SSP User's Manual

Chapter 1 Renesas Synergy Software Package (SSP)

1.1 Renesas Synergy™ Software Package Introduction

1.1.1 Introduction to the SSP User's Manual

This manual describes how to use the Renesas Synergy Software Package for writing applications for the Synergy microcontroller series. In the figure below, the API Reference components of the SSP User's Manual are indicated in blue. Additional components such as the description of the e^2 studio ISDE and tutorials and example applications are included in this manual to guide you through the steps of programming with the SSP.

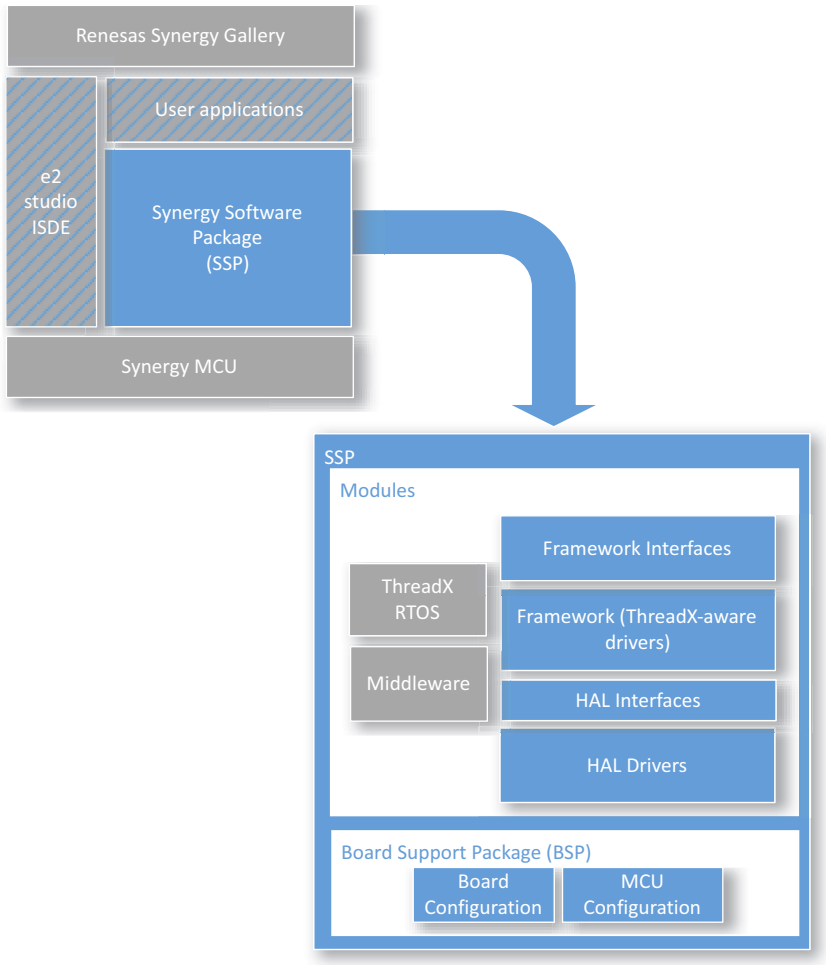

Figure 1: Synergy Software Package (SSP) Documentation

1.1.2 Subjects Covered in this Manual

To learn about the SSP architecture and about board and chip-level support included in the SSP see:

- SSP Architecture
- BSP Architecture

For programming with the SSP and an introduction to the e^2 studio ISDE see:
e^2 studio ISDE User Guide

For introductory tutorials and application examples see:

- Tutorial: Your First Synergy Project - Blinky

- Tutorial: Using HAL Drivers - Programming the WDT

For Module Overviews describing the SSP Modules, see:

- Framework Layer
- HAL Layer

The API reference documentation of the following SSP components is included in this document:

- API Reference: Framework Interfaces for Interfaces to the ThreadX-aware Framework Modules
- API Reference: Framework Layer for ThreadX-aware Framework Driver Modules
- API Reference: HAL Interfaces for Interfaces to the Hardware Abstraction Layer (HAL) Modules
- API Reference: HAL Layer for the RTOS-independent HAL driver Modules
- Board Support Package for the Board Support Package (BSP) which includes board-specific and microcontroller-specific configuration modules

Chapter 2 SSP Overview

Learn how to develop applications with the Synergy Software Package (SSP) using the SSP's module-based architecture and the functional software layers. Integrate SSP applications with multiple boards and Synergy devices using the Board Support Package (BSP).

The following pages describe the fundamental SSP architecture:

- SSP Architecture
- BSP Architecture

2.1 SSP Architecture

2.1.1 SSP Architecture

This section describes the Synergy Software Package (SSP) architecture and how to use the SSP Application Programming Interface (API).

2.1.1.1 Introduction to the SSP

As microcontrollers increase in complexity, so does the breadth of knowledge required to make them operate in the desired way. The Synergy Software Package (SSP) is a software package that we provide to our users for the purpose of allowing them to start their development at a higher level than they have in the past. This does not mean hiding every complexity, but instead presenting it to the user in a way that is easily understandable, and quickly modifiable. Instead of requiring the user to refer to a hardware register at every step, we instead offer a well-documented function call.

2.1.1.2 Prerequisite Information

The following sections provide prerequisite information for using the SSP.

For SSP tools, see e^2 studio ISDE User Guide

2.1.1.3 C99 Use

The SSP uses the ISO/IEC 9899:1999 (C99) C programming language standard. Specific features introduced in C99 that are used include standard integer types (stdint.h), booleans (stdbool.h), designated initializers, and the ability to intermingle declarations and code.

2.1.1.4 Use of const in API parameters

The *const* qualifier is used with API parameters whenever possible. An example case is shown below.

```
ssp_err_t (* open)(flash_ctrl_t * const p_ctrl,

    flash_cfg_t const * const p_cfg);
```

While not fool-proof by any means this does provide some extra checking inside the SSP code to ensure that arguments that should not be altered are treated as such.

2.1.1.5 Doxygen

Doxygen is the default documentation tool used by SSP. You can find Doxygen comments throughout the document when exploring the SSP source.

2.1.1.6 Weak Symbols

Weak symbols are used occasionally in and with the SSP. They are used to ensure that a project builds even when the user has not defined an optional function.

2.1.1.7 SSP Terms

Term	Description	Reference
Module	Modules can be peripheral drivers, purely software, or anything in between. Each Module consists of a folder with source code, documentation, and anything else that the customer needs to use the code effectively. Modules are independent units, but they may depend on other Modules. Example SSP Modules are the UART driver (UART Interface), Audio Framework which relies on timer, DMA, and DAC drivers (Audio Framework Interface), or the Messaging Framework (Messaging Framework Interface). Applications can be built by combining multiple modules to provide the user with the features they need.	SSP Modules
BSP	Short for Board Support Package. In the SSP the BSP provides just enough foundation to allow other SSP modules to work together without issue.	BSP Architecture

Term	Description	Reference
Callback Function	This term refers to a function that is called when an event occurs. For example, the bus error interrupt handler is implemented in the r_bsp. The user will likely want to know when a bus error occurs. To alert the user, a callback function can be supplied to the r_bsp. When a bus error occurs the r_bsp will jump to the provided callback function and the user can handle the error. Interrupt callback functions should be kept short and be handled carefully because when they are called the MCU will still be inside of an interrupt and therefore will be delaying any pending interrupts.	-
Interface	See SSP Interfaces section: SSP Interfaces. All interfaces in the SSP are listed here: API Reference: Framework Interfaces and API Reference: HAL Interfaces	SSP Interfaces
Instance	See SSP Instances section: SSP Instances	SSP Instances
Module Instance	Single and independent configuration of a Module.	-
Application	Code that is owned and maintained by the user. Application code may be based off sample application code provided by Renesas, but is the responsibility of the user.	An example for a simple application is included as tutorial in this manual: Tutorial: Using HAL Drivers - Programming the WDT
Driver	A Driver is a specific kind of Module that directly modifies registers on the MCU.	-
Stacks	The SSP architecture is designed such that Modules work together to form a Stack. Starting with the uppermost Module and going to the bottommost dependency forms a specific Stack.	SSP Stacks

Term	Description	Reference
Layer/Level	Stacks are made of multiple layers of Modules. A Layer can consist of one or multiple Modules depending on the requirements of the next Layer up. Layer and Level are used interchangeably.	SSP Predefined Layers

2.1.1.8 SSP Modules

Modules are the core building block of SSP. Modules can do many different things, but all Modules share the basic concept of providing functionality upwards and requiring functionality from below.

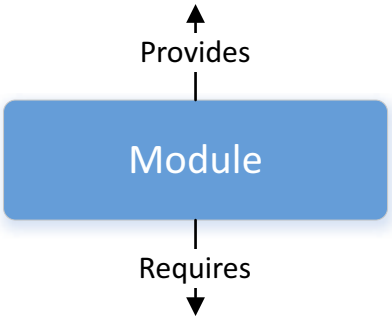

Figure 2: Modules

The amount of functionality provided by a Module is not limited though there are usually points where separation makes sense. If too much functionality is provided, then reuse of the Module can become difficult in the future. If not enough functionality is provided, then unnecessary complexity and overhead may be added in order to make the Modules work as expected.

The simplest SSP application consists of one Module with the user application on top.

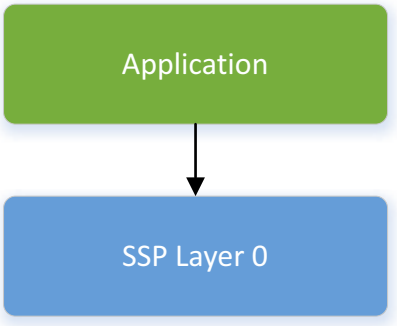

Figure 3: Module with application

For simplicity, ignore the Board Support Package (BSP) for now because it is a requirement of any SSP project. In the picture above, the BSP is located underneath the bottom layer, SSP Layer 0.

2.1.1.9 SSP Stacks

When Modules are layered atop one another, an SSP Stack is formed. The stacking process is performed by matching what one Module provides with what another Module requires. For example, the Audio Playback Framework Module requires a Transfer Interface which can be fulfilled by the Data Transfer Controller (DTC) Driver Module. Instead of including the DTC code in the Audio Playback Module, we split these into two Modules. This allows for reuse of the underlying Modules which has many benefits.

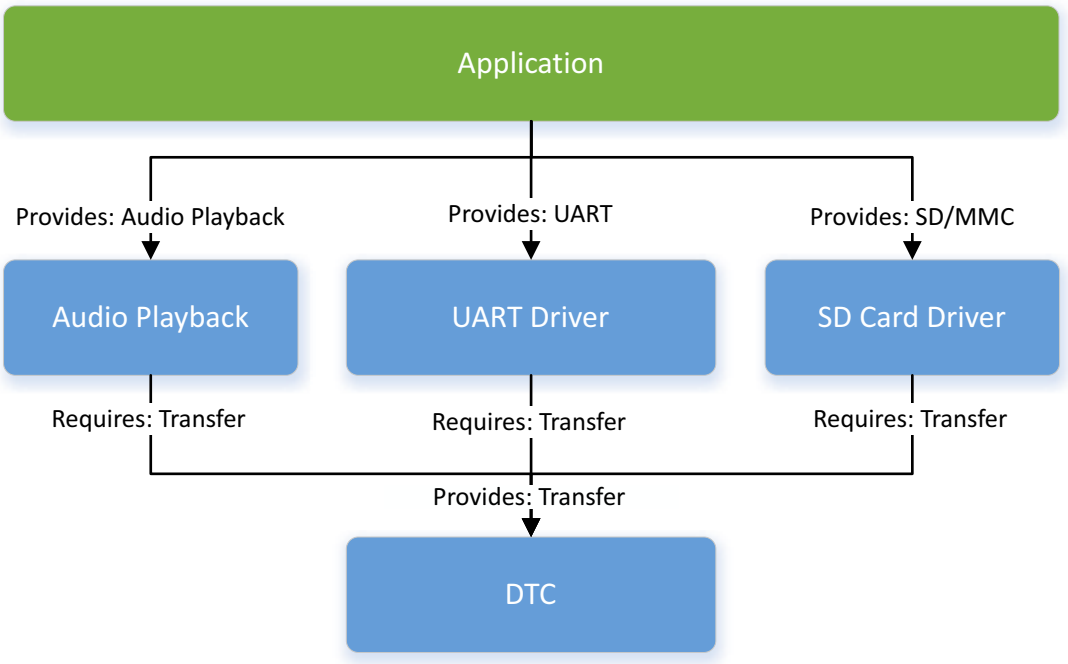

Figure 4: Stacks – Audio playback

By continuing to add layers to the Stack using SSP Modules, you can interface with the Synergy hardware at a high level.

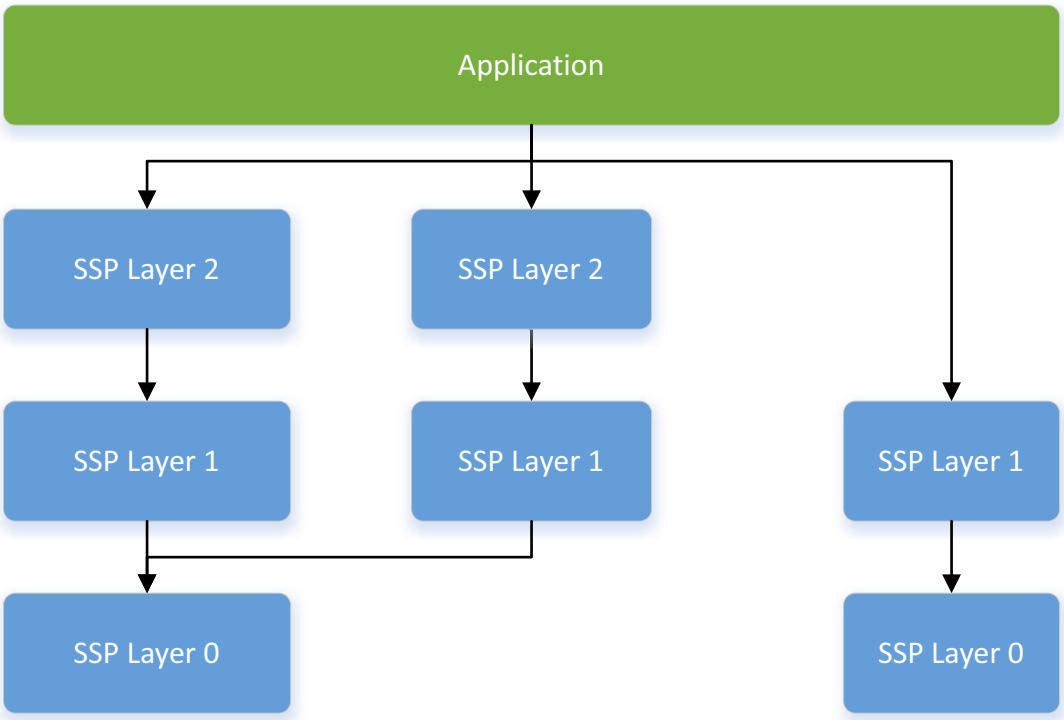

Figure 5: Stacks

The ability to stack modules has great benefit because it ensures the flexibility of the architecture as a whole. If modules are directly dependent upon other modules, then issues arise when application features must work across different user designs. To ensure that modules are reusable the modules must be capable of being swapped out for other modules that provide the same features. The SSP architecture provides this flexibility to swap modules in and out through the use of SSP Interfaces.

2.1.1.10 SSP Interfaces

At the architecture level, Interfaces are the way that Modules provide common features. This commonality allows Modules that adhere to the same Interface to be used interchangeably. Interfaces can be thought of as a contract between two Modules. The Modules agree to work together using the information that was agreed upon in the contract.

On Synergy hardware there is occasionally an overlap of features between different peripherals. For example, I2C communications can be achieved through use of the IIC peripheral or the SCI peripheral in its Simple I2C mode. There is a difference in the level of features provided by both peripherals. In I2C mode the SCI peripheral will only support a subset of the features of the full-featured IIC.

Interfaces aim to provide support for the common features that most users would expect. This means that some of the advanced features of a peripheral, such as the IIC, might not be available in the Interface. In most cases these features are still available through Interface Extensions.

In design, Interfaces are implemented as header files. All Interface header filenames end with '*_api.h'. The following sections detail what makes up an Interface.

SSP Interface Enumerations

Whenever possible, Interfaces use typed enumerations for function parameters and structure members.

```
typedef enum e_i2c_addr_mode

{

    I2C_ADDR_MODE_7BIT = 1, // Use 7-bit addressing mode

    I2C_ADDR_MODE_10BIT     // Use 10-bit addressing mode

} i2c_addr_mode_t;
```

Enumerations remove any uncertainty when deciding what values are available for a parameter. Also note that enumeration options follow a strict naming convention where the name of the type is prefixed on the available options. Combining the naming convention with the autocomplete feature available in e^2 studio provides the benefits of rapid coding while maintaining highly readable code.

SSP Interface Data Structures

At a minimum, all SSP Interfaces include three data structures: a control structure, a configuration structure, and an instance structure.

The control structure is used as a unique identifier for using the module. If SSP modules were only peripheral drivers then this control structure might be replaced with a channel number. All function calls for that module would then take a channel number so that the code could determine which peripheral channel to operate on. SSP modules are not restricted to device drivers and therefore the control structure is used. The user allocates storage for a control structure and then sends a pointer to it into the open() call for a Module. At this point, the Module initializes the structure as needed. The user must then send in a pointer to the control structure for all subsequent Module calls. The contents of the control structure are used by the Module and must not be altered by the user.

The contents of a control structure vary depending on the Module. Modules that implement device drivers may have very small control structures which only identify the channel being used. Usually this means that the Module will be statically allocating memory internally. In this case, the Module knows exactly how many channels are available. Purely software Modules cannot operate that way because the number of instances is typically only limited by amount of memory available. Dynamic memory allocation through use of the malloc() and free() functions are not used in SSP modules.

The configuration structure is used for the initial configuration of a Module during the open() call. The structure consists of members such as: channel, bitrate, and operating mode. The structure is used purely for input into the Module. This structure does not have to be unique and could be discarded by the user after initialization if desired.

```
typedef struct st_i2c_cfg

{

/* Generic configuration */

    uint32_t channel; // Identifier recognizable by underlying instance

    i2c_rate_t rate;  // Device's maximum clock rate in Hz, i.e. 400000

    uint16_t slave; // The address the device will respond to
```

```
    i2c_addr_mode_t addr_mode; // Indicates how slave fields should be interpret
ed

    /* Parameters to control software behavior */

    void (*p_callback)(i2c_callback_args_t * p_args); // Pointer to callback fun
ction

    void const * p_context; // Pointer to the user-provided context

    /* Instance-specific configuration */

    void const * p_extend; // Any configuration data needed by underlying hardwa
re

} i2c_cfg_t;
```

Above is an example configuration structure for the I2C Interface. The last three structure members (p_callback, p_context, and p_extend) are common to almost all module configurations.

The *p_callback* and *p_context* members are described in the SSP Interface Callback Functions section.

The *p_extend* member is used for extending the current Interface for a specific Instance. Interfaces are designed to support the most common features. There are cases where an Instance of an Interface requires extra information to properly configure itself. There are also cases where the extra information is not required, but users might need it to adjust the module for their specific application. When this is the case, the user can provide the underlying Instance with more configuration information by passing it through the *p_extend* member. The information that is passed through this member is defined by the underlying Instance, and therefore the user must adhere to its structure. If invalid information is passed to the underlying driver, then the Instance is not able to successfully use the data and proper operation cannot be guaranteed. Refer to the Interface Extensions section for more information.

It is also important that configuration structures only have members that apply to the current Interface. If multiple layers in the same stack define the same configuration parameters then it becomes difficult to know where to modify the option. For example, the baud rate for a UART is only be defined at the Driver layer. Any layers that use the UART Interface rely on the baud rate being provided at the Driver layer and do not offer it in their own configuration structures.

SSP Interface Callback Functions

Callback functions allow Modules to asynchronously alert the user application when an event has occurred. An example for an event is when a byte has been received over a UART channel. Callbacks are required to allow user application code to react to interrupts. SSP Modules define and handle the interrupts for Synergy MCU peripherals. If the user tries to define the interrupt service routine at the same time as a SSP Module, then the code does not build. Therefore SSP Modules allow the user application to respond to interrupts by registering a function to be called when an interrupt occurs.

Callback functions must be defined in the user application. They always return *void* and take a structure for their one parameter. The structure typedef is provided in the Interface for the Module and is named * <interface>_callback_args_t*. The contents of the structure may vary depending on the Interface, but two members are common: *event* and *p_context*.

The *event* member is used by the application to determine why the callback was called. Using the UART example again, the callback could have been triggered because a byte was received, all bytes had been transmitted, or a framing error has occurred. The *event* member is an enumeration provided by the Interface.

The *p_context* member is used for providing user-specified data to the callback function. In many cases a callback function is shared between multiple channels or Module Instances. When the callback occurs, the code handling the callback needs context information so that it can figure out which Module Instance the callback is for. For example, if the callback wanted

to make a SSP API call in the callback, then at a minimum the callback must use the control structure. To make this easy, the user can provide a pointer to the control structure as the *p_context*. When the callback occurs, the control structure is available as it will be passed in the callback structure.

Callback functions are called from within an interrupt service routine. For this reason callback functions should be kept as short as possible so they do not affect the real time performance of the user's system. An example skeleton function for the Flash Interface callback is shown below.

```
static void flash_callback (flash_callback_args_t * p_args)

{

    /* See what event caused this callback. */

    switch (p_args->event)

    {

        case FLASH_EVENT_ERASE_COMPLETE:

        /* Handle event. */

        break;

        case FLASH_EVENT_WRITE_COMPLETE:

        /* Handle event. */

        break;

        case FLASH_EVENT_BLANK:

        /* Handle event. */

        break;

        case FLASH_EVENT_NOT_BLANK:

        /* Handle event. */

        break;

        case FLASH_EVENT_ERR_DF_ACCESS:

        /* Handle error. */

        break;

        case FLASH_EVENT_ERR_CF_ACCESS:

        /* Handle error. */
```

```
        break;

        case FLASH_EVENT_ERR_CMD_LOCKED:

        /* Handle error. */

        break;

    }

}
```

When a Module is not directly used in the user application (it is not the top layer of the stack) then its callback function will be handled by the Module above. If there is a Console Interface Module that requires a UART Interface Module then the Console Module will control and use the UART's callback function. In this case the user does not need to create a callback function for the UART Module in their application code.

SSP Interface API Structure

All Interfaces include an API structure which contains function pointers for all the supported Interface functions. An example structure, with the comments removed, for the Digital to Analog Convert (DAC) is shown below.

```
typedef struct st_dac_api

{

    ssp_err_t (*open)(dac_ctrl_t *p_ctrl, dac_cfg_t const *const p_cfg);

    ssp_err_t (*close)(dac_ctrl_t *p_ctrl);

    ssp_err_t (*write)(dac_ctrl_t *p_ctrl, dac_size_t *p_value);

    ssp_err_t (*start)(dac_ctrl_t *p_ctrl);

    ssp_err_t (*stop)(dac_ctrl_t *p_ctrl);

    ssp_err_t (*versionGet)(ssp_version_t *p_version);

} dac_api_t;
```

The API structure is what allows for Modules to easily be swapped in and out for other Modules that are Instances of the same Interface. Let's look at an example application using the DAC Interface above.

Synergy MCUs have an internal DAC peripheral. If the DAC API structure in the DAC Interface were not used, then the application could make calls directly into the module. In the example below the application is making calls to the R_DAC_Write function which is provided in the r_dac module.

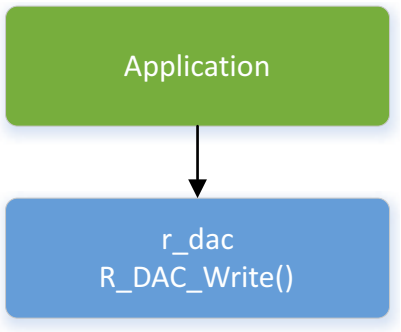

Figure 6: DAC Write example

Now let's assume that the user needs more DAC channels than are available on the MCU by adding a new external DAC module named r_dac_external. The external DAC uses I2C for communications. The application must now distinguish between the two modules, which adds complexity and further dependencies to the application.

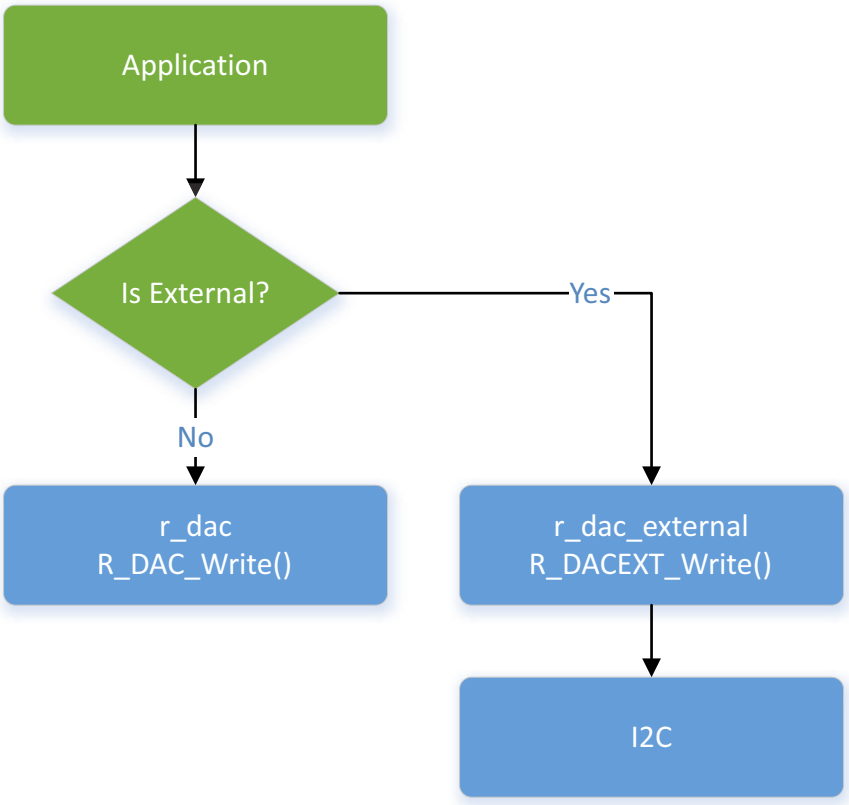

Figure 7: DAC Write with two write modules

The use of Interfaces and the API structure allows for the use of an abstracted DAC. This means that no extra logic is needed and the application no longer depends upon certain hard-coded Modules. Instead the application now depends on the DAC Interface API which can be implemented by any number of Modules.

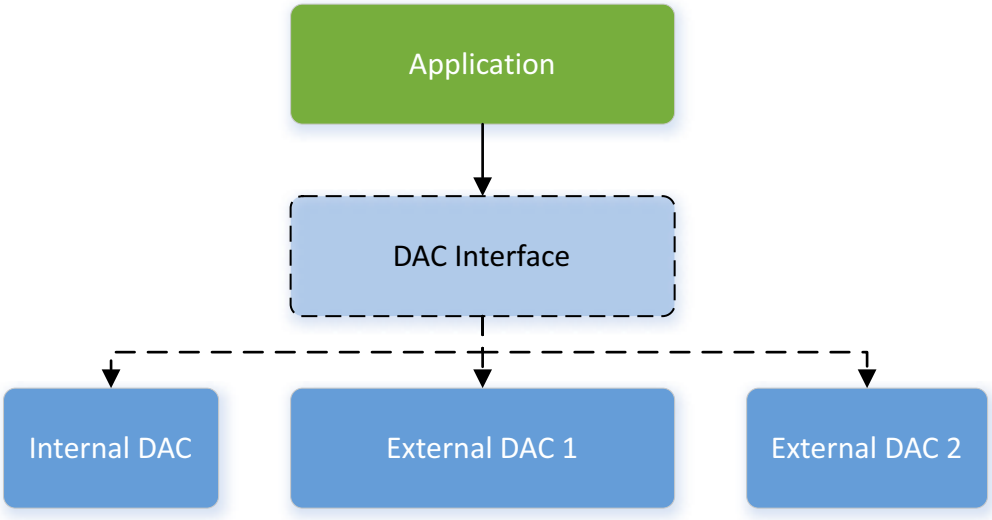

Figure 8: DAC Interface

Functions inside of the API structures follow common names. Most Modules will have a pair of open() and close functions. The open() function must be called before any of the other functions. The only exception is the versionGet() function which is not dependent upon any user provided information.

Other functions that will commonly be found are read(), write(), get(), and set(). Function names are designed to be a noun followed by a verb. Example names include:

- read(), write(), writeRead()
- statusGet()
- calendarAlarmSet(), calendarAlarmGet()
- accessWindowSet(), accessWindowClear()

SSP Interface Version Information

All Interfaces supply a versionGet() function. This function fills in a structure of type *ssp_version_t*. This structure is made up of two versions: one for the Interface (the API) and one for the underlying Instance that is currently being used.

```
typedef union st_ssp_version

{

uint32_t version_id;

struct
```

```
{

    uint8_t code_version_major; // Code major version

    uint8_t code_version_minor; // Code minor version

    uint8_t api_version_major;  // API major version

    uint8_t api_version_minor;  // API minor version

};

} ssp_version_t;
```

The API version ideally never changes, and only rarely if it does. A change to the API may require users to go back and modify their code. The code version, the version of the current Instance, may be updated more frequently. Bug fixes, enhancements, and additional features may all bump the code version. Changes to the code version will only require changes to the user code if the user code is using extended features provided by the Instance.

SSP Instances

While Interfaces dictate the features that are provided, Instances actually implement those features. Each Instance is tied to a specific Interface. Instances use the enumerations, data structures, and API prototypes from the Interface. This allows for an application that uses an Interface to swap out the Instance when needed.

On Synergy MCUs some peripherals will have a one-to-one mapping between the Interface and Instance, while others will have a one-to-many. In the example below the IIC and SPI peripherals map to only one Interface each while the SCI peripheral implements three Interfaces.

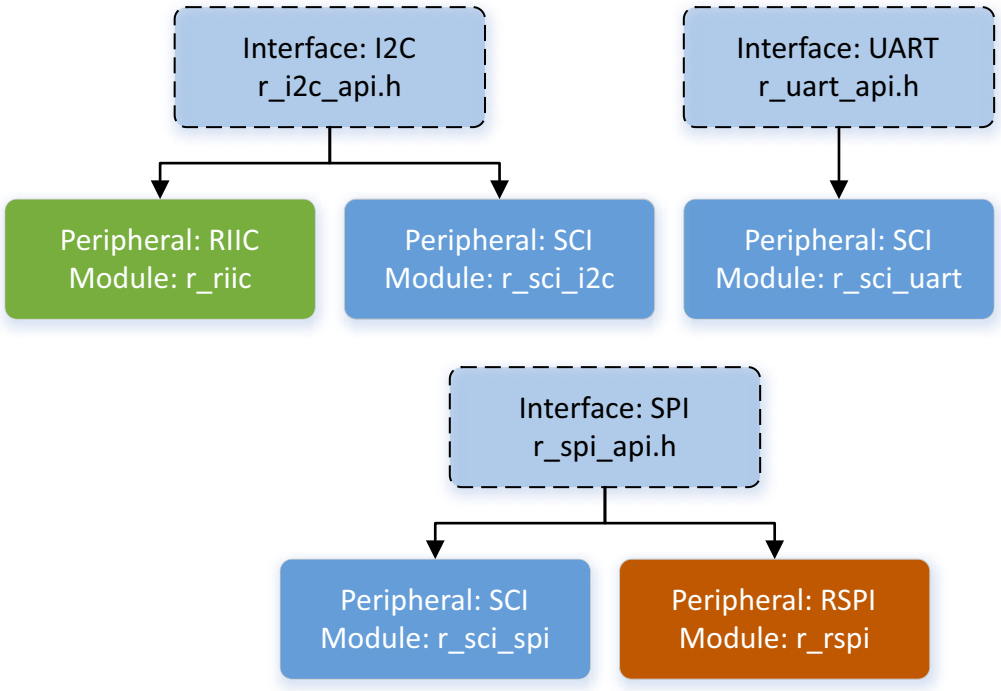

Figure 9: Instances

SSP Instances API Structure

Each Instance includes a constant global structure with its functions that implement the Interface's API. The name of this structure is standardized as g_<*interface*>_on_<*instance*>. Examples include g_spi_on_spi, g_transfer_on_dtc, and g_adc_on_adc. This structure is available to be used through an extern in the instances header file (r_spi.h, r_dtc.h, and r_adc.h respectively).

2.1.1.11 Build Time Configuration

All modules have a build-time configuration header file. Most configuration options are supplied at run time. Some options that are rarely used, or apply to all instances of a module, may be moved to build time. The advantage of using a build-time configuration option is to potentially reduce code size reduction by removing an unused feature.

All modules have at least one build time option, which is whether to enable or disable parameter checking for the module. SSP modules check function arguments for validity when possible. Some users may want to disable this feature when their testing has concluded to save code space and to speed up execution.

2.1.1.12 Interface Extensions

In some cases, Instances require more information than is provided in the Interface. This situation can occur in the following two cases:

- An Instance offers extra features that are not common to most Instances of the Interface.

- An Interface must be very generic out of necessity. As an Interface becomes more generic, the number of possible Instances increases. A prime example of this is the Block Media Interface.

```
typedef struct st_sf_block_media_cfg

{

    uint32_t block_size; // Block size in bytes

    void * p_extend; // Instance dependent configuration

} sf_block_media_cfg_t;
```

The configuration structure for the Block Media Interface is intentionally sparse. This allows for nearly endless Instances. Possible Instances include SD card, SPI Flash, SDRAM, USB, and many more. Different configuration information is needed for each Instance. This is accomplished by supplying the information through the *p_extend* parameter. While the configuration data provided in the *p_extend* is not the same between Instances, the API calls thereafter will be. This means that the change is only required in one place.

Use of Interface extensions is not always necessary. Some Instances do not offer an extension since all functionality is provided in the Interface. In many cases the *p_extend* member can be set to NULL. If NULL is provided and the Instance does offer an extension then the Instance will take this to mean that the default options should be used. The documentation for each Instance indicates whether an Interface extension is provided and whether its use is mandatory or optional.

2.1.1.13 SSP Predefined Layers

The SSP comes with two predefined layers: the Driver layer and the Framework layer. The layers are easily identifiable because the modules reside in different folders and have different prefixes. Driver layer modules are located in the *ssp/src/driver* folder, while Framework level modules are located in the *ssp/src/framework* folder. Modules in the Driver layer start with an *r_* prefix, while Framework level modules start with a *sf_* prefix.

The core difference in the functionality between the layers is that Driver layer modules are restricted to being peripheral drivers that are RTOS aware, but do not use any RTOS objects or make any RTOS API calls. This means that Driver layer modules can be used in applications with, or without, an RTOS.

Framework layer modules are free to use RTOS objects such as semaphores, mutexes, or event flags. Framework modules may also create their own when needed. Framework layer modules that need to access hardware typically do so through a Driver layer Interface. Exceptions can be granted in special cases where multiple peripherals need to be used together in a way that would not be practical through multiple individual Interfaces.

2.1.1.14 SSP File Structure

The high-level file structure of the SSP is shown below.

```
ssp

+---inc

|   +---bsp

|   +---driver
```

```
|   |   +---api
|   |   \---instances
|   \---framework
|       +---api
|       +---el
|       +---instances
|       \---tes
\---src
    +---bsp
    |   +---cmsis
    |   \---mcu
    +---driver
    |   \---r_module
    \---framework
        +---el
        +---sf_module
        \---tes
ssp_cfg
+---bsp
+---driver
\---framework
```

Directly underneath the base *ssp* folder the folders are split into the source and include folders. Include folders are kept separate from the source for easy browsing and easy setup of include paths. The the same set of folders are located in the *ssp/inc* and *ssp/src* folders: *bsp, driver,* and *framework*.

Apart from the BSP, the SSP's two predefined layers, Driver and Framework, are present. Driver layer modules are located in the *ssp/src/driver* folder and Framework layer modules are located in *ssp/src/framework*. Under the include tree, the Driver and Framework layer folders contain two folders each: *api* and *instances*. The *api* folder contains the Interface

header files for that layer. The *instances* folder contains the Instance header files for that layer. Both layers are flat internally which limits the number of include paths required for a project.

The *ssp_cfg* folder is where configuration header files are stored for each module. Its layout is the same as the *ssp* folder where the BSP, Driver, and Framework layers have separate flat directories. See the Build Time Configuration section for information on what is provided in these header files.

2.1.1.15 SSP Connecting Layers

SSP modules are meant to be both reusable and stackable. It is important to remember that modules are not dependent upon other modules, but upon other Interfaces. The user is then free to fulfill the Interface using the Instance that best fits their needs.

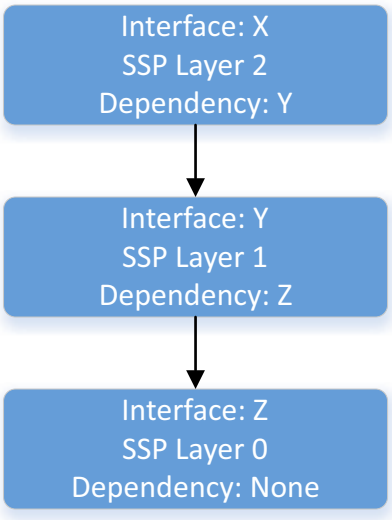

Figure 10: Connecting layers

In the image above Interface Y is a dependency of Interface X and has its own dependency on Interface Z. Interface X only has a dependency on Interface Y. Interface X has no knowledge of Interface Z. This is a requirement for ensuring that layers can easily be swapped out. This is shown in the next diagram.

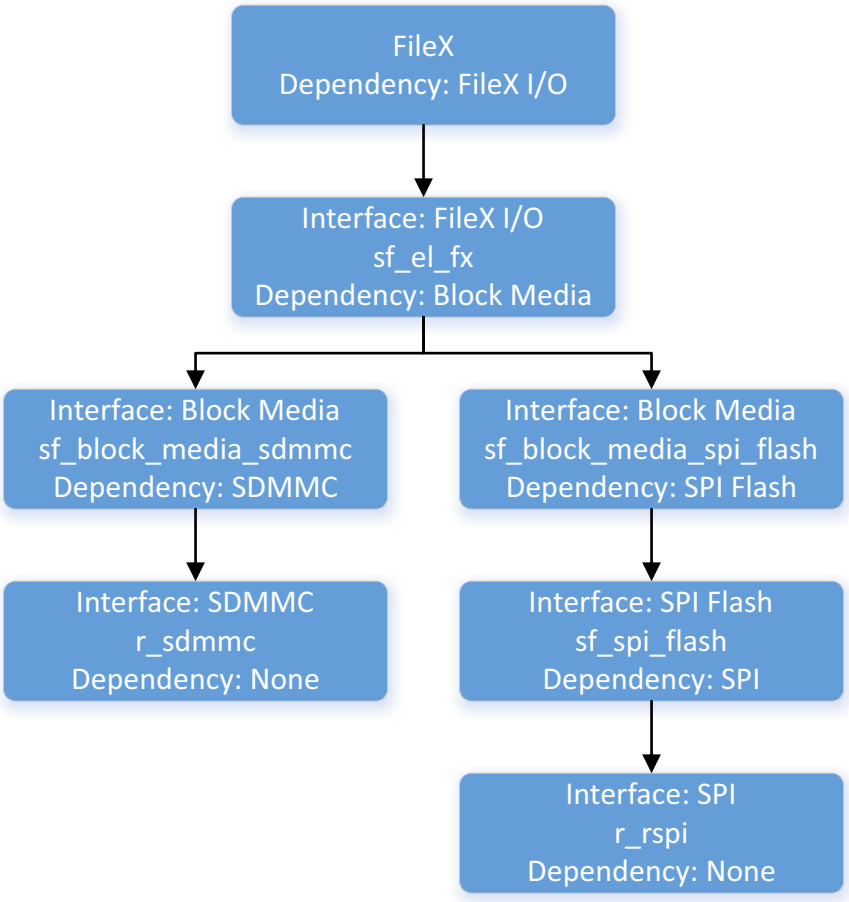

Figure 11: Connecting layers with the FileX interface

In this example we are using the Express Logic, Inc. FileX file system on two storage mediums: SDMMC and SPI Flash. The SPI Flash Interface takes care of the SPI flash protocol but requires a SPI Interface for actual SPI bus communications. The SDMMC Interface takes care of the protocol and the bus communications meaning that it does not have any dependencies.

For details on the SDMMC and FileX Interfaces, see FileX Port Block Media Framework.

2.1.1.16 SSP Architecture In Practice

Each layer in the SSP Stack is responsible for calling the API functions of its dependencies. This can also be described by saying that users are only responsible for calling the API functions at the layer at which they are interfacing. Using the FileX example above, the user is only responsible for calling FileX functions in the application code. Internally, FileX then calls FileX I/O, which in turn calls a Block Media Interface Module. The Block Media Interface can call multiple drivers. At a minimum an upper layer Module calls the *open()* function of the Interface it depends upon.

To write an application using a Module, you must determine the following:

1) Determine which open() function to call. Dependencies are based upon Interfaces which means that a Module must have some way of discerning which Instance to call.
2) Determine the configuration parameters. The Module also needs to know what configuration information to pass down. In some cases the Module requires certain configuration parameters to be set. If this is the case then the module sets these configuration structure members itself before passing on the rest of the structure. The rest of the configuration structure members must be provided outside of the Module.
3) Provide a control structure which is Module Instance specific and therefore can be allocated by the upper layer module.

Putting this all together means that to interact with a Module Instance, the following is needed:

- A pointer to the Instance's API structure
- A pointer to the Module Instance's configuration structure
- A pointer to the Module Instance's control structure

This information is sufficient to use any module. Notice that the API structure is the only structure that is Instance specific; not *Module Instance* specific. This is because the API structure will not vary between multiple uses of the same Instance. If SPI is being used on SCI channels 0 and 2 then both Module Instances will use the same API structure while the configuration and control structures will vary.

To make Module Instances easier to use, all of these pieces are encapsulated in instance structures found in each Interface. These structures have a standardized name of * <interface>_instance_t*. An example from the WDT interface is shown below.

```
typedef struct st_wdt_instance

{

    wdt_ctrl_t *p_ctrl; // Pointer to the control structure for this instance

    wdt_cfg_t const *p_cfg; // Pointer to the configuration structure for this i
nstance

    wdt_api_t const *p_api; // Pointer to the API structure for this instance

} wdt_instance_t;
```

Upper layer modules that have a dependency on an Interface can then use the instance structure to hold everything needed to interact with an Instance of that Interface. Continuing with the WDT example above, below is the Thread Monitor Framework Interface configuration structure. The Thread Monitor Interface is dependent upon the WDT Interface.

```
typedef struct st_sf_thread_monitor_watchdog_type

{

    wdt_instance_t * p_lower_lvl_wdt; // Pointer to lower level watchdog instanc
e
```

```
    bool profiling_mode_enabled;      // Enables or disables profiling mode

    UINT priority;                    // Priority of thread monitor thread

} sf_thread_monitor_cfg_t;
```

The Thread Monitor module has everything it needs to work with the WDT Interface in the *p_lower_lvl_wdt* structure member.

In some cases module dependencies are not be defined in the Interface, but instead in the Instance. An example is the Block Media Interface could be implemented on SDMCC, SPI Flash, or many other Instances (also see). Because of the wide range of implementations, the instance structure for a particular Interface cannot be used directly in the Block Media Interface's configuration structure. The Block Media Interface's configuration structure is shown again below.

```
typedef struct st_sf_block_media_cfg

{

    uint32_t block_size; // Block size in bytes

    void * p_extend; // Instance dependent configuration

} sf_block_media_cfg_t;
```

Notice there are Instance structure pointers provided. The reason for this, as previously mentioned, is that the Block Media Interface is too generic to enforce a dependency upon a particular Interface.

When a Module is an Instance of a generic Interface, such as Block Media, and it has dependencies on other Modules, the module puts the lower-layer pointers in an extension structure that is referenced through the Interface's *p_extend* configuration member. This is required to allow Module stacking while not forcing Interfaces to expand and have many optional configuration members.

```
typedef struct st_block_media_on_sdmmc_cfg

{

    sdmmc_instance_t const * const p_lower_lvl_sdmmc; // Pointer to SDMMC instan
ce structure

} sf_block_media_on_sdmmc_cfg_t;
```

2.1.1.17 Using SSP Modules

This section will give general information on how to use a SSP module.

Pick an Interface

Start by picking an Interface for the functionality that is required. For example, for UART communications use the UART Interface.

Find a suitable Instance of the Interface

After picking an Interface, choose a suitable Instance. The list of known Instances of an Interface is listed in the documentation comments for an Interface. Include the header file of the selected Instance in the source file of the application that uses the Instance.

Allocate control and configuration structures

The e^2 studio ISDE provides a graphical user interface for setting the parameters of the Interface and Instance configuration structures. The ISDE also automatically includes those structures, once they are configured in the GUI, in application-specific header files that you can include into your application code.

To see how the ISDE handles the configuration, see Configuring a Project in the ISDE User's Guide: e^2 studio ISDE User Guide.

The configuration and control structure types follow standard names of <interface>_ctrl_t* and *<interface>_cfg_t* respectively. The ISDE allocates storage for both structures in the application specific header files, which the ISDE creates. Use the ISDE Properties view to set the values for the members of the configuration structure as needed. Many members will be typed enumerations in which case the enumeration can be referenced for available options.

If the Interface has a callback function option then you first need to declare and define the function in their source code. The return value is always of type *void* and the parameter to the function is a typed structure of name *<interface>_callback_args_t*. Once the function has been defined, assign its name to the *p_callback* member of the configuration structure. If any context information is required in the callback then the user can provide a pointer to the *p_context* member. You can assign callback function names through the ISDE Properties window for the selected Module.

Refer to the Instance documentation to see if an Interface extension is provided. If so, then it will be found in the Instance's header file and named *<interface>_on_<instance>_cfg_t*. It may have several members just like the Interface's configuration structure. When you select a driver with a specific Instance, you can select any parameter in the configuration structure of the instance in the ISDE property.

Interact using Interface's Instance Structure

Once the instance structure has been defined, you can interact with the Instance as needed. Below is code that builds up an instance structure for the UART Interface as implemented on SCI. Please note that when using e^2 studio for Synergy, the following code is automatically generated for the user.

```
/* Include the header file of the Instance. */

\#include "r_sci_uart.h" //This will in turn include the r_uart_api.h Interface

/* Allocate control structure. */

uart_ctrl_t my_uart_ctrl;

/* Setup extended UART configuration on SCI. */

uart_on_sci_cfg_t my_uart_extended_cfg =

{

    /* Set extended configuration members... */

};

/* Configure standard UART Interface. */
```

```
uart_cfg_t my_uart_cfg =

{

    .data_bits = UART_DATA_BITS_8,

    /* Continue configuring other members... */

    .p_extend = &my_uart_extended_cfg

};

/* Setup instance structure */

uart_instance_t my_uart = {

    .p_ctrl = &my_uart_ctrl,

    .p_cfg = &my_uart_cfg, //Extended configuration is brought through in p_exte
nd

    .p_api = &g_uart_on_sci //Defined in r_sci_uart.h

};
```

Now that the instance structure is ready, you can interact with the UART Interface. In e^2 studio, the name of the instance structure is the Name* that you provide when configuring the Module Instance in the ISDE Properties window.

```
ssp_err_t err;

/* Initialize UART */

err = my_uart.p_api->open(my_uart.p_ctrl, my_uart.p_cfg);

/* Check return for errors. */

if (SSP_SUCCESS != err)

{

/* Handle error. */

}

/* Use other Interface functions. */

err = my_uart.p_api->write(my_uart.p_ctrl, ...);
```

```
err = my_uart.p_api->read(my_uart.p_ctrl, ...);
```

2.2 BSP Architecture

2.2.1 BSP Architecture

This section describes the BSP or Board Support Package. For the API Reference see Board Support Package. The BSP is board specific and as a result also MCU specific.

2.2.1.1 BSP Related Terminology

Term	Meaning
system_xxxx.c or startup_xxxx.c	The 'xxxx' refers to the MCU type. For example, system_S7G2.c when referencing the S7G2 MCU.
BSP	Short for Board Support Package. BSP's usually have source files related to a specific board.
Callback Function	This term refers to a function that is called when an event occurs. For example, the NMI interrupt handler is implemented in the BSP. The user will likely want to know when an NMI system exception occurs. To alert the user, a callback function can be configured for the group interrupts (a group of exceptions all of which are tied to the NMI). When an NMI occurs the BSP will jump to the provided callback function and the user can handle the error. Interrupt callback functions should be kept short and be handled carefully because when they are called the MCU will still be inside of an interrupt and therefore will be delaying any pending interrupts.

2.2.1.2 What Does the BSP Do?

The BSP is responsible for getting the MCU from reset to the user's application (i.e. the main() function). Before reaching the user's application the BSP sets up the stacks, heap, clocks, interrupts, and C runtime environment. The BSP also configures and sets up the port I/O pins and performs any board specific initializations.

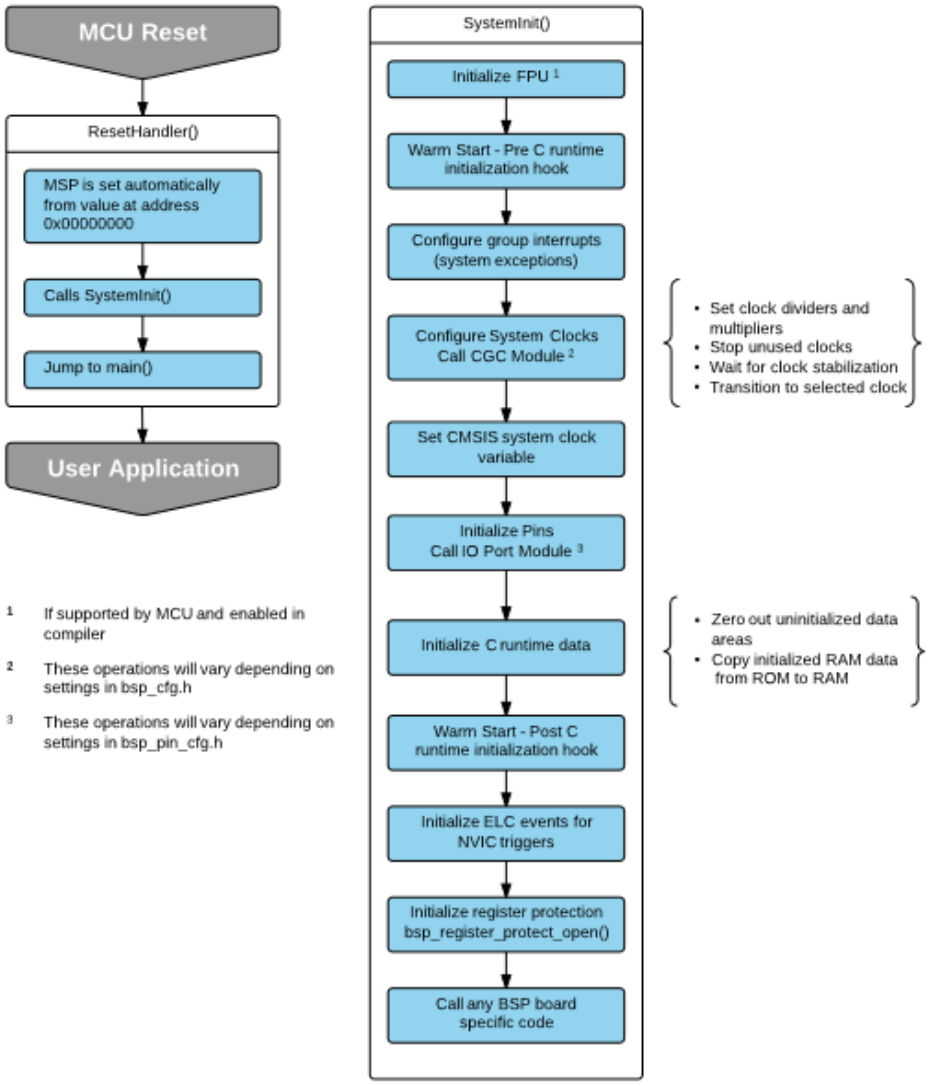

Figure 12: BSP flow

2.2.1.3 BSP Prerequisites

Supported Devices and Boards

The BSP has been tested on all Synergy microcontroller families. It currently supports the following boards:

- PE-HMI1
- DK-S124
- DK-S7G2

- SK-S7G2
- DK-S3A7
- PK-S5D9
- DK-S128
- TB-S3A6
- TB-S5D5
- TB-S3A3
- TB-S3A1
- TB-S1JA

2.2.1.4 BSP Directory Structure

The BSP is organized into folders containing MCU, board specific and CMSIS information.

Synergy is CMSIS-compliant and based on the CMSIS-Core. This requires that we follow CMSIS requirements and naming standards.

- Standardized definitions for processor peripherals
  - NVIC (Nested Vector Interrupt Controller)
  - Systick (System Tick Timer)
  - MPU (Memory Protection Unit)
- Standardized access functions to access processor features
  - NVIC_SetPriority()
  - NVIC_EnableIRQ
- Standardized function names for system exception handlers
  - Reset_Handler()
  - SysTick_Handler()
- Standardized functions for system initialization.
  - SystemInit() – defined in system_S7G2.c for S7G2 MCU's
- Standardized software variables for clock speed information
  - SystemCoreClock

The BSP directory structure is shown below:

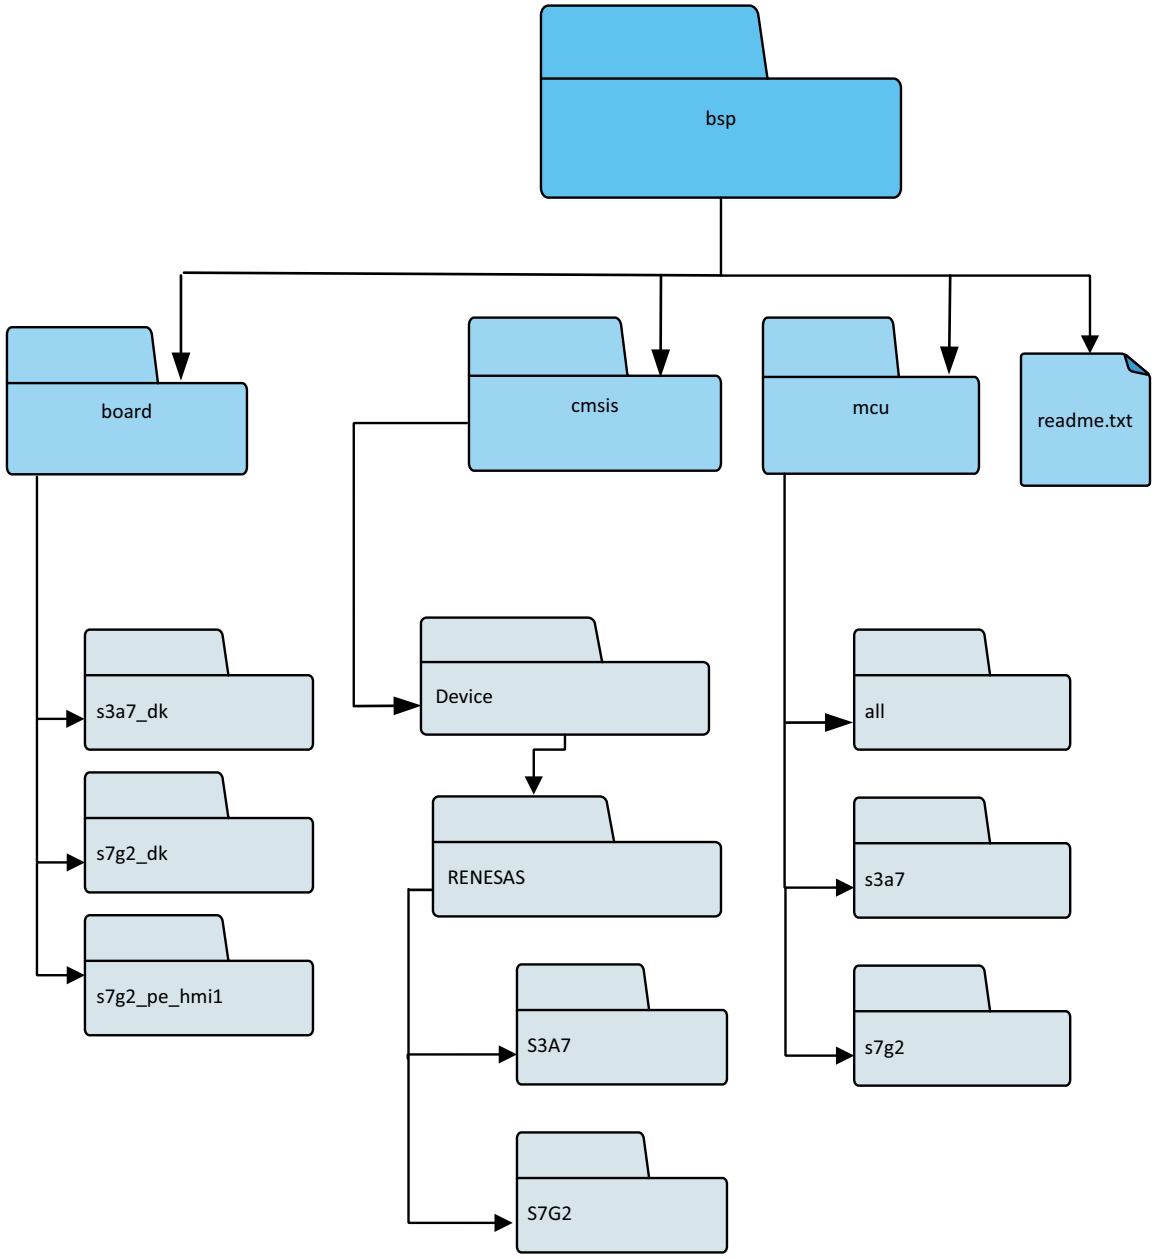

Figure 13: BSP directory structure

2.2.1.5 Configuring the BSP

The BSP is heavily data driven with most features and functionality being configured based on the content from configuration files. Configuration files represent the settings specified by the user and are generated by the ISDE when the Generate Project Content button is clicked.

2.2.1.6 BSP Configuration Settings

The table below describes each of the configurable BSP settings. Many of these settings are MCU specific and there are differences between the settings available for each of the supported MCU's.

Table: BSP Configuration options

BSP Property	Description
Part package	MCU package type and size
Part memory size (ROM/RAM/Data Flash)	Available memory configurations
Core and Frequency	ARM core type and max system frequency
Part series	MCU part series
Main stack size (bytes)	Size of the Main Stack. Must be > 0.
Process stack size (bytes)	Size of the Process Stack. Use of this stack is optional. If 0, then PSP use is disabled
Heap size (bytes)	Size of the heap in bytes. If 0, the heap is disabled.
OFS0 register settings: IWDT Start Mode, IWDT Timeout Period, IWDT Dedicated Clock Frequency Divisor, IWDT Window End Position, IWDT Window Start Position, IWDT Reset Interrupt Request Select, IWDT Stop Control, WDT Start Mode Select, WDT Timeout Period, WDT Clock Frequency Division Ratio, WDT Window End Position, WDT Window Start Position, WDT Reset Interrupt Request, WDT Stop Control	The option-setting memory determines the state of the MCU after a reset. It is allocated to the configuration setting area and the program flash area of the flash memory. See the MCU user manual for details.
OFS1 register settings: Voltage Detection 0 Circuit Start, Voltage Detection 0 Level, HOCO Oscillation Enable. S3 MPU has MPU configuration settings.	See the MCU user manual for details.
MPU - Enable or disable PC Region 0	Start block address for access window protection
MPU - PC0 Start, MPU - PC0 End, MPU - Enable or disable PC Region 1, MPU - PC1 Start, MPU - PC1 End, MPU - Enable or disable Memory Region 0, MPU - Memory Region 0 Start, MPU - Memory Region 0 End, MPU - Enable or disable Memory Region 1, MPU - Memory Region 1 Start, MPU - Memory Region 1 End, MPU - Enable or disable Memory Region 2, MPU - Memory Region 2 Start, MPU - Memory Region 2 End, MPU - Enable or disable Memory Region 3, MPU - Memory Region 3 Start, MPU - Memory Region 3 End	Secure MPU ROM register settings. See user manual for details.

BSP Property	Description
ID code 1, ID code 2, ID code 3, ID code 4	Sets the ID Code for boot mode and debugger access protection.
MCU Vcc (mV)	Some Modules (e.g. LVD) need to know the voltage supplied to the MCU. This information is obtained from here.
Parameter checking	Defines whether the global setting for parameter checking is enabled or disabled. Local modules will take this value by default but can be locally overridden.
RTOS being used	Defines whether or not an RTOS is being used with this BSP.
Assert Failures	Defines what happens when an assertion failure occurs.
Error Log	Defines whether or not errors are logged to ssp_error_log.

2.2.1.7 BSP Configuration Files

Configuration files are used by the BSP to set up ROM registers, clocks, interrupts, ELC events and initial pin configurations. These configuration files can be found in ssp_cfg\bsp.

Bsp_cfg.h

This configuration file represents the values for BSP system settings. These are the settings that can be modified from the ISDE BSP properties tab. They include ROM register settings, stack size, parameter checking and control of error logging.

The BSP tab and the Properties window are shown below.

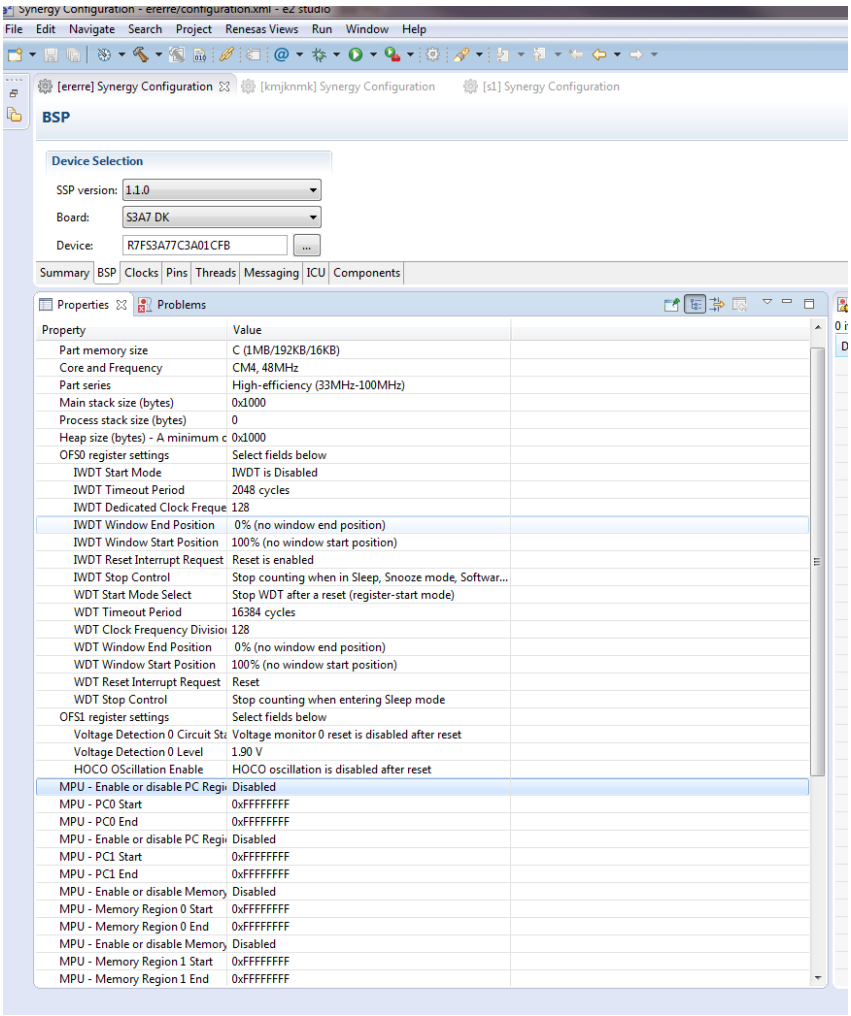

Figure 14: BSP Properties window

Some registers are located in ROM and therefore must be set at compile-time. These include some option-setting memory (OFS) registers as well as certain memory protection registers.

Option-setting memory determines the state of the MCU after a reset. For example, the IWDT can be configured and enabled, voltage detection can be enabled, and HOCO oscillation can be enabled. When these registers are set the operations are completed before the MCU's reset vector is fetched and execution begins.

Some Synergy MCUs include a Memory Protection Unit (MPU). The MPU is a programmable device that can be used to define memory access permissions (i.e. privileged access only or full access) and memory attributes (i.e. bufferable, cacheable) for different memory regions. The MPU can support up to eight programmable memory regions, each with their own programmable starting addresses, sizes and settings.

The ISDE configures these memory areas by setting values for the provided MPU settings. You must be careful when setting these registers. Incorrect settings can prevent access to required memory areas or prevent access to the MCU entirely.

Synergy MCUs have two mechanisms for protecting MCU memory from being read after production:

1) The use of ID codes. The ID code is 16 byte value that can be used to protect the MCU from being connected to a debugger or from connecting in Serial Boot Mode. There are different settings that can be set for the ID code; please refer to the hardware manual for your device for available options.
2) The use of a 4 byte value called ROM Code Protection. This value determines what read and write access parallel programmers have to the MCU.

2.2.1.8 BSP Pin Configuration

You can configure the pins used in your application through the ISDE pin configurator. See Configuring Pins.

Bsp_pin_cfg.h

This configuration file contains an array of pin configurations. During start-up, and before main() is executed, the BSP iterates over this array and initializes the MCU's port pins based on the settings in the array. Initially, before any pin configuration by the user, the ISDE **Pins** tab displays the initial reference configuration defined for the selected board type (see Configuring Pins). Once the user modifies the pin configuration and clicks **Generate Project**, a new bsp_pin_cfg.h file is generated containing the new pin configuration. The BSP always uses the bsp_pin_cfg.h file from ssp_cfg\bsp as the source for its pin configuration information, but the pin information generated by clicking **Generate Project** is written to a bsp_pin_cfg.h file in the hidden folder ssp\cfg\bsp\ .out.

In this way, the user can manually edit the bsp_pin_cfg.h in ssp\bsp without the fear of the file being overwritten by the project generation, while the Pin Configuration information generated by the ISDE also remains available for view or merging with the user's config file.

2.2.1.9 BSP Clock Configuration

All system clocks are set up during BSP initialization based on the settings in bsp_clock_cfg.h. These settings are derived from clock configuration information provided from the ISDE **Clocks** tab setting.

- Clock configuration is performed prior to initializing the C runtime environment to speed up the startup process, as it is possible to start up on a relatively slow (i.e. 32 kHz) clock.
- The BSP implements the required delays to allow the selected clock to stabilize.

Bsp_clock_cfg.h

This configuration file represents the values for system clock settings. These are the settings that can be modified from the ISDE **Clocks** tab. See: Configuring Clocks

2.2.1.10 System Interrupts

As Synergy MCUs are based on the Cortex-M ARM architecture, the NVIC Nested Vectored Interrupt Controller (NVIC) handles exceptions and interrupt configuration, prioritization and interrupt masking. In the ARM architecture, the NVIC handles exceptions. Some exceptions are known as System Exceptions. System exceptions are statically located at the "top" of the vector table and occupy vector numbers 1 to 15. Vector zero is reserved for the MSP Main Stack Pointer (MSP). The remaining 15 system exceptions are shown below:

- Reset
- NMI
- Cortex-M4 Hard Fault Handler

- Cortex-M4 MPU Fault Handler
- Cortex-M4 Bus Fault Handler
- Cortex-M4 Usage Fault Handler
- Reserved
- Reserved
- Reserved
- Reserved
- Cortex-M4 SVCall Handler
- Cortex-M4 Debug Monitor Handler
- Reserved
- Cortex-M4 PendSV Handler
- Cortex-M4 SysTick Handler

NMI and Hard Fault exceptions are enabled out of reset and have fixed priorities. Other exceptions have configurable priorities and some can be disabled.

2.2.1.11 Group Interrupts

Group interrupt is the term used to describe the 12 sources that can trigger the Non-Maskable Interrupt (NMI). When an NMI occurs the NMI Handler examines the NMISR (status register) to determine the source of the interrupt. NMI interrupts take precedence over all interrupts, are usable only as CPU interrupts, and cannot activate the Synergy peripherals Data Transfer Controller (DTC) or Direct Memory Access Controller (DMAC).

Possible group interrupt sources include:

- IWDT Underflow/Refresh Error
- WDT Underflow/Refresh Error
- Voltage-Monitoring 1 Interrupt
- Voltage-Monitoring 2 Interrupt
- VBATT monitor Interrupt
- Oscillation Stop is detected
- NMI pin
- RAM Parity Error
- RAM ECC Error
- MPU Bus Slave Error
- MPU Bus Master Error
- MPU Stack Error

A user may enable notification for one or more group interrupts by registering a callback using the BSP API function R_BSP_GroupIrqWrite. When an NMI interrupt occurs, the NMI handler checks to see if there is a callback registered for the cause of the interrupt and if so calls the registered callback function.

As mentioned earlier, the first 16 slots in the vector table are already accounted for by the system exceptions. Beginning with slot 16 are user configurable interrupts. These may be external, or peripheral generated interrupts.

The size of the NVIC interrupt table varies across Synergy MCU types (shown below).

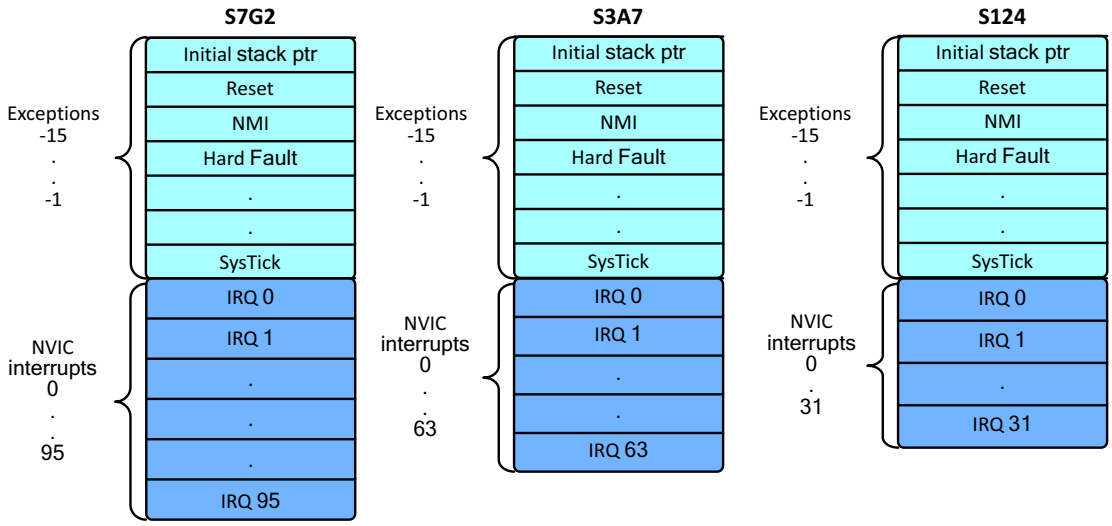

Figure 15: NVIC Interrupt vector table

Although the number of available slots for the NVIC interrupt vector table may seem small, the BSP defines up to 512 events that are capable of generating an interrupt. By using Event Mapping, the BSP maps user enabled events to NVIC interrupts. For an S7G2 MCU, only 96 of these events may be active at any one time, but the user has flexibility by choosing which events generate the active event.

The diagram below shows the interrupt vector table for the S7G2:

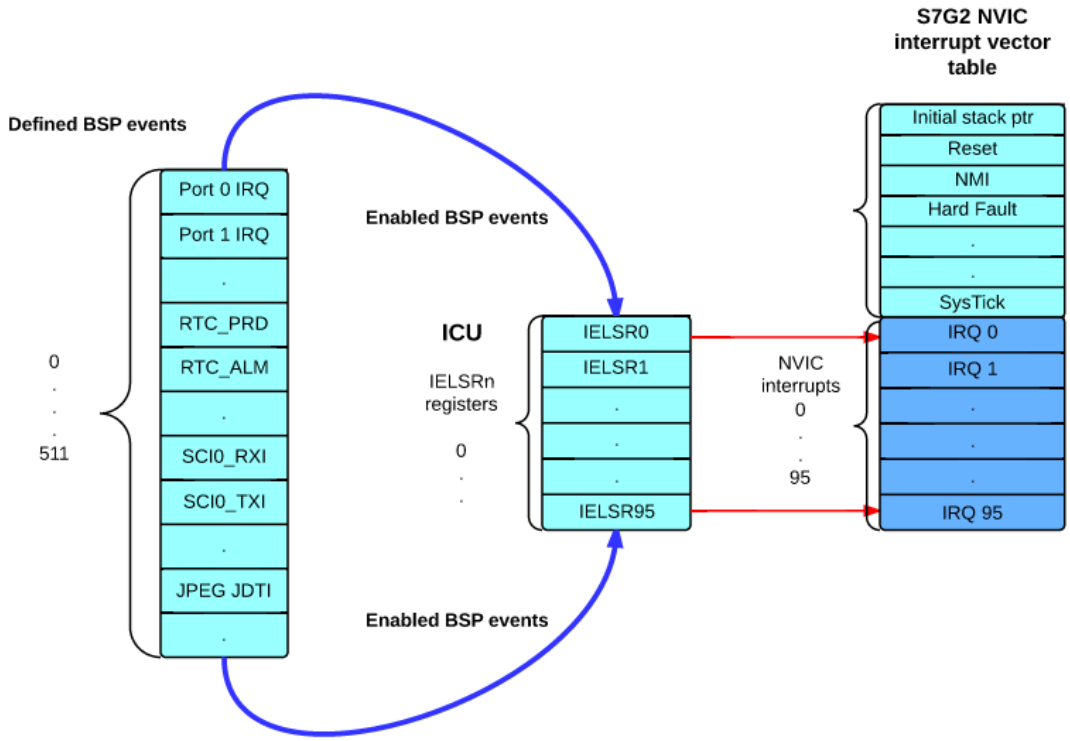

Figure 16: NVIC Interrupt vector table

By allowing the user to select only the events they are interested in as interrupt sources, we are able to provide an interrupt service routine that is fast and event specific.

For example, on other microcontrollers a standard NVIC interrupt vector table might contain a single vector entry for the SCI0 (Serial Communications Interface) peripheral. The interrupt service routine for this would have to check a status register for the 'real' source of the interrupt. In the Synergy implementation there is a vector entry for each of the SCI0 events that we are interested in. The difference between a standard NVIC table and the Synergy S7G2 NVIC table is shown below:

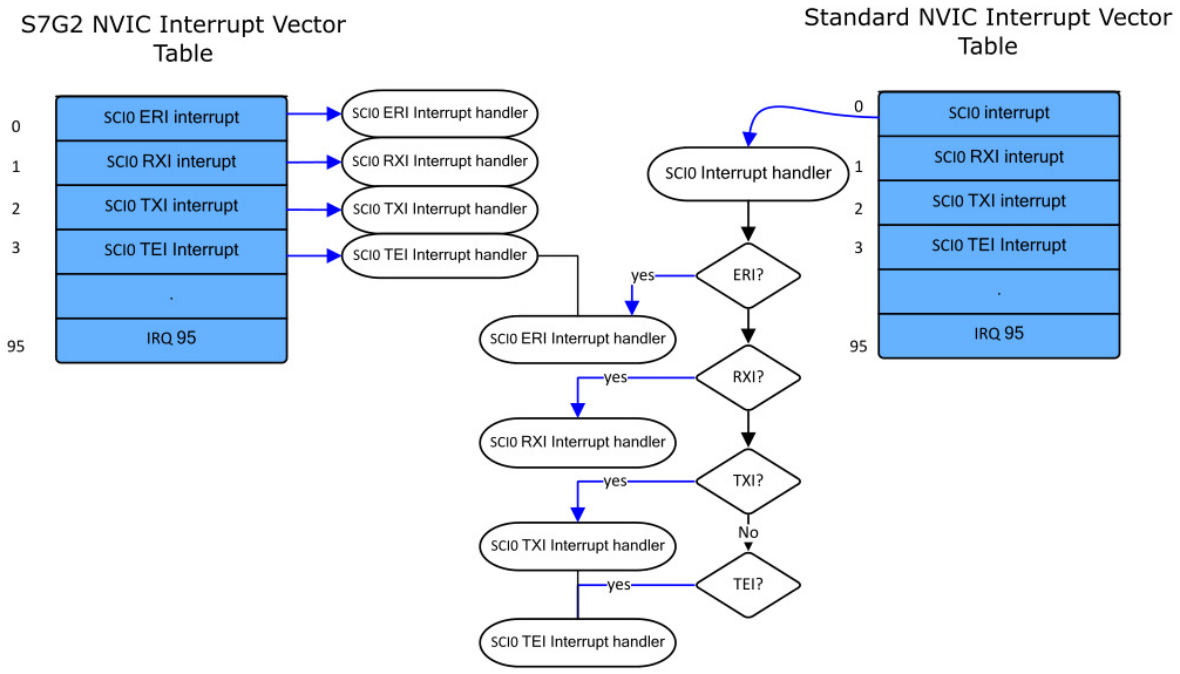

Figure 17: NVIC Interrupt vector table example

Configuration of interrupts is done through the bsp_irq_cfg.h file. For every event given a 'non disabled' priority in the ISDE ICU tab, the BSP generates a corresponding NVIC vector table entry. The BSP iterates over the entire list of possible events, and NVIC slots are assigned in that order with the corresponding event select register updated likewise.

When an interrupt occurs one of the very first operations must be to call R_BSP_IrqStatusClear with the interrupt number corresponding to the NVIC interrupt slot that was assigned by the BSP. The interrupt number is created by the BSP at build time based on the interrupt events that have been enabled in bsp_irq_cfg.h.

R_BSP_IrqStatusClear clears the interrupt status flag (IR) for the given interrupt. When an interrupt is triggered the IR bit is set. If it is not cleared in the ISR then the interrupt will trigger again immediately.

Entries that have been assigned a priority (ie. BSP_IRQ_CFG_ICU_IRQ0) in our example, have their corresponding 'weak handler' address placed in the next available vector slot. All of the possible interrupt sources are iterated over in this manner. Defined interrupts are entered into the vector table.

Bsp_irq_cfg.h

This configuration file contains an entry for every peripheral event that is capable of generating an interrupt. When a peripheral event is given a value other than 'BSP_IRQ_DISABLED' by modifying an peripheral event defined on the ISDE ICU tab, the corresponding entry is updated in bsp_irg_cfg.h. The BSP then iterates through these entries, and peripheral events that have a priority defined (a value other than 'BSP_IRQ_DISABLED') have interrupt service routine entries added to the NVIC Vector table. In addition, the BSP then updates the respective IELSRn register for that NVIC vector number such that it corresponds to the respective peripheral event.

BSP Weak symbols

You might wonder how the BSP is able to place ISR addresses in the NVIC table without the user having explicitly defined one. All that is required by the BSP is that the interrupt event be given a priority.

This is accomplished through the use of the 'weak' attribute. The weak attribute causes the declaration to be emitted as a weak symbol rather than a global. The BSP actually defines an ISR for each of the 512 possible interrupt events in the CMSIS startup_xxxx.c file. A weak symbol is one that can be overridden by an accompanying strong reference with the same name. When the BSP declares a function as weak, user code can define the same function and it will be used in place of the BSP function. By defining all possible interrupt sources as weak, the vector table can be built at compile time and any user declarations (strong references) will be used at runtime.

Weak symbols are supported for ELF targets and also for a.out targets when using the GNU assembler and linker.

Note that in CMSIS system_xxxx.c, there is also a weak definition (and a function body) for the Warm Start callback function R_BSP_WarmStart(). Because this function is defined in the same file as the weak declaration, it will be called as the 'default' implementation. The function may be overridden by the user by copying the body into their user application and modifying it as necessary. The linker identifies this as the 'strong' reference and uses it.

Warm start callbacks

As the BSP is in the process of bringing up the board out of reset, there are two points where the user can request a callback. These are defined as the 'Pre C' and 'Post C' warm start callbacks.

As described above, this function is already weakly defined as R_BSP_WarmStart(), so it is a simple matter of redefining the function or copying the existing body from CMSIS system_xxxx.c into the application code to get a callback. R_BSP_Warmstart() takes an event parameter which describes the type of warm start callback being made.

```
/** Different warm start entry locations in the BSP. */

typedef enum e_bsp_warm_start_event

{

    BSP_WARM_START_PRE_C = 0, // Called almost immediately after reset.

    /* No C runtime environment, clocks, or IRQs. */

    BSP_WARM_START_POST_C // Called after clocks and C runtime environment have
been set up.

} bsp_warm_start_event_t;
```

This function is not enabled/disabled and is always called for both events as part of the BSP startup. Therefore it needs a function body, which will not be called if the user is overriding it. The function body is located in system_xxxx. To use this function just copy this function into your own code and modify it to meet your needs.

Pre C Warm start callback

This callback occurs almost immediately after reset and at this point no C runtime environment, clocks, or IRQs have been setup.

Why would you be interested in a 'Pre C' warm start callback?

Below are a few examples.

- Execution of safety code (ie. destructive memory tests) as part of the startup process.
- Examination of global memory as part of a crash dump investigation.
- Preventing re-initialization of an already running RTC.

Post C Warm start callback

This callback occurs after clocks and the C runtime environment have been setup.

Why would you be interested in a 'Post C' warm start callback?

Below are a few examples.

- Run tests that require that clocks have been setup.
- ADC diagnostics.
- ROM/External memory system checks.

2.2.1.12 Additional BSP Board support

The following Synergy boards are supported:

- DK-S7G2
- PE-HMI1
- DK-S3A7
- DK-S124
- SK-S7G2

2.2.1.13 Custom BSP Board support

What if you're developing your own board based on one of the Synergy MCU's?

There is an external command line utility, the Custom BSP creator tool which can be used to generate a custom BSP that can be used from within e^2 studio. The application note R01AN3044EU0101 describes this process in detail.

2.2.1.14 BSP API functions

The BSP provides public functions, available to any project using the BSP, that allow access to functionality that is common across BSP supported MCU's and boards.

- R_BSP_SoftwareLockInit: The BSP provides API functions to implement atomic locking. These locks can be used to protect critical areas of code as an RTOS semaphore or mutex normally would. This function simply initializes a defined lock structure to BSP_LOCK_UNLOCKED.
- R_BSP_SoftwareLock: Attempt to acquire the lock that has been sent in. The Load-Exclusive and Store-Exclusive instructions are being used to perform an exclusive read-modify-write on the input lock. This process is:
  - Use a load-exclusive (LDREXB) to read the value of the lock.
  - If the lock is available, then modify the lock value so it is reserved. If not available, then issue CLREX.
  - Use a store-exclusive to attempt to write the new value back to memory
  - Test the returned status bit to see if the write was performed or not.
- R_BSP_SoftwareUnlock: Release hold on an existing software lock.
- R_BSP_HardwareLock: Hardware locks are similar to Software locks. In fact the BSP Software lock functions are called by the Hardware lock functions. Hardware locks are specific to a particular peripheral, the list of available

hardware locks being defined in bsp_hw_locks.h. Hardware locks can be used to prevent multiple threads from trying to use a peripheral that is already in use by a process or thread. For example when the Flash API open() function is called it takes the Flash Hardware lock and keeps it until the Flash API close is called.

- R_BSP_HardwareUnlock: Release the hold on an existing hardware lock. In the Flash example above the Flash API close function would call this function.
- R_BSP_GroupIrqWrite: Registers a callback function for one of supported group interrupts. As described earlier, there are 12 of these and they are all mapped to the NMI exception. When an NMI occurs, the NMI_Handler looks at the NMISR (status register) to determine the source of the interrupt. If a callback function has been registered for this group interrupt it will be called. If NULL is passed for the callback argument then any previously registered callbacks are unregistered.
- R_BSP_IrqStatusClear: Clears the interrupt status flag (IR) for a given interrupt. When an interrupt is triggered the IR bit is set. If it is not cleared in the ISR then the interrupt will trigger again immediately.
- R_BSP_SoftwareDelay: Implements a blocking software delay. A delay can be specified in microseconds, milliseconds or seconds. The delay is implemented based on the system clock rate.
- R_BSP_VersionGet: Returns the version of the BSP.
- R_BSP_RegisterProtectEnable: Enables register protection. Registers that are protected cannot be written to. Register protection is enabled by using the Protect Register (PRCR) and the MPC's Write-Protect Register (PWPR). The registers that may be protected are grouped together into one of three groups.
  - BSP_REG_PROTECT_CGC - registers related to the clock generation circuit.
  - BSP_REG_PROTECT_OM_LPC_BATT - registers related to operating modes, low power consumption, and battery backup function.
  - BSP_REG_PROTECT_LVD – registers related to LVD (Low Voltage Detection)

The BSP register protection functions utilize reference counters to ensure that an application which has specified a certain register and subsequently calls another function doesn't have its register protection settings inadvertently modified.

Each time RegisterProtectDisable() is called, the respective reference counter is incremented.

Each time RegisterProtectEnable() is called, the respective reference counter is decremented.

Both functions will only modify the protection state if their reference counter is zero.

As the example below shows, without reference counters MODULE2 would re-protect the registers that MODULE 1 had un-protected, preventing MODULE1 from writing them.

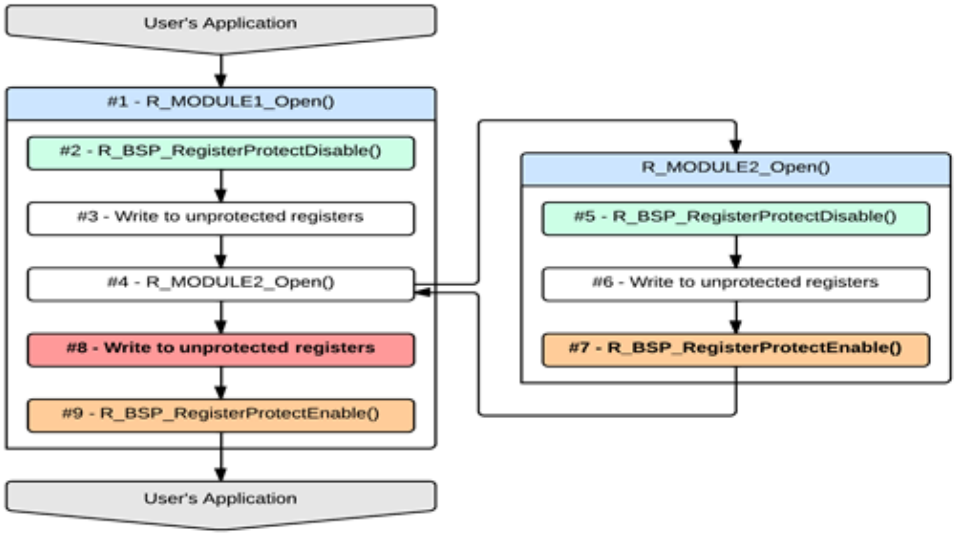

Figure 18: Register protection

- R_BSP_RegisterProtectDisable: Disables register protection. Registers that are not protected can be written to. Register protection is disabled by using the Protect Register (PRCR) and the MPC's Write-Protect Register (PWPR). The register groupings described above still apply.

Chapter 3 Starting Development

To start development with the Renesas Synergy Software Package (SSP), download and install e2 studio, obtain a target Synergy development or evaluation board, and run through the tutorials in this chapter. The e2 studio ISDE user guide and the tutorials include step-by-step instructions for getting started with a simple application. To get started with the SSP, refer to these pages:

- e2 studio ISDE User Guide
- Tutorial: Your First Synergy Project - Blinky
- Tutorial: Using HAL Drivers - Programming the WDT
- IAR Embedded Workbench for Renesas
- What is Synergy Standalone Configurator (SSC)?

3.1 e2 studio ISDE User Guide

This section describes how to use the Renesas e2 studio Integrated Solutions Development Environment (ISDE) to develop applications with the Renesas Synergy Software Package (SSP). The architecture of the SSP directly determines how you use the e2 studio ISDE to develop a Synergy application. See the following documents for details on the SSP architecture included in this manual:

- SSP Architecture
- BSP Architecture

For simple example projects generated and built with e2 studio, see:

- Tutorial: Using HAL Drivers - Programming the WDT
- Tutorial: Your First Synergy Project - Blinky

All User Guides in this manual show how to configure a driver and develop an application using the e2 studio ISDE. See:

- HAL Layer for HAL layer user guides
- Framework Layer for Framework layer user guides

3.1.1 What is the e2 studio ISDE?

The Renesas e2 studio ISDE, or Integrated Solution Development Environment, is a development tool encompassing code development, build, and debug. The ISDE is based on the open-source Eclipse IDE and the associated C/C++ Development Tooling (CDT). Specifically for Synergy MCUs, the ISDE provides a Graphical User Interface (GUI) with numerous wizards for configuring and auto-generating code using the Synergy Software Package (SSP). The ISDE also incorporates a smart manual so that driver and device documentation is available in the form of tooltips right in the code.

Figure 19: e² studio Splash Screen

The e² studio ISDE and the Synergy Project Configurator have been developed to make it as easy as possible to quickly select the SSP modules required for a particular application, include them in a project, and configure them. The ISDE provides a graphical user interface to configure all elements of the SSP for the Synergy MCU applications. In addition to HAL and Framework modules, the ISDE can add and configure RTOS threads, semaphores, mutexes, event flags, and queues. This makes adding RTOS support to an application very straightforward. Once a project has been generated, you can go back and reconfigure any of the modules and settings if required. The ISDE generates the complete and correct configuration code from the selections in the configuration views, so you can focus on writing the application code.

The elements of the SSP are shown in the **Project Explorer** view of the e² studio ISDE. All SSP configuration structures and parameters are mapped to XML files. The XML files enable the ISDE to present a visual list of configurable options that you can select from. In addition to generating code to configure the modules, the XML also provides dependency information for modules.

When you add an SSP module to your project, the e² studio ISDE checks the dependencies of this module and adds all necessary drivers and framework modules to create the appropriate stack. If there is a dependency that requires you to make a choice, this module is highlighted in the Stack window and the ISDE guides your selection by showing the available options.

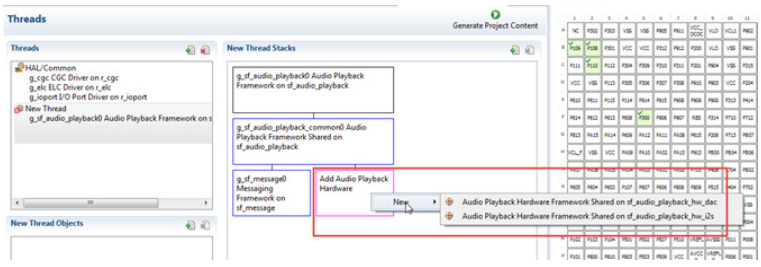

Figure 20: ISDE dependency checking

Errors are flagged next to the Driver name in the HAL/Common Modules or New Thread Modules pane. You can also review errors in the Problems window.

3.1.2 e2 studio ISDE Prerequisites

3.1.2.1 Obtaining a Synergy Kit

To develop applications with the SSP, start with one of the Renesas Synergy Kits. The Renesas Synergy Kits are designed to seamlessly integrate with the e2 studio ISDE. Several types of kits are available:

- Development Kit (DK)
- Starter Kit (SK)
- Product Example (PE)

Ordering information, Quick Start Guides, User Manuals, and other related documents for all Synergy Kits are available at http://renesassynergy.com.

3.1.2.2 PC Requirements

To use the e2 studio ISDE, ensure that your PC meets the following minimum requirements:

- Windows 7 with Intel i5 or i7, or AMD A10-7850K or FX
- Memory: 8 GB DDR3 or DDR4 DRAM (16 GB DDR4/2400 MHz RAM is preferred)
- Minimum 250 GB hard disk

3.1.2.3 Installing e2 studio and the SSP

Detailed installation instructions and installers for the e2 studio ISDE and the SSP are available on the Renesas Synergy Gallery website https://synergygallery.renesas.com. Review the release notes for e2 studio to ensure that the e2 studio version supports the selected SSP version.

See also: Handling SSP Releases

3.1.2.4 Choosing a Toolchain

The e2 studio ISDE can work with several toolchains and toolchain versions such as the GNU ARM compiler and the IAR toolchain. A version of the GNU ARM compiler is included in the e2 studio installer and has been verified to run with the SSP version.

To use the IAR toolchain for ARM, install IAR Embedded Workbench for Renesas Synergy (EWSYN) v7.40.5 (a license from IAR is required). Before starting a Synergy project with IAR, also install the IAR Embedded Workbench for ARM Eclipse plugin (using the IAR Embedded Workbench plugin manager in the 'Help' menu).

3.1.2.5 Licensing

By default, the SSP download includes an evaluation license for the SSP. When prompted for the license file during the Synergy project configuration, refer to the installation instructions for details on licensing. The evaluation license file is located in the following directory: < e2_studio_base_dir >/internal/projectgen/arm/Licenses/.

The evaluation license allows the use of a fully functional version of the SSP. This means that all modules of the SSP can be compiled and linked into your application. However, the source code for modules in the Framework Layer (including Express Logic X-Ware components) is encrypted and cannot be altered. The source code of selected modules is still viewable. This type of encrypted code is called protected code. For details, refer to the license file.

Source code for modules in the HAL Layer is not protected and can be viewed in the e2 studio ISDE by clicking on the respective synergy/ssp/src/< module >/< module>.c file.

Other license types are available which allow you to view protected code in the ISDE during the debug phase with the Secure Debug View or to have full read and write access to selected sources.

The table below shows the available licenses and the functionality they provide.

License Type	Allowed	Not Allowed
Evaluation License	Compiling/Linking	Saving/Editing of protected sources. Not all modules are viewable. For details see the license file.
Development/Production License	Compiling/Linking and viewing of protected sources with the Secure Viewer	Saving/Editing of protected sources
Source License	Compiling/Linking and viewing of protected sources with the Secure Viewer. Selected sources (depending on the source license) can be edited and saved as clear text files.	Saving/editing of protected source files that are not included in the Source License

3.1.2.6 Adding the IAR Embedded Workbench for Renesas Synergy Compiler into e2 studio

The IAR Embedded Workbench for Renesas Synergy compiler (IAR compiler) can now be used from within 2 studio. This allows the developer to have the advantages provided by the IAR compiler without the need to also use the IAR EW for Renesas Synergy ISDE. The installation process involves installing IAR EW for Renesas Synergy, installing e2 studio, and installing the associated IAR plugins for e2 studio. The process is described in the application note found with this search: https://www.renesas.com/en-us/search/keyword-search.html#q=R11AN0272

The application note also includes a description of how to migrate a project that originally used e2 studio and GCC. It also includes a description of how to migrate a project from IAR 7.x to IAR 8.x so it will be successfully opened when using e2 studio 6.2.0.

3.1.3 What is a Project?

In e2 studio, all SSP applications are organized in Synergy projects. Setting up a Synergy project involves:

1) Creating the project
2) Configuring the project

The e2 studio ISDE has many project wizards and configuration windows specifically for Synergy projects. You can create a new Synergy Project with the **Synergy Project Generator** or edit the configuration of an existing project in the **Synergy Project Editor**.

When you launch e2 studio and select a workspace, all projects previously saved in the selected workspace are loaded and displayed in the **Project Explorer** view. Each project has an associated configuration file named configuration.xml which is located in the project's root directory.

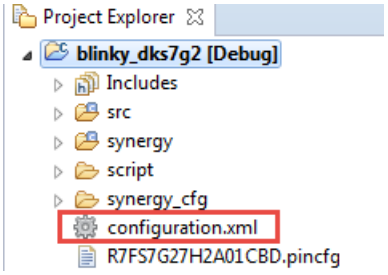

Figure 21: e2 studio Project Configuration file

Double-click on the configuration.xml file to open the Synergy Project Editor and view or modify all configuration settings associated with this project. To edit the project configuration, make sure that the **Synergy Configuration** perspective is selected in the upper right hand corner of the e2 studio window.

Figure 22: e2 studio Synergy Configuration Perspective

The Synergy Project Editor has a number of tabs. The configuration steps and options for individual tabs are discussed in the following sections.

NOTE: Which tabs are available with the Synergy Project Editor depends on the e2 studio version. Version 5.0 of e2 studio supports an additional tab for the Messaging Configurator.

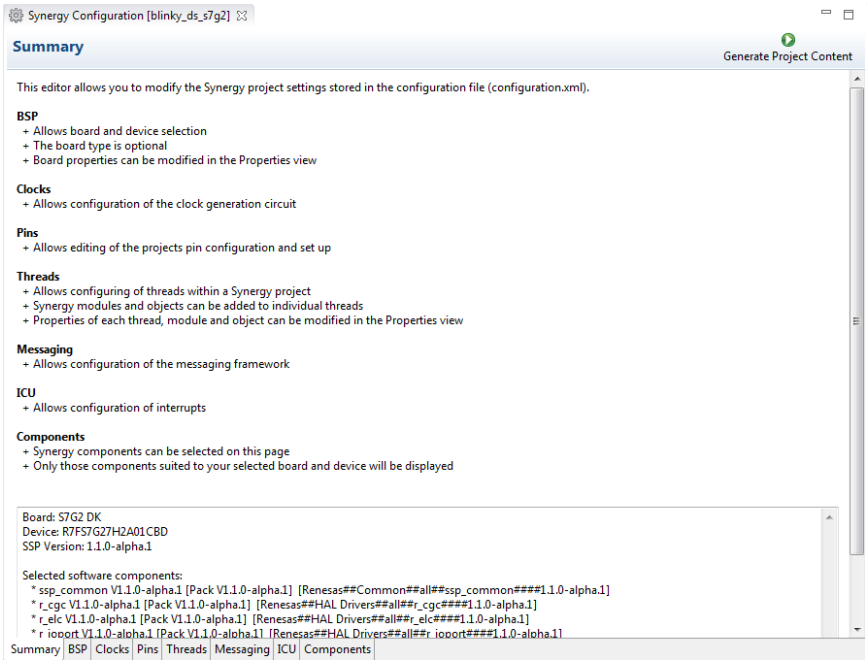

Figure 23: e² studio Project Editor

3.1.4 Creating a Project

This section includes step-by-step instructions for creating a Synergy Project. Once you have created the project, you can easily configure the hardware (clocks, pins, interrupts) and the parameters of all modules that are part of your application.

To create a new Synergy Project with the Synergy Project Generator, select the project name, select the hardware for your application, review or add the license, select the toolchain and choose from preconfigured clock, pin, and MCU related settings by selecting a project template.

3.1.4.1 Creating a New Project

For Synergy applications, always generate a new project as a Synergy Project in the following way:

1) Click on **File > New > Synergy Project**

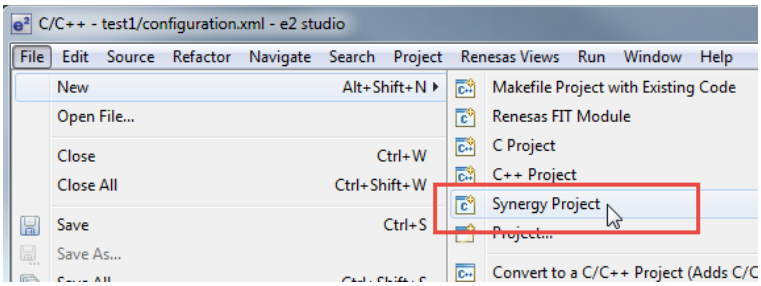

Figure 24: New Synergy Project

2) Select a project name and location.

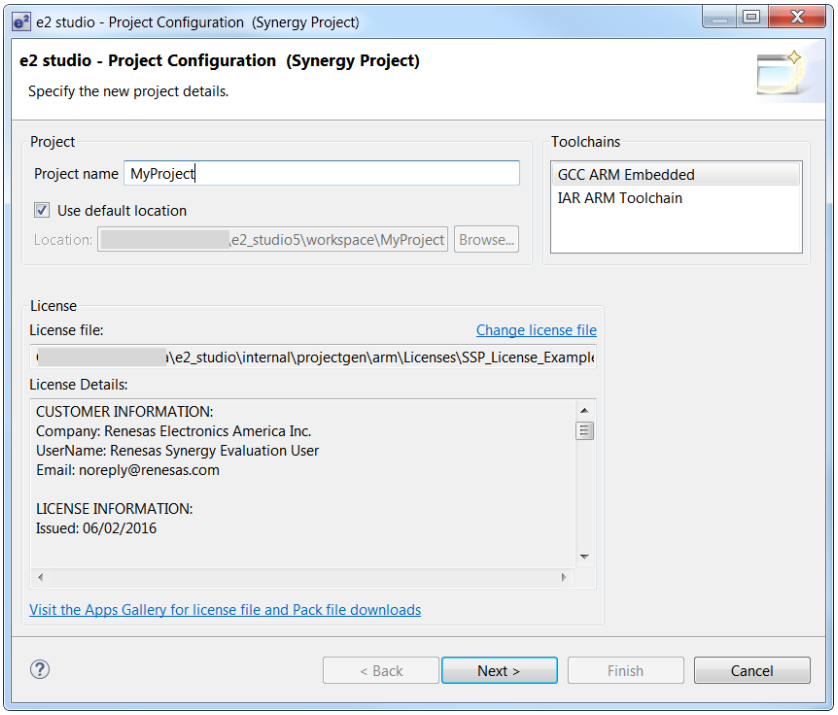

Figure 25: Synergy Project Generator (Screen 1)

3) Ensure that you have the license file for your latest SSP download. An evaluation license is included in the SSP download pack, but other license types such as a Production License and a Source License are available.See the **Installation_Guide** on the Synergy website for instructions how to load the license file. The license pane is blank if you have installed the e2 studio and SSP for the first time. Otherwise, the license pane displays the most recently installed license. You can select from multiple licenses if available. The evaluation license file is located in the following directory: < e2_studio_base_dir >/internal/projectgen/arm/Licenses/See also Licensing.

4) Click **Next**.

3.1.4.2 Selecting a Board and Toolchain

In the next Project Configuration window select the hardware and software environment:

1) Select the **SSP version**.

2) Select the **Board** for your application. You can select an existing Synergy Kit or select Custom User Board for any of the Synergy devices with your own BSP definition.

NOTE: To develop your own BSP, see the following Application Note: "Creating a Custom Board Support Package" at http://renesassynergy.com.

3) Select the **Toolchain version**.
4) Select the **Debugger**. The J-Link ARM Debugger is preselected.
5) Click **Next**.

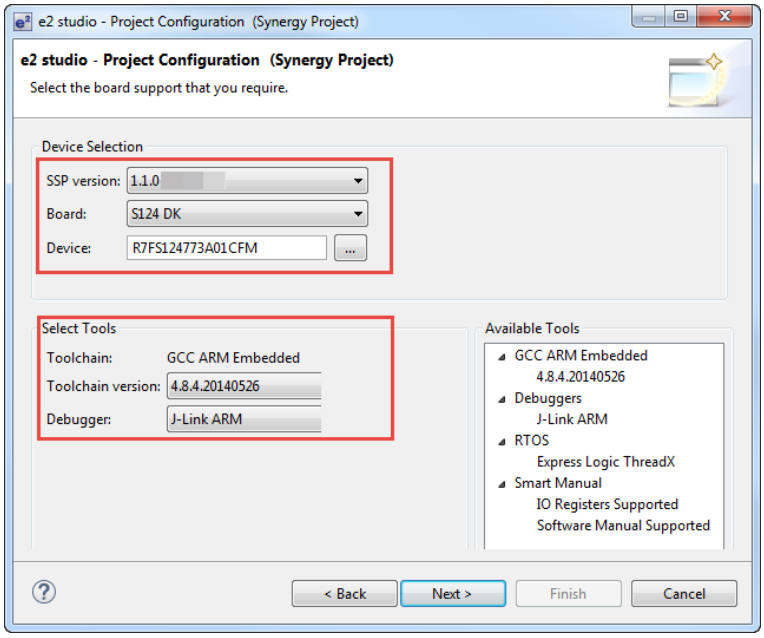

Figure 26: Synergy Project Generator (Screen 2)

3.1.4.3 Selecting a Project Template

In the next window, select a project template from the list of available templates and click **Finish**.

NOTE: If you want to develop your own application, select a basic template for your board, such as S7G2-DK BSP. You can add RTOS support at any time while you configure the modules for your project.

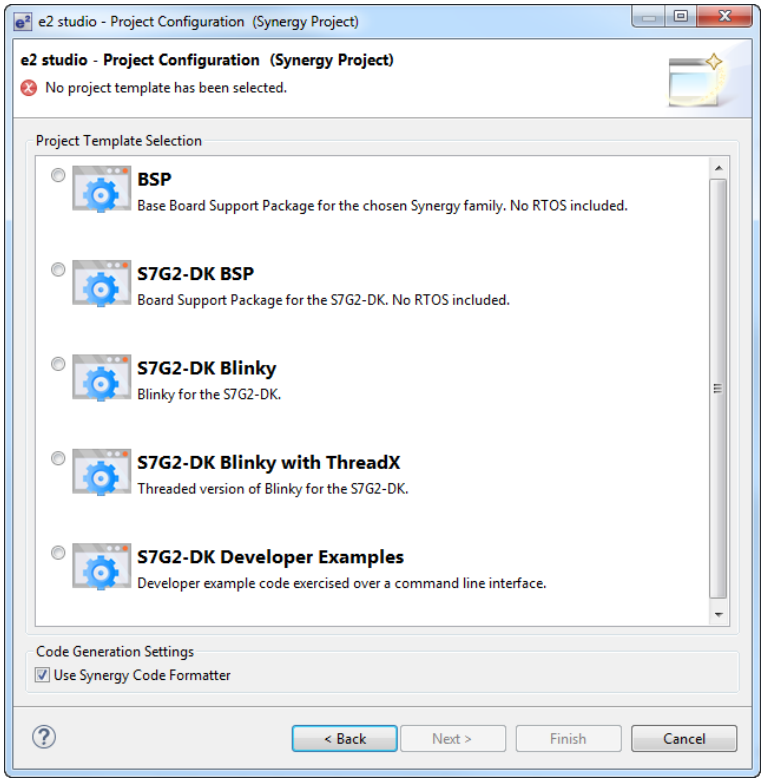

Figure 27: Synergy Project Generator (Screen 3)

By default, this screen shows the templates that are included in your current SSP pack.

When the project is created, the ISDE displays a summary of the current project configuration in the Synergy Project Editor.

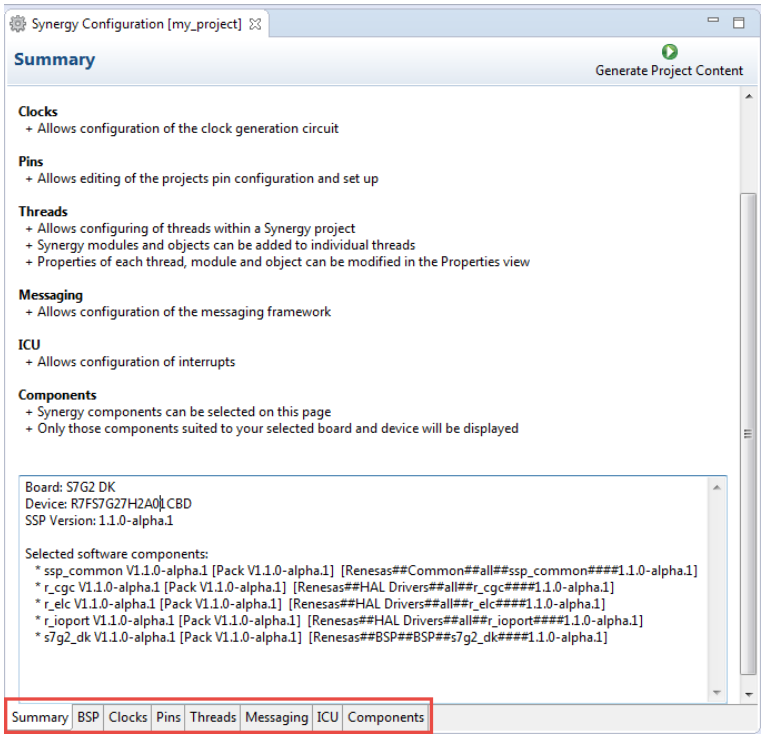

Figure 28: Synergy Project Editor and available editor tabs

On the bottom of the Synergy Project Editor view, you can find the tabs for configuring multiple aspects of your project:

- With the BSP tab, you can change board specific parameters from the initial project selection.
- With the Clocks tab, you can configure the MCU clock settings for your project.
- With the Pins tab, you can configure the electrical characteristics and functions of each port pin.
- With the Threads tab, you can add SSP modules and drivers for RTOS and non-RTOS applications and configure the drivers. For each module or driver selected in this tab, the Properties window provides access to the configuration parameters, interrupt priorities, and pin selections.
- With the Messaging tab, you can configure the Messaging Framework for ThreadX-based projects. The Messaging tab is included in e2 studio version 5.0 and higher.
- With the ICU tab, you can enable interrupts and assign interrupt priorities.
- The Components tab provides an overview of the selected modules. You can also add drivers for specific SSP releases and application sample code here.

3.1.5 Configuring a Project

A project has two levels of configuration.

- The BSP, Clocks, and Pins tabs determine the initial configuration of the MCU after reset and before any user code is executed. By selecting a project template during project creation, the ISDE configures default values as appropriate for the selected board. You can change those default values as needed.
- The Threads allows you to add SSP modules to the project and set the configuration parameters of the module as needed by the application. Because the Messaging Framework is an integral part of many ThreadX-based applications, you can configure the Messaging Framework for each thread requiring messaging in the Messaging tab (for e2 studio versions 5.0 and higher).

3.1.5.1 Configuring the BSP with the ISDE

The **BSP** tab shows the currently selected board (if any) and device. The **Properties** view is located in the lower left of the Project Configurations view as shown below.

NOTE: If the Properties view is not visible, click **Window > Show View > Properties** in the top menu bar.

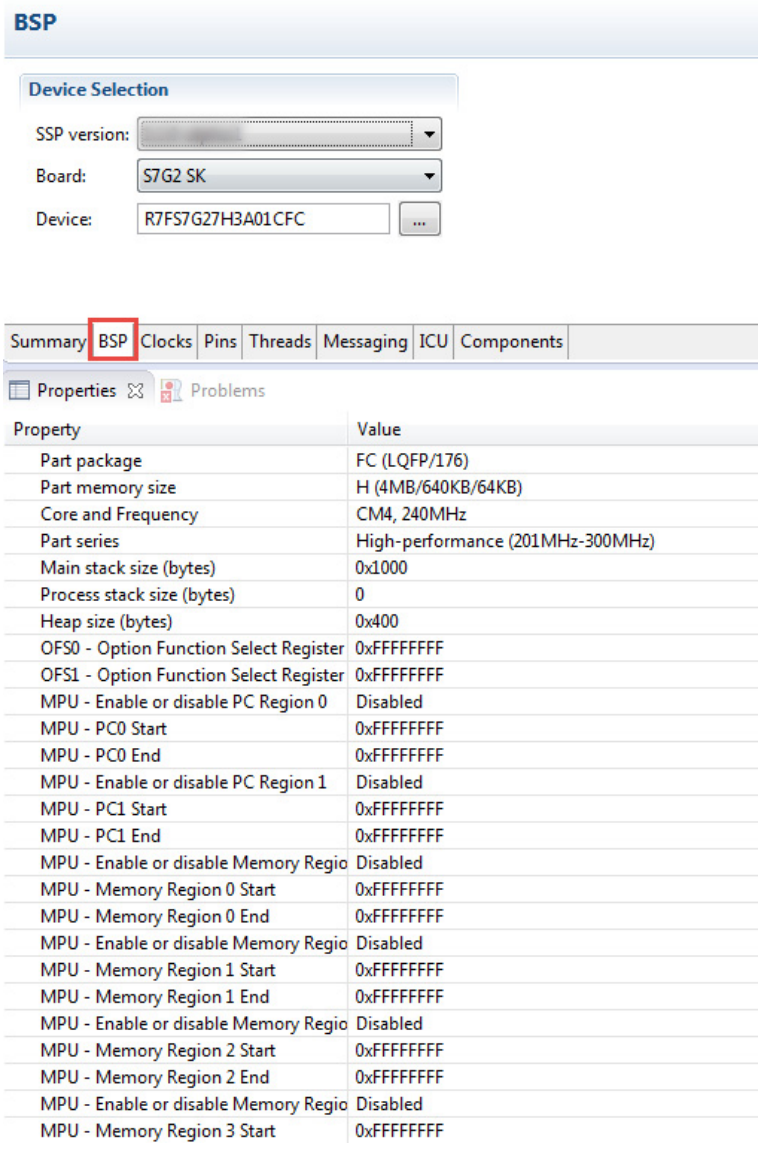

Figure 29: ISDE BSP tab

The Properties view shows the configurable options available for the BSP. These can be changed as required. The BSP is the SSP layer above the MCU hardware. The ISDE checks the entry fields to flag invalid entries. For example, only valid numeric values can be entered for the stack size.

When you press the **Generate Project Content button**, the BSP configuration contents are written to

synergy_cfg/ssp_cfg/bsp/bsp_cfg.h

This file is created if it does not already exist.

ATTENTION: Do not edit this file as it is overwritten whenever the **Generate Project Content** button is pressed.

3.1.5.2 Configuring Clocks

The **Clocks** tab presents a graphical view of the MCU's clock tree, allowing the various clock dividers and sources to be modified. If a clock setting is invalid, the offending clock value is highlighted in red. It is still possible to generate code with this setting, but correct operation cannot be guaranteed. In the figure below, the USB clock UCLK divider has been changed so the resulting clock frequency is 60 MHz instead of the required 48 MHz. This parameter is colored red.

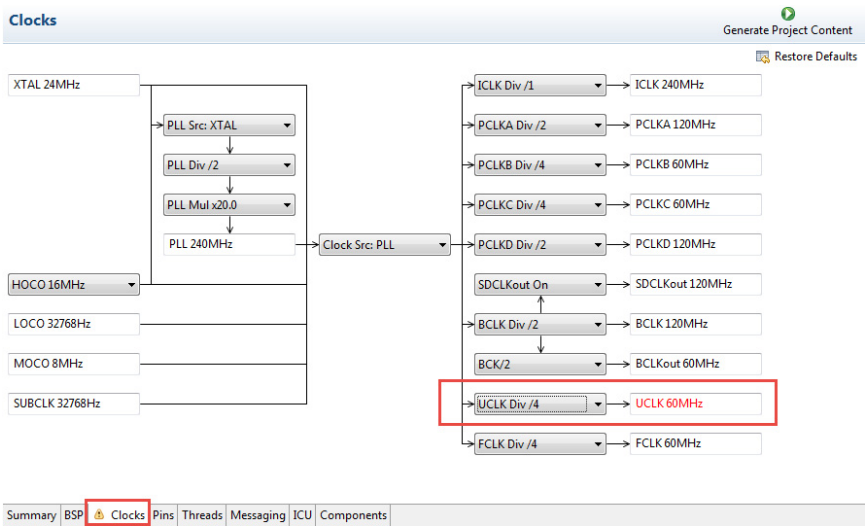

Figure 30: ISDE Clocks tab

When you press the **Generate Project Content** button, the clock configuration contents are written to:

synergy_cfg/ssp_cfg/bsp/bsp_clock_cfg.h

This file will be created if it does not already exist.

ATTENTION: Do not edit this file as it is overwritten whenever the **Generate Project Content** button is pressed.

3.1.5.3 Configuring Pins

The **Pins** tab provides flexible configuration of the MCU's pins. As many pins are able to provide multiple functions, they can be configured on a peripheral basis. For example, selecting a serial channel via the SCI peripheral offers multiple options for the location of the receive and transmit pins for that module and channel. Once a pin is configured, it is shown as green in the **Package** view.

NOTE: If the Package view window is not open in the ISDE, select **Window > Show View > Pin Configurator > Package** from the top menu bar to open it.

The **Pins** tab simplifies the configuration of large packages with highly multiplexed pins by highlighting errors and

presenting the options for each pin or for each peripheral. If you selected a project template for a specific board such as the DK-S7G2, some peripherals connected on the board are preselected.

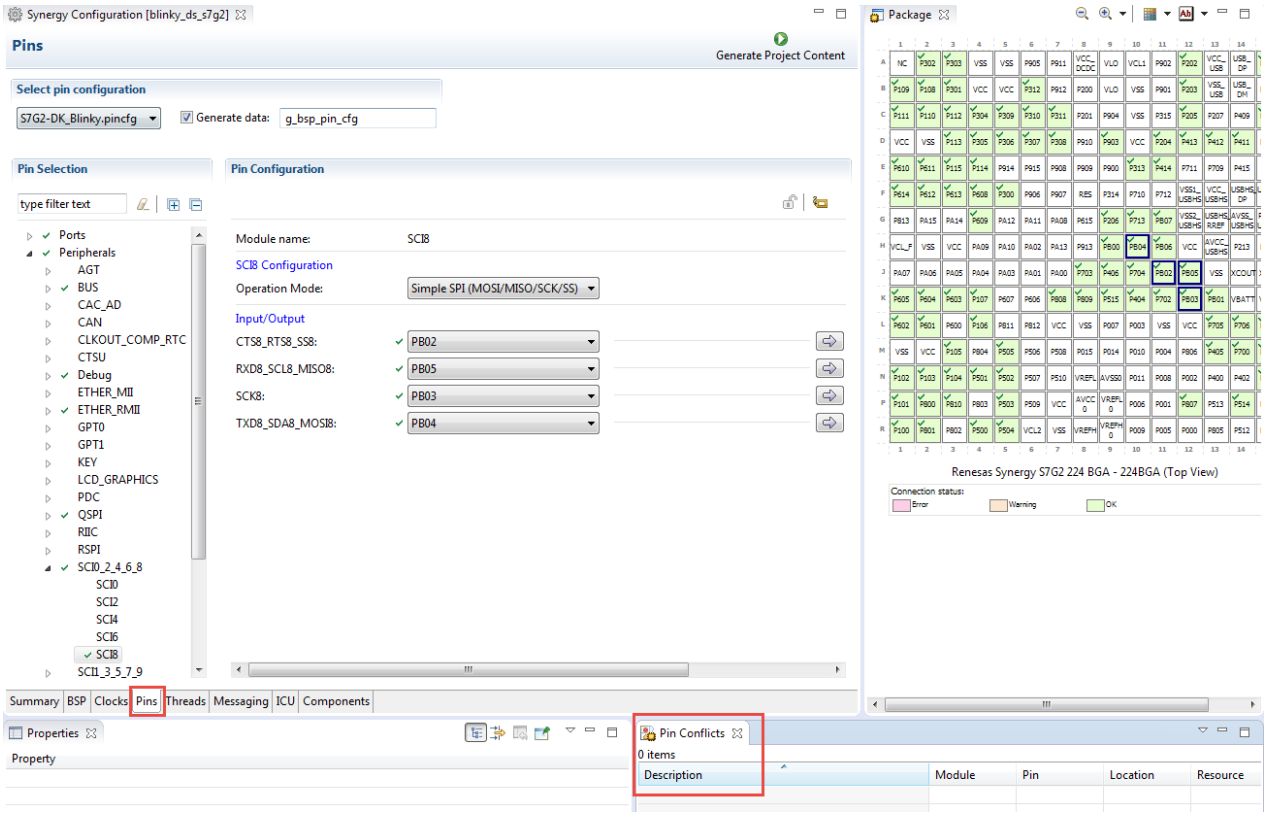

Figure 31: ISDE Pins tab

The pin configurator includes a built-in conflict checker, so if the same pin is allocated to another peripheral or I/O function the pin will be shown as red in the package view and also with white cross in a red square in the **Pin Selection** pane and **Pin Configuration** pane in the main **Pins** tab. The **Pin Conflicts** view provides a list of conflicts, so conflicts can be quickly identified and fixed.

In the example shown below, port P103 is already used by the External Memory peripheral, and the attempt to connect this port to the Serial Communications Interface (SCI) results in a dangling connection error. To fix this error, select another port from the pin drop-down list or disable the External Memory peripheral in the **Pin Selection** pane on the left side of the tab.

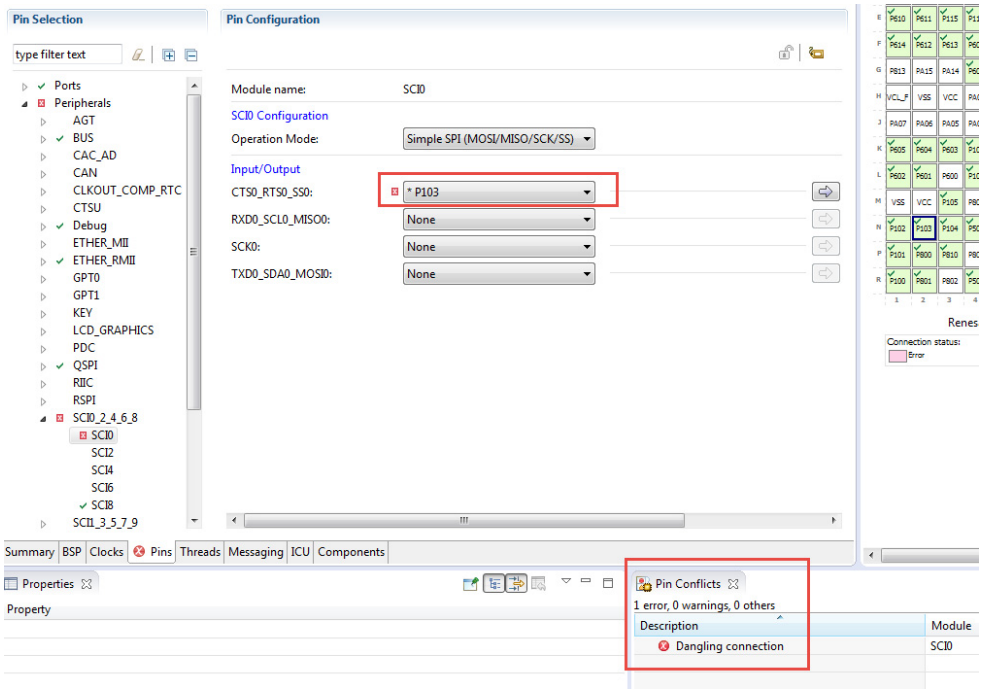

Figure 32: ISDE Pin configurator

The pin configurator also shows a package view and the selected electrical or functional characteristics of each pin.

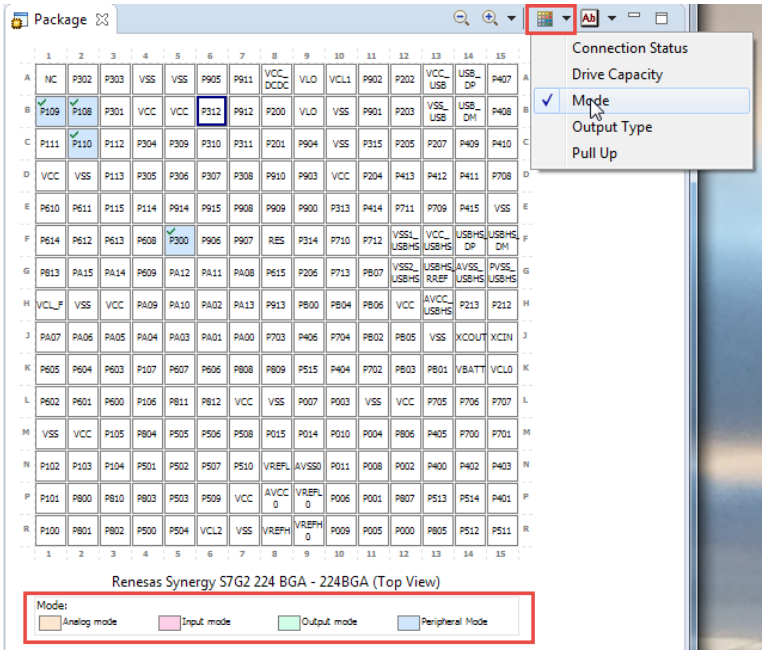

Figure 33: ISDE Pin configurator

When you press the **Generate Project Content** button, the pin configuration contents are written to:

synergy_cfg/ssp_cfg/bsp/bsp_pin_cfg.h

This file will be created if it does not already exist.

ATTENTION: Do not edit this file as it is overwritten whenever the **Generate Project Content** button is pressed.

To make it easy to share pinning information for your project, the ISDE exports your pin configuration settings to a csv format and copies the csv file to synergy_cfg/ssp_cfg/bsp/pincfg_< MCU package>.csv.

3.1.6 Adding Threads and Drivers

Every ThreadX-based Synergy Project includes at least one RTOS Thread and a stack of SSP modules running in that thread. The **Threads** tab is a graphical user interface which helps you to add the right modules to a thread and configure the properties of both the threads and the modules associated with each thread. Once you have configured the thread, the ISDE automatically generates the code reflecting your configuration choices.

For any driver or more generally any module that you add to a thread, the ISDE automatically resolves all dependencies with other modules and creates the appropriate stack. This stack is displayed in the Threads pane, which the ISDE populates with the selected modules and module options for the selected thread. If there is more than one module that can fulfill a dependency requirement, the ISDE prompts you to choose a module from a dropdown menu. For example, when you add the Audio Playback Framework to a thread, you also must pick either the DAC or the I2S framework for playback. The Audio Playback Framework also requires a timer driver, for which you must select either the AGT or GPT driver implementation, and a transfer driver. Whether or not you have a choice of implementations for the transfer driver depends in this example on the selected playback hardware, and the ISDE presents the following:

- If you selected the DAC, you have an option: You can choose between the DMAC and DTC implementations of the transfer driver.
- If you selected the I2S, only the DTC is supported: Two instances of the DTC are required (one for each channel) which are both added by the ISDE.

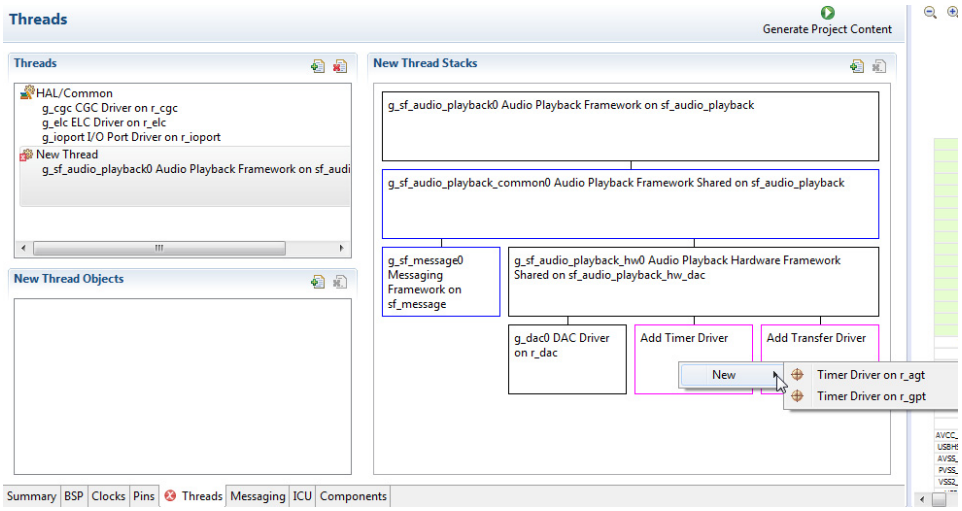

Figure 34: ISDE Project configurator - Overview

The default view of the **Threads** tab includes a Common Thread called **HAL/Common.** This thread includes the drivers for I/O control (IOPORT), clock generation circuit (CGC), and the event link controller (ELC). The default stack is shown

in the **HAL/Common Stacks** pane. The default modules added to the HAL/Common thread are special in that the SSP only requires a single instance of each, which the ISDE then includes in every user-defined thread by default.

In applications that do not use an RTOS or run outside of the RTOS, the HAL/Common thread becomes the default location where you can add additional drivers to your application.

For a detailed description on how to add and configure modules and threads, see the following sections:

- Adding and Configuring HAL Drivers
- Adding Drivers to a Thread and Configuring the Drivers

Once you have added a module either to HAL/Common or to a new thread, you can access the driver's configuration options in the **Properties** view. If you added thread objects, you can access the objects configuration options in the **Properties** view in the same way.

You can find details about how to configure threads here: Configuring Threads

NOTE: Driver and module selections and configuration options are defined in the SSP pack and can therefore change when the SSP version changes.

3.1.6.1 Adding and Configuring HAL Drivers

For applications that run outside or without the RTOS, you can add additional HAL drivers to your application using the HAL/Common thread. To add drivers, follow these steps:

1) Click on the HAL/Common icon in the **Threads** pane. The Modules pane changes to **HAL/Common Stacks**.

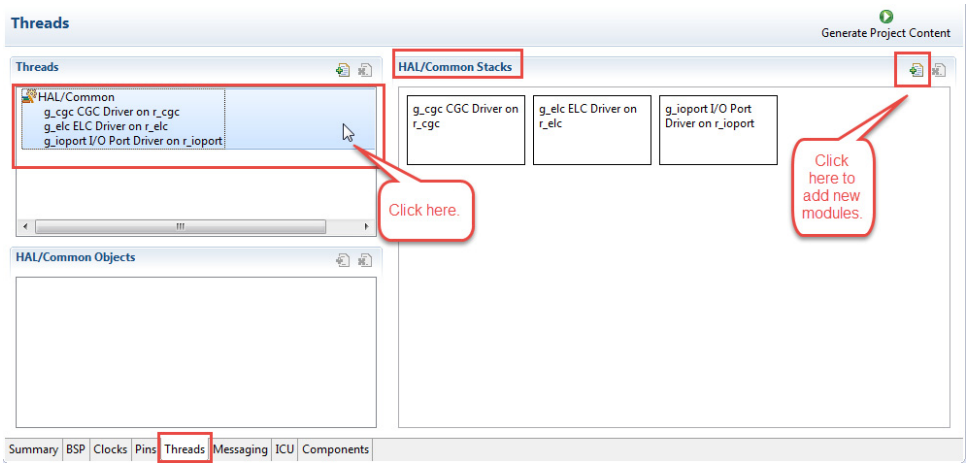

Figure 35: ISDE Project configurator - Adding drivers

2) Click **New Stack** to see a drop-down list of HAL level drivers available in the SSP.

3) Select a driver from the menu **New > Driver**. In addition, you can select the Power Profiles from **New > Framework > Services > Power Profiles Framework** on sf_power_profiles for RTOS independent applications. All other modules can only be added to a thread when ThreadX is present.

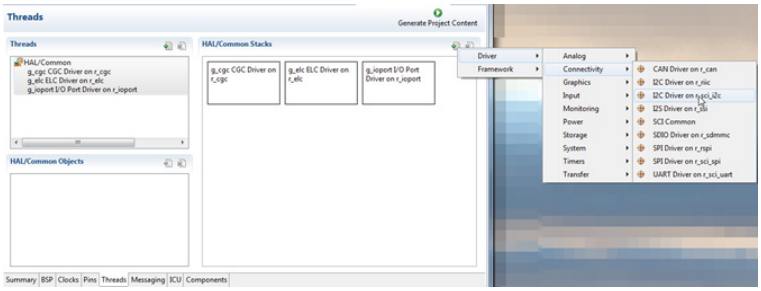

Figure 36: Select a driver

The ISDE creates the stack for the selected driver and alerts you when the driver needs additional resources that must be enabled. In the case below, you can configure the interrupt in the **Properties** view or add missing interrupts using the **ICU** tab later.

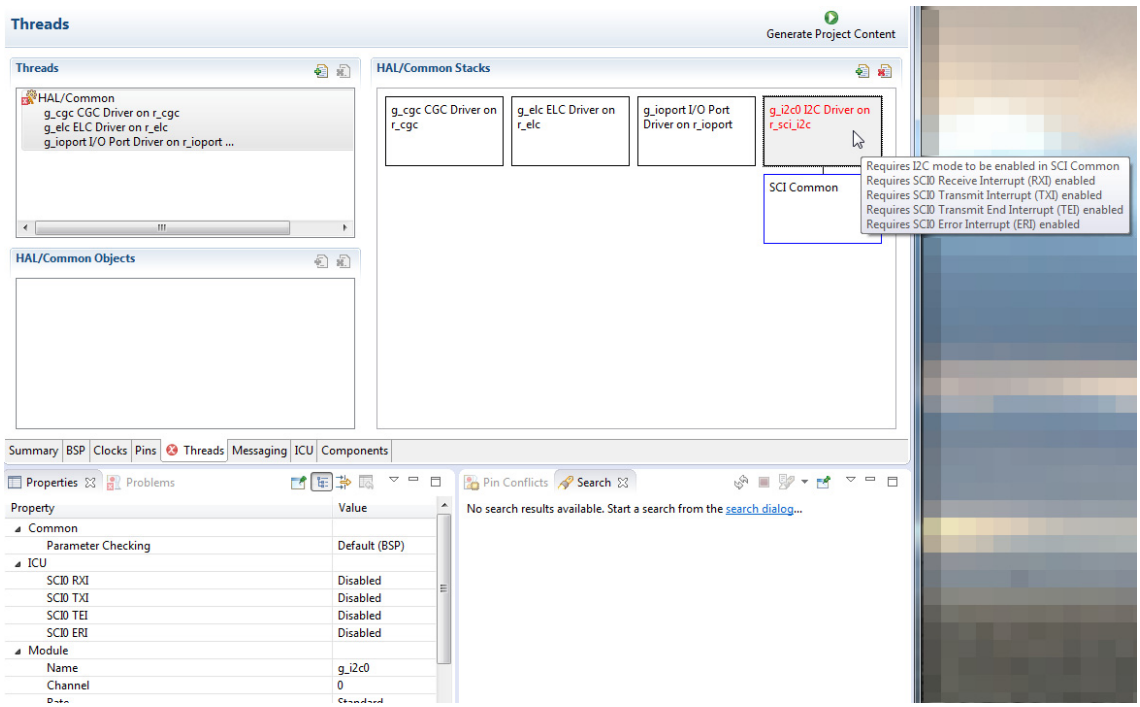

Figure 37: Dependency checking on the Threads tab

4) Select the driver module in the **HAL/Common Modules** pane and configure the driver properties in the **Properties** view.

The ISDE adds the following files when you click the **Generate Project Content** button:

- The selected driver module and its files to the synergy/ssp directory.
- The main() function and configuration structures and header files for your application as shown in the table below.

File	Contents	Overwritten by Generate Project Content?
src/synergy_gen/main.c	Contains main() calling generated and user code. When called, the BSP already has initialized the MCU.	Yes
src/synergy_gen/hal_data.c	Configuration structures for HAL Driver only modules.	Yes
src/synergy_gen/hal_data.h	Header file for HAL driver only modules.	Yes
src/hal_entry.c	User entry point for HAL Driver only code. Add your code here.	No

The configuration header files for all included modules are created or overwritten in this folder:

synergy_cfg/ssp_cfg/driver

3.1.6.2 Adding Drivers to a Thread and Configuring the Drivers

For an application that uses the ThreadX RTOS, you can add one or more threads, and for each thread at least one module that runs in the thread. You can select modules from either the Driver or Framework dropdown menu. To add modules to a thread, follow these steps:

1) In the **Threads** pane, click **New Thread** to add a Thread.

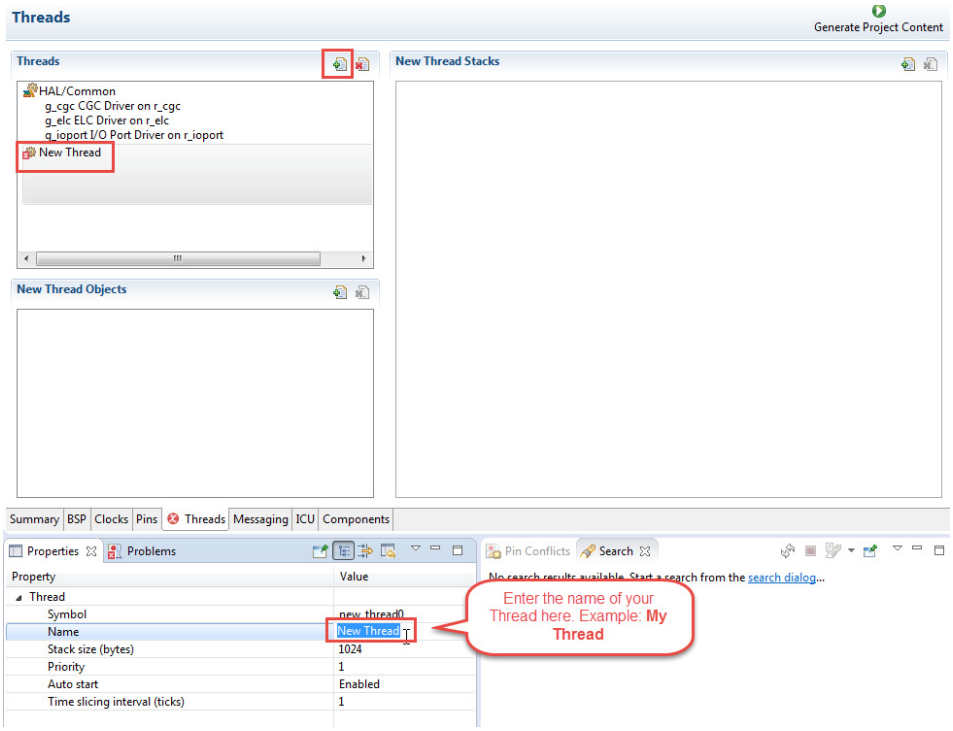

Figure 38: Adding a new RTOS Thread on the Threads tab

2) In the **Properties** view, click on the **Name** and **Symbol** entries and enter a distinctive name and symbol for the new thread.

   NOTE: The ISDE updates the name of the thread stacks pane to **My Thread Stacks**.

3) In the **My Thread Stacks** pane, click on **New** to see a list of modules and drivers. Both Framework-level Modules and HAL-level drivers can be added here.

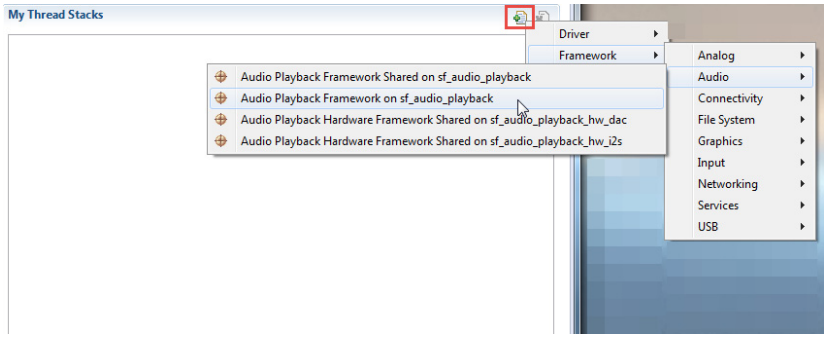

Figure 39: Adding Modules and Drivers to a thread

4) Select a module or driver from the list.

5) If the module or driver indicates a dependency, select the missing resources.

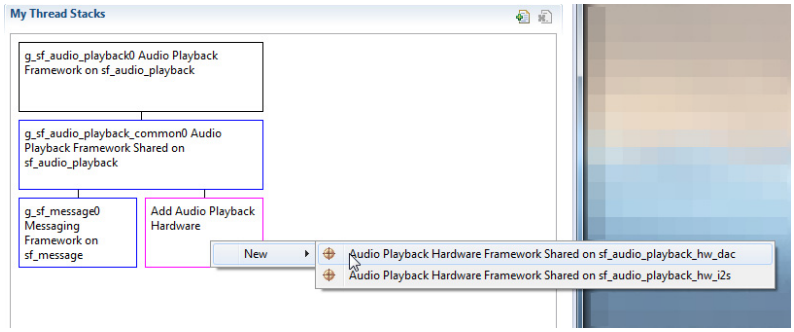

Figure 40: Identifying Module or Driver dependencies on the Threads tab

6) Click on the added driver and configure the driver as required by the application by updating the configuration parameters in the **Properties** view. To see the selected module or driver and be able to edit its properties, make sure the Thread containing the driver is highlighted in the **Threads** pane.

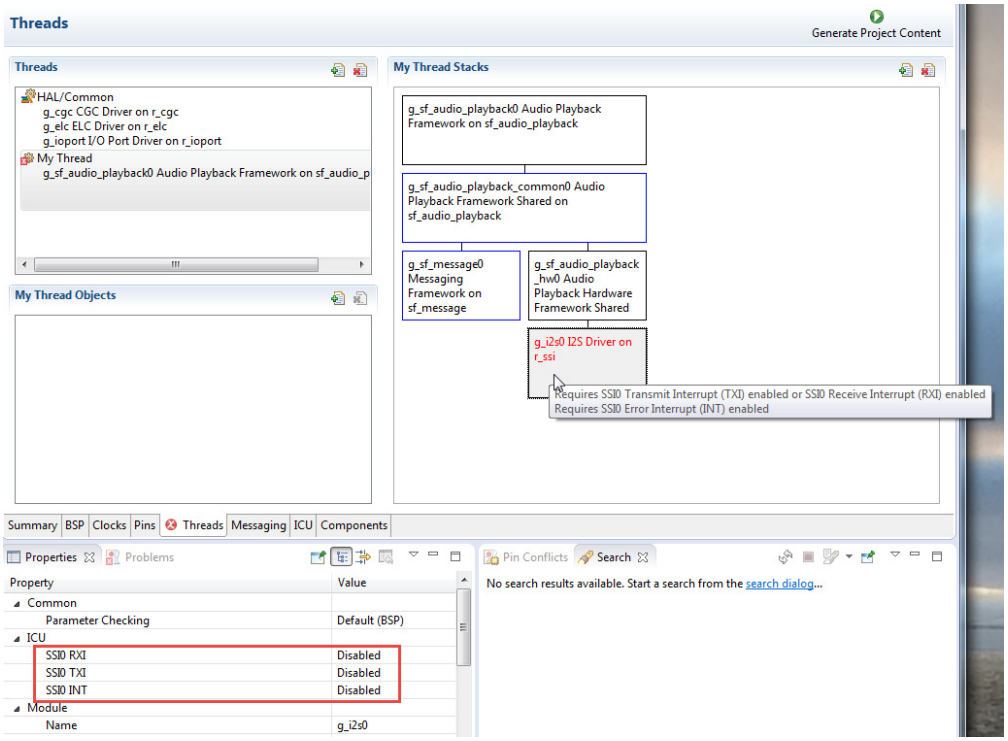

Figure 41: Configuring Module or Driver properties

7) If needed, add another thread by clicking **New** in the **Threads** pane.

When you press the **Generate Project Content** button for the example above, the ISDE creates the files as shown in the following table:

File	Contents	Overwritten by Generate Project Content?
src/synergy_gen/main.c	Contains main() calling generated and user code. When called the BSP will have initialized the MCU.	Yes
src/synergy_gen/my_thread.c	Generated thread "my_thread" and configuration structures for modules added to this thread.	Yes
src/synergy_gen/my_thread.h	Header file for thread "my_thread"	Yes
src/synergy_gen/hal_data.c	Configuration structures for HAL Driver only modules.	Yes

File	Contents	Overwritten by Generate Project Content?
src/synergy_gen/hal_data.h	Header file for HAL Driver only modules.	Yes
src/hal_entry.c	User entry point for HAL Driver only code. Add your code here.	No
src/my_thread_entry.c	User entry point for thread "my_thread". Add your code here.	No

The configuration header files for all included modules and drivers are created or overwritten in the following folders:

synergy_cfg/ssp_cfg/driver

synergy_cfg/ssp_cfg/framework

3.1.6.3 Configuring Threads

If the application uses the ThreadX RTOS, the **Threads** tab can be used to simplify the creation of ThreadX threads, semaphores, mutexes, and event flags.

The components of each thread can be configured from the **Properties** view as shown below.

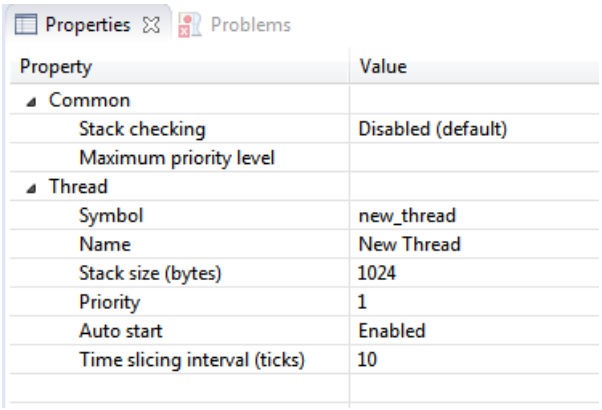

Figure 42: ISDE Thread Properties

The **Properties** view contains settings common for all Threads (**Common**) and settings for this particular thread (**Thread**).

For this thread instance, the thread's name and properties (such as priority level or stack size) can be easily configured. The ISDE checks that the entries in the property field are valid. For example, the ISDE ensures that the field **Priority**, which requires an integer value, only contains numeric values between 0 and 9.

To add ThreadX resources to a Thread, select a thread and click on **New Object** in the Thread Objects pane. The pane takes on the name of the selected thread, in this case **My Thread Objects**.

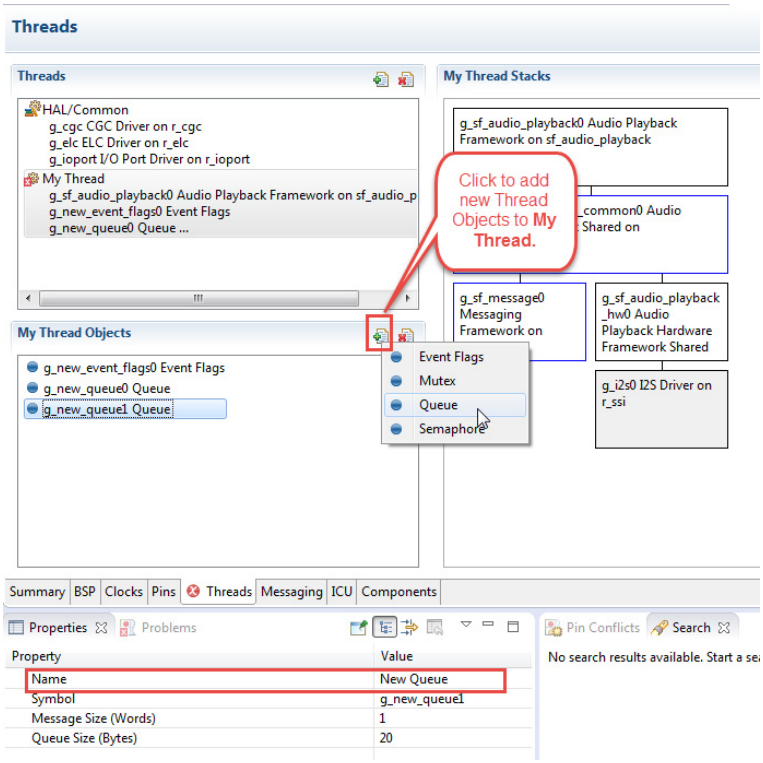

Figure 43: Configuring Thread Object Properties

Make sure to give each thread object a unique name and symbol by updating the **Name** and **Symbol** entries in the **Properties** view.

3.1.6.4 Configuring Interrupts

You can use the **Properties** view in the **Threads** tab or the **ICU** (Interrupt Control Unit) tab to enable interrupts by setting the interrupt priority. Select the thread in the Threads pane to view and edit its properties.

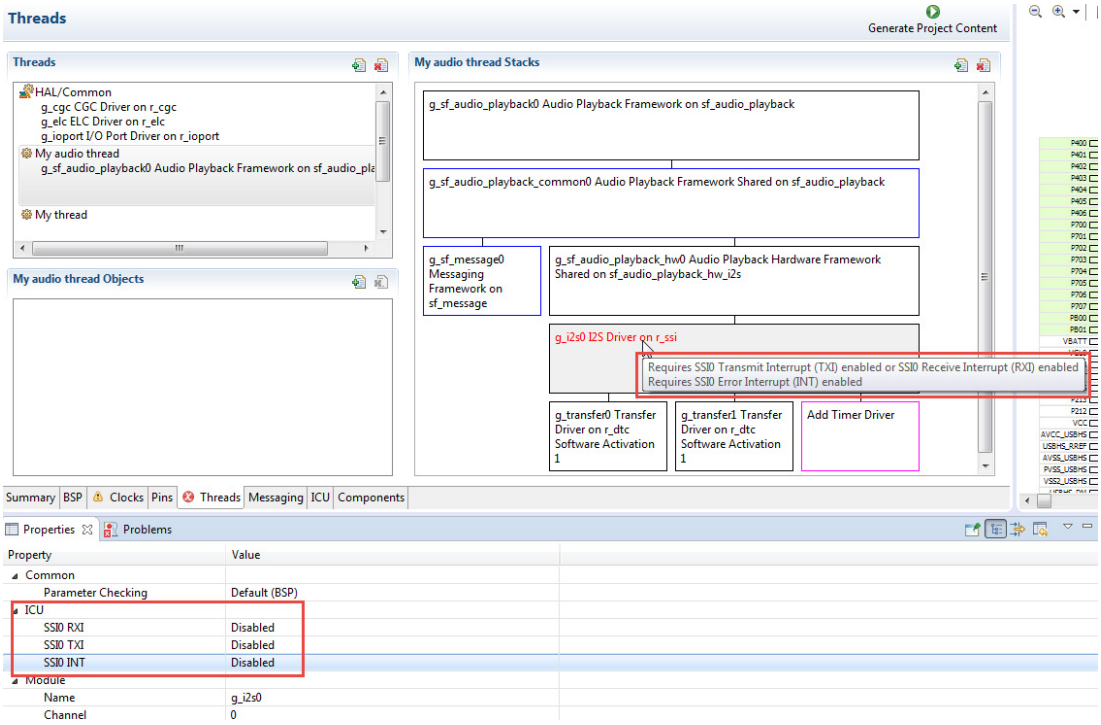

Figure 44: Configuring Interrupt on the Threads tab

3.1.7 Configuring the SSP Messaging Framework

The Messaging Framework extends the ThreadX messaging queue functionality and is one of the most important SSP modules. It provides the mechanism for threads to communicate with each other through exchanging messages. The Messaging Framework allows threads to send (publish) or listen to (pend on) messages when preconfigured or user-configured Events happen. Any thread can publish a message with an attached Event Class that all threads subscribing to this Event class can listen to and act upon. The list of Threads that can listen to a specific Event Class is called the Subscriber List for that Event Class.

To use the Messaging Framework, you first must add one Messaging Framework instance in the **Threads** tab. You may add the Messaging Framework to any thread which is not the HAL/Common thread. All threads in your project can use this instance to communicate with each other. Some modules like the Touch Panel Framework or the Audio Playback Framework require the Messaging Framework and add it automatically to the stack as shown below for the Audio Playback Framework. If your project includes a thread with such a module, you do not need to add another instance of the Messaging Framework even if you add more threads to your application. All threads can share one instance of the Messaging framework.

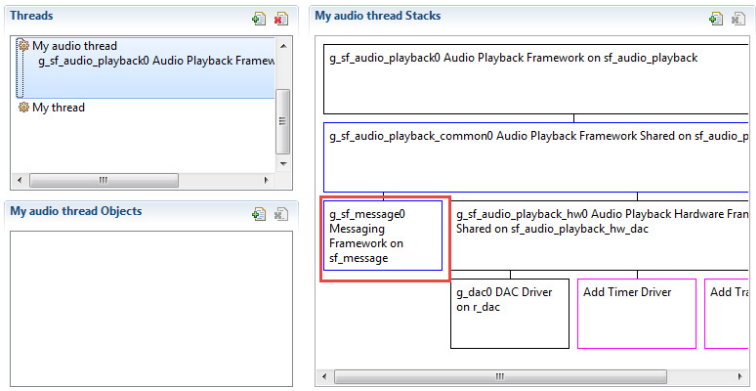

Figure 45: Adding the messaging module to a thread

Once you have added a Messaging Framework instance in the **Threads** tab, you can use the **Messaging** tab to define your own event classes and events and determine which threads can listen to which event class. The SSP contains some predefined event classes and events for the Touch Panel and the Audio Framework modules. If you have added any of these modules, their predefined event classes and events are shown in the Messaging tab as well. The predefined Event Class and Events for the Audio Playback Framework are shown below.

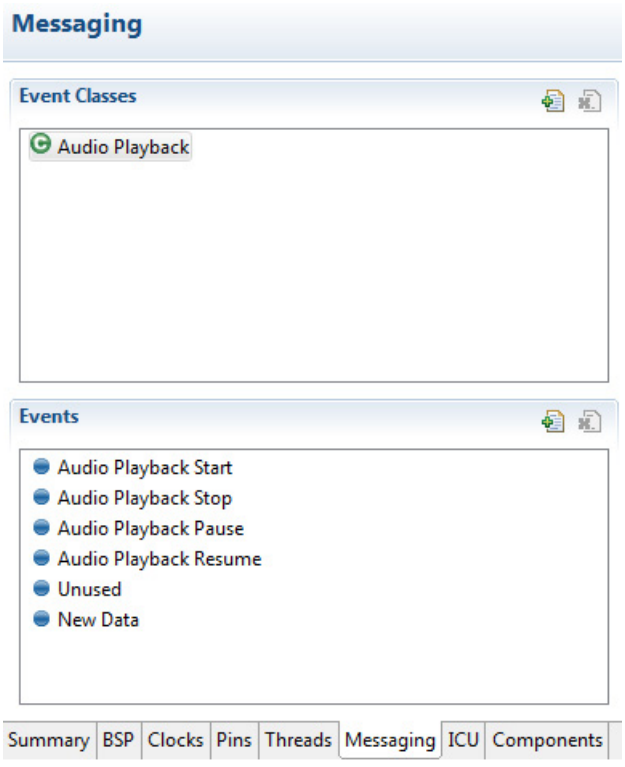

Figure 46: Audio Playback Framework predefined Event Class

3.1.7.1 Adding an Event Class

To add your own user-defined Event Class to the messaging system, follow these steps:

1) In the **Messaging** tab, select the **Event Classes** Pane, and click the add button.
2) Enter a unique name for your event class.
3) Click **OK**.

NOTE: User-defined Event Classes are marked with a golden square on the upper right of the Event Class icon.

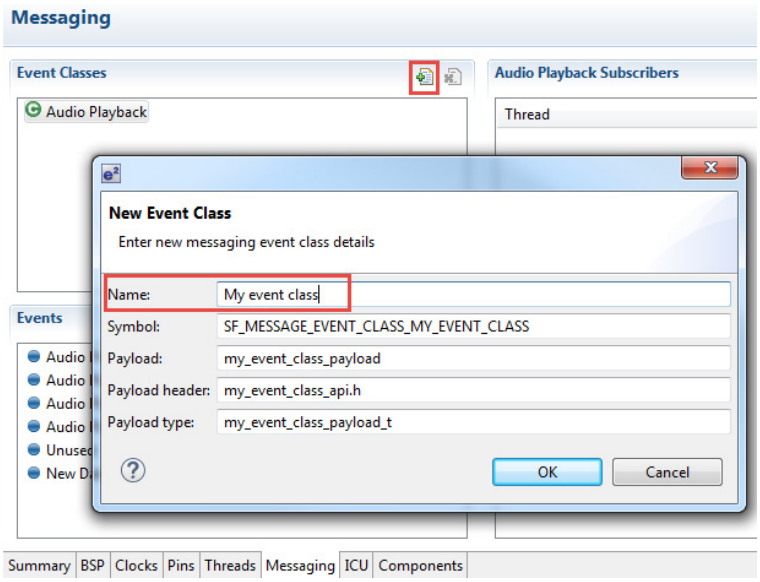

Figure 47: Messaging – Add an Event Class

3.1.7.2 Adding an Event

To add your own user-defined Event to the messaging system, follow these steps:

1) In the **Messaging** tab, select the **Event** Pane, and click the add button.
2) Enter a unique name for your event class.
3) Click **OK**.

NOTE: User-defined Events are marked with a golden square on the upper right of the Events icon.

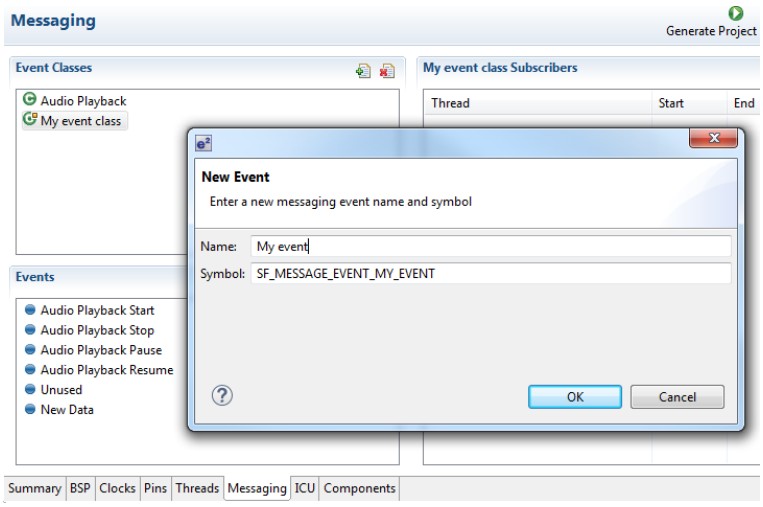

Figure 48: Messaging – Add an Event

3.1.7.3 Configuring the Messaging Subscriber List

In the Subscriber List, you select the threads that are listening to messages from the message publisher. The connection between the publishing thread and the listening thread is established through the Event Class. Therefore you define a subscriber list for each of the Event Classes in your project. All threads in the Subscriber List then can listen and act upon messages belonging to the selected Event Class.

To following assumes that you have two threads defined in the **Threads** tab, one of which uses the Audio Playback Framework:

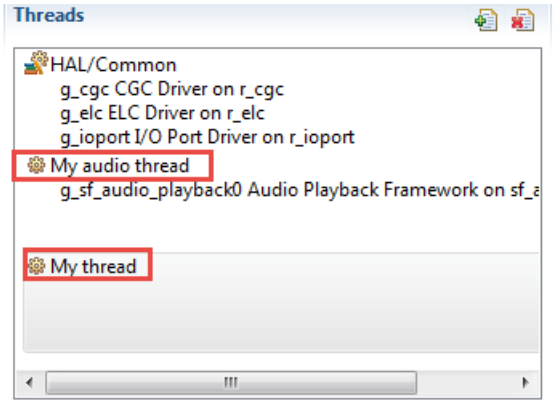

Figure 49: Messaging – Example threads

To configure the Subscriber List for an Event Class, follow these steps:

1) In the **Messaging** tab, select the Event Classes in the Event Classes Pane.The Subscriber List pane takes its name from the selected Event Class.
2) Click the Add Icon.The New Subscriber Dialog box opens.

3) Select the Thread to add to the Subscriber List from the Thread dropdown menu.

4) Fill out the instance range by selecting Start and End.If you only have one instance of an Event Class, keep the Start and End values at their default value (0). See the Messaging Framework User Guide for selecting an instance range if you have more than one Event Class instance. Multiple Event Class instances can be useful in an application that uses the same Event Class multiple times for example for audio streaming on multiple channels.

5) Repeat steps 3 and 4 for each thread that you want to add to the Subscriber List for the selected Event Class.

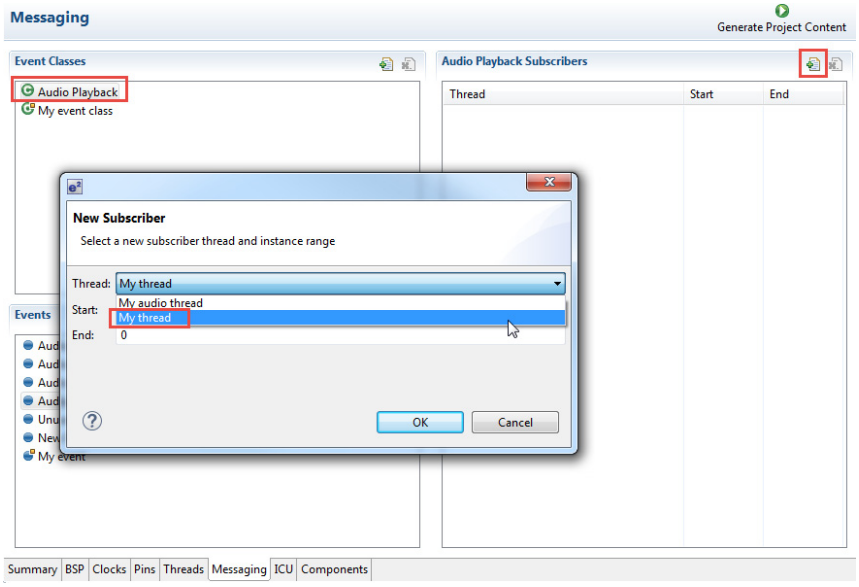

Figure 50: Messaging – Configuring the Subscriber List

3.1.7.4 Generating Files for the Messaging Framework

The ISDE generates the following files for the configured Messaging Framework when you click the Generate Project button:

File	Contents	Overwritten by Generate Project Content?
synergy_cfg/ssp_cfg/framework/sf_message_port.h	Contains the event class and event enumerations	Yes
synergy_cfg/ssp_cfg/framework/sf_message_payloads.h	Contains pointers to the event class payloads.	Yes
synergy_cfg/ssp_cfg/framework/sf_message_payloads.h	Compiler options for the Messaging Framework	Yes

3.1.8 Reviewing and Adding Components

The **Components** tab enables the individual modules required by the application to be included or excluded. Modules common to all Synergy projects are preselected (for example: BSP > BSP > Board-specific BSP and HAL Drivers > all > r_cgc). All modules that are necessary for the modules selected in the **Threads** tab are included automatically. You can include or exclude additional modules by ticking the box next to the required component.

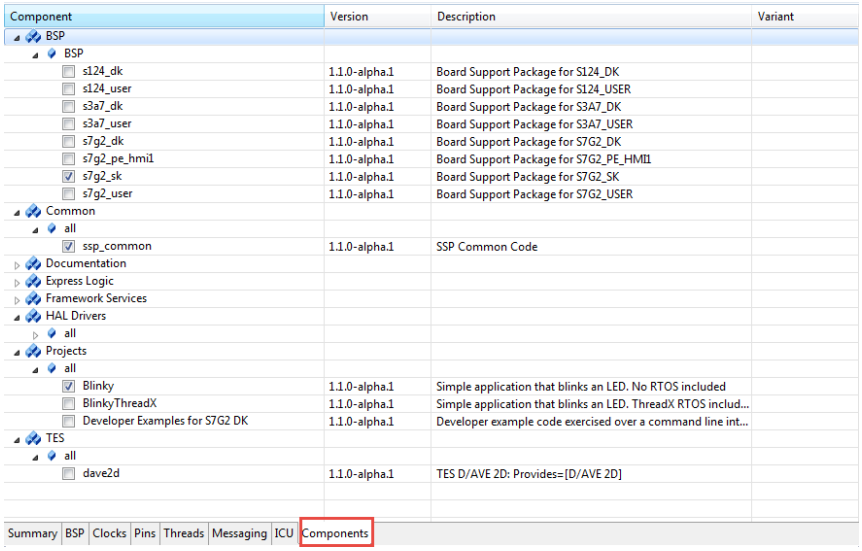

Figure 51: Components Tab

Components at the HAL and Framework layers are available as are components from Express Logic such as the RTOS ThreadX, file system FileX, TCP/IP networking NetX. In addition, you can select documentation to be added to a project or include complete projects.

While the components tab selects modules for a project, you must configure the modules themselves in the other tabs. Pressing the **Generate Project Content** button copies the .c and .h files for each component for a Pack file into the following folders:

synergy/ssp/inc/bsp

synergy/ssp/inc/driver

synergy/ssp/inc/framework

synergy/ssp/src/bsp

synergy/ssp/src/driver

synergy/ssp/src/framework

The ISDE also creates configuration files in the synergy_cfg/ssp_cfg folder with configuration options included from the remaining **Threads** and **ICU** tabs.

3.1.9 Writing the Application

Once you have added Modules and drivers and set their configuration parameters in the Threads tab, you can add the application code that calls the Modules and drivers.

NOTE: To check your configuration, build the project once without errors before adding any of your own application code.

3.1.9.1 RTOS-independent Applications

To write application code:

1) Add all drivers and modules in the **Threads** tab and resolve all dependencies flagged by the ISDE such as missing interrupts or drivers.
2) Configure the drivers in the **Properties** view.
3) In the Project Configuration view, press the **Generate Project Content** button.
4) In the **Project Explorer** view, double-click on the src/hal_entry.c file to edit the source file.

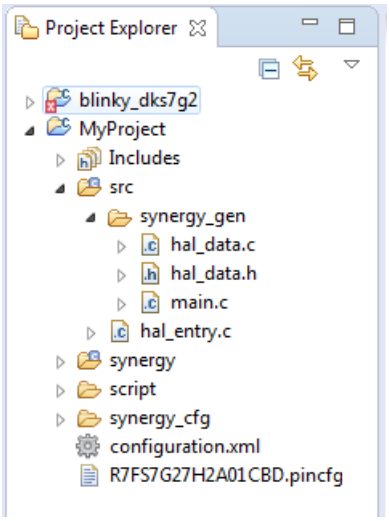

Figure 52: hal_entry.c

NOTE: All configuration structures necessary for the driver to be called in the application are initialized in src/synergy_gen/hal_data.c.

NOTE: Do not modify the files in the directory src/synergy_gen. These files are overwritten every time you push the **Generate Project Content** button.

5) Add your application code here:

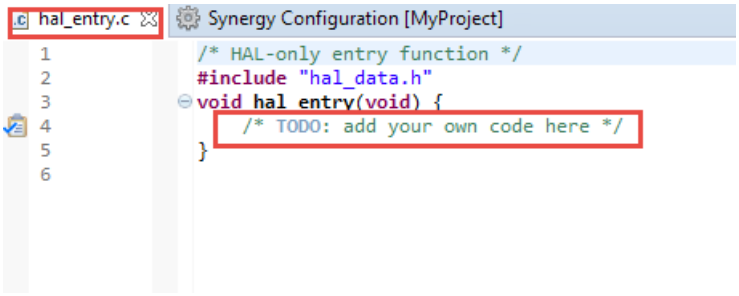

Figure 53: Adding user code to hal_entry.c

6) Build the project without errors by clicking on **Project > Build Project**.

The following tutorial shows how execute the steps above and add application code: Tutorial: Using HAL Drivers - Programming the WDT

The WDT example is a HAL level application which does not use an RTOS. The user guides for each module also include basic application code that you can add to hal_entry.c.

3.1.9.2 ThreadX Applications

To write RTOS-aware application code using ThreadX, follow these steps:

1) Add a thread using the **Threads** tab.
2) Provide a unique name for the thread in the **Properties** view for this thread.
3) Configure all drivers and resources for this thread and resolve all dependencies flagged by the ISDE such as missing interrupts or drivers.
4) Configure the thread objects.
5) Provide unique names for each thread object in the **Properties** view for each object.
6) Add more threads if needed and repeat steps 1 to 5.
7) In the **Synergy Project Editor**, press the **Generate Project Content** button.
8) In the **Project Explorer** view, double-click on the src/my_thread_1_entry.c file to edit the source file.

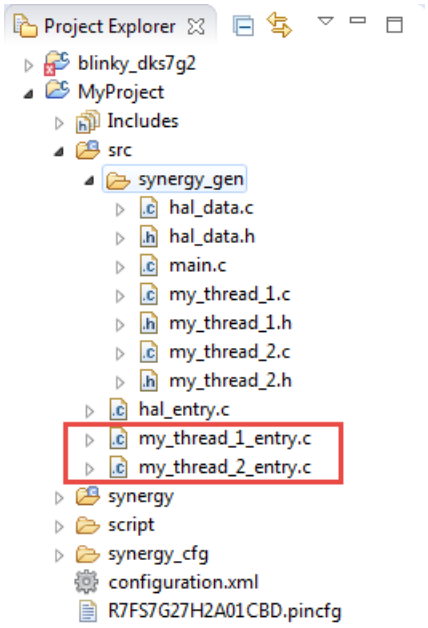

Figure 54: ISDE generated files for an RTOS application

NOTE: All configuration structures necessary for the driver to be called in the application are initialized in synergy_gen/my_thread_1.c and my_thread_2.c

NOTE: Do not modify the files in the directory src/synergy_gen. These files are overwritten every time you push the **Generate Project Content** button.

9) Add your application code here:

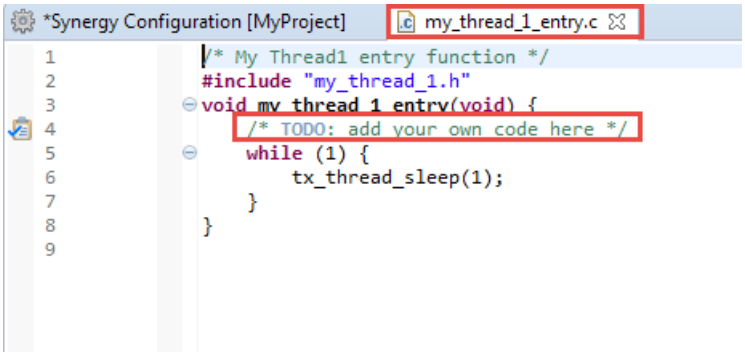

Figure 55: Adding user code to my_thread_1.entry

10) Repeat steps 1 to 9 for the next thread.

11) Build your project without errors by clicking on **Project > Build Project**.

3.1.10 Debugging the Project

Once your project builds without errors, you can use the Debugger to download your application to the board and execute it.

To debug an application follow these steps:

1) On the drop-down list next to the debug icon, select **Debug Configurations**.

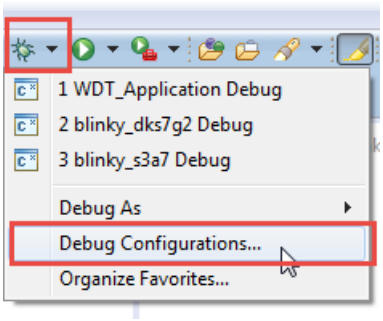

Figure 56: Invoking the Debug Configurations dialog

2) In the **Debug Configurations** view, click on your project listed as **MyProject Debug**.

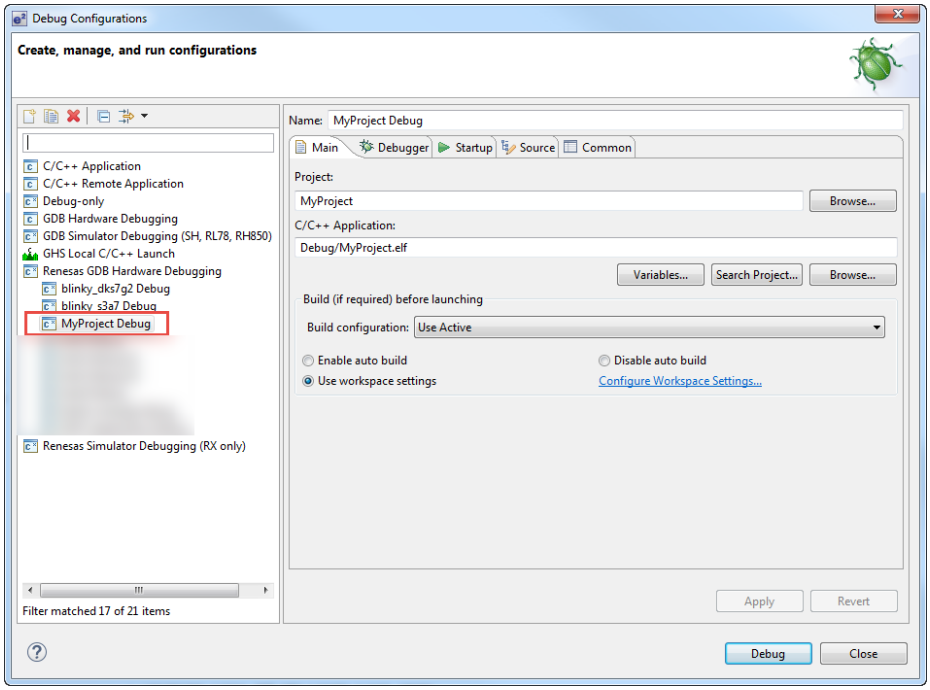

Figure 57: Debug Configuration

3) Connect the board to your PC via either a standalone Segger J-Link debugger or a Segger J-Link On-Board (included on all Synergy DKs and SKs) and click **Debug**.

NOTE: For details on using J-Link and connecting the board to the PC, see the Quick Start Guide included in the Synergy Kit.

3.1.11 Using TraceX with a Synergy Project

NOTE: Before you can use TraceX with your Synergy Project, you must download the TraceX executable file from the Synergy Gallery Website.

TraceX™ is a host-based analysis tool that provides a graphical view of real-time system events. TraceX collects data on the target device and displays the data for inspection and analysis. A TraceX version for Synergy devices is available for downloading on the Synergy Gallery Website and can be used together with the Synergy License.

To use TraceX, do the following:

1) Enable TraceX in the Properties Window of the Thread using the **Threads** tab. Keep the default name for the TraceX buffer as g_tx_trace_buffer.

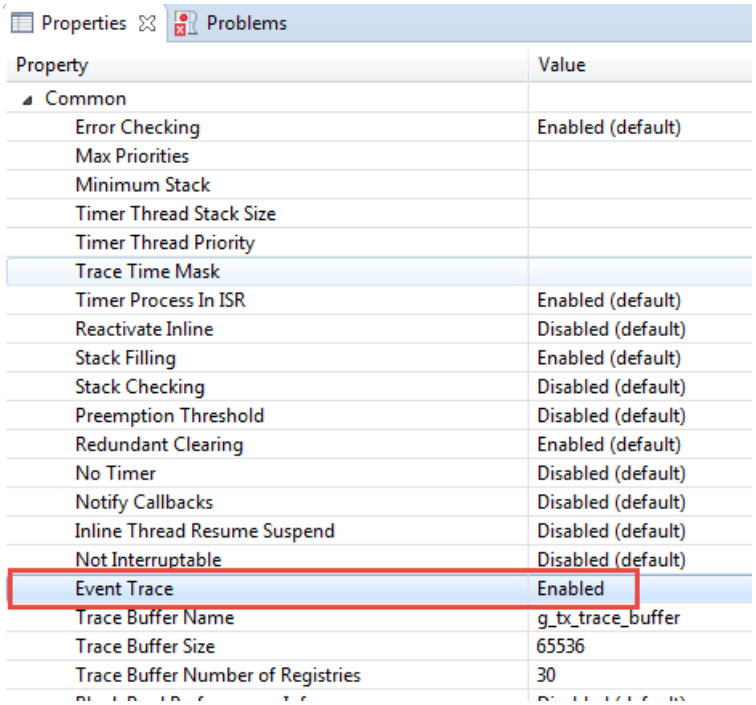

Figure 58: ISDE TraceX Configuration

2) Set the path to the TraceX application in **Window > Preferences > C/C++ > Renesas > TraceX**

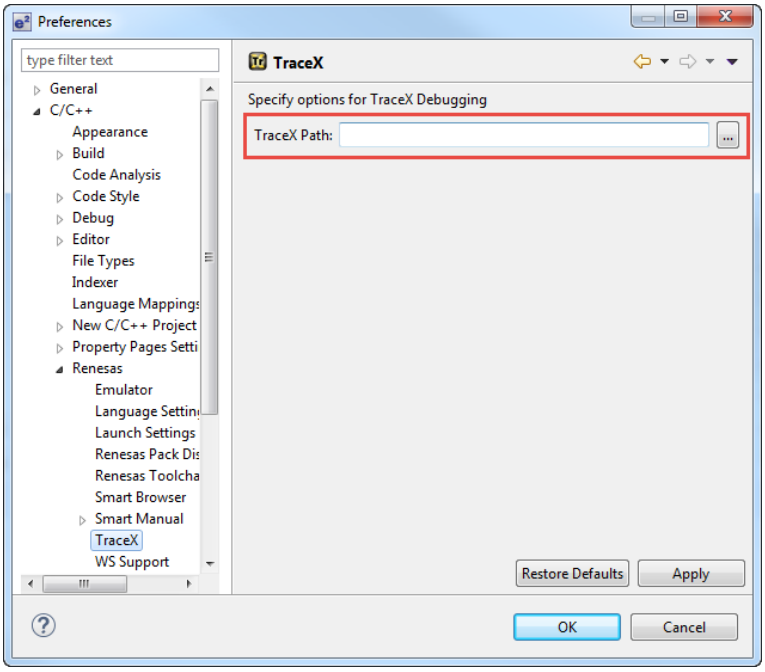

Figure 59: ISDE TraceX Path

3) In **Run > TraceX**, select **Launch TraceX Debugging**

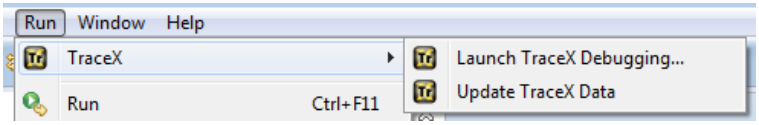

Figure 60: ISDE TraceX Launch

4) In the TraceX Debugging window, set **Buffer Start Address** to &g_tx_trace_buffer.

5) In the TraceX Debugging window, set **Buffer Size (bytes)** to the buffer size selected in the Properties Window in step 1. The default is 65536.

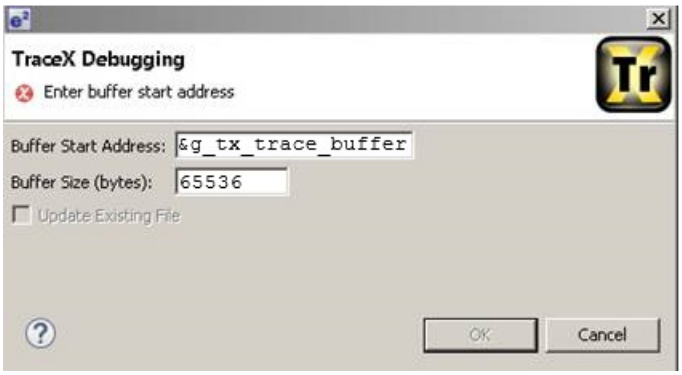

Figure 61: ISDE TraceX Debug

6) Click **OK**.

You can find details on how to use TraceX on the Express Logic website.

3.1.12 Modifying Toolchain Settings

There are instances where it may be necessary to make changes to the toolchain being used (for example, to change optimization level of the compiler or add a library to the linker). Such modifications can be made from within the ISDE through the menu **Project > Renesas Tool Settings** when the project is selected. The following screenshot shows the settings dialog for the GNU ARM toolchain. This dialog will look slightly different depending upon the toolchain being used.

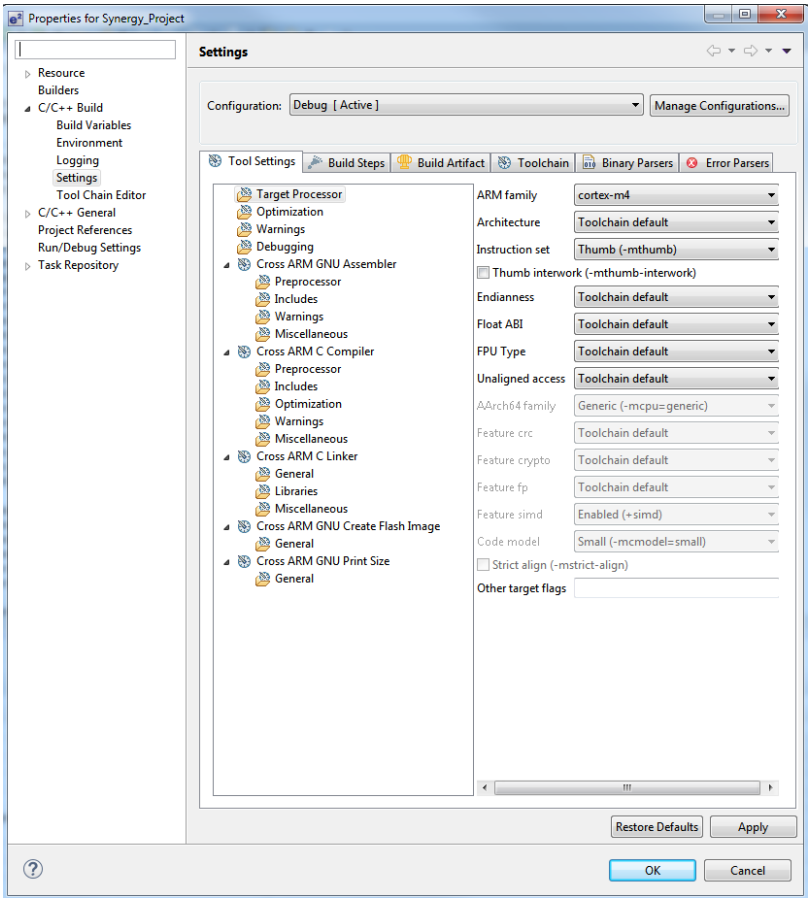

Figure 62: ISDE Project toolchain settings

The scope for the settings is project scope which means that the settings are valid only for the project being modified.

The settings for the linker which control the location of the various memory sections are contained in a script file specific for the device being used. This script file is included in the project when it is created and is found in the script folder (for example, /script/S7G2.ld).

3.1.13 e² studio ISDE Usage Notes

3.1.13.1 Handling SSP Releases

Several release packs of the SSP are available on the Synergy Gallery website.

There are two types of SSP packs:

1) X.Y.0 Gold – Production release with full SQA. Contains only X.Y.0 pack.
2) X.Y.Z – Patch release based on released X.Y.0 version (X=major; Y=minor; Z=patch). Only contains added or updated modules in X.Y.Z pack. (Does not include full X.Y.0 pack.)

You can install multiple X.Y.Z patch releases in addition to the X.Y.0 production release.

For example, you can install the following SSP versions: - SSP v1.0.0: Production release - SSP v1.0.1: First patch release - SSP v1.0.2: Second patch release - SSP v1.0.3: Third patch release

Patch releases may or may not include a Board Support Package (BSP). When you create a new Synergy Project using the Synergy Project Generator, select the highest Patch Release that includes a BSP in the **SSP Version** field. Whether or not an SSP release includes a BSP can be identified by available BSP selections in the **Board** field. If the selected patch release does not contain a BSP (as is the case in patch release v0.91.3), this is indicated by the following message: < No BSP module >

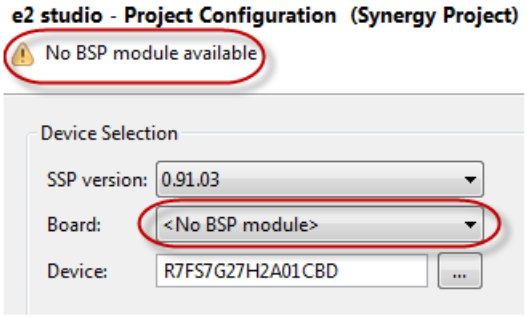

Figure 63: e2 studio installing multiple SSP versions

In this case, select the next-lowest SSP version that includes a BSP. Once you selected an SSP version with a valid BSP, the e2 studio ISDE automatically selects the SSP components from the highest available SSP version to be included in the project. You can verify this by looking up the module in the Components tab.

If any of the SSP components on the Components tab do not match exactly the selected SSP version (including "patch" version), then a warning icon appears next to the SSP Version field on the BSP tab.

In the following example, a driver module has been selected using v0.91.03 on top of SSP version 0.91.02. This selection contains a valid BSP (0.91.02), but the selected component belongs to a newer patch release (0.91.03).

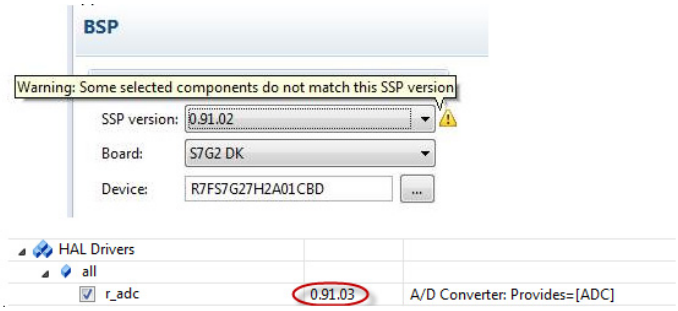

Figure 64: e2 studio Components mismatch when installing multiple SSP versions

ATTENTION: Do not select multiple versions of the same component (from different SSP packs) on the Components tab.

3.1.13.2 Including ThreadX sources

You can use the **Theads** tab to include ThreadX source code in your project as follows:

1) Click on the HAL/Common icon in the **Threads** pane. The Modules pane changes to **HAL/Common Modules**.
2) Select **New** > **Framework** > **RTOS** > **ThreadX Source**.
3) Check the **Properties** window to configure the TheadX RTOS properties.
4) Click **Generate Project**.

The e^2 studio ISDE extracts the ThreadX source code into the following directory: synergy/ssp/src/framework/el/tx

NOTE: You can see and modify the ThreadX source code only with the appropriate license. See Licensing.

NOTE: Extracting the ThreadX sources increases the compile time for your project.

3.2 Tutorial: Your First Synergy Project - Blinky

The goal of this tutorial is to quickly get acquainted with the Synergy Platform by moving through the steps of creating a simple application using e^2 studio and running that application on a Synergy board.

3.2.1 What Does Blinky Do?

The application used in this tutorial is Blinky, traditionally the first program run in a new embedded development environment.

Blinky is the "Hello World" of microcontrollers. If the LED blinks you know that:

- The toolchain is setup correctly and builds a working executable image for your chip.
- The debugger has installed with working drivers and is properly connected to the board.
- The board is powered up and its jumper and switch settings are probably correct.
- The microcontroller is alive, the clocks are running, and the memory is initialized.

The Blinky example application used in this tutorial is designed to run the same way on all boards offered by Renesas that hold the Synergy microcontroller. The code in Blinky is completely board independent. It does the work by calling into the BSP (board support package) for the particular board it is running on. This works because:

- Every board has at least one LED connected to a GPIO pin
- That one LED is always labeled LED1 on the silk screen.
- Every BSP supports an API that returns a list of LEDs on a board, and their port and pin assignments.

3.2.2 Prerequisites

To follow this tutorial, you need:

- Windows based PC
- e^2 studio
- Synergy Software Package
- A Synergy board kit

3.2.3 Create a New Project for Blinky

The creation and configuration of a Synergy project is the first step in the creation of an application. The base SSP pack includes a pre-written Blinky example application that is simple and works on all Renesas Synergy boards.

Follow these steps to create a Synergy project:

1) In e^2 studio ISDE, click **File > New > Synergy Project**
2) Assign a name to this new project. Blinky is a good name to use for this tutorial.
3) Identify the license file if the license window is empty. The license file for this version of the platform can be found in your <ISDE base directory> starting here: ISDE\internal\projectgen\arm\Licenses\SSP_License_Example_EvalLicense_<rev>.xml.
4) Click **Next**. The Project Configuration window shows your selection.

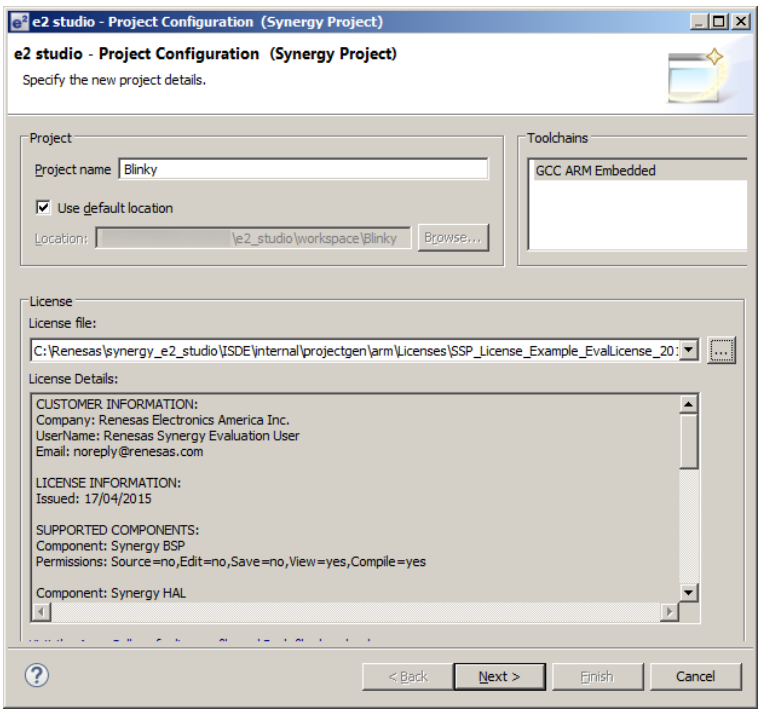

Figure 65: e^2 studio ISDE Project Configuration window (part 1)

5) Select the board support package by selecting the name of your board from the **Device Selection** drop-down list and click **Next**.

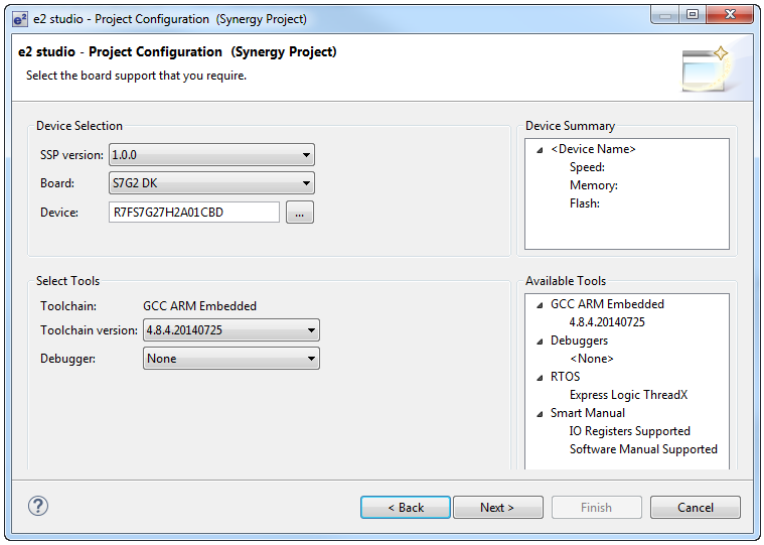

Figure 66: e² studio ISDE Project Configuration window (part 2)

6) Select the Blinky template for your board and click **Finish**.

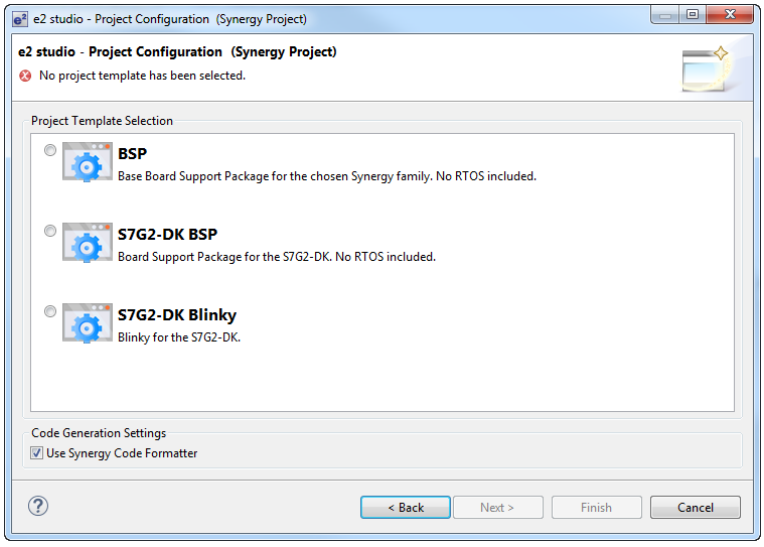

Figure 67: e² studio ISDE Project Configuration window (part 3)

Once the project has been created, the name of the project will show up in the Project Explorer window of the ISDE. Now press the **Generate Project Content** button in the top right corner of the **Project Configuration** window to generate your board specific files.

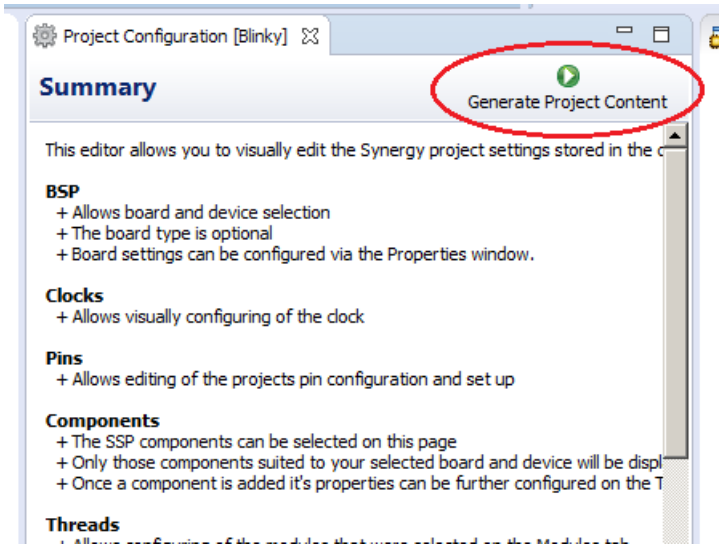

Figure 68: e² studio ISDE Project Configuration tab

Your new project is now created, configured, and ready to build.

3.2.3.1 Details about the Blinky Configuration

The **Generate Project Content** button creates configuration header files, copies source files from templates, and generally configures the project based on the state of the **Project Configuration** screen.

For example, if you check a box next to a module in the **Components** tab and press the **Generate Project Content** button all the files necessary for the inclusion of that module into the project will be copied or created. If that same check box is then unchecked those files will be deleted.

3.2.3.2 Configuring the Blinky Clocks

By selecting the Blinky template, the clocks are configured by the ISDE for the Blinky application. The ISDE clock configuration tab (see Configuring Clocks) shows the Blinky clock configuration. The Blinky clock configuration is stored in the BSP clock configuration file (see BSP Clock Configuration).

3.2.3.3 Configuring the Blinky Pins

By selecting the Blinky template, the GPIO pins used to toggle the LED1 are configured by the ISDE for the Blinky application. The ISDE pin configuration tab shows the pin configuration for the Blinky application (see Configuring Pins). The Blinky pin configuration is stored in the BSP configuration file (see BSP Pin Configuration).

3.2.3.4 Configuring the Parameters for Blinky Components

The Blinky project automatically selects the following HAL components in the ISDE Component:

- r_cgc
- r_elc

- r_ioport

To see the configuration parameters for any of the components, check the Properties tab in the **HAL** window for the respective driver (see Adding and Configuring HAL Drivers).

3.2.3.5 Where is main()?

The main function is located in < project >/src/synergy_gen/main.c. It is one of the files that are generated during the project creation stage and only contains a call to hal_entry(). For more information on generated files Adding and Configuring HAL Drivers .

3.2.3.6 Blinky Example Code

The blinky application is stored in the hal_entry.c file. This file is generated by the ISDE when you select the Blinky Project template and is located in the project's src/ folder.

The application performs the following steps:

1) Get the LED information for the selected board by calling the BSP HAL function R_BSP_LedsGet.
2) Define the output level HIGH for the GPIO pins controlling the LEDs for the selected board.
3) Get the selected system clock speed and scale down the clock, so the LED toggling can be observed.
4) Toggle the LED by writing to the GPIO pin with

```
g_ioport.p_api->pinWrite()
```

3.2.4 Build the Blinky Project

Highlight your new project in the **Project Explorer** window and build it.

There are three ways to build a project:

a. Click on Project in the menu bar and select Build Project.

b. Click on the hammer icon.

c. Right-click on the project and select Build Project.

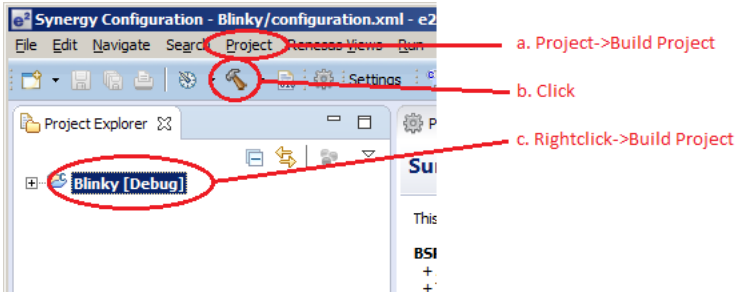

Figure 69: e² studio ISDE Project Explorer window

Once the build is complete a message is displayed in the build **Console** window that displays the final image file name and section sizes in that image.

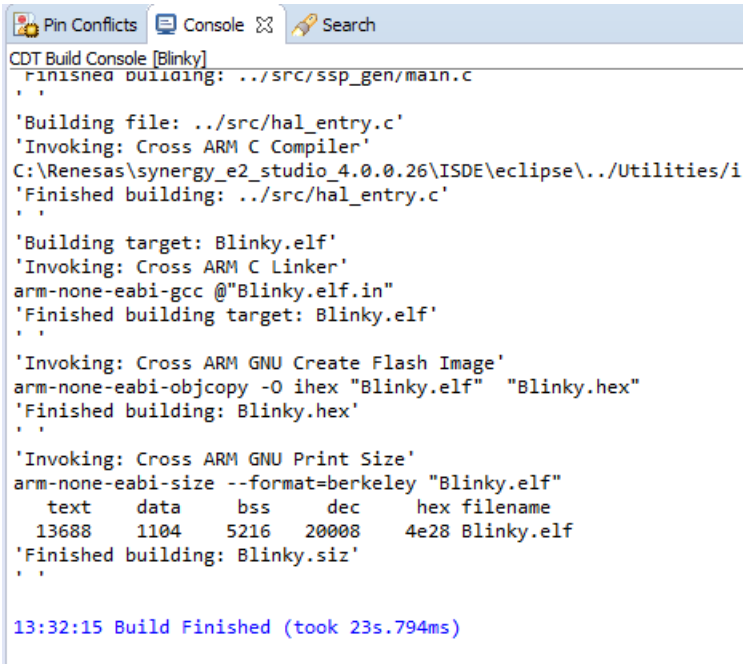

Figure 70: e^2 studio ISDE Project Build console

3.2.5 Debug the Blinky Project

3.2.5.1 Debug prerequisites

To debug the project on a board, you need

- the board to be connected to the ISDE
- the debugger to be configured to talk to the board
- the application to be programmed to the microcontroller

Applications run from the internal flash of your microcontroller. To run or debug the application, the application must first be programmed to the microcontroller's flash. There are two ways to do this:

- JTAG debugger
- Built-in boot-loader via UART or USB

Some boards have an on-board JTAG debugger and others require an external JTAG debugger connected to a header on the board.

Refer to your board's user manual to learn how to connect the JTAG debugger to your ISDE.

3.2.5.2 Debug steps

To debug the Blinky application, follow these steps:

1) Configure the debugger for your project by clicking **Run > Debugger Configurations**...

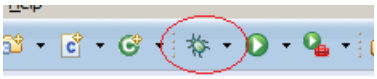

Figure 71: e² studio ISDE Debug icon

… or by selecting the drop-down menu next to the bugicon and selecting **Debugger Configurations**…

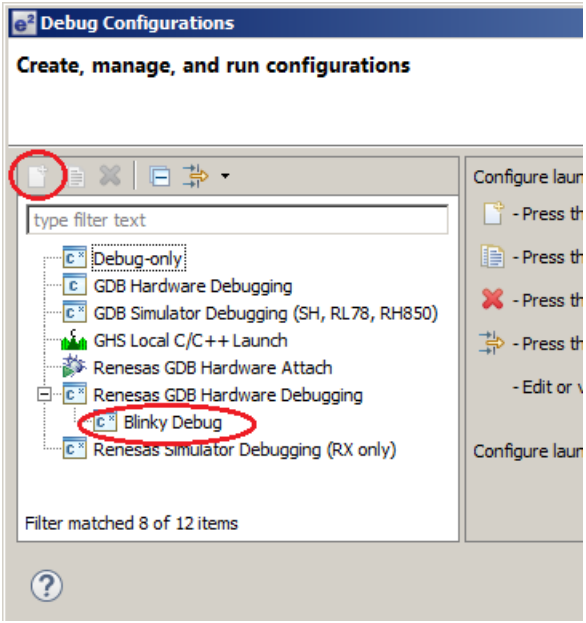

Figure 72: e² studio ISDE Debugger Configurations window

2) Select your debugger configuration in the window. If it is not visible then it must be created by clicking the **New** icon in the top left corner of the window. Once selected, the **Debug Configuration** window displays the Debug configuration for your Blinky project.

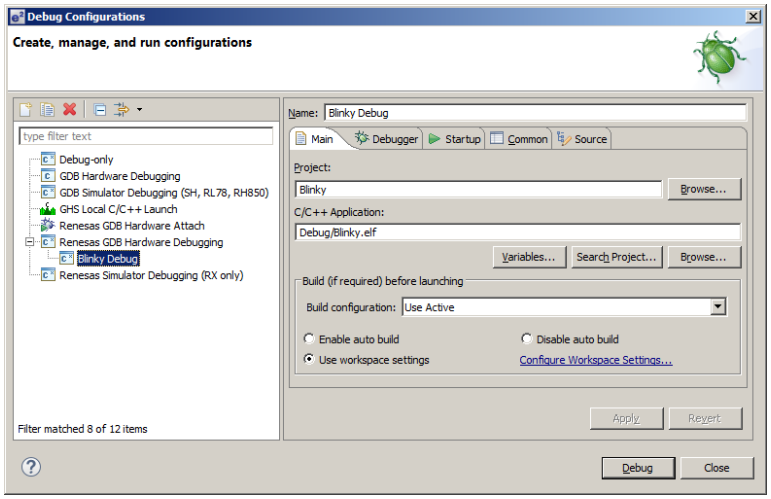

Figure 73: e^2 studio ISDE Debugger Configurations window with Blinky project

3) Press **Debug** to begin debugging the application.

3.2.5.3 Details about the Debug Process

In debug mode, the ISDE executes the following tasks:

1) Downloading the application image to the microcontroller and programming the image to the internal flash memory.
2) Setting a breakpoint at main().
3) Setting the stack pointer register to the stack.
4) Loading the program counter register with the address of the reset vector.
5) Displaying the startup code where the program counter points to.

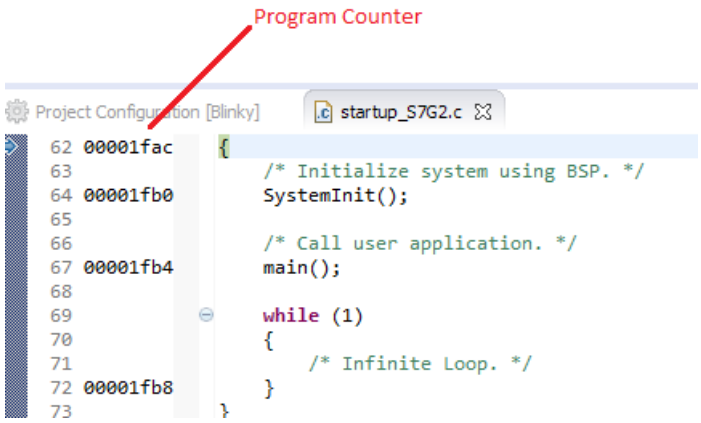

Figure 74: e² studio ISDE Debugger memory window

3.2.6 Run the Blinky Project

While in Debug mode, click **Run > Resume** or click on the Play icon twice.

Figure 75: e² studio ISDE Debugger Play icon

The LED on the board marked LED1 should now be blinking.

3.3 Tutorial: Using HAL Drivers - Programming the WDT

This application uses the WDT Interface implemented by the WDT HAL Driver WDT. This document describes how to use the ISDE and SSP to create an application for the Synergy MCU Watchdog Timer (WDT) peripheral. This application makes use of the following SSP modules:

- Board Support Package (Board Support Package)
- CGC (Clock Generation Circuit)
- WDT (Watchdog Timer)
- IOPORT (GPIO)

3.3.1 Creating a WDT Application Using the Synergy SSP and ISDE

3.3.1.1 Using the SSP and the e^2 studio ISDE

The Synergy Software Package (SSP) from Renesas provides a complete driver library for developing Synergy applications. The SSP provides Hardware Abstraction Layer (HAL) drivers, Board Support Package (BSP) drivers and higher level Framework applications for the developer to use to create applications. The SSP is integrated into the Renesas e^2 studio Integrated Solution Development Environment (ISDE) based on eclipse providing build (editor, compiler and linker) and debug phases with an extended GNU Debug (GDB) interface.

3.3.1.2 The WDT Application

The flowchart for the WDT application is shown below.

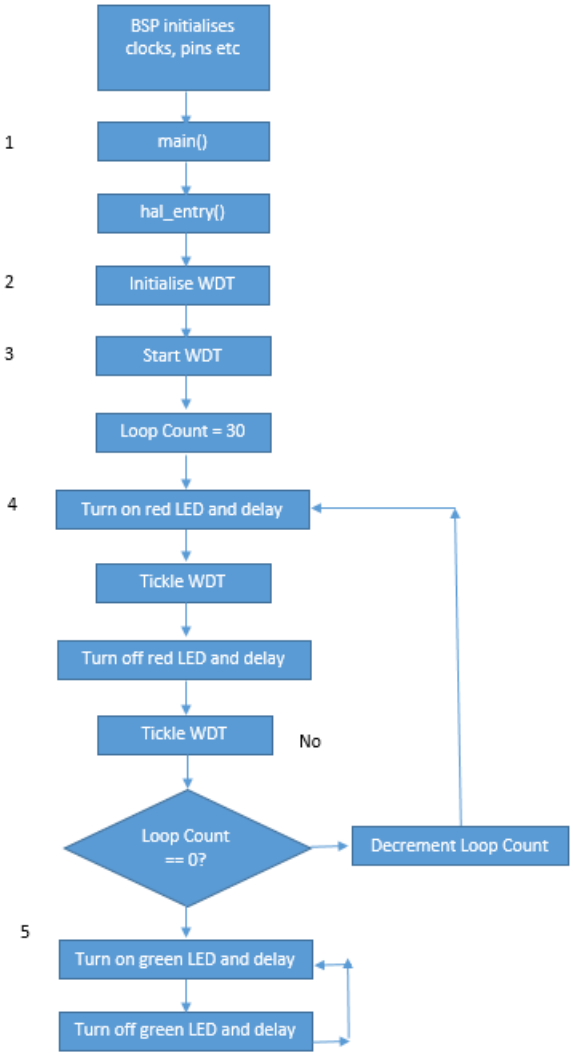

Figure 76: WDT Application flow diagram

3.3.1.3 WDT Application flow

These are the main parts of the WDT application:

1) main() calls hal_entry(). The function hal_entry() is created by the SSP with a placeholder for user code. The code for the WDT will be added to this function.
2) Initialize the WDT, but do not start it.
3) Start the WDT by refreshing it.
4) The red LED is flashed 30 times and refreshes the watchdog each time the LED state is changed.

5) Flash the green LED but DO NOT refresh the watchdog. After the timeout period of the watchdog the device will reset which can be observed by the flashing red LED again as the sequence repeats.

3.3.2 Creating the Project with the ISDE

Start the ISDE and choose a workspace folder in the Workspace Launcher. Configure a new Synergy project as follows.

1) Select **File > New > Synergy Project**

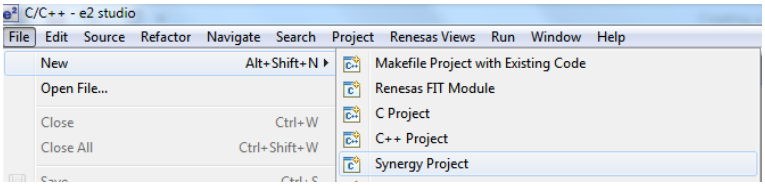

Figure 77: Creating a new project

2) In the ISDE Project **Configuration (Synergy Project)** window enter a project name e.g. WDT_Application. In addition select the toolchain and license file. If you want to choose a new location for the project unselect **Use default location**. Click **Next**.

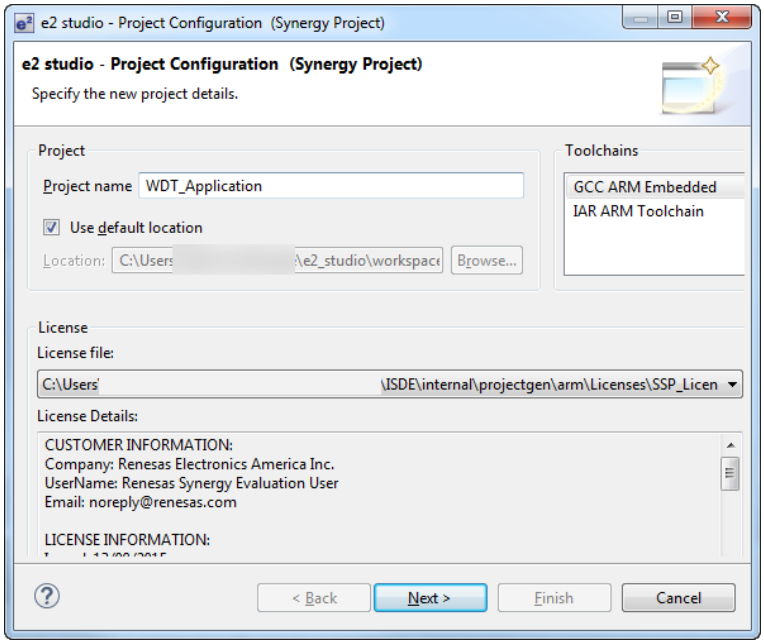

Figure 78: Project configuration (part 1)

3) This application runs on the Synergy S7G2 based DK-S7G2 board. So, for the **Board** select **S7G2 DK**.This will automatically populate the **Device** drop-down with the correct device used on this board. Select the **Toolchain** version. Select **J-Link ARM** as the **Debugger**. No **RTOS** is being used in this application but it can be left at the default **Express Logic ThreadX**. Click **Next** to configure the project.

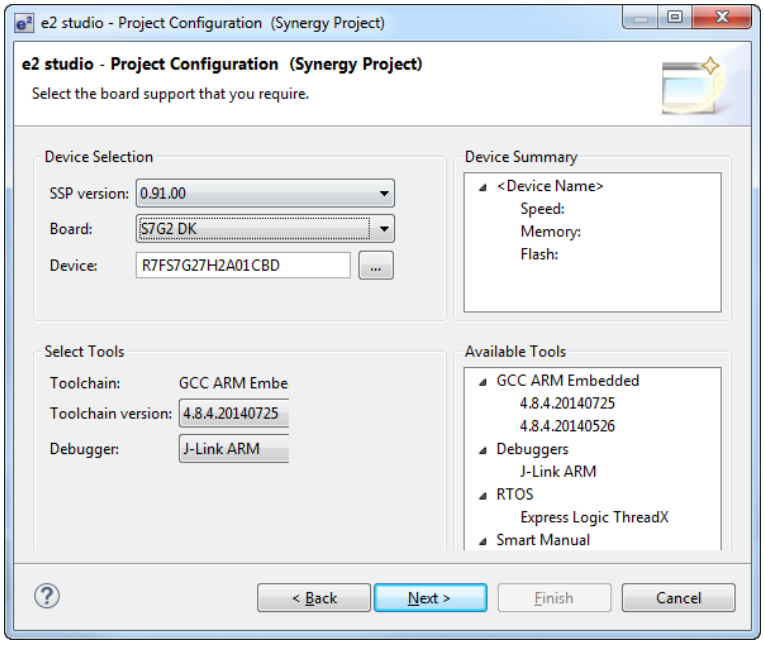

Figure 79: Project configuration (part 2)

The project template is now selected. As no RTOS is required select **S7G2-DK BSP**.

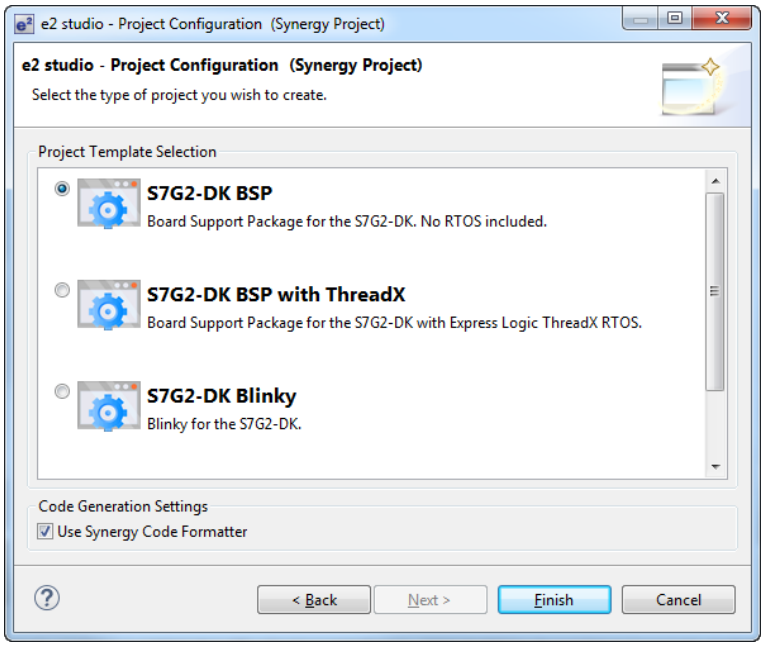

Figure 80: Project configuration (part 3)

4) Click **Finish**.

The ISDE creates the project and opens the **Project Explorer** and Project Configuration Settings** views with the **Summary** page showing a summary of the project configuration.

3.3.3 Configuring the Project with the ISDE

The e^2 studio ISDE simplifies and accelerates the project configuration process by providing a GUI interface for selecting the options to configure the project.

The ISDE offers a selection of perspectives presenting different windows to the user depending on the operation in progress. The default perspectives are **C/C++**, **Synergy Configuration** and **Debug**. The perspective can be changed by selecting a new one from the buttons at the top right of the ISDE.

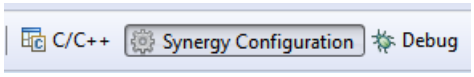

Figure 81: Selecting a perspective

The **C/C++** perspective provides a layout selected for code editing. The **Synergy Configuration** perspective provides elements for configuring a Synergy project, and the **Debug** perspective provides a view suited for debugging.

1) In order to configure the project settings ensure the **Synergy Configuration** perspective is selected.
2) Ensure the **Project Configuration [WDT Application]** is open. It is already open if the Summary information is visible. To open the Project Configuration now or at any time make sure the **Synergy Configuration** perspective is selected and double-click on the **configuration.xml** file in the Project Explorer pane on the right side of the ISDE.

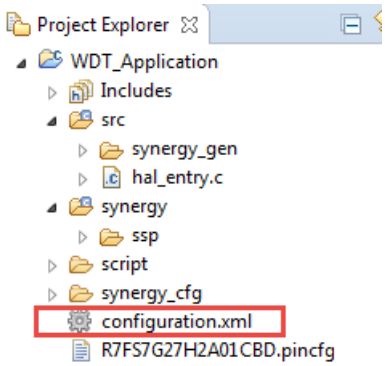

Figure 82: Synergy Project Configuration Settings

At the base of the Project Configuration view there are several tabs for configuring the project. A project may require changes to some or all of these tabs. The tabs are shown below.

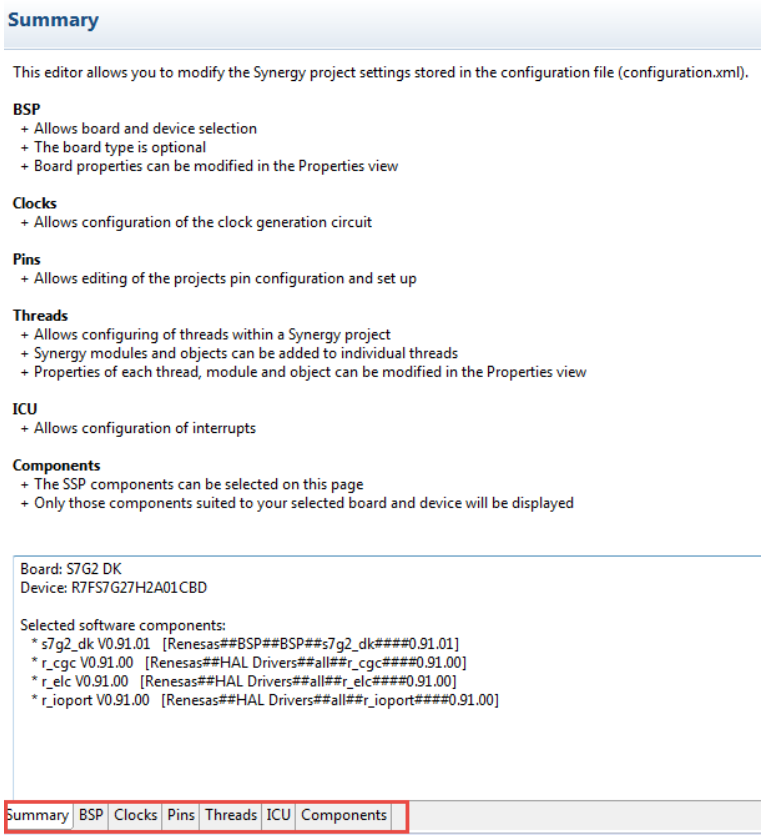

Figure 83: Project Configuration Tabs

3.3.3.1 BSP Tab

The BSP tab allows the Board Support Package (BSP) options to be modified from their defaults. For this particular WDT project no changes are required. However, if you want to use the WDT in auto-start mode, you can configure the settings of the OFS0 (Option Function Select Register 0) register in the BSP tab. See the Synergy Hardware User's Manual for details on the WDT autostart mode.

3.3.3.2 Clocks Tab

The clocks tab presents a graphical view of the clock tree of the device. Using the drop down boxes in the GUI enables configuration of the various clocks. The WDT uses PCLCKB. The default output frequency for this clock is 60 MHz. Ensure this clock is outputting this value.

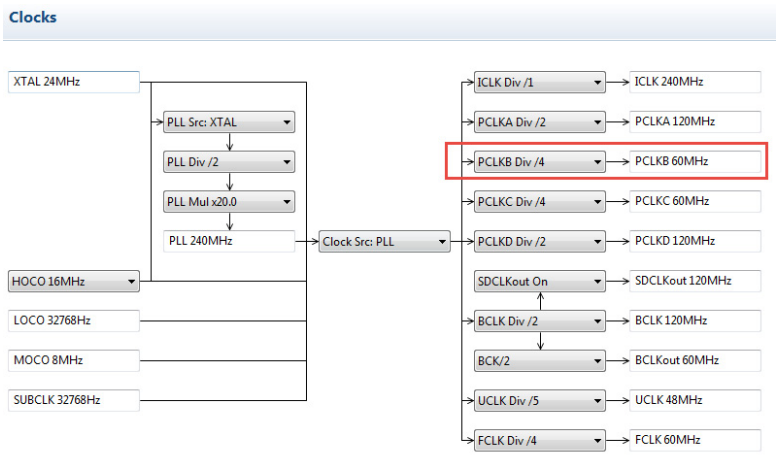

Figure 84: Clock configuration

3.3.3.3 Pins Tab

The Pins tab provides a graphical tool for configuring the functionality of the pins of the device. For the WDT project no pin configuration is required. Although the project uses two LEDs connected to pins on the device, these pins are pre-configured as output GPIO pins by the BSP.

3.3.3.4 Threads Tab

You can add any driver to the project using the Threads tab. The HAL drivers for the Clock Generation Circuit, the Event Link Controller, and the IO port pins are added automatically by the ISDE when the project is configured. The WDT application uses no ThreadX Resources, so you only need to add the HAL WDT driver.

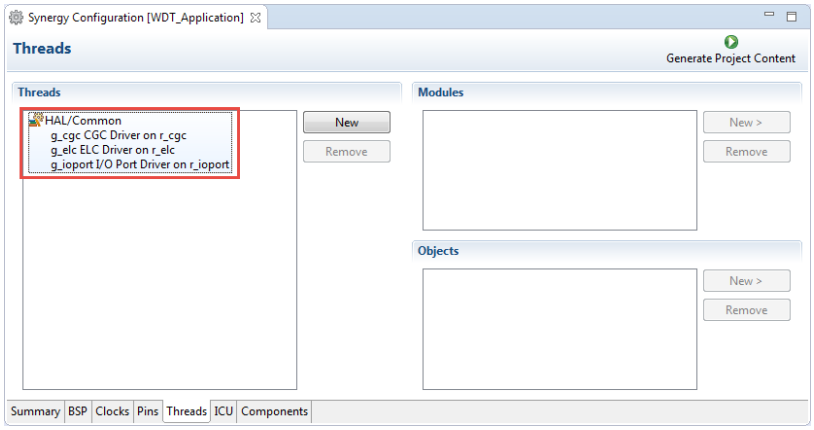

Figure 85: Threads tab

1) Click on the **HAL/Common Panel** in the Threads Window as indicated in the figure above.The Modules Panel becomes a **HAL/Common Modules** panel and is populated with the modules preselected by the ISDE.
2) Click on **New >** to find a pop-up window with the available HAL level drivers.
3) Select **WATCGDOG Driver on WDT**.

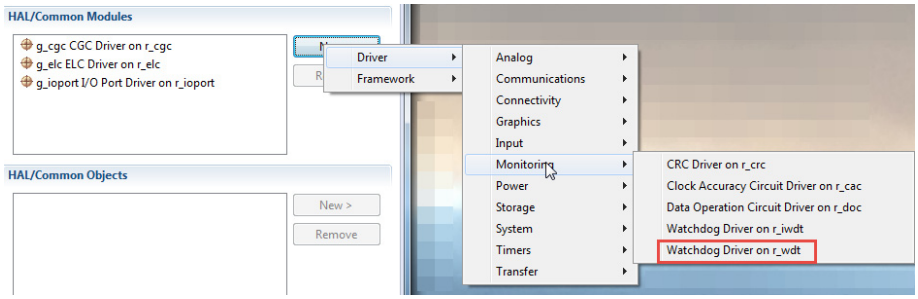

Figure 86: Module Selection

The selected HAL WDT driver is added to the **HAL/Common Modules** Panel and the **Property** Window shows all configuration options for the selected module. The **Property** tab for the WDT should be visible at the bottom left of the screen. If it not visible check that the **Synergy Configuration** perspective is selected.

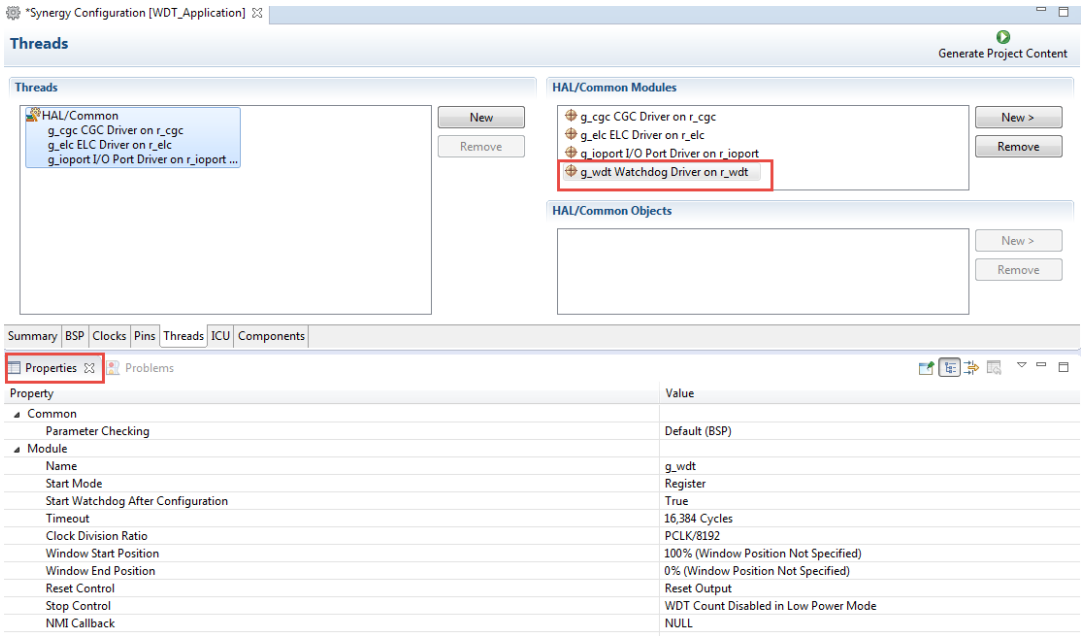

Figure 87: Module Properties

Change parameter **Start Watchdog After Configuration** from **True** to **False**. The other parameters can be left with their default values. Setting **Start Watchdog After Configuration** to **False** instructs the WDT driver (via its open API call) to configure the WDT but not to start it. It will be started later by refreshing it.

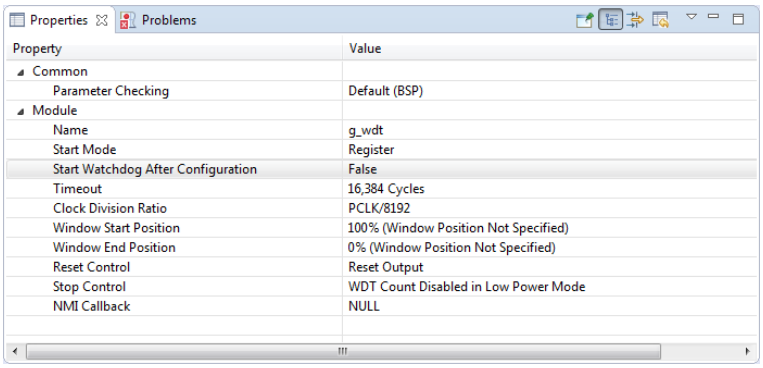

Figure 88: g_wdt WATCHDOG Driver on WDT properties

With PCLKB running at 60 MHz the WDT will reset the device 2.23 seconds after the last refresh.

WDT clock = 60 MHz / 8192 = 7.32 kHz

Cycle time = 1 / 7.324 kHz = 136.53 us

Timeout = 136.53 us x 16384 = 2.23 seconds

Save the **Project Configuration** file and click the **Generate Project Content** button in the top right corner of the **Project Configuration** pane.

Figure 89: Generate Project Content button

The ISDE generates the project files.

3.3.3.5 Components Tab

The components tab is included for reference to see which modules are included in the project. Modules are selected automatically in the Components view when after they are added in the Threads Tab.

For the WDT project ensure that the following modules are selected:

1) HAL_Drivers -> r_cgc
2) HAL_Drivers -> r_elc
3) HAL_Drivers -> r_ioport
4) HAL_Drivers -> r_wdt

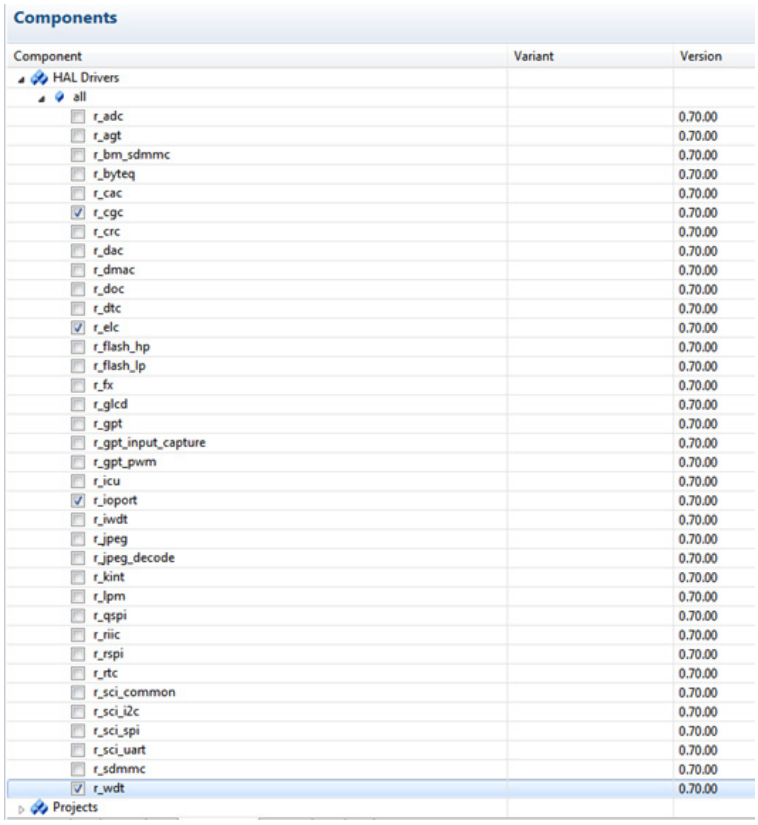

Figure 90: Component Selection

NOTE: The list of modules displayed in the Components tab depends on the installed SSP version.

3.3.4 WDT Generated Project Files

Pressing the Generate Project Content button performs the following tasks.

- r_wdt folder and WDT driver contents created at:
  - synergy/src/driver/
- r_wdt_api.h created in:
  - synergy/inc/api
- r_wdt.h created in:
  - synergy/inc/instances

The above files are the standard files for the WDT HAL module. They contain no specific project contents. They are the driver files for the WDT. Further information on the contents of these files can be found in the documentation for the WDT HAL module.

Configuration information for the WDT HAL module in the WDT project is found in:

- synergy_cfg/driver/r_wdt_cfg.h

The above file's contents are based upon the **Common** settings in the **g_wdt WATCHDOG Driver on WDT Properties** pane.

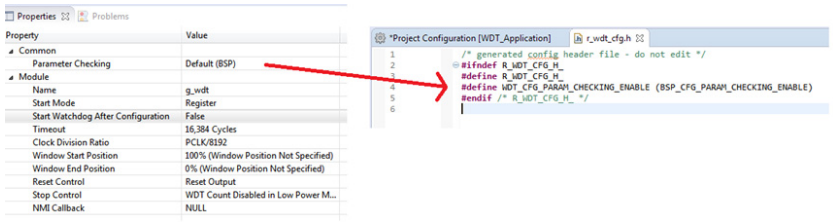

Figure 91: r_wdt_cfg.h contents

ATTENTION: Do not edit any of these files as they are recreated every time the Generate Project Content button is pressed and so any changes will be overwritten.

r_ioport folder is not created at ssp/src/driver as this module is required by the BSP and so already exists. It is included in the WDT project in order to include the correct header file in src/synergy_gen/hal_data.h – see later in this document for further details. For the same reason the other IOPORT header files – synergy/ssp/inc/api/r_ioport_api.h and synergy/ssp/inc/instances/r_ioport.h are not created as they already exist.

In addition to generating the HAL driver files for the WDT and IOPORT files the ISDE also generates files containing configuration data for the WDT and a file where user code can safely be added. These files are shown below.

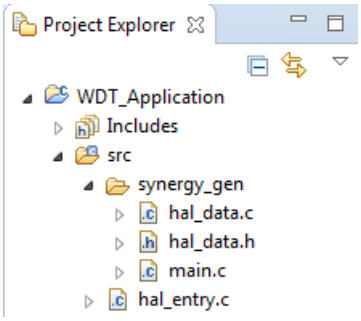

Figure 92: WDT project files

3.3.4.1 WDT hal_data.h

The contents of hal_data.h are shown below.

```
/* generated HAL header file - do not edit */

#ifndef HAL_DATA_H_

#define HAL_DATA_H_

#include <stdint.h>

#include "bsp_api.h"

#include "r_wdt.h"

#include "r_wdt_api.h"

#include "r_ioport.h"

#include "r_ioport_api.h"

#include "r_elc.h"

#include "r_elc_api.h"

#include "r_cgc.h"

#include "r_cgc_api.h"

/** WDT on WDT Instance. */

extern const wdt_instance_t g_wdt;

#ifdef NULL
```

```
#define WATCHDOG_ON_WDT_CALLBACK_USED (0)

#else

#define WATCHDOG_ON_WDT_CALLBACK_USED (1)

#endif

#if WATCHDOG_ON_WDT_CALLBACK_USED

void NULL(wdt_user_cb_data_t * p_args);

#endif

/** IOPORT on IOPORT Instance */

extern const ioport_instance_t g_ioport;

/** Pointer to ELC API */

extern const elc_instance_t g_elc;

#endif /* HAL_DATA_H_ */
```

hal_data.h contains the header files required by the ISDE generated project. In addition this file includes external references to the **g_wdt** instance structure which contains pointers to the configuration, control, api structures used for WDT HAL driver.

ATTENTION: This file is regenerated each time Generate Project Content is pressed and must not be edited.

3.3.4.2 WDT hal_data.c

The contents of hal_data.c are shown below.

```
/* generated HAL source file - do not edit */

#include "hal_data.h"

#if WATCHDOG_ON_WDT_CALLBACK_USED

#if defined(__ICCARM__)

#define NULL_WEAK_ATTRIBUTE

#pragma weak NULL = NULL_internal

#elif defined(__GNUC__)
```

```
#define NULL_WEAK_ATTRIBUTE __attribute__ ((weak,
alias("NULL_internal")))

#endif

void NULL(wdt_user_cb_data_t * p_args) NULL_WEAK_ATTRIBUTE;

#endif

static wdt_ctrl_t g_wdt_ctrl;

static const wdt_cfg_t g_wdt_cfg =

{

    .start_mode = WDT_START_MODE_REGISTER,

    .autostart = false,

    .timeout = WDT_TIMEOUT_16384,

    .clock_division = WDT_CLOCK_DIVISION_8192,

    .window_start = WDT_WINDOW_START_100,

    .window_end = WDT_WINDOW_END_0,

    .reset_control = WDT_RESET_CONTROL_RESET,

    .stop_control = WDT_STOP_CONTROL_DISABLE,

    .p_callback = NULL,

};

/* Instance structure to use this module. */

const wdt_instance_t g_wdt =

{

    .p_ctrl = &g_wdt_ctrl,

    .p_cfg = &g_wdt_cfg,

    .p_api = &g_wdt_on_wdt

};
```

```
#if WATCHDOG_ON_WDT_CALLBACK_USED

/* This is a weak example callback function. It should be */
/* overridden by defining a user callback function  */
/* with the prototype below.  */

/* - void NULL(wdt_user_cb_data_t * p_args) */

/* parameter p_args Callback arguments used to identify what caused the callback
. */

void NULL_internal(wdt_user_cb_data_t * p_args)

{

    /** Do nothing. */

}

#endif

const ioport_instance_t g_ioport =

{

    .p_api = &g_ioport_on_ioport,

    .p_cfg = NULL

};

const elc_instance_t g_elc =

{

    .p_api = &g_elc_on_elc,

    .p_cfg = NULL

};

void g_hal_init(void) {

}
```

hal_data.c contains g_wdt_ctrl which is the control structure for this instance of the WDT HAL driver. This structure should not be initialised as this is done by the driver when it is opened.

The contents of **g_wdt_cfg** are populated in this file using the **g_wdt WATCHDOG Driver on WDT Properties** pane in the **ISDE Project Configuration HAL** tab. If the contents of this structure do not reflect the settings made in the ISDE, ensure the **Project Configuration** settings are saved in the ISDE before pressing the **Generate Project Content** button.

ATTENTION: This file is regenerated each time Generate Project Content is pressed and so should not be edited.

3.3.4.3 WDT main.c

Contains main() called by the BSP start-up code. main() calls hal_entry() which contains user developed code (see next file). Here are the contents of main.c.

```
/* generated main source file - do not edit */

extern void hal_entry(void);

void main(void) {

hal_entry();

}
```

ATTENTION: This file is regenerated each time Generate Project Content is pressed and so should not be edited.

3.3.4.4 WDT hal_entry.c

This file contains the function hal_entry() called from main(). User developed code should be placed in this file and function.

For the WDT project edit the contents of this file to contain the code below. This code implements the flowchart in overview section of this document.

```
/* HAL-only entry function */

#include "hal_data.h"

#define RED_LED_NO_OF_FLASHES 30

#define RED_LED_PIN IOPORT_PORT_08_PIN_08

#define GREEN_LED_PIN IOPORT_PORT_08_PIN_07

#define RED_LED_DELAY_COUNT 1500000

#define GRN_LED_DELAY_COUNT 1200000

volatile uint32_t delay_counter;
```

```
volatile uint16_t loop_counter;

void hal_entry(void) {

    /* TODO: add your own code here */

    /* Open the WDT */

    g_wdt.p_api->open(g_wdt.p_ctrl, (wdt_cfg_t *const)g_wdt.p_cfg);

    /* Start the WDT by refreshing it */

    g_wdt.p_api->refresh(g_wdt.p_ctrl);

    /* Flash the red LED and tickle the WDT for a few seconds */

    for(loop_counter=0; loop_counter<RED_LED_NO_OF_FLASHES; loop_counter++)

    {

        /* Turn red LED on */

        g_ioport.p_api->pinWrite(RED_LED_PIN, IOPORT_LEVEL_HIGH);

        /* Delay */

        for(delay_counter=0; delay_counter<RED_LED_DELAY_COUNT; delay_counter++)
;

        /* Refresh WDT */

        g_wdt.p_api->refresh(g_wdt.p_ctrl);

        /* Turn red off */

        g_ioport.p_api->pinWrite(RED_LED_PIN, IOPORT_LEVEL_LOW);

        /* Delay */

        for(delay_counter=0; delay_counter<RED_LED_DELAY_COUNT; delay_counter++)
;

        /* Refresh WDT */

        g_wdt.p_api->refresh(g_wdt.p_ctrl);

    }
```

```
    /* Flash green LED but STOP tickling the WDT. WDT should reset the
    device */

    while(1)

    {

    /* Turn green LED on */

    g_ioport.p_api->pinWrite(GREEN_LED_PIN, IOPORT_LEVEL_HIGH);

    /* Delay */

    for(delay_counter=0; delay_counter<GRN_LED_DELAY_COUNT; delay_counter++);

    /* Turn green off */

    g_ioport.p_api->pinWrite(GREEN_LED_PIN, IOPORT_LEVEL_LOW);

    /* Delay */

    for(delay_counter=0; delay_counter<GRN_LED_DELAY_COUNT; delay_counter++);

    }

}
```

The WDT HAL driver is called through the interface **g_wdt_on_wdt** defined in **r_wdt.h**. The WDT HAL driver is opened through the open API call using the instance defined in **r_wdt_api.h**:

```
g_wdt.p_api->open(g_wdt.p_ctrl, (wdt_cfg_t *const)g_wdt.p_cfg);
```

The first passed parameter is the pointer to the control structure **g_wdt_ctrl** instantiated in hal_data.c. The second parameter is the pointer to the configuration data **g_wdt_cfg** instantiated in the same hal_data.c file.

The WDT is started and refreshed through the API call:

```
g_wdt.p_api->refresh(g_wdt.p_ctrl);
```

Again the first (and only in this case) parameter passed to this API is the pointer to the control structure of this instance of the driver.

3.3.5 Building and Testing the Project

Build the project in the ISDE **Build > Build Project**. The project should build without errors.

To debug the project

1) Connect the JLink debugger between the target board and host PC. Apply power to the board.
2) In the **Project Explorer** pane on the right side of the ISDE right-click on the WDT project **WDT_Application** and select **Debug As > Debug Configurations**.
3) Under **Renesas GDB Hardware Debugging** select **WDT_Application Debug** as shown below.

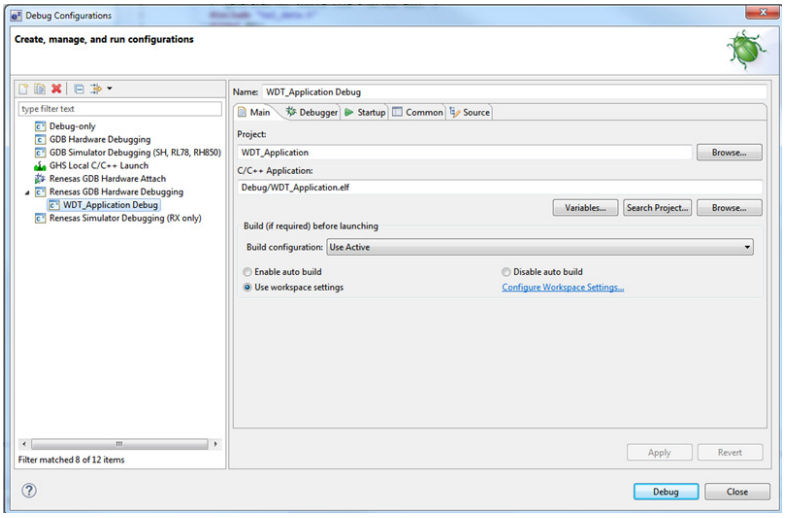

Figure 93: Debug configuration

4) Press the **Debug** button. Switch (Yes) to the Debug perspective if asked.
5) The code should run to the Reset_Handler() function.
6) Resume execution via **Run > Resume**. Execution will stop in main() at the call to **hal_entry()**.
7) Resume execution again.

The red LED should start flashing. After 30 flashes the green LED will start flashing and the red LED will stop flashing.

While the green LED is flashing the WDT will underflow and reset the device resulting in the red LED to flash again as the sequence repeats. However, this sequence does not occur when using the debugger because the WDT does not run when connected to the debugger.

1) Stop the debugger in the ISDE via **Run > Terminate**.
2) Press the reset button on the target board. The LEDs begin flashing.

3.4 IAR Embedded Workbench for Renesas

Synergy User Guide

3.4.1 Using IAR Embedded Workbench for Synergy

This section describes how to use the IAR Embedded Workbench for Renesas Synergy (IAR EW for Synergy) in combination with the Renesas Synergy Standalone Configurator (SSC) to develop applications with the Renesas Synergy Software Package (SSP). The architecture of the SSP directly determines how you use the IAR EW for Synergy and SSC to develop a Synergy application. See the following documents for details on the SSP architecture included in this manual:

- SSP Architecture
- BSP Architecture

3.4.2 What is IAR EW for Synergy?

IAR Embedded Workbench is now completely integrated with the Renesas Synergy Platform. The new product IAR EW for Synergy provides add-on functionality to simplify and accelerate software development, and provide the best performance and smallest code size.

Just like e^2 studio, IAR EW for Synergy offers secure source-level visibility into the Synergy Software Package (SSP) as well as secure source-level debugging. The developer can see protected source code but not modify or save it. Once the application code is developed, IAR EW for Synergy includes IAR C-STAT® and C-RUN® analyzers, tools which help and guide to improve application code quality.

3.4.3 Key Features

- Integrated development environment with project management tools and editor
- Highly optimizing C and C++ compiler and Linker for Renesas Synergy devices
- Integration support for Renesas Synergy Standalone Configurator (SSC)
- C-STAT and C-RUN code analysis tools included
- Extensive HW target system support
- Power debugging to visualize power consumption in correlation with source code
- C-SPY® Debugger with JTAG/SWD support and support for RTOS-aware debugging on hardware
- Support for ETM Trace
- Comprehensive user and reference guides and context-sensitive help function
- Compliant with ARM® Embedded Application Binary Interface (EABI) and ARM Cortex® Microcontroller Software Interface Standard (CMSIS)

For detailed instructions on how to download and install IAR EW for Synergy, see the IAR EW for Synergy Release Notes on the Synergy Gallery.

3.4.4 What is Synergy Standalone Configurator (SSC)?

The Synergy Standalone Configurator (SSC) is an Eclipse Rich Client Platform (RCP) application containing the Synergy Project Generator and the Synergy Project Editor as implemented in the Renesas e^2 studio ISDE. SSC includes configurators like the Clock Configurator, Pin Configurator, RTOS Configurator, SSP Module Selector/Configurator, and Interrupt Control Unit (ICU) Configurator for use with 3rd party IDEs such as IAR EW for Synergy.

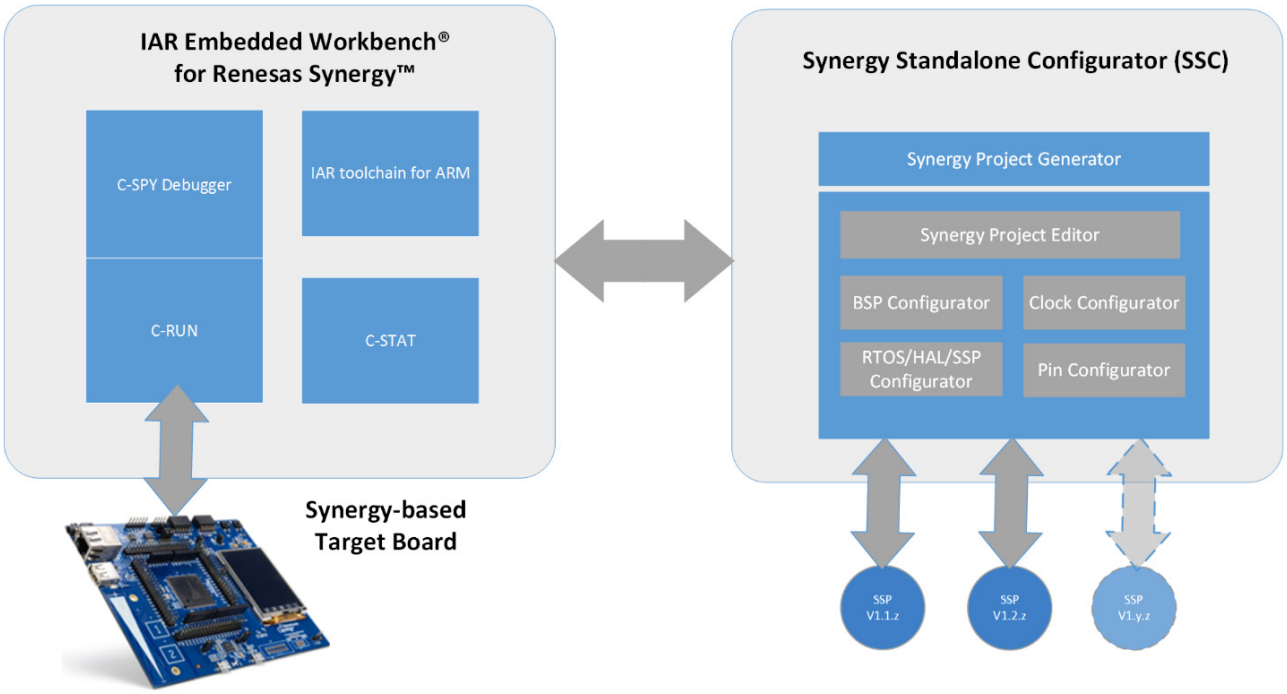

Figure 94: IAR EW for Synergy and SSC functional blockdiagram

Since the functionality of the SSC is identical to the Synergy Project Generator and the Synergy Project Editor as implemented in the Renesas e^2 studio ISDE, refer to e^2 studio ISDE User Guide for information on how to use it.

For detailed instructions on how to download and install the SSC and the SSP to use with IAR EW for Synergy, see the SSC Release Notes and the SSP Release notes on the Synergy Gallery.

3.4.5 Installing the Tools

To install the tools, follow the steps below:

1) Download and install the Renesas Synergy Standalone Configurator (SSC) from the Renesas Synergy Gallery. You can find it under Development Tools. The default installation directory is C:\Renesas\Synergy\SSC_<SSCversion>.
2) Download and install the Renesas Synergy Software Package (SSP) from the Renesas Synergy Gallery. During the installation you will be prompted to specify an installation directory for the SSP. Point the SSP installer to the directory where you just installed the SSC (for example C:\Renesas\Synergy\SSC_<SSCversion>).
3) Download and install IAR Embedded Workbench for Renesas Synergy from the Renesas Synergy Gallery. To install IAR Embedded Workbench:
    a) In your web browser, specify the URL https://synergygallery.renesas.com and download IAR Embedded Workbench for Renesas Synergy from the Renesas Synergy Gallery. You will also find information about how to obtain a license and get a license number.
    b) Execute the installer that is included in the downloaded file.

c) Specify the license number when prompted for in the IAR License Manager.

NOTE: The IAR EW for Synergy license entitles you to use this specific edition of IAR Embedded Workbench, but not the Synergy Standalone Configurator for which separate licenses are required.

3.4.6 Creating a Renesas Synergy Project using IAR EW for Synergy and SSC

To create a Synergy Project using IAR EW for Synergy and SSC, follow the steps below:

1) In the IAR Embedded Workbench IDE, choose **Project>Create New Project**.
2) In the **Create New Project** dialog box, select **Renesas Synergy Project** and click **OK**.

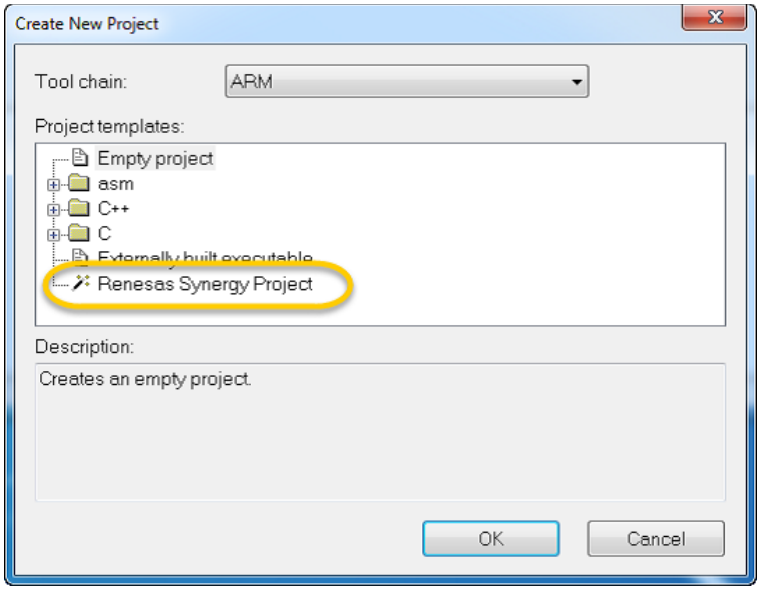

Figure 95: Creating a new Synergy Project using IAR EW for Synergy

3) In the **Save As** dialog box that appears, choose a suitable destination directory for your workspace (the container that holds your project), for example MyWorkspace, and click **Save**.

NOTE: Do not save your workspace in the root directory of your operating system (C:).

4) In the **Renesas Synergy Setting** dialog box that appears, specify:

- The location of your installed Synergy Standalone Configurator (SSC), which by default is installed in C:\Renesas\Synergy\SSC_<SSCversion>.

- The Synergy License File, which you can find in the SSC installation directory, e.g. C:\Renesas\Synergy\SSC_<SSCversion>\internal\projectgen\arm\Licenses.
- Whether or not you would like to replace any encrypted source files with decrypted ones. Note that a Renesas Synergy Source License is required for this function.

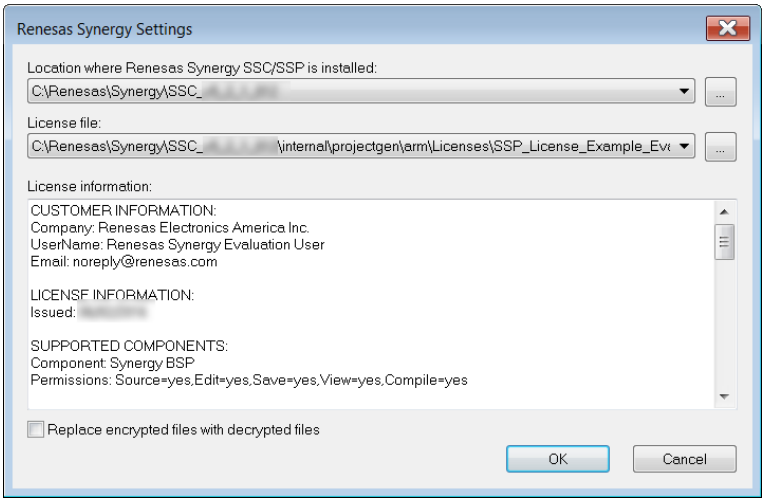

Figure 96: Renesas Synergy Settings in IAR EW for Synergy

5) Click **OK**.
6) In the **Save As** dialog box that appears, specify the name of your project, for example MyProject.

   NOTE: Do not save your project in the root directory of your operating system (C:).

7) The IAR Embedded Workbench IDE now connects with the Renesas Synergy Standalone Configurator (SSC). Specify the board support you require:

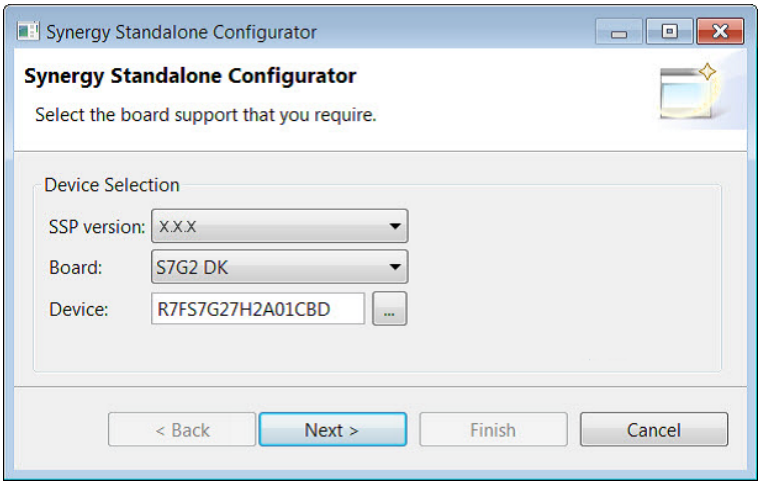

Figure 97: SSC selection dialog for SSP, board, and MCU to be

used"

NOTE: The SSP versions available in the drop-down list correspond to the versions you have previously installed on your computer.

Click **Next**.

8) The Synergy Software Packages come with several example projects, which include source code files, header files, and linker configuration files, adapted for your device. Select the example packages that you want to add to your project:

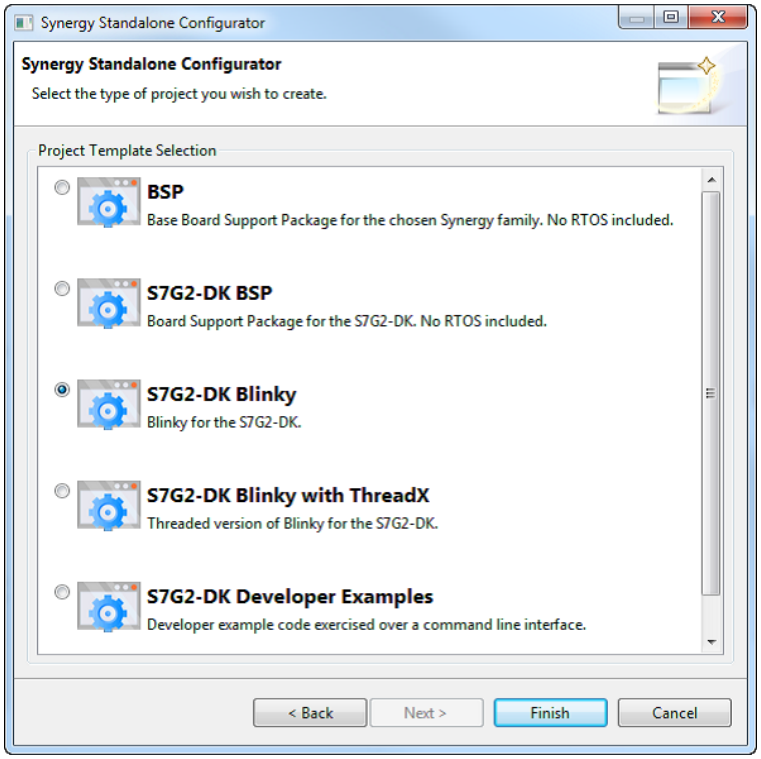

Figure 98: Project Template Selection dialog

Click **Finish**.

9) In the Synergy Project Editor that opens up, you can now configure MCU pin function assignments, clock and peripheral settings, and interrupt source assignments. When finished configuring, click the **Generate Project Content** button. The source code is now generated.

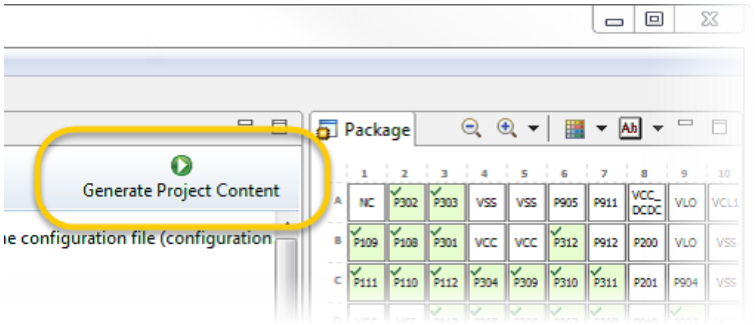

Figure 99: Generate Project Content button

NOTE: You can always add or change the configuration of your Synergy project later on.

10) After a couple of seconds, your Renesas Synergy project is displayed in the IAR EW Workspace window:

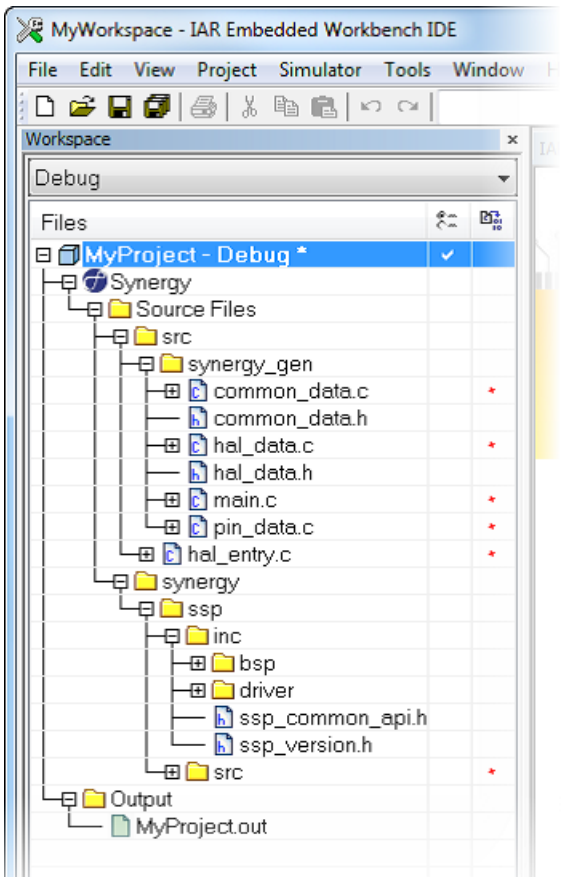

Figure 100:IAR EW for Synergy Workspace and Project window

11) If you close the SSC, you can re-open it again by clicking the Synergy Configuration button

in the toolbar, or by selecting **Renesas Synergy > Configurator** from the menu.

12) Whenever you switch back to the SSC to change configuration settings, click the **Generate Project Content** button when finished. The affected source code files are now re-generated.

13) You can now continue building and debugging according to the standard routines in the IAR Embedded Workbench IDE, see the IAR Embedded Workbench® IDE User Guide on the IAR web site.As the SSC works just like the Synergy Project Editor in e^2 studio, refer to e^2 studio ISDE User Guide for more details on how to use it.Note that the Synergy Project is by default configured for the J-Link debugging probe.If you have another debugging probe, for example I-jet or I-jet Trace, choose **Project>Options>Debugger** in the IDE and select I-jet/JTAGjet from the Driver drop-down list.

Chapter 4 Module Overviews

The Module Overviews for each SSP module have been significantly changed since the last release. The new Module Overviews should provide all the information necessary for a developer to evaluate a specific modules fitness for use in a target application and significantly help with the development process. The intent of these notes is to provide all the information needed to begin develop0ment with the target module in one easy to find location.

Each Module Overview includes the following sections:

1) A short introduction to the module includes a short description, a block diagram of key module components, and a list of features
2) An API table lists all the available APIs, and example use of the API and a short description of the APIs function. A list of some of the key Status Return values is provided to help determine the result of the API call.
3) A functional overview describes key module operations and includes a list of important module limitations.
4) A step-by-step description of how to include the module in an application using the ISDE threads tab and stack selection process.
5) A set of tables showing the configuration parameters for the module and key lower level modules is provided so the developer can easily see the modules key capabilities. Note that these configurable properties vary by MCU series and by SSP Release. Treat the tables in these notes as illustrations and refer to the actual parameters available within the ISDE for your target MCU and for your chosen SSP release. Example pin and clock configuration and selection information is also provided to help guide development.
6) A simple implementation using the target module is provided and shows the steps used in a typical application, the associated flow diagram, and the API use at each step. This helps describe how APIs are commonly used and will give the developer a head start with their implementation.

Module Guide Application Notes

These six sections are also found in the Module Guide Application Notes for a specific module. In the Application Note additional sections provide detailed descriptions of the associated application project that demonstrates the module working in an actual design. Development can be dramatically simplified when the application project is used as a starting point or reference for a new design. Module guide application notes can be found on the Renesas Synergy Tools & Kits page under the sample code tab https://www.renesas.com/en-us/products/synergy/tools-kits.html#sampleCodes More module guide application notes are being added all the time so check back frequently to find when new ones have been released.

Using the Module Guide Module Overviews

The Module Overviews provide sufficient details to begin development, but there will be cases when additional information is useful in implementing a design. The SSP User Manual provides a wealth of information on the details of API implementation, structures, enumerations and more. Simply jump to the API reference section and find your module of interest to find any additional information you might need. Here are some examples for common items and where you would find them:

- API Framework Function Details- API Reference: Framework Interfaces Example- ADC Periodic Framework, chapter 6.2.1.2 provides a list of available APIs. Click on the API in the table to see the API template, description, parameters and instance structures.
- API Framework Function Return Values- API Reference: Framework Example- ADC Periodic Framework, chapter 7.2.1 provides details on defines, return values, and the internal function steps the framework uses. HAL modules have chapters that cover the above topics as well. It is highly recommended that you spend some time looking at the reference material available in ALL the reference chapters so you know where to look when an API

implementation question, not answered in the module guide usage note or associated module guide application note, comes up.

You can find a list of Module Overviews on the following pages:

- Framework Layer
- HAL Layer
- Express Logic Modules

4.1.1 ADC Periodic Framework

The ADC Periodic Framework provides high-level APIs and is implemented on sf_adc_periodic. The module configures the ADC to sample any of the available channels (using the single-scan mode) at a configurable rate and buffers the data for a configurable number of sampling iterations before notifying the application. The ADC Periodic Framework uses the ADC, GPT or AGT, and DTC peripherals on the Renesas Synergy™ Microcontroller hardware. A user-defined callback can be created to process the data each time a new sample is complete.

4.1.1.1 ADC Periodic Framework Module Features

- 14-Bit A/D Converter (S3A7, S124) or 12-Bit A/D Converter (S7G2, S5D9) for the Synergy MCU Group
- Multiple Operation Modes
- Single Scan
- Group Scan
- Continuous Scan
- Multiple Channels
- 13 channels (unit 0), 12 channels (unit 1) for S7G2 and S5D9 Synergy MCU Groups
- 18 channels for S124
- 28 channels for S3A7

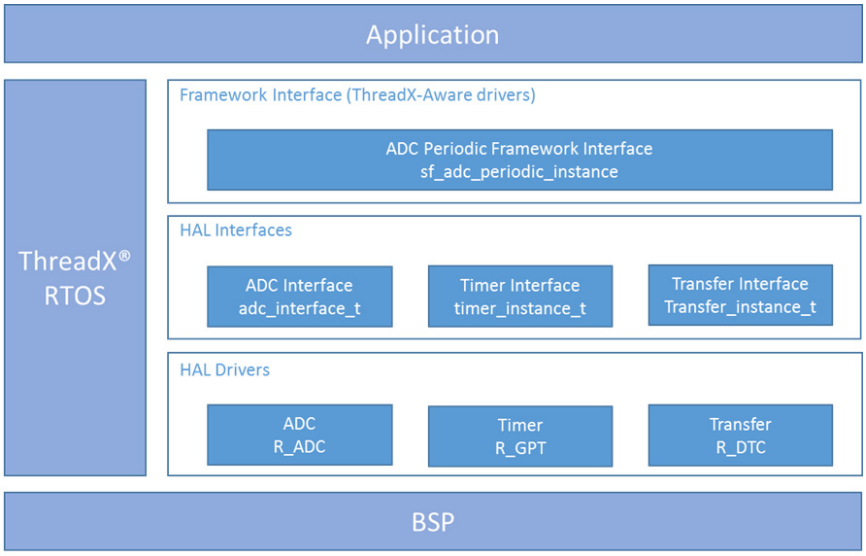

Figure 101: ADC Periodic Framework Module Block Diagram

4.1.1.2 ADC Periodic Framework Module APIs Overview

The ADC Periodic Framework defines APIs for opening, closing, starting, and stopping the ADC scans. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

ADC Periodic Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_adc_periodic.p_api->open(g_sf_adc_periodic.p_ctrl, g_sf_adc_periodic.p_cfg); Acquires mutex, then initializes module at the HAL layer.
start	g_sf_adc_periodic.p_api->start(g_sf_adc_periodic.p_ctrl); Starts the scan.
stop	g_sf_adc_periodic.p_api->stop(g_sf_adc_periodic.p_ctrl); Stops the hardware trigger (timer) from triggering any more ADC scans.
close	g_sf_adc_periodic.p_api->close(g_sf_adc_periodic.p_ctrl); Releases channel mutex and closes channel at HAL layer.
versionGet	g_sf_adc_periodic.p_api->versionGet(&version); Retrieve the API version using the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the *SSP User's Manual* API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful

Name	Description
SSP_ERR_UNSUPPORTED	Command not found in the current menu
SSP_ERR_NOT_OPEN	Driver control block not valid. Call SF_ADC_PERIODIC_Open to configure.
SSP_ERR_ASSERTION	Version get error- p_version was NULL
SSP_ERR_INTERNAL	An internal ThreadX® error has occurred. This is typically a failure to create/use a mutex or to create an internal thread.

NOTE: Lower-level drivers may return common error codes. Refer to the *SSP User's Manual* API References for the associated module for a definition of all relevant status return values.

4.1.1.3 ADC Periodic Framework Module Operational Overview

The ADC Periodic Framework module samples and buffers ADC data. The Framework notifies the application once the configured number of samples are buffered. The ADC Periodic Framework works as follows:

- After initial configuration and the scan process is started, the framework uses a hardware timer to trigger an ADC scan in one-shot mode. Each scan can consist of one or more channels. When each scan is completed, the ADC interrupt is intercepted by the DTC, which moves the result of the scan into the user buffer.
- Each scan is defined as a sampling iteration, and the number of samples generated for each scan is equal to the number of channels. If the channels are sequential (for example, channels 1, 2, 3, 4), the data is captured in order. If the channels are not in sequence (for example, channels 1, 3, 4, 5), then the samples generated by each scan also include data from the unused channels in between. Therefore, in the second example, five samples are stored to the user buffer each time.
- The user specifies the total number of sample iterations that need to occur before being notified. When the specified number of sampling iterations have occurred, and the data for each iteration has been stored into the user buffer, the user is notified via a callback with an index for the valid data in the buffer, and an event indicating that sampling for the specified number of iterations is complete.
- Unless the user stops the scan process, the scan continues to be triggered by the timer (using AGT or GPT), and data will be written into the user buffer, which is treated by the Framework as a circular buffer. The name and length of the buffer are specified via the ISDE configurator.

ADC Periodic Framework Module Operational Notes

1) At least one channel must be chosen while configuring the ADC HAL module to avoid an API return error.
2) When configuring the scan rate for the ADC Periodic Framework (the GPT or AGT timer period), make sure that the period is long enough to accommodate scanning of all selected channels (about 2 microseconds for each channel conversion on a Synergy S7G2 MCU Group device).
3) The ADC Periodic Framework stores data for all the channels from each scan into the user-specified buffer. When the specified number of sample iterations is completed, the user is notified. If five channels are selected (channels

1,2,3,4,5) and the sample count is set to 3, the user will be notified when (5 x 3 =) 15 samples are available. The samples are ordered as follows:

Figure 102: ADC Periodic Operation – Sample Order

When selecting the data buffer length in the ADC Periodic Framework configuration, make sure that the buffer length is at least twice the length of the number of samples that will be generated (15 x 2 = 30 in this example). This is because once the user application is notified that the data is available, the framework keeps buffering in new data at the sample rate. Since the buffer is treated as a circular buffer, you can inadvertently overwrite the data. If the size is not larger than the number of samples generated, the data is overwritten before the application can use it.

The application callback has an index into the appropriate location in the buffer where valid data is present.

ADC Periodic Framework Module Limitations

The ADC Periodic Framework does not currently support the following features:

- The use of group-scan mode
- The use of DMA
- When configuring the ADC channels to be used with this framework, the temperature and voltage sensors must not be selected if any of the other available channels are also selected. It is possible to use only the temperature sensor, only the voltage sensor, or any number of the regular ADC channels.
- Refer to the most recent *SSP Release Notes* for any additional operational limitations for this module.

4.1.1.4 Including the ADC Periodic Framework Module in an Application

This section describes how to include the ADC Periodic Framework module in an application using the SSP configurator.

NOTE: It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the *Getting Started Guide for SSP* given in the References section at the end of this document to learn how to manage each of these important steps in creating SSP-based applications.

To add the ADC Periodic Framework to your application, simply add it to a project thread using the stacks selection sequence given in the following table. (The default name for the ADC Periodic Framework is g_sf_adc_periodic0. This name can be changed in the associated **Properties** window.)

ADC Periodic Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_adc_periodic0 ADC Periopdic Framework	**Threads**	**New Stack> Framework> Analog> ADC Periodic Framework on sf_sdc_periodic**

When the ADC Periodic Framework on sf_adc_periodic is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information will have box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

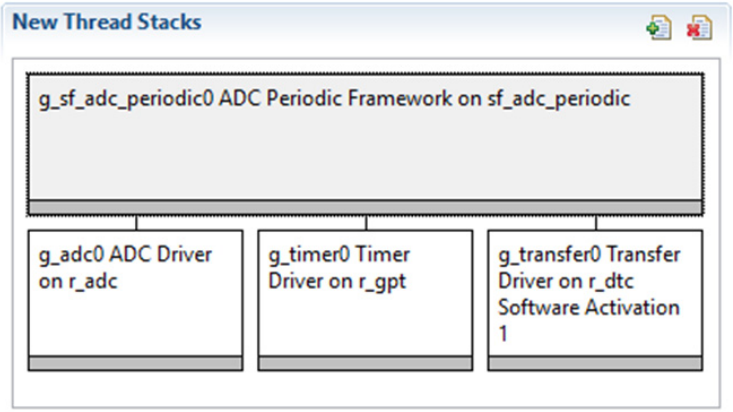

Figure 103: ADC Periodic Framework Module Stack

4.1.1.5 Configuring the ADC Periodic Framework Module

The ADC Periodic Framework module must be configured by you for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only those properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes, and are identified with a **lock** icon for the locked property in the **Properties** window within the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the **Properties** tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority. This configuration setting is available within the **Properties** window of the associated module. Simply select the indicated module and then view the **Properties** window. The interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Note that the interrupt priorities listed in the **Properties** window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE and create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the ADC Periodic Framework Module on sf_adc_periodic

Parameter	Value	Description
Parameter Checking	Enabled, Disabled, BSP (Default: BSP)	Selects if code for parameter checking is to be included in the build

Parameter	Value	Description
Name	Default: g_sf_adc0_periodic0	ADC Periodic Framework module name
Name of the data-buffer to store samples	Default: g_user_buffer	Name of the 16-bit data buffer to store samples
Length of the data-buffer	Default: 128	Length of the buffer to which data is to be stored
Number of sampling iterations	Default: 10	Number of samples captured per iteration
GPT Timer channel used to trigger the scan	Default: Channel 0	Channel used to generate the ELC event entry scan_trigger
Callback	Default: g_adc_framework_user_callback	User function that will be called once the number of sampling iterations of data has been buffered

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select a different ADC unit or enable the averaging function. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

NOTE: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated **Properties** window from the SSP configurator.

The ADC HAL module (r_adc) is used to configure the ADC unit. Most of the default properties are acceptable. The interrupt must be enabled and a name must be assigned to the module. This name is used by the application code to reference the unit.

Configuration Settings for the ADC HAL Module

Configuration Settings for the ADC HAL Module on r_adc

ISDE Property	Value	Description
Parameter Checking	Enabled, Disabled, BSP (Default: BSP)	Selects if code for parameter checking is to be included in the build
Name	Default: g_adc0	Module Name
Unit	Default: 0 (1 for S7G2 MCU)	Specify the ADC Unit to be used. The S7G2 MCU has two units, 0 and 1

ISDE Property	Value	Description
Resolution	8-bit, 10-bit, 12-bit, 14-bit (Select as per the board)	Specify the conversion resolution for this unit
Alignment	Right, Left (Default: Right)	Specify the conversion result alignment
Clear After read	On, Off (Default: On)	Specify if the result register must be automatically cleared after the conversion result is read
Mode	Single Scan, Continuous scan, group scan (Default: Single Scan)	Specify the mode that this ADC unit is used in
Channel Scan Mask Channel 0-27, Temperature sensor, Voltage Sensor	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Normal/Group A trigger	None, Asynchronous external trigger, ELC event, Software	Specify the trigger type to be used for this unit. If group mode is used mode, then this field is used to set the Group A trigger. NOTE: The only valid option in group mode is the ELC trigger.
Group B trigger	Default: ELC event	Specify the group B trigger. This option is only valid if group mode is chosen in mode.
Add Average Count	Disabled, Enabled Default: Disabled	Specify if addition or averaging needs to be done for any of the channels in this unit. The actual channels are specified by using a channel mask add_mask.

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have

different default values and available configuration settings.

ADC HAL Module Configuration Settings continued

ISDE Property	Value	Description
Group Priority	Default: Group A cannot interrupt Group B, Group A can interrupt group B; Group B scan restarts at next trigger, Group A cannot interrupt Group B, Group A can interrupt group B; Group B scan restarts immediately Group A cannot interrupt Group B, Group A can interrupt group B; Group B scan restarts and scans continuously	Determines if an ongoing group B scan can be interrupted by a group A trigger, if it should abort on a group A trigger, or if it should pause to allow group A scan and restart immediately after group A scan is complete. NOTE: This field is valid only in group mode.
Addition/ Average mask Channel 0-27, Temperature sensor, Voltage Sensor	Disabled, Enabled Default: Disabled	This field is valid only if add_average_count is enabled. This filed determines what channels results are to be averaged or summed.
Sample Hold Mask Channel 0-2	Disabled, Enabled Default: Disabled	Determines which of channels 0, 1 and 2 are using the updated sample-and-hold states value specified in sample_hold_states. This field must only be set if it is desired to modify the default sample and hold count value for channels 0, 1 and 2.

ISDE Property	Value	Description
Sample Hold States	4-255	Specifies the updated sample-and-hold count for the channel dedicated sample-and-hold circuit. This field is valid only if sample_hold_mask is not 0. Only channels 0, 1 and 2 have dedicated sample and hold circuits. NOTE: Use this to modify the default number of states (24) for which the value is sampled. Each state is equal to 1/ADCLK time.
Callback	NULL	The ADC Framework preconfigures and locks this field. User should override by defining a user call back function with prototype sf_adc_periodic_cb
Scan End Interrupt Priority	Disabled, Priority 0-15 (Default: BSP)	Specify interrupt to enable adc module
Scan End Group B interrupt priority.	Disabled, Priority 0-15 (Default: BSP)	Specify interrupt to enable adc module in group B

Configuration Settings for the GPT HAL Module

The configuration parameters for the GPT Timer Driver used with the ADC Periodic Framework module can often be used with the default settings. Typically, only a small number of settings need to be modified from the default settings. Note that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table lists the options that must be set to configure the GPT HAL module.

Configuration Settings for the GPT HAL Module

ISDE Property	Value	Description
Parameter Checking	Enabled, Disabled, BSP (Default: BSP)	Selects if code for parameter checking is to be included in the build

ISDE Property	Value	Description
GPT0 COUNTER OVERFLOW	Disabled, Priority 0-15 (Default: BSP)	Selects if code for parameter checking is to be included in the build
Name	g_timer0	Module name
Channel	0	The ADC Framework preconfigures and locks this field.
Mode	Periodic	The ADC Framework preconfigures and locks this field.
Period Value	Default: 10	Configure Timer Period to trigger ADC scans
Period Unit	Raw Counts, Nanoseconds, Microseconds, Milliseconds, Seconds, Hertz, Kilohertz (Default: Milliseconds)	Units for the Period setting
Duty Cycle Value	Default: 50	Value for the duty cycle setting
Duty Cycle Unit	Raw count, unit %, Unit % x 1000 (Default: Raw Counts)	Units used for duty cycle value
Autostart	False	The ADC Framework preconfigures and locks this field.
GTIOCA Output Enabled	True, False (Default: False)	Output is enabled or disabled by this setting
GTIOCA Stop Level	Pin level High, Low or Retained (Default: Low)	Determines output pin level after a transition
GTIOCB Output Enabled	True, False (Default: False)	Output is enabled or disabled by this setting
GTIOCB Stop Level	Pin level High, Low or Retained (Default: Low)	Determines output pin level after a transition

ISDE Property	Value	Description
Callback	NULL	The ADC Framework preconfigures and locks this field.
Interrupt Priority	Priority 0:15	Interrupt Priority

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

DTC HAL Module Configuration Settings

The DTC HAL module is configured internally by the ADC Periodic framework. Therefore, no user configuration is required (other than providing the module name). Refer to the associated property settings within the SSP configuration window for the details.

ADC Periodic Framework Module Pin Configuration

To access a channel, ADC channels must be set in the **Pins** tab of the ISDE. The following table illustrates the method for selecting the pins within the SSP configuration window.

Pin Selection for the ADC HAL Module

Resource	ISDE Tab	Pin selection Sequence
ADC	**Pins**	Select **Peripherals > Analog ADC > ADC0\1 > AN_XX**

NOTE: In the cases of the internal temperature sensor and the internal voltage sensor, there are no pin configurations required.

4.1.1.6 Using the ADC Periodic Framework Module in an Application

The key elements in constructing a simple ADC Periodic Framework module are selecting and configuring the stack, selecting a timer (GPT or AGT), defining the body of the callback function p_callback, initializing the framework, scanning the defined ADC channels, operating on the captured data as required by the application, rescanning periodically, and then stopping if the ADC measurements have been completed. The typical steps in using the ADC Periodic Framework module in an application are:

1) Initialize the ADC using the open API
2) Start the scan of channels using the start API
3) Stop the scan with the stop API
4) Read the results of the conversion using the read API
5) Close the instance using the close API

Often the scan is repeated periodically or stopped between scan operations. These common steps are illustrated in a typical operational flow diagram in the following figure:

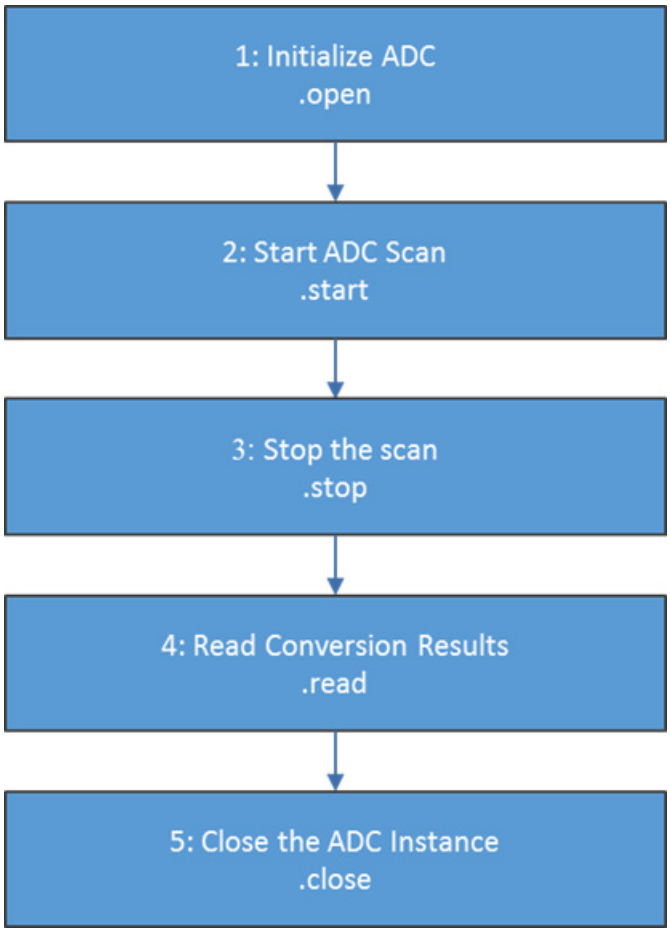

Figure 104: ADC Periodic Framework Module Application Project Flow Diagram

4.1.2 Audio Record ADC Framework

The Audio Record ADC Framework module provides high-level API for audio recording applications and is implemented on sf_adc_periodic. The Audio Record ADC Framework module uses the sf_adc_periodic and its lower layer ADC, GPT and DTC peripherals on the Synergy MCU. A user-defined callback can be created to indicate that the sample count has been completed.

4.1.2.1 Audio Record ADC Framework Module Features

- Records data in 8- or 12-bit PCM
- Uses ADC Periodic Framework to simplify configuration and integration
- Uses ThreadX object, like mutex, to protect hardware from improper access

- APIs for high-level functions simplify coding:
  - open, start
  - stop, infoGet
  - close

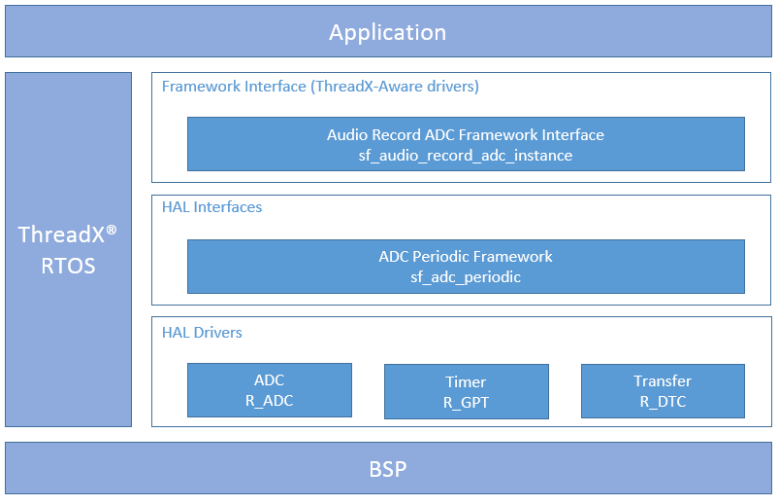

Figure 105: Audio Record ADC Framework Module Organization, Options and Stack Implementations

4.1.2.2 Audio Record ADC Framework Module APIs Overview

The Audio Record ADC Framework module defines APIs for opening, closing, starting, and stopping the record process. A complete list of the available APIs, an example API call, and a short description of each can be found in the table below. A table of status return values follows.

Audio Record ADC Framework Module API Summary

Function Name	Example API Call and Description
.open	g_sf_audio_record_adc.p_api->open(g_sf_audio_record_adc.p_ctrl, g_sf_audio_record_adc.p_cfg); Initialize the module.
.start	g_sf_audio_record_adc.p_api->start(g_sf_audio_record_adc.p_ctrl); Start audio recording.

Function Name	Example API Call and Description
.stop	g_sf_audio_record_adc.p_api->stop(g_sf_audio_record_adc.p_ctrl); Stop audio recording.
.infoGet	g_sf_audio_record_adc.p_api->infoGet(g_sf_audio_record_adc.p_api.*p_ctrl*); Get the channel information (mono or Stereo).
.close	g_sf_audio_record_adc.p_api->close(g_sf_audio_record_adc.p_ctrl); Close the module.
.versionGet	g_sf_audio_record_adc.p_api->versionGet(&version); Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manuals API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_IN_USE	The adc periodic framework mutex may be unavailable for the unit requested. See HAL driver for other possible causes.
SSP_ERR_INTERNAL	An internal ThreadX error has occurred. This is typically a failure to create/use a mutex or to create an internal thread.
SSP_ERR_NOT_OPEN	Unit is not open
SSP_ERR_ASSERTION	The parameter p_ctrl or p_sample is NULL.

Name	Description
SSP_ERR_UNSUPPORTED	This function is not supported by the HAL driver (p_ctrl->p_api->close is NULL).

NOTE: Lower level drivers may return Common Error Codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.2.3 Audio Record ADC Framework Module Operational Overview

The Audio Record ADC Framework module samples audio analog data using the ADC Periodic Framework and the data samples captured are stored in the user buffer. The data is made available for further processing as needed by the application. The Audio Record ADC Framework has a configuration parameter that is initialized during the framework initialization, which also initializes the underlying ADC periodic framework for data capture.

The captured data is stored in a user defined buffer and this is done in the callback function as illustrated below:

Assuming the name of the callback has been configured to be sf_audio_record_user_callback.

```
uint16_t * audio_record_buffer;
void sf_audio_record_user_callback (sf_audio_record_callback_args_t *p_args)
{
audio_record_buffer = ((uint16_t *)g_sf_audio_record_adc.p_cfg->
    p_capture_data_buffer + (p_args->buffer_index/2)); }
```

Audio Record ADC Framework Module Important Operational Notes and Limitations

- The Audio Record ADC Framework Module configuration data can specify the length of the data buffer, data width, sampling rate and the number of sampling iterations.
- Currently the Audio Record ADC only supports the ADC Periodic Framework as the lower level and thus recording via I2S is not supported with the framework.
- The framework currently supports 12-bit ADCs (supports 8, 10, and 12 bits) and 14-bit ADCs (supports 14- or 12-bit PCM data).
- Currently the Audio record ADC only supports Mono Channel.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.2.4 Including the Audio Record ADC Framework Module in an Application

This section describes how to include the Audio Record ADC Framework Module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP based applications.

To add the Audio Record ADC framework module to an application, simply add it to a thread using the Stacks Selection Sequence given in the table below. (The default name for the Audio Record ADC Framework Module is g_audio_record_adc0. This name can be changed in the associated Properties window.)

Audio Record ADC Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_audio_record_adc0 Audio Record ADC Framework on sf_audio_record_adc	Threads	New Stack> Driver> Audio> Audio Record ADC Framework on sf_audio_record_adc

When the Audio Record ADC on sf_audio_record_adc is added to the Thread Stack as shown in the figure below, the configurator automatically adds any needed lower level drivers.

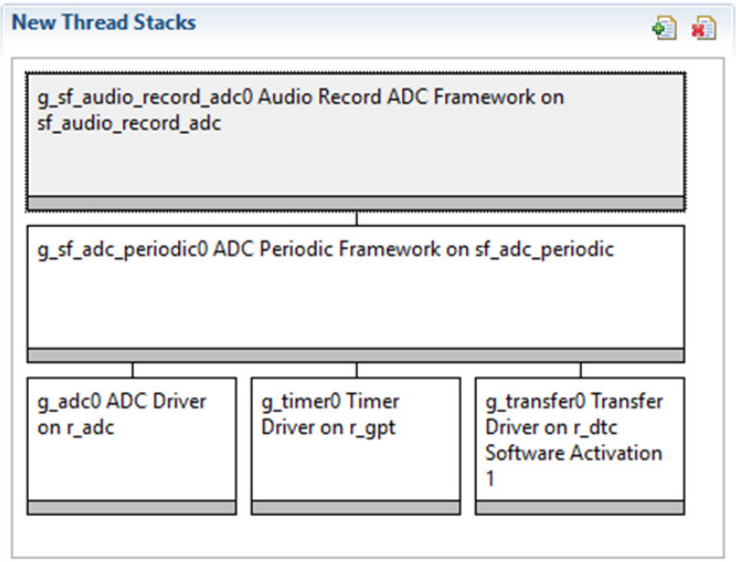

Figure 106: Audio Record ADC Framework Module Stack

4.1.2.5 Configuring the Audio Record ADC Framework Module

The Audio Record ADC Framework Module must be configured by you for the desired operation. The SSP configuration window will automatically identify, by highlighting the block in red, any required configuration selections, such as Interrupts or operating modes, which must be configured for lower level modules, for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the properties tab within the SSP Configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the Interrupt Priority. This configuration setting is available with the Properties window of the associated module. Simply select the indicated module and then view the properties window. The Interrupt settings are often toward the bottom of the properties list, so scroll down until they

become available. Also note that the Interrupt Priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the below configuration properties tables, but is easily visible with the ISDE when configuring Interrupt Priority levels.

NOTE: You may want to open your ISDE and create the module and explore the property settings in parallel with looking over the Configuration Table Settings given below. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for Audio Record ADC Framework Module on sf_audio_record_adc

ISDE Property	Value	Description
Parameter Checking	Enabled, Disabled, BSP Default: BSP	Selects if code for parameter checking is to be included in the build
Name	g_sf_audio_record_adc0	Module name
Name of the data-buffer to store samples	P_capture_data_buffer	Name of the data buffer to store samples
Length of the data-buffer	2048	Length of the buffer to which data is to be stored
Audio Record Data Size	8-bit, 16-bit Default: 8-bit	Data width
Sampling Rate in HZ	8000	Sampling rate
Number of sampling iterations	Default: 256	Number of samples captured per iteration
Callback	g_audio_redord_framework_user_callback	User function that will be called once the number of sampling iterations of data has been buffered.

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for stack modules can be desirable. For example, it might be useful to select different buffer sizes or sample rates. The configurable properties for the lower level stack modules are given in the below sections for completeness and as a reference.

NOTE: Most of the property settings for modules are fairly intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the Audio Record ADC Framework Module Low Level Drivers

Typically, only a small number of settings must be modified from the default for lower level drivers and these are indicated via the red text in the Thread Stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The tables below identify all the settings within the properties section for the module.

Configuration Settings for ADC Periodic Framework on sf_adc_periodic

ISDE Property	Value	Description
Parameter Checking	Enabled, Disabled, BSP Default: BSP	Selects if code for parameter checking is to be included in the build
Name	g_sf_adc_periodic0	Module name
Name of the data-buffer to store samples	g_user_buffer	Name of the data buffer to store samples
Length of the data-buffer	2048	Length of the buffer to which data is to be stored
Number of sampling iterations	256	Number of samples captured per iteration
GPT Timer channel used to trigger scan	Channel 0-12	Channel number
Callback	g_audio_redord_framework_user_callback	User function that will be called once the number of sampling iterations of data has been buffered.

Configuration Settings for the ADC HAL Module on r_adc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: Enabled	If selected code for parameter checking is included in the build.
Name	g_adc0	Module name
Unit	0, 1 (S7G2 Only) Default: 0	Specify the ADC Unit to be used. The S7G2 has two units; 0 and 1.

ISDE Property	Value	Description
Resolution	14-Bit (S3A7/S124 Only), 12-Bit, 10-Bit (S7G2 Only), 8-Bit (S7G2 Only) Default: 8-Bit (S7G2 Only)	Specify the conversion resolution for this unit.
Alignment	Right, Left Default: Right	Specify the conversion result alignment.
Clear after read	Off, On Default: On	Specify if the result register must be automatically cleared after the conversion result is read. NOTE: If this is enabled, then watching the result register using a debugger always results in a 0.
Mode	Single Scan	The ADC Framework preconfigures and locks this field.
Channels 0-6	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channels 7-10 (S3A7/S124 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.

ISDE Property	Value	Description
Channels 11-15 (S3A7 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channels 16-20	Unused, Use in Normal/Group A, Use in Group B (Default: Unused)	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channel 21 (Unit 0 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channel 22 (S3A7/S124 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channels 23-27 (S3A7 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.

ISDE Property	Value	Description
Temperature Sensor	Unused, Use in Normal/Group A, Use in Group B Default: Unused	Temperature sensor use selection for Channel Scan Mask
Voltage Sensor	Unused, Use in Normal/Group A, Use in Group B Default: Unused	Voltage sensor use selection for Channel Scan Mask
Scan Mask Group B	Use #define ADC_MASK_xxx which are defined in r_adc.h. Use (ADC_MASK_xxx / ADC_MASK_xxx) for multiple channels.	Do not use with ADC Framework since the mode is locked to Single Scan Mode.
Normal/Group A Trigger	ELC Event	The ADC Framework preconfigures and locks this field.
Group B Trigger (Valid Only in Group Scan Mode)	ELC Event (The only valid trigger for either group in Group Scan Mode)	The ADC Framework preconfigures and locks this field.
Group Priority (Valid only in Group Scan Mode)	Group A cannot interrupt Group B, Group A can interrupt Group B; Group B scan restarts at next trigger, Group A can interrupt Group B; Group B scan restarts immediately, Group A can interrupt Group B; Group B scan restarts immediately and scans continuously (Default: Group A cannot interrupt Group B)	Do not use with ADC Framework since the mode is locked to Single Scan Mode.
Add/Average Count	Disabled, Add two samples, Add three samples, Add four samples, Add sixteen samples, Average two samples, Average four samples Default: Disabled	Specify if addition or averaging needs to be done for any of the channels in this unit. The actual channels are specified by using a channel mask add_mask.
Channels 0-27	Disabled, Enabled Default: Disabled	This field is valid only if add_average_count is enabled. This field determines what channels results are to be averaged or summed.

ISDE Property	Value	Description
Temperature Sensor	Disabled, Enabled Default: Disabled	Temperature sensor use selection for Addition/Averaging Mask
Voltage Sensor	Disabled, Enabled Default: Disabled	Voltage sensor use selection for Addition/Averaging Mask
Channels 0-2	Disabled, Enabled Default: Disabled	Determines which of channels 0, 1 and 2 are using the updated sample-and-hold states value specified in sample_hold_states. This field must only be set if it is desired to modify the default sample and hold count value for channels 0, 1 and 2.
Sample Hold States (Applies only to the 3 channels selected above)	24	Specifies the updated sample-and-hold count for the channel dedicated sample-and-hold circuit. This field is valid only if sample_hold_mask is not 0. Only channels 0, 1 and 2 have dedicated sample and hold circuits. NOTE: Use this to modify the default number of states (24) for which the value is sampled. Each state is equal to 1/ADCLK time.
Callback	NULL	The ADC Framework uses the callback internally.
Scan End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Scan End Interrupt Priority selection

ISDE Property	Value	Description
Scan End Group B Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Scan End Group B Interrupt Priority selection

Configuration for the GPT HAL Module on r_gpt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_timer0	Module name.
Channel	0	The ADC Framework preconfigures and locks this field based on channel selected in the ADC Framework.
Mode	Periodic	The ADC Framework preconfigures and locks this field.
Period Value	10	Configure timer period to trigger ADC scans.
Period Unit	Raw Counts, Nanoseconds, Microseconds, Milliseconds, Seconds, Hertz, Kilohertz Default: Milliseconds	Configure units of the timer period set above.
Duty Cycle Value	50	Duty cycle value selection
Duty Cycle Unit	Unit Raw Counts, Unit Percent, Unit Percent x 1000 Default: Unit Raw Counts	Duty cycle unit selection

ISDE Property	Value	Description
Auto Start	False	The ADC Framework preconfigures and locks this field.
GTIOCA Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCA Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	Controls output pin level when the timer is stopped.
GTIOCB Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCB Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	Controls output pin level when the timer is stopped.
Callback	NULL	The ADC Framework preconfigures and locks this field.
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Audio Record ADC Framework Module Clock Configuration

The ADC peripheral module uses PCLKC as its clock source.

Audio Record ADC Framework Module Pin Configuration

The ADC peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. ADC pins must be configured as analog pins. The first table below

illustrates the method for selecting the pins within the SSP configuration window and the following table illustrates an example selection for the pins.

NOTE: For some peripherals, the Operation Mode selection mode determines what peripheral signals are available and thus what MCU pins are required.

Pin Selection Sequence for ADC

Resource	ISDE Tab	Pin selection Sequence
ADC	Pins	Select Peripherals > Analog: ADC > ADC/ADC0/ADC1

NOTE: The above selection sequence assumes ADC0 is the desired hardware target for the driver.

Pin Configuration Settings for ADC

Pin Configuration Property	Value	Description
Operation Mode	Disabled, Custom (Default: Custom)	Select operating mode for ADC
ADTRG	None, P407, P102 (Default: None)	ADTRG Pin
AN00-19	None, Pnnn, Pmmm (Default: None)	Analog input pins
PGAVSS0	None, P003 (Default: None)	PGAVSS pin

NOTE: The above example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.1.2.6 Using the Audio Record ADC Framework Module in an Application

The typical steps in using the Audio Record ADC Framework module in an application are:

1) Open the module using the open API
2) Start the recording using the start API
3) Store data in a user buffer with the callback

4) Operate on data as needed
5) Close the module using the close API

The above common steps are illustrated in a typical operational flow diagram in the figure below.

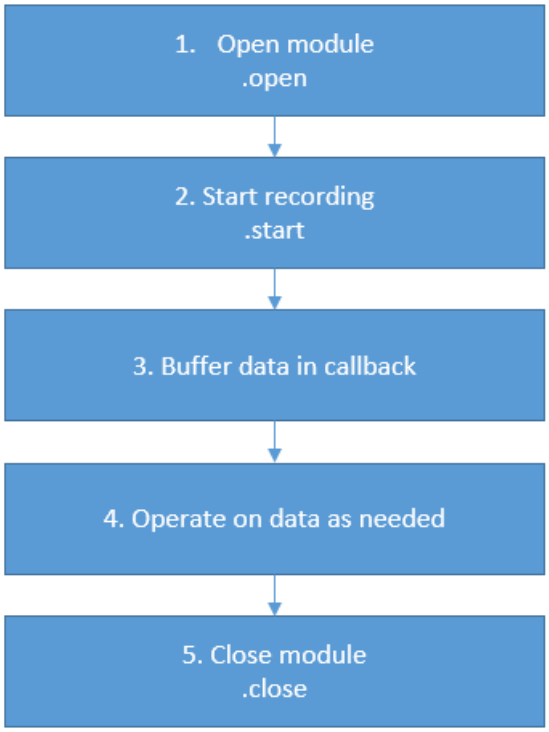

Figure 107: Flow Diagram of a Typical Audio Record ADC Framework Module Application

4.1.3 Audio Record I2S Framework

The Audio Record I2S Framework module provides high-level APIs for audio recording applications and uses the I2S interface. The Audio Record I2S Framework module uses the SSI, GPT and DTC peripherals on the Synergy MCU. A user-defined callback can be created to indicate that new samples are stored in the user buffer..

4.1.3.1 Audio Record I2S Framework Module Features

- Thread safe
- Records data in 8 or 16-bit PCM
- Periodic callback function when new samples are available
- Configurable number of samples (sample count) per callback

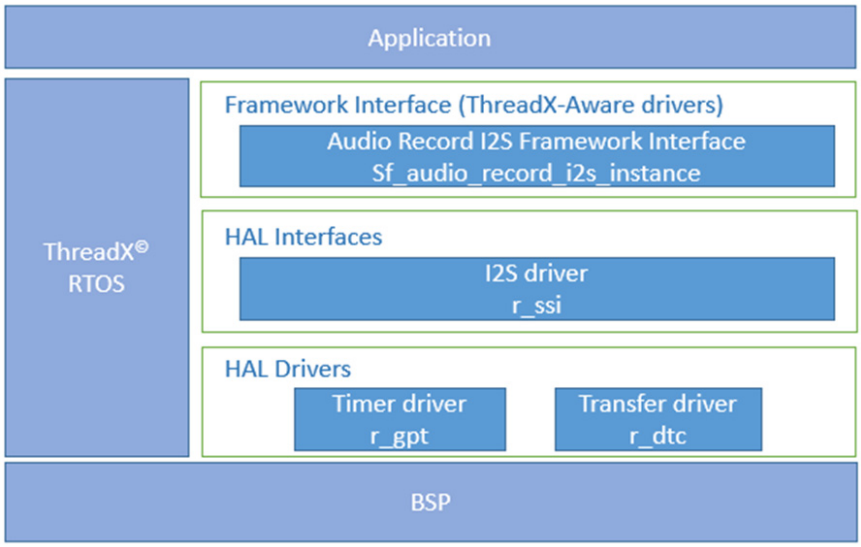

Figure 108: Audio Record I2S Framework Module Block Diagram

4.1.3.2 Audio Record I2S Framework Module APIs Overview

The Audio Record I2S Framework module defines APIs to open, start, stop and close the recording module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Audio Record I2S Framework Module API Summary

Function Name	Example API Call and Description
.open	g_sf_audio_record_i2s0.p_api->open (g_sf_audio_record_i2s0.p_ctrl, g_sf_audio_record_i2s0.p_cfg); Initializes audio recording framework.
.start	g_sf_audio_record_i2s0.p_api->start (g_sf_audio_record_i2s0.p_ctrl); Starts audio recording.

Function Name	Example API Call and Description
.stop	g_ sf_audio_record_i2s0.p_api->stop (g_sf_audio_record_i2s0.p_ctrl); Stops audio recording.
.infoGet	g_sf_audio_record_i2s0.p_api->infoGet (g_sf_audio_record_i2s0.p_ctrl, p_info); Gets channel information (Mono/Stereo).
.close	g_sf_audio_record_i2s0.p_api->close (g_sf_audio_record_i2s0.p_ctrl); Releases channel *mutex* and closes channel at HAL layer.
.versionGet	g_ sf_audio_record_i2s0.p_api->versionGet(&version); Gets version and stores it in provided version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_INTERNAL	An internal TheadX error has occurred.
SSP_ERR_NOT_OPEN	Unit is not open
SSP_ERR_ASSERTION	The parameter p_ctrl or p_sample is NULL.
SSP_ERR_IN_USE	Peripheral is still running in another mode; perform Close first.

Name	Description
SSP_ERR_UNSUPPORTED	Command not supported.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.1.3.3 Audio Record I2S Framework Module Operational Overview

The Audio Record I2S Framework Module uses the I2S HAL layer as the underlying interface for the audio data transfer and the data captured is stored in the user buffer. The data is made available for further processing as needed by the application.

The captured data is stored in a user defined buffer and this is done in the callback function as illustrated below:

Assuming the name of the callback has been configured to be sf_audio_record_user_callback.

```
uint16_t * audio_buffer;
void audio_record_user_callback (sf_audio_record_callback_args_t * p_args)
{
    audio_buffer = ((uint16_t *)sf_audio_record_i2s.p_cfg->p_capture_data_buffer
                    + (p_args->buffer_index));
}
```

Audio Record I2S Framework Module Important Operational Notes and Limitations

The Audio Record I2S Framework Module configuration data can specify the name of the data buffer, length of the data buffer, data size (8-bit or 16-bit samples), sampling iterations and the name of the callback.

- The framework currently supports recording 8 bit or 16 bit PCM data.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.3.4 Including the Audio Record I2S Framework Module in an Application

This section describes how to include the Audio Record I2S Framework module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Audio Record I2S Framework module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the Audio Record I2S Framework module is g_sf_audio_record_i2s0. This name can be changed in the associated Properties window.)

Audio Record I2S Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_audio_record_i2s0 Audio Record I2S Framework on sf_audio_record_i2s	Threads	New Stack> Framework> Audio> Audio Record I2S Framework on sf_audio_record_i2s

When the Audio Record I2S Framework module on sf_audio_record_i2s is added to the thread stack as shown in the following figure, the configurator automatically adds any lower-level drivers that are required. Any drivers that need additional configuration information will be box-text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

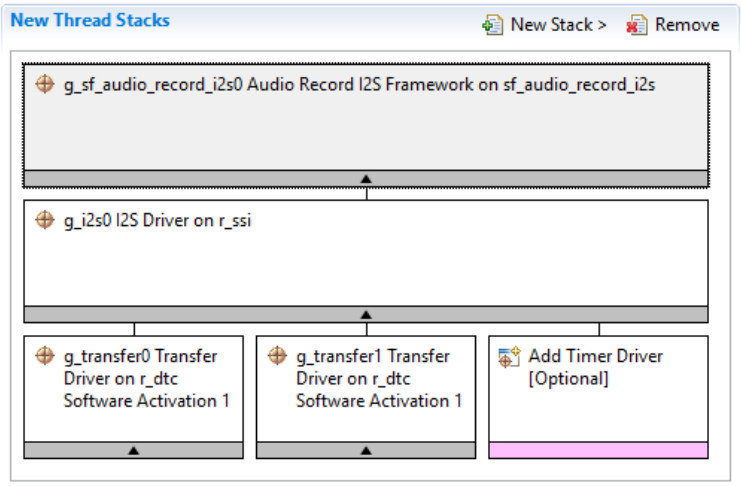

Figure 109: Audio Record I2S Framework Module Stack

4.1.3.5 Configuring the Audio Record I2S Framework Module

The Audio Record I2S Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the Audio Record I2S Framework Module on sf_audio_record_i2s

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_sf_audio_record_i2s0	Module name.
Name of the data-buffer to store samples	p_capture_data_buffer	Data-buffer name.
Length of the data buffer	2048	Length of the data buffer
Audio Record Data Size	8-Bit, 16-Bit Default: 16-Bit	Audio record data size selection
Number of sampling iterations	256	Number of sampling iterations
Callback	g_audio_record_framework_user_callback	Callback name.
Name of generated initialization funcion	sf_audio_record_i2s_init0	Name of generated initialization function.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the I2S HAL Module on r_ssi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_i2s0	Module name.
Channel	0	Physical hardware channel.
Audio Clock Frequency (Hertz)	2822400	Input audio clock frequency, used to generate the I2S clock. Must be a multiple between 1 and 128 of: (sampling_freq_hz * word_length_in_bits)
Sampling Frequecy (Hertz)	44100	Sampling frequency of audio data.
Data Bits	8 bits, 16, 18, 20, 22, 24 Default: 16 bits	Bit depth of audio data, which is the size in bits of one sample of audio data.
Word Length	8 bits, 16, 24, 32 Default: 16 bits	Word length of audio data, must be at least the same size as the bit depth (Data Bits field).
WS Continue Mode	Enabled, Disabled Default: Disabled	Enable WS continue mode to continue to output the word select line when the peripheral is idle. Disable to stop outputting the word select line when the peripheral is idle.
Audio Clock Frequency (Hertz)	External, GTIOC1A Default: External	Select External for external signal to AUDIO_CLK input pin or GTIOCA1.

ISDE Property	Value	Description
Name of I2S callback function to be defined by user	NULL	A user callback function must be registered in open. The callback will be called from the interrupt service routine (ISR) when the transmission FIFO reaches the high watermark point after all data for transmission is transmitted or when reception is complete (the requested number of bytes have been received). Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Transmit interrupt priority selection
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Receive interrupt priority selection
Idle/Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Idle/error interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different

default values and available configuration settings.

Configuration Settings for the DTC HAL Module on r_dtc Software Activation

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer0	Driver name.
Mode	Normal	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	FALSE	Auto enable selection.

ISDE Property	Value	Description
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC software event interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the DTC HAL Module on r_dtc Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer1	Driver name.
Mode	Normal	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.

ISDE Property	Value	Description
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	FALSE	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC software event interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the AGT HAL Module on r_agt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection
Name	g_timer0	Module name

ISDE Property	Value	Description
Channel	0	Channel selection
Mode	Periodic	Mode selection
Period Value	2822400 *2	Period value selection
Period Unit	Hertz	Period unit selection
Auto Start	FALSE	Auto start selection
Count Source	PCLKB, PCLKB/8, PCLKB/2, LOCO, AGT0 Underflow, AGT0 fSub Default: PCLKB	Count source selection
AGTO Output Enabled	True, False Default: False	AGTO output selection
AGTIO Output Enabled	True, False Default: False	AGTIO output selection
Output Inverted	True, False Default: False	Output inverted selection
Enable comparator A output pin	True, False Default: False	Enable comparator A output pin selection
Enable comparator B output pin	True, False Default: False	Enable comparator B output pin selection
Callback	NULL	Callback selection

ISDE Property	Value	Description
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the GPT HAL Module on r_gpt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection
Name	g_timer0	Module name
Channel	0	Channel selection
Mode	Periodic	Mode selection
Period Value	2822400 * 2	Period value selection
Period Unit	Hertz	Period unit selection
Duty Cycle Value	50	Duty cycle value selection
Duty Cycle Unit	Unit Raw Counts, Unit Percent, Unit Percent x 1000 Default: Unit Raw Counts	Duty cycle unit selection
Auto Start	FALSE	Auto start selection
GTIOCA Output Enabled	True, False Default: False	GTIOCA output enabled selection

ISDE Property	Value	Description
GTIOCA Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	GTIOCA stop level selection
GTIOCB Output Enabled	True, False Default: False	GTIOCB output enabled selection
GTIOCB Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	GTIOCB stop level selection
Callback	NULL	Callback selection
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Audio Record I2S Framework Module Clock Configuration

The Audio Record I2S Framework module uses the PCLKB as its clock source.

To change the clock frequency at run-time, use the CGC Interface.

Audio Record I2S Framework Module Pin Configuration

To use the Audio Record I2S Framework module, the port pins for the peripheral inputs and outputs must be set in the pin configurator in the ISDE. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection Sequence for the Audio Record I2S Framework Module

Resource	ISDE Tab	Pin selection Sequence
SSI	Pins	Select Peripherals > Peripherals>Connectivity:SSI>SSI/SSI0/SSI1

4.1.3.6 Using the Audio Record I2S Framework Module in an Application

The typical steps in using the Audio Record I2S Framework module in an application are:

1) Initialize the module using the open API
2) Start the recording using the start API
3) Operate on data from the periodic callback function as needed
4) Close the module using the close API

These common steps are illustrated in a typical operational flow in the following figure:

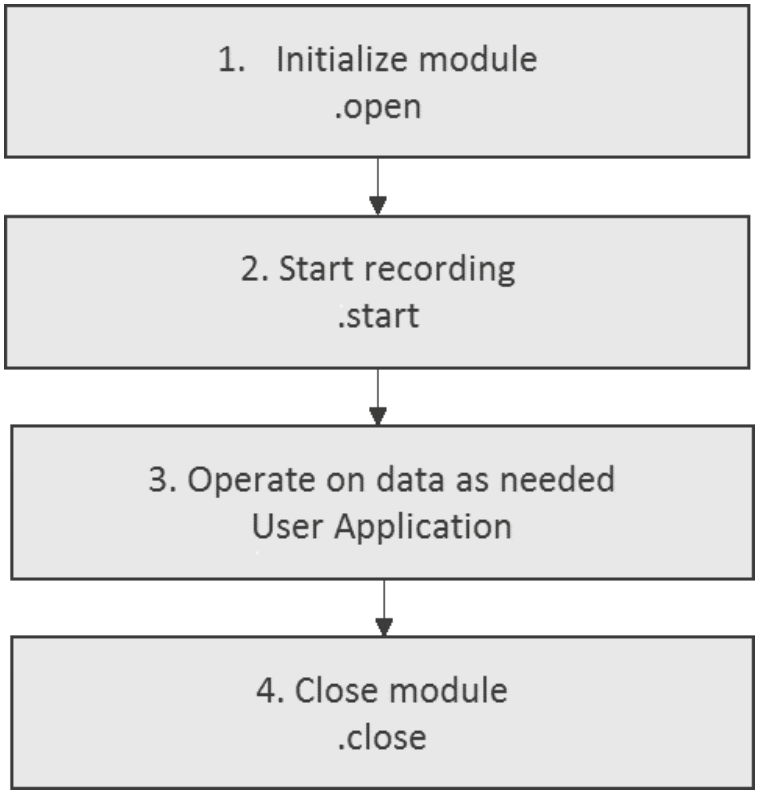

Figure 110: Flow Diagram of a Typical Audio Record I2S Framework Module Application

4.1.4 Audio Playback Framework

The Audio Playback Framework module provides high-level APIs for audio playback applications and is implemented on either sf_audio_playback_hw_dac or sf_audio_playback_hw_i2s. It handles the synchronization needed to play 16-bit and 8-bit pulse-code modulation (PCM) samples. The Audio Playback Framework uses the DAC (DAC12 or DAC8) or I2S, timer (AGT or GPT) and data-transfer (DMA or DTC) peripherals on a Synergy MCU. A user-defined callback can be created to respond to the need for additional data.

4.1.4.1 Audio Playback Framework Module Features

The Audio Playback Framework module supports the following features:

- Plays long buffers by splitting the data into manageable chunks
- Repeats playback until a ThreadX timeout (for repeated audio like sine wave tones or looped background music)
- Requests next data using callback after last buffer playback begins
- Software volume control
- Pause and resume functions
- Scaling, for example to move signed 16-bit PCM data into range of the unsigned 12-bit DAC or unsigned 8-bit DAC8
- Basic mixing for multiple streams.

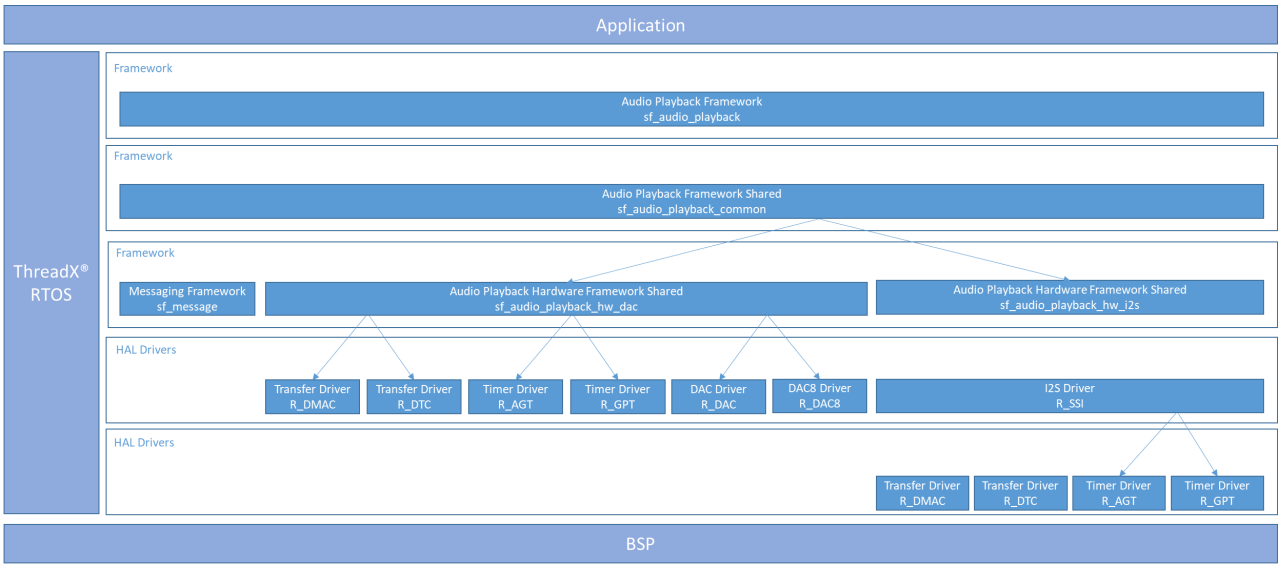

Figure 111: Audio Playback Framework Stack Options

4.1.4.2 Audio Playback Framework Module APIs Overview

The Audio Playback Framework module defines APIs for operations such as opening, starting, playing and stopping. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Audio Playback Framework API Summary

Function Name	Example API Call and Description
.open	g_sf_audio_playback0.p_api->open(g_sf_audio_playback0.p_ctrl, g_sf_audio_playback0.p_cfg); Open a device channel for read/write and control.
.start	g_sf_audio_playback0.p_api->start(g_sf_audio_playback0.p_ctrl, p_data, Timeout); Start Audio Playback Hardware.
.pause	g_sf_audio_playback0.p_api->pause(g_sf_audio_playback0.p_ctrl); Pause Audio Playback Hardware.
.stop	g_sf_audio_playback0.p_api->stop(g_sf_audio_playback0.p_ctrl); Stop Audio Playback Hardware.
.resume	g_sf_audio_playback0.p_api->resume(g_sf_audio_playback0.p_ctrl, &buffer, length); Resume playback.
.volumeSet	g_sf_audio_playback0.p_api->volumeSet(g_sf_audio_playback0.p_ctrl, volume); Sets volume.
.close	g_sf_audio_playback0.p_api->close(g_sf_audio_playback0.p_ctrl); Close the audio module.
.versionGet	g_sf_audio_playback0.p_api->versionGet(&version); Return the version of the module using the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manuals API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_ASSERTION	A pointer is NULL or a parameter is invalid.

Name	Description
SSP_ERR_OUT_OF_MEMORY	The number of streams open at once is limited to SF_AUDIO_PLAYBACK_CFG_MAX_STREAMS. If this number is exceeded, an out of memory error occurs.
SSP_ERR_TIMEOUT	Timeout occurred before playback finished.
SSP_ERR_NOT_OPEN	The stream control block p_ctrl is not initialized.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.4.3 Audio Playback Framework Module Operational Overview

The Audio Playback Framework module creates a thread internally to support audio playback. The following figure shows a flowchart of the audio playback framework thread and its interactions with public Audio Playback Framework APIs.

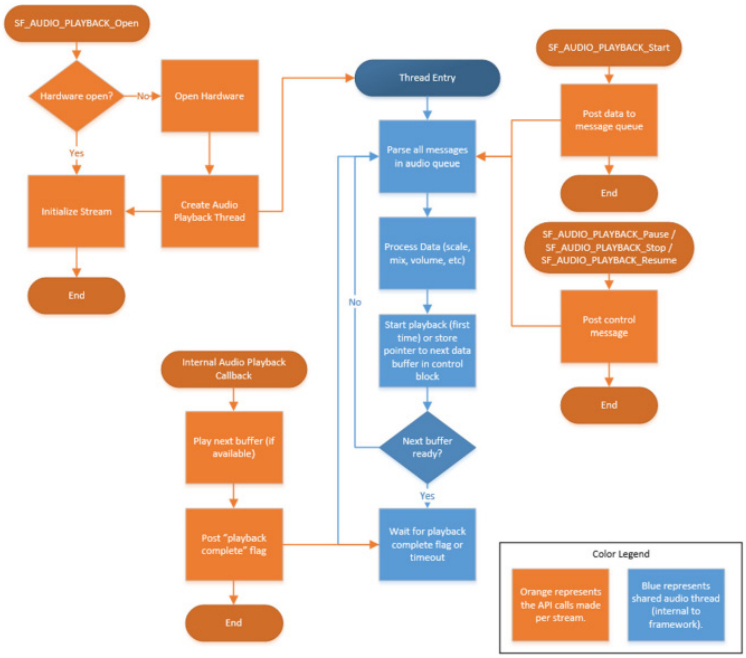

Figure 112: Audio Playback Framework Flowchart

Suggested use of the audio playback framework:

- Create a semaphore (for example, g_sf_audio_playback_semaphore). This can be done on the **Threads** tab. Set the initial value to 2 (the audio playback framework can store up to two data messages per stream).

- Create a callback function (for example, sf_audio_playback_callback). Enter the name of your callback function in the Audio Playback Framework instance. The callback function will be called when the audio playback framework is done with the data. In the callback, put the semaphore created above.
- In your main loop, get the semaphore before playing data. To play data, first acquire a buffer from the messaging framework, then create your audio playback data structure inside the buffer.

The Audio Playback Framework supports multiple audio streams on a single hardware port. A block diagram of the modules required if two streams are used is shown in the following figure:

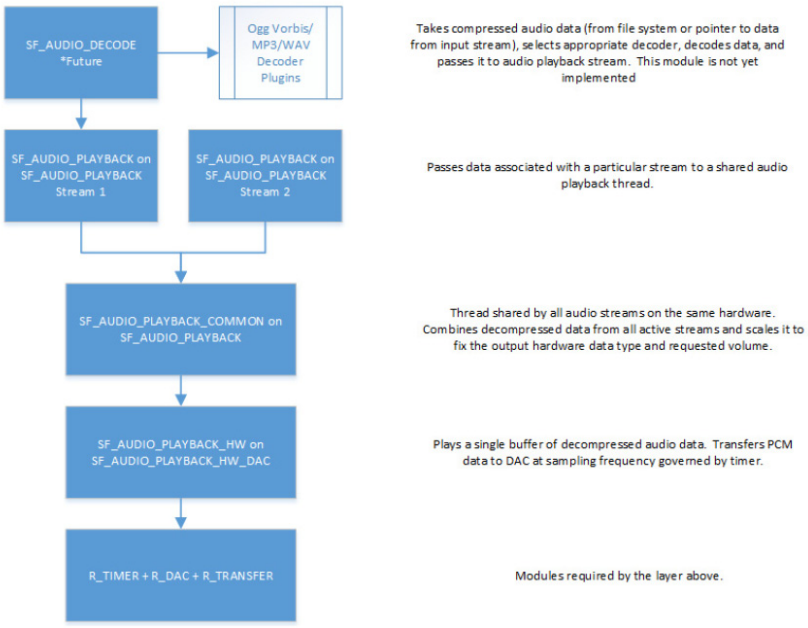

Figure 113: Implementing Multiple Audio Streams

Audio Playback Framework Module Operational Notes

Configuring Messages

Use the Messaging Framework configurator on the Messaging tab to configure the messaging framework:

1) Highlight the Audio Playback event class.
2) Add a new subscriber. Select the following configurations and make sure the Message Class Instance property set in the Properties tab of the Audio Playback Framework on sf_audio_playback module is between the Start and End instance.
   - Thread: Any thread in the application.
   - Start: First audio instance used in application.
   - End: Last audio instance used in application.
3) Highlight the new Subscriber in the Audio Playback Subscribers. Record the Symbol name.
4) Go back to the **Threads** tab.

5) Highlight the Audio Playback Framework Shared module in HAL/Common, and set the Audio Message Queue Name to the Symbol name from the Audio Playback Subscriber.

Using the I2S Implementation

The audio framework I2S hardware port has dependencies on the I2S driver module. The I2S driver module can be accelerated with DTC (recommended).

- Set the ISDE properties for the I2S driver module.
  - Set the Audio Clock Frequency (Hertz) to the frequency of the input audio clock used.
  - Set the Sampling Frequency (Hertz) to the sampling frequency of your audio data.
  - Set the Data Bits and Word Length to 16 bits (audio framework accepts 16 bit samples only).
  - Enable the SSIn TXI and SSIn INT interrupts.
- (Recommended) The Transfer module on r_dtc is added automatically.

Using the DAC Implementation

The audio framework DAC hardware port has dependencies on the Timer, DAC, and Transfer API modules.

- Add a Timer module.
  - Set the Frequency in Hz to the sampling frequency of your audio data.
  - Enable the interrupt if using DTC as the transfer module (recommended).
- Add a DAC (DAC12 or DAC8) module.
- Add a Transfer module on r_dtc.
  - Set Destination pointer to &R_DAC->DADRn[0] if using DAC channel 0 or &R_DAC->DADRn[1] if using DAC channel 1.
  - Set Destination pointer to &R_DAC8->DADRn[2] if using DAC8 channel 2 (DK-S128) or &R_DAC8->DADRn[0] if using DAC8 channel 0 (S1JA).
  - Set the Activation source to the timer interrupt chosen above.

Other Operational Notes

- The Queue used must match the name specified in Properties for Audio Playback Framework Shared on sf_audio_playback (default is g_sf_audio_playback_queue).

Audio Playback Framework Module Limitations

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.4.4 Including the Audio Playback Framework Module in an Application

This section describes how to include the Audio Playback Framework module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few sections of the SSP User's Manual, available as described in the Reference Section at the end of this document to learn how to manage each of these important steps in creating SSP-based applications.

To add the Audio Playback to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Audio Playback is g_sf_audio_playback. This name can be changed in the associated Properties window.)

Audio Playback Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_audio_playback Audio Playback Framework on g_sf_audio_playback	**Threads**	**New Stack> Framework> Audio> Audio Playback Framework on g_sf_audio_playback**

When the Audio Playback Framework module on sf_audio_playback is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information will have box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level drivers; these are either optional or recommended (this is indicated in the block with the inclusion of this text.) If the addition of lower-level drivers is required, the module description will include "Add" in the text. Clicking on any Pink banded modules will bring up the "New" icon and then display the possible choices.

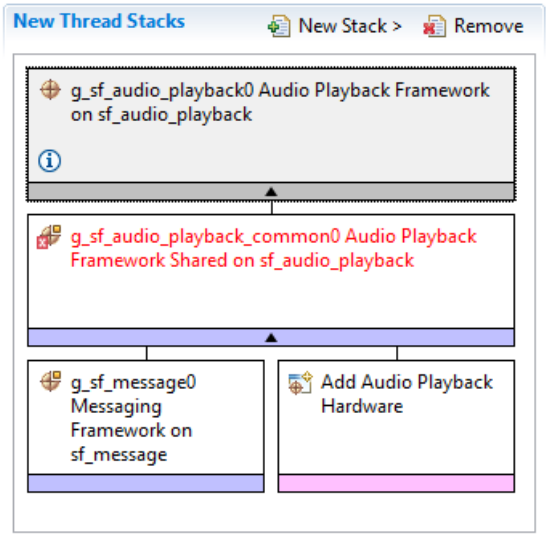

Figure 114: Audio Playback DAC Framework Stack

4.1.4.5 Configuring the Audio Playback Framework Module

The Audio Playback Framework module must be configured by you for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous

'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority: this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for Audio Playback Framework on sf_audio_playback

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking
Buffer Size Bytes	512	Buffer size bytes selection
Maximum Number of Streams	1	Maximum number of streams selection
Thread Stack Size	512	Thread stack size selection
Name	g_sf_audio_playback0	Module name
Message Class Instance	0	Message class instance selection
Callback	NULL	Callback selection.
Name of generated initialization function	sf_audio_playback_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful

to select the DAC Channel based on the target hardware implementation. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

NOTE: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the Audio Playback Framework Low Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module.

Configuration for Audio Playback Framework Shared on sf_audio_playback_common

ISDE Property	Value	Description
Name	g_sf_audio_playback_common0	Module name
Thread Priority	3	Priority for the thread (do not edit)
Audio Message Queue Name	g_sf_audio_playback_queue	Message Queue name

Configuration for Messaging Framework on sf_message

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Message Queue Depth (Total number of messages to be enqueued in a Message Queue)	16	Specify the size of Thread X Message Queue in bytes for Message Subscribers. This value is applied to all the Message Queues.
Name	g_sf_message0	The name of Messaging Framework module control block instance.

ISDE Property	Value	Description
Work memory size in bytes	2048	Specify the work memory size in bytes. Choosing a small number results a small number of buffers which can be allocated at the same time (You can confirm the total buffer number on: sf_message_ctrl_t::number_of_buffers). If the value is smaller than the peak number of messages to be posted at the same time, the Framework occurs a buffer allocation failure affecting system performance.
Pointer to subscriber list array	p_subscriber_lists	Specify the name of pointer to the Subscriber List array.
name of the block pool internally used in the messaging framework	sf_msg_blk_pool	The name of memory block memory the Framework creates in the control block. This parameter might be useful for debugging purpose but NULL can be specified for saving memory.
Name of generated initialization function	sf_message_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Audio Playback Hardware Framework Shared on sf_audio_playback_hw_dac

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking
DMAC Support	Disabled, Enabled Default: Disabled	DMAC support selection
Name	g_sf_audio_playback_hw0	Module name

Configuration for the Transfer Driver on r_dmac (Transfer Driver Option)

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Name	g_transfer0	Module name
Channel	0	Channel selection
Mode	Normal	Mode selection
Transfer Size	2 Bytes	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source	Software Activation, Peripheral Events Default: Software Activation	Activation source selection
Auto Enable	False	Auto enable selection
Callback	NULL	Callback selection

ISDE Property	Value	Description
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection

Configuration Settings for Transfer Driver on r_dtc (Transfer Driver Option)

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Disabled	Software start selection
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section selection
Name	g_transfer0	Module name
Mode	Normal	Mode selection
Transfer Size	2 Bytes	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection

ISDE Property	Value	Description
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Software Activation 1, Software Activation 2, Peripheral Events Default: Software Activation 1	Activation source selection
Auto Enable	True, False Default: True	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection.

Configuration Settings for Timer Driver on r_agt (Timer Driver Option)

ISE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables parameter checking
Name	g_timer0	Module name
Channel	0	Physical hardware channel

ISE Property	Value	Description
Mode	Periodic	Warning: One Shot functionality is not available in the GPT hardware, so it is implemented in software by stopping the timer in the ISR called when the period expires. For this reason, ISR's must be enabled for one-shot mode even if the callback is unused.
Period Value	10	See Timer Period Calculation
Period Unit	Hertz	See Timer Period Calculation
Auto Start	FALSE	Set to true to start the timer after configuring or false to leave the timer stopped until start is called
Count Source	PCLKB, PCLKB/8, PCLKB/2, LOCO, AGT0 Underflow, AGT0 fSub Default: PCLKB	The clock source for the AGT counter
AGTO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTO pin). Set to false for no output of the timer signal
AGTIO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTIO pin). Set to false for no output of the timer signal.
Output Inverted	True, False Default: False	Set to false to start the output signal low. Set to true to start the output signal high.
Enable comparator A output pin	True, False Default: False	Enable comparator A output pin selection
Enable comparator B output pin	True, False Default: False	Enable comparator B output pin selection

ISE Property	Value	Description
Callback	NULL	A user callback function can be registered in open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Timer interrupt priority. 0 is the highest priority.

Configuration Settings for Timer Driver on r_gpt (Timer Driver Option)

ISE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_timer0	Module name.
Channel	0	Channel selection.
Mode	Periodic	Warning: One Shot functionality is not available in the GPT hardware, so it is implemented in software by stopping the timer in the ISR called when the period expires. For this reason, ISR's must be enabled for one-shot mode even if the callback is unused.

ISE Property	Value	Description
Period Value	10	See Timer Period Calculation
Period Unit	Hertz	See Timer Period Calculation
Duty Cycle Value	50	Duty cycle value selection
Duty Cycle Unit	Unit Raw Counts, Unit Percent, Unit Percent x 1000 Default: Unit Raw Counts	Duty cycle unit selection
Auto Start	False	Set to true to start the timer after configuring or false to leave the timer stopped until start is called.
GTIOCA Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCA Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	Controls output pin level when the timer is stopped.
GTIOCB Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCB Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	Controls output pin level when the timer is stopped.

ISE Property	Value	Description
Callback	NULL	A user callback function can be registered in open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection

Configuration Settings for DAC Driver on r_dac

Parameter	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_dac0	Module name.
Channel	0	Set to 0 for output DA0 or 1 for output DA1.
Synchronize with ADC	Enabled, Disabled Default: Disabled	Set to true for anti-interference synchronization with the Analog-to-Digital Converter (ADC) Module. Set to false false if power supply interference between the analog modules is not a problem, or if asynchronous conversion by the DAC Module is desired.

Parameter	Value	Description
Data Format	Right Justified	Set to zero, if 12-bit data values are loaded in bits 11 through 0, or right justified. Set to one, if 12-bit data values are loaded in bits 15 through 4, or left justified.
Output Amplifier	Enable, Disable Default: Disable	Set to true, if output amplifier hardware function is desired. Set to false to bypass output amplifier hardware function.

Configuration Settings for the Audio Playback Framework Shared on sf_audio_playback_hw_i2s

Parameter	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_sf_audio_playback_hw0	Module name.

Configuration Settings for the I2S HAL Module on r_ssi

Parameter	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_i2s0	Module name.
Channel	0	Physical hardware channel.
Audio Clock Frequency (Hertz)	2822400	Input audio clock frequency, used to generate the I2S clock. Must be a multiple between 1 and 128 of: (sampling_freq_hz * word_length_in_bits)
Sampling Frequecy (Hertz)	44100	Sampling frequency of audio data.

Parameter	Value	Description
Data Bits	8 bits, 16, 18, 20, 22, 24 Default: 16 bits	Bit depth of audio data, which is the size in bits of one sample of audio data.
Word Length	8 bits, 16, 24, 32 Default: 16 bits	Word length of audio data, must be at least the same size as the bit depth (Data Bits field).
WS Continue Mode	Enabled, Disabled Default: Disabled	Enable WS continue mode to continue to output the word select line when the peripheral is idle. Disable to stop outputting the word select line when the peripheral is idle.
Audio Clock	External, GTIOC1A Default: External	Select External for external signal to AUDIO_CLK input pin or GTIOC1A for internal connection to GPT channel 1 GTIOC1A.
Name of I2S callback function to be defined by user	NULL	A user callback function must be registered in open. The callback will be called from the interrupt service routine (ISR) when the transmission FIFO reaches the high watermark point after all data for transmission is transmitted or when reception is complete (the requested number of bytes have been received). Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Transmit interrupt priority selection

Parameter	Value	Description
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Receive interrupt priority selection
Idle/Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Idle/error interrupt priority selection

Configuration Settings for the DTC HAL module on r_dtc Software Activation 1

Parameter	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer0	Driver name.
Mode	Normal	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.

Parameter	Value	Description
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC software event interrupt priority selection

Configuration Settings for the DTC HAL Module on r_dtc Software Activation 1

Parameter	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.

Parameter	Value	Description
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer1	Driver name.
Mode	Normal	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.

Parameter	Value	Description
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC software event interrupt priority selection

Configuration Settings for the AGT HAL Module on r_agt

Parameter	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection
Name	g_timer0	Module name
Channel	0	Channel selection
Mode	Periodic	Mode selection
Period Value	2822400 * 2	Period value selection
Period Unit	Hertz	Period unit selection
Auto Start	False	Auto start selection
Count Source	PCLKB, PCLKB/8, PCLKB/2, LOCO, AGT0 Underflow, AGT0 fSub Default: PCLKB	Count source selection
AGTO Output Enabled	True, False Default: False	AGTO output selection
AGTIO Output Enabled	True, False Default: False	AGTIO output selection

Parameter	Value	Description
Output Inverted	True, False Default: False	Output inverted selection
Enable comparator A output pin	True, False Default: False	Enable comparator A output pin selection
Enable comparator B output pin	True, False Default: False	Enable comparator B output pin selection
Callback	NULL	Callback selection
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection

Configuration Settings for the GPT HAL Module on r_gpt

Parameter	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection
Name	g_timer0	Module name
Channel	0	Channel selection
Mode	Periodic	Mode selection
Period Value	2822400 *2	Period value selection
Period Unit	Hertz	Period unit selection
Duty Cycle Value	50	Duty cycle value selection

Parameter	Value	Description
Duty Cycle Unit	Unit Raw Counts, Unit Percent, Unit Percent x 1000 Default: Unit Raw Counts	Duty cycle unit selection
Auto Start	False	Auto start selection
GTIOCA Output Enabled	True, False Default: False	GTIOCA output enabled selection
GTIOCA Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	GTIOCA stop level selection
GTIOCB Output Enabled	True, False Default: False	GTIOCB output enabled selection
GTIOCB Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	GTIOCB stop level selection
Callback	NULL	Callback selection
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 Group MCU. Other MCUs may have different default values and available configuration settings.

Audio Playback Framework Clock Configuration

The Audio Playback Framework hardware modules use the peripheral clocks available from the Clock configuration window.

Audio Playback Framework Pin Configuration

The DAC or SSI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following illustrate the method for selecting the pins within the SSP configuration window and shows an example selection for the associated pins.

NOTE: For some peripherals, the operation mode selection determines what peripheral signals are available and thus what MCU pins are required.

Pin Selection Sequence for DAC

Resource	ISDE Tab	Pin selection Sequence
DAC	Pins	Select **Peripherals > Analog: DAC12 > DAC120/121/122**
SSI	Pins	Select **Peripherals > Connectivity: SSI > SSI/0/1**

Note: The selection sequence assumes DAC0 or DAC1, or SSI0 or SSI1 is the desired hardware target for the driver.

Pin Configuration Settings for DAC driver on DAC

Pin Configuration Property	Value	Description
Operation Mode	Enabled, Disabled	Operation selection
DAC	None, P014 (Default: P014)	DAC pin selection

Note: The example values are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.1.4.6 Using the Audio Playback Framework Module in an Application

The typical steps in using the Audio Playback Framework module in an application are:

1) Initialize an audio stream using the open API
2) Use the callback function to post to a semaphore with an initial count equal to the number of buffers used in the application. Get this semaphore in the application thread before calling the start API.
3) Acquire a buffer from the Messaging Framework using the bufferAcquire API.
4) Create the Audio Framework Data Structure sf_audio_playback_data_t inside the buffer.

5) Start the Audio Playback Framework using the start API.

6) If multiple streams are desired, repeat steps 1-5 for any additional audio streams. A separate audio stream should only be used if the streams may need to play simultaneously using mixing. If audio sounds are always played in sequence and never overlap, the stream can be reused.

These common steps are illustrated in a typical operational flow diagram in the following figure:

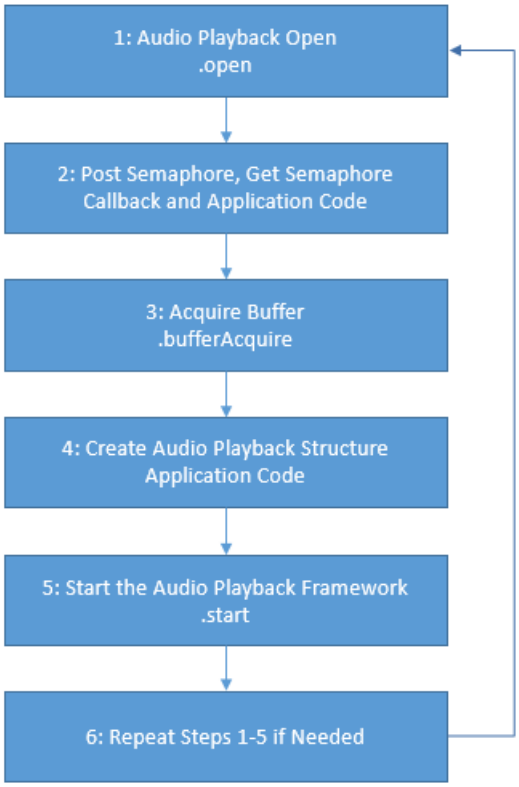

Figure 115: Flow Diagram of a Typical Audio Playback Application

4.1.5 Audio Playback DAC Framework

The Audio Playback DAC Framework module is a high-level API for audio playback applications and is implemented on sf_audio_playback_hw_dac. It handles the synchronization needed to play 16-bit pulse-code modulation (PCM) samples. The Audio Playback DAC Framework uses the DAC, timer (AGT or GPT) and data-transfer (DMA or DTC) peripherals on a Synergy MCU. A user-defined callback can be created to respond to the need for additional data.

4.1.5.1 Audio Playback Hardware DAC Framework Module Features

The Audio Playback Hardware DAC Framework module supports the following features:

- Plays long buffers by splitting the data into manageable chunks.
- Repeats playback until a ThreadX timeout (for repeated audio like sine wave tones or looped background music).

- Requests next data using callback after last buffer playback begins.
- Software volume control.
- Pauses and resumes functions.
- Scaling- for example, to move signed 16-bit PCM data into range of the unsigned 12-bit DAC or unsigned 8-bit DAC8.
- Basic mixing for multiple streams.

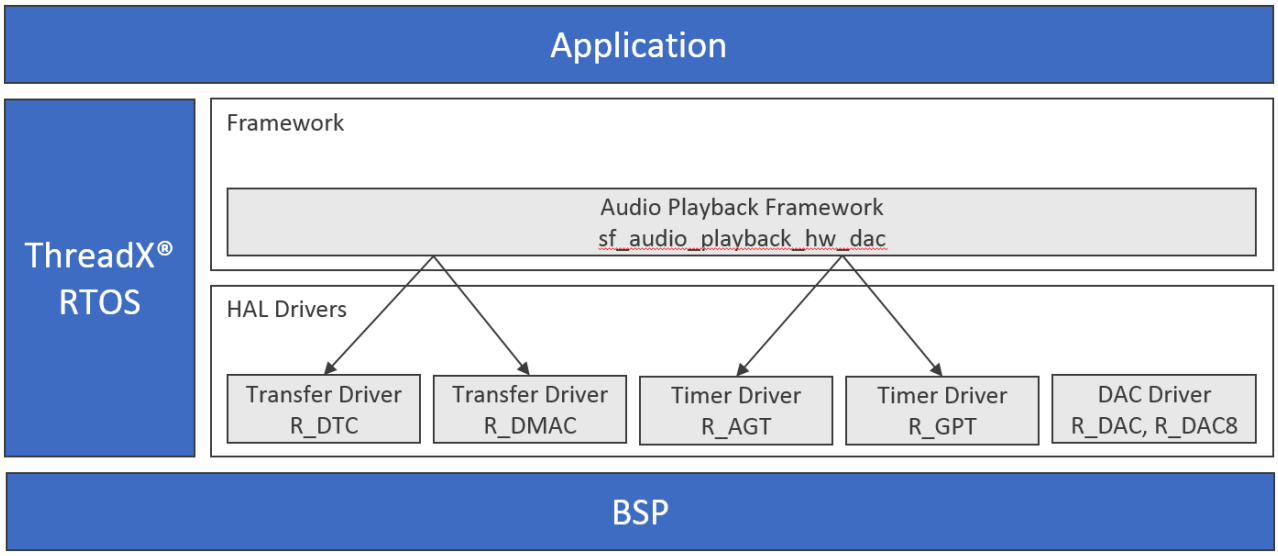

Figure 116: Audio Playback Hardware DAC Framework Module Block Diagram

4.1.5.2 Audio Playback Hardware DAC Framework Module APIs Overview

The Audio Playback DAC Module defines APIs for operations such as opening, starting, playing, and stopping. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Audio Playback Hardware DAC Framework Module API Summary

Function Name	Example API Call and Description
.open	g_sf_audio_playback_hw0.p_api->open(g_sf_audio_playback_hw0.p_ctrl, g_sf_audio_playback_hw0.p_cfg); Open a device channel for read/write and control.

Function Name	Example API Call and Description
.start	g_sf_audio_playback_hw0.p_api->start(g_sf_audio_playback_hw0.p_ctrl, &p_data, Timeout); Start Audio Playback Hardware.
.stop	g_sf_audio_playback_hw0.p_api->stop(g_sf_audio_playback_hw0.p_ctrl); Stop Audio Playback Hardware.
.play	g_sf_audio_playback_hw0.p_api-> stop(g_sf_audio_playback_hw0.p_ctrl, p_buffer, length); Play audio buffer.
. dataTypeGet	g_sf_audio_playback_hw0.p_api->dataTypeGet(g_sf_audio_playback_hw0.p_ctrl, p_data_type); Stores expected data type in provided pointer p_data_type.
.close	g_sf_audio_playback_hw0.p_api->close(g_sf_audio_playback_hw0.p_ctrl); Close the audio module.
.versionGet	g_sf_audio_playback_hw0.p_api->versionGet(&version); Return the version of the module with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.

Name	Description
SSP_ERR_ASSERTION	A pointer is NULL or a parameter is invalid.
SSP_ERR_OUT_OF_MEMORY	The number of streams open at once is limited to SF_AUDIO_PLAYBACK_CFG_MAX_STREAMS. If this number is exceeded, an out of memory error occurs.
SSP_ERR_TIMEOUT	Timeout occurred before playback finished.
SSP_ERR_NOT_OPEN	The stream control block p_ctrl is not initialized.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.5.3 Audio Playback Hardware DAC Framework Module Operational Overview

The Audio Playback Framework module creates a thread internally to support audio playback. The following figure shows a flowchart of the audio playback framework thread and its interactions with public Audio Playback Framework APIs.

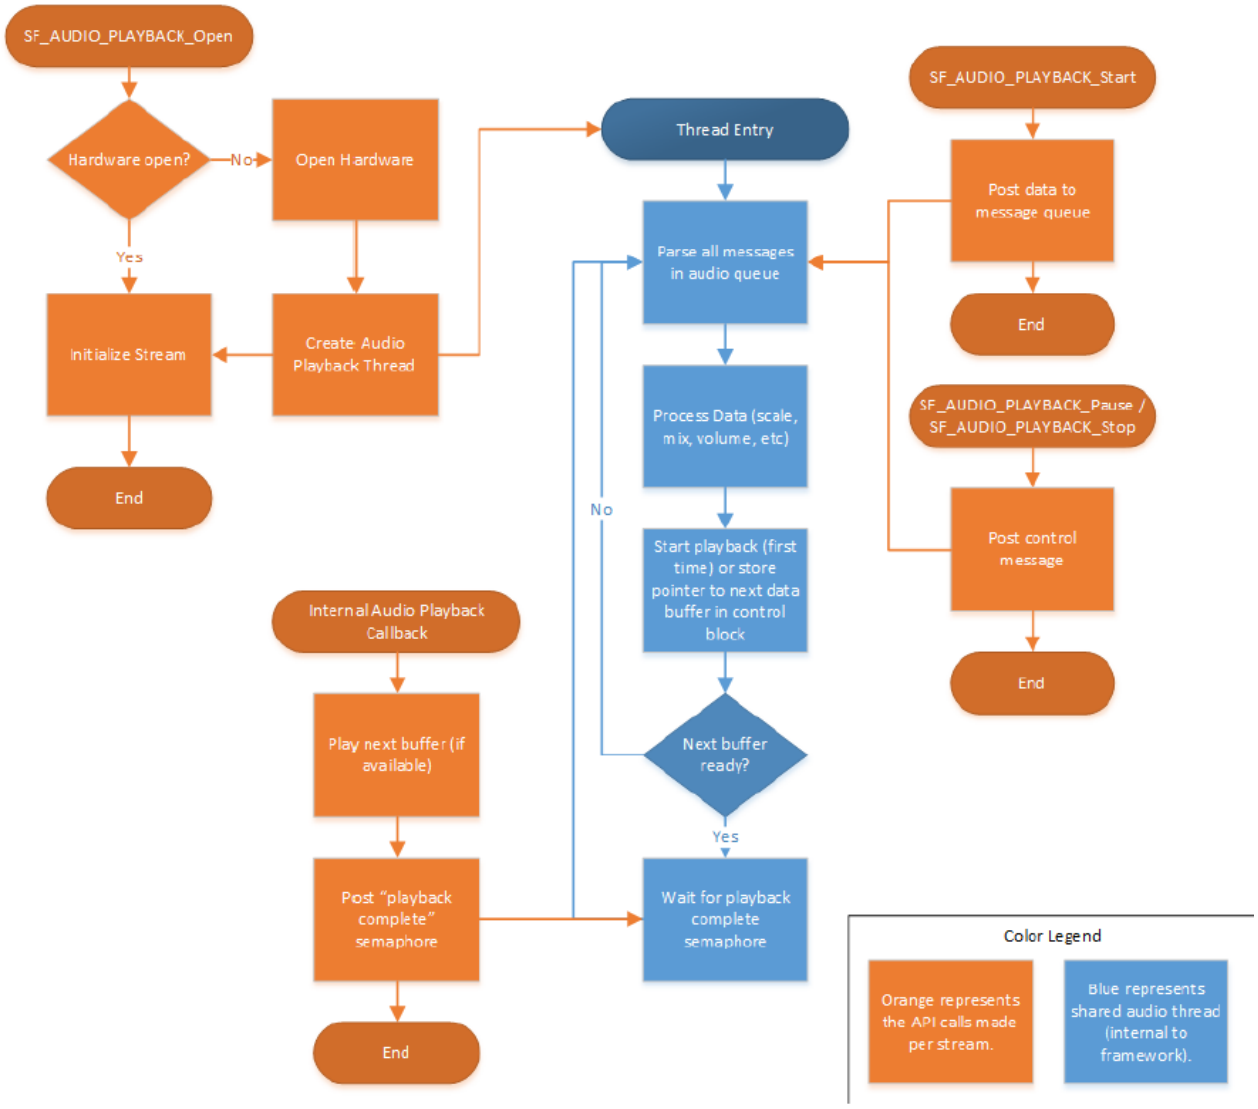

Figure 117: Audio Playback Framework Flowchart

Suggested use of the audio playback framework:

- Create a semaphore (for example g_sf_audio_playback_semaphore). This can be done on the Threads Tab. Set the initial value to 2 (the audio playback framework can store up to two data messages per stream).
- Create a callback function (for example sf_audio_playback_callback). Enter the name of your callback function in the Audio Playback Framework instance. The callback function will be called when the audio playback framework is done with the data. In the callback, put the semaphore created above.
- In your main loop, get the semaphore before playing data. To play data, first acquire a buffer from the messaging framework, then create your audio playback data structure inside the buffer.

The Audio Playback Framework supports multiple audio streams on a single hardware port. A block diagram of the modules required if two streams are used is shown in the following figure:

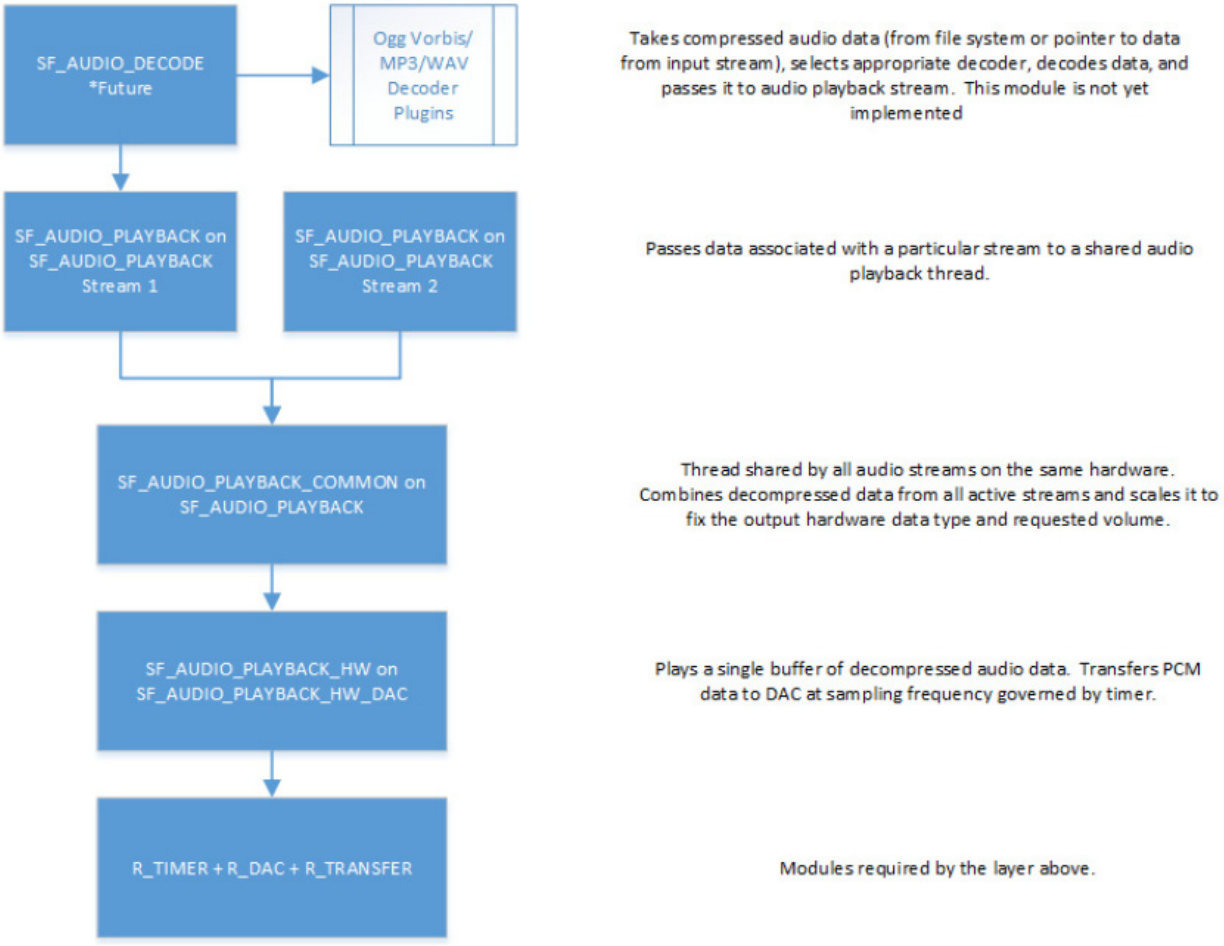

Figure 118: Implementing Multiple Audio Streams

Audio Playback Hardware DAC Framework Module Important Operational Notes and Limitations

- The Audio framework DAC hardware port uses the transfer API to transfer audio data from a playback buffer to DAC at a sampling frequency defined by an internal timer.
- The audio framework DAC hardware port has dependencies on the Timer, DAC, and Transfer API modules.
  - Add a timer module.
  - **Set the Frequency in Hz to the sampling frequency of your audio data.**
  - **Enable the interrupt if using DTC as the transfer module (recommended).**
  - Add a transfer module on r_dtc or r_dmac.

- **For DTC:**
- **Set Destination pointer to &R_DAC->DADRn[0] if using DAC channel 0 or &R_DAC->DADRn[1] if using DAC channel 1.**
- **Set the Activation source to the timer interrupt chosen above.**
- **Set Destination pointer to &R_DAC8->DADRn[2] if using DAC8 channel 2 (DK-S128) or &R_DAC8->DADRn[0] if using DAC8 channel 0 (S1JA).**

```
-   For DMAC:

    -   Enable dmac support

    -   Set Destination pointer to &R\_DAC-&gt;DADRn\[0\] if
        using DAC channel 0 or &R\_DAC-&gt;DADRn\[1\] if using
        DAC channel 1.

    -   Set the Activation source to the timer interrupt chosen
        above.
```

- The Audio Playback Framework is designed to support the following MCU families with no changes to the API:
  - S7G2
  - S5D5, S5D9, S128, S1JA
  - S3A3, S3A6, S3A7, S3D9
  - S124, S128, S1JA
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.5.4 Including the Audio Playback Hardware DAC Framework Module in an Application

This section describes how to include the Audio Playback Hardware DAC Framework module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the Getting Started Guide for SSP given in the References section at the end of this document to learn how to manage each of these important steps in creating SSP-based applications.

To add the Audio Playback Hardware DAC Framework to your application, simply add it to a project thread using the stacks selection sequence given in the following table. (The default name for the Audio Playback Hardware DAC Framework is g_sf_audio_playback_hw0. This name can be changed in the associated **Properties** window.)

Audio Playback Hardware DAC Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_audio_playback_hw0 Audio Playback Hardware Framework on g_sf_audio_playback_hw0	**Threads**	**New Stack> Framework> Audio> Audio Playback Hardware Framework on g_sf_audio_playback_hw_dac**

When the Audio Playback Hardware DAC Framework module on sf_audio_playback_hw_dac is added to the thread stack as shown in the following figure, the configurator automatically adds the needed lower-level drivers. Any drivers that need additional configuration information will be highlighted in red.

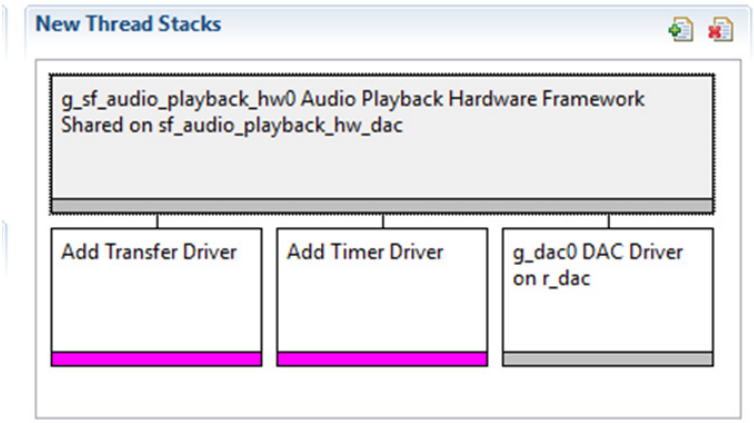

Figure 119: Audio Playback Hardware DAC Framework Module Stack

4.1.5.5 Configuring the Audio Playback Hardware DAC Framework Module

The Audio Playback Hardware DAC Framework module must be configured by you for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manualapproaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the Interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE and create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful hands-on approach to learning

the ins and outs of developing with SSP.

Configuration Settings for the Audio Playback Hardware DAC Framework Module on sf_audio_playback_hw_dac

Parameter	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
DMAC Support	Enabled, Disabled Default: Disabled	DMAC support enabled/disabled.
Name	g_sf_audio_playback_hw0	Module name.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select the DAC Channel based on the target hardware implementation. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Configuration Settings for the Audio Playback DAC Framework Low-Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated with red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module.

Configuration Settings for the DMAC HAL Module on r_dmac Software Activation

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Name	g_transfer0	Module name
Channel	0	Channel selection
Mode	Normal	Mode selection
Transfer Size	2 Bytes	Transfer size selection

ISDE Property	Value	Description
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source	Software Activation, Peripheral Events Default: Software Activation	Activation source selection
Auto Enable	False	Auto enable selection
Callback	NULL	Callback selection
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection

NOTE: The example settings and defaults are for a project using the Synergy SK-S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the DTC HAL Module on r_dtc Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Disabled	Software start selection
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section selection
Name	g_transfer0	Module name
Mode	Normal	Mode selection
Transfer Size	2 Bytes	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Software Activation 1, Software Activation 2, Peripheral Events Default: Software Activation 1	Activation source selection
Auto Enable	False	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection

ISDE Property	Value	Description
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the AGT HAL Module on r_agt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables parameter checking.
Name	g_timer0	Module name.
Channel	0	Physical hardware channel.
Mode	Periodic	Warning: One Shot functionality is not available in the GPT hardware, so it is implemented in software by stopping the timer in the ISR called when the period expires. For this reason, ISRs must be enabled for one-shot mode even if the callback is unused.
Period Value	10	See Timer Period Calculation.
Period Unit	Hertz	See Timer Period Calculation.
Auto Start	FALSE	Set to true to start the timer after configuring or false to leave the timer stopped until start is called.

ISDE Property	Value	Description
Count Source	PCLKB, PCLKB/8, PCLKB/2, LOCO, AGT0 Underflow, AGT0 fSub Default: PCLKB	The clock source for the AGT counter.
AGTO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTO pin). Set to false for no output of the timer signal.
AGTIO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTIO pin). Set to false for no output of the timer signal.
Output Inverted	True, False Default: False	Set to false to start the output signal low. Set to true to start the output signal high.
Callback	NULL	A user callback function can be registered in open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Timer interrupt priority. 0 is the highest priority.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the GPT HAL Module on r_gpt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_timer0	Module name.
Channel	0	Channel selection.
Mode	Periodic	Warning: One-shot functionality is not available in the GPT hardware, so it is implemented in software by stopping the timer in the ISR called when the period expires. For this reason, ISRs must be enabled for one-shot mode even if the callback is unused.
Period Value	10	See Timer Period Calculation
Period Unit	Hertz	See Timer Period Calculation
Duty Cycle Value	50	Duty cycle value selection
Duty Cycle Unit	Unit Raw Counts, Unit Percent, Unit Percent x 1000 Default: Unit Raw Counts	Duty cycle unit selection
Auto Start	False	Set to true to start the timer after configuring or false to leave the timer stopped until start is called.
GTIOCA Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCA Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	Controls output pin level when the timer is stopped.

ISDE Property	Value	Description
GTIOCB Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCB Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	Controls output pin level when the timer is stopped.
Callback	NULL	A user callback function can be registered in open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the DAC HAL Module on r_dac

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.

ISDE Property	Value	Description
Name	g_dac0	Module name.
Channel	0	Set to 0 for output DA0 or 1 for output DA1.
Synchronize with ADC	Enabled, Disabled Default: Disabled	Set to true for anti-interference synchronization with the Analog-to-Digital Converter (ADC) Module. Set to false if power supply interference between the analog modules is not a problem, or if asynchronous conversion by the DAC Module is desired.
Data Format	Right Justified	Set to zero, if 12-bit data values are loaded in bits 11 through 0, or right justified. Set to one, if 12-bit data values are loaded in bits 15 through 4, or left justified.
Output Amplifier	Enable, Disable Default: Disable	Set to true, if output amplifier hardware function is desired. Set to false to bypass output amplifier hardware function.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Audio Playback Hardware DAC Framework Module Clock Configuration

The Audio Playback Framework hardware modules (DAC) use the peripheral clocks available in the Clocks configuration window.

Audio Playback Hardware DAC Framework Module Pin Configuration

The DAC or SSI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the associated pins.

NOTE: For some peripherals, the operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection for DAC

Resource	ISDE Tab	Pin selection Sequence
ADC	Pins	Select **Peripherals > Analog:ADC > ADC0/ADC1**

NOTE: The selection sequence assumes ADC0 or ADC1, or SSI0 or SSI1 is the desired hardware target for the driver.

Pin Configuration Settings for the DAC HAL Module on r_dac

Pin Configuration Property	Value	Description
Operation Mode	Enabled, Disabled	Operation selection

| DA | None, P014
(Default: P014) | DAC pin selection |

NOTE: The above example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.1.5.6 Using the Audio Playback Hardware DAC Framework Module in an Application

The typical steps in using the Audio Playback Hardware DAC Framework module in an application are:

1) Initialize the Audio Playback DAC Framework using the open API
2) Start the low-level hardware of the Audio Playback DAC framework using the start API.
3) Play the PCM audio samples using the play API.
4) PCM audio samples supported by the hardware is provided by the dataTypeGet API.
5) Stop the low-level hardware of the Audio Playback DAC Framework using stop API.
6) Close the Audio Playback DAC framework using the close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

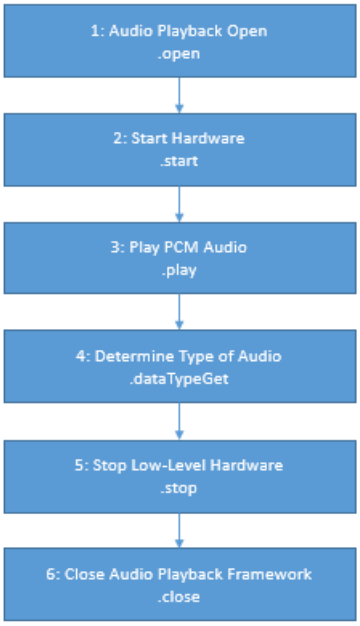

Figure 120: Flow Diagram of a Typical Audio Playback Hardware DAC Framework Module Application

4.1.6 Audio Playback I2S Framework

The Audio Playback I2S Framework module provides high-level APIs for Audio Playback applications and is implemented on sf_audio_playback_hw_i2s. It handles the synchronization needed to play 16-bit pulse-code modulation (PCM) samples. The Audio Playback Framework uses the I2S, Timer (AGT or GPT) and Data Transfer (DMA or DTC) peripherals on a Synergy MCU. A user defined callback can be created to respond to the need for additional data.

This document is divided into the following sections which can be read independently (by a more experienced Synergy developer) or in series (by developers new to the Synergy Platform.)

4.1.6.1 Audio Playback I2S Framework Module Features

The Audio Playback I2S Hardware Framework module supports the following features:

- Play long buffers by splitting the data into manageable chunks.
- Repeat playback until ThreadX timeout (for repeated audio like sine wave tones or looped background music).
- Request next data using callback after last buffer playback begins.
- Software volume control.
- Pause and resume functions.
- Basic mixing for multiple streams.

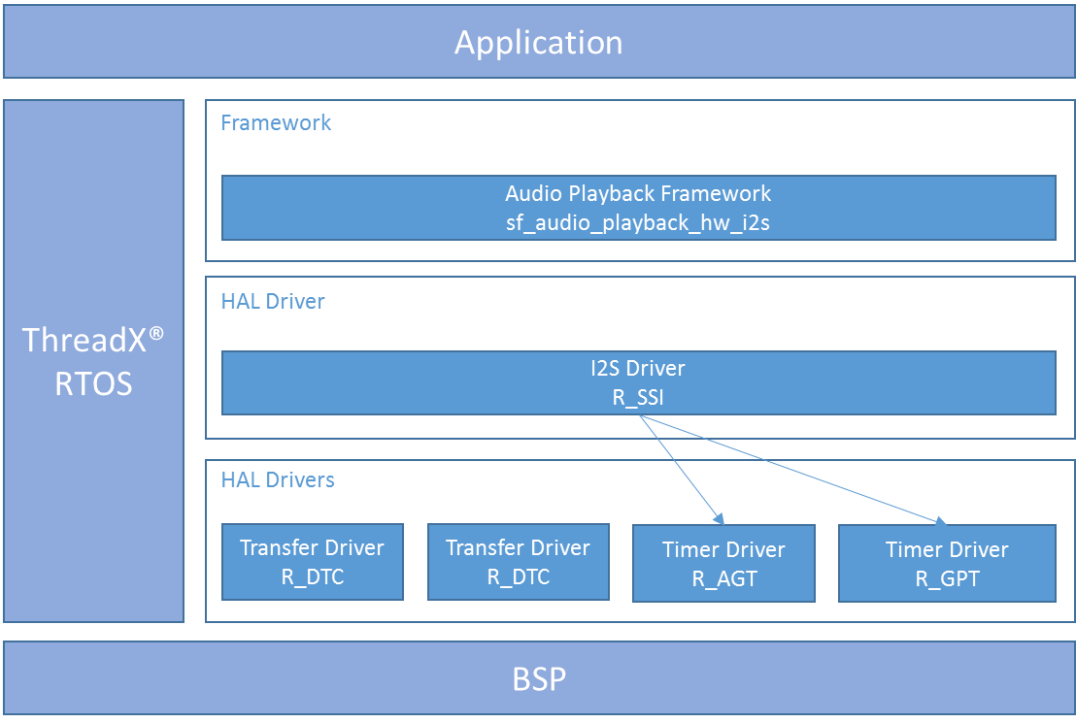

Figure 121: Audio Playback Framework Stack Options

4.1.6.2 Audio Playback I2S Framework APIs Overview

The Audio Playback I2S Framework module defines APIs for operations such as opening, starting, playing, and stopping. A complete list of the available APIs, an example API call, and a short description of each can be found in the table below. A table of status return values follows.

Audio Playback I2S Framework Module API Summary

Function Name	Example API Call and Description
.open	g_sf_audio_playback_hw0.p_api-> open (g_sf_audio_playback_hw0.p_ctrl, g_sf_audio_playback_hw0.p_cfg); Open a device channel for read/write and control.
.start	g_sf_audio_playback_hw0.p_api-> start(g_sf_audio_playback_hw0.p_ctrl); Start Audio Playback Hardware.
.stop	g_sf_audio_playback_hw0.p_api-> stop(g_sf_audio_playback_hw0.p_ctrl); Stop Audio Playback Hardware.

Function Name	Example API Call and Description
.play	g_sf_audio_playback_hw0.p_api-> stop(g_sf_audio_playback_hw0.p_ctrl, p_buffer, length); Play audio buffer.
.dataTypeGet	g_sf_audio_playback_hw0.p_api-> dataTypeGet(g_sf_audio_playback_hw0.p_ctrl, p_data_type); Stores expected data type in provided pointer.
.close	g_sf_audio_playback_hw0.p_api-> close(g_sf_audio_playback_hw0.p_ctrl); Close the audio driver.
.versionGet	g_sf_audio_playback_hw0.p_api-> versionGet(&version); Return the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manuals API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_OUT_OF_MEMORY	The number of streams open at once is limited to SF_AUDIO_PLAYBACK_CFG_MAX_STREAMS. If this number is exceeded, an out of memory error occurs.
SSP_ERR_TIMEOUT	Timeout occurred before playback finished.

NOTE: Lower level drivers may return Common Error Codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.6.3 Audio Playback I2S Framework Module Operational Overview

The Audio Playback I2S Framework module creates a thread internally to support audio playback. The figure below shows a flowchart of the audio playback framework thread and its interactions with public Audio Playback Framework APIs.

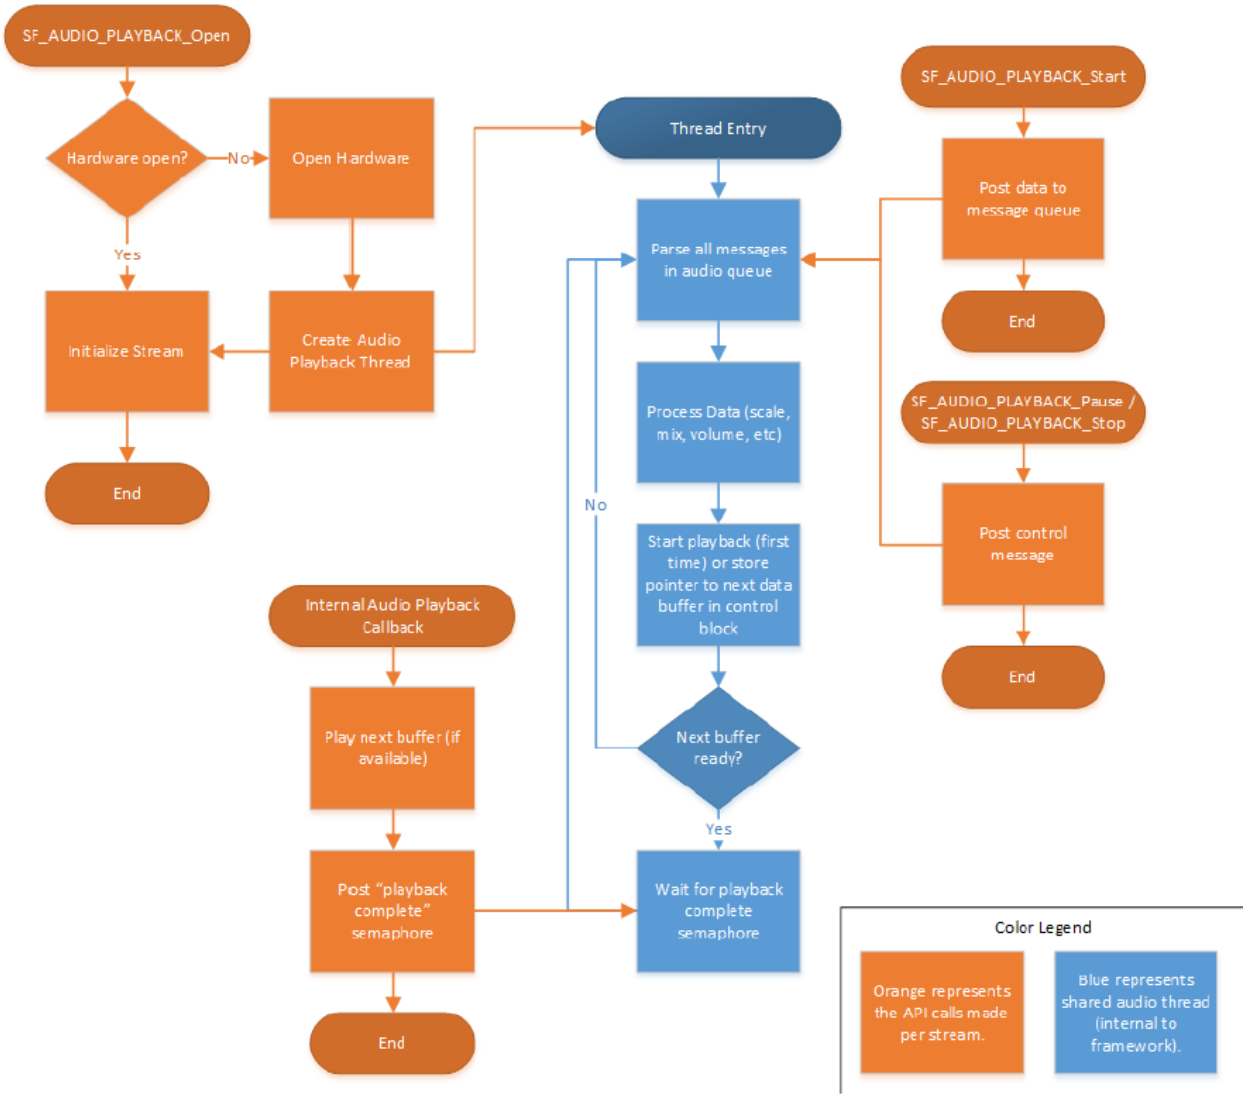

Figure 122: Audio Playback Framework Flowchart

Suggested use of the audio playback framework:

- Create a semaphore (for example, g_sf_audio_playback_semaphore). This can be done on the **Threads** tab. Set the initial value to 2 (the audio playback framework can store up to two data messages per stream).
- Create a callback function (for example, sf_audio_playback_callback). Enter the name of your callback function in the Audio Playback Framework instance. The callback function will be called when the audio playback framework is done with the data. In the callback, put the semaphore created above.
- In your main loop, get the semaphore before playing data. To play data, first acquire a buffer from the messaging framework, then create your audio playback data structure inside the buffer.The Audio Playback Framework

supports multiple audio streams on a single hardware port. A block diagram of the modules required if two streams are used is shown in the figure below.

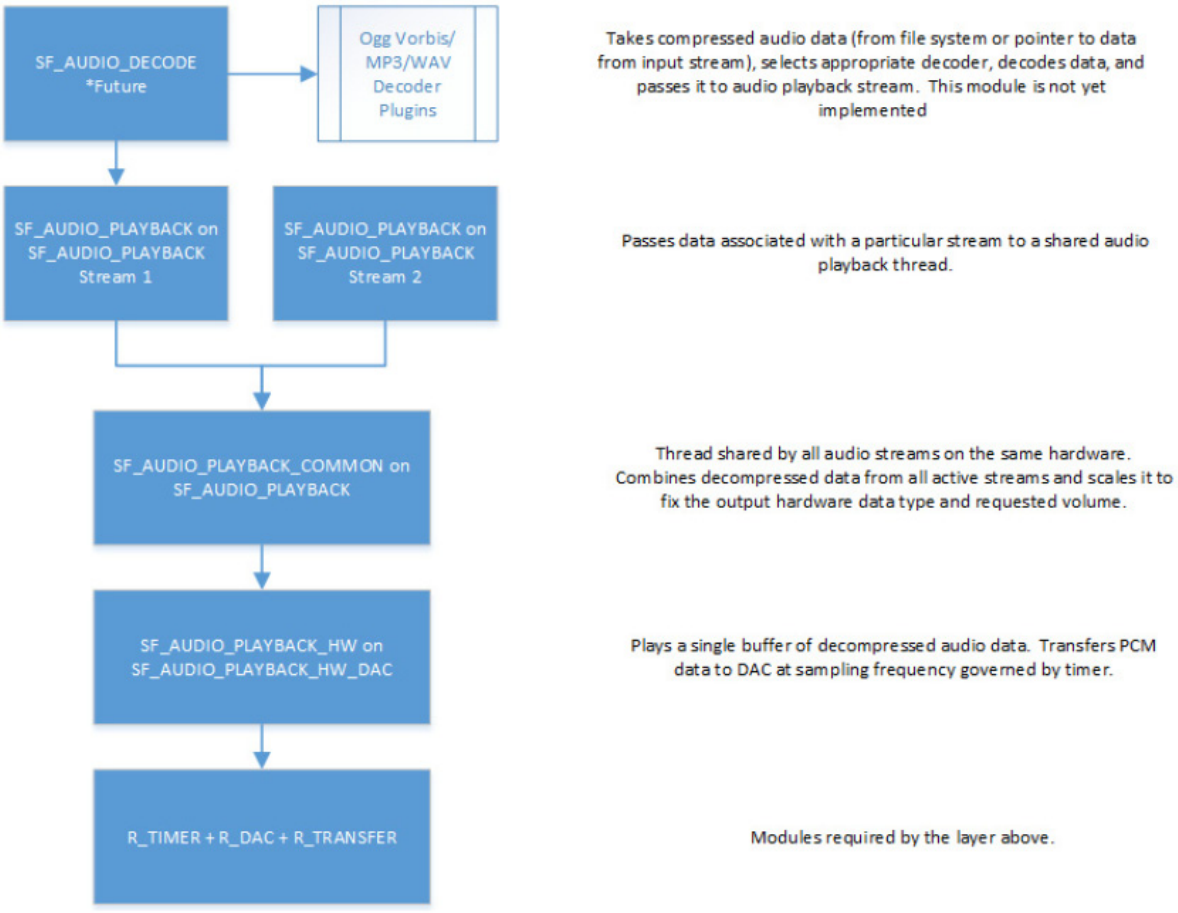

Figure 123: Implementing Multiple Audio Streams

Audio Playback I2S Framework Module Operational Notes

- The Queue used must match the name specified in **Properties** for Audio Playback Framework Shared on sf_audio_playback (default is g_sf_audio_playback_queue).
- The audio framework I2S hardware port has dependencies on the I2S Driver module. The I2S driver module can be accelerated with DTC (recommended).
- I2S driver module.
  - Set the Audio Clock Frequency (Hertz) to the frequency of the input audio clock used.
  - Set the Sampling Frequency (Hertz) to the sampling frequency of your audio data.
  - Set the Data Bits and Word Length to 16 bits (audio framework accepts 16 bit samples only).
  - Enable the SSIn TXI and SSIn INT interrupts.

- Transfer module on r_dtc (recommended).
- Set the Activation source to the SSIn TXI interrupt.
- The Audio Playback I2S Framework is designed to support the following MCU families with no changes to the API:
  - S7G2
  - S5D9, S5D5
  - S3A3, S3A6, S3A7, S3A1

Audio Playback I2S Framework Module Limitations

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.6.4 Including the Audio Playback I2S Framework Module in an Application

This section describes how to include the Audio Playback I2S Framework module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the *Getting Started Guide for SSP* listed in the Reference Section at the end of this document to learn how to manage each of these important steps in creating SSP based applications.

To add the Audio Playback I2S Framework module to an application, simply add it to a thread using the Stacks Selection Sequence given in the table below. (The default name for the Audio Playback is g_sf_audio_playback_hw0. This name can be changed in the associated **Properties** window.)

Audio Playback I2S Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_audio_playback_hw0 Audio Playback Hardware Framework on g_sf_audio_playback_hw0	**Threads**	**New Stack> Framework> Audio> Audio Playback Hardware Framework on g_sf_audio_playback**

When the Audio Playback I2S Framework module on sf_audio_playback_hw_i2s is added to the thread stack as shown in the figure below, the configurator automatically adds any needed lower level modules. Any drivers that need additional configuration information will have text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower level drivers. These are either optional or recommended (this is indicated in the block with the inclusion of this text.) If the addition of lower level drivers is required, the module description includes "Add" in the text. Clicking on any Pink banded modules brings up the "New" icon and then display the possible choices.

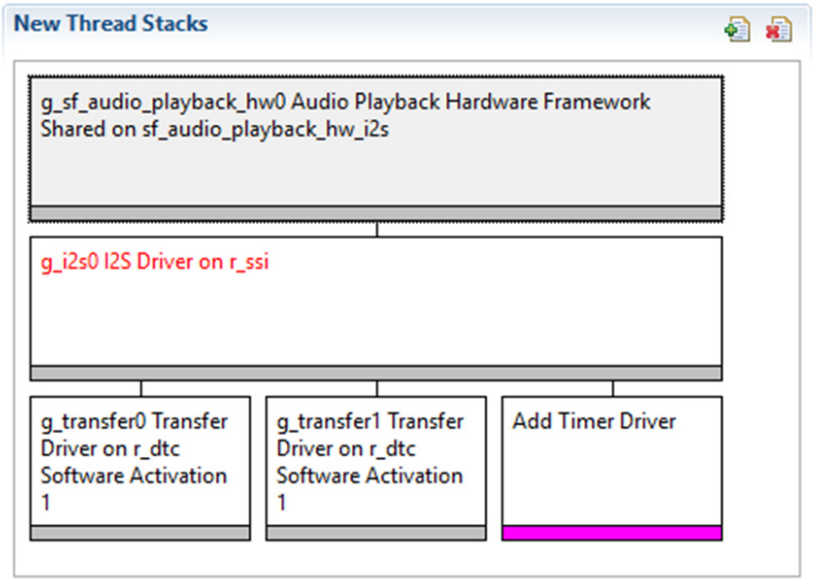

Figure 124: Audio Playback I2S Framework Stack

4.1.6.5 Configuring the Audio Playback I2S Framework Module

The Audio Playback I2S Framework module must be configured by you for the desired operation. The SSP configuration window automatically identifies, by highlighting the block in red, any required configuration selections, such as Interrupts or operating modes, which must be configured for lower level modules, for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the **Properties** tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority. This configuration setting is available with the **Properties** window of the associated module. Simply select the indicated module and then view the **Properties** window. The Interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the Interrupt priorities listed in the **Properties** window in the ISDE includes an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring Interrupt Priority levels.

NOTE: You may want to open your ISDE and create the module and explore the property settings in parallel with looking over the Configuration Table Settings that follow. This will help orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Audio Playback I2S Hardware Framework Module on sf_audio_playback_hw_i2s

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_sf_audio_playback_hw0	Module name.

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower level modules can be desirable. For example, it might be useful to select the DAC or I2S Channel based on the target hardware implementation. The configurable properties for the lower level stack modules are given in the below sections for completeness and as a reference.

NOTE: Most of the property settings for lower level modules are fairly intuitive and can usually be determined by inspection of the associated **Properties** window from the SSP configurator.

4.1.6.6 Configuration Settings for the Audio Playback Framework Low Level Modules

Typically, only a small number of settings must be modified from the default for lower level modules. (These are indicated with red text in the thread stack block.) Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The tables below identify all the settings within the properties section for the module.

Configuration Settings for the I2S HAL Module on r_ssi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_i2s0	Module name.
Channel	0	Physical hardware channel.
Audio Clock Frequency (Hertz)	2,822,400	Input audio clock frequency, used to generate the I2S clock. Must be a multiple between 1 and 128 of: (sampling_freq_hz * word_length_in_bits)

ISDE Property	Value	Description
Sampling Frequecy (Hertz)	44,100	Sampling frequency of audio data.
Data Bits	8 bits, 16, 18, 20, 22, 24 Default: 16 bits	Bit depth of audio data, which is the size in bits of one sample of audio data.
Word Length	8 bits, 16, 24, 32 Default: 16 bits	Word length of audio data, must be at least the same size as the bit depth (Data Bits field).
WS Continue Mode	Enabled, Disabled Default: Disabled	Enable WS continue mode to continue to output the word select line when the peripheral is idle. Disable to stop outputting the word select line when the peripheral is idle.
Name of I2S callback function to be defined by user	NULL	A user callback function must be registered in open. The callback will be called from the interrupt service routine (ISR) when the transmission FIFO reaches the high watermark point after all data for transmission is transmitted or when reception is complete (the requested number of bytes have been received). ATTENTION: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Transmit interrupt priority selection

ISDE Property	Value	Description
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Receive interrupt priority selection
Idle/Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Idle/error interrupt priority selection

Configuration Settings for the DTC HAL Module on r_dtc Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer0	Driver name.
Mode	Normal	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.

ISDE Property	Value	Description
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activiation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	FALSE	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC software event interrupt priority selection

Configuration Settings for the DTC HAL Module on r_dtc Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.

ISDE Property	Value	Description
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer1	Driver name.
Mode	Normal	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activiation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	FALSE	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.

ISDE Property	Value	Description
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC software event interrupt priority selection

Configuration Settings for AGT HAL Module on r_agt

ISE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection
Name	g_timer0	Module name
Channel	0	Channel selection
Mode	Periodic	Mode selection
Period Value	2,822,400 *2	Period value selection
Period Unit	Hertz	Period unit selection
Auto Start	FALSE	Auto start selection
Count Source	PCLKB, PCLKB/8, PCLKB/2, LOCO, AGT0 Underflow, AGT0 fSub Default: PCLKB	Count source selection
AGTO Output Enabled	True, False Default: False	AGTO output selection
AGTIO Output Enabled	True, False Default: False	AGTIO output selection

ISE Property	Value	Description
Output Inverted	True, False Default: False	Output inverted selection
Callback	NULL	Callback selection
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection

Configuration Settings for the GPT HAL Module on r_gpt

ISE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection
Name	g_timer0	Module name
Channel	0	Channel selection
Mode	Periodic	Mode selection
Period Value	2,822,400 *2	Period value selection
Period Unit	Hertz	Period unit selection
Duty Cycle Value	50	Duty cycle value selection
Duty Cycle Unit	Unit Raw Counts, Unit Percent, Unit Percent x 1000 Default: Unit Raw Counts	Duty cycle unit selection
Auto Start	FALSE	Auto start selection

ISE Property	Value	Description
GTIOCA Output Enabled	True, False Default: False	GTIOCA output enabled selection
GTIOCA Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	GTIOCA stop level selection
GTIOCB Output Enabled	True, False Default: False	GTIOCB output enabled selection
GTIOCB Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	GTIOCB stop level selection
Callback	NULL	Callback selection
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

4.1.6.7 Audio Playback I2S Framework Module Clock Configuration

The Audio Playback Framework hardware modules (I2S) use the peripheral clocks available from the Clock configuration window.

4.1.6.8 Audio Playback I2S Framework Module Pin Configuration

The SSI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The first table below illustrates the method for selecting the pins within the SSP configuration window and the following table illustrates an example selection for the associated pins.

Pin Selection Sequence for ADC or I2S

Resource	ISDE Tab	Pin selection Sequence
I2S	Pins	Select **Peripherals > Connectivity:SSI > SSI/SSI0/SSI1**

NOTE: The above selection sequence assumes ADC0 or ADC1, or SSI0 or SSI1 is the desired hardware target for the driver.

Pin Configuration Settings for I2S driver on SSI

Pin Configuration Property	Value	Description
Pin Group Selection	_A only, _B only, Mixed	Pin group for I2S port
Operation Mode	Enabled, Custom, Disabled	Operation selection
SSISCK	None, P204 (Default: None)	SSI Serial Clock
SSIWS	None, P205 (Default: None)	SSI Stereo pin selection
SSIDATA	None, P206 (Default: None)	SSI Data pin selection

NOTE: The above example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.1.6.9 Audio Playback I2S Framework Module Messaging Configuration

Use the Messaging Framework configurator on the **Messaging** tab to configure the messaging framework:

1) Highlight the Audio Playback event class.
2) Add a new subscriber.
3) Select the following configurations and make sure the Message Class Instance property set in the **Properties** tab of the Audio Playback Framework on sf_audio_playback module is between the Start and End instance.
    a) Thread: Any thread in the application.
    b) Start: First audio instance used in application.
    c) End: Last audio instance used in application.
4) Highlight the new Subscriber in the Audio Playback Subscribers. Record the Symbol name.
5) Go back to the **Threads** tab.
6) Highlight the Audio Playback Framework Shared module in HAL/Common, and set the Audio Message Queue Name to the Symbol name from the Audio Playback Subscriber.

4.1.6.10 Using the Audio Playback I2S Framework Module in an Application

The typical steps in using the Audio Playback I2S Framework module in an application are:

1) Initialize the Audio Playback I2S Framework using the open API
2) Start the low-level hardware of the Audio Playback I2S framework using the start API.
3) Play the PCM audio samples using the play API.
4) PCM audio samples supported by the hardware is provided by the dataTypeGet API.
5) Stop the low-level hardware of the Audio Playback I2S Framework using stop API.
6) Close the Audio Playback I2S framework using the close API.

These common steps are illustrated in a typical operational flow diagram in the figure below:

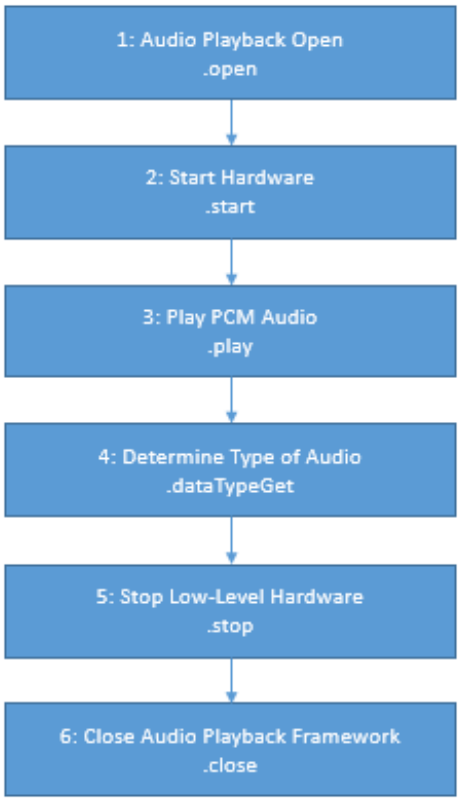

Figure 125: Flow Diagram of a Typical Audio Playback Framework Module Application

4.1.7 Block Media QSPI Framework

The Block Media Framework Module provides high-level APIs for a QSPI channel and supports read, write, and control of the QSPI Flash memory peripheral through the r_qspi driver. The driver has all the functionality needed to interface with a file system through a block media interface.

4.1.7.1 Block Media QSPI Framework Module Features

- Supports the QSPI channel interface for a QSPI flash memory device.
- Supports a file system on QSPI flash memory.

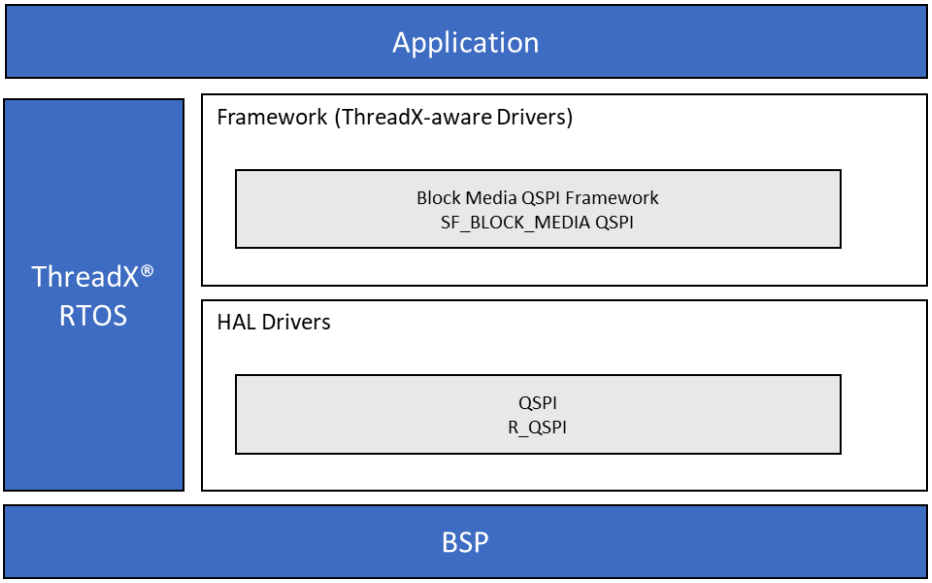

Figure 126: Block Media QSPI Framework Module Block Diagram

4.1.7.2 Block Media QSPI Framework Module APIs Overview

The Block Media QSPI Framework module defines APIs to open, control, read and write to the media. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Block Media QSPI Framework Module API Summary

Function Name	Example API Call and Description
.open	g_sf_block_media_qspi0.p_api->open (g_sf_block_media_qspi0.p_ctrl, g_sf_block_media_qspi0.p_cfg); Open a device channel for read/write and control.
.read	g_sf_block_media_qspi0.p_api->read (g_sf_block_media_qspi0.p_ctrl, p_dest, start_block, block_count); Read data from a media channel.

Function Name	Example API Call and Description
.write	g_sf_block_media_qspi0.p_api->write (g_sf_block_media_qspi0.p_ctrl, p_src, start_block, block_count); Write data to a media channel.
.ioctl	g_sf_block_media_qspi0.p_api->ioctl (g_sf_block_media_qspi0.p_ctrl, command, p_data); Send control commands to and receives the status from the media port.
.close	g_sf_block_media_qspi0.p_api->close (g_sf_block_media_qspi0.p_ctrl); Close the open media channel.
.versionGet	g_sf_block_media_qspi0.p_api->versionGet(&version); Return the version of the driver using the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_INTERNAL	An internal TheadX error has occurred.
SSP_ERR_NOT_OPEN	Unit is not open
SSP_ERR_ASSERTION	The parameter p_ctrl or p_sample is NULL.
SSP_ERR_IN_USE	Peripheral is still running in another mode; perform Close first.
SSP_ERR_UNSUPPORTED	Command not supported.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.1.7.3 Block Media QSPI Framework Module Operational Overview

The Block Media Framework Interface is simply an abstract interface using function pointers instead of direct function calls. Functions are called between FileX and the SSP block media drivers, such as SDMMC, SPI Flash and SDRAM/RAM. The interface remains the same for any media driver so that all media drivers appear functionally identical at file I/O layer and can be interchanged with one another without changing code. Device adaptation drivers, such as sf_block_media_qspi, are accessed through the Block Media Framework Interface and provide device specific code needed to perform media I/O operations. Configuration and control structures passed through block media function calls are generally device specific as well.

Block Media QSPI Framework Module Important Operational Notes and Limitations

The media must be formatted at least once before you can begin creating, writing, and reading files.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.7.4 Including the Block Media QSPI Framework Module in an Application

This section describes how to include the Block Media QSPI Framework module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Block Media QSPI Framework module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the Block Media QSPI Framework module is g_sf_block_media_qspi0. This name can be changed in the associated Properties window.)

Block Media QSPI Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_block_media_qspi0 Block Media Framework on sf_block_media_qspi	Threads	New Stack> Framework> File System> Block Media Framework on sf_block_media_qspi

When the Block Media QSPI Framework module on sf_block_media_qspi is added to the thread stackas shown in the following figure, the configurator automatically adds any lower-level drivers that are required. Any drivers that need additional configuration information will be box-text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

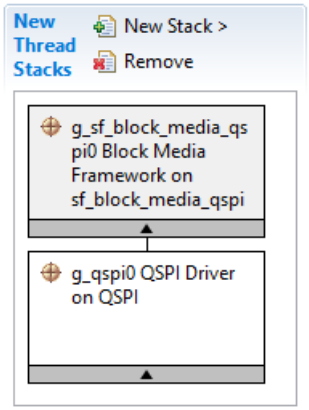

Figure 127: Block Media QSPI Framework Module Stack

4.1.7.5 Configuring the Block Media QSPI Framework Module

The Block Media QSPI Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the Block Media QSPI Framework Module on sf_block_media_qspi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_sf_block_media_qspi	Module name.

ISDE Property	Value	Description
Block size of media in bytes	4096	Block size selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the QSPI HAL Module on r_qspi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_qspi0	Module name.

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Block Media QSPI Framework Module Clock Configuration

The Block Media QSPI Framework module uses the PCLKA as its clock source.

To change the clock frequency at run-time, use the CGC Interface.

Block Media QSPI Framework Module Pin Configuration

To use the Block Media QSPI Framework module, the port pins for the peripheral inputs and outputs must be set in the pin configurator in the ISDE. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection Sequence for the Block Media QSPI Framework Module

Resource	ISDE Tab	Pin selection Sequence
QSPI	Pins	Select Peripherals > Storage:QSPI > QSPI0

4.1.7.6 Using the Block Media QSPI Framework Module in an Application

The typical steps for sf_block_media_qspi framework in an application are:

1) Initialize media using the open API
2) Read media as required using the read API

3) Write media as required using the write API
4) Operate on data as required.
5) Close media as required using the close API

These common steps are illustrated in a typical operational flow in the following figure:

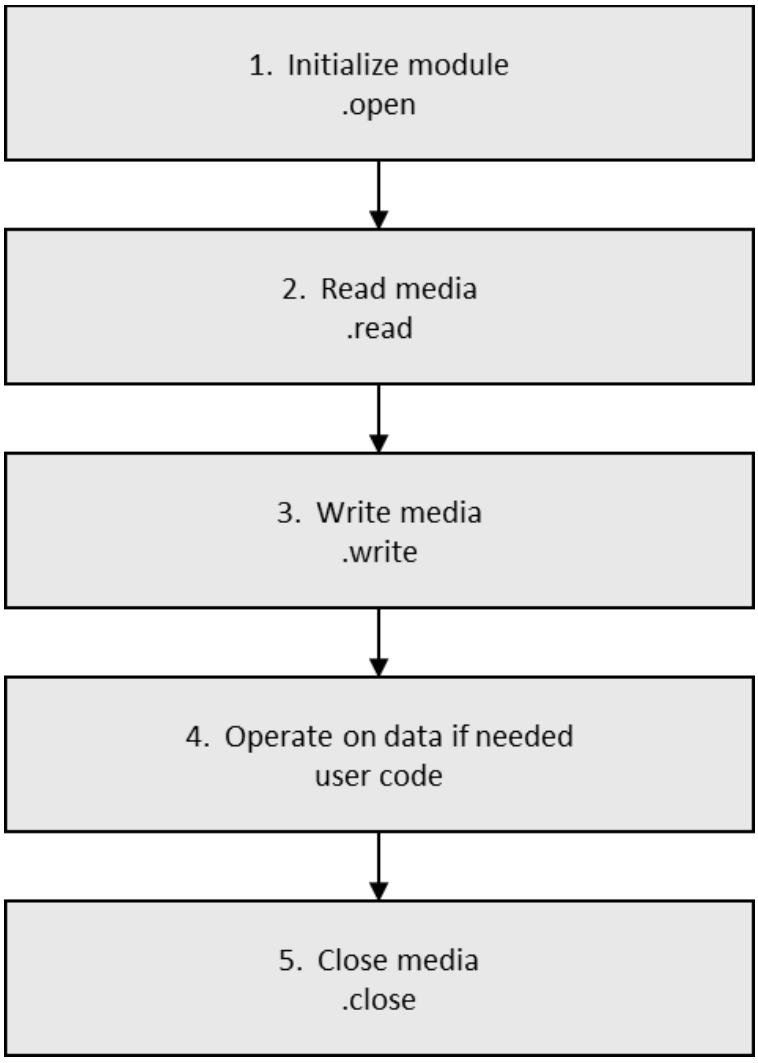

Figure 128: Flow Diagram of a Typical Block Media QSPI Framework Module Application

The typical steps for sf_block_media_qspi using sf_el_fx, in an application are:

1) Initialize media using the FileX API fx_system_initialize (sf_el_fx calls it automatically)
2) Format media using FileX API fx_media_format (sf_el_fx calls it automatically if "Format media during initialization" property is set to Enabled) This Format media is optional if media has already been formatted. Anything on the media will erase while media format.

3) Open the media using FileX API fx_media_open (sf_el_fx opens the media automatically)
4) Read media as required using the read API (Block Media Framework) or one of the FileX API e.g. fx_media_read(), fx_file_read()
5) Write to media as required using the write API (Block Media Framework) or one of the FileX API e.g. fx_media_write(), fx_file_write()

NOTE: After successful fx_media_open call, all FileX APIs can be used, not only read and write.

These common steps are illustrated in a typical operational flow in the following figure:

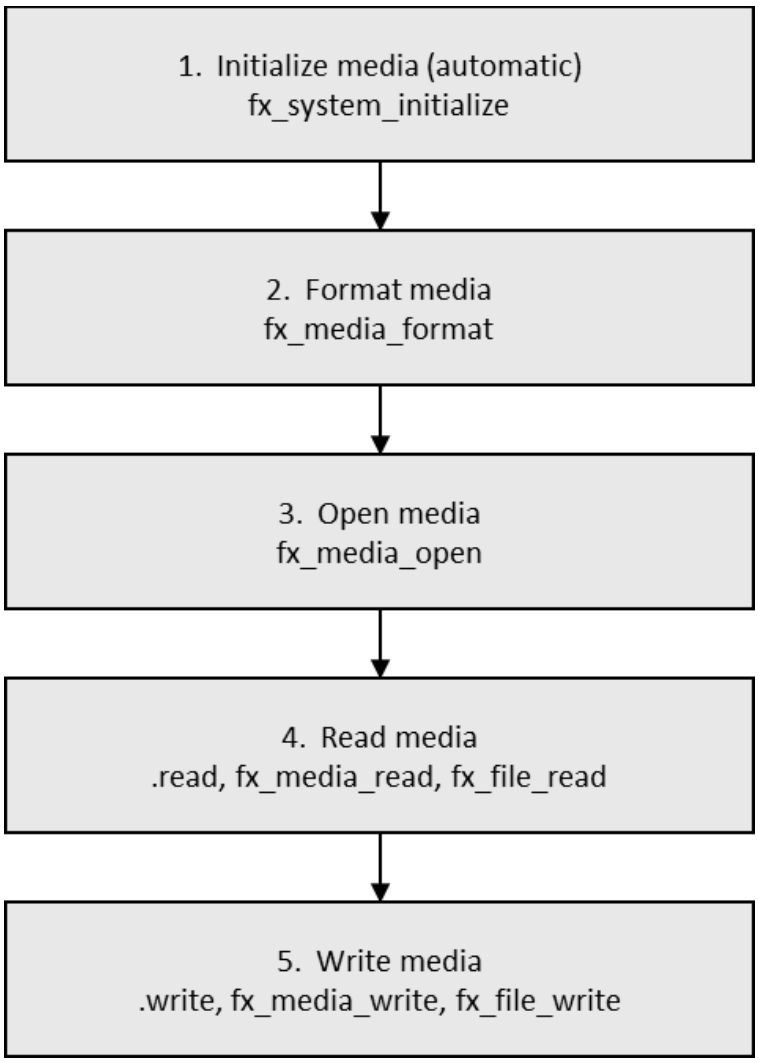

Figure 129: Flow Diagram of a Typical Block Media QSPI Framework Module Application

4.1.8 Block Media RAM Framework

The Block Media Framework Module implements a file system on RAM for read, write, and control of the read/write region of RAM memory. The framework has all the functionality needed to interface with a file system through a block media interface.

4.1.8.1 Block Media RAM Framework Module Features

- Enable FileX to be run on linear memory-mapped devices.
- Temporary and fast storage of data on RAM.

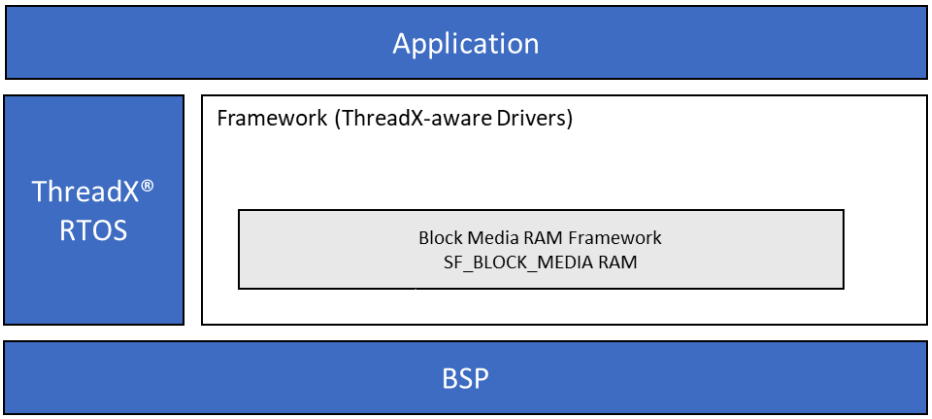

Figure 130: Block Media RAM Framework Module Block Diagram

4.1.8.2 Block Media RAM Framework Module APIs Overview

The Block Media RAM Framework module implements APIs to open, read, write and close the module. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Block Media RAM Framework Module API Summary

Function Name	Example API Call and Description
.open	g_sf_block_media_ram0.p_api->open (g_sf_block_media_ram0.p_ctrl, g_sf_block_media_ram0.p_cfg); Open device for read, write and control.

Function Name	Example API Call and Description
.read	g_sf_block_media_ram0.p_api->read (g_sf_block_media_ram0.p_ctrl, p_dest, start_block, block_count); Read data from RAM buffer.
.write	g_sf_block_media_ram0.p_api->write (g_sf_block_media_ram0.p_ctrl, p_source, start_block, block_count); Write data to RAM buffer.
.ioctl	g_sf_block_media_ram0.p_api->ioctl (g_sf_block_media_ram0.p_ctrl, command, p_data); Send control commands to and receive status of RAM buffer.
.close	g_sf_block_media_ram0.p_api->close (g_sf_block_media_ram0.p_ctrl); Close the framework.
.versionGet	g_sf_block_media_ram0.p_api->versionGet(&version); Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_UNSUPPORTED	Command not supported.
SSP_ERR_NOT_OPEN	Unit is not open
SSP_ERR_ASSERTION	A parameter is NULL.

Name	Description
SSP_ERR_IN_USE	Framework is already open.
SSP_ERR_INVALID_BLOCKS	Invalid block passed.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.1.8.3 Block Media RAM Framework Module Operational Overview

The Block Media Framework Interface is simply an abstract interface using function pointers instead of direct function calls. Functions are called between FileX and the SSP block media drivers, such as SDMMC, SPI Flash and SDRAM/RAM. The interface remains the same for any media driver so that all media drivers appear functionally identical at file I/O layer and can be interchanged with one another without changing code. Device adaptation drivers, such as sf_block_media_ram, are accessed through the Block Media Framework Interface and provide device specific code needed to perform media I/O operations. Configuration and control structures passed through block media function calls are generally device specific as well.

Block Media RAM Framework Module Important Operational Notes and Limitations

The media must be formatted before you can open the media and begin creating, writing, and reading files.

The memory area used must be directly readable and writable by the core. Internal SRAM or SDRAM size should be sufficient for the block media RAM and there will be no persistence of data across the power cycles.

Block count must be assigned by considering the boot record, FAT area, root directory and directory sector. If the File System is used on RAM then the minimum block count must be four, as the first three sectors are reserved for boot record, FAT area and root directory and the fourth sector is used for data sector.

The "Format media during initialization" property needs to be enabled in order to use RAM for FileX.

The "File System is on block media" property needs to be true in order to configure the block count and block size from the block media RAM.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.8.4 Including the Block Media RAM Framework Module in an Application

This section describes how to include the Block Media RAM Framework module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Block Media RAM Framework module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the Block Media RAM Framework module is g_sf_block_media_ram0. This name can be changed in the associated Properties window.)

Block Media RAM Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_ sf_block_media_ram0 Block Media Framework on sf_block_media_ram	Threads	New Stack> Framework> File System> Block Media Framework on sf_block_media_ram

When the Block Media RAM Framework module on sf_block_media_ram is added to the thread stack, as shown in the following figure, the configurator automatically adds any lower-level drivers that are required. Any drivers that need additional configuration information will be box-text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

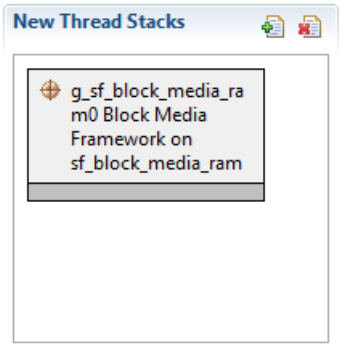

Figure 131: Block Media RAM Framework Module Stack

4.1.8.5 Configuring the Block Media RAM Framework Module

The Block Media RAM Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the Block Media RAM Framework Module on sf_block_media_ram

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: Enabled	If selected code for parameter checking is included in the build.
Name	g_sf_block_media_ram0	Module name
Block size of media in bytes	512	Specify the size of the block used on the target media
Number of blocks to allocate	16	Specify the number of blocks to allocate on the target media. The target must have sufficient storage to support the total number of bytes specified.
Enter the valid section for RAM buffer allocation	noint	Specify the section of RAM to be used as the target media.

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Block Media RAM Framework Module Clock Configuration

The Block Media RAM Framework module uses the ICLK as the source for the internal RAM.

Block Media RAM Framework Module Pin Configuration

The Block Media RAM Framework module uses internal RAM so no external pins are required.

4.1.8.6 Using the Block Media RAM Framework Module in an Application

The "Format media during initialization" property needs to be enabled in order to use RAM for FileX.

The "File System is on block media" property needs to be true in order to configure the block count and block size from the block media RAM.

The typical steps for sf_block_media_ram framework in an application are:

1) Initialize media using the open API
2) Read media as required using the read API
3) Write media as required using the write API
4) Operate on data as required.
5) Close media as required using the close API

These common steps are illustrated in a typical operational flow in the following figure:

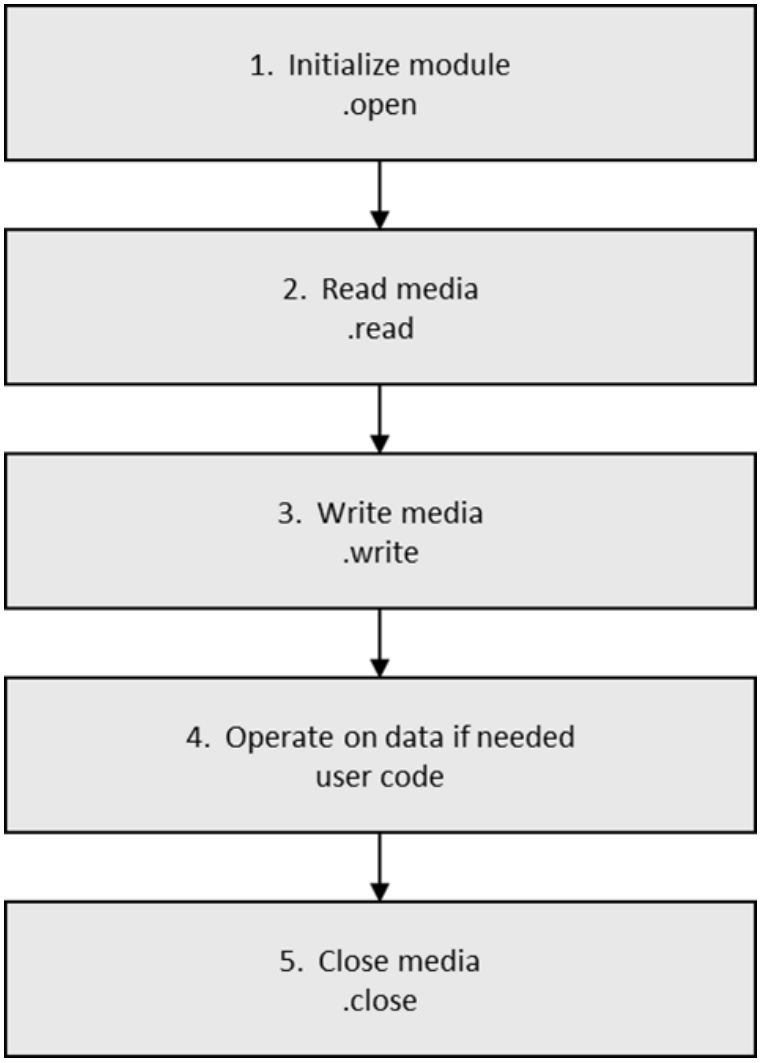

Figure 132: Flow Diagram of a Typical Block Media RAM Framework Module Application

The typical steps for sf_block_media_ram using sf_el_fx, in an application are:

1) Initialize media using the FileX API fx_system_initialize (Synergy generated code calls it automatically)
2) Format media using FileX API fx_media_format (Synergy generated code calls it automatically if "Format media during initialization" property is set to Enabled)
3) Open the media using FileX API fx_media_open (Synergy generated code opens the media automatically if "Auto Initialization" property is set to Enable)
4) Read media as required using the read API (Block Media Framework) or one of the FileX APIs, for example, fx_media_read(), fx_file_read()Write to media as required using the write API (Block Media Framework) or one of the FileX APIs, for example, fx_media_write(), or fx_file_write()

NOTE: After successful fx_media_open call, all FileX APIs can be used, not only FileX read and FileX write.

These common steps are illustrated in a typical operational flow in the following figure:

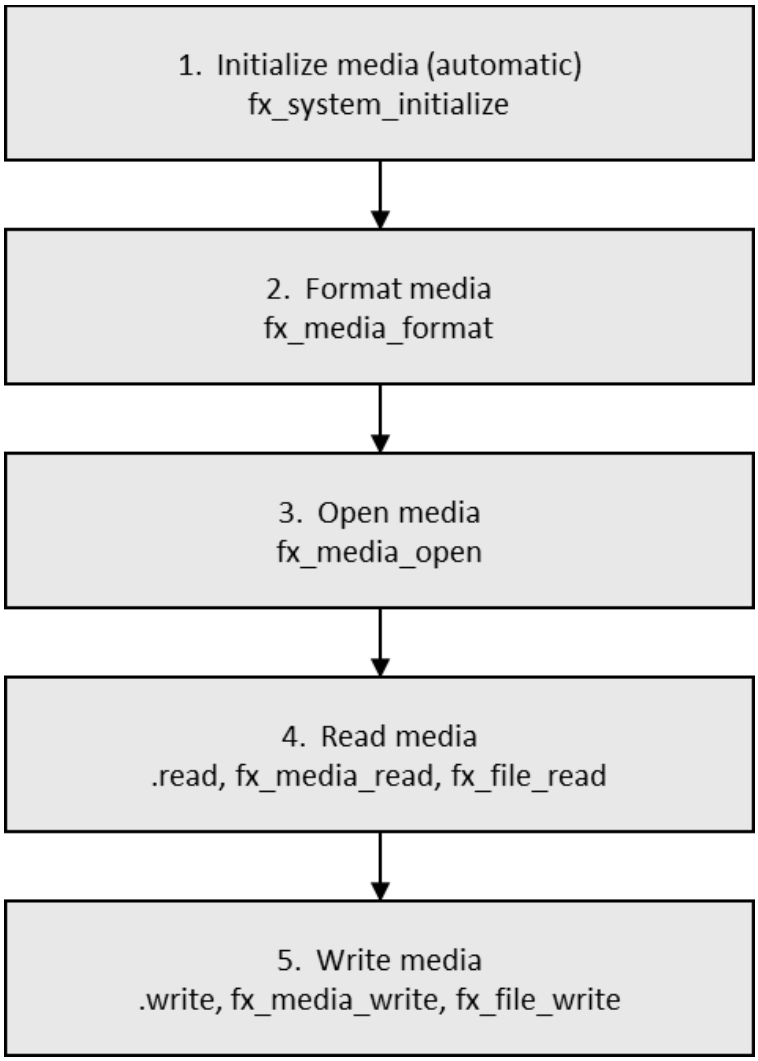

Figure 133: Flow Diagram of a Typical Block Media RAM Framework Module Application for FileX

4.1.9 BLE Framework

Bluetooth® Low Energy (BLE), sometimes referred to as **Bluetooth Smart**, is a light-weight subset of Classic Bluetooth and was introduced as part of the Bluetooth 4.0 core specification. In contrast to Classic Bluetooth, BLE is designed to provide significantly lower power consumption. This allows Internet of Thing (IoT) devices that have stricter power capacity to transfer small amounts of data between nearby devices.

Application developers access the functionality provided by the BLE stack using its APIs. The BLE stack APIs provided by different vendors are not standardized. This results in application developers having to update their code when porting to different BLE stacks.

The Synergy BLE Framework handles this issue by providing a generic interface for the underlying BLE stack provided by various vendors there by preventing coupling between application and vendor-specific BLE stack code. The use of generic APIs makes application development simpler and portable.

The BLE framework provides high-level API for BLE applications, and is implemented as sf_ble_rl78g1d. The BLE framework uses the Synergy Software Package (SSP) communication framework which in turn enables UART driver for communication to the underlying BLE module. It also integrates the generic BLE profile framework (g_sf_ble_onboard_profile) which provides a uniform interface to BLE profiles. For the RL78G1D BLE hardware module, the generic BLE profiles are implemented by the BLE module firmware.

4.1.9.1 Features

The Synergy BLE framework supports the following features:

- ThreadX® RTOS Aware and thread safe
- Bluetooth v4.2 compliant framework.
- Generic Access Profile (GAP) Features
  - User-defined advertising data
  - Security modes 1 and 2
  - Peripheral and central roles
  - White list support up to 6 devices
  - Bonding support
- Generic Attribute Profile (GATT) features
  - GATT client and server
- Generic Attribute Profile (GATT) APIs
- Generic Access Profile (GAP) APIs
- Generic On-board Profiles APIs

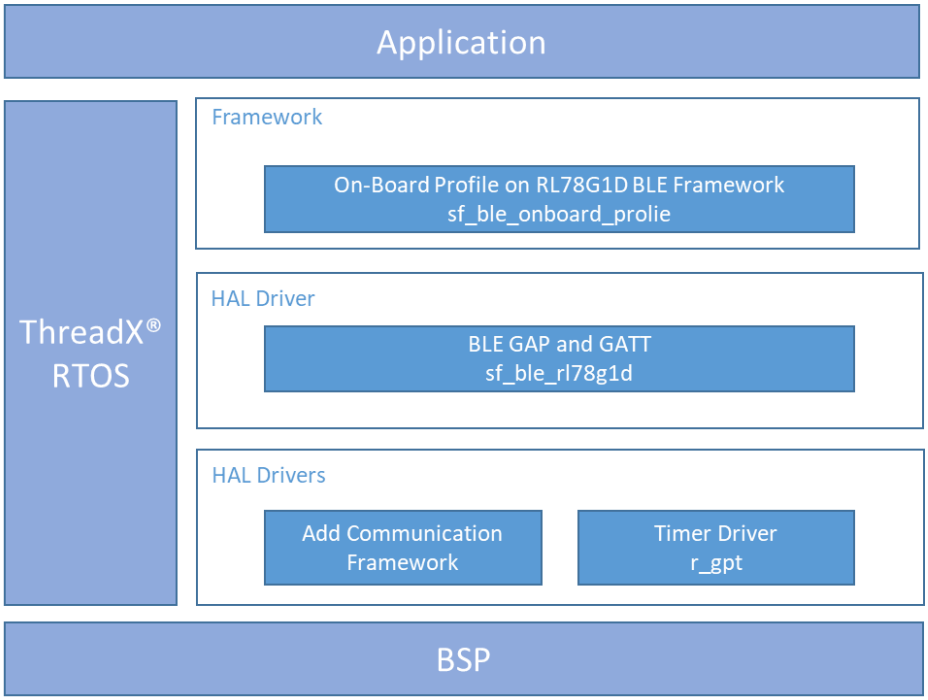

Figure 134: BLE Framework Module Organization, Options and Stack Implementations

4.1.9.2 BLE Framework Module APIs Overview

The BLE Framework defines API's for initializing, setting and getting values and stopping modules. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

BLE Framework Module On-Board Profiles API Summary

Function Name	Example API Call and Description
.open	g_sf_ble_onboard_profile0.p_api->open (g_ sf_ble_onboard_profile0.p_cfg); This API initializes the interface for data transfers.
.close	g_sf_ble_onboard_profile0.p_api->close (g_ sf_ble_onboard_profile0.p_cfg); This API de-initializes the interface and may put it in low power mode or power it off. The API closes the driver, and disables the driver link and interrupt.

Function Name	Example API Call and Description
.onbpEnable	g_sf_ble_onboard_profile0.p_api->onbpEnable (sf_ble_onboard_profile0.p_cfg, p_handle, profile, p_prf_cb, sec); Enables the profile in server mode or client mode.
.onbpServerWriteData	g_sf_ble_onboard_profile0.p_api->onbpServerWriteData (sf_ble_onboard_profile0.p_cfg,p_handle, profile, characteristics, p_data); Updates the value of the characteristic in the local database.
.onbpServerSendNotification	g_sf_ble_onboard_profile0.p_api->onbpServerSendNotification (sf_ble_onboard_profile0.p_cfg, p_handle, profile, characteristics, p_data); Sends notifications.
.onbpServerSendIndication	g_sf_ble_onboard_profile0.p_api->onbpServerSendIndication (sf_ble_onboard_profile0.p_cfg, p_handle, profile, characteristics, p_data); Sends indications.
.onbpClientWriteCCCD	g_sf_ble_onboard_profile0.p_api->onbpClientWriteCCCD (sf_ble_onboard_profile0.p_cfg, p_handle, profile, cccd_char, cccd_val); Sets the Client Configuration Control Descriptor on the remote device.
.onbpDisable	g_sf_ble_onboard_profile0.p_api->onbpDisable (sf_ble_onboard_profile0.p_cfg, p_handle, profile); Disables the profile in server mode and client mode.

Function Name	Example API Call and Description
.onbpClientReadChar	g_sf_ble_onboard_profile0.p_api->onbpClientReadChar (sf_ble_onboard_profile0.p_cfg, p_handle, profile, characteristics); Reads a GATT characteristic associated with the profile or service.
.opbClientWriteChar	g_sf_ble_onboard_profile0.p_api->onbpClientWriteChar (sf_ble_onboard_profile0.p_cfg, p_handle, profile, characteristics); Writes a GATT characteristic associated with the profile or service.
.versionGet	g_sf_ble_onboard_profile0.p_api-> versionGet(&version); Retrieve the API version using the version pointer.

NOTE: 1. All the details related to BLE standard profiles can found in BLE profile specifications.

NOTE: 2. BLE APIs will return "SSP_ERR_UNSUPPORTED" if module does not support that feature.

BLE Framework Module GAP API Summary

Function Name	Example API Call and Description
.open	g_sf_ble0.p_api->open(g_ sf_ble_0.p_cfg); This function initializes and enables the BLE module. It accepts the BLE module configuration as an argument, which has the following parameters: - 48-bit Bluetooth Address - Device scan interval - Device scan window - Device discoverable time - Device connection interval - Slave latency - Supervision timeout - Own address type - Maximum slaves allowed to be connected
.close	g_sf_ble0.p_api->close (g_ sf_ble0.p_cfg); This API de-initialize the interface and may put the BLE module in low power mode or power it off. It also closes the driver, disables the driver link, disable the interrupt in the BLE module driver.

Function Name	Example API Call and Description
.infoGet	g_sf_ble0.p_api->infoGet (g_sf_ble_0.p_cfg, p_handle, p_ble_info); The infoGet API takes the BLE control structure as an argument. It returns the following information obtained from the BLE module: - Chipset/driver information string - RSSI value (unsigned integer 16 bits)
.provisionGet	g_sf_ble0.p_api->provisionGet (g_sf_ble_0.p_cfg, p_ble_provisioning); The provisionGet API gets the BLE GAP provisioning information and takes the BLE control structure as an argument. It returns the following parameters: - Bonding Mode - Security Mode - GAP Role (Central/Master or Peripheral/Slave) - Security Keys

Function Name	Example API Call and Description
.provisionSet	g_sf_ble0.p_api->provisionSet (g_sf_ble_0.p_cfg, p_ble_provisioning); The provisionSet() function provisions BLE module. It takes BLE control structure and provisioning structure as an argument. - Bonding Mode - Security Mode - GAP Role (Central/Master or Peripheral/Slave) - Security Keys - GAP user event callback
.scan	g_sf_ble0.p_api->scan (g_sf_ble_0.p_cfg, p_scan, p_cnt, p_scan_info); The scan() function takes BLE control structure as an argument. Scan() function returns a list of BLE devices scanned by the BLE module with below parameters. - Bluetooth address (48-bits) - RSSI - Scan data - Advertising Event type The scan() function takes device count as an argument which acts as an in/out parameter. It specifies size of scan result array and BLE framework sets it to count indicating number of scan results stored in array. The function takes scan type as argument(Active/Passive).

Function Name	Example API Call and Description
.advertisementStart	g_sf_ble0.p_api->advertisementStart (g_sf_ble_0.p_cfg, p_advt_info); The advertisementStart() function takes following parameters: - Discovery mode (General/Limited) - Filter policy – Support for scan/connect request filtering combinations - Advertisement data - Connection mode - Advertisement intervals - Channel map - Address type - Advertising type - Scan response data
.advertisementStop	g_sf_ble0.p_api->advertisementStop (g_sf_ble_0.p_cfg); Stops advertisement.
.whitelistAdd	g_sf_ble0.p_api->whitelistAdd (g_sf_ble_0.p_cfg, p_bp_addr); The whitelistAdd() function add devices to the whitelist for advertisements, scan requests and connection requests.

Function Name	Example API Call and Description
.whitelistDel	g_sf_ble0.p_api->whitelistDel (g_sf_ble_0.p_cfg, p_bp_addr); The whitelistDel() function deletes devices from the whitelist for advertisements, scan requests and connection requests.
.bondingStart	g_sf_ble0.p_api->bondingStart (g_sf_ble_0.p_cfg, p_handle, p_bp_addr, p_bonding_start); The bondingStart() function start bonding with a remote device.
.bondingResponse	g_sf_ble0.p_api->bondingResponse (g_sf_ble_0.p_cfg, p_handle, p_bp_addr, p_bonding_resp); The bondingResponse () function responds to a bonding request.
.startEncryption	g_sf_ble0.p_api->startEncryption (g_sf_ble_0.p_cfg, p_enc_info); The startEncryption() function begins an encryption operation.
.connect	g_sf_ble0.p_api->connect (g_sf_ble_0.p_cfg, p_handle, p_conn); The connect function connects to a remote device.
.disconnect	g_sf_ble0.p_api->disconnect (g_sf_ble_0.p_cfg, p_handle); The disconnect() function disconnects from a remote device.
.listen	g_sf_ble0.p_api->listen (g_sf_ble_0.p_cfg); The listen function listens for an incoming connect request from a remote device.

Function Name	Example API Call and Description
authorization	g_sf_ble0.p_api->authorization (g_sf_ble_0.p_cfg, &conhandle); The authorization() function authorizes a remote device after connection.
setTxPower	g_sf_ble0.p_api->setTxPower(g_\sf_ble_0.p_cfg, &con_handle, &tx_power_info); The setTxPower() function sets the transmit power for the procedure specified by the connection handle.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables review the SSP Reference Manuals found as described in the Reference Section at the end of this document.

BLE Framework Module GATT API Summary

Function Name	Example API Call and Description
.gattAddCustomProfiles	g_sf_ble0.p_api->gattAddCustomProfiles (g_sf_ble_0.p_cfg, p_handle, p_sf_ble_svc_dscv_req, p_sf_ble_svc_dscv_rsp, p_rsp_cnt); This function adds custom profiles to the GATT database.
.gattServiceDiscovery	g_sf_ble0.p_api->gattServiceDiscovery (g_sf_ble_0.p_cfg, p_handle, p_sf_ble_svc_dscv_req, p_sf_ble_svc_dscv_rsp, p_rsp_cnt); The gattServiceDiscovery() function performs service discovery.
.gattCharDiscovery	g_sf_ble0.p_api->gattCharDiscovery (g_sf_ble_0.p_cfg, p_handle, p_sf_ble_svc_dscv_req, p_sf_ble_svc_dscv_rsp, p_rsp_cnt); The gattCharDiscovery() function performs the Char discovery operation.

Function Name	Example API Call and Description
.gattCharDescDiscovery	g_sf_ble0.p_api->gattCharDescDiscovery (g_sf_ble_0.p_cfg, p_handle, start_handle, end_handle, p_sf_ble_svc_dscv_rsp, p_rsp_cnt); Discovers GATT characteristics descriptor on a remote device.
.gattCharRead	g_sf_ble0.p_api->gattCharRead (g_sf_ble_0.p_cfg, p_handle, start_handle, p_char_read_req, p_char_read_rsp); Reads GATT characteristics on a remote device.
.gattCharWrite	g_sf_ble0.p_api->gattCharWrite (g_sf_ble_0.p_cfg, p_handle, p_char_read_req); Writes GATT characteristics on a remote device.
.gattCharExecuteWrite	g_sf_ble0.p_api->gattCharExecuteWrite (g_sf_ble_0.p_cfg, p_handle, execute_flag); Executes a write (commit) on GATT characteristics on a remote device.
.gattCharWriteLocal	g_sf_ble0.p_api->gattCharWriteLocal (g_sf_ble_0.p_cfg, char_handle, data_length); Update the local GATT database.
.gattSendNotify	g_sf_ble0.p_api->gattSendNotify (g_sf_ble_0.p_cfg, p_handle, char_handle); Sends notifications from local GATT server to remote GATT client.
.gattSendIndicate	g_sf_ble0.p_api->gattSendIndicate (g_sf_ble_0.p_cfg, p_handle, char_handle); Sends indications from local GATT server to remote GATT client.

Function Name	Example API Call and Description
.gattWriteResponse	g_sf_ble0.p_api->gattWriteResponse (g_sf_ble_0.p_cfg, p_handle, char_handle); Responds to the write characteristic value request from the remote GATT client.
.versionGet	g_sf_ble0.p_api->versionGet(&version); Retrieve the API version using the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables review the SSP Reference Manuals found as described in the Reference Section at the end of this document.

Error Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_ASSERTION	Parameter has invalid value.
SSP_ERR_INVALID_PTR	p_version is NULL.

NOTE: Lower level drivers may return Common Error Codes. Refer to the SSP Reference Manual available as described in the Reference Section at the end of this document for a definition of all relevant Error codes.

4.1.9.3 BLE Framework Module Operational Overview

This section provides the Synergy BLE Framework software architecture overview and highlights the major SSP modules used as part of BLE framework along with the operational flow sequence from the user's application level.

NOTE: A more comprehensive description of the operation of the BLE Framework module is available in the BLE Framework- Application Project. The complete project and associated application note can be found by doing a search for r30qan0309eu in the search bar at the top of the http://www.renesas.com home page.

BLE Framework Module Operation Description

The BLE framework provides a common interface for the application. The implementation of the interface is specific for each module. The Synergy BLE framework currently defines an interface implemented for RL78G1D BLE module. Each

implementation interacts with the corresponding BLE device driver. The BLE device driver uses the underlying SSP communication framework (g_sf_comms) which in turn interacts with the SSP HAL components such as Universal Asynchronous Receiver/Transmitter (UART), Data Transfer Controller (DTC), and General PWM Timer (GPT) drivers to communicate with the BLE module. The following figure shows a high-level architectural description of the BLE Framework module.

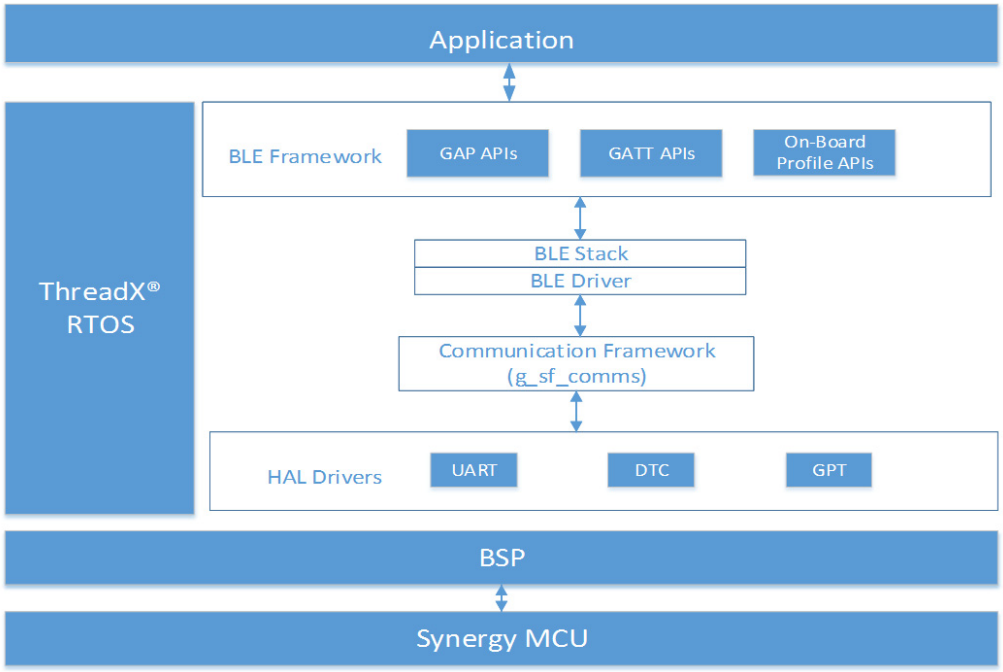

Figure 135: Typical BLE module architecture types

GAP and GATT APIs

The BLE framework provides a generic interface for the application to configure and provision the BLE module. The BLE module has various configuration parameters as specified by the family of Bluetooth Smart standards. It is possible that individual device drivers and/or BLE modules might not support all configuration parameters. At a bare minimum, the provisioning API provides a mechanism to set the operating mode, security mode, security keys, and bonding mode of the BLE interface. It also provides an API for the GAP/GATT layers.

On-board Profiles APIs

The on-board profiles APIs provide a uniform interface to the BLE profiles implemented by the BLE module firmware.

BLE Stack

The BLE module host stack is typically provided by the BLE module vendor. The BLE module typically comes in three different flavors depending on the HW/SW partitioning between the host MCU and BLE module. The RL78G1D BLE module is part of the Network Controller Implementation architecture where the BLE chipset includes all the implementation for the BLE link layer, GAP, GATT, and on-board profiles. The module interfaces with the MCU over sf_comms framework provided by SSP.

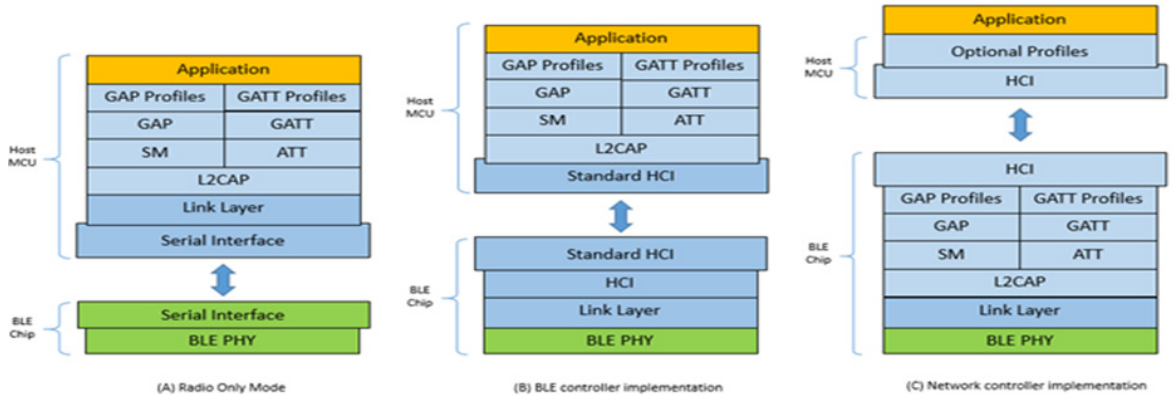

Figure 136: BLE module architecture types

A: BLE radio-only mode

Link layer, L2CAP, GATT, GAP layers, profiles, and application run on the host MCU. Physical layer runs on BLE chipset.

B: BLE controller implementation

Link layer runs on BLE chipset, L2CAP, and higher BLE protocol (GATT, GAP) layers. Profiles and application run on the host MCU.

C: Network controller implementation

Link layer, L2CAP, GATT, GAP layers, and generic profiles run on the BLE chipset. Optional profiles and application run on the host processor.

4.1.9.4 BLE Framework Instances

Application must define the BLE framework instance before using it. The instance is a structure that includes pointers to any of the following:

BLE Framework Control Structure

This structure is used in all BLE framework APIs. This structure includes pointer to driver handle, which is used by framework for storing the required information by the BLE device driver.

BLE Framework Configuration Structure

This structure is passed to open() API and you can use this structure to configure the BLE module. This configuration is applied either during initialization, such as open or provisioning such as provisioningSet. Configuration parameters that are not supported by the BLE module are ignored by the framework.

BLE Framework APIs structure

This structure contains pointers to the BLE Framework APIs that are specific to a given module. See the BLE Framework Module API Overview for more details on these APIs.

BLE Framework Module Operational Flow

The steps for using the BLE Framework module in an application are:

1) Initialize the BLE hardware module.
2) Select the GATT layer role such as GATT client or GATT server. It is most common for the slave (peripheral) device to be the GATT server and the master (central) device to be the GATT client.
3) The application controls operations using generic (on-board) profile APIs or GAP/GATT APIs.

NOTE: The GAP provisioning structure has a BLE user callback that runs in the driver thread context. An application should make sure that callback logic is as minimal as possible without any blocking calls. Print statements or blocking call may introduce delays in BLE driver execution. Make sure that no BLE APIs are called in user callbacks as it may also lead to code failure.

The following BLE module initialization sequence is part of the Synergy auto-generated code:

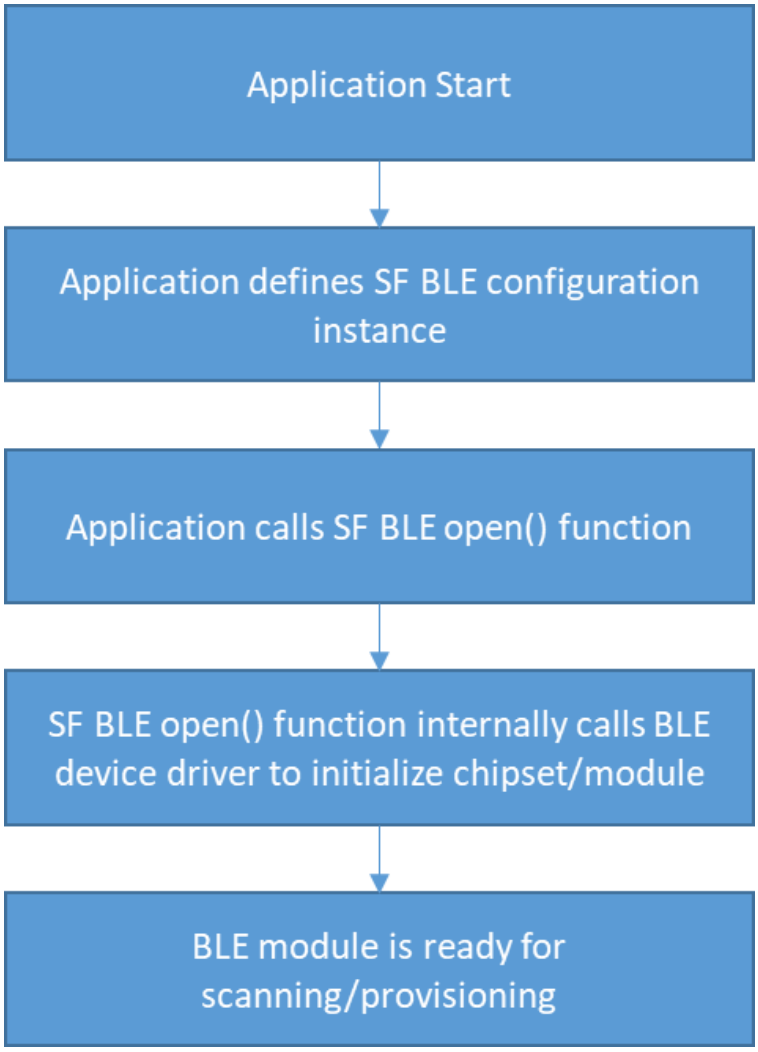

Figure 137: Autogenerated Initialization Sequence Flow Chart

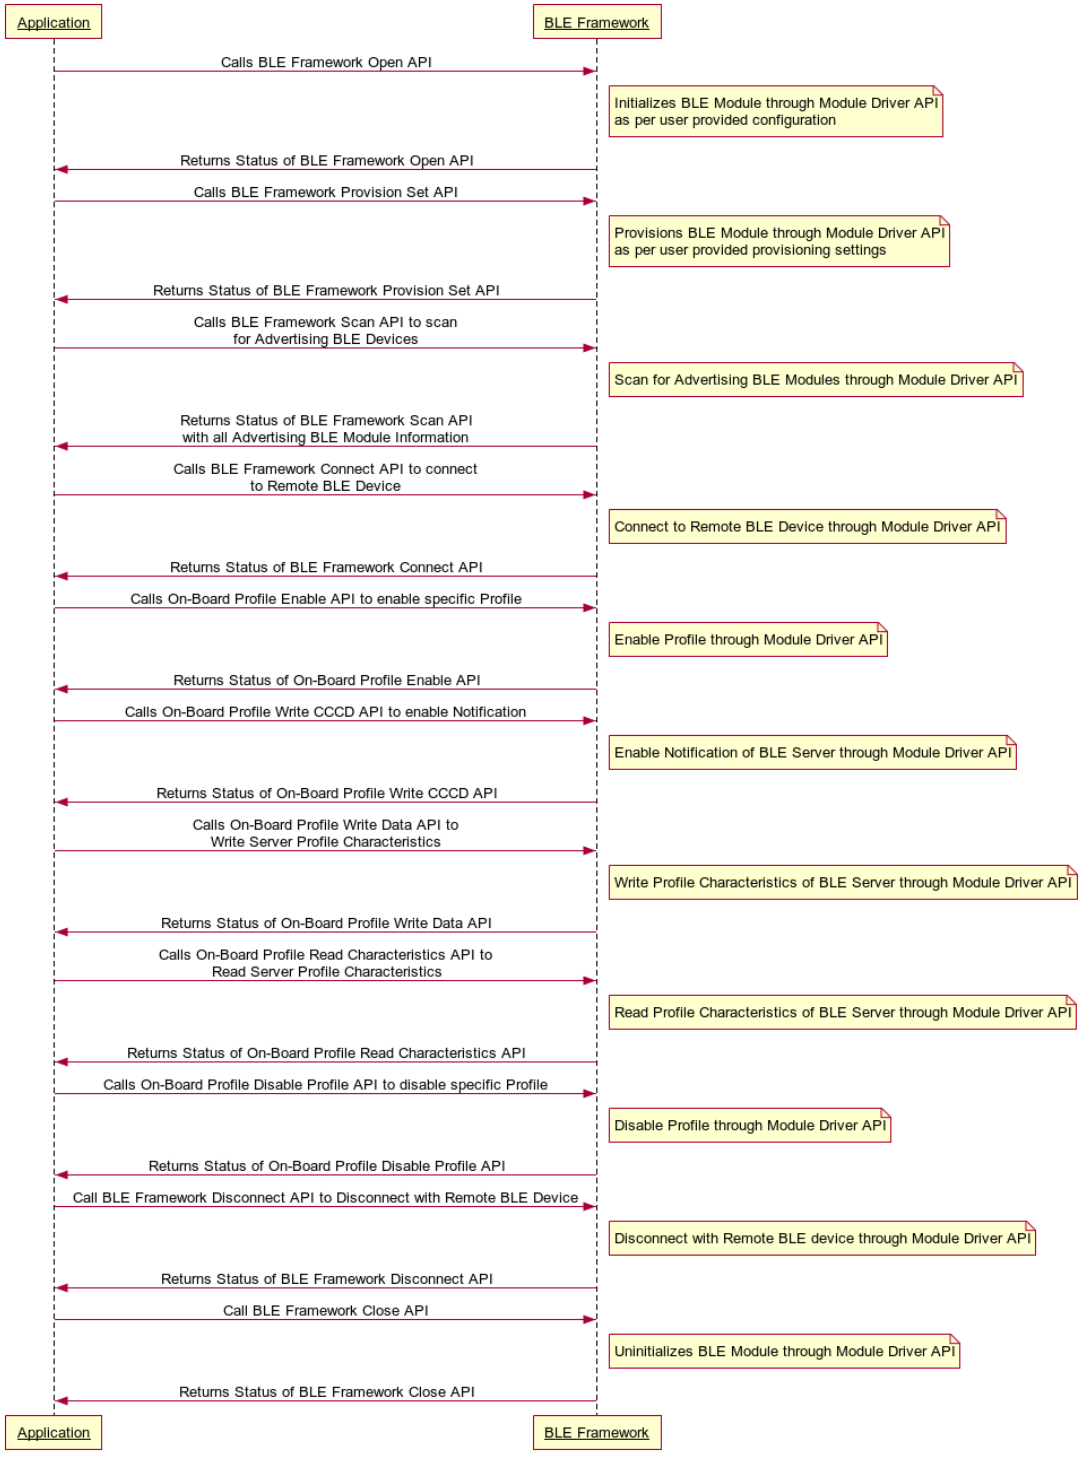

Figure 138: On-Board Profile Client Application Flow

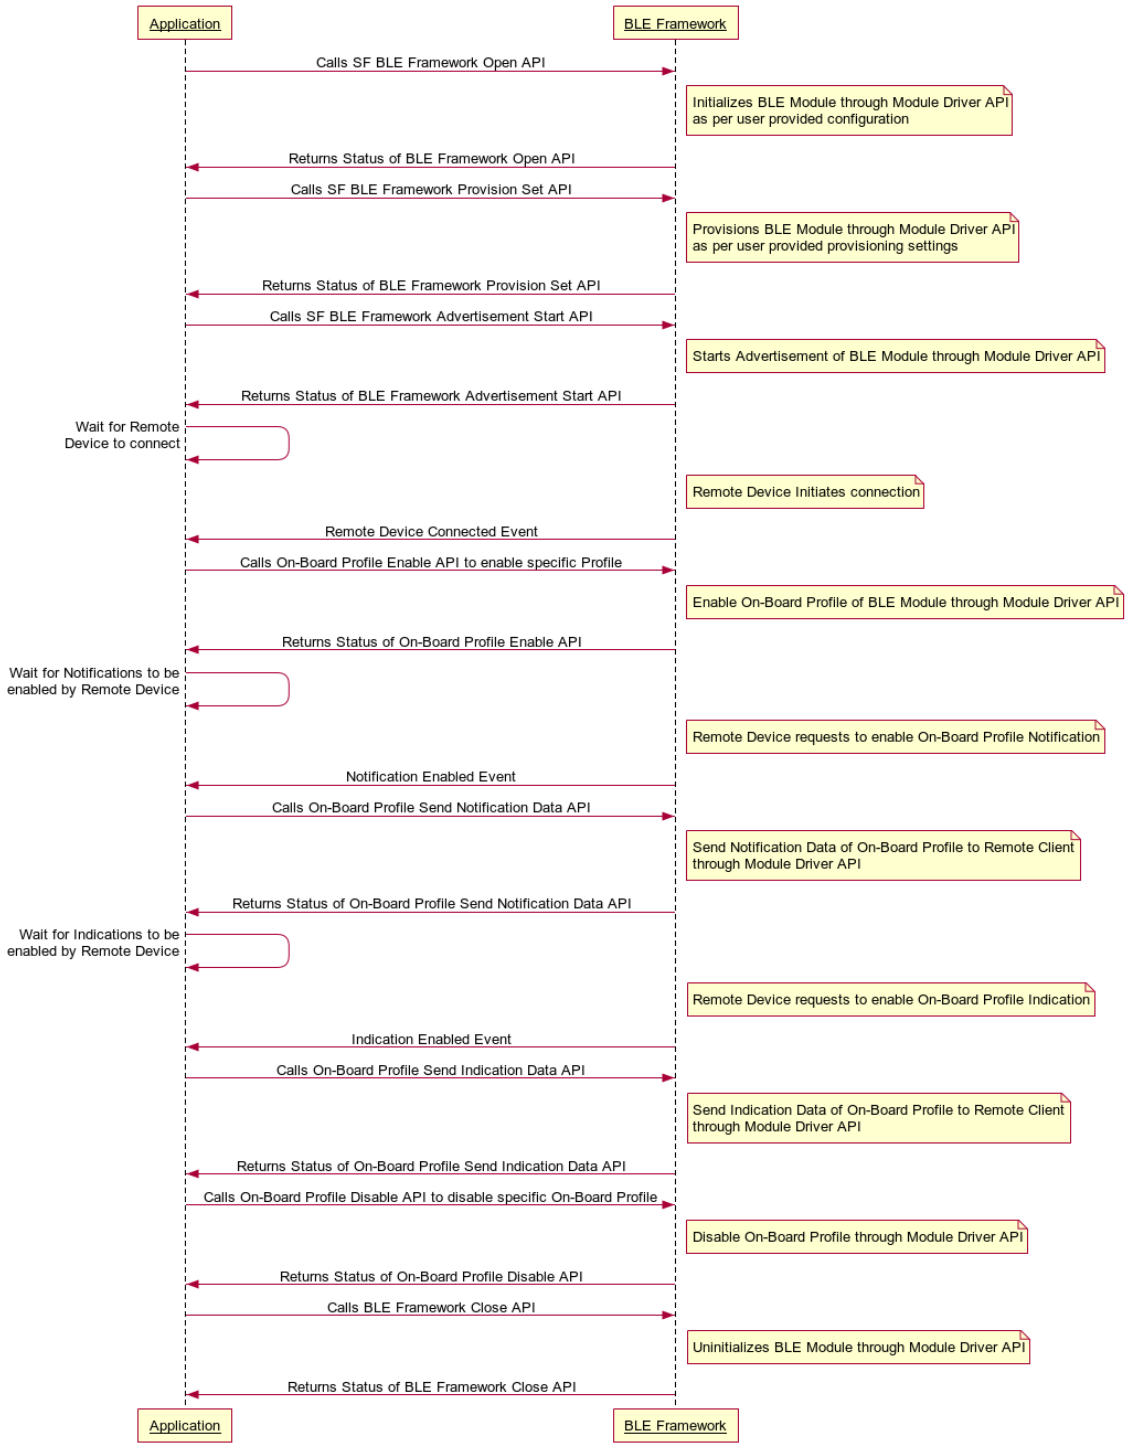

Figure 139: On-Board Profile Server Application Flow

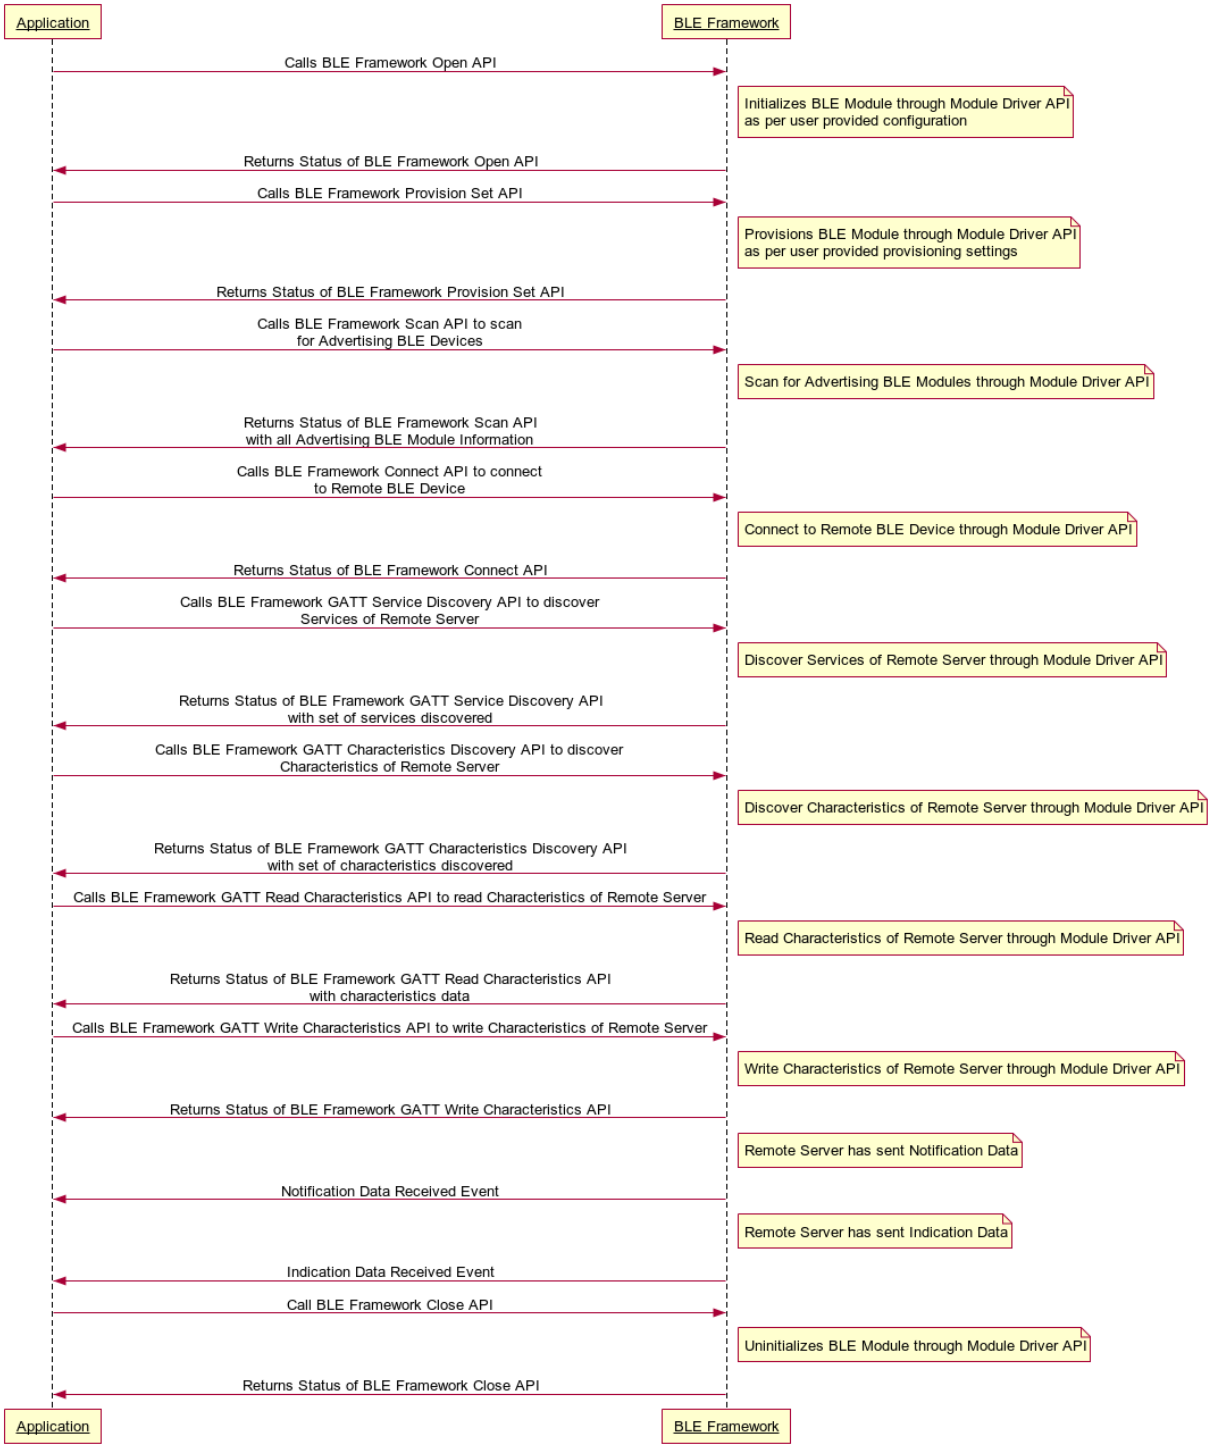

Figure 140: GAP/GATT Client Application Flow

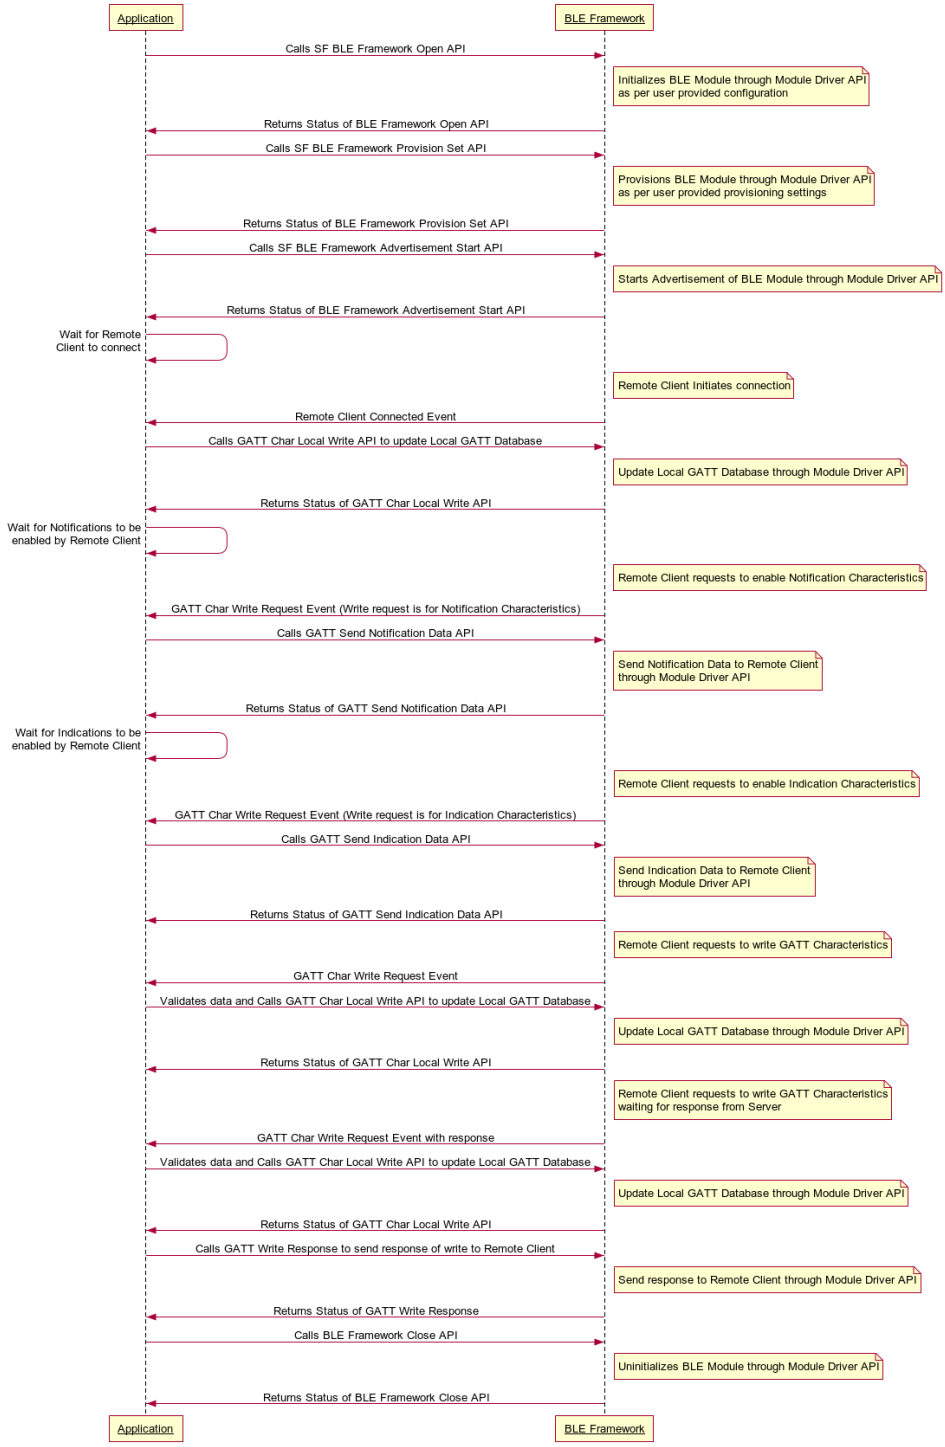

Figure 141: GAP/GATT Server Application Flow

BLE Framework Security

Security Manager provides BLE protocol stack the ability to generate and exchange security keys which is used to encrypt communication link. The Security Manager has two functions:

- **Initiator**
  - This is the GAP Master/Central device
- **Responder**
  - This is the GAP Slave/Peripheral device.

The initiator is the master device that initiate the security procedure, however the slave device can asynchronously request the initiator to begin the security procedure.

BLE Security provides modes with levels associated with each mode. Security mode and level is a combination of support for authenticated or unauthenticated pairing, encryption or data signing. Pairing is required to satisfy various security requirements. Two types of pairing are available:

Authenticated pairing where devices are protected from MITM (Man In The Middle) attacks

Unauthenticated pairing where they are not protected from MITM.

- **Security Mode 1**
  - Security Level 1: No Security
  - Security Level 2: Unauthenticated pairing with encryption
  - Security Level 3: Authenticated pairing with encryption
  - Security Level 4: Authenticated LE secure connections pairing with encryption
- **Security Mode 2**
  - Security Level 1: Unauthenticated pairing with data signing
  - Security Level 2: Authenticated pairing with data signing

NOTE: RL78G1D BLE module does not support Security Mode 1 with Security Level 4

- **On-Board Profile Security Modes**
  - **No Security**: If On-Board Profile security is set to No Security then Profile communication works in unsecured mode regardless of BLE GAP Security Mode and Level.
  - **Unauthenticated**: For this Profile Security method to work any of the BLE GAP Security Method other than Security Mode 1 Level 1 should be used. Module should have completed Pairing with the remote device.
  - **Authenticated**: For this Profile Security method to work any of the following BLE GAP Security Method should be used. Module should have completed Pairing with the remote device.Security Mode 1 Level 3Security Mode 2 Level 2
  - **Authorization**: For this Profile Security method to work the remote device should have been Authorized during GAP connection using BLE Framework authorization API This On-Board profile security parameter is specific to server API only. Refer sample code snippets in section 0 for more details.

– **Encryption**: In this Security procedure Profile will use Encrypted communication. For this Profile Security method to work any of the BLE GAP Security Method other than Security Mode 1 Level 1 should be used. If any security method is used which does not use encryption then Profile works in unencrypted mode.

NOTE: 1. On-Board Profile security can be set in onbpEnable() function. onbpEnable() API enables the profile in server mode or client mode. It is a generic API to enable client and server mode. But, profile security parameter is specific to server API only. Security parameter can be set for server only in driver APIs. So, user needs to set profile security for server enable API.

NOTE: 2. Profile security enums are in bit pattern, so more than one profile security can be set using bitwise operators. There are few points to be kept in mind while setting the profile security. They are listed below:

- If profile security is none, then other security bits should not be set.
- Security bits should not be set to both authenticated and unauthenticated.
-

BLE Security has the following procedures:

Pairing

This procedure is used to generate temporary encryption key to encrypt communication link.

Permanent encryption keys can be shared over this encrypted communication link for additional communication.

Bonding

This is a combination of pairing and storing of permanent keys. After pairing, the permanent keys are stored in a non-volatile memory, which creates a permanent bond between two devices. For subsequent communication, it is not necessary for devices to perform the bonding procedure.

Encryption Establishment

Communication is encrypted using permanent keys.

Pairing creates a secure link that lasts for the lifetime of the connection, whereas bonding creates a permanent association called bond.

BLE Security goes through three phases. Two devices establish connection using the GAP connection procedure, followed by the three phases to establish a secure communication link:

Phase 1 (Pairing Phase, Information Sharing)

Initially in phase 1, all information required to generate the temporary keys are shared between two devices.

Phase 2 (Pairing Phase, Temporary Key Sharing)

In this phase, temporary encryption key (Short Term Key or STK) is generated on both devices. This is used to encrypt the connection. This encrypted link can be used for additional communication. This communication link remains encrypted until the peer devices stay connected.

Phase 3 (Bonding, Sharing and Storage of Permanent keys)

Devices enter this phase if bonding is required. In this phase, permanent keys (Long Term Key or LTK) is exchanged between two devices using the encrypted link which was established in phase 2 using temporary keys. These permanent keys are then stored in non-volatile memory to be made available for the devices over each connection.

4.1.9.5 BLE Framework Limitations

1) The BLE framework is tested only on RL78G1D BLE hardware module. Supported for different BLE modules will be added in later versions.
2) BLE Framework using RL78G1D will see compilation warnings. All the warnings are in the 3rd party RL78G1D driver code. The BLE framework files do not have any warning. These warnings should not impact the user applications.
3) The custom profile support in the BLE framework is limited to RL78G1D type BLE hardware module only.
4) HID profile client mode not supported by RL78G1D BLE hardware module. As a result, the BLE framework implementation of HID profile will also not support HID profile client mode. Applications using BLE framework for RL78G1D will not be able to use the HID profile in client mode.
5) Multiple slave BLE devices cannot be connected to RL78G1D BLE module.
6) The BLE framework is only tested on the following boards:
   - DK-S7G2 Version 3.1
   - DK-S3A7 Version 2.0
   - PK-S5D9 Version 1.0
   - ADK-S3A3
   - TB-S5D5 Version 0.5D
   - TB-S3A6 Version 0.5D
   - DK-S128 Version 0.5b
   - DK-S124 Version 3.1
7) Refer to the most recent SSP release notes for module limitations.

4.1.9.6 Including the BLE Framework Module in an Application

This section describes how to include the BLE Framework Module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the Getting Started Guide for SSP given in the References section at the end of this document to learn how to manage each of these important steps in creating SSP-based applications.

To add the BLE Framework module to an application, simply add it to a project thread using the stacks selection sequence given in the following table. (The default name for the BLE Framework is g_sf_ble0. This name can be changed in the associated Properties window.)

BLE Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_ble0 RL78G1D BLE GAP and GATT on sf_ble_rl78g1d	Threads	New Stack> Framework> Networking> BLE > RL78G1D BLE GAP and GATT on sf_ble_rl78g1d
g_sf_ble_onboard_profile0 On-Board Profile on RL78G1D BLE Framework	Threads	New Stack> Framework> Networking> BLE > On-Board Profile on RL78G1D BLE Framework

When the BLE Framework Module is added to the thread stack as shown in the following figure, the configurator automatically adds the needed lower-level drivers. Any drivers that need additional configuration information will be highlighted in red. Modules with a gray band are individual modules that stand alone. Modules with a blue band are shared or common and need only be added once and can be used by multiple stacks. Modules with a pink band can require the selection of lower-level drivers; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level drivers is required, the module description will include "Add" in the text. Clicking on any pink banded modules will bring up the "New" icon and then display the possible choices.

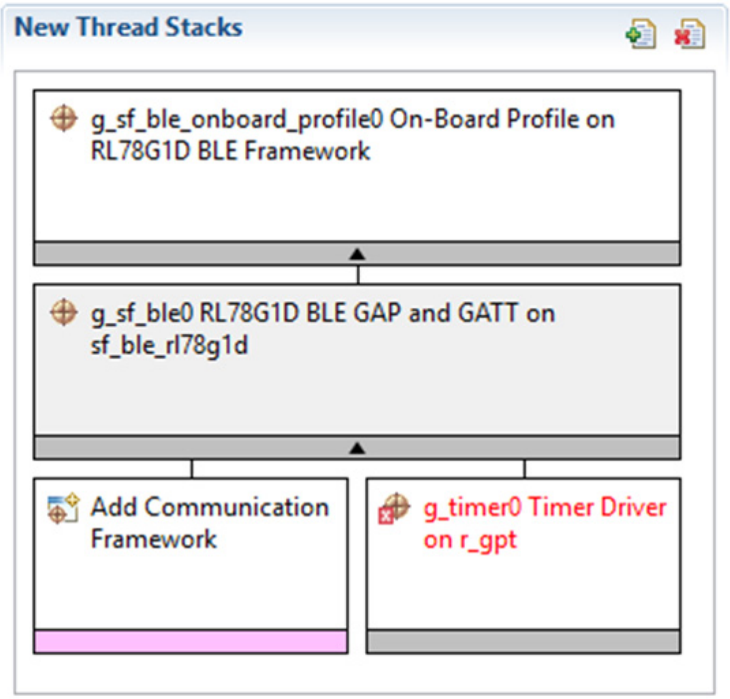

Figure 142: BLE Framework Module Stack

4.1.9.7 Configuring the BLE Framework Module

The BLE Framework Module must be configured by you for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or

operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the Interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the On-Board Profile on RL78G1D BLE Framework

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Heart Rate Profile	Enabled, Disabled Default: Enabled	Heart rate profile selection
Alert Notification Profile	Enabled, Disabled Default: Disabled	Alert notification profile selection
Blood Pressure Profile	Enabled, Disabled Default: Disabled	Blood pressure profile selection
Find Me Profile	Enabled, Disabled Default: Disabled	Find me profile selection
HID Over GATT Profile	Enabled, Disabled Default: Disabled	HID gatt profile selection

ISDE Property	Value	Description
Health Thermometer Profile	Enabled, Disabled Default: Disabled	Health thermometer profile selection
Phone Status Alert Profile	Enabled, Disabled Default: Disabled	Phone alert profile selection
Proximity Profile	Enabled, Disabled Default: Disabled	Proximity proximity profile selection
Scan Parameter Profile	Enabled, Disabled Default: Disabled	Scan parameter profile selection
Time Profile	Enabled, Disabled Default: Disabled	Time time profile selection
Name	g_sf_ble_onboard_profile0	Module name

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the BLE GAP and GATT

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_sf_ble0	Module name
Bluetooth Device Address (Restart Board after first run to see changed Address)	{0x0, 0x0, 0x0, 0x0, 0x0}	Bluetooth device address selection

ISDE Property	Value	Description
Address Type	Public Address, Random Address Default: Public Address	Address type selection
Scan Interval	48	Scan interval selection
Scan Window	48	Scan window selection
Maximum Connection Interval	40	Maximum connection interval selection
Connection Slave Latency	0	Connection slave latency selection
Supervision Timeout	80	Supervision timeout selection
BLE Driver Thread Priority	1	BLE Driver thread priority selection
BLE Serial Thread Priority	1	BLE Serial thread priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the GPT HAL Module on r_gpt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_timer0	Module name.
Channel	0	Channel selection.
Mode	Periodic	Warning: One-shot functionality is not available in the GPT hardware, so it is implemented in software by stopping the timer in the ISR called when the period expires. For this reason, ISR's must be enabled for one-shot mode even if the callback is unused.
Period Value	10	See Timer Period Calculation

ISDE Property	Value	Description
Period Unit	Milliseconds	See Timer Period Calculation
Duty Cycle Value	50	Duty cycle value selection
Duty Cycle Unit	Unit Raw Counts	Duty cycle unit selection
Auto Start	True	Set to true to start the timer after configuring or false to leave the timer stopped until start is called.
GTIOCA Output Enabled	False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCA Stop Level	Pin Level Low	Controls output pin level when the timer is stopped.
GTIOCB Output Enabled	False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCB Stop Level	Pin Level Low	Controls output pin level when the timer is stopped.
Callback	RBLE_Timer_cb	A user callback function can be registered in open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.

ISDE Property	Value	Description
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

BLE Framework Module Clock Configuration

The BLE Framework module uses the clocks specified by the lower-level modules.

BLE Framework Module Pin Configuration

The BLE Framework module uses the pins specified by the lower-level modules.

4.1.9.8 Using the BLE Framework Module in an Application

NOTE: A more comprehensive example of using the BLE Framework module is available in the BLE Framework-Application Project. This complete project and associated application note can be found by doing a search for r30an0309eu in the search bar at the top of the http://www.renesas.com home page.

The typical steps in using the BLE Framework module in a simple application, using the on-board profile server flow, are:

1) Initialization- registration of callback functions, provisioning, and advertisement using the open API
2) Provision the BLE module using the provisionSet API
3) Advertise the module using the advertisementStart API- wait for remote device to connect
4) Enable the on-board profile using the onbpEnable API- wait for notification to be enabled by Remote device
5) Send notification using the onbpServerSendNotification API- wait for Indication to be enabled by Remote device
6) Send indication using the onbpServerSendIndication API
7) Disable the profile using the onbpDisable API
8) Close the BLE module using the close API

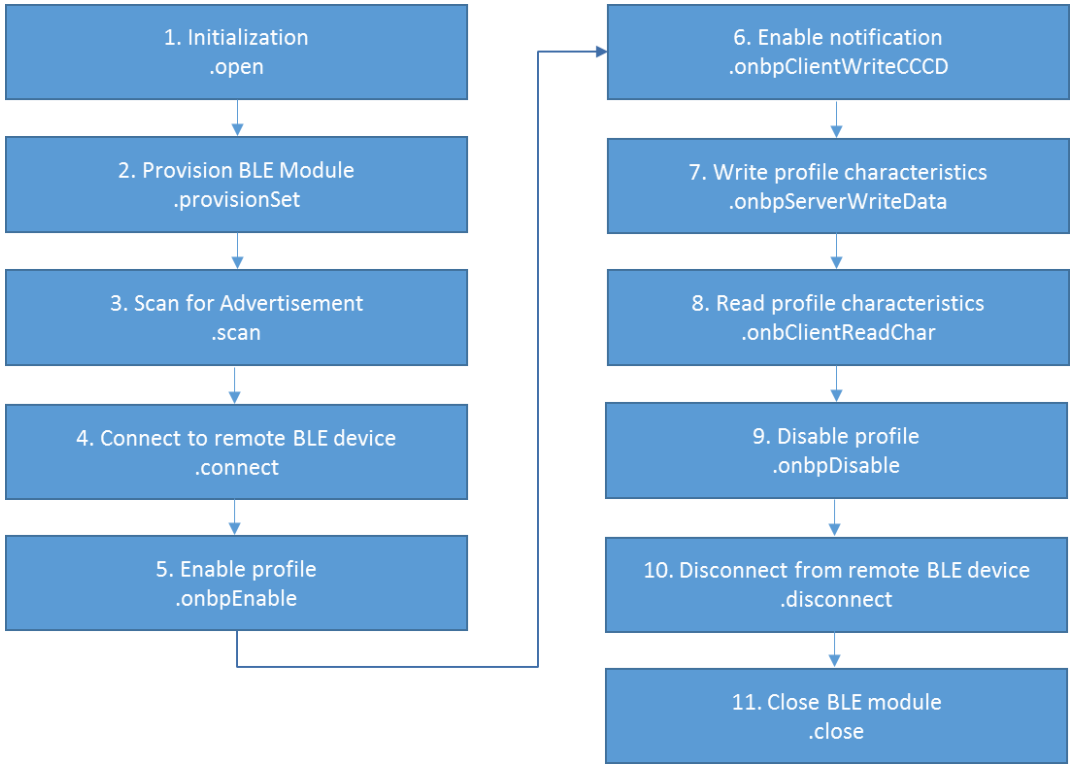

Figure 143: Typical BLE Framework Application Flow for On-Board Profile Client

4.1.10 Cellular Framework

The Cellular Framework module provides a high-level application layer interface for the cellular modem integration in SSP. The Cellular framework provides a common interface for the applications to interface with the Cellular modems from various vendors.

The Cellular Framework provides a set of APIs to provision, configure and communicate with the cellular network for data communication. The Cellular framework uses the Console framework to communicate with Cellular modems over a serial interface by using AT commands. The Cellular framework creates the serial data pipe over serial interface for the data communication, leveraging the PPP WAN protocol provided by NetX™. Data communication using TCP/IP can be established over this Wide Area Network (WAN) link using NetX Application protocols, sockets or IoT protocols such as MQTT.

The Cellular Framework also provides the framework level Socket APIs to communicate with the TCP/IP stack present on-chip (inside cellular hardware module) in certain cellular hardware modules and with the TCP/IP link for the network using socket APIs.

4.1.10.1 Cellular Framework Module Features

- Supports connectivity using:
  - CAT1, CAT3 and CAT M1 Cellular Modems
  - BSD Socket interface for On-Chip stack present on the Cellular Module

  - NetX Stack on Synergy MCU (Host) using NSAL interface
- Supports a common a set of APIs, to interface to the networking stack and generic interface for the different Cellular hardware modules.
- Using generic APIs and abstraction, applications developed for the cellular hardware module can be easily migrated to work with another cellular hardware module.
- Supported Cellular modems:
  - NimbeLink CAT3 (NL-SW-LTE-TSVG) Verizon-US
  - NimbeLink CAT3 (NL-SW-LTE-TEUG) India and Europe
  - NimbeLink CAT1 (NL-SW-LTE-GELS3-B and NL-SW-LTE-GELS3-C) Verizon-US
  - Quectel CAT M1-BG96

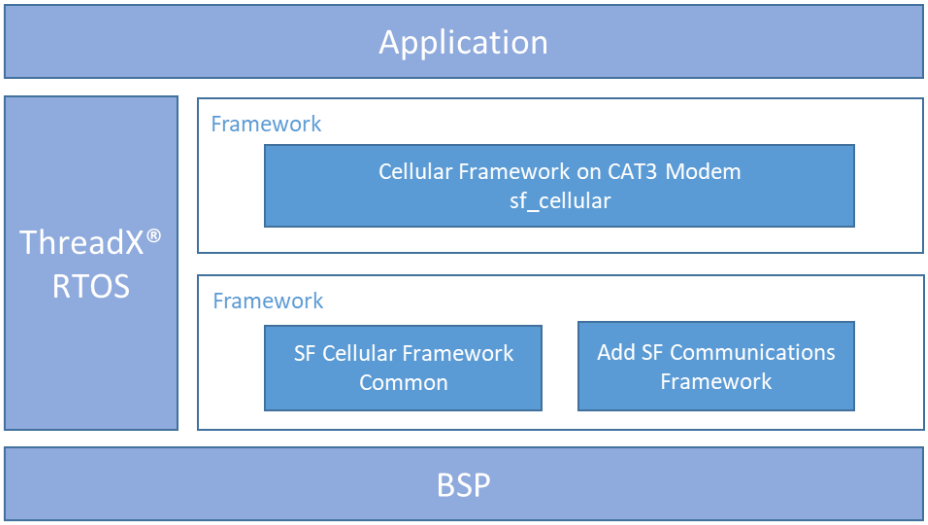

Figure 144: Cellular Framework on CAT3 Modem Module Organization, Options and Stack Implementations

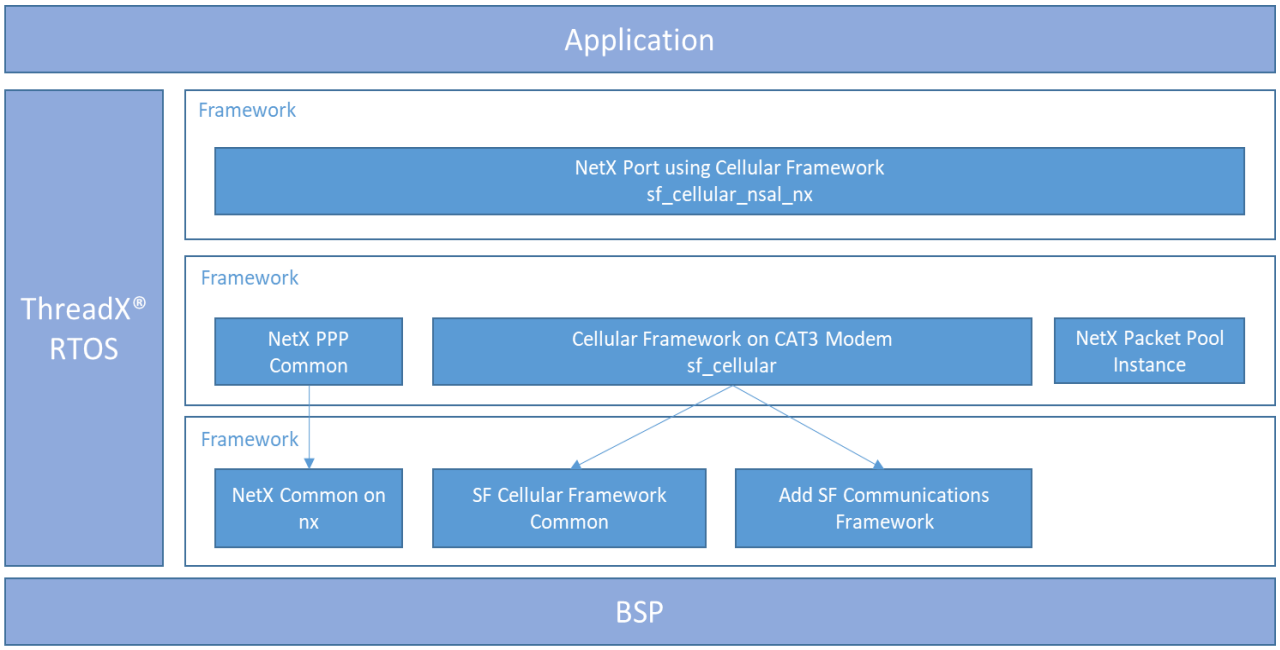

Figure 146: NetX Port using Cellular Framework Module Organization, Options and Stack Implementations

4.1.10.2 Cellular Framework Module APIs Overview

The Cellular Framework defines API's for each of the related modules. The following descriptions explain the operation of each API.

NOTE: A more detailed description of the Cellular framework module APIs are available in the Cellular Application Note downloadable from the Renesas web site. Just search, in the top search bar, for R30AN0311 and the application note and application project will be listed in the search results.

Cellular Framework Module APIs Summary

The Cellular framework provides a generic interface for the network stack and applications. Below are the APIs provided by the framework.

Cellular Framework Module API Summary

Function Name	Example API Call and Description
.open	g_sf_cellular0.p_api->open (g_sf_cellular0.p_ctrl, g_sf_cellular0.p_cfg); This API function initializes and enables the Cellular module. The open function returns the Cellular control structure, uniquely identifying the instance of the Cellular framework. The Cellular framework open function accepts the Cellular module configuration as an argument, with the following parameters: Operator Selection Mode (enumeration) Operator Name Format (enumeration) Operator Name (string) Preferred Operator List (array of structures) Time zone update policy (enumeration)
.close	g_sf_cellular0.p_api->close (g_sf_cellular0.p_ctrl); This API un-initializes the Cellular module and disables it. It takes the Cellular control structure as an argument.

Function Name	Example API Call and Description
.infoGet	g_sf_cellular0.p_api->infoGet (g_sf_cellular0.p_ctrl, p_cellular_info); This API takes the Cellular control structure as an argument and returns the following information obtained from the Cellular module: Chipset/driver information (string) Manufacturer Name (string) Firmware version (string) IMEI Number (string) RSSI value (unsigned integer 16 bits) Bit Error Rate (unsigned integer 16 bits)
.statisticsGet	g_sf_cellular0.p_api->statisticsGet (g_sf_cellular0.p_ctrl, p_stats); This API gets the data statistics from the Cellular module. It takes the Cellular control structure as an argument and returns the following statistics: Received packets (unsigned integer 32 bits) Transmitted packets (unsigned integer 32 bits) Transmit packet errors (unsigned integer 32 bits)

Function Name	Example API Call and Description
.transmit	g_sf_cellular0.p_api->transmit (g_sf_cellular0.p_ctrl, p_buffer, length); This API sends the data/packet out. It takes the Cellular control structure, the data buffer and the data buffer length as an argument. The Cellular framework transmit function passes the data buffer to the PPP driver for transmission.
.provisioningGet	g_sf_cellular0.p_api->provisioningGet (g_sf_cellular0.p_ctrl, p_cellular_provisioninfo); This API takes the Cellular control structure as an argument and returns the following parameters: Authentication type(enumeration) Username (string) Password (string) APN Name(string) PDP Context ID (integer) PDP Context Type (enumeration) Airplane mode (enumeration)

Function Name	Example API Call and Description
.provisioningSet	g_sf_cellular0.p_api->provisioningSet (g_sf_cellular0.p_ctrl, p_cellular_provisioninfo); This API sets the authentication credential information. It takes the Cellular control structure and the following parameters as argument to provision the Cellular module: Authentication type(enumeration) Username (string) Password (string) APN Name(string) PDP Context ID (integer) PDP Context Type (enumeration) Airplane mode (enumeration)
.networkConnect	g_sf_cellular0.p_api-> networkConnect (g_sf_cellular0.p_ctrl); This API establishes the Network connection over Cellular Network using which application can communicate to remote host with the help of Network stack. It takes the Cellular control structure as an argument.
.networkDisconnect	g_sf_cellular0.p_api->networkDisconnect (g_sf_cellular0.p_ctrl); This API terminates the Network connection established using networkConnect API. It takes the Cellular control structure as an argument.

Function Name	Example API Call and Description
.simPinSet	g_sf_cellular0.p_api->simPinSet (g_sf_cellular0.p_ctrl, p_pin); This API allows the application/user to change the PIN required to register on Cellular Network. It takes the Cellular control structure, old PIN and New PIN as arguments.
.simLock	g_sf_cellular0.p_api->simLock (g_sf_cellular0.p_ctrl, p_pin); This API locks the SIM. It takes the Cellular control structure and Sim PIN as arguments.
.simUnlock	g_sf_cellular0.p_api->simUnlock (g_sf_cellular0.p_ctrl, p_pin); This API unlocks the SIM. It takes the Cellular control structure and Sim PIN as arguments.
.simIDGet	g_sf_cellular0.p_api->simIDGet (g_sf_cellular0.p_ctrl, p_sim_id); This API reads the Sim ID from the Cellular module. It takes the Cellular control structure as argument and returns the SIM ID read from the Cellular module.

Function Name	Example API Call and Description
.networkStatusGet	g_sf_cellular0.p_api->networkStatusGet (g_sf_cellular0.p_ctrl, p_status); This API gets Cellular Module Network Status information. It takes the Cellular control structure as argument and returns following parameters: Country code (integer) Operator code (integer) RSSI (integer) Cell ID (string) IMSI (string) Operator name (string) Service Domain (integer) Active Band (integer)
.fotaCheck	g_sf_cellular0.p_api->fotaCheck (g_sf_cellular0.p_ctrl, p_fota_check); This API checks for available firmware Upgrade. It takes the Cellular control structure and fota check specific structure as argument.
.fotaStart	g_sf_cellular0.p_api->fotaStart (g_sf_cellular0.p_ctrl, p_fota_start); This API starts the firmware upgrade. It takes the Cellular control structure and fota start specific structure as argument.

Function Name	Example API Call and Description
.fotaStop	g_sf_cellular0.p_api->fotaStop (g_sf_cellular0.p_ctrl, p_fota_stop); This API stops the firmware upgrade. It takes the Cellular control structure and fota stop specific structure as argument.
.versionGet	g_sf_cellular0.p_api->versionGet (p_version); This API retrieves the version for the API using the version pointer.
.reset	g_sf_cellular0.p_api->reset (g_sf_cellular0.p_ctrl, reset_type); Reset the cellular hardware module.

Cellular Framework Module Socket APIs Summary

The Cellular socket framework provides additional API's as shown in the following table.

Cellular Socket Framework Module API Summary

Function Name	Example API Call and Description
.open	g_sf_cellular_socket0.p_api->open (g_sf_cellular_socket0.p_ctrl, g_sf_cellular_socket0.p_cfg); This API calls the Cellular Framework's lower level Open () API to Initialize the Cellular Device Driver.
.close	g_sf_cellular_socket0.p_api->close (g_sf_cellular_socket0.p_ctrl); This API calls the Cellular Framework's lower level Close () API to close the Cellular Device Driver
.versionGet	g_sf_cellular_socket0.p_api->versionGet (p_version); This API retrieves the version for the API using the version pointer.

Cellular Framework Module Socket APIs Summary

These APIs can be used by application to perform data transfer using sockets. It includes socket APIs which are compliant with BSD APIs:

- socket
- close
- connect
- send
- recv
- sendto
- recvfrom
- select

Cellular Framework Module Error Codes

The table below lists the Cellular Framework specific error codes. These error codes are part of ssp_err_t.

Cellular Framework Error Codes

Error Codes	Description
SSP_SUCCESS	Call successful
SSP_ERR_CELLULAR_CONFIG_FAILED	Configuration failed
SSP_ERR_CELLULAR_INIT_FAILED	Initialization failed
SSP_ERR_CELLULAR_TRANSMIT_FAILED	Transmit failed
SSP_ERR_CELLULAR_FW_UPTODATE	Up to date
SSP_ERR_CELLULAR_FW_UPGRADE_FAILED	Upgrade failed
SSP_ERR_CELLULAR_FAILED	General failure
SSP_ERR_CELLULAR_INVALID_STATE	Invalid state

4.1.10.3 Cellular Framework Module Operational Overview

Cellular Framework Module Operational Introduction

The Cellular framework provides a generic interface for applications to seamlessly communicate with the Cellular hardware module from various vendors without the necessity of changing the applications. The framework mainly consists of a common set of APIs, to interface to the networking stack and different Cellular hardware modules without having to change the applications. This section introduces the Cellular framework's basic blocks and key features that enables you to determine whether the intended Cellular application can be developed using the Cellular framework.

NOTE: Additional operational descriptions of the Cellular framework module are available in the Cellular Application

Note downloadable from the Renesas web site. Just search, in the top search bar, for R30AN0311 and the application note and application project will be listed in the search results.

With the Generic API and abstraction, the applications developed for the cellular hardware module can be easily ported to use another cellular hardware module. The networking stack NetX is also integrated with the framework using the Network Software Abstraction Layer (NSAL).

The Synergy Cellular Framework consists of the following logical blocks:

- Synergy Cellular Framework Application Interface.
- Network Stack Abstraction Layer (NSAL) for NetX TCP/IP stack
- Cellular Device Driver (AT command interface for interacting with the cellular chipset)
- BSD Socket compatible APIs for interfacing with Cellular hardware module that supports on-chip networking stack
- Synergy Software Package(SSP) HAL Interface

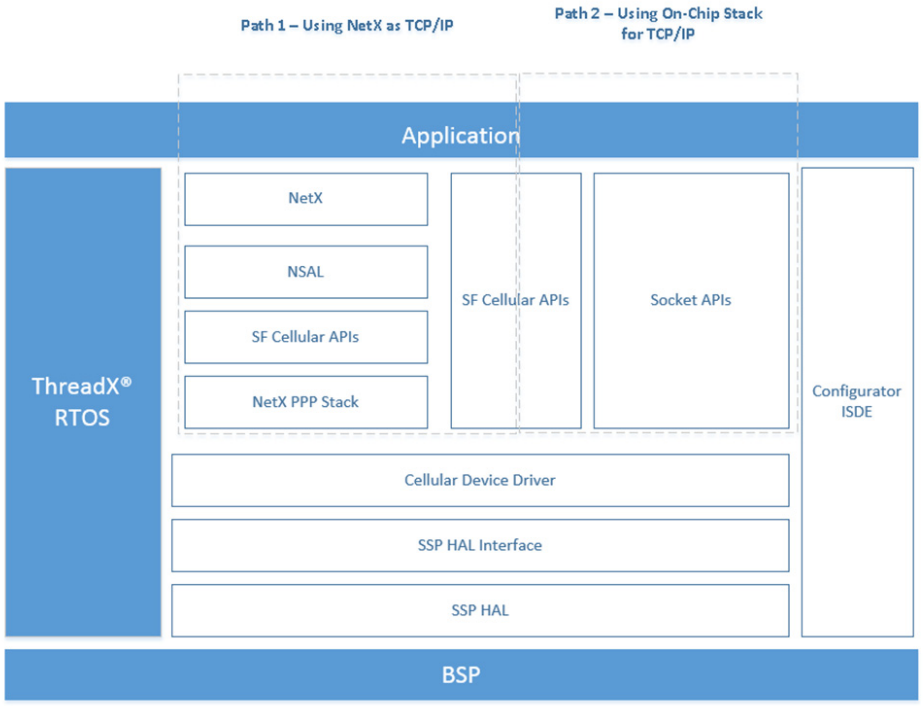

Figure 147: Cellular Framework Module Application Perspective

The Cellular Framework provides a common set of interfaces for the application to configure, provision and to communicate with the Cellular hardware module. By using these Generic interfaces, the user can develop the Cellular based application using Synergy MCUs. The Cellular hardware module has various configuration parameters as specified by the family of 3GPP standards. It is possible that individual device drivers and/or Cellular chipsets/modules will not support configuration of all parameters. At a bare minimum, the network operator, Access Point Name (APN) and security credentials are required to make the module functional.

The Cellular Framework provides a network stack abstraction layer (NSAL). NSAL is layer which connects the NetX and the Cellular driver by using (PPP) stack that is used for the data communication over WAN link.

The Cellular Framework provides a Socket level API for the application to interact with the on-chip networking stack present on the Cellular hardware module. This requires the Cellular hardware module/driver to support an on-chip networking stack and socket interface. When the application uses these APIs, it uses the on-chip networking stack present on the Cellular hardware module and does not use the NSAL or the NetX and its Socket APIs and does not use the Networking stack running on the Synergy MCU Group.

Point to point protocol (PPP) is widely used WAN protocol in the Data communication. PPP Stack is part of NetX available in the SSP. NSAL leverages the PPP stack to communicate over the serial interface to the cellular service provider's network. PPP configuration provides options, for authentication methods like PAP/CHAP for the user. These authentication mechanisms are optional for the link establishment. NSAL makes use of framework APIs to send/receive data from the Cellular hardware module. NSAL allows the cellular device driver to be re-used without any changes specific to the network stack.

Cellular Framework uses the AT command set to interact with the Cellular modem using the serial driver. The serial interface used to interact with the modem is UART. The UART speed used in the framework defaults are up to 115200bits/sec.

Cellular Framework Module Operational Description

From the above figure, illustrating the user application perspective, the application can be used in two different paths for the communication using the framework depending on the support available on the Cellular modems. Some modules provide options to use the TCP/IP stack at the Host end and other modules provide options to use the TCP/IP stack present on the Cellular modem itself. In some cases, cellular hardware module provides both. When the host TCP/IP stack (NetX) is used, the logical layers of NetX, NSAL, PPP are used as described in the Architecture diagram. When the on-chip stack is used, the Socket APIs are used to communicate with the TCP/IP stack present on the Cellular modem. However, the user cannot use both at the same time.

As shown below in the control flow diagram, during the initialization using the configuration supplied by the user as required for the Cellular modem, NetX nx_ip_create is called which internally invokes the NSAL driver entry function that takes care of the link level initialization and initializes the cellular hardware module. In addition, it provisions the module and establishes the Network connection using the PPP interface.

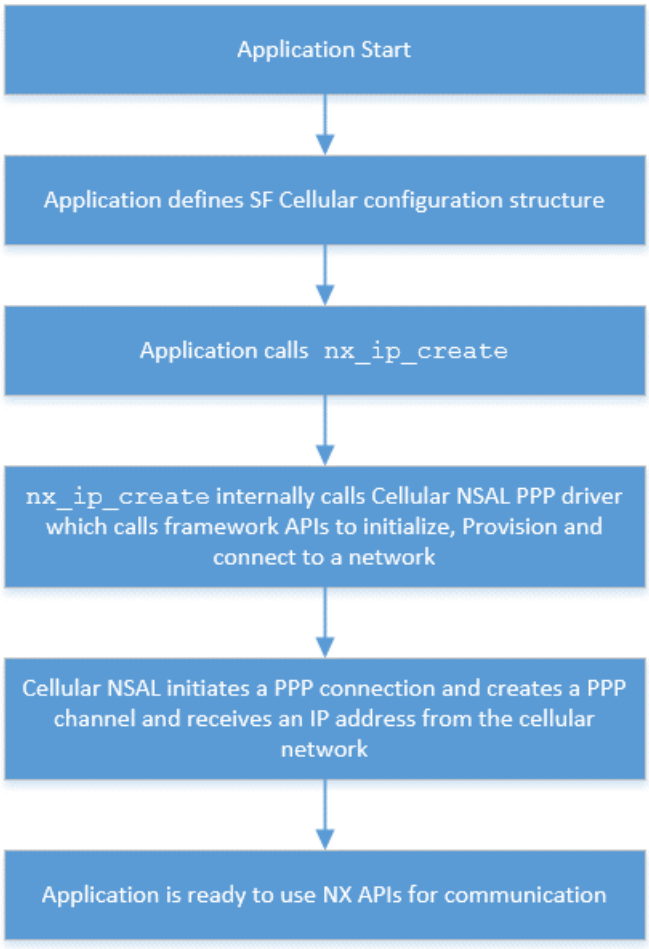

Figure 148: Cellular Framework Module Initialization Sequence

During the provisioning of the Cellular Modem, control structure and user configuration structures are passed as arguments. The details of the user arguments used for provisioning are the authentication, APN, username and password.

The following flow diagram shows the flow for the on-chip stack path usage with the Cellular Socket interface.

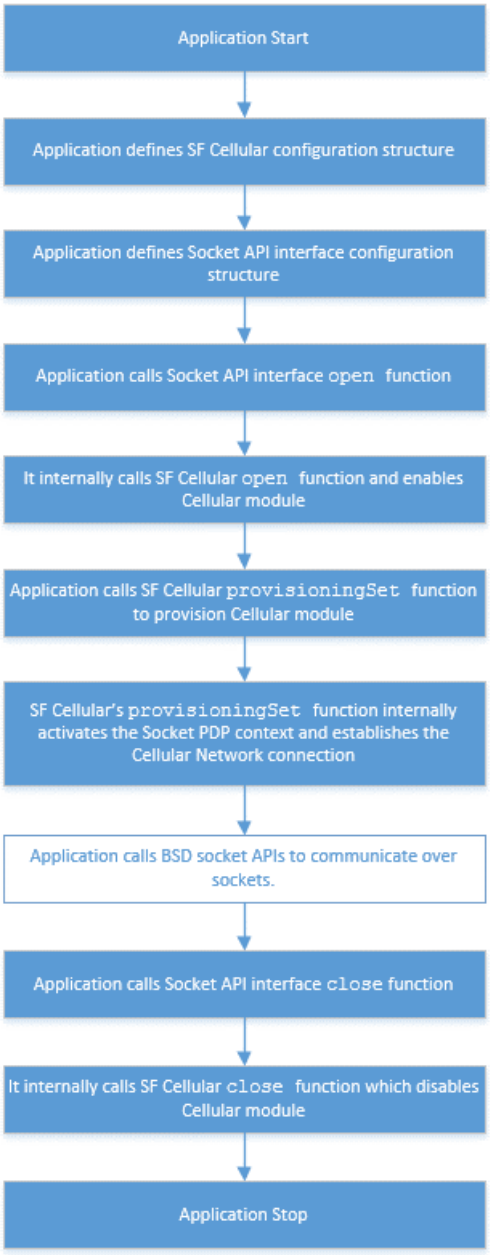

Figure 149: Cellular Framework Module Socket Interface

The following flow diagram shows the sequence of steps that the Packet transmission uses for the NetX application.

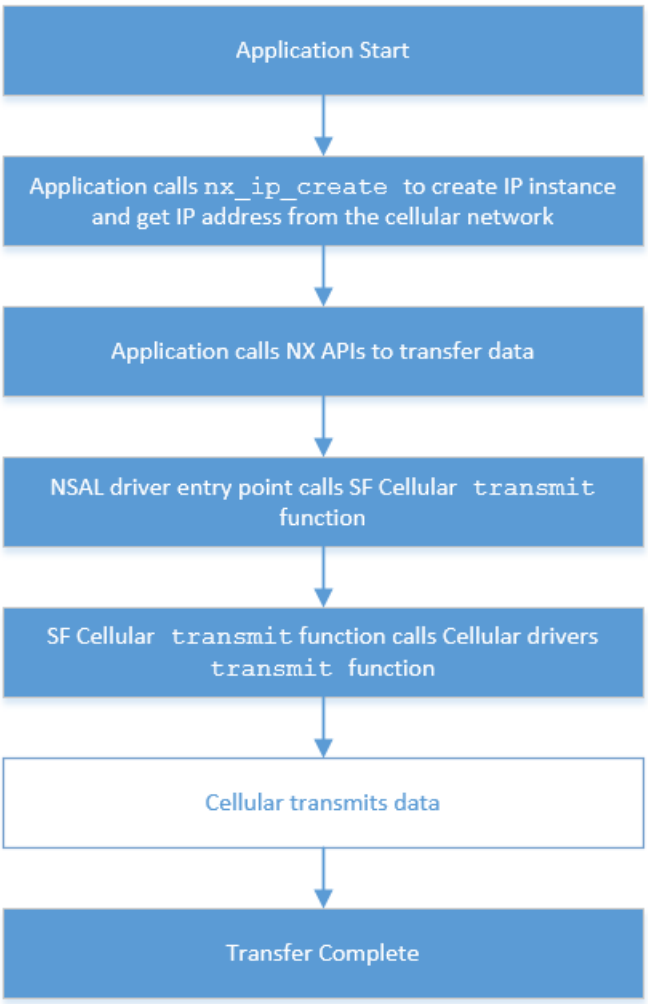

Figure 150: Cellular Framework Packet Transmission Sequence

The following flow diagram shows the Packet reception for the Cellular Framework using NetX. In the case of receive when the data is received on the serial interface, the processing thread triggers the callback function and the callback functions handles the data and sends it to the NetX layers for further processing.

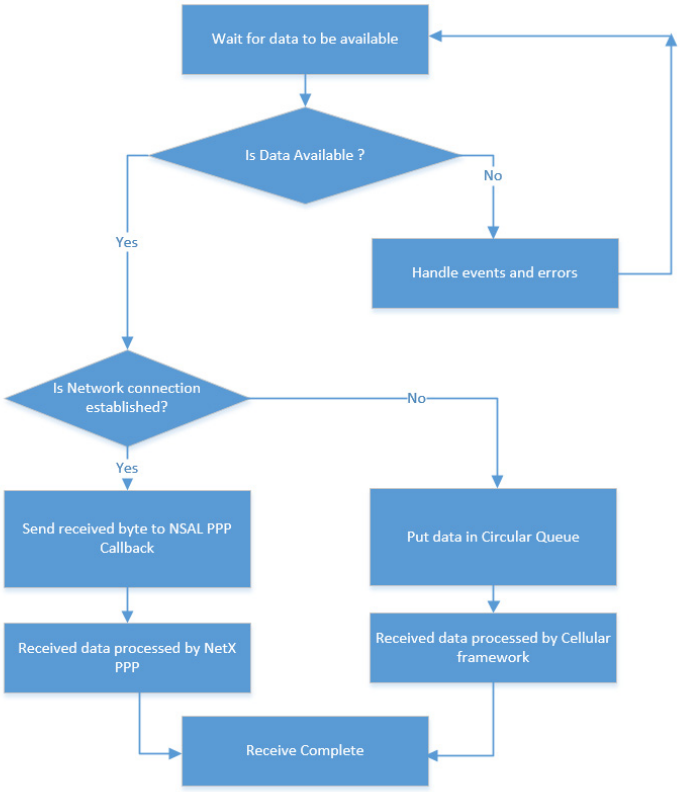

Figure 151: Cellular Framework Packet Reception Sequence

Cellular framework module important operational notes and limitations

- The current framework supports the below Cellular module:
- NimbeLink CAT3 (NL-SW-LTE-TSVG) Verizon-US
- NimbeLink CAT3 (NL-SW-LTE-TEUG) India and Europe
- NimbeLink CAT1 (NL-SW-LTE-GELS3-B and NL-SW-LTE-GELS3-C)
- Quectel CATM1 BG96 Verizon-US
- Firmware upgrade over air (FOTA) is not supported by NimbeLink CAT3 and CAT1 Cellular hardware module.
- Refer to the latest *SSP Release Notes* for any additional limitations for this module.

4.1.10.4 Including the Cellular Framework Module in an Application

This section describes how to include the Cellular Framework module in an application using the SSP configurator.

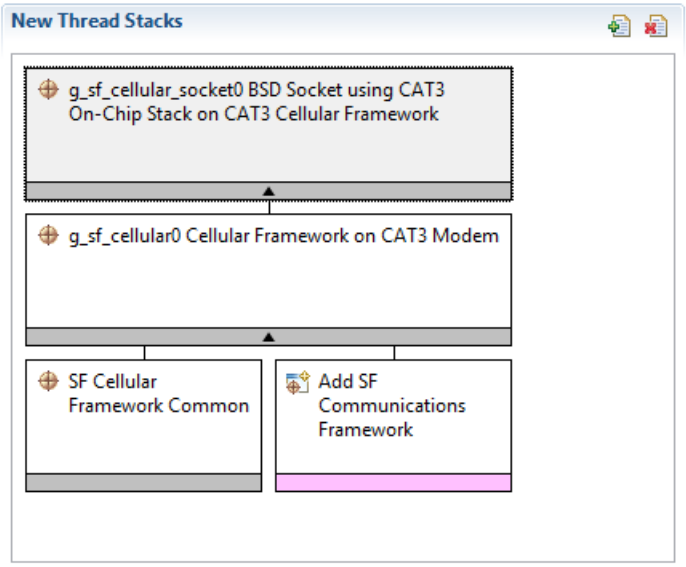
NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. Refer to the first few chapters of the SSP User's Manual if you are unfamiliar with any of these steps.

To add the Cellular Framework module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

Cellular Framework Module Selection Sequences

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_cellular_socket0 BSD Socket using CAT3 On-Chip Stack on CAT3 Cellular Framework	Threads	New Stack> Framework> Networking> Cellular > BSD Socket using CAT3 On-Chip Stack on CAT3 Cellular Framework
g_sf_cellular_0 Cellular Framework on CAT3 Modem	Threads	New Stack> Framework> Networking> Cellular > Cellular Framework on CAT3 Modem
g_sf_el_nx0 NetX Port using Cellular Framework on sf_cellular_nsal_nx	Threads	New Stack> Framework> Networking> Cellular > NetX Port using Cellular Framework on sf_cellular_nsal_nx

When the Cellular framework module is added to the thread stack as shown in the following figure, the configurator automatically adds the needed lower-level drivers. Any drivers that need additional configuration information will be highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Pink band require the selection of an implementation option.



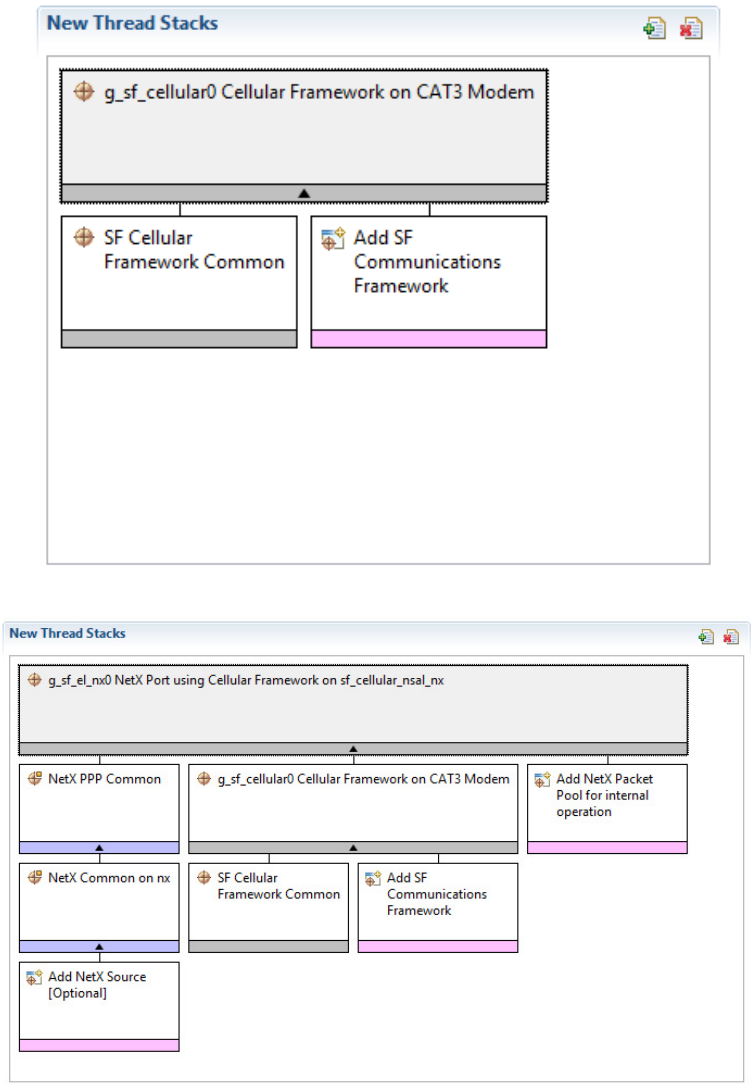


Figure 152: Cellular Framework Module Stack Options

Selecting SF_CELLULAR_NSAL_NX

The sf_cellular_nsal_nx implementation can be used in conjunction with a NetX IP Instance. In this case, it is added as an option underneath the IP Instance stack. Just add the NetX IP instance using the selection steps in the following table:

Resource	ISDE Tab	Stacks Selection Sequence
g_ip0 NetX IP Instance	Threads	New Stack> X-Ware> NetX> NetX IP Instance

Use the available option to add sf_cellular_nsal_nx under the NetX IP Instance as a NetX Network Driver. The resulting stack is shown in the following figure.

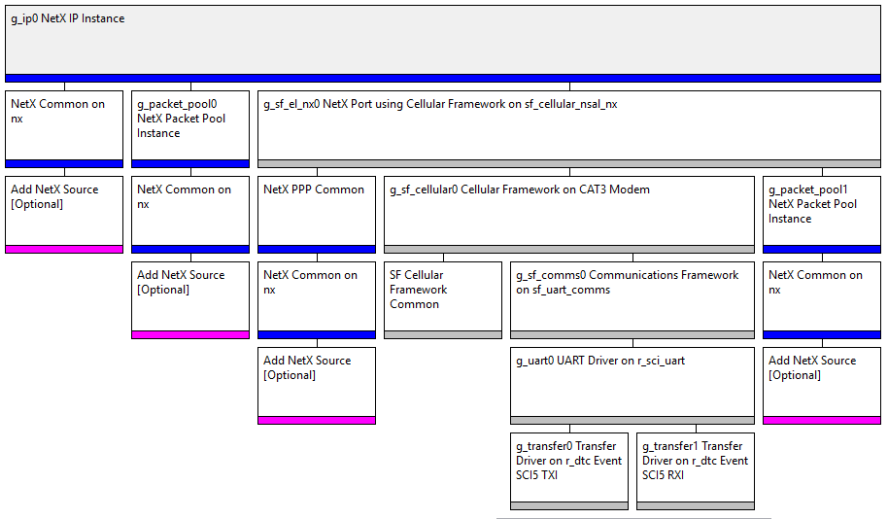

Figure 153: NetX IP Instance use of sf_cellular_nsal_nx

4.1.10.5 Configuring the Cellular Framework Modules

The Cellular framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify, by highlighting the block in red, any required configuration selections, such as Interrupts or operating modes, which must be configured for lower level modules, for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the properties tab within the SSP Configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the Interrupt Priority. This configuration setting is available with the Properties window of the associated module. Simply select the indicated module and then view the properties window. The Interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the Interrupt Priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the below configuration properties tables, but is easily visible with the ISDE when configuring Interrupt Priority levels.

NOTE: You may want to open your ISDE and create the Cellular Framework and explore the property settings in parallel with looking over the Configuration Table Settings given below. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

A separate section is provided below for each of the Cellular framework module implementations.

Configuring the Cellular Framework on CAT3 Modem

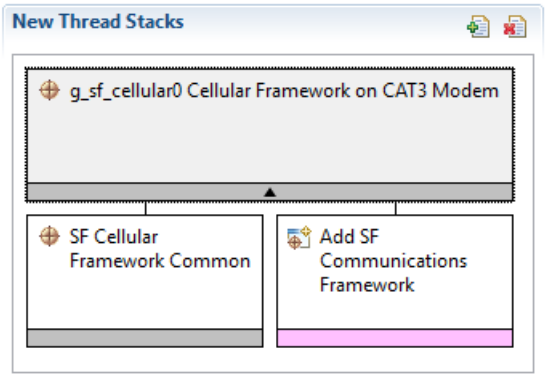

Figure 154: Cellular Framework on CAT3 Modem Thread Stack

Configuration Settings for the Cellular Framework on CAT3 Modem on sf_cellular

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking
On-Chip Stack Support	Enabled, Disabled Default: Disabled	On-chip stack support selection
Modem	TEUG, TSVG Default: TEUG	Modem selection
Name	g_sf_cellular0	Module name
SIM Pin (Used to Unlock SIM)	1111	SIM Pin selection
SIM PUK Pin (Used to Unlock SIM)	12345678	SIM PUK Pin selection
Number of Preferred Operator	0	Number of preferred operator selection
Preferred Operator 1 Name	40422	Preferred operator 1 name selection
Preferred Operator 1 Name Format	Long, Short, Numeric Default: Numeric	Preferred operator 1 name format selection

ISDE Property	Setting	Description
Preferred Operator 2 Name	40424	Preferred operator 2 name selection
Preferred Operator 2 Name Format	Long, Short, Numeric Default: Numeric	Preferred operator 2 name format selection
Preferred Operator 3 Name	40422	Preferred operator 3 name selection
Preferred Operator 3 Name Format	Long, Short, Numeric Default: Numeric	Preferred operator 3 name format selection
Preferred Operator 4 Name	40424	Preferred operator 4 name selection
Preferred Operator 4 Name Format	Long, Short, Numeric Default: Numeric	Preferred operator 4 name format selection
Preferred Operator 5 Name	40422	Preferred operator 5 name selection
Preferred Operator 5 Name Format	Long, Short, Numeric Default: Numeric	Preferred operator 5 name format selection
Operator Select Mode	Auto, Manual, Deregister, Manual Fallback Default: Auto	Operator select mode selection
Operator Name (Manual Mode Selection)	40422	Operator name selection
Operator Name Format (Manual Mode Selection)	Long, Short, Numeric Default: Numeric	Operator name format selection
Time Zone Update Policy	Enabled, Disabled Default: Enabled	Time zone update policy selection
Receive Data Callback	sf_cellular_nsal_recv_callback	Receive data callback selection

ISDE Property	Setting	Description
Provisioning Callback	celr_prov_callback	Provisioning callback selection
Circular Queue Size in Bytes	256	Circular queue size selection
SF Communications Framework Thread Stack Size	512	SF communications framework thread stack size selection
Numerical priority of SF Communication Framework Thread. Legal values range from 0 through (TX_MAX_PRIORITIES-1), where a value of 0 represents the highest priority.	5	Numerical priority of SF communication framework thread selection
Cellular Module Reset IO Pin	IOPORT_PORT_10_PIN_05	Cellular module reset IO pin selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SF Cellular Framework Common

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuring the BSD Socket using CAT3 On-Chip Stack on CAT3 Cellular Framework

Cellular Framework Module Clock Configuration

The Cellular Framework module uses the clocks required for the specific selections of the low-level modules.

Cellular Framework Module Pin Configuration

The Cellular Framework module uses input and output pins depending on the selections of the low-level modules.

4.1.10.6 Using the Cellular Framework Module in an Application

In a typical Cellular application much of the work is done by SSP based on the configured Cellular module stack. When the IP instance along with the Cellular framework is added using the configurator it includes the PPP stack as part of the framework. In addition, it also includes the NSAL and Cellular device driver code. The auto generated code is responsible Cellular initialization.

The user added code is responsible for the data connections and for the ICMP ping. It is responsible for sending the Ping request to the user entered Public IP address and verifying the Ping response. Callback functions can be implemented for PPP link down, PP link up, and cellular provisioning.

The steps in using the Cellular framework module in a simple application are:

Step 0. Initialization from generated code

Step 1. Wait for link to come up using the nx_ip_status_check API

Step 2. Ping the network using the nx_icmp_ping API

Step 3. Check for Event flag using the nx_event_flags_set API

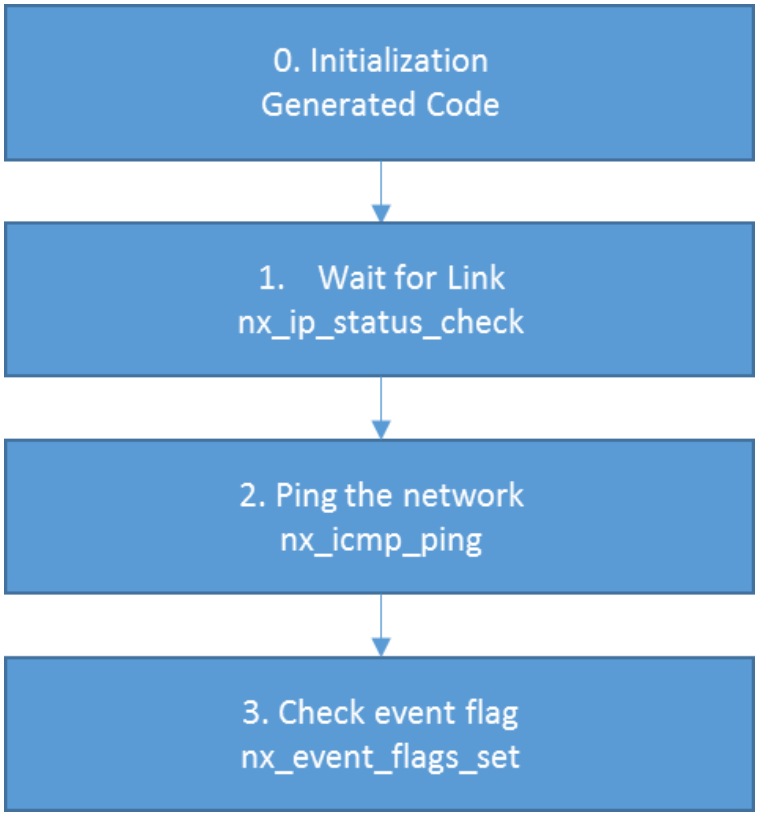

Figure 157: Flow Diagram of a Simple Cellular Framework Module Application

A more detailed description and a complete application project illustrating the typical steps in implementing a Cellular framework application are available in the Cellular Application Note downloadable from the Renesas web site. Just search, in the top search bar, for R30AN0311 and the application note and application project will be listed in the search results.

4.1.11 Communications Framework

The Communications Framework provides high-level APIs for communications applications using the ThreadX RTOS. The Framework is currently implemented on UART (sf_uart_comms), USBX CDC ACM (sf_el_ux_comms), and Telnet (sf_el_nx_comms). This section describes how to configure the Communications Framework using the e^2 studio ISDE and how to include the API functions in your application.

In the project configurator in the e^2 studio ISDE, you can add and configure the Communications Framework Module in the Modules pane of the Threads tab by selecting one of the following modules:

- **New > Framework > Connectivity > Communications Framework on sf_uart_comms**
- **New > Framework > Connectivity > Communications Framework on sf_el_ux_comms**
- **New > Framework > Connectivity > Communications Framework on sf_el_nx_comms**

For details, see: Using e^2 studio to Write an Application with the Communications Framework

You can find the API reference for the Communications Framework in the description of the Communications Framework Interface here: Communications Framework Interface.

To understand how to program with Interfaces in the SSP, see: SSP Architecture

4.1.11.1 What Does the Communications Framework Do?

This module is a ThreadX aware Communications framework. The module uses ThreadX objects like mutex for blocking and synchronization techniques like event flags for the completion of a transaction.

4.1.11.2 Using e^2 studio to Write an Application with the Communications Framework

The driver is integrated into the Synergy Software Package in e^2 studio: e^2 studio ISDE User Guide

In e^2 studio, create and configure a project and add the drivers:

1) Create the project: Creating a Project.
2) Configure the project: Configuring a Project
3) Add the drivers: Adding Drivers to a Thread and Configuring the Drivers

Select one of the sections below depending on which type of communications interface you are using (UART, NetX Telnet Server, or USBX CDC ACM).

Adding the UART Communications Framework

The following resources are required for any application using the UART Framework Interface:

Resource	ISDE Tab	Selection
UART Communications Framework	Threads	**Framework > Connectivity > Communications Framework on sf_uart_comms**

In addition, at least one UART HAL driver is required to create an UART application that can run on the Synergy microcontroller hardware.

Add the following resources when using the UART Framework with the SCI module:

Resource	ISDE Tab	Selection
Driver for UART on SCI	Threads	**UART Driver on r_sci_uart**
SCI Common driver	Threads	SCI Common; enable **Asynchronous Mode(r_sci_uart)** in the Properties window for this driver.
Interrupts	ICU	**SCI > SCIn > SCIn RXI**, **SCIn TXI**, **SCIn TEI**, and **SCIn ERIn** Interrupts for the selected SCI channel n.

Adding the USBX Communications Framework

The following resources are required for any application using the USBX Framework Interface:

Resource	ISDE Tab	Selection
Communications Framework	Threads	**Framework > Connectivity > Communications Framework on sf_el_ux_comms**

Add the following dependent resources when using the USBX CDC ACM Communications Framework with:

Resource	ISDE Tab	Selection
USBX Device Class CDC ACM	Threads	**Framework > USB > USBX Device Class CDC ACM on ux_device_class_cdc_acm**
USBX Stack	Threads	**Framework > USB > USBX on ux**
USBX Port	Threads	**Framework > USB > USBX Port on sf_el_ux**

Highlight the new Communications Framework on sf_el_ux_comms. The properties for this module are described in the table below. In the table, Property refers to the Properties tab name in the ISDE.

USBX Communications Framework configuration

ISDE Property	Setting	Description
Memory Size (Bytes)	Default: 65536	Memory passed to ux_system_initialize(). Recommendation is to start with 65536 if host mode will be used. If device-only macros are defined, recommendation is to start with 3072. Memory size should ultimately be determined by the application.
Read Input Buffer Size (Bytes)	Default: 128	This is the maximum number of bytes that can be received at a time in the read() API.

Adding the Telnet Communications Framework

The following resources are required for any application using the USBX Framework Interface:

Resource	ISDE Tab	Selection
Communications Framework	Threads	**Framework > Connectivity > Communications Framework on sf_el_nx_comms**

Add the following dependent resources when using the USBX CDC ACM Communications Framework with:

Resource	ISDE Tab	Selection
NetX Telnet Server	Threads	**Framework > Networking > NetX Telnet Server on nx**
NetX Stack	Threads	**Framework > Networking > NetX on nx**
NetX Port	Threads	**Framework > Networking > NetX Port on sf_el_nx**

Highlight the new Communications Framework on sf_el_nx_comms. The properties for this module are described in the table below. In the table, Property refers to the Properties tab name in the ISDE.

ISDE Property	Setting	Description
Channel	Default: 0	Underlying channel used by Ethernet driver
IP Address Byte < n >	192.168.0.0	IP address bytes
Subnet Mask Byte < n >	255.255.255.0	Subnet mask bytes

4.1.11.3 Writing a Communications Framework Application

The open call is generated by the ISDE src/synergy_gen/< thread_name >.c file where the module was added. By the time execution reaches src/< thread_name >_entry.c, the module is ready to use, provided the necessary hardware connection is established. To use the communications framework, make calls directly to the API's.

The ISDE configures this instance structure when you generate the project in the ISDE generated source file.

```
/* Instance structure to use this module. */

const sf_comms_instance_t g_sf_comms =

{
```

```
    .p_ctrl = &g_sf_comms_ctrl,

    .p_cfg = &g_sf_comms_cfg,

    .p_api = &g_sf_comms_on_sf_comms

};
```

The following is an example of a write call:

```
char p_src[] = "Hello World!\\r\\n";

g_sf_comms.p_api->write(g_sf_comms.p_ctrl, p_src, sizeof(p_src) - 1, TX_NO_WAIT)
;
```

The following is an example of a blocking read call:

```
char p_dest[10];

g_sf_comms.p_api->read(g_sf_comms.p_ctrl, p_dest, 10, TX_WAIT_FOREVER);
```

4.1.11.4 Limitations for the Communications Framework

There are no know limitations for using this module. For details about the current software version, see the SSP release notes.

4.1.11.5 Supported Devices for the Communications Framework

This communications framework modules has been tested on the Synergy microcontroller family S7G2.

The UART Communications framework is designed to support any Synergy device with an SCI UART and HAL driver with no changes to the API.

The USBX CDC Communications framework is designed to support any Synergy device with a USB controller.

The NetX Telnet Communications framework is designed to support any Synergy device with an Ethernet controller.

4.1.12 Communications Framework on NX

The Communications Framework on NX provides high-level APIs for telnet communications applications and uses the Ethernet peripheral on the Synergy MCU.

4.1.12.1 Express Logic NetX Telnet Communications Framework Module Features

- High level connectivity is supported on Ethernet but is easily changeable to UART and USB connectivity without API modification
- Supports channel locking for exclusive access
- Thread aware implementation uses mutex and event flags internally

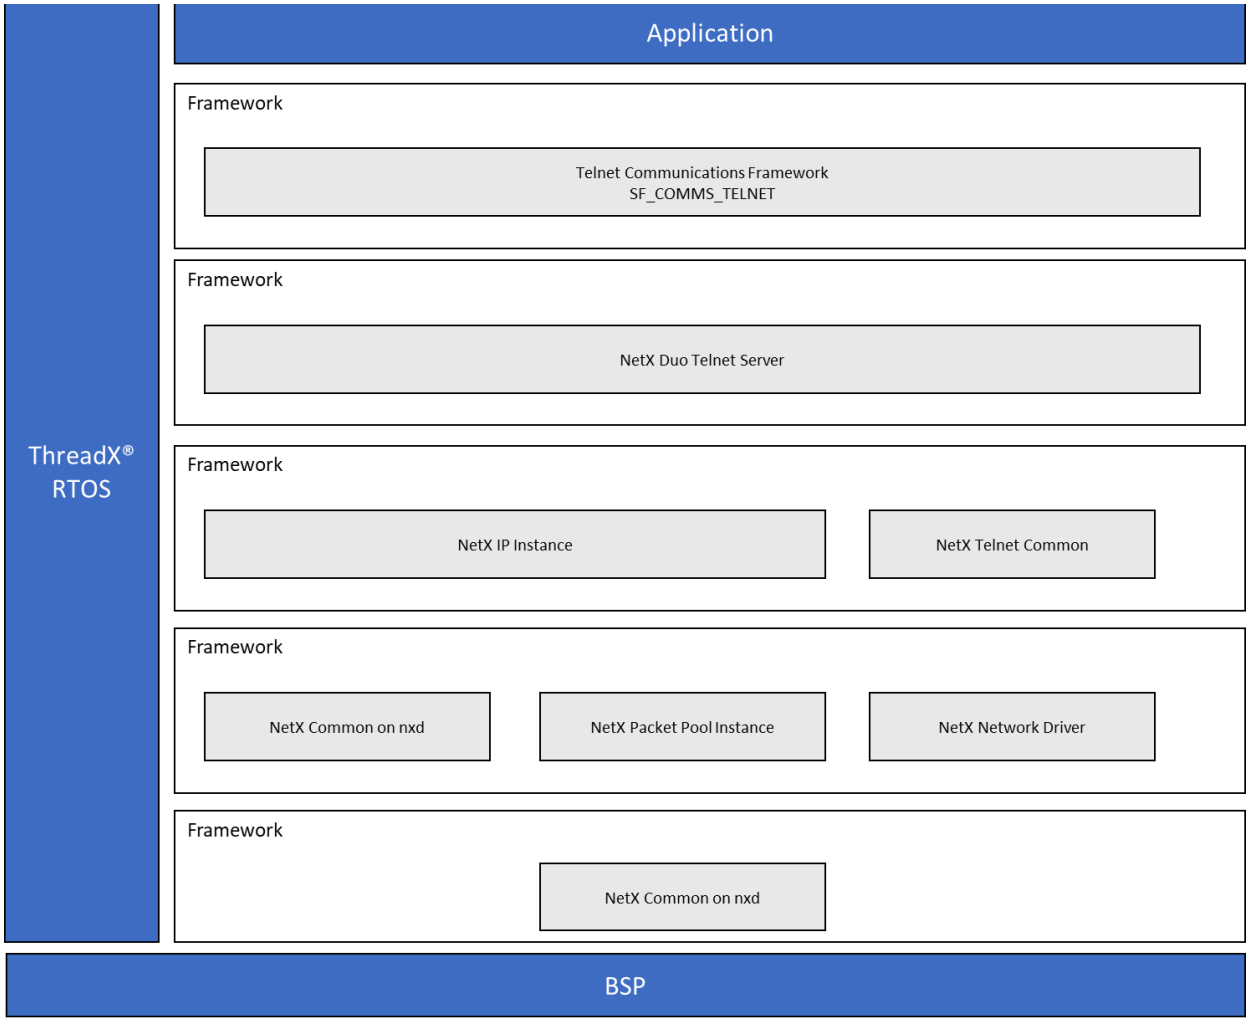

Figure 158: Express Logic NetX Telnet Communications Framework Module Block Diagram

4.1.12.2 Express Logic NetX Telnet Communications Framework Module APIs Overview

The Express Logic NetX Telnet Communications Framework module defines APIs to open, read, write, lock, unlock and close the module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Express Logic NetX Telnet Communications Framework Module API Summary

Function Name	Example API Call and Description
.open	g_sf_comms_telnet0.p_api->open (g_sf_comms_telnet0.p_ctrl, g_sf_comms_telnet0.p_cfg); Initializes module.
.read	g_sf_comms_telnet0.p_api->read (g_sf_comms_telnet0.p_ctrl, p_dest, bytes, timeout); Read a number of bytes of data into the destination.
.write	g_ sf_comms_telnet0.p_api->write (g_sf_comms_telnet0.p_ctrl, P_src, bytes, timeout); Write a number of bytes from the source.
.lock	g_sf_comms_telnet0.p_api->lock (g_sf_comms_telnet0.p_ctrl, locktype, timeout); Acquire lock type for the Telnet comms instance.
.unlock	g_sf_comms_telnet0.p_api->unlock (g_sf_comms_telnet0.p_ctrl, locktype); Release the lock type for the Telnet comms inctance.
.close	g_sf_comms_telnet0.p_api->close (g_sf_comms_telnet0.p_ctrl); Disconnect Telnet server and clean up resources.
.versionGet	g_ sf_comms_telnet0.p_api->versionGet(&version); Gets version and stores it in provided version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_INTERNAL	An internal TheadX error has occurred.
SSP_ERR_NOT_OPEN	Unit is not open
SSP_ERR_ASSERTION	A parameter is NULL.
SSP_ERR_IN_USE	Peripheral is still running in another mode; perform Close first.
SSP_ERR_UNSUPPORTED	Command not supported.
SSP_ERR_OUT_OF_MEMORY	Can't allocate pool memory.
SSP_ERR_TIMEOUT	An event timed out.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.1.12.3 Express Logic NetX Telnet Communications Framework Module Operational Overview

The Communications Framework using Telnet on NX provides an easy-to-use connection over the ethernet port. The high-level APIs are compatible with other connection implementations, such as UART and USB, so that it is easy to switch from one implementation to another without changing APIs. Supported operations include opening the module using the open API and closing the module using the close API. Read is implemented by the read and write by the write API. Unlike read and write, which locks the module only until the called API is in action, the lock API locks the module till the unlock API is called on the same module instance. For the underlying NetX driver, it also lets the user configure the IP address and network mask and choose the Ethernet channel.

Express Logic NetX Telnet Communications Framework Module Important Operational Notes and Limitations

- The Ethernet peripheral can use either RMII or MII depending on MCU capabilities.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.12.4 Including the Express Logic NetX Telnet Communications Framework Module in an Application

This section describes how to include the Express Logic NetX Telnet Communications Framework module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Express Logic NetX Telnet Communications Framework module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the Express Logic NetX Telnet Communications Framework module is sf_comms_telnet0. This name can be changed in the associated Properties window.)

Express Logic NetX Telnet Communications Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
sf_comms_telnet0 Express Logic NetX Telnet Communications Framework on sf_comms_telnet	Threads	New Stack> Framework> Connectivity> Express Logic NetX Telnet Communications Framework on sf_comms_telnet

When the Express Logic NetX Telnet Communications Framework module on sf_comms_telnet is added to the thread stack as shown in the following figure, the configurator automatically adds any lower-level drivers that are required. Any drivers that need additional configuration information will be box-text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

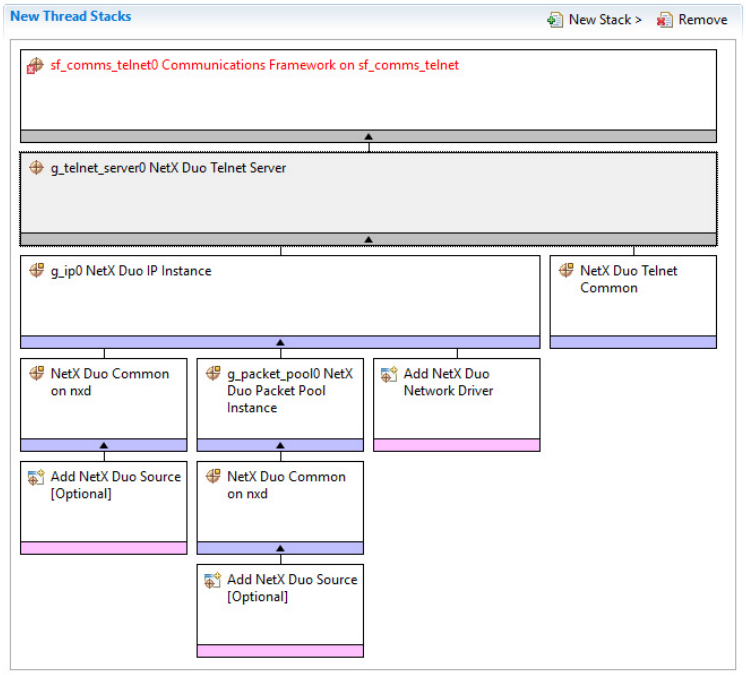

Figure 159: Express Logic NetX Telnet Communications Framework Module Stack

4.1.12.5 Configuring the Express Logic NetX Telnet Communications Framework Module

The Express Logic NetX Telnet Communications Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the Express Logic NetX Telnet Communications Framework Module on sf_comms_telnet

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking
Packet size in pool memory (bytes)	1536	Packet size in pool memory selection
Packets to allocate in pool memory (units)	5	Packets to allocate in pool memory selection
Timeout for internal options (ticks)	10	Timeout for internal options selection
Maximum number of instances	4	Maximum instances that can be open at any given time
Name	sf_comms_telnet0	Module name
Name of generated initialization function	sf_comms_telnet_init0	Name of generated initialization selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX (Duo) Telnet Server on telnet_server

ISDE Property	Value	Description
Internal thread priority	16	Internal thread priority selection
Maximum clients to serve simultaneously	4	Maximum clients to serve simultaneously selection
Socket window size (bytes)	2048	Socket window size selection
Server time out (seconds)	10	Duration internal services will suspend for
Client inactivity timeout (seconds)	600	Client inactivity duration for disconnection

ISDE Property	Value	Description
Timeout check period (seconds)	60	Client activitiy timeout check interval
Option negotiation	Enable, Disable Default: Enable	Option negotiation selection
Use application packet pool	Enable, Disable Default: Disable	Use application packet pool selection
Packet size in the pool (bytes)	300	Telnet Server only creates this packet pool if 'Option negotiation' is enabled
Total packet pool size (bytes)	2048	Telnet Server only creates this packet pool if NX_TELNET_SERVER_OPTION_DISABLE
Name	g_telnet_server0	Module name
Thread Stack Size (bytes)	2048	Thread stack size selection
Name of Client Connect Callback Function	NULL	Name of client connect callback function selection
Name of Receive Data Callback Function	NULL	Name of receive data callback function selection
Name of Client Disconnect Callback Function	NULL	Name of client disconnect callback function selection
Name of generated initialization function	telnet_server_init0	Name of generated initialization function selection
Auto Initialization	Disable	Auto initialization selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX (Duo) IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name

ISDE Property	Value	Description
IPv4 Address (use commas for separation)	0,0,0,0	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable	TCP selection
UDP	Enable, Disable Default: Enable	UDP selection
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection

ISDE Property	Value	Description
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection
Link status change callback	NULL	Link status change callback selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Telnet Common

ISDE Property	Value	Description
Type of Service for TCP requests	Normal, Minimum delay, Maximum data, Maximum reliability, Minimum cost Default: Normal	Type of service UDP requests selection
Fragmentation option	Don't fragment, Fragment okay Default: Don't fragment	Fragment option selection
Server TCP port number	23	Server TCP port number selection
Time to live	128	Time to live selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX (Duo) Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	640	Packet size selection

ISDE Property	Value	Description
Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Common on nx

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Express Logic NetX Telnet Communications Framework Module Clock Configuration

The Express Logic NetX Telnet Communications Framework module uses the Ethernet peripheral which uses PCLKA as its clock source.

To change the clock frequency at run-time, use the CGC Interface.

Express Logic NetX Telnet Communications Framework Module Pin Configuration

To use the Express Logic NetX Telnet Communications Framework module, the port pins for the peripheral inputs and outputs must be set in the pin configurator in the ISDE. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection Sequence for the Express Logic NetX Telnet Communications Framework Module

Resource	ISDE Tab	Pin selection Sequence
SSI	Pins	Select Peripherals > Peripherals>Connectivity:ETHERC> ETHERC0.RMI or ETHERC1.RMII

4.1.12.6 Using the Express Logic NetX Telnet Communications Framework Module in an Application

The typical steps in using the Communications Framework on NX in an application are:

1) Initialize the Communications Framework on NX using the open API
2) Lock the channel for continuous communications using the lock API if needed
3) Receive data using the read API
4) Send data using the write API
5) Unlock the channel from continuous communication using the unlock command if needed
6) Close the channel using the close API

These common steps are illustrated in a typical operational flow in the following figure:

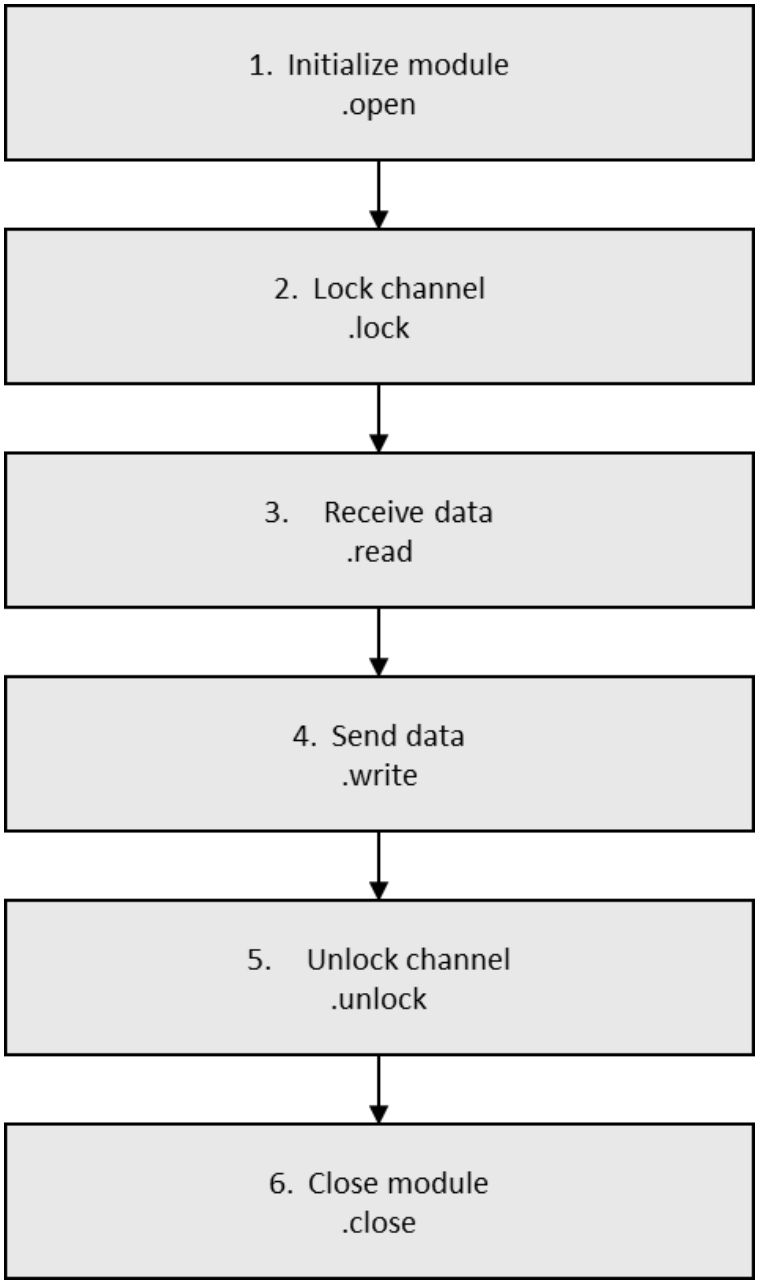

Figure 160: Flow Diagram of a Typical Express Logic NetX Telnet Communications Framework Module Application

4.1.13 UART Communications Framework

The UART communications framework provides an instance of the synergy communication framework APIs on an UART compliant synergy MCU peripheral. It uses r_sci_uart HAL driver, which configures and operates the SCI peripheral of Synergy MCUs to communicate using the UART protocol.

4.1.13.1 UART Communications Framework Module Features

This module is a ThreadX-aware communications framework. It uses ThreadX objects to ensure that the operations are thread safe. Key features include:

- Support for UART Communications Protocol
- Support for locking a channel to reserve exclusive access
- ThreadX aware implementation

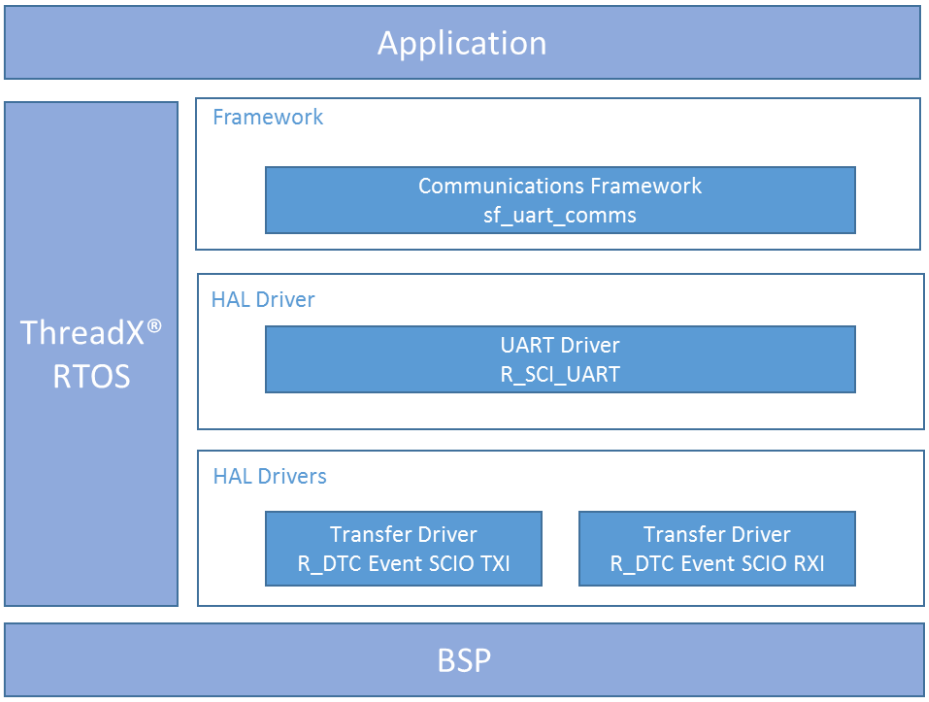

Figure 161: UART Communications Framework Organization, Options and Stack Implementations

4.1.13.2 UART Communications Framework Module APIs Overview

The UART Communications Framework module defines APIs for opening, closing, reading, and writing to the communications channel. A complete list of the available APIs, an example API call, and a short description of each can be found in the table below. A table of status return values follows.

UART Communications Framework API Summary

Function Name	Example API Call and Description
open	g_sf_comms0.p_api->open(g_sf_comms0.p_ctrl, g_sf_comms0.p_cfg); Initialize communications driver.
close	g_sf_comms0.p_api->close(g_sf_comms0.p_ctrl); Clean up communications driver.
read	g_sf_comms0.p_api->read(g_sf_comms0.p_ctrl, &destination, bytes, timeout); Read data from communications driver. This call will return after the number of bytes requested is read or if a timeout occurs while waiting for access to the driver.
write	g_sf_comms0.p_api->write(g_sf_comms0.p_ctrl, &source, bytes, timeout); Write data to communications driver. This call will return after all bytes are written or if a timeout occurs while waiting for access to the driver.

Function Name	Example API Call and Description
lock	g_sf_comms0.p_api->lock(g_sf_comms0.p_ctrl, lock_type, timeout); Lock the communications driver. Reserve exclusive access to the communications driver.
unlock	g_sf_comms0.p_api->unlock(g_sf_comms0.p_ctrl, lock_type); Unlock the communications driver. Release exclusive access to the communications driver.
versionGet	g_sf_comms0.p_api->version(&version); Store the driver version in the provided version.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manuals API References for the associated module.

Error Status Return Values

Name	Description
SSP_SUCCESS	Channel opened successfully.
SSP_ERR_IN_USE	Channel already in use.
SSP_ERR_ASSERTION	Pointer to UART control block or configuration structure is NULL.
SSP_ERR_HW_LOCKED	Channel is locked.
SSP_ERR_INVALID_MODE	Channel is used for non-UART mode or illegal mode is set.

Name	Description
SSP_ERR_INVALID_ARGUMENT	Invalid parameter setting found in the configuration structure.
SSP_ERR_QUEUE_UNAVAILABLE	Cannot open transmit or receive queue or both.
SSP_ERR_INTERNAL	Internal error occurs.
SSP_ERR_TIMEOUT	Timeout error.
SSP_ERR_INSUFFICIENT_DATA	Not enough data in receive circular buffer.
SSP_ERR_RXBUF_OVERFLOW	Receive queue overflow.
SSP_ERR_OVERFLOW	Hardware overflow.
SSP_ERR_FRAMING	Framing error.
SSP_ERR_PARITY	Parity error.
SSP_ERR_INSUFFICIENT_SPACE	Not enough space in transmission circular buffer.

NOTE: Lower level drivers may return Common Error Codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.13.3 UART Communications Framework Module Operational Overview

The UART Framework provides an easy-to-use communication framework using the standard UART protocol. In addition to the high-level APIs to read and write data from the UART device in a thread safe manner, the framework also provides APIs for applications to lock (and unlock) the UART channel to a thread. This is particularly useful when multiple application threads try to communicate with the same UART device and a context switch could upset the high level application protocols and/or state machines implemented on top of the UART (like Kermit, for example).

Important Operational Notes and Limitations for the UART Communications Framework Module

- The UART Framework module is reentrant for any channel.
- The UART framework uses the UART driver on r_sci_uart module for communicating with a UART device. UART driver can be augmented by adding DTC drivers (using synergy configurator in the ISDE) to perform read/write transactions with a UART device without interrupting the CPU. When the UART framework is used to read data from a UART device, it will rely on the UART driver callback feature to read data and **will not use DTC** (Even if the DTC module support is added to the UART driver through the configurator). This is done to avoid any potential timing and synchronization issues that could arise when the driver uses DTC to read data from the device. When using UART framework to write data to a UART device, it will use the DTC to perform the transaction, if the driver is configured to use DTC.
- The ongoing read/write transactions will be aborted when timeout occurs.

- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.13.4 Including the UART Communications Framework Module in an Application

This section describes how to include the UART Communications Framework module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the "Getting Started Guide for SSP" listed in the Reference Section at the end of this document to learn how to manage each of these important steps in creating SSP based applications.

The UART Communications Framework module is implemented on sf_uart_comms. To add the UART Communications Framework module to an application, simply add it to a thread using the Stack Selection Sequence given in the table below. (The default name for the Communications Framework is g_sf_comms0. This name can be changed in the associated Properties window.)

Communications Framework Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_comms0 Communications Framework on sf_uart_comms	Threads	Framework > Connectivity > Communications Framework on sf_uart_comms

When the Communications Framework on Communications Framework is added to the thread stack as shown in the figure below, the configurator automatically adds any needed lower level modules. Any drivers that need additional configuration information will have box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower level drivers; these are either optional or recommended (this is indicated in the block with the inclusion of this text.) If the addition of lower level drivers is required, the module description will include "Add" in the text. Clicking on any Pink banded modules will bring up the "New" icon and then display the possible choices.

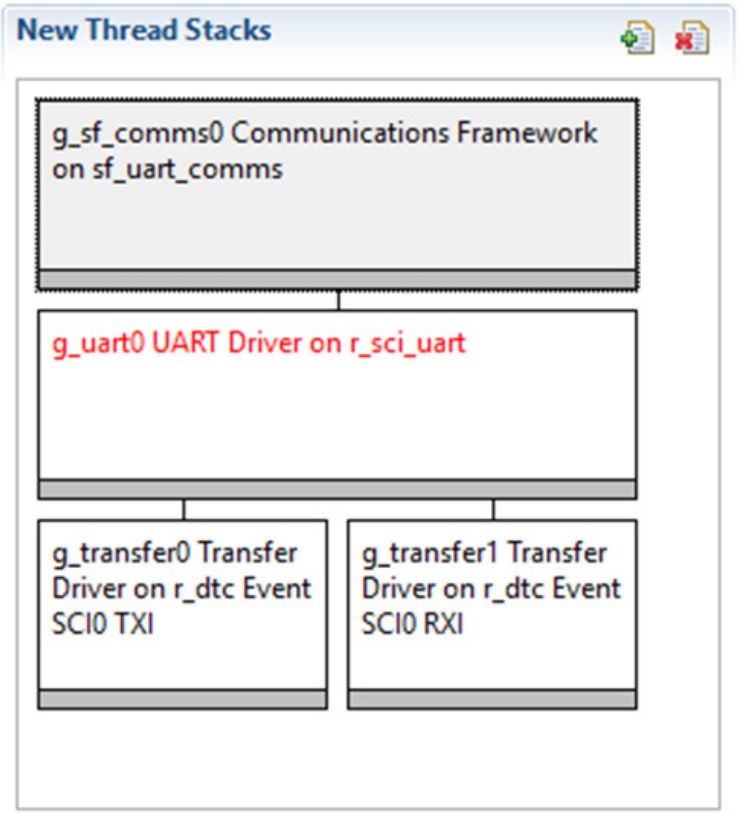

Figure 162: UART Communications Framework Stack Implementation Options

4.1.13.5 Configuring the UART Communications Framework Module

The UART Communications Framework module must be configured by you for the desired operation. The SSP configuration window will automatically identify, by highlighting the block in red, any required configuration selections, such as Interrupts or operating modes, which must be configured for lower level modules, for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority. This configuration setting is available with the properties window of the associated module. Simply select the indicated module and then view the properties window. The Interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the Interrupt priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the below configuration properties tables, but is easily visible with the ISDE when configuring Interrupt Priority levels.

NOTE: You may want to open your ISDE and create the module and explore the property settings in parallel with looking over the Configuration Table Settings given below. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for UART Communications Framework Stack Modules

When the UART Communications Framework stack option is selected for the implementation the following modules are automatically added to the stack. The following tables show the detailed configuration settings available- many of which are populated with default settings that can be used in most common applications.

Configuration Settings for UART Communications Framework (sf_uart_comms)

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if parameter checking is included.
Read Input Queue Size (4-Byte Words)	15	Buffer size for data reception queue. sf_uart_comms utilizes the ThreadX Queue for the queue management.
Name	g_sf_comms0	Name of UART communications framework module.

Configuration Settings for UART Driver (r_sci_uart)

ISDE Property	Value	Description
External RTS Operation	Enable, Disable Default: Disable	Enable an IOPORT pin to be used as RTS signal. For RTS functionality set this configuration parameter to "Enable" and specify the configuration "Name of UART callback function for the RTS external pin control".
Reception	Enable, Disable Default: Enable	Enable or disable UART reception for all UART channels on SCI. Setting this configuration parameter to "Disable" reduces code size because the portion of code for UART reception is not compiled. You cannot set this parameter for individual UART channels.

ISDE Property	Value	Description
Transmission	Enable, Disable Default: Enable	Enable or disable UART transmission for all UART channels on SCI. Setting "Disable" to this configuration allows to get smaller code size due to the portion of code for UART transmission is compiled out, however, you can only set "Disable" to this configuration if any other SCI channels which work as UART ports do not perform the transmission.
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_uart0	The name to be used for UART on SCI module control block instance. This name is also used as the prefix of the other variable instances.
Channel	0-9	SCI channel number.
Baud Rate	9600	Baud rate selection.
Data Bits	7 bits, 8, bits, 9 bits Default: 8 bits	UART data bits.
Parity	None, Odd, Even Default: None	UART parity bits.
Stop Bits	1 bit, 2 bits Default: 1 bit	UART stop bits.

ISDE Property	Value	Description
CTS/RTS Selection	CTS (Note that RTS is available when enabling External RTS Operation mode which uses 1 GPIO pin), RTS (CTS is disabled) Default: RTS (CTS is disabled)	Select CTS or RTS for the CTSn/RTSn pin of SCI channel n. The SCI hardware supports either the CTS or the RTS control signal on this pin but not both. For an application that uses both CTS and RTS, select "CTS" for this configuration parameter and enable the configuration "External RTS Operation" specifying the configuration "Name of UART callback function for the RTS external pin control".
Name of UART callback function to be defined by user	user_uart_callback	Name must be a valid C symbol.
Name of UART callback function for the RTS external pin control to be defined by user	NULL	Name must be a valid C symbol.
Clock Source	Internal Clock, External Clock 8x baudrate, External Clock 16x baudrate Default: Internal Clock	Selection of the clock source to be used in the baud-rate clock generator block.
Baudrate Clock Output from SCK pin	Enable, Disable Default: Disable	Optional setting to output the baud-rate clock on the SCKn pin for the selected channel n.
Start bit detection	Falling Edge, Low Level Default: Falling Edge	Start bit detection mode in the reception, usually set "Falling Edge" to this configuration.
Noise Cancel	Enable, Disable Default: Disable	Enable the digital noise cancellation on RXDn pin. The digital noise filter block in SCI consists of two-stage flip-flop circuits. For detail, refer to the Noise cancellation section in the Renesas Synergy hardware manual.

ISDE Property	Value	Description
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Bit rate modulation enable selection.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Transmit interrupt priority selecition.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Transmit end interrupt priority selection.

ISDE Property	Value	Description
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Error interrupt priority selection.

Configuration Settings for TXI Transfer Driver on r_dtc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Disabled	Software start selection
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table
Name	g_transfer0	Module name
Mode	Normal	Mode selection
Transfer Size	1 Byte	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection

ISDE Property	Value	Description
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SCI0 TXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection.

Configuration Settings for RXI Transfer Driver on r_dtc

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Name	g_transfer1	Module name
Mode	Normal	Mode selection
Transfer Size	1 Byte	Transfer size selection
Destination Address Mode	Incremented	Destination address mode selection
Source Address Mode	Fixed	Source address mode selection

ISDE Property	Setting	Description
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SPI0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection.

UART Communications Framework Module Clock Configuration

The UART Communications Framework has no specific clock configuration requirements.

UART Communications Framework Module Pin Configuration

The UART Communications Framework uses pins on the MCU to communicate to external devices, based on the lower level implementation selected. I/O pins must be selected and configured as required by the external device. The first table below illustrates the method for selecting the pins within the SSP configuration window and the following table illustrates an example selection for the lower level implementation pins.

NOTE: The Operation Mode selection mode determines what peripheral signals are available and thus what MCU pins are required.

Pin Selection Sequence for Communications Framework on UART, USB or Telnet (Receiver)

Resource	ISDE Tab	Pin selection Sequence
UART	Pins	Select **Peripherals > Connectivity: SCI > SCI8**

NOTE: The above selection sequences are examples for selected implementations. Others are also possible depending on the target hardware.

Pin Configuration Settings for UART

Pin Configuration Property	Settings	Description
Pin Group Selection	Mixed, _A Only, _B Only	Pin group selection
Operation Mode	Disabled, Custom, Asynchronous UART, Synchronous UART, Simple I2C, Simple SPI, SmartCard (Default: Disabled)	Select Asynchronous UART as the Operation Mode for a UART Receiver implementation
TXD_MOSI	None, PB05, P105 (Default: None)	TXD Pin P105
RXD_MISO	None, PB05, P104 (Default: None)	RXD Pin P104

Pin Selection Sequence for Communications Framework on UART, USB or Telnet (Transmitter)

Resource	ISDE Tab	Pin selection Sequence
UART	Pins	Select **Peripherals > Connectivity: SCI > SCI3**

NOTE: The above selection sequences are examples for selected implementations. Others are also possible depending on the target hardware.

Pin Configuration Settings for UART

Pin Configuration Property	Settings	Description
Pin Group Selection	Mixed, _A Only, _B Only	Pin group selection
Operation Mode	Disabled, Custom, Asynchronous UART, Synchronous UART, Simple I2C, Simple SPI, SmartCard (Default: Disabled)	Select Asynchronous UART as the Operation Mode for a UART Transmitter implementation
TXD_MOSI	None, P707, P409 (Default: None)	TXD Pin P707
RXD_MISO	None, P706, P408 (Default: None)	RXD Pin P706

NOTE: The above example settings are for a project using the Synergy S7G2 and the DK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.1.13.6 Using the UART Communications Framework Module in an Application

The typical steps in using the UART Communications Framework module in an application are:

1) Initialize the UART Communications Framework using the open API
2) Lock the channel for continuous communications using the lock API if needed
3) Receive data using the read API
4) Send data using the write API
5) Unlock the channel from continuous communication using the unlock API if needed
6) Close the channel using the close API

The above steps are illustrated in a typical operational flow diagram in the figure below:

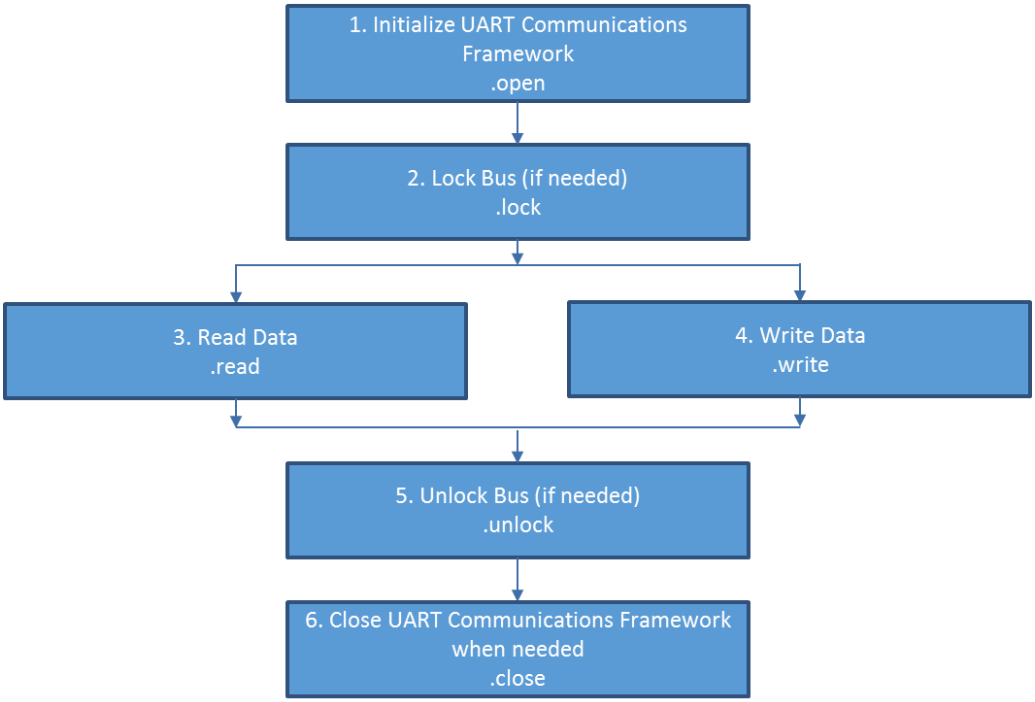

Figure 163: Flow Diagram of a Typical UART Communications Framework Application

4.1.14 Communications Framework on USBX™

The Express Logic USBX Synergy Port framework module (sf_el_ux) is integrated into the SSP. This driver is meant to be used with Express Logic USBX. For more information about USBX, including API reference, refer to the USBX User Guide.

4.1.14.1 Express Logic USBX Synergy Port Framework Module Features

The Express Logic USBX Synergy Port Framework module supports the following features:

- Implements Express Logic USBX in SSP- support USBX APIs
- Supports the Port Device Controller Driver (DCD) for the USBHS peripheral
- Supports the Port Device Controller Driver (DCD) for the USBFS peripheral
- Supports the Port Host Controller Driver (HCD) for the USBHS peripheral
- Supports the Port Host Controller Driver (HCD) for the USBFS peripheral
- Supports transfer module operation (optional)

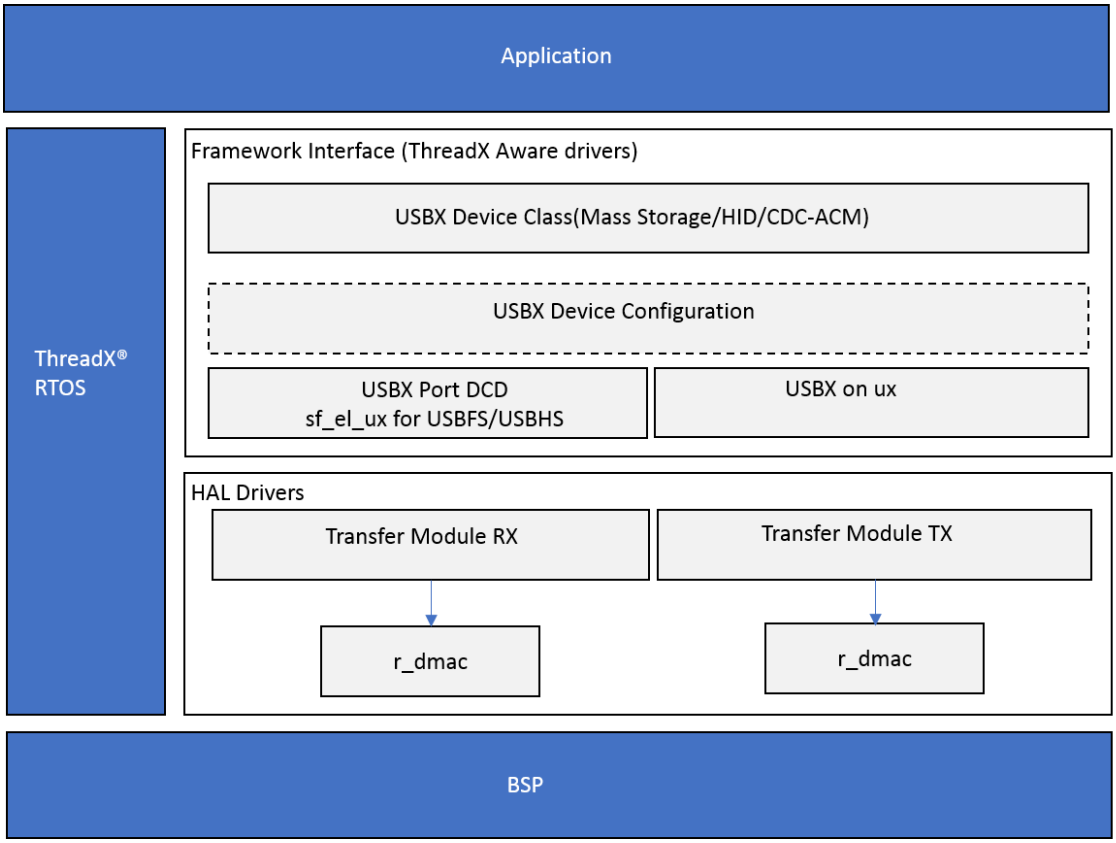

Figure 164: Express Logic USBX Synergy Port Framework Module Organization, Options and Stack Implementations for HCD and DCD

4.1.14.2 Express Logic USBX Synergy Port Framework Module Operational Overview

The Express Logic USBX Synergy Port framework module provides the Synergy USB hardware port functions required to use the USBX stack on Synergy hardware. Application code using this module is expected to use USBX API calls.

Express Logic USBX Synergy Port Framework Module Operational Notes

The Express Logic USBX Synergy Port framework module includes the support for the Express Logic USBX APIs in SSP. Refer to the Express Logic USBX User Manual for a complete description of the available APIs.

The Express Logic USBX Synergy Port framework module supports the Port Device Controller Driver (DCD) on USBHS and USBFS peripherals as well as the Port Host Controller Driver (HCD) for the USBHS on USBFS peripherals.

Users have the option of using the Transfer Module for the USBX Synergy Port framework module to get better USB data throughput by transferring data in the block transfer mode. To enable the Transfer module, just add two instances of transfer components to the USBX Class stack in the Synergy Configuration tool and enable the interrupts in the property. The Synergy Configuration tool auto-generates the driver setup code to enable DMAC or DTC transfer in common_data.c.

NOTE: : The module uses the interrupt of a USB Controller. Set the appropriate interrupt priority level in the Synergy Configuration tool, otherwise it does not work. The module uses the interrupt of a Transfer module (implemented as DMAC or DTC) if it is used. Set the appropriate priority level in the Synergy Configuration tool. The priority level of transfer module must be higher than the priority level for the USB Controller, otherwise it does not work.

Express Logic USBX Synergy Port Framework Module Limitations

- Synergy USB controllers (USBHS and USBFS) have a limited number of PIPEs you can use for the isochronous transfer type (PIPE1 and PIPE2). This will limit the number of UVC devices (two devices) you can connect to.
- The device side driver(sf_el_ux DCD driver) does not support DTC as the transfer interface
- **The isochronous transfer is only supported for USB Host**. The transfer type is not supported for USB Device.
- **The USBFS controller is unlikely to support typical UVC devices.** The maximum packet size of isochronous PIPEs on USBFS controller is limited to 256 bytes. This would impact in the UVC usage.
- **Synergy USB controllers (USBHS and USBFS) do not support high-bandwidth isochronous transfer.** The controllers support 1 transaction per micro-frame if running at High Speed).
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.14.3 Using the Express Logic Synergy Port USBX Framework Module in an Application

Once the Express Logic Synergy Port USBX framework module is added to a thread the Express Logic APIs become available for use.

4.1.15 Console Framework

The Console Framework is a complete API implementation for a menu-driven console command line interface (CLI) using the ThreadX RTOS. The Console Framework module uses a lower-level communications interface which connects to a hardware option for either UART, USB, or Ethernet Telnet connectivity. The Console Framework module has a user-defined menu of commands and various APIs to present a prompt, identify and issue a callback for menu commands, and read, write, and parse input strings.

4.1.15.1 Console Framework Module Features

The console framework supports the following features:

- Creation of a menu-based command-line interface
- Submenus and navigation through multiple menus in a single call
- Menu navigation to go up to the parent menu or back to the root
- A help menu for each menu
- Writing NULL terminated strings and reading until return character is received
- An API to help parse arguments to the command line
- Case-insensitive inputs

The Console Framework module organization, as depicted in the thread stack window in the SSP configurator, is shown in the following figure. Each implementation choice, Ethernet, UART, and USB has its own lower-level modules that are added automatically based on the developer's implementation choice. In most cases, all the needed configuration information is automatically added to the modules leaving the developer with just a few important configuration settings that need to be selected.

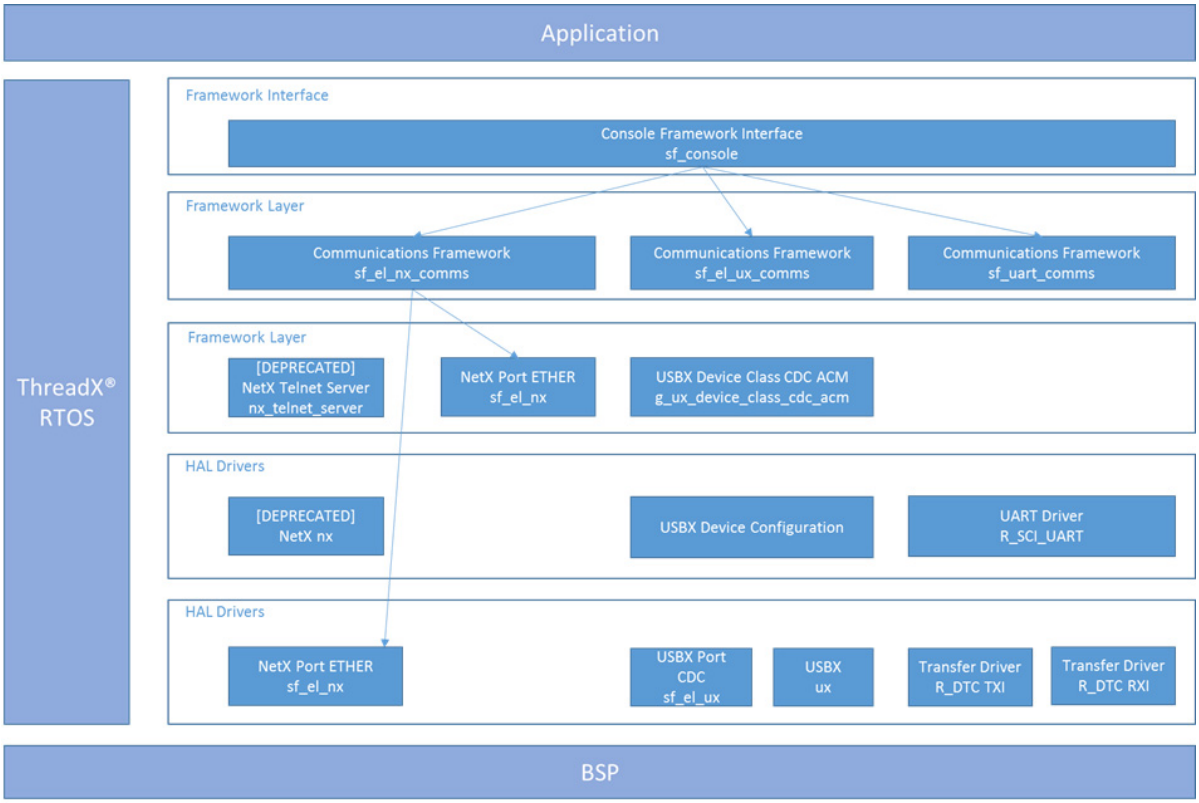

Figure 165: Console Framework Module Block Diagram

4.1.15.2 Console Framework Module APIs Overview

The Console Framework defines APIs for opening, closing, reading, writing, and issuing an input prompt. It also provides some additional functions, such as parse and augumentFind, to assist in processing more complex commands. A complete list of the available APIs, an example API call, a short description of each can be found in the following tables. A table of status return values follows.

Console Framework Module API Summary

Function Name	Example API Call and Definition
open	g_sf_console0.p_api->open(g_sf_console0.p_ctrl, g_sf_console0.p_cfg) The open API configures the console. This function must be called before any other console functions. NOTE: This call is made automatically during system initialization, prior to entering the users thread. Unless the user closes the console, open will not need to be called.

Function Name	Example API Call and Definition
close	g_sf_console0.p_api->close(g_sf_console0.p_ctrl); The close API handles the clean-up of internal driver data.
.prompt	g_sf_console0.p_api->prompt(g_sf_console0.p_ctrl, NULL, TX_WAIT_FOREVER); The prompt API prints the prompt string from the menu, waits for input, parses the input based on the menu, and calls the appropriate callback function if a command is identified.
parse	g_sf_console0.p_api->parse(g_sf_console0.p_ctrl, commands, input, s_length); The parse API looks for an input string in the command menu and, if one is found, calls the appropriate callback function.
read	g_sf_console0.p_api->read(g_sf_console0.p_ctrl, ch, 1, TX_WAIT_FOREVER); The read API puts data into the destination, byte-by-byte and echoes the input to the console. Backspace, delete, and left/right arrow keys are supported. Read completes when a line ending with CR, CR+LF, or CR+NULL is received, or when the input exceeds the number of bytes allowed. If the buffer overflows SF_CONSOLE_MAX_INPUT_LENGTH, the read will return an error code.
write	g_sf_console0.p_api->write(g_sf_console0.p_ctrl, (uint8_t*)data_string, TX_WAIT_FOREVER); The write API gets the buffer mutex object and handles data transmission at the HAL layer. It obtains the event flag to synchronize the completion of a data transfer.
argumentFind	g_sf_console0.p_api->argumentFind("LED", p_args->p_remaining_string, NULL, &led_num); The argumentFind API locates a command line argument in an input string and returns the index of the character immediately following the argument. Any string numbers are converted to integers.
versionGet	g_sf_console0.p_api->versionGet(&version); Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_ASSERTION	p_ctrl is NULL.
SSP_ERR_UNSUPPORTED	Command not found in the current menu.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.15.3 Console Framework Module Operational Overview

The Console Framework module is a ThreadX-aware Command Line Interface (CLI). The module uses ThreadX objects like mutex for blocking and synchronization techniques like event flags for the completion of a transaction. The key operational elements of the Console Framework are initialization and input processing, each of which are described in the following sections.

Console Framework Module Initialization

The open call is automatically generated by the ISDE and is in the src/synergy_gen/toggle_thread.c file where the module was added. The open call requires the application to define a root menu with a variable name that matches the one in the configurator (g_sf_console_root_menu) by default. By the time execution reaches src/ toggle_thread_entry.c, the module is ready to use, provided the necessary hardware connection is established.

Console Framework Module Input Processing

The Console Framework module requires a set of menus, command structures, and callbacks. The Console Framework module typically operates from the prompt, often located within a while loop in the entry thread. The framework prompt API will print the current menu as a prompt, then read input and echo it back to the console (unless echo is disabled in the properties.)

Following operations are performed against the user input:

While the console is accepting input,

- Backspace will remove characters before the cursor.
- Delete will remove characters after the cursor.
- The left and right arrow keys move the cursor.
- The up-arrow key will fill in the last command only when nothing else has been entered.

NOTE: There is no history beyond the last command; if the up-arrow key is pressed twice, the console does not know what command was entered prior to the last command and it will continue to display the last command.

When the console sees a return character on the read input, it parses the input string and calls the associated callback or switches to the next menu if SF_CONSOLE_CALLBACK_NEXT_FUNCTION is used in place of the callback for the command. The console will continue parsing until a callback function is called. If prompt API is called again, it will prompt using the menu that contains the callback function. To navigate up to the parent menu, enter '^'. To navigate to the root menu from any submenu, enter '~'.

Creating Console Framework Module Required Structures – The Menu

The Console Framework requires a menu and it is up to the developer to create the structure that is used by the Console Framework to implement the menu. The Console Menu structure (depicted in the following figure) includes a pointer to the previous menu, (for creating multi-level menus) a name for the menu, the number of commands in the menu, and a pointer to an array of command structures. As seen in the following figure, each entry in the array of commands includes pointers to the command name string, the help command description string, the associated command callback function, and a context parameter provided to the callback.

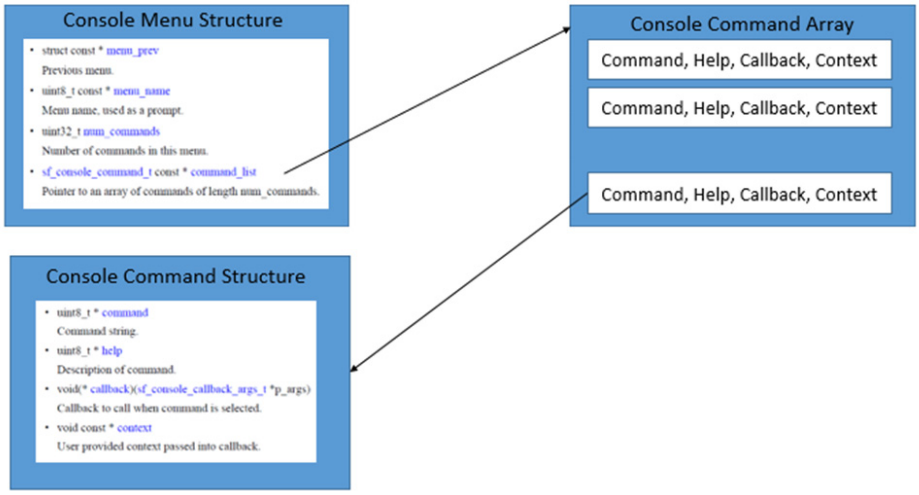

Figure 166: Console Framework Module Menu Structures

The application project example illustrates a Console Framework with a single menu; it controls the toggle of an LED from the CLI. The console command array (g_sf_console_commands, seen on the right in the following figure) stores the array of commands (in this case just a single command.) The command structure defines the command as "LED TOGGLE", the help description as "Toggle an LED", the callback as led_toggle_callback, and the context as NULL, since it is unused for this example.

The root menu, seen on the left side of the following figure, is identified by the g_sf_console_root_menu structure. The structure defines the menu_prev entry as NULL, since there is only the single menu, the menu_name as "Root", the num_commands as the size of the array divided by the size of an entry (to determine the total number of entries) as "1", and the command_list starting address as "address", the location of the first entry in the command array.

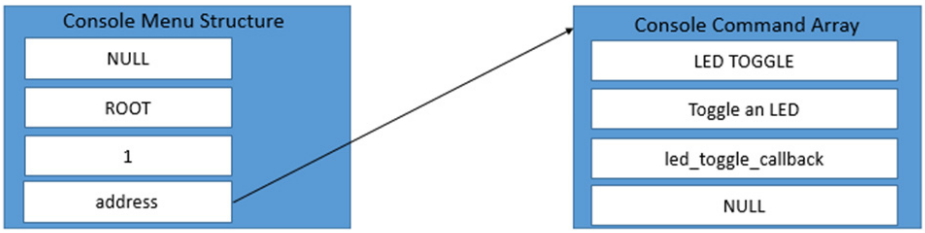

Figure 167: Menu Structure Example Diagram

Console Framework Module Important Operational Notes and Limitations

To use the Console Framework module prompt API, first set up the menu, command structures, and callbacks.

There are no known limitations for using this module.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.15.4 Including the Console Framework Module in an Application

This section describes how to include the Console Framework module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Console Framework module to your application, simply add it to a project thread using the stacks selection sequence provided in the following table. (The default name for the console framework module is g_sf_console0. This name can be changed in the associated Properties window.)

Console Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_console0 Console Framework on sf_console	Threads	New Stack > Framework > Services > Console Framework on sf_console

When the console framework on sf_console is added to the thread stack as shown in the following figure, the configurator reports (via the Add Communications Framework block) that at least one Communications Framework is required to complete the Console Framework. The Communications Framework determines the type of communications interface (and the underlying hardware implementation) the Console Framework will use. Any low-level modules that need additional configuration information will have box text highlighted in red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended (this is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description will include "Add" in the text. Clicking on any Pink banded modules will bring up the "New" icon and then display the possible choices.

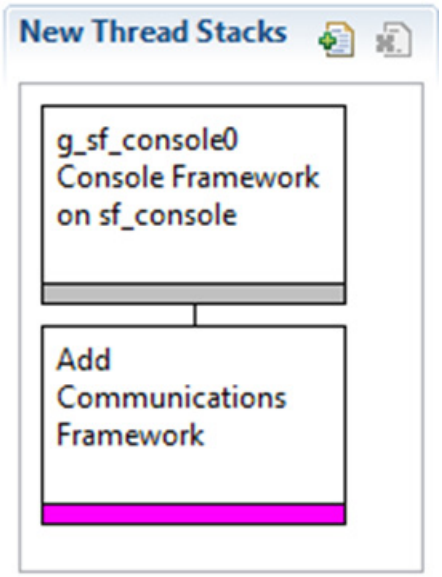

Figure 168: Console Framework Module Stack

Currently there are three possible Communications Frameworks available that the Console Framework can select: UART, USB, or Telnet. Configurations for each are shown in the following thread stack illustrations and they can be easily imported by clicking the Add Communications Framework block and selecting the desired Communications Framework. (Note that the Telnet option uses a deprecated implementation. This will function correctly, but is indicated as deprecated since it will be replaced in a future release. Designs using the deprecated module will need to be updated to the new implementation after that release.) Other Communications Frameworks are being added and may show up when available.

Communications Framework Module Options

4.1.15.5 Configuring the Console Framework Module

The Console Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for-lower level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+.) This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the configuration table settings in the following table. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Console Framework Module on sf_console

Parameter	Value	Description
Parameter Checking	BSP, Enable, Disable Default: BSP	Selects if code for parameter checking is to be included in the build.
Maximum Input String Length	128	Input string length.
Maximum Write String Length	128	Output string length.
Name	g_sf_console0	Console Framework module name.
Name of Initial Menu (Application Defined)	g_sf_console_root_menu	Name of starting menu.
Echo	True, False Default: True	Enable or disable echo to terminal from the prompt.
Autostart	True, False Default: False	If True, the prompt will occur using the top-level menu after initialization. If False, the prompt needs to be called in the application.
Name of the sf_console Initialization Function	sf_console_init0	Name of the sf_console initialization function selection.
Auto sf_console Initialization	Enable, Disable Default: Enable	Auto sf_console initialization selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, the IP address for the Telnet connection or the baud rate of the UART might need to be modified. The configurable properties for the lower-level stack modules are displayed for completeness and as a reference.

NOTE: Most of the property settings for modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the Console Framework Stack Modules

Typically, only a small number of settings must be modified from the default for lower-level modules as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module.

When the Telnet option is selected for the low-level implementation, the following modules are automatically added to the stack. The following tables show the detailed configuration settings available, many of which are populated with default settings that can be used in most common applications.

Configuration Settings for the Telnet Option (sf_el_nx_comms)

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled	Enable or disable the parameter checking.
	Default: BSP	
Name	g_sf_comms0	Module name.
Channel	0	Underlying channel used by Ethernet driver.
IP Address Byte 1	192	IP Address Byte 1 selection
IP Address Byte 2	168	IP Address Byte 2 selection
IP Address Byte 3	0	IP Address Byte 3 selection
IP Address Byte 4	0	IP Address Byte 4 selection
Subnet Mask Byte 1	255	Subnet Mask Byte 1 selection
Subnet Mask Byte 2	255	Subnet Mask Byte 2 selection
Subnet Mask Byte 3	255	Subnet Mask Byte 3 selection
Subnet Mask Byte 4	0	Subnet Mask Byte 4 selection

NOTE: Information and a description of valid and common settings for IP Addresses and the associated masks are available in the IP Address Limitations Synergy Platform Knowledge Base article available as described at the end of this document. The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for stack modules can be desirable. For example, it might be useful to have a different IP address. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

NOTE: The following deprecated configurations of the NetX Telnet server module and the NetX module are required when using the Communications Framework module on sf_el_nx_comms. The Communications Framework module on sf_el_nx_comms will be updated in a future release to avoid using deprecated configurations.

Configuration Settings for the NetX Telnet Server Module (nx_telnet_server)

ISDE Property	Value	Description
Name	g_nx_telnet_server0	Module name
Show deprecation warning	Enabled, Disabled Default: Enabled	Show deprecation warning selection

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Module (nx)

ISDE Property	Value	Description
Name	Default: g_nx0	NetX module name.
Show deprecation warning	Enabled, Disabled Default: Enabled	Show deprecation warning selection

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for NetX Port ETHER (sf_el_nx)

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking
Channel 0 Phy Reset Pin	IOPORT_PORT_09_PIN_03	Channel 0 Phy reset pin selection
Channel 0 MAC Address High Bits	0x00002E09	Channel 0 MAC address high bits selection
Channel 0 MAC Address Low Bits	0x0A0076C7	Channel 0 MAC address low bits selection

ISDE Property	Value	Description
Channel 1 Phy Reset Pin	IOPORT_PORT_07_PIN_06	Channel 1 Phy reset pin selection
Channel 1 MAC Address High Bits	0x00002E09	Channel 1 MAC address high bits selection
Channel 1 MAC Address Low Bits	0x0A0076C8	Channel 1 MAC address low bits selection
Number of Receive Buffer Descriptors	8	Number of receive buffer descriptors selection
Number of Transmit Buffer Descriptors	32	Number of transmit buffer descriptors selection
Ethernet Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Ethernet interrupt priority selection
Name	g_sf_el_nx	Module name
Channel	0	Channel selection
Callback	NULL	Callback selection

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

When the USB option is selected for low-level implementation, the following modules are automatically added to the stack. The following tables show the detailed configuration settings available, many of which are populated with default settings that can be used in most common applications.

Configuration Settings for USB Communications Framework Module (sf_el_ux_comms)

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Read Input Buffer Size (Bytes)	128	Maximum number of bytes that can be received at a time in the read() API.
Timeout in ticks	1000	Timeout value to suspend a USBX CDC instance creation in the open() API.
Name	g_sf_comms0	Module name.
Name of the sf_comms initilization function	sf_comms_init0	Name of helper function to initialize Communications Framework. The function will be presented in the auto-generated code in the <xxx_thread>.c, where <xxx_thread> is the name of your thread symbol given to the Thread property. The function is to be called in the auto-generated code if Auto sf_comms Initialization property is Enabled. If Disabled, the function can be called in the user application.
Auto sf-comms Intialization	Enable, Disable Default: Enable	Auto Initialization support of Communications Framework. The helper function above will be called in the auto-generated code if this configuration is enabled. Else, the function will not be called automatically and user can call it sometime later.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration for the USBX Device Class CDC ACM Module (g_ux_device_class_cdc_acm0)

ISDE Property	Value	Description
Name	g_ux_device_class_cdc_acm0	Module name
USBX CDC-ACM instance_activate Function Callback	ux_cdc_device0_instance_activate	USBX CDC-ACM instance_activate Function Callback selection
USBX CDC-ACM instance_deactivate Function Callback	ux-cdc_device0_instance_deactivate	USBX CDC-ACM instance_deactivate Function Callback selection

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Device Configuration

ISDE Property	Value	Description
Vendor ID	0x045B	Vendor ID selection
Product ID	0x0000	Product ID selection
Device Release Number	0x0000	Device Release Number selection
Index of Manufacturing String Descriptor	0x00	Index of Manufacturing String Descriptor selection
Index of Product String Descriptor	0x00	Index of Product String Descriptor selection
Index of Serial Number String Descriptor	0x00	Index of Serial Number String Descriptor selection
Class Code	Device, Communications(CDC), HID, Mass Storage, Miscellaneous, Vendor Specific Default: Communications	Class Code selection
Index of String Descriptor describing this configuration	0x00	Index of String Descriptor describing this configuration selection

ISDE Property	Value	Description
Size of USB Descriptor in bytes for this configuration (Modify this value only for Vendor-specific Class, otherwise set zero)	0x00	Size of USB Descriptor in bytes for this configuration (Modify this value only for Vendor-specific Class, otherwise set zero) selection
Number of Interfaces (Modify this value only for Vendor-specific Class, otherwise set zero)	0x00	Number of Interfaces (Modify this value only for Vendor-specific Class, otherwise set zero) selection
Self-Powered	Enable, Disable Default: Enable	Self-Powered selection
Remote Wakeup	Enable, Disable Default: Disable	Remote Wakeup selection
Maximum Power Consumption (in 2mA units)	50	Maximum Power Consumption (in 2mA units) selection
Supported Language Code	0x0409	Supported Language Code selection
Name of USBX String Framework	NULL	Name of USBX String Framework selection
Total index number of USB String Descriptors in USB String Framework	0	Total index number of USB String Descriptors in USB String Framework selection
Name of USBX Language Framework	NULL	Name of USBX Language Framework selection
Number of Languages to support (US English is applied if zero is set)	0	Number of Languages to support (US English is applied if zero is set) selection

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Interface Configuration

ISDE Property	Value	Description
Name	g_usb_interface_desc_cdcacm_0	Module name
Interface Number of Communications Class interface	0x00	Interface Number of Communications Class interface selection
Interrupt Transfer endpoint to use for Communications Class	Endpoint 1-9 Default: Endpoint 3	Interrupt Transfer endpoint to use for Communications Class selection
Polling period for Interrupt Endpoint (in mS/125us units for FS/HS)	0x0F	Polling period for Interrupt Endpoint (in mS/125us units for FS/HS) selection
Interface Number of Data Class interface	0x01	Interface Number of Data Class interface selection
Bulk In Transfer endpoint to use for Data Class	Endpoint 1-9 Default: Endpoint 1	Bulk In Transfer endpoint to use for Data Class selection
Bulk Out Transfer endpoint to use for Data Class	Endpoint 1-9 Default: Endpoint 2	Bulk Out Transfer endpoint to use for Data Class selection
Index of String Descriptor Describing Communications Class interface (Interface Descriptor: Interface)	0x00	Index of String Descriptor Describing Communications Class interface (Interface Descriptor: Interface) selection
Index of String Descriptor Describing Data Class interface (Interface Descriptor: Interface)	0x00	Index of String Descriptor Describing Data Class interface (Interface Descriptor: Interface) selection

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port DCD on sf_el_ux for USBFS

ISDE Property	Value	Description
Full Speed Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Full speed interrupt priority selection.
Name	g_sf_el_ux_dcd_fs_0	Module name.
USB Controller Selection	USBFS	USB controller selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port DCD on sf_el_ux for USBHS

ISDE Property	Value	Description
High Speed Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	High speed interrupt priority selection.
Name	g_sf_el_ux_dcd_hs_0	Module name.
USB Controller Selection	USBHS	USB controller selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX on ux

ISDE Property	Value	Description
USBX Pool Memory Name	g_ux_pool_memory	USBX pool memory name selection.
USBX Pool Memory Size	18432	USBX pool memory size selection.
User Callback for Host Event Notification (Only valid for USB Host)	NULL	User callback for host event notification (only valid for USB host)

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

When the UART option is selected for low-level implementation, the following modules are automatically added to the stack. The following tables show the detailed configuration settings available, many of which are populated with default settings that can be used in most common applications.

Configuration Settings for the UART Communications Framework Module (sf_uart_comms)

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled	Selects if parameter checking is included.
	Default: BSP	
Read Input Queue Size (4-Byte Words)	15	Buffer size for data reception queue. sf_uart_comms utilizes the ThreadX Queue for the queue management.
Name	g_sf_comms0	Name of UART communications framework module.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the UART Driver Module (r_sci_uart)

ISDE Property	Value	Description
External RTS Operation	Enable, Disable Default: Disable	Enable an IOPORT pin to be used as RTS signal. For RTS functionality set this configuration parameter to "Enable" and specify the configuration "Name of UART callback function for the RTS external pin control".
Reception	Enable, Disable Default: Enable	Enable or disable UART reception for all UART channels on SCI. Setting this configuration parameter to "Disable" reduces code size because the portion of code for UART reception is not compiled. You cannot set this parameter for individual UART channels.
Transmission	Enable, Disable Default: Enable	Enable or disable UART transmission for all UART channels on SCI. Setting "Disable" to this configuration allows to get smaller code size due to the portion of code for UART transmission is compiled out, however, you can only set "Disable" to this configuration if any other SCI channels which work as UART ports do not perform the transmission.
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_uart0	The name to be used for UART on SCI module control block instance. This name is also used as the prefix of the other variable instances.
Channel	0-9	SCI channel number.
Baud Rate	9600	Baud rate selection.

ISDE Property	Value	Description
Data Bits	7 bits, 8, bits, 9 bits Default: 8 bits	UART data bits.
Parity	None, Odd, Even Default: None	UART parity bits.
Stop Bits	1 bit, 2 bits Default: 1 bit	UART stop bits.
CTS/RTS Selection	CTS (Note that RTS is available when enabling External RTS Operation mode which uses 1 GPIO pin), RTS (CTS is disabled) Default: RTS (CTS is disabled)	Select CTS or RTS for the CTSn/RTSn pin of SCI channel n. The SCI hardware supports either the CTS or the RTS control signal on this pin but not both. For an application that uses both CTS and RTS, select "CTS" for this configuration parameter and enable the configuration "External RTS Operation" specifying the configuration "Name of UART callback function for the RTS external pin control".
Name of UART callback function to be defined by user	user_uart_callback	Name must be a valid C symbol.
Name of UART callback function for the RTS external pin control to be defined by user	NULL	Name must be a valid C symbol.
Clock Source	Internal Clock, External Clock 8x baudrate, External Clock 16x baudrate Default: Internal Clock	Selection of the clock source to be used in the baud-rate clock generator block.

ISDE Property	Value	Description
Baudrate Clock Output from SCK pin	Enable, Disable Default: Disable	Optional setting to output the baud-rate clock on the SCKn pin for the selected channel n.
Start bit detection	Falling Edge, Low Level Default: Falling Edge	Start bit detection mode in the reception, usually set "Falling Edge" to this configuration.
Noise Cancel	Enable, Disable Default: Disable	Enable the digital noise cancellation on RXDn pin. The digital noise filter block in SCI consists of two-stage flip-flop circuits. For detail, refer to the Noise cancellation section in the Renesas Synergy hardware manual.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Bit rate modulation enable selection.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Transmit interrupt priority selecition.

ISDE Property	Value	Description
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Transmit end interrupt priority selection.
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Error interrupt priority selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Transfer Driver Module on r_dtc Event SCI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Disabled	Software start selection
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection
Name	g_transfer0	Module name
Mode	Normal	Mode selection

ISDE Property	Value	Description
Transfer Size	1 Byte	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SCI0 TXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Transfer Driver Module on r_dtc Event SCI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Name	g_transfer1	Module name
Mode	Normal	Mode selection
Transfer Size	1 Byte	Transfer size selection
Destination Address Mode	Incremented	Destination address mode selection
Source Address Mode	Fixed	Source address mode selection
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SPI0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection

ISDE Property	Value	Description
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

When the USB option is selected for low-level implementation, the following modules are automatically added to the stack. The following tables show the detailed configuration settings available, many of which are populated with default settings that can be used in most common applications.

Configuration Settings for USB Communications Framework Module (sf_el_ux_comms)

ISDE Property	Value	Description
Parameter Checking	BSP, Enable, Disable Default: BSP	Selects if code for parameter checking is to be included in the build.
Memory Size (Bytes)	65536	Memory size selection.
Timeout in ticks	1000	Timeout value to suspend a USBX CDC instance creation in the open() API.
Read Input Buffer Size (Bytes)	128	This is the maximum number of bytes that can be received at a time in the read() API.
Name	g_sf_comms0	Name for USB communications framework module.
Name of the sf_comms Initialization Function	sf_comms_init0	Name of the sf_comms initialization function selection.
Auto sf_comms Initialization	Enable, Disable Default: Enable	Auto sf_comms initialization selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration for the USBX Device Class CDC ACM Module (g_ux_device_class_cdc_acm0)

ISDE Property	Value	Description
Name	Default: g_ux_device_class_cdc_acm0	USBX device class cdc-acm module name.
Show Deprecation Warning	Enabled, Disabled Default: Enabled	Show deprecation warning selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USXB on ux

ISDE Property	Value	Description
Name	Default: g_ux0	USBX on ux module name.
Show Deprecation Warning	Enabled, Disabled Default: Enabled	Show deprecation warning selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Ports HS and FS on sf_el_ux

ISDE Property	Value	Description
VBUSEN Pin Signal Logic	Active Low, Active High Default: Active High	VBUSEN pin signal logic selection.
High Speed Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	High speed interrupt priority selection.

ISDE Property	Value	Description
Full Speed Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Full speed interrupt priority selection.
Name	Default: g_sf_el_ux	Name for the USBX Ports HS and FS.
Show deprecation warning	Enabled, Disabled Default: Enabled	Show deprecation warning selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

4.1.15.6 Using the Console Framework Module in an Application

The key elements in constructing a simple Console Framework are selecting and configuring the stack, defining the menu structure, writing the code for the menu command callbacks, and using the API calls to implement the desired CLI functions within the target application. The typical steps in using the Console Framework module in an application are:

1) Create menu and command structures.
2) Implement needed callbacks.
3) Initialize the SF_CONSOLE using open API.
4) Use the prompt API to generate the prompt and process commands.
5) Use other APIs (read, write, parse or argumentFind) as needed to process commands.
6) Use close API to close the module if desired.

These common steps are illustrated in a typical operational flow diagram in the following figure:

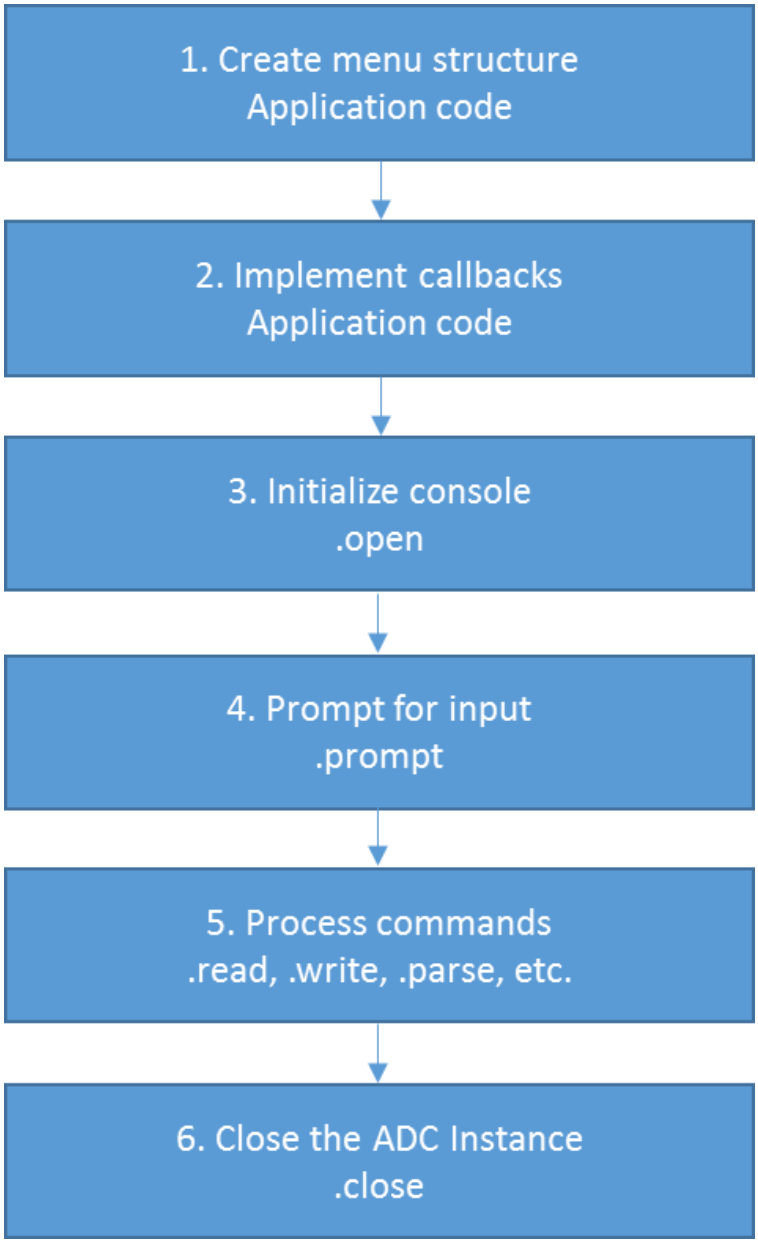

Figure 172: Typical Console Framework Module Application

4.1.16 Crypto Framework

The Crypto Framework layer is composed of multiple Crypto modules providing varied cryptographic services. It includes:

- SF_CRYPTO for resource synchronization between the crypto modules.

- SF_CRYPTO_TRNG for true random number generation.
- SF_CRYPTO_HASH for message digest generation. Provides support for MD5, SHA1, SHA 224, SHA 256 algorithms.
- SF_CRYPTO_KEY for Key Generation services. Provides support for AES, ECC and RSA keys.
- SF_CRYPTO_CIPHER for encryption and decryption services. Provides support for AES and RSA algorithms.
- SF_CRYPTO_SIGNATURE for RSA signature generation and verification services.
- SF_CRYPTO_KEY_INSTALLATION for key installation services. Provides support for AES, ECC and RSA keys.

Refer to SCE HAL module documentation for the cryptographic functions that are supported on different target MCUs.

4.1.16.1 Crypto Framework Module Features

- SF CRYPTO Framework
  - The SF CRYPTO Framework opens the underlying Secure Crypto Engine.
  - Provides services for access to shared resources for other Crypto Framework modules SF_CRYPTO_TRNG, SF_CRYPTO_HASH , SF_CRYPTO_KEY, SF_CRYPTO_CIPHER, SF_CRYPTO_SIGNATURE, and SF_CRYPTO_KEY_INSTALLATION.
- SF CRYPTO TRNG Framework
  - The SF CRYPTO TRNG Framework module uses the TRNG HAL interfaces to the underlying Secure Crypto Engine.
  - Access to shared resources through SF CRYPTO Framework module.
- SF CRYPTO HASH Framework
  - The SF CRYPTO HASH Framework utilizes the underlying Secure Crypto Engine to provide HASH services.
  - This module provides enhancements over the HAL driver such as:
  - Initializing the HASH value
  - **Processing chunks of data through hashUpdate API before finalizing the hash operation.**
  - **Formatting the final block for the final HASH operation.**
- SF CRYPTO KEY Framework Module Features
  - RSA 2048-bit, 1024-bit plain text/raw keys.
  - RSA 2048-bit, 1024-bit standard format wrapped private keys (public keys in plain).
  - AES 128-bit, 192-bit and 256-bit wrapped keys for ECB, CBC, CTR and GCM chaining modes.
  - AES 128-bit and 256-bit wrapped keys for XTS chaining mode.
  - ECC 192-bit, 256-bit wrapped keys.
- SF CRYPTO SIGNATURE Framework Module Features

  - This module currently supports signature generation and signature-verification for RSA algorithm. There is support for both 1024-bits and 2048-bits key lengths for standard format plain-text, standard format wrapped private key and CRT plain-text keys.
  - RSASSA-PKCS1 v1.5 is the supported signature scheme. The input message can be passed as raw message to be signed/verified or can be PKCS1 v1.5 encoded and padded before sign/verify.
  - SHA1, SHA224, SHA256 are the supported hashing algorithms for PKCS1 v1.5 encoding /padding schemes.
  - This module allows signature generation/verification on data which is smaller than a block size.
  - If all of the data is not available at once, update APIs can be used to accumulate the incoming chunks of data and finally sign/verify the message only when all the message is gathered.
  - Allows switching between sign and verify operations with less expensive API calls which are not involved in allocating and deallocating memory.
- SF CRYPTO CIPHER Framework Module Features
  - This module currently supports encryption and decryption for AES and RSA algorithms.
  - This module allows encryption/ decryption of data when available in chunks through the cipherUpdate()API and final() when the last chunk /all the data is gathered.
  - Once the module is opened for a specific key type and key size, the encrypt and decrypt modes can be switched by calling the cipherInit() API.
- SF CRYPTO KEY INSTALLATION Framework Module Features
  - The SF CRYPTO KEY INSTALLATION Framework module uses the KEY INSTALLATION HAL interfaces to the underlying Secure Crypto Engine.
  - Access to shared resources through SF CRYPTO Framework module.
  - This module supports key installation for the following keys:
  - **RSA:**
  - **1024-bit and 2048-bit plain text keys.**
  - **AES:**
  - **128-bit, 192-bit and 256-bit plain text keys for ECB, CBC, CTR and GCM chaining modes.**
  - **128-bit and 256-bit plain text keys for XTS chaining mode.**
  - **ECC:**
  - **192-bit and 256-bit plain text keys.**
  - The user and install keys must be provided to the key installation API in the specified format.
  - Upon installation the key installation service returns a wrapped key to the caller for any future usage of installed key on that device.

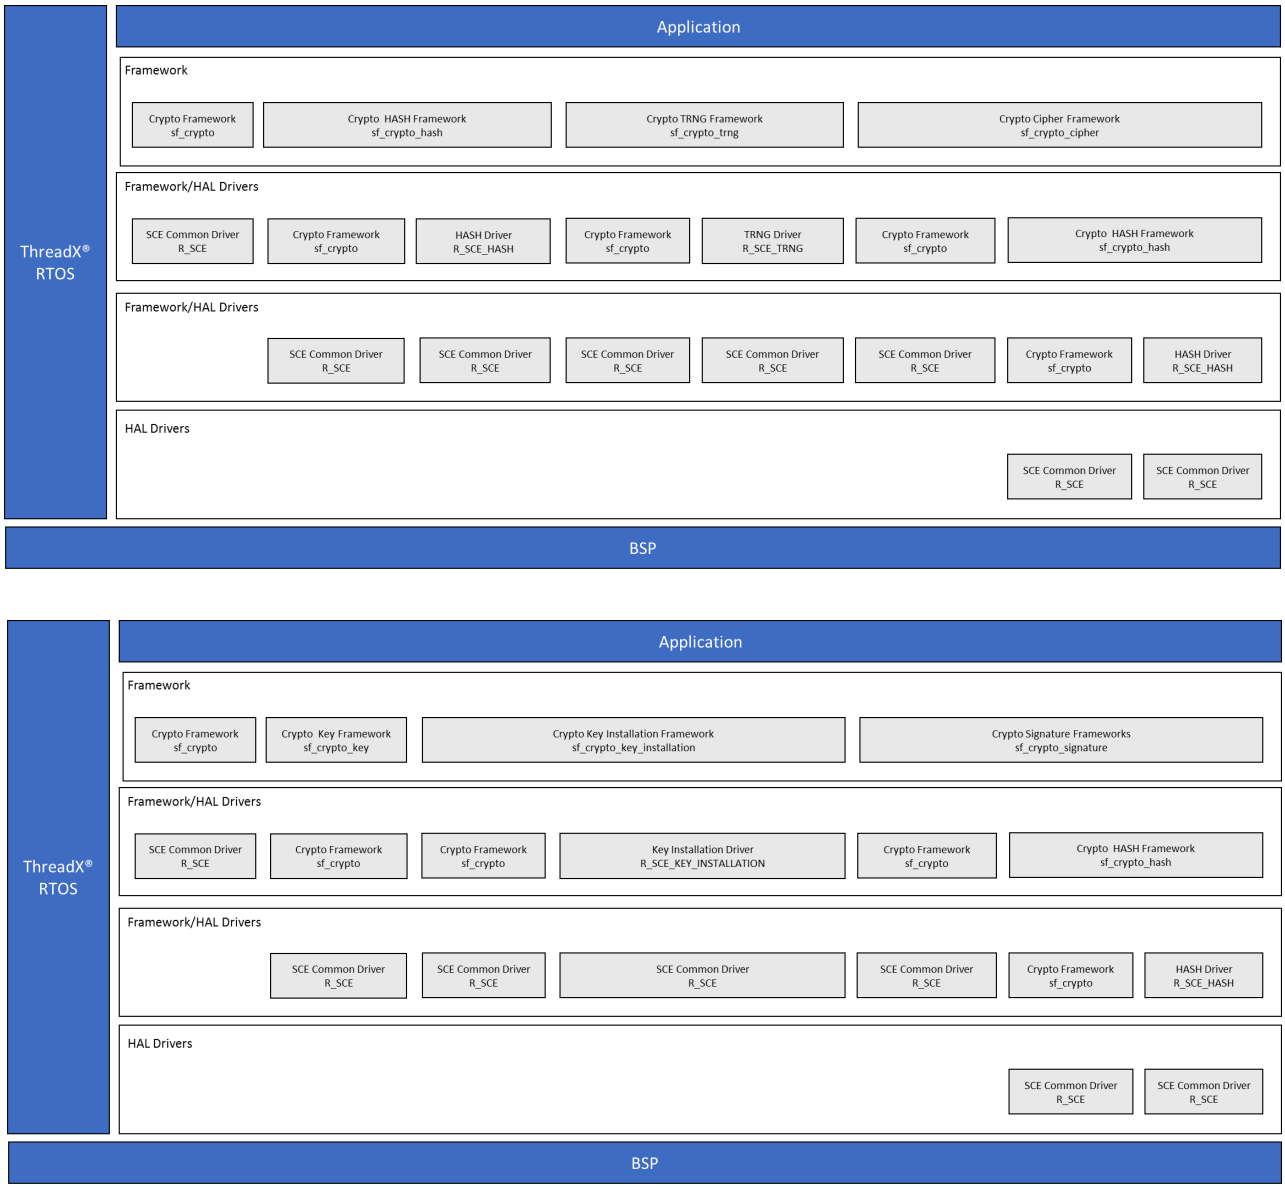

Figure 173: Crypto Framework Module Organization, Options and Stack Implementations

4.1.16.2 Crypto Framework Module APIs Overview

The Crypto Framework Module defines APIs for varied cryptographic services. A complete list of the available APIs, an example API call, and a short description of each can be found in the table below. A table of status return values follows.

Crypto Framework Module API Summary

Function Name	Example API Call and Description
.open	g_sf_crypto0.p_api->open(g_sf_crypto0.p_ctrl, g_sf_crypto0.p_cfg); This function is used to open the crypto framework module and the r_sce HAL module.
.close	g_sf_crypto0.p_api->close(g_sf_crypto0.p_ctrl); This function is used to close the crypto framework module and the r_sce HAL module.
.lock	g_sf_crypto0.p_api->lock(g_sf_crypto0.p_ctrl); This function locks shared resources for Cryptography operations.
.unlock	g_sf_crypto0.p_api->unlock(g_sf_crypto0.p_ctrl); Unlock shared resources for Cryptography operations. .
.getStatus	g_sf_crypto0.p_api->getStatus(g_sf_crypto0.p_ctrl, &p_status); This function gets the status of the Crypto Framework Common Module.
.versionGet	g_sf_crypto0.p_api->versionGet(&version); This function retrieves the API version using the version pointer.

Crypto Framework HASH Module API Summary

Function Name	Example API Call and Description
.open	g_sf_crypto_hash0.p_api->open(g_sf_crypto_hash0.p_ctrl, g_sf_crypto_hash0.p_cfg); This function is used to open the crypto hash framework module.
.close	g_sf_crypto_hash0.p_api->close(g_sf_crypto_hash0.p_ctrl); This function is used to close the crypto hash framework module.
.hashInit	g_sf_crypto_hash0.p_api->hashInit(g_sf_crypto_hash0.p_ctrl); This function initializes the calculation of the hash function. It has to be invoked first and only once, at the beginning of the each new calculation.
.hashUpdate	g_sf_crypto_hash0.p_api->hashUpdate(g_sf_crypto_hash0.p_ctrl, &p_data_in); This function calculates the hash on the data pointed to by the p_data_in pointer.
.hashFinal	g_sf_crypto_hash0.p_api->hashUpdate(g_sf_crypto_hash0.p_ctrl, &p_data_in, &p_size); This function finalizes the hash operation on the data pointed to by the p_data_in pointer and stores the output size in the 32-bit word defined by the p_size pointer.
.versionGet	g_sf_crypto_hash0.p_api->versionGet(&version); This function retrieves the API version using the version pointer.

Crypto Framework TRNG Module API Summary

Function Name	Example API Call and Description
.open	g_sf_crypto_trng0.p_api->open(g_sf_crypto_trng0.p_ctrl, g_sf_crypto_trng0.p_cfg); This function is used to open the crypto TRNG framework module.
.close	g_sf_crypto_trng0.p_api->close(g_sf_crypto_trng0.p_ctrl); This function is used to close the crypto TRNG framework module.
. randomNumberGenerate	g_sf_crypto_trng0.p_api-> randomNumberGenerate (&p_buffer); This function generates the random number and stores it in memory starting at the address defined by the p_buffer pointer.
.versionGet	g_sf_crypto_trng0.p_api->versionGet(&version); This function retrieves the API version using the version pointer.

Crypto Framework KEY Module API Summary

Function Name	Example API Call and Description
.open	g_sf_crypto_key0.p_api->open(g_sf_crypto_key0.p_ctrl, g_sf_crypto_key0.p_cfg); This function is used to open the crypto key framework module.
.keyGenerate	g_sf_crypto_key0.p_api->keyGenerate(g_sf_crypto_key0.p_ctrl, &p_secret_key, &p_public_key); This function is used to generate a key or key pair and store it at the p_secret_key and p_public_key pointers.

Function Name	Example API Call and Description
.close	g_sf_crypto_key0.p_api->close(g_sf_crypto_key0.p_ctrl); This function is used to close the crypto key framework module and the r_sce HAL module.
.versionGet	g_sf_crypto_key0.p_api->versionGet(&version); This function retrieves the API version using the version pointer.

Crypto Framework KEY Installation Module API Summary

Function Name	Example API Call and Description
.open	g_sf_crypto_key_installation.p_api->open(g_sf_crypto_key_installation.p_ctrl, g_sf_crypto_key_installation.p_cfg); This function is used to open the crypto key initialization framework module.
.keyInstall	g_sf_crypto_key_installation.p_api->keyInstall(g_sf_crypto_key_installation.p_ctrl, p_user_key_input, p_install_key_input, p_key_data_out); This function is used to install a key using the p_user_key_input, p_install_key_input and p_key_data_out pointers.
.close	g_sf_crypto_key_installation.p_api->close(g_sf_crypto_key_installation.p_ctrl); This function is used to close the crypto key installation framework module.
.versionGet	g_sf_crypto_key_installation.p_api->versionGet(&version); This function retrieves the API version using the version pointer.

Crypto Framework Cipher Module API Summary

Function Name	Example API Call and Description
.open	g_sf_crypto_cipher.p_api->open(g_sf_crypto_cipher.p_ctrl, g_sf_crypto_cipher.p_cfg); This function is used to open the crypto cipher framework module.
.cipherInit	g_sf_crypto_cipher.p_api->cipherInit(g_sf_crypto_cipher.p_ctrl, mode, p_key, p_params); This function is used to initialize cipher operation. Must be called after open or cipherFinal.
.cipherUpdate	g_sf_crypto_cipher.p_api->cipherUpdate(g_sf_crypto_cipher.p_ctrl, p_data_in, p_data_out); This function is used to encrypt or decrypt input data. Can be called multiple times for additional blocks of data.
.cipherFinal	g_sf_crypto_cipher.p_api->cipherFinal(g_sf_crypto_cipher.p_ctrl, p_data_in, p_data_out); This function is used to encrypt or decrypt all/last block of data.
.cipherAadUpdate	g_sf_crypto_cipher.p_api->cipherAadUpdate(g_sf_crypto_cipher.p_ctrl, p_data_in, p_data_out); This function is used to update AAD (Additional Authentication Data) for AES GCM operation.
.close	g_sf_crypto_cipher.p_api->close(g_sf_crypto_cipher.p_ctrl); This function is used to close the crypto cipher framework module.

Function Name	Example API Call and Description
.versionGet	g_sf_crypto_cipher.p_api->versionGet(&version); This function retrieves the API version using the version pointer.

Crypto Framework Signature Module API Summary

Function Name	Example API Call and Description
.open	g_sf_crypto_signature.p_api->open(g_sf_crypto_signature.p_ctrl, g_sf_crypto_signature.p_cfg); This function is used to open the crypto signature framework module.
.contextInit	g_sf_crypto_signature.p_api->contextInit(g_sf_crypto_signature.p_ctrl, mode, p_params, p_key); This function is used to initialize the crypto signature framework module.
.signUpdate	g_sf_crypto_signature.p_api->signUpdate(g_sf_crypto_signature.p_ctrl, p_message); This function performs the signature update operation. It can be called multiple times to accumulate the message to be signed.
.verifyUpdate	g_sf_crypto_signature.p_api->verifyUpdate(g_sf_crypto_signature.p_ctrl, p_message); This function performs the signature verification update operation. It can be called multiple times to accumulate the message whose signature is to be verified.
.signFinal	g_sf_crypto_signature.p_api->signFinal(g_sf_crypto_signature.p_ctrl, p_message, p_dest); This function generates the signature and writes it to the destination.

Function Name	Example API Call and Description
.verifyFinal	g_sf_crypto_signature.p_api->verifyFinal(g_sf_crypto_signature.p_ctrl, p_signature, p_message); This function performs the signature verify operation.
.close	g_sf_crypto_signature.p_api->close(g_sf_crypto_signature.p_ctrl); This function is used to close the crypto signature framework module.
.versionGet	g_sf_crypto_signature.p_api->versionGet(&version); This function retrieves the API version using the version pointer.

NOTE: For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the *SSP User's Manual* API References for the associated module*._

The Framework APIs return common SSP error codes and in addition may return the following error codes from low level modules. There are also Crypto Framework specific error codes and these are listed at the end of the table.

Status Return Values

Name	Description
SSP_ERR_CRYPTO_CONTINUE	Continue executing function
SSP_ERR_CRYPTO_SCE_RESOURCE_CONFLICT	Hardware resource busy
SSP_ERR_CRYPTO_SCE_FAIL	Internal I/O buffer is not empty
SSP_ERR_CRYPTO_SCE_HRK_INVALID_INDEX	Invalid index
SSP_ERR_CRYPTO_SCE_RETRY	Retry
SSP_ERR_CRYPTO_SCE_VERIFY_FAIL	Verify failed
SSP_ERR_CRYPTO_SCE_ALREADY_OPEN	Crypto Module is already opened
SSP_ERR_CRYPTO_NOT_OPEN	Hardware module is not initialized
SSP_ERR_CRYPTO_UNKNOWN	Some unknown error occurred

Name	Description
SSP_ERR_CRYPTO_NULL_POINTER	Null pointer input as a parameter
SSP_ERR_CRYPTO_NOT_IMPLEMENTED	Algorithm/size not implemented
SSP_ERR_CRYPTO_RNG_INVALID_PARAM	An invalid parameter is specified
SSP_ERR_CRYPTO_RNG_FATAL_ERROR	A fatal error occurred
SSP_ERR_CRYPTO_INVALID_SIZE	Size specified is invalid
SSP_ERR_CRYPTO_INVALID_STATE	Function used in an valid state
SSP_ERR_CRYPTO_ALREADY_OPEN	Control block is already opened
SSP_ERR_CRYPTO_INSTALL_KEY_FAILED	Specified input key is invalid
SSP_ERR_CRYPTO_AUTHENTICATION_FAILED	Authentication failed
Crypto Framework Specific Error Codes	
SSP_ERR_CRYPTO_COMMON_NOT OPENED	Crypto Framework Common is not opened.
SSP_ERR_CRYPTO_HAL_ERROR	Crypto HAL module returned an error.
SSP_ERR_CRYPTO_KEY_BUF_NOT_ENOUGH	Key buffer size isn't large enough to generate a key
SSP_ERR_CRYPTO_BUF_OVERFLOW	Attempt to write data larger than buffer.
SSP_ERR_CRYPTO_INVALID_OPERATION_MODE	Invalid operation.
SSP_ERR_MESSAGE_TO_LONG	Message for RSA encryption is too long.
SSP_ERR_RSA_DECRYPTION_ERROR	RSA Decryption error.

NOTE: Lower level drivers may return Common Error Codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.16.3 Crypto Framework Module Operational Overview

The following notes apply to SF_CRYPTO, SF_CRYPTO_TRNG, SF_CRYPTO_HASH, SF_CRYPTO_KEY, SF_CRYPTO_KEY_INSTALLATION, SF_CRYPTO_CIPHER and SF_CRYPTO_SIGNATURE modules.

Endianness configuration parameter

- In the Synergy Configurator if *only* the Crypto HAL drivers are selected without the Crypto Framework modules, endianness is a configurable parameter and set to *big endian* by default. This is the mode that was supported in previous releases.
- In the Synergy Configurator, if Crypto Framework modules are selected (the respective HAL component is included automatically), the endianness flag is locked to the *little endian* mode where only the byte array format is supported.
- The Crypto Framework Layer APIs support only byte arrays for input and output data.
- The Crypto HAL APIs support WORD/32-bit (uint32_t) arrays for input and output data.
- Users with data in byte array format should use the Crypto Framework modules.
- For any existing projects using the Crypto HAL API without the respective Framework API, Big Endian data may have been used and in that case, it needs to be converted to little Endian to use framework API or continue to use the existing HAL API directly.
- If using the HAL APIs directly, user needs to make sure that the data cast as (uint32_t) matches the endianness of the HAL module used.

Alignment for data buffers

- All data buffers allocated to be passed in as input buffers must be aligned on WORD boundary.***Blocking calls***
- *All Crypto Framework APIs are blocking calls.*

SF CRYPTO Framework Services

- The SF CRYPTO Framework modules include:
  - SF_CRYPTO for HW initialization and resource synchronization between the crypto modules.
  - SF_CRYPTO_TRNG for true random number generation.
  - SF_CRYPTO_HASH for message digest generation. Provides the ability to process data in chunks before finalizing the hash operation.
  - SF_CRYPTO_KEY for RSA, AES. Provides the option to generate wrapped keys in addition to plain text keys. Only the wrapped key support is present for ECC.
  - SF_CRYPTO_KEY_INSTALLATION provides key installation services for RSA, AES and ECC keys.
  - SF_CRYPTO_CIPHER provides encryption and decryption services for AES and RSA keys.
  - SF_CRYPTO_SIGNATURE provides RSA signature generation and verification services.

VersionGet API

- This API can be called at any time, i.e even before a module is opened.

SF CRYPTO Framework Module Overview Description

The SF CRYPTO Framework provides high-level APIs and is implemented on sf_crypto. The SF CRYPTO Framework provides a foundation for the Framework Crypto services through the Secure Cryptographic Engine (SCE) HAL module.

SF CRYPTO Framework Module Features

- The SF CRYPTO Framework opens/ initializes the underlying HW Secure Crypto Engine.

- Provides services for access to shared resources for other Crypto Framework modules SF_CRYPTO_TRNG, SF_CRYPTO_HASH, SF_CRYPTO_KEY, SF_CRYPTO_CIPHER, SF_CRYPTO_SIGNATURE and SF_CRYPTO_KEY_INSTALLATION.

SF CRYPTO Framework Module Operational Notes

- open API is called during initialization because the "Auto Initialization" configuration option is enabled by default.
- lock API and unlock API are for the SF_CRYPTO_XXX modules to to be used.However, if the application is making a direct call to HAL APIs, use lock API just before making the call to HAL module.Use unlock API just after returning from the call to HAL module.
- statusGet API requires the control block/p_ctrl as input parameter. Hence it should be called only after the open API of SF_CRYPTO module is called.

Configuration Settings for the SF CRYPTO Framework Module

Configuration parameter	Description
uint32_t wait_option	Wait option for RTOS service calls Defines how the service behaves if there is not enough memory available. The wait options are defined as follows: TX_NO_WAIT (0x00000000) T X_WAIT_FOREVER (0xFFFFFFFF) timeout value (0x00000001 through 0xFFFFFFFE) Selecting TX_NO_WAIT results in an immediate return from this service regardless of whether or not it was successful. This is the only valid option if the service is called from initialization. Selecting TX_WAIT_FOREVER causes the calling thread to suspend indefinitely until enough memory is available. Selecting a numeric value (1-0xFFFFFFFE) specifies the maximum number of timer-ticks to stay suspended while waiting for the memory. Default set through ISDE is TX_WAIT_FOREVER.

Configuration parameter	Description
crypto_instance_t * p_lower_lvl_crypto	Pointer to a low-level Crypto engine HAL driver instance. Configured by Synergy Configurator.
void const * p_extend	Extension parameter for hardware specific settings. Configured by Synergy Configurator.
void const * p_context	Placeholder for user data. For future expansion.
void * p_memory_pool	Byte pool address. Configured by Synergy Configurator.

Configuration parameter	Description
uint32_t memory_pool_size	Byte pool size. Default set by ISDE is 128 bytes. Caller to allocate pool based on the number of SF_CRYPTO_XXX module instances created. Recommended sizes: **In addition to the default byte pool**: NOTE: An additional 12 bytes per instance is needed for RTOS housekeeping. 24 + 12 bytes per instance of SF_CRYPTO_KEY module if RSA Key is required. 264 +12bytes per instance of SF_CRYPTO_KEY module if AES Key is required. SF_CRYPTO_KEY module if AES Key is required. 112 +12 bytes per instance of SF_CRYPTO_HASH module. 1200 bytes per instance of SF_CRYPTO_CIPHER module for RSA algorithm is required. 600 bytes per instance of SF_CRYPTO_CIPHER module for AES algorithm is required. 1450 bytes per instance of SF_CRYPTO_SIGNATURE module.

Configuration parameter	Description
sf_crypto_close_option_t close_option	Close option Selects how the SCE module can be closed. SF_CRYPTO_CLOSE_OPTION_DEFAULT - Close the module only if none of the other SF_CRYPTO_XXX modules are opened. NOTE: This is the default setting. SF_CRYPTO_CLOSE_OPTION_FORCE_CLOSE - Close the module regardless of SF_CRYPTO_XXX modules status. **Note: With either option, It is the responsibility of the caller to ensure that the SF CRYPTO module is not closed when any of the other Crypto Framework modules are open.**

SF CRYPTO Framework Module Limitations

It is the responsibility of the caller to ensure that the SF CRYPTO module is not closed when any of the other Crypto Framework modules are open.

SF CRYPTO TRNG Framework Module Overview Description

The SF CRYPTO TRNG Framework provides high-level APIs and is implemented on sf_crypto_trng. The SF CRYPTO TRNG Framework provides True Random Number Generation services through the Secure Cryptographic Engine (SCE) HAL module.

SF CRYPTO TRNG Framework Module Features

- The SF CRYPTO TRNG Framework module uses the TRNG HAL interfaces to the underlying Secure Crypto Engine.
- Access to shared resources through SF CRYPTO Framework module.

Configuration Settings for the SF SRYPTO TRNG Framework Module

Configuration parameter	Description
sf_crypto_instance_t * p_lower_lvl_common;	Pointer to a low-level Crypto engine HAL driver instance. Configured by Synergy Configurator.
trng_instance_t * p_lower_lvl_instance;	Pointer to a TRNG HAL driver instance. Configured by Synergy Configurator.
void * p_extend;	Extension parameter for hardware specific settings. For future use.

The configuration is set through the ISDE for TRNG HAL driver.

Configuration parameter	Description
uint32_t num_attempts	Number of attempts within which a true random number is to be generated. Set to 2 by default.

SF CRYPTO HASH Framework Module Overview Description

The SF CRYPTO HASH Framework provides high-level APIs and is implemented on sf_crypto_hash. The SF CRYPTO HASH Framework provides hash/message digest services through the Secure Cryptographic Engine (SCE) HAL module.

The hash functions supported are MD5, SHA-1, SHA-224 and SHA-256.

From FIPS Secure Hash Standard:

All of the algorithms are iterative, one-way hash functions that can process a message to produce a condensed representation called a _message digest*. These algorithms enable the determination of a message's integrity: any change to the message will, with a very high probability, result in a different message digest. This property is useful in the generation and verification of digital signatures and message authentication codes, and in the generation of random numbers or bits.

For the supported hash functions, the message size should be $< 2^{64}$ bits.

The message digest sizes are as follows:

MD5 : 16 bytes

SHA-1 : 20 bytes

SHA-224: 28 bytes

SHA-256: 32 bytes

SF CRYPTO HASH Framework Module Features

- The SF CRYPTO HASH Framework utilizes the underlying Secure Crypto Engine to provide HASH services.
- This module provides enhancements over the HAL driver such as:
  - Initializing the HASH value
  - Processing chunks of data through hashUpdate API before finalizing the hash operation.
  - Formatting the final block for the final HASH operation.

SF CRYPTO HASH Framework Module Operational Notes

Configuration Settings for the SF CRYPTO HASH Framework Module

Configuration parameter	Description
sf_crypto_hash_type_t hash_type;	HASH algorithm type. Select MD5, SHA1, SHA 224 or SHA256. Please refer to the header file for the the definitions.
crypto_instance_t * p_lower_lvl_crypto	Pointer to a low-level Crypto engine HAL driver instance. Configured by Synergy Configurator.
hash_instance_t * p_lower_lvl_instance;	pointer to HASH lower-level module instance. Configured by ISDE.
void * p_extend	Extension parameter for hardware specific settings.Optional. Configured by Synergy Configurator.

SF CRYPTO KEY Framework Module Features

The following key types can be generated using the sevices of the SF CRYPTO KEY module.

- RSA 2048-bit, 1024-bit plain text/raw keys.
- RSA 2048-bit, 1024-bit standard format wrapped private keys(public keys in plain).
- AES 128-bit, 192-bit and 256-bit wrapped keys for ECB, CBC, CTR and GCM chaining modes.
- AES 128-bit and 256-bit wrapped keys for XTS chaining mode.
- ECC 192-bit, 256-bit wrapped keys.

SF CRYPTO KEY Framework Module Operational Notes

The format of RSA plain text keys generated by the keyGenerate API is as follows:

RSA Public Key

Byte 0 to Byte 3 : Public key exponent

Byte 4 : Start of RSA modulus

(128 bytes for RSA 1024-bit and 256 bytes for RSA 2048-bit keys)

RSA Private Key in standard format

Byte 0 : Private key exponent (128 bytes for RSA 1024-bit and 256 bytes for RSA 2048-bit keys)

Followed by RSA modulus. (128 bytes for RSA 1024-bit and 256 bytes for RSA 2048-bit keys)

RSA Private key in CRT format

The components are ordered in the following order with exponent2 at byte 0:

exponent2 // the second factor's CRT exponent, a positive integer

prime2 // the second factor, a positive integer

exponent1 // the first factor's CRT exponent, a positive integer

prime1 // the first factor, a positive integer

coefficient // the (first) CRT coefficient, a positive integer

Configuration Settings for the SF SRYPTO KEY Framework Module

Configuration parameter	Description
sf_crypto_key_type_t key_type	Key type to be generated. Plain text or Wrapped keys. Please refer to the header file for the the definitions.
sf_crypto_key_size_t key_size	Key size to be generated. Please refer to the header file for the the definitions.
sf_crypto_data_handle_t domain_params;	Pointer to domain parameters for the requested key type. Structure contains, pointer to the data (contains the domain data) and data length. Structure contains the domain data in the order a, b, p, n for ECC as defined in FIPS186-3 and data length. To be set to NULL for RSA and AES Key types.

Configuration parameter	Description
sf_crypto_data_handle_t generator_point	Pointer to the generator base point of curve in the order Gx, Gy for ECC (where Gx and Gy are x and y coordinates respectively) and data length. To be set to NULL for RSA and AES key types.
sf_crypto_instance_t * p_lower_lvl_crypto_common	Pointer to a Crypto Framework common instance. Configured by Synergy Configurator.
void const * p_extend	Extension parameter for hardware specific settings (Reserved for future use). Configured by Synergy Configurator.

SF CRYPTO KEY Framework Module Limitations

1) For ECC only the wrapped keys are supported at present.

SF Crypto Signature Framework Module Overview Description

The SF CRYPTO Signature Framework provides high-level APIs and is implemented on sf_crypto_signature. This module is in the SSP framework layer that interfaces with Synergy HAL drivers for the hardware level cryptography operations. The module functions specified herein are used to sign/verify message that is provided as input.

SF Crypto Signature Module Features

- This module currently supports signature generation and signature-verification for RSA algorithm. There is support for both 1024-bits and 2048-bits key lengths for standard format plain-text, standard format wrapped private key and CRT plain-text keys.
- RSASSA-PKCS1 v1.5 is the supported signature scheme. The input message can be passed as raw message to be signed/verified or can be PKCS1 v1.5 encoded and padded before sign/verify.
- SHA1, SHA224, SHA256 are the supported hashing algorithms for PKCS1 v1.5 encoding /padding schemes.
- This module allows signature generation/verification on data which is smaller than a block size.
- If all of the data is not available at once, update APIs can be used to accumulate the incoming chunks of data and finally sign/verify the message only when all the message is gathered.
- Module allows to switching between sign and verify operations with less expensive API calls which are not involved in allocating and deallocating memory.

Configuration parameter	Description
sf_crypto_key_type_t key_type;	Type of Key RSA plain text or wrapped. Please refer to the header file for the the definitions.
sf_crypto_key_size_t key_size	Size of Key RSA 1024-bit /2048-bit key. Please refer to the header file for the the definitions.
sf_crypto_hash_instance_t * p_lower_lvl_sf_crypto_hash	Pointer to the Crypto Hash framework module instance structure. Configured by Synergy Configurator.
sf_crypto_instance_t * p_lower_lvl_crypto_common	pointer to Crypto Common module instance. Configured by Synergy Configurator.
void const * p_extend	Extension parameter for hardware specific settings.Optional. Configured by Synergy Configurator.

Configuration Settings for the SF CRYPTO Signature Framework Module

1) Operation modes for Signature Framework Module:
   a) SF_CRYPTO_SIGNATURE_MODE_SIGN
   b) SF_CRYPTO_SIGNATURE_MODE_VERIFY
2) Input Message Format to the Signature Framework APIs to perform sign or verify operation:
   a) SF_CRYPTO_SIGNATURE_MESSAGE_OPERATION_NONE
   b) SF_CRYPTO_SIGNATURE_MESSAGE_OPERATION_RSA_SHA1_PKCS1_1_5
   c) SF_CRYPTO_SIGNATURE_MESSAGE_OPERATION_RSA_SHA224_PKCS1_1_5
   d) SF_CRYPTO_SIGNATURE_MESSAGE_OPERATION_RSA_SHA256_PKCS1_1_5

SF Crypto Cipher Framework Module Overview Description

The SF CRYPTO Cipher Framework provides high-level APIs and is implemented on sf_crypto_cipher. This module is in the SSP framework layer and provides encryption and decryption services through the Secure Cryptographic Engine (SCE) HAL module.

SF Crypto Cipher Module Features

- This module currently supports encryption and decryption for AES and RSA algorithms.
- This module allows encryption/ decryption of data when available in chunks through the cipherUpdate()API and final() when the last chunk /all the data is gathered.
- Once the module is opened for a specific key type and key size, the encrypt and decrypt modes can be switched by calling the cipherInit() API.

AES algorithm support:

- AES 128-bit, 192-bit and 256-bit plain text and wrapped keys for the following chaining modes:
  - ECB (Electronic Code Book)
  - CBC (Cipher Block Chaining)
  - CTR (Counter Mode)
  - GCM (Galois Counter Mode)
- AES 128-bit and 256-bit plain text and wrapped keys for XTS (XEX-based tweaked code-book mode with ciphertext stealing) are supported.
- IV provided for AES GCM operations can be either 96-bits or a 96-bit IV formatted to 128-bits.
  - Example:
  - **96-bit IV: 94c1935afc061cbf254b936f**
  - **96-bit IV formatted to 128-bits: 94c1935afc061cbf254b936f00000001**
- PKCS#7 padding scheme is supported for ECB and CBC modes. This scheme can be used when the data is
- No padding option is supported for all modes where the data is exactly a multiple of the AES block size.
  - For GCM, no padding option is to be selected even when the data is not a multiple of the block size.

RSA algorithm support:

- RSA 1024-bit and 2048-bit plain-text standard format, plain-text CRT format and standard format wrapped keys are supported.
- RSA encrypt operation requires RSA public key and RSA decrypt operation requires RSA private key.

RSAES-PKCS1-v1_5 (RSA Encryption Scheme)

RSA-PKCS1 v1.5 encoding /padding scheme is supported.

- The input raw message is encoded and formatted to be encrypted. It requires that the message be less than k-11 where k is the length of the modulus of the selected key.

No padding option should be selected when an encoded and formatted block (exactly the size as the modulus of the selected key) needs to be encrypted/decrypted.

Configuration settings for SF Crypto Cipher Framework Module

Configuration parameter	Description
sf_crypto_key_type_t key_type	Key type for cipher operation: AES or RSA plain text or wrapped. Please refer to the header file for the the definitions.
sf_crypto_key_size_t key_size	Key size for cipher operation: AES 128-bit/192-bit/256-bit key or RSA 1024-bit /2048-bit key. Please refer to the header file for the the definitions.
sf_crypto_cipher_mode_t cipher_chaining_mode	Applicable only to AES algorithm: ECB, CBC, CTR, XTS or GCM chaining modes Set to ECB for RSA. Please refer to the header file for the the definitions.
sf_crypto_instance_t * p_lower_lvl_crypto_common	Pointer to Crypto Framework Common module instance. Configured by Synergy Configurator.
sf_crypto_trng_instance_t * p_lower_lvl_crypto_trng	Pointer to Crypto Framework TRNG module instance. Configured by Synergy Configurator.
void const * p_extend	Extension parameter for hardware specific settings.Optional. Configured by Synergy Configurator.

SF CRYPTO Cipher Framework Module Limitations

AES XTS mode only supports lengths which are a multiple of 32-bits/4 bytes.

SF CRYPTO KEY INSTALLATION Framework Module Overview Description

The SF CRYPTO KEY INSTALLATION Framework provides high-level APIs and is implemented on sf_crypto_key_installation. The SF CRYPTO KEY INSTALLATION Framework Key Installation services through the Secure Cryptographic Engine (SCE) HAL module.

NOTE:

1) The API returns the wrapped key to user and does not store the key for future use.It is the responsibility of the application to store the wrapped key in non-volatile memory for future use.
2) This Framework module provides the same level of service as the Crypto HAL module without any enhancements. It is provided for thread safe operation and for completeness of Crypto support in the Framework layer.

SF CRYPTO KEY INSTALLATION Framework Module Features

- The SF CRYPTO KEY INSTALLATION Framework module uses the KEY INSTALLATION HAL interfaces to the underlying Secure Crypto Engine.
- Access to shared resources through SF CRYPTO Framework module.
- This module supports key installation for the following keys:
  - RSA:
  - **1024-bit and 2048-bit plain text keys.**
  - AES:
  - **128-bit, 192-bit and 256-bit plain text keys for ECB, CBC, CTR and GCM chaining modes.**
  - **128-bit and 256-bit plain text keys for XTS chaining mode.**
  - ECC:
  - **192-bit and 256-bit plain text keys.**
- The user and install keys must be provided to the key installation API in the specified format.
- Upon installation the key installation service returns a wrapped key to the caller for any future usage of installed key on that device.

Configuration Settings for the SF SRYPTO KEY INSTALLATION Framework Module

Configuration parameter	Description
sf_crypto_key_type_t key_type;	Type of key to be installed. The prepared key will be of the encrypted type. Please refer to the header file for the the definitions.
sf_crypto_key_size_t key_size;	Size of key to be installed. Please refer to the header file for the the definitions.

Configuration parameter	Description
sf_crypto_instance_t * p_lower_lvl_common;	Pointer to a Crypto Framework common instance. Configured by Synergy Configurator.
key_installation_instance_t * p_lower_lvl_instance;	Pointer to Crypto Key Install HAL instance Configured by Synergy Configurator.
void const * p_extend;	Extension parameter for hardware specific settings. For future use.

Crypto Framework Module Important Operational Notes and Limitations

- The lock API and unlock API are for use with the SF_CRYPTO_XXX modules. However, if the application is making a direct call to HAL APIs which are not yet supported in the Framework layer, use the lock API just before making the call to HAL module. Use the unlock API just after returning from the call to HAL module.
- The statusGet API requires the control block/p_ctrl as an input parameter. Hence it should be called only after the open API of SF_CRYPTO module is called.
- All Crypto Framework APIs are blocking calls.
- Refer to the current SSP Release notes for limitations on this module.

4.1.16.4 Including the Crypto Framework Module in an Application

This section describes how to include the Crypto Framework Module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP based applications.

To add the Crypto Framework Module to an application, simply add it to a thread using the sacks selection sequence given in the following table. (The default name for the Crypto Framework Module is g_sf_crypt0 as shown in the following table. This name can be changed in the associated Properties window.)

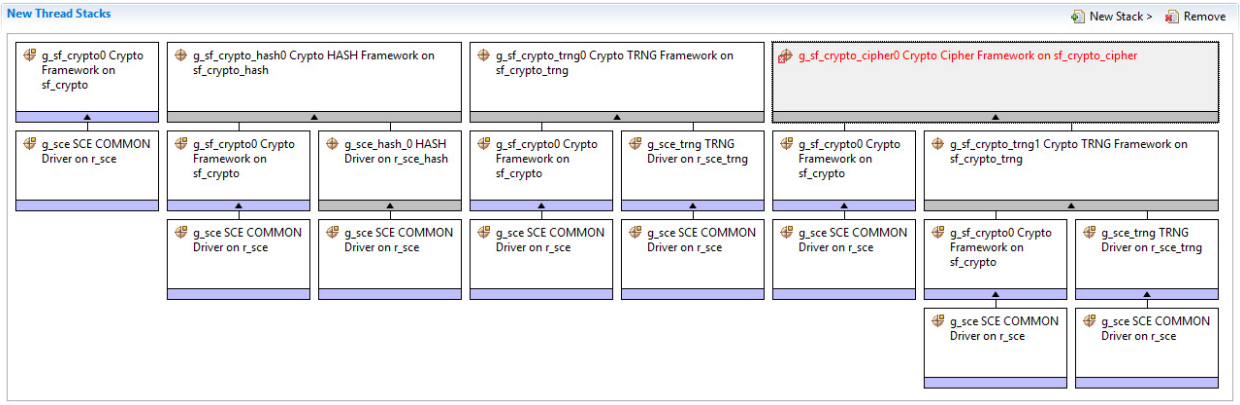
Crypto Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_crypt0 Crypto Framework on sf_crypto	Threads	New Stack> Framework> Crypto > Crypto Framework on sf_crypto

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_crypt_key0 Crypto Key Framework on sf_crypto_key	Threads	New Stack> Framework> Crypto > Crypto Key Framework on sf_crypto_key
g_sf_crypt0 Crypto TRNG Framework on sf_crypto_trng	Threads	New Stack> Framework> Crypto > Crypto TRNG Framework
g_sf_crypt0 Crypto HASH Framework on sf_crypto_hash	Threads	New Stack> Framework> Crypto > Crypto HASH Framework
g_sf_crypt_key0 Crypto Key Installation Framework on sf_crypto_key_installation	Threads	New Stack> Framework> Crypto > Crypto Key Installation Framework on sf_crypto_key_installation
g_sf_crypt0 Crypto cipher Framework on sf_crypto_cipher	Threads	New Stack> Framework> Crypto > Crypto cipher Framework
g_sf_crypt0 Crypto signature Framework on sf_crypto_signature	Threads	New Stack> Framework> Crypto > Crypto signature Framework

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

When the Crypto Framework Module is added to the Thread Stack, as shown in the figure below, the configurator automatically adds the needed lower level drivers. Any drivers that need additional configuration information will be box text highlighted in red. Modules with a gray band are individual modules that stand alone. Modules with a blue band are shared or common and need only be added once, since they can be used by multiple stacks. Modules with a pink band can require the selection of lower level drivers. Sometimes these are optional or recommended and this is indicated in the block with the inclusion of this text. If the addition of lower level drivers is required, the module description will include "Add" in the text. Clicking on any pink banded modules will bring up the "New" icon and then will show the possible choices.



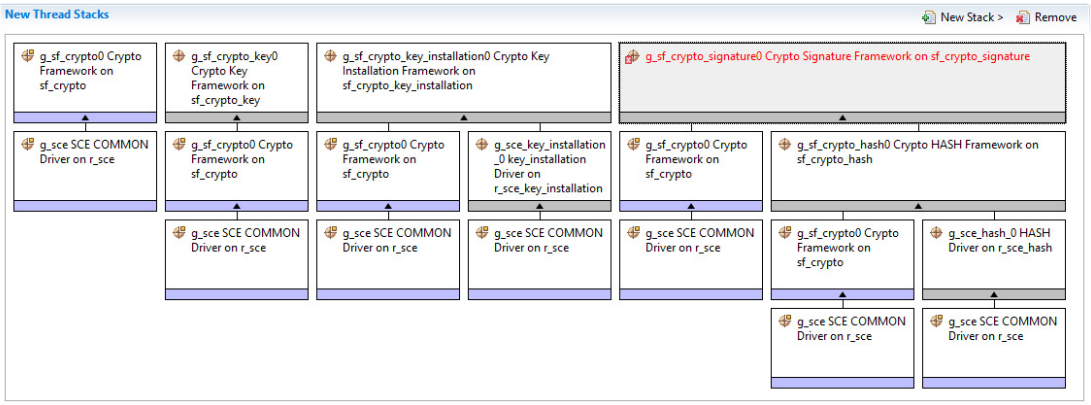


Figure 174: Crypto Framework Modules Stack- Crypto, Hash, Key and TRNG

4.1.16.5 Configuring the Crypto Framework Module

The Crypto Framework Module has configurable properties used to define operation parameters.

NOTE: You may want to open your ISDE and create the Crypto Framework Module and explore the property settings in parallel with looking over the Configuration Table Settings given below. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the SF CRYPTO Framework Module

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_sf_crypto0	Module name.
Wait time	TX_WAIT_FOREVER	Value must be a non-negative integer.
Byte Pool Size	128	Byte pool size selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

ISDE Property	Value	Description
Force Closure Support	Default, Force Close Default: Default	Force closure support selection.

Configuration Settings for the SF SRYPTO HASH Framework Module

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Instance Name	g_sf_crypto_hash0	Module name.
Name of generated initialization function	sf_crypto_hash_init0	Name of generated initialization function
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Configuration Settings for the SF CRYPTO KEY Framework Module

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_sf_crypto_key0	Module name.
Key type (For AES, Byte Pool size in sf_crypto mst be > = 280 bytes)	RSA Plain text, RSA CRT Plain text, RSA Wrapped, AES Wrapped, ECC Plain text, ECC Wrapped Default: RSA Plain text	Key type selection.

ISDE Property	Value	Description
Key size	RSA 1024-bits, RSA 2048-bits, AES 128-bits, AES XTS 128-bits, AES 192-bits, AES 256-bits, AES XTS 256-bits, ECC 192-bits, ECC 256-bits Default: RSA 2048-bits	Key size selection.
Name of generated initialization function	sf_crypto_key_init0	Name of generated initialization function
Name of Domain Parameter (Applicable only for ECC)	sf_crypto_key_domain_params0	Name of domain parameter
Name of Generator Point (Applicable only for ECC)	sf_crypto_key_generator_point0	Name of generator point
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Configuration Settings for the SF CRYPTO KEY INSTALLATION Framework Module

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_sf_crypto_key_installation0	Module name.
Key type	Encrypted RSA Key, Encrypted AES Key, Encrypted ECC Key Default: Encrypted RSA Key	Key type selection.
Key size	RSA 1024-bits, RSA 2048-bits, AES 128-bits, AES XTS 128-bits, AES 192-bits, AES 256-bits, AES XTS 256-bits, ECC 192-bits, ECC 256-bits Default: RSA 2048-bits	Key size selection.

ISDE Property	Value	Description
Name of generated initialization function	sf_crypto_key_installation_init0	Name of generated initialization function.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Configuration Settings for the SF CRYPTO TRNG Framework Module

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_sf_crypto_trng0	Module name.
Name of generated initialization function	sf_crypt_trng_init0	Name of generated initalization function
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Configuration Settings for the SF CRYPTO Cipher Framework Module

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_sf_crypto_cipher0	Module name.
Key type	RSA Plain text, RSA CRT Plain text, RSA Wrapped, AES Wrapped Default: RSA Plain text	Key type selection.

ISDE Property	Value	Description
Key size	RSA 1024-bits, RSA 2048-bits, AES 128-bits, AES XTS 128-bits, AES 192-bits, AES 256-bits, AES XTS 256-bits Default: RSA 2048-bits	Key size selection.
Cipher chaining mode	ECB, CBC, CTR, GCM, XTS Default: ECB	Cipher chaining mode selection.
Name of generated initialization function	sf_crypto_cipher_init0	Name of generated initialization function.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Configuration Settings for the SF CRYPTO Signature Framework Module

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_sf_crypto_signature0	Module name.
Key type (Byte Pool size in sf_crypto must be > = 1450 bytes)	RSA Plain text, RSA CRT Plain text, RSA Wrapped Default: RSA Plain text	Key type selection.
Key size	RSA 1024-bits, RSA 2048-bits Default: RSA 2048-bits	Key size selection.
Name of generated initialization function	sf_crypto_signature_init0	Name of generated initialization function.

ISDE Property	Value	Description
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Configuration Settings for the R_SCE Common Module

ISDE Property	Value	Description
Name	g_sce	Module name
Endian flag	CRYPTO_WORD_ENDIAN_LITTLE	Endian flag selection (locked)

Crypto Framework Module Clock Configuration

The CRYPTO Framework module uses the same clock as the SCE.

Crypto Framework Module Pin Configuration

The CRYPTO Framework module doesn't use any external pins.

4.1.16.6 Using the Crypto Framework Module in an Application

To use the SF CRYPTO module:

- Ensure that the configuration parameters are set as per the needs of the application.
- Use the open API to Initialize the SF_CRYPTO and the SCE HAL module (R_SCE) through the SCE common driver. This is done by Synergy Configurator when the Auto Initialize setting is at default.
- The little endian mode is set by default. It is locked and not configurable.
- The open function cannot be called again until the module is closed.Use the close API to close the Crypto Framework services and the HW SCE.

Using the SF CRYPTO TRNG Framework Module in an Application

The typical steps in using the SF CRYPTO TRNG Framework module in an application are:

1) Use the open API to Initialize the SF_CRYPTO_TRNG and the SCE TRNG HAL module (R_SCE_TRNG). This is done by ISDE when the Auto Initialize setting is at default.

   - NOTE: The little endian mode is set by default. It is locked and not configurable. (Please refer to note on endianness and data format in the Module Operational Notes.)

   - NOTE: The open function cannot be called again until the module is closed.

2) Use the randomNumberGenerate API to generate random numbers. The minimum length of random number bytes that can be requested is 1.
3) Use the close API to close the Crypto Framework services and the SCE when the TRNG services are no longer required.

NOTE: In the rare event that the RandomNumberGenerate API returns an error, all the CRYPTO Framework modules must be closed and the SF CRYPTO module re-opened.

NOTE: There will be only one instance of the HAL TRNG driver. Hence the configuration parameter set of each SF CRYPTO TRNG instance will be overwriting the one configured previously. The last value configured is applicable to all instances.

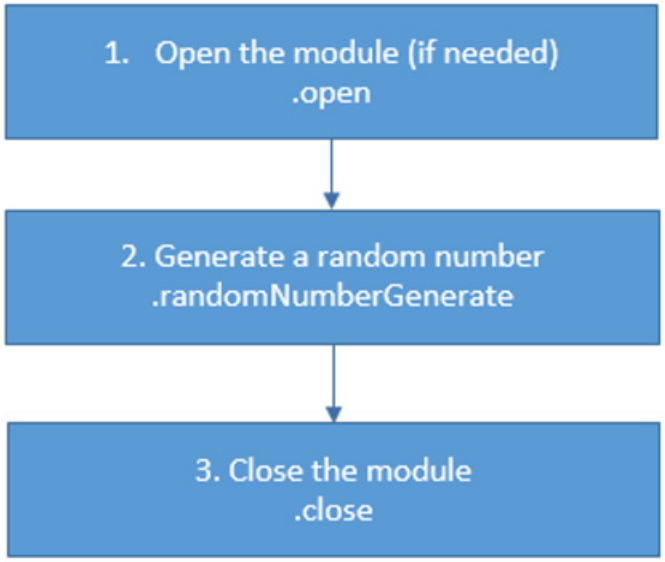

Figure 175: Crypto TRNG Framework Typical

Additional descriptions of some other Crypto functions are given in the following sections. No flow diagrams are provided however in the interest of brevity.

Using the SF CRYPTO HASH Framework Module in an Application

The typical steps in using the SF CRYPTO HASH Framework module in an application are:

Calling the APIs in this order: open->hashInit->hashUpdate->hashFinal->close.

Details:

- Add SF_CRYPTO HASH Framework module in the Synergy Configurator. The HASH algorithm for this instance is set to SHA 256 by default.

- The little endian mode is set by default. It is locked and not configurable. (Please refer to note on endianness and data format in the Module Operational Notes.)
- The SF CRYPTO Module has to be first opened.
  - Synergy Configurator will do this provided the Auto start option set by default is retained.
- Set the chosen HASH algorithm as the configuration parameter for the module open API.
- Use the open API to Initialize the SF CRYPTO HASH Framework module and the SCE HASH HAL module (R_SCE_HASH) through the SCE HASH driver.
  - Synergy Configurator will do this provided the Auto init option set by default is retained.
- The open function cannot be called again until the module is closed.
- Use the hashInit API to initialize the HASH operation for the chosen HASH algorithm.
  - The hashInit can be called after open API or hashUpdate API or hashFinal API to initialize a new operation with the configured HASH algorithm.
- Use the hashUpdate API to hash input data. It can be called multiple times till all the data is completely used up.
- Use the hashFinal API to get the message digest for all the data hashed with the hashUpdate API.
  - Once the hashFinal API is called, either the hashInit can be called to initialize operation for the next set of data using the same HASH algorithm or close API can be called to close the module. It can then be re-opened for a different HASH algorithm.
- Use close API to close the Crypto HASH Framework services.

NOTE: On a particular thread a single instance of SF CRYPTO HASH module can be re-used for different HASH algorithms without having to create multiple instances.

Using the SF CRYPTO KEY Framework Module in an Application

The typical steps in using the SF CRYPTO KEY Framework module in an application are:

Calling the APIs in this order: open->keyGenerate->close.

Details:

- Please refer to note on endianness and data format in the Module Operational Notes.
- The SF CRYPTO Module has to be first opened. ISDE will do this provided the Auto initialize option set by default is retained. Refer to the section Using the SF CRYPTO Framework Module in an Application.
- Set the configuration parameters as per the needs of the application required for the module open API.
- Use the open API to Initialize the SF CRYPTO KEY Framework module (This is done by ISDE when the Auto start option is at default setting) and the SCE HAL modules through the SCE drivers.
- The open function cannot be called again until the module is closed.
- Use the keyGenerate API to generate the cryptographic keys of the type and size set by the configuration parameters at the open call.
- Use close API to close the Crypto Key Framework Module services.

NOTE: On a particular thread a single instance of SF CRYPTO KEY module can be re-used for generating different key

types without having to create multiple instances.

Using the SF CRYPTO SIGNATURE Framework Module in an Application

The typical steps in using the SF CRYPTO Signature Framework module in an application are:

Calling the APIs in this order: open->contextInit->signUpdate->signFinal->close.

Calling the APIs in this order: open->contextInit->verifyUpdate->verifyFinal->close.

Details:

- Please refer to note on endianness and data format in the Module Operational Notes.
- The SF CRYPTO Module has to be first opened. ISDE will do this provided the Auto initialize option set by default is retained. Refer to the section Using the SF CRYPTO Framework Module in an Application.
- Set the configuration parameters as per the needs of the application required for the module open API.
- Use the open API to Open the SF CRYPTO Signature Framework module (This is done by ISDE when the Auto start option is at default setting) and the SCE HAL modules through the SCE drivers.
- The open function cannot be called again until the module is closed.
- Use the contextInit API to initialize the context by assigning appropriate operation mode, key (public key for verify operation mode and private key for sign operation mode), message formatting option.
- If the data is coming in as smaller chunks for sign operation mode, use the Update APIs - signUpdate API to accumulate the data for future signing operation or for verify operation mode use the verifyUpdate API to accumulate the data for future signatureverification.
- In order to complete the sign or verify operation call the Final APIs - signFinal or verifyFinal API respectively. These APIs support accepting last chunk of incoming data. In case all the data has been passed through one of the Update APIs the parameter for last message chunk can be set to NULL.
- In case all the data to be signer or verified is available at once, signFinal or verifyFinal API can be called directly without using any of the Update APIs.
- Use close API to close the Crypto Signature Framework Module services.

NOTE: On a particular thread a single instance of SF CRYPTO Signature module can be re-used for alternately performing sign or verify operations by appropriately setting/re-setting the operation mode and other related parameters. In order to perform sign or verify operations simultaneously two instances of SF Crypto Signature module need to be used.

Using the SF CRYPTO CIPHER Framework Module in an Application

The typical steps in using the SF CRYPTO Cipher Framework module in an application are:

Calling the APIs in this order: open->cipherInit->cipherUpdate->cipherFinal->close.

Details:

- Please refer to note on endianness and data format in the Module Operational Notes.
- The SF CRYPTO Module has to be first opened. ISDE will do this provided the Auto initialize option set by default is retained. Refer to the section Using the SF CRYPTO Framework Module in an Application.
- Set the configuration parameters for the module open API as per the needs of the application.
- Use the open API to open the SF CRYPTO Cipher Framework module (This is done by ISDE when the Auto start option is at default setting) and the SCE HAL modules through the SCE drivers.
- The open function cannot be called again until the module is closed.

- Use the ciphertInit API to initialize the context by assigning appropriate operation mode, key and padding scheme option and algorithm specific parameters.
- If the data for encrypt/decrypt operation is not available all at once but is available in chunks, use the cipherUpdate API. The cipherUpdate API can be called multiple times.

  NOTE: For RSA operations, no data is output from the cipherUpdate API. The message will only be accumulated till the cipherFinal API is called.

- In order to complete the encrypt/decrypt operation call the cipherFinal API. This API accepts last chunk of incoming data. In case all the data has been passed through the cipherUpdate APIs the length for last message chunk can be set to 0.
- In case all the data to be encrypted/decrypted is available at once, cipherFinal API can be called directly without using the cipherUpdate API.
- Use close API to close the Crypto Cipher Framework Module services.

  NOTE: AES GCM operation specifics:

- For AES GCM encrypt/decrypt operations, AAD (Additional Authenticated Data) is optional. If it is to be used, it has to be provided for the cipher operation through the cipherAadUpdate API after the cipherInit is called and prior to calling the cipherUpdate or cipherFinal APIs.
- For AES GCM encrypt operation, the tag (Authentication Tag) will be generated when cipherFinal API is executed. The caller has to supply the buffer to hold the tag through the cipherInit API.
- For AES GCM decrypt operation, the tag has to be provided prior to providing any ciphertext data through the cipherUpdate / cipherFinal APIs. Hence the caller is required to provide the the tag through the cipherInit API.
- The AES GCM decrypt operation may output plain text data through the cipherUpdate/cipherFinal APIs but it should not be consumed if the decrypt operation returns an error code. This is to ensure that the tag is verified before the data is used.

  NOTE: On a particular thread a single instance of SF CRYPTO Cipher module can be re-used for alternately performing encrypt or decrypt operations by appropriately setting/re-setting the operation mode and other related parameters or two instances of SF Crypto Cipher module can be used.

4.1.17 Capacitive Touch Framework

The Capacitive Touch Framework provides high-level APIs for Capacitive Touch applications using the ThreadX RTOS. The Capacitive Touch Framework supports the CTSU peripherals on the Synergy microcontroller hardware and is implemented on sf_touch_ctsu. This framework is designed to be used in conjunction with the configuration data

generated by the **Workbench 6** tool. This section describes how to configure the Framework CTSU Interface using the e2 studio ISDE and how to include the API functions in your application.

In the Project Configurator in the e2 studio ISDE, you can add and configure a Capacitive Touch Framework Module in the Modules pane of the Threads tab by selecting **New > Framework > Input > Cap Touch Framework on sf_touch_ctsu**. For details, see: Using e2 studio to Write an Application with the Capacitive Touch Framework

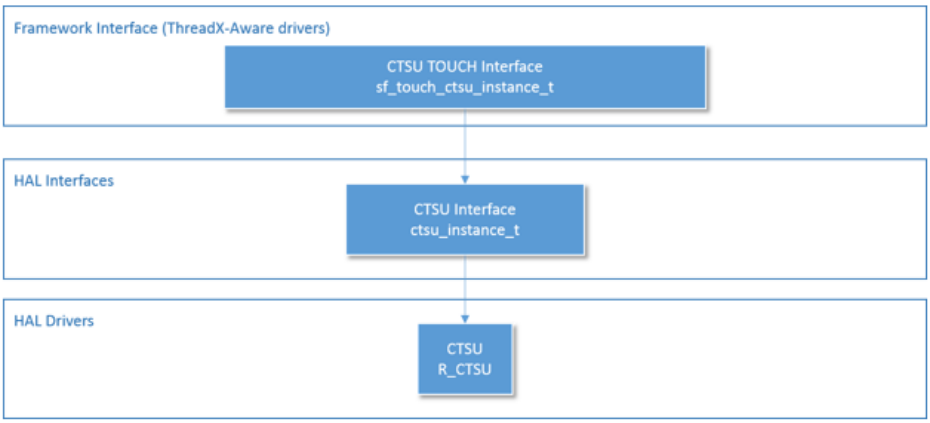

Figure 176: Capacitive Touch Framework – Block Diagram

You can find the API reference for the Framework CTSU Interface here: CTSU Framework Interface.

Also see CTSU Driver.

To understand how to program with Interfaces in the SSP, see: SSP Architecture

4.1.17.1 What Does the Capacitive Touch Framework Do?

The CTSU Framework Interface creates a private thread which drives a hardware scan of a capacitive touch panel and updates the panel at a periodic rate. The Framework Module reads the scanned results using the HAL Layer CTSU driver.

When a scan is completed, the callback registered by the application layer is invoked. If multiple upper layers are using this framework (for example: button, slider, wheel), this layer invokes the callbacks for each of those layers (if not NULL) in the order that they initialized this layer. Note that the frequency of the internal thread (update_hz) is set/modified with each subsequent open() call made to this framework.

4.1.17.2 Using e2 studio to Write an Application with the Capacitive Touch Framework

The driver is integrated into the Synergy Software Package in e2 studio: e2 studio ISDE User Guide

In e2 studio, create and configure a project and add the drivers:

1) Create the project: Creating a Project.
2) Configure the project: Configuring a Project
3) Add the drivers: Adding Drivers to a Thread and Configuring the Drivers

The following resources are required for any application using the CTSU Framework Interface:

Resource	ISDE Tab	Selection
Framework CTSU Driver	Threads	**Framework > Input > Cap Touch Framework on sf_touch_ctsu**
CTSU Interrupts	ICU	See Configuring the Interrupts for the Capacitive Touch Framework

Configuring the Clock for the Capacitive Touch Framework

The CTSU framework uses the same configuration as the CTSU HAL driver: Set the CTSU clock speed to match the the clock speed selected in the capacitive touch tuning tool **Workbench 6**.

See CTSU Driver.

Configuring the Pins for the Capacitive Touch Framework

The CTSU framework uses the same configuration as the CTSU HAL driver: Set the pins as touch sensor pins TSxx and enable the TSCAP function.

See CTSU Driver.

Configuring the Interrupts for the Capacitive Touch Framework

The CTSU framework uses the same configuration as the CTSU HAL driver: Enable the three CTSU interrupts in the ICU tab by setting them all to the same priority. Any value works.

See CTSU Driver.

Configuring the Capacitive Touch Framework Parameters

Use the e^2 studio ISDE to configure the Capacitive Touch Framework parameters: Adding Drivers to a Thread and Configuring the Drivers

The Capacitive Touch Framework is configured by passing a pointer of type sf_ctsu_cfg_t in the SF_CTSU_Open() API.

Capacitive Touch Framework configuration

ISDE Property	Configuration	Setting	Description
Name	-	Arbitrary symbol	Driver name
Lower Level Touch Driver Name	p_ctsu_instance	Name of lower level driver	-
Thread Priority	priority	ThreadX Priority:	User determined based on priority of other threads in system. Recommend high priority.

ISDE Property	Configuration	Setting	Description
Update Hz	update_hz	>10 Hz	Rate at which the CTSU hardware scans should occur
Callback	p_callback	>10 Hz	Name of user callback that will be called when each scan is complete and also when new processed data is available. Can be NULL if not used.

Configuring the CTSU HAL Driver Parameters

Use the e^2 studio ISDE to configure the HAL layer CTSU driver parameters: Adding Drivers to a Thread and Configuring the Drivers

Writing a Capacitive Touch Framework Application

1) Ensure that a folder with the data generated by **Workbench 6** exists in the ${PROJECT_ROOT}\src folder and is included in the build.
2) In the Threads tab create a new thread or add to an existing thread **Cap Touch Framework on sf_touch_ctsu**. Note the thread **Name**
3) In the same thread add a **Touch Driver on r_ctsu**.
4) Using the **Properties** tab for the Touch Driver on CTSU, note the Name** of the module and **CTSU Configuration Used**. (For more information on configuring the CTSU HAL module, refer to the usage notes for the CTSU HAL module).
5) Using the **Properties** tab for the **Cap Touch Framework on sf_touch_ctsu**, set the **Name** for this driver.
6) Ensure that the Lower Level Touch Driver Name provided is the same as the Touch Driver on CTSU Module entry.
7) Set the Thread Priority field to a high priority...e.g. 5.
8) Set the Update Hz field to 100.
9) Click Generate Project Content to generate the required structures.
10) Open **Thread_name.h** file under ssp_gen to see the generated structures that you need to use.
11) Build the Project.
12) Use SF_TOUCH_CTSU **Name.api->read** in the application thread to read the scanned data.
13) Connect the hardware, download the executable and run.
14) Add the data read from **Name.api->read** to a watch window.

Touching your Capacitive Touch Sensors now causes the binary bit mask to change according to configuration.

4.1.17.3 CTSU Framework Limitations

There are no known limitations for using this module. Also see the SSP release notes.

4.1.17.4 CTSU Framework Interface Files

During the project configuration, the ISDE extracts the files shown in the following table to the /ssp directory.

Module	Directory
CTSU Framework Interface	synergy/ssp/inc/framework/api/sf_touch_ctsu_api.h
CTSU Framework Instance	synergy/ssp/inc/framework/instances/sf_touch_ctsu.h
CTSU Framework Driver	synergy/ssp/src/framework/sf_touch_ctsu
CTSU HAL Interface	synergy/ssp/inc/driver/spi/r_ctsu_api.h
CTSU HAL Instance	synergy/ssp/inc/driver/instances/r_ctsu.h
CTSU HAL Driver	synergy/ssp/src/driver/r_ctsu

4.1.17.5 CTSU Framework Supported Devices

The driver is designed to support the following families with no changes to the API:

- S7G2
- S3A7
- S124

The CTSU Framework is designed to support any Synergy device with a CTSU peripheral and CTSU Driver with no changes to the API.

4.1.18 Capacitive Touch Button Framework

The Capacitive Touch Button Framework module provides high-level ThreadX-aware APIs for Capacitive Touch Button applications and is implemented on sf_touch_ctsu using the ThreadX RTOS. The Capacitive Touch Button Framework module uses the CTSU peripheral on the Synergy MCU. A user-defined callback can be created to respond to each button in the order in which they are present.

4.1.18.1 Capacitive Touch Button Framework Module Features

The Capacitive Touch Button Framework module is used to interpret the CTSU data for all the buttons that are present in the system. Some of the key features are:

- Works in conjunction with the Capacitive Touch Workbench for Renesas Synergy (CTW) tool which generates configuration data.

  - Supports S124, S128, S3A6, S3A7, S5D5, S5D9 and S7G2
- Provides a callback function to events.
  - Performs de-bouncing
  - Supports multiple types of events including Press, Release, and LongTouch
  - Calls the callback for each button in the order in which they are present in the button configuration table.

The Capacitive Touch Button Framework requires the Capacitive Touch framework. In most cases, all the needed configuration information is automatically added to the modules. The ISDE configuration options are described further in this document.

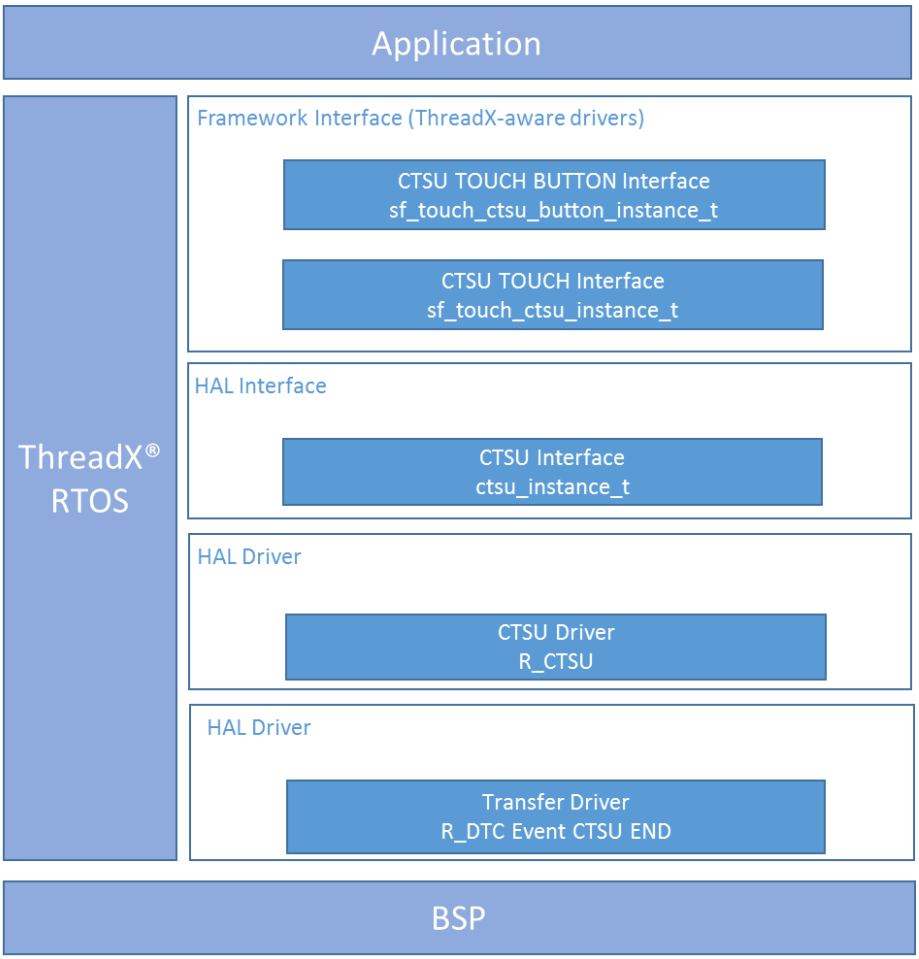

Figure 177: Capacitive Touch Button Organization, Options and Stack Implementations

4.1.18.2 Capacitive Touch Button Framework Module APIs Overview

The Capacitive Touch Button defines APIs for open, enable, disable and close. A complete list of the available APIs, an example API call, and a short description of each can be found in the table below. A table of status return values follows.

Capacitive Touch Button Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_touch_button0.p_api->open(g_sf_touch_button0.p_ctrl, g_sf_touch_button0.p_cfg); Initialize the Touch CTSU Button Framework; configures the lower level hardware and registers callback functions for all the buttons.
enable	g_sf_touch_button0.p_api->enable(g_sf_touch_button0.p_ctrl, button_id); Enable callback notification for a configured button.
disable	g_sf_touch_button0.p_api->disable(g_sf_touch_button0.p_ctrl, button_id); Disable callback notification for a configured button.
close	g_sf_touch_button0.p_api->open(g_sf_touch_button0.p_ctrl); Close the Touch CTSU Button Framework; Closes the button framework and lower layers if no other modules are using it.
versionGet	g_sf_touch_button0.p_api->versionGet(&p_version); Get version and store it in provided pointer p_version.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables review the SSP Users Manuals API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_ASSERTION	Assertion error.

Name	Description
SSP_ERR_IN_USE	The framework has already been initialized by this particular widget.
SSP_ERR_NOT_OPEN	Device not open.
SSP_ERR_INTERNAL	Internal error.

NOTE: Lower level drivers may return Common Error Codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.18.3 Capacitive Touch Button Framework Module Operational Overview

The Capacitive Touch Button Framework is used to interpret the CTSU data for all the buttons that are present in the system. It also initializes the CTSU framework layer which in turn initializes the hardware layer. The Capacitive Touch Button Framework registers a callback with the CTSU Framework layer which will be called each time processed data is available. The Capacitive Touch Button Framework then uses this processed data (binary) to perform de-bouncing and to determine which of the configured events (Press, Release, LongTouch and so forth) are valid for each button.

The Framework calls the callback for each button in the order in which they are present in the button configuration table. Unless the user stops the scan process, the scan continues to be triggered by the timer and data will be written into the user buffer, which is treated by the Framework as a circular buffer. The name and length of the buffer are specified via the ISDE configurator.

Capacitive Touch Button Framework Module Operational Notes

This framework is designed to be used in conjunction with the configuration data generated by the Capacitive Touch Workbench for Renesas Synergy tool which you can download from the Renesas Synergy Gallery in the SSP Utilities tab.

Capacitive Touch Button Framework Module Limitations

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.18.4 Including the Capacitive Touch Button Framework Module in an Application

This section describes how to include the Capacitive Touch Button in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP based applications.

To add the Capacitive Touch Button to an application, simply add it to a thread using the Stacks Selection Sequence given in the table below. (The default name for the Capacitive Touch Button is g_sf_touch_button0. This name can be changed in the associated **Properties** window.)

Capacitive Touch Button Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_touch_button0 Capacitive Touch Button Framework on sf_touch_ctsu_button	**Threads**	**New Stack > Framework > Input > Capacitive Touch Button Framework on sf_touch_ctsu_button**

When the Capacitive Touch Button Framework module on sf_touch_ctsu_button is added to the thread stack as shown in the figure below, the configurator automatically adds any needed lower level modules. Any drivers that need additional configuration information will have box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower level drivers. These are either optional or recommended (this is indicated in the block with the inclusion of this text.) If the addition of lower level drivers is required, the module description will include "Add" in the text. Clicking on any Pink banded modules will bring up the "New" icon and then display the possible choices.

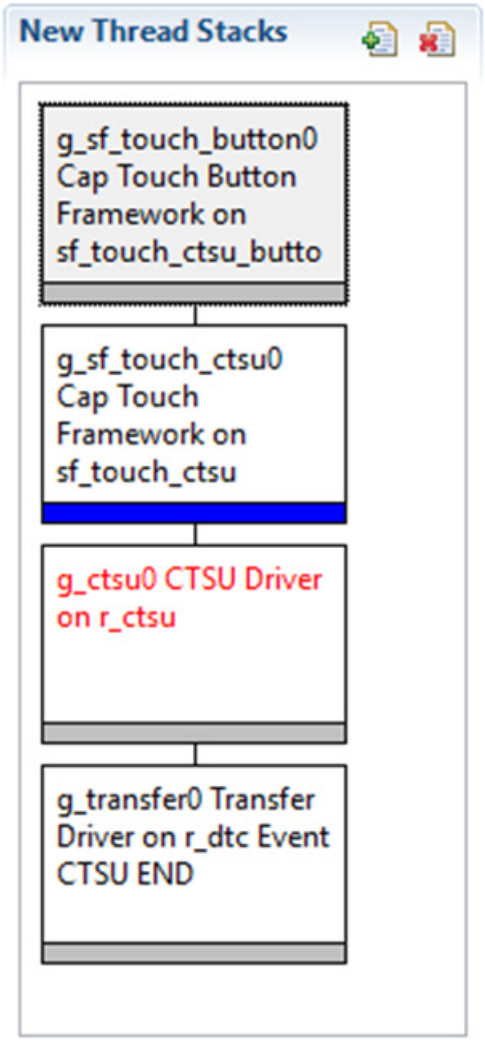

Figure 178: Capacitive Touch Button Framework Module Stack

4.1.18.5 Configuring the Capacitive Touch Button Framework Module

The Capacitive Touch Button module must be configured by you for the desired operation. The SSP configuration window will automatically identify, by highlighting the block in red, any required configuration selections, such as Interrupts or operating modes, which must be configured for lower level modules, for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the **Properties** tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority. This configuration setting is available with the properties window of the associated module. Simply select the indicated module and then view the properties window. The Interrupt settings are often toward the bottom of the properties list, so scroll down until they

become available. Also note that the Interrupt priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the below configuration properties tables, but is easily visible with the ISDE when configuring Interrupt Priority levels.

NOTE: You may want to open your ISDE and create the module and explore the property settings in parallel with looking over the Configuration Table Settings given below. This will help orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Capacitive Touch Button Framework on sf_touch_ctsu_button

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Controls whether to include code for API parameter checking
Number of Buttons	1	Number of buttons configured in CTW
Short hold debounce multiplier	1	Specify the multiplier for a button short-hold event
Long hold debouce multiplier	5	Specify the multiplier for a button long-hold event
Stuck in debounce multiplier	10	Multiplier used in debounce function
Multi touch enable	Enabled, Disabled Default: Disabled	Enables or disables multi-touch detection
Enable stuck at condition detection	Enabled, Disabled Default: Disabled	Specify the multiplier for a button stuck-at event
Name	g_sf_touch_button0	Module name
Button Configuration Structure Name	touch_buttons	Name of button configuration structure generated by CTW
Callback	g_button_framework_user_callback	Name of callback function created by user application

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower level modules can be desirable. The configurable properties for the lower level stack modules are given in the below sections for completeness and as a reference.

NOTE: Most of the property settings for lower level modules are fairly intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the Capacitive Touch Button Framework Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers and these are indicated via the red text in the Thread Stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The table below identifies all the settings within the properties section for the module.

Configuration Settings for the Capacitive Touch Framework on sf_touch_ctsu

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter error checking.
Name	g_sf_touch_ctsu0	Module name.
Thread Priority	3	User determined based on priority of other threads in system. Recommend high priority.

ISDE Property	Value	Description
Update Hz	50	Rate at which the CTSU hardware scans should occur. The maximum scan rate should be less than the tick rate set for ThreadX. The total time to complete a hardware scan is determined by the number of channels used. Each channel takes approximately 600 usec to complete a scan. Thus if 10 channels are used for 10 buttons in self-capacitance mode, the total hardware scan time is ~6 milliseconds or 166 Hz. Similarly, if 7 channels are used for 5 buttons in mutual-capacitance mode (5x2 layout), the total hardware scan time is ~4.2 milliseconds or 250 Hz.The software processing time is additional and will vary depending on the core clock and the software filter depth used by the CTSU. Thus the maximum scan rate should be lesser than the time required to scan and process all the channels used in the configuration and lesser than the RTOS tick rate.
Callback	NULL	Name of user callback that will be called when each scan is complete and also when new processed data is available. Can be NULL if not used.

Configuration Settings for the CTSU HAL Module on r_ctsu

ISDE Property	Value	Description
Parameter Checking Enable	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Offset Adjustment	Enabled, Disabled Default: Enabled	Used to enable or disable offset adjustment. Leave as enabled unless you are tuning the board. (Rate is determined by *Runtime rate of tuning of sensor values*.)

ISDE Property	Value	Description
Drift Compensation	Enabled, Disabled Default: Enabled	Used to enable or disable drift compensation. Leave as enabled unless you are tuning the board. Drift compensation allows the baseline values used to determine the presence or absence of a touch to change over time as the board or surface ages or with changes in temperature and environment. Drift compensation rate is determined by *Steady state drift compensation rate*, *Startup drift compensation rate*, and *Channel release compensation rate*.
Drift Compensation Method (valid only if Drift Compensation is enabled above)	Alternate Method 1	Drift Compensation algorithms provided. Only Alternate 1 is currently supported. Other options may be supported in future releases. Drift compensation method Alternate 1 allows for different rates of drift compensation for the following events: steady state, startup, and channel release.
Steady state drift compensation rate, drift compensation will be applied per n scans	500	Determines the rate of drift compensation (applied every n scans) when the channel is in steady state. (Dependent on the scan rate.)
Startup drift compensation rate (Should be less than the steady state drift compensation)	5	Determines the rate of drift compensation (applied every n scans) when the driver is performing its initialization. (Should be less than the *Steady state drift compensation rate*.)
Channel release compensation rate (Should be less than the steady state drift compensation rate)	500	Determines the rate of drift compensation (applied every n scans) when a channel transitions from pressed to released. (Should be less than or equal to the *Steady state drift compensation rate*.)

ISDE Property	Value	Description
Default filter depth (used in sensor count filter provided by driver)	1	Used in the software sensor count filter provided by driver. This default filter is a modification of the relatively common "leaky integrator" software filter. A depth of 4 equates to an approximate filter constant of 16. When the input is a constant value of 16 or greater, the filter output will reach 68-69 % of the constant input value after 16 cycles/iterations of the filter.
Runtime rate of tuning of sensor values (if drift compensation is used this value is overridden to be twice the rate of the steady state drift compensation)	800	Rate of offset adjustment. (If drift compensation is used this value is set to twice the rate of the steady state drift compensation.)
Perform auto-tune and drift compensation only when all channels are untouched	True, False Default: True	Perform auto-tune and drift compensation only when all channels are untouched.
Max. active channels	1	Specify the maximum number of channels that are to be used by the application. In Self Capacitance Mode, this is the number of channels used. In Mutual Capacitance Mode, this is the multiplication result of the Rx and Tx channels. For example: 4 Rx and 3 Tx channels = 12 Maximum Active Channels.
Name	g_ctsu0	Module name.
CTSU configuration used	g_ctsu0_config	Name of the configuration structure generated by CTW.
Callback	NULL	The user callback function that will be invoked each time the scan is complete as well as when newly processed data is available. Can be set to NULL if not used.

ISDE Property	Value	Description
Data Processing Option	Default Processing (recommended), No Processing (tuning only) Default: Default Processing	Can be used to specify if scans should start after the data from the previous one is completed, if auto-calibration should be run between scans. Use the Default Processing unless you are tuning.
Write Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Write interrupt priority selection.
Read Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Read interrupt priority selection.
End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	End interrupt priority selection.

Configuration Settings for the DTC HAL Module on r_dtc EVENT CTSU END

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build

ISDE Property	Value	Description
Software Start	Enabled, Disabled Default: Enabled	Software start selection
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table
Name	g_transfer0	Module name
Mode	Block	Mode selection
Transfer Size	2 Bytes	Transfer size selection
Destination Address Mode	Incremented	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode)	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	1	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	1	Number of blocks selection
Activation Source (Must enable IRQ)	Event CTSU END	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC software event interrupt priority selection

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Capacitive Touch Button Framework Module Clock Configuration

The CTSU Button framework uses the same configuration as the CTSU HAL driver: Set the CTSU clock speed to match the clock speed selected in the capacitive touch tuning tool Capacitive Touch Workbench for Renesas Synergy.

Capacitive Touch Button Framework Module Pin Configuration

The CTSU framework uses the same configuration as the CTSU HAL driver: Set the pins as touch sensor pins TSxx and enable the TSCAP function as required by the external device. The first table below illustrates the method for selecting the pins within the SSP configuration window and the following table illustrates an example selection for the I2C pins.

NOTE: The Operation Mode selection mode determines what peripheral signals are available and thus what MCU pins are required.

Pin Selection Sequence for Capacitive Touch Sensing Unit (CTSU)

Resource	ISDE Tab	Pin selection Sequence
CTSU	**Pins**	Select **Peripherals > Input: CTSU > CTSU0**

Pin Configuration Settings for CTSU

Pin Configuration Property	Value	Description
Operation Mode	Disabled, Enabled (Default: Disabled)	Select Enabled as the Operation Mode for CTSU
TS00 to TS11	None, Pn, Pm (Default: P204, P206, P207, None, P408, P409, None, None, None, P414, P415)	TS Pins
TSCAP	None, Pn, Pm (Default: None)	TSCAP Pin

NOTE: The above example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.1.18.6 Using the Capacitive Touch Button Framework Module in an Application

Before using the Capacitive Touch Button framework, add the framework to your project in ISDE, make sure that the configuration data from CTW is added to the project and update the Properties of the framework including the number of buttons, the name of the configuration structure generated by CTW and the callback to be used. Once this is accomplished the typical steps in using the Capacitive Touch Button Framework module in an application are:

1) Initialize the Capacitive Touch Button Framework module using the open API.
2) Detect and Handle Touch Button events with the Callback Function.
3) Disable the Callback for a Button using the disable API (Optional).
4) Enable the Callback for a Button using the enable API (Optional).
5) Close the Capacitive Touch Button framework module using the close API.

These common steps are illustrated in a typical operational flow diagram in the figure below:

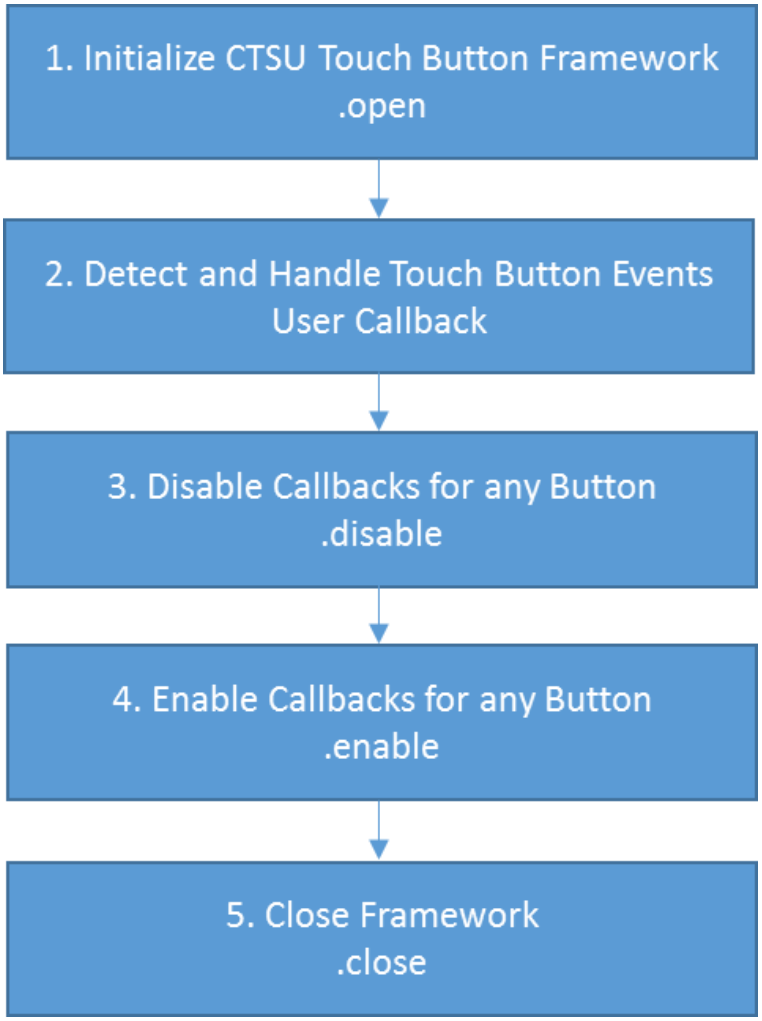

Figure 179: Flow Diagram of a Typical Capacitive Touch Button Framework Module Application

4.1.19 Capacitive Touch Slider Framework

The Capacitive Touch Slider Framework module provides high-level ThreadX-aware APIs for Capacitive Touch slider and wheel applications and is implemented on sf_touch_ctsu_slider. The Capacitive Touch Slider Framework module uses the CTSU on the Synergy MCU. This framework is designed to be used with the configuration data generated by the Capacitive Touch Workbench for Renesas Synergy (CTW) tool. Sliders, wheels, and channels used, are configured in the tool. A user-defined callback can be created to process data when it is available from the hardware after a scan.

This document is divided into the following sections which can be read independently (by a more experienced Synergy developer) or in series (by developers new to the Synergy Platform.)

4.1.19.1 Capacitive Touch Slider Framework Module Features

The Capacitive Touch Slider Framework module is used to interpret the CTSU data for all the slider configurations initialized by the system. Key features include the following:

- Support for slider and wheel
- Support for multiple instances of sliders and wheels
- Callbacks are used to simplify touch processing
  - Use configuration data generated from CTW
  - When a state changes a callback is generated
  - Callbacks are associated with each slider and include the event and position
  - Callbacks are called in the order they appear in the configuration table
- Supports multi-touch detection (can be optionally disabled at build-time)
- Supports S124, S128, S3A6, S3A7, S5D5, S5D9 and S7G2

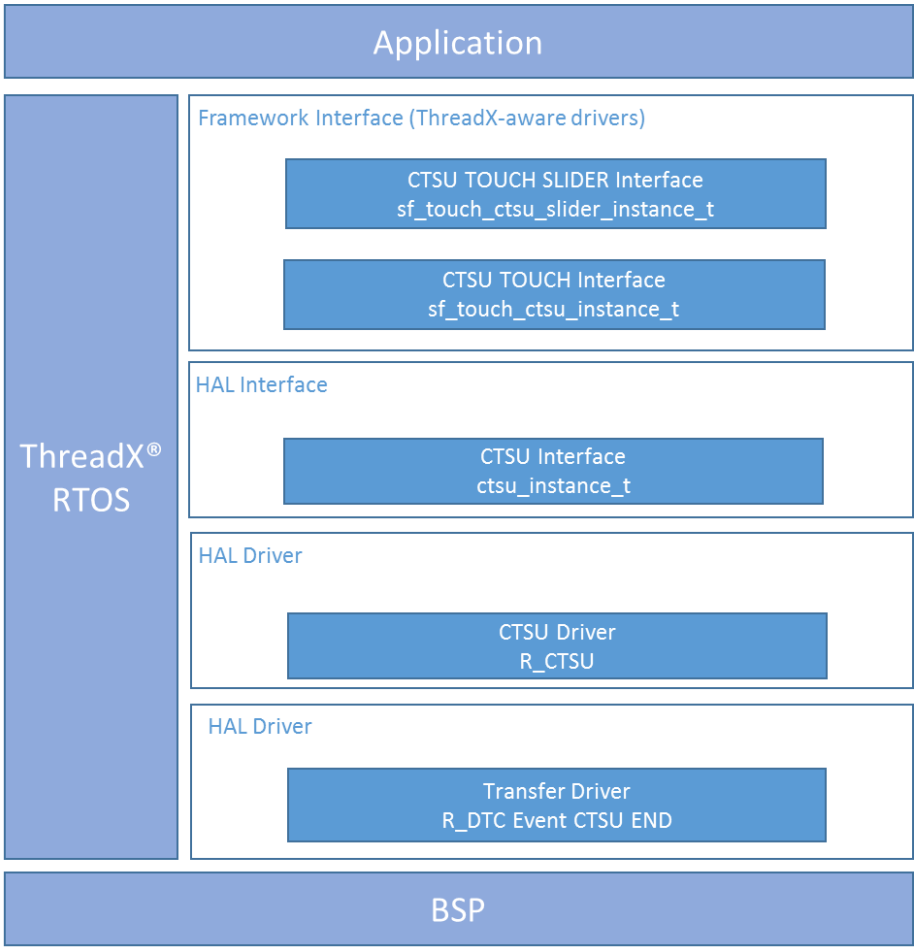

Figure 180: Capacitive Touch Slider Framework Organization, Options and Stack Implementations

4.1.19.2 Capacitive Touch Slider Framework Module APIs Overview

The Capacitive Touch Slider Framework defines APIs for open, close, enable and disable. A complete list of the available APIs, an example API call, and a short description of each can be found in the table below. A table of status return values follows.

Capacitive Touch Slider Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_touch_slider0.p_api->open(g_sf_touch_slider0.p_ctrl, g_sf_touch_slider0.p_cfg); Initialize the Touch CTSU Button Framework; configures the lower level hardware and registers callback functions for all the buttons.
enable	g_sf_touch_slider0.p_api->enable(g_sf_touch_slider0.p_ctrl, slider_id); Enable callback notification for a configured button.
disable	g_sf_touch_slider0.p_api->disable(g_sf_touch_slider0.p_ctrl, slider_id); Disable callback notification for a configured button.
close	g_sf_touch_slider0.p_api->close(g_sf_touch_slider0.p_ctrl); Close the Touch CTSU Button Framework; Closes the button framework and lower layers if no other modules are using it.
versionGet	g_sf_touch_slider0.p_api->versionGet(&p_version); Get version and store it in provided pointer p_version.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables review the SSP Users Manuals API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_ASSERTION	Assertion error.
SSP_ERR_IN_USE	Framework already in use.

Name	Description
SSP_ERR_NOT_OPEN	Device not open.
SSP_ERR_INTERNAL	Internal error.
SSP_ERR_UNSUPPORTED	Device unsupported.
SSP_ERR_INVALID_ARGUMENT	Invalid argument.

NOTE: Lower level drivers may return Common Error Codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.19.3 Capacitive Touch Slider Framework Module Operational Overview

The Capacitive Touch Slider Framework module is used to interpret the CTSU data for all the slider configurations initialized by the system. It also initializes the CTSU Framework layer. The Capacitive Touch Slider Framework registers a callback with the CTSU Framework layer, which will be called each time processed data is available. The Slider Framework then uses this data (raw values) to determine if a touch or release occurred and, if so, where it occurred. If there is a state change, the Framework calls the callback for each slider, in the order in which they are present in the slider configuration table, with the event and the position. The slider framework executes the callback at the update rate (sf_touch_ctsu configuration update_hz) between the touch and release events. The application code should use these callbacks to track the position along the slider. The slider framework executes the callback at the update rate (update_hz) between the touch and release events. This feature can be optionally disabled at build-time.

Capacitive Touch Slider Framework Module Operational Notes

This framework is designed to be used in conjunction with the configuration data generated by the Capacitive Touch Workbench for Renesas Synergy tool which you can download from the Renesas Synergy Gallery in the SSP Utilities tab.

Capacitive Touch Slider Framework Module Limitations

The Framework only supports capacitive touch sliders/wheels that are laid out for self-capacitance mode of operation. There are no other known limitations for using this module. See the most recent SSP release notes for additional limitations.

4.1.19.4 Including the Capacitive Touch Slider Framework Module in an Application

This section describes how to include the Capacitive Touch Slider Framework module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP based applications.

To add the Capacitive Touch Slider Framework module to an application, simply add it to a thread using the Stacks Selection Sequence given in the table below. (The default name for the Capacitive Touch Slider Framework module is g_sf_touch_slider0. This name can be changed in the associated **Properties** window.)

Capacitive Touch Slider Framework Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_touch_slider0 Capacitive Touch Slider/Wheel Framework on sf_touch_ctsu_slider	**Threads**	**New Stack> Framework> Input> Capacitive Touch Slider Framework on sf_touch_ctsu_slider**

When the Capacitive Touch Slider Framework module on sf_touch_ctsu_slider is added to the thread stack as shown in the figure below, the configurator automatically adds any needed lower level modules. Any drivers that need additional configuration information will have box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower level drivers; these are either optional or recommended (this is indicated in the block with the inclusion of this text.) If the addition of lower level drivers is required, the module description will include "Add" in the text. Clicking on any Pink banded modules will bring up the "New" icon and then display the possible choices.

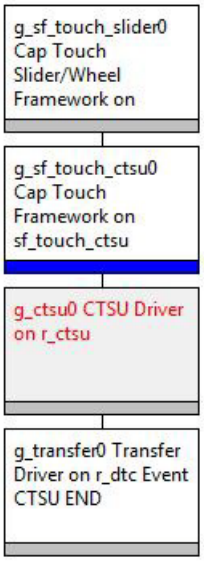

Figure 181: Capacitive Touch Slider Framework Module Stack

4.1.19.5 Configuring the Capacitive Touch Slider Framework Module

The Capacitive Touch Slider Framework module must be configured by you for the desired operation. The SSP configuration window will automatically identify, by highlighting the block in red, any required configuration selections, such as Interrupts or operating modes, which must be configured for lower level modules, for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the **Properties** tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority. This configuration setting is available with the properties window of the associated module. Simply select the indicated module and then view the properties window. The Interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the Interrupt priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the below configuration properties tables, but is easily visible with the ISDE when configuring Interrupt Priority levels.

NOTE: You may want to open your ISDE and create the module and explore the property settings in parallel with looking over the Configuration Table Settings given below. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Capacitive Touch Slider Framework Module on sf_touch_ctsu_slider

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Controls whether to include code for API parameter checking
Number of Sliders/Wheels	1	Number of sliders configured in CTW
Multi touch enable	Enabled, Disabled Default: Enabled	Enables or disables multi-touch detection
Name	g_sf_touch_slider0	Framework name
Slider/Wheel Configuration Structure Name (generated by Workbench)	all_sliders	Name of slider configuration structure generated by CTW
Callback	g_slider_framework_user_callback	Name of callback function created by user application

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Since lower level properties are configured by Capacitive Touch Workbench for Renesas Synergy (CTW), it is best not to make any configuration changes without a detailed knowledge of CTSU operation. The configurable properties for the lower level stack modules are given in the below sections for completeness and as a reference.

NOTE: Most of the property settings for lower level modules are fairly intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the Capacitive Touch Slider Framework Module

Typically, only a small number of settings must be modified from the default for lower level modules. (These are indicated via the red text in the thread stack block.) Notice that some of the configuration properties must be set to a certain value

for proper framework operation and will be locked to prevent user modification. The tables below identify all the settings within the properties section for the module.

Configuration Settings for the Capacitive Touch Framework on sf_touch_ctsu

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter error checking.
Name	g_sf_touch_ctsu0	Module name.
Thread Priority	3	User determined based on priority of other threads in system. Recommend high priority.
Update Hz	50	Rate at which the CTSU hardware scans should occur. The maximum scan rate should be less than the tick rate set for ThreadX. The total time to complete a hardware scan is determined by the number of channels used. Each channel takes approximately 600 usec to complete a scan. Thus if 10 channels are used for 10 buttons in self-capacitance mode, the total hardware scan time is ~6 milliseconds or 166 Hz. Similarly, if 7 channels are used for 5 buttons in mutual-capacitance mode (5x2 layout), the total hardware scan time is ~4.2 milliseconds or 250 Hz. The software processing time is additional and will vary depending on the core clock and the software filter depth used by the CTSU. Thus, the maximum scan rate should be lesser than the time required to scan and process all the channels used in the configuration and lesser than the RTOS tick rate.
Callback	NULL	Name of user callback that will be called when each scan is complete and also when new processed data is available. Can be NULL if not used.

Configuration Settings for the CTSU HAL Module on r_ctsu

ISDE Property	Value	Description
Parameter Checking Enable	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Offset Adjustment	Enabled, Disabled Default: Enabled	Used to enable or disable offset adjustment. Leave as enabled unless you are tuning the board. (Rate is determined by *Runtime rate of tuning of sensor values*.)
Drift Compensation	Enabled, Disabled Default: Enabled	Used to enable or disable drift compensation. Leave as enabled unless you are tuning the board. Drift compensation allows the baseline values used to determine the presence or absence of a touch to change over time as the board or surface ages or with changes in temperature and environment. Drift compensation rate is determined by *Steady state drift compensation rate*, *Startup drift compensation rate*, and *Channel release compensation rate*.
Drift Compensation Method (valid only if Drift Compensation is enabled above)	Alternate Method 1	Drift Compensation algorithms provided. Only Alternate 1 is currently supported. Other options may be supported in future releases. Drift compensation method Alternate 1 allows for different rates of drift compensation for the following events: steady state, startup, and channel release.
Steady state drift compensation rate, drift compensation will be applied per n scans	500	Determines the rate of drift compensation (applied every n scans) when the channel is in steady state. (Dependent on the scan rate.)
Startup drift compensation rate (Should be less than the steady state drift compensation)	5	Determines the rate of drift compensation (applied every n scans) when the driver is performing its initialization. (Should be less than the *Steady state drift compensation rate*.)

ISDE Property	Value	Description
Channel release compensation rate (Should be less than the steady state drift compensation rate)	500	Determines the rate of drift compensation (applied every n scans) when a channel transitions from pressed to released. (Should be less than or equal to the *Steady state drift compensation rate*.)
Default filter depth (used in sensor count filter provided by driver)	1	Used in the software sensor count filter provided by driver. This default filter is a modification of the relatively common "leaky integrator" software filter. A depth of 4 equates to an approximate filter constant of 16. When the input is a constant value of 16 or greater, the filter output will reach 68-69% of the constant input value after 16 cycles/iterations of the filter.
Runtime rate of tuning of sensor values (if drift compensation is used this value is overrriden to be twice the rate of the steady state drift compensation)	800	Rate of offset adjustment. (If drift compensation is used this value is set to twice the rate of the steady state drift compensation.)
Perform auto-tune and drift compensation only when all channels are untouched	True, False Default: True	Perform auto-tune and drift compensation only when all channels are untouched.
Max. active channels	1	Specify the maximum number of channels that are to be used by the application. In Self Capacitance Mode, this is the number of channels used. In Mutual Capacitance Mode, this is the multiplication result of the Rx and Tx channels. For example: 4 Rx and 3 Tx channels = 12 Maximum Active Channels.
Name	g_ctsu0	Module name.
CTSU configuration used	g_ctsu0_config	Name of the configuration structure generated by CTW.

ISDE Property	Value	Description
Callback	NULL	The user callback function that will be invoked each time the scan is complete as well as when newly processed data is available. Can be set to NULL if not used.
Data Processing Option	Default Processing (recommended), No Processing (tuning only) Default: Default Processing	Can be used to specify if scans should start after the data from the previous one is completed, if auto-calibration should be run between scans etc. Use the Default Processing unless you are tuning.
Write Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Write interrupt priority selection.
Read Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Read interrupt priority selection.
End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	End interrupt priority selection.

Configuration Settings for the DTC HAL Module on r_dtc EVENT CTSU END

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Enabled	Software start selection
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table
Name	g_transfer0	Module name
Mode	Block	Mode selection
Transfer Size	2 Bytes	Transfer size selection
Destination Address Mode	Incremented	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	1	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	1	Number of blocks selection
Activation Source (Must enable IRQ)	Event CTSU END	Activation source selection

Callback (Only valid with Software start)	NULL	Callback selection

ISDE Property	Value	Description
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC software event interrupt priority selection

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Capacitive Touch Slider Framework Module Clock Configuration

The CTSU Slider framework uses the same configuration as the CTSU HAL driver. Set the CTSU clock speed to match the clock speed selected in the capacitive touch tuning tool.

Capacitive Touch Slider Framework Module Pin Configuration

The CTSU framework uses the same configuration as the CTSU HAL driver. Set the pins as touch sensor pins TSxx and enable the TSCAP function as required by the external device. The first table below illustrates the method for selecting the pins within the SSP configuration window and the following table illustrates an example selection for the CTSU pins.

NOTE: The Operation Mode selection mode determines what peripheral signals are available and thus what MCU pins are required.

Pin Selection Sequence for Capacitive Touch Sensing Unit (CTSU)

Resource	ISDE Tab	Pin selection Sequence
CTSU	Pins	Select **Peripherals > CTSU> Cap_Touch_Sensing_Unit**

Pin Configuration Settings for CTSU

Pin Configuration Property	Value	Description
Operation Mode	Disabled, Enabled (Default: Disabled)	Select Enabled as the Operation Mode for CTSU

Pin Configuration Property	Value	Description
TS00 to TS11	None, Pn, Pm (Default: None)	TS Pins
TSCAP	None, P205, P203 (Default: P205)	TSCAP Pin

NOTE: The above example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.1.19.6 Using the Capacitive Touch Slider Framework Module in an Application

Before using the Capacitive Touch Slider framework, add the framework to your project in ISDE, make sure that the configuration data from CTW is added to the project and update the Properties of the framework including the number of sliders, the name of the configuration structure generated by CTW and the callback to be used. Once this is accomplished the typical steps in using the Capacitive Touch Slider Framework module in an application are:

1) Initialize the Capacitive Touch Slider Framework module using the open API.
2) Detect and Handle Touch Slider events through the Callback Function.
3) Disable Callback for the Slider with the disable API (optional).
4) Enable Callback for the Slider with the enable API (optional).
5) Close Capacitive Touch Button Framework module using the close API.

These common steps are illustrated in a typical operational flow diagram in the figure below:

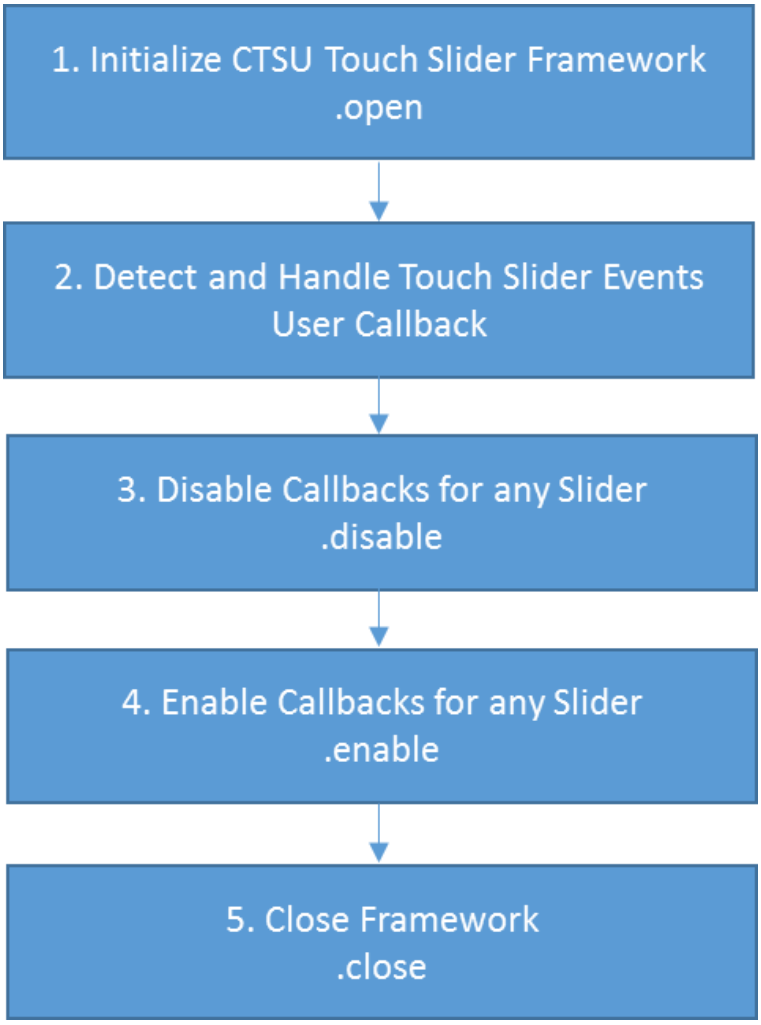

Figure 182: Flow Diagram of a Typical Capacitive Touch Slider Framework Application

4.1.20 External IRQ Framework

The External IRQ Framework provides high-level APIs for applications using the external pin interrupts with the ThreadX RTOS. The Framework is implemented on sf_external_irq and supports the external IRQ pins on the Synergy microcontroller. A callback function (sf_external_irq_callback) is available that will be called from the interrupt service routine (ISR) each time the IRQn triggers.

4.1.20.1 External IRQ Framework Module Features

- Responds to external interrupt inputs
- RTOS aware implementation using an internal semaphore for thread synchronization
  - Can signal internal threads

  - Can trigger transfers via the Event Link Controller (ELC)
- Uses the port pins available on Synergy MCUs
  - Pins may differ between MCUs so refer to MCU User's Manuals for specifics
- Supports several hardware features such as
  - Channel selection
  - Trigger conditions
  - Digital filtering
  - Auto start

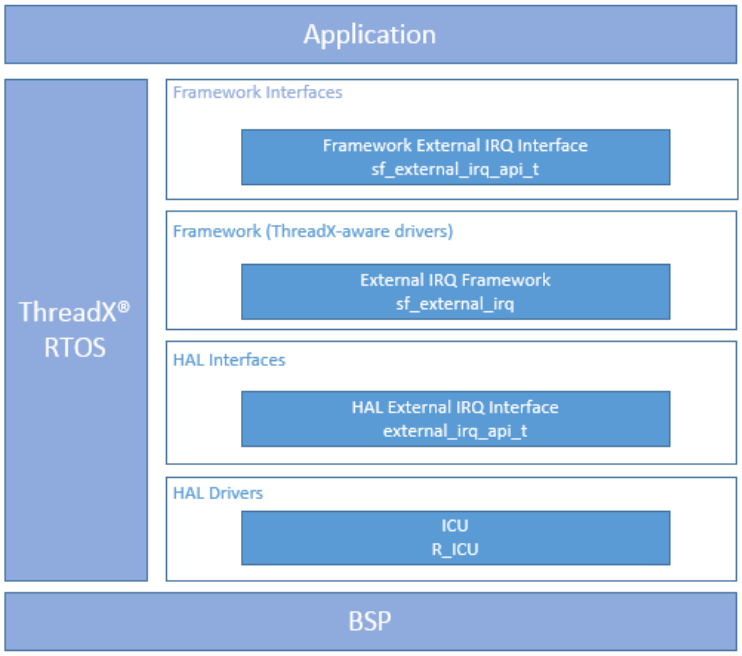

Figure 183: External IRQ Framework Organization, Options, and Stack Implementations

4.1.20.2 External IRQ Framework Module APIs Overview

The External IRQ framework module defines APIs for opening, waiting or closing the module. A complete list of the available APIs, an example API call, and a short description of each can be found in the table below. A table of status return values follows.

External IRQ Framework API Summary

Function Name	Example API Call and Description
open	g_sf_external_irq.p_api->open(g_sf_external_irq.p_ctrl, g_sf_external_irq.p_cfg); Acquire mutex, then handle driver initialization at the HAL layer.
wait	g_sf_external_irq.p_api->wait(g_sf_external_irq.p_ctrl, TX_WAIT_FOREVER); Wait for the next external interrupt expiration, then return.
versionGet	g_sf_external_irq.p_api->versionGet(&version); Retrieve the API version and store it in the version pointer.
close	g_sf_external_irq.p_api->close(g_sf_external_irq.p_ctrl); Release channel mutex and close channel at HAL layer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manuals API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_ASSERTION	Assertion error.
SSP_ERR_IN_USE	Device in use.
SSP_ERR_NOT_OPEN	Device unopened.
SSP_ERR_TIMEOUT	Timeout error.
SSP_ERR_WAIT_ABORTED	Suspension aborted.
SSP_ERR_UNSUPPORTED	Function unsupported by the HAL driver.

NOTE: Lower level drivers may return Common Error Codes. Refer to the API Reference section for the associated module for a definition of all relevant status return values.

4.1.20.3 External IRQ Framework Module Operational Overview

The External IRQ framework is a set of ThreadX aware framework APIs. With the External IRQ Framework external inputs such as switches can signal, via an internal semaphore, threads or trigger transfers via the Event Link Controller (ELC). Both the External IRQ framework module and the External IRQ HAL module need to be configured for proper operation. The HAL configuration settings allow control over hardware options such as triggering level and digital filtering settings.

External IRQ Framework Module Important Operational Notes and Limitations

- Refer to the Datasheet for the Synergy device to be programmed to find the port pins which support the external interrupt functions and to obtain the External IRQ number for a given port pin.
- The External IRQ number corresponds to the Channel setting in the ISDE Properties window for the External IRQ driver.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.20.4 Including the External IRQ Framework Module in an Application

This section describes how to include the External IRQ Framework in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP based applications.

To add the External IRQ Framework to your application simply add it to a project Thread using the Stacks Selection Sequence given in the table below. (The default name for the External IRQ Framework is g_sf_cexternal_irq0 and this is shown in the below table. This name can be changed in the associated **Properties** window).

External IRQ Framework Configuration Settings

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_external_irq0 External IRQ Framework on sf_external_irq	**Threads**	**New Stack> Framework> Input> External IRQ Framework on sf_external_irq**

When the External IRQ Framework on sf_external_irq is added to the thread stack as shown in the figure below, the configurator automatically adds any needed lower level modules. Any drivers that need additional configuration information will have box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

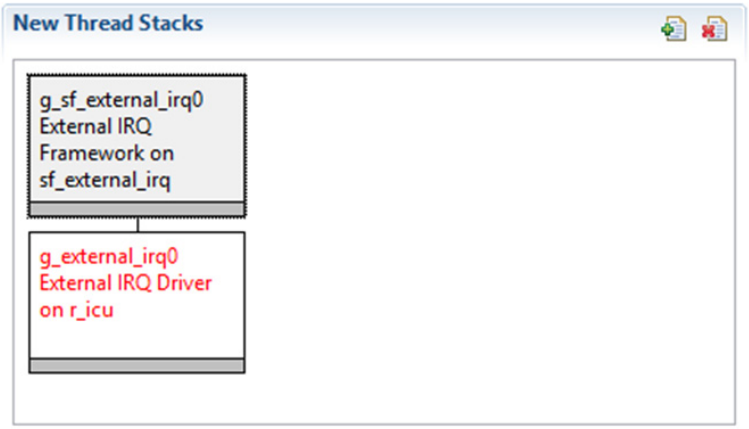

Figure 184: External IRQ Framework Thread Stack

4.1.20.5 Configuring the External IRQ Framework Module

The External IRQ framework module must be configured by you for the desired operation. The SSP configuration window will automatically identify, by highlighting the block in red, any required configuration selections, such as Interrupts or operating modes, which must be configured for lower level modules, for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the **Properties** tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority. This configuration setting is available with the **Properties** window of the associated module. Simply select the indicated module and then view the **Properties** window. The Interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the Interrupt priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring Interrupt Priority levels.

NOTE: You may want to open your ISDE and create the module and explore the property settings in parallel with looking over the Configuration Table Settings given below. This will help orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for External IRQ Framework on sf_external_irq

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Parameter selection.
Name	g_sf_external_irq0	Framework name.

ISDE Property	Value	Description
Event	Semaphore Put, None (Default: Semaphore Put)	Event selection.

NOTE: The above value examples and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

In some cases, values other than the defaults for stack modules can be desirable. For example, it might be useful to select the triggering setting or digital filtering value. The configurable properties for the lower level stack modules are given in the below sections for completeness and as a reference.

NOTE: Most of the property settings for modules are fairly intuitive and can usually be determined by inspection of the associated properties window from the SSP configurator.

4.1.20.6 Configuration Settings for the External IRQ Framework Module Low Level Drivers

Typically, only a small number of settings must be modified from the default for lower level modules. (These are indicated with red text in the thread stack block.) Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The tables below identify all the settings within the properties section for the module.

Configuration Settings for External IRQ Driver on r_icu

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Parameter selection.
ICU IRQ0	Priority 0 (highest), 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 (lowest, not valid if using Thread X), Disabled (Default: Disabled)	ICU selection.
Name	g_external_irq0	Driver name.
Channel	0	Specifies the hardware IRQ channel used.

ISDE Property	Setting	Description
Trigger	Falling, Rising, Both Edges, Low Level (Default: Rising)	Trigger selection.
Digital Filtering	Enabled, Disabled (Default: Disabled)	Digital filter enable/disable.
Digital Filtering Sample Clock (Only valid when Digital Filtering is Enabled)	PCLK/1, PLCK/8, PLCK/32, PCLK/64 (Default: PCKL/64)	Sets noise filter sampling period.
Interrupt enabled after initialization	True, False (Default: True)	Interrupt enable selection.
Callback	NULL	Callback selection.

NOTE: The preceding value examples and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

4.1.20.7 Using External IRQ Framework Module in an Application

The typical steps in using the External IRQ framework module in an application are:

1) Open the External IRQ framework module with the open API
2) Wait for an interrupt using the wait API
3) Process External IRQ event
4) Close the module using the close API

The above common steps are illustrated in a typical operational flow diagram in the figure below.

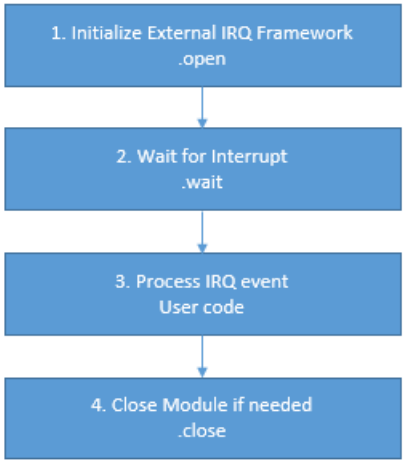

Figure 185: Flow Diagram of a Typical External IRQ Framework Module Application

4.1.21 I2C Framework

The I2C Framework module provides high-level ThreadX®-aware APIs for I2C Framework applications and is implemented on sf_i2c. The I2C HAL module configures the I2C peripheral to enable serial communication to be used by the framework. The I2C Framework module uses the I2C and SCI peripherals on the Synergy MCU.

4.1.21.1 I2C Framework Module Features

- ThreadX-aware framework
- Handles integration and synchronization of multiple I2C peripherals on the I2C bus
- Provides a single interface to access both SCI I2C and RIIC drivers
- The I2C framework module configures I2C communication in master mode
- The I2C framework module supports three data rates: 100 kbps, 400 kbps, and 1 Mbps
- The I2C framework module supports both 7-bit addressing and 10-bit addressing
- The I2C framework module also provides support for callbacks internally. User defined callback is not used. The callback functions are called with the following events i2c_event_t:
  - Transfer aborted
  - Transmit complete
  - Receive complete
- The callback structure i2c_callback_args_t also provides the number of bytes that were sent or received
- Implemented by:
  - Simple I2C on SCI
  - RIIC

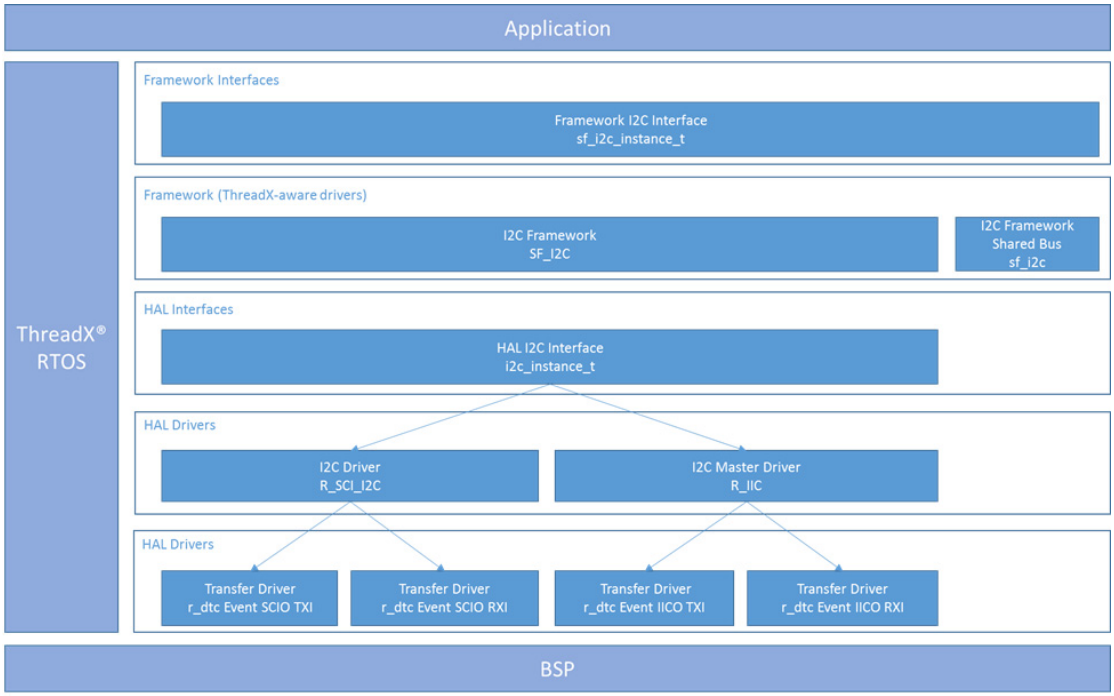

Figure 186:I2C Framework Module Block Diagram

4.1.21.2 I2C Framework Module APIs Overview

The I2C Framework interface defines APIs for opening, closing, reading, writing, locking, unlocking, and resetting the bus using the I2C Framework. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows.

I2C Framework Module API Summary

Function Name	Example API Call and Definition
open	g_sf_i2c_device.p_api->open(g_sf_i2c_device.p_ctrl, g_sf_i2c_device.p_cfg) Opens a designated I2C device on the bus.
close	g_sf_i2c_device.p_api->close (g_sf_i2c_device.p_ctrl); Disables I2C device designated by control handle. Closes the RTOS services used by the bus if no devices are connected to the bus.
read	g_sf_i2c_device.p_api->read (g_sf_i2c_device.p_ctrl, &reg, no_of_bytes_to_read, 0, TX_WAIT_FOREVER); Receives data from I2C device.

Function Name	Example API Call and Definition
write	g_sf_i2c_device.p_api->write (g_sf_i2c_device.p_ctrl, command, no_of_bytes_to_write , false, TX_WAIT_FOREVER); Transmits data to I2C device.
lock	g_sf_i2c_device.p_api->lock (g_sf_i2c_device.p_ctrl); Lock sthe bus for a device. Locking reserves the bus until unlocking and allows several reads and writes without interrupt.
unlock	g_sf_i2c_device.p_api->unlock (g_sf_i2c_device.p_ctrl); Unlocks the bus from a particular device and makes it available for other devices.
reset	g_sf_i2c_device.p_api->reset (g_sf_i2c_device.p_ctrl, TX_NO_WAIT); Aborts any in-progress transfer and forces the I2C peripheral into ready state.
version	g_sf_i2c_device.p_api->version(version); Retrieves the version information using the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the *SSP User's Manual API References* for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	I2C function performed successfully
SSP_ERR_INVALID_MODE	Illegal I2C mode is specified
SSP_ERR_INVALID_CHANNEL	Omitted I2C channel is specified
SSP_ERR_IN_USE	I2C channel has already been opened
SSP_ERR_INVALID_ARGUMENT	Argument is not one of the predefined values
SSP_ERR_INVALID_POINTER	Null pointer(s) is (are) given
SSP_ERR_INTERNAL	Internal error has occurred
SSP_ERR_ASSERTION	A critical assertion has failed
SSP_ERR_NOT_OPEN	Device instance not opened
SSP_ERR_TRANSFER_ABORTED	The data transfer was aborted

Name	Description
SSP_ERR_INVALID_RATE	The requested rate cannot be set
SSP_ERR_TIMEOUT	Timeout error occurs.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.21.3 I2C Framework Module Operational Overview

The I2C Framework module complies with the layered driver architecture of the SSP. It uses the lower-level I2C HAL modules to communicate with I2C peripherals and Controls the I2C-capable peripherals on a Synergy microcontroller, as configured by a user. With the I2C Framework module, one or more I2C buses can be created and multiple I2C peripherals can be connected to each I2C bus. The I2C Framework module APIs use a ThreadX-Mutex to acquire and release the shared bus for I2C Slave devices. Acquire and release are implemented by lock and unlock APIs respectively in the I2C Framework module.

As the I2C framework module configures I2C communication in master mode, this allows the user to:

- Initialize the driver
- Read from a slave device
- Write to a slave device
- Reset the I2C peripheral
- Lock the I2C Bus
- Unlock the I2C Bus

The I2C Framework module works with the Synergy MCU I2C hardware modules; the RIIC and SCI HAL modules. Both I2C modules support the I2C fast-mode with bit rates of up to 400 kbps. The IIC peripheral and the RIIC HAL module support fast-mode plus with 1-Mbps bit-rates. The module supports only master mode for both implementations.

The I2C Framework module uses a bus and device on bus architecture. Every device is linked to the bus to which it will be connected. The user must configure the framework shared-bus and the lower-level I2C HAL layer for each framework device connecting to the bus. The user can add the existing framework shared-bus when configuring multiple devices on the same bus. A common start and stop procedure is used for all I2C data-transfer operations. Only one device is configured to the lower level and the remaining devices perform read or write operations by switching the device address within the framework.

All I2C Framework devices on the same bus must use the same lower-level configuration settings, (for example, the I2C HAL module) except for the slave address and addressing mode. The framework will use the configuration of the first device that it opens in the application to configure the bus; this means that all I2C Framework devices on the same bus must have the same lower-level configuration settings (except for the slave address and addressing mode). If different configurations are used, proper operation cannot be guaranteed.

The I2C Framework supports bus-locking functionality, meaning the bus can be locked for a given peripheral. The locking allows devices to reserve a bus to themselves for a given period of time (between lock and unlock.) This allows devices to complete several reads and writes on the bus without interruption (which is required in some instances.)

I2C Framework Module Important Operational Notes and Limitations

- The closest possible baud rate that can be achieved (less than or equal to the requested rate) at the current PCLKB settings is calculated and used. If a valid clock rate could not be calculated, an error is returned.
- The I2C can trigger the start of other peripherals available from the ELC. See the ELC Module Guide for further information.
- The I2C Framework can support multiple I2C devices on the same bus if the clock rate remains the same for all the devices. That means multiple devices can be opened in the same bus if they are of the same clock rate. If devices have different clock rates, only one device can be opened at a time.
- SDA and SCL output pin type should be n-channel open drain when using I2C on SCI.
- In the I2C Framework configuration, the channel number given to this bus overrides the channel number given in the HAL module.
- Shared bus can be used by multiple slave devices with the respective configuration. The framework also handles mutual exclusion in lock and unlock APIs when multiple devices are using the same I2C channel.
- To configure multiple I2C devices on the same bus, add and configure the following modules for each device connecting to the bus:
  - I2C Framework device module
  - Configure the I2C shared bus module for the first device being configured, then use the same bus for the remaining devices.
  - I2C HAL module
  - DTC module(Optional)
- Lock functionality will be effective for devices from different threads. If multiple devices connected to the bus are from the same thread, the I2C bus will be locked for all devices from that thread. In such cases even if bus is locked all devices from same thread can access the bus.

NOTE: Each I2C Framework device must be configured with a unique name in the ISDE configurator.

NOTE: Provide the same configuration settings for all the devices connected on the same bus (except the slave address and addressing modes.)

The I2C framework module does not currently support the following features:

- The use of any timer other than the GPT
- The use of DMA
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.21.4 Including the I2C Framework Module in an Application

This section describes how to include the I2C Framework module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and

configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.*

To add the I2C framework module to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the I2C framework module is g_sf_i2c_device0. This name can be changed in the associated Properties window.)

I2C Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_i2c_device0 I2C Framework on sf_i2c	Threads	New Stack> Framework> Connectivity> I2C Device Framework on sf_i2c

When the I2C Framework module on sf_i2c is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information will have box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks.

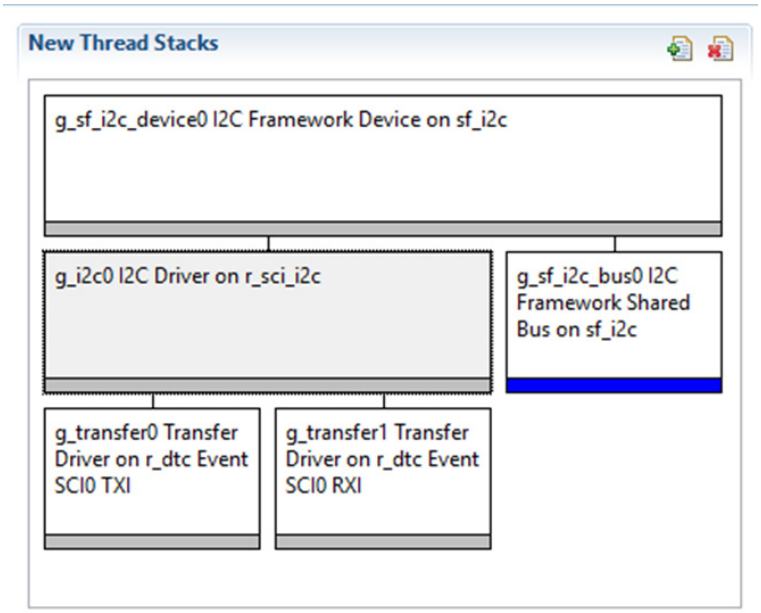

Figure 187:I2C Framework Module Stack

4.1.21.5 Configuring the I2C Framework Module

The I2C framework module must be configured by you for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches

to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority. This configuration setting is available with the Properties window of the associated module. Simply select the indicated module and then view the Properties window. The interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE and create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the I2C Framework Module on sf_i2c

Parameter	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: Enabled	Enable or disable parameter error checking.
Name	g_sf_i2c_device0	Give a name to identify the I2C Framework device. API, Config and Control instances will be created based on this name.

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select different byte ordering or pixel-color format. The configurable properties for the lower-level modules are given in the following sections for completeness and as a reference.

NOTE: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated Properties window with the SSP configurator.

Configuration Settings for the I2C Framework Lower-Level Drivers

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated by the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the I2C Master HAL Module on r_sci_i2c

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.
Name	g_i2c0	Module name.
Channel	0 to 9	Specify the SCI channel to be used with this configuration. SCI has channels as follows: Series S7: 0 1 2 3 4 5 6 7 8 9; Series S3: 0 1 2 3 4 - - - - 9; Series S1: 0 1 - - - - - - - 9.
Rate	Standard, Fast-mode Default: Standard	Standard and Fast.
Slave Address	0x00	Address of the slave device.
Address Mode	7-Bit, 10-Bit Default: 7-Bit	Only 7-bit addresses are currently supported.
SDA Output Delay (nano seconds)	300	SDA output delay in nanoseconds.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Enables bitrate modulation function.

ISDE Property	Value	Description
Callback	NULL	A user callback function can be registered in open. If this callback function is provided, it will be called from the interrupt service routine (ISR) for each of the conditions defined in i2c_event_t. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection.

ISDE Property	Value	Description
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit end interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the I2C Master HAL Module on r_riic

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.
Name	g_i2c0	Module name.
Channel	0 to 9	Specify the SCI channel to be used with this configuration. SCI has channels as follows: Series S7: 0 1 2 3 4 5 6 7 8 9; Series S3: 0 1 2 3 4 - - - - 9; Series S1: 0 1 - - - - - - - 9.
Rate	Standard, Fast-mode Default: Standard	Standard and Fast.
Slave Address	0x00	Address of the slave device.

ISDE Property	Value	Description
Address Mode	7-Bit, 10-Bit Default: 7-Bit	Only 7-bit addresses are currently supported.
SDA Output Delay (nano seconds)	300	SDA output delay in nanoseconds.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Enables bitrate modulation function.
Callback	NULL	A user callback function can be registered in open. If this callback function is provided, it will be called from the interrupt service routine (ISR) for each of the conditions defined in i2c_event_t. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Receive interrupt priority selection.

ISDE Property	Value	Description
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit end interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the I2C Framework Shared Bus on sf_i2c

ISDE Property	Value	Description
Name	g_sf_i2c_bus0	Give a name to identify the bus. This bus name is used in the Framework configuration to link the I2C peripheral to a bus.
I2C Implementation	SCI I2C, RIIC Default: RIIC	Choose any low-level interface to use in the Framework.

ISDE Property	Value	Description
Channel	0-9	SCI or RIIC Channel number to which the device has been connected. In framework, the channel number given in this bus configuration will overrides the channel number given in the HAL driver.

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

I2C Framework Module Clock Configuration

The SCI peripheral module uses PCLKB as its clock source. The PCLKB frequency is set by using the SSP configurator clock tab prior to a build, or by using the CGC Interface at run-time. During configuration, the I2C transfer rate is calculated and set internally by the driver, based on the user-selected PCLB rate and the user-selected transfer rate. If the PCLKB is configured in such a manner that the user-selected rate cannot be achieved, an error will be returned when initializing the driver.

I2C Framework Module Pin Configuration

The SCI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the pins.

Note: For some peripherals, the operation-mode selection determines what peripheral signals are available and thus what MCU pins are required.

Pin Selection Sequence for SCI1

Resource	ISDE Tab	Pin Selection Sequence
SCI	Pins	Select Peripherals > SCI1_3_5_7_9 > SCI1

NOTE: The selection sequence assumes SCI1 is the desired hardware target for the driver.

Pin Configuration Settings for the I2C Framework Module on SCI

Pin Configuration Property	Value	Description
Operation Mode	Disabled, Asynchronous UART, Synchronous UART, Simple I2C, Simple SPI, SmartCard Default: Disabled	Select Simple I2C as the Operation Mode for I2C on SCI
RXD1_SCL1_MISO1	None, P212, P708 (Default: None)	SCL Pin
TXD1_SDA1_MOSI1	None, P213, P709 (Default: None)	SDA Pin

NOTE: The example values are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

I2C Framework Module Other Settings

In addition to the SCL and SDA pins, an I2C RESET signal may be required to reset the I2C slave device. If this is the case, the RESET signal can be added using a GPIO pin and must be controlled directly by the application program. The external device reset function is not supported within the r_sci_i2c module.

4.1.21.6 Using the I2C Framework Module in an Application

Once the module has been configured and the files generated and I2C pins are configured, the I2C Framework module is ready to be used in an application. The typical steps in using the I2C module in an application are as follows:

1) Initialize the I2C module using the open API
2) Reset the module using reset API (if needed)
3) Lock the bus using the lock API (if needed)
4) Configure the channel using the write API

5) Unlock the bus using the unlock API (if needed)
6) If a read is desired, lock the bus with the lock API (if needed)
7) The program starts a read from the buffer using the read API
8) Unlock the bus using the unlock API (if needed)
9) The module can be closed if desired using the close API.

These common steps are illustrated in a typical operational flow diagram in the figure below:

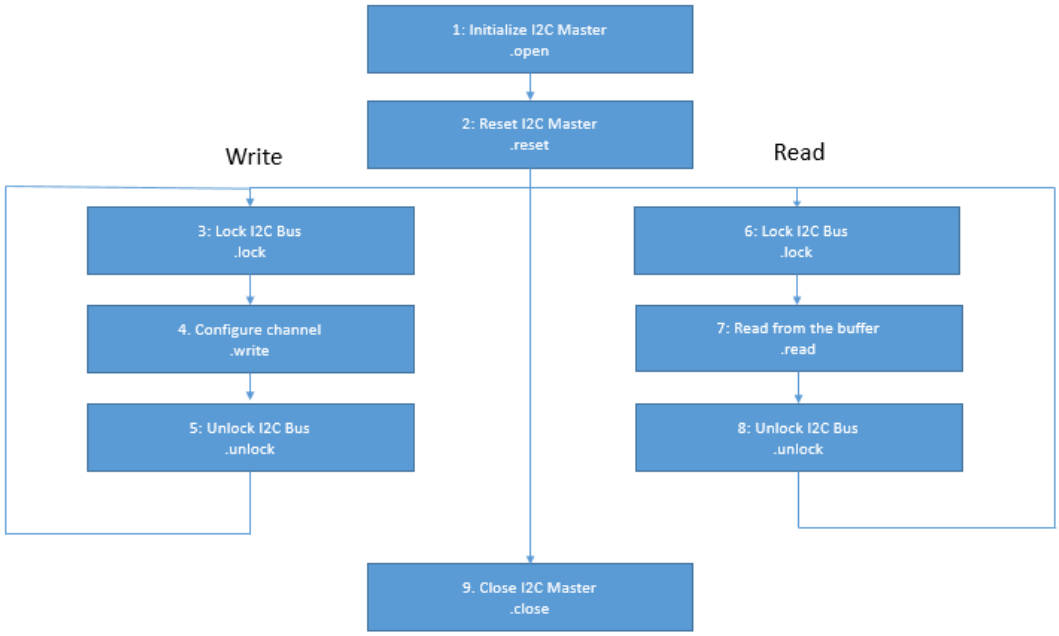

Figure 188: Flow Diagram of a Typical I2C Framework Module Application

4.1.22 JPEG Decode Framework

The JPEG Decode HAL module provides high-level APIs for JPEG decode processing implemented on r_jpeg. (The JPEG Decode HAL module supports the JPEG Codec peripheral.) The JPEG Decode Framework Module is a ThreadX®-aware high-level API for JPEG framework module applications and is implemented on sf_jpeg_decode; it provides thread-safe access to the Synergy JPEG hardware on a Synergy MCU Group. A user-defined callback can be created to detect hardware supported events.

4.1.22.1 JPEG Decode Framework Module Features

- Provides thread-safe access to the Synergy JPEG hardware.
- Supports JPEG decompression using the JPEG Decode HAL module.
- Supports a polling mode that allows an application to wait for the JPEG Decoder to complete.
- Supports an interrupt mode with user-supplied callback functions.

- Configures parameters such as horizontal and vertical subsample values, horizontal stride, decoded pixel format, input and output data format, and color space.
- Obtains the size of the image prior to decoding it.
- Supports putting coded data in an input buffer and an output buffer to store the decoded image frame.
- Supports streaming coded data into the JPEG Decoder module. This feature allows an application to read a coded JPEG image from a file or from a network without buffering the entire image.
- Configures the number of image lines to decode. This feature enables the application to process the decoded image on the fly without buffering the entire frame.
- Supports the input decoded formats YCbCr444, YCbCr422, YCbCr420 and YCbCr411.
- Supports the output formats ARGB8888 and RGB565.
- Returns an error when the JPEG image's size, height, and width don't meet the requirements.
- Supports the wait API function to suspend/resume the thread for synchronizing with the JPEG hardware supported events.

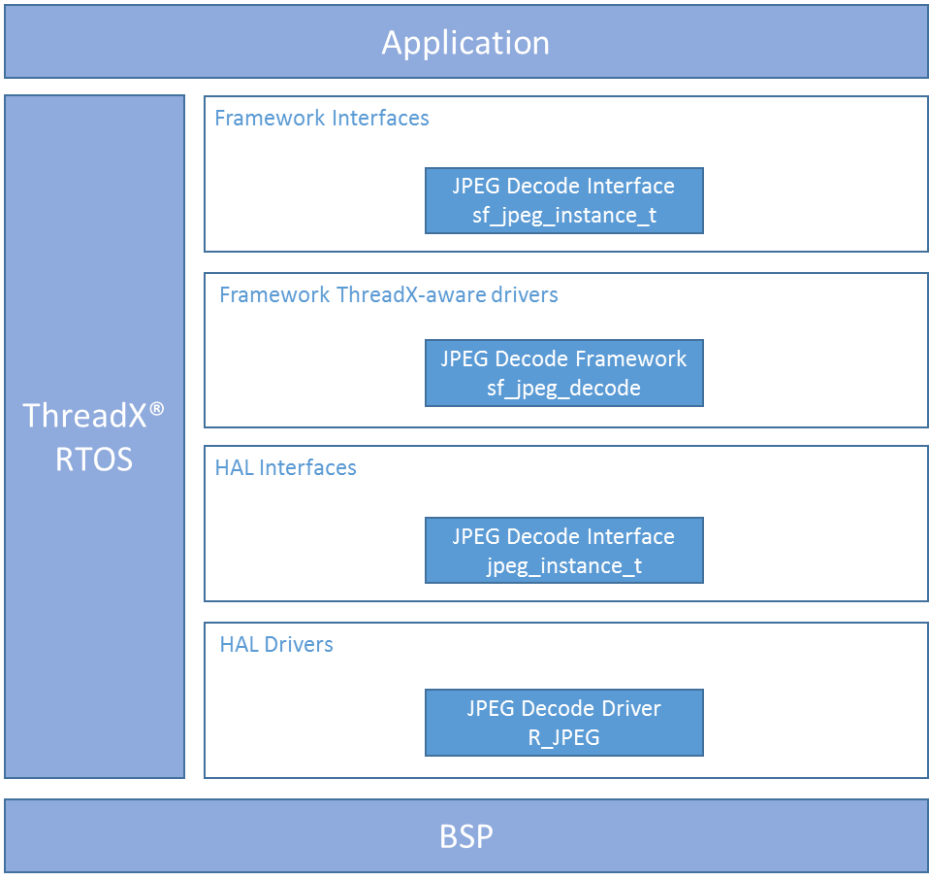

Figure 189: JPEG Decode Framework Module Block Diagram

4.1.22.2 JPEG Decode Framework Module APIs Overview

The JPEG Decode Framework module defines APIs for opening, closing, setting alarms and starting and stopping RTC operations. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

JPEG Decode Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_jpeg_decode.p_api->open(g_sf_jpeg_decode.p_ctrl , g_sf_jpeg_decode.p_cfg); Open the JPEG Decode Framework.
close	g_sf_jpeg_decode.p_api->close(g_sf_jpeg_decode.p_ctrl); Close the JPEG Decode Framework.
inputBufferSet	g_sf_jpeg_decode.p_api->inputBufferSet(g_sf_jpeg_dec ode.p_ctrl, &buffer, size); Feed data into JPEG codec.
outputBufferSet	g_sf_jpeg_decode.p_api->outputBufferSet(g_sf_jpe\g_de code.p_ctrl, &buffer, size); Read processed data from JPEG codec.
linesDecodedGet	g_sf_jpeg_decode.p_api->linesDecodedGet(g_sf_jpeg_d ecode.p_ctrl, &lines); Obtain number of lines decoded.
horizontalStrideSet	g_sf_jpeg_decode.p_api->horizontalStrideSet(g_sf_jpeg_ decode.p_ctrl, stride); Configure stride value.
imageSubsampleSet	g_sf_jpeg_decode.p_api->imageSubsampleSet(g_sf_jpe g_decode.p_ctrl, h_sub, v_sub); Start the calendar counter.
wait	g_sf_jpeg_decode.p_api->wait(g_sf_jpeg_decode.p_ctrl, timeout); Wait for current operation.
statusGet	g_sf_jpeg_decode.p_api->statusGet(g_sf_jpeg_decode.p _ctrl, &status); Obtain JPEG codec status.
versionGet	g_sf_jpeg_decode.p_api->versionGet(&version); Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the *SSP User's Manual*, **API References** for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	JPEG Decode driver is successfully opened.
SSP_ERR_ASSERTION	Assertion error.
SSP_ERR_IN_USE	Module already in use.
SSP_ERR_TIMEOUT	The wait operation times out, the underlying driver did not respond in time.
SSP_ERR_WAIT_ABORTED	System internal error occurred.

NOTE: Lower-level drivers may return common error codes. See *SSP User's Manual*, **API References** for the associated module for a definition of all relevant status return values.

4.1.22.3 JPEG Decode Framework Module Operational Overview

The JPEG Decode Framework module implements the standard JPEG decode operation. It takes the data in an input buffer and applies the defined JPEG decode algorithm to the buffer; the output is then delivered to the defined output buffer location. A wait API function can be used to suspend/resume the thread for synchronization with JPEG hardware supported events.

JPEG Decode Framework Module Important Operational Notes and Limitations

- Start decoding JPEG-encoded data by calling the open API. To open the module, use the JPEG Decode Framework module instance, that includes the API function pointer, the pointer to the control block and static configuration that is generated through the Synergy Project configurator in the e^2 studio for ISDE.
- Stop the JPEG Decode Framework module by calling the close API.
- An input buffer-streaming mode is available when an input-centric function is needed.
- An output buffer-streaming mode is available when an output-centric function is needed.
- Supports RGB565 and ARGBB888 output data-color formats.
- The JPEG Decode Framework module has a status flag in the control block; you can get the current status of the module through statusGet API. The status is also reported through a user-callback function when specific events occur in the module.
- The JPEG Decode Framework module supports buffer-streaming mode for the input buffer in cases when the input buffer is smaller than the source image size. Set the next input frame as an input buffer every time there is a hardware-generated INPUT_PAUSE interrupt.
- The JPEG Decode Framework module supports buffer-streaming mode for the output buffer in cases when the resultant image is larger than the output buffer-size. Read and store data from the output buffer to make space for upcoming data every time there is a hardware generated OUTPUT_PAUSE interrupt.

- The input and output buffers should be 8-bytes aligned for the JPEG Decode Framework module to be successful. Otherwise, APIs will return error codes that indicate unsuccessful execution.
- The JPEG Framework module does not support JPEG-encode processing.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.22.4 Including the JPEG Decode Framework Module in an Application

This section describes how to include the JPEG Decode Framework module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the *SSP User's Manual* to learn how to manage each of these important steps in creating SSP-based applications.

To add the JPEG Decode Framework module to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the JPEG Decode Framework module is g_sf_jpeg_decode0. This name can be changed in the associated **Properties** window.)

RTC Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_jpeg_decode0 JPEG Framework	Threads	New Stack> Framework> Graphics> JPEG Decode Framework on sf_jpeg_decode

When the JPEG Decode Framework module on sf_jpeg_decode is added to the thread stack as shown in the following figure, the configurator automatically adds the needed lower-level drivers. Any drivers that need additional configuration information will be highlighted in Red. The specific settings required can be viewed by hovering the cursor over the highlighted text or suggested in the highlighted stack frame. For this stack, the reported requirements for the JPEG HAL module are to enable the decompression-interrupt priority and the data-transfer interrupt-priority interrupts.

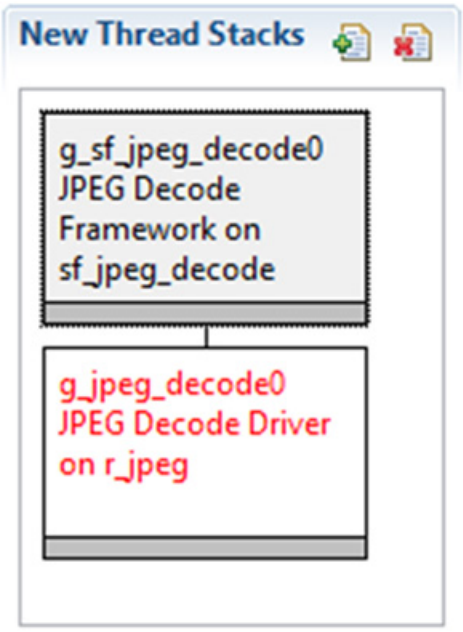

Figure 190: JPEG Decode Framework Module Stack

Decompression Process Interrupt (JEDI)

The JPEG decompression-process interrupt occurs when:

- The current decompression process is successfully completed.
- An error happens in the decompression process.
- Image size and pixel format are successfully read out.

Data Transfer Interrupt (JDTI)

The JPEG data-transfer interrupt occurs when:

- All the JPEG-coded data has successfully completed.
- The number of output image-data lines specified by linesDecodedGet has been transferred.
- The number of input image-data lines specified by inputBufferSet has been transferred.

4.1.22.5 Configuring the JPEG Decode Framework Module

The JPEG Decode Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, that must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a 'lock' icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the **Properties** tab within the SSP Configurator and are shown in the following tables for easy reference.

NOTE: You may want to open your ISDE and create the JPEG Decode Framework and explore the property settings in parallel with looking over the configuration table settings in the following table. This will help orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration for the JPEG HAL Module on r_jpeg

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Enable or disable the parameter error checking.
Name	g_jpeg_decode0	The name to be used for a JPEG Decode module instance.
Byte Order for Input Data Format	Normal byte order (1)(2)(3)(4)(5)(6)(7)(8), Byte Swap (2)(1)(4)(3)(6)(5)(8)(7), Word Swap (3)(4)(1)(2)(7)(8)(5)(6), Word-Byte Swap (4)(3)(2)(1)(8)(7)(6)(5), Longword Swap (5)(6)(7)(8)(1)(2)(3)(4), Longword-Byte Swap (6)(5)(8)(7)(2)(1)(4)(3), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2) (Default: Normal Byte order)	Specify the byte order for input data. The order is swapped as specified in every 8-byte.
Byte Order for Output Data Format	Normal byte order (1)(2)(3)(4)(5)(6)(7)(8), Byte Swap (2)(1)(4)(3)(6)(5)(8)(7), Word Swap (3)(4)(1)(2)(7)(8)(5)(6), Word-Byte Swap (4)(3)(2)(1)(8)(7)(6)(5), Longword Swap (5)(6)(7)(8)(1)(2)(3)(4), Longword-Byte Swap (6)(5)(8)(7)(2)(1)(4)(3), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2) (Default: Normal Byte order)	Specify the byte order for output data. The order is swapped as specified in every 8-byte.
Output Data Color Format	Pixel Data RGB565 format, Pixel Data ARGBB888 format (Default: Pixel Data RGB565 format)	Specify the output data format.

ISDE Property	Value	Description
Alpha value to be applied to decoded pixel data (only valid for ARGB8888 format)	255	Specify the alpha value for the output data format (only valid for ARGB8888 format).
Name of user callback function	NULL	Specify the name of user callback function.
Decompression Interrupt Priority	Priority 0 (highest), 1,2,3,4,5,6,7,8,9,10,11,12,13,14,15 (lowest, not valid if using Thread X), Disabled (Default: Disabled)	JPEG JEDI Interrupt selection
Data Transfer Interrupt priority	Priority 0 (highest), 1,2,3,4,5,6,7,8,9,10,11,12,13,14,15 (lowest, not valid if using Thread X), Disabled (Default: Disabled)	JPEG JDTI Interrupt selection

JPEG Decode Framework Module Clock Configuration

The JPEG Framework module uses the peripheral module clock A (PCLKA) to run the internal logic.

JPEG Decode Framework Module Interrupt Configuration

To enable interrupts, set the priority of the decompression interrupt and the data-transfer interrupt in the Properties window of the JPEG Decode Framework module in the ISDE.

JPEG Decode Framework Module Pin Configuration

The JPEG Decode Framework module does not use any pins.

4.1.22.6 Using the JPEG Decode Framework Module in an Application

The typical steps in using the JPEG Decode Framework module in an application are:

1) Initialize the JPEG Decode peripheral using the open API.
2) Set Image Subsample using the imageSubSampleSet API.
3) Set Horizontal stride using the horizontalStrideSet API.
4) Set output buffer using the outputBufferSet API.
5) Set Input buffer using the inputBufferSet API.
6) Wait for decode to complete with the wait API.
7) Check decode status with the statusGet API.
8) Close the instance with the close API (if needed).

These common steps are illustrated in a typical operational flow diagram in the following figure:

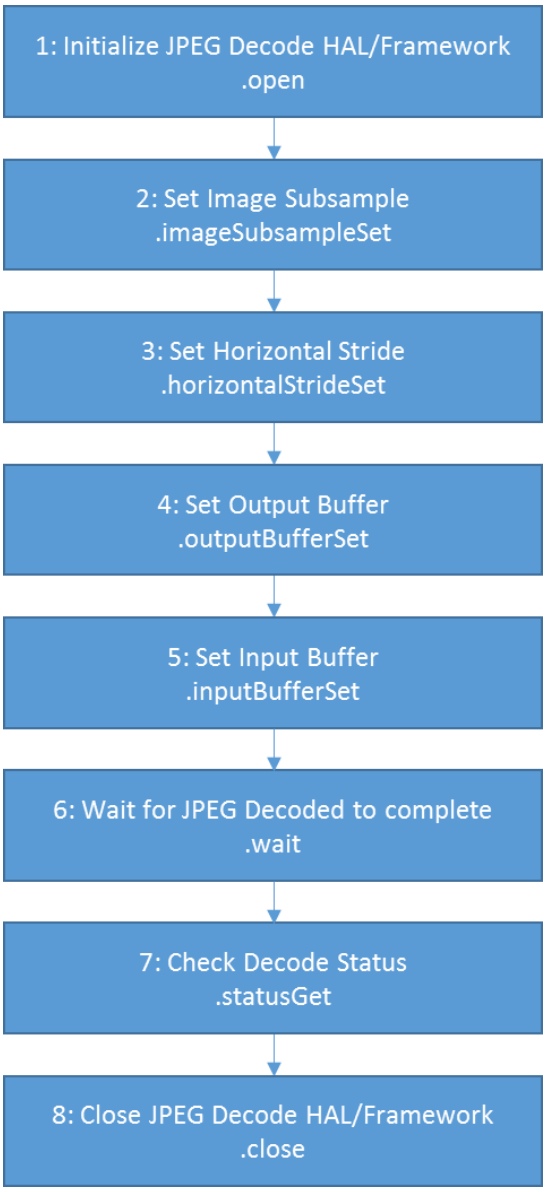

Figure 191: Flow Diagram of a Typical JPEG HAL/Framework Module ApplicationS

4.1.23 Messaging Framework

The Messaging Framework module is implemented on sf_message and provides a lightweight and event-driven framework API for passing messages between threads. The Messaging Framework module allows applications to communicate messages between two or more threads. The framework uses the ThreadX® message-queue primitive for message passing and provides more benefits than the ThreadX RTOS message-queue services alone. The Messaging Framework API is purely a software API and does not access any hardware peripherals. The Messaging Framework

callback is used to allow an event-producer thread and a message-subscriber thread to handshake after the message passing is done.

You can use the messaging tab to either create your own custom event classes, events, and subscribers for the Messaging Framework module or to customize preconfigured events such as the touch event used by the Touch Panel Framework module.

4.1.23.1 Messaging Framework Module Features

The Messaging Framework module supports the following functions:

- Inter-Thread Communication - The framework allows application threads which control disparate devices or manage subsystems to communicate with each other.
- Publishing/Subscribe scheme - The framework design is based on the loosely-coupled messaging paradigm. The design allows multiple threads to listen to an event class. The message producer thread does not need to know who is subscribing to a message for the event class. Subscribers do not need to know who produces the message.
- Message management - The framework supports buffer control blocks to manage each message including flags to control the buffer and a callback function pointer for handshaking.
- Message buffering - The framework manages buffer allocation and release for messaging. An application can make use of the allocated buffer to write a message and discard the message if it is no longer needed.
- Synchronous communication - The framework supports asynchronous messaging by using the ThreadX message-queue but also provides an option to create a handshake between a message producer and a subscriber thread. The handshake is implemented by invoking a user-callback function of the producer thread from a subscriber thread.
- Message formatting - The framework provides a predefined common message header. It also provides some typical payload structure templates as examples.
- Message Priority - The framework can send a high-priority message so that a subscriber thread can retrieve the message prior to other messages which are located in the message queue.

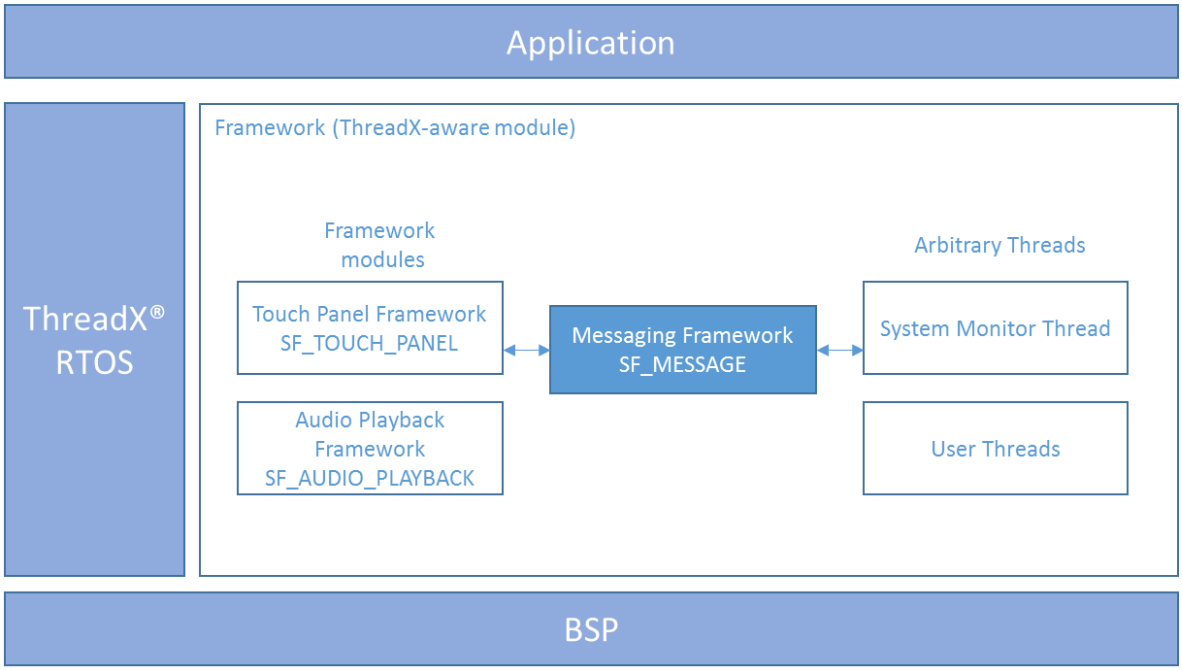

Figure 192: Messaging Framework Module Organization and Use Example

4.1.23.2 Messaging Framework Module APIs Overview

The Messaging Framework module defines APIs for opening and closing the framework, acquiring and releasing buffers, and posting messages to subscribers. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows.

Messaging Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_message.p_api->open (g_sf_message.p_ctrl, g_sf_message.p_cfg); Initialize message framework. Initiate the messaging framework control block, configure the work memory corresponding to the configuration parameters.
close	g_sf_message.p_api->close (g_sf_message.p_ctrl); Finalize message framework.

Function Name	Example API Call and Description
bufferAcquire	g_sf_message.p_api->bufferAcquire (g_sf_message.p_ctrl, &p_buffer, &acquire_cfg, wait_option); Acquire buffer for message passing from the block.
bufferRelease	g_sf_message.p_api->bufferRelease (g_sf_message.p_ctrl, &p_buffer, option); Release buffer obtained from bufferAcquire.
post	g_sf_message.p_api->post (g_sf_message.p_ctrl, (sf_message_header_t *) p_payload, &post_cfg, &err_post, wait_option); Post message to the subscribers.
pend	g_sf_message.p_api->pend (g_sf_message.p_ctrl, &my_queue, &p_buffer, wait_option); Pend message.
versionGet	g_sf_message.p_api->versionGet (&version); Retrieve the API version with the version pointer.

NOTE: For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the *SSP User's Manual***API References** for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API call successful.
SSP_ERR_ASSERTION	Required pointer is NULL.
SSP_ERR_BUFFER_RELEASED	The buffer is released.
SSP_ERR_ILLEGAL_SUBSCRIBER_LISTS	Message subscriber lists is illegal.

Name	Description
SSP_ERR_IN_USE	The messaging framework is in use.
SSP_ERR_INTERNAL	OS service call fails.
SSP_ERR_INVALID_MSG_BUFFER_SIZE	Message buffer size is invalid.
SSP_ERR_INVALID_WORKBUFFER_SIZE	Invalid work buffer size.
SSP_ERR_MESSAGE_QUEUE_EMPTY	Queue is empty. (Timeout occurs before receiving a message if timeout option is specified.)
SSP_ERR_MESSAGE_QUEUE_FULL	Queue is full. (Timeout occurs before sending a message if timeout option is specified.)
SSP_ERR_NO_MORE_BUFFER	No more buffer found in the memory block pool.
SSP_ERR_NO_SUBSCRIBER_FOUND	No subscriber found.
SSP_ERR_NOT_OPEN	Message framework module has yet to be opened.
SSP_ERR_TIMEOUT	OS service call returns timeout.
SSP_ERR_TOO_MANY_BUFFERS	Too many message buffers.

NOTE: Lower-level drivers may return common error codes. Refer to the *SSP User's Manual***API References** for the associated module for a definition of all relevant status return values.

4.1.23.3 Messaging Framework Module Operational Overview

The following figure shows the overview of the messaging data flow between a message producer thread and subscriber thread(s) in the system making use of the Messaging Framework module.

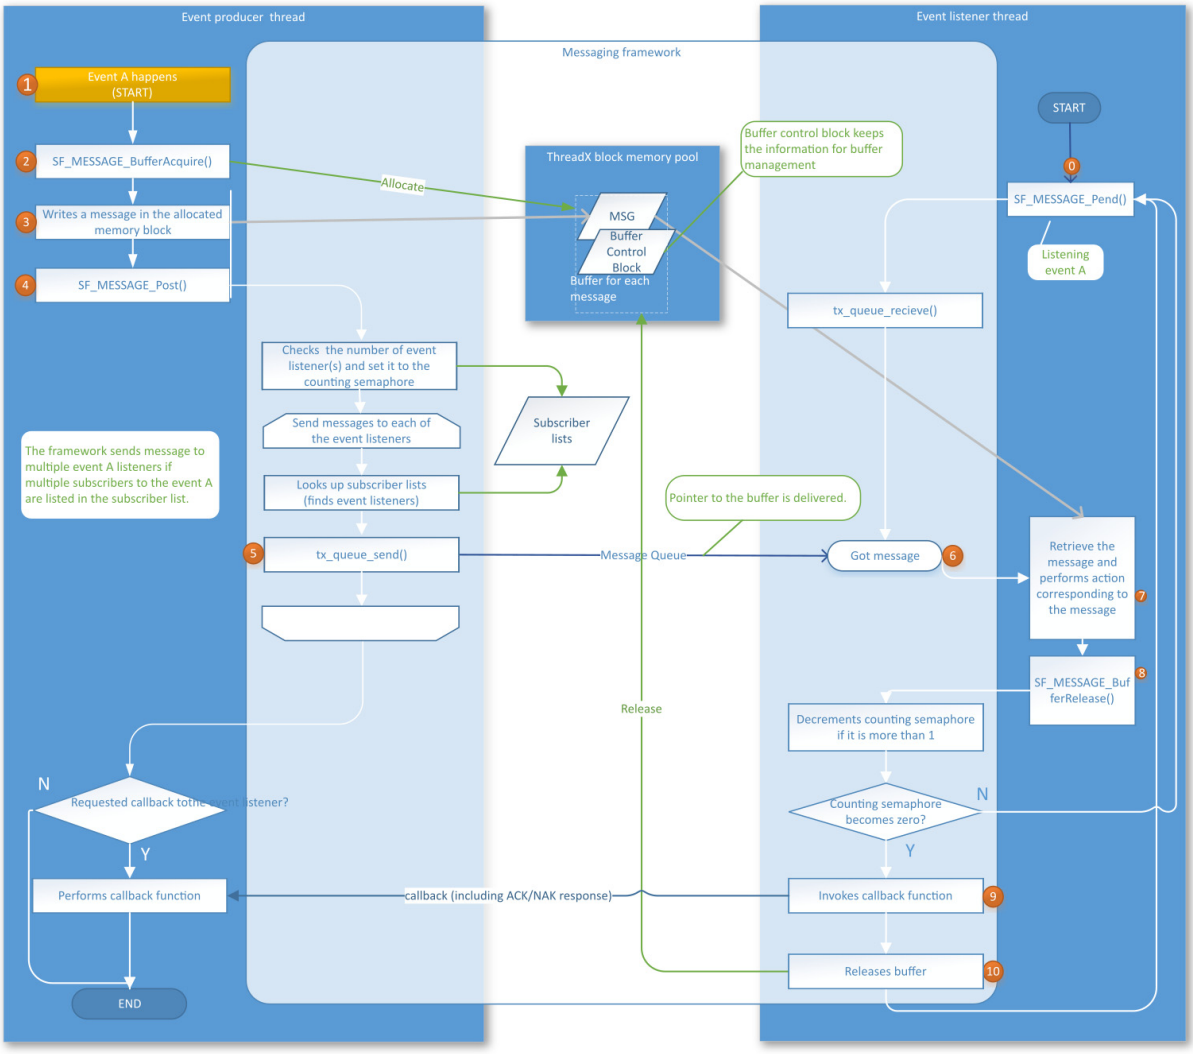

Figure 193: Messaging Framework - Data Flow

The following is a description for each stage of the message passing procedure:

NOTE: A thread in the system has been called using the open API and message subscriber threads have called the pend API to pend on a message for the event class.

1) An event (Event A) happens on a message producer thread.
2) A message producer thread calls bufferAcquire to acquire a buffer from the ThreadX memory pool managed by the Messaging Framework module; bufferAcquire returns the address of allocated buffer.
3) A message producer writes the message to the allocated buffer.
4) A message producer calls post to post the message.
5) The Messaging Framework module looks up the event subscriber list and sends a message to the message queue of the message subscriber threads using the ThreadX message-queue primitive. The framework just sends the pointer to the buffer but does not send the entire message, thereby performing lightweight message passing.
6) The message reaches the message queue of the message subscriber threads and the message subscriber threads return from pend. The API function returns the buffer address where the message is stored to message subscriber threads.
7) The message subscriber threads receive the message and perform an action corresponding to the event.
8) The message subscriber threads call bufferRelease to try to release the allocated buffer for the message. If the message subscriber thread is not the last one subscribing to the message, the framework does not release the buffer as the message has to be kept in the buffer until all subscribers have received the message.
9) The Messaging Framework module invokes a user-callback function which is specified by an event producer thread if the message subscriber thread is the last one in the message subscriber group.
10) The Messaging Framework module releases the buffer if the message subscriber thread is the last one in the message subscriber group. (There is an option 'SF_MESSAGE_ACQUIRE_OPTION_KEEP' for not to release the buffer.)

Messaging Framework Module Message Producer and Subscribers

The Message Framework module is an inter-thread messaging system based on the publish/subscribe model. A message is posted with an event class code by an event producer thread. The message subscriber threads can check for pending messages which subscribe to the event class. Subscribers are registered in the subscriber list, which is referred to by the framework. The subscriber list allows the framework to deliver a message to multiple subscribers.

Every thread which joins the Messaging Framework module system network can send a message, and all threads in the network can listen to the message.

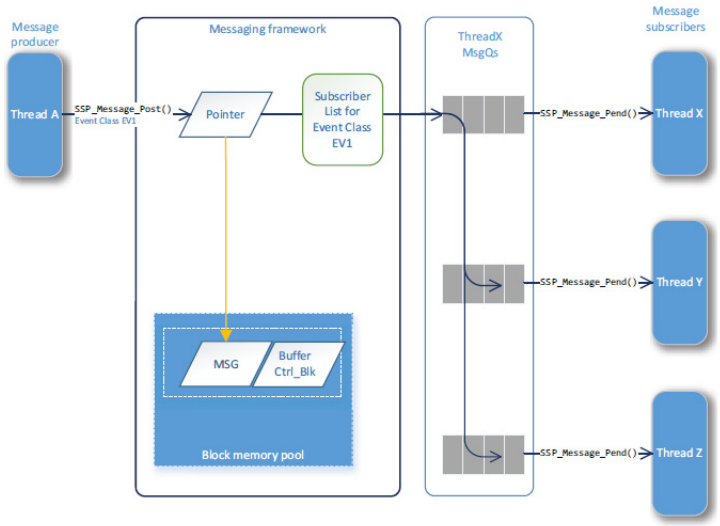

Figure 194: Messaging Framework — Subscribing

Messaging Framework Module Events, Subscribers, and Messages

The event class code is the most important definition for the Messaging module. The Messaging module uses the event class code as the mechanism to connect a message producer with subscribers; the event class code is the class definition of the events which occur in the application. The classification of the event class relies on the user definition, but it is intended to be the group name of the particular events which can occur in a subsystem. For example, you can use the following event classes:

- The 'touch' event class which is part of the touch subsystems. The Touch Event Class is automatically loaded into the event classes' window. This window is available on the **Messaging** tab the Project Configurator when you add the Touch Panel Framework to your Synergy project.
- The 'time' event class is part of the subsystem that manages time-related applications.

The event class code is defined in the sf_message_event_class_t enumeration and has a prefix SF_MESSAGE_EVENT_CLASS_XXX. Since the definition of the event class code is different for each system, the framework does not provide a concrete event class code but instead provides a set of event class codes as examples. (See the Configuring the Messaging Framework Module section.) The maximum number for the event class is 255.

An application can use the event class code as follows:

- The message producer thread sets the event class code to the event_b.class_code bit fields in the sf_message_header_t type common message header before posting the message.
- The message subscriber-thread branches to the event processing corresponding to the event class code which is set to the message header after receiving the message.
- The subscribers for the event class code must be grouped and registered in the subscriber list so that the Message Framework can deliver the message to the subscribers.

The following figure shows how you can configure an event class using the ISDE.

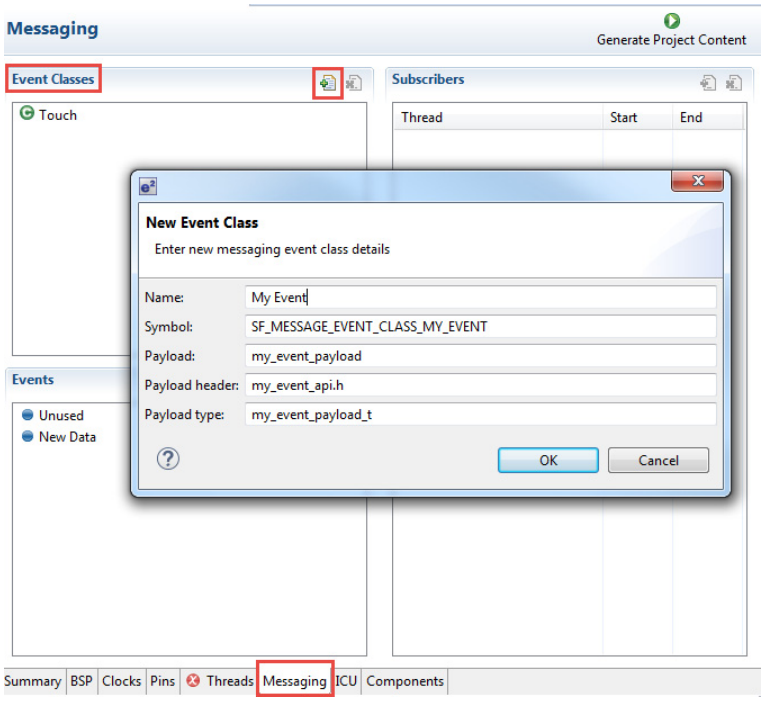

Figure 195: Messaging — ISDE Event Class Configuration

Messaging Framework Module Event Class Instance Number

The event class instance number is used when an application needs to have different event class instances. For example, the audio streaming event class can have instance *N* which represents the streaming channel N. Message subscribers can receive a message only if the event class instance number in the message common header matches to the number it owns.

In other words, messages for which the event class instance number is out of range for the subscriber are filtered out and not delivered to the subscriber even though it is the event class subscriber. The maximum for the event class instance number is 255.

NOTE: The Touch Panel Framework typically only has one instance, and therefore the event class instance number is 0 with the start and end values of the subscriber list set to 0.

An application can use the event class instance number as follows:

- The message producer thread sets the event class instance number to the event_b.class_instance bit fields in the sf_message_header_t type common message header before posting the message.
- Each subscriber instance in the Subscriber List has to specify the range of the event class instance numbers to receive the message (sf_message_subscriber_t:: instance_range.start and sf_message_subscriber_t::instance_range.end).
- If there is no need for multiple instances for an event class, just specify zero to sf_message_header_t::event_b.class_instance, sf_message_subscriber_t::instance_range.start, and sf_message_subscriber_t::instance_range.end in the subscriber instance for the subscriber list.

Messaging Framework Module Event Code

The event code includes the details of the event definition. For instance, the event codes for the audio playback event class are "playback start" and "playback stop." Another example is 'set' or 'get' for the 'time' Event Class. The event code is enumerated in the sf_message_event_t and has a prefix SF_MESSAGE_EVENT_XXX. The definition of the event code relies on the user code as well as the event class code. The framework provides some code as examples. See Configuring the event class code and event code for configuring the event code. The maximum for the event class instance number is 65535.

The Touch Panel Framework uses new data as the only event code.

An application can use the event code as follows:

- The message producer thread sets the event code to the event_b.code bit fields in the sf_message_header_t type common message header before posting the message.
- The message subscriber thread performs an action corresponding to the event code which is set to the message header after receiving the message.

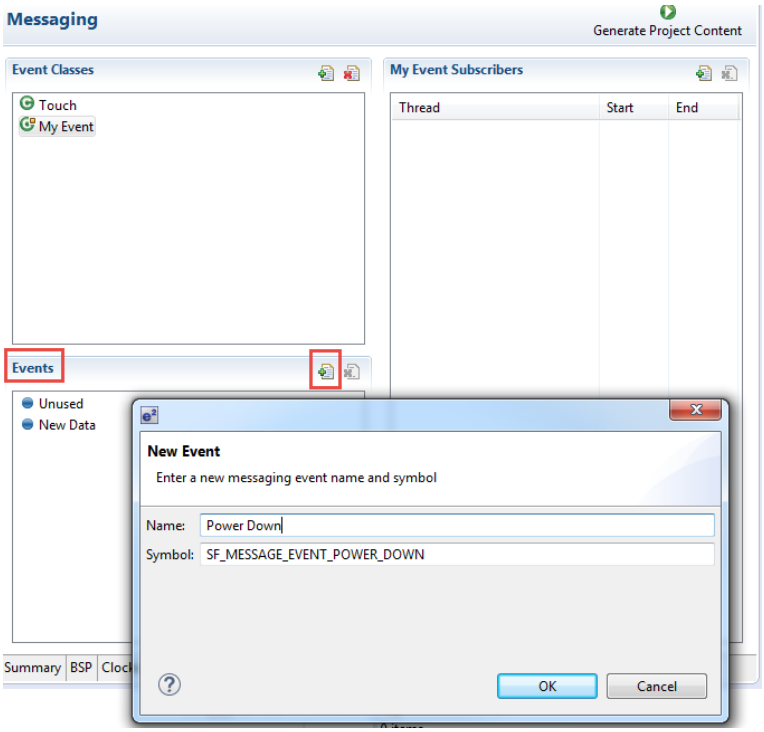

Figure 196: Messaging — ISDE Event Configuration

Messaging Framework Module Subscriber List

The subscriber list is used for message delivery and is looked up by the framework.

The framework starts to look up the message queues of each subscriber thread from the subscriber group listed in the head of the pointer array to the sf_message_subscriber_list_t instance. The important point of the subscriber list is that it is grouped by event class code (event_class).

When the framework looks up the subscriber list in the post API function at runtime, it compares the Event Class code in the message header (sf_message_header_t::event_b.class_code), which is included in the message payload data, with the one in the subscriber group instance (event_class). If there is a match, the Framework goes to the next level to get the message queue instance (sf_message_subscriber_t::queue) until the iterations reach number_of_nodes). If there is no

match, the framework looks up the next subscriber group and continues until encountering a NULL in the pointer array to the sf_message_subscriber_list_t instance.

In the look-up procedure, the subscriber group listed at the head of the Subscriber List gets the highest throughput for messaging, but lower subscriber groups encounter a penalty and get lower throughput for messaging.

The subscriber list is the look-up table for all message subscribers. The subscriber list is configured at compile time. It is statically mapped to the memory and looked up by the framework when the post API function is called. The subscriber list allows the framework to determine message queues to deliver a message to. The subscriber list consists of two structures sf_message_subscriber_list_t and sf_message_subscriber_t as shown in the following figure:

- A queue for a subscriber thread is registered in sf_message_subscriber_t instance.
- The instances above for the same event class code are grouped and listed in a pointer array.
- The pointer array for a subscriber group is registered in a sf_message_subscriber_list_t instance.
- The subscriber list is the pointer array to the subscriber group structures. Subscribers are grouped by the event class code.
- The pointer array must be terminated by NULL.

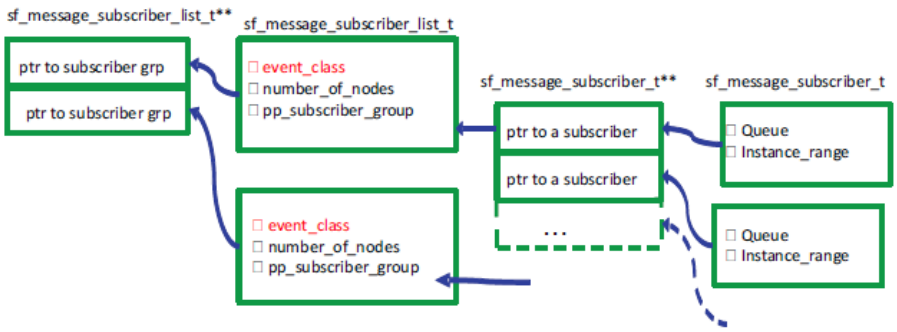

Figure 197: Message Framework — Subscriber List

In the ISDE, you can configure a subscriber grouped by the event class for the thread you named in the **Threads** tab. In the following example, the thread is named "My Thread" in the **Threads** tab. The start and end values reflect the event class instance numbers this thread accepts.

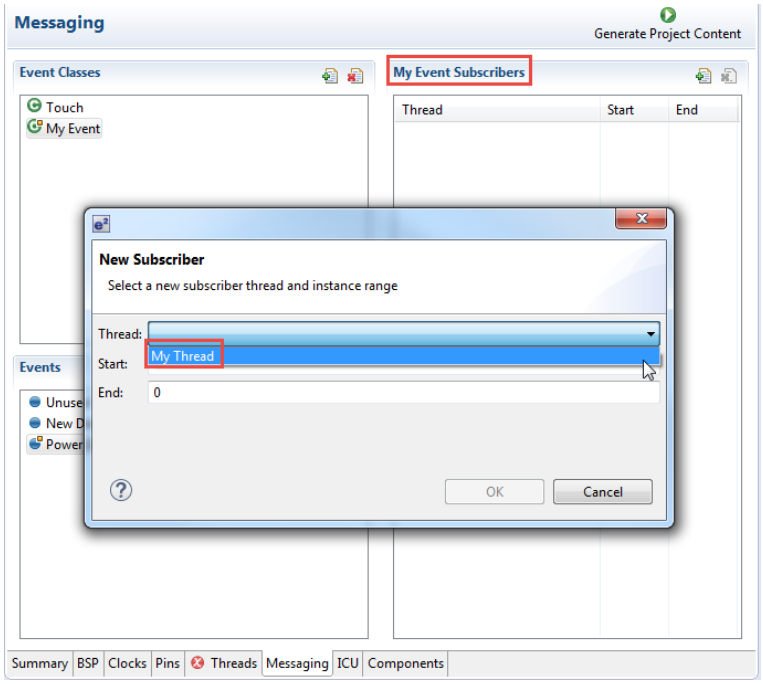

Figure 198: Messaging — ISDE Subscriber Configuration

Messaging Framework Module Message Payload

The message payload is structured data used by the message producer and the message subscribers to communicate with each other. The message payload contains event class and event code in the common header (sf_message_header_t type data, see event class and event code) so that a message producer can post a message to the subscribers to inform the subscribers which event happened.

You must define a system specific message payload structure except for modules for which the SSP provides predefined structures such as the Touch Panel Framework and the audio playback modules. The message payload can contain additional data, which are required for the event processing, in addition to the common header.

The SSP contains the following predefined message payload structures:

- sf_touch_panel_payload_t type for the Touch Panel Framework module
- sf_audio_playback_data_t type for the Audio Playback Framework module

These framework modules use the Messaging Framework internally and define suitable message payload structures. An application thread which subscribes to touch event messages from the Touch Panel Framework module can use the predefined message payload by including the header file sf_touch_panel_api.h. Likewise, an application thread which posts audio event messages to the Audio Playback Framework module can use sf_audio_playback_api.h.

You must define a message payload structure for each event class code; exceptions include the SSP predefined payloads described previously or payloads that require only the common header. To create a new message payload structure, add a common message header (sf_message_header_t type structure) at the head in the user-specific message payload structure. The size of the header is 4 bytes.

NOTE: The payload size must not be greater than the buffer size.

The buffer size limit is critical; oversized data written beyond the buffer may destroy data in the block memory pool, which

is required by ThreadX kernel. Violating the size limit results in a hard fault exception. The buffer size can be configured in sf_message_ctrl_t::buffer_size.

Messaging Framework Module Important Operational Notes and Limitations

Messaging Framework and OS Message Queue Service

The Messaging Framework module uses the ThreadX primitive-message queue and kernel services and supports some enhancement over the ThreadX RTOS features. For this reason, the Messaging Framework module does not work exactly the same as the ThreadX message-queue service. However, a messaging system with the Messaging Framework module can work simultaneously with the ThreadX message queue services in an application if the two messaging systems are separated.

API Calls Contexts

- The open API can only be called from a thread; it can be called only once per the message framework control block instance. The behavior is undefined if the function is called twice.
- The close API can only be called from a thread.
- The bufferAcquire API can be called from a thread and an ISR.
- The bufferRelease API can only be called from a thread.
- The post API can be called from a thread and an ISR.
- The pend API can be called from a thread and an ISR.

Estimating the Number of Buffers

The number of buffers available to be allocated in the work memory should be estimated properly when designing the messaging system. The number of buffers is estimated as follows:

$$N \approx \frac{W_m}{M_b + B_{cb} + T_x} = \frac{W_m}{M_b + 12\ bytes + 4\ bytes}$$

Figure 199: Estimating Buffers Available in Work Memory

where:

N – number of buffers,

Wm – work memory size (in bytes),

Mb – message buffer size (in bytes),

Bcb = 12 bytes – size of buffer control block,

Tx = 4 bytes – reserved bytes for ThreadX.

The maximum number possible for buffers allocated at the same time equals the total amount of depth of message queues in the system. Ideally, the number of buffers for a robust system should be the sum of the depths of the message queues in the system.

Message Queue Size and Depth Setting

The Messaging Framework module needs a 4-byte memory block on the message queue as it delivers the pointer to the buffer which contains a message payload. For this reason, the size of the message queue should be fixed to 4 bytes. A size greater than 4 bytes negatively affects the performance, as the extra memory copy resides in the ThreadX message queue service, which is internally invoked by the Messaging Framework API functions.

The depth of the message queue is arbitrary, but it should accommodate the number of queued messages at runtime. As a guideline, estimate the value as follows:

$$D \approx \frac{P_{avg}}{S_{avg}}$$

Figure 200: Estimating Message Depth Value

where:

D – queue depth,

*P*avg – average message delivery rate from producers,

*S*avg – average event loop completion time in the subscriber.

Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.1.23.4 Including the Messaging Framework Module in an Application

This section describes how to include the Messaging Framework module in an application using the SSP configurator. The Messaging Framework can be used by all threads when added to a single thread.

NOTE: It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the *SSP User's Manual* to learn how to manage each of these important steps in creating SSP-based applications.

To add the Messaging Framework to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Messaging Framework is g_sf_message0. This name can be changed in the associated Properties window.)

Messaging Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_message0 Messaging Framework on sf_message	Threads	New Stack> Framework> Services> Messaging Framework on sf_message

When the Messaging Framework module on sf_message is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information will have box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks.

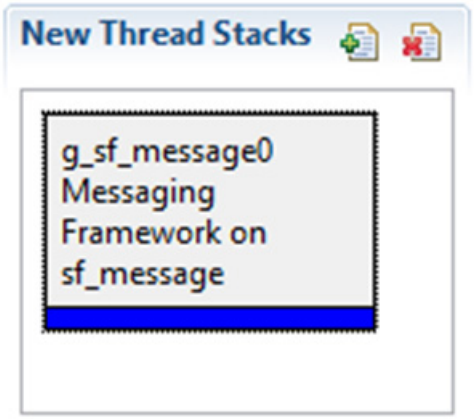

Figure 201: Messaging Framework Module Stack

4.1.23.5 Configuring the Messaging Framework Module

The Messaging Framework module must be configured by you for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules, for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available with the Properties window of the associated module. Simply select the indicated module and then view the Properties window. The interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE and create the module and explore the property settings in parallel with looking over the following configuration table settings. This helps to orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Messaging Framework Module on sf_message

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.

ISDE Property	Value	Description
Message Queue Depth (Total number of messages to be enqueued in a Message Queue)	16	Specify the size of Thread X Message Queue in bytes for Message Subscribers. This value is applied to all the Message Queues.
Name	g_sf_message0	The name of Messaging Framework module control block instance.
Work memory size in bytes	2048	Specify the work memory size in bytes. Choosing a small number results a small number of buffers which can be allocated at the same time (You can confirm the total buffer number on: sf_message_ctrl_t::number_of_buffers). If the value is smaller than the peak number of messages to be posted at the same time, the Framework occurs a buffer allocation failure affecting system performance.
Pointer to subscriber list array	p_subscriber_lists	Specify the name of pointer to the Subscriber List array.
name of the block pool internally used in the messaging framework	sf_msg_blk_pool	The name of memory block memory the Framework creates in the control block. This parameter might be useful for debugging purpose but NULL can be specified for saving memory.

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Messaging Framework Module Creating a Messaging Queue

The messaging configurator automatically creates the message queue for the subscribers.

Messaging Framework Module Configuring an Event Class and Event

To use the Messaging Framework with your own event class, use the **Threads** tab and the **Messaging** tab of the project configurator in the ISDE.

In the **Threads** tab, do the following:

1) Add a new thread in the **Threads** window and give it a unique name.
2) Add the **Messaging Framewor** component in the **Thread Stacks** panel of the **Threads** window.
3) In the **Messaging** tab (see event class code), do the following:A. In the **Event Class** window, add a class event.B. Enter the name of the event class for your thread to subscribe to in the **New Event** Class dialog box.

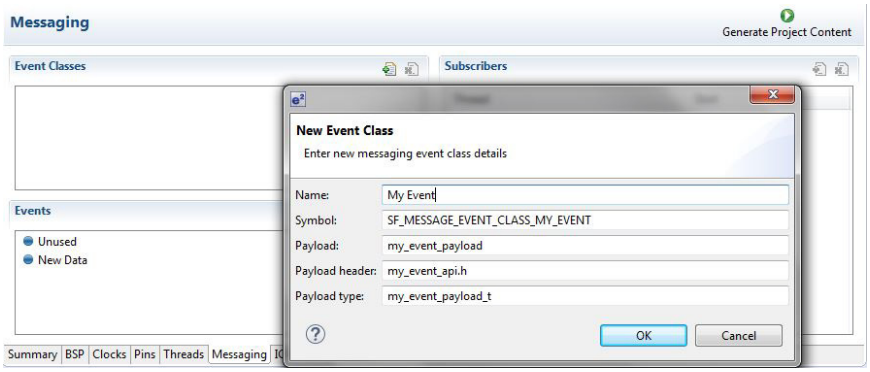

Figure 202: Messaging — e² studio New Event Class Configuration

4) In the **Events** window, add any events that your application may support (see event code).

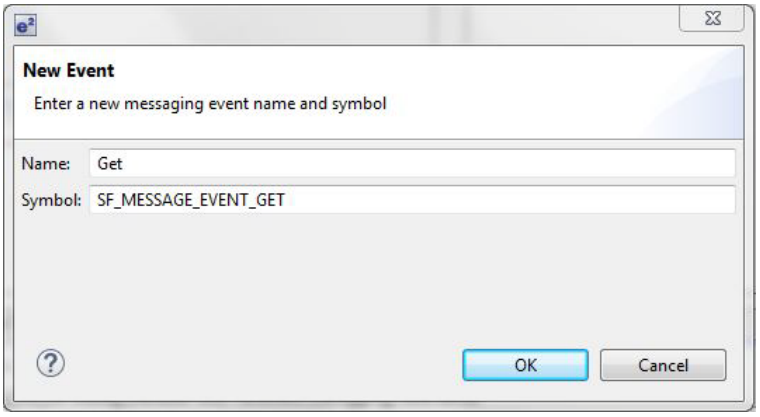

Figure 203: Messaging – e² studio New Event Configuration

Your custom event class code and event code are stored in a file named sf_message_port.h. The audio playback and the touch event classes are two predefined event classes in the SSP. The Touch Event Class only uses the new data event, SF_MESSAGE_EVENT_NEW_DATA.

Messaging Framework Module Configuring the Subscriber List

In the **Messaging** tab (see also Subscriber List), do the following:

1) Select the event class in the **Event Classes** window and configure a thread for the subscriber list in the event class **Subscribers** window.
2) Select your thread from the drop-down list in the **Threads** dialog box.
3) Next to start, enter the start number of the event class instance(s). If your system does not use multiple event class instances for the event class, or you are not sure what number to specify, just keep the default number (0.) Allowed values range from 0 to 255.

4) Next to End, enter the last number of the event class instance(s). If your system does not use multiple event class instances for the event class, or you are not sure what number to specify, just keep the default number (0.) Allowed values range from 0 to 255.
5) Click OK. A subscriber for your specified event is added in the subscriber list.
6) Repeat these steps for all event class instances if there are more than one.

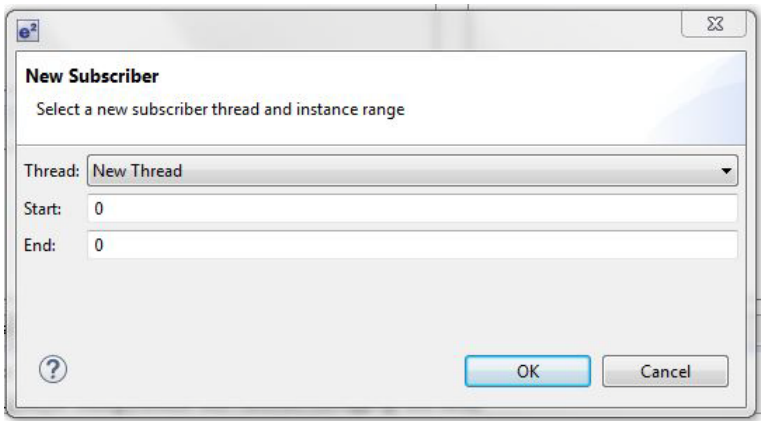

Figure 204: Messaging — e² studio New Subscriber Configuration

Messaging Framework Module Configuring the Event Class Code and Event Code

You can define your own message payload structure. Every user-defined message structure must include the sf_message_header_t type structure as one of the members, but the other members are entirely user-definable. The Messaging Framework does not care where the message payload structures are defined. You can include the file which defines your own message payload structure in the source file for your message producer and subscriber threads.

Configure the sf_message_cfg_t type configuration parameters to match your system. You can generate code for the configuration structure through the Synergy Configuration tool. Add a Messaging Framework component to the thread stacks in the **Threads** tab and modify the properties for the Messaging Framework module in the Properties window. When you press the **Generate Project Content** button, the code for the Messaging Framework module is generated on the thread code.

Before posting a message, an event producer thread must acquire a buffer for the message from the Messaging Framework module. An event producer thread can acquire the buffer by calling bufferAcquire.

When the API function returns SSP_SUCCESS, the buffer with message buffer size in bytes configured on Synergy Configuration tool is allocated in the memory pool managed by the Messaging Framework. The maximum number allowed to be allocated depends on the configuration **Work memory size in bytes** specified on the Synergy Configuration tool. For the estimation of the maximum number, see Estimating the Number of Buffers.

The bufferAcquire API has several options to change the message passing behavior:

- **buffer keep:** This option allows the application thread to hold the buffer not to be released by the API function bufferRelease if set to true. Typically, the buffer is to be released by bufferRelease when the message passing is done; however, in a scenario to have periodical or repeated message passing between threads, we can reuse the same buffer for the messaging without allocating and releasing the buffer each time. Enabling this option reduces the overhead in the buffer allocation/release operation and improve the system throughput.
- **wait_options:** This is the wait time option which is valid if all buffers have been acquired. Any arbitrary thread tick count, TX_WAIT_FOREVER, TX_NO_WAIT can be set for this option.

After message subscriber threads receive a message posted by an event producer, the message subscriber threads must release the buffer to the framework. Buffer releasing is performed by calling bufferRelease. Since the API function can be called multiple times if there are multiple event subscribers in the system, the actual buffer release is performed only by the last message subscriber thread in the event subscribers. For instance, if there were three subscribers in the subscriber group for the event class, the first and second thread which call bufferRelease do not release the buffer. Only the third thread releases the buffer. Note, if the**buffer keep** option is specified by bufferAcquire, the buffer is never being released except when option SF_MESSAGE_RELEASE_OPTION_FORCED_RELEASE is passed to the API function argument option. (Also see Messaging Framework callbacks for bufferRelease API function usage.)

The API is also used for invoking a user-callback function to create a handshake between an event producer thread and a message subscriber thread.

Posting a message

1) After getting a buffer by bufferAcquire, an event producer can write the message payload data to the buffer location.
2) **ATTENTION:** Writing data to the buffer is the user's responsibility and writing more data than the buffer size causes a fatal error in the Messaging Framework module.
3) Write an event class code to the sf_message_header_t::event_b.class_code in the payload structure.
4) Write an event code to the sf_message_header_t::event_b.code in the payload structure. It is not mandatory to specify this but necessary in most cases.
5) Write an event class instance number to sf_message_header_t::event_b.class_instance. Specify a number from 0 to 255 if your system has multiple instances for an event class. Specify 0 if your system simply uses single event class instance.
6) Post the message by the post API. Note that the pointer to the buffer needs to be casted with sf_message_header_t * type when given to the API. The message will be delivered to the message subscribers which are registered in the message subscriber list. The post API has several options to change the message passing behavior.
    - **Message priority:** Message can take two level message priority, SF_MESSAGE_PRIORITY_NORMAL or SF_MESSAGE_PRIORITY_HIGH. When SF_MESSAGE_PRIORITY_HIGH is specified, the message is queued at the front of the message queue of the message subscriber. This is typically used for the emergency message to make the message subscribers handle the event prior to the events which might have been queued in the message queue.
    - **User-callback function:** This function is registered in the buffer control block of the Messaging Framework module. The callback function is invoked by bufferRelease. This function can be used for handshaking between an event producer thread and a message subscriber thread.
    - **Wait_options:** This is the wait time option which is valid if a message queue of the message subscriber thread is full. Any arbitrary ThreadX tick count, TX_WAIT_FOREVER and TX_NO_WAIT can be set to this option.

Checking for a Pending Message

1) After the Messaging Framework module is opened, the message subscriber threads can wait for a message by calling pend. In general use, the second API argument specifies the pointer to a message queue, which you configured for the message subscriber thread in the Thread Subscribers pane in the **Messaging** tab, but you can specify the other message queues instead if required.
2) When a message is delivered from an event producer, the thread returns from pend.
3) The API returns the pointer to the buffer which contains the message to the thread through the third argument of the API.

4) The message subscriber casts the pointer above with a pointer type for the user custom message payload structure and does the event processing corresponding to the Event Class code sf_message_header_t::event_b.class_code, Event code sf_message_header_t::event_b.code and the user defined arbitrary data in the message.

NOTE: Pend has the wait_option to change the behavior of the API function:

The fourth argument of **pend** is the wait time option, which is only valid if the message queue of the message subscriber thread is empty. Any arbitrary ThreadX tick count, TX_WAIT_FOREVER, and TX_NO_WAIT can be set to this option. For details, see tx_queue_receive() ThreadX service call in the ThreadX User Guide.

Messaging Framework Module Interrupts

The Messaging Framework module does not use any interrupts.

4.1.23.6 Using the Messaging Framework Module in an Application

The typical steps in using the Messaging Framework module in an application are to first configure all the required settings as follows:

- Create a Message Queue
- Configure the Event Class and Event
- Configure the Subscriber List
- Configure the Event Class Code and Event Code

Once configuration is complete, the module's APIs can be used in the target application as follows:

1) Initialize the Messaging Framework with the open API
2) Acquire a buffer with the bufferAcquire API
3) Post a message with the post API
4) Check for a pending message with the pend API
5) Release a buffer using the bufferRelease API
6) Close the Messaging Framework with the close API

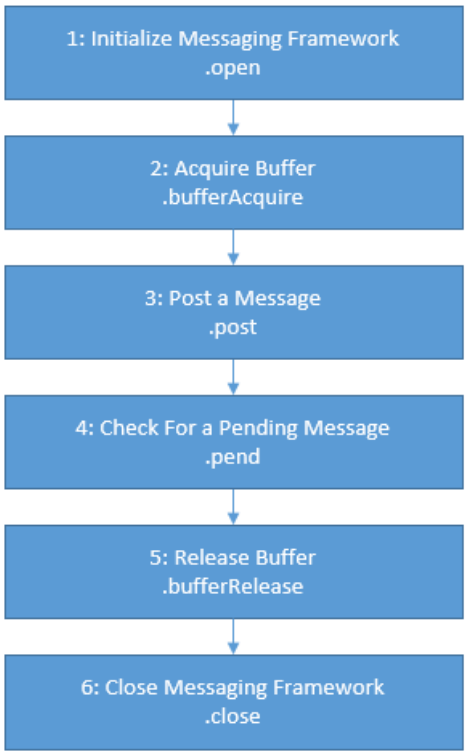

Figure 205: Flow Diagram of a Typical Messaging Framework Module Application

4.1.24 Power Profiles Framework

The Power Profiles Framework provides high-level APIs that can be configured to allow the MCU to be placed in lower power Software Standby mode. The module is implemented on sf_power_profiles.

This module is marked as [DEPRECATED]. We highly recommend that it not be used for development. The module is provided in this release only for backward compatibility with existing projects, which were developed with previous SSP releases. For all new projects we highly recommend the use of the replacement module, Power Profiles V2, since it is expected to be supported in future releases.

This document is divided into the following sections which can be read independently by a more experienced Synergy developer or in series by developers new to the Synergy Platform.

Power Profiles Framework Module Features

- Supports Software Standby operations
- Supports multiple operating modes
  - Run
  - RTC
  - External Interrupt
- Selects clocks and peripherals to disable during Software Standby

- Selects output pin state prior to and after exiting Software Standby

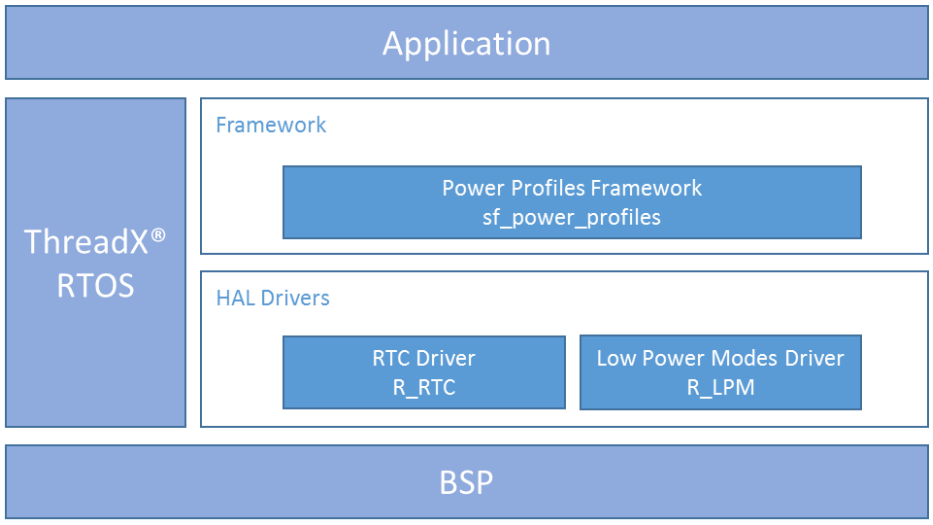

Figure 206: Power Profiles Organization, Options, and Stack Implementations

4.1.24.1 Power Profiles Framework Module APIs Overview

The Power Profiles section defines APIs for common functions such as open, sleep, and close. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values is also provided.

Power Profiles Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_power_profiles0.p_api->open(g_sf_power_profiles0 .p_ctrl, g_sf_power_profiles0.p_cfg); Initialize the Power Profiles Framework.
sleep	g_sf_power_profiles0.p_api->sleep(g_sf_power_profiles0 .p_ctrl); Places the MCU in software standby mode.
close	g_sf_power_profiles0.p_api->close(g_sf_power_profiles0 .p_ctrl); Close the PowerProfiles Framework.

Function Name	Example API Call and Description
versionGet	g_sf_power_profiles0.p_api->versionGet(&p_version); Get version and store it in provided pointer p_version.

NOTE: For more detailed descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables review the SSP Users Manuals API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_ASSERTION	Assertion error.
SSP_ERR_IN_USE	The framework has already been initialized.
SSP_ERR_INVALID_HW_CONDITION	Incompatible system clock configuration.
SSP_ERR_NOT_OPEN	Device not open.
SSP_ERR_UNSUPPORTED	The function is not supported by the module.
SSP_ERR_INTERNAL	Internal error.

NOTE: Lower level drivers may return Common Error Codes. Refer to the API Reference section for the associated module for a definition of all relevant status return values.

4.1.24.2 Power Profiles Framework Module Operational Overview

The Power Profile Framework uses the RTC, LPM, IOPORT and CGC peripherals on the Synergy microcontroller hardware and provides an easy-to-use software interface to access the low power operating modes. The Power Profiles Framework configures the system such that it enters and exits Software Standby mode in a predefined state. You can use the Power Profiles framework in both a threaded and non-threaded environment.

The Power Profiles module works as follows: the initial configuration, provided by the user determines the operating mode (RTC or External interrupt). In the Power Profiles module, you can define two pin configuration tables (Software Standby and wakeup). The configuration tables define the state of the MCU port pins while in Software Standby mode and subsequent to wake up. Both tables can be generated by using a bsp_pin_cfg.h file as a base and modifying the entries accordingly, including the name of the table.

Pointers to those tables are provided on the Power Profiles properties for Wakeup and Software Standby pin configuration. It is not a requirement to define the pin configuration tables. Providing NULL for one or both of these pointers prevents any pin re-configuration for the respective Sleep/Wake state.

Power Profiles Framework Module Operational Notes

With the Power Profiles Framework, you can place the MCU in Software Standby mode where it uses very low power while still retaining all the RAM and operating parameters. External Interrupt mode is the mode using the least amount of power, primarily because the RTC and both of its possible clock sources (LOCO or Sub-clock) are off.

In RTC mode, the RTC is allowed to run and as a result uses more power. Any peripherals or clocks that the MCU normally allows to remain operating in Software Standby mode are turned off by the Power Profiles module before entering Software Standby mode and subsequently restored upon waking up.

If you need a different operation outside of this behavior (for example, keeping LOCO running during Software Standby), you can configure this behavior by using either the SF_POWER_PROFILES_EVENT_PRE_SLEEP or SF_POWER_PROFILES_EVENT_POST_SLEEP callback events to include this specific behavior.

NOTE: The Power Profiles module does not enable wake up by numbered IRQs (IRQ0-IRQ15...), so extra work is required. To wake the MCU using a numbered IRQ, the application must use the r_lpm API functions wupenGet and wupenSet to enable wake up from standby mode by a numbered IRQ.

Power Profiles Framework Supported Operating Systems

When used with ThreadX, this framework uses ThreadX intrinsic objects like mutexes. Operation with ThreadX is optional.

Entering and Exiting Sleep Mode

The following block diagram illustrates the process flow for entering Sleep (Software Standby) mode.

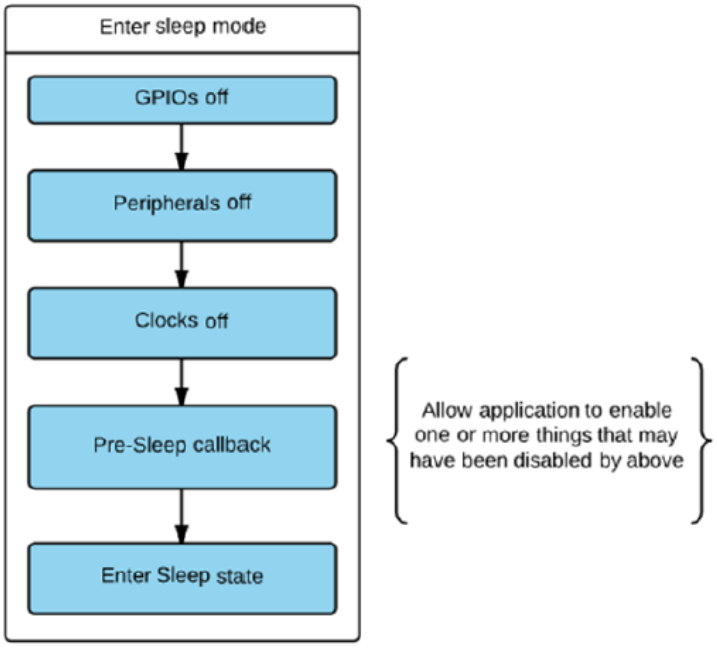

Figure 207: Entering Sleep Mode

The following block diagram illustrates the process flow for waking from Sleep (Software Standby) mode.

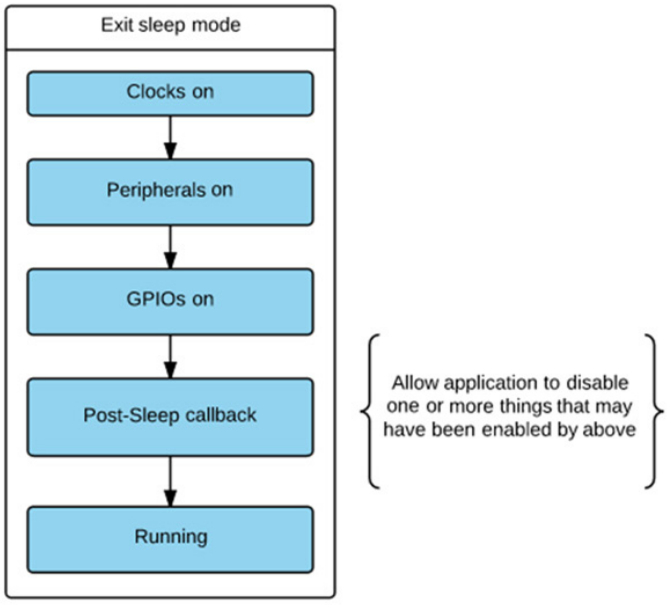

Figure 208: Exiting Sleep Mode

Power Profiles Framework Module Limitations

The Power Profiles Framework does not currently support any sleep mode other than Software Standby.

SF_POWER_PROFILES framework is superseded by SF_POWER_PROFILES_V2 framework. Projects that use SF_POWER_PROFILES can continue to do so, however it is recommended to update to SF_POWER_PROFILES_V2. Any new projects should be using SF_POWER_PROFILES_V2 instead of SF_POWER_PROFILES. SF_POWER_PROFILES has to be used with R_LPM whereas SF_POWER_PROFILES_V2 has to be used with R_LPM_V2. See the SF_POWER_PROFILES V2 usage notes for differences and features.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.24.3 Including the Power Profiles Framework Module in an Application

This section describes how to include the Power Profiles in an application using the SSP configurator.

NOTE: This section assumes that you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP based applications.

To add the Power Profiles framework module to an application, simply add it to a thread using the Stacks Selection Sequence given in the following table. (The default name for the Power Profiles is g_sf_touch_button0. This name can be changed in the associated **Properties** window.)

Power Profiles Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_power_profiles0 Power Profiles Framework on sf_power_profiles	**Threads**	**New Stack > Framework > Services > Power Profiles Framework on sf_power_profiles**

When the Power Profiles Framework module on sf_power_profiles is added to the thread stack as shown in the figure below, the configurator automatically adds any needed lower level modules. Any drivers that need additional configuration information will have a text box highlighted in Red. Modules with a Gray band are individual modules that stand alone.

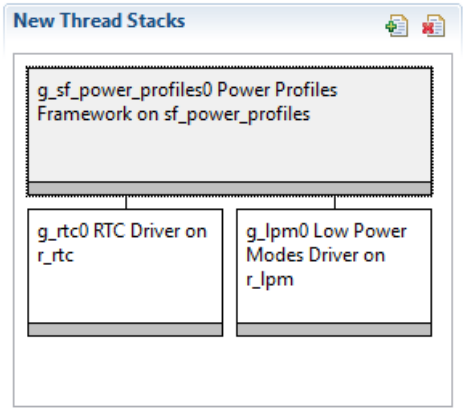

Figure 209: Power Profiles Framework Module Stack

4.1.24.4 Configuring the Power Profiles Framework Module

You must configure the Power Profiles module for the desired operation. The SSP configuration window automatically identifies any required configuration selections, such as Interrupts or operating modes, which must be configured for lower level modules, for successful operation, by highlighting the block in red. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the **Properties** tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority. This configuration setting is available with the **Properties** window of the associated module. Simply select the indicated module and then view the **Properties** window. The Interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the Interrupt priorities listed in the **Properties** window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring Interrupt Priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the Configuration Table Settings given below. This will help orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Power Profiles Framework on sf_power_profiles

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Enables or disables the parameter error checking
RTC Support	Disabled, Enabled (Default: Disabled)	Enable or disable RTC support
Name	g_sf_power_profiles0	Module name
Callback	3	User determined based on priority of other threads in system. Recommend high priority.
Wakeup pin config table	NULL	Location of Wake-up pin config table
Sleep pin config table	NULL	Location of Sleep pin config table
Operating mode	Run, RTC, External (Default: Run)	Operating mode

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2. MCU Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower level modules can be desirable. The configurable properties for the lower level stack modules are given in the following sections for completeness, and as a reference.

NOTE: Most of the property settings for lower level modules are fairly intuitive and can usually be determined by the inspection of the associated properties window from the SSP configurator.

Configuration Settings for the Power Profiles Framework Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers and these are indicated with red text in the Thread Stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The table below identifies all the settings within the properties section for the module.

Configuration Settings for the RTC Driver on r_rtc

ISDE Property	Value	Description
Parameter Checking Enable	BSP, Enabled, Disabled (Default: BSP)	Enable or disable the parameter error checking
Name	r_rtc0	Name for the module
Clock Source	Sub Clock, LOCO, (Default: LOCO)	Select clock source for RTC module
Error Adjustment Value [DEPRECATED]	0	Select error adjustment value
Error Adjustment Type [DEPRECATED]	None	Select adjustment type
Callback	NULL	Callback name
Alarm Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) (Default: Disabled)	Set priority level for alarm event
Period Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) (Default: Disabled)	Set priority level for period event

ISDE Property	Value	Description
Carry Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) (Default: Disabled)	Set priority level for carry event

Configuration Settings for the Low Power Modes Driver on r_lpm

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Selects if code for parameter checking is to be included in the build
Name	g_lpm0	Module name
Operating power mode	High speed operating mode, Middle speed operating mode, Low speed operating mode, low voltage operating mode (Default: High speed operating mode)	Select operating mode
Sub oscillator mode	Sub oscillator mode not enabled, Sub oscillator mode enabled (Default: Sub oscillator mode not enabled)	Select sub oscillator mode

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Power Profiles Framework Module Clock Configuration

The Power Profiles framework does not require any specific clock settings.

Power Profiles Framework Module Pin Configuration

The application may optionally provide Software Standby and wakeup pin configuration tables to be used in setting the port pin states before entering Software Standby and after waking from Software Standby.

4.1.24.5 Using the Power Profiles Framework Module in an Application

Once you configure the modules and the ISDE has generated the files, follow the steps below to use the Power Profiles framework in a thread. Optionally, you can use the Power Profiles in a standalone (non-thread) application.

Define the body of the callback function configured the Power Profiles Framework field p_callback. The callback function notifies the application when the MCU is about to enter Software Standby mode and when the MCU just woke up from Software Standby mode. Using a callback is optional, but if you define a callback in the Power Profiles properties, then there must be a definition for it.

NOTE: Power Profiles does not enable wake up by numbered IRQs (IRQ0-IRQ15...). To wake the MCU using a numbered IRQ, the application must use the r_lpm API functions wupenGet and wupenSet to enable wake from standby mode by a numbered IRQ.

1) In the application thread, initialize the framework using the open function call.
2) Enter Software Standby mode by the sleep function.
3) Close the framework by calling the close function.

These common steps are illustrated in a typical operational flow diagram in the figure below:

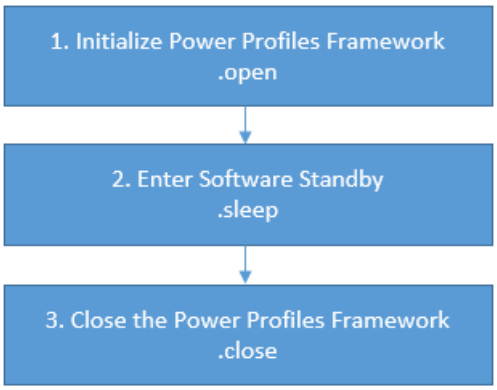

Figure 210: Flow Diagram of a Typical Power Profiles Framework Module Application

4.1.25 Power Profiles V2 Framework

The Power profiles V2 (PPv2) Framework provides more control for users to set a power control mode and the LPM mode in the Synergy MCU. The PPv2 Framework supports all the features of the Power Profiles v1 available in the current release of the Synergy Software Program (SSP) Framework using the LPM v1 driver. The Power Profiles v1 and PPv2 Framework are not compatible. Power Profiles v1 and PPv2 Framework cannot be used in the same project. For all new projects, it is recommended that applications use PPv2 Framework.

4.1.25.1 Power Profiles V2 Framework Module Features

- Configurable options to set different MCU power control modes with customizable clock domains.
- Configurable options to set different MCU low power modes with different IO port or pin configurations.
- Supports both threaded and non-threaded operations

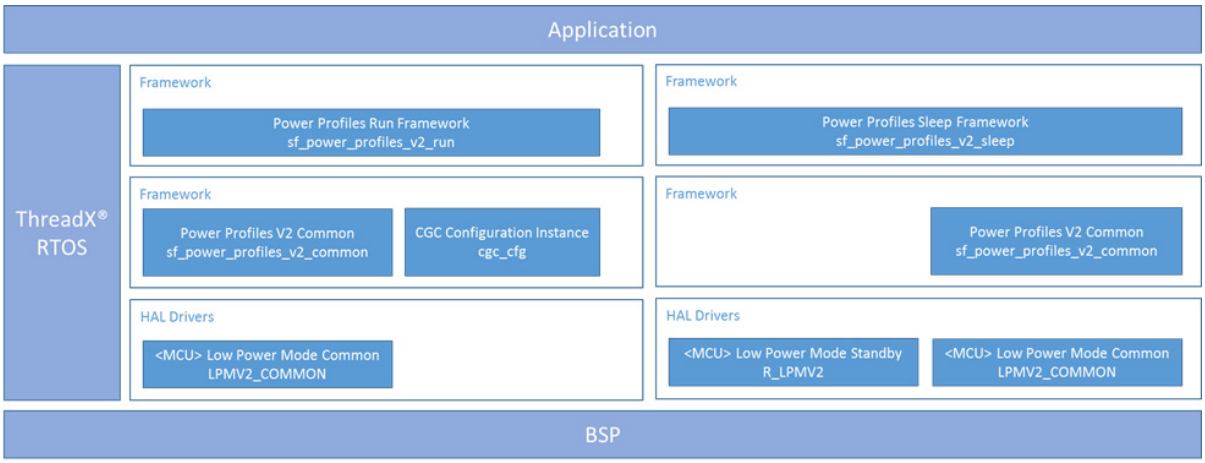

Figure 211: Power Profiles V2 Framework Organization, Options and Stack Implementations

Note that because there are many options for lower level LPMV2 HAL modules, since they are available for different MCUs, they are not all shown on the above diagram. The short-hand <MCU> indicator is replaced with the CPU name (like S7G2) in the actual framework implementation.

4.1.25.2 Power Profiles V2 Framework Module APIs Overview

There are different low-level LPM V2 HAL modules used in the framework depending on the target MCU. These are shown in the below table.

MCU	Driver
S124	S124 Low Power Mode Sleep on r_lpmv2
S124	S124 Low Power Mode Standby on r_lpmv2
S128	S128 Low Power Mode Sleep on r_lpmv2
S128	S128 Low Power Mode Standby on r_lpmv2
S3A3	S3A3 Low Power Mode Sleep on r_lpmv2
S3A3	S3A3 Low Power Mode Standby on r_lpmv2
S3A7	S3A7 Low Power Mode Sleep on r_lpmv2

MCU	Driver
S3A7	S3A7 Low Power Mode Standby on r_lpmv2
S5D9	S5D9 Low Power Mode Sleep on r_lpmv2
S5D9	S5D9 Low Power Mode Standby on r_lpmv2
S5D9	S5D9 Low Power Mode Deep Standby on r_lpmv2
S7G2	S7G2 Low Power Mode Sleep on r_lpmv2
S7G2	S7G2 Low Power Mode Standby on r_lpmv2
S7G2	S7G2 Low Power Mode Deep Standby on r_lpmv2

Because of the large number of lower level LPM V2 HAL modules available it would be difficult to identify separate APIs and configuration settings. This module guide only goes into details for the S7G2 MCU. All the APIs and configuration settings are the same (except for those MCUs that don't support Deep Standby) it should be easy to extrapolate to any target MCU.

The Power Profiles defines APIs for common functions such as open, sleep, and close. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values is also provided.

Power Profiles V2 Framework Module API Summary

Function Name	Example API Call and Description
.open	g_sf_power_profiles_v2_common.p_api->open(g_sf_power_profiles_v2_low_power_0.p_ctrl, g_sf_power_profiles0.p_cfg); Initialize the Power Profiles V2 Framework.
.runApply	g_sf_power_profiles_v2_common.p_api->runApply(g_sf_power_profiles_v2_common.p_ctrl, &g_sf_power_profiles_v2_run_0); Apply the selected run power profile.
.lowPowerApply	g_sf_power_profiles_v2_common.p_api->lowPowerApply (g_sf_power_profiles_v2_common.p_ctrl, &g_sf_power_profiles_v2_low_power_0); Apply the selected low power profile.

Function Name	Example API Call and Description
.close	g_sf_power_profiles_v2_common.p_api->close(g_sf_power_profiles_v2_common.p_ctrl); Close the module.
.versionGet	g_sf_power_profiles_v2_common.p_api->versionGet(&p_version); Get version and store it in provided pointer p_version.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables review the SSP Users Manuals API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_ASSERTION	Assertion error.
SSP_ERR_IN_USE	The framework has already been initialized.
SSP_ERR_INVALID_HW_CONDITION	Incompatible system clock configuration.
SSP_ERR_NOT_OPEN	Device not open.
SSP_ERR_UNSUPPORTED	The function is not supported by the module.
SSP_ERR_INTERNAL	Internal error.

NOTE: Lower level drivers may return Common Error Codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.25.3 Power Profiles V2 Framework Module Operational Overview

The PPv2 Framework provides a generic API for supporting low level power profiles in the Synergy MCU, when used with the LPM v2 Driver, CGC Driver, and IO Port Driver. It can be considered as an advanced control interface over the power consumption of the MCU, and can be used both in an application with or without ThreadX RTOS. Internally, it relies on the LPM v2, IOPORT, and CGC Drivers of the SSP, and provides an easy-to-use software interface to control the power modes of the MCU.

PPv2 Framework Run Profile

The **Run Profile** uses a CGC Clocks configuration and an IO Port pin configuration to set the system clocks and IO Port pins of the MCU in the normal running modes. Its function is implemented in the RunApply() API to perform the following tasks in the specified order.

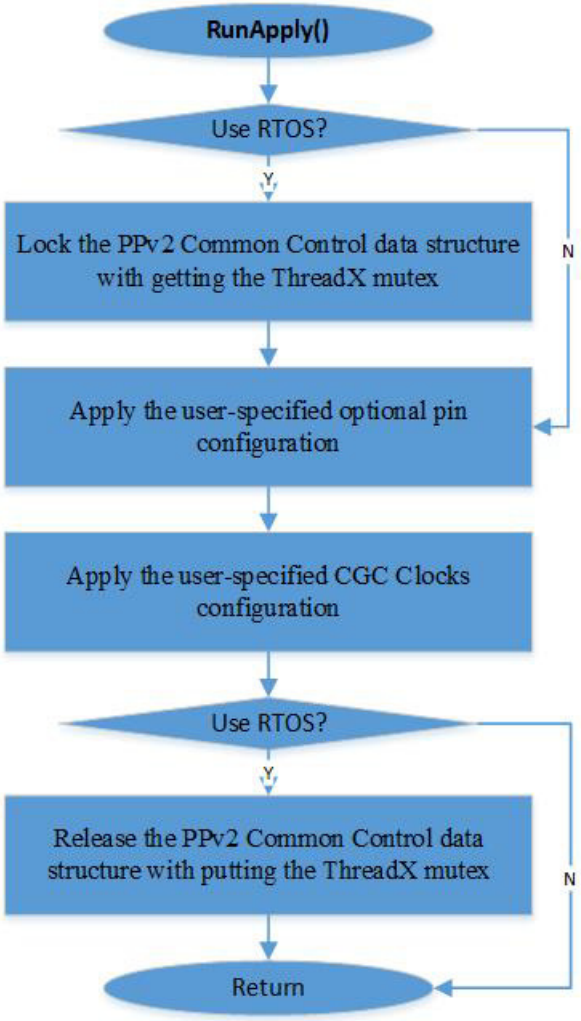

Figure 212: PPv2 RunApply() Process

PPv2 Framework Low Power Profile

The **Low Power Profile** uses an LPM v2 configuration and a pre-LPM and a post-LPM IO port configuration to set the low power mode and IO port pins before entering the configured Low Power mode and after waking up from the Low Power mode. See the *SSP User's Manual* and the corresponding Synergy Microcontroller Group, User's Manuals for details on the available Low Power modes.

The internal function LowPowerApply()API performs the following tasks in order.

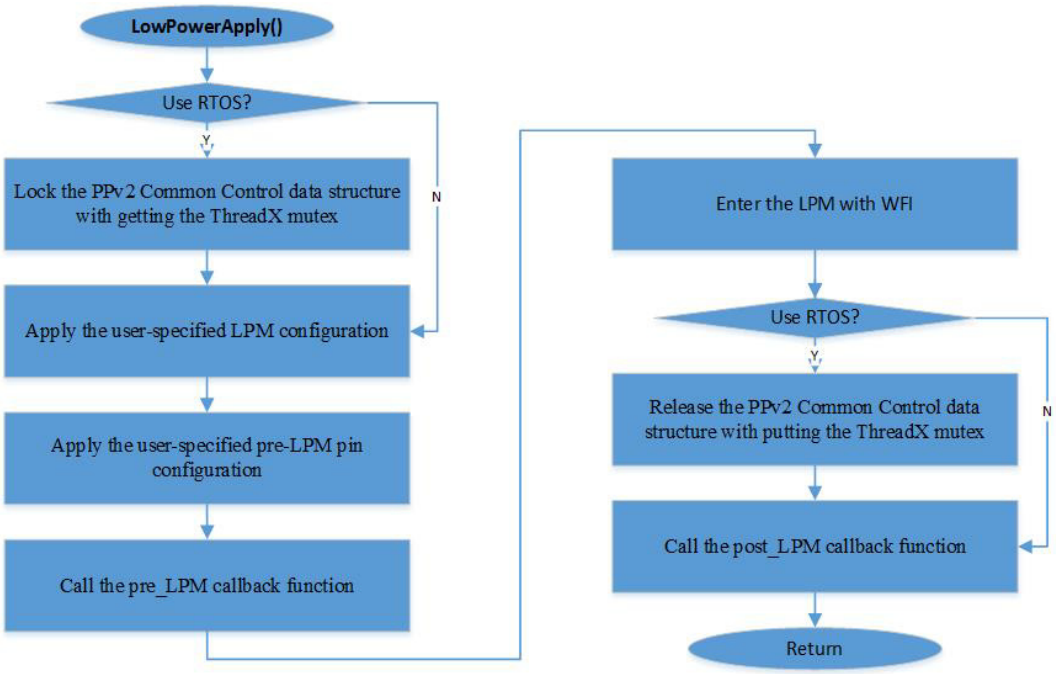

Figure 213: The PPv2 LowPowerApply() process

PPv2 Framework Operational Notes

The following operational notes are based on observations of the current release of the PPv2 framework and driver. It will be updated as more user feedback is received, and new versions of the power profiles package are released.

Power Profile v1 and PPv2

The Power Profiles v1 and PPv2 framework are not compatible, so do not use PPv1 and PPv2 framework in the same project. For all new projects, it is recommended that applications use PPv2 Framework.

An LPM v2 driver instance is added to PPv2 applications by default

This MCU specific LPM v2 driver defines configurations and APIs for configuring, enabling and disabling LPM operations in structures of lpmv2_mcu_cfg_t and lpmv2_api_t, then will be instantiated in the automatically generated file common_data.c. So, the PPv2 Framework instance is based on an LPM v2 Driver instance.

Additional CGC driver instance for using PPv2 runApply() function

A default CGC driver is included in all Synergy application projects, and instantiated in the file common_data.c, that will not increase the code size of a project. Another instance of the CGC Driver is required for a CGC Clocks configuration of a PPv2 runApply() function.

I/O Port Driver instance for different pin configurations

Different pin configuration tables can be defined in the PPv2 power profiles, but only one I/O port driver instance ioport_instance_t is instantiated in the automatically generated file common_data.c.

Operation with ThreadX

As shown in the above RunApply() and LowPowerApply() processes, the PPv2 Framework APIs uses a ThreadX intrinsic objects like a mutex for multithread applications when used with ThreadX.

Special Consideration on Multithreads Applications

In following the LPM modes: Software Standby, Deep Software Standby, or Snooze modes; the source clock for Systick may be configured to be disabled. Special consideration is needed when implementing a multithread RTOS project with the PPv2 LPM modes.

Debugger Usage in LPM Modes

By default, debuggers will prevent MCUs from entering LPM modes since Arm® Core is accessed by CoreSight™ debugging elements. There are two approaches to disconnect their attachment.

- Perform a full power-on reset cycle by unplugging and plugging the USB connection for JTAG;
- Enable Low Power Handling in the Synergy e^2 studio debugger and utilize a provided J-LINK script in **Debugger tab > Connection Settings**, as shown below.

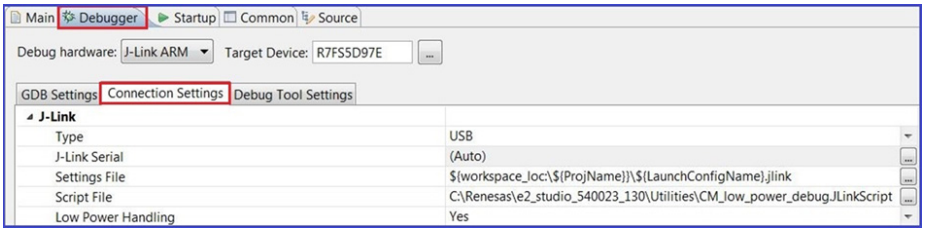

Figure 214: Enabling Low Power Handling in Synergy e^2 studio Debugger

Where the script CM_low_power_debug.JLinkScript will be provided per your request.

PPv2 Framework Limitations

- The Power Profiles V2 Framework open function will not be called automatically prior to the main if the project does not use ThreadX. The initialization must be done explicitly by calling g_common_init() or by explicitly calling the API function open(). This is not a PPv2 limitation, but a general approach of initializing a Framework module without using ThreadX RTOS.
- The PPv2 Framework does not handle starting or stopping MCU peripherals, since no property view is available to select which peripherals to be stopped in a LPM mode, so users must stop them manually.
- Current version of PPv2 Framework only support following Synergy MCUs: S124, S128, S3A7, S5D9, and S7G2.
- Current version of PPv2 Framework doesn't support the transition from the Snooze to the Normal in a LPM Standby mode.

4.1.25.4 Including the Power Profiles V2 Framework Module in an Application

This section describes how to include the Power Profiles in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP based applications.

To add the Power Profiles framework module to an application, simply add it to a thread using the Stacks Selection Sequence given in the table below. (The default name for the Power Profiles is g_sf_power_profiles_low_power_0 . This name can be changed in the associated Properties window.)

Power Profiles V2 Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_power_profiles_v2_low_power_0 Power Profiles V2 Low Power Profile	Threads	New Stack > Framework > Services > Power Profiles V2 Low Power Profile
g_sf_power_profiles_v2_run_0 Power Profiles V2 Run Profile	Threads	New Stack > Framework > Services > Power Profiles V2 Run Profile
g_sf_power_profiles_v2_common Power Profiles V2 Common	Threads	New Stack> Framework> Services> Power Profiles V2 Common

When the Power Profiles V2 low power or run module is added to the thread stack as shown in the figure below, the configurator automatically adds any needed lower level modules. Any drivers that need additional configuration information will have box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

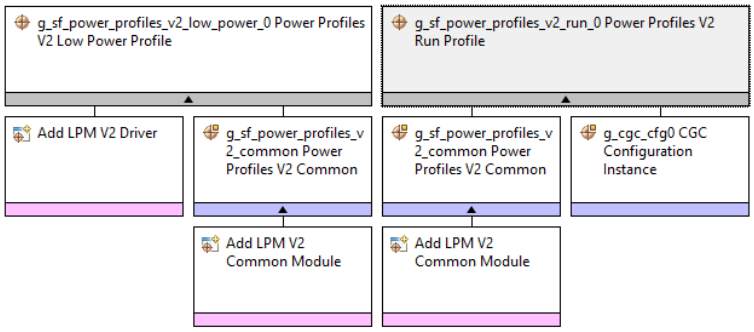

Figure 215: Power Profiles V2 Framework Module Stack

4.1.25.5 Configuring the Power Profiles V2 Framework Module

The Power Profiles V2 run and low power modules must be configured by you for the desired operation. The SSP configuration window will automatically identify, by highlighting the block in red, any required configuration selections, such as Interrupts or operating modes, which must be configured for lower level modules, for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority. This configuration setting is available with the properties window of the associated module. Simply select the indicated module and then view the properties window. The Interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the Interrupt priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the below configuration properties tables, but is easily visible with the ISDE when configuring Interrupt Priority levels.

NOTE: You may want to open your ISDE and create the module and explore the property settings in parallel with looking over the Configuration Table Settings given below. This will help orient you and can be a useful 'hands-on' approach to

learning the ins and outs of developing with SSP.

There are two different stack selections for the Power Profiles V2 Framework, the Run Profile and the Low Power Profile. Their respective configuration settings will be covered separately in the following sections.

Configuration Settings for the Power Profiles V2 Run Profile

Typically, only a small number of settings must be modified from the default for lower level drivers and these are indicated via the red text in the Thread Stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The table below identifies all the settings within the properties section for the module.

Configuration Settings for the Power Profiles V2 Run Profile

ISDE Property	Value	Description
Name	g_sf_power_profiles_v2_run_0	Module name
Pin configuration table	NULL	Pin configuration table selection

A pin configuration table can be created for a power mode, and linked into the Run profile property. Otherwise, the power mode uses the default pin assignment given by g_bsp_pin_cfg.

Basic steps to create a custom pin configuration table are as follows:

- Copy a given board pin configuration file, such as S5D9-PK.pincfg by clicking the right mouse button and selecting the **Copy** operation, then **Paste** it into the same project.
- Rename this new pin configuration file, S5D9-PK_RUN.pincfg.

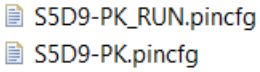

Figure 216: Create a New Pin Configuration File with Copy and Paste

- Select the new pin configuration from the pull-down menu on the Pins tab of SSP Configurator, then specify a pin configuration name to be generated as shown below.

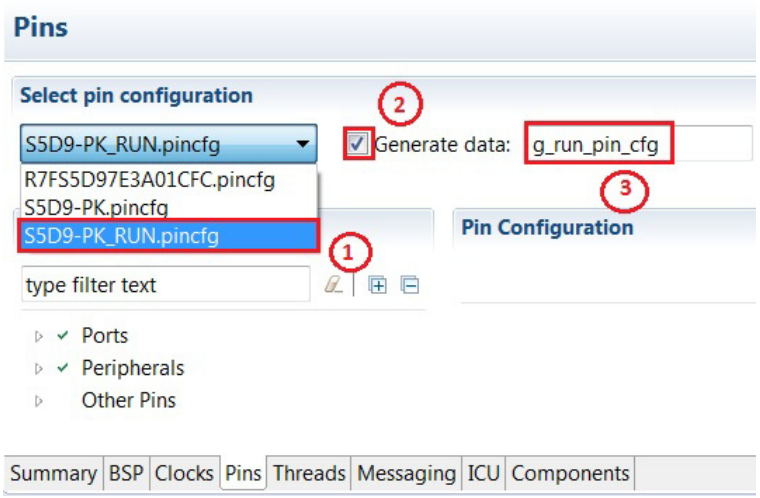

Figure 217: Select a New Pin Configuration File to be Assigned

- Configure the I/O functions on each pin, then generate a new pin configuration when you press the button **Generate Project Content** on the SSP Configurator as specified in the *Synergy SSP User's Manual.

A power control mode of this Run Profile can be defined using the property view of a CGC Configuration Instance.

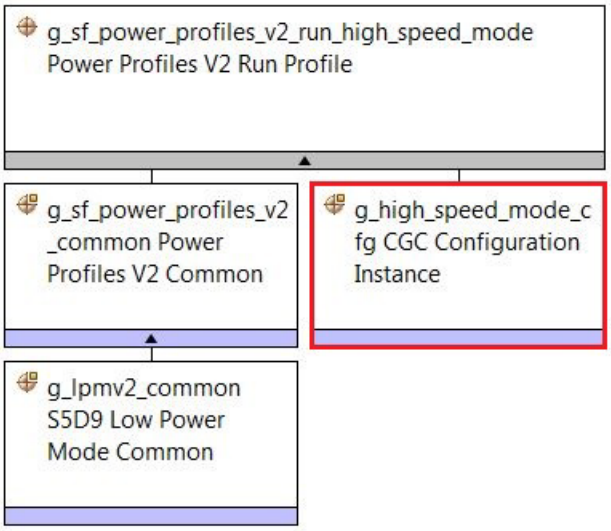

Figure 218: CGC Configuration Instance in the Run Profile Module

The parameters of the CGC configuration property view are shown as follows:

CGC Configuration Settings on a Run Profile Module

ISDE Property	Value	Description
Name	g_cgc_cfg0	Module name
System Clock	HOCO, MOCO, LOCO, Main Oscillator, Sub Clock, PLL Default: HOCO	Set the system clock source
LOCO State Change	None, Start, Stop Default: None	LOCO state change selection
MOCO State Change	None, Start, Stop Default: None	MOCO state change selection
HOCO State Change	None, Start, Stop Default: None	HOCO state change selection
Sub-Clock State Change	None, Start, Stop Default: None	Sub-clock state change selection
Main Clock State Change	None, Start, Stop Default: None	Main clock state change selection
PLL State Change	None, Start, Stop Default: None	PLL source clock selection
PLL Source Clock	HOCO, MOCO, LOCO, Main Oscillator, Sub Clock, PLL Default: HOCO	Set the PLL source

ISDE Property	Value	Description
PLL Divisor	1, 2, 3, 4 Default: 1	PLL Output Frequency Division
PLL Multiplier	10.0, 10.5, 11.0, 11.5, 12.0, 12.5, 13.0, 13.5, 14.0, 14.5, 15.0, 15.5, 16.0, 16.5, 17.0, 17.5, 18.0, 18.5, 19.0, 19.5, 20.0, 20.5, 21.0 , 21.5, 22.0, 22.5, 23.0, 23.5, 24.0, 24.5, 25.0, 25.5, 26.0, 26.5, 27.0, 27.5, 28.0, 28.5, 29.0, 29.5, 30.0, 31.0 Default: 10.0	PLL Output Frequency Multiplication
PCLKA Divisor	1, 2, 4, 8, 16, 64 Default: 1	Peripheral Clock A Division
PCKLB Divisor	1, 2, 4, 8, 16, 64 Default: 1	Peripheral Clock B Division
PCLKC Divisor	1, 2, 4, 8, 16, 64 Default: 1	Peripheral Clock C Division
PCLKD Divisor	1, 2, 4, 8, 16, 64 Default: 1	Peripheral Clock D Division
BCLK Divisor	1, 2, 4, 8, 16, 64 Default: 1	External Bus Clock Division
FCLK Divisor	1, 2, 4, 8, 16, 64 Default: 1	Flash Clock Division

ISDE Property	Value	Description
ICLK Divisor	1, 2, 4, 8, 16, 64 Default: 1	System Clock Division

NOTE: The assignments on these CGC parameters must be satisfied with oscillator availability for each power control mode, and the expected frequencies of each operating clock. Their relationships are illustrated in a CGC Block Diagram in the corresponding Synergy MCU User's Manual.

The maximum operating frequency range for these clocks should not be outside the given ranges in the corresponding MCU User's Manual. The *S5D9 Microcontroller Group User's Manual* lists this specification in the following table.

Maximum Operating Frequency Range for Synergy S5D9 MCU Group Internal Clocks

Parameter	Clock sources	Clock supply	Specifications
Peripheral module clock A (PCLKA)	MOSC, SOSC, HOCO, MOCO, LOCO, PLL	Peripheral modules (ETHERC, EDMAC, USBHS, QSPI, SPI, SCI, SCE7, GLCDC, SDHI, CRC, JPEG engine, DRW, irDA, GPY bus-clock)	Up to 120 MHz*2 Division ratios: 1, 2, 4, 8, 16, 32, 64
Peripheral module clock B (PCLKB)	MOSC, SOSC, HOCO, MOCO, LOCO, PLL	Peripheral modules (IIC, SSIE, SRC, DOC, CAC, CAN, DAC12, POEG, CTSU, AGT, Standby SCRAM, ELC, I/O Ports, RTC, WDT, IWDT, ADC12, KINT, USBFS, ACMPHS, TSN, PDC)	Up to 60 MHz Division ratios: 1, 2, 4, 8, 16, 32, 64
Peripheral module clock C (PCLKC)	MOSC, SOSC, HOCO, MOCO, LOCO, PLL	Peripheral module (ADC12 conversion clock)	Up to 60 MHz Division ratios: 1, 2, 4, 8, 16, 32, 64
Peripheral module clock D (PCLKD)	MOSC, SOSC, HOCO, MOCO, LOCO, PLL	Peripheral module (GPT count-clock)	Up to 120 MHz Division ratios: 1, 2, 4, 8, 16, 32, 64

Parameter	Clock sources	Clock supply	Specifications
Flash interface clock (FCLK)	MOSC, SOSC, HOCO, MOCO, LOCO, PLL	Flash interface	Up to 60 MHz (P/E) Up to 60 MHz (read) *1 Division ratios: 1, 2, 4, 8, 16, 32, 64
External bus clock (BCLK)	MOSC, SOSC, HOCO, MOCO, LOCO, PLL	External bus	Up to 120 MHz Division ratios: 1, 2, 4, 8, 16, 32, 64
EBCLK pin output (EBCLK)	BCLK or ½ BCLK	EBCLK pin	Up to 60 MHz Division ratios: 1, 2
SDCLK pin output (SDCLK)	BCLK	SDCLK pin	Up to 120 MHz
USB clock (CABMCLK)	PLL	USB	48 MHz Division ratios: 3, 4, 5,
USB-PHY clock (USBMCLCK)	MOSC	USB-PHY	12, 20, 25 MHz
Can CLOCK (CANMCLK)	MOSC	CAN	8 to 24 MHz
LCD_CLCK pin output (LCD_CLK) and graphic LCD pixel clock (PXCLK)	LCD_EXTCLK, PLL output	LCD_CLK pin, peripheral module (Graphics LLCD Controller)	Up to 54 MHz (parallel RGB) Up to 60 MHz (serial RGB) LCD_CLK : PXCLK = 1.1 (parallel RGB)

As the current property view does not validate your assignments automatically, you can use the CGC panel of the SSP Configurator to check your assignments first. The following screen shot of the CGC configuration is an example of the High-Speed mode.

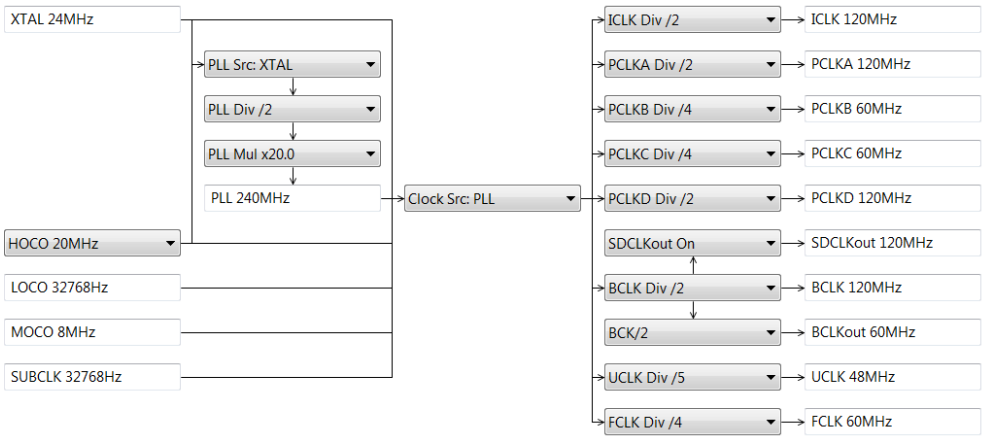

Figure 219: Checking the clock setting for a power control mode

Similarly, you can define the CGC configuration for other power control modes.

Configuration of PPv2 Framework Low Power Profile

Depending on the selected Synergy MCU Group, you may have 3 LPM modes: Sleep, Software Standby, and Deep Software Standby modes, available in the pull-down menu of the Low Power Profile module.

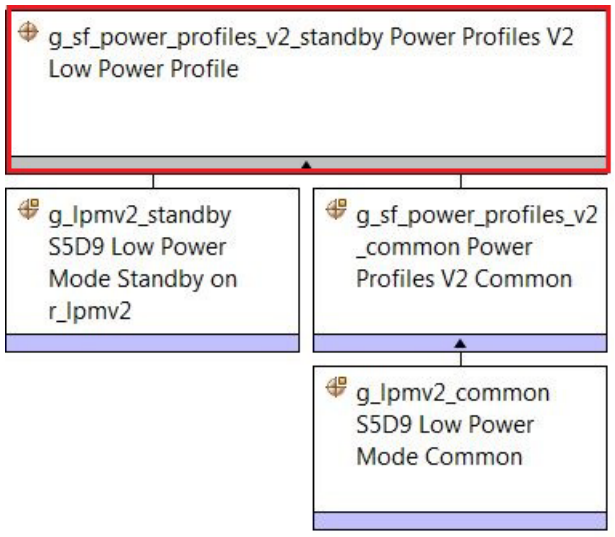

Figure 220: PPv2 Low Power Profile Standby Module

Assuming that a Low Power Profile module is already added into a thread, it will have the following configurations.

Configuration settings on the PPv2 Low Power Profile module

ISDE Property	Value	Description
Name	g_sf_power_profiles_v2_low_power_0	Module name
Callback (Low Power Exit Event N/A when using Deep Software Standby)	NULL	Callback selection
Low power entry pin configuration table	NULL	Low power entry pin configuration table selection
Low power exit pin configuration table	NULL	Low power exit pin configuration table selection

The callback function can be used for handling the following events:

- SF_POWER_PROFILES_V2_EVENT_PRE_LOW_POWER
- SF_POWER_PROFILES_V2_EVENT_POST_LOW_POWER

You can change the IO port functionality with the following two pin configuration tables:

- Low power entry pin configuration table
- Low power exit pin configuration table

They will be used internally in the PPv2 API function LowPowerApply().

The configuration of the LPM Sleep mode is simple, since any interrupt wakes the MCU from the Sleep mode. So only the module name can be renamed.

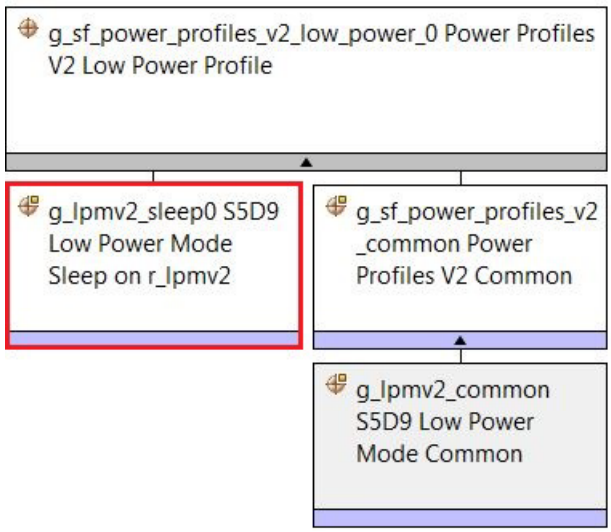

Figure 221: PPv2 Low Power Profile Sleep Driver r_lpmv2

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking
Name	g_lpmv2_standby0	Module name
Choose the low power mode	Standby, Standby with snooze Enabled Default: Standby	Low power mode selection
Output port state in standby and deep standby, applies to address output, data output, and other bus control output pins	High impedance state, No change Default: No change	Output port state selection
IRQ1-15	Enabled, Disabled Default: Disabled	IRQ1-15 selection
IWDT	Enabled, Disabled Default: Disabled	IWDT selection
Key Interrupt	Enabled, Disabled Default: Disabled	Key Interrupt selection
LVD1 Interrupt	Enabled, Disabled Default: Disabled	LVD1 Interrupt selection
LVD2 Interrupt	Enabled, Disabled Default: Disabled	LVD2 Interrupt selection
Analog Comparator High-speed 0 Interrupt	Enabled, Disabled Default: Disabled	Analog Comparator High-speed 0 Interrupt selection

ISDE Property	Value	Description
RTC Alarm	Enabled, Disabled Default: Disabled	RTC Alarm selection
RTC Period	Enabled, Disabled Default: Disabled	RTC Period selection
USB High-speed	Enabled, Disabled Default: Disabled	USB High-speed selection
USB Full-speed	Enabled, Disabled Default: Disabled	USB Full-speed selection
AGT1 underflow	Enabled, Disabled Default: Disabled	AGT1 underflow selection
AGT1 Compare Match A	Enabled, Disabled Default: Disabled	AGT1 Compare Match A selection
AGT1 Compare Match B	Enabled, Disabled Default: Disabled	AGT1 Compare Match B selection
12C 0	Enabled, Disabled Default: Disabled	12C 0 selection
Snooze Entry Source	RXD0 falling edge, IRQ0-IRQ15, KINT, ACMPHS0, RTC Alarm, RTC Period, AGT1 Underflow, AGT1 Compare Match A, AGT1 Compare Match B Default: RXD0 falling edge	Snooze Entry Source selection

ISDE Property	Value	Description
AGT1 Underflow	Enabled, Disabled Default: Disabled	AGT1 Underflow selection
DTC Transfer Completion	Enabled, Disabled Default: Disabled	DTC Transfer Completion selection
DTC Transfer Completion Negated Signal	Enabled, Disabled Default: Disabled	DTC Transfer Completion Negated Signal selection
ADC0 Compare Match	Enabled, Disabled Default: Disabled	ADC0 Compare Match selection
ADC0 Compare Mismatch	Enabled, Disabled Default: Disabled	ADC0 Compare Mismatch selection
ADC1 Compare Match	Enabled, Disabled Default: Disabled	ADC1 Compare Match selection
ADC1 Compare Mismatch	Enabled, Disabled Default: Disabled	ADC1 Compare Mismatch selection
SCI0 Address Match	Enabled, Disabled Default: Disabled	SCI0 Address Match selection
DTC state in Snoooze Mode	Enabled, Disabled Default: Disabled	DTC state in Snoooze Mode selection

Configuration Settings on the PPv2 Profile Sleep module

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking
Name	g_lpmv2_sleep0	Module name

The Standby mode configuration sets up the exit triggers, and some transition conditions between the Standby and the Snooze mode, which are treated as a special case of the Standby mode in the current release of the PPv2. More discussion on the Snooze configuration is provided in the next section.

As an example, a S5D9 MCU Standby module is shown in the following figure.

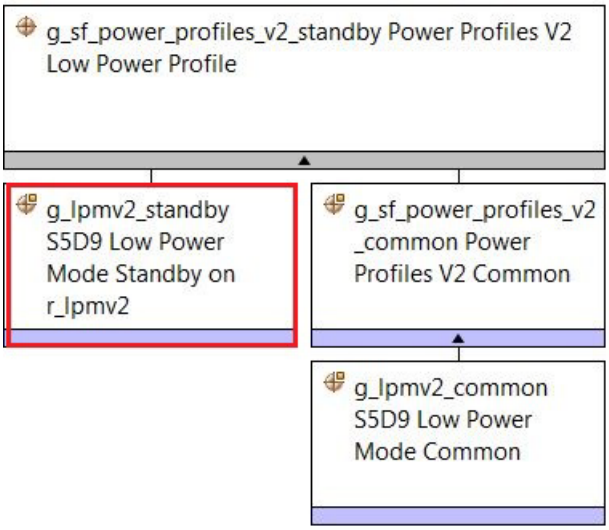

Figure 222: PPv2 Low Power Profile Standby Driver r_lpmv2

Configuration Settings on the PPv2 Profile Standby Module

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking
Name	g_lpmv2_standby0	Module name

ISDE Property	Value	Description
Choose the low power mode	Standby, Standby with snooze Enabled Default: Standby	Low power mode selection
Output port state in standby and deep standby, applies to address output, data output, and other bus control output pins	High impedance state, No change Default: No change	Output port state selection
IRQ1-15	Enabled, Disabled Default: Disabled	IRQ1-15 selection
IWDT	Enabled, Disabled Default: Disabled	IWDT selection
Key Interrupt	Enabled, Disabled Default: Disabled	Key Interrupt selection
LVD1 Interrupt	Enabled, Disabled Default: Disabled	LVD1 Interrupt selection
LVD2 Interrupt	Enabled, Disabled Default: Disabled	LVD2 Interrupt selection
Analog Comparator High-speed 0 Interrupt	Enabled, Disabled Default: Disabled	Analog Comparator High-speed 0 Interrupt selection
RTC Alarm	Enabled, Disabled Default: Disabled	RTC Alarm selection

ISDE Property	Value	Description
RTC Period	Enabled, Disabled Default: Disabled	RTC Period selection
USB High-speed	Enabled, Disabled Default: Disabled	USB High-speed selection
USB Full-speed	Enabled, Disabled Default: Disabled	USB Full-speed selection
AGT1 underflow	Enabled, Disabled Default: Disabled	AGT1 underflow selection
AGT1 Compare Match A	Enabled, Disabled Default: Disabled	AGT1 Compare Match A selection
AGT1 Compare Match B	Enabled, Disabled Default: Disabled	AGT1 Compare Match B selection
12C 0	Enabled, Disabled Default: Disabled	12C 0 selection
Snooze Entry Source	RXD0 falling edge, IRQ0-IRQ15, KINT, ACMPHS0, RTC Alarm, RTC Period, AGT1 Underflow, AGT1 Compare Match A, AGT1 Compare Match B Default: RXD0 falling edge	Snooze Entry Source selection
AGT1 Underflow	Enabled, Disabled Default: Disabled	AGT1 Underflow selection

ISDE Property	Value	Description
DTC Transfer Completion	Enabled, Disabled Default: Disabled	DTC Transfer Completion selection
DTC Transfer Completion Negated Signal	Enabled, Disabled Default: Disabled	DTC Transfer Completion Negated Signal selection
ADC0 Compare Match	Enabled, Disabled Default: Disabled	ADC0 Compare Match selection
ADC0 Compare Mismatch	Enabled, Disabled Default: Disabled	ADC0 Compare Mismatch selection
ADC1 Compare Match	Enabled, Disabled Default: Disabled	ADC1 Compare Match selection
ADC1 Compare Mismatch	Enabled, Disabled Default: Disabled	ADC1 Compare Mismatch selection
SCI0 Address Match	Enabled, Disabled Default: Disabled	SCI0 Address Match selection
DTC state in Snoooze Mode	Enabled, Disabled Default: Disabled	DTC state in Snoooze Mode selection

Currently, the Snooze mode is enabled in the property view of the PPv2 Software Standby mode by selecting **Standby with Snooze Enabled** in the field of the **Choose the low power mode** as shown in the following figure.

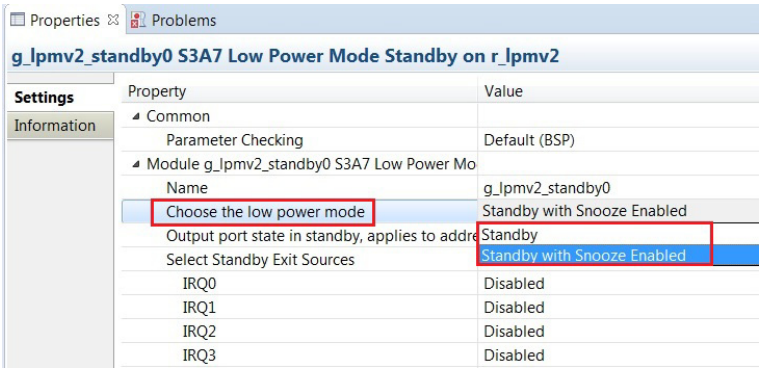

Figure 223: Create a Snooze mode in the Software Standby mode

The configuration on the Deep Software Standby mode is to set the exit triggers of the Deep Software Standby mode, and the internal power supply options. Use the PPv2 Framework on the S5D9 as an example to show the possible configurations as follows.

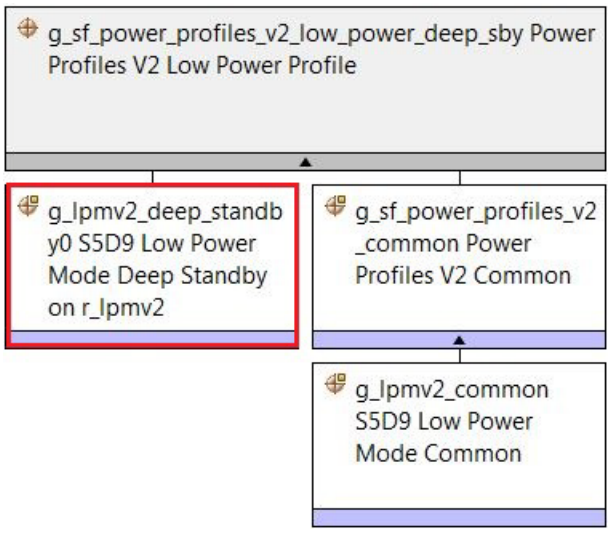

Figure 224: PPv2 Low Power Profile Deep Software Standby driver r_lpmv2

Configuration settings on the PPv2 Profile Deep Software Standby module

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking
Name	g_lpmv2_deep_standby	Module name

ISDE Property	Value	Description
Output port state in standby and deep standby, applies to address output, data output, and other bus control output pins	High impedance state, No change Default: No change	Output port state setting in Standby and Deep Software Standby
Maintain or reset the IO port states on exit from deep standby mode	Maintain the IO port states, Reset the IO port states Default: Maintain the IO port states	Output port state setting exit
Internal power supply control in deep standby mode	Maintain the internal power supply, Cut the power supply to standby RAM, low-speed on-chip oscillator, AGTn, and USPFS/HS resume detecting unit, Cut the power supply to LVDn, standby RAM, low-speed on-chip oscillator, AGTn, and USBFS/HS resume detecting unit Default: Maintain the internal power supply	Internal power supply control in Deep Software Standby mode setting
IRQ0-15	Enabled, Disabled Default: Disabled	IRQ0-15 selection
IRQ0-15 Edge	Disabled, Rising Edge, Falling Edge Default: Disabled	IRQ0-15 Edge selection
LVD1	Enabled, Disabled Default: Disabled	LVD1 selection
LVD1 Edge	Disabled, Rising Edge, Falling Edge Default: Disabled	LVD1 Edge selection
LVD2	Enabled, Disabled Default: Disabled	LVD2 selection

ISDE Property	Value	Description
LVD2 Edge	Disabled, Rising Edge, Falling Edge Default: Disabled	LVD2 Edge selection
RTC Interval	Enabled, Disabled Default: Disabled	RTC Interval selection
RTC Alarm	Enabled, Disabled Default: Disabled	RTC Alarm selection
NMI	Enabled, Disabled Default: Disabled	NMI selection
NMI Edge	Disabled, Rising Edge, Falling Edge Default: Disabled	NMI Edge selection
USBFS	Enabled, Disabled Default: Disabled	USBFS selection
UBSHS	Enabled, Disabled Default: Disabled	UBSHS selection
AGT11	Enabled, Disabled Default: Disabled	AGT11 selection

NOTE: The property dialog of the PPv2 Framework provides two predefined configurations for internal power supply control in Deep Software Standby mode. More selections for stopping power supply to internal components are listed in the *Synergy Microcontroller Group User's Manual*, such as in Table 11.2 of the *Synergy S5D9 Microcontroller Group User's Manual*.

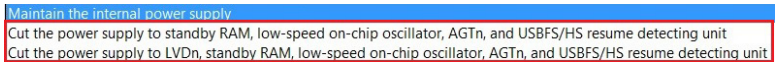

Figure 225: Predefined internal power supply options in the PPv2 Framework Deep Software Standby mode

Configuration of PPv2 Framework Common Modules

There are two Common modules shared among PPv2 Framework Run/Low Power Profile modules:

- **Automatically Generated Power Profile V2 Common Module**

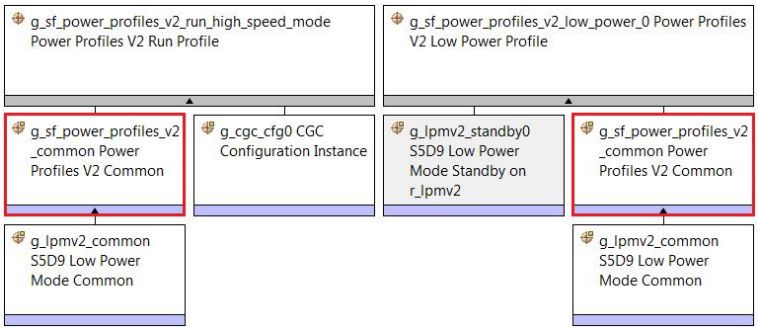

Figure 226: PPv2 Common module of PPv2 Run/Low Power Profile modules

Their configurations are displayed as follows:

Configuration settings for the Power Profiles V2 Common

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_sf_power_profiles_v2_common	Module name

- **Users Added MCU Specific Low Power Mode Common Module**

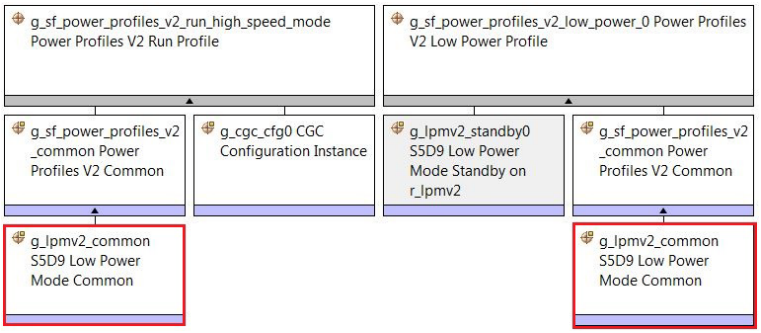

Figure 227: LPM Common Module of PPv2 Run/Low Power Profile Modules

Their configurations are displayed as follows:

Configuration Settings for the Low Power Mode Common

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_lpmv2_common	Module name.

NOTE: The Synergy MCU S5D9 LPM module is already added in Figure 13 when adding a PPv2 Framework Run profile module.

The Power Profiles V2 framework does not require any specific clock settings.

The application may optionally maintain the Io Port state during a low power mode.

4.1.25.6 Using the Power Profiles V2 Framework Module in an Application

Once you have configured the modules and the ISDE has generated the files, follow the steps below to use the Power Profiles V2 Framework in a thread. The steps below assume that the user defined name for the Power Profiles V2 Framework common instance is g_sf_power_profiles_v2_common. The steps below assume that the user defined names for the Power Profiles V2 framework Low Power and Run profiles are g_sf_power_profiles_v2_low_power_0 and g_sf_power_profiles_v2_run_0.

Before using any APIs, you must define the body of the callback function configured in the Low Power profile. The callback function notifies the application when the MCU is about to enter a low power mode and when the MCU just woke

up from a low power mode. Using a callback is optional, but if you define a callback in the Power Profiles V2 properties, then there must be a definition for it.

1) If ThreadX is being used, the Power Profiles V2 Framework open API function will be called by the Synergy generated code before the user application code is reached. If ThreadX is not used, the application must call the open function.

2) Apply a Run Profile at any time using the runApply() API. The runApply() API accepts a Run Profile as its second parameter. The parameter can be any valid Run Profile, allowing the application to easily switch between Run Profiles.

```
g_sf_power_profiles_v2_common.p_api->runApply(g_sf_power_profiles_v2_common.p_ct
rl,
&g_sf_power_profiles_v2_run_0);
```

3) Apply a Low Power Profile using the lowPowerApply() API. The lowPowerApply() API accepts a Low Power Profile as its second parameter. The parameter can be any valid Low Power Profile, allowing the application to easily switch between Low Power Profiles.

```
g_sf_power_profiles_v2_common.p_api->lowPowerApply(g_sf_power_profiles_v2_common
.p_ctrl,
&g_sf_power_profiles_v2_low_power_0);
```

4) *Optional*: Close the framework by calling the close function.

```
g_sf_power_profiles_v2_common.p_api->close(g_sf_power_profiles_v2_common.p_ctrl)
;
```

These common steps are illustrated in a typical operational flow diagram in the figure below:

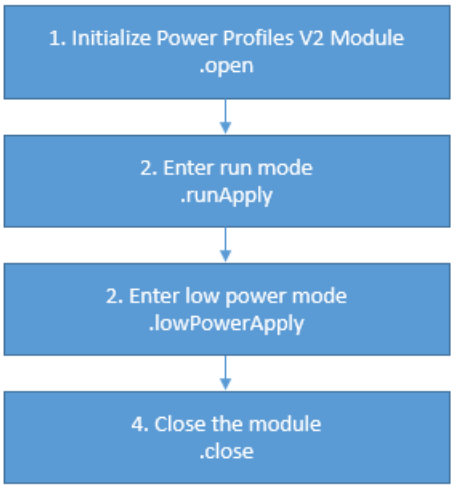

Figure 228: Flow Diagram of a Typical Power Profiles V2 Framework Module Application

4.1.26 SPI Framework

The SPI Framework module provides set of ThreadX-aware framework APIs and is implemented on SF_SPI. The SPI Framework module handles the integration and synchronization of multiple SPI peripherals on an SPI bus, including chip-select handling and its level activation. With the SPI Framework, one or more SPI buses can be created and multiple SPI peripherals can be connected to the SPI bus. The SPI Framework module uses a single interface to access both SCI SPI and RSPI drivers. The SPI Framework module uses the SCI and RSPI peripherals on the Synergy MCU.

4.1.26.1 SPI Framework Module Features

The SPI Framework module uses either the SCI in SPI mode (together with the SCI common lower-level modules) or the RSPI lower-level driver module to communicate with the SPI peripherals on the Synergy microcontroller.

- Supports multiple devices on a bus
- Provides high-level APIs for initialization, transfers, and closing the module
- Supports synchronized transfers
- Supports chip-select operations
- Supports bus-locking

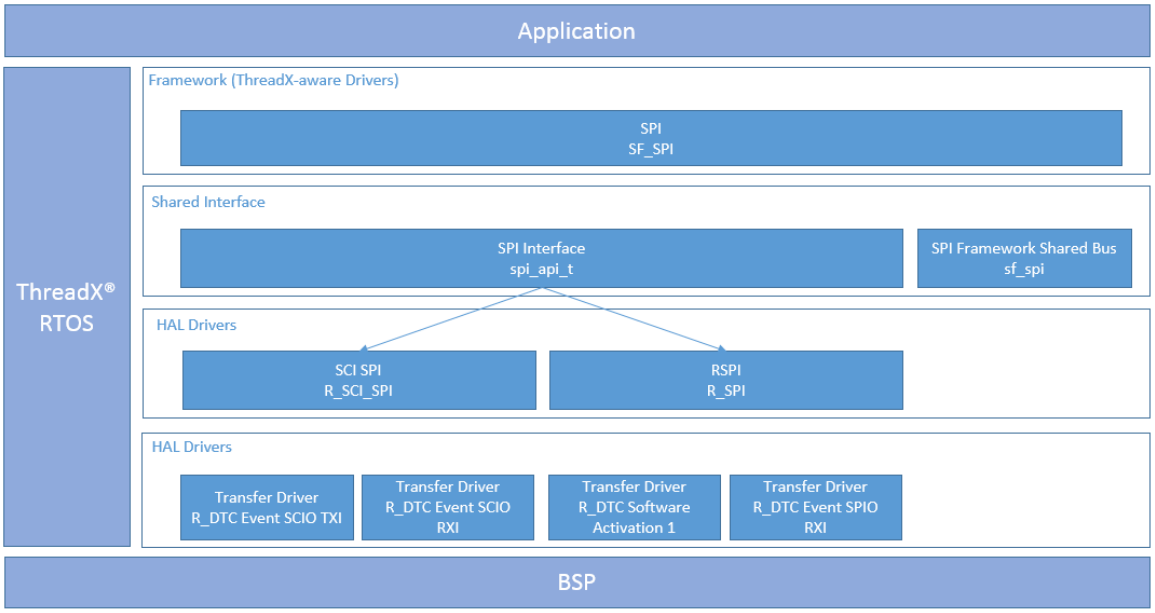

Figure 229: SPI Framework Module Block Diagram

4.1.26.2 SPI Framework Module APIs Overview

The SPI Framework module defines APIs for opening, closing, reading, writing, and other useful functions. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

SPI Framework Module API Summary

Function Name	Example API Call and Description
.open	g_sf_spi_device.p_api->open(g_sf_spi_device.p_cntl, g_sf_spi_device.p_cfg); Open a designated SPI device on a bus.
.read	g_sf_spi_device.p_api->read(g_sf_spi_device.p_cntl, dst8, length, SPI_BIT_WIDTH_8_BITS, TX_WAIT_FOREVER); Receive data from SPI device.
.write	g_sf_spi_device.p_api->write(g_sf_spi_device.p_cntl, src8, length, SPI_BIT_WIDTH_8_BITS, TX_WAIT_FOREVER); Transmit data to SPI device.
.writeRead	g_sf_spi_device.p_api->writeRead (g_sf_spi_device.p_cntl, &source, &destination, length, SPI_BIT_WIDTH_8_BITS, TX_WAIT_FOREVER); Simultaneously transmits data to an SPI device while receiving data from an SPI device (full duplex). The writeread API gets a mutex object, handles the SPI data transmission at SPI HAL layer, and receives data from the SPI HAL layer. The API uses the event flag wait to synchronize to completion of data transfer.
.close	g_sf_spi_device.p_api->close(g_sf_spi_device.p_cntl); Disable the SPI device designated by the control handle and close the RTOS services used by the bus, if no devices are connected to the bus. This function removes power to the SPI channel designated by the handle and disables the associated interrupts.

Function Name	Example API Call and Description
.lock	g_sf_spi_device.p_api->lock(g_sf_spi_device.p_cntl); Lock the bus for a device. The locking allows devices to reserve a bus to themselves for a given period of time (such as between lock and unlock). This allows devices to complete several reads and writes on the bus without an interrupt.
.unlock	g_sf_spi_device.p_api->unlock(g_sf_spi_device.p_cntl); Unlock the bus for a particular device and make the bus usable for other devices.
.versionGet	g_sf_spi_device.p_api->versionGet(&version); Retrieve the API version with the version pointer.

NOTE: Details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the *SSP User's Manual* API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function completed successfully
SSP_ERR_INVALID_MODE	Invalid mode
SSP_ERR_INVALID_CHANNEL	Invalid channel
SSP_ERR_IN_USE	In-use error
SSP_ERR_INVALID_ARGUMENT	Invalid argument
SSP_ERR_QUEUE_UNAVAILABLE	Queue unavailable
SSP_ERR_INVALID_POINTER	Invalid pointer
SSP_ERR_INTERNAL	Internal error
SSP_ERR_TRANSFER_ABORTED	Transfer aborted
SSP_ERR_MODE_FAULT	Mode fault

Name	Description
SSP_ERR_READ_OVF	Read overflow
SSP_ERR_PARITY	Parity error
SSP_ERR_OVERRUN	Overrun error
SSP_ERR_UNDEF	Unknown error
SSP_ERR_TIMEOUT	Timeout error
SSP_ERR_NOT_OPEN	Device not opened

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual* API References for the associated module for a definition of all relevant status return values.

4.1.26.3 SPI Framework Module Operational Overview

The SPI Framework module complies with the layered-driver architecture of the SSP. It uses either the SCI on SPI module or the RSPI module to communicate with the SPI peripherals on the Synergy microcontroller.

The framework-driver architecture uses a "bus" and "device on bus" architecture. Only one device is configured to the lower level at a time, and remaining devices are reconfigured upon read or write operation if required. The Device can be reconfigured only when the bus is not locked. Every device is linked to the bus to which it will be connected. The user must configure the bus, the framework, and the lower-level module for each device connecting to the bus. The user can add the existing framework shared-bus when configuring multiple devices on the same bus. Each SPI framework must be configured with a unique name in the ISDE configurator.

A common start and stop procedure is used for all SPI data-transfer operations (read, write and writeRead). During the start process, the Framework module checks whether reconfiguration is required. Chip select is asserted during the transfer-start process and de-asserted during the transfer-end process if bus is not locked. The user must configure the chip-select IO pin and chip-select active level.

The SPI Framework module supports the bus-locking functionality, meaning that the user can lock the bus for a given peripheral. The locking allows devices to reserve a bus to themselves for a given period of time (between lock and unlock.) This allows devices to complete several reads and writes on the bus without any intervention from other devices on the same bus, which is required in some instances. The chip select becomes active during lock and becomes inactive when unlocked. Writes and reads in between the lock and unlock do not alter the chip-select line.

SPI Framework Module Important Operational Notes and Limitations

- Multiple SPI devices can be configured to share a common bus. Once the SPI Framework bus module is configured, different SPI peripherals (devices) can be connected to that bus.
- For each SPI device connected to the bus, one SPI HAL module (new or shared) and one SPI Framework device module must be added.
- User-defined callback is not required as it has been internally taken care of by the framework.
- Setting the interrupts to different priority levels could result in improper operation.

- Refer to the MCU specification manual for identifying SPI bus compatibility. Device compatibility with the SPI bus is not checked in the framework hence incompatible SPI device may result in improper operation.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.26.4 Including the SPI Framework Module in an Application

This section describes how to include the SPI Framework module in an application using the SSP configurator.

NOTE: It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the *SSP User's Manual* to learn how to manage each of these important steps in creating SSP-based applications.

To add the SPI Framework module to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the SPI Framework is g_sf_spi_device0. This name can be changed in the associated **Properties** window.)

SPI Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_spi_device0 on sf_spi	**Threads**	**New Stack> Framework> Connectivity> SPI Framework Device on sf_spi**

When the SPI Framework module on sf_spi is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information will have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower level drivers; these are either optional or recommended (this is indicated in the block with the inclusion of this text.) If the addition of lower-level drivers is required, the module description will include **Add** in the text. Clicking on any Pink banded modules brings up the **New** icon and displays possible choices.

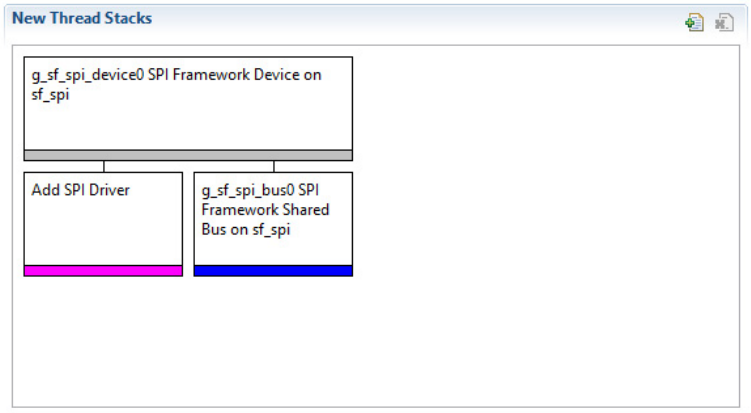

Figure 230: SPI Framework Module Stack (No Driver Selected)

Once the desired lower-level module has been selected, the module stack displays as following figures illustrate.

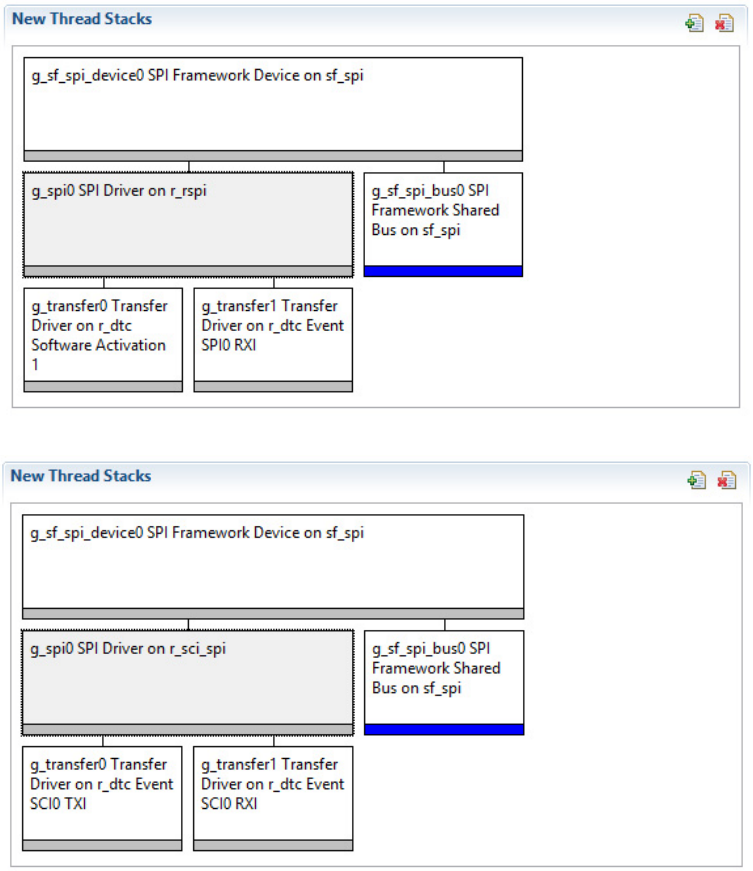

Figure 231: SPI Framework Implementations

4.1.26.5 Configuring the SPI Framework Module

The SPI Framework module must be configured by you for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes, and these are identified with a lock icon for the 'locked' property in the Properties** window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties** tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties** window of the associated module. Simply select the indicated module and then view the **Properties** window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the **Properties** window in the ISDE indicate the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE and create the module and explore the property settings in parallel with looking over the configuration table settings in the following table. This helps to orient you, and can be a useful hands-on approach

to learning the ins and outs of developing with SSP.

Configuration Settings for the SPI Framework Module on sf_spi

Parameter	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Parameter checking setting determines if code is added to check that parameters are within appropriate limits
Name	g_sf_spi_device0	Module name
Chip Select Port	00 thru 11 (Default: 00)	Select GPIO port used for the chip select.
Chip Select Pin	00 thru 15 (Default: 00)	Select GPIO pin used for the chip select.
Chip Select Active Level	Low, High (Default: Low)	Polarity of the chip select signal, active high or low.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, values other than the defaults for stack modules can be desirable. For example, it might be useful to select different chip-select GPIOs or levels. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

NOTE: Most of the property settings for modules are fairly intuitive and usually can be determined by inspection of the associated **Properties** window from the SSP configurator.

SPI Framework Module Configuration Settings for Lower-Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the SPI HAL Module on r_rspi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Parameter checking setting determines if code is added to check that parameters are within appropriate limits
Name	g_spi0	Module name
Channel	0	Channel number
Operating Mode	Master, Slave (Default: Master)	Operating mode selection
Clock Phase	Data sampling on odd edge/ data variation on edge, Data sampling on even edge, data variation on odd edge (Default: odd/even)	Clock phase selection
Clock Polarity	Low when idle, high when idle (Default: Low when idle)	Clock polarity selection
Mode Fault Error	Enable, Disable (Default: Disable)	Mode fault error selection
Bit Order	MSB First, LSB First (Default: MSB First)	Bit order selection
Bitrate	500000	Bit rate selection
Callback	NULL	Callback function name
SPI Mode	SPI Operation, Clock Synchronous operation (Default: SPI Operation)	SPI mode selection
SPI Communication Mode	Full Duplex, Transmit Only (Default: Full Duplex)	SPI communication mode selection

ISDE Property	Value	Description
Slave Select Polarity (SSL0)	Active Low, Active High (Default: Active Low)	Slave select polarity selection 0
Slave Select Polarity (SSL1)	Active Low, Active High (Default: Active Low)	Slave select polarity selection 1
Slave Select Polarity (SSL2)	Active Low, Active High (Default: Active Low)	Slave select polarity selection 2
Slave Select Polarity (SSL3)	Active Low, Active High (Default: Active Low)	Slave select polarity selection 3
Select Loopback 1	Normal, Inverted (Default: Normal)	Loopback 1 selection
Select Loopback 2	Normal, Inverted (Default: Normal)	Loopback 2 selection
Enable MOSI Idle	Enable, Disable (Default: Disable)	Enable MOSI idle selection
MOSI Idle State	MOSI Low, MOSI High (Default: MOSI Low)	Enable MOSI idle state selection
Enable Parity	Enable, Disable (Default: Disable)	Enable parity selection
Parity Mode	Parity Odd, Parity Even (Default: Parity Odd)	Enable parity mode selection

ISDE Property	Value	Description
Select SSL (Slave Select)	SSL0, SSL1, SSL2, SSL3 (Default: SSL0)	Select SSL selection
Select SSL Level After Transfer	SSL Level Keep, SSL Level Do Not Keep (Default: Do Not Keep)	Select SSL level after transfer selection
Clock Delay Enable	Enable, Disable (Default: Disable)	Clock delay enable selection
Clock Delay Count	Clock Delay 1 RSPCK thru Clock Delay 8 RSPCK (Default: Clock Delay 1 RSPCK)	Clock delay count selection
SSL Negation Delay Enable	Enable, Disable (Default: Disable)	SSL Negation Delay Enable selection
Negation Delay Count	Negation Delay 1 RSPCK thru Negation Delay 8 RSPCK (Default: Negation Delay 1 RSPCK)	Negation Delay Count selection
Next Access Delay Enable	Enable, Disable (Default: Disable)	Next Access Delay Enable selection
Next Access Delay Count	Next Access Delay 1 RSPCK thru Next Access Delay 8 RSPCK (Default: Next Access Delay 1 RSPCK)	Next Access Delay Count selection

ISDE Property	Value	Description
Receive Interrupt Priority	Priority 0 (highest), 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 (lowest, not valid if using Thread X), Disabled (Default: Priority 2)	Receive Interrupt Priority selection.
Transmit Interrupt Priority	Priority 0 (highest), 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 (lowest, not valid if using Thread X), Disabled (Default: Priority 2)	Transmit Interrupt Priority selection.
Error Interrupt Priority	Priority 0 (highest), 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 (lowest, not valid if using Thread X), Disabled (Default: Priority 2)	Error Interrupt Priority selection.

NOTE: The example settings and defaults are for a project using the Synergy SK-S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the DTC HAL Module on r_dtc Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled (Default: Disabled)	Software start selection
Link section to keep DTC vector table	.ssp_dtc_vector_table	Link section to keep DTC vector table selection
Name	g_transfer0	Module name
Mode	Normal	Mode selection
Transfer Size	4 Bytes	Transfer size selection

ISDE Property	Value	Description
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Software Activation 1	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection

NOTE: The example settings and defaults are for a project using the Synergy S7 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the DTC HAL Module on r_dtc Event SCI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled (Default: Disabled)	Software start selection
Link section to keep DTC vector table	.ssp_dtc_vector_table	Link section to keep DTC vector table selection
Name	g_transfer0	Module name
Mode	Normal	Mode selection

ISDE Property	Value	Description
Transfer Size	1 Bytes	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode)	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SPI0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SPI Framework Shared Bus on sf_spi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Selects if code for parameter checking is to be included in the build
Name	g_sf_spi_bus0	Module name
SPI Implementation	SCI SPI	SPI implementation selection
Channel	0	Channel selection

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SPI HAL Module on r_sci_spi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Parameter checking setting determines if code is added to check that parameters are within appropriate limits
Name	g_spi0	Module name
Channel	0	Channel number
Operating Mode	Master, Slave (Default: Master)	Operating mode selection
Clock Phase	Data sampling on odd edge/ data variation on even edge, Data sampling on even edge, data variation on odd edge (Default: odd/even)	Clock phase selection
Clock Polarity	Low when idle, high when idle (Default: Low when idle)	Clock polarity selection
Mode Fault Error	Enable, Disable (Default: Disable)	Mode fault error selection
Bit Order	MSB First, LSB First (Default: MSB First)	Bit order selection
Bitrate	100000	Bit rate selection
Callback	NULL	Callback function name
Receive Interrupt Priority	Priority 0 (highest), 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 (lowest, not valid if using Thread X), Disabled (Default: Priority 2)	Receive Interrupt Priority selection.
Transmit Interrupt Priority	Priority 0 (highest), 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 (lowest, not valid if using Thread X), Disabled (Default: Priority 2)	Transmit Interrupt Priority selection.

ISDE Property	Value	Description
Transmit End Interrupt Priority	Priority 0 (highest), 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 (lowest, not valid if using Thread X), Disabled (Default: Priority 2)	Transmit End Interrupt Priority selection.
Error Interrupt Priority	Priority 0 (highest), 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 (lowest, not valid if using Thread X), Disabled (Default: Priority 2)	Error Interrupt Priority selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

DTC HAL Module on r_dtc Event SCI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled (Default: Disabled)	Software start selection
Link section to keep DTC vector table	.ssp_dtc_vector_table	Link section to keep DTC vector table selection
Name	g_transfer0	Module name
Mode	Normal	Mode selection
Transfer Size	1 Byte	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection

ISDE Property	Value	Description
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SCI0 TXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

DTC HAL Module on r_dtc Event SCI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled (Default: Disabled)	Software start selection
Link section to keep DTC vector table	.ssp_dtc_vector_table	Link section to keep DTC vector table selection
Name	g_transfer0	Module name
Mode	Normal	Mode selection
Transfer Size	1 Bytes	Transfer size selection
Destination Address Mode	Incremented	Destination address mode selection
Source Address Mode	Fixed	Source address mode selection
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection

ISDE Property	Value	Description
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SPI0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

SPI Framework Module Clock Configuration

The SPI peripheral module uses PCLKB as its clock source. The PCLKB frequency is set by using the SSP configurator clock tab prior to a build, or by using the CGC Interface at run-time.

SPI Framework Module Pin Configuration

The SPI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the SPI pins.

NOTE: For some peripherals, the operation mode selection determines what peripheral signals are available and thus what MCU pins are required.

Pin Selection for the SPI Framework Module

Resource	ISDE Tab	Pin selection Sequence
SCI	Pins	Select **Peripherals > Connectivity: SCI> SCI1**
RSPI	Pins	Select **Peripherals > Connectivity: SPI > SPI0**

NOTE: The top selection sequence assumes SCI1 and SPI0 are the desired hardware targets for the driver and the bottom

selection sequence assumes SPI0 is the desired target.

Pin Configuration Settings for the SPI Framework Module

Property	Settings	Description
Operation Mode	Disabled, Asynchronous UART, Synchronous UART, Simple I2C, Simple SPI, SmartCard (Default: Disabled)	Select Simple SPI as the Operation Mode for SPI on SCI
CTS0_RTS0_SS0	None, P103, P413 (Default: None)	SS0 Pin selection
RXD0_SCL0_MISO0	None, P100, P410 (Default: None)	MISO0 Pin selection
SCK0	None, P102, P412 (Default: None)	SCK0 Pin selection
TXD1_SDA1_MOSI0	None, P213, P709 (Default: None)	MOSI0 Pin selection

Other Settings for the SPI Framework Module

If external chip selects are being used, configure the chip select pins as GPIO outputs.

4.1.26.6 Using the SPI Framework Module in an Application

The typical steps in using the SPI Framework module in an application are:

1) Initialize the SPI Framework module using the open API
2) Lock the bus for continuous transfer using the lock API if needed
3) Read data using read API
4) Write data using write API
5) Write/read data simultaneously using writeRead API
6) Unlock the bus from continuous transfer using the unlock API if needed

7) Close the module using the close API

These common steps are illustrated in a typical operational flow diagram in the figure below:

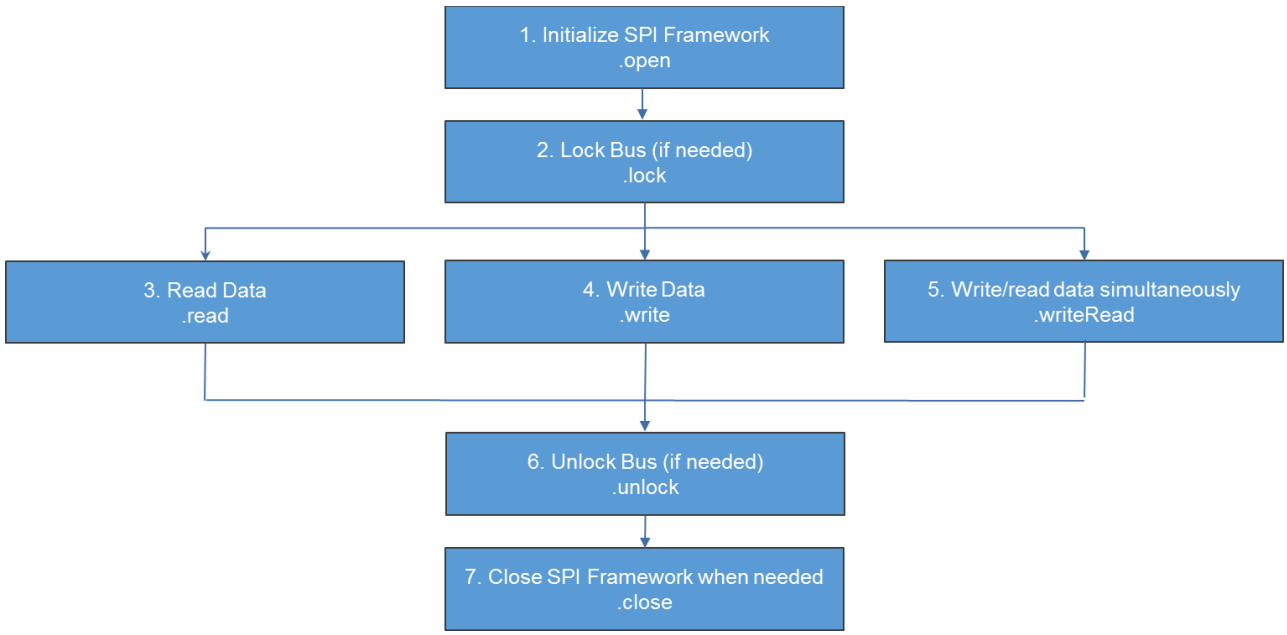

Figure 232: Flow Diagram of a Typical SPI Framework Application

4.1.27 Thread Monitor Framework

The Thread Monitor Framework provides high-level APIs for thread monitor framework applications and is implemented on sf_thread_monitor. The framework configures the watchdog timer (WDT) or independent watchdog timer (IWDT). The Thread Monitor Framework uses WDT or IWDT peripherals on the Synergy MCU device.

4.1.27.1 Thread Monitor Framework Module Features

The Thread Monitor Framework supports the following features:

- The Thread Monitor Framework interface monitors RTOS threads using a watchdog timer. The Thread Monitor forces a watchdog reset of the microcontroller when any of the monitored threads do not behave as expected.
- The Thread Monitor is designed to support any Synergy device with either a WDT or IWDT peripheral, and a HAL module with no changes to the API.
- In profiling mode, the minimum and maximum counter values for registered threads can be determined. When in profiling mode, the watchdog timer is always refreshed and does not reset the device.
- Both the WDT and IWDT HAL modules are supported by this framework module.

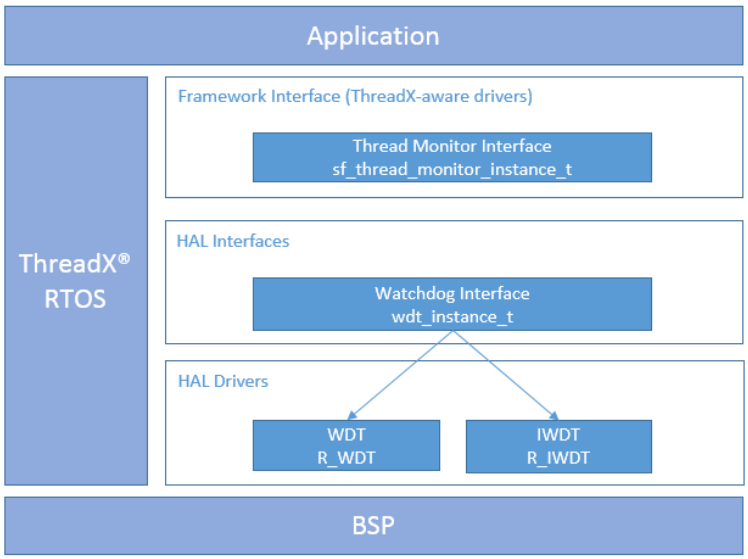

Figure 233: Thread Monitor Framework Module Block Diagram

4.1.27.2 Thread Monitor Framework Module APIs Overview

The Thread Monitor Framework defines API's for opening and closing the framework and registering and unregistering threads for monitoring. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of return status values follows the API summary table.

Console Framework Module API Summary

Function Name	Example API Call and Definition
open	g_sf_thread_monitor.p_api->open (g_sf_thread_monitor.p_ctrl,g_sf_thread_monitor.p_cfg); Configures the WDT or IWDT module. From the configuration data, the timeout period of the WDT/IWDT is determined. A thread created to monitor registered threads.
close	g_sf_thread_monitor.p_api->close (g_sf_thread_monitor.p_ctrl); Suspends the thread monitoring thread. The watchdog peripheral no longer refreshes.

Function Name	Example API Call and Definition
threadRegister	g_sf_thread_monitor.p_api-> threadRegister (g_sf_thread_monitor.p_ctrl, &p_min_max_struct); Registers a thread for monitoring.
threadUnregister	g_sf_thread_monitor.p_api-> threadUnregister (g_sf_thread_monitor.p_ctrl); Removes a thread from monitoring.
countIncrement	g_sf_thread_monitor.p_api-> countIncrement (g_sf_thread_monitor.p_ctrl); Safely increments a monitored thread's count value.
versionGet	g_sf_thread_monitor.p_api-> versionGet(&version); Retrieves the API version and stores it in the version pointer.

NOTE: For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the *SSP User's Manual***API References** for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_ASSERTION	Pointer is null.
SSP_ERR_IN_USE	Thread monitor has already been opened.
SSP_ERR_INVALID_MODE	Low-level watchdog peripheral returns an error when opened.
SSP_ERR_UNSUPPORTED	Data structure could not be allocated.
SSP_ERR_INVALID_ARGUMENT	One or more configuration options is invalid for the low-level driver.

Name	Description
SSP_ERR_NOT_OPEN	SF_THREAD_MONITOR_Open has either not been called or it was not called successfully.
SSP_ERR_INSUFFICIENT_SPACE	Not enough entries in threads-to-be-monitored array to add to this thread. Increases value of THREAD_MONITOR_CFG_MAX_NUMBER_OF_THREADS in sf_thread_moinitor_cfg.h

NOTE: Lower-level drivers may return common error codes. See *SSP User's Manual***API References** for the associated module for a definition of all relevant status return values.

4.1.27.3 Thread Monitor Framework Module Operational Overview

The Thread Monitor works as follows: A thread registers a counter variable with the Thread Monitor along with minimum and maximum expected values for this counter variable. The thread which is monitored increments the counter variable while it runs. At a period of half the watchdog timeout period, the Thread Monitor checks the counter variables of registered threads. If any fall outside of the minimum and maximum values, the watchdog timer is allowed to reset the microcontroller. If all fall within their expected range, the watchdog timer is refreshed and the counter variables are cleared to zero.

Thread Monitor Framework Module Important Operational Notes and Limitations

The following figure shows a flowchart for the operation of the Thread Monitor Framework module.

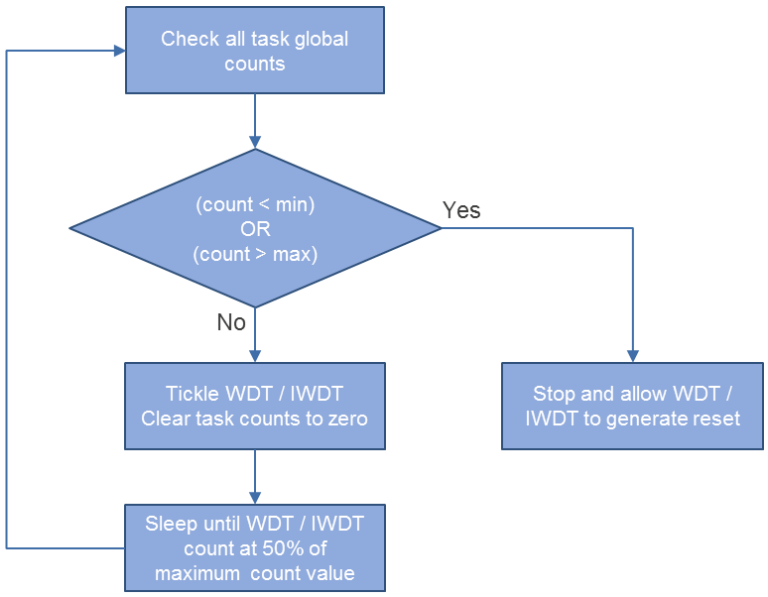

Figure 234: Thread Monitor Framework Operation Diagram

The following figure shows when the WDT/IWDT refreshes. Note that the valid refresh period is the central 50% of the count period, 25% on either side of the 50% count value.

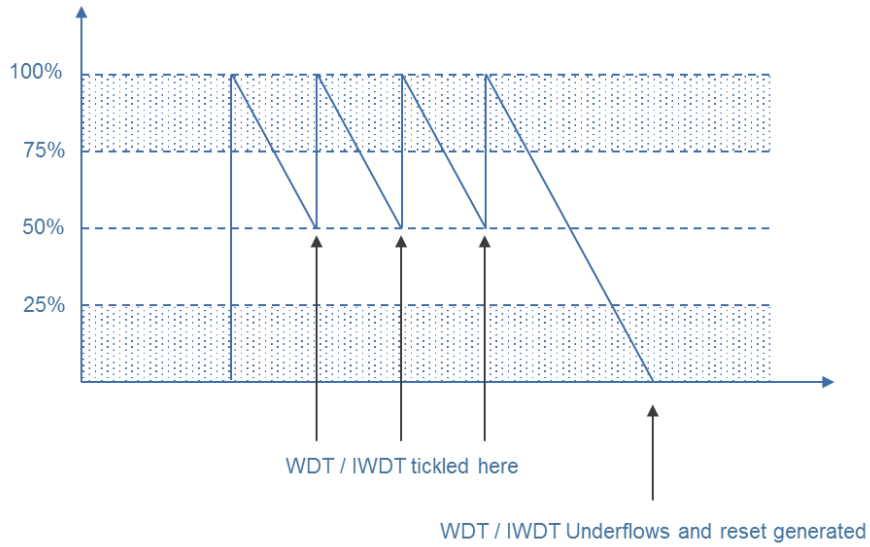

Figure 235: WDT/IWDT Operation Diagram

- The IWDT has its own clock source to improve safety.
- The WDT can be started from the application.
- When the thread is not executing sleep mode, set the stop-control property of the WDT to >WDT Count Enabled in Low Power Mode. When the thread is not executing (asleep), the ThreadX® executes a WFI instruction effectively putting the device into soft sleep, which causes the WDT to stop counting.

NOTE: Do not open or refresh the WDT in a monitored thread file; it is done automatically by the Thread Monitor Framework.

- Internally, the Thread Monitor Framework runs at the rate of half of the watchdog timer reset period. This rate ensures the Thread Monitor Framework runs at 50% of the watchdog count value—well within the valid refresh window. The Thread Monitor calculates the reset period internally by querying the lower-level watchdog driver.
- The Thread Monitor Framework has a close API call. When WDT and IWDT are being used, it is not possible to stop them. If the Thread Monitor Framework is closed, some other provision for refreshing the watchdog must be made or the device resets.
- Debugging mode-support is required when running with a JLink on some devices; WDT/IWDT does not count when using JLink debugging hardware. The Thread Monitor Framework thread typically synchronizes to the WDT/IWDT counter, but skips this synchronization step when it is running with JLink.
- Assign a high priority (low number in ThreadX) to the Thread Monitor Framework thread; any delays in running the Thread Monitor Framework could refresh the watchdog outside of the valid refresh window, causing the microcontroller to reset. The Thread Monitor Framework thread does not run for long and does not impact the performance of the system.

- Refer to the latest *SSP Release Notes* for any additional operational limitations for this module.

4.1.27.4 Including the Thread Monitor Framework Module in an Application

This section describes how to include the Thread Monitor Framework in an application using the SSP configurator.

NOTE: It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these tasks, refer to the first few chapters of the *SSP User's Manual* to learn how to manage each of these important steps in creating SSP-based applications.

To add the Thread Monitor Framework to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Thread Monitor Framework is g_thread_monitor0. This name can be changed in the associated Properties window.)

Thread Monitor Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_thread_monitor0 Thread Monitor Framework	Threads	New Stack> Framework> Services> Thread Monitor Framework on sf_thread_monitor

When the Thread Monitor Framework on sf_thread_monitor is added to the thread stack as shown in the following figure, the configurator reports (via the **Add WDT** block) that at least one watch dog timer is required to complete the stack. Any lower-level modules that need additional configuration information have box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended (this is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description includes **Add** in the text. Clicking on any Pink banded modules brings up the **New** icon and displays possible choices.

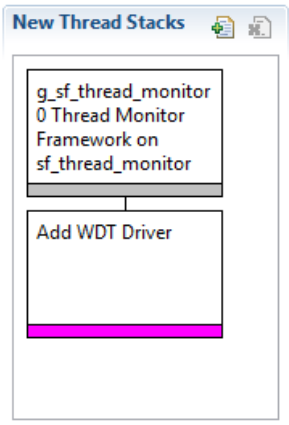

Figure 236: Thread Monitor Framework Module Stack

4.1.27.5 Configuring the Thread Monitor Framework Module

The Thread Monitor Framework module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only those properties that can be changed without causing conflicts are available for modification. Other properties are locked and are not available for changes, and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP Configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available.

Also, note that the interrupt priorities listed in the Properties window in the ISDE includes the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not in the following configuration properties table, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel while looking over the following configuration table settings. This helps to orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Thread Monitor Framework Module on sf_thread_monitor

Parameter	Value	Description
Parameter Checking	Enabled, Disabled, BSP (Default: BSP)	Controls whether to include code for API parameter checking.
Maximum Number of Monitored Threads	5	Maximum number of threads that can be monitored.
Name	g_sf_thread_monitor0	Module name.
Profiling Mode	Enabled, Disabled, (Default: Disabled)	Whether profiling mode should be enabled.
Thread Monitor Thread Priority	1	Priority of thread monitor internal thread.

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Settings other than the defaults for lower-level modules can be desirable in some cases. For example, it might be useful to set the maximum number of monitored threads to a desired value. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

NOTE: Most of the property settings for modules are fairly intuitive and usually can be determined by inspection of the associated Properties window from the SSP configurator.

Configuration Settings for the Thread Monitor Framework Low Level Modules

Typically, only a small number of settings must be modified from the default for lower-level modules as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following tables identify all the settings within the properties section for the module.

Configuration Settings for the Independent Watchdog Timer on r_iwdt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Include parameter checking code
Name	g_wdt0	Module Name
NMI Callback	NULL	Callback Name

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Watchdog Timer on r_wdt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Include parameter checking code
Name	g_wdt0	Module Name
Start Mode	Register, Auto (Default: Register)	Configures the start mode as register start or auto-start.
Start Watchdog After Configuration	True, False (Default: True)	Controls whether WDT is started during initialization
Timeout	1024 cycles, 4096 cycles, 8192 cycles, 16384 cycles (Default: 16384 cycles)	WDT timeout period.
Clock Division Ratio	PCLK/4, PCLK/64, PCLK/128, PCLK/512, PCLK/2048, PCLK/8192 (Default: PCLK/8192)	WDT clock divider

ISDE Property	Value	Description
Window Start Position	100% (Window Position Not Specified); 75%, 50%, 25% (Default: 100%)	Permitted refresh period start position.
Window End Position	0% (Window Position Not Specified; 25%, 50%, 75% (Default: 0%)	Permitted refresh period end position.
Reset Control	Reset Output, NMI Generated (Default: Reset Output)	Select whether WDT should reset the MCU or generate an NMI.
Stop Control	WDT Count Enabled in Low Power Mode, WDT Count Disabled in Low Power Mode (Default: Disabled)	Select whether the WDT should stop counting in low power modes.
NMI Callback	NULL	Callback. A user callback function can be registered in open. If this callback function is provided, it is called from the interrupt service routine (ISR) each time the IRQn triggers. ATTENTION: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Most of the property settings for modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Thread Monitor Framework Module Clock Configuration

Use the ISDE to configure the WDT clock using the **Clocks** tab.

The WDT is initially based on the PCLKB frequency. Set the PCLKB frequency in e^2 studio Integrated Solution Developer Environment (ISDE) using the clock configurator Configuring Clocks or the CGC Interface at run time.

With PCLKB running at 60 MHz, the WDT maximum timeout period is approximately 2.24 seconds.

The IWDT clock runs at 15 kHz resulting in a maximum possible timeout period of just under 35 seconds.

Thread Monitor Framework Module Pin Configuration

The Thread Monitor Framework does not require any pins for its operation.

Threads for the Thread Monitor Framework Module Application

Any thread monitored by the Thread Monitor Framework must be instrumented to work with the monitoring module. When a thread to be monitored is registered with the Thread Monitor, the expected minimum and maximum count values are passed via a pointer to a structure of type sf_thread_monitor_counter_min_max_t containing the values.

The thread's counter and minimum and maximum values must be registered with the Thread Monitor Framework by calling g_sf_thread_monitor.p_api->threadRegister().

Each time round the monitored thread's loop, the counter value should be updated by calling g_sf_thread_monitor.p_api->countIncrement().

Other Thread Monitor Framework Module Settings

The Thread Monitor Framework does not use any interrupts; the WDT/IWDT must be configured to generate a reset.

4.1.27.6 Using the Thread Monitor Framework Module in an Application

The typical steps in using the Thread Monitor Framework in an application are:

1) Initialize the Thread Monitor using the open API
2) Register thread that needs to be monitored with the threadRegister API
3) Use the countIncrement API to increment the count every time the registered thread is executed.
4) Unregister the thread with the threadUnregister API when there is no longer a need to monitor the registered thread.
5) Close the Thread Monitor with the close API (only if the Thread Monitor is no longer required in an application).

Often, the increment count step is repeated periodically. The following figure illustrates these common steps in a typical operational flow.

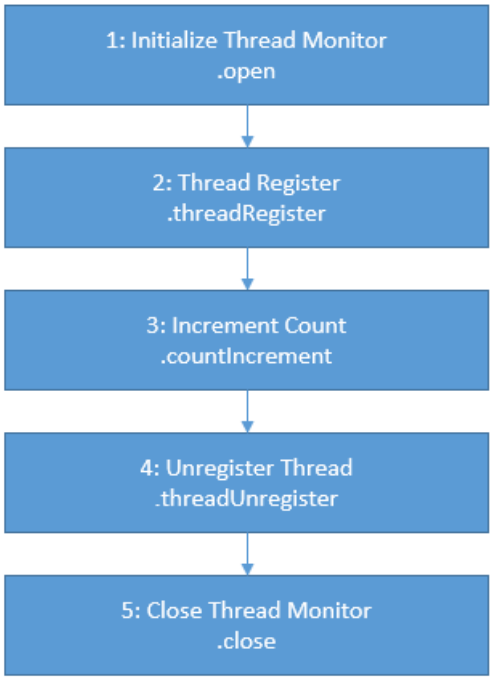

Figure 237: Typical Thread Monitor Framework Module Application

4.1.28 Touch Panel Framework

The Touch Panel Framework module provides a high-level API for reading messages from a touch controller and is implemented using an I2C port. The Touch Panel Framework module uses the IIC or SCI peripherals on the Synergy MCU.

4.1.28.1 Touch Panel Framework Module Features

The Touch Panel Framework supports the following features:

- Reads data from a touch controller and publishes touch messages to any queue subscribed to touch events in the messaging framework
- Provides position data (X and Y coordinates)
- Provides the touch event type (down, up, move, hold, or invalid)
- Supports I2C-based touch panel implementations with external interrupts

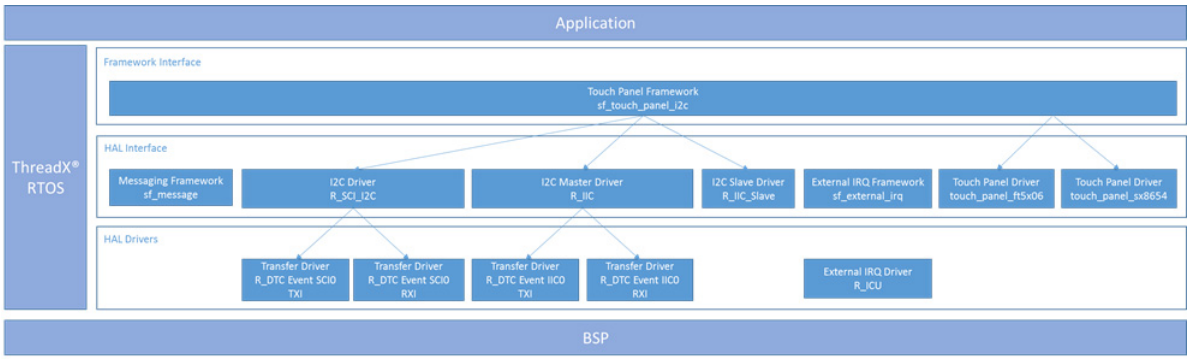

Figure 238: Touch Panel Framework Module Block Diagram

4.1.28.2 Touch Panel Framework Module APIs Overview

The Touch Panel Framework module defines APIs for key functions such as opening, calibrating, starting, stopping or closing. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows.

Touch Panel Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_touch_panel_i2c0.p_api->open(g_sf_touch_panel_i2c0.p_ctrl, g_sf_touch_panel_i2c0.p_cfg); Create required RTOS objects, call lower level module for hardware specific initialization, and create a thread to post touch data to a message queue.

Function Name	Example API Call and Description
calibrate	g_sf_touch_panel_i2c0.p_api->calibrate(g_sf_touch_panel_i2c0.p_ctrl, &expected, &actual, timeout); Begin calibration routine based on provided expected coordinates. Returns SSP_SUCCESS only if the tolerance is longer than the distance from the expected touch point to the actual touch point (using the followng formula: p_calibrate->tolerance_pixels \^ 2 > (p_calibrate->x - x_measured) \^ 2 + (p_calibrate->y - y_measured) \^ 2
start	g_sf_touch_panel_i2c0.p_api->start(g_sf_touch_panel_i2c0.p_ctrl); Start scanning for touch events.
stop	g_sf_touch_panel_i2c0.p_api->stop (g_sf_touch_panel_i2c0.p_ctrl); Stop scanning for touch events.
reset	g_sf_touch_panel_i2c0.p_api->reset(g_sf_touch_panel_i2c0.p_ctrl); Reset touch controller if reset pin is provided, and resets the I2C bus.
close	g_sf_touch_panel_i2c0.p_api->close(g_sf_touch_panel_i2c0.p_ctrl); Terminate touch thread and close channel at HAL layer.
versionGet	g_sf_touch_panel_i2c0.p_api->versionGet(&version); Retrieves API version and stores it in the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API call successful.
SSP_ERR_ASSERTION	A pointer parameter was NULL, or a lower level driver reported this error.
SSP_ERR_INTERNAL	The touch panel thread or event flags could not be created, or a lower level driver reported this error.
SSP_ERR_CALIBRATE_FAILED	Actual touch value was not in expected range.
SSP_ERR_NOT_OPEN	Touch panel is not configured. Call SF_TOUCH_PANEL_I2C_Open.
SSP_ERR_IN_USE	Mutex was not available, or a lower level driver reported this error.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.28.3 Touch Panel Framework Module Operational Overview

The Touch Panel Framework module reads data from a touch controller and publishes touch messages to any queue subscribed to touch events in the messaging framework. The touch event contains position data (X and Y coordinates) and the touch event type (down, up, move, hold, or invalid). The Touch Panel Framework supports I2C-based touch panel implementations with external interrupts. The Touch Panel Framework creates a thread internally to read the touch controller.

The typical flow when using the Touch Framework is:

1) Pend on a touch message.
2) Parse the touch message.

Touch Panel Framework Module Important Operational Notes and Limitations

Initial Configuration

The e^2 studio ISDE automatically generates the Touch Event Class and the New Data Event in the Messaging tab of the Project Configurator when you add the Touch Panel Framework to your project. Use the following steps to configure Touch Event message subscriber(s) in your project:

- Select the Touch Event Class on the Event Classed pane in e^2^ studio Synergy Configurator Messaging tab.
- Check the check box of subscriber thread on the Touch Subscribers Pane in Messaging tab. (If no thread is shown in the pane, add the thread by clicking the "New" icon located at the top right of the Touch Subscriber pane.)

Create a Custom Touch Panel Chip Driver

To create your custom Touch Chip Driver, refer to the existing touch driver code in SSP which is located at synergy/ssp_supplemental/ touch_drivers (Note that this directory will only be visible if any existing touch chip driver is selected in synergy configurator, to do this go to synergy configurator select New > Framework > Input > Touch Panel Framework on sf_touch_panel_i2c> Add Touch Driver and select any existing touch driver for reference and generate project content), the following instructions and pseudo code to connect it to the Touch Panel Framework:

- Implement Touch Chip Driver Instance to enable the Touch Panel Framework to attach the driver.
- Implement the payloadGet function to obtain touch events and touch coordinates from a Touch Panel Controller device through the I2C interface.
- Implement a reset function to reset a Touch Panel Controller device by an associated GPIO pin and I2C interface

Configure the Custom Touch Panel Chip Driver

To configure a custom touch chip driver to a project, use the following steps:

1) Create a **Synergy C** project.
2) Update existing touch driver XML for the custom touch driver by following these steps to modify any existing touch XML.A. Go to .module_descriptions folder under the project root folderB. Edit touch driver XML: Renesas##HAL Drivers##touch panel##touch_panel_i2c_ft5x06####<version> OR Renesas##HAL Drivers##touch panel##touch_panel_i2c_sx8654####<version>C. Change name of the instance structure in the **value** field with the name of custom driver instance structure.D. Add the new instance declaration after the property tabE. Rename all touch chip number in the XML with custom touch chip number.F. Save and close the XML file
3) Open project configurator and add touch panel framework, by selecting New > Framework > Input > Touch Panel Framework on sf_touch_panel_i2c (If the configurator was already opened, close and open it again).
4) Configure all components.
5) Add the custom touch panel chip driver to the **Add Touch Driver** box. (The custom touch driver open will be visible if XML is modified correctly as described above).
6) Generate Project Content and add new directory (for ex. touch_panel_i2c_xxxxxx) structure under synergy/ ssp_-supplemental/ touch_drivers, the directory structure will look like this: synergy/ ssp_supplemental/ touch_drivers/ touch_panel_i2c_xxxxxx (replace xxxxxx with touch controller part no).
7) Add the custom driver code into this directory (code created as described in the above section **Create a custom Touch Panel Chip Driver**, simply copy and paste to ssp_supplemental/ touch_drivers/ touch_panel_i2c_xxxxxx).
8) Exclude existing driver from build if any (right-click the .c file > Exclude from build… > Select all > OK).
9) Build the code.

- User callback is not available in the I2C-bus communication procedure.
- The reset API is only available after the following conditions are satisfied: (1) The stop API is called. (2) A touch event happened and the Touch Panel Framework posts a touch event message.
- The add-on directory for the Touch Panel driver was changed from renesas_sybd (in SSPv1.2.0-b.1) to ssp_supplemental (SSPv1.2.0). If both SSPv1.2.0-b.1 and SSPv1.2.0 are installed in the development environment, both touch panel modules will be selected in the component tab. In your project, exclude the renesas_sybd folder from the build. Right click on renesas_sybd folder -> Exclude from build->Select all->OK**.**
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.28.4 Including the Touch Panel Framework Module in an Application

This section describes how to include the Touch Panel Framework module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the "Getting Started Guide for SSP" listed in the References section at the end of this document to learn how to manage each of these important steps in creating SSP-based applications.

To add the Touch Panel Framework to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Touch Panel Framework is sf_touch_panel_i2c. This name can be changed in the associated Properties window.)

Touch Panel Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_touch_panel_i2c0 Touch Panel Framework on sf_touch_panel_i2c	Threads	New Stack> Framework> Input> Touch Panel Framework on sf_touch_panel_i2c

When the Touch Panel Framework on sf_touch_panel_i2c is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower level modules. Any drivers that need additional configuration information will have box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower level drivers; these are either optional or recommended (this is indicated in the block with the inclusion of this text.) If the addition of lower level drivers is required, the module description will include "Add" in the text. Clicking on any Pink banded modules will bring up the "New" icon and then display the possible choices.

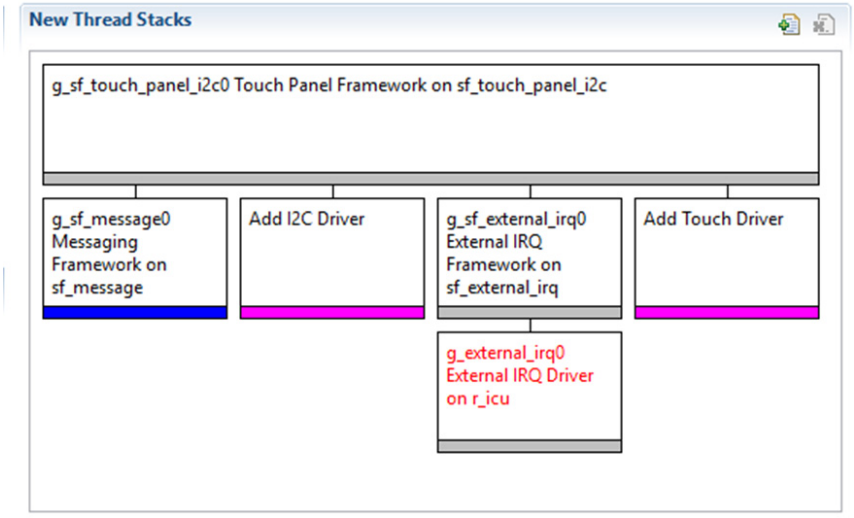

Figure 239: Touch Panel Framework Module Stack

4.1.28.5 Configuring the Touch Panel Framework Module

The Touch Panel Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify, by highlighting the block in red, any required configuration selections, such as Interrupts or operating modes, which must be configured for lower level modules, for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are **locked** and not available for changes and are identified with a lock icon for the **locked** property in the Property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous **manual** approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the properties tab within the SSP Configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the Interrupt Priority. This configuration setting is available with the Properties window of the associated module. Simply select the indicated module and then view the properties window. The Interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the Interrupt Priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring Interrupt Priority levels.

NOTE: You may want to open your ISDE and create the Touch Panel Framework and explore the property settings in parallel with looking over the following Configuration Table Settings. This will help orient you and can be a useful **hands-on** approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Touch Panel Framework Module on sf_touch_panel_i2c

Parameter	Value	Description
Parameter Checking	BSP, Enabled, Disabled ;Default: BSP	Enable or disable the parameter checking.
Name	g_sf_touch_panel_i2c0	Module name.
Thread Priority	Default: 3	Thread priority selection.
Hsize Pixels	Default: 800	Hsize pixels selection.
Vsize Pixels	Default: 480	Vsize pixels selection.
Update Hz	Default: 10	Update hz selection.
Reset Pin	IOPORT_PORT_10_PIN_02	Reset pin selection.
Touch Event Class Instance Number	0	Touch event class instance number selection.
Touch Coordinate Rotation Angle (Clockwise)	0, 90 (select this if 'Screen Rotation Angle' in GUIX Port is '270'), 180, 270 (select this if 'Screen Rotation Angle' in GUIX Port is '90') Default: 0	Touch coordinate rotation angle selection.

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults can be desirable. For example, it might be useful to select different screen sizes. The configurable properties for the lower level stack modules are given in the following sections for completeness and as a reference.

NOTE: Most of the property settings for lower level modules are fairly intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the Touch Panel Framework Low Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers and these are indicated via the red text in the Thread Stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The Touch Panel Framework consists of the following low level drivers:

- Messaging Framework on sf_message
- I2C Driver: I2C Master Driver on riic or I2C Master Driver on r_sci_i2c
- External IRQ Framework on sf_external_irq
- Touch Panel Driver

The following table identifies all the settings for the lower level drivers within the properties section for the module.

Configuration for the Messaging Framework on sf_message

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Message Queue Depth (Total number of messages to be enqueued in a Message Queue)	16	Specify the size of Thread X Message Queue in bytes for Message Subscribers. This value is applied to all the Message Queues.
Name	g_sf_message0	The name of Messaging Framework module control block instance.

ISDE Property	Value	Description
Work memory size in bytes	2048	Specify the work memory size in bytes. Choosing a small number results a small number of buffers which can be allocated at the same time (You can confirm the total buffer number on: sf_message_ctrl_t::number_of_buffers). If the value is smaller than the peak number of messages to be posted at the same time, the Framework occurs a buffer allocation failure affecting system performance.
Pointer to subscriber list array	p_subscriber_lists	Specify the name of pointer to the Subscriber List array.
name of the block pool internally used in the messaging framework	sf_msg_blk_pool	The name of memory block memory the Framework creates in the control block. This parameter might be useful for debugging purpose but NULL can be specified for saving memory.

Configuration for the I2C Driver on r_sci_i2c

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.
Name	g_i2c0	Module name.
Channel	0 to 9 Default: 0	Specify the SCI channel to be used with this configuration. SCI has channels as follows: Series S7 : 0 1 2 3 4 5 6 7 8 9; Series S3 : 0 1 2 3 4 - - - - 9; Series S1 : 0 1 - - - - - - - 9 .
Rate	Standard, Fast-mode Default: Standard	Standard and Fast.
Slave Address	0x00	Address of the slave device.

ISDE Property	Value	Description
Address Mode	7-Bit, 10-Bit Default: 7-Bit	Only 7-bit addresses are currently supported.
SDA Output Delay (nano seconds)	300	SDA output delay in nanoseconds.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Enables bitrate modulation function.
Callback	NULL	A user callback function can be registered in open. If this callback function is provided, it will be called from the interrupt service routine (ISR) for each of the conditions defined in i2c_event_t. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection.

ISDE Property	Value	Description
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit end interrupt priority selection.

Configuration for the DTC HAL Module on r_dtc Event SCI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled / /Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled / /Default: Enabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer0	Module name
Mode	Normal	Mode selection
Transfer Size	1 Byte	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection

ISDE Property	Value	Description
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SCI0 TXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC software event interrupt priority selection.

Configuration for the DTC HAL Module on r_dtc Event SCI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer1	Module name
Mode	Normal	Mode selection
Transfer Size	1 Byte	Transfer size selection
Destination Address Mode	Incremented	Destination address mode selection

ISDE Property	Value	Description
Source Address Mode	Fixed	Source address mode selection
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SCI0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC software event interrupt priority selection.

Configuration for the I2C Master Driver on r_riic

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.
Name	g_i2c0	Module name.
Channel	0, 1, or 2	Specify the IIC channel to be used with this configuration.

ISDE Property	Value	Description
Rate	Standard, Fast-mode, Fast-mode Plus Default: Standard	Standard, Fast, and Fast-plus. (See IIC Rate Calculation.)
Slave Address	0x00	Set the address of the slave device the I2C master will be communicating with.
Address Mode	7-Bit, 10-Bit Default: 7-Bit	Only 7-bit addresses are currently supported.
Callback	NULL	A user callback function can be registered in open. If this callback function is provided, it will be called from the interrupt service routine (ISR) for each of the conditions defined in i2c_event_t. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection.

ISDE Property	Value	Description
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit end interrupt priority selection.
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Error interrupt priority selection.

Configuration for the DTC HAL Module on r_dtc IIC0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Enabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer0	Module name
Mode	Normal	Mode selection
Transfer Size	1 Byte	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection

ISDE Property	Value	Description
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event IIC0 TXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC software event interrupt priority selection.

Configuration for the DTC HAL Module on r_dtc IIC0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.

ISDE Property	Value	Description
Name	g_transfer1	Module name
Mode	Normal	Mode selection
Transfer Size	1 Byte	Transfer size selection
Destination Address Mode	Incremented	Destination address mode selection
Source Address Mode	Fixed	Source address mode selection
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event IIC0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC software event interrupt priority selection.

Configuration for the External IRQ Framework on sf_external_irq

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Controls whether to include code for API parameter checking.
Name	g_sf_external_irq0	Framework name.
Event	None, Semaphore Put Default: Semaphore Put	Event selection.

Configuration for the External IRQ HAL Module on r_icu

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter checking setting enables or disables the addition of parameter checking code.
Name	g_external_irq0	Module name.
Channel	0	Specifies the hardware IRQ channel used.
Trigger	Falling, Rising, Both Edges, Low Level Default: Rising	Configures edge or level triggering.
Digital Filtering	Enabled, Disabled Default: Disabled	Digital filter enable/disable.
Digital Filtering Sample Clock (Only valid when Digital Filtering is Enabled)	PCLK/1, PLCK/8, PLCK/32, PCLK/64 Default: PCKL/64	Sets noise filter sampling period.

ISDE Property	Value	Description
Interrupt enabled after initialization	True, False Default: True	Determines if the interrupt is enabled immediately after initialization.
Callback	NULL	A user callback function can be registered in open. If this callback function is provided, it is called from the interrupt service routine (ISR) each time the IRQn triggers. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	An Interrupt priority can be registered in irq_ipl.

Configuration for the Touch Panel Driver on touch_panel_ft5x06

ISDE Property	Value	Description
Name	g_sf_touch_panel_i2c_chip_ft5x06	Module name.

Configuration for the Touch Panel Driver on touch_panel_sx8654

ISDE Property	Value	Description
Name	g_sf_touch_panel_i2c_chip_sx8654	Module name.

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

NOTE: Most of the property settings for modules are fairly intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Clock Configuration for the Touch Panel Framework

An example implementation of the I2C interface uses the SCI peripheral and is described here. Other implementation choices might have different selections, but can be inferred from the following example. The SCI peripheral module uses PCLKB as its clock source. The PCLKB frequency is set by using the SSP configurator clock tab, prior to a build, or by using the CGC Interface at run-time. During configuration, the I2C transfer rate is calculated and set internally by the driver, based on the user selected PCLB rate and the user selected transfer rate. If the PCLKB is configured in such a manner that the user selected rate cannot be achieved, an error will be returned when initializing the driver.

Pin Configuration for the Touch Panel Framework

An example implementation of the I2C interface uses the SCI peripheral and is described here. Other implementation choices might have different selections, but can be inferred from the following example. Synergy Kit specific settings for pins are shown in the following section. The SCI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table lists the method for selecting the pins within the SSP configuration window and the subsequent table lists an example indicating selection of the I2C pins. The following example settings demonstrate a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings

NOTE: Operation Mode selection mode determines what peripheral signals are available and thus what MCU pins are required.

Pin Selection Sequence for I2C Master Driver on SCI

Resource	ISDE Tab	Pin selection Sequence
SCI0	Pins	Select **Peripherals > Connectivity:SCI > SCI0**

NOTE: The above selection sequence assumes SCI0 is the desired hardware target for the driver.

Pin Configuration Settings for I2C Master Driver on SCI

Pin Configuration Property	Value	Description
Operation Mode	Disabled, Asynchronous UART, Synchronous UART, Simple I2C, Simple SPI, SmartCard (Default: Disabled) Simple I2C	Select Simple I2C as the Operation Mode for SPI on SCI
RXD1_SCL1_MISO1	None, P212, P708 (Default: None)	SCL Pin
TXD1_SDA1_MOSI1	None, P213, P709 (Default: None)	SDA Pin

NOTE: The above example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

Touch Panel Framework Module Synergy Kit Specific Settings

In addition to the above selections some kits specific settings may be needed, based on the touch chip used. These settings are summarized in the following examples of how you may need to configure these for your own custom touch controller device.

Configure the following External IRQ Settings.

For the DK-S7G2 (Touch Chip SX8654), select:

- Channel: 7
- Trigger: Falling

For the SK-S7G2 (Touch Chip SX8654), select:

- Channel: 9
- Trigger: Falling

For the PE-HMI1-S7G2 (Touch Chip FT5x06), select:

- Channel: 12
- Trigger: Falling

Common setting for all boards:

- Digital Filter settings: Any
- Interrupt enabled after initialization: True
- Callback: NULL

Configure the following I2C driver settings.

For the DK-S7G2, select r_sci_i2c:

- Channel: 7
- Rate: Standard
- Slave Address: 0x48
- Address Mode: 7-bit

For the SK- S7G2, select r_riic:

- Channel: 2
- Rate: Standard
- Slave Address: 0x48
- Address Mode: 7-bit

For the PE-HMI1-S7G2, select r_riic:

- Channel: 1

- Rate: Fast-Mode
- Slave Address: 0x38
- Address Mode: 7-bit

Common setting for all boards:

- Callback: NULL

Configure the following Touch Panel Framework module settings.

For the DK-S7G2:

- Touch Chip: g_sf_touch_panel_i2c_chip_sx8654
- H size Pixels: 480
- V size Pixels: 272
- Reset Pin: IOPORT_PORT_07_PIN_11

For the SK-S7G2:

- Touch Chip: g_sf_touch_panel_i2c_chip_sx8654
- H size Pixels: 240
- V size Pixels: 320
- Reset Pin: IOPORT_PORT_06_PIN_09

For the PE-HMI1-S7G2:

- Touch Chip: g_sf_touch_panel_i2c_chip_ft5x06
- H size Pixels: 800
- V size Pixels: 480
- Reset Pin: IOPORT_PORT_10_PIN_02

Common setting for boards:

- Thread Priority: Any

The Touch Chip Drivers for SX8654 and FT5x06 are built-in drivers in the SSP and can be selected when configuring the module.

4.1.28.6 Using the Touch Panel Framework Module in an Application

Once the module has been configured and the files generated, the touch panel framework is ready to be used in an application. Touch panel framework open automatically from the synergy generated file ones the application starts.

Suggested use of the Touch Panel Framework module:

1) Start the touch panel framework using start API of touch panel framework.
2) Pend on a touch message using the pend API
3) Parse the touch message with application code
4) Operate on the received data as needed by the application. Go to step 2.

These common steps in a typical operational flow diagram are shown in the following figure.

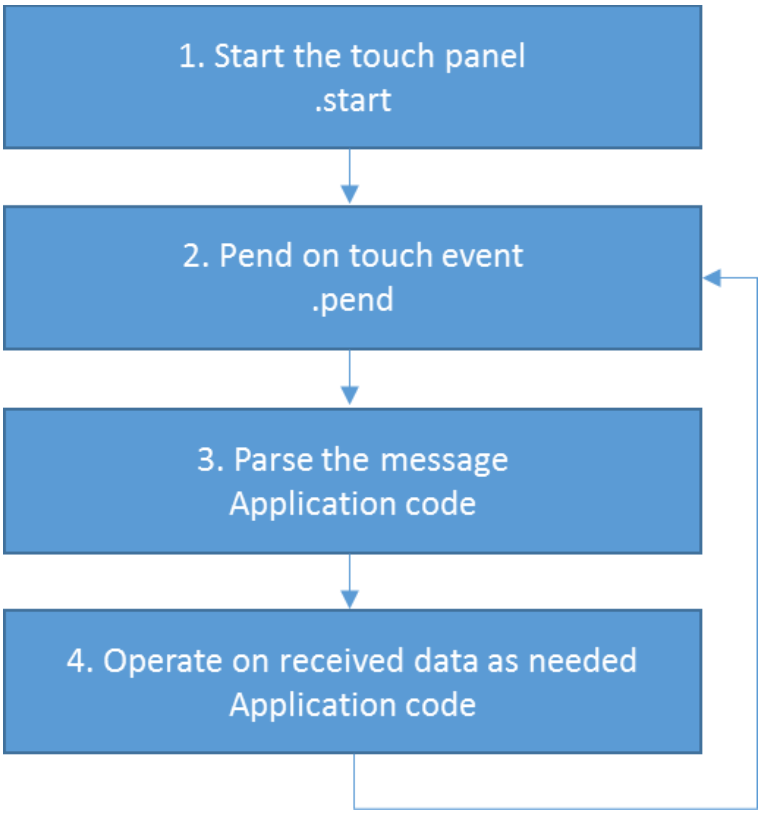

Figure 240: Flow Diagram of a Typical Touch Panel Framework Module Application

4.1.29 Wi-Fi Framework

The Wi-Fi framework provides high-level APIs for configuring and provisioning Wi-Fi modules as well as perform data transfers with or without on-chip networking capability. Currently, only the Qualcomm GT202 module is supported. The Wi-Fi framework communicates through SPI with the underlying GT202 module.

4.1.29.1 Wi-Fi Framework Module Features

The WiFi framework module has the following key features:

- Provides high-level APIs to configure and provision a WiFi module
- Provides four different implementations for:
  - A Wi-Fi device driver stack using the sf_wifi_gt202 framework
  - An on-chip stack using the sf_wifi_onchip_stack framework
  - A BSD socket stack using the sf_wifi_onchip_stack framework
  - A NetX and NetX Duo port using the sf_wifi_nsal_nx framework

- Using NetX and NASL:
  - Allows the same application code to be used across different Wi-Fi modules
  - Allows easy migration of the Ethernet-based application to a Wi-Fi based application
  - Allows for debugging and fine-tuning the application and TCP/IP stack as required by the application.
  - The current NSAL implementation only provides NetX NSAL. Adding support for a new network stack requires implementing the appropriate NSAL.
- Using the On-chip networking stack:
  - Is beneficial when using MCUs with a small memory footprint
  - Provides a BSD sockets interface to create socket-based applications with the On-chip TCP/UDP
  - Provides an option to integrate 3rd-party application protocols on top of TCP/IP such as MQTT and COAP without using the NetX stack.

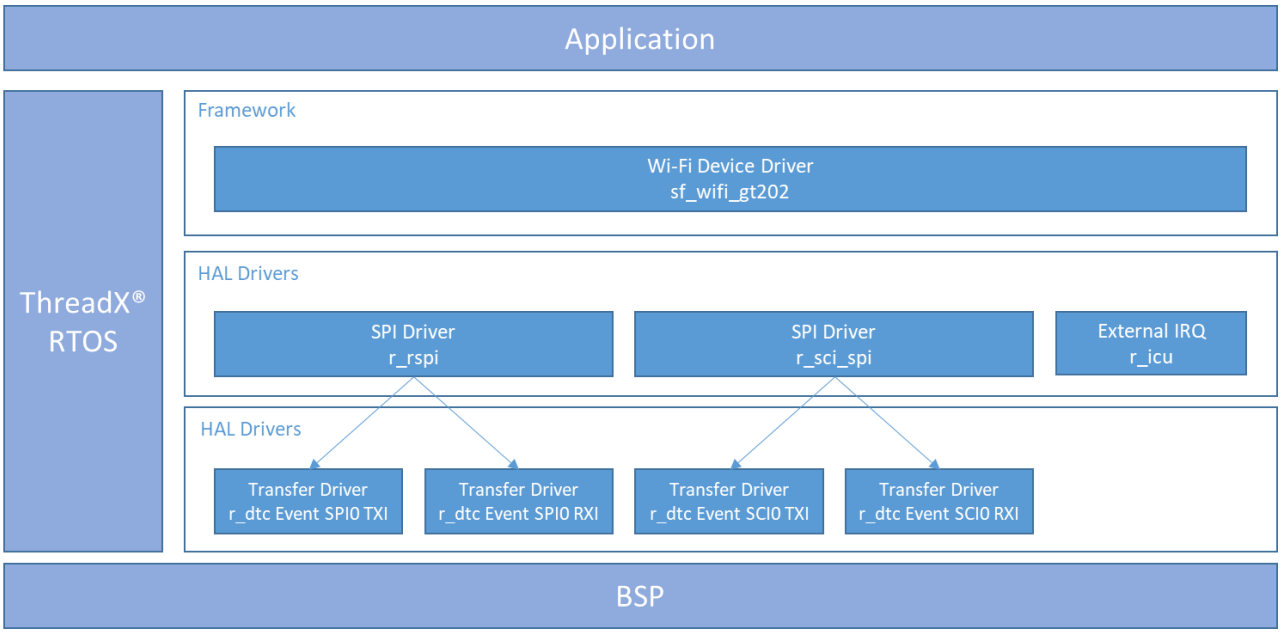

Figure 241:Wi-Fi Device Driver Implementation

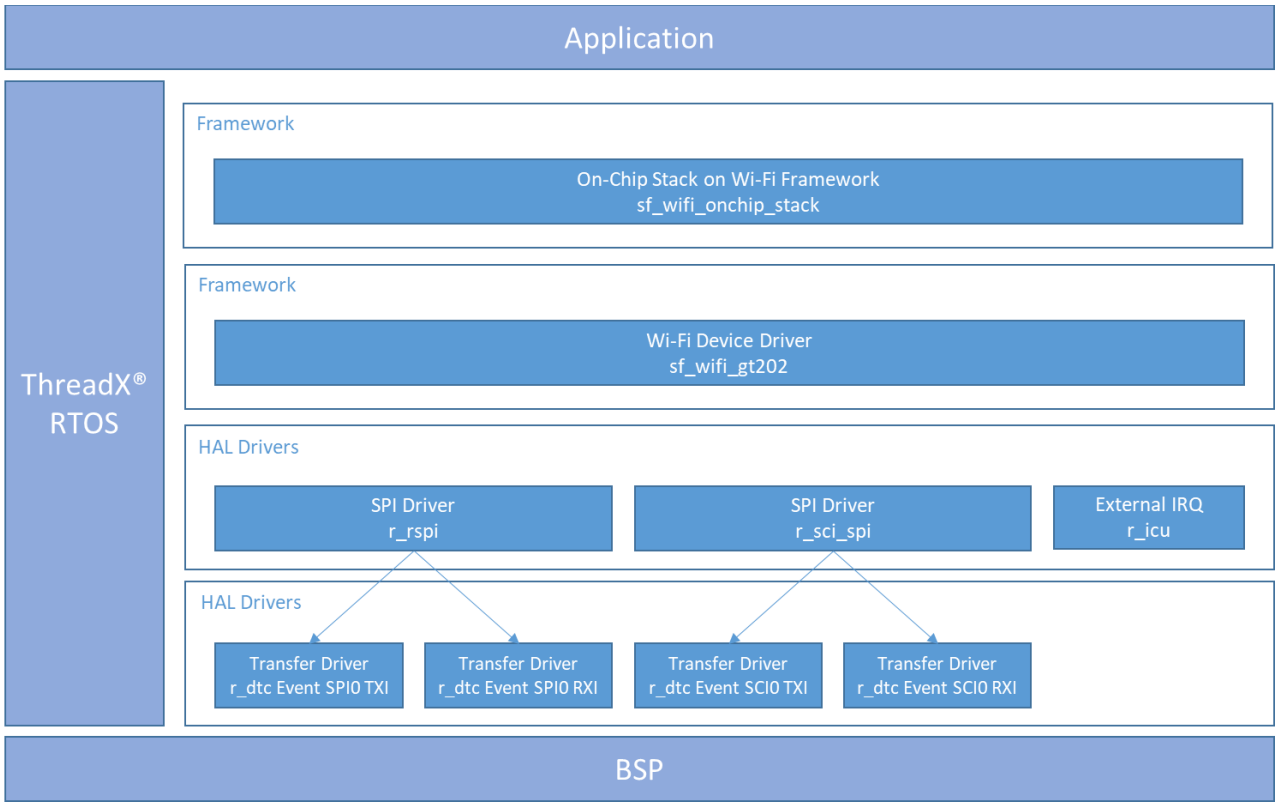

Figure 242: Wi-Fi On-Chip Stack Implementation

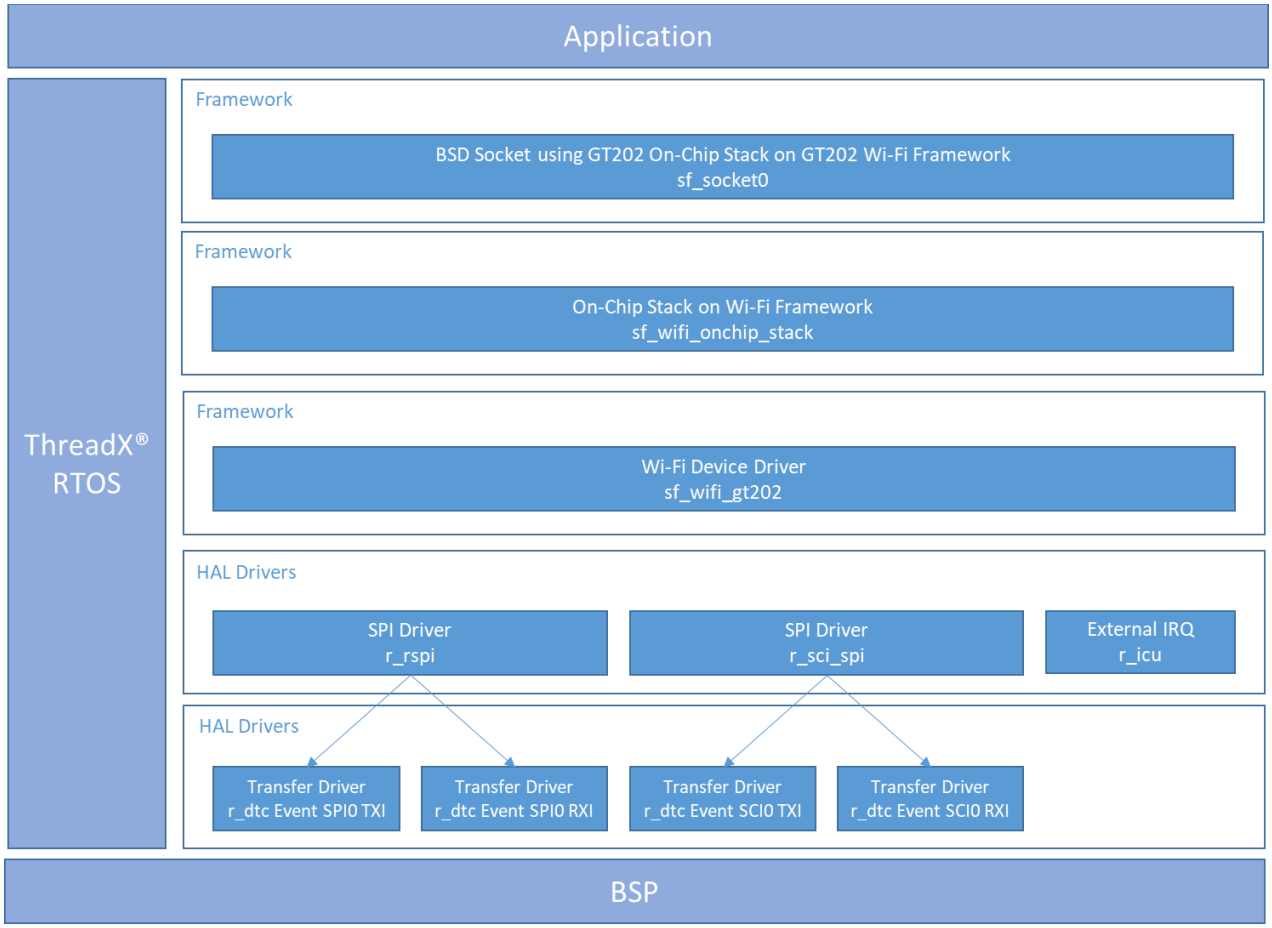

Figure 243: Wi-Fi BSD Socket Implementation

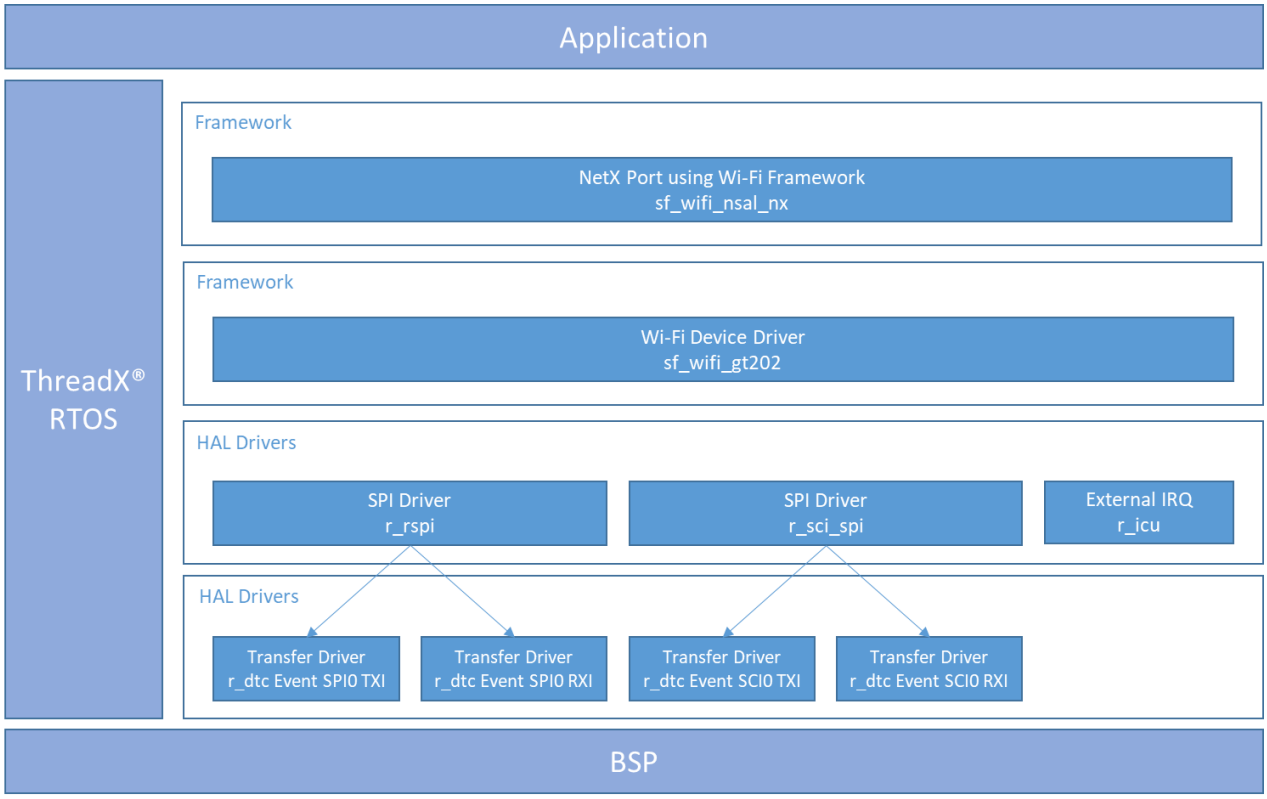

Figure 244:Wi-Fi NetX Port Implementation with NSAL

4.1.29.2 Wi-Fi Framework Module APIs Overview

The Wi-Fi Framework defines APIs for each of the related modules. The following descriptions explain the operation of each API. A table of common return codes follows at the end of the section. Refer to the API reference section for the associated module for additional details.

Additionally, a more detailed API description, along with a working example application (which is too lengthy to include in this document), is available on the Renesas web site. Just search for the associated application note document number, r11an0226eu, in the top page search bar on http://www.Renesas.com. It is highly recommended that you use the application note to augment the summary descriptions found in this document.

Wi-Fi Framework Module APIs

The Wi-Fi framework module provides a high-level interface for the network stack and applications irrespective of the Wi-Fi module. Below are the APIs exposed by the framework.

Wi-Fi Framework Module API Summary

Function Name	Example API Call and Description
.open	g_sf_wifi0.p_api->open (g_sf_wifi0.p_ctrl, g_sf_wifi0.p_cfg); This API initializes and enables the Wi-Fi module. The open function returns the Wi-Fi control structure, uniquely identifying the instance of the Wi-Fi framework.
.close	g_sf_wifi0.p_api->close(g_sf_wifi0.p_ctrl); This API un-initializes the Wi-Fi module and powers it off.
.infoGet	g_sf_wifi0.p_api->infoGet (g_sf_wifi0.p_ctrl, wifi_info); This API takes the WiFi control structure as an argument and returns the following information obtained from the WiFi module: Chipset/driver information string RSSI value (unsigned integer 16 bits) Noise level (unsigned integer 16 bits) Link Quality (unsigned integer 16 bits)
.statisticsGet	g_sf_wifi0.p_api->statisticsGet (g_sf_wifi0.p_ctrl, p_stats); This API gets the data statistics from the Wi-Fi module. It takes the Wi-Fi control structure as an argument and returns the following statistics: Received packets (unsigned integer 32 bits) Transmitted packets (unsigned integer 32 bits) Transmit packet errors (unsigned integer 32 bits)

Function Name	Example API Call and Description
.transmit	g_sf_wifi0.p_api->transmit (g_sf_wifi0.p_ctrl, p_buffer, length); This API sends the data/packet out. This function takes the Wi-Fi control structure as an argument. It takes the network packet buffer, and the network packet buffer length as arguments. The Wi-Fi framework transmit function passes the packet buffer to the Wi-Fi driver for transmission.
.receiveCallback	This is a callback API, which gets called when the data/packet is received by the Wi-Fi module. This function receives packet buffer and packet length as arguments.
.provisioningGet	g_sf_wifi0.p_api->provisioningGet (g_sf_wifi0.p_ctrl, &sf_wifi_provisioninfo); This API takes the Wi-Fi control structure as an argument and returns the following parameters: Mode (enumeration, that is, AP or client) Channel (unsigned integer 8 bits) SSID (string) Security type (enumeration) Encryption type (enumeration) Security key (string)

Function Name	Example API Call and Description
.provisioningSet	g_sf_wifi0.p_api->provisioningSet (g_sf_wifi0.p_ctrl, &g_sf_wifi_provisioninfo); This API sets the Wi-Fi module in the given mode AP/Station. The provisioningSet function uses the following parameters to provision the WiFi module: Mode (enumeration, that is, AP or client) Channel (unsigned integer 8 bits), only used in AP mode SSID (string) Security type (enumeration) Encryption type (enumeration) Security key (sting). Connection Status Notification Callback function: Used to get connection status change notification *See note at the end of this table.

Function Name	Example API Call and Description
.scan	g_sf_wifi0.p_api->scan (g_sf_wifi0.p_ctrl, p_scan, p_count); This API scans the available SSIDs (that is, access points) in range. This function takes the Wi-Fi control structure as an argument and returns a list of SSIDs scanned by the WiFi module with the following parameters: HW mode (enumeration a/b/g/n) RSSI (unsigned integer 16 bits) SSID (string) BSSID (byte array of size 6 bytes) Channel (unsigned integer 8 bits) Security type (enumeration) Encryption type(enumeration) BSS type (enumeration) The Wi-Fi framework scan function takes the SSID count as an argument, which acts as an in/out parameter. It specifies the size of the scan result array and the Wi-Fi framework sets it to count the indicating number of scan results stored in the array.
.ACLAdd	g_sf_wifi0.p_api->ACLAdd (g_sf_wifi0.p_ctrl, peer_device_mac); This API adds the given MAC address to the access control list. This function takes the Wi-Fi control structure and the MAC address as arguments.

Function Name	Example API Call and Description
.ACLDelete	g_sf_wifi0.p_api->ACLDelete (g_sf_wifi0.p_ctrl, peer_device_mac); This API deletes the given MAC address from the access control list. This function takes the Wi-Fi control structure and MAC address as arguments.
.multicastListAdd	g_sf_wifi0.p_api->multicastListAdd (g_sf_wifi0.p_ctrl, p_mac_addr); This API adds the given Multicast IP address to the multicast filer list. This function takes the Wi-Fi control structure and MAC address as arguments.
.multicastListDelete	g_sf_wifi0.p_api->multicastListDelete (g_sf_wifi0.p_ctrl, p_mac_addr); This API deletes the given Multicast IP address from the multicast filer list. This function takes the Wi-Fi control structure and MAC address as arguments.
.macAddressGet	g_sf_wifi0.p_api->macAddressGet (g_sf_wifi0.p_ctrl, p_mac); This API reads MAC address from WiFi module. This function takes the Wi-Fi control structure as argument and returns MAC address read from Wi-Fi module.
.macAddressSet	g_sf_wifi0.p_api->macAddressSet (g_sf_wifi0.p_ctrl, p_mac); This API sets Wi-Fi module's MAC address. This function takes the Wi-Fi control structure and MAC address as arguments.

Note on Provisioning: When device is provisioned in client mode then callback will be called when connection with AP is lost and established back. When device is provisioned in AP mode, this callback is called when any client connects/disconnects with AP. When device is provisioned in client mode then arguments passed to callback will have only below valid field,

- event = SF_WIFI_EVENT_AP_CONNECT or SF_WIFI_AP_DISCONNECT

When device is provisioned in AP mode then arguments passed to callback will have only below valid fields,

- event = SF_WIFI_EVENT_CLIENT_CONNECT or SF_WIFI_CLIENT_DISCONNECT

- mac_addr = MAC address of client.

NOTE: While calling the provisioningSet() API to provision the device in client mode, the framework will not call the callback function on successful association with AP or on failure.

When the device is provisioned in AP mode, if the client tries to connect with the AP using wrong password then callback will be called twice, first with connected event and then immediately after this with disconnected event.

On chip Networking Stack Support APIs

These APIs can be used to configure the Wi-Fi module when using an on-chip networking stack, which helps to configure the IP address for the interface, and start/stop DHCP server (when configured in the AP mode).

On Chip Networking Stack Support Wi-Fi Framework Module API Summary

Function Name	Example API Call and Description
.open	g_sf_wifi_onchip_stack0.p_api->open (g_sf_wifionchip_stack0.p_ctrl, g_sf_wifi_onchip_stack0.p_cfg); This API calls the WiFi framework open API which initializes the Wi-Fi module.
.close	g_sf_wifi_onchip_stack0.p_api->close(g_sf_wifi_onchip_ stack0.p_ctrl); This API calls the Wi-Fi framework close API which un-initializes the Wi-Fi module.
.ipAddressCfg	g_sf_wifi_onchip_stack0.p_api->ipAddressCfg (g_sf_wifi_onchip_stack0.p_ctrl, p_cfg); This API configures the IP address of the interface using an on-chip networking stack. It provides facility to configure static IP address or using DHCP.
.dhcpServerStart	g_sf_wifi_onchip_stack0.p_api->dhcpServer (g_sf_wifi_onchip_stack0.p_ctrl, p_start_ip, p_end_ip); This API starts the DHCP server on the interface (when configured in AP mode) using on-chip networking stack. It takes the range of IP addresses to be used by DHCP server.

Function Name	Example API Call and Description
.dhcpServerStop	g_sf_wifi_onchip_stack0.p_api->dhcpServerStop (g_sf_wifi_onchip_stack0.p_ctrl); This API stops the DHCP server.
.versionGet	g_sf_wifi_onchip_stack0.p_api->versionGet (&version); Retrieves the API version with the version pointer.

BSD Socket APIs

These APIs can be used for BSD socket support using the GT202 on-chip stack implementation.

BSD Socket using GT202 On-Chip Stack Wi-Fi Framework Module API Summary

Function Name	Example API Call and Description
.open	g_sf_socket0.p_api->open (g_sf_socket0.p_ctrl, g_sf_socket0.p_cfg); This API initializes the networking interface.
.close	g_sf_socket0.p_api->close(g_sf_socket0.p_ctrl); This API closes the network interface.
.versionGet	g_sf_socket0.p_api->versionGet (&version); Retrieves the API version with the version pointer.

Additionally, this implementation includes socket APIs which are compliant with BSD APIs. These APIs can be used by the application to perform data transfer using sockets. The following APIs are available:

- socket
- close
- bind
- listen
- accept
- connect
- send

- recv
- recvfrom
- sendto
- setsockopt
- getsockopt
- select

NOTE: While using on chip networking stack, application can use all BSD Socket APIs, all on chip Networking Stack support APIs and few Synergy Wi-Fi framework APIs. The Synergy Wi-Fi framework APIs which application can use are provisioningSet(), provisioningGet(), scan(), macAddressGet(), macAddressSet() and infoGet()

More information is available for these APIs as described in the NetX BSD 4.3 Sockets API Compliancy Wrapper for NetX User Guide which can be found on the Synergy Gallery on the SSP page under the documentation tab in the X-Ware ™ Component Documents for Renesas Synergy zip file.

Wi-Fi NSAL

The Synergy Wi-Fi framework supports the NetX/NetX-Duo Network Services Abstraction Layer. This includes the NetX/NetX-Duo driver, packet transmit and receive callback functions implementation.

NetX/NetX-Duo Driver Function

The NetX/NetX-Duo driver function takes the NetX IP instance, WiFi framework instance and NSAL configuration as arguments. The NSAL configuration controls the behavior of transmit and receive callback functions. The NSAL configuration includes flags which indicates zero-copy support is enabled or disabled in transmit and receive path. The NetX/NetX-Duo driver functions implement various IP driver commands used by NetX/NetX-Duo. The interface attach command calls the WiFi framework open API to initialize the Wi-Fi module. The initialize command calls the Wi-Fi framework macAddressGet API to read MAC address from the WiFi module. The un-initialize command calls the WiFi framework close API which de-initializes the WiFi module. The multicast-join command calls the Wi-Fi framework multicastListAdd API to add the given MAC address to multicast list. The multicast-leave command calls the Wi-Fi framework multicastListDelete API to delete the given MAC address from the multicast list. The Send/Broadcast command calls the WiFi framework transmit API to transmit a packet.

NSAL Transmit Function

The NSAL transmit function takes the NetX IP instance, the NetX packet, the Wi-Fi framework instance and the NSAL configuration as arguments. If zero-copy support is enabled then the same NetX packet is transferred from NetX to the WiFi driver. If zero-copy is not supported then it copies data from the NetX packet to the driver buffer. It calls the Wi-Fi framework transmit API, which passes the buffer/packet to the Wi-Fi driver for further transmission.

NSAL Receive Callback

The NSAL receive callback function takes the NetX IP instance, the packet buffer, the packet buffer length and the NSAL configuration as arguments. This callback is called from the Wi-Fi device driver. If zero-copy support is enabled then the same NetX packet is transferred from the WiFi driver to NetX. If zero-copy is not supported then it copies data from the driver buffer to the NetX packet and then passes the NetX stack for further processing. It calls the Wi-Fi framework transmit API, which passes the buffer to the Wi-Fi driver for further transmission.

More information is available for these APIs as described in the NetX User Guide which can be found on the Synergy Gallery on the SSP page under the documentation tab in the X-Ware ™ Component Documents for Renesas Synergy zip file.

Wi-Fi Framework Error Codes

The table below lists the Wi-Fi Framework specific error codes. These error codes are part of ssp_err_t.

WiFi framework Error Codes

Error Codes	Description
SSP_ERR_WIFI_CONFIG_FAILED	Configuration failed
SSP_ERR_WIFI_INIT_FAILED	Initialization failed
SSP_ERR_WIFI_TRANSMIT_FAILED	Transmission failed
SSP_ERR_WIFI_INVALID_MODE	Invalid mode specified
SSP_ERR_WIFI_FAILED	Wifi failed

4.1.29.3 Wi-Fi Framework Module Operational Overview

The following operational overview is a summary of the operation of the Wi-Fi module. A more detailed description, along with a working example application (which is too lengthy to include in this document), is available on the Renesas web site. Just search for the associated application note document number, r11an0226eu, in the top page search bar on http://www.Renesas.com. It is highly recommended that you use the application note to augment the summary descriptions found in this document.

Wi-Fi Framework Module Operational Introduction

The Wi-Fi framework provides a high-level interface for the application to configure the Wi-Fi module, provision the Wi-Fi module and perform data transfers. This simplifies application development and allows the same application code to be used across different Wi-Fi modules.

The following figure provides an overview of the Synergy Wi-Fi framework layered architecture:

- The Wi-Fi framework includes the enclosed 5 blocks in the middle of the architecture graph: NSAL, Wi-Fi Framework API, Wi-Fi on-chip Stack API, BSD Socket API, and the Wi-Fi Device Driver Interface.
- The vendor-provided Wi-Fi device drivers are included in the SSP package under SSP_Supplemental.

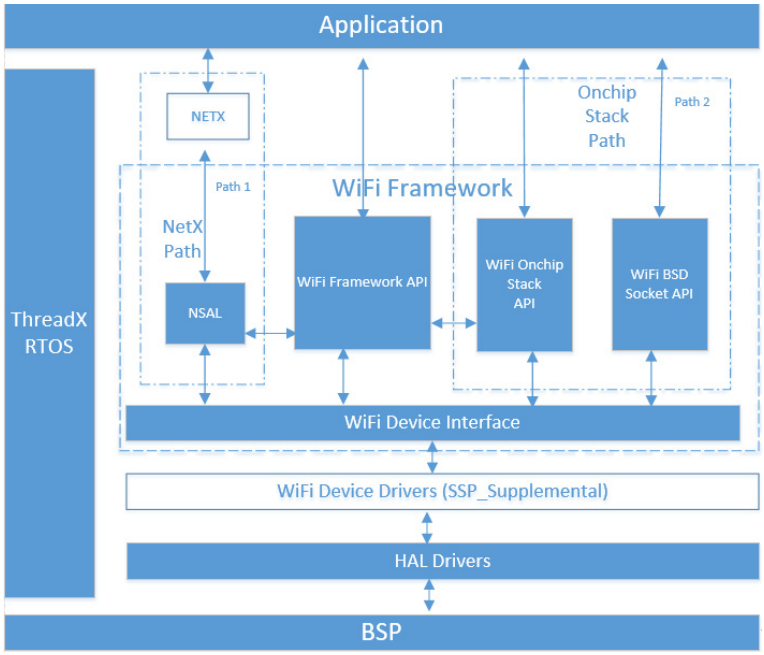

Figure 245: Wi-Fi framework organization, options and stack implementation

The Wi-Fi framework implementation allows Wi-Fi modules with or without On-chip networking stack support to be integrated with the SSP low-level support blocks.

- Path 1: Using NetX™/NetX Duo™, NSAL in addition to the Wi-Fi framework APIs blocks as shown in in the previous figure. To simplify the description, throughout this document, NetX refers to both NetX and NetX-Duo when the comment applies to both.
- Path 2: Using On-chip networking stack support API and the BSD Socket APIs as shown in the previous figure.

Wi-Fi Framework Module Operational Notes and Limitations

- The Wi-Fi module has various parameters as specified by 802.11 standards. It is possible that individual device drivers and Wi-Fi chipsets might not support the configuration of all the functions.
- For the Wi-Fi interface to become active, at least the channel, Service Set Identifier (SSID), security scheme, and security credentials must be configured.
- The current NSAL implementation includes support for NetX (IPv4) and NetX-Duo (IPv6). NetX and NetX Duo support IPv4, however NetX Duo also supports IPv6. Adding support for a new network stack requires implementing the appropriate NSAL.
- For the security setting, WEP keys can be entered in either ASCII or Hex format and can be configured to use either 40 or 104 bit keys. A WEP key has a 24-bit initialization vector in addition to the secret key. Because of this and depending on the vendor, 64-bit WEP keys can be referred to as 40 bit keys and 128-bit WEP keys can be referred to as 104 bit keys. The Wi-Fi framework accepts 1 to 4 WEP keys of a specific format and type. In the provisioning structure, you must fill in the security type as SF_WIFI_SECURITY_TYPE_WEP and at least one (maximum is four) WEP key in the key buffer.

Wi-Fi Framework Module APIs

- OpenWhen using the Wi-Fi framework module with NSAL i.e. with NetX/NeXDuo, the application should not call the Wi-Fi framework module open() API directly, instead it should call the NetX nx_ip_create() API which internally calls open() from the NetX driver.When using the On chip networking stack, the application should call the open() API from the BSD socket interface, which internally calls the Wi-Fi framework open() API.
- CloseWhen using the Wi-Fi framework module with NSAL i.e. with NetX, the application should not call the Wi-Fi framework module close API directly, instead it should call the NetX nx_ip_delete() API which internally calls close from the NetX driver.When using the On chip networking stack, the application should call the close API from the BSD socket interface, which internally calls the Wi-Fi framework module close API.
- ProvisioningSetWhen the device is provisioned in client mode the callback will be called when the connection with the AP is lost and re-established. When the device is provisioned in AP mode, this callback is called when any client connects/disconnects with the AP. When the device is provisioned in client mode the arguments passed to the callback will only have the below valid field:

  – event = SF_WIFI_EVENT_AP_CONNECT or SF_WIFI_AP_DISCONNECT

  When the device is provisioned in AP mode the arguments passed to the callback will only have the below valid fields:

  – event = SF_WIFI_EVENT_CLIENT_CONNECT or SF_WIFI_CLIENT_DISCONNECT

  – mac_addr = MAC address of client.

  While calling the provisioningSet() API to provision the device in client mode, the framework will not call the call-back function on successful association with the AP or on a failure.When the device is provisioned in AP mode, if the client tries to connect with the AP using the wrong password the callback will be called twice, first with the connected event and then immediately after this with the disconnected event.

BSD Socket APIs

While using on chip networking stack, application can use all BSD Socket APIs, all on chip Networking Stack support APIs and few Synergy Wi-Fi framework APIs. The Wi-Fi framework APIs which application can use are provisioningSet(), provisioningGet(), scan(), macAddressGet(), macAddressSet() and infoGet().

- The Wi-Fi framework does not support the Synergy S1 MCU Series due to memory constraints when working with GT202.
- Due to memory constraints S3A6 and S128 MCUs will support only on-chip networking stack (i.e. Path 2 for Wi-Fi use, where networking stack runs on Wi-Fi chipset)
- When RSPI is used for the Wi-Fi module driver, the DTC components that are auto-filled for the dependencies, must be removed because of the limitation in the WiFi module SPI driver. The limitation is that when DTC is used with RSPI, 32-bit transfers are required but GT202 vendor code (that is, WiFi module SPI driver) uses 8-bit transfers only.
- Synergy Wi-Fi Framework APIs implemented for GT-202 are not re-entrant. All these APIs make call to driver APIs to do the requested operation. If GT-202 driver is working on behalf any Wi-Fi framework API and other Wi-Fi framework API is called, then it will return SPP_ERR_IN_USE error until the ongoing operation is finished.
- Synergy Wi-Fi framework provisioningSet() API for GT-202, may fail if peripheral and IO pins' drive capacity is not set to Medium.
- While configuring GT-202 with SPI driver on r_rspi, set drive capacity of slave select pin, reset pin and SPI pins (i.e. MISO, MOSI and RSPCK) to medium. While configuring GT-202 with SPI driver on r_sci_spi, set drive capacity of slave select pin, reset pin and SCI pins (i.e. TXD_MOSI and RXD_MISO) to medium. Do not change the drive capacity of SCK pin when r_sci_spi driver is used.

4.1.29.4 Including the Wi-Fi Framework Module in an Application

This section describes how to include the Wi-Fi framework module in an application using the SSP configurator.

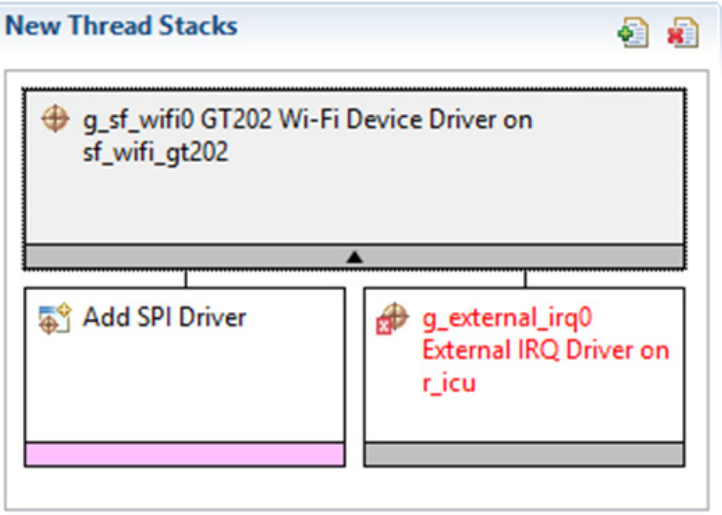
NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to perform these important steps when creating SSP-based applications.

To add the Wi-Fi framework module to an application, simply add it to a thread using the stacks selection sequence given in the following table. There are four different options so four sequences are shown.

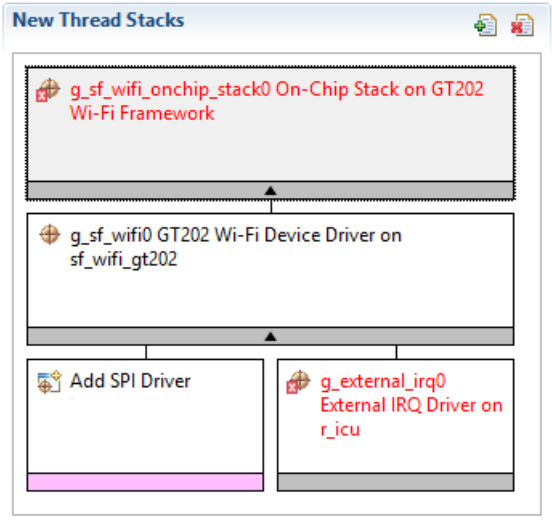
Wi-Fi Framework Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_wifi0 GT202 Wi-Fi Device Driver on sf_wifi_gt202	Threads	New Stack> Framework> Networking> WiFi> GT202 Wi-Fi Device Driver on sf_wifi_gt202
g_sf_wifi_onchip_stack0 On-Chip Stack on Gt202 Wi-Fi Framework	Threads	New Stack> Framework> Networking> WiFi> On-Chip Stack on Gt202 Wi-Fi Framework
g_sf_socket0 BSD Socket using On-Chip Stack on Gt202 Wi-Fi Framework	Threads	New Stack> Framework> Networking> WiFi> BSD Socket using On-Chip Stack on Gt202 Wi-Fi Framework
g_sf_el_nx0 NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx	Threads	New Stack> Framework> Networking> WiFi> NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

When the Wi-Fi framework module is added to the thread stack as shown in the following figure, the configurator automatically adds the needed lower-level drivers. Any drivers that need additional configuration information will be highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Pink band require the selection of an implementation option.



New Thread Stacks
g_sf_wifi0 GT202 Wi-Fi Device Driver on sf_wifi_gt202
Add SPI Driver
g_external_irq0 External IRQ Driver on r_icu



New Thread Stacks
g_sf_wifi_onchip_stack0 On-Chip Stack on GT202 Wi-Fi Framework
g_sf_wifi0 GT202 Wi-Fi Device Driver on sf_wifi_gt202
Add SPI Driver
g_external_irq0 External IRQ Driver on r_icu

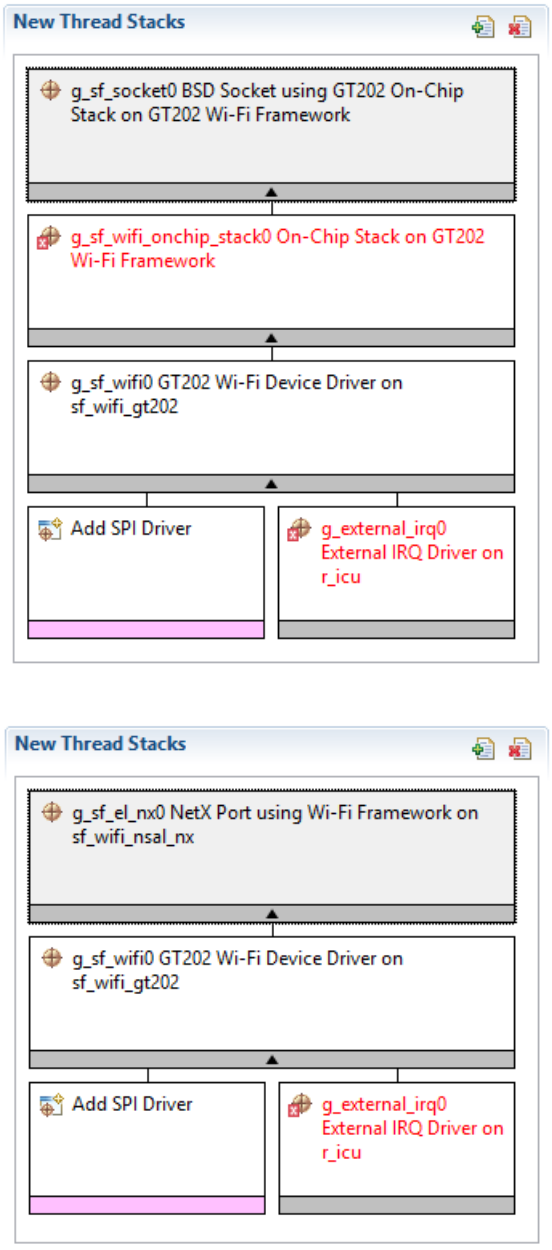


Figure 246: The Four Wi-Fi Framework Module Stack Options

Selecting SF_WIFI_NSAL_NX

The sf_wifi_nsal_nx implementation can be used in conjunction with a NetX IP Instance. In this case, it is added as an option underneath the IP Instance stack. Just add the NetX IP instance using the selection steps in the following table.

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_wifi0 GT202 Wi-Fi Device Driver on sf_wifi_gt202	Threads	New Stack> X-Ware> NetX> NetX IP Instance

Use the available option to add sf_wifi_nsal_nx under the NetX IP Instance as a NetX Network Driver.

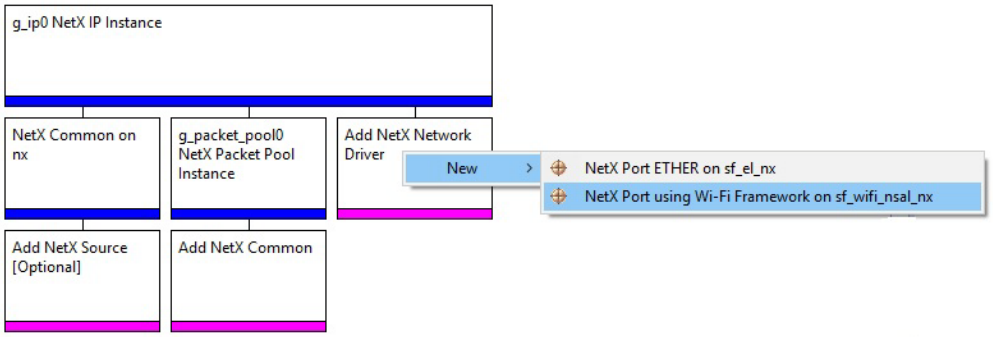

Figure 247: NetX IP Instance use of sf_wifi_nsal_nx

The lower level modules are filled in automatically as shown in the following figure.

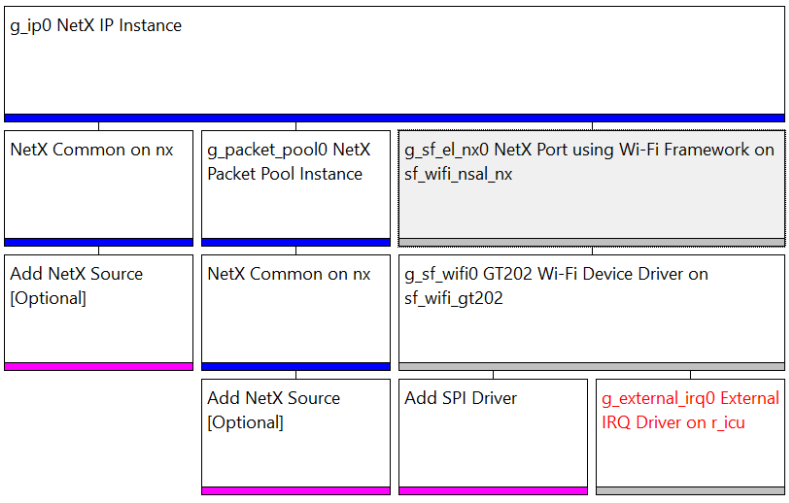

Figure 248: NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.1.29.5 Configuring the Wi-Fi Framework Modules

The Wi-Fi framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify, by highlighting the block in red, any required configuration selections, such as Interrupts or operating modes, which must be configured for lower level modules, for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the properties tab within the SSP Configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the Interrupt Priority. This configuration setting is available with the Properties window of the associated module. Simply select the indicated module and then view the properties window. The Interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the Interrupt Priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the below configuration properties tables, but is easily visible with the ISDE when configuring Interrupt Priority levels.

NOTE: You may want to open your ISDE and create the Low Power Mode Driver and explore the property settings in parallel with looking over the Configuration Table Settings given below. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration properties for each of the four WiFi implementations supported by the WiFi framework is provided in the following four sections.

Configuring the GT202 Wi-Fi Device Driver

This section shows the configuration settings for the on-chip stack on the GT202 implementation of the Wi-Fi framework.

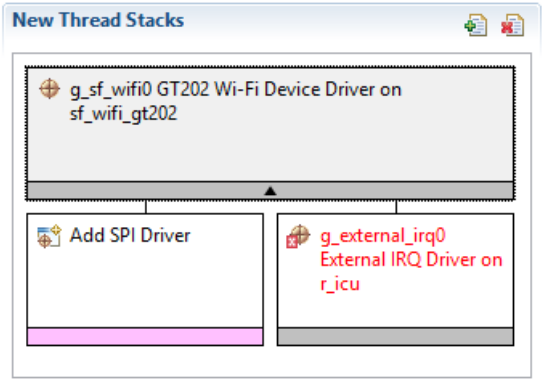

Figure 249: GT202 Wi-Fi Device Driver Thread Stack

Configuration Settings for the Wi-Fi Device Driver on sf_wifi_gt202

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
On-Chip Stack Support	Enabled, Disabled Default: Disabled	On-chip stack support selection
Driver Heap Size in Bytes (Minimum 8192 bytes)	8192	Driver heap size selection
Name (Must be a valid C symbol)	g_sf_wifi0	Module name
Hardware Mode	802.11a, 802.11b, 802.11g, 802.11n Default: 802.11n	Hardware mode selection
Transmit (TX) Power (Valid Range 1-17)	10	Transmit power selection
Ready/Clear to Send (RTS/CTS) Flag	Enabled, Disabled Default: Enabled	Ready/Clear to send selection
Delivery Traffic Indication Message (DTIM) Interval (Valid Range: 1-255)	3	Delivery traffic indication message interval selection
Broadcast SSID (AP mode only)	Enabled, Disabled Default: Enabled	Broadcast SSID selection
Beacon Interval in Microseconds (AP mode only and must be greater than 1023)	1024	Beacon interval in microseconds selection
Station inactivity timeout in seconds (AP mode only and must be greater than 0)	100	Station inactivity timeout selection

ISDE Property	Setting	Description
Requested High Throughput	Enabled, Disabled Default: Disabled	Requested high throughput selection
Reset Pin (must be a valid C symbol)	IOPORT_PORT_06_PIN_00	Reset pin selection
Slave Select Pin (SSL)(Must be a valid C symbol)	IOPORT_PORT_01_PIN_03	Slave select pin selection
GT202 Driver Task Thread Priority (Modifying Task Thread Priority may cause Driver to malfunction)	5	GT202 driver task thread priority selection
Callback	NULL	Callback selection
Support NetX Packet Chaining	Enabled, Disabled Default: Enabled	Support NetX packet chaining selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SPI HAL Driver on r_rspi

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_spi0	Module name
Channel	0	SCI or SPI Channel number to which the device has been connected.

ISDE Property	Setting	Description
Operating Mode	Master	Configure as a Master or Slave device . NOTE: Current version of SSP supports only SPI Master mode.
Clock Phase	Data sampling on even edge, data variation on odd edge	Data sampling on odd or even clock edge.
Clock Polarity	High when idle	Clock level when idle.
Mode Fault Error	Disable	Indicates Mode fault error (master/slave conflict) flag.
Bit Order	MSB First	Select transmit order MSB/LSB first
Bitrate	500000	Transmission or reception rate. Bits per second.
Callback	NULL	Optional Callback function pointer.
SPI Mode	Clock synchronous operation	Select spi or clock syn mode operation.
SPI Communication Mode	Full Duplex	Select full-duplex or transmit-only communication.
Slave Select Polarity(SSL0)	Active Low	Select SSL0 signal polarity
Slave Select Polarity(SSL1)	Active Low	Select SSL1 signal polarity
Slave Select Polarity(SSL2)	Active Low	Select SSL2 signal polarity
Slave Select Polarity(SSL3)	Active Low	Select SSL3 signal polarity
Select Loopback1	Normal	Select loopback1
Select Loopback2	Normal	Select loopback2
Enable MOSI Idle State	Disable	Select MOSI idle fixed value and selection
MOSI Idle State	MOSI Low	Select mosi idle fixed value and selection

ISDE Property	Setting	Description
Enable Parity	Disable	Enable/disable parity
Parity Mode	Parity Even	Select parity
Select SSL(Slave Select)	SSL0	Select which slave to use; 0-SSL0; 1-SSL1; 2-SSL2; 3-SSL3
Select SSL Level After Transfer	SSL Level Do Not Keep	Select SSL level after transfer completion; 0-negate; 1-keep
Clock Delay Enable	Clock Delay Disable	Clock delay enable selection
Clock Delay Count	Clock Delay 1 RSPCK	Clock delay count selection
SSL Negation Delay Enable	Negation Delay Disable	SSL negation delay enable selection
Negation Delay Count	Negation Delay 1 RSPCK	Negation delay count selection
Next Access Delay Enable	Next Access Delay Disable	Next access delay enable selection
Next Access Delay Count	Next Access Delay 1 RSPCK	Next access delay count selection
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Receive interrupt priority selection
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection

ISDE Property	Setting	Description
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Error interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SPI0 TXI

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Disabled	Software start selection
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection
Name	g_transfer0	Module name
Mode	Normal	Mode selection
Transfer Size	4 Bytes	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	
Destination Pointer	NULL	Destination pointer selection

ISDE Property	Setting	Description
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SPI0 TXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SPI0 RXI

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Name	g_transfer1	Module name
Mode	Normal	Mode selection
Transfer Size	4 Bytes	Transfer size selection
Destination Address Mode	Incremented	Destination address mode selection
Source Address Mode	Fixed	Source address mode selection

ISDE Property	Setting	Description
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SPI0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SPI HAL Module on r_sci_spi

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_spi0	Module name

ISDE Property	Setting	Description
Channel	0	SCI or SPI Channel number to which the device has been connected.
Operating Mode	Master	Configure as a Master or Slave device . NOTE: Current version of SSP supports only SPI Master mode.
Clock Phase	Data sampling on even edge, data variation on odd edge	Data sampling on odd or even clock edge.
Clock Polarity	High when idle	Clock level when idle.
Mode Fault Error	Disable	Indicates Mode fault error (master/slave conflict) flag.
Bit Order	MSB First	Select transmit order MSB/LSB first
Bitrate	100000	Transmission or reception rate. Bits per second.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Bitrate Modulation Function enable or disable
Callback	NULL	Optional Call back function pointer.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Bitrate Modulation Function enable or disable. NOTE: This is applicable only for SCI SPI.

ISDE Property	Setting	Description
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit end interrupt priority selection
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Error interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 TXI

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_spi0	Module name
Channel	0	SCI or SPI Channel number to which the device has been connected.

ISDE Property	Setting	Description
Operating Mode	Master	Configure as a Master or Slave device . NOTE: Current version of SSP supports only SPI Master mode.
Clock Phase	Data sampling on even edge, data variation on odd edge	Data sampling on odd or even clock edge.
Clock Polarity	High when idle	Clock level when idle.
Mode Fault Error	Disable	Indicates Mode fault error (master/slave conflict) flag.
Bit Order	MSB First	Select transmit order MSB/LSB first
Bitrate	100000	Transmission or reception rate. Bits per second.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Bitrate Modulation Function enable or disable
Callback	NULL	Optional Call back function pointer.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Bitrate Modulation Function enable or disable. NOTE: This is applicable only for SCI SPI.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection.

ISDE Property	Setting	Description
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit end interrupt priority selection
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Error interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 RXI

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Disabled	Software start selection

Destination Address Mode	Incremented	Destination address mode selection
Source Address Mode	Fixed	Source address mode selection
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SCI0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Softare Event interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the External IRQ HAL Module on r_icu

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter checking setting enables or disables the addition of parameter checking code.

ISDE Property	Setting	Description
Name	g_external_irq0	Module name.
Channel	0	Specifies the hardware IRQ channel used.
Trigger	Falling	Selection for trigger event mode
Digital Filtering	Disabled	Digital filter enable/disable.
Digital Filtering Sample Clock (Only valid when Digital Filtering is Enabled)	PCKL/64	Sets noise filter sampling period.
Interrupt enabled after initialization	TRUE	Determines if the interrupt is enabled immediately after initialization.
Callback	custom_hw_irq_isr	A user callback function can be registered in open. If this callback function is provided, it is called from the interrupt service routine (ISR) each time the IRQn triggers. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuring the On-Chip Stack on GT202 Wi-Fi Framework

This section shows the configuration settings for the on-chip stack on the GT202 implementation of the Wi-Fi framework.

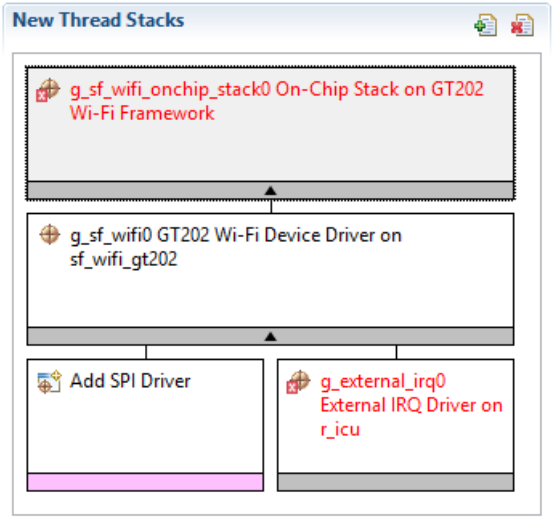

Figure 250: On-Chip Stack on GT202 Wi-Fi Framework Thread Stack

Configuration Settings for the On-Chip Stack on GT202 Wi-Fi Framework

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name (Must be a valid C Symbol)	g_sf_wifi_onchip_stack0	Module name

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Wi-Fi Device Driver

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.

ISDE Property	Setting	Description
On-Chip Stack Support	Enabled, Disabled Default: Disabled	On-chip stack support selection
Driver Heap Size in Bytes (Minimum 8192 bytes)	8192	Driver heap size selection
Name (Must be a valid C symbol)	g_sf_wifi0	Module name
Hardware Mode	802.11a, 802.11b, 802.11g, 802.11n Default: 802.11n	Hardware mode selection
Transmit (TX) Power (Valid Range 1-17)	10	Transmit power selection
Ready/Clear to Send (RTS/CTS) Flag	Enabled, Disabled Default: Enabled	Ready/Clear to send selection
Delivery Traffic Indication Message (DTIM) Interval (Valid Range: 1-255)	3	Delivery traffic indication message interval selection
Broadcast SSID (AP mode only)	Enabled, Disabled Default: Enabled	Broadcast SSID selection
Beacon Interval in Microseconds (AP mode only and must be greater than 1023)	1024	Beacon interval in microseconds selection
Station inactivity timeout in seconds (AP mode only and must be greater than 0)	100	Station inactivity timeout selection
Requested High Throughput	Enabled, Disabled Default: Disabled	Requested high throughput selection
Reset Pin (must be a valid C symbol)	IOPORT_PORT_06_PIN_00	Reset pin selection
Slave Select Pin (SSL)(Must be a valid C symbol)	IOPORT_PORT_01_PIN_03	Slave select pin selection

ISDE Property	Setting	Description
GT202 Driver Task Thread Priority (Modifying Task Thread Priority may cause Driver to malfunction)	5	GT202 driver task thread priority selection
Callback	NULL	Callback selection
Support NetX Packet Chaining	Enabled, Disabled Default: Enabled	Support NetX packet chaining selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SPI HAL Driver on r_rspi

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_spi0	Module name
Channel	0	SCI or SPI Channel number to which the device has been connected.
Operating Mode	Master	Configure as a Master or Slave device . NOTE: Current version of SSP supports only SPI Master mode.
Clock Phase	Data sampling on even edge, data variation on odd edge	Data sampling on odd or even clock edge.
Clock Polarity	High when idle	Clock level when idle.
Mode Fault Error	Disable	Indicates Mode fault error (master/slave conflict) flag.

ISDE Property	Setting	Description
Bit Order	MSB First	Select transmit order MSB/LSB first
Bitrate	500000	Transmission or reception rate. Bits per second.
Callback	NULL	Optional Callback function pointer.
SPI Mode	Clock synchronous operation	Select spi or clock syn mode operation.
SPI Communication Mode	Full Duplex	Select full-duplex or transmit-only communication.
Slave Select Polarity(SSL0)	Active Low	Select SSL0 signal polarity
Slave Select Polarity(SSL1)	Active Low	Select SSL1 signal polarity
Slave Select Polarity(SSL2)	Active Low	Select SSL2 signal polarity
Slave Select Polarity(SSL3)	Active Low	Select SSL3 signal polarity
Select Loopback1	Normal	Select loopback1
Select Loopback2	Normal	Select loopback2
Enable MOSI Idle State	Disable	Select MOSI idle fixed value and selection
MOSI Idle State	MOSI Low	Select mosi idle fixed value and selection
Enable Parity	Disable	Enable/disable parity
Parity Mode	Parity Even	Select parity
Select SSL(Slave Select)	SSL0	Select which slave to use; 0-SSL0; 1-SSL1; 2-SSL2; 3-SSL3
Select SSL Level After Transfer	SSL Level Do Not Keep	Select SSL level after transfer completion; 0-negate; 1-keep
Clock Delay Enable	Clock Delay Disable	Clock delay enable selection
Clock Delay Count	Clock Delay 1 RSPCK	Clock delay count selection
SSL Negation Delay Enable	Negation Delay Disable	SSL negation delay enable selection
Negation Delay Count	Negation Delay 1 RSPCK	Negation delay count selection

ISDE Property	Setting	Description
Next Access Delay Enable	Next Access Delay Disable	Next access delay enable selection
Next Access Delay Count	Next Access Delay 1 RSPCK	Next access delay count selection
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Receive interrupt priority selection
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Error interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SPI0 TXI

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build

ISDE Property	Setting	Description
Software Start	Enabled, Disabled Default: Disabled	Software start selection
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection
Name	g_transfer0	Module name
Mode	Normal	Mode selection
Transfer Size	4 Bytes	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SPI0 TXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SPI0 RXI

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Name	g_transfer1	Module name
Mode	Normal	Mode selection
Transfer Size	4 Bytes	Transfer size selection
Destination Address Mode	Incremented	Destination address mode selection
Source Address Mode	Fixed	Source address mode selection
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SPI0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection

ISDE Property	Setting	Description
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SPI HAL Module on r_sci_spi

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_spi0	Module name
Channel	0	SCI or SPI Channel number to which the device has been connected.
Operating Mode	Master	Configure as a Master or Slave device . NOTE: Current version of SSP supports only SPI Master mode.
Clock Phase	Data sampling on even edge, data variation on odd edge	Data sampling on odd or even clock edge.
Clock Polarity	High when idle	Clock level when idle.
Mode Fault Error	Disable	Indicates Mode fault error (master/slave conflict) flag.
Bit Order	MSB First	Select transmit order MSB/LSB first

ISDE Property	Setting	Description
Bitrate	100000	Transmission or reception rate. Bits per second.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Bitrate Modulation Function enable or disable
Callback	NULL	Optional Call back function pointer.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Bitrate Modulation Function enable or disable. NOTE: This is applicable only for SCI SPI.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit end interrupt priority selection
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Error interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 TXI

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_spi0	Module name
Channel	0	SCI or SPI Channel number to which the device has been connected.
Operating Mode	Master	Configure as a Master or Slave device . NOTE: Current version of SSP supports only SPI Master mode.
Clock Phase	Data sampling on even edge, data variation on odd edge	Data sampling on odd or even clock edge.
Clock Polarity	High when idle	Clock level when idle.
Mode Fault Error	Disable	Indicates Mode fault error (master/slave conflict) flag.
Bit Order	MSB First	Select transmit order MSB/LSB first
Bitrate	100000	Transmission or reception rate. Bits per second.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Bitrate Modulation Function enable or disable
Callback	NULL	Optional Call back function pointer.

ISDE Property	Setting	Description
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Bitrate Modulation Function enable or disable. NOTE: This is applicable only for SCI SPI.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit end interrupt priority selection
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Error interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 RXI

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Disabled	Software start selection
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection
Name	g_transfer1	Module name
Mode	Normal	Mode selection
Transfer Size	1 Byte	Transfer size selection
Destination Address Mode	Incremented	Destination address mode selection
Source Address Mode	Fixed	Source address mode selection
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SCI0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection

ISDE Property	Setting	Description
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Softare Event interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the External IRQ HAL Module on r_icu

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter checking setting enables or disables the addition of parameter checking code.
Name	g_external_irq0	Module name.
Channel	0	Specifies the hardware IRQ channel used.
Trigger	Falling	Selection for trigger event mode
Digital Filtering	Disabled	Digital filter enable/disable.
Digital Filtering Sample Clock (Only valid when Digital Filtering is Enabled)	PCKL/64	Sets noise filter sampling period.
Interrupt enabled after initialization	TRUE	Determines if the interrupt is enabled immediately after initialization.

ISDE Property	Setting	Description
Callback	custom_hw_irq_isr	A user callback function can be registered in open. If this callback function is provided, it is called from the interrupt service routine (ISR) each time the IRQn triggers. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuring the BSD Socket using GT202 On-Chip Stack on GT202 Wi-Fi Framework

This section shows the configuration settings for the BSD socket using the GT202 on-chip stack implementation of the Wi-Fi framework.

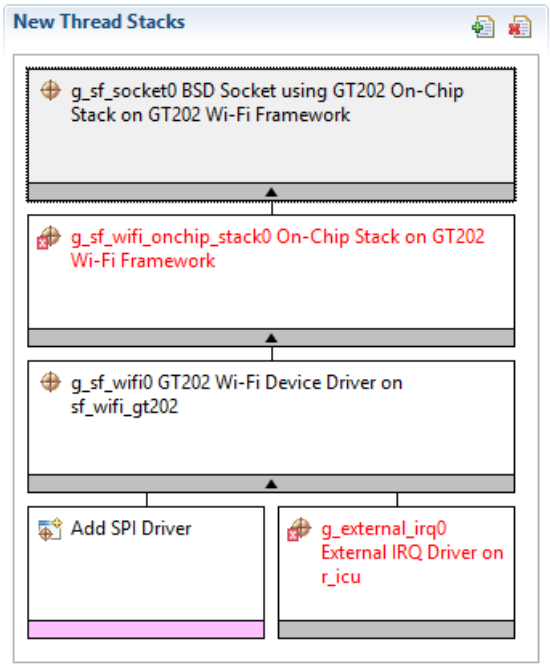

Figure 251: BSD Socket using GT202 On-Chip Stack on GT202 Wi-Fi Framework

Configuration Settings for the BSD Socket using GT202 On-Chip Stack on GT202 Wi-Fi Framework

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name (Must be a valid C Symbol)	g_sf_socket0	Module name

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the On-Chip Stack on GT202 Wi-Fi Framework

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name (Must be a valid C Symbol)	g_sf_wifi_onchip_stack0	Module name

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Wi-Fi Device Driver

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
On-Chip Stack Support	Enabled, Disabled Default: Disabled	On-chip stack support selection
Driver Heap Size in Bytes (Minimum 8192 bytes)	8192	Driver heap size selection
Name (Must be a valid C symbol)	g_sf_wifi0	Module name
Hardware Mode	802.11a, 802.11b, 802.11g, 802.11n Default: 802.11n	Hardware mode selection
Transmit (TX) Power (Valid Range 1-17)	10	Transmit power selection
Ready/Clear to Send (RTS/CTS) Flag	Enabled, Disabled Default: Enabled	Ready/Clear to send selection
Delivery Traffic Indication Message (DTIM) Interval (Valid Range: 1-255)	3	Delivery traffic indication message interval selection

ISDE Property	Setting	Description
Broadcast SSID (AP mode only)	Enabled, Disabled Default: Enabled	Broadcast SSID selection
Beacon Interval in Microseconds (AP mode only and must be greater than 1023)	1024	Beacon interval in microseconds selection
Station inactivity timeout in seconds (AP mode only and must be greater than 0)	100	Station inactivity timeout selection
Requested High Throughput	Enabled, Disabled Default: Disabled	Requested high throughput selection
Reset Pin (must be a valid C symbol)	IOPORT_PORT_06_PIN_00	Reset pin selection
Slave Select Pin (SSL)(Must be a valid C symbol)	IOPORT_PORT_01_PIN_03	Slave select pin selection
GT202 Driver Task Thread Priority (Modifying Task Thread Priority may cause Driver to malfunction)	5	GT202 driver task thread priority selection
Callback	NULL	Callback selection
Support NetX Packet Chaining	Enabled, Disabled Default: Enabled	Support NetX packet chaining selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SPI HAL Driver on r_rspi

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.

ISDE Property	Setting	Description
Name	g_spi0	Module name
Channel	0	SCI or SPI Channel number to which the device has been connected.
Operating Mode	Master	Configure as a Master or Slave device . NOTE: Current version of SSP supports only SPI Master mode.
Clock Phase	Data sampling on even edge, data variation on odd edge	Data sampling on odd or even clock edge.
Clock Polarity	High when idle	Clock level when idle.
Mode Fault Error	Disable	Indicates Mode fault error (master/slave conflict) flag.
Bit Order	MSB First	Select transmit order MSB/LSB first
Bitrate	500000	Transmission or reception rate. Bits per second.
Callback	NULL	Optional Callback function pointer.
SPI Mode	Clock synchronous operation	Select spi or clock syn mode operation.
SPI Communication Mode	Full Duplex	Select full-duplex or transmit-only communication.
Slave Select Polarity(SSL0)	Active Low	Select SSL0 signal polarity
Slave Select Polarity(SSL1)	Active Low	Select SSL1 signal polarity
Slave Select Polarity(SSL2)	Active Low	Select SSL2 signal polarity
Slave Select Polarity(SSL3)	Active Low	Select SSL3 signal polarity
Select Loopback1	Normal	Select loopback1
Select Loopback2	Normal	Select loopback2

ISDE Property	Setting	Description
Enable MOSI Idle State	Disable	Select MOSI idle fixed value and selection
MOSI Idle State	MOSI Low	Select mosi idle fixed value and selection
Enable Parity	Disable	Enable/disable parity
Parity Mode	Parity Even	Select parity
Select SSL(Slave Select)	SSL0	Select which slave to use; 0-SSL0; 1-SSL1; 2-SSL2; 3-SSL3
Select SSL Level After Transfer	SSL Level Do Not Keep	Select SSL level after transfer completion; 0-negate; 1-keep
Clock Delay Enable	Clock Delay Disable	Clock delay enable selection
Clock Delay Count	Clock Delay 1 RSPCK	Clock delay count selection
SSL Negation Delay Enable	Negation Delay Disable	SSL negation delay enable selection
Negation Delay Count	Negation Delay 1 RSPCK	Negation delay count selection
Next Access Delay Enable	Next Access Delay Disable	Next access delay enable selection
Next Access Delay Count	Next Access Delay 1 RSPCK	Next access delay count selection
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Receive interrupt priority selection
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection

ISDE Property	Setting	Description
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Error interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SPI0 TXI

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Disabled	Software start selection
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection
Name	g_transfer0	Module name
Mode	Normal	Mode selection
Transfer Size	4 Bytes	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	
Destination Pointer	NULL	Destination pointer selection

ISDE Property	Setting	Description
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SPI0 TXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SPI0 RXI

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Name	g_transfer1	Module name
Mode	Normal	Mode selection
Transfer Size	4 Bytes	Transfer size selection
Destination Address Mode	Incremented	Destination address mode selection
Source Address Mode	Fixed	Source address mode selection

ISDE Property	Setting	Description
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SPI0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SPI HAL Module on r_sci_spi

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_spi0	Module name

ISDE Property	Setting	Description
Channel	0	SCI or SPI Channel number to which the device has been connected.
Operating Mode	Master	Configure as a Master or Slave device . NOTE: Current version of SSP supports only SPI Master mode.
Clock Phase	Data sampling on even edge, data variation on odd edge	Data sampling on odd or even clock edge.
Clock Polarity	High when idle	Clock level when idle.
Mode Fault Error	Disable	Indicates Mode fault error (master/slave conflict) flag.
Bit Order	MSB First	Select transmit order MSB/LSB first
Bitrate	100000	Transmission or reception rate. Bits per second.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Bitrate Modulation Function enable or disable
Callback	NULL	Optional Call back function pointer.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Bitrate Modulation Function enable or disable. NOTE: This is applicable only for SCI SPI.

ISDE Property	Setting	Description
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit end interrupt priority selection
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Error interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 TXI

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_spi0	Module name
Channel	0	SCI or SPI Channel number to which the device has been connected.

ISDE Property	Setting	Description
Operating Mode	Master	Configure as a Master or Slave device . NOTE: Current version of SSP supports only SPI Master mode.
Clock Phase	Data sampling on even edge, data variation on odd edge	Data sampling on odd or even clock edge.
Clock Polarity	High when idle	Clock level when idle.
Mode Fault Error	Disable	Indicates Mode fault error (master/slave conflict) flag.
Bit Order	MSB First	Select transmit order MSB/LSB first
Bitrate	100000	Transmission or reception rate. Bits per second.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Bitrate Modulation Function enable or disable
Callback	NULL	Optional Call back function pointer.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Bitrate Modulation Function enable or disable. NOTE: This is applicable only for SCI SPI.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection.

ISDE Property	Setting	Description
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit end interrupt priority selection
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Error interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 RXI

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Disabled	Software start selection
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection
Name	g_transfer1	Module name
Mode	Normal	Mode selection
Transfer Size	1 Byte	Transfer size selection

ISDE Property	Setting	Description
Destination Address Mode	Incremented	Destination address mode selection
Source Address Mode	Fixed	Source address mode selection
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SCI0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Softare Event interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the External IRQ HAL Module on r_icu

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter checking setting enables or disables the addition of parameter checking code.

ISDE Property	Setting	Description
Name	g_external_irq0	Module name.
Channel	0	Specifies the hardware IRQ channel used.
Trigger	Falling	Selection for trigger event mode
Digital Filtering	Disabled	Digital filter enable/disable.
Digital Filtering Sample Clock (Only valid when Digital Filtering is Enabled)	PCKL/64	Sets noise filter sampling period.
Interrupt enabled after initialization	TRUE	Determines if the interrupt is enabled immediately after initialization.
Callback	custom_hw_irq_isr	A user callback function can be registered in open. If this callback function is provided, it is called from the interrupt service routine (ISR) each time the IRQn triggers. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuring the NetX Port using Wi-Fi Framework

This section shows the configuration settings for the NetX Port implementation of the Wi-Fi framework.

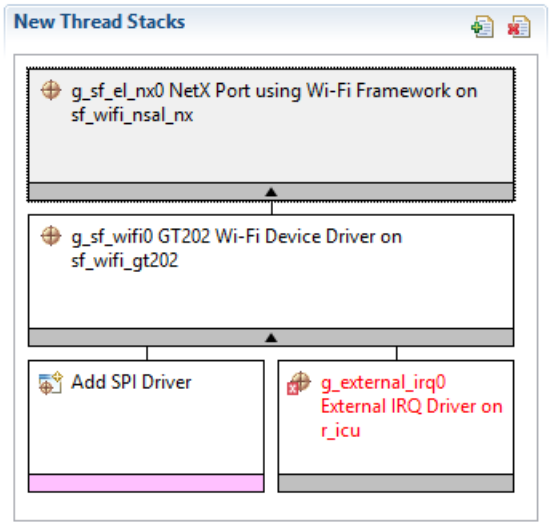

Figure 252: NetX Port using Wi-Fi Framework

Configuration Settings for the NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name (Must be a valid C Symbol)	g_sf_el_nx0	Module name

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Wi-Fi Device Driver

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.

ISDE Property	Setting	Description
On-Chip Stack Support	Enabled, Disabled Default: Disabled	On-chip stack support selection
Driver Heap Size in Bytes (Minimum 8192 bytes)	8192	Driver heap size selection
Name (Must be a valid C symbol)	g_sf_wifi0	Module name
Hardware Mode	802.11a, 802.11b, 802.11g, 802.11n Default: 802.11n	Hardware mode selection
Transmit (TX) Power (Valid Range 1-17)	10	Transmit power selection
Ready/Clear to Send (RTS/CTS) Flag	Enabled, Disabled Default: Enabled	Ready/Clear to send selection
Delivery Traffic Indication Message (DTIM) Interval (Valid Range: 1-255)	3	Delivery traffic indication message interval selection
Broadcast SSID (AP mode only)	Enabled, Disabled Default: Enabled	Broadcast SSID selection
Beacon Interval in Microseconds (AP mode only and must be greater than 1023)	1024	Beacon interval in microseconds selection
Station inactivity timeout in seconds (AP mode only and must be greater than 0)	100	Station inactivity timeout selection
Requested High Throughput	Enabled, Disabled Default: Disabled	Requested high throughput selection
Reset Pin (must be a valid C symbol)	IOPORT_PORT_06_PIN_00	Reset pin selection
Slave Select Pin (SSL)(Must be a valid C symbol)	IOPORT_PORT_01_PIN_03	Slave select pin selection

ISDE Property	Setting	Description
GT202 Driver Task Thread Priority (Modifying Task Thread Priority may cause Driver to malfunction)	5	GT202 driver task thread priority selection
Callback	NULL	Callback selection
Support NetX Packet Chaining	Enabled, Disabled Default: Enabled	Support NetX packet chaining selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SPI HAL Driver on r_rspi

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_spi0	Module name
Channel	0	SCI or SPI Channel number to which the device has been connected.
Operating Mode	Master	Configure as a Master or Slave device . NOTE: Current version of SSP supports only SPI Master mode.
Clock Phase	Data sampling on even edge, data variation on odd edge	Data sampling on odd or even clock edge.
Clock Polarity	High when idle	Clock level when idle.
Mode Fault Error	Disable	Indicates Mode fault error (master/slave conflict) flag.

ISDE Property	Setting	Description
Bit Order	MSB First	Select transmit order MSB/LSB first
Bitrate	500000	Transmission or reception rate. Bits per second.
Callback	NULL	Optional Callback function pointer.
SPI Mode	Clock synchronous operation	Select spi or clock syn mode operation.
SPI Communication Mode	Full Duplex	Select full-duplex or transmit-only communication.
Slave Select Polarity(SSL0)	Active Low	Select SSL0 signal polarity
Slave Select Polarity(SSL1)	Active Low	Select SSL1 signal polarity
Slave Select Polarity(SSL2)	Active Low	Select SSL2 signal polarity
Slave Select Polarity(SSL3)	Active Low	Select SSL3 signal polarity
Select Loopback1	Normal	Select loopback1
Select Loopback2	Normal	Select loopback2
Enable MOSI Idle State	Disable	Select MOSI idle fixed value and selection
MOSI Idle State	MOSI Low	Select mosi idle fixed value and selection
Enable Parity	Disable	Enable/disable parity
Parity Mode	Parity Even	Select parity
Select SSL(Slave Select)	SSL0	Select which slave to use; 0-SSL0; 1-SSL1; 2-SSL2; 3-SSL3
Select SSL Level After Transfer	SSL Level Do Not Keep	Select SSL level after transfer completion; 0-negate; 1-keep
Clock Delay Enable	Clock Delay Disable	Clock delay enable selection
Clock Delay Count	Clock Delay 1 RSPCK	Clock delay count selection
SSL Negation Delay Enable	Negation Delay Disable	SSL negation delay enable selection
Negation Delay Count	Negation Delay 1 RSPCK	Negation delay count selection

ISDE Property	Setting	Description
Next Access Delay Enable	Next Access Delay Disable	Next access delay enable selection
Next Access Delay Count	Next Access Delay 1 RSPCK	Next access delay count selection
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Receive interrupt priority selection
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Error interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SPI0 TXI

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build

ISDE Property	Setting	Description
Software Start	Enabled, Disabled Default: Disabled	Software start selection
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection
Name	g_transfer0	Module name
Mode	Normal	Mode selection
Transfer Size	4 Bytes	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SPI0 TXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SPI0 RXI

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Name	g_transfer1	Module name
Mode	Normal	Mode selection
Transfer Size	4 Bytes	Transfer size selection
Destination Address Mode	Incremented	Destination address mode selection
Source Address Mode	Fixed	Source address mode selection
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SPI0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection

ISDE Property	Setting	Description
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SPI HAL Module on r_sci_spi

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_spi0	Module name
Channel	0	SCI or SPI Channel number to which the device has been connected.
Operating Mode	Master	Configure as a Master or Slave device . NOTE: Current version of SSP supports only SPI Master mode.
Clock Phase	Data sampling on even edge, data variation on odd edge	Data sampling on odd or even clock edge.
Clock Polarity	High when idle	Clock level when idle.
Mode Fault Error	Disable	Indicates Mode fault error (master/slave conflict) flag.
Bit Order	MSB First	Select transmit order MSB/LSB first

ISDE Property	Setting	Description
Bitrate	100000	Transmission or reception rate. Bits per second.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Bitrate Modulation Function enable or disable
Callback	NULL	Optional Call back function pointer.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Bitrate Modulation Function enable or disable. NOTE: This is applicable only for SCI SPI.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit end interrupt priority selection
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Error interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 TXI

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_spi0	Module name
Channel	0	SCI or SPI Channel number to which the device has been connected.
Operating Mode	Master	Configure as a Master or Slave device . NOTE: Current version of SSP supports only SPI Master mode.
Clock Phase	Data sampling on even edge, data variation on odd edge	Data sampling on odd or even clock edge.
Clock Polarity	High when idle	Clock level when idle.
Mode Fault Error	Disable	Indicates Mode fault error (master/slave conflict) flag.
Bit Order	MSB First	Select transmit order MSB/LSB first
Bitrate	100000	Transmission or reception rate. Bits per second.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Bitrate Modulation Function enable or disable
Callback	NULL	Optional Call back function pointer.

ISDE Property	Setting	Description
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Bitrate Modulation Function enable or disable. NOTE: This is applicable only for SCI SPI.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit end interrupt priority selection
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Error interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 RXI

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Disabled	Software start selection
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection
Name	g_transfer1	Module name
Mode	Normal	Mode selection
Transfer Size	1 Byte	Transfer size selection
Destination Address Mode	Incremented	Destination address mode selection
Source Address Mode	Fixed	Source address mode selection
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SCI0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection

ISDE Property	Setting	Description
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Softare Event interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the External IRQ HAL Module on r_icu

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter checking setting enables or disables the addition of parameter checking code.
Name	g_external_irq0	Module name.
Channel	0	Specifies the hardware IRQ channel used.
Trigger	Falling	Selection for trigger event mode
Digital Filtering	Disabled	Digital filter enable/disable.
Digital Filtering Sample Clock (Only valid when Digital Filtering is Enabled)	PCKL/64	Sets noise filter sampling period.
Interrupt enabled after initialization	TRUE	Determines if the interrupt is enabled immediately after initialization.

ISDE Property	Setting	Description
Callback	custom_hw_irq_isr	A user callback function can be registered in open. If this callback function is provided, it is called from the interrupt service routine (ISR) each time the IRQn triggers. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

Wi-Fi Framework Module Clock Configuration

The Wi-Fi Framework module uses the clocks required for the specific selections of the low-level modules such as SPI.

Wi-Fi Framework Module Pin Configuration

The Wi-Fi Framework module uses input and output pins depending on the selections of the low-level modules such as SPI or IRQ.

4.1.29.6 Using the Wi-Fi Framework Module in an Application

The following description is a high-level overview of some typical Wi-Fi use cases. A more detailed description and a working application project (which is too lengthy to include in this document), is available on the Renesas web site. Just search for the associated application note document number, r11an0226eu, in the top page search bar on http://www.Renesas.com. It is highly recommended that you use the application note to augment the summary descriptions found in this document.

Each of the Wi-Fi framework implementations are treated differently in a target application. The typical control flow for initialization, packet transmission using NetX/NetX Duo, packet reception using NetX/NetX Duo, and using an on-chip networking stack are of particular interest. Example flow diagrams for some typical implementations of these functions are shown as follows:

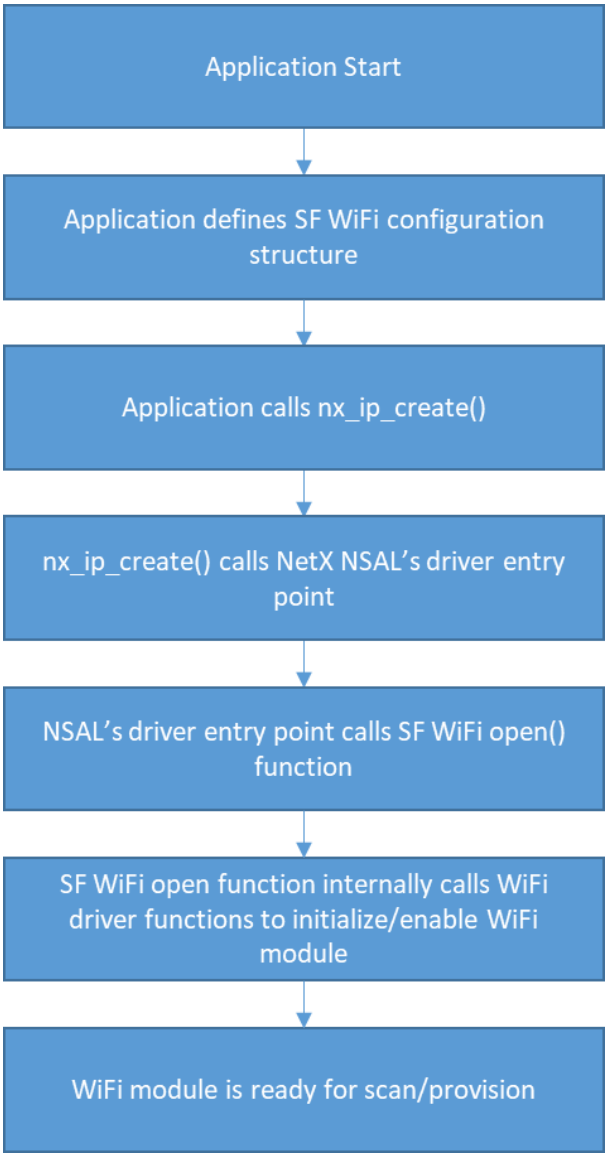

Figure 253: Application Control Flow using Wi-Fi module initialization

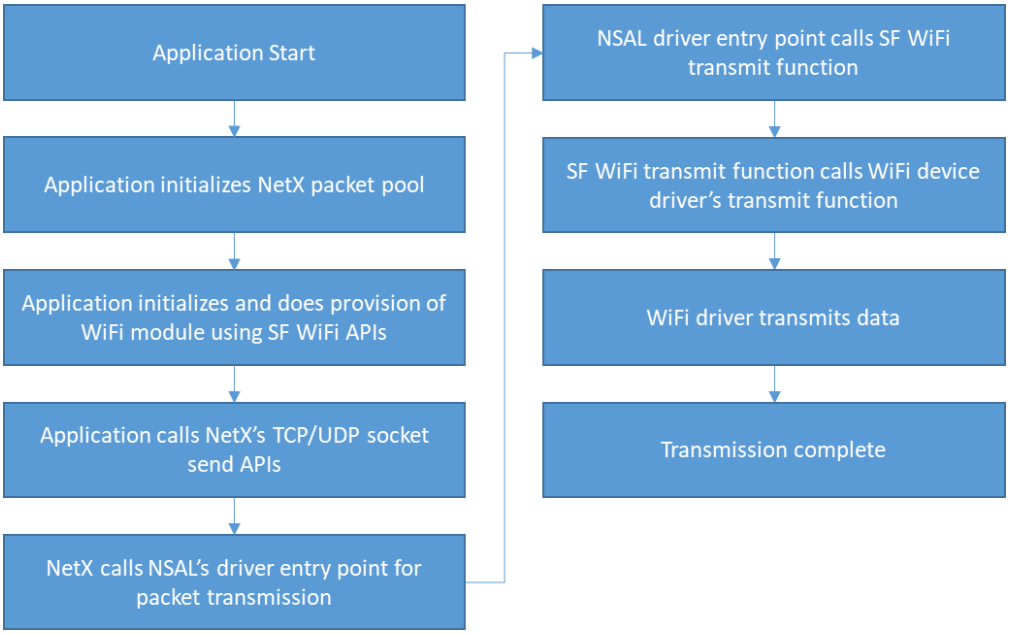

Figure 254: Application Control Flow doing packet transmission using NetX

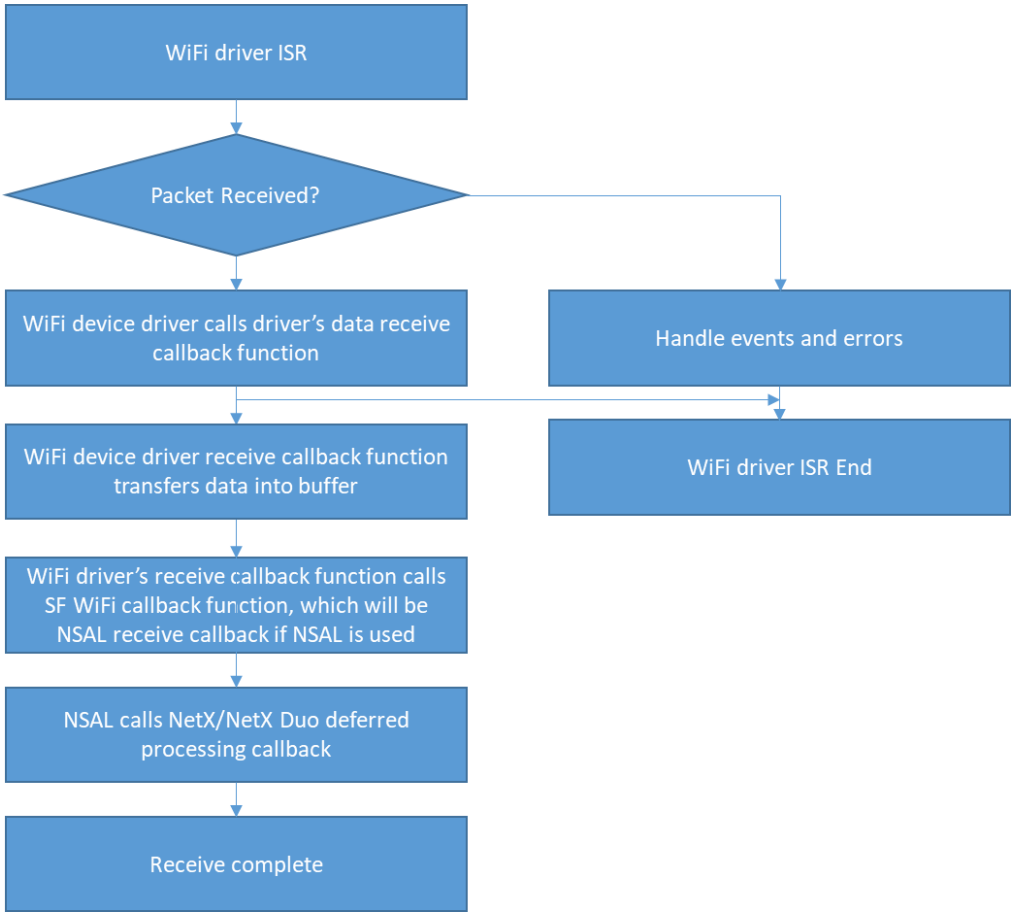

Figure 255: Application control flow receiving packet using NetX

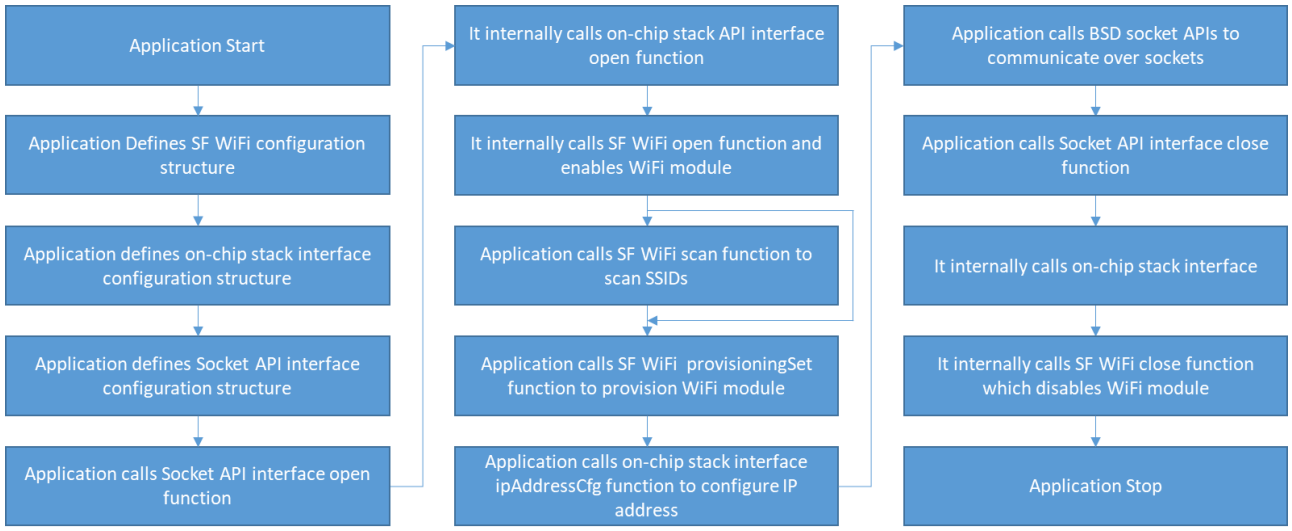

Figure 256: Application Flow Control using On-Chip Networking Stack

4.1.30 USBX Port DCD/HCD for USBFS/USBHS Framework

The Express Logic USBX Synergy Port framework module (sf_el_ux) is integrated into the SSP. This driver is meant to be used with Express Logic USBX. For more information about USBX, including API references, refer to the USBX User Guide.

4.1.30.1 Express Logic USBX Synergy Port Framework Module Features

The Express Logic USBX Synergy Port Framework module supports the following features:

- Implements Express Logic USBX in SSP- support USBX APIs
- Supports the Port Device Controller Driver (DCD) for the USBHS peripheral
- Supports the Port Device Controller Driver (DCD) for the USBFS peripheral
- Supports the Port Host Controller Driver (HCD) for the USBHS peripheral
- Supports the Port Host Controller Driver (HCD) for the USBFS peripheral
- Supports transfer module operation (optional)

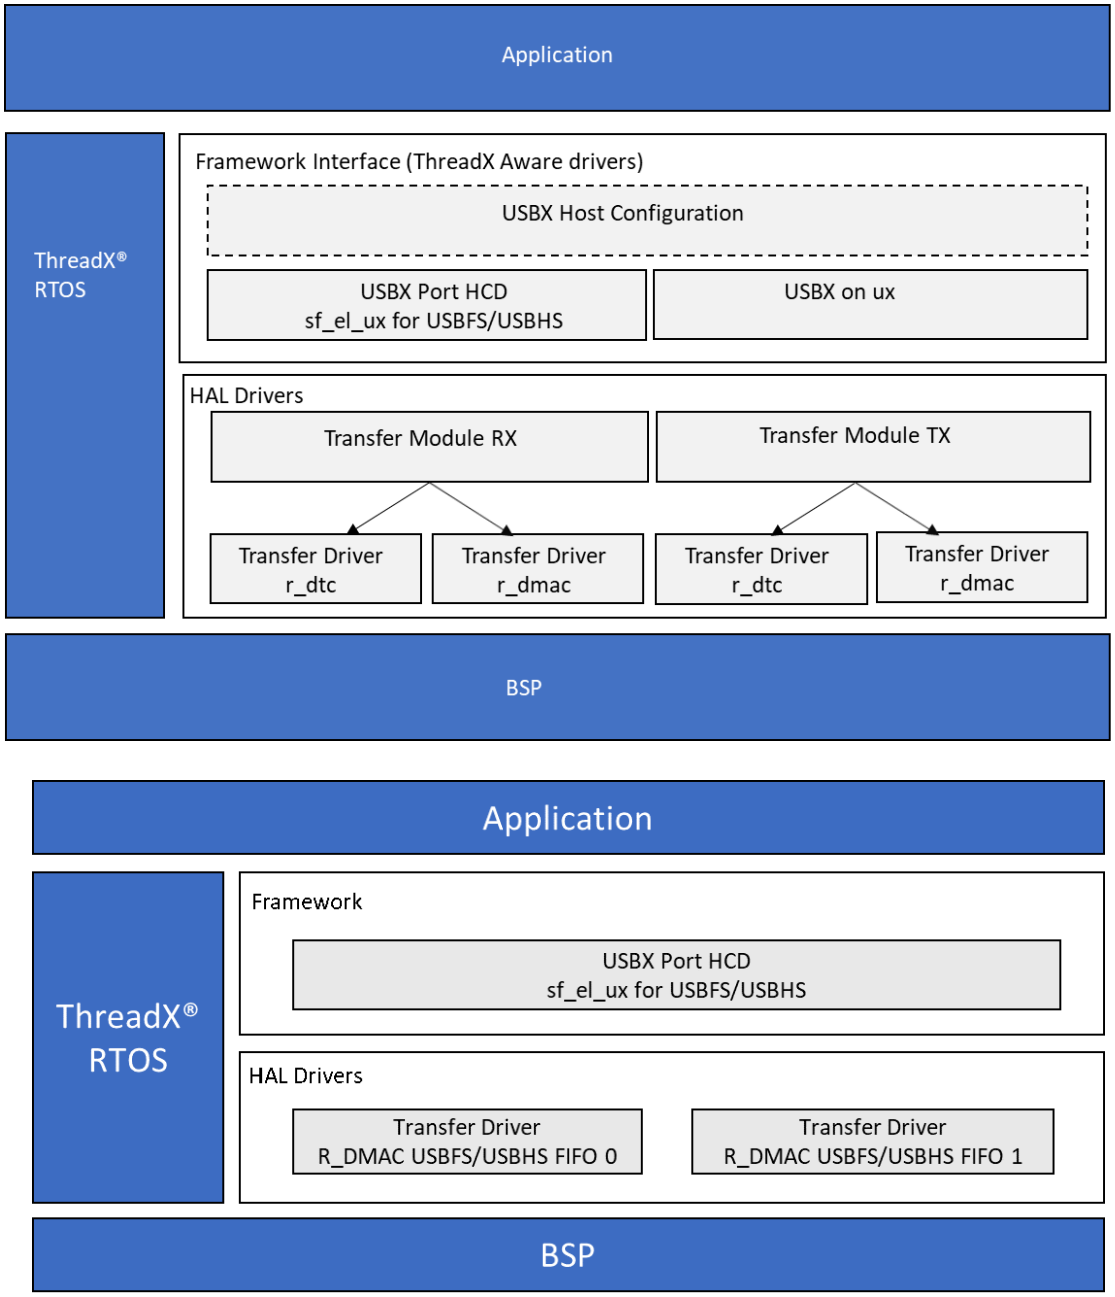

Figure 257: Express Logic USBX Synergy Port Framework Organization, Options and Stack Implementation for DCD and HCD

4.1.30.2 Express Logic USBX Synergy Port Framework Module APIs Overview

The Express Logic USBX Synergy Port Framework module doesn't have API calls of its own- it implements the API calls for the Express Logic USBX API calls. Documentation on these APIs is available in the Express Logic USBX User Manual.

4.1.30.3 Express Logic USBX Synergy Port Framework Module Operational Overview

The Express Logic USBX Synergy Port framework module provides the Synergy USB hardware port functions required to use the USBX stack on Synergy hardware. Application code using this module is expected to use USBX API calls.

Important Operational Notes and Limitations for the Express Logic USBX Synergy Port Framework Module

The Express Logic USBX Synergy Port framework module includes the support for the Express Logic USBX APIs in SSP. Refer to the Express Logic USBX User Manual for a complete description of the available APIs.

The Express Logic USBX Synergy Port framework module supports the Port Device Controller Driver (DCD) on USBHS and USBFS peripherals as well as the Port Host Controller Driver (HCD) for the USBHS on USBFS peripherals.

Users have the option of using the Transfer Module for the USBX Synergy Port framework module to get better USB data throughput by transferring data in the block transfer mode. To enable the Transfer module, just add two instances of transfer components to the USBX Class stack in the Synergy Configuration tool and enable the interrupts in the property. The Synergy Configuration tool auto-generates the driver setup code to enable DMAC or DTC transfer in common_data.c.

NOTE: The module uses the interrupt of a USB Controller. Set the appropriate interrupt priority level in the Synergy Configuration tool, otherwise it does not work.

The module uses the interrupt of a Transfer module (implemented as DMAC or DTC) if it is used. Set the appropriate priority level in the Synergy Configuration tool. The level must be higher than the level for the USB Controller, otherwise it does not work.

- Synergy USB controllers (USBHS and USBFS) have a limited number of PIPEs you can use for the isochronous transfer type (PIPE1 and PIPE2). This will limit the number of UVC devices (two devices) you can connect to.
- The device side driver (sf_el_ux DCD driver) does not support DTC as the transfer interface.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.30.4 Including the Express Logic USBX Synergy Port Framework Module in an Application

This section describes how to include the Express Logic USBX Synergy Port Framework module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few sections of the *SSP User's Manual* to learn how to manage each of these important steps in creating SSP-based applications.

The configurator has the capability to hide some modules from the user. This is done to simplify the selection of modules based on the context of the project. For example, some modules are not available for some MCUs, so if one of those MCUs is selected, these modules won't be made available to add to a thread. The Express Logic USBX Synergy Port framework module is usually not added as a standalone module- it is usually added as a lower level module to a higher-level USB module. For the advanced user, a mode can be set to show all modules, not just those the configurator 'thinks' are appropriate for the current project. This mode must be enabled in order to see the Synergy Port module, as illustrated in the following figures.

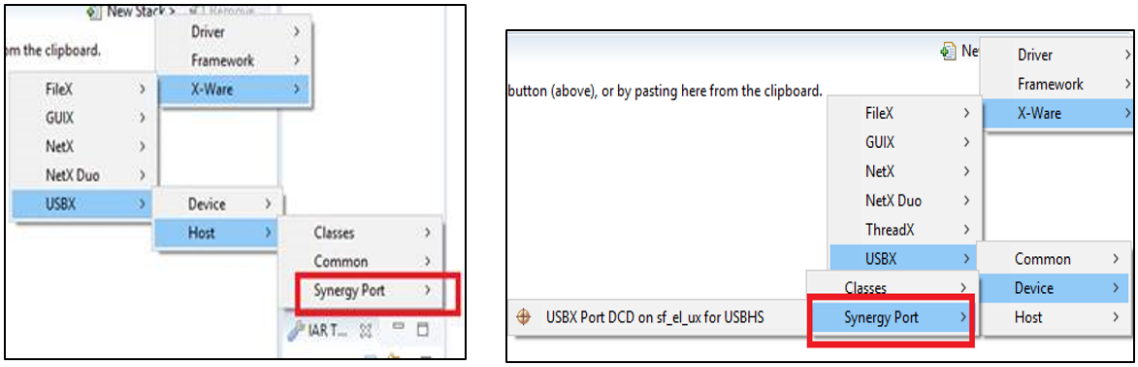

Figure 258: Selecting the USBX Synergy Port Module When Hidden

This mode can be enabled by turning on the Synergy module developer mode. Simply select the Window dropdown on the top line of the ISDE and then select Preferences>C/C++> Renesas>Synergy Configurator Editor. Then check the box for Synergy module developer mode. Then click Apply. This will allow the configurator to show all modules, not just those useable in the current project. Make sure to come back and disable this mode, after using it for a specific case, to continue to benefit from the context aware view.

Once you can view the Synergy Port selections, to use the USBX Synergy Port in an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the USBX Synergy Port is g_sf_el_ux_hcd/dcd_hs/fs_0. This name can be changed in the associated Properties window.)

USBX Synergy Port Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_el_ux_hcd_hs_0 USBX Port HCD on sf_el_ux for USBHS	Threads	New Stack> X-Ware> USBX> Host > Synergy Port> USBX Port HCD on sf_el_ux for USBHS
g_sf_el_ux_hcd_fs_0 USBX Port HCD on sf_el_ux for USBFS	Threads	New Stack> X-Ware> USBX> Host > Synergy Port> USBX Port HCD on sf_el_ux for USBFS
g_sf_el_ux_dcd_hs_0 USBX Port HCD on sf_el_ux for USBHS	Threads	New Stack> X-Ware> USBX> Device > Synergy Port> USBX Port HCD on sf_el_ux for USBHS
g_sf_el_ux_dcd_fs_0 USBX Port HCD on sf_el_ux for USBFS	Threads	New Stack> X-Ware> USBX> Device > Synergy Port> USBX Port HCD on sf_el_ux for USBFS

When the USBX Synergy Port Framework module on sf_el_ux is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information will have box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level drivers; these are either optional or recommended (this is indicated in the block with the inclusion of this text.) If the addition of lower-level drivers is

required, the module description will include "Add" in the text. Clicking on any Pink banded modules will bring up the "New" icon and then display the possible choices.

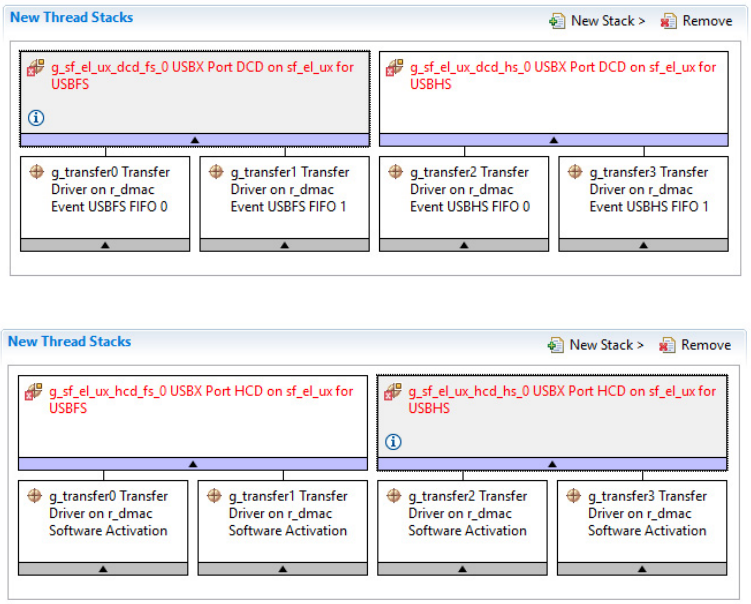

Figure 259: Express Logic USBX Synergy Port Framework Stacks

4.1.30.5 Configuring the Express Logic USBX Synergy Port Framework Module

The USBX Synergy Port Framework module must be configured by you for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority: this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for Express Logic USBX Port DCD on sf_el_ux for USBFS

ISDE Property	Value	Description
Full Speed Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Select the priority level of the full speed interrupt.
LDO Regulator (Only for S3 and S1 MCUs)	Enable, Disable Default: Disable	Select if the USB LDO regulator will be enabled.
Name	g_sf_el_ux_dcd_fs_0	Module name.
USB Controller Selection	USBFS	Select the USB controller.

Configuration Settings for Express Logic USBX Port DCD on sf_el_ux for USBHS

ISDE Property	Value	Description
Full Speed Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Select the interrupt priority for high speed USB.
Name	g_sf_el_ux_dcd_hs_0	Module name.
USB Controller Selection	USBHS	Select the USB controller.

Configuration Settings for Express Logic USBX Port HCD on sf_el_ux for USBFS

ISDE Property	Value	Description
High Speed Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Select the interrupt priority for full speed USB.
VBUSEN pin Signal Logic	Active High, Active Low (Default: Active High)	Select the VBUSEN pin signal logic.
LDO Regulator (Only for S3 and S1 MCUs)	Enable, Disable Default: Disable	Select if the LDO regulator will be enabled.
Name	g_sf_el_ux_hcd_fs_0	Module name.
USB Controller Selection	USBFS	Select the USB controller.

Configuration Settings for Express Logic USBX Port HCD on sf_el_ux for USBHS

ISDE Property	Value	Description
High Speed Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Select the interrupt priority for high speed USB.
FIFO size for Bulk/Isochronous Pipes	512, 1024, 1536, 2048 bytes Default: 512 bytes	Select the FIFO size for bulk and isochronous transfers.

ISDE Property	Value	Description
Number of Isochronous Pipes Reserved	0,1,2 Default: 0	Select the number of isochronous pipes to reserve.
VBUSEN pin Signal Logic	Active High, Active Low (Default: Active High)	Select the VBUSEN pin signal logic.
Enable High Speed	Enable, Disable Default: Enable	Select if high speed should be enabled.
Name	g_sf_el_ux_dcd_fs_0	Module name.
USB Controller Selection	USBFS	Select the USB controller.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Express Logic USBX Synergy Port Framework Low Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module.

NOTE: One implementation of each of the lower level transfer drivers is provided. The other set of transfer drivers is very similar to the ones provided, with only minor changes. View the properties in the SSP configuration window to see the differences.

Configuration for the Transfer Driver on r_dmac Software Activation

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Name	g_transfer0	Module name
Channel	0	Channel selection

ISDE Property	Value	Description
Mode	Block	Mode selection
Transfer Size	1 Byte	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source	Software Activation	Activation source selection
Auto Enable	False	Auto enable selection
Callback	NULL	Callback selection
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection

Configuration Settings for Transfer Driver on r_dmac Software Activation

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Name	g_transfer0	Module name

ISDE Property	Value	Description
Channel	1	Channel selection
Mode	Block	Mode selection
Transfer Size	1 Byte	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source	Software Activation	Activation source selection
Auto Enable	False	Auto enable selection
Callback	NULL	Callback selection
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

Express Logic USBX Synergy Port Framework Clock Configuration

The USB peripheral module uses UCLK as its clock source. The clock frequency must be set to 48 MHz and this can be done in the Clocks tab of the configuration window.

Express Logic USBX Synergy Port Framework Pin Configuration

The USB peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window (depending on the USB function desired- USBFS or USBHS) and the subsequent tables illustrate example selections for the USB pins in each function.

NOTE: The operation mode determines what peripheral signals are available and thus what MCU pins are required. The operation mode selection must be consistent with the mode used by the USBX Device module.

Pin Selection Sequence for USBFS and USBHS

Resource	ISDE Tab	Pin
USBFS	Pins	Select Peripherals > Connectivity: USBFS> USBFS0
USBHS	Pins	Select Peripherals > Connectivity: USBHS> USBHS0

NOTE: The selection sequence assumes USBFS0 or USBHS0 are the desired hardware target for the driver.

Pin Configuration Settings for the USBX Device Module on USBFS0

Properties	Value	Description
Operation Mode	Device	Select Device as the Operation Mode
USBDP	USBDP	USPDP
USBDM	USBDM	USBDM
OVRCURB	None	OVRCURB
OVRCURA	None	OVRCURA
VBUSEN	None	VBUSEN
VBUS	None, P407 (Default: P407)	VBUS
EXICEN	None	EXICEN
ID	None	ID
VCCUSB	VCCUSB	VCCUSB

Properties	Value	Description
VSSUSB	VSSUSB	VSSUSB

NOTE: The example values are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

Pin Configuration Settings for the USBX Device USBHS0

Pin Configuration Property	Value	Description
Operation Mode	Device	Select Device as the Operation Mode
USBHSDP	USBHSDP	USBHSDP
USBHSDM	USBHSDM	USBHSDM
OVRCURB	None	OVRCURB
OVRCURA	None	OVRCURA
VBUSEN	None	VBUSEN
VBUS	None, PB01 (Default: PB01)	VBUS
EXICEN	None	EXICEN
ID	None	ID
USBHSRREF	USBHSRREF	USBHSRREF
AVCCUSBHS	AVCCUSBHS	AVCCUSBHS
AVSSUSBHS	AVSSUSBHS	AVSSUSBHS
PVSSUSBHS	PVSSUSBHS	PVSSUSBHS
VCCUSBHS	VCCUSBHS	VCCUSBHS
VSS1USBHS	VSS1USBHS	VSS1USBHS
VSS2USBHS	VSS2USBHS	VSS2USBHS

NOTE: The example values are for a project using the Synergy S7G2 Group and the SK-S7G2 Kit. Other Synergy Kits

and other Synergy MCUs may have different available pin configuration settings.

4.1.30.6 Using the Express Logic USBX Synergy Port Framework Module in an Application

Once the Express Logic Synergy Port USBX framework module is added to a thread the Express Logic APIs become available for use by higher level modules. There is usually no need to use the Express Logic Synergy Port USBX framework module directly in application code. Refer to the Express Logic USBX User manual if you need to use the module stand-alone and need to access the associated APIs directly.

4.2.1 ACMPHS Driver

The ACMPHS HAL module implements the Comparator API for signal processing applications on r_acmphs. It supports the ACMPHS peripheral available on the Synergy microcontroller hardware. A callback is available to signal the user application on transition events.

4.2.1.1 ACMPHS HAL Module Features

- Callback on rising edge, falling edge, or both
- Configurable debounce filter
- Option to include comparator output on VCOUT pin

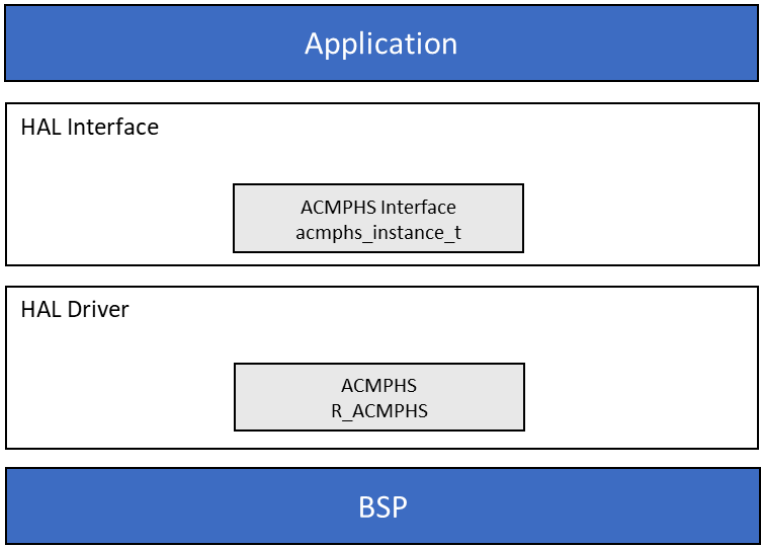

Figure 260: ACMPHS HAL Module Block Diagram

4.2.1.2 ACMPHS HAL Module APIs Overview

The ACMPHS HAL module defines APIs to open, enable, get status, and close the module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

ACMPHS HAL Module API Summary

Function Name	Example API Call and Description
.open	g_comparator0.p_api->open(g_comparator0.p_ctrl, g_comparator0.p_cfg); Configures the comparator and starts operation. Callbacks and pin output are not active until outputEnable() is called. outputEnable() should be called after the output has stabilized.
.outputEnable	g_comparator0.p_api->outputEnable(g_comparator0.p_ctrl); Enables the comparator output, which can be polled using statusGet(). Also enables pin output and interrupts as configured during open().

Function Name	Example API Call and Description
.infoGet	g_comparator0.p_api->infoGet(g_comparator0.p_ctrl, p_info); Provides the minimum stabilization wait time in microseconds..
.statusGet	g_comparator0.p_api->statusGet(g_comparator0.p_ctrl, p_status); Provides the operating status of the comparator.
.close	g_comparator0.p_api->close(g_comparator0.p_ctrl); Close the module.
.versionGet	g_comparator0.p_api->read(&version); Retrieves the version using the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_NOT_OPEN	Unit is not open
SSP_ERR_ASSERTION	An input pointer is NULL.
SSP_ERR_IN_USE	Peripheral is in use or hardware lock is taken.
SSP_ERR_TIMEOUT	The debounce filter is off and 2 consecutive matching values were not read within 1024 attempts.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.2.1.3 ACMPHS HAL Module Operational Overview

The ACMPHS HAL module controls the ACMPHS peripheral on a Synergy microcontroller. It directly controls the ACMPHS hardware without using any RTOS elements and provides convenient APIs to simplify development.

ACMPHS HAL Module Important Operational Notes and Limitations

Comparator Output on VCOUT Pin

The signal on the VCOUT pin is OR'd signal of all comparators with pin output enabled.

Interrupts and Callbacks

When a comparator event occurs, the ACMPHS HAL module calls the callback (comparator_api_t::p_callback) with the argument comparator_callback_args_t.

This module only works for selected Synergy MCUs. Consult the release notes for your current SSP release to see which MCUs are supported by this module. Additionally, the MCU Hardware Manual shows which peripherals are available.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.1.4 Including the ACMPHS HAL Module in an Application

This section describes how to include the ACMPHS HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the ACMPHS HAL module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the ACMPHS HAL module is g_comparator0. This name can be changed in the associated Properties window.)

ACMPHS HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_comparator0 Comparator Driver on r_acmphs	Threads	New Stack> Driver> Analog> Comparator Driver on r_acmphs

When the ACMPHS HAL module on r_acmphs is added to the thread stack as shown in the following figure, the configurator automatically adds any lower-level drivers that are required. Any drivers that need additional configuration information will be box-text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

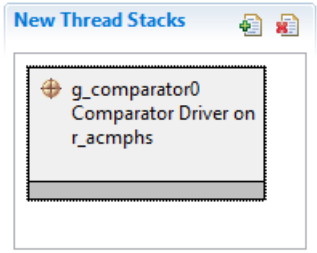

Figure 261: ACMPHS HAL Module Stack

4.2.1.5 Configuring the ACMPHS HAL Module

The ACMPHS HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the ACMPHS HAL Module on r_acmphs

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Controls whether to include code for API parameter checking.
Name	g_comparator	Module name.
Channel	0	Select the hardware channel.

ISDE Property	Value	Description
Trigger Edge	Rising, Falling, Both Edge Default: Both Edge	The trigger specifies when a comparator callback event should occur. Unused if the interrupt priority is disabled or the callback is NULL.
Debounce Filter	No Filter, 8, 16, 32 Default: No Filter	Select the PCLK divisor for the hardware digital debounce filter. Larger divisors provide a longer debounce and take longer for the output to update.
Invert	Not Inverted, Inverted Default: Not Inverted	Turns this on to invest comparator output. This affects the output read from StatusGet(), the pin output level, and the edge trigger.
Pin Output	Disabled, Enabled Default: Disabled	Turn this on to include the output from this comparator on VCOUT. The comparator output on VCOUT is ORed with output from all other ACMPHS and ACMPLP comparators.
Callback	NULL	Define this function in the application. It is called when the Trigger event occurs.
Comparator Interrupt Priority	Priority 0 (highest), Priority 1, Priority 2, Priority 3 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for the comparator interrupt.

NOTE: The example values and defaults are for a project using the Synergy S1JA. Other MCUs may have different default values and available configuration settings.

ACMPHS HAL Module Clock Configuration

The ACMPHS HAL module uses the PCLKB as its clock source.

To change the clock frequency at run-time, use the CGC Interface.

ACMPHS HAL Module Pin Configuration

To use the ACMPHS HAL module, the port pins for the channels receiving the analog input must be set as input pins in the pin configurator in the ISDE. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection Sequence for the ACMPHS HAL Module

Resource	ISDE Tab	Pin selection Sequence
ACMPHS	Pins	Select Peripherals > Analog:ACMP

4.2.1.6 Using the ACMPHS HAL Module in an Application

Once the module has been configured and the files generated, the ACMPHS is ready to be used in an application.

The typical steps in using the ACMPHS HAL module in an application are:

1) Initialize the ACMPHS using the open API.
2) Before enabling the output, consult the hardware manual to configure the internal connections by setting the CMPSELn registers directly. If the internal reference voltage is used, set CPIOC.VREFEN.
3) After configuring the modules and internal connections, wait for the minimum stabilization wait time before enabling output. The minimum stabilization wait time can be queried using the infoGet API.
4) Enable the comparator output using the outputEnable API. This enables pin output, interrupts and the statusGet API as configured during the open API call.
5) [Optional] Use the statusGet API to poll comparator status.
6) [Optional] Use the close API to disable the comparator and power down the peripheral.

These common steps are illustrated in a typical operational flow in the following figure:

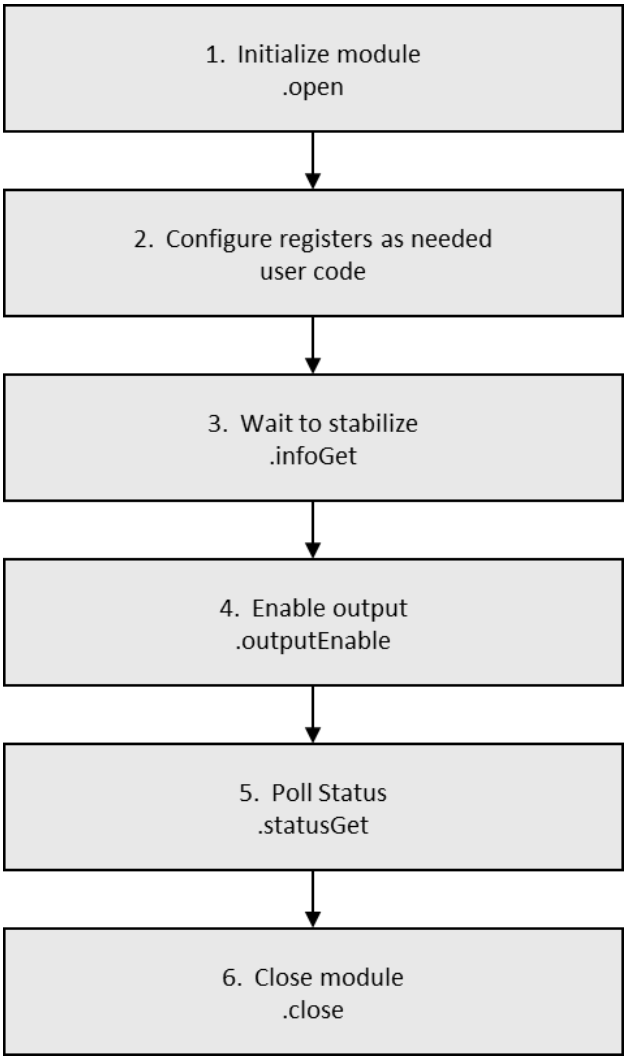

Figure 262: Flow Diagram of a Typical ACMPHS HAL Module Application

4.2.2 ACMPLP Driver

The ACMPLP HAL module implements the Comparator API for signal processing applications on r_acmplp. It supports the ACMPLP peripheral available on the Synergy microcontroller hardware. A callback is available to signal the user application on transition events.

4.2.2.1 ACMPLP HAL Module Features

- Normal mode or window mode
- Callback on rising edge, falling edge, or both
- Configurable debounce filter

- Option to include comparator output on VCOUT pin

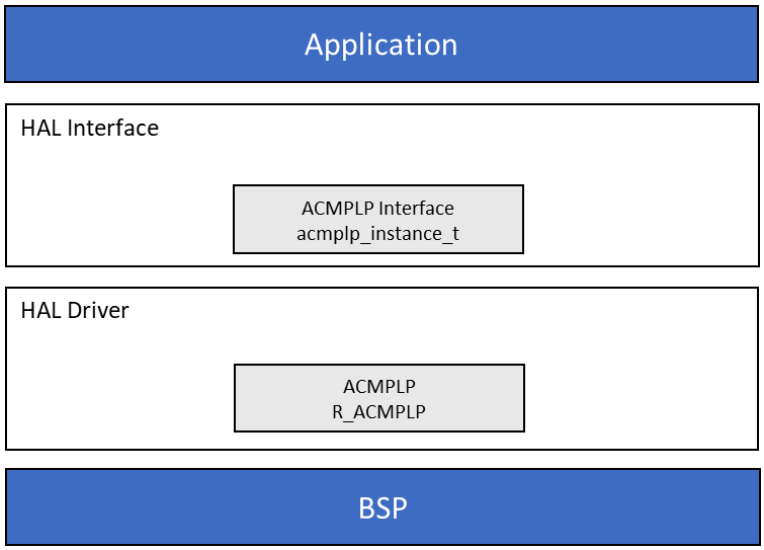

Figure 263: ACMPLP HAL Module Block Diagram

4.2.2.2 ACMPLP HAL Module APIs Overview

The ACMPHS HAL module defines APIs to open, enable, get status, and close the module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

ACMPLP HAL Module API Summary

Function Name	Example API Call and Description
.open	g_comparator0.p_api->open(g_comparator0.p_ctrl, g_comparator0.p_cfg); Configures the comparator and starts operation. Callbacks and pin output are not active until outputEnable() is called. outputEnable() should be called after the output has stabilized.
.outputEnable	g_comparator0.p_api->outputEnable(g_comparator0.p_ctrl); Enables the comparator output, which can be polled using statusGet(). Also enables pin output and interrupts as configured during open().

Function Name	Example API Call and Description
.infoGet	g_comparator0.p_api->infoGet(g_comparator0.p_ctrl, p_info); Provides the minimum stabilization wait time in microseconds..
.statusGet	g_comparator0.p_api->statusGet(g_comparator0.p_ctrl, p_status); Provides the operating status of the comparator.
.close	g_comparator0.p_api->close(g_comparator0.p_ctrl); Close the module.
.versionGet	g_comparator0.p_api->read(&version); Retrieves the version using the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_NOT_OPEN	Unit is not open
SSP_ERR_ASSERTION	An input pointer is NULL.
SSP_ERR_IN_USE	Peripheral is in use or hardware lock is taken.
SSP_ERR_TIMEOUT	The debounce filter is off and 2 consecutive matching values were not read within 1024 attempts.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.2.2.3 ACMPLP HAL Module Operational Overview

The ACMPLP HAL module controls the ACMPLP peripheral on a Synergy microcontroller. It directly controls the ACMPLP hardware without using any RTOS elements and provides convenient APIs to simplify development.

ACMPLP HAL Module Important Operational Notes and Limitations

Comparator Output on VCOUT Pin

The signal on the VCOUT pin is ORed signal of all comparators with pin output enabled.

Interrupts and Callbacks

When a comparator event occurs, the ACMPLP HAL module calls the callback (comparator_api_t::p_callback) with the argument comparator_callback_args_t.

This module only works for selected Synergy MCUs. Consult the release notes for your current SSP release to see which MCUs are supported by this module. Additionally, the MCU Hardware Manual shows which peripherals are available.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.2.4 Including the ACMPLP HAL Module in an Application

This section describes how to include the ACMPLP HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the ACMPLP HAL module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the ACMPLP HAL module is g_comparator0. This name can be changed in the associated Properties window.)

ACMPLP HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_comparator0 Comparator Driver on r_acmplp	Threads	New Stack> Driver> Analog> Comparator Driver on r_acmplp

When the ACMPLP HAL module on r_acmplp is added to the thread stack as shown in the following figure, the configurator automatically adds any lower-level drivers that are required. Any drivers that need additional configuration information will be box-text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

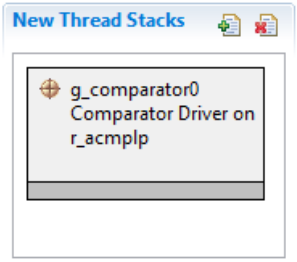

Figure 264: ACMPLP HAL Module Stack

4.2.2.5 Configuring the ACMPLP HAL Module

The ACMPLP HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the ACMPLP HAL Module on r_acmplp

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Controls whether to include code for API parameter checking.
Name	g_comparator	Module name.
Channel	0	Select the hardware channel.

ISDE Property	Value	Description
Mode	Mode Normal, Mode Window Default: Mode Normal	In normal mode, comparator output is high if VCMP > VREF. In window mode, comparator output is high if VCMP is outside the range of VREF0 to VREF1.
Trigger	Trigger Rising, Trigger Falling, Trigger Both Edge Default: Trigger Both Edge	The trigger specifies when a comparator callback event should occur. Unused if the interrupt priority is disabled or the callback is NULL.
Filter	Filter Off, Filter 1, Filter 8, Filter 16, Filter 32 Default: Filter Off	Select the PCLK divisor for the hardware digital debounce filter. Larger divisors provide a longer debounce and take longer for the output to update.
Invert	Off, On Default: Off	Turns this on to invest comparator output. This affects the output read from StatusGet(), the pin output level, and the edge trigger.
Pin Output	Off, On Default: Off	Turn this on to include the output from this comparator on VCOUT. The comparator output on VCOUT is ORed with output from all other ACMPHS and ACMPLP comparators.
Callback	NULL	Define this function in the application. It is called when the Trigger event occurs.
Comparator Interrupt Priority	Priority 0 (highest), Priority 1, Priority 2, Priority 3 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for the comparator interrupt.

NOTE: The example values and defaults are for a project using the Synergy S1JA. Other MCUs may have different default values and available configuration settings.

ACMPLP HAL Module Clock Configuration

The ACMPHS HAL module uses the PCLKB as its clock source.

To change the clock frequency at run-time, use the CGC Interface.

ACMPLP HAL Module Pin Configuration

To use the ACMPLP HAL module, the port pins for the channels receiving the analog input must be set as input pins in the pin configurator in the ISDE. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection Sequence for the ACMPLP HAL Module

Resource	ISDE Tab	Pin selection Sequence
ACMPLP	Pins	Select Peripherals > Analog:ACMP

4.2.2.6 Using the ACMPLP HAL Module in an Application

Once the module has been configured and the files generated, the ACMPLP is ready to be used in an application.

The typical steps in using the ACMPLP HAL module in an application are:

1) Initialize the ACMPLP using the open API.
2) Before enabling the output, consult the hardware manual to configure the internal connections by setting the COMPSELn registers directly. If the internal reference voltage is used, set COMPMDR.CiVRF.
3) After configuring the modules and internal connections, wait for the minimum stabilization wait time before enabling output. The minimum stabilization wait time can be queried using the infoGet API.
4) Enable the comparator output using the outputEnable API. This enables pin output, interrupts and the statusGet API as configured during the open API call.
5) [Optional] Use the statusGet API to poll comparator status.
6) [Optional] Use the close API to disable the comparator and power down the peripheral.

These common steps are illustrated in a typical operational flow in the following figure:

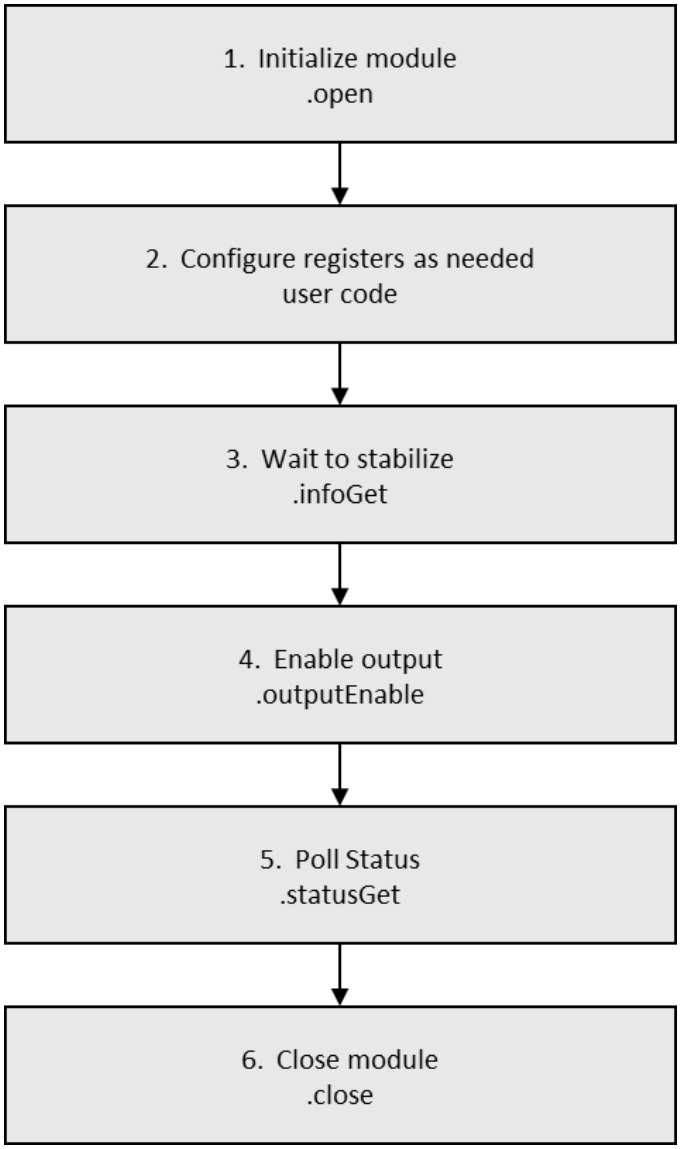

Figure 265: Flow Diagram of a Typical ACMPLP HAL Module Application

4.2.3 ADC Driver

The ADC HAL module implements APIs for analog-to-digital conversions. It supports the ADC12, ADC14 and ADC16 for the associated peripherals available on Synergy MCUs. A user-defined callback can be used to process the data each time a new sample is complete.

4.2.3.1 ADC HAL Module Features

- 16-Bit A/D Converter (S1JA), 14-Bit A/D Converter (S3A7,S3A3,S3A6,S3A1,S128,S124) and 12-Bit A/D Converter (S7G2,S5D9,S5D5)
- Multiple Operation Modes
  - Single Scan
  - Group Scan
  - Continuous Scan
- Multiple Channels
  - All analog channels on MCU
  - **13 channels (unit 0) or 12 channels (unit 1) for S7G2**
  - **17 channels for S1JA**
  - **18 channels for S124**
  - **28 channels for S3A7**
  - Temperature sensor channel
  - Voltage sensor channel

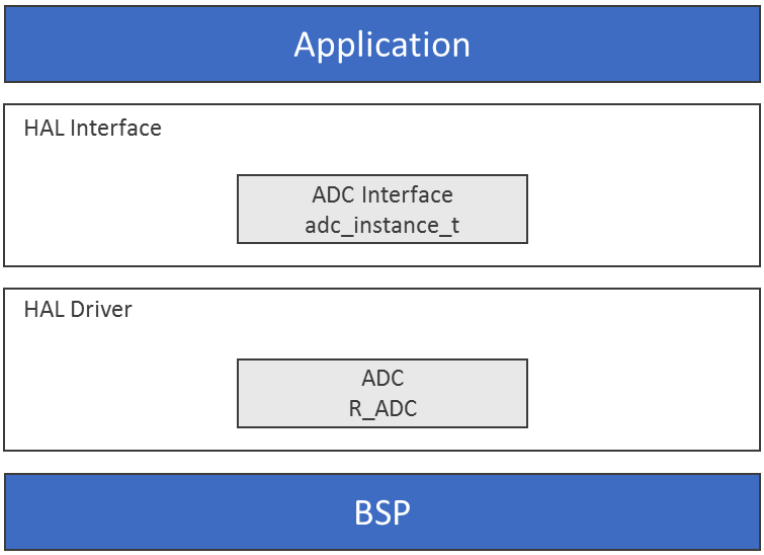

Figure 266: ADC HAL Module Block Diagram

4.2.3.2 ADC HAL Module APIs Overview

The ADC HAL module defines APIs to open, configure scans, start scans, stop scans, read the conversion results the ADC scans, and close the ADC unit. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

ADC HAL Module API Summary

Function Name	Example API Call and Description
.open	g_adc.p_api->open(g_adc.p_ctrl, g_adc.p_cfg); Initialize ADC Unit; apply power, set the operational mode, trigger sources, interrupt priority, and configurations common to all channels and sensors.
.scanCfg	g_adc.p_api->scanCfg(g_adc.p_ctrl, g_adc.*p*_channel_cfg); Configure the scan including the channels, groups and scan triggers to be used for the unit that was initialized in the open call.
.scanStart	g_adc.p_api->scanStart(g_adc.p_ctrl); Start the scan (in case of a software trigger), or enable the hardware trigger.
.scanStop	g_adc.p_api->scanStop(g_adc.*p_ctrl*); Stop the ADC scan (in case of a software trigger), or disable the hardware trigger.
.scanStatusGet	g_adc.p_api->scanStatusGet(g_adc.p_ctrl); Check scan status.
.read	g_adc.p_api->read(g_adc.p_ctrl, ADC_REG_CHANNEL_13, &adc_data); Read ADC conversion result(s).
.sampleStateCountSet	g_adc.p_api-> sampleStateCountSet(g_adc.p_ctrl,&adc_sample); Set the sample state count for the specified channel.

Function Name	Example API Call and Description
.close	g_adc.p_api->close(g_adc.p_ctrl); Close the specified ADC unit by ending any scan in progress, disabling interrupts, and removing power to the specified A/D unit.
.infoGet	g_adc.p_api->infoGet(g_adc.p_ctrl, &adc_info); Return the ADC data register address of the first (lowest number) channel and the total number of bytes to be read for the DTC/DMAC to read the conversion results of all configured channels.
.versionGet	g_adc.p_api->versionGet(&version); Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_NOT_OPEN	Unit is not open
SSP_ERR_ASSERTION	The parameter p_ctrl or p_sample is NULL.
SSP_ERR_IN_USE	Peripheral is still running in another mode; perform R_ADC_Close first.
SSP_ERR_INVALID_POINTER	The parameter p_data is NULL.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.2.3.3 ADC HAL Module Operational Overview

The ADC HAL module controls the ADC units on a Synergy microcontroller, as configured by the user. It directly controls the ADC hardware without using any RTOS elements and provides convenient APIs to simplify development. The driver supports three operation modes: single-scan, continuous-scan, and group-scan modes.

- Single-scan mode sequentially converts the analog inputs of selected channels in the ascending order of the channel number once per trigger.
- Continuous-scan mode sequentially converts the analog inputs of selected channels continuously in the ascending order of the channel numbers. A single trigger is required to start off the scan.
- Group-scan mode allows the user to add channels to one of two groups (A and B) and converts the analog inputs of the selected channels for each group in the ascending order of the channel number when the specified start trigger for that group is received.

In group-mode, operation channels can be assigned to one of two groups: group-A or group-B. A trigger is assigned for each group to start the scan. In group mode, only hardware triggers can be used, as opposed to normal mode, where software triggers or an external trigger can be used. With the priority configuration parameter, you can specify:

- Whether a trigger for one group can interrupt an ongoing scan for the other group.
- Whether an interrupted scan resumes or restarts or simply aborts the current scan and waits for the next trigger.

Interrupts and Callbacks

When a scan or calibration (on supported MCUs) is complete and a callback is provided to the user, (with interrupts enabled) the ADC HAL module invokes the callback (p_callback) with the argument adc_callback_args_t, indicating the unit and the event (adc_cb_event_t). If interrupts are not enabled, the scanStatusGet API supports checking the scan status to poll if the scan is complete and provides a function to read the converted ADC result. For MCUs that support Calibration, if the interrupts are not enabled, the user application must wait 24ms and then check the status of calibration using the infoGet API to see if the calibration is complete before using another API.

The ADC driver supports two interrupts:

- Normal/Group A Interrupt which fires when a scan is completed in single scan more or when a group A scan is completed in group mode or at the end of calibration for supported MCUs.
- Group B Interrupt which fires when a scan is completed a group B scan is completed in group mode.

Interrupts function differently in each mode:

- In single-scan mode, the Normal interrupt is triggered when the scan is completed.
- In continuous scan-mode, the hardware will constantly scan the selected channels. In this mode, the driver will return an error if interrupts are enabled and so must be disabled.
- In group mode, the ADC unit supports two interrupts: the Normal interrupt (also called group-A interrupt) and the group-B interrupt. The group-A interrupt is triggered when a group-A scan is completed. The group-B interrupt is triggered when a group-B scan is completed. In group mode, the normal interrupt is referred to as the group-A interrupt even though it is the same vector.

You must enable the ADC scan-complete interrupt for the selected unit in the BSP in the following situations:

- To get an interrupt when a normal scan is completed.
- To get an interrupt when a group scan is completed.
- To get an interrupt when a calibration is completed (for supported MCUs).

ADC HAL Module Important Operational Notes and Limitations

Sample-State Count Setting

The user can modify the setting of the sample-state count by calling the sampleStateCountSet API. You only need to modify the sample-state count settings from their default values if you want to increase the sampling time, either because the impedance of the input signal is too high to secure sufficient sampling time or the ADCLK is too slow. To modify the sample-state count for a given channel, set the channel number (adc_sample_state_reg_t) and the number of states (num_states). Valid sample state counts are 7-255. (Although the hardware supports minimum number of sample states as 5, it is 7 for some MCUs. It is fixed to 7 since at the lowest ADC conversion clock supported (1 MHz), this extra state will lead to at worst a "1 microsecond" increase in conversion time. At 60 MHz the extra sample state will add 16.7 ns to the conversion time). If you want to change the sample state count for multiple channels, call the sampleStateCountSet API repeatedly with modified arguments for each channel.

Triggering a Data Transfer with the ADC

To trigger a transfer of data when the ADC scan completes, configure the data transfer with activation_source set to ELC_EVENT_ADCn_SCAN_END or ELC_EVENT_ADCn_SCAN_END_B (where n is the ADC channel number). The ELC events are listed under elc_event_t. To retrieve the ADC unit-specific information to use with the transfer API, use the infoGet function call in the transfer API.

Triggering ELC Events with the ADC

The ADC unit can trigger the start of other peripherals listed in elc_peripheral_t. Refer to the "ELC Interface" in the SSP User's Manual for more information.

Using the Temperature Sensor with the ADC

The ADC HAL module supports reading the data from the on-chip temperature sensor. The value returned from the sensor can be converted into degrees Celsius or Fahrenheit by the user application using the following formula, T = (Vs – V1)/slope + T1, where

- T: Measured temperature (°C)
- Vs: Voltage output by the temperature sensor at the time of temperature measurement (Volts)
- T1: Temperature experimentally measured at one point (°C)
- V1: Voltage output by the temperature sensor at the time of measurement of T1 (Volts)
- T2: Temperature at the experimental measurement of another point (°C)
- V2: Voltage output by the temperature sensor at the time of measurement of T2 (Volts)
- Slope: Temperature gradient of the temperature sensor (V/°C); slope = (V2 – V1)/ (T2 – T1)

The slope value can be obtained from the hardware manual for each device under Electrical Characteristics, TSN Characteristics. The slope is positive for the S7/S5 devices and negative for the S3/S1 devices.

When configuring the ADC channels to be used with the ADC HAL module, the temperature and voltage sensors must not be selected if any of the other available channels are also selected. It is possible to only use the temperature sensor, voltage sensor, or any number of the regular ADC channels.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.3.4 Including the ADC HAL Module in an Application

This section describes how to include the ADC HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the ADC HAL module to an application, simply add it to a HAL /Common thread using the stacks selection

sequence given in the following table. (The default name for the ADC HAL module is g_adc0. This name can be changed in the associated Properties window.)

ADC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_adc0 ADC Driver on r_adc	Threads	New Stack> Driver> Analog> ADC Driver on r_adc

When the ADC HAL module on r_adc is added to the thread stack, as shown in the following figure, the configurator automatically adds any lower-level drivers that are required. Any drivers that need additional configuration information will be box-text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

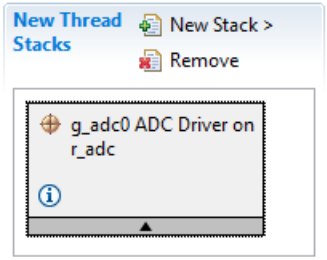

Figure 267: ADC HAL Module Stack

4.2.3.5 Configuring the ADC HAL Module

The ADC HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the ADC HAL Module on r_adc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: Enabled	If selected code for parameter checking is included in the build.
Name	g_adc0	Module name
Unit	0, 1 (S7G2 Only) Default: 0	Specify the ADC Unit to be used. The s7g2 has two units; 0 and 1.
Resolution (resolution varies by MCU)	14-Bit, 12-Bit, 10-Bit, 8_Bit Default: 8-Bit	Specify the conversion resolution for this unit.
Alignment	Right, Left Default: Right	Specify the conversion result alignment.
Clear after read	Off, On Default: On	Specify if the result register must be automatically cleared after the conversion result is read. NOTE: If this is enabled, then watching the result register using a debugger always results in a 0.
Mode	Single Scan, Continuous Scan, Group Scan Default: Single Scan	Specify the mode that this ADC unit is used in.
Internal Calibration During Open()	Enabled, Disabled Default: Enabled	Enable or Disable internal calibration during open. If enabled, open will only return after calibration is completed. The calibration times vary depending on PCLKB and ADCLK.

ISDE Property	Value	Description
Channels 0-13	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channel 14 (S3 Series Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channel 15 (S3A7/S3A3 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channels 16-20	Unused, Use in Normal/Group A, Use in Group B (Default: Unused)	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channel 21 (Unit 0 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.

ISDE Property	Value	Description
Channels 22-24	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channel 25 (S3 series only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channel 26 (S3A7/S3A3 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channel 27 (S3A7/S3A3 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Temperature Sensor	Unused, Use in Normal/Group A, Use in Group B Default: Unused	Temperature sensor use selection for Channel Scan Mask
Voltage Sensor	Unused, Use in Normal/Group A, Use in Group B Default: Unused	Voltage sensor use selection for Channel Scan Mask

ISDE Property	Value	Description
Normal/Group A Trigger	None, Asynchronous External Trigger 0, ELC Event, Software Default: Software	Specify the trigger type to be used for this unit. If group mode is used mode, then this field is used to set the Group A trigger. NOTE: The only valid option in group mode is the ELC trigger.
Group B Trigger (Valid Only in Group Scan Mode)	ELC Event (The only valid trigger for either group in Group Scan Mode)	Specify the group B trigger. This option is only valid if group mode is chosen in mode.
Group Priority (Valid only in Group Scan Mode)	Group A cannot interrupt Group B, Group A can interrupt Group B; Group B scan restarts at next trigger, Group A can interrupt Group B; Group B scan restarts immediately, Group A can interrupt Group B; Group B scan restarts immediately and scans continuously (Default: Group A cannot interrupt Group B)	Determines whether an ongoing group B scan can be interrupted by a group A trigger, whether it should abort on a group A trigger, or if it should pause to allow group A scan and restart immediately after group A scan is complete. NOTE: This field is valid only in group mode.
Add/Average Count	Disabled, Add two samples, Add three samples, Add four samples, Add sixteen samples, Average two samples, Average four samples Default: Disabled	Specify if addition or averaging needs to be done for any of the channels in this unit. The actual channels are specified by using a channel mask add_mask.
Channels 0-27	Disabled, Enabled Default: Disabled	This field is valid only if add_average_count is enabled. This field determines what channels results are to be averaged or summed.
Temperature Sensor	Disabled, Enabled Default: Disabled	Temperature sensor use selection for Addition/Averaging Mask

ISDE Property	Value	Description
Voltage Sensor	Disabled, Enabled Default: Disabled	Voltage sensor use selection for Addition/Averaging Mask
Channels 0-2	Disabled, Enabled Default: Disabled	Determines which of channels 0, 1 and 2 are using the updated sample-and-hold states value specified in sample_hold_states. This field must only be set if it is desired to modify the default sample and hold count value for channels 0, 1 and 2.
Sample Hold States (Applies only to the 3 channels selected above)	24	Specifies the updated sample-and-hold count for the channel dedicated sample-and-hold circuit. This field is valid only if sample_hold_mask is not 0. Only channels 0, 1 and 2 have dedicated sample and hold circuits. NOTE: Use this to modify the default number of states (24) for which the value is sampled. Each state is equal to 1/ADCLK time.
Callback	NULL	A user callback function can be registered in open. If this callback function is provided, it is called from the interrupt service routine (ISR) each time the ADC scan completes. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.

ISDE Property	Value	Description
Scan End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Scan End Interrupt Priority selection
Scan End Group B Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Scan End Group B Interrupt Priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

ADC HAL Module Clock Configuration

The ADC HAL module uses the PCLKC as its clock source (ADCLK.) The only restriction when configuring this clock is that it should be set to less than the max ADC clock; there is also a restriction on the ratio of the PCLKC and PCLKB clocks specified in the hardware manual.

The ADC-conversion time depends on the PCLKC setting.

To set the PCLKB and PCLKC frequencies, use the clock configurator in the ISDE.

To change the clock frequency at run-time, use the CGC Interface.

ADC HAL Module Pin Configuration

To use the ADC HAL module, the port pins for the channels receiving the analog input must be set as input pins in the pin configurator in the ISDE. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection Sequence for the ADC HAL Module

Resource	ISDE Tab	Pin selection Sequence
ADC	Pins	Select Peripherals > Analog Pins>ADC0/1>AN_XX

4.2.3.6 Using the ADC HAL Module in an Application

Once the module has been configured and the files generated, the ADC is ready to be used in an application.

The typical steps in using the ADC HAL module in an application are:

1) Initialize the ADC using the open API (If Calibration is enabled in the configuration, it will be performed as a part of the open call for the MCUs that support calibration).
2) Configure the channels using the scanCfg API. For MCUs that support calibration, if the calibration was not enabled in the configuration, then it must be performed before starting the first scan. Start the calibration (for supported MCUs) using the calibrate API.a. If interrupts are disabled wait for at least 24ms (for 32MHz PCLKB), check status using the infoGet API to insure the calibration is complete before using other ADC APIs.b. If interrupts are enabled, the callback will be invoked when the calibration is complete
3) Start a conversion using the desired trigger with the scanStart API. a If a hardware trigger is used, this call enables the ADC unit to b triggered by the hardware trigger. If a software trigger is used, then this call starts the ADC scan.
4) If interrupts are disabled, use the scanStatusGet API to determine if the scan is complete.
5) If interrupts are enabled, the callback will be invoked when the scan is complete
6) Read the results of the conversion using the read API
7) Stop the ADC scan by calling the scanStop APIa. This prevents the ADC from being triggered by an external trigger or a hardware trigger; it also forces a stop of a software-triggered scan if one is ongoing.
8) Operate on the received data as needed by the application.
9) Use the close API to power down the peripheral.

These common steps are illustrated in a typical operational flow in the following figure:

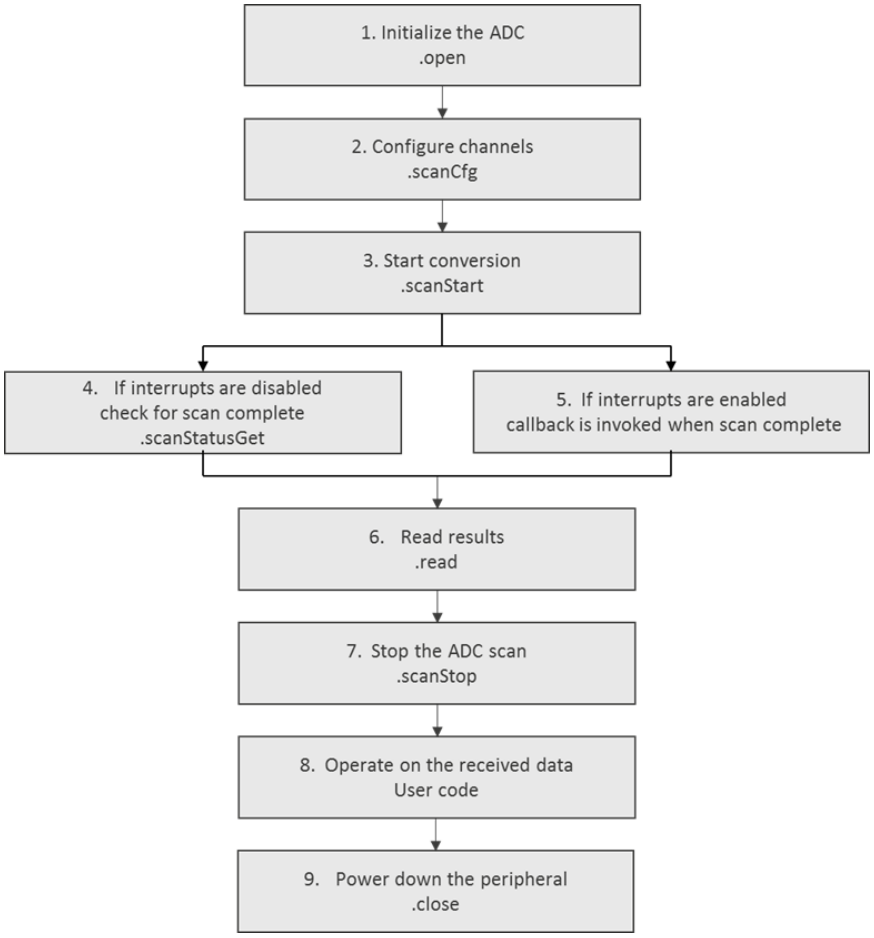

Figure 268: Flow Diagram of a Typical ADC HAL Module Application

4.2.4 AGT Driver

The AGT HAL module implements a high-level API for timing applications and is implemented on r_agt. The AGT HAL module uses the AGT peripheral on the Synergy MCU. A user-defined callback can be created to respond to a timer event.

The AGT HAL module configures a timer to a user-specified period. When the period elapses, any of the following events can occur:

- Interrupt the CPU, which calls a user-callback function (if provided)
- Toggle a port pin
- Transfer data using DMAC/DTC (if configured with transfer Interface)
- Start another peripheral (if configured with events and peripheral definitions)

4.2.4.1 AGT HAL Module Features

- Multiple Channels: 16-bit x 2 channels
  - Channel 1 can be clocked by the channel 0 underflow, creating a cascaded 32-bit timer
- Core Clock: Can be clocked using PCLKB, LOCO, or Fsub. When clocked by LOCO or Fsub, it can be used to wake up the MCU from sleep modes

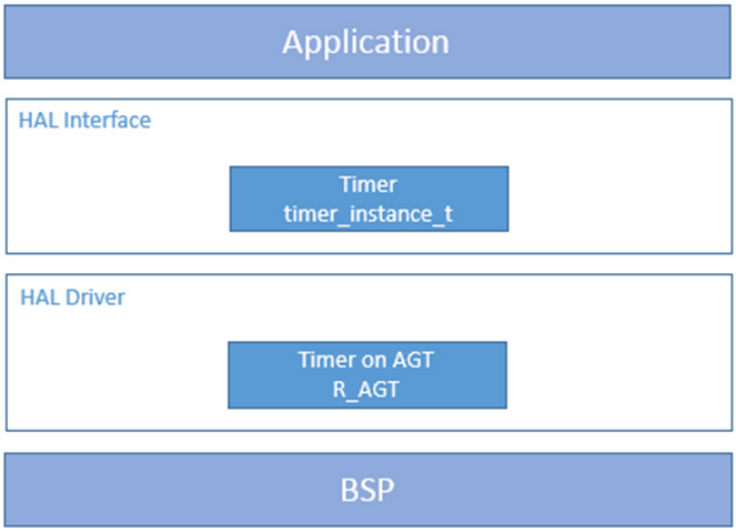

Figure 269: AGT HAL Module Block Diagram

4.2.4.2 AGT HAL Module APIs Overview

The AGT HAL module defines APIs for opening, closing, starting, and stopping timers. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows.

AGT HAL Module API Summary

Function Name	Example API Call and Description
open	g_timer0.p_api->open(g_timer0.p_ctrl, g_timer0.p_cfg) Initial configuration.
stop	g_timer0.p_api->stop(g_timer0.p_ctrl) Stop the counter.

Function Name	Example API Call and Description
start	g_timer0.p_api->start(g_timer0.p_ctrl) Start the counter.
reset	g_timer0.p_api->reset(g_timer0.p_ctrl) Reset the counter initial value.
counterGet	g_timer0.p_api->counterGet(g_timer0.p_ctrl, &value) Get current counter value and store it in the provided pointer, value.
periodSet	g_timer0.p_api->periodSet(g_timer0.p_ctrl, period, unit) Set the time until the timer expires.
dutyCycleSet	g_timer0.p_api->dutyCycleSet(g_timer0.p_ctrl, period, unit, pin) Sets the time until the duty cycle expires on the defined pin.
infoGet	g_timer0.p_api->infoGet(g_timer0.p_ctrl, &info) Get the time until the timer expires in clock counts and store it in provided pointer, info.
close	g_timer0.p_api->close(g_timer0.p_ctrl) Allows driver to be reconfigured and may reduce power consumption.
versionGet	g_timer0.p_api->versionGet(&version) Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Operation is successful
SSP_ERR_ASSERTION	Parameter is NULL or configuration setting is not allowed
SSP_ERR_IN_USE	The channel specified is already open
SSP_ERR_IRQ_BSP_DISABLED	A required interrupt is not enabled in the BSP
SSP_ERROR_NOT_OPEN	The channel is not open
SSP_ERR_INVALID_ARG	Invalid argument provided
SSP_ERR_INVALID_HW_CONDITION	Invalid hardware setting detected
SSP_ERR_INVALID_PTR	A pointer parameter was NULL, but needed a non-NULL value

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.4.3 AGT HAL Module Operational Overview

The AGT HAL module configures a timer to a user-specified period. When the period elapses, the CPU can be interrupted, a port pin can be toggled, a transfer of data using the DMAC or DTC can be initiated, or another peripheral can be triggered to begin operation.

The following figure shows a flowchart for toggling a port pin or generating a CPU interrupt after a specified period. This flowchart is appropriate for both AGT and GPT counters. (Replace the GPT references with AGT references for AGT operation and AGT is a down counter.)

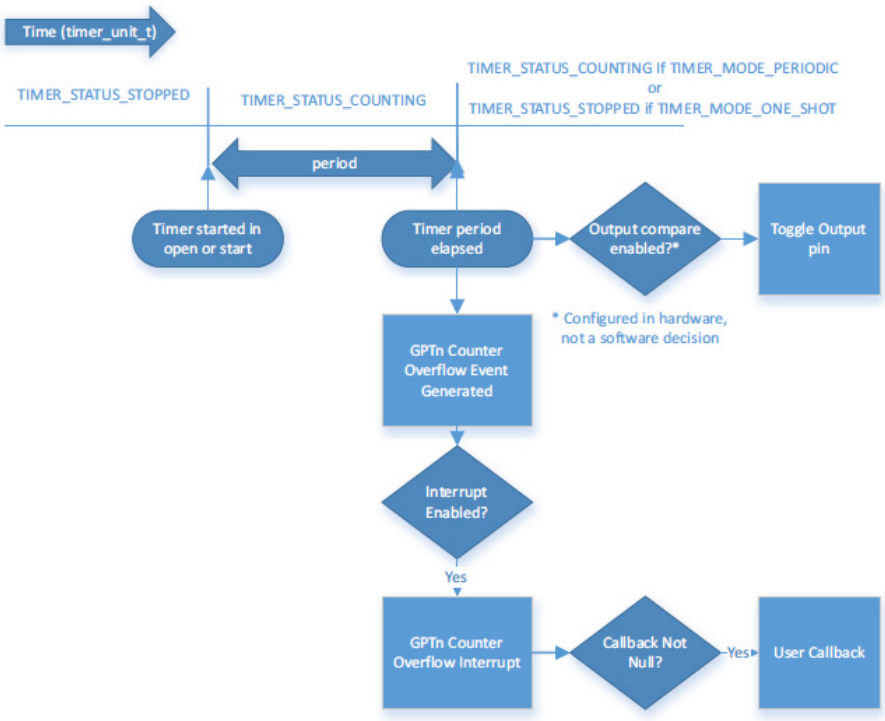

Figure 270: GPT Timer-Periodic or One-Shot Mode

Two different timer modules, the GPT and the AGT, are supported in the SSP. The following sections provide information on both modules so that the developer can compare and contrast the capabilities of each module for a particular application. For additional information on the GPT, refer to the GPT User's Guide.

The GPT module is recommended for most generic timer applications, but either module can be used for a basic timer functionality. The use cases in which one timer module would be preferred over the other are described as follows:

Selecting the GPT Timer Module

The GPT module uses a high-resolution 32-bit counter that can only be clocked by PCLKA. There are more GPT channels than AGT channels on Synergy devices, so using the GPT is less likely to cause a resource conflict.

Selecting the AGT Timer Module

The AGT module uses a 16-bit counter that can be clocked by PCLKB, LOCO, or Fsub. If clocked by LOCO or Fsub, the AGT interrupt can be used to wake the MCU from sleep modes. There are two channels, and channel 1 can be clocked by channel 0 underflow, effectively creating a 32-bit cascaded timer.

AGT HAL Module Important Operational Notes and Limitations

The maximum time period depends on the timer type and the input clock frequency.

- On a GPT with 32-bit resolution with PCLKA running at 120 MHz, the maximum period is approximately 36650 seconds, which is just over 10 hours.
- On a GPT with 16-bit resolution with PCLKA running at 32 MHz, the maximum period is approximately 2.09 seconds.
- On an AGT with 16-bit resolution with PCLKB running at 60 MHz, the maximum period is approximately 8.7 ms.

- On an AGT with 16-bit resolution with Fsub running at 32 kHz, the maximum period is approximately 2.0 seconds.

The AGT counter underflow interrupt for the selected channel used must be enabled in the BSP in the following situations:

1) To get a software interrupt when the timer period has elapsed.

2) To use one-shot mode.

When the AGTn AGTI interrupt is enabled in the BSP, the corresponding ISR is defined in the timer driver. The ISR calls a user-callback function if one was registered in open.

NOTE: Interrupts may be skipped when used with the DTC peripheral with the IRQ set to TRANSFER_IRQ_END.

AGT Output Timer Signal

If the timer output is configured, (AGTO Output Enabled set to true) the output pin starts at a high level if the output inverted is configured to True and a low level if it is configured to False. The output pin toggles every time the period elapses, beginning with the first time the period elapses after the timer is started.

In one-shot mode, the output is also configured to toggle when the timer starts counting. This generates a pulse - the timer toggles from the stop level when counting begins and toggles back to the stop level when counting ends.

Timer Period Calculation

The timer period is defined as the time until the timer expires. When output compare is used, the output pin toggles once per period, so the traditional period (from rising edge to rising edge) is twice the period specified in the software.

Runtime period calculation based on the current clock settings is available from open and periodSet.

If the specified timer period is different than the raw counts, the period is calculated using the current timer clock frequency (see Configuring the GPT Clocks or Configuring the AGT Clocks). The current timer clock frequency is determined using systemClockFreqGet. This frequency is used in the appropriate formula from the following table as clk_freq_hz.

Timer period calculation

Timer Units	Description
TIMER_UNIT_PERIOD_NSEC	Counts = (period * clk_freq_hz)/ 1000000000
TIMER_UNIT_PERIOD_USEC	Counts = (period * clk_freq_hz)/ 1000000
TIMER_UNIT_PERIOD_MSEC	Counts = (period * clk_freq_hz)/ 1000
TIMER_UNIT_PERIOD_SEC	Counts = (period * clk_freq_hz)
TIMER_UNIT_FREQUENCY_HZ	Counts = (clk_freq_hz)/ period
TIMER_UNIT_FREQUENCY_KHZ	Counts = (clk_freq_hz)/ (1000 * period)

If the requested period is larger than the counter size (32-bit or 16-bit), the driver selects the smallest divisor that allows the result to fit in the counter size. If the counter value is larger than the counter size with the largest divisor (1024), an error code (SSP_ERR_INVALID_ARGUMENT) is returned.

Triggering DMAC/DTC with GPT

To trigger a transfer of data using the DMAC or DTC peripheral when the timer period elapses, configure the DMAC/DTC transfer with activation_source set to ELC_EVENT_GPTn_COUNTER_OVERFLOW (where n is the GPT channel number). See the DMAC or DTC guides for further information.

NOTE: If you use the timer in one-shot mode with the DTC, the entire transfer completes before the interrupt stops the timer if the IRQ is set to TRANSFER_IRQ_END. To generate only one transfer after the timer period elapses, set the IRQ to TRANSFER_IRQ_EACH or use the DMAC for the transfer.

Triggering ELC Events with GPT

The GPT timer can trigger the start of other peripherals. The ELC guide provides a list of all available peripherals.

Triggering DMAC/DTC with AGT

To trigger a transfer of data using the DMAC or DTC peripheral when the timer period elapses, configure the DMAC/DTC transfer with activation_source set to ELC_EVENT_AGTn_AGTI (where n is the AGT channel number). See the Transfer Interface for further information.

NOTE: If you use the timer in one-shot mode with the DTC, the entire transfer completes before the interrupt stops the timer if irq is set to TRANSFER_IRQ_END. To generate only one transfer after the timer period elapses, set irq to TRANSFER_IRQ_EACH, or use the DMAC for the transfer.

Triggering ELC Events with AGT

The AGT timer can trigger the start of other peripherals. The ELC guide provides a list of all available peripherals listed in elc_peripheral_t. (See events and peripheral definitions for further information.)

Cascaded AGT Timers creating a 32-bit timer

AGT Channel 1 can be clocked by the AGT Channel 0 underflow, creating a cascaded 32-bit timer.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.4.4 Including the AGT HAL Module in an Application

This section describes how to include the AGT HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the AGT Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the AGT Driver is g_timer0. This name can be changed in the associated Properties window.)

AGT Driver Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
r_agt0 AGT Driver on r_agt	**Threads**	**New Stack> Driver> Timers> AGT Driver on r_agt**

When the AGT HAL module on r_agt is added to the thread stack as shown in the figure below, the configurator automatically adds any needed lower-level drivers. Any drivers that need additional configuration information will be box text highlighted in Red.

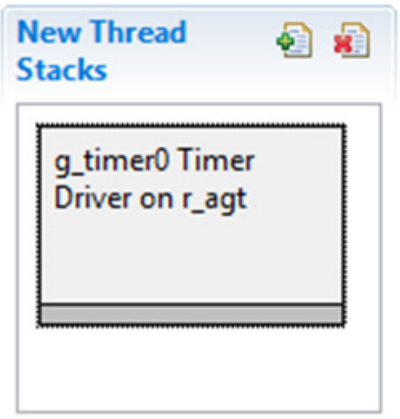

Figure 271: AGT HAL Module Stack

4.2.4.5 Configuring the AGT HAL Module

The AGT HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP Configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the AGT HAL Module on r_agt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables parameter checking.
Name	g_timer0	Module name.

ISDE Property	Value	Description
Channel	0	Physical hardware channel.
Mode	Periodic, One Shot Default: Periodic	Warning: One Shot functionality is not available in the GPT hardware, so it is implemented in software by stopping the timer in the ISR called when the period expires. For this reason, ISR's must be enabled for one-shot mode even if the callback is unused.
Period Value	10	See Timer Period Calculation
Period Unit	Raw Counts, Nanoseconds, Microseconds, Milliseconds, Seconds, Hertz, Kilohertz Default: Microseconds	See Timer Period Calculation
Auto Start	True, False Default: True	Set to true to start the timer after configuring or false to leave the timer stopped until start is called.
Count Source	PCLKB, PCLKB/8, PCLKB/2, LOCO, AGT0 Underflow, AGT0 fSub Default: PCLKB	The clock source for the AGT counter.
AGTO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTO pin). Set to false for no output of the timer signal.
AGTIO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTIO pin). Set to false for no output of the timer signal.
Output Inverted	True, False Default: False	Set to false to start the output signal low. Set to true to start the output signal high.

ISDE Property	Value	Description
Callback	NULL	A user callback function can be registered in open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Timer interrupt priority. 0 is the highest priority.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults can be desirable. For example, it might be useful to select different period or duty cycle values. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

AGT HAL Module Clock Configuration

The AGT timer is clocked based on the PCLKB, LOCO, Fsub, or AGT Underflow frequency. The AGT clock is selectable in the Properties window in e^2 studio. You can set the clock frequencies using the clock configurator in e^2 studio Configuring Clocks or the CGC Interface at run-time.

AGT HAL Module Pin Configuration

The AGT peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the associated pins.

NOTE: The operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection Sequence for AGT HAL Driver

Resource	ISDE Tab	Pin selection Sequence
AGT	Pins	Select **Peripherals > Timer: AGT>AGT0**

NOTE: The selection sequence assumes AGT0 is the desired hardware target for the driver.

Pin Configuration Settings for AGT HAL Driver

Pin Configuration Property	Value	Description
Operation Mode	Disabled, Custom, Timer Output, Compare Match, Count Measurement, Gated Count (Default: Disabled)	Select timer operation mode
AGTIO	None (Default: None)	AGTIO Pin
AGTO	None, P102 (Default: P102)	AGTO Pin
AGTOA	None (Default: None)	AGTOA Pin
AGTOB	None (Default: None)	AGTOB Pin
AGTEE	None, P101 (Default: P101)	AGTEE Pin

NOTE: The example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.4.6 Using the AGT HAL Module in an Application

The typical steps for using the AGT HAL module in an application are:

1) Initialize the AGT HAL module using the open API.
2) Start the AGT HAL module by calling the start API.
3) Read the counter value by calling the counterGet API.
4) Set the period value by using the periodSet API
5) Set the duty cycle (duty_cycle_counts) by using dutyCycleSet API
6) Get the timer information using infoGet API
7) Respond to the AGT HAL module callback as needed.
8) Resets the counter value using the reset API
9) Stop the AGT channel using stop API
10) Use the close call to power down the peripheral.

NOTE: The timer-period and duty-cycle parameters can be reconfigured based on the application's needs.

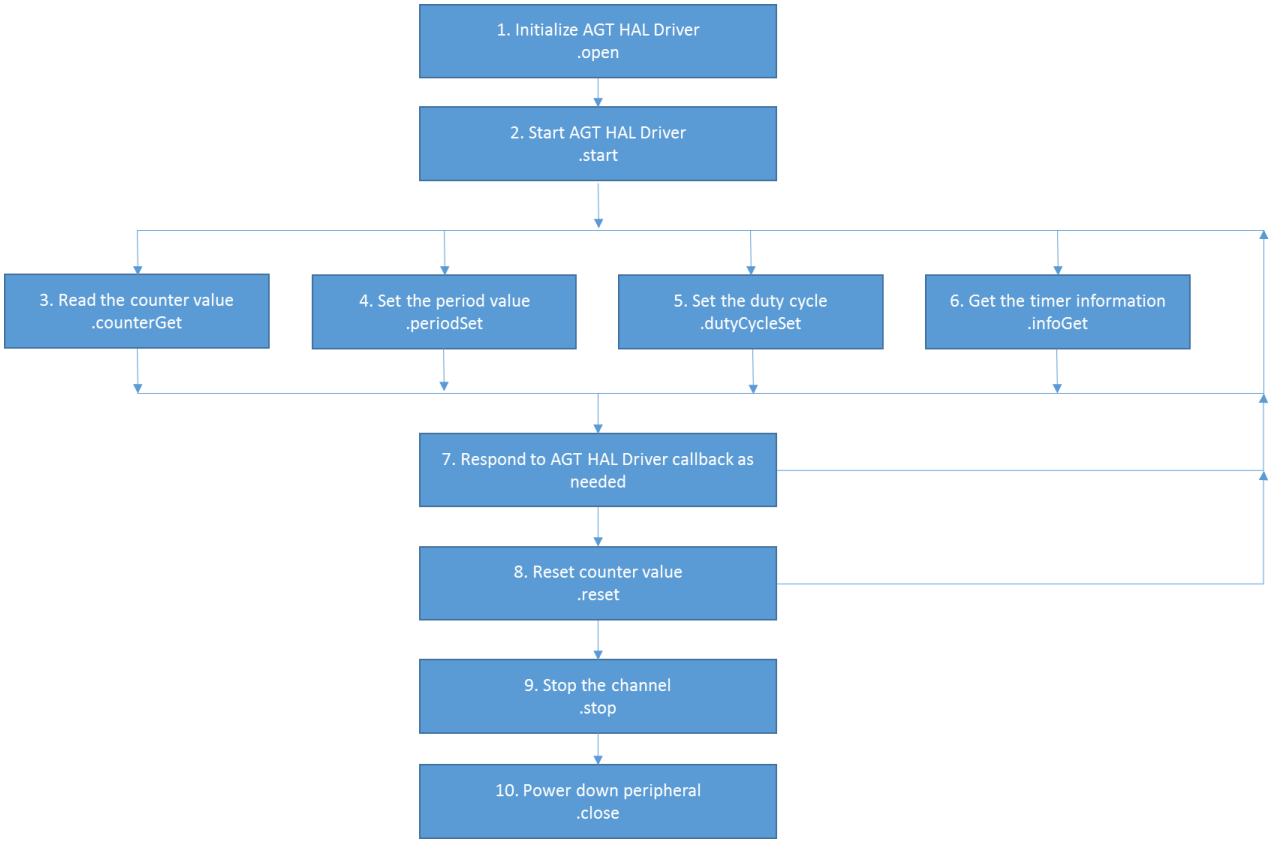

Figure 272: Typical AGT HAL Module Application Flow Chart

4.2.5 CAC Driver

The CAC HAL module is a high-level API for clock accuracy-control applications and is implemented on r_cac. The module uses the Clock Frequency Accuracy Measurement Circuit (CAC) peripheral on the Synergy MCU which is useful in implementing a fail-safe mechanism for reliability-oriented applications. A user-defined callback can be created to respond to various error indications.

4.2.5.1 CAC HAL Module Features

The CAC HAL module API interfaces with a clock frequency-measurement circuit capable of monitoring the clock frequency based on a reference-signal input. The reference signal may be an externally supplied clock source or one of several available internal clock sources. An interrupt request may optionally be generated by a completed measurement, a detected frequency error, or a counter overflow. A digital filter is available for an externally supplied reference clock, and dividers are available for both internally supplied measurement and reference clocks. Edge-detection options for the reference clock are configurable as rising, falling, or both.

The frequency of the following clocks can be measured:

- Clock output from main-clock oscillator (main clock)
- Clock output from sub-clock oscillator (sub clock)

- Clock output from high-speed on-chip oscillator (HOCO clock)
- Clock output from mid-speed on-chip oscillator (MOCO clock)
- Clock output from low-speed on-chip oscillator (LOCO clock)
- Clock output from IWDT-dedicated on-chip oscillator (IWDTCLK clock)
- Peripheral module clock (PCLKB)

The measurement clock is monitored using a reference clock. The reference clock may be an external clock (supplied on the CACREF input pin) or one of the following internal clocks:

- Clock output from main-clock oscillator (main clock)
- Clock output from sub-clock oscillator (sub clock)
- Clock output from high-speed on-chip oscillator (HOCO clock)
- Clock output from mid-speed on-chip oscillator (MOCO clock)
- Clock output from low-speed on-chip oscillator (LOCO clock)
- Clock output from IWDT-dedicated on-chip oscillator (IWDTCLK clock)
- Peripheral module clock (PCLKB)

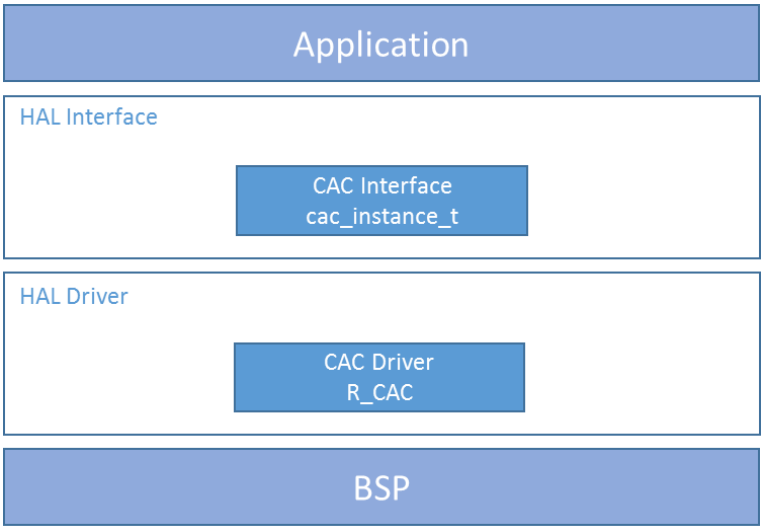

Figure 273: CAC HAL Module Block Diagram

4.2.5.2 CAC HAL Module APIs Overview

The CAC HAL module defines APIs for opening, closing, reading, starting, stopping, and resetting the CAC. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follow the API summary table.

CAC HAL Module API Summary

Function Name	Example API Call and Description
open	g_cac0.p_api->open(g_cac0.p_ctrl, g_cac0.p_cfg) Open function for CAC device.
read	g_cac0.p_api->read(g_cac0.p_ctrl, &cac0_status, &cac0_counter) Read function for CAC peripheral.
close	g_cac0.p_api->close(g_cac0.p_ctrl) Close function for CAC device.
stopMeasurement	g_cac0.p_api->stopMeasurement(g_cac0.p_ctrl) Ends a measurement for the CAC peripheral.
startMeasurement	g_cac0.p_api->startMeasurement(g_cac0.p_ctrl) Begin a measurement for the CAC peripheral.
reset	g_cac0.p_api->reset(g_cac0.p_ctrl) Reset function for CAC device.
versionGet	g_cac0.p_api->versionGet(&cac0_version) Get the CAC API and code version information.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful

Name	Description
SSP_ERR_INVALID_ARGUMENT	One or more configuration options are invalid
SSP_ERR_NOT_OPEN	Open has not been successfully called
SSP_ERR_ASSERTION	Null provided for p_ctrl, p_cfg and others
SSP_ERR_INVALID_POINTER	Interrupt specified with NULL callback
SSP_ERR_HW_LOCKED	Hardware lock for CAC peripheral is already taken
SSP_ERR_INVALID_CAC_REF_CLOCK	Measured clock rate smaller than reference clock rate

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.5.3 CAC HAL Module Operational Overview

The main function of the CAC HAL module is to measure the operation and accuracy of a selected clock. Once the measurement is requested, counting begins on the first valid edge detected for the reference clock and ends on the next valid edge. A valid edge can be configured to be rising, falling, or both. The count is incremented at each cycle of the measurement clock after it has passed through the divider circuit which is capable of dividing the clock by 1, 4, 8, or 32. An internally supplied reference clock also passes through a divider circuit which is capable of dividing the clock by 32, 128, 1024, or 8192. An externally supplied reference clock does not pass through a divider circuit, but may pass through a digital filter if it is configured to do so.

For example, if the sub-clock is specified as the measurement clock (32 kHz) and a divisor of 1 is specified, then the counter will increment at a 32 kHz rate. If a reference clock of 1 kHz is provided, then after one cycle of the reference clock you would expect the counter to be 32. This is where the CAC upper and lower-limit settings are examined. Part of the setup for a CAC measurement is the specification of an upper and lower limit for the measurement. When a measurement is complete, the CAC compares the counter contents to the limits configured for the measurement. If the counter is both ≤ upper limit and ≥ lower limit, then the measurement has completed without error and the measured frequency is operating within the defined limits. If the counter fails to meet these requirements, then a frequency error is indicated. A completed measurement may be identified by making API calls to poll the driver, or by establishing a callback function.

CAC HAL Module Important Operational Notes and Limitations

Continuous Mode

The CAC module may be operated in either a single or continuous measurement mode. In continuous mode, the measuring process is restarted after each completed measurement. In non-continuous, or single measurement mode, measuring stops after the first completed measurement. The continuous_mode configuration member controls this feature.

Interrupts and Callbacks

When a measurement is complete and a callback is provided by the user, (with one or more interrupts enabled) the CAC HAL module invokes the callback (p_callback) with the argument cac_callback_args_t, indicating the event cac_event_t. If interrupts are not enabled, the API supports checking the measurement status to poll if the measurement is complete (read), which will provide both the status of the measurement and the current value of the CAC counter register.

The CAC driver supports three interrupts:

- A Frequency error interrupt occurs when a measurement completes and the CAC counter register value is outside of the range that was specified as part of the CAC driver open. The configuration ferr_interrupt_enabled member provided in the open call must be enabled for this interrupt to be generated.
- An Overflow error interrupt occurs when the CAC counter register overflows its maximum (0xFFFF) value. The configuration ovf_interrupt_enabled member provided in the open call must be enabled for this interrupt to be generated.
- A measurement complete interrupt occurs when a measurement completes and the CAC counter register value is within the range that was specified as part of the CAC driver open. The configuration mei_interrupt_enabled member provided in the open call must be enabled for this interrupt to be generated.

Reset

The reset API can be used to reset the overflow, measurement end, and frequency Error interrupt flags after measurement has been stopped to eliminate any false triggers.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.5.4 Including the CAC HAL Module in an Application

This section describes how to include the CAC HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the CAC driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the CAC is g_cac0. This name can be changed in the associated Properties window.)

CAC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_cac0 CAC Driver on r_cac	Threads > HAL/Common	New Stack > Driver> Monitoring > Clock Accuracy Circuit Driver on r_cac

When the CAC HAL module on r_cac is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information will be box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

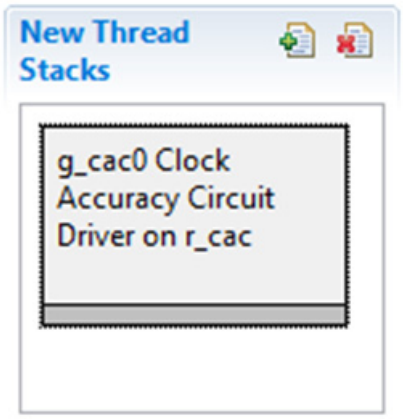

Figure 274: CAC HAL Module Stack

4.2.5.5 Configuring the CAC HAL Module

The CAC HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the configuration table settings given below. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the CAC HAL Module on r_cac

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Controls whether to include code for API parameter checking.
Name	g_cac0	Identifies this instance

ISDE Property	Value	Description
Continuous Measurement Operation	Enabled, Disabled Default: Enabled	If Enabled, measurement will continuously restart after completing
Measurement Complete Interrupt	Enabled, Disabled Default: Enabled	Enabling allows the CAC driver to generate an interrupt when a measurement is complete, providing the CAC MEASUREMENT END interrupt is enabled in the ICU.
Overflow Interrupt	Enabled, Disabled Default: Enabled	Enabling allows the CAC driver to generate an interrupt when a CAC overflow occurs, providing the CAC OVERFLOW interrupt is enabled in the ICU.
Frequency Error Interrupt	Enabled, Disabled Default: Enabled	Enabling allows the CAC driver to generate an interrupt when a frequency error occurs, providing the CAC FREQUENCY ERROR interrupt is enabled in the ICU.
Upper Limit Threshold	0 – 0xFFFF Default: 0	Top end of allowable range for measurement complete
Lower Limit Threshold	0 – 0xFFFF, must be < Upper Limit threshold Default: 0	Bottom end of allowable range for measurement complete
Reference Clock Source	Main Oscillator, Sub-clock, HOCO, MOCO, LOCO, PCLKB, IWDT Default: Main Oscillator	Reference clock source
Reference Clock Divider	32,128,1024,8192 Default: 32	Reference clock divider
Reference Clock Edge Detect	Rising, Falling, Both Default: Rising	Reference clock edge detection

ISDE Property	Value	Description
Reference Clock Digital Filter	Disabled, Sampling clock = Measuring freq, Sampling clock = Measuring freq/4, Sampling clock = Measuring freq/16 Default: Disabled	Reference clock Digital filter
Measurement Clock Source	Main Oscillator, Sub-clock, HOCO, MOCO, LOCO, PCLKB, IWDT Default: HOCO	Measurement clock source
Measurement Clock Divider	1,4,8,32 Default: 1	Measurement clock divider
Callback	Null	Function name for callback
Frequency Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid), Disabled Default: Disabled	CAC Frequency Error interrupt priority
Measurement End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid), Disabled Default: Disabled	CAC Measurement End interrupt priority

ISDE Property	Value	Description
Overflow Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid), Disabled Default: Disabled	CAC Overflow interrupt priority

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for the module can be desirable. For example, it might be useful to select different clock sources and dividers.

CAC HAL Module Clock Configuration

Clocks are selected from the Clock tab as needed by the application.

CAC HAL Module Pin Configuration

The pins for the CAC HAL module are selected as shown in the following table; the pin settings are shown in the subsequent table. If CACREF is used to the input pin of reference clock, you must configure this pin.

Pin Selection Sequence for the CAC HAL Module

Resource	ISDE Tab	Pin selection Sequence
CAC HAL Module	Pins	Peripherals > Monitoring: CAC > CAC0

NOTE: The selection sequence assumes CAC0 is the desired hardware target for the driver.

Pin Configuration Settings for the CAC HAL Module

Pin Configuration Property	Value	Description
Operation Mode	Disabled, External Reference (Default: Disabled)	Select Enable as the Operation Mode for CAC

Pin Configuration Property	Value	Description
CACREF:	None, P204 (Default: None)	CACREF Pin

NOTE: The example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.5.6 Using the CAC HAL Module in an Application

The typical steps in using the CAC HAL module in an application are:

1) Initialize the CAC HAL module using the open API
2) Start a measurement using the startMeasurement API
3) Poll using the CGC read function to look for the measurement result or get measurement status and result using callback function called in ISR
4) Stop the measurement using the CGC stopMeasurement API
5) Reset the overflow, measurement end, and frequency error interrupt flags using the CGC reset API
6) Close the CAC HAL module if no more measurements are needed using the CGC close API

These common steps for using the CAC HAL module are illustrated in a typical operational flow diagram in the figure below:

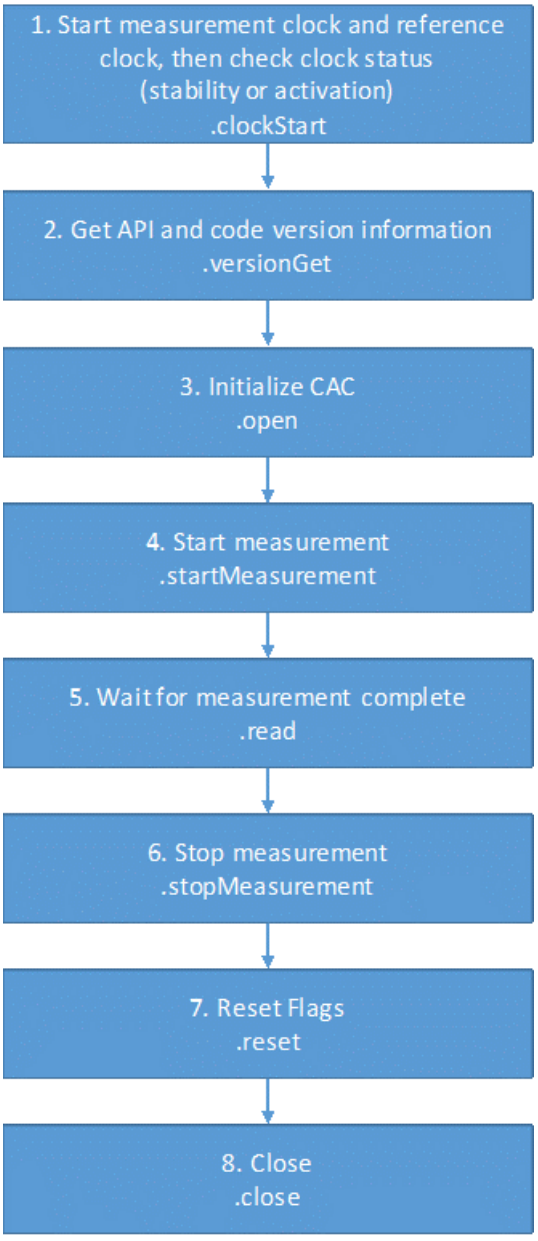

Figure 275: Flow Diagram of a Typical CAC HAL Module Application

4.2.6 CAN Driver

The CAN HAL module provides high-level APIs for a CAN network. The CAN HAL module is implemented on r_can and supports the CAN peripherals available on the Synergy microcontroller hardware. A user-callback function must be defined, which the driver will invoke when transmit, receive or error interrupts are received. The callback returns with a parameter which indicates the channel, mailbox and event.

4.2.6.1 CAN HAL Module Features

- Supports both standard (11-bit) and extended (29-bit) messaging format
- Support for bit-timing configuration as defined in the CAN specification
- Support for up to 32 transmit or receive mailboxes with standard or extended ID frames
- Receive mailboxes can be configured to capture either data or remote CAN frames
- Supports a user-callback function when transmit, receive or error interrupts are received

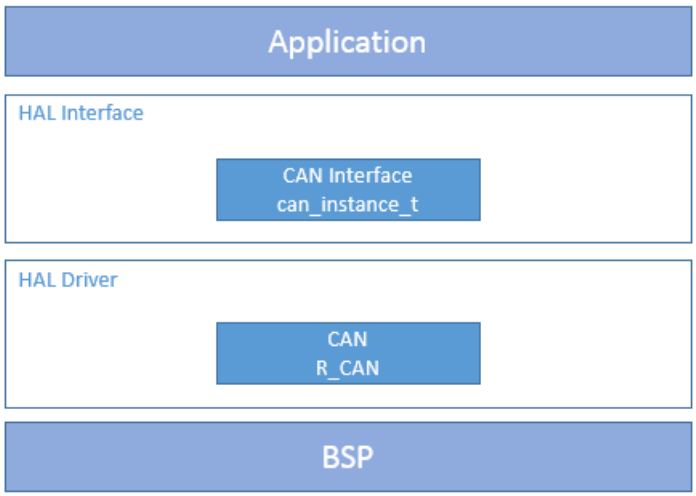

Figure 276: CAN HAL Module Organization, Options, and Stack Implementations

4.2.6.2 CAN HAL Module APIs Overview

The CAN HAL defines APIs for opening, closing, writing, (transmitting) and reading (receiving) CAN data; it also provides some additional functions, such as control, Infoget and VersionGet to assist in processing more complex commands. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

CAN HAL Module API Summary

Function Name	Example API Call and Description
open	g_can0.p_api->open(g_can0.p_ctrl, g_can0.p_cfg) The open API configures CAN Channel 0. This function must be called before any other CAN functions. Note: This call is made automatically during system initialization, prior to entering the users thread. Unless the user closes the module, open will not need to be called.
close	g_can0.p_api->close(g_can0.p_ctrl) The close API handles the clean-up of internal driver data.
read	g_can0.p_api->read (g_can0.p_ctrl, p_args->mailbox, &receiveFrame) The read API reads received CAN data.
write	g_can0.p_api->write (g_can0.p_ctrl, 0, &transmitFrame) The write API write data into the CAN transmit frame buffer and send it out.

control	g_can0.p_api->control(g_can0.p_ctrl, CAN_COMMAND_MODE_SWITCH, &mode);
	
	with can_mode_t mode = CAN_MODE_LOOPBACK_INTERNAL;
	
	The control API will be able to change the CAN mode of operation.

infoGet	g_can0.p_api->infoGet(g_can0.p_ctrl, p_info) The infoGet API retrieves the CAN mode of operation.

Function Name	Example API Call and Description
versionGet	g_can0.p_api->versionGet(version) The versionGet API retrieves the module version information.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_HW_LOCKED	Lock already owned by another user.
SSP_ERR_CAN_MODE_SWITCH_FAILED	Channel failed to switch modes.
SSP_ERR_CAN_INIT_FAILED	Channel failed to initialize.
SSP_ERR_ASSERTION	Null pointer presented.
SSP_ERR_NOT_OPEN	Port is not open.
SSP_ERR_CAN_DATA_UNAVAILABLE	No data available.
SSP_ERR_CAN_TRANSMIT_MAILBOX	Mailbox is not setup for receive.
SSP_ERR_CAN_TRANSMIT_NOT_READY	Transmit in progress, cannot write data at this time.
SSP_ERR_CAN_RECEIVE_MAILBOX	Mailbox is setup for receive and cannot send.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.6.3 CAN HAL Module Operational Overview

The CAN HAL module controls the CAN peripherals on Synergy microcontrollers according to the user configuration. The API provides open, close, read, write, control and information functions. The driver allows for bit-timing configuration as defined in the CAN specification; it can be configured for up to 32 transmit or receive mailboxes with

standard or extended ID frames. Receive mailboxes can be configured to capture either data or remote CAN frames. The user callback is invoked with the channel, mailbox and event information when a transmit, receive or error interrupt occurs.

Using the CAN IDs and Masks

Each CAN Mailbox configured to receive messages has an ID and Mask set. Incoming messages will be placed in the lowest mailbox where the following is true:

Incoming ID & Mailbox Mask == Mailbox ID & Mailbox Mask

Example 1: A mailbox with an ID of 0x25 and a mask of 0x1FFFFFFF can receive messages with IDs of 0x25.

Example 2: A mailbox with an ID of 0x25 and a mask of 0x1FFFFFF0 can receive messages with IDs of 0x20 through 0x2F.

Using the CAN HAL Module Test Modes

The CAN Module has three test modes: listen only, external loopback and internal loopback.

- In listen-only mode, valid data frames and remote frames can be received; however, only recessive bits can be sent on the CAN bus. The ACK bit, overload flag, and active error flag cannot be sent. Listen-only mode can be used for baud rate detection
- In external-loopback mode, the protocol module treats its own transmitted messages as those received by the CAN transceiver and stores them into the receive mailbox. To be independent from external stimulation, the protocol module generates the ACK bit. Connect the CTX and CRX pins to the transceiver.
- Internal-loopback mode is similar to external-loopback mode, excepting that the protocol controller performs internal loopback from the internal CTX pin to the internal CRX pin. The input value of the external CRX pin is ignored. The external CTX pin outputs only recessive bits. The CTX and CRX pins are not required to be connected to the CAN bus or any external device.

Changing the CAN HAL Module Operating Modes

The CAN Module can be switched between modes using the control API. Pass CAN_COMMAND_MODE_SWITCH and a pointer to a can_mode_t variable set to the desired mode into the control API.

Mode	can_mode_t value	Reason for use
Normal	CAN_MODE_NORMAL	Normal operation mode
Internal Loopback	CAN_MODE_LOOPBACK_INTERNAL	Internal loopback testing
External Loopback	CAN_MODE_LOOPBACK_EXTERNAL	External loopback testing
Listen Only	CAN_MODE_LISTEN	Baud rate detection
Halt	CAN_MODE_HALT	Mailbox configuration and test mode setting
Sleep	CAN_MODE_SLEEP	Stops the clock supply to the CAN module reducing current consumption

Mode	can_mode_t value	Reason for use
Exit Sleep	CAN_MODE_EXIT_SLEEP	Internal use only
Reset	CAN_MODE_RESET	Communication configuration

NOTE: To see an example use of the control API for setting the loopback mode, refer to the CAN HAL Module API Summary table presented earlier in this document.

CAN HAL Module Important Operational Notes and Limitations

- The user application must start the main-clock oscillator (CANMCLK or XTAL) at run-time using the CGC Interface if it has not already started (for example, if it is not used as the MCU clock source.)
- For S7, S5, S3 and S1 MCUs, the following clock restriction must be satisfied for the CAN HAL module when the clock source is the main-clock oscillator (CANMCLK): fPCLKB >= fCANCLK (XTAL / Baud Rate Prescaler)
- For S7, S5 and S3 MCUs, the source of the peripheral module clocks must be PLL for the CAN HAL module when the clock source is PCLKB.
- For S3 MCUs, the clock frequency ratio of PCLKA and PCLKB must be 2:1 when using the CAN HAL module. Operation is not guaranteed for other settings.
- For S1 MCUs, the clock frequency ratio of ICLK and PCLKB must be 2:1 when using the CAN HAL module. Operation is not guaranteed for other settings.
- SJW (Synchronization Jump Width) is often given by the bus administrator. Select 1 <= SJW <= 4.
  - Time segment and SJW settings must adhere to the following constraints: TS1 > TS2 >= SJW.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.6.4 Including the CAN HAL Module in an Application

This section describes how to include the CAN HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the CAN HAL module to an application, simply add it to a HAL/ Common Stack or any thread using the stacks selection sequence given in the following table. (The default name for the CAN HAL module is g_can0. This name can be changed in the associated Properties window.)

CAN HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_can0 CAN Driver on r_can	Threads	New Stack> Driver> Connectivity> CAN Driver on r_can

When the CAN HAL module on r_can is added to the thread stack as shown in the following figure, the configurator automatically adds the needed lower-level drivers. Any drivers that need additional configuration information will be highlighted in red.

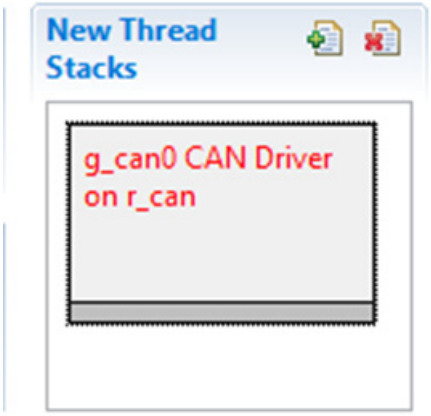

Figure 277: CAN HAL Module Stack

4.2.6.5 Configuring the CAN HAL Module

The CAN HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less-error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP Configurator, and are shown in the following tables for easy reference.

NOTE: You may want to open your ISDE, create the CAN HAL module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the CAN HAL Module on r_can

ISDE Property	Value	Description
Parameter Checking	Enabled, Disabled, BSP (Default: BSP)	Selects if code for parameter checking is to be included in the build.
Error Interrupt Priority	Disabled, Priority 0-15 (Default: Disabled)	Specify the error interrupt priority 0-15 (required).

ISDE Property	Value	Description
Receive Mailbox Interrupt Priority	Disabled, Priority 0-15 (Default: Disabled)	Specify the error interrupt priority 0-15 (required).
Transmit Mailbox Interrupt Priority	Disabled, Priority 0-15 (Default: Disabled)	Specify the error interrupt priority 0-15 (required).
Name	Default: g_can0	CAN driver module name.
Channel	0, 1	Specify if the CAN channel to use. 0 or 1(S7G2 only).
Baud Rate Prescaler	Default 5	Specify the baud rate prescaler(0-1023).
Time Segment 1	15 Time Quanta	Specify the time segment 1 value. (4-16).
Time Segment 2	8 Time Quanta	Specify the time segment 2 value (2-8).
Synchronization Jump Width	2 Time Quanta	Specify the Synchronization Jump Width value (1-4).
Clock Source	PCLKB (S7G2, S5D9, S5D5, S3A7, and S3A7 only), CANMCLK Default: CANMCLK	CAN clock source, CANMCLK or PCLKB (S7G2, S5D9, S5D5, S3A7, and S3A7 only).
Callback	NULL	A user callback function can be registered in can_api_t::open. If this callback function is provided, it is called from the interrupt service routine (ISR) each time any interrupt occurs.
Overwrite/Overrun mode	Overwrite Mode, Overrun mode Default: Overwrite mode	Select whether receive mailbox will be overwritten or overrun if data is not read in time.

ISDE Property	Value	Description
Standard or Extended ID Mode	Standard ID Mode, Extended ID Mode Default: Standard ID Mode	Select whether the driver will be using CAN standard or extended IDs.
Number of Mailboxes	32 Mailboxes	Select 4, 8, 16 or 32 mailboxes.
Mailbox [0] ID … Mailbox [31] ID	Default n	Select the receive ID for mailbox 0, between 0 and 0x7ff when using standard IDs, between 0 and 0x1FFFFFFF when using extended IDs. Value is not used when the mailbox is set as transmit type.
Mailbox [0] Type … Mailbox [31] Type	N = 0: Transmit Mailbox; N = 1 …31: Receive Mailbox	Select whether the mailbox is used for receive or transmit.
Mailbox [0] Frame Type … Mailbox [31] Frame Type	N = 0: Remote Mailbox; N = 1 …31: Data Mailbox	Select whether the mailbox is used to capture data frames or remote frames (receive only).
Mailbox 0-3 Group Mask	Default: 0x1FFF FFFF	Select the Mask for mailboxes 0-3.
Mailbox 4 - 7 Group Mask	Default: 0x1FFF FFFF	Select the Mask for mailboxes 4-7.
Mailbox 8 - 11 Group Mask	Default: 0x1FFF FFFF	Select the Mask for mailboxes 8 -11.
Mailbox 12 - 15 Group Mask	Default: 0x1FFF FFFF	Select the Mask for mailboxes 12 -15.
Mailbox 16 - 19 Group Mask	Default: 0x1FFF FFFF	Select the Mask for mailboxes 16 -19.
Mailbox 20 - 23 Group Mask	Default: 0x1FFF FFFF	Select the Mask for mailboxes 20 -23.
Mailbox 24 - 27 Group Mask	Default: 0x1FFF FFFF	Select the Mask for mailboxes 24 -27.
Mailbox 28 - 31 Group Mask	Default: 0x1FFF FFFF	Select the Mask for mailboxes 28 -31.

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings. Most of the property settings for lower-level modules are fairly intuitive and usually can be determined by inspection of the associated Properties window from the SSP configurator.

CAN HAL Module Clock Configuration

The CAN peripheral uses the CANMCLK (main-clock oscillator) or PCLKB (S7G2, S5D9, S5D5, S3A7, and S3A7 only) as its clock source (fCAN, CAN System Clock.) Using the PCLKB with the default of 60 MHz and the Synergy default, (S7G2 DK) CAN configuration will provide a CAN bit rate of 500 Kbit.

To set the PCLKB frequency, use the clock configurator in e^2 studio (Clocks tab in the configurator.)

To change the clock frequency at run-time, use the CGC Interface. Refer to the CGC module guide for more information on configuring clocks.

CAN HAL Module Pin Configuration

The CAN peripheral module uses the pins on the MCU to communicate to external devices connected on the CAN bus. Under Peripherals, select CAN and then CAN0 for channel 0 or CAN1 (S7G2 and S3A7 only) for channel 1. The operation mode for the channel must be enabled and the CRXn and CTXn pins must be selected to match your PC board layout. The pin configurator sets appropriate CAN pin configuration in the pin_cfg field for the associated pin. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the CAN pins.

NOTE: The operation mode selection determines what peripheral signals are available and thus what MCU pins are required.

Pin Selection Sequence for CAN Driver on r_can

Resource	ISDE Tab	Pin selection Sequence
CAN	Pins	Select **Peripherals > Connectivity CAN>CAN0**

NOTE: The selection sequence assumes CAN0 is the desired hardware target for the driver.

Pin Configuration Settings for CAN0

Pin Configuration Property	Value	Description
Operation Mode	Disabled, Enabled	Enable the mode to use CAN0
CRX	None, P202, P402 (Default: P402)	CAN0_CRX0
CTX	None, P203 P401 (Default: P401)	CAN0_CTX0

NOTE: The example values are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

CAN Bit Rate Calculation

A time quanta (Tq) is one bit-time of the CAN communication clock, fCANCLK. This is not the CAN bit-time but the internal clock period of the CAN peripheral. The frequency is determined by the baud-rate prescaler value and the CAN source clock, fCAN (CANMCLK or PCLKB). One bit-time is divided into a number of time quanta, Tqtot. One time

quantum is equal to the period of the fCANCLK. Each bitrate register is then given a certain number of Tq of the total of Tq that make up one CAN-bit period. The default ISDE bitrate setting (S7G2 DK template) is 500 Kbps for a fCAN at 60 MHz (using PCLKB.)

The formulas to calculate the bitrate register settings are as follows:

fCAN = (fPCLKB or fCANMCLK)

The baud-rate prescaler scales the CAN peripheral clock down.

fCANCLK = fCAN/ Baud Rate Prescaler = 60 MHz (default)/ 5(default) = 12 MHz

One time quantum is one clock period of the CAN clock.

Tqtot =1/fCANCLK

Tqtot is the total number of CAN peripheral clock cycles during one CAN bit time and is by the peripheral built by the sum of the "time segments" and "SS" which is always 1.

Tqtot = TSEG1 + TSEG2 + SS (TSEG1 must be > TSEG2) = 15 + 8 + 1 = 24 (default)

The bitrate is then:

Bitrate = fCANCLK/Tqtot = 12 MHz / 24 = 500Kbps

Important notes:

- The user application must start the main-clock oscillator (CANMCLK or XTAL) at run-time using the CGC Interface if it is not already started (for example, if it is not used as the MCU clock source.)
- For S7G2, S3A7 and S124 MCUs, the following clock restriction must be satisfied for the CAN module when the clock source is the main-clock oscillator (CANMCLK): fPCLKB >= fCANCLK (fCAN / baud-rate prescaler)
- For S7G2 and S3A7 MCUs, the source of the peripheral module clocks must be PLL for the CAN HAL module when the clock source is PCLKB.
- For S3A7 MCUs, the clock frequency ratio, PCLKA and PCLKB must be 2:1 when using the CAN HAL module. Operation is not guaranteed for other settings.
- For S124 MCUs, the clock frequency ratio of ICLK and PCLKB must be 2:1 when using the CAN HAL module. Operation is not guaranteed for other settings.
- SJW (Synchronization Jump Width) is often given by the bus administrator. Select 1 <= SJW <= 4.

Configurator sample values for different CAN bit-rate

fCAN (either PCLKB or CAN MCLK)	Baud Rate Prescalar	fCANCLK = fCAN/Baud e Rate Prescalar	Time Segment 1 (TSEG1)	Time Segment 2 (TSEG2)	Synchroni zation Jump Width (SS)	Tqtot = TSEG1 + TSEG2 +SS	Bitrate = fCANCLK/ Tqtot
240	10	24	15	8	1	24	1 Mbps
60	5	12	15	8	1	24	500 kbps
240	48	5	16	2	2	20	250 kbps
240	96	2.5	16	2	2	20	125 kbps

Setting the Mailbox Group Masks

There are 8 mailbox group-masks, one for each group of 4 mailboxes. These masks allow the mailboxes to be configured to receive more than one ID. If the mask is all ones (0x7ff for standard IDs or 0x1FFFFFFF for extended ID) the mailboxes within the group do not mask any bits of the ID, requiring all bits of the mailbox ID to match the mailbox ID before a message is captured. If any bits of the mask are set to zero, those bits will not be necessary to match the same bits of the mailbox ID. For example, if Mailbox ID 1 is set to 0x7ff and Mailbox 0-3 Group Mask is set to 0x7ff, mailbox 1 will only capture messages with the ID of 0x7ff. If the mailbox 0-3 group mask is set to 0x7fe, mailbox 1 will still capture messages with IDs of 0x7f but will also capture messages with IDs of 0x7fe.

4.2.6.6 Using the CAN HAL Module in an Application

A CAN application requires a minimum of two nodes to demonstrate CAN communication. One node can be a transmitter, while the other can be a receiver (or both can behave as transmitter and receiver.)

The typical steps in using the CAN module in an application are:

1) Initialize the CAN HAL module using the open API.
2) (Optional) Enter internal loopback or external loopback test modes using control API.
3) (Optional) Information about the module status, including bit rate, can be retrieved using the infoGet API.
4) To transmit a message:a. Create and configure the CAN frame ensuring correct ID and frame type.b. Write the CAN frame to a mailbox configured in transmit mode using the write API.
5) To receive a message:a. Read from a mailbox that has received a frame using the read API.
6) Close the CAN HAL module using the close API (if needed.)

These common steps are illustrated in a typical operational flow diagram in the following figure:

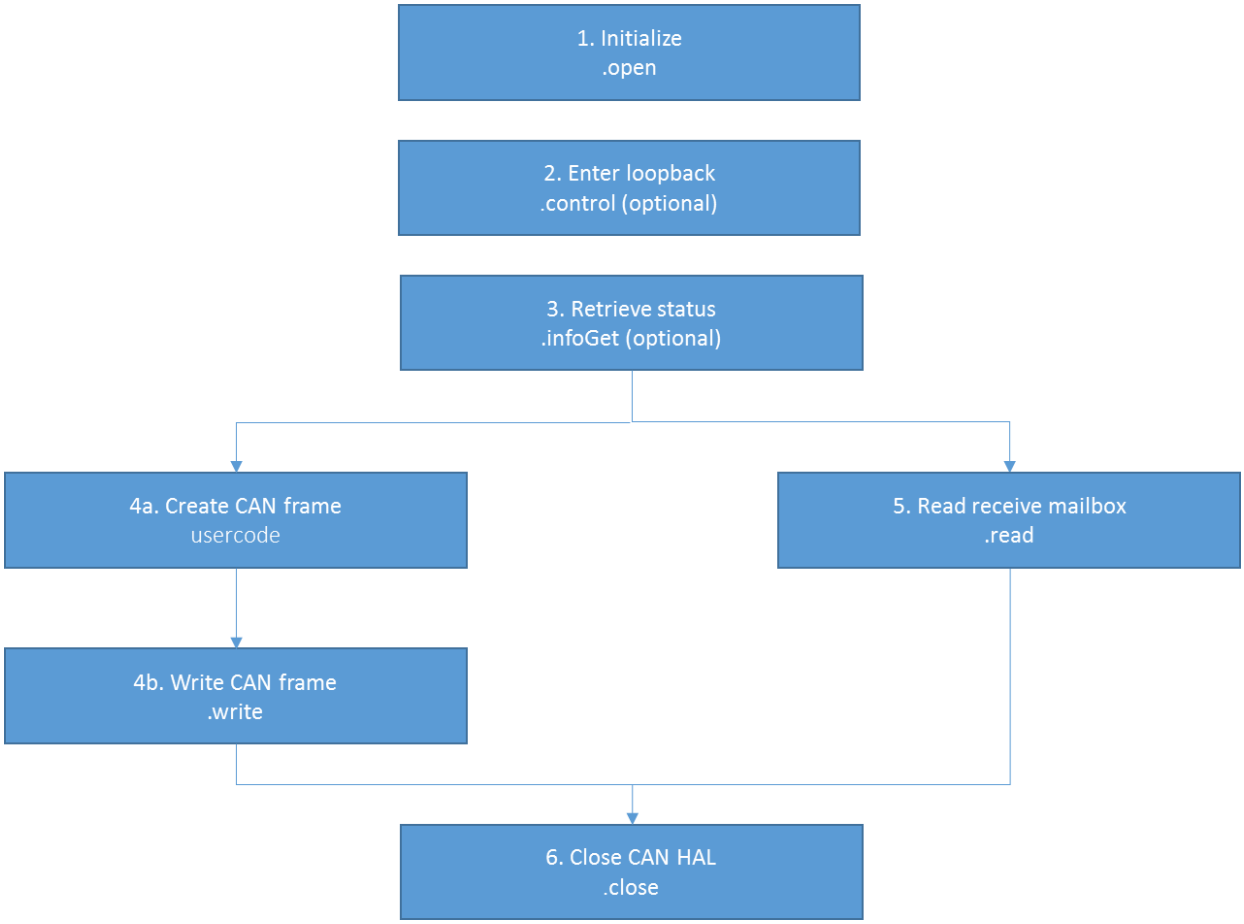

Figure 278: Flow Diagram of a Typical CAN HAL Module Application

4.2.7 CGC Driver

The CGC HAL module provides high-level APIs for clock-control applications and is implemented on r_cgc. The CGC HAL module configures and controls the clock-control functions of a Synergy MCU using the clock-control peripheral. Since every project requires a clock function, the CGC HAL module is added to a project by default. (The module is configured in the ISDE.) A user-defined callback can be created to signal when the main oscillator has stopped.

4.2.7.1 CGC HAL Module Features

The CGC HAL module supports the configuration and control of the various clocking function on the Synergy MCU. Key features include the following:

- Select the system clock source
  - HOCO (high-speed on-chip oscillator), MOCO (middle-speed on-chip oscillator), LOCO (low-speed on-chip oscillator), Main Clock, PLL, or Sub-Oscillator
- Configure internal clocks and turn them on or off

- Configure the output clocks
- Set up the Oscillation Stop Detection feature
- Set up clock divisors on each of the up to six clock domains
- Some Synergy MCUs also support controllable external clock outputs, which may have independent divisors

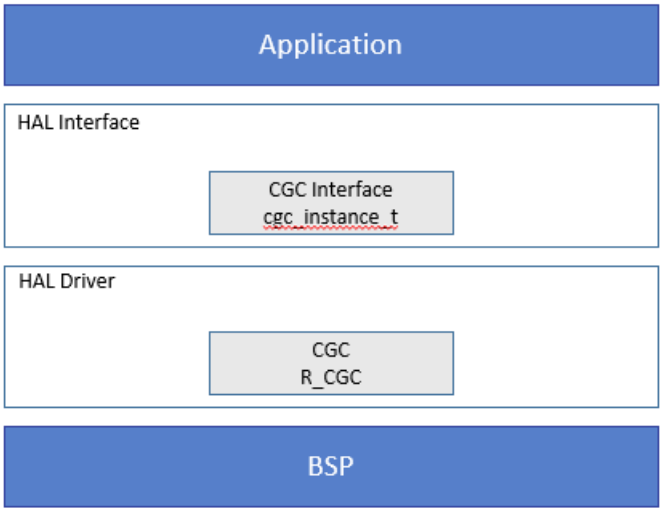

Figure 279: CGC HAL Module Block Diagram

4.2.7.2 CGC HAL Module APIs Overview

The CGC HAL module defines APIs for initializing, starting, controlling, and stopping the MCU clock. A complete list of the available APIs, an example API call, and a short description of each can be found in the following API Summary table. A table of status return values are listed after the API summary.

CGC HAL Module API Summary

Function Name	Example API Call and Description
.init	g_cgc.p_api->init(); Initial clock configuration called by BSP automatically.
.clocksCfg	g_cgc.p_api->clocksCfg(&p_clock_cfg); The BSP calls this function at startup, but it can also be called from the application to change clocks at runtime.

Function Name	Example API Call and Description
.clockStart	g_cgc.p_api->clockStart(clock_source, &p_clock_cfg); Start a clock.
.clockStop	g_cgc.p_api->clockStop(clock_source); Stop a clock.
.systemClockSet	g_cgc.p_api->systemClockSet(clock_source, &p_clock_cfg); Set the system clock.
.systemClockGet	g_cgc.p_api->systemClockGet(&clock_source, &clock_config); Get the system clock information.
.systemClockFreqGet	g_cgc.p_api->systemClockFreqGet(&clock_source, &frequency_hz); Return the frequency of the selected clock.
.clockCheck	g_cgc.p_api->clockCheck(clock_source); Check the stability of the selected clock.
.oscStopDetect	g_cgc.p_api->oscStopDetect(callback, enable); Configure the Main Oscillator stop detection.
.oscStopStatusClear	g_cgc.p_api->oscStopStatusClear(); Clear the oscillator stop detection flag.

Function Name	Example API Call and Description
.busClockOutCfg	g_cgc.p_api->busClockOutCfg (divider); Configure the bus clock output secondary divider. The primary divider is set using the BSP clock configuration and the systemClockSet function (S7G2 and S3A7 MCU only).
.busClockOutEnable	g_cgc.p_api->busClockOutEnable (); Enable the bus clock output (S7G2 and S3A7 MCU only).
.busClockOutDisable	g_cgc.p_api->busClockOutDisable (); Disable the bus clock output (S7G2 and S3A7 MCU only).
.clockOutCfg	g_cgc.p_api->clockOutCfg(clock_source, clock_dividers); Configure clockOut.
.clockOutEnable	g_cgc.p_api->clockOutEnable(); Enable clock output on the CLKOUT pin. The source of the clock is controlled by clockOutCfg.
.clockOutDisable	g_cgc.p_api->clockOutDisable(); Disable clock output on the CLKOUT pin. The source of the clock is controlled by clockOutCfg.
.lcdClockCfg	g_cgc.p_api->lcdClockCfg(clock); Configure the segment LCD Clock (S3A7 and S124 MCUs only).
.lcdClockEnable	g_cgc.p_api->lcdClockEnable(); Enable the LCD clock (S3A7 and S124 MCUs only).

Function Name	Example API Call and Description
.lcdClockDisable	g_cgc.p_api->lcdClockDisable(); Disables the LCD clock (S3A7 and S124 MCUs only).
.sdramClockOutEnable	g_cgc.p_api->sdramClockOutEnable(); Enables the SDRAM clock output (S7G2 MCU only).
.sdramClockOutDisable	g_cgc.p_api->sdramClockOutDisable(); Disables the SDRAM clock (S7G2 only).
.usbClockCfg	g_cgc.p_api->usbClockCfg(divider); Configures the USB clock (S7G2 only).
.systickUpdate	g_cgc.p_api->ssystickUpdate(period_count, units); Update the Systick timer.
.versionGet	g_cgc.p_api->versionGet(&version); Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_ABORTED	Attempt to update systick timer failed.
SSP_ERR_HARDWARE_TIMEOUT	Hardware timed out.
SSP_ERR_STABILIZED	Clock stabilized.
SSP_ERR_CLOCK_INACTIVE	Clock not turned on.

Name	Description
SSP_ERR_MAIN_OCO_INACTIVE	Main OCO off/unstable.
SSP_ERR_CLOCK_ACTIVE	Clock active.
SSP_ERR_NOT_STABILIZED	Clock source un-stabilized.
SSP_ERR_CLKOUT_EXCEEDED	Clock out exceeded.
SSP_ERR_NULL_PTR	Pointer null.
SSP_ERR_OSC_DET_ENABLED	Oscillation stop detection enabled.
SSP_ERR_OSC_STOP_DETECTED	The Oscillation stop detect status flag is set. Under this condition it is not possible to disable the Oscillation stop detection function.
SSP_ERR_OSC_STOP_CLOCK_ACTIVE	The Oscillation Detect Status flag cannot be cleared if the Main Osc or PLL is set as the system clock. Change the system clock before attempting to clear this bit.
SSP_ERR_INVALID_ARGUMENT	Invalid argument.
SSP_ERR_INVALID_MODE	Attempt to start a clock in a restricted operating power control mode.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.7.3 CGC HAL Module Operational Overview

The CGC HAL module interface provides the ability to configure and use all of the CGC HAL module's capabilities. Among those capabilities are the selection of several clock sources to use as the system clock source; additionally, the system clocks can be divided down to provide a wide range of frequencies for various system and peripheral needs.

Clock stability can be checked and clocks may also be stopped to save power when not needed. The API has a function to return the frequency of the system and system peripheral clocks at run time. There is also a feature to detect when the main oscillator has stopped, with the option of calling a user provided callback function.

The CGC HAL module to configure and control clock features:

- Configure any of the available clocks (HOCO, MOCO, LOCO, Main Clock, PLL, Sub-Oscillator) as the system clock source
- Configure the internal clocks (ICLK, PCLK, and so on)
- Switch the clocks on and off
- Configure the output clocks

- Set up the Oscillation Stop Detection feature

The Clock Generation Circuit peripheral features the following oscillators and clock generators:

- Main oscillator input of up to 24 MHz
- A 32.768 kHz sub-clock oscillator
- HOCO running at up to 64 MHz (depending on the device version)
- MOCO running at 8 MHz
- LOCO running at 32.768 kHz
- PLL circuit output running between 24 MHz and 240 MHz, depending on the device

The Synergy microcontrollers have six internal clock domains. Each of them has independent divisors but are dependent upon the clock input selected in the System Clock Control Register. These are:

- ICLK – The core clock, for CPU, DMAC, ROM and RAM (max 32/48/240 MHz)
- PCLKA – Peripheral clock for modules including EtherC, EDMAC, USB2.0 HS, QSPI and SCIF (max 32/48/120MHz)
- PCLKB – Peripheral clock for modules like IIC, CAN, DAC12, RTC, USBFS, I/O Ports, WDT and IWDT (max 32/60 MHz)
- PCLKC – Peripheral clock for ADC12 conversion clock (max 64/60 MHz)
- PCLKD – Peripheral clock for GPT count clock (max 64/120 MHz)
- FCLK –Clock source for the flash memory (max 32/60 MHz)

In addition, some of the Synergy microcontrollers also support controllable external clock outputs, some of which have independent divisors. These are:

- CLKOUT – CLOCKOUT/BUZZER clock (max 24 MHz) (independent clock selector and divisor)
- BCLK – External bus clock to external bus controller (max 16/120 MHz)
- SDCLK – SDRAM clock (max 120 MHz)
- UCLK – USB clock (max 120 MHz) (independent divisor/selector on Synergy version 2)
- LCD_CLK – LCD Clock (independent clock selector but no divisor)

Changing the System Clock Peripheral Clock Divisors at Runtime

The CGC HAL module also has the option to change the system clock and clock tree settings at runtime via the clocksCfg API function. Choose New Stack>System>CGC Configuration Instance to create a configuration structure for use with the clocksCfg API function.

The clocksCfg function allows changes to the system clock, the peripheral clock dividers, the PLL multiplier and divider, and the state of the system clocks (stop/start) (HOCO, Main Oscillator, Subclock oscillator, and so on). The options in the following figure show an example where the system clock is being changed from HOCO to MOCO, and the peripheral clock dividers are also being updated. The options for each clock are Start, Stop, and None (meaning no change.) Not all clocks are available on all MCUs. Not all peripheral clocks are available on all MCUs.

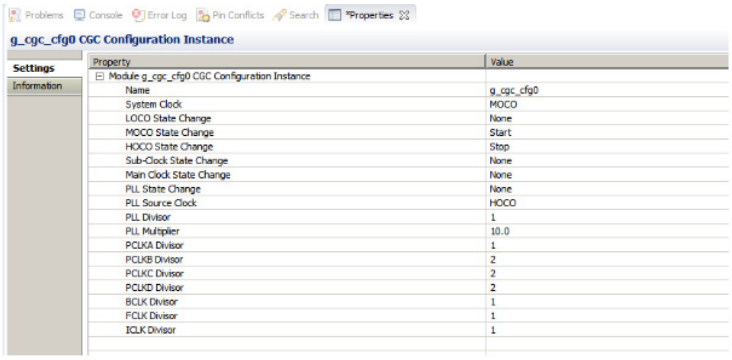

Figure 280: CGC Configuration Properties

The function call for the above example is:

```
g_cgc.p_api > clocksCfg(&g_cgc_cfg0);
```

Option Setting Memory

Synergy microcontrollers all include an Option-Setting Memory, this memory can be used to set the operating state of peripherals after a reset. The OFS can be used to set the state of the IWDT, WDT, LVD and CGC HOCO. The following table lists CGC HOCO parameters that can be configured by OFS registers.

OFS register setting possibilities

Control	Description
HOCO oscillation enable	Automatically starts the HOCO after a Reset, if enabled

Control	Description
HOCO Frequency	S7 and S5 Series - 16MHz - 18MHz - 20MHz S3 and S1 Series - 24 MHz - 32 MH - 48 MHz - 64 MHz

You can set the OFS register values through the properties dialog, the properties dialog is available on the Synergy Configuration editor when you select the BSP tab.

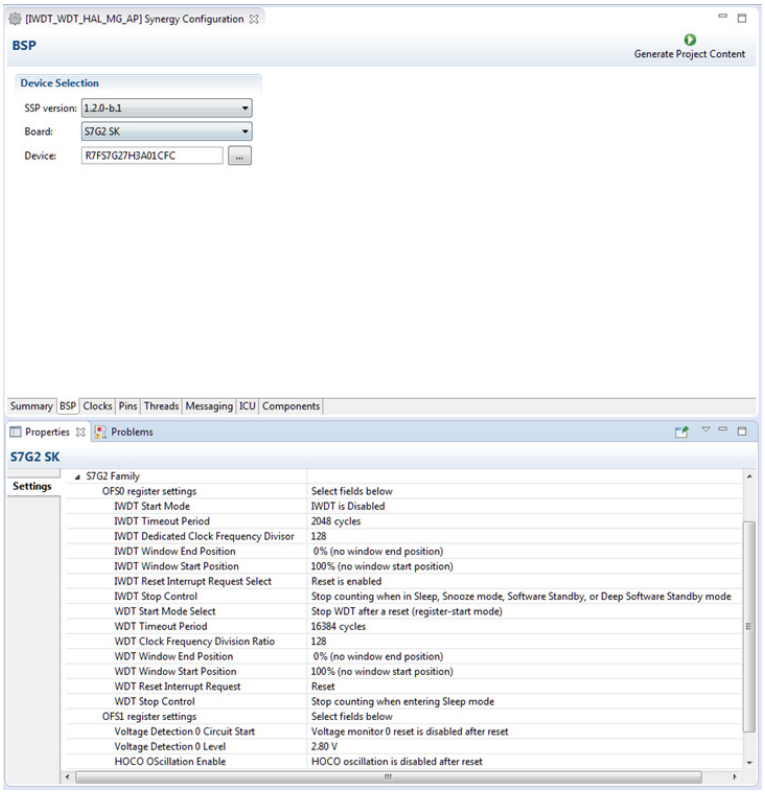

Figure 281: OFS Register Settings

The CGC HAL module also handles operating power control modes of the MCU since the Low Power Modes Version 2 HAL module will no longer handle operation-power control modes of the MCU.

CGC HAL Module Important Operational Notes and Limitations

- The CGC HAL module has no dependencies with respect to the ThreadX RTOS.
- The CGC HAL module is a core function of the MCU and is set after by the BSP initialization process. It is quite possible that the CGC can be left unchanged. However, the CGC HAL module provides functions that change the clock configuration that can balance the requirements of operating speed and power consumption, depending on application requirements.
- The CGC peripheral of the Synergy microcontrollers support Oscillator Stop Detection. If enabled in the application, the Oscillator Stop Detection function will automatically detect if the Main/PLL clock has stopped and switches operation to the MOCO. When enabling this functionality in the SSP a callback function has to be manually created by the user. The following steps detail this procedure.

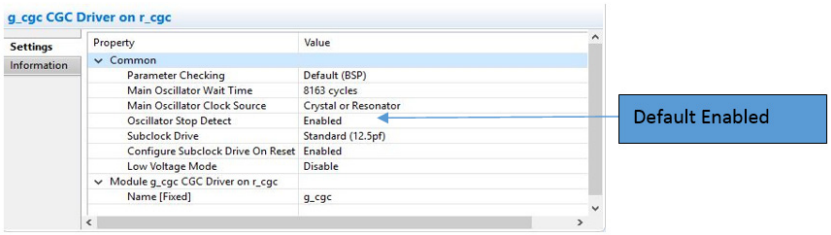

Figure 282: Oscillator Stop Detect Enable/Disable

NOTE: In SSP 1.4.0 and later the Oscillator Stop Detect property is set to default as Enabled. Previous versions of SSP set the default to Disabled.

- If the Configure Subclock Drive on Reset is set to Disabled, then the subclock will not be configured at startup. In order to configure the subclock user has to create a definition of weakly linked function R_BSP_WarmStart(). In this function if the argument is "BSP_WARM_START_POST_C", user can call the API R_CGC_ClockStart to start the subclock.

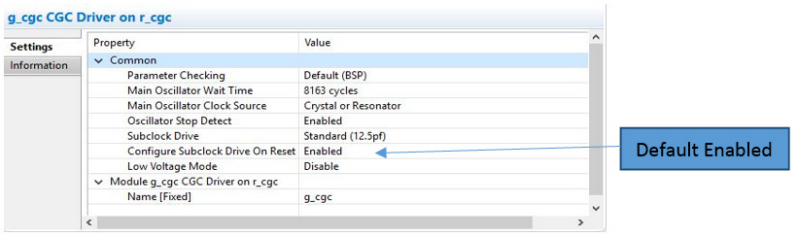

Figure 283: Configure Sub-clock drive on Reset

In the application code, create a callback function. In this example, it is called osc_stop_callback.

```
void osc_stop_callback(cgc_callback_args_t * p_args)

{

/* perform Oscillator Stop Detection processing */

}
```

Enable the oscillator stop detection by calling the API with the previously declared callback.

```
/* Enable the Osc Stop Detect functionality */

g_cgc.p_api-&gt;oscStopDetect( osc_stop_callback, true );
```

Enable the interrupt within the ICU

```
/* Osc Stop Detect is an NMI interrupt. Enable the NMI in ICU */

R_ICU->NMIER_b.OSTEN = 1;
```

Refer to the most recent SSP release notes for limitations on the use of this module.

4.2.7.4 Including the CGC HAL Module in an Application

This section describes how to include the CGC HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

The CGC Driver is automatically added to the HAL/Common thread, so it only needs to be added to a new thread if it has been removed. (The default name for the CGC is g_cgc. This name can be changed in the associated Properties window.)

CGC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_cgc CGC HAL on r_cgc	Threads	New Stack> Driver> System> CGC Driver on r_cgc

The CGC Driver on g_cgc is automatically added to the HAL/Common Stack, as shown in the following figure:

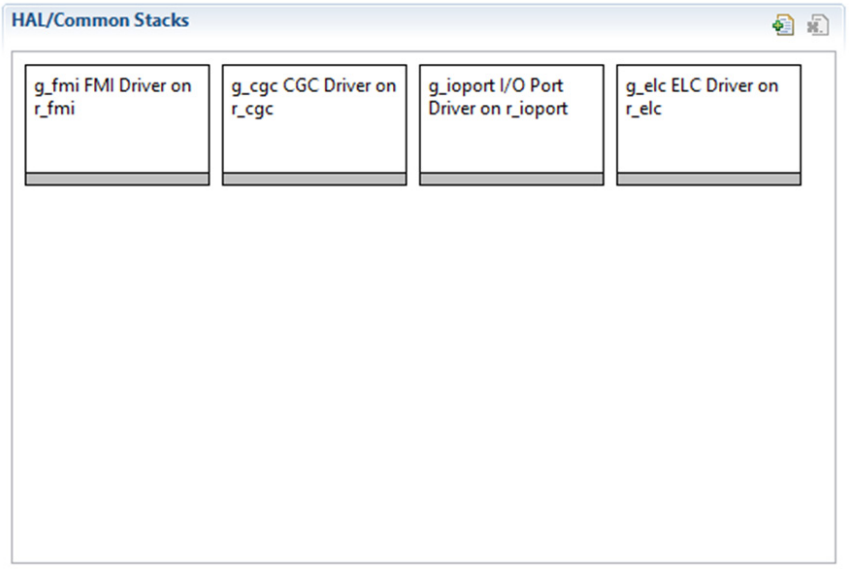

Figure 284: CGC HAL Module Stack

4.2.7.5 Configuring the CGC HAL Module

The CGC HAL module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the CGC HAL Module on r_cgc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Enable or disable the parameter error checking.
Main Oscillator Wait Time	3,35,67,131,259,547,1059,2147,4291,8163 cycles (Default: 8163 cycles)	Set to one of these values. It should be at least as long as the main clock stabilization time. This delay will be configured only if #define CGC_CFG_MAIN_OSC_CLOCK_SOURCE is set to 0, indicating that a resonator/ crystal is used. Set the main clock oscillation stabilization time to longer than or equal to the stabilization time recommended by the oscillator manufacturer.
Main Oscillator Clock Source	External Oscillator, Crystal or Resonator (Default: Crystal or Resonator)	Set to 0 if a resonator, or crystal, is used. Set to 1 if an external oscillator input is used
Oscillator Stop Detect	Enabled, Disabled (Default: Enabled)	This allows the R_CGC_OscStopDetect function code to be generated if enabled. The user must call this function with a callback pointer to use this feature.
Subclock Drive	Standard (12.5pf), Middle (4.4pf) (Default: Standard)	This setting is for matching the subclock oscillator drive capacitance based on the crystal parameters #define CGC_CFG_SUBCLOCK_DRIVE.

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have

different default values and available configuration settings.

In some cases, settings other than the defaults for the CGC HAL module can be desirable. For example, it might be useful to selectively turn clocks on or off or change frequency to optimize power and performance characteristics.

NOTE: Most of the property settings for modules are fairly intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

CGC HAL Module Clock Configuration

The default CGC HAL module clock frequencies that will be set by the BSP initialization process are configurable in the ISDE by using the Clocks tab in the configurator. Invalid selections are indicated in red when selected.

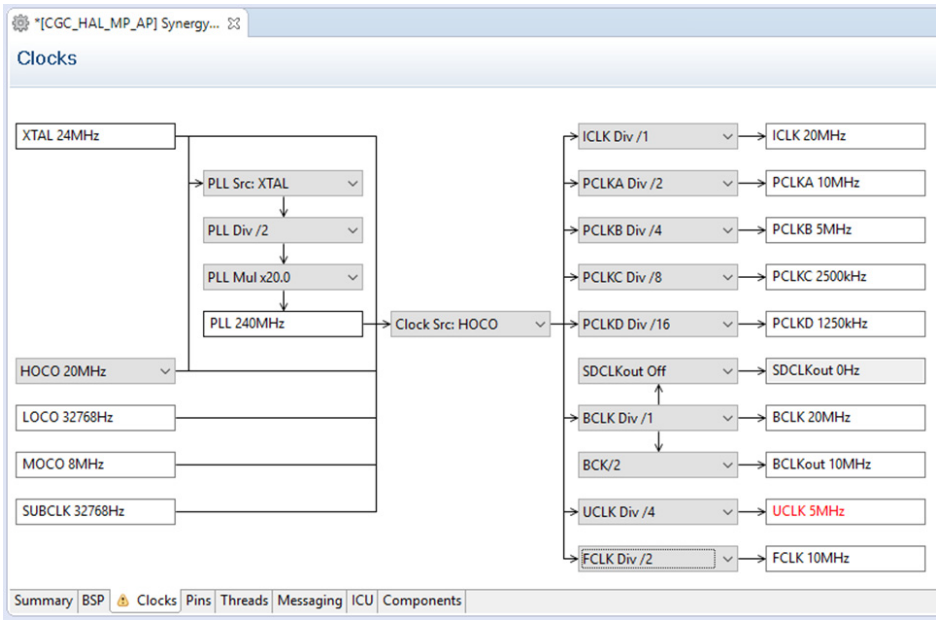

Figure 285: Default Clock Settings via the Clocks tab

In this example, the Clock Source is HOCO, and various clock dividers are chosen for the peripheral clocks. If a valid USB Clock (UCLK) cannot be achieved, it is highlighted in RED. It should be noted that this is only advisory, and the project will still build, as such a clock frequency may be required.

CGC HAL Module Pin Configuration

The CGC peripheral module controls the output of BCLK and SDCLK signals. Use the Clocks tab to enable/disable this functionality. The BCLK_SDCLK I/O pin must be selected and configured as required via the Pins tab.

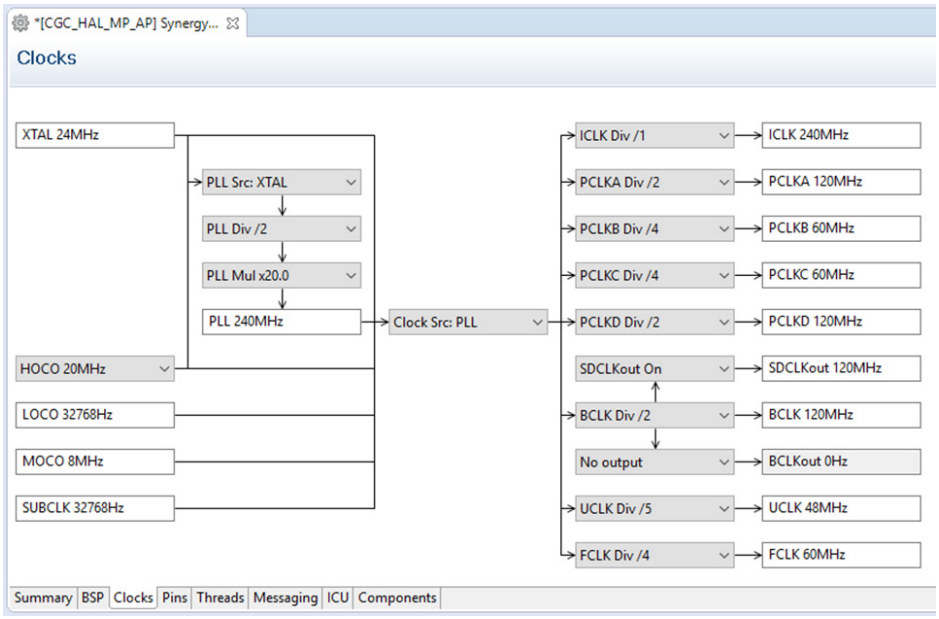

Figure 286: Enabling/Disabling SDCLK and BCLK via the Clock tab

In this example, SDRAM Clock is enabled, BUS Clock is disabled.

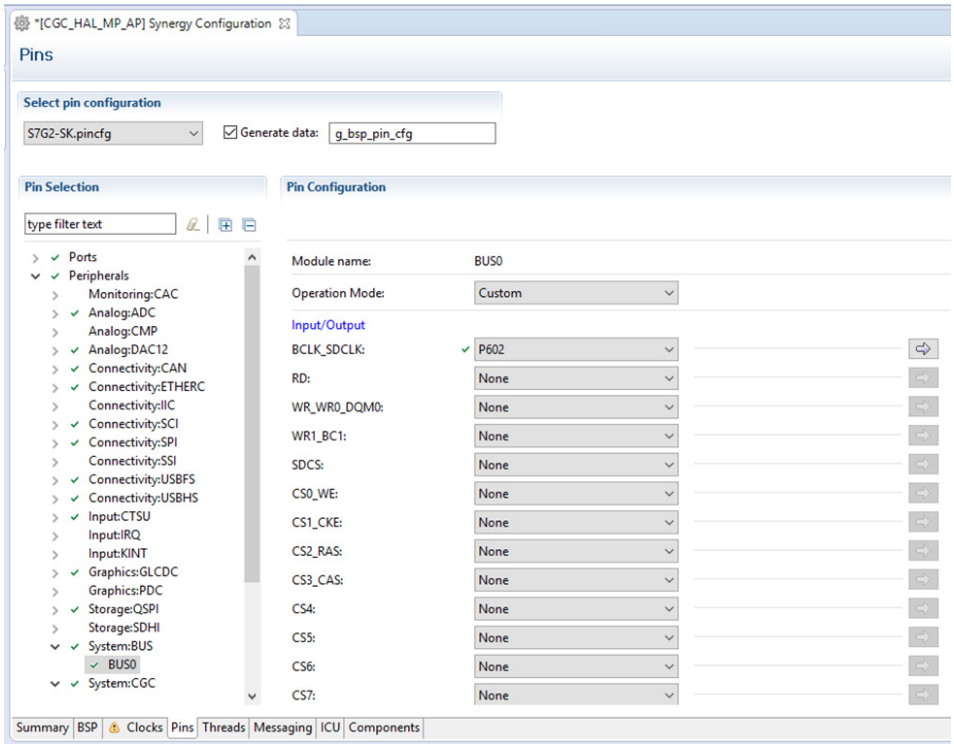

Figure 287: Enabling/Disabling SDCLK and BCLK via the Pins tab

In this example, SDRAM Clock/BUS Clock is enabled on P602.

Additional pin settings associated to the CGC allow for the enabling / disabling of the external oscillator pins and the setting of the system Clock Out pin.

The Synergy devices can run from its on chip oscillators, in which case there is no requirement for the main clock external oscillator pins XTAL and EXTAL. These could be used as input pins by the application. The functionality of the sub clock external oscillator pins XCIN and XCOUT is fixed.

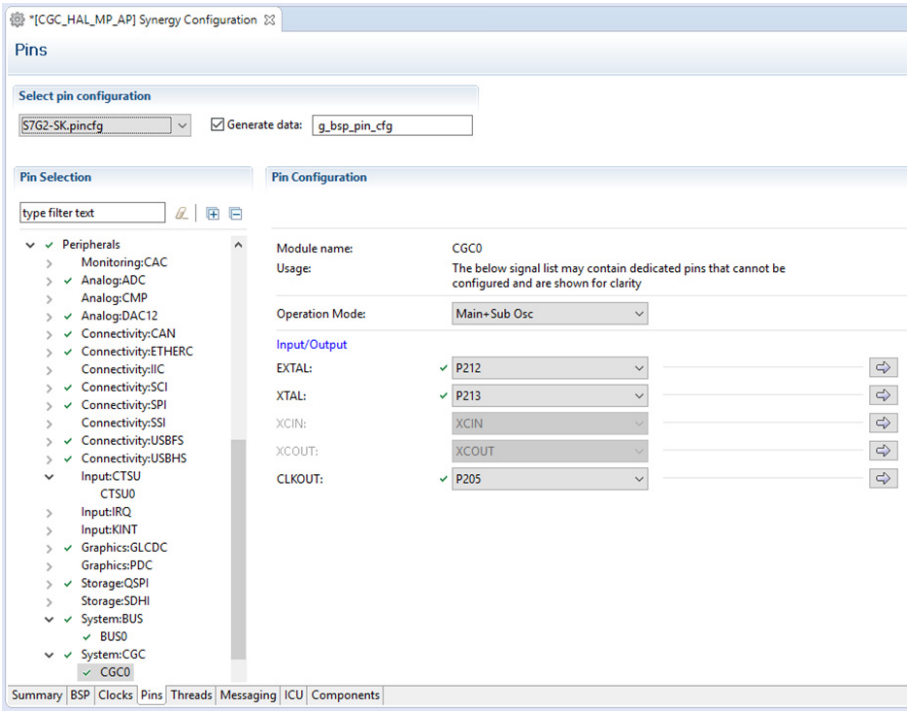

Figure 288: Enabling/Disabling EXTAL, XTAL and CLKOUT via the Pins tab

In this example, an external Main Oscillator is used via pins P212 and P213 and the CLKOUT is enabled on P205.

NOTE: The example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and Synergy MCUs may have different available pin configuration settings.

4.2.7.6 Using the CGC Module in an Application

The typical steps in using the CGC HAL module in an application are:

1) The CGC is automatically set after Reset.
2) Configure the clock as desired using the clocksCfg API.
3) Start clocks using the clockStart API.
4) Stop clocks using the clockStop API.

5) Other CGC functions as needed.

These common steps are illustrated in a typical operational flow diagram in the following figure:

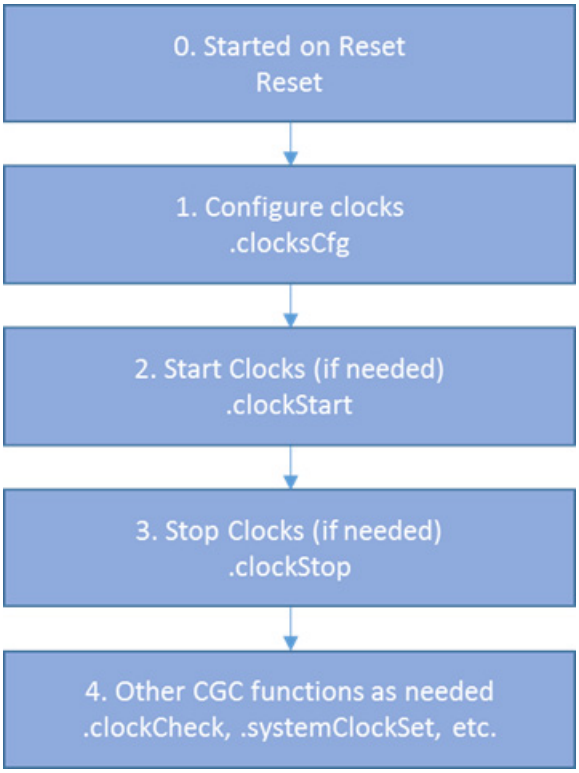

Figure 289: Flow Diagram of a Typical CGC HAL Module Application

4.2.8 CRC Driver

The CRC HAL module provides high-level APIs used to calculate 8, 16, and 32-bit CRC values on a block of data in memory or a stream of data over a Serial Communication Interface (SCI) channel using various types of industry-standard polynomials. The CRC HAL module is implemented on r_crc and uses the CRC peripheral on the Synergy MCU.

- CRC HAL module can calculate CRC on a block of data in memory.
- CRC HAL module can calculate CRC on a stream of data being transmitted or received over a serial communication Interface (SCI) channel (snoop mode).
- CRC HAL module supports the following 8 and 16 bit CRC polynomials which operates on 8-bit data in parallel
  - $X^8 + X^2 + X + 1$ (CRC-8)
  - $X^{16} + X^{15} + X^2 + 1$ (CRC-16)
  - $X^{16} + X^{12} + X^5 + 1$ (CRC-CCITT)
- CRC HAL module supports the following 32 bit CRC polynomials which operates on 32-bit data in parallel
  - $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$ (CRC-32)

– $X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^{9} + X^{8} + X^{6} + 1$ (CRC-32C)

- CRC HAL module can calculate CRC with LSB first or MSB first bit order.

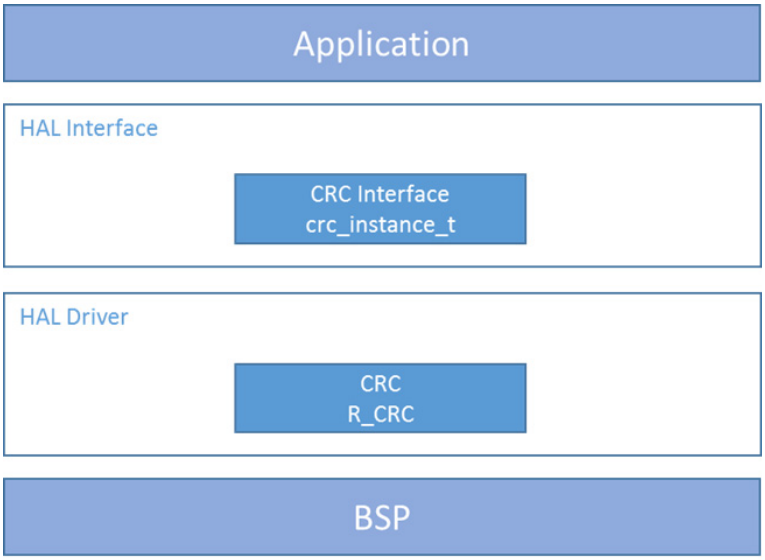

Figure 290: CRC HAL Module Block Diagram

4.2.8.1 CRC APIs Overview

The CRC HAL module defines APIs for **opening**, **closing**, **enabling**, and **calculating**. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows.

CRC HAL Module API Summary

Function Name	Example API Call and Description
open	g_crc.p_api->open(g_crc.p_ctrl, g_crc.p_cfg); Open the CRC driver module.
close	g_crc.p_api->close(g_crc.p_ctrl); Close the CRC module driver.
crcResultGet	g_crc.p_api->crcResultGet(g_crc.p_ctrl, &result); Return the current calculated value.

Function Name	Example API Call and Description
snoopEnable	g_crc.p_api->snoopEnable(g_crc.p_ctrl, seed); Enable snooping.
snoopDisable	g_crc.p_api->snoopDisable(g_crc.p_ctrl); Disable snooping.
snoopCfg	g_crc.p_api->snoopCfg(g_crc.p_ctrl, g_crc.p_cfg); Configure the snoop channel and direction.
calculate	g_crc.p_api->calculate(g_crc.p_ctrl, &input_buffer, num_bytes, crc_seed, &crc_result); Perform a CRC calculation on a block of data.
versionGet	g_crc.p_api->versionGet(&version); Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the *SSP User's Manual* API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Configuration was successful.
SSP_ERR_ASSERTION	Assertion error.
SSP_ERR_INVALID_ARGUMENT	Invalid argument error.
SSP_ERR_NOT_OPEN	The driver is not opened.
SSP_ERR_IN_USE	If driver is already open.

NOTE: Lower-level drivers may return common error codes. Refer to the *SSP User's Manual* API References for the

associated module for a definition of all relevant status return values.

4.2.8.2 CRC HAL Module Operational Overview

When the CRC HAL module is used to calculate the CRC value for a block of data in memory, the calculate API can be used which takes the input buffer pointer, length and the CRC seed value as input and outputs the calculated CRC value.

When CRC HAL module is used to calculate CRC on a stream of data being transmitted or received over a serial communication Interface (SCI) channel (snoop mode), then first the module should be configured to be in snoop mode by calling snoopCfg followed by snoopEnable APIs. After the requested number of data is transmitted or received on the SCI channel, the calculated CRC value can be polled from the module using crcResultGet API.

CRC HAL Module Important Operational Notes and Limitations

- The CRC block does not use any interrupts.
- There is no clock configuration for the CRC module.
- There are no callbacks for the CRC module.
- When using 32-bit CRC polynomials for calculating CRC values of data block in memory, the data block is interpreted using little-endian byte order.
- Refer to the most recent *SSP Release Notes* for any additional operational limitations for this module.

4.2.8.3 Including the CRC HAL Module in an Application

This section describes how to include the CRC HAL module in an application using the *SSP configurator*.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the *SSP User's Manual* to learn how to manage each of these important steps in creating SSP-based applications.

To add the CRC HAL module to an application, simply add it to a thread using the stacks selection sequence provided in the following table. (The default name for the CRC Driver is g_crc0. This name can be changed in the associated **Properties** window.)

CRC Driver Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
r_crc0 CRC Driver on r_crc	**Threads**	**New Stack> Driver> Monitoring> CRC Driver on r_crc**

When the CRC Driver on r_crc is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules.

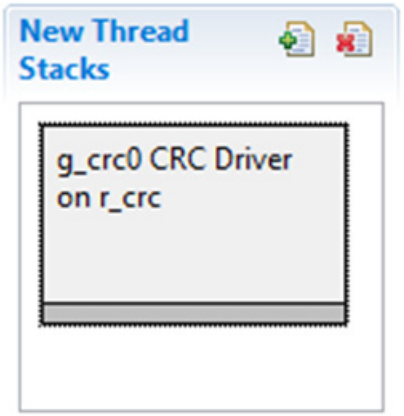

Figure 291: CRC HAL Module Stack

4.2.8.4 Configuring the CRC HAL Module

The CRC HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are locked and are not available for changes, and are identified with a lock icon for the locked property in the **Properties** window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the **Properties** tab within the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority. This configuration setting is available within the **Properties** window of the associated module. Simply select the indicated module and then view the **Properties** window. The interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Note that the interrupt priorities listed in the **Properties** window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+.) This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the Property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the CRC HAL Module on r_crc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g-crc0	Module name.

ISDE Property	Value	Description
CRC Polynomial	CRC-8, CRC-16, CRC-CCITT, CRC-32, CRC-32C Default: CRC-32C	Specify the polynomial to use for calculation.
Bit Order	LSB, MSB Default: MSB	Specify the bit order of the calculation.

NOTE: The example settings and defaults are for a project using the S7G2 Synergy MSU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for a module can be desirable. For example, it might be useful to select a different clock source than the default. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

CRC HAL Module Clock Configuration

The CRC HAL module is clocked via the Peripheral Clock A (PCLKA.)

The CRC HAL module does not support any APIs for setting the frequency at which it operates.

CRC HAL Module Pin Configuration

The CRC HAL module does not have any configurable pins.

4.2.8.5 Using the CRC HAL Module in an Application

The typical steps in using the CRC HAL module for computing CRC of data block in memory are:

1) Initialize the CRC HAL module using the open API
2) Compute the CRC HAL module using the calculate API
3) Close the CRC HAL module using the close API

These common steps are illustrated in a typical operational flow diagram in the following figure:

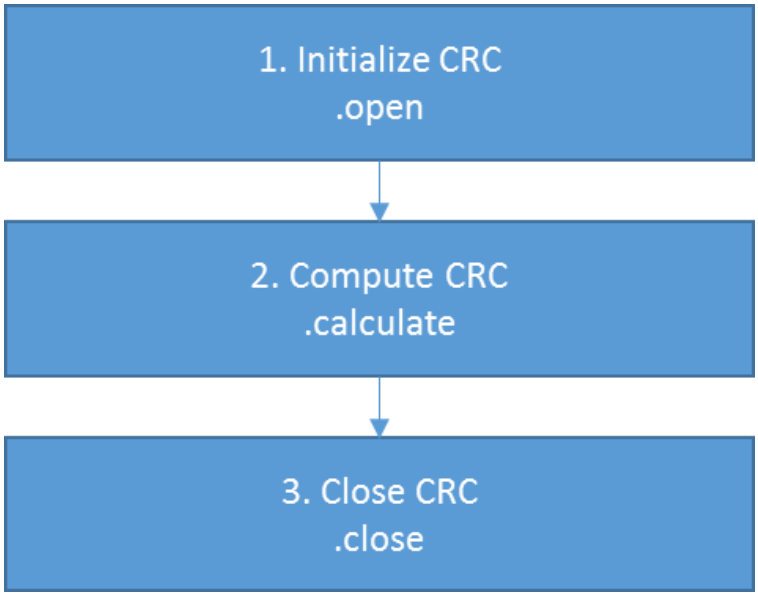

Figure 292: Flow Diagram of a Typical CRC HAL Module Application

The typical steps in using the CRC HAL module for computing CRC in snoop mode are:

1) Initialize the CRC HAL module using the open API.
2) Configure CRC module to snoop an SCI channel (and its direction) using snoopCfg API.
3) Enable snooping of the SCI channel using snoopEnable API.
4) Once the required number of bytes are transmitted or received on the SCI channel, get the calculated CRC value using crcResultGet API.
5) Disable the snooping operation using snoopDisable API.
6) Close the CRC HAL module using the close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

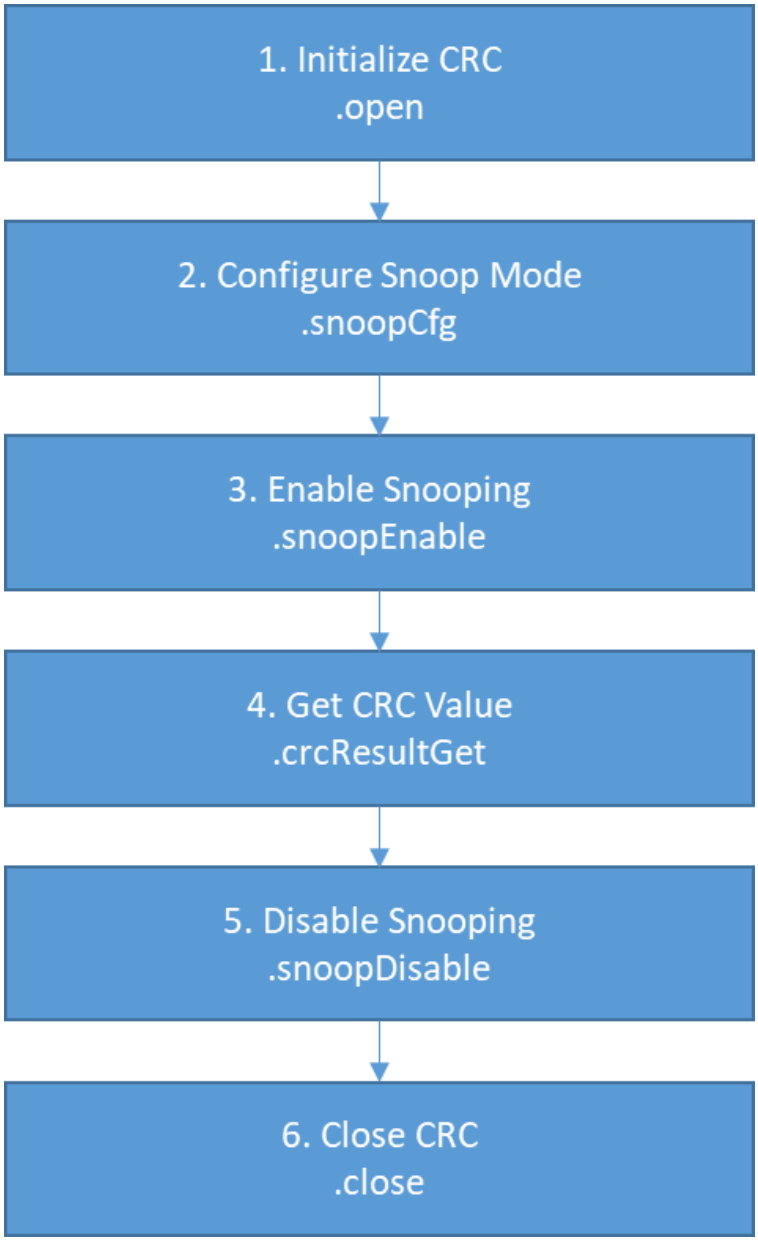

Figure 293: Flow Diagram of a Typical CRC HAL Module Snoop Mode Application

4.2.8.6 The CRC HAL Module Application Project

The application project associated with this module guide demonstrates the steps in a full design. The project can be found using the link provided in the References section at the end of this document. You may want to import and open the application project within the ISDE and view the configuration settings for the CRC HAL module. You can also read over the code (in crc_hal.c) which is used to illustrate the CRC HAL module APIs in a complete design.

The application project demonstrates the typical use of the CRC HAL module APIs. The application project main-thread entry initializes the CRC HAL module and periodically computes the CRC. The CRC is initially computed for a data buffer that is filled with generated bytes, then the data is copied to the so-called receive buffer, (the application simulates data transmission) and once again the CRC is computed. Both CRCs are compared, and based on the result, the **green** (CRCs are equal) or red (CRCs are different) LED is lit. The simulation of data transmission can introduce errors which result in lighting the red LED. The following table identifies the target versions for the associated software and hardware used by the application project.

Software and Hardware Resources Used by the Application Project

Resource	Revision	Description
e^2 studio	5.3.1	Integrated Solution Development Environment (ISDE)
SSP	1.2.0	Synergy Software Platform
IAR EW for Synergy	7.71.1	IAR Embedded Workbench® for Renesas Synergy™
SSC	5.2.1.016	Synergy Standalone Configurator
SK-S7G2	v3.0 to v3.1	Starter Kit

A simple flow diagram of the application project is given in the following figure:

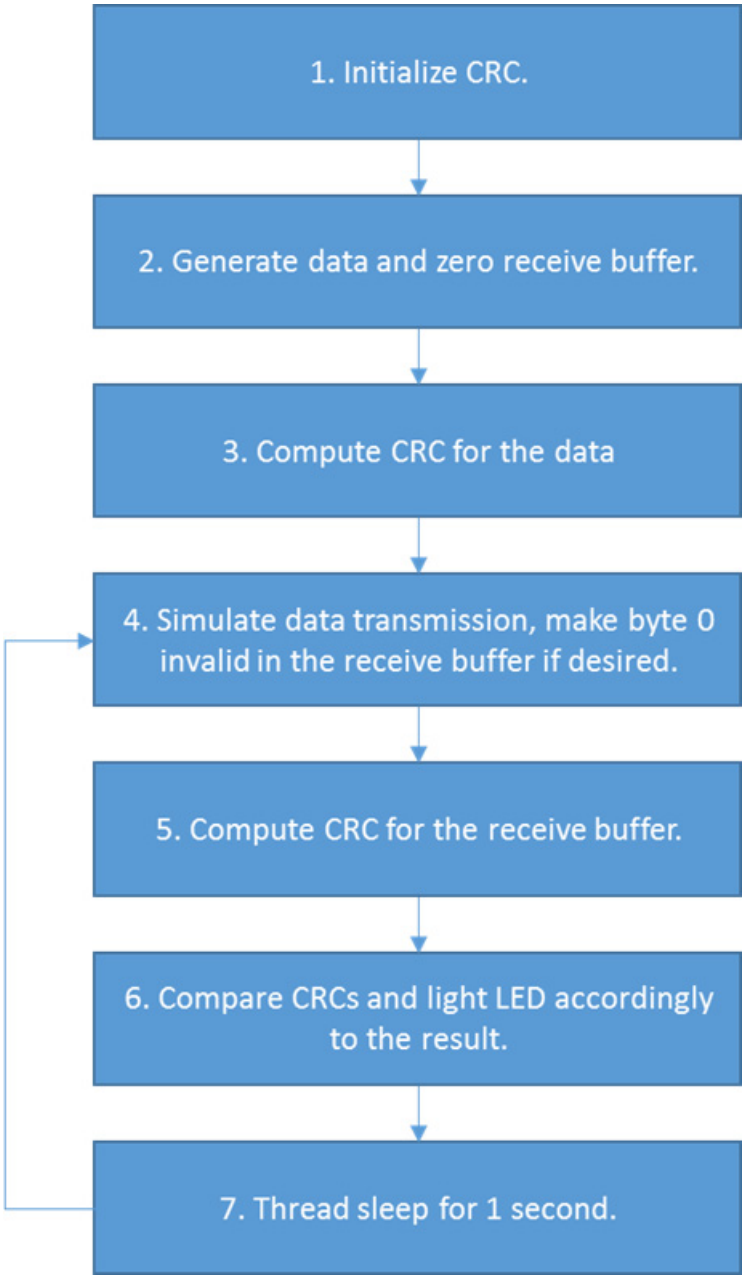

Figure 294: CRC Application Project Flow Diagram

The complete application project can be found using the link provided in the References section at the end of this document. The crc_hal.c file is located in the project once it has been imported into the ISDE. You can open this file, within the ISDE and follow along with the following description to help identify key uses of APIs.

In the application project, main-thread entry, the CRC HAL module is initialized using the open API right after the data array and receive buffer are set up. The data array contains growing numbers, as bytes, starting with 0, and the receive buffer is initialized with zeros. When the data is ready and the CRC HAL module is initialized, a CRC is computed for

the data. After that is code, the application flow enters a loop which simulates data transmission and fills the receive buffer, computes the CRC for the buffer, and lights the green (CRCs are equal) or red (CRCs are different) LED, according to the CRC comparison result. The application is initially configured not to introduce data-transmission errors. This can be changed by setting the makeError variable to true. Then, after copying bytes from the data array to the receive buffer, the byte at index 0 in the buffer is altered. This results in a different CRC, and lighting the red LED afterwards.

The CRC application project uses the CRC HAL module default property-values. No extra activities must be performed by the user.

4.2.9 CTSU Driver

This section describes how to configure and program the CTSU Driver using the e^2 studio ISDE.

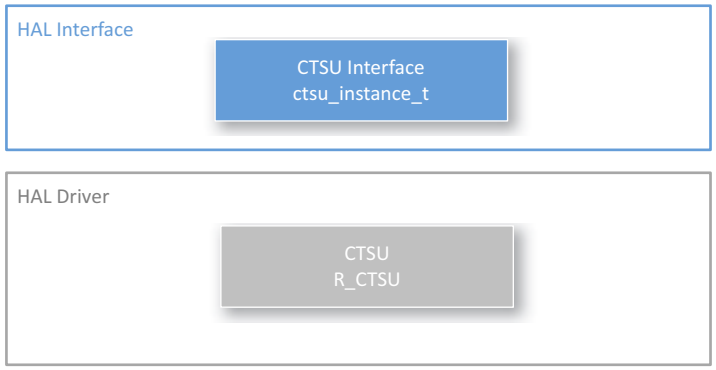

Figure 295: CTSU Driver – Block Diagram

The CTSU Driver is a generic driver implemented on r_ctsu for capacitive touch sensing applications and supports the CTSU peripheral on the Synergy microcontroller hardware. It is designed to be used in conjunction with the **Workbench 6** tool which generates the requisite structures that will be used by this module for initialization and operation.

In the Project Configurator in the e^2 studio ISDE, you can add and configure a CTSU Driver Module in the Modules pane of the Threads tab by selecting **New > Driver > Input > CTSU Driver on r_ctsu**. For details, see: Using e^2 studio to Write an Application with the CTSU Driver

For tuning the capacitive touch sensor, use the **Workbench 6** tool which can be downloaded separately from http://renesassynergy.com

You can find the API reference in the description of the CTSU Interface here: CTSU Interface

4.2.9.1 What Does the CTSU Driver Do?

The CTSU Driver is used to initialize the CTSU peripheral to detect a change in capacitance on any of the configured (and enabled) channels, perform requisite filtering and generate a variety of data that can be used by higher level widget layers like buttons wheel and sliders. To support the different types of data required by these layers, the implementation provides a Read() function that allows upper level layers to read different types of processed data based on their need. The driver also provides a callback when each scan is complete and when new processing data is available. These callbacks can be used by upper layers to read the data.

The CTSU Driver allows the user to configure the CTSU channels for all the supported operation modes including Mutual and Self Capacitance. The driver will scan the configured channels, move the data using the DTC, perform filtering, drift

compensation, auto-tuning and notify the user via a callback once each iteration is completed. The driver also allows the user to provide their own filtering and auto-tuning algorithms and integrate it into the process. The driver can only support one configuration at a time, but the user can reopen the driver with multiple channel configurations as required by the application.

4.2.9.2 Using e² studio to Write an Application with the CTSU Driver

The driver is integrated into the Synergy Software Package in e² studio: e² studio ISDE User Guide.

In e² studio, create and configure a project and add the drivers:

1) Create the project: Creating a Project.
2) Configure the project: Configuring a Project
3) Add the drivers: Adding Threads and Drivers

The following resources are required for any application using the CTSU Driver:

Resource	ISDE Tab	Selection
CTSU Driver	Threads	**Driver > Input > CTSU Driver on r_ctsu**
Interrupts	Threads	**CTSU WRITE, CTSU READ, CTSU END**
CTSU Clock	Clocks	See Configuring the CTSU Clocks
CTSU Pins	Pins	See Configuring the CTSU Pins

Configuring the CTSU Clocks

Set the CTSU clock speed to match the clock speed selected in the capacitive touch tuning tool **Workbench 6**.

Configuring the CTSU Pins

Set the pins as touch sensor pins TSxx and enable the TSCAP function pin.

Configuring the CTSU Interrupt

Enable the three CTSU interrupts in the ICU tab by setting them all, to the same priority. Any value will work.

Configuring the CTSU Parameters

Use the e² studio ISDE to configure the CTSU Driver Parameters.

For applications that do not use an RTOS: Adding and Configuring HAL Drivers

For ThreadX applications: Adding Drivers to a Thread and Configuring the Drivers.

Ensure that a **file/folder** with the **CTSU Configuration** generated by Workbench exists in the ${PROJECT_ROOT}\src folder and is included in the build

To use the SSP to configure the CTSU parameters, do the following:

1) See the file r_ctsu_api.h for details of the structure type ctsu_cfg_t.
2) Create a local variable of the type ctsu_cfg_t with the configuration set as below.

CTSU Common/Build-time configuration parameters

ISDE Property	Configuration	Setting	Description
Parameter Checking	-	Enabled (Default), Disabled	Enable or disable the parameter error checking.
Offset Adjustment	-	Enabled (Default), Disabled	Used to enable or disable offset adjustment. Leave as enabled unless you are tuning the board. (Rate is determined by *Runtime rate of tuning of sensor values*)
Drift Compensation	-	Enabled (Default), Disabled	Used to enable or disable drift compensation. Leave as enabled unless you are tuning the board. Drift compensation allows the baseline values used to determine the presence or absence of a touch to change over time as the board or surface ages or with changes in temperature and environment. Drift compensation rate is determined by *Steady state drift compensation rate*, *Startup drift compensation rate*, and *Channel release compensation rate*.

ISDE Property	Configuration	Setting	Description
Drift Compensation Methods	-	Alternate 1	Drift Compensation algorithms provided. Only Alternate 1 is currently supported. Other options may be supported in future releases. Drift compensation method Alternate 1 allows for different rates of drift compensation for the following events: steady state, startup, and channel release.
Dynamic Memory Usage	-	Enabled, Disabled (Default)	Used to save memory in applications where channels are dynamically enabled and disabled. Dynamic Memory Usage is currently not supported.
Perform auto-tune and drift compensation only when all channels are untouched	-	Enabled (Default), Disabled	Perform auto-tune and drift compensation only when all channels are untouched.
DTC Usage	-	Enabled (Default), Disabled	Allows the DTC to be used to move data in and out of the CTSU minimizing CPU overhead. This option cannot be currently disabled.
Maximum Active Channels	-	-	Specify the maximum number of channels that are to be used by the application. In Self Capacitance Mode, this is the number of channels used. In Mutual Capacitance Mode, this is the multiplication result of the Rx and Tx channels. For example: 4 Rx and 3 Tx channels = 12 Maximum Active Channels.

ISDE Property	Configuration	Setting	Description
Steady state drift compensation rate	-	Defaults to 500	Determines the rate of drift compensation (applied every n scans) when the channel is in steady state. (dependent on the scan rate)
Startup drift compensation rate	-	Defaults to 5	Determines the rate of drift compensation (applied every n scans) when the driver is performing its initialization. (Should be less than the *Steady state drift compensation rate*)
Channel release compensation rate	-	Defaults to 500	Determines the rate of drift compensation (applied every n scans) when a channel transitions from pressed to released. (Should be less than or equal to the *Steady state drift compensation rate*)
Default filter depth	-	Defaults to 14	Used in the software sensor count filter provided by driver. This default filter is a modification of the relatively common "leaky integrator" software filter. A depth of 4 equates to an approximate filter constant of 16. When the input is a constant value of 16 or greater, the filter output will reach 68-69% of the constant input value after 16 cycles/iterations of the filter.
Runtime rate of tuning of sensor values	-	Defaults to 800	Rate of offset adjustment.(If drift compensation is used this value is set to twice the rate of the steady state drift compensation)

ISDE Property	Configuration	Setting	Description
DTC Usage for CTSU	-	Defaults to *true*	DTC is required for use of r_ctsu in this release. Future releases may support r-ctsu data transfer without DTC.

CTSU Module configuration parameters

ISDE Property	Configuration	Setting	Property. Description
Transfer Instance for DTC Read	p_lower_lvl_transfer_read	-	Name of the Transfer Instance that will be used by the CTSU driver to read out data
Transfer Instance for DTC Write	p_lower_lvl_transfer_write	-	Name of the Transfer Instance that will be used by the CTSU driver to write configuration data
CTSU Hardware Configuration	p_ctsu_hw_cfg	-	Name of the configuration structure generated by Workbench
Processing Functions	p_ctsu_functions	-	Any processing functions the user would like to use to replace the default internal processing functions. Can be set to NULL if not used.
Callback	p_callback	-	The user callback function that will be invoked each time the scan is complete as well as when newly processed data is available. Can be set to NULL if not used.
Processing Option	ctsu_soft_option	-	Can be used to specify if scans should start after the data from the previous one is completed, if auto-calibration should be run between scans etc. Use the Default Setting for most cases.

ISDE Property	Configuration	Setting	Property. Description
Closing Option	ctsu_close_option	-	Can be used to specify if register states should be reset or maintained (higher power/memory consumption but quicker re-enable time) on closing.

4.2.9.3 Writing a CTSU Application

1) Generate a Synergy project.
2) Open the Synergy Configuration.
3) Go to the CTSU section in the Pins tab and enable the GPIO pins to be used as touch sensor pins TSxx.
4) Ensure that the TSCAP pin is enabled as well.
5) Ensure that the Clock speeds for the MCU match those selected in the external CapTouch Tuning Tool Workbench 6.
6) Add the DTC Transfer module from **Driver > Transfer > Transfer Driver on r_dtc**. No configuration is required.
7) Add the CTSU HAL driver to the HAL modules or to a thread from **Driver > Input > CTSU driver on r_ctsu**.
8) Ensure that a file/folder with the CTSU Configuration generated by Workbench exists in the ${PROJECT_-ROOT}\src folder and is included in the build.
9) Enable the three CTSU interrupts in the ICU tab by setting them all, to the same priority. Any value will work.
10) Using the Properties tab for the CTSU driver on r_ctsu, adjust the Maximum number of channels (or channel combinations if in Mutual Mode) used by any configuration.
11) Set the callback field to a user defined function.
12) Set the DTC Transfer name field to the name of the DTC module
13) Set the CTSU Configuration Used field to the name of the configuration generated by WorkBench.
14) Click Generate Project Content to generate the requisite structures.
15) Open hal_data.h (or thread_name.c) to see the structures that are generated to use this driver. For an overview of how to use SSP modules, refer to the SSP user manual.
16) Call Name.api->open ensuring properly initialized arguments are provided through a ctsu_cfg_t structure instance. This must be done before entering the main while loop.
17) From the main while loop keep calling Name.api->scan periodically to start a new scan. It is better to use a timer to run this task periodically which will determine the scan rate.
18) At the end of each scan, the user callback will be invoked. In the callback, check the event for the callback and call the Name.api->update to run processing on the data.
19) When the processing is complete the user callback will again be invoked with a different argument indicating that the data has been processed.

4.2.9.4 CTSU Driver Limitations

The driver only supports Mutual Capacitance Mode and Self Capacitance multi-scan mode. The driver does not support Dynamic memory allocation mode that would allow efficient memory usage in applications where the number of channels used changes dynamically. Also see the SSP release notes.

4.2.9.5 CTSU Driver Files

During the project configuration, the ISDE extracts the files shown in the following table to the /ssp directory.

Module	Directory
CTSU HAL Interface	synergy/ssp/inc/driver/spi/r_ctsu_api.h
CTSU HAL Instance	synergy/ssp/inc/driver/instances/r_ctsu.h
CTSU HAL Driver	synergy/ssp/src/driver/r_ctsu

4.2.9.6 Supported Devices for the CTSU Driver

The driver is designed to support the following families with no changes to the API:

- S7G2
- S3A7
- S128
- S124

The CTSU Framework is designed to support any Synergy device with a CTSU peripheral with no changes to the API.

4.2.10 SCE Crypto Driver

The Secure Cryptographic Engine (SCE) HAL module provides high-level APIs for random number generation, digest computation (hash), data encryption and decryption, digital signing and verification, key generation (using RSA, AES and ECC algorithms) and key installation (for RSA, AES and ECC keys). The SCE is a dedicated hardware block and the functionality provided by the SCE varies across the supported MCUs .

4.2.10.1 SCE HAL Module Features

The SCE HAL module configures the cryptographic module, which allows user to build cryptographic protocols for security with the following cryptographic primitives:

- Random-number generation
- Data encryption and decryption using AES or Triple DES (3DES) or ARC4 algorithms
- Signature generation and verification using the ECC, RSA or DSA algorithms
- Message-digest computation using HASH algorithms MD5, SHA1, SHA224, or SHA256

- Key generation - AES wrapped keys, RSA plain text and wrapped keys, ECC plain text and wrapped keys
- Installing the encrypted user key on to the Synergy platform.

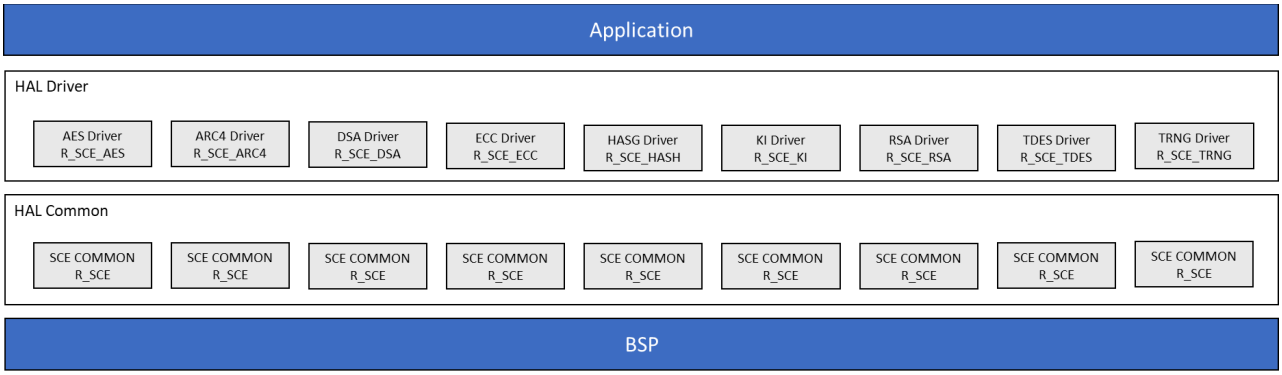

Figure 296: SCE HAL Module Block Diagram

NOTE: The above diagram includes all 9 available crypto modules. The SCE COMMON module is repeated for each one since it is included when the module is added to a thread stack. Common modules can be referenced by multiple other module instances across multiple Synergy stacks.

4.2.10.2 SCE APIs Overview

The SCE interface provides a common API for SCE HAL modules. The SCE interface supports multiple operations depending on the chosen module (AES, ARC4, RSA, DSA, HASH, TDES or TRNG.)

The AES interface defines APIs for opening, closing, generating wrapped keys, encrypting, and decrypting data using the AES algorithm. It uses a 128-bit, 192-bit, or 256-bit key and ECB, CBC, CTR, GCM, or XTS chaining-mode options. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. For return status values refer to the SCE API reference section of the SSP User's Manual.

SCE COMMON API Summary

Function Name	Example API Call and Description
.open	g_sce.p_api->open(g_sce.p_ctrl, g_sce.p_cfg); SCE Common module open function. Must be called before performing any other crypto operations.
.close	g_sce.p_api->close(g_sce.p_ctrl, num_words, p_key); Close the SCE Common module.

Function Name	Example API Call and Description
.interfaceGet	g_sce.p_api->interfaceGet(g_sce_aes.p_ctrl, p_interface_info, p_interface); Get the interface structure for the interface info provided.
.statusGet	g_sce.p_api->statusGet (g_sce.p_ctrl, p_status); Get status of SCE initialization.
.versionGet	g_sce.p_api->versionGet(p_version); Gets the module code and API version and stores it in provided pointer p_version

AES HAL Module API Summary

Function Name	Example API Call and Description
.open	g_sce_aes.p_api->open(g_sce_aes.p_ctrl, g_sce_aes.p_cfg); AES module open function. Must be called before performing any encrypt/decrypt operations.
.createKey	g_sce_aes.p_api->close(g_sce_aes.p_ctrl, num_words, p_key); Generate an AES key for encrypt / decrypt operations.
.encrypt	g_sce_aes.p_api->encrypt(g_sce_aes.p_ctrl, p_key, p_vi, num_words, p_source, p_dest); AES encryption using the chaining mode and padding mode specified in the open() function call.
.addAdditionalAuthenticationData	g_sce_aes.p_api->addAdditionalAuthenticationData (g_sce_aes.p_ctrl, p_key, p_vi, num_words, p_source); Add additional authentication data (called before starting an encryption or decryption operation).

Function Name	Example API Call and Description
.encryptFinal	g_sce_aes.p_api->encryptFinal(g_sce_aes.p_ctrl, p_key, p_iv, input_num_words, p_source, output_num_words, p_dest); AES final encryption using the chaining mode and padding mode specified in the open() function call.
.decrypt	g_sce_aes.p_api->decrypt(g_sce_aes.p_ctrl, p_key, p_iv, num_words, p_source, p_dest); AES decryption.
.setGcmTag	g_sce_aes.p_api-> setGcmTag(g_sce_aes.p_ctrl,num_words, p_source); Set authentication tag data.
.getGcmTag	g_sce_aes.p_api-> getGcmTag(g_sce_aes.p_ctrl,num_words, p_dest); Get authentication tag data.

Function Name	Example API Call and Description
.zeroPaddingEncrypt	g_sce_aes.p_api->zeroPaddingEncrypt(g_sce_aes.p_ctrl, p_key, p_iv, num_bytes, p_source, p_dest) AES zero padding encryption using the chaining mode and padding mode specified. Implementation for GCM mode only API usage - 1. To provide any Add Authentication Data (AAD): set p_dest = NULL 2. Encryption: set p_source to input data and p_dest will return encrypted data 3. Get/Compute Tag: set p_source = NULL

Function Name	Example API Call and Description
.zeroPaddingDecrypt	g_sce_aes.p_api->zeroPaddingDecrypt(g_sce_aes.p_ctrl, p_key, p_iv, num_words, p_source, p_dest); AES zero padding decryption using the chaining mode and padding mode specified. Implementation for GCM mode only API usage - 1. Set expected tag value using the setGcmTag() function 2. To provide any Add Authentication Data (AAD), invoke this API using p_dest = NULL 3. Decryption: set p_source to input encrypted data, decrypted data will be returned in p_dest 4. To verify the tag, invoke this API using p_source = NULL and p_dest = NULL, the return value indicates authentication tag verification status.
.versionGet	g_sce_aes.p_api->versionGet(p_version); Gets the module code and API version and stores it in provided pointer p_version
.close	g_sce_aes.p_api->close(g_sce_aes.p_ctrl); Close the AES module.

The ARC4 interface defines APIs for opening, closing, setting a key, and processing data. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table.

ARC4 HAL Module API Summary

Function Name	Example API Call and Description
.open	g_sce_arc4.p_api->open(g_sce_arc4.p_ctrl, g_sce_trng.p_cfg); Open the ARC4 module.
.keySet	g_sce_arc4.p_api->keySet(g_sce_arc4.p_ctrl, &rngbuf, nbytes); Set the key to be used by the ARC4 module.
.arc4Process	g_sce_arc4.p_api-> arc4Process(g_sce_arc4.p_ctrl, nbytes, &source, &destination); Encrypt or decrypt data using the ARC4 module.
.close	g_sce_arc4.p_api->close(g_sce_arc4.p_ctrl); Close the ARC4 module.
.versionGet	g_sce_arc4.p_api->versionGet (&version); Retrieve the version using the version pointer.

The DSA interface defines APIs for opening, closing, digital-signing, and verification. Available options include a 1024-bit public key and a 160-bit private key, a 2048-bit public key and a 224-bit private key, or a 2048-bit public key and a 256-bit private key. A complete list of the available APIs, an example API call and a short description of each can be found in the following table.

DSA HAL Module API Summary

Function Name	Example API Call and Description
.open	g_sce_dsa.p_api->open(g_sce_dsa.p_ctrl, g_sce_dsa.p_cfg); DSA module open function. Must be called before performing any sign/verify operations.

Function Name	Example API Call and Description
.verify	g_sce_dsa.p_api->verify(p_key, p_domain, num_words, p_signature, p_paddedHash); DSA signature verification using given DSA public key. This function is deprecated. The function hashVerify should be used instead.
.hashVerify	g_sce_dsa.p_api->hashVerify(g_sce_dsa.p_ctrl, p_key, p_domain, num_words, p_signature, p_paddedHash); DSA signature verification using given DSA public key.
.sign	g_sce_dsa.p_api->sign(p_key, p_domain, num_words, p_padded_hash, p_dest); DSA Signature generation using DSA private key. This function is deprecated. The function hashSign should be used instead.
.hashSign	g_sce_dsa.p_api->hashSign(g_sce_rsa.p_ctrl, p_key, p_domain, num_words, p_padded_hash, p_dest); DSA Signature generation using DSA private key.
.close	g_sce_dsa.p_api->close(g_sce_dsa.p_ctrl); Close the DSA module.
.versionGet	g_sce_dsa.p_api->versionGet(p_version); Gets version and stores it in provided pointer p_version.

The HASH interface defines APIs for calculating hash values for a given data-set. Available options include SHA1 and SHA256 algorithms. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table.

HASH HAL Module API Summary

Function Name	Example API Call and Description
.open	g_sce_hash.p_api->open(g_sce_hash.p_ctrl, g_sce_hash.p_cfg); HASH module open function. Must be called before performing any sign/verify operations.
.updateHash	g_sce_hash.p_api->updateHash(p_source, num_words, p_dest); Update hash for the num_words words from source buffer p_source. This function is deprecated. The function hashUpdate should be used instead.
.hashUpdate	g_sce_hash.p_api->hashUpdate(g_sce_hash.p_ctrl, p_source, num_words, p_dest); Update hash for the num_words words from source buffer p_source.
.close	g_sce_hash.p_api->close(g_sce_hash.p_ctrl); HASH module close function.
.versionGet	g_sce_hash.p_api->versionGet(p_version); Gets version and stores it in provided pointer p_version.

The RSA interface defines APIs for opening, closing, encrypting, and decrypting data using an RSA algorithm as well as digitally signing and verifying the algorithm. The RSA interface employs a 1024-bit or 2048-bit key. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table.

RSA HAL Module API Summary

Function Name	Example API Call and Description
.open	g_sce_rsa.p_api->open(g_sce_rsa.p_ctrl, g_sce_rsa.p_cfg); RSA module open function. Must be called before performing any encrypt/decrypt or sign/verify operations.

Function Name	Example API Call and Description
.encrypt	g_sce_rsa.p_api->encrypt(g_sce_rsa.p_ctrl, p_key, p_domain, num_words, p_source, p_dest); Encrypt source data from p_source using an RSA public key from p_key and write the results to destination buffer p_dest.
.decrypt	g_sce_rsa.p_api->decrypt (g_sce_rsa.p_ctrl, p_key, p_domain, num_words, p_source, p_dest); Decrypt source data from p_source using an RSA private key from p_key and write the results to destination buffer p_dest.
.decryptCrt	g_sce_rsa.p_api->decryptCrt(g_sce_rsa.p_ctrl, p_key, p_domain, num_words, p_source, p_dest); Decrypt source data from p_source using an RSA private key from p_key and write the results to destination buffer p_dest. RSA private key data is specified in CRT format.
.verify	g_sce_rsa.p_api->verify(g_sce_rsa.p_ctrl, p_key, p_domain, num_words, p_signature, p_padded_hash); Verify signature given in buffer p_signature using the RSA public key p_key for the given padded message hash from buffer p_padded_hash.
.sign	g_sce_rsa.p_api->sign(g_sce_rsa.p_ctrl, p_key, p_domain, num_words, p_padded_hash, p_dest); Generate signature for the given padded hash buffer p_padded_hash using the RSA private key p_key. Write the results to the buffer p_dest.
.signCrt	g_sce_rsa.p_api->signCrt(g_sce_rsa.p_ctrl, p_key, p_domain, num_words, p_padded_hash, p_dest); Generate signature for the given padded hash buffer p_padded_hash using the RSA private key p_key. RSA private key p_key is assumed to be in CRT format. Write the results to the buffer p_dest.

Function Name	Example API Call and Description
.close	g_sce_rsa.p_api->close(g_sce_rsa.p_ctrl); Close the RSA module.
.keyCreate	g_sce_rsa.p_api->keyCreate(g_sce_rsa.p_ctrl, p_private_key, p_public_key); Generates an RSA key pair.
.versionGet	g_sce_rsa.p_api->versionGet(p_version); Gets version and stores it in provided pointer p_version.

The TDES interface defines APIs for encrypting and decrypting data according to the TDES standard. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table.

TDES HAL Module API Summary

Function Name	Example API Call and Description
.open	g_sce_tdes.p_api->open(g_sce_tdes.p_ctrl, g_sce_tdes.p_cfg); Open the TDES module.
.encrypt	g_sce_tdes.p_api-> encrypt(g_sce_tdes.p_ctrl, &key, &iv, nwords, &source, &destination); Encrypt the data.
.decrypt	g_sce_trng.p_api-> decrypt(g_sce_tdes.p_ctrl, &key, &iv, nwords, &source, &destination); Decrypt the data.

Function Name	Example API Call and Description
.close	g_sce_tdes.p_api->close(g_sce_tdes.p_ctrl); Close the TDES module.
.versionGet	g_sce_tdes.p_api->versionGet(p_version); Gets version and stores it in provided pointer p_version.

The TRNG interface defines APIs for computing the random-number generator. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table.

TRNG HAL Module API Summary

Function Name	Example API Call and Description
.open	g_sce_trng.p_api->open(g_sce_trng.p_ctrl, g_sce_trng.p_cfg); Open the TRNG driver for reading random data from the hardware TRNG module.
.read	g_sce_trng.p_api->read(g_sce_trng.p_ctrl, p_rngbuf, nbytes); Generate nbytes of random number bytes and store them in p_rngbuf buffer.
.close	g_sce_trng.p_api->close(g_sce_trng.p_ctrl); Close the TRNG interface driver.
.versionGet	g_sce_trng.p_api->versionGet(p_version); Gets version and stores it in provided pointer p_version.

4.2.10.3 SCE HAL Module Operational Overview

Different cryptographic functions are available for different target MCUs; the following table shows the functionality that is available for each individual MCU-series:

Function	S7G2, S5D9, S5D5	S3A1, S3A3, S3A7, S3A6	S124, S128, S1JA	Notes
TRNG	Generate and read random number	Generate and read random number	Generate and read random number	Generate and read random number
AES	Encryption, decryption, Key Generation - wrapped keys	Encryption, decryption, Key Generation - wrapped keys	Encryption, decryption	Symmetric Key Encryption based on AES standard
AES Key Size	128-bit, 192-bit, 256-bit	128-bit, 256-bit	128-bit, 256-bit	
AES Key Type	Plain text / raw key, Wrapped key	Plain text / raw key, Wrapped key	Plain text / raw key	
AES Chaining Modes	ECB, CBC, CTR, GCM, XTS NOTE: XTS is supported for 128-bit and 256-bit keys only	ECB, CBC, CTR, GCM, XTS	ECB, CBC, CTR	
ARC4	Encryption, decryption	NA	NA	
TDES	Encryption, decryption	NA	NA	
TDES Key Size	192-bit	NA	NA	
TDES Chaining Modes	ECB, CBC, CTR	NA	NA	

Function	S7G2, S5D9, S5D5	S3A1, S3A3, S3A7, S3A6	S124, S128, S1JA	Notes
RSA	Signature Generation, Signature Verification, Public-key Encryption, Private-key Decryption, Key Generation - plain text and wrapped keys	NA	NA	Supports CRT keys and standard keys for private key operations
RSA Key Size	1024-bit, 2048-bit	NA	NA	
RSA Key Type	Plain text / raw key, Wrapped key	NA	NA	
DSA	Signature Generation, Signature Verification	NA	NA	
DSA Key Size	(1024, 128)-bit, (2048, 224)-bit, (2048, 256)-bit	NA	NA	
HASH	MD5, SHA1, SHA224, SHA256	NA	NA	Message digest algorithms
ECC	Key Generation – plain text and wrapped keys, Scalar Multiplication, ECDSA- Signature Generation, ECDSA -Signature Verification,	NA	NA	

Function	S7G2, S5D9, S5D5	S3A1, S3A3, S3A7, S3A6	S124, S128, S1JA	Notes
ECC Key Size	192-bit, 256-bit	NA	NA	
ECC Key Type	Plain Text / Raw Key, Wrapped Key			
Key Installation	AES, ECC, RSA keys (Plain text keys to be prepared as specified in the Appendix)	AES keys (Plain text keys to be prepared as specified in the Appendix)	NA	

Configuration Settings for the R_SCE Module

The endianness of the SCE is set to big endian by default. It can be set to little endian mode.

Please refer to the operational notes on endianness configuration parameter usage.

Configuration Settings for the TRNG Module

Random number-generation can be configured for the maximum number of attempts it makes to the underlying hardware to generate a unique 16-byte random number that differs from the previously-generated random number. On reaching the maximum number of attempts, the read API will return an error code to the caller, otherwise a success code is returned and the generated random number will be transferred to the caller-supplied data buffer.

Configuration Settings for the AES Module

The AES module can be configured for a user-specified key-length, key type (plain text or wrapped key) and chaining modes.

Configuration Settings for the RSA Module

The RSA module can be configured for a user-specified key length and key type: plain text or wrapped keys.

Configuration Settings for the DSA Module

The DSA module can be configured for a user-specified key length.

Configuration Settings for the HASH Module

The HASH module can be configured for a user specified HASH algorithm (depending on the target MCU).

Configuration Settings for the TDES Module

The TDES module can be configured for a user-specified chaining mode.

Configuration Settings for the Key Installation Module

The Key Installation module can be configured to install the user's encrypted key.

Configuration Settings for the ECC Module

The ECC module can be configured for a user-specified key length and key type.

SCE HAL Module Operational Notes and Limitations

- Synergy S7 and S5 devices have the SCE7 and therefore support AES, TRNG, RSA, HASH, DSA, ECC and Key Installation.
- Synergy S3 devices have the SCE5 and therefore support AES, TRNG, & GHASH. GHASH is supported as part of the AES GCM mode. Key Installation is supported as part of AES GCM, ECB, CTR, XTS, CBC chaining modes. Synergy S3 devices do not support MD5, SHA1 / SHA256 HASH functionality.
- Synergy S1 devices only support AES (ECB, CBC and CTR) and TRNG.
- If an unsupported module is added to the project, then a compiler warning will be generated indicating this fact.
- All modules support versionGet API which can be called even before a module is opened.
- R_SCE module interfaceGet API is provided for use by the Framework layer SF CRYPTO modules.InterfaceGet API is used to request a crypto HAL interface. The example below shows usage of this API:

```
crypto_instance_t          * p_crypto;  /* R_SCE  instance */
void * p_interface = NULL;    /* Declare a pointer to hold the output interface
structure object */
crypto_interface_get_param_t     param;
param.hash_type = CRYPTO_TYPE_HASH_256; /* Requesting SHA 256 interface*/
/* It is mandatory for the address of the p_interface pointer be passed to the A
PI */
p_crypto->p_api->interfaceGet(&param, &p_interface);
```

- All crypto APIs may return SSP_ERR_ASSERTION on null pointer input or invalid input parameters. All APIs return error codes documented in sf_crypto_err_t or ssp_err_t which are within the width of the type uint32_t.
- Crypto hardware engine does not support reentrancy. When the crypto hardware engine is busy performing a task, any new request will receive a status error code SSP_ERR_CRYPTO_SCE_RESOURCE_CONFLICT.

Endianness configuration parameter usage:

- The default mode is big endian where the input and output parameters (example: keys, payload and IV) are required to be in uint32_t data type.
- The little endian mode allows the user to have uint8_t / byte array for input and output parameters (example: keys, payload and IV) and they should be cast to (uint32_t *).
- The endianness configuration is set at the initialization of the SCE module and remains in effect until the module is closed. Hence all data should be formatted accordingly.Example:
  - Select the Big endian mode when the data is in uint32_t and big endian format:

```
uint32\_t test\_data\[5\] = {0x84983E44, 0x1C3BD26E, 0xBAAE4AA1,
0xF95129E5, 0xE54670F1};
```

  - Select the Little endian mode when the same data is in byte array format

```
uint8\_t test\_data\_byte\_array\[20\] =
{0x84, 0x98, 0x3E, 0x44, 0x1C, 0x3B, 0xD2, 0x6E, 0xBA, 0xAE, 0x4A,
0xA1, 0xF9, 0x51, 0x29, 0xE5, 0xE5, 0x46, 0x70, 0xF1};
```

- The format of RSA keys generated by the keyCreate API is as follows:

NOTE: The endianness is the same as that set during SCE initialization.

RSA key format:**RSA Public key format**:WORD 0 : Public key exponentWORD 1: Start of RSA modulus(128 bytes for RSA 1024-bit and 256 bytes for RSA 2048-bit keys)**RSA Private key in plain text standard format** WORD 0 : Private key exponent (128 bytes for RSA 1024-bit and 256 bytes for RSA 2048-bit keys)Followed by RSA modulus. (128 bytes for RSA 1024-bit and 256 bytes for RSA 2048-bit keys)RSA Private key in plain text CRT formatThe components are ordered in the following order with exponent2 at byte 0:

```
exponent2 // the second factor's CRT exponent, a positive integer

prime2 // the second factor, a positive integer

exponent1 // the first factor's CRT exponent, a positive integer

prime1 // the first factor, a positive integer coefficient // the (first) CRT
coefficient, a positive integer
```

- The AES encrypt() and decrypt() functions do not support data padding. These functions operate on data lengths that are multiples of 16 bytes. (Data padding needs to be handled by the user application.) AES GCM mode may require support for authentication data that may not be a multiple of 16 bytes. To support this, zeroPaddingEncrypt() and zeroPaddingDecrypt() function APIs are provided only for the AES GCM mode.
  - For AES GCM, when using uint32_t arrays in big endian mode, if the number of bytes of data is not a multiple of 4 (WORD length) it should be zero padded.
- The TDES encrypt() and decrypt() functions do not support data padding. These functions operate on data lengths that are multiples of 8 bytes. (Data padding needs to be handled by the user application.)
- HASH Module - MD5
  - MD5 requires byte swapping of the final message digest output. Intermediate updates (partial updates) are not required to be byte swapped.
  - MD5 also requires length field within the formatted final block to be in big endian format before calling the hash hashUpdate API.
- ECC Module:
  - The data buffers for the keyCreate API need to be the exact length of the key that will be generated.
- Refer to the most recent SSP release notes for the most up-to-date limitations on this module.

4.2.10.4 Including the SCE HAL Module in an Application

This section describes how to include the SCE HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack.

To add the SCE Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the SCE HAL module is r_sce. This name can be changed in the associated Properties window.)

SCE Driver Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sce_aes_0 AES Driver on r_sce_aes	Threads	New Stack> Driver> Crypto> AES Driver on r_sce_aes
g_sce_arc4_0 ARC4 Driver on r_sce_arc4	Threads	New Stack> Driver> Crypto> ARC4 Driver on r_sce_arc4
g_sce_dsa_0 DSA Driver on r_sce_dsa	Threads	New Stack> Driver> Crypto> DSA Driver on r_sce_dsa
g_sce_ecc_0 ECC Driver on r_sce_ecc	Threads	New Stack> Driver> Crypto> ECC Driver on r_sce_ecc
g_sce_hash_0 HASH Driver on r_sce_hash	Threads	New Stack> Driver> Crypto> HASH Driver on r_sce_hash
g_sce_key_initialization_0 ECC Driver on r_sce_key_initialization	Threads	New Stack> Driver> Crypto> Key Initialization Driver on r_sce_key_initialization
g_sce_rsa_0 RSA Driver on r_sce_rsa	Threads	New Stack> Driver> Crypto> RSA Driver on r_sce_rsa
g_sce_tdes TDES Driver on r_sce_tdes	Threads	New Stack> Driver> Crypto> TDES Driver on r_sce_tdes
g_sce_trng TRNG Driver on r_sce_trng	Threads	New Stack> Driver> Crypto> TRNG Driver on r_sce_trng

When the Crypto Drivers on r_sce are added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information will be box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks.

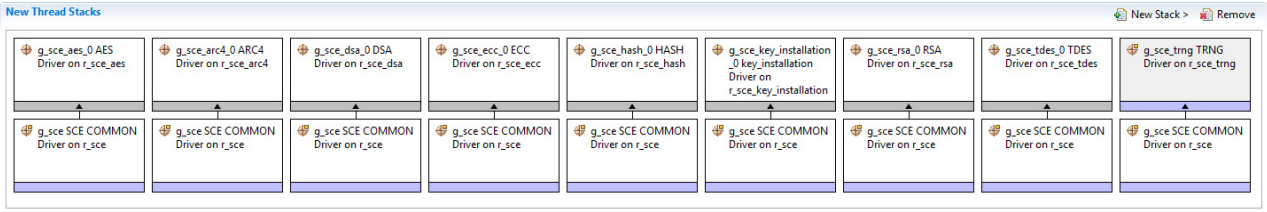

Figure 297: SCE HAL Module Stack (AES, ARC, DSA, ECC, HASH, Key Installation, RSA, TDES, and TRNG included)

4.2.10.5 Configuring the SCE HAL Module

The SCE HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for reference.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

AES HAL Module Parameters and Settings

ISDE Property	Value	Description
Name	g_sce_aes_0	Module name
Key Length	User defined, default is 128 bits. Allowed values for S7G2 and S5D9 devices: 128, 192, or 256 bits. Allowed values for S3A7 and S124 devices: 128 or 256 bits	Key length used for encryption/decryption operations by this instance of the driver
Channel	User defined, default is CBC. Allowed values for S7G2 and S5D9 devices: ECB, CBC, CTR, GCM, XTS. Allowed values for S3A7 device: ECB, CBC, CTR, GCM. Allowed values for S124 device: ECB, CBC, CTR	Block cipher chaining mode used for encryption/decryption operations by this instance of the driver

ISDE Property	Value	Description
Key Format	Plain Text Key, Wrapped Key (Not available for S1 MCU Series) Default: Plain Text Key	Key format selection

ARC4 HAL Module Parameters and Settings

ISDE Property	Value	Description
Name	g_sce_arc4_0	Module name
Key Length	Default 0	Key length in number of bytes
Key Name	g_arc4_0_key	Key name- must be defined as unit8_array type data in user code

DSA HAL Module Parameters and Settings

Parameter	Value	Description
Name	g_sce_dsa_0	Module name
Key Length	User defined, default is (2048, 256) bits. Allowed values for S7G2 and S5D9 devices: (1024, 160), (2048, 224) or (2048, 256) bits Allowed values for S3A7 and S124 devices: Not available.	Key length used for signing/verification operations by this instance of the driver.

ECC HAL Module Parameters and Settings

ISDE Property	Value	Description
Name	g_sce_ecc_0	Module name
Key Length	192, 256 Default: 256	Key length used for encryption/decryption operations by this instance of the driver

ISDE Property	Value	Description
Key Format	Plain Text Key, Wrapped Key (Not available for S1 MCU Series) Default: Plain Text Key	Key format selection

HASH HAL Module Parameters and Settings

Parameter	Value	Description
Name	g_sce_hash_0	Module Name
Algorithm	User defined, default is SHA256. Allowed values for S7G2 and S5D9 devices: SHA1, or SHA256. Allowed values for S3A7 and S124 devices: Not available.	Algorithm used for computing the message digest/hash on the message data.

Key Installation HAL Module Parameters and Settings (Not supported for S1 Series MCUs)

Parameter	Value	Description
Name	g_sce_key_installation_0	Module Name

RSA HAL Module Parameters and Settings

Parameter	Value	Description
Name	g_sce_rsa_0	Module Name
Key Length	User defined, default is 2048 bits. Allowed values for S7G2 and S5D9 devices: 1024 or 2048 bits. Allowed values for S3A7 and S124 devices: Not available.	Key length used for signing/verification/encryption/decryption operations by this instance of the driver
Key Format	Plain Text Key, Wrapped Key (Not available for S1 MCU Series) Default: Plain Text Key	Key format selection

TDES HAL Module Parameters and Settings

Parameter	Value	Description
Name	g_sce_tdes_0	Module Name
Chaining Mode	ECB, CBC, CTR Default: CBC	Chaining mode selection

TRNG HAL Module Parameters and Settings

Parameter	Value	Description
Name	g_sce_trng_0	Module Name
Max. Attempts	User defined, default is 2	Sets the maximum number of attempts when a newly generated random number differs from the previously generated random number

4.2.10.6 Using the SCE HAL Module in an Application

The SCE COMMON module must be initialized prior to calling any other crypto operation. This is done by using the open API. (For example, g_sce.p_api->open(g_sce.p_ctrl, g_sce.p_cfg);

Other SCE COMMON APIs can be used to determine SCE operation. For example, the initialization status of the SCE module can be obtained by using the statusGet API. The interfaceGet API can be used to obtain interface information. See the SCE COMMON API table for additional information.

The typical steps in using the SCE HAL module in an example AES application are:

1) Use the SCE open API to initialize the SCE COMMON module. This must be called prior to any other crypto operation.
2) Specify parameters using the associate API (AES addAdditionalAuthenticationData, for example).
3) Use the AES open API to start the AES module.
4) Encrypt data using the encrypt API.
5) Decrypt data using the decrypt API.
6) Close the SCE instance using the SCE close API.

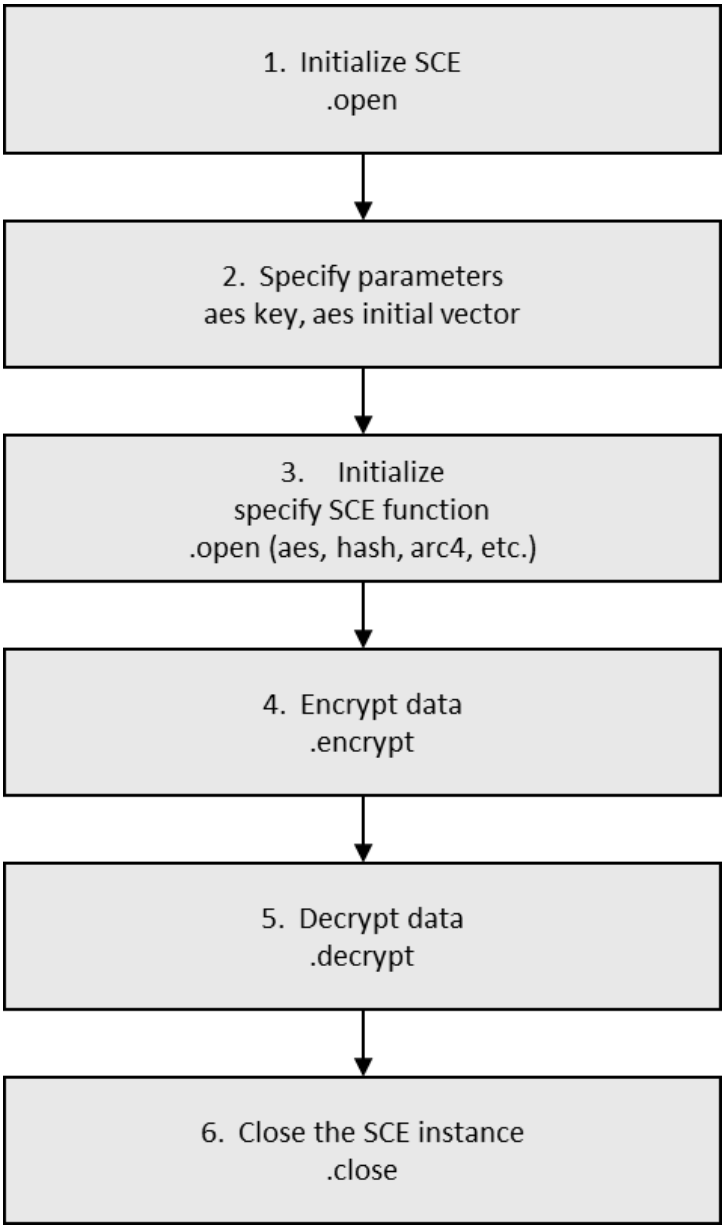

Figure 298: Flow Diagram of a Typical Cryptography Application

Specific cryptographic flows and associated use notes are given below:.

1) To use the SCE module:

- Use the open API to Initialize the SCE and the SCE HAL module (R_SCE) through the SCE common driver.

- Configure the endianness (little-endian or big-endian) for the input /output data for all the HAL APIs. The big endian mode is configured by default. See HAL Module Operational notes for details on endianness configuration.
- The open function cannot be called again until the module is closed.

2) To use the AES functions:

- Initialize an AES interface instance with open API.
- Specify the configuration parameters for the instance to use the associated APIs. AES key sizes available are 128-bit, 192-bit or 256-bit. Chaining modes supported are ECB, CBC, CTR, GCM and XTS.
- To encrypt data, use the encrypt API.
- To decrypt data, use the decrypt API.
- To generate keys, use the createKey API.

NOTE: The createKey API in the AES module creates AES wrapped keys.

AES plain text keys can be generated with the services of the TRNG module.

- Close the interface instance with close API.
- IV provided for AES GCM operations can be either 96-bits or a 96-bit IV formatted to 128-bits.

– **Example:**

– **96-bit IV: 94c1935afc061cbf254b936f**

– **96-bit IV formatted to 128-bits: 94c1935afc061cbf254b936f00000001**

Note that subtle differences exist in GCM operations as follows.

AES GCM encryption:

1) AAD (Additional Authenticated Data) is optional. If it is to be used, it has to be provided prior to encrypting / decrypting any data by setting p_dest = NULL
2) Encryption: set p_source to input data and p_dest will return encrypted data
3) Get/Compute Tag: set p_source = NULL.

AES GCM decryption:

1) Set expected tag value using the setGcmTag() function
2) Provide any Add Authentication Data (AAD), invoke this API using p_dest = NULL
3) Decryption: set p_source to input encrypted data, decrypted data will be returned in p_dest
4) To verify the tag, invoke this API using p_source = NULL and p_dest = NULL. The return value indicates authentication tag verification status.The decrypted data is to be used only if the tag is verified successfully.zeroPaddingEncrypt/zeroPaddingDecrypt APIs can be used for GCM operations when the data is not a multiple of the block size.
5) To use the TDES functions:

- Initialize the TDES interface instance with open API.
- Specify the configuration parameters for the instance to use the associated APIs. Select the TDES chaining mode ECB, CBC or CTR.
- Encrypt data using the encrypt API.
- Decrypt data using the decrypt API
- Close the interface instance with close API.

6) To use the ARC4 functions:

- Initialize an ARC4 interface instance with open API.
- Specify the configuration parameters for the instance to use the associated APIs. ARC4 key can be specified by length (anywhere from 64-bits, 2048-bits) and location.
- The key to be used can be set through the keySet API.
- To encrypt or decrypt data use the arc4Process API.
- Close the interface instance with close API.

7) To use the RSA functions:

- Supported key-lengths are 1024-bits and 2048-bits.

  NOTE: For encryptAPI, decrypt API, decryptCrt API, sign and signCrt API: The size of the data buffer is indicated in num_words. It must be 32 words /128 bytes/1024-bits for 1024-bit keys and 64 words /256 bytes/2048-bits for the 2048-bit keys.

- Select the RSA interface instance based on the desired key length and initialize the selected RSA interface instance with open API.
- To encrypt data using RSA public Key use the encrypt API.
- To Decrypt data using RSA private Key use the decrypt API.
- To Decrypt data using RSA private Key which is in the CRT format use the decryptCrt API.
- To generate signature for a given padded hash using RSA private Key which is in the standard format use the sign API.
- To generate signature for a given padded hash using RSA private Key which is in the CRT format use the signCrt API.
- To verify signature for a given padded hash using RSA public Key which is in the standard format use the verify API.

– **To generate keys use the keyCreateKey API.**

  NOTE: keyCreate API in RSA module creates RSA plain-text keys or wrapped keys based on the input parameters to the API.

- Close the interface instance with close API.

8) To use the DSA functions:
   - Supported key-lengths are (1024,160)-bits, (2048,224)-bits and (2048,256)-bits
   - Select the DSA interface instance based on the desired key length and initialize the selected DSA interface instance with open API.
   - To generate signature using the DSA private key use hashSign API.
   - To verify signature using the DSA public key use hashVerify API.
   - Close the interface instance with close API.
9) To use the HASH algorithms:
   - MD5, SHA1 and SHA256 hash methods are supported. Select the desired
   - To compute the message digest use hashUpdate API.
   - Close the interface instance with close API.
10) To use the True Random Number Generator functions:
   - Initialize an TRNG interface instance with open API.
   - Generate random number with read API.
   - Close the interface instance with close API.
11) To use the Key Installation API:
   - Initialize Key Installation interface instance with open API.
   - Specify Key installation key structures for the user's encrypted key and Renesas provided key index (key size, key format, pointer to buffer and buffer length).
   - Specify Output key structure with pointer to buffer and buffer length.
   - To install the key use keyInstall API.
   - Close the interface instance with close API.
12) To use the ECC functions:
   - To generate the domain parameters for NIST curves, use OpenSSL command to generate curves as shown below.
   - **ECC P-192: openssl ecparam -name secp192r1 -param_enc explicit -text | more**
   - **ECC P-256: openssl ecparam -name secp256r1 -param_enc explicit -text | more**
   - Supported key sizes are 192-bits and 256-bits.

NOTE: For scalarMultiplication API keyCreate, sign and verify API: The size of the data buffer is indicated in data_length field of r_crypto_data_handle_t. The actual buffer must be pointed by p_data field of r_cryp-

to_data_handle_t. Select the ECC interface instance based on the desired key length and key type and initialize the selected ECC interface instance with open API.

- To perform ECC Scalar Multiplication use the scalarMultiplication API.
- To generate signature for a given padded hash using ECC private Key which is in the standard format use the sign API.
- To verify signature for a given padded hash using ECC public Key which is in the standard format use the verify API.
- To generate ECC keys use the keyCreate API.
- Close the interface instance with close API.

Close the SCE and the SCE HAL module using the close API.

4.2.11 DAC Driver

The DAC HAL module provides high-level APIs for digital-to-analog conversion applications implemented on r_dac. The DAC HAL module supports a dual-channel 12-bit D/A converter (DAC12) peripheral on Synergy MCUs.

4.2.11.1 DAC HAL Module Features

This module configures the dual-channel 12-bit D/A Converter (DAC12) to output one of 4096 voltage levels between the positive and negative reference voltages. The module include configuration settings to:

- Set either a left-justified or right-justified 12-bit value format for the 16-bit input data registers
- Enable or disable output amplifiers
- Operate in synchronous anti-interference mode with the Analog-to-Digital Converter (ADC) module.

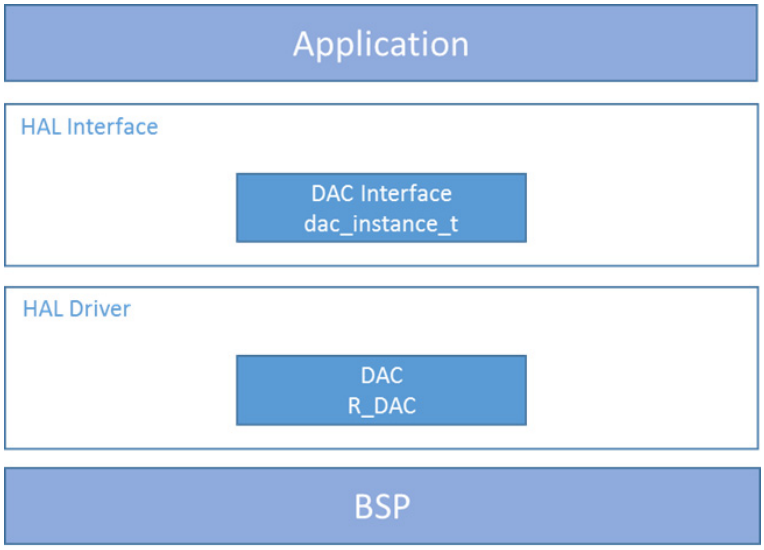

Figure 299: DAC HAL Module Block Diagram

4.2.11.2 DAC HAL Module APIs Overview

The DAC HAL module defines APIs to open, close, start, stop and write to the DAC. The following table lists each of the APIs available with an example call and a short description. A listing of status return values follows the API summary table.

DAC HAL Module API Summary

Function Name	Example API Call and Description
open	g_dac.p_api->open(g_dac.p_ctrl, g_dac.p_cfg) Initial Configuration.
close	g_dac.p_api->close(g_dac.p_ctrl) Close the D/A Converter.
write	g_dac.p_api->write(g_dac.p_ctrl, val) Write Sample value to the D/A Converter.

Function Name	Example API Call and Description
start	g_dac.p_api->start(g_dac.p_ctrl) Start the D/A Converter if it has not been started yet.
stop	g_dac.p_api->stop(g_dac.p_ctrl) Stop the D/A Converter if the converter is running.
versionGet	g_dac.p_api->versionGet(&version) Retrieve the API version with the version pointer.

NOTE: Review the *SSP User's Manual* API References for the associated module. The SSP defines operations, function data structures, typedefs, defines, API data, API structures, and function variables.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	Wrong parameter.
SSP_ERR_IN_USE	DAC resource is locked.

NOTE: Lower-level drivers may return common error codes. Refer to API References in the *SSP User's Manual* for a definition of relevant status return values in the associated module.

4.2.11.3 DAC HAL Module Operational Overview

The DAC HAL module configures the dual-channel 12-bit D/A converter (DAC12) to output one of 4096 voltage levels between positive and negative reference voltages. The module can be used to configure the 12-bit output to left-or-right-justified format for 16-bit input data registers. The DAC HAL module can also enable or disable output amplifiers or operate in synchronous anti-interference mode with the ADC HAL module.

DAC HAL Module Important Operational Notes and Limitations

The DAC HAL module requires the following initialization steps:

- DAC module stop-bit cleared to zero.

- DAC channel output-enable set to one.

The DAC module stop-bit is cleared to zero at the time of an open call when the driver's instance counter is zero. The driver's instance counter is initialized to zero, incremented when a channel open returns successfully, and decremented when a channel close is called. The DAC module stop-bit is set to one when the driver's instance counter is decremented to zero on a close call.

The DAC channel output-enable is set to one when a channel write is called the first time after open was called successfully. The open call writes a zero to the dac_ctrl_t structure element channel_started. When write is called with channel_started cleared to zero, the DAC output-enable bit for that channel is set to one. The DAC output-enable for the channel is cleared to zero on close and stop calls.

- Pin configuration is not implemented for the DAC HAL module. Currently, DA0 and DA1 outputs are enabled by the reset values in the pin configuration control register's ASEL field.
- Voltage reference selection for the DAC HAL module is not implemented. Currently, no reference is selected by the reset values in the D/A VREF control register (DAVREFCR) which is a valid condition.
- Configuration of DAC input-event triggering for conversion is not currently implemented. The default reset value (zero) of the control register DAE bit allows individual triggering for each channel.
- Event signal-input for synchronization of the DAC HAL module conversions is not currently implemented.
- Refer to the latest SSP Release Notes for operational limitations related to this module.

4.2.11.4 Including the DAC HAL Module in an Application

This section describes how to include the DAC HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications

To add the DAC Driver to an application, use the stacks selection sequence in the following table. (The default name for the DAC is g_dac0. This name can be changed in the associated Properties window.)

Tale DAC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_dac0 DAC Driver on r_dac	Threads	New Stack > Driver > Analog > DAC Driver on r_dac

When the DAC HAL module on DAC is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level drivers. Any drivers that need additional configuration information will be box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

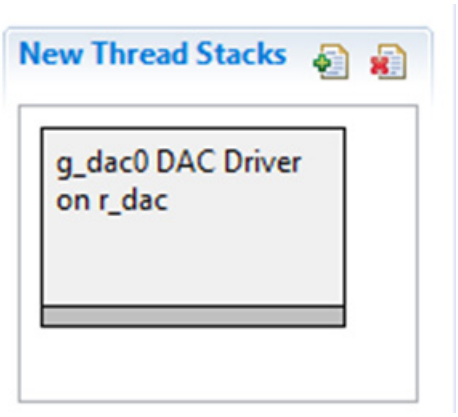

Figure 300: DAC HAL Module Stack

4.2.11.5 Configuring the DAC HAL Module

The DAC HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window. The interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+.) This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the DAC HAL Module on r_dac

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Enables or disables the parameter checking.
Name	g_dac0	Module Name.

ISDE Property	Value	Description
Channel	0,1	Set to 0 for output DA0 or 1 for output DA1.
Synchronize with ADC	Enabled, Disabled (Default: Disabled)	Set to true for anti-interference synchronization with the Analog-to-Digital Converter (ADC) Module. Set to false if the power supply interference between the analog modules is not a problem, or if the asynchronous conversion by the DAC Module is desired.
Data Format	Right Justified, Left Justified (Default: Right Justified)	Set to zero if 12-bit data values are loaded in bits 11 through 0, or right justified. Set to one, if 12-bit data values are loaded in bits 15 through 4, or left justified.
Output Amplifier	Enable, Disable (Default: Disable)	Set to true, if output amplifier hardware function is desired. Set to false to bypass output amplifier hardware function.

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults can be desirable. For example, it might be useful to select different events, depending on the operation desired.

DAC HAL Module Clock Configuration

The DAC HAL module does not require any specific clock configuration.

DAC HAL Module Pin Configuration

To use the DAC HAL module, the port pins for the channels receiving the analog input must be set as analog pins in the pin configurator. The following table lists a method to select pins within the SSP configuration window. The subsequent table illustrates configuration settings for DAC pins.

Pin Selection Sequence for the DAC Driver on r_dac

Resource	ISDE Tab	Pin Selection Sequence
DAC	Pins	Select Peripherals > Analog: DAC12 > DAC120

Pin Configuration Settings for the DAC Driver on r_dac

Property	Value	Description
Module Name	DAC120	DAC Peripheral Module.
Operation Mode	Enabled, Disabled (Default: Enabled)	DAC Peripheral operation mode.
DA0	None, DA0 (Default: None)	DAC Output Pin.
DA1	None, DA1 (Default: None)	DAC Output Pin.

NOTE: The example settings illustrate a project using the Synergy S7G2 and SK-S7G2 Kits. Other Synergy Kits and Synergy MCUs may have pin configuration settings that differ in availability.

4.2.11.6 Using the DAC HAL Module in an Application

The typical steps in using the DAC HAL module in an application are:

1) Initialize the DAC HAL module using the open API.
2) Write a data value using the write API.
3) Start writing data using the start API.
4) Continue writing data values as needed using the write API.
5) Stop writing data using the stop API.
6) Close the DAC HAL module using the close API.

The following figure shows common steps in a typical operational flow:

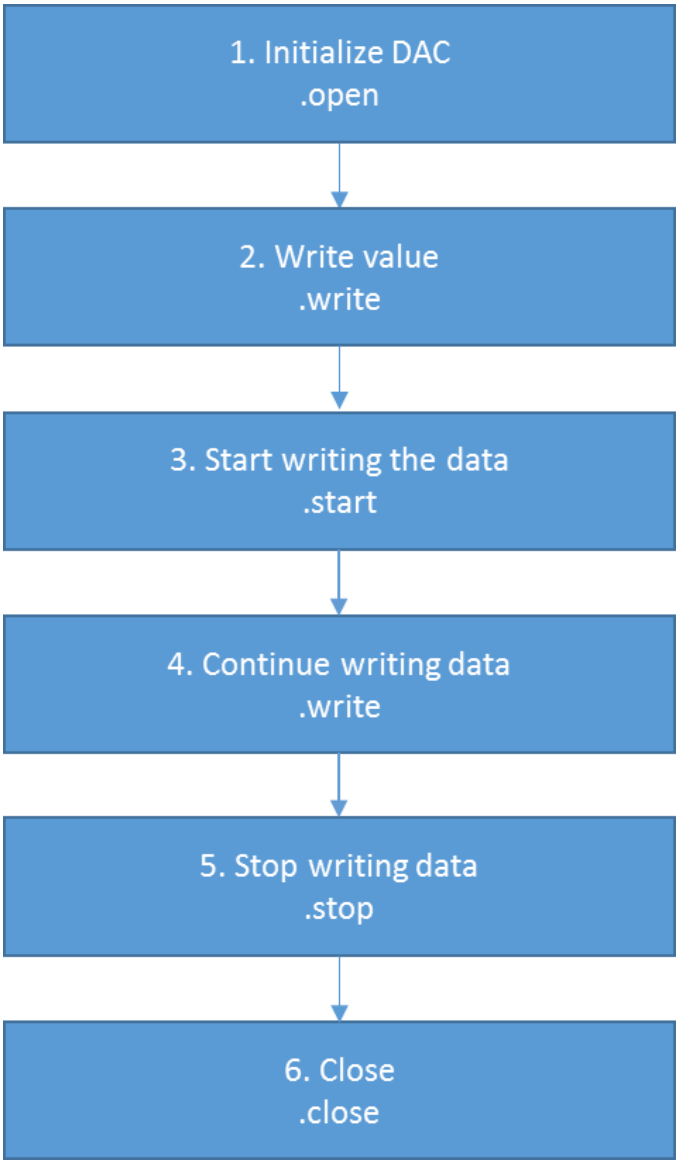

Figure 301: Typical DAC HAL Module application flow diagram

4.2.12 DAC 8 Driver

4.2.12.1 DAC 8 Driver

The DAC 8 HAL module provides high-level APIs for digital-to-analog conversion applications implemented on r_dac8. The DAC 8 HAL module supports an 8-bit D/A converter (DAC 8) peripheral on Synergy S128 MCUs.

4.2.12.2 DAC 8 HAL Module Features

- Available on the Synergy S128 MCU
- 8-Bit D/A Converter- three channels
- Left-Justified or Right-Justified Input Data Format
- Synchronization with the Analog-to-Digital Converter (ADC) module
- Multiple Operation Modes
  - Normal
  - Real-Time (Event Link)
- Charge Pump Control

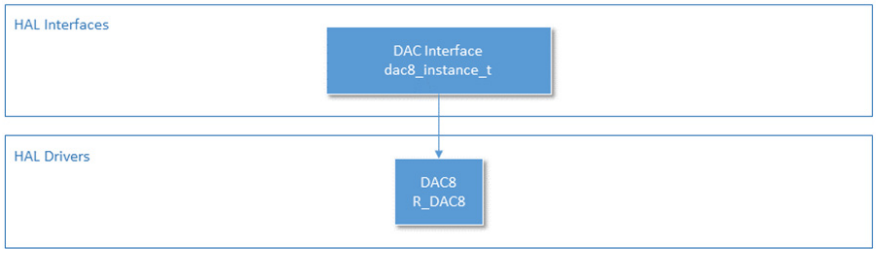

Figure 302: DAC 8 HAL Module Organization, Options and Stack Implementations

4.2.12.3 DAC 8 HAL Module APIs Overview

The DAC 8 HAL module defines APIs for opening, closing, starting, stopping, and writing to the DAC. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows.

DAC 8 API HAL Module Summary

Function Name	Example API Call and Description
open	g_dac8.p_api->open(g_dac8.p_ctrl, g_dac8.p_cfg) Initial Configuration.
close	g_dac8.p_api->close(g_dac8.p_ctrl) Close the D/A Converter.

Function Name	Example API Call and Description
write	g_dac8.p_api->write(g_dac8.p_ctrl, val) Write Sample value to the D/A Converter.
start	g_dac8.p_api->start(g_dac8.p_ctrl) Start the D/A Converter if it has not been started yet.
stop	g_dac8.p_api->stop(g_dac8.p_ctrl) Stop the D/A Converter if the converter is running.
versionGet	g_dac8.p_api->versionGet(&version) Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the *SSP User's Manual* API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_HW_LOCKED	DAC resource is locked.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	Wrong parameter.
SSP_ERR_IP_CHANNEL_NOT_PRESENT	Wrong channel selected.

NOTE: Lower level drivers may return Common Error Codes. Refer to SSP User's Manual* API References for the associated module for a definition of all relevant status return values.

4.2.12.4 DAC 8 HAL Module Operational Overview

The DAC 8 HAL module configures the 8-bit D/A converter (DAC 8) to output one of 256 voltage levels between positive and negative reference voltages. The driver can be configured to accept the 8-bit output data in left-or-right-justified format in a 16-bit input data. The driver supports two modes for the DAC.

- Normal mode – The D/A output is updated on writes to the data register.
- Real-Time (Event Link) – The D/A output is updated on an Event Link event. While in this mode the data register can be written at any time. An Event Link event triggers the start of conversion. Refer to the "ELC Interface" in the *SSP User's Manual* for more information.

To reduce the noise present in ADC readings the driver can configure synchronous anti-interference mode with the ADC module. This reduces conversion noise by disabling the DAC charge while the ADC is sampling. Check the hardware manual to determine if this feature is supported.

For operation at low AVCC voltage the driver can enable or disable the hardware charge pump.

4.2.12.5 DAC 8 HAL Module Important Operational Notes and Limitations

4.2.12.6 DAC 8 HAL Module Operational Notes

The DAC 8 channel output is enabled during dac8_api_t::start() and dac8_api_t::write() and disabled during dac8_api_t::stop() and dac8_api_t::close().

4.2.12.7 DAC 8 HAL Module Limitations

- The DAC 8 uses the DAC 8 peripheral available on the Synergy S128 MCU.
- The DAC 8 driver does not configure the output pins for analog output.
- The DAC 8 driver does not configure the ELC peripheral for real-time mode. The user needs to configure the Event Link Controller in addition to enabling real-time mode in the DAC 8 module.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.12.8 Including the DAC 8 HAL Module in an Application

This section describes how to include the DAC 8 HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the *SSP User's Manual* to learn how to manage each of these important steps in creating SSP based applications.

To add the DAC 8 Driver to an application, simply add it to a thread using the Stacks Selection Sequence provided in the following table. (The default name for the DAC is g_dac8_0. This name can be changed in the associated Properties window.)

DAC Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_dac8_0 DAC Driver on r_dac8	Threads	New Stack > Driver > Analog > DAC Driver on r_dac8

When the DAC HAL module on DAC is added to the Thread Stack as shown in the following figure, the configurator automatically adds any needed lower level drivers. Any drivers that need additional configuration information is box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

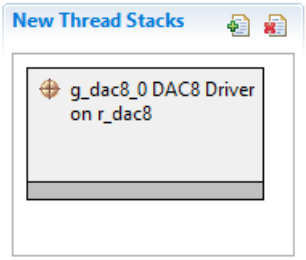

Figure 303: DAC 8 HAL Module Stack

4.2.12.9 Configuring the DAC 8 HAL Module

The DAC 8 HAL module must be configured by you for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections (such as interrupts or operating modes) which must be configured for lower level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the properties tab within the SSP Configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the properties window of the associated module. Simply select the indicated module and then view the properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the properties window in the ISDE includes an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+.) This level of detail is not included in the configuration properties tables below, but is easily visible with the ISDE when configuring interrupt priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the Configuration Table Settings given below. This helps to orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for DAC 8 HAL Module

Parameter	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Enable or disable the parameter error checking.

Parameter	Value	Description
Name	g_dac8_0	Module name
Channel	0	Channel selection- three channels are supported.
Synchronize with ADC	Enabled, Disabled (Default: Disabled)	Choose whether to sync with the ADC module
Data Format	Right Justified, Left Justified (Default: Right Justified)	Data format selection
DAC Mode	Normal Mode, Real-time (Event Link) Mode (Default: Normal Mode)	DAC mode selection
Charge Pump Enabled (Requires MOCO active)	Enabled, Disabled (Default: Enabled)	Enable or disable the charge pump

NOTE: The above setting examples and defaults are for a project using the Synergy S1 MCU Family.

In some cases, settings other than the defaults for module properties can be desirable. For example, it might be useful to enable the output amplifier in some applications.

4.2.12.10 DAC 8 HAL Module Clock Configuration

The DAC 8 HAL module requires no specific clock configuration.

4.2.12.11 DAC 8 HAL Module Pin Configuration

To use the DAC 8 HAL module, the port pins for the channels receiving the analog input must be set as analog pins in the pin configurator. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table has an example selection for the DAC pins.

Pin Selection Sequence for the DAC 8 Driver on r_dac8

Resource	ISDE Tab	Pin Selection Sequence
DAC 8	Pins	Select Peripherals > Analog:DAC8 > DAC80

Pin Configuration Settings for the DAC 8 Driver on r_dac8

Property	Value	Description
Module Name	DAC80	DAC Peripheral Module.
Operation Mode	Enabled, Disabled (Default: Enabled)	DAC Peripheral operation mode.
DA0	None, DA0 (Default: None)	DAC Output Pin.
DA1	None, DA1 (Default: None)	DAC Output Pin.

NOTE: The above example settings are for a project using the Synergy S128 MCU and the DK-S128 Kit.

4.2.12.12 Using the DAC 8 HAL Module in an Application

The typical steps in using the DAC 8 HAL module in an application are:

1) Initialize the DAC 8 HAL module using the dac8_api_t::open API.
2) Write a value using the dac8_api_t::write API.
3) Start a conversion using the dac8_api_t::start API.
4) Continue writing values as needed using the dac8_api_t::write API.
5) Stop conversion using the dac8_api_t::stop API.
6) Use the dac8_api_t::close call to power down the peripheral.

The preceding steps are shown in a typical operational flow diagram in the following figure.

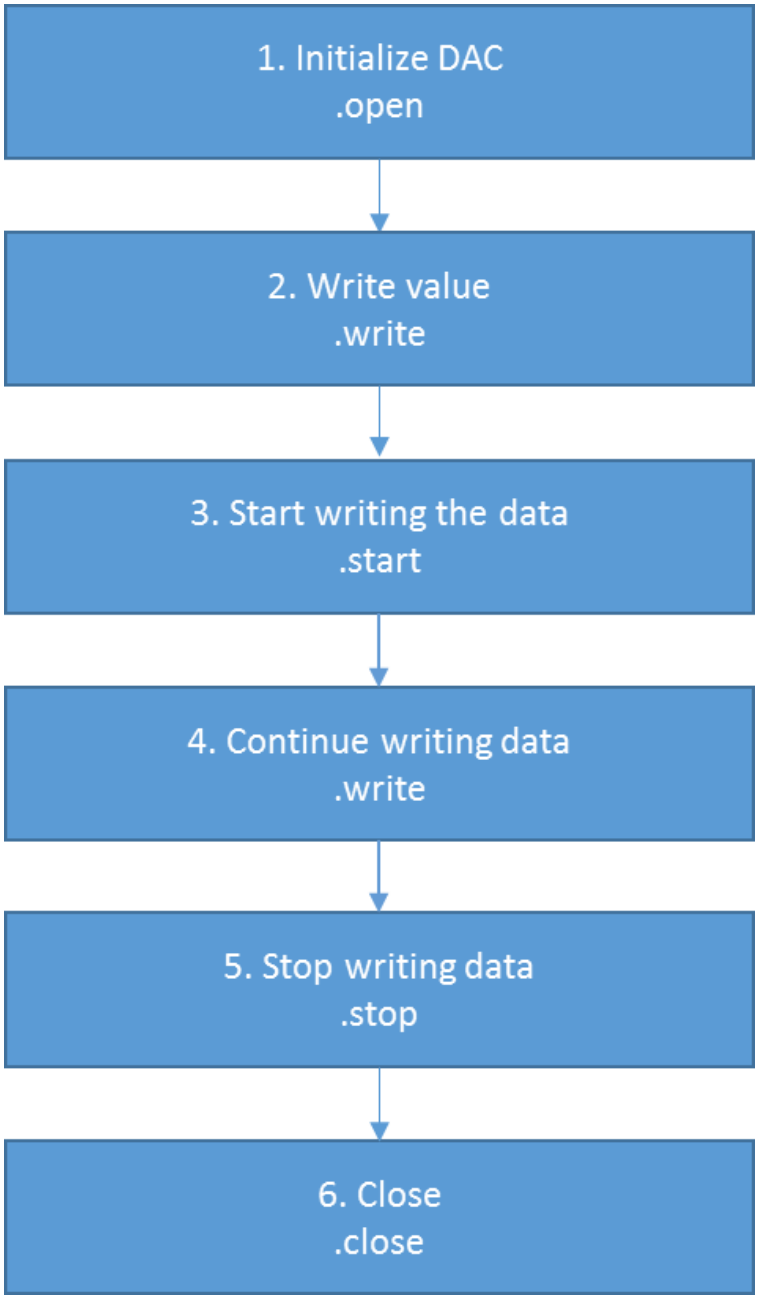

Figure 304: Flow Diagram of a Typical DAC 8 HAL Module Application

4.2.13 GLCDC Display Driver

The Graphics LCD Controller (GLCDC) HAL module is a high-level API for GLCDC applications and is implemented on r_glcd. The GLCDC HAL module uses the Graphics LCD Driver peripheral on the Synergy MCU. A user-defined callback can be created to handle frame buffer switching and underflow detection.

4.2.13.1 GLCDC HAL Module Features

- Supports LCD panels with RGB interface (up to 24 bits) and sync signals (HSYNC, VSYNC, and Data Enable (optional)
- Supports various color formats for input graphics planes (RGB888, ARGB888, RGB565, ARGB1555, ARGB4444, CLUT8, CLUT4, CLUT1)
- Supports the Color Look-Up Table (CLUT) usage for input graphics planes with 512 words (32 bits/word)
- Supports various color formats for output (RGB888, RGB666, RGB565, Serial RGB)
- Can input two graphics planes on top of the background plane and blend them on the screen
- Generates a dot clock to the panel. The clock source is selectable from internal or external (LCD_EXTCLK)
- Supports brightness adjustment, contrast adjustment and gamma correction
- Supports GLCDC interrupts to handle frame-buffer switching or underflow detection

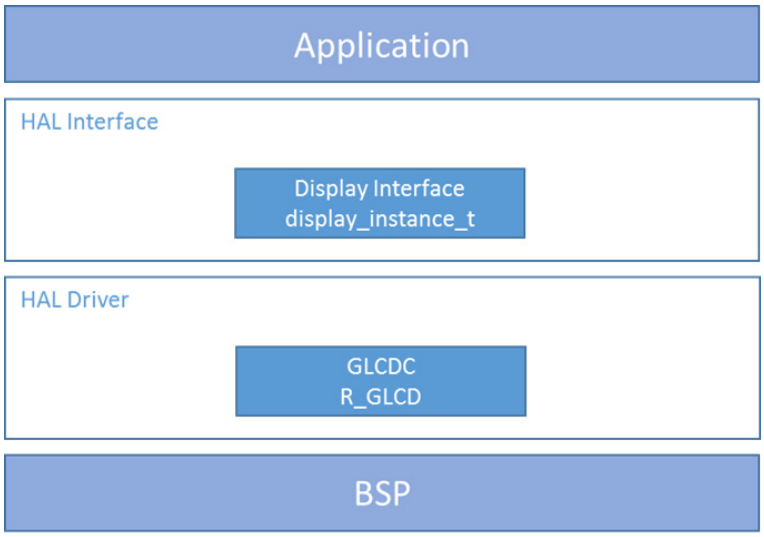

Figure 305: GLCDC HAL Module Block Diagram

4.2.13.2 GLCDC HAL Module APIs Overview

The GLCDC HAL module defines APIs for opening, closing, starting, stopping and controlling the display of information on an LCD panel. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

GLCDC HAL Module API Summary

Function Name	Example API Call and Description
open	g_display.p_api->open (g_display.p_ctrl, g_display.p_cfg); Open display device.
close	g_display.p_api->close (g_display.p_ctrl); Close display device.
start	g_display.p_api->start(g_display.p_ctrl); Display start.
stop	g_display.p_api->stop(g_display.p_ctrl); Display stop.
layerChange	g_display.p_api->layerChange(g_display.p_ctrl, &layercng, frame) Change layer parameters at runtime.
correction	g_display.p_api->correction(g_display.p_ctrl, &display_correction) Color correction.
clut	g_display.p_api->clut(g_display.p_ctrl, &clut, frame) Set CLUT for display device.
statusGet	g_display.p_api->statusGet(g_display.p_ctrl, &status) Get status for display device.
versionGet	g_display.p_api->versionGet(&version) Retrieve the API version using the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API call successful.
SSP_ERR_ASSERTION	Parameter has invalid value.
SSP_ERR_INVALID_ARGUMENT	Invalid parameter in the argument.
SSP_ERR_HW_LOCKED	GLCDCC resource is locked.
SSP_ERR_CLOCK_GENERATION	Dot clock cannot be generated from clock source.
SSP_ERR_INVALID_TIMING_SETTING	Invalid panel timing parameter.
SSP_ERR_INVALID_LAYER_SETTING	Invalid layer setting found.
SSP_ERR_INVALID_LAYER_FORMAT	Invalid format is specified.
SSP_ERR_INVALID_GAMMA_SETTING	Invalid gamma correction setting found.
SSP_ERR_NOT_OPEN	The function call is performed when the driver state is equal to DISPLAY_STATE_CLOSED.
SSP_ERR_INVALID_UPDATE_TIMING	A function call is performed when the GLCDC is updating register values internally.
SSP_ERR_INVALID_MODE	Function call is performed when the driver state is not DISPLAY_STATE_OPENED.
SSP_ERR_INVALID_CLUT_ACCESS	Illegal CLUT entry or size is specified.
p_version	The version number.

NOTE: Lower level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.13.3 GLCDC HAL Module Operational Overview

The GLCDC HAL module controls an LCD panel. The following figure shows an overview of the graphics data flow using the GLCDC HAL module. The module supports reading graphics frame image data from memory (up to two frames)

and blending those images on top of the monochrome background screen. The driver supports CLUT memory and specifies the graphic frame format for the CLUT.

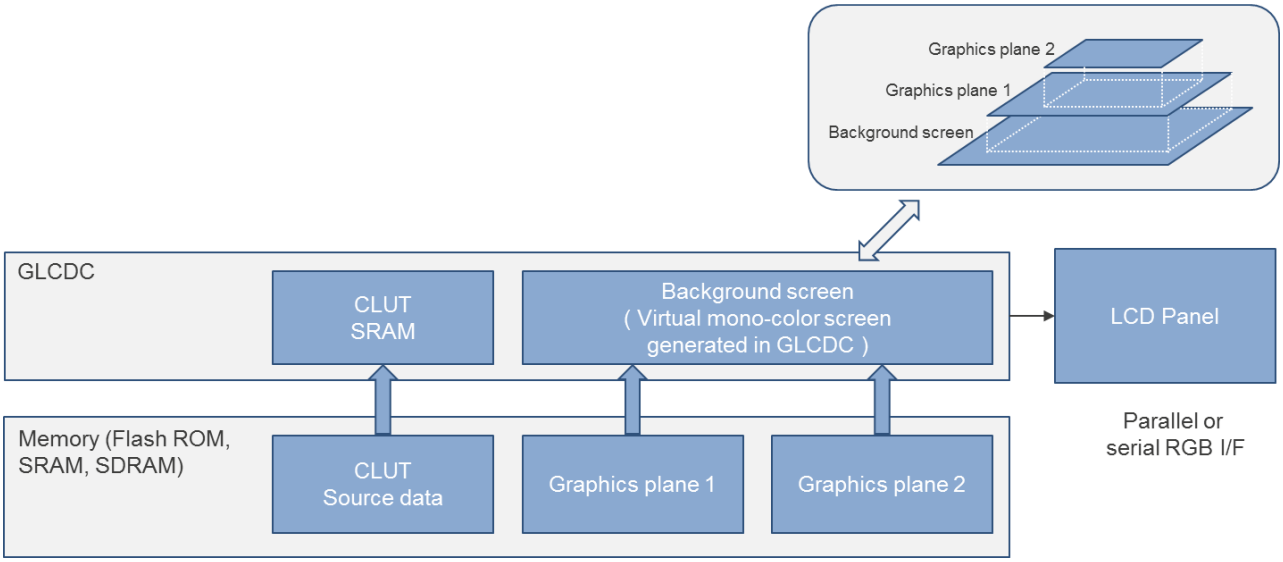

Figure 306: GLCDC Data Flow

The following figure shows a display system with a ping-pong frame buffer. It is recommended to have more than two frame buffers in a display system to avoid image tearing, which happens in a single frame buffer display system. In such designs, the GLCDC hardware can read a graphics frame image from one of the frame buffers while the image drawing engines (e.g. DRW and JPEG), CPU or DMAC/DTC transfer a graphics frame image to another frame buffer simultaneously. The module supports frame buffer toggling by the layerChange API at run-time.

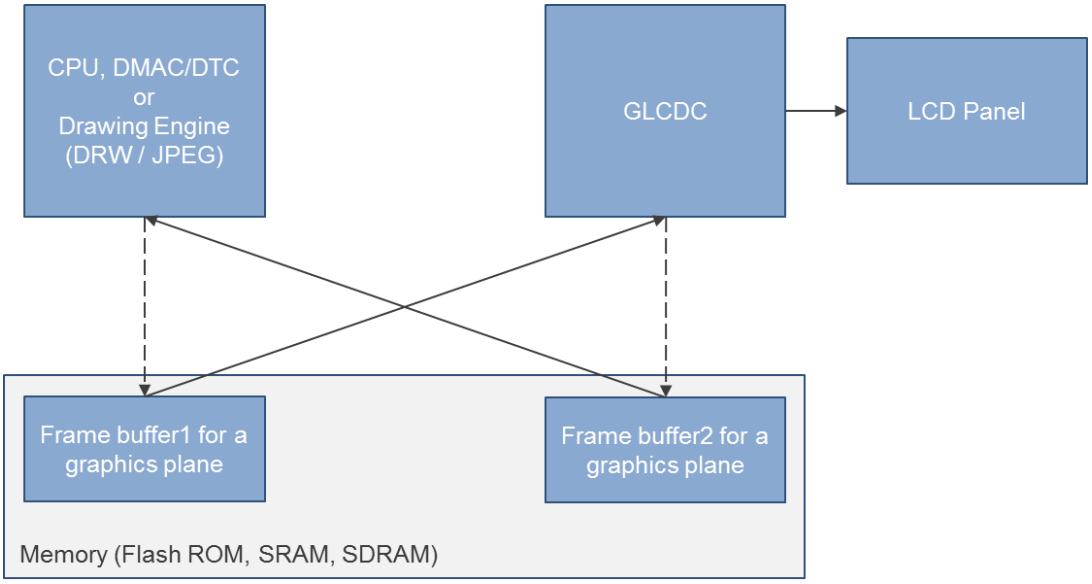

Figure 307: GLCDC Display- Typical ping-pong buffer system using GLCDC

Screen Format

The following figure shows the relationship between the LCD screen format and LCD timing parameters of the GLCDC module. The module has generic timing parameters for the LCD panel setting that support a variety of LCD panels.

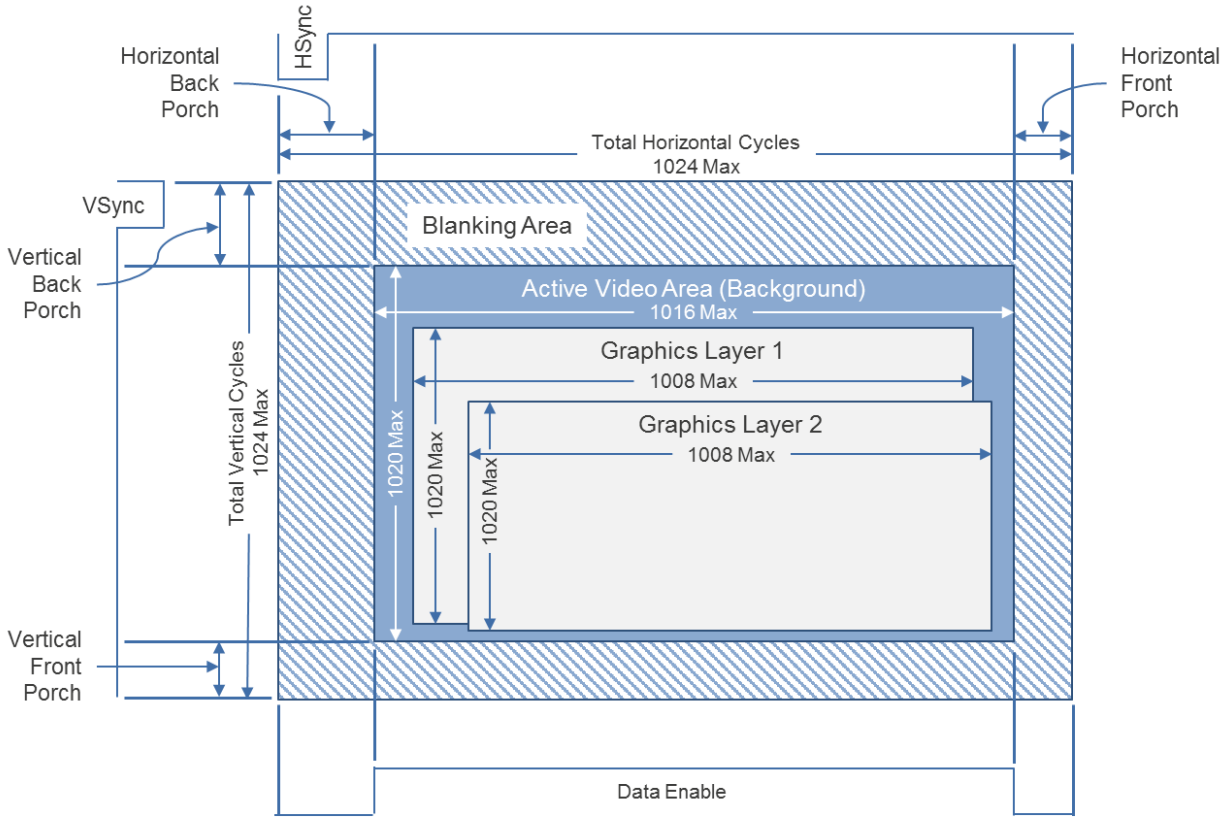

Figure 308: GLCDC Screen Format

Front Porch Period

The GLCDC module does not have a setting for horizontal/vertical front porch cycles/lines. Those cycles/lines must be included in the total horizontal cycles/vertical lines setting.

NOTE: The module requires setting the back porch cycles/lines based on the GLCDC hardware specification. Since typical LCD panels have a greater number of back porch cycles/lines than described, this is not a true limitation of the module.

- Number of the horizontal back porch cycles >= 3
- Number of the vertical back porch lines >= 2

Example Parameter Settings

PE-HMI1 v2.0 board (LXD Research & Display, LLC, M7504A):

The following example adjusts the horizontal total cycles, vertical total lines, and panel clock division ratio to generate an LCD panel refresh rate of 60 Hz. Regarding symbols for the LCD panel, see the M7504A data sheet.

LCD Panel Parameter Settings — PE-HMI1 v2.0 Board

ISDE Property	Setting
Panel clock source select	Internal clock
Graphics screen1/2 input horizontal size	800(thd)
Graphics screen1/2 input vertical size	480(tvd)
Graphics screen1/2 input horizontal stride	800(thd)
Horizontal total cycles	976(th)
Horizontal active video cycles	800(thd)
Horizontal back porch cycles	46(thp + thb)
Horizontal sync signal cycles	20(thp)
Horizontal sync signal polarity	Low active
Vertical total lines	512(tv)
Vertical active video lines	480(tvd)
Vertical back porch cycles	23(tvp + tvb)
Vertical sync signal lines	10(tvp)
Vertical sync signal polarity	Low active
Output Format	24bits RGB888
Data Enable Signal Polarity	High active
Sync edge	Rising edge
TCON - Hsync pin select	LCD_TCON0
TCON - Vsync pin select	LCD_TCON1
TCON - DataEnable pin select	LCD_TCON2
TCON - Panel clock division ratio	1/8

DK-S7G2 v3.0 board (LXD Research & Display, LLC, M7190A):

The following example adjusts the horizontal total cycles, vertical total lines, and panel clock division ration to generate an LCD panel refresh rate of 60 Hz. Regarding symbols for the LCD panel, see the M7190A data sheet.

LCD Panel Parameter Settings — DK-S7G2 v3.0 Board

ISDE Property	Setting
Panel clock source select	Internal clock
Graphics screen N input horizontal size	480(thd)
Graphics screen N input vertical size	272(tvd)
Graphics screen N input horizontal stride	480(thd)
Horizontal total cycles	582(th)
Horizontal active video cycles	480(thd)
Horizontal back porch cycles	43(thp + thb)
Horizontal sync signal cycles	41(thp)
Horizontal sync signal polarity	Low active
Vertical total lines	286(tv)
Vertical active video lines	272(tvd)
Vertical back porch cycles	12(tvp + tvb)
Vertical sync signal lines	10(tvp)
Vertical sync signal polarity	Low active
Output Format	16bits RGB565
Data Enable Signal Polarity	High active
Sync edge	Rising edge
TCON - Hsync pin select	LCD_TCON1
TCON - Vsync pin select	LCD_TCON2
TCON - DataEnable pin select	LCD_TCON0
TCON - Panel clock division ratio	1/24

SK-S7G2 v2.0 board (ILI Technology Corp., IL9341C):

The following example sets the horizontal total cycles and vertical total lines as large as allowed for the panel for an LCD panel refresh rate of about 76.8 Hz. Regarding symbols for the LCD panel, see the LIL9314V data sheet.

LCD Panel Parameter Settings — SK-S7G2 v2.0 Board

ISDE Property	Setting
Panel clock source select	Internal clock
Graphics screen N input horizontal size	256(See note)
Graphics screen N input vertical size	320(VAdr)
Graphics screen N input horizontal stride	256(See note)
Horizontal total cycles	290(HAdr + Hsync(16) + HBP(24) + HFP(16))
Horizontal active video cycles	240(HAdr)
Horizontal back porch cycles	40(Hsync(16) + HBP(24))
Horizontal sync signal cycles	16(Hsync)
Horizontal sync signal polarity	Low active
Vertical total lines	330(VAdr + Vsync(4) + VBP(2) + VFP(4))
Vertical active video lines	320(VAdr)
Vertical back porch cycles	6(Vsync + VBP)
Vertical sync signal lines	4(Vsync)
Vertical sync signal polarity	Low active
Output Format	16bits RGB565
Data Enable Signal Polarity	High active
Sync edge	Rising edge
TCON - Hsync pin select	LCD_TCON2
TCON - Vsync pin select	LCD_TCON1
TCON - DataEnable pin select	LCD_TCON0
TCON - Panel clock division ratio	1/32

NOTE: The input horizontal size and stride are intentionally set to 256 pixels, even though the parameter should be 240 pixels for the panel. This is because a horizontal line has to be 64-byte aligned for GLCDC hardware. Only 240 pixels from the beginning in a line are valid and the rest of the pixels in the line (16 pixels) don't care.

CLUT

The GLCDC module supports a Color Look-Up table that is used if the color format is ARGB1555, CLUT8, CLUT4 or CLUT1. The CLUT API can update CLUT0/CLUT1 SRAM (implemented inside the GLCDC hardware) for each of the graphics foreground or background screens.

NOTE: Make sure to call the CLUT API if you select a color format that uses the CLUT, before using the start API; otherwise, CLUT0 and CLUT1 become an unknown condition and the graphics do not display properly.

You can also call the CLUT API at run-time to update CLUT SRAM.

NOTE: The API copies the source of CLUT data to the CLUT SRAM, which is not currently used (each CLUT SRAM consists of a ping-pong buffer). After completing the CLUT data update, the API automatically switches the CLUT SRAM to be read by the GLCDC hardware from the next frame to avoid tearing of the image.

Line Repeating Mode

Line repeating is an important mode, especially for a system that does not have enough memory. In this mode, the GLCDC module reads a raster image, which has fewer pixels than the LCD panel screen size, and displays the raster repeatedly on the screen. The following figure shows an example of a screen image constructed by reading a small raster image repeatedly in the background graphics plane.

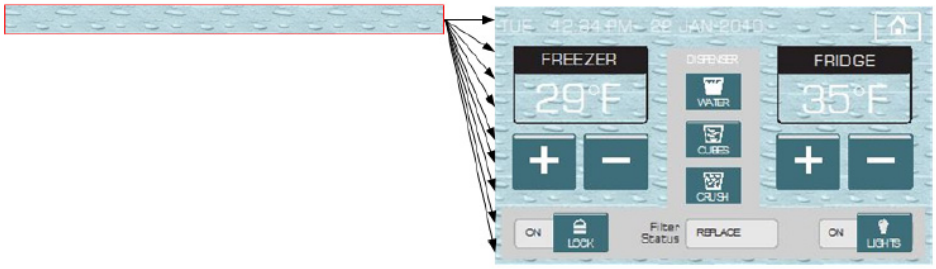

Figure 309: GLCDC Line Repeating Mode

NOTE: To enable this mode, set the GLCDC module property "Input - Graphics screen N input lines repeat" (where N = 1 or 2) to ON with the Synergy configurator. Also specify the repeat times to read a raster image to: "Input - Graphics screen N input lines repeat times". Specify the horizontal pixel size of the raster image in "Input - Graphics screen N input horizontal size" and "Input - Graphics screen N input horizontal stride," and then specify the vertical pixel size of the raster image in "Input - Graphics screen N input vertical size."

Gamma Correction

Gamma Correction is used to change the color characteristic of LCD panels to a flat characteristic. The following figure shows the gamma correction curve which can be configured by the GLCDC module. The module supports 16 threshold values for the input color level for each (R, G, B) color and defines the gain level for each of 16 areas divided by thresholds.

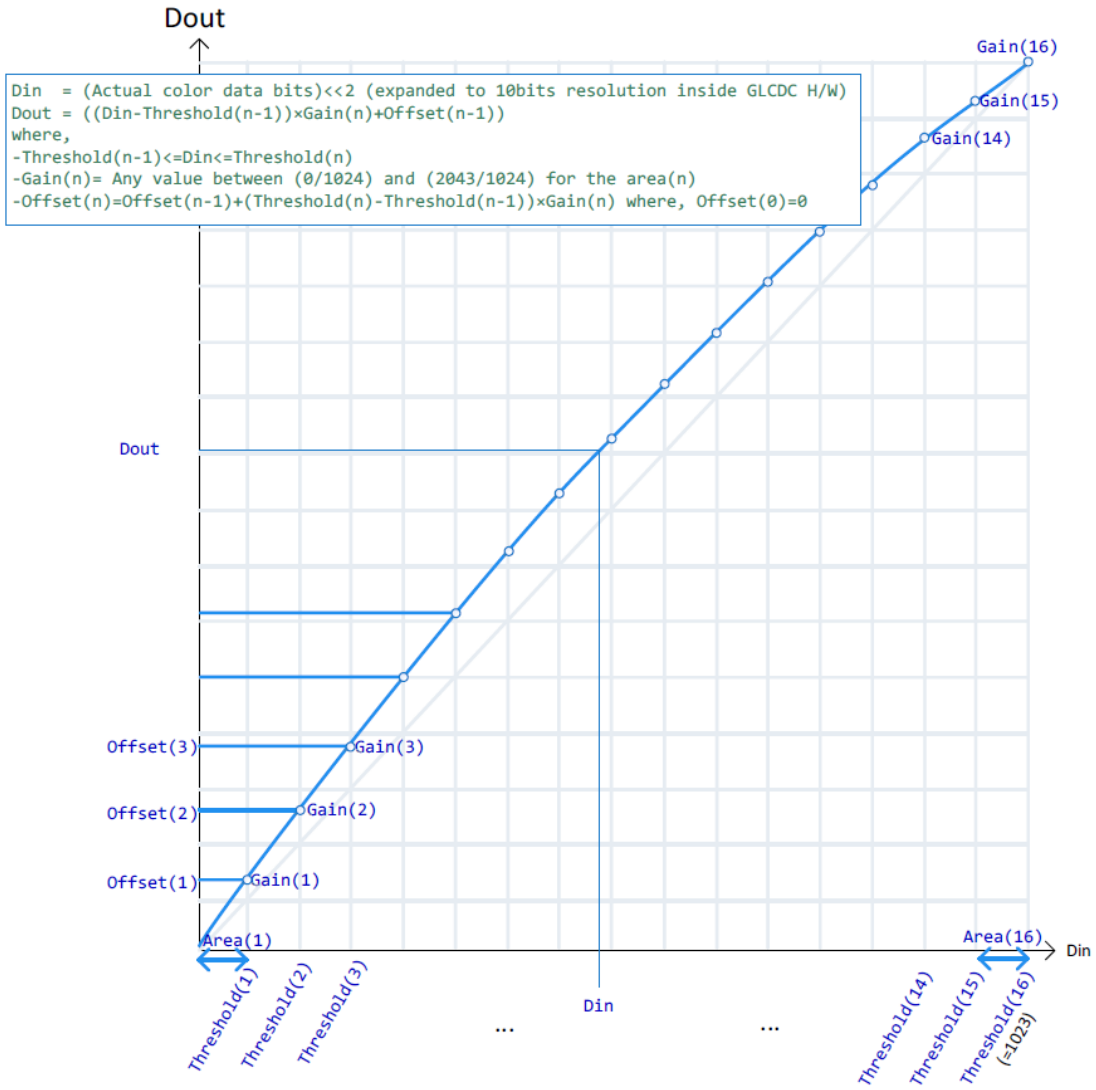

Figure 310: GLCDC Gamma Correction Curve

NOTE: To enable the gamma correction for each channel (R, G, B), set the GLCDC module property "Color correction – Gamma correction (R, G, B)" to ON using the Synergy configurator. Thresholds (total 16) are set to "Color correction – Gamma correction threshold (R, G, B) \[n\]" where, n=[0..15]. The gain value for each of areas are set to "Color correction – Gamma correction gain (R, G, B) \[n\]," where, n= [0..15].

GLCDC HAL Module Important Operational Notes and Limitations

You have the option to configure multiple GLCDC interrupts covered in the following sections.

Line Detection Interrupt

The line-detection interrupt is used to indicate when the GLCDC finishes outputting all lines to the LCD panel and goes into the blanking period. Use this interrupt to handle frame buffer switching in a graphics system and uses frame buffers with more than two frames.

Layer1 or Layer2 Line Buffer Underflow Interrupt

You can use the GLCDC layer1 or layer2 buffer underflow interrupt to detect a lack of memory bandwidth in your system. The buffer underflow occurs when the graphics data transfer from memory (for example, SDRAM or SRAM) to the GLCDC internal line buffer is blocked by the other data transfer, and not enough against the data transfer from GLCDC line buffer to the LCD panel interface. You have to design the graphics system to prevent this interrupt from occurring.

GLCDC Callbacks

A user-callback function can be registered in open. If a user-callback function is provided, the callback function is called from the interrupt service routine (ISR) each time an interrupt happens. The argument of the callback function event can take the following enumerated value listed in the table, so that a user can identify which event occurred in the graphics system. The DISPLAY_EVENT_LINE_DETECTION event is used for switching frame buffers to update the screen, and the DISPLAY_EVENT_GRn_UNDERFLOW event is used for error handling if an underflow occurs.

Event and Interrupt Summary

Name of Event	Name of Interrupt	Condition for the Event
DISPLAY_EVENT_LINE_DETECTION	Line detection	When GLCDC is done outputting the last line in the active video region
DISPLAY_EVENT_GR1_UNDERFLOW	Graphics 1 underflow	When GLCDC underflows during reading the data for graphics1 plane
DISPLAY_EVENT_GR2_UNDERFLOW	Graphics 2 underflow	When GLCDC underflows during reading the data for graphics2 plane

NOTE: Since the callback is called from an ISR, be careful not to use blocking calls or lengthy processing. Spending an excessive time in an ISR can affect the responsiveness of the system.

- The Display driver on r_GLCDC does not support RGB-index chroma key.
- The Display driver on r_GLCDC does not support the event-link function.
- Refer to the latest SSP Release Notes for any additional operational limitations applicable to this module.

4.2.13.4 Including the GLCDC HAL Module in an Application

This section describes how to include the GLCDC HAL module in an application using the SSP configurator.
NOTE: It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the GLCDC HAL module to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Display Driver is g_display0. This name can be changed in the associated Properties window.)

GLCDC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_display0 Display Driver on r_glcdc	Threads	New Stack> Driver> Graphics> Display Driver on r_glcdc

When the GLCDC HAL module on r_glcdc is added to the thread stack as shown in the following figure, the configurator automatically adds any required lower-level modules. Any drivers that need additional configuration information are box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

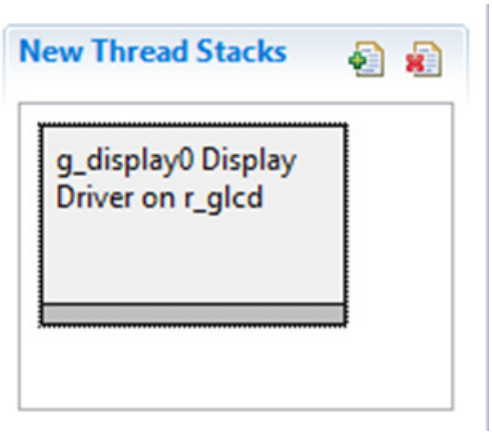

Figure 311: GLCDC HAL Module Stack

4.2.13.5 Configuring the GLCDC HAL Module

The GLCDC HAL module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this helps to orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the GLCDC HAL Module on r_glcdc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Enable or disable the parameter checking.
Name	g_display0	The name to be used for a GLCDC module control block instance. This name is also used as the prefix of the other variable instances.
Name of display callback function to be defined by user	NULL	Name must be a valid C symbol.
Input – Panel clock source select	Internal clock(GLCDCLK), External clock(LCD_EXTCLK) (Default: Internal clock)	Choose the panel clock source depends on your system.
Input – Graphics screen1	Used, Not used (Default: Used)	Specify "Used" if the graphics screen N is used. Then the frame buffer named "display_fb_background" for graphics screen1 and "display_fb_foreground" for graphics screen2 is auto-generated by ISDE. If not using either of the graphics screens, specify "Not used." The frame buffer is then not created. Note that there is no memory read access to the frame buffer when you specify "Not used," which reduces the consumption of bus bandwidth.
Input – Graphics screen1 frame buffer name	fb_background	Custom name for frame buffer.
Input – Number of Graphics screen1 frame buffer	2	Graphics screen1 frame buffer number
Input – section where Graphics screen1 frame buffer allocated	sdram	Specify the section name to allocate the frame buffer. This is valid if "Input – Graphics screen1" is set as "Used."
Input – Graphics screen1 input horizontal size	800	Specify the number of horizontal pixels. Default value is the size for an image with 800x480 pixels.
Input – Graphics screen1 vertical size	480	Specify the number of vertical pixels. Default value is the size for an image with 800x480 pixels.

ISDE Property	Value	Description
Input – Graphics screen1 input horizontal stride (not bytes but pixels)	800	Specify the memory stride for a horizontal line. This value must be specified with the number of pixels, not actual bytes. Typically, this parameter is set to same number as parameter 'input horizontal size'. Default value is the size for an image with 800x480 pixels.
Input – Graphics screen1 input format	32 bits ARGB888, 32 bits RGB888, 16 bits RGB565, 16 bits ARGB1555, 16 bits ARGB4444, CLUT 8, CLUT 4, CLUT 1 (Default: 16 bits RGB565)	Specify the graphics screen Input format. If selecting CLUT formats, you must write CLUT data using clut before performing start. Default setting supports a RGB565 formatted image.
Input – Graphics screen1 input line descending	Used, Not used (Default: Not used)	Specify "On" if image data descends from the bottom line to the top line in the frame buffer. Usually "Off."
Input – Graphics screen1 input line repeat	On, Off (Default: Off)	Specify "On" if expecting to repeatedly read a raster image which is smaller than the LCD panel size. Usually "Off". For details, see the description of Line Repeating function.
Input – Graphics screen1 input line repeat times	0	Specify the number of repeating times for a raster image which is read repeatedly in a frame.
Input – Graphics screen1 layer coordinate X	0	Specify the horizontal offset in pixels of the graphics screen from the background screen.
Input – Graphics screen1 layer coordinate Y	0	Specify the vertical offset in pixels of the graphics screen from the background screen.
Input – Graphics screen1 layer background color alpha	255	Based on the alpha value, either the graphics screen2 (foreground graphics screen) is blended into the graphics screen1 (background graphics screen) or the graphics screen1 is blended into the monochrome background screen.
Input – Graphics screen1 layer background color Red	255	Specify the background color in the graphics screen N.

ISDE Property	Value	Description
Input – Graphics screen1 layer background color Green	255	Specify the background color in the graphics screen N.
Input – Graphics screen1 layer background color Blue	255	Specify the background color in the graphics screen N.
Input – Graphics screen1 layer fading control	None, Fade-in, Fade-out (Default: None)	Specify "On" when performing a fade-in for the graphics screen. The transparent screen changes gradually to opaque. Specify "Off" when performing the fade-out for the graphics screen. The opaque screen changes gradually to transparent. Note that this processing is accelerated by the GLCDC hardware and cannot stop once started. The transition status can be monitored by statusGet.
Input – Graphics screen1 layer fade speed	0	Specify the number of frames for the fading transition to complete.
Input – Graphics screen2	Used, Not used (Default: Not used)	Specify "Used" if the graphics screen N is used. Then the frame buffer named "display_fb_background" for graphics screen1 and "display_fb_foreground" for graphics screen2 is auto-generated by ISDE. If not using either of the graphics screens, specify "Not used." Then, the frame buffer is not created. Note that there is no memory read access to the frame buffer when you specify "Not used", which reduces the consumption of bus bandwidth.
Input – Graphics screen2 frame buffer name	fb_foreground	Custom name for frame buffer.
Input – Number of Graphics screen2 frame buffer	2	Graphics screen2 frame buffer n umber
Input – section where Graphics screen2 frame buffer allocated	sdram	Specify the section name to allocate the frame buffer. This is valid if "Input – Graphics screen1" is set as "Used."
Input – Graphics screen2 input horizontal size	800	Specify the number of horizontal pixels. Default value is the size for an image with 800x480 pixels.

ISDE Property	Value	Description
Input – Graphics screen2 vertical size	480	Specify the number of vertical pixels. Default value is the size for an image with 800x480 pixels.
Input – Graphics screen2 input horizontal stride (not bytes but pixels)	800	Specify the memory stride for a horizontal line. This value must be specified with the number of pixels, not actual bytes. Typically, this parameter is set to same number as parameter 'input horizontal size'. Default value is the size for an image with 800x480 pixels.
Input – Graphics screen2 input format	32 bits ARGB888, 32 bits RGB888, 16 bits RGB565, 16 bits ARGB1555, 16 bits ARGB4444, CLUT 8, CLUT 4, CLUT 1 (Default: 16 bits RGB565)	Specify the graphics screen Input format. If selecting CLUT formats, you must write CLUT data using clut before performing start. Default setting supports a RGB565 formatted image.
Input – Graphics screen2 input line descending	On, Off (Default: Off)	Specify "On" if image data descends from the bottom line to the top line in the frame buffer. Usually "Off."
Input – Graphics screen2 input line repeat	On, Off (Default: Off)	Specify "On" if expecting to repeatedly read a raster image, which is smaller than the LCD panel size. Usually "Off." For details, see the description of Line Repeating function.
Input – Graphics screen2 input line repeat times	0	Specify the number of repeating times for a raster image which is read repeatedly in a frame.
Input – Graphics screen2 layer coordinate X	0	Specify the horizontal offset in pixels of the graphics screen from the background screen.
Input – Graphics screen2 layer coordinate Y	0	Specify the vertical offset in pixels of the graphics screen from the background screen.

ISDE Property	Value	Description
Input – Graphics screen2 layer background color alpha	255	Based on the alpha value, either the graphics screen2 (foreground graphics screen) is blended into the graphics screen1 (background graphics screen) or the graphics screen1 is blended into the monochrome background screen.
Input – Graphics screen2 layer background color Red	255	Specify the background color in the graphics screen N.
Input – Graphics screen2 layer background color Green	255	Specify the background color in the graphics screen N.
Input – Graphics screen2 layer background color Blue	255	Specify the background color in the graphics screen N.
Input – Graphics screen2 layer fading control	None, Fade-in, Fade-out (Default: None)	Specify "On" when performing a fade-in for the graphics screen. The transparent screen changes gradually to opaque. Specify "Off" when performing the fade-out for the graphics screen. The opaque screen changes gradually to transparent. Note that this processing is accelerated by the GLCDC hardware and cannot stop once started. The transition status can be monitored by statusGet.
Input – Graphics screen2 layer fade speed	0	Specify the number of frames for the fading transition to complete.
Output – Horizontal total cycles	1024	Specify the total cycles in a horizontal line. Set to the number of cycles defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output – Horizontal active video cycles	800	Specify the number of active video cycles in a horizontal line. Set to the number of cycles defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.

ISDE Property	Value	Description
Output – Horizontal back porch cycles	46	Specify the number of back porch cycles in a horizontal line. Back porch starts from the beginning of Hsync cycles, which means back porch cycles contain Hsync cycles. Set to the number of cycles defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output – Horizontal sync signal cycles	20	Specify the number of Hsync signal assertion cycles. Set to the number of cycles defined in the data sheet of LCD panel sheet in your system. Default value matches LCD panel on S7G2 PE-HMI1 board.
Output – Horizontal sync signal polarity	Low active, High active (Default: Low active)	Select the polarity of Hsync signal to match your system. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output – Vertical total lines	525	Specify number of total lines in a frame. Set to the number of lines defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output – Vertical active video lines	480	Specify the number of active video lines in a frame. Set to the number of lines defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output – Vertical back porch lines	23	Specify the number of back porch lines in a frame. Back porch starts from the beginning of Vsync lines, which means back porch lines contain Vsync lines. Set to the number of lines defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.

ISDE Property	Value	Description
Output – Vertical sync signal lines	10	Specify the Vsync signal assertion lines in a frame. Set to the number of lines defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output – Vertical sync signal polarity	Low active, High active (Default: Low active)	Select the polarity of Vsync signal to match to your system. Default setting matches LCD panel on S7G2 PE-HMI1 board.
Output – Format	24bits RGB888, 18bits RGB666, 16 bits RGB565, 8bits serial (Default: 24bits RGB888)	Specify the graphics screen output format to match to your LCD panel. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output – Endian	Little endian, Big endian (Default: Little endian)	Select data endian for output signal to LCD panel. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output – Color order	RGB, BGR (Default: RGB)	Select data order for output signal to LCD panel. The order of blue and red can be swapped if needed. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output – Data Enable Signal Polarity	Low active, High active (Default: High active)	Select the polarity of Data Enable signal to match to your system. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output – Sync edge	Rising Edge, Falling Edge (Default: Rising Edge)	Select the polarity of Sync signals to match to your system. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output – Background color alpha channel	255	Specify the background color of the background screens.
Output – Background color R channel	0	Specify the background color of the background screens.
Output – Background color G channel	0	Specify the background color of the background screens.
Output – Background color B channel	0	Specify the background color of the background screens.

ISDE Property	Value	Description
CLUT	Used, Not used (Default: Not used)	Specify "Used" if selecting CLUT formats for a graphics screen input format. Then, a buffer named "CLUT_buffer" for the CLUT source data is generated in the ISDE auto-generated source file.
CLUT - CLUT buffer size	256	Specify the number of entries for the CLUT source data buffer. Each entries consumes 4 bytes (1 word). Words of CLUT source data specified by this parameter are generated in the ISDE auto-generated source file.
TCON – Hsync pin select	Not used, LCD_TCON0, LCD_TCON1, LCD_TCON2, LCD_TCON3 (Default: LCD_TCON0)	Select the TCON pin used for the Hsync signal to match to your system. Default setting is for LCD panel on S7G2 PE-HMI1 board.
TCON – Vsync pin select	Not used, LCD_TCON0, LCD_TCON1, LCD_TCON2, LCD_TCON3 (Default: LCD_TCON1)	Select TCON pin used for Vsync signal to match to your system. Default setting is for LCD panel on S7G2 PE-HMI1 board.
TCON – DataEnable pin select	Not used, LCD_TCON0, LCD_TCON1, LCD_TCON2, LCD_TCON3 (Default: LCD_TCON2)	Select TCON pin used for DataEnable signal to match to your system. Default setting is for LCD panel on S7G2 PE-HMI1 board.
TCON – Panel clock division ratio	8-Jan	Select the clock source divider value. See the note at bottom of this table about the source clock for the pixel clock.
Color correction – Brightness	Off, On (Default: Off)	Specify "On" when performing brightness control. If specifying "Off", the setting below does not affect the output color.
Color correction – Brightness R channel	512	Output color level is calculated as follows: Output color level = Input color level +/ - 512. Set the value for each R, G, and B channel.
Color correction – Brightness G channel	512	Output color level is calculated as follows: Output color level = Input color level +/ - 512. Set the value for each R, G, and B channel.

ISDE Property	Value	Description
Color correction – Brightness B channel	512	Output color level is calculated as follows: Output color level = Input color level +/ - 512. Set the value for each R, G, and B channel.
Color correction – Contrast	Off	Specify "On" when performing contrast control. If specifying "Off", the setting below does not affect the output color.
Color correction – Contrast(gain) R channel	128	Output color level is calculated as follows: Output color level = Input color level x (/128). Set the value for each R, G, and B channel.
Color correction – Contrast(gain) G channel	128	Output color level is calculated as follows: Output color level = Input color level x (/128). Set value for each R, G, and B channel.
Color correction – Contrast(gain) B channel	128	Output color level is calculated as follows: Output color level = Input color level x (/128). Set the value for each R, G, and B channel.
Color correction – Gamma correction(Red)	Off, On (Default: Off)	Control for each channel R/G/B. Specify "On" when performing gamma correction for the red channel. If specifying "Off," the settings for gain and threshold do not affect the output color.
Color correction – Gamma gain R[0-15]	0	Set the gain value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data, with a color level between ((Gamma threshold R[N-1])<<2) and ((Gamma threshold R[N])<<2). The output value is calculated as: Output color level = Input color level / 1024 (/128).

ISDE Property	Value	Description
Color correction – Gamma threshold R[0-15]	0	Set the threshold value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between Gamma threshold R[N-1] and Gamma threshold R[N]. The output value is calculated as: Output color level = Input color level / 1024 (/128).
Color correction – Gamma correction(Green)	Off	Control for each channel R/G/B. Specify "On" when performing gamma correction for the red channel. If specifying "Off," the settings for gain and threshold do not affect the output color.
Color correction – Gamma gain G[0-15]	0	Set the gain value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data, with a color level between ((Gamma threshold R[N-1])<<2) and ((Gamma threshold R[N])<<2). The output value is calculated as: Output color level = Input color level / 1024 (/128).
Color correction – Gamma threshold G[0-15]	0	Set the threshold value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between Gamma threshold R[N-1] and Gamma threshold R[N]. The output value is calculated as: Output color level = Input color level / 1024 (/128).
Color correction – Gamma correction(Blue)	Off, On (Default: Off)	Control for each channel R/G/B. Specify "On" when performing gamma correction for the red channel. If specifying "Off", the settings for gain and threshold do not affect the output color.

ISDE Property	Value	Description
Color correction – Gamma gain B[0-15]	0	Set the gain value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between ((Gamma threshold R[N-1])<<2) and ((Gamma threshold R[N])<<2). The output value is calculated as follows: Output color level = Input color level / 1024 (/128).
Color correction – Gamma threshold B[0-15]	0	Set the threshold value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between Gamma threshold R[N-1] and Gamma threshold R[N]. The output value is calculated as: Output color level = Input color level / 1024 (/128).
Dithering	Off, On (Default: Off)	Dithering enable. Specify "On" when applying the dither effect to reduce the banding in case of selecting RGB666 or RGB565 output formats. Dithering can be applied when converting. If specified "Off", the settings for dithering below do not affect the output. For details on the dither effect, see Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Dithering – Mode	Truncate, Round off, 2x2 Pattern (Default: Truncate)	Specify the dither mode. For detail, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Dithering – Pattern A	Pattern 00, Pattern 01, Pattern 10, Pattern 11 (Default: Pattern 11)	Specify the dither pattern for 2X2 pattern mode. For details, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.

ISDE Property	Value	Description
Dithering – Pattern B	Pattern 00, Pattern 01, Pattern 10, Pattern 11 (Default: Pattern 11)	Specify the dither pattern for 2X2 pattern mode. For details, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Dithering – Pattern C	Pattern 00, Pattern 01, Pattern 10, Pattern 11 (Default: Pattern 11)	Specify the dither pattern for 2X2 pattern mode. For details, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Dithering – Pattern D	Pattern 00, Pattern 01, Pattern 10, Pattern 11 (Default: Pattern 11)	Specify the dither pattern for 2X2 pattern mode. For details, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Misc – Correction Process Order	Brightness and Contrast then Gamma, Gamma then Brightness and Contrast (Default: Brightness and Contrast then Gamma)	Specify the color correction processing order if needed.
Line Detect Interrupt Priority	Priority 0(highest)-15(lowest), Disabled (Default: Disabled)	Line detect interrupt priority selection.
Underflow 1 Interrupt Priority	Priority 0(highest)-15(lowest), Disabled (Default: Disabled)	Underflow 1 interrupt priority selection.

| Underflow 2 Interrupt Priority | Priority 0(highest)-15(lowest), Disabled (Default: Disabled) | Underflow 2 interrupt priority selection. | |

NOTE: The example values and defaults are from a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and different configuration settings available.

GLCDC HAL Module Clock Configuration

The GLCDC module can generate the pixel clock from either of the following clock sources. The source clock selection is available through Synergy Configuration in e^2 studio.

- Internal clock source (PLLOUT; 240 MHz)
- External clock source from the LCD_EXTCLK pin

NOTE: The internal clock is different in S7G2 WS1 (Working Sample1) chip and the WS2 (Working Sample2) chip or later. WS1 chip uses PCLKB (max. 60 MHz), but WS2 or later chips use PLLOUT (max. 240 MHz).

GLCDC HAL Module Pin Configuration

The GLCDC module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The pin selection table lists methods to select pins within the SSP configuration window and the configuration settings table lists an example depicting selection of GLCDC pins.

Pin Selection Sequence for the GLCDC HAL Module

Resource	ISDE Tab	Pin selection Sequence
GLCDC	Pins	Select Peripherals > Graphics: GLCDC> GLCDC0

NOTE: The selection sequence assumes GLCDC0 is the desired hardware target for the driver.

Pin Configuration Settings for the GLCDC HAL Module

Property	Value	Description
Pin Group Selection	Mixed, _A Only, _B Only (Default: Mixed)	Pin group selection
Operation Mode	Disabled, Custom, RGB888, RGB666, RGB565 (Default: Disabled)	Select desired operation mode
LCD_CLK	None, P900, P101 (Default: None)	LCD_CLK Pin
LCD_DATA00:15	None, Pn, Pm (Default: None)	LCD_DATA Pins
LCD_TCON0:3	None, Pn, Pm (Default: None)	LCD_TCON Pins
LCD_EXTCLK	None, Pn, Pm (Default: None)	LCD_EXTCLK Pin

NOTE: The example values in the table are from a project using the Synergy S7G2 and SK-S7G2 Kits. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

NOTE: To use the GLCDC module on the S7G2 PE-HMI1 board, be sure to set up PORT10 pin3 (PA03) and pin5 (PA05) as IOPORT pins with the output level HIGH. Pin PA03 controls the DISP signal (Display on/off) and Pin PA05 controls the backlight of LCD panel. For details, see the schematics of S7G2 PE-HMI1 board.

4.2.13.6 Using the GLCD HAL Module in an Application

The typical steps in using the GLCDC HAL module in an application are:

1) Initialize the GLCDC HAL module with the open API.
2) Draw a primary image in the frame buffer with application code.
3) Start the image displaying using the start API.
4) Draw a new image in the frame buffer to update the display with application code. Typical user systems consist of the ping-pong frame buffer system, so draw the image to another frame buffer which is not used for displaying at the point.
5) Request the frame buffer toggling to GLCDC hardware with the layerChange API.
6) The GLCDC hardware toggles frame buffer and display a new image from the next frame.

To synchronize application code to the completion of drawing current frame buffer, use the line-detection interrupt and notify the timing to application code through the GLCDC callback.

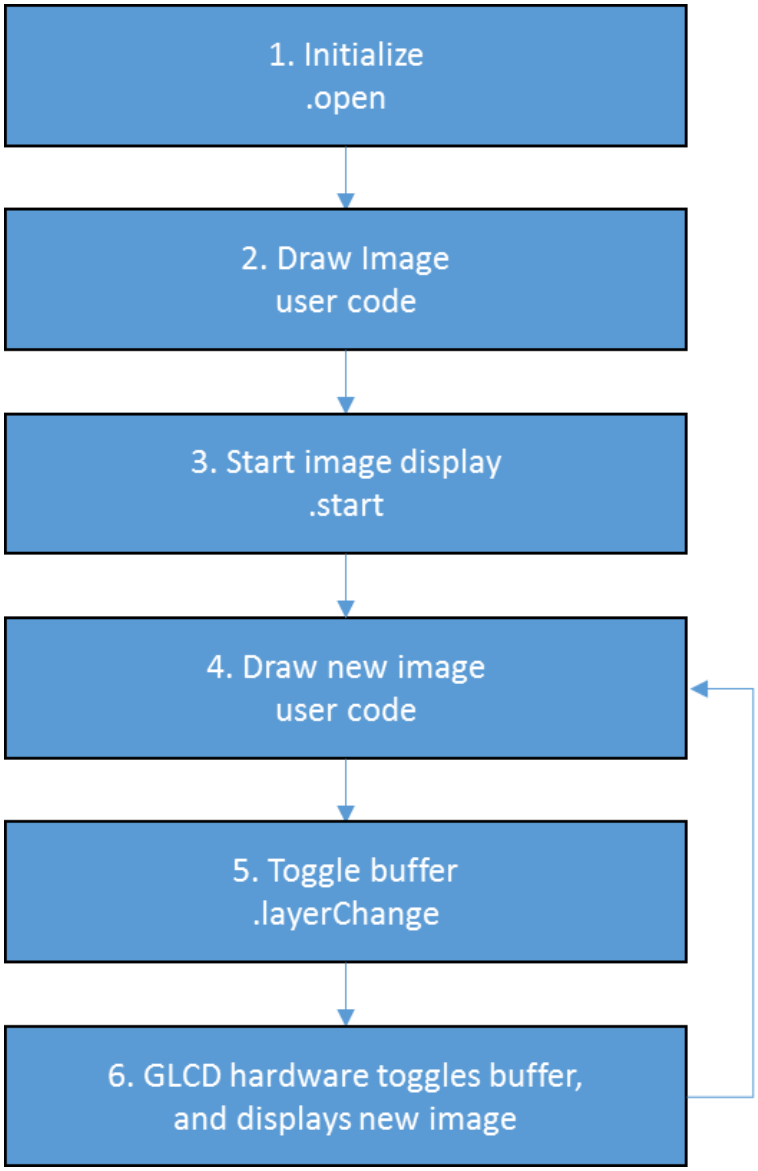

Figure 312: Flow Diagram of a Typical GLCDC HAL Module Application

4.2.14 Data Operation Circuit Driver

The Data Operation Circuit (DOC) HAL module provides high-level APIs for DOC applications and is implemented on r_doc. The DOC HAL module uses the DOC peripherals on the Renesas Synergy™ MCU device. A user-defined callback can be created to inform the CPU when an event occurs.

4.2.14.1 DOC HAL Module Features

The DOC HAL module peripheral is used to compare 16-bit data and can detect the following events:

- A mismatch or match between data values
- Overflow of an addition operation
- Underflow of a subtraction operation

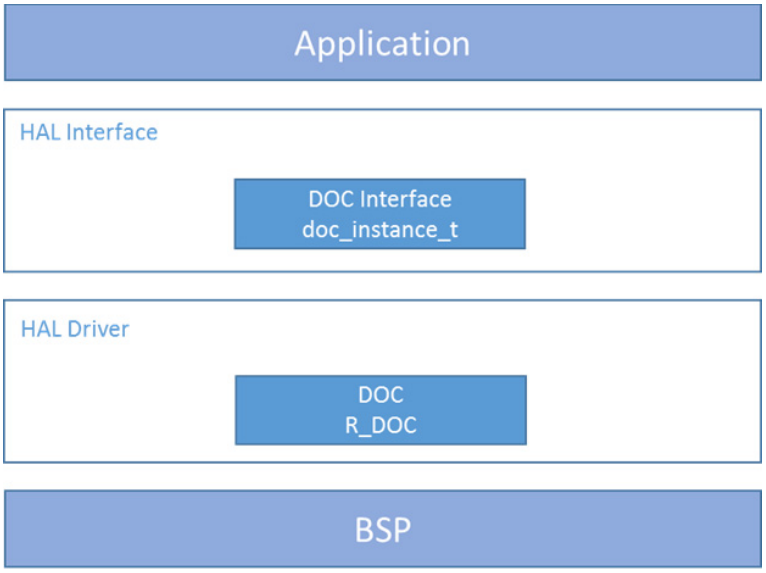

Figure 313: DOC HAL Module Block Diagram

4.2.14.2 DOC HAL Module APIs Overview

The DOC HAL module defines APIs for opening, closing, checking the status of, and writing data to the data operation circuit. The DOC HAL module uses the DOC peripheral on the Synergy MCU. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

DOC HAL Module API Summary

Function Name	Example API Call and Description
open	g_doc.p_api->open(g_doc.p_ctrl, g_doc.p_cfg) Initial configuration.
close	g_doc.p_api->close(g_doc.p_ctrl) Allow the driver to be reconfigured. Will reduce power consumption.

Function Name	Example API Call and Description
statusGet	g_doc.p_api->statusGet(g_doc.p_ctrl, &my_Status) Get the DOC status and stores it in the provided pointer p_status.
statusClear	g_doc.p_api->statusClear(g_doc.p_ctrl) Clear DOPCF status flag.
write	g_doc.p_api->write(g_doc.p_ctrl, &value) Write to the DODIR and DODSR registers.
inputRegisterWrite	g_doc.p_api->inputRegisterWrite(g_doc.p_ctrl, doc_values) Write to the DODIR register.
versionGet	g_doc.p_api->versionGet(g_doc.p_ctrl, &version) Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	DOC successfully configured.
SSP_ERR_IN_USE	Module already open.
SSP_ERR_ASSERTION	One or more pointers point to NULL.
SSP_ERR_INVALID_ARGUMENT	ISR is not enabled. Enable the ISR in bsp_irq_cfg.h.
SSP_ERR_HW_LOCKED	DOC resource is locked.
SSP_ERR_NOT_OPEN	Driver not open.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.14.3 DOC HAL Module Operational Overview

The DOC HAL module controls the DOC peripheral on a Synergy MCU. It is used to compare 16-bit data and can detect a mismatch between data values, an overflow of an addition value, or an underflow of a subtraction operation. If a callback is available and the associated interrupt is enabled, the callback function will be called in response to a DOC event.

The DOC uses two data registers to perform operations: the DOC Data Input Register (DOCDIR) holds the data to be operated on and the DOC Data Setting Register (DOCDSR) holds the value that is used to operate on the input data. In addition and subtraction modes, this register stores the results of data operations. (Both these registers are 16-bits wide.)

DOC HAL Module Important Operational Notes and Limitations

The initial setting of comparison data is written to the DOC by calling the write API. The write API writes to the DOC DODSR and DODIR registers. The write API uses a variable of type doc_data_t.

```
doc_data_t g_doc_values;

   g_doc_values.dodir = 0x1000;

   g_doc_values.dodsr = 0x1000;

   g_doc.p_api->write(g_doc.p_ctrl, &g_doc_values)
```

If the data to be compared does not change, there is no need to re-write it each time a comparison is required. The input data value can be written to the DOC by using the inputRegisterWrite API. The inputRegisterWrite API writes only to the DOC data-input register.

Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.14.4 Including the DOC HAL Module in an Application

This section describes how to include the DOC HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the DOC Driver to an application, simply add it to a thread using the stacks selection sequence provided in the following table. (The default name for the DOC Driver is g_doc0. This name can be changed in the associated Properties window.)

DOC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_doc0 Data Operation Circuit Driver on r_doc	Threads	New Stack > Driver > Monitoring > Data Operation Circuit Driver on r_doc

When the DOC HAL module on r_doc is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information will be box text highlighted in Red.

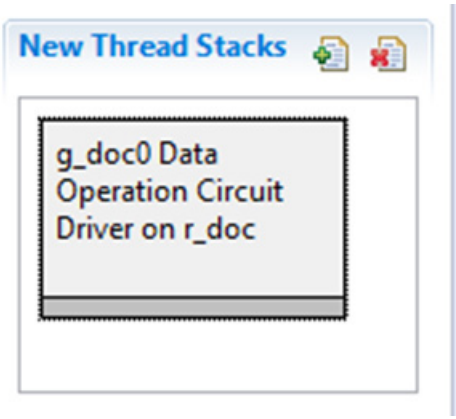

Figure 314: DOC HAL Module Stack

4.2.14.5 Configuring the DOC HAL Module

The DOC HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE indicates the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the following configuration table settings. This helps to orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the DOC HAL Module on r_doc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Enable or disable the parameter error checking.
Name	g_doc0	Module name.

ISDE Property	Value	Description
Event	Comparison mismatch, Comparison match, Addition overflow, Subtraction underflow (Default: Comparison mismatch)	Specify the event which will trigger the DOC interrupt.
Callback	NULL	A user callback function can be defined here. If this callback function is provided, it is called from the interrupt service routine (ISR) when the configured DOC event occurs. NOTE: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
DOC Interrupt Priority	Priority 0 (highest), 1,2,3,4,5,6,7,8,9,10,11,12,13,14,15 (lowest, not valid if using Thread X), Disabled (Default: Disabled)	Use the pull down to set the DOC interrupt priority.

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults can be desirable. For example, it might be useful to select different events depending on the operation desired.

DOC HAL Module Clock Configuration

The DOC HAL module does not require any specific clock configuration.

DOC HAL Module Pin Configuration

The DOC HAL module does not require and specific pin configurations.

4.2.14.6 Using the DOC HAL Module in an Application

The typical steps in using the DOC HAL module in an application are:

1) Initialize the DOC using the open API.
2) Set register values in DODIR and DODSR using the write API.
3) Steam data to the DOC using the inputRegisterWrite API.

4) Read the status of the comparison using the statusGet API or in the callback if enabled.
5) Clear status flags using the statusClear API.
6) Close the module using the close API.

The following figure illustrates these common steps in a typical operational flow diagram.

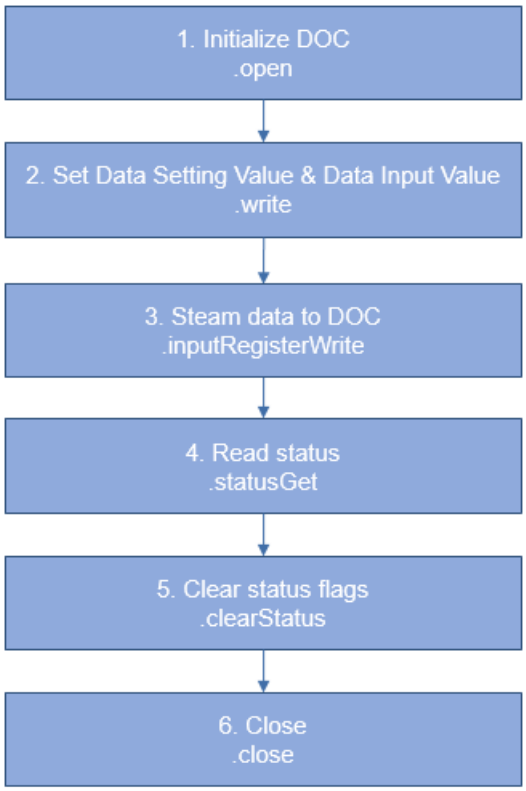

Figure 315: Flow Diagram of a Typical DOC HAL Module Application

4.2.15 DMAC Driver

4.2.15.1 DMAC Driver

The Direct Memory Access Controller or DMAC HAL module provcides high-level APIs for data-transfer applications and is implemented on r_dmac. The DMAC HAL module uses the DMAC peripheral on the Synergy MCU. A user-defined callback can be created to inform the CPU when transfer events occur.

4.2.15.2 DMAC HAL Module Features

The DMAC HAL module moves data from a user-specified source to a user-specified destination when an interrupt or event occurs. The DMAC HAL module supports the following:

- DMAC module on a Synergy MCU

- Interrupts, if desired
- Multiple transfer modes
  - Single Transfer
  - Repeat Transfer
  - Block Transfer
  - Address increment or fixed modes
- Multiple channels, with the number depending on the MCU used

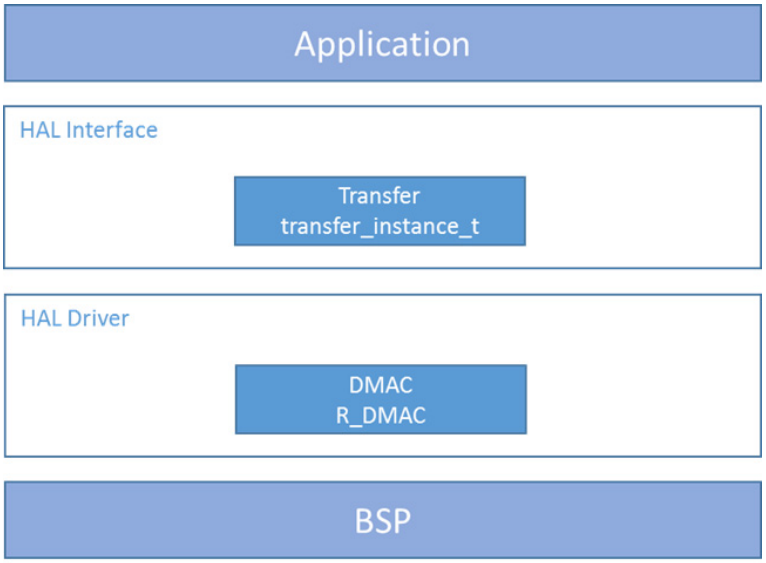

Figure 316: DMAC HAL Module Block Diagram

4.2.15.3 DMAC HAL Module APIs Overview

The DMAC HAL module defines APIs for opening, closing, starting, and stopping timers. Note that the Data Transfer Controller (DTC) and the DMAC use the same transfer interface; sharing an interface makes it easier to change between DTC and DMA implementations. The API calls are the same independent of the lower level implementations. A complete list of the available APIs, an example API call, and a short description of each function can be found in the following API summary table. A table of status return values follows the API summary.

DMAC HAL Module API Summary

Function Name	Example API Call and Description
open	g_transfer0.api->open(g_transfer0.p_ctrl, g_transfer0.p_cfg) Open device channel. Initialize driver and hardware on first call.
close	g_transfer0.api->close(g_transfer0.p_ctrl) Close device channel. Turns off hardware if last channel open.
reset	g_transfer0.api->reset(g_transfer0.p_ctrl, &source, &destination, number_of_transfers) Reset channel settings.
start	g_transfer0.api->start(g_transfer0.p_ctrl, mode) Start data transfer.
stop	g_transfer0.api->stop(g_transfer0.p_ctrl) Stop data transfer.
enable	g_transfer0.api->enable(g_transfer0.p_ctrl) Enable channel.
disable	g_transfer0.api->disable(g_transfer0.p_ctrl) Disable channel.
versionGet	g_transfer0.api->versionGet(&version) Retrieve the API version with the version pointer.
infoGet	g_transfer0.api->infoGet(g_transfer0.p_ctrl, &info) Get transfer channel info.

Function Name	Example API Call and Description
blockReset	g_transfer0.api->blockReset(g_transfer0.p_ctrl, &source, &destination, length, size, number_of_transfers) Reset Block Transfer parameters.

NOTE: Review the *SSP User's Manual* API References for the associated module, where there are detail descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_ASSERTION	Parameter has invalid value.
SSP_ERR_NOT_OPEN	The channel is not opened.
SSP_ERR_UNSUPPORTED	Operation not configured correctly.
SSP_ERR_IN_USE	The channel specified has already been opened. No configurations were changed. Call the associated Close function or use associated Control commands to reconfigure the channel.
SSP_ERR_IRQ_BSP_DISABLED	IRQ not enabled in BSP.
SSP_ERR_NOT_ENABLED	Operation failed.
SSP_ERR_NOT_OPEN	The channel is not opened.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual* API References for the associated module to view definitions of all relevant status return values.

4.2.15.4 DMAC HAL Module Operational Overview

The DMAC HAL module moves data from a user-specified source to a user-specified destination when an interrupt or event occurs. The DMAC HAL module uses DMAC peripheral registers, so the number of transfers in the system is limited to the number of DMAC channels on the device. The activation source does not have to be enabled to use the DMAC. When the DMAC transfer completes, a DMAC interrupt is called. If the activation source interrupt is enabled, it fires at the same time the transfer is triggered. If the DMAC interrupt is enabled, it fires after all transfers are complete.

For example, if a normal mode transfer, with a length of 16 is triggered by a timer, the timer interrupt fires at the same time each transfer occurs and the DMAC interrupt fires after the 16th transfer completes. The DMAC does not support chained transfers.

DMAC HAL Module Important Operational Notes and Limitations

DMAC HAL Module Operational Notes

Normal Mode

In normal mode, a single transfer triggers each time an activation source event occurs. A single transfer is 1 byte, 2 bytes, or 4 bytes, depending on the setting selected in the size parameter. Each time a transfer occurs, the transfer length decrements by 1. When the transfer length reaches 0, the transfer is complete.

Repeat Mode

In repeat mode, a single transfer triggers each time an activation source event occurs. A single transfer is 1 byte, 2 bytes, or 4 bytes, depending on the setting selected in the size parameter. Each time a transfer occurs, the transfer length decrements by 1. When transfer length reaches 0, the transfer length reloads with its initial value and the transfer restarts. If the repeat area is set to source, the source register also reloads with its initial value when the transfer restarts. Alternatively, if the repeat area is set to destination, the destination register reloads with its initial value when the transfer restarts.

Block Mode

In block mode, the entire transfer length transfers each time an activation source event occurs. For example, if a transfer is configured in the block mode with a timer as the activation source, a 2-byte size and 12-byte length, 24 bytes transfer each time the activation source event occurs. Each time a transfer occurs, the transfer length decrements by 1. When the length reaches 0, the transfer length is reloaded with its initial value and the transfer restarts. If the repeat area is set to source, the source register is also reloaded with its initial value when the transfer restarts. Alternatively, if the repeat area is set to destination, the destination register reloads with its initial value when the transfer restarts.

Address Mode

After each transfer of size (1 byte, 2 bytes, or 4 bytes), the source pointer and destination pointer adjust by src_addr_mode and dest_addr_mode, respectively.

For example, if src_addr_mode is set to:

TRANSFER_ADDR_MODE_INCREMENTED, and size is set to TRANSFER_SIZE_4_BYTES, the p_dest pointer is incremented by 4 (the transfer size) after each transfer.

The pointer does not change if set to TRANSFER_ADDR_MODE_FIXED.

DMAC HAL Module Limitations

Refer to the latest *SSP Release Notes* for any additional operational limitations for this module.

4.2.15.5 Including the DMAC HAL Module in an Application

This section describes how to include the DMAC Driver in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the Starting Development section in the *SSP User's Manual* to learn how to manage each of these important steps in creating SSP based applications.

To add the DMAC Driver to an application, simply add it to a thread using the **Stacks Selection Sequence** provided in the table below. (The default name for the DMAC Driver is g_transfer0. This name can be changed in the associated **Properties** window.)

Table 3 GPT Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_ transfer0 Transfer Driver on r_dmac	Threads	New Stack > Driver > Transfer> Transfer Driver on r_dmac

When the DMAC Driver on r_dmac is added to the **New Thread Stack** as shown in the figure below, the configurator automatically adds any needed lower level drivers. Any drivers that need additional configuration information are box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

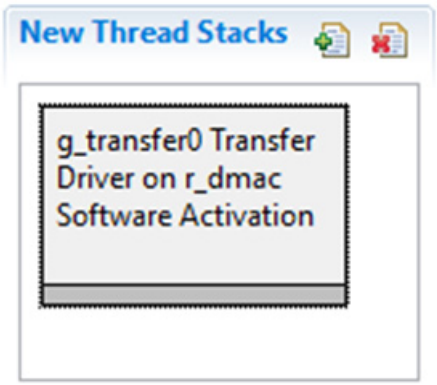

Figure 317: DMAC HAL Module Stack

4.2.15.6 Configuring the DMAC HAL Module

The DMAC HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections (such as interrupts or operating modes) which must be configured for lower level modules for successful operation. Only those properties that can be changed without causing conflicts are available for modification. Other properties are **locked** and are not available for changes, and are identified with a lock icon for the **locked property** in the property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the **Properties tab** within the SSP Configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority. This configuration setting is available within the properties window of the associated module. Simply select the indicated module and then view the properties window. The interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Note that the interrupt priorities listed in the properties window in the ISDE indicate the validity of the setting based on the targeted MCU (CM4 or CM0+.) This level of detail is not included in the configuration properties following tables, but is easily visible within the ISDE when configuring interrupt priority levels.

NOTE: **Property Settings** in parallel with looking over the following configuration settings table. The configuration settings in the table can help orient you and provide a useful hands-on approach to learning the ins and outs of developing with the SSP.

Table 4 Configuration Settings for the DMAC HAL Module on r_dmac

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Selects if code for parameter checking is to be included in the build
Name	g_transfer0	Module name.
Channel	0	
Mode	Block	Mode selection
Transfer Size	1 Byte	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Software Activation	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection

| Interrupt Priority | Priority 0 (highest), 1,2,3,4,5,6,7,8,9,10,11,12,13,14,15 (lowest, not valid if using Thread X), Disabled (Default: Disabled) | ||

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

DMAC HAL Module Clock Configuration

The DMAC peripheral module use ICLK as the clock source. The ICLK frequency is set by using the SSP configurator clock tab, prior to a build, or by using the CGC Interface at run-time.

DMAC HAL Module Pin Configuration

The DMAC HAL Module is not associated with any pins.

4.2.15.7 Using the DMAC HAL Module in an Application

The typical steps in using the DMAC HAL module in an application are:

1) Initialize the DMAC HAL module using the open API.
2) Enable the DMAC HAL module using the enable API (if not auto enabled).
3) Manage transfers using other APIs as needed.
4) Close the DMAC HAL module when needed.

The following operational flow diagram shows common steps in using the DMAC driver.

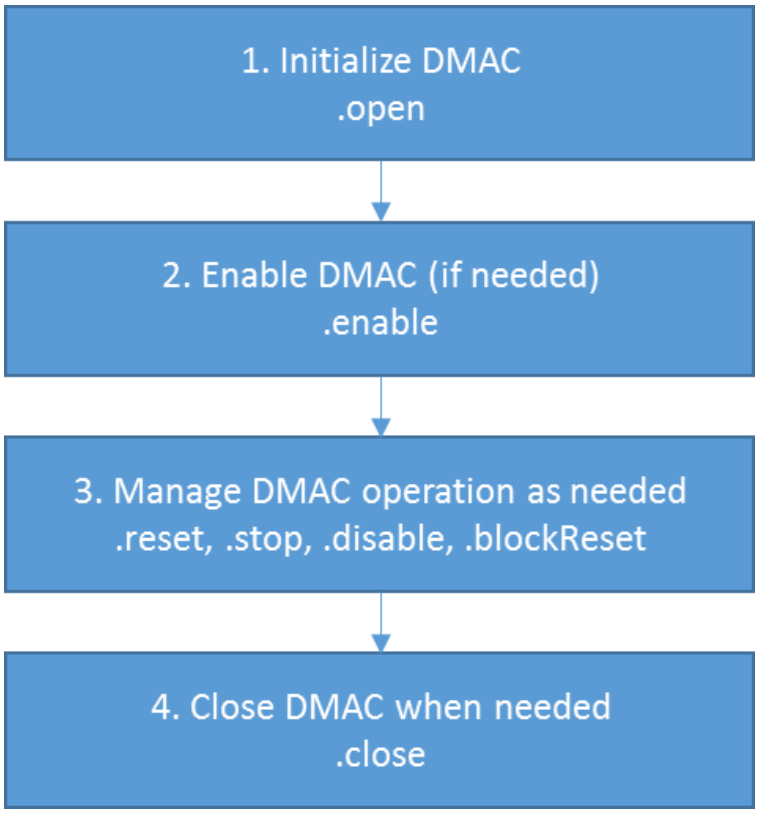

Figure 318: Flow Diagram of a Typical DMAC HAL Module Application

4.2.16 DTC Driver

The Data Transfer Controller (DTC) HAL module provides high-level APIs for data-transfer applications and is implemented on r_dtc. The DTC HAL module uses the DTC peripheral on the Synergy MCU. A user-defined callback can be created to inform the CPU when transfer events occur.

4.2.16.1 DTC HAL Module Features

The Data Transfer Controller (DTC) HAL module moves data from a user-specified source to a user-specified destination when an interrupt or event occurs.

- Supports the DTC module on a Synergy MCU
- Supports interrupts if needed
- Supports multiple transfer modes
  - Single transfer
  - Repeat transfer
  - Block transfer
  - Address increment or fixed modes
  - Chain transfers
- Supports multiple channels (depending on selected implementation)
  - Number of channels is limited only by the size of the RAM-based vector table

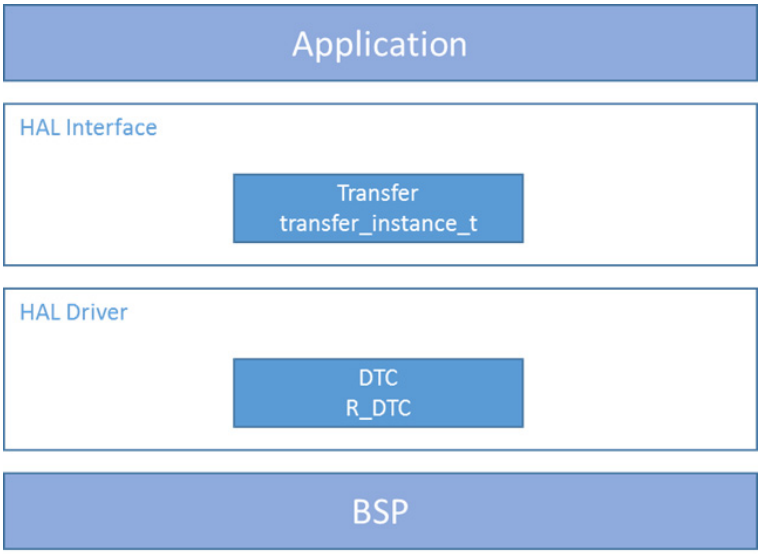

Figure 319: DTC HAL Module Block Diagram

4.2.16.2 DTC HAL Module APIs Overview

The DTC HAL module defines APIs for opening, closing, reset, enabling, disabling, starting, and stopping. Note that the DTC and the DMAC use the same transfer interface to make it easier to change between DTC and DMA implementations. The API calls are the same independent of the lower-level implementations. A complete list of the available APIs, an example API call, and a short description of each can be found in the table below. A table of status return values follows.

DTC HAL Module API Summary

Function Name	Example API Call and Description
open	g_transfer0.api->open(g_transfer0.p_ctrl, g_transfer0.p_cfg) Initial configuration. Enables the transfer if auto_enable is true and p_src, p_dest, and length are valid. Transfers can also be enabled using enable or reset.
close	g_transfer0.api->close(g_transfer0.p_ctrl) Close device channel. Turns off hardware if last channel open.
reset	g_transfer0.api->reset(g_transfer0.p_ctrl, &source, &destination, number_of_transfers) Reset source address pointer, destination address pointer, and/or length, keeping all other settings the same. Enable the transfer if p_src, p_dest, and length are valid.
.start	g_transfer0.api->start(g_transfer0.p_ctrl, mode) Start transfer in software.
stop	g_transfer0.api->stop(g_transfer0.p_ctrl) Stop transfer in software. The transfer will stop after completion of the current transfer.
enable	g_transfer0.api->enable(g_transfer0.p_ctrl) Enable transfer. Transfers occur after the activation source event (or when start is called if ELC_EVENT_ELC_SOFTWARE_EVENT_0 or ELC_EVENT_ELC_SOFTWARE_EVENT_0 is chosen as activation source).

Function Name	Example API Call and Description
disable	g_transfer0.api->disable(g_transfer0.p_ctrl) Disable transfer. Transfers do not occur after the transfer_info_t::activation source event (or when start is called if ELC_EVENT_ELC_SOFTWARE_EVENT_0 or ELC_EVENT_ELC_SOFTWARE_EVENT_0 is chosen as transfer_info_t::activation_source).
versionGet	g_transfer0.api->versionGet(&version) Gets version and stores it in provided pointer version.
infoGet	g_transfer0.api->infoGet(g_transfer0.p_ctrl, &info) Provides information about this transfer.
blockReset	g_transfer0.api->blockReset(g_transfer0.p_ctrl, &source, &destination, length, size, number_of_transfers) Reset source address pointer, destination address pointer, and/or length, for block transfer keeping all other settings the same. Enable the transfer if p_src, p_dest, and length are valid.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_ASSERTION	Parameter has invalid value.
SSP_ERR_NOT_OPEN	The channel is not opened.
SSP_ERR_UNSUPPORTED	Operation not configured correctly.

Name	Description
SSP_ERR_IN_USE	The channel specified has already been opened. No configurations were changed. Call the associated Close function or use associated Control commands to reconfigure the channel.
SSP_ERR_HW_LOCKED	The DTC hardware resource is locked.
SSP_ERR_IRQ_BSP_DISABLED	IRQ not enabled in BSP.
SSP_ERR_NOT_ENABLED	Operation failed.
SSP_ERR_NOT_OPEN	The channel is not opened.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API references for the associated module for a definition of all relevant status return values.

4.2.16.3 DTC HAL Module Operational Overview

The Direct Memory Access Controller (DMAC) and the Data Transfer Controller (DTC) can be used to move data within the Synergy MCU. There are some considerations when selecting between these implementations; the following operational overview includes information on each to help you determine which implementation is best for your application. The DTC module is recommended for most generic transfer applications, but either module can be used for basic transfer functionality. The use-cases for each transfer module are given below:

Selecting the DTC HAL Module

The DTC HAL module uses a RAM-based vector table with slots for every interrupt in the system. When the DTC transfer completes, the activation source interrupt is called. The activation source interrupt must be enabled to use the DTC. The activation source interrupt is generally muted by the DTC until the transfer completes, unless TRANSFER_IRQ_EACH is specified in the configuration. For example, if a normal-mode transfer with a length of 16 is triggered by a timer, the timer interrupt does not fire the first 15 times while the transfer is in effect. After the 16th transfer, the timer interrupt fires. The DTC also allows chained transfers, meaning that more than one transfer can occur after a single activation-source interrupt. This feature is supported by the driver but must be configured outside the ISDE.

Selecting the DMAC HAL Module

The DMAC HAL module moves data from a user-specified source to a user-specified destination when an interrupt or event occurs. The DMAC HAL module uses DMAC peripheral registers, so the number of transfers in the system is limited to the number of DMAC channels on the device. The activation source does not have to be enabled to use the DMAC. When the DMAC transfer completes, a DMAC interrupt is called. If the activation source interrupt is enabled, it fires at the same time the transfer is triggered. If the DMAC interrupt is enabled, it fires after all transfers are complete. For example, if a normal-mode transfer with a length of 16 is triggered by a timer, the timer interrupt fires at the same time each transfer occurs and the DMAC interrupt fires after the 16th transfer completes. The DMAC HAL module does not support chained transfers.

DTC HAL Module Important Operational Notes and Limitations

Normal Mode

In normal mode, a single transfer is triggered each time an activation-source event occurs. A single transfer is 1 byte, 2 bytes, or 4 bytes, depending on the setting selected in the size parameter. Each time a transfer occurs, the transfer length is decremented by 1. When the transfer length reaches 0, the transfer is complete.

Repeat Mode

In repeat mode, a single transfer is triggered each time an activation-source event occurs. A single transfer is 1 byte, 2 bytes, or 4 bytes, depending on the setting selected in the size parameter. Each time a transfer occurs, the transfer length is decremented by 1. When the transfer length reaches 0, the transfer length is reloaded with its initial value and the transfer restarts. If the repeat area is set to source, the source register is also reloaded with its initial value when the transfer restarts. Alternatively, if the repeat area is set to destination, the destination register is reloaded with its initial value when the transfer restarts.

Block Mode

In the block mode, the entire transfer length is transferred each time an activation-source event occurs. For example, if a transfer is configured in block mode with the timer as the activation source, a 2-byte size, and a 12-byte length, 24 bytes are transferred each time the activation source event occurs. Each time a transfer occurs, the transfer length is decremented by 1. When the transfer length reaches 0, the transfer length is reloaded with its initial value and the transfer restarts. If the repeat area is set to source, the source register is also reloaded with its initial value when the transfer restarts. Alternatively, if the repeat area is set to destination, the destination register is reloaded with its initial value when the transfer restarts.

Address Mode

After each transfer of size (1 byte, 2 bytes, or 4 bytes), the source pointer and destination pointer are adjusted by src_addr_mode and dest_addr_mode, respectively. For example, if src_addr_mode is set to TRANSFER_ADDR_MODE_INCREMENTED and size is set to TRANSFER_SIZE_4_BYTES, the p_dest pointer is incremented by 4 (the transfer size) after each transfer. The pointer does not change if set to TRANSFER_ADDR_MODE_FIXED.

Chained Transfers

Chained transfers are only supported by the DTC. To use a chained transfer, create an array of transfer_info_t structures. Set chain_mode to TRANSFER_CHAIN_MODE_ENABLED for all transfers except the last transfer. Set p_info to the base of the first structure in the array for transfer_info_t structures.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.16.4 Including the DTC HAL Module in an Application

This section describes how to include the DTC HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the DTC HAL driver to an application, simply add it to a thread using the Stacks Selection Sequence provided in the table below. (The default name for the Transfer Driver is g_transfer0. This name can be changed in the associated **Properties** window.)

DTC HAL Driver Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_ transfer0 DTC Driver on r_dtc	**Threads > HAL/Common**	**New Stack > Driver > Transfer > Transfer Driver on r_dtc**

When the DTC HAL module on r_dtc is added to the thread stack as shown in the figure below, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information will be box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

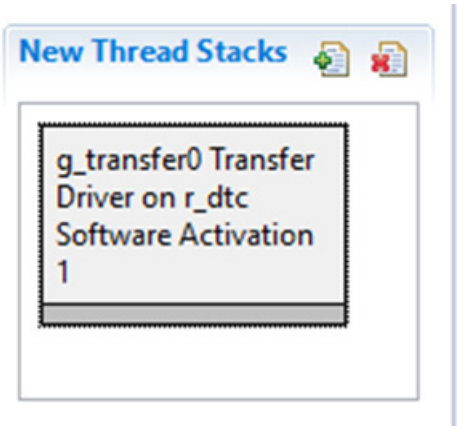

Figure 320: DTC HAL Module Stack

4.2.16.5 Configuring the DTC HAL Module

The DTC HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the **Properties** window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the **Properties** tab in the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the **Properties** window of the associated module. Simply select the indicated module and then view the **Properties** window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the **Properties** window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+.) This level of detail is not included in the configuration properties tables below, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the configuration table settings given below. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the DTC HAL Module on r_dtc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Selects if code for parameter checking is to be included in the build.

ISDE Property	Value	Description
Software Start	Disabled, Enabled (Default: Disabled)	Selects if Software Start to be enabled
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Section to place dtc vector table in
Name	g_transfer0	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte, 2 Bytes, 4 Bytes (Default: 2 Bytes)	Transfer size selection.
Destination Address Mode	Fixed, Incremented, Decremented (Default: Fixed)	Destination address mode selection.
Source Address Mode	Fixed, Incremented, Decremented (Default: Fixed)	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source, Destination (Default: Source)	Repeat area selection.
Interrupt Frequency	After all transfers have completed, After each transfer (Default: After all transfers have completed)	Defines when an interrupt occurs.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.

ISDE Property	Value	Description
Activation Source (Must enable IRQ)	The full list of interrupt activation sources can be found in Table 14.4 of the MCU user manual. (Default: Software Activation 1)	Activation source selection.
Auto Enable	True, False (Default: True)	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 (lowest, not valid if using Thread X), Disabled (Default: Disabled)	Interrupt priority.

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

DTC HAL Module Clock Configuration

The DTC peripheral module use ICLK as the clock source. The ICLK frequency is set by using the SSP configurator **Clocks** tab prior to a build, or by using the CGC Interface at run-time.

DTC HAL Module Pin Configuration

The DTC is not associated with any pins.

4.2.16.6 Using the DTC HAL Module in an Application

The typical steps in using the DTC HAL module in an application are:

1) Initialize the DTC using the open API.
2) Enable the DTC using the enable API (if not auto enabled).
3) Manage transfers using other APIs as needed.
4) Close the DTC when needed using the close API.

The common steps for using the DTC HAL module are illustrated in a typical operational flow diagram in the following figure:

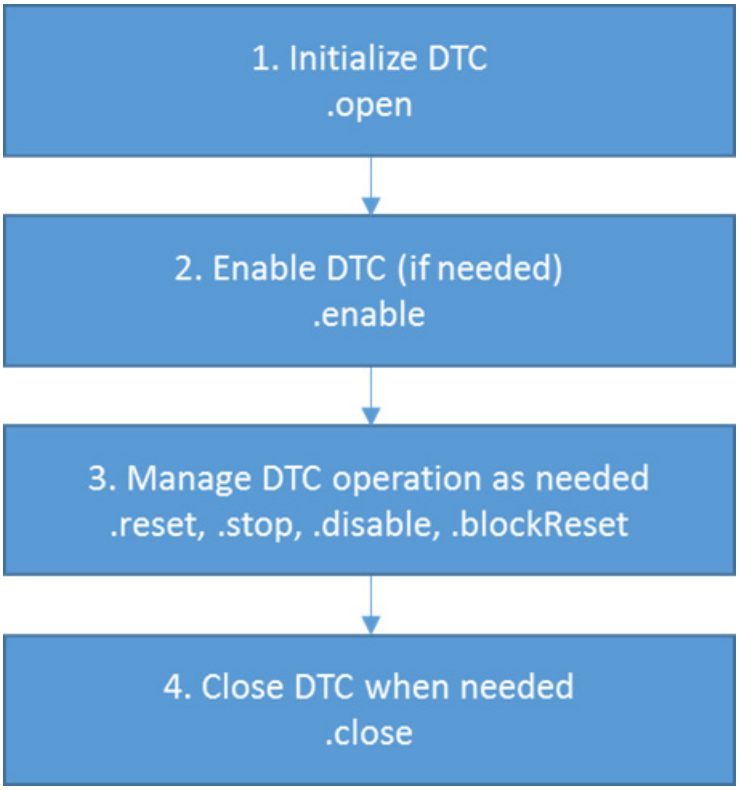

Figure 321: Flow Diagram of a Typical DTC HAL Module Application

4.2.17 ELC Driver

The Event Link Controller (ELC) HAL module provides high-level APIs for ELC HAL applications and is implemented on r_elc. The ELC HAL module uses the ELC peripheral on the Synergy MCU. There are no callbacks associated with the ELC HAL module. The project configurator in the e^2 studio Integrated Solution Development Environment (ISDE), includes the ELC HAL module in every project by default. To configure the ELC HAL module, select it in the HAL/Common module in the **Threads** tab, and then click on it in the HAL/Common Stacks window.

4.2.17.1 ELC HAL Module Features

The ELC HAL module supports the following functions:

- Create an event link between two blocks.
- Break that event link between two blocks.
- Generate one of two software events that interrupt the CPU.

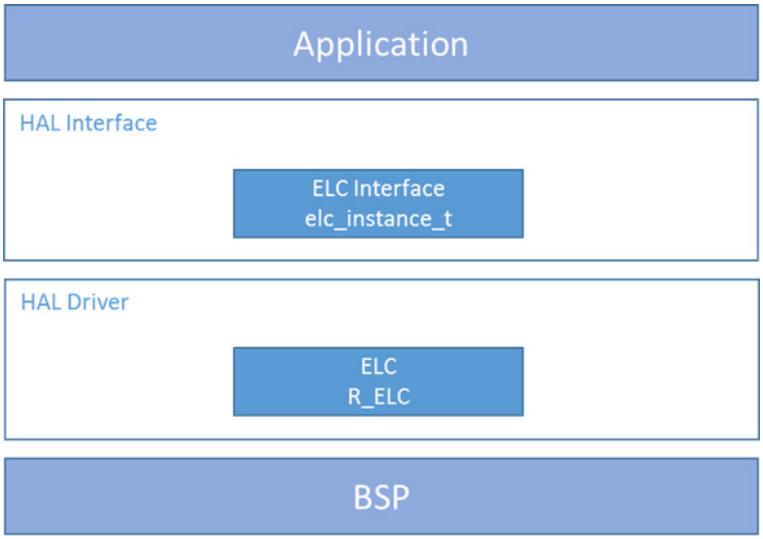

Figure 322: ELC HAL Module Block Diagram

4.2.17.2 ELC HAL Module APIs Overview

The ELC HAL module defines APIs for initializing, enabling, disabling, and creating or breaking event links between modules. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

ELC HAL Module API Summary

Function Name	Example API Call and Description
init	g\elc.p_api->init(g_elc.p_cfg) Initialize all links in the Event Link Controller.
softwareEventGenerate	g_elc.p_api->softwareEventGenerate(event_num) Generate a software event in the Event Link Controller.
linkSet	g_elc.p_api->linkSet(peripheral, signal) Create a single event link.
linkBreak	g_elc.p_api->linkBreak(peripheral) Break an event link.

Function Name	Example API Call and Description
enable	g_elc.p_api->enable() Enable the operation of the Event Link Controller.
disable	g_elc.p_api->disable() Disable the operation of the Event Link Controller.
versionGet	g_elc.p_api->versionGet(&version) Retrieve the API version with the version pointer.

NOTE: For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successfully completed.
SSP_ERR_ASSERTION	p_version is NULL.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.17.3 ELC HAL Module Operational Overview

The ELC HAL module allows the developer to link various peripheral operations by using events generated by one peripheral to trigger the start of operation of another peripheral within the Synergy MCU. The ELC HAL module APIs make it easy to create a link between two blocks (for example, from a timer to an ADC to control a periodic scan interval). By connecting various peripherals in this way, intelligent functions can be constructed that require little, if any, CPU intervention.

The following figure shows a simplified block diagram of the ELC, showing the input event sources and the peripherals that can be triggered by these events. (The number of input and output triggers is specific to the S7G2 MCU.) Other Synergy devices support a different number of events.

Figure 323: ELC Hardware Block Diagram

The application project associated with this module guide shows an example of the ELC in use.

It is possible to find the mapping of ELC peripherals in the file, bsp_elc.h, in the Synergy-generated code. The event list and peripherals for the S7G2 microcontroller unit (MCU) follows. Additional information on ELC operation is also available in the associated MCU user's manual.

```
/** Possible peripherals to be linked to event signals */
typedef enum e_elc_peripheral
{
    ELC_PERIPHERAL_GPT_A                                    =    (0),
    ELC_PERIPHERAL_GPT_B                                    =    (1),
    ELC_PERIPHERAL_GPT_C                                    =    (2),
    ELC_PERIPHERAL_GPT_D                                    =    (3),
    ELC_PERIPHERAL_GPT_E                                    =    (4),
    ELC_PERIPHERAL_GPT_F                                    =    (5),
    ELC_PERIPHERAL_GPT_G                                    =    (6),
    ELC_PERIPHERAL_GPT_H                                    =    (7),
    ELC_PERIPHERAL_ADC0                                     =    (8),
    ELC_PERIPHERAL_ADC0_B                                   =    (9),
    ELC_PERIPHERAL_ADC1                                     =   (10),
    ELC_PERIPHERAL_ADC1_B                                   =   (11),
    ELC_PERIPHERAL_DAC0                                     =   (12),
    ELC_PERIPHERAL_DAC1                                     =   (13),
    ELC_PERIPHERAL_IOPORT1                                  =   (14),
    ELC_PERIPHERAL_IOPORT2                                  =   (15),
    ELC_PERIPHERAL_IOPORT3                                  =   (16),
    ELC_PERIPHERAL_IOPORT4                                  =   (17),
    ELC_PERIPHERAL_CTSU                                     =   (18),
} elc_peripheral_t;

/** Sources of event signals to be linked to other peripherals or the CPU1
 * @note This list may change based on device. This list is for S7G2.
 * */
typedef enum e_elc_event
{
    ELC_EVENT_ICU_IRQ0                                      =    (1),
    ELC_EVENT_ICU_IRQ1                                      =    (2),
    ELC_EVENT_ICU_IRQ2                                      =    (3),
    ELC_EVENT_ICU_IRQ3                                      =    (4),
.
.
.
    ELC_EVENT_ICU_IRQ12                                     =   (13),
    ELC_EVENT_ICU_IRQ13                                     =   (14),
    ELC_EVENT_ICU_IRQ14                                     =   (15),
    ELC_EVENT_ICU_IRQ15                                     =   (16),
.
.
.
    ELC_EVENT_GLCDC_LINE_DETECT                             =  (506),
    ELC_EVENT_GLCDC_UNDERFLOW_1                             =  (507),
    ELC_EVENT_GLCDC_UNDERFLOW_2                             =  (508),
    ELC_EVENT_DRW_INT                                       =  (509),
    ELC_EVENT_JPEG_JEDI                                     =  (510),
    ELC_EVENT_JPEG_JDTI                                     =  (511),
} elc_event_t;
```

Figure 324: Mapping of ELC Peripherals in bsp_elc.h example

ELC HAL Module Important Operational Notes and Limitations

The ELC HAL module needs no pin, clocking, or interrupt configuration. It is just a 'connect' mechanism between peripherals. However, if linking I/O Ports via the ELC, the I/O pins need to be configured as inputs or outputs.

Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.17.4 Including the ELC HAL Module in an Application

The ISDE automatically adds the necessary ELC HAL module to the HAL/Common thread in the project by default; as such, the steps described later in this section are not necessary or even forbidden (if the ELC HAL module is already configured in terms of the HAL/Common thread — only one driver instance is allowed). The following descriptions are provided for completeness and in case the ELC HAL module is mistakenly removed.

This section describes how to include the ELC HAL module in an application using the SSP configurator.

NOTE: It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these tasks, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications*. *

To add the ELC Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the ELC HAL module is g_elc. This name can be changed in the associated Properties window.)

ELC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_elc ELC Driver on r_elc	Threads	New Stack> Driver> System> ELC Driver on r_elc

When the ELC HAL Driver on r_elc is added to the thread stack as shown in the following figure, the configurator will automatically display the options dialog. The only available change to the ELC HAL module is to enable or disable parameter checking.

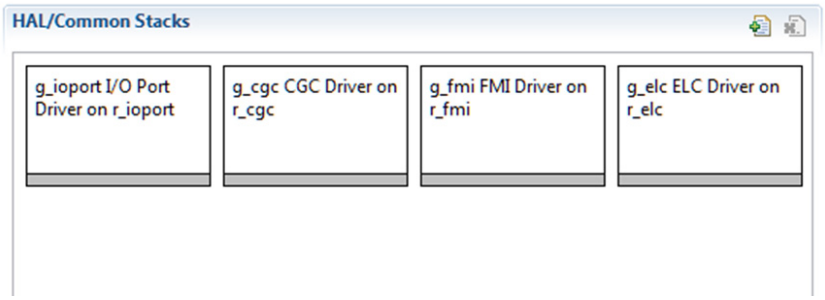

Figure 325: ELC HAL Module Stack

4.2.17.5 Configuring the ELC HAL Module

The ELC HAL module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or

operating modes, which must be configured for lower-level modules for successful operation. Only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP Configurator, and are shown in the following tables for easy reference.

NOTE: You may want to open your ISDE and create the ELC HAL module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the ELC HAL Module on r_elc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Enable or disable the parameter error checking.
Name	g_elc	Module name.

NOTE: The example settings and defaults are for a project using the Synergy S7G2 Group. Other MCUs may have different default values and available configuration settings.

ELC HAL Module Clock Configuration

There is no clock configuration for the ELC block.

ELC HAL Module Pin Configuration

There are no pins associated directly with the ELC HAL Module that require configuration.

4.2.17.6 Using the HAL Module in an Application

The typical steps in using the ELC HAL module in an application are:

1) Initialize the ELC using the init and enable APIs (automatically done by ISDE).
2) Link a peripheral with an event using the linkSet API.
3) Enable the linkage with the enable API.

The following figures illustrates the common steps in a typical operational flow diagram.

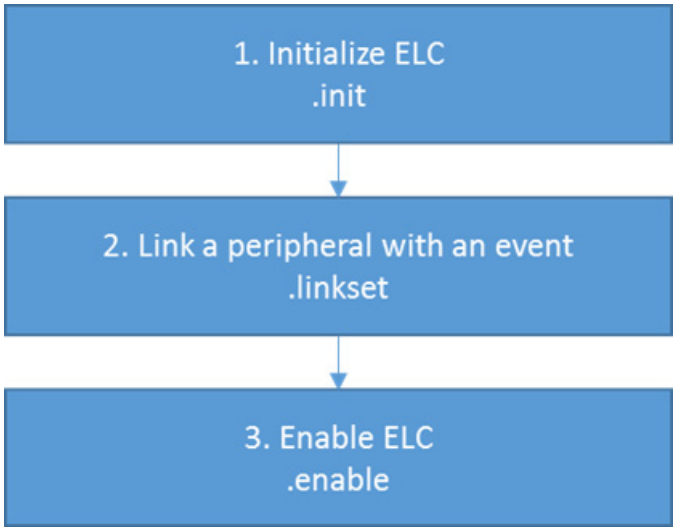

Figure 326: Flow Diagram of a Typical ELC HAL Module Application

4.2.18 External IRQ Driver

The External IRQ HAL module provides high-level APIs for configuring and using external IRQ pins on Synergy MCUs. The External IRQ HAL module is implemented on r_icu and uses the Interrupt Controller Unit (ICU) of the Synergy MCU.

4.2.18.1 External IRQ HAL Module Features

- Supports the external interrupt pins available on the target Synergy MCU
- Supports multiple function options:
  - Enabling and disabling generation of an interrupt
  - Enabling and disabling the IRQ noise filter
  - Setting external pin IRQ trigger (Rising edge, falling edge or low level on the IRQ pin)
- Supports configuring a user callback function, which will be invoked by the HAL module when an external pin interrupt is generated.

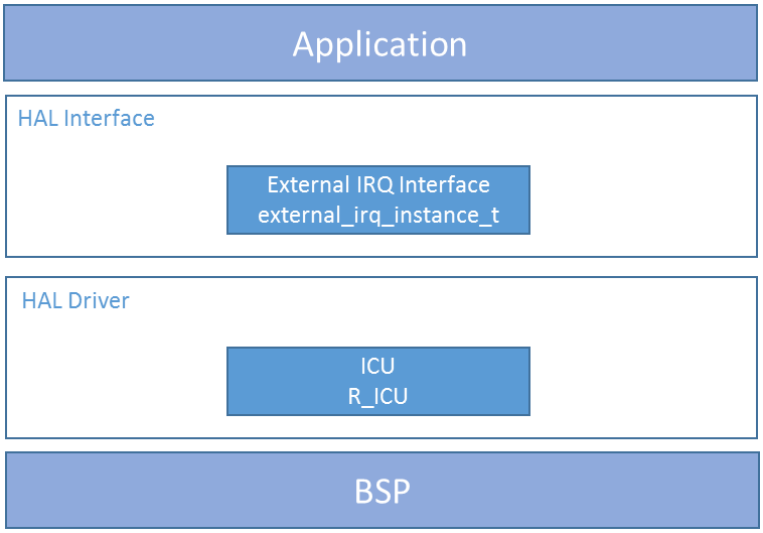

Figure 327: External IRQ HAL Module Block Diagram

4.2.18.2 External IRQ HAL Module APIs Overview

The External IRQ HAL module defines APIs for opening, closing, and waiting for interrupt events from external pins. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows.

External IRQ HAL Module API Summary

Function Name	Example API Call and Description
open	g_external_irq.p_api->open(g_external_irq.p_ctrl, g_external_irq.p_cfg) Open instance and initialize.
enable	g_external_irq.p_api->enable(g_external_irq.p_ctrl) Enable callback when IRQ occurs.
disable	g_external_irq.p_api->disable(g_external_irq.p_ctrl) Disable callback when IRQ occurs.

Function Name	Example API Call and Description
triggerSet	g_external_irq.p_api->triggerSet(g_external_irq.p_ctrl, trigger) Set trigger.
filterEnable	g_external_irq.p_api->filterEnable(g_external_irq.p_ctrl) Enable noise filter.
filterDisable	g_external_irq.p_api->filterDisable(g_external_irq.p_ctrl) Disable noise filter.
close	g_external_irq.p_api->close(g_external_irq.p_ctrl); Close instance.
versionGet	g_external_irq.p_api->wait(&version); Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_ASSERTION	Assertion error.
SSP_ERR_INVALID_ARGUMENT	Callback is not NULL but ISR is not enabled.
SSP_ERR_IN_USE	Device in use.
SSP_ERR_NOT_OPEN	Device unopened.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API references for the associated module for a definition of all relevant status return values.

4.2.18.3 External IRQ HAL Module Operational Overview

The External IRQ HAL module provides a set of APIs for controlling external interrupts. Interrupts can be triggered on rising edge, falling edge, both edges or low level of the input signal on the external IRQ pin. A digital-filtering function can be enabled to eliminate some noise on the input signal. A user-callback function is supported and is triggered each time an IRQ event occurs.

To trigger a transfer of data using the DMAC or DTC peripheral when the configured external IRQ event occurs, configure the DMAC or DTC transfer with the activation source set to ELC_EVENT_PORTn_IRQ (where n is the IRQ channel number.)

Other peripherals can be triggered to start from an external interrupt using the Event Link Controller (ELC.) Refer to the SSP User Manual User Guide for the ELC HAL module for more information.

External IRQ HAL Module Important Operational Notes and Limitations

- Refer to the datasheet for the Synergy device to be programmed to find the port pins which support the external interrupt functions and to obtain the external IRQ number for a given port pin.
- The external IRQ number corresponds to the channel setting in the ISDE Properties window for the External IRQ HAL module.
- The PORTn (where n is the IRQ number) interrupt must be enabled in the BSP to notify the module that the anticipated hardware event has occurred.
- A user-callback function can be registered in the open API. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the IRQn triggers. NOTE: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can adversely affect the responsiveness of the system.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.18.4 Including the External IRQ HAL Module in an Application

This section describes how to include the External IRQ HAL module in an application using the SSP configurator.

Note: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the External IRQ HAL driver to an application, simply add it to a thread using the Stacks Selection Sequence given in the table below. (The default name for the module is g_external_irq0. This name can be changed in the associated Properties window.)

External IRQ HAL Driver Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
r_icu0 External IRQ Driver on r_icu	Threads	New Stack> Driver> Input> External IRQ Driver on r_icu

When the External IRQ HAL module on r_icu is added to the thread stack as shown in the figure below, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information will be box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

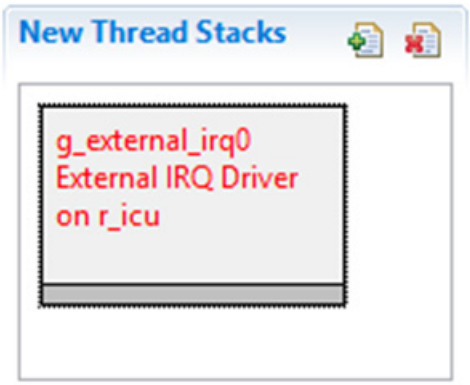

Figure 328: External IRQ HAL Module Stack

4.2.18.5 Configuring the External IRQ HAL Module

The External IRQ HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+.) This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt priority levels.

Note: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the configuration table settings given below. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the External IRQ HAL Module on r_icu

ISDE Property	Value	Description
Parameter Checking	Default, Enabled, Disabled ; (Default: Default)	Parameter Checking
Name	g_external_irq0	Driver name.

ISDE Property	Value	Description
Channel	0	Specifies the hardware IRQ channel used.
Trigger condition	Falling, Rising, Both Edges, Low Level; (Default: Rising)	Trigger selection.
Digital Filtering	Enabled, Disabled ; (Default: Disabled)	Digital filter enable/disable.
Digital Filtering Sample Clock (Only valid when Digital Filtering is Enabled)	PCLK/1, PLCK/8, PLCK/32, PCLK/64;(Default: PCKL/64)	Sets noise filter sampling period.
Interrupt enabled after initialization	True, False ; (Default: True)	Interrupt enable selection.
Callback	NULL	A user callback function can be registered using the open API. If this callback function is provided, it is called from the interrupt service routine (ISR) each time the IRQn triggers. Note: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Enabled, Disabled ; (Default: Disabled)	Interrupt priority setting

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

External IRQ HAL Module Clock Configuration

The IRQ peripheral module doesn't require any specific clock settings.

External IRQ HAL Module Pin Configuration

The External IRQ peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the IRQ pins.

Selection Sequence for the External IRQ HAL Driver on r_icu

Resource	ISDE Tab	Pin selection Sequence
IRQ	Pins	Select Peripherals > Input: IRQ > IRQ0

NOTE: The selection sequence assumes IRQ0 is the desired hardware target for the driver.

Pin Configuration Settings for External IRQ Driver on r_icu

Pin Configuration Property	Value	Description
Operation Mode	Disabled, Enabled; (Default: Disabled)	Select Enabled to enable interrupts
NMI	None, P200; (Default: None)	Non-maskable interrupt Pin
IRQ00:14	None, Pnn, Pmm; Default: None	Interrupt request Pin

NOTE: The example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.18.6 Using the External IRQ HAL Module in an Application

The typical steps in using the External IRQ HAL module in an application are:

The typical steps in using the External IRQ HAL module in an application are:

1) Initialize the External IRQ HAL module using the open API
2) Enable the IRQ (if needed) with the enable API
3) Enable the noise filter (if needed) with the filterEnable API
4) Change the trigger condition (only if the module is closed previously to avoid any false events) with the triggerSet API
5) Disable the noise filter (if enabled) with filterDisable API
6) Close the module (if needed) with the close API

These common steps are illustrated in a typical operational flow diagram in the figure below:

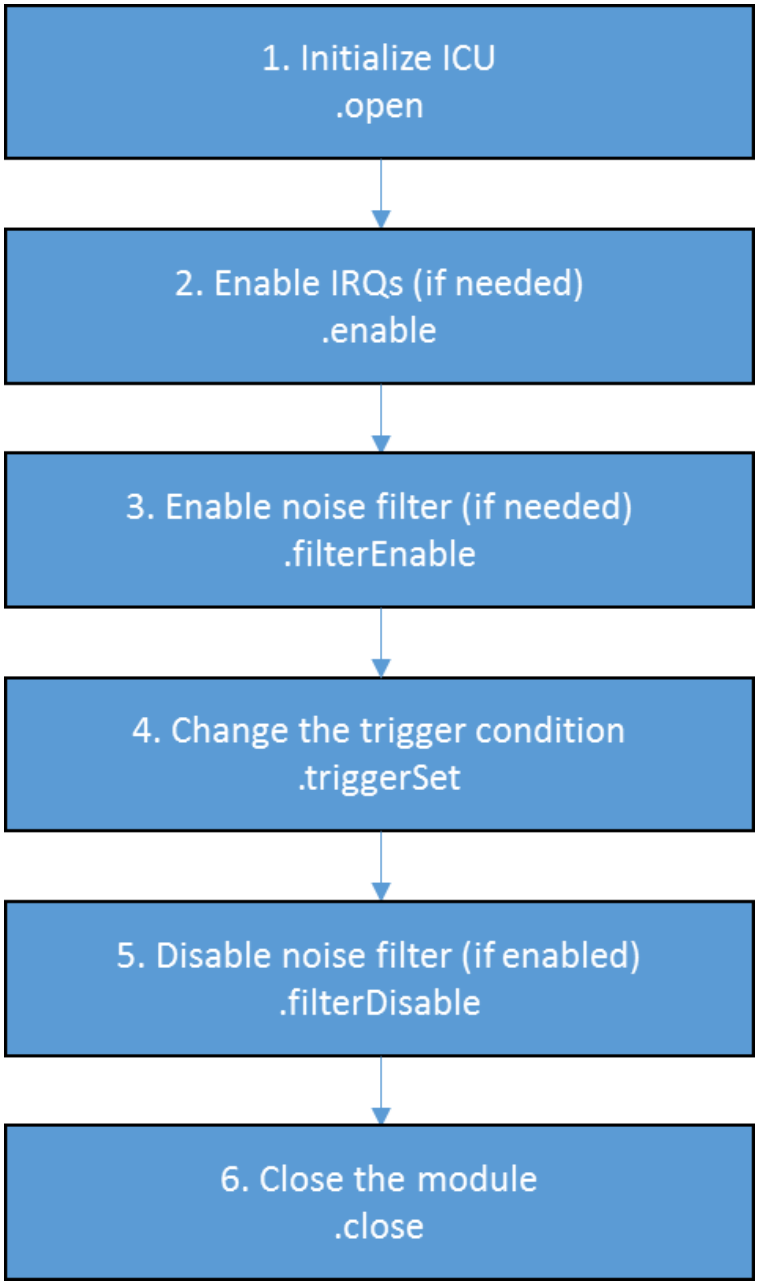

Figure 329: Typical External IRQ HAL Module Application Flow Chart

4.2.19 Flash Driver

There are two separate Flash modules: r_flash_lp and r_flash_hp. The High-Performance Flash module (Flash_HP) is used for programming the S7 and S5 family of MCUs. The Low-Power Flash module (Flash_LP) is used for programming

the S3 and S1 family of MCUs. The two are not interchangeable, although the APIs and other features of the modules are very similar. This guide covers the operation of both of these HAL modules.

4.2.19.1 Flash HAL Module Features

The Flash HAL modules APIs allow an application to read, write, and erase both the data and ROM flash areas that reside within the MCU. The amount of flash memory available varies across MCU parts, but the API functions apply to all devices. Key features of the Flash HAL modules are listed below:

- Support for block erasing, reading, writing, and blank checking of code flash (ROM).
- Support for both blocking and non-blocking erasing, reading, writing, and blank checking of data flash.
- Support for blocking erasing, reading, writing, and blank checking of code flash.
- Support for callback functions for completion of non-blocking data-flash operations.
- Support for access window (write protection) for ROM Flash, allowing only specified areas of code flash to be erased or written.
- Support for boot block-swapping which allows safe rewriting of the startup program without first erasing it.

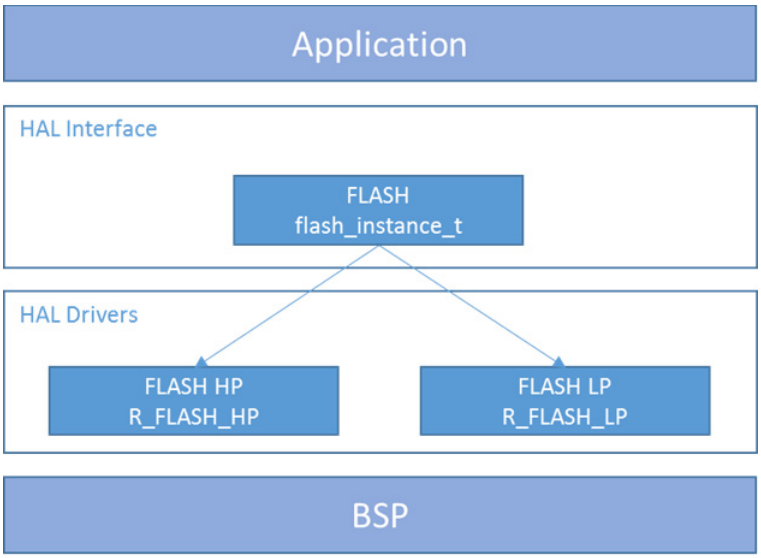

Figure 330: Flash HAL Module Block Diagram

4.2.19.2 Flash HAL Module APIs Overview

The Flash HAL module defines APIs for several operations including opening, reading, erasing, and closing the flash memory. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows.

Flash HAL Module API Summary

Function Name	Example API Call and Description
open	g_flash0.p_api->open(g_flash0.p_ctrl, g_flash0.p_cfg); Open FLASH device.
write	g_flash0.p_api->write(g_flash0.p_ctrl,(uint32_t) write_buffer, FLASH_CF_32KB_BLOCK55, CODE_BLOCK_SIZE_32KB); Write FLASH device.
read	g_flash0.p_api->read(g_flash0.p_ctrl, read_buffer, DATA_FLASH_ADDR, num_bytes); Read FLASH device.
read	g_flash0.p_api->erase(g_flash0.p_ctrl, FLASH_CF_32KB_BLOCK55,num_sectors); Erase FLASH device.
blankCheck	g_flash0.p_api->blankCheck(g_flash0.p_ctrl, FLASH_CF_32KB_BLOCK55, FLASH_DATA_BLOCK_SIZE, &blankCheck); Blank check FLASH device.
close	g_flash0.p_api->close(g_flash0.p_ctrl); Close FLASH device.
statusGet	g_flash0.p_api->statusGet(g_flash0.p_ctrl); Get Status for FLASH device.
accessWindowSet	g_flash0.p_api->accessWindowSet(g_flash0.p_ctrl, FLASH_CF_32KB_BLOCK1, FLASH_CF_32KB_BLOCK3); Set Access Window for FLASH device.

Function Name	Example API Call and Description
accessWindowClear	g_flash0.p_api->accessWindowClear(g_flash0.p_ctrl); Clear any existing code-flash access window for FLASH device.
reset	g_flash0.p_api->reset(g_flash0.p_ctrl); Reset function for FLASH device.
updateFlashClockFreq	g_flash0.p_api-> updateFlashClockFreq (g_flash0.p_ctrl); Update Flash clock frequency (FCLK) and recalculate timeout values.
startupAreaSelect	g_flash0.p_api->startupAreaSelect(g_flash0.p_ctrl, FLASH_STARTUP_AREA_BLOCK1, true); Select which block - Default (Block 0) or Alternate (Block 1) is used as the start-up area block. Refer to the table below for all the possible values for parameter2.
versionGet	g_flash0.p_api->versionGet(&version); Retrieve the API version using the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables review the *SSP User's Manual* available as described in the References section at the end of this document.

.setupAreaSelect parameter2 options

Swap Type	Is_temporary	Operation
FLASH_STARTUP_AREA_BLOCK0	False	On next reset, Startup area will be Block 0.
FLASH_STARTUP_AREA_BLOCK0	False	On next reset, Startup area will be Block 0.

Swap Type	Is_temporary	Operation
FLASH_STARTUP_AREA_BLOCK1	False	On next reset, Startup area will be Block 1.
FLASH_STARTUP_AREA_BLOCK1	True	Startup area is immediately, but temporarily switched to Block 1.
FLASH_STARTUP_AREA_BTFLG	True	Startup area is immediately, but temporarily switched to the Block determined by the Configuration BTFLG.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_IN_USE	Device in use error.
SSP_FLASH_ERR_FAILURE	Flash failure error.
SSP_ERR_FCLK	FCLK must be a minimum of 4 MHz for Flash operations.
SSP_ERR_TIMEOUT	Timeout error.
SSP_ERR_INVALID_SIZE	Invalid size error.
SSP_ERR_INVALID_ADDRESS	Invalid address error.
SSP_ERR_ASSERTION	Assertion error.
SSP_ERR_INVALID_BLOCKS	Invalid number of blocks specified.
SSP_ERR_INVALID_ARGUMENT	Invalid argument error.
SSP_ERR_HW_LOCKED	Peripheral already in use.
SSP_ERR_CMD_LOCKED	FCU is in locked state, typically as a result of attempting to Erase an area that is protected by an Access Window.
SSP_ERR_NOT_OPEN	Flash has not yet been opened.
SSP_ERR_IRQ_BSP_DISABLED	Caller is requesting BGO (background mode operation) but the Flash interrupt is not enabled.

Name	Description
SSP_ERR_WRITE_FAILED	Write operation failed. This may be returned if the requested Flash area is not blank.
SSP_ERR_PE_FAILURE	Failed to enter P/E mode
false	Supplied address is valid flash address on this MCU.
true	Supplied address is valid and p_block info contains the details on this address's block.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API Reference section for the associated module for a definition of all relevant status return values.

4.2.19.3 Flash HAL Module Operational Overview

The Flash API makes the process of programming and erasing on-chip flash areas easy. Both code (User ROM) and data-flash areas are supported. The API, in its simplest form, can be used to perform blocking erase and program operations. The term "blocking" means that when a program or erase function is called, the function does not return until the operation has finished. This API supports blocking for both code and data-flash, with BGO (background-mode operation) available for data-flash operations only. When a code-flash operation is on-going, you cannot access that code-flash area. If you attempt to access the code-flash area while a code-flash operation is in progress, the flash-control unit will transition into an error state.

It is important to keep in mind that even though a code-flash operation is blocking, there are several situations where the code-flash could still end up being accessed while the operation is blocking and these must be prevented. This includes:

- Vector table access if the Vector table is located in ROM.
- ROM access by an interrupt vectoring to a ROM address, even if the vector table itself is not in ROM.

A multithreaded application where multiple threads are allowed to continue to run while a code-flash operation is blocking.

Flash HAL Module Important Operational Notes and Limitations

startupAreaSelect() swaps Data in to Block 0. Be sure that the swapped-in data is valid if you use startupAreaSelect().

Data-Flash BGO Precautions

When using the data-flash BGO, the User ROM, RAM and external memory can still be accessed. You must ensure that the data-flash is not accessed during a data-flash operation. This includes interrupts that may access the data-flash.

Code-Flash Precautions

BGO mode is not supported for code-flash, so a code-flash operation will not return before the operation has completed. By default, the vector table resides in the User ROM (code-flash.) If an interrupt occurs during the ROM operation, then ROM will be accessed to fetch the interrupt's starting address and an error will occur.

The simplest work-around is to disable interrupts during code-flash operations. Another option is to copy the vector table to RAM, update the VTOR (Vector Table Offset Register) accordingly and ensure that any interrupt service routines execute out of RAM. Similarly, you must insure that if in a multithreaded environment, threads running from ROM cannot become active while a code-flash operation is in progress.

Blank Checking

The blankCheck API function checks whether code or data-flash contents are blank. Note that it is not possible to write to flash (code or data) without first erasing it. The blankCheck function determines whether a specified area is blank and therefore writable. In almost all cases, it is not sufficient to compare flash contents to 0xFF to determine whether the area is blank. The one exception is Flash HP code-flash. A 0xFF in Flash_HP code-flash does indicate blank. Renesas recommends strongly using the blankCheck API function in all cases.

Flash Status

The statusGet API function allows the application to query the 'Ready' status of the flash. This is useful in data-flash BGO operations when you choose not to use a callback function, so there is no asynchronous notification of a completed data-flash operation. In this case, the data-flash is configured to operate in BGO mode, so once the operation is started (an erase, for example), the call returns immediately with the operation executing in the background. By calling the statusGet API function, you can determine when the operation has safely completed or generated an error, and it is now safe to proceed with another flash operation.

Swap Blocks

The startupAreaSelect API function allows the user to select which block - default (Block 0) or alternate (Block 1) - is used as the startup-area block. The provided parameters determine which block will become the active startup block and whether that action will be immediate (but temporary) or permanent subsequent to the next reset.

Doing a temporary switch might appear to have limited usefulness; however, if there is an access window in place such that Block 0 is write-protected, then you could do a temporary switch, update the block, and switch them back without having to touch the access window.

Flash Clock (FCLK)

The FCLK is the clock used by the Flash peripheral in performing all Flash operations. It must be >= 4 MHz for successful flash operations. As part of the open function the Flash clock is checked and if < 4 MHz open will return SSP_ERR_FCLK. Once the Flash API has been opened, if the FCLK frequency is changed, the updateFlashClockFreq API function must be called to inform the API of the change. Failure to do so could result in flash operation failures and possibly damage the part.

Interrupts

Enable the flash ready interrupt only if you plan to use the data-flash BGO. In this mode, the application can initiate a data-flash operation and then be asynchronously notified of its completion, or an error, using a user supplied-callback function. The callback function is passed a structure containing event information that indicates the source of the callback event (that is,FLASH_EVENT_ERASE_COMPLETE)

When the FLASH FRDYI interrupt is enabled, the corresponding ISR will be defined in the flash driver. The ISR will call a user-callback function if one was registered with the open API.

NOTE: The Flash HP supports an additional flash-error interrupt and if the BGO mode is enabled for the FLASH HP then both FRDYI and FIFERR interrupts must be given a priority.

AccessWindow

An access window defines a contiguous area in Code Flash for which programming/erase is enabled. This area is on block boundaries with a starting and ending address being provided to accessWindowSet. The block containing the start address is the first block. The block containing the end address is the last block. The access window then becomes the first block – last block inclusive. Anything outside this range is write protected. Invalid address information provided to accessWindowSet will return SSP_ERR_INVALID_ADDRESS. An access window may be removed by calling the accessWindowClear API function.

- The High-Performance Flash module (Flash_HP) is the API used for programming the S7 and S5 family of MCUs.
- The Low-Power Flash module (Flash_LP) is the API used for programming the S3 and S1 family of MCUs.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.19.4 Including the Flash HAL Module in an Application

This section describes how to include the Flash HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Flash Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Flash Driver is g_flash0. This name can be changed in the associated Properties window.)

Flash Driver Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_flash0 Flash Driver on r_rflash_hp	Threads	New Stack > Driver > Storage > Flash Driver on r_flash_hp
g_flash0 Flash Driver on r_rflash_lp	Threads	New Stack > Driver > Storage > Flash Driver on r_flash_lp

When the Flash HAL modules on r_flash_hp or r_flash_lp are added to the thread stack as shown in the figure below, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information will be box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

NOTE: Both Flash HAL modules are shown in the figure below, but only one should be used, depending on the selected MCU; they are shown together only for completeness.

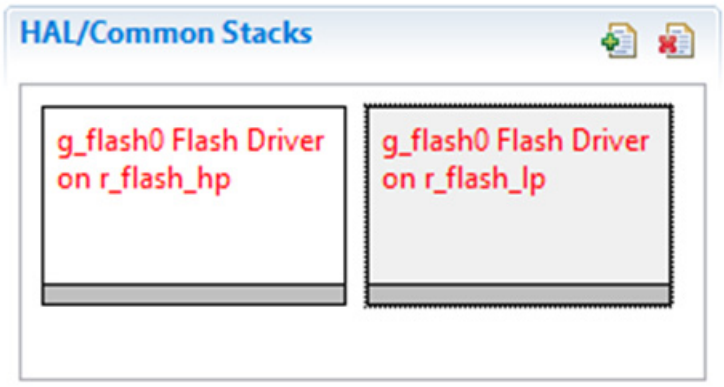

Figure 331: Flash HAL Module Stack

4.2.19.5 Configuring the Flash HAL Module

The Flash HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+.) This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the configuration table settings in the following tables. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

The Flash HAL Driver is implemented on one of two different modules, the r_flash_hp and the r_flash_lp, and the configuration settings for these implementations are given in the following tables:

Table 5 Configuration Settings for the Flash HAL Module on r_flash_hp

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Controls whether to include code for API parameter checking.
code-flash Programming Enable	Enable, Disabled Default: Disabled	Controls whether or not code-flash programming is enabled. Disabling reduces the amount of ROM used by the API.
Name	g_flash0	Module name.
data-flash Background Operation	Enabled, Disabled Default: Enabled	Enabling allows Flash API calls that reference data-flash to return immediately, with the operation continuing in the background.

ISDE Property	Value	Description
Callback	NULL	Callback function called when a data-flash BGO operation completes or errors. A user callback function can be registered in open. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Flash Ready Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Flash ready interrupt priority selection.
Flash Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Flash error interrupt priority selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration for the Flash HAL Module on r_flash_lp

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Controls whether to include code for API parameter checking.

ISDE Property	Value	Description
code-flash Programming Enable	Enable, Disabled Default: Disabled	Controls whether or not code-flash programming is enabled. Disabling reduces the amount of ROM used by the API.
Name	g_flash0	Module name.
data-flash Background Operation	Enabled, Disabled Default: Enabled	Enabling allows Flash API calls that reference data-flash to return immediately, with the operation continuing in the background.
Callback	NULL	Callback function called when a data-flash BGO operation completes or errors. A user callback function can be registered in open. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Flash Ready Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Flash ready interrupt priority selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration for the Flash HAL Module on r_flash_lp

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Controls whether to include code for API parameter checking.

ISDE Property	Value	Description
code-flash Programming Enable	Enable, Disabled Default: Disabled	Controls whether or not code-flash programming is enabled. Disabling reduces the amount of ROM used by the API.
Name	g_flash0	Module name.
data-flash Background Operation	Enabled, Disabled Default: Enabled	Enabling allows Flash API calls that reference data-flash to return immediately, with the operation continuing in the background.
Callback	NULL	Callback function called when a data-flash BGO operation completes or errors. A user callback function can be registered in open. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Flash Ready Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Flash ready interrupt priority selection.

NOTE: The example settings and defaults are for a project using the Synergy S3A7 MCU. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults can be desirable. For example, it might be useful to disable code-flash programming to reduce the code size of the driver.

Flash HAL Module Clock Configuration

Enable the flash-ready interrupt only if you plan to use the data-flash BGO (background mode operation.) In this mode, the application can initiate a data-flash operation and then be asynchronously notified of its completion (or an error) using a user-supplied callback function. The callback function is passed a structure containing event information that indicates the source of the callback event (for example, FLASH_EVENT_ERASE_COMPLETE.)

To enable interrupts, set the priority of the FCU > FRDYI interrupt on the ICU tab of the Project Configurator in e^2 studio. This sets BSP_IRQ_CFG_FCU_FRDYI in synergy_cfg/ssp_cfg/bsp/bsp_irq_cfg.h to the priority level selected.

When the FLASH FRDYI interrupt is enabled in the BSP, the corresponding ISR will be defined in the flash driver. The ISR will call a user-callback function if one was registered in open.

NOTE: Flash HP supports an additional flash-error interrupt and if BGO mode is enabled for FLASH HP, then both FRDYI and FIFERR interrupts must be given a priority.

Flash HAL Module Clock Configuration

The flash circuit uses FCLK as its clock. FCLK must be <= 4 MHz. If this clock rate changes after the flash Open() function is called, then you must call updateFlashClockFreq() to inform the flash API of the change.

Flash HAL Module Pin Configuration

The flash circuit does not use any MCU pins.

4.2.19.6 Using the Flash HAL Module in an Application

Some typical steps in using the Flash HAL module in an application are:

1) Initialize the Flash HAL using the open API.
2) Disable Interrupts.
3) Blank check a code flash area with the blankCheck API.
4) Erase one or more code-flash blocks with the erase API.
5) Write to code-flash with the write API.
6) Enable Interrupts.
7) Blank check a data flash area with the blankCheck API.
8) Erase one or more data-flash blocks using the erase API.
9) Write to data-flash using the write API.
10) Close using the close API if finished with all Flash operations.

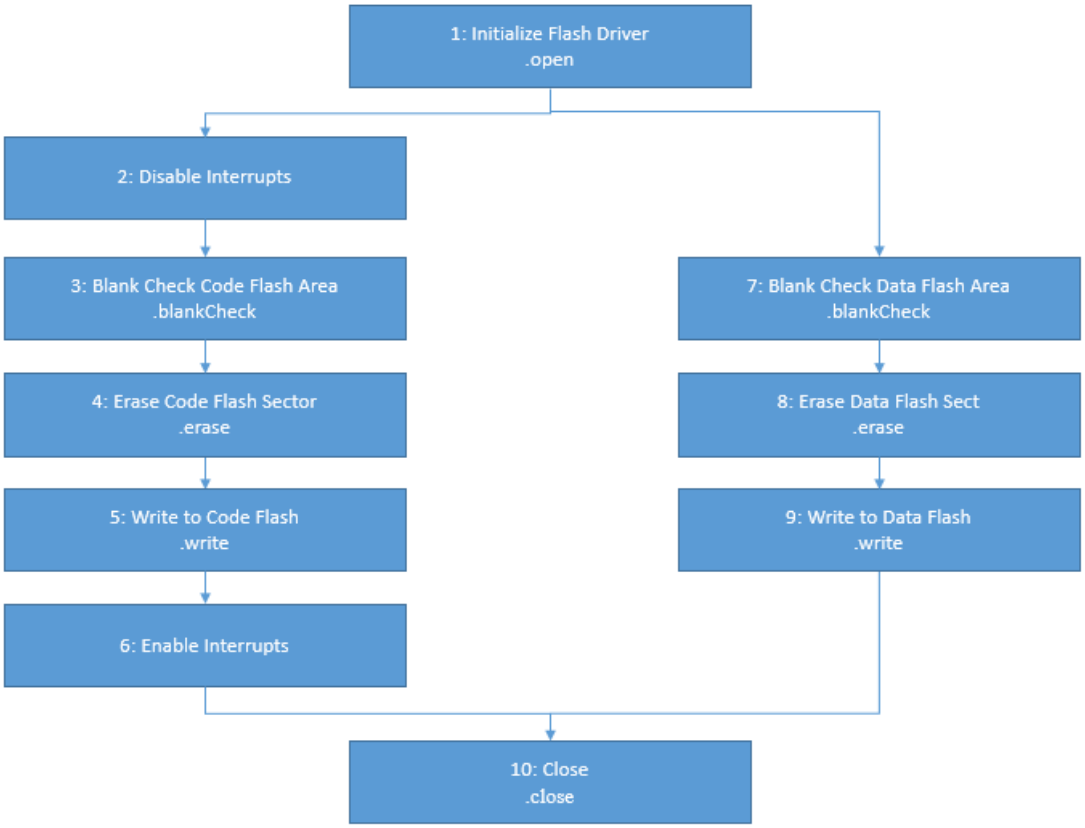

Figure 332: Flow Diagram of a Typical Flash HP HAL Module Application

4.2.20 FMI Driver

The FMI HAL module is a high-level API for applications that read records from the Factory MCU Information Flash Table. The FMI HAL module is implemented on r_fmi. The FMI HAL module uses the Flash Interface on the Synergy MCU.

4.2.20.1 FMI HAL Module Features

The FMI HAL module reads the FMIFRT (Factory MCU Information Flash Root Table) on a Synergy microcontroller, looking up the address of the start of the table in flash. The module sets the caller's pointer to the Product Information record from the table. This information may be used to determine the capabilities of features specific to this MCU package. Information available from the FMI HAL module includes:

- Product Information: Product Name, Package, Pin count, and Temperature range
- Product Features: Version major, Version minor, and Variant data
- Event Information such as Interrupts and Events

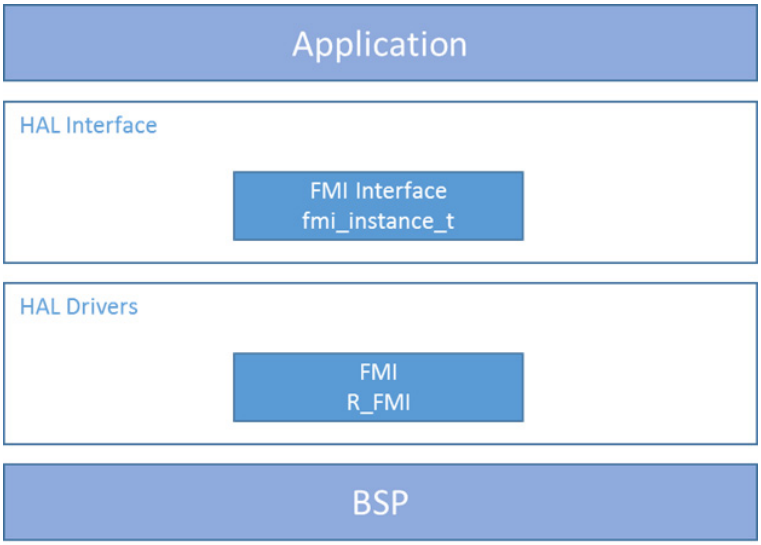

Figure 333: FMI HAL Module Block Diagram

4.2.20.2 FMI HAL Module APIs Overview

The FMI HAL module defines an API for accessing the FMIFRT. The following table has a complete list of the available APIs, an API call example, and a brief description of each API. Following the API summary table is a table listing status return values.

FMI HAL Module API Summary

Function Name	Example API Call and Description
init	g_fmi.p_api->init(); Initialize the FMI base pointer.
productInfoGet	g_fmi.p_api->productInfoGet(&g_pp_product_info); Get product information record address into g_pp_product_info pointer.
uniqueIdGet	g_fmi.p_api->uniqueIdGet(&g_p_unique_id); Copy the unique ID into the g_p_unique_id pointer.

Function Name	Example API Call and Description
productFeatureGet	g_fmi.p_api->productFeatureGet(&g_ssp_feature, &g_feature_info); Get feature information and store it in g_feature_info pointer.
eventInfoGet	g_fmi.p_api->peventInfoGet(&g_ssp_feature,SSP_SIGNAL_GPT_COUNTER_OVERFLOW, &g_event_info); Get event information and store it in g_event_info pointer.
versionGet	g_fmi.p_api->versionGet(&g_p_version); Get the driver version based on compile time macros.

NOTE: Review the SSP User's Manual API References for the associated module to learn more about operations and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_INVALID_FMI_DATA	The FMI data table provided is not valid
SSP_ERR_IP_CHANNEL_NOT_PRESENT	Requested channel does not exist on this MCU
SSP_ERR_IP_UNIT_NOT_PRESENT	Requested unit does not exist on this MCU
SSP_ERR_INTERNAL	Requested feature is in a format not supported at this time
SSP_ERR_IRQ_BSP_DISABLED	Event information could not be found
SSP_ERR_ASSERTION	Caller's pointer is null
SSP_ERR_INVALID_FACTORY_FLASH	Factory flash is not valid

NOTE: Lower level drivers may return Common Error Codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.20.3 FMI HAL Module Operational Overview

The FMI HAL module retrieves the product information record address and populates the fmi_product_info_t structure using the productInfoGet API.

The FMI HAL module copies unique ID and populates the fmi_unique_id_t structure using the uniqueIdGet API.

The FMI HAL module gets feature information and populates the fmi_feature_info_t structure using the productFeatureGet API.

The FMI HAL module fetches event information and populates the fmi_event_info_t structure using the eventInfoGet API.

The FMI HAL module gets code version and API version in ssp_version_t structure using the versionGet API.

FMI HAL Module Important Operational Notes and Limitations

The fmi_product_info_t::unique_id is deprecated. It does not contain a unique ID if the factory MCU information is linked in by the application code. Use uniqueIdGet for the unique ID.

- For limitations of the FMI HAL Interface and its implementation, see the latest SSP release notes.
- The FMI Driver has been tested on the S7G2 (WS2) Synergy microcontroller family using the FMIFRT peripheral register. It is the only Synergy MCU that is currently programmed with data in the Factory MCU Information Table.
- For the S5D9 MCU, the uniqueIdGet API of the r_fmi module returns an error. There is no workaround.

4.2.20.4 Including the FMI HAL Module in an Application

This section describes how to include the FMI HAL module in an application using the SSP configurator.

NOTE: This process assumes that you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack.

To add the FMI to an application, simply add it to a thread using the Stacks Selection Sequence given in the following table. (The default name for the FMI is r_fmi0. This name can be changed in the associated **Properties** window.)

Flash Driver Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
r_fmi FMI Driver on r_fmi	**Threads > HAL/Common**	**New Stack> Driver> System> FMI Driver on r_fmi**

The following figure shows that the FMI Driver on r_fmi is automatically added to the HAL/Common Stack when a new project is created, since every design requires the message to be supplied by the FMI HAL module.

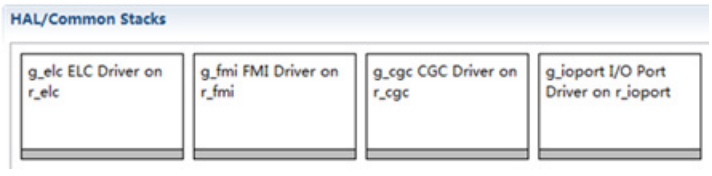

Figure 334: FMI HAL Module Stack

4.2.20.5 Configuring the FMI HAL Module

The FMI HAL module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user accessible properties are given in the **Properties** tab within the SSP configurator and are shown in the following tables for easy reference.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the Configuration Table Settings given below. This can help orient you and provide a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the FMI HAL Module on r_fmi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Controls whether to include code for API parameter checking.
SSP MCU Information Symbol Name	g_fmi_data (Default)	This symbol maps to the base address where the factory flash table information is found. It should not be modified.
Part Number Mask	0xFE00 (Default)	Each bit represents one character in the Synergy part number, where the MSB is the first character in the part number ('R'). Set bits to ensure the part number in the MCU factory flash matches the part number in the SSP MCU Information. The default mask checks everything except operating temperature, software ID, and quality ID.
Name	g_fmi (Default)	Module instance name.

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

FMI HAL Module Clock Configuration

No specific clock configurations are required for the FMI HAL Driver.

FMI HAL Module Pin Configuration

No specific pin configurations are required for the FMI HAL Driver.

4.2.20.6 Using the FMI HAL Module in an Application

The typical steps in using the FMI in an application are:

1) Initialize the FMI using the init API. It is automatically initialized after Reset.
2) Use the productInfoGet API to get product information.
3) Use the uniqueIdGet API to get unique ID.
4) Use the productFeatureGet API to get feature information.
5) Use the eventInfoGet API to get event information.
6) Use the versionGet API to get driver version information.

The following figure illustrates these common steps in a typical operational flow diagram.

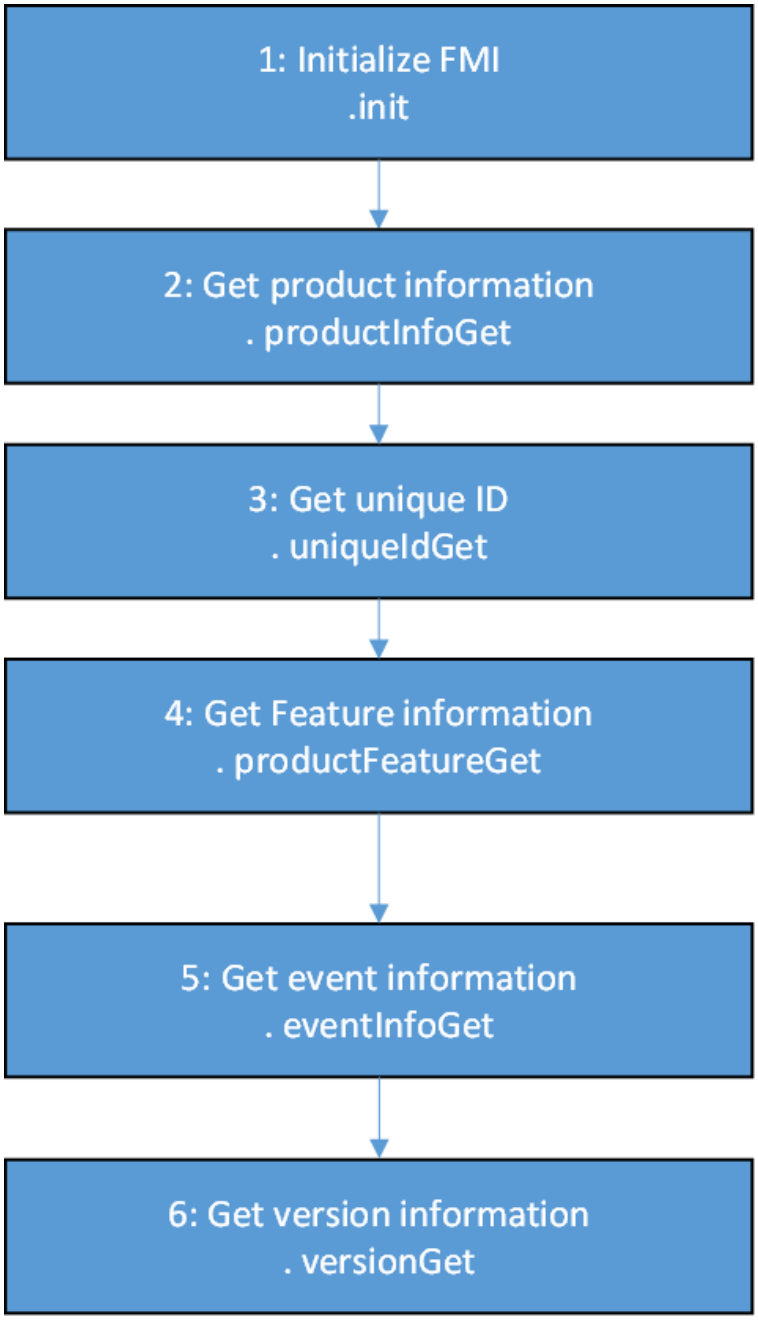

Figure 335: Flow Diagram of a Typical FMI HAL Module Application

4.2.21 GPT Driver

The General PWM Timer (GPT) HAL module provides high-level APIs for timer applications and is implemented on r_gpt. The GPT HAL module uses the GPT peripheral on the Synergy MCU. A user-defined callback can be created to respond to a timer event.

4.2.21.1 GPT HAL Module Features

The GPT HAL module configures a timer to a user-specified period. When the period elapses, any of the following events can occur:

- CPU interrupt that calls a user callback function, if provided
- Toggle a port pin
- Data transfer using DMAC/DTC if configured with Transfer Interface
- Starting of another peripheral if configured with events and peripheral definitions

General PWM Timer (GPT)

- Multiple Channels
  - S7G2: 32-bit x 14 channels
  - S5D9: 32-bit x 14 channels
  - S3A7: 32-bit x 10 channels
  - S124: 32-bit x 1 channel and 16-bit x 6 channels
- PCLKD as core clock
- Two I/O pins per channel
- Up/down-counting saw/triangle waves
- Two output compare and input capture registers
- Can be configured as a response to 8 Event Link Controllers (ELCs), and as an event in ELC

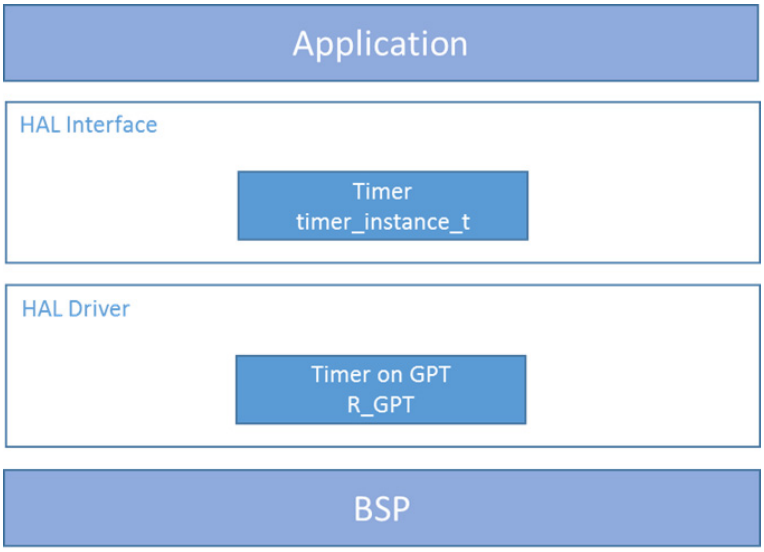

Figure 336: GPT HAL Module Block Diagram

4.2.21.2 GPT HAL Module APIs Overview

The GPT HAL module defines APIs for opening, closing, starting, and stopping timers. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

GPT HAL Module API Summary

Function Name	Example API Call and Description
open	g_timer0.p_api->open(g_timer0.p_ctrl, g_timer0.p_cfg) Initial configuration.
stop	g_timer0.p_api->stop(g_timer0.p_ctrl) Stop the counter.
start	g_timer0.p_api->start(g_timer0.p_ctrl) Start the counter.

Function Name	Example API Call and Description
reset	g_timer0.p_api->reset(g_timer0.p_ctrl) Reset the counter to the initial value.
counterGet	g_timer0.p_api->counterGet(g_timer0.p_ctrl, &value) Get current counter value and store it in provided pointer value.
periodSet	g_timer0.p_api->periodSet(g_timer0.p_ctrl, period, unit) Set the time until the timer expires.
dutyCycleSet	g_timer0.p_api->dutyCycleSet(g_timer0.p_ctrl, duty_cycle, duty_cycle_unit, pin) Sets the time until the duty cycle expires.
infoGet	g_timer0.p_api->infoGet(g_timer0.p_ctrl, &info) Get the time until the timer expires in clock counts and store it in provided pointer info.
close	g_timer0.p_api->close(g_timer0.p_ctrl) Allows driver to be reconfigured and may reduce power consumption.
versionGet	g_timer0.p_api->versionGet(&version) Get version and store it in provided pointer version.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Table Status Return Values

Name	Description
SSP_SUCCESS	Operation is successful.
SSP_ERR_ASSERTION	Parameter is NULL or configuration setting is not allowed.
SSP_ERR_IN_USE	The channel specified has already been opened.
SSP_ERROR_NOT_OPEN	The channel is not open.
SSP_ERR_INVALID_ARGUMENT	Invalid argument provided.

NOTE: Lower level drivers may return Common Error Codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.21.3 GPT HAL Module Operational Overview

The GPT HAL module configures a timer to a user-specified period. When the period elapses, the CPU can be interrupted, a port pin can be toggled, a transfer of data using the DMAC or DTC can be initiated, or another peripheral can be triggered to begin operation.

The following figure shows a flowchart for toggling a port pin or generating a CPU interrupt after a specified period.

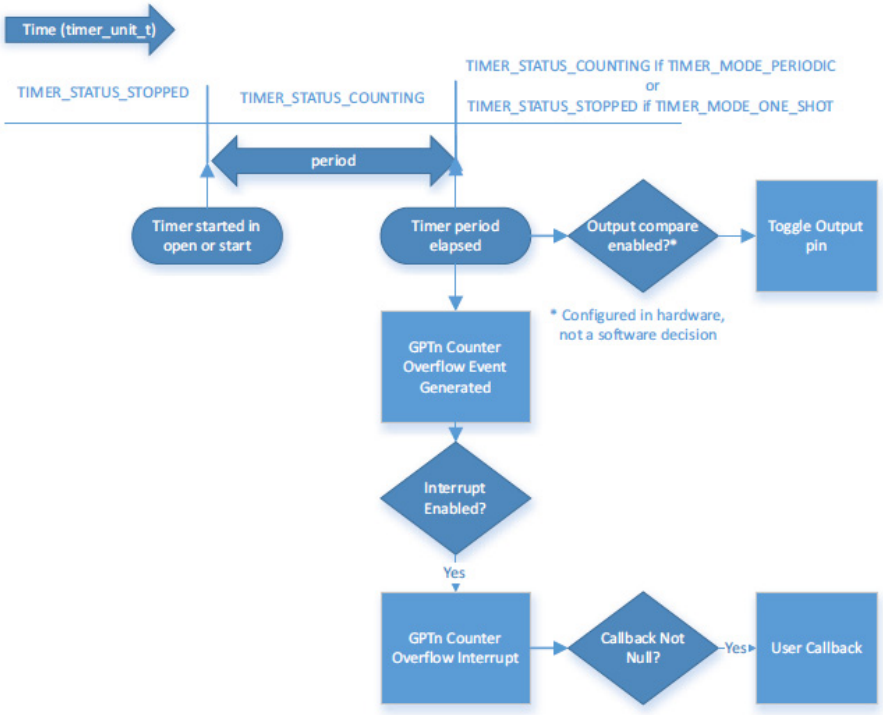

Figure 337: GPT Timer-Periodic or One-Shot Mode

Two different timer modules, the GPT and the AGT, are supported in the SSP. The following sections provide information on both modules so that the developer can compare and contrast the capabilities of each module for a particular application. For additional information on the AGT, refer to the AGT User's Guide.

The GPT module is recommended for most generic timer applications, but either module can be used for a basic timer functionality. The following use cases describe why one timer module would be preferred over the other.

Selecting the GPT Timer Module

The GPT module uses a high-resolution 32-bit counter that can only be clocked by PCLKD. There are more GPT channels than AGT channels on Synergy devices, so using GPT is less likely to cause a resource conflict.

Selecting the AGT Timer Module

The AGT module uses a 16-bit counter that can be clocked by PCLKB, LOCO, or Fsub. If clocked by LOCO or Fsub, the AGT interrupt can be used to wake the MCU from sleep modes. There are two channels, and channel 1 can be clocked by channel 0 underflow, effectively creating a 32-bit cascaded timer.

GPT HAL Module Important Operational Notes and Limitations

The maximum time period depends on the timer type and the input clock frequency.

- On a GPT with 32-bit resolution with PCLKD running at 120 MHz, the maximum period is approximately 36650 seconds, which is just over 10 hours (AGT Count Clock is PCLKD/1024).
- On a GPT with 16-bit resolution with PCLKD running at 32 MHz, the maximum period is approximately 2.09 seconds (AGT Count Clock is PCLKD/1024).

- On an AGT with 16-bit resolution with PCLKB running at 60 MHz, the maximum period is approximately 8.7 ms (AGT Count Clock is PCLKB/8).
- On an AGT with 16-bit resolution with Fsub running at 32 kHz, the maximum period is approximately 2.0 seconds (AGT Count Clock is AGTSCLK/128).

The AGT counter underflow interrupt for the selected channel used must be enabled in the BSP in the following situations:

1) To get a software interrupt when the timer period has elapsed.
2) To use one-shot mode

When the AGTn AGTI interrupt is enabled in the BSP, the corresponding ISR will be defined in the timer driver. The ISR will call a user callback function if one was registered in open.

NOTE: Interrupts may be skipped when used with the DTC peripheral with irq set to TRANSFER_IRQ_END.

GPT Output Timer Signal

If the timer output is configured (GTIOCA/B Output Enabled set to True), the output pin will start at the GTIOCA/B Stop Level and toggle every time the period elapses, beginning with the first time the period elapses after the timer is started.

In one-shot mode, the output is also configured to toggle when the timer starts counting. This generates a pulse - the timer toggles from the stop level when counting begins and toggles back to the stop level when counting ends.

Timer Period Calculation

The timer period is defined as the time until the timer expires. When output compare is used, the output pin will toggle once per period, so the traditional period (from rising edge to rising edge) is twice the period specified in the software.

Runtime period calculation based on the current clock settings is available from open and periodSet.

If the specified timer period is different than the raw counts, the period is calculated using the current timer clock frequency (see Configuring the GPT Clocks or Configuring the AGT Clocks). The current timer clock frequency is determined using systemClockFreqGet. This frequency will be used in the appropriate formula from the following table as clk_freq_hz.

Timer period calculation

Timer Units	Formula
TIMER_UNIT_PERIOD_NSEC	Counts = (period * clk_freq_hz) / 1000000000
TIMER_UNIT_PERIOD_USEC	Counts = (period * clk_freq_hz) / 1000000
TIMER_UNIT_PERIOD_MSEC	Counts = (period * clk_freq_hz) / 1000
TIMER_UNIT_PERIOD_SEC	Counts = (period * clk_freq_hz)
TIMER_UNIT_FREQUENCY_HZ	Counts = (clk_freq_hz) / period
TIMER_UNIT_FREQUENCY_KHZ	Counts = (clk_freq_hz) / 1000 * period

If the requested period is larger than the counter size (32-bit or 16-bit), the driver selects the smallest divisor that allows the result to fit in the counter size. If the counter value is larger than the counter size with the largest divisor (1024), an error code (SSP_ERR_INVALID_ARGUMENT) is returned.

Triggering DMAC/DTC with GPT

To trigger a transfer of data using the DMAC or DTC peripheral when the timer period elapses, configure the DMAC/DTC transfer with activation_source set to ELC_EVENT_GPTn_COUNTER_OVERFLOW (where n is the GPT channel number). See the DMAC or DTC guides for further information.

NOTE: If you use the timer in one-shot mode with the DTC, the entire transfer will complete before the interrupt stops the timer if irq is set to TRANSFER_IRQ_END. To generate only one transfer after the timer period elapses, set irq to TRANSFER_IRQ_EACH, or use the DMAC for the transfer.

Triggering ELC Events with GPT

The GPT timer can trigger the start of other peripherals. The ELC guide provides a list of all available peripherals.

Triggering DMAC/DTC with AGT

To trigger a transfer of data using the DMAC or DTC peripheral when the timer period elapses, configure the DMAC/DTC transfer with activation_source set to ELC_EVENT_AGTn_AGTI (where n is the AGT channel number). See Transfer Interface for further information.

NOTE: If you use the timer in one-shot mode with the DTC, the entire transfer completes before the interrupt stops the timer if irq is set to TRANSFER_IRQ_END. To generate only one transfer after the timer period elapses, set irq to TRANSFER_IRQ_EACH, or use the DMAC for the transfer.

Triggering ELC Events with AGT

The AGT timer can trigger the start of other peripherals. The ELC guide provides a list of all available peripherals listed in elc_peripheral_t. See events and peripheral definitions for further information.

Cascaded AGT Timers creating a 32-bit timer

AGT Channel 1 can be clocked by the AGT Channel 0 underflow, creating a cascaded 32-bit timer.

For GPT Power Down, the GPT module does not set the Module Stop bit (MSTP) for GPT in the close API. This is intentional because the GPT module stop bits control the power to multiple GPT channels, and the GPT module cannot know if other GPT modules are used in the application. Use the following procedure to set the module stop bit for GPT to reduce power consumption when no GPT channels are in use:

1) In the hardware manual for your MCU, go to the Low Power Modes chapter, and look in the Register Descriptions chapter for Module Stop Control Register D.
2) Look at MSTPD5 and MSTPD6. Identify which of these bits contains the channel used by your application.
3) Add the LPM driver to your project on the Threads tab of the Synergy Configuration tool:
4) New> Driver > Power > Low Power Modes Driver on r_lpm.
5) In the application code, confirm that no other GPT channels in the MSTP bit identified in step 2 are currently used by the application. If no channels are being used, use the LPM API to power down the set of GPT channels:

    a) To power down GPT channels controlled by MSTPD5 with an LPM module named g_lpm0, call: g_lpm0.p_api->moduleStop(LPM_MSTP_GPT_CH7_0); // Ignore the channel numbers in the enum value – this is for MSTPD5

    a) To power down GPT channels controlled by MSTPD6, call: g_lpm0.p_api->moduleStop(LPM_MST-P_GPT_CH13_8); // Ignore the channel numbers in the enum value – this is for MSTPD6

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.21.4 Including the GPT HAL Module in an Application

This section describes how to include the GPT HAL module in an application using the SSP configurator.

NOTE: This section assumes that you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack.

To add the GPT HAL module to an application, simply add it to a thread using the Stacks Selection Sequence given in the following table. (The default name for the Timer Driver is g_timer0 is indicated. This name can be changed in the associated Properties window.)

GPT Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_timer0 Timer Driver on r_gpt	Threads -> HAL/Common	New Stack> Driver> Timers> Timer Driver on r_gpt

When the GPT HAL module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower level modules. Any drivers that need additional configuration information will be box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

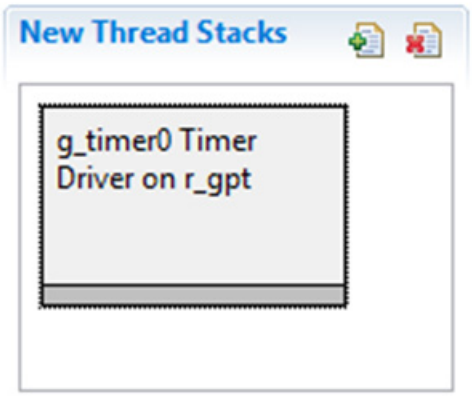

Figure 338: GPT HAL Module Stack

4.2.21.5 Configuring the GPT HAL Module

The GPT HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections (such as interrupts or operating modes) which must be configured for lower level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the properties window of the associated module. Simply select the indicated module and then view the

properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+.) This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the following Configuration Table Settings given. These property settings will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Table Configuration Settings for the GPT HAL Module on r_gpt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Parameter selection.
Name	g_timer0	Module name.
Channel	0	Physical hardware channel. 0-13 for S7G2, 0-9 for S3A7, 0-6 for S124
Mode	Periodic, One Shot, PWM (Default: Periodic)	Mode selection. NOTE: One Shot functionality is not available in the GPT hardware, so it is implemented in software by stopping the timer in the ISR called when the period expires. For this reason, ISR's must be enabled for one-shot mode even if the callback is unused.
Period Value	10	Period value selection. See the Timer Period Calculation section earlier in this document.

ISDE Property	Value	Description
Period Unit	Raw Counts, Nanoseconds, Microseconds, Milliseconds, Seconds, Hertz, Kilohertz (Default: Milliseconds)	Period unit selection. See the Timer Period Calculation section earlier in this document.
Duty Cycle Value	50	Duty cycle value selection.
Duty Cycle Unit	Unit Raw Counts, Unit Percent, Unit Percent x 1000 (Default: Unit Raw Counts)	Duty cycle unit selection.
Auto Start	True, FALSE (Default: True)	Auto start selection. Set to true to start the timer after configuring or false to leave the timer stopped until start is called.
GTIOCA Output Enabled	True, False (Default: False)	GTIOCA output enabled selection. Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCA Stop Level	Pin Level Low, Pin Level High, Pin Level Retained (Default: Pin Level Low)	Controls output pin level when the timer is stopped.
GTIOCB Output Enabled	True, False (Default: False)	GTIOCB output enabled selection.
GTIOCB Stop Level	Pin Level Low, Pin Level High, Pin Level Retained (Default: Pin Level Low)	GTIOCB stop level selection.
Callback	NULL	Callback selection. A user callback function can be registered in open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the timer period elapses.

ISDE Property	Value	Description
Interrupt Priority	Priority 0(highest)-15(lowest), Disabled (Default: Disabled)	Interrupt priority selection.

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for a module can be desirable. For example, it might be useful to select a different clock source than the default. The configurable properties for the lower level stack modules are given in the following sections for completeness and as a reference.

GPT HAL Module Clock Configuration

The GPT timer is clocked based on the PCLKD frequency. You can set the PCLKD frequency using the clock configurator in the ISDE Configuring Clocks tab, or the CGC Interface at run-time.

GPT HAL Module Pin Configuration

The GPT peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The first table lists the method used to select pins within the SSP configuration window and the following table lists an example selection for the associated pins.

NOTE: The Operation Mode selection mode determines what peripheral signals are available and what MCU pins are required.

Pin Selection Sequence for GPT HAL Driver

Resource	ISDE Tab	Pin selection Sequence
GPT	Pins	Select Peripherals > Timer: GPT>GPT0

NOTE: The above selection sequence assumes GPT0 is the desired hardware target for the driver.

Pin Configuration Settings for GPT HAL Driver

Property	Value	Description
Pin Group Selection	Mixed, _A Only, _B Only (Default: Mixed)	Select pin group mapping.

Property	Value	Description
Operation Mode	Disabled, GTIOCA or GTIOCB, GTIOCA and GTIOCB (Default: Disabled)	Select timer operation mode.
GTIOCA:	None, P300, P512 (Default: P512)	GTIOCA Pin.
GTIOCB:	None, P108, P511 (Default: P511)	GTIOCB Pin.

NOTE: The above example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.21.6 Using the GPT Module in an Application

The typical steps in using the GPT HAL module in an application are:

1) Initialize the GPT HAL module using the open API.
2) Start the GPT HAL module by calling the start API.
3) Respond to the timer callback as needed (user code).

NOTE: The GPT period and duty cycle parameters can be reconfigured based on the application needs.

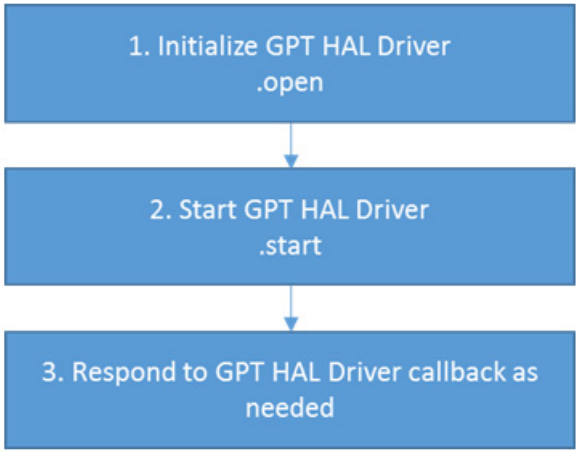

Figure 339: Typical GPT HAL Module Application Flow Chart

4.2.22 I2C SCI Driver

The I2C SCI HAL module implements provides high-level APIs for I2C Master applications with the module implemented on r_sci_i2c. The I2C SCI HAL module uses the SCI peripheral on the Synergy MCU device. Callbacks are provided for transmit complete and receive complete.

4.2.22.1 I2C SCI HAL Module Features

- Support for I2C SCI operations
- Supports the following operations with a slave I2C SCI device
  - Read
  - Write
  - Reset
- Callback support
  - Transfer aborted
  - Transmit complete (number of bytes transmitted provided)
  - Receive complete (number of bytes received provided)

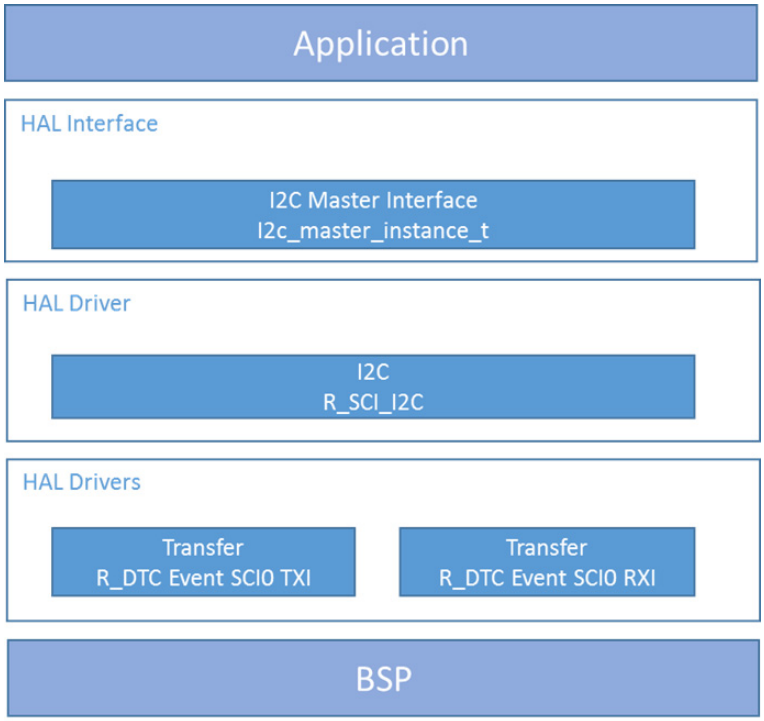

Figure 340:I2C SCI HAL Module Block Diagram

4.2.22.2 I2C SCI HAL Module APIs Overview

The I2C SCI HAL module defines APIs for reading and writing using a master I2C device. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

I2C SCI HAL Module API Summary

Function Name	Example API Call and Description
.open	g_i2c.p_api->open(g_i2c.p_ctrl, g_i2c.p_cfg); Open the instance and initialize the hardware.
.close	g_i2c.p_api->close(g_i2c.p_ctrl); Closes the driver and releases the I2C device.

Function Name	Example API Call and Description
.read	g_i2c.p_api->read(g_i2c.p_ctrl, &destination, bytes, restart); Performs a read operation on an I2C device.
.write	g_i2c.p_api->write(g_i2c.p_ctrl, &destination, bytes, restart); Performs a write operation on an I2C device.
.reset	g_i2c.p_api->reset(g_i2c.p_ctrl); Reset the peripheral.
.versionGet	g_i2c.p_api->versionGet(&version); Retrieve the API version with the version pointer.

NOTE: For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the *SSP User's Manual* API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_IN_USE	Attempted to open an already open device instance.
SSP_ERR_ABORTED	Device was closed while a transfer was in progress.
SSP_ERR_INVALID_RATE	The requested rate cannot be set
SSP_ERR_ASSERTION	The parameter p_ctrl is NULL.
SSP_ERR_NOT_OPEN	Device was not even opened.
SSP_ERR_IRQ_BSP_DISABLED	Event information could not be found.

NOTE: Lower-level drivers may return common error codes. Refer to the *SSP User's Manual* API References for the associated module for a definition of all relevant status return values.

4.2.22.3 I2C SCI HAL Module Operational Overview

The I2C SCI HAL module supports transactions with an I2C slave device. Callbacks are provided to interrupt the CPU when a transmission has been completed or aborted, or receive completed. The I2C SCI HAL module invokes the callback with the argument i2c_callback_args_t, indicating the number of received or transmitted bytes in buffer, pointer to user provided context, and the event 2c_event_t.

I2C SCI HAL Module Important Operational Notes and Limitations

I2C SCI HAL Module Operational Notes

Interrupts

- The I2C interrupts (SCI Error (EEI), Receive Buffer Full (RXI), Transmit Buffer Empty (TXI), and Transmit End (TEI)) for the selected channel must be enabled in the board support package (BSP), without consideration of whether the user wants to use callbacks.
- Setting the interrupts to different priority levels could result in improper operation.

IIC Rate Calculation

- The I2C SCI HAL module calculates the internal baud-rate setting based on the configured transfer rate and passes this to open. The closest possible baud rate that can be achieved (less than or equal to the requested rate) at the current PCLKB settings is calculated and used.
- If a valid clock rate could not be calculated, an error is returned.

Triggering DMAC/DTC with the IIC

- DTC transfer support is added by default in the configurator, this can be removed for CPU transfer cases. The DTC is configured in the module. No user configuration is required for this.
- DMA transfer is not supported.

Triggering ELC Events with the IIC

- The I2C SCI HAL module can trigger the start of other peripherals. See the ELC User Guide for further information.

Multiple Devices on the Bus

- An API slaveAddressSet() can be used to switch the slave devices without reconfiguring (no need to close and open) the bus in an application for using multiple slave devices on the same bus.
- Control instance and bus configuration remains the same, but the slave address and addressing mode changes.
- Other ways of communication with different slave devices can be used by closing the first device and opening a new device. This is recommended if slaves are having different configurations.
- Applications using multiple devices connected on the same channel need to define the following macro in the pre-processor settings of your project (or the project may not build correctly):SSP_SUPPRESS_ISR_<device_name>Where <device_name> is the name of the additional device connected to the same channel.

The I2C SCI HAL module in IRQ mode may not work with certain slave devices; you need to enable DTC transfer mode to work with such devices.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.22.4 Including the I2C SCI HAL Module in an Application

This section describes how to include the I2C SCI HAL module in an application using the SSP configurator.

NOTE: It is assumed that you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these steps, refer to the first few chapters of the SSP User's Manual to learn how to manage these important steps in creating SSP-based applications.

To add the I2C SCI Driver to an application, simply add it to a thread using the stacks selection sequence in the following table. (The default name for the I2C SCI HAL Driver is g_i2c0. This name can be changed in the associated Properties window.)

I2C SCI HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_i2c0 I2C Master Driver on r_sci_i2c	Threads	New Stack> Driver> Communications> I2C Master Driver on r_sci_i2c

When the I2C SCI HAL Module on r_sci_i2c is added to the thread stack as shown in the following figure; the configurator automatically adds any needed lower-level drivers. Any drivers that need additional configuration information are box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

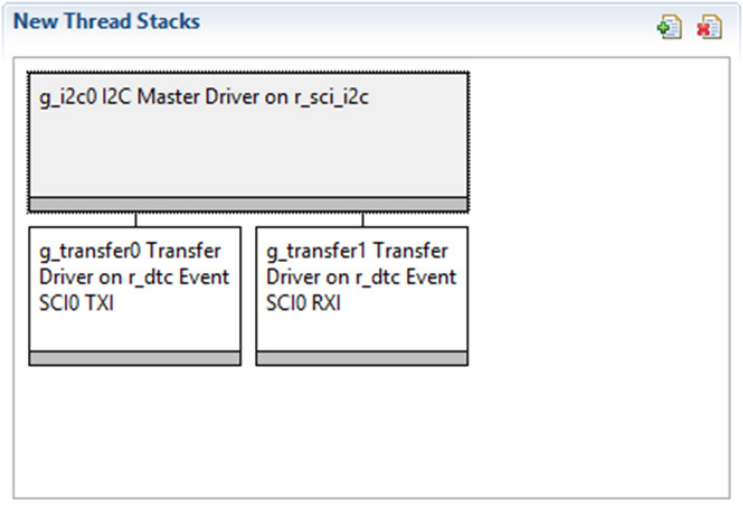

Figure 341: I2C SCI HAL Module Stack

4.2.22.5 Configuring the I2C SCI HAL Module

The I2C SCI HAL module must be configured by you for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or

operating modes, which must be configured for lower-level modules for successful operation. Only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP Configurator and are shown in the table later in this document for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE includes an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE and create the module and explore the property settings in parallel with looking over the following configuration table settings. This step helps to orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the I2C SCI HAL Module on r_sci_i2c

ISDE Property	Value	Description
Parameter Checking	Enabled, Disabled, BSP (Default: BSP)	Selects if code for parameter checking is to be included in the build
Name	Default: g_i2c0	Module name
Channel	0	Channel Number
Rate	Standard, Fast mode (Default: Standard)	Rate selection
Slave Address	Default: 0x00	Slave address
Address Mode	7-bit, 10-bit (Default: 7-bit)	Address mode
SDA Output Delay (nanoseconds)	300	SDA output delay value
Bit Rate Modulation Enable	Enabled, Disable (Default: Enable)	Bit rate modulation setting
Callback	Default: NULL	User defined callback

ISDE Property	Value	Description
Receive Interrupt Priority	Priority 0 (highest)-15 (lowest), Disabled (Default: Priority 2)	Receive Interrupt priority
Transmit Interrupt Priority	Priority 0 (highest)-15 (lowest), Disabled (Default: Priority 2)	Transmit Interrupt priority
Transmit End Interrupt Priority	Priority 0 (highest)-15 (lowest), Disabled (Default: Priority 2)	Transmit end interrupt priority

NOTE: The example settings and defaults are for a project using the Synergy S7G2 Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for stack modules can be desirable. For example, it might be useful to select different slave addresses or address modes. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

NOTE: Most property settings for modules are fairly intuitive and usually can be determined by inspection of the associated Properties window from the SSP configurator.

Transfer Driver on r_dtc Event SCI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled (Default: Disabled)	Software start selection
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section selection
Name	g_transfer0	Module name
Mode	Normal	Mode selection
Transfer Size	1 Byte	Transfer size selection

ISDE Property	Value	Description
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SCI0 TXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0(highest)-15(lowest), Disabled (Default: Disabled)	Interrupt priority for ELC Event

NOTE: The example settings and defaults are for a project using the Synergy S7 MCU Group. Other MCUs may have different default values and available configuration settings.

Transfer Driver on r_dtc Event SCI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled (Default: Disabled)	Software start selection
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section selection
Name	g_transfer1	Module name

ISDE Property	Value	Description
Mode	Normal	Mode selection
Transfer Size	1 Byte	Transfer size selection
Destination Address Mode	Incremented	Destination address mode selection
Source Address Mode	Fixed	Source address mode selection
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SCI0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest) -15 (lowest), Disabled (Default: Disabled)	Interrupt priority for ELC Event

I2C SCI HAL Module Clock Configuration

The SCI peripheral module uses PCLKB as its clock source. The actual I2C transfer rate is calculated and set internally by the driver (depending on the selected transfer rate). If the PCLKB is configured in such a manner that the selected internal rate cannot be achieved, an error is returned when initializing the driver.

I2C SCI HAL Module Pin Configuration

The SCI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the pins.

NOTE: For some peripherals, the operation mode selection determines what peripheral signals are available and thus what MCU pins are required for the I2C SCI HAL Module.

Pin Selection Sequence for the I2C SCI HAL Module

Resource	ISDE Tab	Pin selection Sequence
SCI	Pins	Select Peripherals > Connectivity: SCI > SCI0

NOTE: The selection sequence assumes SCI0 is the desired hardware target for the driver.

Pin Configuration Settings for the I2C SCI HAL Module

Property	Value	Description
Pin Group Selection	_A only, _B only, Mixed (Default: _A only)	Pin group selection
Operation Mode	Enabled, Disabled (Default: Disabled)	Enable or disable peripheral module
SDA	None, P401, P407 (Default: None)	SDA Pin
SCL	None, P400, P204 (Default: None)	SCL Pin

NOTE: The example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.22.6 Using the I2C SCI HAL Module in an Application

The typical steps in using the I2C SCI HAL module in an application are:

1) Initialize and open the I2C SCI HAL module using the open API.
2) Transfer data to the slave using the write API.
3) Receive data from the slave using the read API.
4) Operate on the received data as needed by the application.
5) Reset the instance with the reset API (if needed).
6) Perform transactions with slave device (if needed).
7) Close the channel using the close API.

NOTE: Optionally change the slave address using the slaveAddressSet API and then perform read/write transactions with the new slave device.

The following figure illustrates these common steps within a typical operational flow diagram.

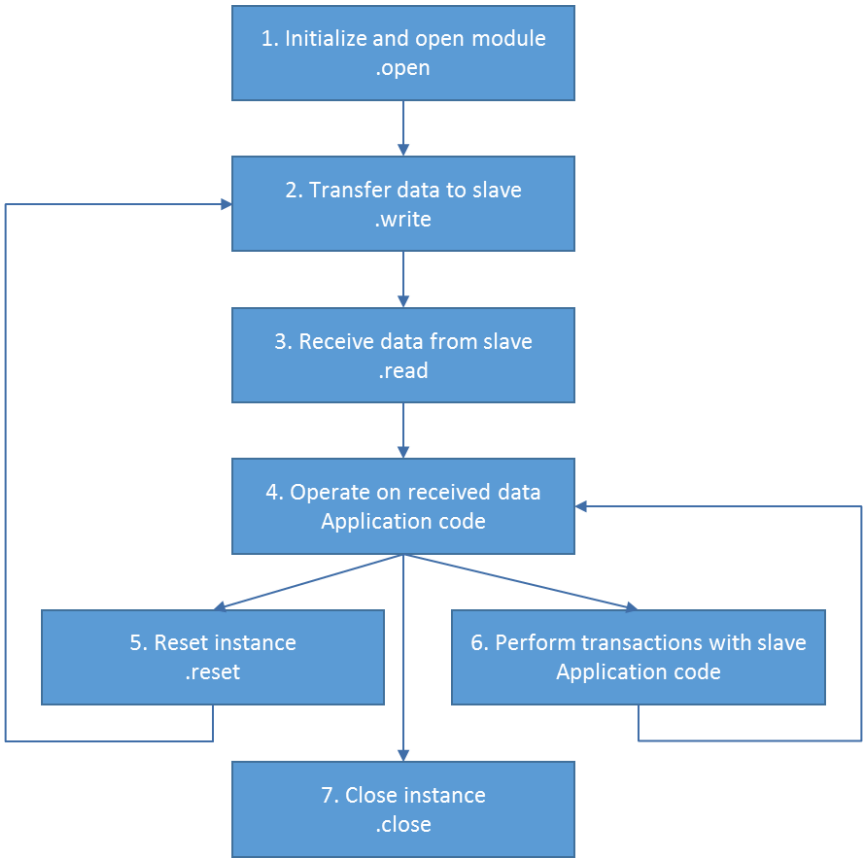

Figure 342: Flow Diagram of a Typical I2C SCI HAL Module Application

4.2.23 I2C Master Driver

The I2C Master HAL module provides high-level APIs for I2C Master applications and is implemented on r_riic. The I2C Master RIIC module uses the IIC peripheral on the Synergy MCU. Callbacks are provided for transmit complete and receive complete event notification.

4.2.23.1 I2C Master HAL Module Features

- Support for I2C RIIC operations
  - Standard (up to 100 kHz)
  - I2C fast-mode (up to 400 kHz)
  - I2C fast-mode plus (up to 1 MHz on channel 0 (SCL0-A, SDA0-A) of S7G2 and S5D9 MCU families)

- Initialization of the RIIC module
- Read from a slave device
- Write to a slave device
- Reset the I2C peripheral
- Set the address of the slave device
- Callback support
  - Transfer aborted
  - Transmit complete (number of bytes transmitted provided)
  - Receive complete (number of bytes received provided)

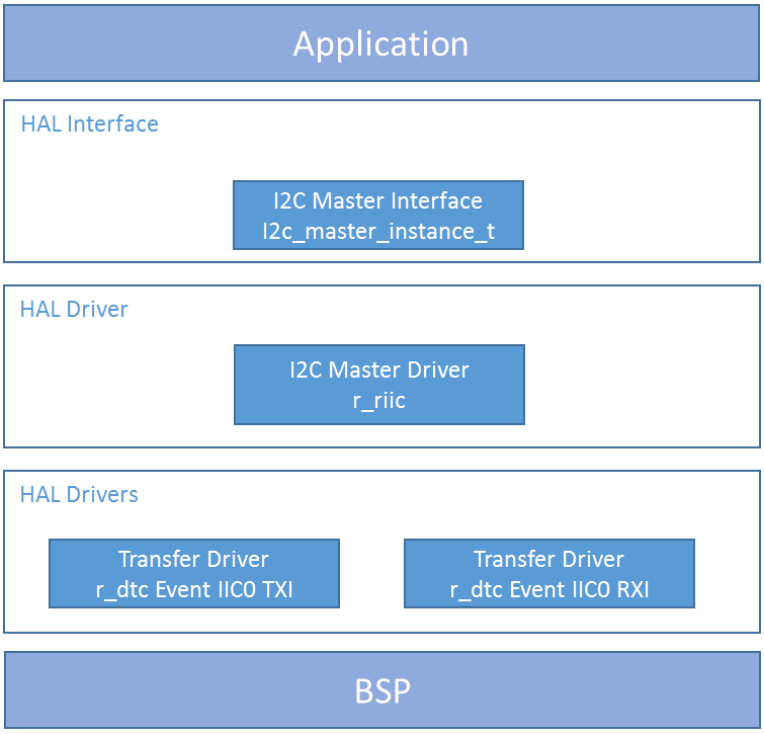

Figure 343:I2C Master HAL Module Block Diagram

4.2.23.2 I2C Master HAL Module APIs Overview

The I2C Master HAL module defines APIs including reading and writing using a master I2C device. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows.

I2C Master HAL Module API Summary

Function Name	Example API Call and Description
.open	g_i2c.p_api->open(g_i2c.p_ctrl, g_i2c.p_cfg); Open the instance and initialize the hardware.
.close	g_i2c.p_api->close(g_i2c.p_ctrl); Closes the driver and releases the I2C device.
.read	g_i2c.p_api->read(g_i2c.p_ctrl, &destination, bytes, restart); Performs a read operation on an I2C device.
.write	g_i2c.p_api->write(g_i2c.p_ctrl, &destination, bytes, restart); Performs a write operation on an I2C device.
.reset	g_i2c.p_api->reset(g_i2c.p_ctrl); Reset the peripheral.
.versionGet	g_i2c.p_api->versionGet(&version); Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_INVALID_POINTER	Pointer is NULL
SSP_ERR_IN_USE	Attempted to open an already open device instance.

Name	Description
SSP_ERR_ABORTED	Device was closed while a transfer was in progress.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value
SSP_ERR_INVALID_RATE	The requested rate cannot be set

NOTE: Lower-level drivers may return common error Codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.23.3 I2C Master HAL Module Operational Overview

The I2C master HAL module supports transactions with an I2C Slave device. Callbacks are provided to interrupt the CPU when a transmission or receive has been completed. The RIIC HAL module invokes the callback with the argument i2c_callback_args_t, indicating the number of received or transmitted bytes in buffer, pointer to user provided context, and the event i2c_event_t.

I2C Master HAL Module Important Operational Notes and Limitations

Interrupts

- The RIIC error (EEI), receive buffer full (RXI), transmit buffer empty (TXI), and transmit end (TEI) interrupts for the selected channel used must be enabled in the properties of the selected device irrespective of whether the user wants to use callbacks.
- Set equal priority levels for all the interrupts mentioned above. Setting the interrupts to different priority levels could result in improper operation.

IIC Rate Calculation

- The I2C Master module calculates the internal baud-rate setting based on the configured transfer rate and passed to open. The closest possible baud-rate that can be achieved (less than or equal to the requested rate) at the current PCLKB settings is calculated and used.
- If a valid clock rate could not be calculated, an error is returned.

Triggering DMAC/DTC with the IIC

- DTC transfer support added by default in the configurator. This can be removed for CPU transfer cases. The DTC is configured in the module. No user configuration is required for this.
- DMA transfer is not supported.

Triggering ELC Events with the IIC

- The I2C Master module can trigger the start of other peripherals. See events and peripheral definitions in the ELC User Guide for further information.

Multiple Devices on the Bus

- If multiple devices are connected on the same bus, only one device can be opened at a time.

Usage of Restart Condition

- Passing value 'true' to the restart parameter of write/read API will generate restart condition after specified number (length) of bytes. Master will continue to hold the bus busy (low) without timeout so that current master can trigger next write/read API.

Multi-Master Support

- If multiple masters are connected on the same bus, the I2C Master is capable of detecting bus busy state before initiating the communication.
- Any of the supported IIC channel can be configured for either Master or Slave mode operation but not for both.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.23.4 Including the I2C Master HAL Module in an Application

This section describes how to include the I2C RIIC HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the I2C Master Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the I2C RIIC HAL Module is g_i2c0. This name can be changed in the associated Properties window).

I2C Master HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_i2c0 I2C Master Driver on r_riic	Threads	New Stack> Driver> Communications> I2C Master Driver on r_riic

NOTE: When the I2C RIIC HAL module on r_riic is added to the thread stack as shown in the figure below, the configurator automatically adds any needed lower-level drivers.

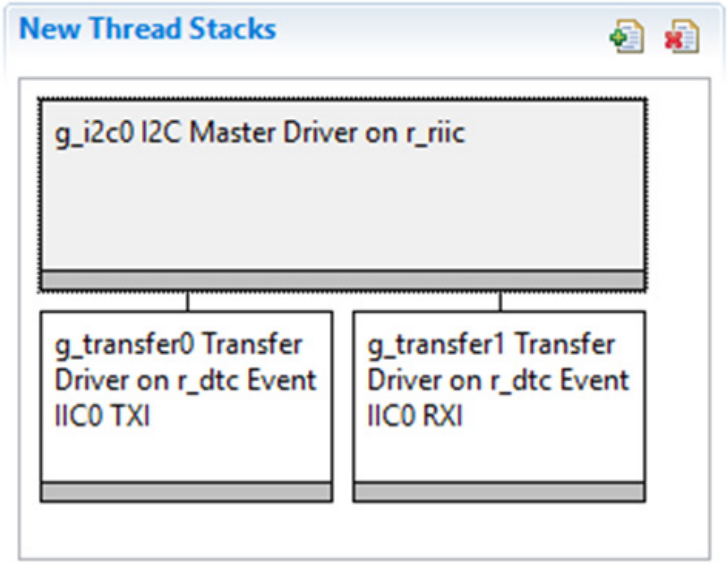

Figure 344: I2C Master HAL Module Stack

4.2.23.5 Configuring the I2C Master HAL Module

The I2C RIIC HAL module must be configured by you for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operations. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the table later in this document for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority. This configuration setting is available with the Properties window of the associated module. Simply select the indicated module and then view the Properties window. The interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+.) This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE and create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the I2C Master HAL Module on r_riic

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.
Name	g_i2c0	Module name.
Channel	0, 1, or 2	Specify the IIC channel to be used with this configuration.
Rate	Standard, Fast-mode, Fast-mode Plus Default: Standard	Standard, Fast, and Fast-plus. (See IIC Rate Calculation.)
Slave Address	0x00	Set the address of the slave device the I2C master will be communicating with.
Address Mode	7-Bit, 10-Bit Default: 7-Bit	Only 7-bit addresses are currently supported.
Callback	NULL	A user callback function can be registered in open. If this callback function is provided, it will be called from the interrupt service routine (ISR) for each of the conditions defined in i2c_event_t. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Receive interrupt priority selection.

ISDE Property	Value	Description
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit end interrupt priority selection.
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Error interrupt priority selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the DTC HAL Module on r_dtc Event IIC0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Enabled	Software start selection.

ISDE Property	Value	Description
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer0	Module name
Mode	Normal	Mode selection
Transfer Size	1 Byte	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event IICI0 TXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC software event interrupt priority selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the RTC HAL Module on r_dtc Event IIC0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer1	Module name
Mode	Normal	Mode selection
Transfer Size	1 Byte	Transfer size selection
Destination Address Mode	Incremented	Destination address mode selection
Source Address Mode	Fixed	Source address mode selection
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event IIC0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection

ISDE Property	Value	Description
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC software event interrupt priority selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for the module can be desirable. For example, it might be useful to select different slave addresses or address modes. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

I2C Master HAL Module Clock Configuration

The IIC peripheral module uses PCLKB as its clock source. The actual I2C transfer rate will be calculated and set internally by the driver depending on the selected transfer rate. If the PCLKB is configured in such a manner that the selected internal rate cannot be achieved, an error will be returned when initializing the driver.

I2C Master HAL Module Pin Configuration

The IIC peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the pins.

NOTE: For some peripherals, the operation mode selection determines what peripheral signals are available and thus what MCU pins are required.

Pin Selection Sequence for I2C Master HAL Module

Resource	ISDE Tab	Pin selection Sequence
IIC	Pins	Select Peripherals > Connectivity: IIC > IIC0

NOTE: The selection sequence assumes IIC0 is the desired hardware target for the driver.

Pin Configuration Settings for I2C Master HAL Module

Pin Configuration Property	Value	Description
Pin Group Selection	_A only, _B only, Mixed (Default: _A only)	Pin group selection
Operation Mode	Enabled, Disabled (Default: Disabled)	Enable or disable peripheral module
SDA	None, P401, P407 (Default: None)	SDA Pin
SCL	None, P400, P204 (Default: None)	SCL Pin

NOTE: The example settings are for a project using the Synergy S7G2 MCU. Other Synergy MCUs may have different available pin configuration settings.

4.2.23.6 Using the I2C Master HAL Module in an Application

The typical steps in using the I2C RIIC HAL Module in an application are:

1) Initialize and open the I2C RIIC HAL Module using the open API
2) Transfer data to the slave using the write API
3) Receive data from the slave using the read API
4) Reset the instance with the reset API (if needed)
5) Close the channel using the close API

NOTE: If the application wants to switch the device without opening and closing the bus, use the slaveAddressSet API where g_i2c.p_ctrl is the same control instance that was used in the last opened device. The module will use the same bus configuration to communicate with the new device. In this case, you can use the same control instance to communicate with different slave devices by setting the new slave address and calling the read or write APIs.

These common steps to communicate with a slave device are illustrated in a typical operational flow in the figure below:

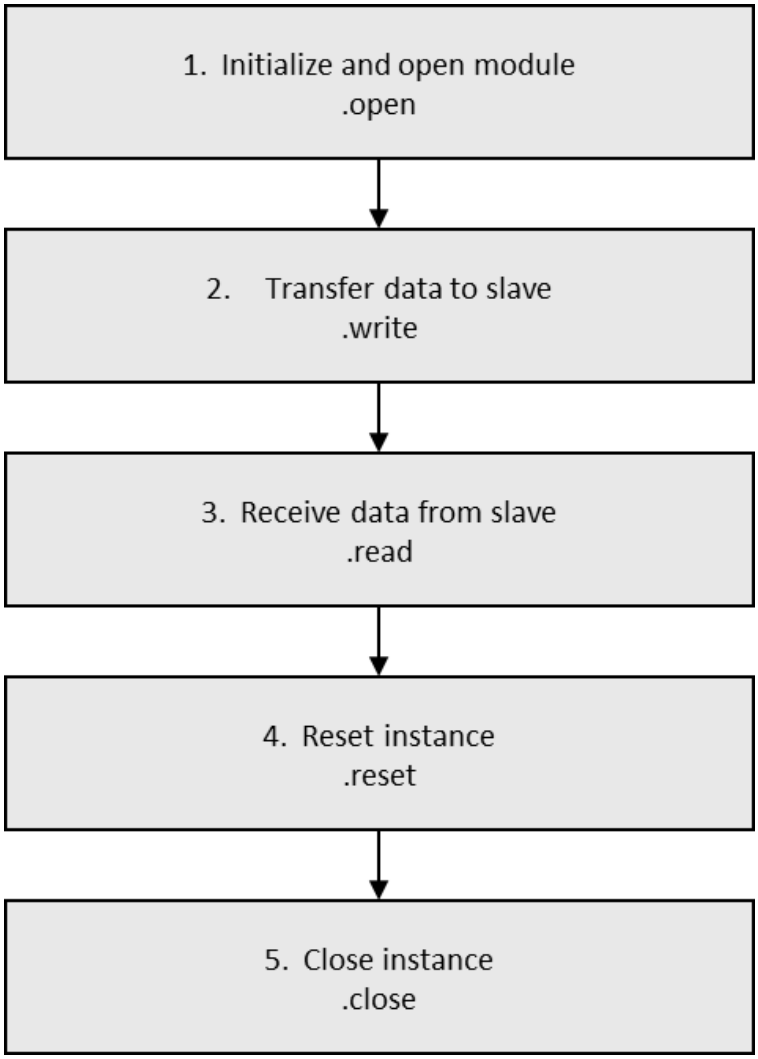

Figure 345: Flow Diagram of a Typical I2C Master HAL Module Application

4.2.24 I2C Slave Driver

The I2C Slave HAL Module provides high-level API for I2C slave applications and is implemented on r_riic_slave. The I2C Slave Module uses the RIIC peripheral on the Synergy MCU. Callbacks are provided for transmit complete and receive complete notification.

4.2.24.1 I2C RIIC Slave HAL Module Features

- Support for I2C Slave operations
- Support transactions with a I2C master device
  - Read

  - Write
- Callback support
  - Transmit complete (number of bytes transmitted provided)
  - Receive complete (number of bytes received provided)

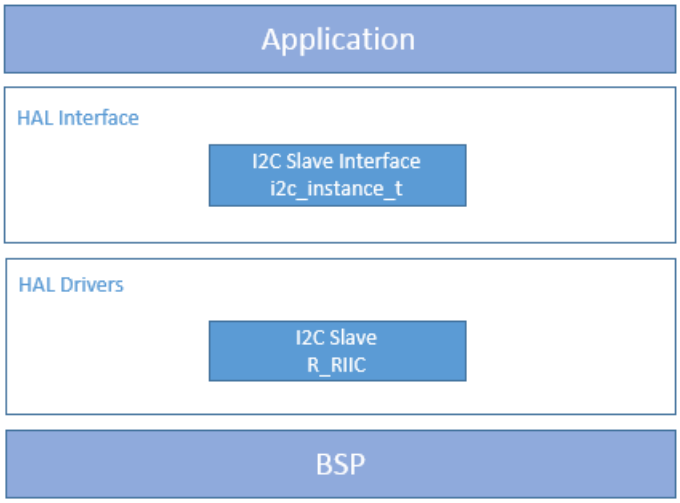

Figure 346:I2C RIIC Slave HAL Module Organization, Options and Stack Implementations

4.2.24.2 I2C RIIC Slave HAL Module APIs Overview

The I2C RIIC Slave HAL Module defines APIs for reading and writing to a master I2C device. A complete list of the available APIs, an example API call, and a short description of each can be found in the table below. A table of status return values follows.

I2C RIIC Slave HAL Module API Summary

Function Name	Example API Call and Description
.open	g_i2c.p_api->open(g_i2c.p_ctrl, g_i2c.p_cfg); Open the instance and initialize the hardware..
.close	g_i2c.p_api->close(g_i2c.p_ctrl); Closes the driver and releases the I2C device.

Function Name	Example API Call and Description
.masterWriteSlaveRead	g_i2c.p_api->masterWriteSlaveRead(g_i2c.p_ctrl, &source, bytes); Performs a read operation on an I2C device.
.masterReadSlaveWrite	g_i2c.p_api->masterReadSlaveWrite(g_i2c.p_ctrl, &source, bytes); Performs a write operation on an I2C device.
.versionGet	g_i2c.p_api->versionGet(&version); Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_INVALID_POINTER	Pointer is NULL
SSP_ERR_IN_USE	Attempted to open an already open device instance.
SSP_ERR_ABORTED	Device was closed while a transfer was in progress.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value

NOTE: Lower level drivers may return Common Error Codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.24.3 I2C RIIC Slave HAL Module Operational Overview

The I2C RIIC Slave HAL Module supports transfers to an I2C Master device. Callbacks are provided to interrupt the CPU when a transmission has been completed, or when a receive has been completed.

I2C RIIC Slave HAL Module Important Operational Notes and Limitations

- The RIIC Error (EEI), Receive Buffer Full (RXI), Transmit Buffer Empty (TXI) and Transmit End (TEI) interrupts for the selected channel used must be enabled in the BSP irrespective of whether the user wants to use callbacks.
- Set equal priority levels for all the interrupts mentioned above. Setting the interrupts to different priority levels could result in improper operation.
- If you are using RIIC and RIIC_Slave modules on the same board, we suggest setting equal interrupt priority for TXI, TEI, and EI and set RXI interrupt priority higher than these.

This is the initial version of I2C RIIC Slave Driver with only basic functionality implemented. The following limitations are known:

1) The Driver will lock up the I2C bus when any of the following operations occur:
   - When Master is Reading 'M' bytes and Slave has 'N' Bytes available to write. In this case (M < N) or (M > N).
   - When Master and Slave are both writing to the bus at same time.
   - When Master and Slave are both reading from the bus at same time.

   NOTE: To come out of bus lock-up situation, it is suggested to use callback during configuration. Application can decide time-out for callback wait and after timeout application can close the slave module instance and re-open for further operations.

2) Any of the supported IIC channel can be configured for either Master or Slave mode operation but not for both.
3) Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.24.4 Including the I2C RIIC Slave HAL Module in an Application

This section describes how to include the I2C RIIC Slave HAL Module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP based applications.

To add the I2C RIIC Slave HAL Module to an application, simply add it to a thread using the Stacks Selection Sequence given in the table below. (The default name for the I2C RIIC Slave HAL Module is g_i2c0 and this is shown in the below table. This name can be changed in the associated Properties window).

I2C RIIC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_i2c0 I2C Slave Driver on r_riic_slave	Threads	New Stack> Driver> Communications> I2C Slave Driver on r_riic_slave

When the I2C Slave HAL Module on r_riic_slave is added to the Thread Stack, as shown in the figure below, the configurator automatically adds any needed lower level drivers.

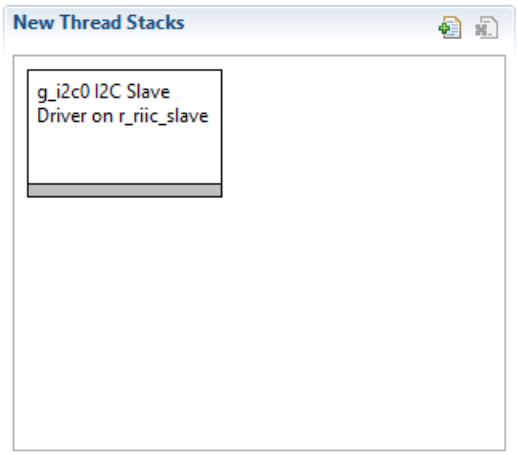

Figure 347:I2C RIIC Slave HAL Module Stack

4.2.24.5 Configuring the I2C RIIC Slave HAL Module

The I2C RIIC Slave HAL Module must be configured by you for the desired operation. The SSP configuration window will automatically identify, by highlighting the block in red, any required configuration selections, such as Interrupts or operating modes, which must be configured for lower level modules, for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the properties tab within the SSP Configurator and are shown in the table later in this document for easy reference.

One of the properties most often identified as requiring a change is the Interrupt Priority. This configuration setting is available with the Properties window of the associated module. Simply select the indicated module and then view the properties window. The Interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the Interrupt Priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the below configuration properties tables, but is easily visible with the ISDE when configuring Interrupt Priority levels.

NOTE: You may want to open your ISDE and create the module and explore the property settings in parallel with looking over the Configuration Table Settings given below. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for I2C Slave HAL Module on r_i2c

ISDE Property	Value	Description
Parameter Checking	Enabled, Disabled, BSP (Default: BSP)	Selects if code for parameter checking is to be included in the build

ISDE Property	Value	Description
Name	Default: g_i2c0	Module name
Channel	0	Channel number
Rate	Standard, Fast mode, Fast mode plus (Default: Standard)	Rate selection
Slave Address	0x00	Slave address
Address Mode	7-bit, 10-bit (Default: 7-bit)	Address mode
Callback	NULL	Callback function
Receive Interrupt Priority	Priority 0(highest)-15(lowest), Disabled (Default: 2)	Receive Interrupt priority
Transmit Interrupt Priority	Priority 0(highest)-15(lowest), Disabled (Default: 2)	Transmit Interrupt priority
Error Interrupt Priority	Priority 0(highest)-15(lowest), Disabled (Default: 2)	Error Interrupt priority

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for stack modules can be desirable. For example, it might be useful to select different slave addresses or address mode.

I2C RIIC Slave HAL Module Clock Configuration

The RIIC peripheral module uses PCLKB as its clock source.

I2C RIIC Slave HAL Module Pin Configuration

The RIIC peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The first table below illustrates the method for selecting the pins within the SSP configuration window and the following table illustrates an example selection for the pins.

NOTE: For some peripherals, the Operation Mode selection mode determines what peripheral signals are available and thus what MCU pins are required.

Pin Selection Sequence for I2C RIIC Slave HAL Module

Resource	ISDE Tab	Pin selection Sequence
I2C	Pins	Select Peripherals > Connectivity: IIC > IIC0

NOTE: The above selection sequence assumes IIC0 is the desired hardware target for the driver.

Pin Configuration Settings for I2C RIIC Slave HAL Module on r_riic_slave

Pin Configuration Property	Value	Description
Pin Group Selection	_A only, _B only, Mixed (Default: _A only)	Select Simple I2C as the Operation Mode for I2C on SCI
Operation Mode	Enabled, Disabled (Default: Disabled)	Enable or disable peripheral module
SDA	None, P401, P407 (Default: None)	SDA Pin
SCL	None, P400, P204 (Default: None)	SCL Pin

NOTE: The above example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.24.6 Using the I2C RIIC Slave HAL Module in an Application

The typical steps in using the I2C RIIC Slave HAL Module in an application are:

1) Initialize and open the I2C Slave HAL Module using the open API
2) Transfer data to the master using the write API
3) Receive data from the master using the read API
4) Close the channel using the close API

The above common steps are illustrated in a typical operational flow diagram in the figure below.

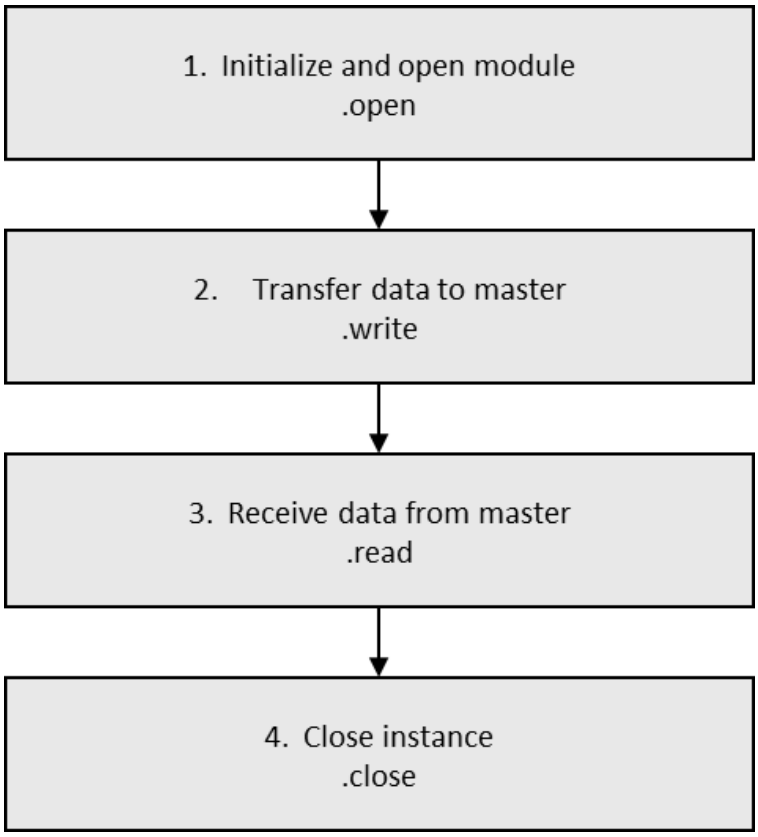

Figure 348: Flow Diagram of a Typical I2C RIIC Slave HAL Module Application

4.2.25 I2S Driver

The I2S HAL Driver module provides high-level APIs for the generic I2S audio serial communication protocol; it is used to send or receive uncompressed audio data in master mode.

4.2.25.1 I2S HAL Module Features

The I2S Driver used with the SSI peripheral in I2S master mode supports the following features in addition to the standard I2S protocol:

- Full-duplex I2S communication (SSI channel 0 only)
- Interrupt driven data transmission and reception
- Integration with the DTC transfer module.
- A user-defined callback can be created to respond to the need for additional data.

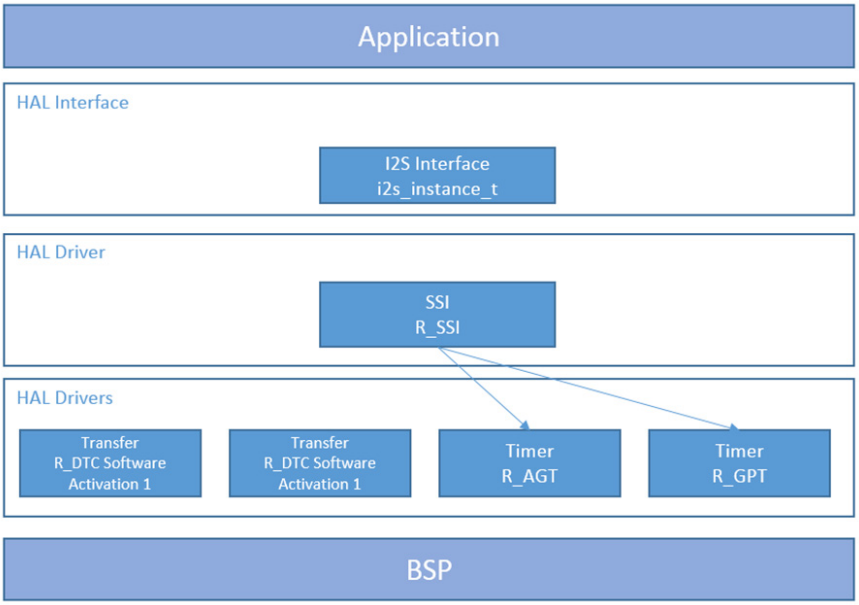

Figure 349:I2S HAL Module Block Diagram

4.2.25.2 I2S HAL Module APIs Overview

The I2S HAL module defines APIs for operations such as opening, muting, writing, and reading. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows.

I2S HAL Module API Summary

Function Name	Example API Call and Description
open	g_i2s0.p_api->open(g_i2s0.p_ctrl, g_i2s0.p_cfg); Initial configuration.

Function Name	Example API Call and Description
stop	g_i2s0.p_api->stop(g_i2s0.p_ctrl, direction_to_stop); Stop communication. Transmission is stopped when callback is called with I2S_EVENT_IDLE. Reception is stopped when callback is called with I2S_EVENT_RX_EMPTY.
mute	g_i2s0.p_api->mute(g_i2s0.p_ctrl, mute_enable); Enable or disable mute.
write	g_i2s0.p_api->write(g_i2s0.p_ctrl, &data, bytes); Write I2S data. All transmit data is queued when callback is called with I2S_EVENT_TX_EMPTY. Transmission is complete when callback is called with I2S_EVENT_IDLE.
read	g_i2s0.p_api->read(g_i2s0.p_ctrl, &data, bytes); Read I2S data. Reception is complete when callback is called with I2S_EVENT_RX_EMPTY.
writeRead	g_i2s0.p_api->writeRead(g_i2s0.p_ctrl, &source, &destination, bytes); Simultaneously write and read I2S data. Transmission and reception are complete when callback is called with I2S_EVENT_IDLE.
infoGet	g_i2s0.p_api->infoGet(g_i2s0.p_ctrl, &info); Get instance specific information and store it in provided pointer info.
close	g_i2s0.p_api->close(g_i2s0.p_ctrl); Allows driver to be reconfigured and may reduce power consumption.

Function Name	Example API Call and Description
versionGet	g_i2s0.p_api->versionGet(&version); Get version and store it in provided pointer version.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_OUT_OF_MEMORY	The number of streams open at once is limited to SF_AUDIO_PLAYBACK_CFG_MAX_STREAMS. If this number is exceeded, an out of memory error occurs.
SSP_ERR_TIMEOUT	Timeout occurred before playback finished.
SSP_ERR_ASSERTION	A critical assertion has failed
SSP_ERR_IN_USE	Channel is running/busy
SSP_NOT_OPEN	Requested channel is not configured or API not open

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.25.3 I2S HAL Module Operational Overview

The I2S HAL module supports audio communications using the I2S protocol. The driver supports the SSI Peripheral on a Synergy MCU in I2S master mode. It can send and receive uncompressed audio data. It provides full-duplex I2S communication (SSI channel 0 only), interrupt driven data transmission and reception and integration with the DTC transfer module.

I2S HAL Module Important Operational Notes and Limitations

To enable audio data reception on channel 0, enable the SSI0 RXI interrupt. To enable audio data transmission on channel 0, enable the SSI0 TXI interrupt. To enable both transmission and reception on channel 0, enable both the SSI0 TXI and SSI0 RXI interrupts. To enable transmission or reception on channel 1, enable the SSIn TXI RXI interrupt. In all cases, enable the SSIn INT interrupt.

When the interrupts are enabled in the BSP, the corresponding ISRs will be defined in the I2S driver. The ISR will call the user callback function registered in open.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.25.4 Including the I2S HAL Module in an Application

This section describes how to include the I2S HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack.

To add the I2S HAL driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the I2S HAL Driver is g_i2s0. This name can be changed in the associated Properties window.)

I2S HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_i2s0 I2S Driver on r_ssi	Threads-> HAL/Common Stacks	New Stack> Driver> Connectivity> I2S Driver on r_ssi

When the I2S HAL module on r_ssi is added to the HAL/Common Stack or a thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information will be box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level drivers; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level drivers is required, the module description will include "Add" in the text. Clicking on any Pink banded modules will bring up the "New" icon and then display the possible choices.

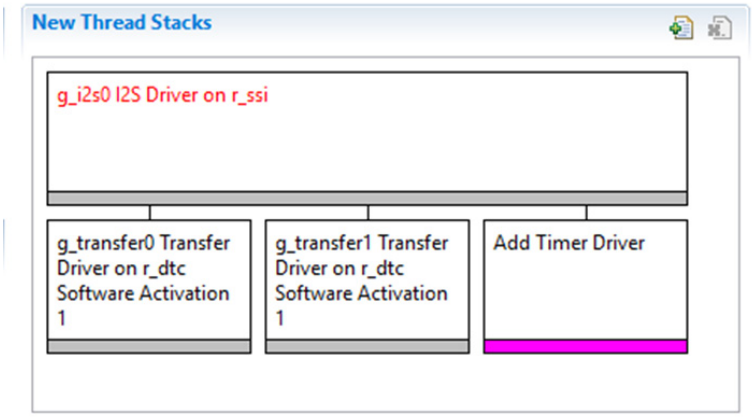

Figure 350:I2S HAL Module Stack

4.2.25.5 Configuring the I2S HAL Module

The I2S HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or

operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the properties window of the associated module. Simply select the indicated module and then view the properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the configuration properties tables below, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the I2S HAL Module on r_ssi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_i2s0	Module name.
Channel	0	Physical hardware channel.
Audio Clock Frequency (Hertz)	2822400	Input audio clock frequency, used to generate the I2S clock. Must be a multiple between 1 and 128 of: (sampling_freq_hz * word_length_in_bits)
Sampling Frequency (Hertz)	44100	Sampling frequency of audio data.
Data Bits	8 bits, 16, 18, 20, 22, 24 Default: 16 bits	Bit depth of audio data, which is the size in bits of one sample of audio data.
Word Length	8 bits, 16, 24, 32 Default: 16 bits	Word length of audio data, must be at least the same size as the bit depth (Data Bits field).

ISDE Property	Value	Description
WS Continue Mode	Enabled, Disabled Default: Disabled	Enable WS continue mode to continue to output the word select line when the peripheral is idle. Disable to stop outputting the word select line when the peripheral is idle.
Name of I2S callback function to be defined by user	NULL	A user callback function must be registered in open. The callback will be called from the interrupt service routine (ISR) when the transmission FIFO reaches the high watermark point after all data for transmission is transmitted or when reception is complete (the requested number of bytes have been received). Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Transmit interrupt priority selection
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Receive interrupt priority selection

ISDE Property	Value	Description
Idle/Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Idle/error interrupt priority selection

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower level modules can be desirable. For example, it might be useful to select the DAC or I2S Channel based on the target hardware implementation. The configurable properties for the lower level stack modules are given in the below sections for completeness and as a reference.

NOTE: Most of the property settings for modules are fairly intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the I2S HAL Module Low-Level Modules

There are two implementation choices for the Timer Driver used with the I2S HAL module and each of these options requires different configuration settings for the associated low-level drivers. The configuration options for these two options are provided in the following tables.

Typically, only a small number of settings must be modified from the default for lower-level drivers and these are indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module.

Table 5 Configuration Settings for the DTC HAL Module on r_dtc Software Activation

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Name	g_transfer0	Driver name.
Mode	Normal	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.

ISDE Property	Value	Description
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	FALSE	Auto enable selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC software event interrupt priority selection
Callback (Only valid with Software start)	NULL	Callback selection

NOTE: The example settings and defaults are for a project using the Synergy S7 MCU Family. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the DTC HAL Module on r_dtc Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Name	g_transfer1	Driver name.
Mode	Normal	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	FALSE	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.

ISDE Property	Value	Description
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC software event interrupt priority selection

NOTE: The example settings and defaults are for a project using the Synergy S7 MCU Family. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the AGT HAL Module on r_agt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection
Name	g_timer0	Module name
Channel	0	Channel selection
Mode	Periodic	Mode selection
Period Value	2822400 *2	Period value selection
Period Unit	Hertz	Period unit selection
Auto Start	False	Auto start selection
Count Source	PCLKB, PCLKB/8, PCLKB/2, LOCO, AGT0 Underflow, AGT0 fSUB Default: PCLKB	Count source selection
AGTO Output Enabled	True, False Default: False	AGTO output selection

ISDE Property	Value	Description
AGTIO Output Enabled	True, False Default: False	AGTIO output selection
Output Inverted	True, False Default: False	Output inverted selection
Callback	NULL	Callback selection
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection

NOTE: The example settings and defaults are for a project using the Synergy S7 MCU Family. Other MCUs may have different default values and available configuration settings.

Configuration Settings for Timer Driver on r_gpt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection
Name	g_timer0	Module name
Channel	0	Channel selection
Mode	Periodic	Mode selection
Period Value	2822400 *2	Period value selection
Period Unit	Hertz	Period unit selection
Duty Cycle Value	50	Duty cycle value selection

ISDE Property	Value	Description
Duty Cycle Unit	Unit Raw Counts, Unit Percent, Unit Percent x 1000 Default: Unit Raw Counts	Duty cycle unit selection
Auto Start	False	Auto start selection
GTIOCA Output Enabled	True, False Default: False	GTIOCA output enabled selection
GTIOCA Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	GTIOCA stop level selection
GTIOCB Output Enabled	True, False Default: False	GTIOCB output enabled selection
GTIOCB Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	GTIOCB stop level selection
Callback	NULL	Callback selection
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection

NOTE: The example settings and defaults are for a project using the Synergy S7 MCU Family. Other MCUs may have different default values and available configuration settings.

I2S HAL Module Clock Configuration

The SSI module uses the peripheral clock (PCLKB) available from the Clock configuration window. It also uses an external clock input to the AUDIO_CLK pin.

I2S HAL Module Pin Configuration

The SSI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device.

Configure the SSI RX and/or TX pins for the selected SSI channel (Pins Tab > Peripherals > SSI > SSIn > SSITXD0/SSIRXD0). For channel 0, enable one or both of these pins. For channel 1, enable the SSIDATA1 pin.

Configure the word select and clock pins (Pins Tab > Peripherals > SSI > SSIn > SSITWSn and SSISCKn). Both of these pins are required in most cases. Consult the datasheet of the I2S device used for the required pins.

Configure the audio clock pin (Pins Tab > Peripherals > SSI > SSI0_SSI1_AUDIO_CLK) for SSI. Connect an external audio clock to this clock input pin. If a GPT timer is used to generate the audio clock, configure the GPT timer output pin (Pins tab > Peripherals > GPT1 > GPTn > GTIOCx) and connect the GPT output pin used to the audio clock input pin.

The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the associated pins.

Pin Selection Sequence for the I2S HAL Module

Resource	ISDE Tab	Pin selection Sequence
I2S	Pins	Select Peripherals > Connectivity:SSI > SSI0/SSI1
I2S	Pins	Select Peripherals > Connectivity:SSI > SSI0_SSI1_AUDIO_CLK

NOTE: The selection sequence assumes SCI0 is the desired hardware target for the driver.

Pin Configuration Settings for I2S Driver on SSI

Pin Configuration Property	Settings	Description
Pin Group Selection	_A only, Mixed	Pin group for I2S port.
Operation Mode	Custom, Disabled	Operation selection.
SSISCK	None, P400 (Default: None)	AUDIO_CLK pin(P400), used in this application

NOTE: The above example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

Pin Configuration Settings for I2S Driver on SSI0

Pin Configuration Property	Settings	Description
Pin Group Selection	_A only, _B only, Mixed	Pin group for I2S port.
Operation Mode	Enabled, Custom, Disabled	Operation selection.
SSISCK	None, P112 (Default: None)	SSISCK pin(P112), used in this application
SSIWS	None, P113 (Default: None)	SSIWS pin(P113), used in this application
SSITXD	None, P115 (Default: None)	SSITXD pin(P115), used in this application
SSIRXD	None,P114 (Default:None)	SSIRXD pin(P114), used in this application

NOTE: The above example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

Pin Configuration Settings for I2S Driver on SSI1

Pin Configuration Property	Settings	Description
Pin Group Selection	_A only, _B only, Mixed	Pin group for I2S port.
Operation Mode	Enabled, Custom, Disabled	Operation selection.
SSISCK	None, P204 (Default: None)	SSI Serial Clock, not used in this application.

Pin Configuration Property	Settings	Description
SSIWS	None, P205 (Default: None)	SSI Stereo pin selection, not used in this application.
SSIDATA	None, P206 (Default: None)	SSI Data pin selection, not used in this application.

NOTE: The above example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.25.6 Using the I2S HAL Module in an Application

The typical steps in using the I2S HAL module in an application are:

1) Open the I2S HAL module using the open API.
2) Use the write API to write audio data to the I2S bus.
3) Wait for callback with I2S_EVENT_TX_EMPTY and free the source buffer.
4) Use the read API to read data from the I2S bus.
5) Wait for callback with I2S_EVENT_RX_FULL before accessing the destination buffer or reading the next buffer.
6) Use other APIs as needed by the application.
7) Close the module with the close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

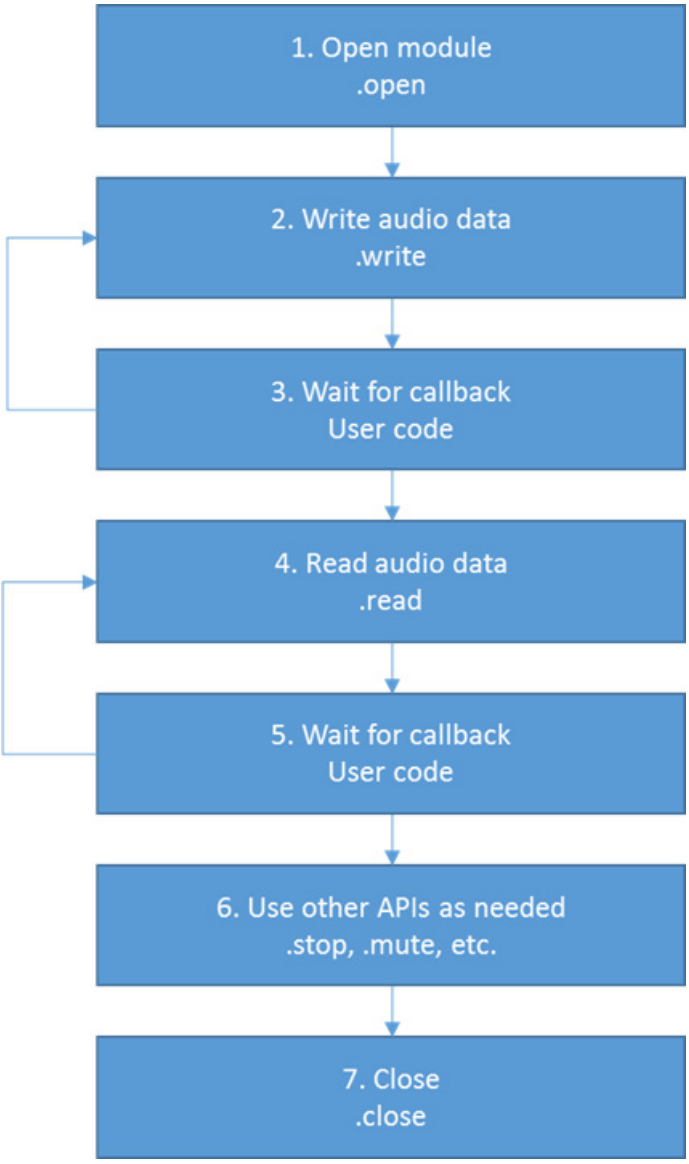

Figure 351: Flow Diagram of a Typical I2S HAL Module Application

4.2.26 Input Capture Driver

The Input Capture HAL module provides high-level APIs used for measuring input pulse-width and pulse-period measurement. The Input Capture HAL module configures the input capture parameters to use with the GPT peripheral on the Synergy MCU. A user-defined callback can be created to acquire the value each time a new measurement is complete.

4.2.26.1 Input Capture HAL Module Features

The Input Capture HAL module configures the GPT for an input capture function.

- The Input Capture HAL allows the user to perform the following tasks:
  - Initialize the module
  - Enable input capture measurement
  - Disable input capture measurement
  - Get the status (running or not) of the measurement counter
  - Get the last captured timer/overflows counter value
  - Close the input capture operation
- The Input Capture HAL module supports:
  - Pulse-width measurement and pulse-period measurement
  - Rising-edge or falling-edge measurement start
  - One-shot or periodic mode
  - Hardware-enable signals to enable captures (low enable/high enable)
  - Callback function with the following events:
  - **Counter overflow**
  - **Input capture occur**
  - Callback structure (input_capture_callback_args_t) that provides data on the interrupting event, including which interrupt occurs and the associated counter values.

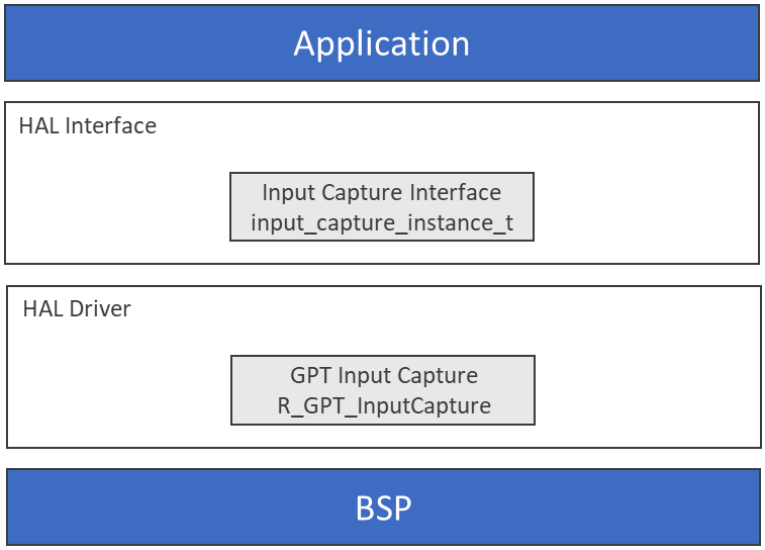

Figure 352: Input Capture HAL Module Block Diagram

4.2.26.2 Input Capture HAL Module APIs Overview

The Input Capture HAL module interface defines APIs for opening, closing, enabling, disabling, accessing status information and last-capture value accessing using the General PWM Timer (GPT) with Input Capture. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the HAL Module API Summary.

Input Capture HAL Module API Summary

Function Name	Example API Call and Description
.open	g_input_capture.p_api->open(g_input_capture.p_ctrl, g_input_capture.p_cfg); Opens the Input Capture HAL and initializes configuration.
.close	g_input_capture.p_api->close(g_input_capture.p_ctrl); Closes the input capture operation. Allow drive to be reconfigured, and may reduce power consumption.
.enable	g_input_capture.p_api->enable(g_input_capture.p_ctrl); Enables input capture measurement.
.disable	g_input_capture.p_api-> disable(g_input_capture.p_ctrl); Disables input capture measurement.
.infoGet	g_input_capture.p_api->infoGet(g_input_capture.p_ctrl, &input_capture_info); Gets the status (running or not) of the measurement counter.

Function Name	Example API Call and Description
.lastCaptureGet	g_input_capture.p_api->lastCaptureGet(g_input_capture.p_ctrl, &input_capture_counter); Gets the last captured timer/overflows counter value.
.versionGet	g_input_capture.p_api->versionGet(&input_capture_version); Retrieve the API version with the input_capture_version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the Synergy Software Platform (SSP) User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_ASSERTION	One of the parameters is NULL. Or the channel requested in the p_cfg parameter may not be available on the device selected in r_bsp_cfg.h. Or, p_cfg->mode is invalid.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value. Or ISR is not enabled.
SSP_ERR_IN_USE	Attempted to open an already open device instance.
SSP_ERR_NOT_OPEN	The channel is not opened.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.26.3 Input Capture HAL Module Operational Overview

The Input Capture HAL module controls the GPT HAL module units on a Synergy microcontroller (as configured by the user). It directly accesses the GPT hardware without using any RTOS elements and provides convenient APIs to simplify development.

When a normal measurement is complete and a callback is available (with interrupts enabled,) the Input Capture HAL module invokes the callback with the argument input_capture_callback_args_t.

The argument (input_capture_callback_args_t) indicates the channel, the event (input_capture_event_t) , the value of the timer captured when the interrupt occurred, and the number of counter overflows that occurred during this measurement.

If the interrupts are not enabled, the values read by the APIs would be the last captured timer/overflows counter value.

Input Capture HAL Module Important Operational Notes and Limitations

GPT Input Capture Measurement Mode

The input capture interface provides support for one-shot measurement and periodic measurement. The GPT hardware does not natively support one-shot functionality. Code is automatically included in the interrupt service routine (ISR) to stop and clear the timer. For this reason, ISRs must be enabled for one-shot mode, even when the callback is unused.

GPT Input Capture Signal

The input capture measurement starts when the input capture signal edge (rising or falling) is detected on the input capture signal pin (GTIOCA/GTIOCB) and the enable condition is met. The enable condition is defined by the enable level and can be disabled (none), or a specified low or high level on the input capture enable pin (GTIOCA/GTIOCB). The input capture enable pin is the pin not used as the input capture signal pin.

Converting Measurement Counts to Time

When a measurement completes, the raw-count data and the number of overflows is returned to the user in the callback function.

If desired, the raw measurement data can be converted to logical time units in the callback or user application. To convert the raw data, the current PCLKD clock frequency and its pre-scaler value, number of overflows, maximum counter value, and measurement counts should be considered. The measurement counts and the number of overflows are provided in the callback arguments input_capture_callback_args_t.

The recommended method to obtain the current PCLKD frequency is to use the systemClockFreqGet API. The input clock frequency is the PCLKD frequency divided by the pre-scalar value and is represented as clk_freq_hz in the following Input Capture Time Calculation table.

The maximum counter value on the S7G2 (all channels), S3A7 (all channels), and S124 (channel 0) is 0xFFFFFFFF. The maximum counter value for S124 (channels 1 - 6) is 0xFFFF. This maximum counter value plus one (since counter starts from zero) is represented as max_counts in the following table:

Input Capture Time Calculation

Desired Time Units	Formula
Nanoseconds (ns)	time_ns = ((overflows * max_counts) + counter) * 1000000000/clk_freq_hz
Microseconds (us)	time_ns = ((overflows * max_counts) + counter) * 1000000/clk_freq_hz
Milliseconds (ms)	time_ns = ((overflows * max_counts) + counter) * 1000/clk_freq_hz

Desired Time Units	Formula
Seconds (s)	time_ns = ((overflows * max_counts) + counter)/clk_freq_hz

- Currently, the Input Capture HAL module supports only pulse-width measurement and pulse-period measurement.
- Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.26.4 Including the Input Capture HAL Module in an Application

This section describes how to include the Input Capture HAL module in an application using the SSP configurator.

NOTE: It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Input Capture Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Input Capture Driver is g_input_capture. This name can be changed in the associated Properties window.)

Input Capture HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_input_capture Input Capture Driver on r_gpt_input_capture	Threads -> HAL/Common Stacks	Highlight Threads > HAL/Common Stacks and select New Stack > Driver > Timers > Input Capture Driver on r_gpt_input_capture

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_input_capture	Module name.
Channel	0	Physical hardware channel.
Mode	Pulse Width	Measures inputs from the Signal edge until the opposite edge.

ISDE Property	Value	Description
Signal Edge	Rising, Falling Default: Rising	Start measurement on rising or falling edge. Measurement stops on the opposite edge.
Repetition	Periodic, One Shot Default: Periodic	Capture a single measurement, then disable captures (one shot) until enable is called, or capture measurements continuously (periodic).
Auto Start	True, False Default: True	Set to true to enable measurements after configuring or false to leave the measurements disabled until enable is called.
Callback	NULL	A user callback function must be registered in open. The callback will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Input Capture Signal Pin	GTIOCA, GTIOCB Default: GTIOCA	Select the input pin used to trigger the start of a measurement.
GTIOCx Signal Filter	None, PCLK/1, PCLK/4, PCLK/16, PCLK/64 Default: None	The noise filter samples the external signal at intervals of the PCLK divided by one of the values. When 3 consecutive samples are at the same level (high or low), that level is passed on as the observed state of the signal.
Clock Divider	PCLK/1, PCLK/4, PCLK/16, PCLK/64, PCKL/256, PCLK/1024 Default: PCLK/1	Clock divider used to scale the measurement counter.

ISDE Property	Value	Description
Input Capture Enable Level	None, Low, High Default: None	Each GPT channel has 2 I/O pins (GTIOCA and GTIOCB). One must be selected as the Input Capture Signal Pin. The other GPT I/O pin can be used as a hardware enable signal to enable captures. Select None and captures are always enabled, select low and captures are enabled only while the enable input pin is low, select high and captures are enabled only while the enable input pin is high.
Input Capture Enable Filter	None (No filtering), PCLK/1 (Fast sampling), PCLK/4, PCLK/16, PCLK/64 (Slow sampling) Default: None (No filtering)	The enable filter samples the enable signal at intervals of the PCLK divided by one of the values. When 3 consecutive samples are at the same level (high or low), that level is passed on as the observed state of the signal.
Capture Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Default: Priority 12	Capture interrupt priority selection.
Overflow Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Default: Priority 12	Overflow interrupt priority selection.

The following figure shows when the Input Capture HAL module on r_gpt_input_capture is added to the thread stack, the configurator automatically adds any lower-level drivers needed. Any drivers requiring configuration information are box text highlighted in Red. Modules with a Gray band are standalone modules. Items with a Blue band are shared or common modules; they only need to be added once and can be used by multiple stacks.

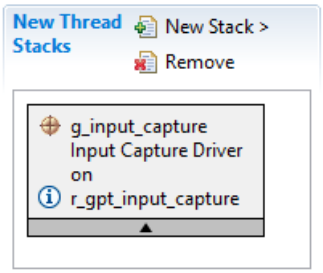

Figure 353: Input Capture HAL Module Stack

4.2.26.5 Configuring the Input Capture HAL Module

The user configures the Input Capture HAL module for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in Red) any configuration selections required, such as interrupts or operating modes, for lower-level modules to achieve successful operation. Only properties that can be changed without causing a conflict are available for modification. Properties that are 'locked' are identified with a lock icon in the **Properties** window and cannot be changed in the ISDE. This approach simplifies the configuration process, making it much less error prone than previous 'manual' approaches to configuration. The **Properties** tab within the SSP Configurator show all available user-accessible properties. The configuration settings and defaults for these properties are given in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority. This configuration setting is available in the **Properties** window of the associated module. Simply select the indicated module, then view the Properties window. Note that the **Properties** window the interrupt priorities also indicate the validity of the setting based on the MCU targeted (CM4 or CM0+).

NOTE: You may want to open your ISDE. and create the module and explore the property settings in parallel with looking over the following configuration table settings. This can help orient you and can also be a useful 'hands-on' approach as you learn the ins and outs of developing with SSP.

Configuration Settings for the Input Capture HAL Module on r_gpt_input_capture

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_input_capture	Module name.
Channel	0	Physical hardware channel.
Mode	Pulse Width	Measures inputs from the Signal edge until the opposite edge.

ISDE Property	Value	Description
Signal Edge	Rising, Falling Default: Rising	Start measurement on rising or falling edge. Measurement stops on the opposite edge.
Repetition	Periodic, One Shot Default: Periodic	Capture a single measurement, then disable captures (one shot) until enable is called, or capture measurements continuously (periodic).
Auto Start	True, False Default: True	Set to true to enable measurements after configuring or false to leave the measurements disabled until enable is called.
Callback	NULL	A user callback function must be registered in open. The callback will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Input Capture Signal Pin	GTIOCA, GTIOCB Default: GTIOCA	Select the input pin used to trigger the start of a measurement.
GTIOCx Signal Filter	None, PCLK/1, PCLK/4, PCLK/16, PCLK/64 Default: None	The noise filter samples the external signal at intervals of the PCLK divided by one of the values. When 3 consecutive samples are at the same level (high or low), that level is passed on as the observed state of the signal.
Clock Divider	PCLK/1, PCLK/4, PCLK/16, PCLK/64, PCKL/256, PCLK/1024 Default: PCLK/1	Clock divider used to scale the measurement counter.

ISDE Property	Value	Description
Input Capture Enable Level	None, Low, High Default: None	Each GPT channel has 2 I/O pins (GTIOCA and GTIOCB). One must be selected as the Input Capture Signal Pin. The other GPT I/O pin can be used as a hardware enable signal to enable captures. Select None and captures are always enabled, select low and captures are enabled only while the enable input pin is low, select high and captures are enabled only while the enable input pin is high.
Input Capture Enable Filter	None (No filtering), PCLK/1 (Fast sampling), PCLK/4, PCLK/16, PCLK/64 (Slow sampling) Default: None (No filtering)	The enable filter samples the enable signal at intervals of the PCLK divided by one of the values. When 3 consecutive samples are at the same level (high or low), that level is passed on as the observed state of the signal.
Capture Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Default: Priority 12	Capture interrupt priority selection.
Overflow Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Default: Priority 12	Overflow interrupt priority selection.

NOTE: The example values and defaults listed in the table are for a project using the Synergy S7G2 MCU family. Other MCUs may have different default values and available configuration settings.

Input Capture HAL Module Clock Configuration

The GPT HAL module uses the PCLKD as its clock source. The PCLKD frequency is set using the SSP configurator clocks tab prior to a build, or using the CGC Interface at run-time.

Input Capture HAL Module Pin Configuration

To access a particular channel and pin, the GTIOCx pins must be set in the Pins tab of the ISDE. The following table has the method for selecting the pins within the SSP configuration window, with the subsequent table listing an example selection for GTIOCx pins.

Pin Selection Sequence for Input Capture HAL Module

Resource	ISDE Tab	Pin selection Sequence
GPT Input Capture	Pins	Select **Peripherals > Timer: GPT > GPT0**

NOTE: The selection sequence assumes GPT0 is the desired hardware target for the driver.

Pin Configuration Settings for Input Capture HAL Module

Property	Value	Description
Pin Group Selection	Mixed, _A Only, _B Only (Default: Mixed)	Pin grouping selection
Operation Mode	Disabled, GTIOCA or GTIOCB, GTIOCA and GTIOCB (Default: Disable)	Select GTIOCA or GTIOCB as the Operation Mode for Input Capture on GPT
GTIOCA	None, P300, P512 (Default: None)	GTIOCA Pin
GTIOCB	None, P108, P511 (Default: None)	GTIOCB Pin

NOTE: The example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.26.6 Using the Input Capture HAL Module in an Application

Once the module has been configured and the files generated, the Input Capture HAL module is ready to be used in an application. The typical steps to using the Input Capture HAL module in an application are:

1) Initialize the module using the open API
2) The desired value can be found either in the main loop routine using the lastCaptureGet API or in the callback function

3) The capture and overflow interrupt can be disabled and the timer stopped using the disable API.
4) The capture and overflow interrupt can be enabled and the timer started using the enable API.
5) The status of the captured counter (running or stopped) can be queried using infoGet API
6) The module can be closed using the close API once done.

The following figure illustrates these common steps in a typical operational flow:

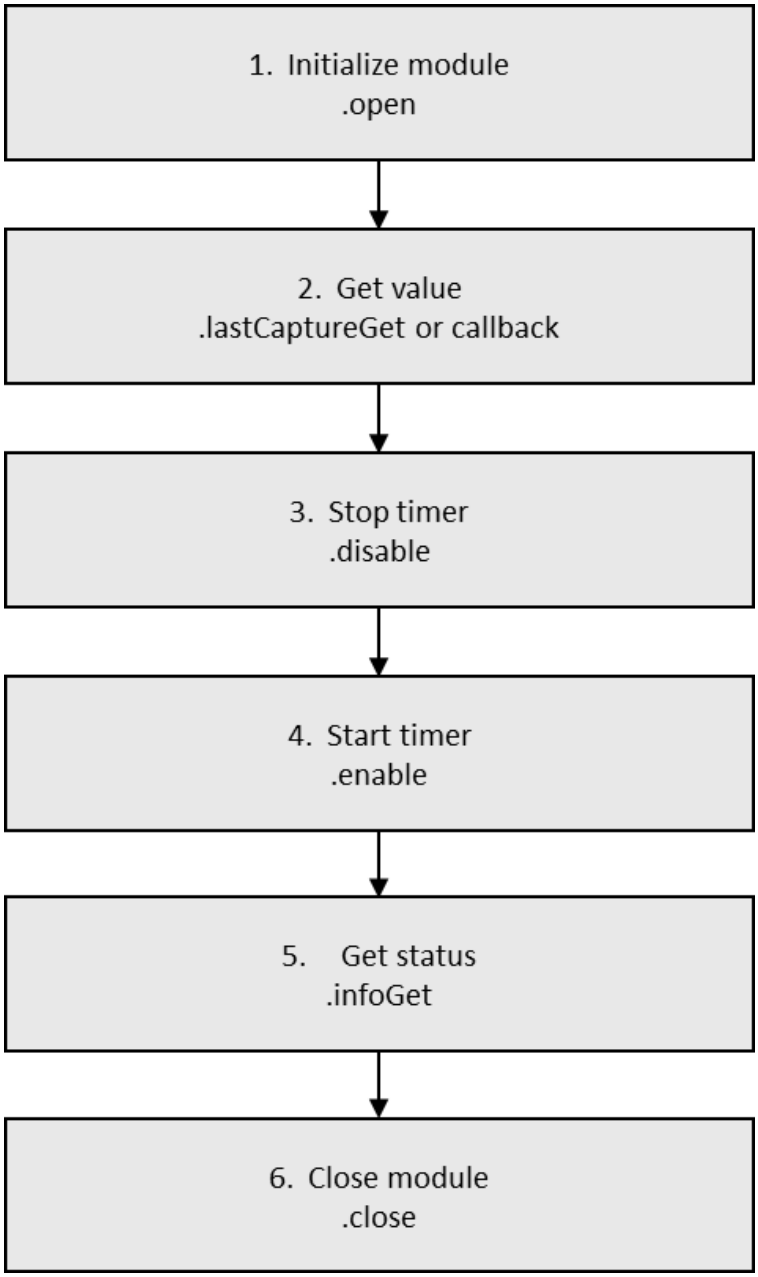

Figure 354: Flow Diagram of a Typical Input Capture HAL Module Application

4.2.27 I/O Port Driver

The I/O Port HAL module provides high-level APIs for controlling I/O pins and is implemented on r_ioport. The I/O Port HAL module configures the board's pins and provides functions for manipulating them. The operating state of the I/O

pins can be set via the Synergy configurator. When the Synergy project is built, a pin configuration file is created, and when the application runs, the BSP will configure the IO port accordingly, using the same APIs detailed in this document.

4.2.27.1 I/O Port HAL Module Features

This module configures one or more I/O pins. The direction of the pin or pins can be configured along with a number of other options provided as follows:

- Pull-up
- NMOS/PMOS
- Drive strength
- Event edge trigger (falling, rising or both)
- Whether the pin is to be used as an IRQ pin
- Whether the pin is to be used as an analog pin
- Whether the pin is to be used as a peripheral pin and which peripheral

The module also provides the following functionality:

- Changes the direction of one or more pins on a port
- Writes to one or more pins on a port
- Reads from one or more pins on a port
- Sets event output data
- Reads event input data

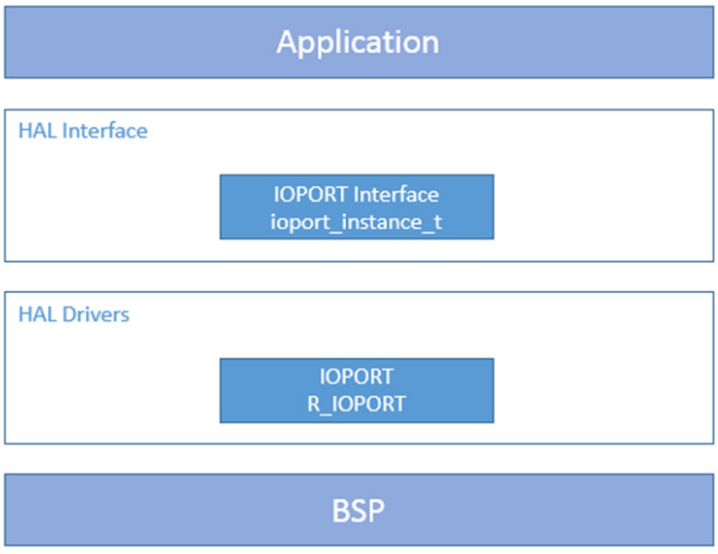

Figure 355:I/O Port HAL Module Block Diagram

4.2.27.2 I/O Port HAL Module APIs Overview

The I/O Port HAL module defines APIs for reading and writing from particular pins and ports. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of return status values follows the API summary table.

I/O Port HAL Module API Summary

Function Name	Example API Call and Description
init	g_ioport.p_api->init(g_ioport.p_cfg); Initialize configuration of multiple pins.
pinCfg	g_ioport.p_api->pinCfg(IOPORT_PORT_00_PIN_00, IOPORT_CFG_IRQ_ENABLE \ IOPORT_CFG_PORT_DIRECTION_INPUT); Configure settings for an individual pin.
pinsCfg	g_ioport.p_api->pinsCfg(&pin_config); Configure settings for a set of pins.
pinDirectionSet	g_ioport.p_api->pinDirectionSet(IOPORT_PORT_00_PIN_00, IOPORT_DIRECTION_INPUT); Set the pin direction of a pin.
pinEventInputRead	g_ioport.p_api->pinEventInputRead(IOPORT_PORT_00_PIN_00, &pin_level); Read the event (ELC) input data of the specified pin and return the level.
pinEventOutputWrite	g_ioport.p_api->pinEventOutputWrite(IOPORT_PORT_00_PIN_00, IOPORT_PIN_LEVEL_HIGH); Write pin event (ELC) data.
pinEthernetModeCfg	g_ioport.p_api->pinEthernetModeCfg(IOPORT_ETHERNET_CHANNEL_0, IOPORT_ETHERNET_MODE_MII); Configure the PHY mode of the Ethernet channels.

Function Name	Example API Call and Description
pinRead	g_ioport.p_api->pinRead(IOPORT_PORT_00_PIN_00, &pin_level); Read level of a pin.
pinWrite	g_ioport.p_api->pinWrite(IOPORT_PORT_00_PIN_00, IOPORT_PIN_LEVEL_HIGH); Write specified level to a pin.
portDirectionSet	g_ioport.p_api->portDirectionSet(IOPORT_PORT_00, direction_values, mask); Set the direction of one or more pins on a port.
portEventInputRead	g_ioport.p_api->portEventInputRead(IOPORT_PORT_00, &pin_levels); Read captured event (ELC) data for a port.
portEventOutputWrite	g_ioport.p_api->portEventOutputWrite(IOPORT_PORT_00, pin_levels, mask); Write event (ELC) output data for a port.
portRead	g_ioport.p_api->portRead(IOPORT_PORT_00, &pin_levels); Read states of pins on the specified port.
portWrite	g_ioport.p_api->portWrite(IOPORT_PORT_00, pin_levels, mask); Write to multiple pins on a port.
versionGet	g_ioport.p_api->versionGet(&version); Retrieve version information using the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines,

API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	The port/pin/mask/direction/level (etc.) not valid.
SSP_ERR_ASSERTION	Unexpected null pointer.
SSP_ERR_UNSUPPORTED	Feature not supported – for instance Ethernet configuration not supported on the device.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.27.3 I/O Port HAL Module Operational Overview

The I/O Port HAL module provides the ability to access the I/O ports of a device at both bit and port level; both port and pin direction can be changed. In addition, a number of configuration APIs are provided to change the functionality of individual pins.

The I/O Port HAL module provides the following operations for configuring pins:

- Initializes the driver – performed by calling init:
  - Performs parameter checking and processes error conditions.
  - Handles VBATT domain pin configuration.
  - Writes PFS registers for pins.
- Configures pin – performed by calling pinCfg API:
  - Performs parameter checking and processes error conditions (checks pin number pin, VBATT support).
  - Writes PFS register for the pin.
- Reads pin level – performed by calling pinRead API:
  - Performs parameter checking and processes error conditions (checks pin number pin).
  - Reads PFS register for the pin.
- Reads all pin levels on a port – performed by calling portRead API:
  - Performs parameter checking and processes error conditions (checks port number port).
  - Reads current value of PCNTR register value for the specified port.

- Writes pin level – performed by calling pinWrite API :
  - Performs parameter checking and processes error conditions (check pin number pin and written level level).
  - Write to PFS register for the pin.
- Write multiple pin levels on a port – performed by calling portWrite v:
  - Performs parameter checking and processes error conditions (checks port number port and pin mask mask).
  - Reads current configuration from the PCNTR register for the specified port.
  - Writes the pin levels to the PCNTR register for the specified port accordingly to the mask, preserving pin levels out of the scope.
- Sets the direction of multiple pins on a port – performed by calling portDirectionSet API :
  - Performs parameter checking and processes error conditions (checks port number port and pin mask mask).
  - Reads current configuration from the PCNTR register for the specified port.
  - Writes the pin levels to the PCNTR register for the specified port accordingly to the mask, preserving pin directions out of the scope.
- Writes pin direction – performed by calling pinDirectionSet API:
  - Performs parameter checking and processes error conditions (checks pin number pin and written direction direction).
  - Writes to the PFS register for the pin.
- Reads event (ELC) port input – performed by calling portEventInputRead API :
  - Performs parameter checking and processes error conditions (checks port number port).
  - Reads current value of the PCNTR register value for the specified port.
- Reads event (ELC) pin input – performed by calling pinEventInputRead API :
  - Performs parameter checking and processes error conditions (checks pin number pin).
  - Reads current value of the PCNTR register value for the specified pin's port.
  - Gets the pin level by applying a pin mask to the PCNTR register value.
- Writes event (ELC) port output – performed by calling portEventOutputWrite API :
  - Performs parameter checking and processes error conditions (checks port number port and pin mask mask_value).
  - Reads current configuration from the PCNTR register for the specified port.
  - Writes the pin levels to the PCNTR register for the specified port accordingly to the mask preserving pin levels out of the event scope.
- Writes event (ELC) pin output – performed by calling pinEventOutputWrite API:
  - Performs parameter checking and processes error conditions (checks pin number pin and written level pin_value).

  - Writes the pin level to the PCNTR register for the specified pin's port accordingly to the mask that is preserving pin levels out of the event scope.
- Configures Ethernet channel PHY mode – performed by calling ethernetModeCfg API:
  - Performs parameter checking and processes error conditions (checks Ethernet channel channel and mode mode).
  - Updates the Ethernet Control Register (PFENET).

I/O Port HAL Module Important Operational Notes and Limitations

- A bit mask of 16 bits needs to be applied in order to read and write to a specific pin on a port; ports are numbered from 0 (LSB) to 15 (MSB).
- Ethernet configuration may not be supported on some devices.

Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.27.4 Including the I/O Port HAL Module in an Application

The e^2 studio Integrated Solution Developer Environment (ISDE) automatically adds the necessary I/O Port stack to the HAL/Common thread in the project and the stack is ready by default to operate. If the I/O Port Driver was inadvertently removed, the following process is available to add the driver to the HAL/Common Thread.

NOTE: It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the *SSP User's Manual* to learn how to manage each of these important steps in creating SSP-based applications.

To add the I/O Port HAL Driver to your application, simply add it to a project Thread using the stacks selection sequence given in the following table. (The default name for the I/O Port is g_ioport.)

I/O Port HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_ioport I/O Port driver on r_ioport	Threads	Highlight HAL/Common and select New > Driver > System > I/O Port Driver on r_ioport

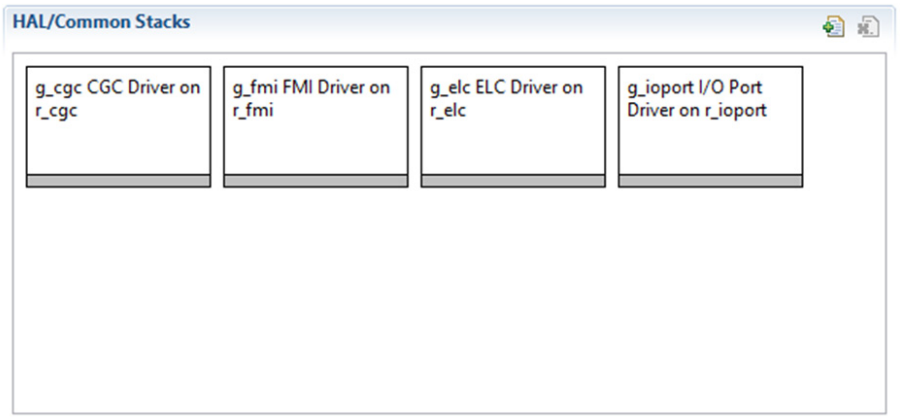

Figure 356: I/O Port HAL Module Stack

No additional lower-level modules need to be added or configured.

4.2.27.5 Configuring the I/O Port HAL Module

The module does not need any additional configuration. All the pin configuration is generated in the src/synergy_gen/pin_data.c file according to the BSP.

4.2.27.6 Using the I/O Port HAL Module in an Application

The typical steps in using the I/O Port HAL module in an application are:

1) Initialize the driver using the init API.
2) Configure the pins using the pinCfg API.
3) Read from specified pins and ports using the pinRead, or portRead API.
4) Write to specified pins and ports using the pinWrite, or portWrite API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

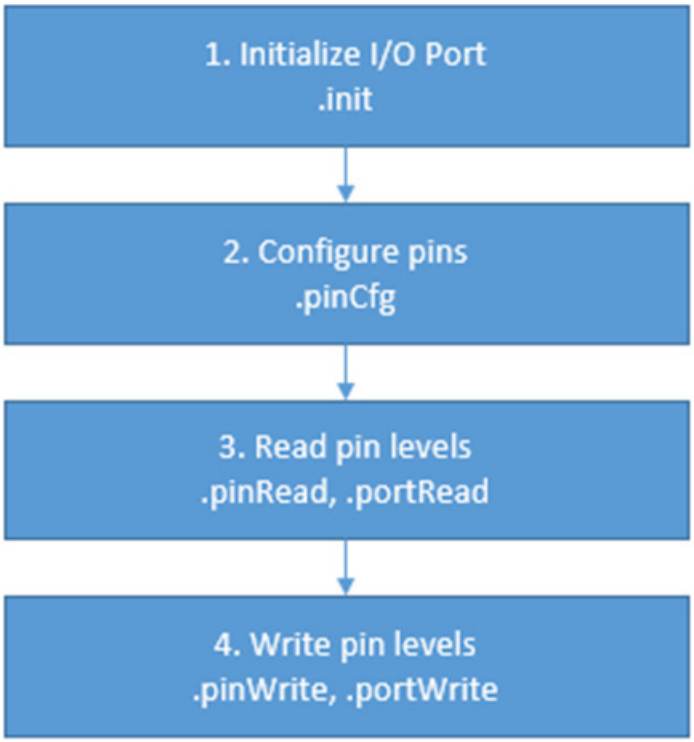

Figure 357: Flow Diagram of a Typical I/O Port HAL Module Application

4.2.28 Independent Watchdog Driver

4.2.28.1 Independent Watchdog Driver

The Independent Watchdog Timer (IWDT) HAL module provides high-level APIs for watchdog timer applications and is implemented on r_iwdt. The Watchdog Timer uses the IWDT peripheral on the Synergy MCU. A user-defined callback can be created to respond to event notifications.

4.2.28.2 IWDT HAL Module Features

The IWDT HAL module has the following key features:

- When the WDT underflows or is refreshed outside of the permitted refresh window, one of the following events can occur:
  - Device reset
  - NMI generation
- Supports the internal Watchdog timer peripheral (IWDT), which has its own clock source which improves safety.
- Supports automatic hardware configuration after reset.

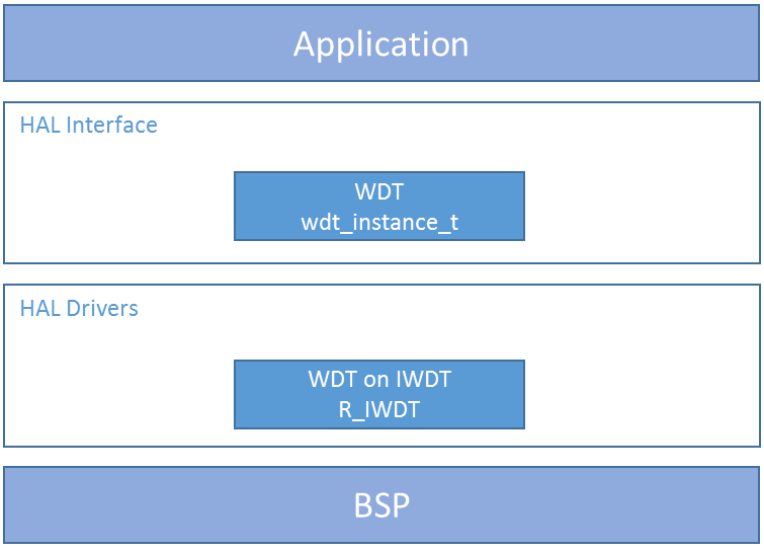

Figure 358: IWDT HAL Module Organization and Stack Implementations

4.2.28.3 IWDT HAL Module APIs Overview

The IWDT HAL module defines APIs for open, refresh, read, and get status. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows.

IWDT HAL Module Timer API Summary

Function Name	Example API Call and Description
cfgGet	g_wdt0.p_api->cfgGet(g_wdt0.p_ctrl, g_wdt0.p_cfg); Initialize the iWDT in register start mode. In auto-start mode with NMI output it registers the NMI callback.
open	g_wdt0.p_api->open(g_wdt0.p_ctrl, g_wdt0.p_cfg); Initialize the iWDT in register start mode. In auto-start mode with NMI output it registers the NMI callback.
refresh	g_wdt0.p_api->refresh(g_wdt0.p_ctrl); Refresh the watchdog timer.

Function Name	Example API Call and Description
statusGet	g_wdt0.p_api->statusGet(g_wdt0.p_ctrl, &status); Read the status of the iWDT.
statusClear	g_wdt0.p_api->statusClear(g_wdt0.p_ctrl, clear); Clear the status flags of the iWDT.
counterGet	g_wdt0.p_api->counterGet(g_wdt0.p_ctrl, &counter); Read the current iWDT counter value.
timeoutGet	g_wdt0.p_api->timeoutGet(g_wdt0.p_ctrl, &timeout); Read the watchdog timeout values.
versionGet	g_wdt0.p_api->versionGet(&version); Retrieve the API version using the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successfully executed.
SSP_ERR_ASSERTION	Null Pointer(s).
SSP_ERR_INVALID_ARGUMENT	One or more configuration options is invalid.
SSP_ERR_INVALID_MODE	An attempt to open the WDT in register-start mode when the OFS0 register is configured for auto-start mode. Or to open the WDT in auto-start mode when the OSF0 is configured for register start mode.
SSP_ERR_ABORTED	Invalid clock divider for this watchdog

NOTE: Lower level drivers may return Common Error Codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.28.4 IWDT HAL Module Operational Overview

The IWDT HAL module configures the IWDT Interface. When the IWDT underflows or is refreshed outside of the permitted refresh window, one of the following events can occur:

- Resetting of the device
- Generation of an NMI

The following figure shows an example of the operation of the IWDT. When refreshed in the valid refresh period of the counter the timer count value is reset. If the count is allowed to underflow or refresh occurs outside of the valid refresh period, the IWDT resets the device or generates an NMI.

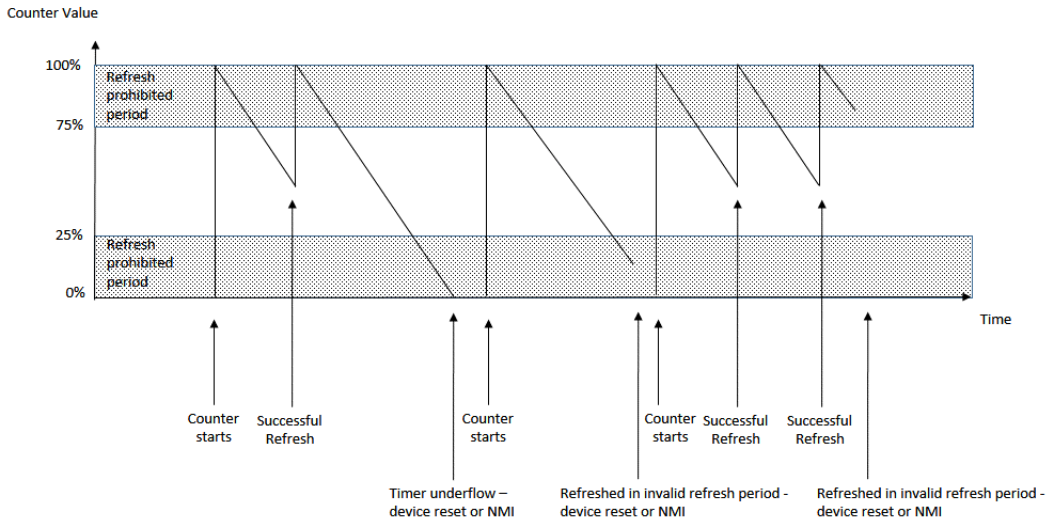

Figure 359: Independent Watchdog Timer Operational Diagram

All series of Synergy microcontrollers have an option-setting Memory which can be used to set the operating state of peripherals after a reset. The OFS can be used to set the state of the IWDT, WDT, LVD and CGC HOCO.

The following table details which parameters of the IWDT can be configured by the OFS registers.

NOTE: The IWDT can only be configured via the OFS registers. The IWDT does not support Register Start mode.

Control	Description
IWDT Start Mode Select	Automatically starts the IWDT after a Reset, if enabled.
IWDT Timeout Period	Specifies the IWDT timeout (number of clock cycles) 128 cycles 512 cycles 1024 cycles 2048 cycles
IWDT-Dedicated Clock Frequency Division Ratio	1 1/16 1/32 1/64 1/128 1/256
IWDT Window End Position	25% 50% 75% 100% (no window end position set)
IWDT Window Start Position	25% 50% 75% 100% (no window start position set)
IWDT Reset Interrupt Request	The IWDT can either generate an Interrupt Signal or a Reset signal.
IWDT Stop Control	The IWDT can continue to count or Stop counting in Low Power Mode.

NOTE: For further information on the contents of the OFS0 register see the Synergy MCU hardware manual.

The OFS register values are set in the Synergy Configuration editor via properties on the BSP tab.

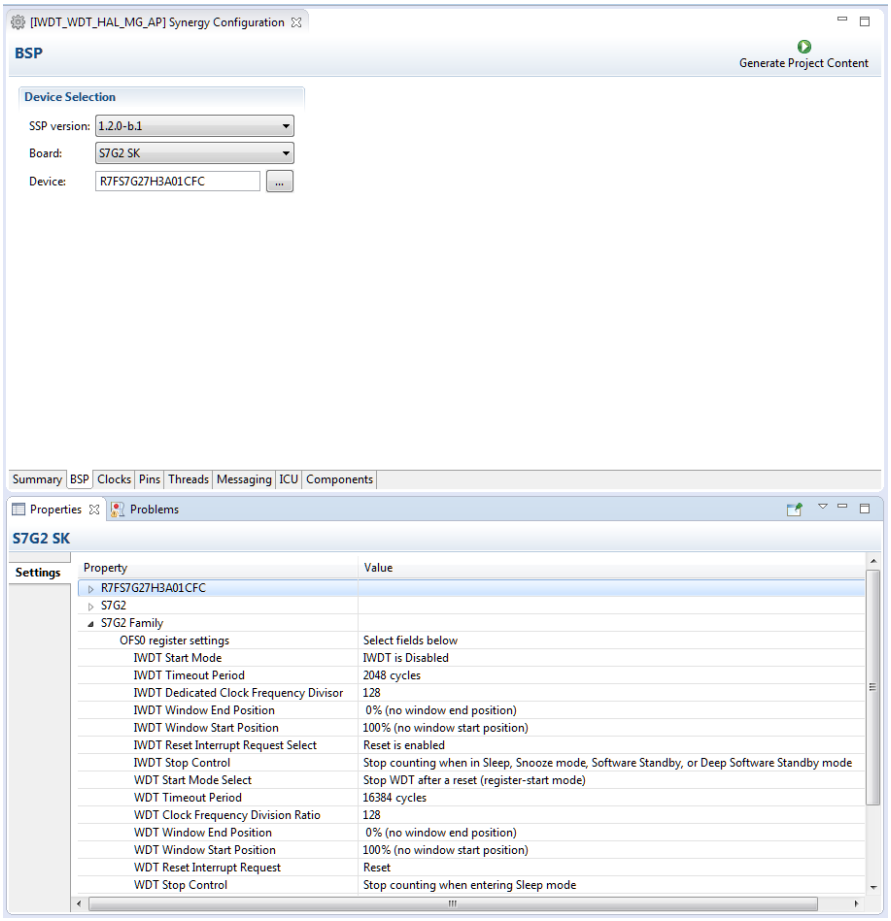

Figure 360: OFS Register Value Settings

4.2.28.5 IWDT HAL Module Important Operational Notes and Limitations

4.2.28.6 IWDT HAL Module Period Calculation

The IWDT operates from IWDTCLK. Assuming the largest parameters for the WDT and an IWDTCLK frequency of 15 kHz, the time from the last refresh to device reset or NMI generation is under 35 seconds. The clock specifications for the IWDT module period are as follows:

IWDTLCK = 15 kHz

Clock division ratio = IWTCLK/256

Timeout period = 2048 cycles

IWDT clock frequency = 15 kHz / 256 = 58.59 Hz

Cycle time = 1 / 58.59 Hz = 17.07 ms

Timeout = 17.07 ms x 2048 cycles = 34.95 seconds

4.2.28.7 Triggering DMAC/DTC with the IWDT HAL Module

To trigger a transfer of data using the DMAC or DTC peripheral when the watchdog counter underflows or when a refresh is attempted outside of the valid refresh period, configure the DMAC/DTC transfer with activation_source set to ELC_EVENT_IWDT_UNDERFLOW. See the appropriate module User Guide for additional information.

4.2.28.8 Triggering ELC Events with the IWDT HAL Module

The IWDT can trigger the start of other peripherals as available with the Event Link Controller (ELC). For details, see the ELC HAL module guide.

4.2.28.9 IWDT HAL Module Limitations

- When using a JLink debugger the IWDT counter does not count and therefore will not reset the device or generate an NMI.
- When there is no active task ready to run, ThreadX puts the MCU into sleep mode. If the IWDT is configured to stop the counter in low-power mode, then your application must restart the timer when used with the ThreadX RTOS.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.28.10 Including the IWDT HAL Module in an Application

This section describes how to include the IWDT HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack.

To add the IWDT HAL module to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the IWDT HAL module is r_iwdt as shown in the table below. This name can be changed in the associated properties window.)

Watchdog Timer Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_wdt0 IWDT HAL on r_iwdt	Threads	New Stack> Driver> Monitoring> IWDT HAL on r_iwdt

When the IWDT HAL module on r_iwdt is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower level modules. Any drivers that need additional configuration information will be box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

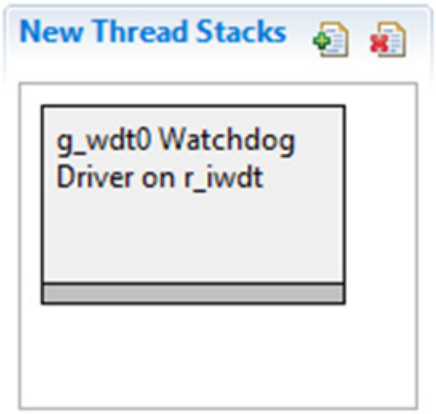

Figure 361:IWDT HAL Module Stack

4.2.28.11 Configuring the IWDT HAL Module

The IWDT HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections (such as interrupts or operating modes) which must be configured for lower level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the properties window of the associated module. Simply select the indicated module and then view the properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+.) This level of detail is not included in the configuration properties tables below, but is easily visible with the ISDE when configuring interrupt priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the Configuration Table Settings given below. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration settings for IWDT implementation are given in the below tables.

Configuration Settings for the IWDT HAL Module on r_iwdt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Include parameter checking code
Name	g_wdt0	Module Name

ISDE Property	Value	Description
NMI Callback	NULL	Callback. A user callback function can be registered in the open API. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the IRQn triggers.

Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system. |

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

4.2.28.12 Configure Option Function Select Register 0 (OFS0)

All series of Synergy microcontrollers have an Option-Setting Memory which can be used to set the operating state of peripherals after a reset. The OFS can be used to set the state of the IWDT, WDT, LVD and CGC HOCO.

4.2.28.13 Configure the Interrupts for the IWDT HAL Module

Use the ISDE to configure the IWDT interrupts in the same way as configuring the other options for the IWDT module. If the IWDT is configured to generate an NMI interrupt on underflow or invalid refresh the interrupt must be enabled in the BSP.

NOTE: To enable interrupts, set the priority of the IWDT > IWDT NMIUNDF N. This sets BSP_IRQ_CFG_IWDT_UNDERFLOW in ssp_cfg/bsp/bsp_irq_cfg.h to the priority level selected.

When the IWDT NMIUNDF N interrupt is enabled in the BSP, the corresponding ISR will be defined. The ISR will call a user callback function if one was registered in the open API.

4.2.28.14 IWDT HAL Module Clock Configuration

The IWDT has its own dedicated clock operating at a set frequency which cannot be modified.

4.2.28.15 IWDT HAL Module Pin Configuration

4.2.28.16 IWDT does not require pins for its operation.

4.2.28.17 Using the IWDT HAL Module in an Application

The typical steps in using the IWDT HAL module in an application are:

1) Register the IWDT NMI callback using the open API.
2) Read the configuration of the IWDT HAL module using the cfgGet API.
3) Refresh the independent watchdog timer using the refresh API.
4) Read the IWDT status flags using the statusGet API.
5) Clear the IWDT Status and error flags using the statusClear API.
6) Read the current count value of the IWDT using the counterGet API.
7) Read the timeout values of the IWDT HAL module using the timeoutGet API.

The above steps are illustrated in a typical operational flow in the following figure:

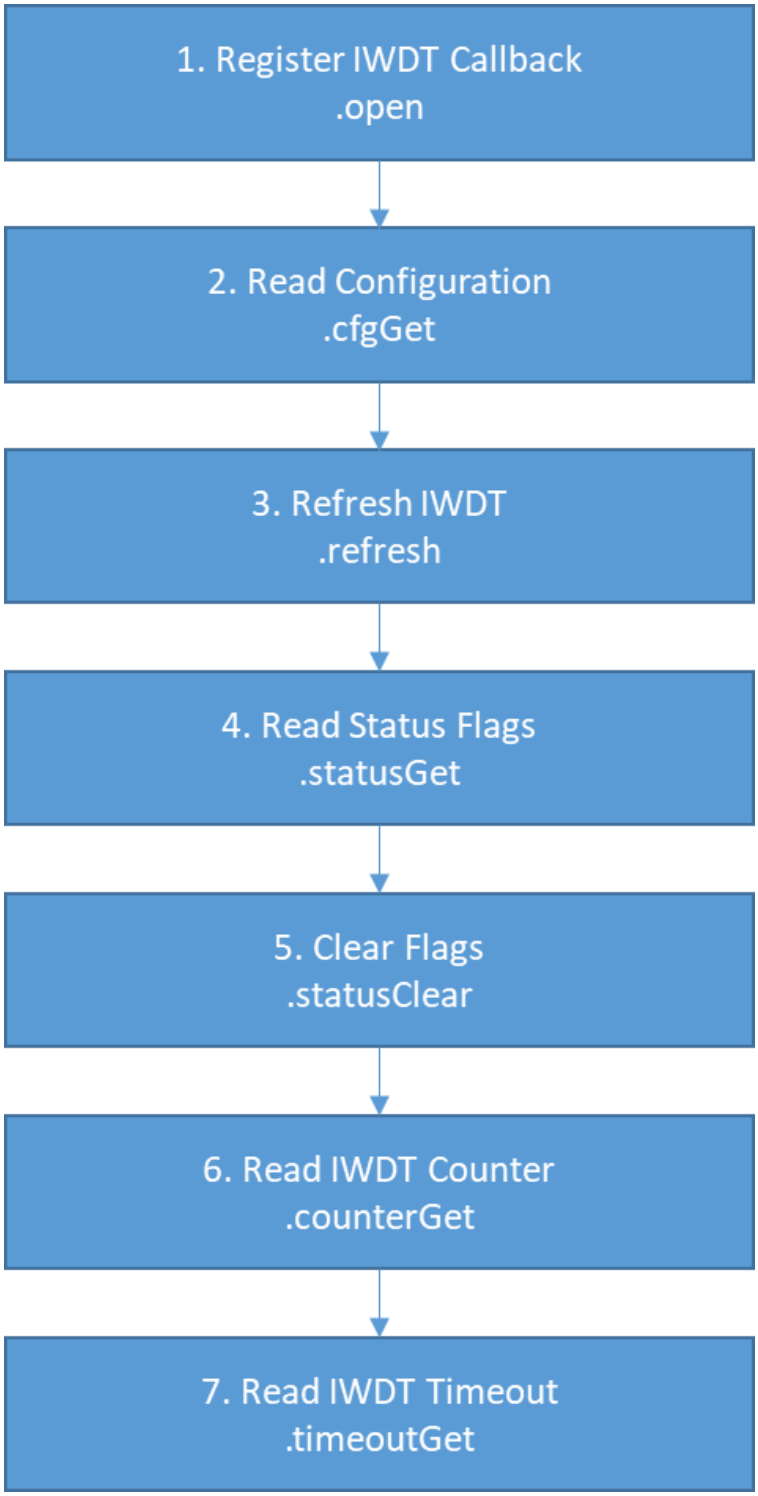

Figure 362: Flow Diagram of a Typical IWDT HAL Module Application

4.2.29 JPEG Decode Driver

The JPEG Decode HAL module provides high-level APIs for JPEG Decode image processing. The JPEG Decode HAL module uses the Synergy MCU JPEG Codec peripheral. A user callback function is available to inform the application program of key processing events.

4.2.29.1 JPEG Decode HAL Module Features

- Supports JPEG decompression.
- Supports polling mode that allows an application to wait for JPEG Decoder to complete.
- Supports interrupt mode with user-supplied callback functions.
- Configures parameters such as horizontal and vertical subsample values, horizontal stride, decoded pixel format, input and output data format, and color space.
- Obtains the size of the image prior to decoding it.
- Supports putting coded data in an input buffer and an output buffer to store the decoded image frame.
- Supports streaming coded data into JPEG Decoder module. This feature allows an application to read coded JPEG image from a file or from network without buffering the entire image.
- Configures the number of image lines to decode. This feature enables the application to process the decoded image on the fly without buffering the entire frame.
- Supports the input decoded format YCbCr444, YCbCr422, YCbCr420, YCbCr411.
- Supports the output format ARGB8888, RGB565.
- Returns error when the JPEG image's size, height and width don't meet the requirements.

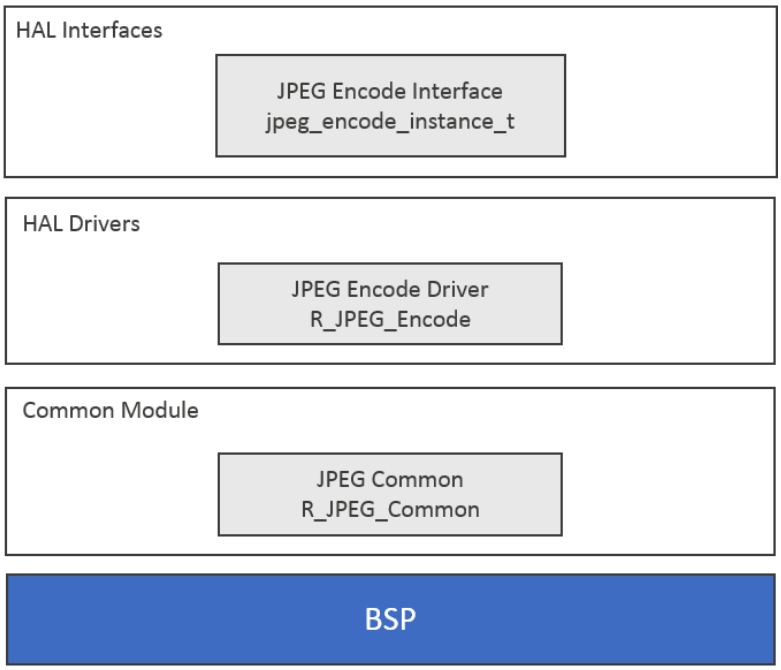

Figure 363: JPEG Decode HAL Module Block Diagram

4.2.29.2 JPEG Decode HAL Module APIs Overview

The JPEG Decode HAL Module implements APIs to open, set processing parameters, start processing, get processing statusand close the module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

JPEG Decode HAL Module API Summary

Function Name	Example API Call and Description
.open	g_jpeg_decode0.p_api->open(g_jpeg_decode0.p_ctrl, g_jpeg_decode0.p_cfg); Initial configuration.
.outputBufferSet	g_jpeg_decode0.p_api->outputBufferSet(g_jpeg_decode0.p_ctrl, p_buffer, buffer_size); Assign output buffer to JPEG *codec* for storing output data.

Function Name	Example API Call and Description
.horizontalStrideSet	g_jpeg_decode0.p_api->horizontalStrideSet(g_jpeg_decode0.p_ctrl, stride); Configure the horizontal stride value.
.imageSubsampleSet	g_jpeg_decode0.p_api->imageSubsampleSet(g_jpeg_decode0.p_ctrl, horizontal, vertical); Configure the horizontal and vertical *subsample* settings.
.inputBufferSet	g_jpeg_decode0.p_api->inputBufferSet(g_jpeg_decode0.p_ctrl, p_buffer, size); Assign input data buffer to JPEG *codec*.
.linesDecodedGet	g_jpeg_decode0.p_api->linesDecodedGet g_jpeg_decode0.p_ctrl, p_lines); Return the number of lines decoded into the output buffer.
.imageSizeGet	g_jpeg_decode0.p_api->imageSizeGet(g_jpeg_decode0.p_ctrl, p_horizontal, p_vertical); Retrieve image size during decoding operation.
.statusGet	g_jpeg_decode0.p_api->statusGet(g_jpeg_decode0.p_ctrl, p_status); Retrieve current status of the JPEG *codec* module.
.close	g_jpeg_decode0.p_api->close(g_jpeg_decode0.p_ctrl); Cancel an outstanding operation.
.versionGet	g_jpeg_decode0.p_api->versionGet(&version); Get version and store it in provided pointer p_version.

Function Name	Example API Call and Description
.pixelFormatGet	g_jpeg_decode0.p_api->pixelFormatGet(g_jpeg_decode0.p_ctrl, p_color_space); Get the input pixel format.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_INVALID_ALIGNMENT	Horizantal stride is not 8-byte aligned.
SSP_ERR_NOT_OPEN	Unit is not open
SSP_ERR_ASSERTION	An input pointer is NULL.
SSP_ERR_IN_USE	Peripheral is in use or hardware lock is taken.
SSP_ERR_HW_LOCKED	JPEG Codec resource is locked.
SSP_ERR_INVALID_CALL	An invalid call has been made, Codec output buffer address is attempted to change during codec operation. Or set output buffer first.
SSP_ERR_JPEG_IMAGE_SIZE_ERROR	Image size is not supported by JPEG codec.
SSP_ERR_JPEG_BUFFERSIZE_NOT_ENOUGH	Invalid buffer size
SSP_ERR_INVALID_MODE	JPEG Codec module is not decoding.
SSP_ERR_IMAGE_SIZE_UNKNOWN	The image size is unknown. More input data may be needed.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.2.29.3 JPEG Decode HAL Module Operational Overview

The JPEG Decoder HAL module can be used in the Input Buffer Streaming mode or JPEG Output Buffer Streaming mode.

Input Buffer Streaming Mode Operational Description

In this scenario the JPEG image data resides on a file, or is received from network. The HAL-layer driver is able to handle this scenario without requiring the input data to be stored in memory first.

Output Buffer Streaming Mode Operational Description

In this scenario the application needs to write the decoded image data to a file or to a network. The HAL-layer driver does not require the application to allocate memory for the entire frame. Instead the application may choose to decode one or more lines at a time. With this feature the amount of memory needed for the output data is greatly reduced.

MJPEG Decode operational Description

In this scenario, the application needs to display a continuous stream of JPEG images on the native display. The JPEG images can reside in a file or can be received from the network. The HAL driver can handle this by using Input Buffer Streaming Mode.

The basic flow to achieve this would be:

1) Open the JPEG driver.
2) Set the image parameters to: horizontal stride, image sub-samples.
3) Set the input buffer which holds the jpeg image frame.
4) Set the output buffer to hold the raw image.
5) Display the decoded image.
6) Close the JPEG driver
7) Start the process from step 1.

JPEG Decode HAL Module Important Operational Notes and Limitations

JPEG Decode Callbacks

A user callback function can be registered in the open API. If a user callback function is provided, the callback function will be called from the interrupt service routine (ISR) each time an interrupt happens. The argument of the callback function status can take the enumerated values listed below so that user can identify which event occurred in the decoding procedure.

Event Name Event Condition

JPEG_DECODE_STATUS_ERROR JPEG: Decode module encountered an error.

JPEG_DECODE_STATUS_IMAGE_SIZE_READY: JPEG Decode obtained the image size of data to be Decoded, and paused.

JPEG_DECODE_STATUS_INPUT_PAUSE: JPEG Decode paused waiting for more input data.

JPEG_DECODE_STATUS_OUTPUT_PAUSE: JPEG Decode paused after decoded the number of lines specified by user.

JPEG_DECODE_STATUS_DONE: JPEG Decode operation has successfully completed.

NOTE: Since a user callback function is called from an ISR, be careful not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.

- The JPEG Decode HAL module only support JPEG decoding processing, for Encoding please JPEG Encode driver.
- In application if both driver is used, JPEG Encode driver needs to be close to use JPEG Decode driver or vice versa, as both driver shares the same IP.
- Refer to the most recent SSP Release notes for the most up to date limitations for this module.

4.2.29.4 Including the JPEG Decode HAL Module in an Application

This section describes how to include the JPEG Decode HAL Module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the JPEG Decode HAL Module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the JPEG Decode HAL Module is g_jpeg_decode0. This name can be changed in the associated Properties window.)

JPEG Decode HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_jpeg_decode0 JPEG Decode Driver on r_jpeg_decode	Threads	New Stack> Driver> Graphics> JPEG Dencode Driver

When the JPEG Decode HAL Module on r_jpeg_decode is added to the thread stack as shown in the following figure, the configurator automatically adds any lower-level drivers that are required. Any drivers that need additional configuration information will be box-text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

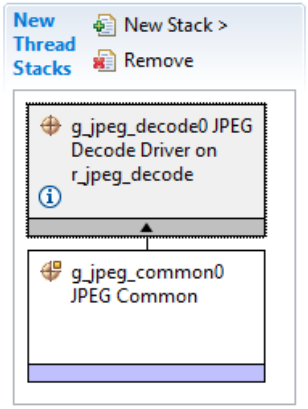

Figure 364: JPEG Decode HAL Module Stack

4.2.29.5 Configuring the JPEG Decode HAL Module

The JPEG Decode HAL Module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the JPEG Decode HAL Module on r_jpeg_decode

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_jpeg_decode0	The name to be used for a JPEG Decode module instance.

ISDE Property	Value	Description
Byte Order for Input Data Format	Normal byte order (1)(2)(3)(4)(5)(6)(7)(8), Byte Swap (2)(1)(4)(3)(6)(5)(8)(7), Word Swap (3)(4)(1)(2)(7)(8)(5)(6), Word-Byte Swap (4)(3)(2)(1)(8)(7)(6)(5), Longword Swap (5)(6)(7)(8)(1)(2)(3)(4), Longword-Byte Swap (6)(5)(8)(7)(2)(1)(4)(3), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2) Default: Normal Byte order	Specify the byte order for input data. The order is swapped as specified in every 8-byte.

ISDE Property	Value	Description
Byte Order for Output Data Format	Normal byte order (1)(2)(3)(4)(5)(6)(7)(8), Byte Swap (2)(1)(4)(3)(6)(5)(8)(7), Word Swap (3)(4)(1)(2)(7)(8)(5)(6), Word-Byte Swap (4)(3)(2)(1)(8)(7)(6)(5), Longword Swap (5)(6)(7)(8)(1)(2)(3)(4), Longword-Byte Swap (6)(5)(8)(7)(2)(1)(4)(3), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2) Default: Normal Byte order	Specify the byte order for output data. The order is swapped as specified in every 8-byte.
Output Data Color Format	Pixel Data RGB565 format, Pixel Data ARGBB888 format Default: Pixel Data RGB565 format	Specify the output data format.
Alpha value to be applied to decoded pixel data (only valid for ARGB8888 format)	255	Specify the alpha value for the output data format (only valid for ARGB8888 format).
Name of user callback function	NULL	Specify the name of user callback function.
Decompression Interrupt Priority	Priority 0 (highest), Priority 2:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Decompression interrupt priority selection.

ISDE Property	Value	Description
Data Transfer Interrupt Priority	Priority 0 (highest), Priority 2:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Data transfer interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S1JA. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the JPEG Common Module

ISDE Property	Value	Description
Name	g_jpeg_common0	Module name

NOTE: The example values and defaults are for a project using the Synergy S1JA. Other MCUs may have different default values and available configuration settings.

JPEG Decode HAL Module Clock Configuration

The JPEG Decode HAL Module uses the PCLKA as its clock source.

To change the clock frequency at run-time, use the CGC Interface.

JPEG Decode HAL Module Pin Configuration

The JPEG Decode HAL Module has no configurable input or output pins.

4.2.29.6 Using the JPEG Decode HAL Module in an Application

Once the module has been configured and the files generated, the JPEG Decode is ready to be used in an application. The typical steps in using the JPEG Decoder HAL module in an application are initializing the JPEG Decode using the open API, configure the horizontal stride, image sub-sample, input buffer and output buffer. Once the input and output buffers are set, the JPEG codec triggers the decode operation and stores the decoded image to the output buffer. The statusGet API can be used to poll the status of the JPEG operation.

The typical steps in using the JPEG Decode module in an application are:

1) Initialize the JPEG Decode using the open API.
2) Set the horizontal stride using the horizontalStrideSet API.
3) Set vertical and horizontal image sub-sample using the imageSubsampleSet API.
4) Set the input buffer address (which contains the JPEG image) using the inputBufferSet API.

5) Set the output buffer (should be large enough to hold the raw image data) using the outputBufferSet API.
6) The statusGet API can be used to get the JPEG operation. It returns an enumerated value (described above) to notify the user.
   a) The status JPEG_DECODE_STATUS_DONE returned from the statusGet API shows that the Decode operation is complete.
   b) The status JPEG_DECODE_STATUS_INPUT_PAUSE or JPEG_DECODE_STATUS_OUTPUT_PAUSE returned from the statusGet API shows that the Decode operation is not complete.
7) Operate on the received raw image data as needed by the application.
8) Close the module using the close API.

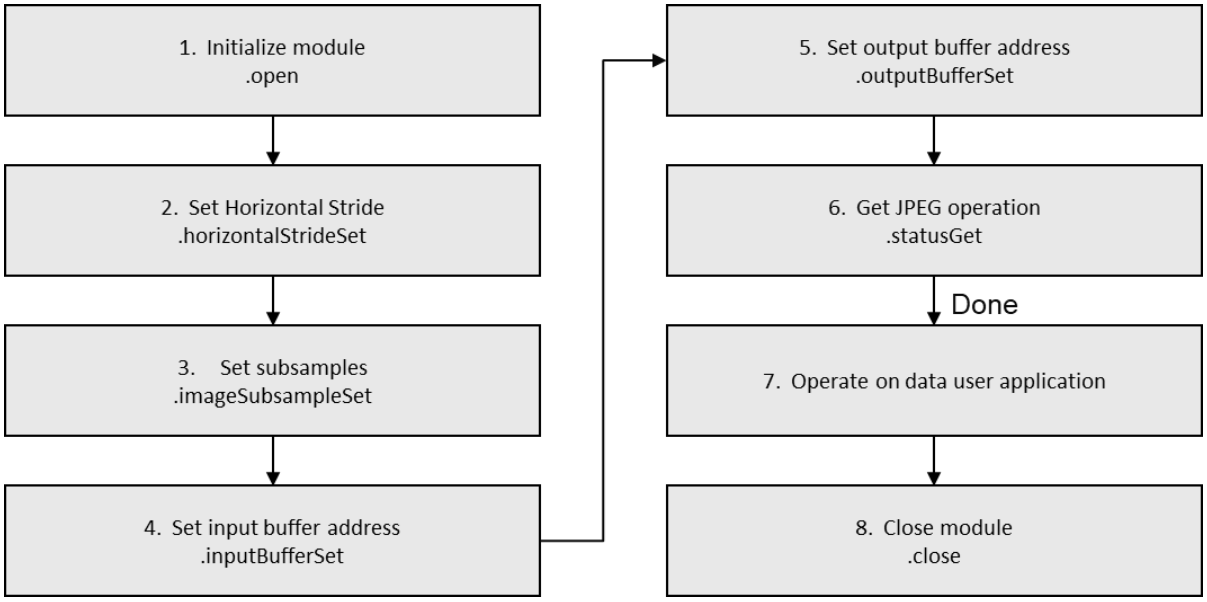

Figure 365: Flow Diagram of a Typical JPEG Decode HAL Module Application

4.2.30 JPEG Encode Driver

The JPEG Encode HAL module provides high-level APIs for JPEG Encode image. The JPEG Encode HAL module uses the Synergy MCU JPEG Codec peripheral. A user callback function is available to inform the application program of key processing events.

4.2.30.1 JPEG Encode HAL Module Features

- Supports JPEG Compression.
- Supports polling mode that allows an application to wait for JPEG Encoder to complete.
- Supports interrupt mode with user-supplied callback functions.
- Configures parameters such as horizontal and vertical resolution, horizontal stride, and Quality factor.

- Supports putting raw image data in an input buffer and an output buffer to store the encoded/compressed jpeg image.
- Supports streaming raw image data into JPEG Encoder module. This feature allows an application to read coded raw image from a capture device or camera or from network without buffering the entire image.
- Only supports the YCbCr422 color space to input.
- Support DRI Maker for RTP streaming application.
- Support quality factor configuration: The quality factor value determines the quality of output image.

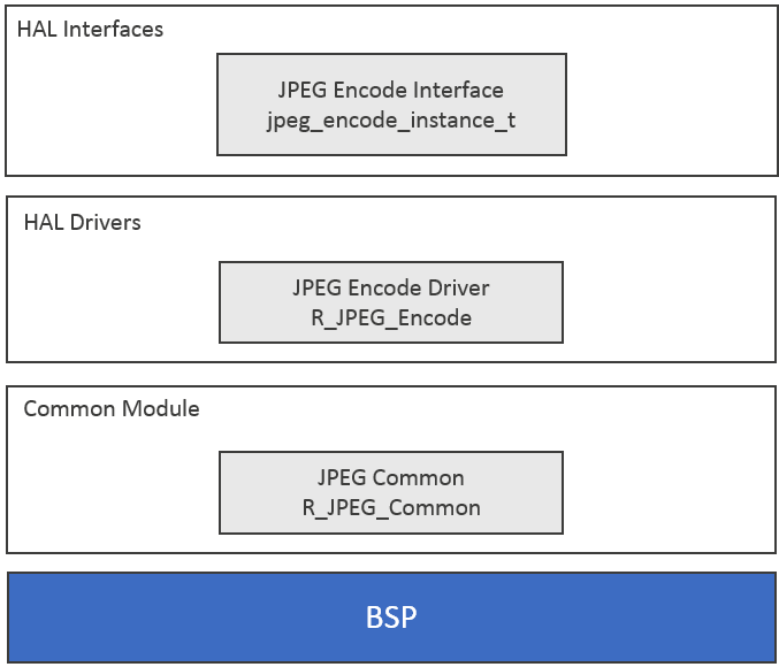

Figure 366: JPEG Encode HAL Module Block Diagram

4.2.30.2 JPEG Encode HAL Module APIs Overview

The JPEG Encode HAL Module defines APIs to open, set up processing parameters, process, get statusand close the module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

JPEG Encode HAL Module API Summary

Function Name	Example API Call and Description
.open	g_jpeg_encode0.p_api->open(g_jpeg_encode0.p_ctrl, g_jpeg_encode0.p_cfg); Initial configuration.

Function Name	Example API Call and Description
.imageParameterSet	g_jpeg_encode0.p_api->imageParameterSet(g_jpeg_encode0.p_ctrl, p_image_parameters); Set image parameters to JPEG Codec.
.outputBufferSet	g_jpeg_encode0.p_api->outputBufferSet(g_jpeg_encode0.p_ctrl, p_buffer); Assign output buffer to JPEG Codec for storing output data..
.inputBufferSet	g_jpeg_encode0.p_api->statusGet(g_jpeg_encode0.p_ctrl, p_buffer, buffer_size); Assign input data buffer to JPEG Codec.
.statusGet	g_jpeg_encode0.p_api->close(g_jpeg_encode0.p_ctrl); Retrieve current status of the JPEG Codec module.
.close	g_jpeg_encode0.p_api->read(&version); Cancel an outstanding operation.
.versionGet	g_jpeg_encode0.p_api->outputEnable(&version); Get version and store it in provided pointer p_version.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_INVALID_ALIGNMENT	Horizantal stride is not 8-byte aligned.

Name	Description
SSP_ERR_NOT_OPEN	Unit is not open
SSP_ERR_ASSERTION	An input pointer is NULL.
SSP_ERR_IN_USE	Peripheral is in use or hardware lock is taken.
SSP_ERR_HW_LOCKED	JPEG Codec resource is locked.
SSP_ERR_INVALID_CALL	An invalid call has been made, Codec output buffer address is attempted to change during codec operation. Or set output buffer first.
SSP_ERR_JPEG_IMAGE_SIZE_ERROR	Image size is not supported by JPEG codec.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.2.30.3 JPEG Encode HAL Module Operational Overview

The JPEG Encoder HAL module can be used in the Input Buffer Streaming mode or normal mode.

Input Buffer Streaming Mode Operational Description

In this scenario the raw image data coming from network, file or capturing device in chunks. The HAL-layer driver is able to handle this scenario without requiring the input data to be stored in memory first.

Normal Operational Description

In this scenario raw image coming from network, file or capturing device is a complete frame. The HAL-layer driver is able to handle this scenario and can compressed entire raw image frame.

MJPEG Encoding Operational Description

The JPEG Encoder can be used for Motion JPEG (MJPEG) format by configuring and using the driver in the following fashion:

1) Open the JPEG Encoder driver with the desired quality factor value (default = 50)
2) Set up the image resolution (optional if already configured in Thread stack window)
3) Initialize the Capturing device for capturing YCbCr422 image (like PDC camera Ov7670)
4) Set the output buffer to hold the jpeg image using the outputBufferSet API.
5) Capture the image.
6) Set the input buffer which holds the RAW YCbCr 422 image captured from the capturing device using the input-BufferSet API.
7) Check the status of the encode operation. If DONE send the image to rendering device
8) Continue the process from step 5.

JPEG Encode HAL Module Important Operational Notes and Limitations

JPEG Encode Callbacks

A user callback function can be registered in the open API. If a user callback function is provided, the callback function will be called from the interrupt service routine (ISR) each time an interrupt happens. The argument of the callback function status can take the enumerated values listed below so that user can identify which event occurred in the encoding procedure.

Event Name	Event Condition	
JPEG_ENCODE_STATUS_INPUT_PAUSE	JPEG Encode paused waiting for more input data.	
JPEG_ENCODE_STATUS_DONE		JPEG Encode operation has successfully completed.

NOTE: Since a user callback function is called from an ISR, be careful not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.

- The JPEG Encode HAL module only support JPEG Encode processing. For decoding please use the JPEG Decode HAL module.
- In an Application where both the encode and decode modules are used, JPEG Decode module needs to be closed for the application to use JPEG Encode driver (or vice versa) as both modules share the same MCU peripheral.
- The JPEG Encode HAL module only supports the "Normal byte order" for output data format in the thread stack window. Other option may result in an invalid image.

4.2.30.4 Including the JPEG Encode HAL Module in an Application

This section describes how to include the JPEG Encode HAL Module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the JPEG Encode HAL Module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the JPEG Encode HAL Module is g_jpeg_encode0. This name can be changed in the associated Properties window.)

JPEG Encode HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_jpeg_encode0 JPEG Encode Driver on r_jpeg_encode	Threads	New Stack> Driver> Graphics> JPEG Encode Driver

When the JPEG Encode HAL Module on r_jpeg_encode is added to the thread stack as shown in the following figure, the configurator automatically adds any lower-level drivers that are required. Any drivers that need additional configuration information will be box-text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

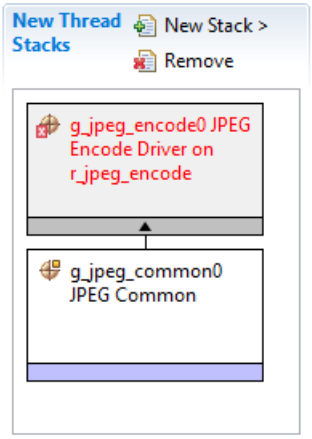

Figure 367: JPEG Encode HAL Module Stack

4.2.30.5 Configuring the JPEG Encode HAL Module

The JPEG Encode HAL Module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the JPEG Encode HAL Module on r_jpeg_encode

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_jpeg_encode0	Module name.
RAW Image Vertical Resolution	800	RAW image vertical resolution selection
RAW Image Horizontal Resolution	480	RAW image horizontal resolution selection
Byte Order for Input Data Format	Normal byte order (1)(2)(3)(4)(5)(6)(7)(8), Byte Swap (2)(1)(4)(3)(6)(5)(8)(7), Word Swap (3)(4)(1)(2)(7)(8)(5)(6), Word-Byte Swap (4)(3)(2)(1)(8)(7)(6)(5), Longword Swap (5)(6)(7)(8)(1)(2)(3)(4), Longword-Byte Swap (6)(5)(8)(7)(2)(1)(4)(3), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2) Default: Normal Byte order	Byte order for input data format selection

ISDE Property	Value	Description
Byte Order for Output Data Format	Normal byte order (1)(2)(3)(4)(5)(6)(7)(8), Byte Swap (2)(1)(4)(3)(6)(5)(8)(7), Word Swap (3)(4)(1)(2)(7)(8)(5)(6), Word-Byte Swap (4)(3)(2)(1)(8)(7)(6)(5), Longword Swap (5)(6)(7)(8)(1)(2)(3)(4), Longword-Byte Swap (6)(5)(8)(7)(2)(1)(4)(3), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2) Default: Normal Byte order	Byte order for output data format selection
Define Restart Marker	512	Define restart marker selection
Quality Factor	50	Quality factor selection
Name of user callback function	NULL	Name of user callback function selection
Decompression Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Decompression interrupt priority selection.

ISDE Property	Value	Description
Data Transfer Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Data transfer interrupt priority selection.

NOTE: The example values and defaults are for a project using the Synergy S1JA. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the JPEG Common Module

ISDE Property	Value	Description
Name	g_jpeg_common0	Module name.

NOTE: The example values and defaults are for a project using the Synergy S1JA. Other MCUs may have different default values and available configuration settings.

JPEG Encode HAL Module Clock Configuration

The JPEG Encode HAL Module uses the PCLKA as its clock source.

To change the clock frequency at run-time, use the CGC Interface.

JPEG Encode HAL Module Pin Configuration

The JPEG Encode HAL module has no configurable input or output pins on the device.

4.2.30.6 Using the JPEG Encode HAL Module in an Application

Once the module has been configured and the files generated, the JPEG Encode is ready to be used in an application. The typical steps in using the JPEG Encode HAL module in an application are to initialize the JPEG Encode module using the open API, and configure the output buffer and the input buffer. Once the input and output buffers are set, the JPEG codec triggers the compression operation and stores the encoded image to the output buffer. The statusGet API can be used to poll the status of JPEG operation.

The typical steps in using the JPEG Encode module in an application are:

1) Initialize the JPEG Encode using open API.
   a) Configures the quality factor, horizontal stride, horizontal and vertical resolution.
2) Set the output buffer address (should be large enough to hold compressed jpeg image) using the outputBufferSet API.

3) Set the input buffer to start the encoding operation (address of raw image data and size) using the inputBufferSet API.
4) The statusGet API can be used to get the JPEG operation, the statusGet API return an enumerated value (described above) to notify user.
   a) Status JPEG_ENCODE_STATUS_DONE from the statusGet API shows that the encode operation is complete.
   b) Status JPEG_ENCODE_STATUS_INPUT_PAUSE from the statusGet API shows that driver is waiting for more input – Go to step 3 and set the input buffer with remaining data.
5) Operate on the received JPEG image data as needed by the application.
6) Close the module using the close API.

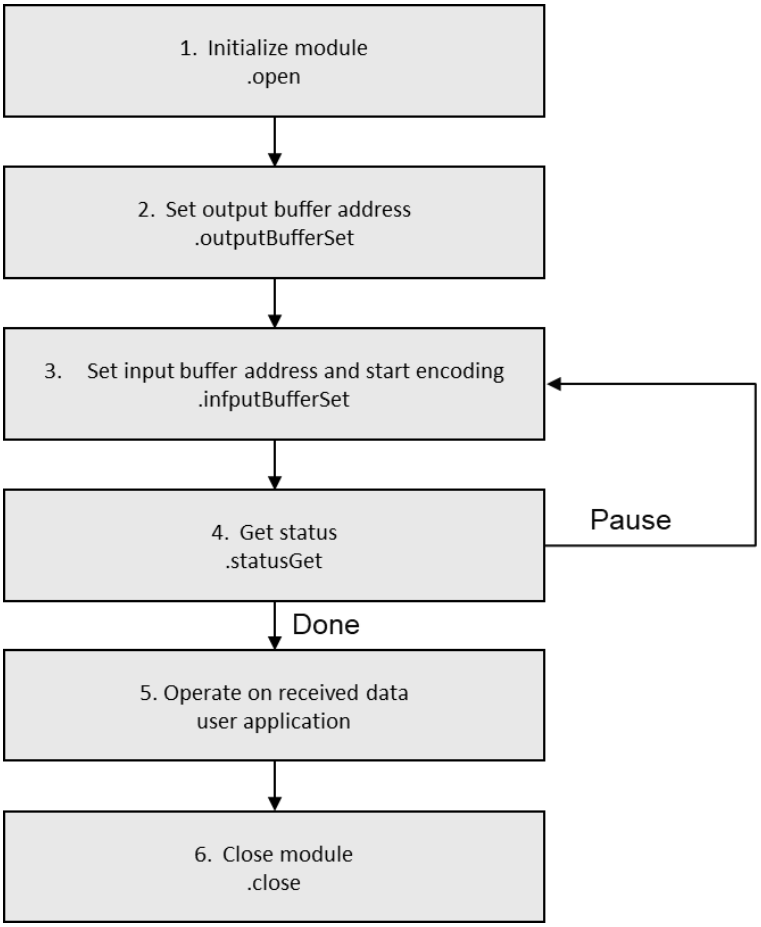

Figure 368: Flow Diagram of a Typical JPEG Encode HAL Module Application

4.2.31 Key Matrix Driver

The Key Matrix HAL module provides high-level APIs for Key Matrix HAL applications and is implemented on r_kint. The Key Matrix HAL module uses the key-interrupt function peripheral on the Synergy MCU. A user-defined callback can be created to inform the CPU of a key press event.

4.2.31.1 Key Matrix HAL Module Features

This Key Matrix HAL module configures and controls the Key Interrupt (KINT) peripheral. It implements the following key functions:

- Supports both rising and falling edges on KINT channels
- Supports interrupt-based event notification
- Supports a bit-masking function to capture multiple events efficiently
- Supports a matrix keypad with edges on any two channels

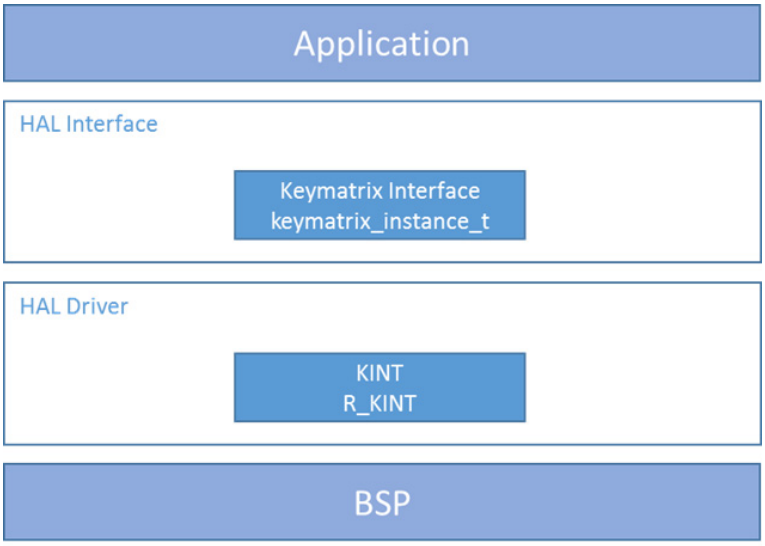

Figure 369: Key Matrix HAL Module Block Diagram

4.2.31.2 Key Matrix HAL Module APIs Overview

The Key Matrix HAL module defines APIs for opening, closing, enabling, and disabling key-interrupt functions. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Key Matrix HAL Module API Summary

Function Name	Example API Call and Description
.open	g_keymatrix_on_kint.p_api->open(&g_kint.p_ctrl, g_kint.p_cfg_cfg) Initial configuration.
.enable	g_keymatrix_on_kint.p_api->enable(&g_kint.p_ctrl) Enable Key interrupt.
.disable	g_keymatrix_on_kint.p_api->disable(g_kint.p_ctrl) Disable Key interrupt.
.triggerSet	g_keymatrix_on_kint.p_api->triggerSet() Set trigger for Key interrupt.
.close	g_keymatrix_on_kint.p_api->close(&g_ keymatrix) Allow driver to be reconfigured. May reduce power consumption.
.versionGet	g_keymatrix_on_kint.p_api->versionGet(&version) Get version and store it in provided pointer version.

NOTE: For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the *SSP User's Manual* API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successfully completed.
SSP_ERR_ASSERTION	Parameter has invalid value.
SSP_ERR_INVALID_ARGUMENT	Argument is invalid.

Name	Description
SSP_ERR_HW_LOCKED	The API has already been opened. It must be closed before it can be opened again.
SSP_ERR_NOT_OPEN	The peripheral is not opened.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual* API References for the associated module for a definition of all relevant status return values.

4.2.31.3 HAL Module Operational Overview

The Key Matrix HAL module configures the Key Interrupt (KINT) peripheral to detect rising or falling edges on any of the KINT channels. When such an event is detected on any of the configured pins, the module generates an interrupt; the interrupt then calls the user callback (p_callback) with the callback argument keymatrix_callback_args_t that specifies the channel(s) on which the edge was detected using a bitmask.

Even though detection of an edge on any one channel generates the interrupt, the callback returns a bitmask keymatrix_channels_t of all the pins that were triggered at that time if any other pins also detected an edge. Thus, an interrupt is not necessarily generated for edge detection on each pin if an edge was also detected on another pin before the callback was called. If a new edge is detected after the callback was called, then the interrupt is triggered again, resulting in a new callback. The bit mask in the user callback should be checked to identify the interrupt source channels.

This module can be used to implement a matrix keypad with edges on any two channels indicating the actual key that was pressed; alternatively, the module can be used as a single input to detect an edge on an input pin.

Key Matrix HAL Module Important Operational Notes and Limitations

- To trigger a transfer of data using the DMAC or DTC peripheral when a trigger edge is detected, configure the DMAC/DTC transfer with activation_source set to ELC_EVENT_KEY_INT.
- The KINT module can trigger the start of other peripherals available to the ELC. For details, see the ELC User's Guide in the *SSP User's Manual*.
- You must enable the KINT (INTKR) interrupt in the BSP for this module to operate, regardless of whether a callback is used in the open call.
- This module does not support polling-mode operation.
- Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.31.4 Including the Key Matrix HAL Module in an Application

This section describes how to include the Key Matrix HAL module in an application using the SSP configurator.

NOTE: It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the *SSP User's Manual* to learn how to manage each of these important steps in creating SSP-based applications.

To add the Key Matrix Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Key Matrix Driver is g_kint0. This name can be changed in the associated Properties window.)

Key Matrix HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_kint0 Key Matrix Driver on r_kint	Threads	New Stack> Driver> Input> Key Matrix Driver on r_kint

When the Key Matrix Driver on r_kint is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information is box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

Figure 370: Key Matrix HAL Module Stack

4.2.31.5 Configuring the Key Matrix HAL Module

The Key Matrix HAL module on r_kint must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the Integrated Solution Developer Environment (ISDE). This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the Properties window in the ISDE includes an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the following configuration table settings. This helps to orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Key Matrix HAL Module on r_kint

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Enable or disable the parameter error checking.
Name	g_kint0	A user callback function can be registered using the open API. If this callback function is provided, it is called from the interrupt service routine (ISR) each time a configured edge is detected on any of the channels. NOTE: Without callback, the application cannot determine whether an event has occurred. Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Keymatrix Channel Mask	Select Channels Below	This is a bit-mask with each bit specifying if that channel is to be enabled or not. Select the channels to be used.
Channel 0:7	Unused, Used (Default: Unused)	Channel 0:7 selection.
Trigger Type	Rising Edge, Falling Edge (Default: Rising Edge)	Specify if the enabled channels detect a rising edge or a falling edge. NOTE: Either all channels detecting a rising edge or all channels detecting a falling edge.

ISDE Property	Value	Description
Interrupt enabled after initialization	True, False (Default: False)	Specify if the module interrupts must be enabled as part of the open call.
Callback	NULL	Callback selection.
Interrupt Priority	Priority 0 (highest), 1,2,3,4,5,6,7,8,9,10,11,12,13,14,15 (lowest, not valid if using Thread X), Disabled (Default: Disabled)	Interrupt priority selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

Key Matrix HAL Module Clock Configuration

The Key Matrix HAL module does not require a specific clock configuration.

Key Matrix HAL Module Pin Configuration

The KINT peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the KINT pins.

Pin Selection for the Key Matrix HAL Module on r_kint

Resource	ISDE Tab	Pin selection Sequence
KINT	Pins	Select Peripherals > Input:KINT> KINT0

NOTE: The selection sequence assumes KINT0 is the desired hardware target for the driver.

Pin Configuration Settings for the Key Matrix HAL Module on r_kint

Property	Value	Description
Operation Mode	Disabled, Custom (Default: Disabled) Custom	Select Custom as the Operation Mode
KRM0:7	None, Pnn (Default: None)	Key Interrupt Pin selection

NOTE: The example settings are for a project using the Synergy S7G2 MCU Family and the SK-S7G2 Kit. Other Synergy MCUs and Synergy Kits may have different available pin configuration settings.

4.2.31.6 Using the Key Matrix HAL Module in an Application

The typical steps in using the Key Matrix HAL module in an application are:

1) Initialize the Key Matrix HAL module using the open API
2) If the autostart configuration setting is true, the module starts operation immediately
3) If the autostart is not set, use enable API to enable operation
4) Respond to key inputs
5) Disable operation using the disable API
6) To modify trigger edge after initialization, use the triggerSet API
7) Close the module by using the close API

The following figure illustrates these common steps are illustrated in a typical operational flow diagram.

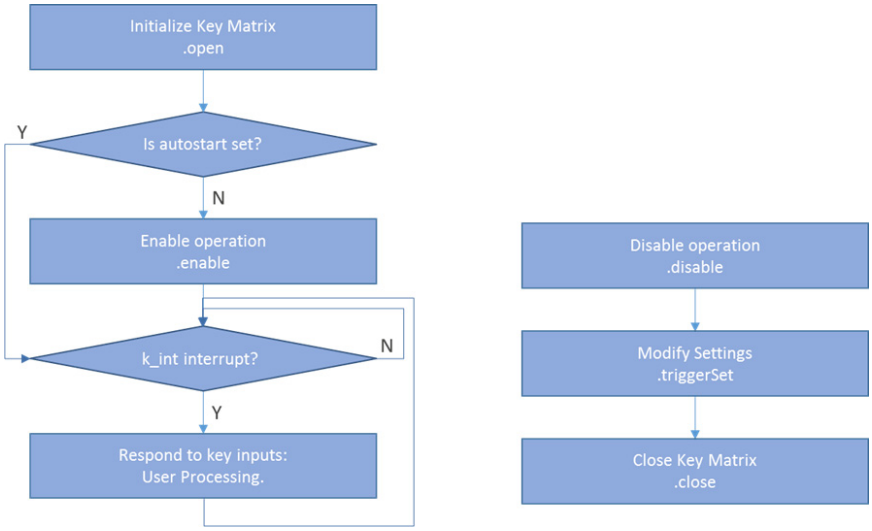

Figure 371: Flow Diagram of a Typical Key Matrix HAL Module Application

4.2.32 Low Power Modes Driver

The Low Power Modes HAL module provides high-level APIs for low-power mode applications and is implemented on r_lpm. The Low Power Modes HAL module uses the low-power mode hardware peripheral on the Synergy MCU.

4.2.32.1 Low Power Modes HAL Module Features

The LPM HAL module supports configuration of MCU operating power control modes and MCU low power modes using the Low Power Mode hardware peripheral.

The LPM driver supports the following operating power control modes:

- Low-voltage mode
- Low-speed mode
- Middle-speed mode
- High-speed mode
- Subosc-speed mode

The LPM driver supports the following low power modes:

- Deep Software Standby mode
- Software Standby mode
- Sleep mode
- Snooze mode

NOTE: Not all operating modes are available on all MCUs.

NOTE: Not all low power modes are available on all MCUs.

NOTE: This is a deprecated module and must not be used for new projects; use the lpm_v2 module instead.

This document is divided into the following sections which can be read independently (by a more experienced Synergy developer) or in series (by developers new to the Synergy Platform).

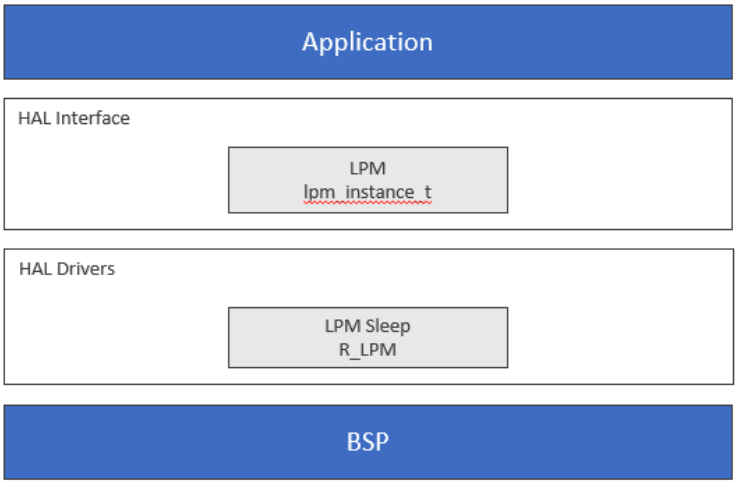

Figure 372: Low Power Modes Driver Organization, Options, and Stack Implementations

4.2.32.2 Low Power Modes HAL Module APIs Overview

The Low Power Modes Driver defines API's for initializing, setting and getting values and stopping modules. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of return status values is also provided.

Low Power Modes HAL Module API Summary

Function Name	Example API Call and Description
init	g_lpm0.p_api->init(g_lpm0.p_cfg); Open the LPM driver module Initialized the LPM block according to the passed in config structure.
mstpcrSet	g_lpm0.p_api->mstpcrSet(value1, value2, value3, value4); Set the value of all the Module Stop Control Registers.

Function Name	Example API Call and Description
mstpcrGet	g_lpm0.p_api->mstpcrSet(&value1, &value2, &value3, &value4); Get the values of all the Module Stop Control Registers.
moduleStop	g_lpm0.p_api->moduleStop(module); Stop a module.
moduleStart	g_lpm0.p_api->moduleStart(module); Run the specified module.
operatingPowerModeSet	g_lpm0.p_api->operatingPowerModeSet(power, osc); Set the operating power mode and oscillator.
snoozeEnable	g_lpm0.p_api->snoozeEnable(rdx0_mode, dtc_mode, requests, triggers); Configure and enable snooze mode.
snoozeDisable	g_lpm0.p_api->snoozeDisable(); Disable snooze mode.
lowPowerCfg	g_lpm0.p_api->lowPowerCfg(power_mode, output_port_enable, power_supply, io_port_state); Configure a low power mode.
wupenSet	g_lpm0.p_api->wupenSet(wupen_value); Set the value of the Wake Up Interrupt Enable Register WUPEN.
wupenGet	g_lpm0.p_api->wupenGet(&wupen_value); Get the value of the Wake Up Interrupt Enable Register WUPEN.

Function Name	Example API Call and Description
deepStandbyCancelRequestEnable	g_lpm0.p_api-> deepStandbyCancelRequestEnable (pin_signal, rising_falling); Enable a Deep Standby Cancel Request.
deepStandbyCancelRequestDisable	g_lpm0.p_api-> deepStandbyCancelRequestDisable (pin_signal); Disable a Deep Standby Cancel Request.
lowPowerModeEnter	g_lpm0.p_api-> lowPowerModeEnter (); Enter low power mode (sleep/standby/deep standby) using WFI macro. Function will return after waking from low power mode.
versionGet	g_lpm0.p_api->versionGet(&version); Retrieve the API version using the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables review the SSP Reference Manuals found as described in the Reference Section at the end of this document.

Error Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_ASSERTION	Parameter has invalid value.
SSP_ERR_INVALID_PTR	p_version is NULL.

NOTE: Lower level drivers may return Common Error Codes. Refer to the SSP Reference Manual available as described in the Reference Section at the end of this document for a definition of all relevant Error codes.

4.2.32.3 Low Power Modes HAL Module Operational Overview

The LPM HAL module APIs supports the configuration of MCU operating power control modes and MCU low power modes using the Low Power Mode hardware peripheral.

LPM Initialization

The LPM API function init should be called before calling any other LPM function. The init function handles initialization of internal variables and locks.

Sleep low-power mode

By default, at power on, sleep mode is enabled as the low-power mode. Sleep mode is the most convenient low-power mode available, as it does not require any special configuration (other than configuring and enabling a suitable interrupt or event to wake the MCU from sleep) to return to normal program-execution mode. The states of the SRAM, the processor registers, and the hardware peripherals are all maintained in sleep mode, and the time needed to enter and wake from sleep is minimal. Any interrupt causes the MCU device to wake from sleep mode, including the Systick interrupt used by the ThreadX® thread scheduler. The LPM API function init should be called before any other function. The LPM API function, lowPowerCfg, can be used to configure the MCU to use sleep as its low-power mode. The LPM API function lowPowerModeEnter should be used to directly enter sleep mode.

```
/* HAL-only entry function */

#include "hal_data.h"

void hal_entry(void)

{

/* Not shown: Enable any interrupt to wake from sleep mode */

/* Configure LPM peripheral for sleep mode */

g_lpm_on_hal.p_api->lowPowerCfg(LPM_LOW_POWER_MODE_SLEEP,

LPM_OUTPUT_PORT_ENABLE_RETAIN,

LPM_POWER_SUPPLY_DEEPCUT0,

LPM_IO_PORT_NO_CHANGE);

/* Enter sleep mode */

g_lpm_on_hal.p_api->lowPowerModeEnter();

}
```

Software Standby Mode

In software standby mode, the CPU, most of the on-chip peripheral functions, and all of the internal oscillators are stopped. However, the contents of the CPU internal registers and SRAM data, the states of on-chip peripheral functions and the I/O Ports are retained. Software Standby Mode allows significant reduction in power consumption because most of the oscillators are stopped in this mode. Like sleep mode, standby mode also requires that an interrupt or event be configured and enabled in order to wake from standby mode. See the table Interrupt Sources To Transition To Normal Mode from Snooze and Software Standby Mode in the MCU Synergy Hardware User's Manual for the complete list of events and

interrupts that can wake the MCU from sleep mode. The Wake Up Interrupt Enable Register (WUPEN) must be modified before entering software standby mode. See Wake Up Interrupt Enable Register (WUPEN) and section Software Standby Mode of MCU Synergy User's Manual: Microcontrollers for more information.

NOTE: The ThreadX idle thread and the ThreadX function tx_thread_sleep() expect the MCU to be configured for sleep as the low power mode. See the following usage notes for more information.

```
/* HAL-only entry function */

#include "hal_data.h"

#define WUPEN_AGT1_UNDERFLOW_MASK (1 << 28)

void hal_entry(void)

{

uint32_t wupen_value = 0;

/* Not shown: Configuration of the interrupt or event to wake from standby */

/* Set bit in WUPEN register to allow mcu to wake from standby through a specifi
c interrupt or event. AGT1 underflow is used in this example. */

/* Get current value of WUPEN register */

g_lpm.p_api->wupenGet(&wupen_value);

/* Set wake by AGT1 underflow bit in WUPEN register */

g_lpm.p_api->wupenSet(wupen_value | WUPEN_AGT1_UNDERFLOW_MASK);

/* Configure LPM peripheral for standby mode */

g_lpm.p_api->lowPowerCfg(LPM_LOW_POWER_MODE_STANDBY,

LPM_OUTPUT_PORT_ENABLE_RETAIN,

LPM_POWER_SUPPLY_DEEPCUT0,

LPM_IO_PORT_NO_CHANGE);

/* Enter standby mode */

g_lpm.p_api->lowPowerModeEnter();

}
```

Snooze Mode with Software Standby Mode

Snooze mode can be used with some MCU peripherals to execute basic tasks while keeping the MCU in a low power state. ADC, DTC, and other peripherals can be enabled in Snooze mode. The following code shows the process of enabling Snooze mode and running DTC while in Snooze. The process of setting up the timer AGT1 is not shown. Once the MCU is in Software Standby mode, Snooze is entered when the Compare Match A of AGT1 is detected. The MCU will leave Snooze mode when the DTC transfer is complete. For more details about the DTC, please refer to the DTC usage notes. The ISDE configures this instance structure when you include the g_transfer_on_dtc driver and generate the project in the ISDE generated source file.

NOTE: The ThreadX idle thread and the ThreadX function tx_thread_sleep() expect the MCU to be configured for sleep as the low power mode. See the following usage notes for more information.

```
#define WUPEN_AGT1_UNDERFLOW_MASK (1 << 28)

/* DTC settings */

g_transfer.p_cfg->p_info->p_src = &my_tx_data[0];

g_transfer.p_cfg->p_info->p_dest = &my_rx_data[0];

g_transfer.p_cfg->p_info->length = TRANSFER_SIZE;

g_transfer.p_api->open(g_transfer.p_ctrl, g_transfer.p_cfg);

/* snooze settings */

lpm_snooze_rxd0_t rdx0_mode = LPM_SNOOZE_RXD0_FALLING_EDGE_IGNORE;

lpm_snooze_dtc_t dtc_mode = LPM_SNOOZE_DTC_ENABLE;

lpm_snooze_request_t requests = LPM_SNOOZE_REQUEST_AGT1_COMPARE_A;

lpm_snooze_end_t triggers = LPM_SNOOZE_END_DTC_TRANS_COMPLETE;

g_lpm.p_api->snoozeEnable(rdx0_mode, dtc_mode, requests, triggers);

/* standby settings */

lpm_low_power_mode_t power_mode = LPM_LOW_POWER_MODE_STANDBY;

lpm_output_port_enable_t output_port_enable = LPM_OUTPUT_PORT_ENABLE_RETAIN;

lpm_power_supply_t power_supply = LPM_POWER_SUPPLY_DEEPCUT0;

lpm_io_port_t io_port_state = LPM_IO_PORT_RESET;

g_lpm.p_api->lowPowerCfg(power_mode, output_port_enable, power_supply, io_port_s
tate);
```

```
/* Clear WUPEN */

g_lpm.p_api->wupenSet(0);

/* Wake from AGT1 interrupt underflow */

g_lpm.p_api->wupenSet(WUPEN_AGT1_UNDERFLOW_MASK);
```

Deep Software Standby Mode

Deep Software Standby Mode is only available on the S7G2 MCU, and is a low power mode than Software Standby. The MCU always wakes from Deep Software Standby Mode by going through reset, either by the negation of the reset pin or by one of a set of wake up events as described by the API typedef lpm_deep_standby_t. The following code demonstrate how to enable and enter Deep Software Standby Mode using AGT1 underflow to wake the MCU from Deep Standby Mode. The MCU will reset once AGT1 expires and cause the MCU to reset.

NOTE: The ThreadX idle thread and the ThreadX function tx_thread_sleep() expect the MCU to be configured for sleep as the low power mode. See the following usage notes for more information.

```
#define WUPEN_AGT1_UNDERFLOW_MASK (1 << 28)

/* Deep standby wake signal (wake will cause reset) */

g_lpm.p_api->deepStandbyCancelRequestEnable(LPM_DEEP_STANDBY_AGT1,

LPM_CANCEL_REQUEST_EDGE_RISING);

/* Deep standby settings */

lpm_low_power_mode_t power_mode = LPM_LOW_POWER_MODE_DEEP;

lpm_output_port_enable_t output_port_enable = LPM_OUTPUT_PORT_ENABLE_RETAIN;

lpm_power_supply_t power_supply = LPM_POWER_SUPPLY_DEEPCUT0;

lpm_io_port_t io_port_state = LPM_IO_PORT_RESET;

g_lpm.p_api->lowPowerCfg(power_mode, output_port_enable, power_supply, io_port_s
tate);

/* Clear WUPEN */

g_lpm.p_api->wupenSet(0);

/* Wake from AGT1 interrupt underflow */

g_lpm.p_api->wupenSet(WUPEN_AGT1_UNDERFLOW_MASK);
```

```
g_lpm.p_api->lowPowerModeEnter();
```

Operational Notes Low Power Modes HAL Module

Using this module to change operating modes requires use of the CGC module. Please review the usage notes for the CGC driver as well. Please review the section "Function for Lower Operating Power Consumption" of the MCU Synergy Hardware User's Manual for detailed information about the sequence of events required to properly change the MCU's operating mode.

Using this driver to configure the LPM peripheral based on an interrupt requires the use of the BSP to configure and enable the interrupt.

Calling the LPM API function init only sets the operating mode of the MCU. The init function does not configure the low power modes.

Use the LPM API function lowPowerCfg to configure the low power mode. Once configured, the LPM API function lowPowerModeEnter can be used at any time to enter the low power mode.

Using deep standby or snooze requires additional configuration of the LPM peripheral via the LPM API functions deepStandbyCancelRequestEnable and snoozeEnable.

You must modify the Wake Up Interrupt Enable Register (WUPEN) before entering Software Standby mode. See Wake Up Interrupt Enable Register (WUPEN) and section "Software Standby Mode of the MCU Synergy User's Manual: Microcontrollers" for more information.

To enter the sub-oscillator Power control mode, you must stop the MOCO and HOCO clocks using the CGC module prior to calling the API function operatingPowerModeSet.

If the main oscillator or PLL with main oscillator source is used for the system clock, the wake time from standby mode can be affected by the Main Oscillator Wait Time Setting in the MOSCWTCR register. This register setting is available to be changed through the Main Oscillator Wait Time setting in the CGC driver properties. See the "Wakeup Timing and Duration" table in Electrical Characteristics for more information.

Important: When a project uses ThreadX, the application should only switch to LPM_LOW_POWER_MODE_STANDBY or LPM_LOW_POWER_MODE_DEEP immediately before calling the API function lowPowerModeEnter. If LPM_LOW_POWER_MODE_STANDBY or LPM_LOW_POWER_MODE_DEEP are used with ThreadX then the user must make sure to revert the low power mode to LPM_LOW_POWER_MODE_SLEEP immediately after the MCU wakes from LPM_LOW_POWER_MODE_STANDBY.

Limitations Low Power Modes HAL Module

- Flash stop (code flash disable) is not supported. See the section, "Flash Operation Control Register (FLSTOP)" in the S124, S128, S3A3, or S3A7 Synergy Hardware User's Manual.
- Reduced SRAM retention area in software standby mode is not supported. See the section, "Power Save Memory Control Register (PSMCR)" of the S3A7 or S3A3 Synergy Hardware User's Manual.
- The MCU may not enter or stay in Software Standby and Deep Software Standby modes with the debugger attached. Instead, the MCU may be woken from Software Standby and Deep Software Standby modes by the debugger. To properly test and verify Software Standby and Deep Software Standby modes, the debugger must not be attached.
- If the main oscillator or PLL with main oscillator source is used for the system clock, the wake time from standby mode can be affected by the Main Oscillator Wait Time Setting in the MOSCWTCR register. This register setting is available to be changed through the Main Oscillator Wait Time setting in the CGC HAL module properties. See the "Wakeup Timing and Duration" table in Electrical Characteristics for more information.
- Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.32.4 Including the Low Power Modes Driver in an Application

This section describes how to include the Low Power Modes Driver in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual available as described in the Reference Section at the end of this document to learn how to manage each of these important steps in creating SSP based applications.

To add the Low Power Modes Driver to an application, simply add it to a thread using the Stacks Selection Sequence given in the table below. (The default name for the Low Power Modes Driver is <name> and this is shown in the following table. This name can be changed in the associated **Properties** window). When the driver is added it shows up in the thread as illustrated in the following figure.

Low Power Modes HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_lpm0 Low Power Modes Driver on r_lpm	**Threads**	**New Stack> Driver> Power> Low Power Modes on r_lpm**

When the Low Power Modes HAL module on r_lpm is added to the Thread Stack, as shown in the figure below, the configurator automatically adds the needed lower level drivers. Any drivers that need additional configuration information will be box text highlighted in red. Modules with a gray band are individual modules that stand alone. Modules with a blue band are shared or common and need only be added once, since they can be used by multiple stacks.

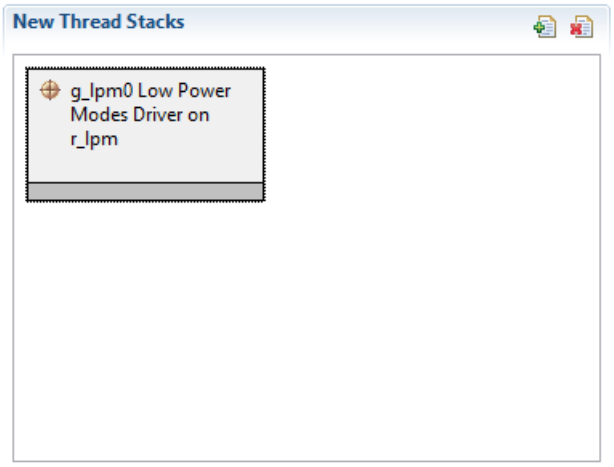

Figure 373: Low Power Modes HAL Module Stack

4.2.32.5 Configuring the Low Power Modes HAL Module

The Low Power Modes HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify, by highlighting the block in red, any required configuration selections, such as Interrupts or operating modes, which must be configured for lower level modules, for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are

'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the **Properties** tab within the SSP Configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the Interrupt Priority. This configuration setting is available with the **Properties** window of the associated module. Simply select the indicated module and then view the **Properties** window. The Interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the Interrupt Priorities listed in the **properties** window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring Interrupt Priority levels.

NOTE: You may want to open your ISDE and create the Low Power Modes Driver and explore the property settings in parallel with looking over the Configuration Table Settings given below. This will help orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for Low Power Mode Deep Standby Driver on r_lpmv2

ISDE Property	Setting	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Enables or disables the parameter checking
Name	g_lpm0	Module name
Operating power mode	High speed operating mode, Middle speed operating mode, Low speed operating mode, Low voltage operating mode (Default: High speed operating mode)	Select operating power mode
Sub oscillator mode	Sub oscillator mode not enabled, Sub oscillator mode enabled (Default: Sub oscillator mode not enabled)	Select sub oscillator mode

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

LPM Clock Configuration

The Low Power Mode module does not have a configurable clock input.

LPM Pin Configuration

The Low Power Mode module does not have specific input and output pins that need configuration.

4.2.32.6 Using the Low Power Modes Driver in an Application

The typical steps in using the Low Power Modes HAL module in an application are:

1) Initialize the Low Power Modes HAL module using the init API.
2) Configure a low-power mode with the lowPowerCfg API.
3) Enter a low-power mode with the lowPowerModeEnter API.

These common steps are illustrated in a typical operational flow diagram in the following figure.

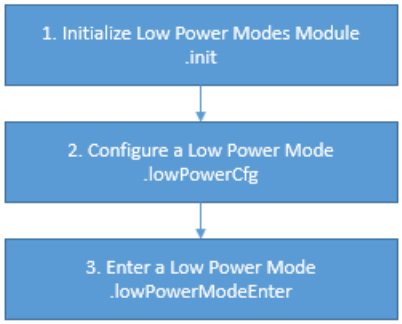

Figure 374: Flow Diagram of a Typical Low Power Modes Driver Application

4.2.33 Low Power Modes V2 Driver

The Low Power Modes V2 HAL module provides high-level APIs for low-power mode applications and is implemented on r_lpm2. The Low Power Modes HAL module uses the low-power mode hardware peripheral on the Synergy MCU.

4.2.33.1 Low Power Modes V2 HAL Module Features

The LPM V2 HAL module supports configuration of MCU operating power-control modes and MCU low-power modes using the low-power mode hardware peripheral.

The LPM V2 HAL module supports the following low power modes:

- Deep Software Standby mode
- Software Standby mode
- Sleep mode
- Snooze mode

The LPM V2 HAL module supports reducing power consumption when in deep stand-by mode through internal power-supply control and by resetting the states of I/O ports. The LPM V2 HAL module supports disabling and enabling of the MCU's other hardware peripherals.

NOTE: Not all low-power V2 modes are available on all MCUs Groups.

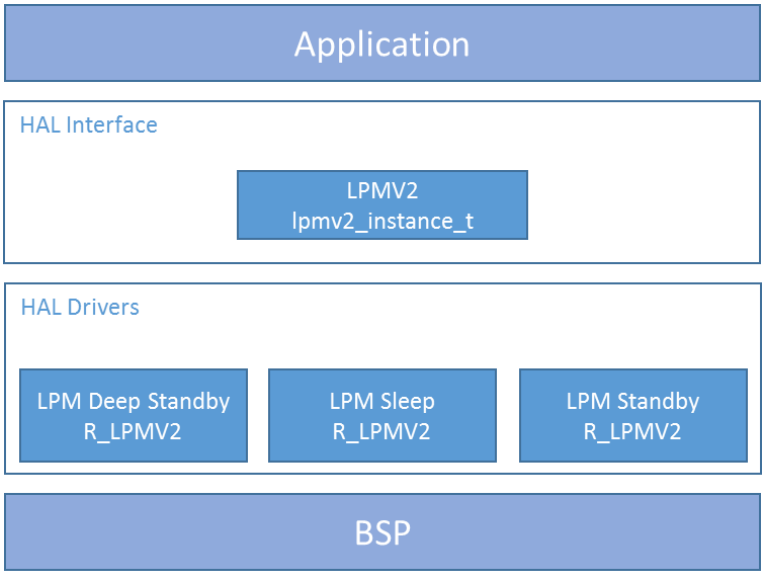

Figure 375: Low Power Modes V2 Module Block Diagram

4.2.33.2 Low Power Modes V2 HAL Module APIs Overview

The Low Power Modes V2 HAL module defines APIs for configuring operations and enabling and disabling low-power operations. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of return status values follows the API summary table.

NOTE: The Low Power Modes V2 HAL module will no longer handle operating power-control modes of the MCU; these are now handled by the CGC HAL module.

The following API examples illustrate sleep-mode use; "deep_standby" and "standby" can be substituted for "sleep" in the API examples to create examples for those modes.

Low Power Modes V2 Module API Summary

Function Name	Example API Call and Description
init	g_lpmv2_sleep0.p_api->init(g_lpmv2_sleep0.p_cfg); Open the LPM driver module Initialized the LPM block according to the passed in config structure.

Function Name	Example API Call and Description
lowPowerCfg	g_lpmv2_sleep0.p_api->lowPowerCfg(g_lpmv2_sleep0.p_cfg); Configure a low power mode.
lowPowerModeEnter	g_lpmv2_sleep0.p_api->lowPowerModeEnter(void); Enter low power mode (sleep/standby/deep standby) using WFI macro. Function will return after waking from low power mode.
versionGet	g_lpmv2_sleep0.p_api->versionGet(&version); Get the driver version and place it at the pointer version.

NOTE: For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_INVALID_POINTER	Pointer is NULL
SSP_ERR_INVALID_MODE	Invalid settings for specified mode
SSP_ERR_INVALID_HW_CONDITION	OPCMTSF and SOPCMTSF flags are not cleared within internally set timeout.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.33.3 Low Power Modes V2 HAL Module Operational Overview

LPM V2 Initialization

The LPM V2 API function lpm_v2_api_t::init should be called before calling any other LPM V2 function. The init function handles initialization of internal variables and locks.

Sleep low-power mode

By default, at power on, sleep mode is enabled as the low-power mode. Sleep mode is the most convenient low-power mode available, as it does not require any special configuration (other than configuring and enabling a suitable interrupt or event to wake the MCU from sleep) to return to normal program-execution mode. Any interrupt wakes the MCU device from sleep low-power mode. The states of the SRAM, the processor registers, and the hardware peripherals are all maintained in sleep mode, and the time needed to enter and wake from sleep is minimal. Any interrupt causes the MCU device to wake from sleep mode, including the Systick interrupt used by the ThreadX® thread scheduler. The LPM API function lpm_v2_api_t::init should be called before any other function. The LPM API function, lpm_v2_api_t::lowPowerCfg, can be used to configure the MCU to use sleep as its low-power mode. The LPM API function lpm_v2_api_t::lowPowerModeEnter should be used to directly enter sleep mode.

The following code example configures sleep as a low-power mode and enters low-power mode sleep. In this example, the LPM V2 sleep module uses the name g_lpmv2_sleep0.

```
/* HAL-only entry function */
#include "hal_data.h"
void hal_entry(void)
{
ssp_err_t error = SSP_SUCCESS;
/* Initialize the LPM V2 Driver */
error = g_lpmv2_sleep0.p_api->init();
/* Handle error if any */
/* Configure LPM peripheral for sleep mode */
error = g_lpmv2_sleep0.p_api->lowPowerCfg(g_lpmv2_sleep0.p_cfg);
/* Handle error if any */
/* Entry sleep mode */
error = g_lpmv2_sleep0.p_api->lowPowerModeEnter();
/* Handle error if any */
}
```

Software Standby Mode for LPM V2

In software-standby mode, the CPU, as well as most of the on-chip peripheral functions and all of the internal oscillators, are stopped. Retained are the contents of the CPU internal registers and SRAM data, the states of on-chip peripheral functions, and I/O Ports. Software-standby mode allows significant reduction in power consumption, because most of the oscillators are stopped in this mode. Like sleep mode, standby mode requires an interrupt or event be configured and enabled to wake from standby mode.

The possible triggers for waking from standby mode are enumerated in the **Properties** window for convenience; multiple triggers can be enabled.

The following code example is for configuring standby as the low-power mode and entering low-power mode standby. In this example, the LPM V2 standby module with name g_lpmv2_standby0 is used. The code for using the standby module with snooze enabled is identical.

```
/* HAL-only entry function */
#include "hal_data.h"
void hal_entry(void)
{
```

```
ssp_err_t error = SSP_SUCCESS;
/* Initialize the LPM V2 Driver */
error = g_lpmv2_standby0.p_api->init();
/* Handle error if any */
/* Configure LPM peripheral for standby mode */
error = g_lpmv2_standby0.p_api->lowPowerCfg(g_lpmv2_standby0.p_cfg);
/* Handle error if any */
/* Entry standby mode */
error = g_lpmv2_standby0.p_api->lowPowerModeEnter();
/* Handle error if any */
}
```

Snooze Mode with Software Standby Mode for LPM V2

Snooze mode is available through the standby mode LPM V2 instance. Choose "Standby with Snooze Enabled" for "Choose the low power mode" in the **Properties** window. Snooze mode can be used with some MCU peripherals to execute basic tasks, while keeping the MCU in a low-power state. The snooze settings are below the standby settings in the **Properties** window. The ADC, DTC, and other peripherals can be enabled in snooze mode. All the settings for snooze are available through configuration properties for the standby instance, with the exception of the Event Link Controller settings for registers SELSR0 and IELSRn. Snooze is considered an advanced feature.

The Snooze Mode Settings are only used if the low-power mode choice is **Standby with Snooze Enabled** as shown in the following screen capture:

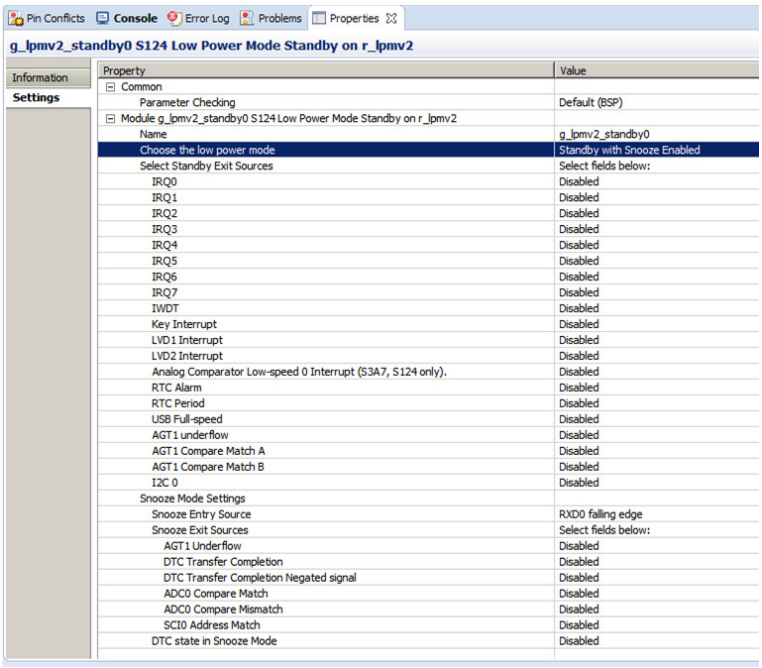

Figure 376: Standby mode with Snooze setting enabled

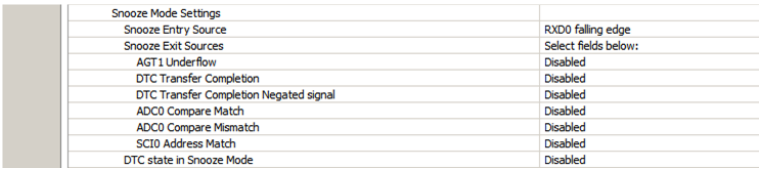
Snooze is a feature of standby mode that allows some peripherals to run even though the MCU core is not executing instructions. The low-power mode peripheral options related to snooze mode are shown in the following image. Only one snooze-entry source can be enabled; multiple snooze-exit sources can be enabled. The DTC peripheral can be enabled in snooze mode as well.



Snooze Mode Settings	
Snooze Entry Source	RXD0 falling edge
Snooze Exit Sources	Select fields below:
AGT1 Underflow	Disabled
DTC Transfer Completion	Disabled
DTC Transfer Completion Negated signal	Disabled
ADC0 Compare Match	Disabled
ADC0 Compare Mismatch	Disabled
SCI0 Address Match	Disabled
DTC state in Snooze Mode	Disabled

Figure 377: Snooze Mode Settings

Deep Software Standby Mode for LPM V2

Deep Software Standby Mode is only available on some MCU devices. The MCU device always wakes from Deep Software Standby Mode by going through reset, either by the negation of the reset pin or by one of a set of wake up events displayed in the configuration **Properties** window for the LPM deep standby instance.

The possible triggers for waking from deep standby mode are enumerated in the **Properties** window for convenience. Multiple triggers can be enabled. Some triggers have an associated edge type, falling or rising. These options are enumerated also as shown above and below.

The following code example is for configuring deep standby as the low power mode and entering low power mode deep standby. In this example, the LPM V2 deep standby module with name g_lpmv2_deep_standby0 is used.

```
/* HAL-only entry function */
#include "hal_data.h"
void hal_entry(void)
{
ssp_err_t error = SSP_SUCCESS;
/* Initialize the LPM V2 Driver */
error = g_lpmv2_deep_standby0.p_api->init();
/* Handle error if any */
/* Configure LPM peripheral for deep sleep mode */
error = g_lpmv2_deep_standby0.p_api->lowPowerCfg(g_lpmv2_deep_standby0.p_cfg);
/* Handle error if any */
/* Entry deep sleep mode */
error = g_lpmv2_deep_standby0.p_api->lowPowerModeEnter();
/* Handle error if any */
```

Low Power Modes V2 HAL Module Important Operational Notes and Limitations

Using this driver to configure the LPM peripheral to wake the MCU from standby mode through interrupts requires the interrupt to be configured and enable by the peripheral driver or framework that uses that interrupt. For example, to wake from standby through AGT1 underflow, that interrupt must be enabled through the configuration of the AGT timer module.

If the main oscillator or PLL with main-oscillator source is used for the system clock, the wake time from standby mode can be affected by the Main Oscillator Wait Time Setting in the MOSCWTCR register. This register setting is available to be changed through the Main Oscillator Wait Time setting in the CGC HAL module properties. See the Wakeup Timing and Duration table in Electrical Characteristics for more information.

NOTE: When a project uses ThreadX and the low-power mode standby, deep standby, or standby with snooze enabled, the call to the lpm_v2_api_t::lowPowerCfg API function should occur immediately before the call to the lpm_v2_api_t::lowPowerModeEnter API function. This is necessary since ThreadX also uses low-power modes in its idle loop and tx_thread_sleep function; ThreadX expects the MCU device to be configured for the low-power mode sleep. When a project uses ThreadX and the low-power mode standby or standby with snooze enabled, the low-power mode should be reverted to sleep after the MCU device wakes from standby after returning from the

lpm_v2_api_t::lowPowerModeEnter function. This is necessary since ThreadX also uses low-power modes in its idle loop and tx_thread_sleep function; ThreadX expects the MCU device to be configured for the low-power mode sleep. The API function lpm_v2_api_t::lowPowerCfg needs to be called again before lpm_v2_api_t::lowPowerModeEnter to re-configure the low-power mode to sleep, if the tx_thread_sleep function is used in the project, or if there may not always be a thread ready to run.

Detailed information about the expected power consumption of the MCU device in operating states and in Low Power Modes V2 can be found in the Operating and Standby Current section within the Electrical Characteristics section of the MCU Synergy Hardware User's Manual.

- Flash stop (code flash disable) is not supported. See the section *Flash Operation Control Register (FLSTOP)* of the S1/S3 Synergy Hardware User's Manual.
- Reduced SRAM retention area in software standby mode is not supported. See the section *Power Save Memory Control Register (PSMCR)* of the S3 Synergy Hardware User's Manual.
- The MCU may not enter or stay in Software Standby and Deep Software Standby modes with the debugger attached. Instead, the MCU may be woken from Software Standby and Deep Software Standby modes by the debugger. To properly test and verify Software Standby and Deep Software Standby modes, the debugger must not be attached.
- If the main oscillator or PLL with main oscillator source is used for the system clock, the wake time from standby mode can be affected by the Main Oscillator Wait Time Setting in the MOSCWTCR register. This register setting is available to be changed through the Main Oscillator Wait Time setting in the CGC HAL module properties. See the Wakeup Timing and Duration table in Electrical Characteristics for more information.

Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.33.4 Including the Low Power Modes V2 HAL Module in an Application

This section describes how to include the Low Power Modes V2 HAL module in an application using the SSP configurator.

NOTE: It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few sections of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add a Low Power Modes V2 Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Low Power Modes Driver is g_lpmv2_<mode>0. This name can be changed in the associated **Properties** window.)

Low Power Modes V2 Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_lpmv2_deep_standby0 S7G2 Low Power Mode Sleep on r_lpmv2	Threads	**New Stack> Driver> Power> Low Power Mode Deep Standby on r_lpmv2**
g_lpmv2_sleep0 S7G2 Low Power Mode Sleep on r_lpmv2	Threads	**New Stack> Driver> Power> Low Power Mode Sleep on r_lpmv2**

Resource	ISDE Tab	Stacks Selection Sequence
g_lpmv2_standby0 S7G2 Low Power Mode Sleep on r_lpmv2	Threads	**New Stack> Driver> Power> Low Power Mode Standby on r_lpmv2**

NOTE: The selection sequences lists modes available for the S7G2 Group. Other MCUs will have a different selection sequence available in the ISDE. If you add the LPM V2 HAL module to more than one thread, or to a thread and to HAL/Common, give each instance of the LPM V2 Driver a unique name by highlighting the instance of the driver in the Modules window and changing the entry for name in the **Properties** view. The default settings for the LPM V2 HAL module configuration structure can also be changed using this view.

When the Low Power Modes V2 HAL module on r_lpmv2 is added to the thread stack as shown in the following figure. (The figure shows the three available low power modes for the S7G2 MCU. These modules can be added individually or in groups. This figure shows all three for completeness; the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information will be box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks.

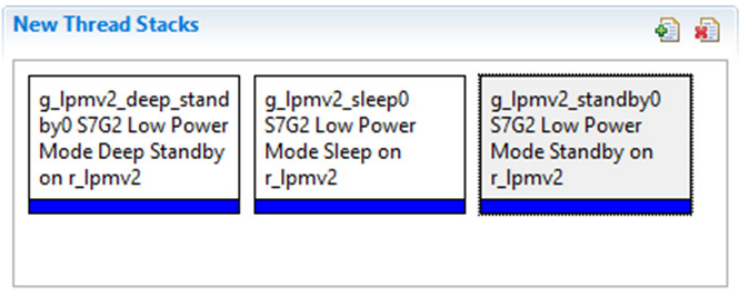


Figure 378: Low Power Modes V2 Module Stack

4.2.33.5 Configuring the Low Power Modes V2 HAL Module

The Low Power Modes V2 Driver module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the **Properties** window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the **Properties** window of the associated module. Simply select the indicated module and then view the **Properties** window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the **Properties** window in the ISDE includes an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the following configuration table settings. This helps orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Low Power Mode Deep Standby Module on r_lpmv2

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Enables or disables the parameter checking
Name	g_lpmv2_deep_standby0	Module name
Output port state in standby and deep standby, applies to address output, data output, and other bus control output pins	High impedance state, No change (Default: No change)	Output port state setting in Standby and Deep Standby
Maintain or reset the IO port states on exit from deep standby mode	Maintain the IO port states, Reset the IO port states (Default: Maintain the IO port states)	Output port state setting exit
Internal power supply control in deep standby mode	Maintain the internal power supply, Cut the power supply to standby RAM, low-speed on-chip oscillator, AGTn, and USBFS/HS resume detecting unit, Cut the power supply to LVDn, standby RAM, low-speed on-chip oscillator, AGTn, and USBFS/HS resume detecting unit (Default: Maintain the internal power supply)	Internal power supply control in deep standby mode setting
Deep Standby Cancel Sources/Edges: Select Fields Below		
IRQ0	Enabled, Disabled (Default: Disabled)	IRQ0 selection
IRQ0 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	IRQ0 Edge selection

ISDE Property	Value	Description
IRQ1	Enabled, Disabled (Default: Disabled)	IRQ1 selection
IRQ1 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	IRQ1 Edge selection
IRQ2	Enabled, Disabled (Default: Disabled)	IRQ2 selection
IRQ2 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	IRQ2 Edge selection
IRQ3	Enabled, Disabled (Default: Disabled)	IRQ3 selection
IRQ3 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	IRQ3 Edge selection
IRQ4	Enabled, Disabled (Default: Disabled)	IRQ4 selection
IRQ4 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	IRQ4 Edge selection
IRQ5	Enabled, Disabled (Default: Disabled)	IRQ5 selection
IRQ5 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	IRQ5 Edge selection

ISDE Property	Value	Description
IRQ6	Enabled, Disabled (Default: Disabled)	IRQ6 selection
IRQ6 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	IRQ6 Edge selection
IRQ7	Enabled, Disabled (Default: Disabled)	IRQ7 selection
IRQ7 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	IRQ7 Edge selection
IRQ8	Enabled, Disabled (Default: Disabled)	IRQ8 selection
IRQ8 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	IRQ8 Edge selection
IRQ9	Enabled, Disabled (Default: Disabled)	IRQ9 selection
IRQ9 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	IRQ9 Edge selection
IRQ10	Enabled, Disabled (Default: Disabled)	IRQ10 selection
IRQ10 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	IRQ10 Edge selection

ISDE Property	Value	Description
IRQ11	Enabled, Disabled (Default: Disabled)	IRQ11 selection
IRQ11 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	IRQ11 Edge selection
IRQ12	Enabled, Disabled (Default: Disabled)	IRQ12 selection
IRQ12 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	IRQ12 Edge selection
IRQ13	Enabled, Disabled (Default: Disabled)	IRQ13 selection
IRQ13 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	IRQ13 Edge selection
IRQ14	Enabled, Disabled (Default: Disabled)	IRQ14 selection
IRQ14 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	IRQ14 Edge selection
IRQ15	Enabled, Disabled (Default: Disabled)	IRQ15 selection
IRQ15 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	IRQ15 Edge selection

ISDE Property	Value	Description
LVD1	Enabled, Disabled (Default: Disabled)	LVD1 selection
LVD1 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	LVD1 Edge selection
LVD2	Enabled, Disabled (Default: Disabled)	LVD2 selection
LVD2 Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	LVD2 Edge selection
RTC Interval	Enabled, Disabled (Default: Disabled)	RTC Interval selection
RTC Alarm	Enabled, Disabled (Default: Disabled)	RTC Alarm selection
NMI	Enabled, Disabled (Default: Disabled)	NMI selection
NMI Edge	Disabled, Rising Edge, Falling Edge (Default: Disabled)	NMI Edge selection
USBFS	Enabled, Disabled (Default: Disabled)	USBFS selection
UBSHS	Enabled, Disabled (Default: Disabled)	UBSHS selection

ISDE Property	Value	Description
AGT1	Enabled, Disabled (Default: Disabled)	AGT1 selection

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

Configuration Settings for Low Power Mode Sleep Driver on r_lpmv2

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Enables or disables the parameter checking
Name	g_lpmv2_sleep0	Module name

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for Low Power Mode Standby Driver on r_lpmv2

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Enables or disables the parameter checking
Name	g_lpmv2_standby0	Module name
Choose the low power mode	Standby, Standby with Snooze enabled (Default: Standby)	Low power mode selection
Output port state in standby and deep standby, applies to address output, data output, and other bus control pins	No Change, High Impedance state (Default: No Change)	Output port state selection

ISDE Property	Value	Description
Select Standby Exit Sources: Select Fields below		
IRQ0:15	Enabled, Disabled (Default: Disabled)	IRQ0:16 selection
IWDT	Enabled, Disabled (Default: Disabled)	IWDT selection
Key Interrupt	Enabled, Disabled (Default: Disabled)	Key Interrupt selection
LVD1 Interrupt	Enabled, Disabled (Default: Disabled)	LVD1 selection
LVD2 Interrupt	Enabled, Disabled (Default: Disabled)	LVD2 selection
Analog Comparator High-speed 0 Interrupt	Enabled, Disabled (Default: Disabled)	Analog Comparator selection
RTC Period	Enabled, Disabled (Default: Disabled)	RTC Period selection
RTC Alarm	Enabled, Disabled (Default: Disabled)	RTC Alarm selection
USBFS	Enabled, Disabled (Default: Disabled)	USBFS selection

ISDE Property	Value	Description
UBSHS	Enabled, Disabled (Default: Disabled)	UBSHS selection
AGT1 Underflow	Enabled, Disabled (Default: Disabled)	AGT1 Underflow selection
AGT1 Compare Match A	Enabled, Disabled (Default: Disabled)	AGT1 CMA selection
AGT1 Compare Match B	Enabled, Disabled (Default: Disabled)	AGT1 CMB selection
I2C 0	Enabled, Disabled (Default: Disabled)	I2C 0 selection
Snooze Mode Settings		
Snooze Entry Source	RXD0 falling edge, IRQ0:15, KINT (Key Interrupt), ACMPHS0 (High-speed Analog Comparator 0), RTC Alarm, RTC Period, AGT1 Underflow, AGT1 Compare Match A, AGT1 Compare Match B (Default: RXD0 falling edge)	Source of Snooze mode entry
Snooze Exit Sources: Select fields below		
AGT1 Underflow	Enabled, Disabled (Default: Disabled)	AGT1 Underflow selection
DTC Transfer Completion	Enabled, Disabled (Default: Disabled)	DTC Transfer Completion selection

ISDE Property	Value	Description
DTC Transfer Completion Negated signal	Enabled, Disabled (Default: Disabled)	DTC Transfer Completion Negated signal selection
ADC0 Compare Match	Enabled, Disabled (Default: Disabled)	ADC0 Compare Match selection
ADC0 Compare Mismatch	Enabled, Disabled (Default: Disabled)	ADC0 Compare Mismatch selection
ADC1 Compare Match	Enabled, Disabled (Default: Disabled)	ADC1 Compare Match selection
ADC1 Compare Mismatch	Enabled, Disabled (Default: Disabled)	ADC1 Compare Mismatch selection
SCI0 Address Match	Enabled, Disabled (Default: Disabled)	SCI0 Address Match selection
DTC State Selection		
DTC state in Snooze Mode	Enabled, Disabled (Default: Disabled)	DTC state in Snooze Mode selection

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults can be desirable. For example, it might be useful to select different states for entering or exiting low-power states.

Low Power Modes V2 HAL Module Clock Configuration

The Low Power Modes V2 peripheral module does not have any selectable clock sources.

Low Power Modes V2 HAL Module Pin Configuration

The Low Power Modes V2 peripheral module needs no pin assignments. Pin function selections are done in the properties configuration window.

4.2.33.6 Using the Low Power Modes V2 HAL Module in an Application

The typical steps in using the Low Power Modes V2 HAL module in an application are:

1) Initialize the Low Power Modes V2 HAL module using the lpm_v2_api_t::init API
2) Configure a low-power mode with the lpm_v2_api_t::lowPowerCfg API
3) Enter a low-power mode with the lpm_v2_api_t::lowPowerModeEnter API

These common steps are illustrated in a typical operational flow diagram in the figure below:

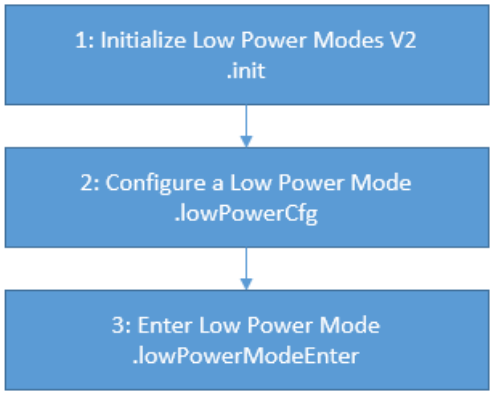

Figure 379: Flow Diagram of a Typical Low Power Modes V2 Module Application

4.2.34 Low Voltage Detection Driver

The Low Voltage Detection (LVD) HAL module is a high-level API for voltage-detection applications and is implemented on r_lvd. The LVD HAL module uses the LVD peripheral on the Synergy MCU. A user-defined callback can be created to notify the CPU when a voltage-detection event is triggered. The VCC is the source for all voltage-detection functions.

4.2.34.1 LVD HAL Module Features

The LVD HAL module supports the following functions:

- VCC as the voltage-detection input
- One build-time configurable low-voltage detector (via OFS1 register)
- Two run-time configurable low-voltage detectors
- Two result flags; one for a threshold check and one for the current state
- Support for both interrupt or polling-event checking

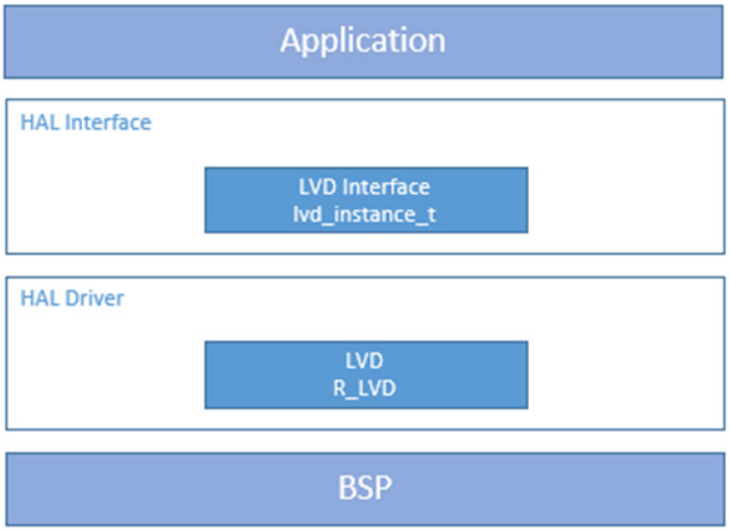

Figure 380: LVD HAL Module Block Diagram

4.2.34.2 LVD HAL Module APIs Overview

The LVD HAL module defines APIs for opening, closing, statusGet, and statusClear. The following table includes a complete list of the available APIs, an example API call, and a short description of each API. A table of status return values follows the API summary table.

LVD HAL Module API Summary

Function Name	Example API Call and Description
open	g_lvd.p_api->open(g_lvd.p_ctrl, g_lvd.p_cfg; Initializes a low voltage detection driver according to the passed in configuration structure. Enables an LVD peripheral based on configuration structure.
statusGet	g_lvd.p_api->statusGet(g_lvd.p_ctrl, &monitor_status); Get the current state of the monitor, (threshold crossing detected, voltage currently within range) Can be used to poll the state of the LVD monitor at any time. Must be used if the peripheral was initialized with the lvd_response_t set to LVD_RESPONSE_NONE.

Function Name	Example API Call and Description
statusClear	g_lvd.p_api->statusClear(g_lvd.p_ctrl); Clears the latched status of the monitor. Must be used if the peripheral was initialized with lvd_response_t set to LVD_RESPONSE_NONE.
close	g_lvd.p_api->close(g_lvd.p_ctrl, g_lvd.p_cfg); Disables the LVD peripheral. Closes the driver instance.
versionGet	g_lvd.p_api->versionGet(&version); Retrieve the API version with the version pointer.

NOTE: For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the *SSP User's Manual* API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_IN_USE	Driver already open or unable to acquire hardware lock
SSP_ERR_NOT_OPEN	Unit is not open
SSP_ERR_ASSERTION	Invalid configuration value
SSP_ERR_INVALID_MODE	If the attempted mode is invalid for this configuration

NOTE: Lower-level drivers may return common error codes. Refer to the *SSP User's Manual* API References for the associated module for a definition of all relevant status return values.

4.2.34.3 LVD HAL Module Operational Overview

The LVD HAL module supports the configuration and operation of LVD monitors in the Synergy MCUs. The LVD HAL module provide configuration structures with all the information needed to fully configure a single LVD monitor. There is one instance of the LVD HAL module per LVD monitor instance, with the exception of the LVD0 monitor. The LVD0 monitor is not configurable at runtime; it must be configured at compile time via the OFS1 register.

Both the LVD1 and LVD2 monitors are configurable at runtime by this module. The open function allows the user to configure and enable an LVD monitor with a single function call; the close function disables the LVD monitor. The statusGet function returns the current status of the LVD monitor. The statusGet function should be used if the module is in polling mode, i.e. without the LVD monitor interrupt enabled. The monitor status consists of two flags. The first flag is a latched flag called crossing_detected which indicates whether or not the voltage being monitored has crossed the voltage threshold. In polling mode, this flag must be cleared via a call to statusClear. The flag does not need to be cleared explicitly if the LVD interrupt is in use; it clears in the LVD interrupt by the driver code after the user-callback function is called. The second flag, current_state, is the instantaneous status of the monitored voltage with respect to the voltage threshold; this flag is not latched and its status changes with the monitored voltage changes.

The LVD HAL module can be configured to enable one or several of the LVD peripheral interrupts. If using an interrupt, the user should provide a callback function for that monitor. Separate callback routines should be provided for each LVD monitor.

The LVD HAL module requires functionality provided by the BSP; this driver makes use of the BSP hardware locks for locking registers, as well as enabling and clearing interrupts.

LVD HAL Module Important Operational Notes and Limitations

- Once the appropriate values are chosen for these LVD settings, you should add the code to call the LVD HAL module open API function for your project. This function should be called once early in the application.
- The module can be closed and opened whenever the configuration of an LVD monitor needs to be changed. Calling the LVD open API function configures and enables the LVD hardware peripheral the specified LVD monitor.
- The close function disables the LVD monitor and closes the driver.
- Using this module to configure the LVD peripheral to generate an interrupt requires the corresponding interrupt to be enabled in the module **Properties** tab.
- When using the LVD interrupts a callback function is not required, but is recommended.
- A unique callback function for each LVD interrupt is not required, but is recommended.
- Clock system initialization, configuration, and runtime modification are handled outside this module. This driver makes changes to the digital filter sample clock based on the user's choice of a sample clock divisor. The digital filter sample clock is derived from the low-speed on-chip oscillator (LOCO) system clock.
- Not all voltage thresholds are available on all MCU's.
- Digital filtering of the VCC input to the LVD monitor is not available on all Synergy MCU devices.
- The LVD driver requires functionality provided by the BSP; it makes use of hardware locks provided by the BSP for register locks, as well as enabling and clearing interrupts.
- Configuring and enabling a LVD monitor requires specific timing constraints and register write ordering. Due to the constraints, the entire process of configuring and enabling a voltage monitor is most effective when performed by a single function. The open API function performs configuration and enables the monitor and properly enforces the timing and register write ordering constraints.
- All the Synergy MCU Series include **Option-Setting Memory** that can be used to set the operating state of peripherals after a reset. The (option function select) OFS can be used to set the state of the IWDT, WDT, LVD, and CGC high-speed on-chip oscillator (HOCO).

See the latest SSP Release Notes for any additional operational limitations for this module.

NOTE: The LVD0 can only be configured via the OFS registers. The LVD0 does not support Register Start mode.

OFS Settings for Low Voltage Detection

Control	Description	
LVD0 detection level	S7 & S5 Series 2.94 V 2.87 V 2.80 V	S3 & S1 Series 3.84 V 2.82 V 2.51 V 1.90 1.70 V
LVD0 detection start	Automatically starts the LVD0 after a Reset, if enabled	

Set the OFS register values in the Synergy Configuration editor via the BSP tab **Properties** dialog box.

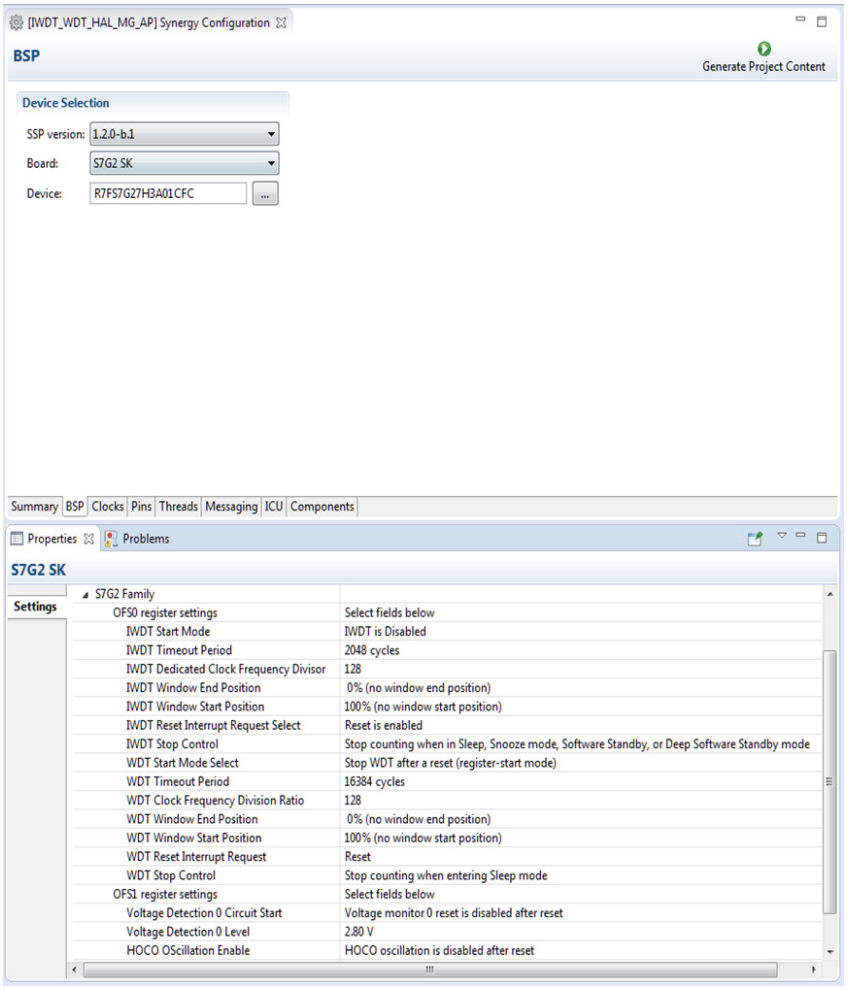

Figure 381: OFS Register Settings

4.2.34.4 Including the LVD HAL Module in an Application

This section describes how to include the LVD HAL Module in an application using the SSP configurator.

NOTE: It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the *SSP User's Manual* to learn how to manage each of these important steps in creating SSP-based applications.

To add the LVD Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the LVD HAL module is g_lvd. This name can be changed in the associated **Properties** window.)

Table 4 LVD Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_lvd Low Voltage Detection Driver on r_lvd	Threads	New Stack> Driver> Power> Low Voltage Detection Driver on r_lvd

When the LVD Driver on r_lvd is added to the thread stack, as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information are box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

Figure 382: LVD HAL Module Stack

4.2.34.5 Configuring the LVD HAL Module

The LVD HAL module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the Properties window in the ISDE includes an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the following configuration table settings. This helps to orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Table 5 Configuration Settings for the LVD HAL Module on r_lvd

ISDE Property	Value	Description
Parameter Checking	Enabled, Disabled, BSP (Default: BSP)	Selects if code for parameter checking is to be included in the build
Name	Default: g_lvd	LVD Driver module name
Monitor Number	1	Monitor number selection
Digital Filter, enable by selecting a valid sample clock rate (S7G2 only).	Enabled with clock LOCO/2/4/8/16, Disabled (Default: Disabled)	Digital filter selection
Voltage Threshold	2.85V (Vdet1_13) (S7G2 only).	Voltage threshold level selection
Detection Response, either reset, interrupt, non-maskable interrupt, or no response (polling mode).	Maskable interrupt is triggered when the voltage crosses the detection threshold. The non-maskable interrupt is triggered when voltage crosses the detection threshold. The MCU resets when the voltage falls below the detection threshold. No response: the driver is in polled mode (using statusGet and statusClear functions.) (Default: Maskable interrupt)	Detection response selection
Voltage Slope	Threshold crossing detected with decreasing voltage. Threshold crossing detected with increasing voltage. Threshold crossing detected with increasing or decreasing voltage. (Default: Threshold crossing detected with decreasing voltage.)	Direction of voltage slope for threshold detection
Negation of Monitor Signal	Negation of reset signal is based on delay from the reset. Negation of reset signal is based on delay from voltage returning to normal range. (Default: Negation of reset signal is based on delay from reset.)	Negation option selection
Monitor Interrupt Callback	NULL	Interrupt callback function name
LVD Monitor Interrupt Priority	Priority 0 (highest), 1,2,3,4,5,6,7,8,9,10,11,12,13,14,15 (lowest, not valid if using Thread X), Disabled (Default: Disabled)	Interrupt priority setting

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings (other than the defaults) for a module can be desirable. For example, it might be useful to select a voltage level appropriate for the target system.

LVD HAL Module Clock Configuration

Clock system clock initialization, configuration, and runtime modification are handled outside this module. This module only makes changes to the digital filter sample clock based on the user's choice of sample clock divisor. The digital filter sample clock is derived from the LOCO system clock.

LVD HAL Module Pin Configuration

The LVD HAL module measures the voltage on the VCC pin only and doesn't need to be configured.

4.2.34.6 Using the LVD HAL Module in an Application

The typical steps in using the LVD HAL module in an application are:

1) Initialize the LVD HAL module using the open API.
2) If using software polling, monitor the LVD status flags with the statusGet API and process accordingly. If using the interrupt mode, process accordingly within the callback function which will return both the monitor number as well as the status.
3) Process as needed
4) Close the LVD Instance with the close API

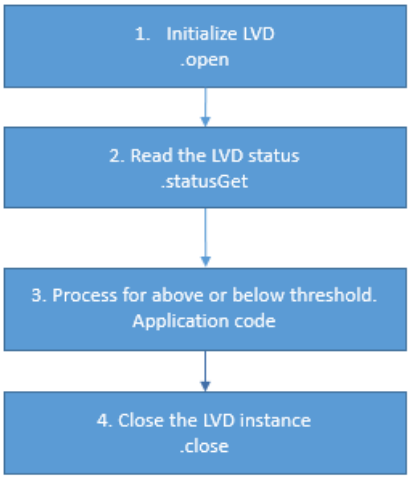

Figure 383: Flow Diagram of a Typical LVD HAL Module in software polling mode

4.2.35 OPAMP Driver

The OPAMP HAL module implements the OPAMP API for signal amplification applications on r_opamp. It supports the OPAMP peripheral available on Synergy MCUs.

4.2.35.1 OPAMP HAL Module Features

- Low power or high-speed mode
- Start by software or AGT compare match
- Stop by software or ADC conversion end (stop by ADC conversion end only supported on op-amp channels configured to start by AGT compare match)
- Trimming available on some MCUs (see hardware manual)

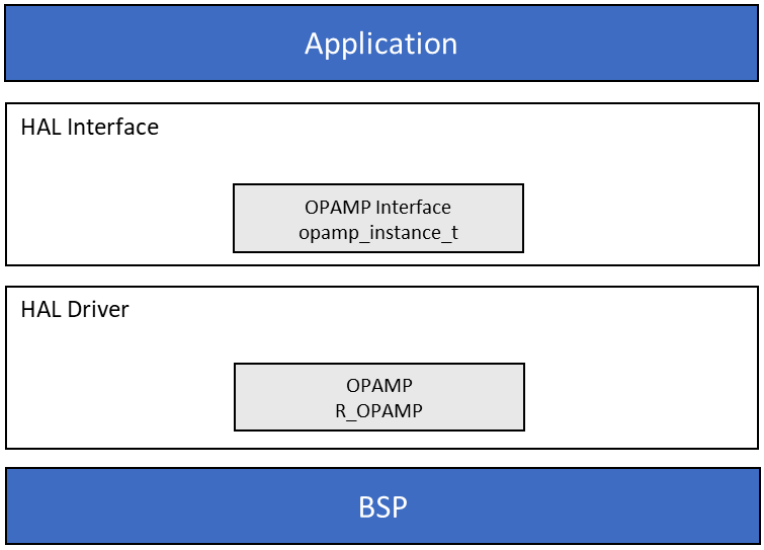

Figure 384: OPAMP HAL Module Block Diagram

4.2.35.2 OPAMP HAL Module APIs Overview

The OPAMP HAL module defines APIs to open, start, stop, read status, trim, and close the ADC module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

OPAMP HAL Module API Summary

Function Name	Example API Call and Description
.open	g_opamp0.p_api->open(g_opamp0.p_ctrl, g_opamp0.p_cfg); Applies power to the OPAMP and initializes the hardware based on the user configuration.

Function Name	Example API Call and Description
.start	g_opamp0.p_api->start(g_opamp0.p_ctrl, channel_mask); If the OPAMP is configured for hardware triggers, enables hardware triggers. Otherwise, starts the op-amp.
.stop	g_opamp0.p_api->stop(g_opamp0.p_ctrl, channel_mask); Stops the op-amp. If the OPAMP is configured for hardware triggers, disables hardware triggers.
.trim	g_opamp0.p_api->trim(g_opamp0.p_ctrl, cmd, p_args); On MCUs that support trimming, the op-amp trim register is set to the factory default after open(). This function allows the application to trim the operational amplifier to a user setting, which overwrites the factory default factory trim values. See Operational Notes for important details.
.infoGet	g_opamp0.p_api->infoGet(g_opamp0.p_ctrl, p_info); Provides the minimum stabilization wait time in microseconds.
.statusGet	g_opamp0.p_api->statusGet(g_opamp0.p_ctrl, p_status); Provides the operating status for each op-amp in a bitmask. This bit is set when operation begins, before the stabilization wait time has elapsed.
.close	g_opamp0.p_api-> close(g_opamp0.p_ctrl); Stops the op-amps.
.versionGet	g_opamp0.p_api->versionGet(&version); Retrieve the module version using the version pointer

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_NOT_OPEN	Unit is not open
SSP_ERR_ASSERTION	An input pointer is NULL.
SSP_ERR_IN_USE	Peripheral is in use or hardware lock is taken.
SSP_ERR_INVALID_POINTER	The parameter p_data is NULL.
SSP_ERR_INVALID_STATE	The command is not valid for the current state of the trim function.
SSP_ERR_INVALID_MODE	Trim is not allowed in low power mode.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.2.35.3 OPAMP HAL Module Operational Overview

The OPAMP HAL module controls the OPAMP peripheral on a Synergy microcontroller. It directly controls the OPAMP hardware without using any RTOS elements and provides convenient APIs to simplify development.

OPAMP HAL Module Important Operational Notes and Limitations

Trimming the OPAMP

On MCUs that support trimming, the op-amp trim register is set to the factory default after open(). This function allows the application to trim the operational amplifier to a user setting, which overwrites the factory default factory trim values.

Trimming is not supported on all MCUs. See hardware manual for details. It is not supported if configured for low power mode (OPAMP_MODE_LOW_POWER).

This function is not reentrant. Only one side of one op-amp can be trimmed at a time. Complete the procedure for one side of one channel before calling trim() with command OPAMP_TRIM_CMD_START again.

The trim procedure works as follows:

- Call trim() for the Pch (+) side input with command OPAMP_TRIM_CMD_START.
- Connect a fixed voltage to the Pch (+) input.

- Connect the Nch (-) input to the op-amp output to create a voltage follower.
- Ensure the op-amp is operating and stabilized.
- Call trim() for the Pch (+) side input with command OPAMP_TRIM_CMD_START.
- Measure the fixed voltage connected to the Pch (+) input using the SAR ADC and save the value (referred to as A later in this procedure).
- Iterate over the following loop 5 times:
  - Call trim() for the Pch (+) side input with command OPAMP_TRIM_CMD_NEXT_STEP.
  - Measure the op-amp output using the SAR ADC (referred to as B in the next step).
  - If A <= B, call trim() for the Pch (+) side input with command OPAMP_TRIM_CMD_CLEAR_BIT.
- Call trim() for the Nch (-) side input with command OPAMP_TRIM_CMD_START.
- Measure the fixed voltage connected to the Pch (+) input using the SAR ADC and save the value (referred to as A later in this procedure).
- Iterate over the following loop 5 times:
  - Call trim() for the Nch (-) side input with command OPAMP_TRIM_CMD_NEXT_STEP.
  - Measure the op-amp output using the SAR ADC (referred to as B in the next step).
  - If A <= B, call trim() for the Nch (-) side input with command OPAMP_TRIM_CMD_CLEAR_BIT.

The following Status Return values are associated with the trim API.

SSP_SUCCESS: Conversion result in p_data.

SSP_ERR_UNSUPPORTED: Trimming is not supported on this MCU.

SSP_ERR_INVALID_STATE: The command is not valid in the current state of the trim state machine.

SSP_ERR_INVALID_ARGUMENT:The requested channel is not operating or the trim procedure is not in progress for this channel/input combination.

SSP_ERR_INVALID_MODE: Trim is not allowed in low power mode.

SSP_ERR_ASSERTION: An input pointer was NULL.

SSP_ERR_NOT_OPEN: Instance control block is not open. Trimming is not supported on all MCUs.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.35.4 Including the OPAMP HAL Module in an Application

This section describes how to include the OPAMP HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the OPAMP HAL module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the OPAMP HAL module is g_opamp0. This name can be changed in the associated Properties window.)

OPAMP HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_opamp0 OPAMP Driver on r_opamp	Threads	New Stack> Driver> Analog> OPAMP Driver on r_opamp

When the OPAMP HAL module on r_opamp is added to the thread stack as shown in the following figure, the configurator automatically adds any lower-level drivers that are required. Any drivers that need additional configuration information will be box-text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

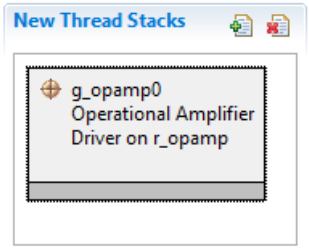

Figure 385: OPAMP HAL Module Stack

4.2.35.5 Configuring the OPAMP HAL Module

The OPAMP HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the OPAMP HAL Module on r_opamp

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_opamp	Module name
AGT Start Trigger Configuration (N/A unless AGT Start Trigger is Selected for the Channel)	AGT1 Compare Match Starts OPAMPs 0 and 2 if configured for AGT Start/AGT0 Compare Match Starts OMPAMPs 1 and 3 if configured for AGT Start AGT1 Compare Match Starts OPAMPs 0 and 1 if configured for AGT Start/AGT0 Compare Match Starts OPAMPs 2 and 3 if configured for AGT Start AGT1 Compare Match Starts all OPAMPs configured for AGT Start Default: AGT1 Compare Match Starts all OPAMPs configured for AGT Start	Configure which AGT channel event triggers op-amp channel. The AGT compare match event only starts the op-amp channel if the AGT Start trigger is selected in the Trigger configuration for the channel.
Power Mode	Low Power, Middle Speed, High Speed Default: High Speed	Configure the op-amp based on power or speed requirements. This setting affects the minimum required stabilization and trim time. Middle speed is not available for all MCUs.
Trigger Channel 0	Software Start Software Stop, AGT Start Software Stop, AGT Start ADC Stop Default: Software Start Software Stop	Select the event triggers to start or stop op-amp channel 0. If the event trigger is selected for start, the start() API enables the event trigger for this channel. If the event trigger is selected for stop, the stop() API disables the event trigger for this channel.

ISDE Property	Value	Description
Trigger Channel 1	Software Start Software Stop, AGT Start Software Stop, AGT Start ADC Stop Default: Software Start Software Stop	Select the event triggers to start or stop op-amp channel 1. If the event trigger is selected for start, the start() API enables the event trigger for this channel. If the event trigger is selected for stop, the stop() API disables the event trigger for this channel.
Trigger Channel 2	Software Start Software Stop, AGT Start Software Stop, AGT Start ADC Stop Default: Software Start Software Stop	Select the event triggers to start or stop op-amp channel 2. If the event trigger is selected for start, the start() API enables the event trigger for this channel. If the event trigger is selected for stop, the stop() API disables the event trigger for this channel.
Trigger Channel 3	Software Start Software Stop, AGT Start Software Stop, AGT Start ADC Stop Default: Software Start Software Stop	Select the event triggers to start or stop op-amp channel 3. If the event trigger is selected for start, the start() API enables the event trigger for this channel. If the event trigger is selected for stop, the stop() API disables the event trigger for this channel.

NOTE: The example values and defaults are for a project using the Synergy S1JA. Other MCUs may have different default values and available configuration settings.

OPAMP HAL Module Clock Configuration

The OPAMP HAL module does not require a clock for module operation.

OPAMP HAL Module Pin Configuration

To use the OPAMP HAL module, the port pins for the channels receiving the analog input must be set as input pins in the pin configurator in the ISDE. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection Sequence for the OPAMP HAL Module

Resource	ISDE Tab	Pin selection Sequence
OPAMP	Pins	Select Peripherals > Analog: OPAMP0/1/2

4.2.35.6 Using the OPAMP HAL Module in an Application

Once the module has been configured and the files generated, the OPAMP is ready to be used in an application.

The typical steps in using the OPAMP HAL module in an application are:

1) Initialize the OPAMP using the open API.
2) Before starting any op-amp, consult the hardware manual to determine if the MCU used has internal connections switches in the OPAMP peripheral. If the OPAMP peripheral does have internal connection switches, configure the internal connections by setting the AMPnMS, AMPnPS, and AMP0OS registers directly.
3) Start the OPAMP channel(s) using the desired trigger with the start API.
    a) If AGT compare match start is used, this call enables the OPAMP to be triggered by the AGT compare match. If a software trigger is used, then this call starts OPAMP channel(s).
4) [Optional] Stop the OPAMP channel(s) by calling the stop API.
    a) This stops the OPAMP regardless of if ADC conversion end triggers are enabled to stop the OPAMP.
5) [Optional] Use the close API to power down the peripheral.

These common steps are illustrated in a typical operational flow in the following figure:

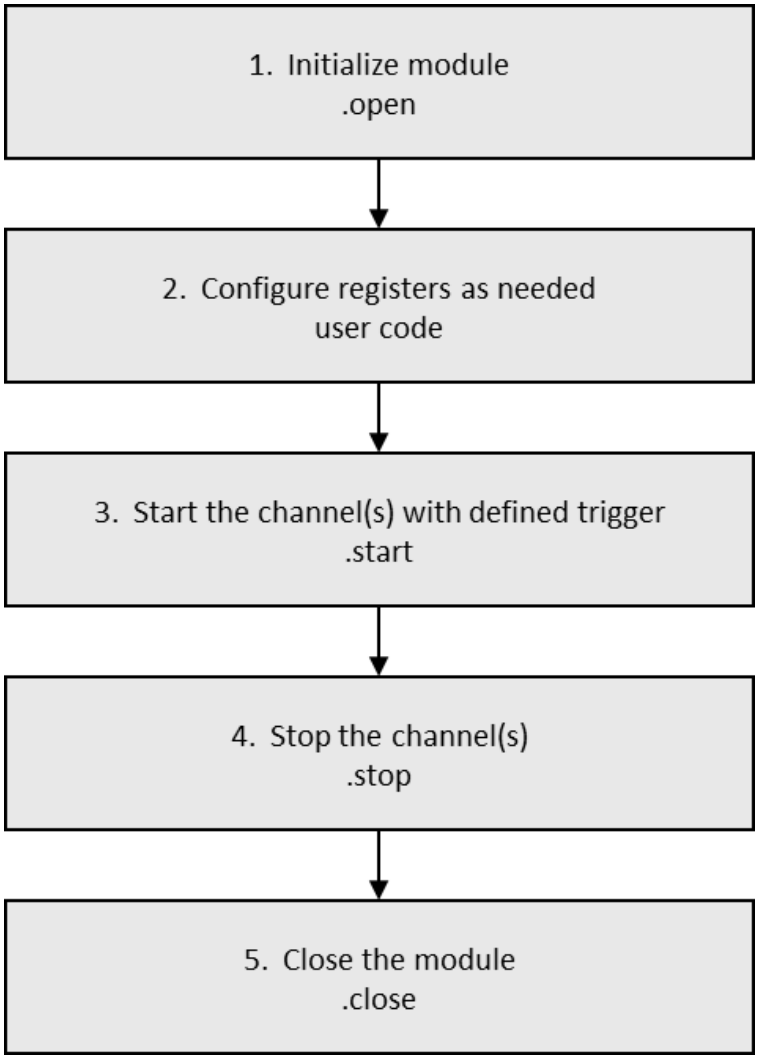

Figure 386: Flow Diagram of a Typical OPAMP HAL Module Application

4.2.36 PDC Driver

The Parallel Data Capture Unit (PDC) HAL module provides high-level APIs to capture images from a camera application and is implemented on r_pdc. The PDC HAL module uses the PDC peripherals on the Synergy MCU. A user-defined callback can be created to inform the CPU when a capture has been completed.

4.2.36.1 PDC HAL Module Features

This PDC HAL module controls the PDC on a Synergy microcontroller and has the following key features:

- Supports capture from a connected and configured camera.
- Supports a callback that informs the CPU when a capture is complete

- Provides a pointer to the capture buffer
- Provides an indication of the event triggering the callback

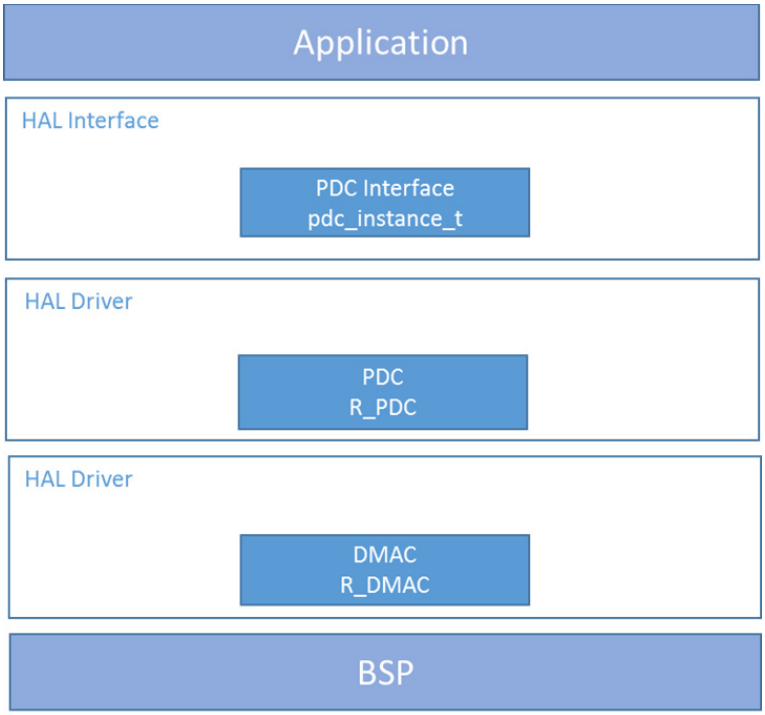

Figure 387: PDC HAL Module Block Diagram

4.2.36.2 PDC HAL Module APIs Overview

The PDC HAL module defines APIs for opening, closing, and starting data capture. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API Summary table.

PDC HAL Module API Summary

Function Name	Example API Call and Description
open	g_pdc.p_api->open(g_pdc.p_ctrl, g_pdc.p_cfg) Initial configuration.
close	g_pdc.p_api->close(g_pdc.p_ctrl)) Closes the driver and allows reconfiguration. May reduce power consumption.

Function Name	Example API Call and Description
captureStart	g_pdc.p_api->captureStart(g_pdc.p_ctrl, &buffer) Start a capture.
stateGet	g_pdc.p_api->stateGet(g_pdc.p_ctrl, &state_data) Get the state of VSYNC and HSYNC pins.
versionGet	g_pdc.p_api->versionGet(&version) Return the API version using the version pointer.

NOTE: Review the SSP User's Manual API References for the associated module to learn more about operations and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_ASSERTION	The parameter p_ctrl or p_sample is NULL.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ALREADY_OPEN	Unit is already open.
SSP_ERR_HW_LOCKED	Unable to reserve BSP hardware lock.
SSP_ERR_TIMEOUT	Reset Operation timed out.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.36.3 PDC HAL Module Operational Overview

The capture operation requires a configured external camera connected to the Synergy microcontroller. Before performing a capture, it is important the camera is configured and generating a PIXCLK-clock input into the microcontroller. In some instances, a camera requires a running-clock input before it can be configured.

Use the call open, which configures and starts the PCKO-clock output from the PDC into the camera, before initializing the camera. Once the camera is configured, captureStart can be called to capture an image. Configuration of a camera module may require the use of an I^2C or SPI interface.

PDC HAL Module Important Operational Notes and Limitations

In most instances, the data rate from a camera and from the PDC peripheral is too fast to be serviced by the CPU in an interrupt service routine (ISR). Therefore, this module requires an implementation of the transfer driver on the DMAC to perform a high-speed transfer from the PDC peripheral and memory.

You must enable both the PDC frame-end and PDC error interrupts to generate interrupts in the following situations:

- An interrupt when an image is captured (frame end)
- An interrupt when an error occurs

Data Buffer Setting

If p_buffer is set to anything other than NULL, one or more data buffers are created to store image data. The size of each buffer is calculated using the following formula:

Buffer size (bytes) = x_capture_pixels x y_capture_pixels x bytes_per_pixel

For large resolution cameras, the captured image could result in a large amount of data. It may be necessary to locate the buffer(s) in external memory (such as, SDRAM). Consideration should be given to bus bandwidth when using external memory.

For example, when using a high frame-rate camera to do an image capture via the PDC into SDRAM, and using SDRAM to hold the display buffer for an LCD display with a high refresh rate, may cause a data bottleneck from the PDC to memory that results in an overrun-error condition.

NOTE: If p_buffer is set to NULL, no memory is allocated to store the captured image data. The user's responsibility is to ensure that there is suitable memory of sufficient size available to the PDC. The PDC could capture directly into the display buffer of a connected LCD panel.

For PDC HAL module operational limitations, refer to the latest SSP Release Notes.

4.2.36.4 Including the PDC HAL Module in an Application

This section describes how to include the PDC HAL module in an application using the SSP configurator.

NOTE: This process assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the PDC Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the PDC is r_pdc0. This name can be changed in the associated Properties window.)

CRC Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
r_pdc0 PDCDriver on r_pdc	Threads	New Stack> Driver> Graphics> PDC Driver on r_pdc

As shown in the following figure, when the PDC HAL module on r_pdc is added to the thread stack, the configurator automatically adds the needed lower-level drivers. Any drivers needing additional configuration information are highlighted in Red. Modules with a Gray band are individual standalone modules.

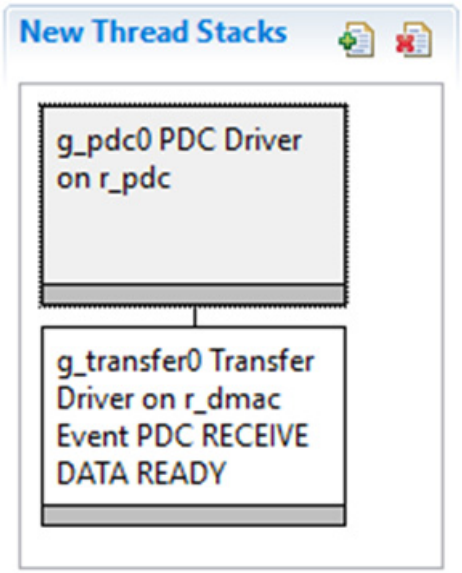

Figure 388: PDC HAL Module Stack

4.2.36.5 Configuring the PDC HAL Module

The PDC HAL module is configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, configured for lower-level modules to enable successful operation. Only properties that can be changed without causing conflicts are available for modification. Properties that cannot be changed are 'locked' and identified with a lock icon to indicate the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process, making it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the Properties window in the ISDE includes an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+.) This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking

over the following configuration table settings. This helps orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the PDC HAL Module on r_pdc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_pdc0	The name of the PDC module instance. Specify arbitrary C symbol.
Name of the data buffer to store image data	g_user_buffer	Specify the name of the data buffer to create or set to NULL, if it is to be created by the user external to the PDC driver.
Section where data buffer is allocated	sdram	Specify the RAM section for the image data buffer. Typically BSS (internal RAM) or SDRAM.
Number of bytes per pixel	2	Specify the number of bytes per pixel of the captured image data.
Number of image data buffers	1	Specify the number of buffers to create.
Clock Divider	CLK/2, CLK/4, CLK/6, CLK/8, CLK10, CLK12, CLK14, CLK16 Default: CLK/2	Specify the clock divider of the clock input to the PDC peripheral.
Endian of image data	Little, Big Default: Little	Specify the endian of the captured image data.
HYSNC signal polarity	High, Low Default: High	Specify the active polarity of the HSYNC signal.
VSYNC signal polarity	High, Low Default: High	Specify the active polarity of the VSYNC signal.

ISDE Property	Value	Description
Number of pixels to capture horizontally	640	Number of horizontal pixels to capture.
Number of lines to capture vertically	480	Number of vertical lines to capture.
Horizontal pixel to start capture from	0	Horizontal pixel to start capturing image data from. Allows an image smaller than the native resolution of a camera to be captured.
Line to start capture from	0	Vertical line to start capturing image data from. Allows an image smaller than the native resolution of a camera to be captured.
Callback	g_pdc_user_callback	A user callback function can be registered in open. If this callback function is provided, it is called from the interrupt service routine (ISR) each time a frame is captured and ready to be processed. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Frame End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	The driver needs a valid interrupt priority setting. It won't function if disabled.
PDC Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	The driver needs a valid interrupt priority setting. It won't function if disabled.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for a module can be desirable. For example, it might be useful to select a different clock source than the default. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

When configuring settings for the PDC HAL Module Low-Level Driver, typically, only a small number of settings must be modified from the default for lower-level drivers and these are indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module.

Configuration Settings for the DMAC HAL Module

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Name	g_transfer0	Driver name.
Mode	Block	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	8	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	1	Number of blocks selection.
Activation Source (Must enable IRQ)	Event PDC RECEIVE DATA READY	Activation source selection.
Auto Enable	FALSE	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.

ISDE Property	Value	Description
Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Interrupt priority selection

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

PDC HAL Module Clock Configuration

The PDC uses PCLKB as its clock source. The only restriction when configuring this clock is that the PIXCLCK should be less than 0.6 x PCLKB so the PCLKB frequency should be set accordingly.

PDC HAL Module Pin Configuration

The PDC peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table depicts the method to select pins within the SSP configuration window. The subsequent table gives an example selection for PDC pins.

NOTE: The operation mode selection determines the peripheral signals available and the MCU pins required.

Pin Selection Sequence for the PDC HAL Module

Resource	ISDE Tab	Pin selection Sequence
PDC	Pins	Select **Peripherals > Graphics: PDC > PDC0**

NOTE: The selection sequence assumes PDC0 is the desired hardware target for the driver.

Pin Configuration Settings for the PDC HAL Module

Property	Value	Description
Pin Group Selection	Mixed, _A Only (Default: Mixed)	Pin group selection

Property	Value	Description
Operation Mode	Disabled, Custom, Enabled (Default: Disabled)	Select Enabled as the Operation Mode for PDC
HSYNC	None, P704 (Default: None)	HSYNC Pin
PCKO	None, P511 (Default: P511)	PCKO Pin
PIXCLK	None, P705 (Default: None)	PIXCLK Pin
VSYNC	None, P512 (Default: P512)	VSNC Pin
PIXD0:7	None, Pnnn (Default: None)	PIX Data0:7 Pins

NOTE: The example settings are for a project using the Synergy S7G2 and the DK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.36.6 Using the PDC HAL Module in an Application

The typical steps in using the PDC HAL module in an application are:

1) Initialize the PDC HAL module using the open API
2) Configure the camera as needed
3) Start image capture using the captureStart API
4) Callback is called when image is captured
5) Read state of HSYNC and VSTNC using stateGet API
6) Process data as needed

7) Close using the close API

These common steps are illustrated in a typical operational flow diagram in the figure below:

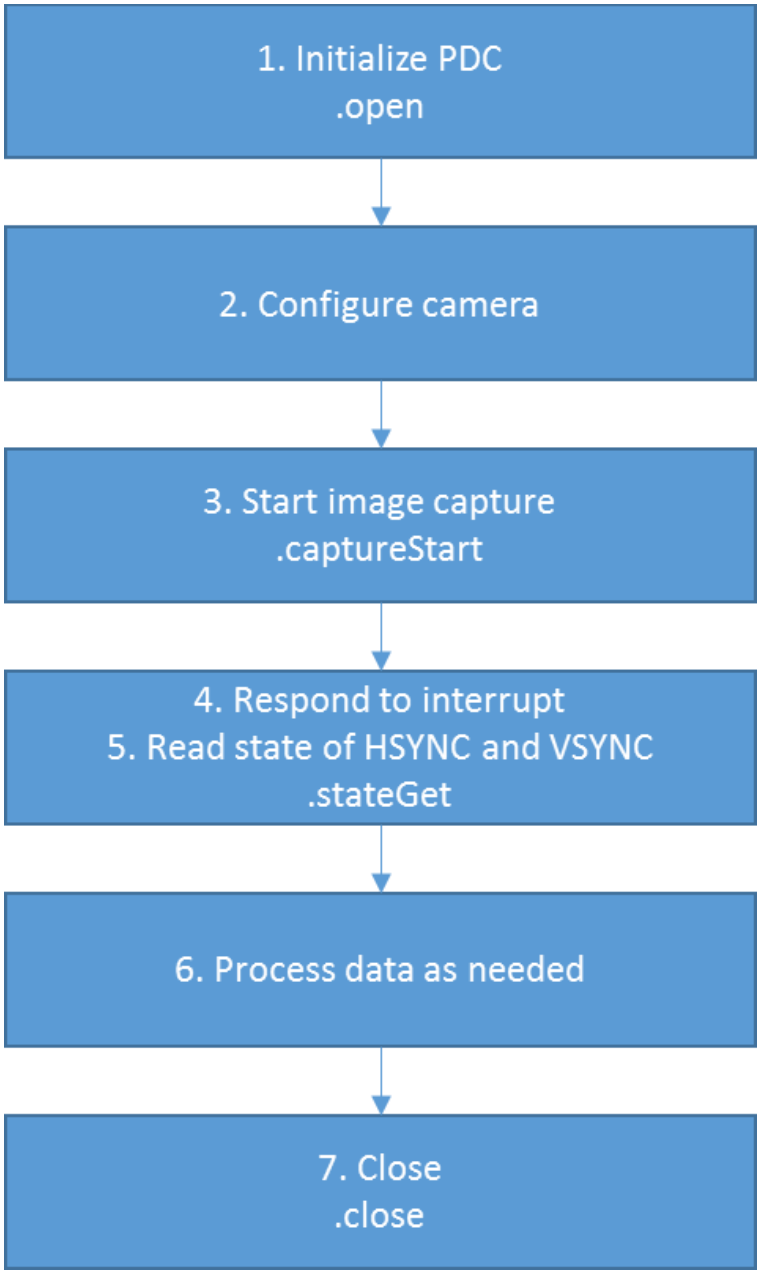

Figure 389: Flow Diagram of a Typical PDC HAL Module Application

4.2.37 QSPI Driver

The Quad SPI (QSPI) HAL module is a high-level API for erasing and programming the contents of a QSPI flash device connected to the microcontroller and is implemented on the r_qspi peripheral on the Synergy MCU. Unlike many other modules, there is no callback function for the QSPI.

4.2.37.1 QSPI HAL Module Features

The QSPI HAL Module is used to initialize the QSPI peripheral that allows erasing and programming the contents of a QSPI flash device connected to the microcontroller over the Quad SPI interface. Key features include:

- Access Quad SPI flash devices using Direct Communication Mode
- Read data from a QSPI flash device
- Program the page of a QSPI flash device
- Erase sectors of a QSPI flash device
- Select a bank to control access to a QSPI flash device

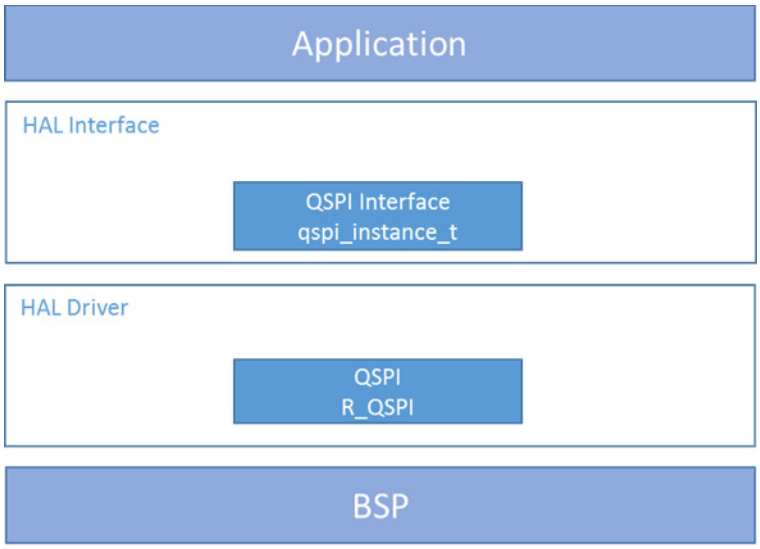

Figure 390: QSPI HAL Module Block Diagram

4.2.37.2 QSPI HAL Module APIs Overview

The QSPI interface defines APIs for opening, closing, reading, writing, erasing, and device bank selection using the QSPI HAL module. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

QSPI HAL Module API Summary

Function Name	Example API Call and Description
open	g_qspi0.p_api->open(g_qspi0.p_ctrl, g_qspi0.p_cfg); Open the QSPI HAL module.
close	g_qspi0.p_api->close(g_qspi0.p_ctrl); Close the QSPI HAL module.
read	g_qspi0.p_api->read(g_qspi0.p_ctrl, (uint8_t *) QSPI_DEVICE_ADDRESS, readBuffer, BUFFER_LENGTH); Read data from the flash.
pageProgram	g_qspi0.p_api->pageProgram(g_qspi0.p_ctrl, (uint8_t *) QSPI_DEVICE_ADDRESS, writeBuffer, BUFFER_LENGTH); Program a page of data to the flash.
sectorErase	g_qspi0.p_api->sectorErase(g_qspi0.p_ctrl, (uint8_t *) QSPI_DEVICE_ADDRESS); Erase a sector on the flash.
erase	g_qspi0.p_api->erase(g_qspi0.p_ctrl, (uint8_t *) QSPI_DEVICE_ADDRESS, *BYTE_COUNT*); Erase a block of memory depending on the input argument "byte_count"
statusGet	g_qspi0.p_api->statusGet(g_qspi0.p_ctrl, &in_progress); Get the write or erase status of the flash.
bankSelect	g_qspi0.p_api->bankSelect(0); Select the bank to access.

Function Name	Example API Call and Description
infoGet	g_qspi0.p_api->infoGet(g_qspi0.p_ctrl, &qspi_info); Provides information about the underlying QSPI flash, as specified in bsp_qspi.c
versionGet	g_qspi0.p_api->versionGet(& ssp_version); Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Invalid parameter is passed.
SSP_ERR_ASSERTION	p_cfg was NULL.
SSP_ERR_NOT_OPEN	Driver is not opened.
SSP_ERR_UNSUPPORTED	Driver not able to query the following information from the flash manufacturer id, memory capacity and memory type.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.37.3 QSPI HAL Module Operational Overview

The QSPI HAL module is used to initialize the QSPI peripheral so that the Synergy device can communicate (read, write, erase data) with a QSPI serial flash device.

The driver supports three operation modes: page program (write), read and erase.

- *Page program* programs a single page of data to the flash device. Page size is specific to flash memory and may vary from vendor to vendor. Typical page sizes of flash are 128,256 and 512 bytes. Use the infoGet API to get the supported page size for the underlying flash device.

- *Read* operation will read the data from the flash and store it to the user-provided buffer.
- *Erase* operation will erase the block of data from the flash. Use infoGet API to get the supported erase size for the underlying flash device.

NOTE: After any erase/write operation and before starting the next operation, it is advisable to use the statusGet API to poll the status of operation; not doing this may corrupt user data.

QSPI HAL Module Important Operational Notes and Limitations

In the case of using a board supported by the SSP and a BSP based project (SK-S7G2 and DK-S7G2), and the board having a QSPI memory device pre-installed, the BSP initializes and places the QSPI peripheral in ROM access mode with XIP (execute in place) enabled. This process enables the memory to be read like standard memory, meaning the QSPI HAL Module is only be needed when erasing and programming the QSPI flash device.

The typical QSPI application programs or erases data on the QSPI flash device. When this driver is not open, the QSPI flash device contents get mapped to 0x60000000 and can be read as if ordinary memory.

This driver has been tested on the S7G2 and S3A7 Synergy microcontroller groups using the QSPI peripheral block and the Micron N25Q256A QSPI flash device.

Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.37.4 Including the QSPI HAL Module in an Application

This section describes how to include the QSPI HAL module in an application using the SSP configurator.

NOTE: The process assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the QSPI Driver to an application, add it to a thread using the stacks selection sequence given in the following table. (The default name for the QSPI Driver g_qspi0. This name can be changed in the associated Properties window).

QSPI HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_qspi0	Threads	Select HAL/Common and select New > Driver > Storage > QSPI HAL on QSPI

Drivers that need additional configuration information are highlighted in Red. The QSPI does not require additional configuration.

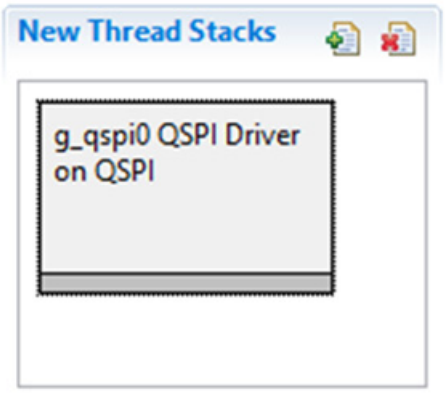

Figure 391: QSPI HAL Module Stack

4.2.37.5 Configuring the QSPI HAL Module

No component options of the QSPI HAL module need to be changed. The driver does not use the QSPI interrupt, so it is not enabled. Consider changing only the name of the driver instance for easier source code development.

The SSP configuration window automatically highlights any selections, such as interrupts or operating modes, requiring configuration for lower-level modules to achieve successful operation. In most applications, the default values for modules in the lower layers of the stack can be accepted. The following tables detail the available options that can be specified in the Properties window.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the configuration settings in the following table. This helps to orient you and provides a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the QSPI HAL Module on r_qspi

ISDE Property	Value	Description
Parameter Checking	Default (BSP)	Parameter checking level.
Name	g_qspi0	Name of the QSPI HAL instance. This may be edited to an application specific name if required.

NOTE: The example values and defaults given for settings come from a project using the Synergy S7G2 MCU. Other MCUs may have different default values and available configuration settings.

QSPI HAL Module Pin Configuration

The QSPI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table indicates the method for selecting pins within the SSP configuration window. The subsequent table lists an example selection sequence for the QSPI pins.

Pin Selection Sequence for the QSPI HAL Module

Resource	ISDE Tab	Pin selection Sequence
QSPI	Pins	Select Peripherals > Storage:QSPI > QSPI0

NOTE: The selection sequence assumes the QSPI0 is the desired hardware target for the driver.

Pin Configuration Settings for the QSPI HAL Module

Property	Value	Description
Pin Group Selection	- Mixed - _A only	Pin group selection.
Operation Mode	- Disabled - Custom - Single or Dual - Quad	Operation mode.
QSPCLK	None, P500	QSPI clock output pin.
QSSL	None, P501	QSPI slave select pin.
QIO0	None, P502	Data 0 input/output.
QIO1	None, P503	Data 1 input/output.
QIO2	None, P504	Data 2 input/output.
QIO3	None, P505	Data 3 input/output.

NOTE: The example settings come from a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.37.6 Using the QSPI HAL Module in an Application

Once the module has been configured and the files generated, the QSPI is ready to be used in an application.

The typical steps in using the QSPI HAL module in an application are:

1) Initialize the QSPI HAL module using the open API call.
2) Read a block of data using the read API call.
3) Erase a sector of data using the sectorErase API call.
4) Erase n bytes of data using the erase API call.
    a) infoGet can be used to get the supported erase sizes by the underlying flash.
    b) statusGet API can be used to poll the status of ease operation applicable for sectorErase API also.
5) Program a page of data using the pageProgram API call.
    a) Use infoGet API to get the page size supported by the underlying flash.
    b) statusGet API can be used to poll the status of write operation.
6) Close the QSPI HAL module using the close API call.

NOTE: It is advisable to use erase API instead of sectorErase API as the Sector is not a standard size for flash device and it varies with different vendors.

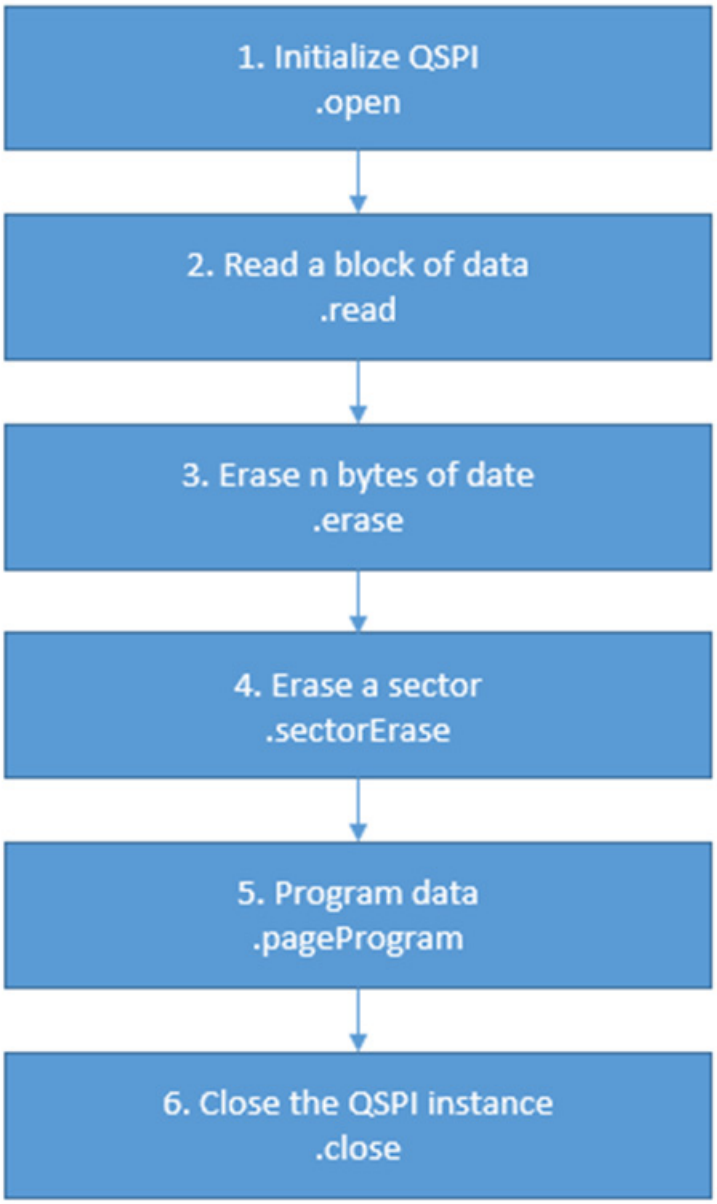

Figure 392: Flow Diagram of a Typical QSPI HAL Module Application

4.2.38 RTC Driver

The Real-Time Clock (RTC) HAL module provides high-level APIs for timing applications. The RTC HAL module configures the RTC peripheral and controls clock, calendar and alarm functions. The RTC uses the real-time clock peripheral on the Synergy MCU. A callback can be used to respond to any of the three supported interrupt types: alarm, periodic or carry.

4.2.38.1 RTC HAL Module Features

The RTC HAL module supports the following functions of the real-time clock:

- RTC peripheral configuration
- RTC time and date get and set
- RTC time and date alarm get and set
- RTC time counter start and stop
- RTC alarm, periodic, and carry event notification
- RTC event type enable and disable
- RTC event rate configuration
- RTC clock source get and set
- RTC sub-clock error adjustment
- RTC status get

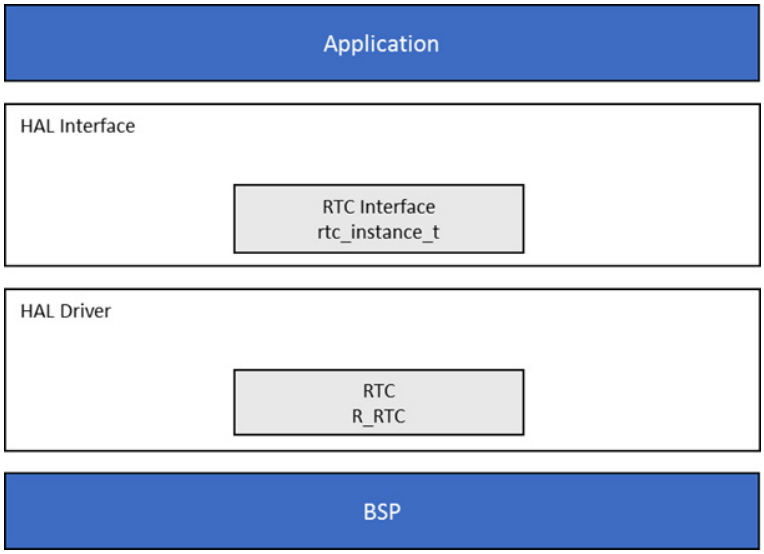

Figure 393: RTC HAL Module Block Diagram

4.2.38.2 RTC APIs Overview

The RTC HAL module defines APIs for opening, closing, setting alarms, starting, and stopping RTC operations. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of all applicable status return values follows.

RTC HAL Module API Summary

Function Name	Example API Call and Description
.open	g_rtc0.p_api->open(g_rtc0.p_ctrl, g_rtc0.p_cfg); Open the RTC HAL.
.close	g_rtc0.p_api->close(g_rtc0.p_ctrl); Close the RTC HAL.
.configure	g_rtc0.p_api->configure(g_rtc0.p_ctrl, p_extend); Configure the RTC HAL.
.calendarTimeSet	g_rtc0.p_api->calendarTimeSet(g_rtc0.p_ctrl, &start_time_struct_in, true); Set the calendar time.
.calendarTimeGet	g_rtc0.p_api->calendarTimeGet(g_rtc0.p_ctrl, &current_time_struct_out); Get the calendar time.
.calendarAlarmSet	g_rtc0.p_api->calendarAlarmSet(g_rtc0.p_ctrl, &in_alarm_time_struct_in, true); Set the calendar alarm time.
.calendarAlarmGet	g_rtc0.p_api->calendarAlarmGet(g_rtc0.p_ctrl, &get_alarm_time_struct_out); Get the calendar alarm time.
.calendarCounterStart	g_rtc0.p_api->calendarCounterStart(g_rtc0.p_ctrl); Start the calendar counter.
.calendarCounterStop	g_rtc0.p_api->calendarCounterStop(g_rtc0.p_ctrl); Stop the calendar counter.

Function Name	Example API Call and Description
.irqEnable	g_rtc0.p_api->irqEnable(g_rtc0.p_ctrl, CALLBACK); Enable the alarm irq.
.irqDisable	g_rtc0.p_api->irqDisable(g_rtc0.p_ctrl, CALLBACK); Disable the alarm irq.
.periodicIrqRateSet	g_rtc0.p_api->periodicIrqRateSet(g_rtc0.p_ctrl, Rate); Set the periodic irq rate.
.infoGet	g_rtc0.p_api->infoGet(g_rtc0.p_ctrl, clk_src); Return the currently configure clock source for the RTC.
.errorAdjustmentModeSet	g_rtc0.p_api->errorAdjustmentModeSet(g_rtc0.p_ctrl, p_mode); Set time error adjustment mode.
.errorAdjustmentSet	g_rtc0.p_api->errorAdjustmentSet(g_rtc0.p_ctrl, p_config); Set time error adjustment.
.versionGet	g_rtc0.p_api->versionGet(&version); Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function executed successfully

Name	Description
SSP_ERR_ASSERTION	API dependent error
SSP_ERR_INVALID MODE	Invalid mode.
SSP_ERR_INVALID_PTR	Invalid parameter.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.38.3 RTC HAL Module Operational Overview

The RTC HAL module controls the operation of the real-time clock module on a Synergy MCU. The typical RTC application configures the real-time clock controller periodically based on a system configuration driven by the user. Common operations include setting the time, setting an alarm, configuring a periodic interrupt, and starting or stopping operation. An RTC application usually consists of calls to the RTC HAL module and an optional callback from the ISR handler.

- The RTC HAL module can use two main clock sources
  - A Low Speed On-Chip Oscillator (LOCO) with lower power, but with less accuracy
  - A sub-clock oscillator with higher power, increased accuracy, and more cost (external crystal required)
- The RTC HAL module supports three different interrupt types
  - An alarm interrupt generated on a match of any combination of year, month, day, day of the week, hour, minute or second
  - A periodic interrupt generated every 2, 1, 1/2, 1/4, 1/8, 1/16, 1/32, 1/64, 1/128, or 1/256 second(s)
  - A carry interrupt when either a carry to the second counter occurs or when a carry to the R64CNT counter occurs during a read access to the 64 Hz counter

A user-defined callback function can be registered (in the open API call) and will be called from the interrupt service routine (ISR) for any supported interrupt type. When called, it is passed a pointer to a structure (rtc_callback_args_t) that holds a user-defined context pointer and an indication of which type of interrupt was fired.

NOTE: Carry interrupt priority must be set to avoid incorrect time returned from calendarTimeGet API during roll-over.

RTC HAL Module Important Operational Notes and Limitations

The RTC HAL module must be opened before any of the other RTC module APIs can be called. A configuration structure is passed to the open call which specifies the clock source, the name of the user callback from the ISR handler, and a user-specified context for the callback. Configuration structures can be either manually defined or generated by the ISDE based on user input during the configuration process.

Functions in the driver can be accessed by either making direct calls to the HAL layer or by using the RTC interface structure. The name of this interface structure is based on the name setting entered in the module's configuration. For example, if name = g_rtc, then the interface structure is called g_rtc_api.

The user may miss a carry event callback if a carry interrupt occurs when the calendarTimeGet API is in progress.

This module has no support for the following functions:

- Binary-count mode
- Binary alarm set and get
- Binary time get and set
- LOCLO clock-error correction
- 1 Hz/64 Hz Clock output

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.38.4 Including the RTC HAL Module in an Application

This section describes how to include the RTC HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the RTC Driver to an application, simply add it to a thread using the stacks selection sequence given in the table below. (The default name for the RTC is r_rtc0. This name can be changed in the associated Properties window.)

RTC Driver Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
r_rtc0 RTC HAL on r_rtc	Threads	New Stack> Driver> Timers> RTC HAL on r_rtc

When the RTC HAL module on r_rtc is added to the thread stack as shown in following figure, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information will be box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

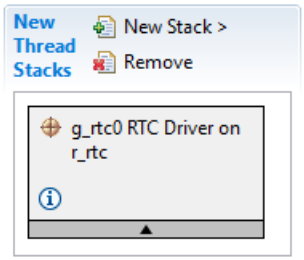

Figure 394: RTC HAL Module Stack

4.2.38.5 Configuring the RTC HAL Module

The RTC HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+.) This level of detail is not included in the configuration properties tables below, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the RTC HAL Module on r_rtc

Parameter	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.
Name	g_rtc0	The name to be used for the RTC module control block instance. This name is also used as the prefix of the other variable instances. See the example code below
Clock Source	LOCO, Sub-clock Default: LOCO	Clock source for the RTC block.
Configure RTC hardware in open() call	Yes, No Default: Yes	If enabled, the RTC registers and clock source will be initialized in the open() call. If disabled, the user call must call the configure() api to initialize the hardware.
Error Adjustment Value	0	Warning: Deprecated configuration field. Must be 0.

Parameter	Value	Description
Error Adjustment Type	None	Warning: Deprecated configuration field. Must be 0.
Callback	NULL	The name of the ISR that is called when one of the three interrupts fire. The argument passed into this ISR has an indication of which interrupt caused it to be called. See the example code below.
Alarm Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Alarm interrupt priority selection
Period Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Period interrupt priority selection
Carry Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Default: Priority 12	Carry interrupt priority selection

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for a module can be desirable. For example, it might be useful to select a different clock source than the default. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

RTC HAL Module Clock Configuration

The RTC HAL module can use the following clock sources:

- LOCO (Low Speed On-Chip Oscillator)
  - Lower-power consumption
  - Less accurate
- Sub-clock oscillator
  - Higher-power consumption

– More accurate

– More cost (requires a crystal)

The LOCO is the default selection during configuration.

RTC HAL Module Pin Configuration

The RTC doesn't currently support outputs, so no output pin selections are available.

4.2.38.6 Using the RTC HAL Module in an Application

General usage

The typical RTC application configures the real-time clock controller periodically based on a system configuration driven by the user. Examples include setting the time, setting an alarm, configuring a periodic interrupt, etc. An RTC application consists of calls to the RTC module and an optional callback.

The RTC module must be opened before any of the other APIs can be called. A configuration structure is passed to the open call which specifies the clock source, the name of the callbacks, and user-specified context for the handler. Configuration structures can be either manually defined or generated by the ISDE based on user input during the configuration process. Functions in the module can be accessed by using the RTC interface structure. The name of this interface structure is based on the name setting entered in the module's configuration.

Avoid drift issue after reset

To avoid drift in RTC time across MCU reset, the application needs to follow the steps given below.

Make these changes to module configuration settings:

1) Disable the "Configure Subclock Drive On Reset" option in the CGC stack element of the ISDE configurator.

2) Disable the "Configure RTC hardware in open() call" option in the RTC stack element of the ISDE configurator.

Make these calls in the application code:

1) Call the RTC open API as usual.

2) Call the RTC configure API only on a cold start. This will initialize the RTC only in a cold start condition.

The aforementioned steps can be performed by using the following initialization sequence in the application:

```
g_rtc.p_api->open(g_rtc.p_ctrl,g_rtc.p_cfg);
g_rtc.p_api->infoGet(g_rtc.p_ctrl,&info1);
/* initialize RTC if its status is stopped state i.e. on cold start */
if(RTC_STATUS_STOPPED == info1.status)
{
/* if the RTC clock source is sub-clock, stop it so that the sub-clock drive cap
acity is set correctly in the configure API */
       g_cgc.p_api->clockStop(CGC_CLOCK_SUBCLOCK);

       g_rtc.p_api->configure(g_rtc.p_ctrl);
       g_rtc.p_api->calendarTimeSet(g_rtc.p_ctrl,&rt_time,true);
}
```

An alternative way to determine cold start condition (instead of status) is to obtain the information from the reset status registers (RSTSRx).

Date and Time validation

The "Parameter Checking" needs to be enabled in the ISDE configurator if date and time validation is required for calendarTimeSet and calendarAlarmSet APIs. If "Parameter Checking" is enabled, the 'day of the week' field is automatically calculated and updated by the driver for the provided date. When using the calendarAlarmSet API, only the fields which have their corresponding match flag set are written to the registers. Other register fields are reset to default value.

Sub-Clock error adjustment

The errorAdjustmentModeSet and errorAdjustmentSet APIs can be used to correct the error in the RTC sub-clock source. These APIs need to be used only after the RTC is configured and time is set.

The error adjustment is reset every time RTC is reconfigured or time is set.

Usage Note: The configuration property 'Configure RTC hardware in open() call' in the RTC stack of ISDE configurator controls the behavior of open API. If enabled, the RTC peripheral is configured in the open API. If disabled, it is the responsibility of the application to make sure that RTC is configured before usage, by using the configure API.

The typical steps in using the RTC Alarm IRQ in an application are:

1) Initialize the RTC using the open API
2) Set calendar time using the calendarTime Set API
3) Set alarm time using the calendarAlarmSet API
4) Start calendar counter using the calendarCounterStart API

These common steps are illustrated in a typical operational flow diagram in the following figure:

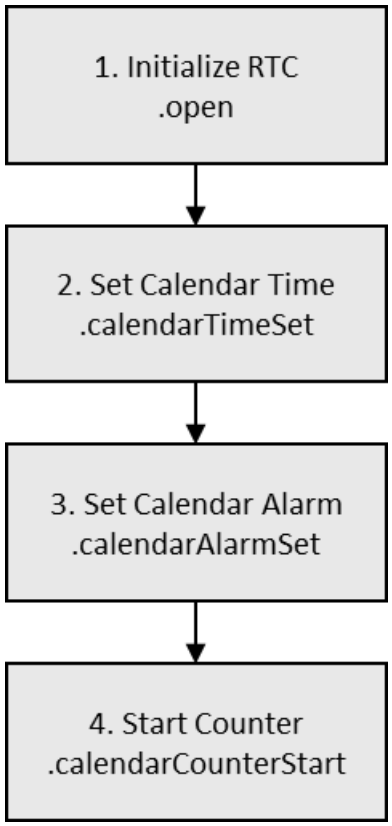

Figure 395: Flow Diagram of a Typical RTC Alarm Interrupt Application

The typical steps in using the RTC periodic IRQ in an application are:

1) Initialize the RTC using the open API
2) Set periodic IRQ rate using the periodicIrqRateSet API
3) Start calendar counter using the calendarCounterStart API
4) Enable interrupt using the irqEnable API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

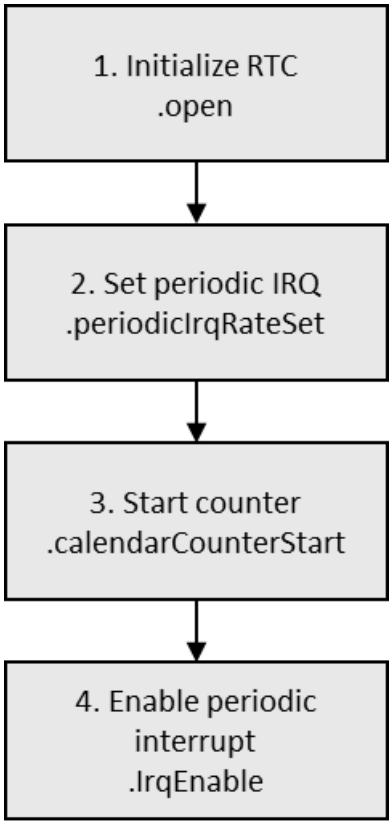

Figure 396: Flow Diagram of a Typical RTC Periodic Interrupt Application

4.2.39 SDADC Driver

The SDADC HAL module implements the ADC API for analog-to-digital conversions on r_sdadc. It supports the SDADC24 peripheral available on the Synergy microcontroller hardware. A user-defined callback can be created to process the data each time a new sample is available.

4.2.39.1 SDADC HAL Module Features

- 24-bit sigma delta A/D Converter
- Single scan or continuous scan operation mode

- Single-ended or differential input
- Gain of up to 32 on differential inputs
- Oversampling ratio configurable on differential inputs

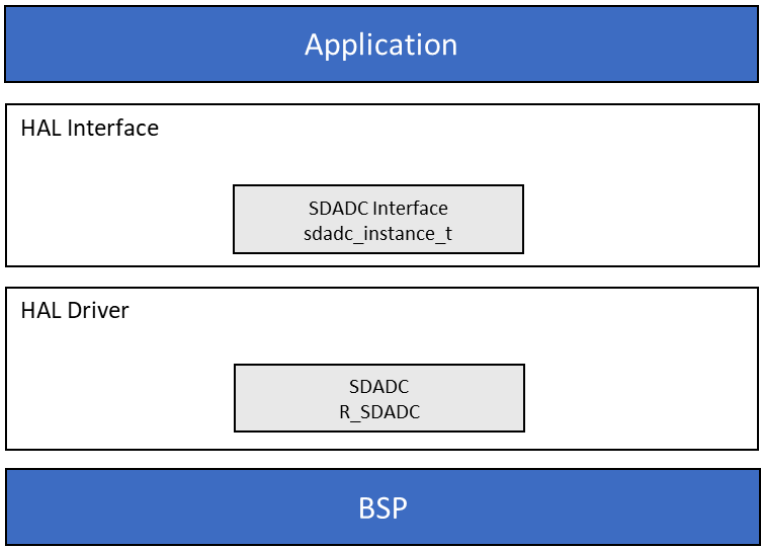

Figure 397: SDADC HAL Module Block Diagram

4.2.39.2 SDADC HAL Module APIs Overview

The SDADC HAL module defines APIs to open, configure scans, start scans, stop scans, read the conversion results the ADC scans, and close the ADC unit. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

SDADC HAL Module API Summary

Function Name	Example API Call and Description
.open	g_adc.p_api->open(g_adc.p_ctrl, g_adc.p_cfg); Initialize ADC Unit; apply power, set the operational mode, trigger sources, interrupt priority, and configurations common to all channels and sensors.
.scanCfg	g_adc.p_api->scanCfg(g_adc.p_ctrl, g_adc.*p*_channel_cfg); Configure the scan including the channels, groups and scan triggers to be used for the unit that was initialized in the open call.

Function Name	Example API Call and Description
.scanStart	g_adc.p_api->scanStart(g_adc.p_ctrl); Start the scan (in case of a software trigger), or enable the hardware trigger.
.scanStop	g_adc.p_api->scanStop(g_adc.*p_ctrl*); Stop the ADC scan (in case of a software trigger), or disable the hardware trigger.
.scanStatusGet	g_adc.p_api->scanStatusGet(g_adc.p_ctrl); Check scan status.
.read	g_adc.p_api->read(g_adc.p_ctrl, ADC_REG_CHANNEL_13, &adc_data); Read ADC conversion result.
.read32	g_adc.p_api->read32(g_adc.p_ctrl, ADC_REG_CHANNEL_13, &adc_data); Read ADC conversion result into a 32-bit word.
.sampleStateCountSet	g_adc.p_api-> sampleStateCountSet(g_adc.p_ctrl,&adc_sample); Set the sample state count for the specified channel.
.calibrate	g_adc.p_api-> calibrate(g_adc.p_ctrl, reg_id, offset); Calibrate ADC or associated PGA (programmable gain amplifier). The driver may require implementation specific arguments to the p_extend input.
.offsetSet	g_adc.p_api-> offsetSet(g_adc.p_ctrl, p_extend); Set offset for input PGA configured for differential input.

Function Name	Example API Call and Description
.close	g_adc.p_api->close(g_adc.p_ctrl); Close the specified ADC unit by ending any scan in progress, disabling interrupts, and removing power to the specified A/D unit.
.infoGet	g_adc.p_api->infoGet(g_adc.p_ctrl, &adc_info); Return the ADC data register address of the first (lowest number) channel and the total number of bytes to be read for the DTC/DMAC to read the conversion results of all configured channels.
.versionGet	g_adc.p_api->versionGet(&version); Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_NOT_OPEN	Unit is not open
SSP_ERR_ASSERTION	The parameter p_ctrl or p_sample is NULL.
SSP_ERR_IN_USE	Peripheral is still running in another mode; perform R_ADC_Close first.
SSP_ERR_INVALID_POINTER	The parameter p_data is NULL.
SSP_ERR_CALIBRATION_FAILED	Calibration failed.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.2.39.3 SDADC HAL Module Operational Overview

The SDADC HAL module controls the SDADC peripheral on a Synergy microcontroller. It directly controls the SDADC hardware without using any RTOS elements and provides convenient APIs to simplify development.

In this document, the term 'scan' refers to the AUTOSCAN feature of the SDADC, which works as follows:

1) Conversions are performed on enabled channels in ascending order of channel number. All conversions required for a single channel are completed before the sequencer moves to the next channel.
2) Conversions are performed at the rate (in Hz) of the SDADC oversampling clock frequency / oversampling ratio (configured per channel). The SSP uses the normal mode SDADC oversampling clock frequency.
3) If averaging is enabled for the channel, the number of conversions to average are performed before each conversion end interrupt occurs.
4) If the number of conversions for the channel is more than 1, performs the number of conversions requested. If averaging is enabled for the channel, each averaged result counts as a single conversion.
5) Continues to the next enabled channel only after completing all conversions requested.
6) After all enabled channels are scanned, a scan end interrupt occurs.

The driver supports single-scan and continuous scan operation modes.

- Single-scan mode performs one scan per trigger (hardware trigger or software start using scanStart).
- In continuous scan mode, the scan is restarted after each scan completes. A single trigger is required to start continuous operation of the SDADC.

Interrupts and Callbacks

When a conversion is complete and a callback is provided by the user, the SDADC HAL module calls the callback (adc_api_t::p_callback) with the argument adc_callback_args_t, indicating the unit and the event adc_cb_event_t.

The SDADC driver supports the following callback events:

- ADC_EVENT_CONVERSION_COMPLETE to notify the application that new conversion data is available.
- ADC_EVENT_SCAN_COMPLETE to notify the application when a scan is complete.
- ADC_EVENT_CALIBRATION_COMPLETE to notify the application that the calibration process is complete.

SDADC HAL Module Important Operational Notes and Limitations

Triggering a Data Transfer with the SDADC

To trigger a transfer of data when the SDADC scan completes, configure the data transfer with activation_source set to ELC_EVENT_SDADCn_SCAN_END. The ELC events are listed under elc_event_t. To retrieve the SDADC specific information to use with the transfer API, use the infoGet function call in the transfer API.

Triggering ELC Events with the SDADC

The SDADC unit can trigger the start of other peripherals listed in elc_peripheral_t. Refer to the "ELC Interface" in the SSP User's Manual for more information.

This module only works for selected Synergy MCUs. Consult the release notes for your current SSP release to see which MCUs are supported by this module. Additionally, the MCU Hardware Manual shows which peripherals are available.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.39.4 Including the SDADC HAL Module in an Application

This section describes how to include the SDADC HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the SDADC HAL module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the SDADC HAL module is g_sdadc0. This name can be changed in the associated Properties window.)

SDADC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sdadc0 SDADC Driver on r_adc	Threads	New Stack> Driver> Analog> SDADC Driver on r_sdadc

When the SDADC HAL module on r_sdadc is added to the thread stack as shown in the following figure, the configurator automatically adds any lower-level drivers that are required. Any drivers that need additional configuration information will be box-text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

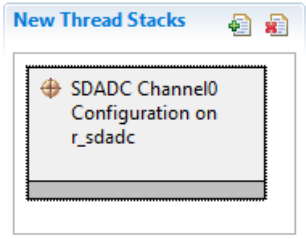

Figure 398: SDADC HAL Module Stack

4.2.39.5 Configuring the SDADC HAL Module

The SDADC HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included

in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the SDADC HAL Module on r_sdadc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.
Name	g_adc0	Module name.
Mode	Single Scan, Continuous Scan Default: Continuous Scan	In single scan mode, all channels are converted once per start trigger, and conversion stops after all enabled channels are scanned. In continuous scan mode, conversion starts after a start trigger, then continues until stopped in software.
Resolution	16 Bit, 24 Bit Default: 24 Bit	Select 24-bit or 16-bit resolution.
Alignment	Right, Left Default: Right	Select left or right alignment.
Trigger	ELC Hardware Event, Software Default: Software	Select conversion start trigger. Conversion can be started in software, or conversion can be started when a hardware event occurs if the hardware event is linked to the SDADC peripheral using the ELC API.
Vref Source	Internal, External Default: Internal	Vref can be sourced internally and output on the SBIAS pin, or Vref can be input from VREFI.

ISDE Property	Value	Description
Vref Voltage	0.8V, 1.0V, 1.2V, 1.4V, 1.6V, 1.8V, 2.0V, 2.2V, 2.4V Default: 1.0V	Select Vref voltage. If Vref is input externally, the voltage on VREFI must match the voltage selected within 3%.
Internal Calibration During Open()	Enabled, Disabled Default: Enabled	Calibration is required for all channels configured for differential input. Internal calibration is performed automatically during open for these channels unless it is disabled here.
Callback	NULL	Enter the name of the callback function to be called when conversion completes or a scan ends.
Conversion End Interrupt Priority	Priority 0 (highest), Priority 1, Priority 2, Priority 3 (lowest - not valid if using ThreadX) Default: Priority 2	Select the interrupt priority for the conversion end interrupt. [Required]
Scan End Interrupt Priority	Priority 0 (highest), Priority 1, Priority 2, Priority 3 (lowest - not valid if using ThreadX), Disabled Default: Priority 2	Select the interrupt priority for the scan end interrupt. [Required]
Calibration End Interrupt Priority	Priority 0 (highest), Priority 1, Priority 2, Priority 3 (lowest - not valid if using ThreadX), Disabled Default: Priority 2	Select the interrupt priority for the calibration end interrupt. [Required]

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SDADC Channel Configuration on r_sdadc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.
Input	Differential, Single-Ended Default: Differential	Select differential or single-ended input.
Stage 1 Gain	1,2,3,4,8, Default: 1	Select the gain for stage 1 of the PGA. Must be 1 for single-ended input.
Stage 2 Gain	1,2,3,4,8, Default: 1	Select the gain for stage 2 of the PGA. Must be 1 for single-ended input.
Oversampling	64, 128, 256, 512, 1024, 2048 Default: 256	Select the oversampling ratio for the PGA. Must be 256 for single-ended input.
Polarity (Valid for Single-Ended Input Only)	Positive, Negative Default: Positive	Select positive or negative polarity for single-ended input. VBIAS (1.0 v typical) is connected on the opposite input.
Conversions to Average per Result	Do Not Average (Interrupt after Each Conversion), Average 8, Average 16, Average 32, Average 64	Select the number of conversions to average for each result. The ADC_EVENT_CONVERSION_END event occurs after each average, or after each individual conversion if averaging is disabled.
Invert (Valid for Negative Single-Ended Input Only)	Result Not Inverted, Result Inverted Default: Result Not Inverted	Select whether to invert negative single-ended input. When the result is inverted, the lowest measurable voltage gives a result of 0, and the highest measurable voltage gives a result of 2 carrot resolution -1.

ISDE Property	Value	Description
Number of Conversions Per Scan	Default: 1	Number of conversions on this channel before AUTOSCAN moves to the next channel. When all conversions of all channels are complete, the ADC_EVENT_SCAN_END event occurs.

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

SDADC HAL Module Clock Configuration

The SDADC HAL module uses the SDADCCLK as its clock source and it must be set to 4MHz.

SDADC HAL Module Pin Configuration

To use the SDADC HAL module, the port pins for the channels receiving the analog input must be set as input pins in the pin configurator in the ISDE. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection Sequence for the SDADC HAL Module

Resource	ISDE Tab	Pin selection Sequence
SDADC	Pins	Select Peripherals > Analog:SDADC>SDADCn where n is the channel number

4.2.39.6 Using the SDADC HAL Module in an Application

Once the module has been configured and the files generated, the SDADC is ready to be used in an application.

The typical steps in using the SDADC HAL module in an application are:

1) Initialize the SDADC using open. Calibration is performed on all channels configured for differential input during this function unless calibration during open is disabled in the configuration.
2) If calibration during open is disabled in the configuration, calibrate each channel configured for differential input using calibrate. Wait for a calibration complete interrupt after calibrating each channel. See R_SDADC_Calibrate for details regarding the calibration procedure.
3) [Optional] Configure active channels using scanCfg.

4) Start a conversion using the desired trigger with scanStart.
   a) If a hardware trigger is used, this call enables the ADC unit to be triggered by the hardware trigger. If a software trigger is used, then this call starts the ADC scan.
5) The callback will be called after each conversion, and when the entire scan is complete.
6) Read the results of the conversion using read.
7) [Optional] Stop the ADC scan by calling scanStop.
   a) This prevents the ADC from being triggered by an external trigger or a hardware trigger; it also forces a stop of a software-triggered scan if one is ongoing.
8) Operate on the received data as needed by the application.
9) [Optional] Use close to power down the peripheral.

These common steps are illustrated in a typical operational flow in the following figure:

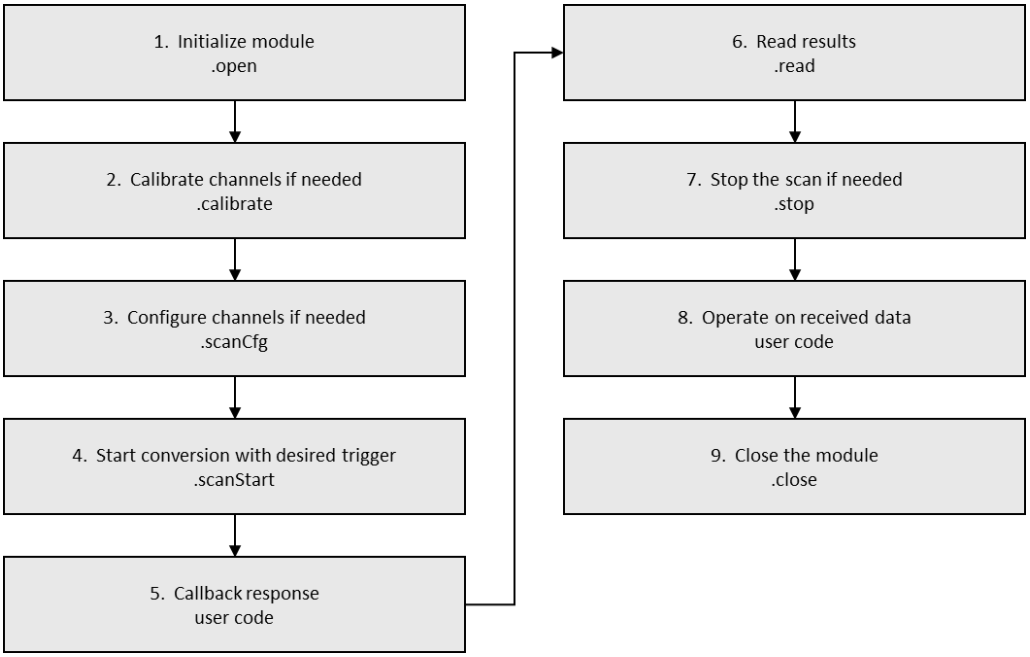

Figure 399: Flow Diagram of a Typical SDADC HAL Module Application

4.2.40 SD/MMC Driver and SDIO Driver

The SDMMC (SD/MMC and SDIO) module is implemented on r_sdmmc and is used to read/write and control SD/MMC media devices as well as SDIO cards. The SDMMC module can be used as a standalone SD card, or eMMC, media driver or it can be used with FileX™, or any other compatible file system. The r_sdmmc module uses the SD/MMC peripheral on the Synergy MCU.

4.2.40.1 SDMMC HAL Module Features

- Supports the following memory devices: SDSC (SD Standard Capacity), SDHC (SD High Capacity), SDXC (SD Extended Capacity), and eMMC (embedded Multi Media Card)
  - Supports reading, writing, and erasing SD and eMMC memory devices
  - Supports 1, 4, or 8 bit data bus (8-bit bus is supported for eMMC only)
  - Supports detection of hardware write protection (SD cards only)
  - Automatically selects between backwards compatible mode and high-speed SRD mode (eMMC)
- Supports SDIO
  - Supports SDIO single register access (CMD52)
  - Supports SDIO multiple register access (CMD53)
  - Supports SDIO interrupts
- Automatically configures the clock to the maximum clock rate supported by both host (MCU) and device

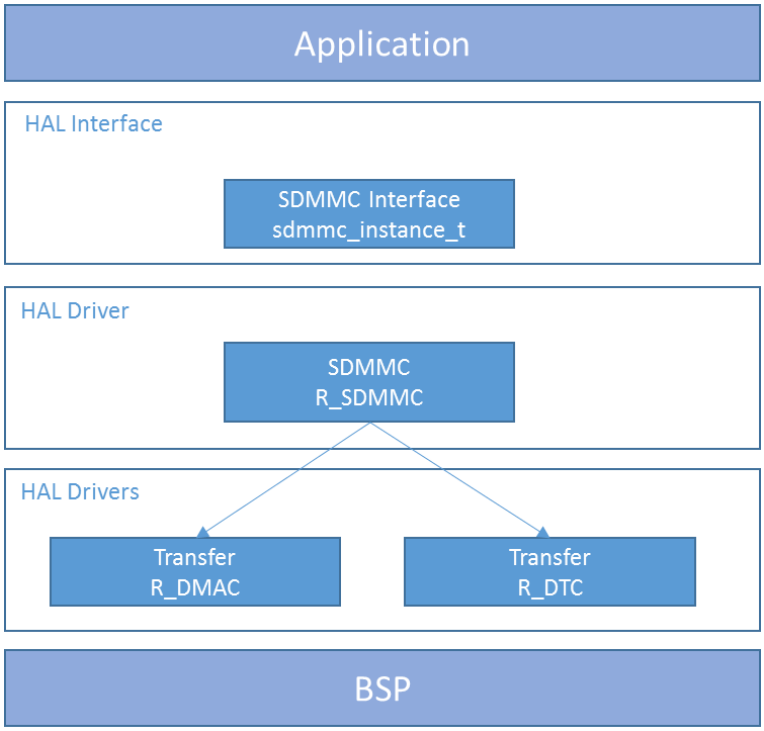

Figure 400: SDMMC HAL Organization, Options and Stack Implementations

4.2.40.2 SDMMC HAL Module APIs Overview

This document is divided into the following sections which can be read independently (by a more experienced Synergy developer) or in series (by developers new to the Synergy Platform). SD/MMC Driver and SDIO Driver APIs Overview

SD/MMC Driver API Summary

Function Name	Example API Call and Description
open	g_sdmmc.p_api->open(g_sdmmc.p_ctrl, g_sdmmc.p_cfg); Open device channel for read/write and control. Initialize driver and hardware on first call.
read	g_sdmmc.p_api->read(g_sdmmc.p_ctrl, &destination, start, count); Read data from SD/MMC channel.
write	g_sdmmc.p_api->write(g_sdmmc.p_ctrl, &source, start, count); Write data to SDMMC channel.
control	g_sdmmc.p_api->control(g_sdmmc.p_ctrl, command, &data); Send control commands to the SD/MMC port and receive the status of the SD/MMC port.
close	g_sdmmc.p_api->close(g_sdmmc.p_ctrl); Close open SDMMC channel. Turns off hardware if last channel open.
versionGet	g_sdmmc.p_api->versionGet(&version); Get version of Block Media SD/MMC driver.
readIo	g_sdmmc.p_api->readIo(g_sdmmc.p_ctrl, &data, function, address); Read I/O data from an SDMMC channel.

Function Name	Example API Call and Description
writeIo	g_sdmmc.p_api->writeIo(g_sdmmc.p_ctrl, &data, function, address, read_after_write); Write I/O data to SDMMC channel.
readIoExt	g_sdmmc.p_api->readIoExt(g_sdmmc.p_ctrl, &destination, function, address, count, transfer_mode, address_mode); Read I/O data, extended, from an SDMMC channel.
writeIoExt	g_sdmmc.p_api->writeIoExt(g_sdmmc.p_ctrl, &source, function, address, count, transfer_mode, address_mode); Write I/O data, extended, to SDMMC channel.
ioIntEnable	g_sdmmc.p_api->ioIntEnable(g_sdmmc.p_ctrl, enable); Enables SDIO interrupt for SDMMC channel.
infoGet	g_sdmmc.p_api->infoGet(g_sdmmc.p_ctrl, &info); Get SDMMC channel info.
erase	g_sdmmc.p_api->erase(g_sdmmc.p_ctrl, start, count); Erase SDMMC sectors.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables review the SSP Reference Manual listed in the Reference Section at the end of this document. For FileX API documentation refer to X-Ware and NetX Component Documents for Renesas Synergy listed in the Reference Section as well.

Error Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.

Name	Description
SSP_ERR_IN_USE	The channel specified has already been opened. No configurations were changed. Call the associated Close function or use associated Control commands to reconfigure the channel.
SSP_ERR_ASSERTION	The pointer is NULL.
SSP_ERR_WRITE_PROTECTED	SD or MMC card is Write Protected.
SF_INFO_NOT_AVAILABLE	Information not available possibly because card has been removed or is defective.
SSP_ERR_NOT_OPEN	The channel is not opened.
SSP_ERR_HW_LOCKED	The hardware lock has already been acquired.
SSP_ERR_TRANSFER_BUSY	The transfer is in progress.
SSP_ERR_CARD_NOT_READY	The card is not ready yet.
SSP_ERR_NOT_ENABLED	SDIO interrupt enable failed.
SSP_ERR_READ_FAILED	Read operation failed.
SSP_ERR_WRITE_FAILED	Write operation failed.

NOTE: Lower level drivers may return Common Error Codes. Refer to the SSP Reference Manual listed in the Reference Section at the end of this document for a definition of all relevant Error codes.

4.2.40.3 SDMMC HAL Module Operational Overview

The following descriptions cover the operational functions and requirements when using the SDMMC HAL module.

4.2.40.4 SDMMC HAL Module Interrupt Configurations

The interrupts required are:

- Using SD/MMC with DTC:
  - Access Interrupt
  - DTC Interrupt
- Using SD/MMC with DMAC:
  - Access Interrupt

  - DMAC Interrupt (in DMAC instance)
- Using SDIO with DTC:
  - Access Interrupt
  - SDIO Interrupt
  - DTC Interrupt
- Using SDIO with DMAC:
  - Access Interrupt
  - SDIO Interrupt
  - DMAC Interrupt (in DMAC instance)

The Card interrupt is optional, and only available on MCU packages that have the SDHIn CD pin (n = channel number) available on the Pins tab of the Synergy Configuration Tool.

4.2.40.5 SDMMC HAL Module Block Size Configuration

Block size configuration is provided for use with SDIO cards only. For SDIO cards, block size may be configured to 1-512 bytes. Block size must remain at the default 512 bytes for SD cards and e/MMC memory devices.

4.2.40.6 SDMMC HAL Module Card Detection Configuration

See Card Detection Limitations before using card detection in the r_sdmmc driver. If card detection is not available or not desired for the application, Card Detection must be set to Not Used in the Properties for the r_sdmmc instance in the Synergy Configuration Tool. To enable card detection, set Card Detection to CD Pin and Media Type to Card in the Properties for the r_sdmmc instance in the Synergy Configuration Tool.

4.2.40.7 SDMMC HAL Module Access Interrupt Priority

When data transfers are not 4-byte aligned or not a multiple of 4 bytes, a software copy of the block size (up to 512 bytes) is done in the access interrupt. This blocks other interrupts that are a lower or equal priority to the access interrupt until the software copy is complete.

4.2.40.8 SDMMC HAL Module General Timing Notes

Several functions in this driver block. open and erase block until the entire operation is complete. read,write,readIo,writeIo,readIoExt, and writeIoExt block for a single command response cycle. In a multithreaded system, care should be taken to use this driver in a lower priority thread if other threads require a response time faster than the time this driver could block for during one of these function calls.

4.2.40.9 SDMMC HAL Module Timing Notes for Open

The open API completes the entire device identification and configuration process. This involves several command-response cycles at a bus width of 1-bit and a bus speed of 400 kHz or less.

4.2.40.10 SDMMC HAL Module Timing Notes for Read, Write, ReadIoExt, and WriteIoExt

The read and write media (read and write) and extended read and write SDIO APIs (readIoExt and writeIoExt) block until the response is received from the device. The data transfer operation is non-blocking and requires interrupts and a transfer instance, either DMAC or DTC. These APIs return SSP_SUCCESS to indicate that the initial operations have started successfully. The application must wait for a callback with the event SDMMC_EVENT_TRANSFER_COMPLETE or SDMMC_EVENT_TRANSFER_ERROR to indicate completion of the read or write.

4.2.40.11 SDMMC HAL Module Timing Notes for ReadIo and WriteIo

The SDIO readIo and writeIo APIs block until the response is received from the device. The read or write operation is complete when these APIs return.

4.2.40.12 SDMMC HAL Module Timing Notes for Erase

The erase API blocks until the erase operation is complete. This may be several seconds or more depending on how many sectors are being erased.

4.2.40.13 SDMMC HAL Module SDIO Interrupts

Many SDIO cards use level interrupts, meaning the interrupt is not deasserted until the interrupt is cleared on the device. In order to ensure SDIO interrupts are cleared appropriately, one of the following methods are recommended:

- Ensure the SDIO interrupt is cleared on the device before exiting the callback function with the event SDMMC_EVENT_SDIO. If this method is chosen and any SDIO API must be used in the interrupt, the access interrupt must be a higher priority than the SDIO interrupt.
- Disable the SDIO interrupt in the callback function with the event SDMMC_EVENT_SDIO using IoIntEnable. Clear the SDIO interrupt elsewhere in the application, then re-enable SDIO interrupts if desired using IoIntEnable.

4.2.40.14 Important Operational Notes and Limitations

SDMMC HAL Module Operational Notes

SD HALA Compliance

When developing host devices that are compliant with the SD Specifications, the host must comply with the SD Host/Ancillary Product License Agreement (SD HALA).

SDMMC HAL Module Limitations

Data Alignment and Size

Data transfers should be 4-byte aligned and a multiple of 4 bytes in size whenever possible. This recommendation applies to the read(), write(), readIoExt(), and writeIoExt() APIs. When data transfers are 4-byte aligned and a multiple of 4-bytes, the r_sdmmc driver is zero copy and takes full advantage of hardware acceleration by the DMAC or DTC. When data transfers are not 4-byte aligned or not a multiple of 4 bytes an extra CPU interrupt is required for each block transferred (see Access Interrupt Priority).

Card Detection Limitations

Card detection support in the r_sdmmc driver is limited. Card detection is only available after open is complete, and open() cannot be completed unless a card is inserted. Card detection in the r_sdmmc driver is therefore only useful to detect card removal and reinsertion. After reinsertion is detected, the driver must be closed and reopened, and card detection will not be available until the reopen is complete. Card detection is available only on MCU packages that have the SDHIn CD pin (n = channel number) available on the Pins tab of the Synergy Configuration Tool. If the MCU does not have the SDHIn

CD pin, or card detection is not desired for the application, card detection must be disabled in the Properties for the r_sdmmc instance in the Synergy Configuration Tool. An alternative to using the card detection feature of the r_sdmmc driver is to use an External IRQ instance and handle card detection at the application layer. If card detection is handled at the application layer, the open should be called after card insertion is detected, and the close should be called after card removal is detected.

Refer to the most recent SSP Release notes for the most up to date limitations for this module.

4.2.40.15 Including the SDMMC HAL Module in an Application

This section describes how to include the SDMMC HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the "SSP User's Manual", available as described in the Reference Section at the end of this document to learn how to manage each of these important steps in creating SSP based applications.

To add the module to an application, simply add it to a thread using the Stacks Selection Sequence given in the following table. (The default name for the modules is shown in the following table. This name can be changed in the associated Properties window). When the driver is added it shows up in the thread as illustrated in the following figure.

Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sdmmc0 SD/MMC driver on r_sdmmc	Threads	New Stack> Driver> Storage> SD/MMC Driver on r_sdmmc

When the SD/MMC driver on r_sdmmc is added to the Thread Stack, as shown in the following figure, the configurator automatically adds the needed lower level drivers. Any drivers that need additional configuration information will be box text highlighted in red. Modules with a gray band are individual modules that stand alone. Modules with a blue band are shared or common and need only be added once, since they can be used by multiple stacks. Modules with a pink band can require the selection of lower level drivers. Sometimes these are optional or recommended and this is indicated in the block with the inclusion of this text. If the addition of lower level drivers is required, the module description will include "Add" in the text. Clicking on any pink banded modules will bring up the "New" icon and then will show the possible choices.

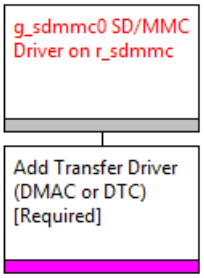

Figure 401: SD/MMC Driver on r_sdmmc Stack

4.2.40.16 Configuring the SDMMC HAL Module

The module must be configured by the user for the desired operation. The SSP configuration window will automatically identify, by highlighting the block in red, any required configuration selections, such as Interrupts or operating modes, which must be configured for lower level modules, for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the properties tab within the SSP Configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the Interrupt Priority. This configuration setting is available with the Properties window of the associated module. Simply select the indicated module and then view the properties window. The Interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the Interrupt Priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the below configuration properties tables, but is easily visible with the ISDE when configuring Interrupt Priority levels.

NOTE: You may want to open your ISDE and create the SDMMC HAL module and explore the property settings in parallel with reviewing the following table. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration for the SD/MMC and SDIO Driver

ISDE Property	Setting	Description
Parameter Checking	Enabled, Disabled, BSP (Default: BSP)	Selects if code for parameter checking is to be included in the build
Name	Default: g_sdmmc0	Module name
Channel	0,1 (Default: 1)	Channel of SDMMC peripheral, channel 0 or 1
Media type	Embedded, Card (Default: Embedded)	Media is a card or an embedded device. This allows to firmware to know whether to look for card insertion/removal and write protect pins.
Bus Width	1 bit, 4 bits, 8 bits	Data bus with as defined by hardware interface. (8 Bits for eMMC only)
Block Size	512	Size of block

ISDE Property	Setting	Description
Callback	NULL (default) Name of user callback function.	(Not required if using FileX) Set to name of user callback function. Provides event that caused interrupt: SDMMC_EVENT_CARD_REMOVED, SDMMC_EVENT_CARD_INSERTED, SDMMC_EVENT_ACCESS, SDMMC_EVENT_SDIO, SDMMC_EVENT_TRANSFER_COMPLETE, SDMMC_EVENT_TRANSFER_ERROR
Access Interrupt Priority	Priority level 0-15 (Default: Disabled)	Interrupt level priority required for reading, writing, and errors for SD, eMMC and SDIO. Calls the interrupt callback if enabled.
Card Interrupt Priority	Priority level 0-15 (Default: Disabled)	(Optional) Interrupt for card removal. Automatically closes device when card is removed. Calls the interrupt callback if enabled.
DMA Interrupt Priority	Priority level 0-15 (Default: Disabled)	Interrupt priority level required for SDIO reading, writing, and errors. Calls the interrupt callback if enabled. Not used for memory cards.

NOTE: The examples and defaults listed apply to projects using the Synergy S7 MCU. Other MCUs may have different default values and available configuration settings.

4.2.40.17 SDMMC HAL Module Clock Configuration

The SDMMC MCU peripheral (SDHI) uses PCLKA for its clock source. There is no need to configure the clock specifically for the SDMMC peripheral, unless you need to optimize the data rate. The SDMMC driver selects the appropriate built-in divider based on the PCLKA frequency and the maximum clock rate allowed by the SD, SDIO, or eMMC device, obtained at media device initialization.

4.2.40.18 SDMMC HAL Module Pin Configuration

Use the ISDE pin configurator to configure the I/O pins for SDMMC peripheral (SDHI). The drive capacity for each pin should be set to "Medium" or "High" for most boards and high-speed memory and SDIO devices. The following tables illustrate the method for selecting the pins and configuring the pins within the associated SSP configuration window.

NOTE: The Operation Mode selection mode determines what peripheral signals are available and thus what MCU pins are required.

Pin Selection Sequence for SDHI Peripheral

Resource	ISDE Tab	Pin selection Sequence
SDHI	Pins	Select **Peripherals > Storage:SHDI > SDHI0**

NOTE: The selection sequence assumes the SCI1 is the desired hardware target for the driver.

Pin Configuration Settings for SDHI Peripheral

Pin Configuration Property	Settings	Description
Operation Mode	Disabled,	Select mode as per application
	Custom,	
	SD_MMC 1 bit	
	SD_MMC 4 bit	
	MMC 8 bit (Default: Custom)	
CLK	None, P413 (Default: P413)	Clock Pin
CMD	None, P412 (Default: P412)	Command Pin
DAT0-7	None, PXXX (Default: PXXX)	Data Pin
CD	None, P903 (Default: P903)	Card detection Pin
WP	None, P414 (Default: P414)	Card write protection pin

NOTE: The settings listed apply to a project using the Synergy S7G2 MCU and the DK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.40.19 Using the SDMMC HAL Module in an Application

The typical steps for using the r_sdmmc driver with an SD or eMMC memory device are:

1) Open the driver using the open API.
2) Read data from the card using the read API or write data to the card using write API.

3) Wait for a callback with the event SDMMC_EVENT_TRANSFER_COMPLETE (meaning the operation completed successfully) or SDMMC_EVENT_TRANSFER_ERROR (meaning the operation did not complete successfully) after each time the read API or the write API is called.

These common steps are shown in a typical operational flow in the following figure.

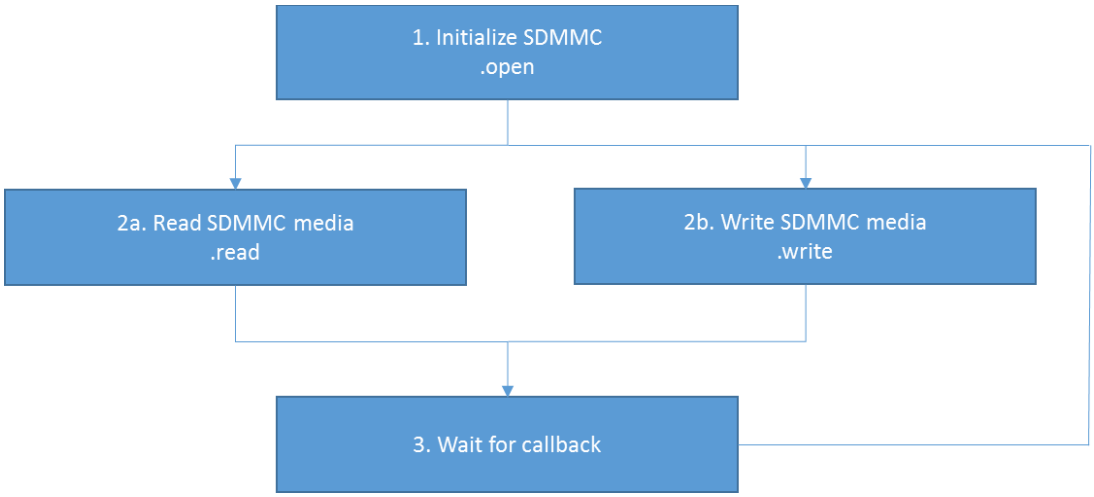

Figure 402: Flow for Typical SDMMC HAL Module Application for SD or

eMMC memory devices"

The typical steps for using the r_sdmmc driver with an SDIO card are:

1) Open the driver using the open API.
2) Set or read back single registers using the readIo API or the writeIo API. The operation is complete immediately after these calls and there is no need to wait for a callback.
3) Set or read back multiple registers using the readIoExt API or the writeIoExt API. The block size can be changed using the control API between calls if necessary.
4) Wait for a callback with the event SDMMC_EVENT_TRANSFER_COMPLETE (meaning the operation completed successfully) or SDMMC_EVENT_TRANSFER_ERROR (meaning the operation did not complete successfully) after each time the readIoExt API or the writeIoExt API is called.
5) If the card requests an interrupt, the callback is called with the event SDMMC_EVENT_SDIO. Handle the SDIO interrupt as described in the documentation for the card (see the SDIO Interrupts section of this documentation). SDIO interrupts from the card can be enabled or disabled at any time using the IoIntEnable API.

These common steps are illustrated in a typical operational flow diagram in the following figure.

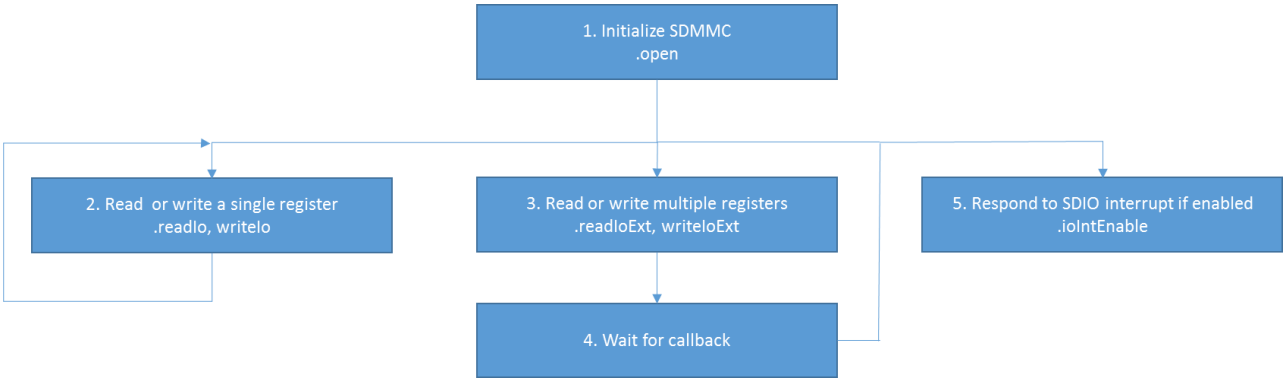

Figure 403: Flow for Typical SDMMC HAL Module Application for SDIO Card

4.2.40.20 FileX Port Block Media Framework Application Project

The Application Project associated with this Module Guide demonstrates the above steps in a full design. The project can be found using the link provided in the Reference Section at the end of this document. You may want to import and open the Application Project within ISDE and view the configuration settings for the FileX Port Block Media Framework Module. You can also read over the code, in sdmmc_thread_entry.c, which is used to illustrate the FileX on Block Media API's in a complete design.

The Application Project demonstrates the typical use of the FileX on Block Media Framework APIs. The Application Project auto-generated code initializes FileX framework using the FileX Port Block Media Framework. It is a driver which aims to implement FileX-specific accesses using the Block Media Framework. The underlying implementation of the Block Media Framework uses SD/MMC Driver. Specifically, the Application Project is designed to work with onboard eMMC memory, however it is easy to change configuration settings to access SD card. The following table identifies the target versions for the associated software and hardware used by the Application Project.

Software and Hardware Resources Used by the Application Project

Resource	Revision	Description
e^2 studio	5.3.1.002	Integrated Solution Development Environment
IAR Workbench	7.71.1.11989	IAR Workbench IDE for Synergy platform
SSP	1.2.0	Synergy Software Platform
SSC	5.3.1.002	Synergy Standalone Configurator
DK-S7G2	3.0	Development Kit

A simple flow diagram of the Application project is given in the following figure, below.

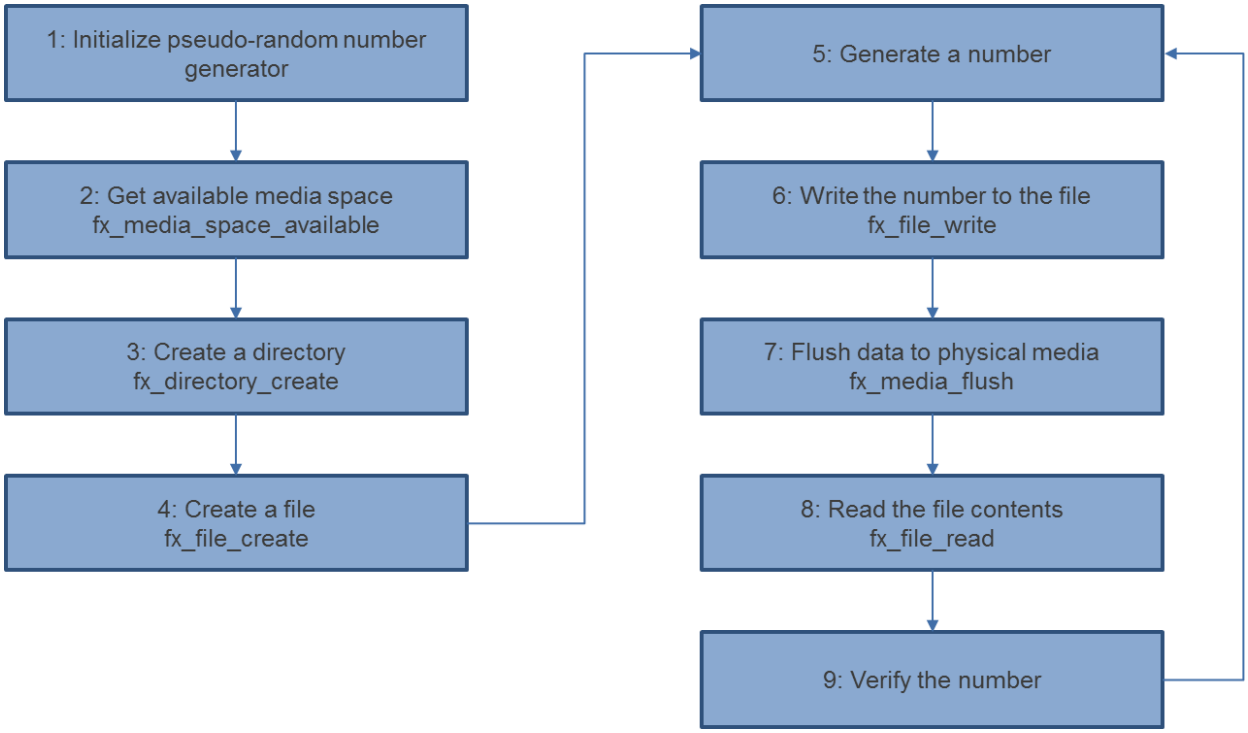

Figure 404: FileX Port Block Media Application Project Flow Diagram

NOTE: FileX initialization is done automatically in the generated code.

The complete Application Project can be found using the link provided in the Reference Section at the end of this document. The sdmmc_thread_entry.c file is located in the project once it has been imported into the ISDE. You can open this file, within the ISDE, and follow along with the below description, to help identify key uses of APIs.

The first section of sdmmc_thread_entry.c has the header files which references the FileX Media structure and a code section which allows semi-hosting to display results using printf(). The next section contains macro constants and variable definitions. Afterwards there are function prototypes. The first function generates a pseudo-random number. Then two functions for two-way conversion between integers and strings are defined. There is also simple code section for error handling. If the semi-hosting is enabled, it displays the error code. The next function is used for writing a number to a file. At first, the number is converted into a string. Then it accesses FileX APIs in order to open, clear, write, close the file and flush data to physical media. The last step is necessary because FileX operations are buffered and after reset, not all recent changes might be reflected. Alternatively, FileX flushes data when fx_media_close is called. The following function is very similar to the previous one, except it is used for reading a number from given file instead of performing a write.

The last section is the thread entry function section. At the beginning, pseudo-random number generator is initialized using predefined number. If the semi-hosting is enabled, available space is displayed. Then the application needs to create a file, but beforehand a directory is created. Then the software enters the 'forever' while loop, it starts with generating a number. This number is then written to the previously created file. Afterwards the number is read and verified with the generated one. In case of error the message is provided. Then a thread sleep function pauses execution for several ThreadX timer ticks and then the while loop functions are repeated.

NOTE: The above description assumes you are familiar with using printf() the Debug Console in the Synergy Software Package. If you are unfamiliar with this, refer to the "How do I Use Printf() with the Debug Console in the Synergy Software Package" given in the Reference Section at the end of this document. Alternatively, the user can see results via

the watch variables in the debug mode.

A few key properties are configured in this Application Project to support the required operations and the physical properties of the target board and MCU. Below are the properties with the values set for this specific project. You can also open the Application Project and view these settings in the property window as a hands-on exercise.

FileX Port Block Media Framework Configuration Settings for the Application Project

ISDE Property	Value Set
Name	g_fx_media
Format System is on SDMMC	True
Volume Name	Volume 1
Number of FATs	1
Directory Entries	256
Hidden Sectors	0
Total Sectors	500000
Bytes per Sector	512
Sectors per Cluster	1
Working media memory size	512

SD/MMC Driver on r_sdmmc Configuration Settings for the Application Project

ISDE Property	Value Set
Parameter Checking Enable	Default (BSP)

4.2.41 Segment LCD Driver

The Segment LCD Controller HAL module provides high-level APIs for Segment LCD applications and is implemented on r_slcdc. The Segment LCD Controller HAL module displays data on a Segment LCD and modifies the displayed data. The Segment LCD Controller HAL module uses the Segment LCD Controller module on a Synergy MCU.

4.2.41.1 SLCDC HAL Module Features

The SLCDC HAL module uses the Segment LCD Controller (SLCDC) to display data on a Segment LCD. The driver initializes the LCD for displaying data and configures the drive-voltage generator, the display waveform, the number of time slices, and the bias methods to drive the LCD. This module provides functions to display data to a specified set of segments, to update existing segment data, to enable and disable display, to set the display area, and to adjust the contrast.

This module supports the following features:

- Internal voltage-boosting for the LCD driver voltage generator: select the capacitor split method or the external resistance division.
- Display bias: select the 1/2 bias method, 1/3 bias method, or 1/4 bias method.
- Time slice of the display: select static, 2-time slice, 3-time slice, 4-time slice, or 8-time slice.
- Display waveform: select waveform A or waveform B.
- Display data area: select A-pattern, B-pattern, or blinking. You can switch the display data area.
- Use the RTC periodic interrupt (PRD) to generate a blinking display with A-pattern and B-pattern.
- Adjust the reference voltage (which is generated when operating the voltage boost circuit) in 16 steps (contrast adjustment).

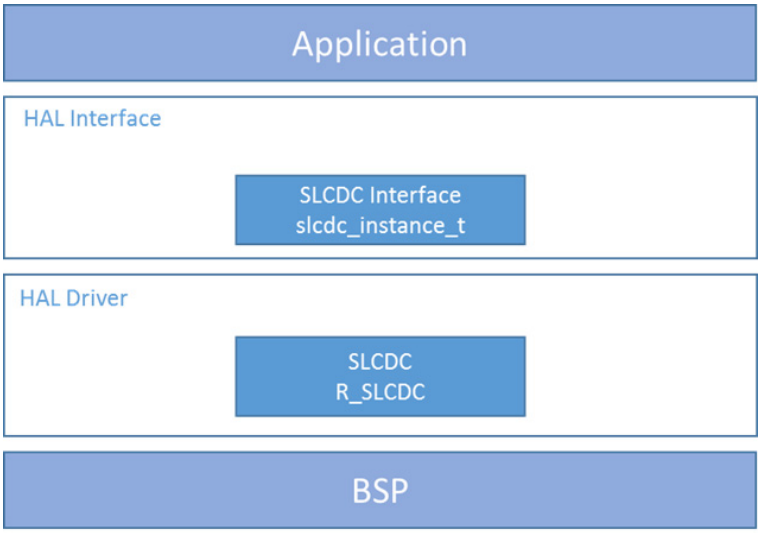

Figure 405: SLCD HAL Module Block Diagram

4.2.41.2 SLCDC HAL Module APIs Overview

The Segment LCD Controller HAL module defines APIs for functions such as opening, writing, starting, modifying, and closing. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows.

SLCDC HAL Module API Summary

Function Name	Example API Call and Description
open	g_slcdc.p_api->open(g_slcdc.p_ctrl, g_slcdc.p_cfg); Open SLCD device.
write	g_slcdc.p_api->write(g_slcdc.p_ctrl, start_segment, &data, segment_count); Write data to SLCD segments. Specifies the initial display data. The data parameter is a pointer to an array of bytes consisting at least segment_count items, in which each byte is associated with one segment data register. When the number of time slices is static, 2, 3 or 4, the lower 4 bits of the data become an A-pattern area and the upper 4 bits become a B-pattern area. See .setdisplayArea for setting a display area.
modify	g_slcdc.p_api->modify(g_slcdc.p_ctrl, segment, data_mask, data); Rewrite data in the SLCD segment. Rewrites the LCD display data in 1-bit units. If a bit is not specified for rewriting, the value stored in the bit is held as it is. Specifies the data to rewrite.
start	g_slcdc.p_api->start(g_slcdc.p_ctrl); Enable display on the SLCD. Displays the specified data on the LCD. Before that data should be written to the segments.

Function Name	Example API Call and Description
stop	g_slcdc.p_api->stop(g_slcdc.p_ctrl); Disable display on the SLCD. Stops displaying data on the SLCD.
contrastIncrease	g_slcdc.p_api->contrastIncrease(g_slcdc.p_ctrl); Increase the display contrast. Increase by 1 unit. This function can be selected when the internal voltage boosting method is used for the drive voltage generator.
contrastDecrease	g_slcdc.p_api->contrastDecrease(g_slcdc.p_ctrl); Decrease the display contrast. Decrease by 1 unit. This function can be selected when the internal voltage boosting method is used for the drive voltage generator.
setdisplayArea	g_slcdc.p_api->setdisplayArea(g_slcdc.p_ctrl, display_area); Set LCD display area. This function sets a specified display area, A-pattern or B-pattern. This function can be used to set blink on where A-pattern and B-pattern area data will be alternately displayed. When using blinking, the RTC is required to operate before this function is executed. To configure the RTC, follow the steps below. 1) Open RTC 2) Set Periodic interrupt request, ½ second 3) Start RTC counter 4) Enable IRQ, RTC_EVENT_PERIODIC_IRQ Refer to the User's Manual: Microcontrollers for the detailed procedure.
close	g_slcdc.p_api->close(g_slcdc.p_ctrl); Close display device.

Function Name	Example API Call and Description
versionGet	g_slcdc.p_api->versionGet(&version); Retrieve the API version using the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful
SSP_ERR_ASSERTION	Assertion error
SSP_ERR_INVALID_ARGUMENT	Invalid Argument
SSP_ERR_HW_LOCKED	SLCDC resource is locked
SSP_ERR_NOT_OPEN	Device is not opened or initialized
SSP_ERR_UNSUPPORTED	Unsupported operation
SSP_ERR_NOT_ENABLED	RTC not enabled for blink operation

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.41.3 SLCDC HAL Module Operational Overview

This module uses the Segment LCD controller (SLCDC) to display data on a Segment LCD. The driver initializes the LCD for displaying data and configures the drive-voltage generator, the display waveform, the number of time slices, and the bias methods to drive the LCD. This module provides functions to display data to a specified set of segments, to modify existing segment data, to enable and disable display, to set the display area, and to adjust the contrast. The information displayed on the LCD can be modified by changing the contents of the LCD display data registers.

SLCDC HAL Module Important Operational Notes and Limitations

- This driver is a HAL driver and has no dependencies with the ThreadX RTOS. You can add the Segment LCD HAL module to a thread in the ThreadX RTOS if it is desirable.

- To write to a sequence of segments, give start segment number and number of segments to be written in the write API.
- There are no known limitations in the SLCDC HAL module.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.41.4 Including the SLCDC HAL Module in an Application

This section describes how to include the Segment LCD Controller HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the *Getting Started Guide for SSP* listed in the References section at the end of this document to learn how to manage each of these important steps in creating SSP-based applications.

To add the Segment LCD Controller HAL Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Segment LCD HAL module is g_slcdc0. This name can be changed in the associated **Properties** window.)

SLCD HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_slcdc0 Segment LCD Driver on r_slcdc	**Threads**	**New Stack> Driver> Graphics> Segment LCD Driver on r_slcdc**

When the Segment LCD Controller HAL Module on r_slcdc is added to the Thread Stack as shown in the figure below, the configurator automatically adds the needed lower-level modules. Any drivers that need additional configuration information will be highlighted in Red. Modules with a Gray band are individual modules that stand alone.

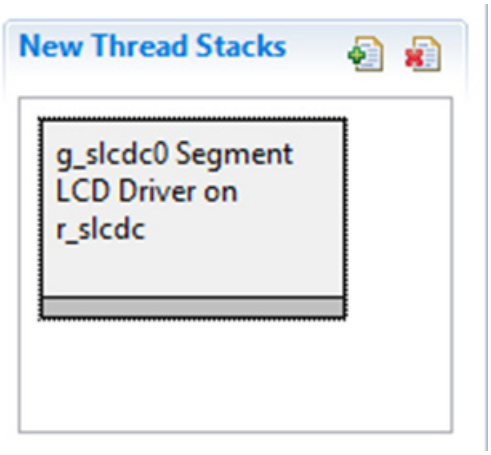

Figure 406: SLCD HAL Module Stack

4.2.41.5 Configuring the SLCDC HAL Module

The SLCD Controller HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify *by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the **Properties** window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the **Properties** tab within the SSP Configurator, and are shown in the following tables for easy reference.

NOTE: You may want to open your ISDE and create the Segment LCD Controller HAL module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the SLCDC HAL Module on r_slcdc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Select if extra code will be added to check parameter values
Name	g_slcdc0	Module Name
Slcdc Clock	Clock LOCO, Clock SOSC, Clock MOSC, Clock HOCO (Default: Clock HOCO)	SLCD clock source (LCDSCKSEL)
Slcdc Clock Divisor	Clk Divisor LOCO 4/8/16/32/64/128/256/512/1,024 Clk Divisor HOCO 256/1,024/2,048/4,096/8,192/16,384/32,768/65,536/13,1072/262,144/524,288 (Default: Clk Divisor Hoco 16,384)	LCD clock setting (LCDC0), clock divisor
Bias Method	Bias 2, Bias 3, Bias 4 (Default: Bias 2)	LCD display bias method select (LBAS bit)

ISDE Property	Value	Description
Time Slice	Static, Slice 2, Slice 3, Slice 4 (Default: Static)	Time slice of LCD display select (LDTY bit)
Wave Form	Wave A, Wave B (Default: Wave A)	LCD display waveform select (LWAVE bit)
Slcdc Drive Voltage Generator	External resistance division, Internal voltage boosting, Capacitor Split (Default: External resistance division)	LCD Drive Voltage Generator Select (MDSTET bit)

NOTE: The example settings and defaults are for a project using the Synergy S3A7 MCU and the DK-S3A7 Kit. Other MCUs may have different default values and available configuration settings.

SLCDC HAL Module Clock Configuration

The SLCDC clock cannot be configured from the **Clocks** Tab. Configure the clock in the **Properties** window of the g_slcdc driver. The operating clock of the Segment LCD HAL Module is specified by the SLCDC Clock and SLCDC Clock Divisor settings in the **Properties** window. The Segment LCD HAL module-source clock can be configured as the main (MOSC), HOCO (high-speed clock oscillator), LOCO (Low-speed clock oscillator), or sub-clock (SOSC) using the ISDE configurator. For HOCO and LOCO settings, several clock divisors are available.

SLCDC HAL Module Pin Configuration

The SLCDC peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the pins.

NOTE: For some peripherals, the operation mode selection determines what peripheral signals are available and thus what MCU pins are required.

Pin Selection Sequence for the SLCDC HAL Module

Resource	ISDE Tab	Pin selection Sequence
SLCDC	Pins	Select **Peripherals > Graphics: SLCDC > SLCDC0**

NOTE: The selection sequence assumes SLCDC0 is the desired hardware target for the driver.

Pin Configuration Settings for the SLCDC HAL Module

Pin Configuration Property	Value	Description
Operation Mode	Disabled, Custom, Static, 2x Slice, 3x Slice, 4x Slice, 8x Slice (Default: Custom)	Select operation mode enable or disable
CAPH	None, P111 (Default: None)	Capacitor connection pin
CAPL	None, P112 (Default: P112)	Capacitor connection pin
COM0:3	None, Pn (Default: P104:107)	Common pins
COM4:7	None, Pn (Default: None)	Common pins
VL1:4	None, Pn (Default: P100:103)	Power supply pins
SEG00:02, SEG06:07, SEG16:17, SEG21:25, SEG46:51	None, Pn (Default: None)	Segment pins

Pin Configuration Property	Value	Description
SEG03	None, P303 (Default: P303)	Segment pin
SEG04:05	None, Pn (Default: P314:315)	Segment pins
SEG08	None, P902 (Default: P902)	Segment pin
SEG09:15	None, Pn (Default: P312:306)	Segment pins
SEG18:19	None, Pn (Default: P808:809)	Segment pins
SEG20	None, P313 (Default: P313)	Segment pin
SEG26:27	None, Pn (Default: P806:807)	Segment pins
SEG28:34	None, Pn (Default: P608:614)	Segment pins
SEG35:41	None, Pn (Default: P606:600)	Segment pins
SEG42:43	None, Pn (Default: P805:804)	Segment pins

Pin Configuration Property	Value	Description
SEG44:45	None, Pn (Default: P800:801)	Segment pins

NOTE: The example settings are for a project using the Synergy S3A7 MCU and the DK-S3A7 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.41.6 Using the SLCDC HAL Module in an Application

The typical steps in using the Segment LCD Controller HAL module in an application are:

1) Initialize the SLCDC HAL module using the open API
2) Write a sequence of segments using the write API
3) Change the display area or blinking display using the setdisplayArea API
4) Enable the display by using the start API
5) Adjust contrast using the contrastIncrease or contrastDecrease APIs
6) Disable the display by using the stop API
7) Close the driver using the close API

These common steps are illustrated in a typical operational flow diagram in the figure below:

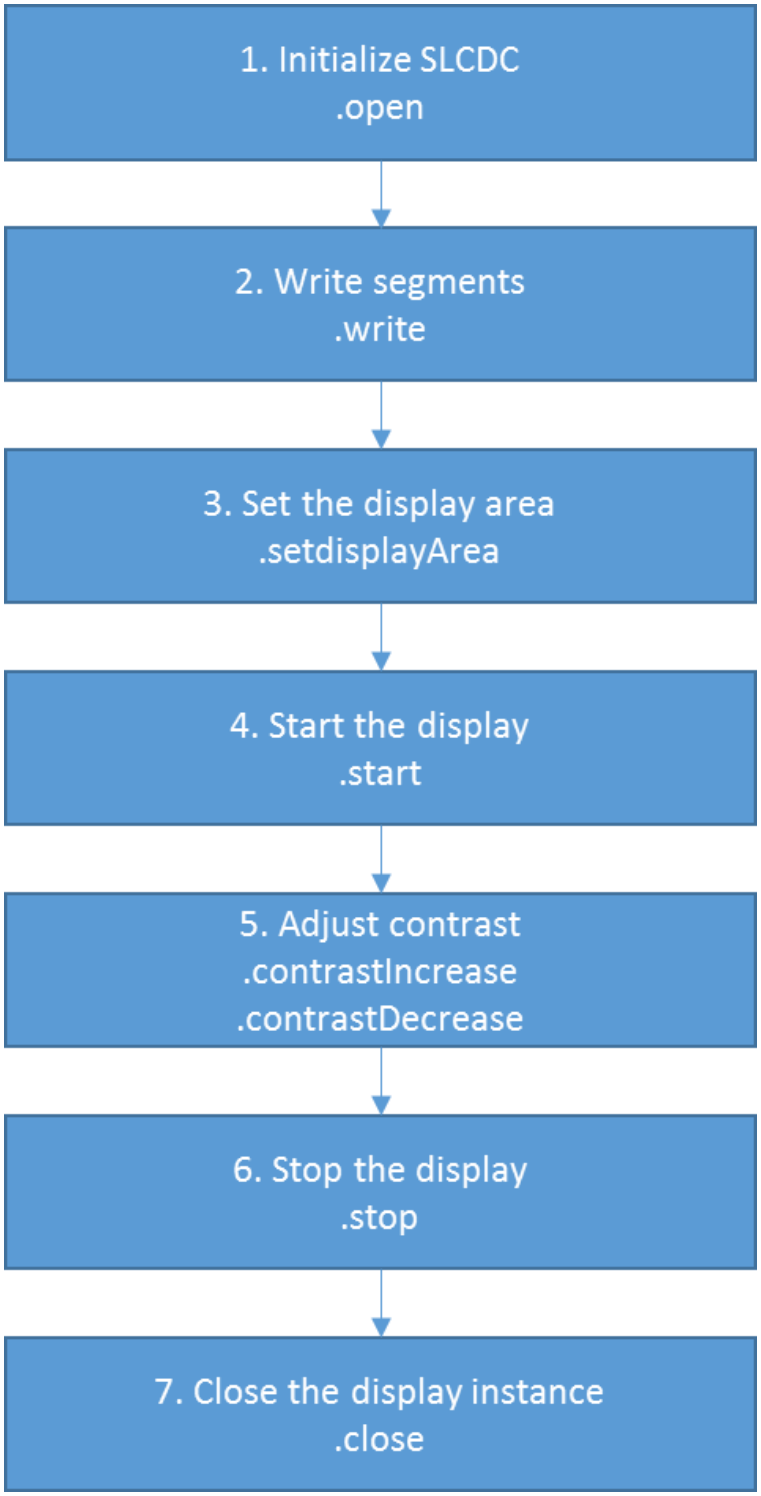

Figure 407: Flow Diagram of a Typical Segment LCDC HAL Module Application

4.2.42 SCI SPI Driver

The SCI SPI HAL module provides high-level APIs for master-based SPI serial communications and is implemented on the r_sci_spi (simple SPI) module. The SCI SPI HAL module configures and controls the SPI functionality of a Synergy MCU using the SCI (Serial Communications Interface) peripheral. The module is configured in the ISDE. A user-defined callback can be created to signal when the SPI has transmitted data, aborted a data transfer, or detected an error condition.

The SCI SPI HAL modules are enabled with a data transfer support by incorporating the DTC HAL module of the MCU. This performs SCI SPI transfer through DTC without intervention of the CPU.

4.2.42.1 SCI SPI HAL Module Features

The SCI SPI HAL module supports the configuration and control of the various SPI functionality on the Synergy MCU. Key features include the following:

- Driver initialization
- Serial communication through SPI operation using 8-bit data transfers
- Configurable among four clock phase and clock polarity settings
- Support for callbacks. The callback functions are called with the following events:
  - Transfer aborted
  - Transfer complete
  - Over run error
- SPI communication in master mode.

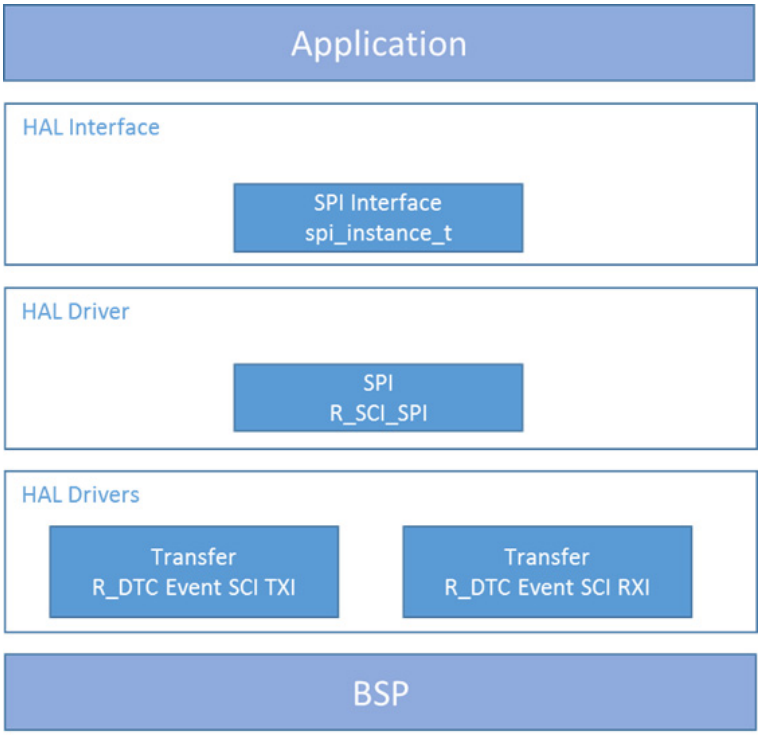

Figure 408: SCI SPI HAL Module Block Diagram

4.2.42.2 SCI SPI Module APIs Overview

The SPI defines APIs for opening and closing the SCI peripheral and transmitting and receiving data. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows.

SCI SPI HAL Module API Summary

Function Name	Example API Call and Description
open	g_spi.p_api->open(g_spi.p_ctrl, g_spi.p_cfg); Opens the SPI driver and initializes the hardware.
close	g_spi.p_api->close(g_spi.p_ctrl); Closes the driver and releases the SPI device.
read	g_spi.p_api->read(g_spi.p_ctrl, &read_buffer, number_of_bytes_to_read, bit_width); Performs a read operation on an SPI device.

Function Name	Example API Call and Description
write	g_spi.p_api->write(g_spi.p_ctrl, &write_buffer, number_of_bytes_to_write, bit_width); Performs a write operation on an SPI device.
writeRead	g_spi.p_api->writeRead(g_spi.p_ctrl, &read_buffer, &write_buffer, number_of_bytes_to_read_and_write, bit_width); Performs a read and write (full duplex) operations on an SPI device.
versionGet	g_spi.p_api->versionGet(&version); Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_IN_USE	Attempted to open an already open device instance OR Another transfer was in progress.
SSP_ERR_INVALID_POINTER	p_version is NULL.
SSP_INVALID_ARGUMENT	Channel number invalid.
SSP_ERR_HW_LOCKED	The lock could not be acquired. The channel is busy.
SSP_ERR_CH_NOT_OPEN	The channel has not been opened. Open channel first.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.42.3 SCI SPI HAL Module Operational Overview

The SCI SPI interface provides the ability to configure and use the SPI functionality of the Synergy MCU. The HAL module enables communication with a peripheral device using the SPI communications protocol. After opening the SCI SPI HAL module instance, the SCI SPI module handle is used to perform various transfer operations. The device control handle will be used within the API calls to indicate the specific SCI SPI device to communicate with.

The Driver allows the user to:

- Initialize the driver.
- Serial Communication through SPI operation. Read from and write to (and simultaneous read/write – full duplex) a SPI device – performed by calling the read, write, and writeRead APIs.

The Driver also provides support for callbacks. The callback functions are called with the following events:

- Transfer aborted
- Transfer complete
- Overrun error

The SCI SPI Modules support only 8-bit data transfer operations. SCI SPI Modules uses GPIO pins configured as chip selects.

Clock settings:

The SCI SPI uses PCLKA as its clock source. You can set the PCLKA frequency using the clock configurator in e^2 studio or the CGC Interface at run-time.

IO Port settings:

To use with the SPI, the I/O port pin(s) used as output pins must be configured as SCI SPI peripheral pins in the pin configurator. For external chip select, configure Chip select pin as GPIO output.

SCI SPI Interrupts:

To enable interrupts of SCI SPI, highlight the driver module and set the priority of the SCI RXI, TXI, TEI and ERI interrupts on the Threads tab of the Project Configurator in e^2 studio: Configuring Interrupts.

This sets the corresponding interrupts in ssp_cfg/bsp/bsp_irq_cfg.h to the priority level selected.

ATTENTION: Setting the interrupts to different priority levels could result in improper operation.

SCI SPI HAL Module Important Operational Notes and Limitations

- Chip select outputs are supported using GPIOs
- The SPI on SCI module uses only 8-bit data transfers.
- Setting the interrupts to different priority levels could result in improper operation.
- The SCI SPI HAL module is enabled with a data transfer support by incorporating the Data Transfer Controller module of the MCU. This performs SPI transfers through the DTC without intervention of the CPU. The DTC transfer is enabled by default, the user has to remove it from the configurator for an IRQ mode transfer.
- When implementing SPI on SCI, only the master mode is supported.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.42.4 Including the SCI SPI HAL Module in an Application

This section describes how to include the SPI HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack.

To add the SPI Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for a SPI is g_spi0. This name can be changed in the associated Properties window.)

SPI Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_spi0 SPI Driver on g_sci_spi	Threads	New Stack> Driver> Connectivity> SPI Driver on g_sci_spi

When the SPI HAL module is added to the thread stack as shown in the following figure, the configurator automatically adds the needed lower-level drivers. Any drivers that need additional configuration information will be highlighted in Red. Modules with a Gray band are individual modules that stand alone.

The following figure shows the SPI on SCI drivers added to the HAL/Common Thread. The resource name is g_spi0. The SPI HAL module can support a transfer driver, whereas the data-transfer controller can be used to transmit and receive data between the hardware peripherals and data buffers in RAM (rather than the CPU performing the transfers.) By default, a transfer driver is added for both transmit and receive.

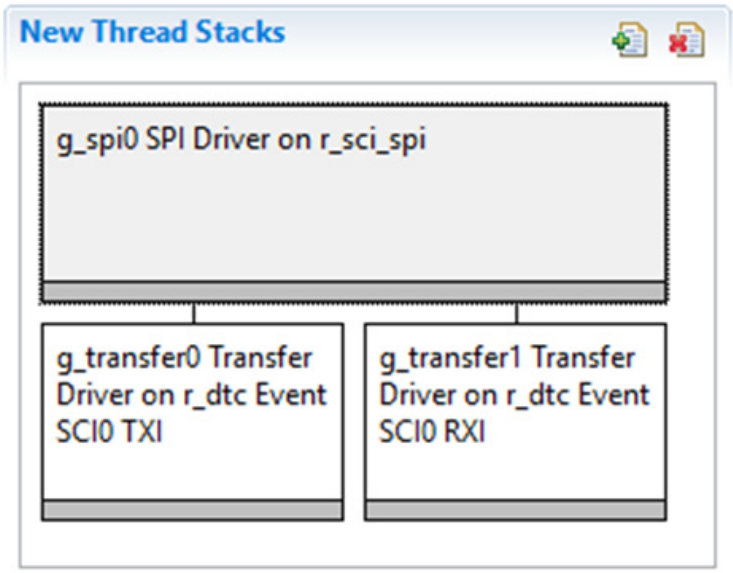

Figure 409: SCI SPI HAL Module Stack

4.2.42.5 Configuring the SCI SPI HAL Module

The SPI HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in Red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator, and are shown in the following tables for easy reference.

NOTE: You may want to open your ISDE and create the SPI and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the SCI SPI HAL Module on r_sci_spi

ISDE Property	Value	Description
Parameter Checking	Default (BSP), Enabled, Disabled	Enable or disable the parameter error checking.
Name	g_spi0	Instance name of driver. Can be renamed by user.
Channel	0	SCI channel number to be used for SPI communication.
Operating Mode	Master	How the SPI driver operates – master or slave (not supported).
Clock Phase	Data sampling on odd edge, data variation on even edge Data sampling on even edge, data variation on odd edge (Default: Data sampling on odd edge, data variation on even edge)	How the clock signal is working in terms of clock signal edges and data operations.
Clock Polarity	Low when idle, High when idle (Default: Low when idle)	High output when no operations are performed. Alternative: low output when no operations are performed.
Mode Fault Error	Disable, Enable (Default: Disable)	How errors are handled.
Bit Order	MSB First, LSB First (Default: MSB First)	Bit order within transmitted/received bytes.
Bitrate	100000	Transmission speed in bits per second.
Bit Rate Modulation Enable	Enable, Disable (Default: Disable)	The bit rate can be evenly corrected using the MDDR register. This will help to reduce error on baud rates in data communications. Beneficial for systems with none standard crystal frequencies and for lower baud rate communications.

ISDE Property	Value	Description
Callback	NULL	A user callback function can be registered in open. If this callback function is provided, it will be called from the interrupt service routine (ISR) for each of the conditions defined in spi_event_t.
Receive Interrupt Priority	Priority 0 > 15 (Default: Priority 2)	The SPI driver is interrupt driven. MCU interrupt priority level.
Transmit Interrupt Priority	Priority 0 > 15 (Default: Priority 2)	The SPI driver is interrupt driven. MCU interrupt priority level.
Transmit End Interrupt Priority	Priority 0 > 15 (Default: Priority 2)	The SPI driver is interrupt driven. MCU interrupt priority level.
Error Interrupt Priority	Priority 0 > 15 (Default: Priority 2)	The SPI driver is interrupt driven. MCU interrupt priority level.

NOTE: The example settings and defaults are for a project using the Synergy S7 MCU Family. Other MCUs may have different default values and available configuration settings.

In many cases, settings other than the defaults for the SPI Driver will be required to communicate via the SPI. For example, changes to the bit rate, clock polarity, and bit order may differ between slave devices.

SCI SPI HAL Module Clock Configuration

The SCI peripheral is clocked via the Peripheral Clock A (PCLKA.) The clock frequencies are configurable in the ISDE by using the Clocks tab in the configurator. Invalid selections are indicated in red when selected. Ensure that desired SPI bitrate can be achieved with the stated value of PCLKA. The ISDE will not be indicated if the specified bitrate is not achievable. At run time, the SPI HAL module will attempt to configure the SCI peripherals to the correct bitrate and will return an error if the desired bitrate cannot be set. The bitrate is calculated via the equations in the following table. If the result of the equation (N) is in the range of 0 to 255, then the bit rate can be achieved.

Baud Rate Calculation Equations

SPI HAL	Bitrate calculation	Description
SPI on SCI	$N = \frac{PCLKA\ (MHz)}{8 * 2^{(2n-1)} * \left(\frac{256}{M}\right) * B} - 1$ **Figure 410: N = Peripheral register value. This must be in the range of 0 to 255 PLCKA = value of PLCKA in MHz n = 0, 1, 2 or 3 M = Bit Rate Modulation Index 128 < M < 256 If the Bit Rate Modulation is disabled, then M=256 B = Desired Bit Rate**	

SCI SPI HAL Module Pin Configuration

The SCI peripheral use pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the SPI pins.

Pin Selection Sequence for SCI SPI HAL Driver

Resource	ISDE Tab	Pin selection Sequence
SPI on SCI	Pins	Select Peripherals > Connectivity:SCI > SCIx Where x is the required SCI peripheral channel.

Pin Configuration Settings for SPI on SCI – Example Case of using SCI0

Pin Configuration Property	Value	Description
Pin Group Selection	Mixed, _A only, _B only	Synergy devices support peripheral functionality via multiple pins location, identified by _A, _B. Selecting Mixed allows the user to select any combination of locations (_A and _B). Selecting _A allows the user to select only _A locations. Selecting _B allows the user to select only _B locations.
Operation Mode	Disabled Custom Asynchronous UART Simple SPI Simple I2C Synchronous UART Smart Card	Set the operating mode to: Simple SPI.
TXD_MOSI	None, P411, P101	Specify the port pin to be used as MOSI.
RXD_MISO	None, P410, P100	Specify the port pin to be used as MISO.
SCK	None, P412, P102	Specify the port pin to be used as CLK.
CTS_RTS_SS	None, P413, P103	Specify the port pin to be used as SS.

NOTE: The example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.42.6 Using the SCI SPI HAL Module in an Application

A sample procedure for using the SCI SPI in an application is as follows.

The g_spi.p_api->open() function must be called first. The rest of the calls may be used in any order depending on the application requirements:

1) Open a SPI instance with the SPI implemented by SCI SPI. The SCI SPI driver is called through the SPI Interface

```
g_spi.p_api->open (g_spi.p_ctrl, g_spi.p_cfg)
```

where p_ctrl and p_cfg are the instances of control and configuration structures autogenerated after the configuration step.

2) Initiate a write to a slave device by calling

```
g_spi.p_api->write (g_spi.p_ctrl, source, length,
SPI_BIT_WIDTH_8_BITS);
```

where g_spi.p_ctrl is the same control instance that was used in the open call.

3) Initiate a read from a slave device by calling

```
g_spi.p_api->read(g_spi.p_ctrl, dst, length,
SPI_BIT_WIDTH_8_BITS);
```

where g_spi.p_ctrl is the same control instance that was used in the open call.

4) Initiate a simultaneous transfer from and to a slave device by calling

```
g_spi.p_api->writeRead(g_spi.p_ctrl, source,
   dst, length, SPI_BIT_WIDTH_8_BITS);
```

where g_spi.p_ctrl is the same control instance that was used in the open call.

5) To close the SPI channel, do so by calling

```
g_spi.p_api->close(g_spi,p_ctrl)
```

where g_spi.p_ctrl is the same control structure that was used in the open call.

The following flow diagram illustrates the previously described common steps:

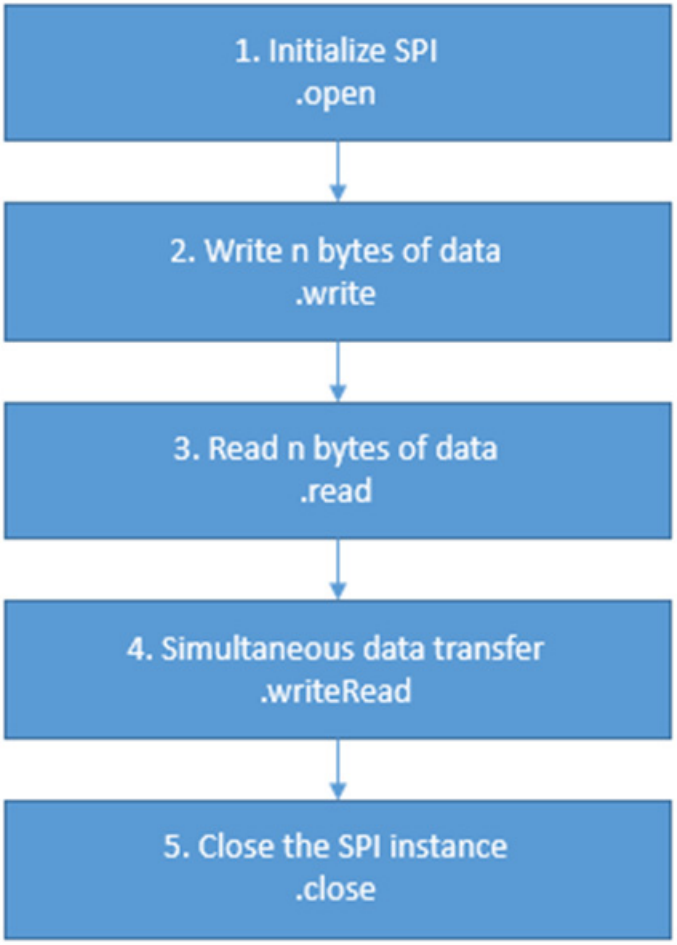

Figure 411: Flow Diagram of a Typical SPI Application

4.2.43 SPI Driver

The SPI HAL module provides high-level APIs for communication using the SPI protocol. The module supports both the SPI and SCI peripherals available on the Synergy microcontroller hardware, and is implemented on r_rspi and r_sci_spi. This section refers to the r_rspi HAL module, which is referred as the SPI module (formerly known as RSPI). The SPI HAL module supports standard SPI master and slave mode communications functions. Callbacks are provided for transfer events.

The SPI HAL modules are enabled with data-transfer support by incorporating the Data Transfer Controller (DTC) module of the MCU. This performs SPI transfers through the DTC without requiring interrupt processing, by the CPU, for each frame.

4.2.43.1 RSPI HAL Module Features

The SPI HAL module support following key features:

- Initialization of the driver
- SPI transfer functions:
  - Allows serial communication through the SPI operation using the four-wire method
  - Capable of serial communication in master and slave modes
  - Switching the polarity of the serial transfer clock
  - Switching the phase of the serial transfer clock
- Data Format
  - MSB-first/LSB-first selectable
  - Transfer bit length is selectable as 8, 16 and 32 bits
- Error Detection
  - Mode fault detection
  - Overrun error detection
  - Parity error detection
- SSL control functions
  - Internally select up to four SSL signals (SSLn0 to SSLn3) for each channel in master mode
  - External hardware slave select can be used in master mode
- Interrupts
  - RSPI receive interrupt (receive buffer full)
  - RSPI transmit interrupt (transmit buffer empty)
  - RSPI error interrupt (mode fault, overrun and parity error)
- Delays
  - Add SPI clock delay
  - Add slave select negation delay
  - Add next-access delay

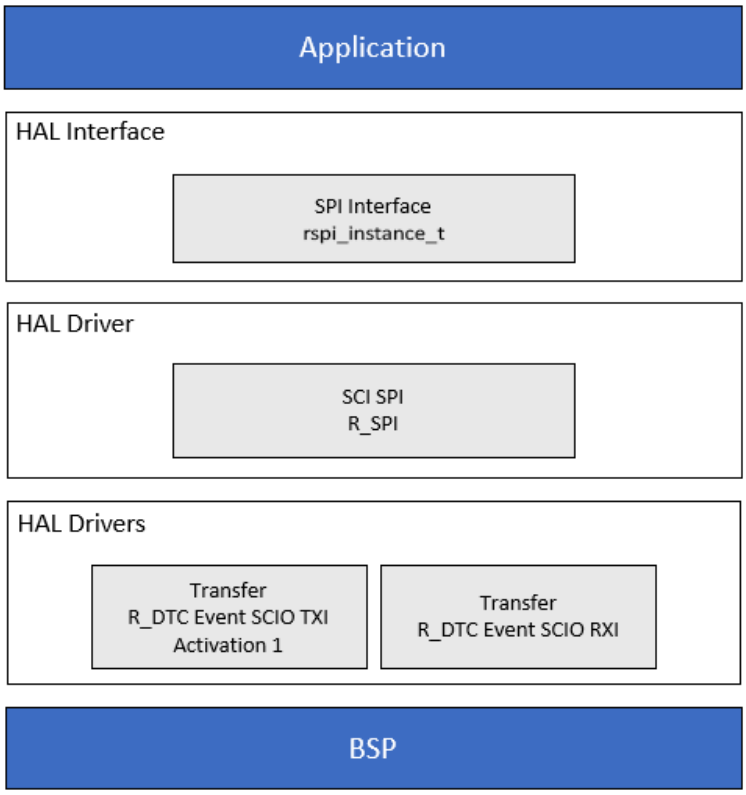

Figure 412: RSPI HAL Module Block Diagram

4.2.43.2 RSPI HAL Module APIs Overview

The RSPI HAL module defines APIs for opening, closing, reading, writing and other useful functions. A complete list of the available APIs, an example API call, and a short description of each can be found in the follow table. A subsequent table of status return values is listed afterwards.

RSPI HAL Module API Summary

Function Name	Example API Call and Description
open	g_spi.p_api ->open(g_spi.p_cntl, g_spi.p_cfg); Open a designated SPI device.
read	g_spi.p_api->read(g_spi.p_ctrl, dst16, length, SPI_BIT_WIDTH_16_BITS); Receive data from SPI device.

Function Name	Example API Call and Description
write	g_spi.p_api->write (g_spi.p_ctrl, source, length, SPI_BIT_WIDTH_8_BITS); Transmit data to SPI device
writeRead	g_spi.p_api ->writeRead (g_spi.p_cntl, &source, &destination, length, SPI_BIT_WIDTH_8_BITS, TX_WAIT_FOREVER); Simultaneously transmits data to an SPI device, while receiving data from an SPI device (full duplex). The writeRead API fetches the mutex object, handles SPI data transmission at SPI HAL layer, and receives data from the SPI HAL layer. The API uses the event flag wait to synchronize to complete the data transfer.
close	g_spi.p_api->close(g_spi,p_ctrl) Disable the SPI device designated by the control handle and close the RTOS services used by the bus if no devices are connected to the bus. This function removes power to the SPI channel designated by the handle and disables the associated interrupts.
versionGet	g_spi.p_api ->versionGet (&version); Get the version information of the underlying driver.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function completed successfully
SSP_ERR_INVALID_MODE	Invalid mode
SSP_ERR_INVALID_CHANNEL	Invalid channel
SSP_ERR_IN_USE	In-use error

Name	Description
SSP_ERR_INVALID_ARGUMENT	Invalid argument
SSP_ERR_QUEUE_UNAVAILABLE	Queue unavailable
SSP_ERR_INVALID_POINTER	Invalid pointer
SSP_ERR_INTERNAL	Internal error
SSP_ERR_TRANSFER_ABORTED	Transfer aborted
SSP_ERR_MODE_FAULT	Mode fault
SSP_ERR_READ_OVF	Read overflow
SSP_ERR_PARITY	Parity error
SSP_ERR_OVERRUN	Overrun error
SSP_ERR_UNDEF	Unknown error
SSP_ERR_TIMEOUT	Timeout error
SSP_ERR_NOT_OPEN	Device not opened

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.43.3 RSPI HAL Module Operational Overview

The SPI HAL module enables communication with a peripheral device using the SPI communications protocol. After opening the SPI HAL module instance, the SPI module handle is used to perform various transfer operations. The device control handle will be used within the API calls to indicate the specific SPI device to communicate with.

The Driver allows the user to:

- Initialize the driver.
- Serial Communication through SPI operation.

The Driver also provides support for callbacks. The callback functions are called with the following events- spi_event_t:

- Transfer aborted
- Transfer complete
- Mode fault
- Error events

The SPI module supports 8, 16, and 32 bit data transfers. The SPI Module supports GPIO pins configured as chip selects. In addition, the SPI peripheral supports dedicated chip select signals SSLn0 to SSLn3. When SSL pins are enabled in the SPI peripheral, all chip select handling is performed by the hardware.

Clock settings:

The SPI uses PCLKA as its clock source. You can set the PCLKA frequency using the clock configurator in e^2 studio or the CGC_API at run-time.

NOTE: For S1 devices the SPI clock source is PCLKB.

IO Port settings:

To use with the SPI, the I/O port pin(s) used as output pins must be configured as SPI peripheral pins in the pin configurator. If you are using an external chip select, configure Chip select pin as GPIO output.

Extended configuration:

A number of extended hardware specific configurations are present for SPI Driver.

NOTE: All parameters are set in the SPI extended driver configuration structure spi_on_rspi_cfg_t.

RSPI HAL Module Important Operational Notes and Limitations

While configuring SPI HAL drivers, setting the interrupts to different priority levels could result in improper operation.

The SPI HAL driver module is enabled with a data transfer support by incorporating the Data Transfer Controller module of the MCU. This performs SPI transfer through DTC without intervention of the CPU.

In the application, data transfer over DTC is used in the same way as for normal SPI transfer. To enable DTC transfer, add the DTC module under the SPI HAL module.

SPI module supports 8, 16 and 32-bit data transfer in both CPU and DTC based transfer modes. Renesas recommends using the DTC with SPI to reduce CPU interrupt processing time, and configuring the SPI peripheral for 8-bit transfers to ensure data is transferred with the expected endianness.

Important Note: 16 and 32 bit transfers will be endian swapped.

SPI HAL Module Performance Notes

The R_RSPI module can be configured for several different modes each with different performance characteristics. DTC transfers take slightly longer to setup than CPU based transfers due to resetting the DTC, but DTC transfers offer greater performance for transfers larger than 1 frame because no intervention is required from the CPU.

Write operations will configure the module for transmit only mode, disabling the receive interrupt and ignoring incoming data. CPU based write operations at high bitrates can result in the transmit ISR being constantly called, blocking other code from running. WriteRead and Read operations will configure the module for full duplex mode.

There is a lower limit of 3 SPI clock cycles between transfers resulting in an effective bitrate slower than configured. At high bitrates, especially for CPU based transfers, the time between transfers can be longer.

The module will wait for the hardware to enter an idle state when in master mode, or all data to be transmitted or received when in slave mode, before invoking the callback.

- When using R_RSPI in slave mode either the data must be sampled on the even clock edge or the master must de-assert the slave select line between frames. This is a hardware limitation.
- S124, S128 and S3A6 do not support SSL Level Keep.
- Once the driver has been opened using DTC, all transfers must use the transfer width the DTC is configured for.
- 16- and 32-bit transfers will be endian swapped.

- The R_RSPI bit rate value must be positive integer less than 30 MHz or PCLK/2, whichever is minimum.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.43.4 Including the RSPI HAL Module in an Application

This section describes how to include the RSPI HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the "Getting Started Guide for SSP" listed in the Reference Section at the end of this document to learn how to manage each of these important steps in creating SSP based applications.

To add the RSPI HAL Driver to an application, simply add it to a thread using the Stacks Selection Sequence given in the following table. (The default name for the SPI Framework is g_spi0. This name can be changed in the associated Properties window.)

RSPI HAL Driver Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_spi0 SPI Driver on r_rspi	Threads	New Stack> Driver> Connectivity> SPI Driver on r_rspi

The following figure shows when the RSPI HAL module on r_rspi is added to the Thread Stack, the configurator automatically adds the needed lower level drivers. Any drivers that need additional configuration information are box text highlighted in red. Modules with a gray band are individual modules that stand alone. Modules with a blue band are shared or common and need only be added once, since they can be used by multiple stacks. Modules with a pink band can require the selection of lower level drivers. Sometimes these are optional or recommended and this is indicated in the block with the inclusion of this text. If the addition of lower level drivers is required, the module description includes "Add" in the text. Clicking on any pink banded modules brings up the "New" icon and shows possible choices.

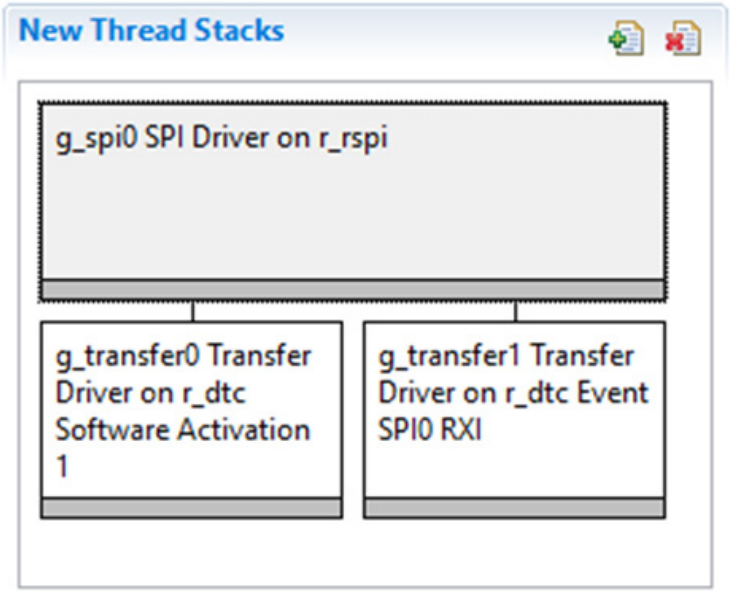

Figure 413: RSPI HAL Module Stack

4.2.43.5 Configuring the RSPI HAL Module

Configure RSPI HAL module on r_rspi for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any configurations (such as interrupts or operating modes) for lower level modules required for successful operation. Only properties that can be changed without causing conflicts are available for modification. Properties that cannot be modified are 'locked' with a lock icon displayed for the 'locked' property in the ISDE property window. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the properties window of the associated module. Simply select the indicated module and then view the properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+.) This level of detail is not included in the configuration properties tables below, but is easily visible with the ISDE when configuring interrupt priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the Configuration Table Settings given below. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the RSPI HAL Module on r_rspi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_spi0	Module name
Channel	0	SCI or SPI Channel number to which the device has been connected.
Operating Mode	Master, Slave Default: Master	Configure as a Master or Slave device.
Clock Phase	Data sampling on odd edge, data variation on even edge/Data sampling on even edge, data variation on odd edge Default: Data sampling on odd edge, data variation on even edge	Data sampling on odd or even clock edge.
Clock Polarity	Low when idle, High when idle Default: Low when idle	Clock level when idle.
Mode Fault Error	Enable, Disable Default: Disable	Indicates Mode fault error (master/slave conflict) flag.
Bit Order	MSB First, LSB First Default: MSB First	Select transmit order MSB/LSB first
Bitrate	500000	Transmission or reception rate. Bits per second.
Callback	NULL	Optional Callback function pointer.

ISDE Property	Value	Description
SPI Mode	SPI Operation, Clock synchronous operation Default: SPI Operation	Select SPI or clock sync mode operation.
SPI Communication Mode	Full Duplex, Transmit Only Default: Full Duplex	Select full-duplex or transmit-only communication.
Slave Select Polarity(SSL0)	Active Low, Active High Default: Active Low	Select SSL0 signal polarity
Slave Select Polarity(SSL1)	Active Low, Active High Default: Active Low	Select SSL1 signal polarity
Slave Select Polarity(SSL2)	Active Low, Active High Default: Active Low	Select SSL2 signal polarity
Slave Select Polarity(SSL3)	Active Low, Active High Default: Active Low	Select SSL3 signal polarity
Select Loopback1	Normal, Inverted Default: Normal	Select loopback1
Select Loopback2	Normal, Inverted Default: Normal	Select loopback2
Enable MOSI Idle State	Enable, Disable Default: Disable	Select MOSI idle fixed value and selection

ISDE Property	Value	Description
MOSI Idle State	MOSI Low, MOSI High Default: MOSI Low	Select MOSI idle fixed value and selection
Enable Parity	Enable, Disable Default: Disable	Enable/disable parity
Parity Mode	Parity Odd, Parity Even Default: Parity Odd	Select parity
Select SSL(Slave Select)	SSL0, SSL1, SSL2, SSL3 Default: SSL0	Select which slave to use; 0-SSL0; 1-SSL1; 2-SSL2; 3-SSL3
Select SSL Level After Transfer	SSL Level Keep, SSL Level Do Not Keep Default: SSL Level Do Not Keep	Select SSL level after transfer completion; 0-negate; 1-keep
Clock Delay Enable	Clock Delay Enable, Clock Delay Disable Default: Clock Delay Disable	Clock delay enable selection
Clock Delay Count	Clock Delay 1 thru 8 RSPCK Default: Clock Delay 1 RSPCK	Clock delay count selection
SSL Negation Delay Enable	Negation Delay Enable, Negation Delay Disable Default: Negation Delay Disable	SSL negation delay enable selection
Negation Delay Count	Negation Delay 1 thru 8 RSPCK Default: Negation Delay 1 RSPCK	Negation delay count selection

ISDE Property	Value	Description
Next Access Delay Enable	Next Access Delay Enable, Next Access Delay Disable Default: Next Access Delay Disable	Next access delay enable selection
Next Access Delay Count	Next Access Delay 1 thru 8 RSPCK Default: Next Access Delay 1 RSPCK	Next access delay count selection
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Receive interrupt priority selection
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Transmit interrupt priority selection

ISDE Property	Value	Description
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Priority 2	Error interrupt priority selection

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the DTC HAL Module on r_dtc Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Disabled	Software start selection
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection
Name	g_transfer0	Module name
Mode	Normal	Mode selection
Transfer Size	4 Bytes	Transfer size selection

ISDE Property	Value	Description
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Software Activation 1	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection.

Configuration Settings for the DTC HAL Module on r_dtc Event SCI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Name	g_transfer1	Module name

ISDE Property	Value	Description
Mode	Normal	Mode selection
Transfer Size	4 Bytes	Transfer size selection
Destination Address Mode	Incremented	Destination address mode selection
Source Address Mode	Fixed	Source address mode selection
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SPI0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection.

RSPI HAL Module Clock Configuration

The SPI peripheral is clocked via Peripheral Clock A (PCLKA). The clock frequencies are configurable in the ISDE by using the Clocks Tab in the configurator. Invalid selections are indicated in red when selected. Ensure that desired SPI bitrate can be achieved with the stated value of PCLKA. The ISDE will not be indicated if the specified bitrate is not achievable. At run time, the SPI driver will attempt to configure the SPI peripheral to the correct bitrate and will return an error if the desired bitrate cannot be set. The bitrate is calculated via the equations in the table below. If the result of the equation (n) is in the range of 0 to 255, then the bit rate can be achieved.

Baud Rate Calculation Equations

SPI HAL	Bitrate calculation	Description
SPI on SPI	$n = \frac{PCLKA\ (MHz)}{2 * 2^N * B} - 1$	n = Peripheral register value. This has to be in the range of 0 to 255 PLCKA = value of PLCKA in MHz N = 0, 1, 2 or 3 B = Desired Bit Rate

RSPI HAL Module Pin Configuration

The SPI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example listing a selection for SPI pins.

Pin Selection Sequence for the RSPI HAL Module

Resource	ISDE Tab	Pin selection Sequence
RSPI	Pins	Select Peripherals > RSPI > SPI0_Pin_Option_A/B

NOTE: The top selection sequence assumes SPIO is the desired hardware target for the driver and the bottom selection sequence assumes SPI_0 is the desired target.

Pin Configuration Settings for the RSPI HAL Module

Property	Value	Description
Operation Mode	Disabled, Custom, Enabled (Default: Disabled)	Select Enabled for SPI Operation
MISO	None, P100, P410 (Default: None)	MISO Pin selection
MOSI	None, P101, P411 (Default: None)	MOSI Pin selection

Property	Value	Description
RSPCLK	None, P102, P412 (Default: None)	RSPCLK Pin selection
SSL0:3	None, P103:106, P413:415 (Default: None)	SSL0:3 Pin selections

NOTE: The example lists settings for a project using the Synergy S7G2 Series 7 Group MCU and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.43.6 Using the RSPI Module in an Application

To write a SPI application using the SPI, follow these steps. The g_spi.p_api->open() function must be called first. The rest of the calls may be used in any order depending on the application requirements:

1) Open an SPI instance with the SPI implemented by SPI. The SPI driver is called through the SPI Interface

```
g\_spi.p\_api-&gt;open
   (g\_spi.p\_ctrl, g\_spi.p\_cfg)
```

where p_ctrl and p_cfg are the instances of control and configuration structures autogenerated after the SPI configuration step.

2) Initiate a write to a slave device by calling

```
g\_spi.p\_api-&gt;write (g\_spi.p\_ctrl, source, length,
SPI\_BIT\_WIDTH\_8\_BITS);
```

where g_spi.p_ctrl is the same control instance that was used in the open call.

3) Initiate a read from a slave device by calling

```
g\_spi.p\_api-&gt;read(g\_spi.p\_ctrl, dst16, length,
SPI\_BIT\_WIDTH\_16\_BITS);
```

where g_spi.p_ctrl is the same control instance that was used in the open call.

4) Initiate a simultaneous transfer from and to a slave device by calling

```
g\_spi.p\_api-&gt;writeRead(g\_spi.p\_ctrl, source,
   dst16, length, SPI\_BIT\_WIDTH\_8\_BITS, TX\_WAIT\_FOREVER);
```

where g_spi.p_ctrl is the same control instance that was used in the open call.

5) To close the SPI channel, do so by calling

```
g\_spi.p\_api-&gt;close(g\_spi,p\_ctrl);
```

where g_spi.p_ctrl is the same control structure that was used in the open call.

The following figure illustrates these steps in a typical operational flow.

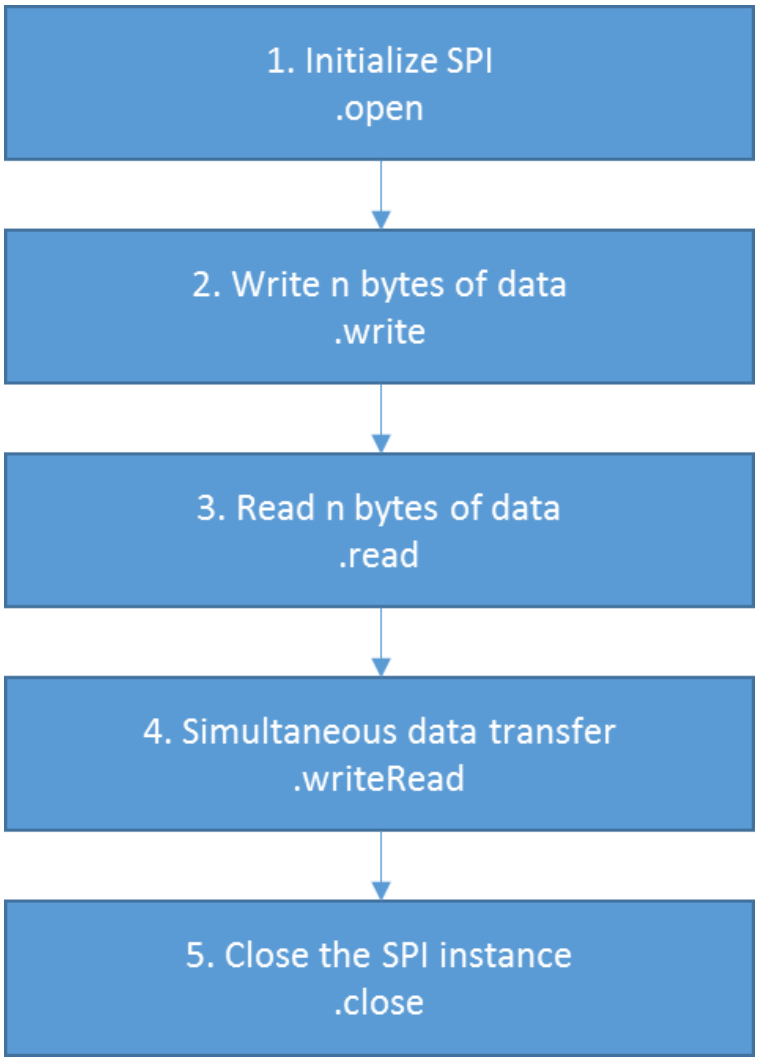

Figure 414: Flow Diagram of a Typical RSPI HAL Module Application

4.2.44 Transfer Driver

The Transfer Driver is a generic Driver for Transfer applications and supports the two Transfer peripherals available on the Synergy microcontroller hardware: DMAC and DTC. The Driver can be therefore implemented on r_dmac and r_dtc. This section describes how to configure the Transfer Driver using the e^2 studio ISDE and how to include the API functions in your application.

In the project configurator in the e^2 studio ISDE, you can add and configure a Transfer Driver Module in the Modules pane of the Threads tab by selecting **New > Driver > Transfer > Transfer Driver on r_dmac** or **New > Driver > Transfer > Transfer Driver on r_dtc**. For details, see: Using e^2 studio to write an application with the Transfer Driver

You can find the API reference in the description of the Transfer Interface here: Transfer Interface.

To understand how to program with Interfaces in the SSP, see: SSP Architecture

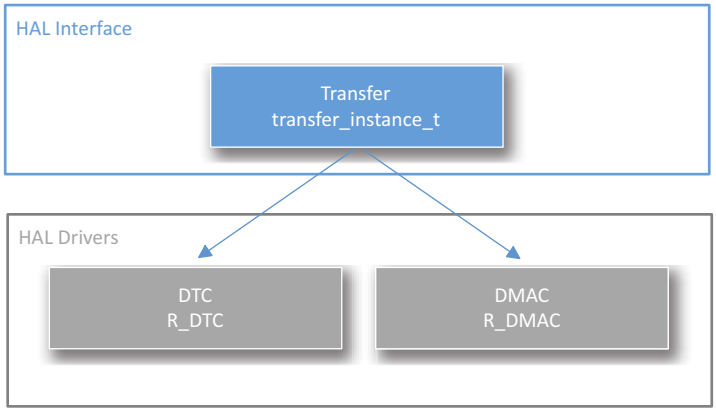

Figure 415: TransferDriver - Block diagram

4.2.44.1 What Does the Transfer Driver Do?

The Transfer Driver moves data from a user specified source to a user specified destination when an interrupt or event occurs.

4.2.44.2 Selecting a Module for the Transfer Driver

The DTC module is recommended for most generic Transfer applications, but either module can be used for basic Transfer functionality. The use cases in which one Transfer module would be preferred over the other are described below.

Selecting the DTC Transfer Module

The DTC module uses a RAM based vector table, with slots for every interrupt in the system. When the DTC transfer completes, the activation source interrupt is called. The activation source interrupt must be enabled to use the DTC. The activation source interrupt is generally muted by the DTC until the transfer completes, unless TRANSFER_IRQ_EACH is specified in the configuration. For example, if a normal mode transfer with a length of 16 is triggered by a timer, the timer interrupt does not fire the first 15 times while the transfer is in effect. After the 16th transfer, the timer interrupt fires. The DTC also allows chained transfers, meaning that more than one transfer can occur after a single activation source interrupt. This feature is supported by the driver, but must be configured outside the e^2 studio IDE.

Selecting the DMAC Transfer Module

The DMAC module uses DMAC peripheral registers, so the number of transfers in the system is limited to the number of DMAC channels on the device. The activation source does not have to be enabled to use the DMAC. When the DMAC transfer completes, a DMAC interrupt is called. If the activation source interrupt is enabled, it fires at the same time the transfer is triggered. If the DMAC interrupt is enabled, it fires after all transfers are complete. For example, if a normal

mode transfer with a length of 16 is triggered by a timer, the timer interrupt fires at the same time each transfer occurs and the DMAC interrupt fires after the 16th transfer completes. The DMAC does not support chained transfers.

4.2.44.3 Using e2 studio to write an application with the Transfer Driver

The driver is integrated into the e2 studio ISDE: e2 studio ISDE User Guide.

In e2 studio, create and configure a project and add the drivers:

1) Create the project: Creating a Project.
2) Configure the project: Configuring a Project
3) Add the drivers: Adding Threads and Drivers

The following resources are required for an application that uses the Transfer Driver with the DTC:

Resource	ISDE Tab	Selection
DTC Driver	Threads	**Driver > Transfer > Transfer Driver on r_dtc**. If you add more than one Transfer driver, make sure to create a unique name for each driver in the Name field of the Properties editor.
Interrupts	Threads	The interrupt corresponding to the activation source must be enabled.
DTC Clock	Clocks	See Configuring the DTC Clocks
DTC Pins	Pins	See Configuring the DTC Pins

The following resources are required for an application that uses the Transfer Driver with the DMAC:

Resource	ISDE Tab	Selection
DMAC Driver	Threads	**Driver > Transfer > Transfer Driver on r_dmac**. If you add more than one Transfer driver, make sure to create a unique name for each driver in the Name field of the Properties editor.
Interrupts	Threads	**DMAC > DMACn > DMACn INT** Underflow Interrupt.
DMAC Clock	Clocks	See Configuring the DMAC Clocks
DMAC Pins	Pins	See Configuring the DMAC Pins

Configuring the DTC Clocks

Use the e^2 studio ISDE to configure the DTC clock using the Clocks tab: Configuring Clocks.

The DTC is clocked based on the ICLK frequency. You can set the ICLK frequency using the clock configurator in e^2 studio Configuring Clocks or the CGC Interface at run-time.

Configuring the DTC Pins

The DTC is not associated with any pins.

Configuring the DTC Interrupts

Use the e^2 studio ISDE to configure the DTC interrupts using the ICU tab: Configuring Interrupts.

The activation source interrupt must be enabled to use the DTC.

ATTENTION: Interrupts may be skipped when used with the DTC peripheral with irq set to TRANSFER_IRQ_END.

Configuring the DMAC Clocks

Use the e^2 studio ISDE to configure the DMAC clock using the Clocks tab: Configuring Clocks.

The DMAC is clocked based on the ICLK frequency. You can set the ICLK frequency using the clock configurator in e^2 studio Configuring Clocks or the CGC Interface at run-time.

Configuring the DMAC Pins

The DMAC is not associated with any pins.

Configuring the DMAC Interrupts

Interrupts are not required to use the DMAC. To receive an interrupt when a transfer completes, enable the DMAC > DMACn > DMACn INT interrupt (where n is the DMAC channel number) on the ICU tab of the Project Configurator in e^2 studio.

When the DMACn INT interrupt is enabled in the BSP, the corresponding ISR is defined in the DMAC driver. The ISR calls a user callback function if one was registered in open.

4.2.44.4 Transfer Driver Usage Notes

Normal Mode

In normal mode, a single transfer is triggered each time an activation source event occurs. A single transfer is 1 byte, 2 bytes, or 4 bytes depending on the setting selected in size. Each time a transfer occurs, length is decremented by 1. When length reaches 0, the transfer is complete.

Repeat Mode

In repeat mode, a single transfer is triggered each time an activation source event occurs. A single transfer is 1 byte, 2 bytes, or 4 bytes depending on the setting selected in size. Each time a transfer occurs, length is decremented by 1. When length reaches 0, length is reloaded with its initial value and the transfer restarts. If the repeat area is set to source, the source register is also reloaded with its initial value when the transfer restarts. Alternatively, if the repeat area is set to destination, the destination register is reloaded with its initial value when the transfer restarts.

Block Mode

In block mode, the entire transfer length is transferred each time an activation source event occurs. For example, if a transfer is configured in block mode with timer as the activation source, a 2 byte size, and a 12 byte length, 24 bytes are transferred each time the activation source event occurs. Each time a transfer occurs, length is decremented by 1. When length reaches 0, length is reloaded with its initial value and the transfer restarts. If the repeat area is set to source, the source register is also reloaded with its initial value when the transfer restarts. Alternatively, if the repeat area is set to destination, the destination register is reloaded with its initial value when the transfer restarts.

Address Modes

After each transfer of size (1 byte, 2 bytes, or 4 bytes), the source pointer and destination pointer is adjusted by src_addr_mode and dest_addr_mode respectively. For example, if src_addr_mode is set to TRANSFER_ADDR_MODE_INCREMENTED and size is set to TRANSFER_SIZE_4_BYTES, the p_dest pointer is incremented by 4 (the transfer size) after each transfer. The pointer does not change if set to TRANSFER_ADDR_MODE_FIXED.

Chained Transfers

Chained transfers are only supported by DTC. To use a chained transfer, create an array of transfer_info_t structures. Set chain_mode to TRANSFER_CHAIN_MODE_ENABLED for all transfers except the last transfer. Set p_info to the base of the first structure in the array for transfer_info_t structures.

4.2.44.5 Writing a Transfer Driver Application

The ISDE configures this instance structure when you generate the project in the ISDE generated source file.

```
/* Instance structure to use this module. */

const transfer_instance_t g_transfer =

{

    .p_ctrl = &g_transfer_ctrl,

    .p_cfg = &g_transfer_cfg,

    .p_api = &g_transfer_on_dtc

};
```

To write a Transfer application using the DTC, follow these steps:

1) Configure the module as described above.Once the module is configured, the module related header and configuration files are generated automatically (containing the structure transfer_cfg_t).

2) Open the Transfer instance using the name given to the Transfer during configuration.The appropriate driver is called through the Transfer interface. For a Transfer called g_transfer, this looks like

```
g_transfer.p_api->open(g_transfer.p_ctrl, g_transfer.p_cfg)
```

where g_transfer.p_ctrl and g_transfer.p_cfg are auto-generated after the Transfer configuration step.

3) If Auto Enable was configured to be False, enable the transfer by calling

```
g_transfer.p_api->enable(g_transfer.p_ctrl)
```

or

```
g_transfer.p_api->reset(g_transfer.p_ctrl, p_src, p_dest, length)
```

4) Use other APIs from transfer_api_t as desired.

4.2.44.6 Supported Devices for the Transfer Driver

This driver has been tested on the Synergy microcontroller family S7G2 and S3A7.

The Transfer Driver is designed to support the following families with no changes to the API:

- S124

4.2.44.7 Transfer Driver Files

During the project configuration, the ISDE extracts the files shown in the following table to the /ssp directory.

Module	Directory
HAL Transfer Interface API	synergy/ssp/inc/driver/api/r_transfer_api.h
DTC Instance	synergy/ssp/inc/driver/instances/r_dtc.h
DTC Driver	synergy/ssp/src/driver/r_dtc/r_dtc.c
DMAC Instance	synergy/ssp/inc/driver/instances/r_dmac.h
DMAC Driver	synergy/ssp/src/driver/r_dmac/r_dmac.c

4.2.45 UART Driver

The UART HAL Module is a high-level API for UART applications and is implemented on r_sci_uart. The UART HAL module uses the SCI peripherals on the Synergy MCU. A user-defined callback can be created to manage hardware-handshake and data operation, if needed.

4.2.45.1 UART HAL Module Features

The UART HAL module supports the standard UART protocol. The UART HAL module used in concert with the SCI peripheral in UART mode (UART on SCI) supports the following features (in addition to the standard UART protocol):

- Full-duplex UART communication
  - Simultaneous communication with multiple channels
  - Interrupt-driven data transmission and reception

– Invoking the user-callback function with an event code in the argument
– Baud-rate change at run-time
– Hardware resource locking during UART transaction
– CTS/RTS hardware flow control (with an associated IOPORT pin and supported by user-defined callback function)
– Integration with the DTC transfer module
– Abort in-progress read/write operations

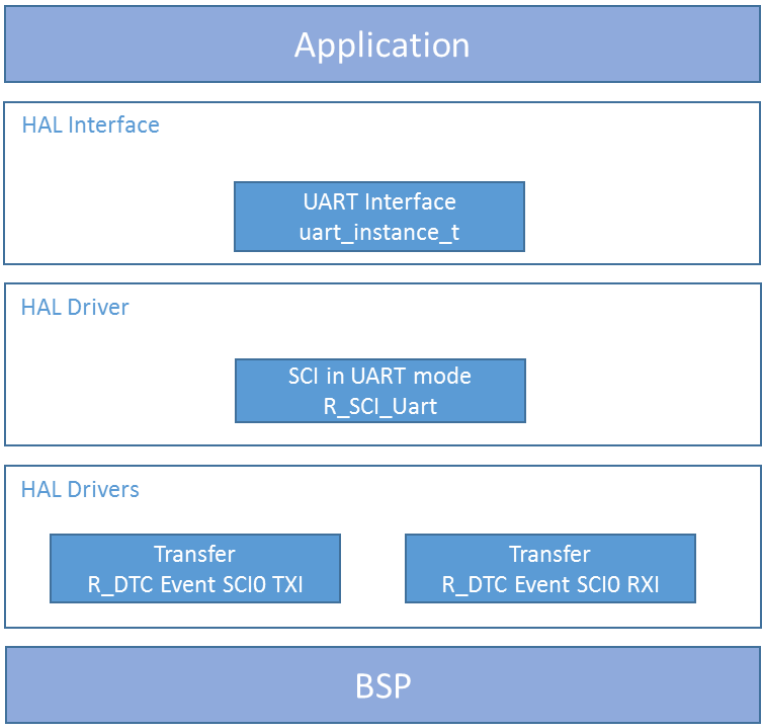

Figure 416: UART HAL Module Block Diagram

4.2.45.2 UART HAL Module APIs Overview

The UART HAL module interface defines APIs for key features such as opening, closing, reading, writing, and setting the baud rate. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

UART HAL Module API Summary

Function Name	Example API Call and Description
.open	g_uart0.p_api->open(g_uart0.p_ctrl, g_uart0.p_cfg); Open UART device.
.read	g_uart0.p_api->read(g_uart0.p_ctrl, uart0_buf, uart0_rcv_num); Read from UART device. If a transfer instance is used for reception, the received bytes are stored directly in the read input buffer, uart0_buf. When a transfer is complete, the callback is called with event UART_EVENT_RX_COMPLETE. Bytes received outside an active transfer are received in the callback function with event UART_EVENT_RX_CHAR.
.write	g_uart0.p_api->write(g_uart0.p_ctrl, uart0_buf, uart0_send_num) Write to UART device. The write buffer is used until write is complete. Do not overwrite write buffer contents until the write is finished. When the write is complete (all bytes are fully transmitted on the wire), the callback called with event UART_EVENT_TX_COMPLETE.
.baudSet	g_uart0.p_api->baudSet(g_uart0.p_ctrl, (uint32_t)9600); Change baud rate.
.infoGet	g_uart0.p_api->infoGet(g_uart0.p_ctrl, &uart_info); Get the driver specific information.
.close	g_uart0.p_api->close(g_uart0.p_ctrl); Close UART device.
.versionGet	g_uart0.p_api->versionGet(&uart_version); Retrieve the API version with the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Channel operates successfully.
SSP_ERR_IN_USE	Control block has already been opened or channel is being used by another instance.
SSP_ERR_ASSERTION	Pointer to UART control block is NULL or configuration structure is NULL.
SSP_ERR_HW_LOCKED	Channel is locked.
SSP_ERR_INVALID_MODE	Channel is used for non-UART mode or illegal mode is set.
SSP_ERR_INVALID_ARGUMENT	Invalid parameter setting found in the configuration structure. Or source/destination address or data size is invalid against data length.
SSP_ERR_NOT_OPEN	The control block has not been opened.
SSP_ERR_UNSUPPORTED	SCI_UART_CFG_RX_ENABLE is set to 0.

NOTE: Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.45.3 UART HAL Module Operational Overview

The UART HAL Module manages data flow using the standard UART protocol. The high-level APIs are used to read, write, and set the baud rate for the UART interface. In addition, interrupts are typically used to simplify the management of low-level activities.

NOTE: Interrupts need to be enabled for the following functions to operate successfully.

UART on SCI RXI interrupt

The RXI interrupt is used to control the flow of data received from the UART port. When the amount of received data reaches the expected read length, the ISR invokes a user-defined callback (p_callback) with the argument uart_callback_args_t to indicate that the received data is complete. When the External RTS Operation option is enabled, the ISR invokes the UART callback function for the RTS external pin control twice: once at the top of ISR and once at the bottom. You can use the callback function to emulate the RTS function (see the UART on SCI hardware flow-control

section); this interrupt is activated in the open API as long as the reception is enabled in the SCI_UART_CFG_RX_ENABLE configuration parameter.

UART on SCI TXI interrupt

The TXI interrupt handles consecutive transmissions of data to the UART port as requested by the write API. When no data is left in the transmit circular buffer, the ISR deactivates the TXI interrupt and activates the TEI interrupt to handle the last sequence in the data transmission. This interrupt is activated in the write API as long as the transmission is enabled by the SCI_UART_CFG_TX_ENABLE configuration parameter.

UART on SCI TEI interrupt

The TEI interrupt is used to handle a last data transmission to the UART port requested by write API; this interrupt is activated by TXI ISR and deactivates itself. The ISR invokes a user-defined callback (p_callback) with the argument uart_callback_args_t to indicate that the end of data is transmit.

UART on SCI ERI interrupt

The ERI interrupt is used to handle errors that occur in the UART reception. This interrupt is activated in the open API as long as the reception is enabled by the SCI_UART_CFG_RX_ENABLE configuration parameter. The ISR invokes a user-defined callback (p_callback) with the argument uart_callback_args_t to indicate uart_event_t cause of an error.

UART HAL Module Important Operational Notes and Limitations

UART on SCI Hardware Flow Control

The SCI hardware module supports hardware flow-control for only one of the RTS or CTS signals at a time. CTS and RTS are multiplexed on the CTSn/RTSn pin so that one of the hardware flow-control signals can be used exclusively depending on the use-case. The UART HAL module expands this specification and allows control of both the CTS and the RTS signal by enabling an additional pin for the RTS signal. To enable this mode, set the UART on SCI configurations as follows:

- Set SCI_UART_CFG_EXTERNAL_RTS_OPERATION to Enable.
- Set ctsrts_en to CTS (true).
- Specify a user-callback function name to "Name of UART callback function for the RTS external pin control" in p_extpin_ctrl.

The UART on SCI HAL module invokes the user-callback function from the RXI ISR at the top and at the end of processing.

The callback function argument "level" refers to the signal level on the RTS pin for the selected SCI channel.

NOTE: The HAL module does not handle the GPIO pin-initialization or control it; instead, the user needs to initialize the GPIO pin before starting the UART reception.

The following figure shows the timing diagram of CTS/RTS hardware flow-control with an external GPIO pin used as the RTS signal:

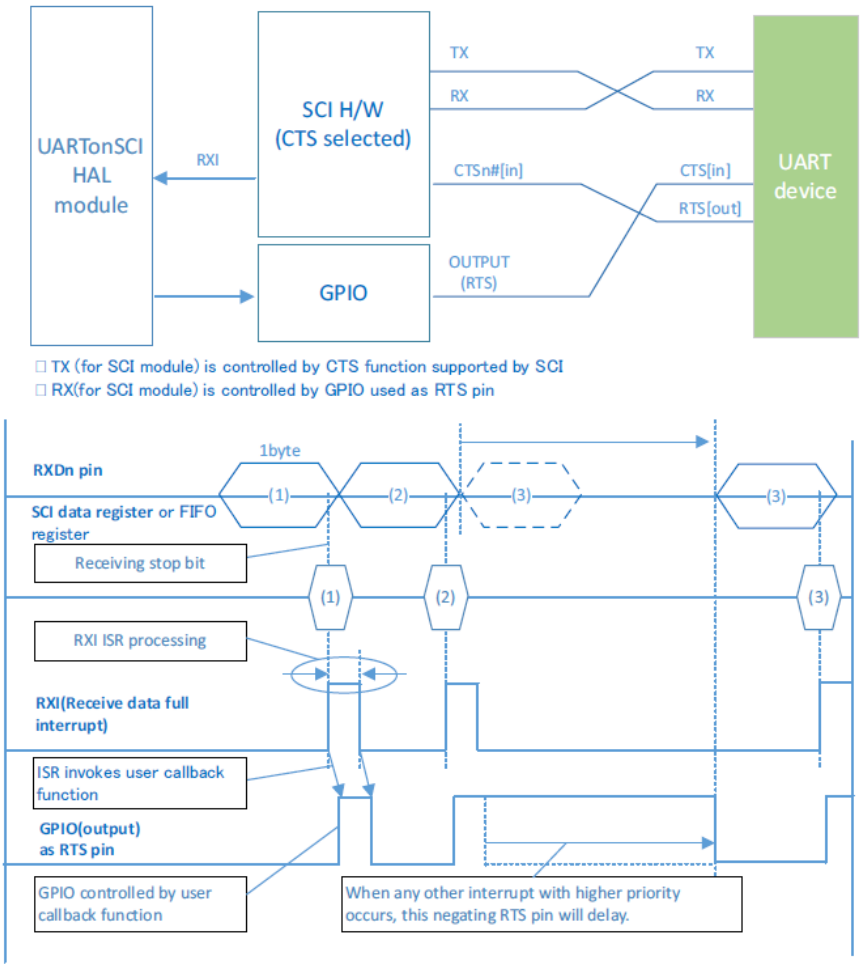

Figure 417: CTS/RTS Hardware Control with an External GPIO

NOTE: The UART on SCI module on the SK-S7G2 board uses PORT8 pin0 (pin P800) and J8 to activate the RS232C port on the RS-232C transceiver. Connect pin 1 and pin 2 of J8. Configure pins P800 as IOPORT pins and set its level for the desired operation.

- The module supports interrupt-based operation but does not support a polled UART mode.
- The module does not support non-buffered UART mode.
- The module does not support Event Link functionality.
- Transfer size must be less than or equal to 64 Kbytes if DTC interface is used for transfer. infoGet API can be used to get the max transfer size allowed

- Reception is still enabled after communicationAbort API is called. Any characters received after abort and before the next call to read, will arrive via the callback function with event UART_EVENT_RX_CHAR.
- There is a 64k limit to the block size that can be sent to the r_sci_uart driver if the DTC is being used. This limit can be retrieved using the infoGet API.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.45.4 Including the UART HAL Module in an Application

This section describes how to include the UART HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the UART Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the UART HAL is g_uart0. This name can be changed in the associated Properties window.)

UART Driver Stack Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_uart0 UART on r_sci_uart	**Threads > HAL/Common Stacks**	Highlight **Threads > HAL/Common Stacks** and select **New Stack > Driver > Connectivity > UART Driver on r_sci_uart**

When the UART HAL module on r_sci_uart is added to a thread as shown in the following figure, the configurator automatically adds the needed lower-level drivers. Any drivers that need additional configuration information will be box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks.

When the mouse is docked to the Red position, the required operations for correcting the configuration will display. Please follow the instructions to enable the SCI Receive Interrupt (RXI), SCI Transmit Interrupt (TXI), and SCI Transmit End Interrupt (TEI) in the Properties window to complete a valid configuration.

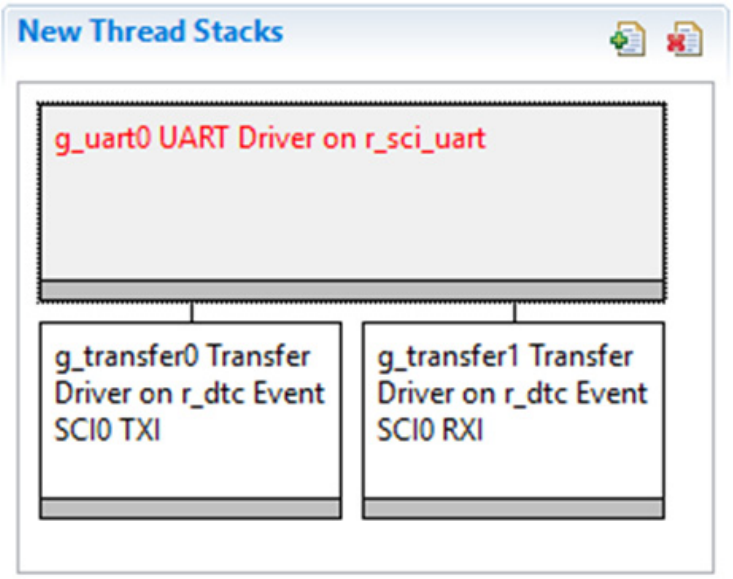

Figure 418: UART HAL Module Stack

4.2.45.5 Configuring the UART HAL Module

The UART HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator, and are shown in the following tables for easy reference.

NOTE: You may want to open your ISDE and create the UART HAL module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for UART HAL Module on r_sci_uart

ISDE Property	Value	Description
External RTS Operation	Enable, Disable Default: Disable	Enable an IOPORT pin to be used as RTS signal. For RTS functionality set this configuration parameter to **Enable** and specify the configuration **Name of UART callback function for the RTS external pin control**.

ISDE Property	Value	Description
Reception	Enable, Disable Default: Enable	Enable or disable UART reception for all UART channels on SCI. Setting this configuration parameter to **Disable** reduces code size because the portion of code for UART reception is not compiled. You cannot set this parameter for individual UART channels.
Transmission	Enable, Disable Default: Enable	Enable or disable UART transmission for all UART channels on SCI. Setting **Disable** to this configuration allows to get smaller code size due to the portion of code for UART transmission is compiled out, however, you can only set **Disable** to this configuration if any other SCI channels which work as UART ports do not perform the transmission.
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_uart0	The name to be used for UART on SCI module control block instance. This name is also used as the prefix of the other variable instances.
Channel	0-9	SCI channel number.
Baud Rate	9600	Baud rate selection.
Data Bits	7 bits, 8, bits, 9 bits Default: 8 bits	UART data bits.
Parity	None, Odd, Even Default: None	UART parity bits.
Stop Bits	1 bit, 2 bits Default: 1 bit	UART stop bits.

ISDE Property	Value	Description
CTS/RTS Selection	CTS (Note that RTS is available when enabling External RTS Operation mode which uses 1 GPIO pin), RTS (CTS is disabled) Default: RTS (CTS is disabled)	Select CTS or RTS for the CTSn/RTSn pin of SCI channel n. The SCI hardware supports either the CTS or the RTS control signal on this pin but not both. For an application that uses both CTS and RTS, select **CTS** for this configuration parameter and enable the configuration **External RTS Operation** specifying the configuration **Name of UART callback function for the RTS external pin control**.
Name of UART callback function to be defined by user	user_uart_callback	Name must be a valid C symbol.
Name of UART callback function for the RTS external pin control to be defined by user	NULL	Name must be a valid C symbol.
Clock Source	Internal Clock, External Clock 8x baudrate, External Clock 16x baudrate Default: Internal Clock	Selection of the clock source to be used in the baud-rate clock generator block.
Baudrate Clock Output from SCK pin	Enable, Disable Default: Disable	Optional setting to output the baud-rate clock on the SCKn pin for the selected channel n.
Start bit detection	Falling Edge, Low Level Default: Falling Edge	Start bit detection mode in the reception, usually set **Falling Edge** to this configuration.
Noise Cancel	Enable, Disable Default: Disable	Enable the digital noise cancellation on RXDn pin. The digital noise filter block in SCI consists of two-stage flip-flop circuits. For detail, refer to the Noise cancellation section in the Renesas Synergy hardware manual.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Bit rate modulation enable selection.

ISDE Property	Value	Description
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Transmit end interrupt priority selection.
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Error interrupt priority selection.

NOTE: The example settings and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select different noise cancellation settings. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

NOTE: Most of the property settings for lower-level modules are fairly intuitive and usually can be determined by inspection of the associated Properties window from the SSP configurator.

Configuration Settings for the UART HAL Module Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower-level modules as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module.

Configuration for the Transfer Driver on r_dtc Event SCI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Disabled	Set start mode
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section setting
Name	g_transfer0	Module name
Mode	Normal	Mode selection
Transfer Size	1 Bytes	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode)	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SCI0 TXI	Activation source selection

ISDE Property	Value	Description
Auto Enable	True, False Default: True	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

Configuration for the Transfer Driver on r_dtc Event SCI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Disabled	Set start mode
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section setting
Name	g_transfer1	Module name
Mode	Normal	Mode selection
Transfer Size	1 Bytes	Transfer size selection
Destination Address Mode	Incremented	Destination address mode selection

ISDE Property	Value	Description
Source Address Mode	Fixed	Source address mode selection
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SCI0 RXI	Activation source selection
Auto Enable	FALSE	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0(highest), Priority 1-2, Priority 3 (CM4: valid, CM0+: lowest – not valid if using ThreadX), Priority 4-14 (CM4: valid, CM0+? invalid), Priority 15 (CM4: lowest, not valid if using Thread X, CM0: invalid), Disabled Default: Disable	Interrupt priority for ELC SW event

NOTE: The example settings and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

When using the UART with CTS and RTS function simultaneously, the transfer driver cannot be used; please delete all transfer drivers on the low level. After being deleted, the optional transfer driver will display in pink, meaning the driver is recommended but optional, as in the following figure:

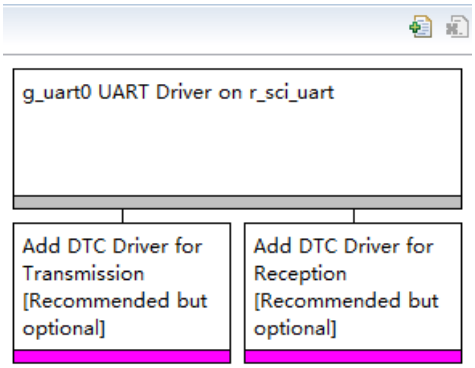

Figure 419: UART Stack with the CTS and RTS Functions

UART HAL Module Clock Configuration

The SCI UART peripheral uses PCLKA as its clock source (PCLKB for S124) or an external clock from the SCKn pin for the selected channel n.

UART HAL Module Pin Configuration

The SCI UART peripheral uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent tables illustrate an example selection for the UART pins.

NOTE: The operation mode selection determines what peripheral signals are available and thus what MCU pins are required.

Pin Selection Sequence for UART HAL Module on SCI

Resource	ISDE Tab	Pin selection Sequence
SCI	Pins	Select **Peripherals > Connectivity: SCI > SCI0**

Pin Configuration Settings for UART HAL Module on SCI

Pin Configuration Property	Value	Description
Pin Group Selection	Mixed, _A Only, _B Only (Default: Mixed)	Pin grouping selection

Pin Configuration Property	Value	Description
Operation Mode	Disabled, Custom, Asynchronous UART, Simple SPI, Simple I2C, Synchronous UART, SmartCard (Default: Simple SPI)	Select Operation Mode for UART on SCI
TXD_MOSI	None, P411, P101 (Default: P411)	TXD Pin
RXD_MISO	None, P410, P100 (Default: P410)	RXD Pin
SCK	None, P412, P102 (Default: P412)	SCK Pin
CTS_RTS_SS	None, P413, P103 (Default: None)	CTS Pin
SDA	Disabled	SDA Pin (when Simple I2C is used)
SCL	Disabled	SCL Pin (when Simple I2C is used)

NOTE: The example settings are for a project using the Synergy S7G2 and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.45.6 Using the UART HAL Module in an Application

Once the module has been configured and the files generated, the UART HAL module is ready to be used in an application. The typical steps in using the UART HAL module in an application are:

1) Initialize the UART HAL Module using the open API.
2) Set Baud Rate with the baudSet API (if needed.)
3) Read and Write data as needed using the read and write APIs and callbacks.
4) Close the UART HAL module using the close API as needed.

NOTE: Read or Write operations can be aborted using communicationAbort API if required. These common steps are illustrated in a typical operational flow diagram in the following figure:

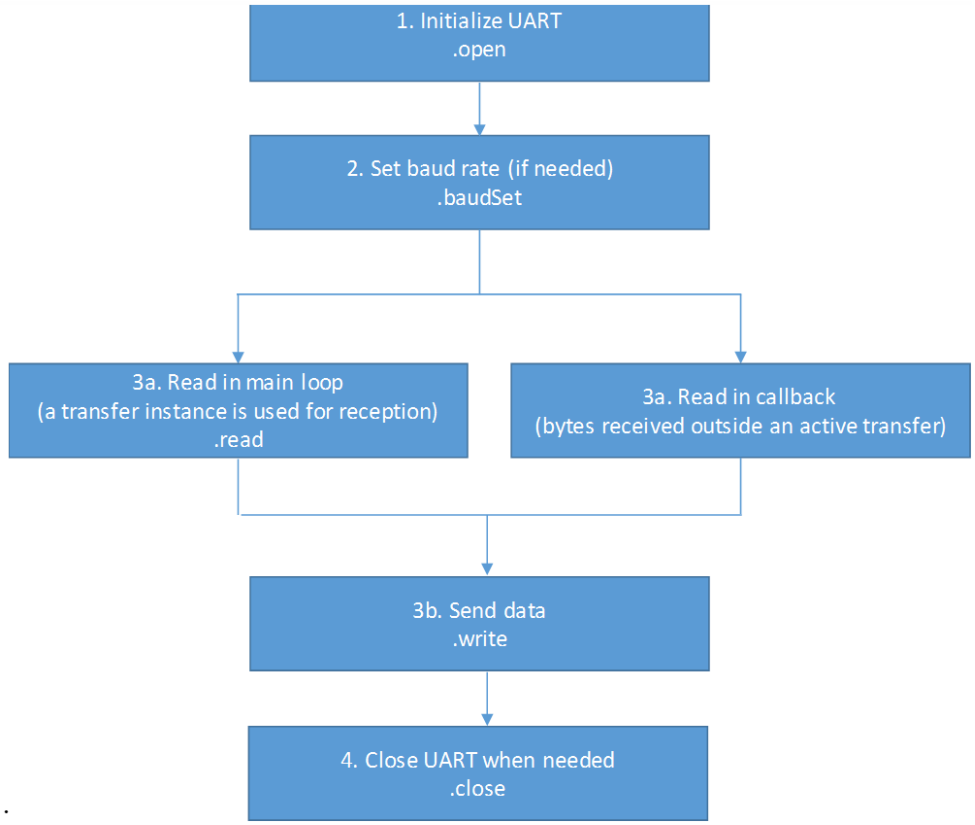

Figure 420: Flow Diagram of a Typical UART HAL Module Application

4.2.46 Watchdog Driver

4.2.46.1 Watchdog Driver

The WDT (Watchdog Timer) HAL module provides high-level APIs for WDT The WDT (Watchdog Timer) HAL module provides high-level APIs for WDT applications and is implemented on r_wdt. The WDT HAL module uses the WDT peripheral on the Synergy MCU. A user-defined callback can be created to respond to event notifications.

4.2.46.2 WDT HAL Module Features

The WDT HAL module has the following key features:

- When the WDT underflows or is refreshed outside of the permitted refresh window, one of the following events can occur:

  - Resetting of the device
  - Generation of an NMI
- Supports the Watchdog Timer (WDT) peripheral, which uses an external clock.
- The WDT can be configured in register start mode through the WDT registers.
- Supports automatic hardware configuration after reset.
- The WDT can be started from the application.

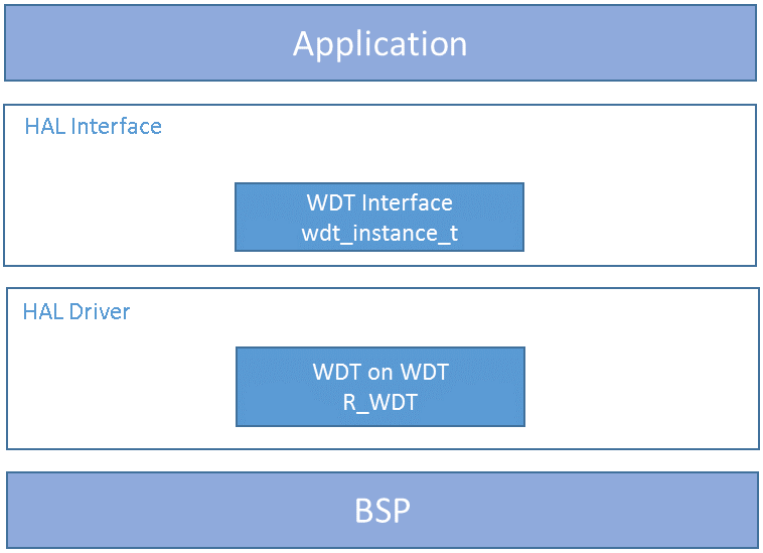

Figure 421:WDT HAL Module Organization, Options, and Stack Implementations

4.2.46.3 WDT HAL Module APIs Overview

The WDT HAL module defines APIs for opening, refreshing, reading, and getting status. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows.

WDT HAL Module API Summary

Function Name	Example API Call and Description
cfgGet	g_wdt0.p_api->cfgGet(g_wdt0.p_ctrl, g_wdt0.p_cfg); Initialize the WDT in register start mode. In auto-start mode with NMI output it registers the NMI callback.
open	g_wdt0.p_api->open(g_wdt0.p_ctrl, g_wdt0.p_cfg); Initialize the WDT in register start mode. In auto-start mode with NMI output it registers the NMI callback.

Function Name	Example API Call and Description
refresh	g_wdt0.p_api->refresh(g_wdt0.p_ctrl); Refresh the watchdog timer.
statusGet	g_wdt0.p_api->statusGet(g_wdt0.p_ctrl, &status); Read the status of the WDT.
statusClear	g_wdt0.p_api->statusClear(g_wdt0.p_ctrl, clear); Clear the status flags of the WDT.
counterGet	g_wdt0.p_api->counterGet(g_wdt0.p_ctrl, &counter); Read the current WDT counter value.
timeoutGet	g_wdt0.p_api->timeoutGet(g_wdt0.p_ctrl, &timeout); Read the watchdog timeout values.
versionGet	g_wdt0.p_api->versionGet(&version); Retrieve the API version using the version pointer.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successfully executed.
SSP_ERR_ASSERTION	Null Pointer(s).
SSP_ERR_INVALID_ARGUMENT	One or more configuration options is invalid.
SSP_ERR_INVALID_MODE	An attempt to open the WDT in register-start mode when the OFS0 register is configured for auto-start mode. Or to open the WDT in auto-start mode when the OSF0 is configured for register start mode.
SSP_ERR_ABORTED	Invalid clock divider for this watchdog

NOTE: Lower level drivers may return Common Error Codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.46.4 WDT HAL Module Operational Overview

Synergy MCUs have two watchdog peripherals- the watchdog timer (WDT) and the independent watchdog timer (IWDT). When selecting between them consider these points:

- The WDT can be started from the application.
- The WDT can be configured in register start mode through the WDT registers. The WDT can also be configured by hardware automatically after reset using parameters stored in Option Function Select Register 0 (OFS0).
- The IWDT has its own clock source which improves safety.
- The IWDT is configured by hardware automatically after reset using parameters stored in the Option Function Select Register 0 (OFS0).

4.2.46.5 WDT HAL Module Operation

The WDT HAL module configures the WDT Interface. When the WDT underflows or is refreshed outside of the permitted refresh window, one of the following events can occur:

- Resetting of the device
- Generation of an NMI

The figure below shows an example of the operation of the WDT. When refreshed in the valid refresh period of the counter the timer count value is reset. If the count is allowed to underflow or refresh occurs outside of the valid refresh period, the WDT resets the device or generates an NMI.

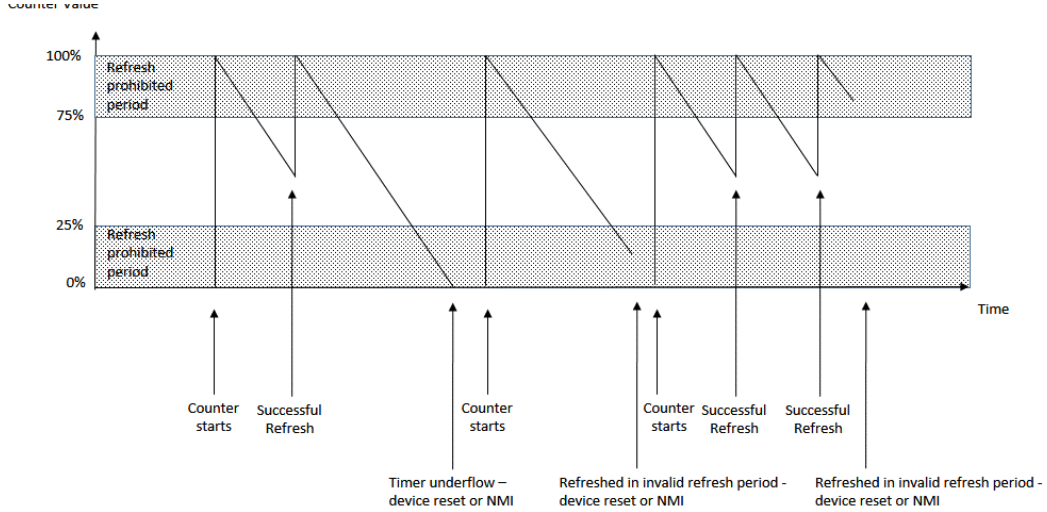

Figure 422: WDT HAL Module Operation

The WDT can be configured in register start mode through the WDT registers. The WDT can also be configured by hardware automatically after reset using parameters stored in Option Function Select Register 0 (OFS0) as shown in the below table.

All series of Synergy microcontrollers have an Option-Setting Memory which can be used to set the operating state of peripherals after a reset. The OFS can be used to set the state of the IWDT, WDT, LVD and CGC HOCO.

The following table details which parameters of the WDT can be configured by the OFS registers:

WDT Parameters

Control	Description
WDT Start Mode Select	Automatically starts the WDT after a Reset in enabled.
WDT Timeout Period	Specifies the WDT timeout (number of clock cycles). 128 cycles 512 cycles 1024 cycles 2048 cycles
WDT-Clock Frequency Division Ratio (The WDT is clocked from PCLKB)	PCLKB / 1 PCLKB / 64 PCLKB / 128 PCLKB / 512 PCLKB / 2048 PCLKB / 8192
WDT Window End Position	25% 50% 75% 100% (no window end position set)
WDT Window Start Position	25% 50% 75% 100% (no window start position set)
WDT Reset Interrupt Request	The WDT can either generate an Interrupt Signal or a Reset signal.
WDT Stop Control	The WDT can continue to count or Stop counting in Low Power Mode.

NOTE: For further information on the contents of the OFS0 register see the Synergy MCU hardware manual.

The OFS register values are set in the Synergy Configuration editor via properties on the BSP tab.

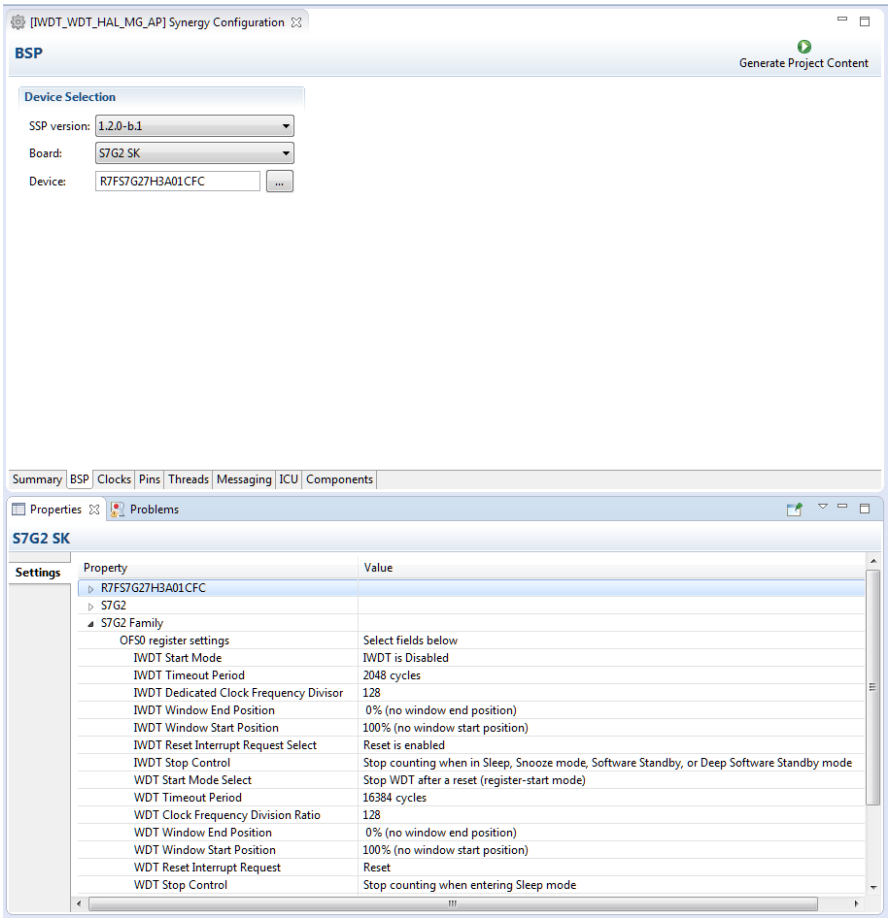

Figure 423: OFS Register Value Settings

4.2.46.6 WDT HAL Module Important Operational Notes and Limitations

4.2.46.7 WDT HAL Module Period Calculation

The WDT operates from PCLKB. Assuming largest parameters for the WDT and a PCLKB of 60 MHz, the time from the last refresh to device reset or NMI generation will be just over 2.2 seconds as detailed below.

PLCKB = 60 MHz

Clock division ratio = PCLKB/8192

Timeout period = 16384 cycles

WDT clock frequency = 60 MHz / 8192 = 7.324 kHz

Cycle time = 1 / 7.324 kHz = 136.53 us

Timeout = 136.53 us x 16384 cycles = 2.23 seconds

4.2.46.8 Triggering DMAC/DTC with the WDT HAL Module

To trigger a transfer of data using the DMAC or DTC peripheral when the WDT counter underflows or when a refresh is attempted outside of the valid refresh period, configure the WDT to generate an NMI and configure the DMAC/DTC transfer with activation_source set to ELC_EVENT_WDT_UNDERFLOW. See the associated User Guide (DMAC, DTC) for further information.

4.2.46.9 Triggering Event Link Controller Events with the WDT HAL Module

The WDT can trigger the start of another peripheral using the Event Link Controller (ELC). Refer to the ELC User Guide for a complete list of available peripherals.

4.2.46.10 WDT HAL Module Limitations

- When using a JLink debugger the WDT counter does not count and therefore will not reset the device or generate an NMI.
- When there is no active task ready to run, ThreadX puts the MCU into sleep mode. If the WDT is configured to stop the counter in low power mode, then your application must restart the timer when used with the ThreadX RTOS.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.46.11 Including the WDT HAL Module in an Application

This section describes how to include the WDT HAL module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP based applications.

To add the WDT HAL module to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the WDT HAL module is g_wdt0 as shown in the table below. This name can be changed in the associated properties window.)

Watchdog Timer Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_wdt0 Watchdog Driver on r_wdt	Threads	New Stack>Driver>Monitoring>Watchdog Driver on r_wdt

When the WDT HAL module on r_wdt is added to the thread stack as shown in the figure below, the configurator automatically adds any needed lower level modules. Any drivers that need additional configuration information will be box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

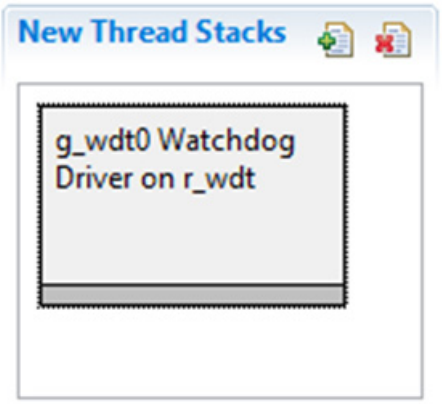

Figure 424: WDT HAL Module Timer Stack

4.2.46.12 Configuring the WDT HAL Module

The WDT HAL module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections (such as interrupts or operating modes) which must be configured for lower level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the properties window of the associated module. Simply select the indicated module and then view the properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+.) This level of detail is not included in the configuration properties tables below, but is easily visible with the ISDE when configuring interrupt priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the following Configuration Table Settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration for the WDT HAL Module

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Include parameter checking code.
Name	g_wdt0	Module Name.
Start Mode	Register, Auto (Default: Register)	Configures the start mode as register start or auto-start.

ISDE Property	Value	Description
Start Watchdog After Configuration	True, False (Default: True)	Controls whether WDT is started during initialization.
Timeout	1024 cycles, 4096 cycles, 8192 cycles, 16384 cycles (Default: 16384 cycles)	WDT timeout period.
Clock Division Ratio	PCLK/4, PCLK/64, PCLK/128, PCLK/512, PCLK/2048, PCLK/8192 (Default: PCLK/8192)	WDT clock divider.
Window Start Position	100% (Window Position Not Specified), 75%, 50%, 25% (Default: 100%)	Permitted refresh period start position.
Window End Position	0% (Window Position Not Specified, 25%, 50%, 75% (Default: 0%)	Permitted refresh period end position.
Reset Control	Reset Output, NMI Generated (Default: Reset Output)	Select whether WDT should reset the MCU or generate an NMI.
Stop Control	WDT Count Enabled in Low Power Mode, WDT Count Disabled in Low Power Mode (Default: Disabled)	Select whether the WDT should stop counting in low power modes.
NMI Callback	NULL	Callback. A user callback function can be registered in open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the IRQn triggers. NSince the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

4.2.46.13 Configuring the Option Function Select Register 0 (OFS0)

All series of Synergy microcontrollers have an Option-Setting Memory which can be used to set the operating state of peripherals after a reset. The OFS can be used to set the state of the IWDT, WDT, LVD and CGC HOCO. See the description in the operational overview section earlier in this document.

4.2.46.14 Configuring the Interrupts for the WDT HAL Module

Configure the WDT interrupts in the same way as configuring the other options for the WDT module. If the WDT is configured to generate an NMI interrupt on underflow or invalid refresh, the interrupt must be enabled in the BSP.

To enable interrupts, set the priority of the CWDT > CWDT NMIUNDF N n. This sets BSP_IRQ_CFG_WDT_UNDERFLOW in ssp_cfg/bsp/bsp_irq_cfg.h to the priority level selected.

When the CWDT NMIUNDF N interrupt is enabled in the BSP, the corresponding ISR will be defined. The ISR will call a user callback function if one was registered in the open API.

4.2.46.15 WDT HAL Module Clock Configuration

The WDT clock is based on the PCLKB frequency. You can set the PCLKB frequency using the clock configurator in the ISDE or using the CGC Interface at run-time. The maximum timeout period with PCLKB running at 60 MHz is approximately 2.2 seconds.

4.2.46.16 WDT HAL Module Pin Configuration

The WDT does not require pins for their operation.

4.2.46.17 Using the WDT HAL Module in an Application

The typical steps in using the WDT HAL module in an application are:

1) Initialize the WDT HAL module in either register start mode or auto-start mode using the open API.
2) Read the configuration of the WDT HAL module in either register start mode or auto start mode with the cfgGet API.
3) Refresh the watchdog timer using the refresh API.
4) Read the WDT status flags using the statusGet API.
5) Clear the status flags and error flags of the WDT HAL module using the statusClear API.
6) Read the current WDT counter value using the counterGet API.
7) Read the watchdog timeout values using the timeoutGet API.

These steps are illustrated in a typical operational flow diagram shown below:

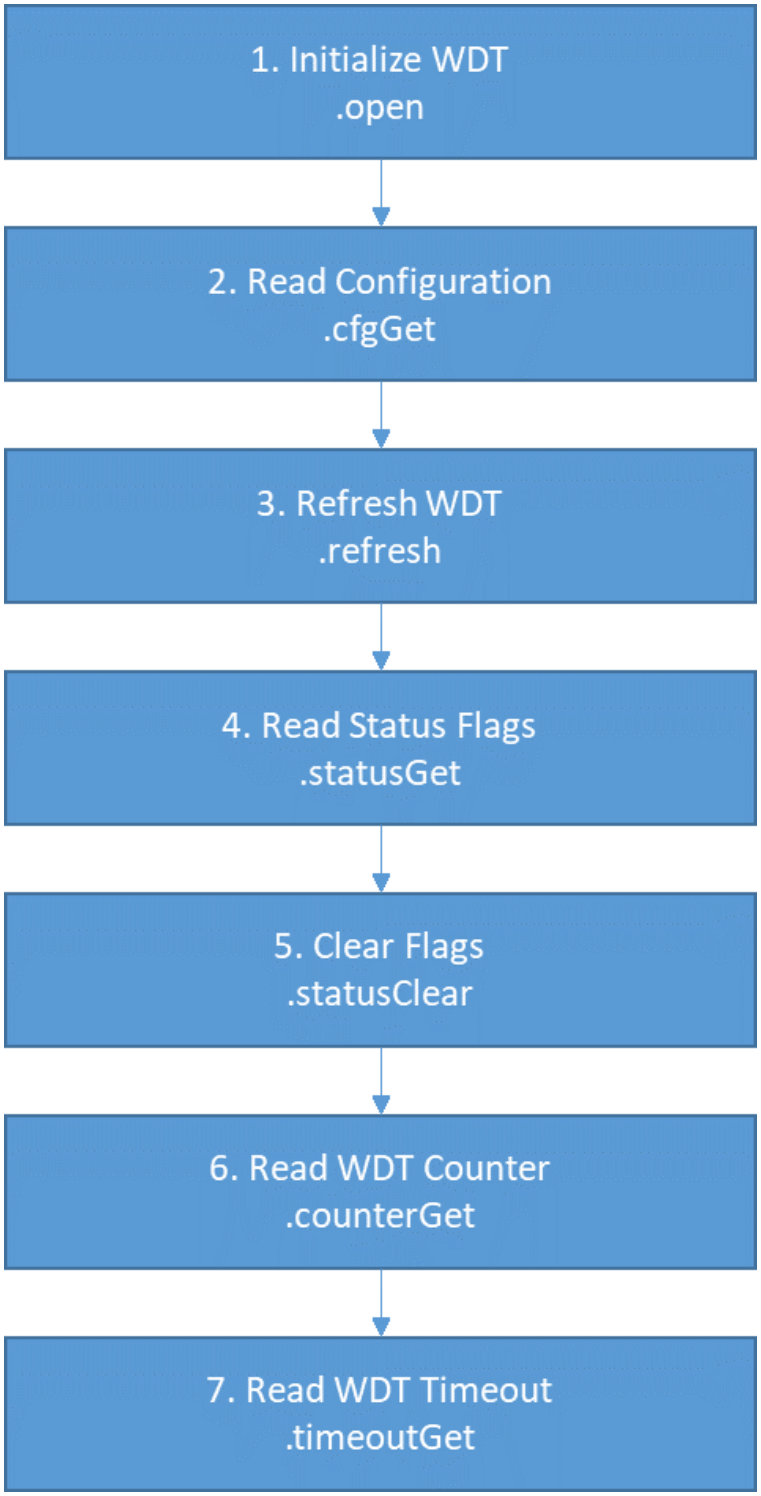

Figure 425: Flow Diagram of a Typical WDT HAL Module Application

4.3 Express Logic Modules

4.3.1 FileX Port Block Media Framework

The FileX Port Block Media Framework module, implemented on sf_el_fx, supports the Express Logic FileX system, a complete FAT format media and file management system for deeply embedded applications. The FileX Port Block Media Framework module provides I/O calls for FileX to access Synergy Media drivers through the Block Media Interface and adaptation layers. The SD/MMC HAL module and the SDIO HAL module are implemented on r_sdmmc and are used to read/write and control SD/MMC media devices as well as SDIO cards. The sf_el_fx module uses the SD/MMC peripherals on the Synergy MCU.

This document is divided into the following sections which can be read independently by a more experienced Synergy developer or in series by developers new to the Synergy Platform.

4.3.1.1 FileX Port Block Media Framework Features

- The FileX Port Block Media Framework module features include:
  - Support for FAT32, FAT16 and FAT12
  - Supports mounting the first FAT partition on a given media
  - Unlimited FileX objects (media, directories, and files)
  - Dynamic FileX object creation/deletion
  - Flexible memory usage
  - Size scales automatically
  - Small footprint
  - Complete integration with ThreadX
- SD card interface
  - Compatible with SD, SDHC, and SDXC formats

  - Supports 1-bit and 4-bit bus width
  - Card detect function when supported by the hardware
  - Write protect support
- eMMC interface
  - Supports 1-bit, 4-bit and 8-bit bus width
- SD bus interface
  - Compatible with SD memory card and SDIO card
  - Transfer bus mode selectable from 4-bit wide bus mode or 1-bit default bus mode
  - Compatible with SD, SDHC, and SDXC formats
- SD and MMC shared
  - DMAC and DTC triggerable by the SBFAI interrupt SD buffer is read and write accessible using the DMAC

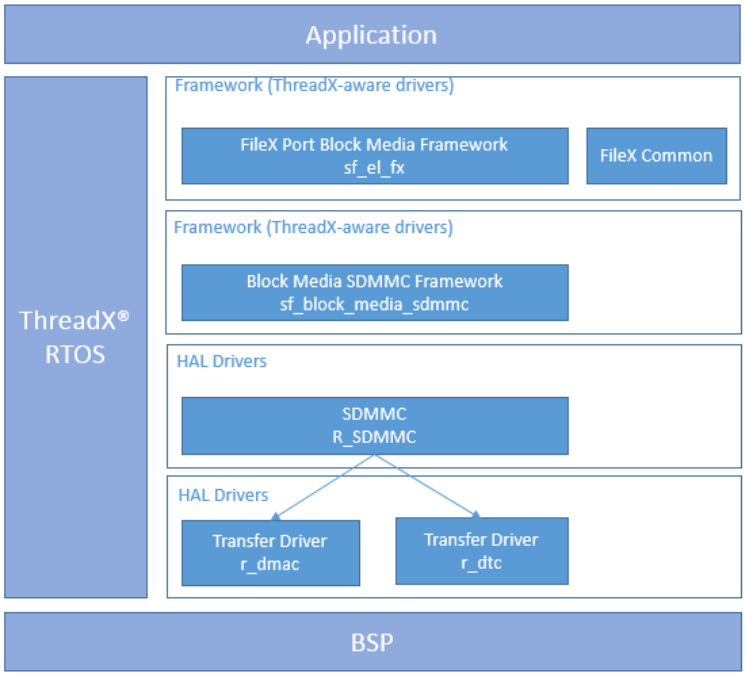

Figure 426: FileX Port Block Media Framework Stack with sf_block_media_sdmmc

4.3.1.2 FileX Port Block Media Framework APIs Overview

The FileX Port Block Media Framework implements the Express Logic FileX operations for file organization and access. The complete list of FileX related APIs is too long to provide here, so only some of the most important are provided in the below table, refer to the FileX User's Manual, available as described in the Reference section of this document.

FileX Port Block Media Framework API Summary (selected examples only)

Function Name	Example API Call and Description
fx_directory_attributes_read	fx_directory_attributes_read(&my_media, "mydir", &attributes); Read the directory attributes from the specified media
fx_file_open	fx_file_open(&my_media, &my_file, "myfile.txt", FX_OPEN_FOR_READ); Open "myfile.txt" file for read
fx_file_create	fx_file_create(&my_media, "myfile.txt"); Create file with name "myfile.txt"
fx_media_read	fx_media_read(&my_media, 22, my_buffer); Read the logic sector (in this example from sector 22) from media specified by &my_media, and places it into the buffer my_buffer

NOTE: For more complete descriptions of operation, status return values and definitions for the function data structures, typedefs, defines, API data, API structures and function variables review the SSP Reference Manual as described in the Reference Section at the end of this document. For FileX API documentation refer to X-Ware and NetX Component Documents for Renesas Synergy found as described in the Reference Section.

4.3.1.3 FileX Port Block Media and R_SDMMC Operational Overviews

FileX Port Block Media Operational Overview

FileX is a complete File Allocation Table (FAT) format media and file management system for deeply embedded applications. FileX supports an unlimited number of media devices at the same time:

- RAM disks
- FLASH managers
- Multiple other physical devices.

FileX supports 12-, 16-, and 32-bit FAT formats and contiguous file allocation. FileX is highly optimized for both size and performance. You can find the API reference for the FileX module in the FileX User's manual available as described in the References section at the end of this document.

FileX Port Block Media Framework Operational Notes

The media must be formatted to either a FAT12, FAT16 or FAT32 filesystem before it can be opened. This can be done prior to inserting the media or at run time.

FileX Block Media Framework Limitations

- SF_EL_FX does not currently support exFAT.
- When using SF_EL_FX with SD/eMMC the FileX block size must be 512 bytes.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

SDMMC HAL Module Operational Overview

The SD/MMC Driver and the SDIO Driver are implemented on r_sdmmc and are used to read/write and control SD/MMC media devices as well as SDIO cards. The SD/MMC module can be used as a standalone driver, or it can be used with FileX or any other compatible file system.

The SDMMC HAL Module supports the following memory devices:

- SDSC (SD Standard Capacity), SDHC (SD High Capacity), SDXC (SD Extended Capacity), and eMMC (embedded Multi Media Card)
  - Supports reading, writing, and erasing SD and eMMC memory devices
  - Supports 1, 4, or 8 bit data bus (8-bit bus is supported for eMMC only)
  - Supports detection of hardware write protection (SD cards only)
  - Automatically selects between backwards compatible mode and high speed SRD mode (eMMC)
- Supports SDIO
  - Supports SDIO single register access (CMD52)
  - Supports SDIO multiple register access (CMD53)
  - Supports SDIO interrupts
- Automatically configures the clock to the maximum clock rate supported by both host (MCU) and device

Interrupt Configurations

When using FileX, sf_el_fx and sf_block_media_sdmmc, the callback is implemented at the sf_block_media_sdmmc layer and does not have to be set up at the SDMMC module level. However, the interrupts and transfer drivers still must be configured. The interrupts required are:

Using SD/MMC with DTC:

- Access Interrupt
- DTC Interrupt

Using SD/MMC with DMAC:

- Access Interrupt
- DMAC Interrupt (in DMAC instance)

Using SDIO with DTC:

- Access Interrupt
- SDIO Interrupt
- DTC Interrupt

Using SDIO with DMAC:

- Access Interrupt
- SDIO Interrupt
- DMAC Interrupt (in DMAC instance)

The Card interrupt is optional, and only available on MCU packages that have the SDHIn CD pin (n = channel number) available on the Pins tab of the Synergy Configuration Tool.

Block Size Configuration

Block size configuration is provided for use with SDIO cards only. For SDIO cards, block size may be configured to 1-512 bytes. Block size must remain at the default 512 bytes for SD cards and e/MMC memory devices.

Card Detection Configuration

See Card Detection Limitations before using card detection in the r_sdmmc driver. If card detection is not available or not desired for the application, Card Detection must be set to Not Used in the Properties for the r_sdmmc instance in the Synergy Configuration Tool. To enable card detection, set Card Detection to CD Pin and Media Type to Card in the Properties for the r_sdmmc instance in the Synergy Configuration Tool.

Access Interrupt Priority

When data transfers are not 4-byte aligned or not a multiple of 4 bytes, a software copy of the block size (up to 512 bytes) is done in the access interrupt. This blocks other interrupts that are a lower or equal priority to the access interrupt until the software copy is complete.

General Timing Notes

Several functions in this driver block. open and erase block until the entire operation is complete. read,write, readIo,writeIo, readIoExt, and writeIoExt block for a single command response cycle. In a multithreaded system, care should be taken to use this driver in a lower priority thread if other threads require a response time faster than the time this driver could block for during one of these function calls.

Timing Notes for Open

The open API completes the entire device identification and configuration process. This involves several command-response cycles at a bus width of 1-bit and a bus speed of 400 kHz or less.

Timing Notes for Read, Write, ReadIoExt, and WriteIoExt

The read and write media (read and write) and extended read and write SDIO APIs (readIoExt and writeIoExt) block until the response is received from the device. The data transfer operation is non-blocking and requires interrupts and a transfer instance, either DMAC or DTC. These APIs return SSP_SUCCESS to indicate that the initial operations have started successfully. The application must wait for a callback with the event SDMMC_EVENT_TRANSFER_COMPLETE or SDMMC_EVENT_TRANSFER_ERROR to indicate completion of the read or write.

Timing Notes for ReadIo and WriteIo

The SDIO readIo and writeIo APIs block until the response is received from the device. The read or write operation is complete when these APIs return.

Timing Notes for Erase

The erase API blocks until the erase operation is complete. This may be several seconds or more depending on how many sectors are being erased.

SDIO Interrupts

Many SDIO cards use level interrupts, meaning the interrupt is not deasserted until the interrupt is cleared on the device. In order to ensure SDIO interrupts are cleared appropriately, one of the following methods are recommended:

- Ensure the SDIO interrupt is cleared on the device before exiting the callback function with the event SDMMC_EVENT_SDIO. If this method is chosen and any SDIO API must be used in the interrupt, the access interrupt must be a higher priority than the SDIO interrupt.
- Disable the SDIO interrupt in the callback function with the event SDMMC_EVENT_SDIO using IoIntEnable. Clear the SDIO interrupt elsewhere in the application, then re-enable SDIO interrupts if desired using IoIntEnable.

SD HALA Compliance

When developing host devices that are compliant with the SD Specifications, the host must comply with the SD Host/Ancillary Product License Agreement (SD HALA).

Data Alignment and Size

Data transfers should be 4-byte aligned and a multiple of 4 bytes in size whenever possible. This recommendation applies to the read(), write(), readIoExt(), and writeIoExt() APIs. When data transfers are 4-byte aligned and a multiple of 4-bytes, the r_sdmmc driver is zero copy and takes full advantage of hardware acceleration by the DMAC or DTC. When data transfers are not 4-byte aligned or not a multiple of 4 bytes an extra CPU interrupt is required for each block transferred (see Access Interrupt Priority).

Card Detection Limitations

Card detection support in the r_sdmmc driver is limited. Card detection is only available after open is complete, and open() cannot be completed unless a card is inserted. Card detection in the r_sdmmc driver is therefore only useful to detect card removal and reinsertion. After reinsertion is detected, the driver must be closed and reopened, and card detection will not be available until the reopen is complete. Card detection is available only on MCU packages that have the SDHIn CD pin (n = channel number) available on the Pins tab of the Synergy Configuration Tool. If the MCU does not have the SDHIn CD pin, or card detection is not desired for the application, card detection must be disabled in the Properties for the r_sdmmc instance in the Synergy Configuration Tool. An alternative to using the card detection feature of the r_sdmmc driver is to use an External IRQ instance and handle card detection at the application layer. If card detection is handled at the application layer, the open should be called after card insertion is detected, and the close should be called after card removal is detected.

Other Limitations

Refer to the most recent SSP Release notes for the most up to date limitations for this module.

4.3.1.4 Including the FileX Port Block Media Framework in an Application

This section describes how to include the FileX Port Block Media Framework in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User Manual available as described in the Reference Section at the end of this document to learn how to manage each of these important steps in creating SSP based applications.

To add the module to an application, simply add it to a thread using the Stacks Selection Sequence given in the table below. (The default name for the modules is shown in the table below. This name can be changed in the associated Properties window). When the driver is added it shows up in the thread as illustrated in the following figure.

Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_el_fx0 FileX Port Block Media Framework on sf_el_fx	**Threads**	**New Stack> Framework > File System> FileX Port Block Media Framework on sf_el_fx**

When the FileX Port Block Media Framework on sf_el_fx is added to the Thread Stack, as shown in the figure below, the configurator automatically adds the needed lower level drivers. Any drivers that need additional configuration information will be box text highlighted in red. Modules with a gray band are individual modules that stand alone. Modules with a blue band are shared or common and need only be added once, since they can be used by multiple stacks. Modules with a pink band can require the selection of lower level drivers. Sometimes these are optional or recommended and this is indicated in the block with the inclusion of this text. If the addition of lower level drivers is required, the module description will include "Add" in the text. Clicking on any pink banded modules will bring up the "New" icon and then will show the possible choices.

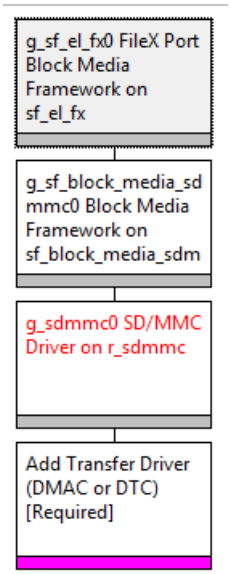

Figure 427: FileX Port Block Media Framework Stack

4.3.1.5 Configuring the FileX Port Block Media Framework Module

The module must be configured by the user for the desired operation. The SSP configuration window will automatically identify, by highlighting the block in red, any required configuration selections, such as Interrupts or operating modes, which must be configured for lower level modules, for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the properties tab within the SSP Configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the Interrupt Priority. This configuration setting is available with the Properties window of the associated module. Simply select the indicated module and then view the

properties window. The Interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the Interrupt Priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the below configuration properties tables, but is easily visible with the ISDE when configuring Interrupt Priority levels.

NOTE: You may want to open your ISDE and create the FileX Port Block Media and explore the property settings in parallel with looking over the Configuration Table Settings given below. This will help orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for FileX Port Block Media Module

ISDE Property	Setting	Description
Parameter Checking	Enabled, Disabled, BSP (Default: BSP)	Selects if code for parameter checking is to be included in the build
Name	Default: g_sf_el_fx0	FileX Port Block Media framework Module name

Configuration Settings for the Block Media Framework on sf_block_media_sdmmc Module

ISDE Property	Setting	Description
Parameter Checking	Enabled, Disabled, BSP (Default: BSP)	Selects if code for parameter checking is to be included in the build
Name	Default: g_sf_block_media_sdmmc0	Block Media framework Module name
Block size of media in bytes	512	Media Block size

NOTE: The above setting examples and defaults are for a project using the Synergy S7. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower level modules can be desirable. For example, the bus width can be different for different media types. The configurable properties for the lower level stack modules are given in the below sections for completeness and as a reference.

NOTE: Most of the property settings for lower level modules are fairly intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

4.3.1.6 Configuration Settings for the SD/MMC Driver and SDIO Driver

Typically, only a small number of settings must be modified from the default for lower level drivers and these are indicated via the red text in the Thread Stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The table below identifies all the settings within the properties section for the module.

Configuration for the SD/MMC and SDIO Driver

ISDE Property	Setting	Description
Parameter Checking	Enabled, Disabled, BSP (Default: BSP)	Selects if code for parameter checking is to be included in the build
Name	Default: g_sdmmc0	Module name
Channel	0,1 Default 1	Channel of SDMMC peripheral, channel 0 or 1
Media type	Embedded, Card Default: Embedded	Media is a card or an embedded device. This allows to firmware to know whether to look for card insertion/removal and write protect pins.
Bus Width	1 bit, 4 bits, 8 bits	Data bus with as defined by hardware interface. (8 Bits for eMMC only)
Block Size	512	Size of block

ISDE Property	Setting	Description
Callback	NULL (default) Name of user callback function.	(Not required if using FileX) Set to name of user callback function. Provides event that caused interrupt: SDMMC_EVENT_CARD_REMOVED, SDMMC_EVENT_CARD_INSERTED, SDMMC_EVENT_ACCESS, SDMMC_EVENT_SDIO, SDMMC_EVENT_TRANSFER_COMPLETE, SDMMC_EVENT_TRANSFER_ERROR
Access Interrupt Priority	Priority level 0-15 Default: Disabled	Interrupt level priority required for reading, writing, and errors for SD, eMMC and SDIO. Calls the interrupt callback if enabled.
Card Interrupt Priority	Priority level 0-15 Default: Disabled	(Optional) Interrupt for card removal. Automatically closes device when card is removed. Calls the interrupt callback if enabled.
DMA Request Interrupt Priority	Priority level 0-15 Default: Disabled	Interrupt priority level required for SDIO reading, writing, and errors. Calls the interrupt callback if enabled. Not used for memory cards.

NOTE: The above setting examples and defaults are for a project using the Synergy S7. Other MCUs may have different default values and available configuration settings.

SDHI Clock Configuration

The SDHI uses PCLKA for its clock source. There is no need to configure the clock specifically for the SDMMC peripheral, unless you need to optimize the data rate. The SDMMC driver selects the appropriate built-in divider based on

the PCLKA frequency and the maximum clock rate allowed by the SD, SDIO, or eMMC device, obtained at media device initialization.

SDMMC Pin Configuration

Use the e^2 studio pin configurator to configure the I/O pins for SDMMC peripheral. The drive capacity for each pin should be set to "Medium" or "High" for most boards and high-speed memory and SDIO devices. The following tables illustrate the method for selecting the pins within the SSP configuration window and provides an example selection for the module pins.

NOTE: The Operation Mode selection mode determines what peripheral signals are available and thus what MCU pins are required.

Pin Selection Sequence for SDHI Peripheral

Resource	ISDE Tab	Pin selection Sequence
SDHI	**Pins**	Select **Peripherals > Storage:SHDI > SDHI0**

NOTE: The above selection sequence assumes SDHI0 is the desired hardware target for the driver.

Pin Configuration Settings for SDHI Peripheral

Pin Configuration Property	Settings	Description
Operation Mode	Disabled, Custom, SD_MMC 1 bit SD_MMC 4 bit MMC 8 bit (Default: Custom)	Select mode as per application
CLK	None, P413 (Default: P413)	Clock Pin

Pin Configuration Property	Settings	Description
CMD	None, P412 (Default: P412)	Command Pin
DAT0-7	None, PXXX (Default: PXXX)	Data Pin
CD	None, P903 (Default: P903)	Card detection Pin
WP	None, P414 (Default: P414)	Card write protection pin

NOTE: The above example settings are for a project using the Synergy S7G2 and the DK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

Other Settings

The read and write media (R_SDMMC_Read and R_SDMMC_Write) and extended read and write SDIO functions (R_SDMMC_ReadIoExt and R_SDMMC_WriteIoExt) have been made non-blocking in Release 1.1.0 and now require interrupts and a transfer function, either DMAC or DTC. The read and write functions return SSP_SUCCESS to indicate that the initial operations have started successfully. However, the user application must wait for the user callback and check for event SDMMC_EVENT_TRANSFER_COMPLETE or SDMMC_EVENT_TRANSFER_ERROR to indicate completion of the read or write.

4.3.1.7 Using the FileX Port Block Media Framework Module or SDMMC HAL Module in an Application

The typical steps in using the FileX Port Block Media Framework Module on sf_el_fx in an application are:

1) Initialize the media using the FileX API fx_system_initialize (sf_el_fx calls it automatically if "Auto Initialization" property is set to Enabled in "FileX Common on fx").
2) Optionally, format the media using the FileX API fx_media_format
   - sf_el_fx automatically formats the media during the generated initialization function if "Format media during initialization" property is set to Enabled).
   - If "Filesystem on SDMMC" is enabled the entire media after the hidden sectors will be formatted and the "Total Sectors" configuration in "FileX on Block Media" is ignored.
3) Open the media using the FileX API fx_media_open (sf_el_fx opens the media automatically if "Auto Initialization" is set to Enabled in the FileX on Block Media instance).

4) Create and delete files and directories as required using one of the FileX APIs (for example, fx_file_create, fx_file_delete, fx_directory_create, fx_directory_delete).
5) Read from and write to files on the media as required using one of the FileX API (for example, fx_file_read or fx_file_write).
6) Read from and write to the media directly as required using one of the FileX API (for example, fx_media_read or fx_media_write).
7) Close the physical media using the FileX API fx_media_close.

NOTE: After a successful fx_media_open call all FileX file and directory related APIs can be used. Refer to the FileX User Guide for documentation on all available functions.

These common steps are illustrated in a typical operational flow diagram in the following figure.

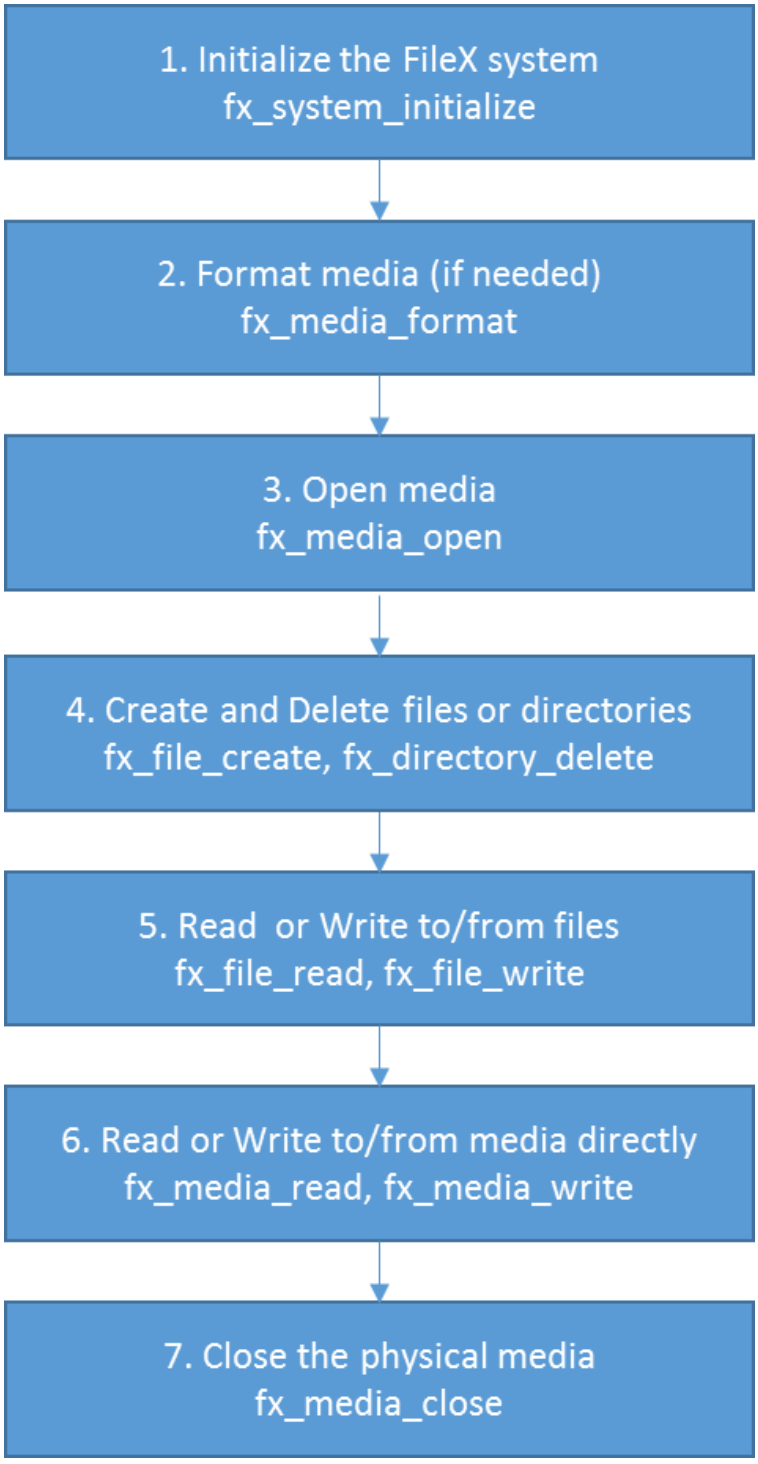

Figure 428: Flow Diagram of a Typical FileX Port Block Media Application

The typical steps for using the r_sdmmc driver with an SD or eMMC memory device are:

1) Open the driver using open.
2) Read data from the card using read or write data to the card using write.
3) Wait for a callback with the event SDMMC_EVENT_TRANSFER_COMPLETE (meaning the operation completed successfully) or SDMMC_EVENT_TRANSFER_ERROR (meaning the operation did not complete successfully) after each time read or write is called.

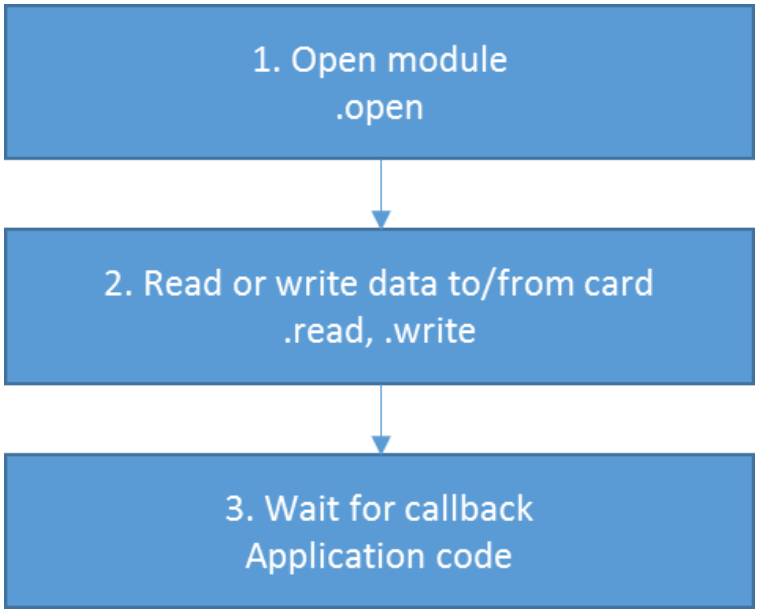

Figure 429: Flow Diagram of a Typical SDMMC SD or eMMC Application

The typical steps for using the r_sdmmc driver with an SDIO card are:

1) Open the driver using open.
2) Set or read back single registers using readIo or writeIo. The operation is complete immediately after these calls and there is no need to wait for a callback.
3) Set or read back multiple registers using readIoExt or writeIoExt. The block size can be changed using control between calls if necessary.
4) Wait for a callback with the event SDMMC_EVENT_TRANSFER_COMPLETE (meaning the operation completed successfully) or SDMMC_EVENT_TRANSFER_ERROR (meaning the operation did not complete successfully) after each time readIoExt or writeIoExt is called.
5) If the card requests an interrupt, the callback is called with the event SDMMC_EVENT_SDIO. Handle the SDIO interrupt as described in the documentation for the card (see the SDIO Interrupts section of this documentation). SDIO interrupts from the card can be enabled or disabled at any time using IoIntEnable.

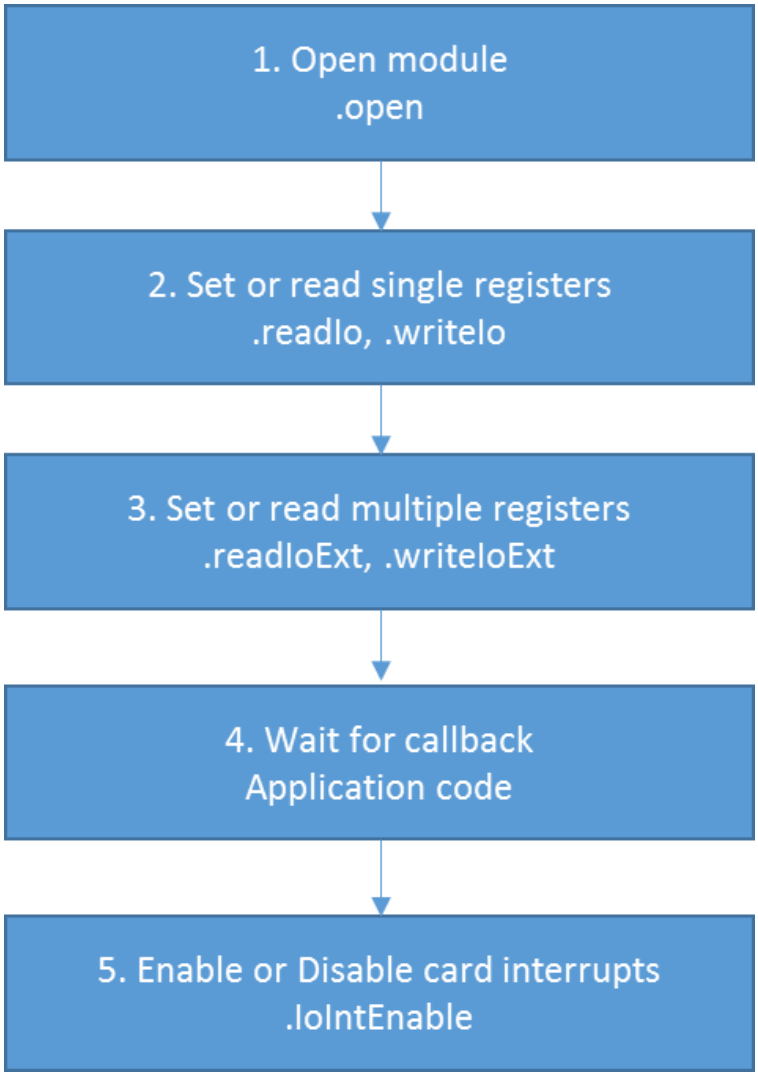

Figure 430: Flow Diagram of a Typical SDMMC SDIO Application

4.3.2 GUIX Port Framework

The Express Logic GUIX Synergy Port Module, SF_EL_GX, is the Express Logic GUIX™ adaptation layer for Synergy MCU groups, which have graphics engines GLCDC, DRW (2DG engine) or a JPEG decode engine. The APIs it provides support graphics hardware engine setup for GUIX and support graphics rendering and displaying accelerated by hardware engines. The module defines full-set of GUIX low-level display driver functions which draw graphics accelerated by DRW (2DG engine) or JPEG, or displays graphics with GLCDC (See the GUIX User Guide Chapter 5: GUIX Display Drivers). The module encourages the hardware acceleration for graphics rendering but also allows software processing without hardware support.

4.3.2.1 GUIX Synergy Port Framework Module Features

The GUIX Synergy Port Framework module includes the following key functions:

- Adapts GUIX to the SSP Framework
- Attaches the SSP Display Interface driver to GUIX Display Driver Interface
- Allows GUIX to draw widgets accelerated by the Synergy D2W (2DG) engine
- Allows GUIX to draw widgets accelerated by the Synergy JPEG engine
- Supports double-buffer toggling control for screen transitions without tearing
- Supports screen rotation (90/180/270 degree)
- Supports various output color formats
  - 32bpp (ARGB8888, RGB-888)
  - 16bpp (RGB565)
  - 8bpp (8bit Palette (CLUT))
- Support for user callback functions

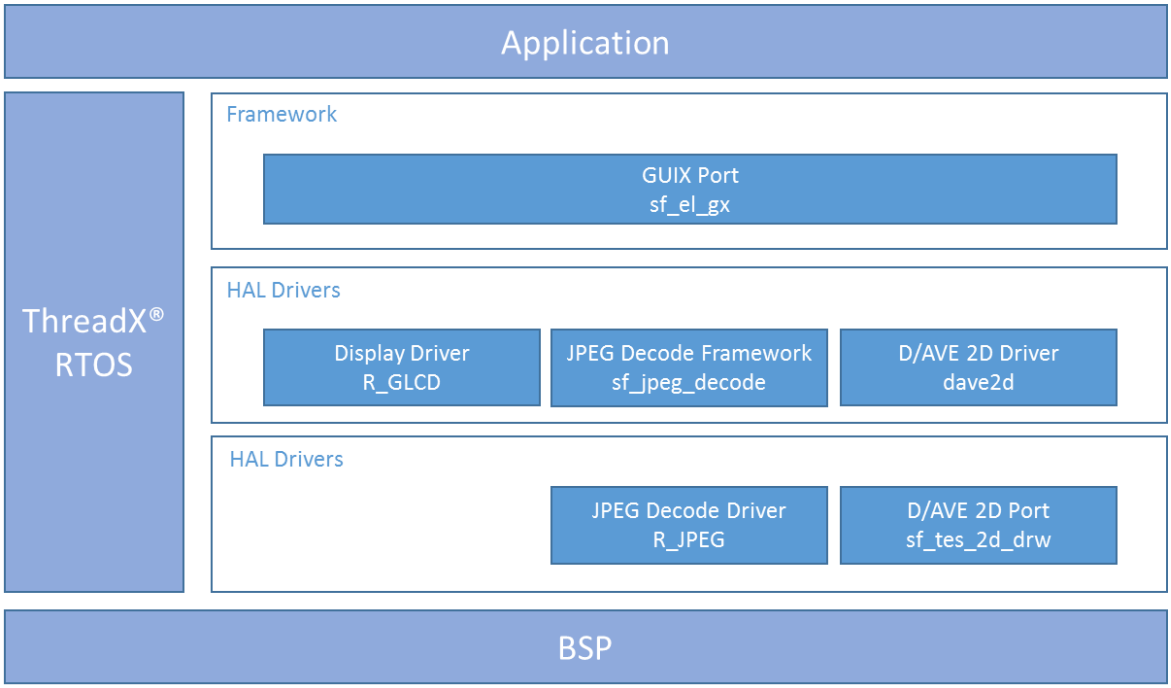

Figure 431: GUIX Synergy Port Framework Organization, Options and Stack Implementations

4.3.2.2 GUIX Synergy Port Framework Module APIs Overview

The GUIX Synergy Port Framework defines APIs for opening, closing, setup and initialization. A complete list of the available APIs, an example API call, and a short description of each can be found in the table below. A table of status return values follows.

GUIX Synergy Port Framework Module API Summary

Function Name	Example API Call and Description
.open	g_sf_el_gx.p_api->open(g_sf_el_gx.p_ctrl, g_sf_el_gx.p_cfg); Opens the SF_EL_GX Module. The API can only be called from a thread. The API passes the configuration pointer to define low-level graphics device drivers and frame buffers and register the user callback function. This function does not actually initialize low-level drivers. Instead, the API setup initializes the low-level drivers. The reason is described in the explanation for setup below.
.close	g_sf_el_gx.p_api->close(g_sf_el_gx.p_ctrl); Closes the SF_EL_GX Module. This API closes the low-level drivers. Normally, the API is not called since GUIX will not be closed once initialized.
.versionGet	g_sf_el_gx.p_api->versionGet(&version); Returns the version of the Module in the version pointer.

Function Name	Example API Call and Description
.setup	gx_studio_display_configure (MAIN_DISPLAY, g_sf_el_gx.p_api->setup, LANGUAGE_ENGLISH, MAIN_DISPLAY_THEME_1, &p_window_root); This is the interface to initialize low-level graphics device drivers and must be passed to GUIX through GUIX (Studio) service call gx_studio_display_configure() as the function pointer. GUIX then calls the API back and, at that moment, the API configures the SSP device drivers based on the configuration passed by open. The reason for this procedure to initialize low-level drivers is that the API has the GUIX-compliant argument (GX_DISPLAY *) type and does not allow applying the detailed configuration of the SSP graphics device drivers generated from e^2 studio.
.canvasInit	g_sf_el_gx.p_api->canvasInit(g_sf_el_gx.p_ctrl, p_window_root); This is the GUIX helper API to determine the memory address of GUIX canvas. The API has an argument with (GX_WINDOW_ROOT *) type and the API provides GUIX the start address of canvas memory, which is needed for the low-level graphics device drivers to draw/display images.

NOTE: For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables review the SSP Users Manuals API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API call successful.
SSP_ERR_ASSERTION	NULL pointer error happens.
SSP_ERR_IN_USE	SF_EL_GX is in-use.

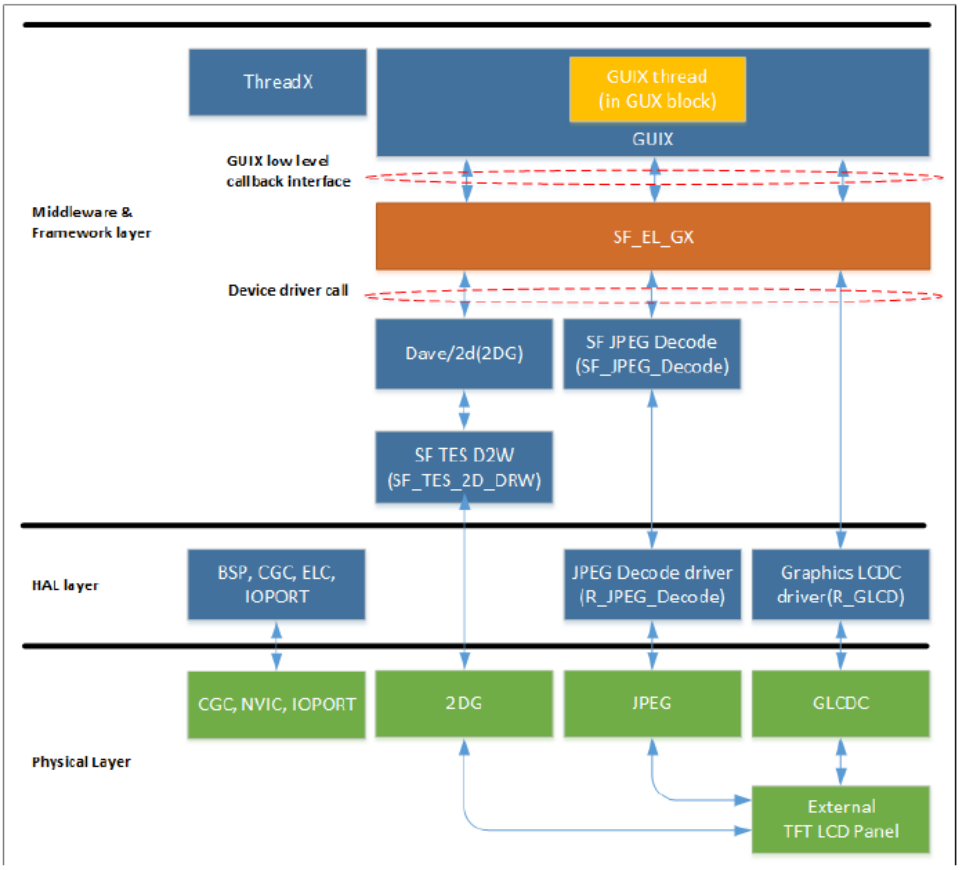
Name	Description
SSP_ERR_INTERNAL	Error happen in Kernel service calls.
SSP_ERR_NOT_OPEN	SF_EL_GX is not opened.
SSP_ERR_TIMEOUT	A task times out (or exceeds retry limit) before completion in display driver.
SSP_ERR_D2D_ERROR_DEINT	Error occurred in D/AVE 2D driver.
GX_SUCCESS	Device driver setup is successfully done.
GX_FAILURE	Device driver setup failed.
SSP_ERR_INVALID_CALL	Function call was made when the driver is not in SF_EL_GX_CONFIGURED state.
SSP_ERR_D2D_RENDERING	The D/AVE 2D returns error at opening a display list buffer
SSP_ERR_INVALID_ARGUEMENT	Invalid non-pointer (e.g. parameter) input
SSP_ERR_UNSUPPORTED	Specified color format is not supported
SSP_ERR_D2D_ERROR_INIT	The D/AVE 2D returns error at the initialization.

NOTE: Lower level drivers may return Common Error Codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.3.2.3 GUIX Synergy Port Framework Module and JPEG Decoder HAL Module Operational Overviews

GUIX Synergy Port Framework Module Overview

The figure below shows the components for a Synergy graphics solution and the flow of graphics data in this solution:



- Module initialization

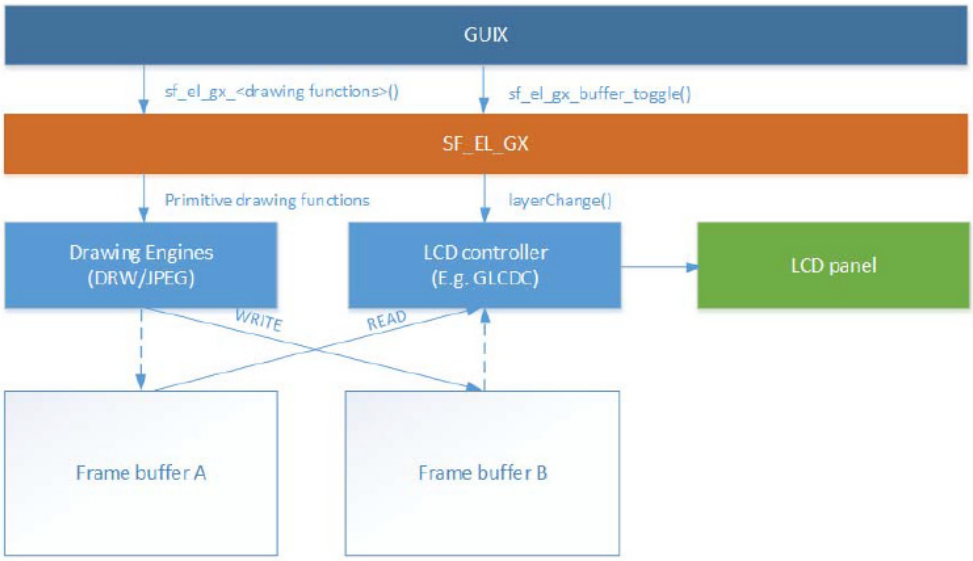
The SF_EL_GX supports the Synergy graphics hardware setup, which is required to run the GUIX system. The module has a dependency with Express Logic GUIX™ and GUIX Studio™ generated code. The GUIX system initialization needs to follow the sequence below as a general guidance.

1) 'open' SF_EL_GX module to initialize SF_EL_UX control block and pass module configurations.
2) Initialize GUIX Display object by GUIX Studio generated API gx_studio_display_configure. Through this API, SF_EL_GX 'setup' API is inputted to GUIX and Synergy graphics hardware setup will complete. Also, the root window initialized by GUIX is outputted to a user application.
3) Initialize the primary memory address of a GUIX Canvas Buffer by canvasInit API.
4) Create the root window by GUIX Studio generated API gx_studio_named_widget_create.
5) Show the root window by GUIX API gx_window_show API.
6) Start the GUIX system by GUIXAPI gx_system_start.

- Ping-Pong Frame Buffer Management

The SF_EL_GX module manages the buffer toggling operation in the graphics system with a ping-pong frame buffer. The figure below shows a ping-pong buffer graphics system managed by the SF_EL_GX module. The module uses GUIX and

the low-level display driver functions to draw an image (2D Drawing engine(DRW) or JPEG) and display the image (DISPLAY module, for example: GLCDC). A design with a single frame buffer is also possible in the SF_EL_GX configuration. However, it is better to use two frame buffers to avoid the tearing issue that could occur in a single frame buffer system.



Synergy 2D Drawing Engine Support

The module can draw graphics image accelerated by 2D Drawing engine (DRW) to get better graphics performance. Users can enable 2D Drawing engine with following configurations. The configuration is available through Synergy Configurator.

- Define GX_USE_SYNEGY_DRW (1) in gx_user.h
- Set DRW (SF_TES_2D_DRW) interrupt priority

Make sure to select "Renesas Synergy" in "Target CPU" setting in the "Configure Project" window and check "Enable Graphics Accelerator" in the "Synergy Advanced Settings" window on the Express Logic GUIX Studio (v5.2.8 or later). For the Pixelmap Output Format in the "Edit Pixel map" window (Right-click on pixelmap->edit settings. This will open the window), select "Compress Output". Do not select "Raw Format". This configuration allows the GUIX Studio to generate Targa RLE formatted encoded image resource data. The 2D Drawing engine hardware can read this format and decode and draw the image on the frame buffer.

Synergy JPEG Support

The module can draw graphics image accelerated by JPEG engine to get better graphics performance if a JPEG encoded image is used as a GUIX image resource. Users can enable JPEG engine with following configurations. The configuration is available through Synergy Configurator.

- Define GX_USE_SYNEGY_JPEG (1) in gx_user.h
- Set JPEG (R_JPEG_DECODE) interrupt priority

Make sure to select "Renesas Synergy" in "Target CPU" setting in the "Configure Project" window and select "Hardware JPEG Decoder" in the "Decoder Types JPEG:" drop-down menu on the Express Logic GUIX Studio (v5.2.8 or later). For the Pixelmap Output Format in the "Exit Pixel map" window (Right-click on pixelmap->edit settings. This will open the window), select "Raw Format". This configuration allows the GUIX Studio to generate raw JPEG encoded image resource data. JPEG hardware can read this format and decode and draw the image on the frame buffer.

GUIX Canvas Buffer

The module supports GUIX Canvas buffer which is used to rotate the graphics screen image. The size of GUIX Canvas Buffer must be exactly same as a frame buffer for the DISPLAY module. Note that, the use of a GUIX Canvas impacts to the graphics performance because of additional graphics image processing being required. Therefore, GUIX Canvas buffer should be only used if the screen rotation is required. Otherwise set NULL to p_canvas to let GUIX draw an image directly to frame buffers.

Screen Rotation

The module supports the screen rotation. The GUIX draws a screen image on a GUIX Canvas buffer as designed in the GUIX Studio, but SF_EL_GX module can perform the screen rotation and draw the rotated screen image on frame buffers. For example, a GUI screen designed as a landscape image in GUIX Studio can be rotated and displayed on a LCD panel with portrait shape dimension. Supported rotation angle is either of 90, 180, 270 degree in counter clockwise way and configured through open. Dynamic screen rotation is not supported. To enable the screen rotation feature, a GUIX Canvas Buffer must be used. GUIX draws screen update on a canvas first and then GUIX Port processes the screen copy to a frame buffer with rotating the image in counter clockwise way. If *Synergy 2D Drawing Engine Support* is enabled (GX_USE_SYNEGY_DRW = 1), the rotation is processed by 2D Drawing engine with texture mapping. If not enabled (GX_USE_SYNEGY_DRW = 0), the rotation is processed by software copy.

Note that, the configuration (rotation_angle = 0) and (p_canvas = non-NULL value) is allowed but should not be done. This configuration just consumes extra bus bandwidth for screen image copy from a GUIX Canvas buffer to frame buffers. Therefore, set NULL to p_canvas to not use a GUIX Canvas buffer.

Size of JPEG Work Buffer

The JPEG work buffer trades off the JPEG decode speed against the buffer size. When a widget on the screen is formatted in JPEG, the JPEG work buffer is used as a temporary storage memory to create the decoded image. If the buffer size is not large enough for decoding an entire image, JPEG decoding is performed in the output buffer streaming mode. BitBLT operation by 2D Drawing engine decodes a piece of JPEG raster image in the buffer, then transfers it to the frame buffer. The minimum size of JPEG work buffer is {(The number of pixels in the horizontal line) x (bpp (bytes per pixel) of the display format) x 8 (lines)}. For instance, if the decoded image is 800 pixels in a horizontal line and RGB565 format, the number is 800 x 2 x 8= 12 800 (byte). If the buffer size was smaller than this number, JPEG decoding will not be processed. To get better throughput, parameter "Size of the JPEG Work Buffer" should be set as much as larger because it improves the JPEG decode throughput. The JPEG output buffer streaming mode repeats partial JPEG decode operations and the repletion comes to be overhead.

D/AVE 2D buffer cache

The D/AVE 2D buffer cache can be enabled or disabled through following configuration in Synergy Configurator. Disable it when images with high resolution and 32 bit ARGB8888 color format are used.

- D/AVE 2D Frame Buffer Cache(Valid if D/AVE 2D Drawing Engine is enabled)

Screen Tearing in Single Buffer Designs

Screen tearing is a visual artifact in video display where a display device shows information from multiple frames in a single screen draw. In general, a system with a single frame buffer can cause the screen tearing issue on a LCD panel. The module allows users to have single frame buffer (set NULL to p_framebuffer_b) but does not care for the screen tearing. It is recommended to have a ping-pong frame buffer system to consist of two frame buffers.

- SF_EL_GX is only applicable for the Synergy MCU with GLCDC (mandatory), 2D Drawing engine or JPEG engine (optional)
- SF_EL_GX does not support a system with more than two frame buffers.
- SF_EL_GX supports only one GUIX canvas system.
- SF_EL_GX makes use of only one layer in DISPAY module.
- Do not access the TES D/AVE 2D module and TES D/AVE 2D Port module directly if GUIX uses the Modules.
- Do not access the JPEG Decode Framework module and JPEG Decode HAL module directly if GUIX uses the Modules.

- Refer to the most recent SSP Release notes for additional limitations when using this module.

JPEG Decoder HAL Module Operational Overview

The JPEG Decode HAL module is a high-level API for JPEG Decode processing implemented on r_jpeg. The module supports the Synergy JPEG Codec peripheral. It has the following features:

- Supports JPEG decompression.
- Supports polling mode that allows an application to wait for JPEG Decoder to complete.
- Supports interrupt mode with user-supplied callback functions.
- Configures parameters such as horizontal and vertical subsample values, horizontal stride, decoded pixel format, input and output data format, and color space.
- Obtains the size of the image prior to decoding it.
- Supports putting coded data in an input buffer and an output buffer to store the decoded image frame.
- Supports streaming coded data into JPEG Decoder module. This feature allows an application to read coded JPEG image from a file or from network without buffering the entire image.
- Configures the number of image lines to decode. This feature enables the application to process the decoded image on the fly without buffering the entire frame.
- Supports the input decoded format YCbCr444, YCbCr422, YCbCr420, YCbCr411.
- Supports the output format ARGB8888, RGB565.
- Returns error when the JPEG image's size, height and width don't meet the requirements.

The JPEG Decoder HAL module can be used in the Input Buffer Streaming mode or JPEG Output Buffer Streaming mode.

Input Buffer Streaming Mode Operational Description

In this scenario the JPEG image data resides on a file, or is received from network. The HAL-layer driver is able to handle this scenario without requiring the input data to be stored in memory first.

Output Buffer Streaming Mode Operational Description

In this scenario the application needs to write the decoded image data to a file or to a network. The HAL-layer driver does not require the application to allocate memory for the entire frame. Instead the application may choose to decode one or more lines at a time. With this feature the amount of memory needed for the output data is greatly reduced.

JPEG Decoder HAL Module Operational Notes

JPEG Decode Callbacks

A user callback function can be registered in the open API. If a user callback function is provided, the callback function will be called from the interrupt service routine (ISR) each time an interrupt happens. The argument of the callback function status can take the enumerated values listed below so that user can identify which event occurred in the decoding procedure.

Event Name	Event Condition
JPEG_DECODE_STATUS_ERROR JPEG	Decode module encountered an error.
JPEG_DECODE_STATUS_IMAGE_SIZE_READY JPEG	Decode obtained the image size of data to be decoded, and paused.

Event Name	Event Condition
JPEG_DECODE_STATUS_INPUT_PAUSE JPEG	Decode paused waiting for more input data.
JPEG_DECODE_STATUS_OUTPUT_PAUSE JPEG	Decode paused after decoded the number of lines specified by user.
JPEG_DECODE_STATUS_DONE JPEG	Decode operation has successfully completed.

NOTE: Since a user callback function is called from an ISR, be careful not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.

- The JPEG Decode HAL module does not support JPEG Encode processing.
- Refer to the most recent SSP Release notes for the most up to date limitations for this module.

4.3.2.4 Including the GUIX Framework Module in an Application

This section describes how to include the GUIX Framework module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP based applications.

To add the GUIX Framework module to an application, simply add it to a thread using the Stacks Selection Sequence given in the table below. (The default name for the GUIX Framework is g_sf_el_gx0. This name can be changed in the associated **Properties** window.)

GUIX Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_el_gx0 GUIX Port on sf_el_gx	**Threads**	**New Stack> Framework> Graphics> GUIX Port on sf_el_gx**

When the GUIX Synergy Port Framework module on sf_el_gx is added to the thread stack as shown in the figure below, the configurator automatically adds any needed lower level modules. Any drivers that need additional configuration information will have box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower level drivers; these are either optional or recommended (this is indicated in the block with the inclusion of this text.) If the addition of lower level drivers is required, the module description will include "Add" in the text. Clicking on any Pink banded modules will bring up the "New" icon and then display the possible choices.

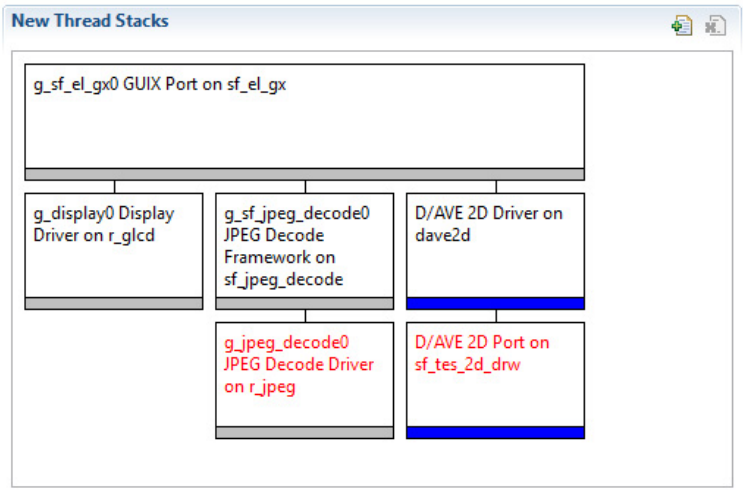


Figure 432: GUIX Synergy Port Framework Module Stack

4.3.2.5 Configuring the GUIX Synergy Port Framework Module

The GUIX Synergy Port Framework module must be configured by you for the desired operation. The SSP configuration window will automatically identify, by highlighting the block in red, any required configuration selections, such as Interrupts or operating modes, which must be configured for lower level modules, for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority. This configuration setting is available with the properties window of the associated module. Simply select the indicated module and then view the properties window. The Interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the Interrupt priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the below configuration properties tables, but is easily visible with the ISDE when configuring Interrupt Priority levels.

NOTE: You may want to open your ISDE and create the module and explore the property settings in parallel with looking over the Configuration Table Settings given below. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration for the GUIX Synergy Port Framework Module on GUIX on gx

ISDE Property	Value	Description
Enable Synergy 2D Drawing Engine Support	Yes, No Default: No	If Synergy 2D Drawing Engine (DRW) Support is enabled, the rotation is processed by Synergy DRW with texture mapping. If not enabled, the rotation is processed by software copy.
Enable Synergy JPEG Support	Yes, No Default: No	Enabling this places restrictions on JPEG image size, width modulus, format, output alignment, etc. It also limited to only decoding the JPEG image into the frame buffer. (The software decoder doesn't have any of those restrictions, but of course it uses more CPU time.)

Configuration for the GUIX Synergy Port Framework Module on sf_el_gx

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_sf_el_gx0	Name of SF_EL_GX instance which will be generated by ISDE. Specify the instance name of this module. Name must be a valid C symbol.
Name of Display Driver Run-time Configuration (Must be a valid symbol)	g_display0_runtime_cfg_bg	Specify the name of run-time configuration for the DISPLAY module you specified in the Synergy Configuration. Name must be a valid C symbol and NULL is not allowed to be set.
Name of Frame Buffer A (Must be a valid symbol)	g_display0_fb_background[0]	Specify the name of frame buffer. A DISPLAY module configuration in the Synergy Configuration contains the name of frame buffer to create. Set the name of frame buffer here. Name must be a valid C symbol and NULL is not allowed to be set.

ISDE Property	Value	Description
Name of Frame Buffer B (NULL allowed if consisting a single frame buffer system)	g_display0_fb_background[1]	Specify the name of another frame buffer. If you want to design your graphics system with a single frame buffer, set NULL to this parameter, or set same frame buffer name with parameter "Name of Frame Buffer A". See Tearing in Single Buffer Designs
Name of User Callback function	NULL	Name of User Callback function invoked by the Module when events happen. It must be a valid C symbol and NULL is allowed.
Screen Rotation Angle (Clockwise)	0, 90, 180, 270 Default: 0	Angle of screen rotation (degree). If non-zero value is selected, screen rotation is enabled and GUIX draws screen image on a frame buffer, rotating the image with the angle in the counter clockwise way.
GUIX Canvas Buffer (required if rotation angle is not zero)	Not used; Used Default: Not used	If enabling the screen rotation, a canvas buffer must be used. The size of canvas buffer must be exactly the same as a frame buffer for the display module.
Size of JPEG Work Buffer (valid if JPEG hardware acceleration enabled)	768000	The JPEG work buffer size in bytes. Value must be a valid integer value and zero is allowed to be set if JPEG acceleration is not used. Larger buffer size shortens the drawing time. See Size of JPEG Work Buffer
Memory section for GUIX Canvas Buffer	sdram, bss, … Default: sdram	Name of memory section where you want to allocate the GUIX Canvas Buffer. Enter a valid section name defined in the linker script file. Name must be a valid C symbol.
Memory section for JPEG Work Buffer	Sdram, bss, … Default: sdram	Name of memory section where you want to allocate the JPEG Work Buffer. Enter a valid section name defined in the linker script file. Name must be a valid C symbol.

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2 Family. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower level modules can be desirable. For example, the it might be useful

to select different screen sizes or input formats. The configurable properties for the lower level stack modules are given in the below sections for completeness and as a reference.

NOTE: Most of the property settings for lower level modules are fairly intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the GUIX Synergy Port Framework Module Low Level Drivers

Typically, only a small number of settings must be modified from the default for lower level drivers and these are indicated with red text in the Thread Stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The table below identifies all the settings within the properties section for the module.

Configuration for the GLCD HAL Module on r_glcd

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_display0	The name to be used for a GLCDC module control block instance. This name is also used as the prefix of the other variable instances.
Name of display callback function to be defined by user	NULL	Name must be a valid C symbol.
Input - Panel clock source select	Internal clock(GLCDCLK), External clock(LCD_EXTCLK) Default: Internal clock (GLCDCLK)	Choose the panel clock source depends on your system.
Input - Graphics screen1	Used, Not used Default: Used	Specify "Used" if the graphics screen N is used. Then the frame buffer named "display_fb_background" for graphics screen1 and "display_fb_foreground" for graphics screen2 is auto-generated by ISDE. If not using either of the graphics screens, specify "Not used". Then the frame buffer is not created. Note that there is no memory read access to the frame buffer when you specify "Not used", which reduces the consumption of bus bandwidth.
Input - Graphics screen1 frame buffer name	fb_background	Custom name for frame buffer.

ISDE Property	Value	Description
Input - Number of Graphics screen1 frame buffer	2	Number of graphics selection.
Input - section where Graphics screen1 frame buffer allocated	sdram	Specify the section name to allocate the frame buffer. This is valid if "Input - Graphics screen1" is set as "Used."
Input - Graphics screen1 input horizontal size	800	Specify the number of horizontal pixels. Default value is the size for an image with 800x480 pixels
Input - Graphics screen1 vertical size	480	Specify the number of vertical pixels. Default value is the size for an image with 800x480 pixels.
Input - Graphics screen1 input horizontal stride (not bytes but pixels)	800	Specify the memory stride for a horizontal line. This value must be specified with the number of pixels, not actual bytes. Typically this parameter is set to same number as parameter 'input horizontal size'. Default value is the size for an image with 800x480 pixels.
Input - Graphics screen1 input format	32bits ARGB888, 32bits RGB888, 16bits RGB565, 16bits ARGB1555, 16bits ARGB4444, CLUT 8, CLUT 4, CLUT 1 Default: 16bits RGB565	Specify the graphics screen Input format. If selecting CLUT formats, you must write CLUT data using clut before performing start. Default setting supports a RGB565 formatted image.
Input - Graphics screen1 input line descending	Used, Not used Default: Not used	Specify "On" if image data descends from the bottom line to the top line in the frame buffer. Usually "Off".
Input - Graphics screen1 input line repeat	On, Off Default: Off	Specify "On" if expecting to repeatedly read a raster image which is smaller than the LCD panel size. Usually "Off". For details, see the description of Line Repeating function.
Input - Graphics screen1 input line repeat times	0	Specify the number of repeating times for a raster image which is read repeatedly in a frame.

ISDE Property	Value	Description
Input - Graphics screen1 layer coordinate X	0	Specify the horizontal offset in pixels of the graphics screen from the background screen.
Input - Graphics screen1 layer coordinate Y	0	Specify the vertical offset in pixels of the graphics screen from the background screen.
Input - Graphics screen1 layer background color alpha	255	Based on the alpha value, either the graphics screen2 (foreground graphics screen) is blended into the graphics screen1 (background graphics screen) or the graphics screen1 is blended into the monochrome background screen.
Input - Graphics screen1 layer background color Red	255	Specify the background color in the graphics screen N.
Input - Graphics screen1 layer background color Green	255	Specify the background color in the graphics screen N.
Input - Graphics screen1 layer background color Blue	255	Specify the background color in the graphics screen N.
Input - Graphics screen1 layer fading control	None, Fade-in, Fade-out Default: None	Specify "On" when performing a fade-in for the graphics screen. The transparent screen changes gradually to opaque. Specify "Off" when performing the fade-out for the graphics screen. The opaque screen changes gradually to transparent. Note that this processing is accelerated by the GLCDC hardware and cannot stop once started. The transition status can be monitored by statusGet.
Input - Graphics screen1 layer fade speed	0	Specify the number of frames for the fading transition to complete.

ISDE Property	Value	Description
Input - Graphics screen2	Used, Not used Default: Not used	Specify "Used" if the graphics screen N is used. Then the frame buffer named "display_fb_background" for graphics screen1 and "display_fb_foreground" for graphics screen2 is auto-generated by ISDE. If not using either of the graphics screens, specify "Not used". Then the frame buffer is not created. Note that there is no memory read access to the frame buffer when you specify "Not used", which reduces the consumption of bus bandwidth.
Input - Graphics screen2 frame buffer name	fb_foreground	Custom name for frame buffer.
Input - Number of Graphics screen2 frame buffer	2	Number of graphics selection.
Input - section where Graphics screen2 frame buffer allocated	sdram	Specify the section name to allocate the frame buffer. This is valid if "Input - Graphics screen1" is set as "Used."
Input - Graphics screen2 input horizontal size	800	Specify the number of horizontal pixels. Default value is the size for an image with 800x480 pixels
Input - Graphics screen2 vertical size	480	Specify the number of vertical pixels. Default value is the size for an image with 800x480 pixels.
Input - Graphics screen2 input horizontal stride (not bytes but pixels)	800	Specify the memory stride for a horizontal line. This value must be specified with the number of pixels, not actual bytes. Typically this parameter is set to same number as parameter 'input horizontal size'. Default value is the size for an image with 800x480 pixels.
Input - Graphics screen2 input format	32bits ARGB888, 32bits RGB888, 16bits RGB565, 16bits ARGB1555, 16bits ARGB4444, CLUT 8, CLUT 4, CLUT 1 Default: 16bits RGB565	Specify the graphics screen Input format. If selecting CLUT formats, you must write CLUT data using clut before performing start. Default setting supports a RGB565 formatted image.

ISDE Property	Value	Description
Input - Graphics screen2 input line descending	On, Off Default: Off	Specify "On" if image data descends from the bottom line to the top line in the frame buffer. Usually "Off".
Input - Graphics screen2 input line repeat	On, Off Default: Off	Specify "On" if expecting to repeatedly read a raster image which is smaller than the LCD panel size. Usually "Off". For details, see the description of Line Repeating function.
Input - Graphics screen2 input line repeat times	0	Specify the number of repeating times for a raster image which is read repeatedly in a frame.
Input - Graphics screen2 layer coordinate X	0	Specify the horizontal offset in pixels of the graphics screen from the background screen.
Input - Graphics screen2 layer coordinate Y	0	Specify the vertical offset in pixels of the graphics screen from the background screen.
Input - Graphics screen2 layer background color alpha	255	Based on the alpha value, either the graphics screen2 (foreground graphics screen) is blended into the graphics screen1 (background graphics screen) or the graphics screen1 is blended into the monochrome background screen.
Input - Graphics screen2 layer background color Red	255	Specify the background color in the graphics screen N.
Input - Graphics screen2 layer background color Green	255	Specify the background color in the graphics screen N.
Input - Graphics screen2 layer background color Blue	255	Specify the background color in the graphics screen N.

ISDE Property	Value	Description
Input - Graphics screen2 layer fading control	None, Fade-in, Fade-out Default: None	Specify "On" when performing a fade-in for the graphics screen. The transparent screen changes gradually to opaque. Specify "Off" when performing the fade-out for the graphics screen. The opaque screen changes gradually to transparent. Note that this processing is accelerated by the GLCDC hardware and cannot stop once started. The transition status can be monitored by statusGet.
Input - Graphics screen2 layer fade speed	0	Specify the number of frames for the fading transition to complete.
Output - Horizontal total cycles	1024	Specify the total cycles in a horizontal line. Set to the number of cycles defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Horizontal active video cycles	800	Specify the number of active video cycles in a horizontal line. Set to the number of cycles defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Horizontal back porch cycles	46	Specify the number of back porch cycles in a horizontal line. Back porch starts from the beginning of Hsync cycles, which means back porch cycles contain Hsync cycles. Set to the number of cycles defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Horizontal sync signal cycles	20	Specify the number of Hsync signal assertion cycles. Set to the number of cycles defined in the data sheet of LCD panel sheet in your system. Default value matches LCD panel on S7G2 PE-HMI1 board.

ISDE Property	Value	Description
Output - Horizontal sync signal polarity	Low active, High active Default: Low active	Select the polarity of Hsync signal to match your system. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output - Vertical total lines	525	Specify number of total lines in a frame. Set to the number of lines defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Vertical active video lines	480	Specify the number of active video lines in a frame. Set to the number of lines defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Vertical back porch lines	23	Specify the number of back porch lines in a frame. Back porch starts from the beginning of Vsync lines, which means back porch lines contain Vsync lines. Set to the number of lines defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Vertical sync signal lines	10	Specify the Vsync signal assertion lines in a frame. Set to the number of lines defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Vertical sync signal polarity	Low active, High active Default: Low active	Select the polarity of Vsync signal to match to your system. Default setting matches LCD panel on S7G2 PE-HMI1 board.
Output - Format	24bits RGB888, 18bits RGB666, 16bits RGB565, 8bits serial Default: 24bits RGB888	Specify the graphics screen output format to match to your LCD panel. Default setting matches the LCD panel on S7G2 PE-HMI1 board.

ISDE Property	Value	Description
Output - Endian	Little endian, Big endian Default: Little endian	Select data endian for output signal to LCD panel. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output - Color order	RGB, BGR Default: RGB	Select data order for output signal to LCD panel. The order of blue and red can be swapped if needed. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output - Data Enable Signal Polarity	Low active, High active Default: High active	Select the polarity of Data Enable signal to match to your system. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output - Sync edge	Rising Edge, Falling Edge Default: Rising Edge	Select the polarity of Sync signals to match to your system. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output - Background color alpha channel	255	Specify the background color of the background screens.
Output - Background color R channel	0	Specify the background color of the background screens.
Output - Background color G channel	0	Specify the background color of the background screens.
Output - Background color B channel	0	Specify the background color of the background screens.
CLUT	Used, Not used Default: Not used	Specify "Used" if selecting CLUT formats for a graphics screen input format. Then, a buffer named "CLUT_buffer" for the CLUT source data is generated in the ISDE auto-generated source file.
CLUT - CLUT buffer size	256	Specify the number of entries for the CLUT source data buffer. Each entries consumes 4 bytes (1 word). Words of CLUT source data specified by this parameter are generated in the ISDE auto-generated source file.

ISDE Property	Value	Description
TCON - Hsync pin select	Not used, LCD_TCON0, LCD_TCON1, LCD_TCON2, LCD_TCON3 Default: LCD_TCON0	Select the TCON pin used for the Hsync signal to match to your system. Default setting is for LCD panel on S7G2 PE-HMI1 board.
TCON - Vsync pin select	Not used, LCD_TCON0, LCD_TCON1, LCD_TCON2, LCD_TCON3 Default: LCD_TCON1	Select TCON pin used for Vsync signal to match to your system. Default setting is for LCD panel on S7G2 PE-HMI1 board.
TCON - DataEnable pin select	Not used, LCD_TCON0, LCD_TCON1, LCD_TCON2, LCD_TCON3 Default: LCD_TCON2	Select TCON pin used for DataEnable signal to match to your system. Default setting is for LCD panel on S7G2 PE-HMI1 board.
TCON - Panel clock division ratio	1/1, 1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8, 1/9, 1/12, 1/16, 1/24, 1/32 Default: 1/8	Select the clock source divider value. See the note at bottom of this table about the source clock for the pixel clock.
Color correction - Brightness	Off, On Default: Off	Specify "On" when performing brightness control. If specifying "Off", the setting below does not affect the output color.
Color correction - Brightness R channel	512	Output color level is calculated as follows: Output color level = Input color level +/ - 512. Set the value for each of R, G, B channels.
Color correction - Brightness G channel	512	Output color level is calculated as follows: Output color level = Input color level +/ - 512. Set the value for each of R, G, B channels.
Color correction - Brightness B channel	512	Output color level is calculated as follows: Output color level = Input color level +/ - 512. Set the value for each of R, G, B channels.

ISDE Property	Value	Description
Color correction - Contrast	Off, On Default: Off	Specify "On" when performing contrast control. If specifying "Off", the setting below does not affect the output color.
Color correction - Contrast(gain) R channel	128	Output color level is calculated as follows: Output color level = Input color level x (/128). Set the value for each of R, G, B channels.
Color correction - Contrast(gain) G channel	128	Output color level is calculated as follows: Output color level = Input color level x (/128). Set the value for each of R, G, B channels.
Color correction - Contrast(gain) B channel	128	Output color level is calculated as follows: Output color level = Input color level x (/128). Set the value for each of R, G, B channels.
Color correction - Gamma correction(Red)	Off, On Default: Off	Control for each channel R/G/B. Specify "On" when performing gamma correction for the red channel. If specifying "Off", the settings for gain and threshold do not affect the output color.
Color correction - Gamma gain R[0-15]	0	Set the gain value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between ((Gamma threshold R[N-1])<<2) and ((Gamma threshold R[N])<<2). The output value is calculated as follows: Output color level = Input color level / 1024 (/128).
Color correction - Gamma threshold R[0-15]	0	Set the threshold value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between Gamma threshold R[N-1] and Gamma threshold R[N]. The output value is calculated as follows: Output color level = Input color level / 1024 (/128).

ISDE Property	Value	Description
Color correction - Gamma correction(Green)	Off, On Default: Off	Control for each channel R/G/B. Specify "On" when performing gamma correction for the red channel. If specifying "Off", the settings for gain and threshold do not affect the output color.
Color correction - Gamma gain G[0-15]	0	Set the gain value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between ((Gamma threshold R[N-1])<<2) and ((Gamma threshold R[N])<<2). The output value is calculated as follows: Output color level = Input color level / 1024 (/128).
Color correction - Gamma threshold G[0-15]	0	Set the threshold value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between Gamma threshold R[N-1] and Gamma threshold R[N]. The output value is calculated as follows: Output color level = Input color level / 1024 (/128).
Color correction - Gamma correction(Blue)	Off, On Default: Off	Control for each channel R/G/B. Specify "On" when performing gamma correction for the red channel. If specifying "Off", the settings for gain and threshold do not affect the output color.
Color correction - Gamma gain B[0-15]	0	Set the gain value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between ((Gamma threshold R[N-1])<<2) and ((Gamma threshold R[N])<<2). The output value is calculated as follows: Output color level = Input color level / 1024 (/128).

ISDE Property	Value	Description
Color correction - Gamma threshold B[0-15]	0	Set the threshold value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between Gamma threshold R[N-1] and Gamma threshold R[N]. The output value is calculated as follows: Output color level = Input color level / 1024 (/128).
Dithering	Off, On Default: Off	Dithering enable. Specify "On" when applying the dither effect to reduce the banding in case of selecting RGB666 or RGB565 output formats. Dithering can be applied when converting. If specified "Off", the settings for dithering below do not affect the output. For details on the dither effect, see Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Dithering - Mode	Truncate, Round off, 2x2 Pattern Default: Truncate	Specify the dither mode. For detail, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Dithering - Pattern A	Pattern 00, Pattern 01, Pattern 10, Pattern 11 Default: Pattern 11	Specify the dither pattern for 2X2 pattern mode. Forndetails, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Dithering - Pattern B	Pattern 00, Pattern 01, Pattern 10, Pattern 11 Default: Pattern 11	Specify the dither pattern for 2X2 pattern mode. Forndetails, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Dithering - Pattern C	Pattern 00, Pattern 01, Pattern 10, Pattern 11 Default: Pattern 11	Specify the dither pattern for 2X2 pattern mode. Forndetails, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.

ISDE Property	Value	Description
Dithering - Pattern D	Pattern 00, Pattern 01, Pattern 10, Pattern 11 Default: Pattern 11	Specify the dither pattern for 2X2 pattern mode. Forndetails, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Misc - Correction Process Order	Brightness and Contrast then Gamma, Gamma then Brightness and Contrast Default: Brightness and Contrast then Gamma	Specify the color correction processing order if needed.
Line Detect Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	The driver needs valid interrupt priority setting and it won't work if disabled.
Underflow 1 Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	The driver needs valid interrupt priority setting and it won't work if disabled.
Underflow 2 Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	The driver needs valid interrupt priority setting and it won't work if disabled.

Configuration for the JPEG Decode Framework Module on sf_jpeg_decode

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_sf_jpeg_decode0	The name to be used for a JPEG Decode Framework module instance.

Configuration for the JPEG Decode HAL Module on r_jpeg

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_jpeg_decode0	The name to be used for a JPEG Decode module instance.

ISDE Property	Value	Description
Byte Order for Input Data Format	Normal byte order (1)(2)(3)(4)(5)(6)(7)(8), Byte Swap (2)(1)(4)(3)(6)(5)(8)(7), Word Swap (3)(4)(1)(2)(7)(8)(5)(6), Word-Byte Swap (4)(3)(2)(1)(8)(7)(6)(5), Longword Swap (5)(6)(7)(8)(1)(2)(3)(4), Longword-Byte Swap (6)(5)(8)(7)(2)(1)(4)(3), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2) Default: Normal Byte order	Specify the byte order for input data. The order is swapped as specified in every 8-byte.

ISDE Property	Value	Description
Byte Order for Output Data Format	Normal byte order (1)(2)(3)(4)(5)(6)(7)(8), Byte Swap (2)(1)(4)(3)(6)(5)(8)(7), Word Swap (3)(4)(1)(2)(7)(8)(5)(6), Word-Byte Swap (4)(3)(2)(1)(8)(7)(6)(5), Longword Swap (5)(6)(7)(8)(1)(2)(3)(4), Longword-Byte Swap (6)(5)(8)(7)(2)(1)(4)(3), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2) Default: Normal Byte order	Specify the byte order for output data. The order is swapped as specified in every 8-byte.
Output Data Color Format	Pixel Data RGB565 format, Pixel Data ARGBB888 format Default: Pixel Data RGB565 format	Specify the output data format.
Alpha value to be applied to decoded pixel data (only valid for ARGB8888 format)	255	Specify the alpha value for the output data format (only valid for ARGB8888 format).
Name of user callback function	NULL	Specify the name of user callback function.

ISDE Property	Value	Description
Decompression Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Decompression interrupt priority selection.
Data Transfer Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Data transfer interrupt priority selection.

Table 6: Configuration for the D/AVE 2D Driver on dave2d

ISDE Property	Value	Description
No configurable settings		

Configuration for the D/AVE 2D Port on sf_tes_2d_drw

ISDE Property	Value	Description
Work memory size for display lists in bytes	32768	Work memory size for display lists selection
DRW Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	DRW INT selection

NOTE: The above setting examples and defaults are for a project using the Synergy S7G2 Family. Other MCUs may have

different default values and available configuration settings.

GUIX Synergy Port Framework Module Clock Configuration

The GUIX Synergy Port Module is a logical module and therefore does not require any hardware setting except setting the ARM Cortex-M core SysTick timer.

GUIX Synergy Port Framework Module Pin Configuration

The GUIX Synergy Port Module is a logical module and therefore does not require pin settings.

4.3.2.6 Using the GUIX Framework Module or JPEG Decode HAL Module in an Application

The typical steps in using the GUIX Framework module in an application are (assuming the instance of the GUIX driver is g_sf_el_ux0 and the instance of the SPI driver for the LCD is g_rspi_lcdc):

Step 0. Initialize GUIX with the gx_system_initialize function

Step 1. Initialize GUIX drivers using the open API (g_sf_el_ux0.p_api -> open)

Step 2. Configure the GUIX system with the gx_studio_display_configure function using the setup API

Step 3. Initialize the memory address of the canvas with the canvasInit API (g_sf_el_ux0.p_api -> canvasInit)

Step 4. Create the primary screen with the gx_studio_named_widget_create function

Step 5. Show the root window using the gx_widget_show function

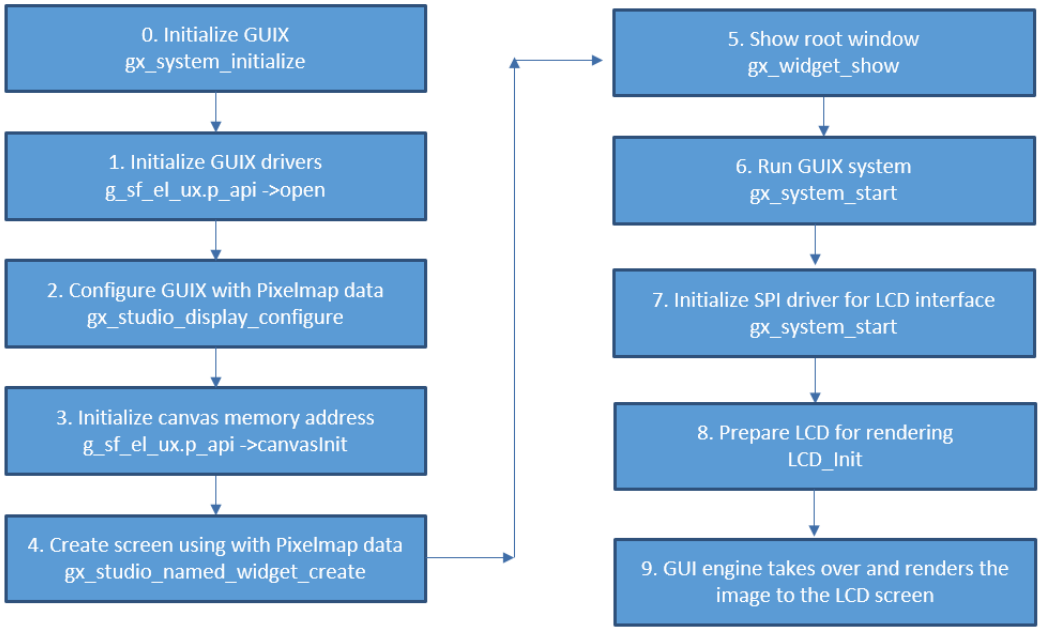
Step 6. Start the GUIX system with the gx_system_start function

Step 7. Initialize the SPI interface with the LCD display with the open API (g_rspi_lcdc.p_api -> open)

Step 8. Initialize the LCD hardware with the LCD_Init call.

Step 9. GUI engine takes over and renders the image on the LCD screen

These common steps are illustrated in a typical operational flow diagram in the following figure:



Once the JPEG Decode HAL module has been configured and the files generated, the JPEG Decode is ready to be used in an application. The typical steps in using the JPEG Decoder HAL module in an application are initializing the JPEG Decode using the open API, configure the horizontal stride, image sub-sample, input buffer and output buffer, once the input and output buffers are set, JPEG codec trigger the decode operation and store the decoded image to the output buffer, statusGet API can be used to poll the status of JPEG operation.

The typical steps in using the JPEG Decode HAL module in an application are:

Step 1. Initialize the JPEG Decode HAL module using open API.

Step 3. Set vertical and horizontal image sub-sample using imageSubsampleSet API.

Step 4. Set the input buffer address (which contains the JPEG image) using inputBufferSet API.

Step 5. Set the output buffer (should be large enough to hold the raw image data) using outputBufferSet API.

Step 6. statusGet API can be used to get the JPEG operation, statusGet API return an enumerated value (described above) to notify user. Status JPEG_DECODE_STATUS_DONE from statusGet API shows that the Decode operation is complete.

Step 7. Operate on the received raw image data as needed by the application.

These common steps are illustrated in a typical operational flow diagram in the following figure:

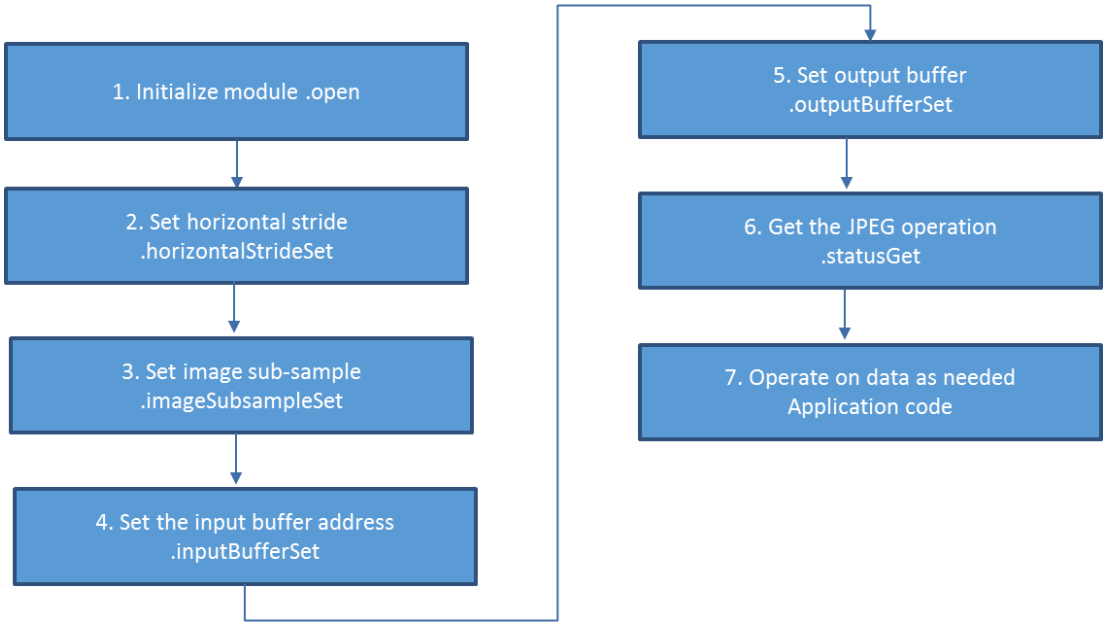


Figure 433: Flow Diagram of a Typical JPEG Decode HAL Module Application

4.3.3 NetX

The Express Logic NetX networking stack (nx) is integrated into the SSP. For more information about NetX, including API reference, refer to the *NetX User Guide*.

4.3.3.1 What Does the Express Logic NetX Module Do?

NetX is a high-performance real-time implementation of the TCP/IP standards designed exclusively for embedded ThreadX-based applications.

4.3.3.2 Using e^2 studio to write an Application with Express Logic NetX

The Express Logic NetX module is integrated into the Synergy Software Package in e^2 studio:e^2 studio ISDE User Guide.

In e^2 studio, create and configure a project and add the drivers:

1) Create the project: Creating a Project.
2) Configure the project: Configuring a Project.
3) Add the drivers: Adding Drivers to a Thread and Configuring the Drivers.

During the configuration of the project, add the following modules in the ISDE: Adding Drivers to a Thread and Configuring the Drivers.

Resource	ISDE Tab	Selection
Express Logic NetX (mandatory)	Threads	**Framework > Networking > NetX on UX**
NetX Driver (mandatory)	Threads	**Framework > Networking > NetX Port <ETHER> on sf_el_nx**
Express Logic NetX Source Code (optional, for advanced configurations or source level debugging support)	Threads	**Framework > Networking > NetX Source**

Adding NetX Application Layer Modules

To add NetX Application Layer modules, go to the **Components** tab of the Synergy Configuration tool (configuration.xml), and select any of the application layer modules:

- nx_auto_ip: Refer to the *NetX Auto IP User Guide*.
- nx_bsd: Refer to the *NetX BSD User Guide*. See Express Logic NetX Limitations section.
- nx_dhcp: Refer to the *NetX Dynamic Host Configuration Protocol for Clients User Guide*.
- nx_dhcp_server: Refer to the *NetX Dynamic Host Configuration Protocol for Servers (NetX DHCP Server) User Guide*.
- nx_dns: Refer to the *NetX DNS (Domain Name System) Client User Guide*.
- nx_ftp_client: Refer to the *NetX File Transfer Protocol (FTP) User Guide*.
- nx_ftp_server: Refer to the *NetX File Transfer Protocol (FTP) User Guide*.
- nx_http_client: Refer to the *NetX Hypertext Transfer Protocol (HTTP) User Guide*.
- nx_http_server: Refer to the *NetX Hypertext Transfer Protocol (HTTP) User Guide*.
- nx_pop3: Refer to the *NetX Post Office Protocol Version 3 Client (NetX POP3 Client) User Guide*.
- nx_ppp: Refer to the *NetX Point-to-Point Protocol (PPP) User Guide*.
- nx_smtp: Refer to the *NetX Simple Mail Transfer Protocol for Clients (NetX SMTP Client) User Guide*.
- nx_sntp: Refer to the *NetX Simple Network Time Protocol (SNTP) Client User Guide*.
- nx_telnet_client: Refer to the *NetX Telnet Protocol (Telnet) User Guide*.
- nx_telnet_server: Refer to the *NetX Telnet Protocol (Telnet) User Guide*.
- nx_tftp_client: Refer to the *NetX Trivial File Transfer Protocol (TFTP) User Guide*.
- nx_tftp_server: Refer to the *NetX Trivial File Transfer Protocol (TFTP) User Guide*.

When the components above are added, a prebuilt library of the application code is added. For each component listed above, there is an analogous component ending in '_src' that contains protected source files. The '_src' component can be added in addition to the prebuilt library module. Do not add the '_src' component without the prebuilt library module.

4.3.3.3 Express Logic NetX Configuration Notes

NetX Source Advanced Configurations

If the NetX Source module is added to the project, the Properties window provides advanced configurations for the NetX source library. Highlight a configuration option to view a description of the option in the bottom left corner of the e^2 studio GUI. If the configuration option is empty, the default value is used. The default values of configuration options are defined in ssp/inc/framework/el/nx/nx_port.h. Refer to the Configuration Options chapter of the *NetX User Guide* for more information.

4.3.3.4 Express Logic NetX Limitations

- Express Logic NetX cannot be used in the same application as Express Logic NetX Duo. Only one or the other can be used per application.
- When using NetX BSD with the GCC compiler, build with the macro _POSIX_SOURCE defined to avoid compilation errors.
- See SSP Release Notes for known limitations.

4.3.3.5 Express Logic NetX Supported Devices

The module is designed to support the following families:

- S7G2

4.3.4 NetX Duo

The Express Logic NetX Duo networking stack (nxd) is integrated into the SSP. For more information about NetX Duo, including API reference, refer to the *NetX Duo User Guide*.

4.3.4.1 What Does the Express Logic NetX Duo Module Do?

NetX Duo is a high-performance real-time implementation of the TCP/IP standards designed exclusively for embedded ThreadX-based applications.

4.3.4.2 Using e^2 studio to write an Application with Express Logic NetX Duo

The Express Logic NetX Duo module is integrated into the Synergy Software Package in e^2 studio:e^2 studio ISDE User Guide.

In e^2 studio, create and configure a project and add the drivers:

1) Create the project: Creating a Project.
2) Configure the project: Configuring a Project.
3) Add the drivers: Adding Drivers to a Thread and Configuring the Drivers.

During the configuration of the project, add the following modules in the ISDE: Adding Drivers to a Thread and Configuring the Drivers.

Resource	ISDE Tab	Selection
Express Logic NetX Duo (mandatory)	Components	**Express Logic > all > nxd**
NetX Driver (mandatory)	Threads	**Framework > Networking > NetX Port <ETHER> on sf_el_nx**
Express Logic NetX Duo Source Code (optional, for advanced configurations or source level debugging support)	Components	**Express Logic > all > nxd_src**

Adding NetX Duo Application Layer Modules

To add NetX Duo Application Layer modules, go to the **Components** tab of the Synergy Configuration tool (configuration.xml), and select any of the application layer modules:

- nxd_auto_ip: Refer to the *NetX Duo Auto IP User Guide*.
- nxd_bsd: Refer to the *NetX Duo BSD User Guide*. See Express Logic NetX Duo Limitations section.
- nxd_dhcp: Refer to the *NetX Duo Dynamic Host Configuration Protocol for Clients User Guide*.
- nxd_dhcp_server: Refer to the *NetX Duo Dynamic Host Configuration Protocol for Servers (NetX Duo DHCP Server) User Guide*.
- nxd_dns: Refer to the *NetX Duo DNS (Domain Name System) Client User Guide*.
- nxd_ftp_client: Refer to the *NetX Duo File Transfer Protocol (FTP) User Guide*.
- nxd_ftp_server: Refer to the *NetX Duo File Transfer Protocol (FTP) User Guide*.
- nxd_http_client: Refer to the *NetX Duo Hypertext Transfer Protocol (HTTP) User Guide*.
- nxd_http_server: Refer to the *NetX Duo Hypertext Transfer Protocol (HTTP) User Guide*.
- nxd_pop3: *Refer to the NetX Duo Post Office Protocol Version 3 Client (NetX Duo POP3 Client) User Guide*.
- nxd_ppp: Refer to the *NetX Duo Point-to-Point Protocol (PPP) User Guide*.
- nxd_smtp: Refer to the *NetX Duo Simple Mail Transfer Protocol for Clients (NetX Duo SMTP Client) User Guide*.
- nxd_sntp: Refer to the *NetX Duo Simple Network Time Protocol (SNTP) Client User Guide*.
- nxd_telnet_client: Refer to the *NetX Duo Telnet Protocol (Telnet) User Guide*.
- nxd_telnet_server: Refer to the *NetX Duo Telnet Protocol (Telnet) User Guide*.
- nxd_tftp_client: Refer to the *NetX Duo Trivial File Transfer Protocol (TFTP) User Guide*.
- nxd_tftp_server: Refer to the *NetX Duo Trivial File Transfer Protocol (TFTP) User Guide*.

When the components above are added, a prebuilt library of the application code is added. For each component listed above, there is an analogous component ending in '_src' that contains protected source files. The '_src' component can be added in addition to the prebuilt library module. Do not add the '_src' component without the prebuilt library module.

4.3.4.3 Express Logic NetX Duo Limitations

- Express Logic NetX Duo cannot be used in the same application as Express Logic NetX. Only one or the other can be used per application.
- When using NetX Duo BSD with the GCC compiler, build with the macro _POSIX_SOURCE defined to avoid compilation errors.
- See SSP Release Notes for known limitations.

4.3.4.4 Express Logic NetX Duo Supported Devices

The module is designed to support the following families:

- S7G2

4.3.5 NetX Duo MQTT Client

The NetX Duo MQTT Client module provides high-level APIs for a Message Queuing Telemetry Transport (MQTT) protocol-based client. The MQTT protocol works on top of TCP/IP and therefore the MQTT client is implemented on top of NetX Duo IP and NetX Duo Packet Pool. NetX Duo IP attaches itself to the appropriate link layer driver such as Ethernet, Wi-Fi or cellular. The MQTT client can optionally connect to an MQTT server over a secure connection and in such case, it uses the service provided by NetX Duo TLS Common.

4.3.5.1 NetX Duo MQTT Client Module Features

- Compliant with OASIS MQTT Version 3.1.1 Oct 29th, 2014. The specification can be found at: http://mqtt.org/
- Provides option to enable/disable TLS for secure communications using NetX Duo Secure in SSP
- Supports Quality of Service (QoS) levels 0 and 1 and provides the ability to choose the levels that can be selected while publishing the message
- Internally buffers and maintains queue of received messages
- Provides mechanism to register callback when a new message is received
- Provides mechanism to register callback when the connection with the broker is terminated.

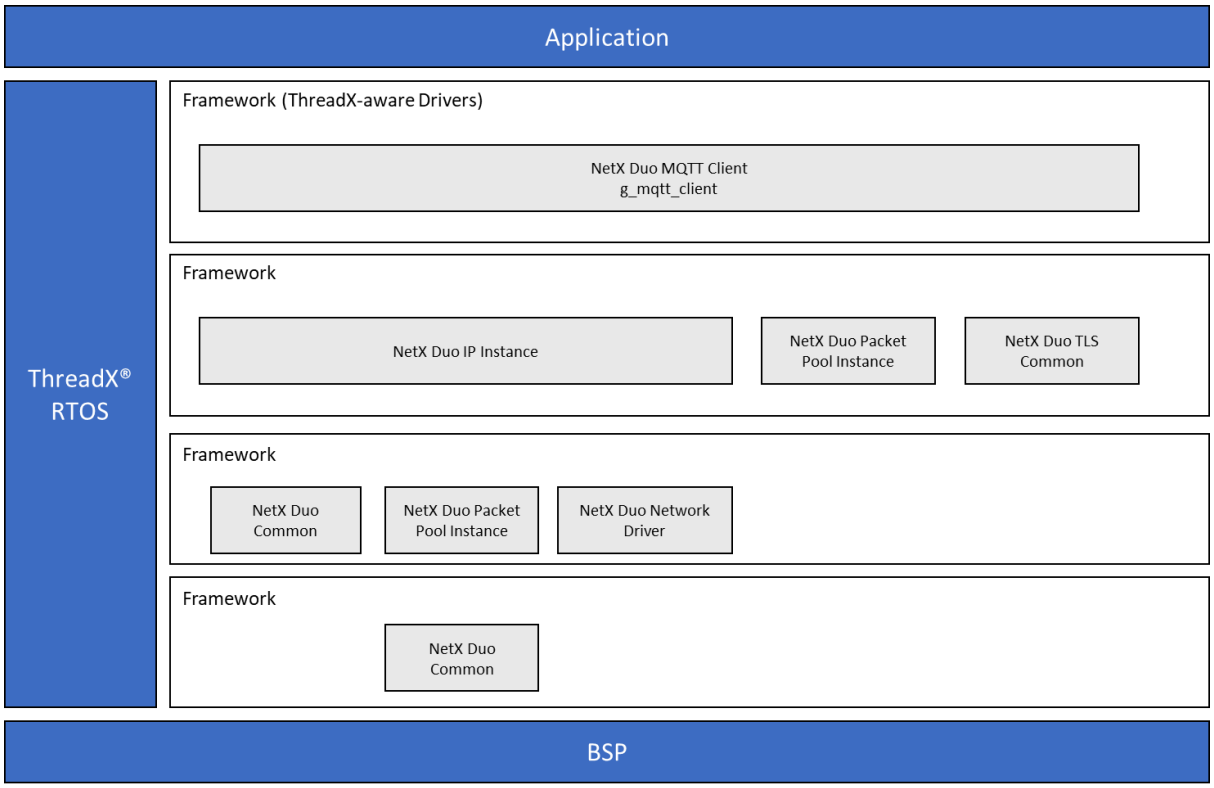

Figure 434: NetX Duo MQTT Client Module Block Diagram

4.3.5.2 NetX Duo MQTT Client Module APIs Overview

A complete list of MQTT APIs, parameters and return values is available from the Synergy Gallery in the X-Ware Component Documents for Renesas Synergy. Here is an overview of the available APIs:

API	Function
nxd_mqtt_client_create	Create MQTT client instance
nxd_mqtt_client_client_login_set	Set MQTT client login username and password
nxd_mqtt_client_connect	Connect MQTT Client to the broker
nxd_mqtt_client_secure_connect	Connect MQTT client to the broker with TLS security
nxd_mqtt_client_publish	Publish a message through the broker.
nxd_mqtt_client_subscribe	Subscribe to a topic
nxd_mqtt_client_unsubscribe	Unsubscribe from a topic

API	Function
nxd_mqtt_client_receive_notify_set	Set MQTT message receive notify callback function
nxd_mqtt_client_message_get	Retrieve a message from the broker
nxd_mqtt_client_disconnect_notify_set	Set MQTT message disconnect notify callback function
nxd_mqtt_client_disconnect	Disconnect MQTT client from the broker
nxd_mqtt_client_delete	Delete the MQTT client instance

4.3.5.3 NetX Duo MQTT Client Module Operational Overview

MQTT (Message Queue Telemetry Transport) is based on a publisher/subscriber model. A client can publish information to other clients through a broker. A client, if interested in a topic, can subscribe to the topic through the broker. A broker is responsible for delivering published messages to its clients who subscribe to the topic. In this publisher/subscriber model, multiple clients may publish data with the same topic. A client will receive a message it publishes if the client subscribes to the same topic.

The following figure provides an overview of the MQTT Client publish/subscribe model

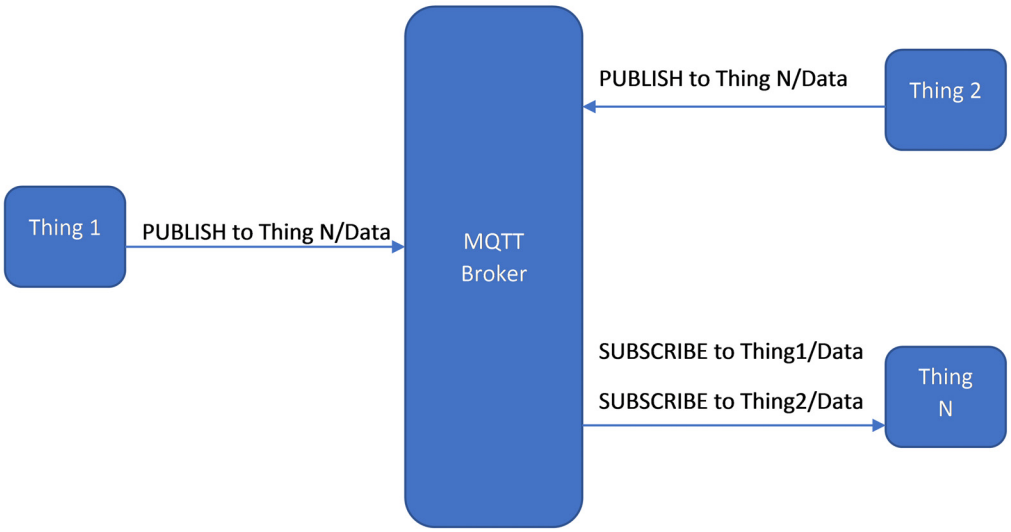

Figure 435: MQTT Client Publish/Subscribe Model

The NetX Duo MQTT client module can be used in the normal mode or the secure mode.

NetX Duo MQTT client module Normal Mode Operational Description

In normal mode, the communication between the MQTT client and broker is not secure.

NetX Duo MQTT client module Secure Mode Operational Description

In Secure mode, the communication between the MQTT client and broker is secured using the TLS protocol. In the thread pane, the TLS protocol is represented by "Add NetX Duo TLS common \[Optional\]" block as shown in the figure below.

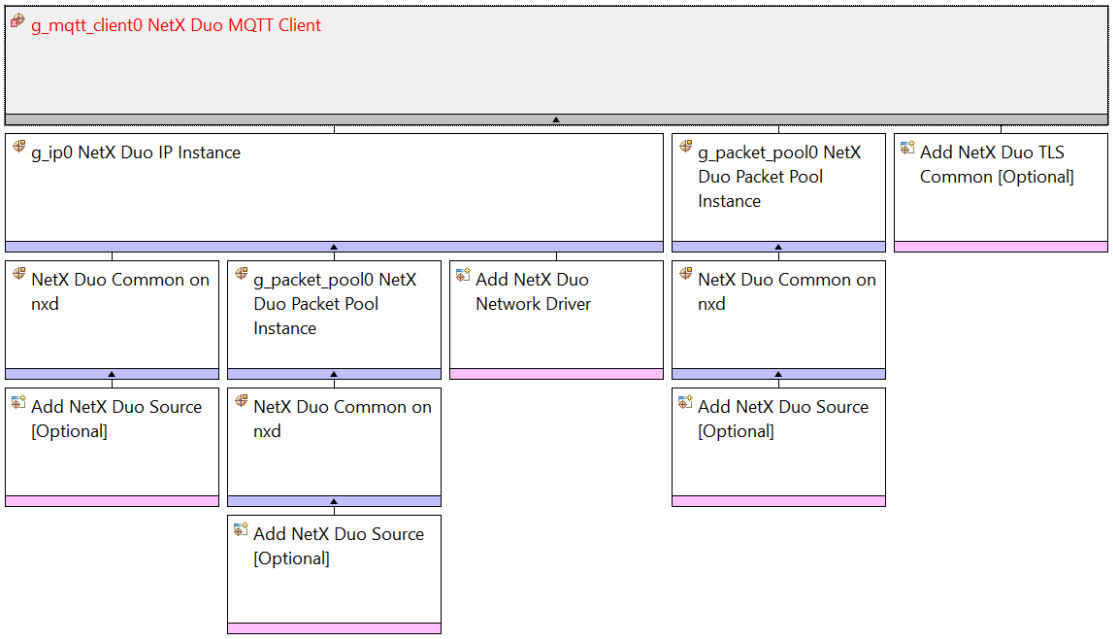

Figure 436: NetX Duo MQTT Client Component thread-pane view

Adding the NetX Duo TLS Common block enables TLS support and internally defines the NX_SECURE_ENABLE macro. The figure below shows the thread pane view of the MQTT client with TLS support enabled.

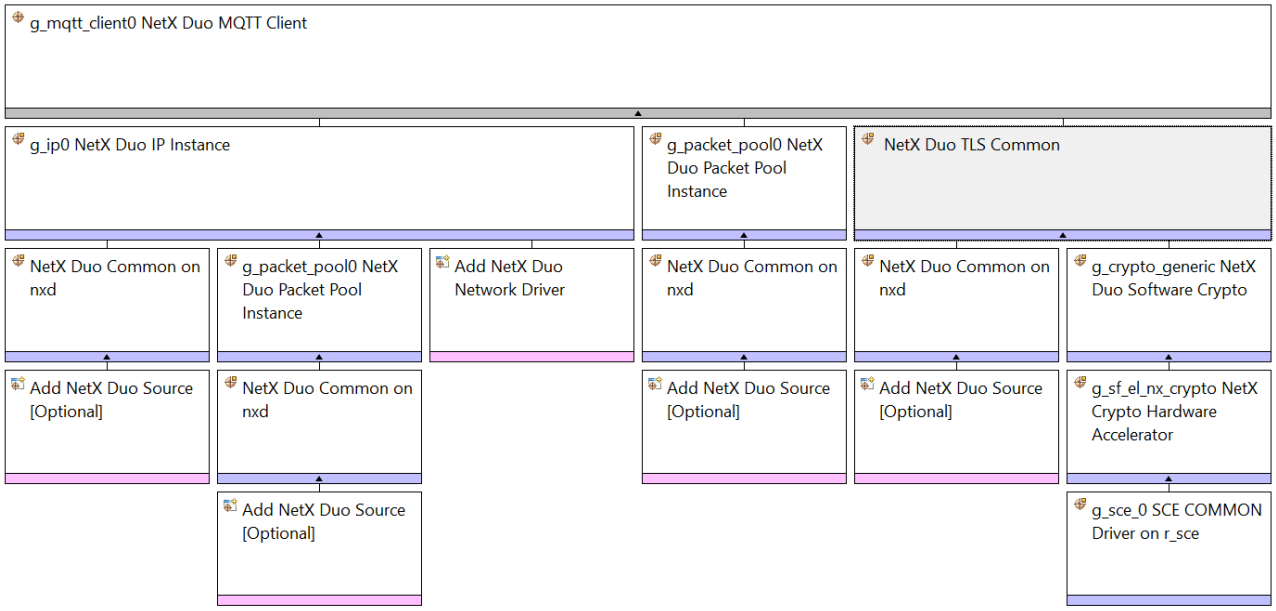

Figure 437: NetX Duo MQTT Client Component with TLS support enabled

NetX Duo MQTT Client Module Operational Notes

To secure the communication between MQTT client and broker, the TLS protocol is required. Please note that MQTT client does not add the NetX Duo TLS Session block. It only adds NetX Duo TLS Common block. This block defines/controls the common properties of NetX Secure. Please refer to the NetX Secure user notes for a detailed description of these properties. The NetX Duo TLS Session block is not added, so code to generate TLS session is not auto-generated. User/Application code should create the TLS session manually. The user code can perform the TLS session creation, configure security parameters and load relevant certificates under the TLS setup callback provided by the nxd_mqtt_client_secure_connect() API.

Before the TLS session is created, the metadata buffer must be allocated. The size of the metadata can be set using the properties pane. Also, the user can use NetX Secure nx_secure_metadata_size_calculate() API to calculate the size of the metadata buffer. Please refer to the NetX Duo MQTT Client user guide for more details. Refer to Using NetX Duo MQTT Client Module in an Application for a description of the callback.

Setting unique Client ID

The MQTT client instance is created using the nxd_mqtt_client_create() API. This API has a unique client ID as one of the parameters which is used by the MQTT broker to uniquely identify the client. The MQTT client component provides properties like Client ID Callback and Client ID Max Length, which are used to get unique client ID. Please refer to the following image.

Module g_mqtt_client0 NetX Duo MQTT Client	
Name	g_mqtt_client0
Name of generated initialization function	mqtt_client_init0
Auto Initialization	Enable
Client ID Callback	mqtt_client_id_callback
Client ID Max Length	12
Client Thread Stack Size	4096
Number of Messages to be stored in memory	1
Client thread priority	2

Figure 438: MQTT Client ID properties

ISDE auto generated code calls this Client ID callback before calling nxd_mqtt_client_create(). The prototype for Client ID callback is as follows:

```
void mqtt_client_id_callback(char * p_client_id, uint32_t * p_client_id_length);
```

Here client_id is an output parameter which will be filled in by this callback function and client_id_length is an input/output parameter.

Refer to Using NetX Duo MQTT Client Module in an Application for a description of the callback.

NetX Duo MQTT Client Limitations

- Refer to the associated SSP Release notes for the limitations on this module.

4.3.5.4 Including the NetX Duo MQTT Client Module in an Application

This section describes how to include the NetX Duo MQTT Client module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few sections of the SSP User's Manual, available as described in the Reference Section at the end of this document to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX Duo MQTT Client module to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the NetX Duo MQTT Client module is g_mqtt_client0. This name can be changed in the associated Properties window.)

TLS Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_mqtt_client NetX Duo MQTT Client on g_mqtt_client	Threads	New Stack> X-Ware> NetX Duo> Protocols > NetX Duo MQTT Client on g_mqtt_client

When the NetX Duo MQTT Client module on g_mqtt_client is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration

information will have box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level drivers; these are either optional or recommended (this is indicated in the block with the inclusion of this text.) If the addition of lower-level drivers is required, the module description will include "Add" in the text. Clicking on any Pink banded modules will bring up the "New" icon and then display the possible choices.

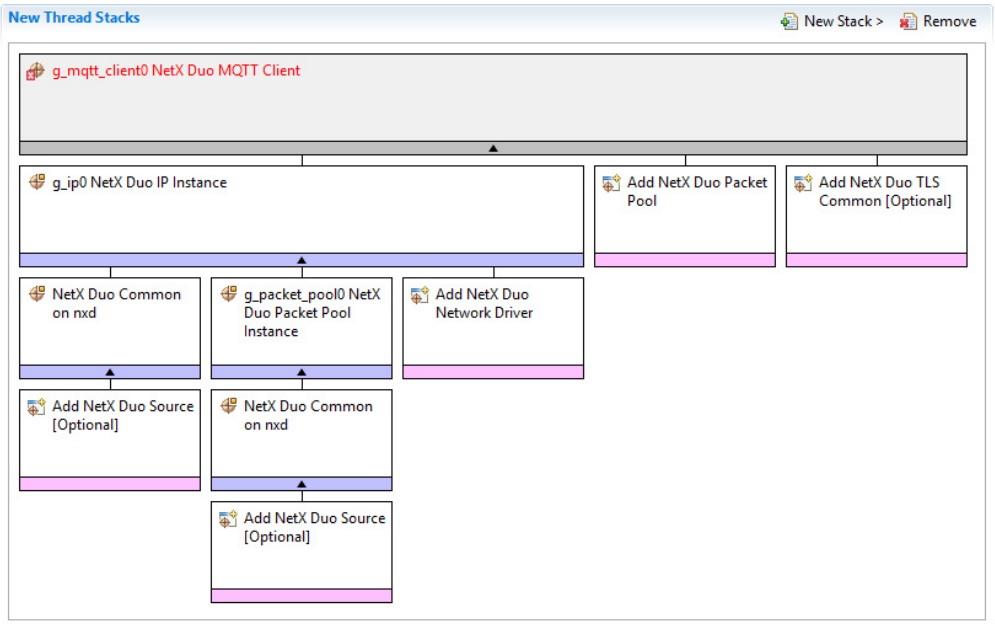

Figure 439: NetX MQTT Client Module Stack

4.3.5.5 Configuring the NetX Duo MQTT Client Module

The NetX Duo MQTT Client module must be configured by you for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority: this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX Duo MQTT Client Module

ISDE Property	Value	Description
Parameter Checking	Enable, Disable, BSP Default: BSP	Add parameter checking code
NX Secure	Enable, Disable Default: Enable	NX secure selection
Topic Name Max Length	12	Topic name max length selection
Message Max Length	32	Message max length selection
Keepalive Timer Rate(s)	1	Keepalive timer rate(s) selection
Ping Timeout Delay(s)	1	Ping timeout delay(s) selection
Socket Timeout (in timer ticks)	0xFFFFFFFF	Specify desired timeout using timer ticks
Name	g_mqtt_client0	Module name
Name of generated initialization function	mqtt_client_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection
Client ID Callback	mqtt_client_id_callback	Client ID callback selection
Client ID Max Length	12	Client ID max length selection
Client Thread Stack Size	4096	Client thread stack size selection
Number of Messages to be stored in memory	1	Number of messages to be stored in memory selection
Client thread priority	2	Client thread priority selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Configuration Settings for the MQTT Client Module Low Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module.

Configuration Settings for the NetX IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	192,168,0,2	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable, Disable Default: Enable	TCP selection
UDP	Enable	UDP selection

ISDE Property	Value	Description
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection
Link status change callback	NULL	Link status change callback selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Common

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	640	Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Port ETHER

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Enable or disable the parameter checking
Channel 0 Phy Reset Pin	IOPORT_PORT_09_PIN_03	Channel 0 Phy reset pin selection
Channel 0 MAC Address High Bits	0x00002E09	Channel 0 MAC address high bits selection
Channel 0 MAC Address Low Bits	0x0A0076C7	Channel 0 MAC address low bits selection
Channel 1 Phy Reset Pin	IOPORT_PORT_07_PIN_06	Channel 1 Phy reset pin selection
Channel 1 MAC Address High Bits	0x00002E09	Channel 1 MAC address high bits selection
Channel 1 MAC Address Low Bits	0x0A0076C8	Channel 1 MAC address low bits selection
Number of Receive Buffer Descriptors	8	Number of receive buffer descriptors selection

ISDE Property	Value	Description
Number of Transmit Buffer Descriptors	32	Number of transmit buffer descriptors selection
Ethernet Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Ethernet interrupt priority selection
Name	g_sf_el_nx	Module name
Channel	0	Channel selection
Callback	NULL	Callback selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

4.3.5.6 Using NetX Duo MQTT Client Module in an Application

Once the module has been configured and the files auto generated, the NetX Duo MQTT client Module is ready to be used in an application. Note that the auto generated code includes the initialization function with the name specified under the Name of generated initialization function property. This function internally calls the nxd_mqtt_client_create() API to create a MQTT client instance with the name specified under the Name property. Calls to this initialization function will be enabled or disabled depending the Auto Initialization property value.

The application need to implement the TLS setup callback function.

The application needs to implement the Client ID callback function which will be called by the initialization function prior to calling nxd_mqtt_client_create() API. This client ID callback should return a unique client ID, for example, MAC address.

Once the client instance is created, the typical steps in using the MQTT client module in an application are:

1) The application can connect to the broker by invoking nxd_mqtt_client_connect().
2) After connecting to the broker, the client can subscribe to a MQTT topic by invoking nxd_mqtt_client_subscribe()
3) After connecting to the broker, the client can publish a MQTT topic by invoking nxd_mqtt_client_publish()
4) The Incoming MQTT messages are stored in the receive queue in the MQTT client instance. The Application retrieves these message by invoking nxd_mqtt_client_message_get(). After consuming the data, the application must release the packet
5) To disconnect MQTT client, the application should invoke nxd_mqtt_client_disconnect(). This ensure that TCP connection to the broker is terminated.

6) The application should invoke nxd_mqtt_client_delete() to delete all the resources associated with MQTT client instance.

These common steps are illustrated in a typical operational flow diagram in the following figure:

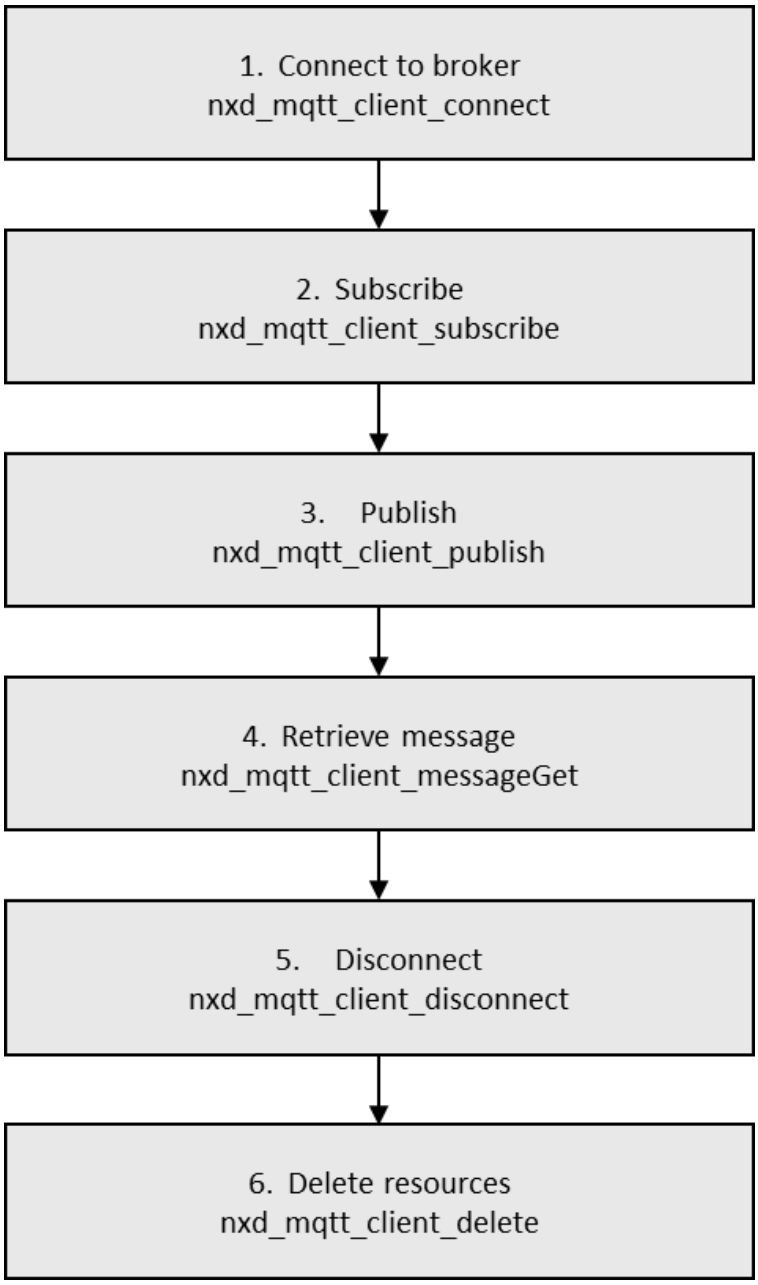

Figure 440: MQTT Client Typical Use Flow Diagram

The following illustrations provide guidance for understanding how to structure the callbacks described for TLS set-up and Client ID processing. Do not copy and paste these illustrations into your own code as they are not meant for that purpose.

Illustration of initialization in TLS setup callback:

```
/* Cipher Suite Variables  */
 extern const NX_SECURE_TLS_CRYPTO nx_crypto_tls_ciphers_synergys7;
 extern const NX_SECURE_TLS_CRYPTO nx_crypto_tls_ciphers;
UINT tls_setup(NXD_MQTT_CLIENT *client_ptr, NX_SECURE_TLS_SESSION *tls_session,
               NX_SECURE_X509_CERT *certificate, NX_SECURE_X509_CERT *trusted_ce
rtificate)
{
    status = nx_secure_tls_session_create(tls_session,
                                          &nx_crypto_tls_ciphers_synergys7,
                                          crypto_metadata,
                                          sizeof(crypto_metadata));
    if (status)
    {
        sprintf(str,"Error in creating TLS Session: 0x%02x\n", status);
        print_to_console(str);
        return(1);
    }
    else
    {
        sprintf(str,"TLS Session has been created. \r\n");
        print_to_console(str);
    }
    /* Allocate space for packet reassembly. */
    status = nx_secure_tls_session_packet_buffer_set(&(client_ptr->nxd_mqtt_tls_
session), tls_packet_buffer, sizeof(tls_packet_buffer));
    /* Check for error.  */
    if (status)
    {
        sprintf(str,"Error in setting Packet Buffer for TLS : %d \r\n",status);
        print_to_console(str);
        return(1);
    }
    else
    {
        sprintf(str,"Packet Buffer for TLS Has been set \r\n");
        print_to_console(str);
    }
    /* Need to allocate space for the certificate coming in from the remote host
. */

    nx_secure_tls_remote_certificate_allocate(tls_session, &remote_certificate,
remote_cert_buffer, sizeof(remote_cert_buffer));
    nx_secure_tls_remote_certificate_allocate(tls_session, &remote_issuer, remot
e_issuer_buffer, sizeof(remote_issuer_buffer));
```

```
    /* Add a CA Certificate to our trusted store for verifying incoming server c
ertificates. */
    nx_secure_x509_certificate_initialize(trusted_certificate, ca_cert_der, ca_c
ert_der_len, NX_NULL, 0, NULL, 0);
    nx_secure_tls_trusted_certificate_add(tls_session, trusted_certificate);

    /* Add the local certificate for client authentication. */
    nx_secure_x509_certificate_initialize(certificate, cert_der, cert_der_len, N
X_NULL, 0, private_key_der, private_key_der_len);
    nx_secure_tls_local_certificate_add(tls_session, certificate);

    /* Add a timestamp function for time checking and timestamps in the TLS hand
shake. */
    nx_secure_tls_timestamp_function_set(tls_session, tls_timestamp_function);

    /* Setup the callback invoked when TLS has a certificate it wants to verify
so we can
       do additional checks not done automatically by TLS. */
    nx_secure_tls_session_certificate_callback_set(tls_session, certificate_veri
fication_callback);

    return NX_SUCCESS;
}
```

Illustration of client Id callback:

```
void mqtt_client_id_callback(char * p_client_id, uint32_t * p_client_id_length)
{
    uint32_t id_length = 0;
    if (*p_client_id_length < sizeof(mac_id))
    {
       id_length = *p_client_id_length;
    }
    else
    {
        id_length = sizeof(mac_id);
    }
    /** Copy MAC address to Client ID and update Client ID length */
    memcpy(p_client_id, mac_id, id_length);
    *p_client_id_length = id_length;
}
```

4.3.6 NetX Duo TLS Session

The NetX Duo TLS Session Module provides high level APIs for Transport Layer Security (TLS) protocol-based client. It uses services provided by the Synergy Crypto Engine (SCE) to carry out hardware-accelerated encryption and decryption.

The NetX Duo TLS Session module is based on ThreadX "NetX Duo Secure" which implements the Secure Socket Layer(SSL) and its replacement Transport Layer Security (TLS) protocol as described in RFCs 2246 (version 1.0), and 5246 (version 1.2). NetX Duo Secure also includes routines for basic X.509 (RFC 5280). NetX Duo Secure is intended for applications using the ThreadX RTOS.

The TLS/SSL protocol provides privacy and reliability between two communicating applications. It has the following basic properties:

- Encryption: The messages exchanged between communicating applications are encrypted to ensure that the connection is private. Symmetric cryptography mechanism such as AES (Advanced Encryption Standard is used for data encryption.
- Authentication: A mechanism to check the peer's identity using certificates
- Integrity: A mechanism to detect message tampering and forgery to ensure that connection is reliable. Message Authentication Code (MAC) such as Secure Hash Algorithm (SHA) is used to ensure message integrity

An Application project that demonstrates the use of TLS as part of an MQTT client is available on the Renesas web site. The "Synergy Enterprise Cloud Toolbox" application project and application note can be found by searching the Renesas web site for R20AN0485.

4.3.6.1 NetX Duo TLS Session Module Features

- RFC 2246- The TLS Protocol Version 1.0
- RFC 5246- The Transport Layer Security (TLS) Protocol Version 1.2
- RFC 5280 X.509 PKI Certificates (v3)
- RFC 3268 Advanced Encryption Standard (AES) Cipher suites for Transport Layer Security (TLS)
- RFC 3447 Public-Key Cryptography Standards (PKCS) #1: RSA Cryptography Specifications Version 2.1
- RFC 2104 HMAC: Keyed-Hashing for Message Authentication
- RFC 6234 US Secure Hash Algorithms (SHA and SHA-based HMAC and HKDF)
- RFC 4279 Pre-Shared Key Cipher suites for TLS
- Supports TLS extensions for:
  - Secure Renegotiation Indication: This extension mitigates a Man-in-the-Middle attack vulnerability that could occur during a renegotiation handshake.
  - Server Name Indication: This extension allows a TLS Client to supply a specific DNS name to a TLS Server, allowing the server to select the correct credentials (assumes the server has multiple identity certificates and network entrypoints).
  - Signature Algorithms: This extension enables a TLS Client to provide a list of acceptable signature and hash algorithms to a TLS Server
- Supports X.509 extensions for:
  - Key Usage: Provides acceptable uses for a certificate's public key in a bitfield

– Extended Key Usage: Provides additional acceptable uses for a certificate's public key using OIDs
– Subject Alternative Name: Provides alternative DNS names that are also represented by the certificate

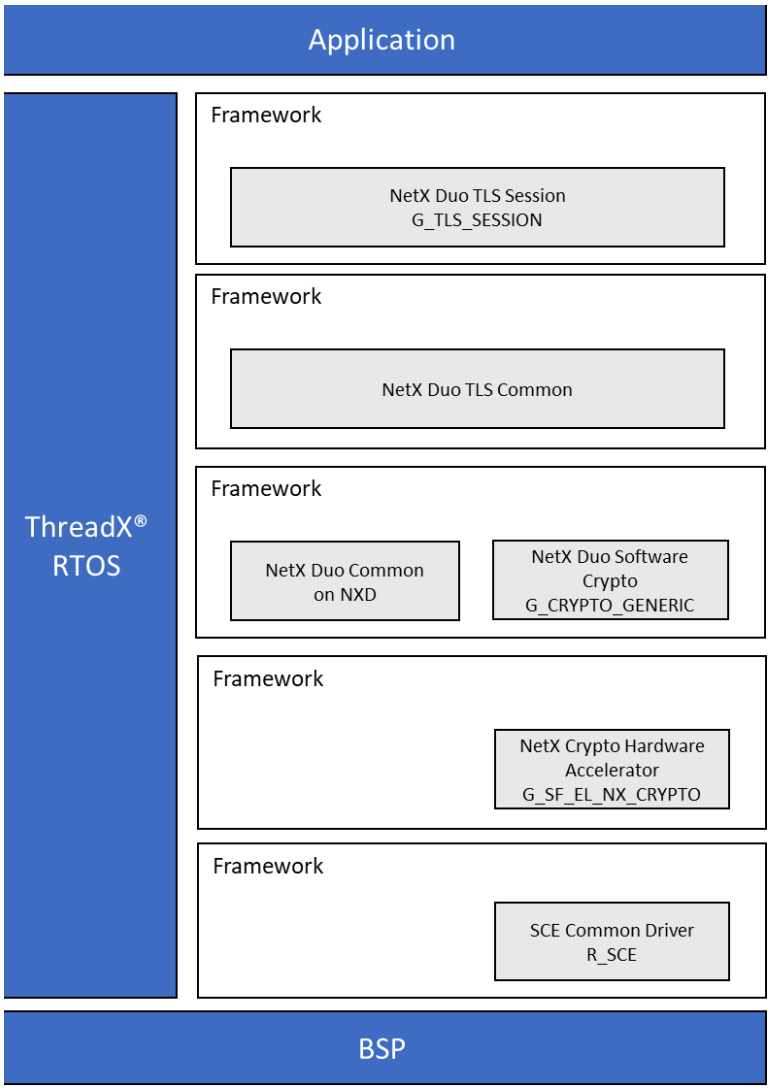

Figure 441: NetX Duo TLS Session Module Block Diagram

4.3.6.2 NetX Duo TLS Session Module APIs Overview

The NetX Duo TLS Support module defines APIs for creating and setting up a TLS security session. A complete list of the available APIs, an example API call, and a short description of each can be found in the table below. A table of status return values follows.

Function Name	Example API Call and Description
nx_secure_tls_local_certificate_add	**nx_secure_tls_local_certificate_add**(tls_session, certificate); Adds an initialized certificate to a TLS session for use as a local identification certificate - the TLS Server certificate for TLS servers, and the Client certificate for TLS clients.
nx_secure_tls_local_certificate_remove	**nx_secure_tls_local_certificate_remove**(tls_session, common_name, common_name_length); Removes a certificate instance from the local certificates list, keyed on the Common Name field.
nx_secure_tls_metadata_size_calculate	**nx_secure_tls_metadata_size_calculate**(cipher_table, metadata_size); Determines the size of the buffer needed by TLS for encryption metadata for a given ciphersuite table
nx_secure_tls_packet_allocate	**nx_secure_tls_packet_allocate**(tls_session, pool_ptr, packet_ptr, wait_option);Allocates a packet for a TLS application such that it allows additional room for the TLS header
nx_secure_tls_remote_ certificate_allocate	**nx_secure_tls_remote_certificate_allocate**(tls_session, certificate, raw_certificate_buffer, buffer_size); Adds an uninitialized certificate instance to a TLS session for the purpose of allocating space for certificates provided by a remote host during a TLS session
nx_secure_tls_session_ certificate_callback_set	**nx_secure_tls_session_certificate_callback_set**(tls_session, session); Sets up a function pointer that TLS will invoke when a certificate is received from a remote host, allowing the application to perform validation checks such as certificate revocation and certificate policy enforcement

Function Name	Example API Call and Description
nx_secure_tls_session_create	**nx_secure_tls_session_create**(session_ptr, cipher_table, metadata_area, metadata_size); Initializes a TLS session control block for later use in establishing a secure TLS session over a TCP socket or other lower-level networking protocol
nx_secure_tls_session_client_verify_disable	**nx_secure_tls_session_client_verify_ disable**(tls_session); Disables Client Certificate Verification for a particular TLS Session which previously had it enabled.
nx_secure_tls_session_client_verify_enable	**nx_secure_tls_session_client_verify_enable**(tls_session); Enables Client Certificate Verification for TLS Server instances. If enabled, the TLS Server will request and verify a remote TLS Client Certificate using all available crypto signature routines.
nx_secure_tls_session_delete	**nx_secure_tls_session_delete**(tls_session); Deletes a TLS session object, returning any resources to the system
nx_secure_tls_session_end	**nx_secure_tls_session_end**(tls_session, wait_option); Ends an active TLS session by sending the TLS CloseNotify alert to the remote host, then waiting for the response CloseNotify before returning.
nx_secure_tls_session_packet_buffer_set	**nx_secure_tls_session_packet_buffer_set**(session_ptr, buffer_ptr, buffer_size); Sets the buffer TLS uses to reassemble incoming messages which may span multiple TCP packets.

Function Name	Example API Call and Description
nx_secure_tls_session_protocol_version_override	**nx_secure_tls_session_protocol_version_override**(tls_session, protocol_version); Overrides the TLS protocol version to use for the TLS session. This allows for a different version of TLS to be utilized even if a newer version is enabled.
nx_secure_tls_session_receive	**nx_secure_tls_session_receive**(tls_session, packet_ptr_ptr, wait_option); Receives data from an active TLS session, handling all decryption and verification before returning the data to the caller in the supplied NX_PACKET structure
nx_secure_tls_session_reset	**nx_secure_tls_session_reset**(session_ptr); Resets a TLS session object, clearing out all data for initialization or re-use.
nx_secure_tls_session_send	**nx_secure_tls_session_send**(tls_session, packet_ptr, wait_option); Sends data using an active TLS session, handling all encryption and hashing before sending data over the established TCP socket connection
nx_secure_tls_session_start	**nx_secure_tls_session_start**(tls_session, tcp_socket, wait_option); Starts a TLS session given a TCP socket. The TCP connection must be established before calling this function or the TLS handshake will fail.
nx_secure_tls_session_time_function_set	**nx_secure_tls_session_time_function_set(**tls_session, time_func_ptr)** **Sets up a function pointer that TLS will invoke when it needs to get the current time, which is used in various TLS handshake messages and for verification of certificates.**

Function Name	Example API Call and Description
**nx_secure_tls_trusted_ certificate_add	**nx_secure_tls_trusted_certificate_add**(tls_session, certificate); Adds an initialized certificate to a TLS session for use as a trusted Root Certificate
**nx_secure_tls_trusted_ certificate_remove	**nx_secure_tls_trusted_certificate_remove**(tls_session, common_name, common_name_length); Removes a certificate instance from the trusted certificates store, keyed on the Common Name field.
nx_secure_tls_remote_certificate_free_all**	Release certificates previously registered with the TLS session.
**nx_secure_tls_psk_add	**nx_secure_tls_psk_add**(tls_session, pre_shared_key, psk_length, psk_identity, identity_length, hint, hint_length); Adds a pre-shared key (PSK) to a TLS session for use with a PSK ciphersuite. The second parameter is the PSK identity used during the TLS handshake to select the proper key.
**nx_secure_tls_psk_find	**nx_secure_tls_psk_find**(tls_session, psk_data, psk_length,psk_identity, identity_length); Finds a pre-shared key (PSK) in a TLS session for use with a PSK ciphersuite. The PSK is found using an "identity hint" that should match a field in the PSK structure in the TLS session.
**nx_secure_tls_client_psk_set	**nx_secure_tls_client_psk_set**(tls_session, pre_shared_key, psk_length, psk_identity, identity_length, hint, hint_length); Sets the pre-shared key (PSK) for a TLS Client in a TLS session control block for use with a remote server that is sing a PSK ciphersuite.
nx_secure_x509_certificate_initialize	Initialize X.509 Certificate for NetX Secure TLS
nx_secure_x509_common_name_dns_check	Check DNS name against X.509 Certificate

Function Name	Example API Call and Description
nx_secure_x509_crl_revocation_ check	Check X.509 Certificate against a supplied Certificate Revocation List

NOTE: ** Requires that the property PSK Cipher Suite of the TLS Common component be enabled.

4.3.6.3 NetX Duo TLS Session Module Operational Overview

TLS uses TCP and provides secure communications for application layer protocols such as HTTP and MQTT. TLS can also be used in 'bare' TCP socket applications to send and receive TCP packets in a secure session to another TCP peer. The module guide for this project uses this simplified application of TLS to demonstrate a TLS Client TCP and TLS Server TCP sockets exchanging data to a TCP peer.

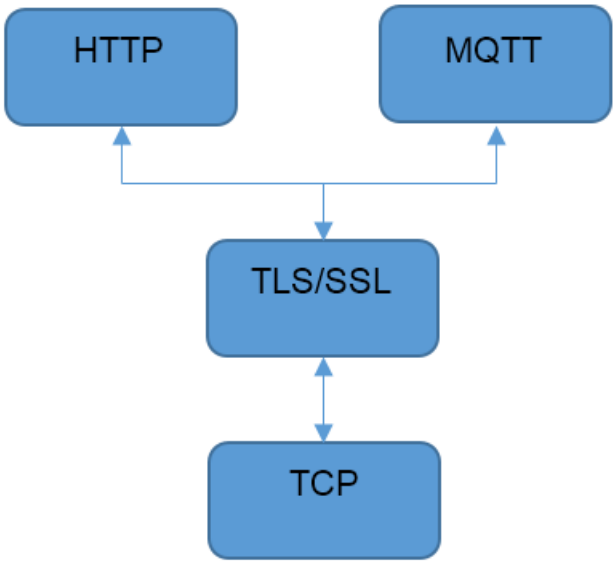

Figure 442: TLS/SSL Layering

TLS does not have a well-known port number. Instead it uses the designated port number of the secure variant of the higher layer protocol. For example, port number 443 for secure HTTP, port number 8883 for MQTT etc.

When a secure connection is established using TLS/SSL, for example using HTTPS, messages are exchanged between the client (which always initiates the connection) and a server. The first set of messages execute a Handshake Protocol after which the client and server can securely send/receive data bidirectionally as shown in the following figure.

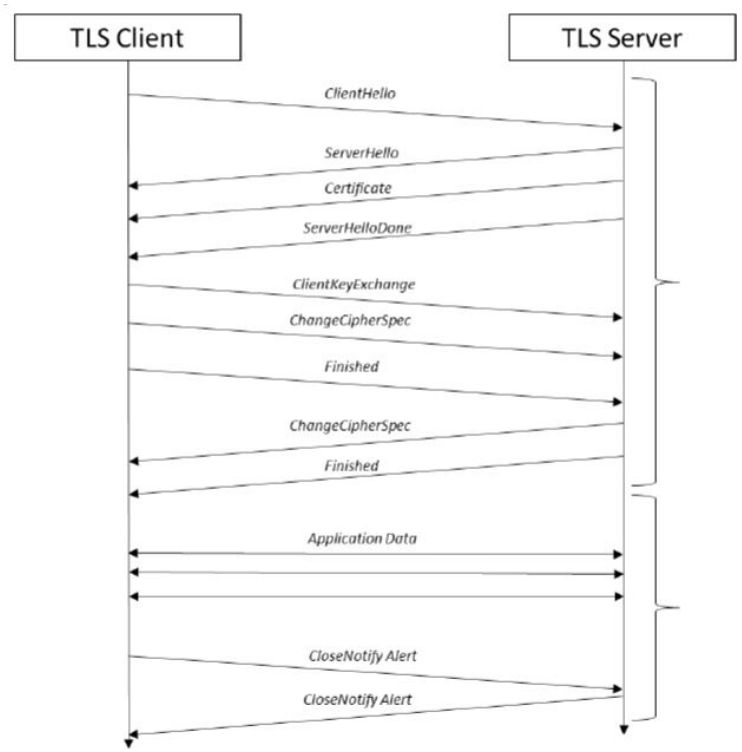

Figure 443: TLS Protocol Sequences

NetX Duo TLS Session Module Operational Notes

- Before the TLS session is created, the metadata buffer must be allocated. The size of meta data can be set using the properties pane. Also, the user can use NetX Duo Secure nx_secure_metadata_size_calculate API to calculate the required size of metadata buffer. The Metadata size is specified in the "Meta data size" of the TLS session component, or in the nx_secure_tls_session_create call; the default value is 4k but to handle most servers, 8k is recommended if the memory space is available.
- To associate a packet reassembly buffer to a TLS session, use the nx_secure_tls_session_packet_buffer_set API. The reassembly buffer is used to place the incoming TLS records which may span multiple TCP packets. If an incoming TLS record is larger than the supplied buffer, the TLS session will end with an error. A reasonable packet buffer size is 6-8k.
- Also, before starting a TLS client session, the application must allocate memory for processing Server certificate data in the nx_secure_tls_remote_certificate_allocate call. A reasonable size for most certificates is 2k. The TLS client application should allow for 2-3 certificates from most servers.
- For any incoming certificate, the NetX Duo Secure TLS will perform basic X.509 path validation.
- Additionally, at each stage in the verification process the expiration date of each certificate is checked against the time provided by the application timestamp function. The nx_secure_tls_session_time_function_set API is used to optionally set up a function pointer for application timestamp function that TLS will invoke when it needs to get the current time. The current time is used in some TLS handshake messages for verification of certificates. If a timestamp function is registered with the TLS session, a timestamp will be used in the generation of the Server or Client Hello, and in verifying the remote certificate.

- Before attempting to reconnect to the same or another TLS server, the TLS client must clear the TLS session. This is most easily done by calling nx_secure_tls_session_end. It is recommended to delete the TLS session and recreate it before making another connection attempt. For applications using SSP 1.3.x, the nx_secure_tls_session_create call should be preceded by a memset call on the TLS session to clear the session completely:

```
memset(tls\_session\_ptr, 0, sizeof(NXD\_SECURE\_TLS\_SESSION));
```

NetX Duo TLS Session Limitations

- Due to the nature of embedded devices, some systems may not have adequate memory to support the maximum TLS record size of 16 KB. NetX Duo TLS Secure can handle 16KB records on devices with sufficient resources.
- NetX Duo Secure performs basic certificate verification only. NetX Duo TLS Secure will perform basic X.509 chain verification on a certificate to assure that the certificate is valid and signed by a trusted Certificate Authority, and can provide the certificate Common Name for the application to compare against the Top-Level Domain Name of the remote host. However, verification of certificate extensions and other data is the responsibility of the application implementer. Refer to the Express Logic NetX Duo TLS Secure User Guide available from the Synergy Gallery for more details.
- Software-based cryptography is processor-intensive and not available. Therefore hardware-based cryptography is used for optimal performance of NetX Duo TLS Secure.
- The Self-Signed Certificates should be disabled in the final application. However, in MQTT Client in SSP 1.3.2 – 1.4.0, this option is automatically enabled even if set to Disabled. To disable this feature, modify the nx_secure_tls.h file in the project synergy\ssp\src\framework\el\nxd_application_layer\nxd_tls_secure directory to comment out NX_SECURE_ALLOW_SELF_SIGNED_CERTIFICATES directly. Make the file read only so it is not overwritten in the e^2 studio environment.
- Refer to the most recent SSP release notes for additional limitations on this module.

4.3.6.4 Including the NetX Duo TLS Session Module in an Application

This section describes how to include the NetX Duo TLS Session module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few sections of the SSP User's Manual, available as described in the Reference Section at the end of this document to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX Duo TLS Session module to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the NetX Duo TLS Session module is g_tls_session0. This name can be changed in the associated Properties window.)

Audio Playback Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_tls_session0 NetX Duo TLS Session on g_tls_session	Threads	New Stack> X-Ware> NetX Duo> Protocols > NetX Duo TLS Session on g_tls_session0

When the NetX Duo TLS Session module on g_tls_session0 is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any drivers that need additional configuration information will have box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common and need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level drivers; these are either optional or recommended (this is indicated in the block with the inclusion of this text.) If the addition of lower-level drivers is required, the module description will include "Add" in the text. Clicking on any Pink banded modules will bring up the "New" icon and then display the possible choices.

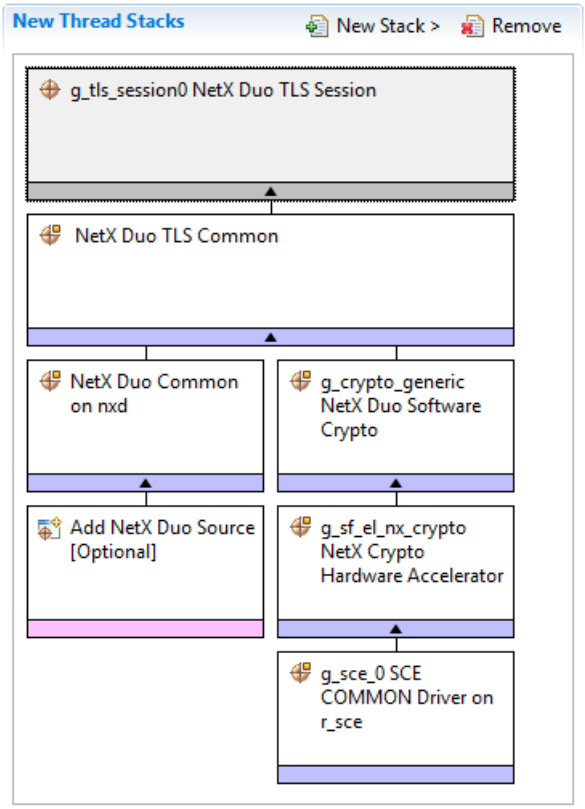

Figure 444: NetX MQTT Client Module Stack

To use TLS Secure with 'bare' TCP sockets, you will need to add an IP instance:

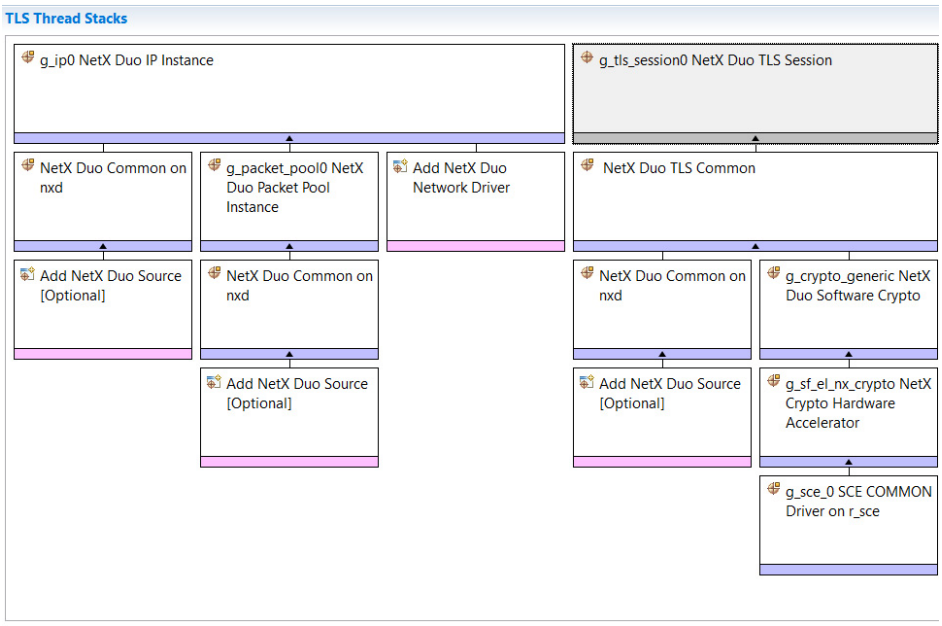

Figure 445: TLS Secure session using NetX Duo sockets directly

4.3.6.5 Configuring the NetX Duo TLS Session Module

The NetX Duo TLS Session module must be configured by you for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and not available for changes and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority: this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX Duo TLS Session Module

ISDE Property	Value	Description
Name	g_tls_session0	Module name
Meta data size	4000	Meta data size selection
Name of Timestamp Function	tls_timestamp_callback0	Name of timestamp function
Name of Certificate Verification function	certificate_verification_callback0	Name of certificate verification function
Name of generated initialization function	tls_dtls_session_init0	Name of generated initialization function
Auto initialization	Enable, Disable Default: Enable	Auto initialization selection

Configuration Settings for the NetX Duo TLS Server Session Module

ISDE Property	Value	Description
Name	g_tls_session1	Module name
Meta data size	4000	Meta data size selection
Name of Timestamp Function	NULL	Name of callback for setting timestamp
Name of Certificate Verification Function	NULL	Name of callback for verifying the remote certificate
Name of generated initialization function	tls_dtls_session_init0	Name of generated initialization function selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

NOTE: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the TLS Session Module Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module.

Configuration Settings for the NetX TLS Common

ISDE Property	Value	Description
Crypto Engine	Hardware	Crypto engine selection
Self-Signed Certificates	Enable, Disable Default: Disable	Self-signed certificates selection*
PSK Cipher Suite	Enable, Disable Default: Disable	PSK cipher suite selection
X509 Strict Name Compare	Enable, Disable Default: Disable	X509 strict name compare selection
X509 Extended Distinguished Names	Enable, Disable Default: Disable	X509 extended distinguished names selection
Maximum RSA Modulus size (bits)	1024, 2048, 3072, 4096 Default: 4096	Maximum RSA modulus size (bits) selection
TLS v 1.0	Enable, Disable Default: Disable	TLS v 1.0 selection
TLS v 1.1	Enable, Disable Default: Disable	TLS v 1.1 selection

ISDE Property	Value	Description
Server Mode	Enable, Disable Default: Enable	Server mode selection
Client Mode	Enable, Disable Default: Enable	Client mode selection
Name of generated initialization function	nx_secure_common_init	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

NOTE: * This option MUST be disabled. Enabling this option is a serious security risk and is only intended for development and testing. However, in MQTT Client in SSP 1.3.2 – 1.4.0, this option is automatically enabled even if set to Disabled. To disable this feature, modify the nx_secure_tls.h file in the project synergy\ssp\src\framework\el\nxd_application_layer\nxd_tls_secure directory to comment out NX_SECURE_ALLOW_SELF_SIGNED_CERTIFICATES directly. Make the file read only so it is not overwritten in the e^2 studio environment.

Configuration Settings for the NetX Common

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Software Crypto

ISDE Property	Value	Description
Name	g_crypto_generic	Module name
Name	g_packet_pool0	Module name

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Crypto Hardware Accelerator

ISDE Property	Value	Description
Name	g_sf_el_nx_crypto	Module name

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SCE Common Driver on r_sce

ISDE Property	Value	Description
Name	g_sce_0	Module name
Endian Flag	CRYPTO_WORD_ENDIAN_BIG, CRYPTO_WORD_ENDIAN_LITTLE Default: CRYPT_WORD_ENDIAN_BIG	Endian flag selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Important Note: **Bolded** properties in the next set of tables need to be configured for your system.

Configuration Settings for the NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name

ISDE Property	Value	Description
IPv4 Address (use commas for separation)	192,168,0,2	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
IPv6 Global Address (use commas for separation) *	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
IPv6 Link Local Address (use commas for separation, All zeros means NetX Duo will create the LLA address using the device MAC address) *	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection. This will be configured automatically if left at the default value, based on the device MAC address.
IP Helper Thread Stack Size (bytes)	1024	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable	TCP selection
UDP	Enable, Disable Default: Enable	UDP selection
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection

ISDE Property	Value	Description
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

NOTE: *Only necessary if using IPv6 network connections

Configuration Settings for the NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Configuration Settings for the NetX and NetX Duo Packet Pool Instance g_packet_pool0

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	1532	Packet size selection – certificate packets can be quite large, exceeding the default 640 bytes. So to avoid packet chaining overhead, set the packet payload to the device MTU, which is usually 1518 or so

ISDE Property	Value	Description
Number of Packets in Pool	16	Number of packets in pool selection. For servers with very large certificates, e.g. 4k bytes it might be necessary to increase this number accordingly.
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Configuration Settings for the NetX Port ETHER

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking
Channel 0 Phy Reset Pin	IOPORT_PORT_09_PIN_03	Channel 0 Phy reset pin selection
Channel 0 MAC Address High Bits	0x00002E09	Channel 0 MAC address high bits selection
Channel 0 MAC Address Low Bits	0x0A0076C7	Channel 0 MAC address low bits selection
Channel 1 Phy Reset Pin**	IOPORT_PORT_08_PIN_06	Channel 1 Phy reset pin selection
Channel 1 MAC Address High Bits	0x00002E09	Channel 1 MAC address high bits selection
Channel 1 MAC Address Low Bits	0x0A0076C8	Channel 1 MAC address low bits selection
Number of Receive Buffer Descriptors	8	Number of receive buffer descriptors selection
Number of Transmit Buffer Descriptors	32	Number of transmit buffer descriptors selection

ISDE Property	Value	Description
Ethernet Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled Recommend Priority 3 for most applications	Ethernet interrupt priority selection. Change from Disabled for the network driver to send and receive packets.
Name	g_sf_el_nx	Module name
Channel**	1	Channel selection
Callback	NULL	Callback selection

NOTE: ** This is specific to the SK-S7G2 MCU. The DK-S7G2 default values need not be modified.

For Wi-Fi networks, please refer to the Synergy Wi-Fi Application Project for SK-S7G2 - Application Project on the Renesas Gallery for more information on setting network parameters.

NetX Duo TLS Session Module Clock Configuration

The ETHERC peripheral module uses PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator clock tab prior to a build, or by using the CGC interface at run-time.

NetX Duo TLS Session Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I^2C pins.

NOTE: The selected operation mode determines the peripheral signals available and the MCU pins required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin selection Sequence
ETHERC	Pins	Select Peripherals > Connectivity:ETHERC > ETHERC1.RMII

NOTE: The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII (Default: Disabled)	Select RMII as the Operation Mode for ETHERC1
Pin Group Selection	Mixed, _A only (Default: _A only)	Pin group selection
REF50CK	P701	REF50CK Pin
TXD0	P700	TXD0 Pin
TXD1	P406	TXD1 Pin
TXD_EN	P405	TXD_EN Pin
RXD0	P702	RXD0 Pin
RXD1	P703	RXD1 Pin
RX_ER	P704	RX_ER Pin
CRS_DV	P705	CRS_DV Pin
MDC	P403	MDC Pin
MDIO	P404	MDIO Pin

NOTE: Example settings are for a project using the Synergy S7G2 MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.6.6 Using NetX Duo TLS Session Module in an Application

Autogenerated code includes the initialization function with the name as specified in the "Name of generated initialization function" property, for example, tls_dlts_session_init0(). The TLS Session instance variable specified using the "Name" property of the TLS Session is passed as input to the initialization function and this instance variable can be passed as input to several APIs of the TLS layer. The initialization function internally calls the nx_secure_tls_session_create () API

to create a TLS session. Calls to the initialization function will be enabled or disabled depending on the "Auto Initialization" property value.

Once the client instance is created, the typical steps in using the NetX Duo TLS Session module in an application are:

1) Packet the reassembly buffer for TLS session using the nx_secure_tls_session_packet_buffer_set API
2) Initialize the root CA certificate using the nx_secure_x509_certificate_initialize API
3) Load the root CA certificate to a trusted store using the nx_secure_tls_trusted_certificate_add API
4) Allocate space for certificates sent by remote server using the nx_secure_tls_remote_certificate_allocate API
5) Start the TLS session using the nx_secure_tls_session_start API
6) Send data over the secure connection using the nx_secure_tls_session_send API
7) Receive data over the secure connection using the nx_secure_tls_session_receive API
8) End the session using the nx_secure_tls_session_end API

These common steps are illustrated in a typical operational flow diagram in the following figure:

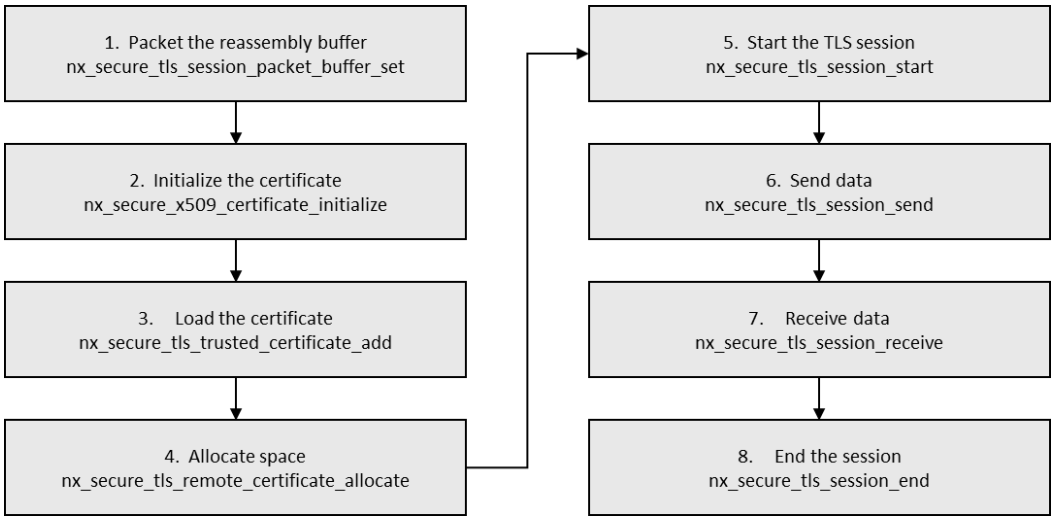

Figure 446: TLS Session Typical Use Flow Diagram

An Application project that demonstrates the use of TLS as part of an MQTT client is available on the Renesas web site. The "Synergy Enterprise Cloud Toolbox" application project and application note can be found by searching the Renesas web site for R20AN0485.

4.3.7 NetX Port Ethernet

The Synergy NetX Port Ether module (sf_el_nx) for NetX and NetX Duo is integrated into the SSP. Its function is to interface the generic NetX and NetX Duo software with the hardware. This module includes the MAC driver, the PHY driver, additional glue logic and utility functions.

NOTE: Unless otherwise stated there is no difference in how this module works in NetX or NetX Duo projects.

4.3.7.1 NetX Port Ether Module Features

- NetX services are implemented as a library, so only code that is needed is added to the project
  - For most applications, this results in an instruction image from between 5k bytes and 30k bytes, with IPV6 and ICMPv6 enabled, the size is from 30k bytes to 45k bytes.
- NetX supports a variety of RFCs including the following:
  - RFC 1112 Host Extensions for IP Multicasting (IGMPv1)
  - RFC 1122 Requirements for Internet Hosts - Communication Layers
  - RFC 2236 Internet Group Management Protocol, Version 2
  - RFC 768 User Datagram Protocol (UDP)
  - RFC 791 Internet Protocol (IP)
  - RFC 792 Internet Control Message Protocol (ICMP)
  - RFC 793 Transmission Control Protocol (TCP)
  - RFC 826 Ethernet Address Resolution Protocol (ARP)
  - RFC 903 Reverse Address Resolution Protocol (RARP)
  - RFC 2460 Internet Protocol v6 (IPv6) Specification (NetX Duo only)
  - RFC 4443 Internet Control Message Protocol (ICMPV6) (NetX Duo only)
  - RFC 4861 Neighbor Discovery for IPv6 (NetX Duo only)
  - RFC 4862 IPv6 Stateless Address Auto Configuration (NetX Duo only)
- Packet-based zero-copy implementation of TCP/IP (buffers are not copied inside NetX as they travel across the stack or from the stack to the user application, freeing up memory and processing cycles for example, significantly improves transmission rates)
- Fast UDP processing

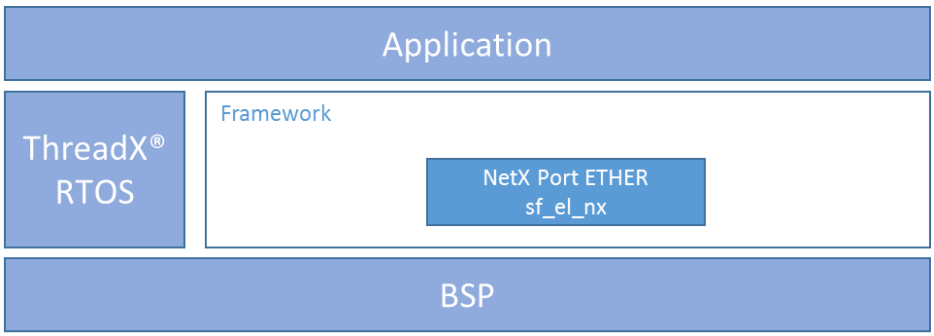

Figure 447: Net X Port Ether Module Organization, Options and Stack Implementations

4.3.7.2 NetX Port Ether Module APIs

The NetX Port Ether module has a narrow API, used internally by NetX and by the module itself. It includes the Ethernet driver entry point (nx_ether_driver_eth0, nx_ether_driver_eth1), the Ethernet interrupt handler and other functions used internally by the module but externally visible.

4.3.7.3 NetX Port Ether Module Operational Overview

The NetX Port Ether module is a high-performance real-time implementation of the NetX Ethernet driver for the Renesas Synergy software and Synergy Ethernet IP.

NOTE: NetX assumes the existence of ThreadX and depends on its thread execution, suspension, periodic timers, and mutual exclusion facilities.

Each IP instance in NetX has a primary interface which is identified by its device driver specified in the nx_ip_create service. The network driver is responsible for handling various NetX requests, including packet transmission, packet reception, and requests for status and control.

For a multi-home system, the IP instance can be configured for multiple interfaces, each with an associated network driver that performs these tasks for the respective interface. The network driver must also handle asynchronous events occurring on the media. Asynchronous events from the media include packet reception, packet transmission completion, and status changes. NetX provides the network driver with several access functions to handle various events. These functions are designed to be called from the interrupt service routine portion of the network driver. For IP networks, the network driver should forward all ARP packets received to the _nx_arp_packet_deferred_receive internal function. All RARP packets should be forwarded to _nx_rarp_packet_deferred_receive internal function. There are two options for IP packets:

If fast dispatch of IP packets is required, incoming IP packets are forwarded to _nx_ip_packet_receive for immediate processing; this greatly improves NetX performance in handling IP packets. Otherwise, IP packets are forwarded to _nx_ip_packet_deferred_receive. This service places the IP packet in the deferred processing queue where it is then handled by the internal IP thread, which results in the least amount of ISR processing time.

The network driver can also defer interrupt processing to run out of the context of the IP thread. In this mode, the ISR shall save the necessary information, call the internal function _nx_ip_driver_deferred_processing, and acknowledge the interrupt controller. This service notifies IP thread to schedule a callback to the device driver to complete the process of the event that causes the interrupt.

Some network controllers are capable of performing TCP/UDP/IP header checksum computation and validation in hardware without taking up valuable CPU resources. To take advantage of the hardware capability feature, NetX provides options to enable or disable various software checksum computation at compilation time, as well as turning on/off checksum computation at run time. See the "NetX Network Drivers" section in the NetX User Guide for more detailed information on writing NetX network drivers.

NetX Port Ether Module Important Operational Notes and Limitations

A summary of some key operational notes is given below. Refer to the *NetX User Guide for the Renesas Synergy™ Platform* and *NetX Duo User Guide for the Renesas Synergy™ Platform* for more details on each of these topics. The source code symbol is provided in addition to the NetX Source property for each feature below. For example, to change the number of physical network interfaces, you can either set the *Maximum Physical Interfaces* property in the NetX Source or NetX Duo Source element, or you can define the source code symbol NX_MAX_PHSYCIAL_INTERFACES directly. In either case, it is still necessary to include the NetX and NetX Duo Source component, generate the project files and to rebuild the NetX library.

NetX Source Level settings

The options below are in the NetX and NetX Duo Source components.

- **Multiple Network Interface Support**NetX supports systems connected to multiple physical devices using a single IP instance. Each physical interface is assigned to an interface control block in the IP instance. Applications wishing to use a multi-home system must define the value for the *Maximum Physical Interfaces* property (or

NX_MAX_PHSYCIAL_INTERFACES) to the number of physical devices attached to the system, and then rebuild the NetX library. If the library is not rebuilt, this has no effect. The default value is 1.

- **Loopback Interface**The loopback interface is a special network interface without a physical link attached to. The loopback interface allows applications to communicate using the IP loopback address 127.0.0.1 To utilize a logical loopback interface, either set the Loopback property to enabled (the default setting) or ensure the symbol NX_DISABLE_LOOPBACK_INTERFACE is not defined.
- **Enabling IPv6 (NetX Duo only)**By default, IPv6 is enabled on the IP instance in NetX Duo. The IP instance can be disabled or enabled for IPv6 by setting the *NetX Duo IPV6 Support* property in the NetX Duo Source component. Other IPv6 related properties may be enabled (checksum on ICMPv6 packets, Duplicate Address Detection, etc). See the *NetX Duo User Guide for the Renesas Synergy™ Platform* for details on IPv6 networking.

Interface Control Blocks: The number of interface control blocks in the IP instance is the number of physical interfaces (defined by NX_MAX_PHYSICAL_INTERFACES) plus the loopback interface if it is enabled. The total number of interfaces is defined in the symbol NX_MAX_IP_INTERFACES. This value should **not** be modified directly. NetX will define this symbol internally based on the NX_MAX_PHSYCIAL_INTERFACES and NX_DISABLE_LOOPBACK_INTERFACE settings.

NetX Port Ether settings

- **Channel**This determines which interface the ethernet driver is applied to. It may need to be modified from the default value of zero. See Configuring the NetX Port Ether Framework Module.
- **Channel 0/1 Phy Reset Pin**This property to be set depends on the value of the Channel property above. It may need to be modified from the default value. See Configuring the NetX Port Ether Framework Module.
- **Channel 0/1 MAC Address High Bits**
- **Channel 0/1 MAC Address Low Bits**These properties set the device MAC address on the respective channel interface at compile time. To set the MAC address at run time, see the description of the *Callback* property below.
- **Dynamic MAC Address Callback**This property defines the user defined callback function which sets MAC address at runtime (network link initialization). The default value is NULL and the MAC address is assigned using the Channel MAC Address High/Low Bits settings.
- **Unknown Ethernet packet receive Callback**This property configures the callback allowing the user to process unsupported/custom EtherType packets. This call-back can be used in conjugation with the nx_ether_custom_packet_send Ethernet API to send and receive custom Ethernet packet types.
- **Name**This property names the instance of the NetX Port ETHER driver. For an IP instance configured with multiple network interfaces, the application must add an instance of the driver and give it a unique name (or compile errors will result). The default name is g_sf_el_nx.
- **Ethernet Interrupt Priority**This property sets the driver interrupt priority. The default value is Priority 4. The dropdown list indicates what are valid and invalid priorities depending on the MCU target.
- **Link status monitoring**This property allows the user to choose the link status monitoring method. There are two options available:
  - PHY Polling: The PHY polling utilizes an internal monitoring thread for auto negotiation to notify the user when a link is lost or established.
  - PHY Interrupt (Uses LINKSTA Pin): The PHY Interrupt method requires the PHY status pin to be connected to the LINKSTA pin of the Ethernet controller and utilize the Ethernet interrupt to notify the user when the link is lost or established. This notification uses the callback registered with the IP instance.
- **Number of Receive Buffer Descriptors**

- **Number of Transmit Buffer Descriptors**These properties set the number of buffer descriptors (BDs) for receiving and transmitting packets. When the Receive BDs are initialized, the driver allocates a packet for each BD. Therefore, the number of receive BDs should not deplete the IP instance packet pool from which it allocates packets.The NetX Port ETHER driver supports packet chaining for both receiving and transmitting packets (where packets are chained in the application layer). If a packet is received on the network that exceeds the size of the IP default packet pool payload, the driver can allocate additional packets and process the incoming packet as a packet chain.
- **Parameter Checking**This is low level error checking for each component of the project hardware layer. By default, it is set to Default (BSP) which means this property inherits the same property in the BSP.

Refer to the most recent SSP release notes for any additional operational limitations for this module.

4.3.7.4 Including the NetX Port Ether Module in an Application

This section describes how to include the NetX Port Ether Module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP based applications.

The NetX Port Ether Framework is used as a lower level module and is not available to add as a separate stack. An example is illustrated in the following figure where a module must be selected to Add NetX Network Driver. The figures following the below diagram show the selection of the NetX Port Ether Framework to complete the stack for NetX and NetX Duo.

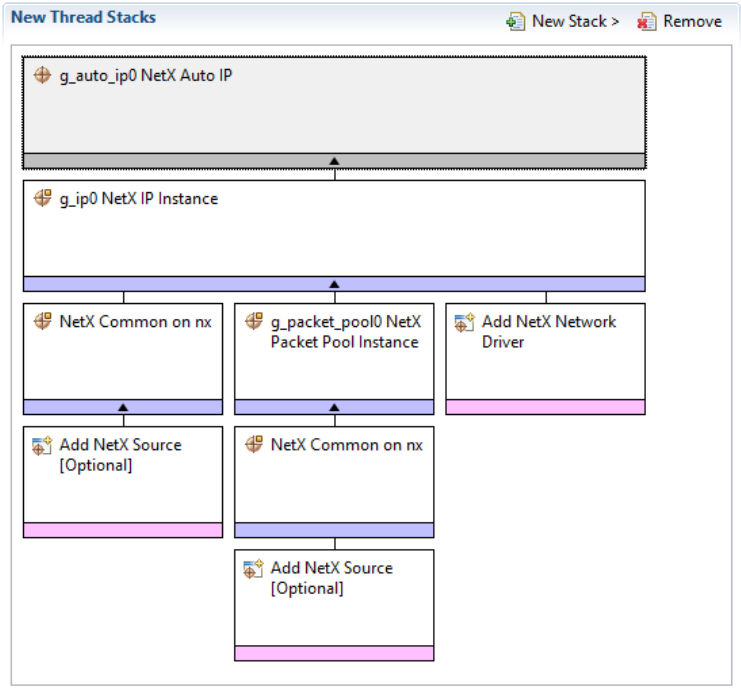

Figure 448: NetX Port Ether is an Option for Add NetX Network Driver

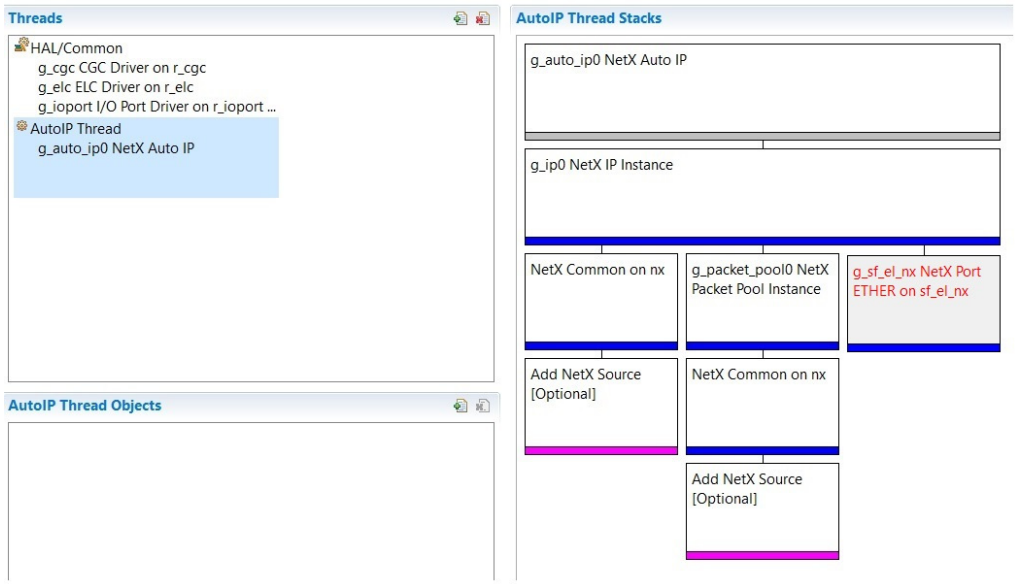

Figure 449: NetX Port Ether Application using NetX Auto IP

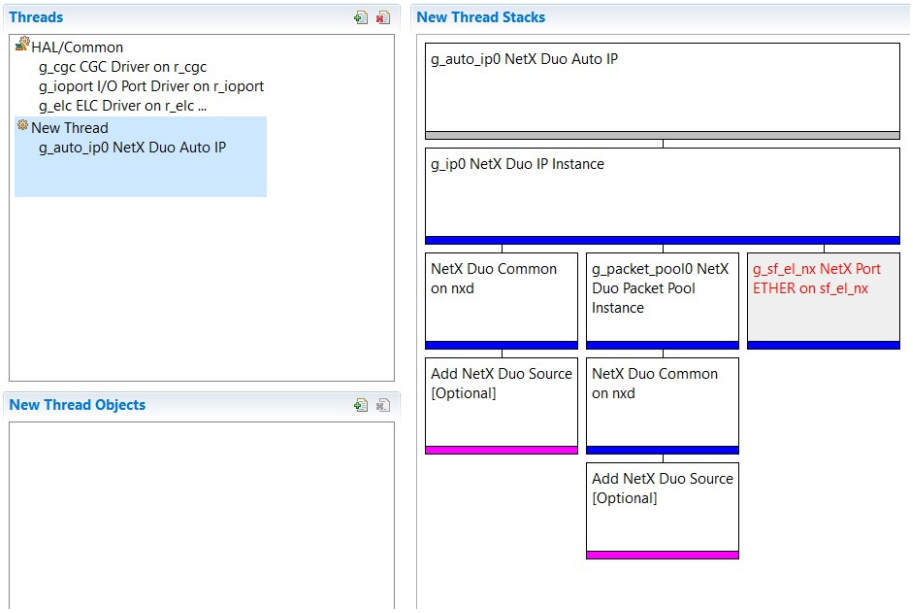

Figure 450: NetX Port Ether Application using NetX Duo Auto IP.

4.3.7.5 Configuring the NetX Port Ether Framework Module

The NetX Port Ether Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) those components which must be configured for

lower level modules for successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the property window in the ISDE. This approach simplifies the configuration process and makes it much less error prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user accessible properties are given in the properties tab within the SSP Configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the properties window of the associated module. Simply select the indicated module and then view the properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+.) This level of detail is not included in the configuration properties tables below, but is easily visible with the ISDE when configuring interrupt priority levels.

NOTE: You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the Configuration Table Settings given below. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Default Configuration Settings for NetX Port Ether Module on sf_el_nx

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled ~~~~Default: BSP	Enable or disable the parameter checking
Channel 0 Phy Reset Pin	IOPORT_PORT_09_PIN_03	Channel 0 Phy reset pin selection
Channel 0 MAC Address High Bits	0x00002E09	Channel 0 MAC address high bits selection
Channel 0 MAC Address Low Bits	0x0A0076C7	Channel 0 MAC address low bits selection
Channel 1 Phy Reset Pin	IOPORT_PORT_07_PIN_06	Channel 1 Phy reset pin selection
Channel 1 MAC Address High Bits	0x00002E09	Channel 1 MAC address high bits selection
Channel 1 MAC Address Low Bits	0x0A0076C8	Channel 1 MAC address low bits selection
Number of Receive Buffer Descriptors	8	Number of receive buffer descriptors selection
Number of Transmit Buffer Descriptors	32	Number of transmit buffer descriptors selection
Ethernet Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 lowest - not valid if using ThreadX)~~~~Default: Priority 12	Ethernet interrupt priority selection

ISDE Property	Value	Description
Link status monitoring method	PHY Interrupt (Uses LINKSTA Pin), PHY Polling~~~~Default: PHY Polling	PHY interrupt requires LINKSTA Pin connection to PHY
Name	g_sf_el_nx	Module name
Channel	0	Channel selection
MAC address change callback	NULL	MAC address change callback selection
Unknown packet receive callback	NULL	Unknown packet receive callback selection

NOTE: The example values and defaults are for a project using the Synergy S7G2 Family. Other MCUs may have different default values and available configuration settings.

4.3.7.6 Using the NetX Port Ether Module in an Application

The NetX Port Ether Module should be used in combination with NetX. The steps performed by the SSP automatically in a NetX application support are:

1) Initialize the system with nx_system_initialize
2) Create a packet pool with nx_packet_pool_create. This creates the IP default packet pool, to be used by the IP instance and the ethernet driver.
3) Create an IP Instance with nx_ip_create
4) Enable ARP with nx_arp_enable
5) Enable Link status change notify call back with nx_ip_link_status_change_notify_set
6) Set gateway IP address for created IP instance nx_ip_gateway_address_set
7) Create an AutoIP instance with nx_auto_ip_create

The steps below are performed directly by the application to set up and run the Auto IP thread task.

1) Check if the network link is enabled with the nx_ip_interface_status_check API.
2) Verify the device does not have an IP address by calling the nx_ip_interface_address_get API.
3) Set the IP address notification callback by calling the nx_ip_address_change_notify API.
4) Start the Auto IP instance with the nx_auto_ip_start API.
5) Wait for the IP address change callback to set the flag that the IP instance has an IP address.
6) Stop the AutoIP task by calling the nx_auto_ip_stop API.

7) Verify the IP instance has a non-zero IP address by calling the nx_ip_interface_address_get API again.

The above common steps are illustrated in the operational flow diagram in the figure below:

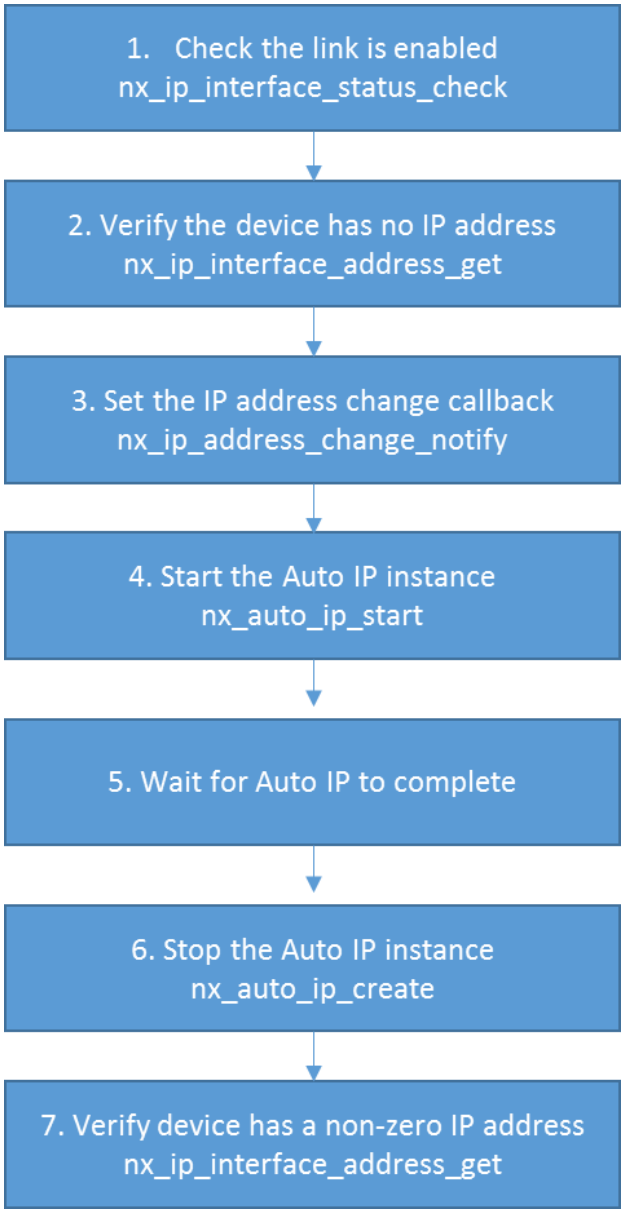

Figure 451: Flow Diagram of a Simple NetX Application using Auto IP

4.3.8 NetX and NetX Duo SNMP Agent

The NetX and NetX Duo SNMP Agent module provides high-level APIs for implementing the SNMP agent for the SSP architecture. It's part of the NetX and NetX Duo application bundle included in the SSP X-Ware integration. This module is MCU independent, so any MCU supports NetX and NetX Duo can implement the SNMP agent.

4.3.8.1 NetX and NetX Duo SNMP Agent Module Features

- The NetX and NetX Duo SNMP agent module is compliant with RFC1155, RFC1157, RFC1215, RFC1901, RFC1905, RFC1906, RFC1907, RFC1908, RFC2571, RFC2572, RFC2574, RFC2575, RFC 3414 and related RFCs.
- The SNMP agent module operates only in UDP. TCP is not supported.
- The SNMP agent module doesn't support Transport Layer Security (TLS) or Datagram Transport Layer Security (DTLS)
- The NetX and NetX Duo SNMP protocol implements SNMP Version 1, 2, and 3. The SNMPv3 implementation supports MD5 and Secure Hash Algorithm 1(SHA-1) authentication, and Data Encryption Standard (DES) encryption. This version of the NetX and NetX Duo SNMP Agent has the following constraints:
  - One SNMP Agent per NetX IP Instance.
  - No support for RMON.
  - SNMP v3 Inform messages are not supported
- Provides a mechanism to register callbacks for handling username, get, set and getnext when creating a SNMP agent.

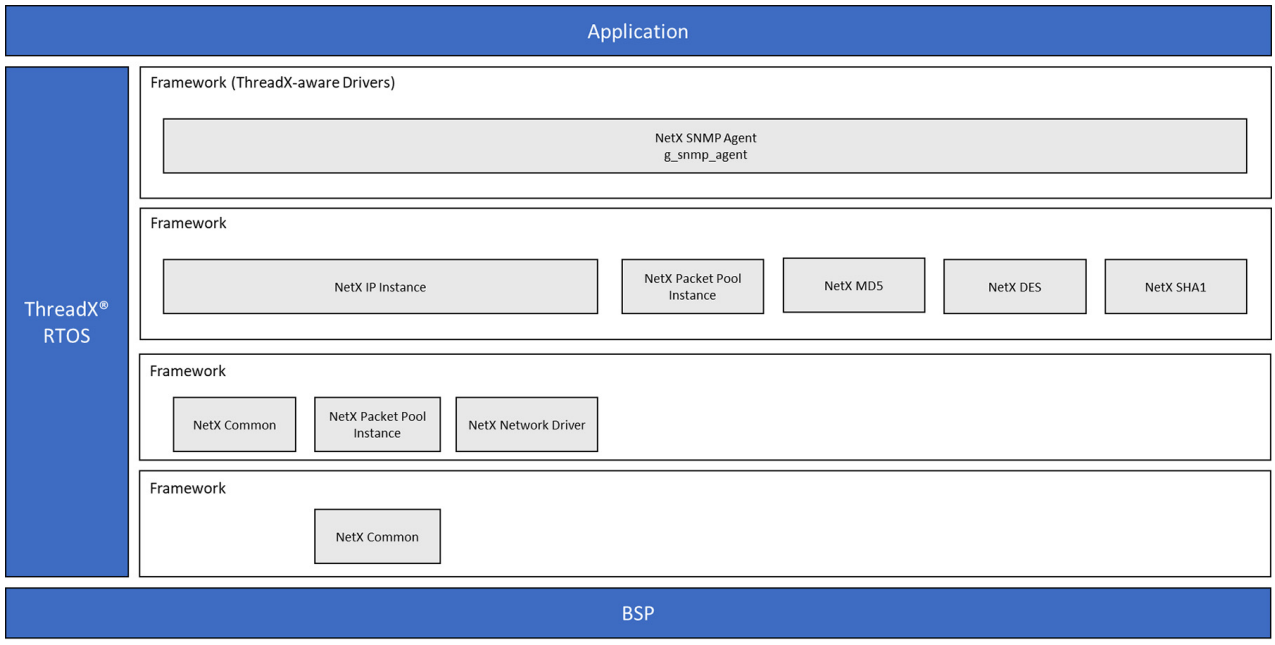

Figure 452: NetX and NetX Duo SNMP Agent Module Block Diagram

4.3.8.2 NetX and NetX Duo SNMP Agent Module APIs Overview

The NetX and NetX Duo SNMP Agent module defines APIs to create, delete and manage SNMP operations. For a list of APIs and a description of their functions and return values refer to the Express Logic SNMP user manual available for download on the Synergy Gallery in the X-Ware zip file.

4.3.8.3 NetX and NetX Duo SNMP Agent Module Operational Overview

The SNMP agent module make use of the underlying NetX/NetX Duo stack to perform the operations. Along with the IP stack, it makes use of NetX MD5, NetX SHA1 and NetX DES modules for authentication and encryption in SNMP v3 operation.

The SNMP agent module can be created with the nx_snmp_agent_create API. For the implementation of the SNMP agent the user need to define the handler functions for username, get, getnext and set operations.

NetX and NetX Duo SNMP Agent Module Important Operational Notes and Limitations

Disabling SNMP Version 1

The SNMP agent module can disable processing of version 1 requests by selecting "Disable" in the configuration properties for the SNMP agent for "SNMP Version 1". By default, this is enabled. When disabled the SNMP agent simply drops the packet with version 1, resulting in a timeout for the SNMP manager.

Disabling SNMP Version 2

The SNMP agent module can disable processing of version 2 requests by selecting "Disable" in the configuration properties for the SNMP agent for "SNMP Version 2". By default, this is enabled. When disabled the SNMP agent simply drops the packet with version 2, resulting in a timeout for the SNMP manager.

Disabling SNMP Version 3

The SNMP agent can disable processing of version 3 requests by selecting "Disable" in the configuration properties for the SNMP agent for "SNMP Version 3". By default, this is enabled. When disabled the SNMP agent simply drops the packet with version 3 resulting in a timeout for the SNMP manager. Enabling SNMP version 3 requires MD5, SHA1 authentication and DES encryption.

- One SNMP Agent per NetX IP Instance.
- No support for RMON
- SNMP v3 Informs are not supported
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.3.8.4 Including the NetX and NetX Duo SNMP Agent Module in an Application

This section describes how to include the NetX and NetX Duo SNMP Agent Module in an application using the SSP configurator.

NOTE: This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX and NetX Duo SNMP Agent Module to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the NetX and NetX Duo SNMP Agent Module is g_sf_snmp_agent0. This name can be changed in the associated Properties window.)

NetX and NetX Duo SNMP Agent Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_snmp_agent0 NetX SNMP Agent	Threads	New Stack> X-Ware> NetX/NetX Duo> Protocols> NetX/NetX Duo SNMP Agent

When the NetX and NetX Duo SNMP Agent module on sf_snmp_agent is added to the thread stack as shown in the following figure, the configurator automatically adds any lower-level drivers that are required. Any drivers that need additional configuration information will be box-text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

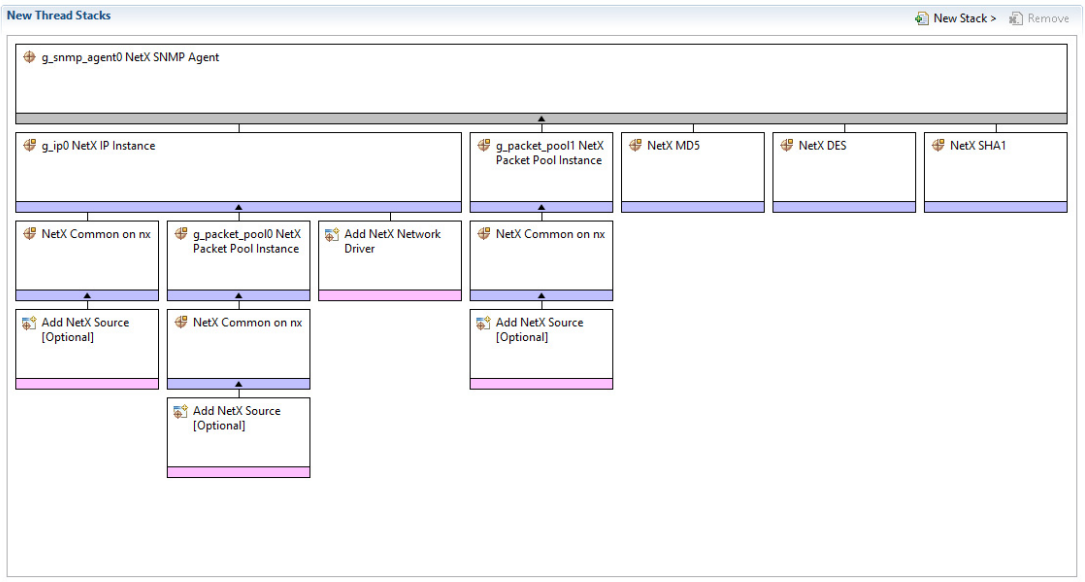

Figure 453: NetX SNMP Agent Module Stack (NetX Duo is similar)

4.3.8.5 Configuring the NetX and NetX Duo SNMP Agent Module

The NetX and NetX Duo SNMP Agent Module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available within the Properties window of the associated module. Simply select the indicated module and then view the Properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available. Also, note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the targeted MCU (CM4 or CM0+). This level of detail is not included

in the following configuration properties tables, but is easily visible within the ISDE when configuring interrupt-priority levels.

NOTE: You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the NetX and NetX Duo SNMP Agent Module on sf_snmp_agent

ISDE Property	Value	Description
Internal thread stack size (bytes)	4096	Internal thread stack size selection
SNMP agent priority	16	SNMP agent priority selection
Type of service for SNMP responses	Normal, Minimum Delay, Maximum Delay, Maximum Reliability, Minimum Cost Default: Normal	Type of service for SNMP responses selection
Fragment enable for SNMP PDU requests	Fragment, Don't Fragment Default: Don't Fragment	Fragment enable for SNMP PDU requests selection
SNMP socket time to live	128	SNMP socket time to live selection
Agent timeout	100	Agent timeout selection
Max octet string size	255	Max octet string size selection
Max content string size	32	Max content string size selection
Max User name Size	64	Max User name Size selection
Max security Key Size	64	Max security Key Size selection
Minimum SNMP packet size	560	Minimum SNMP packet size selection (Value must be between 560 to 1500)
UDP port number	161	UDP port number selection (Value must be between 1 to 65535)
Trap destination port	162	Trap destination port selection
Max trap Name Size	64	Max trap Name Size selection

ISDE Property	Value	Description
Max trap Key Size	64	Max trap Key Size selection
Inveral between SNMP packet processing timer ticks	100	Inveral between SNMP packet processing timer ticks selection
SNMP Version 1	Enable, Disable Default: Enable	SNMP Version 1 selection
SNMP Version 2	Enable, Disable Default: Enable	SNMP Version 2 selection
SNMP Version 3	Enable, Disable Default: Enable	SNMP Version 3 selection
Name	g_snmp_agent0	Name selection
Read Community String	public	Read Community String selection (Must be less than 64 chars)
Write Community String	private	Write Community String selection (Must be less than 64 chars)
Name of SNMP Username Handler	sf_snmp0_username_handler	Name of SNMP Username Handler selection
Name of SNMP GET Handler	sf_snmp0_get_handler	Name of SNMP GET Handler selection
Name of SNMP GETNEXT Handler	sf_snmp0_getnext_handler	Name of SNMP GETNEXT Handler selection
Name of SNMP SET Handler	sf_snmp0_set_handler	Name of SNMP SET Handler selection
Name of generated initialization function	snmp_agent_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto Initialization selection

ISDE Property	Value	Description
SNMP agent instance id	0	SNMP agent instance id selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	192,168,0,2	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable, Disable Default: Enable	TCP selection
UDP	Enable	UDP selection

ISDE Property	Value	Description
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection
Link status change callback	NULL	Link status change callback selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX MD5

ISDE Property	Value	Description
No configurable settings		

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX DES

ISDE Property	Value	Description
No configurable settings		

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX SHA1

ISDE Property	Value	Description
No configurable settings		

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Common

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	640	Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Port ETHER

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Enable or disable the parameter checking
Channel 0 Phy Reset Pin	IOPORT_PORT_09_PIN_03	Channel 0 Phy reset pin selection
Channel 0 MAC Address High Bits	0x00002E09	Channel 0 MAC address high bits selection
Channel 0 MAC Address Low Bits	0x0A0076C7	Channel 0 MAC address low bits selection
Channel 1 Phy Reset Pin	IOPORT_PORT_07_PIN_06	Channel 1 Phy reset pin selection
Channel 1 MAC Address High Bits	0x00002E09	Channel 1 MAC address high bits selection
Channel 1 MAC Address Low Bits	0x0A0076C8	Channel 1 MAC address low bits selection
Number of Receive Buffer Descriptors	8	Number of receive buffer descriptors selection
Number of Transmit Buffer Descriptors	32	Number of transmit buffer descriptors selection
Ethernet Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest-not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Ethernet interrupt priority selection
Name	g_sf_el_nx	Module name
Channel	0	Channel selection
Callback	NULL	Callback selection

NOTE: The example values and defaults are for a project using the Synergy S7G2. Other MCUs may have different default values and available configuration settings.

NetX and NetX Duo SNMP Agent Module Clock Configuration

The NetX and NetX Duo SNMP Agent module ETHERC peripheral uses the PCLKA as its clock source.

To change the clock frequency at run-time, use the CGC Interface.

NetX and NetX Duo SNMP Agent Module Pin Configuration

To use the NetX and NetX Duo SNMP Agent Module, the port pins for the peripheral inputs and outputs must be set in the pin configurator in the ISDE. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection Sequence for the NetX and NetX Duo SNMP Agent Module

Resource	ISDE Tab	Pin selection Sequence
ETHERC	Pins	Select Peripherals > Peripherals>Connectivity:ETHERC> ETHERC0/1

4.3.8.6 Using the NetX and NetX Duo SNMP Agent Module in an Application

Once the module has been configured and the files generated, the SNMP module is ready to be used in an application. The typical steps to using the SNMP module in an application are:

1) Create an agent with nx_snmp_agent_create API
2) Define handler functions
    a) username handler function nx_snmp_agent_username_process in user code
    b) get handler function nx_snmp_agent_get_process in user code
    c) getnext handler function nx_snmp_agent_getnext_process in user code
    d) set handler function nx_snmp_agent_set_process in user code
3) Create a structure to map OIDs to action handlers in user code
4) Configure read, write community strings nx_snmp_agent_public_string_set and nx_snmp_agent_private_string_set
5) If the user wants to use SNMPv3, they must create the keys using the nx_snmp_agent_md5_key_create API or the nx_snmp_agent_sha_key_create and associate the keys with authentication, encryption and trap services nx_snmp_agent_authenticate_key_use, nx_snmp_agent_privacy_key_use, nx_snmp_agent_auth_trap_key_use and nx_snmp_agent_priv_trap_key_use
6) Start the SNMP agent using the nx_snmp_agent_start API

These common steps are illustrated in a typical operational flow in the following figure:

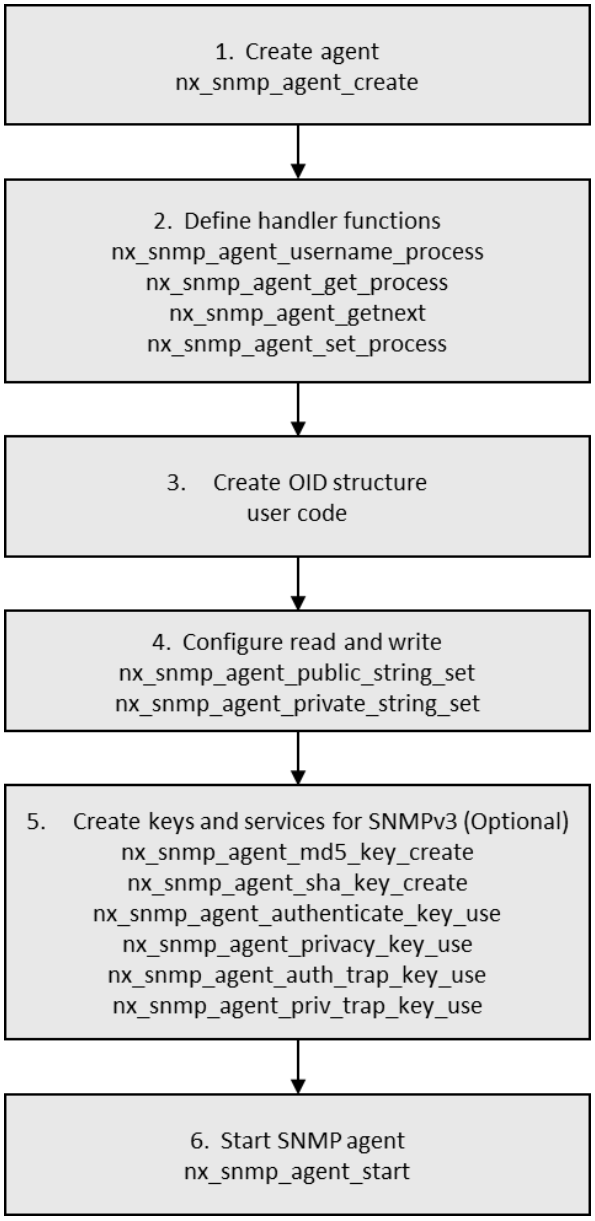

Figure 454: Flow Diagram of a Typical NetX and NetX Duo SNMP Agent Module Application

4.3.9 ThreadX

The Express Logic ThreadX kernel (tx) is integrated into the SSP. For more information about ThreadX, including API reference, refer to the *ThreadX User Guide*.

4.3.9.1 What Does the Express Logic ThreadX Module Do?

The Express Logic ThreadX kernel is the foundation of multi-threaded SSP applications. It provides thread creation and synchronization services, including message queues, counting semaphores, mutexes, event flags, memory block pools, memory byte pools, and application timers.

4.3.9.2 Using e^2 studio to write an Application with Express Logic ThreadX

The Express Logic ThreadX module is integrated into the Synergy Software Package in e^2 studio:e^2 studio ISDE User Guide

In e^2 studio, create and configure a project and add the drivers:

1) Create the project: Creating a Project.
2) Configure the project: Configuring a Project.
3) Add Threads and ThreadX will be added automatically.

During the configuration of the project, ThreadX is added automatically when a new Thread is created. To create a new thread, click **New Thread** in the Threads section of the **Threads** tab of the Synergy Configuration tool (configuration.xml). To add ThreadX source code, add the ThreadX source module as described in the table below.

Resource	ISDE Tab	Selection
Express Logic ThreadX Source Code (optional, for advanced configurations or source level debugging support)	Threads (HAL/Common)	**Framework > RTOS > ThreadX Source**

Adding Objects to Threads

ThreadX objects, including mutexes, semaphores, event flags, and queues, can be added to Threads in the <Thread Name> Objects section, where <Thread Name> represents the name of an application thread. For example, to add a new queue to a thread, highlight the thread and select **New Object > Queue**.

To access the queue from a different thread, include the header file of the thread where the queue is defined. For example, if an application has a thread named main_thread with a queue named message_queue, a file named main_thread.h will be generated with an extern for message_queue. If the application also has a thread named background_thread, and the background_thread requires access to the message_queue, main_thread.h should be included in background_thread_entry.c to ensure background_thread_entry.c has access to the definition of message_queue.

4.3.9.3 Express Logic ThreadX Configuration Notes

IAR Library Support (IAR Only)

Thread-safe support for the IAR tools is easily enabled by making the following setting in the **Properties** of the ThreadX Source Module. In the table, ISDE Property refers to the **Properties** tab name in the e^2 studio ISDE.

ThreadX Source IAR Library Support configuration

ISDE Property	Setting	Description
IAR Library Support	Enabled, Disabled, Default: Disabled	If enabled, defines TX_ENABLE_IAR_LIBRARY_SUPPORT to provide thread safe access to IAR standard library functions such as malloc() and printf().

Also, add the following line to the linker control file (if not already in place):

```
initialize by copy with packing = none { section __DLIB_PERTHREAD };
// Required in a multi-threaded application.
```

@ note Make sure the ThreadX Source module is added to the **Threads** tab (HAL/Common) before modifying TX_ENABLE_IAR_LIBRARY_SUPPORT.

ThreadX Source Advanced Configurations

If the ThreadX Source module is added to the project, the Properties window provides advanced configurations for the ThreadX source library. Highlight a configuration option to view a description of the option in the bottom left corner of the e^2 studio GUI. If the configuration option entry field is empty, the default value will be used. The default values of configuration options are defined in ssp/inc/framework/el/cm<core>_<compiler>/tx_port.h, where <core> is the ARM cortex number of the MCU used ('4' or '0plus') and <compiler> is the compiler used ('gcc' or 'iar'). Refer to the Configuration Options chapter of the *ThreadX User Guide* for more information.

At the end of the advanced properties, there are TX_<COMPONENT>_EXTENSION macros, where <COMPONENT> identifies the type of extension. These extension macros are for advanced use cases only. In most projects, they are not modified. Some cases, such as BSD support for NetX, require use of extension macros and explicitly describe how they should be used.

4.3.9.4 Express Logic ThreadX Limitations

- See SSP Release Notes for known limitations.

4.3.9.5 Express Logic ThreadX Supported Devices

The module is supported on the following families:

- S7G2
- S3A7
- S124

4.3.10 USBX

The Express Logic USBX USB stack (ux) is integrated into the SSP. For more information about the USBX, including API reference, refer to the *USBX User Guide*.

4.3.10.1 What Does the Express Logic USBX Module Do?

USBX supports the two existing USB specifications: 1.1 and 2.0. It is designed to be scalable and will accommodate simple USB topologies with only one connected device as well as complex topologies with multiple devices and cascading hubs. USBX supports both the host side and the device side.

4.3.10.2 Supported USB Classes in Express Logic USBX

The USBX class modules listed below are fully supported in the Synergy Configuration tool. To use these USBX class modules, go to the **Threads** tab of the Synergy Configuration tool (configuration.xml), and select any of the USB class modules:

- ux_device_class_cdc_acm
- ux_device_class_hid
- ux_device_class_storage
- ux_host_class_cdc_acm
- ux_host_class_hid
- ux_host_class_storage
- ux_host_class_video
- ux_host_class_hub

Refer to the *USBX Device Class User Guide* or *USBX Host Class User Guide* for more information about the USBX Class specification.

The USBX class modules listed below are experimental modules for Synergy parts. The experimental modules are not currently supported in Synergy Configuration. To experiment with these USBX class modules, go to the Components tab of the Synergy Configuration tool (configuration.xml), and select any of the USB class modules:

- ux_device_class_cdc_ecm
- ux_device_class_rndis
- ux_host_class_audio
- ux_host_class_gser
- ux_host_class_printer
- ux_host_class_prolific
- ux_host_class_swar
- ux_network_driver

NOTE: Any USB classes shown above are experimental and not yet tested for Synergy parts. Because of that, it is not recommended to use them for product developments.

When the components above are added, a prebuilt library of the application code is added. For each component listed above, there is an analogous component ending in '_src' that contains protected source files. The '_src' component can be added in addition to the prebuilt library module.

4.3.10.3 Using e^2 studio to write an Application with Express Logic USBX

The Express Logic USBX module is integrated into the Synergy Software Package in e^2 studio: e^2 studio ISDE User Guide.

Write an Application with USBX Device Class Stack

To add USBX Device Class modules, go to the **Threads** tab of the Synergy Configuration tool (configuration.xml), and select any of the class modules:

In e^2 studio, create and configure a project and add the drivers:

Step 1. Create the project: Creating a Project.

Step 2. Configure the project: Configuring a Project.

Step 3. Add following either or multiple of USBX Device Class components in Synergy Configuration tool: Adding Drivers to a Thread and Configuring the Drivers.

Resource	ISDE Tab	Selection
USBX Device Class CDC-ACM (mandatory for CDC-ACM)	Threads	**X-Ware > USBX > Device > Classes > CDC-ACM >USBX Device Class CDC ACM**
USBX Device Class HID (mandatory for HID class)	Threads	**X-Ware > USBX > Device > Classes > HID >USBX Device Class HID**
USBX Device Class Mass Storage (mandatory for Mass Storage class)	Threads	**X-Ware > USBX > Device > Classes > Mass Storage >USBX Device Class Mass Storage**

To fill in the USBX class stack in the Synergy Configurator, the following components will be used:

- USBX Device Configuration component (mandatory)
- USBX Interface Configuration component (mandatory)
- USBX on ux (mandatory)

Step 4. Add a USB Port DCD (Device Controller Driver) component to the stack. You may have two choices if the Synergy part has two USB peripherals. Click the component box written as "Add USBX Port DCD". Select **New** and choose one of the USBX Port DCD components (mandatory) below:

- USBX Port DCD on sf_el_ux for USBHS (if available for the parts)
- USBX Port DCD on sf_el_ux for USBFS

Step 5. It is optional but recommended to add Transfer Modules for both of Tx and Rx channels. You may have two choices if the Synergy part has DMAC and DTC. Click the component box "Add Transfer Module for Tx (or Rx)". Select **New** and choose either of Transfer Driver components (optional) below:

- Transfer Driver on r_dmac (if available for the parts)

- Transfer Driver on r_dtc (if available for the parts)(Either of components above is option to use)

Step 6. Users have the option of adding USBX Source if they wish to build from source instead of using the provided USBX library.

Step 7. Configure each component to complete the USB stack configuration. See sections "Express Logic USBX Configuration Notes" and "Express Logic USBX Synergy Port Driver Configuration" in the SF_EL_UX_usage_notes for more inofrmation.

Write an Application with USBX Host Class Stack

The Express Logic USBX module is integrated into the Synergy Software Package in e^2 studio: e^2 studio ISDE User Guide.

In e^2 studio, create and configure a project and add the drivers:

Step 1. Create the project: Creating a Project.

Step 2. Configure the project: Configuring a Project.

Step 3. Add following either or multiple of USBX Host Class components in Synergy Configuration tool: Adding Drivers to a Thread and Configuring the Drivers.

Resource	ISDE Tab	Selection
USBX Host Class CDC-ACM	Threads	**X-Ware > USBX > Host > Classes > CDC-ACM >USBX Host Class CDC ACM**
USBX Host Class HID	Threads	**X-Ware > USBX > Host > Classes > HID >USBX Host Class HID**
USBX Host Class Mass Storage	Threads	**X-Ware > FileX > FileX on USB Mass Storage**
USBX Host Class Video	Threads	**X-Ware > USBX > Host > Classes > Video > USBX Host Class Video**
USBX Host Class HUB	Threads	**X-Ware > USBX > Host > Classes > HUB >USBX Host Class HUB**

To fill in the USBX class stack in the Synergy Configurator, the following components will be used:

- USBX Host Configuration component (mandatory)
- USBX on ux (mandatory)

NOTE: The stack for USBX Host Class Mass Storage is different from the other Class stacks and needs FileX on USB Mass Storage Class on top of it. Select **X-Ware > FileX > FileX on USB Mass Storage** component, not **X-Ware > USBX > Host > Classes > Mass Storage > USBX Host Class Mass Storage**.

Step 4. Add a USB Port HCD (Host Controller Driver) component to the stack. You may have two choices if the Synergy part has two USB peripherals. Click the component box "Add USBX Port HCD". Select **New** and choose one of the USBX Port HCD components (mandatory) listed below:

- USBX Port HCD on sf_el_ux for USBHS (if available for the parts)

- USBX Port HCD on sf_el_ux for USBFS

Step 5. It is optional but recommended to add a Transfer Module for both of Tx and RX channels. You may have two choices if the Synergy part has DMAC and DTC. Click the component box "Add Transfer Module for TX (or RX)". Select **New** and choose one of the Transfer Driver components (optional) listed below:

- Transfer Driver on r_dmac (if available for the parts)
- Transfer Driver on r_dtc (if available for the parts)(Either of components above is option to use)

Step 6. You have the option of adding USBX Source if you wish to build from source instead of using the provided USBX library.

Step 7. Configure each component to complete the USB stack configuration. See sections "Express Logic USBX Configuration Notes" and "Express Logic USBX Synergy Port Driver Configuration" for more information.

Write an Application with Deprecated Modules

In the SSP version 1.2.0 or later, the USBX stack configuration is supported in the Synergy Configuration tool and the few USBX relevant components, which were defined in previous SSP versions are now treated as [DEPRECATED] components. They are kept in the SSP version today to provide you with backward compatibility. Anyone using a new version of SSP and want to keep their existing application code compatible to an existing SSP version, can use [DEPRECATED] components.

In e^2 studio, create and configure a project and add the drivers:

Step 1. Create the project: Creating a Project.

Step 2. Configure the project: Configuring a Project.

Step 3. Add the following components, if required, the same way as was done when using an existing version of SSP: Adding Drivers to a Thread and Configuring the Drivers.

Express Logic USBX Device Class CDC-ACM(option)	**Threads**	**Framework > USB > [DEPRECATED] USBX Device Class CDC-ACM on ux_device_class_cdc_acm**
Express Logic USBX (option)	Threads	**Framework > USB > [DEPRECATED] USBX on ux**

NOTE: Do not use components marked as [DEPRECATED] for new development. Only use these components for existing user applications which were developed with previous SSP releases.

4.3.10.4 Express Logic USBX Configuration Notes

USB Class Stack Configuration Overview

The figure below shows the interface diagram of the USBX device class Stack. The stack consists of one USBX device class components (ux_device_class_xxx) on the top, the USBX (ux) in the middle, and the USBX Port driver (sf_el_ux Device Controller Driver (DCD)) on the bottom of the device class stack. As a recommended option, the SSP Transfer module (r_dmac) supports data transfer between memory and hardware FIFO in Synergy USB peripherals (USBHS or USBFS). To support the USB device stack configuration, there are some components named USBX Device Configuration

and USBX Interface Configuration. These two components do not represent actual software modules in SSP but virtual modules to handle the code generation.

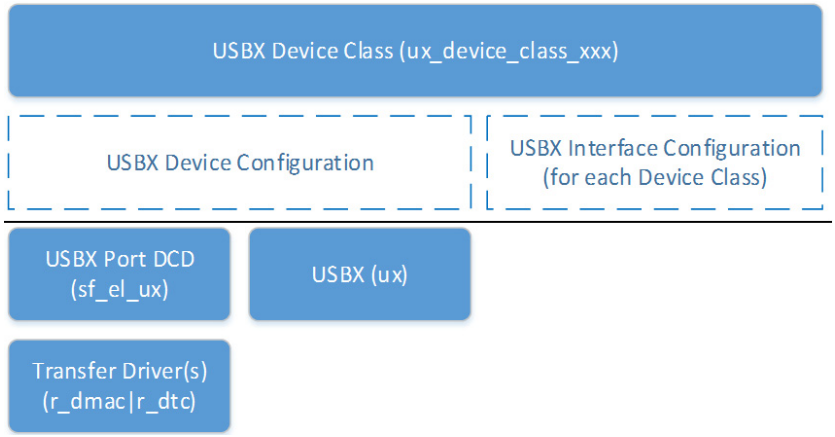

Figure 455: USBX Device Class Stack Configuration

NOTE: Currently r_dtc is not supported for device side driver (only r_dmac is supported)

This figure below shows the interface diagram of the USBX host class Stack. The stack consists of one of the USBX host class components (ux_host_class_xxx) on the top, the USBX (ux) in the middle, and the USBX Port driver component (sf_el_ux Host Controller Driver (HCD)) on the bottom of the host class stack. As a recommended option, the SSP Transfer module (r_dmac or r_dtc) supports data transfer between memory and hardware FIFO in Synergy USB peripherals (USBHS or USBFS). To support the USB host stack configuration, there is a component named USBX host configuration, which is a virtual component to handle the code generation:

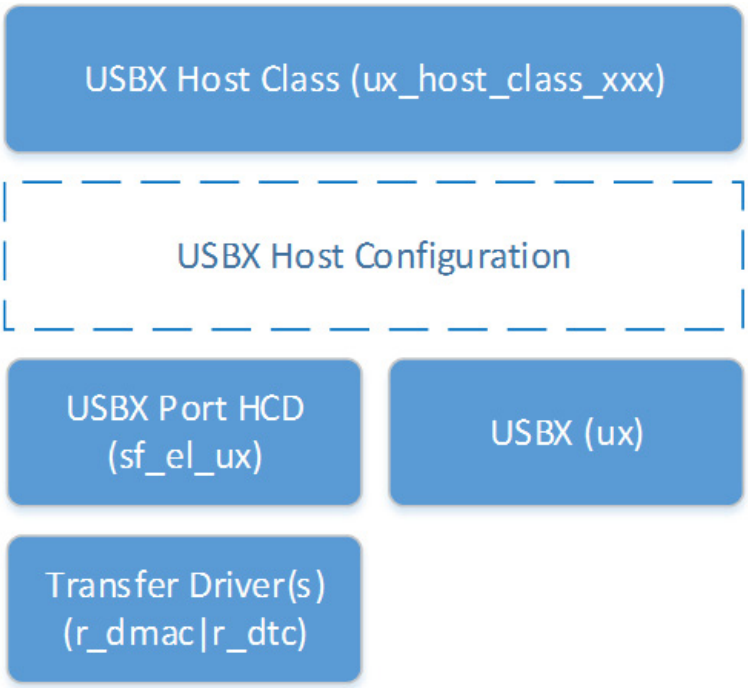

Figure 456: USBX Host Class Stack Configuration

USB Common Configuration

Write an Application with USBX Host Stack

The Express Logic USBX module is integrated into the Synergy Software Package in e^2 studio: e^2 studio ISDE User Guide.

In e^2 studio, create and configure a project and add the drivers:

Step 1. Create the project: Creating a Project.

Step 2. Configure the project: Configuring a Project.

Step 3. Add following either or multiple of USBX Host Class components in Synergy Configuration tool: Adding Drivers to a Thread and Configuring the Drivers.

Resource	ISDE Tab	Selection
USBX Host Configuration	Threads	**X-Ware > USBX > Host > Common>USBX Host Configuration**

To fill in the USBX stack in the Synergy Configurator, the following components will be used:

- USBX on ux (mandatory)
- Add a USB Port HCD (Host Controller Driver) component to the stack. You may have two choices if the Synergy part has two USB peripherals. Click the component box "Add USBX Port HCD". Select **New** and choose one of

the USBX Port HCD components (mandatory) listed below: USBX Port HCD on sf_el_ux for USBHS (if available for the parts)

- USBX Port HCD on sf_el_ux for USBFS

Step 4. It is optional but recommended to add a Transfer Module for both of Tx and RX channels. You may have two choices if the Synergy part has DMAC and DTC. Click the component box "Add Transfer Module for TX (or RX)". You may select **New** and choose other Transfer Driver component (optional) listed below:

- Transfer Driver on r_dmac (if available for the parts)
- Transfer Driver on r_dtc (if available for the parts)(Either of components above is option to use)

Step 5. You have the option of adding USBX Source if you wish to build from source instead of using the provided USBX library.

Step 6. Configure each component to complete the USB stack configuration. See sections "Express Logic USBX Synergy Port Driver Configuration" for more information.

The USBX on ux component has configurations for USBX core library module as shown in the table below.

USBX on ux

Configuration	Settings	Description
USBX Pool Memory Name	Arbitrary symbol name (Default: "g_ux_pool_memory0")	Name must be a valid C symbol.
USBX Pool Memory Size	Any integer value (Default: 18432)	See section "Express Logic USBX Memory Requirements" for the required memory size for each classes.
User Callback for Host Event Notification (Only valid for USB Host)	Arbitrary symbol name (Default: "NULL")	Name must be a valid C symbol. The name of User defined USBX Host event notification can be given to this property.

USB Device Classes Configuration

The USBX Device Class CDC-ACM component has configurations to setup USB Device Class CDC-ACM shown in the table below. It can be configured through the Synergy Configuration tool.

USBX Device Class CDC-ACM configuration

Configuration	Settings	Description
Name	Arbitrary symbol name (Default: "g_ux_device_class_cdc_acm0")	Specify the name of USBX Device CDC-ACM Class module instance. It must be a valid C symbol.

Configuration	Settings	Description
USBX CDC-ACM instance_activate Function Callback	Arbitrary symbol name (Default: "ux_cdc_device_instance_activate")	Specify the name of instance_activate user callback function for the USBX Device CDC-ACM Class module. Name must be a valid C symbol. See the USBX Stack User's Manual *Chapter 5: USBX Device Class Considerations USB Device CDC-ACM Class* for more information about the instance_activate callback function.
USBX CDC-ACM instance_deactivate Function Callback	Arbitrary symbol name (Default: "ux_cdc_device_instance_deactivate ")	Specify the name of instance_deactivate user callback function for the USBX Device CDC-ACM Class module. Name must be a valid C symbol. Refer to the USBX Stack User's Manual *Chapter 5: USBX Device Class Considerations USB Device CDC-ACM Class* for more information about the instance_activate callback function

The USBX Device Class Mass Storage component has configurations to setup USB Device Mass Storage Class shown in the table below. Parameters are available to configure through the Synergy Configuration tool.

USBX Device Class Mass Storage Configuration

Configuration	Settings	Description
Name	Arbitrary symbol name (Default: "g_ux_device_class_storage")	Specify the name of USBX Interface Descriptor for Mass Storage Class. It must be a valid C symbol.
Mass Storage Class Parameter Setup	Auto (Default), Manual	Manual (User Manual Setup if LUN is greater than 1). Simple Auto Setup if LUN is 1.
User Setup Callback (Only valid if Parameter Setup is Auto)	Arbitrary C symbol name (Default: ux_device_class_storage_user_setup)	Specify the name of user callback function to setup the storage parameter setup. This parameter is only valid when the configuration "Mass Storage Class Parameter Setup" is "Auto".

Configuration	Settings	Description
