The ISL85403 is a 40V, 2.5A synchronous buck or boost buck controller with an integrated high-side MOSFET and low-side driver. In Buck mode, the ISL85403 supports a wide input range of 3V to 40V. In Boost-Buck mode, the input range can be extended down to 2.5V and output regulation can be maintained when VIN drops below VOUT, enabling sensitive electronics to remain on in low input voltage conditions.

The ISL85403 has a flexible selection of Forced PWM mode and PFM mode. In PFM mode, the quiescent input current is as low as 180µA (AUXVCC connected to VOUT). The load boundary between PFM and PWM can be programmed to cover wide applications.

The low-side driver can either be used to drive an external low-side MOSFET for a synchronous buck or left unused for a standard non-synchronous buck. The low-side driver can also be used to drive a boost converter as a preregulator followed by a buck controlled by the same IC, which greatly expands the operating input voltage range down to 2.5V or lower (See Figure 5 on page 3).

ISL85403 offers robust current protection. It uses peak current mode control with cycle-by-cycle current limiting. It is implemented with frequency foldback under current limit condition; also, the hiccup overcurrent mode ensures reliable operations under harsh short conditions.

The ISL85403 has comprehensive protections against various faults including overvoltage and over-temperature protections.

**Related Literature**

For a full list of related documents, visit our website:

- ISL85403 device page

**Features**

- Buck mode: input voltage range 3V to 40V (See "Input Voltage" on page 15 for more details)
- Boost mode expands operating input voltage lower than 2.5V (See "Input Voltage" on page 15 for more details)
- Selectable Forced PWM mode or PFM mode
- 300µA IC quiescent current (PFM, no load); 180µA input quiescent current (PFM, no load, VOUT tied to AUXVCC)
- Less than 5µA (MAX) shutdown input current (IC disabled)
- Operational topologies
  - Synchronous buck
  - Non-synchronous buck
  - Two-stage boost buck
  - Non-inverting single inductor buck boost
- Programmable frequency from 200kHz to 2.2MHz and frequency synchronization capability
- ±1% tight voltage regulation accuracy
- Reliable overcurrent protection
  - Temperature compensated current sense
  - Cycle-by-cycle current limiting with frequency foldback
  - Hiccup mode for worst case short condition
- 20 Ld 4x4 QFN package
- Pb-free (RoHS compliant)

**Applications**

- General purpose
- 24V bus power
- Battery power
- Point-of-load
- Embedded processor and I/O supplies

NOTES:
1. See TB347 for details about reel specifications.
2. These Pb-free plastic packaged products employ special Pb-free material sets, molding compounds/die attach materials, and 100% matte tin plate plus anneal (e3 termination finish, which is RoHS compliant and compatible with both SnPb and Pb-free soldering operations). Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.
3. For Moisture Sensitivity Level (MSL), see the ISL85403 device page. For more information about MSL see TB363.

Pin Configuration

Functional Pin Descriptions

<table>
<thead>
<tr>
<th>PIN NAME</th>
<th>PIN #</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>EN</td>
<td>1</td>
<td>Enable the IC by leaving the EN pin floating or pulling it HIGH. Disable the IC by pulling this pin LOW. Range: 0V to 5.5V.</td>
</tr>
<tr>
<td>FS</td>
<td>2</td>
<td>Force the IC to have a 500kHz switching frequency by connecting the FS pin to VCC or GND, or by leaving the FS pin open. Program the oscillator switching frequency by adjusting the resistor from this pin to GND.</td>
</tr>
<tr>
<td>SS</td>
<td>3</td>
<td>Connect a capacitor from this pin to ground. The capacitor, along with an internal 5µA current source, sets the converter's soft-start interval. Also, this pin can be used to track a ramp on this pin.</td>
</tr>
<tr>
<td>FB</td>
<td>4</td>
<td>The inverting input of the voltage feedback error amplifier. With a properly selected resistor divider connected from VOUT to FB, the output voltage can be set to any voltage between the power rail (reduced by maximum duty cycle and voltage drop) and the 0.8V reference. Connect an R-C network across COMP and FB for loop compensation. The FB pin is also monitored for overvoltage events.</td>
</tr>
<tr>
<td>COMP</td>
<td>5</td>
<td>Output of the voltage feedback error amplifier.</td>
</tr>
<tr>
<td>PIN NAME</td>
<td>PIN #</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>----------</td>
<td>-------</td>
<td>-------------</td>
</tr>
<tr>
<td>ILIMIT</td>
<td>6</td>
<td>Programmable current limit pin. With this pin connected to the VCC pin, or to GND, or left open, the current limiting threshold is set to default of 3.6A; the current limiting threshold can be programmed with a resistor from this pin to GND.</td>
</tr>
<tr>
<td>MODE</td>
<td>7</td>
<td>Mode selection pin. Pull this pin to GND for Forced PWM mode; leave it floating or connected to VCC to enable PFM mode when the peak inductor current is below the default threshold of 700mA. The current boundary threshold between PFM and PWM can also be programmed with a resistor at this pin to ground. See &quot;PFM Mode Operation&quot; on page 14 for more details.</td>
</tr>
<tr>
<td>PGOOD</td>
<td>8</td>
<td>An open-drain output and pull-up pin with a resistor to VCC for proper function. PGOOD is pulled low when the output is out of regulation (OV or UV) or the EN pin is pulled low. PGOOD rising has a fixed 128 cycle delay.</td>
</tr>
<tr>
<td>PHASE</td>
<td>9, 10</td>
<td>The PHASE pins are the PHASE nodes that should be connected to the output inductor. These pins are connected to the source of the high-side N-channel MOSFET.</td>
</tr>
<tr>
<td>EXT_BOOT</td>
<td>11</td>
<td>Set Boost mode and monitors the battery voltage that is the input of the boost converter. After VCC POR, the controller detects the voltage on this pin; if the voltage on this pin is below 200mV, the controller is set in synchronous/non-synchronous Buck mode and latches in this state unless VCC is below POR falling threshold; if the voltage on this pin after VCC POR is above 200mV, the controller is set in Boost mode and latches in this state. In Boost mode, the low-side driver outputs PWM with the same duty cycle as the upper-side driver to drive the boost switch. In Boost mode, this pin is used to monitor input voltage through a resistor divider. By setting the resistor divider, the high threshold and hysteresis can be programmed. When voltage on this pin is above 0.8V, the PWM output (LGATE) for the boost converter is disabled. When voltage on this pin is below 0.8V minus the hysteresis, the boost PWM is enabled. In Boost mode operation, PFM is disabled when boost PWM is enabled. Check the &quot;2-Stage Boost Buck Converter Operation&quot; on page 16 for more details.</td>
</tr>
<tr>
<td>SYNC</td>
<td>12</td>
<td>This pin can be used to synchronize two or more ISL85403 controllers. Multiple ISL85403s can be synchronized with their SYNC pins connected together. 180° phase shift is automatically generated between the master and slave ICs. The internal oscillator can also lock to an external frequency source applied on this pin with a square pulse waveform (with frequency 10% higher than the IC's local frequency, and pulse width higher than 150ns). Range: 0V to 5.5V. Leave this pin floating if not used.</td>
</tr>
<tr>
<td>LGATE</td>
<td>13</td>
<td>In synchronous Buck mode, this pin is used to drive the lower side MOSFET to improve efficiency. Add a 5.1k or smaller value resistor to connect LGATE to ground to avoid falsely turning on LGATE caused by coupling noise. When a diode is used as the bottom side power device in non-synchronous Buck mode, connect this pin to VCC through a resistor (less than 5k) before IC start-up to disable the low-side driver (LGATE). In Boost mode, this pin can drive the boost power MOSFET. The boost control PWM is the same with the buck control PWM.</td>
</tr>
<tr>
<td>PGND</td>
<td>14</td>
<td>The ground connection of the power flow, including the driver. Connect this pin to a large ground plane.</td>
</tr>
<tr>
<td>BOOT</td>
<td>15</td>
<td>Provides bias voltage to the high-side MOSFET driver. A bootstrap circuit creates a voltage suitable to drive the internal N-channel MOSFET. The boot charge circuitries are integrated inside of the IC. No external boot diode is needed. A 1µF ceramic capacitor is recommended between BOOT and PHASE pin.</td>
</tr>
<tr>
<td>VIN</td>
<td>16, 17</td>
<td>Connected to the drain of the integrated high-side MOSFET as well as the source for the internal linear regulator that provides the bias of the IC. Connect the input rail to these VIN pins. Range: 3V to 40V. With the part switching, the operating input voltage applied to the VIN pins must be under 40V. This recommendation allows for short voltage ringing spikes (within a couple of ns time range) due to switching while not exceeding the &quot;Absolute Maximum Ratings&quot; on page 7.</td>
</tr>
<tr>
<td>SGND</td>
<td>18</td>
<td>Provides the return path for the control and monitor portions of the IC. Connect it to a quiet ground plane.</td>
</tr>
<tr>
<td>VCC</td>
<td>19</td>
<td>Output of the internal linear regulator that supplies the bias for the IC including the driver. A minimum 4.7µF decoupling ceramic capacitor is recommended between VCC to ground.</td>
</tr>
<tr>
<td>AUXVCC</td>
<td>20</td>
<td>Input of the auxiliary internal linear regulator, which can be supplied by the regulator output after power-up. With such configuration, the power dissipation inside of the IC is reduced. The input range for this LDO is 3V to 20V. In Boost mode operation, this pin works as a boost output overvoltage detection pin. It detects the boost output through a resistor divider. When voltage on this pin is above 0.8V, the boost PWM is disabled; when voltage on this pin is below 0.8V minus the hysteresis, the boost PWM is enabled. Range: 0V to 20V.</td>
</tr>
<tr>
<td>PAD</td>
<td></td>
<td>Bottom thermal pad. It is not connected to any electrical potential of the IC. In layout it must be connected to a PCB ground copper plane with an area as large as possible to effectively reduce the thermal impedance.</td>
</tr>
</tbody>
</table>
Absolute Maximum Ratings

VIN, PHASE ........................................... GND - 0.3V to +44V
VCC ...................................................... GND - 0.3V to +6.0V
AUXVCC .............................................. GND - 0.3V to +22V
Absolute Boot Voltage, V_BOOT - V_PHASE ......... +50.0V
Upper Driver Supply Voltage, V_BOOT - V_PHASE . . . . +6.0V
All Other Pins ........................................ GND - 0.3V to VCC + 0.3V

ESD Rating

Human Body Model (Tested per JESD22-A114F) ....... 2.5kV
Machine Model (Tested per JESD22-A115C) .......... 250V
Charged Device Model (Tested per JESD22-C101E) .... 1kV
Latch-Up Rating (Tested per JESD78B; Class II, Level A) . . . . . . . . . . . 100mA

CAUTION: Do not operate at or near the maximum ratings listed for extended periods of time. Exposure to such conditions can adversely impact product reliability and result in failures not covered by warranty.

NOTES:
4. $\theta_{JA}$ is measured in free air with the component mounted on a high-effective thermal conductivity test board with “direct attach” features. See TB379.
5. For $\theta_{JC}$, the “case temp” location is the center of the exposed metal pad on the package underside.

## Functional Description

### Initialization
 Initially the ISL85403 continually monitors the voltage at the EN pin. When the voltage on the EN pin exceeds its rising ON threshold, the internal LDO starts up to build up VCC. Soft-starts initiate after Power-on Reset (POR) circuits detect that VCC voltage has exceeded the POR threshold.

### Soft-Start

The soft-start (SS) ramp is built up in the external capacitor on the SS pin, which is charged by an internal 5μA current source.

The SS ramp starts from 0V to a voltage above 0.8V. When SS reaches 0.8V, the bandgap reference takes over and the IC begins steady state operation. The soft-start time refers to the duration that the SS pin ramps from 0V to 0.8V while the output voltage ramps up with the same rate from 0V to the target regulated voltage. The required capacitance at the SS pin can be calculated from \[ C_{SS}[\mu F] = 6.5 \times I_{SS}[mA] \] \[ \text{(EQ. 1)} \]

The SS plays a vital role in Hiccup mode. The IC applies cycle-by-cycle peak current limiting at over load conditions. When a harsh condition occurs and the current in the upper side MOSFET reaches the second overcurrent threshold, the SS pin is pulled to ground and a dummy soft-start cycle is initiated. During the dummy SS cycle, the current to charge soft-start capacitor is reduced to 1/5 of its normal value. Thus, a dummy SS cycle takes five times as long as the regular SS cycle. During the dummy SS period, the control loop is disabled and there is no PWM output. At the end of this cycle, it starts the normal SS. Hiccup mode persists until the second overcurrent threshold is no longer reached.

The ISL85403 is capable of starting up with prebiased output.

### PWM Control

Pull the MODE pin to GND directly or with a resistor no greater than 10kΩ to set the IC in Forced PWM mode. The ISL85403 employs the Peak Current mode PWM control for fast transient response and cycle-by-cycle current limiting. See Figure 6 on page 4.

The PWM operation is initialized by the clock from the oscillator. The upper MOSFET is turned on by the clock at the beginning of a PWM cycle and the current in the MOSFET starts to ramp up. When the sum of the current sense signal and the slope compensation signal reaches the error amplifier output voltage level, the PWM comparator is triggered to shut down the PWM logic to turn off the high-side MOSFET. The high-side MOSFET stays off until the next clock signal comes for the next cycle.

The output voltage is sensed by a resistor divider from VOUT to the FB pin. The difference between the FB voltage and the 0.8V reference is amplified and compensated to generate the error voltage signal at the COMP pin. Then the COMP pin signal is compared with the current ramp signal to shut down the PWM.

### PFM Mode Operation

Pull the MODE pin HIGH (>2.5V) or leave the MODE pin floating to set the IC to have PFM (Pulse Frequency Modulation) operation in light load. In PFM mode, the switching frequency is dramatically reduced to minimize the switching loss. The ISL85403 enters PFM mode when the MOSFET peak current is lower than the PWM/PFM boundary current threshold. The default threshold is 700mA when there is no programming resistor at the MODE pin.

The current threshold for the PWM/PFM boundary can be programmed by connecting a resistor between the MODE pin and ground. The MODE pin resistor value can be calculated using Equation 2.

\[ R_{MODE} = \frac{118500}{I_{PFM} + 0.2} \] \[ \text{(EQ. 2)} \]

where \( I_{PFM} \) is the required PWM/PFM boundary current threshold and \( R_{MODE} \) is the programming resistor. The usable resistor value range to program the PFM current threshold is 150kΩ to 200kΩ. Do not use \( R_{MODE} \) values outside this range.

For applications with output voltages higher than 5V and rated load currents below 1A, Renesas recommends non-synchronous operation by using a diode for the low-side device instead of a MOSFET. If the rated load current is higher than 1A, synchronous operation with a low-side MOSFET can be used but Forced PWM mode must be enabled by connecting the MODE pin to GND.

### Synchronous and Non-Synchronous Buck

The ISL85403 supports both Synchronous and Non-Synchronous buck operations.

In Synchronous buck configuration, add a 5.1k or smaller value resistor from the LGATE to ground to avoid false turn-on of the LGATE caused by coupling noise.

For a non-synchronous buck operation when a power diode is used as the low-side power device, the LGATE driver can be disabled with the LGATE connected to VCC (before IC start-up). For non-synchronous buck operation, the phase node shows oscillations after the high-side device turns off (as shown in Figure 21 on page 12 - blue trace). This is normal due to the oscillations among the parasitic capacitors at phase node and output inductor. An RC snubber (200Ω and 2.2nF as typical) at the phase node can reduce ringing.
AUXVCC Switchover

The ISL85403 has an auxiliary LDO integrated as shown in the Figure 6 on page 4. It is used to replace the internal MAIN LDO function after the IC start-up. Figure 4 on page 3 shows its basic application setup with output voltage connected to AUXVCC. After IC soft-start is done and the output voltage is built up to steady state, and when the AUXVCC pin voltage is over the AUX LDO Switchover Rising Threshold, the MAIN LDO is shut off and the AUXILIARY LDO is activated to bias VCC. Because the AUXVCC pin voltage is lower than the input voltage VIN, the internal LDO dropout voltage and the consequent power loss are reduced. This feature brings substantial efficiency improvements in light load range, especially at high input voltage applications.

When the voltage at AUXVCC falls below the AUX LDO Switchover Falling Threshold, the AUXILIARY LDO is shut off and the MAIN LDO is reactivated to bias VCC. At the OV/UV fault events, the IC also switches back from AUXILIARY LDO to MAIN LDO.

The AUXVCC switchover function is offered in buck configuration. It is not offered in boost configuration when the AUXVCC pin is used to monitor the boost output voltage for OVP.

Input Voltage

With the part switching, the operating ISL85403 input voltage must be under 40V. This recommendation allows for short voltage ringing spikes (within a couple of ns time range) due to the part switching while not exceeding the 44V, as stated in the “Absolute Maximum Ratings” on page 7.

The lowest IC operating input voltage (VIN pin) depends on the VCC voltage and the Rising and Falling VCC POR Threshold in Electrical Specifications table on page 8. At IC start-up when VCC is just over the rising POR threshold, there is no switching before soft-start. Therefore, the IC minimum start-up voltage on the VIN pin is 3.05V (MAX of Rising VCC POR). When the soft-start is initiated, the regulator is switching and the dropout voltage across the internal LDO increases due to driving current. Thus, the VIN pin shutdown voltage is related to driving current and VCC POR falling threshold. The internal upper side MOSFET has a typical 10mΩ gate drive. For a typical example of synchronous buck with 4nΩ lower MOSFET gate drive and 500kHz switching frequency, the driving current is 7mA total, causing a 70mV drop across internal LDO under 3V VIN. Then the IC shutdown voltage on the VIN pin is 2.87V (2.8V + 0.07V). In practical design, extra room should be taken into account with concern to voltage spikes at VIN.

In boost buck configuration, the input voltage range can be expanded further down to 2.5V or lower depending on the boost stage voltage drop upon maximum duty cycle. Because the boost output voltage is connected to the VIN pin as the buck inputs, after the IC starts up, the IC keeps operating and switching as long as the boost output voltage can keep the VCC voltage higher than the falling threshold. See “2-Stage Boost Buck Converter Operation” on page 16 for more details.

Output Voltage

The output voltage can be programmed down to 0.8V by a resistor divider from VOUT to FB. For a buck converter, the maximum achievable voltage is (VIN*DMAX - VDROP), where VDROP is the voltage drop in the power path including mainly the MOSFET rDS(ON) and inductor DCR. The maximum duty cycle DMAX is (1 - fSW * tMIN(OFF)).

For applications with output voltages higher than 5V and rated load currents below 1A, Renesas recommends use non-synchronous operation by using a diode for the low-side device instead of a MOSFET. If the rated load current is higher than 1A, synchronous operation with a low-side MOSFET can be used but Forced PWM mode must be enabled by connecting the MODE pin to GND.

Output Current

With the high-side MOSFET integrated, the maximum output current the ISL85403 can support is decided by the package and many operating conditions including input voltage, output voltage, duty cycle, switching frequency and temperature. The die temperature should not exceed +125°C with the power loss dissipated inside of the IC.

Note that more temperature rise is expected at higher ambient temperature due to more conduction loss caused by rDS(ON) increase.

The die temperature is equal to the sum of the ambient temperature and the temperature rise resulting from the power dissipated by the IC package with a certain junction to ambient thermal impedance θJA. The power dissipated in the IC is related to the MOSFET switching loss, conduction loss, and the internal LDO loss. Besides the load, these losses are also related to input voltage, output voltage, duty cycle, switching frequency, and temperature. With the exposed pad at the bottom, the heat of the IC mainly goes through the bottom pad and θJA is greatly reduced. The θJA is highly related to layout and air flow conditions. In layout, multiple vias (≥9) are strongly recommended in the IC bottom pad. The bottom pad with its vias should be placed in the ground copper plane with an area as large as possible across multiple layers. The θJA can be reduced further with air flow. See Figures 12 and 13 for the thermal performance with 100 CFM air flow.

For applications with high output current and bad operating conditions (such as compact board size or high ambient temperature), synchronous buck is highly recommended because the external low-side MOSFET generates less heat than the external low-side power diode. This helps to reduce PCB temperature rise around the ISL85403 and reduce junction temperature rise.
2-Stage Boost Buck Converter Operation

The Figure 5 on page 3, shows the boost function circuits. Schematic (a) shows a boost working as a pre-stage to provide input to the following Buck stage. This is for applications when the input voltage could drop to a very low voltage in some constants (for example, in some battery powered systems), causing the output voltage to drop out of regulation. The boost converter can be enabled to boost the input voltage up to keep the output voltage in regulation. When system input voltage recovers back to normal, the boost stage is disabled while only the buck stage is switching.

The EXT_BOOST pin is used to set Boost mode and monitor the boost input voltage. At IC start-up before soft-start, the controller is latched in Boost mode when the voltage is at or above 200mV; it latches in synchronous Buck mode if the voltage on the EXT_BOOST pin is below 200mV. In Boost mode, the low-side driver output PWM has the same PWM signal as the buck regulator.

In Boost mode, the EXT_BOOST pin is used to monitor boost input voltage to turn on and turn off the boost PWM. The AUXVCC pin is used to monitor the boost output voltage to turn on and turn off the boost PWM.

Referring to Figure 29, a resistor divider from the boost input voltage to the EXT_BOOST pin is used to detect the boost input voltage. When the voltage on the EXT_BOOST pin is below 0.8V, the boost PWM is enabled with a fixed 500μs soft-start and the boost duty cycle increases linearly from MIN(ON)*Fs to ~50%. A 3μA sinking current is enabled at the EXT_BOOST pin for hysteresis purposes. When the voltage on the EXT_BOOST pin recovers to be above 0.8V, boost PWM is disabled immediately.

Use Equation 3 to calculate the upper resistor $R_{UP}$ (R1 in Figure 29) for a required hysteresis $V_{HYS}$ at the boost input voltage.

$$R_{UP} = \frac{V_{HYS}}{3 \mu A} \quad \text{(EQ. 3)}$$

Use Equation 4 to calculate the lower resistor $R_{LOW}$ (R2 in Figure 29) according to a required boost enable threshold.

$$R_{LOW} = \frac{R_{UP} \times 0.8}{\text{VFTH} - 0.8} \quad \text{(EQ. 4)}$$

where VFTH is the required falling threshold on boost input voltage to turn on the boost, 3μA is the hysteresis current, and 0.8V is the reference voltage to be compared with.

Note that the boost start-up threshold has to be selected in a way that the buck is operating correctly and kept in close loop regulation before boost start-up. Otherwise, a large inrush current at boost start-up can occur at boost input due to the buck open loop saturation. Set the boost start-up input voltage threshold high enough to cover the boost inductor and diode DC voltage drop, and the buck’s maximum duty cycle and voltage conduction drop. This ensures the buck does not reach maximum duty cycle before boost start-up.

Similarly, a resistor divider from the boost output voltage to the AUXVCC pin is used to detect the boost output voltage. When the voltage on the AUXVCC pin is below 0.8V, the boost PWM is enabled with a fixed 500μs soft-start and a 3μA sinking current is enabled at AUXVCC pin for hysteresis purposes. When the voltage on the AUXVCC pin recovers to be above 0.8V, boost PWM is disabled immediately.

Use Equation 3 to calculate the upper resistor $R_{UP}$ (R3 in Figure 29) according to a required hysteresis $V_{HY}$ at boost output voltage.

Use Equation 4 to calculate the lower resistor $R_{LOW}$ (R4 in Figure 29) according to a required boost enable threshold at boost output.

Assuming $V_{BAT}$ is the boost input voltage, $V_{OUT_BST}$ is the boost output voltage and $V_{OUT}$ is the buck output voltage, the steady state DC transfer function are:

$$V_{OUT_{BST}} = \frac{1}{1-D} \times V_{BAT} \quad \text{(EQ. 5)}$$

$$V_{OUT} = D \times V_{OUT_{BST}} = \frac{D}{1-D} \times V_{BAT} \quad \text{(EQ. 6)}$$
From Equations 5 and 6, Equation 7 can be derived to estimate the steady state boost output voltage as a function of $V_{BAT}$ and $V_{OUT}$:

$$V_{OUT} = V_{BAT} + V_{OUT}$$  \hspace{1cm} (EQ. 7)

After the IC starts up, the boost buck converters can keep working when the battery voltage drops extremely low because the IC’s bias (VCC) LDO is powered by the boost output. For example, if a 3.3V output application battery drops to 2V and the VIN pin voltage is powered by the 5.2V boost output voltage (Equation 7), the VIN pin (buck input) still sees 5.2V to keep the IC working.

Note that in the previously mentioned case, the boost input current could be high because the input voltage is very low ($V_{IN} = V_{OUT} / \text{Efficiency}$). For the design to achieve the low input operation with full load, the inductor and MOSFET have to be selected with enough current ratings to handle the high current appearing at boost input. The boost inductor current is the same with the boost input current, which can be estimated as Equation 8, where $P_{OUT}$ is the output power, $V_{BAT}$ is the boost input voltage, and EFF is the estimated efficiency of the whole boost and buck stages.

$$I_{IN} = \frac{P_{OUT}}{V_{BAT} \times \text{EFF}}$$  \hspace{1cm} (EQ. 8)

Based on the same concerns of boost input current, the start-up sequence must follow the rule that the IC is enabled after the boost input voltage rise above a certain level. The shutdown sequence must follow the rule that the IC is disabled first before the boost input power source is turned off. In Boost mode applications where there is no external control signal to enable/disable the IC, an external input UVLO circuit must be implemented for the start-up and shutdown sequence.

**Non-Inverting Single Inductor Buck Boost Converter Operation**

In Figure 5 on page 3, schematic (b) shows a non-inverting single inductor buck boost configuration. The recommended setting is to use 1MΩ and 130kΩ resistor dividers (as shown in TYP Schematic III b) connecting from VCC to both the EXT_BOOST and AUXVCC pins (the EXT_BOOST and AUXVCC pins are directly connected). In this way, the EXT_BOOST pin voltage is a fixed voltage of 0.52V that is higher than the Boost mode detection threshold of 0.2V to set the IC in Boost mode and lower than the boost switching threshold of 800mV to have boost being constantly switching (during and after soft-start).

Similar to 2-stage boost Buck mode, LGATE switches ON the same phase that the upper FETs switch ON, meaning both upper and lower side FETs are ON and OFF at the same time with the same duty cycle. When both FETs are ON, input voltage charges the inductor current ramping up for duration of DT; when both FETs are OFF, the inductor current is free wheeling through the two power diodes to output and output voltage discharge the inductor current ramping down for $(1-D)T$ (in CCM mode). The steady state DC transfer function is:

$$V_{OUT} = \frac{D}{1-D} \times V_{IN}$$  \hspace{1cm} (EQ. 9)

where $V_{IN}$ is the input voltage, $V_{OUT}$ is the buck boost output voltage, and D is duty cycle.

Use Equation 10 to calculate the inductor DC current as below:

$$I_{DC} = \frac{1}{1-D} \times I_{OUT}$$  \hspace{1cm} (EQ. 10)

where $I_{DC}$ is the inductor DC current and $I_{OUT}$ is the output DC current.

Equation 10 shows the inductor current is charging output only during $(1-D)T$, which means inductor current has larger DC current than output load current. Thus, for this IC with high-side FET integrated, the non-inverting buck boost configuration has less load current capability compared with buck and 2-stage boost buck configurations. Its load current capability depends mainly on the duty cycle and inductor current.

Inductor ripple current can be calculated using Equation 11:

$$I_{RIPPLE} = \frac{V_{OUT}(1-D)T}{L}$$  \hspace{1cm} (EQ. 11)

The inductor peak current is:

$$I_{PEAK} = I_{DC} + \frac{1}{2} I_{RIPPLE}$$  \hspace{1cm} (EQ. 12)

In power stage DC calculations, use Equation 9 to calculate D, then use Equation 10 to calculate $I_{DC}$. D and $I_{DC}$ are useful for estimating the high-side FET’s power losses and checking if the part can meet the load current requirements.

**Oscillator and Synchronization**

The oscillator has a default frequency of 500kHz with the FS pin connected to VCC or ground, or floating. The frequency can be programmed to any frequency between 200kHz and 2.2MHz with a resistor from the FS pin to GND.

$$R_{FS} [\text{kΩ}] = \frac{145000}{16 \times f_{SW} [\text{kHz}]}$$  \hspace{1cm} (EQ. 13)

![FIGURE 30. RFS vs FREQUENCY](image)

The SYNC pin is bidirectional and it outputs the IC’s default or programmed local clock signal when it is free running. The IC locks to an external clock injected to the SYNC pin (external clock frequency is recommended to be 10% higher than the free running frequency). The delay from the rising edge of the external clock signal to the PHASE rising edge is half of the free running switching period pulse 220ns, (0.5$f_{SW}$+220ns). The maximum...
external clock frequency is recommended to be 1.6 times of the free running frequency.

When the part enters PFM pulse skipping mode, the synchronization function is shut off and no clock signal is output in SYNC pin.

With the SYNC pins connected together, multiple ISL85403s can be synchronized. The slave ICs automatically have 180° phase shift with respect to the master IC.

**PGOOD**

The PGOOD pin is the output of an open-drain transistor (See Figure 6 on page 4). An external resistor is required to be pulled up to VCC for proper PGOOD function. At start-up, PGOOD is turned HIGH (internal PGOOD open-drain transistor is turned off) with 128 cycles delay after soft-start is finished (soft-start ramp reaches 1.02V) and the FB voltage is within the OV/UV window (90%REF < FB < 110%REF).

At normal operation, PGOOD is pulled low with one cycle (minimum) and six cycles (maximum) delay if any of the OV (110%) or UV (90%) comparators are tripped. PGOOD is released HIGH with 128 cycles delay after FB recovers to be within the OV/UV window (90%REF < FB < 110%REF). When EN is pulled low or VCC is below POR, PGOOD is pulled low with no delay.

If the PGOOD pin is pulled up by the external bias supply instead of VCC by itself, when the part is disabled, the internal PGOOD open-drain transistor is off, the external bias supply can charge PGOOD pin HIGH. This is known as false PGOOD reporting. At start-up when VCC rises from 0V, PGOOD is pulled low when VCC reaches 1V. After EN is pulled low and VCC is falling, the PGOOD internal open-drain transistor opens with high impedance when VCC falls below 1V. The time between when EN is pulled low and PGOOD OPEN depends on the VCC falling time to 1V.

**Fault Protection**

**Overcurrent Protection**

The overcurrent function protects against any overload condition and output short at worst case by monitoring the current flowing through the upper MOSFET.

There are two current limiting thresholds: \( I_{OC1} \) and \( I_{OC2} \). \( I_{OC1} \) limits the high-side MOSFET peak current cycle-by-cycle. The current limit threshold is set at 3.6A (default) with the ILIMIT pin connected to GND or VCC, or left open. The current limit threshold can also be programmed by a resistor, \( R_{LIM} \), at the ILIMIT pin to ground. Use Equation 14 to calculate the resistor.

\[
R_{LIM} = \frac{300000}{I_{OC1}[A]} + 0.018 \quad (EQ. 14)
\]

Note that \( I_{OC1} \) is higher with lower \( R_{LIM} \). The resistor value range to program the OC1 peak current threshold is 40kΩ to 330kΩ. \( R_{LIM} \) values out of this range are not recommended.

The second current protection threshold, \( I_{OC2} \), is 15% higher than \( I_{OC1} \). Instantly after the high-side MOSFET current reaches \( I_{OC2} \), the PWM is shut off after a two-cycle delay and the IC enters Hiccup mode. In Hiccup mode, the PWM is disabled for a dummy soft-start cycle that is equal to five regular soft-start periods. After this dummy soft-start cycle, the true soft-start cycle is attempted again. The \( I_{OC2} \) offers a robust and reliable protection against the worst case conditions.

The frequency foldback is implemented on the ISL85403. When overcurrent limiting, the switching frequency is reduced to be proportional to the output voltage to keep the inductor current under the limit threshold during an overload condition. The low frequency limit under frequency foldback operation is 40kHz.

**Overvoltage Protection**

If the voltage detected on the FB pin is over 110% or 120% of reference, the high-side and low-side drivers shut down immediately and stay off until the FB voltage drops to 0.8V. When the FB voltage drops to 0.8V, the drivers are released ON. 110% OVP is off during soft-start and active after soft-start is complete. 120% OVP is active during and after soft-start.

**Thermal Protection**

The ISL85403 PWM is disabled if the junction temperature reaches +160°C. There is +20°C hysteresis for OTP. The part restarts after the junction temperature drops below +140°C.

**Component Selections**

The ISL85403 iSim model can be used to simulate for both the time domain behaviors and small signal loop stability analysis.

**Output Capacitors - Buck**

An output capacitor is required to filter the inductor current. Output ripple voltage and transient response are two critical factors when considering output capacitance choice. The current mode control loop allows for the usage of low ESR ceramic capacitors and thus smaller board layout. Electrolytic and polymer capacitors can also be used.

Additional consideration applies to ceramic capacitors. While they offer excellent overall performance and reliability, the actual in-circuit capacitance must be considered. Ceramic capacitors are rated using large peak-to-peak voltage swings with no DC bias. In DC/DC converter applications, these conditions do not reflect reality. As a result, the actual capacitance may be considerably lower than the advertised value. Consult the manufacturer's datasheet to determine the actual in-application capacitance. Most manufacturers publish capacitance vs DC bias.
so this effect can be easily accommodated. The effects of AC voltage are not frequently published, but an assumption of ~20% further reduction generally suffices. The result of these considerations can easily result in an effective capacitance 50% lower than the rated value. Nonetheless, ceramic capacitors are a very good choice in many applications due to their reliability and extremely low ESR.

In buck topology, the following equations allow calculation of the required capacitance to meet a required ripple voltage level. Additional capacitance may be used.

For the ceramic capacitors (low ESR):

\[
V_{\text{OUT}} \text{ripple} = \frac{\Delta I}{8f_{\text{SW}} \times C_{\text{OUT}}}
\]  
(EQ. 15)

where \( \Delta I \) is the inductor’s peak-to-peak ripple current, \( f_{\text{SW}} \) is the switching frequency, and \( C_{\text{OUT}} \) is the output capacitor.

If using electrolytic capacitors then:

\[
V_{\text{OUT}} \text{ripple} = \frac{\Delta I \times \text{ESR}}{8f_{\text{SW}} \times C_{\text{OUT}}}
\]  
(EQ. 16)

Regarding transient response needs, a good starting point is to determine the allowable overshoot in \( V_{\text{OUT}} \) if the load is suddenly removed. In this case, energy stored in the inductor is transferred to \( C_{\text{OUT}} \), causing its voltage to rise. After calculating capacitance required for both ripple and transient needs, choose the larger of the calculated values. **Equation 17** determines the required output capacitor value to achieve a wanted overshoot relative to the regulated voltage.

\[
C_{\text{OUT}} = \frac{I_{\text{OUT}}^2 \times L}{V_{\text{OUT}}^2 \times (V_{\text{OUTMAX}}/V_{\text{OUT}})^2 - 1}
\]  
(EQ. 17)

where \( V_{\text{OUTMAX}}/V_{\text{OUT}} \) is the relative maximum overshoot allowed during the removal of the load.

**Input Capacitors - Buck**

Depending on the system input power rail conditions, the aluminum electrolytic type capacitor is normally needed to provide the stable input voltage. Thus, restrict the switching frequency pulse current in a small area over the input traces for better EMC performance. The input capacitor should be able to handle the RMS current from the switching power devices.

Ceramic capacitors must be used at the VIN pin of the IC and multiple capacitors including 1µF and 0.1µF are recommended. Place these capacitors as close as possible to the IC.

**Output Inductor - Buck**

The inductor value determines the converter’s ripple current. Choosing an inductor current requires a somewhat arbitrary choice of ripple current, \( \Delta I \). A reasonable starting point is 30% to 40% of total load current. The inductor value is calculated using **Equation 18**:

\[
L = \frac{V_{\text{IN}} - V_{\text{OUT}}}{f_{\text{SW}} \times \Delta I} \times \frac{V_{\text{OUT}}}{V_{\text{IN}}}
\]  
(EQ. 18)

Increasing the value of inductance reduces the ripple current and therefore the ripple voltage. However, the larger inductance value may reduce the converter’s response time to a load transient.

The inductor current rating should not saturate in overcurrent conditions.

**Low-Side Power MOSFET**

In a synchronous buck application, a power N MOSFET is needed as the synchronous low-side MOSFET and a good one should have low Qgd, low \( r_{\text{DS(ON)}} \), and small \( R_g \) (\( R_g \_\text{typ} < 1.5\Omega \) recommended). The \( V_{g\text{th, min}} \) is recommended to be 1.2V or higher. A good example is SQS462EN.

Add a 5.1k or smaller value resistor to connect LGATE to ground to avoid false turn-on of the LGATE caused by coupling noise.

**Output Voltage Feedback Resistor Divider**

The output voltage can be programmed down to 0.8V by a resistor divider from \( V_{\text{OUT}} \) to FB according to **Equation 19**.

\[
V_{\text{OUT}} = 0.8 \times \left( 1 + \frac{R_{\text{UP}}}{R_{\text{LOW}}} \right)
\]  
(EQ. 19)

In an application requiring low input quiescent current, use large resistors for the divider. Generally, a resistor value of 10k to 30k can be used for the upper resistor.

**Boost Inductor (2-Stage Boost Buck)**

Besides the need to sustain the current ripple to be within a certain range (30% to 50%), the boost inductor current at its soft-start is a more important perspective to be considered in selection of the boost inductor. Each time the boost starts up, there is a fixed 500μs soft-start time when the duty cycle increases linearly from \( t_{\text{MIN(ON)}} \times f_{\text{SW}} \) to ~50%. Before and after boost start-up, the boost output voltage jumps from \( V_{\text{IN,BOOST}} \) to voltage \( (V_{\text{IN,BOOST}} + V_{\text{OUT,BOOST}}) \). The design target in boost soft-start is to ensure the boost input current is sustained to a minimum but is able to charge the boost output voltage to have a voltage step equaling to \( V_{\text{OUT,BOOST}} \). A large inductor prevents the inductor current from increasing and is not high enough to be able to charge the output capacitor to the final steady state value \( V_{\text{IN,BOOST}} + V_{\text{OUT,BOOST}} \) within 500μs. A 6.8μH inductor is a good starting point for its selection in design. Check the boost inductor current at start-up with an oscilloscope to ensure it is under an acceptable range. It is suggested to run the ISL85403 iSim model (use the ISL85403 iSim model) to assist in the proper inductor value.

**Boost Output Capacitor (2-Stage Boost Buck)**

Based on the same theory in boost start-up, a large capacitor at boost output causes high inrush current at boost PWM start-up. 22µF is a good choice for applications with a buck output voltage less than 10V. Also some minimum amount of capacitance has to be used in boost output to keep the system stable. Renesas recommends running the iSim model to assist in designing the proper capacitor value.
Loop Compensation Design - Buck

The ISL85403 uses constant frequency peak current mode control architecture to achieve fast loop transient response. An accurate current sensing pilot device in parallel with the upper MOSFET is used for peak current control signal and overcurrent protection. The inductor is not considered a state variable because its peak current is constant and the system becomes a single order system. It is much easier to design the compensator to stabilize the loop compared with voltage mode control. Peak current mode control has an inherent input voltage feed-forward function to achieve good line regulation. Figure 32 shows the small signal model of a buck regulator.

PWM Comparator Gain \( F_m \)

The PWM comparator gain, \( F_m \), for peak current mode control is given by Equation 20:

\[
F_m = \frac{d}{v_{comp}} = \frac{1}{(S_e + S_n/T_s)}
\]  
\[(EQ. 20)\]

where \( S_e \) is the slew rate of the slope compensation and \( S_n \) is given by Equation 21:

\[
S_n = \frac{R_t}{R_c} \frac{V_{in} - V_o}{L п}
\]  
\[(EQ. 21)\]

where \( R_t \) is the gain of the current amplifier.

Current Sampling Transfer Function \( H_e(S) \)

In a current loop, the current signal is sampled every switching cycle. It has the following transfer function in Equation 22:

\[
H_e(S) = \frac{S^2}{\omega_n^2 + \frac{S}{\omega_n Q_n} + 1}
\]  
\[(EQ. 22)\]

where \( Q_n \) and \( \omega_n \) are given by

\[
Q_n = 2 \cdot \frac{\omega_n}{\pi f_{SW}}
\]

Power Stage Transfer Functions

Transfer function \( F_1(S) \) from control to output voltage is:

\[
F_1(S) = \frac{V_o}{V_{in}} = \frac{1 + \frac{S}{\omega_{esr}}}{\frac{S^2}{\omega_n^2} + \frac{S}{\omega_n Q_n} + 1}
\]  
\[(EQ. 23)\]

where:

\[
\omega_{esr} = \frac{1}{R_c C_o} \frac{Q_n}{L п} \omega_o - \frac{1}{\sqrt{L п C_o}}
\]

Transfer function \( F_2(S) \) from control to inductor current is given by Equation 24:

\[
F_2(S) = \frac{i_o}{V_{in}} = \frac{1 + \frac{S}{\omega_z}}{\frac{S^2}{\omega_o^2} + \frac{1}{\omega_o Q_p} + 1}
\]  
\[(EQ. 24)\]

where \( \omega_z = \frac{1}{R_c C_o} \).  

Current loop gain \( T_i(S) \) is expressed as Equation 25:

\[
T_i(S) = R_t F_m F_2(S) H_e(S)
\]  
\[(EQ. 25)\]

The voltage loop gain with open current loop is expressed in Equation 26:

\[
T_v(S) = K F_m F_1(S) A_v(S)
\]  
\[(EQ. 26)\]

The Voltage loop gain with current loop closed is given by Equation 27:

\[
L_v(S) = \frac{T_v(S)}{1 + T_i(S)}
\]  
\[(EQ. 27)\]

If \( T_i(S)>>1 \), then Equation 27 can be simplified as Equation 28:

\[
L_v(S) = \frac{R_o + R_{LP}}{R_t} \frac{1 - \frac{1}{\omega_{esr} A_v(S)} - \frac{1}{\omega_o Q_p} - \frac{1}{\omega_o}}{1 + \frac{1}{\omega_o H_e(S)} - \frac{1}{\omega_o}}
\]  
\[(EQ. 28)\]

Equation 28 shows that the system is a single order system. Therefore, a simple type II compensator can be easily used to stabilize the system. A type III compensator is needed to expand the bandwidth for current mode control in some cases.

A compensator with two zeros and one pole is recommended for this part, as shown in Figure 33.
Its transfer function is expressed as Equation 29:

$$A_v(S) = \frac{v_{\text{comp}}}{v_O} = \frac{1}{SR_1C_1} \frac{1 + \frac{S}{\omega_{cz1}}}{1 + \frac{S}{\omega_{cz2}}} = \frac{1}{SR_1C_1} \frac{1 + \frac{S}{\omega_{cz1}}}{1 + \frac{S}{\omega_{cz2}}}$$

(EQ. 29)

where:

$$\omega_{cz1} = \frac{1}{R_2C_1}, \quad \omega_{cz2} = \frac{1}{(R_1 + R_3)C_3}, \quad \omega_{cp} = \frac{1}{R_3C_3}$$

Compensator design goal:

- Loop bandwidth $f_c = \frac{1}{4\pi R_1 C_1} f_{SW}$
- Gain margin: $>10$ dB
- Phase margin: $45^\circ$

The compensator design procedure is as follows:

1. Position $\omega_{cz2}$ and $\omega_{cp}$ to derive $R_3$ and $C_3$.

   - Put the compensator zero $\omega_{cz2}$ at $(1$ to $3)/(R_0C_0)$
     
     $$\omega_{cz2} = \frac{3}{R_0C_0}$$  
     (EQ. 30)

   - Put the compensator pole $\omega_{cp}$ at ESR zero or $0.35$ to $0.5$ times of switching frequency, whichever is lower. In an all-ceramic-cap design, the ESR zero is normally higher than half of the switching frequency. $R_3$ and $C_3$ can be derived as follows:

     - **Case A:** ESR zero $\frac{1}{2\pi R_c C_o}$ less than $(0.35$ to $0.5)f_{SW}$
       
       $$C_3 = \frac{R_oC_o - 3R_1C_o}{3R_1}$$  
       (EQ. 31)

       $$R_3 = \frac{3R_oR_1}{R_o - 3R_c}$$  
       (EQ. 32)

     - **Case B:** ESR zero $\frac{1}{2\pi R_c C_o}$ larger than $(0.35$ to $0.5)f_{SW}$
       
       $$C_3 = \frac{0.33R_o f_{SW} - 0.46}{f_{SW}R_1}$$  
       (EQ. 33)

       $$R_3 = \frac{R_1}{0.73R_o f_s - 1}$$  
       (EQ. 34)

2. Derive $R_2$ and $C_1$.

   - The loop gain $L_v(S)$ at crossover frequency of $f_c$ has unity gain. Therefore, $C_1$ is determined by Equation 35.
     
     $$C_1 = \frac{(R_4 + R_3)C_3}{2\pi f_c R_1 R_3 C_o}$$  
     (EQ. 35)

   - The compensator zero $\omega_{cz1}$ can boost the phase margin and bandwidth. To put $\omega_{cz1}$ at two times of crossover frequency $f_c$ is a good starting point. It can be adjusted according to the specific design. $R_1$ can be derived from Equation 36.
     
     $$R_2 = \frac{1}{4\pi f_c C_1}$$  
     (EQ. 36)

Example: $V_{IN} = 12V$, $V_o = 5V$, $I_o = 2A$, $f_{SW} = 500kHz$, $C_o = 60\mu F/3m\Omega$, $L = 10\mu H$, $R_t = 0.20V/A$, $f_c = 50kHz$, $R_1 = 105k$, $R_{BIAS} = 20k\Omega$.

Select the crossover frequency to be 35kHz. Because the output capacitors are all ceramic, use Equations 33 and 34 to derive $R_3$ to be 20k and $C_3$ to be 470pF.

Then use Equations 35 and 36 to calculate $C_1$ to be 180pF and $R_2$ to be 12.7k. Select 150pF for $C_1$ and 15k for $R_2$.

There is approximately 30pF parasitic capacitance between COMP to FB pins that contributes to a high frequency pole. Any extra external capacitor is not recommended between COMP and FB.

Figure 34 shows the simulated Bode plot of the loop. It has 26kHz loop bandwidth with 70° phase margin and -28 dB gain margin.

Note in applications where the PFM mode is required especially when type III compensation network is used, the value of the capacitor between the COMP pin and the FB pin (not the capacitor in series with the resistor between COMP and FB) should be minimal to reduce the noise coupling for proper PFM operation. No external capacitor between COMP and FB is recommended for PFM applications.

In PFM mode operations, an RC filter from FB to ground (R in series with C, connecting from FB to ground) can help reduce the noise effects injected to FB pin. The recommended values for the filter are 499Ω to 1k for the R and 470pF for the C.
Loop Compensation Design for 2-Stage Boost Buck and Single-Stage Buck Boost

For 2-stage boost buck and single-stage non-inverting buck boost configurations, it is highly recommended to use the iSim model to evaluate the loop bandwidth and phase margin.

Layout Suggestions

1. Place the input ceramic capacitors as close as possible to the IC VIN pin and power ground connecting to the power MOSFET or diode. Keep this loop (input ceramic capacitor, IC VIN pin and MOSFET/diode) as small as possible to achieve the fewest voltage spikes induced by the trace parasitic inductance.

2. Place the input aluminum capacitors as close as possible to the IC VIN pin.

3. Keep the phase node copper area small but large enough to handle the load current.

4. Place the output ceramic and aluminum capacitors close to the power stage components as well.

5. Place vias (≥9) in the bottom pad of the IC. Place the bottom pad in the ground copper plane with an area as large as possible in multiple layers to effectively reduce the thermal impedance.

6. Place the 4.7µF ceramic decoupling capacitor at the VCC pin (the closest place to the IC). Put multiple vias (≥3) close to the ground pad of this capacitor.

7. Keep the bootstrap capacitor close to the IC.

8. Keep the LGATE drive trace as short as possible and try to avoid using vias in the LGATE drive path to achieve the lowest impedance.

9. Place the positive voltage sense trace close to the place that is strictly regulated.

10. Place all the peripheral control components close to the IC.

NOTES:
1. Dimensions are in millimeters.
   Dimensions in ( ) for Reference Only.
2. Dimensioning and tolerancing conform to AMSE Y14.5m-1994.
3. Unless otherwise specified, tolerance: Decimal ± 0.05
4. Dimension b applies to the metallized terminal and is measured between 0.15mm and 0.30mm from the terminal tip.
5. Tiebar shown (if present) is a non-functional feature.
6. The configuration of the pin #1 identifier is optional, but must be located within the zone indicated. The pin #1 identifier may be either a mold or mark feature.
Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation or any other use of the circuits, software, and information in the design of your product or system. Renesas Electronics disclaims any and all liability for any losses and damages incurred by you or third parties arising from the use of these circuits, software, or information.

2. Renesas Electronics hereby expressly disclaims any warranties against and liability for infringement or any other claims involving patents, copyrights, or other intellectual property rights of third parties, by or arising from the use of Renesas Electronics products or technical information described in this document, including but not limited to, the product data, drawings, charts, programs, algorithms, and application examples.

3. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.

4. You shall not alter, modify, copy, or reverse engineer any Renesas Electronics product, whether in whole or in part. Renesas Electronics disclaims any and all liability for any losses or damages incurred by you or third parties arising from such alteration, modification, copying or reverse engineering.

5. Renesas Electronics products are classified according to the following two quality grades. “Standard” and “High Quality”. The intended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below.

   "Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; industrial robots; etc.

   "High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control (traffic lights); large-scale communication equipment; key financial terminal systems; safety control equipment; etc.

   Unless expressly designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not intended or authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems; surgical implantations; etc.), or may cause serious property damage (space system; undersea repeaters; nuclear power control systems; aircraft control systems; key plant systems; military equipment; etc.). Renesas Electronics disclaims any and all liability for any damages or losses incurred by you or any third parties arising from the use of any Renesas Electronics product that is inconsistent with any Renesas Electronics data sheet, user’s manual or other Renesas Electronics document.

6. When using Renesas Electronics products, refer to the latest product information (data sheets, user’s manuals, application notes, “General Notes for Handling and Using Semiconductor Devices” in the reliability handbook, etc.), and ensure that usage conditions are within the ranges specified by Renesas Electronics with respect to maximum ratings, operating power supply voltage range, heat dissipation characteristics, installation, etc. Renesas Electronics disclaims any and all liability for any failures, failure or accident arising out of the use of Renesas Electronics products outside of such specified ranges.

7. Although Renesas Electronics endeavors to improve the quality and reliability of Renesas Electronics products, semiconductor products have specific characteristics, such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Unless designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not subject to radiation resistance design. You are responsible for implementing safety measures to guard against the possibility of bodily injury, injury or damage caused by fire, and/or danger to the public in the event of a failure or malfunction of Renesas Electronics products, such as safety design for hardware and software, including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer component alone is very difficult and impractical, you are responsible for evaluating the safety of the final products or systems manufactured by you.

8. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. You are responsible for carefully and sufficiently investigating applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive, and using Renesas Electronics products in compliance with all these applicable laws and regulations. Renesas Electronics disclaims any and all liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.

9. Renesas Electronics products and technologies shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You shall comply with any applicable export control laws and regulations promulgated and administered by the governments of any countries asserting jurisdiction over the parties or transactions.

10. It is the responsibility of the buyer or distributor of Renesas Electronics products, or any other party who distributes, disposes of, or otherwise sells or transfers the product to a third party, to notify such third party in advance of the contents and conditions set forth in this document.

11. This document shall not be reprinted, reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.

12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products.

(Note1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its directly or indirectly controlled subsidiaries.

(Note2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.
