**Introduction**

**Communication Satellite Frequency Allocation**
Communication satellites operate within two frequency bands for TV/Broadband service broadcast signals, C Band and Ku Band. The C Band overall frequency spectrum is 4.0GHz to 8.0GHz, while the Ku Band overall frequency spectrum is 11.7GHz to 18.0GHz.

Within these bands, each satellite will have specific uplink and downlink frequency allocation. For example, the North American DBS system has categories assigned as follows: Ku Band high power downlink is 12.2GHz to 12.7GHz and 17.3GHz to 17.8GHz as the uplink frequency, C Band downlink frequency is 3.7GHz to 4.2GHz and 5.925GHz to 6.425GHz as uplink frequency.

Also, to use the frequencies that are available for satellite broadcast as efficiently as possible, and to accommodate an additional number of channels within a given frequency band, the transmission signal can be formatted to be either vertical and horizontal, or circular right-hand and circular left-hand simultaneously per frequency.

**What is a Low Noise Block (LNB)?**
An LNB is a low noise block module, placed on the focus of the dish antenna (parabola) that provides the following functions:

- Down conversion of the incoming signal from GHz range to the 910MHz to 2150MHz (for Europe) range called “first conversion signal.” This conversion allows the signal to be carried by an inexpensive coaxial cable towards the receiver.

- Signal amplification with good noise figure. The LNB improves the first conversion signal level through the use of a built-in low noise amplifier.

- Selection of Vertical or Horizontal polarization.

- Selects operating band by switching its internal oscillator from Low band to High band when the LNB “receives” a 22kHz tone. Specifically, the local oscillator (LO) frequency changes from 9.75GHz to 10.6GHz.
  - C Band - LO frequency 9.75GHz
  - Ku Band - LO frequency 10.6GHz

- Miscellaneous functions based on 22kHz tone PPM encoding, as discussed later in this paper.

**Polarization Selection**
Polarization is a way to give a transmission signal specific direction. It increases the beam concentration. The signal transmitted by satellite can be polarized in one of four different ways: Linear (horizontal or vertical) or Circular (right-hand or left-hand). Consequently, the satellite can broadcast both H and V or LH and RH polarized signals on one frequency.

The “universal” LNB switches the polarization by looking at the voltage that it receives from the receiver.

- 12V - Horizontal, 18V - Vertical
- 13V - Circular right-hand, 20V - Circular left-hand

Generally, only two (12V and 18V or 13V and 20V) will be used with one type of antenna. Also, 1V can be added from a receiver to any of above voltages to compensate for the voltage drop in the coaxial cable, i.e., it could be 13V (12V), 14V (13V), 19V (18V) or 21V (20V) instead.

**22kHz Tone and DiSEqC™ (Digital Satellite Equipment Control) Encoding**
In addition to selecting the polarization, the LNB needs to select the operating band. This is done with the use of a 22kHz tone frequency. A 22kHz pulse-position modulated signal of about 0.6V amplitude is superimposed on the LNB’s DC power rail. Its coding scheme allows the remote electronics to perform more complex functions like varying the down conversion frequency to select one of multiple LNB’s for dual-dish systems or physically rotating the antenna assembly. Traditionally, when other encoding functions do not require using 22kHz tone, simple presence or absence of this tone selects the operating band by changing the local oscillator frequency of the LNB.

The complex encoding of the 22kHz burst is done with a more sophisticated communication bus protocol named the DiSEqC standard (Digital Satellite Equipment Control). The open DiSEqC standard developed by the European Telecommunication Satellite Organization is a well accepted worldwide standard for communication between satellite receivers and satellite peripheral equipment.

The 22kHz oscillator has to be a tone generator with specific rise and fall time. The wave shape will be a quasi-square wave. (Sine with flat-top). The required frequency tolerance is ±2kHz over line and temperature variations. Burst coding of this signal is accomplished by input from the microcontroller at the DSQIN pin of the IC or by setting the ENT bit of the system register through the I2C bus as detailed in the ISL6421A datasheet.

**22kHz WAVE SHAPE AND DETAILS (See Figures 1 and 2)**
Carrier frequency: 22kHz ±2kHz over line and temperature
Carrier amplitude: 650mVpp ±250mV
Modulation mark period: 500µs ±100µs
Modulation space period: 1ms ±200µs
**Methods of Modulation**

![DiSEqC™ MODULATION SCHEME](image1)

**ISL6421A - Provides a Complete Power Solution for LNB Control**

The ISL6421A is a highly integrated solution for supplying power and control signals from advanced satellite set-top box (STB) modules to the low noise block (LNB) of the antenna port. The device is comprised of a current-mode boost PWM and a low-noise linear regulator along with the circuitry required for I2C device interfacing and for providing DiSEqC standard control signals to the LNB.

The regulator output voltage is available at the output terminal (VOUT) to support operation of the antenna port in advanced satellite STBs. The regulator output for the PWM is set to 13V or 18V by a voltage select command (VSEL) through the I2C bus. Additionally, to compensate for the voltage drop in the coaxial cable, the selected voltage may be increased by 1V with the line length compensation (LLC) feature. An enable command sent on the I2C bus provides standby mode control for the PWM and linear combination, disabling the output to conserve power.

The current-mode boost converter provides the linear regulator with input voltage that is set to the output voltage, plus typically 1.2V dropout to insure minimum power dissipation across the linear regulator. This maintains constant voltage drop across the linear pass element while permitting adequate voltage range for tone injection.

Please refer to the ISL6421A datasheet, FN9130, for more information.

---

**Quick Start Evaluation**

**Out Of The Box**

The ISL6421A evaluation board is shipped in a “ready-to-test” state. The board requires an input voltage ranging from 8V to 14V and a 3.3V/5V supply. The use of an electronic load enables evaluation over a wide range of operating conditions. The evaluation kit ISL6405I2C-KIT-EVAL includes a PC to I2C bus interface board (USB-I2CIO), PC to I2C bus software, a USB cable, and a connector cable to connect the USB-I2CIO board and the ISL6421AEVAL1Z board, along with relevant application notes.

**Required Test Equipment**

To fully test the ISL6421A functionality, the following equipment is needed:

- 4 channel oscilloscope with probes
- 1 electronic load
- 2 bench power supplies
- Precision digital multi-meters
- I2C bus read/write capability

**Power and Load Connections**

The ISL6421A evaluation board has three sets of terminal posts used to supply the input voltages and to monitor and load the outputs.

**Jumper Settings** - JP1, JP2, and JP3 will be shorted with shunt jumpers pulling the ADDR, SEL18V, and the DISQIN pins low.

**Input Voltage** - Adjust two power supplies to provide the 5V/3.3V and 12V input voltages of the evaluation board. With the power supplies turned off, connect the positive lead of the 12V supply to the VIN post (P1) and the ground lead to the GND post (P2).

The second supply set for either 5V or 3.3V provides the pull-up voltage for the I2C bus clock and data line. Connect the positive lead of the second supply to the +5V/+3.3V post (P7) and the ground lead to the SGND post (P8).
Output Voltage Loading and Monitoring - To exercise and monitor VOUT, connect the positive lead of one of the electronic loads and the positive lead of a digital multimeter to the VOUT post (P3) and the ground lead to the GND post (P4).

I^2C Bus Communication Setup

To control and exercise the ISL6421A requires communication through the I^2C bus clock (SCL) and data (SDA) pins. Refer to the ISL6421A datasheet for more information about the I^2C bus specification. You can use existing I^2C hardware/software, a word generator, or use the PC to I^2C hardware/software included in the ISL6421A evaluation kit to produce the necessary I^2C waveforms.

USB-I2CIO board driver installation - To use a PC to control the I^2C bus to communicate with the ISL6421A you will have to install the drivers of the USB-I2CIO board included in the kit. You will need a Windows 98/XP/2000 machine with a standard USB port.

1. The evaluation kit comes with a CD containing the software and drivers to control the I^2C bus. Copy the contents of the CD to some directory, e.g., C:\'some directory'.

2. Applying power to the USB-I2CIO board: The USB-I2CIO board has the option of being powered with 3.3V through the USB bus of the PC or externally with 5V connected to the +5 test point and GND test point. The I^2C bus can operate at 3.3V or 5V logic levels. If you use an external 5V supply then place a shunt jumper shorting pins 2 and 3 of JP3. If you are using an external 5V supply to power the USB-I2CIO board, place a shunt jumper shorting pins 1 and 2 of JP3.

3. After the USB-I2CIO board is powered up, connect the USB cable to the USB port of a PC.

4. Windows should detect the new USB device and the ‘Found New Hardware Wizard’ should begin. This will help you install the drivers. Follow the directions on the screen until it asks you where to search for the drivers. At this point, you should select the ‘choose location’ option and browse to the C:\'some directory’ created in step one and select the drivers folder.

5. Follow the remaining directions and the driver should be installed and the USB-I2CIO detected by your PC.

6. If this is successful, another ‘Found New Hardware Wizard’ window will appear. Repeat steps 4 and 5. At this point, the USB-I2CIO board should be ready to use.

7. To connect the USB-I2CIO board to the ISL6421A evaluation board, use the 5 lead to 4 lead connector cable. Connect the 5 lead connector to J4 on the USB-I2CIO board and the 4 lead connector to J1 on the ISL6421A evaluation board.

8. Turn on the power supplies to power up the ISL6421A evaluation board.

9. Run the ISL6421A_I2C.exe program copied to C:\'some directory’. Figure 3 shows the PC to I^2C software application window. Click the ‘Open Device’ button.

10. If you receive a ‘No USB Device Detected’ error:
    • Make sure the drivers were installed correctly. If Windows did not detect your USB device, try running the Add/Remove Hardware Wizard in the control panel.
    • Make sure the USB board is powered up (internally or externally, not both).

11. If you receive the ‘Incorrect Return Value’ error:
    • The ISL6421A evaluation board may not be powered up. Check the power connections.
    • Make sure SCL and SDA are connected correctly. The 5-pin connector to the USB-I2CIO board only fits one way. Try reversing the 4 lead connector at J1 of the ISL6421A evaluation board.

Using the PC to I^2C Application

After opening the application window and clicking on the ‘Open Device’ button, the program will detect the USB-I2CIO board and initialize the I^2C system registers of the ISL6421A. To evaluate the ISL6421A functionality, toggle the system register bits as needed and then click on the ‘Write I2C’ button to write to the system registers. The lower portion of the application window shows the current values of the system register bits. They are read and updated continuously. The OLF1 and OTF flag in system register 1 and 2 are read only bits and provide diagnostic status of the ISL6421A.
**Performance Characterization**

**Startup**
The ISL6421A features internal soft-start to reduce the external number of components. Figure 4 shows a typical soft-start waveform. Typical soft-start time is 4.6ms.

![FIGURE 4. SOFT-START](image)

**Shutdown**
The LNB output of the ISL6421A can be shut down using the EN bit via $I^2C$. Figure 5 shows a typical shutdown waveform.

![FIGURE 5. SHUTDOWN USING $I^2C$ ENABLE](image)

**Boost PWM Efficiency**
The Boost PWM architecture allows close to 90% efficiency at full load as shown in Figure 6.

![FIGURE 6. BOOST PWM EFFICIENCY vs LOAD](image)

**DiSEqC Implementation**
The ISL6421A has a built-in 22kHz tone generator that can be controlled either by the $I^2C$ interface or by a dedicated pin (DSQIN) that allows immediate DiSEqC data encoding for the DiSEqC compliance. When the $I^2C$ tone enable bit (ENT) is set to HIGH, a continuous 22kHz tone is generated regardless of the status of the DSQIN pin. The ENT pin must be LOW when DSQIN pin is being used for DiSEqC encoding. Figure 7 shows the 22kHz tone waveform with 450mA load.

![FIGURE 7. 22kHz TONE OPERATION](image)
Overcurrent Hiccup Mode
Figure 8 shows a typical overcurrent trip.

When the DCL (dynamic current limiting) bit is set LOW, the overcurrent protection circuit works dynamically in a hiccup mode; as soon as an overload is detected, the output is shutdown for a time $t_{OFF}$, typically 900ms. The output is resumed for a time $t_{ON}$ = 20ms. At the end of $t_{ON}$, if the overload condition is still detected, the protection circuit will cycle again through $t_{OFF}$ and $t_{ON}$. Figure 9 shows the typical waveforms for the overcurrent hiccup mode.

Output Ripple
Figure 10 shows the typical output ripple waveforms. VOUT is set to 13V and 450mA load.

External Back-Bias Protection
Some applications may need to be able to protect the ISL6421A from an inadvertent back-bias voltage condition. For the case where a DC supply is connected to the output of the ISL6421A, a series connected diode as shown in Figure 11 will protect the IC. The LLC bit can be set high through the I2C bus to increase the output voltage by 1V to compensate for the diode voltage drop.

The DiSEqC standard recommends a maximum bus load of 0.25µF. For the circuit in Figure 11 to provide proper 22kHz tone operation, the bus would have to have a minimum loading of 12mA.

If tone operation is required at zero load conditions, a resistor can be placed from the cathode of the protection diode to ground, scaled to provide the minimum 12mA. To avoid the added dissipation of this method, a capacitor can be placed in parallel with the back-bias protection diode as shown in Figure 12. This capacitor should be scaled with the capacitive load present on the DiSEqC bus line. For a load of 0.25µF, use a 10µF capacitor. Consider the maximum load of 0.25µF and the highest output voltage of 19V and a 0.5V drop across the Schottky diode. After the tone rise time,

$$Q_d(\text{rise}) = 19\text{V} \times 0.25\mu\text{F} = 4750\text{nC}$$
During the tone fall time, the capacitors are essentially in series so the charge will try to equally distribute between $C_d$ and $C_{load}$. $C_{load}$ will discharge allowing current to flow to $C_d$ to match the falling voltage at the anode of the diode. You will have to choose a capacitor, $C_d$, that is large enough to absorb the $C_{load}$ discharging current and to minimize the voltage drop created during the minimum tone fall time specification, 5µs. A good choice would be to use a capacitor for $C_d$ that is 40 times the value of $C_{load}$.

Figure 13 shows the tone mode operation at the cathode of the protection diode in a zero load condition and the charging current between $C_d$ and $C_{load}$. Large current transients may occur from a fast $dV/dt$ created if a DC supply were connected to the output of the ISL6421A, therefore, to use the circuit in Figure 13, the DC supply would have to be limited to 1A maximum current during the $dV/dt$ voltage transient to fully protect the IC.

**Figure 12. DC BACK-BIAS PROTECTION CIRCUIT FOR ZERO LOAD CONDITION**

Component Selection Guidelines

The ISL6421AEVAL application schematics show the configuration for a single LNB power supply.

**TCAP Capacitor**

A capacitor connected to the TCAP pin sets the transition time from 13V to 18V. A 1µF minimum capacitor is recommended for smooth transition with reduced peak currents. Figure 14 shows the transition time versus capacitor value.

![Graph showing the relationship between TCAP capacitor value and output transition time.](image)

**Figure 14. TCAP Capacitor Value vs Output Transition Time**

The programmable output voltage rise and fall times can be set by an external capacitor. The output rise and fall times will be approximately 3400 times the TCAP value. For the recommended range of 0.47µF to 2.2µF, the rise and fall time would be 1.6ms to 7.6ms. Use of a 0.47µF capacitor insures the PWM will stay below its overcurrent threshold when charging a 120µF VSW filter cap during the worst case 13V to 19V transition. This feature only affects the turn-on and programmed voltage rise and fall times. Figure 15 shows the 13V to 18V transition with $TCAP = 1\mu F$.

![Graph showing the 13V to 18V transition.](image)

**Figure 15. 13V to 18V Transition**
Inductor
The ISL6421A operates with a 33µH standard inductor over the entire range of supply voltages and load currents. Choose an inductor that can handle at least the peak switch current without saturating, and ensure that the inductor has a low DCR (series resistance) to maximize efficiency. The inductor saturation current must be greater than the switch peak current,

\[ I_{\text{PEAK}} = \frac{V_{\text{SW(max)}}}{n \cdot V_{\text{IN(min)}}} \cdot I_{\text{OUT}} + \frac{V_{\text{IN(min)}}}{2L \cdot f_{\text{SW}}} \left( 1 - \frac{V_{\text{SW(max)}}}{V_{\text{SW(max)}}} \right) \]  
(EQ. 1)

where,
- L = Inductance, 33µH
- f_{SW} = PWM switching frequency, 220kHz Typical
- n = Efficiency, 92% at maximum load

Output Capacitors
The most important parameter for the output capacitors is effective series resistance (ESR). The output ripple is directly proportional to output capacitor ESR value.

A 68µF or less aluminum electrolytic output filter capacitor with ESR lower than 80mΩ in parallel with a 470nF ceramic capacitor is a good choice in most application conditions. The ceramic capacitor is necessary to reduce the high frequency switching noise.

A high output capacitance and low ESR will strongly reduce the output ripple voltage and output switching noise and will improve efficiency. Use the lowest possible ESR capacitor for best performance.

The maximum value output capacitor is restricted by transition time specifications between 13V to 18V. With a high output capacitor the boost circuit will need higher peak current from input supply to make transition from 13V to 18V in a given transition time as set by TCAP value. Figure 14 shows the TCAP capacitor value versus transition time. Use high TCAP capacitor value for high output capacitors to allow sufficient time to charge the output capacitors in maximum load conditions.

The capacitor’s voltage rating should be at least 35V, but higher voltage electrolytic capacitors generally have lower ESR numbers, and for this reason, to improve efficiency and output ripple, select a capacitor with higher voltage ratings.

Sense Resistor
The current sense resistor provides current loop feedback and sets the overcurrent limit for static current mode. This resistor value is calculated based on peak switch current per Equation 2,

\[ R_{\text{SC}} < \frac{V_{\text{SENSE}}}{I_{\text{PEAK}}} \]  
(EQ. 2)

where \( V_{\text{SENSE}} \) is 200mV typ. (See datasheet specification table) and \( I_{\text{PEAK}} \) is calculated from Equation 1. Make sure the Rsc value is always lower than the \( V_{\text{SENSE}}/I_{\text{PEAK}} \) ratio.

For the typical application conditions (VCC = 12V, IOUT (max) = 450mA) a 100mΩ Rsc value is a good choice.

If VIN < 10.5V the inductor peak current can be close to 2A, then, it is necessary to decrease the R_{SC} value.

See Table 4 for some suggested SMD resistor part numbers.

Layout Guidelines
Just like all switching power supplies, a proper PC board layout is very important for a single channel ISL6421A based power supply implementation. Protect sensitive analog grounds by using a star ground configuration. Also, minimize lead lengths to reduce stray capacitance, trace resistance, and radiated noise. Minimize ground noise by connecting PGND, the input bypass capacitor ground lead, and the output filter capacitor ground lead to a single point. Place bypass capacitors as close as possible to the BYP pin and PGND and the DC/DC output capacitor as close as possible to VSW.

Place the TCAP capacitor very close to the IC pins and use the shortest possible ground return path.
Thermal Design

During normal operation, the ISL6421A dissipates some power. The power dissipation of the output linear regulator dominates the total power dissipated in the ISL6421A. At the maximum rated output current, the voltage drop on the linear regulator leads to a total dissipated power that is about 1.2V*750mA = 0.9W. At 350mA maximum current, this power will be 1.2V*350mA = 0.42W. The heat needs to be removed with a heatsink to keep the junction temperature below the over-temperature threshold.

The simplest solution is to use a large, continuous copper area of the ground layer to dissipate the heat. This area can be the inner ground of multi-layered PCBs, or in a dual layer PCB, an unbroken ground area on the opposite side of the board where the IC is placed. In both cases, the thermal path between the IC ground pins and the dissipating copper area must exhibit a low thermal resistance.

Conclusion

The ISL6421A voltage regulator makes an ideal choice for advanced satellite set-top box and personal video recorder applications. The ISL6421AEVAL1Z is a complete reference design for providing power and control functions to the LNB in advanced satellite set-top box applications.

Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation or any other use of the circuits, software, and information in the design of your product or system. Renesas Electronics disclaims any and all liability for any losses and damages incurred by you or third parties arising from the use of these circuits, software, or information.

2. Renesas Electronics hereby expressly disclaims any warranty against and liability for infringement or any other claims involving patents, copyrights, or other intellectual property rights of third parties, by or arising from the use of Renesas Electronics products or technical information described in this document, including but not limited to, the product data, drawings, charts, programs, algorithms, and application examples.

3. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.

4. You shall not alter, modify, copy, or reverse engineer any Renesas Electronics product, whether in whole or in part. Renesas Electronics disclaims any and all liability for any losses or damages incurred by you or third parties arising from such alteration, modification, copying or reverse engineering.

5. Renesas Electronics products are classified according to the following two quality grades: “Standard” and “High Quality.” The intended applications for each Renesas Electronics product depends on the product’s quality grade, as indicated below.

   “Standard”: Computers, office equipment, communications equipment, test and measurement equipment, audio and visual equipment, home electronic appliances, machine tools, personal electronic equipment, industrial robots, etc.

   “High Quality”: Transportation equipment (automobiles, trains, ships, etc.); traffic control (traffic lights); large-scale communication equipment; key financial terminal systems; safety control equipment; etc.

   Unless expressly designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not intended or authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems; surgical implantations, etc.), or may cause serious property damage (space systems; undersea repeaters; nuclear power control systems; aircraft control systems; key plant systems; military equipment, etc.). Renesas Electronics disclaims any and all liability for any damages or losses incurred by you or any third parties arising from the use of any Renesas Electronics product that is inconsistent with any Renesas Electronics data sheet, user’s manual or other Renesas Electronics document.

6. When using Renesas Electronics products, refer to the latest product information (data sheets, user’s manuals, application notes, “General Notes for Handling and Using Semiconductor Devices” in the reliability handbook, etc.), and ensure that usage conditions are within the ranges specified by Renesas Electronics with respect to maximum ratings, operating power supply voltage range, heat dissipation characteristics, installation, etc. Renesas Electronics disclaims any and all liability for any malfunctions, failure or accident arising out of the use of Renesas Electronics products outside of such specified ranges.

7. Although Renesas Electronics endeavors to improve the quality and reliability of Renesas Electronics products, semiconductor products have specific characteristics, such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Unless designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not subject to radiation resistance design. You are responsible for implementing safety measures to guard against the possibility of bodily injury, injury or damage caused by fire, and/or danger to the public in the event of a failure or malfunction of Renesas Electronics products, such as safety design for hardware and software, including but not limited to, redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of micromachine semiconductor alone is very difficult and impractical, you are responsible for evaluating the safety of the final products or systems manufactured by you.

8. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. You are responsible for carefully and sufficiently investigating applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive, and using Renesas Electronics products in compliance with all these applicable laws and regulations. Renesas Electronics disclaims any and all liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.

9. Renesas Electronics products and technologies shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You shall comply with any applicable export control laws and regulations promulgated and administered by the governments of any countries asserting jurisdiction over the parties or transactions.

10. It is the responsibility of the buyer or distributor of Renesas Electronics products, or any other party who distributes, disposes of, or otherwise sells or transfers the product to a third party, to notify such third party in advance of the contents and conditions set forth in this document.

11. This document shall not be reprinted, reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.

12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products.

(Rev.4.0-1 November 2017)
