

Application Note

Automatic Air Freshener

AN-CM-316

Abstract

This application note describes the High Voltage GreenPAK IC configured as a control unit for an Automatic Air Freshener, reducing the number of external components and adding new features.

The application note comes complete with a design file that can be found in the Reference section.

Automatic Air Freshener

3 Introduction

This application note describes the SLG47105V High Voltage GreenPAK IC configured as a control unit for an Automatic Air Freshener, reducing the number of external components and adding a new function. According to SC Johnson, the manufacturer of Glade, the purpose of this spray is:

Glade® Automatic Spray **Figure 1** offers the confidence that your bathroom has freshness that won't disappear. The automatically time-released fragrance creates an environment that has more freshness, less worry. Whenever you need a controlled burst of fragrance, just use the boost button so that freshness lingers, but odors don't. (Source: <https://www.glade.com/en/products/sprays/automatic-spray>)

Figure 1: Automatic Air Freshener

The device can be set to spray every 9, 18, or 36 minutes, or users can spray at will by pushing the Boost button. **Figure 2** shows the original printed circuit board (PCB) containing 1 IC, 8 resistors, 4 capacitors, 1 diode, and an H-bridge built of 4 MOSFET transistors. This application note offers an alternative design that reduces the component count down to 1 IC, 1 resistor, and 1 capacitor, reducing cost and simplifying the design. It also offers the possibility to connect a passive infrared

Automatic Air Freshener

(PIR) motion sensor as a trigger. In this case, the device will spray only when motion is detected with an interval of no less than 9, 18, or 36 minutes.

In the original design, the time delay for the motor is 1 second. However, the motor speed is voltage-dependent and usually takes less than 1 second to spray. In this case, the motor will be mechanically forced to stop, causing a huge current through the H-Bridge. That requires the use of much more powerful transistors, increasing the overall cost of the device and significantly reducing battery life. These issues do not exist in the proposed design, thanks to current protection.

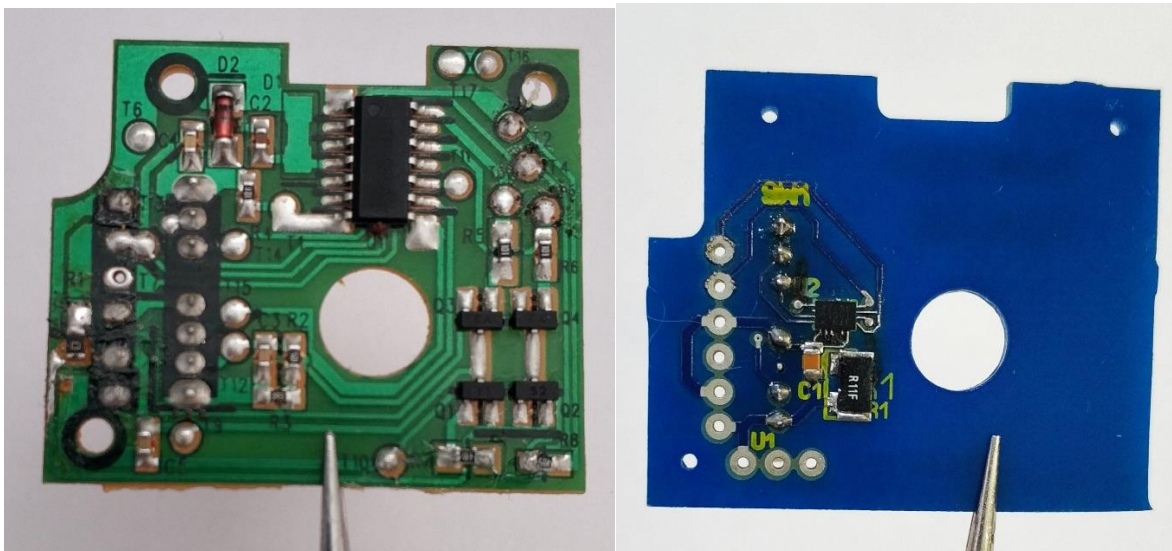

Figure 2: Original PCB (left) and Modified PCB (right)

4 Schematic Diagram and Design

In this design, the SLG47105V works below the specification. The device is powered from two AA size batteries connected in series, providing 3 V when fresh and 2.5 V when the batteries are low. The SLG47105V's high voltage performance is guaranteed down to only 3 V, but in this design the output current is no higher than 240 mA (guaranteed by current protection) and the two H-Bridges are connected in parallel. This allows us to reduce the H-Bridge output resistance and therefore the device can easily operate below 3 V.

The schematic diagram can be found in [Figure 3](#). For the HV GreenPAK design refer to [Figure 4](#).

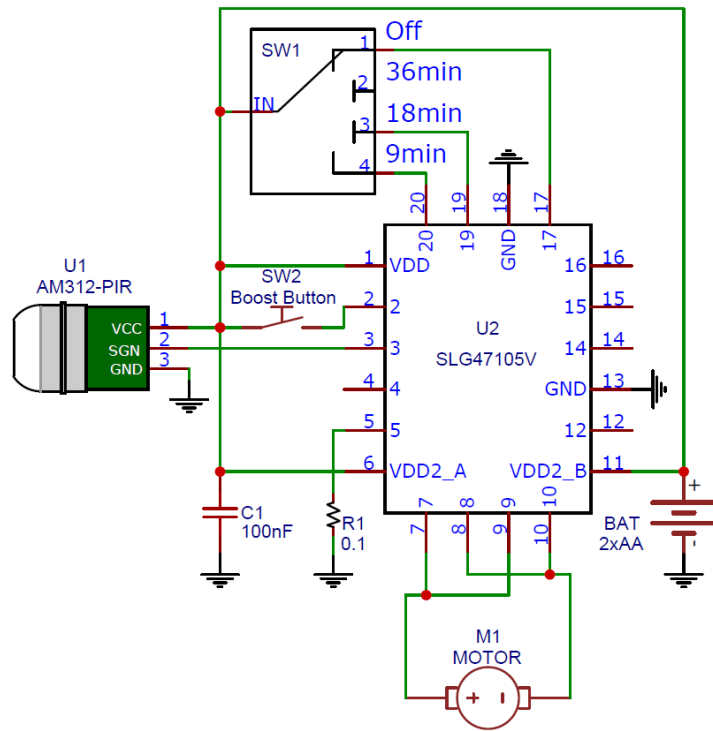

Figure 3: Schematic Diagram

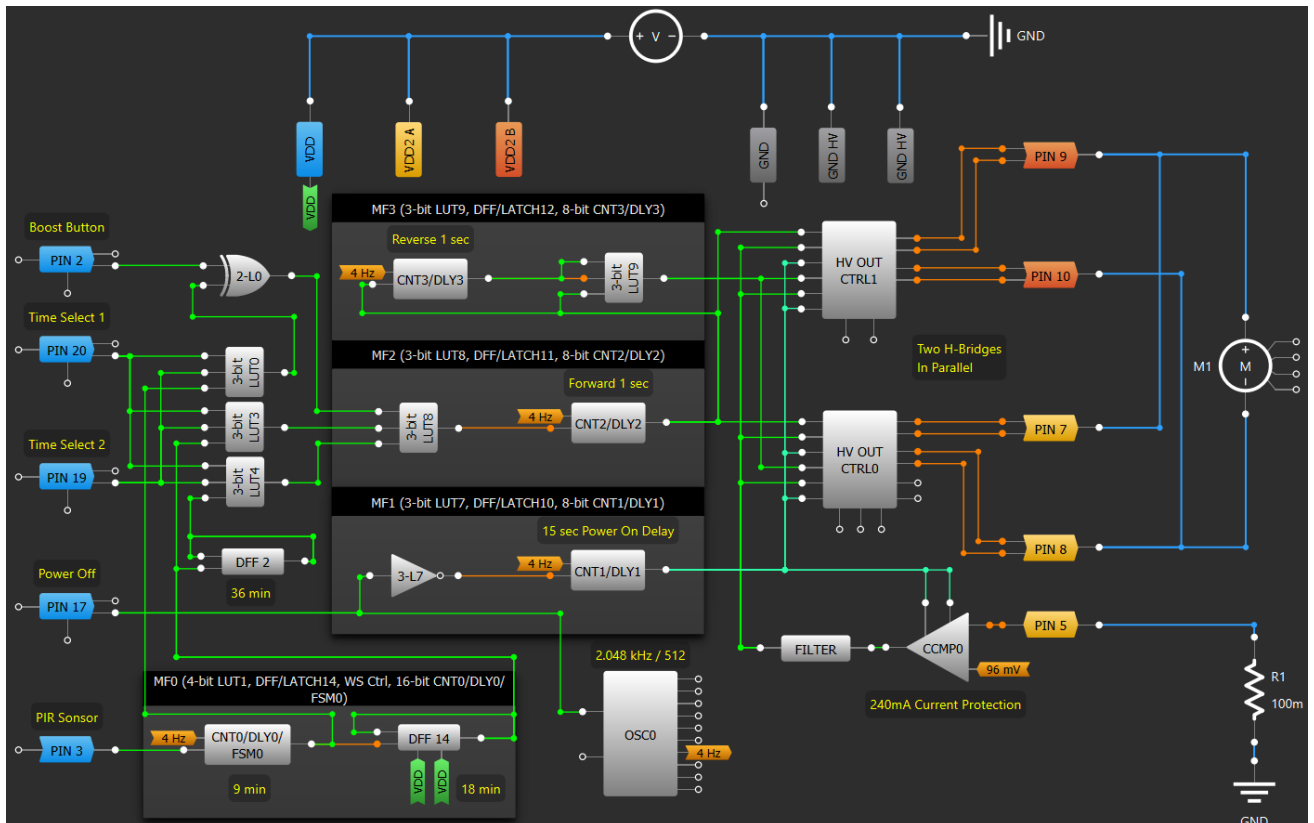

Figure 4: GreenPAK Designer Project

Automatic Air Freshener

**Figure 5: Prototype**

The design has five control inputs and one analog input for the current sensor:

- PIN#2 – Boost button, allows spraying at will despite the set time delay
- PIN#3 – PIR sensor input
- PIN#5 – current sensor input
- PIN#17 – power control; off when HIGH, on when LOW
- PIN#19 – time select 2
- PIN#20 – time select 1

For PIN configuration refer to [Table 1](#).

4.1 Design Operation

The CNT0/DLY0/FSM0 macrocell (part of MF0) provides a 9 minute time delay. It can be configured as a Counter/FSM for periodic spray, or as a One Shot when using a PIR sensor as a trigger (see the [Macrocell Configuration](#) subsection). DFF 14 (part of MF0) and DFF 2 are configured as frequency dividers (divide by 2), thus providing two more time intervals of 18 and 36 minutes respectively.

The 3-bit LUTs 0, 3, 4, and 8 (part of MF2), along with the 2-bit LUT0 serve to decode the position of the four-way switch SW1, allowing us to power on the device and choose the desired time delay as well as to bypass the delay by pressing the Boost button SW2.

Automatic Air Freshener

CNT1/DLY1, along with the 3-bit LUT7 (both part of MF1), are designed to delay power on by 15 seconds, preventing spraying at the user right after the device is powered on.

CNT2/DLY2 (part of MF2) is set to One Shot, which turns on the motor via HV OUT for 1 second. That causes the device to spray. Then CNT3/DLY3 (part of MF3) gives a signal to reverse the motor (also for 1 second via HV OUT), setting the device into the initial position.

In this design, both HV OUTs work in parallel, and their output pins must be externally connected: PIN9 to PIN7 and PIN10 to PIN8.

CCMP0 is used to protect the output stage from current higher than 240 mA.

The FILTER is added after CCMP0 to filter out spikes and ripples that may appear while sensing high currents.

The 1-second delay for the motor to go forward and 1 second to reverse is designed for low battery operation. When the batteries are fresh, it takes less than 1 second to spray and go back to the initial position. In this case, the motor will be blocked mechanically and the current consumption will rise significantly. This may damage the output stage. However, the designed current protection will prevent this from happening and prolong battery life.

All time-dependent microcells are clocked from a single oscillator at 2.048 kHz divided by 512.

4.2 Macrocell Configuration

Table 1: PIN Settings

Properties	PIN 2	PIN 3, 17, 19, and 20	PIN 5	PIN 7, 8, 9 and 10
I/O selection	Digital input	Digital input	Analog input/output	Digital output
Input mode OE=0	Digital in with Schmitt trigger	Digital in with Schmitt trigger	Analog input/output	None
Output mode OE=1	None	None	Analog input/output	HIGH and LOW side on
Resistor	10k	1M	Floating	--
Resistor value	Pull Down	Pull Down	Floating	--
OCP deglitch time enable	--	--	--	Without deglitch time
Control delay of OCP retry	--	--	--	Delay 492 μ s

VREF source selection	Static from registers
IN- source	96 mV

Table 8: HV Output Settings

Properties	HV OUT CTRL0	HV OUT CTRL1
Slew rate	Slow for motor drive	Slow for motor drive
HV OUT mode	Half-bridge	Half-bridge
Mode control	IN-IN	IN-IN
Thermal shutdown	Enable	None

5 Conclusions

This app note shows how easy it is to design an improved and lower cost version of the control unit used in automatic air fresheners by using the SLG47105 High Voltage GreenPAK. Lower costs are achieved by reducing the external component count, and adding a current sensor prolongs battery life and protects the device from overcurrent and short circuit at the output. In addition, adding a trigger (whether it's a PIR motion sensor, simple switch, or any other external device) improves the device operation by preventing spraying when no one is around, thus saving battery and conserving the spray liquid.
