/RXD)
  Since the transceivers communicate with each other in UART mode in CXPI-NRZ mode, the slave node cannot detect the CXPI clock at the pins for use in the communication. Therefore, the CXPI clock shall be detected at the external interrupt pin of the LSI to switch the CXPI operating mode.
  (Since the specifications for the clock detection function of the transceiver differ from one manufacturer to another, handle the pin based on the specifications. The clock signal is output from the CLK pin or the RXD pin.)

30.5.2 CXPI Operation Overview

The access method can be selected from the event trigger method and the polling method.

The functions and operations differ between the access methods.

The following overviews the operation in each access method.

30.5.2.1 Event Trigger Method (CXP1nMODE.CXP1nACC = 0_B)

In the event trigger method, each node can transmit a PID freely when it is in the transmission/ reception stopped (IDLE) state.

The master node outputs CXPI clock signals. A slave node operates in synchronization with the CXPI clock signal sent from the master node.

The figure below shows the sequence in the event trigger method.

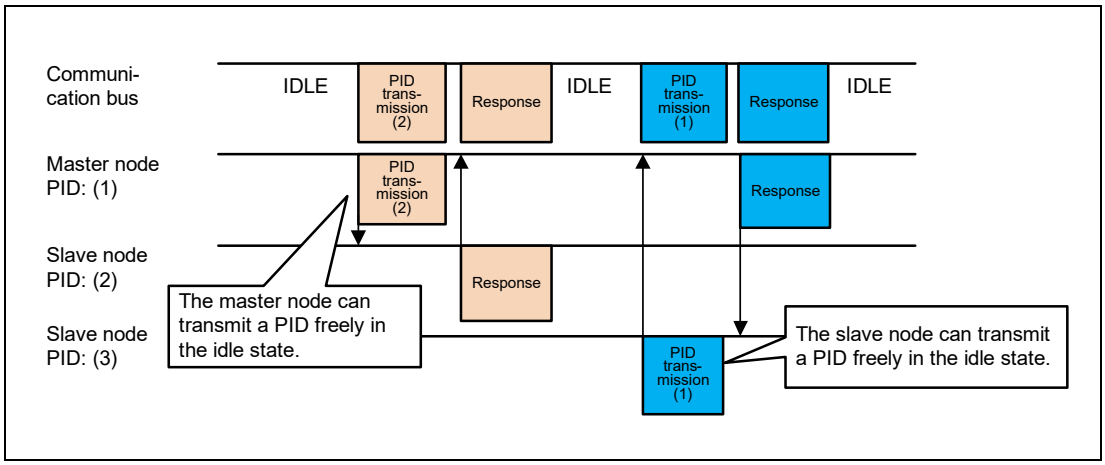


Figure 30.7 Sequence in the Event Trigger Method

30.5.2.2 Polling Method (CXP1nMODE.CXP1nACC = 1_B)

In the polling method, the master node can transmit frames freely when it is in the transmission/ reception stopped (IDLE) state, as in the event trigger method.

When the master node has transmitted a PTYPE field, the slave node can transmit PID freely.

Any slave node that has not received the PTYPE field cannot transmit a PID by hardware protection.

The figure below shows the sequence in the polling method.

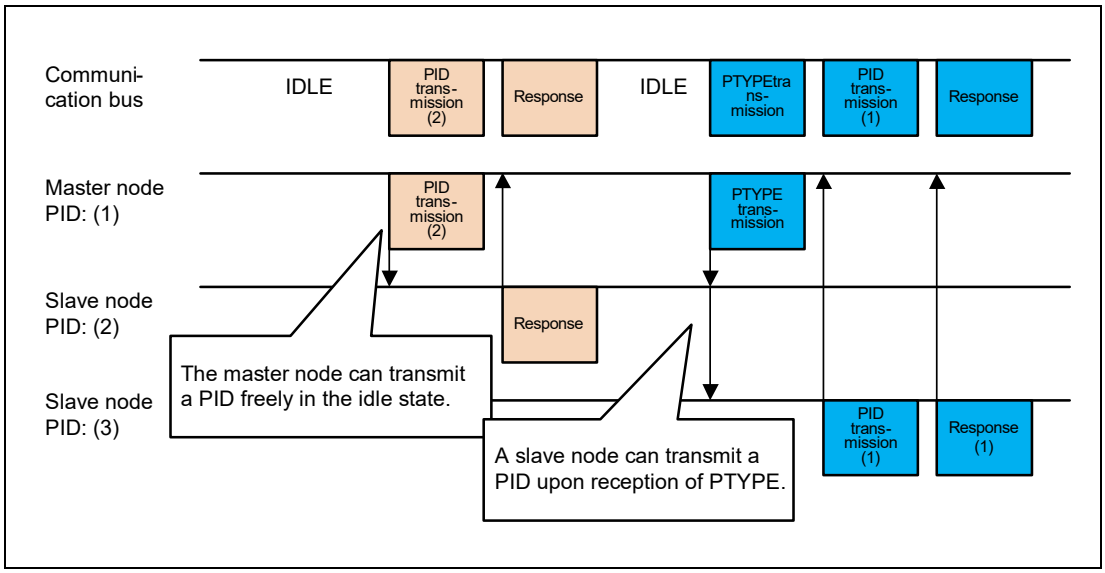

Figure 30.8 Sequence in the Polling Method

30.5.3 Functions

The available functions of this IP differ depending on the transfer mode, access method, and master node/slave node selection. The table below lists the functions (features) that are valid in each setting.

Table 30.71 Functions

Condition			CXPI-PWM Mode				CXPI-NRZ Mode			
			Event Trigger		Polling		Event Trigger		Polling	
			Master	Slave	Master	Slave	Master	Slave	Master	Slave
Basic functions	Protocol		Compliant with *the JASO D015 specification*							
	Baud rate		9.6 kbits/s / 10.4 kbits/s / 19.2 kbits/s / 20 kbits/s							
	Clock sharing		Supported				Not supported (supported by the transceiver)			
	PWM encoding/decoding		Supported				Not supported (supported by the transceiver)			
Data functions	PID		Provided with registers in which frame IDs can be set. Transmission: 1 Reception: 16 (4 registers have a frame ID filtering function.) Automatic response: 1							
	Data buffer		Transmission: 16 bytes / reception: 16 bytes / automatic response: 12 bytes							
	Frame structure		Normal frame, long frame, sleep frame							
	Number of data byes in the response field		Normal frame: variable from 0 to 12 bytes / Long frame: variable from 0 to 255 bytes Sleep frame: fixed to 8 bytes							
	Error detection method		Normal frame and sleep frame: 8-bit CRC Long frame: 16-bit CRC							
Control functions	Transmission	Clock transmission	Supported	Not supported	Supported	Not supported	Not supported			
		CXPI clock detection notification	Not supported				Supported			
		PID transmission	Supported							
		Frame transmission	Supported							
		Automatic response	Supported							
		Manual response	Supported							
		PTYPE transmission	Not supported		Supported	Not supported	Not supported		Supported	Not supported
	Arbitration		Bit basis				Byte basis **NOTE:** Bit-basis arbitration is performed by the transceiver.			
	IFS and IBS setting function		Supported							
	Error detection		Supported							
	Confinement on errors		Supported							
	Wake up / Sleep functions	Wakeup pulse transmission	Not supported	Supported	Not supported	Supported	Not supported	Supported	Not supported	Supported
		Wakeup pulse reception	Not supported (supported by the transceiver)							
		Sleep frame request	Supported	Not supported	Supported	Not supported	Supported	Not supported	Supported	Not supported
		Sleep frame reception	Not supported	Supported	Not supported	Supported	Not supported	Supported	Not supported	Supported
	Bus monitoring		Supported							
	Failure management		Supported							
	Error bit function		Not supported							
Extended functions	Frame ID filtering function		Supported							
	Noise filter		Supported				Not supported			
	Diagnostic function		A readable error counter is installed.							
	Software reset		A forced reset is possible by writing to a register. A simple reset is possible by writing to a register.							
	Status		The operating status of each hardware unit can be read.							
Interrupts			Supported							

30.5.4 Overall Operation

The CXPI operates differently depending on the wakeup factor.

The following describes the CXPI operation for each wakeup factor.

The hardware and software behaviors are different according to each operation. Operations triggered by each wakeup factor are outlined in the following pages.

Table 30.72 Operation Triggered by Each Wakeup Factor

No.	Wakeup Factor	Operation		Described in Section
		Operation after Wakeup	Continued Operation	
1	CXPI activation	Initial Setting	-	**30.5.10.2**
2	PID transmission (CXP1nSND.CXP1nSIDREQ = 1)	PID transmission	Response reception	**30.5.4.1(1)**
			No response from the target node	**30.5.4.1(2)**
3	Frame transmission (CXP1nSND.CXP1nSFRREQ = 1)	PID transmission	Response transmission	**30.5.4.2(1)**
4	Manual response (CXP1nSND.CXP1nSRSREQ = 1)	PID reception	Response transmission	**30.5.4.3(1)**
			Own node is not the target.	**30.5.4.3(2)**
5	Automatic response (Automatically judged when receiving a PID)	PID reception	Response transmission	**30.5.4.4(1)**
			Own node is not the target.	**30.5.4.4(2)**
6	PID reception (frame reception) (Automatically judged when receiving a PID)	PID reception	Response reception	**30.5.4.5(1)**
			Own node is not the target.	**30.5.4.5(2)**
7	PTYPE transmission (CXP1nSND.CXP1nSPTREQ = 1)	PTYPE transmission	No. 4 to No. 6	**30.5.4.6(1)**
			No response from the target node	**30.5.4.6(2)**
8	PTYPE reception	PTYPE reception	No. 2 and No. 3	**30.5.4.7(1)**
			PID not transmitted	**30.5.4.7(2)**
9	Sleep frame transmission	PID transmission	Response transmission	**30.5.4.8**
10	Sleep frame reception	PID reception	Response reception	**30.5.4.9**
11	Wakeup pulse transmission (CXP1nWUP.CXP1nWUPREQ = 1)	Wakeup pulse transmission	Starts another node.	**30.5.4.10**
12	Wakeup pulse reception	Wakeup pulse reception	Own node starts up.	**30.5.4.11**

30.5.4.1 PID Transmission

(1) PID Transmission to Response Reception

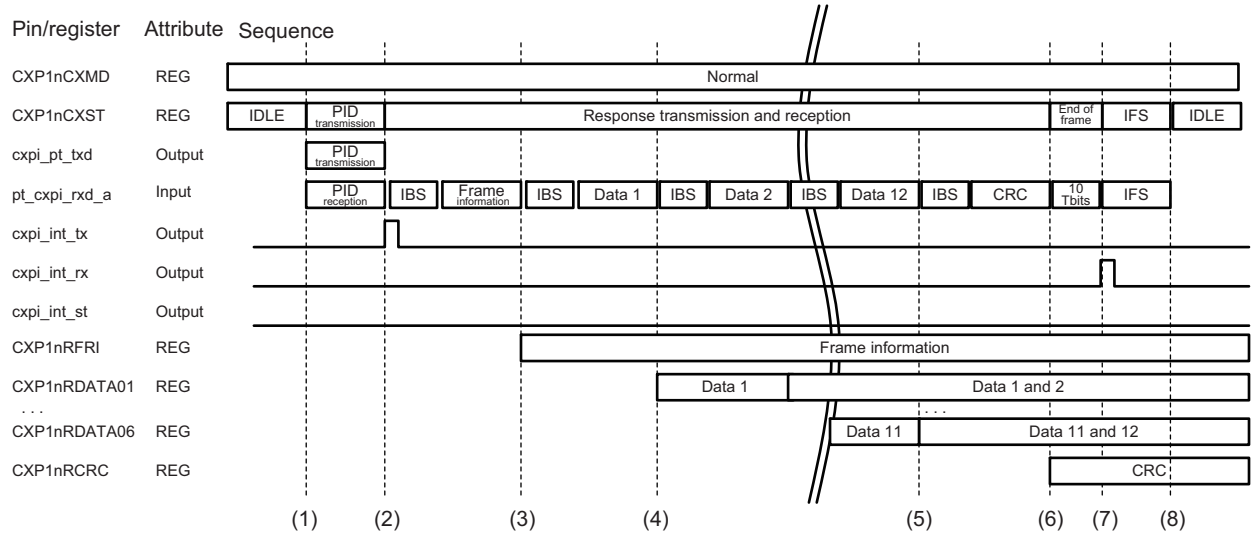
The CXPI can receive data of another node by transmitting a PID.

A normal frame or a long frame is received as a response according to the frame information (CXP1nRFRI.CXP1nRDLC1).

This section provides an overview of the hardware and software operation in each frame structure.

(a) Normal Frame

The following provides an overview of the hardware and software operation when the frame structure is the normal frame structure.



Note: IBS: IBS controlled by another node

Figure 30.9 Operation Sequence from PID Transmission to Response Reception (Normal Frame)

Operation

Operation setting: Frame structure: Normal frame
($CXP1nRFRI.CXP1nRDLC1 \neq F_H$)*1

Number of data bytes in the response: 12 bytes
($CXP1nRFRI.CXP1nRDLC1 = C_H$)*1

Note 1. The frame structure and the number of data bytes are determined based on the received data.

(1) Writes 1 to CXP1nSND.CXP1nSIDREQ and makes a PID transmission request. For control, see **Section 30.6.2.4, Restriction of Transmission Request**.
It starts transmission immediately because $CXP1nFLW1.CXP1nCXST = 010_B$ (IDLE).
(If $CXP1nFLW1.CXP1nCXST$ is not 010_B (IDLE), the hardware puts transmission on hold.)

(2) A PID transmission completion interrupt is generated. CXP1nINT.CXP1nSIDINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nSIDINT to 0.

(3) Frame information is received, and is stored in CXP1nRFRI.

(4) The first-byte data is received. The received data is stored in CXP1nRDATA01.

NOTE

After that, data is stored in CXP1nRDATAm (m = 01 to 06) as each byte is received.

(5) The 12th-byte data is received. The received data is stored in CXP1nRDATA06.

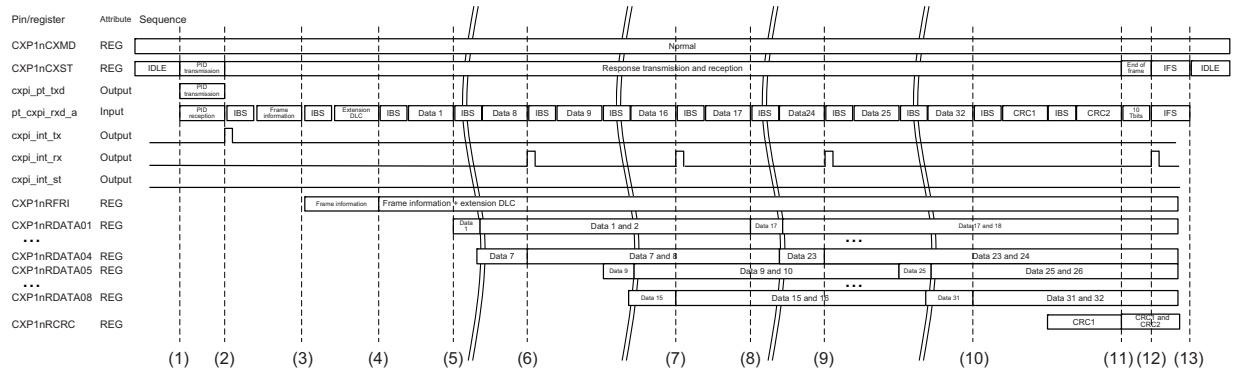
(6) The CRC value is received. The CRC value is stored in CXP1nRCRC.

(7) 10 Tbits (fixed value determined by the hardware) have passed after receiving the CRC value.
A frame reception completion interrupt is generated and CXP1nINT.CXP1nRFRINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nRFRINT to 0.

(8) Wait for IFS to elapse.
Counting is started at the CXPI nominal bit (Tbit) time from CRC value is received, and the state changes to the idle state after the time specified by the CXP1nFRMW.CXP1nIFS bit has passed.
Communication is possible after the state transitions to the idle state.

(b) Long frame

The following provides an overview of the hardware and software operation when the frame structure is the long frame structure.



Note: IBS: IBS controlled by another node

Figure 30.10 Operation Sequence from PID Transmission to Response Reception (Long Frame)

Operation

Operation setting: Frame structure: Long frame
($CXP1nRFRI.CXP1nRDLC1 = F_H$)*1

Number of data bytes in the response: 32 bytes
($CXP1nRFRI.CXP1nRDLC\ 2 = 20_H$)*1

Note 1. The frame structure and the number of data bytes are determined based on the received data

(1) Writes 1 to CXP1nSND.CXP1nSIDREQ and makes a PID transmission request. For control, see **Section 30.6.2.4, Restriction of Transmission Request**.
It starts transmission immediately because $CXP1nFLW1.CXP1nCXST = 010_B$ (IDLE).
(If $CXP1nFLW1.CXP1nCXST$ is not 010_B (IDLE), the hardware puts transmission on hold.)

(2) A PID transmission completion interrupt is generated and CXP1nINT.CXP1nSIDINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nSIDINT to 0.

(3) Frame information is received, and is stored in CXP1nRFRI.

(4) Extension DLC is received, and is stored in CXP1nRFRI.

(5) The first-byte data is received. The received data is stored in CXP1nRDATA01.

(6) The 8th-byte data is received. The received data is stored in CXP1nRDATA04.
A received data save request interrupt is generated and CXP1nINT.CXP1nRFQINT is set to 1.
The software reads CXP1nRDATA01 to CXP1nRDATA04 and saves the received data.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nRFQINT to 0.

(7) The 16th-byte data is received. The received data is stored in CXP1nRDATA08.
A received data save request interrupt is generated and CXP1nINT.CXP1nRFQINT is set to 1.
The software reads CXP1nRDATA05 to CXP1nRDATA08 and saves the received data since an interrupt is output at a level, the software clears CXP1nINT.CXP1nSIDINT to 0.

(8) The 17th-byte data is received. The received data is stored (overwritten) in CXP1nRDATA01.

(9) The 24th-byte data is received. The received data is stored in CXP1nRDATA04.
A received data save request interrupt is generated and CXP1nINT.CXP1nRFQINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nRFQINT to 0.
The software reads CXP1nRDATA01 to CXP1nRDATA04 and saves the received data.

(10) The 32nd-byte data is received. The received data is stored in CXP1nRDATA08.
No received data save request interrupt is generated because this is the last data.

(11) The CRC value is received. The received CRC is stored in CXP1nRCRC.

(12) 10 Tbits (fixed value determined by the hardware) have passed after receiving the CRC value.
A frame reception completion interrupt is generated and CXP1nINT.CXP1nRFRINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nRFRINT to 0.

(13) Wait for IFS to elapse.
Counting is started at the CXPI nominal bit (Tbit) time from CRC value is received, and the state changes to the idle state after the time specified by the CXP1nFRMW.CXP1nIFS bit has passed.
Communication is possible after the state transitions to the idle state.

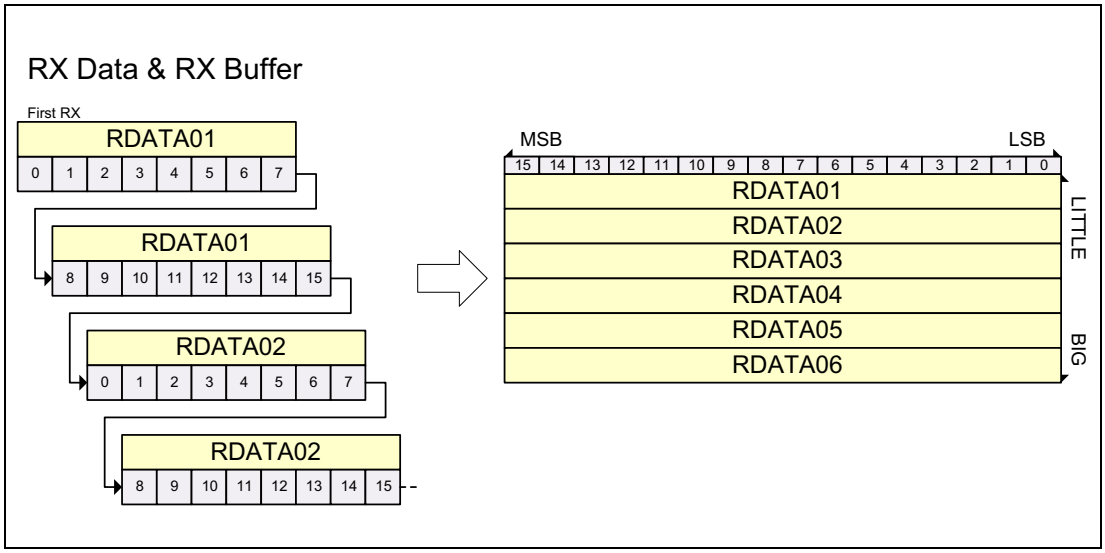


Figure 30.11 Received DATA and Received BUFFER

(2) PID Transmission to No Response from the Target Node

The CXPI may not receive a response from the target node after transmitting a PID.

This section provides an overview of the hardware and software operation when no response is received from the target node after transmitting a PID.

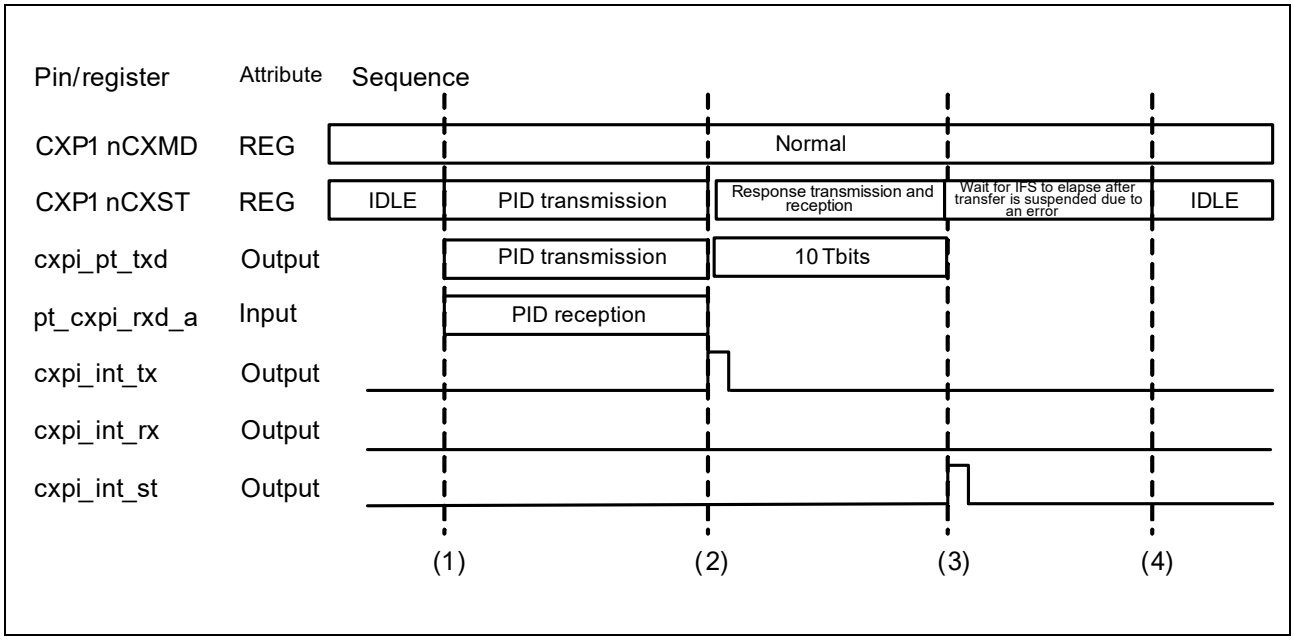

Figure 30.12 PID Transmission to No Response from the Target Node

Operation

(1) Writes 1 to CXP1nSND.CXP1nSIDREQ and makes a PID transmission request. For control, see **Section 30.6.2.4, Restriction of Transmission Request**.
It starts transmission immediately because CXP1nFLW1.CXP1nCXST = 010_B (IDLE).
(If CXP1nFLW1.CXP1nCXST is not 010_B (IDLE), the hardware puts transmission on hold.)

(2) A PID transmission completion interrupt is generated and CXP1nINT.CXP1nSIDINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nSIDINT to 0.

(3) 10 Tbits (fixed value determined by the hardware) have passed (a time longer than IBS has passed).
An error detection interrupt (data length error or bit error) is generated and CXP1nINT.CXP1nERRINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nERRINT to 0.

(4) Wait for IFS to elapse.
Counting is started at the CXPI nominal bit (Tbit) time after detect error, and the state changes to the idle state after the time specified by the CXP1nFRMW.CXP1nIFS bit has passed.
Communication is possible after the state transitions to the idle state.

30.5.4.2 Frame Transmission

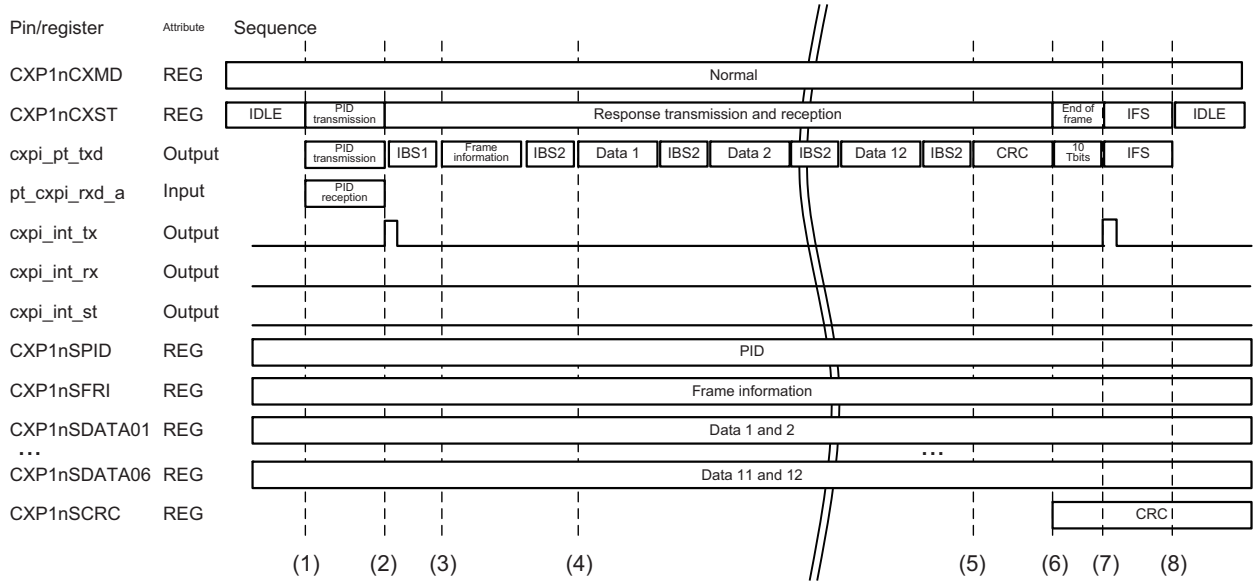
(1) PID Transmission to Response Transmission

The CXPI can transmit a response to the target node by transmitting a PID.

A normal frame or a long frame can be transmitted as a response according to the frame information (DLC) setting. This section provides an overview of the hardware and software operation in each frame structure.

(a) Normal Frame

The following provides an overview of the hardware and software operation when the frame structure is the normal frame structure.



Note: IBS: IBS controlled by another node
IBS1: Counting is performed at the CXPI nominal bit (Tbit) time, and logical 1 is output for the time specified by the CXP1nFRMW.CXP1nIBS1 bit. Then, the next data is transmitted.
IBS2: Counting is performed at the CXPI nominal bit (Tbit) time, and logical 1 is output for the time specified by the CXP1nFRMW.CXP1nIBS2 bit. Then, the next data is transmitted.

Figure 30.13 Operation Sequence from PID Transmission to Response Transmission (Normal Frame)

Operation

Operation setting: Frame structure: Normal frame
($CXP1nSFRI.CXP1nSDLC1 \neq F_H$)

Number of data bytes in the response: 12 bytes
($CXP1nSFRI.CXP1nSDLC1 = C_H$)

(1) Writes 1 to CXP1nSND.CXP1nSFRREQ and makes a frame transmission request. For control, see **Section 30.6.2.4, Restriction of Transmission Request**.
It starts transmission immediately because $CXP1nFLW1.CXP1nCXST = 010_B$ (IDLE).
(If $CXP1nFLW1.CXP1nCXST$ is not 010_B (IDLE), the hardware puts transmission on hold.)

(2) A PID transmission completion interrupt is generated. CXP1nINT.CXP1nSIDINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nSIDINT to 0.

(3) Frame information is transmitted. (Data in CXP1nSFRI[7:0] is transmitted.)

(4) The first-byte data is transmitted. (Data in CXP1nSDATA01[7:0] is transmitted.)
Note: Then, data in CXP1nSDATAm (m = 01 to 06) is transmitted on a byte basis.

(5) The CRC value is transmitted. (The CRC value calculated within the circuit is transmitted.)

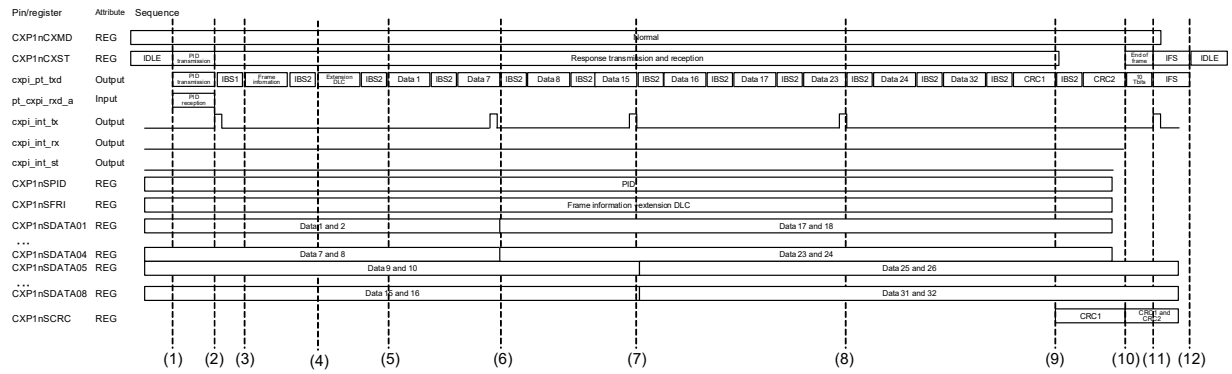
(6) CRC value transmission is completed. The transmitted CRC value is stored in CXP1nSCRC.

(7) 10 Tbits (fixed value determined by the hardware) have passed after transmitting the CRC value.
A frame transmit completion interrupt is generated and CXP1nINT.CXP1nSFRINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nSFRINT to 0.

(8) Wait for IFS to elapse.
Counting is started at the CXPI nominal bit (Tbit) time, and the state changes to the idle state after the time specified by the CXP1nFRMW.CXP1nIFS bit has passed.
Communication is possible after the state transitions to the idle state.

(b) Long Frame

The following provides an overview of the hardware and software operation when the frame structure is the long frame structure.



Note: IBS: IBS controlled by another node
IBS1: Counting is performed at the CXPI nominal bit (Tbit) time, and logical 1 is output for the time specified by the CXP1nFRMW.CXP1nIBS1 bit.
Then, the next data is transmitted.
IBS2: Counting is performed at the CXPI nominal bit (Tbit) time, and logical 1 is output for the time specified by the CXP1nFRMW.CXP1nIBS2 bit.
Then, the next data is transmitted.

Figure 30.14 Operation Sequence from PID Transmission to Response Transmission (Long Frame)

Operation

Operation setting: Frame structure: Long frame
(CXP1nSFRI.CXP1nSDLC1 = F_H)

Number of data bytes in the response: 32 bytes
(CXP1nSFRI.CXP1nSDLC 2 = 20_H)

(1) Writes 1 to CXP1nSND.CXP1nSFRREQ and makes a frame transmission request. For control, see **Section 30.6.2.4, Restriction of Transmission Request**.
It starts transmission immediately because CXP1nFLW1.CXP1nCXST = 010_B (IDLE).
(If CXP1nFLW1.CXP1nCXST is not 010_B (IDLE), the hardware puts transmission on hold.)

(2) A PID transmission completion interrupt is generated. CXP1nINT.CXP1nSIDINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nSIDINT to 0.

(3) Frame information is transmitted. (Data in CXP1nSFRI[7:0] is transmitted.)

(4) Extension DLC is transmitted. (Data in CXP1nSFRI[15:0] is transmitted.)

(5) The first-byte data is transmitted. (Data in CXP1nSDATA01[7:0] is transmitted.)

NOTE

Then, data in CXP1nSDATAm (m = 01 to 08) is transmitted on a byte basis.

(6) The 7 th-byte data transmitted.
A received data save request interrupt is generated and CXP1nSFQINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nSFQINT to 0.
The 16th-byte to 24th-byte data is set in CXP1nSDATA01 to CXP1nSDATA04.

(7) The 15 th-byte data transmitted.
A transmission data setting request interrupt is generated and CXP1nSFQINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nSFQINT to 0.
The 25th-byte to 32nd-byte data is set in CXP1nSDATA05 to CXP1nSDATA08.

(8) The 23th-byte data transmitted.
A transmission data setting request interrupt is generated and CXP1nSFQINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nSFQINT to 0.

NOTE

This processing flow handles 32-byte transmission. It does not set the transmission data.

(9) CRC1 transmission is completed. (The CRC value calculated within the circuit is transmitted.)
The transmitted CRC value is stored in CXP1nSCRC.

(10) CRC2 transmission is completed. (The CRC value calculated within the circuit is transmitted.)
The transmitted CRC value is stored in CXP1nSCRC.

(11) 10 Tbits (fixed value determined by the hardware) have passed after transmitting the CRC value.
A frame transmission completion interrupt is generated and CXP1nINT.CXP1nSFRINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nSFRINT to 0.

(12) Wait for IFS to elapse.
Counting is started at the CXPI nominal bit (Tbit) time after CRC value transmission is completed, and the state changes to the idle state after the time specified by the CXP1nFRMW.CXP1nIFS bit has passed.
Communication is possible after the state transitions to the idle state.

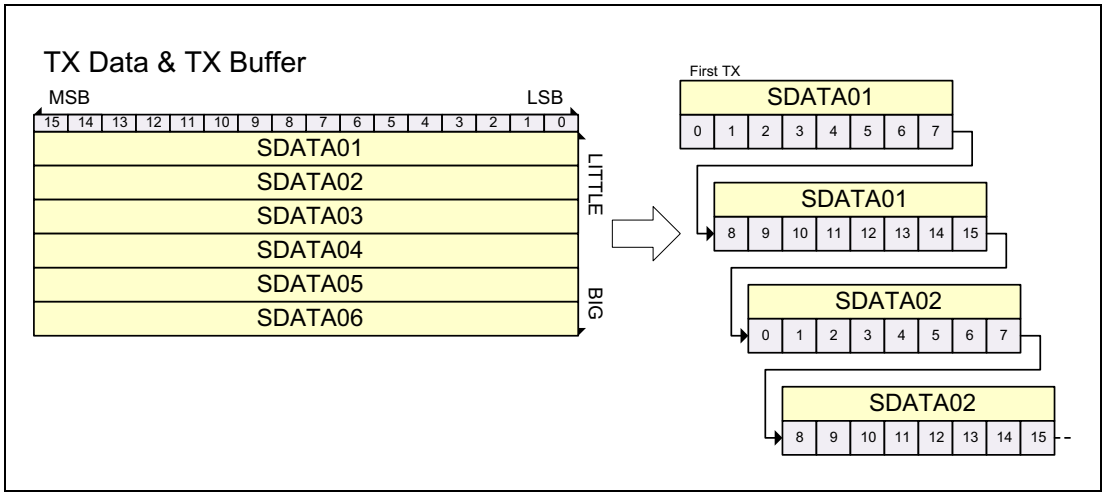


Figure 30.15 Transmit DATA and Transmit BUFFER

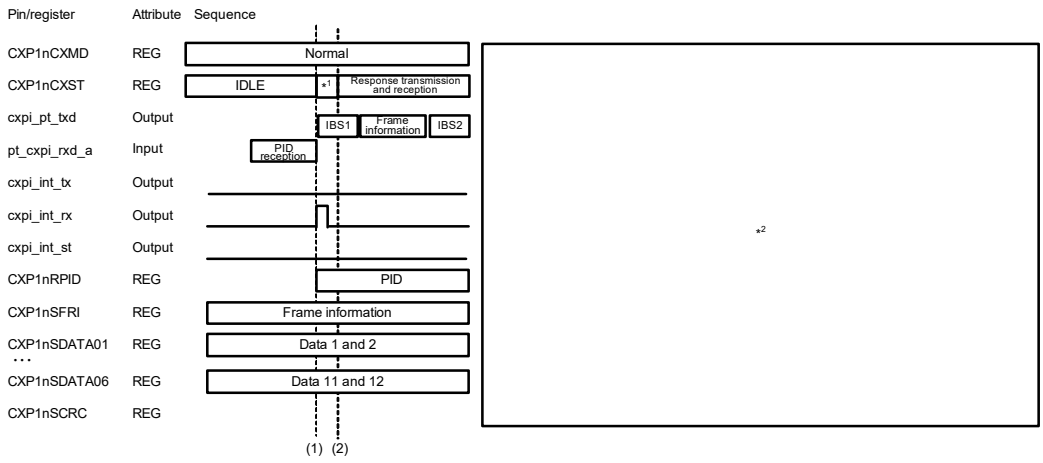
30.5.4.3 Manual Response

(1) PID Reception — Response Transmission

The CXP1 can transmit a response through software judgment when the PID of its own node was specified by another node. A normal frame or a long frame can be transmitted as a response according to the frame information (DLC) setting.

The following provides an overview of the hardware and software operation in the sequence from PID reception to response transmission (manual response).



Note: IBS: IBS controlled by another node
IBS1: Counting is performed at the CXPI nominal bit (Tbit) time, and logical 1 is output for the time specified by the CXP1nFRMW.CXP1nIBS1 bit. Then, the next data is transmitted.
IBS2: Counting is performed at the CXPI nominal bit (Tbit) time, and logical 1 is output for the time specified by the CXP1nFRMW.CXP1nIBS2 bit. Then, the next data is transmitted.

Note 1. Waiting for response judgment/response data setting.
Note 2. The same operation as step (3) and the rest in **Figure 30.13**.
The same operation as step (3) and the rest in **Figure 30.14**.

Figure 30.16 PID Reception — Response Transmission (Manual Response)

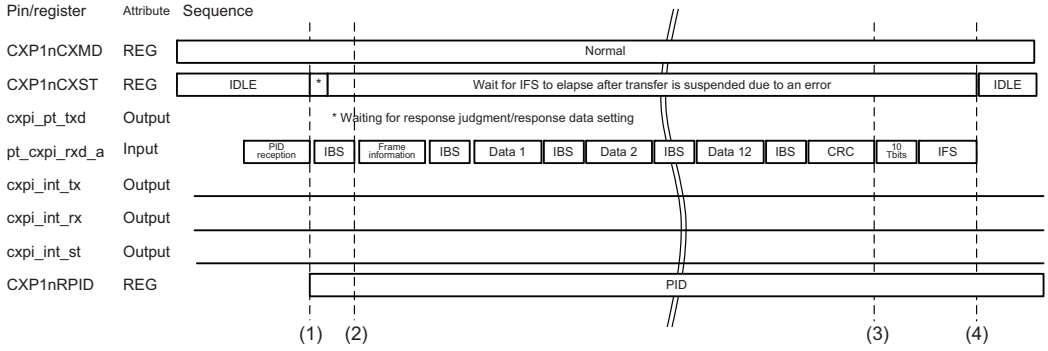
Operation

(1) A PID is received.
When the received PID matches the PID set in CXP1nRPIDF1m (m = 01 to 12) or CXP1nRPIDF2m (m = 01 to 04), a PID reception completion interrupt is generated and CXP1nINT.CXP1nRIDINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nRIDINT to 0.
The software determines if the received PID is to be responded.
If the PID is to be responded, the software sets CXP1nSFRI (frame information) and CXP1nSDATA01 to CXP1nSDATA08 (transmission data), writes 1 to CXP1nSND.CXP1nSRSREQ, and makes a response transmission request.
(If the PID is to be received, the software receives the response.) For details, see **Figure 30.19** and **Figure 30.20**.

(2) Transmission of response data is started.

(2) PID Reception — Own Node is Not the Target

The following provides an overview of the hardware operation performed when the received PID is not for the own node and a response is not made or received. This sequence does not involve software processing. (No notification is made from the hardware.)



Note: IBS: IBS controlled by another node

Figure 30.17 Operation Sequence from PID Reception when Own Node is Not the Target

Operation

(1) A PID is received. No PID reception completion interrupt is generated because the received PID does not match the frame ID in CXP1nRPIDF1m (m = 01 to 12) or CXP1nRPIDF2m (m = 01 to 04).

(2) Response reception is started.
The received data is not stored in CXP1nRFRI and CXP1nRDATAm (m = 01 to 06).

(3) CRC reception is completed.
The received CRC is not stored in CXP1nRCRC.

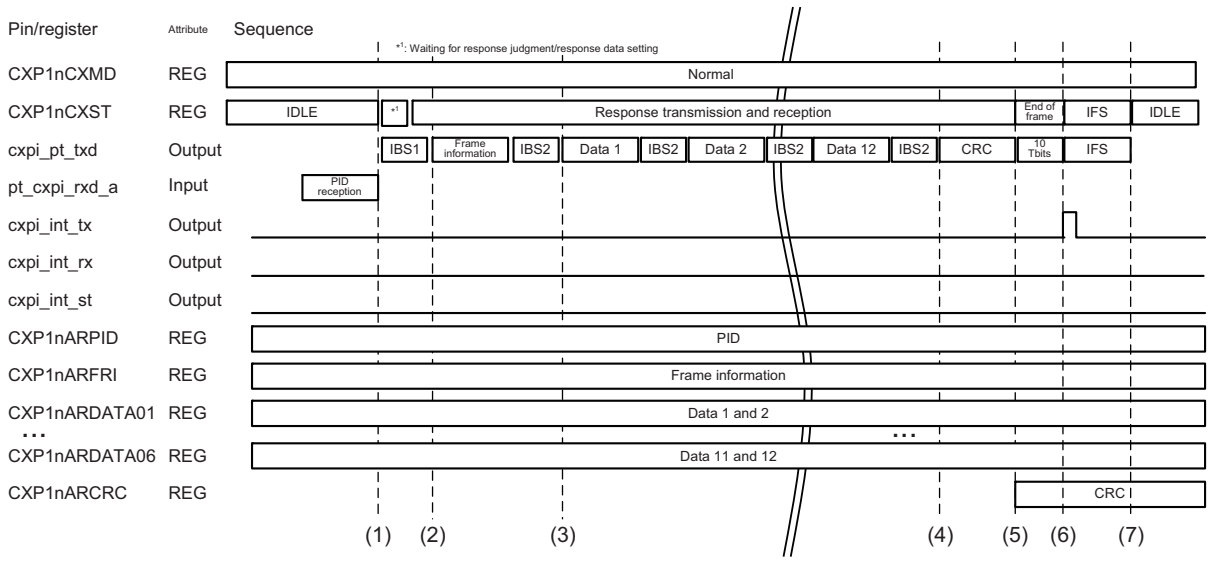
(4) Wait for IFS to elapse.
Counting is started at the CXPI nominal bit (Tbit) time from CRC value is received, and the state changes to the idle state (CXP1nFLW1.CXP1nCXST=010_B) after the time specified by the CXP1nFRMW.CXP1nIFS bit has passed. Transition is possible.

30.5.4.4 Automatic Response

(1) PID Reception to Response Transmission

The CXPI can makes an automatic response upon receiving a PID by enabling the automatic response (CXP1nMODE.CXP1nARESEN = 1_B) and setting the automatic response PID in CXP1nARPID.

Only the normal frame is used as the frame structure of automatic response. The long frame is not supported.



Note: IBS: IBS controlled by another node
IBS1: Counting is performed at the CXPI nominal bit (Tbit) time, and logical 1 is output for the time specified by the CXP1nFRMW.CXP1nIBS1 bit. Then, the next data is transmitted.
IBS2: Counting is performed at the CXPI nominal bit (Tbit) time, and logical 1 is output for the time specified by the CXP1nFRMW.CXP1nIBS2 bit. Then, the next data is transmitted.

Figure 30.18 PID Reception — Response Transmission (Automatic Response)

Operation

Operation setting: Automatic response enabled: CXP1nMODE.CXP1nARESEN = 1_B

Frame structure: Normal frame (CXP1nARFRI.CXP1nASDLC ≠ F_H)

Number of data bytes in the response: 12 bytes (CXP1nARFRI.CXP1nASDLC = C_H)

(1) A PID is received. When the received PID matches the PID set in CXP1nARPID, automatic response is started.
No PID reception completion interrupt is generated when the received PID matches the PID set in CXP1nARPID.

(2) Frame information is transmitted. (Data in CXP1nARFRI[7:0] is transmitted.)

(3) The first-byte data is transmitted. (Data in CXP1nARDATA01[7:0] is transmitted.)

NOTE

Then, data in CXP1nARDATAn (n = 01 to 06) is transmitted on a byte basis.

(4) The CRC value is transmitted. (The CRC value calculated within the circuit is transmitted.)

(5) CRC value transmission is completed. The transmitted CRC value is stored in CXP1nARCRC.

(6) 10 Tbits have passed after transmitting the CRC value.
A frame retransmission completion interrupt is generated and CXP1nINT.CXP1nSFRINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nSFRINT to 0.

(7) Wait for IFS to elapse.
Counting is started at the CXPI nominal bit (Tbit) time after CRC value transmission is completed, and the state changes to the idle state after the time specified by the CXP1nFRMW.CXP1nIFS bit has passed. Communication is possible after the state transitions to the idle state.

(2) PID Reception — Own Node is Not the Target

The operation is the same as for manual response.

For details, see **Section 30.5.4.3(2), PID Reception — Own Node is Not the Target**.

30.5.4.5 PID Reception

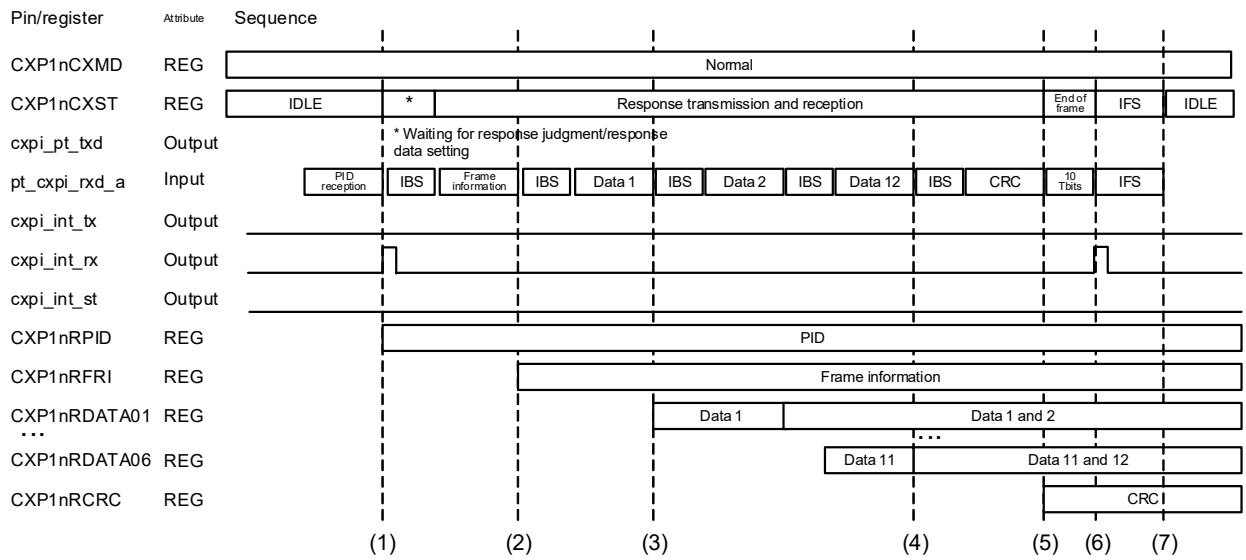
(1) PID Reception — Response Reception (Frame Reception)

The CXPI can receive a response from another node when the PID of its own node was specified by another node. A normal frame or a long frame is received as a response according to the received frame information (DLC).

This section provides an overview of the hardware and software operation in each frame structure.

(a) Normal Frame

The following provides an overview of the hardware and software operation when the frame structure is the normal frame structure.



Note: IBS: IBS controlled by another node

Figure 30.19 Operation Sequence from PID Reception to Response Reception (Normal Frame)

Operation

Operation setting: Frame structure: Normal frame
($CXP1nRFRI.CXP1nRDLC1 \neq F_H$)*1

Number of data bytes in the response: 12 bytes
($CXP1nRFRI.CXP1nRDLC1 = C_H$)*1

Note 1. The frame structure and the number of data bytes are determined based on the received data.

(1) A PID is received. When the received PID matches the PID set in CXP1nRPIDF1m (m = 01 to 12) or CXP1nRPIDF2m (m = 01 to 04), a PID reception completion interrupt is generated and CXP1nINT.CXP1nRIDINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nRIDINT to 0.

(2) Frame information is received, and is stored in CXP1nRFRI.
The frame structure and the number of data bytes (12) are determined based on the received data (Frame information).

(3) The first-byte data is received. The received data is stored in CXP1nRDATA01.

NOTE

After that, data is stored in CXP1nRDATAm (m = 01 to 06) as each byte is received.

(4) The 12th-byte data is received. The received data is stored in CXP1nRDATA06.

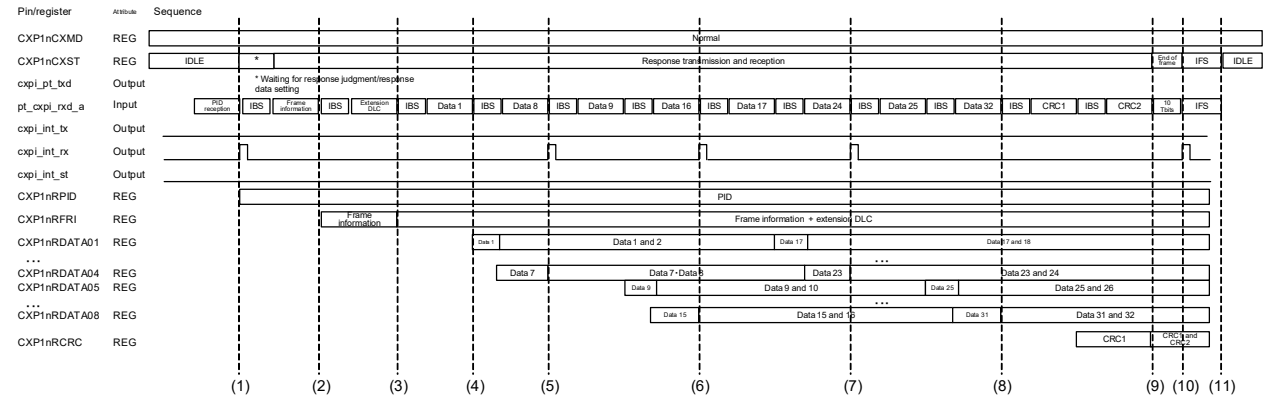
(5) The CRC value is received. The CRC value is stored in CXP1nRCRC.

(6) 10 Tbits (fixed value determined by the hardware) have passed after receiving the CRC value.
A frame reception completion interrupt is generated and CXP1nINT.CXP1nRFRINT is set to 1.
Reception is possible.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nRFRINT to 0.
Frame information can be read from CXP1nRFRI.
Received data can be read from CXP1nRDATAm (m = 01-06).

(7) Wait for IFS to elapse.
Counting is started at the CXPI nominal bit (Tbit) time from CRC value is received, and the state changes to the idle state after the time specified by the CXP1nFRMW.CXP1nIFS bit has passed.
Transition is possible.

(b) Long Frame

The following provides an overview of the hardware and software operation when the frame structure is the long frame structure.



Note: IBS: IBS controlled by another node

Figure 30.20 Operation Sequence from PID Reception to Response Reception (Long Frame)

Operation

Operation setting: Frame structure: Long frame
(CXP1nRFRI.CXP1nRDLC1 = F_H)*1

Number of data bytes in the response: 32 bytes
(CXP1nRFRI.CXP1nRDLC2 = 20_H)*1

Note 1. The frame structure and the number of data bytes are determined based on the received data.

(1) A PID is received. When the received PID matches the PID set in CXP1nRPIDF1m (m = 01 to 12) or CXP1nRPIDF2m (m = 01 to 04), a PID reception completion interrupt is generated and CXP1nINT.CXP1nRIDINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nRIDINT to 0.

(2) Frame information is received, and is stored in CXP1nRFRI.

(3) Extension DLC is received, and is stored in CXP1nRFRI[15:8].
The frame structure (long frame) and the number of data bytes (32) are determined based on the received data (Frame information).

(4) The first-byte data is received. The received data is stored in CXP1nRDATA01[7:0].
Then, data is stored in CXP1nRDATAm (m = 01 to 04) as each byte is received.
(See **Figure 30.11, Received DATA and Received BUFFER**)

(5) The 8th-byte data is received. The received data is stored in CXP1nRDATA04[15:8].
A received data save request interrupt is generated and CXP1nINT.CXP1nRFQINT is set to 1.
Then, data is stored in CXP1nRDATAm (m = 05 to 08) as each byte is received.
(See **Figure 30.11, Received DATA and Received BUFFER**)
The software reads CXP1nRDATA01 to CXP1nRDATA04 and saves the received data.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nRFQINT to 0.

(6) The 16th-byte data is received. The received data is stored in CXP1nRDATA08[15:8].
A received data save request interrupt is generated and CXP1nINT.CXP1nRFQINT is set to 1.
Then, data is stored in CXP1nRDATAm (m = 01 to 04) as each byte is received.
(See **Figure 30.11, Received DATA and Received BUFFER**)
The software reads CXP1nRDATA05 to CXP1nRDATA08 and saves the received data.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nRFQINT to 0.

(7) The 24th-byte data is received. The received data is stored in CXP1nRDATA04[15:8].
A received data save request interrupt is generated and CXP1nINT.CXP1nRFQINT is set to 1.
Then, data is stored in CXP1nRDATAm (m = 05 to 08) as each byte is received.
(See **Figure 30.11, Received DATA and Received BUFFER**)
The software reads CXP1nRDATA01 to CXP1nRDATA04 and saves the received data.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nRFQINT to 0.

(8) The 32nd-byte data is received. The received data is stored in CXP1nRDATA08[15:8].
No received data save request interrupt is generated because this is the last data.

(9) The CRC value is received. The received CRC is stored in CXP1nRCRC.

(10) 10 Tbits have passed after receiving the CRC value.
A frame reception completion interrupt is generated and CXP1nINT.CXP1nRFRINT is set to 1.
The software reads CXP1nRDATAm(05-08) and frame information (CXP1nRFRI).
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nRFRINT to 0.

(11) Wait for IFS to elapse.
Counting is started at the CXPI nominal bit (Tbit) time from CRC value is received, and the state changes to the idle state (CXP1nFLW1.CXP1nCXST=010B) after the time specified by the CXP1nFRMW.CXP1nIFS bit has passed.
Transition is possible.

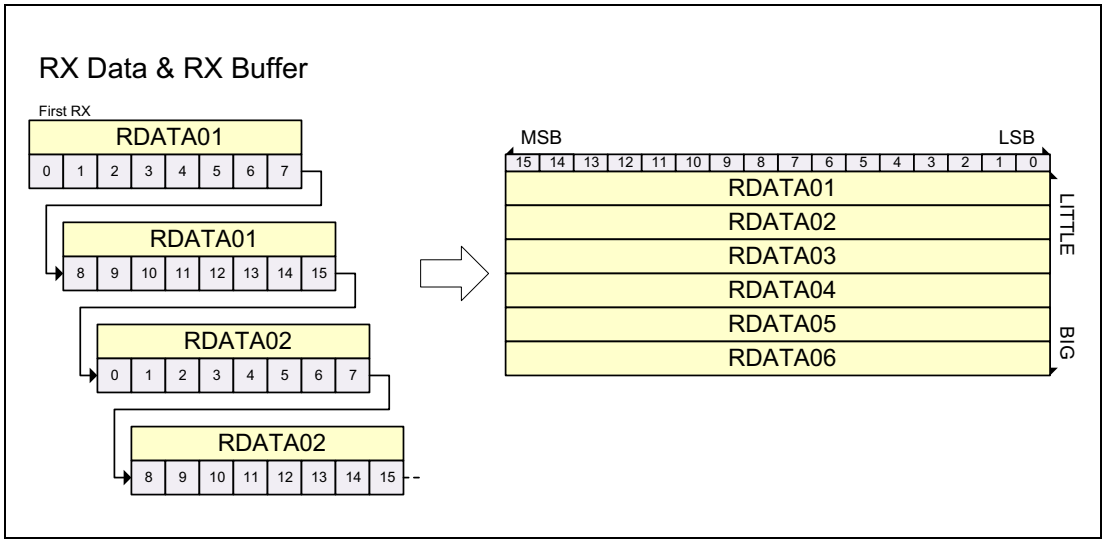


Figure 30.21 Received DATA and Received BUFFER

(2) PID Reception — Own Node is Not the Target

The operation is the same as that for manual response.

For details, see **Section 30.5.4.3(2), PID Reception — Own Node is Not the Target**.

30.5.4.6 PTYPE Transmission

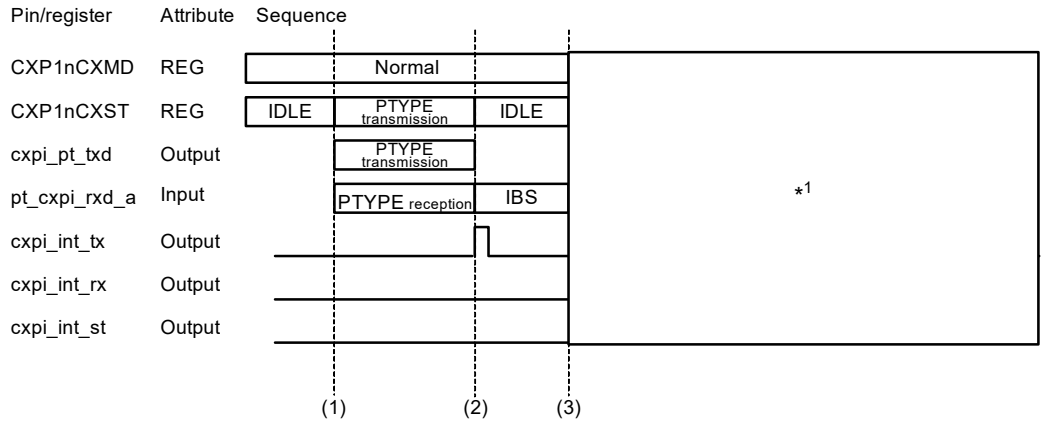
The PTYPE field is used to allow the master node to enable a slave node to transmit a PID in the polling method. The slave node can transmit a PID only during the IBS time immediately after receiving the PTYPE field.

In the event trigger method, the PTYPE field cannot be transmitted because it is protected by the hardware. Also, the slave node cannot transmit the PTYPE field because it is protected by the hardware. This section provides an overview of the hardware and software operation performed in each frame structure when the master node transmits a PTYPE field.

(1) When There is a Response from the Slave Node after Transmitting PTYPE

The following provides an overview of the hardware and software operation for PTYPE transmission.

The following figure shows the sequence when there is a response from the slave node after transmitting the PTYPE field.



Note: IBS: IBS controlled by another node

Note 1. The same operation as in **Figure 30.16**, **Figure 30.18**, **Figure 30.19**, or **Figure 30.20**.

Figure 30.22 Operation Sequence of PTYPE Transmission (When There is a Response)

Operation

(1) Writes 1 to CXP1nSND.CXP1nSPTREQ and makes a PTYPE transmission request. For control, see **Section 30.6.2.4, Restriction of Transmission Request**.
It starts transmission immediately because CXP1nFLW1.CXP1nCXST = 010_B (IDLE).
(If CXP1nFLW1.CXP1nCXST is not 010_B (IDLE), the hardware puts transmission on hold.)

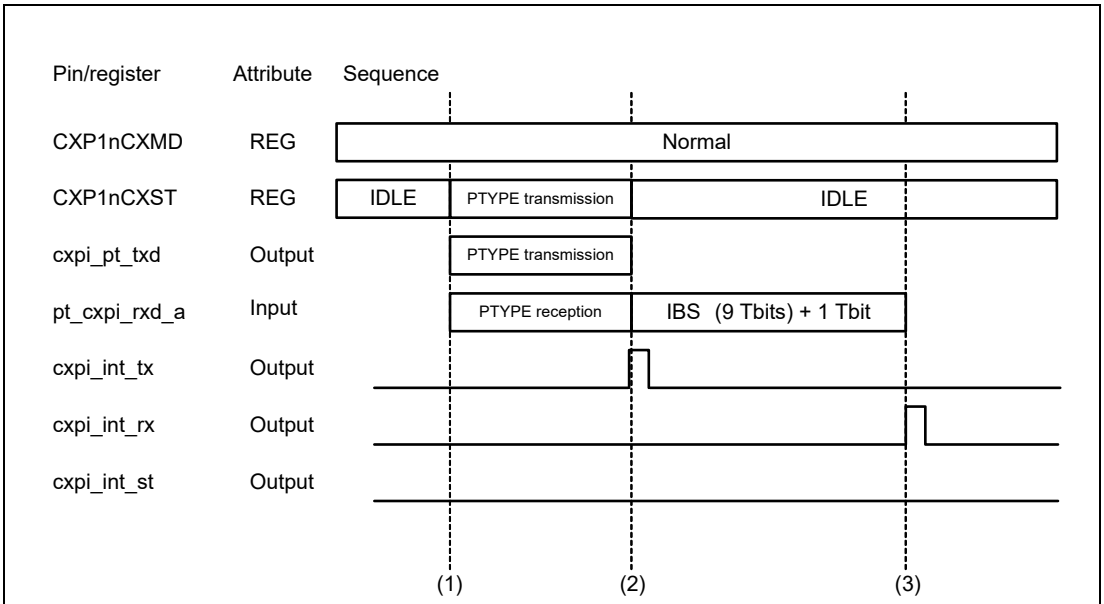
(2) A PTYPE transmission completion interrupt is generated and CXP1nINT.CXP1nSPTINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nSPTINT to 0.

(3) The sequence after * is the same as shown in the timing charts indicated below the figure.

(2) When There is No Response from the Slave Node after Transmitting PTYPE

The following provides an overview of the hardware and software operation for PTYPE transmission.

The following figure shows the sequence when there is no response from the slave node after the master node transmits a PTYPE field.



Note: IBS: IBS controlled by another node

Figure 30.23 Operation Sequence of PTYPE Transmission (When There is No Response)

Operation

(1) Writes 1 to CXP1nSND.CXP1nSPTREQ and makes a PTYPE transmission request. For control, see **Section 30.6.2.4, Restriction of Transmission Request**.
It starts transmission immediately because CXP1nFLW1.CXP1nCXST = 010_B (IDLE).
(If CXP1nFLW1.CXP1nCXST is not 010_B (IDLE), the hardware puts transmission on hold.)

(2) A PTYPE transmission completion interrupt is generated and CXP1nINT.CXP1nSPTINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nSPTINT to 0.

(3) If the start bit of the PID is not received within 10 Tbits after PTYPE transmission is completed, a PTYPE valid period completion interrupt is generated and CXP1nINT.CXP1nREXINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nREXINT to 0.

After detecting PTYPE validity completion interrupt after a PTYPE transmission, the transmission the IDLE state saves and by which PID and a frame is possible by a CXPI controller. Therefore send PID or a frame after a IFS period on the bus is measured by software.

30.5.4.7 PTYPE Reception

A PTYPE field is used to allow the master node to enable a slave node to transmit a PID in the polling method. The slave node can transmit a PID only during the IBS time immediately after receiving a PTYPE field.

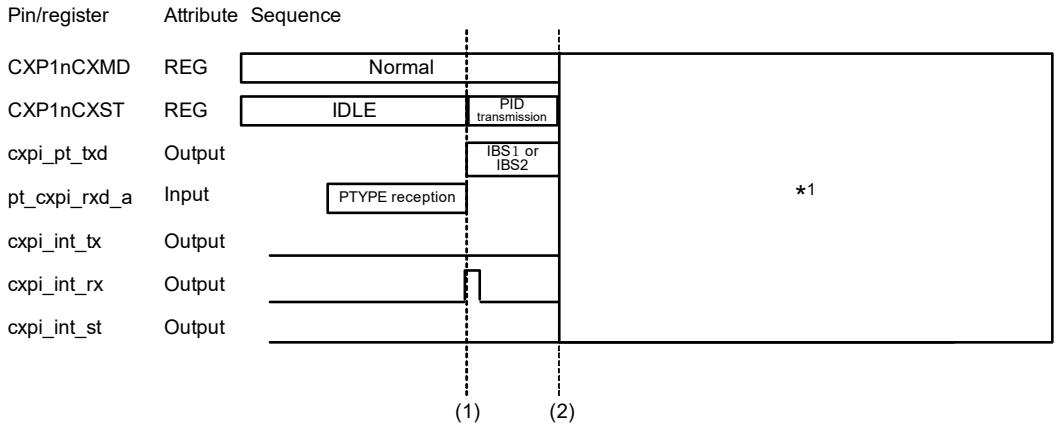
It is not used in the event trigger method.

This section provides an overview of the hardware and software operation performed in each frame structure when the slave node receives a PTYPE field.

(1) When Transmitting PID after Receiving PTYPE

The following provides an overview of the hardware and software operation for PTYPE reception.

The figure below shows the sequence of PID transmission after receiving a PTYPE field.



Note: IBS1 or IBS2: Counting is performed at the CXPI nominal bit (Tbit) time, and logical 1 is output for the time specified by the CXP1nFRMW.CXP1nIBS1 or CXP1nFRMW.CXP1nIBS2 bit. Then, the next data is transmitted.

Note 1. The selection of IBS1 or IBS2 is as follows:
IBS2 to transmit a frame in *1 (CXP1nSFRREQ = 1)
IBS1 to transmit a PID in *1 (CXP1nPIDREQ = 1)
*1: The same operation as in **Figure 30.9**, **Figure 30.10**, **Figure 30.13**, or **Figure 30.14**.

Figure 30.24 Operation Sequence of PTYPE Reception (PID is Transmitted)

Operation

(1) PTYPE is received.
A PTYPE reception completion interrupt is generated and CXP1nINT.CXP1nRPTINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nRPTINT to 0.

(2) The sequence after *1 is the same as shown in the timing charts indicated below the figure.

(2) When Not Transmitting PID after Receiving PTYPE

The following provides an overview of the hardware and software operation for PTYPE reception.

The figure below shows the sequence of not transmitting PID after receiving a PTYPE field.

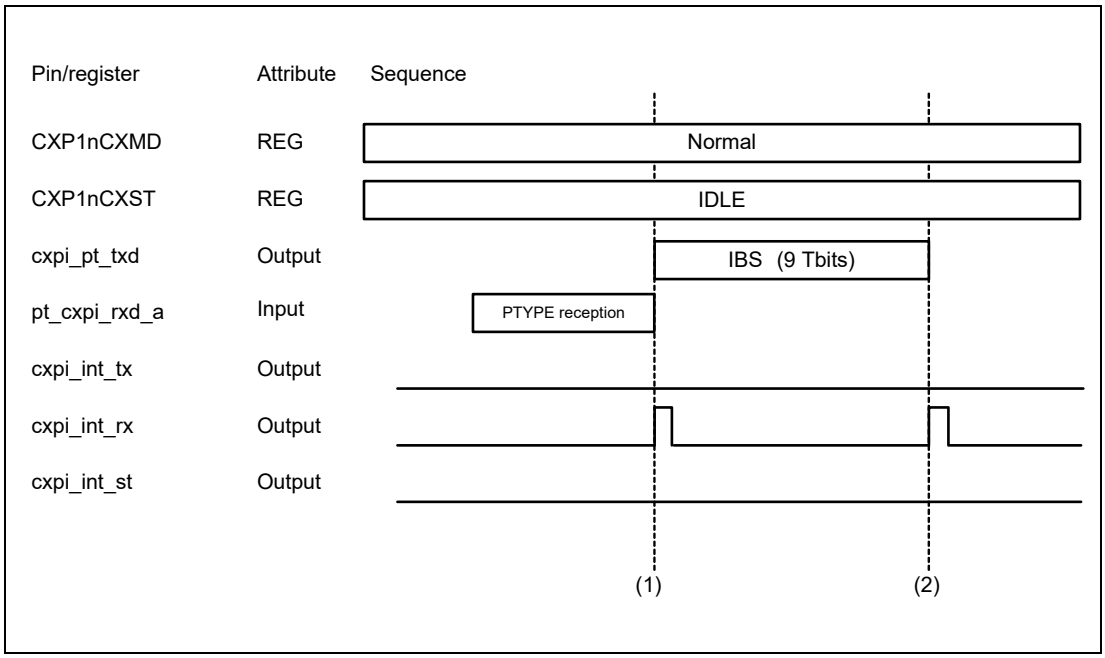


Figure 30.25 Operation Sequence of PTYPE Reception (PID is Not Transmitted)

Operation

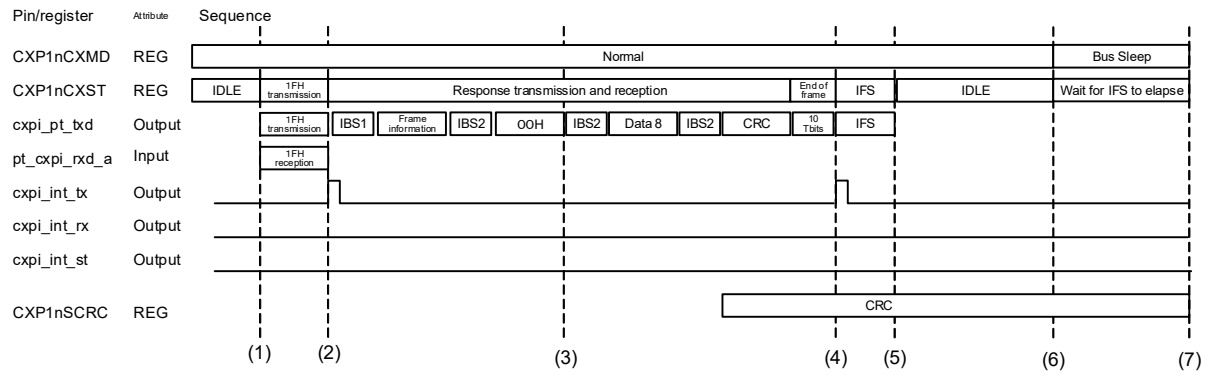
(1) A PTYPE field is received. A PTYPE reception completion interrupt is generated and CXP1nINT.CXP1nRPTINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nRPTINT to 0.

(2) If no PID transmission request is made within 9 Tbits (fixed value determined by the hardware) after PTYPE reception is completed, a PTYPE valid period completion interrupt is generated and CXP1nINT.CXP1nREXINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nREXINT to 0.

30.5.4.8 Sleep Frame Transmission Operation

The master node uses a sleep frame to transition each slave node from normal mode to bus sleep mode. After a sleep frame is transmitted and received, the master node and each slave node enter bus sleep mode.

This section provides an overview of the hardware and software operation performed in each frame structure when the master node transmits a sleep frame.



Note: IBS: IBS controlled by another node
IBS1: Counting is performed at the CXPI nominal bit (Tbit) time, and logical 1 is output for the time specified by the CXP1nFRMW.CXP1nIBS1 bit. Then, the next data is transmitted.
IBS2: Counting is performed at the CXPI nominal bit (Tbit) time, and logical 1 is output for the time specified by the CXP1nFRMW.CXP1nIBS2 bit. Then, the next data is transmitted.

Figure 30.26 Operation Sequence of Sleep Frame Transmission

Operation

(1) Setting sleep frame as following.
Writes 1 to CXP1nSND.CXP1nSFRREQ, and makes a sleep frame transmission request.
PID transmission.
(If CXP1nFLW1.CXP1nCXST is not 010_B (IDLE), the hardware puts transmission on hold.)

PID Field	Frame Information	Data	CRC
1 byte **NOTE**: The parity bit is the same as the normal frame. The frame ID is $1F_H$ (fixed).	1 byte **NOTE**: Same as the normal frame. DLC is fixed to 1000_B.	8 bytes **NOTE**: The first byte is 00_H (fixed). The second and following bytes are FF_H (fixed).	1 byte **NOTE**: Same as the normal frame.

(2) A PID transmission completion interrupt is generated and CXP1nINT.CXP1nSIDINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nSIDINT to 0.

(3) Data 1 (00_H) is transmitted. At this time, the receiving side completes sleep frame reception.

(4) 10 Tbits (fixed value determined by the hardware) have passed after transmitting the CRC value.
A frame transmit completion interrupt is generated and CXP1nINT.CXP1nSFRINT is set to 1.
Reception is possible.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nSFRINT to 0.

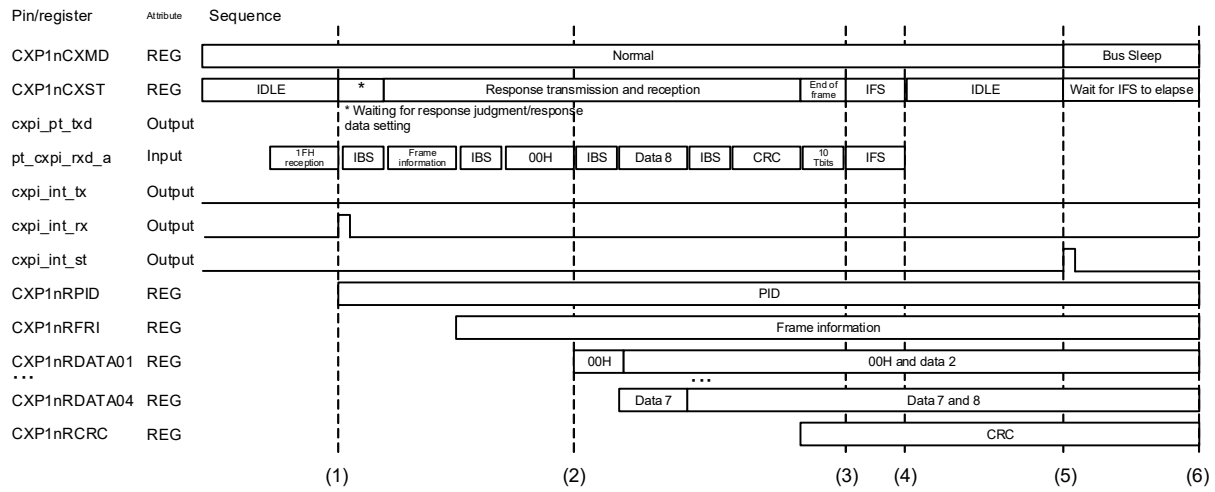
(5) Wait for IFS to elapse.
Counting is started at the CXPI nominal bit (Tbit) time after CRC value transmission is completed, and the state changes to the idle state after the time specified by the CXP1nFRMW.CXP1nIFS bit has passed.
Communication is possible after the state transitions to the idle state.

(6) Stop clock.
Write CXP1nWUP.CXP1nCLKOFF to 1, and the CXPI enters bus sleep mode.

30.5.4.9 Sleep Frame Reception Operation

The master node uses a sleep frame to transition each slave node from normal mode to bus sleep mode. After a sleep frame is transmitted and received, the master node and each slave node enter bus sleep mode.

This section provides an overview of the hardware and software operation performed in each frame structure when the slave node receives a sleep frame.



Note: IBS: IBS controlled by another node

Figure 30.27 Operation Sequence of Sleep Frame Reception

Operation

(1) A PID is received. If PID = $1F_H$ is received, a PID reception completion interrupt is generated even if there is no matched PID in CXP1nRPIDF1m (m = 01 to 12) and CXP1nRPIDF2m (m = 01 to 04).
A PID reception completion interrupt is generated and CXP1nINT.CXP1nRIDINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nRIDINT to 0.

(2) The first-byte data (00_H) is received. At this time, it is determined that a sleep frame has been received.

NOTE

Data is stored in CXP1nRDATAm (m = 01 to 04) as each byte is received.
For the second and following bytes, an arbitrary value is received because no data value is specified.

(3) The CRC value is received. The CRC value is stored in CXP1nRCRC.
A sleep frame reception is completed. (No frame reception completion interrupt is generated.)

(4) Wait for IFS to elapse.
Counting is started at the CXPI nominal bit (Tbit) time, and the state changes to the idle state after the time specified by the CXP1nFRMW.CXP1nIFS bit has passed.

(5) The time specified in the CXP1nSLP.CXP1nSLPWAIT bits has passed since (3).
A sleep transition completion interrupt is generated and CXP1nINT.CXP1nSLPINT is set to 1.
Since an interrupt is output at a level, the software clears CXP1nINT.CXP1nSLPINT to 0.
(If it is a frame reception completion interrupt instead of a sleep transition completion interrupt, process it as a diagnostic request.)
The CXPI transitions from bus sleep mode to normal mode.

(6) Transit transceiver to the standby mode. (See transceiver specification).
The software outputs LOW to the NSLP pin of the CXPI transceiver. Implemented by an external function outside this IP.

NOTES

1. If a PID is received between (3) and (5), operation for reception proceeds, but the CXPI enters bus sleep mode forcibly after the sleep transition time has passed.
2. Don't transmit request or write 1 to CXP1nWUP.CXP1nCLKOFF between (3) and (5).

30.5.4.10 Wakeup Pulse Transmission Operation

The CXPI can wake up other nodes by sending a wakeup pulse.

The wakeup pulse transmission operation differs depending on the transfer mode and master node/ slave node selection.

This section describes the wakeup pulse transmission operation under each operating condition.

(1) CXPI-PWM Mode

This section describes the wakeup pulse transmission operation in CXPI-PWM mode.

(a) Master Node

The CXPI in the master node wakes up a slave node by transmitting the clock signal.

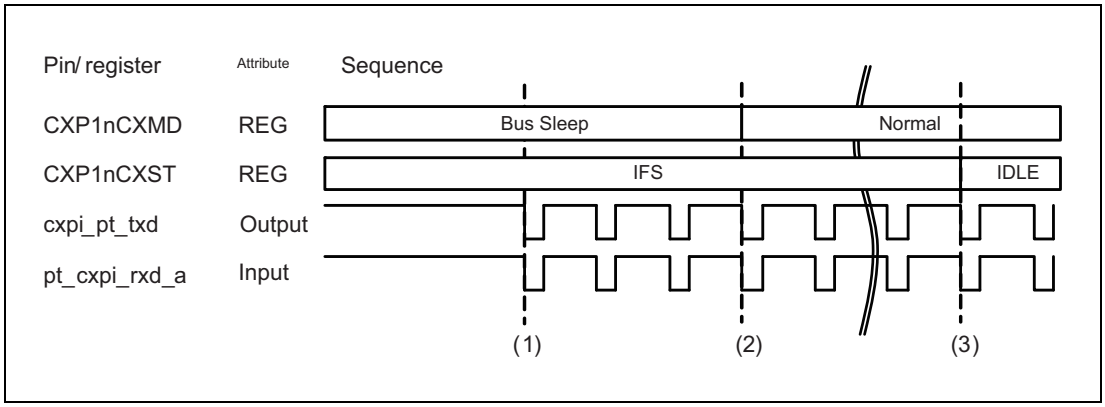


Figure 30.28 Wakeup Pulse Transmission Operation (Master Node in CXPI-PWM Mode)

Operation

(1) The software verifies that CXP1nFLW1.CXP1nCXMD = 01_B (bus sleep mode).
It then writes 1 to the CXP1nWUP.CXP1nCLKON bit to request clock transmission.
It transmits the clock signal immediately after requesting clock transmission.

(2) The CXPI transitions from bus sleep mode to normal mode by detecting the looped-back clock signal after transmitting the clock signal. (Four or five falling edges of pt_cxpi_rxd_a are detected.)

(3) Wait for IFS to elapse.
Counting is started at the CXPI nominal bit (Tbit) time after entering normal mode, and the state changes to the idle state after the time specified by the CXP1nFRMW.CXP1nIFS bit has passed.
Communication is possible after the state transitions to the idle state.

(b) Slave Node

A slave node wakes up other nodes by sending a wakeup pulse.

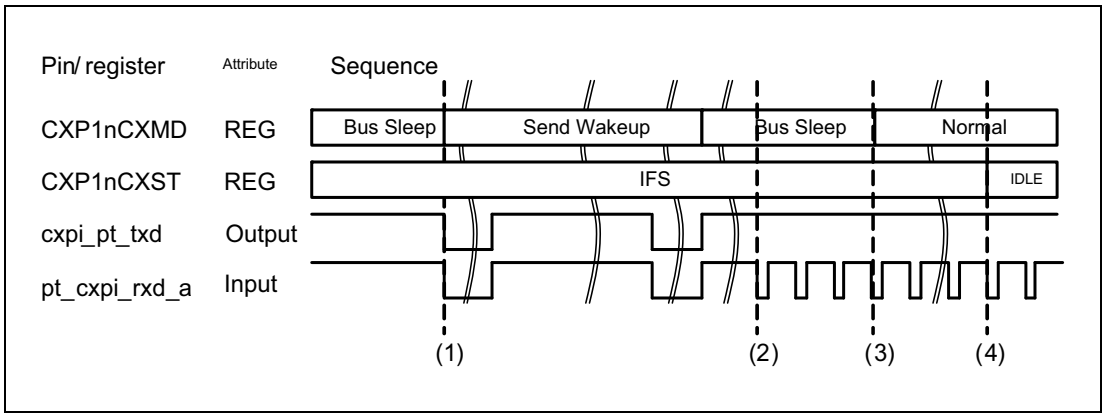

Figure 30.29 Wakeup Pulse Transmission Operation (Slave Node in CXPI-PWM Mode)

The pulse width of the wakeup pulse is specified by the CXP1nWU register.

Width of dominant level: CXPI nominal bit (Tbit) time × CXP1nWU.CXP1nWTXDOM

Width of recessive level: CXPI nominal bit (Tbit) time × CXP1nWU.CXP1nWTXREC

Operation

(1) The software verifies that CXP1nFLW1.CXP1nCXMD = 01_B (bus sleep mode).
Then, it writes 1 to CXP1nWUP.CXP1nWUPREQ and makes a wakeup pulse transmission request.
It transmits a wakeup pulse immediately after requesting wakeup pulse transmission.
It keeps polling until CXP1nFLW1.CXP1nCXMD = 11_B (normal mode).

(2) The clock signal is input from the master node that has detected a wakeup pulse.

NOTE

If this IP does not enter normal mode within the specified time, restart from (1).

(3) This IP transitions from bus sleep mode to normal mode by detecting the clock signal. (Four falling edges of pt_cxpi_rxd_a are detected.)

NOTE

If detecting a clock signal while transmitting a wakeup pulse, the IP transitions from send wakeup mode to normal mode and stops the wakeup pulse transmission.

(4) Wait for IFS to elapse.
Counting is started at the CXPI nominal bit (Tbit) time after entering normal mode, and the state changes to the idle state after the time specified by the CXP1nFRMW.CXP1nIFS bit has passed.
Communication is possible after the state transitions to the idle state.

(2) CXPI-NRZ Mode

This section describes the wakeup pulse transmission operation in CXPI-NRZ mode.

(a) Master Node

In CXPI-NRZ mode, a wakeup pulse is transmitted by transmitting the clock signal to the CLK pin of the CXPI transceiver from the PWM output pin of the LSI.

The following provides an overview of the hardware and software operation under control of the LSI and CXPI transceiver.

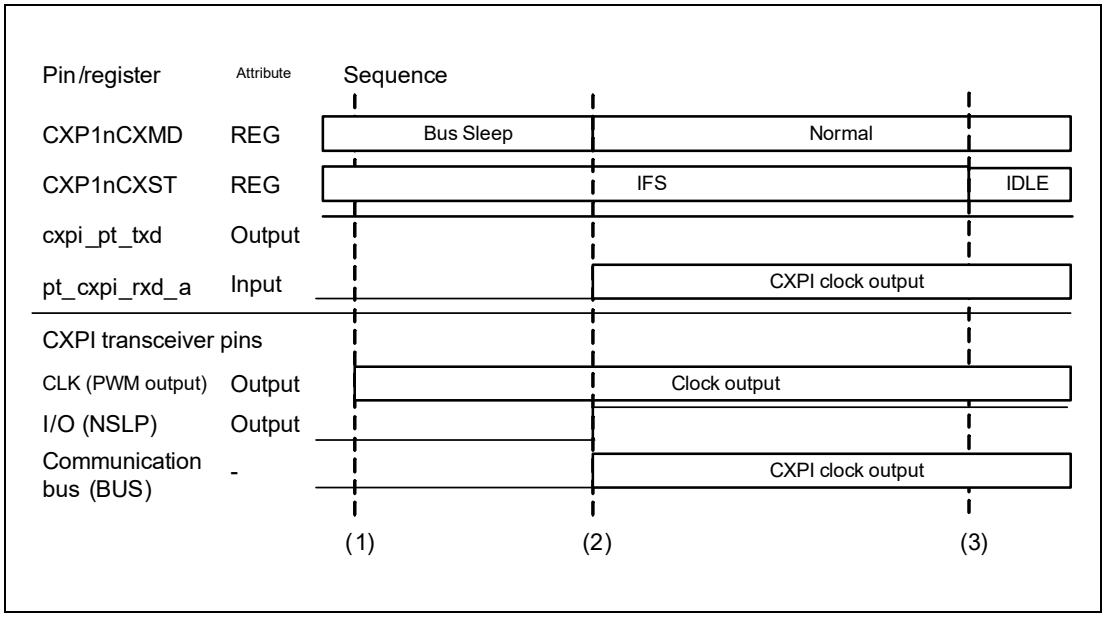

Figure 30.30 Wakeup Pulse Transmission Operation (Master Node in CXPI-NRZ Mode)

Operation

(1) The software starts the PWM macro and outputs bit rate cycles from the PWM output pin.*1

(2) The software outputs HIGH to the NSLP pin of the CXPI transceiver. *1
The CXPI transceiver outputs the CXPI clock to the communication bus because the NSLP pin went high.
The software verifies that CXP1nFLW1.CXP1nCXMD = 01_B (bus sleep mode).
It then writes 1 to the CXP1nWUP.CXP1nCLKON bit to notify clock detection.
This IP transitions from bus sleep mode to normal mode by notifying the clock detection.

(3) Wait for IFS to elapse.
Counting is started at the CXPI nominal bit (Tbit) time after entering normal mode, and the state changes to the idle state after the time specified by the CXP1nFRMW.CXP1nIFS bit has passed.
Communication is possible after the state transitions to the idle state.

Note 1. Implemented by a module other than this IP.

(b) Slave Node

In CXPI-NRZ mode, the CXPI transceiver detects the clock on the communication bus and the IP detects the clock by the clock signal output from the CLK pin or RXD pin.

The following provides an overview of the hardware and software operation under control of the LSI and CXPI transceiver.

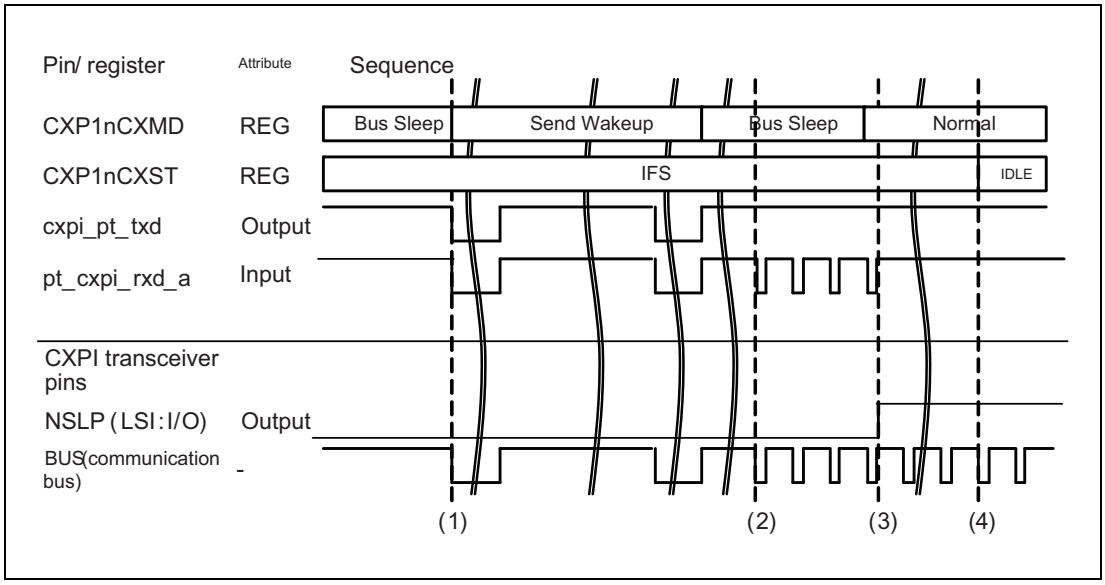

Figure 30.31 Wakeup Pulse Transmission Operation (Slave Node in CXPI-NRZ Mode)

The pulse width of the wakeup pulse is specified by the CXP1nWU register.

Width of dominant level: CXPI nominal bit (Tbit) time × CXP1nWU.CXP1nWTXDOM

Width of recessive level: CXPI nominal bit (Tbit) time × CXP1nWU.CXP1nWTXREC

Operation

(1) The software verifies that CXP1nFLW1.CXP1nCXMD = 01_B (bus sleep mode).
Then, it writes 1 to CXP1nWUP.CXP1nWUPREQ and makes a wakeup pulse transmission request.
It transmits a wakeup pulse immediately after requesting wakeup pulse transmission.

(2) The clock signal is input from the master node that has detected a wakeup pulse.

NOTE

If this IP does not enter normal mode within the specified time, restart from (1).

(3) An external function outside this IP detects the CXPI clock (the clock detection sequence differs from one system to another).
The software writes 1 to the CXP1nWUP.CXP1nCLKON bit to notify clock detection.
This IP transitions from bus sleep mode to normal mode after notifying clock detection.(Four or five falling edges of pt_cxpi_rxd_a are detected.)

NOTE

The software outputs High to the NSLP pin of the CXPI transceiver (this is implemented by a module other than this IP).

(4) Wait for IFS to elapse.
Counting is started at the CXPI nominal bit (Tbit) time after entering normal mode, and the state changes to the idle state after the time specified by the CXP1nFRMW.CXP1nIFS bit has passed. Communication is possible after the state transitions to the idle state.

30.5.4.11 Wakeup Pulse Reception Operation

This IP does not have the wakeup pulse reception function. It detects a wakeup pulse by using the CXPI transceiver and a module other than this IP. For the detailed operation, see **Section 30.5.1, CXPI System Configuration**.

30.5.5 Basic Functions

This section describes the basic functions defined in the Protocol Specification.

30.5.5.1 Baud Rate

The CXPI baud rate can be selected from the following. For the detailed baud rate setting, see **Section 30.4.1.2, CXP1nBRT — CXPI Baud Rate Setting Register**.

- 9.6 kbits/s
- 10.4 kbits/s
- 19.2 kbits/s
- 20 kbits/s

30.5.5.2 Node Selection

The CXP1nMODE.CXP1nMS bit allows node selection from the master node and the slave node.

For the hardware function differences by node selection, see **Section 30.5.3, Functions**.

30.5.5.3 Clock Sharing

For details on clock sharing, see *Section 5.1.4* in *the JASO D015-3 Protocol Specification*.

30.5.5.4 Access Method

The CXPI access method can be selected from the event trigger method and the polling method.

For details on the access method, see **Section 30.5.2, CXPI Operation Overview**.

30.5.5.5 PWM Encoding/Decoding

The PWM encoding/decoding function is used to output and sample the PWM waveform.

The table below lists the functions for PWM encoding/decoding.

Table 30.73 List of Functions for PWM Encoding/Decoding

No.	Function		Description
1	PWM waveform generation	Generation of logical value 1	For details, see **Section 30.4.1.3, CXP1nV1LW — CXPI Logical Value 1 Setting Register**.
2		Generation of logical value 0	For details, see **Section 30.4.1.4, CXP1nV0LW — CXPI Logical Value 0 Setting Register**.
3	PWM waveform sampling		For details, see **Section 30.4.1.5, CXP1nSAMP — CXPI Sampling Setting Register**.

Note that PWM encoding/decoding does not work as hardware in CXPI-NRZ mode.

The communication operation in CXPI-NRZ mode is as follows:

In CXPI-NRZ mode, UART communication is performed and the CXPI transceiver handles PWM encoding/decoding.

The UART reception operation in the CXPI-NRZ mode performs sampling at the center of the baud rate set by the CXP1nBRT register.

NOTE

The CXP1nSAMP register in which the sampling timing is set is valid only in CXPI-PWM mode.
It sets the sampling timing for the PWM waveform.

30.5.6 Data Functions

This section describes the PID and data buffers defined in the Protocol Specification.

30.5.6.1 PID

The table below lists the registers related with the PID. For detailed operation, see the relevant section.

Table 30.74 Registers Related to PID

Register Name	Description	Described in Section
CXP1nSPID	Sets the transmitting PID when transmitting a PID and frame.	**30.4.1.21**
CXP1nRPID	Stores the received PID when a PID is received.	**30.4.1.20**
CXP1nRPIDF1m (m = 01 to 12)	Sets the PID to be received and responded to. Sets the PID to be transmitting.	**30.4.1.22**
CXP1nRPIDF2m (m = 01 to 04)	Sets the PID to be received and responded to. **NOTE:** A frame ID filtering function is provided.	**30.4.1.23**
CXP1nARPID	Sets the PID for automatic response.	**30.4.1.24**

30.5.6.2 Data Buffer

The table below lists the data buffers.

Table 30.75 Data Buffers

Type	No. of Bytes	Register Name	Usage
Transmission	16 bytes	CXP1nSDATAm (m = 01 to 08)	Normal frame (see **Section 30.5.4.2(1)(a)**) Long frame (see **Section 30.5.4.2(1)(b)**)
Reception	16 bytes	CXP1nRDATAm (m = 01 to 08)	Normal frame (see **Section 30.5.4.5(1)(a)**) Long frame (see **Section 30.5.4.5(1)(b)**)
Automatic Response	12 bytes	CXP1nARDATAm (m = 01 to 06)	Normal frame (see **Section 30.5.4.4(1)**) The long frame is not supported.

30.5.6.3 Number of Data Byes in the Response

The table below lists the number of data byes in the response for each type of communication.

Table 30.76 Number of Data Byes in the Response

Type	Frame Structure	Number of Data Byes in the Response
Transmission/manual response	Normal frame	0 byte to 12 bytes
	Long frame	0 byte to 255 bytes
	Sleep frame	Fixed to 8 bytes
Automatic response	Normal frame	0 byte to 12 bytes
Reception	Normal frame	0 byte to 12 bytes
	Long frame	0 byte to 255 bytes
	Sleep frame	Fixed to 8 bytes

30.5.7 Control Functions

This section describes the functions to control the CXPI.

30.5.7.1 Transmission

The table below lists the functions provided by this IP for transmission control.

For how to use them, see the relevant section.

Table 30.77 Control Functions

Transmission Control Functions	Register that Makes a Transmission Request	Described in Section
CXPI clock transmission	CXP1nWUP.CXP1nCLKON	**30.5.4.10**
PID transmission	CXP1nSND.CXP1nPIDREQ	**30.5.4.1**
Frame transmission	CXP1nSND.CXP1nSFRREQ	**30.5.4.2**
Automatic response of the response when receiving a PID	— (Automatic response is enabled when the received PID matches the value in CXP1nARPID.)	**30.5.4.4**
Manual response of the response when receiving a PID	CXP1nSND.CXP1nSRSREQ	**30.5.4.3**
PTYPE transmission	CXP1nSND.CXP1nSPTREQ	**30.5.4.6**

30.5.7.2 IFS and IBS Setting Function

For details on the IFS and IBS setting function, see **Section 30.4.1.8, CXP1nFRMW — CXP1 Inter-Frame Setting Register**.

For the actual operation, see **Section 30.5.4, Overall Operation**.

30.5.7.3 Retransmission Processing

The IP module can perform retransmission processing automatically in response to a loss in arbitration or an error. It handles retransmission when a retransmission factor occurs in the communications listed in the table below.

Table 30.78 Targets and Factors of Retransmission Processing

No.	Target Communication	Retransmission Factor	
1	Frame transmission (PID transmission → response reception)	During PID transmission	Transmission stopped because of a loss in arbitration
2			Transmission stopped because a bit error occurred
3			Transmission stopped because a parity error occurred
4			Transmission stopped because a framing error occurred
5		During response transmission	Transmission stopped because a bit error occurred
6			Transmission stopped because a framing error occurred
7			Transmission stopped because a data length error occurred
8	PID transmission (PID transmission → response reception)	During PID transmission	Transmission stopped because of a loss in arbitration
9			Transmission stopped because a bit error occurred
10			Transmission stopped because a parity error occurred
11			Transmission stopped because a framing error occurred
12		During response reception	Reception stopped because a data length error occurred
13			Reception stopped because a CRC error occurred
14			Reception stopped because a framing error occurred
15			Reception stopped because an overrun error occurred

The table below lists the functions for retransmission processing.

Table 30.79 Functions for Retransmission Processing

No.	Retransmission Function	Related Registers
1	Two modes of retransmission not judged (mode in which the number of retransmissions (retries) is fixed to unlimited) and retransmission judged (mode in which Nos. 2 and 3 below are valid)	CXP1nMODE.CXP1nREPOP
2	The number of retransmissions (retries) can be specified. As the number of retries, 0, 1, 2 or unlimited can be specified.	CXP1nSND.CXP1nREPSEL CXP1nREP
3	Indication of retransmission status (remaining number of retransmissions, etc.)	CXP1nFLG2
4	Retransmission can be canceled during communication.	CXP1nSND CXP1nFLG2

For the specifications for the related registers, see **Section 30.4.1.1, CXP1nMODE —CXPI Operating Mode Select Register**, **Section 30.4.1.10, CXP1nREP — CXPI Retransmission Setting Register**, **Section 30.4.1.12, CXP1nSND — CXPI Transmission Control Register**, and **Section 30.4.1.16, CXP1nFLG2 — CXPI Flag Register 2**. For the retransmission processing setting procedure through software, see **Section 30.5.10.2, Initial Settings**.

The hardware operation overview is provided below for four different retransmission operations.

- Retransmission after a loss in arbitration (retransmission not judged)
- Retransmission after a loss in arbitration (retransmission judged)
- Retransmission after an error occurred (retransmission not judged)
- Retransmission after an error occurred (retransmission judged)

NOTE

If a bit error occurred in PID/PTYPE transmission in PWM slave mode, the CXPI transmits a PID/PTYPE only once after retransmission was canceled.

(1) Retransmission after a Loss in Arbitration (Retransmission Not Judged)

The figure below shows the operation sequence of retransmission after a loss in arbitration (retransmission not judged) during frame transmission (No. 1 in **Table 30.78**).

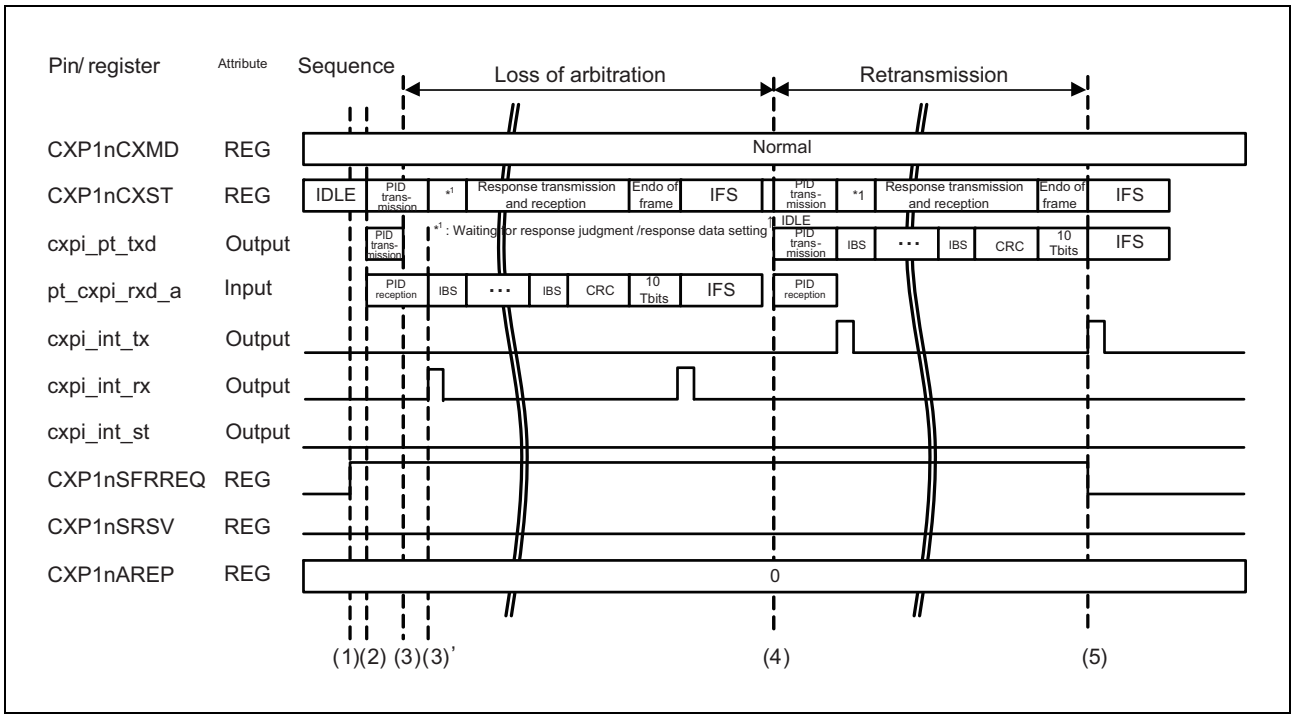

Figure 30.32 Retransmission Operation Sequence (Retransmission after a Loss in Arbitration (Retransmission Not Judged))

Operation

Conditions: The IP module loses in arbitration while transmitting a frame with the setting of "retransmission not judged". Frame transmission succeeds in the first round of retransmission.
($CXP1nMODE.CXP1nREPOP = 0_B$)

(1) 1 is written to CXP1nSND.CXP1nSFRREQ to request frame transmission.

(2) Frame transmission is started. CXP1nSND.CXP1nSFRREQ is not cleared at the start of transmission with the setting of "retransmission not judged".

(3) Arbitration was lost.
(Only in CXPI-PWM mode, the cxpi_pt_txd output is stopped because of a loss in arbitration during PID transmission as shown in the figure. In CXPI-NRZ mode, arbitration is made on a byte basis, so cxpi_pt_txd is output up to (3)'.)
A PID is received.
After that, it is equivalent to the processing flow of PID reception. Confirm the necessity of re-transmission cancellation.

(4) CXP1nCXST indicates an idle state after communication has been completed in response to a loss in arbitration and IFS has passed.
If 1 is written to CXP1nSND.CXP1nSFRREQ when CXP1nCXST indicates an idle state, retransmission is started immediately.
(Retransmission is not performed immediately in a slave node in polling mode, but performed after the IBS time has passed after PTYPE reception.)
After that, it is equivalent to the processing flow of frame transmission.

(5) When frame transmission initiated by retransmission has been normally completed, CXP1nSND.CXP1nSFRREQ is cleared to 0. The IFS time has passed, CXP1nCXST indicates an idle state. (No more retransmission is performed because frame transmission was successful.)

CXP1nSRSV and CXP1nAREP do not operate because retransmission is not judged.

- Retransmission cancellation
  When 0 is written to TCXP1nSND.CXP1nSFRREQ when CXP1nSND.CXP1nSFRREQ = 1, the next and following retransmissions are canceled.
- PID retransmission (No. 8 in **Table 30.78, Targets and Factors of Retransmission Processing**)
  The retransmission operation sequence of PID transmission is the same as the operation sequence for frame transmission except:
  - Read CXP1nSFRREQ as CXP1nSIDREQ.
  - Read CXP1nSRSV as CXP1nRRSV.
  - Read transmission as reception in the response operation during retransmission described for cxpi_pt_txd and pt_cxpi_rxd_a.

(2) Retransmission after a Loss in Arbitration (Retransmission Judged)

The figure below shows the operation sequence of retransmission after a loss in arbitration (retransmission judged) during frame transmission (No. 1 in **Table 30.78**).

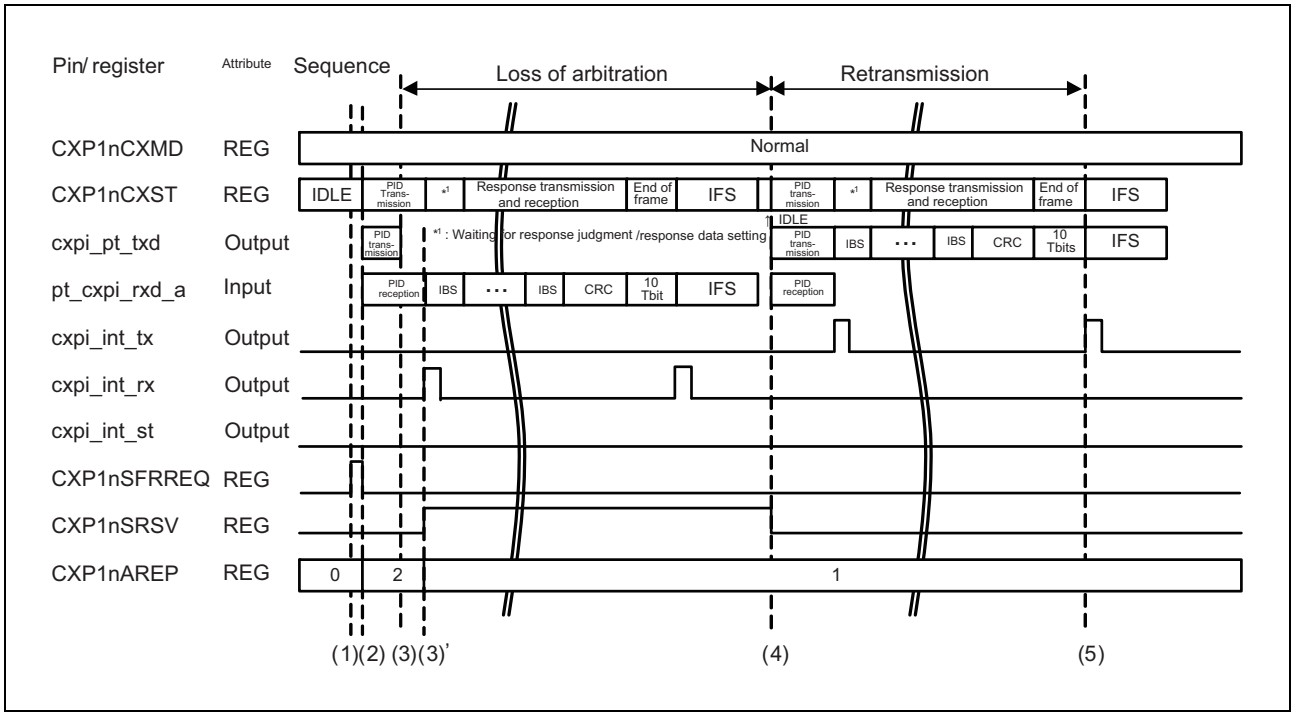

Figure 30.33 Retransmission Operation Sequence (Retransmission after a Loss in Arbitration (Retransmission Judged))

Operation

Conditions: The IP module loses in arbitration while transmitting a frame with the settings of "retransmission judged" and "the number of retransmissions is 2". Frame transmission succeeds in the first round of retransmission.
(CXP1nMODE.CXP1nREPOP = 1_B, CXP1nREP.CXP1nAIREP = 10_B or CXP1nREP.CXP1nARREP = 10_B)

(1) 1 is written to CXP1nSND.CXP1nSFRREQ to request frame transmission.

(2) Frame transmission is started. When "retransmission judged" is set, CXP1nSND.CXP1nSFRREQ is cleared at the start of transmission. The value set in the CXP1nREP.CXP1nAIREP bit or the CXP1nREP.CXP1nARREP bit is transferred to CXP1nFLG2.CXP1nAREP. (The transfer destination is determined by the value set in CXP1nSND.CXP1nREPSEL at the time of frame transmission request.)

(3) Arbitration was lost. If CXP1nFLG2.CXP1nAREP indicates 1 or more, CXP1nFLG2.CXP1nSRSV is set to make reservation for retransmission. Also, if CXP1nFLG2.CXP1nAREP is 1 or 2, the number of retransmissions is decremented.
(If CXP1nFLG2.CXP1nAREP indicates 3, the number of retransmissions is not decremented but retransmissions are carried out unlimitedly.)
(When CXP1nFLG2.CXP1nAREP is 0, CXP1nFLG2.CXP1nSRSV is not set because retransmission is not performed.)
(Only in CXPI-PWM mode, the cxpi_pt_txd output is stopped because of a loss in arbitration during PID transmission as shown in the figure. In CXPI-NRZ mode, arbitration is made on a byte basis, so cxpi_pt_txd is output up to (3)'. Also, CXP1nFLG2.CXP1nAREP and CXP1nFLG2.CXP1nSRSV change at (3)'.)
A PID is received.

After that, it is equivalent to the processing flow of PID reception. Confirm the necessity of re-transmission cancellation.

(4) CXP1nCXST indicates an idle state after communication has been completed in response to a loss in arbitration and IFS has passed.
If 1 is written to CXP1nFLG2.CXP1nSRSV when CXP1nCXST indicates an idle state, retransmission is started immediately and, at the same time, CXP1nFLG2.CXP1nSRSV is cleared to 0.
(Retransmission is not performed immediately in a slave node in polling mode, but performed after the IBS time has passed after PTYPE reception.)
After that, it is equivalent to the processing flow of frame transmission.

(5) When frame transmission initiated by retransmission has been normally completed and the IFS time has passed, CXP1nCXST indicates an idle state. No retransmission is initiated because CXP1nFLG2.CXP1nSRSV = 0.

- Retransmission cancellation
  - When 0 is written to CXP1nFLG2.CXP1nSRSV when CXP1nFLG2.CXP1nSRSV = 1, the next and following retransmissions are canceled.
  - When 0 is written to CXP1nFLG2.CXP1nEREP when CXP1nFLG2.CXP1nSRSV = 0, the next and following retransmissions are canceled.
  - When 0 is written to CXP1nFLG2.CXP1nEREP when CXP1nFLG2.CXP1nSRSV = 1, the next retransmission is initiated but the following retransmissions are canceled.
- PID retransmission (No. 8 in **Table 30.78**)
  The retransmission operation sequence of PID transmission is the same as the operation sequence for frame transmission except:
  - Read CXP1nSFRREQ as CXP1nSIDREQ.
  - Read CXP1nSRSV as CXP1nRRSV.
  - Read transmission as reception in the response operation during retransmission described for cxpi_pt_txd and pt_cxpi_rxd_a.

(3) Retransmission after an Error Occurred (Retransmission Not Judged)

The figure below shows the operation sequence of retransmission after an error occurred (retransmission not judged) during frame transmission (No. 5 in **Table 30.78**).

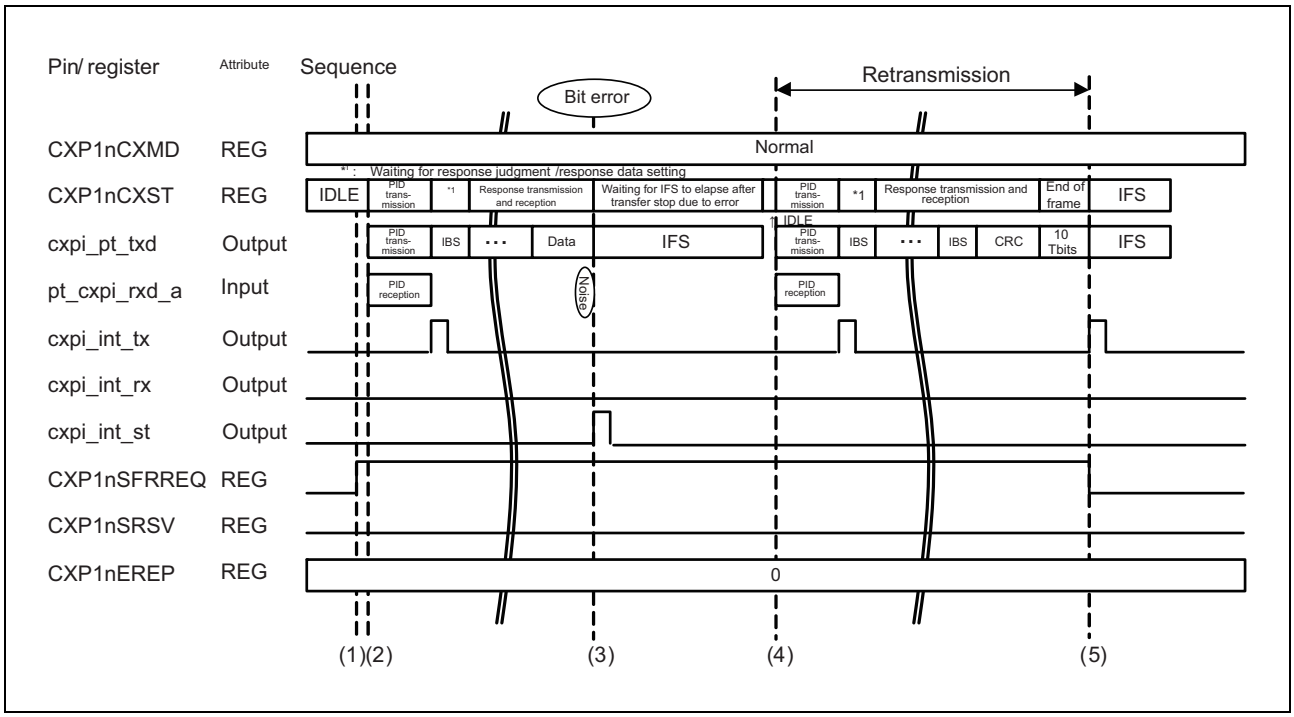

Figure 30.34 Retransmission Operation Sequence (Retransmission after an Error Occurred (Retransmission Not Judged))

Operation

Conditions: The IP has a bit error while transmitting a frame with the setting of “retransmission not judged”. Frame transmission succeeds in the first round of retransmission. (CXP1nMODE.CXP1nREPOP = 0_B)

(1) 1 is written to CXP1nSND.CXP1nSFRREQ to request frame transmission.

(2) Frame transmission is started. CXP1nSND.CXP1nSFRREQ is not cleared at the start of transmission with the setting of “retransmission not judged”.

(3) A bit error occurred.
An error detection interrupt is generated. CXP1nINT.CXP1nERRINT and CXP1nERR.CXP1nBITERR are set to 1.
Error status is set in CXP1nFLG1 and CXP1nERR register.
To clear them, the software write 0 to CXP1nINT.CXP1nERRINT and CXP1nERR.CXP1nBITERR.

(4) CXP1nCXST indicates an idle state after communication is stopped due to a bit error and IFS has passed.
If CXP1nSND.CXP1nSFRREQ = 1 when CXP1nCXST indicates an idle state, retransmission is started immediately.
(Retransmission is not performed immediately in a slave node in polling mode, but performed after the IBS time has passed after PTYPE reception.)

(5) When frame transmission initiated by retransmission is normally completed and the IFS time has passed, CXP1nCXST indicates an idle state and, at the same time, CXP1nSND.CXP1nSFRREQ

is cleared to 0. (No more retransmission is performed because frame transmission was successful.)

CXP1nSRSV and CXP1nEREP do not operate because retransmission is not judged.

- Retransmission cancellation
  When 0 is written to CXP1nSND.CXP1nSFRREQ when it is 1, the next and following retransmissions are canceled.
- Retransmission operation when another error occurred in frame transmission (Nos. 3 to 7 in **Table 30.78**)
  Even if a different error occurred, the IP retransmits the frame when CXP1nCXST indicates an idle state the IFS time after the error detection, as with No. 5. (For a bit error in PID, the IP may become idle state before the IFS time has passed.) The operation timing of CXP1nSND.CXP1nSFRREQ is the same as that for No. 5.
- PID retransmission (Nos. 9 to 15 in **Table 30.78**)
  The retransmission operation sequence of PID transmission is the same as the operation sequence for frame transmission except:
  - Read CXP1nSFRREQ as CXP1nSIDREQ.
  - Read CXP1nSRSV as CXP1nRRSV.
  - Read transmission as reception in the response operation during retransmission described for cxpi_pt_txd and pt_cxpi_rxd_a.

  If an error occurred during response reception, CXP1nCXST indicates an idle state and the IP performs retransmission the IFS time after having received the remaining data after the error.

(4) Retransmission after an Error Occurred (Retransmission Judged)

The figure below shows the operation sequence of retransmission after an error occurred (retransmission judged) during frame transmission (No. 5 in **Table 30.78**).

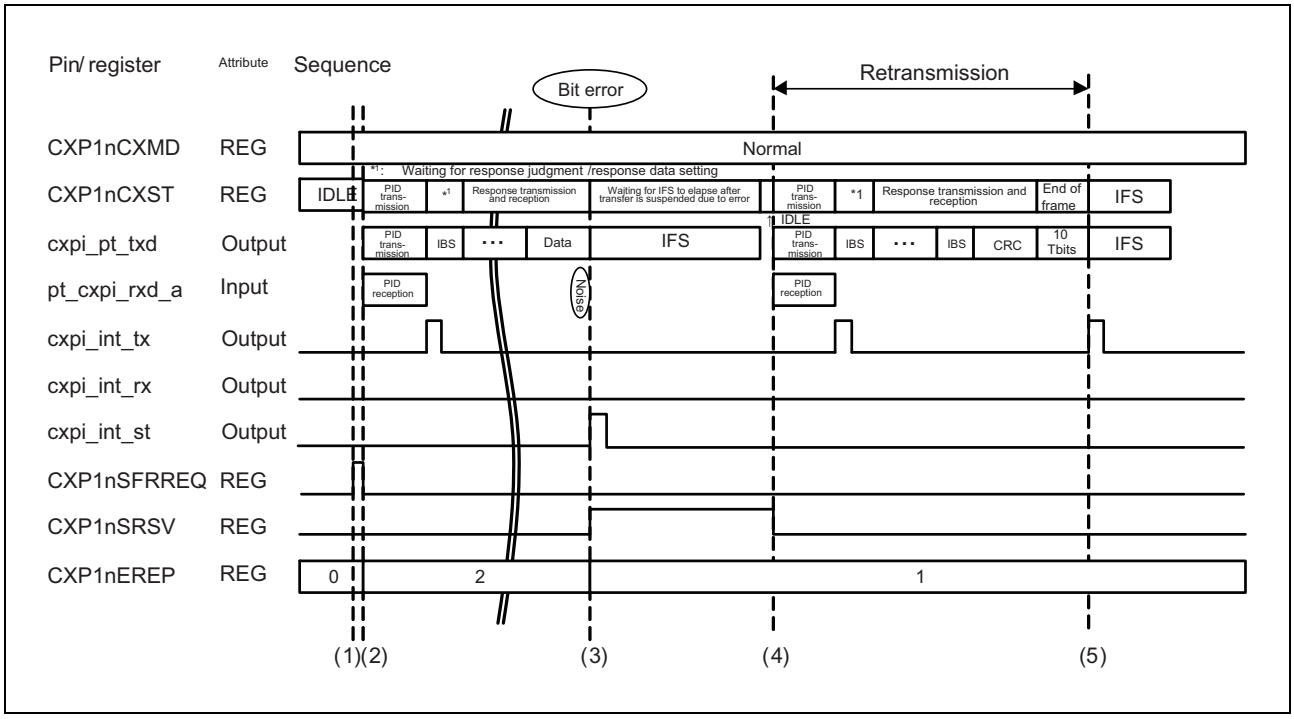

Figure 30.35 Retransmission Operation Sequence (Retransmission after an Error Occurred (Retransmission Judged))

Operation

Conditions: The IP has a bit error while transmitting a frame with the settings of “retransmission judged” and “the number of retransmissions is 2”. Frame transmission succeeds in the first round of retransmission.
(CXP1nMODE.CXP1nREPOP = 1_B, CXP1nREP.CXP1nAIREP = 10_B or CXP1nREP.CXP1nARREP = 10_B)

(1) 1 is written to CXP1nSND.CXP1nSFRREQ to request frame transmission.

(2) Frame transmission is started. When “retransmission judged” is set, CXP1nSND.CXP1nSFRREQ is cleared at the start of transmission. The value set in the CXP1nREP.CXP1nEIREP bit or the CXP1nREP.CXP1nERREP bit is transferred to CXP1nFLG2.CXP1nEREP. (The transfer destination is determined by the value set in CXP1nSND.CXP1nREPSEL at the time of frame transmission request.)

(3) A bit error occurred. If CXP1nFLG2.CXP1nEREP indicates 1 or more, CXP1nFLG2.CXP1nSRSV is set to make reservation for retransmission. Also, if CXP1nFLG2.CXP1nEREP is 1 or 2, the number of retransmissions is decremented.
(If CXP1nFLG2.CXP1nEREP indicates 3, the number of retransmissions is not decremented but retransmissions are carried out unlimitedly.)
(When CXP1nFLG2.CXP1nEREP is 0, CXP1nFLG2.CXP1nSRSV is not set because retransmission is not performed.)
An error detection interrupt is generated. CXP1nINT.CXP1nERRINT and CXP1nERR.CXP1nBITERR are set to 1.
Error status is set in CXP1nFLG1 and CXP1nERR register.
To clear them, the software write 0 to CXP1nINT.CXP1nERRINT and CXP1nERR.CXP1nBITERR.

(4) CXP1nCXST indicates an idle state after communication is stopped due to a bit error and IFS has passed.
If CXP1nFLG2.CXP1nSRSV = 1 when CXP1nCXST indicates an idle state, retransmission is started immediately and, at the same time, CXP1nFLG2.CXP1nSRSV is cleared to 0.
(Retransmission is not performed immediately in a slave node in polling mode, but performed after the IBS time has passed after PTYPE reception.)

(5) When frame transmission initiated by retransmission is normally completed and the IFS time has passed, CXP1nCXST indicates an idle state. No retransmission is initiated because CXP1nFLG2.CXP1nSRSV = 0.

- Retransmission cancellation
  - When 0 is written to CXP1nFLG2.CXP1nSRSV when CXP1nFLG2.CXP1nSRSV = 1, the next and following retransmissions are canceled.
  - When 0 is written to CXP1nFLG2.CXP1nEREP when CXP1nFLG2.CXP1nSRSV = 0, the next and following retransmissions are canceled.
  - When 0 is written to CXP1nFLG2.CXP1nEREP when CXP1nFLG2.CXP1nSRSV = 1, the next retransmission is initiated but the following retransmissions are canceled.
- Retransmission operation when another error occurred in frame transmission (No. 3 to 7 in **Table 30.78, Targets and Factors of Retransmission Processing**)
  Even if a different error occurred, the IP retransmits the frame when CXP1nCXST indicates an idle state the IFS time after the error detection, as with No. 5. (For a bit error in PID, the IP may become idle before the IFS time has passed.) The operation timing of

CXP1nSND.CXP1nSFRREQ, CXP1nFLG2.CXP1nSRSV and CXP1nFLG2.CXP1nEREP is the same as for No. 5.

- PID retransmission (Nos. 9 to 15 in **Table 30.78**)
  The retransmission operation sequence of PID transmission is the same as the operation sequence for frame transmission except:
  - Read CXP1nSFRREQ as CXP1nSIDREQ.
  - Read CXP1nSRSV as CXP1nRRSV.
  - Read transmission as reception in the response operation during retransmission described for cxpi_pt_txd and pt_cxpi_rxd_a.

  If an error occurred during response reception, CXP1nCXST indicates an idle state and the IP performs retransmission after the IFS time has passed following the reception of the remaining data after the error.

30.5.7.4 Error Detection

This section describes the error detection mechanism, the operation of major bits in the CXP1nFLW1 register when detecting an error, and the flow from communication suspension to communication restart.

For software processing procedure for errors, see **Section 30.5.10.15, Error Handling**.

[The operation of an error detection]

(a) The following condition is satisfied CXP1nFLW1.CXP1nCXST = 001_B (MSK_IFS state) and start time the IFS when detected UART stop bit, and detect value 1 for the ten time in a row, and transfers to CXP1nFLW1.CXP1nCXST = 000_B (IFS state). When MSK_IFS state, transmit operation be stopped and receive operation cannot be performed. If detect start bit when MSK_IFS, restart waiting IFS from stop bit.

(b) It performs counting at the CXPI nominal bit (Tbit) time and transitions to CXP1nFLW1.CXP1nCXST = 010_B (IDLE state) after the time (specified by CXP1nFRMW.CXP1nIFS – 10Tbit) has passed. PTYPE reception and PID reception become possible in IFS state.

(c) Communicate (SW Transmission or HW Retransmission) become possible in IDLE state.

(1) Bit Error

Since the bit error detection mechanism differs depending on the mode (CXPI-PWM mode or CXPI-NRZ mode), it will be described separately.

CXPI-PWM mode

In CXPI-PWM mode, bit errors are detected and transmission is stopped on a bit basis.

During transmission, the value of the transmit bit and the value of the received bit are compared. A bit error is detected if they do not match: The CXP1nERR.CXP1nBITERR bit is set when the next bit is transmitted (at the falling edge of cxpi_pt_txd) and an error detection interrupt is generated. Any other interrupt that indicates a transmission completion is not generated.

The error detection node, the range of the error detection is start bit of PTYPE or PID field. The other range of bit error detection are shown in the following.

- Loss-of-arbitration: Frame ID or Frame TYPE.
- Parity error: Parity bit.
- Framing error: Stop bit.

The value of the transmit bit and the value of the received bit do not match in response field: The IP detect a framing error, not bit error

Table 30.80 and **Table 30.81** summarizes the flow from transmission stop to restart which differs depending on the bit error location.

[Detected bit error by start bit of PID or PTYPE]

The following condition is satisfied CXP1nFLW1.CXP1nCXST = 000_B (IFS) when detected bit error. Communication is possible immediately without waiting IFS (The following condition is satisfied CXP1nFLW1.CXP1nCXST = 010_B (IDLE)).

[Detected bit error by other than those above]

The following condition is satisfied CXP1nFLW1.CXP1nCXST = 001_B (MSK_IFS).

For more information, see above explanation at [The operation of an error detection]

CXPI-NRZ mode

In CXPI-NRZ mode, the CXPI transceiver handles bit-basis bit error detection and transmission stop, and the IP performs byte-basis detection. In CXPI-NRZ mode, transmission stop is delayed because loopback to the IP is not made within 1 Tbit, so the transceiver handles bit-basis detection.

During transmit PTYPE or PID, a bit error is detected if the IBS time has passed and looped-back all bit is high level (recessive).

During transmit response, the looped-back stop bit is sampled and transmit data and received data are compared on a byte basis. A bit error is detected if they do not match.

A bit error is detected if the IBS time has passed and looped-back all bit is high level (recessive).

If bit error is detected, the CXP1nERR.CXP1nBITERR bit is set and an error detection interrupt is generated. Any other interrupt that indicates a transmission completion is not generated.

Table 30.80 and **Table 30.81** summarizes the flow from transmission stop to restart which differs depending on the bit error location.

The following condition is satisfied CXP1nFLW1.CXP1nCXST = 001_B (MSK_IFS). For more information, see above explanation at [The operation of an error detection].

Table 30.80 Flow from Transmission Stop to be available for transmission After Detecting a Bit Error

No.	Transfer Mode	Access Method	Bit Error Detection Bit		When Transmit is Enabled after Communication Stop (Transmission by software instruction, and retransmission)
1	CXPI-PWM mode	Event trigger method	PID	Start bit	Error → transmission stop → Transmit enabled from the next bit (first bit of data)
2			Other than above		Error → transmission stop → after IFS passed from the errored bit
3		Polling method	PTYPE	Start bit	Error → transmission stop → Transmit enabled from the next bit (first bit of data)
4			PID	Start bit	Error → transmission stop → after IFS passed (max)
5			PID after PTYPE	Start bit	Prohibited.
6			Other than above		Error → transmission stop → after IFS passed from the errored bit
7	CXPI-NRZ mode	All	All		Error at the stop bit → communication stop→ after IFS passed

Table 30.81 Flow from Transmission Stop to be available for receive After Detecting a Bit Error

No.	Transfer Mode	Access Method	Bit Error Detection Bit		When Receive is Enabled after Communication Stop (PID reception and PTYPE reception by hardware are enabled)
1	CXPI-PWM mode	Event trigger method	PID	Start bit	Error → transmission stop → Receive enabled from the next bit (first bit of data)
2			Other than above		Error → transmission stop → after 10 Tbit passed from the errored bit *1
3		Polling method	PTYPE	Start bit	Error → transmission stop → Receive enabled from the next bit (first bit of data)
4			PID	Start bit	Error → transmission stop → after 10 Tbit passed (max)
5			PID after PTYPE	Start bit	Prohibited.
6			Other than above		Error → transmission stop → after 10 Tbit passed from the errored bit *1
7	CXPI-NRZ mode	All	All		Error → transmission stop → after 10 Tbit passed *1

Note 1. When a bit error is detected, all received data are discarded before 10 Tbit passed (not stored in registers CXP1nRPID, CXP1nRFRI, CXP1nRDATAm (m = 01-08), CXP1nRCRC).

(2) CRC Error

The receiving node compares the result of CRC calculation done by the IP with the received CRC value. It detects a CRC error if they do not match. Even if an error occurred, the received CRC value is stored in the CXP1nRCRC register. 10 Tbits after the CRC stop bit reception is completed, the CXP1nERR.CXP1nCRCERR bit is set and an error detection interrupt is generated. No frame reception completion interrupt is generated.

When an interrupt is generated (CRC error detection), the CXP1nFLW1.CXP1nCXST bit is set to 000_B(IFS). For more information, see above explanation at [The operation of an error detection].

(3) Parity Error

The IP in a receiving node checks the number of bits with logical value “1” in the received PID and PTYPE fields, detects a parity error if it is an even number, sets the CXP1nERR.CXP1nPTYERR bit during stop bit reception, and generates an error detection interrupt. No PTYPE reception completion or PID reception completion interrupt is generated. If the PTYPE field results in an error, the succeeding PID transmission is impossible. If the PID field results in an error, it is stored in the CXP1nRPID register, but no response is transmitted afterward, and all received responses are discarded (not stored in registers).

When the IP is a transmitting node, it detects a parity error on the PID of the looped-back received data. It stops transmission if detecting a parity error. The other operations are the same as those already described for the receiving node.

When a parity error is detected, the CXP1nFLW1.CXP1nCXST bit is set to 001_B(MSK_IFS). For more information, see above explanation at [The operation of an error detection].

(4) Physical Bus Error (Not Supported)

The hardware does not detect physical bus errors. The software shall monitor the communication status by checking the IP interrupt status and performing polling to registers to detect physical bus errors.

(5) Data Length Error

The following describes the data length error generation mechanisms in the transmitting node and the receiving node.

Transmitting node

The IP detects a data length error based on the following two factors:

- Factor 1 (the received data is longer than the DLC)
  The IP detects a data length error if it receives a start bit within 10 Tbits after transmitting the CRC value in the response field. It sets the CXP1nERR.CXP1nDLNERR bit when it samples the start bit to generate an error detection interrupt. No frame transmit completion interrupt is generated. The CXP1nFLW1.CXP1nCXST bit is set to 001_B (MSK_IFS) when detecting a data length error. For more information, see above explanation at [The operation of an error detection].
- Factor 2 (an underrun occurred during long frame transmission)
  If the CXP1nINT.CXP1nSFQINT bit was not cleared when another 7-byte data have been transmitted after transmitting 7-byte data and the CXP1nINT.CXP1nSFQINT was set during long frame transmission, the IP detects a data length error, judging transmit data was not set in time. During stop bit transmission of the 8th-byte data, the CXP1nERR.CXP1nDLNERR bit is set and an error detection interrupt is generated. When a data length error is detected, the CXP1nFLW1.CXP1nCXST bit is set to 001_B (MSK_IFS). For more information, see above explanation at [The operation of an error detection].

- Factor 3 (the received loopback data is shorter than the DLC)
  CXPI-NRZ mode: The IP detects a data length error if the received loopback data is shorter than the DLC.
  CXPI-PWM mode: Substituted by detection of bit error.
  The IP detects a data length error if it does not receive a start bit in the response field in the IBS time (10 Tbits) of the PID field (Local node isn't a target.) or it does not receive a start bit in the IBS time (10 Tbits) of the response field. It sets the CXP1nERR.CXP1nDLNERR bit in the ending of the IBS to generate an error detection interrupt. If the CXP1nFLW1.CXP1nCXST bit is set to 000_B (IFS) when detecting a data length error. For more information, see above explanation at [The operation of an error detection].

Receiving node

The IP detects a data length error based on the following two factors:

- Factor 1 (the received data is longer than the DLC)
  The IP detects a data length error if it receives a start bit within 10 Tbits after receiving the CRC value in the response field. It sets the CXP1nERR.CXP1nDLNERR bit when it samples the start bit to generate an error detection interrupt. If the CXP1nFLW1.CXP1nCXST bit is set to 001_B (MSK_IFS) when detecting a data length error. For more information, see above explanation at [The operation of an error detection].
- Factor 2 (the received data is shorter than the DLC, or the response field is not received)
  After transmission of PID, the IP detects a data length error if it does not receive a start bit in the response field in the IBS time (10 Tbits) of the PID field (the response field is no received) or it does not receive a start bit in the IBS time (10 Tbits) of the response field. After reception of PID, the IP detects a data length error if it does not receive a start bit in the IBS time (10 Tbits) of the response field (Local node isn't a target.). It sets the CXP1nERR.CXP1nDLNERR bit in the ending of the IBS to generate an error detection interrupt. If the CXP1nFLW1.CXP1nCXST bit is set to 000_B (IFS) when detecting a data length error. For more information, see above explanation at [The operation of an error detection].

(6) Counter Error (Not Supported)

This IP does not detect counter errors. The software shall monitor the status of the CXP1nRFRI.CXP1nRCT bit to detect counter errors.

(7) Overrun Error

If the CXP1nINT.CXP1nRFQINT bit was not cleared when receiving another 8-byte data was received after receiving 8-byte data and the CXP1nINT.CXP1nRFQINT was set during long frame reception, the IP detects an overrun error, judging that received data was not saved in time. When the 8th-byte received data is sampled, the CXP1nERR.CXP1nORNERR bit is set and an error detection interrupt is generated. The data that has been received before the CXP1nERR.CXP1nORNERR bit is set is stored in CXP1nRDATAm (m = 01 to 08) and the subsequently received data is not stored in registers. If the CXP1nFLW1.CXP1nCXST bit is set to 001_B when detecting an overrun error. For more information, see above explanation at [The operation of an error detection].

(8) Framing Error

The following describes the framing error generation mechanisms in the transmitting node and the receiving node.

Transmitting node

The IP detects a framing error if the logical value of the stop bit which is looped back and received during transmission is 0. It sets the CXP1nERR.CXP1nFRMERR bit when it samples the start bit to generate an error detection interrupt. Any other interrupt that indicates a transmission completion is not generated. When a framing error is detected, the CXP1nFLW1.CXP1nCXST bit is set to 001_B. For more information, see above explanation at [The operation of an error detection].

Receiving node

The IP detects a framing error if the logical value of the received stop bit is 0. It sets the CXP1nERR.CXP1nFRMERR bit when it samples the start bit to generate an error detection interrupt. Any other interrupt that indicates a reception completion is not generated. If the PTYPE field results in an error, the succeeding PID transmission is impossible. If the PID field results in an error, it is stored in the CXP1nRPID register, but no response is transmitted afterward. Also, all the received responses are discarded (not stored in registers). If the response results in an error, the received data with an error and the subsequently received data are discarded (not stored in registers). When detecting a framing error, the IP sets the CXP1nFLW1.CXP1nCXST bit to 001_B. For more information, see above explanation at [The operation of an error detection].

(9) State Error (Not Defined in CXPI Specifications)

A state error occurs due to the following factors:

- Factor 1
  A PTYPE field is received in event trigger mode.
- Factor 2
  A PTYPE field is received by the master node.
- Factor 3
  When the IP in a slave node starts PID transmission because it receives a PTYPE field in polling mode, it receives the PTYPE field again and loses an arbitration.

For each factor, the CXP1nFLG1.CXP1nSTERR bit is set and an error detection interrupt is generated when the stop bit of PTYPE is sampled. No PTYPE reception completion interrupt is generated. After state error is detected, write 0_B to CXP1nMODE.CXP1nEN initializes the internal circuits.

(10) Fatal Error (Not Defined in CXPI Specifications)

This error only occurs due to an IP failure or a bit error of an IP internal signal.

Perform a reset when detecting a fatal error. If the error persists, the IP may be malfunctioning.

As soon as the condition is satisfied, the CXP1nFLG1.CXP1nFTERR bit is set and an error detection interrupt is generated.

The possible factors for fatal errors are as follows:

After fatal error is detected, write 0_B to CXP1nMODE.CXP1nEN initializes all.

- Factor 1
  CXP1nFLW2.CXP1nFRMPHS becomes 11_B (undefined) during response transmission or reception.

- Factor 2
  The frame counter in the IP (frm_cnt_reg: incremented as each byte is transmitted or received) indicates 4 or more while transmitting or receiving a response and CXP1nFLW2.CXP1nFRMPHS = 00_B (frame information/extension DLC) or 10_B (CRC).

30.5.7.5 Bus Monitoring

It is possible to receive all PIDs on the communication bus. This generates a PID reception completion interrupt each time a PID is received. This also enables a response to be transmitted or received after receiving each PID. The received response is stored in CXP1nRFRI, CXP1nRDATAm (m = 01 to 08) and CXP1nRCRC.

Setting the CXP1nRPIDF2m.CXP1nFIDMSK bit (m = 01 to 04) to 1111111_B enables bus monitoring setting. For the register specifications, see **Section 30.4.1.23, CXP1nRPIDF2m —CXPI Received Frame ID Setting Register 2m (m = 01 to 04)**.

30.5.7.6 Failure Management Function

For the failure management function, the IP has the CXP1nERR.CXP1nERRCNT bit (error counter) and the CXP1nFLG1.CXP1nFAIL bit (which indicates the transmission disabled state). For the register specifications, see **Section 30.4.1.15, CXP1nFLG1 — CXPI Flag Register 1** and **Section 30.4.1.19, CXP1nERR — CXPI Error Register**.

If detecting a bit error, a framing error or a data length error during transmission, the IP increments the error counter by 8 when a relevant bit of the CXP1nERR register is set. When the IP transmits the PTYPE field, the PID field or a response normally, it decrements the error counter by 1 when a relevant bit of CXP1nINT register is set (when a transmission completion interrupt source is generated). If an error occurs when the error counter value is 248 or more, the error counter is set to 255 and the CXP1nFLG1.CXP1nFAIL bit is set to disable transmission.

The table below lists the operations which are disabled in the transmission disabled state. Clock transmission is not stopped.

Table 30.82 Transmission Operations Disabled When CXP1nFLG1.CXP1nFAIL = 1

No.	Transmission Operations Disabled When CXP1nFLG1.CXP1nFAIL = 1
1	Frame transmission
2	PID transmission
3	Response transmission
4	Automatic response
5	PTYPE transmission
6	Sleep frame transmission
7	Retransmission of frame transmission
8	Retransmission of PID transmission

The figure below shows the release from failure (The transmission disabled) state.

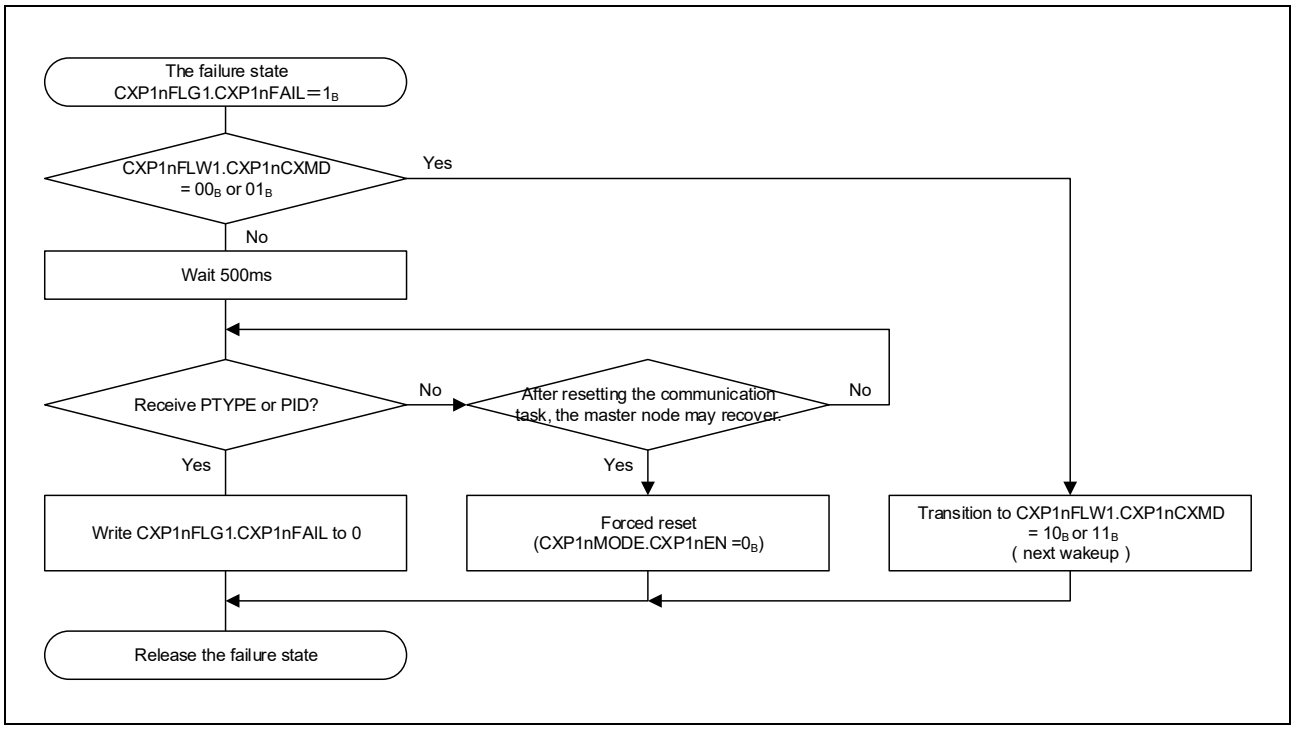

Figure 30.36 Release the failure state

30.5.7.7 Error Bit Function (Not Supported)

This IP does not support the error bit function.

The software shall check whether or not an error occurred when transmitting or receiving a frame.

30.5.8 Extension Functions

This section describes the extended functions which are not defined in the Protocol Specification but installed solely in the IP.

30.5.8.1 Frame ID Filtering Function

The frame ID filtering function sets an ID mask value for the target PID of reception or manual response.

No PID comparison is made for the ID-masked bit. For details on the frame ID filtering function, see **Section 30.4.1.23, CXP1nRPIDF2m —CXPI Received Frame ID Setting Register 2m (m = 01 to 04)**.

30.5.8.2 Noise Filter

The receive pin (pt_cxpi_rxd_a) of the CXPI is provided with a noise filter that can eliminate noise for up to 12.775 µs (PCLK = 40 MHz). For details on the noise filter, see **Section 30.4.1.6, CXP1nFIL — CXPI Input Filter Setting Register**.

The receive pin (pt_cxpi_rxd_a) has a chattering removal function of two logic coincidence on a PCLK standard.

30.5.8.3 Offset Sampling

CXPI has auto remediation function for offset sampling.

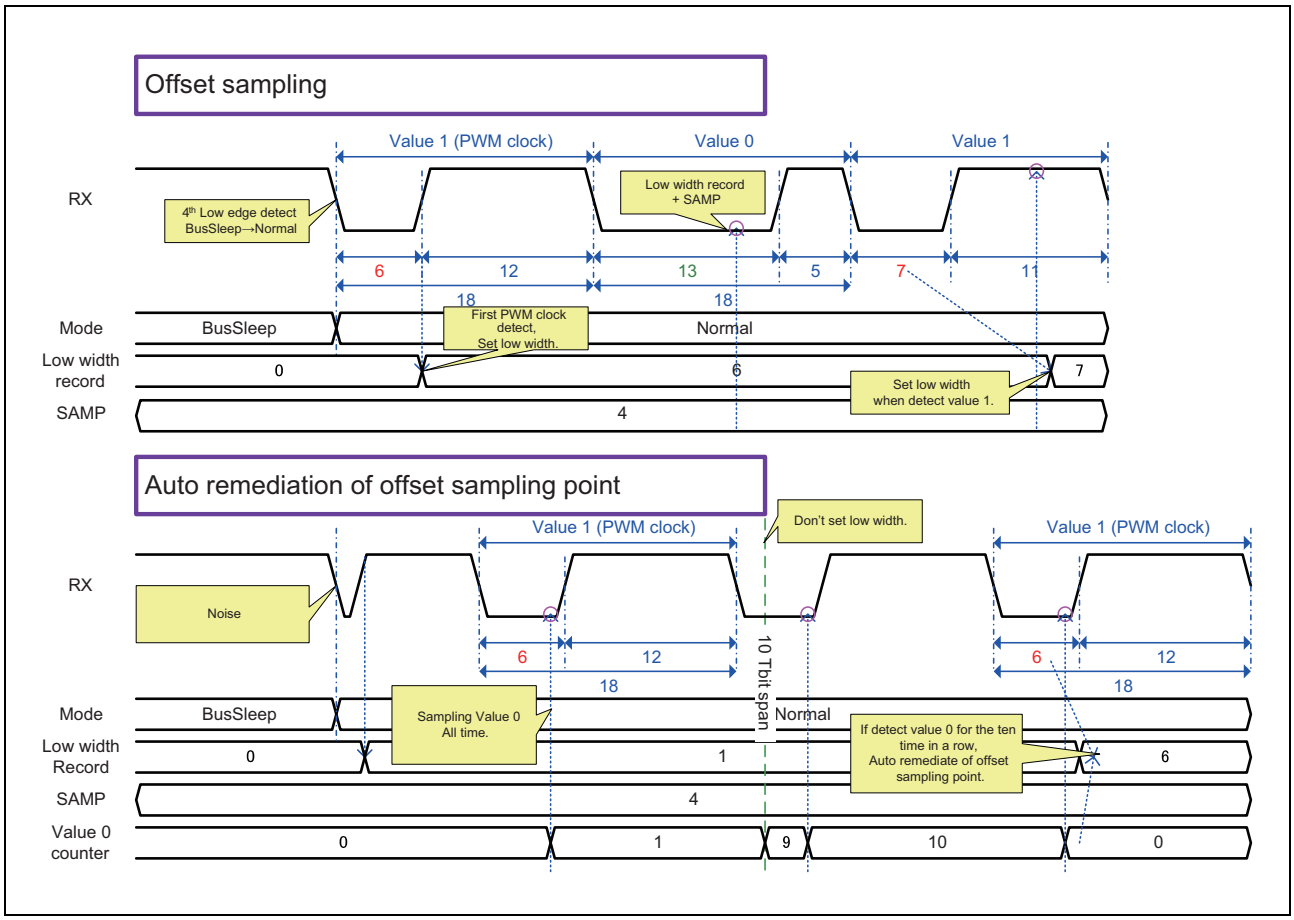

Figure 30.37 Offset sampling function

Note that if noise occurs during transmission operation in offset sampling and CXPI-PWM mode, normal receive operation cannot be performed for maximum 10Tbit + IFS period because, initialization of internal sequence and detection of PWM clock for 10Tbit is required after reset release.

Also, framing error might be detected at the time of initialization period completion.

1. Issue noise during transmission.
2. To initialize sampling counter, re-write threshold value (Low width record) of offset sampling. Here, threshold value becomes extremely small due to state clear timing and it is judged as logical value 0, irrespective of logical value 0/1 on transmission bus.
3. Receive logical value 0 for 10Tbit period (write-back threshold value to initial value)
4. Wait for IFS period from here
5. Transmission possible (error process is required if framing error is detected)

When the extremely large Low width (Serge noise filter + Low period of logic value 0 + Sampling timing setup (CXP1nSAMP.CXP1nSMP) more than or equal to 1Tbit period) has been recorded, since it becomes impossible to sample normally, be careful of a sampling timing setup (CXP1nSAMP.CXP1nSMP).

30.5.8.4 PWM Encoding/Decoding ON/OFF Function

The PWM encoding/decoding ON/OFF function enables or disables PWM encoding/decoding.

For details on the PWM encoding/decoding ON/OFF function, see **Section 30.5.1, CXPI System Configuration**.

30.5.8.5 Control Pins for NRZ Mode (Not Supported)

In CXPI-NRZ mode, a pin that controls the CXPI transceiver is required. Since the IP supports only communication pins, the control pins for CXPI-NRZ mode must be supported by a module other than this IP. For the details about the control pins for CXPI-NRZ mode, see **Section 30.5.1, CXPI System Configuration**.

30.5.8.6 Diagnostic Function

Since the diagnostic function is the same as the failure management function, see **Section 30.5.7.6, Failure Management Function**.

30.5.8.7 Software Reset

Two types of reset are available: a forced reset that initializes the entire IP, and a simple reset that resets some functions after detecting an error and returns the IP to the communication enabled state.

- Forced reset:
  Setting CXP1nMODE.CXP1nEN to 0 initializes the internal circuits related to the associated registers.
  For details on the associated registers, see **Table 30.83**.
  As long as CXP1nMODE.CXP1nEN = 0, the IP remains initialized.
- Simple reset:
  Writing 1 to CXP1nWUP.CXP1nSTCLR initializes the internal circuits related to the associated registers.
  For details on the associated registers, see **Table 30.83**.
  Initialization occurs only once when 1 is written to CXP1nWUP.CXP1nSTCLR.

When the software has detected a physical bus error and transition to bus sleep mode is prohibited[*1], a simple reset is issued to initialize some functions of the IP.

Note 1. The software manages the prohibition of transition to bus sleep mode.

The table below shows the ranges covered by the two types of reset.

Table 30.83 Ranges Affected by Software Resets

Target to Be Initialized	Forced Reset CXP1nMODE.CXP1nEN = 0_B	Simple Reset CXP1nWUP.CXP1nSTCLR = 1_B
CXP1nMODE	No	No
CXP1nBRT	Yes	No
CXP1nV1LW	Yes	No
CXP1nV0LW	Yes	No
CXP1nSAMP	Yes	No
CXP1nFIL	Yes	No
CXP1nWU	Yes	No
CXP1nFRMW	Yes	No
CXP1nSLP	Yes	No
CXP1nREP	Yes	No
CXP1nWUP	Yes	No
CXP1nSND	Yes	Yes
CXP1nIMSK	Yes	No
CXP1nINT	Yes	No
CXP1nFLG1	*1	No
CXP1nFLG2	Yes	Yes
CXP1nFLW1	Yes	Yes (Only CXP1nFLW1.CXP1nCXMD is not initialized)
CXP1nFLW2	Yes	Yes
CXP1nERR	*2	No
CXP1nRPID	Yes	No
CXP1nSPID	Yes	No
CXP1nRPIDF1m (m = 01 to 12)	Yes	No
CXP1nRPIDF2m (m = 01 to 04)	Yes	No
CXP1nARPID	Yes	No
CXP1nRFRI	Yes	No
CXP1nSFRI	Yes	No
CXP1nARFRI	Yes	No
CXP1nRCRC	Yes	No
CXP1nSCRC	Yes	No
CXP1nARCRC	Yes	No
CXP1nRDATAm (m = 01 to 08)	Yes	No
CXP1nSDATAm (m = 01 to 08)	Yes	No
CXP1nARDATAm (m = 01 to 06)	Yes	No

Note: Yes: Initialized
No: Not initialized

Note 1. The CXP1nFLG1.CXP1nFAIL bit is initialized only in the IP in the master node.

Note 2. The CXP1nERR.CXP1nERRCNT bit is initialized only in the IP in the master node.

30.5.8.8 Status

The CXPI has several statuses to indicate the operating mode and operation state.

This section describes the operating mode and the state transition of operation states.

(1) Operating Mode (CXP1nFLW1.CXP1nCXMD)

The CXPI controls the bus sleep/wakeup mode and communication enabled state by operating mode.

The figure below shows the state transition of operating mode. Each state (1) to (4), and transition condition are described below.

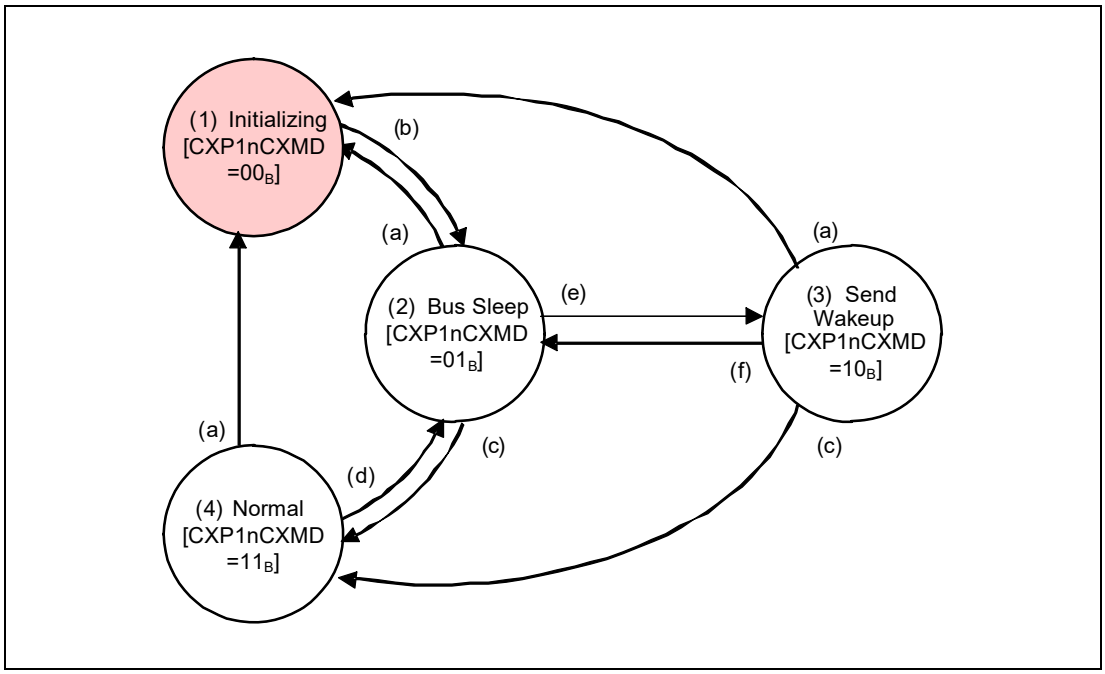

Figure 30.38 State Transition of Operating Mode

(1) Initializing mode

In initializing mode, the CXPI is not in an operational state. This is the state in which a reset is being released or is the first state after a reset has been released.

The following are transition conditions (the following transition conditions are listed in the order of priority).

(b) Enabling the CXPI operation (CXP1nMODE.CXP1nEN = 1) triggers the transition to bus sleep mode.

(2) Bus sleep mode

Bus sleep mode is power-saving mode in which data transmission and reception are stopped. This mode is used to initialize the IP.

The following are transition conditions (the following transition conditions are listed in the order of priority).

(a) The CXPI transitions to initializing mode when a reset = 0 or when a forced reset is issued (CXP1nMODE.CXP1nEN = 0_B).

(c) This transition condition differs depending on the transfer mode. The following are transition conditions for each transfer mode.

CXPI-PWM mode: The CXPI transitions to normal mode when detecting the clock 4 or 5 times.

CXPI-NRZ mode: Writing 1_B to CXP1nWUP.CXP1nCLKON triggers a transition to normal mode.

(e) A slave node transitions to send wakeup mode at the start of wakeup pulse transmission (CXP1nWUP.CXP1nWUPREQ = 1_B).

(3) Send wakeup mode

Send wakeup mode indicates that the slave node is transmitting a wakeup pulse.
Note that send wakeup mode is part of standby mode specified in the Protocol Specification.
The following are transition conditions (the following transition conditions are listed in the order of priority).

(a) The CXPI transitions to initializing mode when a reset = 0 or when a forced reset is issued (CXP1nMODE.CXP1nEN = 0_B).

(c) This transition condition differs depending on the transfer mode. The following are transition conditions for each transfer mode.

CXPI-PWM mode: The CXPI transitions to normal mode when detecting the clock.

CXPI-NRZ mode: Writing 1_B to CXP1nWUP.CXP1nCLKON triggers a transition to normal mode.

(f) Upon completion of wakeup pulse transmission, the CXPI transitions to bus sleep mode.

(4) Normal mode

Normal mode indicates that the CXPI can communicate.
The following are transition conditions (the following transition conditions are listed in the order of priority).

(a) The CXPI transitions to initializing mode when a reset = 0 or when a forced reset is issued (CXP1nMODE.CXP1nEN = 0_B).

(d) This transition condition differs depending on the setting of each operation. The following are transition conditions depending on each operation setting.

Master node: Transitions to bus sleep mode when writing 1 to CXP1nWUP.CXP1nCLKOFF.

Slave node: Transitions to bus sleep mode the sleep transition time after receiving a sleep frame.

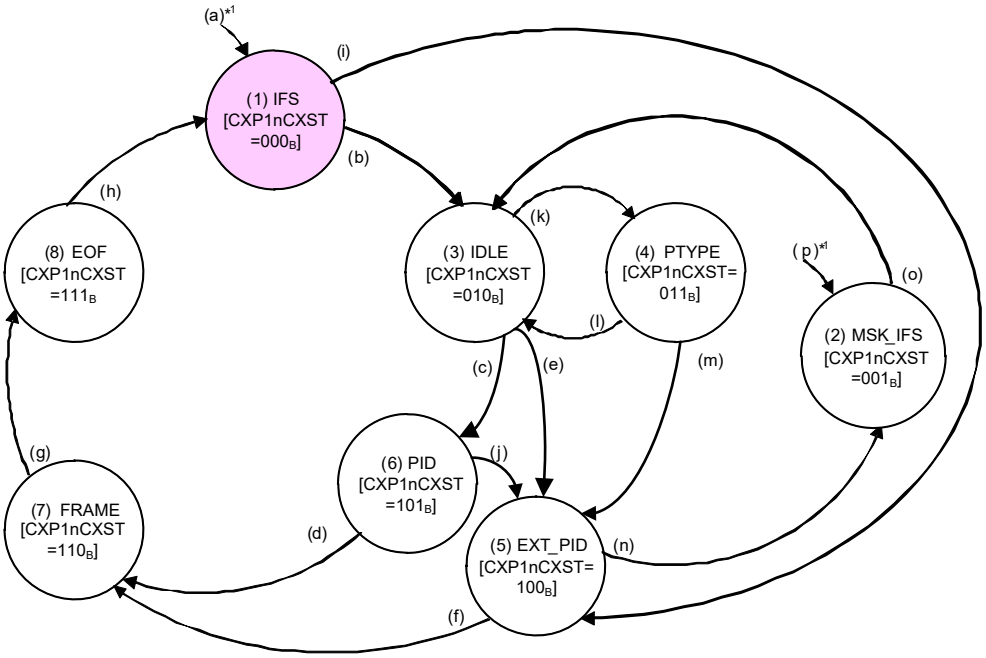
CXPI-PWM mode: The CXPI transitions to bus sleep mode when not detecting the clock signal.

CXPI-NRZ mode: The CXPI transitions to bus sleep mode when 1 is written to CXP1nWUP.CLKOFF.

(2) Operating State (CXP1nFLW1.CXP1nCXST)

The CXPI controls transmission and reception according to the operating state.

This section describes the operating states. Each state (1) to (8), and transition condition are described below.



Note 1. Transition occurs when conditions are satisfied in each state.

Figure 30.39 State Transition of Operating State

(1) Waiting for IFS to elapse (IFS in the figure)

The CXPI first transitions to this state after a reset is released and CXP1nCXMD = 11_B (normal mode).

This state waits for the IFS time to elapse. The CXPI transitions to the idle state after the IFS time has passed.

Note that it transitions to another state if detecting a PID or PTYPE before the IFS time has passed.

Then IP isn't possible to receive the just after IFS period (CXP1nIFS set value +1) when transferred to CXP1nCXMD = BusSleep in CXP1nCXMD = Normal.

The following are transition conditions (the following transition conditions are listed in the order of priority).

(p) The CXPI transitions to the MSK_IFS state if a simple reset is issued (CXP1nWUP.CXP1nSTCLR = 1) or a transfer error*1 occurred.

Note 1. The following are included in the transfer error. (This applies to other states.)
Bit error (other than start bit of PID or PTYPE)
Parity error
Data length error (other than not received response)
Framing error
Overrun error
State error
Fatal error

(i) The CXPI transitions to the EXT_PID state when receiving a PID.

(b) It performs counting at the CXPI nominal bit (Tbit) time and transitions to the idle state after the time specified by CXP1nFRMW.CXP1nIFS has passed.
It transitions to the idle state when receiving a PTYPE field.

(2) Waiting for IFS to elapse after transfer is suspended due to an error (MSK_IFS in the figure)
This state waits for the IFS time to elapse when an error occurred or after a simple reset was issued (CXP1nSTCLR = 1). If detected CRC error, (o) cause immediate.
The following are transition conditions (the following transition conditions are listed in the order of priority).

(a) It transitions to the IFS when a forced reset (CXP1nMODE.CXP1nEN = 0_B) or a reset = 0 is issued.

(o) Detect value 1 for the ten time in a row, change to IFS state.

(3) Transmission/reception stopped (IDLE) (IDLE in the figure)
In the transmission/reception stopped (IDLE) state, the CXPI can communicate.
The following are transition conditions (the following transition conditions are listed in the order of priority).

(a) It transitions to the IFS when a forced reset (CXP1nMODE.CXP1nEN = 0_B) or a reset = 0 or bit error detected by start bit of PID or PTYPE is issued.

(p) It transitions to the MSK_IFS state if a simple reset is issued (CXP1nWUP.CXP1nSTCLR = 1) or a transfer error occurred.

(e) It transitions to the EXT_PID state when receiving a PID.

(k) It transitions to the PTYPE state when transmitting a PTYPE field (CXP1nSND.SPTREQ = 1).

(c) It transitions to the PID state when transmitting a PID (when transmission is accepted after writing 1 to CXP1nSND.SIDREQ).

(4) Transmitting PTYPE (PTYPE in the figure)
In the “transmitting PTYPE” state, the CXPI is transmitting a PTYPE field.
It transitions to the idle state after it has transmitted a PTYPE field.
The following are transition conditions (the following transition conditions are listed in the order of priority).

(a) It transitions to the IFS when a forced reset (CXP1nMODE.CXP1nEN = 0_B) or a reset = 0 is issued.

(p) It transitions to the MSK_IFS state if a simple reset is issued (CXP1nWUP.CXP1nSTCLR = 1) or a transfer error occurred.

(m) It transitions to the EXT_PID state when receiving a PID.

(l) It transitions to the idle state when detecting a PTYPE field in the received data looped back for PTYPE transmission.

(5) Waiting for response judgment/response data setting (EXT_PID in the figure)

(a) It transitions to the IFS when a forced reset (CXP1nMODE.CXP1nEN = 0_B) or a reset = 0 or bit error detected by start bit of PID or PTYPE is issued.

(p) It transitions to the MSK_IFS state if a simple reset is issued (CXP1nWUP.CXP1nSTCLR = 1) or a transfer error occurred.

(n) It transitions to the MSK_IFS state when the following conditions are satisfied:

- The IBS time has passed.
- The received PID does not match the PID set in CXP1nRPIDF1m (m = 01 to 12), CXP1nRPIDF2m (m = 01 to 04) or CXP1nARPID.
- CXP1nFLG1.CXP1nFAIL = 1
- When 9 Tbits have passed after receiving a PID, if the following condition of (f) is not satisfied.

(f) It transitions to the FRAME state at the start of manual response (CXP1nSND.CXP1nSRESERQ = 1). Or, it transitions to the FRAME state at the start of response reception (when detecting a start bit).

(6) PID transmission (PID in the figure)
In the “PTYPE transmission” state, the CXPI is transmitting a PID.
The following are transition conditions (the following transition conditions are listed in the order of priority).

(a) It transitions to the IFS when a forced reset (CXP1nMODE.CXP1nEN = 0_B) or a reset = 0 is issued.

(p) It transitions to the MSK_IFS state if a simple reset is issued (CXP1nWUP.CXP1nSTCLR = 1) or a transfer error occurred.

(j) It transitions to the EXT_PID state when the received PID matches the PID set in CXP1nRPIDF1m (m = 01 to 12), CXP1nRPIDF2m (m = 01 to 04) or CXP1nARPID.

(d) It transitions to the FRAME state when it has transmitted the PID.

(7) Response (frame information/extension DLC/data/CRC) transmission/reception (FRAME in the figure)
In the response state, the CXPI is transmitting or receiving a response.
The following are transition conditions (the following transition conditions are listed in the order of priority).

(a) It transitions to the IFS when a forced reset (CXP1nMODE.CXP1nEN = 0_B) or a reset = 0 is issued.

(p) It transitions to the MSK_IFS state if a simple reset is issued (CXP1nWUP.CXP1nSTCLR = 1) or a transfer error occurred.

(g) It transitions to the EOF state when it has transmitted or received a response.

(8) Frame completion (waiting for IBS to elapse) (EOF in the figure)

(a) It transitions to the IFS when a forced reset (CXP1nMODE.CXP1nEN = 0_B) or a reset = 0 is issued.

(p) It transitions to the MSK_IFS state if a simple reset is issued (CXP1nWUP.CXP1nSTCLR = 1) or a transfer error occurred.

(h) It transitions to the IFS state 10 Tbits (fixed value determined by the hardware) after it has transmitted or received a response.

30.5.9 Interrupts

30.5.9.1 Transmission

(1) PTYPE Transmission Completion

When the CXPI has transmitted a PTYPE field, it outputs an interrupt request at a level.

For detailed operation, see **Section 30.5.4.6, PTYPE Transmission**.

(2) PID Transmission Completion

When the CXPI has transmitted a PID field, it outputs an interrupt request at a level.

For detailed operation, see **Section 30.5.4.1, PID Transmission** or **Section 30.5.4.2, Frame Transmission**.

(3) Transmission Data Setting Request

When the CXPI transmits a normal frame, or a long frame for manual response, it outputs an interrupt request at a level each time it has transmitted eight bytes. For detailed operation, see **Section 30.5.4.2, Frame Transmission**, or **Section 30.5.4.3, Manual Response**.

(4) Frame Transmission Completion

When the CXPI has transmitted a response, it outputs an interrupt request at a level.

For detailed operation, see **Section 30.5.4.2, Frame Transmission**, **Section 30.5.4.3, Manual Response**, or **Section 30.5.4.4, Automatic Response**.

30.5.9.2 Reception

(1) PTYPE Reception Completion

When the CXPI has received a PTYPE field, it outputs an interrupt request at a level.

For details, see **Section 30.5.4.7, PTYPE Reception**.

(2) PID Reception Completion

When the CXPI has received a PID field, it outputs an interrupt request at a level.

For detailed operation, see **Section 30.5.4.5, PID Reception**, or **Section 30.5.4.3, Manual Response**.

(3) Received Data Save Request

When the CXPI has received a long-frame response, it outputs an interrupt request at a level each time it receives eight bytes.

For detailed operation, see **Section 30.5.4.5, PID Reception**, or **Section 30.5.4.1, PID Transmission**.

(4) Frame Reception Completion

When the CXPI has received a response, it outputs an interrupt request at a level.

For detailed operation, see **Section 30.5.4.5, PID Reception**, or **Section 30.5.4.1, PID Transmission**.

(5) PTYPE Valid Period Completion

When the CXPI has transmitted a PTYPE field or the valid period after detecting a PTYPE field is ended, it outputs an interrupt request at a level.

For detailed operation, see **Section 30.5.4.6(2), When There is No Response from the Slave Node after Transmitting PTYPE**, or **Section 30.5.4.7(2), When Not Transmitting PID after Receiving PTYPE**.

(6) Wakeup Pulse Detection (Not Supported)

This IP does not support the wakeup pulse detection interrupt. It receives a wakeup pulse by using the CXPI transceiver and a module other than this IP.

30.5.9.3 Status

(1) Error Detection

When the CXPI has detected an error, it outputs an interrupt request at a level.

For details, see **Section 30.5.7.4, Error Detection**.

(2) Sleep Transition Completion

The CXPI outputs an interrupt request at a level the sleep transition time after it has transmitted or received a sleep frame. For detailed operation, see **Section 30.5.4.8, Sleep Frame Transmission Operation**, or **Section 30.5.4.9, Sleep Frame Reception Operation**.

30.5.10 Software Processing Flow

This section describes the software processing flow of the CXPI.

30.5.10.1 Overall Correlation Diagram

Each operation is designed by combining software processes. This section describes how software processes are combined for each operation.

(1) At Startup

The figure below is an overall correlation diagram at startup.

(a) Startup by Own Node

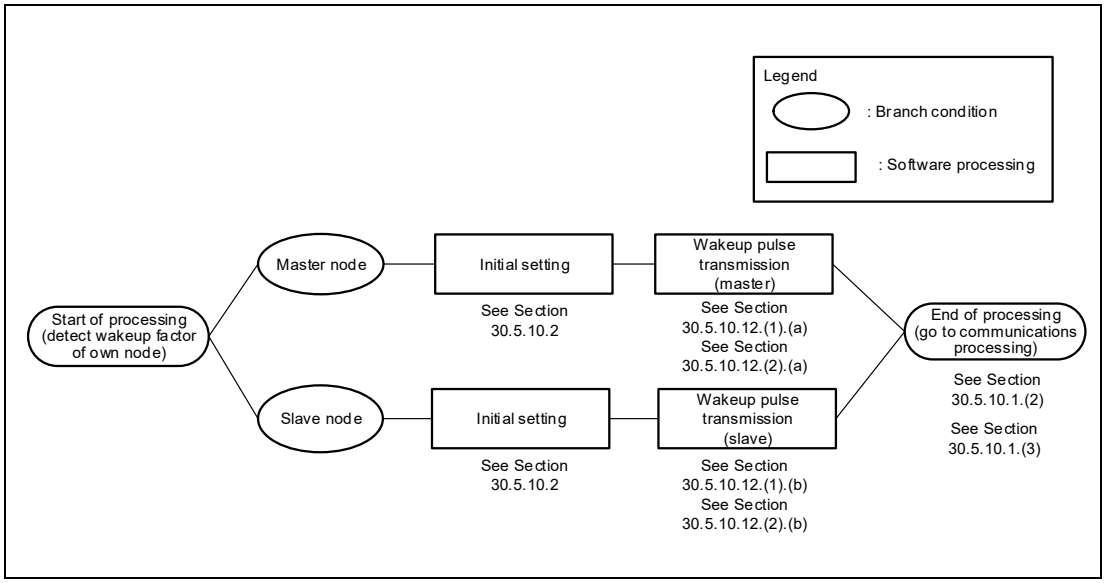


Figure 30.40 Overall Correlation Diagram at Startup by Own Node

(b) Startup by Other Node

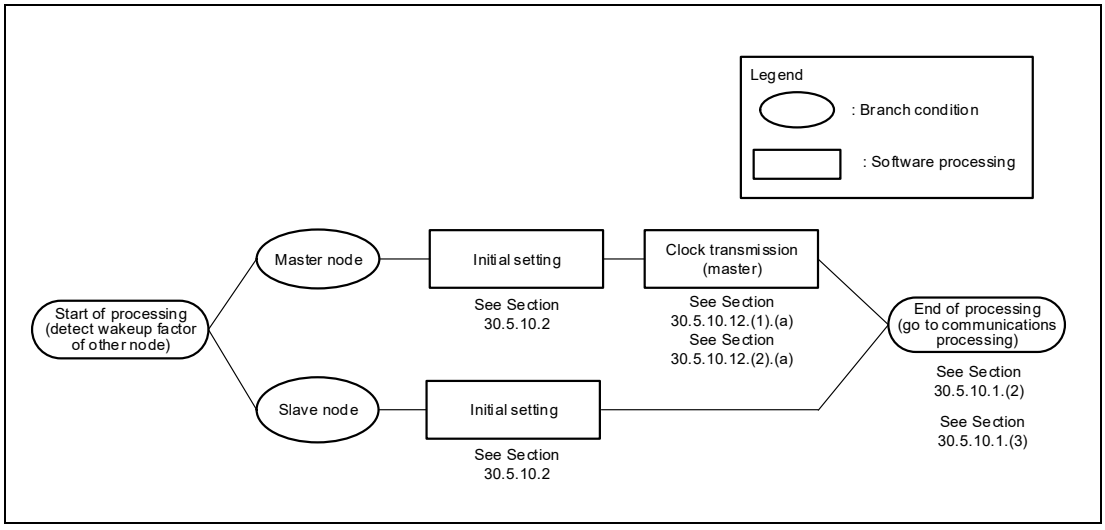

Figure 30.41 Overall Correlation Diagram at Startup by Other Node

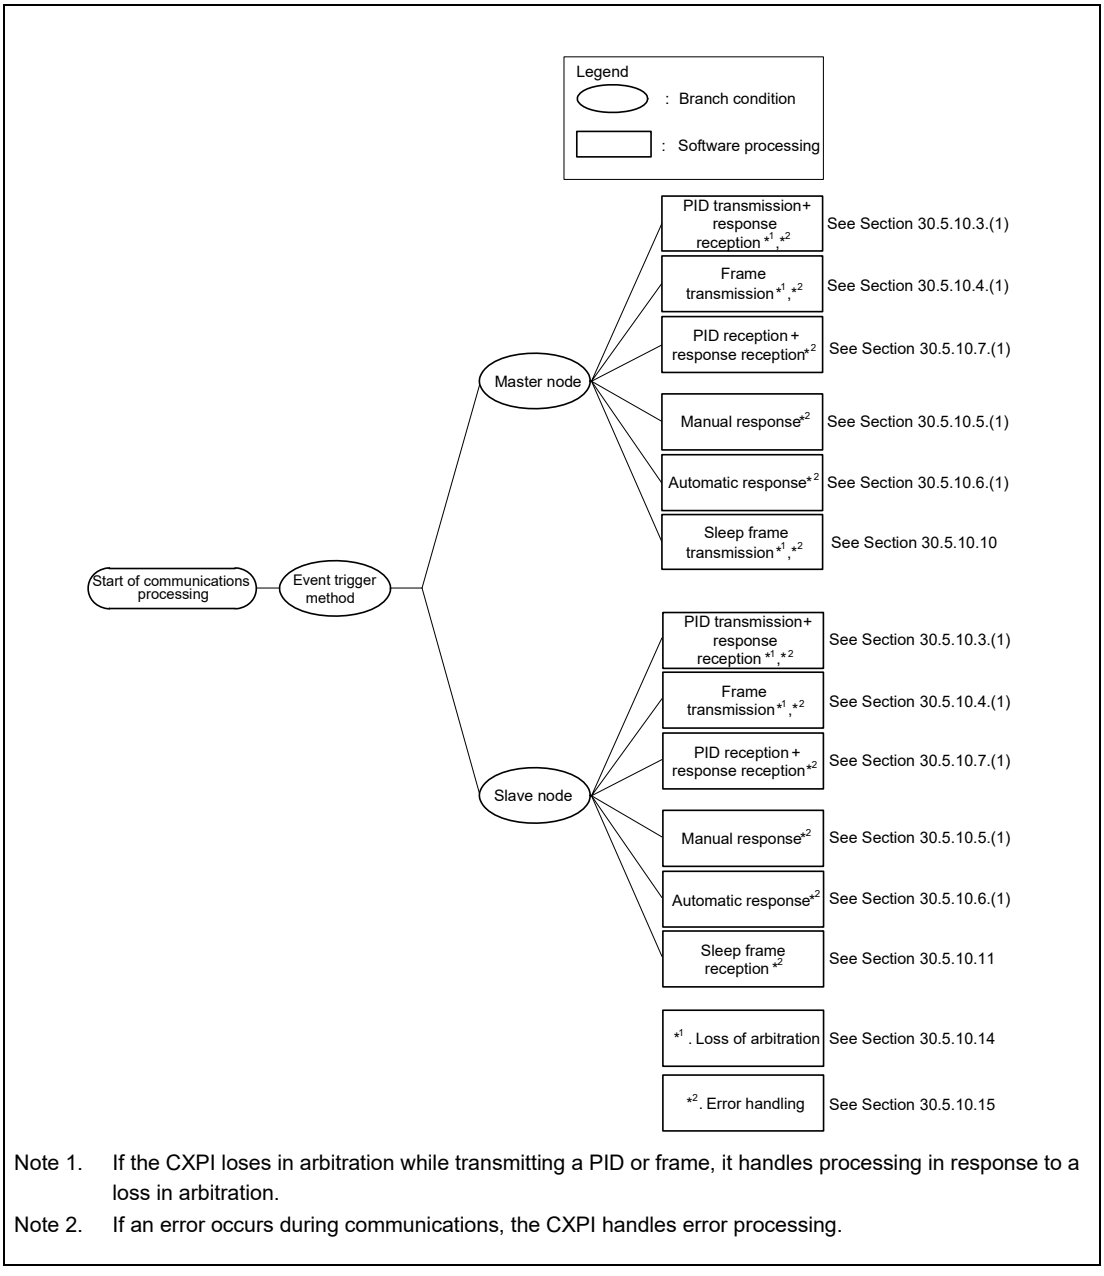
(2) Communication Flow in the Event Trigger Method (CXP1nMODE.CXP1nACC = 0_B)

The figure below shows the communication flow in the event trigger method.



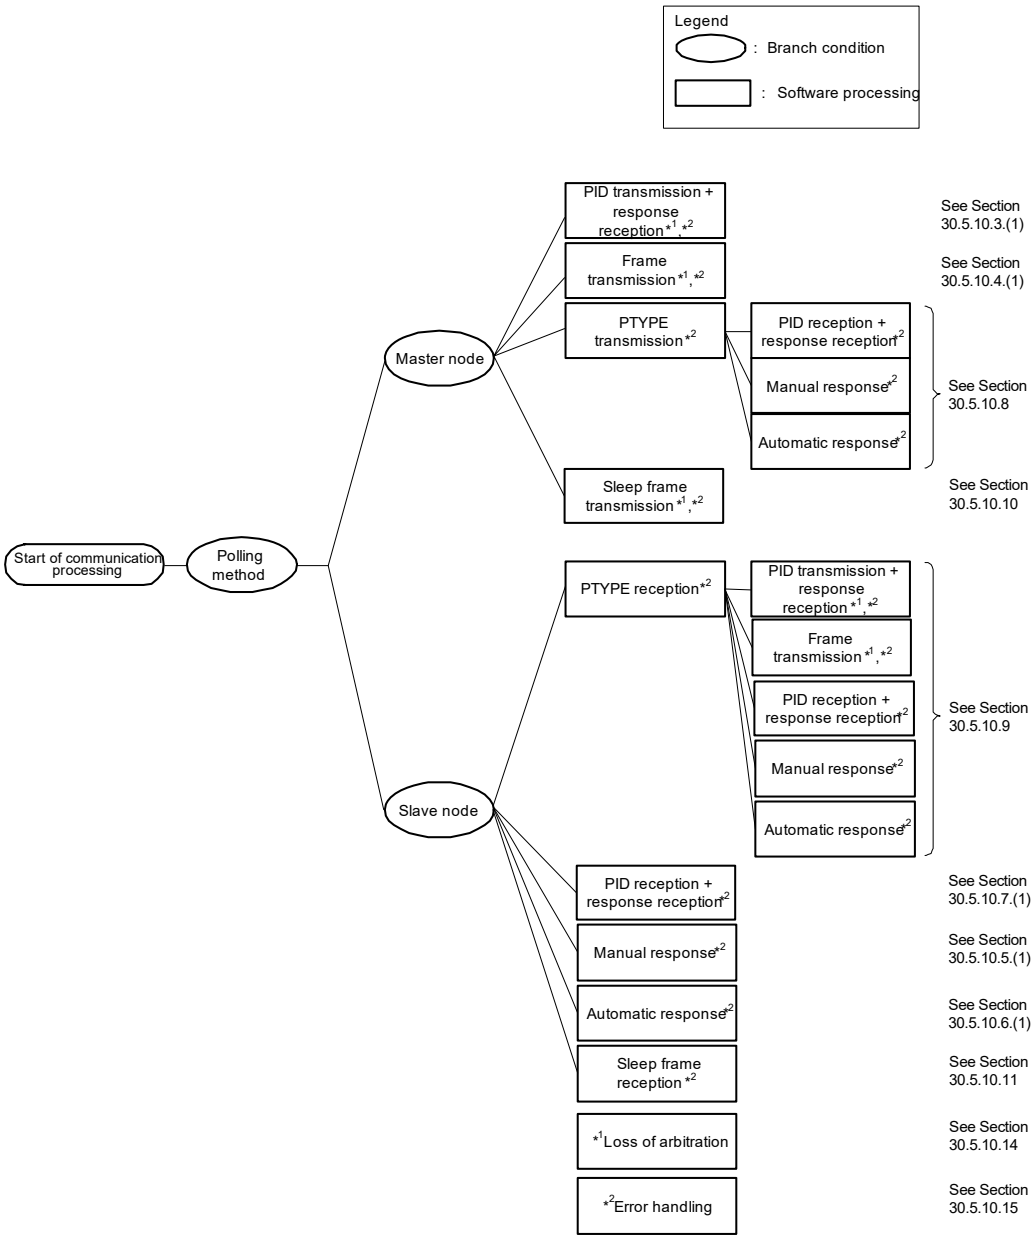
Note 1. If the CXPI loses in arbitration while transmitting a PID or frame, it handles processing in response to a loss in arbitration.

Note 2. If an error occurs during communications, the CXPI handles error processing.

Figure 30.42 Overall Correlation Diagram in the Event Trigger Method

(3) Communication Flow in the Polling Method (CXP1nMODE.CXP1nACC = 1_B)

The figure below shows the communication flow in the polling method.



Note 1. If the CXPI loses in arbitration while transmitting a PID or frame, it handles processing in response to a loss in arbitration.

Note 2. If an error occurs during communications, the CXPI handles error processing.

Figure 30.43 Overall Correlation Diagram in the Polling Method

30.5.10.2 Initial Settings

The initial settings differ depending on the transfer mode. This section describes the initial settings in each transfer mode.

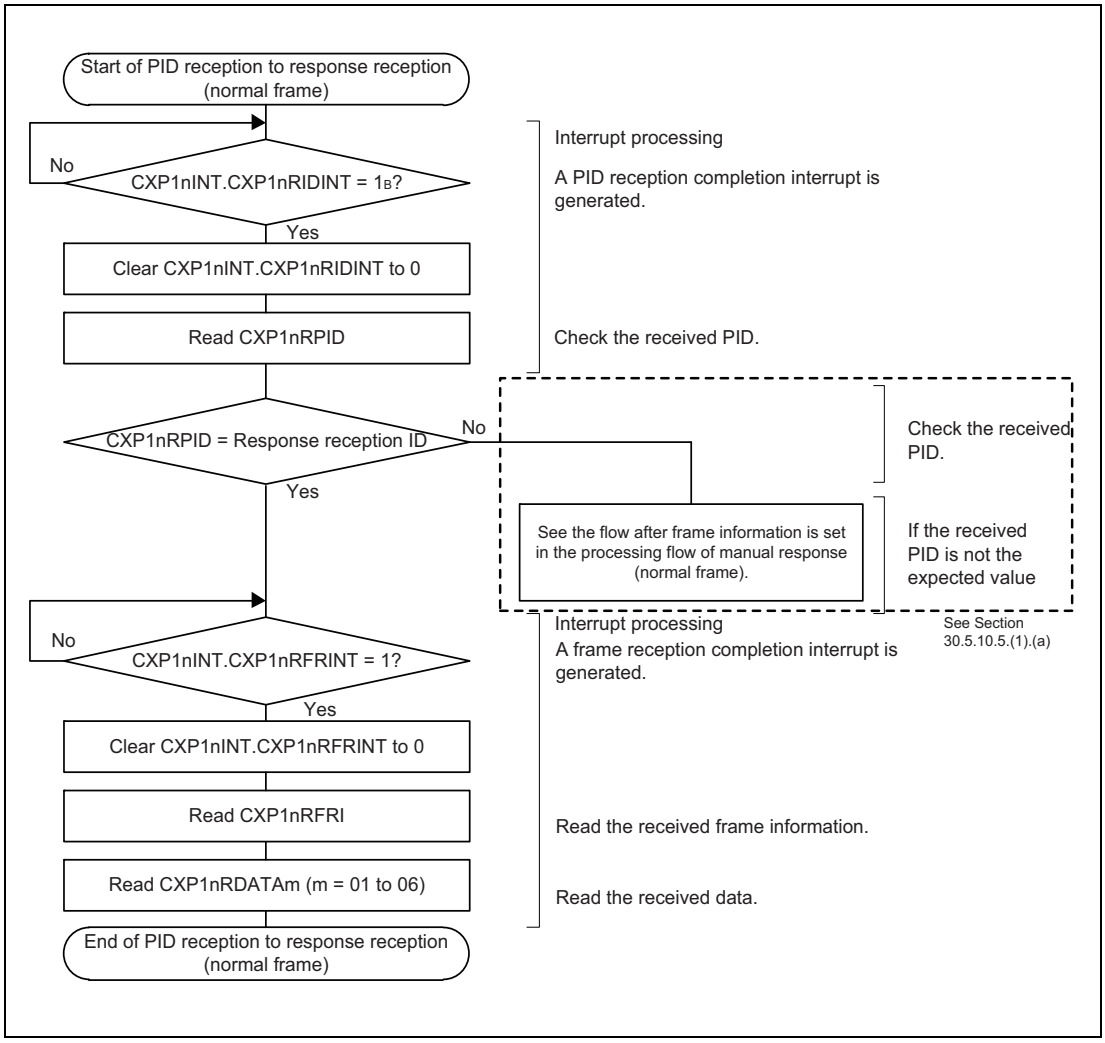

Figure 30.52 Processing Flow from PID Reception to Response Reception (Normal Frame)

(b) Long Frame

The figure below shows the processing flow from PID reception to response reception (for a long frame).

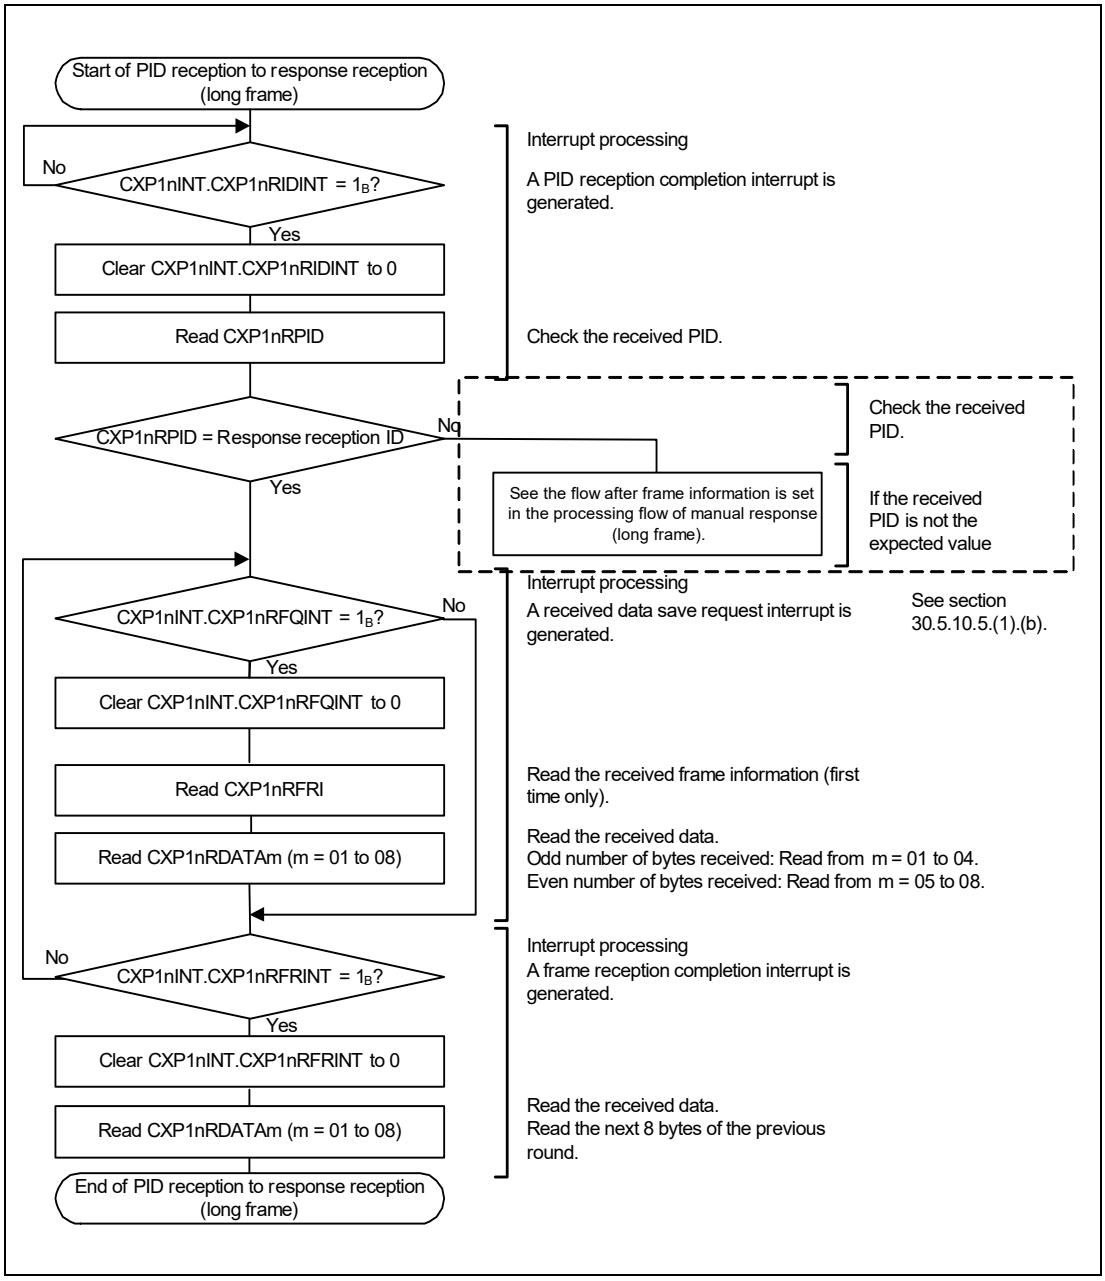

Figure 30.53 Processing Flow from PID Reception to Response Reception (Long Frame)

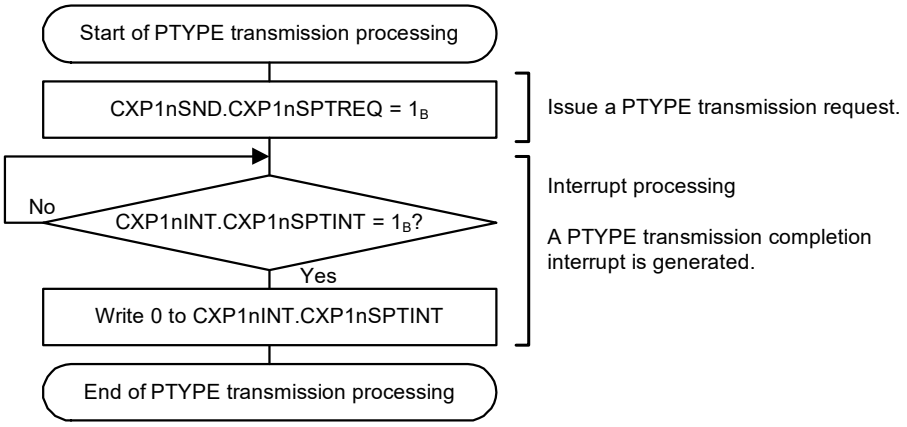
30.5.10.8 PTYPE Transmission

The figure below shows the processing flow for PTYPE transmission.

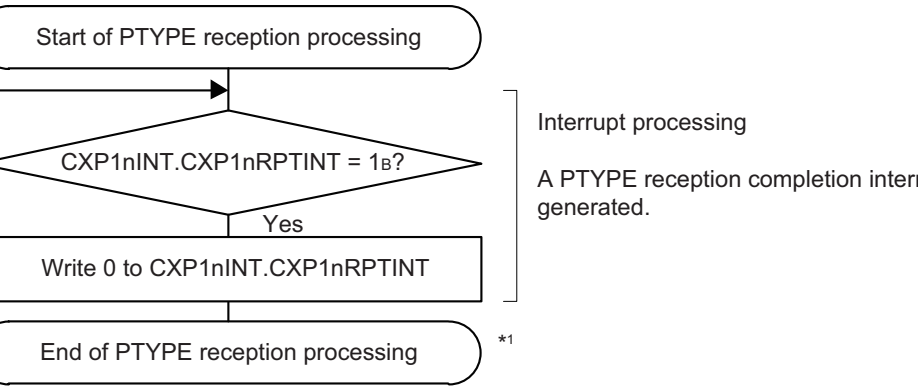


Note 1. If there is a response from the slave node after PTYPE transmission, any of the processing flows described in the following sections follows.
Section 30.5.10.5, Manual Response, **Section 30.5.10.6, Automatic Response**, or **Section 30.5.10.7, PID Reception**.

Figure 30.54 PTYPE Transmission Flow

30.5.10.9 PTYPE Reception

The figure below shows the processing flow for PTYPE reception.



Note 1. If the CXPI transmits a PID after receiving a PTYPE field and the PTYPE valid period hasn't passed (not CXP1nINT.CXP1nREXINT = 1), any of the processing flows follows.
Section 30.5.10.3, PID Transmission, **Section 30.5.10.4, Frame Transmission**, **Section 30.5.10.5, Manual Response**, **Section 30.5.10.6, Automatic Response**, or **Section 30.5.10.7, PID Reception**.

Figure 30.55 PTYPE Reception Flow

30.5.10.10 Sleep Frame Transmission

The figure below shows the processing flow for sleep frame transmission.

Don’t retransmit for sleep frame transmission.

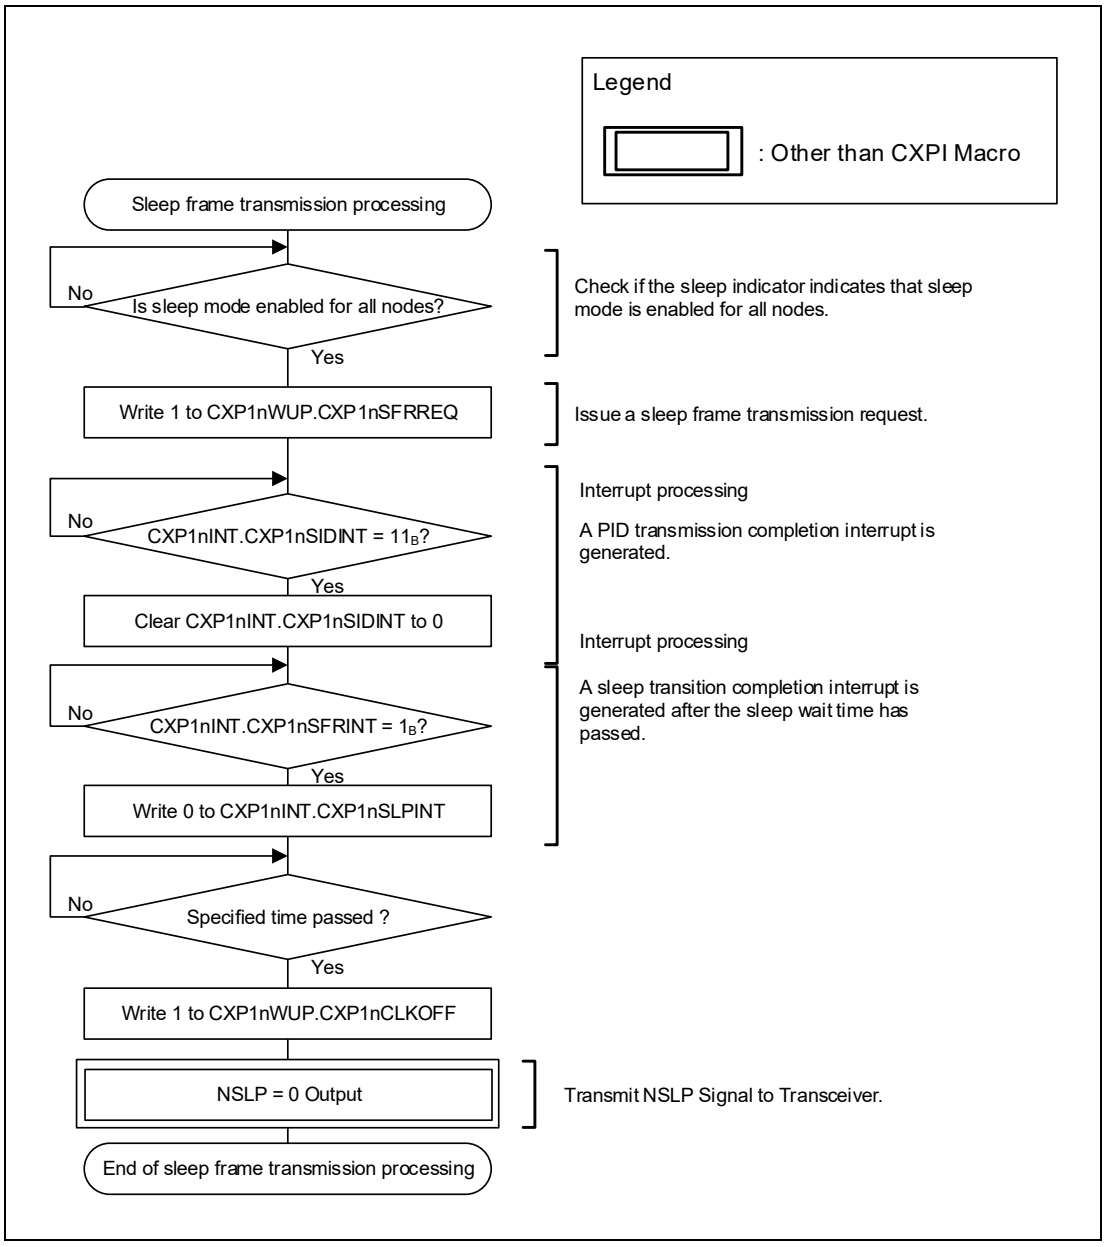


Figure 30.56 Sleep Frame Transmission Flow

30.5.10.11 Sleep Frame Reception

The figure below shows the processing flow for sleep frame reception.

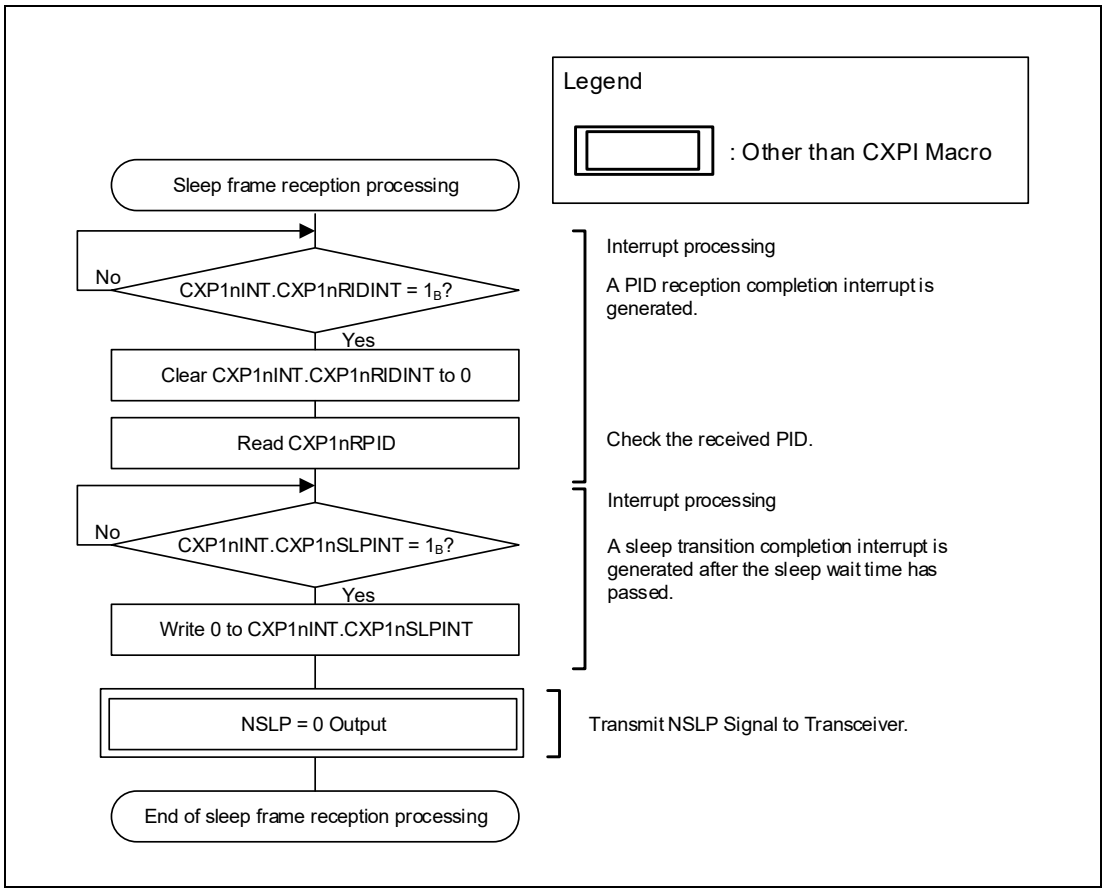

Figure 30.57 Sleep Frame Reception Flow

30.5.10.12 Wakeup Pulse Transmission

The wakeup pulse transmission operation differs depending on the transfer mode and master node/ slave node selection.

This section describes the wakeup pulse transmission operation under each operating condition.

(1) CXPI-PWM Mode

(a) Master Node

The figure below shows the processing flow for wakeup pulse transmission (by the master node).

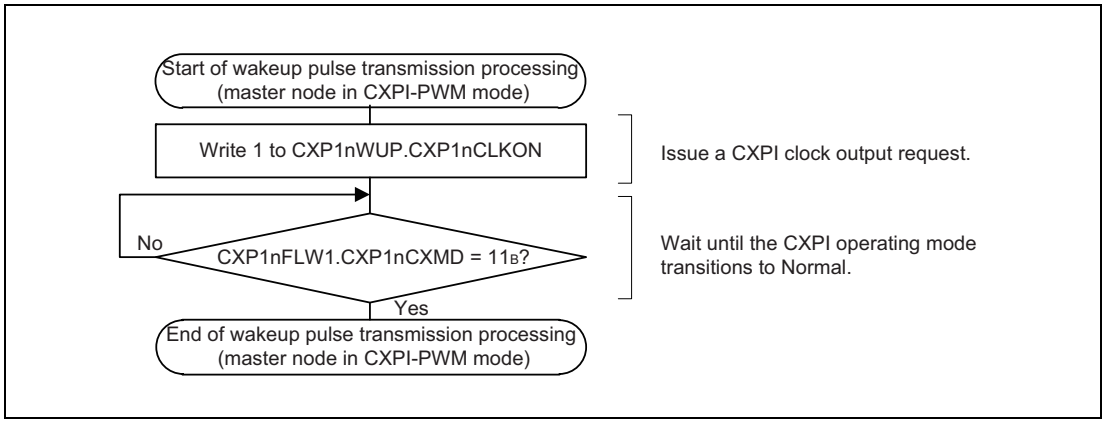

Figure 30.58 Flow of Wakeup Pulse Transmission (by Master Node in CXPI-PWM Mode)

(b) Slave Node

The figure below shows the processing flow for wakeup pulse transmission (by a slave node).

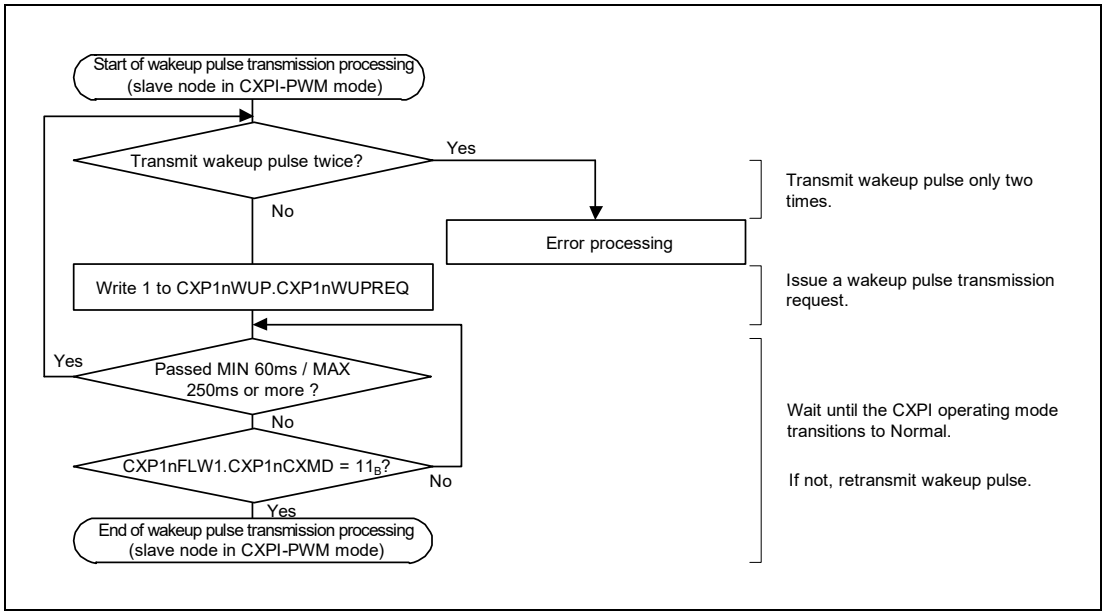

Figure 30.59 Flow of Wakeup Pulse Transmission (by Slave Node in CXPI-PWM Mode)

(2) CXPI-NRZ Mode

In CXPI-NRZ mode, the IP module controls the wakeup pulse transmission by controlling the CXPI transceiver and a module other than this IP. For the detailed operation, see **Section 30.5.1, CXPI System Configuration**.

(a) Master Node

The figure below shows the processing flow for wakeup pulse transmission (by the master node).

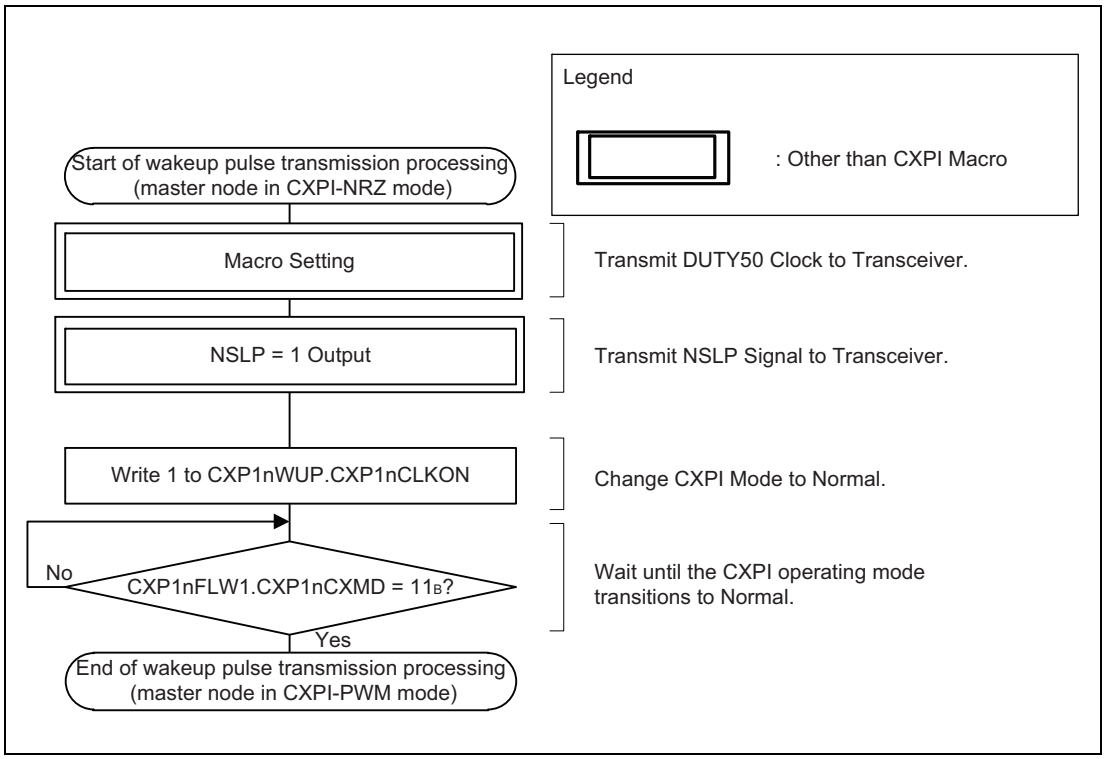

Figure 30.60 Flow of Wakeup Pulse Transmission (by Master Node in CXPI-NRZ Mode)

(b) Slave Node

The figure below shows the processing flow for wakeup pulse transmission (by a slave node).

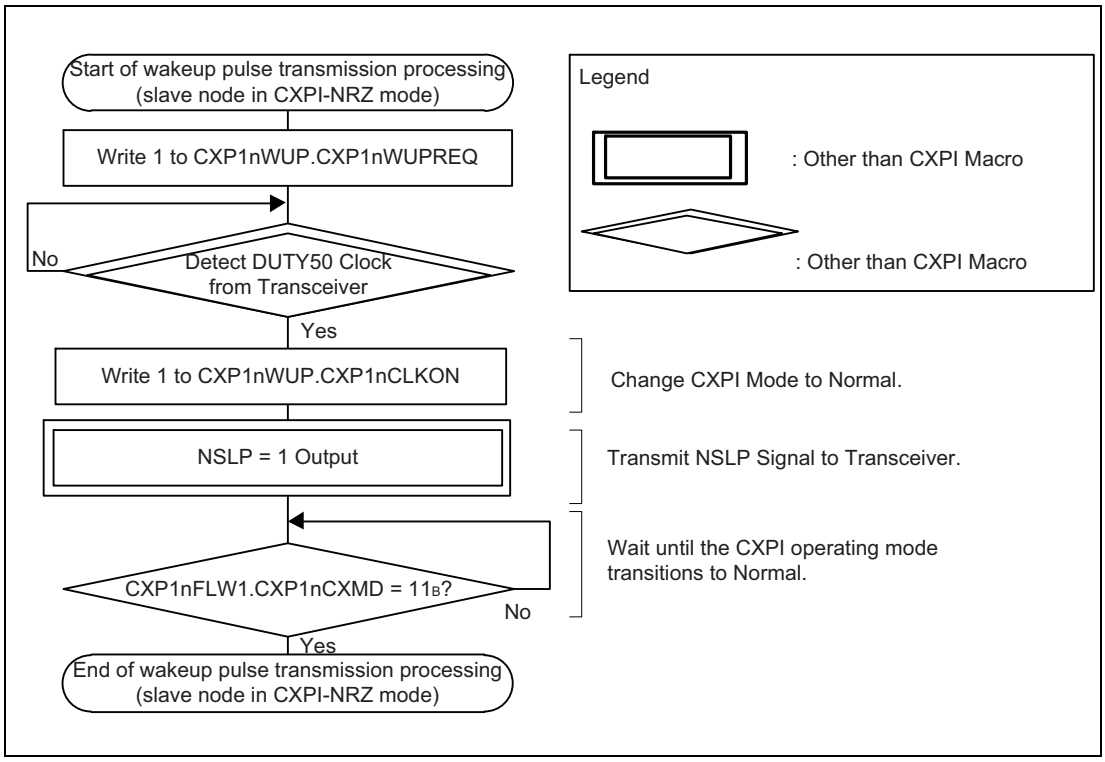

Figure 30.61 Flow of Wakeup Pulse Transmission (by Slave Node in CXPI-NRZ Mode)

30.5.10.13 Wakeup Pulse Reception

This IP does not have the wakeup pulse reception function. It detects a wakeup pulse by using the CXPI transceiver and an external function outside this IP. For the detailed operation, see **Section 30.5.1, CXPI System Configuration**.

30.5.10.14 Processing in Response to a Loss in Arbitration

The CXPI handles processing in response to a loss in arbitration if it has completed reception of a PID or frame while transmitting a PID.

The figure below shows the flow of processing in response to a loss in arbitration.

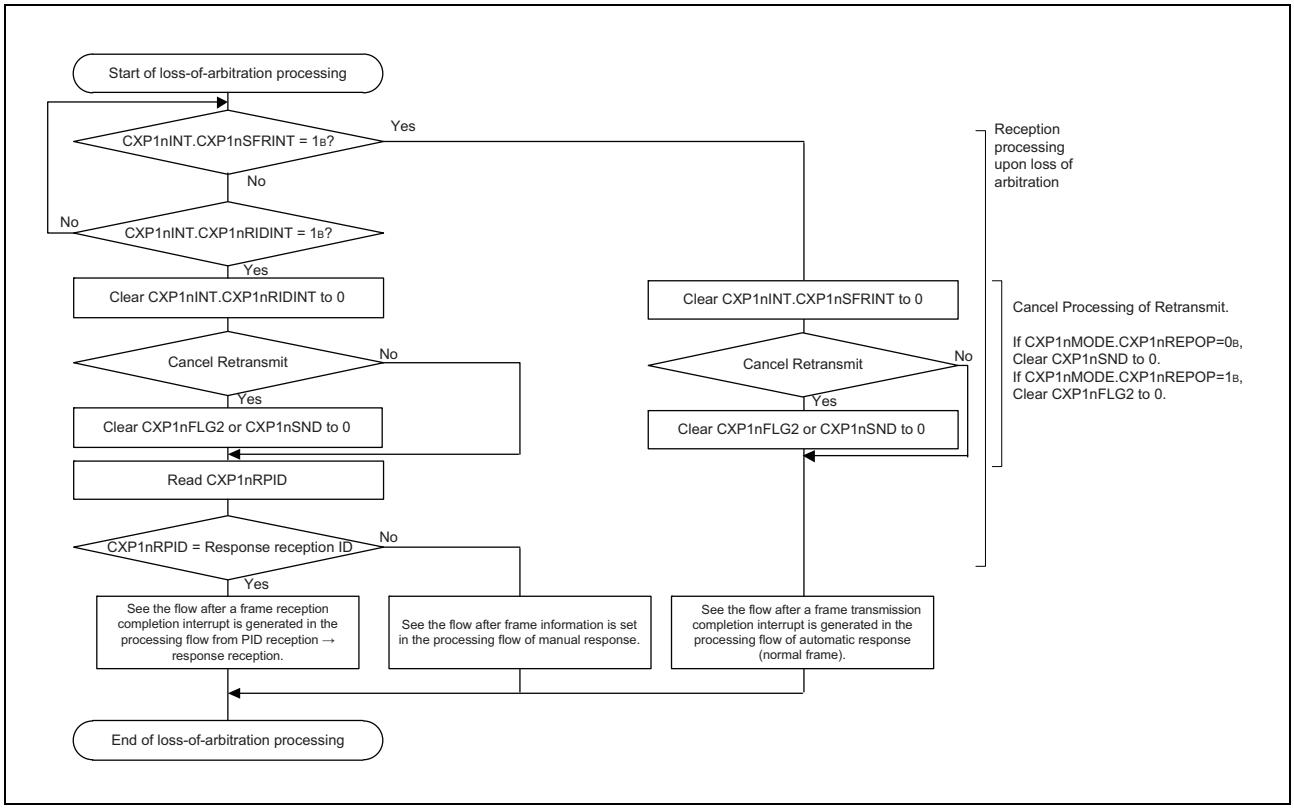

Figure 30.62 Flow of Processing in Response to a Loss in Arbitration

30.5.10.15 Error Handling

The figure below shows the error handling flow.

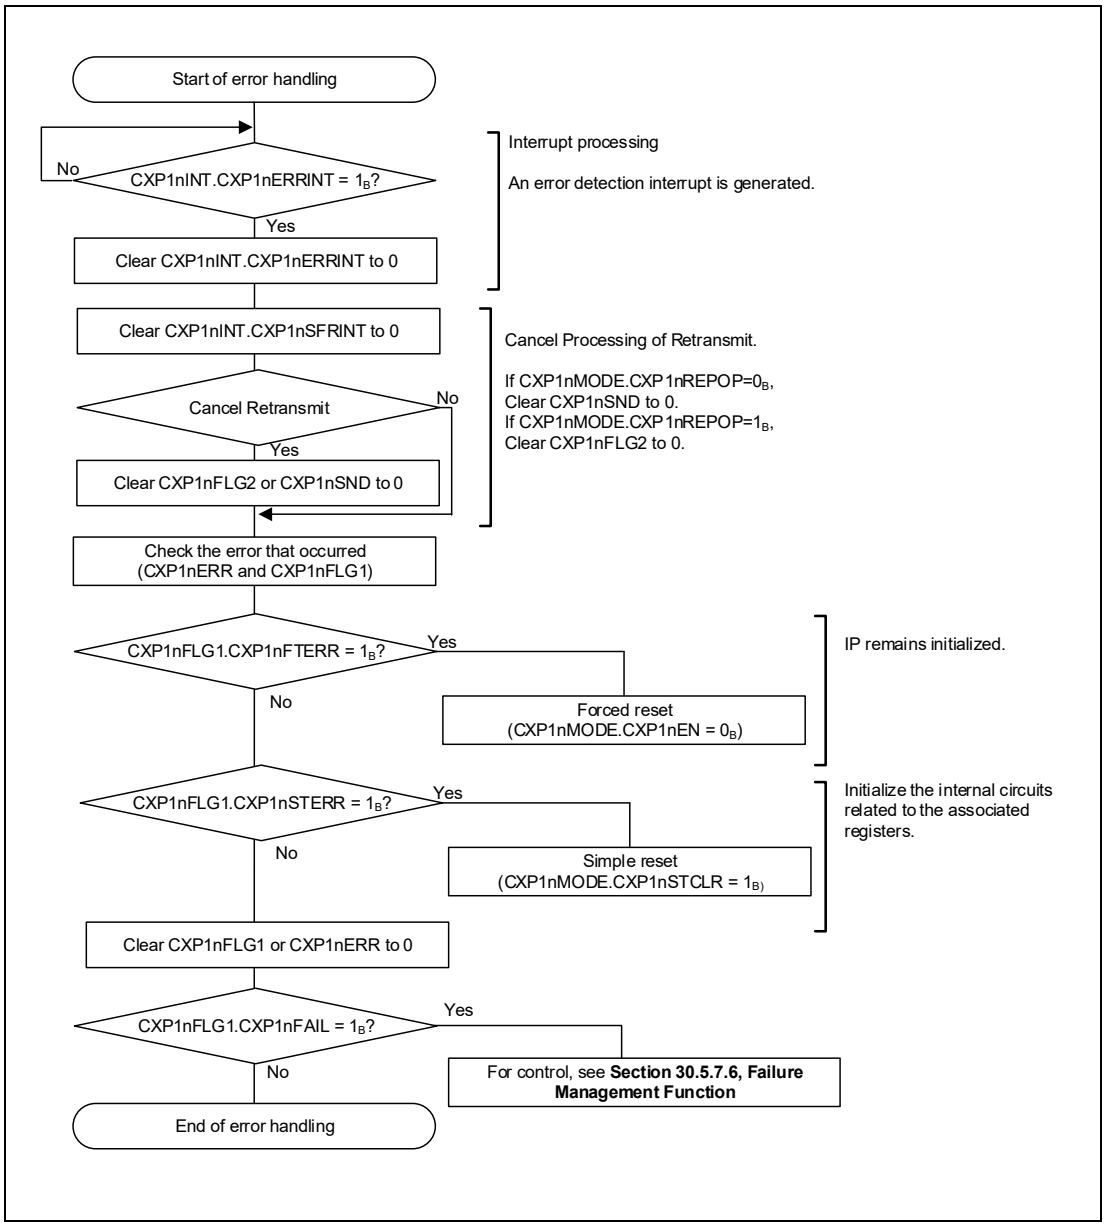

Figure 30.63 Error Handling Flow

30.6 Notes

30.6.1 Supplement Notes

30.6.1.1 On-Board Noise

The specification of the CXPI controller is on the assumption of negligible on-board noise between the LSI chip and the CXPI transceiver (the lines in the red broken-line boxes in the following figure). If on-board noise is present, take measures against it.

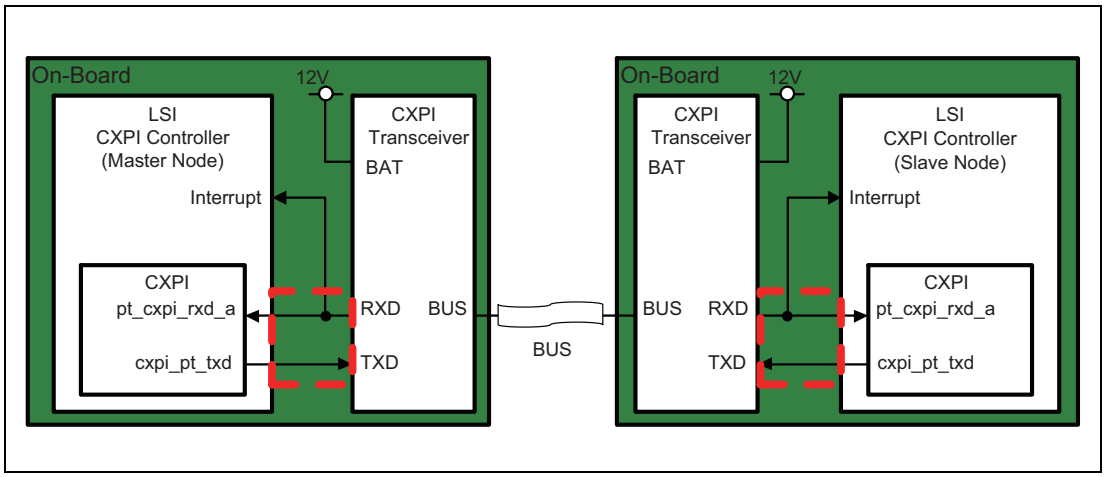

Figure 30.64 On-Board Noise

The following gives example of operations when on-board noise occurred between the LSI and the CXPI transceiver.

Operating conditions:

- CXPI-PWM mode
- Noise occurring during transmission of the start bit of a PID.
- Operation for retransmission being enabled.

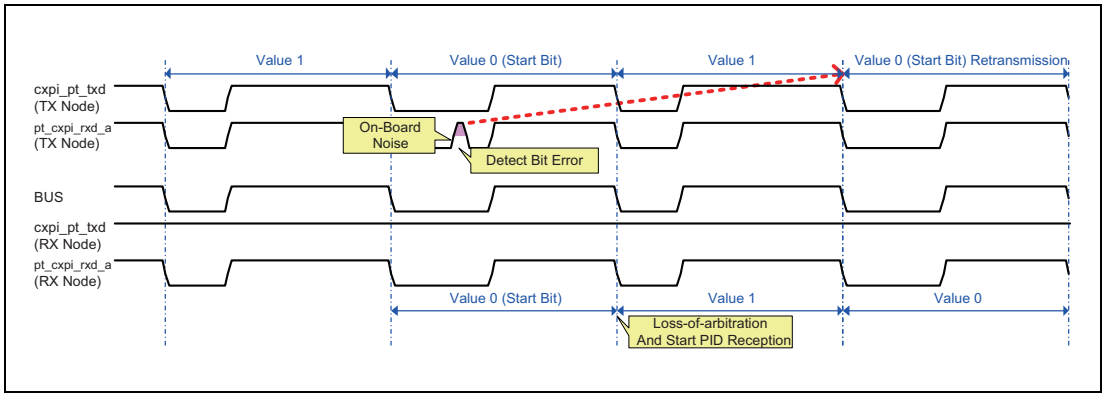

Figure 30.65 Example of Operations when On-Board Noise Occurred

If noise occurs in start bit of PID transmission in CXPI-PWM mode, local node detects bit error and performs re-transmission immediately. However, since logical value 0 (start bit) is transmitted on transmission bus, other nodes switch to receive operation from initial start bit. Therefore, other nodes receive in the order of start bits according to previous start bit + logical value 1 (interval until re-transmission) + re-transmission and receives unexpected PID.

As CXPI standard compliant operation, re-transmission should be performed at the time of bit error detection, after waiting until IFS period if logical value 0 is transmitted to transmission bus. But, because the specification does not take into consideration the board noise, this IP does not support this operation.

30.6.1.2 Loss in Arbitration in CXPI-PWM Mode

For CXPI standard arbitration, arbitration fail is judged if transmitted data and received data are not matching. Since this IP is also compliant with that standard, following abnormal operation may occur.

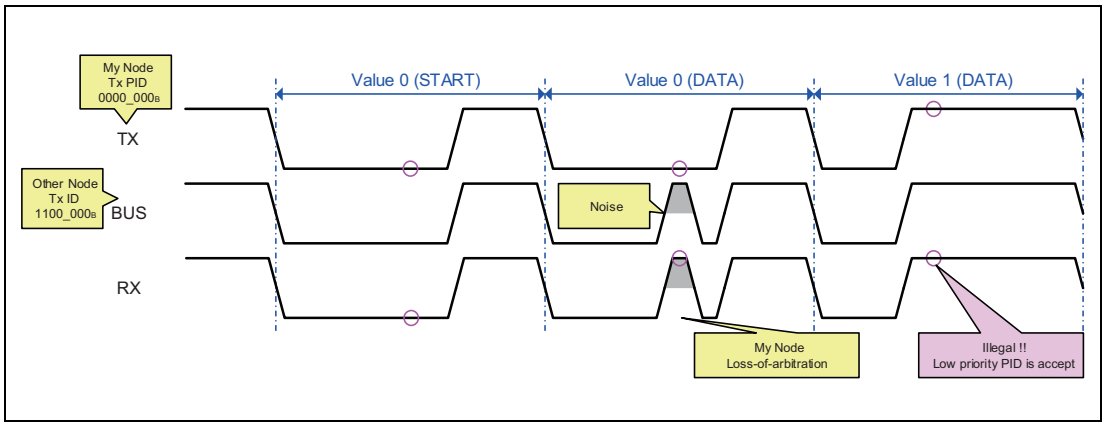

Figure 30.66 Low priority PID is transmitted case

When local node transmits dominant level output (high priority PID 0000000_B) and other node transmits recessive level output (low priority PID 1100010_B) PID, if recessive level noise occurs in transmission bus, local node judge's arbitration fail from mismatch of transmitted data and received data, stops transmission and starts receive. Other node continues PID transmission since transmitted data and received data are matching. Therefore, arbitration fail occurs for high priority PID but low priority PID is transmitted on transmission bus.

In addition, due to same reason, following unexpected communication may be established when only local node transmits PID.

If noise occurs in transmission bus during PID transmission, local node will judge arbitration fail and stop transmission (bit error is generated if noise occurs in start bit). Unexpected PID is transmitted on transmission bus because PID transmission is stopped and PID transmitted by other node is received normally (in case of data without parity error). Therefore, transmission may be established with unexpected PID but since this is considered as normal data transmission on communication bus, there is no problem with the operation.

30.6.2 Restrictions

30.6.2.1 Restriction of Register RMW (read-modify-write)

In case of RMW to a register with HW set clear conditions, values changed in HW may be overwritten unintentionally. Take care in case of RMW of following registers. It overwrites values not checked with SW read.

- CXPI Transmission Control Register (CXP1nSND)
  Observe the notes (**Section 30.6.2.5, Restriction of the Transmission Holding**).
- CXPI Interrupt Source Register (CXP1nINT)
  Since CXP1nINT.CXP1nERRINT and other bits change at the shortest 1 Tbit, complete RMW in the meantime.
- CXPI Flag Register 1 (CXP1nFLG1)
  When CXP1nFLG1.CXP1nRFTFID RMW, ignore the other bits. When referring to registers other than CXP1nFLG1.CXP1nRFTFID, do not RMW to CXP1nFLG1.CXP1nRFTFID.
- CXPI Flag Register 2 (CXP1nFLG2)
  Observe the notes (**Section 30.4.1.16, CXP1nFLG2 — CXPI Flag Register 2**).
- CXPI Error Register (CXP1nERR)
  Complete RMW within the interval (8 Tbit) at which each error is set.

30.6.2.2 Restriction of IFS Period and IBS Period Associated with Transceiver Delay

Although IFS period and IBS period are compliant with CXPI standards and throughout the manual they are explained with Tbit unit which is the basic bit, IFS period and IBS period are different per modes as given below.

- At the time of CXPI-PWM mode
  (CXP1nFRMW.CXP1nIFS setting value + 1) × IFS period of basic bit
- At the time of CXPI-NRZ mode
  (CXP1nFRMW.CXP1nIFS setting value + 1) × IFS period of basic bit
- At the time of CXPI-PWM mode
  CXP1nFRMW.CXP1nIBS1orIBS2 setting value × IBS period of basic bit
- At the time of CXPI-NRZ mode
  CXP1nFRMW.CXP1nIBS1orIBS2 setting value × IBS period of basic bit

Also, as shown in follow figure, IFS period and IBS period on transmission bus vary considerably due to transceiver delay. Note that the transceiver delay is not taken into consideration in this manual and the explanation is based on input output terminals of microcomputer.

Moreover, when the delay difference of less than 1 Tbit exists in TX and RX, per the delay difference, the reception start condition / PTYPE term of validity of an IFS period / IBS period / frame get mixed up 1 Tbit.

Build the system which secured the IFS period and the IBS period which is generous in consideration (more than or equal to 1 Tbit) of these delays.

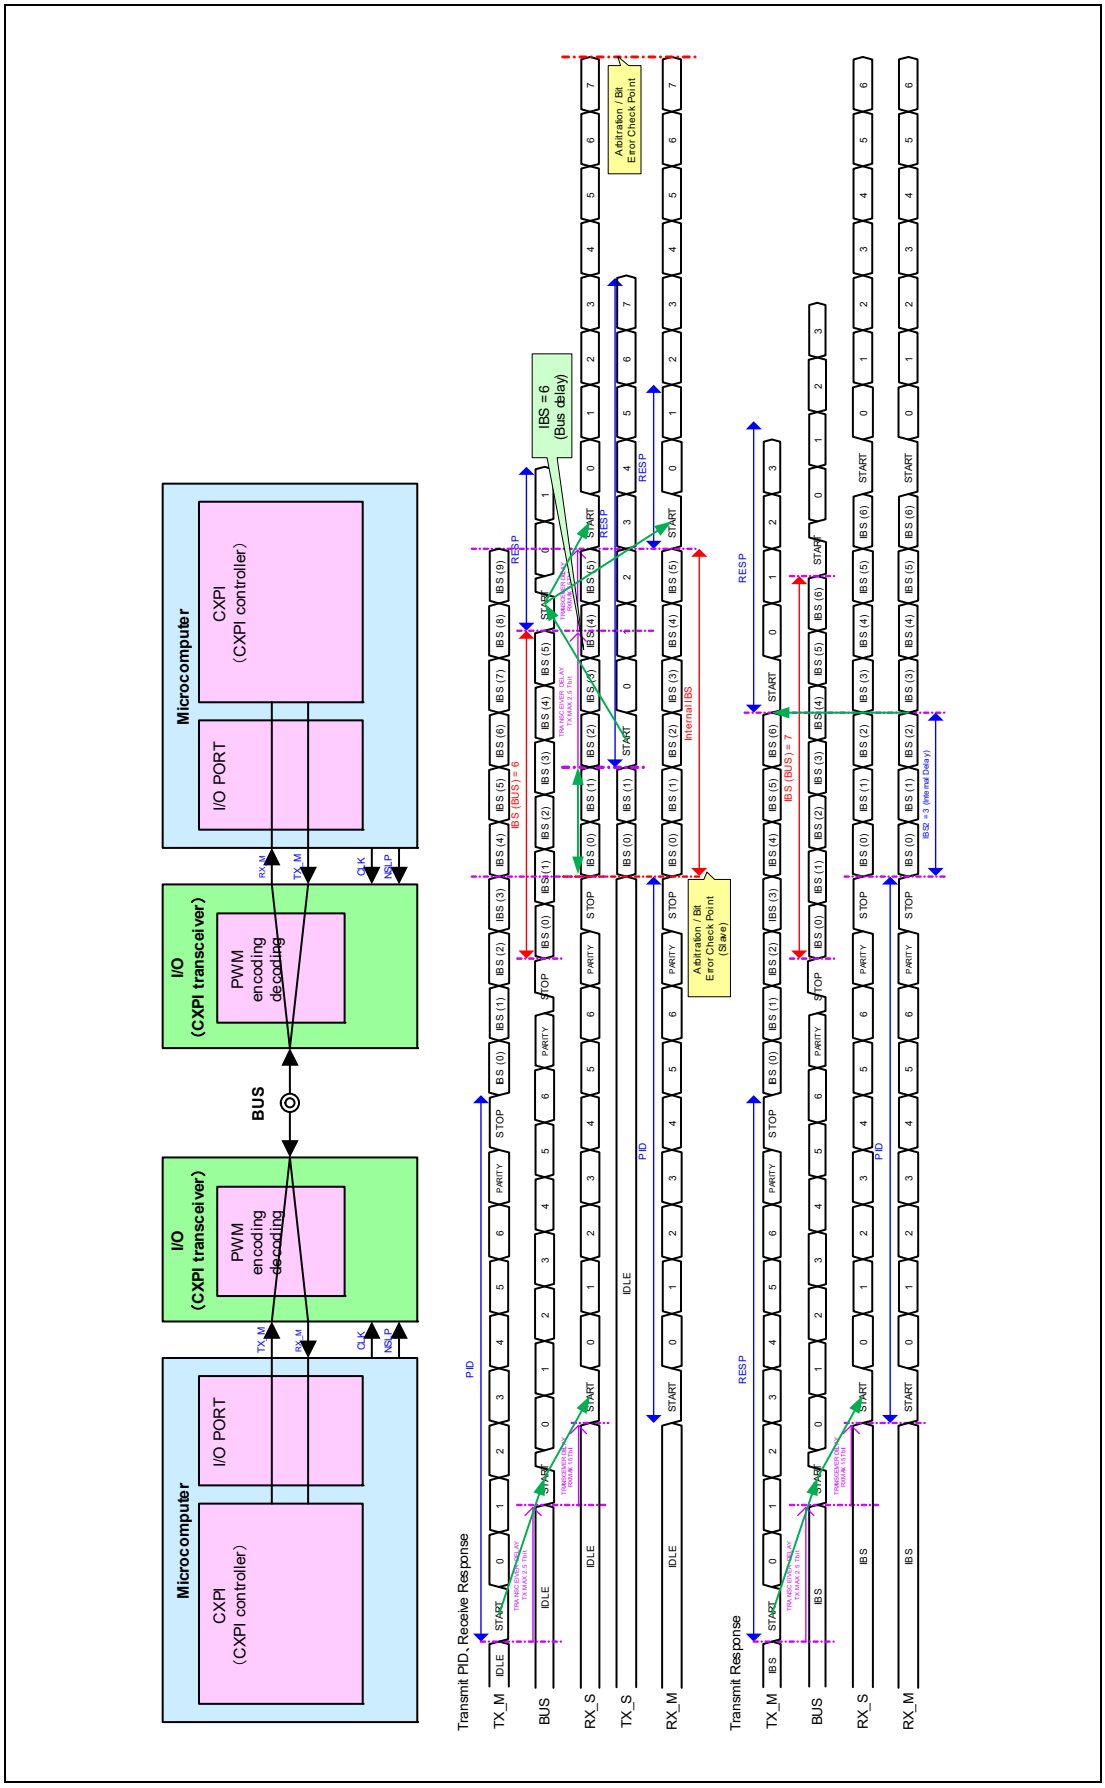

Figure 30.67 Effect of transceiver delay in NRZ mode

30.6.2.3 Restriction of PID Transmit after PTYPE Transmit and Receive

About the control after PTYPE transmission, note following that.

1. To Less than 10 Tbit after transition PTYPE, frame or PID transmit is prohibited.
2. After detecting PTYPE validity completion interrupt after a PTYPE transmission, the transmission the idle state saves and by which PID and a frame is possible by a CXPI controller. Therefore please send PID or a frame after a IFS period on the bus is measured by software.

About the control after PTYPE reception, note following that.

1. The PID transmitting operation after PTYPE reception should build a system with sufficient margin for IBS period.
2. When detecting PID reception complete before PTYPE transmission completion, please break the communication behavior. There is a possibility that a slave node is sending PID without PTYPE reception (though that does not follow CXPI standard spec), but this module has no function to detect it as an error though PID can receive normally.

30.6.2.4 Restriction of Transmission Request

When CXPI bus not idle (CXP1nFLW1.RXIDLE = 0_B) and IDLE state (CXP1nFLW1.CXP1nCXST = IDLE), transmission (write 1 to CXP1nSND. CXP1nSPTREQ CXP1nSND. CXP1nSFRREQ CXP1nSND. CXP1nSIDREQ) is prohibited.

30.6.2.5 Restriction of the Transmission Holding

This IP have the function of the transmission holding as follows: Write 1 to CXP1nSND register, Loss-of-arbitration retransmission remaining, Error retransmission remaining.

Note the more than one transmission holding cause difficulties. Be sure to set the transmission request of CXP1nSND one by one (one hot).

30.6.2.6 Restriction of Retransmission

Note follow these.

1. Both CXP1nFLG2.CXP1nEREP and CXP1nFLG2.CXP1nAREP are used for retransmission when detecting bit error with PID transmission of CXPI-NRZ mode.
2. Clear CXP1nFLG2.CXP1nEREP when frame or PID transmission is finished with “Retransmission After an Error Occurred (Retransmission Judged)”.

30.6.2.7 Restriction of Request Frame ID

The master node can transmit request frame ID (PID = $1F_H$). The slave node can receive request frame ID (PID = $1F_H$).

Use “Frame Transmission” if transmit request function ID.

When a response is not able to receipt by abnormalities after receive frame ID (PID = $1F_H$), be forced reset (CXP1nMODE.CXP1nEN = 0).

Section 31 Window Watchdog Timer (WDTB)

This section contains a generic description of the Window Watchdog Timer (WDTB).

The first part of this section describes properties specific to the RH850/U2A-EVA, such as the number of units, register base addresses, etc.

The remainder of the section describes the functions and registers of the WDTB.

31.1 Features WDTB for RH850/U2A-EVA

31.1.1 Number of Units and Channels

This microcontroller has the following number of WDTB units.

Each WDTB unit has one channel interface.

Table 31.1 Number of Units

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of Units	5 (n = 0 to 3, A)	5 (n = 0 to 3, A)	5 (n = 0 to 3, A)	5 (n = 0 to 3, A)	3 (n = 0, 1, A)	3 (n = 0, 1, A)	3 (n = 0, 1, A)	3 (n = 0, 1, A)	3 (n = 0, 1, A)	3 (n = 0, 1, A)
Name	WDTBn/WDTBA									

Table 31.2 Index

Index	Description
n	In ISO domain, the individual units of window watchdog timer are identified by the index “n”, For example, WDTBnWDTE for the WDTBn enable register. Throughout this section, “n” will range from 0 to 3.
A	In AWO domain, the window watchdog timer unit is identified by the index “A”, For example, WDTBAWDTE for the WDTBA enable register.

31.1.2 Register Base Addresses

WDTBn/WDTBA base addresses are listed in the following table.

WDTBn/WDTBA register addresses are given as offsets from the base addresses.

Table 31.3 Register Base Addresses

Base Address Name	Base Address	Bus Group
<WDTB0_base>	FFBF 1000_H	P-Bus Group 5
<WDTB1_base>	FFBF 1100_H	P-Bus Group 5
<WDTB2_base>	FFBF 1200_H	P-Bus Group 5
<WDTB3_base>	FFBF 1300_H	P-Bus Group 5
<WDTBA_base>	FF9A 5000_H	P-Bus Group 2L

31.1.3 Clock Supply

The window watch dog timer uses WDTBTCKI and PCLK as a clock input.

Table 31.4 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
WDTBA	PCLK	CLK_LSB
	WDTBTCKI	CLKA_WDT
WDTBn	PCLK	CLK_HSB
	WDTBTCKI	CLK_WDT

Note: For details of the clock, see **Section 13, Clock Controller**.

31.1.4 Interrupt Requests and Error Notifications

WDTBn/WDTBA interrupt requests are listed in the following table.

Table 31.5 Interrupt Requests

Interrupt Symbol Name	Unit Interrupt Signal	Description	Interrupt Number	DMA Trigger Number	Wake up
INTWDTB0TIT	WDTB0TIT	WDTB0 interrupt	22	—	—
INTWDTB1TIT	WDTB1TIT	WDTB1 interrupt	22	—	—
INTWDTB2TIT	WDTB2TIT	WDTB2 interrupt	22	—	—
INTWDTB3TIT	WDTB3TIT	WDTB3 interrupt	22	—	—
INTWDTBATIT	WDTBATIT	WDTBA interrupt	705	—	√

The error notifications of this module are listed in the following table.

Table 31.6 Error Notifications

Error Notification	Description	ECM Error Number	Error Response to bus master
Watchdog timer error (PE0)	WDTB0 error	228	—
Watchdog timer error (PE1)	WDTB1 error	260	—
Watchdog timer error (PE2)	WDTB2 error	292	—
Watchdog timer error (PE3)	WDTB3 error	324	—

Note: WDTBA does not send error notification to ECM.

31.1.5 Reset Sources

WDTB reset sources are listed in the following table. WDTB is initialized by these reset sources.

Table 31.7 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
WDTBn	All registers	√	√	√	√	√	—	—
WDTBA	All registers	√	√	√	√	—	—	—

31.1.6 Correspondence of WDTBn/WDTBA and CPU

Table 31.8 Correspondence of WDTB and CPU

WDTB	CPU Unit										ISO/ AWO domain
	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)	
WDTB0	CPU0	CPU0	CPU0	CPU0	CPU0	CPU0	CPU0	CPU0	CPU0	CPU0	ISO
WDTB1	CPU1	CPU1	CPU1	CPU1	CPU1	CPU1	CPU1	CPU1	CPU1	CPU1	ISO
WDTB2	CPU2	CPU2	CPU2	CPU2	—	—	—	—	—	—	ISO
WDTB3	CPU3	CPU3	CPU3	CPU3	—	—	—	—	—	—	ISO
WDTBA	selectable	selectable	selectable	selectable	selectable	selectable	selectable	selectable	selectable	selectable	AWO

31.1.7 Internal Input/Output Signals

Table 31.9 Internal Input/Output Signals

Unit Signal Name	Description	Connection
WDTBATRES	WDTBA error	Reset Controller
WDTB0TRES	WDTB0 error	ECM
WDTB1TRES	WDTB1 error	ECM
WDTB2TRES	WDTB2 error	ECM
WDTB3TRES	WDTB3 error	ECM
WDTB0TNMI	WDTB0 error for non-maskable interrupt	PIC1
WDTB1TNMI	WDTB1 error for non-maskable interrupt	PIC1
WDTB2TNMI	WDTB2 error for non-maskable interrupt	PIC1
WDTB3TNMI	WDTB3 error for non-maskable interrupt	PIC1

31.2 Overview

31.2.1 Functional Overview

The window watchdog timer has the following functions:

- Selection of the operation mode after reset, by using the option bytes
  - Enabling/disabling of WDTB, starting/stopping of the counter after reset, setting of the counter overflow time, and enabling/disabling of the VAC function can be selected. WDTB startup options to be set by the option bytes.
- WDTB trigger function
  - Writing an activation code to the WDTB trigger register starts WDTB and restarts the counter. Activation codes include fixed activation codes and variable activation codes (VAC function). In a variable activation code, a different value from the previous time (variable value) is written to the WDTB trigger register, which causes the counter to be restarted.
- Interrupt request signal
  - An interrupt request signal can be generated when the WDTB counter reaches a specific number or 75% of the overflow interval time (these two options can be set by WDTBnMD.WDTBnWMS/WDTBAMD.WDTBAWMS and WDTBnWIS/WDTBAWIS).
  - This function can be enabled/disabled by the setting of WDTBnMD.WDTBnWIE/ WDTBAMD.WDTBAWIE.
- Window function
  - The period during which writing to the WDTB trigger register is valid (window open period) can be set. Writing to the WDTB trigger register during a period other than the window open period causes an error.
- WDTB error detection function
  - When an error is detected, a non-maskable interrupt request or an internal reset is generated.

31.2.2 Block Diagram

Figure 31.1 and **Figure 31.2** show the main components of the WDTB.

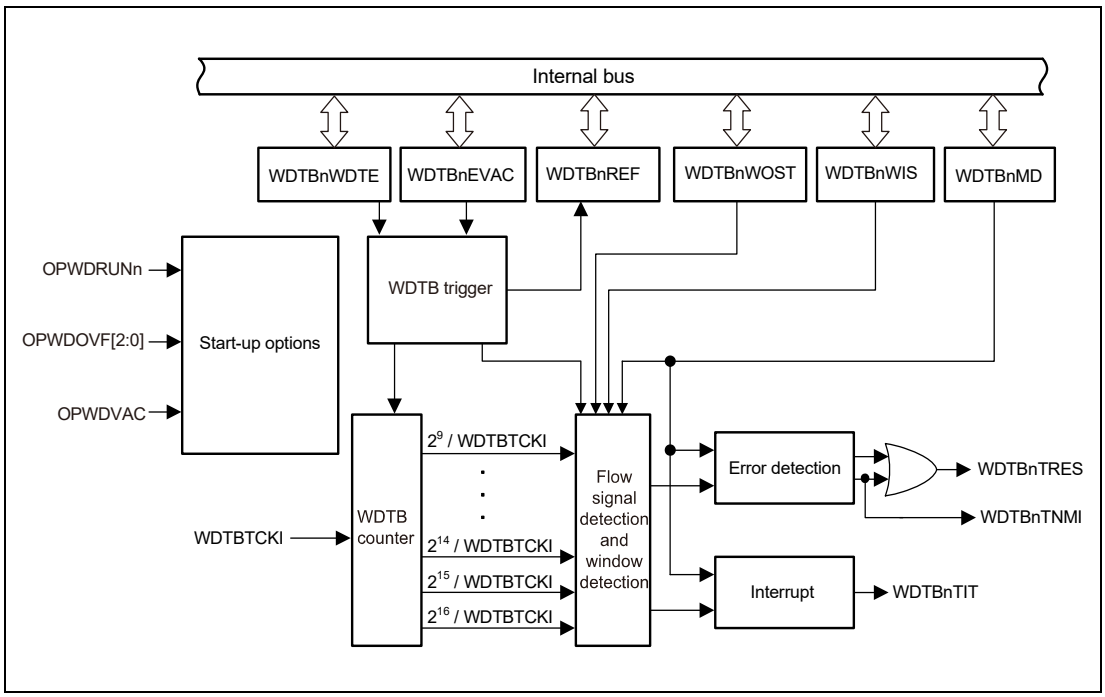

Figure 31.1 Block Diagram of WDTBn

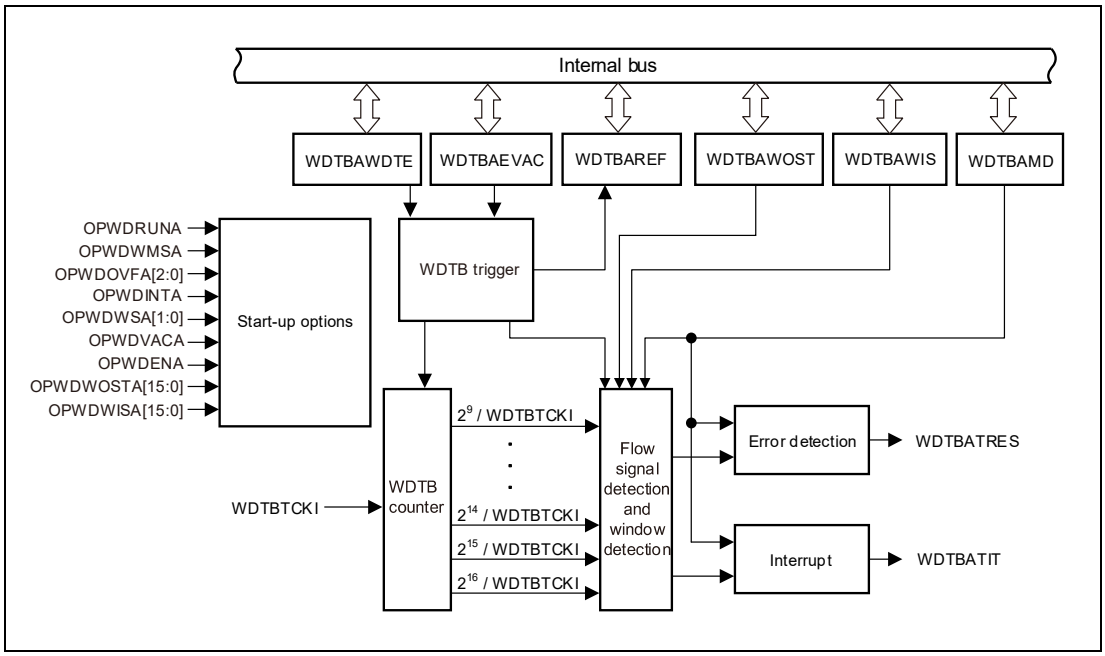

Figure 31.2 Block Diagram of WDTBA

31.3 Registers

The WDTB is controlled and operated by the following registers.

31.3.1 List of Registers

The following shows the list of registers and the memory address of WDTB.

For the base addresses, see **Table 31.3**.

The actual address can be obtained by adding the offset shown in the table to this base address.

Table 31.10 List of Registers

Module Name	Register Name	Symbol	Address	Access Size	Access Protection	
					PBG	Other
WDTB	WDTB Enable register	WDTBnWDTE	<WDTBn_base> + 0000_H	8	*1	—
	WDTB enable register for VAC	WDTBnEVAC	<WDTBn_base> + 0004_H	8	*1	—
	WDTB reference value register	WDTBnREF	<WDTBn_base> + 0008_H	8	*1	—
	WDTB Mode register	WDTBnMD	<WDTBn_base> + $000C_H$	8	*1	—
	WDTB Window Open Start register	WDTBnWOST	<WDTBn_base> + 0010_H	16	*1	—
	WDTB Interrupt Output Timing Setting register	WDTBnWIS	<WDTBn_base> + 0014_H	16	*1	—
	WDTB Enable register	WDTBAWDTE	<WDTBA_base> + 0000_H	8	PBG20#11	—
	WDTB enable register for VAC	WDTBAEVAC	<WDTBA_base> + 0004_H	8	PBG20#11	—
	WDTB reference value register	WDTBAREF	<WDTBA_base> + 0008_H	8	PBG20#11	—
	WDTB Mode register	WDTBAMD	<WDTBA_base> + $000C_H$	8	PBG20#11	—
	WDTB Window Open Start register	WDTBAWOST	<WDTBA_base> + 0010_H	16	PBG20#11	—
	WDTB Interrupt Output Timing Setting register	WDTBAWIS	<WDTBA_base> + 0014_H	16	PBG20#11	—
	WDTB Option Byte Monitor Register 0	WDTBAOPBMON0	FF9A 5208_H	32	PBG20#11	—
	WDTB Option Byte Monitor Register 1	WDTBAOPBMON1	FF9A $520C_H$	32	PBG20#11	—

Note 1. n = 0 PBG50#2
n = 1 PBG50#3
n = 2 PBG50#4
n = 3 PBG50#5

31.3.2 Detail of Registers

31.3.2.1 WDTBnWDTE/WDTBAWDTE — WDTB Enable Register

This register is the WDTB trigger register when the VAC function is not used.

Writing AC_H to this register generates a WDTB trigger and starts or restarts the WDTB counter.

Refer to **Section 31.4.2, WDTB Trigger** for details.

The value that can be written in this register is only AC_H.

Access: This register can be read or written in 8-bit units.

Address: <WDTBn_base> + 0000_H
<WDTBA_base> + 0000_H

Value after reset: The initial value depends on the start-up options (OPWDENA, OPWDRUNn/OPWDRUNA and OPWDVAC/OPWDVACA). See **Table 31.12, Values of WDTBnRUN[7]/WDTBARUN[7] after Reset**.

Bit	7	6	5	4	3	2	1	0
	WDTBnRUN[7:0]/WDTBARUN[7:0]							
Value after reset	0/1*1	0	1	0	1	1	0	0
R/W	R/W	R	R	R	R	R	R	R

Note 1. WDTBnRUN[7]/WDTBARUN[7] depends on start-up options.

Table 31.11 WDTBnWDTE/WDTBAWDTE Register Contents

Bit Position	Bit Name	Function
7 to 0	WDTBnRUN[7:0]/ WDTBARUN[7:0]	Writing the fixed activation code (AC_H) generates the WDTB trigger and starts/ restarts the WDTB counter. Writing a value other than AC_H generates an error. The WDTB cannot be stopped once it is started.

The value after WDTBnRUN[7] /WDTBARUN[7] bit different according to the start-up option after reset is indicated in the following table.

Table 31.12 Values of WDTBnRUN[7]/WDTBARUN[7] after Reset

Start-Up Options			Value after Reset
OPWDVAC		**OPWDRUNn**	**WDTBnRUN[7]**
1		×	0
0		0	0
		1	1
OPWDENA	**OPWDVACA**	**OPWDRUNA**	**WDTBARUN[7]**
0	×	×	0
1	1	×	0
	0	0	0
		1	1

- If OPWDVAC/OPWDVACA = 0 (VAC is disabled), this register is enabled.
- When “1” is written on WDTBnRUN[7]/WDTBARUN[7], the watchdog timer starts counting.
- To clear (= trigger) the counter, AC_H must be written to this register.
- Writing wrong value or writing while window is closed leads to error detection.
- IF OPWDVAC/OPWDVACA = 1 (VAC is enabled), this register is disabled. Return Value is 2C (WDTBnRUN[7]/WDTBARUN[7] = 0).

NOTE

2 cycles are necessary with PCLK before initial value is reflected on the WDTBnRUN[7]/ WDTBARUN[7] bit after reset release.

31.3.2.2 WDTBnEVAC/WDTBAEVAC — WDTB Enable VAC Register

This register is a trigger register when VAC function is used.

Writing a correct activation code to this register generates a WDTB trigger and starts or restarts the WDTB counter.

Refer to **Section 31.4.2, WDTB Trigger** for details.

Access: This register can be read or written in 8-bit units.

Address: <WDTBn_base> + 0004_H
<WDTBA_base> + 0004_H

Value after reset: The initial value depends on the start-up options (OPWDENA, OPWDRUNn/OPWDRUNA and OPWDVAC/OPWDVACA). See **Table 31.14, Values of WDTBnEVAC[7]/WDTBAEVAC[7] after Reset**.

Bit	7	6	5	4	3	2	1	0
	WDTBnEVAC[7:0]/WDTBAEVAC[7:0]							
Value after reset	0/1*1	0	1	0	1	1	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. WDTBnEVAC[7]/WDTBAEVAC[7] depends on start-up options.

Table 31.13 WDTBnEVAC/WDTBAEVAC Register Contents

Bit Position	Bit Name	Function
7 to 0	WDTBnEVAC[7:0]/ WDTBAEVAC[7:0]	Writing a variable activation code generates the WDTB trigger and starts/ restarts the WDTB counter. Writing an incorrect activation code generates an error. The WDTB cannot be stopped once it is started.

The value after WDTBnEVAC[7]/WDTBAEVAC[7] bit different according to the start-up option after reset is indicated in the following table.

Table 31.14 Values of WDTBnEVAC[7]/WDTBAEVAC[7] after Reset

Start-Up Options			Value after Reset
OPWDVAC		OPWDRUNn	WDTBnEVAC[7]
0		×	0
1		0	0
		1	1
OPWDENA	**OPWDVACA**	**OPWDRUNA**	**WDTBAEVAC[7]**
0	×	×	0
1	0	×	0
	1	0	0
		1	1

- If OPWDVAC/OPWDVACA = 1 (VAC is enabled), this register is enabled.
- When “1” is written on WDTBnEVAC[7]/WDTBAEVAC[7], the watchdog timer starts counting.
- Writing the correct value on this register can clear the counter.
- Writing wrong value or writing while window is closed leads to error detection.
- When this register is enabled, the reading value just after reset is Initial value. After write to this register, the last time written value is returned.
- If OPWDVAC/OPWDVACA = 0 (VAC is disabled), this register is disabled. Return Value is $2C_H$.

NOTE

2 cycles are necessary with PCLK before initial value is reflected on the WDTBnEVAC[7]/ WDTBAEVAC[7] bit after reset release.

31.3.2.3 WDTBnREF/WDTBAREF — WDTB Reference Value Register

This register is Reference Value register for VAC function. It is automatically after every trigger operation. See **Section 31.4.6.2, Calculating an Activation Code when the VAC Function is Used**.

Access: This register is a read-only register that can be read in 8-bit units.

Address: <WDTBn_base> + 0008_H
<WDTBA_base> + 0008_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	WDTBnREF[7:0]/WDTBAREF[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 31.15 WDTBnREF/WDTBAREF Register Contents

Bit Position	Bit Name	Function
7 to 0	WDTBnREF[7:0]/ WDTBAREF[7:0]	Reference value for activation code calculation for the VAC function.

- If OPWDVAC/OPWDVACA = 1 (VAC is enabled), this register is enabled.
- The reference value of the start code operation to count trigger is indicated.
- Whenever the start code is written in the WDTBnEVAC/WDTBAEVAC register, the reference value calculated based on the expected value is returned.
- If OPWDVAC/OPWDVACA = 0 (VAC is disabled), this register is disabled. Return Value is reset value (00_H).

31.3.2.4 WDTBnMD/WDTBAMD — WDTB Mode Register

This register specifies the overflow interval time, enabling or disabling of the interrupt, window open function mode selection, and the window open period.

Access: This register can be read or written in 8-bit units.

Address: <WDTBn_base> + $000C_H$
<WDTBA_base> + $000C_H$

Value after reset: WDTBnMD: The initial value of WDTBnMD[6:4] bits depends on the start-up options (OPWDOVF).
WDTBAMD: The initial value depends on the start-up options (OPWDWMSA, OPWDOVFA, OPWDINTA and OPWDWSA).

Bit	7	6	5	4	3	2	1	0
	WDTBnWMS/ WDTBAWMS	WDTBnOVF[2:0]/WDTBAOVF[2:0]			WDTBnWIE/ WDTBAWIE	WDTBnERM/ —*5	WDTBnWS[1:0]/ WDTBAWS[1:0]	
Value after reset	0*1	1*2	1*2	1*2	1*3	1	1*4	1*4
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. WDTBAWMS depends on OPWDWMSA.
Note 2. WDTBnOVF[2:0]/WDTBAOVF[2:0] depends on OPWDOVF[2:0]/OPWDOVFA[2:0].
Note 3. WDTBAWIE depends on OPWDINTA.
Note 4. WDTBAWS[1:0] depends on OPWDWSA[1:0].
Note 5. NMI function only support WDTBn.

Table 31.16 WDTBnMD/WDTBAMD Register Contents (1/2)

Bit Position	Bit Name	Function
7	WDTBnWMS/ WDTBAWMS	Window Open function mode selection 0: Window size of Window Open function is set by WDTBnWS[1:0]/ WDTBAWS[1:0]. WDTBnTIT/WDTBATIT outputs when the counter reaches 75% of the overflow setting defined by WDTBnMD.WDTBnOVF[2:0]/ WDTBAMD.WDTBAOVF[2:0]. 1: Window size of Window Open function is set by WDTBnWOST/ WDTBAWOST register. WDTBnTIT/WDTBATIT outputs when WDTBnWIS/ WDTBAWIS matches WDTB counter
6 to 4	WDTBnOVF[2:0]/ WDTBAOVF[2:0]	These bits select the overflow interval time.
3	WDTBnWIE/ WDTBAWIE	Enables/disables the interrupt request WDTBnTIT/WDTBATIT 0: WDTBnTIT/WDTBATIT is disabled. 1: WDTBnTIT/WDTBATIT is enabled.
2	WDTBnERM*1/ Reserved	WDTBn Error mode setting 0: NMI mode 1: Reset mode (Default) WDTBAMD[2]: When read, the value after reset is return. When writing, write the value after reset.

WDTBnOVF2/ WDTBAOVF2	WDTBnOVF1/ WDTBAOVF1	WDTBnOVF0/ WDTBAOVF0	Overflow Interval Time
0	0	0	2^9 / WDTBTCKI
0	0	1	2^{10} / WDTBTCKI
0	1	0	2^{11} / WDTBTCKI
0	1	1	2^{12} / WDTBTCKI
1	0	0	2^{13} / WDTBTCKI
1	0	1	2^{14} / WDTBTCKI
1	1	0	2^{15} / WDTBTCKI
1	1	1	2^{16} / WDTBTCKI

Table 31.16 WDTBnMD/WDTBAMD Register Contents (2/2)

Bit Position	Bit Name	Function
1, 0	WDTBnWS[1:0]/ WDTBAWS[1:0]	These bits select the period over which the window is open. If WDTBnWMS/WDTBAWMS = 1, this register is disabled.

WDTBnWS1/ WDTBAWS1	WDTBnWS0/ WDTBAWS0	Window Open Period
0	0	25%
0	1	50%
1	0	75%
1	1	100%

Note 1. NMI function only support WDTBn

WDTBnMD/WDTBAMD register update timing

- Default start mode: WDTBnMD/WDTBAMD register can not be updated after any resets.
- Software trigger start mode: WDTBnMD/WDTBAMD register can be updated only once before first write to trigger register.

The WDTBnWS[1:0]/WDTBAWS[1:0] setting applies after the first trigger.

NOTE

3 cycles are necessary with PCLK before initial value is reflected on each bit after reset release.

31.3.2.5 WDTBnWOST/WDTBAWOST — WDTB Window Open Start Register

This register is Window Open Start register for setting the start timing of the window open.

Refer to **Section 31.4.5, Window Function** for details.

Access: This register can be read or written in 16-bit units.

Address: <WDTBn_base> + 0010_H
<WDTBA_base> + 0010_H

Value after reset: WDTBnWOST: 0010_H
WDTBAWOST: The initial value depends on the start-up options (OPWDWOSTA).

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WDTBnWOST[15:0]/WDTBAWOST[15:0]															
Value after reset	0*1	0*1	0*1	0*1	0*1	0*1	0*1	0*1	0*1	0*1	0*1	1*1	0*1	0*1	0*1	0*1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. WDTBAWOST[15:0] depends on OPWDWOSTA[15:0].

Table 31.17 WDTBnWOST/WDTBAWOST Register Contents

Bit Position	Bit Name	Function
15 to 0	WDTBnWOST [15:0] / WDTBAWOST [15:0]	If WDTBnMD.WDTBnWMS/WDTBAMD.WDTBAWMS = 1, this register is enabled. When WDTB counter value ≥ WDTBnWOST/WDTBAWOST, WDT window open.

NOTE

WDTBnWOST/WDTBAWOST register update timing

- Default start mode: WDTBnWOST/WDTBAWOST register can not be updated after any resets.
- Software trigger start mode: WDTBnWOST/WDTBAWOST register can be updated only once before first WDTB trigger.

WDTBnWOST/WDTBAWOST register must be set more than 0010_H (When WDTBnMD.WDTBnWMS/WDTBAMD.WDTBAWMS = 1).

WDTBnWOST/WDTBAWOST register setting applies after the first trigger.

31.3.2.6 WDTBnWIS/WDTBAWIS — WDTB Interrupt Output Timing Setting Register

This register configures the timing of the WDTB interrupt (WDTBnTIT/WDTBATIT) generation.

Access: This register can be read or written in 16-bit units.

Address: <WDTBn_base> + 0014_H
<WDTBA_base> + 0014_H

Value after reset: WDTBnWIS: 0000_H
WDTBAWIS: The initial value depends on the start-up options (OPWDWISA).

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WDTBnWIS[15:0]/WDTBAWIS[15:0]															
Value after reset	0*1	0*1	0*1	0*1	0*1	0*1	0*1	0*1	0*1	0*1	0*1	0*1	0*1	0*1	0*1	0*1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. WDTBAWIS[15:0] depends on OPWDWISA[15:0].

Table 31.18 WDTBnWIS/WDTBAWIS Register Contents

Bit Position	Bit Name	Function
15 to 0	WDTBnWIS [15:0] / WDTBAWIS [15:0]	If WDTBnMD.WDTBnWMS/WDTBAMD.WDTBAWMS = 1 and WDTBnMD.WDTBnWIE/WDTBAMD.WDTBAWIE = 1, this register is enabled. When WDTB counter value = WDTBnWIS[15:0]/WDTBAWIS[15:0], interrupt request WDTBnTIT/WDTBATIT is generated.

NOTE

WDTBnWIS/WDTBAWIS register update timing

- Default start mode: WDTBnWIS/WDTBAWIS register can not be updated after any resets.
- Software trigger start mode: WDTBnWIS/WDTBAWIS register can be updated only once before first WDTB trigger.

CAUTIONS

The register value after reset is 0000_H.
If this register is enabled, it must be set more than 0001_H.

31.3.2.7 WDTBAOPBMON0 — WDTB Option Byte Monitor Register 0

This register is the option byte monitor of the WDTBA.

Access: This register is a read-only register that can be read in 32-bit units.

Address: FF9A 5208$_H$

Value after reset: The initial value depends on the start-up options (OPWDOVFA, OPWDWSA, OPWDENA, OPWDVACA, OPWDINTA, OPWDWMSA and OPWDRUNA).
The initial state value of OPWDVACA bit, OPWDWMSA bit and OPWDRUNA bit are set to 0_B; the values of OPWDOVFA[2:0] bits, OPWDWSA[1:0] bits, OPWDENA bit and OPWDINTA bit are set to 1_B.
Therefore, the register value after reset of WDTBAOPBMON0 at shipment is 0000 07D4$_H$.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	OPWDOVFA[2:0]			OPWDWSA[1:0]		—	OPWD ENA	OPWD VACA	OPWD INTA	OPWD WMSA	OPWD RUNA
Value after reset	0	0	0	0	0	1	1	1	1	1	0	1	0	1	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 31.19 WDTBAOPBMON0 Register Contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is returned.
10 to 8	OPWDOVFA [2:0]	For monitor Select the overflow interval time option byte.
7, 6	OPWDWSA[1:0]	For monitor WDTBA window size setting option byte.
5	Reserved	When read, the value after reset is returned.
4	OPWDENA	For monitor WDTBA macro enable option byte.
3	OPWDVACA	For monitor WDTBA VAC enable option byte.
2	OPWDINTA	For monitor WDTBATIT enabled option byte.
1	OPWDWMSA	For monitor WDTBA Window mode select option byte.
0	OPWDRUNA	For monitor WDTBA Automatic start after reset option byte.

For details of the option bytes, see **Section 51, Flash Memory**.

31.3.2.8 WDTBAOPBMON1 — WDTB Option Byte Monitor Register 1

This register is the option byte monitor of the WDTBA.

Access: This register is a read-only register that can be read in 32-bit units.

Address: FF9A 520C$_H$

Value after reset: The initial value depends on the start-up options (OPWDWOSTA and OPWDWISA).
The initial state values of OPWDWOSTA[15:0] bits at shipment is 0010$_H$.
The initial state values of OPWDWISA[15:0] bits at shipment is 0000$_H$
Therefore the register value after reset of WDTBAOPBMON1 at shipment is = 0010 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OPWDWOSTA[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OPWDWISA[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 31.20 WDTBAOPBMON1 Register Contents

Bit Position	Bit Name	Function
31 to 16	OPWDWOSTA [15:0]	For monitor WDTBA setting window open start timing option byte.
15 to 0	OPWDWISA [15:0]	For monitor WDTBATIT output timing option byte.

For details of the option bytes, see **Section 51, Flash Memory**.

31.4 Operation

31.4.1 WDTB after Reset Release

31.4.1.1 Start Modes

The WDTB provided two modes for the counter start after release from the reset state:

- Software trigger start mode
  The counter value remains 0000_H after reset release.
  The counter is started with the first WDTB trigger.
- Default start mode
  The counter starts automatically after release from the reset state.
  However, default start mode is disabled in serial programming mode even if OPWDRUNn/OPWDRUNA is set to 1_B for the start-up options.

31.4.1.2 Start Mode Selection

The start mode can be selected by the start-up options.

The following **Table 31.21** shows the selection of the start mode.

Table 31.21 Start Mode Selection

Start-up Options OPWDRUNn/OPWDRUNA	Start Mode	WDTB Settings
0	Software trigger	Can be changed only once before the first WDTB trigger
1	Default	Can not be changed after any resets

31.4.1.3 WDTB Settings after Reset Release

The following table shows the setting of WDTB during the reset release and the first trigger generation.

Table 31.22 Setting of WDTB after the Reset Release (1/2)

Bit Name	Function	Setting after WDTBn is Reset	Setting after WDTBA is Reset
—	Start mode	Specified by OPWDRUNn	Specified by OPWDRUNA
WDTBnOVF[2:0]/ WDTBAOVF[2:0]	Overflow interval time	Specified by OPWDOVF[2:0]	Specified by OPWDOVFA[2:0]
WDTBnWIE/ WDTBAWIE	Interrupt mode	1_B: Interrupt enabled	Specified by OPWDINTA
WDTBnWS[1:0]/ WDTBAWS[1:0]	Window open period	11_B: 100%	Specified by OPWDWSA[1:0]
WDTBnWMS/ WDTBAWMS	Window open function mode selection	0_B: Window size of Window Open function is set by WDTBnMD.WDTBnWS[1:0] and interrupt is generated when the counter reaches 75% of the overflow setting.	Specified by OPWDWMSA[1:0]
WDTBnWOST/ WDTBAWOST	Counter value of window open start	0010_H	Specified by OPWDWOSTA[15:0]
WDTBnWIS/ WDTBAWIS	Counter value of WDTB interrupt output timing	0000_H*1	Specified by OPWDWISA[15:0]*1

Table 31.22 Setting of WDTB after the Reset Release (2/2)

Bit Name	Function	Setting after WDTBn is Reset	Setting after WDTBA is Reset
—	Specifies the trigger register for the generation of counter re-start triggers to keep the counter from overflowing	Specified by OPWDVAC	Specified by OPWDVACA

Note 1. If WDTBnWIS/WDTBAWIS is used, it must be set more than 0001_H.

For details of the option bytes, see **Section 51, Flash Memory**.

31.4.1.4 Default Start Mode Timing

The following **Figure 31.3** shows the timing of the default start mode.

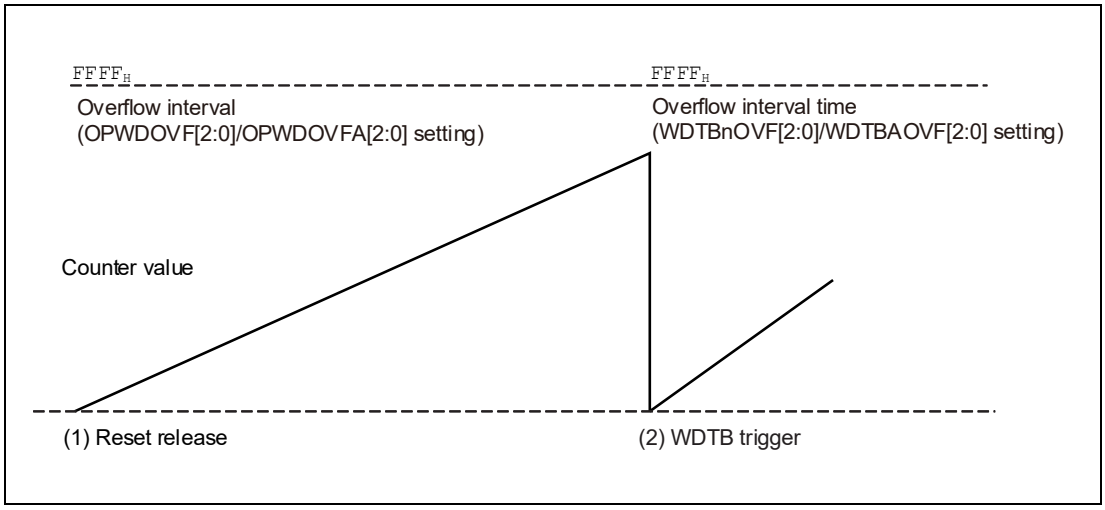

Figure 31.3 Timing Diagram of WDTB Start in Default Start Mode

The timing chart of **Figure 31.3** shows the following behaviors:

(1) In default start mode, the WDTB counter starts after release from the reset state. The overflow interval after release from the reset state is set by start-up options.

Example: overflow interval time after release from the reset state
$= 2^{16}$ / WDTBTCKI (OPWDOVF[2:0]/OPWDOVFA[2:0] = 111_B)

In default start mode, after reset release the WDTBnMD/WDTBAMD register can not be change because the WDTBnRUN/WDTBARUN = 1.

(2) Write to the WDTB trigger register before the WDTB counter overflows.
The WDTB counter restart with the WDTB trigger.

Example: overflow interval time after a WDTB trigger is generated
$= 2^{16}$ / WDTBTCKI (WDTBnOVF[2:0]/WDTBAOVF[2:0] = 111_B)

31.4.1.5 Software Trigger Start Mode Timing (Common to all WDTBn/WDTBA)

The following **Figure 31.4** shows the timing of the software trigger start mode and the change to the WDTB setting.

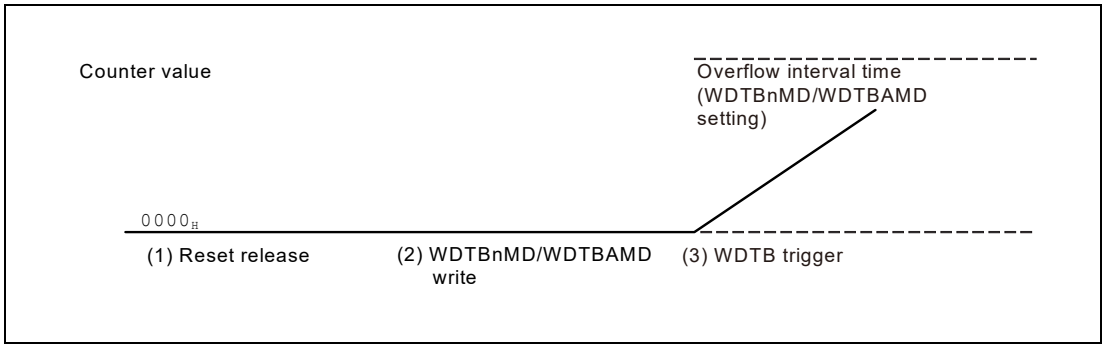

Figure 31.4 Timing Diagram of WDTB Start in Software Trigger Start Mode

The timing diagram in **Figure 31.4** shows the following:

(1) After release from the reset state, the counter remains 0000_H until the first WDTB trigger.
The overflow interval time is set by using the start-up options, but it does not have any effect.

(2) WDTBnMD/WDTBAMD is set before the first WDTB trigger. However, the settings are not applied immediately.

(3) The WDTB counter starts at the first WDTB trigger.
The overflow interval time and other settings specified in WDTBnMD/WDTBAMD are applied.

31.4.2 WDTB Trigger

The WDTB trigger is generated in WDTB enable register (WDTBnWDTE/WDTBAWDTE) and WDTB enable VAC register (WDTBnEVAC/WDTBAEVAC) by writing the specific value that is called a start code.

The WDTB trigger has the following functions:

- Starting the WDTB counter in software trigger start mode
- Restarting the WDTB counter
- Setting the WDTB mode specified by the WDTBnMD/WDTBAMD register in software trigger start mode (only for the first WDTB trigger after release from the reset state).

The WDTB trigger register, which generates a WDTB trigger, is specified by the start-up option OPWDVAC/OPWDVACA.

NOTE

6 PCLKs + 6 WDTBTCKI cycles are necessary until next counter clearing from counter clearing by WDTBnWDTE/WDTBAWDTE or WDTBnEVAC/WDTBAEVAC register writing.

Table 31.23 Trigger Register and Activation Code

Type of Activation Code	Trigger Register	Activation Code
Fixed (OPWDVAC/OPWDVACA = 0)	WDTBnWDTE/WDTBAWDTE	AC_H
Variable (OPWDVAC/OPWDVACA = 1)	WDTBnEVAC/WDTBAEVAC	For details, see **Section 31.4.6.2, Calculating an Activation Code when the VAC Function is Used**.

31.4.3 WDTB Error Detection

The WDTB detects an overflow of the WDTB counter and illegal operations as an error.

The conditions for error detection are:

- WDTB counter overflow
- Wrong activation code is written to the WDTB trigger register
- Writing to the trigger register at the time outside the window open period
  (For details, see **Section 31.4.5, Window Function**.)
- Illegal update of WDTBnMD/WDTBAMD, WDTBnWOST/WDTBAWOST and WDTBnWIS/WDTBAWIS registers

Following charts describes illegal update of WDTBnMD/WDTBAMD, WDTBnWOST/WDTBAWOST and WDTBnWIS/WDTBAWIS registers.

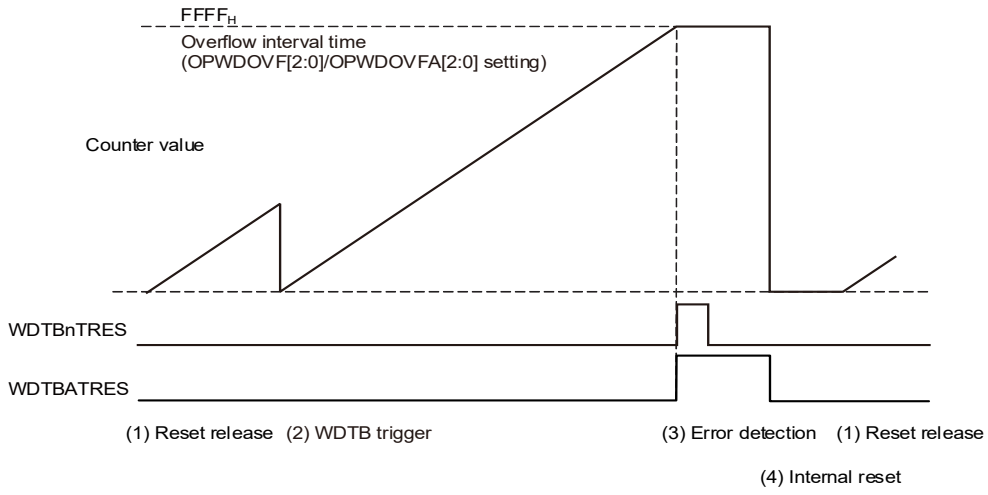
Table 31.24 Condition of WDTB Error Detection

Condition				
Start Mode	**WDTBnRUN/ WDTBARUN**	**Register Write First or Second**	**Write Value**	**Error Detection**
Default	0	This condition does not happen.		
	1	—	Same	Not Detect
		—	Another	Detect
Software Trigger	0	First	Same	Not Detect
			Another	Not Detect
		Second	Same	Not Detect
			Another	Detect
	1	—	Same	Not Detect
		—	Another	Detect

31.4.3.1 WDTB counter overflow

When an error is detected, the error is notified to the ECM by the WDTBnTRES signal, to the PIC by the WDTBnTNMI signal, or to the Reset Controller by the WDTBATRES signal.

The following **Figure 31.5** shows the generation of reset when the counter overflows when the default start mode has been selected.



Note: In RH850/U2A-EVA, output width of WDTBATRES is same as WDTBnTRES.

Figure 31.5 Timing Diagram of WDTB Internal Reset Generation

The timing diagram of **Figure 31.5** shows the following:

(1) After reset is released, the WDTB counter is started in the default start mode. The overflow interval time after released from the reset state is set by the start options.

(2) The counter restarts with the WDTB trigger.

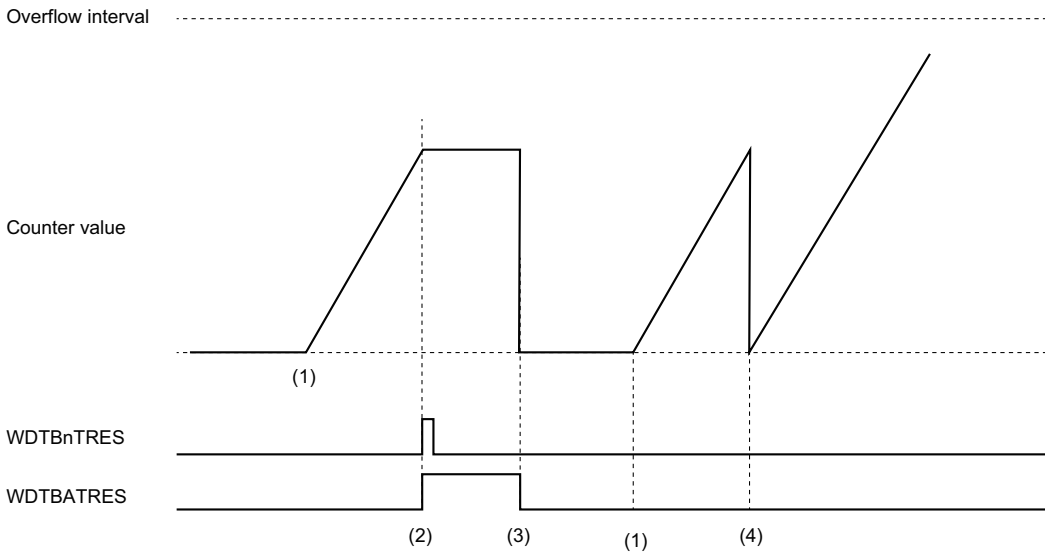
(3) The error is notified to the ECM by the WDTBnTRES signal, to the PIC by the WDTBnTNMI signal, or to the Reset Controller by WDTBATRES signal. The counter value does not change until internal reset is generated.

(4) It stops until the counter is cleared when internal reset is generated by the factor such as ECM, and reset is released.

31.4.3.2 WDTB wrong activation code

When an error is detected , the error is notified to the ECM by the WDTBnTRES signal, to the PIC by the WDTBnTNMI signal, or to the Reset Controller by the WDTBATRES signal.

The following **Figure 31.6** shows the generation of reset when writing wrong activation code when the default start mode has been selected.



Note: In RH850/U2A-EVA, output width of WDTBATRES is same as WDTBnTRES.

Figure 31.6 Timing Diagram of WDTB wrong activation code when the default start mode has been selected

The timing diagram of **Figure 31.6** shows the following:

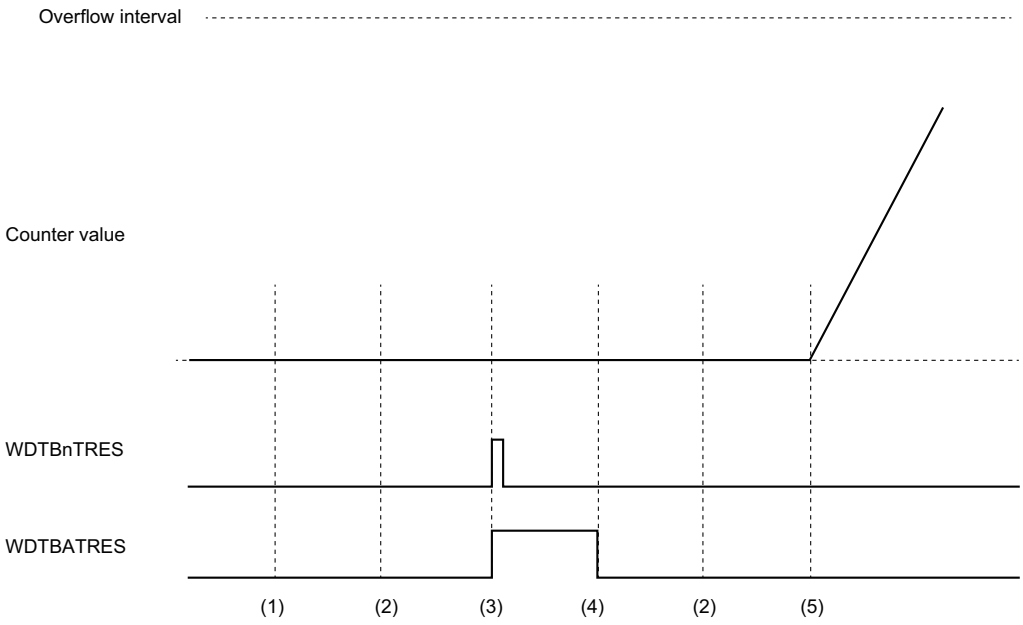
(1) After reset is released, the WDTB counter is started in the default start mode. The overflow interval time after released from the reset state is set by the start options.

(2) WDTB trigger with wrong activation code
The error is notified to the ECM by the WDTBnTRES signal, to the PIC by the WDTBnTNMI signal, or to the Reset Controller by WDTBATRES signal. The counter value does not change until internal reset is generated.

(3) It stops until the counter is cleared when internal reset is generated by the factor such as ECM, and reset is released.

(4) The setting of WDTBnMD/WDTBAMD is applied with the WDTB trigger.

The following **Figure 31.7** shows the generation of reset when writing wrong activation code when the software start mode has been selected.



Note: In RH850/U2A-EVA, output width of WDTBATRES is same as WDTBnTRES.

Figure 31.7 Timing Diagram of WDTB wrong activation code when the software start mode has been selected

The timing diagram of **Figure 31.7** shows the following:

(1) After release from the reset state, the counter remains 0000_H until the first WDTB trigger.

(2) WDTBnMD/WDTBAMD is set before the first WDTB trigger. However, the setting are not applied immediately.

(3) WDTB trigger with wrong activation code
The error is notified to the ECM by the WDTBnTRES signal, to the PIC by the WDTBnTNMI signal, or to the Reset Controller by WDTBATRES signal. The counter value does not change until internal reset is generated.

(4) It stops until the counter is cleared when internal reset is generated by the factor such as ECM, and reset is released.

(5) The WDTB counter starts at the WDTB trigger.

The overflow interval time and other settings specified in WDTBnMD/WDTBAMD are applied.

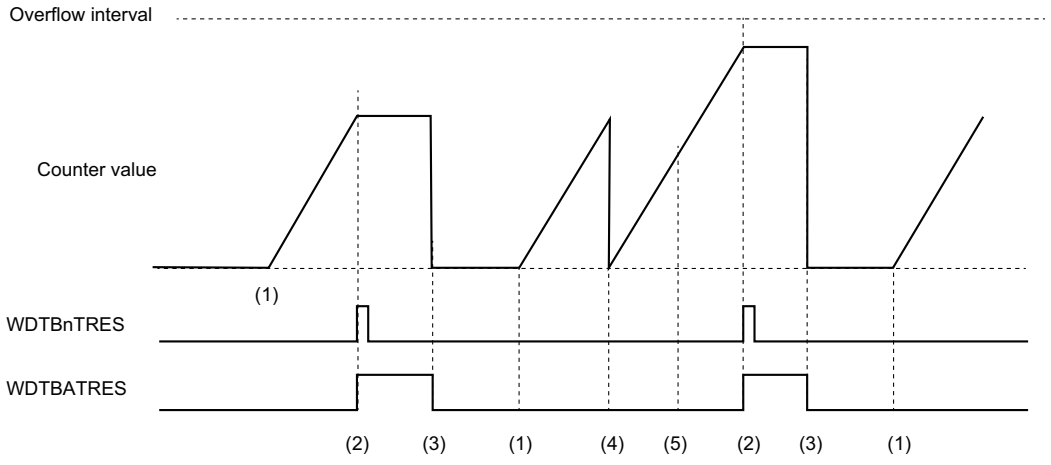
31.4.3.3 WDTB trigger counter outside the window open period

For details, see **Section 31.4.5, Window Function**.

31.4.3.4 WDTB illegal update register

When an error is detected , the error is notified to the ECM by the WDTBnTRES signal, to the PIC by the WDTBnTNMI signal, or to the Reset Controller by the WDTBATRES signal.

The following **Figure 31.8** shows the generation of reset when Illegal update register when the default start mode has been selected.



Note: In RH850/U2A-EVA, output width of WDTBATRES is same as WDTBnTRES.

Figure 31.8 Timing Diagram of WDTB illegal register when the default start mode has been selected

The timing diagram of **Figure 31.8** shows the following:

(1) After reset is released, the WDTB counter is started in the default start mode. The overflow interval time after released from the reset state is set by the start options.

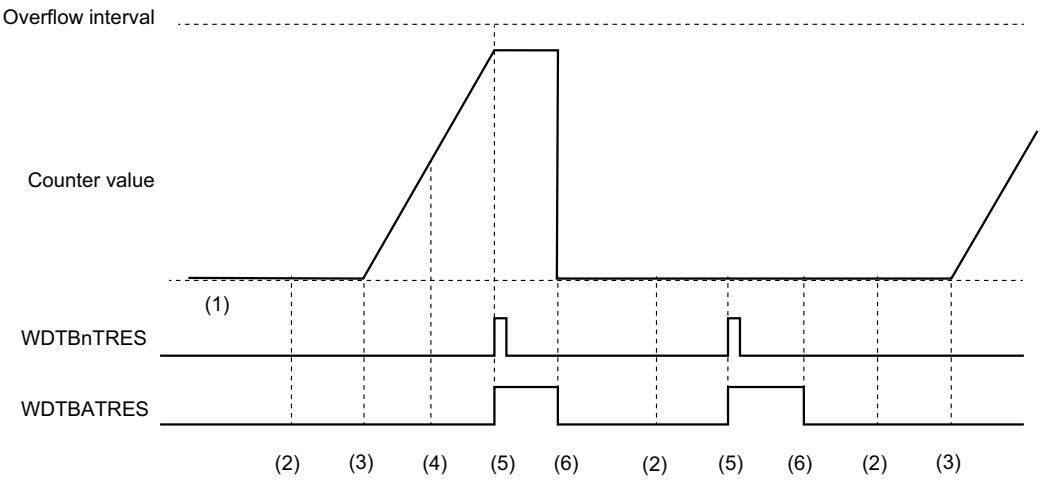
(2) Update WDTBnMD/WDTBAMD, WDTBnWOST/WDTBAWOST and WDTBnWIS/WDTBAWIS registers with value different with default value.
Ex: default value of WDTBnMD[7:0]/WDTBAMD[7:0] = 7F, write to WDTBnMD[7:0]/WDTBAMD[7:0] with value FF.
The error is notified to the ECM by the WDTBnTRES signal, to the PIC by the WDTBnTNMI signal, or to the Reset Controller by WDTBATRES signal. The counter value does not change until internal reset is generated.

(3) It stops until the counter is cleared when internal reset is generated by the factor such as ECM, and reset is released.

(4) The setting of WDTBnMD/WDTBAMD is applied with the WDTB trigger.

(5) Update WDTBnMD/WDTBAMD, WDTBnWOST/WDTBAWOST and WDTBnWIS/WDTBAWIS registers with value same as default value. There is no thing happen.
Ex: default value of WDTBnMD[7:0]/WDTBAMD[7:0] = 7F, write to WDTBnMD[7:0]/WDTBAMD[7:0] with value 7F.

The following **Figure 31.9** shows the generation of reset when Illegal update register when the software start mode has been selected.



Note: In RH850/U2A-EVA, output width of WDTBATRES is same as WDTBnTRES.

Figure 31.9 Timing Diagram of WDTB illegal update register when the software start mode has been selected

The timing diagram of **Figure 31.9** shows the following:

(1) After release from the reset state, the counter remains 0000_H until the first WDTB trigger.

(2) WDTBnMD/WDTBAMD is set before the first WDTB trigger. However, the setting are not applied immediately.

(3) The WDTB counter starts at the first WDTB trigger.
The overflow interval time and other settings specified in WDTBnMD/WDTBAMD are applied.

(4) Update WDTBnMD/WDTBAMD, WDTBnWOST/WDTBAWOST and WDTBnWIS/WDTBAWIS registers with value same as old value. There is no thing happen.
– Ex: old value of WDTBnMD[7:0]/WDTBAMD[7:0] = 7F, write to WDTBnMD[7:0]/WDTBAMD[7:0] with value 7F.

(5) Update WDTBnMD/WDTBAMD, WDTBnWOST/WDTBAWOST and WDTBnWIS/WDTBAWIS registers with value different with old value.
Ex: old value of WDTBnMD[7:0]/WDTBAMD[7:0] = 7F, write to WDTBnMD[7:0]/WDTBAMD[7:0] with value FF.
The error is notified to the ECM by the WDTBnTRES signal, to the PIC by the WDTBnTNMI signal, or to the Reset Controller by WDTBATRES signal. The counter value does not change until internal reset is generated.

(6) It stops until the counter is cleared when internal reset is generated by the factor such as ECM, and reset is released.

31.4.4 WDTB Interrupt Output

An interrupt request signal WDTBnTIT/WDTBATIT is generated when:

- WDTB counter reaches 75% of overflow interval set time and WDTBnWMS/WDTBAWMS = 0.
- WDTB counter = WDTBnWIS/WDTBAWIS and WDTBnWMS/WDTBAWMS = 1.

This function can be enabled/disabled by the WDTBnMD.WDTBnWIE/WDTBAMD.WDTBAWIE register.

The following **Figure 31.10** and **Figure 31.11** show the generation of the interrupt request under the following condition:

- The default start mode is selected.
- Interrupt request is enabled after the first WDTB trigger is generated.
- WDTB overflow time of interval: 2^{16} / WDTBTCKI

31.4.4.1 For case WDTBnWMS/WDTBAWMS = 0:

When the WDTB counter reaches 75% of overflow interval set time and WDTBnWMS/WDTBAWMS = 0, interrupt request WDTBnTIT/WDTBATIT is generated.

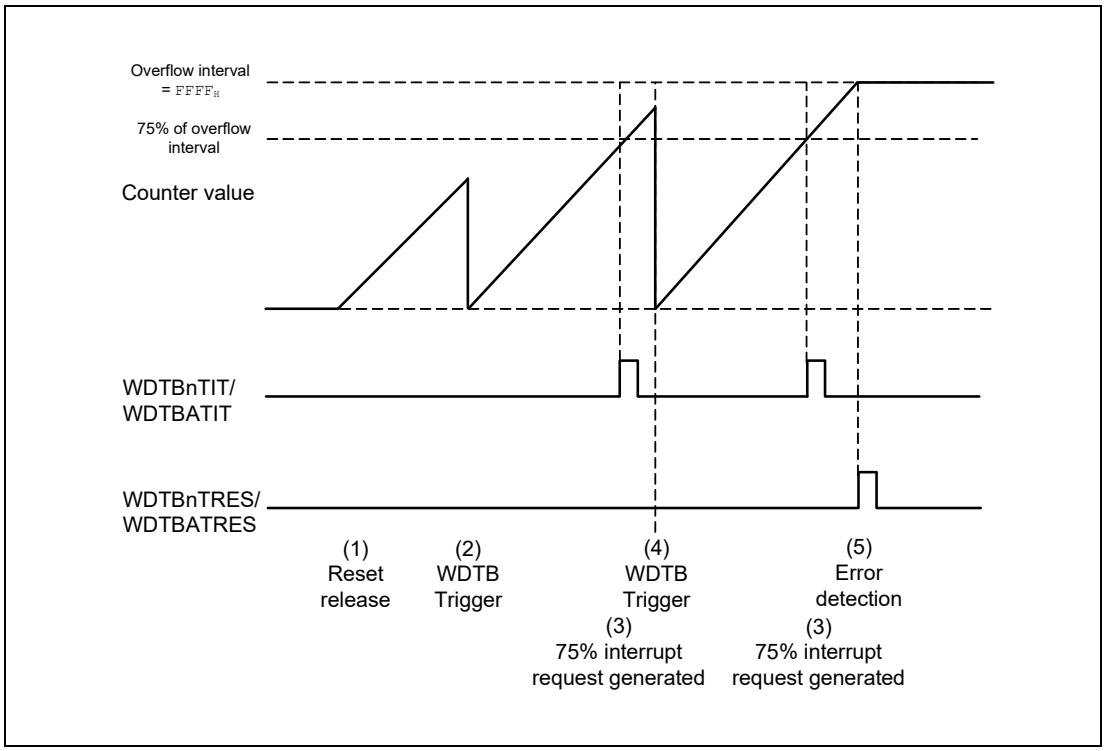


Figure 31.10 Timing Diagram of WDTB Interrupt Request Signals (WDTBnWMS/ WDTBAWMS = 0)

(1) After reset is released, the WDTB counter is started in the default start mode. The overflow interval time after released from the reset state is set by the start options.

(2) The counter restarts with the WDTB trigger.

(3) When the WDTB counter reaches 75% of overflow interval set time, interrupt request WDTBnTIT/WDTBATIT is generated.

(4) The count restarts with the WDTB trigger.

(5) The error is detected when the counter overflows.
The error is notified to the ECM by the WDTBnTRES signal, to the PIC by the WDTBnTNMI signal, or to the Reset Controller by WDTBATRES signal. The counter value does not change until internal reset is generated.

31.4.4.2 For case WDTBnWMS/WDTBAWMS = 1:

When the WDTB counter = WDTBnWIS/WDTBAWIS and WDTBnWMS/WDTBAWMS = 1, an interrupt request WDTBnTIT/WDTBATIT is generated.

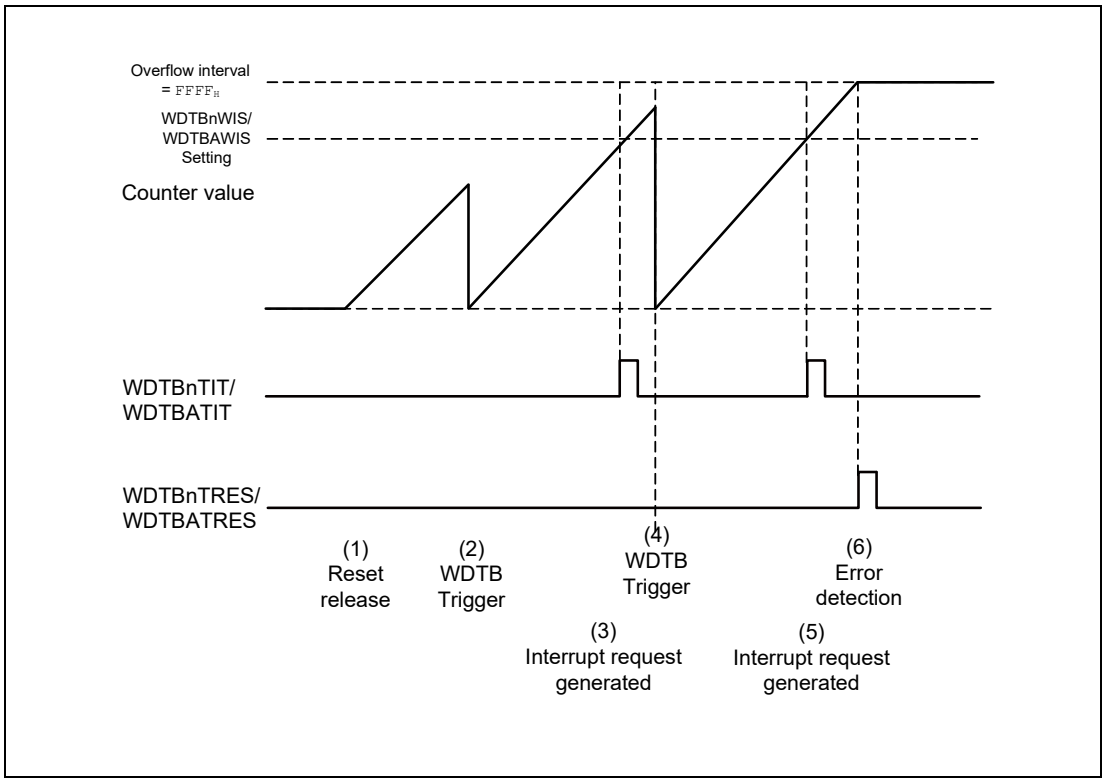

Figure 31.11 Timing Diagram of WDTB Interrupt Request Signals (WDTBnWMS/ WDTBAWMS = 1)

(1) After reset is released, the WDTB counter is started in the default start mode. The overflow interval time after released from the reset state is set by the start options.

(2) The counter restarts with the WDTB trigger.

(3) When the WDTB counter value = WDTBnWIS[15:0]/WDTBAWIS[15:0], an interrupt request WDTBnTIT/WDTBATIT is generated.

(4) The count restarts with the WDTB trigger.

(5) When the WDTB counter value = WDTBnWIS[15:0]/WDTBAWIS[15:0], an interrupt request WDTBnTIT/WDTBATIT is generated.

(6) The error is detected when the counter overflows.
The error notification is notified to the ECM by the WDTBnTRES signal, to the PIC by the WDTBnTNMI signal, or to the Reset Controller by WDTBATRES signal. The counter value does not change until an internal reset is generated.

31.4.5 Window Function

The period when a WDTB trigger is valid (window open period) can be set. If the window open period is set to a value less than 100%, an error is occurred by the writing the WDTB trigger outside the window open period.

The window open period after reset release is 100%. The period is set to the value configured by the WDTBnMD.WDTBnWS[1:0] /WDTBAMD.WDTBAWS[1:0] or the WDTBnWOST/WDTBAWOST register setting after the first WDTB trigger is generated.

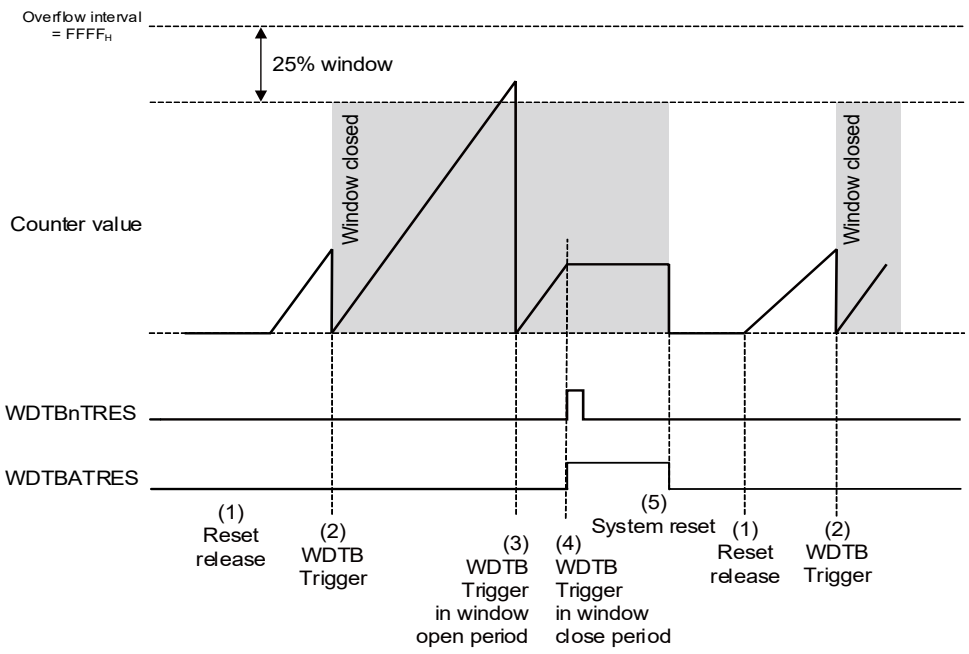
Figure 31.12 and **Figure 31.13** show the window function operation under the following condition.

- The default start mode is selected.
- 25% window opening period is effective after the first WDTB trigger (WDTBnWS[1:0]/ WDTBAWS[1:0] = 00_B).
- WDTB overflow interval: 2^{16} / WDTBTCKI

31.4.5.1 For case WDTBnWMS = 0:

The window open period is set to the value configured by the WDTBnMD.WDTBnWS[1:0]/ WDTBAMD.WDTBAWS[1:0] setting after the first WDTB trigger is generated.

This example setting WDTBnWS[1:0]/WDTBAWS[1:0] = 00_B has window open period is 25%, meaning WDTB trigger only allowed when counter value larger than 75% of overflow value (outside window closed period and inside window open period).



Note: In U2A-EVA, output width of WDTBATRES is same as WDTBnTRES

Figure 31.12 Timing Diagram of WDTB Window Function

(1) In default start mode, the WDTB counter starts after reset is released.
The overflow interval time period after reset is released is set by the start-up options.

(2) The WDTBnMD.WDTBnWS[1:0]/WDTBAMD.WDTBAWS[1:0] setting is applied at the WDTB trigger.

(3) The WDTB counter restarts at the WDTB trigger during the window open period.

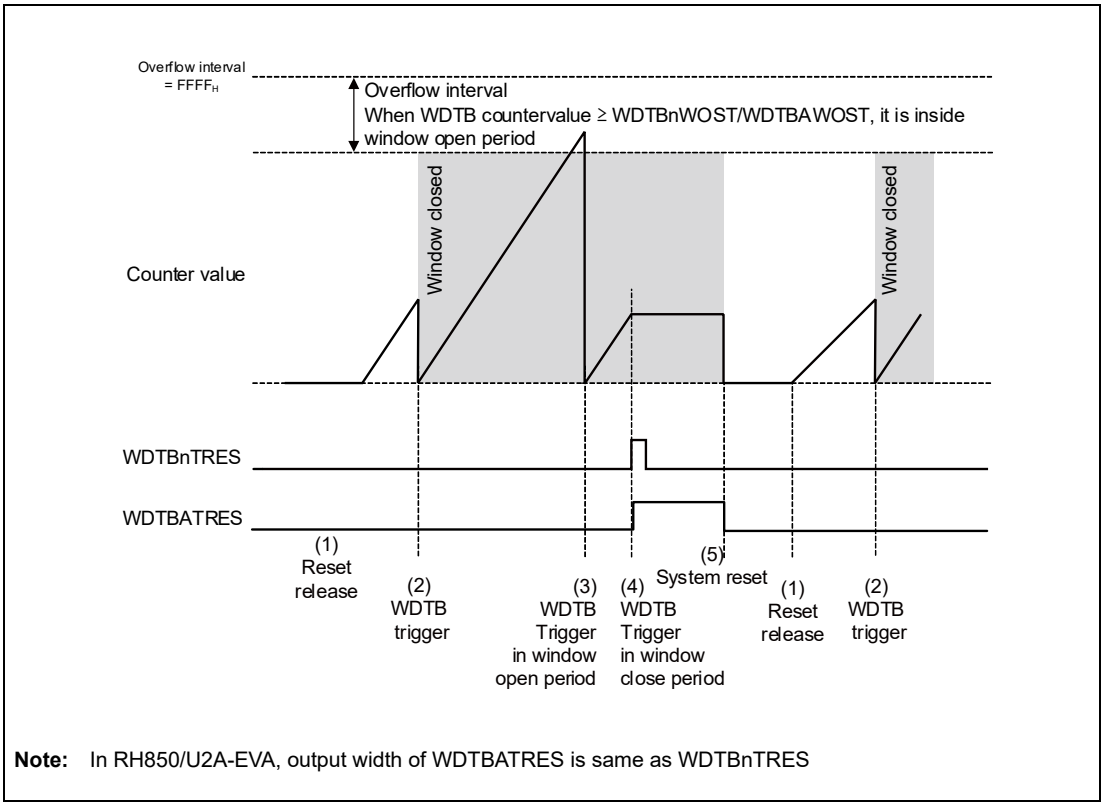
(4) An error is detected at the WDTB trigger during the window close period, the error is notified to the ECM by the WDTBnTRES signal, to the PIC by the WDTBnTNMI signal, or to the Reset Controller by WDTBATRES signal. The counter value does not change until internal reset is generated.

(5) If an internal reset occurs due to the ECM and other sources, the counter is cleared and stopped until release from the reset state.

31.4.5.2 For case WDTBnWMS/WDTBAWMS = 1:

The period is set to the value configured by WDTBnWOST[15:0]/WDTBAWOST[15:0] setting after the first WDTB trigger is generated.

In this case, WDTB trigger is only allowed when the counter value is equal or larger than the value of WDTBnWOST[15:0]/WDTBAWOST[15:0].



Note: In RH850/U2A-EVA, output width of WDTBATRES is same as WDTBnTRES

Figure 31.13 Timing Diagram of WDTB Window Function

(1) In default start mode, the WDTB counter starts after reset is released.
The overflow interval time after reset is released is set by the start-up options.

(2) The WDTBnWOST/WDTBAWOST register setting is applied at the WDTB trigger.

(3) The WDTB counter restarts at the WDTB trigger during the window open period.

(4) An error is detected at the WDTB trigger during the window close period, the error is notified to the ECM by the WDTBnTRES signal, to the PIC by the WDTBnTNMI signal, or to the Reset Controller by WDTBATRES signal. The counter value does not change until internal reset is generated.

(5) If an internal reset occurs due to the ECM and other sources, the counter is cleared and stopped until release from the reset state.

31.4.6 Varying Activation Code (VAC)

31.4.6.1 About VAC Function

If enabled by option byte, a fixed activation code (AC_H) is replaced by varying activation code.

This generates a sequence of 122 different numbers that have to be used to re-trigger the Watchdog timer. This calculation requires a computation in the CPU and therefore gives additional security against program and CPU malfunction.

If OPWDVAC/OPWDVACA = 1, VAC can be used. The WDTBnEVAC/WDTBAEVAC register in VAC module replaces WDTBnWDTE/WDTBAWDTE register's functionality. That means, the activation code must be written on WDTBnEVAC/WDTBAEVAC instead of WDTBnWDTE/ WDTBAWDTE. (In this case access to WDTBnWDTE /WDTBAWDTE is ignored.)

31.4.6.2 Calculating an Activation Code when the VAC Function is Used

Use the following expression to calculate the variable activation code (Expected WDTE) to be set in the WDTB trigger register (WDTBnEVAC/WDTBAEVAC) when the VAC function is used, by using the WDTB reference value register (WDTBnREF/WDTBAREF):

Expected WDTE = AC_H - WDTBnREF/WDTBAREF (previous)

Note that the value in the WDTBnREF/WDTBAREF register is updated every time a start-code is written to the trigger register WDTBnEVAC/WDTBAEVAC. Use the following expression to calculate the updated value of the WDTBnREF/WDTBAREF register.

WDTBnREF/WDTBAREF (following) = (rotate the value of Expected WDTE to the left by 1 bit)

Table 31.25 Expected Variable Activation code Development

No*1	WDTBnREF/WDTBAREF (Previous)		Expected WDTE (AC_H - WDTBnREF/WDTBAREF)		WDTBnREF/WDTBAREF (Following)	
0	0000 0000	00_H	1010 1100	AC_H	0101 1001	59_H
1	0101 1001	59_H	0101 0011	53_H	1010 0110	$A6_H$
2	1010 0110	$A6_H$	0000 0110	06_H	0000 1100	$0C_H$
...	...	...	...	...	...	...

Note 1. Number of triggers after reset

NOTE

Writing an incorrect activation code generates an error.

Even when the writing value to WDTBnEVAC/WDTBAEVAC is different from the expected value, the WDTBnREF/WDTBAREF value returns the calculation value from the expected value.

31.4.7 NMI or Reset Interrupt Output

When an error is detected, WDTBn can generate a non-maskable interrupt request or an internal reset. The output signals are configurated by WDTBnMD.WDTBnERM as follow:

- In NMI mode, WDTBnTNMI is output alongside with WDTBnTRES signal.
- In Reset mode, only WDTBnTRES is generated.

The output width of WDTBnTRES/WDTBnTNMI signal is equal to the pulse width of 1 WDTBTCKI.

For WDTBA, it will only run in Reset mode by default. When an error is detected, WDTBATRES signal will keep “high” until internal reset is generated.

The following **Figure 31.14** shows the generation of reset and NMI signals when the counter overflows in NMI mode and default start mode has been selected.

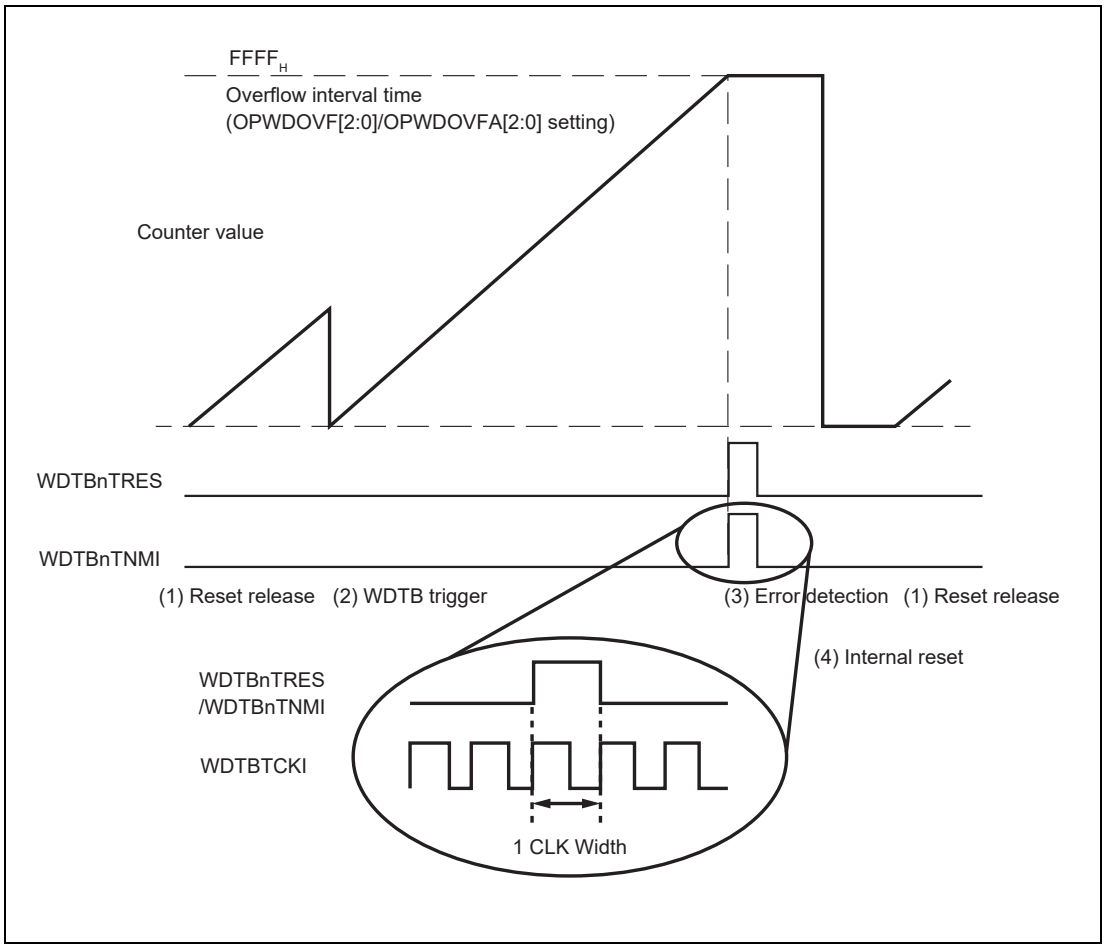


Figure 31.14 NMI or Reset Interrupt output timing of WDTBn

The timing diagram of **Figure 31.14** shows the following:

(1) After reset is released, the WDTB counter is started in the default start mode. The overflow interval time after released from the reset state is set by the start options.

(2) The counter restarts with the WDTB trigger.

(3) The error is detected when the counter overflows.
The error is notified to the ECM by the WDTBnTRES signal, and to PIC by the WDTBnTNMI signal. The counter value does not change until internal reset is generated.

(4) It stops until the counter is cleared when internal reset is generated by the factor such as ECM, and reset is released.

Section 32 OS Timer (OSTM)

This section contains a generic description of the OS Timer (OSTM).

The first part of this section describes all RH850/U2A-EVA specific properties, such as the number of units, register base addresses, etc.

The remainder of the section describes the functions and registers of the OSTM.

32.1 Features OSTM for RH850/U2A-EVA

32.1.1 Number of Units

This microcontroller has the following number of OSTM units.

Each OSTM unit has one channel OSTM. “Number of channels” is used with the same meaning as “number of units” in this section.

Table 32.1 Number of Units

Product	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144pins)
Number of Units	10 (n = 0 to 9)	10 (n = 0 to 9)	10 (n = 0 to 9)	10 (n = 0 to 9)	8 (n = 0 to 5, 8, 9)	8 (n = 0 to 5, 8, 9)	8 (n = 0 to 5, 8, 9)	8 (n = 0 to 5, 8, 9)	8 (n = 0 to 5, 8, 9)	8 (n = 0 to 5, 8, 9)
Name	OSTMn									

Table 32.2 Index

Index	Description
n	Throughout this section, the individual units of the OS timer are identified by the index "n" (n = 0 to 9), for example, OSTMnTO for the OS timer n output register.

32.1.2 Register Base Addresses

All OS timer register addresses are given as address offsets from the individual base addresses <OSTMn_base>.

The register base address of each OSTMn is listed in the following table.

Table 32.3 Register Base Addresses

Base Address Name	Base Address	Bus Group
<OSTM0_base>	FFBF 0000$_H$	P-Bus Group 5
<OSTM1_base>	FFBF 0100$_H$	P-Bus Group 5
<OSTM2_base>	FFBF 0200$_H$	P-Bus Group 5
<OSTM3_base>	FFBF 0300$_H$	P-Bus Group 5
<OSTM4_base>	FFBF 0400$_H$	P-Bus Group 5
<OSTM5_base>	FFBF 0500$_H$	P-Bus Group 5
<OSTM6_base>	FFBF 0600$_H$	P-Bus Group 5
<OSTM7_base>	FFBF 0700$_H$	P-Bus Group 5
<OSTM8_base>	FFBF 0800$_H$	P-Bus Group 5
<OSTM9_base>	FFBF 0900$_H$	P-Bus Group 5

32.1.3 Clock Supply

Clock supply by and to OSTMn is listed in the following table.

Table 32.4 Clock Supply

Unit Name	Clock for the Unit	Supply Clock Name
OSTMn	PCLK	CLK_HSB
	Register access clock	CLK_HSB

32.1.4 Interrupt Requests and Error Notifications

OSTMn interrupt requests are listed in the following table.

Table 32.5 Interrupt and DMA/DTS Requests

Unit Interrupt Name	Unit Interrupt Signal	Description	Interrupt Number	sDMA Trigger Number	DTS Trigger Number
INTOSTM0TINT	OSTM0TINT	OSTM0 interrupt	199	Group0-157	Group3-82
INTOSTM1TINT	OSTM1TINT	OSTM1 interrupt	200	Group0-158	Group3-83
INTOSTM2TINT	OSTM2TINT	OSTM2 interrupt	201	Group0-159	Group3-84
INTOSTM3TINT	OSTM3TINT	OSTM3 interrupt	202	Group0-160	Group3-85
INTOSTM4TINT	OSTM4TINT	OSTM4 interrupt	203	Group0-161	Group3-86
INTOSTM5TINT	OSTM5TINT	OSTM5 interrupt	204	Group0-162	Group3-87
INTOSTM6TINT	OSTM6TINT	OSTM6 interrupt	205	Group0-163	Group3-88
INTOSTM7TINT	OSTM7TINT	OSTM7 interrupt	206	Group0-164	Group3-89
INTOSTM8TINT	OSTM8TINT	OSTM8 interrupt	207	Group0-165	Group3-90
INTOSTM9TINT	OSTM9TINT	OSTM9 interrupt	208	Group0-166	Group3-91

The error notifications of this module are listed in the following table.

Table 32.6 Error Notifications

Error Notification	Description	ECM Error Number	Error Response to bus master
OS timer 1 interrupt	OSTM1 interrupt	56	—
OS timer 2 interrupt	OSTM2 interrupt	57	—
OS timer 3 interrupt	OSTM3 interrupt	58	—
OS timer 4 interrupt	OSTM4 interrupt	59	—
OS timer 5 interrupt	OSTM5 interrupt	60	—
OS timer 6 interrupt	OSTM6 interrupt	61	—
OS timer 7 interrupt	OSTM7 interrupt	62	—
OS timer 8 interrupt	OSTM8 interrupt	63	—
OS timer 9 interrupt	OSTM9 interrupt	64	—

NOTE

OSTM0 does not send error notification to ECM. However, its output can determine the output wave of ERROROUT_M and ERROROUT_C pin of ECM. For more detail, refer to **Section 45, Error Control Module (ECM)**.

32.1.5 Reset Sources

OSTM reset sources are listed in the following table.

Table 32.7 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
OSTMn	All registers	√	√	√	√	√	√	—

32.1.6 External Input/Output Signals

An OSTMn input/output signals are listed in the following table.

Table 32.8 External Input/Output Signals

Unit Signal Name	I/O	Description	Alternative Port Pin Signal Name
OSTM8:			
OSTM8TTOUT	O	OSTM8 output	OSTM8O
OSTM9:			
OSTM9TTOUT	O	OSTM9 output	OSTM9O

32.2 Overview

32.2.1 Functional Overview

- OSTM has two operating modes.
  - Interval timer mode
  - Free-run compare mode
- All OS timers are running at the same frequency.
- Simultaneous starting of multiple units of the OS timer (timer synchronization of PIC) for OSTM8 and OSTM9.
- Interrupt and sDMA/DTS notification when counting by the counter is started, restarted, or ends
- Notifying the ECM of errors when an OSTMn (n = 1 to 9) interrupt occurs
- Generation of output waveform from the $\overline{\text{ERROROUT\_M}}$ and $\overline{\text{ERROROUT\_C}}$ pins with the OSTM0TTOUT signal of OSTM0 when ECM is in dynamic mode
- OS timer is cleared by a reset source defined in **Table 32.7, Reset Sources**.
- Counter start and restart of OSTM can be performed by software.
- The counter value at counter operation start can be set by software.
- Interrupt request of OSTM will be notified to the corresponding CPU.
  - Interrupt request of OSTM0 assigned to all CPU
  - Interrupt request of OSTM1 assigned to all CPU
  - Interrupt request of OSTM2 assigned to all CPU
  - Interrupt request of OSTM3 assigned to all CPU
  - Interrupt request of OSTM4 assigned to all CPU
  - Interrupt request of OSTM5 assigned to all CPU
  - Interrupt request of OSTM6 assigned to all CPU
  - Interrupt request of OSTM7 assigned to all CPU
  - Interrupt request of OSTM8 assigned to all CPU
  - Interrupt request of OSTM9 assigned to all CPU

32.2.2 Block Diagram

The following block diagram shows the main components of the OSTMn.

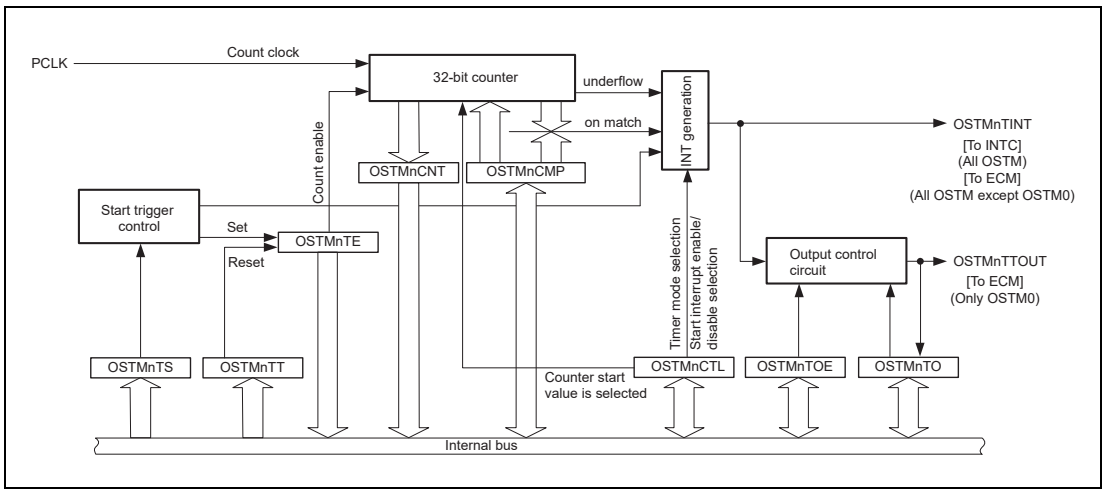

Figure 32.1 Block Diagram of the OSTMn (OSTM0 to OSTM7)

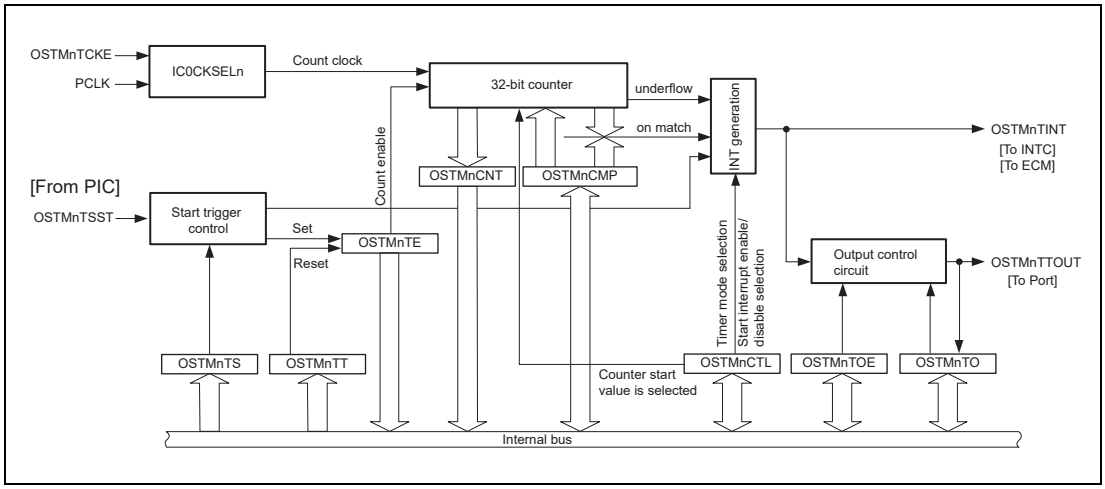

Figure 32.2 Block Diagram of the OSTMn (OSTM8, OSTM9)

32.2.3 Output Modes (only for OSTM0, OSTM8 and OSTM9)

The OSTMn has the following output modes. The mode is selected by the setting of the OSTMnTOE.OSTMnTOE bit.

- Software control mode (the OSTMnTOE.OSTMnTOE bit is 0): The value set in the OSTMnTO.OSTMnTO bit is output to OSTMnTTOUT.
- Timer-output toggling mode (the OSTMnTOE.OSTMnTOE bit is 1): The OSTMnTTOUT output is toggled each time an OSTMnTINT request is generated.

Both output modes are illustrated in the following figure.

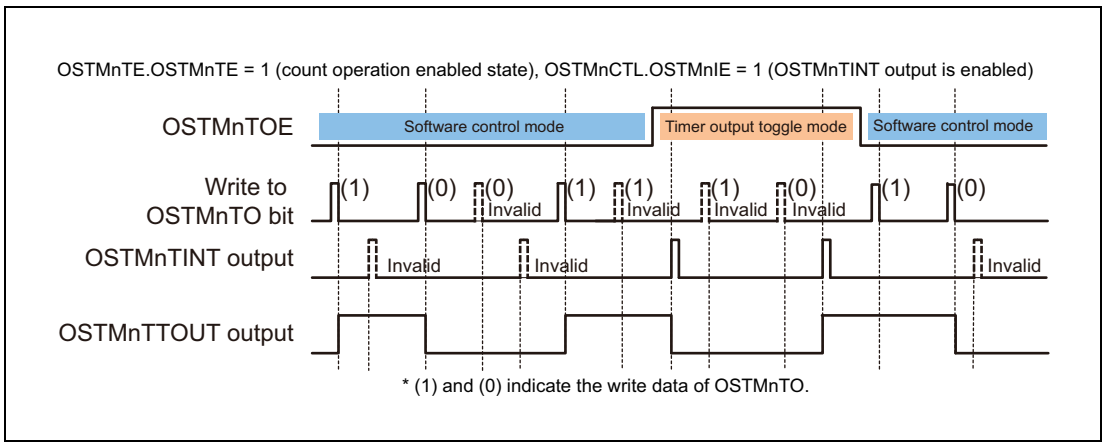

Figure 32.3 Timing Diagram of Output Modes

The above timing diagram shows the following operations.

- In software control mode, the level of the OSTMnTTOUT output changes in accord with the value set in the OSTMnTO.OSTMnTO bit.
- In timer-output toggling mode, the value of the OSTMnTO.OSTMnTO bit and level of the OSTMnTTOUT output are toggled each time an OSTMnTINT interrupt request is generated.

32.2.4 Interrupt Requests (OSTMnTINT)

An OSTMnTINT interrupt request is generated whenever the counter reaches 0000 0000_H (in interval timer mode) or matches the comparison value (in free-run compare mode).

An interrupt request can also be generated on starting and restarting of the counter. This is controlled by the OSTMnCTL.OSTMnMD0 bit.

Since OSTMnTINT triggers toggling of the OSTMnTTOUT output in timer output toggling mode (OSTMnTOE.OSTMnTOE is 1), the setting of the OSTMnCTL.OSTMnMD0 bit also affects the output (OSTMnTTOUT).

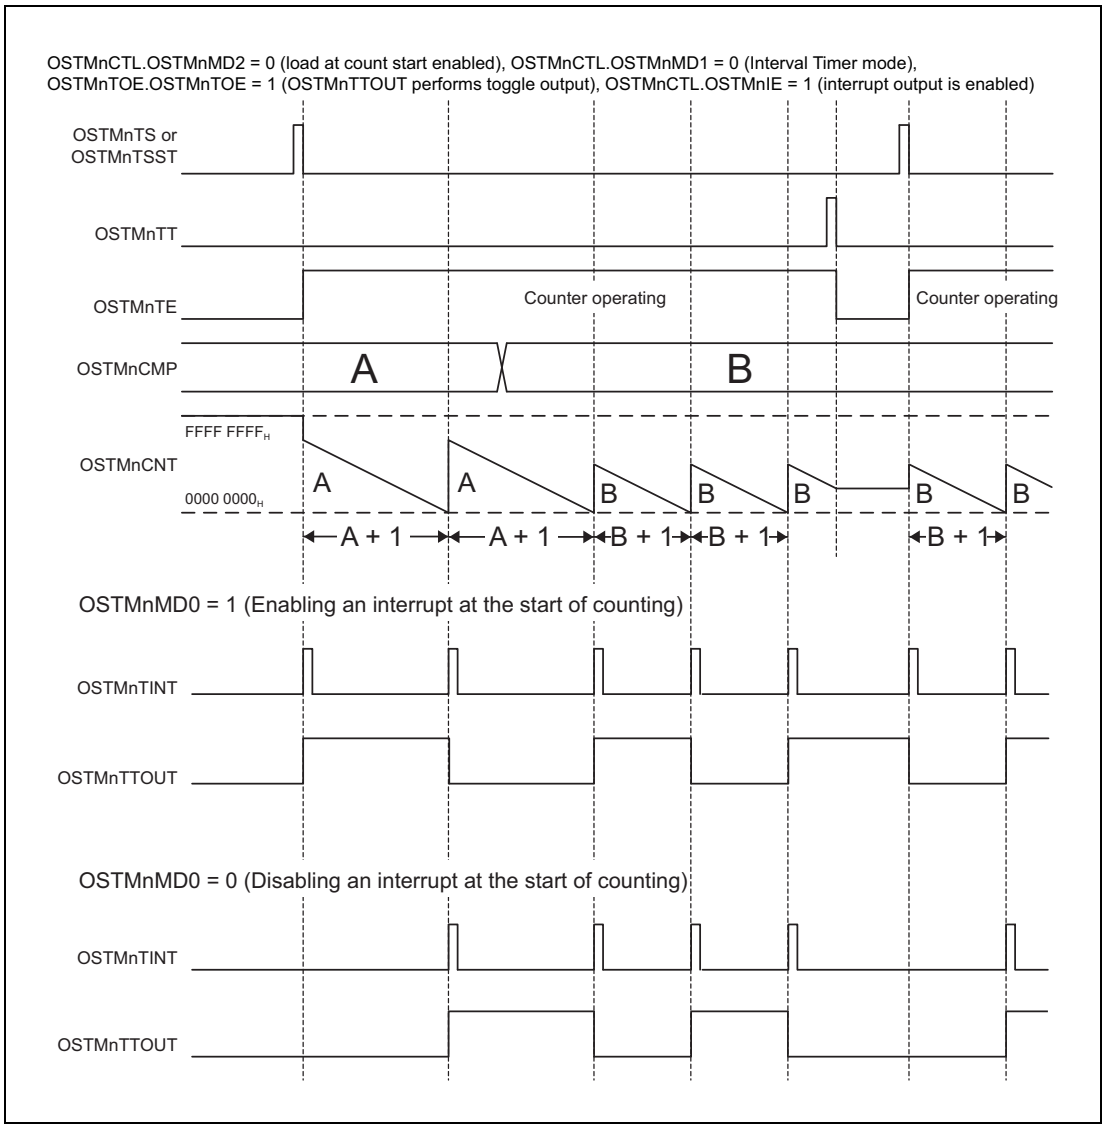

Figure 32.4 Generating an Interrupt when Counting Starts (Interval Timer Mode)

32.2.5 Counter clock

The clock signals for counting by OSTM8 and OSTM9 are defined by PCLK and OSTMnTCKE in the following ways. The count signals for counting by OSTM0 to OSTM7 are always defined by PCLK.

- If IC0CKSELn.IC0TMENn = 0, the OSTMnTCKE signal being at the high level (logical 1) selects counting of cycles of PCLK.
- IC0CKSELn.IC0TMENn being set to 1 selects the TAUDn or TAUJn signal as the counter-clock-enable signal, OSTMnTCKE. The cycles of the clock signals for counting by OSTMn are synchronized with the cycles of the clock signals generated as TAUDn or TAUJn (any from among CK0 to CK3).

This is illustrated in the following figures.

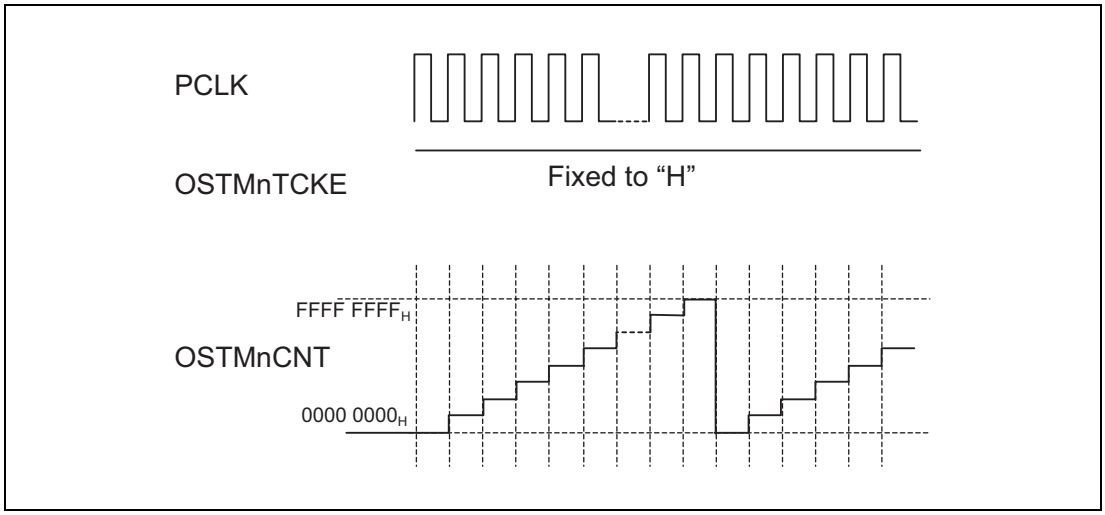

Figure 32.5 Counting when OSTMnTCKE is Fixed to H

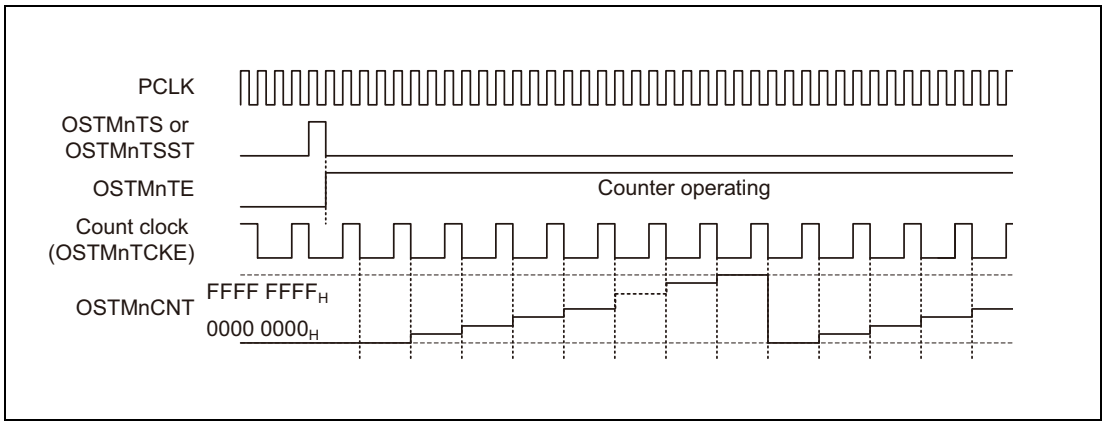

Figure 32.6 Counting in Response to Transitions of the OSTMnTCKE Input Signal

The counter-clock-enable signal (OSTMnTCKE) for each OSTMn can be selected by the IC0CKSEL8 or IC0CKSEL9 register from among 40 channels: 16 channels from each of TAUD0 and TAUD1, and 4 channels from each of TAUJ0 and TAUJ1.

For the counter-clock-enable signals for TAUDn and TAUJn (TAUDnTCKENm and TAUJnTCKENm) and the clock signals generated in TAUDn and TAUJn (CK0 to CK3), see **Figure 33.2, Block Diagram of the TAUD** and **Figure 34.2, Block Diagram of the TAUJ**.

CAUTIONS

1. **Select a counter-clock-enable signal for OSTMn while the operation of OSTMn is stopped (the OSTMnTE.OSTMnTE bit is 0).**
2. **After using the IC0CKSELn.IC0TMSELn[1:0], IC0CKSELn.IC0CKSELn3[1:0], IC0CKSELn.IC0CKSELn2[1:0], IC0CKSELn.IC0CKSELn1[3:0], and IC0CKSELn.IC0CKSELn0[3:0] bits to select the counter-clock-enable signal for OSTMn, set the IC0CKSELn.IC0TMENn bit to 1.**
3. **If TAUDn or TAUJn is selected as the source of the counter-clock-enable signal for OSTMn (the IC0CKSELn.IC0TMENn bit is 1), do not change the operation of TAUDn or TAUJn while the OSTMn is operating (the OSTMnTE.OSTMnTE bit is 1).**

   [Setting procedure]

   (1) Confirm that the OSTMnTE.OSTMnTE bit is 0 (OSTMn operation is stopped).
   (2) Set the IC0CKSELn.IC0TMSELn[1:0], IC0CKSELn.IC0CKSELn3[1:0], IC0CKSELn.IC0CKSELn2[1:0], IC0CKSELn.IC0CKSELn1[3:0], and IC0CKSELn.IC0CKSELn0[3:0] bits to select the counter-clock enable signal for the OSTMn.
   (3) Set the IC0CKSELn.IC0TMENn bit to 1.
   (4) Enable OSTMn operation by setting the OSTMnTS.OSTMnTS bit to 1.
4. **Operating system timers OSTM0 to OSTM7 do not have IC0CKSELn registers. Only PCLK is available as the clock for counting.**

32.3 Registers

The OS timers are controlled and operated by the following registers.

32.3.1 List of Registers

The list of OSTMn (n = 0 to 9) registers and the memory addresses are as follows.

For the base addresses, see **Table 32.3**.

Table 32.9 List of Registers

Module Name	Register Name	Symbol	Address	Access Size	Access Protection	
					PBG	Other
OSTM	OSTMn compare register	OSTMnCMP	<OSTMn_base> + 00_H	32	*1	—
	OSTMn counter register	OSTMnCNT	<OSTMn_base> + 04_H	32	*1	—
	OSTMn output register	OSTMnTO	<OSTMn_base> + 08_H	8	*1	—
	OSTMn output enable register	OSTMnTOE	<OSTMn_base> + $0C_H$	8	*1	—
	OSTMn count enable status register	OSTMnTE	<OSTMn_base> + 10_H	8	*1	—
	OSTMn count start trigger register	OSTMnTS	<OSTMn_base> + 14_H	8	*1	—
	OSTMn count stop trigger register	OSTMnTT	<OSTMn_base> + 18_H	8	*1	—
	OSTMn control register	OSTMnCTL	<OSTMn_base> + 20_H	8	*1	—
	OSTM8 clock select register	IC0CKSEL8	FFBF $08C0_H$	16	PBG 50#15	—
	OSTM9 clock select register	IC0CKSEL9	FFBF $09C0_H$	16	PBG 51#0	—

Note 1. n = 0: PBG50#7
n = 1: PBG50#8
n = 2: PBG50#9
n = 3: PBG50#10
n = 4: PBG50#11
n = 5: PBG50#12
n = 6: PBG50#13
n = 7: PBG50#14
n = 8: PBG50#15
n = 9: PBG51#0

32.3.2 Details of OSTMn Registers

32.3.2.1 OSTMnCMP — OSTMn Compare Register

Depending on the mode of operation, this register holds the start value for the down-counter or the value for comparison with that of the counter.

Access: This register can be read or written in 32-bit units.

Address: <OSTMn_base> + 00_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OSTMnCMP[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OSTMnCMP[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 32.10 OSTMnCMP Register Contents

Bit Position	Bit Name	Function
31 to 0	OSTMnCMP [31:0]	• In interval timer mode: Start value of the down-counter • In free-run compare mode: Value for comparison

32.3.2.2 OSTMnCNT — OSTMn Counter Register

This register indicates the counter value of the timer.

Access: This register can be read or written in 32-bit units. Writing can only proceed when the counter is disabled (OSTMnTE.OSTMnTE = 0).

Address: <OSTMn_base> + 04_H

Value after reset: FFFF $FFFF_H$

Table 32.11 OSTMnCNT Register Contents

Bit Position	Bit Name	Function
31 to 0	OSTMnCNT [31:0]	32-bit counter value

When the operation mode of the counter is changed with OSTMnCTL.OSTMnMD2 = 1, write any value to OSTMnCNT register before counter operation start.

Table 32.12 lists the correspondence between the OSTM operating mode, counting direction, and start value.

The start value indicates the value to be read after the operating mode is changed.

Table 32.12 Correspondence between Operating Mode, Counting Direction and Start Value

Timer operating mode	OSTMnCTL.OSTMnMD1	Counting direction	Start value*2
Interval timer mode	0*1	Down count	FFFF $FFFF_H$
Free-run compare mode	1	Up count	0000 0000_H

Note 1. Value after reset.

Note 2. The start value is the value that is read after the operating mode has been changed following reset input.
When OSTMnTE.OSTMnTE = 0 (counter stop status), the OSTMnCNT register can be written.
When the operation mode of the counter is changed with OSTMnCTL.OSTMnMD2 = 1, write any value to the OSTMnCNT register before the counter operation starts.

32.3.2.3 OSTMnTO — OSTMn Output Register

The OSTM output register is used to specify and read the level of an OSTMnTTOUT output signals. The setting of this register is only valid in OSTM0, OSTM8 and OSTM9.

Access: This register can be read or written in 8-bit units. Writing can only proceed when the software control mode is selected (OSTMnTOE.OSTMnTOE = 0).

Address: <OSTMn_base>+ 08_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OSTMnTO
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 32.13 OSTMnTO Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	OSTMnTO	This bit specifies/reads the level of OSTMnTTOUT output signals. 0: Low level 1: High level

32.3.2.4 OSTMnTOE — OSTMn Output Enable Register

The OSTM output enable register specifies OSTMnTTOUT output mode. The setting of this register is only valid in OSTM0, OSTM8 and OSTM9.

Access: This register can be read or written in 8-bit units.

Address: <OSTMn_base>+ $0C_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OSTMnTOE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 32.14 OSTMnTOE Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	OSTMnTOE	This bit specifies the OSTMnTTOUT output mode. 0: Software control mode: The level corresponding to the setting of OSTMnTO.OSTMnTO is output to OSTMnTTOUT. 1: Timer-output toggling mode: OSTMnTTOUT output is toggled whenever an OSTMnTINT interrupt request is generated.

32.3.2.5 OSTMnTE — OSTMn Count Enable Status Register

This register indicates whether the counter is enabled or disabled.

Access: This register is a read-only register that can be read in 8-bit units.

Address: <OSTMn_base> + 10_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OSTMnTE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 32.15 OSTMnTE Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned.
0	OSTMnTE	This bit indicates whether the counter is enabled or disabled. 0: Counter disabled 1: Counter enabled This bit is set to 1 in response to OSTMnTS.OSTMnTS being set to 1, or to the OSTMnTSST signal (when timer synchronization of PIC is in use) becoming 1. This bit is reset to 0 when the OSTMnTT.OSTMnTT bit is set to 1.

NOTE

When OSTMnTE.OSTMnTE = 0, the counter retains its value.

If the counter is restarted when the OSTMnCTL.OSTMnMD2 = 0,

- It restarts counting down from the value in the OSTMnCMP register in interval timer mode
- It restarts counting up from the counter value 0000 0000_H in free-run compare mode

If OSTMnCTL.OSTMnMD2 = 1, the counter is not initialized.

32.3.2.6 OSTMnTS — OSTMn Count Start Trigger Register

This register starts the counter.

Access: This register is a write-only register that can be written in 8-bit units. It is always read as 00_H.

Address: <OSTMn_base> + 14_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OSTMnTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 32.16 OSTMnTS Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	OSTMnTS	This bit starts the counter. 0: This setting is invalid. 1: Starts the counter and sets OSTMnTE.OSTMnTE = 1. • In interval timer mode, a forced restart is executed if this bit is set while OSTMnTE.OSTMnTE = 1. • In free-run compare mode, setting this bit is ignored as long as OSTMnTE.OSTMnTE = 1.

32.3.2.7 OSTMnTT — OSTMn Count Stop Trigger Register

This register stops the counter.

Access: This register is a write-only register that can be written in 8-bit units. It is always read as 00_H.

Address: <OSTMn_base> + 18_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OSTMnTT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 32.17 OSTMnTT Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	OSTMnTT	Stops the counter: 0: This setting is invalid. 1: Stops the counter and clears the OSTMnTE.OSTMnTE bit.

32.3.2.8 OSTMnCTL — OSTMn Control Register

This register specifies the operating mode for the counter and controls the generation of OSTMnTINT interrupt requests when counting starts.

Although this register is readable and writable, writing to it is only possible when OSTMnTE.OSTMnTE = 0; that is, the register becomes read-only when OSTMnTE.OSTMnTE = 1.

Access: This register can be read or written in 8-bit units.

Address: <OSTMn_base> + 20_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	OSTMnIE	—	—	—	—	OSTMnMD2	OSTMnMD1	OSTMnMD0
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R/W	R/W	R/W

Table 32.18 OSTMnCTL Register Contents

Bit Position	Bit Name	Function
7	OSTMnIE	OSTM Interrupt enable This bit is the enable bit of the OSTM Interrupt (OSTMnTINT) 0: OSTMn interrupt request is disabled. 1: OSTMn interrupt request is enabled.
6 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	OSTMnMD2	Control of the counter operation at counter operation start This bit controls the counter operation at counter operation start regardless of whether the counter currently is disabled or enabled (OSTMnTE.OSTMnTE = 0 to 1). 0: OSTMnCNT is loaded into at counter operation start The following describes the value of the counter at counter operation start. – Interval timer mode: The OSTMnCMP[31:0] value is loaded to OSTMnCNT[31:0] at counter start. – Free-run compare mode: The value of $0000\ 0000_H$ is loaded to OSTMnCNT[31:0] at counter operation start. 1: OSTMnCNT is not loaded into at counter operation start
1	OSTMnMD1	Specifies the operating mode for the counter: 0: Interval timer mode 1: Free-run compare mode
0	OSTMnMD0	Controls enabling/disabling of OSTMnTINT interrupt requests when counting starts. 0: Disables the interrupts when counting starts. 1: Enables the interrupts when counting starts.

32.3.2.9 IC0CKSEL8 — OSTM8 Clock Select Register

This register selects the counter-clock-enable signal as the clock source to drive counting for the OSTM8 counter.

Access: This register can be read or written in 16-bit units.

Address: FFBF $08C0_H$

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

32.4 Operation

Each OS timer is a 32-bit timer/counter.

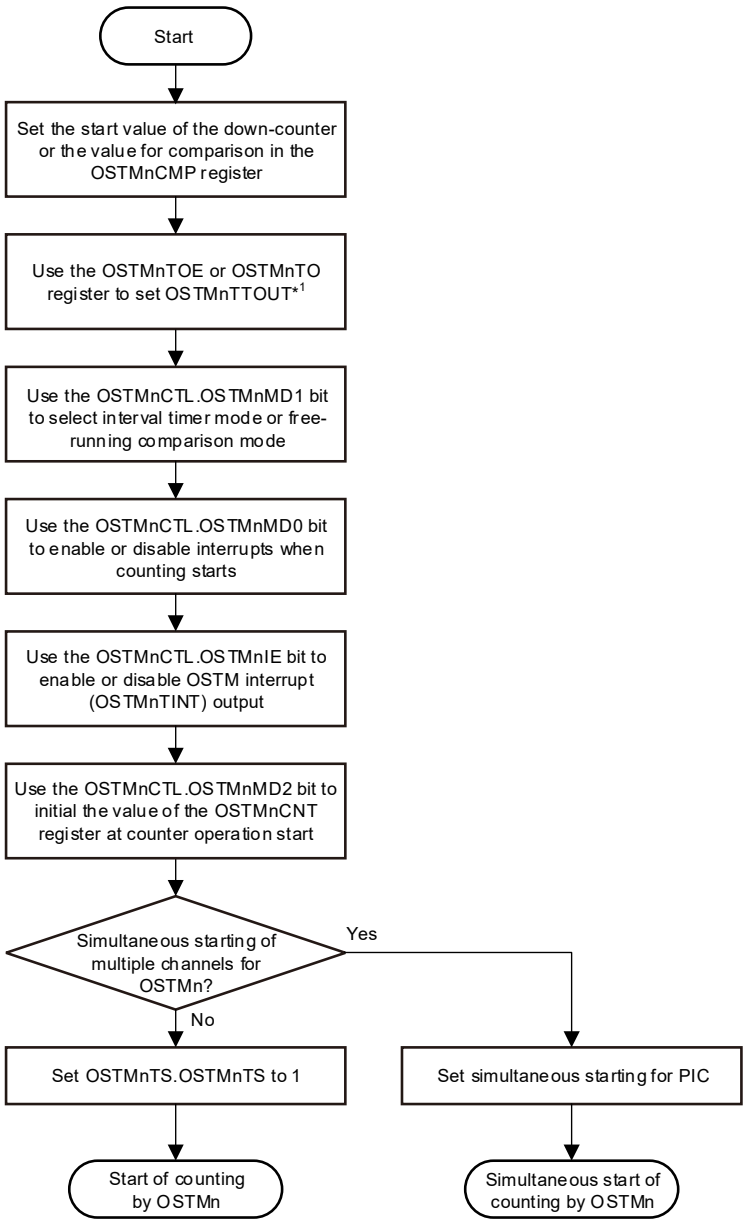
The settings for the operating mode specify the direction of counting (up or down) and the generation of interrupt requests.

32.4.1 Starting and Stopping OSTMn

The OSTMn is started and stopped as follows:

Starting the timer

Figure 32.7, Flow of Starting the OS Timer shows the flow of starting the counter of OSTMn. For details on the operations of the timer in interval timer mode and free-run compare mode in a given step of the figure, see the descriptions in **Section 32.4.2, Interval Timer Mode** and **Section 32.4.3, Free-Run Compare Mode**.



Note 1. For generating an output waveform on the $\overline{\text{ERROROUT\_M}}$ pin or $\overline{\text{ERROROUT\_C}}$ pin and output waveform for OSTM8 and OSTM9, make settings for only OSTM0, OSTM8 and OSTM9 to control OSTM0TTOUT, OSTM8TTOUT and OSTM9TTOUT.
This setting is not required for OSTMn (n = 1 to 7).

Figure 32.7 Flow of Starting the OS Timer

Stopping the timer

Setting the OSTMnTT.OSTMnTT bit to 1 stops the timer and clears the OSTMnTE.OSTMnTE status flag bit.

Timer Synchronization (PIC)

The OSTMnTSST signal can be used to start multiple timers at the same time. For detailed connections, refer to **Section 41, Peripheral Interconnect (PIC)**.

32.4.2 Interval Timer Mode

Select the interval timer mode when an OS timer is to be used as a reference timer for generating interrupt requests at a fixed interval.

32.4.2.1 Basic Operation in Interval Timer Mode

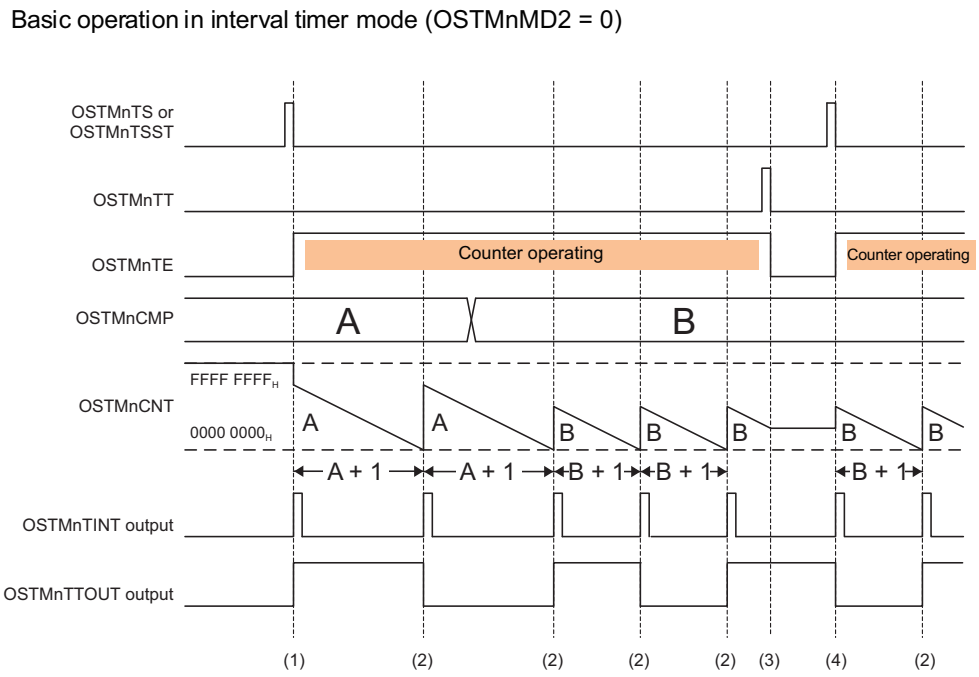
The interval timer mode is set when count mode selection bit OSTMnMD1 is set to “0”. In the interval timer mode, the OSTM can be used as the reference timer generating the OSTMnTINT interrupt at fixed intervals. Upon occurrence of an interrupt, OSTMnTTOUT performs a toggle operation and outputs a square wave. The periods of OSTMnTINT and OSTMnTTOUT are as follows.

- OSTMnTINT generation cycle = Count-clock cycle × (OSTMnCMP + 1)
- OSTMnTTOUT output cycle = OSTMnTINT generation period × 2

OSTMnCMP can be rewritten at any timing, and if it is rewritten during OSTMnCNT operation (OSTMnTE = 1), OSTMnCNT reloads the new OSTMnCMP value upon the next 0000 0000H match detection, and the count operation continues. Then, when “1” is written to OSTMnTT to clear OSTMnTE to “0”, the counter and OSTMnTO stops operation while holding their values as they are.

When OSTMnMD2 = 0, OSTMnCMP[31:0] value is stored to OSTMnCNT at counter operation start.

When OSTMnMD2 = 1, OSTMnCMP[31:0] value is not stored to OSTMnCNT at counter operation start.



Note 1. OSTMnMD0 = 1 (interrupts at count start enabled), OSTMnTOE = 1 (OSTMnTTOUT performs toggle output), OSTMnIE = 1 (interrupt output is enabled)

Figure 32.8 Timing Diagram of OSTMn in Interval Timer Mode (OSTMnMD2 = 0)

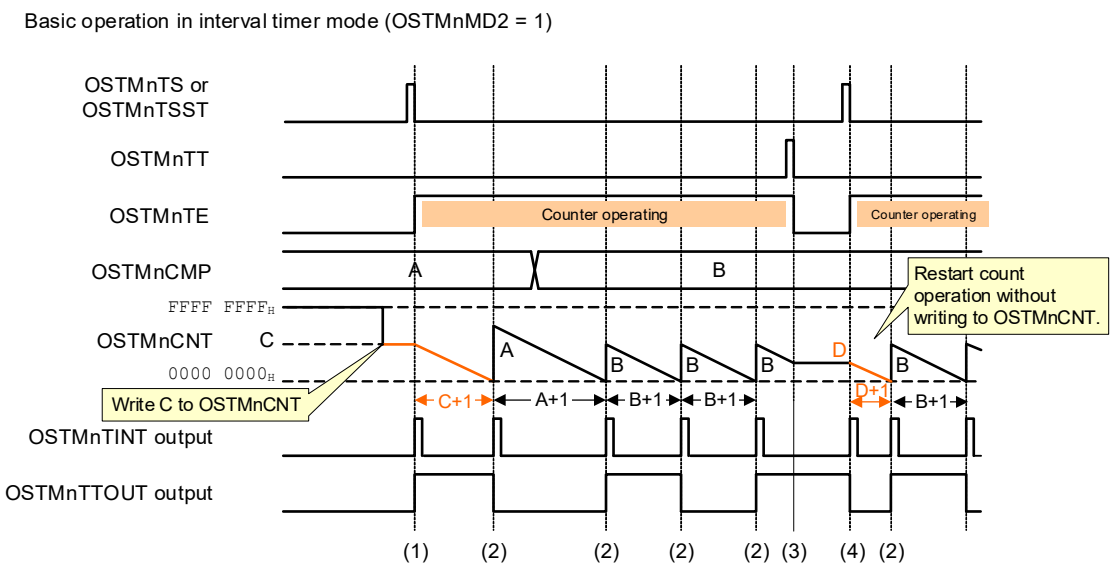
The timing diagram above shows the following:

(1) The counter starts counting when OSTMnTS.OSTMnTS = 1 or OSTMnTSST = 1. The OSTMnTE.OSTMnTE bit is set to indicate enabling of the counter.
The counter starts counting-down from the value of OSTMnCMP.
If OSTMnCTL.OSTMnMD0 is 1, OSTMnTINT interrupt requests are generated at the start of counting and the OSTMnTTOUT signal is toggled. The OSTMnCNT register indicates the counter value.

(2) When the counter reaches 0000 0000_H, an OSTMnTINT interrupt request is generated and the OSTMnTTOUT signal is toggled. The counter loads the new start value from OSTMnCMP and continues counting down.

(3) When the counter is stopped (OSTMnTT.OSTMnTT = 1), the OSTMnTE.OSTMnTE bit is cleared to indicate disabling of the counter. The counter retains its current value until it is restarted.

(4) When counting is restarted (OSTMnTS.OSTMnTS = 1, or OSTMnTSST = 1), the counter loads the new start value from OSTMnCMP and starts counting down.



Note: OSTMnMD0 = 1 (interrupts at count start enabled), OSTMnTOE = 1 (OSTMnTTOUT performs toggle output), OSTMnIE = 1 (interrupt output is enabled)

Figure 32.9 Timing Diagram of OSTMn in Interval Timer Mode (OSTMnMD2 = 1)

The timing diagram above shows the following:

(1) The counter starts counting when OSTMnTS.OSTMnTS = 1 or OSTMnTSST = 1. The OSTMnTE.OSTMnTE bit is set to indicate enabling of the counter.
The counter starts counting-down from the value written to OSTMnCNT.
If OSTMnCTL.OSTMnMD0 is 1, OSTMnTINT interrupt requests are generated at the start of counting and the OSTMnTTOUT signal is toggled. The OSTMnCNT register contains the current value as the counter.

(2) When the counter reaches 0000 0000_H, an OSTMnTINT interrupt request is generated and the OSTMnTTOUT signal is toggled. The counter loads the new start value from OSTMnCMP and continues counting down.

(3) When the counter is stopped (OSTMnTT.OSTMnTT = 1), the OSTMnTE.OSTMnTE bit is cleared to indicate disabling of the counter. The counter retains its current value until it is restarted.

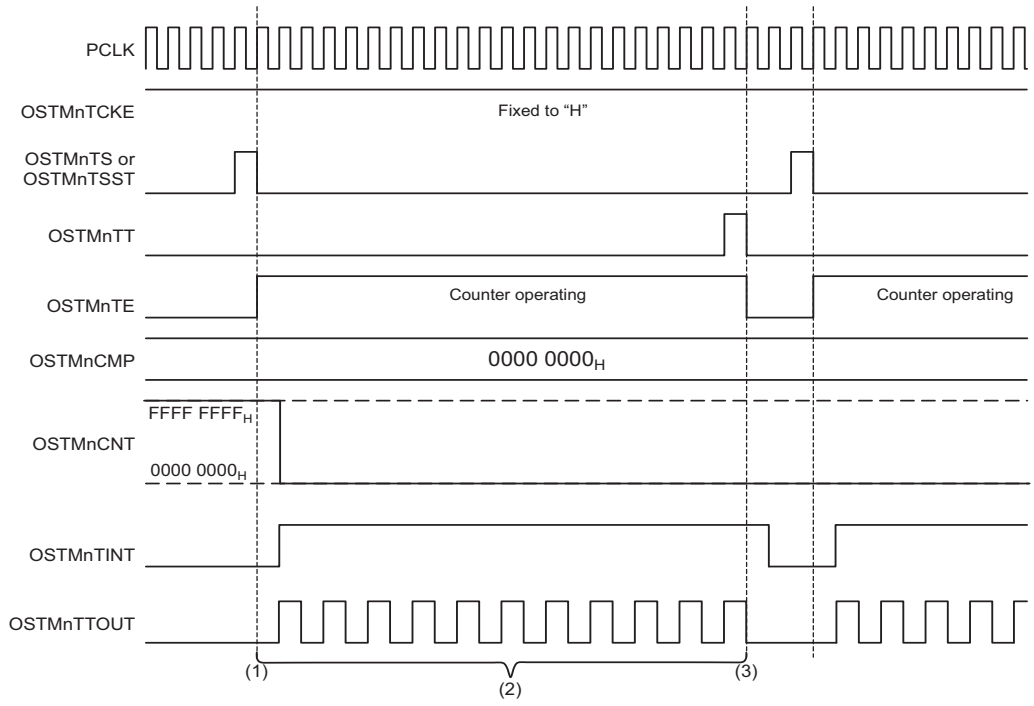
(4) When counting is restarted (OSTMnTS.OSTMnTS = 1, or OSTMnTSST = 1), the counter keeps the value when it was stopped and starts counting down.

32.4.2.2 Operation when OSTMnCMP = 0000 0000$_H$

When PCLK is selected as the source of the clock signal for counting and OSTMnCMP = 0000 0000$_H$, the OS timer behaves as follows.

If the counter is enabled, the OSTMnTINT interrupt request will always be set to 1. However, the timer (OSTMnTTOUT) output signal can still be used. Timer (OSTMnTTOUT) output using timer output toggling mode results in OSTMnTTOUT being toggled on every cycle of the counter clock.

The following figure shows operations of the OSTMn when PCLK is selected as the source of the clock signal for counting and OSTMnCMP = 0000 0000$_H$, the counter start interrupt is enabled (OSTMnCTL.OSTMnMD0 = 1), and the timer is in timer output toggling mode, where OSTMnTTOUT is toggled (OSTMnTOE.OSTMnTOE = 1).



Note: OSTMnMD2 = 0 (load at count start enabled), OSTMnMD0 = 1 (interrupts at count start enabled), OSTMnTOE = 1 (OSTMnTTOUT performs toggle output), OSTMnIE = 1 (interrupt output is enabled)

Figure 32.10 Timing Diagram when OSTMnCMP = 0000 0000$_H$ in Interval Timer Mode

The timing diagram above shows the following operations:

(1) The counter is reloaded with the value in OSTMnCMP as soon as it starts counting, so the value 0000 0000$_H$ is retained in OSTMnCNT.

(2) While the OSTMnTINT interrupt request signal is continuously asserted, OSTMnTTOUT is toggled (in **Figure 32.10**, OSTMnTINT is fixed to the high level because PCLK is selected as the counter clock).

(3) After the counter stops, the OSTMnTINT interrupt request signal is deasserted and the output level of the OSTMnTTOUT signal is maintained.

When an interrupt is prohibited when the counter starts, 1 clock cycle of the counter clock is not generated at the start timing of the counter.

32.4.2.3 Forced Restart Operation in Interval Timer Mode

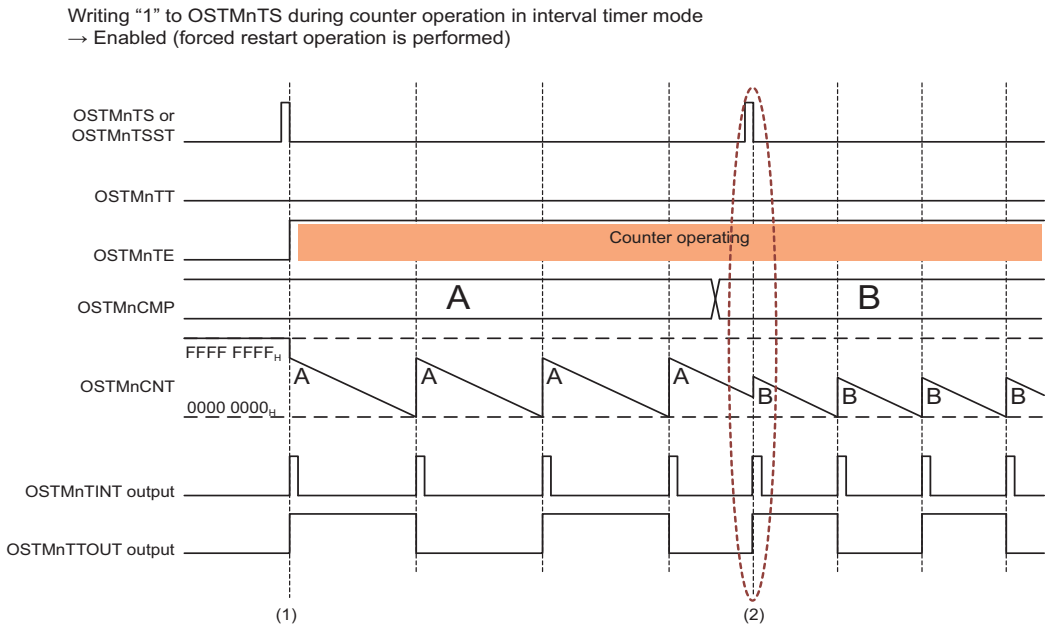
Forced restart operation is performed by writing “1” to the OSTMnTS count start register during the count operation (OSTMnTE = 1) in the interval timer mode. At this time, the OSTMnCNT counter immediately reloads the OSTMnCMP compare register and the count operation continues.

CAUTION

If the OSTMnTS.OSTMnTS bit for a desired channel is set to 1 while simultaneous starting of multiple channels of the timer is in progress, the individual channels are forcibly restarted, so synchronous operation between the channels is not guaranteed.

If simultaneous starting of PIC is used while multiple channels of the timer start individually, the timers set for simultaneous starting are forcibly restarted at the same time.

For OSTM0 to OSTM7, forced restart operation is performed regardless of the value of OSTMnCTL.OSTMnMD2.
For OSTM8 to OSTM9, forced restart operation is performed regardless of the value of OSTMnCTL.OSTMnMD2 when IC0CKSELn.IC0TMENn = 0. Otherwise, forced restart operation is performed before count start in OSTMnCTL.OSTMnMD2 = 1, OSTMnCNT not loads OSTMnCMP value, but starts counting at any value. See **Figure 32.12, Forced Restart Operation while OSTMnMD2 = 1 in Interval Timer Mode (for OSTM8 and OSTM9 only)**.



Note: OSTMnMD0 = 1 (interrupts at count start enabled), OSTMnTOE = 1 (OSTMnTTOUT performs toggle output), OSTMnIE = 1 (interrupt output is enabled).

Figure 32.11 Forced Restart Operation in Interval Timer Mode

The operations shown in the above timing diagram are as follows.

(1) The counter is started and stopped as described under **Figure 32.8** or **Figure 32.9**.

(2) Setting OSTMnTS.OSTMnTS = 1 or OSTMnTSST = 1 restarts the counter while counting is in progress (i.e. while OSTMnTE.OSTMnTE = 1).
The counter immediately restarts counting down, starting with the current value of OSTMnCMP.
When OSTMnCTL.OSTMnMD0 = 1, an OSTMnTINT interrupt request is generated when counting starts and the OSTMnTTOUT signal is toggled.

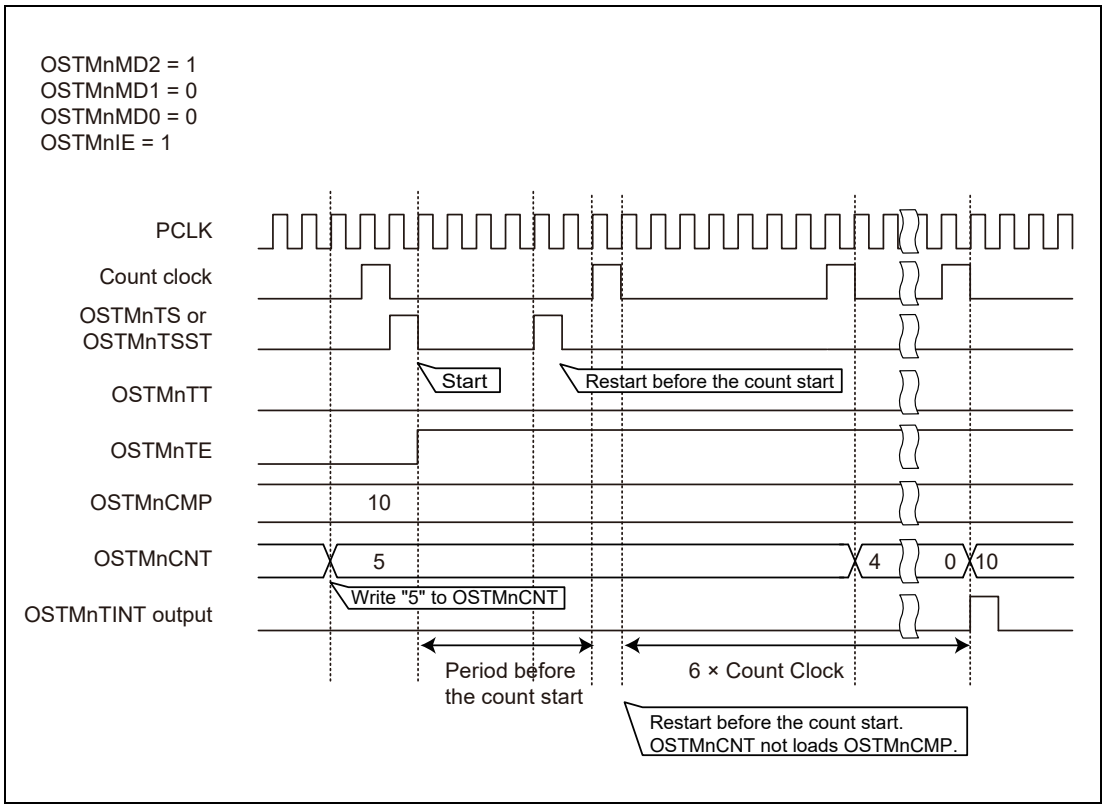


Figure 32.12 Forced Restart Operation while OSTMnMD2 = 1 in Interval Timer Mode (for OSTM8 and OSTM9 only)

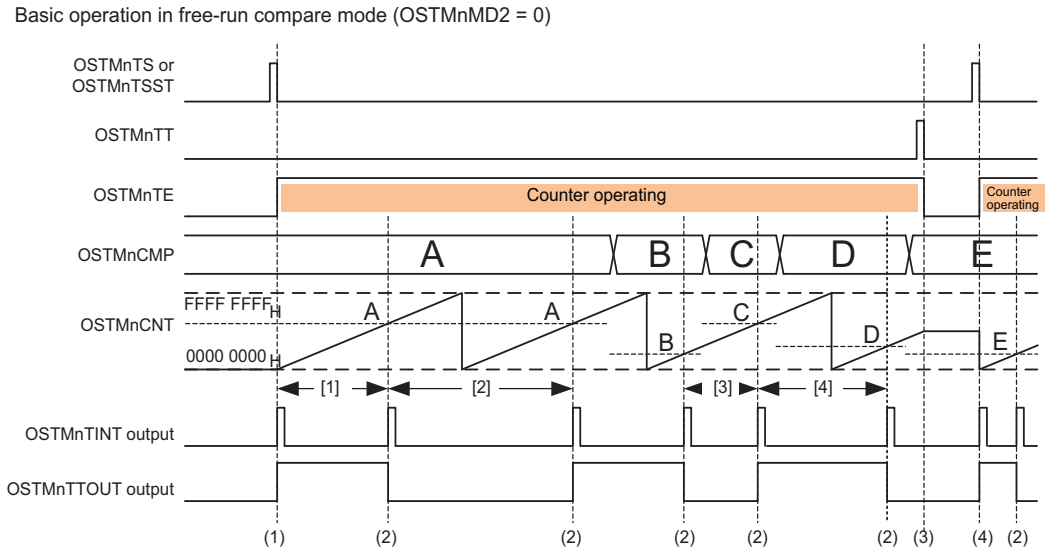
32.4.3 Free-Run Compare Mode

32.4.3.1 Basic Operation in Free-Run Compare Mode

The free-run compare mode is set when count mode selection bit OSTMnMD1 is set to “1”. In the free-run compare mode, the OSTMnTINT interrupt is output when the value of the OSTMnCMP compare register and the count value match. OSTMnTTOUT performs a toggle operation.

When OSTMnMD2 = 0, OSTMnCNT[31:0] is cleared to 0000 0000_H at counter operation start.

When OSTMnMD2 = 1, OSTMnCNT is not cleared at counter operation start.



Note: OSTMnMD0 = 1 (interrupts at count start enabled), OSTMnTOE = 1 (OSTMnTTOUT performs toggle output), OSTMnIE = 1 (interrupt output is enabled).

Figure 32.13 Timing Diagram of OSTMn in Free-Run Compare Mode (OSTMnMD2 = 0)

The timing diagram above shows the following:

(1) The counter starts counting when OSTMnTS.OSTMnTS = 1, or when OSTMnTSST = 1. The OSTMnTE.OSTMnTE bit is set to indicate enabling of the counter. The counter counts up from 0000 0000_H to FFFF $FFFF_H$. The OSTMnCNT register indicates the counter value. When the OSTMnCTL.OSTMnMD0 set to 1, the interrupt request OSTMnTINT is generated when the counting starts.

(2) When the current counter value matches the value in the OSTMnCMP register, an OSTMnTINT interrupt request is generated and the OSTMnTTOUT signal is toggled.

(3) When the counter is stopped (OSTMnTT.OSTMnTT = 1), the OSTMnTE.OSTMnTE bit is cleared to indicate disabling of the counter.
The counter retains its current value until it is restarted.

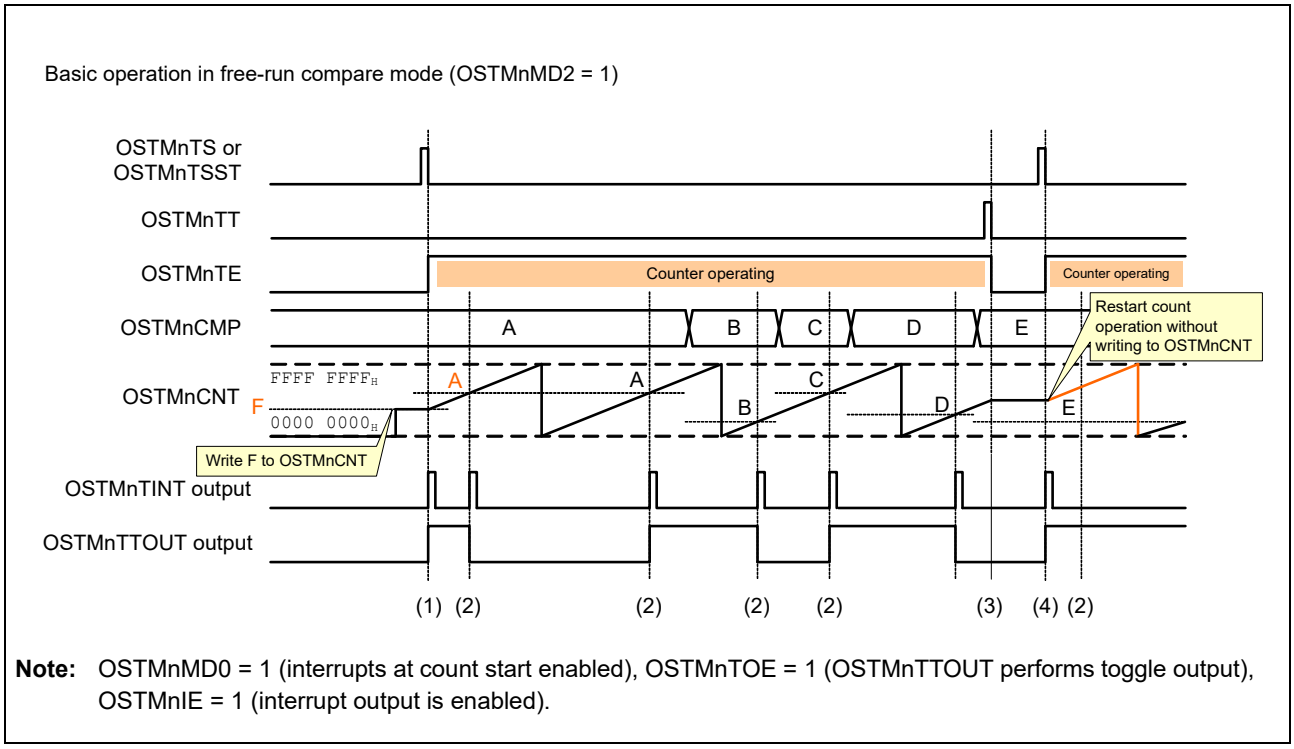
(4) When restarting the counter by setting OSTMnTS.OSTMnTS = 1, the counter starts from 0000 0000_H.

The OSTMnTINT and OSTMnTTOUT occurrence timing in the free-run compare mode may not be a constant period depending on the usage conditions. This occurs at count start and when OSTMnCMP is rewritten during the count operation. This is explained using **Figure 32.13**.

Table 32.21 Timing of OSTMnTINT Generation

Old value for comparison	New value for comparison	Counter value at time of rewriting	Period of OSTMnTINT Generation	Label in timing diagram
Counter starts			(A + 1) × counter clock period	[1]
A	A	No rewriting	(FFFF FFFF$_H$ + 1) × counter clock period	[2]
B	C > B	B < counter value < C	(C - B) × counter clock period	[3]
C	D < C	Counter value > D,C	(FFFF FFFF$_H$ - C + D + 1) × counter clock period	[4]

Even during the count operation, OSTMnCMP rewrite is immediately reflected, and OSTMnCNT match judgment is executed. When "1" is written to OSTMnTT to set OSTMnTE = 0, the counter and OSTMnTO stop operation while holding their values.



Note: OSTMnMD0 = 1 (interrupts at count start enabled), OSTMnTOE = 1 (OSTMnTTOUT performs toggle output), OSTMnIE = 1 (interrupt output is enabled).

Figure 32.14 Timing Diagram of OSTMn in Free-Run Compare Mode (OSTMnMD2 = 1)

The timing diagram above shows the following:

(1) The counter starts counting when OSTMnTS.OSTMnTS = 1, or when OSTMnTSST = 1. The OSTMnTE.OSTMnTE bit is set to indicate enabling of the counter. The counter starts count up to FFFF FFFF$_H$ from the value written to the OSTMnCNT register. The OSTMnCNT register is the counter, so it contains the current value. When the OSTMnCTL.OSTMnMD0 set to 1, the OSTMnTINT interrupt request is generated when counting starts.

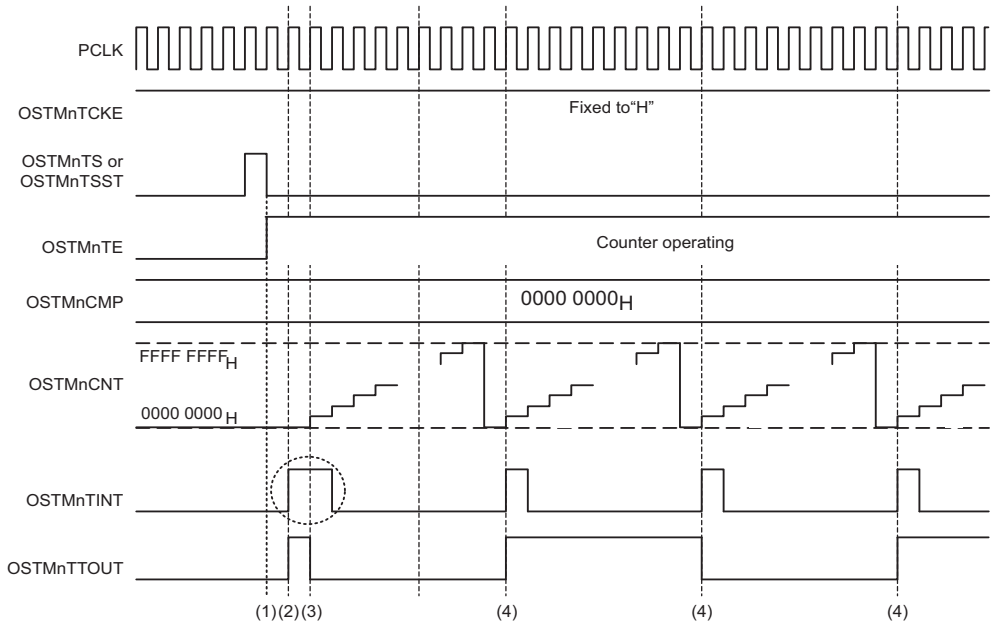
(2) When the current counter value matches the value in the OSTMnCMP register, an OSTMnTINT interrupt request is generated and the OSTMnTTOUT signal is toggled.

(3) When the counter is stopped (OSTMnTT.OSTMnTT = 1), the OSTMnTE.OSTMnTE bit is cleared to indicate disabling of the counter. The counter retains its current value until it is restarted.

(4) Counting by the counter restarts from the value at which counting stopped when OSTMnTS.OSTMnTS = 1, or when OSTMnTSST = 1.

32.4.3.2 Operation when OSTMnCMP = 0000 0000$_H$

The following figure shows the operation of OSTMn when PCLK is selected as the source of the clock signal for counting and OSTMnCMP = 0000 0000$_H$, counter-start interrupts are enabled (OSTMnCTL.OSTMnMD0 = 1) and the timer is in timer output toggling mode, where OSTMnTTOUT is toggled (OSTMnTOE.OSTMnTOE = 1).



Note: OSTMnMD2 = 0 (load at count start enabled), OSTMnMD0 = 1 (interrupts at count start enabled), OSTMnTOE = 1 (OSTMnTTOUT performs toggle output), OSTMnIE=1 (interrupt output is enabled)

Figure 32.15 Timing Diagram when OSTMnCMP = 0000 0000H in Free-Run Compare Mode

The timing diagram above shows the following operations.

(1) Once the counter starts, it counts up from 0000 0000$_H$ to FFFF FFFF$_H$.

(2) An OSTMnTINT interrupt request is generated when counting starts and the OSTMnTTOUT signal is toggled.

(3) If the current counter value matches OSTMnCMP, the interrupt request OSTMnTINT is generated.
If OSTMnCMP = 0000 0000$_H$ as shown above, OSTMnTINT is generated over two clock cycles and the OSTMnTTOUT signal is toggled.

(4) For every (FFFF FFFF$_H$ + 1) clock cycles, the OSTMnTINT interrupt request signal is asserted and the OSTMnTTOUT signal is toggled.

When an interrupt is prohibited when the counter starts, 1 clock cycle of the counter clock is not generated at the start timing of the counter.

32.4.3.3 Forced Restart Operation in Free-Run Compare Mode

In the free-run compare mode, forced restart operation is not performed even when “1” is written to OSTMnTS during the count operation (OSTMnTS = 1). The OSTMnCNT counter continues counting at this time.

Forced restart operation is not performed regardless of the value of OSTMnCTL.OSTMnMD2.

Section 33 Timer Array Unit D (TAUD)

This section contains a generic description of the Timer Array Unit D (TAUD).

The first part of this section describes all RH850/U2A-EVA specific properties, such as the number of units, register base addresses, etc.

The remainder of the section describes the functions and registers of the TAUD.

33.1 Features TAUD for RH850/U2A-EVA

33.1.1 Number of Units and Channels

This microcontroller has the following number of TAUD units.

Table 33.1 Number of Units

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of Units	3 (n = 0 to 2)	3 (n = 0 to 2)	3 (n = 0 to 2)	3 (n = 0 to 2)	3 (n = 0 to 2)	3 (n = 0 to 2)	3 (n = 0 to 2)	3 (n = 0 to 2)	3 (n = 0 to 2)	3 (n = 0 to 2)
Name	TAUDn									

TAUDn has the following timers for the quantity of channels of timers.

Table 33.2 TAUDn Unit Configurations and Channels

Unit Name (Channel Name) TAUDn	Channels per Unit	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
TAUD0	16	16	16	16	16	16	16	16	16	16	16
TAUD1	16	16	16	16	16	16	16	16	16	16	16
TAUD2	16	16	16	16	16	16	16	16	16	16	16

Table 33.3 Index

Index	Description
n	Throughout this section, the individual TAUD units are identified by the index “n” (n = 0 to 2)
m	The TAUD has 16 channels. Throughout this section, the individual channels are identified by the index “m” (m = 0 to 15), thus a certain channel is denoted as CHm. The even numbered channels (m = 0, 2, 4, 6, 8, 10, 12, 14) are denoted as CHm_even. The odd numbered channels (m = 1, 3, 5, 7, 9, 11, 13, 15) are denoted as CHm_odd.

33.1.2 Register Base Addresses

TAUDn base addresses are listed in the following table.

TAUDn register addresses are given as offsets from the base addresses.

Table 33.4 Register Base Addresses

Base Address Name	Base Address	Bus Group
<TAUD0_base>	FFBF 4000_H	P-Bus Group 5
<TAUD1_base>	FFBF 5000_H	P-Bus Group 5
<TAUD2_base>	FFBF 6000_H	P-Bus Group 5

33.1.3 Clock Supply

Clock supply by and to TAUDn is listed in the following table.

Table 33.5 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
TAUDn	PCLK	Peripheral high speed clock CLK_HSB

33.1.4 Interrupt Requests and Error Notifications

TAUDn interrupt requests are listed in the following table.

Table 33.6 Interrupt and DMA/DTS Requests (1/2)

Unit Interrupt Name	Description	Interrupt Number	DMA Trigger Number	DTS Trigger Number
TAUD0				
INTTAUD0I0	Channel 0 interrupt	10	Group 0-192	Group 1-64
INTTAUD0I1	Channel 1 interrupt	376	Group 0-193	Group 1-65
INTTAUD0I2	Channel 2 interrupt	11	Group 0-194	Group 1-66
INTTAUD0I3	Channel 3 interrupt	377	Group 0-195	Group 1-67
INTTAUD0I4	Channel 4 interrupt	12	Group 0-196	Group 1-68
INTTAUD0I5	Channel 5 interrupt	378	Group 0-197	Group 1-69
INTTAUD0I6	Channel 6 interrupt	13	Group 0-198	Group 1-70
INTTAUD0I7	Channel 7 interrupt	379	Group 0-199	Group 1-71
INTTAUD0I8	Channel 8 interrupt	23	Group 0-200	Group 1-72
INTTAUD0I9	Channel 9 interrupt	380	Group 0-201	Group 1-73

INTTAUD2I5	Channel 5 interrupt	405	Group 0-229	Group 1-101
INTTAUD2I6	Channel 6 interrupt	406	Group 0-230	Group 1-102
INTTAUD2I7	Channel 7 interrupt	407	Group 0-231	Group 1-103
INTTAUD2I8	Channel 8 interrupt	408	Group 0-232	Group 1-104
INTTAUD2I9	Channel 9 interrupt	409	Group 0-233	Group 1-105
INTTAUD2I10	Channel 10 interrupt	410	Group 0-234	Group 1-106
INTTAUD2I11	Channel 11 interrupt	411	Group 0-235	Group 1-107
INTTAUD2I12	Channel 12 interrupt	412	Group 0-236	Group 1-108
INTTAUD2I13	Channel 13 interrupt	413	Group 0-237	Group 1-109
INTTAUD2I14	Channel 14 interrupt	414	Group 0-238	Group 1-110
INTTAUD2I15	Channel 15 interrupt	415	Group 0-239	Group 1-111

This module has no error notifications.

33.1.5 Reset Sources

TAUDn reset sources are listed in the following table. TAUDn is initialized by these reset sources.

Table 33.7 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
TAUDn	All registers	√	√	√	√	√	√	—

33.1.6 External Input/Output Signals

External input/output signals of TAUDn are listed below.

Table 33.8 External Input/Output Signals (1/3)

Unit Signal Name	I/O	Description	Alternative Port Pin Signal Name
TAUD0			
TAUD0TTIN0	I	Channel 0 Input*1*2	TAUD0I0

TAUD2TTOUT15	O	Channel 15 output	TAUD2O15

Note 1. Setting of the noise filter for the port is required when the channel input pin is used. For details, **Section 2.7, Noise Filter & Edge/Level Detector**.

Note 2. The input signals can be switched by PIC. For details, see **Section 41.2.3.12, Timer Input Select Function**.

Note 3. The input signals can be switched by PIC. For details, see **Section 41.2.3.14, Timer Output Monitor Function**.

33.1.7 Internal Input/Output Signals

The internal input/output signals of TAUDn are listed below.

Table 33.9 Internal Input/Output Signals

Unit Signal Name	Description	Connected to
TAUDnTSSTm*1	Simultaneous channel start trigger input	PIC
TAUDnTUDCm*1 (m = 0, 2, 8)	TAUD master up/down signal output	PIC

Note 1. n = 0, 1 only. TAUD2TSSTm, TAUD2TUDCm (m = 0, 2, 8) are not connected to PIC.

33.2 Overview

33.2.1 Functional Overview

The TAUD has the following functions:

- 16 channels
- 16-bit counter and 16-bit data register per channel
- Independent channel operation
- Synchronous channel operation (master and slave operation)
- Generation of different types of output signal
- Real-time output
- Counter can be triggered by external signal
- Interrupt generation

The Timer Array Unit D is used to perform various count or timer operations and to output a signal which depends on the result of the operation. It contains one prescaler block for count clock generation and 16 channels, each equipped with a 16-bit counter TAUDnCNTm and a 16-bit data register TAUDnCDRm to hold the start or compare value of the counter.

It also contains several control and status registers.

Independent and synchronous operation

Every channel can operate in different operation modes, either independently or in combination with other channels (synchronously). When one master channel and one or more slave channels operate in combination, the slave channels depend on the master channel.

When a channel is operated independently, its operation mode and functions are not affected by those of other channels. When a channel is operated synchronously it is either a master or a slave. A master channel can have multiple slaves, and the state of one channel affects that of the other channels. For example, this means that one channel can control when another starts to count, is reset, etc.

33.2.2 Terms

In this section, the following terms are used.

Independent / synchronous channel operation

Independent or synchronous channel operation describes the dependency of channels on each other:

- If a channel operates independently of all other channels, this is called independent channel operation.
- If a channel operates depending on other channels, this is called synchronous channel operation.

Channel group

In synchronous channel operation, all channels that depend on each other are referred to as a “channel group”.

A channel group has one master channel and one or more slave channels.

Operation mode

An operation mode can be selected for every channel m. The operation mode defines the basic operation and features of a channel.

In synchronous channel operation, every channel in the channel group can operate in a different operation mode.

Examples are “Capture Mode”, “Event Count Mode”, and “Interval Timer Mode”.

Channel output mode

The channel output mode defines the operation of TAUDnTTOUTm

- of a single channel (independent output operation) or
- of all channels in a channel group (synchronous output operation).

Examples are “Independent Channel Output Mode 1” and “Synchronous Channel Output Mode 2 with Dead Time Output”.

Channel operation function

The channel operation function defines the complete function and all features

- of a single channel (independent channel operation) or
- of all channels in a channel group (synchronous channel operation).

Upper / lower channel

Depending on the channel number m, a channel with a smaller number or with a larger number is referred to as “upper” or “lower” channel, respectively.

- Upper channel: Channel with a smaller channel number
- Lower channel: Channel with a larger channel number

Example:

For channel 5, channel 3 is an upper channel and channel 9 is a lower channel.

33.2.3 Functional List of Timer Operations

This timer provides the following functions by operating each channel independently or by combining multiple channels.

Table 33.10 Functional List of TAUD Operations

Operation Function	Example
Independent Channel Operation Functions	**Section 33.12**
Interval Timer Function	**Section 33.12.1**
TAUDnTTINm Input Interval Timer Function	**Section 33.12.2**
Clock Divide Function	**Section 33.12.3**
External Event Count Function	**Section 33.12.4**
Delay Count Function	**Section 33.12.5**
One-Pulse Output Function	**Section 33.12.6**
TAUDnTTINm Input Pulse Interval Measurement Function	**Section 33.12.7**

33.2.4 TAUD I/O and Interrupt Request Signals

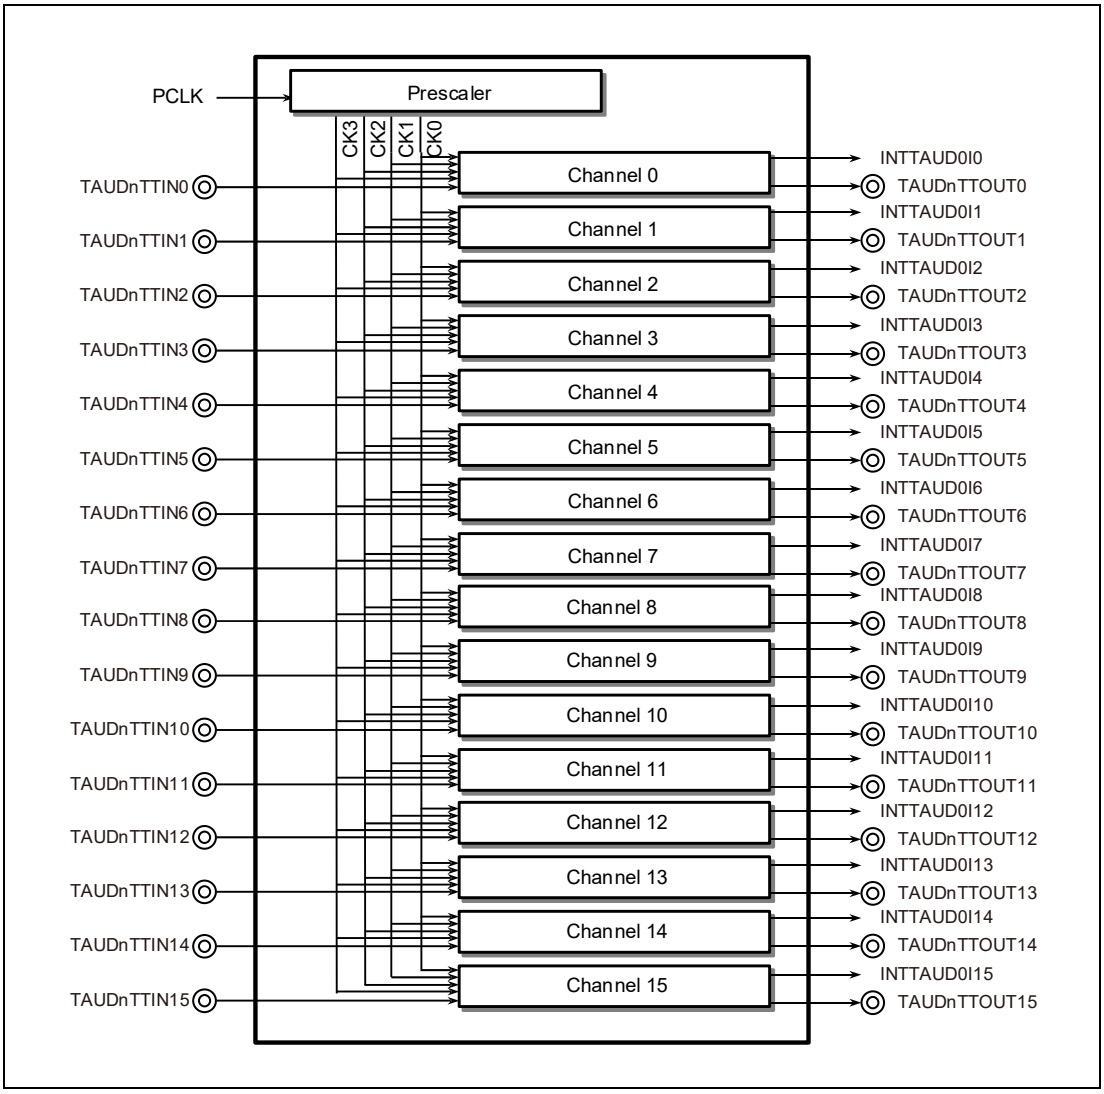

Figure 33.1 TAUD I/O and Interrupt Request Signals

33.2.5 Block Diagram

Figure 33.2, Block Diagram of the TAUD shows the main components of the TAUD.

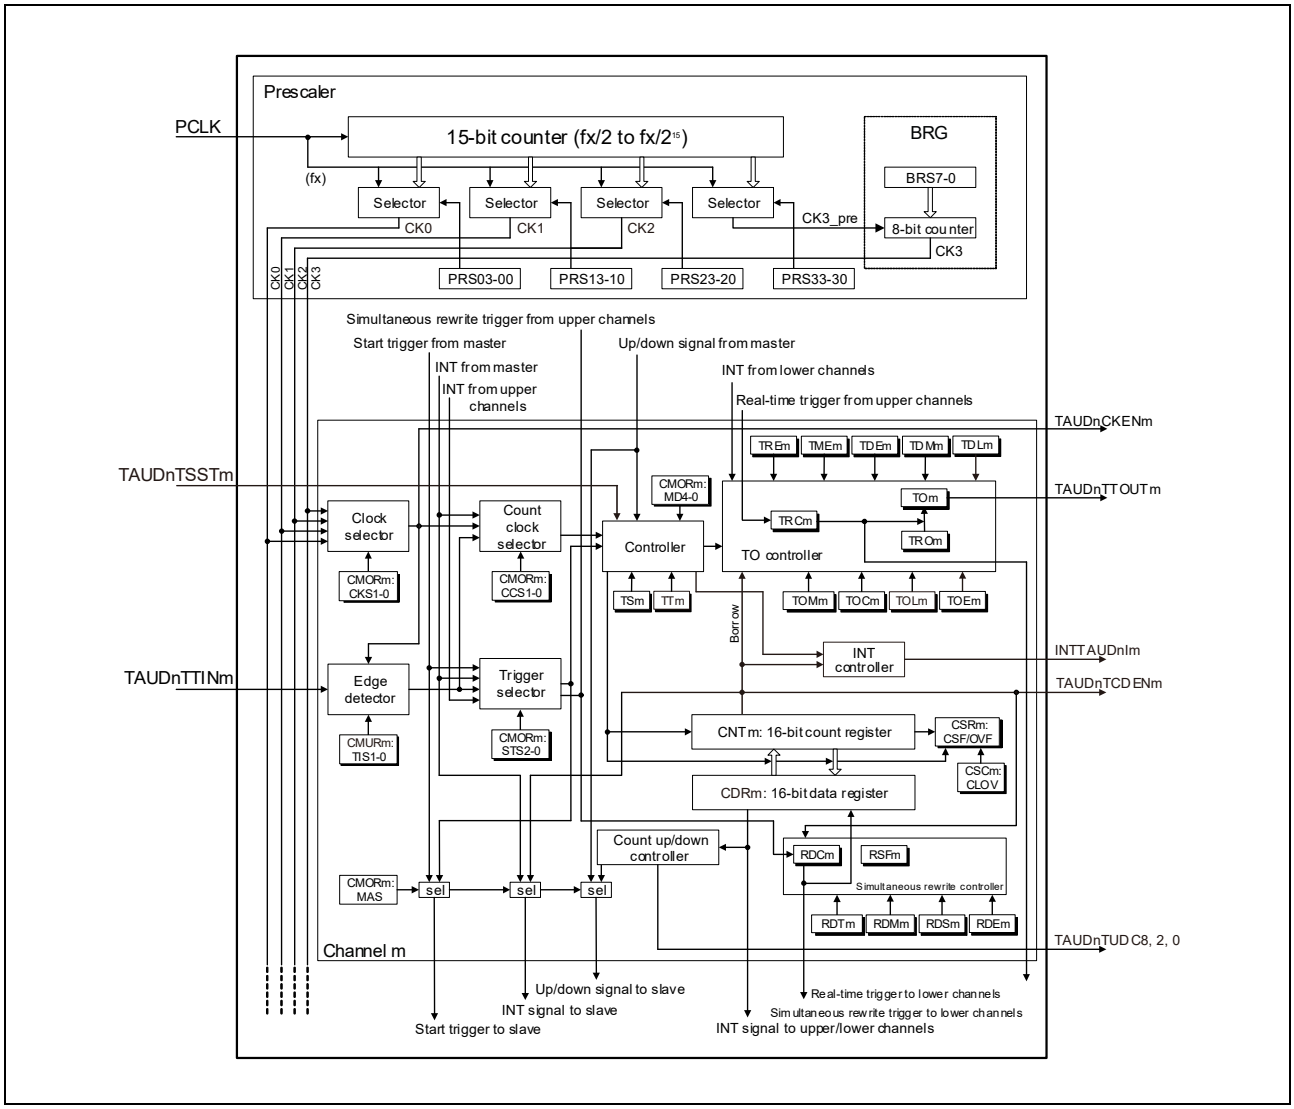

Figure 33.2 Block Diagram of the TAUD

The module name “TAUDn” has been omitted from the register names for the sake of clarity in the above figure.

33.2.6 Description of Blocks

The following describes the functional blocks:

Prescaler block

The prescaler block provides up to four clock signals (CK0 to CK3) that can be used as count clocks for all channels.

Count clocks CK0 to CK2 are derived from PCLK by a configurable prescaler division factor of 2^0 to 2^{15}. The fourth count clock CK3 can be adjusted more precisely by using BRG to set an additional division factor that is not a power of 2.

Clock and count clock selection

For every channel, the count clock selector selects which of the following is used as the clock source:

- One of the clocks CK0 to CK3 (selected by the clock selector)
- INTTAUDnIm from master channel
- TAUDnTTINm input signal valid edge

Controller

The controller controls the main operations of the counter:

- Operation mode (selected by bits TAUDnCMORm.TAUDnMD[4:0])
- Counter start enable (TAUDnTS.TAUDnTSm) and counter stop (TAUDnTT.TAUDnTTm)

When counter start is enabled, status flag TAUDnTE.TAUDnTEm is set.

- Count direction (up/down) (can be controlled by master channel)

Trigger selector

Depending on the selected operation mode, the counter starts automatically when it is enabled (TAUDnTE.TAUDnTEm = 1), or it waits for an external start trigger signal. Any of the following signals can be used as the start trigger.

- Synchronous channel start trigger input TAUDnTSSTm
- TAUDnTTINm input signal valid edge
- INTTAUDnIm from the master or any upper channel
- Up/down output trigger signal of the master channel
- Dead-time output signal of the TAUDnTTOUTm generation unit.

Simultaneous rewrite controller

Simultaneous rewrite control is a function that can be used in synchronous operating modes. The data registers (TAUDnCDRm) of all channels in a channel group can be rewritten at any time. The simultaneous rewrite controller ensures that new data register values of all channels become effective at the same time.

TAUDnTO controller

The output control of every channel enables the generation of various output signal forms such as PWM signals or triangular waves.

33.3 Registers

33.3.1 List of Registers

TAUD registers are listed in the following table.

For details about <TAUDn_base>, see **Section 33.1.2, Register Base Addresses**.

Table 33.11 List of Registers (1/2)

Module Name	Register Name	Symbol	Address	Access Protection	
				PBG	Other
TAUDn Prescaler Registers					
TAUDn	TAUDn Prescaler Clock Select Register	TAUDnTPS	<TAUDn_base> + 240_H	*1	—
	TAUDn Prescaler Baud Rate Setting Register	TAUDnBRS	<TAUDn_base> + 244_H	*1	—
TAUDn Control Registers					
TAUDn	TAUDn Channel Data Register m	TAUDnCDRm	<TAUDn_base> + m × 4_H	*1	—
	TAUDn Channel Counter Register m	TAUDnCNTm	<TAUDn_base> + 80_H + m × 4_H	*1	—
	TAUDn Channel Mode OS Register m	TAUDnCMORm	<TAUDn_base> + 200_H + m × 4_H	*1	—
	TAUDn Channel Mode User Register m	TAUDnCMURm	<TAUDn_base> + $C0_H$ + m × 4_H	*1	—
	TAUDn Channel Status Register m	TAUDnCSRm	<TAUDn_base> + 140_H + m × 4_H	*1	—
	TAUDn Channel Status Clear Trigger Register m	TAUDnCSCm	<TAUDn_base> + 180_H + m × 4_H	*1	—
	TAUDn Channel Start Trigger Register	TAUDnTS	<TAUDn_base> + $1C4_H$	*1	—
	TAUDn Channel Enable Status Register	TAUDnTE	<TAUDn_base> + $1C0_H$	*1	—
	TAUDn Channel Stop Trigger Register	TAUDnTT	<TAUDn_base> + $1C8_H$	*1	—
TAUDn Output Registers					
TAUDn	TAUDn Channel Output Enable Register	TAUDnTOE	<TAUDn_base> + $5C_H$	*1	—
	TAUDn Channel Output Register	TAUDnTO	<TAUDn_base> + 58_H	*1	—
	TAUDn Channel Output Mode Register	TAUDnTOM	<TAUDn_base> + 248_H	*1	—
	TAUDn Channel Output Configuration Register	TAUDnTOC	<TAUDn_base> + $24C_H$	*1	—
	TAUDn Channel Output Active Level Register	TAUDnTOL	<TAUDn_base> + 040_H	*1	—
	TAUDn Channel Dead Time Output Enable Register	TAUDnTDE	<TAUDn_base> + 250_H	*1	—
	TAUDn Channel Dead Time Output Mode Register	TAUDnTDM	<TAUDn_base> + 254_H	*1	—
	TAUDn Channel Dead Time Output Level Register	TAUDnTDL	<TAUDn_base> + 54_H	*1	—
	TAUDn Channel Real-time Output Register	TAUDnTRO	<TAUDn_base> + $4C_H$	*1	—
	TAUDn Channel Real-time Output Enable Register	TAUDnTRE	<TAUDn_base> + 258_H	*1	—
	TAUDn Channel Real-time Output Control Register	TAUDnTRC	<TAUDn_base> + $25C_H$	*1	—
	TAUDn Channel Modulation Output Enable Register	TAUDnTME	<TAUDn_base> + 50_H	*1	—

Table 33.11 List of Registers (2/2)

Module Name	Register Name	Symbol	Address	Access Protection	
				PBG	Other

n = 1: PBG51#2
n = 2: PBG51#3

33.3.2 Details of TAUDn Prescaler Registers

33.3.2.1 TAUDnTPS — TAUDn Prescaler Clock Select Register

This register specifies clocks CK0, CK1, CK2, and CK3_PRE for all channels of the PCLK prescaler. CK3 is generated by dividing CK3_PRE by the factor specified in TAUDnBRS.

Access: This register can be read or written in 16-bit units.

Address: <TAUDn_base> + 240_H

Value after reset: $FFFF_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnPRS3[3:0]				TAUDnPRS2[3:0]				TAUDnPRS1[3:0]				TAUDnPRS0[3:0]			
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 33.12 TAUDnTPS Register Contents (1/3)

Bit Position	Bit Name	Function
15 to 12	TAUDnPRS3 [3:0]	Specifies CK3_PRE clock. CK3_PRE clock is an input clock to BRG unit which supplies the CK3 operation clock to all channels.

TAUDnPRS3[3:0]	CK3_PRE Clock
0000_B	PCLK/2^0
0001_B	PCLK/2^1
0010_B	PCLK/2^2
0011_B	PCLK/2^3
0100_B	PCLK/2^4
0101_B	PCLK/2^5
0110_B	PCLK/2^6
0111_B	PCLK/2^7
1000_B	PCLK/2^8
1001_B	PCLK/2^9
1010_B	PCLK/2^{10}
1011_B	PCLK/2^{11}
1100_B	PCLK/2^{12}
1101_B	PCLK/2^{13}
1110_B	PCLK/2^{14}
1111_B	PCLK/2^{15}

The above bits are rewritable only when all the counters using CK3 are stopped (TAUDnTE.TAUDnTEm = 0).

Table 33.12 TAUDnTPS Register Contents (2/3)

Bit Position	Bit Name	Function
11 to 8	TAUDnPRS2 [3:0]	Specifies the CK2 clock. **TAUDnPRS2[3:0]** / **CK2 Clock** 0000_B / $PCLK/2^0$ 0001_B / $PCLK/2^1$ 0010_B / $PCLK/2^2$ 0011_B / $PCLK/2^3$ 0100_B / $PCLK/2^4$ 0101_B / $PCLK/2^5$ 0110_B / $PCLK/2^6$ 0111_B / $PCLK/2^7$ 1000_B / $PCLK/2^8$ 1001_B / $PCLK/2^9$ 1010_B / $PCLK/2^{10}$ 1011_B / $PCLK/2^{11}$ 1100_B / $PCLK/2^{12}$ 1101_B / $PCLK/2^{13}$ 1110_B / $PCLK/2^{14}$ 1111_B / $PCLK/2^{15}$ The above bits are rewritable only when all the counters using CK2 are stopped (TAUDnTE.TAUDnTEm = 0).
7 to 4	TAUDnPRS1 [3:0]	Specifies the CK1 clock. **TAUDnPRS1[3:0]** / **CK1 Clock** 0000_B / $PCLK/2^0$ 0001_B / $PCLK/2^1$ 0010_B / $PCLK/2^2$ 0011_B / $PCLK/2^3$ 0100_B / $PCLK/2^4$ 0101_B / $PCLK/2^5$ 0110_B / $PCLK/2^6$ 0111_B / $PCLK/2^7$ 1000_B / $PCLK/2^8$ 1001_B / $PCLK/2^9$ 1010_B / $PCLK/2^{10}$ 1011_B / $PCLK/2^{11}$ 1100_B / $PCLK/2^{12}$ 1101_B / $PCLK/2^{13}$ 1110_B / $PCLK/2^{14}$ 1111_B / $PCLK/2^{15}$ The above bits are rewritable only when all the counters using CK1 are stopped (TAUDnTE.TAUDnTEm = 0).

Table 33.12 TAUDnTPS Register Contents (3/3)

Bit Position	Bit Name	Function
3 to 0	TAUDnPRS0 [3:0]	Specifies the CK0 clock.

TAUDnPRS0[3:0]	CK0 Clock
0000_B	PCLK/2^0
0001_B	PCLK/2^1
0010_B	PCLK/2^2
0011_B	PCLK/2^3
0100_B	PCLK/2^4
0101_B	PCLK/2^5
0110_B	PCLK/2^6
0111_B	PCLK/2^7
1000_B	PCLK/2^8
1001_B	PCLK/2^9
1010_B	PCLK/2^{10}
1011_B	PCLK/2^{11}
1100_B	PCLK/2^{12}
1101_B	PCLK/2^{13}
1110_B	PCLK/2^{14}
1111_B	PCLK/2^{15}

The above bits are rewritable only when all the counters using CK0 are stopped (TAUDnTE.TAUDnTEm = 0).

NOTE

The TAUDn clock input PCLK is specified in the first part of this section, **Section 33.1.3, Clock Supply**.

33.3.2.2 TAUDnBRS — TAUDn Prescaler Baud Rate Setting Register

This register specifies the division factor of prescaler clock CK3.

CK3 is generated by dividing CK3_PRE by the factor specified in this register plus one. The PCLK prescaler for CK3_PRE is specified in TAUDnTPS.TAUDnPRS3[3:0].

Access: This register can be read or written in 8-bit units.

Address: <TAUDn_base> + 244_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	TAUDnBRS[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 33.13 TAUDnBRS Register Contents

Bit Position	Bit Name	Function
7 to 0	TAUDnBRS[7:0]	Specifies a CK3_PRE clock division factor for generating CK3.

TAUDnBRS[7:0]	CK3 Clock
$0000\ 0000_B$	CK3_PRE / 1
$0000\ 0001_B$	CK3_PRE / 2
$0000\ 0010_B$	CK3_PRE / 3
$0000\ 0011_B$	CK3_PRE / 4
...	...
$1111\ 1110_B$	CK3_PRE / 255
$1111\ 1111_B$	CK3_PRE / 256

33.3.3 Details of TAUDn Control Registers

33.3.3.1 TAUDnCDRm — TAUDn Channel Data Register m

This register functions either as a compare register or as a capture register, depending on the operating mode specified in TAUDnCMORm.TAUDnMD[4:1].

Access: This register can be read or written in 16-bit units.
- When this register functions as a capture register, only reading is possible. Write operation is ignored.
- When this register functions as a compare register, reading and writing is possible.

Address: <TAUDn_base> + m × 4_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCDR[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 33.14 TAUDnCDRm Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnCDR [15:0]	Data register for capture/compare values

33.3.3.2 TAUDnCNTm — TAUDn Channel Counter Register m

This is a channel m counter register.

Access: This register is a read-only register that can be read in 16-bit units.

Address: <TAUDn_base> + 80_H + m × 4_H

Value after reset: $FFFF_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCNT[15:0]															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 33.15 TAUDnCNTm Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnCNT [15:0]	16-bit counter value

A read value depends on a counter value, a changed operating mode, TAUDnTS.TAUDnTSm or TAUDnTT.TAUDnTTm bit value.

The initial read value of the counter depends on an operating mode and how the counter is stopped.

- Stop by a reset
- Stop by a counter stop trigger (TAUDnTT.TAUDnTTm = 1)

Table 33.16, TAUDnCNTm Read Values after Re-Enabling Counter lists the initial counter read values after the counter is stopped (TAUDnTE.TAUDnTEm = 0) and re-enabled (TAUDnTS.TAUDnTSm = 1).

The table also contains the counter read value one count after the counter is enabled (TAUDnTS.TAUDnTSm = 1) with the counter waiting for a start trigger.

Table 33.16 TAUDnCNTm Read Values after Re-Enabling Counter

Mode Name	Count Method (Up/Down)	TAUDnCNTm Value		
		Start Value*1	After Stop Trigger	After One Count
Interval timer mode	Count down	$FFFF_H$	Stop value	—
Judge mode	Count down	$FFFF_H$	Stop value	—
Capture mode	Count up	0000_H	Stop value	—
Event count mode	Count down	$FFFF_H$	Stop value	—
One-count mode	Count down	$FFFF_H$	Stop value	Stop value
Capture and one-count mode	Count up	0000_H	Stop value	Capture value + 1 (TAUDnCDRm)
Judge and one-count mode	Count down	$FFFF_H$	Stop value	TAUDnCNTm value – 1
Count-up/-down mode	Count down/up	$FFFF_H$	Stop value	—
Pulse one-count mode	Count down	$FFFF_H$	Stop value	0000_H
Count capture mode	Count up	0000_H	Stop value	—
Gate count mode	Count down	$FFFF_H$	Stop value	Stop value
Capture and gate count mode	Count up	0000_H	Stop value	Stop value

Note 1. The value set for TAUDnCNTm when the operating mode is changed after a reset is deasserted.

33.3.3.3 TAUDnCMORm — TAUDn Channel Mode OS Register m

This register controls channel m operation.

Access: This register can be read or written in 16-bit units. Writable only when the counter is stopped (TAUDnTE.TAUDnTEm = 0).

Address: <TAUDn_base> + 200_H + m × 4_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS [1:0]		TAUDnCCS [1:0]		TAUDn MAS	TAUDnSTS[2:0]			TAUDnCOS [1:0]		—	TAUDnMD[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 33.17 TAUDnCMORm Register Contents (1/3)

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Selects an operation clock. An operation clock is used for the TAUDnTTINm input edge detection circuit. Setting of TAUDnCMORm.TAUDnCCS[1:0] bits also allows the operation clock to serve as the TAUDnCNTm counter clock.

TAUDn CKS1	TAUDn CKS0	Selection of Operation Clock
0	0	CK0
0	1	CK1
1	0	CK2
1	1	CK3

Bit Position	Bit Name	Function
13, 12	TAUDnCCS[1:0]	Selects a count clock for TAUDnCNTm counter.

TAUDn CCS1	TAUDn CCS0	Selection of Count Clock
0	0	Operation clock specified by TAUDnCMORm.TAUDnCKS[1:0]
0	1	Valid edge of TAUDnTTINm input signal
1	0	Setting prohibited
1	1	INTTAUDnIm signal of master channel

Bit Position	Bit Name	Function
11	TAUDnMAS	Specifies whether the channel is a master channel or slave channel during synchronous channel operation. 0: Slave 1: Master This bit setting is valid only for even channels (CHm_even). Odd channels (CHm_odd) are fixed to 0.

33.3.3.4 TAUDnCMURm — TAUDn Channel Mode User Register m

This register specifies a type of valid edge detection used for TAUDnTTINm input.

Access: This register can be read or written in 8-bit units.

Address: <TAUDn_base> + $C0_H$ + m × 4_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.18 TAUDnCMURm Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	Specifies a valid edge of TAUDnTTINm input signal.

TAUDn TIS1	TAUDn TIS0	Functional Description
0	0	Falling edge
0	1	Rising edge
1	0	Detection of rising and falling edges (selects low width measurement) • Start trigger: Falling edge • Stop trigger (capture): Rising edge
1	1	Detection of rising and falling edges (selects high width measurement) • Start trigger: Rising edge • Stop trigger (capture): Falling edge

Edge detection of TAUDnTTINm input signal is based on the operation clock selected by TAUDnCMORm.TAUDnCKS[1:0].

33.3.3.5 TAUDnCSRm — TAUDn Channel Status Register m

This register indicates the count direction and overflow status of channel m counter.

Access: This register is a read-only register that can be read in 8-bit units.

Address: <TAUDn_base> + 140_H + m × 4_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnCSF	TAUDnOVF
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 33.19 TAUDnCSRm Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned.
1	TAUDnCSF	Indicates a count direction. 0: Count-up 1: Count-down The read value of this bit is valid only in the following mode: • Count-up/-down mode
0	TAUDnOVF	Indicates counter overflow status. 0: No overflow occurs. 1: Overflow occurs. This bit is used only in the following modes: • Capture mode • Capture and one-count mode The function of this bit depends on the setting of control bit TAUDnCMORm.TAUDnCOS[1:0].

33.3.3.6 TAUDnCSCm — TAUDn Channel Status Clear Trigger Register m

This is a trigger register for clearing the overflow flag TAUDnCSRm.TAUDnOVF of channel m.

Access: This register is a write-only register that can be written in 8-bit units. It is always read as 00_H.

Address: <TAUDn_base> + 180_H + m × 4_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAUDnCLOV
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 33.20 TAUDnCSCm Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TAUDnCLOV	0: No function 1: Clears overflow flag TAUDnCSRm.TAUDnOVF.

33.3.3.7 TAUDnTS — TAUDn Channel Start Trigger Register

This register enables the counter operation of each channel.

Access: This register is a write-only register that can be written in 16-bit units. It is always read as 0000_H.

Address: <TAUDn_base> + $1C4_H$

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnTS15	TAUDnTS14	TAUDnTS13	TAUDnTS12	TAUDnTS11	TAUDnTS10	TAUDnTS09	TAUDnTS08	TAUDnTS07	TAUDnTS06	TAUDnTS05	TAUDnTS04	TAUDnTS03	TAUDnTS02	TAUDnTS01	TAUDnTS00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 33.21 TAUDnTS Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnTSm	Enables the counter operation of channel m. 0: No function 1: Enables the counter operation and sets TAUDnTE.TAUDnTEm to 1. The counter operation is only enabled when TAUDnTE.TAUDnTEm is set to 1. Whether counting is started or not depends on a selected operating mode.

33.3.3.8 TAUDnTE — TAUDn Channel Enable Status Register

This register enables/disables a counter operation.

Access: This register is a read-only register that can be read in 16-bit units.

Address: <TAUDn_base> + $1C0_H$

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 33.22 TAUDnTE Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnTEm	Enables/disables the counter operation of channel m. 0: Disables counter operation. 1: Enables counter operation. This bit is set to 1 when trigger input of TAUDnTSSTm (synchronous channel start trigger signal) is detected or when TAUDnTS.TAUDnTSm is set to 1. This bit is set to 0 when TAUDnTT.TAUDnTTm is set to 1.

33.3.3.9 TAUDnTT — TAUDn Channel Stop Trigger Register

This register stops the counter operation of each channel.

Access: This register is a write-only register that can be written in 16-bit units. It is always read as 0000_H.

Address: <TAUDn_base> + $1C8_H$

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 33.23 TAUDnTT Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnTTm	Stops the counter operation of channel m. 0: No function 1: Stops the counter operation and resets TAUDnTE.TAUDnTEm. TAUDnCNTm, TAUDnTO.TAUDnTOm, and TAUDnTTOUTm retain the values provided before the counter is stopped.

33.3.4 Details of TAUDn Simultaneous Rewrite Registers

33.3.4.1 TAUDnRDE — TAUDn Channel Reload Data Enable Register

This register enables/disables simultaneous rewrite of TAUDnCDRm/TAUDnTOLm data register.

Access: This register can be read or written in 16-bit units. Writable only while TAUDnTE.TAUDnTEm = 0.

Address: <TAUDn_base> + 260_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 33.24 TAUDnRDE Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnRDEm	Enables/disables simultaneous rewrite of the data register of channel m. 0: Disables simultaneous rewrite 1: Enables simultaneous rewrite

33.3.4.2 TAUDnRDS — TAUDn Channel Reload Data Control Channel Select Register

This register selects a channel that controls simultaneous rewrite.

Access: This register can be read or written in 16-bit units. Writable only while TAUDnTE.TAUDnTEm = 0.

Address: <TAUDn_base> + 268_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDn RDS15	TAUDn RDS14	TAUDn RDS13	TAUDn RDS12	TAUDn RDS11	TAUDn RDS10	TAUDn RDS09	TAUDn RDS08	TAUDn RDS07	TAUDn RDS06	TAUDn RDS05	TAUDn RDS04	TAUDn RDS03	TAUDn RDS02	TAUDn RDS01	TAUDn RDS00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 33.25 TAUDnRDS Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnRDSm	Selects a channel that controls a simultaneous rewrite trigger. 0: Master channel 1: Another upper channel

33.3.4.3 TAUDnRDM — TAUDn Channel Reload Data Mode Register

This register selects the timing for generating a simultaneous rewrite control signal.

Access: This register can be read or written in 16-bit units. Writable only while TAUDnTE.TAUDnTEm = 0.

Address: <TAUDn_base> + 264_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDn RDM15	TAUDn RDM14	TAUDn RDM13	TAUDn RDM12	TAUDn RDM11	TAUDn RDM10	TAUDn RDM09	TAUDn RDM08	TAUDn RDM07	TAUDn RDM06	TAUDn RDM05	TAUDn RDM04	TAUDn RDM03	TAUDn RDM02	TAUDn RDM01	TAUDn RDM00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 33.26 TAUDnRDM Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnRDMm	Selects the timing for generating a simultaneous rewrite trigger signal. 0: When the master channel counter starts to count 1: At the peak of cycle of triangular wave These bit settings are applied only when TAUDnRDE.TAUDnRDEm = 1 and TAUDnRDS.TAUDnRDSm = 0.

33.3.4.4 TAUDnRDC — TAUDn Channel Reload Data Control Register

This register specifies a channel which generates an INTTAUDnIm signal to trigger simultaneous rewrite.

Access: This register can be read or written in 16-bit units. Writable only while TAUDnTE.TAUDnTEm = 0.

Address: <TAUDn_base> + $26C_H$

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDn RDC15	TAUDn RDC14	TAUDn RDC13	TAUDn RDC12	TAUDn RDC11	TAUDn RDC10	TAUDn RDC09	TAUDn RDC08	TAUDn RDC07	TAUDn RDC06	TAUDn RDC05	TAUDn RDC04	TAUDn RDC03	TAUDn RDC02	TAUDn RDC01	TAUDn RDC00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 33.27 TAUDnRDC Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnRDCm	Specifies whether the channel generates a simultaneous rewrite trigger signal or not. 0: Does not operate as a simultaneous rewrite trigger channel. 1: Operates as a simultaneous rewrite trigger channel. These bit settings are applied only when TAUDnRDE.TAUDnRDEm = 1 and TAUDnRDS.TAUDnRDSm = 1.

33.3.4.5 TAUDnRDT — TAUDn Channel Reload Data Trigger Register

This register triggers a simultaneous rewrite enabling state.

Access: This register is a write-only register that can be written in 16-bit units. It is always read as 0000_H.

Address: <TAUDn_base> + 044_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDn RDT15	TAUDn RDT14	TAUDn RDT13	TAUDn RDT12	TAUDn RDT11	TAUDn RDT10	TAUDn RDT09	TAUDn RDT08	TAUDn RDT07	TAUDn RDT06	TAUDn RDT05	TAUDn RDT04	TAUDn RDT03	TAUDn RDT02	TAUDn RDT01	TAUDn RDT00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 33.28 TAUDnRDT Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnRDTm	Triggers a simultaneous rewrite enabling state. 0: No function 1: The simultaneous rewrite enabling flag (TAUDnRSFm) is set to 1. The system waits for a simultaneous rewrite trigger. These bits only apply when: • TAUDnRDE.TAUDnRDEm = 1

33.3.4.6 TAUDnRSF — TAUDn Channel Reload Status Register

This flag register indicates simultaneous rewrite status.

Access: This register is a read-only register that can be read in 16-bit units.

Address: <TAUDn_base> + 048_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 33.29 TAUDnRSF Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnRSFm	Indicates simultaneous rewrite status. 0: Indicates that simultaneous rewrite has been completed due to the generation of simultaneous rewrite trigger. 1: Indicates that the system waits for a simultaneous rewrite trigger in the simultaneous rewrite enabling state (TAUDnRDTm = 1).

33.3.5 Details of TAUDn Output Registers

33.3.5.1 TAUDnTOE — TAUDn Channel Output Enable Register

This register enables/disables the independent channel output mode controlled by software.

Access: This register can be read or written in 16-bit units.

Address: <TAUDn_base> + $5C_H$

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnTOE15	TAUDnTOE14	TAUDnTOE13	TAUDnTOE12	TAUDnTOE11	TAUDnTOE10	TAUDnTOE09	TAUDnTOE08	TAUDnTOE07	TAUDnTOE06	TAUDnTOE05	TAUDnTOE04	TAUDnTOE03	TAUDnTOE02	TAUDnTOE01	TAUDnTOE00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 33.30 TAUDnTOE Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnTOEm	Enables or disables the independent channel output function. 0: Disables the independent timer output function (controlled by software). 1: Enables the independent timer output function.

33.3.5.2 TAUDnTO — TAUDn Channel Output Register

This register specifies and reads a TAUDnTTOUTm level.

Access: This register can be read or written in 16-bit units.

Address: <TAUDn_base> + 58_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnTO15	TAUDnTO14	TAUDnTO13	TAUDnTO12	TAUDnTO11	TAUDnTO10	TAUDnTO09	TAUDnTO08	TAUDnTO07	TAUDnTO06	TAUDnTO05	TAUDnTO04	TAUDnTO03	TAUDnTO02	TAUDnTO01	TAUDnTO00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 33.31 TAUDnTO Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnTOm	Specifies and reads a TAUDnTTOUTm level. 0: Low level 1: High level Only TAUDnTOm bits for which Independent Channel Output function is disabled (TAUDnTOEm = 0) can be written.

33.3.5.3 TAUDnTOM — TAUDn Channel Output Mode Register

This register specifies the output mode of each channel.

Access: This register can be read or written in 16-bit units. Writable only while the counter is stopped (TAUDnTE.TAUDnTEm = 0).

Address: <TAUDn_base> + 248_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDn TOM15	TAUDn TOM14	TAUDn TOM13	TAUDn TOM12	TAUDn TOM11	TAUDn TOM10	TAUDn TOM09	TAUDn TOM08	TAUDn TOM07	TAUDn TOM06	TAUDn TOM05	TAUDn TOM04	TAUDn TOM03	TAUDn TOM02	TAUDn TOM01	TAUDn TOM00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 33.32 TAUDnTOM Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnTOMm	Specifies an output mode. 0: Independent channel operation 1: Synchronous channel operation

33.3.5.4 TAUDnTOC — TAUDn Channel Output Configuration Register

This register specifies the output mode of each channel in combination with TAUDnTOMm.

Access: This register can be read or written in 16-bit units. Writable only while the counter is stopped (TAUDnTE.TAUDnTEm = 0).

Address: <TAUDn_base> + $24C_H$

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDn TOC15	TAUDn TOC14	TAUDn TOC13	TAUDn TOC12	TAUDn TOC11	TAUDn TOC10	TAUDn TOC09	TAUDn TOC08	TAUDn TOC07	TAUDn TOC06	TAUDn TOC05	TAUDn TOC04	TAUDn TOC03	TAUDn TOC02	TAUDn TOC01	TAUDn TOC00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 33.33 TAUDnTOC Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnTOCm	Specifies an output mode. 0: Operating mode 1 1: Operating mode 2 As listed below, the output mode depends on the setting of TAUDnTOM.TAUDnTOMm.

TAUDn TOMm	TAUDn TOCm	Functional Description
0	0	Toggle mode: Toggle operation is conducted when INTTAUDnIm occurs.
0	1	Set/reset mode: Set when INTTAUDnIm occurs at the beginning of count operation, and reset when INTTAUDnIm is caused by detection of a match between TAUDnCNTm and TAUDnCDRm.
1	0	Synchronous channel operating mode 1: Set when INT occurs on master channels, and reset when INT occurs on slave channels.
1	1	Synchronous channel operating mode 2: Set when INTTAUDnIm occurs in count-down status, and reset when INTTAUDnIm occurs in count-up status.

33.3.5.5 TAUDnTOL — TAUDn Channel Output Active Level Register

This register specifies the output logic of channel output bit (TAUDnTO.TAUDnTOm).

Access: This register can be read or written in 16-bit units.

Address: <TAUDn_base> + 040_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDn TOL15	TAUDn TOL14	TAUDn TOL13	TAUDn TOL12	TAUDn TOL11	TAUDn TOL10	TAUDn TOL09	TAUDn TOL08	TAUDn TOL07	TAUDn TOL06	TAUDn TOL05	TAUDn TOL04	TAUDn TOL03	TAUDn TOL02	TAUDn TOL01	TAUDn TOL00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 33.34 TAUDnTOL Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnTOLm	Specifies the output logic of channel m output bit (TAUDnTO.TAUDnTOm). 0: Positive logic (active high) 1: Negative logic (active low) The setting of these bits applies to all channel output modes other than independent channel output mode controlled by software and independent channel output mode 1 and independent channel output mode 1 with real-time output.

33.3.6 Details of TAUDn Dead Time Output Registers

33.3.6.1 TAUDnTDE — TAUDn Channel Dead Time Output Enable Register

This register enables/disables the dead time operation of every channel.

Access: This register can be read or written in 16-bit units. Writable only while the counter is stopped (TAUDnTE.TAUDnTEm = 0).

Address: <TAUDn_base> + 250_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDn TDE15	TAUDn TDE14	TAUDn TDE13	TAUDn TDE12	TAUDn TDE11	TAUDn TDE10	TAUDn TDE09	TAUDn TDE08	TAUDn TDE07	TAUDn TDE06	TAUDn TDE05	TAUDn TDE04	TAUDn TDE03	TAUDn TDE02	TAUDn TDE01	TAUDn TDE00

Table 33.35 TAUDnTDE Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnTDEm	Enables/disables the dead time control operation of channel m. 0: Disables dead time operation 1: Enables dead time operation. The same setting should be made for both even and odd slave channels in pairs. These bit settings are applied when: • TAUDnTOE.TAUDnTOEm, TAUDnTOM.TAUDnTOMm, TAUDnTOC.TAUDnTOCm = 1

33.3.6.2 TAUDnTDM — TAUDn Channel Dead Time Output Mode Register

This register specifies the timing to add dead time during dead time output.

Access: This register can be read or written in 16-bit units. Writable only while the counter is stopped (TAUDnTE.TAUDnTEm = 0).

Address: <TAUDn_base> + 254_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 33.36 TAUDnTDM Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnTDMm	Specifies the timing to add dead time during dead time output. 0: When detecting the duty cycle of an upper even channel (duty dead time output). 1: When detecting the TIN input edge of a lower odd channel (one-phase dead time output). The same setting should be made for both even and odd slave channels in pairs. These bit settings are applied when: • TAUDnTOE.TAUDnTOEm, TAUDnTOM.TAUDnTOMm, TAUDnTOC.TAUDnTOCm, TAUDnTDE.TAUDnTDEm = 1

33.3.6.3 TAUDnTDL — TAUDn Channel Dead Time Output Level Register

This register selects a phase in which dead time is added.

Access: This register can be read or written in 16-bit units.

Address: <TAUDn_base> + 54_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 33.37 TAUDnTDL Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnTDLm	Selects a phase in which dead time is added. 0: Normal phase 1: Reverse phase These bit settings are applied when: • TAUDnTOE.TAUDnTOEm, TAUDnTOM.TAUDnTOMm, TAUDnTOC.TAUDnTOCm, TAUDnTDE.TAUDnTDEm = 1

33.3.7 Details of TAUDn Real-time/Modulation Output Registers

33.3.7.1 TAUDnTRE — TAUDn Channel Real-time Output Enable Register

This register enables/disables real-time output.

Access: This register can be read or written in 16-bit units. Writable only while TAUDnTE.TAUDnTEm = 0.

Address: <TAUDn_base> + 258_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDn TRE15	TAUDn TRE14	TAUDn TRE13	TAUDn TRE12	TAUDn TRE11	TAUDn TRE10	TAUDn TRE09	TAUDn TRE08	TAUDn TRE07	TAUDn TRE06	TAUDn TRE05	TAUDn TRE04	TAUDn TRE03	TAUDn TRE02	TAUDn TRE01	TAUDn TRE00

Table 33.38 TAUDnTRE Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnTREm	Enables or disables real-time output of channel m. 0: Disables real-time output 1: Enables real-time output. These bit settings are applied only when TAUDnTOE.TAUDnTOEm = 1. When TAUDnTRE.TAUDnTREm = 0, TAUDnTTOUT.TAUDnTTOUTm is not affected by real-time output. When TAUDnTRE.TAUDnTREm = 1, TAUDnTTOUTm outputs the value of real-time output bit TAUDnTRO.TAUDnTROm in response to a timer operation.

33.3.7.2 TAUDnTRC — TAUDn Channel Real-time Output Control Register

This register controls the real-time output trigger of each channel.

Access: This register can be read or written in 16-bit units. Writable only while TAUDnTE.TAUDnTEm = 0.

Address: <TAUDn_base> + $25C_H$

Value after reset: 0000_H

Table 33.40 TAUDnTRO Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnTROm	Sets a value which is output to TAUDnTTOUTm. 0: Low 1: High TAUDnTROm value is not output to TAUDnTTOUTm when TAUDnTRE.TAUDnTREm = 0, even if a real-time output trigger occurs.

33.3.7.4 TAUDnTME — TAUDn Channel Modulation Output Enable Register

This register enables/disables modulation output for timer output and real-time output.

Access: This register can be read or written in 16-bit units.

Address: <TAUDn_base> + 050_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnTME15	TAUDnTME14	TAUDnTME13	TAUDnTME12	TAUDnTME11	TAUDnTME10	TAUDnTME09	TAUDnTME08	TAUDnTME07	TAUDnTME06	TAUDnTME05	TAUDnTME04	TAUDnTME03	TAUDnTME02	TAUDnTME01	TAUDnTME00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 33.41 TAUDnTME Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnTMEm	Enables/disables modulation output for timer output and real-time output of channel m. 0: Disables modulation 1: Enables modulation These bit settings are applied only when TAUDnTOE.TAUDnTOEm and TAUDnTRE.TAUDnTREm = 1.

33.4 Operating Procedure

The following lists the general operation procedure for the TAUDn.

After reset release, the operation of each channel is stopped. Clock supply is started and writing to each register is enabled. All circuits and registers of all channels are initialized. The control register of TAUDnTTOUTm is also initialized and outputs a low level.

(1) Set the TAUDnTPS and TAUDnBRS registers to specify the clock frequency of CK0 to CK3.

(2) Configure the desired TAUDn function:
- Set the operation mode
- Set the channel output mode
- Set any other control bits

(3) Enable the counter by setting the TAUDnTS.TAUDnTSm bit to 1.
The counter starts to count immediately, or when an appropriate trigger is detected, depending on the bit settings.

(4) If desired, and if possible for the configured function, stop the counter or perform a forced restart operation during count operation. The counter can be stopped by setting the TAUDnTT.TAUDnTTm bit to 1. The counter can be forcibly restarted by setting the TAUDnTS.TAUDnTSm bit to 1.

(5) Stop the function by setting the TAUDnTT.TAUDnTTm bit to 1.

NOTES

1. A detailed description of the required control bits and the operation of the individual functions are given in **Section 33.12, Independent Channel Operation Functions** and **Section 33.15, Synchronous Channel Operation Functions**.
2. The function can be changed while the counter is stopped (TAUDnTE.TAUDnTEm = 0).

33.5 Concepts of Synchronous Channel Operation

The synchronous channel operation function is implemented using a combination of channel groups (consisted of master and slave channels). Several rules apply to the settings of channels. These rules are detailed in **Section 33.5.1, Rules of Synchronous Channel Operation**.

Two special features for synchronous channel operation are detailed in the following:

- **Section 33.5.2, Simultaneous Start and Stop of Synchronous Channel Counters**
- **Section 33.6, Simultaneous Rewrite**

33.5.1 Rules of Synchronous Channel Operation

Number of master and slave channels

- Only even channels (CH0, CH2, CH4, …) can be set as master channels. Any channel apart from CH0 can be set as a slave channel.
- Only channels lower than the master channel can be set as slave channels, and multiple slave channels can be set for one master channel.
  Example: If CH2 is a master channel, CH3 and the lower channels (CH3, CH4, CH5, …) can be set as slave channels.
- If multiple master channels are used, slave channels cannot cross the master channels.
  Example: If CH0 and CH4 are master channels, CH1 to CH3 can be set as slave channels for CH0, but CH5 to CH15 cannot.

Operation clock

- The same operation clock must be set for the master channel and the synchronized slave channel. This is achieved by setting the TAUDnCMORm.TAUDnCKS[1:0] bits of the slave and master channel.

The basic concepts of master/slave usage and operation clocks are illustrated in **Figure 33.3, Grouping of Channels and Assignment of Count Clocks**.

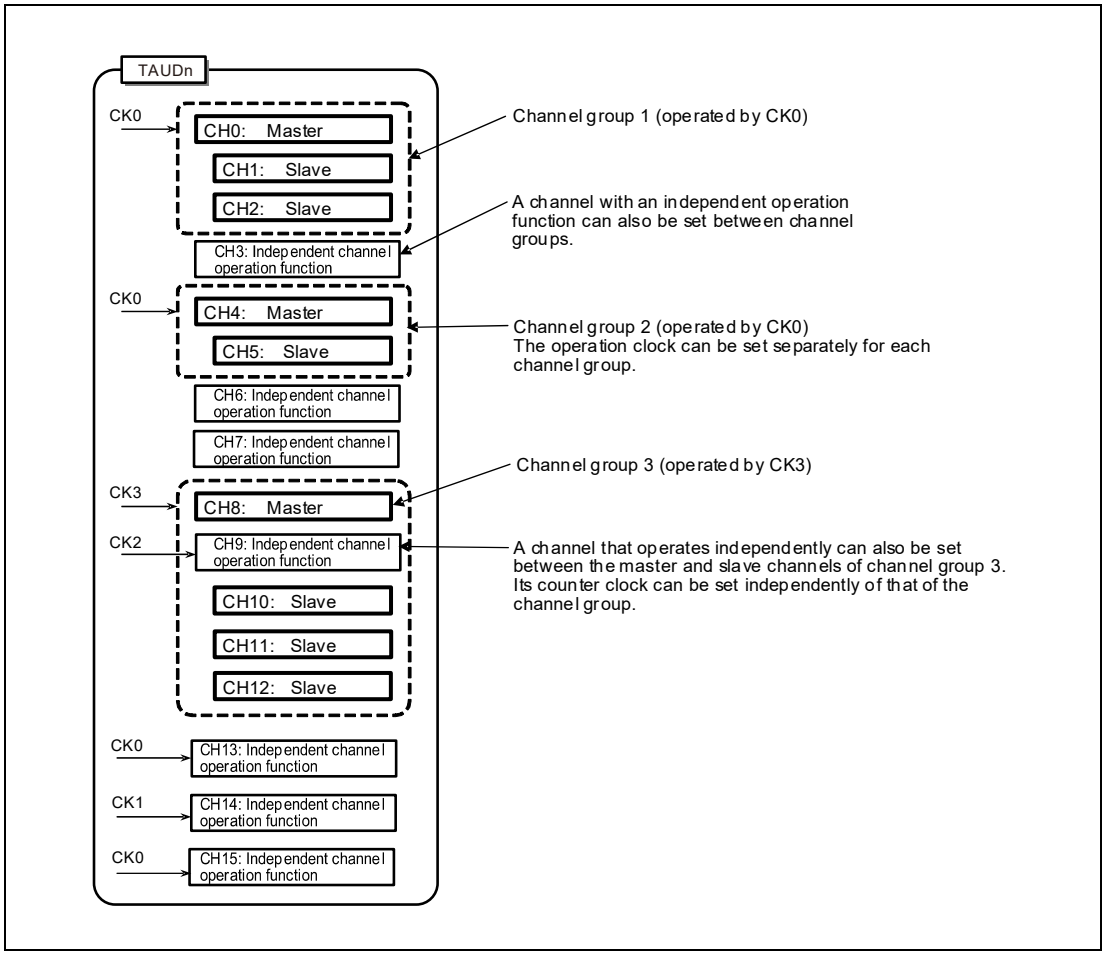

Figure 33.3 Grouping of Channels and Assignment of Count Clocks

Control trigger signal for master/slave channels

- Master channels can output control trigger signals to slave channels.
- Slave channels can use control trigger signals from master channels but cannot output control trigger signals for their own to lower channels.
- Master channels cannot use control trigger signals from upper master channels.

33.5.2 Simultaneous Start and Stop of Synchronous Channel Counters

Channels that are operated synchronously can be started and stopped simultaneously within the same unit and between the units.

33.5.2.1 Simultaneous Start and Stop within the Same Unit

- To simultaneously start synchronized channels, the TAUDnTS.TAUDnTSm bits of the channels should be set at the same time.
- To simultaneously stop synchronized channels, the TAUDnTT.TAUDnTTm bits of the channels should be set at the same time.

Setting to the TAUDnTS.TAUDnTSm bits to 1 also sets the corresponding TAUDnTE.TAUDnTEm bits to 1, enabling counting. The count start timing depends on operating mode.

33.5.2.2 Simultaneous Start between the Units

Counters in different units can also be started simultaneously if the corresponding counters are enabled before receiving the simultaneous trigger signal.

For details about how to perform simultaneous start between the units, **41.2.3.1, Simultaneous Start Trigger Function**.

33.6 Simultaneous Rewrite

33.6.1 Overview of Operations

Simultaneous rewrite describes the ability to change the compare/start value and the output logic of multiple channels at the same time.

The corresponding data and control registers (TAUDnCDRm and TAUDnTOLm) can nevertheless be written at any time. The new value does not affect the counter operation or the output signal until simultaneous rewrite is triggered.

Simultaneous rewrite can be triggered by:

- The counter on the master channel or upper channel (depending on the selected operation mode) reaching a certain value
- INTTAUDnIm being issued on the upper channel specified by TAUDnRDC.TAUDnRDCm

There are four methods for simultaneous rewrite. These are listed in **Table 33.42, Simultaneous Rewrite Methods and when They are Triggered**, along with how to specify them and when they cause simultaneous rewrite to be triggered.

Table 33.42 Simultaneous Rewrite Methods and when They are Triggered

Method	Simultaneous Rewrite Triggered when	TAUDnRDE. TAUDnRDEm	TAUDnRDS. TAUDnRDSm	TAUDnRDM. TAUDnRDMm
—	No simultaneous rewrite	0	0	0
A	The master channel (re)starts counting	1	0	0
B	Counting is started in the master channel. The master channel starts counting down at the peak of triangular cycle of the corresponding slave channel.	1	0	1
C1	INTTAUDnIm is generated on an upper channel specified by TAUDnRDC.TAUDnRDCm	1	1	0/1
C2	INTTAUDnIm is generated on an upper channel specified by TAUDnRDC.TAUDnRDCm that in turn is triggered by an external signal	1	1	0/1

Table 33.43 lists which of these four methods is available for each channel operation function. For more information about the individual channel operation functions, see the corresponding sections in **Section 33.14, Independent Channel Simultaneous Rewrite Functions**, **Section 33.15, Synchronous Channel Operation Functions**, and **Section 33.16, Synchronous Non-Complementary and Complementary Modulation Output Functions**.

Table 33.43 Channel Functions and the Methods They Use for Simultaneous Rewrite

33.6.2 How to Control Simultaneous Rewrite

Figure 33.4, General Procedure for Simultaneous Rewrite shows the general procedure for simultaneous rewrite. The three main blocks (initial settings, start and counter count operation, and simultaneous rewrite) are explained afterwards.

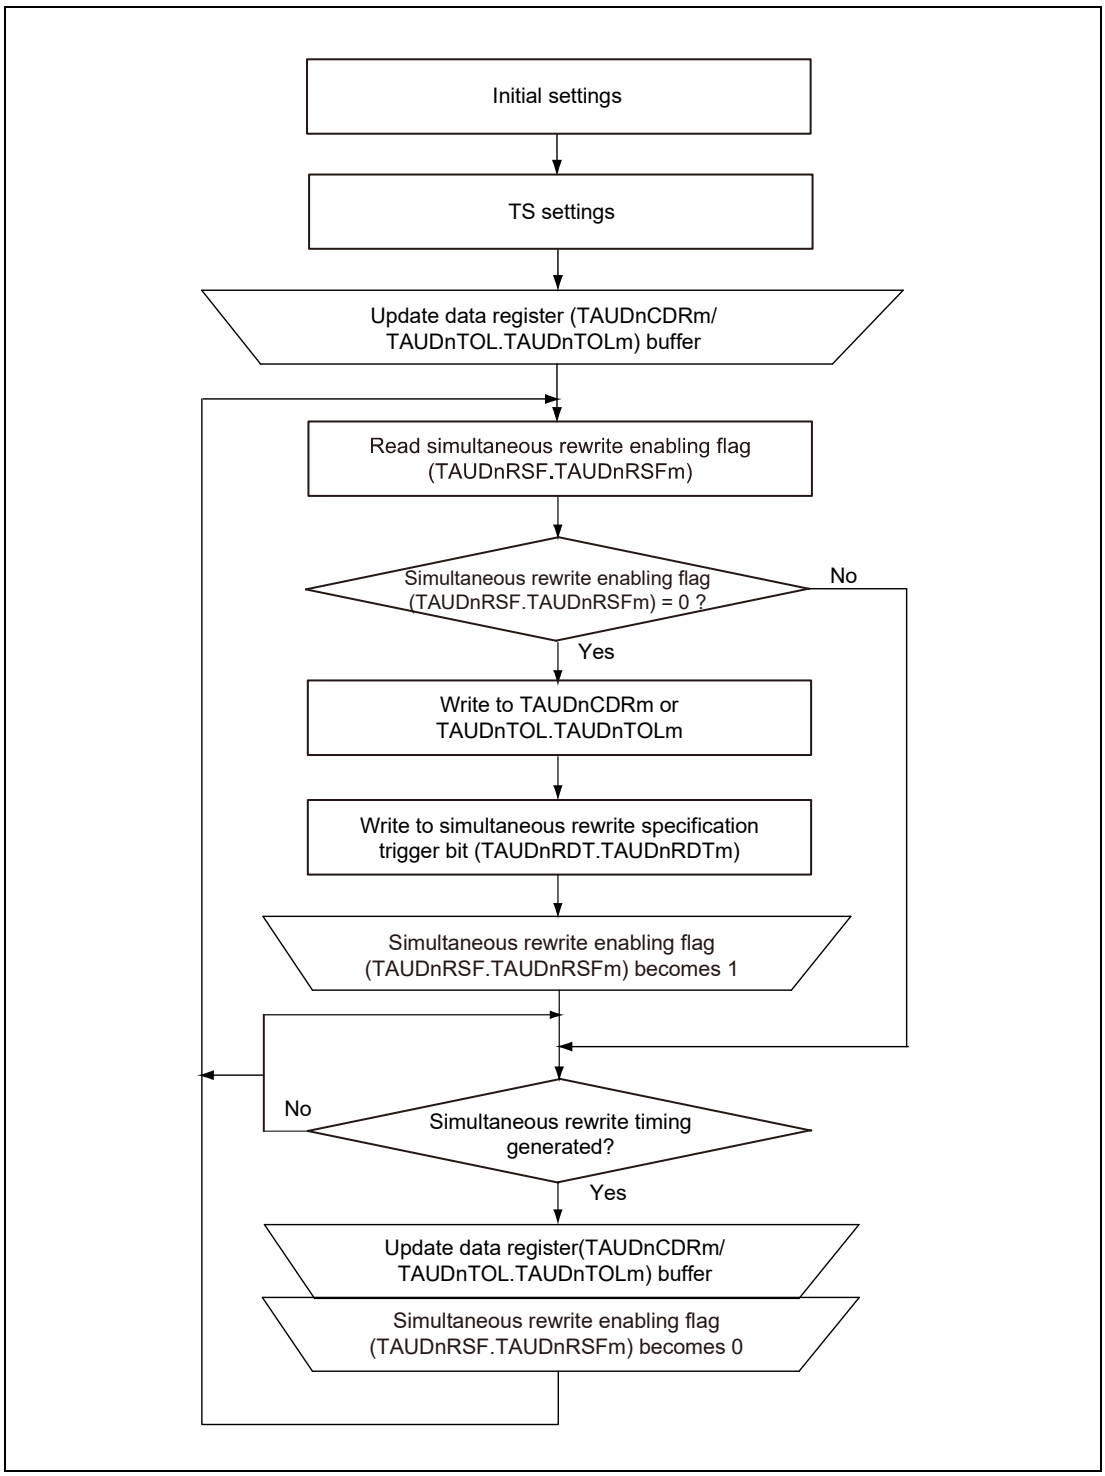

Figure 33.4 General Procedure for Simultaneous Rewrite

33.6.2.1 Initial Settings

- To enable simultaneous rewrite in channel m, set TAUDnRDE.TAUDnRDEm = 1
- To select the type of simultaneous rewrite, set TAUDnRDM.TAUDnRDMm and TAUDnRDS.TAUDnRDSm according to the values listed in **Table 33.42, Simultaneous Rewrite Methods and when They are Triggered**.
- Specify a simultaneous rewrite trigger channel by using TAUDnRDC.TAUDnRDCm. (Prerequisite: TAUDnRDS.TAUDnRDSm has been set to the upper channel.)

33.6.2.2 Start Counter and Count Operation

- To start all the TAUDnCNTm counters of the channel group, set the corresponding TAUDnTS.TAUDnTSm bits to 1. The values of TAUDnTOL.TAUDnTOLm and the data registers (TAUDnCDRm) are loaded into the corresponding TAUDnTOL.TAUDnTOLm buffer (TAUDnTOL.TAUDnTOLm buf) and data buffer registers (TAUDnCDRm buf) and the counters start.
- Setting the reload data trigger bit (TAUDnRDT.TAUDnRDTm) to 1 sets the reload flag (TAUDnRSF.TAUDnRSFm) to 1, enabling simultaneous rewrite. TAUDnRSF.TAUDnRSFm remains set to 1 until simultaneous rewrite is completed.
- When the specified trigger for simultaneous rewrite is detected, the TAUDnRSF.TAUDnRSFm bit is checked to see if simultaneous rewrite is enabled (TAUDnRSF.TAUDnRSFm = 1). If it is, simultaneous rewrite is carried out. Otherwise the simultaneous rewrite is not carried out and waits for the next trigger detection.

33.6.2.3 Simultaneous Rewrite

- When simultaneous rewrite is enabled (TAUDnRSF.TAUDnRSFm = 1) and the simultaneous rewrite trigger is detected, the current values of the data registers are copied to their buffers. These values are then loaded into the corresponding counters and are applied the next time the counter starts or restarts.
- When simultaneous rewrite is complete, the TAUDnRSF.TAUDnRSFm bit is set to 0, and the system awaits the next simultaneous rewrite trigger.

33.6.3 Other General Rules of Simultaneous Rewrite

The following rules also apply:

- TAUDnRDE.TAUDnRDEm, TAUDnRDS.TAUDnRDSm, TAUDnRDM.TAUDnRDMm, and TAUDnRDC.TAUDnRDCm cannot be changed while the counter is in operation (TAUDnTE.TAUDnTEm = 1).
- TAUDnTOL.TAUDnTOLm can only be rewritten during operation with PWM output function or triangle PWM output function. For all other output functions, TAUDnTOL.TAUDnTOLm should be written before the counter starts. If it is rewritten while any other function is used, TAUDnTTOUTm outputs an invalid wave.
- When an upper channel is used as a channel issuing the simultaneous rewrite trigger (TAUDnRDS.TAUDnRDSm = 1), the TAUDnRDC.TAUDnRDCm bit controls all the lower channels. This means that if the TAUDnRDC.TAUDnRDCm bits of CH2 and CH7 are set to 1 and the TAUDnRDC.TAUDnRDCm bits of other channels are set to 0, CH2 and CH7 serve as simultaneous rewrite trigger generation channels. CH2 controls the lower channels CH3 to CH6, and CH7 controls the lower channels CH8 to CH15.
- If simultaneous rewrite is enabled and an upper channel is selected for the simultaneous rewrite trigger (TAUDnRDE.TAUDnRDEm and TAUDnRDS.TAUDnRDSm = 1) but no upper channel is set (TAUDnRDC.TAUDnRDC[15:0] = 0), simultaneous rewrite cannot take place.

33.6.4 Types of Simultaneous Rewrite

In the following section, the four simultaneous rewrite methods are explained using timing diagrams.

33.6.4.1 Simultaneous Rewrite when the Master Channel (Re)starts Counting (Method A)

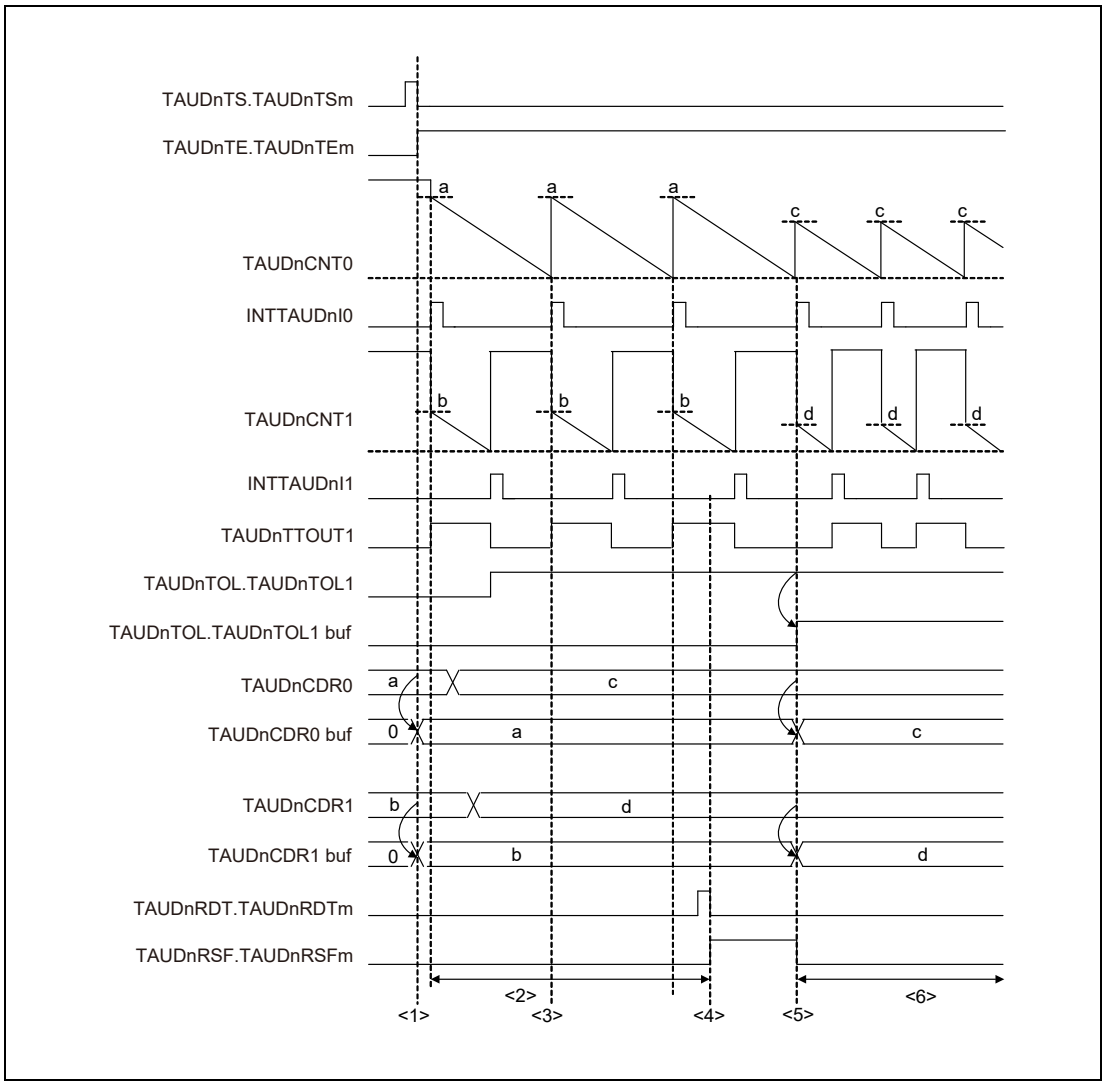

Figure 33.5 Simultaneous Rewrite when the Master Channel (Re)starts Counting

Setting:

CH0 is the master channel, which starts counting down, and CH1 represents an arbitrary slave channel. The simultaneous rewrite method A is applied.

Description:

(1) When TAUDnTS.TAUDnTSm is set to 1, TAUDnCDRm value is copied to the TAUDnCDRm buffer and TAUDnTOL.TAUDnTOLm value is copied to the TAUDnTOL.TAUDnTOLm buffer.

(2) The TAUDnCDRm and TAUDnTOL.TAUDnTOLm registers can be written at any time.

(3) CH0 restarts counting, but simultaneous rewrite does not occur because it is disabled (TAUDnRSF.TAUDnRSFm = 0)

(4) The reload data trigger bit (TAUDnRDT.TAUDnRDTm) is set to 1 which sets the status flag (TAUDnRSF.TAUDnRSFm = 1), enabling simultaneous rewrite.

(5) Because simultaneous rewrite is enabled, it is triggered when CH0 restarts counting. The TAUDnCDRm value is loaded into the TAUDnCDRm buffer and the TAUDnTOL.TAUDnTOLm value is loaded into the TAUDnTOL.TAUDnTOLm buffer.

(6) The counters count down and await the next simultaneous rewrite trigger. The values of TAUDnCDRm and TAUDnTOL.TAUDnTOLm can be changed again.

33.6.4.2 Simultaneous Rewrite at the Peak of a Triangular Wave of Slave Channel (Method B)

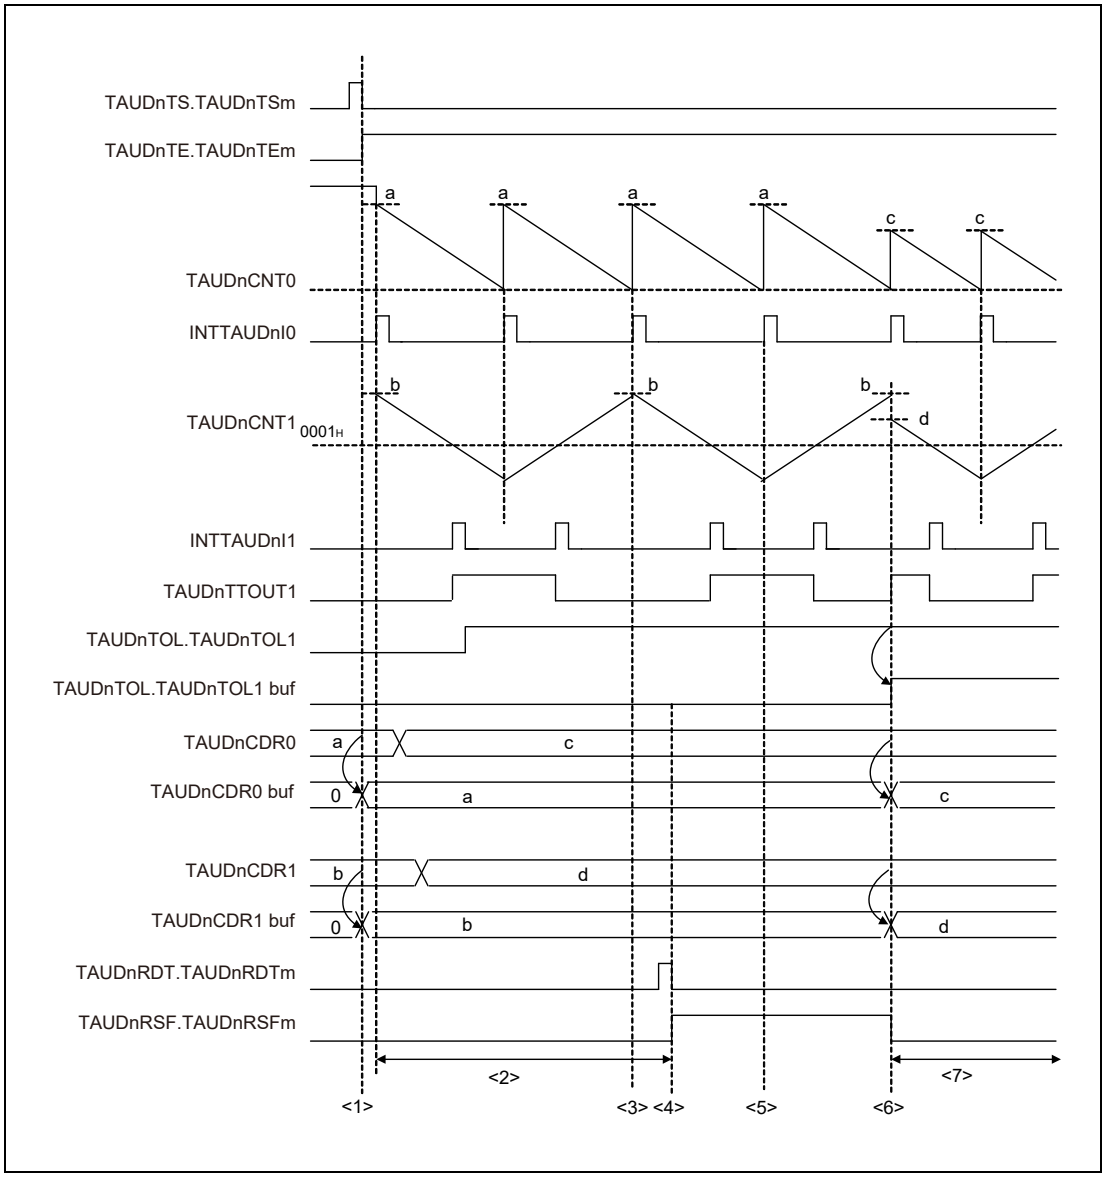

Figure 33.6 Simultaneous Rewrite at the Peak of a Triangular Wave of Slave Channel

Setting:

CH0 is the master channel which performs counting down, and CH1 represents an arbitrary slave channel. The simultaneous rewrite method B is applied.

Description:

(1) When TAUDnTS.TAUDnTSm is set to 1, TAUDnCDRm value is copied to the TAUDnCDRm buffer.

(2) The TAUDnCDRm and TAUDnTOL registers can be written at any time.

(3) Simultaneous rewrite does not occur because it is disabled (TAUDnRSF.TAUDnRSFm = 0).

(4) The reload data trigger bit (TAUDnRDT.TAUDnRDTm) is set to 1 which sets the status flag (TAUDnRSF.TAUDnRSFm = 1), enabling simultaneous rewrite.

(5) Simultaneous rewrite does not take place at the bottom of the triangular cycle.

(6) Simultaneous rewrite takes place at the top of the triangular cycle. The TAUDnCDRm value is loaded into the TAUDnCDRm buffer, the TAUDnTOL.TAUDnTOLm value is loaded into the TAUDnTOL.TAUDnTOLm buffer.

(7) The counters count down and await the next simultaneous rewrite trigger. The values of TAUDnCDRm and TAUDnTOL.TAUDnTOLm can be changed again.

33.6.4.3 Simultaneous Rewrite when INTTAUDnIm is Generated on an Upper Channel Specified by TAUDnRDC.TAUDnRDCm (Method C1)

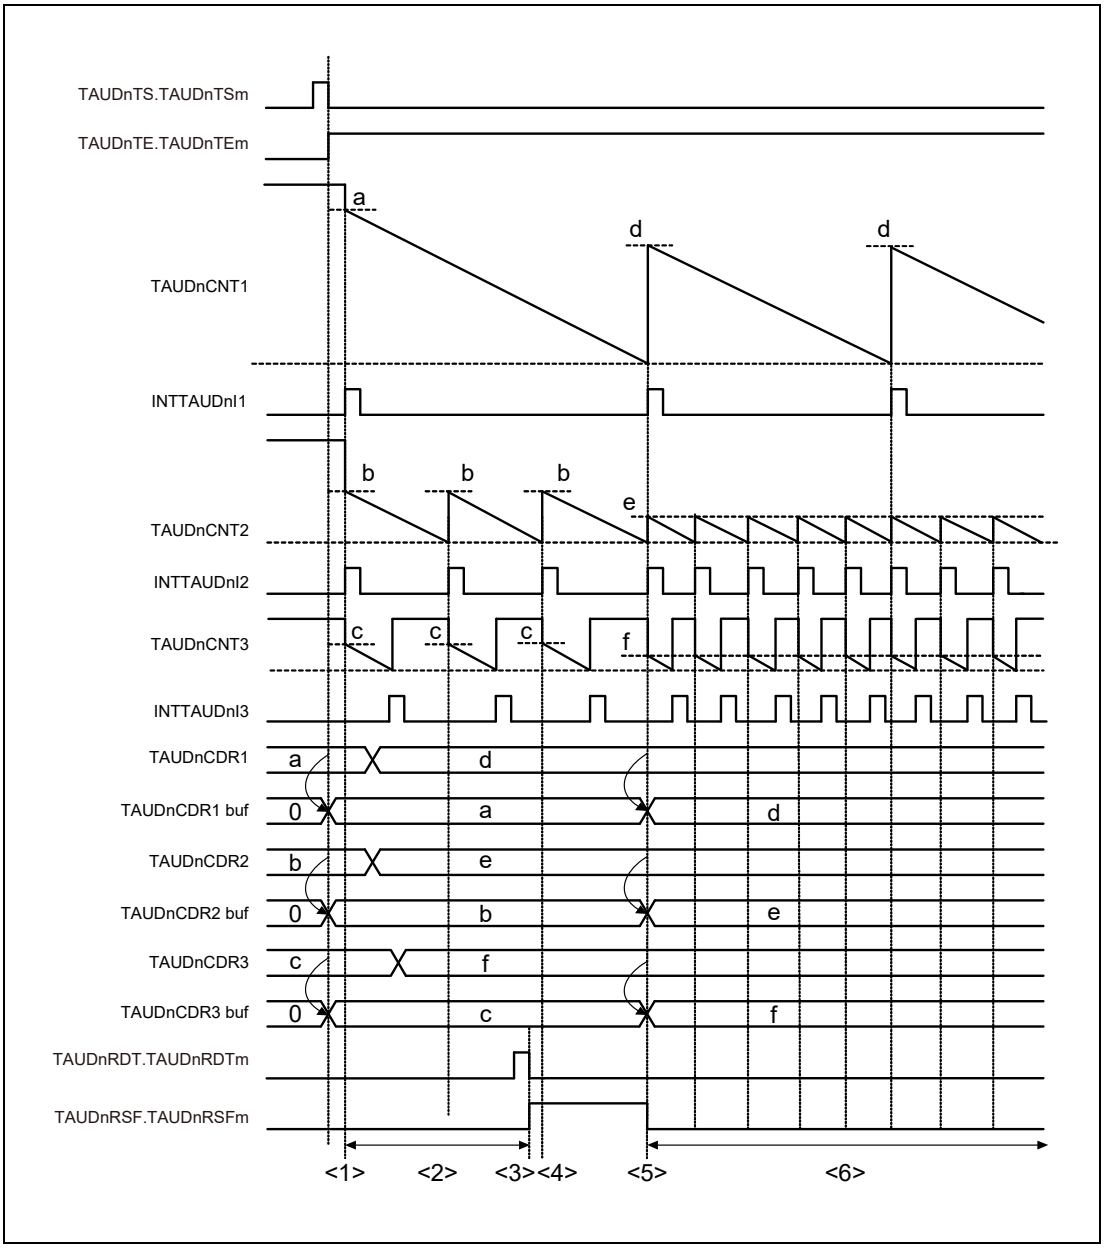

Figure 33.7 Simultaneous Rewrite When INTTAUDnIm Is Generated on an Upper Channel Specified by TAUDnRDC.TAUDnRDCm

Setting:

CH1 is an upper channel which performs counting down, CH2 is a master channel, and CH3 is the slave channel. The simultaneous rewrite method C1 is applied. The TAUDnRDC register specifies a channel which generates simultaneous rewrite triggers.

Description:

(1) When TAUDnTS.TAUDnTSm is set to 1, TAUDnCDRm value is copied to the TAUDnCDRm buffer.

(2) The TAUDnCDRm register is always ready to write.

(3) By setting the reload data trigger bit (TAUDnRDT.TAUDnRDTm) to 1, the status flag is set (TAUDnRSF.TAUDnRSFm = 1) to enable simultaneous rewrite.

(4) Simultaneous rewrite is triggered only by a CH1 interrupt. Therefore, simultaneous rewrite is not conducted even if enabled.

(5) Simultaneous rewrite is triggered by INT1 which is generated when counter 1 reaches 0000_H. The TAUDnCDRm values are loaded into the corresponding TAUDnCDRm buffers.

(6) The counter counts down and awaits the next simultaneous rewrite trigger. The values of the TAUDnCDRm registers can be rechanged.

33.6.4.4 Simultaneous Rewrite when INTTAUDnIm is Generated on an Upper Channel Specified by TAUDnRDC.TAUDnRDCm that in Turn is Triggered by an External Signal (Method C2)

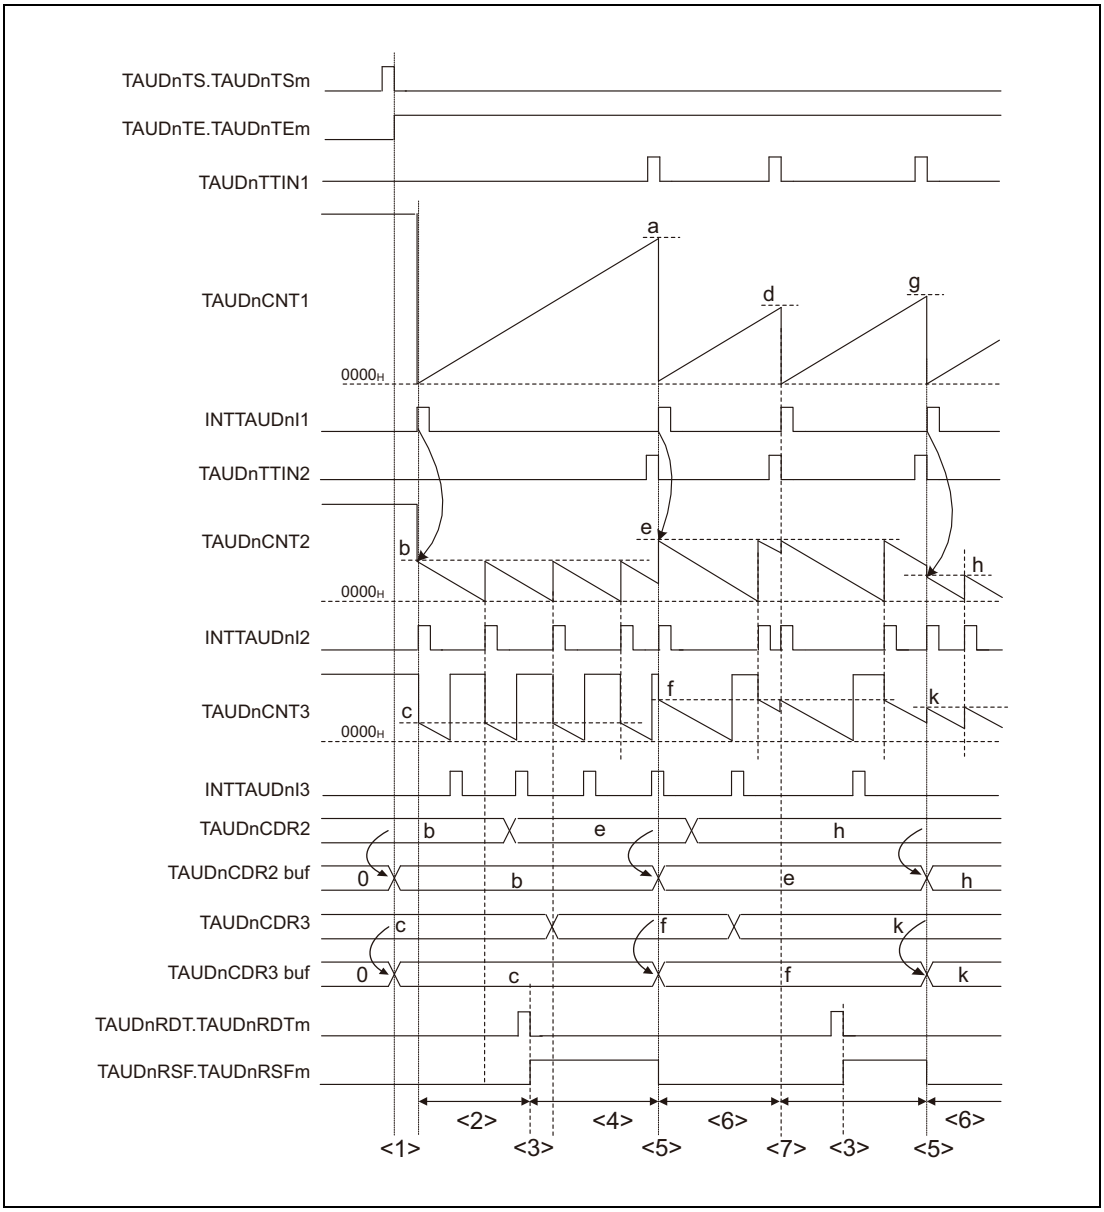

Figure 33.8 Simultaneous Rewrite when INTTAUDnIm is Generated on an Upper Channel Specified by TAUDnRDC.TAUDnRDCm that in Turn is Triggered by an External Signal

Setting:

CH1 is an upper channel which performs counting up, CH2 is a master channel, and CH3 is the slave channel. The synchronous channel operation method C2 is applied. The TAUDnRDC register specifies which upper channel is monitored for an INTTAUDnIm trigger.

Description:

(1) When TAUDnTS.TAUDnTSm is set to 1, TAUDnCDRm value is copied to the TAUDnCDRm buffer. However, as TAUDnCDR1 operates in capture mode, TAUDnCDR1 value is not copied to the TAUDnCDR1 buffer.

(2) The TAUDnCDRm register is always ready to write.

(3) By setting the reload data trigger bit (TAUDnRDT.TAUDnRDTm) to 1, the status flag is set (TAUDnRSF.TAUDnRSFm = 1) to enable simultaneous rewrite.

(4) Simultaneous rewrite is triggered only by a CH1 interrupt. Therefore, simultaneous rewrite is not conducted even if enabled.

(5) Simultaneous rewrite is triggered by INT1 which is caused by external signal TIN1. The TAUDnCDRm values are written to the corresponding TAUDnCDRm buffers.

(6) The counters count down and await the next simultaneous rewrite trigger. The values of the TAUDnCDRm registers can be changed again.

(7) An external signal occurs at TIN2 but simultaneous rewrite does not take place because it is disabled (TAUDnRSF.TAUDnRSFm = 0).

33.7 Channel Output Modes

The output of the TAUDnTTOUTm pin can be controlled in two ways, the latter of which can be further split into individual modes.

- By software (TAUDnTOE.TAUDnTOEm = 0)
  When controlled by software, the value written in the output register bit (TAUDnTO.TAUDnTOm) is sent to the output pin (TAUDnTTOUTm).
- By TAUD signals (TAUDnTOE.TAUDnTOEm = 1)
  When controlled by TAUD signals, the output level of TAUDnTTOUTm is set or reset or toggled by internal signals. The value of TAUDnTO.TAUDnTOm is updated accordingly to reflect the value of TAUDnTTOUTm.
  - Independently (TAUDnTOM.TAUDnTOMm = 0)
    In case of independent operation, the output of the TAUDnTTOUTm pin is only affected by settings of channel m. Therefore, independent channel operation should be selected (TAUDnTOM.TAUDnTOMm = 0).
  - Synchronously (TAUDnTOM.TAUDnTOMm = 1)
    In case of synchronous operation, the output of the TAUDnTTOUTm pin is affected by settings of channel m and those of other channels. Therefore, synchronous channel operation should be selected for all synchronized channels (TAUDnTOM.TAUDnTOMm = 1).

The TAUDnTO.TAUDnTOm bit can always be read to determine the current value of TAUDnTTOUTm, regardless of whether the pin is controlled by software, operated independently, or operated synchronously.

Control bits

The settings of the control bits required to select a specific channel output mode are listed in **Table 33.44, Channel Output Modes**.

The channel output modes are described in details below.

- **Section 33.7.2, Channel Output Modes Controlled Independently by TAUDn Signals**
- **Section 33.7.3, Channel Output Modes Controlled Synchronously by TAUDn Signals**

Batch operation of TAUDnTOm bit

Whether a set value is reflected to the TAUDnTOm bit or not is controlled by the TAUDnTOE.TAUDnTOEm bit.

The TAUDnTOm setting is written only to the bit (channel) set with TAUDnTOE.TAUDnTOEm bit = 0 when a write to the TAUDnTO register is attempted. No TAUDnTOm setting is reflected to the bit (channel) set with TAUDnTOE.TAUDnTOEm bit = 1.

NOTE

TAUDnTO.TAUDnTOm bit is placed so that its bit number corresponds to a channel number.

Output logic

Positive logic or negative logic of the output is specified by control bit TAUDnTOL.TAUDnTOLm.

The value of TAUDnTOL.TAUDnTOLm bit should be set before the counter is started. It can only be changed during operation with PWM output function or triangle PWM output function. Otherwise, changes to TAUDnTOL.TAUDnTOLm result in an undefined TAUDnTTOUTm signal output.

See **Section 33.6, Simultaneous Rewrite**.

The various channel output modes and the channel output control bits are listed in **Table 33.44**.

Table 33.44 Channel Output Modes

Channel Output Mode	TAUDnTOE.TAUDnTOEm	TAUDnTOM.TAUDnTOMm	TAUDnTOC.TAUDnTOCm	TAUDnTDE.TAUDnTDEm	TAUDnTRE.TAUDnTREm	TAUDnTME.TAUDnTMEm	TAUDnTDM.TAUDnTDMm
By software							
Independent channel output mode controlled by software	0	X					
By TAUD signals, independently							
Independent channel output mode 1	1	0	0	0	0	0	0
with real-time output					1		
Independent channel output mode 2			1		0		
By TAUD signals, synchronously							
Synchronous channel output mode 1	1	1	0	0	0	0	0
with non-complementary modulation output					1	X	
Synchronous channel output mode 2			1	0	0	0	0
with dead time output				1			
with one-phase PWM output							1
with complementary modulation output					1	1	0
with non-complementary modulation output			1	0			

- All combinations not listed in this table are forbidden.
- Bits marked with an x can be set to any value.

NOTES

1. The following bits cannot be changed during count operation (TAUDnTE.TAUDnTEm = 1):
   - TAUDnTOM.TAUDnTOMm
   - TAUDnTOC.TAUDnTOCm
   - TAUDnTDE.TAUDnTDEm
   - TAUDnTRE.TAUDnTREm
   - TAUDnTDM.TAUDnTDMm
2. The following bits cannot be changed during count operation (TAUDnTE.TAUDnTEm = 1) except in channel output modes with modulation output:
   - TAUDnTME.TAUDnTMEm
   - TAUDnTDL.TAUDnTDLm

33.7.1 General Procedures for Specifying a Channel Output Mode

This section describes the general procedures for specifying a TAUDnTTOUTm channel output mode. The prerequisite is that timer output operation is disabled (TAUDnTOE.TAUDnTOEm = 0).

(1) Set TAUDnTO.TAUDnTOm to specify the initial level of the TAUDnTTOUTm output.

(2) Set channel output mode according to **Table 33.44, Channel Output Modes**, and the output logic using the TAUDnTOL.TAUDnTOLm bit.

(3) Start the counter (TAUDnTS.TAUDnTSm = 1).

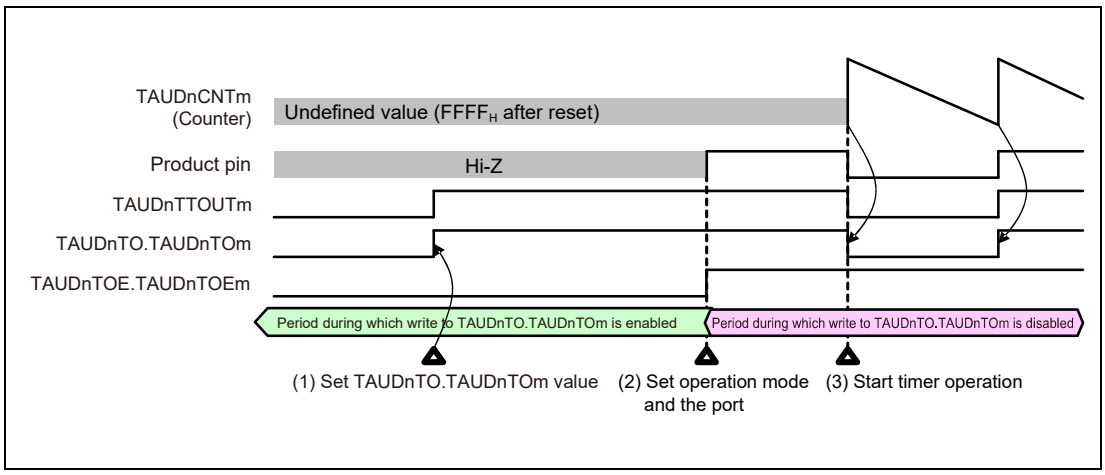

Figure 33.9 General Procedure for Specifying a TAUDnTTOUTm Channel Output Mode

33.7.2 Channel Output Modes Controlled Independently by TAUDn Signals

This section lists the channel output modes that are controlled independently by TAUDn signals. The control bits used to specify a mode are listed in **Table 33.44, Channel Output Modes**.

33.7.2.1 Independent Channel Output Mode 1

Set/reset conditions

In this output mode, TAUDnTTOUTm toggles when INTTAUDnIm is detected. The value of TAUDnTOL.TAUDnTOLm is ignored.

Prerequisites

There are no prerequisites other than those shown in **Table 33.44, Channel Output Modes**.

33.7.2.2 Independent Channel Output Mode 1 with Real-Time Output

In this output mode, the value of TAUDnTRO.TAUDnTROm bit of the trigger channel is output to TAUDnTTOUTm. The trigger channel is specified by setting the corresponding TAUDnTRC.TAUDnTRCm bit to 1. It controls all lower channels for which TAUDnTRC.TAUDnTRCm = 0.

Set/reset conditions

The value of TAUDnTRO.TAUDnTROm bit is sent to TAUDnTTOUTm only when an INTTAUDnIm interrupt occurs on the trigger channel. The interrupt is generated either:

- at certain specified intervals or
- on detection of a valid TAUDnTTINm input edge/counter start

The type of trigger is set using the TAUDnCMORm.TAUDnMD[4:1] bits.

Prerequisites

Both the master and slave channels can be set as a trigger generation channel. A channel for which TAUDnTRC.TAUDnTRCm is set to 1 serves as a trigger generation channel regardless of the value of TAUDnTRE.TAUDnTREm.

If there is no channel for which TAUDnTRC.TAUDnTRCm is set to 1 or if TAUDnTRC.TAUDnTRC0 = 0, real-time output cannot take place.

This can be seen in **Figure 33.10**.

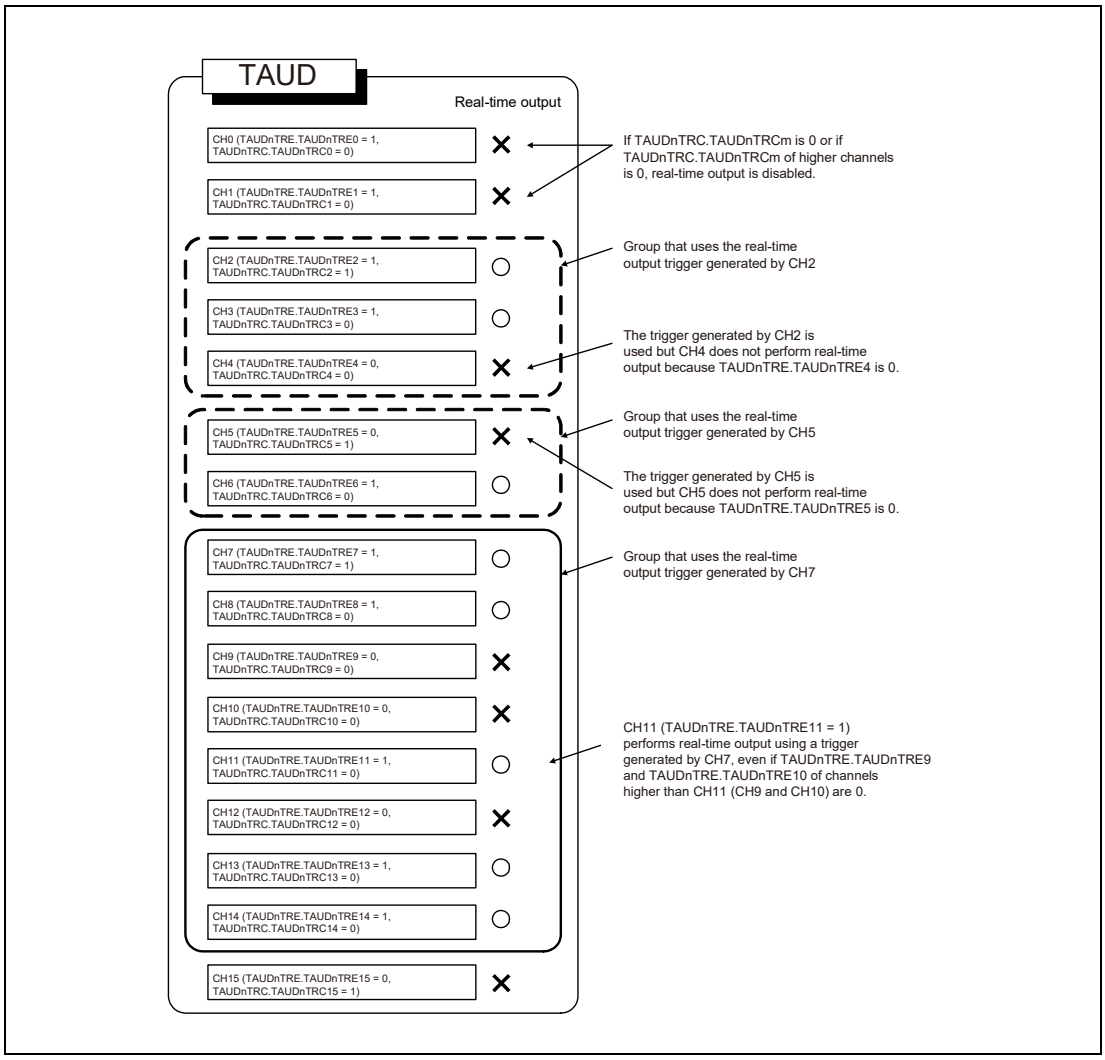

Figure 33.10 Real-Time Output

33.7.2.3 Independent Channel Output Mode 2

Set/reset conditions

In this output mode, TAUDnTTOUTm is set when INTTAUDnIm occurs at the time of count start, and reset when INTTAUDnIm occurs due to a match between TAUDnCNTm and TAUDnCDRm.

Prerequisites

There are no prerequisites other than those shown in **Table 33.44, Channel Output Modes**.

33.7.3 Channel Output Modes Controlled Synchronously by TAUDn Signals

This section lists the channel output modes that are controlled synchronously by TAUDn signals. The control bits used to specify a mode are listed in **Table 33.44, Channel Output Modes**.

33.7.3.1 Synchronous Channel Output Mode 1

Set/reset conditions

In this output mode, INTTAUDnIm of master channel serves as a set signal and INTTAUDnIm of the slave channel as a reset signal. If INTTAUDnIm of master channel and INTTAUDnIm of the slave channel are generated at the same time, INTTAUDnIm of the slave channel (reset signal) has priority over INTTAUDnIm (set signal) of master channel, i.e., the master channel is ignored.

Prerequisites

There are no prerequisites other than those shown in **Table 33.44, Channel Output Modes**.

33.7.3.2 Synchronous Channel Output Mode 1 with Non-Complementary Modulation Output

Set/reset conditions

In this output mode, TAUDnTTOUTm outputs the result of an AND operation between the PWM output and the real-time output bit (TAUDnTRO.TAUDnTROm) of a channel.

The phase period to which the dead time is added is specified using the TAUDnTDL.TAUDnTDLm bit; for positive phase set TAUDnTDL.TAUDnTDLm = 0 and for negative phase set TAUDnTDL.TAUDnTDLm = 1.

Prerequisites

A set of at least three channels is required to generate the PWM output. The master channel and slave channel 1 generate a period, and slave channel 2 generates the duty cycle. In typical applications, five more slave channels are also used that operate in the same manner as slave channel 2.

Only the PWM output and the real-time output bit of the same channel can be combined.

TAUDnTRO.TAUDnTROm, TAUDnTME.TAUDnTMEm, and TAUDnTDL.TAUDnTDLm can only be changed during count operation.

- If TAUDnTME.TAUDnTMEm is changed, its new value is applied upon detection of INTTAUDnIm on the specified channel.
- If TAUDnTME.TAUDnTMEm and TAUDnTDL.TAUDnTDLm are changed, their new values are applied upon detection of INTTAUDnIm on the master channel.

33.7.3.3 Synchronous Channel Output Mode 2

In this output mode, the operating mode should be set to count-up/-down mode. The result is a triangle PWM output at TAUDnTTOUTm. For details, see **Section 33.15.7, Triangle PWM Output Function**.

Set/reset conditions

TAUDnCNTm of the slave channel counts down and up alternatively. When it passes 0001_H it generates an interrupt, causing TAUDnTTOUTm to toggle.

Prerequisites

A set of two channels is required to generate the triangle PWM output. TAUDnTTOUTm should be set to 0 before the function starts.

33.7.3.4 Synchronous Channel Output Mode 2 with Dead Time Output

In this output mode, a dead time delay is added to TAUDnTTOUTm. The set/reset conditions are shown in **Figure 33.11**.

Set/reset conditions

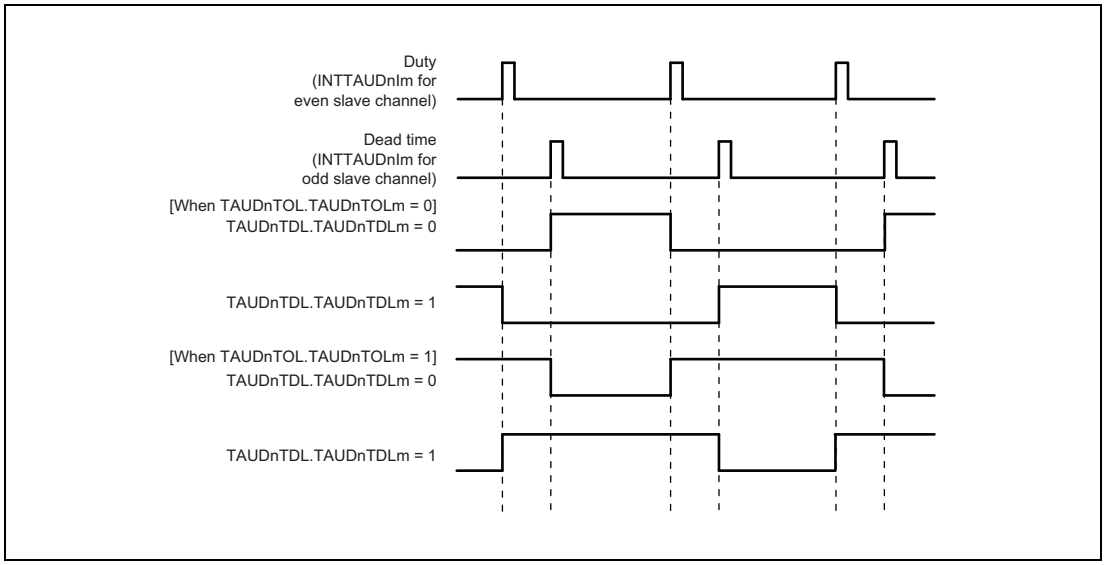

Figure 33.11 Set/Reset Conditions for Synchronous Channel Output Mode 2 with Dead Time Output

With regard to the edge to which dead time is added, set TAUDnTDL.TAUDnTDLm = 0 for rising edges and TAUDnTDL.TAUDnTDLm = 1 for falling edges.

Prerequisites

Dead time control requires a set of three channels, each operating in the following modes:

- One master channel
  The master channel should be set to interval timer mode.
- One even slave channel
  The even slave channel should be set count-up/-down mode.
- One odd slave channel (even channel + 1)
  The odd slave channel should be set to one-count mode.

The values of the following bits should be the same for the odd channel and the even channel:

- TAUDnTOE.TAUDnTOEm
- TAUDnTME.TAUDnTMEm
- TAUDnTRE.TAUDnTREm
- TAUDnTOM.TAUDnTOMm
- TAUDnTOC.TAUDnTOCm
- TAUDnTDE.TAUDnTDEm
- TAUDnTDM.TAUDnTDMm

33.7.3.5 Synchronous Channel Output Mode 2 with One-Phase PWM Output

In this output mode, a dead time delay is added to TAUDnTTOUTm. The set/reset conditions are shown in **Figure 33.12**.

Set/reset conditions

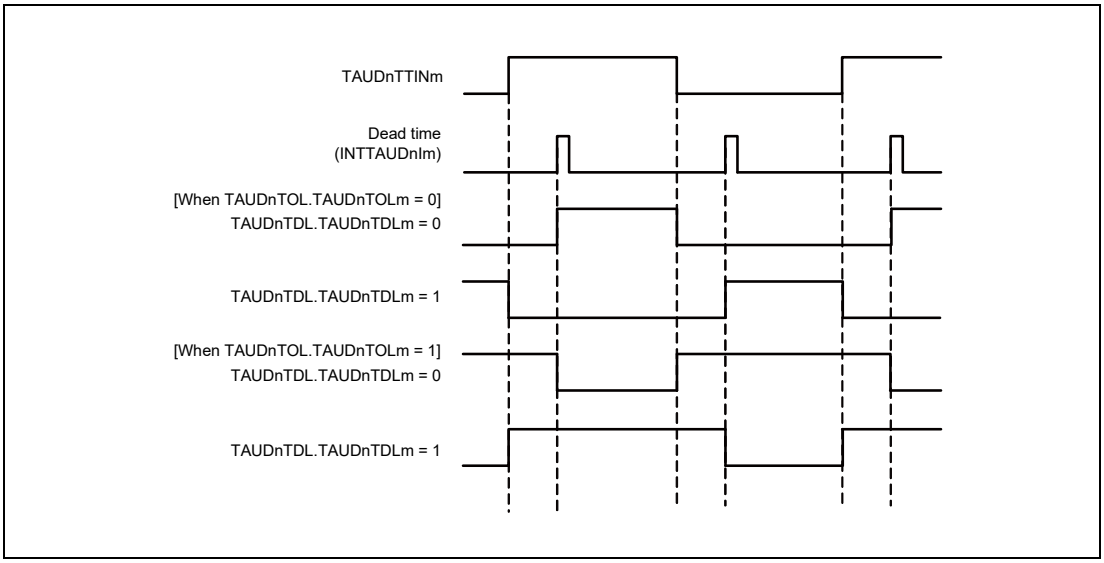

Figure 33.12 Set/Reset Conditions for Synchronous Channel Output Mode 2 with One-Phase PWM Output

With regard to the edge to which dead time is added, set TAUDnTDL.TAUDnTDLm = 0 for rising edges and TAUDnTDL.TAUDnTDLm = 1 for falling edges.

Prerequisites

One-phase PWM output control requires a set of two channels:

- One even slave channel
- One odd slave channel (even channel + 1)
  The odd slave channel should be set to one-count mode.

The values of the following bits should be the same for the odd channel and the even channel:

- TAUDnTOE.TAUDnTOEm
- TAUDnTME.TAUDnTMEm
- TAUDnTRE.TAUDnTREm
- TAUDnTOM.TAUDnTOMm
- TAUDnTOC.TAUDnTOCm
- TAUDnTDE.TAUDnTDEm
- TAUDnTDM.TAUDnTDMm

33.7.3.6 Synchronous Channel Output Mode 2 with Complementary Modulation Output

Set/reset conditions

In this output mode, TAUDnTTOUTm outputs a PWM signal, a high signal, or a low signal depending on the value of real-time output bit (TAUDnTRO.TAUDnTROm), the modulation output bit (TAUDnTME.TAUDnTMEm), and the output level bit (TAUDnTOL.TAUDnTOLm) of a pair of slave channels.

For details, see **Section 33.16.3, Complementary Modulation Output Function**.

Prerequisites

A set of at least four channels is required for this mode. The master channel and slave channel 1 generate a period, slave channel 2 generates a duty cycle, and slave channel 3 generates dead time. Slave channels 2 and 3 are a pair. In typical applications, four more channels are also used, which operates in the same manner as slave channels 2 and 3 respectively.

TAUDnTRO.TAUDnTROm, TAUDnTME.TAUDnTMEm, and TAUDnTDL.TAUDnTDLm can only be changed during count operation.

- If TAUDnTME.TAUDnTMEm is changed during operation, its new value is applied upon detection of INTTAUDnIm at the specified channel.
- If TAUDnTME.TAUDnTMEm and TAUDnTDL.TAUDnTDLm are changed, their new values are applied upon detection of INTTAUDnIm on an even slave channel.

33.7.3.7 Synchronous Channel Output Mode 2 with Non-Complementary Modulation Output

The difference from synchronous channel output mode 1 with non-complementary modulation output is the PWM wave shape.

Mode 1 has a square wave while mode 2 has a triangular wave.

33.8 Start Timing in Each Operating Modes

This section describes the timing at which the counter starts after TAUDnTS.TAUDnTSm is set to 1 in each operating mode.

In all modes, the value of data register and whether or not an interrupt occurs depends on mode and register settings.

CAUTION

The count start timing described in this section is for your reference. Actually, the count start timing depends on the count clock timing.

33.8.1 Interval Timer Mode, Judge Mode, Capture Mode, Count-up/-down Mode, and Count Capture Mode

The counter starts operating with the next count clock cycle after TAUDnTS.TAUDnTSm is set to 1. The value of data register is also loaded when the counter starts.

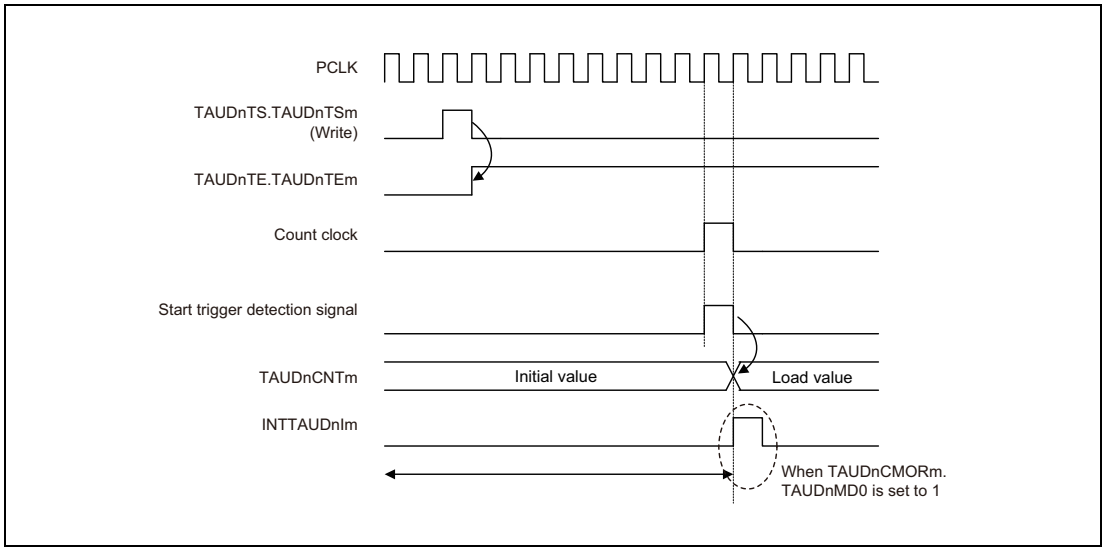

Figure 33.13 Start Timing in Interval Timer Mode, Judge Mode, Capture Mode, Count-up/-down Mode, and Count Capture Mode

NOTE

Make sure to set TAUDnCMORm.TAUDnMD0 to 0 when using the count-up/-down mode.

33.8.2 Event Count Mode

The value of data register is loaded as soon as TAUDnTS.TAUDnTSm is set to 1. The counter also starts immediately. The value of data register decrements when the subsequent count clock cycle starts.

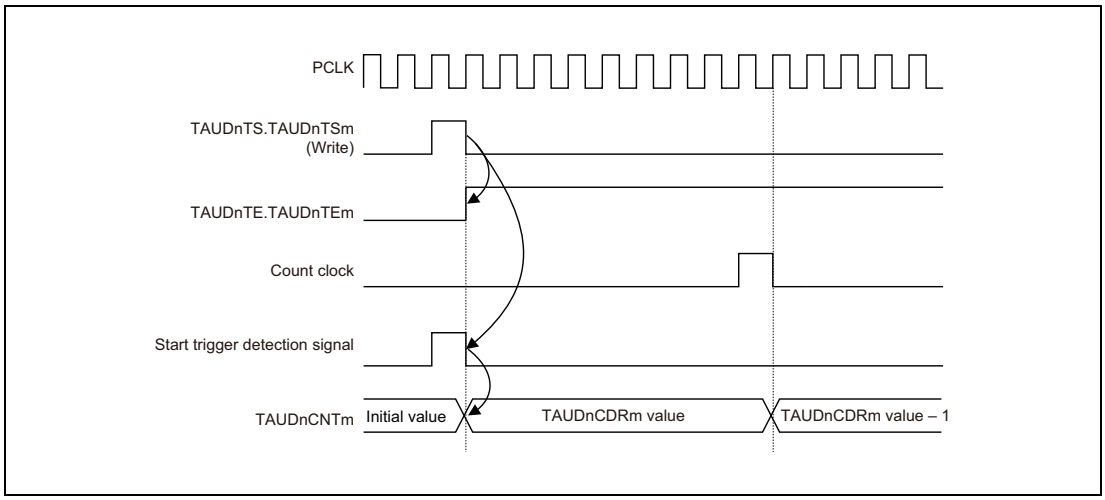

Figure 33.14 Start Timing in Event Count Mode

33.8.3 Other Operating Modes

In other operating modes, the counter operation start timing is triggered only upon detection of a valid edge of TAUDnTTINm. Once the counter starts, the value of data register is also loaded. The count clock cycles, which are irrelevant to start of counter operation, determine the frequency with which all operations take place.

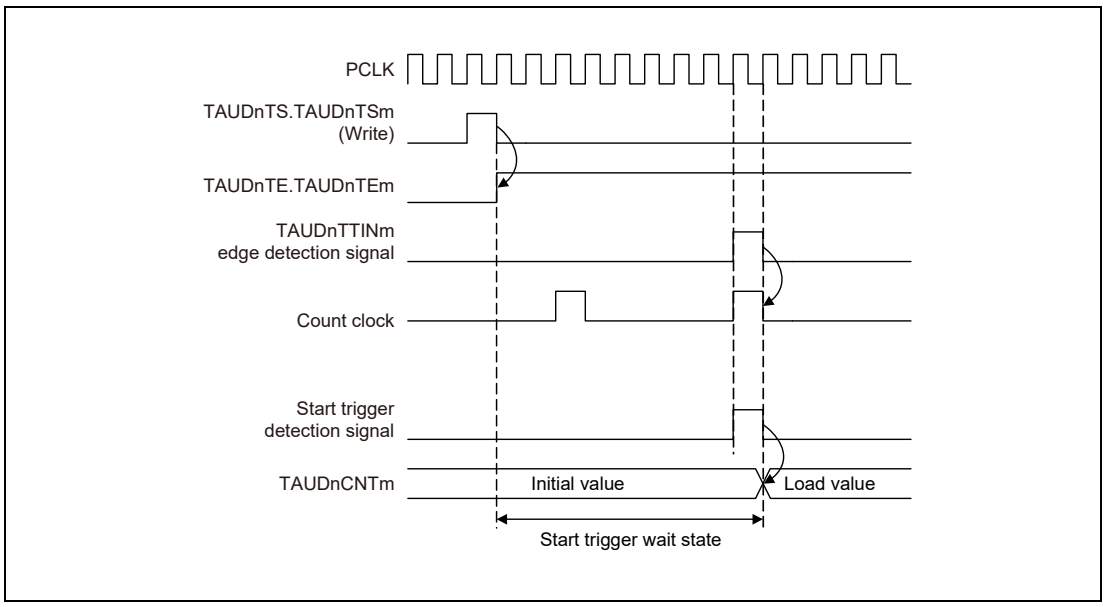

Figure 33.15 Count Start Timing in Other Operating Modes

33.9 TAUDnTTOUTm Output and INTTAUDnIm Generation when Counter Starts or Restarts

When the counter starts, it is possible to specify whether an INTTAUDnIm is generated using the TAUDnCMORm.TAUDnMD0 bit. The generation of INTTAUDnIm when the TAUDnCMORm.TAUDnMD0 bit starts counting and the effect to TAUDnTTOUTm depend on the selected function. For details, refer to the description of TAUDnCMORm.TAUDnMD0 of each function.

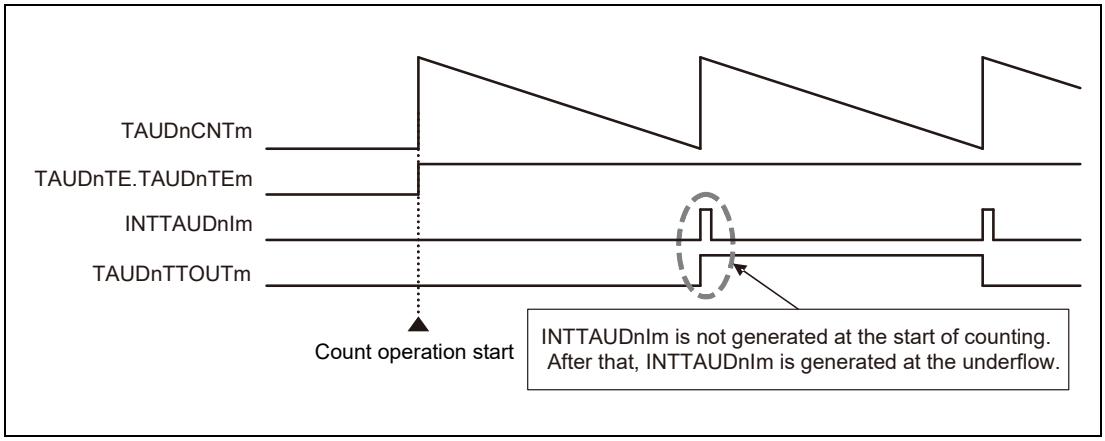

Figure 33.16 INTTAUDnIm Generation Timing (when TAUDnCMORm.TAUDnMD0 = 0)

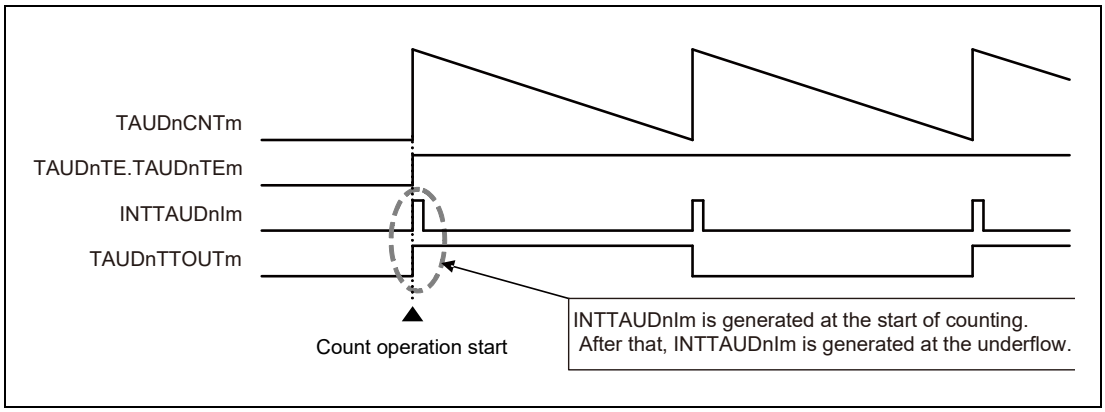

Figure 33.17 INTTAUDnIm Generation Timing (when TAUDnCMORm.TAUDnMD0 = 1)

33.10 Interrupt Generation upon Overflow

In certain independent functions, an interrupt is not generated when the counter value reaches $FFFF_H$ and an overflow occurs during count-up. This section describes how to generate an interrupt by combining channel operation in a mode that counts up and in a mode that counts down.

The appropriate operation mode for the second channel depends on the operation mode of the first channel. Nevertheless, the principle is the same for all combinations:

- Find an operation mode for the second channel that counts down in such a manner, that it reaches 0000_H at the same time as the first channel overflows (TAUDnCNTm = $FFFF_H$).
- Set TAUDnCDRm of the second channel to $FFFF_H$.
- The two channels must count at the same speed (i.e. they must have the same count clock).
- Both channels are triggered by the same TAUDnTTINm input.
- The trigger detection settings (TAUDnCMORm.TAUDnSTS[2:0] and TAUDnCMURm.TAUDnTIS[1:0]) must be identical for both channels.

Result:

The down-counter of the second channel reaches 0000_H at exactly the same time as the up-counter of the first channel overflows (TAUDnCNTm = $FFFF_H$). Thus the second channel generates the desired interrupt.

The following sections list the operating modes that count down that are required to match specific operating modes that count up, as well as example timing diagrams.

33.10.1 Combination of the TAUDnTTINm Input Pulse Interval Measurement Function and the TAUDnTTINm Input Interval Timer Function

When the capture trigger is input simultaneously to TAUDnTTINm of both channels, INTTAUDnIm of the TAUDnTTINm input interval timer function can detect the overflow when TAUDnCNTm of the TAUDnTTINm input pulse interval measurement function exceeds $FFFF_H$.

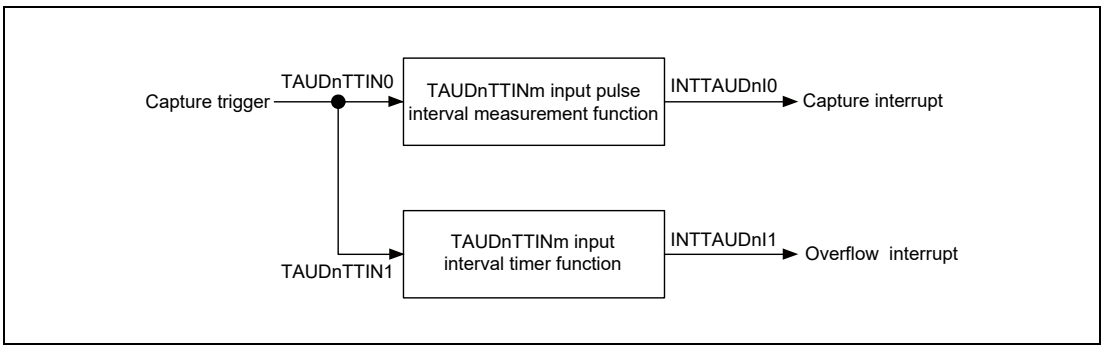

Figure 33.18 Combination of the TAUDnTTINm Input Pulse Interval Measurement Function and the TAUDnTTINm Input Interval Timer Function

Timing diagram

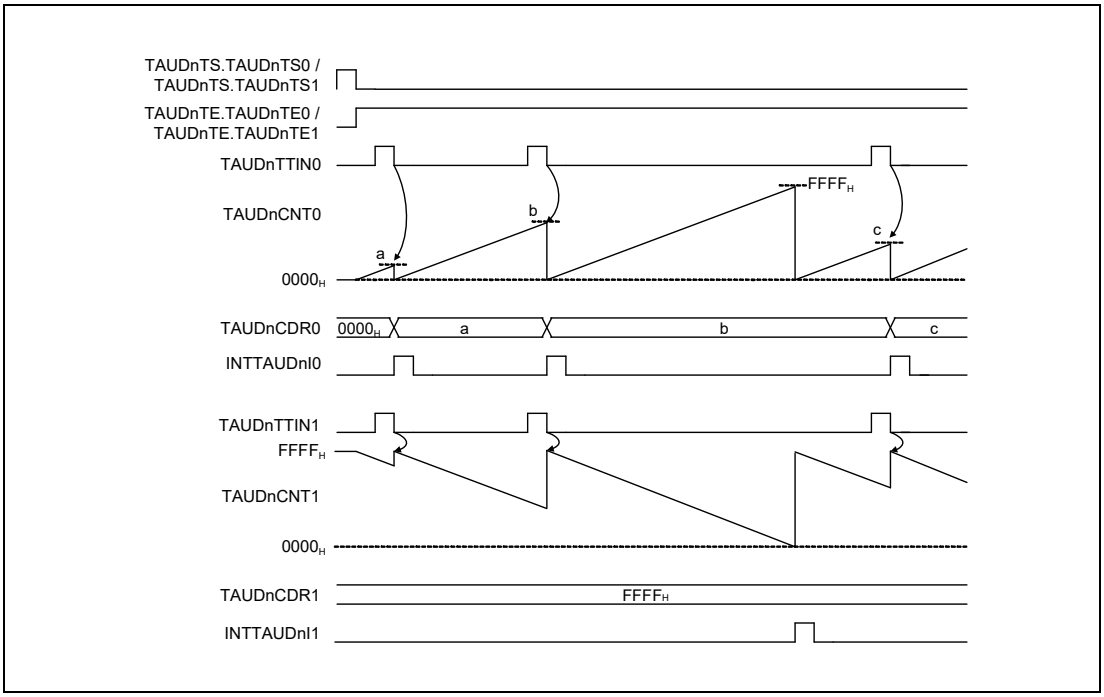

Figure 33.19 Interrupt Generation via Combination of the TAUDnTTINm Input Pulse Interval Measurement Function and the TAUDnTTINm Input Interval Timer Function

33.10.2 Combination of the TAUDnTTINm Input Signal Width Measurement Function and the Overflow Interrupt Output Function (at Measuring the TAUDnTTINm Width)

When the capture trigger is input simultaneously to TAUDnTTINm of both channels, INTTAUDnIm of the overflow interrupt output function (at measuring the TAUDnTTINm width) can detect the overflow when TAUDnCNTm of the TAUDnTTINm input signal width measurement function exceeds $FFFF_H$.

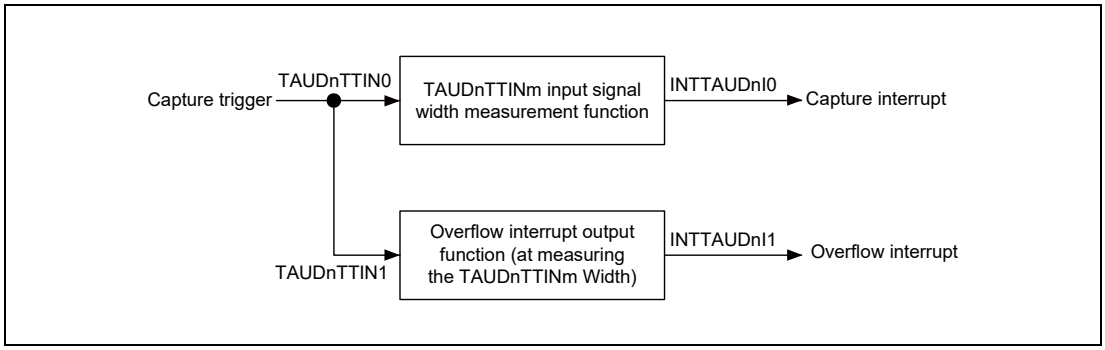

Figure 33.20 Combination of the TAUDnTTINm Input Signal Width Measurement Function and the Overflow Interrupt Output Function (at Measuring the TAUDnTTINm Width)

Timing diagram

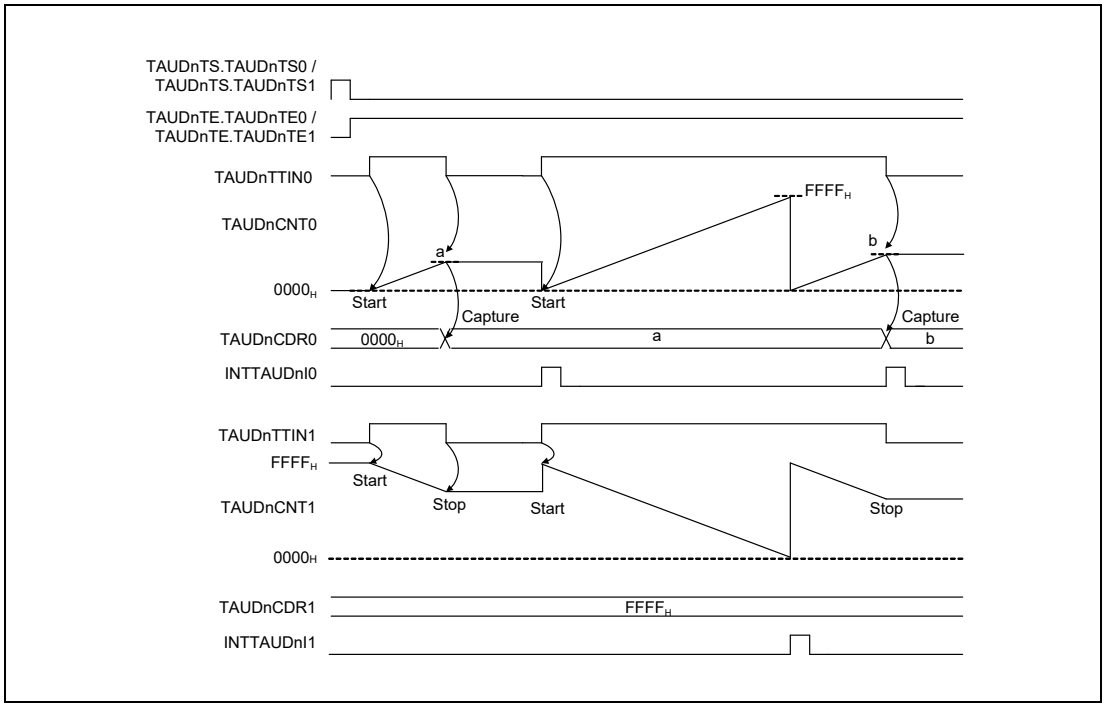

Figure 33.21 Interrupt Generation via Combination of the TAUDnTTINm Input Signal Width Measurement Function and the Overflow Interrupt Output Function (at Measuring the TAUDnTTINm Width)

33.10.3 Combination of the TAUDnTTINm Input Position Detection Function and the Interval Timer Function

When the counters of both channels are enabled simultaneously, INTTAUDnIm of the interval timer function can detect the overflow when TAUDnCNTm of the TAUDnTTINm input position detection function exceeds $FFFF_H$.

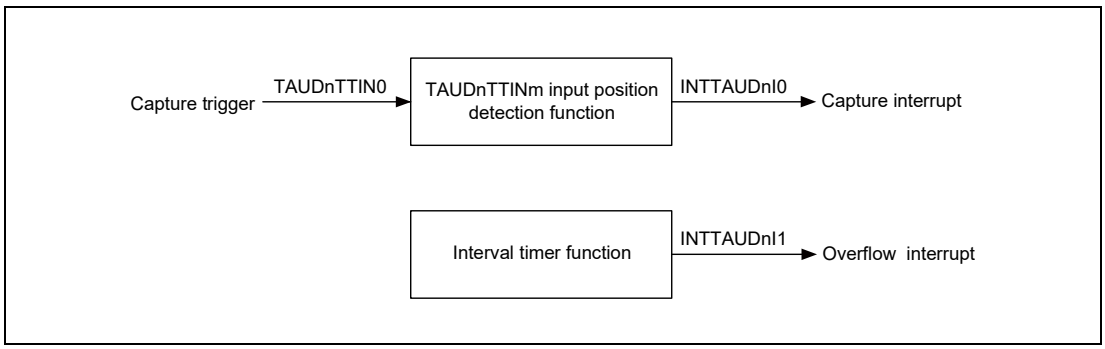

Figure 33.22 Combination of the TAUDnTTINm Input Position Detection Function and the Interval Timer Function

Timing diagram

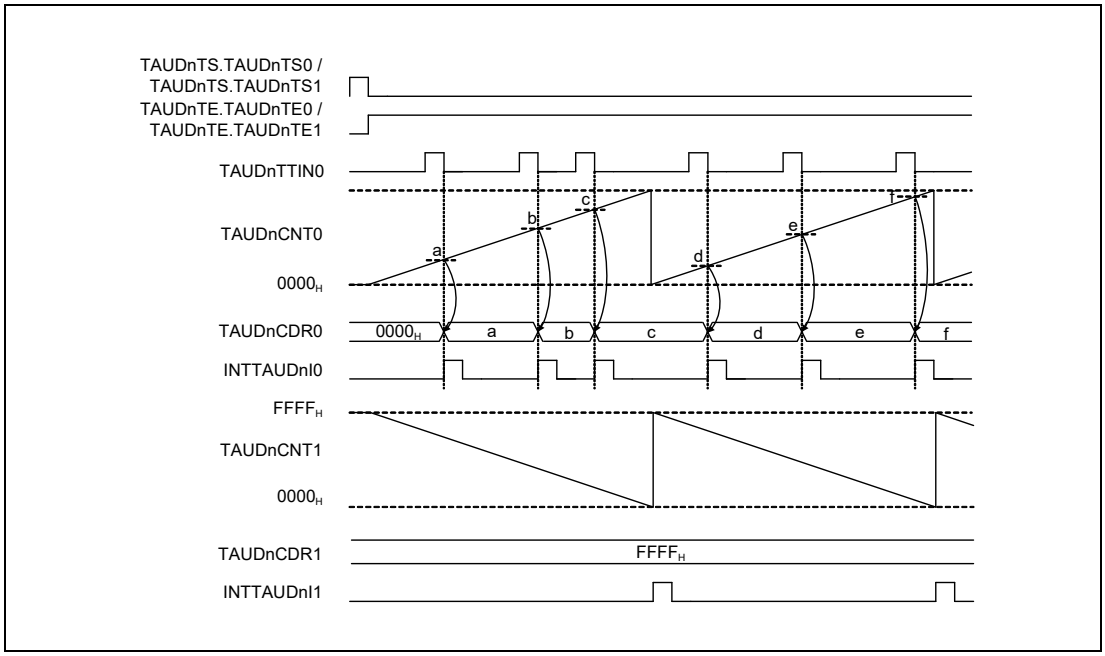

Figure 33.23 Interrupt Generation via Combination of the TAUDnTTINm Input Position Detection Function and the Interval Timer Function

33.10.4 Combination of the TAUDnTTINm Input Period Count Detection Function and the Overflow Interrupt Output Function (at Detecting the TAUDnTTINm Input Period Count)

When the capture trigger is input simultaneously to TAUDnTTINm of both channels, INTTAUDnIm of the overflow interrupt output function (at detecting the TAUDnTTINm input period count) can detect the overflow when TAUDnCNTm of the TAUDnTTINm input period count detection function exceeds $FFFF_H$.

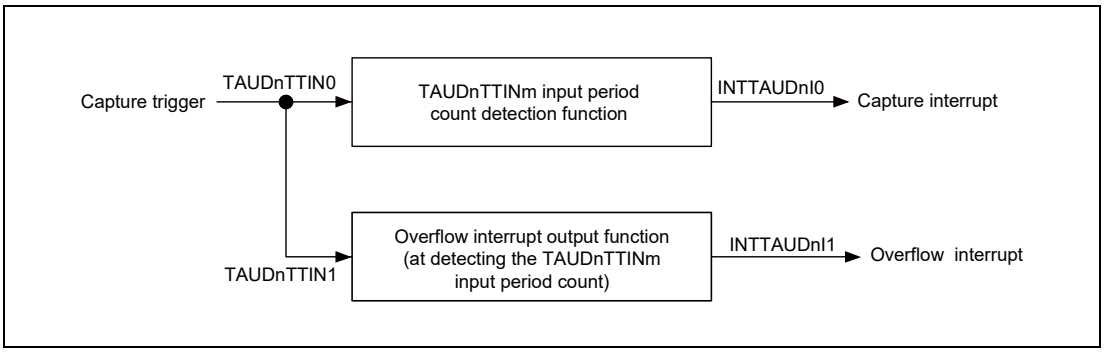

Figure 33.24 Combination of the TAUDnTTINm Input Period Count Detection Function and the Overflow Interrupt Output Function (at Detecting the TAUDnTTINm Input Period Count)

Timing diagram

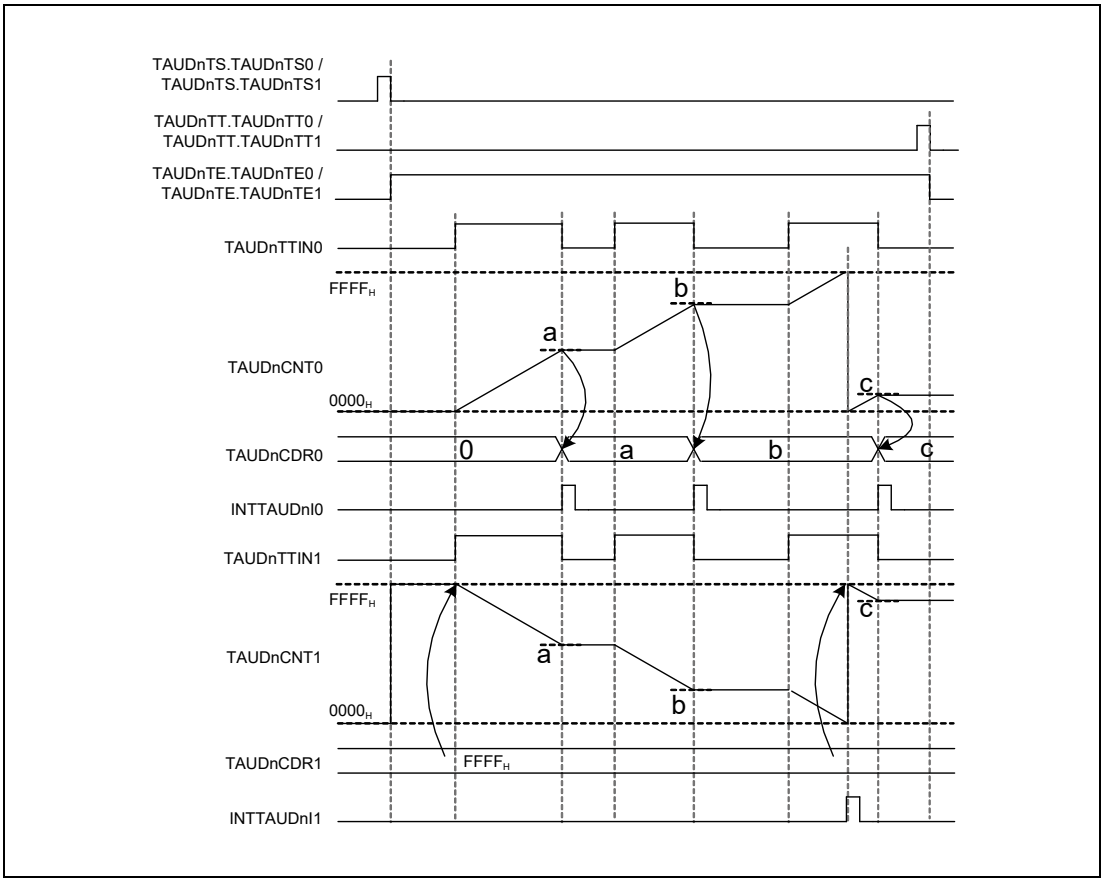

Figure 33.25 Interrupt Generation via Combination of the TAUDnTTINm Input Period Count Detection Function and the Overflow Interrupt Output Function (at Detecting the TAUDnTTINm Input Period Count)

33.11 TAUDnTTINm Edge Detection

Edge detection is based on the operation clock. This means that an edge can only be detected at the next rising edge of the operation clock. This can lead to a maximum delay of one operation clock cycle.

Figure 33.26 shows when edge detection takes place.

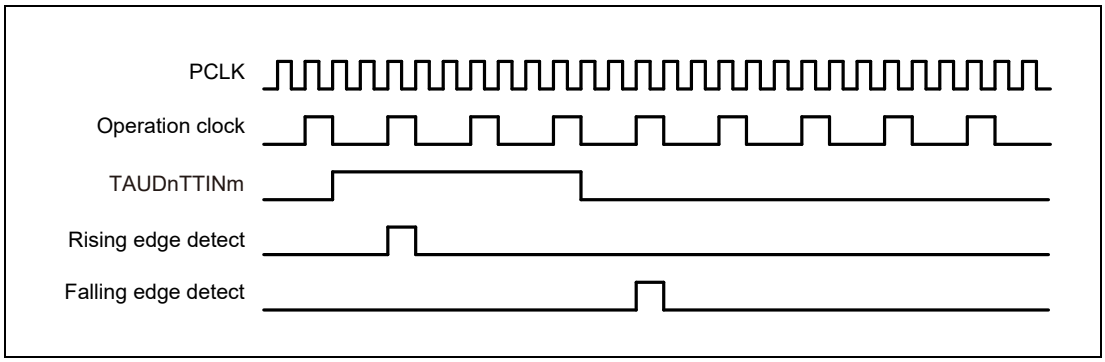

Figure 33.26 Basic Edge Detection Timing

Figure 33.26 shows an operation timing image. Actually, a noise filter or synchronization circuit which is located between the TAUDnIm pin and TAUDn causes a delay time.

33.12 Independent Channel Operation Functions

The following sections list the independent channel operation functions provided by the Timer Array Unit D. For a general overview of independent channel operation, see **Section 33.2, Overview**.

This section describes functions that generate interrupts at regular intervals or with a specified delay.

33.12.1 Interval Timer Function

33.12.1.1 Overview

Summary

This function is used as a reference timer for generating timer interrupts (INTTAUDnIm) at regular intervals. When an interrupt is generated, the TAUDnTTOUTm signal toggles, resulting in a square wave.

Prerequisites

- The operation mode must be set to Interval Timer Mode, see **Table 33.45, Contents of the TAUDnCMORm Register for Interval Timer Function**.
- The channel output mode must be set to Independent Channel Output Mode 1, see **Section 33.7, Channel Output Modes**.

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This in turn sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The current value of TAUDnCDRm is written to TAUDnCNTm and the counter starts to count down from this value.

When the counter reaches 0000_H, INTTAUDnIm is generated and the TAUDnTTOUTm signal toggles. TAUDnCNTm then reloads the TAUDnCDRm value and subsequently continues operation.

The value of TAUDnCDRm can be rewritten at any time, and the changed value of TAUDnCDRm is applied the next time the counter starts to count down.

The counter can be stopped by setting TAUDnTT.TAUDnTTm to 1, which in turn sets TAUDnTE.TAUDnTEm to 0. TAUDnCNTm and TAUDnTTOUTm stop but retain their values. The counter can be restarted by setting TAUDnTS.TAUDnTSm to 1. The counter can also be forcibly restarted (without stopping it first) by setting TAUDnTS.TAUDnTSm to 1 during operation.

Conditions

If the TAUDnCMORm.TAUDnMD0 bit is set to 0, the first interrupt after a start or restart is not generated, and therefore TAUDnTTOUTm does not toggle. This results in a negative TAUDnTTOUTm signal compared to when TAUDnCMORm.TAUDnMD0 is set to 1. For details see **Section 33.9, TAUDnTTOUTm Output and INTTAUDnIm Generation when Counter Starts or Restarts**.

33.12.1.2 Equations

INTTAUDnIm cycle = count clock cycle × (TAUDnCDRm + 1)

TAUDnTTOUTm square wave cycle = count clock cycle × (TAUDnCDRm + 1) × 2

33.12.1.3 Block Diagram and General Timing Diagram

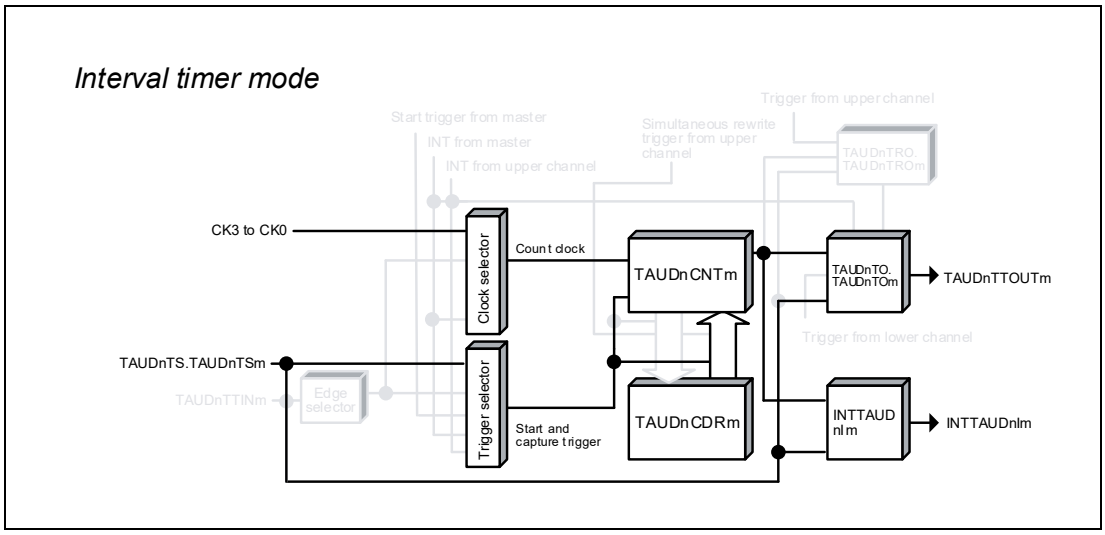

Figure 33.27 Block Diagram of Interval Timer Function

The following settings apply to the general timing diagram.

- INTTAUDnIm is generated at the beginning of operation (TAUDnCMORm.TAUDnMD0 = 1).

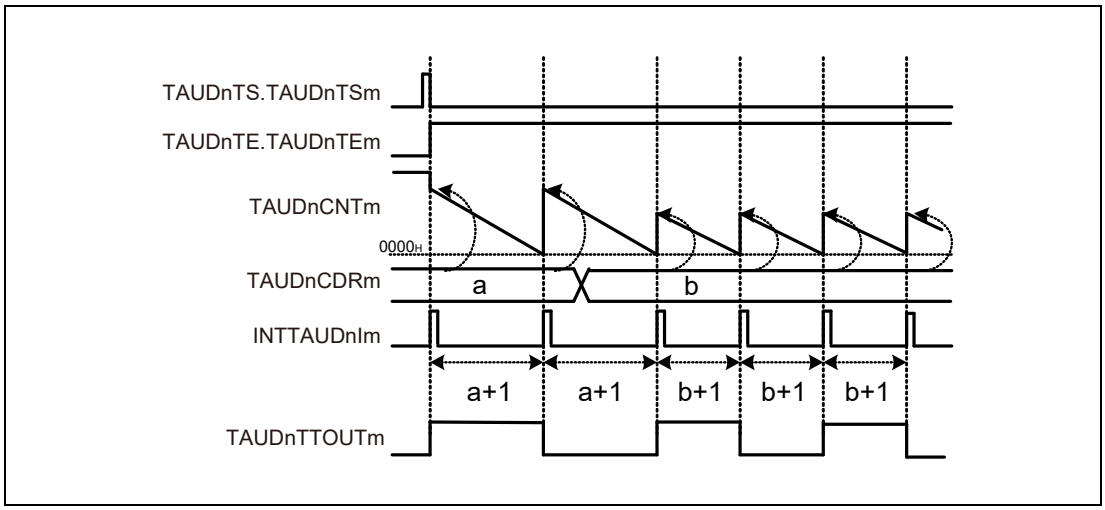

Figure 33.28 General Timing Diagram of Interval Timer Function

33.12.1.4 Register Settings

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode

Table 33.47 Control Bit Settings in Independent Channel Output Mode 1

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	0: Operating mode 1 (Toggle mode if TAUDnTOM.TAUDnTOMm = 0)
TAUDnTOL.TAUDnTOLm	0: The setting is disabled in toggle mode. (The value after reset.)
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set these bits to 0
TAUDnTRC.TAUDnTRCm	
TAUDnTME.TAUDnTMEm	0: Disables modulation

NOTE

The channel output mode can also be set to Channel Output Mode Controlled by Software by setting TAUDnTOE.TAUDnTOEm = 0. TAUDnTTOUTm can then be controlled independently of the interrupts. For details, see **Section 33.7, Channel Output Modes**.

(4) Simultaneous Rewrite

The simultaneous rewrite registers (TAUDnRDE, TAUDnRDS, TAUDnRDM, and TAUDnRDC) cannot be used with the interval timer function. Therefore, these registers should be set to 0.

Table 33.48 Simultaneous Rewrite Settings for Interval Timer Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	0: Disables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: When simultaneous rewrite is disabled (TAUDnRDE.TAUDnRDEm = 0), set these bits to 0.
TAUDnRDM.TAUDnRDMm	
TAUDnRDC.TAUDnRDCm	

33.12.1.5 Operating Procedure for Interval Timer Function

Table 33.49 Operating Procedure for Interval Timer Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in **Table 33.45, Contents of the TAUDnCMORm Register for Interval Timer Function**, and **Table 33.46, Contents of the TAUDnCMURm Register for Interval Timer Function**. Set the value of TAUDnCDRm register. Set channel output mode by setting the control bits as described in **Table 33.47, Control Bit Settings in Independent Channel Output Mode 1**.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and the counter starts. The TAUDnCDRm value is loaded in TAUDnCNTm. When TAUDnCMORm.TAUDnMD0 = 1, INTTAUDnIm is generated and TAUDnTTOUTm toggles.
During Operation	The TAUDnCDRm register value can be changed at any time. The TAUDnCNTm register can be read at all times.	TAUDnCNTm counts down. When the counter reaches 0000_H: • The TAUDnCDRm value is loaded in TAUDnCNTm again and count operation continues. • INTTAUDnIm is generated and TAUDnTTOUTm toggles.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

Restart Operation

33.12.1.6 Specific Timing Diagrams

(1) TAUDnCDRm = 0000_H, count clock = PCLK/2

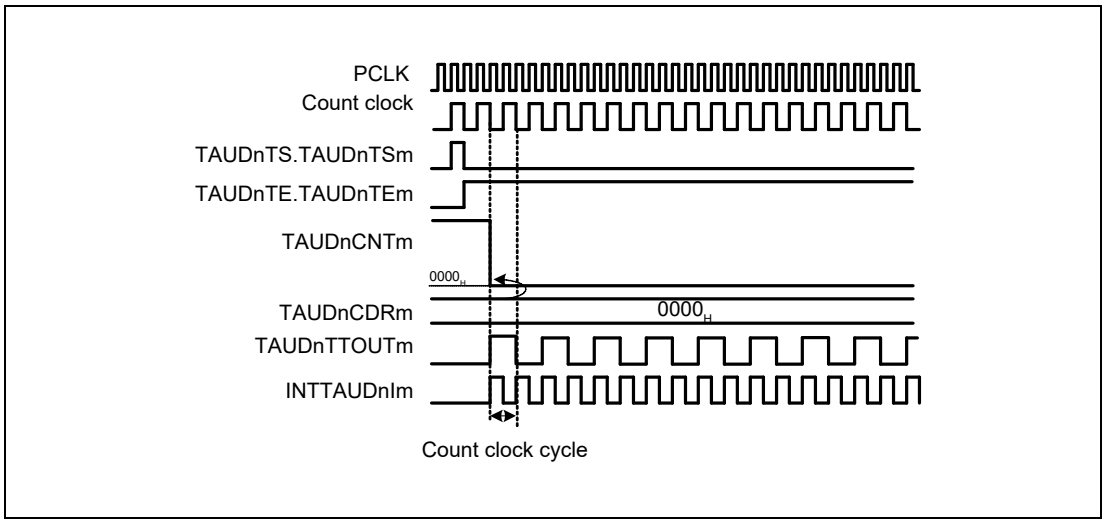

Figure 33.29 TAUDnCDRm = 0000_H, Count Clock = PCLK/2

- If TAUDnCDRm = 0000_H and the count clock = PCLK/2, the TAUDnCDRm value is loaded into TAUDnCNTm every count clock, meaning that TAUDnCNTm is always 0000_H.
- INTTAUDnIm is generated every count clock, resulting in TAUDnTTOUTm toggling every count clock.

(2) TAUDnCDRm = 0000_H, count clock = PCLK

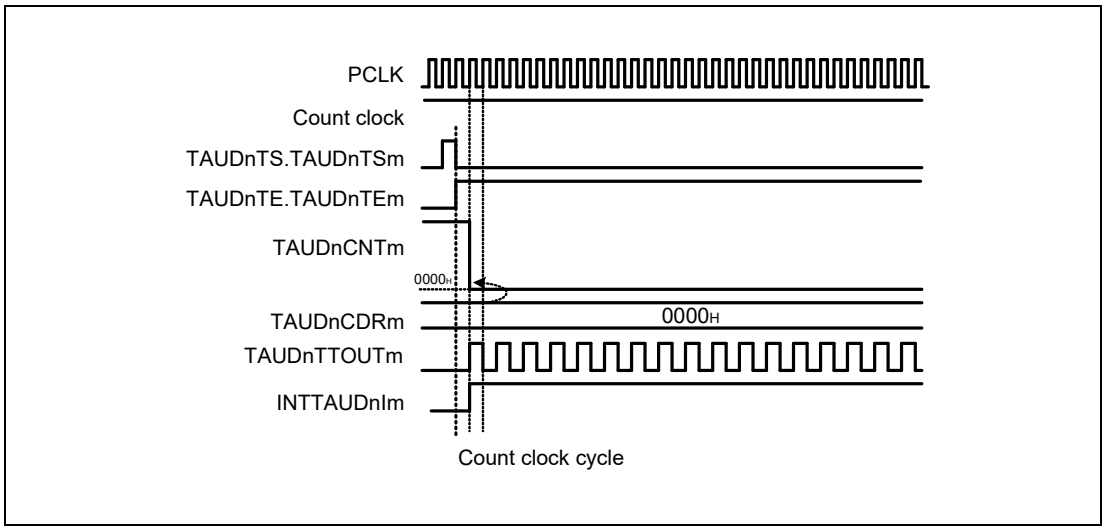

Figure 33.30 TAUDnCDRm = 0000_H, Count Clock = PCLK

- If TAUDnCDRm = 0000_H and the count clock = PCLK, the TAUDnCDRm value is loaded into TAUDnCNTm every PCLK clock, meaning that TAUDnCNTm is always 0000_H.
- INTTAUDnIm is fixed to the high level. Though the first interrupt is generated, subsequent interrupts are not generated.
  TAUDnTTOUTm is toggled every PCLK clock.

(3) Operation Stop and Restart

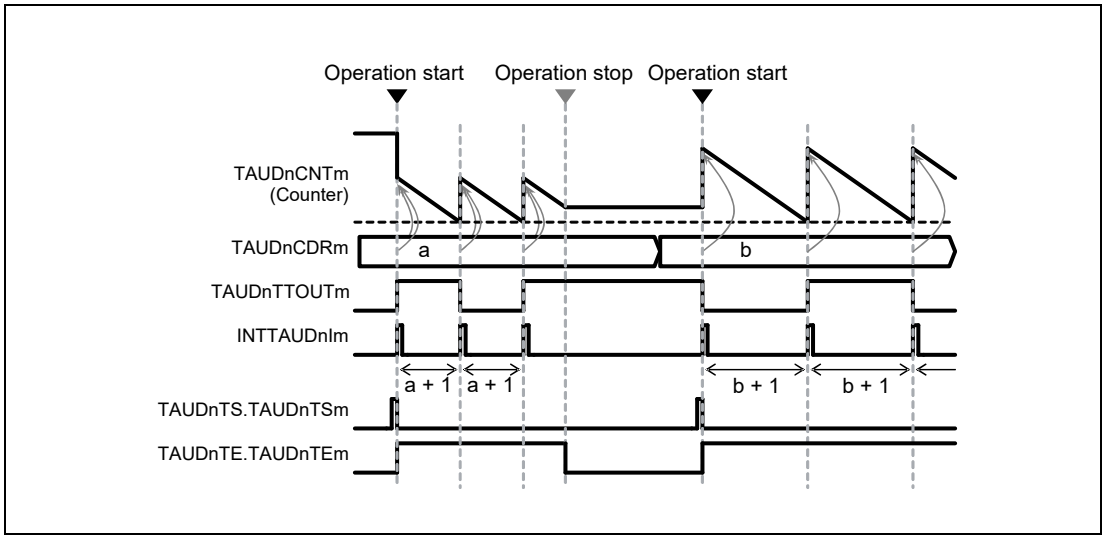

Figure 33.31 Operation Stop and Restart (TAUDnCMORm.TAUDnMD0 = 1)

- The counter can be stopped by setting TAUDnTT.TAUDnTTm to 1. This sets TAUDnTE.TAUDnTEm to 0.
- TAUDnCNTm and TAUDnTTOUTm stop but retain their values.
- The counter can be restarted by setting TAUDnTS.TAUDnTSm to 1.

(4) Forced Restart (TAUDnCMORm.TAUDnMD0 = 1)

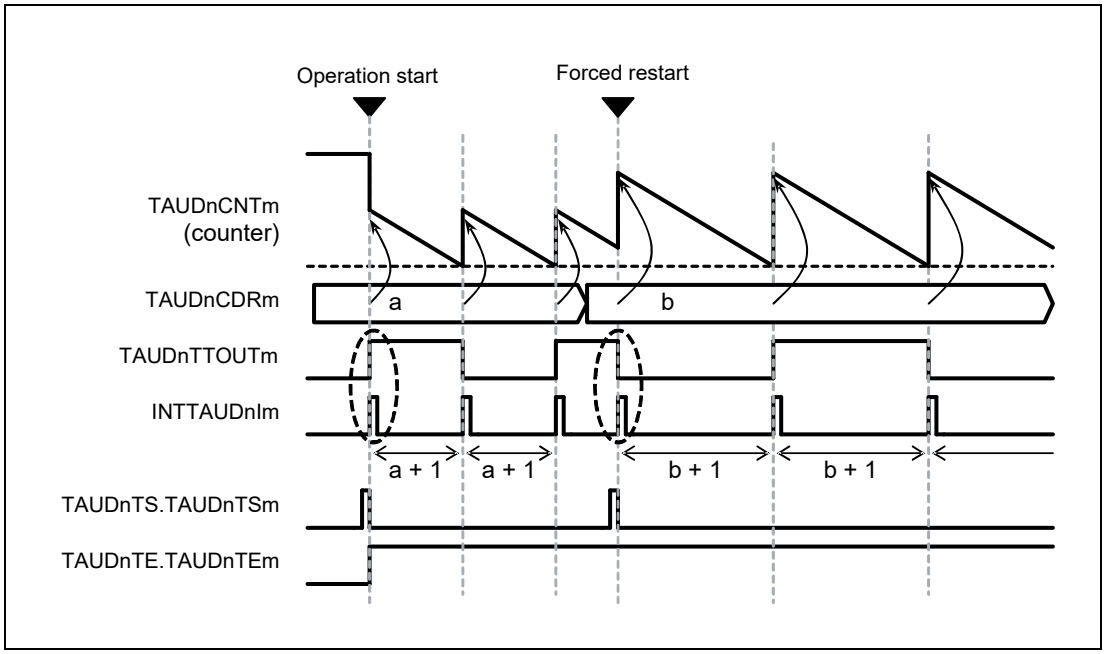

Figure 33.32 Forced Restart Operation (TAUDnCMORm.TAUDnMD0 = 1)

- The counter can be forcibly restarted (without stopping it first) by setting TAUDnTS.TAUDnTSm to 1 during operation.
- If the TAUDnCMORm.TAUDnMD0 bit is set to 1, the first interrupt after a start or restart is generated.
- When a forced restart is made, the TAUDnCDRm value is reflected to TAUDnCNTm and counting starts. Execute a forced restart to reflect the changed TAUDnCDRm value immediately.
- When a forced restart is made, an interrupt (INTTAUDnIm) is generated and TAUDnTTOUTm is inverted.

(5) Forced Restart (TAUDnCMORm.TAUDnMD0 = 0)

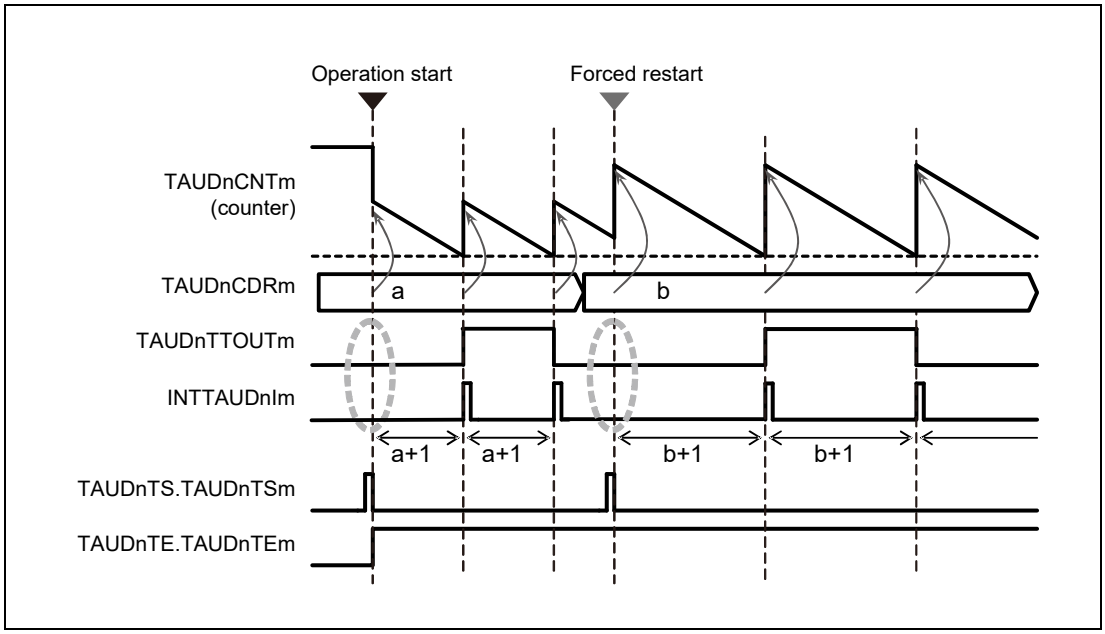

Figure 33.33 Forced Restart Operation (TAUDnCMORm.TAUDnMD0 = 0)

- When a forced restart is made, an interrupt (INTTAUDnIm) is not generated and TAUDnTTOUTm is not inverted.

33.12.2 TAUDnTTINm Input Interval Timer Function

33.12.2.1 Overview

Summary

This function is used as a reference timer for generating timer interrupts (INTTAUDnIm) at regular intervals or when a valid TAUDnTTINm input edge is detected. When an interrupt is generated, the TAUDnTTOUTm signal toggles, resulting in a square wave.

Prerequisites

- The operating mode should be set to interval timer mode. See **Table 33.50, Contents of the TAUDnCMORm Register for TAUDnTTINm Input Interval Timer Function**.
- The channel output mode should be set to independent channel output mode 1. See **Section 33.7, Channel Output Modes**.

Functional description

This function operates in an identical manner to the interval timer function (see **Section 33.12.1, Interval Timer Function**) except that this function is restarted by a valid TAUDnTTINm input edge. The type of edge used as a trigger is specified using the TAUDnCMURm.TAUDnTIS[1:0] bits. Either rising edge, falling edge, or rising and falling edges can be selected.

33.12.2.2 Equations

INTTAUDnIm cycle = count clock cycle × (TAUDnCDRm + 1)

TAUDnTTOUTm square wave cycle = count clock cycle × (TAUDnCDRm + 1) × 2

33.12.2.3 Block Diagram and General Timing Diagram

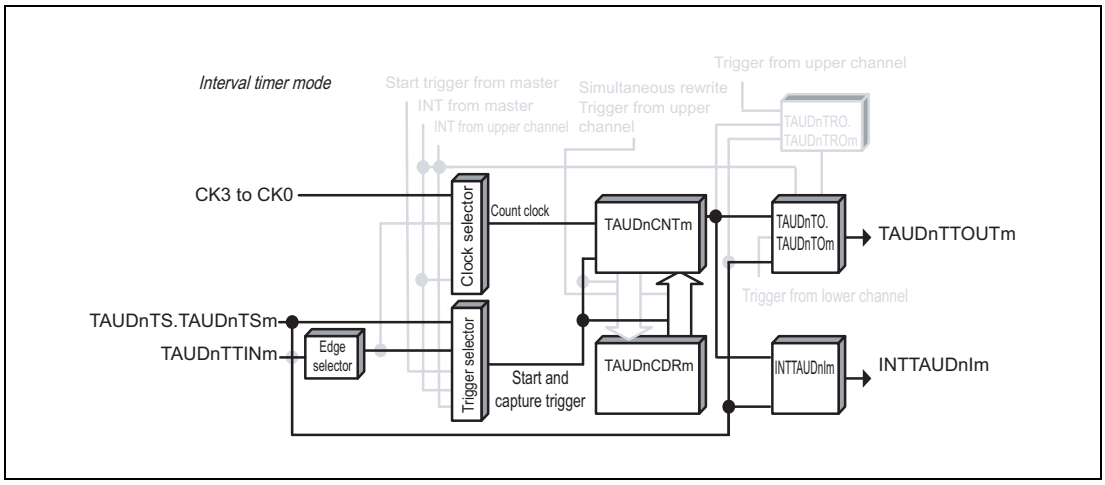

Figure 33.34 Block Diagram of TAUDnTTINm Input Interval Timer Function

The following settings apply to the general timing diagram.

- INTTAUDnIm is generated at the beginning of operation (TAUDnCMORm.TAUDnMD0 = 1).
- Rising edge detection (TAUDnCMURm.TAUDnTIS[1:0] = 01_B)

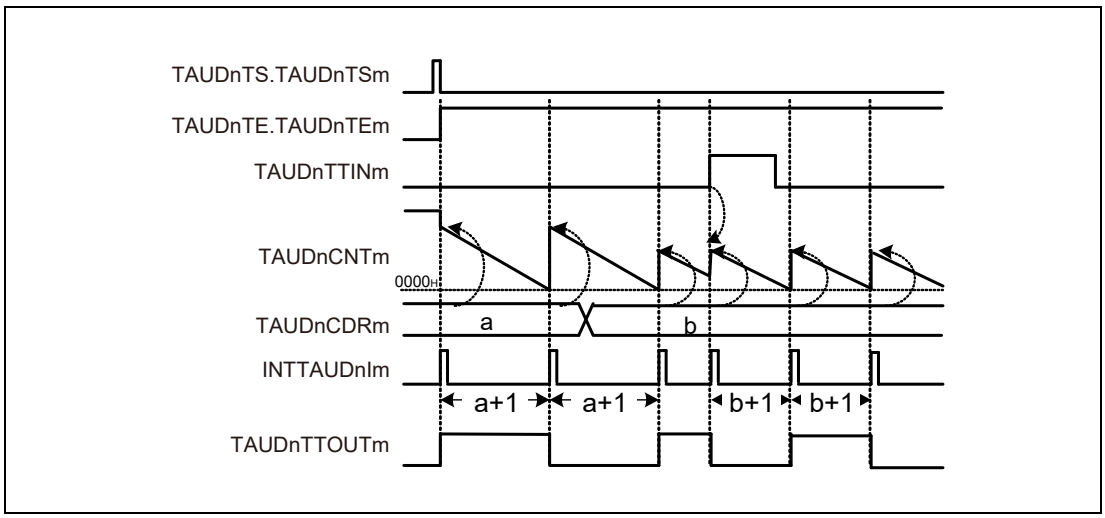

Figure 33.35 General Timing Diagram of TAUDnTTINm Input Interval Timer Function

(3) Channel Output Mode

Table 33.52 Control Bit Settings in Independent Channel Output Mode 1

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	0: Operating mode 1 (Toggle mode if TAUDnTOM.TAUDnTOMm = 0)
TAUDnTOL.TAUDnTOLm	0: The setting is disabled in toggle mode. (The value after reset.)
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set these bits to 0
TAUDnTRC.TAUDnTRCm	
TAUDnTME.TAUDnTMEm	0: Disables modulation

NOTE

The channel output mode can also be set to Channel Output Mode Controlled by Software by setting TAUDnTOE.TAUDnTOEm = 0. TAUDnTTOUTm can then be controlled independently of the interrupts. For details, see **Section 33.7, Channel Output Modes**.

(4) Simultaneous Rewrite

The simultaneous rewrite registers (TAUDnRDE, TAUDnRDS, TAUDnRDM, and TAUDnRDC) cannot be used with the TAUDnTTINm Input Interval Timer Function. Therefore, these registers should be set to 0.

Table 33.53 Simultaneous Rewrite Settings for TAUDnTTINm Input Interval Timer Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	0: Disables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: When simultaneous rewrite is disabled (TAUDnRDE.TAUDnRDEm = 0), set these bits to 0.

TAUDnRDC.TAUDnRDCm	

33.12.2.5 Operating Procedure for TAUDnTTINm Input Interval Timer Function

Table 33.54 Operating Procedure for TAUDnTTINm Input Interval Timer Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in **Table 33.50, Contents of the TAUDnCMORm Register for TAUDnTTINm Input Interval Timer Function**, and **Table 33.51, Contents of the TAUDnCMURm Register for TAUDnTTINm Input Interval Timer Function**. Set the value of TAUDnCDRm register. Set channel output mode by setting the control bits as described in **Table 33.52, Control Bit Settings in Independent Channel Output Mode 1**.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and the counter starts. The TAUDnCDRm value is loaded in TAUDnCNTm. When TAUDnCMORm.TAUDnMD0 = 1, INTTAUDnIm is generated and TAUDnTTOUTm toggles.
During Operation	The values of the TAUDnCMURm.TAUDnTIS[1:0] and the TAUDnCDRm register are changeable at any time. The TAUDnCNTm register can be read at all times. Detection of TAUDnTTINm edge	TAUDnCNTm counts down. When the counter reaches 0000_H: • The TAUDnCDRm value is loaded in TAUDnCNTm again and count operation continues. • INTTAUDnIm is generated and TAUDnTTOUTm toggles. When a TAUDnTTINm input valid edge is detected during count operation, the TAUDnCDRm value is loaded in TAUDnCNTm and count operation continues. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

Restart Operation

33.12.2.6 Specific Timing Diagrams

The timing diagrams in **Section 33.12.1, Interval Timer Function** apply, and in addition the counter can also be restarted by a valid TAUDnTTINm input edge.

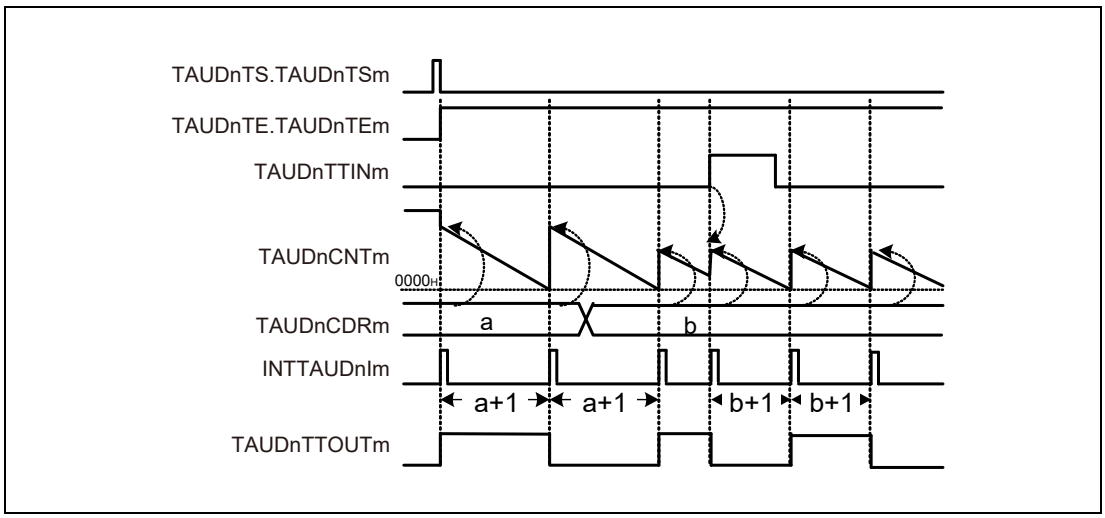

Figure 33.36 Counter Triggered by Rising TAUDnTTINm Input Edge (TAUDnCMURm.TAUDnTIS[1:0] = 01_B), TAUDnCMORm.TAUDnMD0 = 1

- If a valid TAUDnTTINm input edge is detected, an interrupt is generated which causes TAUDnTTOUTm to toggle. In this example, the valid edge is a rising edge (TAUDnCMURm.TAUDnTIS[1:0] = 01_B).

33.12.3 Clock Divide Function

33.12.3.1 Overview

Summary

This function is used as a frequency divider. The frequency of the input signal TAUDnTTINm is divided by a factor related to TAUDnCDRm, and the resulting signal is output to TAUDnTTOUTm.

Prerequisites

- TAUDnTTINm should have a fixed frequency.
- The operating mode should be set to interval timer mode. (See **Table 33.55, Contents of the TAUDnCMORm Register for Clock Divide Function**.)
- The channel output mode should be set to independent channel output mode 1. (See **Section 33.7, Channel Output Modes**.)

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This in turn sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The current value of TAUDnCDRm is loaded into TAUDnCNTm and the counter starts to count down from this value, using TAUDnTTINm as a count clock.

When the counter value reaches 0000_H, INTTAUDnIm occurs and TAUDnTTOUTm signal is toggled. Then, TAUDnCDRm value is loaded into TAUDnCNTm to continue operation subsequently.

The value of TAUDnCDRm can be rewritten at any time. The changed value of TAUDnCDRm is applied when the counter starts to count down next time.

The counter can be stopped by setting TAUDnTT.TAUDnTTm = 1. This sets TAUDnTE.TAUDnTEm = 0. TAUDnCNTm and TAUDnTTOUTm stop but retain their values. The function can be restarted by setting TAUDnTS.TAUDnTSm = 1. The counter can also be forcibly restarted without making a stop by setting TAUDnTS.TAUDnTSm = 1 during operation (forced restart).

Conditions

If the TAUDnCMORm.TAUDnMD0 bit is set to 0, the first interrupt after a start or restart is not generated, and therefore TAUDnTTOUTm does not toggle. This results in a negative TAUDnTTOUTm signal compared to when TAUDnCMORm.TAUDnMD0 is set to 1. For details, see **Section 33.9, TAUDnTTOUTm Output and INTTAUDnIm Generation when Counter Starts or Restarts**.

NOTE

TAUDnTTINm input signals are sampled at the frequency of the operation clock set by TAUDnCMORm.TAUDnCKS[1:0] bits. Therefore, the TAUDnTTOUTm output clock cycle has an error of ± 1 operation clock cycle.

33.12.3.2 Equations

- When rising edge detection is selected:
  TAUDnTTOUTm frequency = TAUDnTTINm frequency/[(TAUDnCDRm + 1) × 2]
- When falling edge detection is selected:
  TAUDnTTOUTm frequency = TAUDnTTINm frequency/[(TAUDnCDRm + 1) × 2]
- When falling and rising edge detection is selected:
  TAUDnTTOUTm frequency = TAUDnTTINm frequency/(TAUDnCDRm + 1)

33.12.3.3 Block Diagram and General Timing Diagram

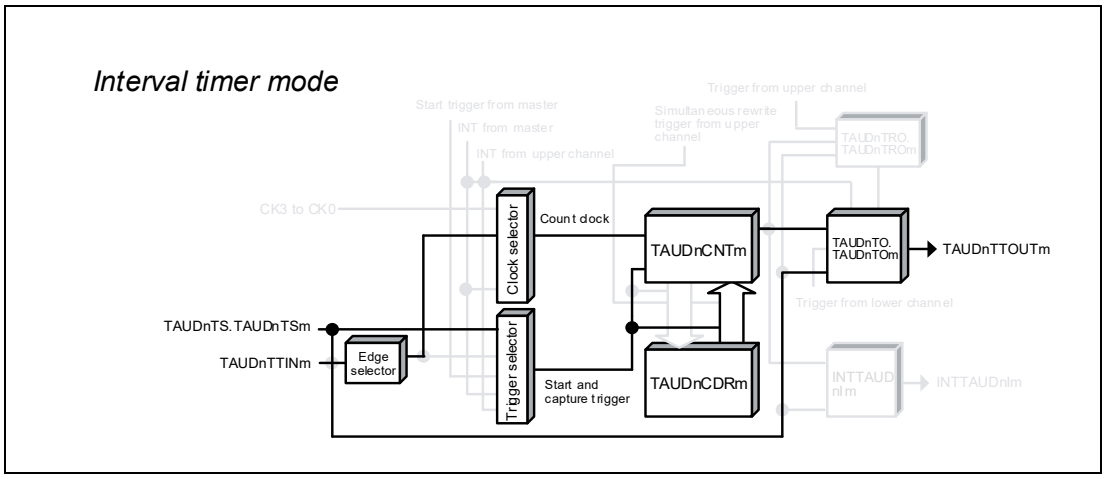

Figure 33.37 Block Diagram of Clock Divide Function

The following settings apply to the general timing diagram.

- INTTAUDnIm is generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 1)
- Detection of rising edge (TAUDnCMURm.TAUDnTIS[1:0] = 01_B)

TAUDnRDC.TAUDnRDCm	

33.12.3.5 Operating Procedure for Clock Divide Function

Table 33.59 Operating Procedure for Clock Divide Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in **Table 33.55, Contents of the TAUDnCMORm Register for Clock Divide Function**, and **Table 33.56, Contents of the TAUDnCMURm Register for Clock Divide Function**. Set the value of TAUDnCDRm register. Set channel output mode by setting the control bits as described in **Table 33.57, Control Bit Settings in Independent Channel Output Mode 1**.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and the counter starts. TAUDnCNTm loads TAUDnCDRm value. If TAUDnCMORm.TAUDnMD0 is set to 1, INTTAUDnIm is generated and TAUDnTTOUTm is toggled.
During Operation	The value of TAUDnCDRm is changeable at any time. The TAUDnCNTm register can be read at all times.	TAUDnCNTm counts down each time TAUDnTTINm input edge is detected. When the counter reaches 0000_H: • TAUDnCDRm value is loaded in TAUDnCNTm and count operation continues. • INTTAUDnIm is generated. • TAUDnTTOUTm is toggled. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops. TAUDnCNTm and TAUDnTTOUTm retain their current values.

Restart Operation

33.12.3.6 Specific Timing Diagrams

(1) TAUDnCDRm = 0000_H

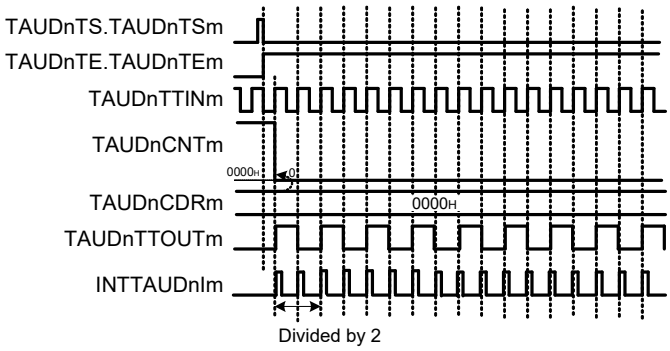

Figure 33.39 TAUDnCDRm = 0000_H, TAUDnCMORm.TAUDnMD0 = 1, TAUDnCMURm.TAUDnTIS[1:0] = 01_B

- If TAUDnCDRm is 0000_H, TAUDnCNTm is always 0000_H.
- INTTAUDnIm is generated every count clock, resulting in TAUDnTTOUTm toggling every count clock.

Figure 33.39 shows an operation timing example. Actually, there is a delay from TINm detection until TOUTm output because of the delay time of a noise filter or synchronization circuit placed between the TAUDnIm pin and TAUDn.

(2) Operation Restart

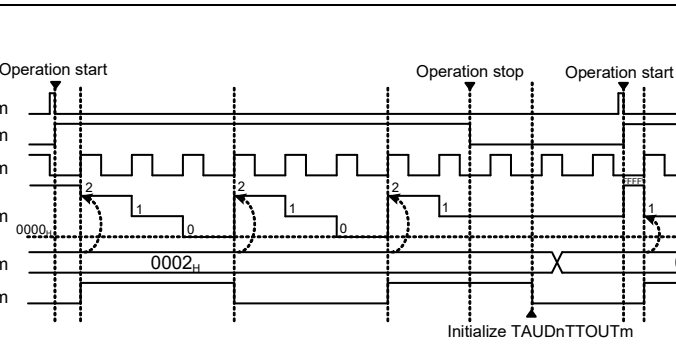

Figure 33.40 Operation Restart (TAUDnCMORm.TAUDnMD0 = 1, TAUDnCMURm.TAUDnTIS[1:0] = 01_B)

To reset the value of TAUDnTTOUTm:

- Set TAUDnTOE.TAUDnTOEm = 0 when the counter is stopped (TAUDnTE.TAUDnTEm = 0).
- Then, write either 0 or 1 to TAUDnTO.TAUDnTOm to set the new start value of TAUDnTTOUTm.

(3) Forced Restart

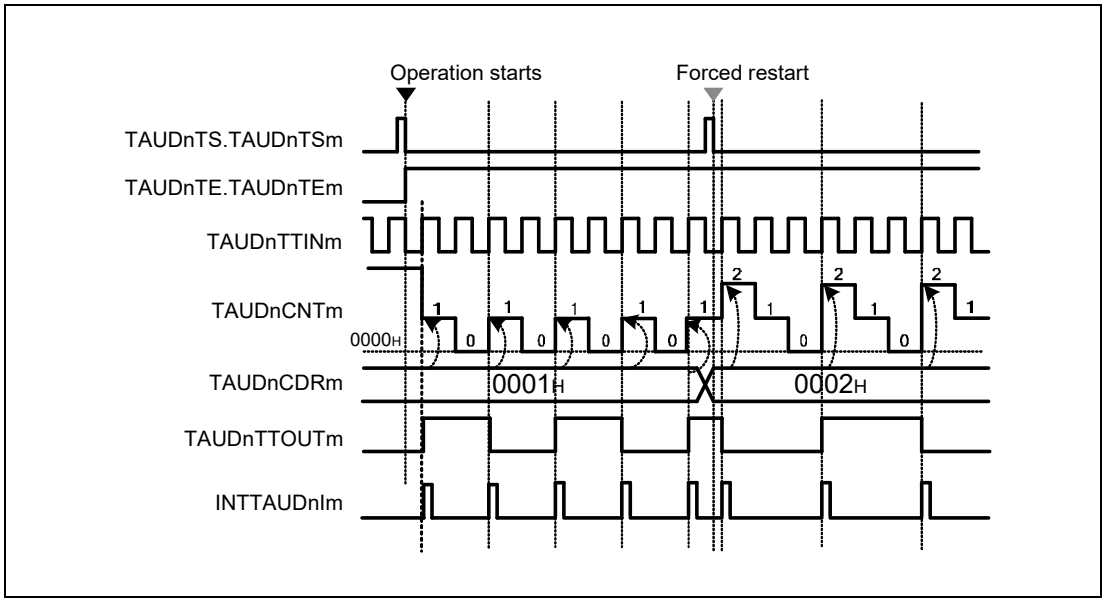

Figure 33.41 Forced Restart Operation (TAUDnCMORm.TAUDnMD0 = 1, TAUDnCMURm.TAUDnTIS[1:0] = 01_B)

- The counter can be forcibly restarted (without stopping it first) by setting TAUDnTS.TAUDnTSm = 1 during operation.
- The value of TAUDnCDRm is written to TAUDnCNTm and the count operation restarts.
- TAUDnTTOUTm restarts at the same level as before the forced restart.

33.12.4 External Event Count Function

33.12.4.1 Overview

Summary

This function is used as an event timer, which generates an interrupt (INTTAUDnIm) when a specific number of valid TAUDnTTINm input edges are detected.

Prerequisites

- The operating mode should be set to the event count mode. (See **Table 33.60, Contents of the TAUDnCMORm Register for External Event Count Function**.)
- TAUDnTTOUTm is not used with this function.

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This in turn sets TAUDnTE.TAUDnTEm = 1, enabling count operation. When the counter starts, the current value of TAUDnCDRm is loaded into TAUDnCNTm.

When a valid TAUDnTTINm input edge is detected, the value of TAUDnCNTm decrements by 1. TAUDnCNTm retains this value until a valid TAUDnTTINm input edge is detected or the counter is restarted.

When the valid edge is detected for the (TAUDnCDRm + 1) times, INTTAUDnIm is generated. Then, TAUDnCDRm value is loaded into TAUDnCNTm to continue operation subsequently.

The counter can be stopped by setting TAUDnTT.TAUDnTTm to 1. This sets TAUDnTE.TAUDnTEm to 0. The counter can be restarted by setting TAUDnTS.TAUDnTSm to 1. The counter can also be restarted without stopping it first (forced restart) by setting TAUDnTS.TAUDnTSm to 1 during operation.

The value of TAUDnCDRm can be rewritten at any time, and the changed value of TAUDnCDRm is applied the next time the counter starts to count down.

Conditions

An edge type used as a trigger is specified by TAUDnCMURm.TAUDnTIS[1:0] bits.

- When TAUDnCMURm.TAUDnTIS[1:0] = 00_B, falling edges are counted.
- When TAUDnCMURm.TAUDnTIS[1:0] = 01_B, rising edges are counted.
- When TAUDnCMURm.TAUDnTIS[1:0] = 10_B, both edges are counted.

33.12.4.2 Equations

Number of valid edges detected before INTTAUDnIm generation = TAUDnCDRm + 1

33.12.4.3 Block Diagram and General Timing Diagram

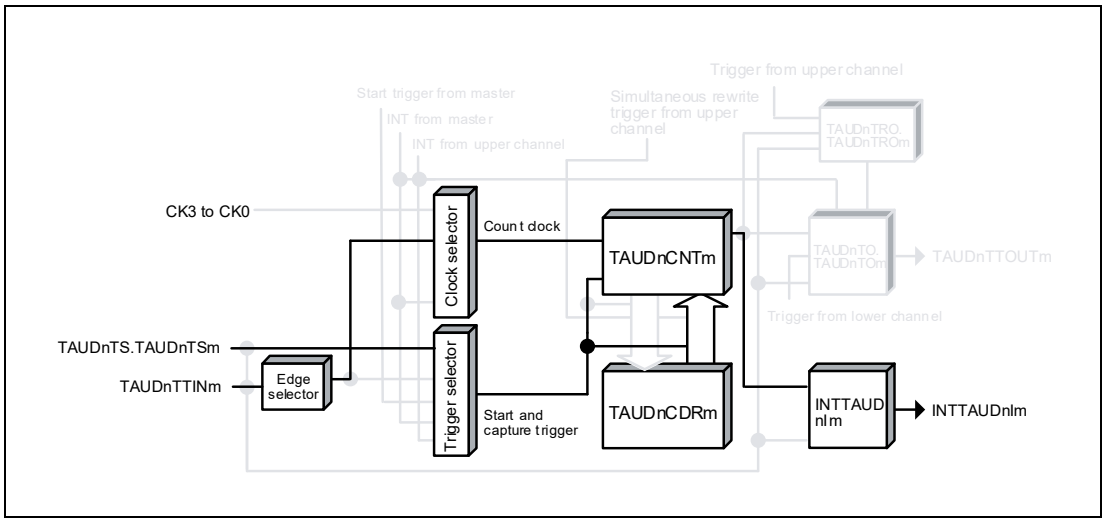

Figure 33.42 Block Diagram of External Event Count Function

The following settings apply to the general timing diagram.

Table 33.63 Operating Procedure for External Event Count Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in **Table 33.60, Contents of the TAUDnCMORm Register for External Event Count Function**, and **Table 33.61, Contents of the TAUDnCMURm Register for External Event Count Function**. Set the value of TAUDnCDRm register.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and the counter starts. TAUDnCNTm loads TAUDnCDRm value and waits for TAUDnTTINm input edge detection.
During Operation	Detection of TAUDnTTINm edge The value of TAUDnCDRm is changeable at any time. The TAUDnCNTm register can be read at any time.	TAUDnCNTm counts down each time TAUDnTTINm input edge is detected. When effective edges are detected (TAUDnCDRm + 1) times: • TAUDnCDRm value is loaded in TAUDnCNTm and count operation continues. • INTTAUDnIm is generated. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and retains its current value.

Restart Operation

33.12.4.6 Specific Timing Diagrams

(1) TAUDnCDRm = 0000_H

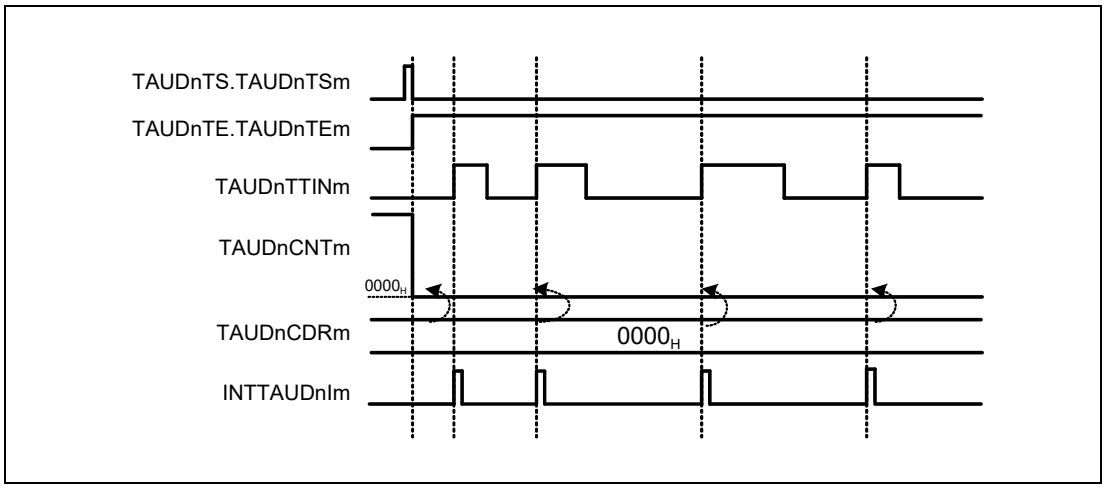

Figure 33.44 TAUDnCDRm = 0000_H, TAUDnCMURm.TAUDnTIS[1:0] = 01_B

- If 0000_H = TAUDnCDRm, 0000_H is loaded into TAUDnCNTm each time a valid TAUDnTTINm input edge is detected.
  In other words, INTTAUDnIm is generated each time a valid TAUDnTTINm input edge is detected.

(2) Operation Stop and Restart

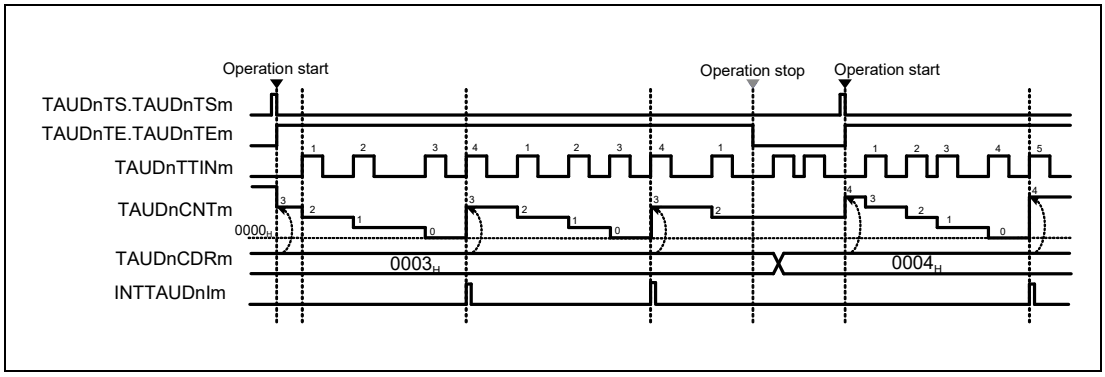

Figure 33.45 Operation Stop and Restart (TAUDnCMURm.TAUDnTIS[1:0] = 01_B)

- The counter can be stopped by setting TAUDnTT.TAUDnTTm to 1. This sets TAUDnTE.TAUDnTEm to 0.
- TAUDnCNTm stops and retains its current value. TAUDnTTINm continues and TAUDnCNTm ignores the valid edge.
- The counter can be restarted by setting TAUDnTS.TAUDnTSm to 1. TAUDnCNTm loads the TAUDnCDRm value and restarts count operation.

(3) Forced Restart

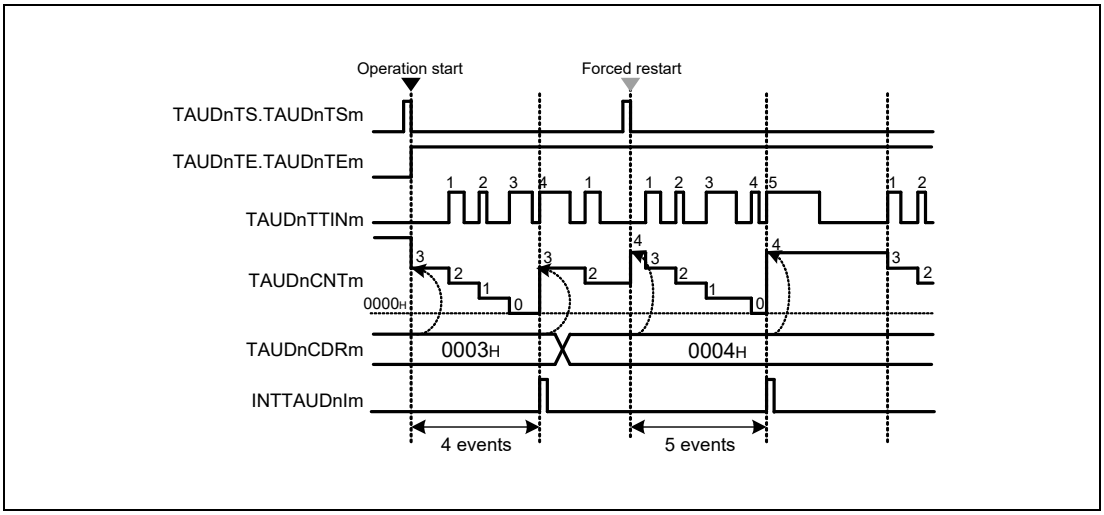

Figure 33.46 Forced Restart Operation (TAUDnCMURm.TAUDnTIS[1:0] = 01_B)

Once a forced restart is made, the changed TAUDnCDRm value is applied to TAUDnCNTm immediately.

- The counter can be restarted without making a stop by setting TAUDnTS.TAUDnTSm to 1 during operation.
- The value of TAUDnCDRm is loaded into TAUDnCNTm and the counter awaits the next valid TAUDnTTINm input edge.

33.12.5 Delay Count Function

33.12.5.1 Overview

Summary

This function generates interrupts (INTTAUDnIm), which have a defined delay to the TAUDnTTINm input signal. TAUDnTTINm input signal pulses that occur within the delay period are ignored.

Prerequisites

- The operating mode should be set to one-count mode. See **Table 33.64, Contents of the TAUDnCMORm Register for Delay Count Function**.
- TAUDnTTOUTm is not used with this function.
- Trigger detection should be disabled during counting (TAUDnCMORn.TAUDnMD0 = 0).

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This sets TAUDnTE.TAUDnTEm = 1, enabling count operation.

The counter starts when a valid TAUDnTTINm input start edge is detected. The value of TAUDnCDRm is loaded into TAUDnCNTm and the counter starts to count down from the TAUDnCDRm value.

When the counter reaches 0000_H, an interrupt is generated. The counter returns to $FFFF_H$ and awaits the next valid TAUDnTTINm input edge.

When the counter is counting down, further TAUDnTTINm input signals are ignored, i.e., the counter does not reset.

The value of TAUDnCDRm can be rewritten at any time, and the changed value of TAUDnCDRm is applied the next time the counter starts to count down.

Conditions

The type of edge used as a trigger is specified by the TAUDnCMURm.TAUDnTIS[1:0] bits.

- If TAUDnCMURm.TAUDnTIS[1:0] = 00_B, falling edges trigger the counter.
- If TAUDnCMURm.TAUDnTIS[1:0] = 01_B, rising edges trigger the counter.
- If TAUDnCMURm.TAUDnTIS[1:0] = 10_B, rising and falling edges trigger the counter.

33.12.5.5 Operating Procedure for Delay Count Function

Table 33.67 Operating Procedure for Delay Count Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in **Table 33.64, Contents of the TAUDnCMORm Register for Delay Count Function**, and **Table 33.65, Contents of the TAUDnCMURm Register for Delay Count Function**. Set the value of TAUDnCDRm register.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0. Detection of TAUDnTTINm start edge	TAUDnTE.TAUDnTEm is set to 1 and TAUDnCNTm waits for detection of the TAUDnTTINm start edge. When a start edge is detected, the TAUDnCDRm value is loaded in TAUDnCNTm.
During Operation	The TAUDnCDRm register value can be changed at any time. The TAUDnCNTm register can be read at all times.	TAUDnCNTm counts down. When the counter reaches 0000_H. INTTAUDnIm is generated. TAUDnCNTm stops counting, returns $FFFF_H$, and waits for a trigger. If a trigger occurs while TAUDnCNTm is counting, the trigger is ignored. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and retains its value.

Restart Operation

33.12.6 One-Pulse Output Function

33.12.6.1 Overview

Summary

This function generates an interrupt (INTTAUDnIm) when a valid TAUDnTTINm input edge is detected and at a defined interval afterward. TAUDnTTINm input signal pulses that occur within the defined interval are ignored. When an interrupt is generated, the TAUDnTTOUTm signal toggles, resulting in a square wave.

Prerequisites

- The operation mode should be set to pulse one-count mode. (See **Table 33.68, Contents of the TAUDnCMORm Register for One-Pulse Output Function**.)
- The channel output mode should be set to independent channel output mode 2. (See **Section 33.7, Channel Output Modes**.)
- Trigger detection should be disabled during counting (TAUDnCMORn.TAUDnMD0 = 0).

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This in turn sets TAUDnTE.TAUDnTEm = 1, enabling count operation.

The counter starts when a valid TAUDnTTINm input edge is detected. The value of TAUDnCDRm is loaded into TAUDnCNTm and the counter starts to count down from the TAUDnCDRm value. An interrupt is generated and TAUDnTTOUTm is set to active level.

When the counter reaches 0001_H, an interrupt is generated and TAUDnTTOUTm is set to the inactive level. The counter stops at 0000_H and awaits the next valid TAUDnTTINm input edge.

When the counter is counting down, further TAUDnTTINm input signals are ignored, i.e., the counter does not reset.

The value of TAUDnCDRm can be rewritten at any time, and the changed value of TAUDnCDRm is applied the next time the counter starts to count down.

Conditions

The type of edge used as a trigger is specified by the TAUDnCMURm.TAUDnTIS[1:0] bits.

- If TAUDnCMURm.TAUDnTIS[1:0] = 00_B, falling edges trigger the counter.
- If TAUDnCMURm.TAUDnTIS[1:0] = 01_B, rising edges trigger the counter.
- If TAUDnCMURm.TAUDnTIS[1:0] = 10_B, rising and falling edges trigger the counter.

33.12.6.2 Equations

Interval between TAUDnTTINm and INTTAUDnIm = TAUDnTTOUTm (timer output) width = count clock cycle × TAUDnCDRm

TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set these bits to 0
TAUDnTRC.TAUDnTRCm	
TAUDnTME.TAUDnTMEm	0: Disables modulation

NOTE

The channel output mode can also be set to channel output mode controlled by software by setting TAUDnTOE.TAUDnTOEm = 0. TAUDnTTOUTm can then be controlled independently of the interrupts. For details, see **Table 33.44, Channel Output Modes**.

(4) Simultaneous Rewrite

The simultaneous rewrite registers (TAUDnRDE, TAUDnRDS, TAUDnRDM, and TAUDnRDC) cannot be used with the One-Pulse Output Function. Therefore, these registers should be set to 0.

Table 33.71 Simultaneous Rewrite Settings for One-Pulse Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	0: Disables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: When simultaneous rewrite is disabled (TAUDnRDE.TAUDnRDEm = 0), set these bits to 0.
TAUDnRDM.TAUDnRDMm	
TAUDnRDC.TAUDnRDCm	

33.12.6.5 Operating Procedure for One-Pulse Output Function

Table 33.72 Operating Procedure for One-Pulse Output Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in **Table 33.68, Contents of the TAUDnCMORm Register for One-Pulse Output Function**, and **Table 33.69, Contents of the TAUDnCMURm Register for One-Pulse Output Function**. Set the value of TAUDnCDRm register. Set channel output mode by setting the control bits as described in **Table 33.70, Control Bit Settings in Independent Channel Output Mode 2**.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0. Detection of TAUDnTTINm start edge	TAUDnTE.TAUDnTEm is set to 1 and TAUDnCNTm waits for detection of the TAUDnTTINm start edge. When a start edge is detected, TAUDnCNTm loads the TAUDnCDRm value.
During Operation	The value of TAUDnCDRm is changeable at any time. The TAUDnCNTm register can be read at all times.	INTTAUDnIm is generated when TAUDnCNTm starts and TAUDnTTOUTm is set to its active level. TAUDnCNTm counts down. When the counter reaches 0001_H: • INTTAUDnIm is generated. • TAUDnTTOUTm is set to its inactive level. TAUDnCNTm stops counting and waits for a trigger. If a trigger occurs while TAUDnCNTm is counting, the trigger is ignored.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

Restart Operation

33.12.7 TAUDnTTINm Input Pulse Interval Measurement Function

33.12.7.1 Overview

Summary

This function captures the count value and uses this value and the overflow bit TAUDnCSRm.TAUDnOVF to measure the interval of the TAUDnTTINm input signals.

Prerequisites

- The operating mode should be set to capture mode. See **Table 33.74, Contents of the TAUDnCMORm Register for TAUDnTTINm Input Pulse Interval Measurement Function**.
- TAUDnTTOUTm is not used with this function.

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This in turn sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The counter TAUDnCNTm starts to count up from 0000_H. When a valid TAUDnTTINm edge is detected, the value of TAUDnCNTm is captured, transferred to TAUDnCDRm, and an interrupt INTTAUDnIm is generated. The counter resets to 0000_H and subsequently continues operation.

If the counter reaches $FFFF_H$ before a valid TAUDnTTINm edge is detected, it overflows to 0000_H. The counter is reset to 0000_H and subsequently continues operation. The values transferred to TAUDnCDRm and TAUDnCSRm.TAUDnOVF respectively depend on the values of bits TAUDnCMORm.TAUDnCOS[1:0].

Table 33.73 Effects of Overflow

TAUDnCMORm.TAUDnCOS[1:0]	When Overflow Occurs		When a Valid TAUDnTTINm Input is Detected	
	TAUDnCDRm	TAUDnCSRm.TAUDnOVF	TAUDnCDRm, TAUDnCNTm	TAUDnCSRm.TAUDnOVF
00	Unchanged	0	TAUDnCNTm loaded into TAUDnCDRm	1
01		1		
10	Set to $FFFF_H$	0	TAUDnCNTm set to 0, TAUDnCDRm unchanged	Unchanged
11		1		

When TAUDnCMORm.TAUDnCOS[0] = 1, the overflow bit (TAUDnCSRm.TAUDnOVF) can be cleared only by setting TAUDnCSCm.TAUDnCLOV = 1.

The combination of the value of TAUDnCDRm and TAUDnCSRm.TAUDnOVF can be used to deduce the interval of the TAUDnTTINm signal. However, if an overflow occurs multiple times before a valid TAUDnTTINm input is detected, the overflow bit TAUDnCSRm.TAUDnOVF cannot indicate the occurrence of multiple overflows.

The function can be stopped by setting TAUDnTT.TAUDnTTm = 1. This sets TAUDnTE.TAUDnTEm = 0. TAUDnCNTm stops but retains its value. While the function is stopped, valid TAUDnTTINm input edge detection and TAUDnCNTm capture are not performed.

The counter is reset to 0000_H and subsequently continues operation.

Conditions

If the TAUDnCMORm.TAUDnMD0 bit is set to 0, the first interrupt after a start or restart is not generated. For details, see **Section 33.9, TAUDnTTOUTm Output and INTTAUDnIm Generation when Counter Starts or Restarts**.

NOTE

When TAUDnCMORm.TAUDnCOS[1:0] = 10_B or 11_B, the value of TAUDnCNTm is not loaded into TAUDnCDRm when the first valid TAUDnTTINm input edge occurs after an overflow. However, an interrupt is generated.

33.12.7.2 Equations

TAUDnTTINm input pulse interval = count clock cycle × [(TAUDnCSRm.TAUDnOVF × ($FFFF_H$ + 1)) + TAUDnCDRm capture value + 1]

33.12.7.3 Block Diagram and General Timing Diagram

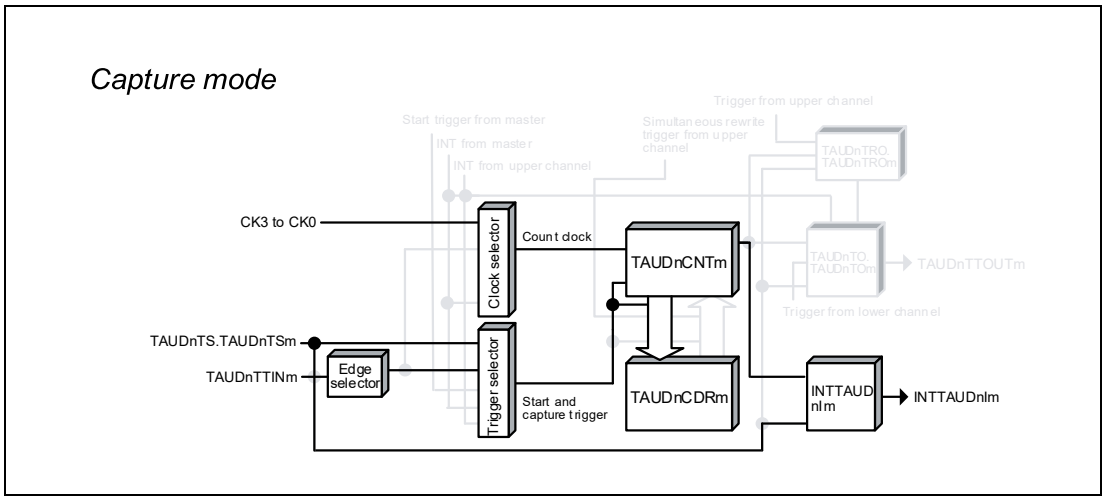

Figure 33.51 Block Diagram of TAUDnTTINm Input Pulse Interval Measurement Function

The following settings apply to the general timing diagram.

- INTTAUDnIm is not generated at the beginning of operation (TAUDnCMORm.TAUDnMD0 = 0).
- Falling edge detection (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)
- When a valid TAUDnTTINm input is detected after an overflow, TAUDnCDRm is changed and TAUDnCSRm.TAUDnOVF is set to 1 (TAUDnCMORm.TAUDnCOS[1:0] = 00_B).

33.12.7.5 Operating Procedure for TAUDnTTINm Input Pulse Interval Measurement Function

Table 33.77 Operating Procedure for TAUDnTTINm Input Pulse Interval Measurement Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in **Table 33.74, Contents of the TAUDnCMORm Register for TAUDnTTINm Input Pulse Interval Measurement Function**, and **Table 33.75, Contents of the TAUDnCMURm Register for TAUDnTTINm Input Pulse Interval Measurement Function**. The TAUDnCDRm register functions as a capture register.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and the counter starts. TAUDnCNTm is cleared to 0000_H. INTTAUDnIm is generated when TAUDnCMORm.TAUDnMD0 is set to 1.
During Operation	Detection of TAUDnTTINm edge The values of TAUDnCMURm.TAUDnTIS[1:0] bits can be changed at any time. The TAUDnCDRm and TAUDnCSRm registers can be read at any time. TAUDnCSCm.TAUDnCLOV can be written to 1. (TAUDnCSRm.TAUDnOVF bit is cleared to 0.)	TAUDnCNTm starts to count up from 0000_H. When a TAUDnTTINm valid edge is detected: • TAUDnCNTm transfers (captures) its value to TAUDnCDRm, and returns to 0000_H. • INTTAUDnIm is then generated. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and both it and TAUDnCSRm.TAUDnOVF retain their current values.

Restart Operation

33.12.7.6 Specific Timing Diagrams: Overflow Operation

(1) TAUDnCMORm.TAUDnCOS[1:0] = 00_B

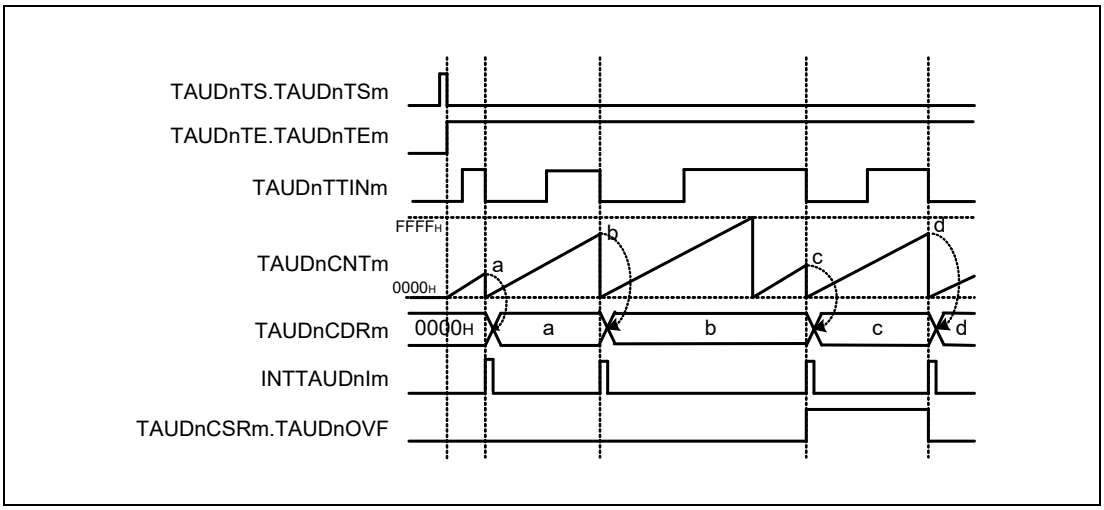

Figure 33.53 TAUDnCMORm.TAUDnCOS[1:0] = 00_B, TAUDnCMORm.TAUDnMD0 = 0, TAUDnCMURm.TAUDnTIS[1:0] = 00_B

- When an overflow occurs, the value of TAUDnCDRm remains unchanged and TAUDnCSRm.TAUDnOVF remains 0.
- Upon detection of the next valid TAUDnTTINm input edge, the value of TAUDnCNTm is loaded into TAUDnCDRm and TAUDnCSRm.TAUDnOVF is set to 1.
- Upon detection of the next valid TAUDnTTINm input edge with no overflow occurring, TAUDnCSRm.TAUDnOVF is cleared to 0.

(2) TAUDnCMORm.TAUDnCOS[1:0] = 01_B

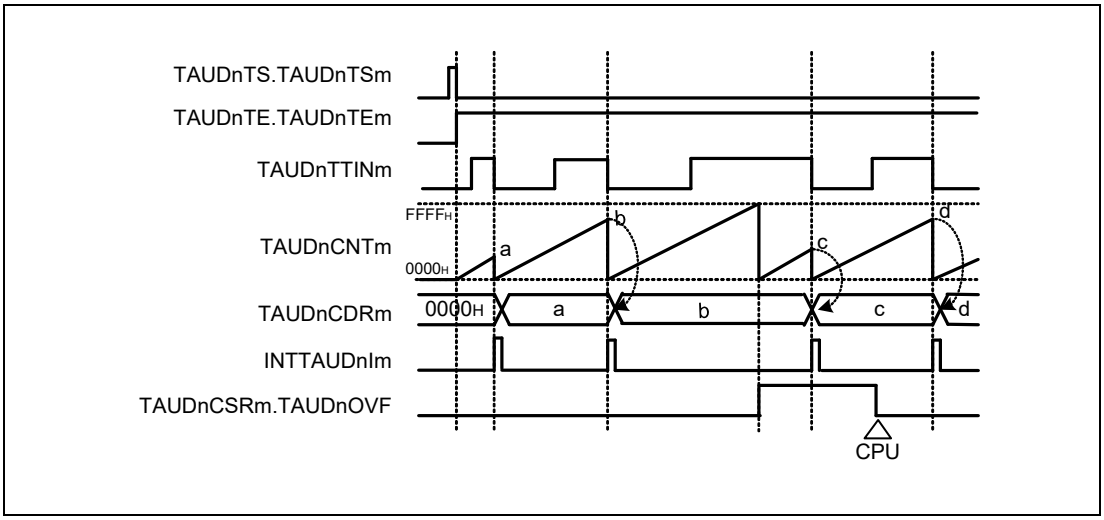

Figure 33.54 TAUDnCMORm.TAUDnCOS[1:0] = 01_B, TAUDnCMORm.TAUDnMD0 = 0, TAUDnCMURm.TAUDnTIS[1:0] = 00_B

- When an overflow occurs, the value of TAUDnCDRm remains unchanged and TAUDnCSRm.TAUDnOVF is set to 1.
- Upon detection of the next valid TAUDnTTINm input edge, the value of TAUDnCNTm is loaded into TAUDnCDRm.
- TAUDnCSRm.TAUDnOVF is only cleared by a CPU command (by setting TAUDnCSCm.TAUDnCLOV bit to 1).

(3) TAUDnCMORm.TAUDnCOS[1:0] = 10_B

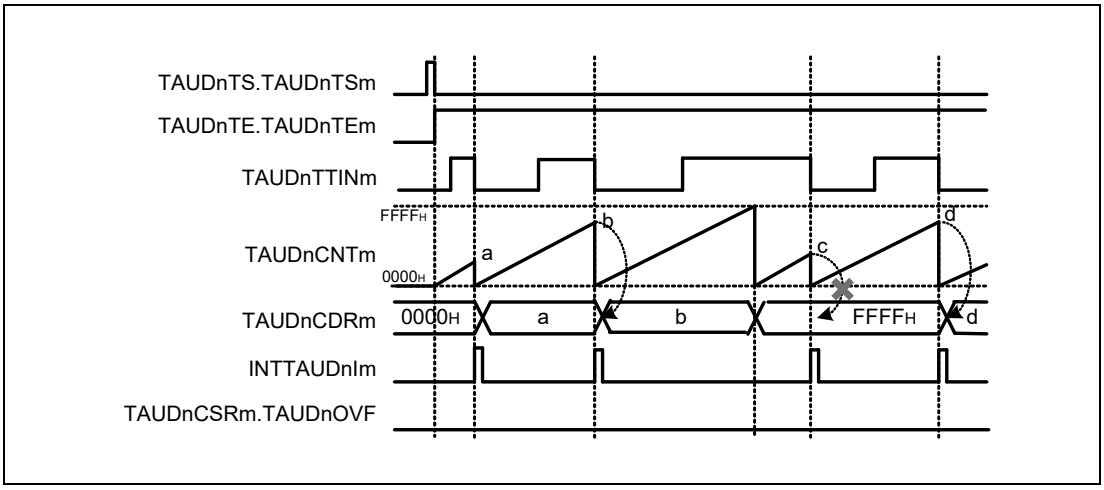

Figure 33.55 TAUDnCMORm.TAUDnCOS[1:0] = 10_B, TAUDnCMORm.TAUDnMD0 = 0, TAUDnCMURm.TAUDnTIS[1:0] = 00_B

- When an overflow occurs, TAUDnCDRm is set to $FFFF_H$ and TAUDnCSRm.TAUDnOVF remains 0.
- Upon detection of the next valid TAUDnTTINm input edge, TAUDnCNTm is reset to 0, but TAUDnCDRm and TAUDnCSRm.TAUDnOVF remain unchanged.
- Thus, the next valid TAUDnTTINm input edge after the overflow is ignored.

(4) TAUDnCMORm.TAUDnCOS[1:0] = 11_B

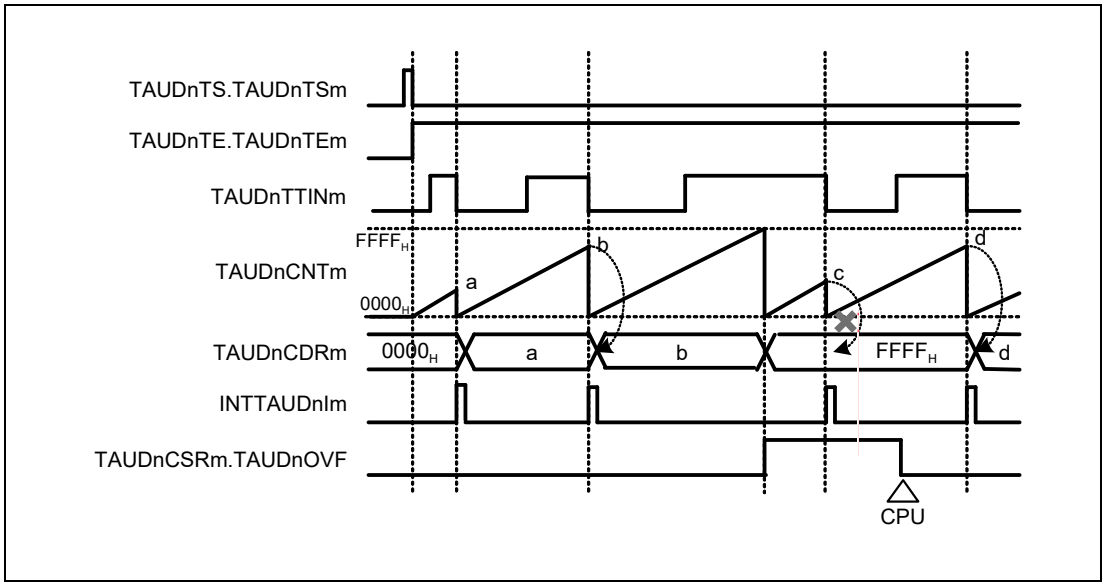

Figure 33.56 TAUDnCMORm.TAUDnCOS[1:0] = 11_B, TAUDnCMORm.TAUDnMD0 = 0, TAUDnCMURm.TAUDnTIS[1:0] = 00_B

- When an overflow occurs, TAUDnCDRm is set to $FFFF_H$ and TAUDnCSRm.TAUDnOVF is set to 1.
- Upon detection of the next valid TAUDnTTINm input edge, TAUDnCNTm is reset to 0, but TAUDnCDRm and TAUDnCSRm.TAUDnOVF remain unchanged.
- Thus, the next valid TAUDnTTINm input edge after the overflow is ignored.
- TAUDnCSRm.TAUDnOVF is cleared by setting TAUDnCSCm.TAUDnCLOV to 1.

33.12.8 TAUDnTTINm Input Signal Width Measurement Function

33.12.8.1 Overview

Summary

This function measures the width of a TAUDnTTINm signal, by starting the count at one edge of TAUDnTTINm and capturing the count value at the other edge.

Prerequisites

- The operating mode should be set to capture and one-count mode. See **Table 33.79, Contents of the TAUDnCMORm Register for TAUDnTTINm Input Signal Width Measurement Function**.
- TAUDnTTOUTm is not used with this function.
- TAUDnCMORm.TAUDnMD0 should be set to 0.

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This in turn sets TAUDnTE.TAUDnTEm = 1, enabling count operation. When a valid TAUDnTTINm start edge is detected, the counter TAUDnCNTm starts to count up from 0000_H. When a valid TAUDnTTINm stop edge is detected, the value of TAUDnCNTm is captured, transferred to TAUDnCDRm, and an interrupt INTTAUDnIm is generated. The counter retains its value (TAUDnCDRm +1) and awaits the next valid TAUDnTTINm input start edge.

If the counter reaches $FFFF_H$ before a valid TAUDnTTINm stop edge is detected, it overflows. The counter is reset to 0000_H and subsequently continues operation. The values transferred to TAUDnCDRm and TAUDnCSRm.TAUDnOVF respectively depend on the values of bits TAUDnCMORm.TAUDnCOS[1:0].

Table 33.78 Effects of Overflow

TAUDnCMORm. TAUDnCOS[1:0]	When Overflow Occurs		When a Valid TAUDnTTINm Input Stop Edge is Detected	
	TAUDnCDRm	TAUDnCSRm. TAUDnOVF	TAUDnCDRm, TAUDnCNTm	TAUDnCSRm. TAUDnOVF
00	Unchanged	0	TAUDnCNTm loaded into TAUDnCDRm	1
01		1		
10	Set to $FFFF_H$	0	TAUDnCNTm stops counting TAUDnCDRm unchanged	Unchanged
11		1		

When TAUDnCMORm.TAUDnCOS[0] = 1, overflow bit TAUDnCSRm.TAUDnOVF can be cleared only by setting TAUDnCSCm.TAUDnCLOV to 1.

The combination of the value of TAUDnCDRm and TAUDnCSRm.TAUDnOVF can be used to deduce the width of the TAUDnTTINm signal. However, if an overflow occurs multiple times before a valid TAUDnTTINm input is detected, overflow bit TAUDnCSRm.TAUDnOVF cannot indicate the occurrence of multiple overflows.

This function cannot be forcibly restarted.

NOTE

When TAUDnCMORm.TAUDnCOS[1] = 1, the value of TAUDnCNTm is not loaded to TAUDnCDRm when the first valid TAUDnTTINm input edge occurs after an overflow. However, an interrupt is generated.

33.12.8.2 Equations

TAUDnTTINm input signal width = count clock cycle × [(TAUDnCSRm.TAUDnOVF × ($FFFF_H$ + 1)) + TAUDnCDRm capture value + 1]

33.12.8.3 Block Diagram and General Timing Diagram

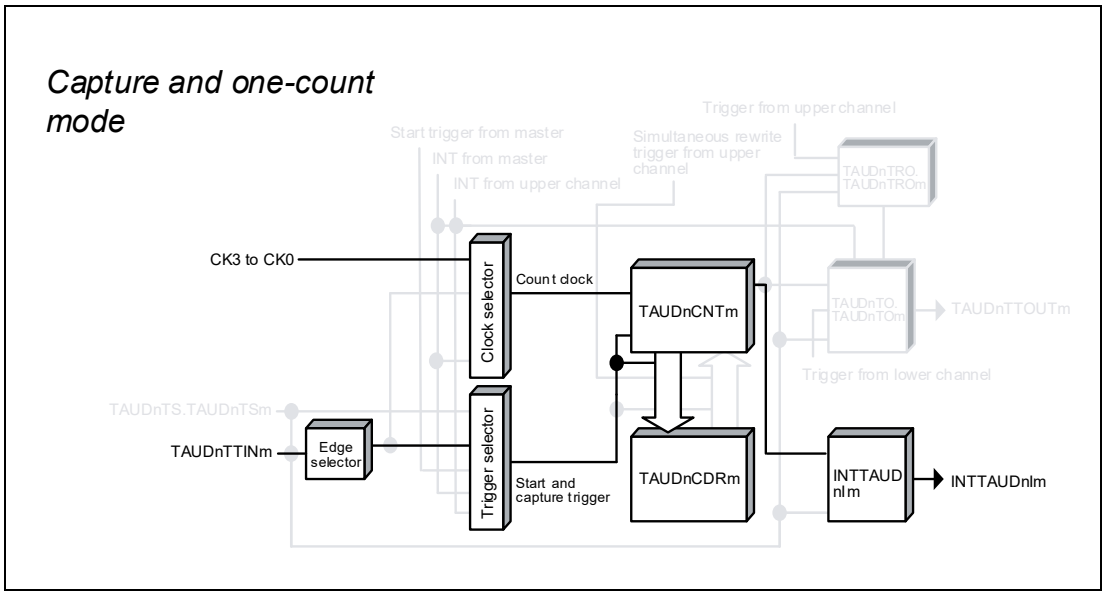

Figure 33.57 Block Diagram of TAUDnTTINm Input Signal Width Measurement Function

The following settings apply to the general timing diagram.

- Detection of rising and falling edges = high width measurement (TAUDnCMURm.TAUDnTIS[1:0] = 11_B)
- When a valid TAUDnTTINm input is detected after an overflow, TAUDnCDRm is changed and TAUDnCSRm.TAUDnOVF is set to 1. (TAUDnCMORm.TAUDnCOS[1:0] = 00_B)

1, 0	TAUDnTIS[1:0]	10: Detection of rising and falling edges (low width measurement) 11: Detection of rising and falling edges (high width measurement)

(3) Channel Output Mode

TAUDnTOE.TAUDnTOEm is set to 0 because the channel output mode is not used with this function.

(4) Simultaneous Rewrite

The simultaneous rewrite registers (TAUDnRDE, TAUDnRDS, TAUDnRDM, and TAUDnRDC) cannot be used with the TAUDnTTINm input signal width measurement function. Therefore, these registers should be set to 0.

Table 33.81 Simultaneous Rewrite Settings for TAUDnTTINm Input Signal Width Measurement Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	0: Disables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: When simultaneous rewrite is disabled (TAUDnRDE.TAUDnRDEm = 0), set these bits to 0.
TAUDnRDM.TAUDnRDMm	
TAUDnRDC.TAUDnRDCm	

33.12.8.5 Operating Procedure for TAUDnTTINm Input Signal Width Measurement Function

Table 33.82 Operating Procedure for TAUDnTTINm Input Signal Width Measurement Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in **Table 33.79, Contents of the TAUDnCMORm Register for TAUDnTTINm Input Signal Width Measurement Function**, and **Table 33.80, Contents of the TAUDnCMURm Register for TAUDnTTINm Input Signal Width Measurement Function**. The TAUDnCDRm register functions as a capture register.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and TAUDnCNTm waits for detection of the TAUDnTTINm start edge. When a TAUDnTTINm start edge is detected, TAUDnCNTm starts to count up.
During Operation	TAUDnCDRm, TAUDnCNTm, and TAUDnCSRm registers can be read at any time. TAUDnCSCm.TAUDnCLOV bit can be set to 1.	TAUDnCNTm starts to count up from 0000_H. When TAUDnTTINm valid edge is detected: • TAUDnCNTm transfers (captures) its value to TAUDnCDRm, and retains its value. INTTAUDnIm is then generated. Counting stops at the “value that transferred to TAUDnCDRm + 1” and TAUDnCNTm waits for detection of the TAUDnTTINm start edge. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and both it and TAUDnCSRm.TAUDnOVF retain their current values.

Restart Operation

33.12.8.6 Specific Timing Diagrams: Overflow Operation

(1) TAUDnCMORm.TAUDnCOS[1:0] = 00_B

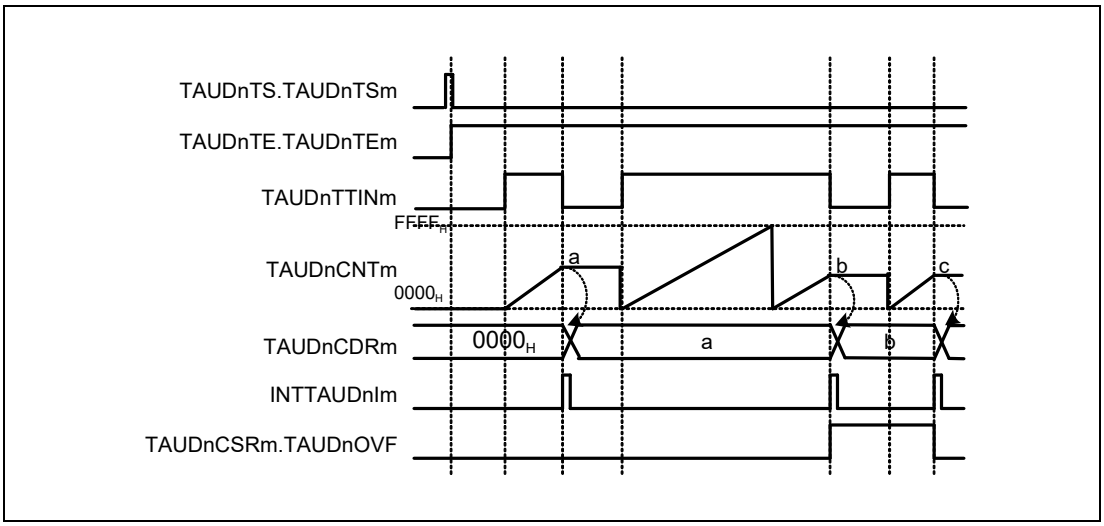

Figure 33.59 TAUDnCMORm.TAUDnCOS[1:0] = 00_B, TAUDnCMORm.TAUDnMD0 = 0, TAUDnCMURm.TAUDnTIS[1:0] = 11_B

- When an overflow occurs, the value of TAUDnCDRm remains unchanged and TAUDnCSRm.TAUDnOVF remains 0.
- Upon detection of the next valid TAUDnTTINm input edge, the value of TAUDnCNTm is loaded into TAUDnCDRm and TAUDnCSRm.TAUDnOVF is set to 1.
- Upon detection of the next valid TAUDnTTINm input edge with no overflow occurring, TAUDnCSRm.TAUDnOVF is cleared to 0.

(2) TAUDnCMORm.TAUDnCOS[1:0] = 01_B

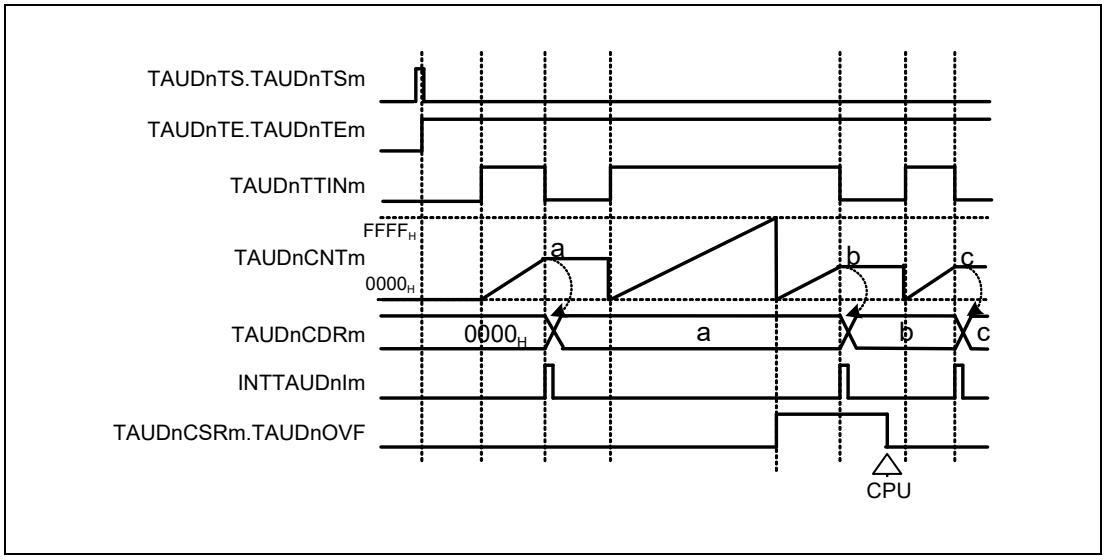

Figure 33.60 TAUDnCMORm.TAUDnCOS[1:0] = 01_B, TAUDnCMORm.TAUDnMD0 = 0, TAUDnCMURm.TAUDnTIS[1:0] = 11_B

- When an overflow occurs, the value of TAUDnCDRm remains unchanged and TAUDnCSRm.TAUDnOVF is set to 1.
- Upon detection of the next valid TAUDnTTINm input edge, the value of TAUDnCNTm is loaded into TAUDnCDRm.
- TAUDnCSRm.TAUDnOVF is only cleared by a CPU command (by setting TAUDnCSCm.TAUDnCLOV bit to 1).

(3) TAUDnCMORm.TAUDnCOS[1:0] = 10_B

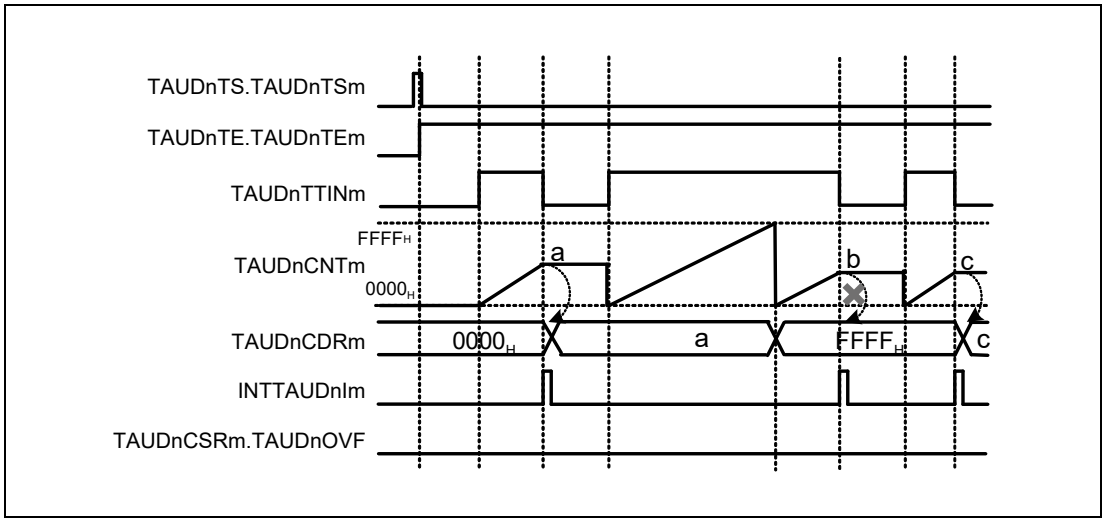

Figure 33.61 TAUDnCMORm.TAUDnCOS[1:0] = 10_B, TAUDnCMORm.TAUDnMD0 = 0, TAUDnCMURm.TAUDnTIS[1:0] = 11_B

- When an overflow occurs, TAUDnCDRm is set to $FFFF_H$ and TAUDnCSRm.TAUDnOVF remains 0.
- Upon detection of the next valid TAUDnTTINm input edge, TAUDnCNTm stops counting, but TAUDnCDRm and TAUDnCSRm.TAUDnOVF remain unchanged.
- Thus, the next valid TAUDnTTINm input edge after the overflow is ignored.

(4) TAUDnCMORm.TAUDnCOS[1:0] = 11_B

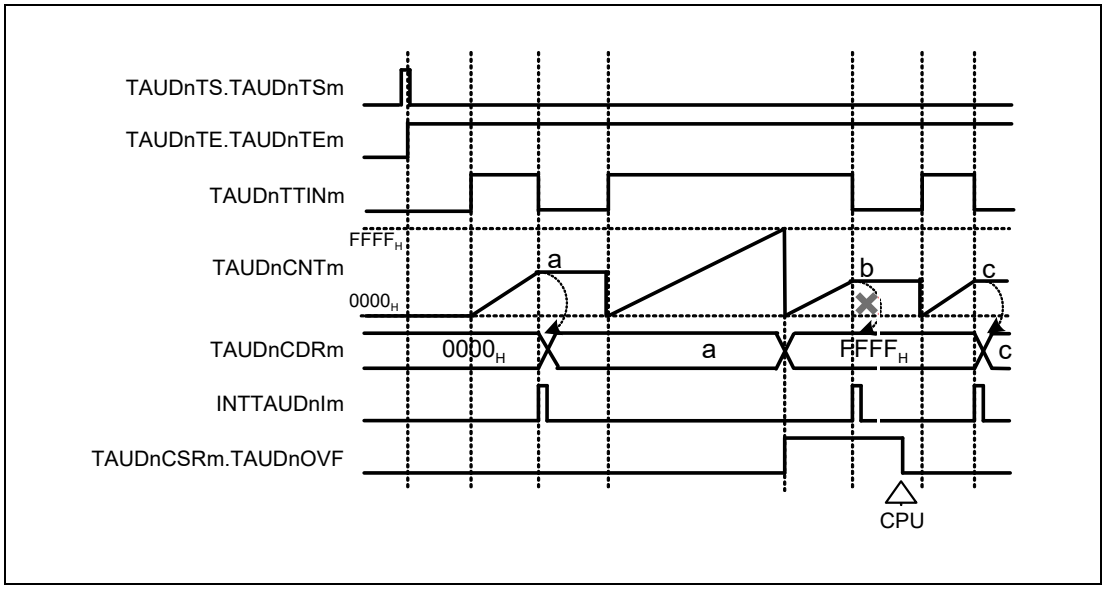

Figure 33.62 TAUDnCMORm.TAUDnCOS[1:0] = 11_B, TAUDnCMORm.TAUDnMD0 = 0, TAUDnCMURm.TAUDnTIS[1:0] = 11_B

- When an overflow occurs, TAUDnCDRm is set to $FFFF_H$ and TAUDnCSRm.TAUDnOVF is set to 1.
- Upon detection of the next valid TAUDnTTINm input edge, TAUDnCNTm stops counting, but TAUDnCDRm and TAUDnCSRm.TAUDnOVF remain unchanged.
- Thus, the next valid TAUDnTTINm input edge after the overflow is ignored.
- TAUDnCSRm.TAUDnOVF is cleared by setting TAUDnCSCm.TAUDnCLOV to 1.

33.12.9 TAUDnTTINm Input Position Detection Function

33.12.9.1 Overview

Summary

This function measures the input signal duration by capturing the count value at the valid edge of TAUDnTTINm.

Prerequisites

- The operating mode should be set to count capture mode. (See **Table 33.83, Contents of the TAUDnCMORm Register for TAUDnTTINm Input Position Detection Function**.)
- TAUDnTTOUTm is not used with this function.

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The counter starts counting from 0000_H. When a valid TAUDnTTINm input edge is detected, the current value of TAUDnCNTm is loaded into TAUDnCDRm and an interrupt (INTTAUDnIm) is generated. The count operation continues.

When the counter reaches $FFFF_H$, the counter restarts from 0000_H.

NOTE

The TAUDnTTINm input signal is sampled at the frequency of the operation clock, specified by TAUDnCMORm.TAUDnCKS[1:0] bits.

Conditions

If the TAUDnCMORm.TAUDnMD0 bit is set to 0, the first interrupt does not occur at the beginning of operation or after restart. For details, see **Section 33.9, TAUDnTTOUTm Output and INTTAUDnIm Generation when Counter Starts or Restarts**.

33.12.9.2 Equations

Functional duration at a TAUDnTTINm input pulse =

count clock cycle × (TAUDnCDRm capture value + 1)

33.12.9.3 Block Diagram and General Timing Diagram

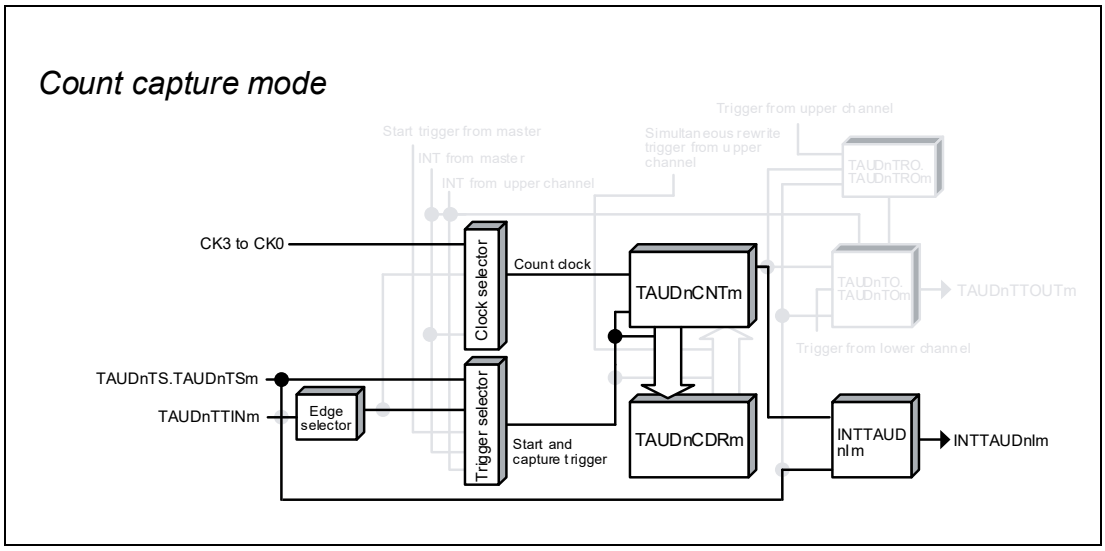

Figure 33.63 Block Diagram of TAUDnTTINm Input Position Detection Function

The following settings apply to the general timing diagram.

- INTTAUDnIm is not generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 0)
- Detection of falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

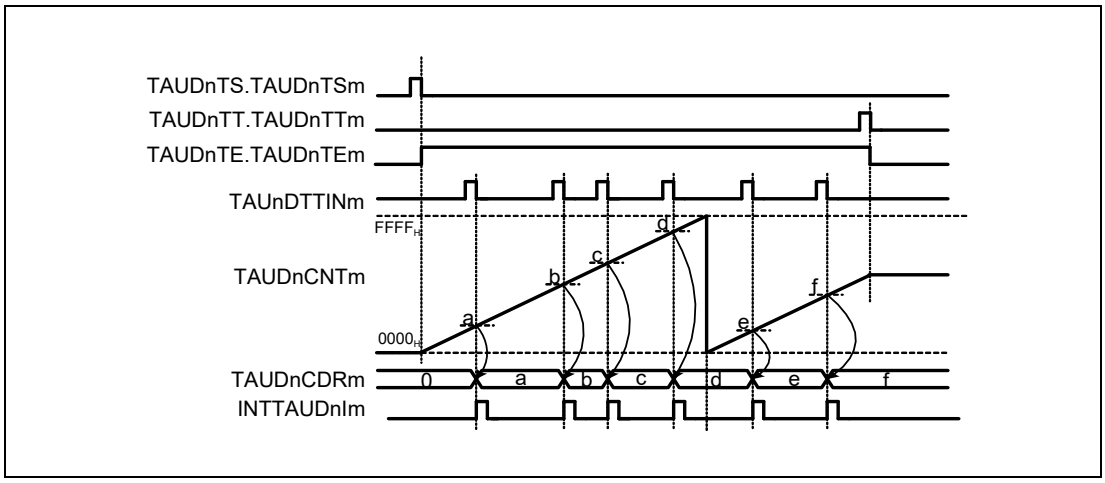

Figure 33.64 General Timing Diagram of TAUDnTTINm Input Position Detection Function

33.12.9.5 Operating Procedure for TAUDnTTINm Input Position Detection Function

Table 33.86 Operating Procedure for TAUDnTTINm Input Position Detection Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in **Table 33.83, Contents of the TAUDnCMORm Register for TAUDnTTINm Input Position Detection Function**, and **Table 33.84, Contents of the TAUDnCMURm Register for TAUDnTTINm Input Position Detection Function**. The TAUDnCDRm register functions as a capture register.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and the counter starts. If TAUDnCMORm.TAUDnMD0 is 1, INTTAUDnIm occurs.
During Operation	The values of TAUDnCMURm.TAUDnTIS[1:0] bits can be changed at any time. The TAUDnCDRm and TAUDnCSRm registers can be read at any time.	TAUDnCNTm starts to count up from 0000_H. When a valid TAUDnTTINm edge is detected: • TAUDnCNTm transfers (captures) its own value to TAUDnCDRm. • Outputs INTTAUDnIm. • The counter is not cleared to 0000_H and TAUDnCNTm continues counting. Afterwards, this procedure is repeated. When TAUDnCNTm reaches $FFFF_H$, the counter restarts from 0000_H.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and retains its current value.

Restart Operation

33.12.9.6 Specific Timing Diagrams

(1) Operation Stop and Restart

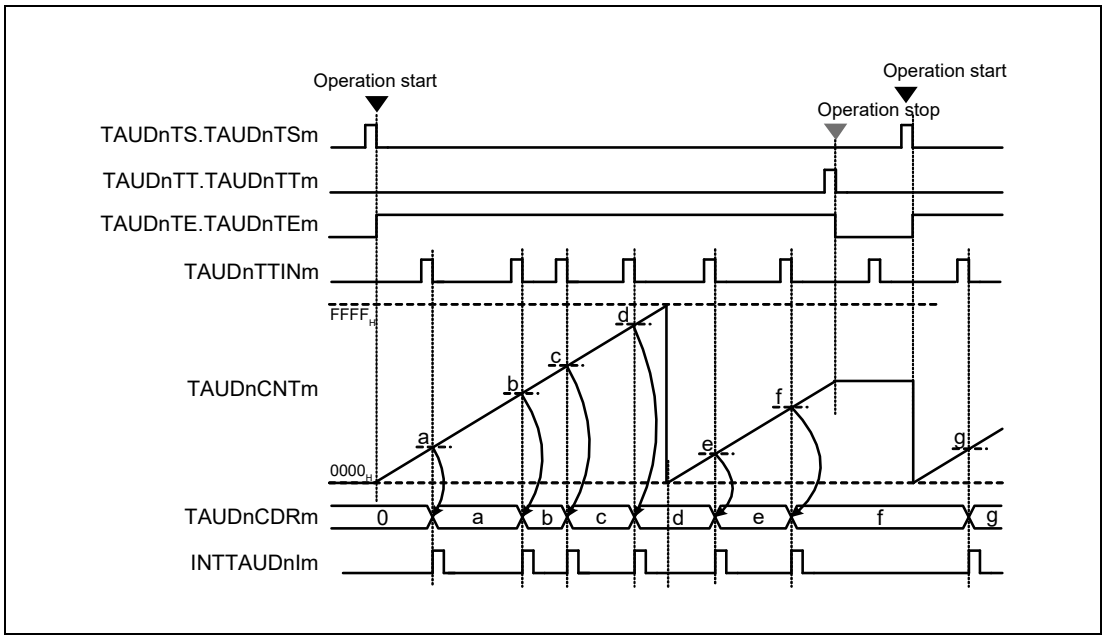

Figure 33.65 Operation Stop and Restart (TAUDnCMORm.TAUDnMD0 = 0, TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

- The counter can stop operating by setting TAUDnTT.TAUDnTTm to 1. This sets TAUDnTE.TAUDnTEm to 0.
- TAUDnCNTm stops and retains its current value.
- If the counter stops operating, valid TAUDnTTINm input edges are ignored.
- The counter can be restarted by setting TAUDnTS.TAUDnTSm to 1. TAUDnCNTm restarts to count from 0000_H.

33.12.10 TAUDnTTINm Input Period Count Detection Function

33.12.10.1 Overview

Summary

This function measures the cumulative width of a TAUDnTTINm input signal.

Prerequisites

- The operating mode should be set to capture and gate count mode. (See **Table 33.87, Contents of the TAUDnCMORm Register for TAUDnTTINm Input Period Count Detection Function**.)
- TAUDnTTOUTm is not used with this function.

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This in turn sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The counter awaits a valid TAUDnTTINm input edge.

When a valid TAUDnTTINm input start edge is detected, the counter starts to count from 0000_H.

When a valid TAUDnTTINm input stop edge is detected, the current TAUDnCNTm value is loaded into TAUDnCDRm and an interrupt (INTTAUDnIm) is generated. The counter stops and retains its value (TAUDnCDRm + 1) until the next valid TAUDnTTINm input start edge is detected.

When the next valid TAUDnTTINm input start edge is detected, the counter restarts to count from the value retained when stopped.

If the counter reaches $FFFF_H$, the counter restarts from 0000_H.

NOTES

1. TAUDnTTINm input signal is sampled at the frequency of an operation clock set by the TAUDnCMORm.TAUDnCKS[1:0] bits.
2. As this function is to measure the TAUDnTTINm input signal width, setting TAUDnTS.TAUDnTSm to 1 is disabled while TAUDnTE.TAUDnTEm = 1.

Conditions

The valid start and stop edges are specified by the TAUDnCMURm.TAUDnTIS[1:0] bits.

- If TAUDnCMURm.TAUDnTIS[1:0] = 10_B, the TAUDnTTINm input low width is measured. The start trigger is a falling edge and the stop trigger is a rising edge.
- If TAUDnCMURm.TAUDnTIS[1:0] = 11_B, the TAUDnTTINm input high width is measured. The start trigger is a rising edge and the stop trigger is a falling edge.

33.12.10.2 Equations

Cumulative TAUDnTTINm input width = count clock cycle × (TAUDnCDRm capture value + 1)

33.12.10.3 Block Diagram and General Timing Diagram

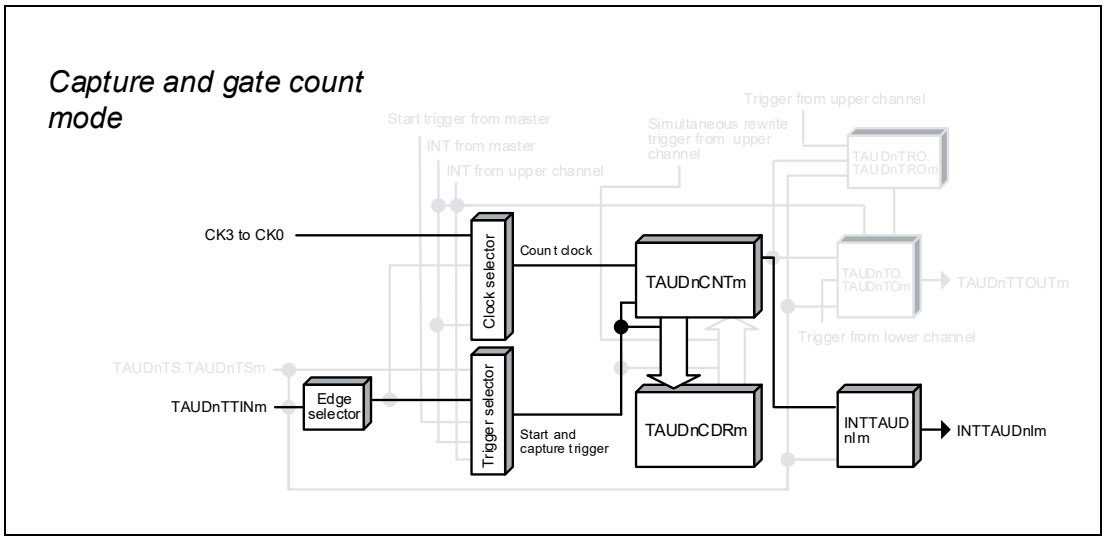

Figure 33.66 Block Diagram of TAUDnTTINm Input Period Count Detection Function

The following settings apply to the general timing diagram.

- Detection of rising and falling edges = high width measurement (TAUDnCMURm.TAUDnTIS[1:0] = 11_B)

Table 33.88 Contents of the TAUDnCMURm Register for TAUDnTTINm Input Period Count Detection Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	10: Detection of rising and falling edges (low width measurement) 11: Detection of rising and falling edges (high width measurement)

(3) Channel Output Mode

TAUDnTOE.TAUDnTOEm is set to 0 because the channel output mode is not used with this function.

(4) Simultaneous Rewrite

Simultaneous rewrite registers (TAUDnRDE, TAUDnRDS, TAUDnRDM, and TAUDnRDC) cannot be used with the TAUDnTTINm input period count detection function. Therefore, these registers should be set to 0.

Table 33.89 Simultaneous Rewrite Settings for TAUDnTTINm Input Period Count Detection Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	0: Disables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: When simultaneous rewrite is disabled (TAUDnRDE.TAUDnRDEm = 0), set these bits to 0.
TAUDnRDM.TAUDnRDMm	
TAUDnRDC.TAUDnRDCm	

33.12.10.5 Operating Procedure for TAUDnTTINm Input Period Count Detection Function

Table 33.90 Operating Procedure for TAUDnTTINm Input Period Count Detection Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in **Table 33.87, Contents of the TAUDnCMORm Register for TAUDnTTINm Input Period Count Detection Function**, and **Table 33.88, Contents of the TAUDnCMURm Register for TAUDnTTINm Input Period Count Detection Function**. The TAUDnCDRm register functions as a capture register.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and TAUDnCNTm waits for detection of the TAUDnTTINm start edge.
During Operation	Detection of TAUDnTTINm edge The TAUDnCDRm, TAUDnCNTm, and TAUDnCSRm registers can be read at any time.	When a TAUDnTTINm start edge (rising edge for high width measurement, falling edge for low width measurement) is detected, TAUDnCNTm starts counting up from the stop value. When TAUDnCNTm detects a stop edge (falling edge for high width measurement, rising edge for low width measurement), it transfers the value to TAUDnCDRm and INTTAUDnIm is generated. Counting stops at the “value transferred to TAUDnCDRm + 1” and TAUDnCNTm waits for detection of the TAUDnTTINm start edge. When TAUDnCNTm reaches $FFFF_H$, the counter restarts from 0000_H. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and retains its current value.

Restart Operation

33.12.10.6 Specific Timing Diagrams

(1) Operation stop and restart

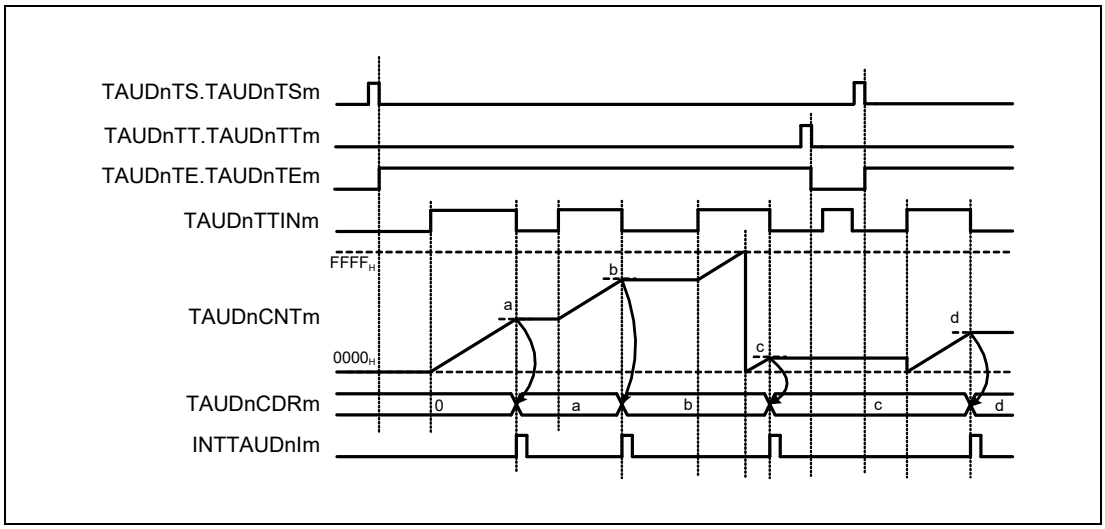

Figure 33.68 Operation Stop and Restart (TAUDnCMURm.TAUDnTIS[1:0] = 11_B)

- The counter can be stopped by setting TAUDnTT.TAUDnTTm to 1. This sets TAUDnTE.TAUDnTEm to 0.
- TAUDnCNTm stops and retains its current value.
- If the counter is stopped, valid TAUDnTTINm input edges are ignored.
- The counter can be restarted by setting TAUDnTS.TAUDnTSm to 1. TAUDnCNTm restarts to count from 0000_H.

33.12.11 TAUDnTTINm Input Pulse Interval Judgment Function

33.12.11.1 Overview

Summary

This function outputs the result of a comparison between the count value (TAUDnCNTm) and the value in the channel data register (TAUDnCDRm) when a TAUDnTTINm input pulse occurs. An interrupt request signal INTTAUDnIm is generated if the result of the comparison is true.

Prerequisites

- The operating mode should be set to judge mode. See **Table 33.91, Contents of the TAUDnCMORm Register for TAUDnTTINm Input Pulse Interval Judgment Function**.
- TAUDnTTOUTm is not used with this function.

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This in turn sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The current value of TAUDnCDRm is loaded into TAUDnCNTm and the counter starts to count down from this value.

When a TAUDnTTINm valid edge is detected or TAUDnTS.TAUDnTSm is set to 1, the function compares the current values of TAUDnCNTm and TAUDnCDRm. An interrupt request signal INTTAUDnIm is generated if the result of the comparison is true. TAUDnCNTm reloads the value of TAUDnCDRm and subsequently continues operation, regardless of the result of the comparison.

If the counter reaches 0000_H before a TAUDnTTINm valid edge is detected, TAUDnCNTm overflows and is set to $FFFF_H$. It then continues to count down.

The value of TAUDnCDRm can be rewritten at any time, and the changed value of TAUDnCDRm is applied the next time the counter starts to count down.

Conditions

The TAUDnCMORm.TAUDnMD0 bit specifies the type of comparison:

- If TAUDnCMORm.TAUDnMD0 = 0, INTTAUDnIm is generated when TAUDnCNTm ≤ TAUDnCDRm.
- If TAUDnCMORm.TAUDnMD0 = 1, INTTAUDnIm is generated when TAUDnCNTm > TAUDnCDRm.

33.12.11.2 Block Diagram and General Timing Diagram

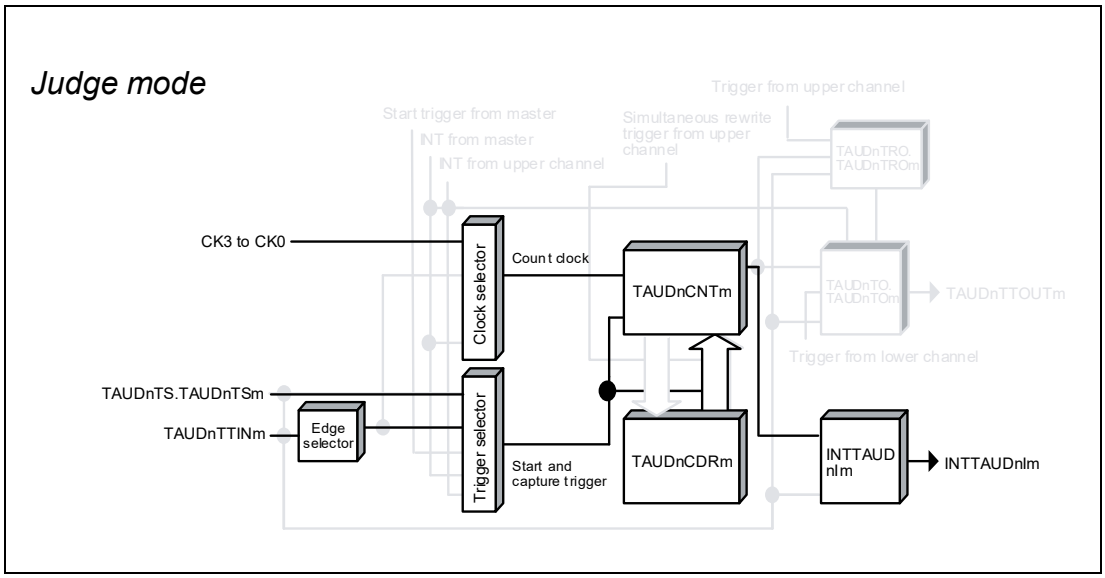

Figure 33.69 Block Diagram of TAUDnTTINm Input Pulse Interval Judgment Function

The following settings apply to the general timing diagram.

- Detection of falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

33.12.11.4 Operating Procedure for TAUDnTTINm Input Pulse Interval Judgment Function

Table 33.94 Operating Procedure for TAUDnTTINm Input Pulse Interval Judgment Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in **Table 33.91, Contents of the TAUDnCMORm Register for TAUDnTTINm Input Pulse Interval Judgment Function**, and **Table 33.92, Contents of the TAUDnCMURm Register for TAUDnTTINm Input Pulse Interval Judgment Function**. Set the value of TAUDnCDRm register.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and the counter starts. TAUDnCDRm value is loaded into TAUDnCNTm.
During Operation	The following register can be changed at any time: • TAUDnCDRm register	When TAUDnCMORm.TAUDnMD0 = 0 If TAUDnCNTm ≤ TAUDnCDRm when a TAUDnTTINm input edge is detected, INTTAUDnIm is generated. When TAUDnCMORm.TAUDnMD0 = 1 If TAUDnCNTm > TAUDnCDRm when a TAUDnTTINm input edge is detected, INTTAUDnIm is generated. If a TAUDnTTINm input edge is detected, then TAUDnCNTm starts to count down from the value of TAUDnCDRm. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and retains its current value.

Restart Operation

33.12.12 TAUDnTTINm Input Signal Width Judgment Function

33.12.12.1 Overview

Summary

This function compares the count value (TAUDnCNTm) for the high or low level width of a TAUDnTTINm input signal and the TAUDnCDRm value, and outputs the judgment result from the interrupt request signal INTTAUDnIm.

Prerequisites

- The operating mode should be set to judge and one-count mode. (See **Table 33.95, Contents of the TAUDnCMORm Register for TAUDnTTINm Input Signal Width Judgment Function**.)
- TAUDnTTOUTm is not used with this function.

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This in turn sets TAUDnTE.TAUDnTEm = 1, enabling count operation. When a valid TAUDnTTINm input start edge is detected, the current value of TAUDnCDRm is loaded into TAUDnCNTm and the counter starts to count down from this value.

When a TAUDnTTINm valid stop edge is detected, the function compares the current values of TAUDnCNTm and TAUDnCDRm. An interrupt request signal INTTAUDnIm is generated if the result of the comparison is true. The counter TAUDnCNTm retains its value until the next valid TAUDnTTINm start edge is detected, regardless of the result of the comparison.

If the counter reaches 0000_H before a valid TAUDnTTINm stop edge is detected, TAUDnCNTm overflows and is set to $FFFF_H$. The counter then continues to count down.

The value of TAUDnCDRm can be rewritten at any time, and the changed value of TAUDnCDRm is applied the next time the counter starts to count down.

Conditions

- The TAUDnCMORm.TAUDnMD0 bit specifies the type of comparison:
  - If TAUDnCMORm.TAUDnMD0 = 0, INTTAUDnIm is generated when TAUDnCNTm ≤ TAUDnCDRm.
  - If TAUDnCMORm.TAUDnMD0 = 1, INTTAUDnIm is generated when TAUDnCNTm > TAUDnCDRm.
- The TAUDnCMURm.TAUDnTIS[1:0] bits specify a type of width measurement:
  - For high width measurement (TAUDnCMURm.TAUDnTIS[1:0] = 11_B), TAUDnTTINm rising edge is used as a start edge and TAUDnTTINm falling edge as a stop edge.
  - For low width measurement (TAUDnCMURm.TAUDnTIS[1:0] = 10_B), TAUDnTTINm falling edge is used as a start edge and TAUDnTTINm rising edge as a stop edge.
- Setting TAUDnTS.TAUDnTSm to 1 is prohibited during operation.

33.12.12.2 Block Diagram and General Timing Diagram

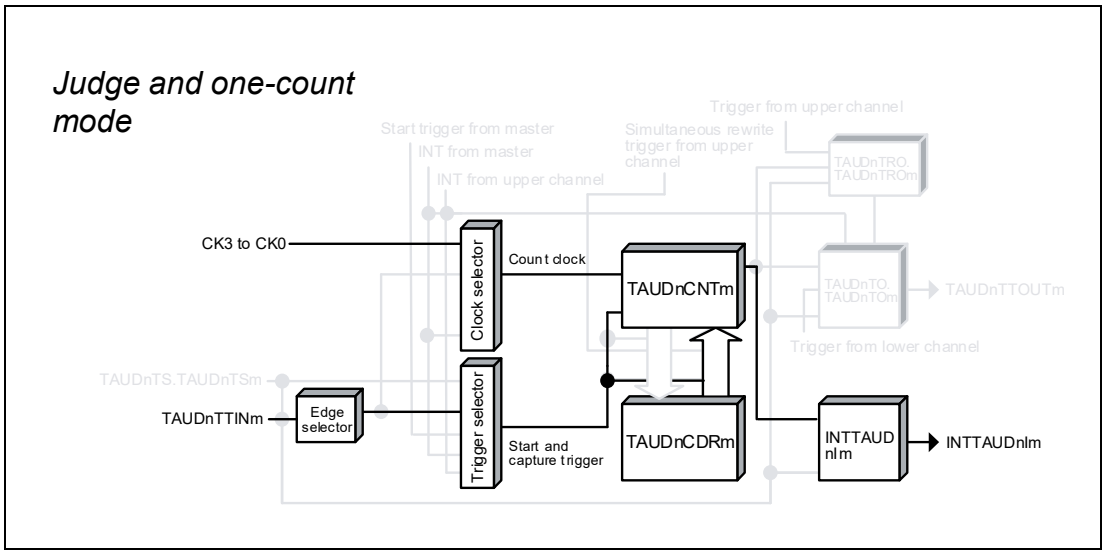

Figure 33.71 Block Diagram of TAUDnTTINm Input Signal Width Judgment Function

The following settings apply to the general timing diagram.

- INTTAUDnIm is generated when TAUDnCNTm ≤ TAUDnCDRm (TAUDnCMORm.TAUDnMD0 = 0).
- TAUDnTTINm valid start edge = rising edge, TAUDnTTINm valid stop edge = falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 11_B)

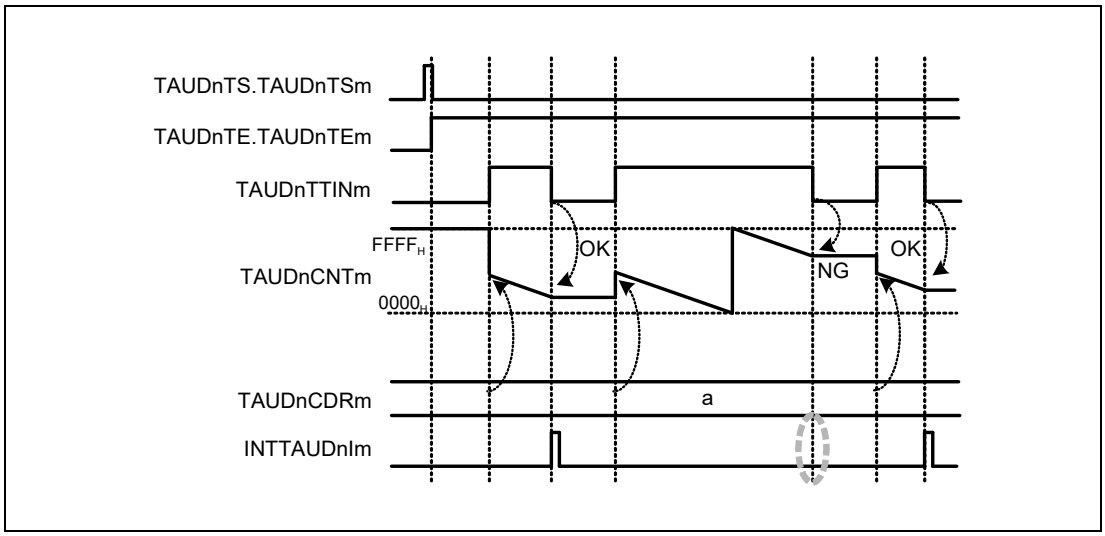

Figure 33.72 General Timing Diagram of TAUDnTTINm Input Signal Width Judgment Function

33.12.12.4 Operating Procedure for TAUDnTTINm Input Signal Width Judgment Function

Table 33.98 Operating Procedure for TAUDnTTINm Input Signal Width Judgment Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in **Table 33.95, Contents of the TAUDnCMORm Register for TAUDnTTINm Input Signal Width Judgment Function**, and **Table 33.96, Contents of the TAUDnCMURm Register for TAUDnTTINm Input Signal Width Judgment Function**. Set the value of TAUDnCDRm register.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and TAUDnCNTm waits for detection of the TAUDnTTINm start edge.
During Operation	The following register can be changed at any time: • TAUDnCDRm register	Upon detection of a TAUDnTTINm start edge, TAUDnCNTm starts count down from the value of TAUDnCDRm. When TAUDnCMORm.TAUDnMD0 = 0 If TAUDnCNTm ≤ TAUDnCDRm when a TAUDnTTINm input stop edge is detected, INTTAUDnIm is generated. When TAUDnCMORm.TAUDnMD0 = 1 If TAUDnCNTm > TAUDnCDRm when a TAUDnTTINm input stop edge is detected, INTTAUDnIm is generated. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and retains its current value.

Restart Operation

33.12.13 Overflow Interrupt Output Function (during TAUDnTTINm Width Measurement)

33.12.13.1 Overview

Summary

This function measures the width of an individual TAUDnTTINm input signal. An interrupt is generated if the TAUDnTTINm input width is longer than $FFFF_H + 1$.

Prerequisites

- The operation mode must be set to One-Count Mode (see **Table 33.99, Contents of the TAUDnCMORm Register for Overflow Interrupt Output Function (during TAUDnTTINm Width Measurement)**).
- TAUDnTTOUTm is not used for this function.
- The value of TAUDnCDRm must be set to $FFFF_H$.

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This in turn sets TAUDnTE.TAUDnTEm = 1, enabling count operation.

The counter starts when a valid TAUDnTTINm input start edge is detected. $FFFF_H$ is loaded to TAUDnCNTm and the counter starts to count down.

When a valid stop edge is detected, the counter stops and retains the current value.

When the next TAUDnTTINm input start edge is detected, TAUDnCNTm loads $FFFF_H$ and starts to count down.

If the counter reaches 0000_H before a stop edge is detected, an interrupt is generated.

Conditions

The valid start and stop edges are specified by the TAUDnCMURm.TAUDnTIS[1:0] bits.

- If TAUDnCMURm.TAUDnTIS[1:0] = 10_B, the TAUDnTTINm input low width is measured. The start trigger is a falling edge and the stop trigger is a rising edge.
- If TAUDnCMURm.TAUDnTIS[1:0] = 11_B, the TAUDnTTINm input high width is measured. The start trigger is a rising edge and the stop trigger is a falling edge.

NOTE

The counter cannot be restarted during operation.

33.12.13.2 Block Diagram and General Timing Diagram

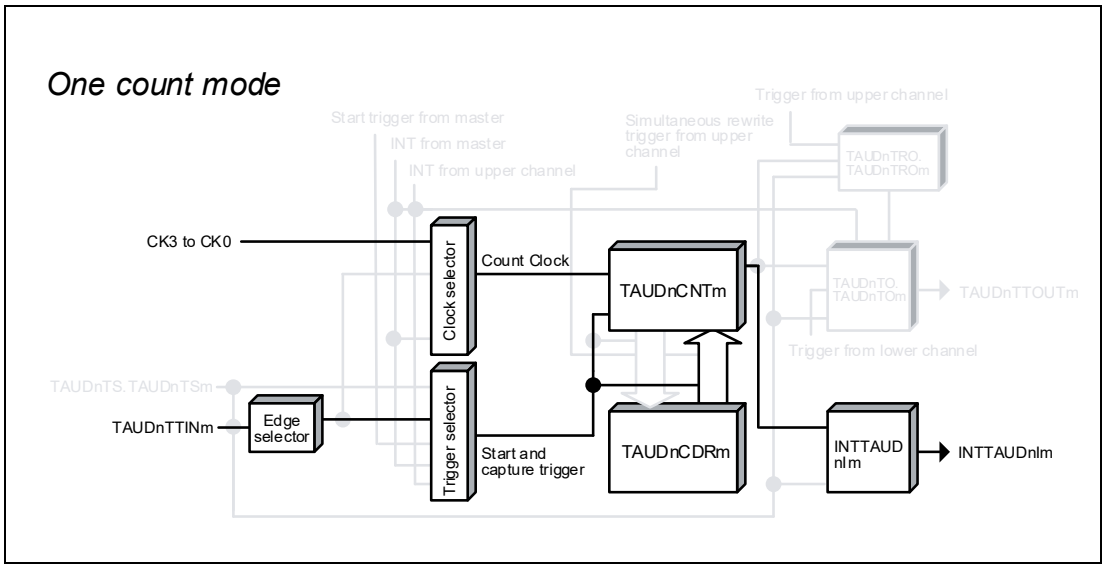

Figure 33.73 Block Diagram for Overflow Interrupt Output Function (during TAUDnTTINm Width Measurement)

The following settings apply to the general timing diagram.

- Detection of rising and falling edges = high width measurement (TAUDnCMURm.TAUDnTIS[1:0] = 11_B)

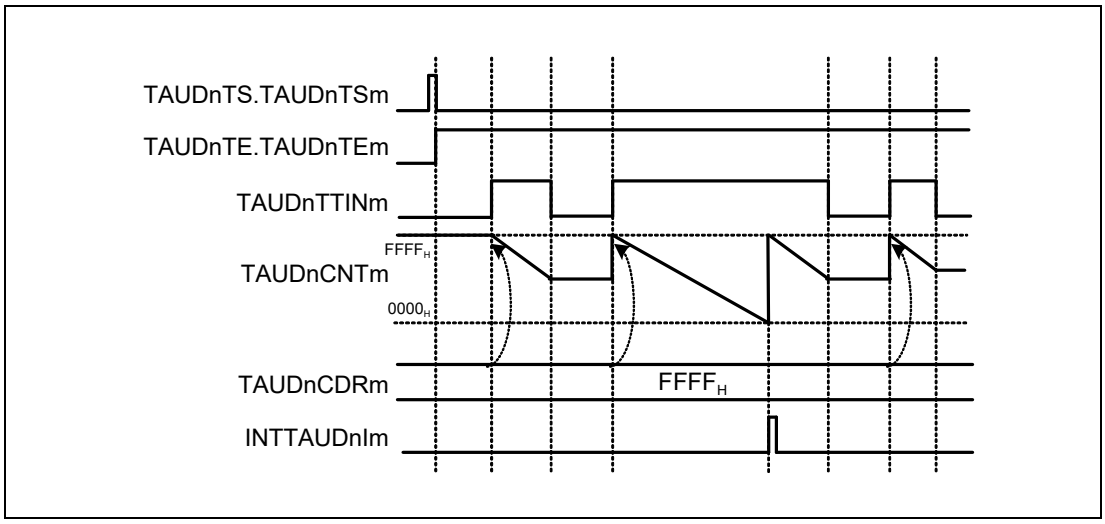

Figure 33.74 General Timing Diagram for Overflow Interrupt Output Function (during TAUDnTTINm Width Measurement)

33.12.13.4 Operating Procedure for Overflow Interrupt Output Function (during TAUDnTTINm Width Measurement)

Table 33.102 Operating Procedure for Overflow Interrupt Output Function (during TAUDnTTINm Width Measurement)

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in **Table 33.99, Contents of the TAUDnCMORm Register for Overflow Interrupt Output Function (during TAUDnTTINm Width Measurement)**, and **Table 33.100, Contents of the TAUDnCMURm Register for Overflow Interrupt Output Function (during TAUDnTTINm Width Measurement)**. Set the value of TAUDnCDRm register to $FFFF_H$.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0. Detection of TAUDnTTINm start edge	TAUDnTE.TAUDnTEm is set to 1 and TAUDnCNTm waits for detection of the start edge. When a start edge is detected, TAUDnCNTm loads the TAUDnCDRm value ($FFFF_H$).
During Operation	The TAUDnCNTm register can be read at any time.	TAUDnCNTm counts down. When the counter reaches 0000_H: INTTAUDnIm is generated. When TAUDnTTINm input stop edge is detected during count operation: • TAUDnCNTm stops and retains its current value. When TAUDnTTINm input start edge is detected while the counter is stopped: • TAUDnCNTm loads the TAUDnCDRm value ($FFFF_H$) again, and continues to count down. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and retains its current value.

Restart Operation

33.12.14 Overflow Interrupt Output Function (during TAUDnTTINm Input Period Count Detection)

33.12.14.1 Overview

Summary

This function measures the cumulative width of a TAUDnTTINm input signal. If the cumulative TAUDnTTINm input width is longer than $FFFF_H$, an interrupt is generated and an overflow interrupt can be output.

Prerequisites

- The operation mode must be set to Gate Count Mode, (see **Table 33.103, Contents of the TAUDnCMORm Register for Overflow Interrupt Output Function (during TAUDnTTINm Input Period Count Detection)**).
- TAUDnTTOUTm is not used with this function.
- The value of TAUDnCDRm must be set to $FFFF_H$.

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This in turn sets TAUDnTE.TAUDnTEm = 1, enabling count operation.

The counter starts when a valid TAUDnTTINm input start edge is detected. $FFFF_H$ is loaded to TAUDnCNTm and the counter starts to count down.

When a valid stop edge is detected, the counter stops and retains the current value. The counter awaits the next TAUDnTTINm input start edge and then continues to count down from the current value.

When the counter reaches 0000_H an interrupt is generated. $FFFF_H$ is loaded to TAUDnCNTm and the counter continues to count down until a TAUDnTTINm input stop edge is detected.

Conditions

The valid start and stop edges are specified by theTAUDnCMURm.TAUDnTIS[1:0] bits.

- If TAUDnCMURm.TAUDnTIS[1:0] = 10_B, the TAUDnTTINm input low width is counted. The start trigger is a falling edge and the stop trigger is a rising edge.
- If TAUDnCMURm.TAUDnTIS[1:0] = 11_B, the TAUDnTTINm input high width is counted. The start trigger is a rising edge and the stop trigger is a falling edge.

NOTE

The counter cannot be restarted during operation.

TAUDnRDC.TAUDnRDCm	

33.12.14.4 Operating Procedure for Overflow Interrupt Output Function (during TAUDnTTINm Input Period Count Detection)

Table 33.106 Operating Procedure for Overflow Interrupt Output Function (during TAUDnTTINm Input Period Count Detection)

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in **Table 33.103, Contents of the TAUDnCMORm Register for Overflow Interrupt Output Function (during TAUDnTTINm Input Period Count Detection)**, and **Table 33.104, Contents of the TAUDnCMURm Register for Overflow Interrupt Output Function (during TAUDnTTINm Input Period Count Detection)**. Set the value of TAUDnCDRm register to $FFFF_H$.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0. Detection of TAUDnTTINm start edge	TAUDnTE.TAUDnTEm is set to 1 and TAUDnCNTm waits for detection of the start edge. When a start edge is detected, TAUDnCNTm loads the TAUDnCDRm value ($FFFF_H$).
During Operation	The TAUDnCNTm register can be read at all times.	TAUDnCNTm counts down. When the counter reaches 0000_H: • INTTAUDnIm is generated. • TAUDnCNTm loads the TAUDnCDRm value ($FFFF_H$) and continues to count down. When TAUDnTTINm input stop edge is detected during count operation: • TAUDnCNTm stops and retains the current value. When TAUDnTTINm input start edge is detected while the counter is stopped: • TAUDnCNTm counts down from the stop value. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and retains its current value.

Restart Operation

33.12.15 One-Phase PWM Output Function

33.12.15.1 Overview

Summary

This function adds dead time to a TAUDnTTINm input signal. The resulting PWM signal is output via TAUDnTTOUTm of the channel and TAUDnTTOUTm of upper channels.

Prerequisites

- Each of two (or more) channels is enabled for dead time control (TAUDnTDE.TAUDnTDEm = 1).
- The operating mode for the lower channel should be set to one-count mode. (See **Table 33.108, Contents of the TAUDnCMORm Register for the Lower Channel of the One-Phase PWM Output Function**.)
- Any operating mode can be set to upper channels.
- Channel output mode for upper and lower channels should be set to synchronous channel output mode 2 with one-phase PWM output. (See **Section 33.7, Channel Output Modes**.)

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This sets TAUDnTE.TAUDnTEm = 1, enabling count operation.

The counter starts when a valid TAUDnTTINm input start edge is detected. The value of TAUDnCDRm is loaded into TAUDnCNTm and the counter starts to count down from the TAUDnCDRm value.

When the counter reaches 0000_H, an interrupt occurs. The counter is reset to $FFFF_H$ and waits for the next valid TAUDnTTINm input start edge.

Table 33.107 TAUDnTTOUTm to which Dead Time is Added and State of TAUDnTTINm

TAUDnCMURm. TAUDnTIS[1:0]	TAUDnTOL. TAUDnTOLm	TAUDnTTOUTm to which Dead Time is Added	TAUDnTDL. TAUDnTDLm	TAUDnTTINm State when Added
10	0	TAUDnTTOUTm low	0	High
			1	Low
	1	TAUDnTTOUTm high	0	High
			1	Low
11	0	TAUDnTTOUTm low	0	Low
			1	High
	1	TAUDnTTOUTm high	0	Low
			1	High

Conditions

- TAUDnCMURm.TAUDnTIS[1:0] bits specify the type of width measurement:
  - TAUDnCMURm.TAUDnTIS[1:0] = 10_B: Uses both edges as valid edges for detection (Low width measurement).
  - TAUDnCMURm.TAUDnTIS[1:0] = 11_B: Uses both edges as valid edges for detection (High width measurement).
- The TAUDnTDL.TAUDnTDLm bit specifies the operation of TAUDnTTOUTm for each channel when an interrupt or valid TAUDnTTINm edge is detected on the lower channel:
  - If TAUDnTDL.TAUDnTDLm = 0, an interrupt is used as a TAUDnTTOUTm set trigger and a valid TAUDnTTINm edge as a TAUDnTTOUTm reset trigger.
  - If TAUDnTDL.TAUDnTDLm = 1, a valid TAUDnTTINm edge is used as a TAUDnTTOUTm set trigger and an interrupt as a TAUDnTTOUTm reset trigger.
- This function cannot make a forced restart.

33.12.15.2 Block Diagram and General Timing Diagram

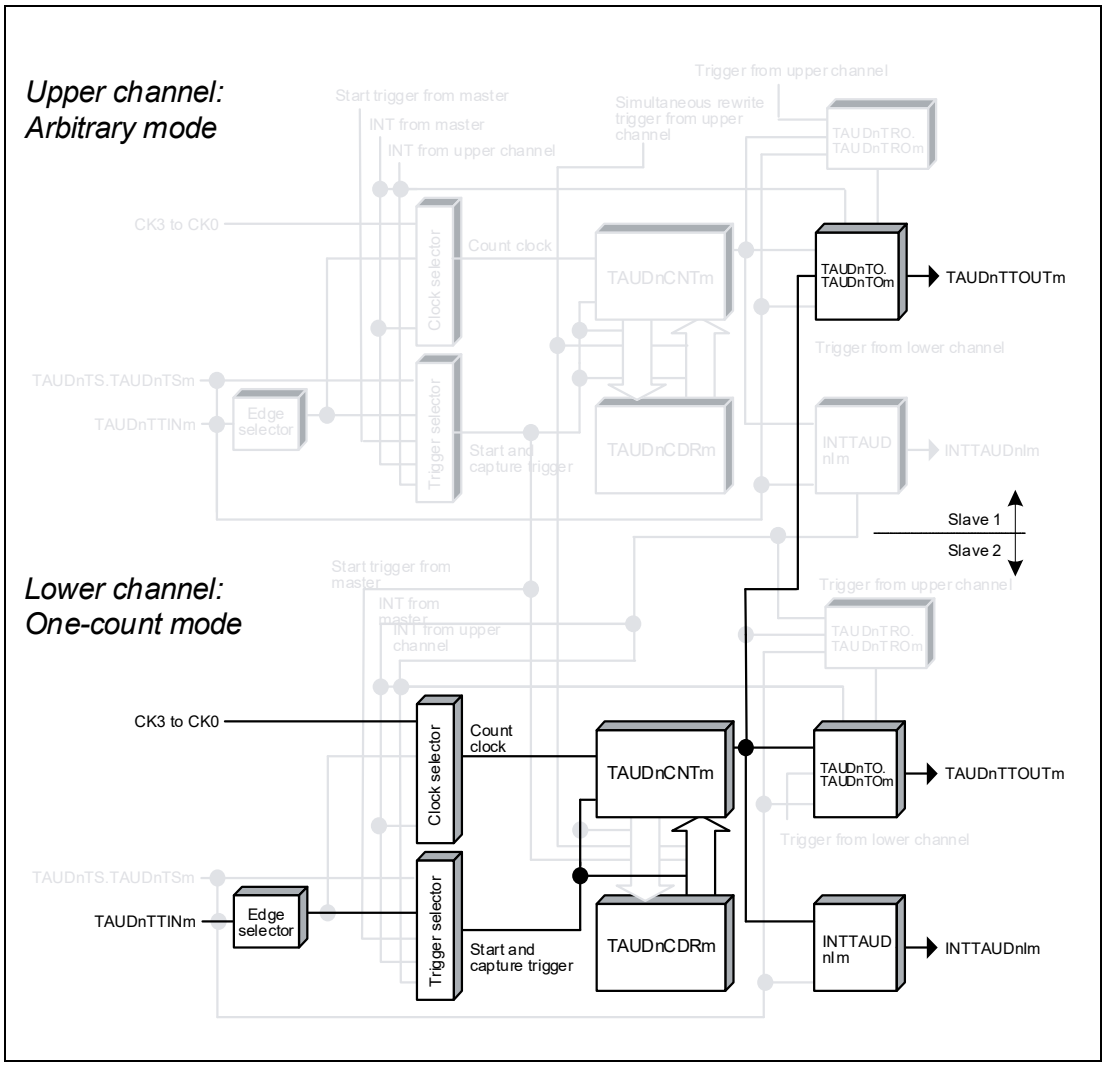

Figure 33.77 Block Diagram of One-Phase PWM Output Function

The following settings apply to the general timing diagram.

- Detection of rising and falling edges = high width measurement (TAUDnCMURm.TAUDnTIS[1:0] = 11_B)

This setting considers a duty as an active high.

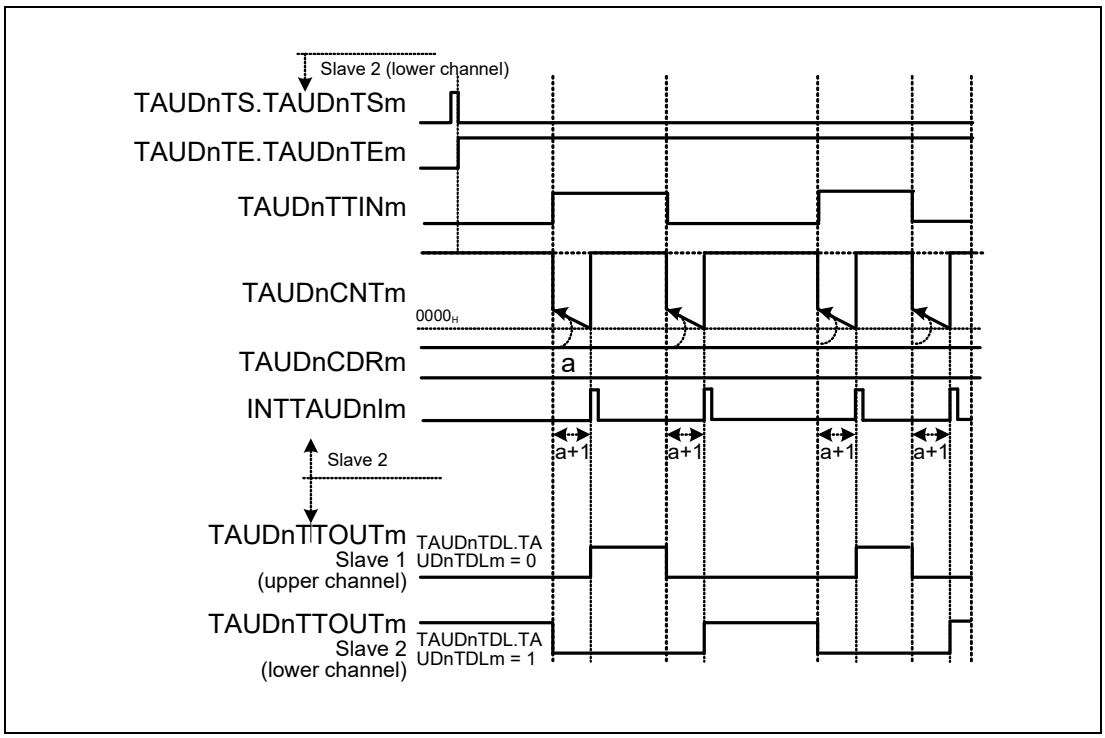

Figure 33.78 General Timing Diagram of One-Phase PWM Output Function

Table 33.109 Contents of the TAUDnCMURm Register for the Lower Channel of the One-Phase PWM Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	10: Detection of rising and falling edges (low width measurement) 11: Detection of rising and falling edges (high width measurement)

(3) Channel Output Mode for Lower Channels

Table 33.110 Control Bit Settings in Synchronous Channel Output Mode 2 with One-Phase PWM Output

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel output
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	1: Enables dead time operation.
TAUDnTDM.TAUDnTDMm	1: Adds dead time upon detection of a TAUDnTTINm input edge on a lower odd channel.
TAUDnTDL.TAUDnTDLm	0: Adds dead time of the positive-phase width 1: Adds dead time of the negative-phase width
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set this bit to 0
TAUDnTRC.TAUDnTRCm	0: Disables the operation as a real-time output trigger channel
TAUDnTME.TAUDnTMEm	0: Disables modulation

CAUTION

Set TAUDnTDL.TAUDnTDLm exclusively from upper channels.

(4) Simultaneous Rewrite for Lower Channels

Simultaneous rewrite registers (TAUDnRDE, TAUDnRDS, TAUDnRDM, and TAUDnRDC) cannot be used with the one-phase PWM output function. Therefore, these registers should be set to 0.

Table 33.111 Simultaneous Rewrite Settings for One-Phase PWM Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	0: Disables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: When simultaneous rewrite is disabled (TAUDnRDE.TAUDnRDEm = 0), set these bits to 0.
TAUDnRDM.TAUDnRDMm	
TAUDnRDC.TAUDnRDCm

(2) TAUDnCMURm for Upper Channels

TAUDnCMURm register for upper channels can be set arbitrarily.

(3) Channel Output Mode for Upper Channels

Table 33.112 Control Bit Settings for Upper Channels in Synchronous Channel Output Mode 2 with One-Phase PWM Output

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel output
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	1: Enables dead time operation.
TAUDnTDM.TAUDnTDMm	1: Adds dead time upon detection of a TAUDnTTINm input edge on a lower odd channel.
TAUDnTDL.TAUDnTDLm	0: Adds dead time of the positive-phase width 1: Adds dead time of the negative-phase width
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set this bit to 0
TAUDnTRC.TAUDnTRCm	0: Disables the operation as a real-time output trigger channel
TAUDnTME.TAUDnTMEm	0: Disables modulation

CAUTION

Set TAUDnTDL.TAUDnTDLm exclusively from lower channels.

(4) Simultaneous Rewrite for Upper Channels

Simultaneous rewrite register for upper channels can be set arbitrarily.

33.12.15.5 Operating Procedure for One-phase PWM Output Function

Table 33.113 Operating Procedure for One-phase PWM Output Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers for the lower channel as described in **Table 33.108, Contents of the TAUDnCMORm Register for the Lower Channel of the One-Phase PWM Output Function**, and **Table 33.109, Contents of the TAUDnCMURm Register for the Lower Channel of the One-Phase PWM Output Function**. Set TAUDnCMORm and TAUDnCMURm registers for the upper channel as described in **Section 33.12.15.4, Register Settings for Upper Channels**. Set the value of TAUDnCDRm register. Set channel output mode by setting the control bits as described in **Table 33.110, Control Bit Settings in Synchronous Channel Output Mode 2 with One-Phase PWM Output**.	Channel operation is stopped.
Start Operation	Set TAUDnTOE.TAUDnTOEm (slave channels 1 and 2) to 1 (at restart time only). Set TAUDnTS.TAUDnTSm = 1 for slave channel 2. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0. Detection of TAUDnTTINm start edge	TAUDnTE.TAUDnTEm is set to 1 (slave channel 2) and TAUDnCNTm waits for detection of TAUDnTTINm start edge. TAUDnCNTm loads TAUDnCDRm value.
During Operation	The TAUDnCDRm register value can be changed at any time. The TAUDnCNTm register can be read at any time.	TAUDnCNTm of slave channel 2 counts down. When the counter reaches 0000_H: • INTTAUDnIm is generated. • TAUDnCNTm stops counting. TAUDnTTOUTm is changed by a TAUDnTTINm edge detection signal and slave channel 2 INTTAUDnIm signal to output one-phase PWM waveform with dead time. Afterwards, this operation is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm = 1 for slave channel 2. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops. TAUDnCNTm and TAUDnTTOUTm retain their current values.

Restart Operation

33.13 Independent Channel Real-Time Functions

This section describes functions that output the value of the TAUDnTRO.TAUDnTROm bit in real time.

33.13.1 Real-Time Output Function Type 1

33.13.1.1 Overview

Summary

This function outputs a value of the TAUDnTRO.TAUDnTROm bit from TAUDnTTOUTm when a specified channel generates an interrupt (INTTAUDnIm). In this function, the interrupt is generated at certain specified intervals.

The upper channel is a channel which generates a real-time output trigger (TAUDnTRC.TAUDnTRCm = 1), and the lower channel is a channel which makes a real-time output in response to the upper channel trigger (TAUDnTRC.TAUDnTRCm = 0).

Prerequisites

- Channels should use the TAUDnTTOUTm control of other channels.
- The operating mode for the upper channel should be set to interval timer mode. (See **Table 33.114, Contents of the TAUDnCMORm Register for the Upper Channel of Real-Time Output Function Type 1**.)
- Any operating mode can be set for lower channels.
- The channel output mode for all the channels should be set to independent channel output mode 1 with real-time output. (See **Section 33.7, Channel Output Modes**.)
- Real-time output should be enabled for the upper channel (TAUDnTRE.TAUDnTREm = 1).

Functional description

The counter of the upper channel is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This in turn sets TAUDnTE.TAUDnTEm to 1, enabling count operation. The current value of the data register of the upper channel (TAUDnCDRm) is loaded into the counter (TAUDnCNTm) and the counter starts to count down from this value.

When the counter of the upper channel reaches 0000_H, INTTAUDnIm is generated and TAUDnTTOUTm outputs the current value of the real-time output bit (TAUDnTRO.TAUDnTROm) of every channel (only channels with TAUDnTRE.TAUDnTREm = 1). TAUDnCNTm then reloads the TAUDnCDRm value to continue operation subsequently.

The TAUDnTTOUTm signal changes only when an interrupt is generated, and when its value is different from the current value of TAUDnTRO.TAUDnTROm at the moment that the interrupt is generated.

Conditions

- The channel which is monitored for INTTAUDnIm occurrence is specified by setting TAUDnTRC.TAUDnTRCm to 1 for the corresponding channel. The TAUDnTRC.TAUDnTRCm bit should be 0 for all other channels that do not generate a real-time output trigger.
- If real-time output of a lower channel is disabled (TAUDnTRE.TAUDnTREm = 0) or if the channel itself is used as a rewrite trigger (TAUDnTRC.TAUDnTRCm = 1), the value of that channel's TAUDnTRO.TAUDnTROm bit is output when INTTAUDnIm is generated in that channel.
- If real-time output of a lower channel is enabled (TAUDnTRE.TAUDnTREm = 1) and TAUDnTRC.TAUDnTRCm = 0, the value of that channel's TAUDnTRO.TAUDnTROm bit is output when INTTAUDnIm is generated in the upper channel.
- If the TAUDnCMORm.TAUDnMD0 bit is set to 0, the first interrupt after a start or restart is not output. For details, see **Section 33.9, TAUDnTTOUTm Output and INTTAUDnIm Generation when Counter Starts or Restarts**.

33.13.1.2 Equations

INTTAUDnIm generation cycle = count clock cycle × (TAUDnCDRm value + 1)

33.13.1.3 Block Diagram and General Timing Diagram

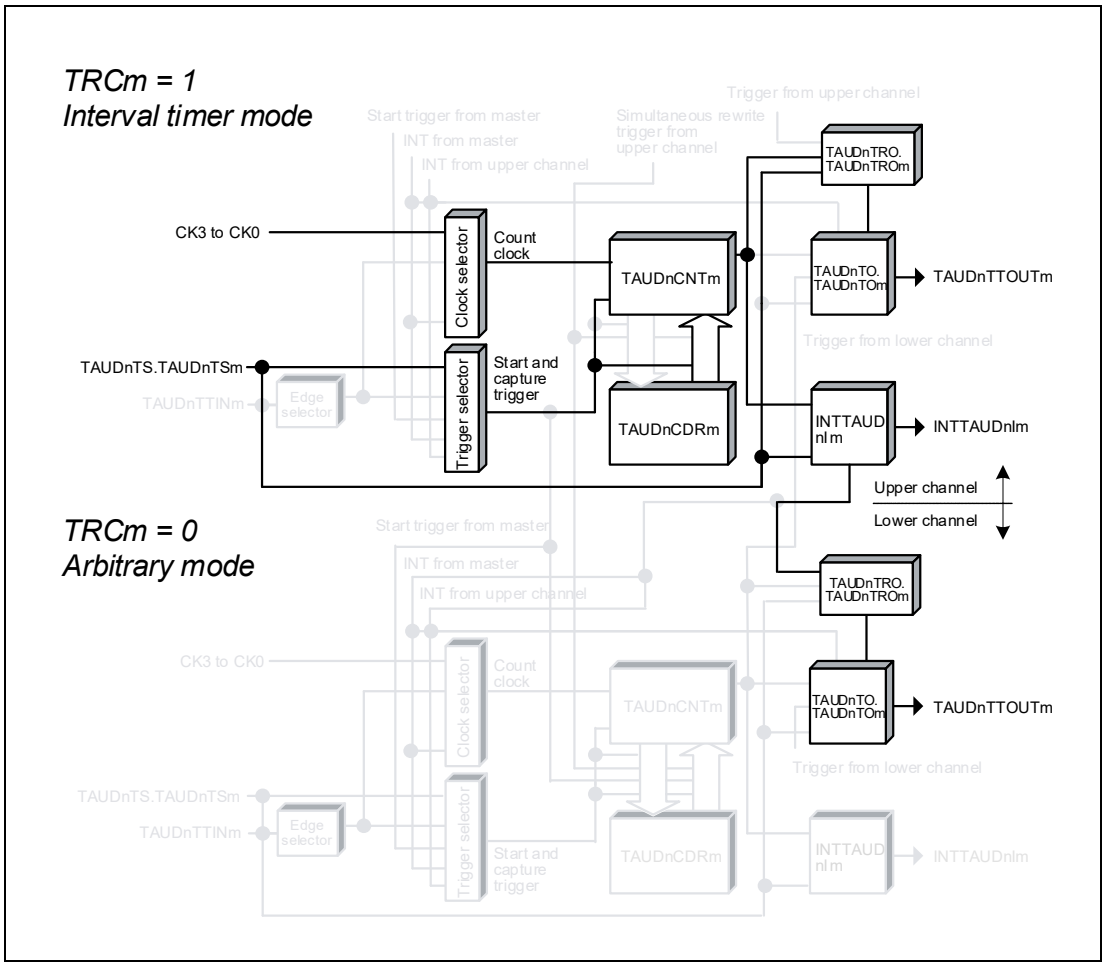

Figure 33.79 Block Diagram of Real-Time Output Function Type 1

The following settings apply to the general timing diagram.

- INTTAUDnIm is generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 1)

Table 33.115 Contents of the TAUDnCMURm Register for the Upper Channel of Real-Time Output Function Type 1

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for Upper Channels

Table 33.116 Control Bit Settings in Independent Channel Output Mode 1 with Real-Time Output

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	0: Operating mode 1 (Toggle mode if TAUDnTOM.TAUDnTOMm = 0)
TAUDnTOL.TAUDnTOLm	0: The setting is disabled in toggle mode. (The value after reset.)
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	1: Enables real-time output
TAUDnTRO.TAUDnTROm	0: Real-time output is low 1: Real-time output is high
TAUDnTRC.TAUDnTRCm	1: Channel m generates a unique real-time output trigger
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous Rewrite for Upper Channels

The simultaneous rewrite registers (TAUDnRDE, TAUDnRDS, TAUDnRDM, and TAUDnRDC) cannot be used with the real-time output function type 1. Therefore, these registers should be set to 0.

Table 33.117 Simultaneous Rewrite Settings for Real-Time Output Function Type 1

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	0: Disables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: When simultaneous rewrite is disabled (TAUDnRDE.TAUDnRDEm = 0), set these bits to 0.
TAUDnRDM.TAUDnRDMm	
TAUDnRDC.TAUDnRDCm	

33.13.1.5 Register Settings for Lower Channels

(1) TAUDnCMORm for Lower Channels

The TAUDnCMORm register for lower channels can be set arbitrarily.

(2) TAUDnCMURm for Lower Channels

The TAUDnCMURm register for lower channels can be set arbitrarily.

(3) Channel Output Mode for Lower Channels

Table 33.118 Control Bit Settings for the Lower Channels in Independent Channel Output Mode 1 with Real-Time Output

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	0: Operating mode 1 (Toggle mode if TAUDnTOM.TAUDnTOMm = 0)
TAUDnTOL.TAUDnTOLm	0: The setting is disabled in toggle mode. (The value after reset.)
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set this bit to 0
TAUDnTDL.TAUDnTDLm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set this bit to 0
TAUDnTRE.TAUDnTREm	1: Enables real-time output
TAUDnTRO.TAUDnTROm	0: Real-time output is low 1: Real-time output is high
TAUDnTRC.TAUDnTRCm	0: Upper channel generates a real-time output trigger for channel m
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous Rewrite for Lower Channels

Simultaneous rewrite registers for lower channels can be set arbitrarily.

33.13.1.6 Operating Procedure for Real-Time Output Function Type 1

Table 33.119 Operating Procedure for Real-Time Output Function Type 1

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers for upper channels as described in **Table 33.114, Contents of the TAUDnCMORm Register for the Upper Channel of Real-Time Output Function Type 1**, and **Table 33.115, Contents of the TAUDnCMURm Register for the Upper Channel of Real-Time Output Function Type 1**. Set TAUDnCMORm and TAUDnCMURm registers for lower channels as described in **Section 33.13.1.5, Register Settings for Lower Channels**. Set the value of TAUDnCDRm register (only channels with TAUDnTRC.TAUDnTRCm = 1) Set channel output mode by setting the control bits as described in **Table 33.116, Control Bit Settings in Independent Channel Output Mode 1 with Real-Time Output**. Set channel output mode by setting the control bits as described in **Table 33.118, Control Bit Settings for the Lower Channels in Independent Channel Output Mode 1 with Real-Time Output**.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm = 1 on the channel with TAUDnTRC.TAUDnTRCm set to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	[Channel with TAUDnTRC.TAUDnTRCm set to 1] TAUDnTE.TAUDnTEm is set to 1 and the counter starts. The TAUDnCDRm value is loaded in TAUDnCNTm. If TAUDnCMORm.TAUDnMD0 is 1, INTTAUDnIm is generated.
During Operation	TAUDnCDRm and TAUDnTRO.TAUDnTROm can be changed at any time. The TAUDnCNTm register can be read at any time.	TAUDnCNTm counts down. When the counter reaches 0000_H: • The TAUDnCDRm value is loaded in TAUDnCNTm again and count operation continues. • INTTAUDnIm is generated. • TAUDnTTOUTm outputs the current value of the real-time output bit TAUDnTRO.TAUDnTROm. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops. Both TAUDnCNTm and TAUDnTTOUTm retain their current values.

Restart Operation

33.13.1.7 Specific Timing Diagrams

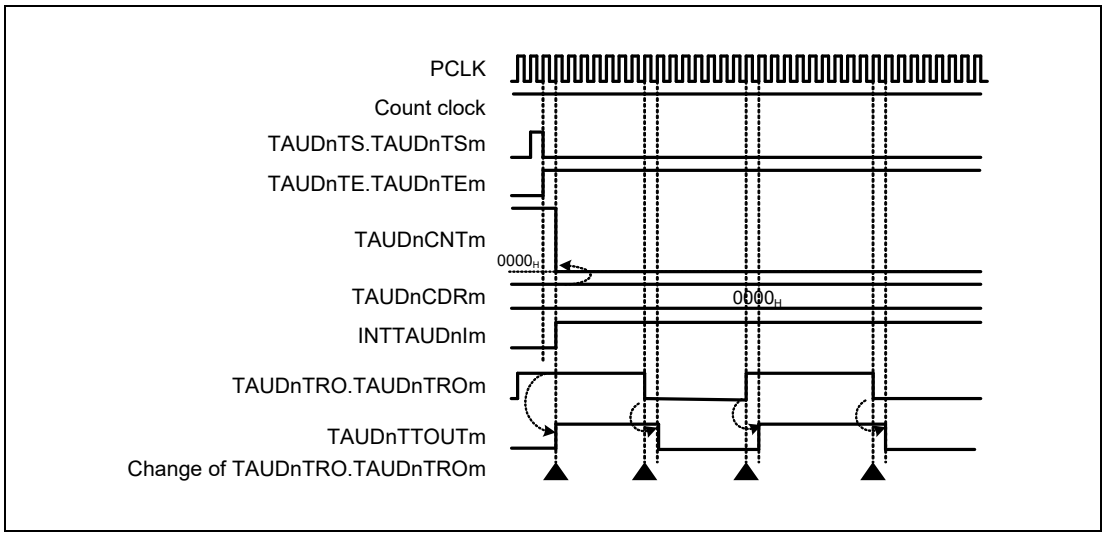

Figure 33.81 TAUDnCDRm = 0000_H, TAUDnCMORm.TAUDnMD0 = 1

- The value of TAUDnTTOUTm changes according to the setting of TAUDnTRO.TAUDnTROm with a delay of one PCLK cycle.

33.13.2 Real-Time Output Function Type 2

33.13.2.1 Overview

Summary

This function outputs the value of TAUDnTRO.TAUDnTROm bit from TAUDnTTOUTm when a specified channel generates an interrupt (INTTAUDnIm). In this function, the interrupt is generated when a valid TAUDnTTINm input edge is detected or the function starts.

The upper channel is a channel which generates a real-time output trigger (TAUDnTRC.TAUDnTRCm = 1), and the lower channel is a channel which makes a real-time output in response to the upper channel trigger (TAUDnTRC.TAUDnTRCm = 0).

Prerequisites

- Channels should use the TAUDnTTOUTm control of the other channels.
- The operating mode for the upper channel should be set to capture mode. (See **Table 33.120, Contents of the TAUDnCMORm Register for the Upper Channel of Real-Time Output Function Type 2**.)
- Any operating mode can be set for lower channels.
- The channel output mode for all the channels should be set to independent channel output mode 1 with real-time output. (See **Section 33.7, Channel Output Modes**.)
- Real-time output should be enabled for the upper channel (TAUDnTRE.TAUDnTREm = 1).

Functional description

The counter for upper channels is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This sets TAUDnTE.TAUDnTEm to 1, enabling count operation. The counter starts to count up.

When a valid TAUDnTTINm input edge is generated on one of upper channels, an interrupt occurs and TAUDnTTOUTm outputs the current value of the real-time output bit (TAUDnTRO.TAUDnTROm) of every channel (only channels with TAUDnTRE.TAUDnTREm = 1).

The TAUDnTTOUTm signal changes only when an interrupt is generated, and when TAUDnTTOUTm value is different from the current value of TAUDnTRO.TAUDnTROm during the occurrence of the interrupt.

Conditions

- The channel which is monitored for INTTAUDnIm occurrence is specified by setting TAUDnTRC.TAUDnTRCm to 1 for the corresponding channel. The TAUDnTRC.TAUDnTRCm bit should be 0 for all other channels that do not generate a real-time output trigger.
- If real-time output of a lower channel is disabled (TAUDnTRE.TAUDnTREm = 0) or if the channel itself is used as a rewrite trigger (TAUDnTRC.TAUDnTRCm = 1), the value of that channel’s TAUDnTRO.TAUDnTROm bit is output when INTTAUDnIm is generated in that channel.
- If real-time output of a lower channel is enabled (TAUDnTRE.TAUDnTREm = 1) and TAUDnTRC.TAUDnTRCm = 0, the value of that channel's TAUDnTRO.TAUDnTROm bit is output when INTTAUDnIm is generated in the upper channel.

- If the TAUDnCMORm.TAUDnMD0 bit is set to 0, the first interrupt after a start or restart is not output. For details, see **Section 33.9, TAUDnTTOUTm Output and INTTAUDnIm Generation when Counter Starts or Restarts**.

TAUDnTOC.TAUDnTOCm	0: Operating mode 1 (Toggle mode if TAUDnTOM.TAUDnTOMm = 0)
TAUDnTOL.TAUDnTOLm	0: The setting is disabled in toggle mode. (The value after reset.)
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	1: Enables real-time output.
TAUDnTRO.TAUDnTROm	0: Real-time output is low 1: Real-time output is high
TAUDnTRC.TAUDnTRCm	0: Upper channel generates a real-time output trigger for channel m
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous Rewrite for Lower Channels

Simultaneous rewrite registers for lower channels can be set arbitrarily.

33.13.2.5 Operating Procedure for Real-Time Output Function Type 2

Table 33.125 Operating Procedure for Real-Time Output Function Type 2

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers for upper channels as described in **Table 33.120, Contents of the TAUDnCMORm Register for the Upper Channel of Real-Time Output Function Type 2**, and **Table 33.121, Contents of the TAUDnCMURm Register for the Upper Channel of Real-Time Output Function Type 2**. Set TAUDnCMORm and TAUDnCMURm registers for the lower channel as described in **Section 33.13.2.4, Register Settings for Lower Channels**. The TAUDnCDRm register functions as a capture register (only channels with TAUDnTRC.TAUDnTRCm = 1). Set channel output mode by setting the control bits as described in **Table 33.122, Control Bit Settings in Independent Channel Output Mode 1 with Real-Time Output**. Set channel output mode by setting the control bits as described in **Table 33.124, Control Bit Settings for Lower Channels in Independent Channel Output Mode 1 with Real-Time Output**.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm = 1 on the channel with TAUDnTRC.TAUDnTRCm set to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	[Channel with TAUDnTRC.TAUDnTRCm set to 1] TAUDnTE.TAUDnTEm is set to 1 and the counter starts. TAUDnCNTm is cleared to 0000_H. If TAUDnCMORm.TAUDnMD0 is 1, INTTAUDnIm is generated.
During Operation	TAUDnTRO.TAUDnTROm can be changed at any time.	TAUDnCNTm starts to count up from 0000_H. When a valid TAUDnTTINm input edge is detected: • TAUDnCNTm captures the TAUDnCDRm value, and the counter is cleared to 0000_H. • INTTAUDnIm is generated. • When the TAUDnTTINm input valid edge is detected immediately after the generation of an overflow, the TAUDnCSRm.TAUDnOVF bit is set to 1. When detected before the generation of an overflow, the TAUDnCSRm.TAUDnOVF bit is cleared to 0. TAUDnTTOUTm outputs the current value of real-time output bit TAUDnTRO.TAUDnTOROm. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops. TAUDnCNTm, TAUDnCSRm.TAUDnOVF, and TAUDnTTOUTm retain their current values.

Restart Operation

33.13.2.6 Specific Timing Diagrams

(1) Operation Start and Stop

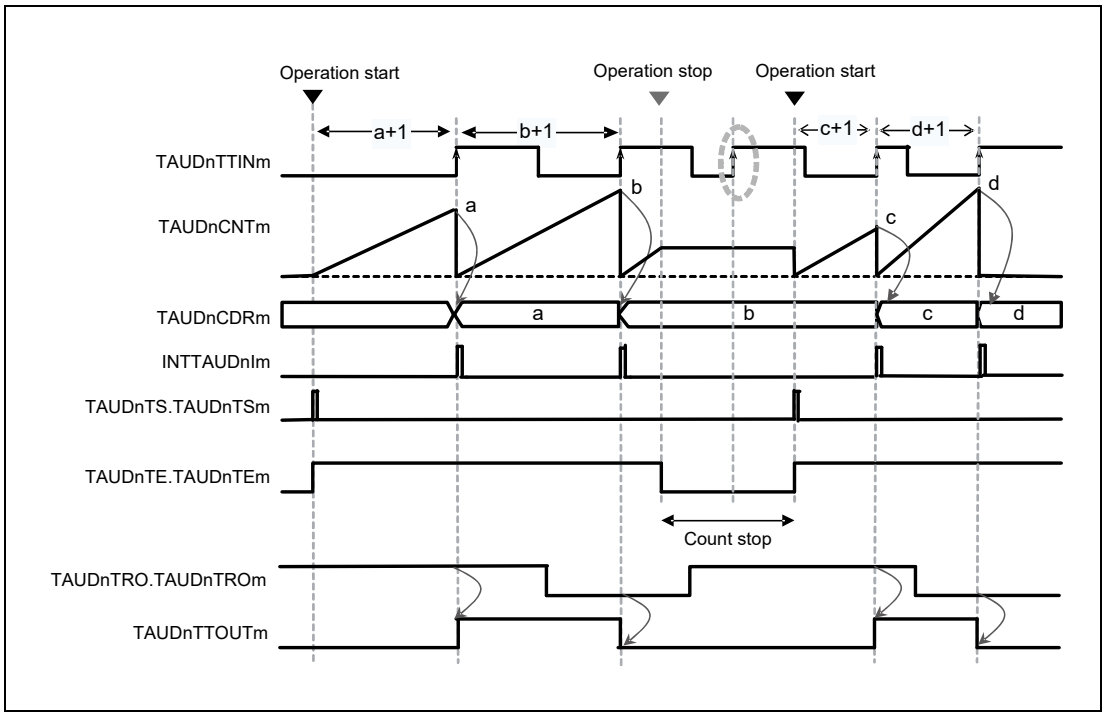

Figure 33.84 Operation Start and Stop (TAUDnCMORm.TAUDnMD0 = 0)

- When TAUDnTS.TAUDnTSm is set to 1, the counter starts counting up.
- When a valid input edge is detected, the current value of the counter is written to the data register (TAUDnCDRm) and an interrupt is generated.
- TAUDnTTOUTm outputs the current value of the real-time output bit (TAUDnTRO.TAUDnTROm) and the counter resets and starts to count up again.
- The TAUDnTTOUTm signal only changes when an interrupt is generated, and then only when its value is different from the current value of TAUDnTRO.TAUDnTROm at the moment that the interrupt is generated.
- If the counter is stopped (TAUDnTE.TAUDnTEm = 0), valid input edges are ignored and no interrupt is generated.

33.14 Independent Channel Simultaneous Rewrite Functions

This section describes functions that carry out simultaneous rewrite.

33.14.1 Simultaneous Rewrite Trigger Generation Function Type 1

33.14.1.1 Overview

Summary

This function generates an interrupt on a specific channel that can be used by lower channels as a simultaneous rewrite trigger. The interrupt is generated at regular intervals.

The upper channel is a channel which generates a simultaneous rewrite trigger (TAUDnRDC.TAUDnRDCm = 1), and the lower channel is a channel which makes a simultaneous rewrite in response to the upper channel trigger (TAUDnRDC.TAUDnRDCm = 0).

Prerequisites

- Two or more channels lower than the channel used as upper channel are enabled for simultaneous rewrite (TAUDnRDE.TAUDnRDEm = 1).
- The operating mode for the upper channel should be set to interval timer mode. (See **Table 33.126, Contents of the TAUDnCMORm Register for the Upper Channel of Simultaneous Rewrite Trigger Generation Function Type 1**.)
- For the operating mode that can be set for lower channels, see **Table 33.43, Channel Functions and the Methods They Use for Simultaneous Rewrite**.
- TAUDnTTOUTm is not used for any channel in this function.

Functional description

The counter operation is enabled by setting the channel trigger bits (TAUDnTS.TAUDnTSm) for upper and lower channels to 1. This sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The current value of the data register buffer for upper channels (TAUDnCDRm buf) is loaded into the counter (TAUDnCNTm) and the counter starts to count down from this value. The counter for lower channels start to count according to the selected operating mode.

Once the counter reaches 0000_H, an interrupt occurs on the channel. The current value of the corresponding TAUDnCDRm buffer is loaded into TAUDnCNTm to continue operation subsequently.

If the channel where an interrupt occurs is specified as a trigger channel for simultaneous rewrite (TAUDnRDC.TAUDnRDCm = 1) and is an upper channel, simultaneous rewrite takes place on all lower channels in which simultaneous rewrite is currently possible (TAUDnRSF.TAUDnRSFm = 1).

The values of the data registers are copied to the corresponding data register buffers. Each time a counter starts to count down, it reads the value in the data register buffer and counts down from this value.

The value of a data register can be changed at any time, but it is only transferred to the corresponding data register buffer when simultaneous rewrite occurs.

Conditions

- The channel which is monitored for INTTAUDnIm occurrence is specified by setting TAUDnRDC.TAUDnRDCm = 1 for the corresponding channel. The TAUDnRDC.TAUDnRDCm bit should be set to 0 for all other channels in which simultaneous rewrite should take place.
- If the TAUDnCMORm.TAUDnMD0 bit is set to 0, the first interrupt after a start or restart is not generated. For details, see **Section 33.9, TAUDnTTOUTm Output and INTTAUDnIm Generation when Counter Starts or Restarts**.

33.14.1.2 Equations

Simultaneous rewrite trigger generation cycle = count clock cycle × (TAUDnCDRm + 1)

To control simultaneous rewrite, the following condition should be satisfied:

[PWM]

TAUDnCDRm = [(value of TAUDnCDRm of master channel subject to simultaneous rewrite + 1) × number of interrupts] – 1

[Triangle PWM]

TAUDnCDRm = [(value of TAUDnCDRm of master channel subject to simultaneous rewrite + 1) × 2 × number of interrupts] – 1

That is, the ratio of TAUDnCDRm + 1 and value of TAUDnCDRm of master channel subject to simultaneous rewrite + 1 must be an integer. This integer corresponds to the number of interrupts.

For triangle PWM, remember that the cycle doubles.

33.14.1.3 Block Diagram and General Timing Diagram

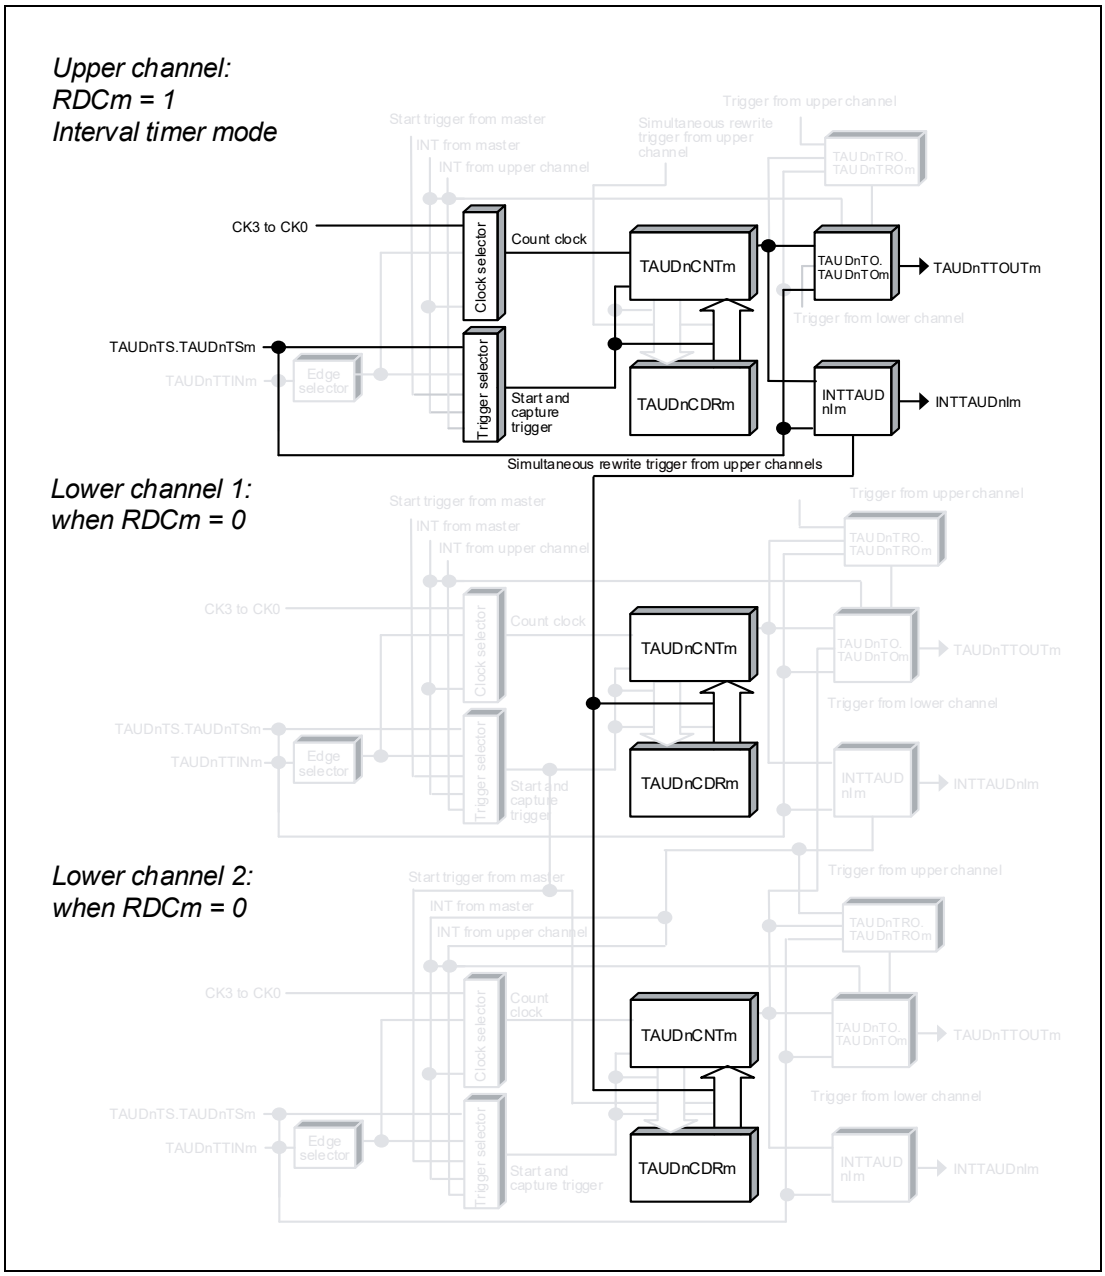

Figure 33.85 Block Diagram of Simultaneous Rewrite Trigger Generation Function Type 1

The following settings apply to the general timing diagram.

- INTTAUDnIm is generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 1)

7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for Upper Channels

TAUDnTOE.TAUDnTOEm is set to 0 because the channel output mode is not used with this function. However, this mode can be used in independent channel output mode controlled by software.

(4) Simultaneous Rewrite for Upper Channels

Table 33.128 Simultaneous Rewrite Settings for Upper Channels in Simultaneous Rewrite Trigger Generation Function Type 1

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	1: Selects one of upper channels as simultaneous rewrite control channel.
TAUDnRDM.TAUDnRDMm	0: Loads a simultaneous rewrite control signal when the master channel starts counting.
TAUDnRDC.TAUDnRDCm	1: Monitors INTTAUDnIm signal which triggers a simultaneous rewrite on the channel.

33.14.1.5 Register Settings for Lower Channels

(1) TAUDnCMORm for Lower Channels

TAUDnCMORm register for lower channels must follow the TAUDnCMORm register settings in the operating mode which can be set. (See **Table 33.43, Channel Functions and the Methods They Use for Simultaneous Rewrite**.)

(2) TAUDnCMURm for Lower Channels

TAUDnCMURm register for lower channels must follow the TAUDnCMURm register settings in the operating mode which can be set. (See **Table 33.43, Channel Functions and the Methods They Use for Simultaneous Rewrite**.)

(3) Channel Output Mode for Lower Channels

Output can be made according to the setting for lower channels (master/slave). As for the available function for simultaneous rewrite trigger generation function type 1, see **Table 33.42, Simultaneous Rewrite Methods and when They are Triggered**.

(4) Simultaneous Rewrite for Lower Channels

Table 33.129 Simultaneous Rewrite Settings for Lower Channels in Simultaneous Rewrite Trigger Generation Function Type 1

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	1: Selects one of upper channels as simultaneous rewrite control channel.
TAUDnRDM.TAUDnRDMm	0: Loads a simultaneous rewrite control signal when the master channel starts counting.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

33.14.1.6 Operating Procedure for Simultaneous Rewrite Trigger Generation Function Type 1

Table 33.130 Operating Procedure for Simultaneous Rewrite Trigger Generation Function Type 1

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers for the upper channel as described in **Table 33.126, Contents of the TAUDnCMORm Register for the Upper Channel of Simultaneous Rewrite Trigger Generation Function Type 1**, and **Table 33.127, Contents of the TAUDnCMURm Register for the Upper Channel of Simultaneous Rewrite Trigger Generation Function Type 1**. Set TAUDnCMORm and TAUDnCMURm registers for lower channels as described in **Section 33.14.1.5, Register Settings for Lower Channels**. Set the value of TAUDnCDRm register.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and the counter starts. TAUDnCDRm value is loaded into TAUDnCNTm. If TAUDnCMORm.TAUDnMD0 = 1, INTTAUDnIm is generated.
During Operation	TAUDnRDT.TAUDnRDTm and TAUDnCDRm.TAUDnCDR are changeable. TAUDnRSF.TAUDnRSFm can be always read.	TAUDnCNTm counts down. When the counter reaches 0000_H: • The TAUDnCDRm value is loaded in TAUDnCNTm again and count operation continues. • INTTAUDnIm is generated. If INTTAUDnIm is generated on the channel where TAUDnRDC.TAUDnRDCm is set to 1, simultaneous rewrite is controlled. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and retains its current value.

Restart Operation

33.14.2 Simultaneous Rewrite Trigger Generation Function Type 2

33.14.2.1 Overview

Summary

This function generates an interrupt on a specific channel that can be used by lower channels as a simultaneous rewrite trigger. In this function, the interrupt is generated when a valid TAUDnTTINm input edge is detected or the function starts.

The upper channel is a channel which generates a simultaneous rewrite trigger (TAUDnRDC.TAUDnRDCm = 1), and the lower channel is a channel which makes a simultaneous rewrite in response to the upper channel trigger (TAUDnRDC.TAUDnRDCm = 0).

Prerequisites

- Two or more channels lower than the channel used as upper channel are enabled for simultaneous rewrite (TAUDnRDE.TAUDnRDEm = 1).
- The operation mode of the upper channel must be set to Capture Mode (see **Table 33.131, Contents of the TAUDnCMORm Register for the Upper Channel of Simultaneous Rewrite Trigger Generation Function Type 2**).
- For the operation mode that can be set for a lower channel, see **Table 33.43, Channel Functions and the Methods They Use for Simultaneous Rewrite**.

Functional description

The counter operation is enabled by setting the channel trigger bits (TAUDnTS.TAUDnTSm) for upper and lower channels to 1. This sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The counter for the upper channel starts to count up, and then the counter for lower channels start to count according to the selected operating mode.

When a TAUDnTTINm input edge occurs on the upper channel, an interrupt is generated. The trigger is detected by the lower channel(s), which then also generate an interrupt.

When TAUDnRDC.TAUDnRDCm = 1 on the upper channel, simultaneous rewrite takes place on all lower channels in which simultaneous rewrite is currently possible (TAUDnRSF.TAUDnRSFm = 1).

The values of the data registers are copied to the corresponding data register buffers.

The value of a data register can be changed at any time, but it is only transferred to the corresponding data register buffer when simultaneous rewrite occurs.

Conditions

- The channel which is monitored for INTTAUDnIm is specified by setting TAUDnRDC.TAUDnRDCm = 1 for the corresponding channel. The TAUDnRDC.TAUDnRDCm bit must be 0 for all other channels in which simultaneous rewrite should take place.
- If the TAUDnCMORm.TAUDnMD0 bit is set to 1, an interrupt is generated when the function starts. For details see **Section 33.9, TAUDnTTOUTm Output and INTTAUDnIm Generation when Counter Starts or Restarts**.

33.14.2.2 Block Diagram and General Timing Diagram

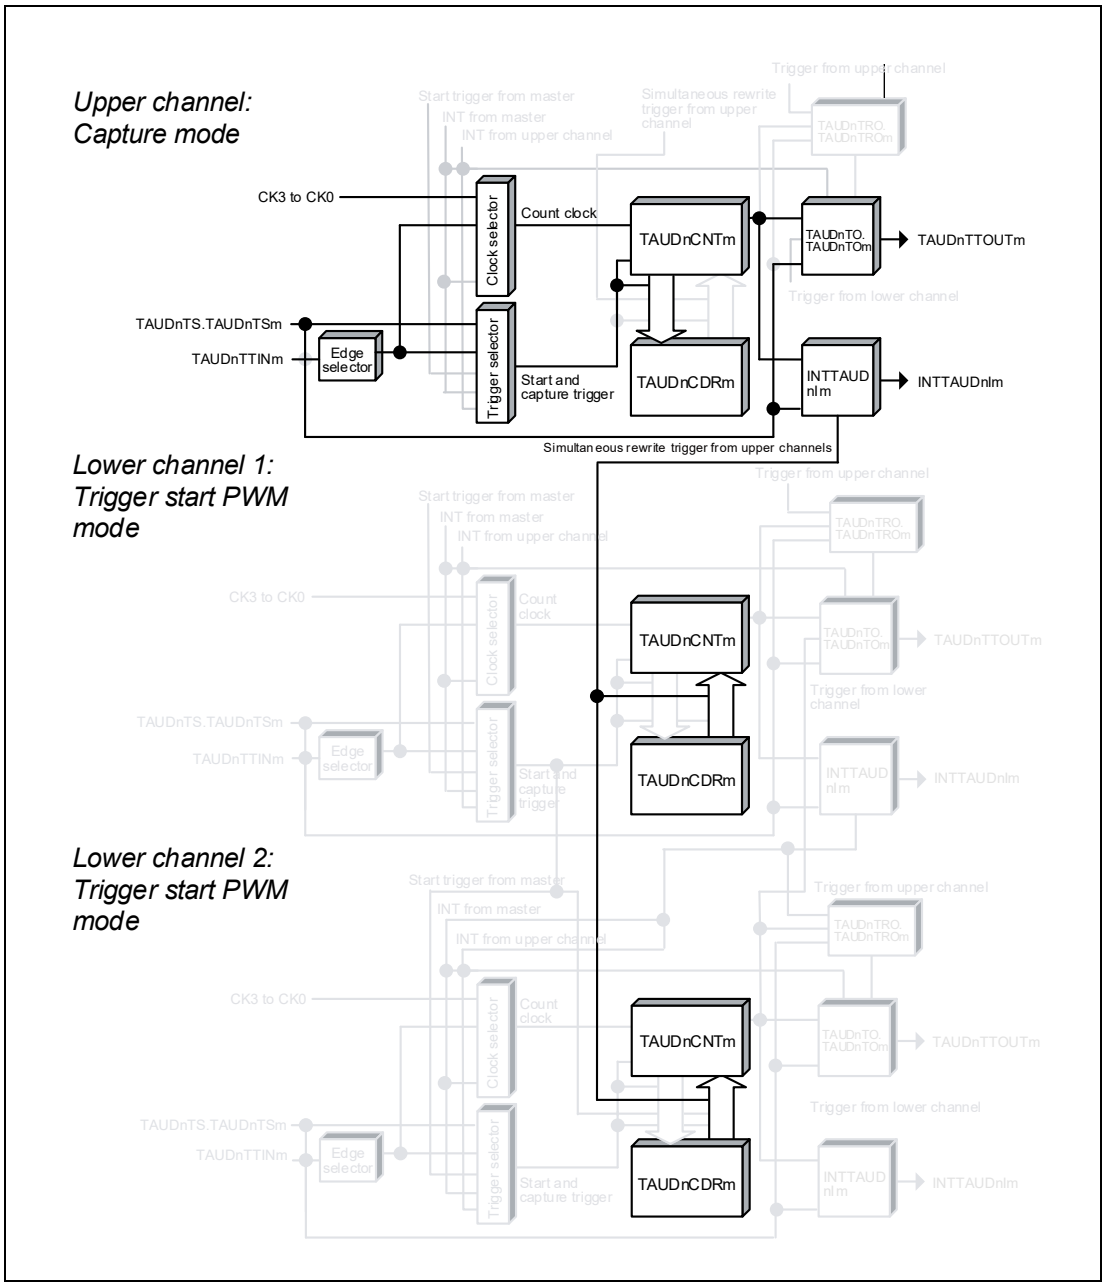

Figure 33.87 Block Diagram for Simultaneous Rewrite Trigger Generation Function Type 2

The following settings apply to the general timing diagram.

- INTTAUDnIm is generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 1)
- Detection of falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)
- Upper channel (CH1) generates simultaneous rewrite trigger.

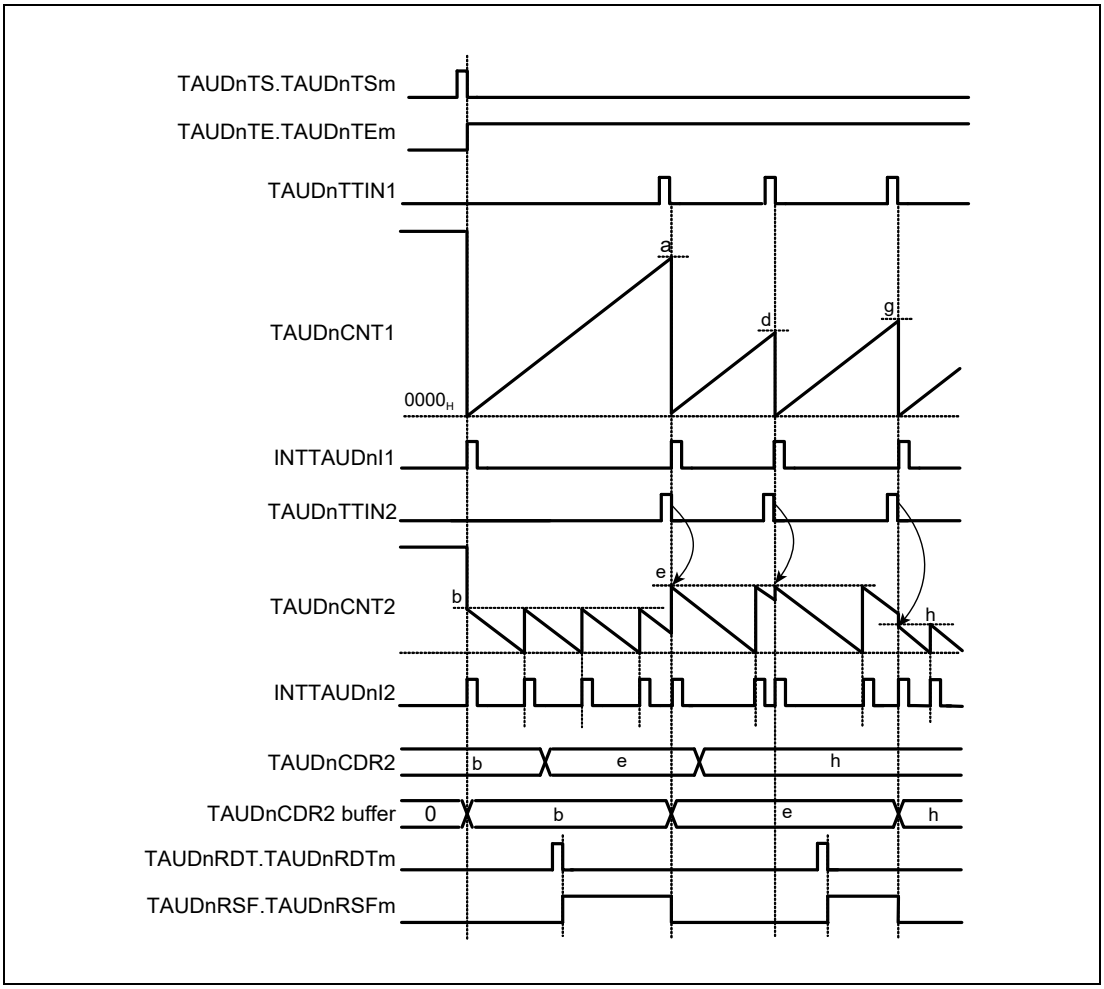

Figure 33.88 General Timing Diagram for Simultaneous Rewrite Trigger Generation Function Type 2

33.14.2.3 Register Settings for Upper Channels

(1) TAUDnCMORm for Upper Channels

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDn MAS	TAUDnSTS[2:0]			TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDn MD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 33.131 Contents of the TAUDnCMORm Register for the Upper Channel of Simultaneous Rewrite Trigger Generation Function Type 2

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3
13, 12	TAUDnCCS[1:0]	00: Uses an operation clock as a count clock
11	TAUDnMAS	0: Independent operation, set to 0.
10 to 8	TAUDnSTS[2:0]	001: Valid edge of the TAUDnTTINm input signal is used as the external capture trigger.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0010: Capture mode
0	TAUDnMD0	0: INTTAUDnIm not generated at the beginning of operation. 1: INTTAUDnIm generated at the beginning of operation.

(2) TAUDnCMURm for Upper Channels

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.132 Contents of the TAUDnCMURm Register for the Upper Channel of Simultaneous Rewrite Trigger Generation Function Type 2

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Detection of falling edge 01: Detection of rising edge 10: Detection of rising and falling edges 11: Setting prohibited

(3) Channel Output Mode for Upper Channels

The channel output mode is not used by this function.

(4) Simultaneous Rewrite for Upper Channels

Table 33.133 Simultaneous Rewrite Settings for Simultaneous Rewrite Trigger Generation Function Type 2

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	1: Selects one of upper channels as simultaneous rewrite control channel.
TAUDnRDM.TAUDnRDMm	0: Loads a simultaneous rewrite control signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	1: Monitors INTTAUDnIm signal which triggers a simultaneous rewrite on the channel.

33.14.2.4 Register Settings for Lower Channels

(1) TAUDnCMORm for Lower Channels

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDn MAS	TAUDnSTS[2:0]			TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDn MD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 33.134 Contents of the TAUDnCMORm Register for the Lower Channel of Simultaneous Rewrite Trigger Generation Function Type 2

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operation clock as a count clock
11	TAUDnMAS	1: Master channel
10 to 8	TAUDnSTS[2:0]	001: Valid TAUDnTTINm input edge signal is used as the start trigger.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0000: Interval timer mode
0	TAUDnMD0	1: INTTAUDnIm generated at the beginning of operation.

(2) TAUDnCMURm for Lower Channels

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.135 Contents of the TAUDnCMURm Register for the Lower Channel of Simultaneous Rewrite Trigger Generation Function Type 2

7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Detection of falling edge 01: Detection of rising edge 10: Detection of rising and falling edges 11: Setting prohibited

(3) Channel Output Mode for Lower Channels

Output can be made according to the trigger start PWM mode setting.

(4) Simultaneous Rewrite for Lower Channels

Table 33.136 Simultaneous Rewrite Settings for the Lower Channel in Simultaneous Rewrite Trigger Generation Function Type 2

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	1: Selects one of upper channels as simultaneous rewrite control channel.
TAUDnRDM.TAUDnRDMm	0: Loads a simultaneous rewrite control signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

33.14.2.5 Operating Procedure for Simultaneous Rewrite Trigger Generation Function Type 2

Table 33.137 Operating Procedure for Simultaneous Rewrite Trigger Generation Function Type 2

		Operation	TAUDn Status
Restart Operation	Initial Channel Setting	Set the TAUDnCMORm and TAUDnCMURm registers for the upper channel as described in **Table 33.131, Contents of the TAUDnCMORm Register for the Upper Channel of Simultaneous Rewrite Trigger Generation Function Type 2** and **Table 33.132, Contents of the TAUDnCMURm Register for the Upper Channel of Simultaneous Rewrite Trigger Generation Function Type 2**. Set the TAUDnCMORm and TAUDnCMURm registers for the lower channel as described in **Table 33.134, Contents of the TAUDnCMORm Register for the Lower Channel of Simultaneous Rewrite Trigger Generation Function Type 2** and **Table 33.135, Contents of the TAUDnCMURm Register for the Lower Channel of Simultaneous Rewrite Trigger Generation Function Type 2**. The TAUDnCDRm register functions as a capture register.	Channel operation is stopped.
	Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and the counter starts. TAUDnCNTm is cleared to 0000_H. INTTAUDnIm is generated when TAUDnCMORm.TAUDnMD0 is set to 1.
	During Operation	TAUDnRDT.TAUDnRDTm can be set at any time. TAUDnRSF.TAUDnRSFm can be read at any time.	TAUDnCNTm counts up from 0000_H. When a TAUDnTTINm valid edge is detected: • TAUDnCNTm transfers (captures) its value to TAUDnCDRm and returns to 0000_H. • INTTAUDnIm is generated. Simultaneous rewrite is controlled when INTTAUDnIm is generated from the channel where TAUDnRDC.TAUDnRDCm is set to 1. Afterwards, this procedure is repeated.
	Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and it retains its current value.

33.15 Synchronous Channel Operation Functions

This section lists all the synchronous channel operation functions provided by the timer array unit D. For a general overview of synchronous channel operation, see **Section 33.2, Overview**.

This section describes functions that generate PWM signals at regular intervals.

33.15.1 PWM Output Function

33.15.1.1 Overview

Summary

This function generates multiple PWM outputs by using a master and multiple slave channels. It enables the pulse cycle (frequency) and the duty cycle of the TAUDnTTOUTm to be set. The pulse cycle is set in the master channel. The duty cycle is set in the slave channel.

Prerequisites

- Two channels
- The operating mode for the master channel should be set to interval timer mode. (See **Table 33.138, Contents of the TAUDnCMORm Register for the Master Channel of the PWM Output Function**.)
- The operating mode for the slave channels should be set to one-count mode. (See **Table 33.141, Contents of the TAUDnCMORm Register for the Slave Channel of the PWM Output Function**.)
- TAUDnTTOUTm is not used with the master channel of this function.
- The channel output mode for slave channels should be set to Synchronous Channel Output Mode 1. (See **Section 33.7, Channel Output Modes**.)

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The current value of TAUDnCDRm is loaded into TAUDnCNTm, and the counter starts counting down from the TAUDnCDRm value. If an INTTAUDnIm is generated on the master channel and TAUDnTTOUTm (slave) is set/reset, PWM output is made.

- Master channel:
  When the master channel counter reaches 0000_H and the pulse cycle time has passed, INTTAUDnIm is generated. The counter loads TAUDnCDRm value into TAUDnCNTm and counts down.
- Slave channel:
  When INTTAUDnIm is generated on the master channel, the counter operation of the slave channel is triggered. The current value of TAUDnCDRm (slave) is loaded into TAUDnCNTm (slave) and the counter starts counting down from the TAUDnCDRm value. TAUDnTTOUTm signal is set to the active level.
  When the counter reaches to 0000_H (duty time has elapsed), INTTAUDnIm is generated and a TAUDnTTOUTm signal is set to an inactive level. The counter is reset to $FFFF_H$ and waits for the next INTTAUDnIm (start of the next pulse cycle) of the master channel.

The counter can stop operating by setting the TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTEm to 0. TAUDnCNTm and TAUDnTTOUTm of master and slave channels stop but their values are retained. The counter can be restarted by setting TAUDnTS.TAUDnTSm to 1.

Conditions

Simultaneous rewrite can be used with this function. See **Section 33.6, Simultaneous Rewrite**.

33.15.1.2 Equations

Pulse cycle = (TAUDnCDRm (master) + 1) × count clock cycle

Duty cycle [%] = (TAUDnCDRm (slave)/(TAUDnCDRm (master) + 1)) × 100

– Duty cycle = 0%
  TAUDnCDRm (slave) = 0000_H
– Duty cycle = 100%
  TAUDnCDRm (slave) ≥ TAUDnCDRm (master) + 1

33.15.1.3 Block Diagram and General Timing Diagram

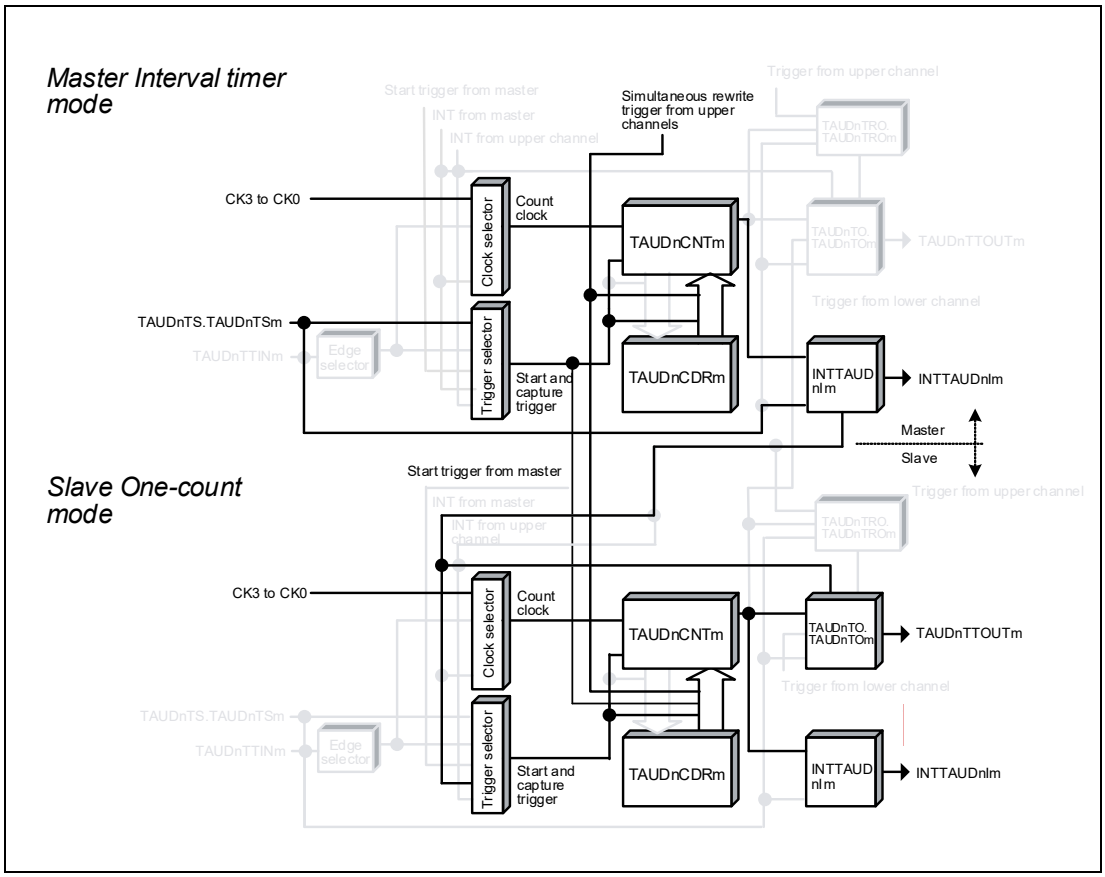

Figure 33.89 Block Diagram of PWM Output Function

The following settings apply to the general timing diagram.

- Slave channel: Positive logic (TAUDnTOL.TAUDnTOLm = 0)

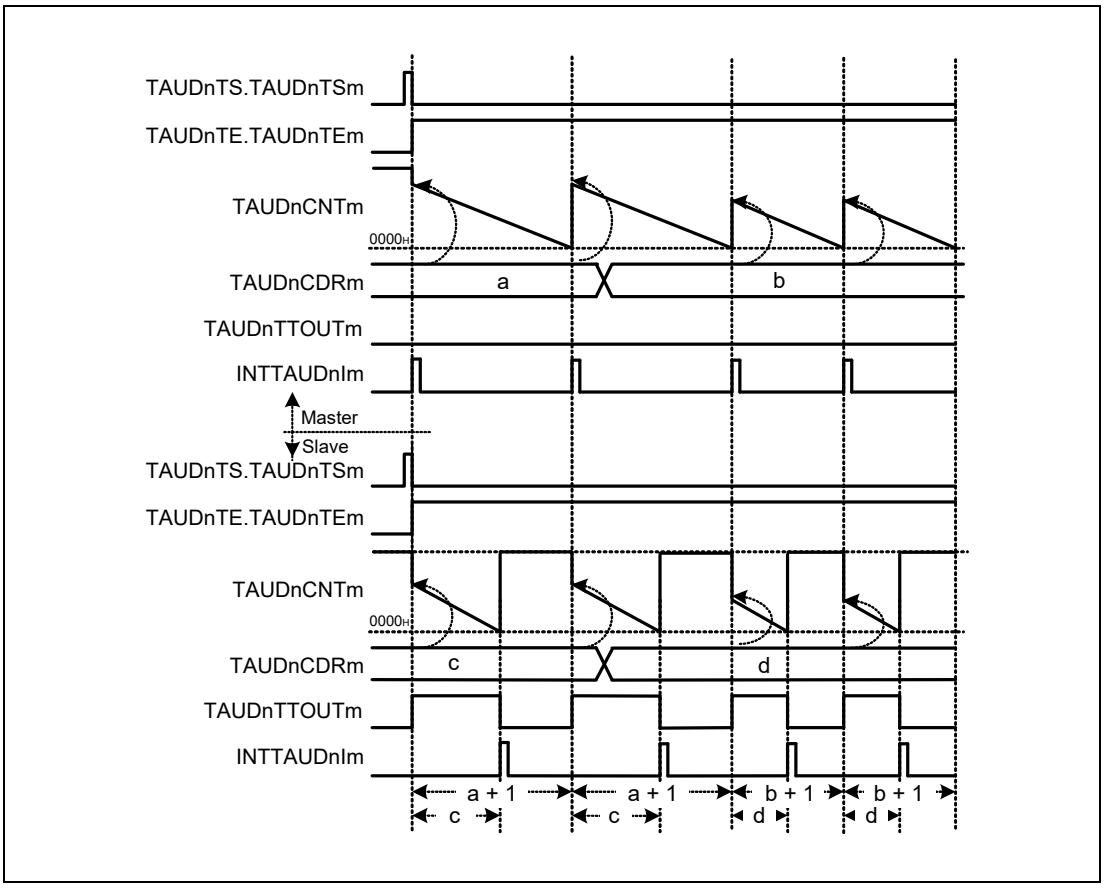

Figure 33.90 General Timing Diagram of PWM Output Function

NOTES

1. The interval between the starting to count and an interrupt being generated is the value of corresponding TAUDnCDRm + 1.
2. TAUDnTTOUTm of the slave channel rises with a delay of one clock count after the rise of INTTAUDnIm of the master channel.

33.15.1.4 Register Settings for the Master Channel

(1) TAUDnCMORm for the Master Channel

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDn MAS	TAUDnSTS[2:0]			TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDn MD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 33.138 Contents of the TAUDnCMORm Register for the Master Channel of the PWM Output Function

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operation clock as a count clock
11	TAUDnMAS	1: Master channel
10 to 8	TAUDnSTS[2:0]	000: Trigger the counter using software.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0000: Interval timer mode
0	TAUDnMD0	1: INTTAUDnIm generated at the beginning of operation.

(2) TAUDnCMURm for the Master Channel

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.139 Contents of the TAUDnCMURm Register for the Master Channel of the PWM Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for the Master Channel

The channel output mode is not used with this function.

(4) Simultaneous Rewrite for the Master Channel

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.140 Simultaneous Rewrite Settings for the Master Channel of the PWM Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects a master channel for simultaneous rewrite triggers. 1: Selects an upper channel outside the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

NOTE

Use with TAUDnRDS.TAUDnRDSm bit = 1 requires a channel higher than the master channel that operates with **Section 33.14.1, Simultaneous Rewrite Trigger Generation Function Type 1**.

Conduct operation settings under the following conditions:

- Simultaneous rewrite trigger output function type 1 setting channel: TAUDnRDCm = 1, TAUDnRDSm = 1
  TAUDnCDRm settings for this channel are as follows:
  = ((TAUDnCDR setting for the master channel targeted for simultaneous rewrite + 1) × interrupt count) - 1
- Master channel: TAUDnRDCm = 0, TAUDnRDSm = 1
- Slave channel: TAUDnRDCm = 0, TAUDnRDSm = 1

If TAUDnCDRm (slave) setting > TAUDnCDRm (master) setting + 1, the duty value (which exceeds 100%) is aggregated to be 100% output.

33.15.1.5 Register Settings for Slave Channels

(1) TAUDnCMORm for Slave Channels

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDnMAS	TAUDnSTS[2:0]			TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDnMD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 33.141 Contents of the TAUDnCMORm Register for the Slave Channel of the PWM Output Function

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operation clock as a count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	100: INTTAUDnIm of master channel is a start trigger.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0100: One-count mode
0	TAUDnMD0	1: Start trigger during operation is valid.

(2) TAUDnCMURm for Slave Channels

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.142 Contents of the TAUDnCMURm Register for the Slave Channel of the PWM Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for Slave Channels

Table 33.143 Control Bit Settings in Synchronous Channel Output Mode 1

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel operation
TAUDnTOC.TAUDnTOCm	0: Operating mode 1
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set these bits to 0
TAUDnTRC.TAUDnTRCm	
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous Rewrite for Slave Channels

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.144 Simultaneous Rewrite Settings for Slave Channels of PWM Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects a master channel for simultaneous rewrite triggers. 1: Selects an upper channel outside the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

33.15.1.6 Operating Procedure for PWM Output Function

Table 33.145 Operating Procedure for PWM Output Function

	Operation	TAUDn Status
Initial Channel Setting	Master channel: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.15.1.4, Register Settings for the Master Channel**. Slave channel: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.15.1.5, Register Settings for Slave Channels**. Set the value of TAUDnCDRm register of every channel.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm (master and slave channels) is set to 1 and the counters of master and slave channels start. INTTAUDnIm is generated on the master channel and TAUDnTTOUTm (slave) is set.
During operation	TAUDnCDRm can be changed at any time. TAUDnTOL.TAUDnTOLm can be changed. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time. TAUDnRDT.TAUDnRDTm can be changed during operation.	TAUDnCNTm of master channel loads TAUDnCDRm value and counts down. When the counter reaches 0000_H: • INTTAUDnIm (master) is generated. • TAUDnCDRm value is loaded into TAUDnCNTm (master) to continue count operation. • TAUDnCDRm value is loaded into TAUDnCNTm (slave) to perform counting down. • TAUDnTTOUTm (slave) is set to the active level. If TAUDnCNTm (slave) reaches 0000_H: • INTTAUDnIm (slave) is generated. • TAUDnTTOUTm (slave) is set to an inactive level. In addition, the counter of slave channel stops.
Stop Operation	Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

Restart Operation

33.15.1.7 Specific Timing Diagrams

(1) Duty cycle = 0%

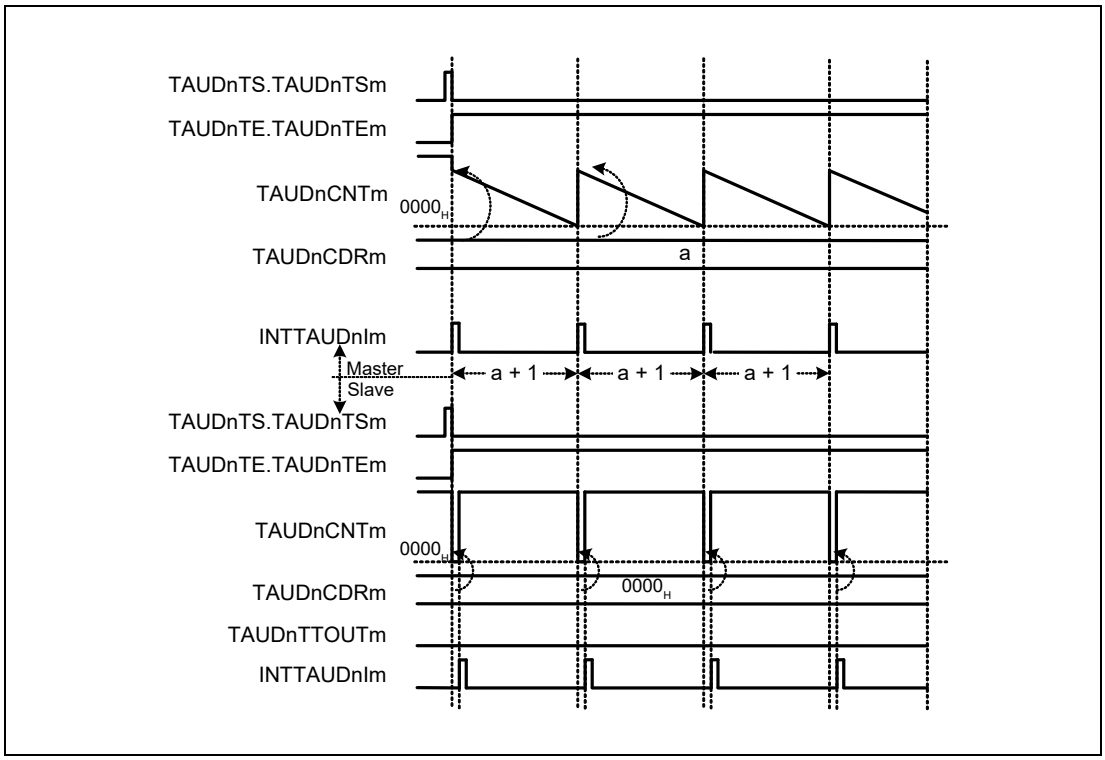

Figure 33.91 TAUDnCDRm (Slave) = 0000_H, Positive Logic (TAUDnTOL.TAUDnTOLm (Slave) = 0)

- Every time the master channel generates an interrupt (INTTAUDnIm), 0000_H is loaded into TAUDnCNTm (slave). As a result, a slave channel interrupt (INTTAUDnIm) is generated at the same time and TAUDnTTOUTm remains inactive.
- TAUDnCDRm value is loaded into TAUDnCNTm (slave) to generate an interrupt.

(2) Duty cycle = 100%

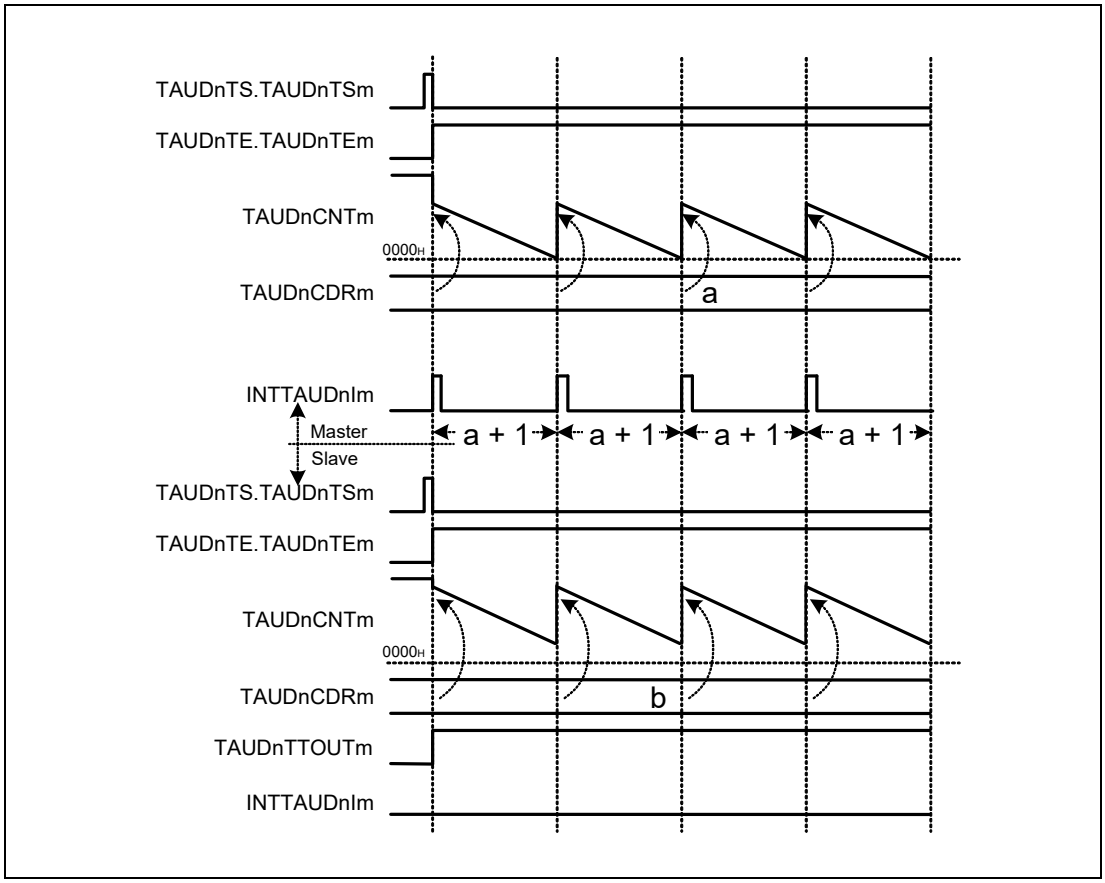

Figure 33.92 TAUDnCDRm (Slave) ≥ TAUDnCDRm (Master) + 1 Positive Logic (TAUDnTOL.TAUDnTOLm (Slave) = 0)

- If TAUDnCDRm (slave) value is greater than TAUDnCDRm (master) value, the slave channel counter does not reach 0000_H and consequently, no interrupt occurs. TAUDnTTOUTm remains active.

(3) Operation stop and restart

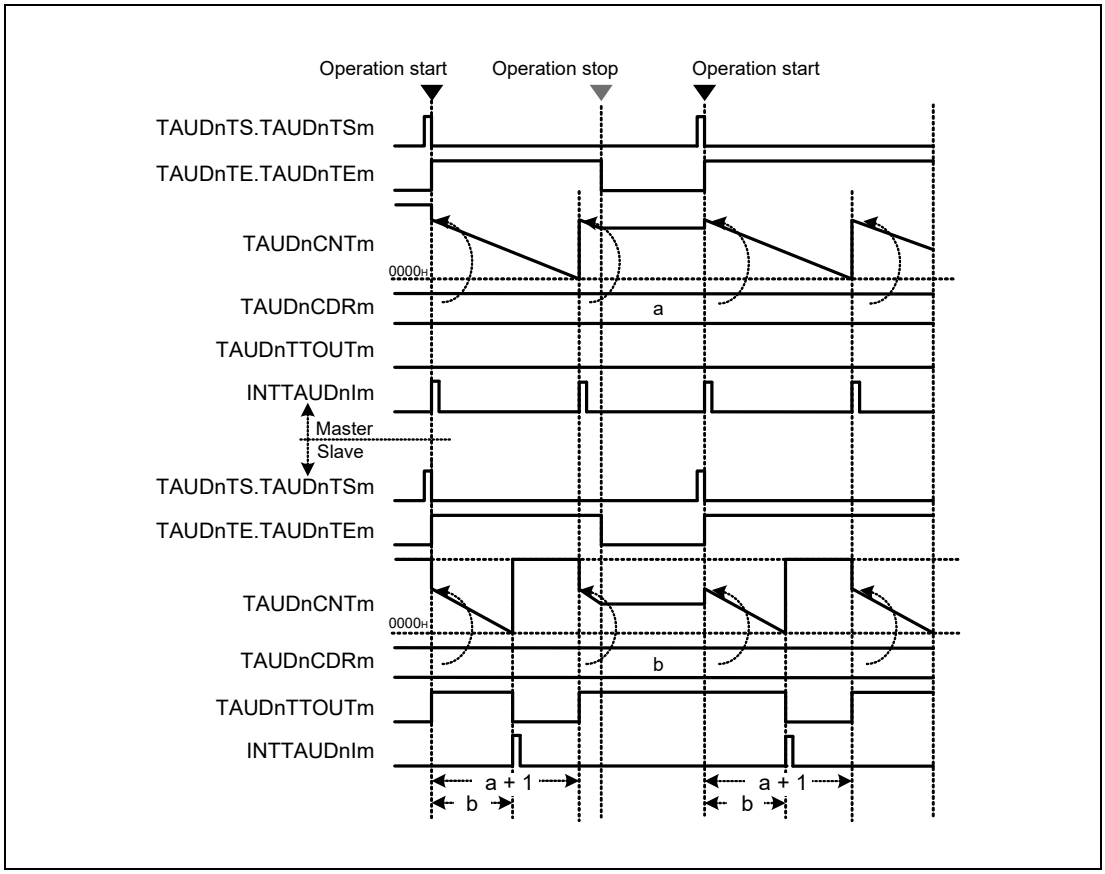

Figure 33.93 Operation Stop and Restart
Positive Logic (TAUDnTOL.TAUDnTOLm (Slave) = 0)

- The counter can be stopped by setting TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTEm to 0.
- TAUDnCNTm and TAUDnTTOUTm of all channels stop and the current values are retained. No interrupts are generated.
- The counter can be restarted by setting TAUDnTS.TAUDnTSm of master and slave channels to 1. TAUDnCDRm values of the master and slave channels are loaded to TAUDnCNTm and start to count down from these values.

33.15.2 One-Shot Pulse Output Function

33.15.2.1 Overview

Summary

This function outputs a signal pulse with a specific pulse width and delay time (both defined relative to an external input signal pulse or software trigger) by using a master and a slave channel. The delay time is specified using the master channel. The pulse width is specified using the slave channel.

Prerequisites

- Two channels
- The operating mode for the master channel should be set to one-count mode. (See **Table 33.146, Contents of the TAUDnCMORm Register for the Master Channel of the One-Shot Pulse Output Function**.)
- The operating mode for slave channels should be set to pulse one-count mode. (See **Table 33.149, Contents of the TAUDnCMORm Register for the Slave Channel of the One-Shot Pulse Output Function**.)
- TAUDnTTOUTm is not used with the master channel of this function.
- The channel output mode for slave channel should be set to independent channel output mode 2. (See **Section 33.7, Channel Output Modes**.)
- TAUDnTTINm (master) has to be detected while TAUDnCNTm (master) and TAUDnCNTm (slave) await a trigger. Furthermore, the slave is only triggered by an interrupt from the master channel and not by TAUDnTTINm (slave).
- When using only the software trigger, do not select TAUDnTTINm with the alternative function of the pins.

Functional description

The counters are enabled by setting the channel trigger bits (TAUDnTS.TAUDnTSm) to 1 for the master and slave channels. This sets TAUDnTE.TAUDnTEm to 1, enabling count operation.

- Master channel:
  When the next valid TAUDnTTINm input edge or software trigger (when TAUDnTE.TAUDnTEm = 1, TAUDnTS.TAUDnTSm = 1 (m: master channel number)) is detected the current value of TAUDnCDRm is loaded into TAUDnCNTm. The counter starts to count down from this value. If TAUDnCMORm.TAUDnMD0 = 0, a trigger (TAUDnTTINm) which is detected within the delay time is ignored.
  When the counter of master channel reaches 0000_H, INTTAUDnIm is generated. The counter is reset to $FFFF_H$ and waits for the next valid TAUDnTTINm input edge or software trigger (when TAUDnTE.TAUDnTEm = 1, TAUDnTS.TAUDnTSm = 1 (m: master channel number)).
- Slave channel:
  INTTAUDnIm generated on master channel triggers the counter operation of slave channel. The current value of TAUDnCDRm (slave) is loaded into TAUDnCNTm (slave). The counter starts counting down from this value. An interrupt occurs and the TAUDnTTOUTm signal is set.
  When the counter reaches 0001_H, INTTAUDnIm is generated and TAUDnTTOUTm signal is reset. The counter stops at 0000_H and waits for the next INTTAUDnIm of master channel.

The counter can be stopped by setting TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTEm to 0. TAUDnCNTm and TAUDnTTOUTm of master and slave channels stop but their values are retained. The counter can be restarted by setting TAUDnTS.TAUDnTSm to 1.

Setting TAUDnTS.TAUDnTSm to 1 while counting allows the counter to restart counting of master channel without making a stop (forced restart).

Conditions

- If TAUDnCMORm.TAUDnMD0 of master channel is set to 0, TAUDnTTINm input edges detected during counting are ignored.
- Simultaneous rewrite can be used with this function. See **Section 33.6, Simultaneous Rewrite**.

33.15.2.2 Equations

Delay from trigger input to pulse output = (TAUDnCDRm (master) + 1) × count clock cycle

Pulse width = (TAUDnCDRm (slave)) × count clock cycle

33.15.2.3 Block Diagram and General Timing Diagram

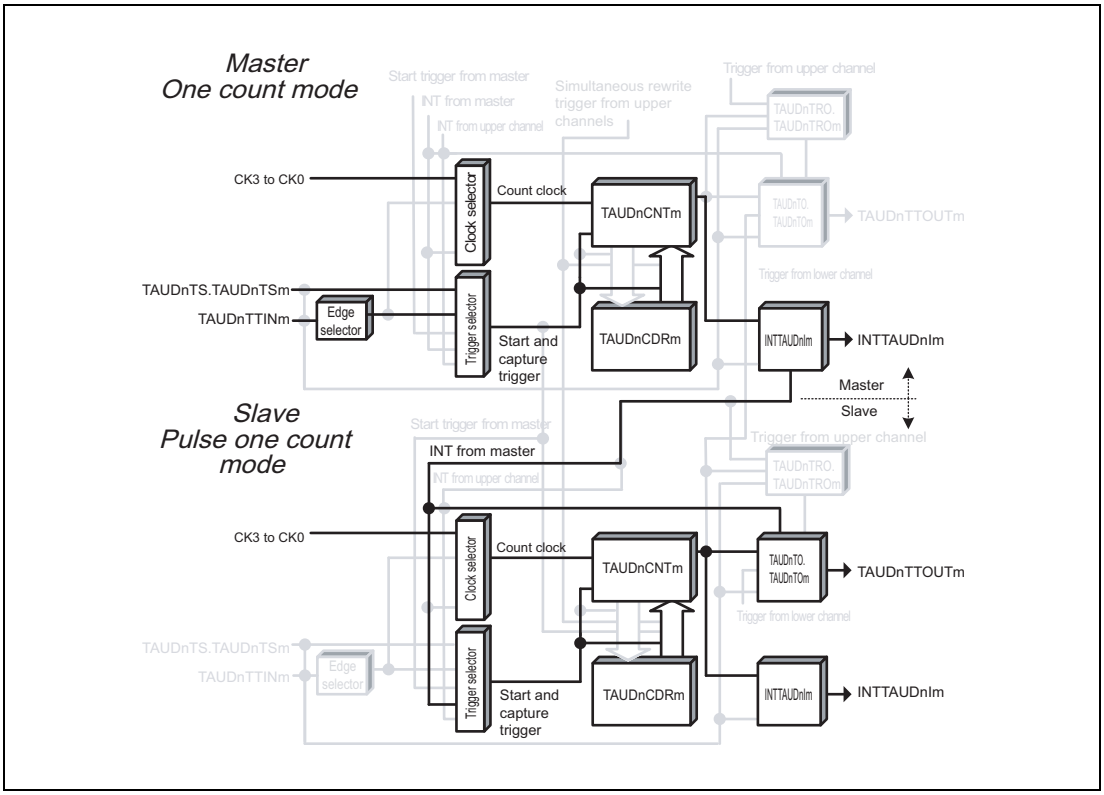

Figure 33.94 Block Diagram of One-Shot Pulse Output Function

The following settings apply to **Figure 33.95, General Timing Diagram of One-Shot Pulse Output Function (External Input Signal)** and **Figure 33.96, General Timing Diagram of One-Shot Pulse Output Function (Software Trigger)**.

- Start trigger detection is disabled during counting (TAUDnCMORm.TAUDnMD0 = 0).
- Detection of falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

33.15.2.4 Register Settings for the Master Channel

(1) TAUDnCMORm for the Master Channel

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDnMAS	TAUDnSTS[2:0]			TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDnMD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 33.146 Contents of the TAUDnCMORm Register for the Master Channel of the One-Shot Pulse Output Function

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operation clock as a count clock
11	TAUDnMAS	1: Master channel
10 to 8	TAUDnSTS[2:0]	001: Valid TAUDnTTINm input edge signal is used as the start trigger
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0100: One-count mode
0	TAUDnMD0	0: Disables detection of start trigger during count operation. 1: Enables detection of start trigger during count operation. The value of the MD0 bits of master and slave channels must be identical.

(2) TAUDnCMURm for the Master Channel

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.147 Contents of the TAUDnCMURm Register for the Master Channel of the One-Shot Pulse Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Detection of falling edge 01: Detection of rising edge 10: Detection of rising and falling edges 11: Setting prohibited

(3) Channel Output Mode for the Master Channel

TAUDnTOE.TAUDnTOEm is set to 0 because channel output mode is not used with this function.

(4) Simultaneous Rewrite for the Master Channel

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.148 Simultaneous Rewrite Settings for the Master Channel of One-Shot Pulse Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Master channel is simultaneous rewrite control channel.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

33.15.2.5 Register Settings for Slave Channels

(1) TAUDnCMORm for Slave Channels

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDn MAS	TAUDnSTS[2:0]			TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDn MD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 33.149 Contents of the TAUDnCMORm Register for the Slave Channel of the One-Shot Pulse Output Function

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operation clock as a count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	100: INTTAUDnIm of master channel is a start trigger.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	1010: Pulse one-count mode
0	TAUDnMD0	0: Disables detection of start trigger during count operation. 1: Enables start trigger detection while counting. The MD0 bits of the master and slave channels must be identical.

(2) TAUDnCMURm for Slave Channels

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.150 Contents of the TAUDnCMURm Register for the Slave Channel of the One-Shot Pulse Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for Slave Channel

Table 33.151 Control Bit Settings in Independent Channel Output Mode 2

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set this bit to 0
TAUDnTDL.TAUDnTDLm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set this bit to 0
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set this bit to 0
TAUDnTRC.TAUDnTRCm	0: Disables the operation as a real-time output trigger channel
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous Rewrite for Slave Channels

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.152 Simultaneous Rewrite Settings for Slave Channels of One-Shot Pulse Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Master channel is simultaneous rewrite control channel.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

33.15.2.6 Operating Procedure for One-Shot Pulse Output Function

Table 33.153 Operating Procedure for One-Shot Pulse Output Function

	Operation	TAUDn Status
Initial Channel Setting	Master channel: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.15.2.4, Register Settings for the Master Channel**. Slave channel: Set TAUDnCMORm and TAUDnCMURm registers and channel output mode as described in **Section 33.15.2.5, Register Settings for Slave Channels**. Set the value of TAUDnCDRm register of every channel.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm (master and slave channels) is set to 1 and the master channel awaits a TAUDnTTINm input.
During Operation	TAUDnCDRm can be changed at any time. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time. TAUDnRDT.TAUDnRDTm can be changed during operation.	When valid TAUDnTTINm input edge is detected, TAUDnCDRm value of master channel is loaded into TAUDnCNTm to perform counting down. When the counter reaches 0000_H: • INTTAUDnIm (master) is generated. • TAUDnCNTm (master) is reset to $FFFF_H$ and waits for the next valid TAUDnTTINm input edge. • TAUDnCDRm value is reloaded into TAUDnCNTm (slave) to perform counting down. • INTTAUDnIm (slave) is generated. • TAUDnTTOUTm (slave) is set to the active level. When TAUDnCNTm (slave) reaches 0001_H: • INTTAUDnIm (slave) is generated. • TAUDnTTOUTm (slave) is set to an inactive level. In addition, the counter of slave channel stops.
Stop Operation	Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

Restart Operation

33.15.2.7 Specific Timing Diagrams

(1) TAUDnCDRm (master) = 0000_H

The following settings apply to this diagram.

- Disables detection of start trigger during count operation. (TAUDnCMORm.TAUDnMD0 = 0)
- Detection of falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

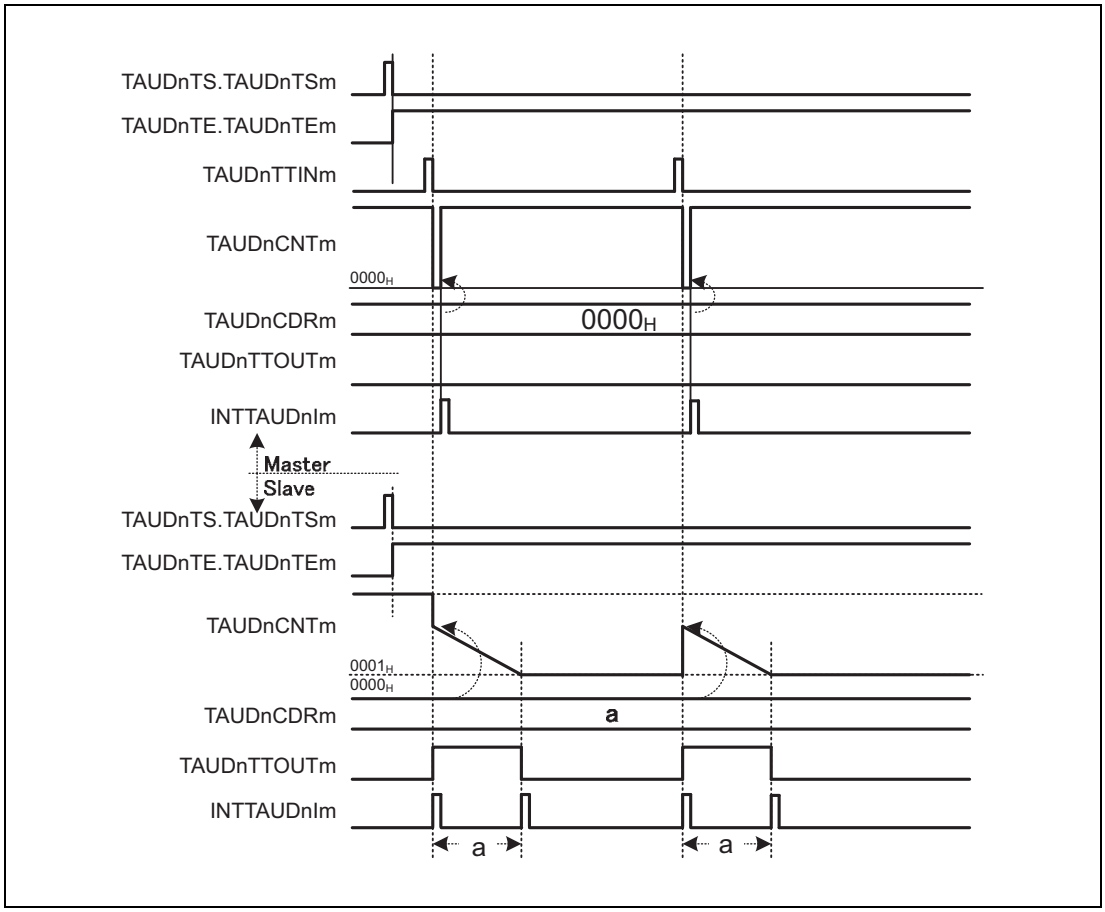

Figure 33.97 TAUDnCDRm (Master) = 0000_H

- When a valid TAUDnTTINm input edge is detected, the value 0000_H is written to TAUDnCNTm (master). The counter is set to 0000_H for one count and returns to $FFFF_H$.
  Thus the slave channel starts to count down one count clock later than TAUDnTTINm (master).

(2) TAUDnCDRm (slave) = 0000_H

The following settings apply to this diagram.

- Disables detection of start trigger during count operation. (TAUDnCMORm.TAUDnMD0 = 0)
- Detection of falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

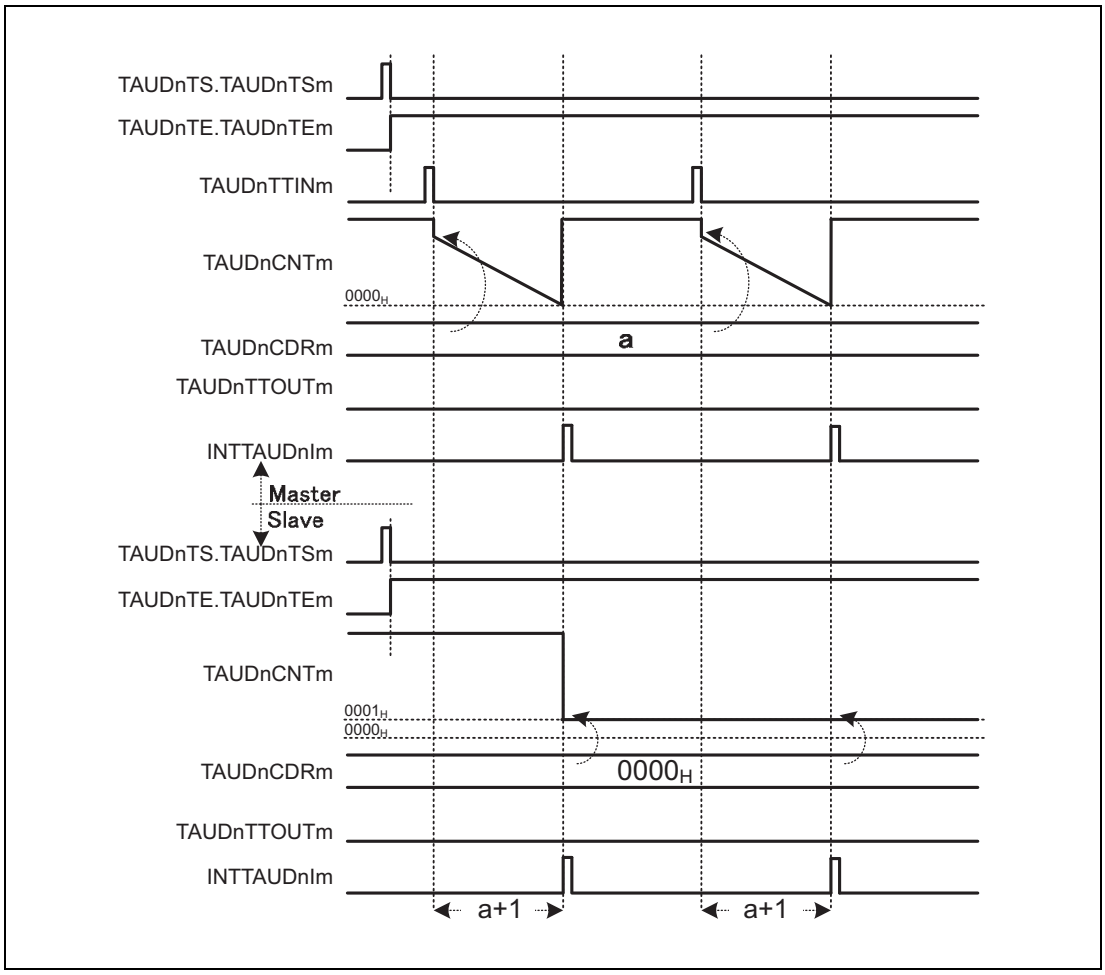

Figure 33.98 TAUDnCDRm (Slave) = 0000_H

- TAUDnTTOUTm remains inactive, because the pulse width is zero.

(3) TAUDnCMORm.TAUDnMD0 = 1

The following settings apply to this diagram.

- Enables start trigger detection while counting. (TAUDnCMORm.TAUDnMD0 = 1)
- Detection of falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

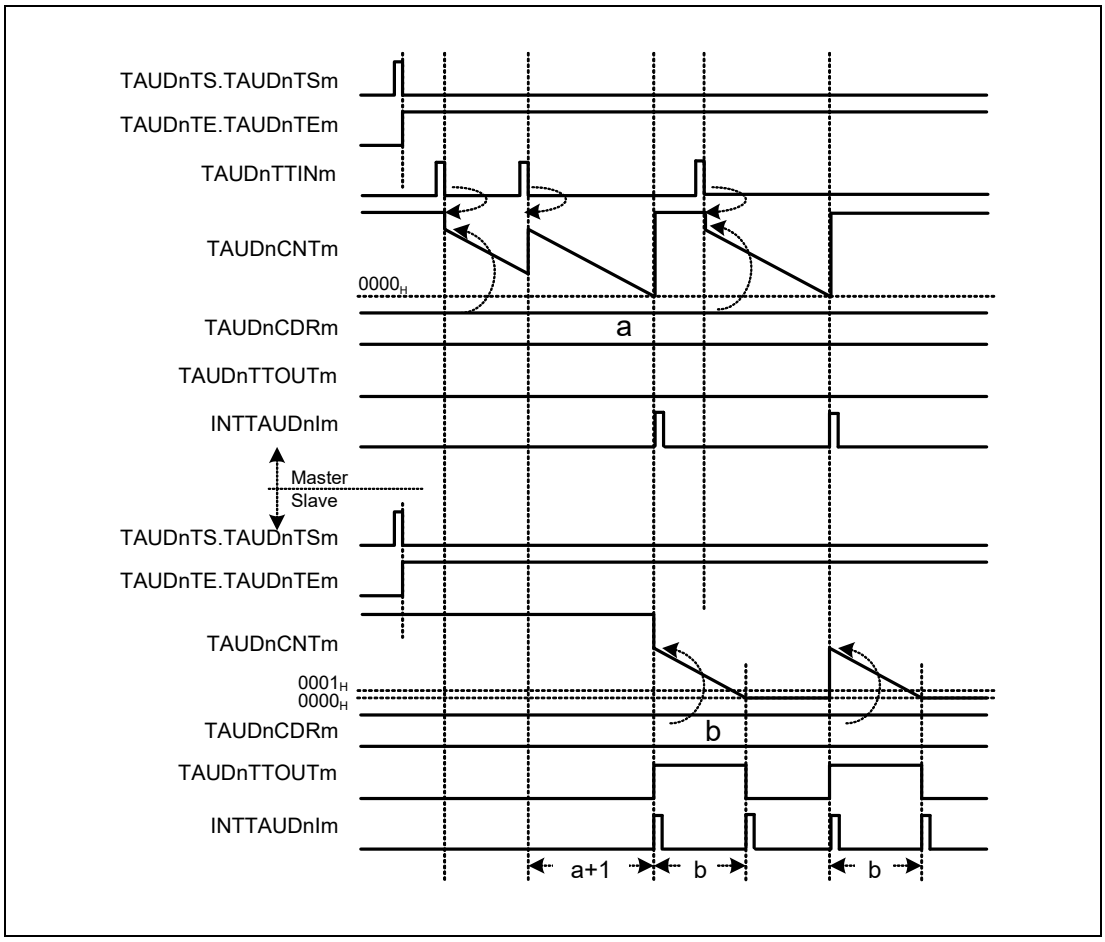

Figure 33.99 TAUDnCMORm.TAUDnMD0 = 1

- If a valid TAUDnTTINm input edge is detected while the counter of the master channel counts down, TAUDnCNTm reloads the value of TAUDnCDRm. The counter restarts to count down. This means the delay is extended by the value of TAUDnCNTm at the time when a valid TAUDnTTINm input edge is detected.

(4) Restarting the Master Channel while the Slave Channel is Counting

The following settings apply to this diagram.

- Disables detection of start trigger during count operation. (TAUDnCMORm.TAUDnMD0 = 0)
- Detection of falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

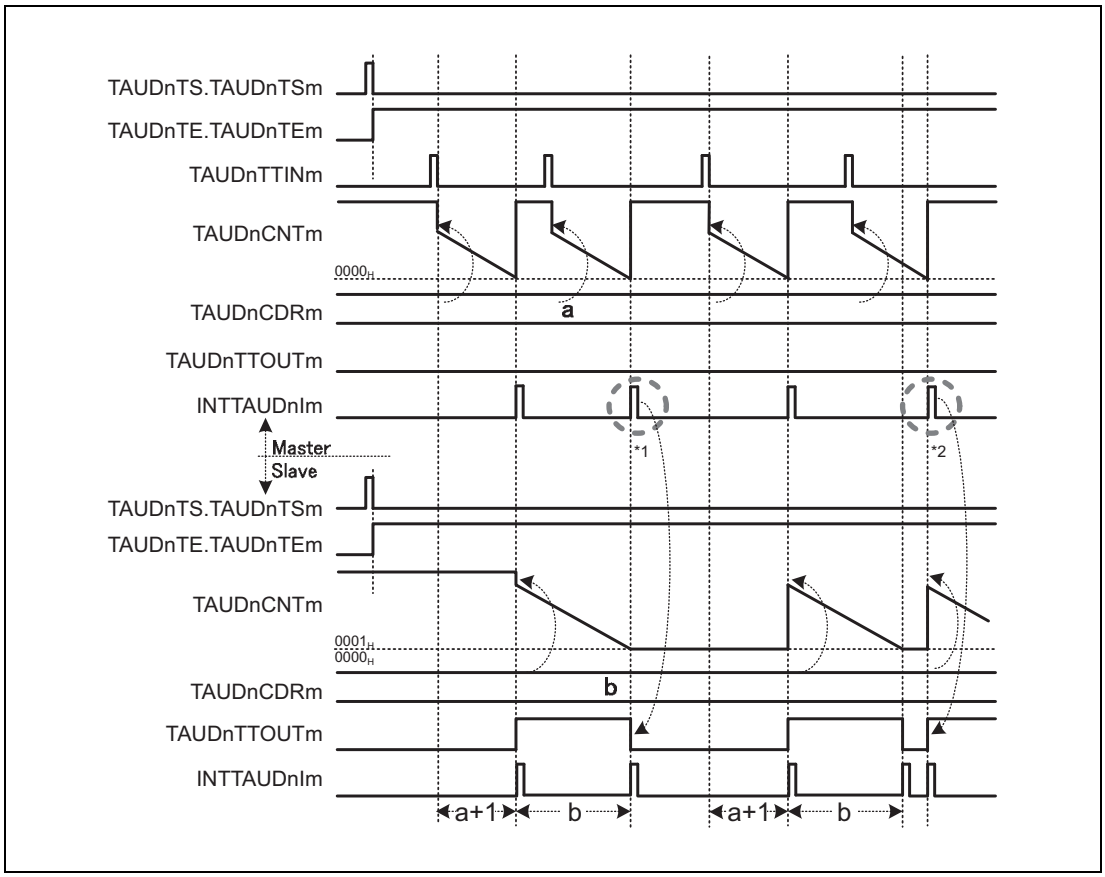

Figure 33.100 TAUDnTTINm input interval ≤ Delay Time + Pulse Width + 1

- If the master channel generates an interrupt before the counter of the slave channel has reached 0001_H or exactly when 0001_H is reached[*1], the interrupt (master) is ignored.
- If an interrupt of the master channel occurs when the counter of the slave channel awaits the next trigger, the value of TAUDnCDRm (slave) is reloaded. An interrupt is generated and TAUDnTTOUTm toggles. If TAUDnCNTm (master) has started to count down while the TAUDnCNTm (slave) is still counting[*2], TAUDnTTOUTm is not output with the expected delay time.
- To generate the correct one-shot pulse, the start trigger for the master channel must be detected while the master and slave channels are waiting for the start trigger, and not while they are counting.

33.15.3 Trigger Start PWM Output Function

33.15.3.1 Overview

Summary

This function generates a PWM output using a master and a slave channel. It enables the pulse cycle (frequency) and the duty of the TAUDnTTOUTm to be set. The pulse cycle is specified using the master channel. The duty is specified using the slave channel. The Trigger Start PWM Output Function is identical to PWM Output Function except that the master channel of this function can be reset by a valid TAUDnTTINm input edge.

Prerequisites

- Two channels
- The operation mode of the master channel must be set to Interval Timer Mode (see **Table 33.154, Contents of the TAUDnCMORm Register for the Master Channel of the Trigger Start PWM Output Function**).
- The operation mode of the slave channel must be set to One-Count Mode (see **Table 33.157, Contents of the TAUDnCMORm Register for the Slave Channel of the Trigger Start PWM Output Function**).
- TAUDnTTOUTm is not used with the master channel of this function.
- The channel output mode of the slave channel must be set to Synchronous Channel Output Mode 1 (see **Section 33.6, Simultaneous Rewrite**).

Functional description

The counters (master and slave) are enabled by setting the channel trigger bits (TAUDnTS.TAUDnTSm) to 1. This in turn sets TAUDnTE.TAUDnTEm to 1, enabling count operation. The current value of TAUDnCDRm is loaded to TAUDnCNTm, and the counter starts to count down from this value. INTTAUDnIm is generated on the master channel, and a PWM output is realized by setting and resetting TAUDnTTOUTm (slave).

- Master channel:
  The current value of TAUDnCDRm is loaded to the counter (TAUDnCNTm), INTTAUDnIm is generated and the counter starts to count down from this value.
  When the counter reaches 0000_H and the pulse cycle time has elapsed, INTTAUDnIm is generated and the counters (master and slave) load the current TAUDnCDRm values.
  If a valid TAUDnTTINm input edge is detected, the counter of the master channel loads the current TAUDnCDRm value, restarts counting down and generates an interrupt.
- Slave channel:
  When the slave detects an interrupt from the master channel, it starts to count down from the current value of TAUDnCDRm. The TAUDnTTOUTm signal is set to the active level.
  When the counter reaches 0000_H (duty time has elapsed), INTTAUDnIm is generated and the TAUDnTTOUTm signal is reset. The counter returns to $FFFF_H$ and awaits the next INTTAUDnIm of the master channel.

The counter can be stopped by setting TAUDnTT.TAUDnTTm to 1 for the master and slave channels, which in turn sets TAUDnTE.TAUDnTEm to 0. TAUDnCNTm and TAUDnTTOUTm of master and slave channels stop but retain their values. The counters can be restarted by setting TAUDnTS.TAUDnTSm to 1.

Conditions

Simultaneous rewrite can be used with this function. See **Section 33.6, Simultaneous Rewrite**.

33.15.3.2 Equations

Pulse cycle = (TAUDnCDRm (master) + 1) × count clock cycle

Duty cycle [%] = [TAUDnCDRm (slave) / (TAUDnCDRm (master) + 1)] × 100

– Duty cycle = 0%
TAUDnCDRm (slave) = 0000_H

– Duty cycle = 100%
TAUDnCDRm (slave) ≥ TAUDnCDRm (master) + 1

33.15.3.3 Block Diagram and General Timing Diagram

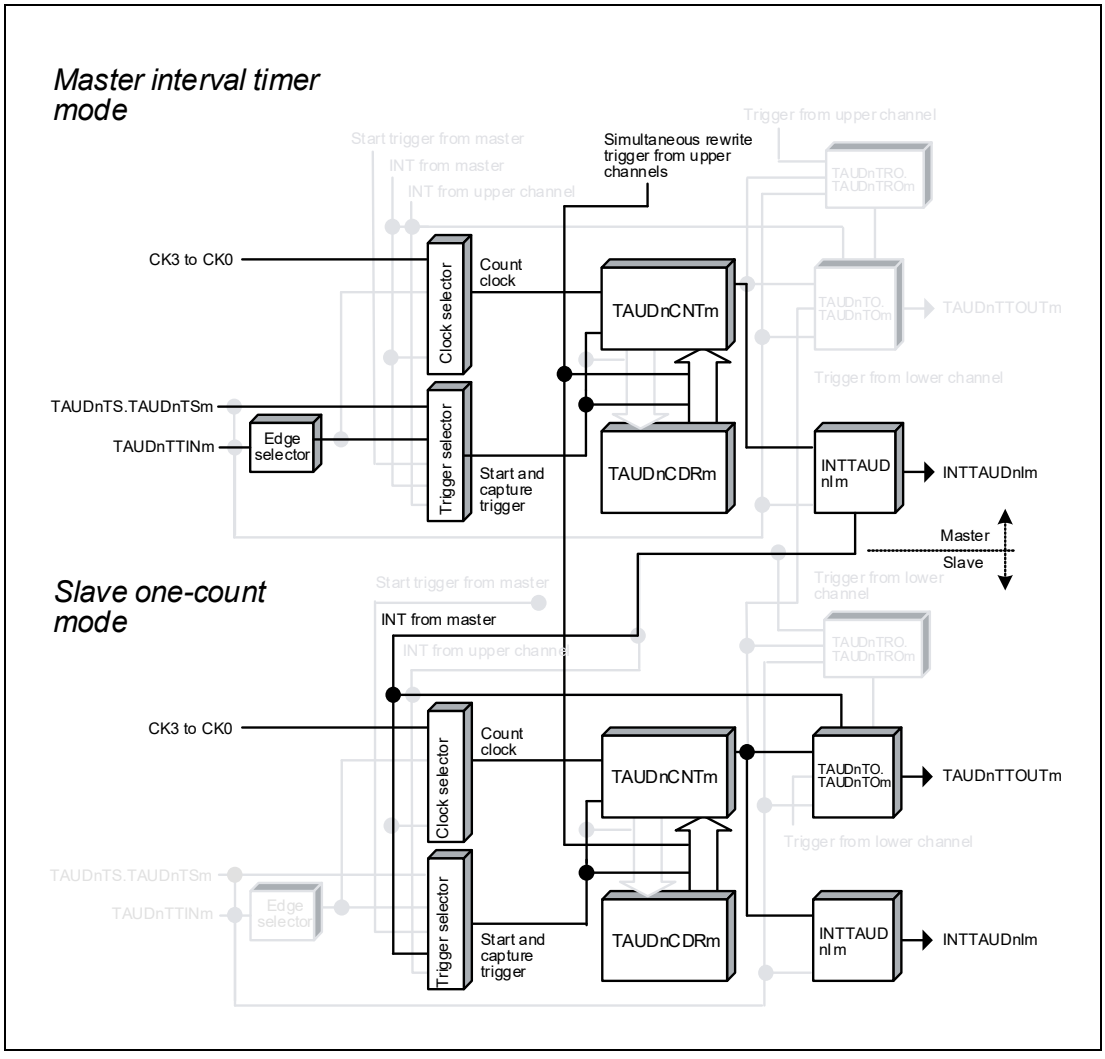

Figure 33.101 Block Diagram for Trigger Start PWM Output Function

The following settings apply to the general timing diagram.

- Detection of rising edge (TAUDnCMURm.TAUDnTIS[1:0] = 01_B)
- Positive logic (TAUDnTOL.TAUDnTOLm (slave) = 0)

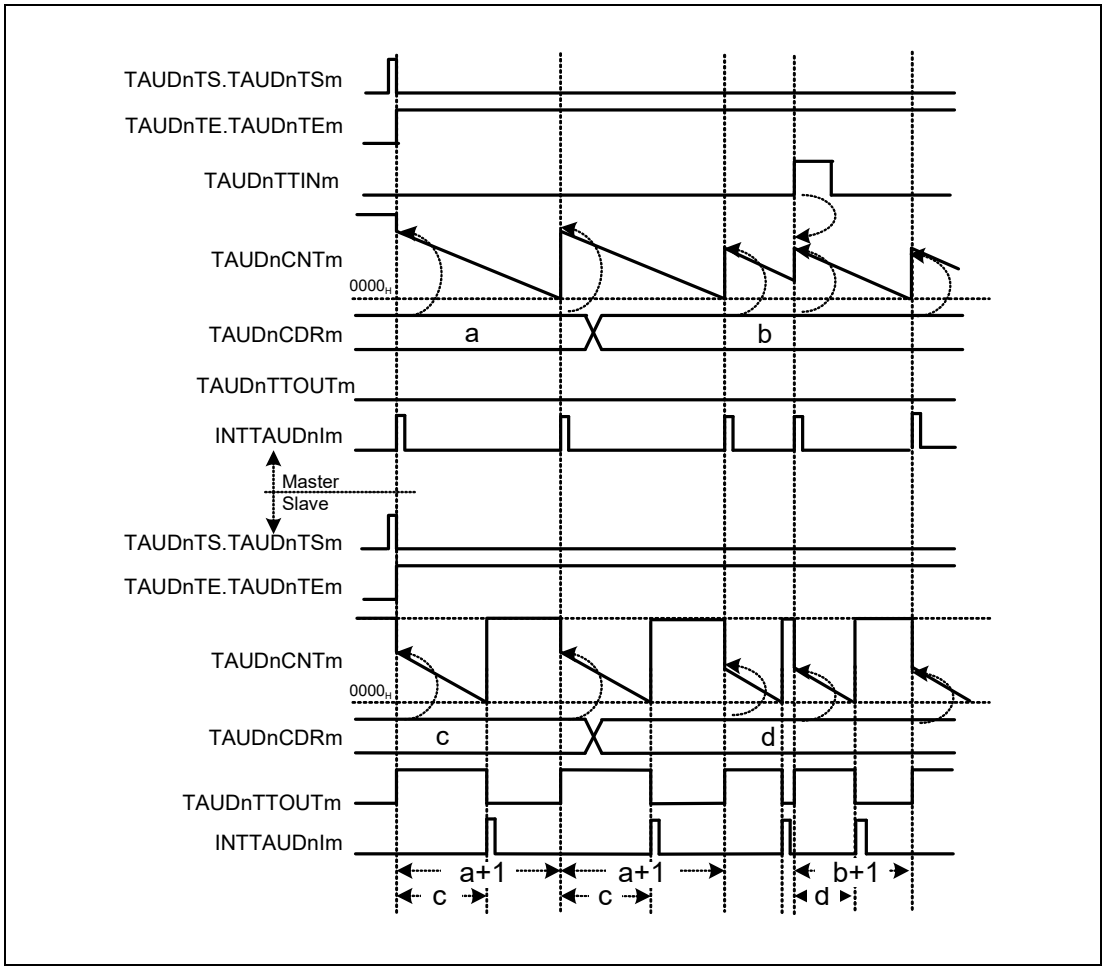

Figure 33.102 General Timing Diagram for Trigger Start PWM Output Function

NOTE

TAUDnTTOUTm of the slave channel rises with a delay of one clock count after the rise of INTTAUDnIm of the master channel.

33.15.3.4 Register Settings for the Master Channel

(1) TAUDnCMORm for the Master Channel

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

1, 0	TAUDnTIS[1:0]	00: Detection of falling edge 01: Detection of rising edge 10: Detection of rising and falling edges 11: Setting prohibited

(3) Channel Output Mode for the Master Channel

The channel output mode is not used by this function.

(4) Simultaneous Rewrite for the Master Channel

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.156 Simultaneous Rewrite Settings for the Master Channel of the Trigger Start PWM Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects a master channel for simultaneous rewrite triggers. 1: Selects an upper channel outside the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

33.15.3.5 Register Settings for Slave Channels

(1) TAUDnCMORm for Slave Channels

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDn MAS	TAUDnSTS[2:0]			TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDn MD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 33.157 Contents of the TAUDnCMORm Register for the Slave Channel of the Trigger Start PWM Output Function

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operation clock as a count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	100: INTTAUDnIm of master channel is a start trigger.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0100: One-count mode
0	TAUDnMD0	1: Start trigger during operation is valid. The value of the TAUDnMD[0] bit of the master and slave channels must be identical.

(2) TAUDnCMURm for Slave Channels

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.158 Contents of the TAUDnCMURm Register for the Slave Channel of the Trigger Start PWM Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for Slave Channel

Table 33.159 Control Bit Settings in Synchronous Channel Output Mode 1

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel operation
TAUDnTOC.TAUDnTOCm	0: Operating mode 1
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set this bit to 0
TAUDnTRC.TAUDnTRCm	0: Disables the operation as a real-time output trigger channel
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous Rewrite for Slave Channels

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.160 Simultaneous Rewrite Settings for Slave Channel of the Trigger Start PWM Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects a master channel for simultaneous rewrite triggers. 1: Selects an upper channel outside the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

33.15.3.6 Operating Procedure for Trigger Start PWM Output Function

Table 33.161 Operating Procedure for Trigger Start PWM Output Function

	Operation	TAUDn Status
Initial Channel Setting	Master channel: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **33.15.3.4, Register Settings for the Master Channel**. Slave channel: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **33.15.3.5, Register Settings for Slave Channels**. Set the value of TAUDnCDRm register of every channel.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm (master and slave channels) is set to 1 and the counters of master and slave channels start. INTTAUDnIm is generated on the master channel.
During Operation	TAUDnCDRm can be changed at any time. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time. TAUDnRDT.TAUDnRDTm can be changed during operation.	TAUDnCNTm of master channel loads TAUDnCDRm value and counts down. When the counter reaches 0000_H: • INTTAUDnIm (master) is generated. • TAUDnCDRm value is loaded into TAUDnCNTm (master) to continue count operation. • TAUDnCNTm (slave) loads the TAUDnCDRm value and starts to count down • TAUDnTTOUTm (slave) is set When TAUDnCNTm of the slave = 0000_H: • INTTAUDnIm (slave) is generated. • TAUDnTTOUTm (slave) is set to an inactive level. In addition, the counter of slave channel stops. If a TAUDnTTINm input is detected on the master channel while TAUDnCNTm of the master channel is counting down: • TAUDnCNTm (master and slave) loads the TAUDnCDRm value and counts down • INTTAUDnIm (master) is generated. • TAUDnTTOUTm (slave) is set to the active level.
Stop Operation	Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

Restart Operation

33.15.3.7 Specific Timing Diagrams

(1) Duty cycle = 0%

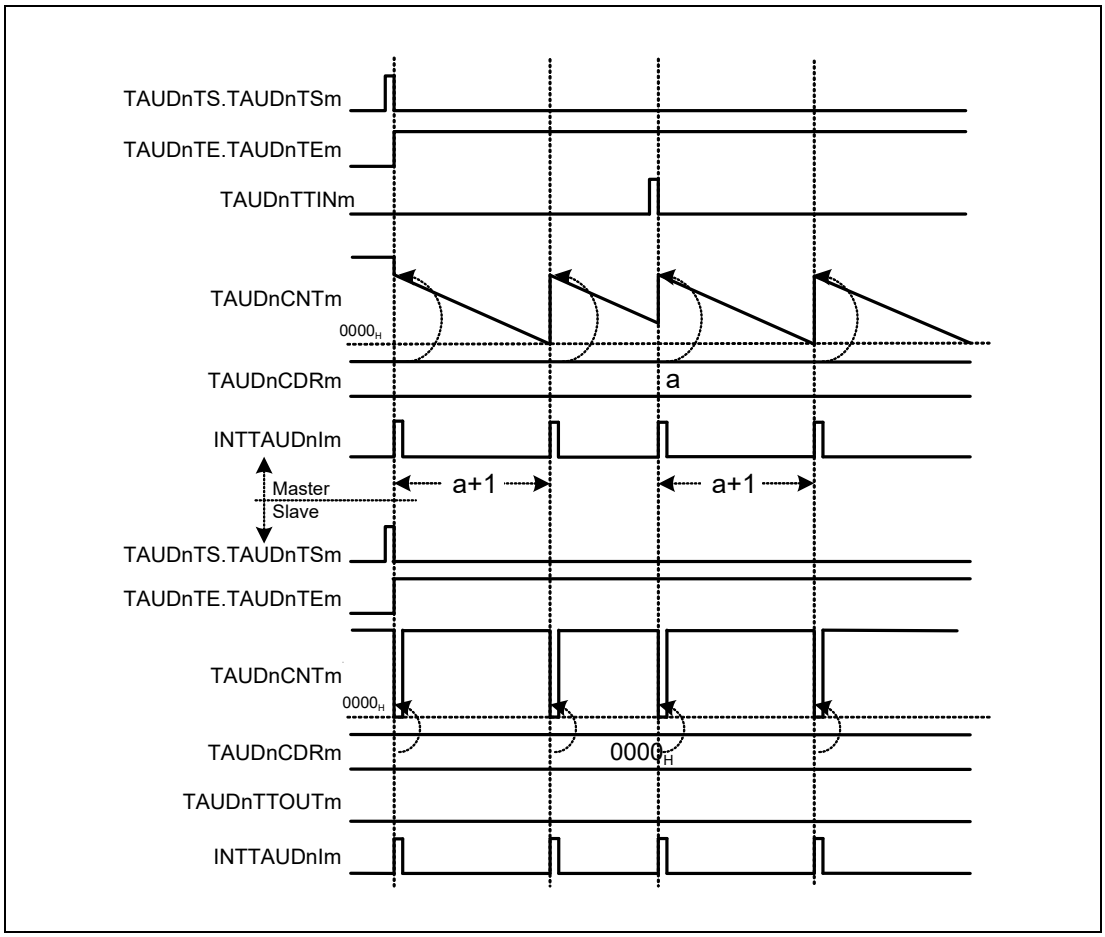

Figure 33.103 TAUDnCDRm (Slave) = 0000_H, Positive Logic (TAUDnTOL.TAUDnTOLm (Slave) = 0) Detection of Falling Edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

- Every time the master channel generates an interrupt (INTTAUDnIm), 0000_H is written to TAUDnCNTm (slave). Therefore, TAUDnCNTm (slave) cannot start to count and TAUDnTTOUTm remains inactive.
- TAUDnCNTm (slave) generates an interrupt every time the value of TAUDnCDRm is reloaded. The detection of a valid TAUDnTTINm input edge has no effect on TAUDnTTOUTm (slave).

(2) Duty cycle = 100%

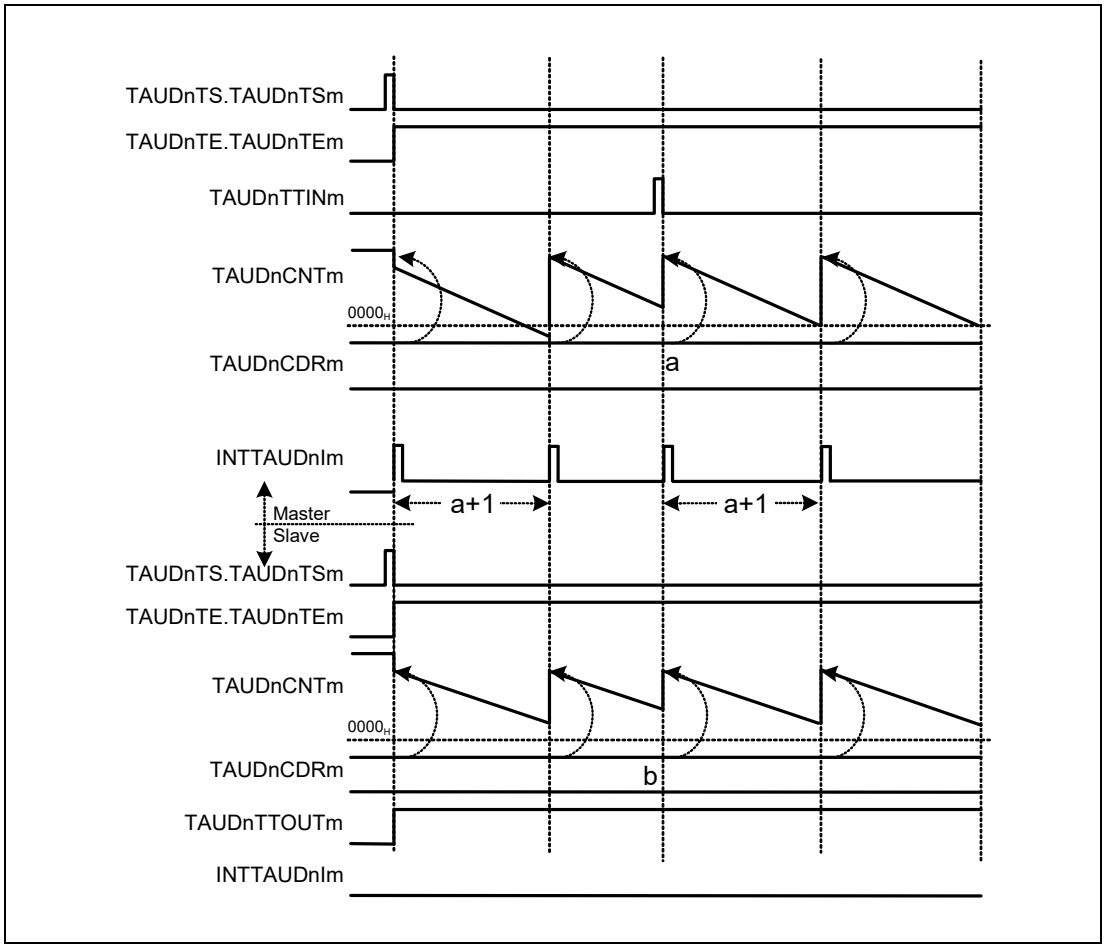

Figure 33.104 TAUDnCDRm (Slave) ≥ TAUDnCDRm (Master) + 1, Positive Logic (TAUDnTOL.TAUDnTOLm (Slave) = 0) Falling Edge Detection (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

- If the value TAUDnCDRm (slave) is higher than the value TAUDnCDRm (master), the counter of the slave channel cannot reach 0000_H and cannot generate interrupts.
  The TAUDnTTOUTm remains at active state.
  The detection of a valid TAUDnTTINm input edge has no effect on TAUDnTTOUTm (slave).

(3) TAUDnTTINm Detection and Active Slave Counter

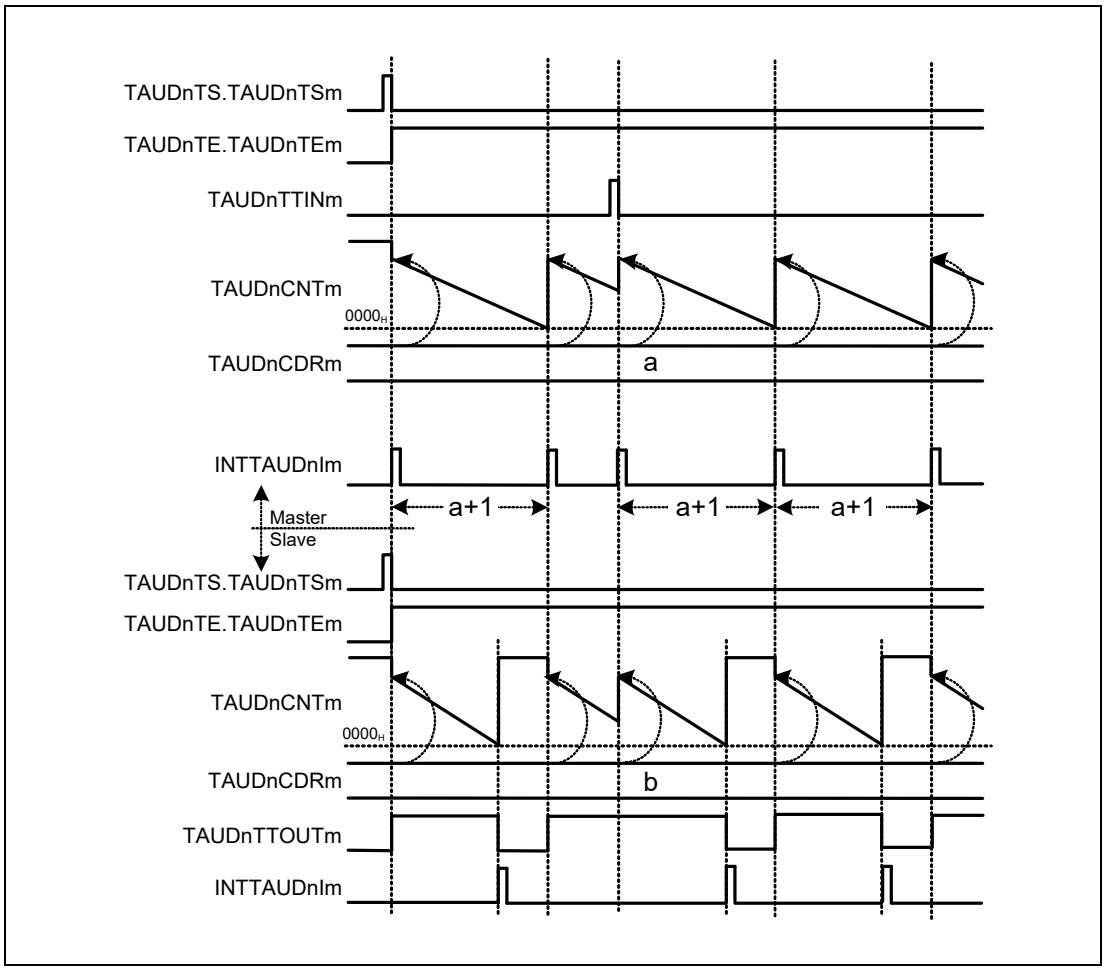

Figure 33.105 Positive Logic (TAUDnTOL.TAUDnTOLm (Slave) = 0)
Detection of Falling Edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

- If TAUDnCNTm (slave) reloads the value TAUDnCDRm (slave) while it is still counting down, TAUDnTTOUTm remains unchanged and extends the duty.
  The duty does not correspond to the value of the slave's data register.

33.15.4 Delay Pulse Output Function

33.15.4.1 Overview

Summary

This function outputs two signals. The pulse width and pulse cycle of the reference signal are defined using the master channel and slave channel 1. Slave channels 2 and 3 output the reference signal with a specified delay. The delay signal is identical to the reference signal, but delayed by the amount specified on slave channel 2.

The signal values are specified in the following way:

- The pulse cycle is specified using the master channel.
- The duty cycle of the reference signal is specified using slave channel 1. The duty cycle of the delay signal is specified using slave channel 3.
- The delay is specified on slave channel 2.

Prerequisites

- Four channels
- The operating mode for the master channel should be set to interval timer mode. (See **Table 33.162, Contents of the TAUDnCMORm Register for the Master Channel of the Delay Pulse Output Function**.)
- The operating mode for slave channels 1 and 2 should be set to one-count mode. (See **Table 33.165, Contents of the TAUDnCMORm Register for Slave Channel 1 of the Delay Pulse Output Function** and **Table 33.169, Contents of the TAUDnCMORm Register for Slave Channel 2 of the Delay Pulse Output Function**.)
- The operating mode for slave channel 3 should be set to pulse one-count mode. (See **Table 33.172, Contents of the TAUDnCMORm Register for Slave Channel 3 of the Delay Pulse Output Function**.)
- TAUDnTTOUTm is not used with the master channel and slave channel 2.
- The channel output mode for slave channel 1 should be set to synchronous channel output mode 1. (See **Section 33.7, Channel Output Modes**.)
- The channel output mode for slave channel 3 should be set to independent channel output mode 2. (See **Section 33.7, Channel Output Modes**.)

Functional description

The counters of the channel group are enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This sets TAUDnTE.TAUDnTEm to 1, enabling count operation.

- Master channel:
  The current value of TAUDnCDRm is loaded into TAUDnCNTm and the counter starts to count down from this value. INTTAUDnIm is generated on the master channel.
  When the counter value of master channel reaches 0000_H and pulse cycle time has elapsed, INTTAUDnIm is generated. The TAUDnCDRm value is reloaded into the counter to perform counting down.

- Slave channels 1 and 2:
  Slave channels 1 and 2 start to count down from the current TAUDnCDRm value when detecting an interrupt from the master channel. TAUDnTTOUTm signal (slave 1) is set.
  - Slave channel 1:
    When the counter of slave channel 1 reaches 0000_H (duty time has elapsed), INTTAUDnIm is generated and TAUDnTTOUTm signal is reset. The counter is reset to $FFFF_H$ and waits for the next INTTAUDnIm of master channel.
  - Slave channel 2:
    When the counter of slave channel 2 reaches 0000_H and delay time has elapsed, INTTAUDnIm is generated. The counter is reset to $FFFF_H$ and waits for the next INTTAUDnIm of master channel.
    Generating INTTAUDnIm (slave channel 2) triggers the counter of slave channel 3.
- Slave channel 3:
  When slave channel 3 detects an interrupt from slave channel 2, its counter starts counting down from the current value of TAUDnCDRm. INTTAUDnIm is generated and the TAUDnTTOUTm signal (slave channel 3) is set.
  When the counter of slave channel 3 reaches 0001_H, INTTAUDnIm is generated and the TAUDnTTOUTm signal is reset.
  The delayed PWM pulse is output from slave channel 3.

The counter can be stopped by setting TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTEm to 0. TAUDnCNTm and TAUDnTTOUTm of master and slave channels stop but their values are retained. The counter can be restarted by setting TAUDnTS.TAUDnTSm to 1.

Conditions

Simultaneous rewrite can be used with this function. See **Section 33.6, Simultaneous Rewrite**.

33.15.4.2 Equations

Pulse cycle = (TAUDnCDRm (master) + 1) × count clock cycle

Duty width 1 = (TAUDnCDRm (slave 1)) × count clock cycle

Delay width = (TAUDnCDRm (slave 2) + 1) × count clock cycle

Duty width 2 = (TAUDnCDRm (slave 3)) × count clock cycle

However, the delay width shall be set within the following range:

$0000_H \leq$ TAUDnCDRm (slave 2) < TAUDnCDRm (master)

NOTES

1. The waveform of TAUDnTTOUTm (slave 3) becomes the waveform made by delaying the waveform of TAUDnTTOUTm (slave 1) by the quantity generated by slave 2. It is impossible to make a delay longer than the pulse cycle.
2. If INTTAUDnIm of slave 2 is generated while slave 3 is counting, slave 3 restarts operation. Therefore, the waveform of TAUDnTTOUTm (slave 3) is retained on the active level. In this case, TAUDnTTOUTm (slave 3) cannot output the waveform generated by delaying the basic pulse of TAUDnTTOUTm (slave 1).

33.15.4.3 Block Diagram and General Timing Diagram

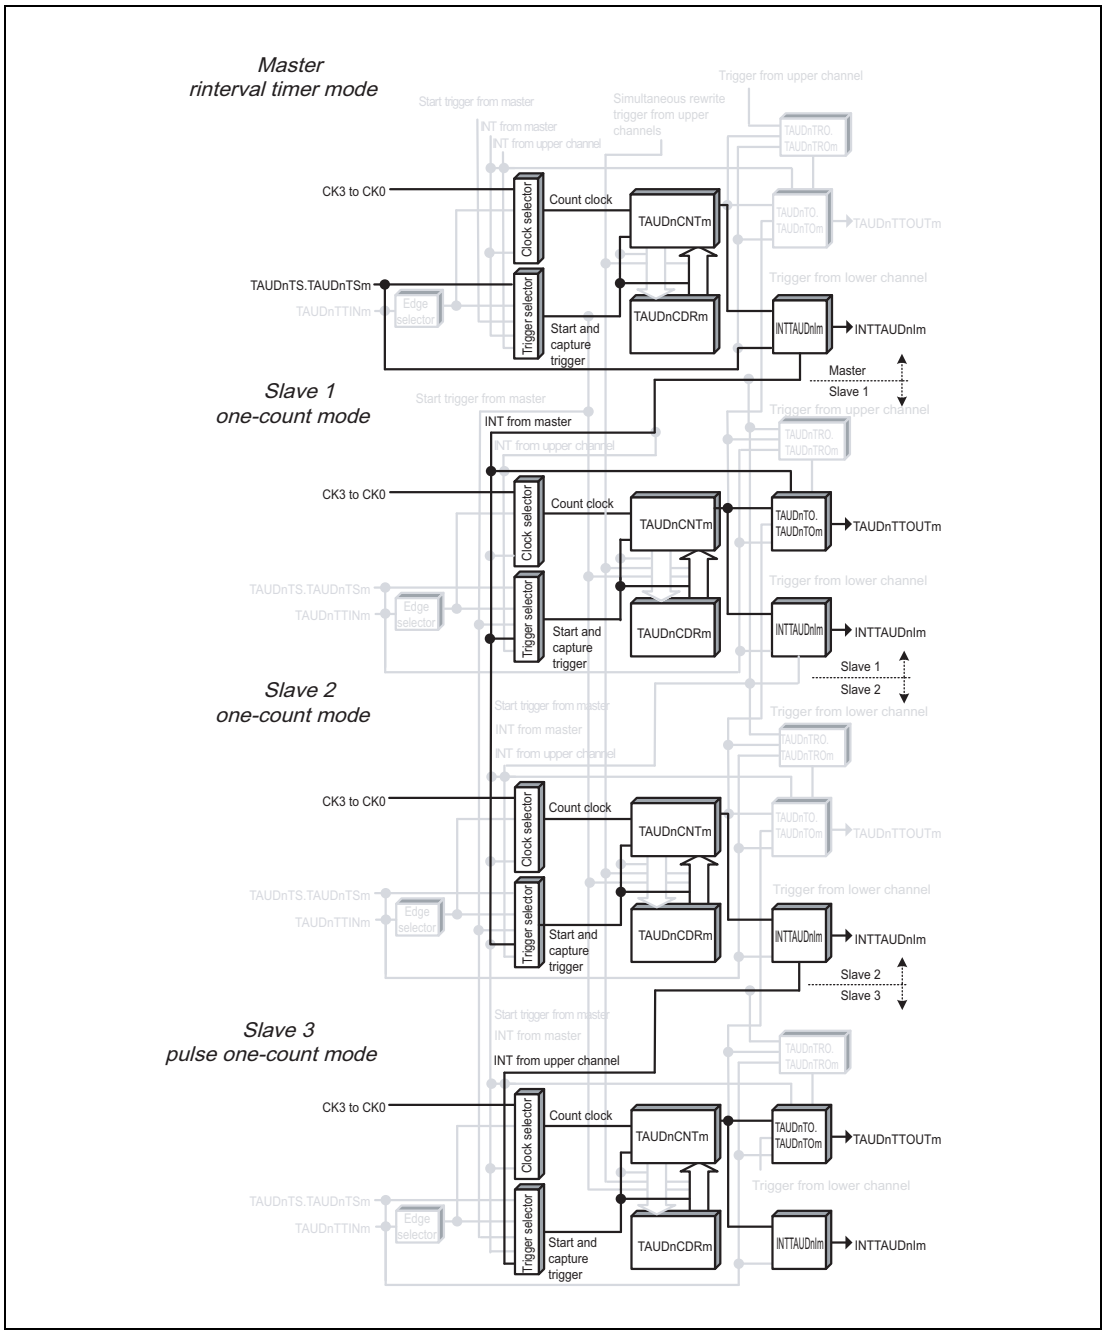

Figure 33.106 Block Diagram of Delay Pulse Output Function

The following settings apply to the general timing diagram.

- Slave channel 1: Positive logic (TAUDnTOL.TAUDnTOLm = 0)
- Slave channel 3: Positive logic (TAUDnTOL.TAUDnTOLm = 0)

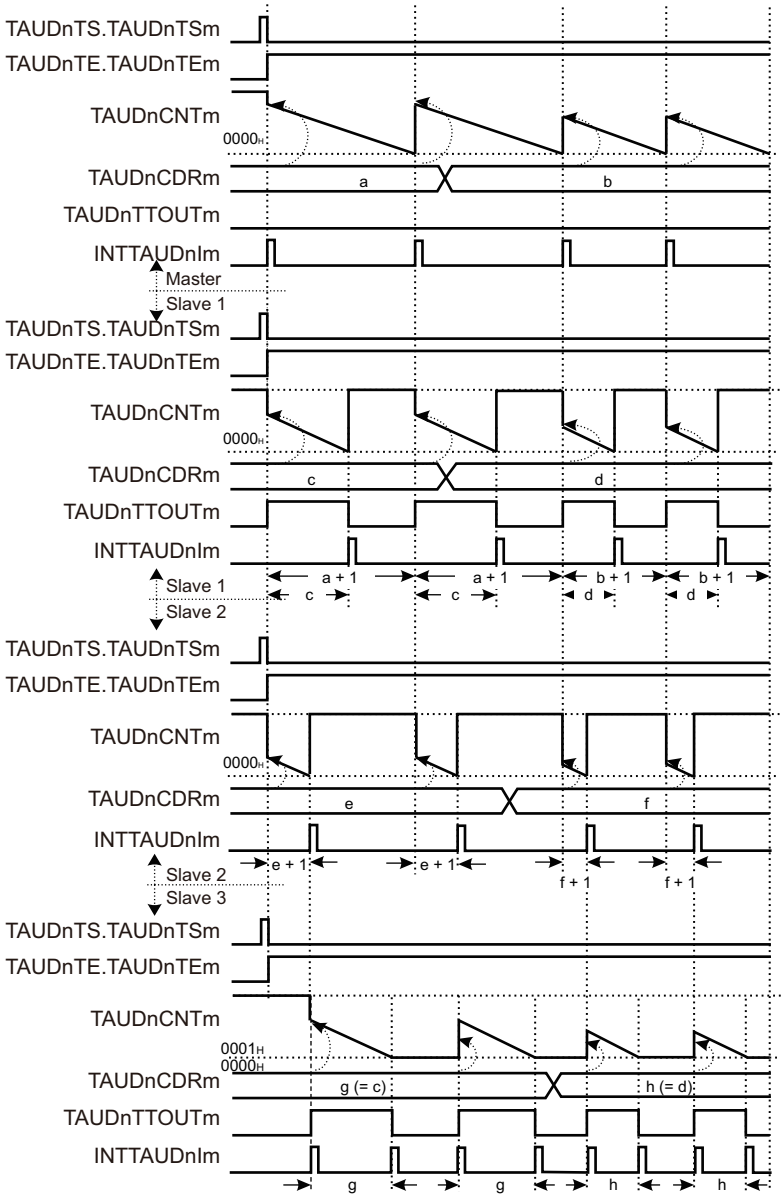

Figure 33.107 General Timing Diagram of Delay Pulse Output Function

NOTE

TAUDnTTOUTm of slave channel 1 rises with a delay of one clock count after the rise of INTTAUDnIm of the master channel.

33.15.4.4 Register Settings for the Master Channel

(1) TAUDnCMORm for the Master Channel

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for Slave Channel 3

Table 33.174 Control Bit Settings in Independent Channel Output Mode 2

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set this bit to 0
TAUDnTRC.TAUDnTRCm	0: Disables the operation as a real-time output trigger channel
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous Rewrite for Slave Channel 3

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.175 Simultaneous Rewrite Settings for Slave Channel 3 of Delay Pulse Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Master channel is simultaneous rewrite control channel.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

33.15.4.8 Operating Procedure for Delay Pulse Output Function

Table 33.176 Operating Procedure for Delay Pulse Output Function (1/2)

	Operation	TAUDn Status
Initial Channel Setting	Master channel: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.15.4.4, Register Settings for the Master Channel**. Slave channel 1: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.15.4.5, Register Settings for Slave Channel 1**. Slave channel 2: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.15.4.6, Register Settings for Slave Channel 2**. Slave channel 3: Set the TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.15.4.7, Register Settings for Slave Channel 3**. Set the value of TAUDnCDRm register of every channel.	Channel operation is stopped.

Table 33.176 Operating Procedure for Delay Pulse Output Function (2/2)

	Operation	TAUDn Status
Start Operation	Set TAUDnTS.TAUDnTSm of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm (master and slave channels) is set to 1 and the counters of master channel and slave channels 1 and 2 start. INTTAUDnIm is generated on the master channel and TAUDnTTOUTm (slave channel 1) is set.
During Operation	TAUDnCDRm can be changed at any time. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time. TAUDnRDT.TAUDnRDTm can be changed during operation.	TAUDnCDRm value of master channel and slave channels 1 and 2 is loaded to TAUDnCNTm and count down. When the counter of master channel reaches 0000_H: • INTTAUDnIm (master) is generated. • TAUDnCDRm value is reloaded into TAUDnCNTm (master) to continue count operation. • TAUDnCDRm value is reloaded into TAUDnCNTm (slave 1/2) to count down. • TAUDnTTOUTm (slave 1) is set. When TAUDnCNTm (slave 1) reaches 0000_H: • INTTAUDnIm (slave 1) is generated. • TAUDnTTOUTm (slave 1) is reset. When TAUDnCNTm (slave 2) reaches 0000_H: • INTTAUDnIm (slave 2) is generated. • INTTAUDnIm (slave 3) is generated. • TAUDnTTOUTm (slave 3) is set. • TAUDnCDRm value is reloaded into TAUDnCNTm (slave 3) to count down operation. When TAUDnCNTm (slave 3) reaches 0001_H: • INTTAUDnIm (slave 3) is generated. • TAUDnTTOUTm (slave 3) is reset.
Stop Operation	Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

Restart Operation

33.15.4.9 Specific Timing Diagrams

(1) Duty cycle (slave 3) = 100%

The following values apply to **Figure 33.108**:

- TAUDnCDRm (master) = $000A_H$
- TAUDnCDRm (slave 1) = $000B_H$
- TAUDnCDRm (slave 2) = 0000_H
- TAUDnCDRm (slave 3) = $000B_H$

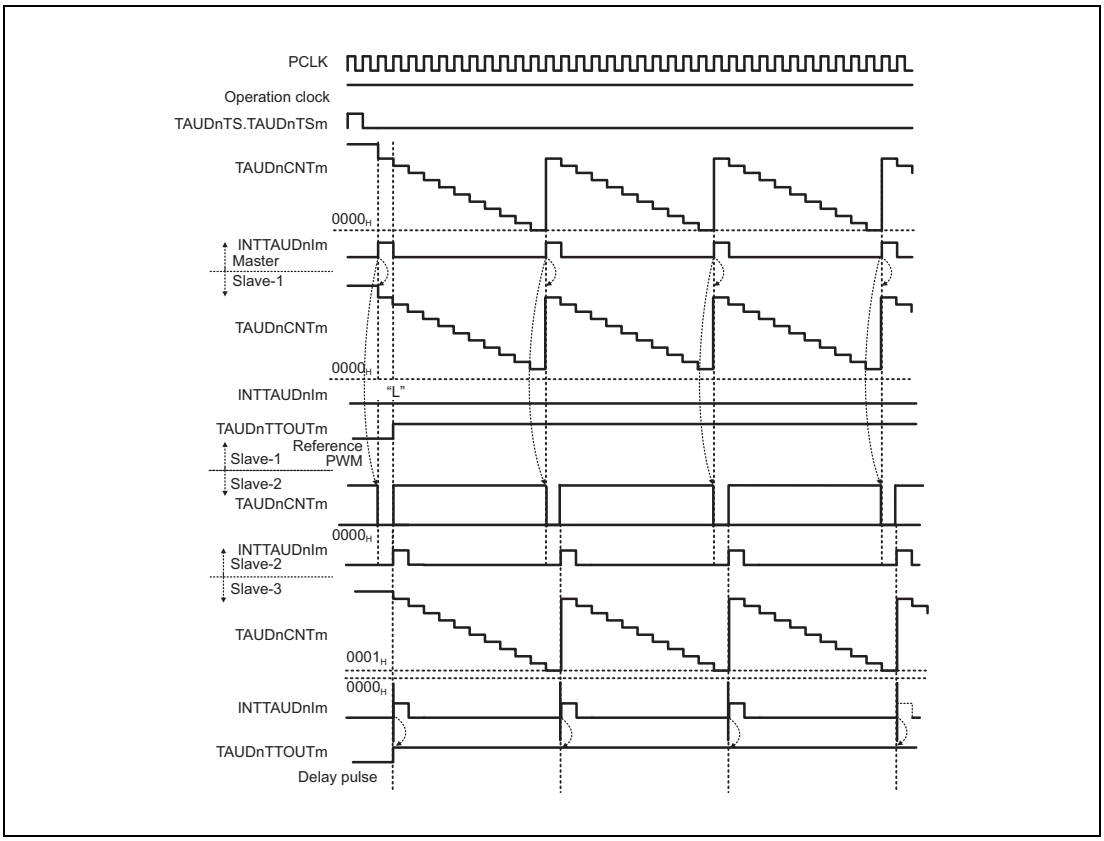

Figure 33.108 Duty Cycle (Slave 3) = 100%

- If the value of TAUDnCDRm (slaves 1 and 3) is higher than the value of TAUDnCDRm (master), the counter of the slave channel 1 cannot reach 0000_H and cannot generate interrupts. TAUDnTTOUTm of channels 1 and 3 remain in the active state.

(2) TAUDnTTOUTm (slave 1) = TAUDnTTOUTm (slave 3)

The following values apply to **Figure 33.109**.

- TAUDnCDRm (master) = $000A_H$
- TAUDnCDRm (slave 1) = 0005_H
- TAUDnCDRm (slave 2) = 0000_H
- TAUDnCDRm (slave 3) = 0005_H

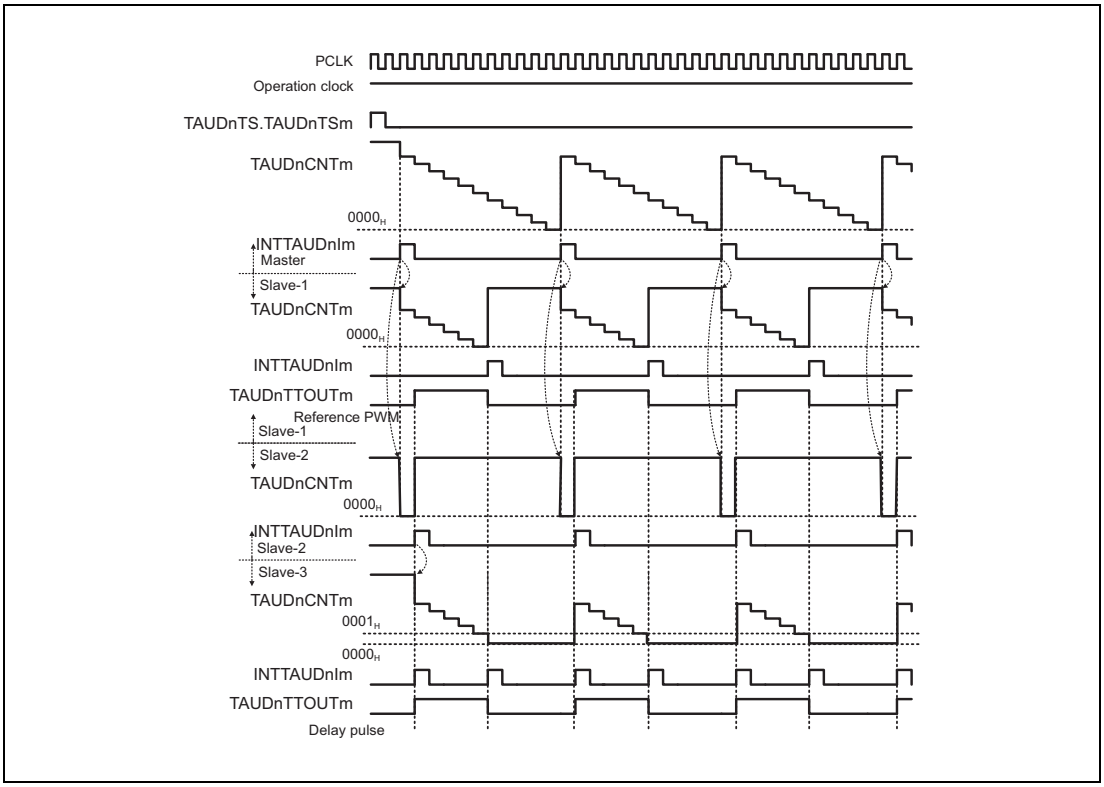

Figure 33.109 TAUDnTTOUTm (Slave 1) = TAUDnTTOUTm (Slave 3)

- If TAUDnCDRm (slave 2) = 0000_H, the counter of slave channel 3 starts counting one count clock later than the counter of slave channel 1. The reference pulse and the delay pulse are output with a delay of one clock count.

33.15.5 Offset Trigger Output Function

33.15.5.1 Overview

Summary

This function generates a PWM output using a master channel and a slave channel, enabling the pulse width (duration) of the TAUDnTTOUTm to be set. The pulse cycle is set by detecting a valid input edge of master channel. The pulse width is specified on the slave channel.

Prerequisites

- Two channels
- The operating mode for the master channel should be set to capture mode. (See **Table 33.177, Contents of the TAUDnCMORm Register for the Master Channel of the Offset Trigger Output Function**.)
- The operating mode for slave channels should be set to one-count mode. (See **Table 33.180, Contents of the TAUDnCMORm Register for the Slave Channel of the Offset Trigger Output Function**.)
- The output mode for slave channels should be set to synchronous channel output mode 1. (See **Section 33.7, Channel Output Modes**.)
- TAUDnTTOUTm is not used with the master channel of this function.

Functional description

The counter can be enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This makes TAUDnTE.TAUDnTEm = 1, enabling count operation. The master channel counter (TAUDnCNTm) starts to count up from 0000_H.

- Master channel:
  When a valid TAUDnTTINm input edge is detected, the current value of the counter (TAUDnCNTm) is loaded into the data register of master channel (TAUDnCDRm). INTTAUDnIm is generated and the counter restarts to count up from 0000_H.
- Slave channel:
  If INTTAUDnIm is generated on the master channel, the TAUDnTTOUTm (slave) signal is set and the counter of the slave channel is triggered. The current value of TAUDnCDRm (slave) is loaded into TAUDnCNTm (slave) and the counter starts to count down from this value.
  When the counter reaches 0000_H (duty time has elapsed), INTTAUDnIm is generated and TAUDnTTOUTm signal is reset. The counter returns to $FFFF_H$ and awaits the next INTTAUDnIm of the master channel.

The counter can be stopped by setting TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTEm to 0. TAUDnCNTm and TAUDnTTOUTm of master and slave channels stop but retain their values. The counters can be restarted by setting TAUDnTS.TAUDnTSm to 1.

33.15.5.2 Equations

Pulse width = (TAUDnCDRm (slave)) × count clock cycle

Duty cycle [%] = [TAUDnCDRm (slave)/(TAUDnCDRm (master) + 1)] × 100

– Duty cycle = 0%
  TAUDnCDRm (slave) = 0000_H
– Duty cycle = 100%
  TAUDnCDRm (slave) ≥ TAUDnCDRm (master) + 1

33.15.5.3 Block Diagram and General Timing Diagram

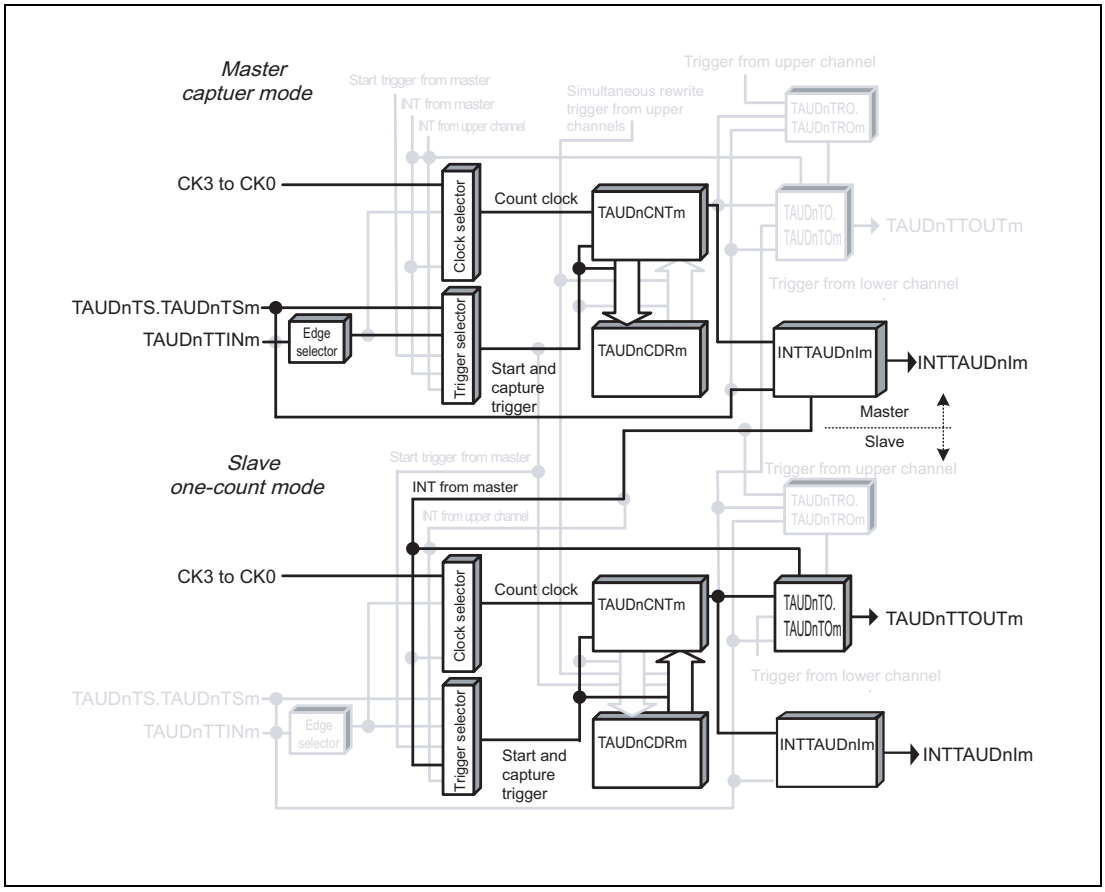

Figure 33.110 Block Diagram of Offset Trigger Output Function

The following settings apply to the general timing diagram.

- Detection of falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

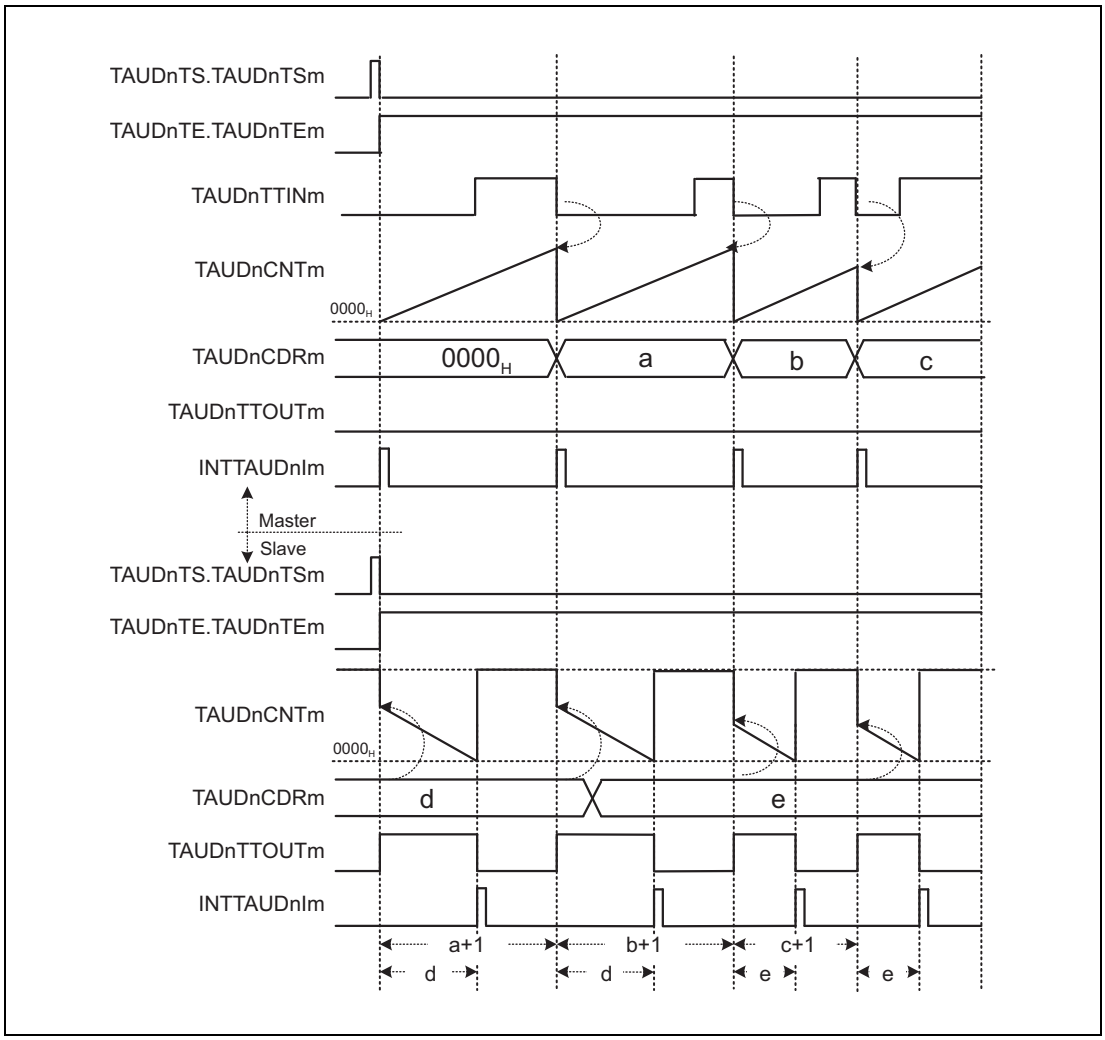

Figure 33.111 General Timing Diagram of Offset Trigger Output Function

NOTE

TAUDnTTOUTm of the slave channel rises with a delay of one clock count after the rise of INTTAUDnIm of the master channel.

33.15.5.4 Register Settings for the Master Channel

(1) TAUDnCMORm for the Master Channel

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS [1:0]		TAUDnCCS [1:0]		TAUDn MAS	TAUDnSTS[2:0]			TAUDnCOS [1:0]		—	TAUDnMD[4:1]				TAUDn MD0

7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for Slave Channels

Table 33.182 Control Bit Settings in Synchronous Channel Output Mode 1

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel operation
TAUDnTOC.TAUDnTOCm	0: Operating mode 1
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set this bit to 0
TAUDnTRC.TAUDnTRCm	0: Disables the operation as a real-time output trigger channel
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous Rewrite for Slave Channels

Simultaneous rewrite registers (TAUDnRDE, TAUDnRDS, TAUDnRDM, and TAUDnRDC) cannot be used with the offset trigger output function. Therefore, these registers should be set to 0.

Table 33.183 Simultaneous Rewrite Settings for Slave Channels of Offset Trigger Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	0: Disables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	When simultaneous rewrite is disabled (TAUDnRDE.TAUDnRDEm = 0), set these bits to 0.
TAUDnRDM.TAUDnRDMm	
TAUDnRDC.TAUDnRDCm	

33.15.5.6 Operating Procedure for Offset Trigger Output Function

Table 33.184 Operating Procedure for Offset Trigger Output Function

	Operation	TAUDn Status
Initial Channel Setting	Master channel: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.15.5.4, Register Settings for the Master Channel**. Slave channel: Set TAUDnCMORm and TAUDnCMURm registers and channel output mode as described in **Section 33.15.5.5, Register Settings for Slave Channels**. The TAUDnCDRm register of master channel functions as a capture register. Set the value of TAUDnCDRm register of slave channel.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm (master and slave channels) is set to 1 and the counters of master and slave channels start: • TAUDnCNTm (master) counts up. • TAUDnCDRm value is loaded into TAUDnCNTm (slave) to perform counting down. INTTAUDnIm is generated on the master channel and TAUDnTTOUTm (slave) is set.
During Operation	TAUDnCDRm can be changed at any time. TAUDnCSCm.TAUDnCLOV can be set to 1. TAUDnCDRm of slave channel can be changed after the generation of INTTAUDnIm (master). TAUDnCNT.TAUDnCNTm and TAUDnCSRm can be read at any time.	When TAUDnCNTm of the slave = 0000_H: • INTTAUDnIm (slave) is generated. • TAUDnTTOUTm (slave) is reset, and the counter of slave channel stops. When TAUDnTTINm input edge is detected on the master channel: • INTTAUDnIm (master) is generated. • TAUDnCNTm (master) is reset to 0000_H and then continues count operation subsequently. • TAUDnCDRm value is reloaded into TAUDnCNTm (slave) to perform counting down. • TAUDnTTOUTm (slave) is set.
Stop Operation	Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

Restart Operation

33.15.5.7 Specific Timing Diagrams

(1) Duty cycle = 0%

The following settings apply to this diagram.

- Detection of falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

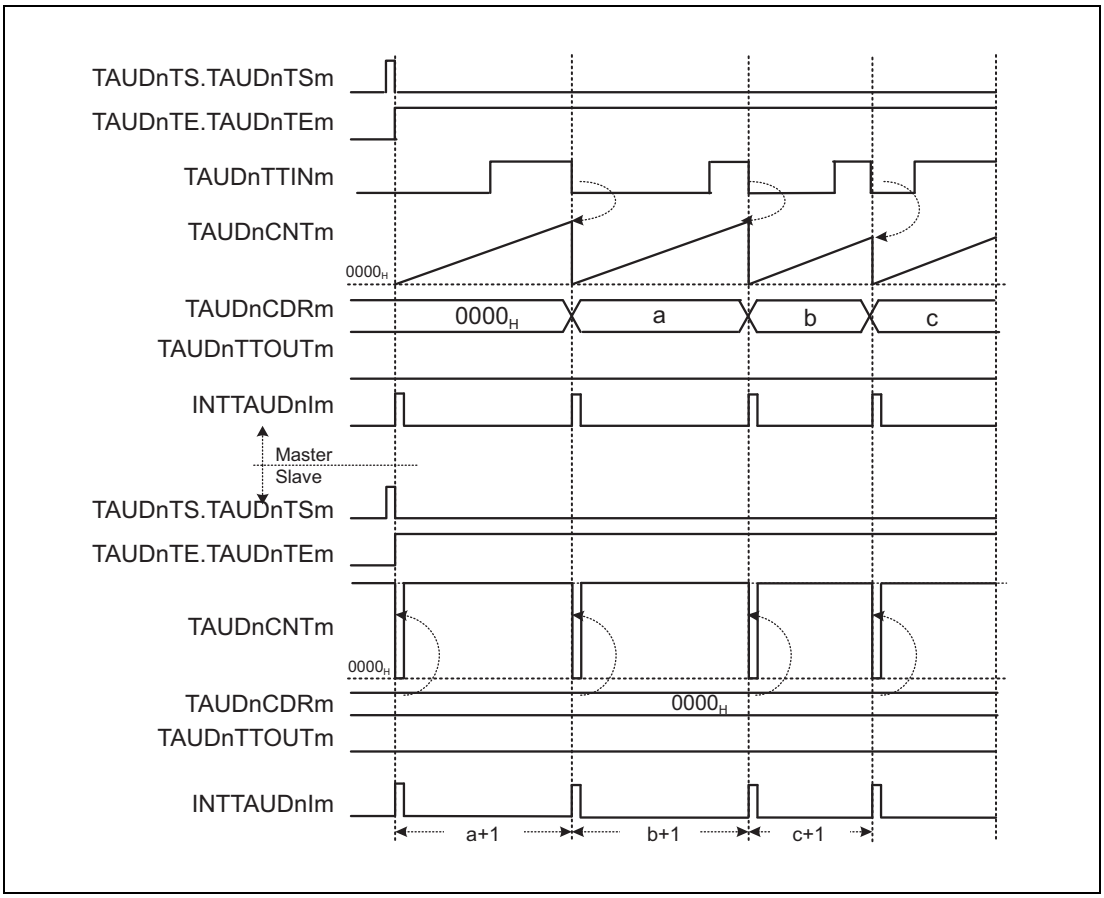

Figure 33.112 TAUDnCDRm (Slave) = 0000_H

- When TAUDnCDRm (slave) = 0000_H, 0000_H is written to TAUDnCNTm every time the master channel generates an interrupt (INTTAUDnIm), and TAUDnCNTm cannot start to count. The TAUDnTTOUTm remains inactive.
- TAUDnCNTm (slave) generates an interrupt every time the value of TAUDnCDRm is reloaded. The slave and the master channels generate interrupts in the same cycle.

(2) Duty cycle = 100%

The following settings apply to this diagram.

- Detection of falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

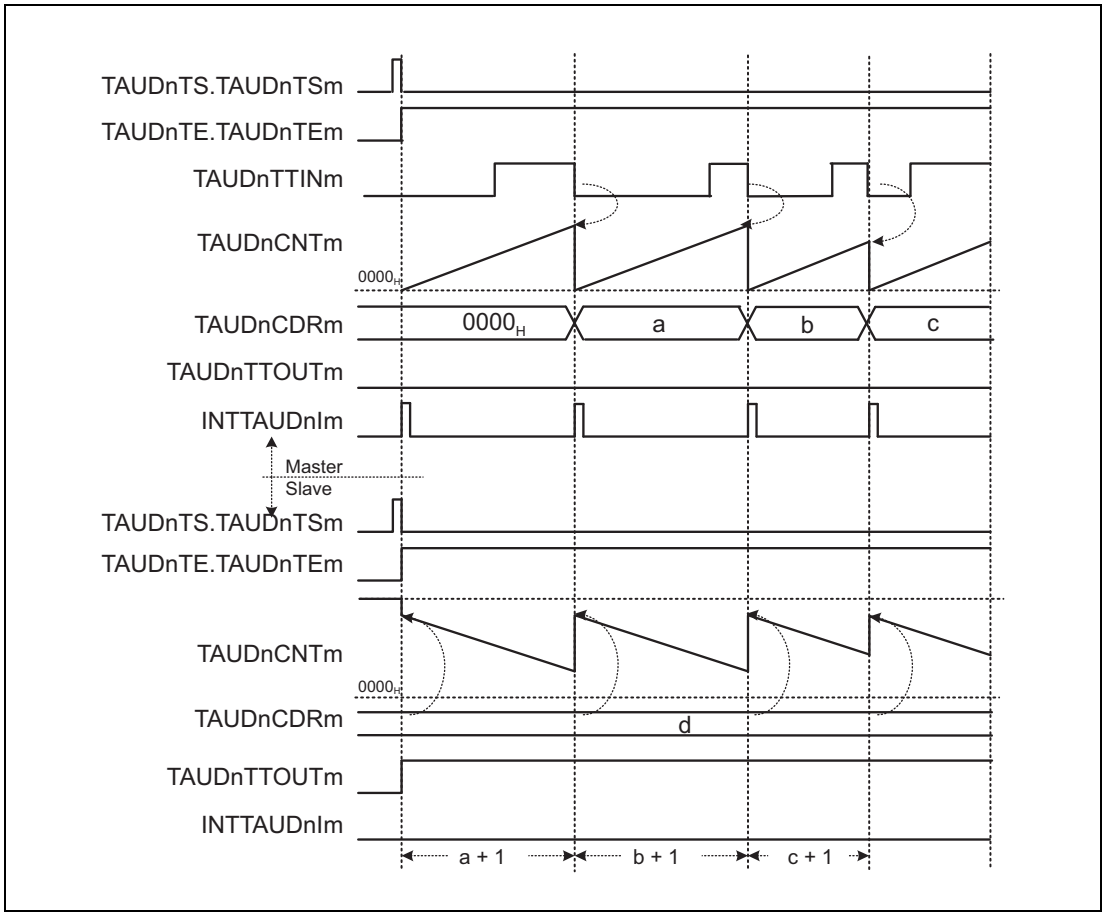

Figure 33.113 TAUDnCDRm (Slave) ≥ TAUDnCDRm (Master) + 1

- If the value TAUDnCDRm (slave) is higher than the interval of valid input edges, the counter of the slave channel cannot reach 0000_H and cannot generate interrupts. The TAUDnTTOUTm remains at active state.

33.15.6 A/D Conversion Trigger Output Function Type 1

33.15.6.1 Overview

Summary

This function is identical to **Section 33.15.1, PWM Output Function**, except that TAUDnTTOUTm is not output.

This function is enabled by setting the channel output mode for slave to independent channel output mode controlled by software.

33.15.6.2 Block Diagram and General Timing Diagram

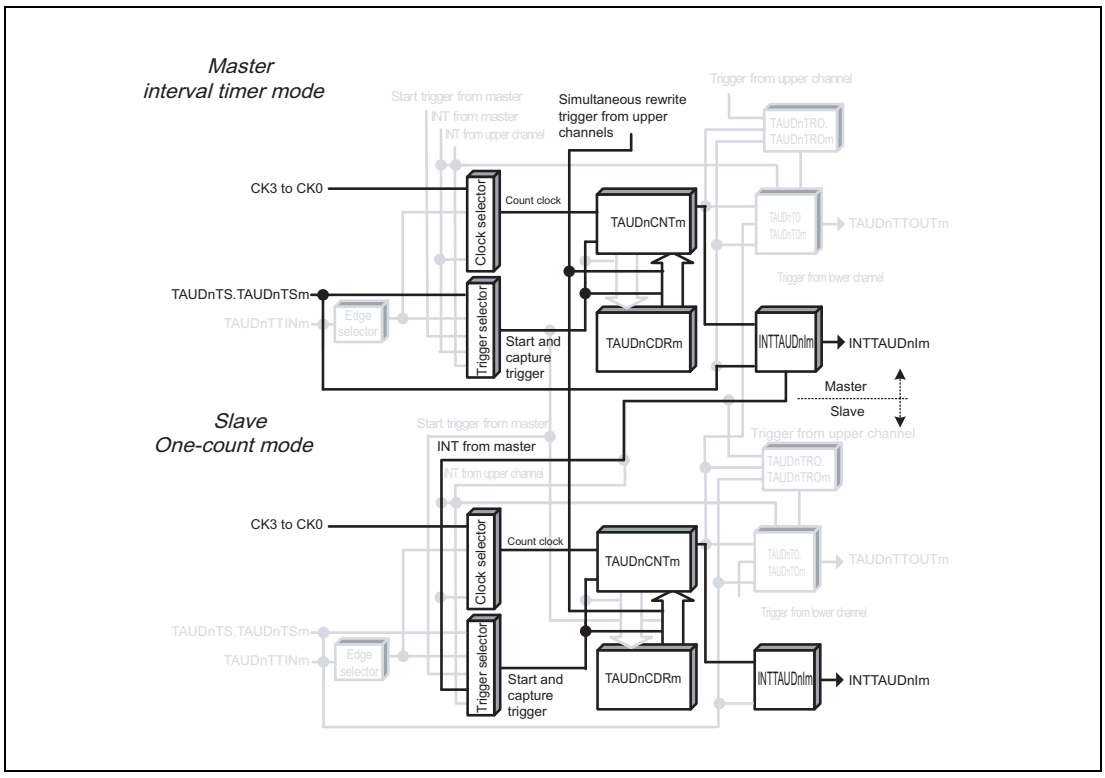

Figure 33.114 Block Diagram of A/D Conversion Trigger Output Function Type 1

The following settings apply to the general timing diagram.

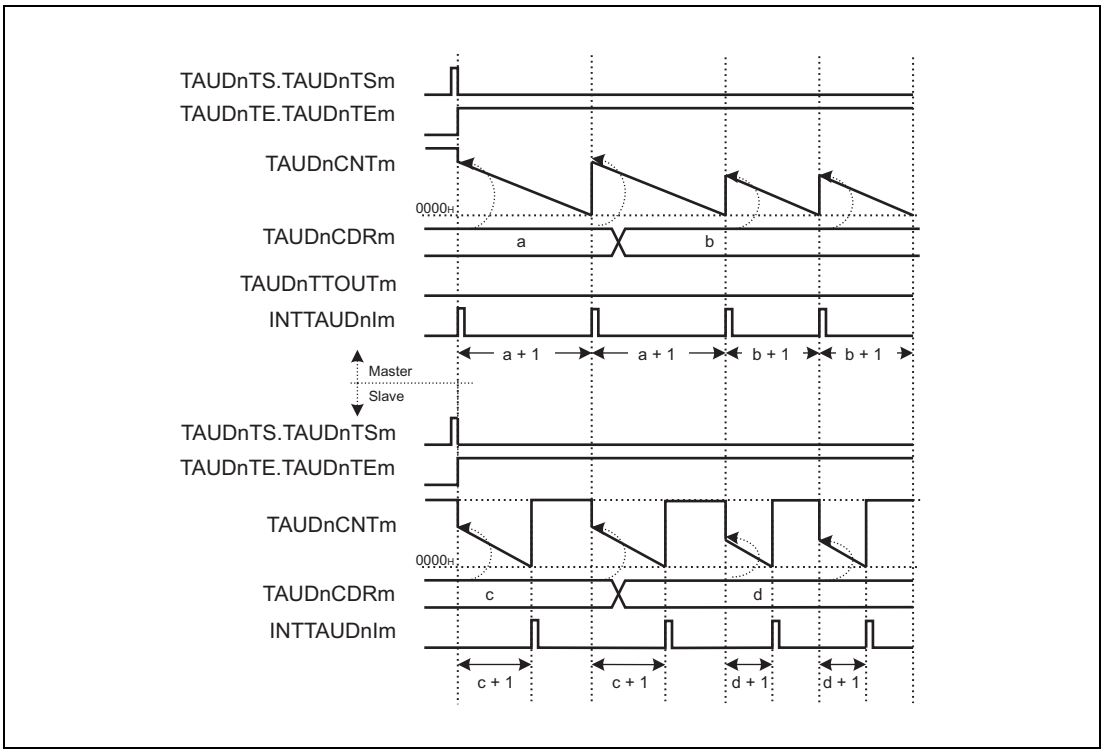

Figure 33.115 General Timing Diagram of A/D Conversion Trigger Output Function Type 1

33.15.7 Triangle PWM Output Function

33.15.7.1 Overview

Summary

This function generates multiple triangle PWM outputs by using a master and one or more slave channels. It enables the pulse cycle (frequency) and the duty cycle of TAUDnTTOUTm to be set using the master and slave channels respectively.

The master channel generates a carrier cycle. The first cycle of the master channel controls the down status and the second cycle controls the up status of the slave counter.

Prerequisites

- Two channels
- The operating mode for the master channels should be set to interval timer mode. (See **Table 33.185, Contents of the TAUDnCMORm Register for the Master Channel of the Triangle PWM Output Function**.)
- The operating mode for slave channels should be set to count-up/-down mode. (See **Table 33.189, Contents of the TAUDnCMORm Register for the Slave Channel of the Triangle PWM Output Function**.)
- The channel output mode for the master channel should be set to independent channel output mode 1. (See **Section 33.7, Channel Output Modes**.)
- The channel output mode for slave channels should be set to synchronous channel output mode 2. (See **Section 33.7, Channel Output Modes**.)
- The following settings allow the TAUDnTTOUTm signal to be at high level during the down status of a carrier cycle.
  - If TAUDnCMORm.TAUDnMD0 (master) bit is set to 0, TAUDnTO.TAUDnTOm should be set to 1 while TAUDnTOE.TAUDnTOEm is set to 0 (recommended setting).
  - If TAUDnCMORm.TAUDnMD0 (master) bit is set to 1, TAUDnTO.TAUDnTOm should be set to 0 while TAUDnTOE.TAUDnTOEm is set to 0.

Functional description

The counters are enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1 for every channel. This in turn sets TAUDnTE.TAUDnTEm, enabling count operation.

The current values of TAUDnCDRm (master and slave) are loaded into TAUDnCNTm (master and slave) and the counters start counting down from these values. When the TAUDnCMORm.TAUDnMD0 bit of master channel is set to 1, an interrupt is generated and TAUDnTTOUTm signal of master toggles.

- Master channel:
  When the counter of master channel reaches 0000_H (pulse cycle time has elapsed), INTTAUDnIm is generated and the TAUDnTTOUTm signal toggles. TAUDnCNTm then reloads the TAUDnCDRm value and counts down.

- Slave channel:
  If INTTAUDnIm is generated on the master channel, the counter of the slave channel is triggered.
  - If the slave counter is counting down, the count direction changes.
  - If the slave counter is counting up, the TAUDnCDRm value is reloaded and the counter starts to count down.

When the counter of the slave channel reaches 0001_H while counting up or down, INTTAUDnIm is generated and the TAUDnTTOUTm (slave) signal is set/reset.
The counter continues count-up/-down and waits for the next INTTAUDnIm of the master channel.
Setting TAUDnTOL.TAUDnTOLm allows TAUDnTTOUTm signal switching between normal phase and reverse phase during operation.

The counter can be stopped by setting TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTEm = 0. TAUDnCNTm and TAUDnTTOUTm of master and slave channels stop but retain their values.

Conditions

This function enables simultaneous rewrite. See **Section 33.6, Simultaneous Rewrite**.

33.15.7.2 Equations

Pulse cycle = (TAUDnCDRm (master) + 1) × count clock cycle

$0000_H \leq$ TAUDnCDRm (master) $< FFFF_H$

Carrier cycle (down/up) = (TAUDnCDRm (master) + 1) × 2 × count clock cycle

Duty cycle [%] =

[(TAUDnCDRm (master) + 1 – TAUDnCDRm (slave))/(TAUDnCDRm (master) + 1)] × 100

- Duty cycle = 100%
  TAUDnCDRm (slave) = 0000_H
- Duty cycle = 0%
  TAUDnCDRm (slave) ≥ TAUDnCDRm (master) + 1

33.15.7.3 Block Diagram and General Timing Diagram

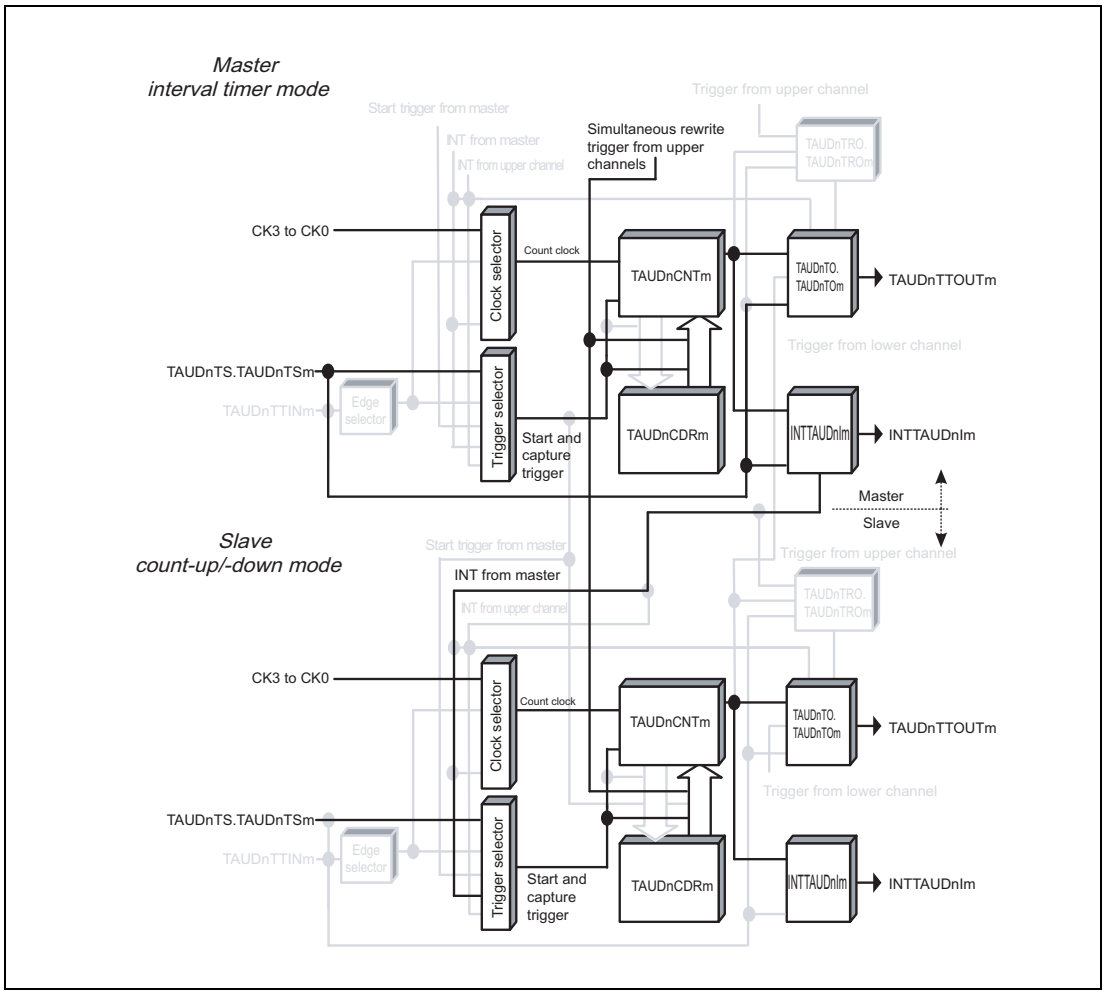

Figure 33.116 Block Diagram of Triangle PWM Output Function

The following settings apply to the general timing diagram.

- Master channel
  - INTTAUDnIm is generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 1)

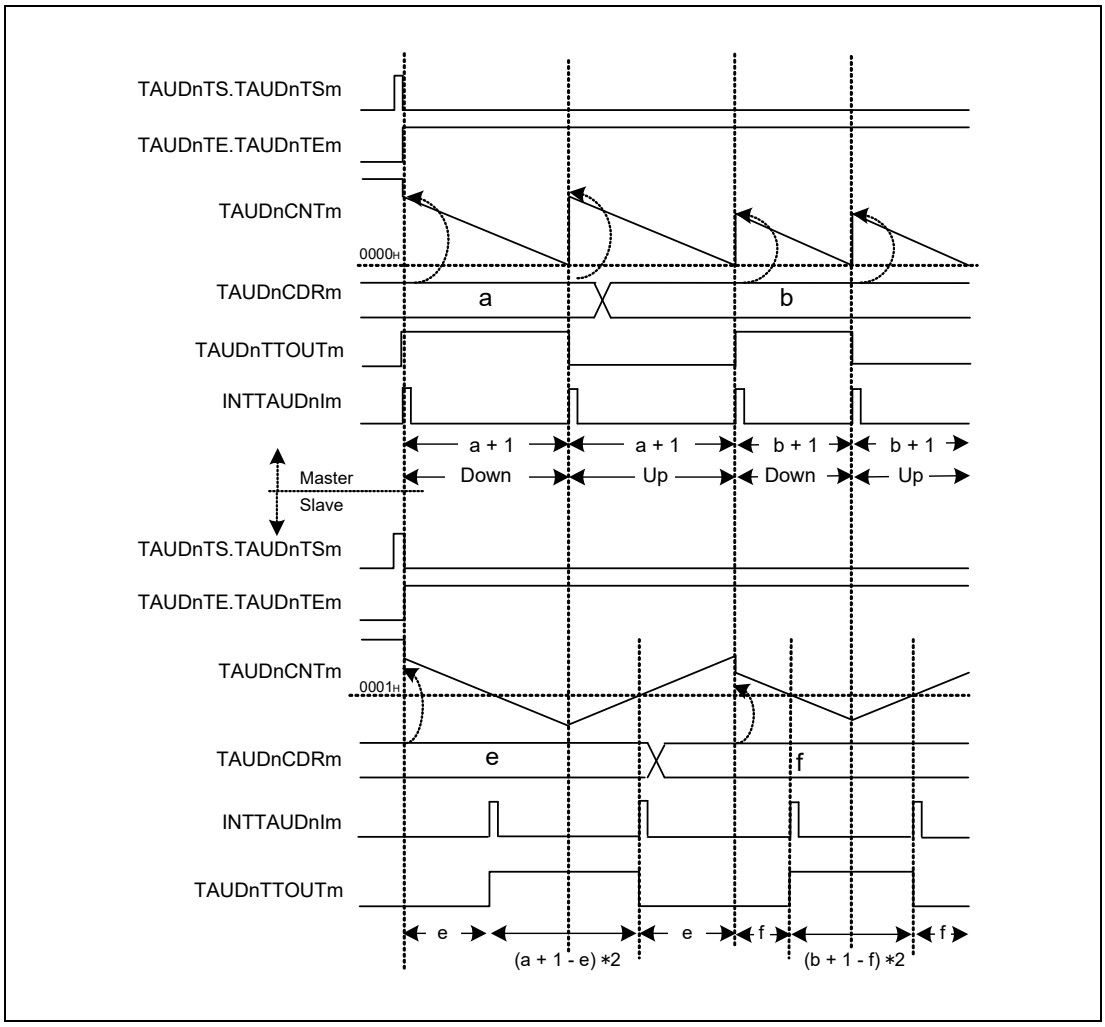

Figure 33.117 General Timing Diagram of Triangle PWM Output Function

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operation clock as a count clock
11	TAUDnMAS	1: Master channel
10 to 8	TAUDnSTS[2:0]	000: Trigger the counter using software.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0000: Interval timer mode
0	TAUDnMD0	0: INTTAUDnIm is not generated to toggle TAUDnTTOUTm at the beginning of an operation. 1: INTTAUDnIm is generated and TAUDnTTOUTm is toggled at the beginning of operation.

(2) TAUDnCMURm for the Master Channel

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.186 Contents of the TAUDnCMURm Register for the Master Channel of the Triangle PWM Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for Slave Channel

Table 33.187 Control Bit Settings in Independent Channel Output Mode 1

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	0: Operating mode 1 (Toggle mode if TAUDnTOM.TAUDnTOMm = 0)
TAUDnTOL.TAUDnTOLm	0: The setting is disabled in toggle mode (the value after reset).
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set this bit to 0
TAUDnTRC.TAUDnTRCm	0: Disables the operation as a real-time output trigger channel
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous Rewrite for Slave Channel

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.188 Simultaneous Rewrite Settings for the Master Channel of Triangle PWM Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects a master channel for simultaneous rewrite triggers. 1: Selects an upper channel outside the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel starts to count and the corresponding slave channel is at the peak of a triangular wave cycle.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

NOTE

If TAUDnRDS.TAUDnRDSm = 1, it is necessary for an upper channel higher than the master channel to generate a simultaneous rewrite trigger signal.

33.15.7.5 Register Settings for Slave Channels

7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for Slave Channels

Table 33.191 Control Bit Settings in Synchronous Channel Output Mode 2

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel operation
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set this bit to 0
TAUDnTRC.TAUDnTRCm	0: Disables the operation as a real-time output trigger channel
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous Rewrite for Slave Channels

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.192 Simultaneous Rewrite Settings for Slave Channels of Triangle PWM Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects a master channel for simultaneous rewrite triggers. 1: Selects an upper channel outside the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel starts to count and the corresponding slave channel is at the peak of a triangular wave cycle.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

33.15.7.6 Operating Procedure for Triangle PWM Output Function

Table 33.193 Operating Procedure for Triangle PWM Output Function

	Operation	TAUDn Status
Initial Channel Setting	Master channel: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.15.7.4, Register Settings for the Master Channel**. Slave channel: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.15.7.5, Register Settings for Slave Channels**. Set the value of TAUDnCDRm register of every channel.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm (master and slave channels) is set to 1 and the counters of master and slave channels start. INTTAUDnIm (master) is generated on the master channel if TAUDnCMORm.TAUDnMD0 is set to 1.
During Operation	TAUDnCDRm can be changed at any time. TAUDnTOL.TAUDnTOLm can be changed. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time. TAUDnRDT.TAUDnRDTm can be changed during operation.	TAUDnCDRm value of master and slave channels is loaded into TAUDnCNTm to count down. When the counter of master channel reaches 0000_H: • INTTAUDnIm (master) is generated. • TAUDnTTOUTm (master) is toggled. • TAUDnCDRm value is reloaded into TAUDnCNTm (master) to continue count operation. • TAUDnCDRm value is reloaded into TAUDnCNTm (slave) or counting is started in opposite direction. When TAUDnCNTm of slave channel reaches 0001_H: • INTTAUDnIm (slave) is generated. • TAUDnTTOUTm (slave) is set in the count-down status or reset in count-up status.
Stop Operation	Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

Restart Operation

33.15.7.7 Specific Timing Diagrams

(1) Duty cycle = 0%

The following settings apply to the general timing diagram.

- Master channel:
  - INTTAUDnIm is generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 1)
  - TAUDnCDRm = a = 5_H
- Slave channel:
  - TAUDnCDRm = 6_H

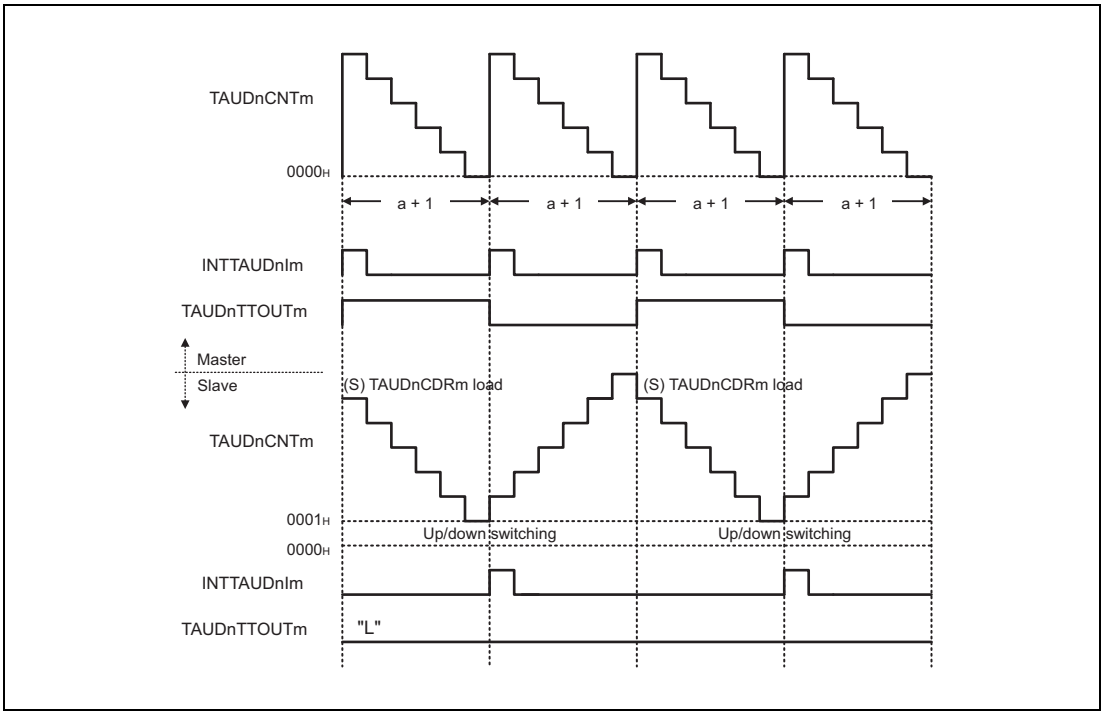

Figure 33.118 TAUDnCDRm (Slave) ≥ TAUDnCDRm (Master) + 1

- If TAUDnCDRm (slave) value ≥ TAUDnCDRm (master) value + 1, INTTAUDnIm of the slave channel is not generated while counting down. TAUDnTTOUTm remains low because there is no set signal to be detected.

(2) Duty cycle = 100%

The following settings apply to the general timing diagram.

- Master channel:
  - INTTAUDnIm is generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 1)
  - TAUDnCDRm = a = 5_H
- Slave channel:
  - TAUDnCDRm = 0_H

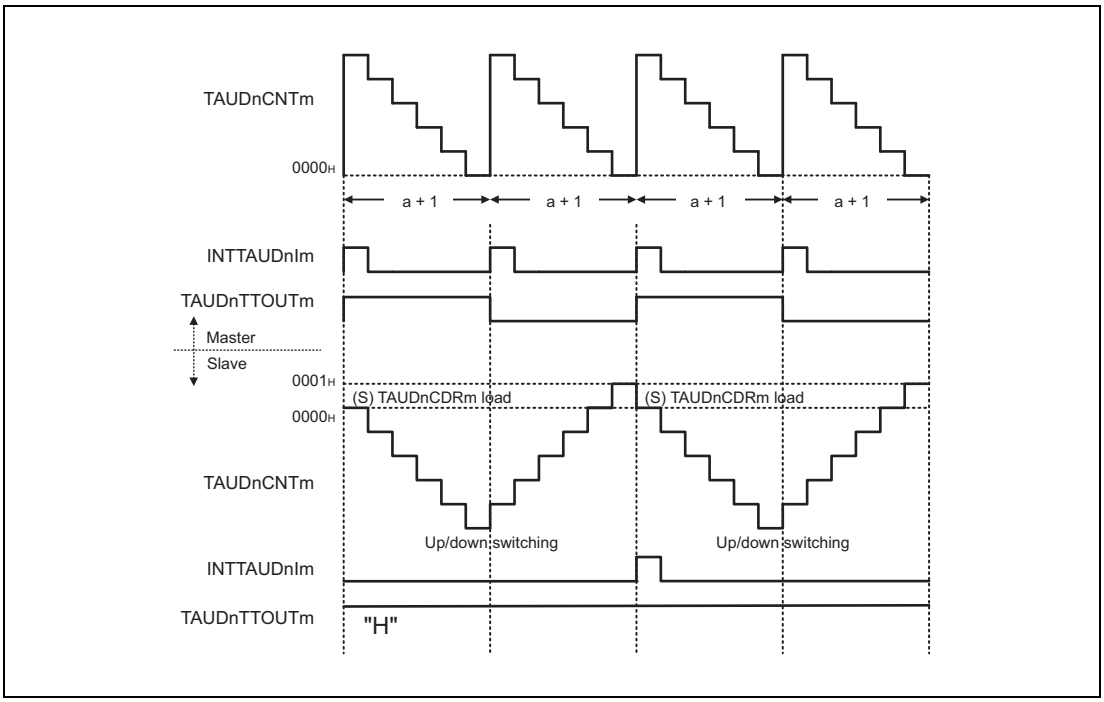

Figure 33.119 TAUDnCDRm (Slave) = 0000_H

- If TAUDnCDRm (slave) = 0000_H, INTTAUDnIm of slave channel is not generated while counting up. TAUDnTTOUTm remains high because there is no reset signal to be detected.

33.15.8 Triangle PWM Output Function with Dead Time

33.15.8.1 Overview

Summary

This function generates multiple triangle PWM outputs with a predefined dead time added by using a master and two or more slave channels. The resulting PWM signals with dead time are output via TAUDnTTOUTm of the slave channels 2 and 3, enabling the pulse cycle (frequency) and the duty cycle of TAUDnTTOUTm to be set using the master and slave channels.

Carrier cycles are generated on the master channel. The first pulse controls the down status of the slave counter and the second one controls the up status.

An interrupt on slave 2 causes TAUDnTTOUTm of slave channels to be set/reset. Depending on the settings of TAUDnTDL.TAUDnTDLm, delay time is added to positive or negative logic side of the signal (i.e., whether TAUDnTTOUTm is set/reset immediately or after dead time has elapsed). The duration of the dead time is specified by slave channel 3.

Prerequisites

- Three channels. For slave channels 2 and 3, select even channel CH (a) and odd channel CH (a + 1).
- The operating mode for the master channel should be set to interval timer mode. (See **Table 33.195, Contents of the TAUDnCMORm Register for the Master Channel of the Triangle PWM Output Function with Dead Time**)
- Slave channel 1 is not used for this function. This ensures that slave channel 2 is an even channel (a), and slave channel 3 is an odd channel (a + 1). Slave channel 1 can be used as a separate timer (independent function).
- The operating mode for slave channel 2 should be set to `count-up/-down` mode (See **Table 33.199, Contents of the TAUDnCMORm Register for Slave Channel 2 of the Triangle PWM Output Function with Dead Time**). Slave channel 2 should be an even channel.
- The operating mode for slave channel 3 should be set to one-count mode (See **Table 33.203, Contents of the TAUDnCMORm Register for Slave Channel 3 of the Triangle PWM Output Function with Dead Time**). Slave channel 3 should be an odd channel.
- The channel output mode for the master channel should be set to independent channel output mode 1. (See **Section 33.7, Channel Output Modes**)
- The output mode for slave channels 2 and 3 should be set to synchronous channel output mode 2 with dead time output. (See **Section 33.7, Channel Output Modes**)

- The following settings make a TAUDnTTOUTm signal at high level during the down status of the carrier cycle:
  - If TAUDnCMORm.TAUDnMD0 (master) bit is set to 0, TAUDnTO.TAUDnTOm should be set to 1 while TAUDnTOE.TAUDnTOEm is set to 0 (recommended setting).
  - If TAUDnCMORm.TAUDnMD0 (master) bit is set to 1, TAUDnTO.TAUDnTOm should be set to 0 while TAUDnTOE.TAUDnTOEm is set to 0.

NOTE

The triangle PWM output function with dead time does not use slave channel 1. Slave channel 1 can be used as a separate timer (independent function).

Functional description

The counter starts by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This makes TAUDnTE.TAUDnTEm = 1, enabling count operation. The current value of TAUDnCDRm is loaded into TAUDnCNTm and the counter starts to count down from the TAUDnCDRm value. If TAUDnCMORm.TAUDnMD0 bit of master channel is set to 1, an interrupt is generated and the master's TAUDnTTOUTm signal is toggled.

- Master channel:
  When the counter of the master channel reaches 0000_H, an INTTAUDnIm is generated and the TAUDnTTOUTm signal is toggled. The TAUDnCDRm value is reloaded to continue counting down.
- Slave channel 2:
  If INTTAUDnIm is generated on the master channel, the counter of slave channel 2 is triggered.
  - If the slave counter is counting down, the counting direction changes.
  - If the slave counter is counting up, the TAUDnCDRm value is reloaded and the counter starts counting down.

  The counter continues to count down/up and waits for the next INTTAUDnIm of the master channel.
  When the counter value of slave channel 2 reaches 0001_H, INTTAUDnIm is generated.
- Slave channel 3:
  If INTTAUDnIm is generated on slave channel 2, the counter of slave channel 3 is triggered. The current value of TAUDnCDRm (slave 3) is loaded into TAUDnCNTm (slave 3) and the counter starts to count down from the TAUDnCDRm value.
  When the counter reaches 0000_H, INTTAUDnIm occurs. The counter returns to $FFFF_H$ and waits for the next INTTAUDnIm of slave channel 2.

As described in **Table 33.194, Operation of TAUDnTTOUTm upon Occurrence of an Interrupt on Slave Channel 2**, the set/reset timing (right after occurrence of an interrupt or after dead time has elapsed) depends on the TAUDnTDL.TAUDnTDLm setting of the corresponding channel.

The setting of TAUDnTOL.TAUDnTOLm also determines whether a high level signal (TAUDnTOL.TAUDnTOLm = 0) or a low level signal (TAUDnTOL.TAUDnTOLm = 1) is output from the corresponding channel.

The counter can be stopped by setting TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTEm to 0. TAUDnCNTm and TAUDnTTOUTm of master and slave channels stop but retain their values.

TAUDnTTOUTm can be 100% output by setting the TAUDnCDRm value of slave channel 2 to 0000_H.

Conditions

This function enables simultaneous rewrite. See **Section 33.6, Simultaneous Rewrite**.

TAUDnTOL.TAUDnTOLm and TAUDnTDL.TAUDnTDLm should be set before start of count operation. Slave channels 2 and 3 should have the opposite settings of TAUDnTDL.TAUDnTDLm.

Table 33.194 Operation of TAUDnTTOUTm upon Occurrence of an Interrupt on Slave Channel 2

TAUDnTDL. TAUDnTDLm	Count Direction of Slave Channel 2 upon Occurrence of Interrupt	TAUDnTTOUTm Set/Reset Timing
0	Down	Set after elapse of dead time
	Up	Reset right after interrupt occurs
1	Down	Set right after interrupt occurs
	Up	Reset after elapse of dead time

33.15.8.2 Equations

Pulse cycle = (TAUDnCDRm (master) + 1) × count clock cycle

$0000_H \leq$ TAUDnCDRm (master) $< FFFF_H$

Carrier cycle (down/up) = (TAUDnCDRm (master) + 1) × 2 × count clock cycle

PWM signal width (normal phase) = [(TAUDnCDRm (master) + 1 – TAUDnCDRm (slave 2)) × 2 – (TAUDnCDRm (slave 3) + 1)] × count clock cycle

PWM signal width (reverse phase) = [(TAUDnCDRm (master) + 1 – TAUDnCDRm (slave 2)) × 2 + (TAUDnCDRm (slave 3) + 1)] × count clock cycle

33.15.8.3 Block Diagram and General Timing Diagram

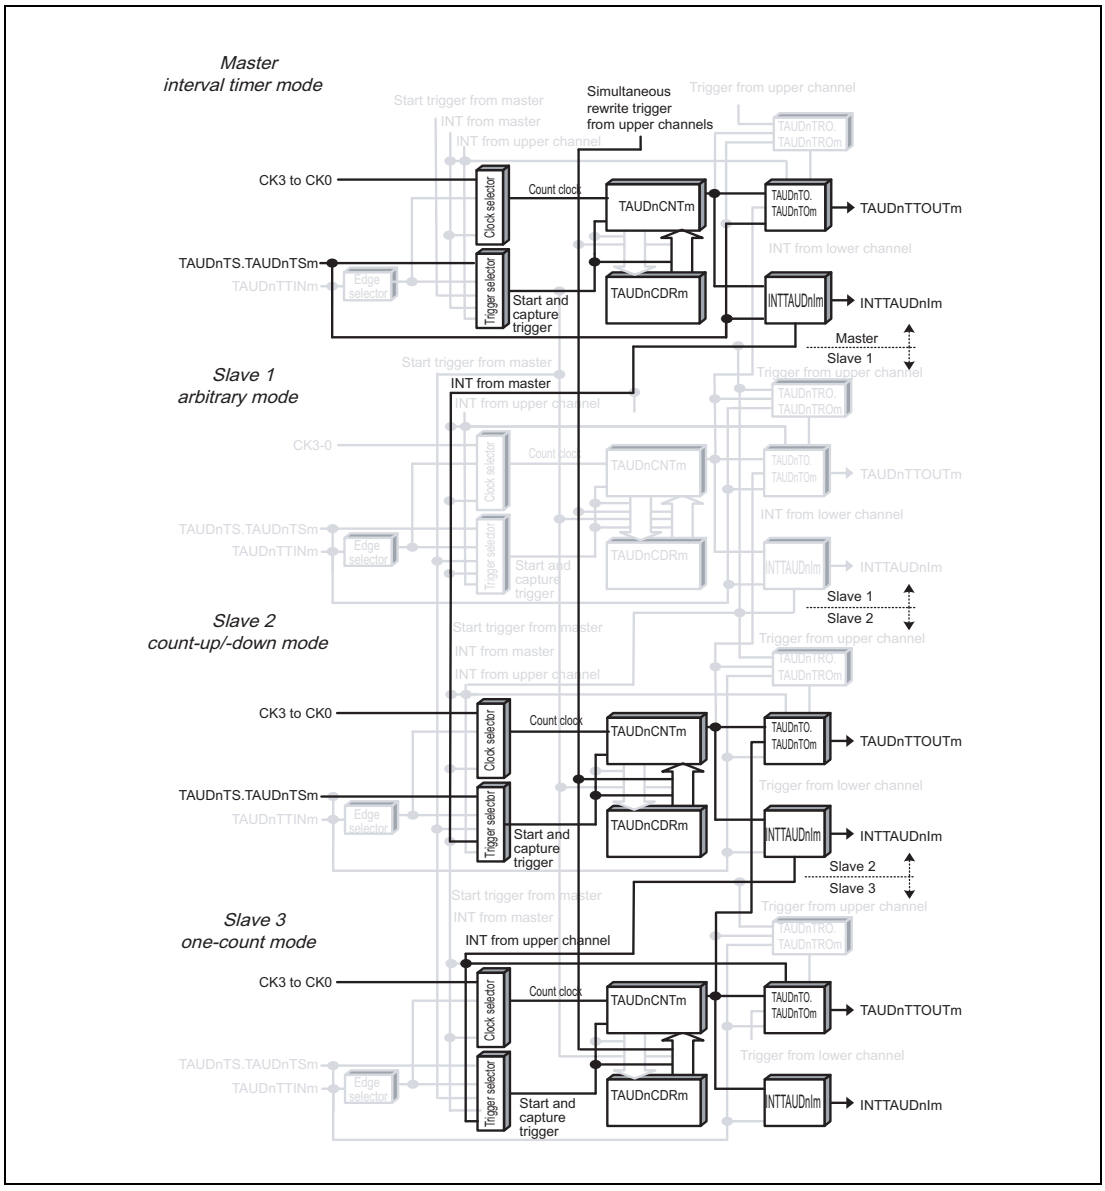

Figure 33.120 Block Diagram of Triangle PWM Output Function with Dead Time

The following settings apply to the general timing diagram.

- Master channel:
  - INTTAUDnIm is generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 1)
- Slave channel 2:
  - INTTAUDnIm not generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 0)
  - TAUDnTDL.TAUDnTDLm = 0
  - Positive logic (TAUDnTOL.TAUDnTOLm = 0)

- Slave channel 3:
  - Enables start trigger detection during counting (TAUDnCMORm.TAUDnMD0 = 1)
  - TAUDnTDL.TAUDnTDLm = 1
  - Positive logic (TAUDnTOL.TAUDnTOLm = 0)

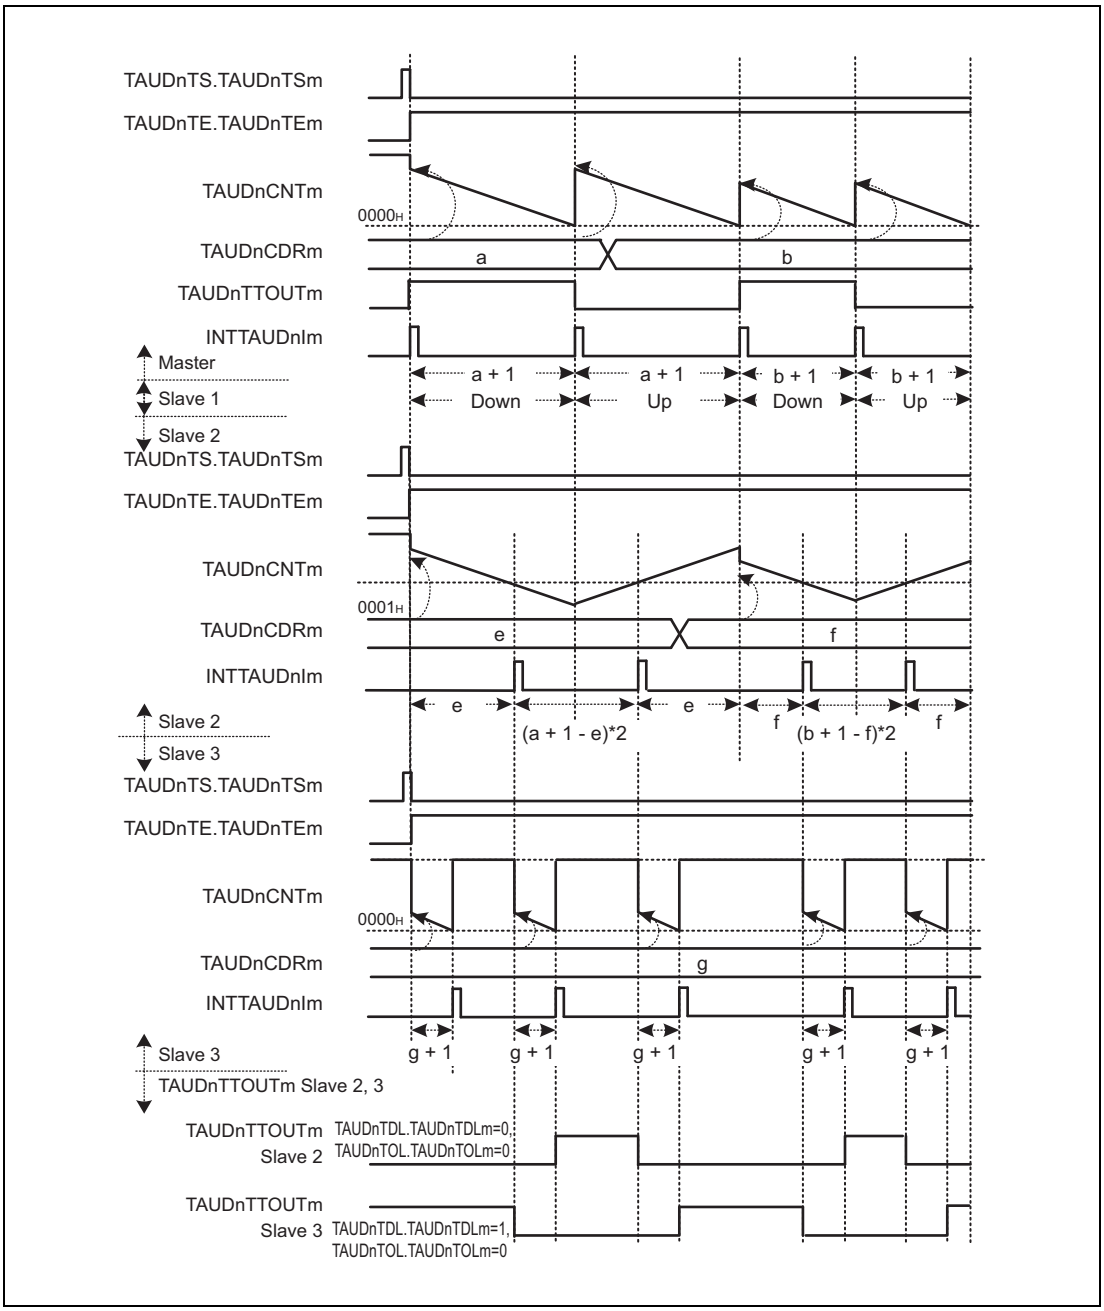

Figure 33.121 General Timing Diagram of Triangle PWM Output Function with Dead Time

33.15.8.4 Register Settings for the Master Channel

(1) TAUDnCMORm for the Master Channel

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operation clock as a count clock
11	TAUDnMAS	1: Master channel
10 to 8	TAUDnSTS[2:0]	000: Trigger the counter using software.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0000: Interval timer mode
0	TAUDnMD0	0: INTTAUDnIm is not generated and TAUDnTTOUTm is not toggled at the beginning of operation. 1: INTTAUDnIm is generated and TAUDnTTOUTm is toggled at the beginning of operation.

(2) TAUDnCMURm for the Master Channel

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.196 Contents of the TAUDnCMURm Register for the Master Channel of the Triangle PWM Output Function with Dead Time

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for the Master Channel

Table 33.197 Control Bit Settings in Independent Channel Output Mode 1

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	0: Operating mode 1 (Toggle mode if TAUDnTOM.TAUDnTOMm = 0)
TAUDnTOL.TAUDnTOLm	0: The setting is disabled in toggle mode (the value after reset).
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set this bit to 0
TAUDnTRC.TAUDnTRCm	0: Disables the operation as a real-time output trigger channel
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous Rewrite for the Master Channel

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.198 Simultaneous Rewrite Setting for the Master Channel of Triangle PWM Output Function with Dead Time

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects a master channel for simultaneous rewrite triggers. 1: Selects an upper channel outside the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel starts to count and the corresponding slave channel is at the peak of a triangular wave cycle.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

NOTE

If TAUDnRDS.TAUDnRDSm = 1, it is necessary for an upper channel higher than the master channel to generate a simultaneous rewrite trigger signal.

33.15.8.5 Register Settings for Slave Channel 2

(1) TAUDnCMORm for Slave Channel 2

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for Slave Channel 2

Table 33.201 Control Bit Settings in Synchronous Channel Output Mode 2 with Dead Time Output

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel operation
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	1: Enables dead time operation.
TAUDnTDM.TAUDnTDMm	0: Adds dead time if an interrupt is detected on an even upper channel and the conditions set by TAUDnTDL.TAUDnTDLm are satisfied.
TAUDnTDL.TAUDnTDLm	0: Adds dead time to normal phase. 1: Adds dead time to reverse phase.
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set this bit to 0
TAUDnTRC.TAUDnTRCm	0: Disables the operation as a real-time output trigger channel
TAUDnTME.TAUDnTMEm	0: Disables modulation

CAUTION

Set TAUDnTDL.TAUDnTDLm exclusively from odd channels.

(4) Simultaneous Rewrite for Slave Channel 2

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.202 Simultaneous Rewrite Settings for Slave Channel 2 of Triangle PWM Output Function with Dead Time

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects a master channel for simultaneous rewrite triggers. 1: Selects an upper channel outside the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel starts to count and the corresponding slave channel is at the peak of a triangular wave cycle.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

33.15.8.6 Register Settings for Slave Channel 3

(1) TAUDnCMORm for Slave Channel 3

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operation clock as a count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	110: Dead time output signal of the TAUDnTTOUTm generation unit
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0100: One-count mode
0	TAUDnMD0	1: Enables start trigger detection while counting.

(2) TAUDnCMURm for Slave Channels 3

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.204 Contents of the TAUDnCMURm Register for Slave Channel 3 of the Triangle PWM Output Function with Dead Time

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for Slave Channel 3

Table 33.205 Control Bit Settings in Synchronous Channel Output Mode 2 with Dead Time Output

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel operation
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	1: Enables dead time operation.
TAUDnTDM.TAUDnTDMm	0: Adds dead time if an interrupt is detected on an even upper channel and the conditions set by TAUDnTDL.TAUDnTDLm are satisfied.
TAUDnTDL.TAUDnTDLm	0: Adds dead time to normal phase. 1: Adds dead time to reverse phase.
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set this bit to 0
TAUDnTRC.TAUDnTRCm	0: Disables the operation as a real-time output trigger channel
TAUDnTME.TAUDnTMEm	0: Disables modulation

CAUTION

Set TAUDnTDL.TAUDnTDLm exclusively from even channels.

(4) Simultaneous Rewrite for Slave Channel 3

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.206 Simultaneous Rewrite Settings for Slave Channel 3 of Triangle PWM Output Function with Dead Time

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects a master channel for simultaneous rewrite triggers. 1: Selects an upper channel outside the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel starts to count and the corresponding slave channel is at the peak of a triangular wave cycle.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

33.15.8.7 Operating Procedure for Triangle PWM Output Function with Dead Time

Table 33.207 Operating Procedure for Triangle PWM Output Function with Dead Time

	Operation	TAUDn Status
Initial Channel Setting	Master channel: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.15.8.4, Register Settings for the Master Channel**. Slave channel 2: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.15.8.5, Register Settings for Slave Channel 2**. Slave channel 3: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.15.8.6, Register Settings for Slave Channel 3**. Set the value of TAUDnCDRm register of every channel.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm (master and slave channels) is set to 1 and the counters of master and slave channels start. INTTAUDnIm (master) is generated on the master channel if TAUDnCMORm.TAUDnMD0 is set to 1.
During Operation	TAUDnCDRm can be changed at any time. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time. TAUDnRDT.TAUDnRDTm can be changed during operation.	TAUDnCDRm value of master channel and slave channel 2 is loaded into TAUDnCNTm to perform counting down. When the counter of master channel reaches 0000_H: • INTTAUDnIm (master) is generated. • TAUDnCDRm value is reloaded into TAUDnCNTm (master) to continue count operation. • TAUDnCDRm value is reloaded into TAUDnCNTm (slave 2) or counting is started in opposite direction. When TAUDnCNTm of slave channel 2 reaches 0001_H: • INTTAUDnIm (slave 2) is generated. • TAUDnCDRm value of slave channel 3 is loaded into TAUDnCNTm perform counting down. When TAUDnCNTm of slave channel 3 reaches 0000_H: • INTTAUDnIm is generated.
Stop Operation	Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

Restart Operation

33.15.8.8 Specific Timing Diagrams

(1) Duty cycle = 0%

The following settings apply to the general timing diagram in **Figure 33.122**.

- Slave channel 2:
  - Positive logic (TAUDnTDL.TAUDnTDLm = 0)
- Slave channel 3:
  - Negative logic (TAUDnTDL.TAUDnTDLm = 1)

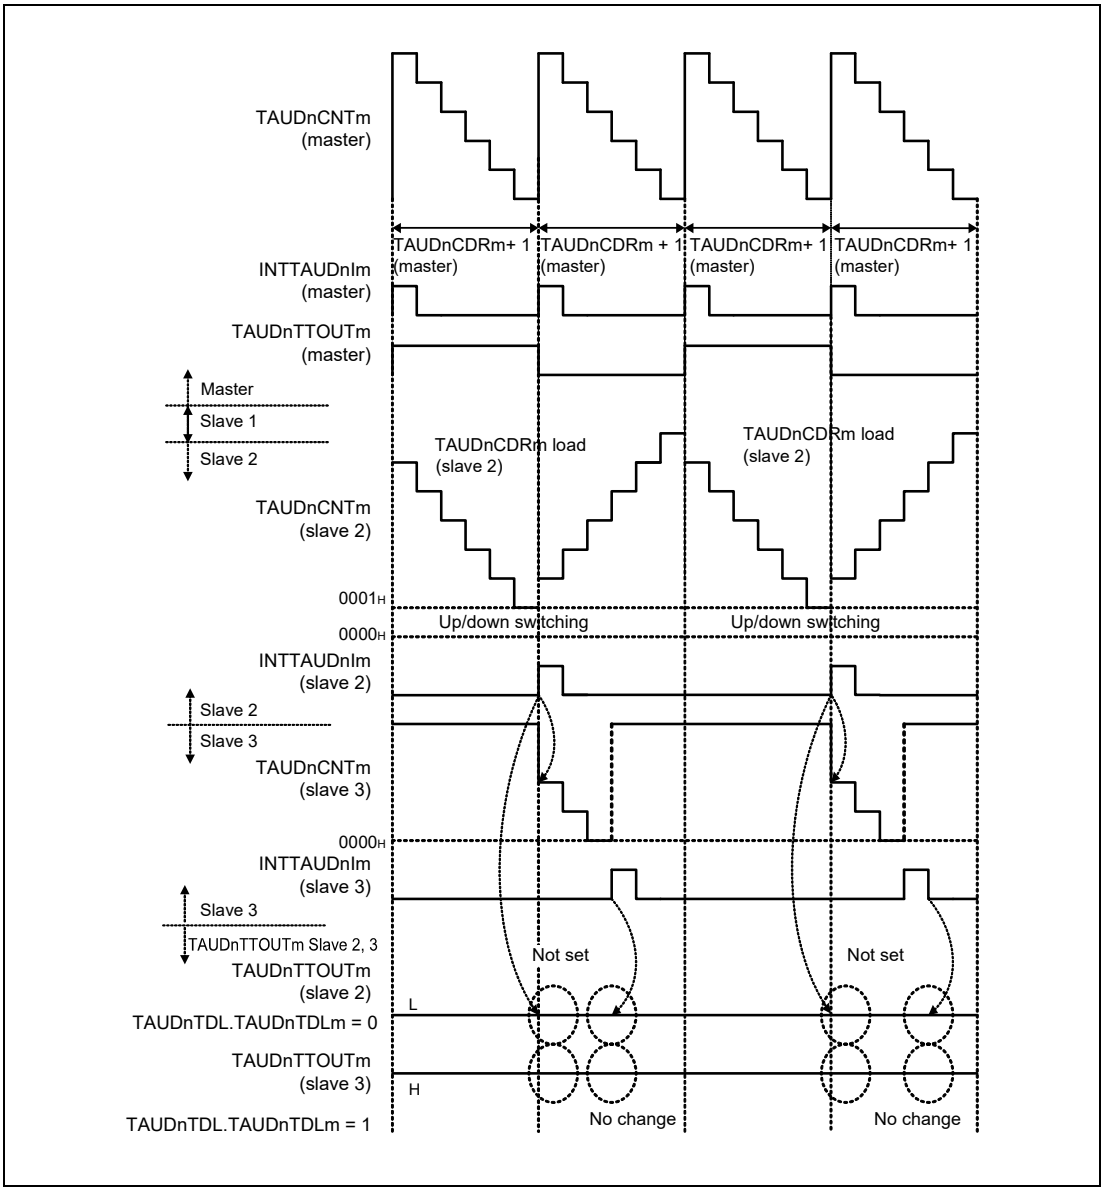

Figure 33.122 TAUDnCDRm (Slave 2) ≥ TAUDnCDRm (Master) + 1

- If TAUDnCDRm (slave 2) is greater than TAUDnCDRm (master), the counter of slave channel does not reach 0000_H while counting down. Therefore, TAUDnTTOUTm signal is not set/reset and remains in the initial state. This signal becomes a reset signal because an interrupt occurs on slave channel 2 during count-up operation.

(2) Duty cycle = 100%

The following settings apply to the general timing diagram in **Figure 33.123**.

- Slave channel 2:
  - Positive logic (TAUDnTDL.TAUDnTDLm = 0)
- Slave channel 3:
  - Negative logic (TAUDnTDL.TAUDnTDLm = 1)

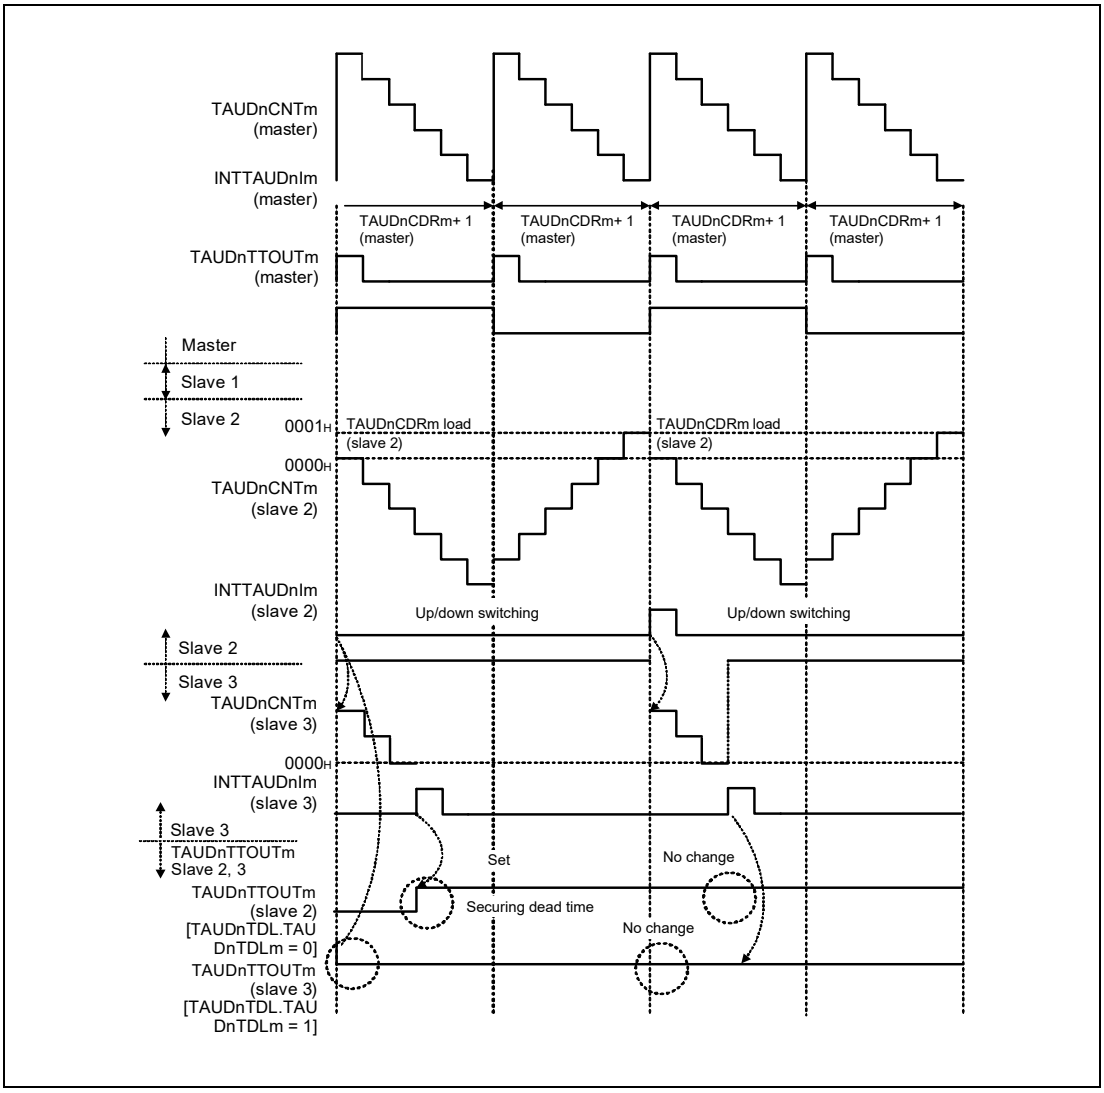

Figure 33.123 TAUDnCDRm (Slave) = 0000_H

- If TAUDnCDRm (slave 2) = 0000_H, the slave channel counter does not reach 0001_H while counting up. Therefore, no INTTAUDnIm is generated during count-up operation.
  - The set conditions for a channel with TAUDnTDL.TAUDnTDLm = 0 are met after elapse of dead time. TAUDnTTOUTm is left in a newly set state even if a set/reset is made because no reset conditions are satisfied on such a channel.
  - Slave channel 3 in the above diagram is set when the counter starts. However, TAUDnTTOUTm is left in an initial state on the slave channel with TAUDnTDL.TAUDnTDLm = 1 because no reset conditions are satisfied on that channel.

33.15.9 A/D Conversion Trigger Output Function Type 2

33.15.9.1 Overview

Summary

This function is identical to **Section 33.15.7, Triangle PWM Output Function**, except that TAUDnTTOUTm is not output.

This function is enabled by setting channel output mode for slave to independent channel output mode controlled by software.

33.15.9.2 Block Diagram and General Timing Diagram

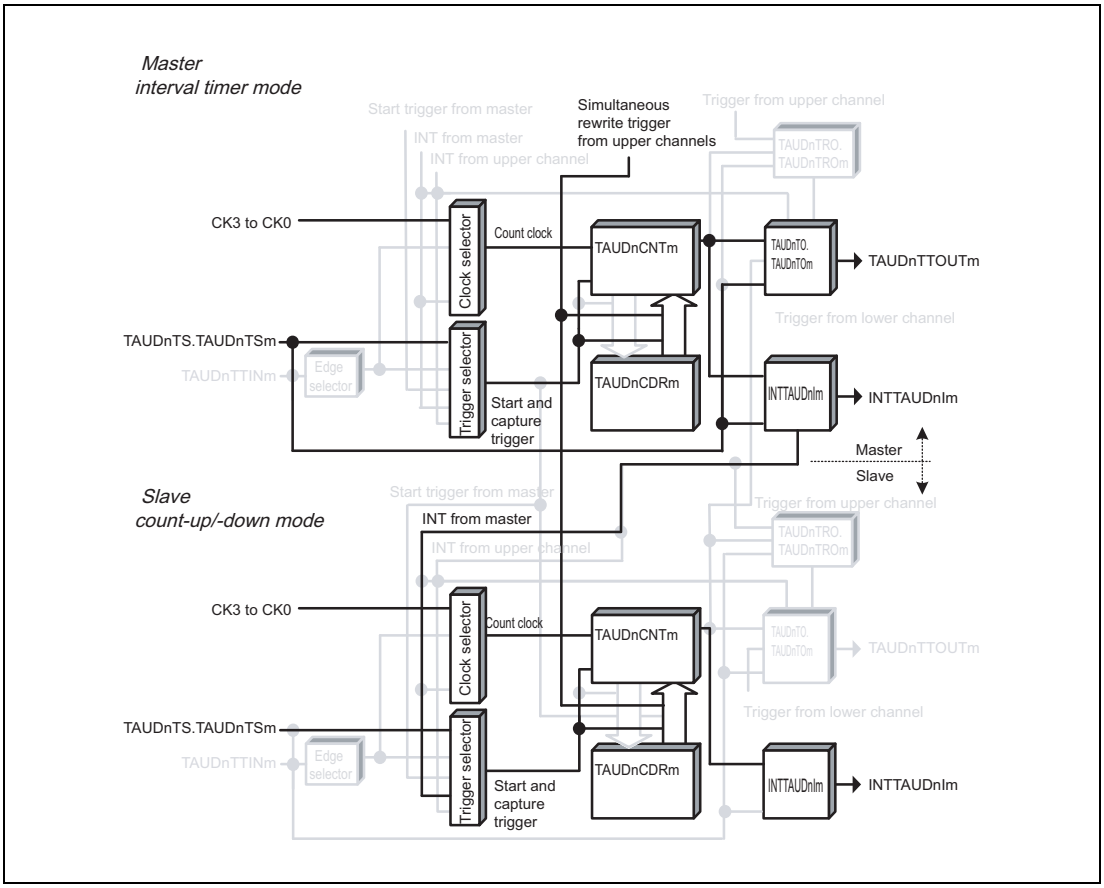

Figure 33.124 Block Diagram of A/D Conversion Trigger Output Function Type 2

The following settings apply to the general timing diagram.

- Master channel
  - INTTAUDnIm is generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 1)

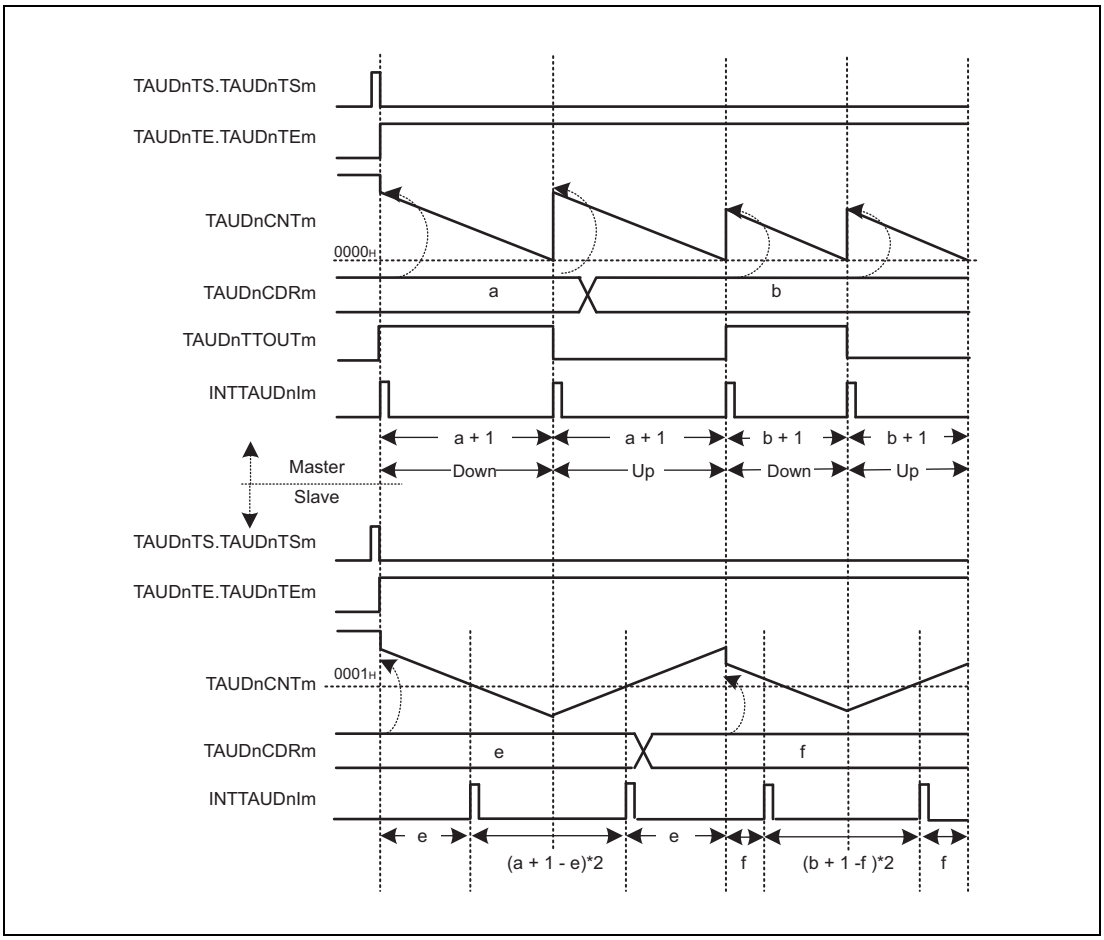

Figure 33.125 General Timing Diagram of A/D Conversion Trigger Output Function Type 2

33.15.10 Interrupt Request Signals Culling Function

33.15.10.1 Overview

Summary

This function divides the number of interrupts of the master channel by a specified value using a slave channel.

The interrupt request signals culling function is a sub function of the following functions:

- PWM Output Function (See **Section 33.15.1, PWM Output Function**)
- Triangle PWM Output Function (See **Section 33.15.7, Triangle PWM Output Function**)
- Triangle PWM Output Function with Dead Time
  (See **Section 33.15.8, Triangle PWM Output Function with Dead Time**)

Prerequisites

- Two channels
- The operation mode of the master channel must be set to interval timer mode. (See **Table 33.208, Contents of the TAUDnCMORm Register for the Master Channel of the Interrupt Request Signals Culling Function**)
- The operation mode of the slave channel must be set to Event Count Mode. (See **Table 33.211, Contents of the TAUDnCMORm Register for the Slave Channel of the Interrupt Request Signals Culling Function**)
- This function does not use TAUDnTTOUTm.

Functional description

The counters (master and slave) are enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1 for both channels. This in turn sets TAUDnTE.TAUDnTEm, enabling count operation. The current value of the data register of the master channel and slave channel (TAUDnCDRm) are written to the counter (TAUDnCNTm).

- Master channel:
  When the counter of the master channel reaches 0000_H, INTTAUDnIm is generated and TAUDnCDRm value is reloaded to TAUDnCNTm.
- Slave channel:
  Every time the master channel generates an INTTAUDnIm, the counter of the slave channel decrements by one. When the counter reaches 0000_H, it awaits the next interrupt from the master channel. This causes TAUDnCNTm (slave) to reload the value of TAUDnCDRm, and an INTTAUDnIm is generated.

Forced restart is not possible for this function. The counter can be stopped by setting TAUDnTT.TAUDnTTm to 1 for the master and slave channels, which in turn sets TAUDnTE.TAUDnTEm to 0. TAUDnCNTm of master and slave channels stops but retains its value.

Conditions

This function enables simultaneous rewrite. See **Section 33.6, Simultaneous Rewrite**.

33.15.10.2 Equations

Interrupt division operator = TAUDnCDRm (slave channel)

– One INTTAUDnIm is generated for the INTTAUDnIm count of the master channel defined by TAUDnCDRm (slave channel) + 1.

33.15.10.3 Block Diagram and General Timing Diagram

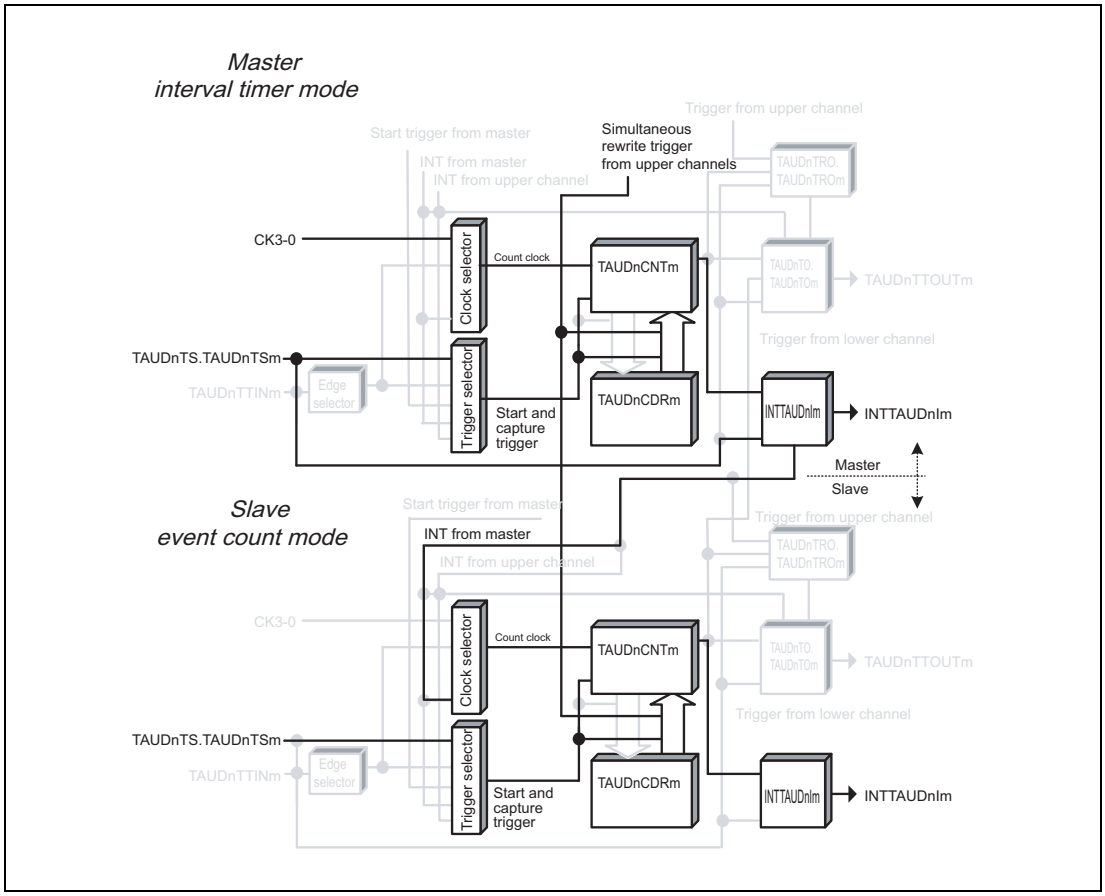

Figure 33.126 Block Diagram of Interrupt Request Signals Culling Function

The following settings apply to the general timing diagram.

Master channel:

- INTTAUDnIm is generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 1)

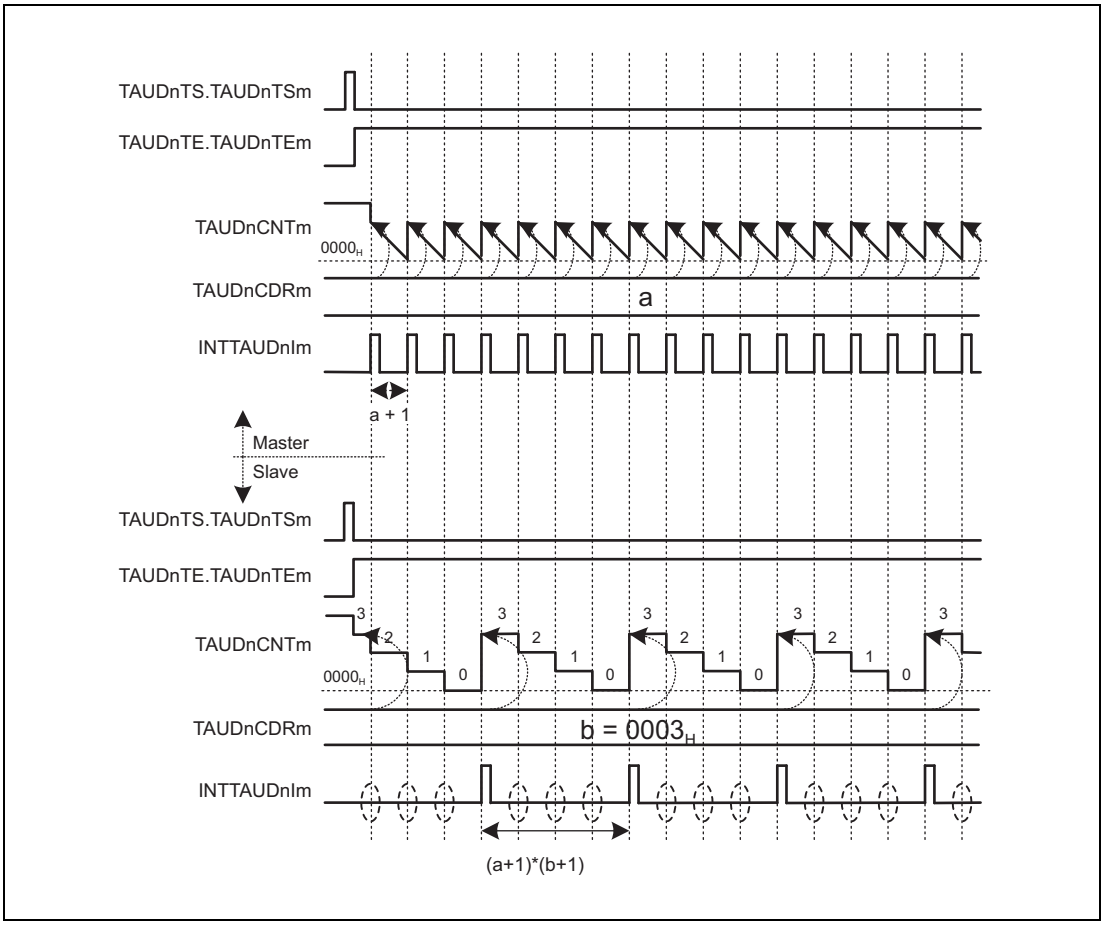

Figure 33.127 General Timing Diagram of Interrupt Request Signals Culling Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for the Master Channel

TAUDnTOE.TAUDnTOEm is set to 0 because the channel output mode is not used with this function.

(4) Simultaneous Rewrite for the Master Channel

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.210 Simultaneous Rewrite Settings for the Master Channel of Interrupt Request Signals Culling Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects a master channel for simultaneous rewrite triggers. 1: Selects an upper channel outside the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count. 1: Simultaneous rewrite trigger signal is generated when master channel counter is started and the corresponding slave channel is at the peak of triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

33.15.10.5 Register Settings for Slave Channel

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for Slave Channel

TAUDnTOE.TAUDnTOEm is set to 0 because the channel output mode is not used with this function.

(4) Simultaneous Rewrite for Slave Channel

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.213 Simultaneous Rewrite Settings for Slave Channel of Interrupt Request Signals Culling Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects a master channel for simultaneous rewrite triggers. 1: Selects an upper channel outside the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count. 1: Simultaneous rewrite trigger signal is generated when master channel counter is started and the corresponding slave channel is at the peak of triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

33.15.10.6 Operating Procedure for Interrupt Request Signals Culling Function

Table 33.214 Operating Procedure for Interrupt Request Signals Culling Function

	Operation	TAUDn Status
Initial Channel Setting	Master channel: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.15.10.4, Register Settings for the Master Channel**. Slave channel: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.15.10.5, Register Settings for Slave Channel**. Set the value of TAUDnCDRm register of every channel.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm (master and slave channels) is set to 1 and the counters of master and slave channels start. INTTAUDnIm is generated on the master channel.
During Operation	TAUDnCDRm can be changed at any time. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time. TAUDnRDT.TAUDnRDTm can be changed during operation.	TAUDnCNTm of master channel loads TAUDnCDRm value and counts down. When the counter reaches 0000_H: • INTTAUDnIm (master) is generated. • TAUDnCNTm (master) loads TAUDnCDRm value and continues count operation. • TAUDnCNTm of slave channels counts down each time INTTAUDnIm of master channel is detected. When TAUDnCNTm of the slave = 0000_H: • INTTAUDnIm (slave) is generated. • The TAUDnCDRm value is loaded in TAUDnCNTm (slave) and count operation continues.
Stop Operation	Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and retains its current value.

Restart Operation

33.15.10.7 Specific Timing Diagrams

(1) Interrupt count (master) = interrupt count (slave)

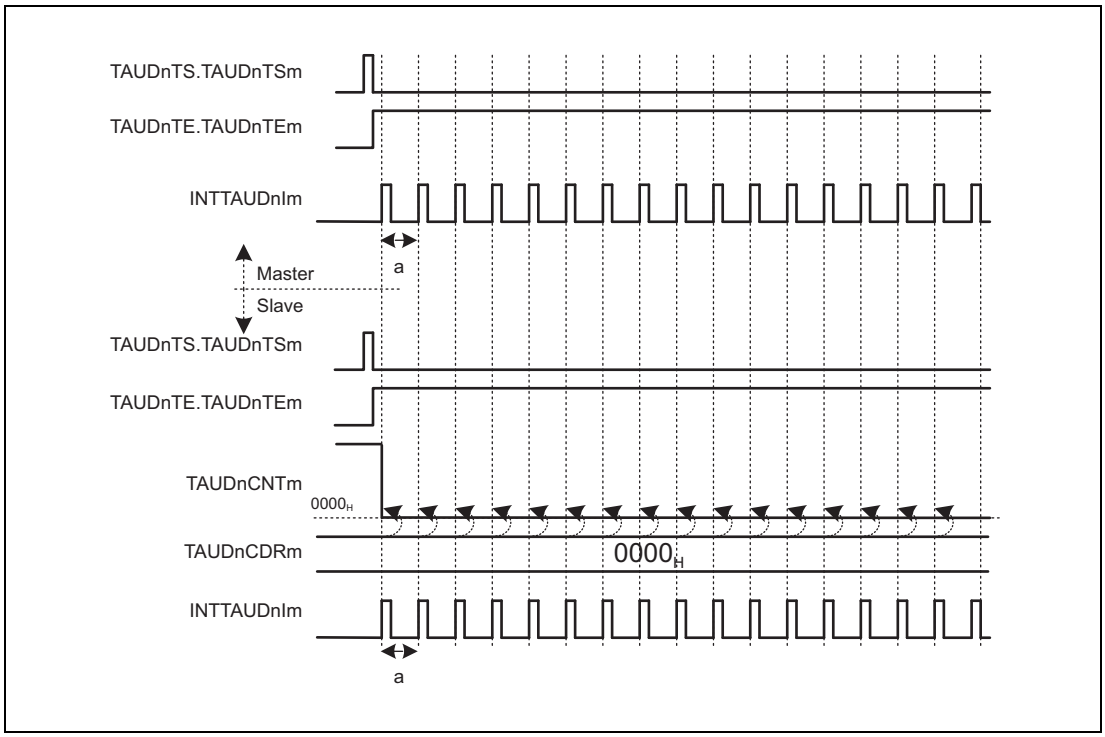

Figure 33.128 TAUDnCDRm (Slave) = 0000_H

- If TAUDnCDRm = 0000_H, the TAUDnCDRm value of slave channel is loaded into TAUDnCNTm each time INTTAUDnIm of master channel is detected. In other words, TAUDnCNTm is always 0000_H.
- Therefore, an interrupt occurs on the master channel and simultaneously an interrupt occurs on slave channels.

33.16 Synchronous Non-Complementary and Complementary Modulation Output Functions

This section describes functions that generate 6-phase PWM output or triangle PWM output using a master channel and seven slave channels.

33.16.1 Non-Complementary Modulation Output Function Type 1

33.16.1.1 Overview

Summary

This function outputs a PWM signal, a high-level signal, or a low-level signal from TAUDnTTOUTm depending on the values of the real-time output bits (TAUDnTRO.TAUDnTROm) and the modulation output enable bits (TAUDnTME.TAUDnTMEm) of a pair of slave channels. Three pairs of channels are typically used.

Prerequisites

- One master channel and seven slave channels
- The operation mode of the master channel must be set to interval timer mode (See **Table 33.216, Contents of the TAUDnCMORm Register for the Master Channel of Non-Complementary Modulation Output Function Type 1**).
- The operating mode for slave channels 1 to 7 should be set to one-count mode (See **Table 33.219, Contents of the TAUDnCMORm Register for Slave Channel 1 of Non-Complementary Modulation Output Function Type 1** and **Table 33.222, Contents of the TAUDnCMORm Register for Slave Channels 2 to 7 of Non-Complementary Modulation Output Function Type 1**).
- TAUDnTTOUTm is not used with the master channel of this function.
- TAUDnTTOUTm of slave channel 1 is not used with this function, but TAUDnTRC.TAUDnTRCm should be set to 1 (See **Section 33.7, Channel Output Modes**).
- The channel output mode for slave channels 2 to 7 should be set to synchronous channel output mode 1 with non-complementary modulation output (See **Section 33.7, Channel Output Modes**).
- TAUDnCDRm of slave channel 1 should be set to 0000_H.

Functional description

The master/slave channel counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The value of data register (TAUDnCDRm) is loaded into the counter (TAUDnCNTm) and the counter starts to count down. When the counter reaches 0000_H, INTTAUDnIm is generated.

- Slave channel 1:
  Slave channel 1 is set as a channel that triggers real-time output (TAUDnTRC.TAUDnTRCm = 1). If an interrupt occurs on slave channel 1 (TAUDnCDRm is fixed to 0000_H), the value of real-time output bit (TAUDnTRO.TAUDnTROm) of the channel that monitors the interrupt on slave channel 1 is reflected to the TAUDnTTOUTm output. After that, the counter returns to $FFFF_H$ and waits for the next interrupt of master channel.

- Slave channel 2:
  Slave channel 2 generates a PWM output. The master channel specifies a PWM output cycle and slave channel 2 specifies a duty cycle. After generating an interrupt, the counter returns to $FFFF_H$ and awaits the next interrupt from the master channel.

Slave channels 3 to 7 operate like slave channel 2.

As described in **Table 33.215, TAUDnTTOUTm Output of Slave Channels for Non-Complementary Modulation Output Function Type 1 (TAUDnTOL.TAUDnTOLm = 0)**, a signal output from TAUDnTTOUTm depends on the value of the real-time output bit (TAUDnTRO.TAUDnTROm) and modulation output bit (TAUDnTME.TAUDnTMEm) of slave channel.

This function cannot use a forced restart. The counter can be stopped by setting TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTEm to 0. TAUDnCNTm and TAUDnTTOUTm of master and slave channels stop but retain their values. The counters can be restarted by setting TAUDnTS.TAUDnTSm to 1.

Conditions

- If TAUDnTME.TAUDnTMEm = 0 on slave channels 2 to 7 (TAUDnTOL.TAUDnTOLm = 0):
  - If the channel's TAUDnTRO.TAUDnTROm is set to 1, TAUDnTTOUTm outputs a high-level signal.
  - If the channel's TAUDnTRO.TAUDnTROm is set to 0, TAUDnTTOUTm outputs a low-level signal.
- If TAUDnTME.TAUDnTMEm = 1 on slave channels 2 to 7 (TAUDnTOL.TAUDnTOLm = 0):
  - If the channel's TAUDnTRO.TAUDnTROm is set to 1, TAUDnTTOUTm outputs PWM corresponding to the channel.
  - If the channel's TAUDnTRO.TAUDnTROm is set to 0, TAUDnTTOUTm outputs a low-level signal.
- If TAUDnTOL.TAUDnTOLm is set to 1, high-level and low-level signals output from TAUDnTTOUTm are inverted. The PWM signal is negative logic. Only the initial setting of TAUDnTOL.TAUDnTOLm is permitted (cannot be changed during operation).

Table 33.215 TAUDnTTOUTm Output of Slave Channels for Non-Complementary Modulation Output Function Type 1 (TAUDnTOL.TAUDnTOLm = 0)

TAUDnTME.TAUDnTMEm	TAUDnTRO.TAUDnTROm	TAUDnTTOUTm Output
0	0	Low level
	1	High level
1	0	Low level
	1	PWM (positive logic)

- This function enables simultaneous rewrite. See **Section 33.6, Simultaneous Rewrite**.
- TAUDnCDRm value of slave channel 1 should be set to 0000_H so that a real-time output is triggered at the same time with PWM generation on slave channels 2 to 7.
- If TAUDnTOL.TAUDnTOLm is set to 0 on slave channels 2 to 7, TAUDnTO.TAUDnTOm is set to 0 (low) before TAUDnTE.TAUDnTEm is set to 0.
- If TAUDnTOL.TAUDnTOLm is set to 1 on slave channels 2 to 7, TAUDnTO.TAUDnTOm is set to 1 (high) before TAUDnTE.TAUDnTEm is set to 0.

33.16.1.2 Equations

Slave channels 2 to 7:

Pulse period = [TAUDnCDRm (master) + 1] × count clock cycle

Duty time = [TAUDnCDRm (slave)] × count clock cycle

33.16.1.3 Block Diagram and General Timing Diagram

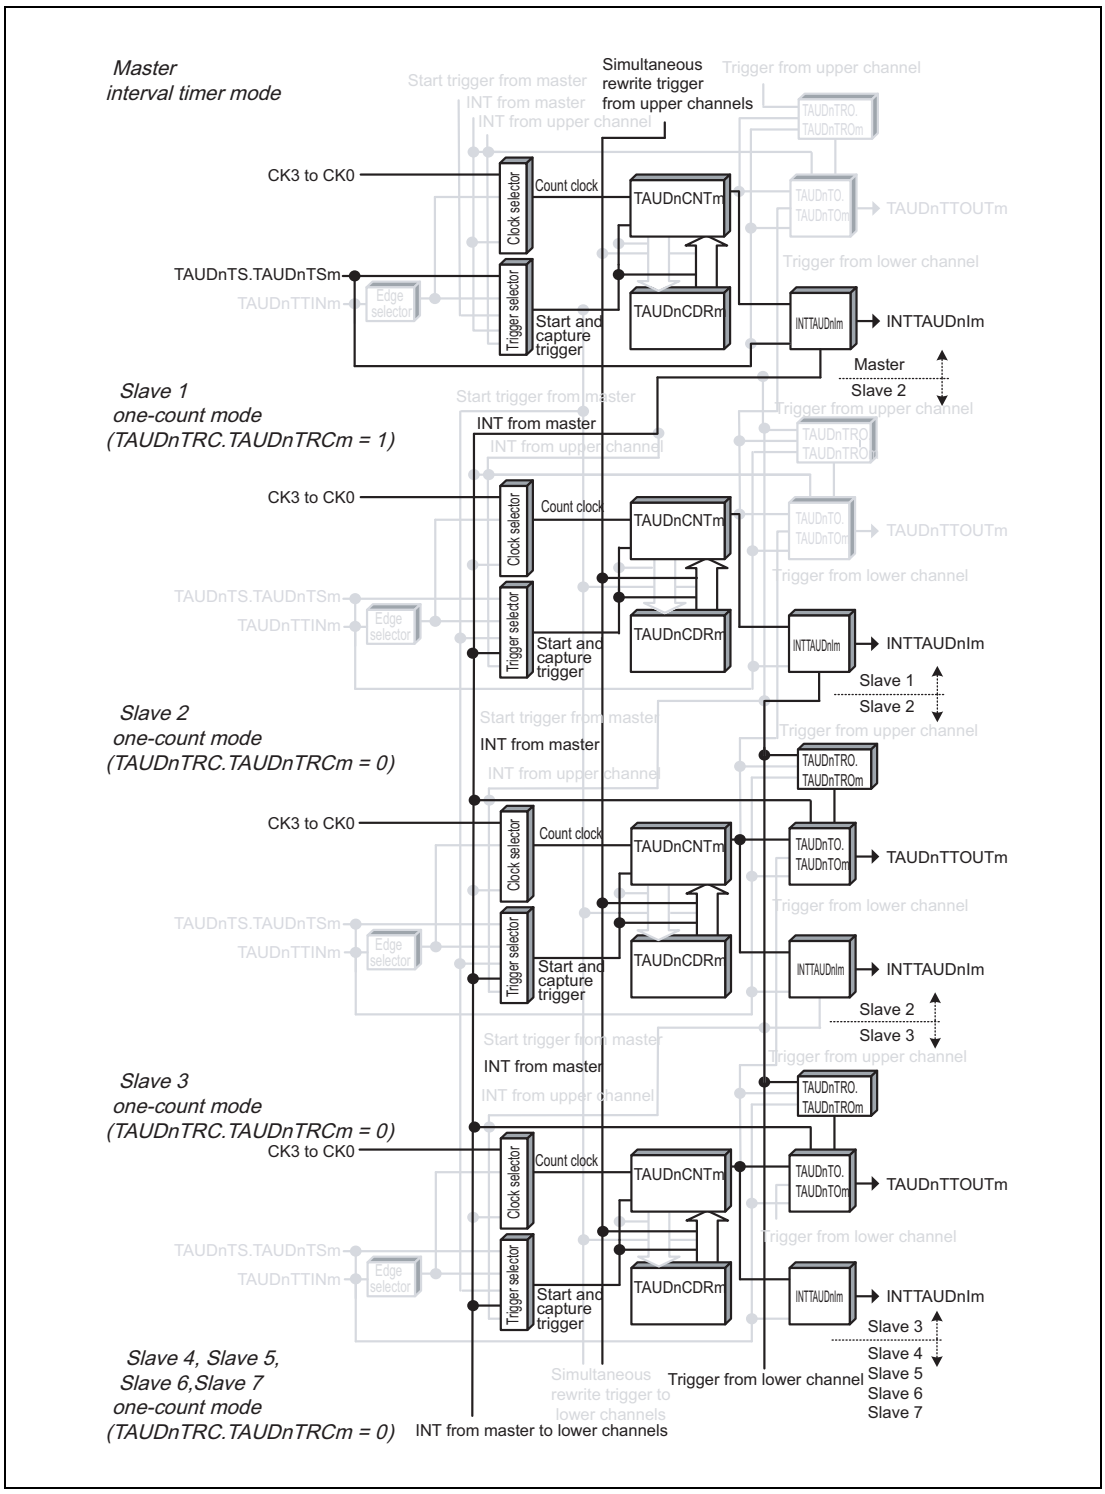

Figure 33.129 Block Diagram of Non-Complementary Modulation Output Function Type 1

The following settings apply to the general timing diagram.

- Slave channels 2 to 7: Positive logic (TAUDnTOL.TAUDnTOLm = 0)

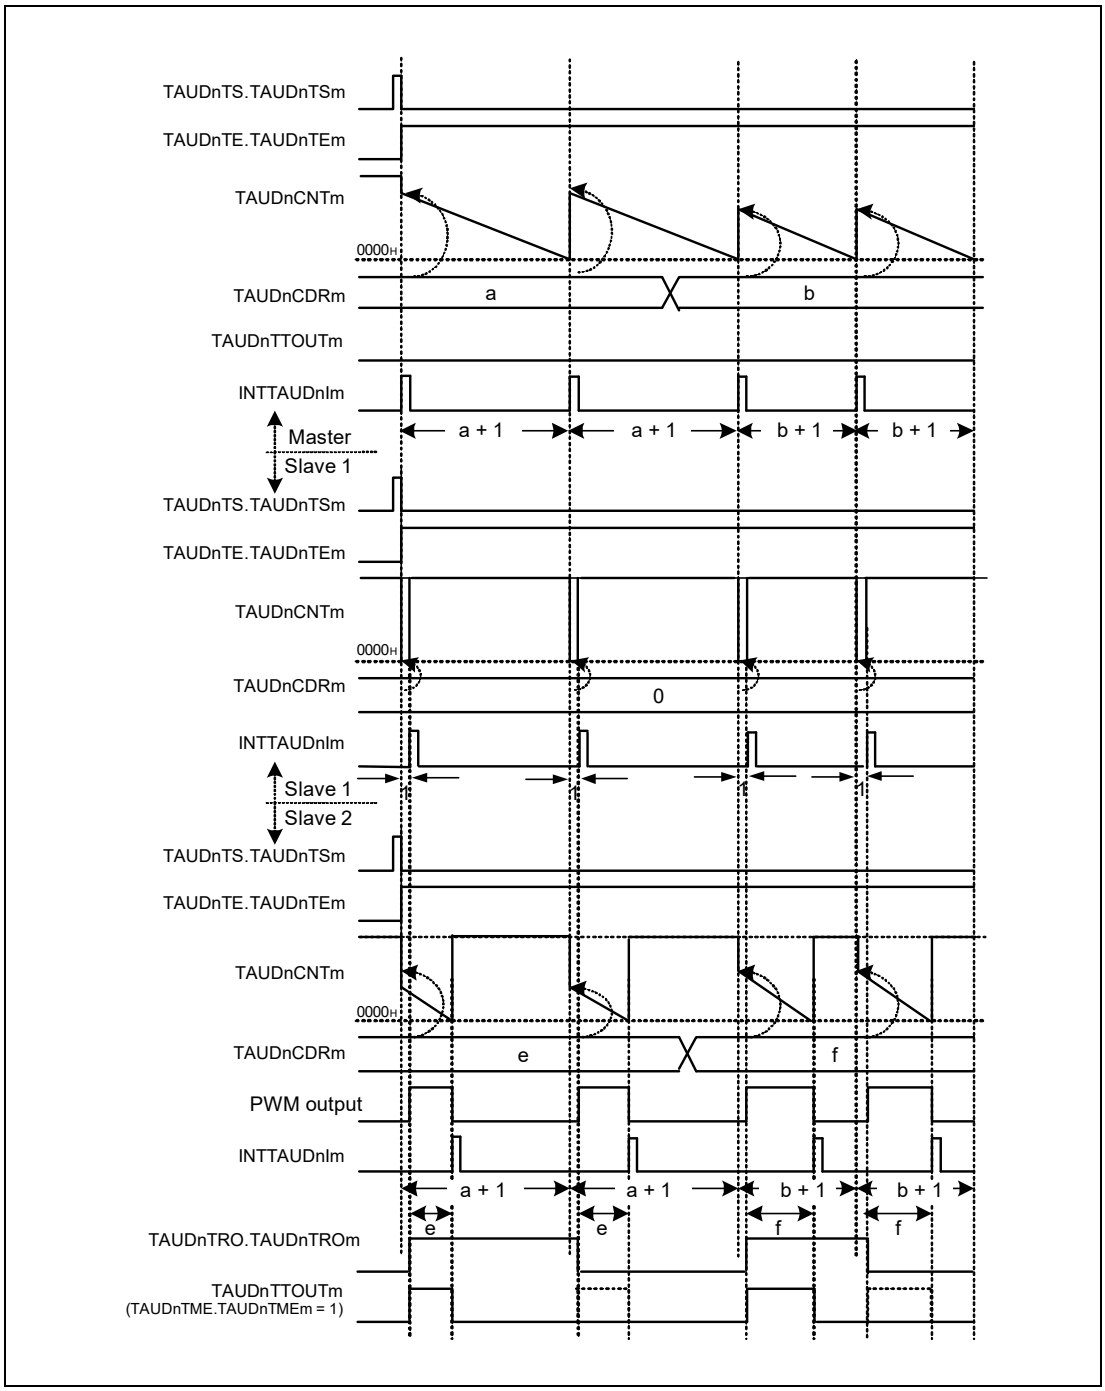

Figure 33.130 General Timing Diagram of Non-Complementary Modulation Output Function Type 1

NOTE

TAUDnTTOUTm of slave channel 2 rises with a delay of one clock count after the rise of INTTAUDnIm of the master channel.

33.16.1.4 Register Settings for the Master Channel

(1) TAUDnCMORm for the Master Channel

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDn MAS	TAUDnSTS[2:0]			TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDn MD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 33.216 Contents of the TAUDnCMORm Register for the Master Channel of Non-Complementary Modulation Output Function Type 1

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operation clock as a count clock
11	TAUDnMAS	1: Master channel
10 to 8	TAUDnSTS[2:0]	000: Trigger the counter using software.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0000: Interval timer mode
0	TAUDnMD0	1: INTTAUDnIm is generated at the beginning of operation or at a restart time.

(2) TAUDnCMURm for the Master Channel

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.217 Contents of the TAUDnCMURm Register for the Master Channel of Non-Complementary Modulation Output Function Type 1

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for the Master Channel

TAUDnTOE.TAUDnTOEm is set to 0 because channel output mode is not used with this function.

(4) Simultaneous Rewrite for the Master Channel

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.218 Simultaneous Rewrite Settings for the Master Channel of Non-Complementary Modulation Output Function Type 1

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. Monitors master channel for simultaneous rewrite triggers, regardless of the value of this bit, when TAUDnRDS.TAUDnRDSm = 0.

NOTE

Use with TAUDnRDS.TAUDnRDSm bit = 1 requires an upper channel higher than the master channel that operates with **Section 33.14.1, Simultaneous Rewrite Trigger Generation Function Type 1**.

Conduct operation settings under the following conditions.

- Simultaneous rewrite trigger output function type 1 setting channel: TAUDnRDCm = 1, TAUDnRDSm = 1
  In addition, TAUDnCDRm settings for this channel are as follows.
  = ((TAUDnCDR setting for the master channel targeted for simultaneous rewrite + 1) × Interrupt count) – 1
- Master channel: TAUDnRDCm = 0, TAUDnRDSm = 1
- Slave channel: TAUDnRDCm = 0, TAUDnRDSm = 1

33.16.1.5 Register Settings for Slave Channel 1

(1) TAUDnCMORm for Slave Channel 1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDn MAS	TAUDnSTS[2:0]			TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDn MD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 33.219 Contents of the TAUDnCMORm Register for Slave Channel 1 of Non-Complementary Modulation Output Function Type 1

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operation clock as a count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	100: INTTAUDnIm of master channel is a start trigger.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0100: One-count mode
0	TAUDnMD0	1: Start trigger during operation is valid.

(2) TAUDnCMURm for Slave Channel 1

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.220 Contents of the TAUDnCMURm Register for Slave Channel 1 of Non-Complementary Modulation Output Function Type 1

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode

TAUDnTOE.TAUDnTOEm is set to 0 because the channel output mode is not used on slave channel 1 with this function. However, this mode can be used in independent channel output mode controlled by software.

CAUTION

TAUDnTRC.TAUDnTRCm should be set to 1 because slave channel 1 is used as a real-time output trigger channel.

(4) Simultaneous Rewrite for Slave Channel 1

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.221 Simultaneous Rewrite Settings for Slave Channel 1 of Non-Complementary Modulation Output Function Type 1

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. Monitors master channel for simultaneous rewrite triggers, regardless of the value of this bit, when TAUDnRDS.TAUDnRDSm = 0.

33.16.1.6 Register Settings for Slave Channels 2 to 7

(1) TAUDnCMORm for Slave Channels 2 to 7

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 33.223 Contents of the TAUDnCMURm Register for Slave Channels 2 to 7 of Non-Complementary Modulation Output Function Type 1

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for Slave Channels 2 to 7

Table 33.224 Control Bit Settings in Synchronous Channel Output Mode 1 with Non-Complementary Modulation Output

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel output
TAUDnTOC.TAUDnTOCm	0: Operating mode 1
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	1: Enables real-time output.
TAUDnTRO.TAUDnTROm	0: Real-time output is low. 1: Real-time output is high.
TAUDnTRC.TAUDnTRCm	0: Upper channel generates a real-time output trigger for channel m.
TAUDnTME.TAUDnTMEm	0: Disables modulation 1: Enables modulation

(4) Simultaneous Rewrite of Slave Channels 2 to 7

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.225 Simultaneous Rewrite Settings for Slave Channels 2 to 7 of Non-Complementary Modulation Output Function Type 1

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. Monitors master channel for simultaneous rewrite triggers, regardless of the value of this bit, when TAUDnRDS.TAUDnRDSm = 0.

33.16.1.7 Operating Procedure for Non-Complementary Modulation Output Function Type 1

Table 33.226 Operating Procedure for Non-Complementary Modulation Output Function Type 1 (1/2)

	Operation	TAUDn Status
Initial Channel Setting	Master channel: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.16.1.4, Register Settings for the Master Channel**. Slave channel 1: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.16.1.5, Register Settings for Slave Channel 1**. Slave channels 2 to 7: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.16.1.6, Register Settings for Slave Channels 2 to 7**. Set the value of TAUDnCDRm register of every channel. Set a pulse cycle with TAUDnCDRm of master channel, 0000_H in TAUDnCDRm of slave channel 1, and duty width with TAUDnCDRm of slave channels 2 to 7. Set TAUDnTRC.TAUDnTRCm to 1 on slave channel 1.	Channel operation is stopped.

Table 33.226 Operating Procedure for Non-Complementary Modulation Output Function Type 1 (2/2)

	Operation	TAUDn Status
Start Operation	Set TAUDnTS.TAUDnTSm of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm of master and slave channels is set to 1 and the counter starts counting down.
During Operation	TAUDnCDRm, TAUDnTRO.TAUDnTROm, and TAUDnTMEm.TAUDnTMEm can be changed at any time. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time. TAUDnRDT.TAUDnRDTm can be changed during operation.	TAUDnCDRm value of master channel, slave channel 1 and slave channels 2 to 7 is loaded into TAUDnCNTm to perform counting down. When the counter of master channel reaches 0000_H: • INTTAUDnIm is generated. • TAUDnCDRm value of master channel is reloaded into TAUDnCNTm to continue counting down. • PWM output signals of slave channels 2 to 7 are set. • TAUDnCDRm value of slave channel 1 is reloaded into TAUDnCNTm to perform counting down. • TAUDnCDRm value of slave channels 2 to 7 is reloaded into TAUDnCNTm to perform counting down. • When the counter of slave channel 1 reaches 0000_H: – INTTAUDnIm is generated. – The TAUDnTRO.TAUDnTROm value of slave channels 2 to 7 is reflected to the TAUDnTTOUTm output. • When the counter of slave channels 2 to 7 reaches 0000_H: – INTTAUDnIm is generated. – PWM output signals of slave channels 2 to 7 are set. TAUDnTTOUTm of slave channels 2 to 7 outputs a PWM signal, a high-level signal or low-level signal depending on the values of real-time output bits (TAUDnTRO.TAUDnTROm) and modulation output bit (TAUDnTME.TAUDnTMEm) of a pair of slave channels.
Stop Operation	Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

Restart Operation

33.16.1.8 Specific Timing Diagrams

The following settings apply to the specific timing diagram.

- Slave channels 2 to 7: Positive logic (TAUDnTOL.TAUDnTOLm = 0)

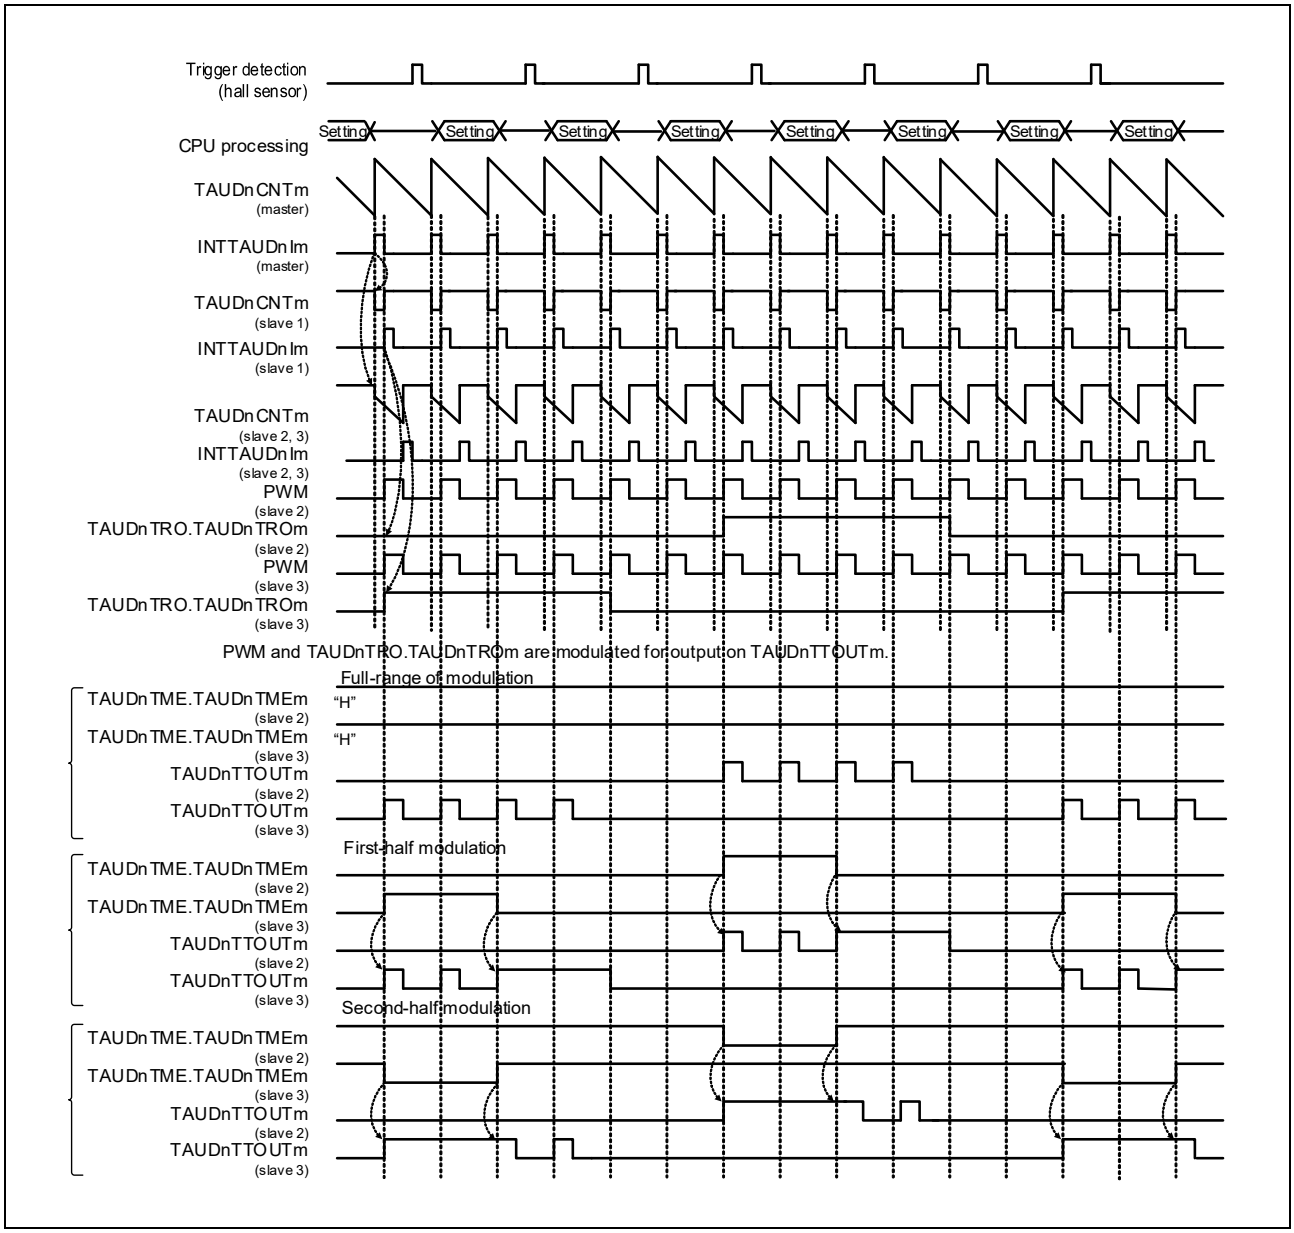

Figure 33.131 Specific Timing Diagram of Non-Complementary Modulation Output Function Type 1

The above timing diagram shows how full modulation, first-half modulation, and second-half modulation can be achieved by modifying the TAUDnTME.TAUDnTMEm bits of lower slave channels during operation.
The "Setting" symbol indicates a time period when the values of TAUDnCDRm, TAUDnTME.TAUDnTMEm, and TAUDnTRO.TAUDnTROm can be changed.
TAUDnTME.TAUDnTMEm setting is reflected by detecting the count start timing and master channel cycle. According to the modified setting, modulation waveforms are output from TAUDnTTOUTm.
A TAUDnTRO.TAUDnTROm bit value is set by software, but a new setting is applied only when an interrupt occurs on slave channel 1.

33.16.2 Non-Complementary Modulation Output Function Type 2

33.16.2.1 Overview

Summary

This function outputs a triangular PWM output signal, a high-level signal, or low-level signal from TAUDnTTOUTm depending on the real-time output bit value (TAUDnTRO.TAUDnTROm) and the modulation output enable bit value (TAUDnTME.TAUDnTMEm) of a pair of slave channels. Three pairs of channels are typically used.

Prerequisites

- One master channel and seven slave channels
- The operation mode of the master channel must be set to interval timer mode (See **Table 33.228, Contents of the TAUDnCMORm Register for the Master Channel of Non-Complementary Modulation Output Function Type 2**).
- The operating mode for slave channel 1 should be set to event count mode (See **Table 33.232, Contents of the TAUDnCMORm Register for Slave Channel 1 of Non-Complementary Modulation Output Function Type 2**).
- The operating mode for slave channels 2 to 7 should be set to count-up/-down mode (See **Table 33.235, Contents of the TAUDnCMORm Register for Slave Channels 2 to 7 of Non-Complementary Modulation Output Function Type 2**).
- The output mode for the master channel should be set to independent channel output mode 1 (See **Section 33.7, Channel Output Modes**).
- This function does not use TAUDnTTOUTm of slave channel 1 but TAUDnTRC.TAUDnTRCm should be set to 1 (See **Section 33.7, Channel Output Modes**).
- The channel output mode for slave channels 2 to 7 should be set to synchronous channel output mode 2 with non-complementary modulation output (See **Section 33.7, Channel Output Modes**).

Functional description

The master/slave channel counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The value of data register (TAUDnCDRm) is loaded into the counter (TAUDnCNTm).

- Master channel:
  The counter of master channel starts to count down. When the counter reaches 0000_H, INTTAUDnIm is generated.
- Slave channel 1:
  When slave channel 1 detects an interrupt from the master channel, the TAUDnCNTm value is decremented. When an interrupt from the master channel is detected (TAUDnCDRm + 1) times, INTTAUDnIm is generated. Then, the TAUDnCDRm value is loaded into TAUDnCNTm to continue operation subsequently.
  Since slave channel 1 is set as a real-time output trigger channel (TAUDnTRC.TAUDnTRCm = 1), if an interrupt occurs on slave channel 1, the real-time output bit (TAUDnTRO.TAUDnTROm) of the channel which monitors an interrupt on the corresponding channel is reflected to the TAUDnTTOUTm output.

- Slave channel 2:
  Once detecting an interrupt from the master channel, TAUDnCNTm counts in the reverse direction. When an interrupt is detected during count-up operation, TAUDnCDRm value is reloaded and then the counter starts to count down.
  If TAUDnCNTm = 0001_H, an interrupt occurs and a PWM output signal is set/reset.

The combined use of the master channel and slave channel 2 generates a PWM output signal. The master channel generates a PWM output cycle and slave channel 2 generate a duty cycle.

Slave channels 3 to 7 operate like slave channel 2.

A signal that is output from TAUDnTTOUTm depends on a real-time output bit value (TAUDnTRO.TAUDnTROm) and a modulation output bit value (TAUDnTME.TAUDnTMEm) of the slave channel, as described in **Table 33.227, TAUDnTTOUTm Output of Slave Channels in Non-Complementary Modulation Output Function Type 2 (TAUDnTOL.TAUDnTOLm = 0)**.

This function cannot make a forced restart. The counter can be stopped by setting TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTEm to 0. TAUDnCNTm and TAUDnTTOUTm of master and slave channels stop but retain their values. The counters can be restarted by setting TAUDnTS.TAUDnTSm to 1.

Conditions

- If TAUDnTME.TAUDnTMEm = 0 on slave channels 2 to 7 (TAUDnTOL.TAUDnTOLm = 0):
  - If the channel's TAUDnTRO.TAUDnTROm is set to 1, TAUDnTTOUTm outputs a high-level signal.
  - If the channel's TAUDnTRO.TAUDnTROm is set to 0, TAUDnTTOUTm outputs a low-level signal.
- If TAUDnTME.TAUDnTMEm = 1 on slave channels 2 to 7 (TAUDnTOL.TAUDnTOLm = 0):
  - If the channel's TAUDnTRO.TAUDnTROm is set to 1, TAUDnTTOUTm outputs PWM (positive logic) corresponding to the channel.
  - If the channel's TAUDnTRO.TAUDnTROm is set to 0, TAUDnTTOUTm outputs a low-level signal.
- If TAUDnTOL.TAUDnTOLm is set to 1, high-level and low-level signals output from TAUDnTTOUTm are inverted. The PWM signal is negative logic. Only the initial setting of TAUDnTOL.TAUDnTOLm is permitted (cannot be changed during operation).

Table 33.227 TAUDnTTOUTm Output of Slave Channels in Non-Complementary Modulation Output Function Type 2 (TAUDnTOL.TAUDnTOLm = 0)

TAUDnTME.TAUDnTMEm	TAUDnTRO.TAUDnTROm	TAUDnTTOUTm Output
0	0	Low level
	1	High level
1	0	Low level
	1	PWM (positive logic)

- This function enables simultaneous rewrite. See **Section 33.6, Simultaneous Rewrite**.
- If TAUDnTOL.TAUDnTOLm is set to 0 on slave channels 2 to 7, TAUDnTO.TAUDnTOm is set to 0 (low) before TAUDnTE.TAUDnTEm is set to 0.
- If TAUDnTOL.TAUDnTOLm is set to 1 on slave channels 2 to 7, TAUDnTO.TAUDnTOm is set to 1 (high) before TAUDnTE.TAUDnTEm is set to 0.

33.16.2.2 Equations

Slave channels 2 to 7:

Carrier cycle (down/up)

= [TAUDnCDRm (master) + 1] × 2 × count clock cycle

Duty time

= [TAUDnCDRm (master) + 1 – TAUDnCDRm (slave)] × 2 × count clock cycle

33.16.2.3 Block Diagram and General Timing Diagram

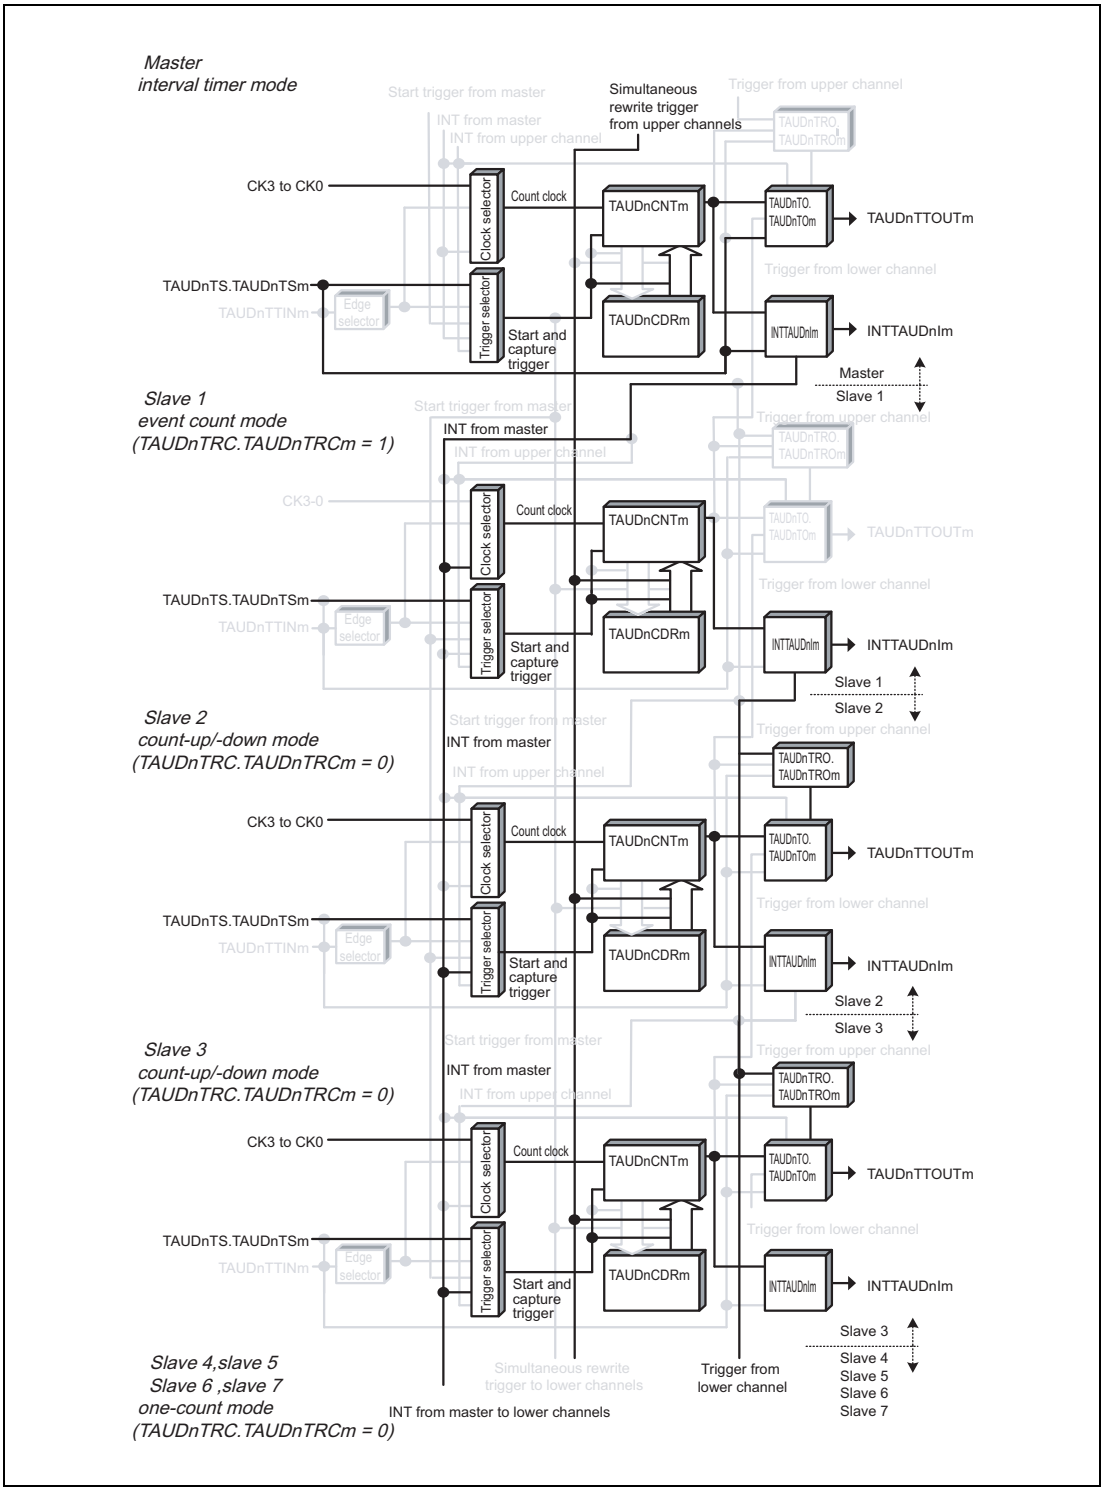

Figure 33.132 Block Diagram of Non-Complementary Modulation Output Function Type 2

The following settings apply to the general timing diagram.

- Master channel: INTTAUDnIm is not generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 0)
- Slave channels 2 to 7: Positive logic (TAUDnTOL.TAUDnTOLm = 0)

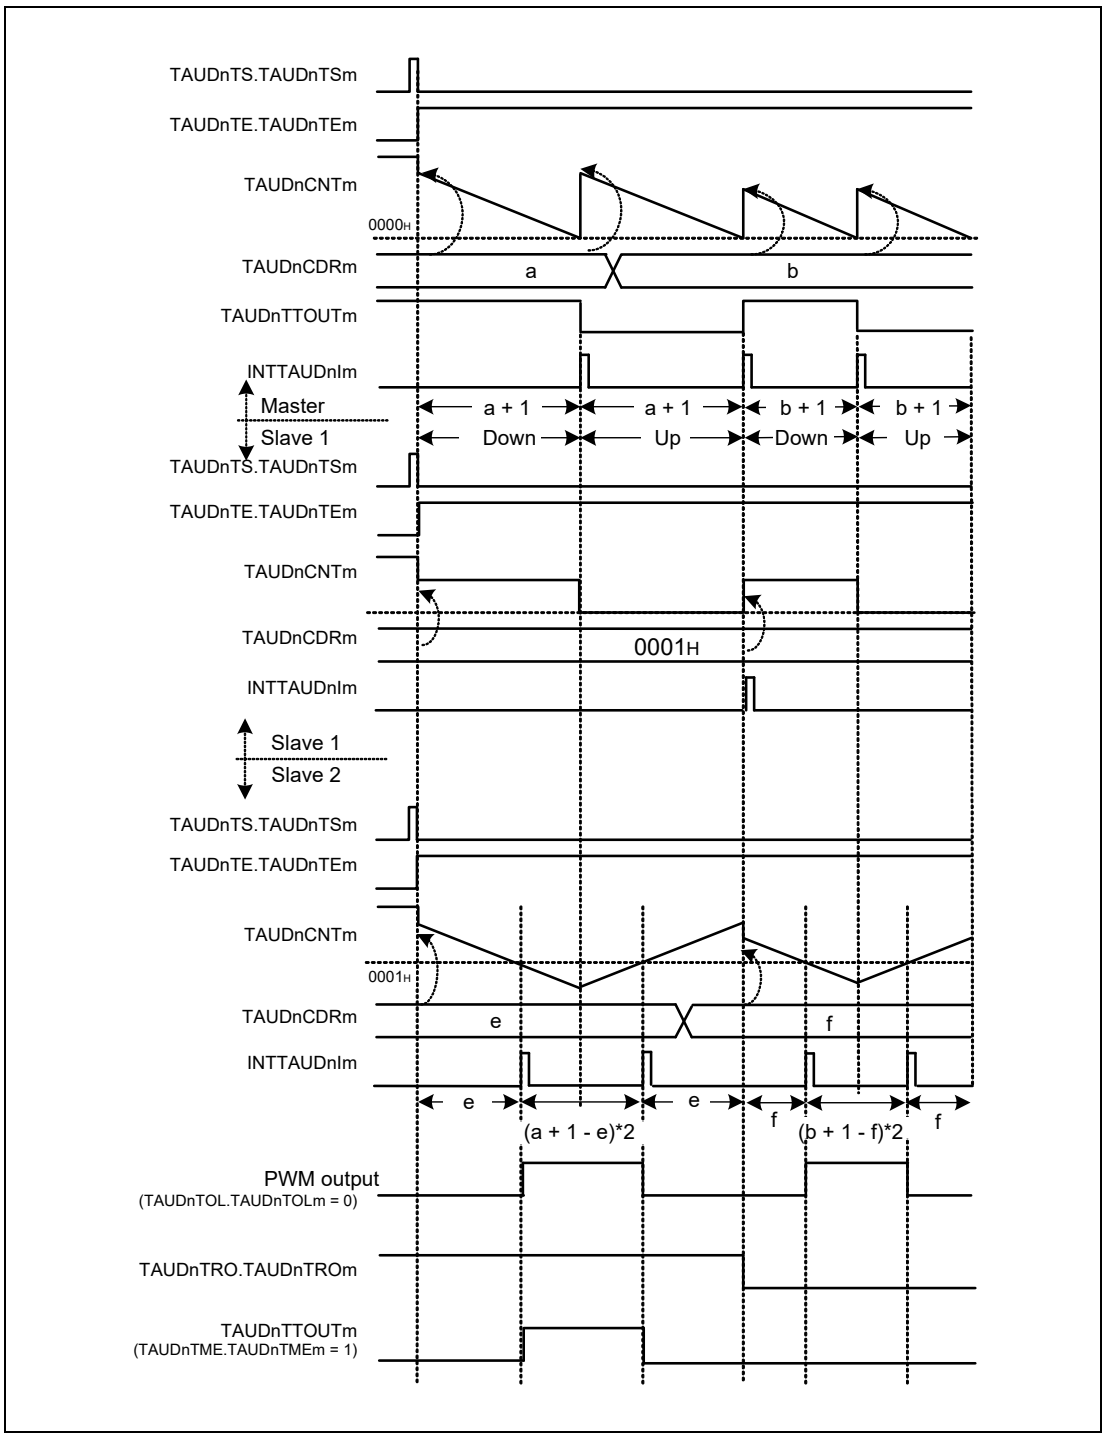

Figure 33.133 General Timing Diagram of Non-Complementary Modulation Output Function Type 2

33.16.2.4 Register Settings for the Master Channel

(1) TAUDnCMORm for the Master Channel

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 33.228 Contents of the TAUDnCMORm Register for the Master Channel of Non-Complementary Modulation Output Function Type 2

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operation clock as a count clock
11	TAUDnMAS	1: Master channel
10 to 8	TAUDnSTS[2:0]	000: Trigger the counter using software.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0000: Interval timer mode
0	TAUDnMD0	0: INTTAUDnIm is not generated at the beginning of operation or at a restart time. 1: INTTAUDnIm is generated at the beginning of operation or at a restart time.

(2) TAUDnCMURm for the Master Channel

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.229 Contents of the TAUDnCMURm Register for the Master Channel of Non-Complementary Modulation Output Function Type 2

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for the Master Channel

Table 33.230 Control Bit Settings for the Master Channel in Non-Complementary Modulation Output Function Type 2

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	0: Operating mode 1 (toggle mode with TAUDnTOM.TAUDnTOMm = 0)
TAUDnTOL.TAUDnTOLm	0: The setting is disabled in toggle mode (the value after reset).
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set these bits to 0.
TAUDnTRC.TAUDnTRCm	
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous Rewrite for the Master Channel

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.231 Simultaneous Rewrite Settings for the Master Channel of Non-Complementary Modulation Output Function Type 2

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel starts to count and the corresponding slave channel is at the peak of a triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

NOTE

If TAUDnRDS.TAUDnRDSm = 1, it is necessary for an upper channel higher than the master channel to generate a simultaneous rewrite trigger signal.

33.16.2.5 Register Settings for Slave Channel 1

(1) TAUDnCMORm for Slave Channel 1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDn MAS	TAUDnSTS[2:0]			TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDn MD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 33.232 Contents of the TAUDnCMORm Register for Slave Channel 1 of Non-Complementary Modulation Output Function Type 2

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	11: INTTAUDnIm of the master channel is used as the count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	000: Trigger the counter using software. 011: Triggers simultaneous rewrite.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0011: Event count mode
0	TAUDnMD0	0: INTTAUDnIm is not generated at the beginning of operation or at a restart time.

(2) TAUDnCMURm for Slave Channel 1

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.233 Contents of the TAUDnCMURm Register for Slave Channel 1 of Non-Complementary Modulation Output Function Type 2

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode

TAUDnTOE.TAUDnTOEm is set to 0 because the channel output mode is not used on slave channel 1 with this function. However, this mode can be used in independent channel output mode controlled by software.

CAUTION

TAUDnTRC.TAUDnTRCm should be set to 1 because slave channel 1 is used as a real-time output trigger channel.

(4) Simultaneous Rewrite for Slave Channel 1

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.234 Simultaneous Rewrite Settings for Slave Channel 1 of Non-Complementary Modulation Output Function Type 2

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: Simultaneous rewrite trigger signal is generated when master channel counter is started and the corresponding slave channel is at the peak of triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. Monitors master channel for simultaneous rewrite triggers, regardless of the value of this bit, when TAUDnRDS.TAUDnRDSm = 0.

33.16.2.6 Register settings for slave channels 2 to 7

(1) TAUDnCMORm for Slave Channels 2 to 7

7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Output Mode for Slave Channels 2 to 7

Table 33.237 Control Bit Settings in Synchronous Channel Output Mode 2 with Non-Complementary Modulation Output

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel output
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	1: Enables real-time output.
TAUDnTRO.TAUDnTROm	0: Real-time output is low. 1: Real-time output is high.
TAUDnTRC.TAUDnTRCm	0: The upper channel generates the real-time output trigger for channel m
TAUDnTME.TAUDnTMEm	0: Disables modulation 1: Enables modulation

(4) Simultaneous Rewrite for Slave Channels 2 to 7

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.238 Simultaneous Rewrite Settings for Slave Channels 2 to 7 of Non-Complementary Modulation Output Function Type 2

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: Simultaneous rewrite trigger signal is generated when master channel counter is started and the corresponding slave channel is at the peak of triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. Monitors master channel for simultaneous rewrite triggers, regardless of the value of this bit, when TAUDnRDS.TAUDnRDSm = 0.

33.16.2.7 Operating Procedure for Non-Complementary Modulation Output Function Type 2

Table 33.239 Operating Procedure for Non-Complementary Modulation Output Function Type 2

	Operation	TAUDn Status
Initial Channel Setting	Master channel: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.16.2.4, Register Settings for the Master Channel**. Slave channel 1: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.16.2.5, Register Settings for Slave Channel 1**. Slave channels 2 to 7: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.16.2.6, Register settings for slave channels 2 to 7**. Set the value of TAUDnCDRm register of every channel. Set pulse cycle in TAUDnCDRm of master channel, and in TAUDnCDRm of slave channel 1, set the number of interrupts from master channel to be ignored before slave channel 1 generates a real-time output trigger. Set duty width in TAUDnCDRm of slave channels 2 to 7. Set TAUDnTRC.TAUDnTRCm to 1 on slave channel 1.	Channel operation is stopped.

Table 33.239 Operating Procedure for Non-Complementary Modulation Output Function Type 2

	Operation	TAUDn Status
Start Operation	Set TAUDnTS.TAUDnTSm of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm of master and slave channels is set to 1 and the counter starts counting down.
During Operation	TAUDnCDRm, TAUDnTRO.TAUDnTROm, and TAUDnTMEm.TAUDnTMEm can be changed at any time. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time. TAUDnRDT.TAUDnRDTm can be changed during operation.	The TAUDnCDRm value of master channel and slave channels 2 to 7 is loaded into TAUDnCNTm to perform counting down. The TAUDnCDRm value of slave channel 1 is loaded and the counter waits for an interrupt from the master channel. When the counter of master channel reaches 0000_H: • INTTAUDnIm is generated. • TAUDnCDRm value is reloaded into TAUDnCNTm to continue counting down. • The TAUDnCNTm value of slave channel 1 decrements by 1 and the counter waits for a next interrupt from the master channel. • TAUDnCNTm of slave channels 2 to 7 reloads the TAUDnCDRm value, or performs counting in opposite direction. • At the same timing when the TAUDnCDRm value is loaded, the TAUDnTME.TAUDnTMEm value of slave channels 2 to 7 is reflected to the TAUDnTTOUTm output. • When slave channel 1 detects an interrupt from the master channel for the (TAUDnCDRm + 1) times: – INTTAUDnIm is generated. – The TAUDnTRO.TAUDnTROm value of slave channels 2 to 7 is reflected to the TAUDnTTOUTm output. • When the counter of slave channels 2 to 7 reaches 0001_H: – INTTAUDnIm is generated. – PWM output signals of slave channels 2 to 7 are set/reset.
Stop Operation	Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

Restart Operation

33.16.2.8 Specific Timing Diagrams

The following settings apply to the general timing diagram.

- Master channel: INTTAUDnIm is not generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 0)
- Slave channels 2 to 7: Positive logic (TAUDnTOL.TAUDnTOLm = 0)

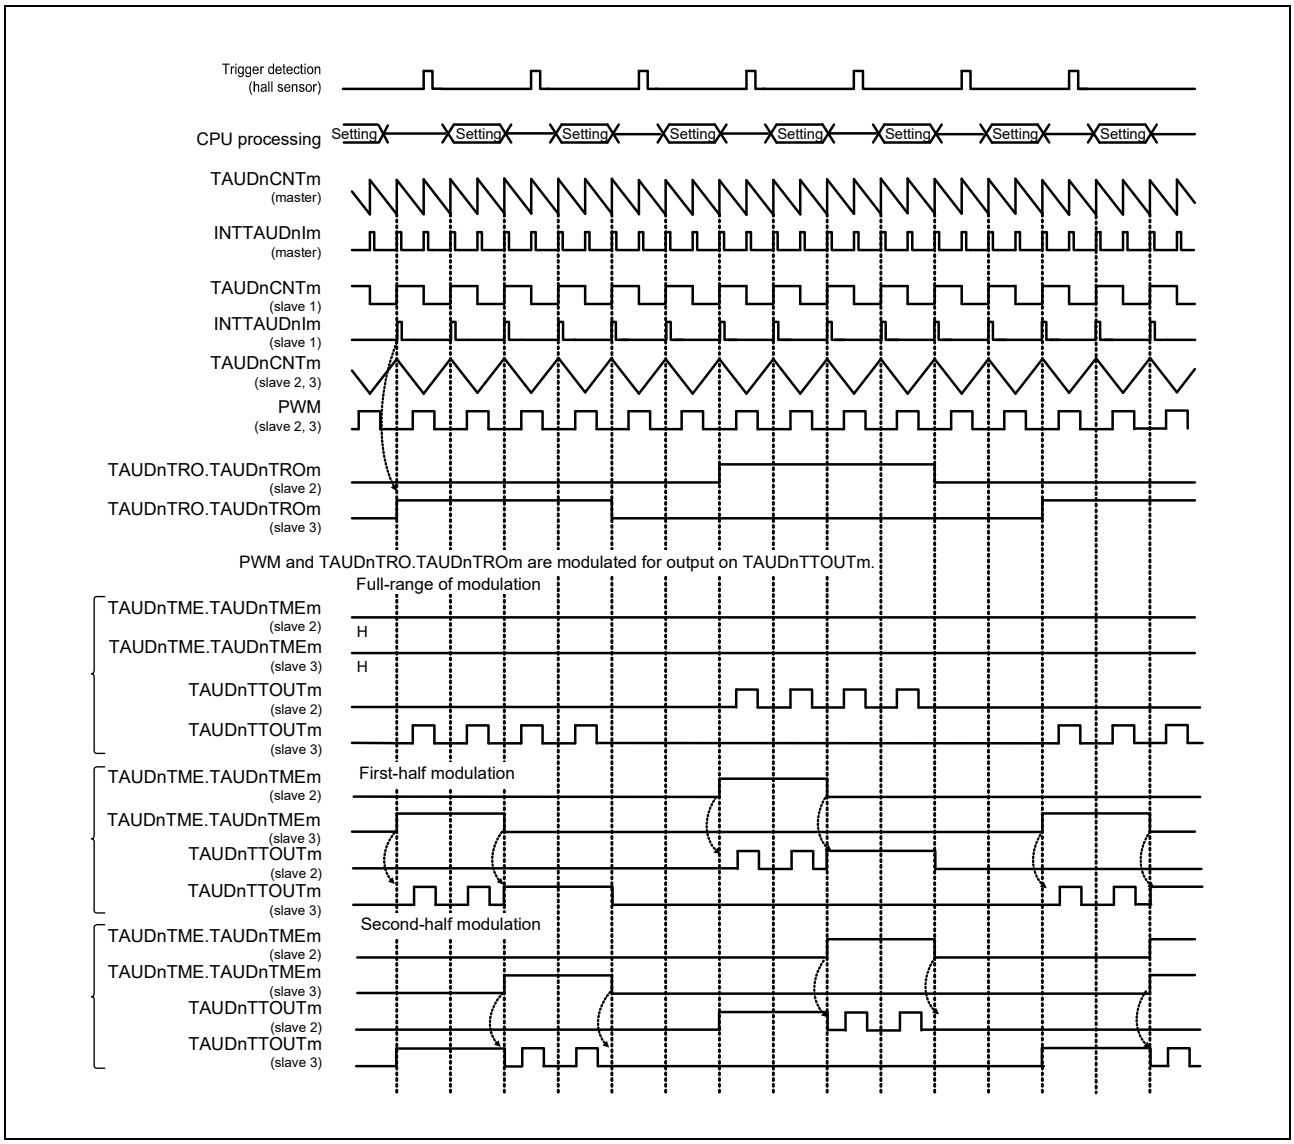

Figure 33.134 Specific Timing Diagram of Non-Complementary Modulation Output Function Type 2

The above timing diagram shows how full modulation, first-half modulation, and second-half modulation can be achieved by modifying the TAUDnTME.TAUDnTMEm bits of lower slave channels during operation.
The “Setting” symbol indicates a time period when the values of TAUDnCDRm, TAUDnTME.TAUDnTMEm, and TAUDnTRO.TAUDnTROm can be changed.
TAUDnTME.TAUDnTMEm setting is reflected by detecting the count start timing and triangle PWM carrier cycle (peak interrupt timing).
TAUDnTRO.TAUDnTROm bit value is set by software, but a new setting is applied only when an interrupt occurs on slave channel 1.

33.16.3 Complementary Modulation Output Function

33.16.3.1 Overview

Summary

This function outputs a triangle PWM output signal, a high-level signal, or low-level signal from TAUDnTTOUTm with dead time added, depending on the real-time output bit value (TAUDnTRO.TAUDnTROm) and the modulation output bit value (TAUDnTME.TAUDnTMEm) of a pair of slave channels, and an output level bit value (TAUDnTDL.TAUDnTDLm). Three pairs of channels are typically used.

Prerequisites

- One master channel and seven slave channels
- The operation mode of the master channel must be set to interval timer mode (See **Table 33.241, Contents of the TAUDnCMORm Register for the Master Channel of the Complementary Modulation Output Function**).
- The operating mode for slave channel 1 should be set to event count mode (See **Table 33.245, Contents of the TAUDnCMORm Register for Slave Channel 1 of the Complementary Modulation Output Function**).
- The operating mode for slave channels 2, 4 and 6 should be set to count-up/-down mode (See **Table 33.248, Contents of the TAUDnCMORm Register for Slave Channel 2, 4, and 6 of the Complementary Modulation Output Function**).
- The operating mode for slave channels 3, 5 and 7 should be set to one-count mode (See **Table 33.252, Contents of the TAUDnCMORm Register for Slave Channels 3, 5, and 7 of the Complementary Modulation Output Function**). In addition, as the number of occurrences of an interrupt for slave channels 3, 5 and 7 within the carrier cycle is not uniquely determined, do not use the interrupt as an interrupt source.
- The output mode for the master channels should be set to independent channel output mode 1 (See **33.7, Channel Output Modes**).
- This function does not use TAUDnTTOUTm of slave channel 1 but TAUDnTRC.TAUDnTRCm should be set to 1 (See **Section 33.7, Channel Output Modes**).
- The channel output mode for slave channels 2 to 7 should be set to synchronous channel output mode 2 with complementary modulation output (See **Section 33.7, Channel Output Modes**).

Functional description

- Master channel:
  The counter of the master channel is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The value of data register (TAUDnCDRm) of the master channel is loaded into the counter (TAUDnCNTm) and the counter starts to count down from this value.
  When the counter of master channel reaches 0000_H, INTTAUDnIm is generated. This decrements the counter value of slave channel 1 by 1 and the counter of slave channel 2 starts to count in the opposite direction.

- Slave channel 1:
  When the counter reaches 0000_H, slave channel 1 waits for the next interrupt from the master channel. And the TAUDnCDRm value is reloaded into TAUDnCNTm (slave 1) and INTTAUDnIm is generated.
  Slave channel 1 is set as a real-time output trigger channel (TAUDnTRC.TAUDnTRCm = 1). The value of real-time output bit (TAUDnTRO.TAUDnTROm) of each channel is applied to the channel that detects the occurrence of an interrupt on slave channel 1 by an interrupt. The real-time output bit value can be changed in any timing by application software but a new value is not applied until an interrupt occurs on slave channel 1.
- Slave channel 2:
  When the slave channel 2 counter reaches 0001_H, the slave channel 3 counter starts counting down. When the slave channel 3 counter reaches 0000_H, an interrupt occurs.
- Slave channels 2 and 3:
  The combined use of the master channel and slave channels 2 and 3 generates a PWM output signal. The master channel generates a PWM output cycle, slave channel 2 generates a duty cycle, and slave channel 3 generates dead time.
- Slave channels 4 to 7:
  Slave channels 4 and 6 operate like slave channel 2. Slave channels 5 and 7 operate like slave channel 3.

A signal that is output from TAUDnTTOUTm depends on a real-time output bit value (TAUDnTRO.TAUDnTROm), a modulation output bit value (TAUDnTME.TAUDnTMEm), and an output level bit value (TAUDnTDL.TAUDnTDLm) of the slave channel, as described in **Table 33.240, TAUDnTTOUTm Output (TAUDnTOL.TAUDnTOLm = 0) for a Pair of Slave Channels of Complementary Modulation Output Function**.

It is, however, prohibited that a high-level signal is output from both channel 2 and channel 3 (in order to prevent a motor driver short circuit).

Forced restart is not possible for this function. The counter can be stopped by setting TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTEm to 0. TAUDnCNTm and TAUDnTTOUTm of master and slave channels stop but retain their values. The counters can be restarted by setting TAUDnTS.TAUDnTSm to 1.

Conditions

- If TAUDnTME.TAUDnTMEm of a pair of channels is set to 1 (TAUDnTOL.TAUDnTOLm = 0):
  - If TAUDnTRO.TAUDnTROm of one channel is set to 1, TAUDnTTOUTm outputs the corresponding PWM of the channel.
  - If TAUDnTRO.TAUDnTROm of both channels is set to 0, TAUDnTTOUTm of a pair outputs a low-level signal.
- If TAUDnTME.TAUDnTMEm of a pair of channels is set to 0 (TAUDnTOL.TAUDnTOLm = 0):
  - If TAUDnTRO.TAUDnTROm is set to 1, TAUDnTTOUTm of the channel outputs a high-level signal.
  - If TAUDnTRO.TAUDnTROm is set to 0, TAUDnTTOUTm of the channel outputs a low-level signal.
- If TAUDnTOL.TAUDnTOLm is set to 1, high-level and low-level signals output from TAUDnTTOUTm are inverted. The PWM signal is negative logic.

Table 33.240 TAUDnTTOUTm Output (TAUDnTOL.TAUDnTOLm = 0) for a Pair of Slave Channels of Complementary Modulation Output Function

TAUDnTME. TAUDnTME02	TAUDnTME. TAUDnTME03	TAUDnTRO. TAUDnTRO02	TAUDnTRO. TAUDnTRO03	TAUDnTDL. TAUDnTDL02	TAUDnTDL. TAUDnTDL03	TAUDnTTOUT2 Output	TAUDnTTOUT3 Output
0	0	0	0	X	X	Low level	Low level
		0	1	1	0	Low level	High level
		1	0	0	1	High level	Low level
		1	1	X	X	Setting prohibited	Setting prohibited
1	1	0	0	X	X	Low level	Low level
		0	1	1	0	~PWM	PWM
		1	0	0	1	PWM	~PWM
		1	1	X	X	Setting prohibited	Setting prohibited

NOTES

1. In the above table, PWM indicates a positive PWM signal and ~PWM indicates an inverted PWM signal (positive logic). PWM and ~PWM are set by TAUDnTDL.TAUDnTDLm.
2. Any settings not listed above are prohibited.

- If TAUDnTME.TAUDnTMEm is continuously set to 1 while TAUDnTRO.TAUDnTROm of one of paired channels is set to 1, full modulation is applied.
- If TAUDnTME.TAUDnTMEm is set to 1 at the first half of the period while TAUDnTRO.TAUDnTROm of one of paired channels is set to 1, first-half modulation is applied.
- If TAUDnTME.TAUDnTMEm is set to 1 at the second half of the period while TAUDnTRO.TAUDnTROm of one of paired channels is set to 1, second-half modulation is applied.

- Whether dead time is added to a normal or reverse phase PWM signal when two channels become high-level signal outputs simultaneously depends on a TAUDnTDL.TAUDnTDLm bit value.
  - If TAUDnTDL.TAUDnTDLm = 0, dead time is added to a normal phase PWM signal.
  - If TAUDnTDL.TAUDnTDLm = 1, dead time is added to a reverse phase PWM signal.
  - The operation defined by a TAUDnTDL.TAUDnTDLm bit value should be conducted by application software during operation. To modify TAUDnTDL.TAUDnTDLm, rewrite it during the period when TAUDnTRO.TAUDnTROm is 00_B.
- The TAUDnCDRm value of slave channel 1 should be set to the value to generate INTTAUDnIm of slave channel 1 at a carrier cycle (peak interrupt timing).
- If TAUDnTOL.TAUDnTOLm is set to 0 on slave channels 2 to 7:
  - If TAUDnTDL.TAUDnTDLm is set to 0, TAUDnTO.TAUDnTOm is set to 0 (low) before TAUDnTE.TAUDnTEm is set to 0.
  - If TAUDnTDL.TAUDnTDLm is set to 1, TAUDnTO.TAUDnTOm is set to 1 (high) before TAUDnTE.TAUDnTEm is set to 0.
- If TAUDnTOL.TAUDnTOLm is set to 1 on slave channels 2 to 7:
  - If TAUDnTDL.TAUDnTDLm is set to 0, TAUDnTO.TAUDnTOm is set to 1 (high) before TAUDnTE.TAUDnTEm is set to 0.
  - If TAUDnTDL.TAUDnTDLm is set to 1, TAUDnTO.TAUDnTOm is set to 0 (low) before TAUDnTE.TAUDnTEm is set to 0.
- This function enables simultaneous rewrite. See **Section 33.6, Simultaneous Rewrite**.

33.16.3.2 Equations

Pulse period = (TAUDnCDRm (master) + 1) × count clock cycle

$0000_H \leq$ TAUDnCDRm (master) $< FFFF_H$

Carrier cycle (down/up) = (TAUDnCDRm (master) + 1) × 2 × count clock cycle

For slave channels 2 and 3:

PWM signal width (positive phase) = [(TAUDnCDRm (master) + 1 – TAUDnCDRm (slave 2)) × 2 – (TAUDnCDRm (slave 3) + 1)] × count clock cycle

PWM signal width (negative phase) = [(TAUDnCDRm (master) + 1 – TAUDnCDRm (slave 2)) × 2 + (TAUDnCDRm (slave 3) + 1)] × count clock cycle

For slave channels 4 to 7:

Slave channels 4 and 6 are calculated in the same way as slave channel 2, whereas slave channels 5 and 7 are calculated as slave channel 3.

33.16.3.3 Block Diagram and General Timing Diagram

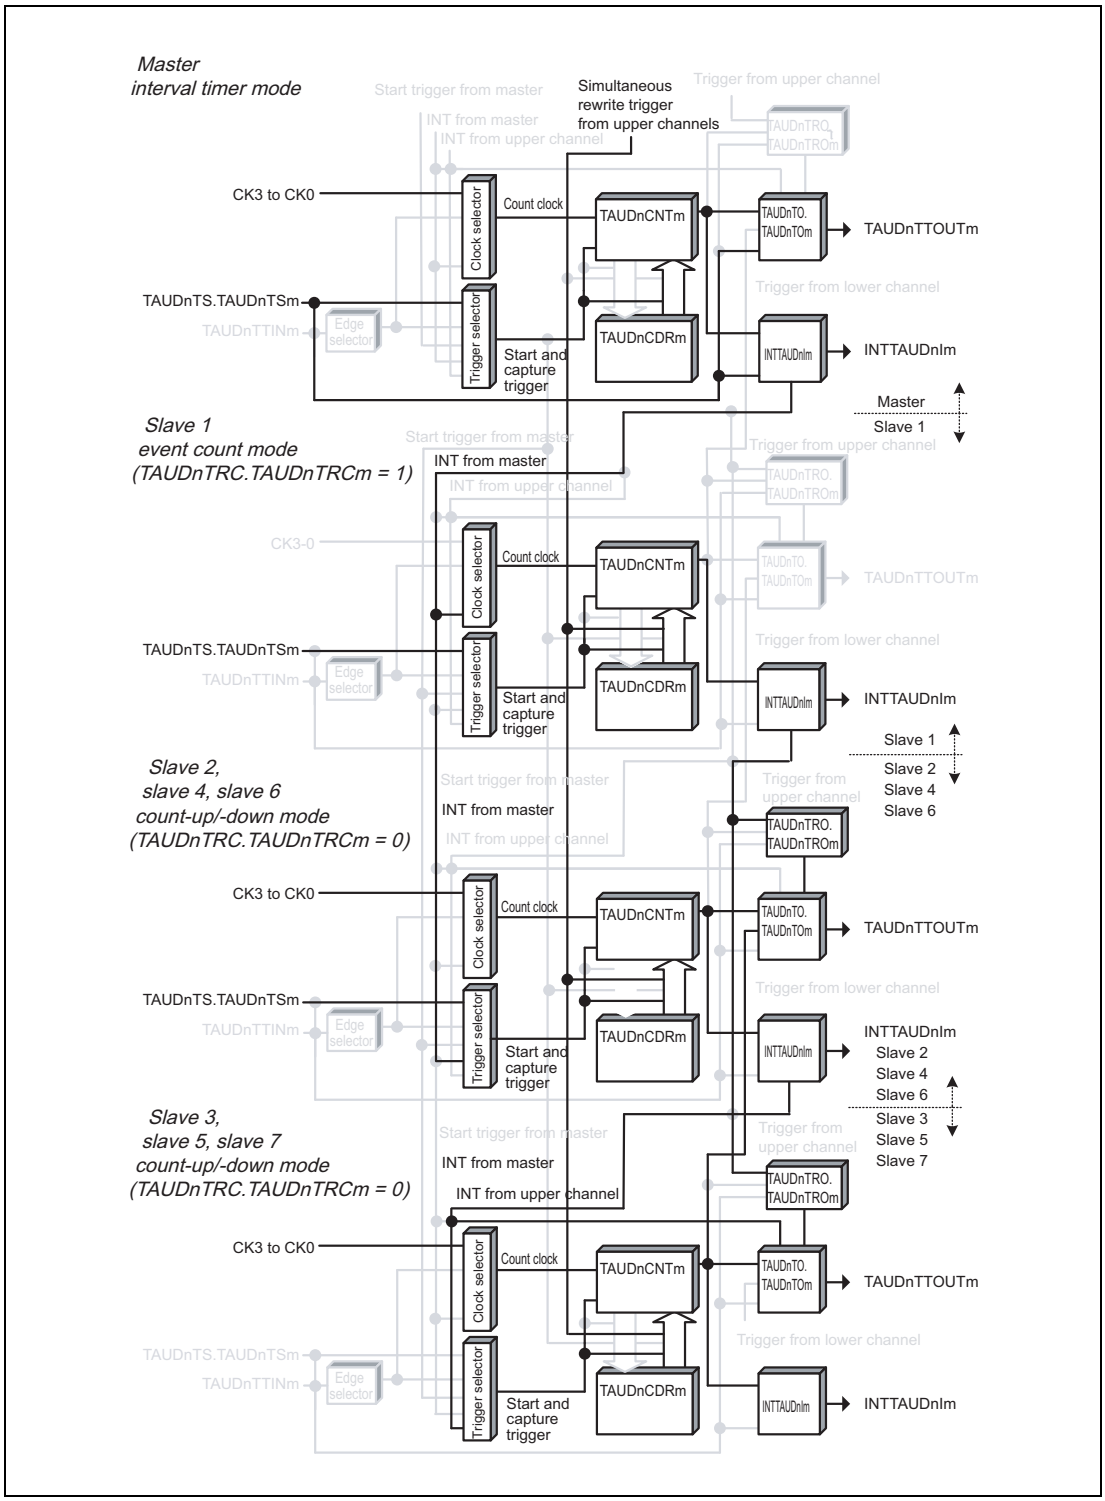

Figure 33.135 Block Diagram of Complementary Modulation Output Function

The following settings apply to the general timing diagram.

- Master channel: INTTAUDnIm is not generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 0)
- Slave channel 1: TAUDnCDRm = 0001_H

- Slave channels 2 to 7: Positive logic (TAUDnTOL.TAUDnTOLm = 0)

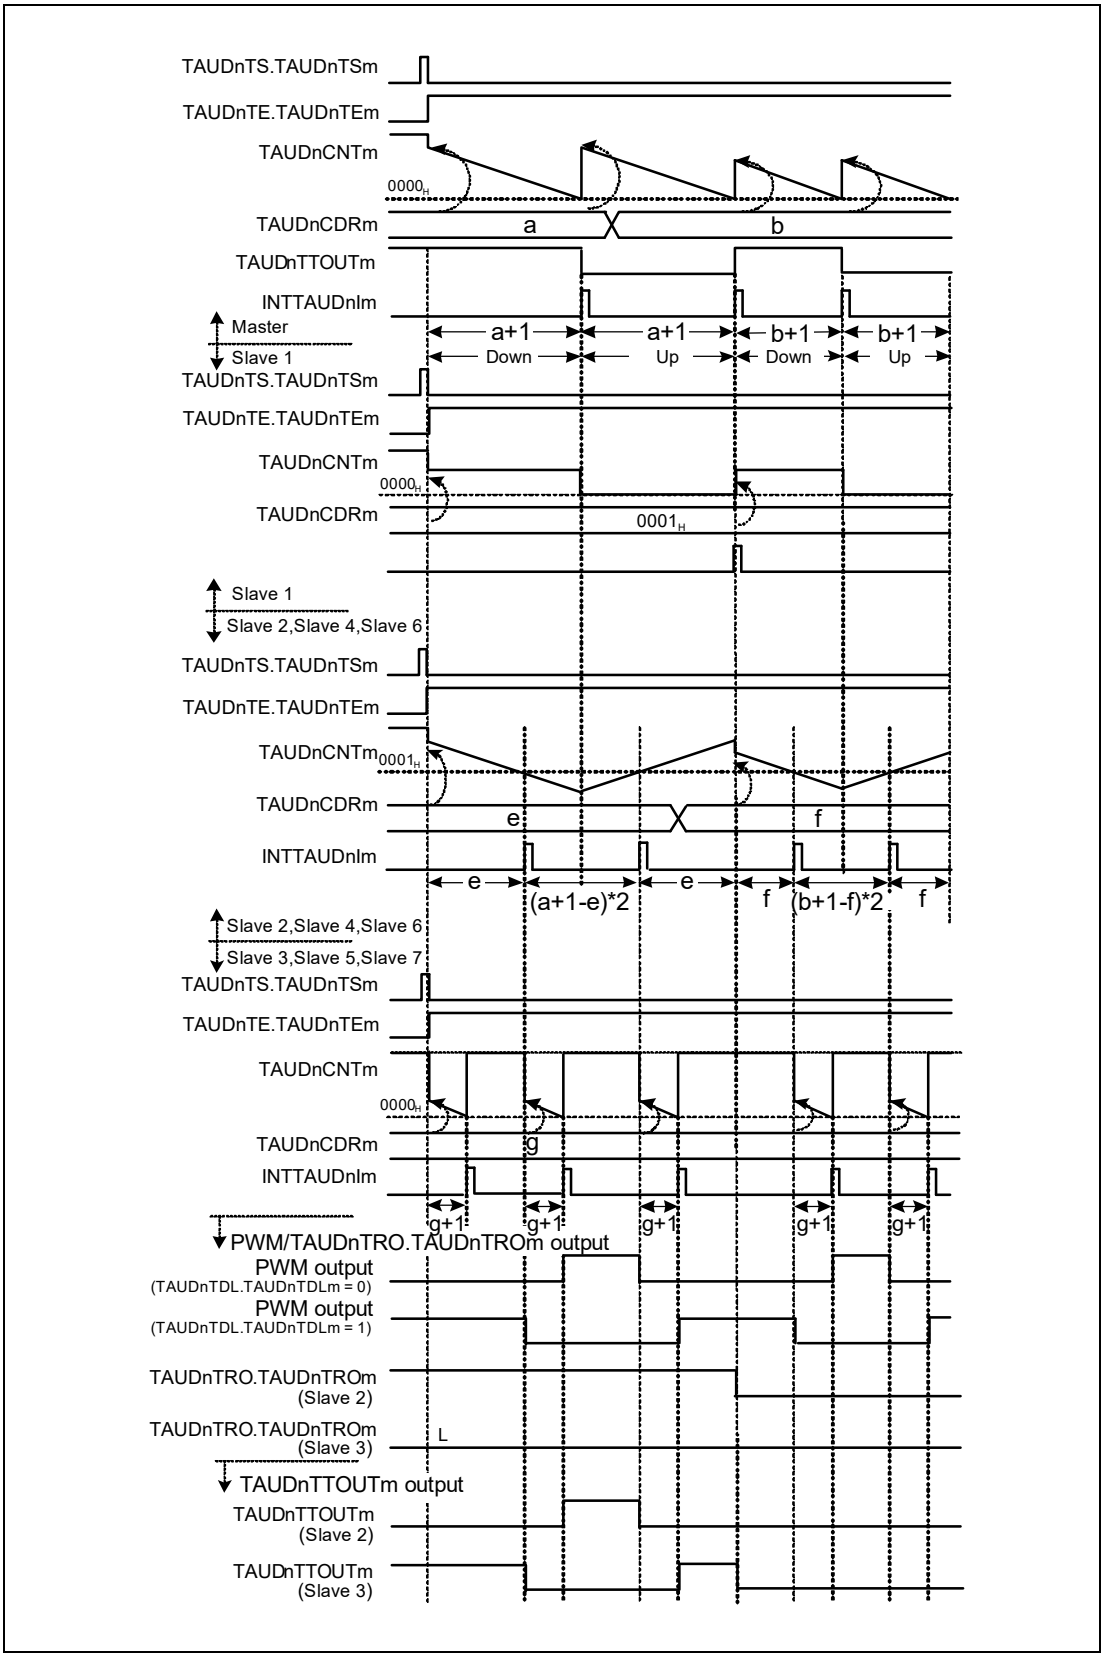

Figure 33.136 General Timing Diagram of Complementary Modulation Output Function

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operation clock as a count clock
11	TAUDnMAS	1: Master channel
10 to 8	TAUDnSTS[2:0]	000: Trigger the counter using software.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0000: Interval timer mode
0	TAUDnMD0	0: INTTAUDnIm is not generated and TAUDnTTOUTm is not toggled at the beginning of operation or at a restart time. 1: INTTAUDnIm is generated to toggle TAUDnTTOUTm at the beginning of an operation.

(2) TAUDnCMURm for the Master Channel

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.242 Contents of the TAUDnCMURm Register for the Master Channel of the Complementary Modulation Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode for The Master Channel

Table 33.243 Control Bit Settings in Independent Channel Output Mode 1

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	0: Operating mode 1 (Toggle mode if TAUDnTOM.TAUDnTOMm = 0)
TAUDnTOL.TAUDnTOLm	0: The setting is disabled in toggle mode (the value after reset).
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set these bits to 0
TAUDnTRC.TAUDnTRCm	
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous Rewrite for the Master Channel

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.244 Simultaneous Rewrite Settings for the Master Channel of Complementary Modulation Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: Simultaneous rewrite trigger signal is generated when master channel counter is started and the corresponding slave channel is at the peak of triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. Monitors master channel for simultaneous rewrite triggers, regardless of the value of this bit, when TAUDnRDS.TAUDnRDSm = 0.

NOTE

If TAUDnRDS.TAUDnRDSm = 1, it is necessary for an upper channel higher than the master channel to generate a simultaneous rewrite trigger signal.

33.16.3.5 Register Settings for Slave Channel 1

(1) TAUDnCMORm for Slave Channel 1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDn MAS	TAUDnSTS[2:0]			TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDn MD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 33.245 Contents of the TAUDnCMORm Register for Slave Channel 1 of the Complementary Modulation Output Function

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	11: INTTAUDnIm of the master channel is used as the count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	000: Trigger the counter using software. 011: Triggers simultaneous rewrite.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0011: Event count mode
0	TAUDnMD0	0: INTTAUDnIm is not generated at the beginning of operation or at a restart time.

(2) TAUDnCMURm for Slave Channel 1

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.246 Contents of the TAUDnCMURm Register for Slave Channel 1 of the Complementary Modulation Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel Output Mode

TAUDnTOE.TAUDnTOEm is set to 0 because the channel output mode is not used on slave channel 1 with this function. However, this mode can be used in independent channel output mode controlled by software.

CAUTION

TAUDnTRC.TAUDnTRCm should be set to 1 because slave channel 1 is used as a real-time output trigger channel.

(4) Simultaneous Rewrite for Slave Channel 1

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.247 Simultaneous Rewrite Settings for Slave Channel 1 of Complementary Modulation Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: Simultaneous rewrite trigger signal is generated when master channel counter is started and the corresponding slave channel is at the peak of triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. Monitors master channel for simultaneous rewrite triggers, regardless of the value of this bit, when TAUDnRDS.TAUDnRDSm = 0.

33.16.3.6 Register Settings for Slave Channels 2, 4, and 6

(1) TAUDnCMORm for Slave Channels 2, 4, and 6

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDn MAS	TAUDnSTS[2:0]			TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDn MD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 33.248 Contents of the TAUDnCMORm Register for Slave Channel 2, 4, and 6 of the Complementary Modulation Output Function

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operation clock as a count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	111: Up/down output trigger signal of master channel
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	1001: Count-up/-down mode
0	TAUDnMD0	0: INTTAUDnIm is not generated at the beginning of operation or at a restart time.

(2) TAUDnCMURm for Slave Channels 2, 4, and 6

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.249 Contents of the TAUDnCMURm Register for Slave Channel 2, 4, and 6 of the Complementary Modulation Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Output mode for Slave Channels 2, 4, and 6

Table 33.250 Control Bit Settings in Synchronous Channel Output Mode 2 with Complementary Modulation Output

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel output
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	1: Enables dead time operation.
TAUDnTDM.TAUDnTDMm	0: Adds dead time if an interrupt is detected on an even upper channel and the conditions set by TAUDnTDL.TAUDnTDLm are satisfied.
TAUDnTDL.TAUDnTDLm	0: Adds dead time to normal phase. 1: Adds dead time to reverse phase.
TAUDnTRE.TAUDnTREm	1: Enables real-time output.
TAUDnTRO.TAUDnTROm	0: Real-time output is low. 1: Real-time output is high.
TAUDnTRC.TAUDnTRCm	0: Upper channel generates a real-time output trigger for channel m.
TAUDnTME.TAUDnTMEm	0: Disables modulation 1: Enables modulation

CAUTION

At the PWM output, set TAUDnTDL.TAUDnTDLm exclusively from odd channels.

(4) Simultaneous Rewrite for Slave Channels 2, 4, and 6

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.251 Simultaneous Rewrite Settings for Slave Channels 2, 4, and 6 of Complementary Modulation Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel counter is started and the corresponding slave channel is at the peak of triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. Monitors master channel for simultaneous rewrite triggers, regardless of the value of this bit, when TAUDnRDS.TAUDnRDSm = 0.

33.16.3.7 Register settings for slave channels 3, 5, and 7

(1) TAUDnCMORm for Slave Channels 3, 5, and 7

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDn MAS	TAUDnSTS[2:0]			TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDn MD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 33.252 Contents of the TAUDnCMORm Register for Slave Channels 3, 5, and 7 of the Complementary Modulation Output Function

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operation Clock Selection 00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operation clock as a count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	110: Dead time trigger
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0100: One-count mode
0	TAUDnMD0	1: Enables start trigger detection while counting.

(2) TAUDnCMURm for Slave Channels 3, 5, and 7

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 33.253 Contents of the TAUDnCMURm Register for Slave Channel 3, 5, and 7 of the Complementary Modulation Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Output Mode for Slave Channels 3, 5, and 7

Table 33.254 Control Bit Settings in Synchronous Channel Output Mode 2 with Complementary Modulation Output

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel output
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	1: Enables dead time operation.
TAUDnTDM.TAUDnTDMm	0: Adds dead time if an interrupt is detected on an even upper channel and the conditions set by TAUDnTDL.TAUDnTDLm are satisfied.
TAUDnTDL.TAUDnTDLm	0: Adds dead time to normal phase. 1: Adds dead time to reverse phase.
TAUDnTRE.TAUDnTREm	1: Enables real-time output.
TAUDnTRO.TAUDnTROm	0: Real-time output is low. 1: Real-time output is high.
TAUDnTRC.TAUDnTRCm	0: Upper channel generates a real-time trigger for channel m.
TAUDnTME.TAUDnTMEm	0: Disables modulation 1: Enables modulation

CAUTION

At the PWM output, set TAUDnTDL.TAUDnTDLm exclusively from even channels.

(4) Simultaneous Rewrite for Slave Channels 3, 5, and 7

Both the master and slave channels should have the same simultaneous rewrite settings.

Table 33.255 Simultaneous Rewrite Settings for Slave Channels 3, 5, and 7 of Complementary Modulation Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: Simultaneous rewrite trigger signal is generated when master channel counter is started corresponding slave channel is at the peak of triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. Monitors master channel for simultaneous rewrite triggers, regardless of the value of this bit, when TAUDnRDS.TAUDnRDSm = 0.

33.16.3.8 Operating Procedure for Complementary Modulation Output Function

Table 33.256 Operating Procedure for Complementary Modulation Output Function (1/2)

	Operation	TAUDn Status
Initial Channel Setting	Master channel: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.16.3.4, Register Settings for the Master Channel**. Slave channel 1: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.16.3.5, Register Settings for Slave Channel 1**. Slave channels 2, 4, and 6: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.16.3.6, Register Settings for Slave Channels 2, 4, and 6**. Slave channels 3, 5, and 7: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in **Section 33.16.3.7, Register settings for slave channels 3, 5, and 7**. Set the value of TAUDnCDRm register of every channel. Set a pulse cycle using TAUDnCDRm of master channel, and an interrupt count of master channel to be ignored using TAUDnCDRm of slave channel 1. Also set a duty width in TAUDnCDRm of slave channels 2, 4, and 6, and a dead time delay on slave channels 3, 5, and 7. Set TAUDnTRC.TAUDnTRCm to 1 on slave channel 1.	Channel operation is stopped.

Table 33.256 Operating Procedure for Complementary Modulation Output Function (2/2)

	Operation	TAUDn Status
Start Operation	Set TAUDnTS.TAUDnTSm of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0	TAUDnTE.TAUDnTEm of master and slave channels is set to 1 and the counter starts counting down.
During Operation	TAUDnCDRm, TAUDnTRO.TAUDnTROm, TAUDnTME.TAUDnTMEm, and TAUDnTDL.TAUDnTDLm can be changed at any time. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time. TAUDnRDT.TAUDnRDTm can be changed during operation.	TAUDnCDRm value of master channel and slave channels 2 to 7 is loaded into TAUDnCNTm to perform counting down. TAUDnCDRm value of slave channel 1 is loaded and the counter waits for a master channel interrupt. When the counter of master channel reaches 0000_H: • INTTAUDnIm is generated. • TAUDnCDRm value is reloaded into TAUDnCNTm to continue counting down. • TAUDnCNTm value of slave channel 1 decrements by 1 and the counter waits for the next master channel interrupt. • TAUDnCNTm of slave channels 2, 4, and 6 reloads the TAUDnCDRm value, or performs counting in opposite direction. • At the same timing when the TAUDnCDRm value of slave channels 2, 4, and 6 is loaded, the TAUDnTME.TAUDnTMEm value of slave channels 2 to 7 is reflected to the TAUDnTTOUTm output. • The counter of slave channel 1 waits for the next interrupt from the master channel when reaching 0000_H. When the interrupt is detected: – TAUDnCDRm value is reloaded into TAUDnCNTm and the counter waits for the next master channel interrupt. – INTTAUDnIm is generated. – TAUDnTRO.TAUDnTROm is changeable. • When the counter of slave channels 2, 4, and 6 reaches 0001_H: – INTTAUDnIm is generated. – PWM output of slave channel m is set/reset (when the specified condition of the channel output mode is matched). – TAUDnCDRm value of slave channels 3, 5, and 7 is loaded into TAUDnCNTm to perform counting down. • When the counter of slave channels 3, 5, and 7 reaches 0000_H: – INTTAUDnIm is generated. – PWM output of slave channel m is set/reset (when the specified condition of the channel output mode is matched).
Stop Operation	Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

Restart Operation

33.16.3.9 Specific Timing Diagrams

The following settings apply to the timing diagram.

- Master channel: INTTAUDnIm is not generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 0).
- Slave channel 1: TAUDnCDRm = 0001_H
- Slave channels 2 to 7: Positive logic (TAUDnTOL.TAUDnTOLm = 0)

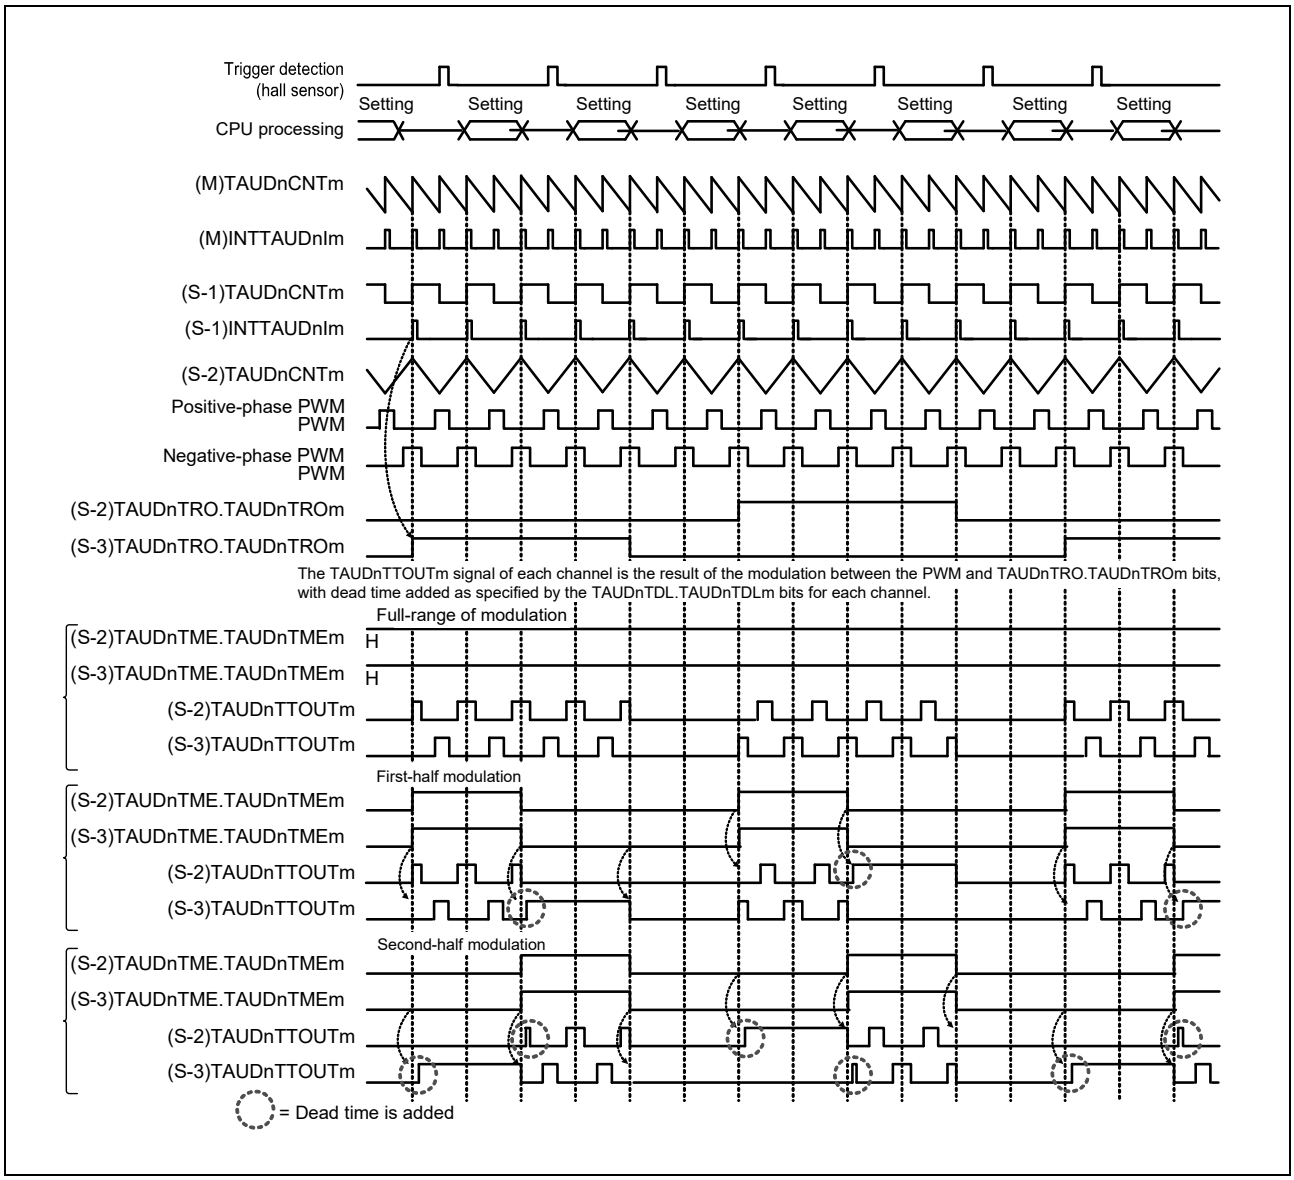

Figure 33.137 Specific Timing Diagram of Complementary Modulation Output Function

The above timing diagram shows how full modulation, first-half modulation, and second-half modulation can be achieved by modifying the TAUDnTME.TAUDnTMEm bits of lower slave channels during operation.

A modulated PWM output signal and TAUDnTRO.TAUDnTROm bit value are output from slave channels 2 and 3.

TAUDnTME.TAUDnTMEm and TAUDnTDL.TAUDnTDLm settings are reflected by detecting the count start timing and triangle PWM carrier cycle (peak interrupt timing).

TAUDnTRO.TAUDnTROm bit value is specified by software, but a new setting is applied only when an interrupt occurs on slave channel 1.

NOTE

Dead time is added to suppress simultaneous change of PWM edges of normal and reverse phases.

The “Setting” symbol indicates a time period when the values of TAUDnCDRm, TAUDnTME.TAUDnTMEm, TAUDnTRO.TAUDnTROm, and TAUDnTDL.TAUDnTDLm can be changed.

Section 34 Timer Array Unit J (TAUJ)

This section contains a generic description of the timer array unit J (TAUJ).

The first part of this section describes the RH850/U2A-EVA specific features, such as the number of units and the register base addresses.

The remainder of the section describes the functions and registers of the TAUJ.

34.1 Features TAUJ for RH850/U2A-EVA

34.1.1 Units and Channels

This microcontroller has the following number of TAUJ units.

Table 34.1 Number of Units

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of Units	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)
Name	TAUJn									

TAUJn has the following number of channels of timers.

Table 34.2 TAUJn Unit Configurations and Channels

Unit Name (Channel Name) TAUJn	Number of Channels per Unit	RH850/ U2A-EVA (516 pins) (16 ch)	RH850/ U2A16 (516 pins) (16 ch)	RH850/ U2A16 (373 pins) (16 ch)	RH850/ U2A16 (292 pins) (16 ch)	RH850/ U2A8 (373 pins) (16 ch)	RH850/ U2A8 (292 pins) (16 ch)	RH850/ U2A6 (292 pins) (16 ch)	RH850/ U2A6 (176 pins) (16 ch)	RH850/ U2A6 (156 pins) (16 ch)	RH850/ U2A6 (144 pins) (16 ch)
TAUJ0	4	√	√	√	√	√	√	√	√	√	√
TAUJ1	4	√	√	√	√	√	√	√	√	√	√
TAUJ2	4	√	√	√	√	√	√	√	√	√	√
TAUJ3	4	√	√	√	√	√	√	√	√	√	√

Table 34.3 Index

Index	Description
n	Throughout this section, the individual TAUJ units are identified by the index “n” (n = 0 to 3); for example, TAUJnTOM is the TAUJn channel output mode register.
m	The TAUJ has 4 channels. Throughout this section, the individual channels are identified by the index “m” (m = 0 to 3), thus a certain channel is denoted as CHm. The even numbered channels (m = 0, 2) are denoted as CHm_even. The odd numbered channels (m = 1, 3) are denoted as CHm_odd.

34.1.2 Register Base Addresses

TAUJn base addresses are listed in the following table.

TAUJn register addresses are given as offsets from the base addresses.

Table 34.4 Register Base Addresses

Base Address Name	Base Address	Bus Group
<TAUJ0_base>	FFBF 7000_H	P-Bus Group 5
<TAUJ1_base>	FFBF 7200_H	P-Bus Group 5
<TAUJ2_base>	FFE8 0000_H	P-Bus Group 2H
<TAUJ3_base>	FFE8 1000_H	P-Bus Group 2H

34.1.3 Clock Supply

The TAUJn clock supply is shown in the following table.

Table 34.5 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name	Description
TAUJ0	PCLK	CLK_HSB	Peripheral high speed clock
TAUJ1	PCLK	CLK_HSB	Peripheral high speed clock
TAUJ2	PCLK	CLKA_TAUJ	TAUJ2 ope. clock
TAUJ3	PCLK	CLKA_TAUJ	TAUJ3 ope. clock

34.1.4 Interrupt Requests and Error Notifications

TAUJn interrupt requests are listed in the following table.

Table 34.6 Interrupt and DMA/DTS Requests

Unit Interrupt Name	Description	Interrupt Number	DMA Trigger Number	DTS Trigger Number
TAUJ0				
INTTAUJ0I0	Channel 0 interrupt	360	Group0-240	Group1-112
INTTAUJ0I1	Channel 1 interrupt	361	Group0-241	Group1-113
INTTAUJ0I2	Channel 2 interrupt	362	Group0-242	Group1-114
INTTAUJ0I3	Channel 3 interrupt	363	Group0-243	Group1-115
TAUJ1				
INTTAUJ1I0	Channel 0 interrupt	364	Group0-244	Group1-116
INTTAUJ1I1	Channel 1 interrupt	365	Group0-245	Group1-117
INTTAUJ1I2	Channel 2 interrupt	366	Group0-246	Group1-118
INTTAUJ1I3	Channel 3 interrupt	367	Group0-247	Group1-119
TAUJ2				
INTTAUJ2I0	Channel 0 interrupt	368	Group0-248	Group1-120
INTTAUJ2I1	Channel 1 interrupt	369	Group0-249	Group1-121
INTTAUJ2I2	Channel 2 interrupt	370	Group0-250	Group1-122
INTTAUJ2I3	Channel 3 interrupt	371	Group0-251	Group1-123
TAUJ3				
INTTAUJ3I0	Channel 0 interrupt	372	Group0-252	Group1-124
INTTAUJ3I1	Channel 1 interrupt	373	Group0-253	Group1-125
INTTAUJ3I2	Channel 2 interrupt	374	Group0-254	Group1-126
INTTAUJ3I3	Channel 3 interrupt	375	Group0-255	Group1-127

This module has no error notifications.

34.1.5 Reset Sources

TAUJn reset sources are listed in the following table. TAUJn is initialized by these reset sources.

Table 34.7 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
TAUJ0	All registers	√	√	√	√	√	√	—
TAUJ1	All registers	√	√	√	√	√	√	—
TAUJ2	All registers	√	√	√	√	—	—	—
TAUJ3	All registers	√	√	√	√	—	—	—

34.1.6 External Input/Output Signals

External input/output signals of TAUJn are listed below.

Table 34.8 External Input/Output Signals (RH850/U2A-EVA) (1/2)

Unit Signal Name	Description	Alternative Port Pin Signal Name
TAUJ0		
TAUJ0TTIN0	Input for channel 0	TAUJ0I0
TAUJ0TTIN1	Input for channel 1	TAUJ0I1
TAUJ0TTIN2	Input for channel 2	TAUJ0I2
TAUJ0TTIN3	Input for channel 3	TAUJ0I3
TAUJ0TTOUT0	Output for channel 0	TAUJ0O0
TAUJ0TTOUT1	Output for channel 1	TAUJ0O1
TAUJ0TTOUT2	Output for channel 2	TAUJ0O2
TAUJ0TTOUT3	Output for channel 3	TAUJ0O3
TAUJ1		
TAUJ1TTIN0	Input for channel 0	TAUJ1I0
TAUJ1TTIN1	Input for channel 1	TAUJ1I1
TAUJ1TTIN2	Input for channel 2	TAUJ1I2
TAUJ1TTIN3	Input for channel 3	TAUJ1I3
TAUJ1TTOUT0	Output for channel 0	TAUJ1O0
TAUJ1TTOUT1	Output for channel 1	TAUJ1O1
TAUJ1TTOUT2	Output for channel 2	TAUJ1O2
TAUJ1TTOUT3	Output for channel 3	TAUJ1O3
TAUJ2		
TAUJ2TTIN0	Input for channel 0	TAUJ2I0*2
TAUJ2TTIN1	Input for channel 1	TAUJ2I1*2
TAUJ2TTIN2	Input for channel 2	TAUJ2I2*2 or TAUJ1TTOUT0*1
TAUJ2TTIN3	Input for channel 3	TAUJ2I3*2 or TAUJ1TTOUT0*1
TAUJ2TTOUT0	Output for channel 0	TAUJ2O0
TAUJ2TTOUT1	Output for channel 1	TAUJ2O1
TAUJ2TTOUT2	Output for channel 2	TAUJ2O2
TAUJ2TTOUT3	Output for channel 3	TAUJ2O3

Table 34.8 External Input/Output Signals (RH850/U2A-EVA) (2/2)

Unit Signal Name	Description	Alternative Port Pin Signal Name
TAUJ3		
TAUJ3TTIN0	Input for channel 0	TAUJ3I0
TAUJ3TTIN1	Input for channel 1	TAUJ3I1
TAUJ3TTIN2	Input for channel 2	TAUJ3I2 or RTCA0OUT*1 or TAUJ0TTOUT0*1
TAUJ3TTIN3	Input for channel 3	TAUJ3I3 or RTCA0OUT*1 or TAUJ0TTOUT0*1
TAUJ3TTOUT0	Output for channel 0	TAUJ3O0
TAUJ3TTOUT1	Output for channel 1	TAUJ3O1
TAUJ3TTOUT2	Output for channel 2	TAUJ3O2
TAUJ3TTOUT3	Output for channel 3	TAUJ3O3

Note 1. For details, see **Section 41.2.3.12, Timer Input Select Function**.

Note 2. External input from pins (TAUJ2I0-3) are not supported in DeepSTOP mode.

34.1.7 Internal Input/Output Signals

The internal input/output signals of TAUJn are listed below.

Table 34.9 Internal Input/Output Signals

Unit Signal Name	Description	Connected to
TAUJnTSSTm	Simultaneous channel start trigger input	PIC

34.2 Overview

34.2.1 Functional Overview

The TAUJ has the following functions:

- Independent channel operation function (operated using a single channel)
- Synchronous channel operation function (operated using a master channel and multiple slave channels)

The timer array unit J is used to perform various count or timer operations and to output a signal which depends on the result of the operation. It contains one prescaler block for count clock generation and 4 channels, each equipped with a 32-bit counter TAUJnCNTm and a 32-bit data register TAUJnCDRm to hold the count start value or compare value.

It also contains several control and status registers.

Independent and synchronous operation

Every channel can operate in two operating modes, either independently or in combination with other channels (synchronously). When one master channel and one or more slave channels operate in combination, the slave channels depend on the master channel.

When a channel is operated independently, it can be operated independent of all other channels.

The synchronous operation function is implemented by using a combination of channel groups (comprised of master and slave channels).

Several rules apply to the settings of channels.

34.2.2 Terms

In this section, the following terms are used.

Independent channel operation function/synchronous operation channel operation function

TAUJ has 4 channels, and provides an independent channel operation function that individual channels operate independently and a synchronous channel operation function that is implemented by using a combination of channels.

- The independent channel operation function can be used any channel independently of all other channels.
- The synchronous channel operation function is implemented by using a combination of channel groups (comprised of master and slave channels).

Several rules apply to the settings of channels.

Channel group

In the synchronous channel operation function, all channels that depend on each other are referred to as a “channel group”.

A channel group has one master channel and one or more slave channels.

Upper/lower channel

Based on the channel number m, a channel with a smaller channel number or higher channel number can be referred to as “upper” or “lower” channel:

- Upper channel: Channel with a smaller channel number
- Lower channel: Channel with a larger channel number

For instance, as to channel 2, channel 1 is an upper channel and channel 3 is a lower channel. Channel 0 is the highest channel and channel 3 is the lowest channel.

34.2.3 Functional List of Timer Operations

This timer provides the following functions by operating each channel independently or by combining multiple channels.

Table 34.10 Functional List of TAUJ Operations

Operation Function		Example
Independent Channel Operation Functions		**Section 34.4.9**
	Interval timer function	**Section 34.4.9.1**
	TAUJnTTINm input interval timer function	**Section 34.4.9.2**
	TAUJnTTINm input pulse interval measurement function	**Section 34.4.9.3**
	TAUJnTTINm input signal width measurement function	**Section 34.4.9.4**
	TAUJnTTINm input position detection function	**Section 34.4.9.5**
	TAUJnTTINm input period count detection function	**Section 34.4.9.6**
	Overflow interrupt output function (during TAUJnTTINm width measurement)	**Section 34.4.9.7**
	Overflow interrupt output function (during TAUJnTTINm input period count detection)	**Section 34.4.9.8**
Synchronous Channel Operation Functions		**Section 34.4.10**
	PWM output function	**Section 34.4.10.1**

34.2.4 TAUJ I/O and Interrupt Request Signals

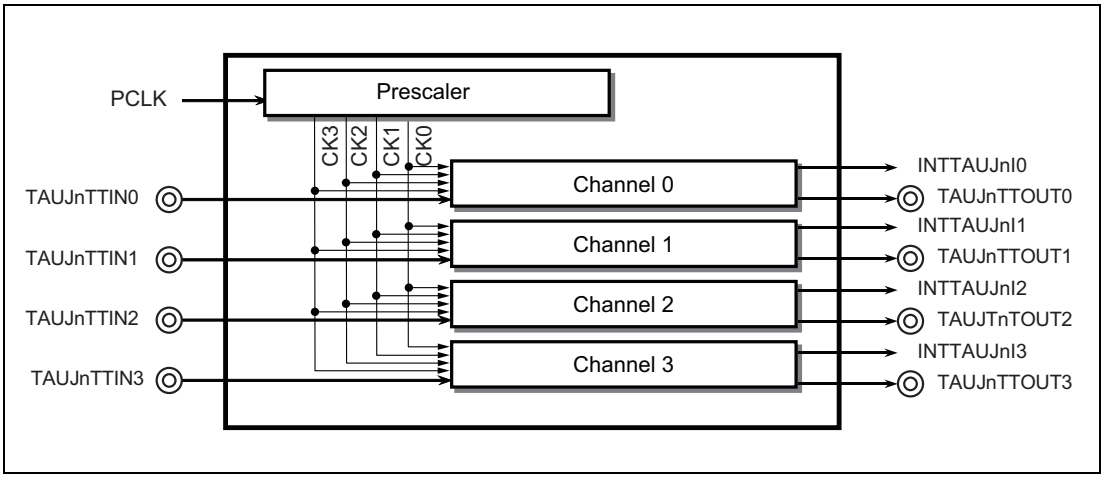

Figure 34.1 TAUJ I/O and Interrupt Request Signals

34.2.5 Block Diagram

The following figure shows the main components of the TAUJ:

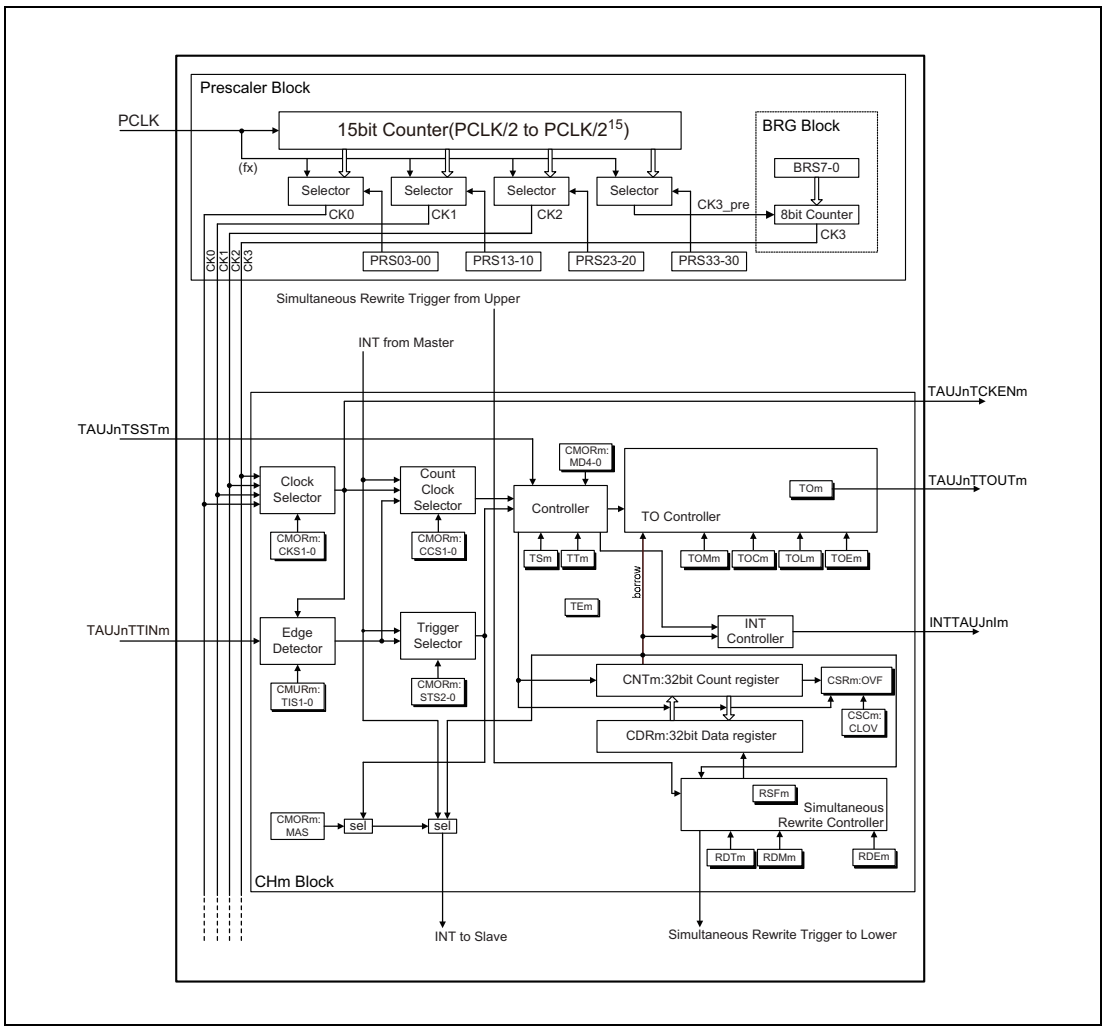

Figure 34.2 Block Diagram of the TAUJ

The prefix “TAUJn” has been omitted from the register names for the sake of clarity in the above figure.

34.2.6 Description of Block Diagram

The following describes the functional blocks.

Prescaler block

The prescaler block provides up to 4 clock signals (CK0 to CK3) that can be used as count clocks for all channels.

Count clocks CK0 to CK2 are derived by dividing PCLK in the prescaler division factor of 2^0 to 2^{15}. The fourth count clock, CK3, is derived by dividing PCLK by a division factor that is not a power of 2 by using the baud rate generator.

Clock and count clock selection

For every channel, the count clock selector selects which of the following is used as the clock source.

- One of CK0 to CK3 clocks (selected by the clock selector)

Controller

The controller controls the main operations of the counter.

- Operating mode (selected with the TAUJnCMORm.TAUJnMD[4:0] bits)
- Counter start enable (TAUJnTS.TAUJnTSm) and counter stop (TAUJnTT.TAUJnTTm)

When counter start is enabled, status flag TAUJnTE.TAUJnTEm is set.

Trigger selector

The counter starts automatically when it is enabled (TAUJnTE.TAUJnTEm = 1), or it waits for an external start trigger signal. Any of the following signals can be used as the start trigger.

- Synchronous channel start trigger input TAUJnTSSTm
- Valid edge of the TAUJnTTINm input signal
- INTTAUJnIm from the master channel

Simultaneous rewrite controller

Simultaneous rewrite control is enabled in synchronous operating modes. The data registers of all channels in a channel group (TAUJnCDRm) can be rewritten at any time. The simultaneous rewrite controller ensures that new data register values of all channels become effective at the same time.

TAUJnTO controller

The output control of every channel enables the generation of various output signals such as PWM signals.

34.3 Registers

34.3.1 List of Registers

TAUJ registers are listed in the following table.

For details about <TAUJn_base>, see **Section 34.1.2, Register Base Addresses**.

Table 34.11 List of Registers

Module Name	Register Name	Symbol	Address	Access Size	Access Protection	
					PBG	Other
TAUJn prescaler registers						
TAUJn	TAUJn prescaler clock select register	TAUJnTPS	<TAUJn_base> + 90_H	16	*1	—
	TAUJn prescaler baud rate setting register	TAUJnBRS	<TAUJn_base> + 94_H	8	*1	—
TAUJn control registers						
TAUJn	TAUJn channel data register m	TAUJnCDRm	<TAUJn_base> + m × 4_H	32	*1	—
	TAUJn channel counter register m	TAUJnCNTm	<TAUJn_base> + 10_H + m × 4_H	32	*1	—
	TAUJn channel mode OS register m	TAUJnCMORm	<TAUJn_base> + 80_H + m × 4_H	16	*1	—
	TAUJn channel mode user register m	TAUJnCMURm	<TAUJn_base> + 20_H + m × 4_H	8	*1	—
	TAUJn channel status register m	TAUJnCSRm	<TAUJn_base> + 30_H + m × 4_H	8	*1	—

34.3.2 Details of TAUJn Prescaler Registers

34.3.2.1 TAUJnTPS — TAUJn Prescaler Clock Select Register

This register specifies clocks CK0, CK1, CK2, and CK3_PRE for all channels of the PCLK prescalers. CK3 is generated by dividing CK3_PRE by the factor specified in TAUJnBRS.

Access: This register can be read or written in 16-bit units.

Address: <TAUJn_base> + 90_H

Value after reset: $FFFF_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUJnPRS3[3:0]				TAUJnPRS2[3:0]				TAUJnPRS1[3:0]				TAUJnPRS0[3:0]			
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 34.12 TAUJnTPS Register Contents (1/3)

Bit Position	Bit Name	Function
15 to 12	TAUJnPRS3 [3:0]	Specifies a CK3_PRE clock. The CK3_PRE clock is an input clock of the BRG unit which supplies CK3 operation clocks to all channels.

TAUJnPRS3[3:0]	CK3_PRE Clock
0000_B	PCLK/2^0
0001_B	PCLK/2^1
0010_B	PCLK/2^2
0011_B	PCLK/2^3
0100_B	PCLK/2^4
0101_B	PCLK/2^5
0110_B	PCLK/2^6
0111_B	PCLK/2^7
1000_B	PCLK/2^8
1001_B	PCLK/2^9
1010_B	PCLK/2^{10}
1011_B	PCLK/2^{11}
1100_B	PCLK/2^{12}
1101_B	PCLK/2^{13}
1110_B	PCLK/2^{14}
1111_B	PCLK/2^{15}

The above bits are rewritable only when all the counters using CK3 are stopped (TAUJnTE.TAUJnTEm = 0).

Table 34.12 TAUJnTPS Register Contents (2/3)

Bit Position	Bit Name	Function
11 to 8	TAUJnPRS2 [3:0]	Specifies a CK2 clock. **TAUJnPRS2[3:0]** / **CK2 Clock** 0000_B PCLK/2^0 0001_B PCLK/2^1 0010_B PCLK/2^2 0011_B PCLK/2^3 0100_B PCLK/2^4 0101_B PCLK/2^5 0110_B PCLK/2^6 0111_B PCLK/2^7 1000_B PCLK/2^8 1001_B PCLK/2^9 1010_B PCLK/2^{10} 1011_B PCLK/2^{11} 1100_B PCLK/2^{12} 1101_B PCLK/2^{13} 1110_B PCLK/2^{14} 1111_B PCLK/2^{15} The above bits are rewritable only when all the counters using CK2 are stopped (TAUJnTE.TAUJnTEm = 0).
7 to 4	TAUJnPRS1 [3:0]	Specifies a CK1 clock. **TAUJnPRS1[3:0]** / **CK1 Clock** 0000_B PCLK/2^0 0001_B PCLK/2^1 0010_B PCLK/2^2 0011_B PCLK/2^3 0100_B PCLK/2^4 0101_B PCLK/2^5 0110_B PCLK/2^6 0111_B PCLK/2^7 1000_B PCLK/2^8 1001_B PCLK/2^9 1010_B PCLK/2^{10} 1011_B PCLK/2^{11} 1100_B PCLK/2^{12} 1101_B PCLK/2^{13} 1110_B PCLK/2^{14} 1111_B PCLK/2^{15} The above bits are rewritable only when all the counters using CK1 are stopped (TAUJnTE.TAUJnTEm = 0).

Table 34.12 TAUJnTPS Register Contents (3/3)

Bit Position	Bit Name	Function
3 to 0	TAUJnPRS0 [3:0]	Specifies a CK0 clock.

TAUJnPRS0[3:0]	CK0 Clock
0000_B	PCLK/2^0
0001_B	PCLK/2^1
0010_B	PCLK/2^2
0011_B	PCLK/2^3
0100_B	PCLK/2^4
0101_B	PCLK/2^5
0110_B	PCLK/2^6
0111_B	PCLK/2^7
1000_B	PCLK/2^8
1001_B	PCLK/2^9
1010_B	PCLK/2^{10}
1011_B	PCLK/2^{11}
1100_B	PCLK/2^{12}
1101_B	PCLK/2^{13}
1110_B	PCLK/2^{14}
1111_B	PCLK/2^{15}

The above bits are rewritable only when all the counters using CK0 are stopped (TAUJnTE.TAUJnTEm = 0).

NOTE

TAUJn clock input PCLK is defined in the first part of this section, **Section 34.1.3, Clock Supply**.

34.3.2.2 TAUJnBRS — TAUJn Prescaler Baud Rate Setting Register

This register specifies the division factor of prescaler clock CK3.

CK3 is generated by dividing CK3_PRE by the factor specified in this register plus one. The PCLK prescaler for CK3_PRE is specified in TAUJnTPS. TAUJnPRS3[3:0].

Access: This register can be read or written in 8-bit units.

Address: <TAUJn_base> + 94_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	TAUJnBRS[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 34.13 TAUJnBRS Register Contents

Bit Position	Bit Name	Function
7 to 0	TAUJnBRS [7:0]	Specifies a CK3_PRE clock division factor for generating CK3.

TAUJnBRS[7:0]	CK3 Clock
$0000\ 0000_B$	CK3_PRE/1
$0000\ 0001_B$	CK3_PRE/2
$0000\ 0010_B$	CK3_PRE/3
$0000\ 0011_B$	CK3_PRE/4
...	...
$1111\ 1110_B$	CK3_PRE/255
$1111\ 1111_B$	CK3_PRE/256

34.3.3 Details of TAUJn Control Registers

34.3.3.1 TAUJnCDRm — TAUJn Channel Data Register m

This register functions either as a compare register or as a capture register, depending on the operating mode specified in TAUJnCMORm.TAUJnMD[4:1].

Access: This register can be read or written in 32-bit units.
- When this register functions as a capture register, only reading is possible. Write operation is ignored.
- When this register functions as a compare register, reading and writing is possible.

Address: <TAUJn_base> + m × 4_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 0	TAUJnCDR [31:0]	Data register for capture/compare values

34.3.3.2 TAUJnCNTm — TAUJn Channel Counter Register m

This is a channel m counter register.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <TAUJn_base> + 10_H + m × 4_H

Value after reset: FFFF $FFFF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 34.15 TAUJnCNTm Register Contents

Bit Position	Bit Name	Function
31 to 0	TAUJnCNT [31:0]	32-bit counter value

The read value depends on a counter, an operating mode change, or TAUJnTS.TAUJnTSm/ TAUJnTT.TAUJnTTm bit value.

The initial counter read value depends on the operating mode and how the counter is stopped.

- By a reset
- By a counter stop trigger (TAUJnTT.TAUJnTTm = 1)

The following table lists the initial counter read values after the counter is stopped (TAUJnTE.TAUJnTEm = 0) and re-enabled (TAUJnTS.TAUJnTSm = 1).

The table also contains the counter read value one count after the counter is enabled (TAUJnTS.TAUJnTSm = 1) with the counter waiting for a start trigger.

Table 34.16 TAUJnCNTm Read Values after Re-Enabling Counter

Mode Name	Count Method (Up/Down)	TAUJnCNTm		
		Start Value*1	After Stop Trigger	After One Count
Interval timer mode	Count down	FFFF FFFF$_H$	Stop value	—
Capture mode	Count up	0000 0000$_H$	Stop value	—
One-count mode	Count down	FFFF FFFF$_H$	Stop value	Stop value
Capture and one-count mode	Count up	0000 0000$_H$	Stop value	Capture value + 1 (TAUJnCDRm)
Count capture mode	Count up	0000 0000$_H$	Stop value	—
Gate count mode	Count down	FFFF FFFF$_H$	Stop value	Stop value
Capture and gate count mode	Count up	0000 0000$_H$	Stop value	Stop value

Note 1. The value set for the TAUJnCNTm when operating mode is changed after a reset is deasserted.

34.3.3.3 TAUJnCMORm — TAUJn Channel Mode OS Register m

This register controls channel m operation.

Access: This register can be read or written in 16-bit units.
Writable only when the counter is stopped (TAUJnTE.TAUJnTEm = 0).

Address: <TAUJn_base> + 80_H + m × 4_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

34.3.3.4 TAUJnCMURm — TAUJn Channel Mode User Register m

This register specifies a type of valid edge detection used for TAUJnTTINm input.

Access: This register can be read or written in 8-bit units.

Address: <TAUJn_base> + 20_H + m × 4_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUJnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 34.18 TAUJnCMURm Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUJnTIS[1:0]	Specifies a valid edge of TAUJnTTINm input signal. **TAUJn TIS1 / TAUJn TIS0 / Functional Description** 0 / 0 / Falling edge 0 / 1 / Rising edge 1 / 0 / Detection of falling and rising edges (selection of low width measurement) Start trigger: Falling edge Stop trigger (capture): Rising edge 1 / 1 / Detection of falling and rising edges (selection of high width measurement) Start trigger: Rising edge Stop trigger (capture): Falling edge Edge detection of TAUJnTTINm input signal is based on the operation clock selected by TAUJnCMORm.TAUJnCKS[1:0].

34.3.3.5 TAUJnCSRm — TAUJn Channel Status Register m

This register indicates the overflow status of channel m.

Access: This register is a read-only register that can be read in 8-bit units.

Address: <TAUJn_base> + 30_H + m × 4_H

Value after reset: $0X_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAUJnOVF
Value after reset	0	0	0	0	0	0	—	0
R/W	R	R	R	R	R	R	R	R

Table 34.19 TAUJnCSRm Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned.
1	Reserved	When read, an undefined value is returned.
0	TAUJnOVF	Indicates the counter overflow status: 0: No overflow occurs 1: Overflow occurs This bit is used only in the following modes: • Capture mode • Capture and one-count mode The function of this bit depends on the setting of control bits TAUJnCMORm.TAUJnCOS[1:0].

34.3.3.6 TAUJnCSCm — TAUJn Channel Status Clear Trigger Register m

This register is a trigger register for clearing the overflow flag TAUJnCSRm.TAUJnOVF of channel m.

Access: This register is a write-only register that can be written in 8-bit units.
The read value is always 00_H.

Address: <TAUJn_base> + 40_H + m × 4_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAUJnCLOV
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 34.20 TAUJnCSCm Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TAUJnCLOV	0: No function 1: Clears the overflow flag TAUJnCSRm.TAUJnOVF

34.3.3.7 TAUJnTS — TAUJn Channel Start Trigger Register

This register enables the counter operation for each channel.

Access: This register is a write-only register that can be written in 8-bit units.
The read value is always 00_H.

Address: <TAUJn_base> + 54_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnTS03	TAUJnTS02	TAUJnTS01	TAUJnTS00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	W	W	W	W

Table 34.21 TAUJnTS Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When writing, write the value after reset.
3 to 0	TAUJnTSm	Enables the counter operation for channel m: 0: No function 1: Enables the counter operation and sets TAUJnTE.TAUJnTEm = 1 Only the counter operation is enabled even if TAUJnTE.TAUJnTEm = 1. Whether the counter is started or not depends on the selected operating mode.

34.3.3.8 TAUJnTE — TAUJn Channel Enable Status Register

This register indicates whether a counter operation is enabled.

Access: This register is a read-only register that can be read in 8-bit units.

Address: <TAUJn_base> + 50_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnTE03	TAUJnTE02	TAUJnTE01	TAUJnTE00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 34.22 TAUJnTE Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is returned.
3 to 0	TAUJnTEm	Indicates whether channel m's counter operation is enabled. 0: Counter operation is disabled 1: Counter operation is enabled This bit is set to 1 when trigger input of TAUJnTSSTm (synchronous channel start trigger signal) is detected or when TAUJnTS.TAUJnTSm is set to 1. This bit is reset to 0 when TAUJnTT.TAUJnTTm is set to 1.

34.3.3.9 TAUJnTT — TAUJn Channel Stop Trigger Register

This register stops the counter operation of each channel.

Access: This register is a write-only register that can be written in 8-bit units.
The read value is always 00_H.

Address: <TAUJn_base> + 58_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnTT03	TAUJnTT02	TAUJnTT01	TAUJnTT00
Value after reset	0	0	0	0	0	0	0	0

Table 34.23 TAUJnTT Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When writing, write the value after reset.
3 to 0	TAUJnTTm	Stops channel m's counter operation. 0: No function 1: Stops the counter operation and resets TAUJnTE.TAUJnTEm TAUJnCNTm, TAUJnTO.TAUJnTOm, and TAUJnTTOUTm retain the values provided before the counter is stopped.

34.3.4 Details of TAUJn Simultaneous Rewrite Register

34.3.4.1 TAUJnRDE — TAUJn Channel Reload Data Enable Register

This register enables and disables simultaneous rewrite of the data register TAUJnCDRm. It also enables and disables simultaneous rewrite of the data register TAUJnTOLm for the PWM output function.

Access: This register can be read or written in 8-bit units.
It can only be written when TAUJnTE.TAUJnTEm = 0.

Address: <TAUJn_base> + $A0_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnRDE03	TAUJnRDE02	TAUJnRDE01	TAUJnRDE00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 34.24 TAUJnRDE Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3 to 0	TAUJnRDEm	Enables/disables simultaneous rewrite of the data register of channel m: 0: Disables simultaneous rewrite 1: Enabled simultaneous rewrite

34.3.4.2 TAUJnRDM — TAUJn Channel Reload Data Mode Register

This register selects when the signal that controls simultaneous rewrite is generated.

Access: This register can be read or written in 8-bit units.
It can only be written when TAUJnTE.TAUJnTEm = 0.

Address: <TAUJn_base> + $A4_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnRDM03	TAUJnRDM02	TAUJnRDM01	TAUJnRDM00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 34.25 TAUJnRDM Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3 to 0	TAUJnRDMm	Specifies when the signal that triggers simultaneous rewrite is generated: 0: When the master channel counter starts counting 1: No function These bits only apply when TAUJnRDE.TAUJnRDEm = 1.

34.3.4.3 TAUJnRDT — TAUJn Channel Reload Data Trigger Register

This register triggers the simultaneous rewrite enabling state.

Access: This register is a write-only register that can be written in 8-bit units. It is always read as 00_H.

Address: <TAUJn_base> + 68_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnRDT03	TAUJnRDT02	TAUJnRDT01	TAUJnRDT00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	W	W	W	W

Table 34.26 TAUJnRDT Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When writing, write the value after reset.
3 to 0	TAUJnRDTm	Triggers the simultaneous rewrite enabling state: 0: No function 1: Simultaneous rewrite enabling state is triggered. The simultaneous rewrite enabling flag (TAUJnRSFm) is set to 1. The system waits for the simultaneous rewrite trigger. These bits only apply when TAUJnRDE.TAUJnRDEm = 1.

34.3.4.4 TAUJnRSF — TAUJn Channel Reload Status Register

This flag register indicates the simultaneous rewrite status.

Access: This register is a read-only register that can be read in 8-bit units.

Address: <TAUJn_base> + $6C_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnRSF03	TAUJnRSF02	TAUJnRSF01	TAUJnRSF00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 34.27 TAUJnRSF Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is returned.
3 to 0	TAUJnRSFm	Indicates the simultaneous rewrite status. 0: Indicates that simultaneous rewrite has been completed due to generation of the simultaneous rewrite trigger. 1: Indicates that the system waits for a simultaneous rewrite trigger in the simultaneous rewrite enabling state (TAUJnRDTm = 1).

34.3.5 Details of TAUJn Output Registers

34.3.5.1 TAUJnTOE — TAUJn Channel Output Enable Register

This register enables and disables independent channel output mode controlled by software.

Access: This register can be read or written in 8-bit units.

Address: <TAUJn_base> + 60_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnTOE03	TAUJnTOE02	TAUJnTOE01	TAUJnTOE00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 34.28 TAUJnTOE Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3 to 0	TAUJnTOEm	Enables/disables Independent Channel Output Function: 0: Disables independent timer output function (controlled by software) 1: Enables independent timer output function

34.3.5.2 TAUJnTO — TAUJn Channel Output Register

This register specifies and reads the level of TAUJnTTOUTm.

Access: This register can be read or written in 8-bit units.

Address: <TAUJn_base> + $5C_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnTO03	TAUJnTO02	TAUJnTO01	TAUJnTO00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 34.29 TAUJnTO Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3 to 0	TAUJnTOm	Specifies and reads the level of TAUJnTTOUTm: 0: Low 1: High Only TAUJnTOm bits for which independent channel output function is disabled (TAUJnTOEm = 0) can be written.

34.3.5.3 TAUJnTOM — TAUJn Channel Output Mode Register

This register specifies the output mode of each channel.

Access: This register can be read or written in 8-bit units.
It can only be written when the counter is stopped (TAUJnTE.TAUJnTEm = 0).

Address: <TAUJn_base> + 98_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnTOM03	TAUJnTOM02	TAUJnTOM01	TAUJnTOM00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 34.30 TAUJnTOM Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3 to 0	TAUJnTOMm	Specifies the channel output mode: 0: Independent channel output mode 1: Synchronous channel output mode The output mode depends on the settings of channel output control (TAUJnTOE.TAUJnTOEm) bits.

34.3.5.4 TAUJnTOC — TAUJn Channel Output Configuration Register

This register specifies the output mode of each channel in combination with TAUJnTOMm.

Access: This register can be read or written in 8-bit units.
It can only be written when the counter is stopped (TAUJnTE.TAUJnTEm = 0).

Address: <TAUJn_base> + $9C_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnTOC03	TAUJnTOC02	TAUJnTOC01	TAUJnTOC00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 34.31 TAUJnTOC Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3 to 0	TAUJnTOCm	Specifies the output mode: 0: Operation mode 1 (= Toggle mode) 1: No function This bit must be set to 0 for all output modes except independent channel output mode controlled by software. The output mode also depends on TAUJnTOM.TAUJnTOMm, as shown in the following table.

TAUJn TOMm	TAUJn TOCm	Functional Description
0	0	Toggle mode: Toggling proceeds when INTTAUJnIm is generated.
0	1	No function
1	0	Synchronous channel operation mode 1: Set when INT generates on the master channel and reset when INT generates on the slave channel.
1	1	No function

34.3.5.5 TAUJnTOL — TAUJn Channel Output Active Level Register

This register specifies the output logic of the channel output bit (TAUJnTO.TAUJnTOm).

Access: This register can be read or written in 8-bit units.

Address: <TAUJn_base> + 64_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnTOL03	TAUJnTOL02	TAUJnTOL01	TAUJnTOL00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 34.32 TAUJnTOL Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3 to 0	TAUJnTOLm	Specifies the output logic of the channel m output bit (TAUJnTO.TAUJnTOm): 0: Positive logic (active high) 1: Negative logic (active low) These bits apply in all channel output modes except independent channel output mode controlled by software and independent channel output mode 1.

34.4 Operation

34.4.1 Operating Procedure

The following lists the general operation procedure for the TAUJn:

After a reset is released, the operation of each channel is stopped. Clock supply is started and writing to each register is enabled. All circuits and registers of all channels are initialized. The control register of TAUJnTTOUTm is also initialized and outputs a low level.

1. Set the TAUJnTPS and TAUJnBRS registers to specify the clock frequency of CK0 to CK3.
2. Configure the desired TAUJn function:
   - Set the operation mode
   - Set any other control bits
3. Enable the counter by setting the TAUJnTS.TAUJnTSm bit to 1.
   The counter starts to count immediately, or when an appropriate trigger is detected, depending on the bit settings.
4. If desired, and if possible for the configured function, stop the counter or perform a forced restart operation during count operation. The counter can be stopped by setting the TAUJnTT.TAUJnTTm bit to 1. The counter can be forcibly restarted by setting the TAUJnTS.TAUJnTSm bit to 1.
5. Stop the function by setting the TAUJnTT.TAUJnTTm bit to 1.

NOTES

1. A detailed description of the required control bits and the operation of the individual functions are given in **Section 34.4.9, Independent Channel Operation Functions** and **Section 34.4.10, Synchronous Channel Operation Functions**.
2. The function can be changed while the counter is stopped (TAUJnTE.TAUJnTEm = 0).

34.4.2 Concepts of Synchronous Channel Operation Function

The synchronous channel operation function is implemented by using a combination of channel groups (comprised of master and slave channels).

Several rules apply to the settings of channels.

These rules are detailed in **Section 34.4.2.1, Rules of Synchronous Channel Operation Function**.

The synchronous channel operation function are detailed in the following section.

- **Section 34.4.10, Synchronous Channel Operation Functions**

34.4.2.1 Rules of Synchronous Channel Operation Function

Number of master and slave channels

- Only even channels (CH0, CH2) can be set as master channels. Any channel other than CH0 can be set as a slave channel.
- Only channels lower than the master channel can be set as slave channels, and multiple slave channels can be set for one master channel.
  Example: If CH2 is a master channel, CH3 can be set as slave channel.
- If two master channels are used, slave channels cannot cross the master.
  Example: If CH0 and CH2 are master channels, CH1 can be set as slave channel for CH0, but CH3 cannot.

Operation clock

- The same operation clock should be set for the master channel and the synchronized slave channel. This is achieved by setting the same value in the TAUJnCMORm.TAUJnCKS[1:0] bits of the master and slave channels.

The basic concepts of master/slave usage and operation clocks are illustrated in **Figure 34.3**.

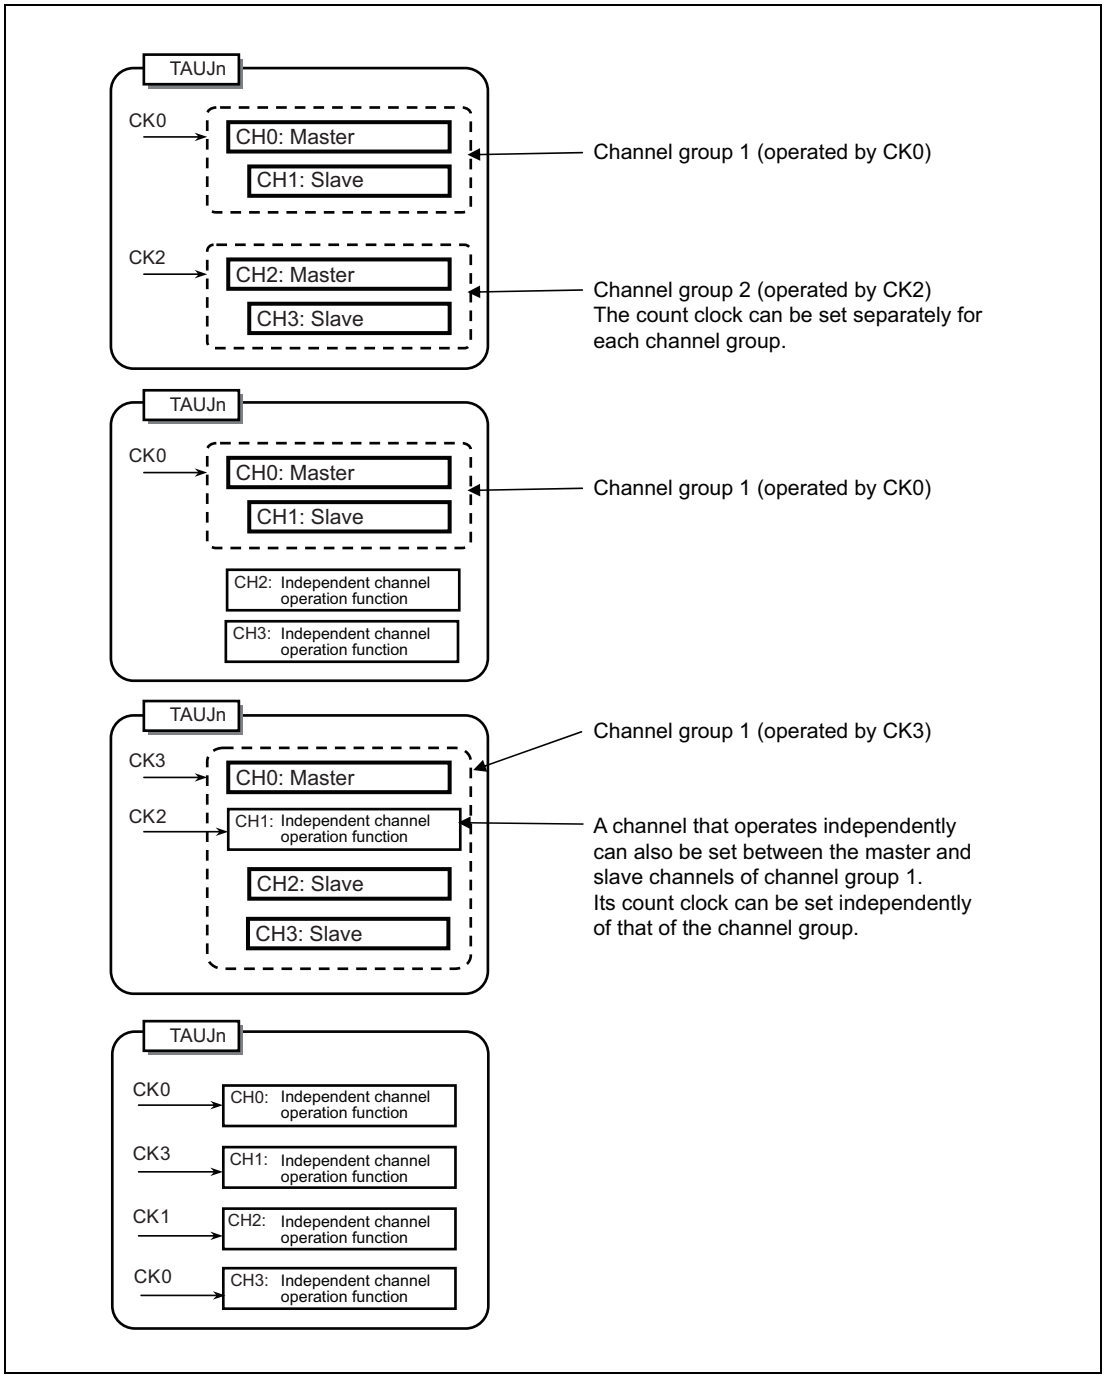

Figure 34.3 Grouping of Channels and Assignment of Operation Clocks

34.4.2.2 Simultaneous Start and Stop of Synchronous Channel Counters

Channels that are operated synchronously can be started and stopped simultaneously, both within a TAUJ unit and between TAUJ units.

(1) Simultaneous Start and Stop within a TAUJ Unit

- To simultaneously start synchronized channels, the TAUJnTS.TAUJnTSm bits of the channels should be set at the same time.
- To simultaneously stop synchronized channels, the TAUJnTT.TAUJnTTm bits of the channels should be set at the same time.

Setting 1 in the TAUJnTS.TAUJnTSm bits sets the corresponding TAUJnTE.TAUJnTEm bits to 1, enabling counting. The count start timing of the counter depends on the operating mode.

(2) Simultaneous Start between TAUJ Units

Counters in different TAUJ units can also be started simultaneously if the corresponding counters are enabled before receiving the simultaneous trigger signal.

34.4.3 Simultaneous Rewrite

34.4.3.1 How to Control Simultaneous Rewrite

The following figure shows the general procedure for simultaneous rewrite. The three main blocks (Initial settings, Start counter & count operation, and Simultaneous rewrite) are explained afterwards.

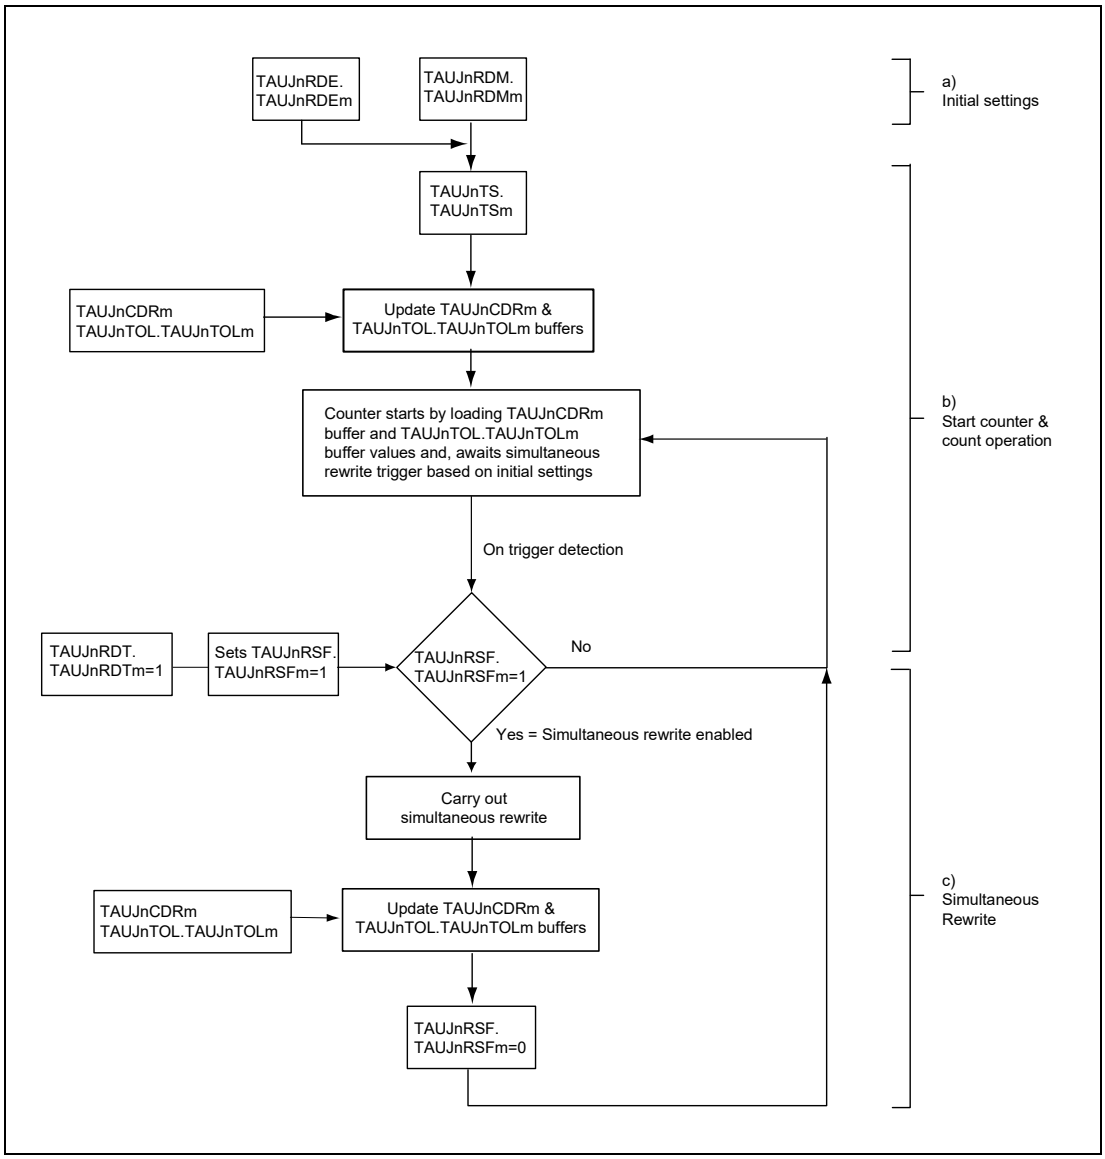

Figure 34.4 General Procedure for Simultaneous Rewrite

(1) Initial Settings

- To enable simultaneous rewrite in channel m, set TAUJnRDE.TAUJnRDEm = 1
- To select simultaneous rewrite when the master channel starts counting, set TAUJnRDM.TAUJnRDMm.

(2) Start Counter and Count Operation

- To start all the TAUJnCNTm counters in the channel group, set the corresponding TAUJnTS.TAUJnTSm bits to 1. The values of TAUJnTOL.TAUJnTOLm and the values in the data registers (TAUJnCDRm) are loaded into the corresponding TAUJnTOL.TAUJnTOLm buffer (TAUJnTOL.TAUJnTOLm buf) and data buffer registers (TAUJnCDRm buf) and the counters start.
- Setting the reload data trigger bit (TAUJnRDT.TAUJnRDTm) to 1 sets the reload flag (TAUJnRSF.TAUJnRSFm) to 1, enabling simultaneous rewrite. TAUJnRSF.TAUJnRSFm remains set to 1 until simultaneous rewrite is completed.
- When a specified trigger for simultaneous rewrite is detected, the TAUJnRSF.TAUJnRSFm bit is checked to see if simultaneous rewrite is enabled (TAUJnRSF.TAUJnRSFm = 1). If enabled, simultaneous rewrite is carried out. Otherwise simultaneous rewrite is not carried out and the system waits for detection of the next simultaneous rewrite trigger.

(3) Simultaneous Rewrite

- When the simultaneous rewrite trigger is detected and simultaneous rewrite is enabled (TAUJnRSF.TAUJnRSFm = 1), the current values of the data registers are copied to their buffers. These values are then loaded into the corresponding counters and the values are applied the next time the counter starts or restarts.
- When the simultaneous rewrite is complete, the TAUJnRSF.TAUJnRSFm bit is set to 0, and the system awaits the next simultaneous rewrite trigger.

34.4.3.2 Other General Rules for Simultaneous Rewrite

The following rules also apply.

- TAUJnRDE.TAUJnRDEm and TAUJnRDM.TAUJnRDMm cannot be changed while the counter is in operation (TAUJnTE.TAUJnTEm = 1).
- TAUJnTOL.TAUJnTOLm can be rewritten only during operation using the PWM output function. For all other functions, TAUJnTOL.TAUJnTOLm should be written before the counter starts. If it is rewritten while any other function is used, TAUJnTTOUTm outputs an invalid waveform.

34.4.3.3 Simultaneous Rewrite Procedure

The simultaneous rewrite procedure with PWM output function is described in the following figure.

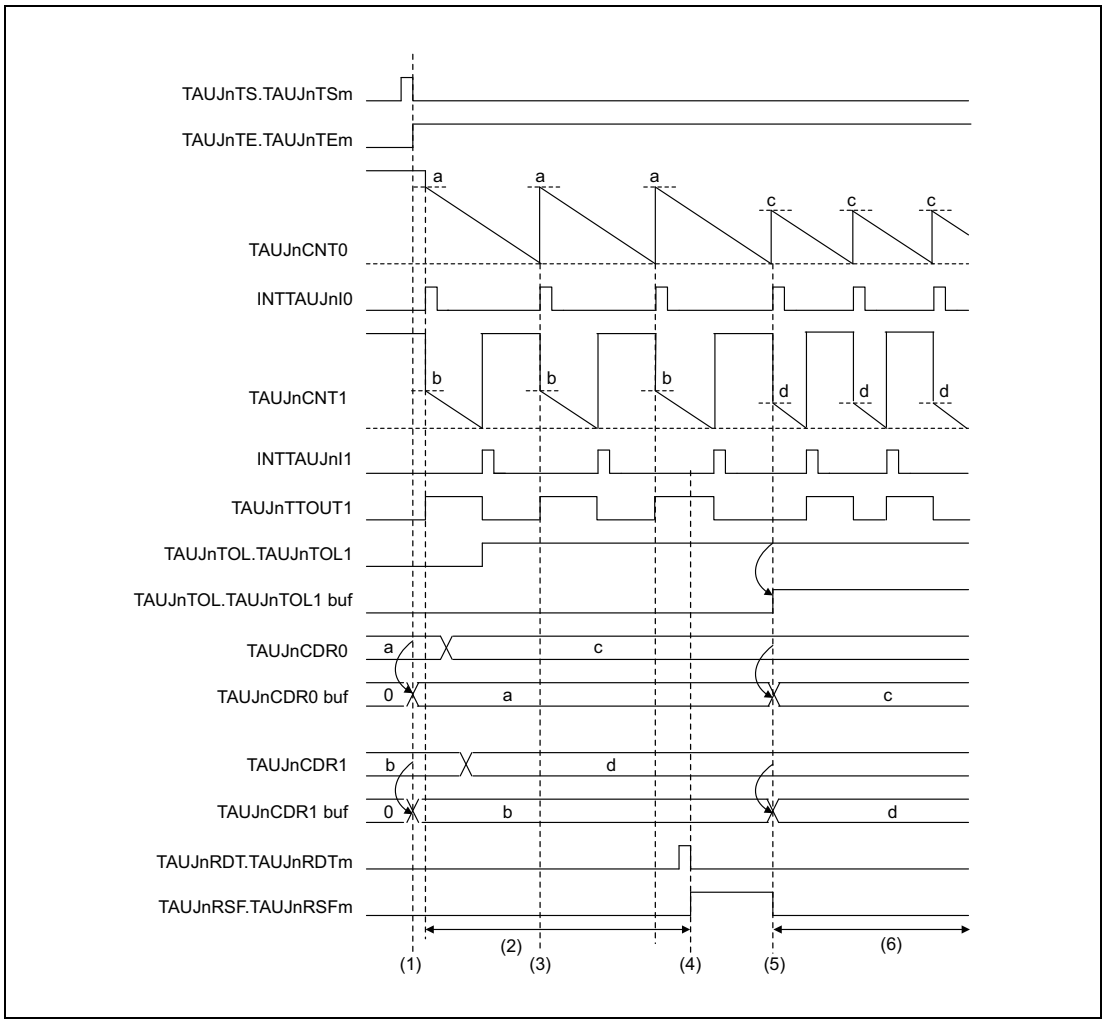

Figure 34.5 Simultaneous Rewrite with PWM Output Function

Setting:

CH0 is a master channel of PWM output function, and CH1 is a slave channel of PWM output function. Simultaneous rewrite is applied when the master channel starts counting.

Description:

(1) When TAUJnTS.TAUJnTSm = 1 is set, the value of TAUJnCDRm is copied to the TAUJnCDRm buffer and the value of TAUJnTOL.TAUJnTOLm is copied to the TAUJnTOL.TAUJnTOLm buffer.

(2) The TAUJnCDRm and TAUJnTOL.TAUJnTOLm registers can be written at any time.

(3) CH0 restarts counting, but simultaneous rewrite does not occur because it is disabled (TAUJnRSF.TAUJnRSFm = 0).

(4) The reload data trigger bit (TAUJnRDT.TAUJnRDTm) is set to 1 which sets the status flag (TAUJnRSF.TAUJnRSFm = 1), enabling simultaneous rewrite.

(5) Simultaneous rewrite is triggered when CH0 restarts counting, because simultaneous rewrite is enabled. The TAUJnCDRm value is loaded into the TAUJnCDRm buffer and the TAUJnTOL.TAUJnTOLm value is loaded into the TAUJnTOL.TAUJnTOLm buffer.

(6) The counters count down and await the next simultaneous rewrite trigger. The values of TAUJnCDRm and TAUJnTOL.TAUJnTOLm can be changed again.

34.4.4 Channel Output Modes

The output of the TAUJnTTOUTm pin can be controlled in two ways, the latter of which can be further split into individual modes.

- By software (TAUJnTOE.TAUJnTOEm = 0)
  When controlled by software, the value written in the output register bit (TAUJnTO.TAUJnTOm) is sent to the output pin (TAUJnTTOUTm).
- By TAUJ signals (TAUJnTOE.TAUJnTOEm = 1)
  When controlled by TAUJ signals, the output level of TAUJnTTOUTm is set or reset or toggled by internal signals. The value of TAUJnTO.TAUJnTOm is updated accordingly to reflect the value of TAUJnTTOUTm.
  - Independently (TAUJnTOM.TAUJnTOMm = 0)
    In case of independent operation, the output of the TAUJnTTOUTm pin is only affected by settings of channel m. Therefore, independent channel operation should be selected (TAUJnTOM.TAUJnTOMm = 0).
  - Synchronously (TAUJnTOM.TAUJnTOMm = 1)
    In case of synchronous operation, the output of the TAUJnTTOUTm pin is affected by settings of channel m and those of other channels. Therefore, synchronous channel operation should be selected for all synchronized channels (TAUJnTOM.TAUJnTOMm = 1).

The TAUJnTO.TAUJnTOm bit can always be read to determine the current value of TAUJnTTOUTm, regardless of whether the pin is controlled by software, operated independently, or operated synchronously.

Control bits

The settings of the control bits required to select a specific channel output mode are listed in **Table 34.33, Channel Output Modes**.

The channel output modes are described in details below.

- **Section 34.4.4.2, Channel Output Modes Controlled Independently by TAUJn Signals**
- **Section 34.4.4.3, Channel Output Modes Controlled Synchronously by TAUJn Signals**

Batch operation of TAUJnTOm bit

Whether a set value is reflected to the TAUJnTO.TAUJnTOm bit or not is controlled by the TAUJnTOE.TAUJnTOEm bit.

The TAUJnTO.TAUJnTOm setting is written only to the bit (channel) set with TAUJnTOE.TAUJnTOEm bit = 0 when a write to the TAUJnTO register is attempted.

No TAUJnTO.TAUJnTOm setting is reflected to the bit (channel) set with TAUJnTOE.TAUJnTOEm bit = 1.

NOTE

TAUJnTO.TAUJnTOm bit is placed so that its bit number corresponds to a channel number.

Output logic

Positive logic or negative logic of the output is specified by control bit TAUJnTOL.TAUJnTOLm.

The value of TAUJnTOL.TAUJnTOLm bit should be set before the counter is started. It can only be changed during operation with PWM output function. Otherwise, changes to TAUJnTOL.TAUJnTOLm result in an undefined TAUJnTTOUTm signal output.

See **Section 34.4.3, Simultaneous Rewrite**.

The various channel output modes and the channel output control bits are listed in **Table 34.33**.

Table 34.33 Channel Output Modes

Channel Output Mode	TAUJnTOE. TAUJnTOEm	TAUJnTOM. TAUJnTOMm
By software		
Independent channel output mode controlled by software	0	x
By TAUJ signals, independently		
Independent channel output mode 1	1	0
By TAUJ signals, synchronously		
Synchronous channel output mode 1	1	1

- All combinations not listed is this table are forbidden.
- Bits marked with an x can be set to any value.

NOTE

The following bits cannot be changed during count operation (TAUJnTE.TAUJnTEm = 1):

- TAUJnTOM.TAUJnTOMm
- TAUJnTOC.TAUJnTOCm

34.4.4.1 General Procedures for Specifying a Channel Output Mode

This section describes the general procedures for specifying a TAUJnTTOUTm channel output mode. The prerequisite is that timer output operation is disabled (TAUJnTOE.TAUJnTOEm = 0).

(1) Set TAUJnTO.TAUJnTOm to specify the initial level of the TAUJnTTOUTm output.

(2) Set channel output mode according to Table 34.33, Channel Output Modes, and the output logic using the TAUJnTOL.TAUJnTOLm bit.

(3) Start the counter (TAUJnTS.TAUJnTSm = 1).

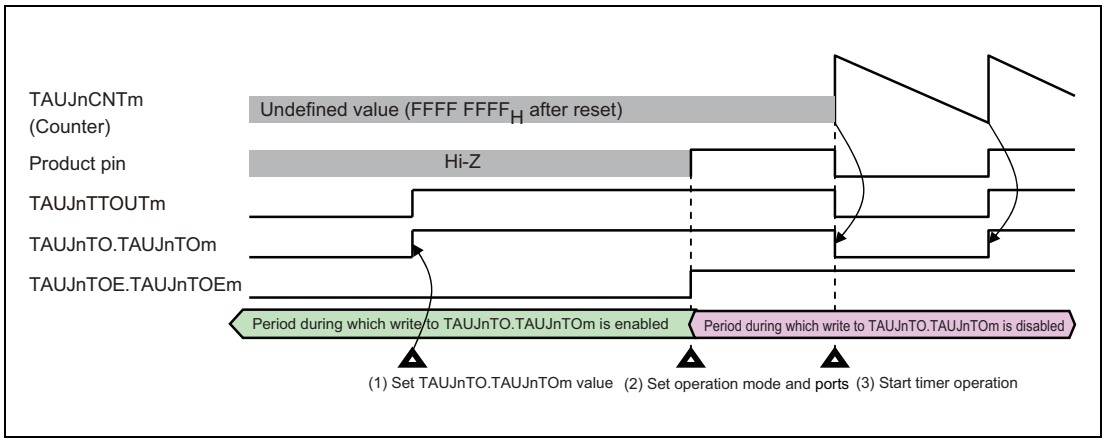

Figure 34.6 General Procedure for Specifying a TAUJnTTOUTm Channel Output Mode

34.4.4.2 Channel Output Modes Controlled Independently by TAUJn Signals

This section lists the channel output modes that are controlled independently by TAUJn signals. The control bits used to specify a mode are listed in **Table 34.33, Channel Output Modes**.

(1) Independent Channel Output Mode 1

Set/reset conditions

In this output mode, TAUJnTTOUTm toggles when INTTAUJnIm is detected.

The value of TAUJnTOL.TAUJnTOLm is ignored.

Prerequisites

There are no prerequisites other than those shown in **Table 34.33, Channel Output Modes**.

34.4.4.3 Channel Output Modes Controlled Synchronously by TAUJn Signals

This section lists the channel output modes that are controlled synchronously by TAUJn signals. The control bits used to specify a mode are listed in **Table 34.33, Channel Output Modes**.

(1) Synchronous Channel Output Mode 1

Set/reset conditions

In this output mode, INTTAUJnIm of master channel serves as a set signal and INTTAUJnIm of the slave channel as a reset signal. If INTTAUJnIm of the master channel and INTTAUJnIm of the slave channel are generated at the same time, INTTAUJnIm of the slave channel (reset signal) has priority over INTTAUJnIm (set signal) of the master channel, i.e., the master channel is ignored.

Prerequisites

There are no prerequisites other than those shown in **Table 34.33, Channel Output Modes**.

34.4.5 Start Timing in Each Operating Modes

This section describes the timing at which the counter starts after TAUJnTS.TAUJnTSm is set to 1 in each operating mode.

In all modes, the value of data register and whether or not an interrupt occurs depends on mode and register settings.

CAUTION

The count start timing described in this section is for your reference. Actually, the count start timing depends on the count clock timing.

34.4.5.1 Interval Timer Mode, Capture Mode, and Count Capture Mode

The counter starts operating with the next count clock cycle after TAUJnTS.TAUJnTSm is set to 1. The value of data register is also loaded when the counter starts.

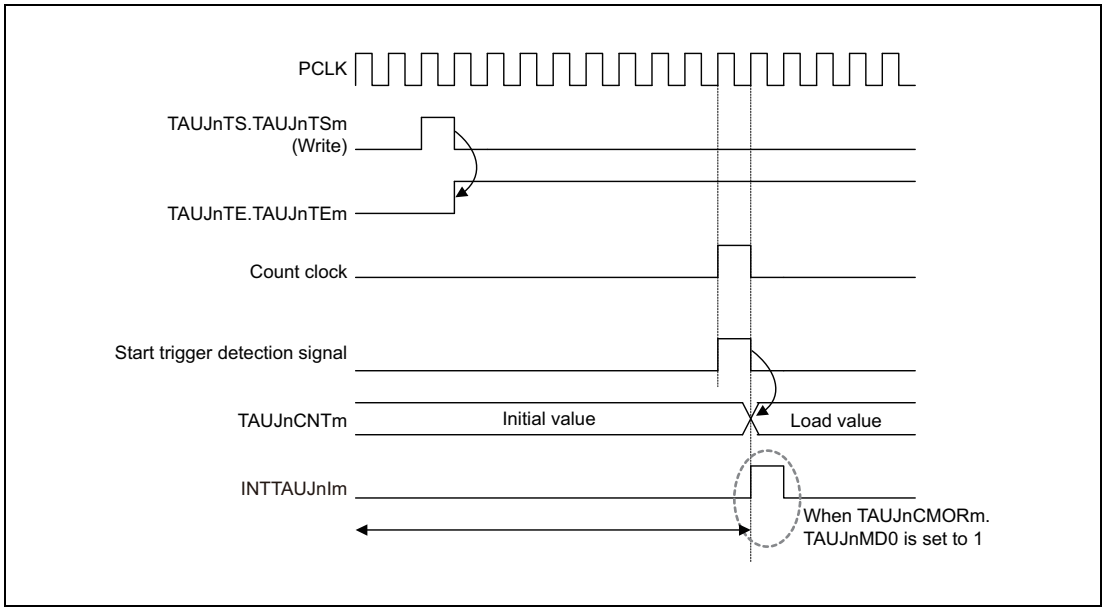

Figure 34.7 Start Timing in Interval Timer Mode, Capture Mode, and Count Capture Mode

34.4.5.2 Other Operating Modes

In other operating modes, count clock cycle is irrelevant to start of counter operation. The counter operation start timing is triggered only upon detection of a valid edge of TAUJnTTINm. Once the counter starts, the value of data register is also loaded. The count clock cycles, which is irrelevant to start of counter operation, determine the frequency with which all operations take place.

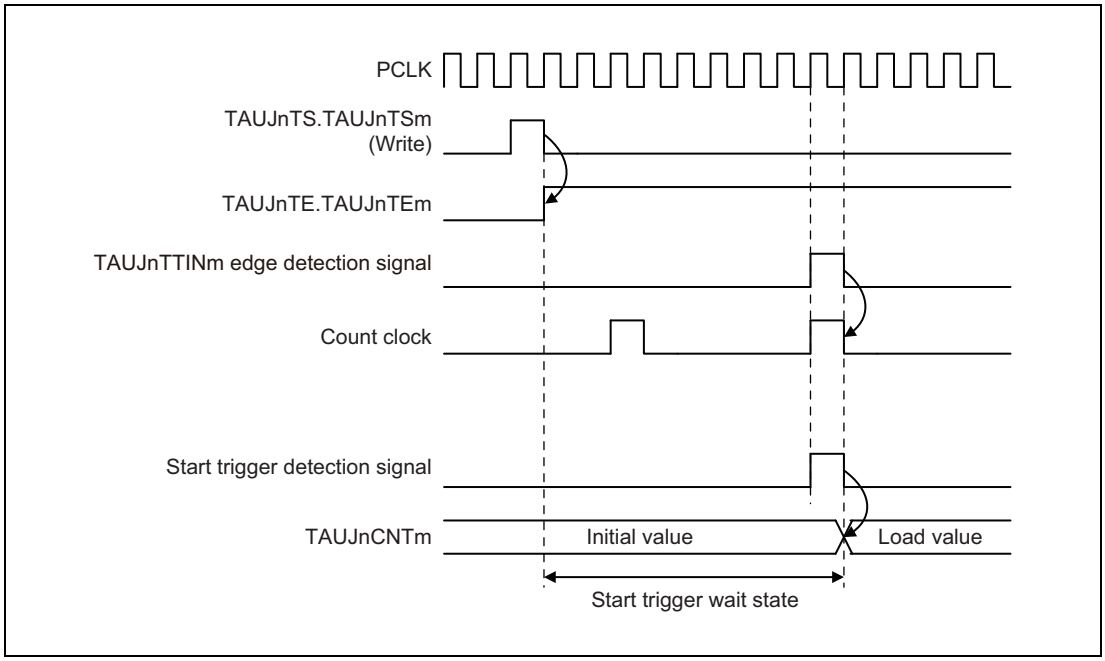

Figure 34.8 Count Start Timing in Other Operating Modes

34.4.6 TAUJnTTOUTm Output and INTTAUJnIm Generation when Counter Starts or Restarts

When the counter starts, it is possible to specify whether an INTTAUJnIm is generated using the TAUJnCMORm.TAUJnMD0 bit. The generation of INTTAUJnIm when the TAUJnCMORm.TAUJnMD0 bit starts counting and the effect to TAUJnTTOUTm depend on the selected function. For details, refer to the description of TAUJnCMORm.TAUJnMD0 of each function.

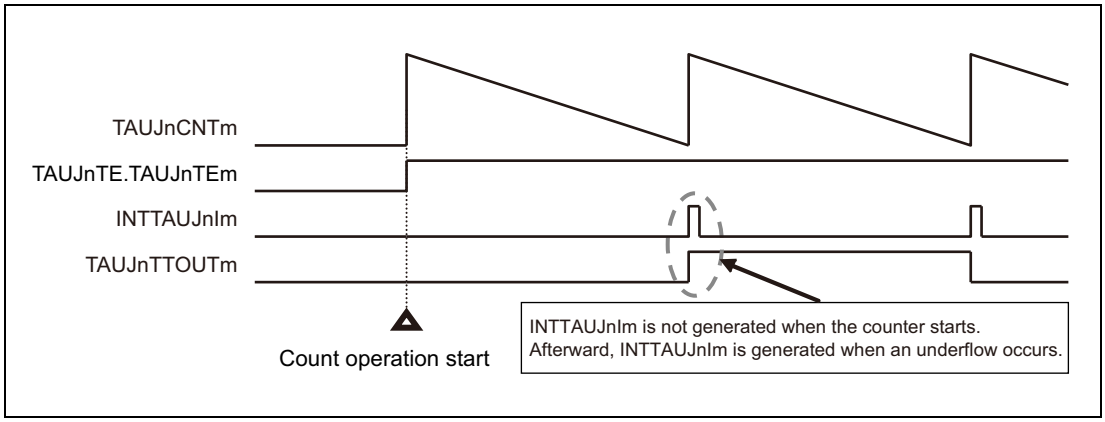

Figure 34.9 INTTAUJnIm Generation Timing (when TAUJnCMORm.TAUJnMD0 = 0)

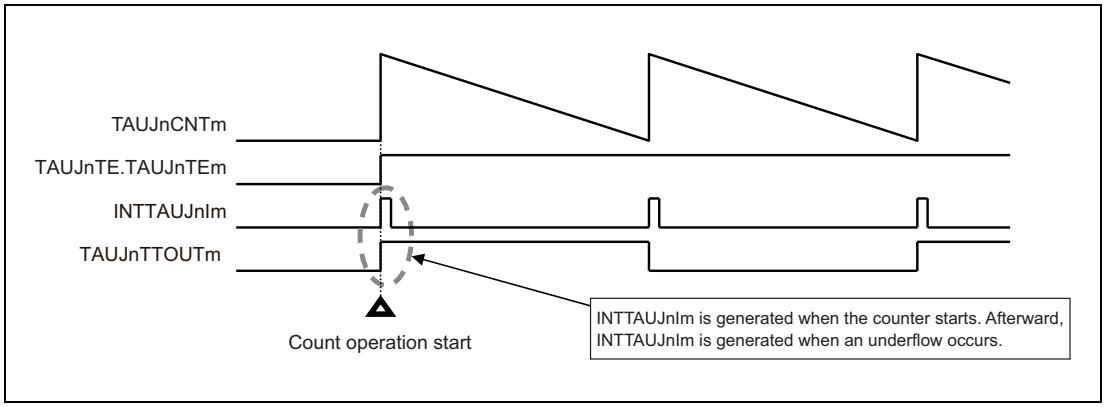

Figure 34.10 INTTAUJnIm Generation Timing (when TAUJnCMORm.TAUJnMD0 = 1)

34.4.7 Interrupt Generation upon Overflow

In certain independent functions, an interrupt is not generated when the counter value reaches FFFF FFFF$_H$ and an overflow occurs during count-up. This section describes how to generate an interrupt by combining channel operations in a mode that counts up and in a mode that counts down.

The appropriate operation mode for the second channel depends on the operation mode of the first channel. Nevertheless, the principle is the same for all combinations:

- Find an operation mode for the second channel that counts down in such a manner, that it reaches 0000 0000$_H$ at the same time as the first channel overflows (TAUJnCNTm = FFFF FFFF$_H$).
- Set TAUJnCDRm of the second channel to FFFF FFFF$_H$.
- The two channels must count at the same speed (i.e. they must have the same count clock).
- Both channels are triggered by the same TAUJnTTINm input.
- The trigger detection settings (TAUJnCMORm.TAUJnSTS[2:0] and TAUJnCMURm.TAUJnTIS[1:0]) must be identical for both channels.

Result:

The down-counter of the second channel reaches 0000 0000$_H$ at exactly the same time as the up-counter of the first channel overflows (TAUJnCNTm = FFFF FFFF$_H$). Thus the second channel generates the desired interrupt.

The following sections list the operating modes that count down that are required to match specific operating modes that count up, as well as example timing diagrams.

34.4.7.1 Combination of the TAUJnTTINm Input Position Detection Function and the Interval Timer Function

When the capture trigger is input simultaneously to TAUJnTTINm of both channels, INTTAUJnIm of the interval timer function can detect the overflow when TAUJnCNTm of the TAUJnTTINm input position detection function exceeds FFFF FFFF$_H$.

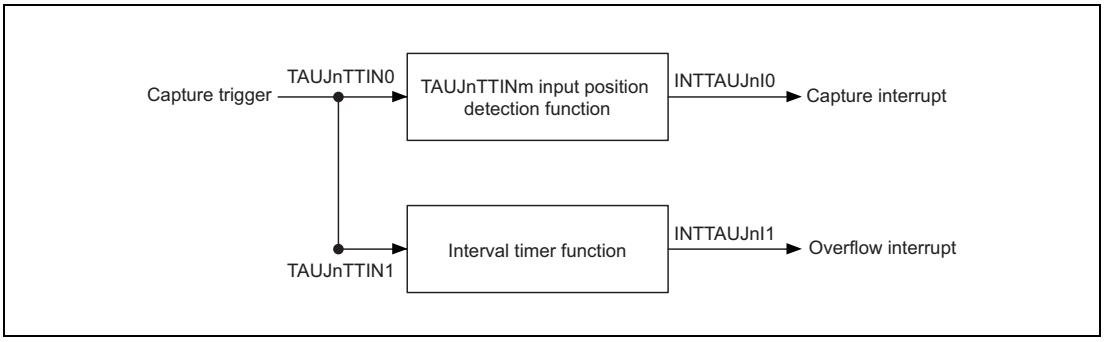

Figure 34.11 Combination of the TAUJnTTINm Input Position Detection Function and the Interval Timer Function

Timing diagram

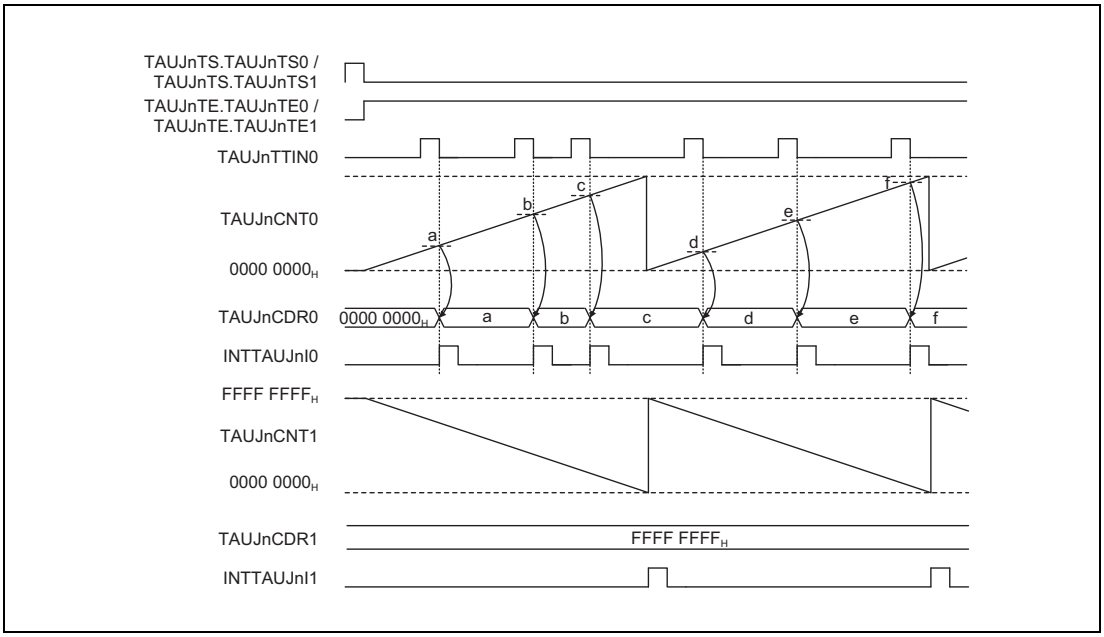

Figure 34.12 Interrupt Generation via Combination of the TAUJnTTINm Input Position Detection Function and the Interval Timer Function

34.4.8 TAUJnTTINm Edge Detection

Edge detection is based on the operation clock. This means that an edge can only be detected at the next rising edge of the operation clock. This can lead to a maximum delay of one operation clock cycle.

The following figure shows when edge detection takes place.

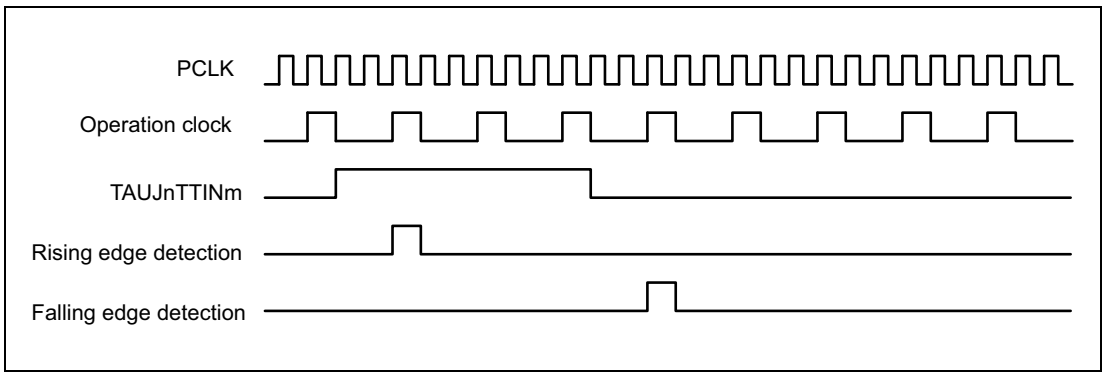

Figure 34.13 Basic Edge Detection Timing

Figure 34.13 shows an image of operation timing. In the actual operation, delay time occurs due to noise filter and synchronization circuit between the TAUJnIm pin and TAUJn.

- Delay time by a noise filter + delay time for edge detection (maximum one operation clock cycle)

34.4.9 Independent Channel Operation Functions

The following sections list the independent channel operation functions provided by the TAUJ. For a general overview of independent channel operation functions, see **Section 34.2, Overview**.

34.4.9.1 Interval Timer Function

(1) Overview

Summary

This function is used as a reference timer for generating timer interrupts (INTTAUJnIm) at regular intervals. When an interrupt is generated, the TAUJnTTOUTm signal toggles, resulting in a square wave.

Functional Description

The counter is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation. The current value of TAUJnCDRm is loaded to TAUJnCNTm and the counter starts to count down from this value.

When the counter reaches 0000 0000_H, INTTAUJnIm is generated and the TAUJnTTOUTm signal toggles. TAUJnCNTm then loads the TAUJnCDRm value and subsequently continues operation.

The value of TAUJnCDRm can be rewritten at any time, and the changed value of TAUJnCDRm is applied the next time the counter starts to count down.

The counter can be stopped by setting TAUJnTT.TAUJnTTm to 1, which in turn sets TAUJnTE.TAUJnTEm to 0. TAUJnCNTm and TAUJnTTOUTm stop but retain their values. The counter can be restarted by setting TAUJnTS.TAUJnTSm to 1. The counter can also be forcibly restarted (without stopping it first) by setting TAUJnTS.TAUJnTSm to 1 during operation.

Conditions

If the TAUJnCMORm.TAUJnMD0 bit is set to 0, the first interrupt after a start or restart is not generated, and therefore TAUJnTTOUTm does not toggle. This results in an reverted TAUJnTTOUTm signal compared to when TAUJnCMORm.TAUJnMD0 is set to 1.

(2) Equations

INTTAUJnIm cycle = count clock cycle × (TAUJnCDRm + 1)

TAUJnTTOUTm square wave cycle = count clock cycle × (TAUJnCDRm + 1) × 2

(3) Block Diagram and General Timing Diagram

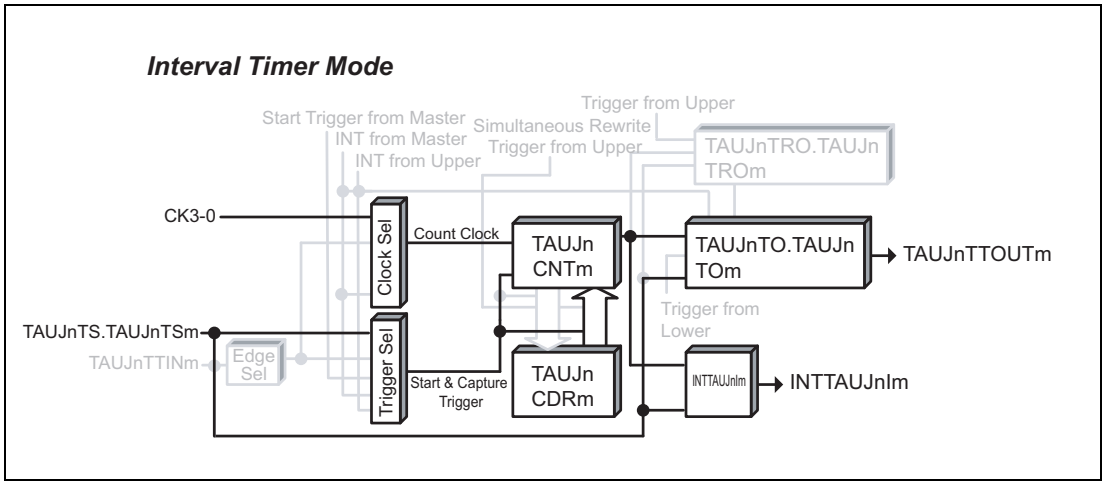

Figure 34.14 Block Diagram for Interval Timer Function

The following settings apply to the general timing diagram.

- INTTAUJnIm is generated at operation start (TAUJnCMORm.TAUJnMD0 = 1)

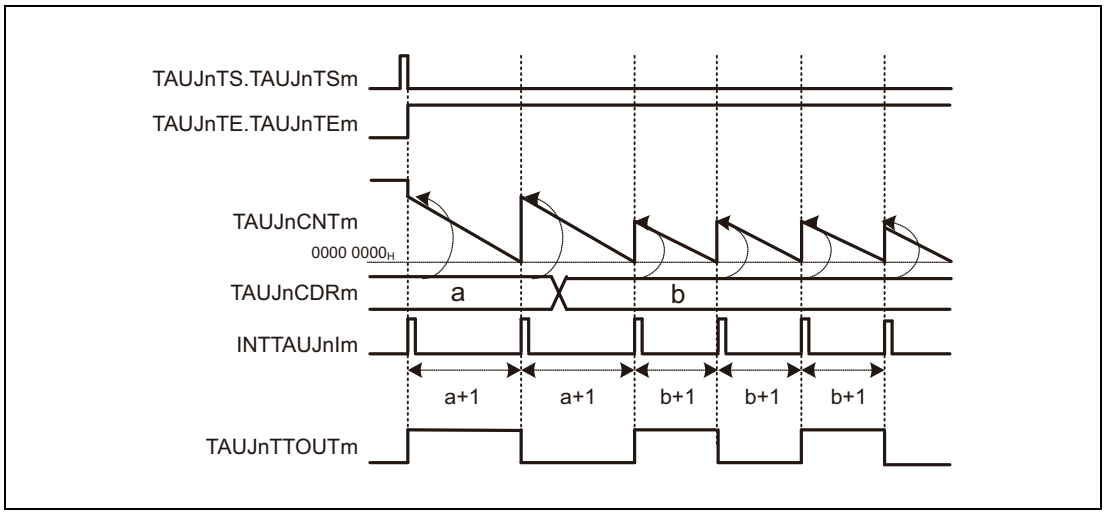

Figure 34.15 General Timing Diagram for Interval Timer Function

7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUJnTIS[1:0]	00: Not used, so set to 00

(c) Channel output mode

Table 34.36 Control Bit Settings in Independent Channel Output Mode 1

Bit name	Setting
TAUJnTOE.TAUJnTOEm	Write 1_B.
TAUJnTOM.TAUJnTOMm	Write 0_B.
TAUJnTOC.TAUJnTOCm	Write 0_B.
TAUJnTOL.TAUJnTOLm	Write 0_B.

NOTE

The channel output mode can also be set to Channel Output Mode Controlled by Software by setting TAUJnTOE.TAUJnTOEm = 0. TAUJnTTOUTm can then be controlled independently of the interrupts. For details, see **Section 34.4.4, Channel Output Modes**.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the interval timer function. Therefore, these registers must be set to 0.

Table 34.37 Simultaneous Rewrite Settings for Interval Timer Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm = 0), set these bits to 0

(5) Operating Procedure for Interval Timer Function

Table 34.38 Operating Procedure for Interval Timer Function

	Operation	Status of TAUJn
Initial channel setting	Set the TAUJnCMORm register and TAUJnCMURm registers as described in **Table 34.34, Contents of the TAUJnCMORm register for Interval Timer Function** and **Table 34.35, Contents of the TAUJnCMURm register for Interval Timer Function**. Set the value of the TAUJnCDRm register. Set the channel output mode by setting the control bits as described in **Table 34.36, Control Bit Settings in Independent Channel Output Mode 1**.	Channel operation is stopped.
Start operation	Set TAUJnTS.TAUJnTSm to 1. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is set to 1 and the counter starts. TAUJnCNTm loads the TAUJnCDRm value. When TAUJnCMORm.TAUJnMD0 = 1, INTTAUJnIm is generated and TAUJnTTOUTm toggles.
During operation	The TAUJnCDRm register value can be changed at any time. The TAUJnCNTm register can be read at all times.	TAUJnCNTm counts down. When the counter reaches 0000 0000_H: • TAUJnCNTm reloads the TAUJnCDRm value and continues count operation. • INTTAUJnIm is generated and TAUJnTTOUTm toggles.
Stop operation	Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm and TAUJnTTOUTm stop and retain their current values.

Restart operation

(6) Specific Timing Diagrams

(a) TAUJnCDRm = 0000 0000_H, Count Clock = PCLK/2

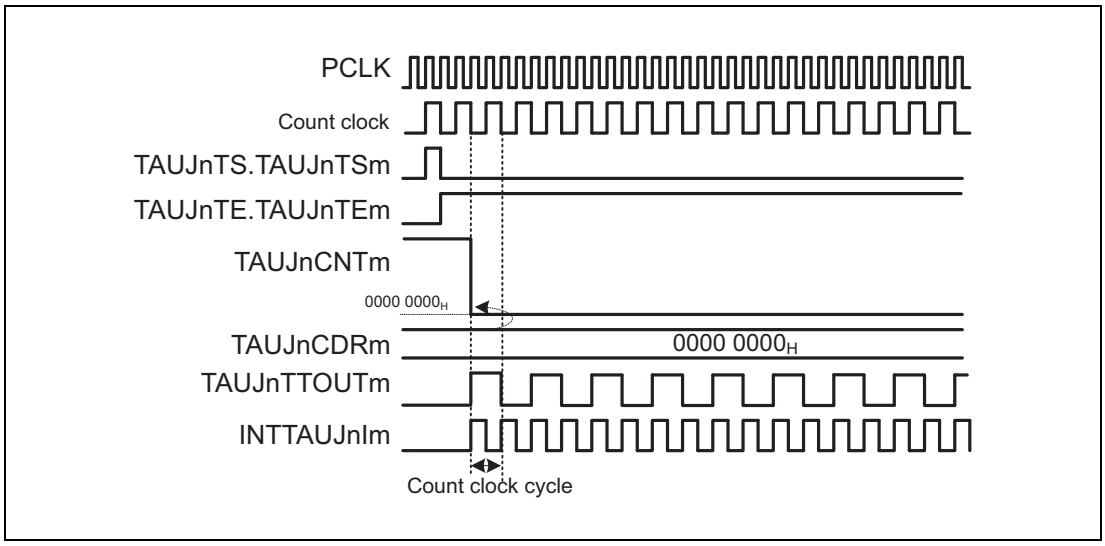

Figure 34.16 TAUJnCDRm = 0000 0000_H, Count Clock = PCLK/2

- If TAUJnCDRm = 0000 0000_H and the count clock = PCLK/2, the TAUJnCDRm value is loaded to TAUJnCNTm every count clock, meaning that TAUJnCNTm is always 0000 0000_H.
- INTTAUJnIm is generated every count clock, resulting in TAUJnTTOUTm toggling every count clock.

(b) TAUJnCDRm = 0000 0000_H, Count Clock = PCLK

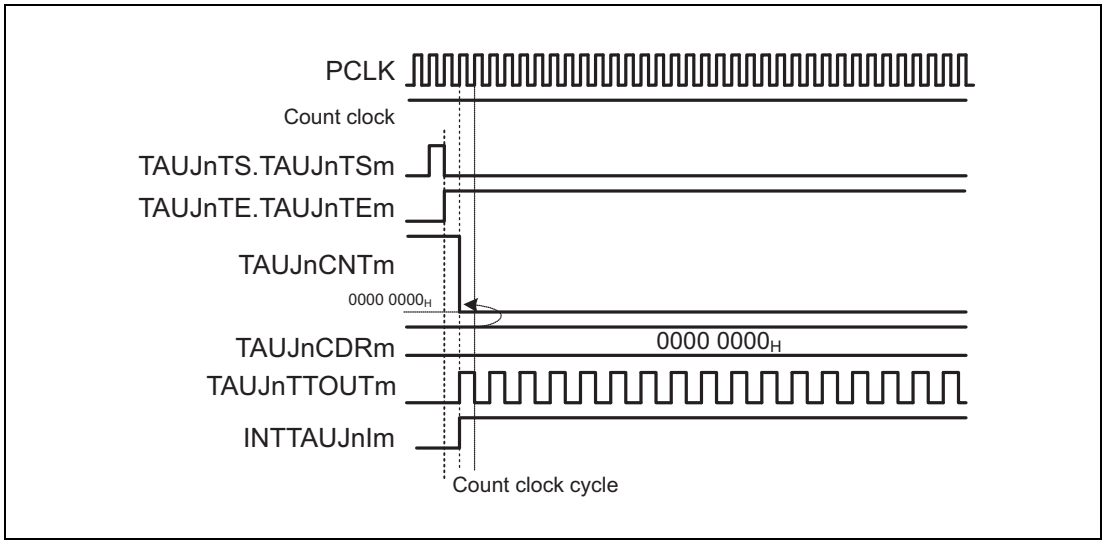

Figure 34.17 TAUJnCDRm = 0000 0000_H, Count Clock = PCLK

- If TAUJnCDRm = 0000 0000_H and the count clock = PCLK, the TAUJnCDRm value is loaded to TAUJnCNTm every PCLK clock, meaning that TAUJnCNTm is always 0000 0000_H.
- INTTAUJnIm is fixed to the high level. Though the first interrupt is generated, subsequent interrupts are not generated. TAUJnTTOUTm is toggled every PCLK clock.

(c) Operation stop and restart

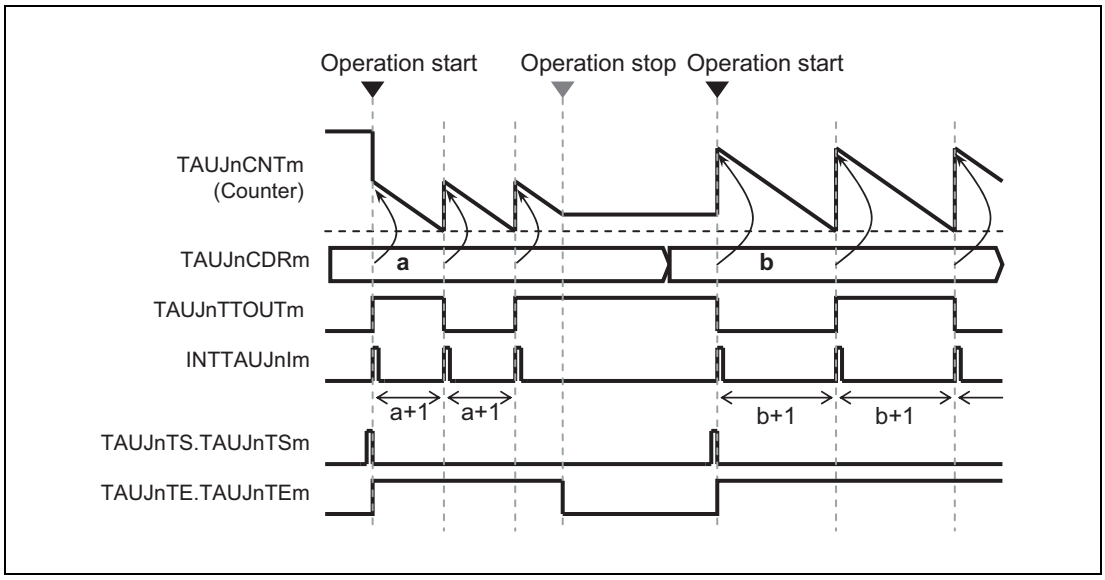

Figure 34.18 Operation Stop and Restart (TAUJnCMORm.TAUJnMD0 = 1)

- The counter can be stopped by setting TAUJnTT.TAUJnTTm to 1, which in turn sets TAUJnTE.TAUJnTEm to 0.
- TAUJnCNTm and TAUJnTTOUTm stop but retain their values.
- The counter can be restarted by setting TAUJnTS.TAUJnTSm to 1.

(d) Forced restart

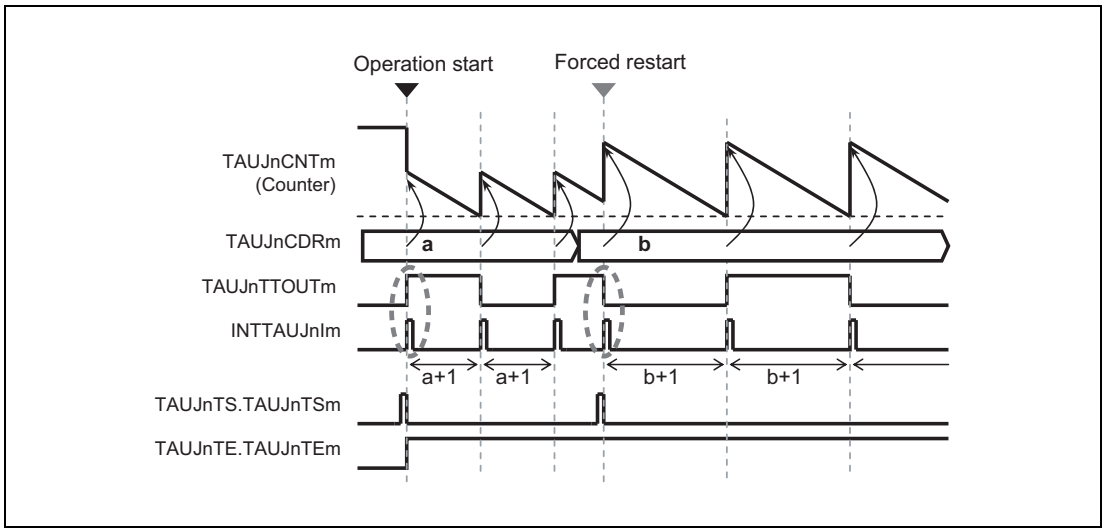

Figure 34.19 Forced Restart Operation (TAUJnCMORm.TAUJnMD0 = 1)

- The counter can be forcibly restarted (without stopping it first) by setting TAUJnTS.TAUJnTSm to 1 during operation.
- If the TAUJnCMORm.TAUJnMD0 bit is set to 1, the first interrupt after a start or restart is generated.
- When a forced restart is made, the TAUJnCDRm value is reflected to TAUJnCNTm and counting starts. Execute a forced restart to reflect the changed TAUJnCDRm value immediately.

34.4.9.2 TAUJnTTINm Input Interval Timer Function

(1) Overview

Summary

This function is used as a reference timer for generating timer interrupts (INTTAUJnIm) at regular intervals or when a valid TAUJnTTINm input edge is detected. When an interrupt is generated, the TAUJnTTOUTm signal toggles*1, resulting in a square wave.

Note 1. Following products do not support output of square waves.
TAUJ0: RH850/U2A16(292 pins), RH850/U2A8(292 pins), RH850/U2A6(292 pins), RH850/U2A6(176 pins), RH850/U2A6(156 pins) and RH850/U2A6(144 pins).
TAUJ1: RH850/U2A16(292 pins), RH850/U2A8(292 pins), RH850/U2A6(292 pins), RH850/U2A6(176 pins), RH850/U2A6(156 pins) and RH850/U2A6(144 pins).

Description

This function operates in an identical manner to the interval timer function (see **Section 34.4.9.1, Interval Timer Function**), except that this function is restarted by a valid TAUJnTTINm input edge. The type of edge used as the trigger is specified using the TAUJnCMURm.TAUJnTIS[1:0] bits. Either rising edge, falling edge, or rising and falling edges can be selected.

(2) Equations

INTTAUJnIm cycle = count clock cycle × (TAUJnCDRm + 1)

TAUJnTTOUTm square wave cycle = count clock cycle × (TAUJnCDRm + 1) × 2

(3) Block Diagram and General Timing Diagram

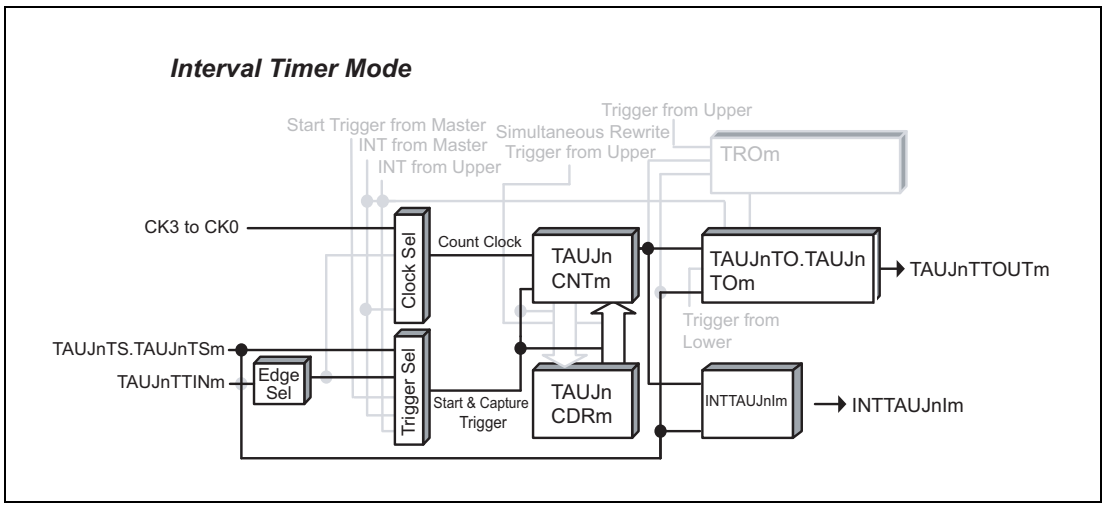

Figure 34.20 Block Diagram for TAUJnTTINm Input Interval Timer Function

The following settings apply to the general timing diagram.

- INTTAUJnIm is generated at operation start (TAUJnCMORm.TAUJnMD0 = 1).
- Rising edge detection (TAUJnCMURm.TAUJnTIS[1:0] = 01_B)

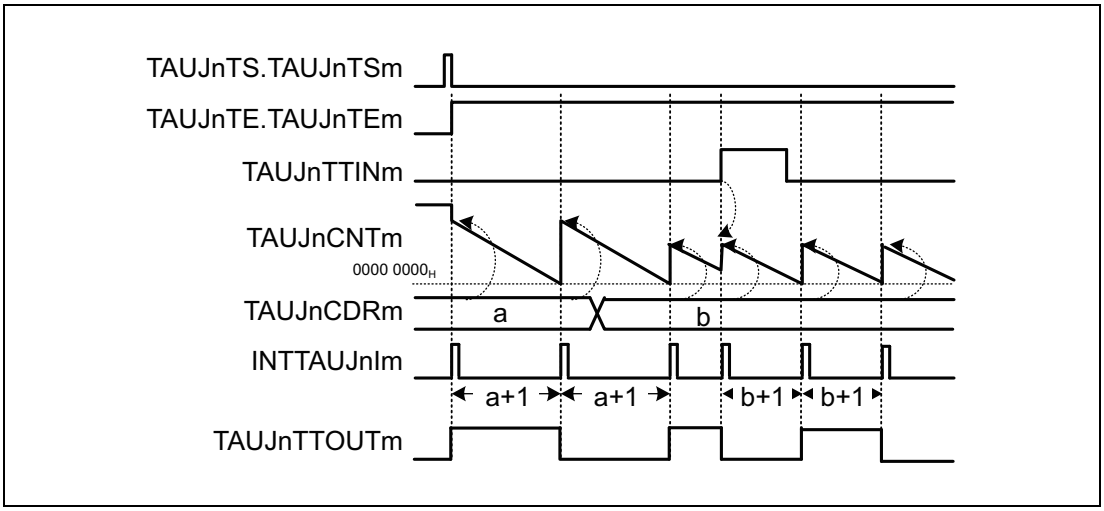

Figure 34.21 General Timing Diagram for TAUJnTTINm Input Interval Timer Function

1, 0	TAUJnTIS[1:0]	00: Falling edge detection 01: Rising edge detection 10: Rising and falling edge detection 11: Setting prohibited

(c) Channel output mode

Table 34.41 Control Bit Settings for Independent Channel Output Mode 1

Bit Name	Setting
TAUJnTOE.TAUJnTOEm	Write 1_B.
TAUJnTOM.TAUJnTOMm	Write 0_B.
TAUJnTOC.TAUJnTOCm	Write 0_B.
TAUJnTOL.TAUJnTOLm	Write 0_B.

NOTE

The channel output mode can also be set to channel output mode controlled by software by setting TAUJnTOE.TAUJnTOEm = 0. TAUJnTTOUTm can then be controlled independently of the interrupts. For details, see **Section 34.4.4, Channel Output Modes**.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the TAUJnTTINm input interval timer function. Therefore, these registers must be set to 0.

Table 34.42 Simultaneous Rewrite Settings for TAUJnTTINm Input Interval Timer Function

Bit Name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm = 0), set these bits to 0

(5) Operating Procedure for TAUJnTTINm Input Interval Timer Function

Table 34.43 Operating Procedure for TAUJnTTINm Input Interval Timer Function

	Operation	Status of TAUJn
Initial channel setting	Set the TAUJnCMORm register and TAUJnCMURm registers as described in **Table 34.39, Contents of the TAUJnCMORm register for TAUJnTTINm Input Interval Timer Function** and **Table 34.40, Contents of the TAUJnCMURm register for TAUJnTTINm Input Interval Timer Function**. Set the value of the TAUJnCDRm register Set the channel output mode by setting the control bits as described in **Table 34.41, Control Bit Settings for Independent Channel Output Mode 1**.	Channel operation is stopped.
Start operation	Set TAUJnTS.TAUJnTSm to 1. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is set to 1 and the counter starts. TAUJnCNTm loads the TAUJnCDRm value. When TAUJnCMORm.TAUJnMD0 = 1, INTTAUJnIm is generated and TAUJnTTOUTm toggles
During operation	The values of the TAUJnCMURm.TAUJnTIS[1:0] and TAUJnCDRm registers can be changed at any time. The TAUJnCNTm register can be read at all times. Detection of TAUJnTTINm edge	TAUJnCNTm counts down. When the counter reaches 0000 0000_H: • TAUJnCNTm reloads the TAUJnCDRm value and continues count operation • INTTAUJnIm is generated and TAUJnTTOUTm toggles When a TAUJnTTINm input valid edge is detected during count operation, TAUJnCNTm reloads the TAUJnCDRm value and continues count operation. Afterwards, this procedure is repeated.
Stop operation	Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm and TAUJnTTOUTm stop and retain their current values.

Restart operation

(6) Specific Timing Diagrams

The timing diagrams in **Section 34.4.9.1, Interval Timer Function** apply, and in addition the counter can also be restarted by a valid TAUJnTTINm input edge.

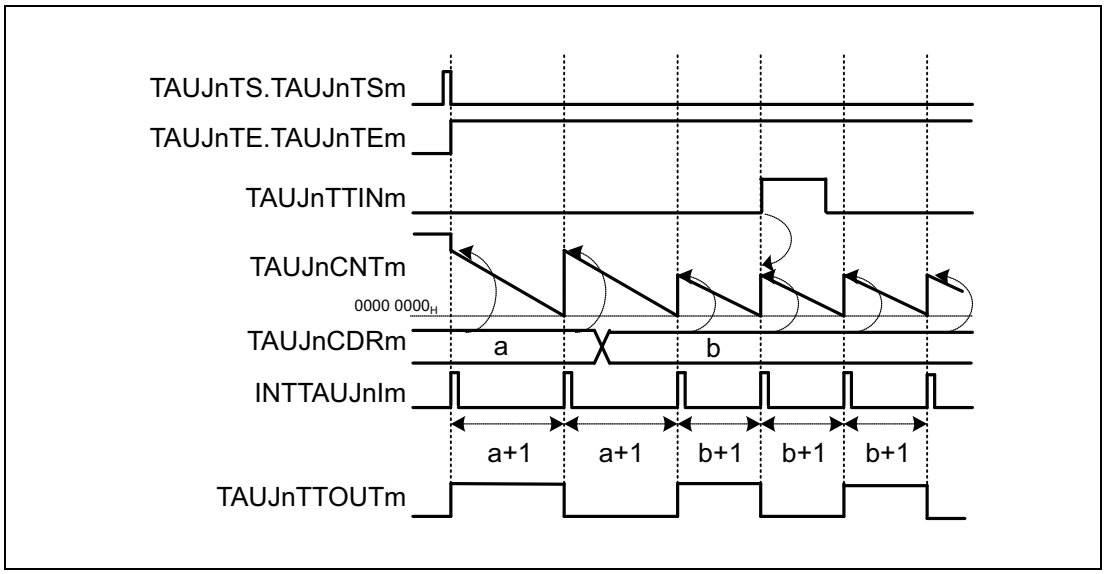

Figure 34.22 Counter Triggered by Rising TAUJnTTINm Input Edge (TAUJnCMURm.TAUJnTIS[1:0] = 01_B), TAUJnCMORm.TAUJnMD0 = 1

If a valid TAUJnTTINm input edge is detected, an interrupt is generated which causes TAUJnTTOUTm to toggle. In this example, the valid edge is a rising edge (TAUJnCMURm.TAUJnTIS[1:0] = 01_B).

34.4.9.3 TAUJnTTINm Input Pulse Interval Measurement Function

(1) Overview

Summary

This function captures the count value and uses this value and the overflow bit TAUJnCSRm.TAUJnOVF to measure the interval of the TAUJnTTINm input signals.

Prerequisites

TAUJnTTOUTm is not used for this function.

Description

The counter is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation. The counter TAUJnCNTm starts counting up from 0000 0000_H. When a valid TAUJnTTINm edge is detected, the value of TAUJnCNTm is captured, transferred to TAUJnCDRm, and an interrupt INTTAUJnIm is generated. The counter resets to 0000 0000_H and subsequently continues operation.

If the counter reaches FFFF $FFFF_H$ before a valid TAUJnTTINm edge is detected, it overflows to 0000 0000_H. The counter is reset to 0000 0000_H and subsequently continues operation. The values transferred to TAUJnCDRm and TAUJnCSRm.TAUJnOVF respectively depend on the values of bits TAUJnCMORm.TAUJnCOS[1:0]:

Table 34.44 Effects of an Overflow

TAUJnCMORm. TAUJnCOS[1:0]	When Overflow Occurs		When a Valid TAUJnTTINm Input is then detected	
	TAUJnCDRm	TAUJnCSRm. TAUJnOVF	TAUJnCDRm and TAUJnCNTm	TAUJnCSRm. TAUJnOVF
00	Unchanged	0	TAUJnCNTm written to TAUJnCDRm	1
01		1		
10	Set to FFFF $FFFF_H$	0	TAUJnCNTm set to 0, TAUJnCDRm unchanged	Unchanged
11		1		

When TAUJnCMORm.TAUJnCOS[0] = 1, the overflow bit TAUJnCSRm.TAUJnOVF can only be cleared by setting TAUJnCSCm.TAUJnCLOV = 1.

The combination of the value of TAUJnCDRm and TAUJnCSRm.TAUJnOVF can be used to deduce the interval of the TAUJnTTINm signal. However, if an overflow occurs multiple times before a valid TAUJnTTINm input is detected, the overflow bit TAUJnCSRm.TAUJnOVF cannot indicate this.

The function can be stopped by setting TAUJnTT.TAUJnTTm = 1, which in turn sets TAUJnTE.TAUJnTEm = 0. TAUJnCNTm stops but retains its value. While the function is stopped, TAUJnTTINm input valid edge detection and TAUJnCNTm capture are not performed.

Conditions

If the TAUJnCMORm.TAUJnMD0 bit is set to 0, the first interrupt after a start or restart is not generated. For details, see **Section 34.4.6, TAUJnTTOUTm Output and INTTAUJnIm Generation when Counter Starts or Restarts**.

NOTE

When TAUJnCMORm.TAUJnCOS[1] = 1, the value of TAUJnCNTm is not loaded to TAUJnCDRm when the first valid TAUJnTTINm input edge occurs after an overflow. However, an interrupt is generated.

(2) Equations

TAUJnTTINm input pulse interval = count clock cycle × [(TAUJnCSRm.TAUJnOVF × (FFFF FFFF$_H$ + 1)) + TAUJnCDRm capture value + 1]

(3) Block Diagram and General Timing Diagram

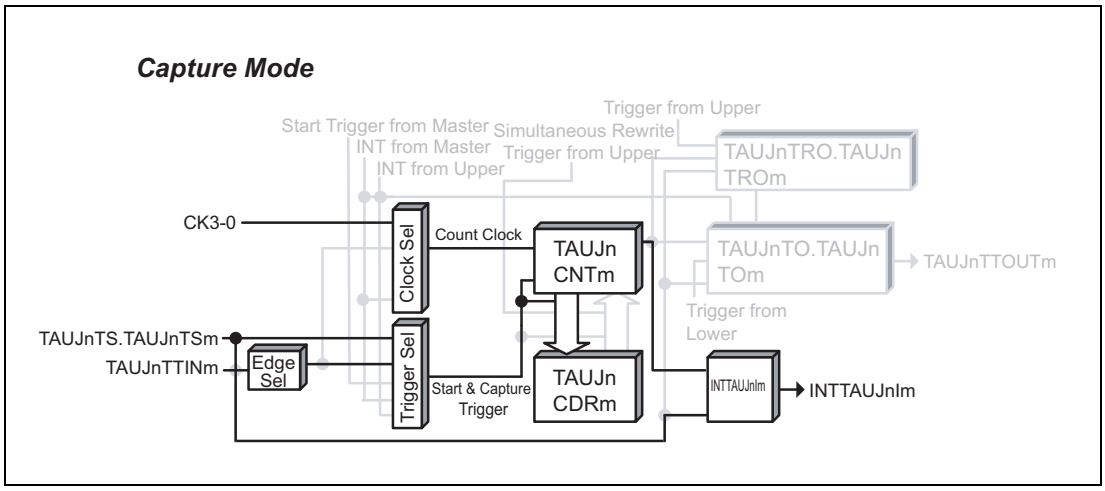

Figure 34.23 Block Diagram for TAUJnTTINm Input Pulse Interval Measurement Function

The following settings apply to the general timing diagram:

- INTTAUJnIm is not generated when operation starts (TAUJnCMORm.TAUJnMD0 = 0)
- Falling edge detection (TAUJnCMURm.TAUJnTIS[1:0] = 00_B)
- When a valid TAUJnTTINm input is detected after an overflow, TAUJnCDRm is changed and TAUJnCSRm.TAUJnOVF is set to 1 (TAUJnCMORm.TAUJnCOS[1:0] = 00_B)

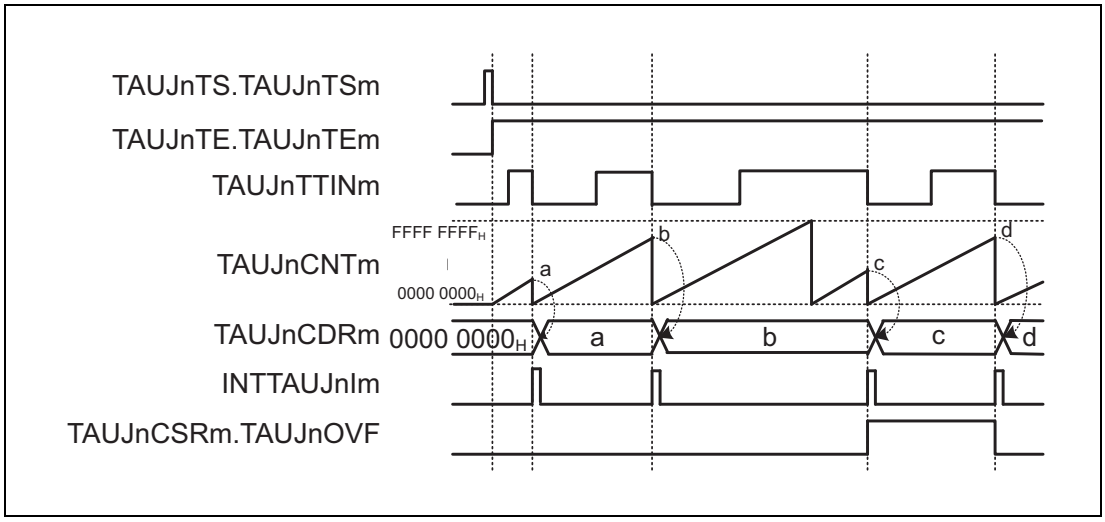

Figure 34.24 General Timing Diagram for TAUJnTTINm Input Pulse Interval Measurement Function

7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	TAUJnTIS[1:0]	00: Falling edge detection 01: Rising edge detection 10: Rising and falling edge detection 11: Setting prohibited

(c) Channel output mode

TAUJnTOE.TAUJnTOEm is set to 0 because the channel output mode is not used by this function.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the TAUJnTTINm input pulse interval measurement function. Therefore, these registers must be set to 0.

Table 34.47 Simultaneous Rewrite Settings for TAUJnTTINm Input Pulse Interval Measurement Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm = 0), set these bits to 0

(5) Operating Procedure for TAUJnTTINm Input Pulse Interval Measurement Function

Table 34.48 Operating Procedure for TAUJnTTINm Input Pulse Interval Measurement Function

	Operation	Status of TAUJn
Initial channel setting	Set the TAUJnCMORm and TAUJnCMURm registers as described in **Table 34.45, Contents of the TAUJnCMORm Register for TAUJnTTINm Input Pulse Interval Measurement Function** and **Table 34.46, Contents of the TAUJnCMURm Register for TAUJnTTINm Input Pulse Interval Measurement Function**. The TAUJnCDRm register functions as a capture register.	Channel operation is stopped.
Start operation	Set TAUJnTS.TAUJnTSm to 1. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is set to 1 and the counter starts. TAUJnCNTm is cleared to 0000 0000_H. INTTAUJnIm is generated when TAUJnCMORm.TAUJnMD0 is set to 1.
During operation	Detection of TAUJnTTINm edges. The values of the TAUJnCMURm.TAUJnTIS[1:0] bits can be changed at any time. The TAUJnCDRm and TAUJnCSRm registers can be read at any time. TAUJnCSCm.TAUJnCLOV bit can be written to 1. (TAUJnCSRm.TAUJnOVF bit is cleared to 0.)	TAUJnCNTm starts to count up from 0000 0000_H. When a TAUJnTTINm valid edge is detected: • TAUJnCNTm transfers (captures) its value to TAUJnCDRm, and returns to 0000 0000_H • INTTAUJnIm is then generated. Afterwards, this procedure is repeated.
Stop operation	Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm stops and both it and TAUJnCSRm.TAUJnOVF retain their current values.

Restart operation

(6) Specific Timing Diagrams: Overflow Behavior

(a) TAUJnCMORm.TAUJnCOS[1:0] = 00_B

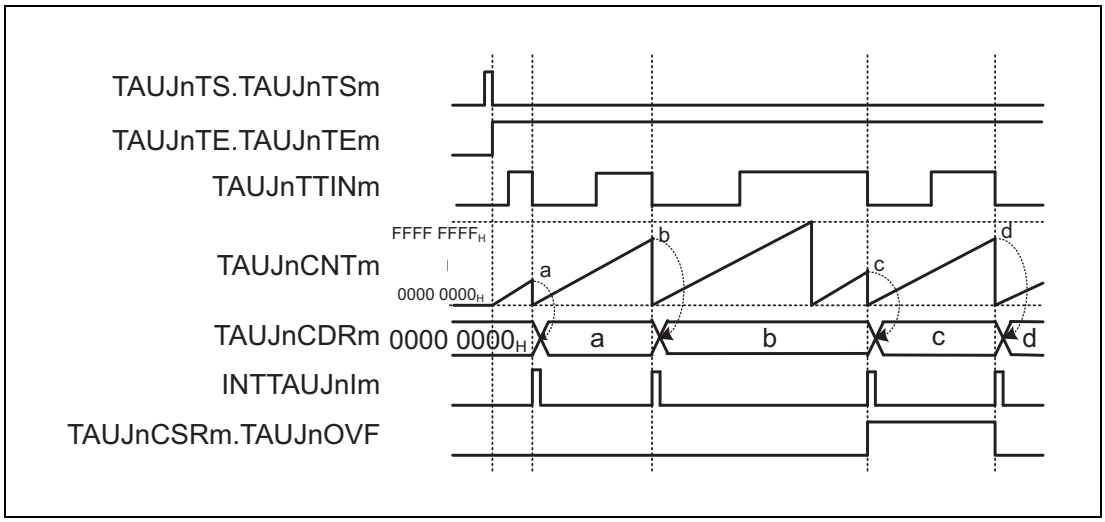

Figure 34.25 TAUJnCMORm.TAUJnCOS[1:0] = 00_B, TAUJnCMORm.TAUJnMD0 = 0, TAUJnCMURm.TAUJnTIS[1:0] = 00_B

- When an overflow occurs, the value of TAUJnCDRm remains unchanged and the value of TAUJnCSRm.TAUJnOVF remains 0.
- Upon detection of the next valid TAUJnTTINm input edge, the value of TAUJnCNTm is loaded to TAUJnCDRm and TAUJnCSRm.TAUJnOVF is set to 1.
- If the next valid TAUJnTTINm input edge is detected when no overflow occurs, TAUJnCSRm.TAUJnOVF is cleared to 0.

(b) TAUJnCMORm.TAUJnCOS[1:0] = 01_B

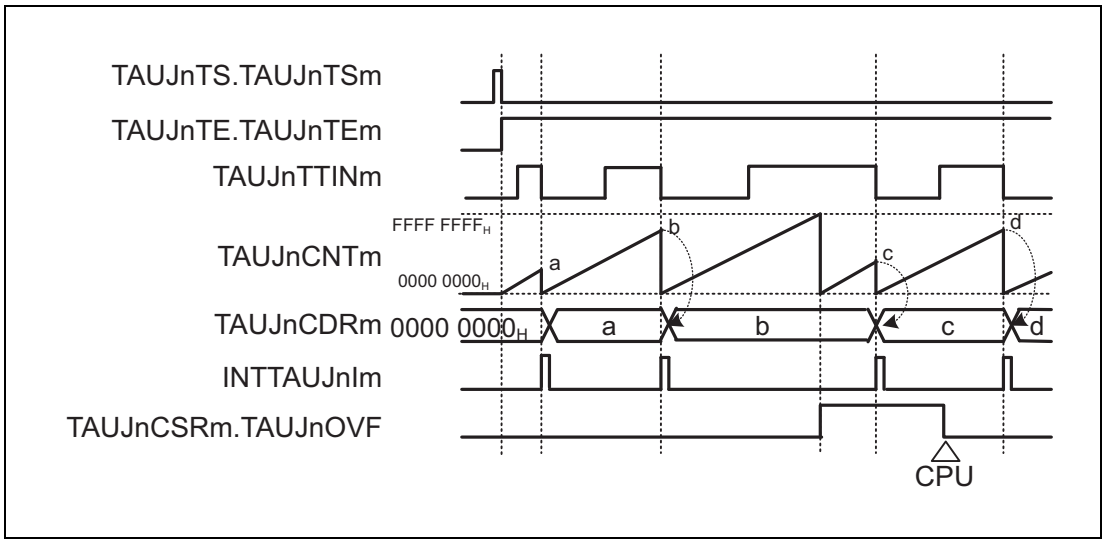

Figure 34.26 TAUJnCMORm.TAUJnCOS[1:0] = 01_B, TAUJnCMORm.TAUJnMD0 = 0, TAUJnCMURm.TAUJnTIS[1:0] = 00_B

- When an overflow occurs, the value of TAUJnCDRm remains unchanged and TAUJnCSRm.TAUJnOVF is set to 1.
- Upon detection of the next valid TAUJnTTINm input edge, the value of TAUJnCNTm is loaded to TAUJnCDRm.
- TAUJnCSRm.TAUJnOVF is only cleared by a CPU command (by setting the TAUJnCSCm.TAUJnCLOV bit to 1).

(c) TAUJnCMORm.TAUJnCOS[1:0] = 10_B

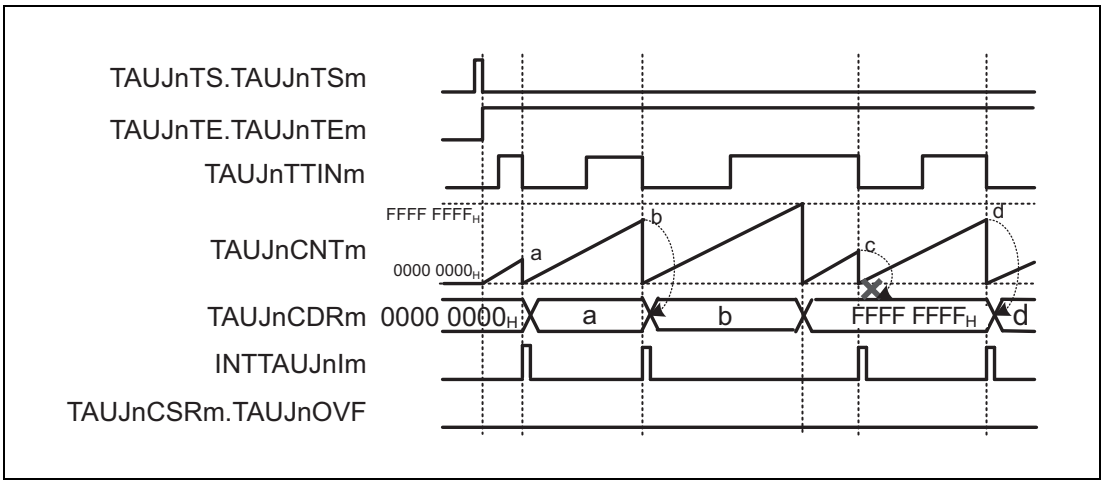

Figure 34.27 TAUJnCMORm.TAUJnCOS[1:0] = 10_B, TAUJnCMORm.TAUJnMD0 = 0, TAUJnCMURm.TAUJnTIS[1:0] = 00_B

- When an overflow occurs, TAUJnCDRm is set to FFFF $FFFF_H$ and the value of TAUJnCSRm.TAUJnOVF remains 0.
- Upon detection of the next valid TAUJnTTINm input edge, TAUJnCNTm is reset to 0, but TAUJnCDRm and TAUJnCSRm.TAUJnOVF remain unchanged.
- Thus, the next TAUJnTTINm input valid edge after the overflow is ignored.

(d) TAUJnCMORm.TAUJnCOS[1:0] = 11_B

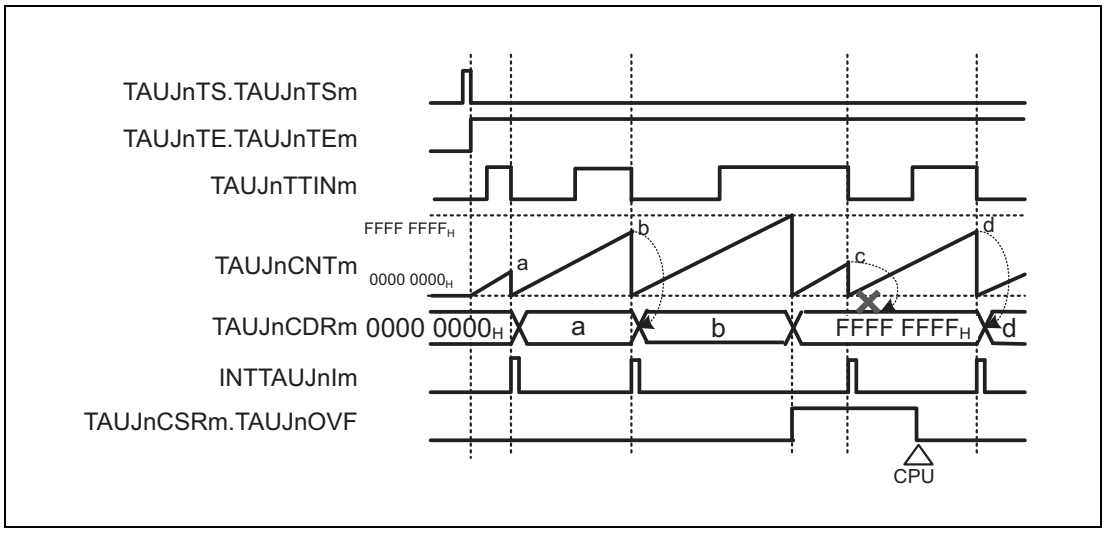

Figure 34.28 TAUJnCMORm.TAUJnCOS[1:0] = 11_B, TAUJnCMORm.TAUJnMD0 = 0, TAUJnCMURm.TAUJnTIS[1:0] = 00_B

- When an overflow occurs, TAUJnCDRm is set to FFFF FFFF$_H$, and TAUJnCSRm.TAUJnOVF is set to 1.
- Upon detection of the next valid TAUJnTTINm input edge, TAUJnCNTm is reset to 0, but TAUJnCDRm and TAUJnCSRm.TAUJnOVF remain unchanged.
- Thus, the next TAUJnTTINm input valid edge after the overflow is ignored.
- TAUJnCSRm.TAUJnOVF is cleared by setting the TAUJnCSCm.TAUJnCLOV bit to 1.

34.4.9.4 TAUJnTTINm Input Signal Width Measurement Function

(1) Overview

Summary

This function measures the width of a TAUJnTTINm signal by starting counting on one edge of the TAUJnTTINm signal and capturing the counter value on the opposite edge.

Prerequisites

- The operation mode must be set to capture and one-count mode, refer to **Table 34.50, Contents of the TAUJnCMORm register for TAUJnTTINm Input Signal Width Measurement Function**.
- TAUJnTTOUTm is not used for this function

Description

The counter is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation. When a valid TAUJnTTINm start edge is detected, the counter TAUJnCNTm starts counting up from 0000 0000_H. When a valid TAUJnTTINm stop edge is detected, the value of TAUJnCNTm is captured, transferred to TAUJnCDRm, and an interrupt INTTAUJnIm is generated. The counter retains its value and awaits the next valid TAUJnTTINm input start edge.

If the counter reaches FFFF $FFFF_H$ before a valid TAUJnTTINm stop edge is detected, it overflows. The counter is reset to 0000 0000_H and subsequently continues operation. The values transferred to TAUJnCDRm and TAUJnCSRm.TAUJnOVF respectively depend on the values of bits TAUJnCMORm.TAUJnCOS[1:0]:

Table 34.49 Effects of an Overflow

TAUJnCMORm. TAUJnCOS[1:0]	When overflow occurs		When a valid TAUJnTTINm input stop edge is detected	
	TAUJnCDRm	TAUJnCSRm. TAUJnOVF	TAUJnCDRm and TAUJnCNTm	TAUJnCSRm. TAUJnOVF
00	Unchanged	0	TAUJnCNTm is loaded to TAUJnCDRm	1
01		1		
10	Set to FFFF $FFFF_H$	0	TAUJnCNTm stops counting TAUJnCDRm unchanged	Unchanged
11		1		

When TAUJnCMORm.TAUJnCOS[0] = 1, the overflow bit TAUJnCSRm.TAUJnOVF can only be cleared by setting TAUJnCSCm.TAUJnCLOV to 1.

The combination of the values of TAUJnCDRm and TAUJnCSRm.TAUJnOVF can be used to deduce the width of the TAUJnTTINm signal. However, if an overflow occurs multiple times before a valid TAUJnTTINm input is detected, the overflow bit TAUJnCSRm.TAUJnOVF cannot indicate this.

This function cannot be forcibly restarted.

NOTE

When TAUJnCMORm.TAUJnCOS[1] = 1, the value of TAUJnCNTm is not loaded to TAUJnCDRm when the first valid TAUJnTTINm input edge occurs after an overflow. However, an interrupt is generated.

(2) Equations

TAUJnTTINm input signal width = count clock cycle × [(TAUJnCSRm.TAUJnOVF × (FFFF $FFFF_H$ + 1)) + TAUJnCDRm capture value + 1]

(3) Block Diagram and General Timing Diagram

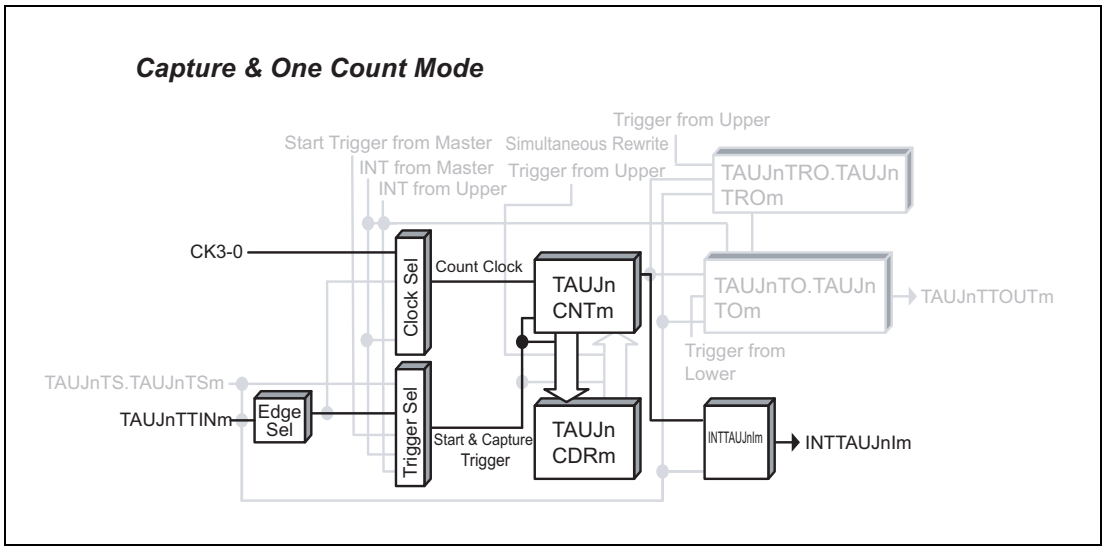

Figure 34.29 Block Diagram for TAUJnTTINm Input Signal Width Measurement Function

The following settings apply to the general timing diagram.

- Rising and falling edge detection = high width measurement (TAUJnCMURm.TAUJnTIS[1:0] = 11_B)
- When a valid TAUJnTTINm input is detected after an overflow, TAUJnCDRm is changed and TAUJnCSRm.TAUJnOVF is set to 1 (TAUJnCMORm.TAUJnCOS[1:0] = 00_B)

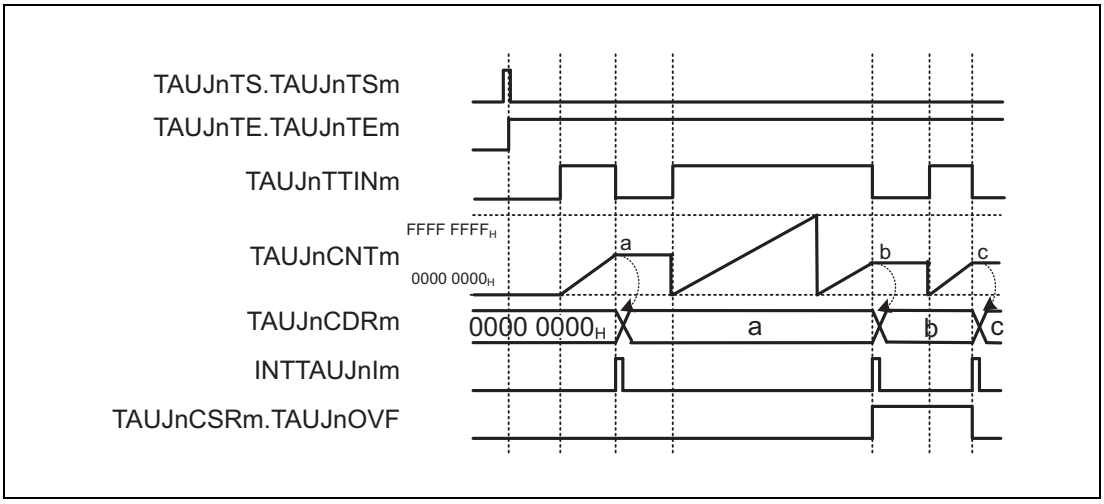

Figure 34.30 General Timing Diagram for TAUJnTTINm Input Signal Width Measurement Function

(4) Register Settings

1, 0	TAUJnTIS[1:0]	10: Rising and falling edge detection (low width measurement) 11: Rising and falling edge detection (high width measurement)

(c) Channel output mode

TAUJnTOE.TAUJnTOEm is set to 0 because the channel output mode is not used with this function.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the TAUJnTTINm input signal width measurement function. Therefore, these registers must be set to 0.

Table 34.52 Simultaneous Rewrite Settings for TAUJnTTINm Input Signal Width Measurement Function

Bit Name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm=0), set these bits to 0

(5) Operating Procedure for TAUJnTTINm Input Signal Width Measurement Function

Table 34.53 Operating Procedure for TAUJnTTINm Input Signal Width Measurement Function

	Operation	Status of TAUJn
Initial channel setting	Set the TAUJnCMORm and TAUJnCMURm registers as described in **Table 34.50, Contents of the TAUJnCMORm register for TAUJnTTINm Input Signal Width Measurement Function** and **Table 34.51, Contents of the TAUJnCMURm Register for TAUJnTTINm Input Signal Width Measurement Function**. The TAUJnCDRm register functions as a capture register.	Channel operation is stopped.
Start operation	Set TAUJnTS.TAUJnTSm to 1. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is set to 1 and TAUJnCNTm waits for detection of the TAUJnTTINm start edge. When a TAUJnTTINm start edge is detected, TAUJnCNTm starts to count up.
During operation	The TAUJnCDRm, TAUJnCNTm, and TAUJnCSRm registers can be read at any time. The TAUJnCSCm.TAUJnCLOV bit can be set to 1.	TAUJnCNTm starts to count up from 0000 0000_H. When a TAUJnTTINm valid edge is detected: • TAUJnCNTm transfers (captures) its value to TAUJnCDRm, and retains its value • INTTAUJnIm is then generated. • Counting stops at the “value that transferred to TAUJnCDRm + 1” and TAUJnCNTm waits for detection of the TAUJnTTINm start edge. Afterwards, this procedure is repeated.
Stop operation	Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm stops and both it and TAUJnCSRm.TAUJnOVF retain their current values.

Restart operation

(6) Specific Timing Diagrams: Overflow Behavior

(a) TAUJnCMORm.TAUJnCOS[1:0] = 00_B

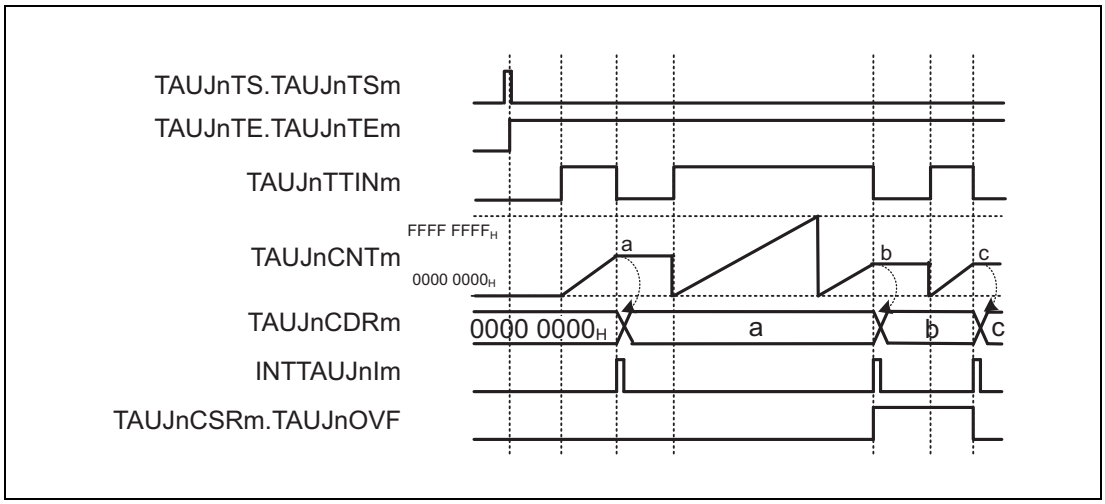

Figure 34.31 TAUJnCMORm.TAUJnCOS[1:0] = 00_B, TAUJnCMORm.TAUJnMD0 = 0, TAUJnCMURm.TAUJnTIS[1:0] = 11_B

- When an overflow occurs, the value of TAUJnCDRm remains unchanged and the value of TAUJnCSRm.TAUJnOVF remains 0.
- Upon detection of the next valid TAUJnTTINm input edge, the value of TAUJnCNTm is loaded to TAUJnCDRm and TAUJnCSRm.TAUJnOVF is set to 1.
- Upon detection of the next valid TAUJnTTINm input edge with no overflow occurring, TAUJnCSRm.TAUJnOVF is cleared to 0.

(b) TAUJnCMORm.TAUJnCOS[1:0] = 01_B

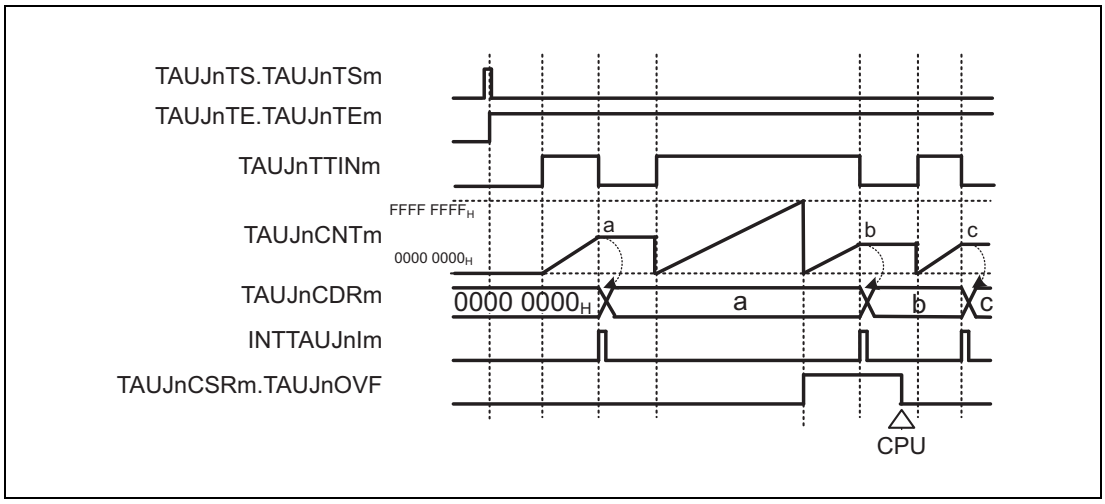

Figure 34.32 TAUJnCMORm.TAUJnCOS[1:0] = 01_B, TAUJnCMORm.TAUJnMD0 = 0, TAUJnCMURm.TAUJnTIS[1:0] = 11_B

- When an overflow occurs, the value of TAUJnCDRm remains unchanged and the value of TAUJnCSRm.TAUJnOVF is set to 1.
- Upon detection of the next valid TAUJnTTINm input edge, the value of TAUJnCNTm is loaded to TAUJnCDRm.
- TAUJnCSRm.TAUJnOVF is only cleared by a CPU command (by setting the TAUJnCSCm.TAUJnCLOV bit to 1).

(c) TAUJnCMORm.TAUJnCOS[1:0] = 10_B

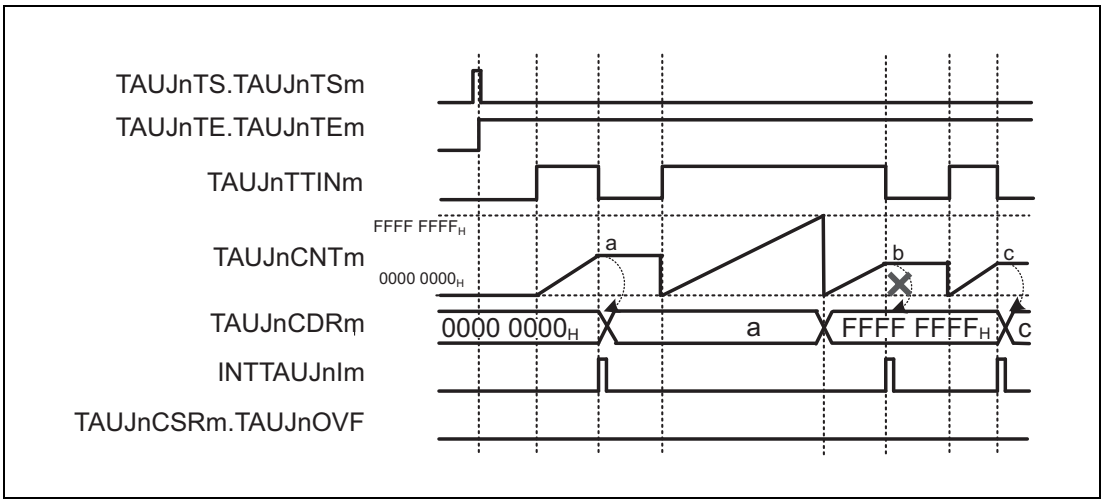

Figure 34.33 TAUJnCMORm.TAUJnCOS[1:0] = 10_B, TAUJnCMORm.TAUJnMD0 = 0, TAUJnCMURm.TAUJnTIS[1:0] = 11_B

- When an overflow occurs, TAUJnCDRm is set to FFFF FFFF$_H$ and the value of TAUJnCSRm.TAUJnOVF remains = 0.
- Upon detection of the next valid TAUJnTTINm input edge, TAUJnCNTm stops counting, but TAUJnCDRm and TAUJnCSRm.TAUJnOVF remain unchanged.
- Thus, the next TAUJnTTINm input valid edge after the overflow is ignored.

(d) TAUJnCMORm.TAUJnCOS[1:0] = 11_B

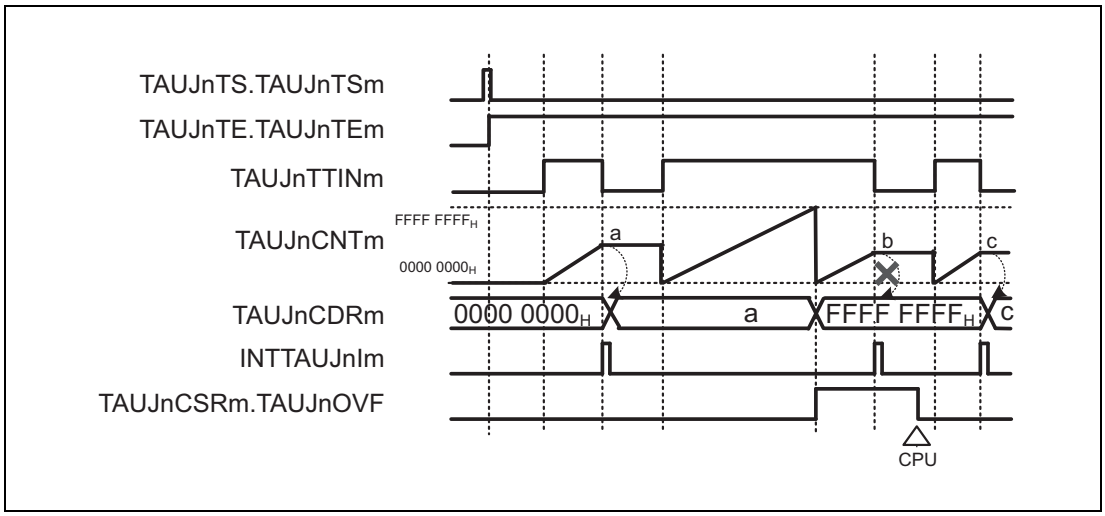

Figure 34.34 TAUJnCMORm.TAUJnCOS[1:0] = 11_B, TAUJnCMORm.TAUJnMD0 = 0, TAUJnCMURm.TAUJnTIS[1:0] = 11_B

- When an overflow occurs, TAUJnCDRm is set to FFFF FFFF$_H$, and TAUJnCSRm.TAUJnOVF is set to 1.
- Upon detection of the next valid TAUJnTTINm input edge, TAUJnCNTm stops counting, but TAUJnCDRm and TAUJnCSRm.TAUJnOVF remain unchanged.
- Thus, the next TAUJnTTINm input valid edge after the overflow is ignored.
- TAUJnCSRm.TAUJnOVF is cleared by setting the TAUJnCSCm.TAUJnCLOV bit to 1.

34.4.9.5 TAUJnTTINm Input Position Detection Function

(1) Overview

Summary

This function measures the interval of input signals by capturing the counter value on a valid edge of the TAUJnTTINm signal.

Prerequisites

TAUJnTTOUTm is not used for this function

Description

The counter is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation. The counter starts to count from 0000 0000_H. When a valid TAUJnTTINm input edge is detected, the current TAUJnCNTm value is loaded to TAUJnCDRm and an interrupt (INTTAUJnIm) is generated. The counter continues to count.

When the counter reaches FFFF $FFFF_H$, the counter restarts from 0000 0000_H.

NOTE

The input TAUJnTTINm is sampled at the frequency of the operation clock, specified by TAUJnCMORm.TAUJnCKS[1:0] bits.

Conditions

If the TAUJnCMORm. TAUJnMD0 bit is set to 0, the first interrupt after a start or restart is not generated. For details, see **Section 34.4.6, TAUJnTTOUTm Output and INTTAUJnIm Generation when Counter Starts or Restarts**.

(2) Equations

Function duration at a TAUJnTTINm input pulse =
count clock cycle × (TAUJnCDRm capture value + 1)

(3) Block Diagram and General Timing Diagram

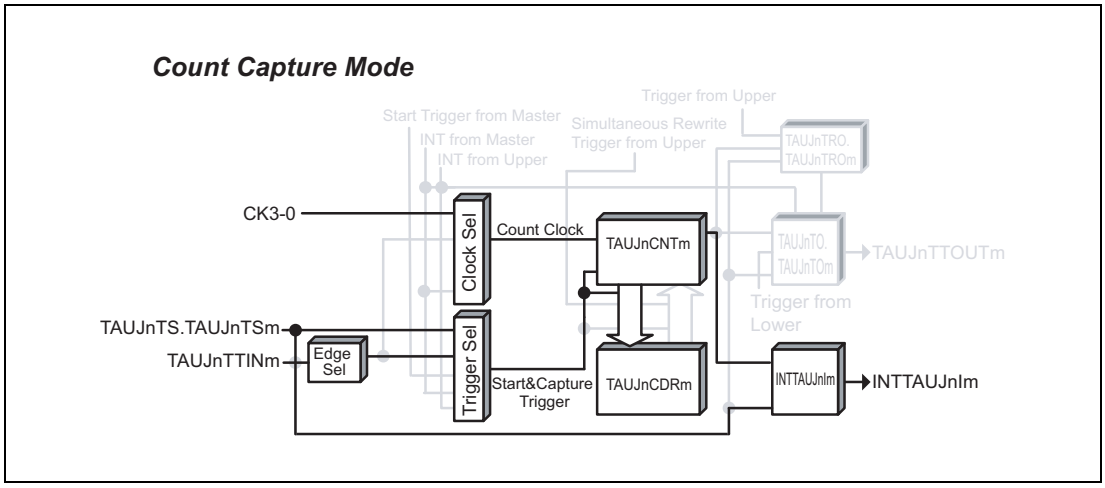

Figure 34.35 Block Diagram of TAUJnTTINm Input Position Detection Function

The following settings apply to the general timing diagram.

- INTTAUJnIm is not generated when operation starts (TAUJnCMORm.TAUJnMD0 = 0)
- Falling edge detection (TAUJnCMURm.TAUJnTIS[1:0] = 00_B)

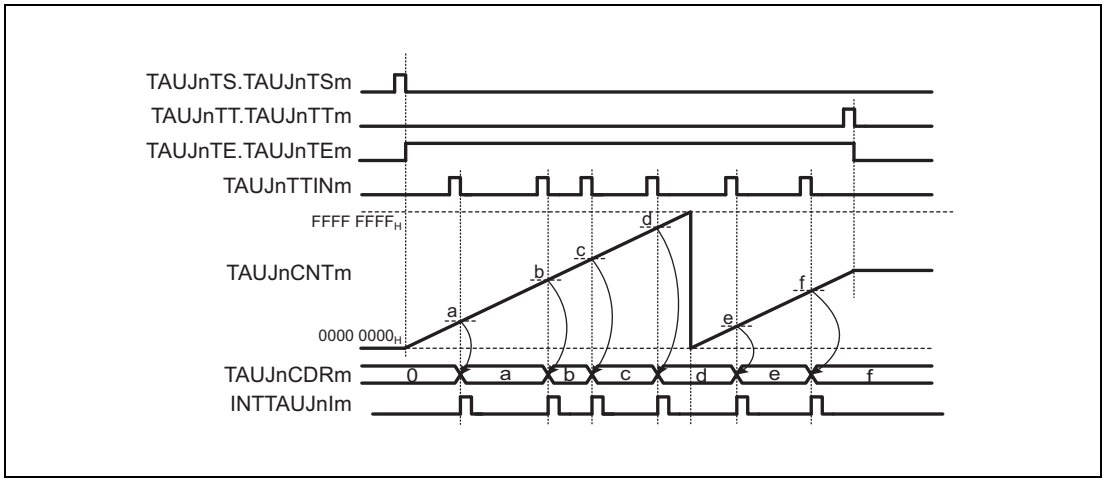

Figure 34.36 General Timing Diagram for TAUJnTTINm Input Position Detection Function

(c) Channel output mode

The channel output mode is not used by this function.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the TAUJnTTINm input position detection function. Therefore, these registers must be set to 0.

Table 34.56 Simultaneous Rewrite Settings for TAUJnTTINm Input Position Detection Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm=0), set these bits to 0

(5) Operating Procedure for TAUJnTTINm Input Position Detection Function

Table 34.57 Operating Procedure for TAUJnTTINm Input Position Detection Function

	Operation	Status of TAUJn
Initial channel setting	Set the TAUJnCMORm register and TAUJnCMURm registers as described in **Table 34.54, Contents of the TAUJnCMORm Register for TAUJnTTINm Input Position Detection Function** and **Table 34.55, Contents of the TAUJnCMURm Register for TAUJnTTINm Input Position Detection Function**. The TAUJnCDRm register operates as a capture register.	Channel operation is stopped.
Start operation	Set TAUJnTS.TAUJnTSm to 1. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is set to 1 and the counter starts. INTTAUJnIm is generated when TAUJnCMORm.TAUJnMD0 is set to 1.
During operation	The TAUJnCMURm.TAUJnTIS[1:0] bits can be changed at any time. The TAUJnCDRm and TAUJnCSRm registers can be read at any time.	TAUJnCNTm starts to count up from 0000 0000_H. When a TAUJnTTINm valid edge is detected: • TAUJnCNTm transfers (captures) its value to TAUJnCDRm • INTTAUJnIm is output. • The counter value is not cleared to 0000 0000_H and TAUJnCNTm continues count operation. Afterwards, this procedure is repeated. When TAUJnCNTm reaches FFFF $FFFF_H$, the counter restarts from 0000 0000_H.
Stop operation	Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm stops and retains its current value.

Restart operation

(6) Specific Timing Diagrams

(a) Operation stop and restart

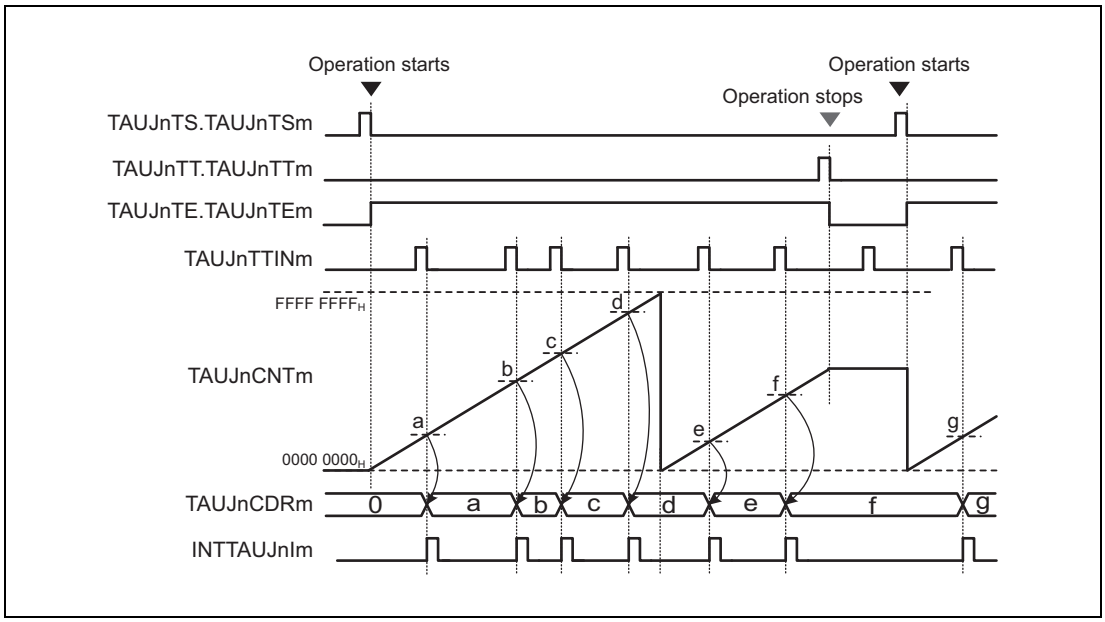

Figure 34.37 Operation Stop and Restart (TAUJnCMORm.TAUJnMD0 = 0, TAUJnCMURm.TAUJnTIS[1:0] = 00_B)

- The counter can be stopped by setting TAUJnTT.TAUJnTTm to 1, which in turn sets TAUJnTE.TAUJnTEm to 0.
- TAUJnCNTm stops and the current value is retained.
- If the counter is stopped, valid TAUJnTTINm input edges are ignored.
- The counter can be restarted by setting TAUJnTS.TAUJnTSm to 1. TAUJnCNTm restarts to count from 0000 0000_H.

34.4.9.6 TAUJnTTINm Input Period Count Detection Function

(1) Overview

Summary

This function measures the cumulative width of a TAUJnTTINm input signal.

Prerequisites

TAUJnTTOUTm is not used for this function.

Description

The counter is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation. The counter awaits a valid TAUJnTTINm input edge.

When a valid TAUJnTTINm input start edge is detected, the counter starts to count from 0000 0000_H.

When a valid TAUJnTTINm input stop edge is detected, the current TAUJnCNTm value is loaded to TAUJnCDRm and an interrupt (INTTAUJnIm) is generated. The counter stops and retains its value until the next valid TAUJnTTINm input start edge is detected.

When the next valid TAUJnTTINm input start edge is detected, the counter restarts counting from the stop value.

When the counter reaches FFFF $FFFF_H$ the counter restarts from 0000 0000_H.

This function cannot be forcibly restarted.

NOTE

The input TAUJnTTINm signal is sampled at the frequency of the operation clock, specified by the TAUJnCMORm.TAUJnCKS[1:0] bits.

Conditions

The valid start and stop edges are specified by the TAUJnCMURm.TAUJnTIS[1:0] bits:

- If TAUJnCMURm.TAUJnTIS[1:0] = 10_B, the TAUJnTTINm input low period is counted. The start trigger is a falling edge and the stop trigger is a rising edge.
- If TAUJnCMURm.TIS[1:0] = 11_B, the TAUJnTTINm input high period is counted. The start trigger is a rising edge and the stop trigger is a falling edge.

(2) Equations

Cumulative TAUJnTTINm input width =
count clock cycle × (TAUJnCDRm capture value + 1)

(3) Block Diagram and General Timing Diagram

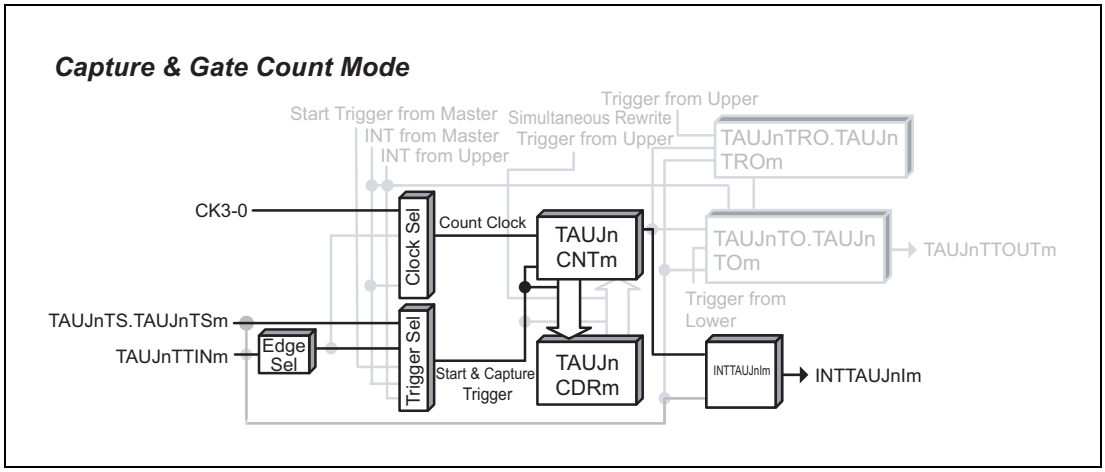

Figure 34.38 Block Diagram for TAUJnTTINm Input Period Count Detection Function

The following settings apply to the general timing diagram.

- Rising and falling edge detection = high width measurement (TAUJnCMURm.TAUJnTIS[1:0] = 11_B)

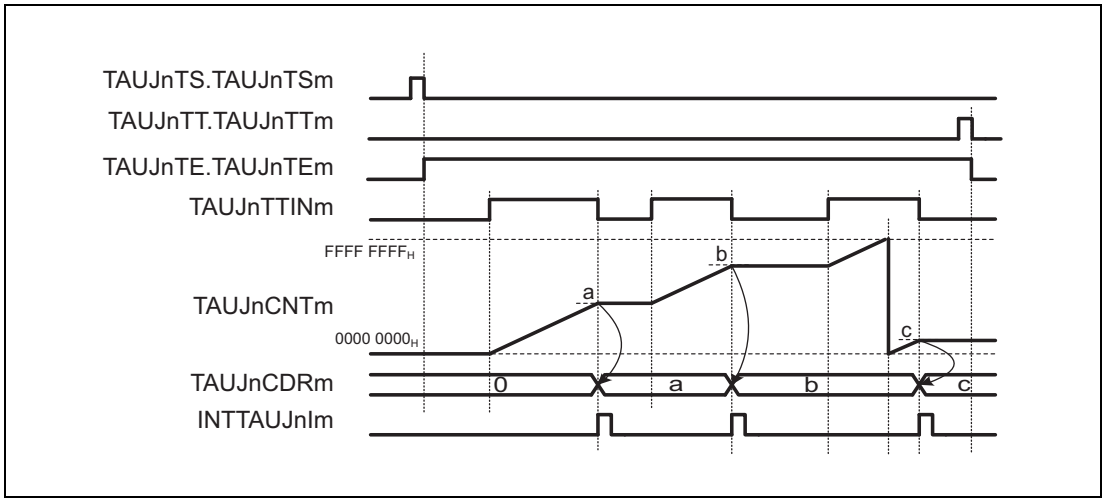

Figure 34.39 General Timing Diagram for TAUJnTTINm Input Period Count Detection Function

(4) Register Settings

1, 0	TAUJnTIS[1:0]	10: Rising and falling edge detection (Low width measurement) 11: Rising and falling edge detection (High width measurement)

(c) Channel output mode

TAUJnTOE.TAUJnTOEm is set to 0 because the channel output mode is not used with this function.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the TAUJnTTINm input period count detection function. Therefore, these registers must be set to 0.

Table 34.60 Simultaneous Rewrite Settings for TAUJnTTINm Input Period Count Detection Function

Bit Name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm=0), set these bits to 0

(5) Operating Procedure for TAUJnTTINm Input Period Count Detection Function

Table 34.61 Operating Procedure for TAUJnTTINm Input Period Count Detection Function

	Operation	Status of TAUJn
Initial channel setting	Set the TAUJnCMORm register and TAUJnCMURm registers as described in **Table 34.58, Contents of the TAUJnCMORm Register for TAUJnTTINm Input Period Count Detection Function** and **Table 34.59, Contents of the TAUJnCMURm Register for TAUJnTTINm Input Period Count Detection Function**. The TAUJnCDRm register operates as a capture register.	Channel operation is stopped.
Start operation	Set TAUJnTS.TAUJnTSm to 1. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is set to 1 and TAUJnCNTm waits for detection of the TAUJnTTINm start edge.
During operation	TAUJnTTINm edge detection The TAUJnCDRm, TAUJnCNTm, and TAUJnCSRm registers can be read at any time.	When a TAUJnTTINm start edge (rising edge for high width measurement, falling edge for low width measurement) is detected, TAUJnCNTm starts to count up from the stop value. When TAUJnCNTm detects a stop edge (falling edge for high width measurement, rising edge for low width measurement), it transfers the value to TAUJnCDRm and INTTAUJnIm is generated. Counting stops at the “value transferred to TAUJnCDRm + 1” and TAUJnCNTm waits for detection of the TAUJnTTINm start edge. If the TAUJnCNTm reaches FFFF FFFF$_H$, it restarts counting from 0000 0000$_H$. Afterwards, this procedure is repeated.
Stop operation	Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm stops and retains its current value.

Restart operation

(6) Specific Timing Diagrams

(a) Operation stop and restart

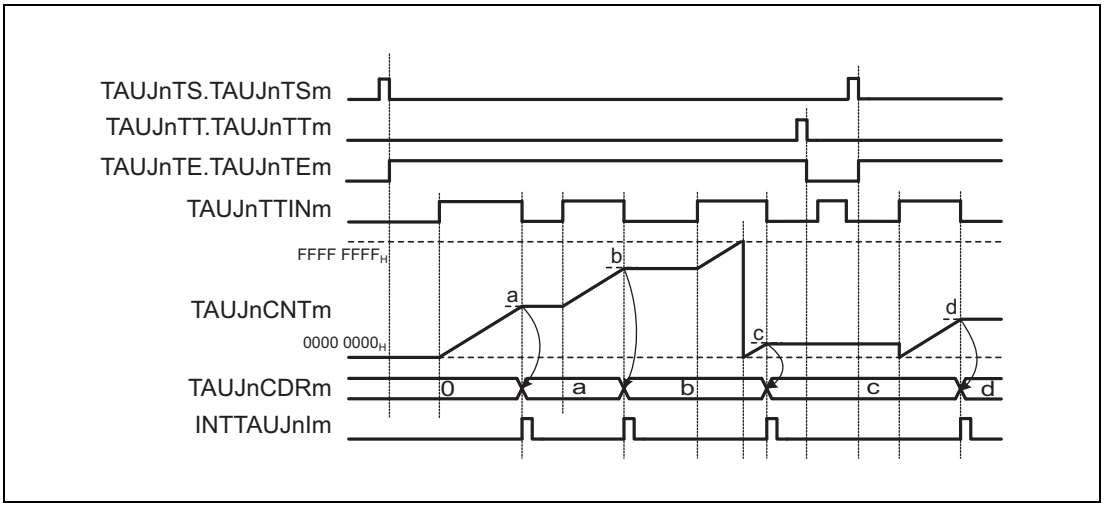

Figure 34.40 Operation Stop and Restart (TAUJnCMURm.TAUJnTIS[1:0] = 11_B)

- The counter can be stopped by setting TAUJnTT.TAUJnTTm to 1, which in turn sets TAUJnTE.TAUJnTEm to 0.
- TAUJnCNTm stops and the current value is retained.
- If the counter is stopped, valid TAUJnTTINm input edges are ignored.
- The counter can be restarted by setting TAUJnTS. TAUJnTSm to 1. TAUJnCNTm restarts to count from 0000 0000_H.

34.4.9.7 Overflow Interrupt Output Function (during TAUJnTTINm Width Measurement)

(1) Overview

Summary

This function measures the width of an individual TAUJnTTINm input signal. An interrupt is generated if the TAUJnTTINm input width is longer than FFFF $FFFF_H$ + 1.

Prerequisites

- TAUJnTTOUTm is not used for this function.
- The value of TAUJnCDRm must be set to FFFF $FFFF_H$.

Description

The counter is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation.

The counter starts when a valid TAUJnTTINm input start edge is detected. FFFF $FFFF_H$ is loaded to TAUJnCNTm and the counter starts to count down.

When a valid stop edge is detected, the counter stops and retains the current value.

When the next TAUJnTTINm input start edge is detected, TAUJnCNTm loads FFFF $FFFF_H$ and starts to count down.

If the counter reaches 0000 0000_H before a stop edge is detected, an interrupt is generated.

Conditions

The valid start and stop edges are specified by the TAUJnCMURm.TAUJnTIS[1:0] bits.

- If TAUJnCMURm.TAUJnTIS[1:0] = 10_B, the TAUJnTTINm input low width is measured. The start trigger is a falling edge and the stop trigger is a rising edge.
- If TAUJnCMURm.TAUJnTIS[1:0] = 11_B, the TAUJnTTINm input high width is measured. The start trigger is a rising edge and the stop trigger is a falling edge.

NOTE

The counter cannot be restarted during operation.

(2) Block Diagram and General Timing Diagram

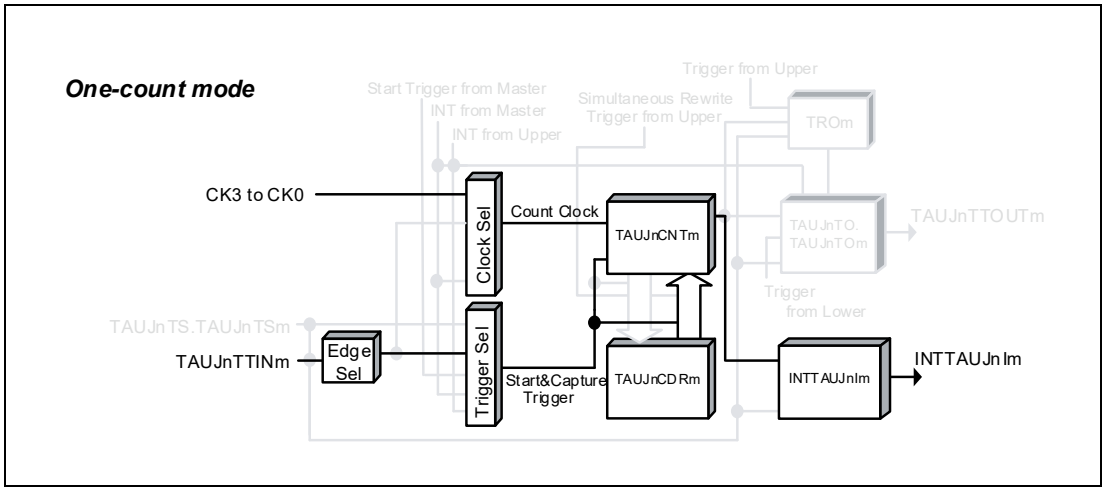

Figure 34.41 Block Diagram for Overflow Interrupt Output Function (during TAUJnTTINm Width Measurement)

The following settings apply to the general timing diagram.

- Rising and falling edge detection = high width measurement (TAUJnCMURm.TAUJnTIS[1:0] = 11_B)

(c) Channel output mode

TAUJnTOE.TAUJnTOEm is set to 0 because the channel output mode is not used with this function.

(d) Simultaneous Rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the overflow interrupt output function (during TAUJnTTINm width measurement). Therefore, these registers must be set to 0.

Table 34.64 Simultaneous Rewrite Settings for Overflow Interrupt Output Function (during TAUJnTTINm Width Measurement)

Bit Name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm = 0), set these bits to 0

(4) Operating Procedure for Overflow Interrupt Output Function (during TAUJnTTINm Width Measurement)

Table 34.65 Operating Procedure for Overflow Interrupt Output Function (during TAUJnTTINm Width Measurement)

	Operation	Status of TAUJn
Initial channel setting	Set the TAUJnCMORm register and TAUJnCMURm registers as described in **Table 34.62, Contents of the TAUJnCMORm Register for Overflow Interrupt Output Function (during TAUJnTTINm Width Measurement)** and **Table 34.63, Contents of the TAUJnCMURm Register for Overflow Interrupt Output Function (during TAUJnTTINm Width Measurement)**. Set the value of the TAUJnCDRm register to FFFF FFFF$_H$.	Channel operation is stopped.
Start operation	Set TAUJnTS.TAUJnTSm to 1. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0. Detection of TAUJnTTINm start edge.	TAUJnTE.TAUJnTEm is set to 1 and TAUJnCNTm waits for detection of the start edge. When a start edge is detected, TAUJnCNTm loads the TAUJnCDRm value (FFFF FFFF$_H$).
During operation	The TAUJnCNTm register can be read at any time.	TAUJnCNTm counts down. When the counter reaches 0000 0000$_H$: • INTTAUJnIm is generated. When a reverse edge of TAUJnTTINm is detected during count operation: • TAUJnCNTm stops counting and waits for a trigger. Afterwards, this procedure is repeated.
Stop operation	Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm stops and retains its current value.

Restart operation

34.4.9.8 Overflow Interrupt Output Function (during TAUJnTTINm Input Period Count Detection)

(1) Overview

Summary

This function measures the cumulative width of a TAUJnTTINm input signal. An interrupt is generated if the cumulative TAUJnTTINm input width is longer than FFFF $FFFF_H$, and an overflow interrupt can be output.

Prerequisites

- TAUJnTTOUTm is not used for this function.
- The value of TAUJnCDRm must be set to FFFF $FFFF_H$.

Description

The counter is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation.

The counter starts when a valid TAUJnTTINm input start edge is detected. FFFF $FFFF_H$ is loaded to TAUJnCNTm and the counter starts to count down.

When a valid stop edge is detected, the counter stops and retains the current value. The counter awaits the next TAUJnTTINm input start edge and then continues to count down from the current value.

When the counter reaches $0000\ 0000_H$ an interrupt is generated. FFFF $FFFF_H$ is loaded to TAUJnCNTm and the counter continues to count down until a TAUJnTTINm input stop edge is detected.

Conditions

The valid start and stop edges are specified by the TAUJnCMURm.TAUJnTIS[1:0] bits.

- If TAUJnCMURm.TAUJnTIS[1:0] = 10_B, the TAUJnTTINm input low period is counted. The start trigger is a falling edge and the stop trigger is a rising edge.
- If TAUJnCMURm.TAUJnTIS[1:0] = 11_B, the TAUJnTTINm input high period is counted. The start trigger is a rising edge and the stop trigger is a falling edge.

NOTE

The counter cannot be restarted during operation.

(2) Block Diagram and General Timing Diagram

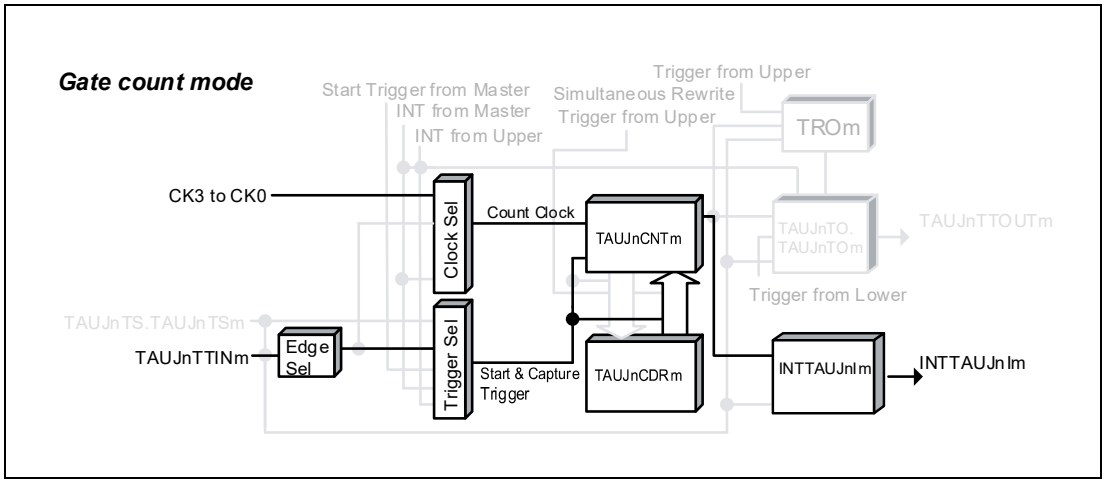

Figure 34.43 Block Diagram for Overflow Interrupt Output Function (during TAUJnTTINm Input Period Count Detection)

The following settings apply to the general timing diagram.

- Rising and falling edge detection = high width measurement (TAUJnCMURm.TAUJnTIS[1:0] = 11_B)

1, 0	TAUJnTIS[1:0]	10: Rising and falling edge detection (Low width measurement) 11: Rising and falling edge detection (High width measurement)

(c) Channel output mode

TAUJnTOE.TAUJnTOEm is set to 0 because the channel output mode is not used with this function.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the Overflow Interrupt Output Function (During TAUJTTINm Input Period Count Detection). Therefore, these registers must be set to 0.

Table 34.68 Simultaneous Rewrite Settings for Overflow Interrupt Output Function (during TAUJnTTINm Input Period Count Detection)

Bit Name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm = 0), set these bits to 0

(4) Operating Procedure for Overflow Interrupt Output Function (during TAUJnTTINm Input Period Count Detection)

Table 34.69 Operating Procedure for Overflow Interrupt Output Function (during TAUJnTTINm Input Period Count Detection)

	Operation	Status of TAUJn
Initial channel setting	Set the TAUJnCMORm and TAUJnCMURm registers as described in **Table 34.66, Contents of the TAUJnCMORm Register for Overflow Interrupt Output Function (during TAUJnTTINm Input Period Count Detection)** and **Table 34.67, Contents of the TAUJnCMURm Register for Overflow Interrupt Output Function (during TAUJnTTINm Input Period Count Detection)**. Set the value of the TAUJnCDRm register to FFFF FFFF$_H$.	Channel operation is stopped.
Start operation	Set TAUJnTS.TAUJnTSm to 1. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0. Detection of TAUJnTTINm start edge.	TAUJnTE.TAUJnTEm is set to 1 and TAUJnCNTm waits for detection of the start edge. When a start edge is detected, the value of TAUJnCDRm (FFFF FFFF$_H$) is loaded to TAUJnCNTm.
During operation	The TAUJnCNTm register can be read at all times.	TAUJnCNTm counts down. When the counter reaches 0000 0000H: ●INTTAUJnIm is generated. ●TAUJnCNTm loads the TAUJnCDRm value (FFFF FFFF$_H$) and continues to count down. When a reverse edge of TAUJnTTINm is detected during count operation: ●TAUJnCNTm stops and retains the stop value. When a TAUJnTTINm valid edge is detected while the counter is stopped: ●TAUJnCNTm counts down from the stop value. Afterwards, this procedure is repeated.
Stop operation	Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm stops and retains its current value.

Restart operation

34.4.10 Synchronous Channel Operation Functions

This section lists all the synchronous channel operation functions provided by the TAUJ. For a general overview of synchronous channel operation, see **Section 34.2, Overview**.

34.4.10.1 PWM output function

(1) Overview

Summary

This function generates multiple PWM outputs by using a master and multiple slave channels. It enables the pulse cycle (frequency) and the duty of the TAUJnTTOUTm to be set. The pulse cycle is set in the master channel. The duty is set in the slave channel.

Prerequisites

- Two channels
- The operation mode for the master channel should be set to interval timer mode (see **Table 34.70, Contents of the TAUJnCMORm Register for the Master Channel of the PWM Output Function**.)
- The operation mode for the slave channel should be set to the one-count mode (see **Table 34.73, Contents of the TAUJnCMORm Register for the Slave Channel of the PWM Output Function**.)
- TAUJnTTOUTm is not used for the master channel of this function.
- The channel output mode for the slave channels should be set to synchronous channel output mode 1 (see **Section 34.4.4, Channel Output Modes**.)

Description

The counters are enabled by setting the channel trigger bits (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation. The current value of TAUJnCDRm is loaded to TAUJnCNTm and the counters start to count down from these values. INTTAUJnIm is generated on the master channel and TAUJnTTOUTm (slave) is set or reset to realize the PWM output.

- Master channel:

  When the counter of the master channel reaches $0000\ 0000_H$ and pulse cycle time has elapsed, INTTAUJnIm is generated. The TAUJnCDRm value is loaded to TAUJnCNTm, and the counter counts down.

- Slave channel(s):

  INTTAUJnIm generated on the master channel triggers the counter of the slave channel(s). The current value of TAUJnCDRm (slave) is loaded to TAUJnCNTm (slave) and the counter starts to count down from this value. The TAUJnTTOUTm signal is set to the active level.
  When the counter reaches $0000\ 0000_H$, i.e. duty time has elapsed, INTTAUJnIm is generated and the TAUJnTTOUTm signal is set to the inactive level. The counter returns to $FFFF\ FFFF_H$ and awaits the next INTTAUJnIm of the master channel, and thus the start of the next pulse cycle.

The counter can be stopped by setting TAUJnTT.TAUJnTTm to 1 for the master and slave channel(s), which in turn sets TAUJnTE.TAUJnTEm to 0. TAUJnCNTm and TAUJnTTOUTm of master and slave channel(s) stop but retain their values. The counters can be restarted by setting TAUJnTS.TAUJnTSm to 1.

Conditions

Simultaneous rewrite can be used with this function. Refer to **Section 34.4.3, Simultaneous Rewrite**.

(2) Equations

Pulse cycle = (TAUJnCDRm (master) + 1) × count clock cycle

Duty cycle [%] = (TAUJnCDRm (slave)/(TAUJnCDRm (master) + 1)) × 100

– Duty cycle = 0%
  TAUJnCDRm (slave) = 0000 0000_H
– Duty cycle = 100%
  TAUJnCDRm (slave) ≥ TAUJnCDRm (master) + 1

(3) Block Diagram and General Timing Diagram

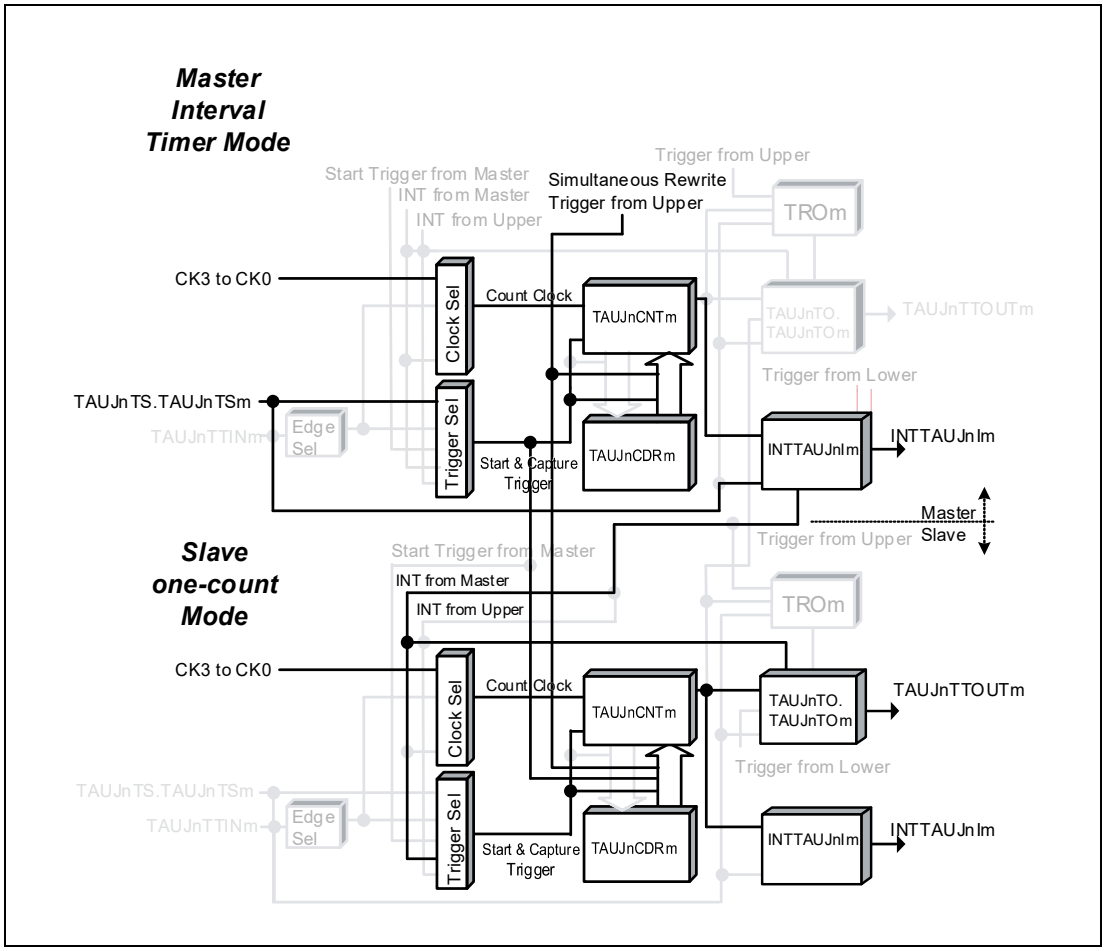

Figure 34.45 Block Diagram for PWM Output Function

The following settings apply to the general timing diagram.

- Slave channel: Positive logic (TAUJnTOL.TAUJnTOLm = 0)

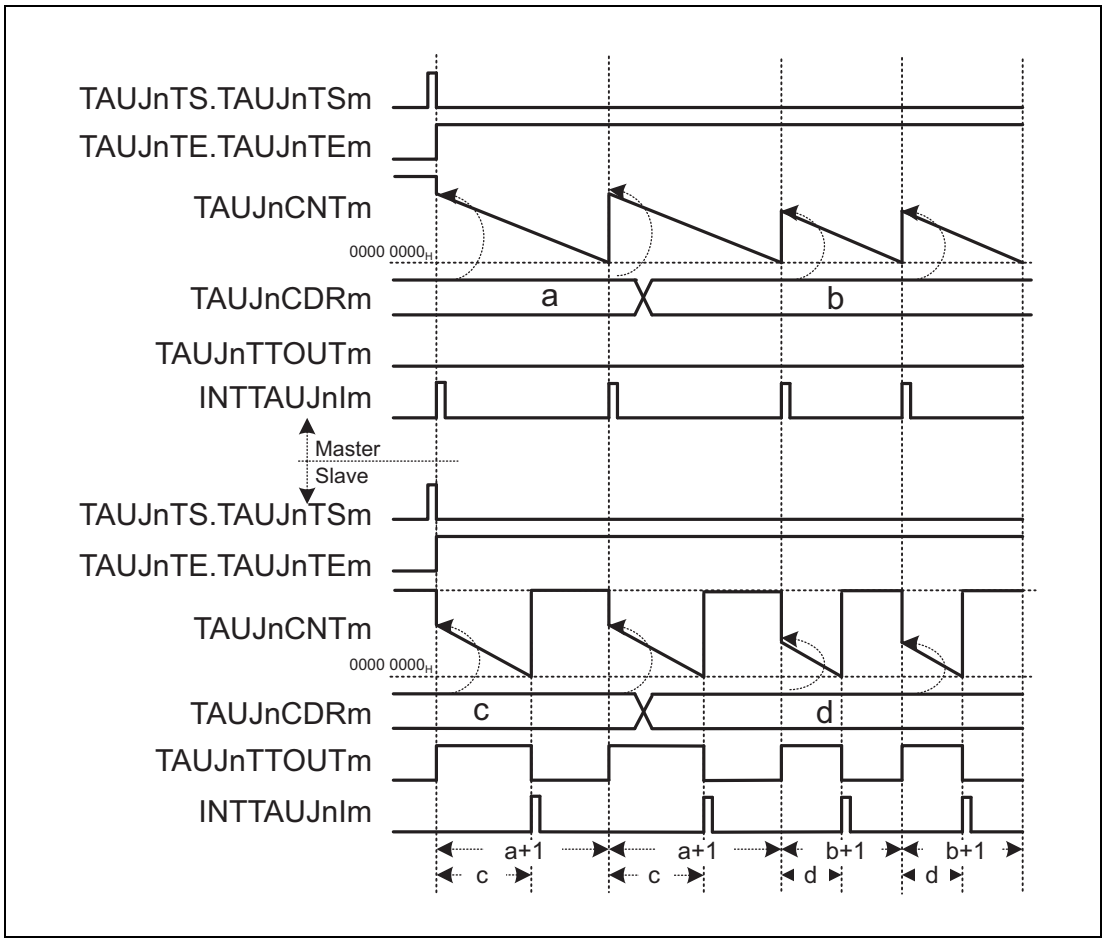

Figure 34.46 General Timing Diagram for PWM Output Function

NOTE

- The interval between the starting to count and an interrupt being generated is the value of corresponding TAUJnCDRm +1.
- TAUJnTTOUTm of the slave channel will rise with a delay of one count clock after the rising of INTTAUJnIm of the master channel.

(4) Register Settings for the Master Channel

(a) TAUJnCMORm for the master channel

(d) Simultaneous rewrite for the slave channel(s)

The simultaneous rewrite settings of the master and slave channels must be identical.

Table 34.76 Simultaneous Rewrite Settings for the Slave Channel of the PWM Output Function

Bit Name	Setting
TAUJnRDE.TAUJnRDEm	1: Enables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: The simultaneous rewrite trigger signal is generated when the master channel starts counting

(6) Operating Procedure for PWM Output Function

Table 34.77 Operating Procedure for PWM Output Function

	Operation	Status of TAUJn
Initial channel setting	Master channel: Set the TAUJnCMORm and TAUJnCMURm registers and the channel output mode as described in **Section (4), Register Settings for the Master Channel**. Slave channel: set the TAUJnCMORm and TAUJnCMURm registers and the channel output mode as described in **Section (5), Register Settings for the Slave Channel(s)**. Set the values of the TAUJnCDRm registers of all channels	Channel operation is stopped.
Start operation	Set TAUJnTS.TAUJnTSm of the master and slave channels to 1 simultaneously. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm (master and slave channels) is set to 1 and the counters of the master and slave channels start. INTTAUJnIm is generated on the master channel and TAUJnTTOUTm (slave) is set.
During operation	TAUJnCDRm can be changed at any time. TAUJnCNTm and TAUJnRSF.TAUJnRSFm can be read at any time. TAUJnRDT.TAUJnRDTm can be changed during operation.	TAUJnCNTm of the master channel loads TAUJnCDRm and counts down. When the counter reaches 0000 0000_H: • INTTAUJnIm (master) is generated • TAUJnCNTm (master) loads the TAUJnCDRm value and continues count operation • TAUJnCNTm (slave) loads the TAUJnCDRm value and counts down • TAUJnTTOUTm (slave) is set to the active level. When TAUJnCNTm (slave) reaches 0000 0000_H: • INTTAUJnIm (slave) is generated • TAUJnTTOUTm (slave) is set to the inactive level.
Stop operation	Set TAUJnTT.TAUJnTTm of the master and slave channels to 1 simultaneously. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm and TAUJnTTOUTm stop and retain their current values.

Restart operation

(7) Specific Timing Diagrams

(a) Duty cycle = 0%

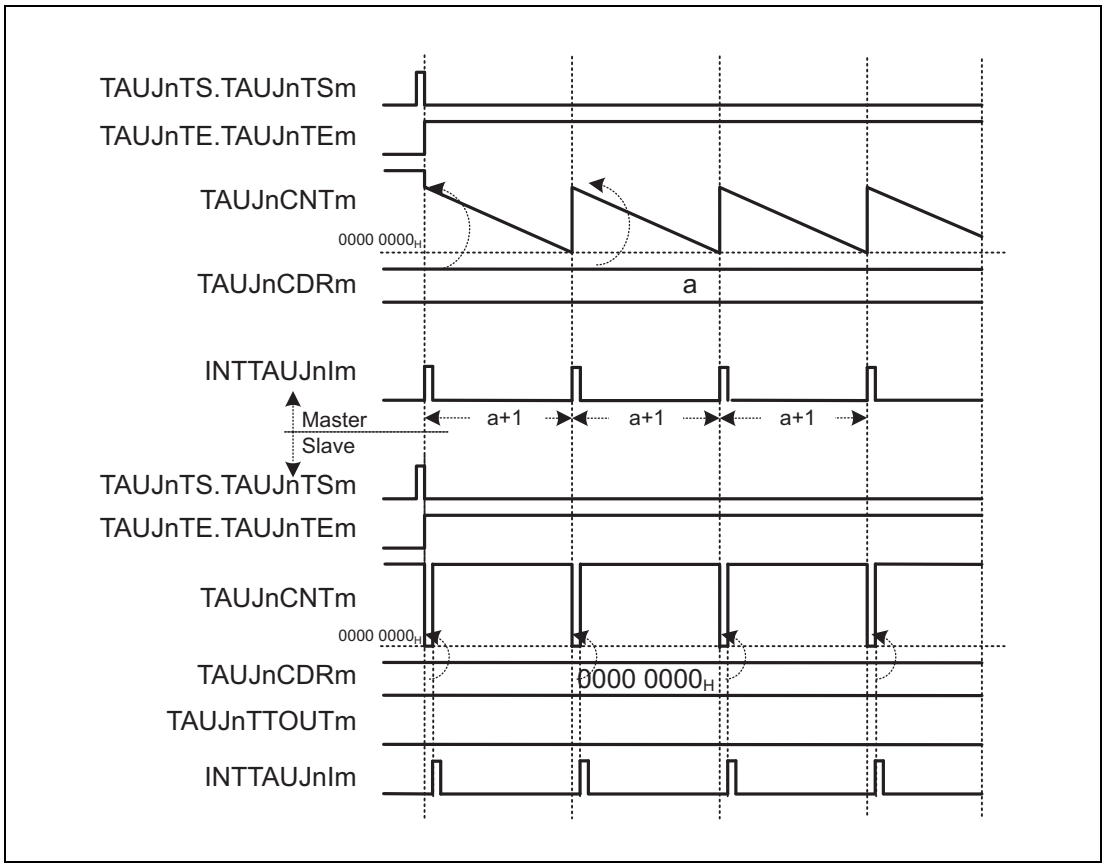

Figure 34.47 TAUJnCDRm (Slave) = 0000 0000$_H$, Positive Logic (TAUJnTOL.TAUJnTOLm (Slave) = 0)

- Every time the master channel generates an interrupt (INTTAUJnIm), 0000 0000$_H$ is loaded to TAUJnCNTm (slave). As a result, a slave channel interrupt (INTTAUJnIm) is generated at the same time and TAUJnTTOUTm remains inactive.
- The value of TAUJnCDRm is loaded into TAUJnCNTm (slave) to generate an interrupt.

(b) Duty cycle = 100%

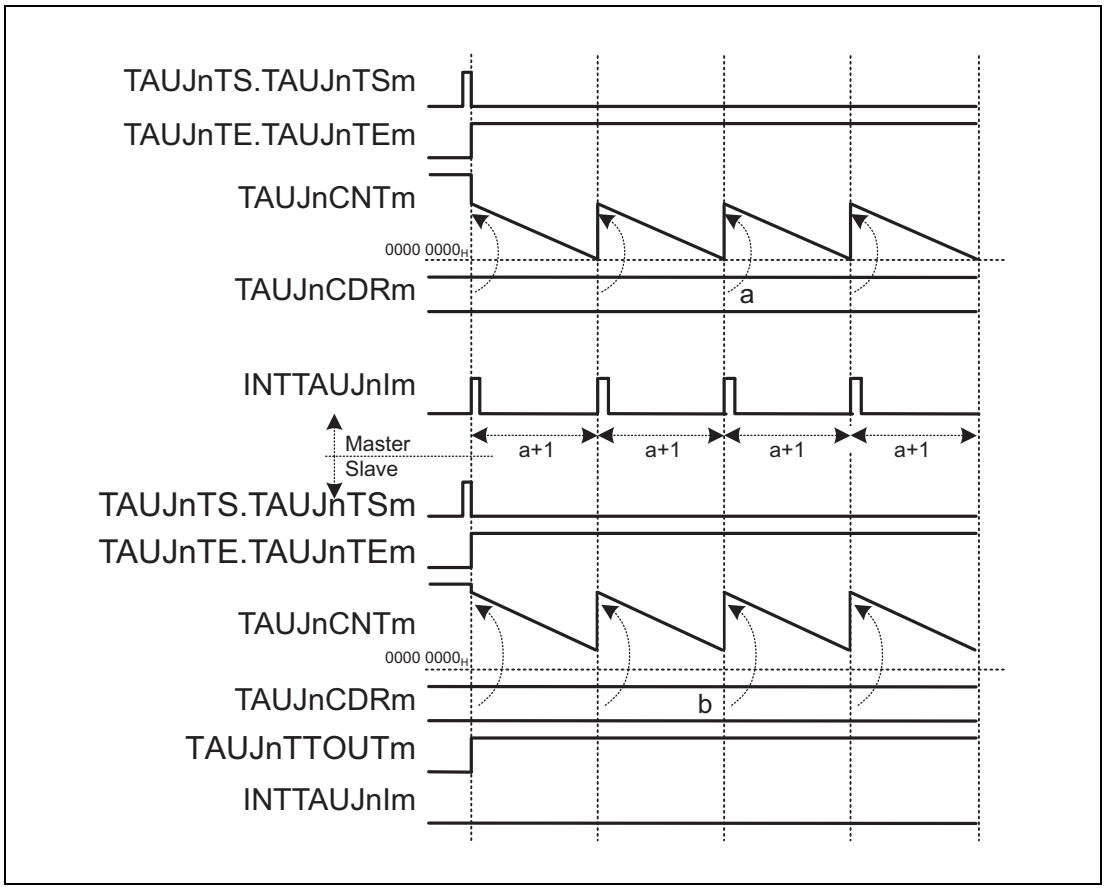

Figure 34.48 TAUJnCDRm (Slave) ≥ TAUJnCDRm (Master) + 1, Positive Logic (TAUJnTOL.TAUJnTOLm (Slave) = 0)

If the TAUJnCDRm (slave) value is greater than the TAUJnCDRm (master) value, no interrupt occurs because the counter of the slave channel does not reach 0000 0000_H. TAUJnTTOUTm remains active.

(c) Operation stop and restart

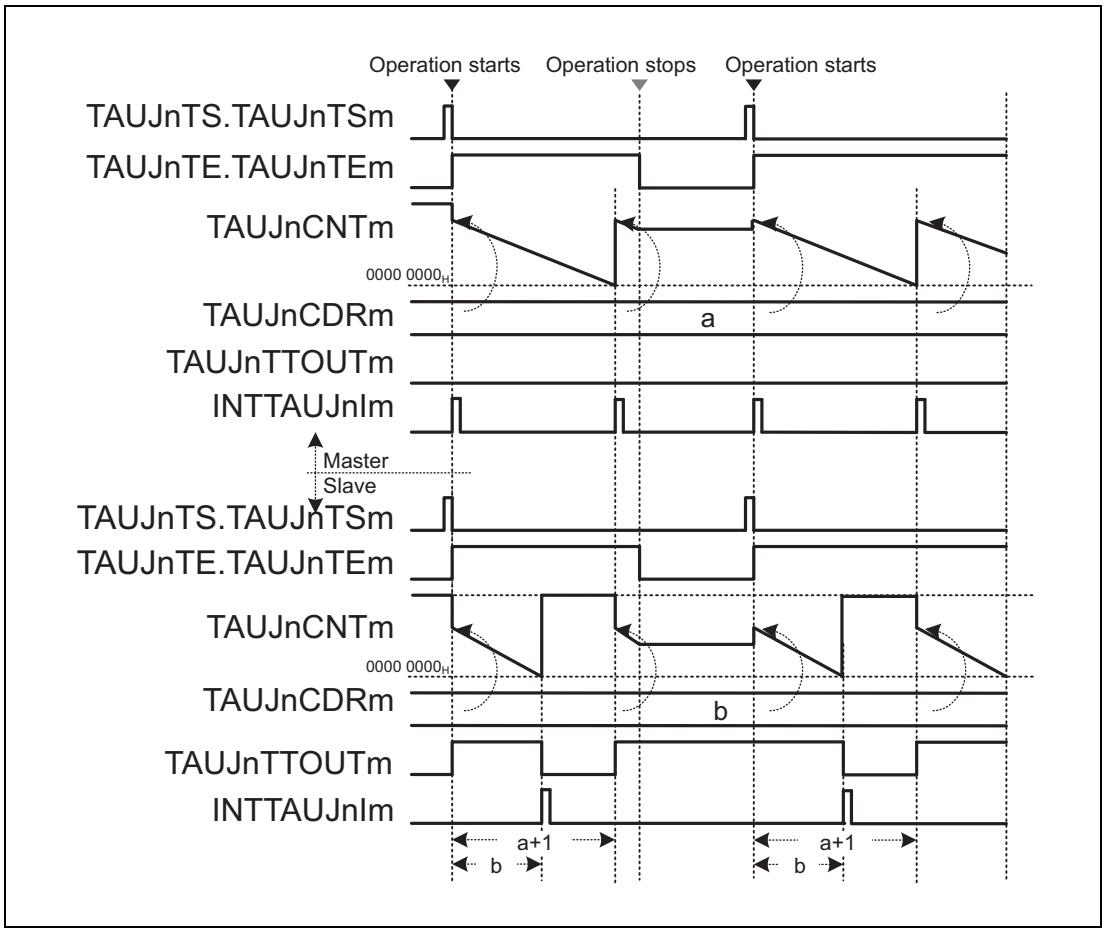

Figure 34.49 Operation Stop and Restart, Positive Logic (TAUJnTOL.TAUJnTOLm (Slave) = 0)

- The counter can be stopped by setting TAUJnTT.TAUJnTTm of master and slave channels to 1. This sets TAUJnTE.TAUJnTEm to 0.
- TAUJnCNTm and TAUJnTTOUTm of every channel stop and retain their current values. No interrupt occurs.
- The counter can be restarted by setting TAUJnTS.TAUJnTSm of master and slave channels to 1. The TAUJnCDRm value of master and slave channels is loaded into TAUJnCNTm. The counter starts to count down from this value.

Section 35 Motor Control Timer (TSG3)

The Motor Control Timer (TSG3) is 18-bit counter which can generate the output corresponding to various motor control systems. TSG3 is implemented 2 units.

35.1 Features TSG3 for RH850/U2A-EVA

35.1.1 Number of Units

This microcontroller has the following number of units of TSG3 units.

Table 35.1 Number of Units

Product	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of Units	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	1 (n = 1)	1 (n = 1)
Name	TSG3n									

Table 35.2 Index

Index	Description
n	Throughout this section, the individual TSG3 units are identified by the index “n” (n = 0, 1), for example, TSG3nCTL0 refers to the TSG3n control register 0.
m, k	Throughout this section, the variables used for description are indicated by the index “m” or “k”, for example, TSG3nCMPmE refers to a specified compare register.

35.1.2 Register Base Addresses

TSG3 base addresses are listed in the following table.

TSG3 register addresses are given as offsets from the base addresses.

Table 35.3 Register Base Addresses

Base Address Name	Base Address	Bus Group
<TSG30_base>	FFBF 8000_H	P-Bus Group 5
<TSG31_base>	FFBF 8800_H	P-Bus Group 5

35.1.3 Clock Supply

Clock supply by and to TSG3 is listed in the following table.

Table 35.4 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
TSG3n	PCLK	High-speed peripheral clock CLK_HSB

35.1.4 Interrupt Requests and Error Notifications

TSG3 interrupt requests are listed in the following table.

Table 35.5 Interrupt and DMA/DTS Requests

Unit Interrupt Name	Description	Interrupt Number	DMA Trigger Number	DTS Trigger Number
TSG30				
INTTSG30I0	TSG30 compare match interrupt 0/ TSG30 period interrupt (in HT-PWM mode only)	165	—	—
INTTSG30I1	TSG30 compare match interrupt 1	166	—	—
INTTSG30I2	TSG30 compare match interrupt 2	167	—	—
INTTSG30I3	TSG30 compare match interrupt 3	168	—	—
INTTSG30I4	TSG30 compare match interrupt 4	169	—	—
INTTSG30I5	TSG30 compare match interrupt 5	170	—	—
INTTSG30I6	TSG30 compare match interrupt 6	171	—	—
INTTSG30I7	TSG30 compare match interrupt 7	172	—	—
INTTSG30I8	TSG30 compare match interrupt 8	173	—	—
INTTSG30I9	TSG30 compare match interrupt 9	174	—	—
INTTSG30I10	TSG30 compare match interrupt 10	175	—	—
INTTSG30I11	TSG30 compare match interrupt 11	176	Group0-173	Group1-46
INTTSG30I12	TSG30 compare match interrupt 12	177	Group0-174	Group1-47
INTTSG30IPEK	TSG30 peak interrupt	178	Group0-175	Group1-48
INTTSG30IVLY	TSG30 valley interrupt	179	Group0-176	Group1-49
INTTSG30IER	TSG30 error interrupt	180	—	—
INTTSG30IWN	TSG30 warning interrupt	181	—	—
TSG31				
INTTSG31I0	TSG31 compare match interrupt 0/ TSG31 period interrupt (in HT-PWM mode only)	182	—	—
INTTSG31I1	TSG31 compare match interrupt 1	183	—	—
INTTSG31I2	TSG31 compare match interrupt 2	184	—	—
INTTSG31I3	TSG31 compare match interrupt 3	185	—	—
INTTSG31I4	TSG31 compare match interrupt 4	186	—	—
INTTSG31I5	TSG31 compare match interrupt 5	187	—	—
INTTSG31I6	TSG31 compare match interrupt 6	188	—	—
INTTSG31I7	TSG31 compare match interrupt 7	189	—	—
INTTSG31I8	TSG31 compare match interrupt 8	190	—	—
INTTSG31I9	TSG31 compare match interrupt 9	191	—	—
INTTSG31I10	TSG31 compare match interrupt 10	192	—	—
INTTSG31I11	TSG31 compare match interrupt 11	193	Group0-177	Group1-50
INTTSG31I12	TSG31 compare match interrupt 12	194	Group0-178	Group1-51
INTTSG31IPEK	TSG31 peak interrupt	195	Group0-179	Group1-52
INTTSG31IVLY	TSG31 valley interrupt	196	Group0-180	Group1-53
INTTSG31IER	TSG31 error interrupt	197	—	—
INTTSG31IWN	TSG31 warning interrupt	198	—	—

This module has no error notifications.

35.1.5 Reset Sources

TSG3 reset sources are listed in the following table. TSG3n is initialized by these reset sources.

Table 35.6 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
TSG3n	All registers	√	√	√	√	√	√	—

35.1.6 External Input/Output Signals

External input/output signals of TSG3 are listed in the following table.

Table 35.7 External Input/Output Signals

Unit Signal Name	I/O	Description	Alternative Port Pin Signal Name
TSG30			
TSG30CLKI	I	Clock enable input	TSG30CLKI
TSG30PTSI0 to TSG30PTSI2	I	External pattern input	ENCA0E0, ENCA0E1, ENCA0EC*1
TSG30O0 to TSG30O7	O	Timer output	TSG30O0 to TSG30O7
TSG31			
TSG31CLKI	I	Clock enable input	TSG31CLKI
TSG31PTSI0 to TSG31PTSI2	I	External pattern input	ENCA1E0, ENCA1E1, ENCA1EC*1
TSG31O0 to TSG31O7	O	Timer output	TSG31O0 to TSG31O7

Note 1. External pattern input is shared with ENCAn input.

35.2 Overview

35.2.1 Functional Overview

The TSG3n is an 18-bit timer counter with various motor control functions.

- Count clock resolution: Minimum 12.5 ns (count clock = 80 MHz)
- Operating mode corresponding to various motor control methods
- Compare registers with reload buffer
- 10-bit dead time counter
  - Dead time counter with reload buffer
  - Independent dead time can be set for positive to negative phase change and negative to positive phase change.
- A/D conversion trigger signal generation
  - Three A/D conversion trigger signals can be generated by the compare registers TSG3nDCMP0E, TSG3nDCMP1E, and TSG3nDCMP2E.
  - Skipping function of A/D conversion trigger signals TSG3nADTRG0 and TSG3nADTRG1 can be set independently. The skipping ratio can be selected among 1/1, 1/2, 1/4, and 1/8.
  - The dedicated pin (TSG3nO7) can be used to output the toggle or diagnostic signal set by the TSG3nADTRG0 signal and reset by the TSG3nADTRG1 signal.
- Interrupt skipping
  - Skipping rate: 1/1 to 1/32
- Forced output stop function
  - Using the timer option (TAPA) function allows high-impedance control of the TSG3nO1 to TSG3nO6 pin outputs.
- Compare value setting
  - Reload (simultaneous rewrite) or anytime rewrite can be selected.
- Reload mode
  - Writing to TSG3nCMP1E (setting the reload request flag (TSG3nRSF)) enables reload, and allows simultaneous transfer of values for multiple registers.
  - Data can be transferred at peak/valley/peak or valley reload timing
  - Reload request flag (TSG3nRSF)
  - Register address assignment allowing DMA transfer
  - Reload skipping
- HT-PWM mode
  - 0 to 100% PWM duty cycle output is possible (with possible dead time reduction).
  - The LSB in the compare register can be used to append an additional pulse to the PWM output during count up, thus improving the output resolution without extra load on software.

- 120-DC control
  - Semi-automatic cruise function (trigger signal can be generated by an offset in conjunction with two-phase encoder, three-phase encoder, or ENCA).
- Three-phase encoder function (hall sensor signals can be input).
- Active level of the output pins TSG3nO1 to TSG3nO6 can be set individually.
- Fail-safe function (warning interrupt or error interrupt can be generated)
  - Simultaneous active output detect function for positive and inverse phases.
  - Abnormal input detection function of the three-phase encoder

NOTE

In this section, active level is indicated as high level.

35.3 Registers

35.3.1 List of Registers

TSG3n registers are listed in the following table.

For <TSG3n_base>, see **Section 35.1.2, Register Base Addresses**.

Table 35.8 List of Registers (1/3)

Module Name	Register Name	Symbol	Address	Reload	Access Protection	
					PBG	Other
TSG3n	TSG3n control register 0	TSG3nCTL0	<TSG3n_base> + 208_H	Disabled	*1	—
TSG3n	TSG3n control register 1	TSG3nCTL1	<TSG3n_base> + $20C_H$	Disabled	*1	—
TSG3n	TSG3n control register 2	TSG3nCTL2	<TSG3n_base> + 078_H	Enabled	*1	—
TSG3n	TSG3n control register 3	TSG3nCTL3	<TSG3n_base> + 004_H	Disabled	*1	—
TSG3n	TSG3n control register 4	TSG3nCTL4	<TSG3n_base> + $07C_H$	Enabled	*1	—
TSG3n	TSG3n control register 5	TSG3nCTL5	<TSG3n_base> + 008_H	Disabled	*1	—
TSG3n	TSG3n control register 6	TSG3nCTL6	<TSG3n_base> + $00C_H$	Disabled	*1	—
TSG3n	TSG3n control register 7	TSG3nCTL7	<TSG3n_base> + 218_H	Disabled	*1	—
TSG3n	TSG3n control register 8	TSG3nCTL8	<TSG3n_base> + $21C_H$	Disabled	*1	—
TSG3n	TSG3n I/O control register 0	TSG3nIOC0	<TSG3n_base> + 200_H	Disabled	*1	—
TSG3n	TSG3n I/O control register 1	TSG3nIOC1	<TSG3n_base> + 204_H	Disabled	*1	—
TSG3n	TSG3n I/O control register 2	TSG3nIOC2	<TSG3n_base> + 000_H	Disabled	*1	—
TSG3n	TSG3n I/O control register 3	TSG3nIOC3	<TSG3n_base> + 074_H	Enabled	*1	—
TSG3n	TSG3n status register 0	TSG3nSTR0	<TSG3n_base> + 010_H	Disabled	*1	—

Note 1. n = 0: PBG51#6
n = 1: PBG51#7

35.3.2 TSG3nCTL0 — TSG3n Control Register 0

This register specifies the pulse width for the diagnostic output and operating mode of the TSG3n.

Access: This register can be read or written in 8-bit units.

Address: <TSG3n_base> + 208_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	TSG3nDWD	—	TSG3nMD[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R	R/W	R/W	R/W

Table 35.9 TSG3nCTL0 Register Contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4	TSG3nDWD	Selects the pulse width for the diagnostic output. 0: The output pulse width is set to 8 clocks. 1: The output pulse width is set to 16 clocks. The setting of this bit is valid when diagnostic output is enabled (TSG3nIOC1.TSG3nTGS = 1).
3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2 to 0	TSG3nMD[2:0]	Selects timer mode

TSG3n MD2	TSG3n MD1	TSG3n MD0	Timer Mode
0	0	0	PWM mode
0	0	1	HT-PWM mode (HT-PWM)
0	1	0	Shift pulse PWM mode (SP-PWM)
0	1	1	120-DC mode
1	0	0	High-accuracy shift pulse PWM mode (HSP-PWM)
Other than above			Setting prohibited

CAUTION

This register should be set when the timer is stopped (TSG3nSTR0.TSG3nTE = 0). Only the same value can be written during timer operation (TSG3nSTR0.TSG3nTE = 1). If the different value is written to this register when TSG3nSTR0.TSG3nTE = 1, timer operation cannot be guaranteed. If this register is erroneously rewritten, set this register again after stopping the timer

35.3.3 TSG3nCTL1 — TSG3n Control Register 1

This register controls the flags of TSG3n.

Access: This register can be read or written in 16-bit units.

Address: <TSG3n_base> + $20C_H$

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TSG3nTBA2	TSG3nTBA1	TSG3nTBA0	TSG3nPPC	TSG3nPEC	TSG3nTDC	TSG3nNDC	TSG3nPRC	TSG3nPTC[1:0]	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 35.10 TSG3nCTL1 Register Contents (1/2)

Bit Position	Bit Name	Function
15 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	TSG3nTBA2	Enables or disables detection of the simultaneous active states of the TSG3nO5 and TSG3nO6 pins. 0: Disables detection of simultaneous active states of the TSG3nO5 and TSG3nO6 pins. 1: Enables detection of simultaneous active states of the TSG3nO5 and TSG3nO6 pins. If the simultaneous active state is detected when the TSG3nIOC1.TSG3nEOC and TSG3nTBA2 bits are 1, the positive phase and inverse phase simultaneous active state detection flag 2 (TSG3nTBF2) is set to 1, and an error interrupt (INTTSG3nIER) is generated.
8	TSG3nTBA1	Enables or disables detection of the simultaneous active states of the TSG3nO3 and TSG3nO4 pins. 0: Disables detection of simultaneous active states of the TSG3nO3 and TSG3nO4 pins. 1: Enables detection of simultaneous active states of the TSG3nO3 and TSG3nO4 pins. If the simultaneous active state is detected when the TSG3nIOC1.TSG3nEOC and TSG3nTBA1bits are 1, the positive phase and inverse phase simultaneous active state detection flag 1 (TSG3nTBF1) is set to 1, and an error interrupt (INTTSG3nIER) is generated.
7	TSG3nTBA0	Enables or disables detection of the simultaneous active states of the TSG3nO1 and TSG3nO2 pins. 0: Disables detection of simultaneous active states of the TSG3nO1 and TSG3nO2 pins. 1: Enables detection of simultaneous active states of the TSG3nO1 and TSG3nO2 pins. If the simultaneous active state is detected when the TSG3nIOC1.TSG3nEOC and TSG3nTBA0 bits are 1, the positive phase and inverse phase simultaneous active state detection flag 0 (TSG3nTBF0) is set to 1, and an error interrupt (INTTSG3nIER) is generated.
6	TSG3nPPC	Enables or disables detection of the pattern phase difference (TSG3nSTR2.TSG3nPPF) between the TSG3nPTSI2-0 and TSG3nOPF2-0. 0: Disables detection of I/O pattern difference. 1: Enables detection of I/O pattern difference
5	TSG3nPEC	Enables or disables detection of the pattern error (TSG3nSTR2.TSG3nPEF) of the TSG3nPTSI2-0 pins. 0: Disables detection of the pattern error of the TSG3nPTSI2-0 pins. 1: Enables detection of the pattern error of the TSG3nPTSI2-0 pins.

Table 35.10 TSG3nCTL1 Register Contents (2/2)

<table>
<tr><th>Bit Position</th><th>Bit Name</th><th>Function</th></tr>

<tr><td>1</td><td>0</td><td>Enables detection of an abnormal toggle of the TSG3nPTSI2-0 pins.</td></tr>
<tr><td>1</td><td>1</td><td>Enables detection of an abnormal toggle of the TSG3nPTSI2-0 pins. When an abnormal toggle is detected, the pattern output switch trigger is automatically switched from trigger switch to pattern switch (TSG3nPOT is switched from 1 to 0.)</td></tr>
</table>
</td></tr>
</table>

CAUTIONS

1. If TSG3nDTC0 or TSG3nDTC1 is set to 0000_H (without dead time), the TSG3nTBA2-0 bits should be set to 0.
2. This register should be set when the timer is stopped (TSG3nSTR0.TSG3nTE = 0). Only the same value can be written during timer operation (TSG3nSTR0.TSG3nTE = 1). If the different value is written to this register when TSG3nSTR0.TSG3nTE = 1, timer operation cannot be guaranteed. If this register is erroneously rewritten, set this register again after stopping the timer

35.3.4 TSG3nCTL2 — TSG3n Control Register 2

This register selects a count clock for TSG3n.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + 078_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSG3nCKS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 35.11 TSG3nCTL2 Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	TSG3nCKS	Selects a count clock 0: Selects PCLK as a count clock. 1: Counted by PCLK when clock enable input (TSG3nCLKI) is high level.

CAUTION

Set the TSG3nCTL2.TSG3nCKS bit to 0 in HT-PWM mode and HSP-PWM mode.

35.3.5 TSG3nCTL3 — TSG3n Control Register 3

This register selects the rewrite method of the compare registers.

Access: This register can be read or written in 8-bit units.

Address: <TSG3n_base> + 004_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TSG3nRIA	TSG3nRMC
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 35.12 TSG3nCTL3 Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	TSG3nRIA	Selects the reload timing of the compare register values. 0: The reload timing is set to peak reload timing (set by TSG3nCTL4.TSG3nPRE) and valley reload timing (set by TSG3nCTL4.TSG3nVRE). 1: The reload timing is set to peak interrupt timing and valley interrupt timing. The setting of this bit is valid in reload mode (TSG3nRMC = 0).
0	TSG3nRMC	Selects the transfer timing of the compare register values. 0: Reload mode (simultaneous rewrite) Writing to registers to be reloaded enables reloading and the register values are rewritten simultaneously at the next reload timing. Writing to any register other than registers to be reloaded does not enable reloading. For the register to be reloaded, see **Section 35.3.1, List of Registers**. 1: Anytime rewrite mode The compare registers are rewritten independently. Whenever a value is written to the compare register, the written value is reflected immediately. TSG3nRSF is cleared. Do not set TSG3nRMC to 1 when operated in 120-DC mode or in HSP-PWM mode.

35.3.6 TSG3nCTL4 — TSG3n Control Register 4

This register enables or disables generation of a peak interrupt and a valley interrupt, and the reload timing.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + $07C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	TSG3n PRE	TSG3n VRE	TSG3n PIE	TSG3n VIE	TSG3nRCC[04:00]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 35.13 TSG3nCTL4 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	TSG3nPRE	Enables or disables the peak reload timing. 0: Disables reload operation at the peak timing of the 18-bit counter. 1: Enables reload operation at the peak timing of the 18-bit counter. • The peak reload timing means the peak timing of the 18-bit counter in HT-PWM mode and the clear timing of the 18-bit counter by compare match in any mode other than HT-PWM mode. • When the reload operation at the peak timing of the 18-bit counter is disabled (TSG3nPRE = 0), reload is not executed in any mode other than HT-PWM mode.
7	TSG3nVRE	Enables or disables the valley reload timing. 0: Disables reload operation at the valley timing of the 18-bit counter. 1: Enables reload operation at the valley timing of the 18-bit counter. The setting of this bit is valid only in HT-PWM mode.
6	TSG3nPIE	Enables or disables generation of a peak interrupt (INTTSG3nIPEK). 0: Disables generation of a peak interrupt (INTTSG3nIPEK) at the peak timing of the 18-bit counter. Interrupts are not skipped. 1: Enables generation of a peak interrupt (INTTSG3nIPEK) at the peak timing of the 18-bit counter. Interrupts are skipped.
5	TSG3nVIE	Enables or disables generation of a valley interrupt (INTTSG3nIVLY). 0: Disables generation of a valley interrupt (INTTSG3nIVLY) at the valley timing of the 18-bit counter. Interrupts are not skipped. 1: Enables generation of a valley interrupt (INTTSG3nIVLY) at the valley timing of the 18-bit counter. Interrupts are skipped. The setting of this bit is valid only in HT-PWM mode.

Table 35.13 TSG3nCTL4 Register Contents (2/2)

<table>
<tr><th>Bit Position</th><th>Bit Name</th><th>Function</th></tr>
<tr><td>4 to 0</td><td>TSG3nRCC [04:00]</td><td>Specifies the skipping rate of the interrupts (INTTSG3nIPEK and INTTSG3nIVLY) and reload.
<table>

</table>
When a write access is made (including a write of the same value to TSG3nRCC04-TSG3nRCC00) to TSG3nCTL4 during timer operation (TSG3nSTR0.TSG3nTE = 1), the interrupt skipping counter is cleared</td></tr>
</table>

35.3.7 TSG3nCTL5 — TSG3n Control Register5

This register controls A/D conversion trigger output (TSG3nADTRG0).

Access: This register can be read or written in 16-bit units.

Address: <TSG3n_base> +008_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	TSG3nACC [01:00]		TSG3n AT09	TSG3n AT08	TSG3n AT07	TSG3n AT06	TSG3n AT05	TSG3n AT04	TSG3n AT03	TSG3n AT02	TSG3n AT01	TSG3n AT00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 35.14 TSG3nCTL5 Register Contents (1/3)

Bit Position	Bit Name	Function
15 to 12	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
11, 10	TSG3nACC [01:00]	Specifies the skipping rate of the A/D conversion trigger (TSG3nADTRG0). **TSG3nACC01 / TSG3nACC00 / Skipping Rate** 0 / 0 / Skipping Disabled 0 / 1 / 1/2 1 / 0 / 1/4 1 / 1 / 1/8 When a write access is made (including a write of the same value to TSG3nACC01 and TSG3nACC00) to TSG3nCTL5 during timer operation (TSG3nSTR0.TSG3nTE = 1), the interrupt skipping counter is cleared.
9	TSG3nAT09	Specifies generation of A/D conversion trigger (TSG3nADTRG0) at the (peak) timing when the 18-bit sub-counter switches from incrementing to decrementing. 0: Disables generation of the A/D conversion trigger at the peak timing of the 18-bit sub-counter. 1: Enables generation of the A/D conversion trigger at the peak timing of the 18-bit sub-counter. • The TSG3nAT09 bit can be set to 1 only in HT-PWM mode. In other modes, the TSG3nAT09 bit should be set to 0. • Do not set the TSG3nAT09 bit to 1 when TSG3nDTC0W is not 0000_H and TSG3nDTC1W is 0000_H. A/D conversion trigger is not generated at the peak timing of the 18-bit sub-counter even if set so.
8	TSG3nAT08	Specifies generation of A/D conversion trigger (TSG3nADTRG0) at the (valley) timing when the 18-bit sub-counter switches from decrementing to incrementing. 0: Disables generation of the A/D conversion trigger at the valley timing of the 18-bit sub-counter. 1: Enables generation of the A/D conversion trigger at the valley timing of the 18-bit sub-counter. • The TSG3nAT08 bit can be set to 1 only in HT-PWM mode. In other modes, the TSG3nAT08 bit should be set to 0. • Do not set the TSG3nAT08 bit to 1 when TSG3nDTC0W is 0000_H and TSG3nDTC1W is not 0000_H. A/D conversion trigger is not generated at the valley timing of the 18-bit sub-counter even if set so.

Table 35.14 TSG3nCTL5 Register Contents (2/3)

Bit Position	Bit Name	Function
7	TSG3nAT07	Specifies generation of A/D conversion trigger (TSG3nADTRG0) at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP2E value. 0: Disables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP2E value. 1: Enables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP2E value. This bit can be set to 1 only in HT-PWM mode. In other modes, this bit should be set to 0.
6	TSG3nAT06	Specifies generation of A/D conversion trigger (TSG3nADTRG0) at the match timing of the 18-bit counter value during incrementation with the TSG3nDCMP2E value. 0: Disables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during incrementation with the TSG3nDCMP2E value. 1: Enables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during incrementation with the TSG3nDCMP2E value
5	TSG3nAT05	Specifies generation of A/D conversion trigger (TSG3nADTRG0) at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP1E value. 0: Disables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP1E value. 1: Enables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP1E value. This bit can be set to 1 only in HT-PWM mode. In other modes, this bit should be set to 0.
4	TSG3nAT04	Specifies generation of A/D conversion trigger (TSG3nADTRG0) at the match timing of the 18-bit counter value during incrementation with the TSG3nDCMP1Evalue. 0: Disables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during incrementation with the TSG3nDCMP1E. 1: Enables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during incrementation with the TSG3nDCMP1E value.
3	TSG3nAT03	Specifies generation of A/D conversion trigger (TSG3nADTRG0) at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP0E value. 0: Disables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP0E value. 1: Enables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP0E value. This bit can be set to 1 only in HT-PWM mode. In other modes, this bit should be set to 0.

Table 35.14 TSG3nCTL5 Register Contents (3/3)

Bit Position	Bit Name	Function
2	TSG3nAT02	Specifies generation of A/D conversion trigger (TSG3nADTRG0) at the match timing of the 18-bit counter value during incrementation with the TSG3nDCMP0E value. 0: Disables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during incrementation with the TSG3nDCMP0E value. 1: Enables generation of the A/D conversion trigger at the timing of the 18-bit counter value during incrementation with the TSG3nDCMP0E.
1	TSG3nAT01	Specifies generation of A/D conversion trigger (TSG3nADTRG0) at the timing (peak interrupt) when the 18-bit counter switches from incrementing to decrementing. 0: Disables generation of the A/D conversion trigger at the timing of a peak interrupt (INTTSG3nIPEK) after being skipped. 1: Enables generation of the A/D conversion trigger at the timing of a peak interrupt (INTTSG3nIPEK) after being skipped.
0	TSG3nAT00	Specifies generation of A/D conversion trigger (TSG3nADTRG0) at the timing (valley interrupt) when the 18-bit counter switches from decrementing to incrementing. 0: Disables generation of the A/D conversion trigger at the timing of a valley interrupt (INTTSG3nIVLY) after being skipped. 1: Enables generation of the A/D conversion trigger at the timing of a valley interrupt (INTTSG3nIVLY) after being skipped. This bit can be set to 1 only in HT-PWM mode. In other modes, this bit should be set to 0.

CAUTION

TSG3nATxx register bits should be set when the timer is stopped (TSG3nSTR0.TSG3nTE = 0).
Only the same value with current setting can be written during timer operation (TSG3nSTR0.TSG3nTE = 1).
If the different value is written to this register when TSG3nSTR0.TSG3nTE = 1, timer operation cannot be guaranteed.

35.3.8 TSG3nCTL6 — TSG3n Control Register 6

This register controls the A/D conversion trigger output (TSG3nADTRG1).

Access: This register can be read or written in 16-bit units.

Address: <TSG3n_base> + $00C_H$

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 35.15 TSG3nCTL6 Register Contents (1/3)

Bit Position	Bit Name	Function
15 to 12	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
11, 10	TSG3nACC [11:10]	Specifies the skipping rate of the A/D conversion trigger (TSG3nADTRG1). **TSG3nACC11 / TSG3nACC10 / Skipping Rate** 0 / 0 / Skipping Disabled 0 / 1 / 1/2 1 / 0 / 1/4 1 / 1 / 1/8 When a write access is made (including a write of the same value to TSG3nACC11 and TSG3nACC10) to TSG3nCTL6 during timer operation (TSG3nSTR0.TSG3nTE = 1), the skipping counter is cleared.
9	TSG3nAT19	Specifies generation of A/D conversion trigger (TSG3nADTRG1) at the (peak) timing when the 18-bit sub-counter switches from incrementing to decrementing. 0: Disables generation of the A/D conversion trigger at the peak timing of the 18-bit sub-counter. 1: Enables generation of the A/D conversion trigger at the peak timing of the 18-bit sub-counter. • The TSG3nAT19 bit can be set to 1 only in HT-PWM mode. In other modes, the TSG3nAT19 bit should be set to 0. • Do not set the TSG3nAT19 bit to 1 when TSG3nDTC0W is not 0000_H and TSG3nDTC1W is 0000_H. A/D conversion trigger is not generated at the peak timing of the 18-bit sub-counter even if set so.
8	TSG3nAT18	Specifies generation of A/D conversion trigger (TSG3nADTRG1) at the (valley) timing when the 18-bit sub-counter switches from decrementing to incrementing. 0: Disables generation of the A/D conversion trigger at the valley timing of the 18-bit sub-counter. 1: Enables generation of the A/D conversion trigger at the valley timing of the 18-bit sub-counter. • The TSG3nAT18 bit can be set to 1 only in HT-PWM mode. In other modes, the TSG3nAT18 bit should be set to 0. • Do not set the TSG3nAT18 bit to 1 when TSG3nDTC0W is 0000_H and TSG3nDTC1W is not 0000_H. A/D conversion trigger is not generated at the valley timing of the 18-bit sub-counter even if set so.

Table 35.15 TSG3nCTL6 Register Contents (2/3)

Bit Position	Bit Name	Function
7	TSG3nAT17	Specifies generation of A/D conversion trigger (TSG3nADTRG1) at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP2E value. 0: Disables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP2E value. 1: Enables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP2E value. This bit can be set to 1 only in HT-PWM mode. In other modes, this bit should be set to 0.
6	TSG3nAT16	Specifies generation of A/D conversion trigger (TSG3nADTRG1) at the match timing of the 18-bit counter value during incrementation with the TSG3nDCMP2E value. 0: Disables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during incrementation with the TSG3nDCMP2E value. 1: Enables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during incrementation with the TSG3nDCMP2E value.
5	TSG3nAT15	Specifies generation of A/D conversion trigger (TSG3nADTRG1) at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP1E value. 0: Disables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP1E value. 1: Enables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP1E value. This bit can be set to 1 only in HT-PWM mode. In other modes, this bit should be set to 0.
4	TSG3nAT14	Specifies generation of A/D conversion trigger (TSG3nADTRG1) at the match timing of the 18-bit counter value during incrementation with the TSG3nDCMP1E value. 0: Disables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during incrementation with the TSG3nDCMP1E value. 1: Enables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during incrementation with the TSG3nDCMP1E value.
3	TSG3nAT13	Specifies generation of A/D conversion trigger (TSG3nADTRG1) at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP0E value. 0: Disables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP0E value. 1: Enables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during decrementation with the TSG3nDCMP0E value. This bit can be set to 1 only in HT-PWM mode. In other modes, this bit should be set to 0.

Table 35.15 TSG3nCTL6 Register Contents (3/3)

Bit Position	Bit Name	Function
2	TSG3nAT12	Specifies generation of A/D conversion trigger (TSG3nADTRG1) at the match timing of the 18-bit counter value during incrementation with the TSG3nDCMP0E. 0: Disables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during incrementation with the TSG3nDCMP0E value. 1: Enables generation of the A/D conversion trigger at the match timing of the 18-bit counter value during incrementation with the TSG3nDCMP0E value.
1	TSG3nAT11	Specifies generation of A/D conversion trigger (TSG3nADTRG1) at the timing (peak interrupt) when the 18-bit counter switches from incrementing to decrementing. 0: Disables generation of the A/D conversion trigger at the timing of a peak interrupt (INTTSG3nIPEK) after being skipped. 1: Enables generation of the A/D conversion trigger at the timing of a peak interrupt (INTTSG3nIPEK) after being skipped.
0	TSG3nAT10	Specifies generation of A/D conversion trigger (TSG3nADTRG1) at the timing (valley interrupt) when the 18-bit counter switches from incrementing to decrementing. 0: Disables generation of the A/D conversion trigger at the timing of a valley interrupt (INTTSG3nIVLY) after being skipped. 1: Enables generation of the A/D conversion trigger at the timing of a valley interrupt (INTTSG3nIVLY) after being skipped. This bit can be set to 1 only in HT-PWM mode. In other modes, this bit must be set to 0.

CAUTION

TSG3nATxx register bits should be set when the timer is stopped (TSG3nSTR0.TSG3nTE = 0).
Only the same value with current setting can be written during timer operation (TSG3nSTR0.TSG3nTE = 1).
If the different value is written to this register when TSG3nSTR0.TSG3nTE = 1, timer operation cannot be guaranteed.

35.3.9 TSG3nCTL7 — TSG3n Control Register 7

This register sets the level of PWM output from the TSG3O1 to TSG3O6 pins at operation start (TSG3nTE is changed from 0 to 1) and at operation restart in SP-PWM mode.

This register can be written only when SP-PWM mode is selected (TSG3nMD2 to TSG3nMD0 = 010) and the timer is stopped (TSG3nTE = 0). Do not rewrite this register in other modes (PWM mode, HT-PWM mode, 120-DC mode, HSP-PWM mode) or while the timer is operating (TSG3nTE = 1).

Access: This register can be read or written in 8-bit units.

Address: <TSG3n_base> + 218_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	TSG3n SPSTL2	TSG3n SPSTL1	TSG3n SPSTL0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 35.16 TSG3nCTL7 Register Contents

Bit Position	Bit Name	Function
7 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	TSG3nSPSTL2	SP-PWM Mode Start Level Control Bit 2 0: TSG3nO5 (W phase) is cleared and TSG3nO6 (WB phase) is set at operation start (TSG3nTE changed from 0 to 1) or restart in SP-PWM mode. 1: TSG3nO5 (W phase) is set and TSG3nO6 (WB phase) is cleared at operation start (TSG3nTE changed from 0 to 1) or restart in SP-PWM mode.
1	TSG3nSPSTL1	SP-PWM Mode Start Level Control Bit 1 0: TSG3nO3 (V phase) is cleared and TSG3nO4 (VB phase) is set at operation start (TSG3nTE changed from 0 to 1) or restart in SP-PWM mode. 1: TSG3nO3 (V phase) is set and TSG3nO4 (VB phase) is cleared at operation start (TSG3nTE changed from 0 to 1) or restart in SP-PWM mode.
0	TSG3nSPSTL0	SP-PWM Mode Start Level Control Bit 0 0: TSG3nO1 (U phase) is cleared and TSG3nO2 (UB phase) is set at operation start (TSG3nTE changed from 0 to 1) or restart in SP-PWM mode. 1: TSG3nO3 (U phase) is set and TSG3nO1 (UB phase) is cleared at operation start (TSG3nTE changed from 0 to 1) or restart in SP-PWM mode.

NOTE

The settings of bits TSG3nSPSTL2 to TSG3nSPSTL0 affect output on the TSG3nO1 to TSG3nO6 pins when operation starts or is restarted. The set dead time is always inserted at these times.

35.3.10 TSG3nCTL8 — TSG3n Control Register 8

This register specifies timer output timing when input patterns are changed in 120-DC mode.

This register can be written only when 120-DC mode is selected (TSG3nMD2-0 = 011) and the timer is stopped (TSG3nTE = 0).

Do not rewrite this register in other modes (PWM mode, SP-PMW mode, HT-PWM mode, HSP-PWM mode) or while the timer is operating (TSG3nTE = 1).

Access: This register can be read or written in 8-bit units.

Address: <TSG3n_base> +$21C_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TSG3n S120DCO
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 35.17 TSG3nCTL8 Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	TSG3n S120DCO	120-DC Mode Control Bit 0 0: When the input patterns are changed while 120-DC mode is selected, the main counter (TSG3nCNTE) is cleared and the change of input patterns is immediately reflected to timer output. 1: When the input patterns are changed while 120-DC mode is selected, the change of input patterns is reflected to timer output after a match of the main counter (TSG3nCNTE) with TSG3nCMP0E (from the next timer period).

CAUTION

When TSG3nS120DCO is set to 1 in 120DC mode, set the TSG3nOPT0.TSG3nSOC bit to 0.

The settings of the TSG3nOPT0.TSG3nSTE and TSG3nOPT0.TSG3nPOT bits must not be changed while the timer is operating (TSG3nSTR0.TSG3nTE = 1).

35.3.11 TSG3nIOC0 — TSG3n I/O Control Register0

This register controls the timer output pins (TSG3nO1 to TSG3nO6).

Access: This register can be read or written in 8-bit units.

Address: <TSG3n_base> +200_H

Value after reset: $7E_H$

Bit	7	6	5	4	3	2	1	0
	—	TSG3nTOE6	TSG3nTOE5	TSG3nTOE4	TSG3nTOE3	TSG3nTOE2	TSG3nTOE1	—
Value after reset	0	1	1	1	1	1	1	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 35.18 TSG3nIOC0 Register Contents

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 1	TSG3nTOE6 to TSG3nTOE1	Enables or disables controlling of TSG3nO6 to TSG3nO1 by TSG3nIOC2. When these bits are 1, rewriting of TSG3nIOC2 is ignored. 0: Controlling is enabled. 1: Controlling is disabled.
0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

CAUTION

This register should be set when the timer is stopped (TSG3nSTR0.TSG3nTE = 0). Only the same value can be written during timer operation (TSG3nSTR0.TSG3nTE = 1). If the different value is written to this register when TSG3nSTR0.TSG3nTE = 1, timer operation cannot be guaranteed. If this register is erroneously rewritten, set this register again after stopping the timer.

35.3.12 TSG3nIOC1 — TSG3n I/O Control Register1

This register controls the timer output pins (TSG3nO1 to TSG3nO6).

Access: This register can be read or written in 8-bit units.

Address: <TSG3n_base> + 204_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	TSG3nPTS	TSG3nEOC	TSG3nWOC	TSG3nTGS	TSG3nTOS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 35.19 TSG3nIOC1 Register Contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4	TSG3nPTS	Enables or disables output of the edge detection signal (TSG3nPTE) of TSG3nPTSI0 to TSG3nPTSI2 and two-phase encoder count signal (TSG3nPEC). 0: Disables output of the toggle signal by edge detection of TSG3nPTSI0 to TSG3nPTSI2. 1: Enables output of the toggle signal by edge detection of TSG3nPTSI0 to TSG3nPTSI2.
3	TSG3nEOC	Enables or disables detection of the error condition at the motor control. 0: Disables generation of an error interrupt (INTTSG3nIER). 1: Enables generation of an error interrupt (INTTSG3nIER). For details on controlling the error interrupt, see **Section 35.4.6.1, Error Interrupt Function**.
2	TSG3nWOC	Enables or disables detection of the warning condition at the motor control. 0: Disables generation of a warning interrupt (INTTSG3nIWN). 1: Enables generation of a warning interrupt (INTTSG3nIWN). For details on the controlling generation of warning interrupt, see **Section 35.4.6.2, Warning Interrupt Function**.
1	TSG3nTGS	Selects the A/D conversion trigger diagnostic output (TSG3nO7) signal. 0: Selects A/D conversion trigger output. 1: Selects diagnostic output.
0	TSG3nTOS	Selects the timer counter increment/decrement status output (TSG3nO0) signal. 0: Outputs the up/down count flag of the 18-bit counter. 1: Outputs the up/down count flag of the 18-bit sub-counter. • When TSG3nTOS is 0, the status of TSG3nSTR0.TSG3nCUF is output to TSG3nO0. When TSG3nTOS is 1, the status of TSG3nSTR0.TSG3nSUF is output to TSG3nO0. • The setting of this bit is valid only in HT-PWM mode.

CAUTION

This register should be set when the timer is stopped (TSG3nSTR0.TSG3nTE = 0). Only the same value can be written during timer operation (TSG3nSTR0.TSG3nTE = 1). If the different value is written to this register when TSG3nSTR0.TSG3nTE = 1, timer operation cannot be guaranteed. If this register is erroneously rewritten, set this register again after stopping the timer.

35.3.13 TSG3nIOC2 — TSG3n I/O Control Register2

This register controls the timer output pins (TSG3nO1 to TSG3nO6).

Access: This register can be read or written in 16-bit units.

Address: <TSG3n_base> + 000_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	TSG3nOL6	TSG3nOL5	TSG3nOL4	TSG3nOL3	TSG3nOL2	TSG3nOL1	—	—	TSG3nTO6	TSG3nTO5	TSG3nTO4	TSG3nTO3	TSG3nTO2	TSG3nTO1	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 35.20 TSG3nIOC2 Register Contents

Bit Position	Bit Name	Function
15	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
14 to 9	TSG3nOL6 to TSG3nOL1	Specifies the active level of TSG3nO6 to TSG3nO1 outputs. 0: Active level is high level 1: Active level is low level
8 to 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 1	TSG3nTO6 to TSG3nTO1	Specifies the latch level of the output buffer of the TSG3nO6 to TSG3nO1. 0: Latch level of output buffer is low level 1: Latch level of output buffer is high level
0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

CAUTION

When the counting is stopped (TSG3nSTR0.TSG3nTE = 0), the TSG3nO1-6 pins maintain their previous output states. The output level should be changed by setting the TSG3nIOC0.TSG3nTOEm bit to 0, using the TSG3nTOm bit. This register can be rewritten when TSG3nIOC0.TSG3nTOEm = 0 (m = 1 to 6).

NOTE

While the timer is stopped (TSG3nSTR0.TSG3nTE = 0) and control of TSG3nOm by rewriting TSG3nIOC2 is enabled (TSG3nIOC0.TSG3nTOEm = 0), TSG3nOLm and TSG3nTOm of TSG3nIOC2 select the output level for the corresponding TSG3nOm output as listed in the table below.

TSG3nOLm	TSG3nTOm	Output level of TSG3nOm
0	0	Low level
0	1	High level
1	0	High level
1	1	Low level

35.3.14 TSG3nIOC3 — TSG3n I/O Control Register3

This register controls timer output pins (TSG3nO1 to TSG3nO6).

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + 074_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	TSG3n TOL6	TSG3n TOL5	TSG3n TOL4	TSG3n TOL3	TSG3n TOL2	TSG3n TOL1	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 35.21 TSG3nIOC3 Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 1	TSG3nTOL6 to TSG3nTOL1	Controls the set/clear level of output. 0: Outputs the normal level. 1: Outputs the reversed level. Setting of this bit is reflected at the start of output. The change of the output level is reflected at the next compare match timing after the change.
0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

CAUTION

TSG3nTOL6 to TSG3nTOL1 should be set to 0 in HT-PWM mode and HSP-PWM mode.

35.3.15 TSG3nSTR0 — TSG3n Status Register 0

This register controls the flags.

Access: This register is a read-only register that can be read in 8-bit units.

Address: <TSG3n_base> + 010_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TSG3nCUF	TSG3nSUF	TSG3nRSF	TSG3nTE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 35.22 TSG3nSTR0 Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is returned.
3	TSG3nCUF	Indicates the count direction of the 18-bit counter. 0: The 18-bit counter is incremented. 1: The 18-bit counter is decremented. TSG3nCUF is valid only in HT-PWM mode. In other modes, it is invalid (TSG3nCUF = 0).
2	TSG3nSUF	Indicates the count direction of the 18-bit sub-counter. 0: The 18-bit sub-counter is incremented. 1: The 18-bit sub-counter is decremented. • TSG3nSUF detects counting of the 18-bit sub-counter from 0000_H to (TSG3nCMP0E value - 0002_H) as up-counting, and counting from the TSG3nCMP0E value to 0002_H as down-counting. • This bit is valid only in HT-PWM mode.
1	TSG3nRSF	Indicates whether there is a reload request. 0: No reload request or reload has completed. 1: There is a reload request. • This bit is valid only in TSG3nRMC = 0. • This bit indicates that the data to be transferred next is held. • This bit is set to 1 by writing to registers to be reloaded, and cleared to 0 when reload has completed. • When TSG3nRMC is changed from 0 to 1 in HT-PWM mode, TSG3nRSF is cleared to 0. For registers to be reloaded, see **Section 35.3.1, List of Registers**.
0	TSG3nTE	Indicates the TSG3n operation status. 0: TSG3n is stopped. 1: TSG3n is operating. This bit is set when TSG3nTRG0.TSG3nTS = 1, and cleared when TSG3nTRG1.TSG3nTT = 1.

35.3.16 TSG3nSTR1 — TSG3n Status Register 1

This register controls the flags.

Access: This register is a read-only register that can be read in 8-bit units.

Address: <TSG3n_base> + 014_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TSG3nTSF	TSG3nOPF[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 35.23 TSG3nSTR1 Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is returned.
3	TSG3nTSF	Indicates the pattern change order of TSG3nPTSI0 to TSG3nPTSI2. 0: Indicates that patterns are input to TSG3nPTSI0 to TSG3nPTSI2 in the normal rotation pattern order 1: Indicates that patterns are input to TSG3nPTSI0 to TSG3nPTSI2 in the reverse rotation pattern order. Normal Rotation → Reverse Rotation ← TSG3nPTSI2-TSG3nPTSI0: [1,0,1] [1,0,0] [1,1,0] [0,1,0] [0,1,1] [0,0,1] Normal or reverse rotation can be detected from the first change of TSG3nPTSI0 to TSG3nPTSI2 after TSG3nTRG0.TSG3nTS has been set to 1. For details, see **Section 35.4.3.5, (b) Detection of Change in Input Pattern Order**.
2 to 0	TSG3nOPF [2:0]	Indicates the output pattern of the timer output pins (TSG3nO1 to TSG3nO6).

35.3.17 TSG3nSTR2 — TSG3n Status Register 2

This register controls the flags.

Access: This register is a read-only register that can be read in 16-bit units.

Address: <TSG3n_base> + 018_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TSG3n TBF2	TSG3n TBF1	TSG3n TBF0	TSG3n PPF	TSG3n PEF	TSG3n TDF	TSG3n NDF	TSG3n PRF	TSG3n PTF	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 35.24 TSG3nSTR2 Register Contents (1/3)

Bit Position	Bit Name	Function
15 to 10	Reserved	When read, the value after reset is returned.
9	TSG3nTBF2	Indicates whether the simultaneous active state of the positive phase and inverse phase is detected when TSG3nCTL1.TSG3nTBA2 is 1. 0: Positive phase (TSG3nO5) and inverse phase (TSG3nO6) are not active simultaneously. 1: Positive phase (TSG3nO5) and inverse phase (TSG3nO6) are active simultaneously. • TSG3nTBF2 is set to 1 when the simultaneous active state of the positive phase (TSG3nO5) and inverse phase (TSG3nO6) is detected, and an error interrupt (INTTSG3nIER) is generated. TSG3nTBF2 can be cleared by changing TSG3nSTR0.TSG3nTE from 0 to 1 (operation start) or by writing 1 to TSG3nSTC.TSG3nTBR2. • The simultaneous active state is not detected when TSG3nTBA2 = 0.
8	TSG3nTBF1	Indicates whether the simultaneous active state of the positive phase and inverse phase is detected when TSG3nCTL1.TSG3nTBA1 is 1. 0: Positive phase (TSG3nO3) and inverse phase (TSG3nO4) are not active simultaneously. 1: Positive phase (TSG3nO3) and inverse phase (TSG3nO4) are active simultaneously. • TSG3nTBF1 is set to 1 when the simultaneous active state of the positive phase (TSG3nO3) and inverse phase (TSG3nO4) is detected, and an error interrupt (INTTSG3nIER) is generated. TSG3nTBF1 can be cleared by changing TSG3nSTR0.TSG3nTE from 0 to 1 (operation start) or by writing 1 to TSG3nSTC.TSG3nTBR1. • The simultaneous active state is not detected when TSG3nTBA1 = 0.
7	TSG3nTBF0	Indicates whether the simultaneous active state of the positive phase and inverse phase is detected when TSG3nCTL1.TSG3nTBA0 is 1. 0: Positive phase (TSG3nO1) and inverse phase (TSG3nO2) are not active simultaneously. 1: Positive phase (TSG3nO1) and inverse phase (TSG3nO2) are active simultaneously. • TSG3nTBF0 is set to 1 when the simultaneous active state of the positive phase (TSG3nO1) and inverse phase (TSG3nO2) is detected, and an error interrupt (INTTSG3nIER) is generated. TSG3nTBF0 can be cleared by changing TSG3nSTR0.TSG3nTE from 0 to 1 (operation start) or by writing 1 to TSG3nSTC.TSG3nTBR0. • The simultaneous active state is not detected when TSG3nTBA0 = 0.

Table 35.24 TSG3nSTR2 Register Contents (2/3)

Bit Position	Bit Name	Function
6	TSG3nPPF	Indicates detection of the difference between the input patterns (TSG3nPTSI0 to TSG3nPTSI2) and the output patterns (TSG3nO1 to TSG3nO6) after they are compared. 0: No phase difference detected between the input patterns (TSG3nPTSI0 to TSG3nPTSI2) and the output patterns (TSG3nO1 to TSG3nO6). 1: A phase difference detected between the input patterns (TSG3nPTSI0 to TSG3nPTSI2) and the output patterns (TSG3nO1 to TSG3nO6). • TSG3nPPF is set to 1 when a difference between input and output patterns is detected, and a warning interrupt (INTTSG3nIWN) is generated. This bit can be cleared either by changing TSG3nSTR0.TSG3nTE from 0 to 1 (operation start), setting TSG3nTRG0.TSG3nTS to 1 (timer start), input to TSG3nTSST (timer restart), or writing 1 to TSG3nSTC.TSG3nPPR.
5	TSG3nPEF	Indicates whether an abnormal input (000_B or 111_B is input to TSG3nPTSI0 to TSG3nPTSI2) is detected. 0: No abnormal input (000_B or 111_B) to TSG3nPTSI0 to TSG3nPTSI2 detected. 1: Abnormal input (000_B or 111_B) to TSG3nPTSI0 to TSG3nPTSI2 detected. TSG3nPEF is set to 1 when an input of 000_B or 111_B to TSG3nPTSI0 to TSG3nPTSI2 is detected, and a warning interrupt (INTTSG3nIWN) is generated. TSG3nPEF can be cleared by changing TSG3nSTR0.TSG3nTE from 0 to 1 (operation start), by setting TSG3nTRG0.TSG3nTS to 1 (starting timer operation), by input to TSG3nTSST (timer restart), or by writing 1 to TSG3nSTC.TSG3nPER. TSG3nPEF is valid when TSG3nCTL1.TSG3nPEC = 1.
4	TSG3nTDF	Indicates whether simultaneous generation of the TSG3nOPCI0 and TSG3nOPCI1 triggers is detected. 0: Simultaneous generation of the TSG3nOPCI0 and TSG3nOPCI1 triggers not detected. 1: Simultaneous generation of the TSG3nOPCI0 and TSG3nOPCI1 triggers detected. TSG3nTDF is set to 1 when simultaneous generation of the TSG3nOPCI0 and TSG3nOPCI1 triggers is detected, and a warning interrupt (INTTSG3nIWN) is generated. TSG3nTDF can be cleared by changing TSG3nSTR0.TSG3nTE from 0 to 1 (operation start), by setting TSG3nTRG0.TSG3nTS to 1 (starting timer operation), by input to TSG3nTSST (timer restart), or by writing 1 to TSG3nSTC.TSG3nTDR. TSG3nTDF is valid when TSG3nCTL1.TSG3nTDC = 1.
3	TSG3nNDF	Indicates whether noise on TSG3nPTSI0 to TSG3nPTSI2 is detected. 0: Noise on TSG3nPTSI0 to TSG3nPTSI2 due to simultaneous change of two or more pins not detected. 1: Noise on TSG3nPTSI0 to TSG3nPTSI2 due to simultaneous change of two or more pins detected. TSG3nNDF is set to 1 when simultaneous change of two or more pins in TSG3nPTSI0 to TSG3nPTSI2 is detected, and a warning interrupt (INTTSG3nIWN) is generated. TSG3nNDF can be cleared by changing TSG3nSTR0.TSG3nTE from 0 to 1 (operation start), by setting TSG3nTRG0.TSG3nTS to 1(starting timer operation), by input to TSG3nTSST (timer restart), or by writing 1 to TSG3nSTC.TSG3nNDR. TSG3nNDF is valid when TSG3nCTL1.TSG3nNDC = 1.

Table 35.24 TSG3nSTR2 Register Contents (3/3)

Bit Position	Bit Name	Function
2	TSG3nPRF	Indicates whether reversal of the TSG3nPTSI0 to TSG3nPTSI2 input order is detected. 0: The reversal of the TSG3nPTSI0 to TSG3nPTSI2 input order not detected. 1: The reversal of the TSG3nPTSI0 to TSG3nPTSI2 input order detected. TSG3nPRF is set to 1 when TSG3nSTR1.TSG3nTSF changes, and a warning interrupt (INTTSG3nIWN) is generated. TSG3nPRF can be cleared by changing TSG3nSTR0.TSG3nTE from 0 to 1 (operation start), by setting TSG3nTRG0.TSG3nTS to 1 (timer operation start), by input to TSG3nTSST(timer restart), or by writing 1 to TSG3nSTC.TSG3nPRR. Detection is possible from the second TSG3nPTSI0 to TSG3nPTSI2 change timing after setting TSG3nTRG0.TSG3nTS = 1. TSG3nPRF is valid when TSG3nCTL1.TSG3nPRC = 1.
1	TSG3nPTF	Indicates whether an abnormal toggle of TSG3nPTSI0 to TSG3nPTSI2 is detected. 0: No abnormal toggle of TSG3nPTSI0 to TSG3nPTSI2 detected. 1: An abnormal toggle of TSG3nPTSI0 to TSG3nPTSI2 detected. TSG3nPTF is set to 1 when TSG3nPTSI0 to TSG3nPTSI2 (TSG3nPTE signal toggle) are changed three times or more during TSG3nOPCI0 trigger or TSG3nPTSI0 to TSG3nPTSI2 (TSG3nPTE signal toggle) are changed three times or more during TSG3nOPCI1 trigger, and a warning interrupt (INTTSG3nIWN) is generated. TSG3nPTF can be cleared by changing TSG3nSTR0.TSG3nTE from 0 to 1 (operation start), by setting TSG3nTRG0.TSG3nTS to 1 (starting timer operation), by input to TSG3nTSST (timer restart), or by writing 1 to TSG3nSTC.TSG3nPTR. TSG3nPTF is valid when TSG3nCTL1.TSG3nPTC[1:0] = 10_B or 11_B.
0	Reserved	When read, the value after reset is returned.

35.3.18 TSG3nSTC — TSG3n Status Clear Trigger Register

This register controls the flags.

Access: This register is a write-only register that can be written in 16-bit units.

Address: <TSG3n_base> + $01C_H$

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TSG3n TBR2	TSG3n TBR1	TSG3n TBR0	TSG3n PPR	TSG3n PER	TSG3n TDR	TSG3n NDR	TSG3n PRR	TSG3n PTR	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	W	W	W	W	W	W	W	W	W	R

Table 35.25 TSG3nSTC Register Contents (1/2)

Bit Position	Bit Name	Function
15 to 10	Reserved	When writing, write the value after reset.
9	TSG3nTBR2	This is a trigger bit that clears TSG3nSTR2.TSG3nTBF2. 0: Does not clear TSG3nTBF2. 1: Clears TSG3nTBF2. When TSG3nTBR2 writing and TSG3nSTR2.TSG3nTBF2 setting occur simultaneously, TSG3nSTR2.TSG3nTBF2 setting has a priority, and the flag is not cleared.
8	TSG3nTBR1	This is a trigger bit that clears TSG3nSTR2.TSG3nTBF1. 0: Does not clear TSG3nTBF1. 1: Clears TSG3nTBF1. When TSG3nTBR1 writing and TSG3nSTR2.TSG3nTBF1 setting occur simultaneously, TSG3nSTR2.TSG3nTBF1 setting has a priority, and the flag is not cleared.
7	TSG3nTBR0	This is a trigger bit that clears TSG3nSTR2.TSG3nTBF0. 0: Does not clear TSG3nTBF0. 1: Clears TSG3nTBF0. When TSG3nTBR0 writing and TSG3nSTR2.TSG3nTBF0 setting occur simultaneously, TSG3nSTR2.TSG3nTBF0 setting has a priority, and the flag is not cleared.
6	TSG3nPPR	This is a trigger bit that clears TSG3nSTR2.TSG3nPPF. 0: Does not clear TSG3nPPF. 1: Clears TSG3nPPF. When TSG3nPPR writing and TSG3nSTR2.TSG3nPPF setting occur simultaneously, TSG3nSTR2.TSG3nPPF setting has a priority, and the flag is not cleared.
5	TSG3nPER	This is a trigger bit that clears TSG3nSTR2.TSG3nPEF. 0: Does not clear TSG3nPEF. 1: Clears TSG3nPEF. When TSG3nPER writing and TSG3nSTR2.TSG3nPEF setting occur simultaneously, TSG3nSTR2.TSG3nPEF setting has a priority, and the flag is not cleared.
4	TSG3nTDR	This is a trigger bit that clears TSG3nSTR2.TSG3nTDF. 0: Does not clear TSG3nTDF. 1: Clears TSG3nTDF. When TSG3nTDR writing and TSG3nSTR2.TSG3nTDF setting occur simultaneously, TSG3nSTR2.TSG3nTDF setting has a priority, and the flag is not cleared.

Table 35.25 TSG3nSTC Register Contents (2/2)

Bit Position	Bit Name	Function
3	TSG3nNDR	This is a trigger bit that clears TSG3nSTR2.TSG3nNDF. 0: Does not clear TSG3nNDF. 1: Clears TSG3nNDF. When TSG3nNDR writing and TSG3nSTR2.TSG3nNDF setting occur simultaneously, TSG3nSTR2.TSG3nNDF setting has a priority, and the flag is not cleared.
2	TSG3nPRR	This is a trigger bit that clears TSG3nSTR2.TSG3nPRF. 0: Does not clear TSG3nPRF. 1: Clears TSG3nPRF. When TSG3nPRR writing and TSG3nSTR2.TSG3nPRF setting occur simultaneously, TSG3nSTR2.TSG3nPRF setting has a priority, and the flag is not cleared.
1	TSG3nPTR	This is a trigger bit that clears TSG3nSTR2.TSG3nPTF. 0: Does not clear TSG3nPTF. 1: Clears TSG3nPTF. When TSG3nPTR writing and TSG3nSTR2.TSG3nPTF setting occur simultaneously, TSG3nSTR2.TSG3nPTF setting has a priority, and the flag is not cleared.
0	Reserved	When writing, write the value after reset.

35.3.19 TSG3nOPT0 — TSG3n Option Register 0

This register sets the optional functions.

Access: This register can be read or written in 8-bit units.

Address: <TSG3n_base> + 020_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	TSG3nSOC	TSG3nSTE	TSG3nPOT	TSG3nPSS	TSG3nIDC	TSG3nPSC	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 35.26 TSG3nOPT0 Register Contents (1/2)

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6	TSG3nSOC	Enables or disables control of the timer output (TSG3nO1 to TSG3nO6 pins) by software. 0: Disables control by software. 1: Enables control by software. When TSG3nSOC is set to 1, timer output is switched to the software control/ trigger control output pattern specified by TSG3nSPC2 to TSG3nSPC0. The dead time is secured by the dead time counter.
5	TSG3nSTE	Enables or disables control by the pattern output trigger. 0: Disables the TSG3nPTSI0 to TSG3nPTSI2 and TSG3nOPCI0, and TSG3nOPCI1 inputs. 1: Enables TSG3nPTSI0 to TSG3nPTSI2 and TSG3nOPCI0, and TSG3nOPCI1 inputs. • The pattern output trigger is selected by TSG3nPOT. • TSG3nSTE is valid in 120-DC mode and when software output control function is enabled.
4	TSG3nPOT	Selects the pattern output trigger. 0: Switches the output pattern by the external pattern input pins (TSG3nPTSI0 to TSG3nPTSI2) (pattern switch method). 1: Switches the output pattern by the rising edge of the TSG3nOPCI0 and TSG3nOPCI1 (trigger switch method).
3	TSG3nPSS	Selects the pattern output order switch factor. 0: The pattern output order is not switched by TSG3nPSC. 1: The pattern output order is switched by TSG3nPSC.
2	TSG3nIDC	Determines the output pattern from the TSG3nO1 to TSG3nO6 pins in combination with the TSG3nIDC and TSG3nSTR1.TSG3nTSF and TSG3nPSC signals. For the timer output order and patterns to be output, see **Figure 35.80** to **Figure 35.83**, Example of Operation in 120-DC Mode, in **Section 35.4.7.4, (5) Operation in 120-DC Mode**.

Table 35.26 TSG3nOPT0 Register Contents (2/2)

Bit Position	Bit Name	Function
1	TSG3nPSC	Selects the pattern output order when the semi-automatic cruise function is enabled. 0: Switches the timer output (TSG3nO1 to TSG3nO6) in the normal rotation. 1: Switches the timer output (TSG3nO1 to TSG3nO6) in the reverse rotation. • TSG3nPSC specifies the timer output pattern order assuming the output pattern specified by TSG3nSPC2 to TSG3nSPC0 as the initial pattern. TSG3nPSC is valid when TSG3nPOT = 1 and TSG3nPSS = 1. • It is recommended to rewrite TSG3nPSC when TSG3nSTR0.TSG3nTE = 0 or TSG3nPOT = 0. If TSG3nPSC is rewritten when TSG3nPOT = 1, unexpected timer output pattern might be caused. • If the signal input to TSG3nPTSI0 to TSG3nPTSI2 changes with TSG3n operation being stopped (TSG3nSTR0.TSG3nTE = 0), the TSG3nTRG0.TSG3nTS bit should be set to 1 after matching the input signal change logic with the TSG3nPSC order. • For output order in normal or reverse rotation, see **Section 35.4.7.4, 120-DC Mode**. Here, normal rotation and reverse rotation refer to the change of output, and they are different from normal rotation and reverse rotation of a motor.
0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

35.3.20 TSG3nOPT1 — TSG3n Option Register 1

This register sets the optional functions.

Access: This register can be read or written in 8-bit units.

Address: <TSG3n_base> +024_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	TSG3nSPC[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 35.27 TSG3nOPT1 Register Contents

Bit Position	Bit Name	Function
7 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2 to 0	TSG3nSPC [2:0]	Specifies the timer output pattern when software output function is enabled and in 120-DC mode. For the output pattern, see **Section 35.4.7.8, Software Output Control Function**, and **Section 35.4.7.4, 120-DC Mode**.

35.3.21 TSG3nTRG0 — TSG3n Trigger Register 0

This register controls the start of the timer.

Access: This register is a write-only register that can be written in 8-bit units.

Address: <TSG3n_base> + 030_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TSG3nTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 35.28 TSG3nTRG0 Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset (or the fixed value).
0	TSG3nTS	This bit is a trigger bit that controls the start of the timer. 0: The timer is not started. 1: The timer is started (restarted if TSG3nSTR0.TSG3nTE = 1). When restarted, the 18-bit counter is initialized. This bit is always read as 0.

35.3.22 TSG3nTRG1 — TSG3n Trigger Register 1

This register controls the stop of the timer.

Access: This register is a write-only register that can be written in 8-bit units.

Address: <TSG3n_base> +034_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TSG3nTT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 35.29 TSG3nTRG1 Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TSG3nTT	This is a trigger bit that controls the stop of the timer. 0: The timer is not stopped. 1: The timer is stopped (TSG3nSTR0.TSG3nTE = 0). This bit is always read as 0.

35.3.23 TSG3nTRG2 — TSG3n Trigger Register 2

TSG3nTRG2 is a trigger bit to reflect the PWM duty setting to TSG3nO1-6 in anytime rewrite mode of HT-PWM mode.

This register can be set to 1 only in HT-PWM mode and when anytime rewrite mode is selected (TSG3nRMC = 1). Do not rewrite this register in other modes (PWM mode, SP-PMW mode, 120-DC mode, HSP-PWM mode) or when reload mode is selected (TSG3nRMC = 0)

Access: This register is a write-only register that can be written in 8-bit units.

Address: <TSG3n_base> + 038_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TSG3nIMT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 35.30 TSG3nTRG2 Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TSG3nIMT	Anytime Rewrite Trigger 0: Disabled 1: Changes in duty settings for U, V, and W phases are reflected to timer output in HT-PWM mode and when anytime rewrite mode is selected.

35.3.24 TSG3nCNT — TSG3n Counter Read Buffer Register

This register can access the 16 lower bits of the 18-bit register TSG3nCNTE.

For the operation of this register, see **Section 35.3.25, TSG3nCNTE — TSG3n Bit Extended Counter Read Buffer Register**.

Access: This register is a read-only register that can be read in 16-bit units.

Address: <TSG3n_base> + 028_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	16-bit counter															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

35.3.25 TSG3nCNTE — TSG3n Bit Extended Counter Read Buffer Register

The counter values can be read from this register. This register mirrors the contents of TSG3nCNT from which the 16 lower bits of this register can be accessed.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <TSG3n_base> + $1A0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSG3nCNTE (18-bit counter)	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSG3nCNTE (18-bit counter)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

18-bit counter

This register is a timer read buffer register from which the 18-bit counter value can be read. In HT-PWM mode, the 18-bit counter provides the triangular waveform control in which the counter value is incremented and decremented by 2. Bit 0 is always read as 0.

In other modes, the 18-bit counter provides the sawtooth waveform control in which the counter value is incremented by 1.

Table 35.31 TSG3nCNTE Register Count Value

Operating mode	At the Beginning	Minimum Value	Maximum value
HT-PWM mode	TSG3nDTC0	TSG3nDTC0	TSG3nDTC0+TSG3nCMP0E[*1]
Other modes	00000_H	00000_H	TSG3nCMP0E

Note 1. Set the value as TSG3nDTC0+TSG3nCMP0E < $3FFFF_H$.

35.3.26 TSG3nSBC — TSG3n Sub-Counter Read Buffer Register

This register can access the 16 lower bits of the 18-bit register TSG3nSBCE.

For the operation of this register, see **Section 35.3.27, TSG3nSBCE — TSG3n Bit Extended Sub-Counter Read Buffer Register**.

Access: This register is a read-only register that can be read in 16-bit units.

Address: <TSG3n_base> + $02C_H$

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	16-bit sub-counter															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

35.3.27 TSG3nSBCE — TSG3n Bit Extended Sub-Counter Read Buffer Register

The sub-counter values can be read from this register. This register mirrors the contents of TSG3nSBC from which the 16 lower bits of this register can be accessed.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <TSG3n_base> + $1A4_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSG3nSBCE (18-bit sub-counter)	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSG3nSBCE (18-bit sub-counter)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

18-bit counter

This register is a timer read buffer register from which the 18-bit sub-counter value can be read. In HT-PWM mode, the 18-bit counter provides the triangular waveform control in which the counter value is incremented and decremented by 2. Bit 0 is always read as 0. (Available only in HT-PWM mode.).

Table 35.32 TSG3nSBCE Register Count Value

Operating mode	At the Beginning	Minimum Value	Maximum Value
HT-PWM mode	TSG3nDTC0	00000_H	TSG3nDTC0 + TSG3nDTC1 + TSG3nCMP0E*1
Other modes	00000_H	00000_H	00000_H

Note 1. Set the value as TSG3nDTC0 + TSG3nDTC1 + TSG3nCMP0E < $3FFFF_H$.

35.3.28 TSG3nCMP0 — TSG3n Compare Register 0

This register can access the 16 lower bits of the 18-bit register TSG3nCMP0E.

For the operation of this register, see **Section 35.3.29, TSG3nCMP0E — TSG3n Bit Extended Compare Register 0**.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + 058_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

35.3.29 TSG3nCMP0E — TSG3n Bit Extended Compare Register 0

This register is an 18-bit compare register that specifies the PWM period in all modes. This register mirrors the contents of TSG3nCMP0 from which the 16 lower bits of this register can be accessed.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> +$14C_H$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSG3nCMP0E (18-bit compare register)	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSG3nCMP0E (18-bit compare register)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 35.33 TSG3nCMP0E Register Setting

Operating mode	At the Beginning	Minimum Value	Maximum Value
HT-PWM mode	TSG3nCMP0E*1	00002_H	$3FFFE_H$
Other modes	TSG3nCMP0E + 1	1 (TSG3nCMP0E = 00000_H)	40000_H (TSG3nCMP0E = $3FFFF_H$)

Note 1. In HT-PWM mode, the lowest bit is ignored.

35.3.30 TSG3nCMP1W — TSG3n Compare Register 1, 2

This register can access the 16 lower bits of the 18-bit register TSG3nCMP1E and TSG3nCMP2E.

For the operation of this register, see **Section 35.3.37, TSG3nCMP1E to TSG3nCMP12E — TSG3n Bit Extended Compare Registers 1 to 12**.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + 040_H

Value after reset: $0000\ 0000_H$

35.3.31 TSG3nCMP3W — TSG3n Compare Register 3, 4

This register can access the 16 lower bits of the 18-bit register TSG3nCMP3E and TSG3nCMP4E.

For the operation of this register, see **Section 35.3.37, TSG3nCMP1E to TSG3nCMP12E — TSG3n Bit Extended Compare Registers 1 to 12**.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + $04C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

35.3.32 TSG3nCMP5W — TSG3n Compare Register 5, 6

This register can access the 16 lower bits of the 18-bit register TSG3nCMP5E and TSG3nCMP6E.

For the operation of this register, see **Section 35.3.37, TSG3nCMP1E to TSG3nCMP12E — TSG3n Bit Extended Compare Registers 1 to 12**.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + 044_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

35.3.33 TSG3nCMP7W — TSG3n Compare Registers 7, 8

This register can access the 16 lower bits of the 18-bit register TSG3nCMP7E and TSG3nCMP8E.

For the operation of this register, see **Section 35.3.37, TSG3nCMP1E to TSG3nCMP12E — TSG3n Bit Extended Compare Registers 1 to 12**.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + 050_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

35.3.35 TSG3nCMP11W — TSG3n Compare Registers 11, 12

This register can access the 16 lower bits of the 18-bit register TSG3nCMP11E and TSG3nCMP12E.

For the operation of this register, see **Section 35.3.37, TSG3nCMP1E to TSG3nCMP12E — TSG3n Bit Extended Compare Registers 1 to 12**.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + 054_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

35.3.36 TSG3nCMP1 to TSG3nCMP12 — TSG3n Compare Registers 1 to 12

These registers can access the 16 lower bits of the 18-bit registers TSG3nCMP1E-12E.

For the operation of these registers, see **Section 35.3.37, TSG3nCMP1E to TSG3nCMP12E — TSG3n Bit Extended Compare Registers 1 to 12**.

Access: This register can be read or written in 16-bit units.

Address:
TSG3nCMP1 <TSG3n_base> + 080_H
TSG3nCMP2 <TSG3n_base> + 084_H
TSG3nCMP3 <TSG3n_base> + 098_H
TSG3nCMP4 <TSG3n_base> + $09C_H$
TSG3nCMP5 <TSG3n_base> + 088_H
TSG3nCMP6 <TSG3n_base> + $08C_H$
TSG3nCMP7 <TSG3n_base> + $0A0_H$
TSG3nCMP8 <TSG3n_base> + $0A4_H$
TSG3nCMP9 <TSG3n_base> + 090_H
TSG3nCMP10 <TSG3n_base> + 094_H
TSG3nCMP11 <TSG3n_base> + $0A8_H$
TSG3nCMP12 <TSG3n_base> + $0AC_H$

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	16-bit compare register															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

35.3.37 TSG3nCMP1E to TSG3nCMP12E — TSG3n Bit Extended Compare Registers 1 to 12

The compare value is set by these registers. These registers mirror the contents of TSG3nCMP1-12, TSG3nCMP1W, 3W, 5W, 7W, 9W, and 11W from which the 16 lower bits of these registers can be accessed.

Access: This register can be read or written in 32-bit units.

Address: TSG3nCMP1E <TSG3n_base> + $17C_H$
TSG3nCMP2E <TSG3n_base> + 178_H
TSG3nCMP3E <TSG3n_base> + 164_H
TSG3nCMP4E <TSG3n_base> + 160_H
TSG3nCMP5E <TSG3n_base> + 174_H
TSG3nCMP6E <TSG3n_base> + 170_H
TSG3nCMP7E <TSG3n_base> + $15C_H$
TSG3nCMP8E <TSG3n_base> + 158_H
TSG3nCMP9E <TSG3n_base> + $16C_H$
TSG3nCMP10E <TSG3n_base> + 168_H
TSG3nCMP11E <TSG3n_base> + 154_H
TSG3nCMP12E <TSG3n_base> + 150_H

Value after reset: $0000\ 0000_H$

Table 35.34 TSG3nCMP1E-TSG3nCMP12E Register Setting (1/2)

Register	PWM Mode	HT-PWM Mode	SP-PWM Mode	120-DC Mode	HSP-PWM Mode
TSG3nCMP1E	TSG3nO1 clear timing	TSG3nO1 clear timing /TSG3nO2 set timing		Duty when TSG3nO1, 3, or 5 output pattern is selected by TSG3nPAT0.	TSG3nO1 clear timing
TSG3nCMP2E	TSG3nO1 set timing	TSG3nO1 set timing/TSG3nO2 clear timing			TSG3nO1 set timing
TSG3nCMP3E	TSG3nO2 clear timing	—		Duty whenTSG3nO2, 4, or 6 output pattern is selected by TSG3nPAT1.	TSG3nO2 clear timing
TSG3nCMP4E	TSG3nO2 set timing	—			TSG3nO2 set timing
TSG3nCMP5E	TSG3nO3 clear timing	TSG3nO3 clear timing/ TSG3nO4 set timing		Duty when TSG3nO1, 3, or 5 output pattern is selected by TSG3nPAT0.	TSG3nO3 clear timing
TSG3nCMP6E	TSG3nO3 set timing	TSG3nO3 set timing/TSG3nO4 clear timing			TSG3nO3 set timing
TSG3nCMP7E	TSG3nO4 clear timing	—		Duty when TSG3nO2, 4, or 6 output pattern is selected by TSG3nPAT1.	TSG3nO4 clear timing
TSG3nCMP8E	TSG3nO4 set timing	—			TSG3nO4 set timing
TSG3nCMP9E	TSG3nO5 clear timing	TSG3nO5 clear timing/ TSG3nO6 set timing		Duty when TSG3nO1, 3, or 5 output pattern is selected by TSG3nPAT0.	TSG3nO5 clear timing
TSG3nCMP10E	TSG3nO5 set timing	TSG3nO5 set timing/TSG3nO6 clear timing			TSG3nO5 set timing

Table 35.34 TSG3nCMP1E-TSG3nCMP12E Register Setting (2/2)

Register	PWM Mode	HT-PWM Mode	SP-PWM Mode	120-DC Mode	HSP-PWM Mode
TSG3nCMP11E	TSG3nO6 clear timing	—		Duty when TSG3nO2, 4, or 6 output pattern is selected by TSG3nPAT1.	TSG3nO6 clear timing
TSG3nCMP12E	TSG3nO6 set timing	—			TSG3nO6 set timing

NOTE

The dead time function is used in all operating modes.

In HT-PWM mode, the compare match signal is generated when a compare match occurs not only with the value of the TSG3nCNTE register but also with the value of the TSG3nSBCE register.

In 120-DC mode, the output from TSG3nO1-6 is controlled by the TSG3nCMPmE, TSG3nPAT0, and TSG3nPAT1 registers.

35.3.38 TSG3nDCMP0W — TSG3n Diagnostic Output Compare Register 0, 1

This register can access the 16 lower bits of the 18-bit register TSG3nDCMP0E and TSG3nDCMP1E.

For the operation of this register, see **Section 35.3.40, TSG3nDCMP0E to 2E — TSG3n Bit Extended Diagnostic Output Compare Register 0 to 2**.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + $05C_H$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

35.3.39 TSG3nDCMP2 — TSG3n Diagnostic Output Compare Register 2

This register can access the 16 lower bits of the 18-bit register TSG3nDCMP2E.

For the operation of this register, see **Section 35.3.40, TSG3nDCMP0E to 2E — TSG3n Bit Extended Diagnostic Output Compare Register 0 to 2**.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + 060_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

35.3.40 TSG3nDCMP0E to 2E — TSG3n Bit Extended Diagnostic Output Compare Register 0 to 2

The compare value is set by these registers. These registers mirror the contents of TSG3nDCMP0W and TSG3nDCMP2 from which the 16 lower bits of these registers can be accessed.

Access: This register can be read or written in 32-bit units.

Address: TSG3nDCMP0E <TSG3n_base> + 148_H
TSG3nDCMP1E <TSG3n_base> + 144_H
TSG3nDCMP2E <TSG3n_base> + 140_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSG3nDCMP0E - TSG3nDCMP2E (18-bit compare register)	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSG3nDCMP0E - TSG3nDCMP2E (18-bit compare register)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

These registers control the diagnostic output timing or AD conversion trigger timing in all modes. A pulse is generated at the match timing of the 18-bit counter value with this register.

35.3.41 TSG3nPAT0W — TSG3n Pattern Register 0

This register specifies the output pattern.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + 064_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PAT5T

	PAT5T	PAT4T			PAT3T			PAT2T			PAT1T			PAT0T		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Output Pattern

This register controls UT/VT/WT output in 120-DC mode.

Table 35.35 TSG3nPAT0W Register Setting value and Output Control

PATmT Value	Output Control
000	Fixed Low level
001	PWM output set by TSG3nCMP1E
010	PWM output set by TSG3nCMP2E
011	PWM output set by TSG3nCMP5E
100	PWM output set by TSG3nCMP6E
101	PWM output set by TSG3nCMP9E
110	PWM output set by TSG3nCMP10E
111	Fixed High level

Note: m = 0, 1, 2, 3, 4, 5

35.3.42 TSG3nPAT1W — TSG3n Pattern Register 1

This register specifies the output pattern.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + 068_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PAT5B	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PAT5B	PAT4B			PAT3B			PAT2B			PAT1B			PAT0B

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Output Pattern

This register controls UB/VB/WB output in 120-DC mode.

Table 35.36 TSG3nPAT1W Register Setting value and Output Control

PATmB Value	Output Control
000	Fixed Low level
001	PWM output set by TSG3nCMP3E
010	PWM output set by TSG3nCMP4E
011	PWM output set by TSG3nCMP7E
100	PWM output set by TSG3nCMP8E
101	PWM output set by TSG3nCMP11E
110	PWM output set by TSG3nCMP12E
111	Fixed High level

Note: m = 0, 1, 2, 3, 4, 5

35.3.43 TSG3nDTC0W — TSG3n Dead Time Control Register 0

This register sets the dead time value (the period from inverse phase inactivation to positive phase activation).

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + $06C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	Write Protection Code Check														
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TSG3nDTC0(10-bit dead time compare)									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

To rewrite TSG3nDTC0W[0:9], set bit 14 to bit 0 and TSG3nDTCM to 0 in TSG3nDTPR, and rewrite the TSG3nDTC0W. At this time, when the rewritten value of TSG3nDTC0W[30:16] and the TSG3nDTPR value match, TSG3nDTC0W is rewritten.

During timer operation (TSG3nSTR0.TSG3nTE = 1), rewriting should be performed in reload mode (TSG3nCTL3.TSG3nRMC = 0).

35.3.44 TSG3nDTC1W — TSG3n Dead Time Control Register 1

This register sets the dead time (the period from positive phase inactivation to inverse phase activation).

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + 070_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	Write Protection Code Check														
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TSG3nDTC1(10-bit dead time compare)									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

To rewrite TSG3nDTC1W[0:9], set bit 14 to bit 0 and TSG3nDTCM to 0 in TSG3nDTPR, and rewrite the TSG3nDTC1W. At this time, when the rewritten value of TSG3nDTC1W[30:16] and the TSG3nDTPR value match, TSG3nDTC1W is rewritten.

During timer operation (TSG3nSTR0.TSG3nTE = 1), rewriting should be performed in reload mode (TSG3nCTL3.TSG3nRMC = 0).

35.3.45 TSG3nCMPU — TSG3n HT-PWM U Phase Compare Register

This register can access the 16 lower bits of the 18-bit register TSG3nCMPUE.

For the operation of this register, see **Section 35.3.48, TSG3nCMPUE — TSG3n Bit Extended HT-PWM U Phase Compare Register**.

Access: This register can be read or written in 16-bit units.

Address: <TSG3n_base> + $0B0_H$

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

35.3.47 TSG3nCMPW — TSG3n HT-PWM W Phase Compare Register

This register can access the 16 lower bits of the 18-bit register TSG3nCMPWE.

For the operation of this register, see **Section 35.3.50, TSG3nCMPWE — TSG3n Bit Extended HT-PWM W Phase Compare Register**.

Access: This register can be read or written in 16-bit units.

Address: <TSG3n_base> + $0B8_H$

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

35.3.48 TSG3nCMPUE — TSG3n Bit Extended HT-PWM U Phase Compare Register

This register sets the compare value for U phase in HT-PWM. In addition to the functions of TSG3nCMP1E and TSG3nCMP2E, this register can access specific registers.

The data written to this register is stored in the TSG3nCMP1E and TSG3nCMP2E registers which allows a generation of symmetry triangular waveform of PWM by one write access (see **Figure 35.2**). When this register is read, the same value as TSG3nCMP1E is returned. This register mirrors the contents of TSG3nCMPU from which the 16 lower bits of this register can be accessed.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> +188_H

Value after reset: 0000 0000_H

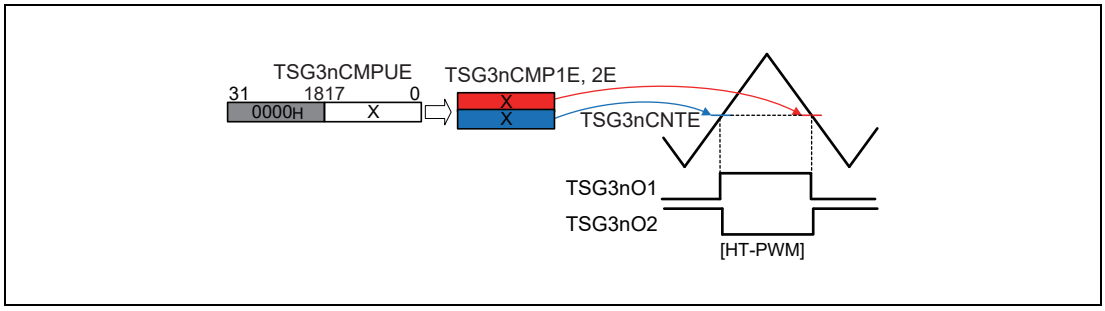

Figure 35.2 TSG3nCMPUE Register Accesses

35.3.49 TSG3nCMPVE — TSG3n Bit Extended HT-PWM V Phase Compare Register

This register sets the compare value for V phase in HT-PWM. In addition to the functions of TSG3nCMP5E and TSG3nCMP6E, this register can access specific registers.

The data written to this register is stored in the TSG3nCMP5E and TSG3nCMP6E registers which allows a generation of symmetry triangular waveform of PWM by one write access (see **Figure 35.3**). When this register is read, the same value as TSG3nCMP5E is returned. This register mirrors the contents of TSG3nCMPV from which the 16 lower bits of this register can be accessed.

Access: This register can be read or written in 32-bit units.

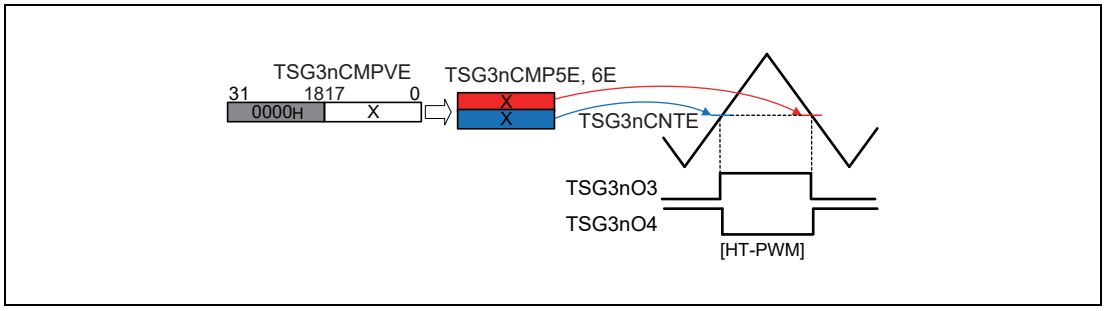

Figure 35.3 TSG3nCMPVE Register Accesses

35.3.50 TSG3nCMPWE — TSG3n Bit Extended HT-PWM W Phase Compare Register

This register sets the compare value for W phase in HT-PWM. In addition to the functions of TSG3nCMP9E and TSG3nCMP10E, this register can access specific registers.

The data written to this register is stored in the TSG3nCMP9E and TSG3nCMP10E registers which allows a generation of symmetry triangular waveform of PWM by one write access (see **Figure 35.4**). When this register is read, the same value as TSG3nCMP9E is returned. This register mirrors the contents of TSG3nCMPW from which the 16 lower bits of this register can be accessed.

Access: This register can be read or written in 32-bit units.

35.3.54 TSG3nUPWE — TSG3n Bit Extended SP-PWM U Phase Active Width Register

This register sets the active width for U phase in SP-PWM mode. The sum of the TSG3nUPWE write data and the TSG3nCMP2E value is stored in TSG3nCMP1E (see **Figure 35.5**). When this register is read, the same value as TSG3nCMP1E is returned. This register mirrors the contents of TSG3nUPW from which the 16 lower bits of this register can be accessed.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + 198_H

Value after reset: $0000\ 0000_H$

35.3.59 TSG3nHSPCMWE — TSG3n HSP-PWM Mode W Phase Compare Register

This register sets the PWM output width for W phase in HSP-PWM mode.

When a write access is made to this register, the values are set to TSG3nCMP9E to TSG3nCMP12E registers according to the formulas described in **Section 35.4.7.6, Compare Register Setting in HSP-PWM Mode**.

When this register is read, the same value as TSG3nCMP9E is returned.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + $12C_H$

Value after reset: 0000 0000_H

35.3.60 TSG3nHSPSHUE — TSG3n HSP-PWM Mode U Phase Shift Register

This register sets the PWM shift width for U phase in HSP-PWM mode.

When a write access is made to TSG3nHSPCMUE after setting the TSG3nHSPSHUE register, the values are set to TSG3nCMP1E to TSG3nCMP4E registers according to the formulas described in **Section 35.4.7.6, Compare Register Setting in HSP-PWM Mode**.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + 128_H

Value after reset: 0000 0000_H

35.3.61 TSG3nHSPSHVE — TSG3n HSP-PWM Mode V Phase Shift Register

This register sets the PWM shift width for V phase in HSP-PWM mode.

When a write access is made to TSG3nHSPCMVE after setting the TSG3nHSPSHVE register, the values are set to TSG3nCMP5E to TSG3nCMP8E registers according to the formulas described in **Section 35.4.7.6, Compare Register Setting in HSP-PWM Mode**.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + 124_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

35.3.62 TSG3nHSPSHWE — TSG3n HSP-PWM Mode W Phase Shift Register

This register sets the PWM shift width for W phase in HSP-PWM mode.

When a write access is made to TSG3nHSPCMWE after setting the TSG3nHSPSHWE register, the values are set to TSG3nCMP9E to TSG3nCMP12E registers according to the formulas described in **Section 35.4.7.6, Compare Register Setting in HSP-PWM Mode**.

Access: This register can be read or written in 32-bit units.

Address: <TSG3n_base> + 120_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

35.3.63 TSG3nDTPR — TSG3n Dead Time Protection Register

This register controls protection of the write access to the dead time register.

Access: This register can be read or written in 16-bit units.

Address: <TSG3n_base> + 210_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSG3n DTCM	TSG3nDTPR (Write Protection Code)

Table 35.37 TSG3nDTPR Register Contents

Bit Position	Bit Name	Function
15	TSG3nDTCM	Enables or disables rewriting of TSG3nDTC0 and TSG3nDTC1. 0: Enables rewriting of TSG3nDTC0 and TSG3nDTC1. 1: Disables rewriting of TSG3nDTC0 and TSG3nDTC1.
14 to 0	TSG3nDTPR [14:0]	Sets the write protection code (any value from 0000_H to $7FFF_H$).

This register protects TSG3nDTC0 and TSG3nDTC1 from illegal rewriting.

Functions are described below.

- TSG3nDTCM enables or disables rewriting of TSG3nDTC0 and TSG3nDTC1.
- Rewriting of TSG3nDTC0 and TSG3nDTC1 is enabled or disabled by double-checking a match of the write protection code (bits 30 to 16) of TSG3nDTC0 and TSG3nDTC1 with the write protection code of TSG3nDTPR, and the TSG3nDTCM setting.

CAUTION

This register should be set when the timer is stopped (TSG3nSTR0.TSG3nTE = 0). Only the same value can be written during timer operation (TSG3nSTR0.TSG3nTE = 1). If the different value is written to this register when TSG3nSTR0.TSG3nTE = 1, timer operation cannot be guaranteed. If this register is erroneously rewritten, set this register again after stopping the timer.

Other than above			Setting prohibited

35.4.1 Basic Operation

35.4.1.1 Basic Operation of 18-Bit Counter

The basic operation of the 18-bit counter is described. For details, see **Section 35.4.7, Operating Modes**.

Counting start

The 18-bit counter of TSG3n starts counting in HT-PWM mode when the initial value is 00000_H and after the TSG3nDTC0 value is loaded. The counter starts counting from the initial value 00000_H in all modes except for HT-PWM mode.

In HT-PWM mode, the counter value is incremented by 2 from the value of TSG3nDTC0 and decremented by 2 down to the value of TSG3nDTC0 after the counter value matches with the value of TSG3nCMP0E + TSG3nDTC0. The counter increments from 00000_H, 00001_H, 00002_H, 00003_H, … in all modes except for HT-PWM mode.

Counter clear

The 18-bit counter is cleared by the match of the counter value and the value of TSG3nCMP0E in all modes except for HT-PWM mode. (Clearing operation is not available in HT-PWM mode.)

Counter read during counting

In the TSG3n, the 18-bit counter value during counting can be read through TSG3nCNTE.

Count stop operation

When count operation is stopped (when TSG3nSTR0.TSG3nTE is changed from 1 to 0), TSG3nCNTE and TSG3nSBCE retain the counter value when stopped.

Interrupt operation

In the TSG3n, the following interrupts are generated.

- INTTSG3nI0: A period interrupt by a match of the 18-bit counter value with the TSG3nDTC0 value in HT-PWM mode. A compare match interrupt of the 18-bit counter value with the TSG3nCMP0E buffer register in any mode other than HT-PWM mode.
- INTTSG3nI1: A compare match interrupt of the 18-bit counter value with the TSG3nCMP1E buffer register.
- INTTSG3nI2: A compare match interrupt of the 18-bit counter value with the TSG3nCMP2E buffer register.
- INTTSG3nI3: A compare match interrupt of the 18-bit counter value with the TSG3nCMP3E buffer register.
- INTTSG3nI4: A compare match interrupt of the 18-bit counter value with the TSG3nCMP4E buffer register.
- INTTSG3nI5: A compare match interrupt of the 18-bit counter value with the TSG3nCMP5E buffer register.
- INTTSG3nI6: A compare match interrupt of the 18-bit counter value with the TSG3nCMP6E buffer register.
- INTTSG3nI7: A compare match interrupt of the 18-bit counter value with the TSG3nCMP7E buffer register.
- INTTSG3nI8: A compare match interrupt of the 18-bit counter value with the TSG3nCMP8E buffer register.
- INTTSG3nI9: A compare match interrupt of the 18-bit counter value with the TSG3nCMP9E buffer register.
- INTTSG3nI10: A compare match interrupt of the 18-bit counter value with the TSG3nCMP10E buffer register.
- INTTSG3nI11: A compare match interrupt of the 18-bit counter value with the TSG3nCMP11E buffer register.
- INTTSG3nI12: A compare match interrupt of the 18-bit counter value with the TSG3nCMP12E buffer register.
- INTTSG3nIPEK: A peak interrupt when the 18-bit counter switches from incrementing to decrementing.
- INTTSG3nIVLY: A valley interrupt when the 18-bit counter switches from decrementing to incrementing.
- INTTSG3nIER: A simultaneous active state detection interrupt of the positive phase and inverse phase
- INTTSG3nIWN: A warning detection interrupt

35.4.1.2 Function of Compare Registers

The functions of the compare registers in each operating mode are shown in the following tables.

Table 35.39 Compare Register Functions in Each Mode (1/7)

Operating Mode	TSG3nCMP0E	TSG3nCMP1E	TSG3nCMP2E
PWM mode	PWM period	TSG3nO1 clear timing	TSG3nO1 set timing

TSG3nCMP5E-8E is set based on the TSG3nHSPCMVE set value and the set values of TSG3nCMP0E, TSG3nDTC0, TSG3nDTC1, and TSG3nHSPSHVE.	TSG3nCMP9E-12E is set based on the TSG3nHSPCMWE set value and the set values of TSG3nCMP0E, TSG3nDTC0, TSG3nDTC1, and TSG3nHSPSHWE.

35.4.1.3 Compare Register Rewrite Operation

TSG3 can be set to reload mode or anytime rewrite mode using theTSG3nRMC bit.

Reload mode is enabled when TSG3nRMC = 0. The registers listed as “Enable” on the “Reload” column in **Section 35.3.1, List of Registers** are simultaneously updated at the reload timing.

Anytime rewrite mode is enabled when TSG3nRMC = 1. The registers are updated independently every time the value is written to the relevant register.

The update timing of the registers to be reloaded in reload mode and anytime rewrite mode in each mode are listed in the following table.

Table 35.40 Updating Timing of Compare Registers by Mode

Mode	Anytime Rewrite TSG3nRMC = 1	Reload TSG3nRMC = 0
PWM mode	TSG3nCMP0E: At the next counter clear timing of the 18-bit counter	At reload timing
	Registers other than TSG3nCMP0E: At a write access to the register	
HT-PWM mode	TSG3nCMP0E: At the next peak or valley timing of TSG3nCNTE	At reload timing
	TSG3nCMP1E, 2E, 5E, 6E, 9E, 10E: At writing 1 to the TSG3nIMT bit	
	Registers other than TSG3nCMP0E,1E, 2E, 5E, 6E, 9E, 10E: At a write access to the register	
SP-PWM mode	TSG3nCMP0E: At the next counter clear timing of the 18-bit counter	At reload timing
	Registers other than TSG3nCMP0E: At a write access to the register	
120-DC mode	Setting prohibited	At reload timing
HSP-PWM mode	Setting prohibited	At reload timing

Anytime Rewrite Mode

In this mode, the compare registers are rewritten independently. Whenever a value is written to the compare register, the written value is reflected at the timing of **Table 35.40**.

Reload mode (Simultaneous Rewrite Function)

Writing to TSG3nCMP1E (TSG3nCMP1, TSG3nCMP1W, TSG3nCMPUE, TSG3nCMPU, TSG3nUPWE, TSG3nUPW, and TSG3nHSPCMUE) enables reload (sets the reload request flag (TSG3nSTR0.TSG3nRSF)), and the values of all the pertinent registers are updated simultaneously at the next reload timing (reload).

The reload timing is the peak or valley timing of the 18-bit counter when the TSG3nTRG0.TSG3nTS bit is changed from 0 to 1. Reloading is controlled by TSG3nCTL4.TSG3nPRE and TSG3nVRE.

Writing to any register other than TSG3nCMP1E (TSG3nCMP1, TSG3nCMP1W, TSG3nCMPUE, TSG3nCMPU, TSG3nUPWE, TSG3nUPW, and TSG3nHSPCMUE) does not enable reloading.

Do not write to the registers to be reloaded until the next reload timing after reloading is enabled by writing to TSG3nCMP1E (TSG3nCMP1, TSG3nCMP1W, TSG3nCMPUE, TSG3nCMPU, TSG3nUPWE, TSG3nUPW, and TSG3nHSPCMUE). The pertinent registers should be rewritten when the reload request flag (TSG3nSTR0.TSG3nRSF) is 0.

Rewriting registers to be reloaded by DMA transfer

Some of the registers to be reloaded can be rewritten by DMA transfer. DMA transfer is performed as follows.

Table 35.41 Example of DMA Transfer Order of Registers to be Reloaded

Address	Register Name	DMA Transfer Order (Example)
<TSG3n_base> + 040_H	TSG3nCMP1W	
<TSG3n_base> + 044_H	TSG3nCMP5W	
<TSG3n_base> + 048_H	TSG3nCMP9W	
<TSG3n_base> + $04C_H$	TSG3nCMP3W	
<TSG3n_base> + 050_H	TSG3nCMP7W	
<TSG3n_base> + 054_H	TSG3nCMP11W	
<TSG3n_base> + 058_H	TSG3nCMP0	
<TSG3n_base> + $05C_H$	TSG3nDCMP0W	
<TSG3n_base> + 060_H	TSG3nDCMP2	
<TSG3n_base> + 064_H	TSG3nPAT0W	
<TSG3n_base> + 068_H	TSG3nPAT1W	
<TSG3n_base> + $06C_H$	TSG3nDTC0W	
<TSG3n_base> + 070_H	TSG3nDTC1W	

Table 35.42 Example of DMA Transfer Order of Registers to be Reloaded

Address	Register Name	DMA Transfer Order (Example)
<TSG3n_base> + 140_H	TSG3nDCMP2E	
<TSG3n_base> + 144_H	TSG3nDCMP1E	
<TSG3n_base> + 148_H	TSG3nDCMP0E	
<TSG3n_base> + $14C_H$	TSG3nCMP0E	
<TSG3n_base> + 150_H	TSG3nCMP12E	
<TSG3n_base> + 154_H	TSG3nCMP11E	
<TSG3n_base> + 158_H	TSG3nCMP8E	
<TSG3n_base> + $15C_H$	TSG3nCMP7E	
<TSG3n_base> + 160_H	TSG3nCMP4E	
<TSG3n_base> + 164_H	TSG3nCMP3E	
<TSG3n_base> + 168_H	TSG3nCMP10E	
<TSG3n_base> + $16C_H$	TSG3nCMP9E	
<TSG3n_base> + 170_H	TSG3nCMP6E	
<TSG3n_base> + 174_H	TSG3nCMP5E	
<TSG3n_base> + 178_H	TSG3nCMP2E	
<TSG3n_base> + $17C_H$	TSG3nCMP1E	

Table 35.43 Duty Setting in HT-PWM Mode

Address	Register Name	DMA Transfer Order (Example)
<TSG3n_base> + 180_H	TSG3nCMPWE	
<TSG3n_base> + 184_H	TSG3nCMPVE	
<TSG3n_base> + 188_H	TSG3nCMPUE

Address	Register Name	DMA Transfer Order (Example)
<TSG3n_base> + 190_H	TSG3nWPWE	
<TSG3n_base> + 194_H	TSG3nVPWE	
<TSG3n_base> + 198_H	TSG3nUPWE	

Table 35.45 Shift Width and Duty Setting in HSP-PWM Mode

Address	Register Name	DMA Transfer Order (Example)
<TSG3n_base> + 120_H	TSG3nHSPSHWE	
<TSG3n_base> + 124_H	TSG3nHSPSHVE	
<TSG3n_base> + 128_H	TSG3nHSPSHUE	
<TSG3n_base> + $12C_H$	TSG3nHSPCMWE	
<TSG3n_base> + 130_H	TSG3nHSPCMVE	
<TSG3n_base> + 134_H	TSG3nHSPCMUE	

NOTES

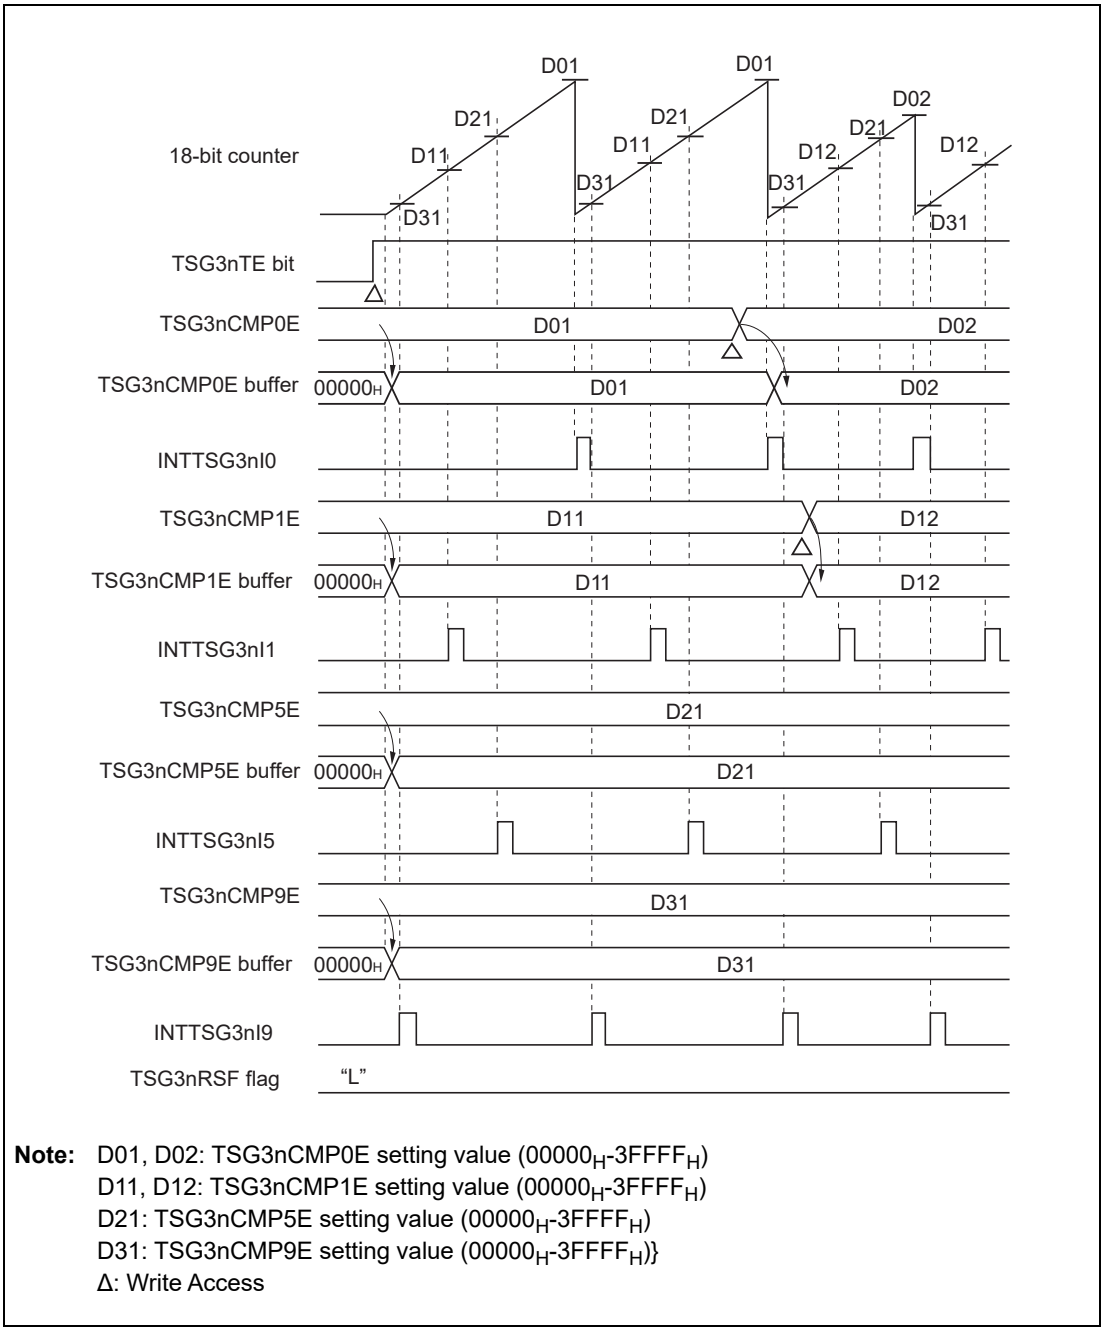
1. TSG3nCTL4 and TSG3nIOC3 should be rewritten individually.
2. Since writing to TSG3nCMP1E (including TSG3nCMP1, TSG3nCMP1W, TSG3nCMPUE, TSG3nCMPU, TSG3nUPWE, TSG3nUPW, and TSG3nHSPCMUE) enables reloading, it should be rewritten after all the other registers to be reloaded have been rewritten (ready to be reloaded)

(1) Example of Operation in Anytime Rewrite Mode

In this mode, the values written to the compare registers (TSG3nCMP1E to TSG3nCMP12E) are transferred to the internal buffer registers immediately, and are compared with the counter value.

The values are transferred to the internal compare buffer registers one clock cycle (PCLK) after being written to the compare registers (TSG3nCMP1E to TSG3nCMP12E).

The transfer timing of the TSG3nCMP0E is the peak or valley timing (only in HT-PWM mode) of the 18-bit counter after being written to the compare registers, or at the match timing of the TSG3nCMP0E value with the 18-bit counter value (in any mode other than HT-PWM mode).



Note: D01, D02: TSG3nCMP0E setting value (00000_H-$3FFFF_H$)
D11, D12: TSG3nCMP1E setting value (00000_H-$3FFFF_H$)
D21: TSG3nCMP5E setting value (00000_H-$3FFFF_H$)
D31: TSG3nCMP9E setting value (00000_H-$3FFFF_H$)}
Δ: Write Access

Figure 35.8 Anytime Rewrite Timing (Example in PWM Mode)

(a) Data reflection on PWM in Anytime Rewrite in HT-PWM

In anytime rewrite operation in HT-PWM mode, the values are transferred to the buffer at the timing when 1 is written to the TSG3nIMT bit after the settings of TSG3nCMP1E, 2E, 5E, 6E, 9E and 10E registers are modified and PWM output is forcibly set/cleared depending on the modified set value.

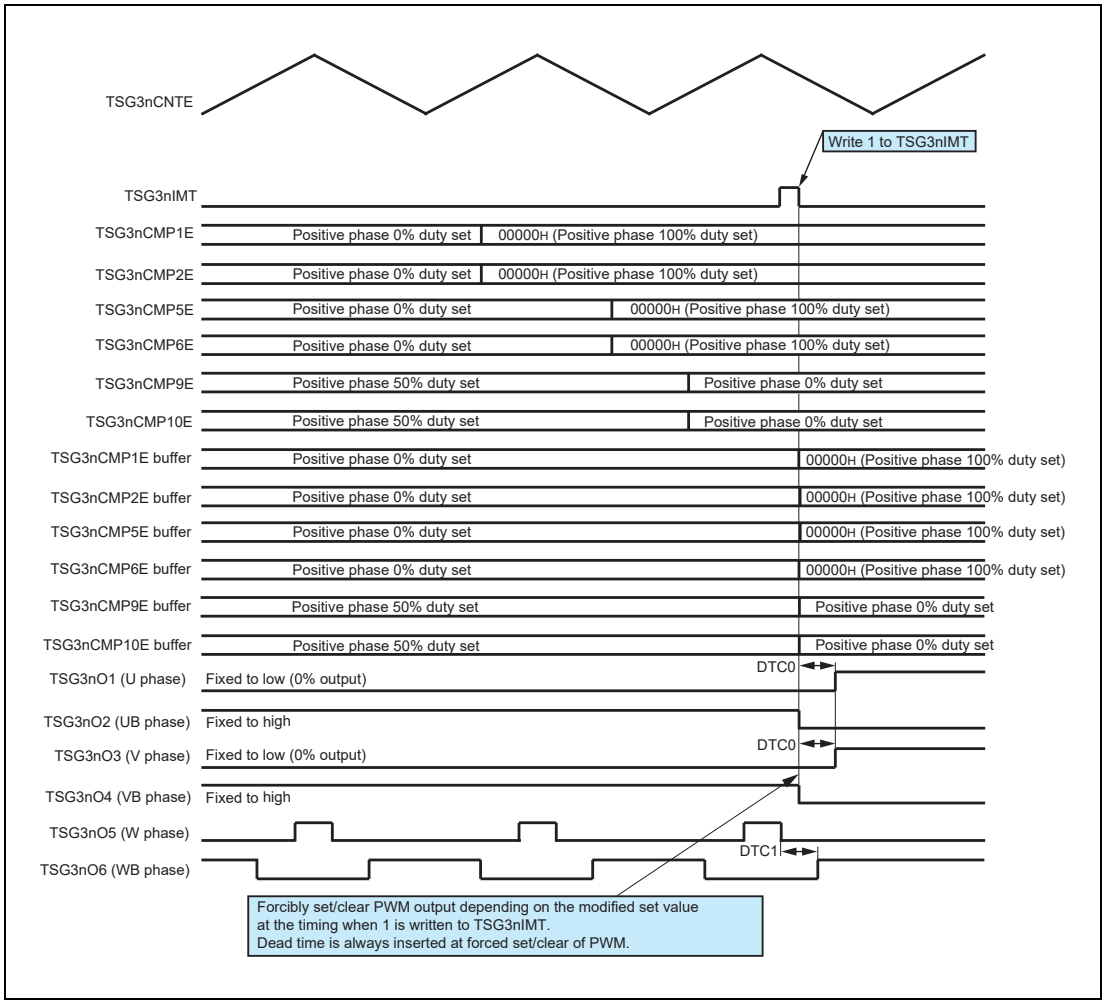


Figure 35.9 Update Timing of TSG3nCMP1E, 2E, 5E, 6E, 9E,and 10E at Anytime Rewrite Operation in HT-PWM Mode

(2) Example of Operation in Reload Mode (Simultaneous Rewrite Function)

The rewritten values of the registers to be reloaded (the registers listed in the **Section 35.3.1, List of Registers** with "Enabled" in the column of "Reload") can be transferred to the corresponding buffer registers simultaneously at the reload timing.

The registers should be rewritten when the pertinent reload request flag (TSG3nSTR0.TSG3nRSF) is 0.

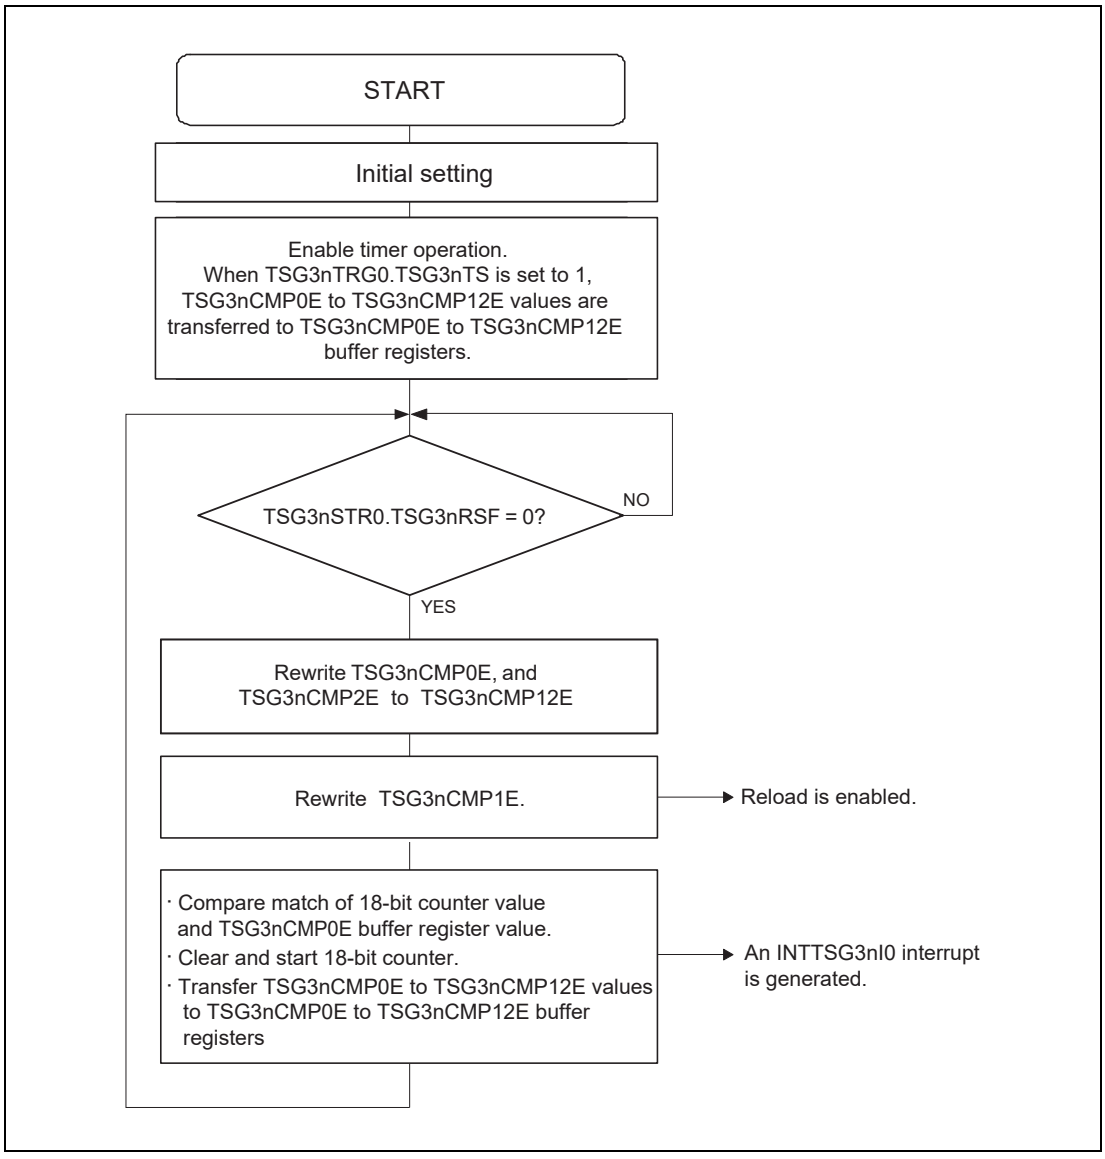

Figure 35.10 Basic Operation Flow in Reload Mode (Simultaneous Rewrite Function) (Example of PWM Mode)

CAUTION

Writing to TSG3nCMP1E also enables reloading. Therefore, TSG3nCMP1E should be rewritten after TSG3nCMP0E and TSG3nCMP2E to TSG3nCMP12E registers have been rewritten.

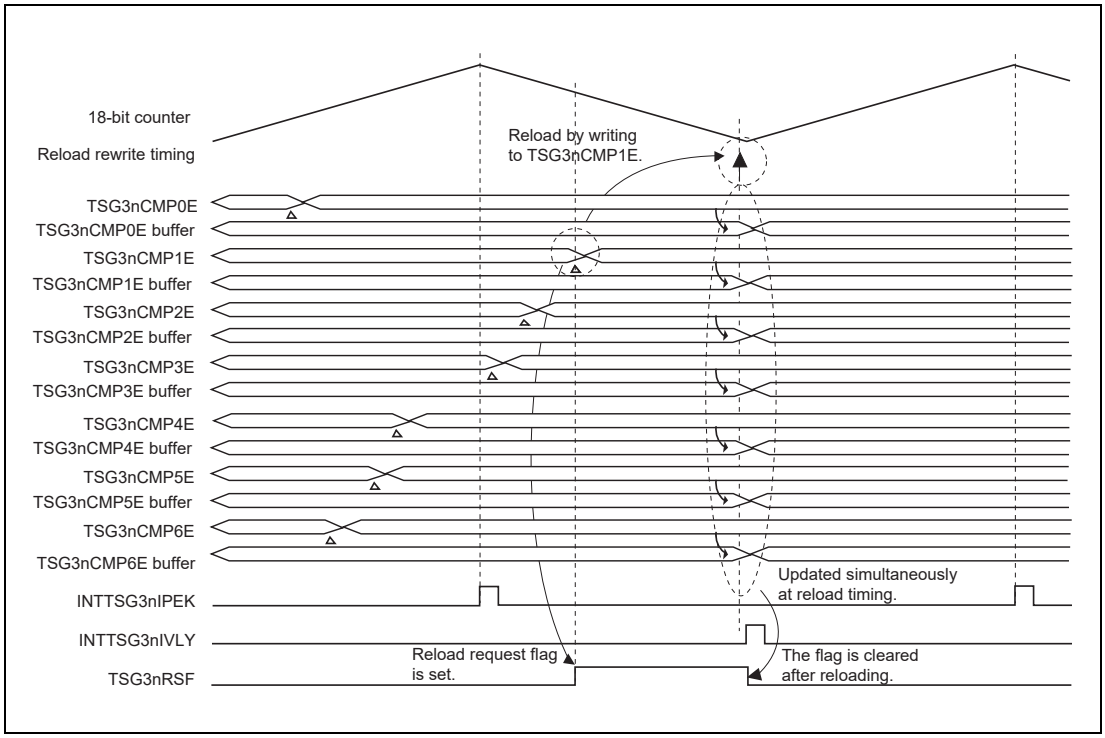

Figure 35.11 Simultaneous Rewrite Timing (Example of HT-PWM Mode) (1/2)

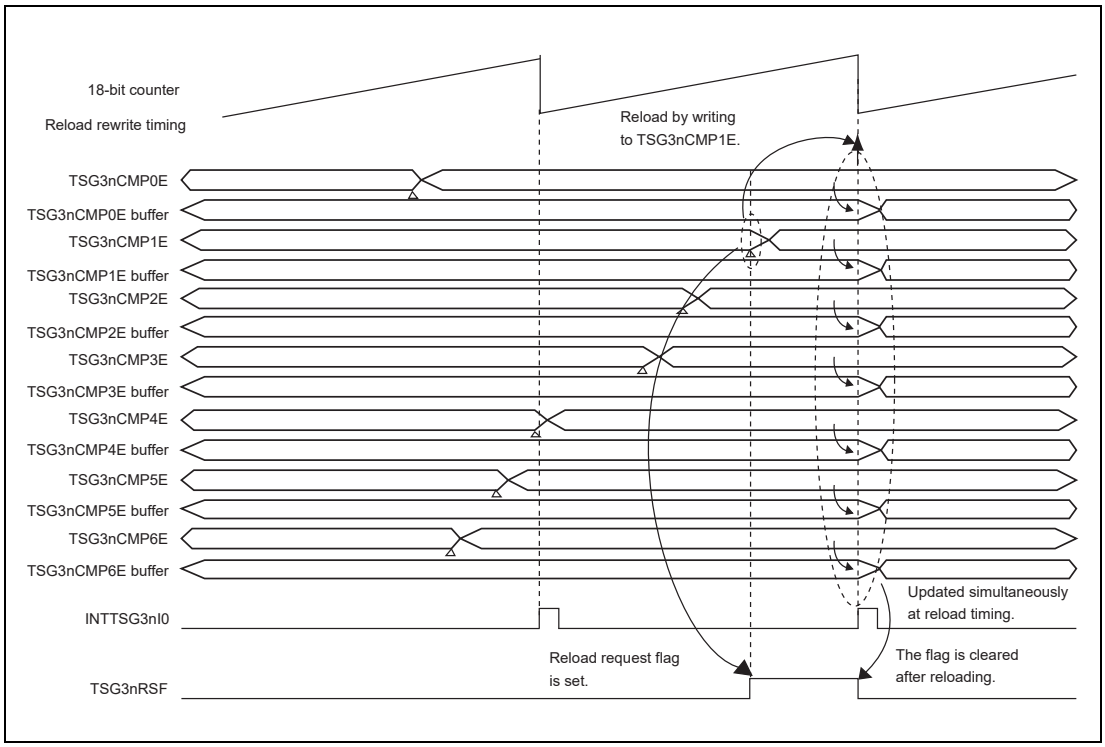

Figure 35.11 Simultaneous Rewrite Timing (Example of PWM Mode) (2/2)

(a) Reload Rewrite Setting Example in Each Mode

Reloading conditions and setting examples are shown in the following tables.

Table 35.46 List of Reload Settings (when TSG3nCTL3.TSG3nRIA = 0)

Mode	TSG3nCTL4. TSG3nPRE	TSG3nCTL4. TSG3nVRE	TSG3nCTL4. TSG3nPIE	TSG3nCTL4. TSG3nVIE	TSG3nCTL4. TSG3nRCC04- TSG3nRCC00	Reload
PWM mode SP-PWM mode 120-DC mode HSP-PWM mode	0	0/1	0/1	0/1	Any value	Setting prohibited
	1	0	0/1	0/1	Any value	When INTTSG3nI0 is generated.
	1	1	0/1	0/1	Any value	When INTTSG3nI0 is generated.
HT-PWM mode	0	0	0/1	0/1	Any value	Setting prohibited
	0	1	0/1	0/1	Any value	When INTTSG3nIVLY is generated.
	1	0	0/1	0/1	Any value	When INTTSG3nIPEK is generated
	1	1	0/1	0/1	Any value	When INTTSG3nIPEK or INTTSG3nIVLY is generated.

Table 35.47 List of Reload Settings (when TSG3nCTL3.TSG3nRIA = 1)

Mode	TSG3nCTL4. TSG3nPRE	TSG3nCTL4. TSG3nVRE	TSG3nCTL4. TSG3nPIE	TSG3nCTL4. TSG3nVIE	TSG3nCTL4. TSG3nRCC04- TSG3nRCC00	Reload
PWM mode SP-PWM mode 120-DC mode HSP-PWM mode	0	0/1	0/1	0/1	Any value	Setting prohibited
	1	0	0	0/1	Any value	Setting prohibited
	1	0	1	0/1	Any value	When INTTSG3nI0 is generated
	1	1	0	0/1	Any value	Setting prohibited
	1	1	1	0/1	Any value	When INTTSG3nI0 is generated
HT-PWM mode	0	0	0/1	0/1	Any value	Setting prohibited
	0	1	0	0	Any value	Setting prohibited
	0	1	0	1	Any value	When INTTSG3nIVLY is generated
	0	1	1	0	Any value	Setting prohibited
	0	1	1	1	Any value	When INTTSG3nIVLY is generated
	1	0	0	0/1	Any value	Setting prohibited
	1	0	1	0/1	Any value	When INTTSG3nIPEK is generated
	1	1	0	0	Any value	Setting prohibited
	1	1	0	1	Any value	When INTTSG3nIVLY is generated
	1	1	1	0	Any value	When INTTSG3nIPEK is generated
	1	1	1	1	Any value	When INTTSG3nIPEK or INTTSG3nIVLY is generated

35.4.1.4 List of Outputs in Each Mode

The list of timer outputs (TSG3nO0-7 pins) in each mode is shown in the following tables.

Table 35.48 List of Timer Outputs in Each mode (1/3)

Operating Mode	TSG3nO0 Pin	TSG3nO1 Pin	TSG3nO2 Pin
PWM mode	— (Fixed to low.)	Outputs a PWM signal by compare match of TSG3nCMP1E and TSG3nCMP2E.	Outputs a PWM signal by compare match of TSG3nCMP3E and TSG3nCMP4E.
HT-PWM mode	Outputs the status indicating whether the 18-bit counter or 18-bit sub-counter is incremented or decremented.	Outputs a positive phase PWM signal (with dead time) by compare match of TSG3nCMP1E and TSG3nCMP2E.	Outputs an inverse phase PWM signal (with dead time) to TSG3nO1 pin.
SP-PWM mode	— (Fixed to low.)	Outputs a positive phase PWM signal (with dead time) by compare match of TSG3nCMP1E and TSG3nCMP2E.	Outputs an inverse phase PWM signal (with dead time) to TSG3nO1.
120-DC mode	— (Fixed to low.)	Outputs a PWM signal by TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, and TSG3nCMP10E.	Outputs a PWM signal by TSG3nCMP3E, TSG3nCMP4E, TSG3nCMP7E, TSG3nCMP8E, TSG3nCMP11E, and TSG3nCMP12E.
HSP-PWM mode	— (Fixed to low.)	Outputs a PWM signal by compare match of TSG3nCMP1E and TSG3nCMP2E.	Outputs a PWM signal by compare match of TSG3nCMP3E and TSG3nCMP4E.

Table 35.48 List of Timer Outputs in Each mode (2/3)

Operating Mode	TSG3nO3 Pin	TSG3nO4 Pin	TSG3nO5 Pin
PWM mode	Outputs a PWM signal by compare match of TSG3nCMP5E and TSG3nCMP6E.	Outputs a PWM signal by compare match of TSG3nCMP7E and TSG3nCMP8E.	Outputs a PWM signal by compare match of TSG3nCMP9E and TSG3nCMP10E.
HT-PWM mode	Outputs a positive phase PWM signal (with dead time) by compare match of TSG3nCMP5E and TSG3nCMP6E.	Outputs an inverse phase PWM signal (with dead time) to TSG3nO3.	Outputs a positive phase PWM signal (with dead time) by compare match of TSG3nCMP9E and TSG3nCMP10E.
SP-PWM mode	Outputs a positive phase PWM signal (with dead time) by compare match of TSG3nCMP5E and TSG3nCMP6E.	Outputs an inverse phase PWM signal (with dead time) to TSG3nO3.	Outputs a positive phase PWM signal (with dead time) by compare match of TSG3nCMP9E and TSG3nCMP10E
120-DC mode	Outputs a PWM signal by TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, and TSG3nCMP10E.	Outputs a PWM signal by TSG3nCMP3E, TSG3nCMP4E, TSG3nCMP7E, TSG3nCMP8E, TSG3nCMP11E, and TSG3nCMP12E.	Outputs a PWM signal by TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, and TSG3nCMP10E
HSP-PWM mode	Outputs a PWM signal by compare match of TSG3nCMP5E and TSG3nCMP6E	Outputs a PWM signal by compare match of TSG3nCMP7E and TSG3nCMP8E	Outputs a PWM signal by compare match of TSG3nCMP9E and TSG3nCMP10E

Table 35.48 List of Timer Outputs in Each mode (3/3)

Operating Mode	TSG3nO6 Pin	TSG3nO7 Pin
PWM mode	Outputs a PWM signal by compare match of TSG3nCMP11E and TSG3nCMP12E	Outputs a diagnostic signal or A/D conversion trigger.*1
HT-PWM mode	Outputs an inverse phase PWM signal (with dead time) to TSG3nO5	Outputs a diagnostic signal or A/D conversion trigger.*1
SP-PWM mode	Outputs an inverse phase PWM signal (with dead time) to TSG3nO5	Outputs a diagnostic signal or A/D conversion trigger*1
120-DC mode	Outputs a PWM signal by TSG3nCMP3E, TSG3nCMP4E, TSG3nCMP7E, TSG3nCMP8E, TSG3nCMP11E, and TSG3nCMP12E	Outputs a diagnostic signal or A/D conversion trigger.*1
HSP-PWM mode	Outputs a PWM signal by compare match of TSG3nCMP11E and TSG3nCMP12E	Outputs a diagnostic signal or A/D conversion trigger*1

Note 1. For TSG3nO7, See **Section 35.4.1.4, (a) TSG3nO7 Pin Output Control**

(a) TSG3nO7 Pin Output Control
