To our customers,

Old Company Name in Catalogs and Other Documents

On April 1st, 2010, NEC Electronics Corporation merged with Renesas Technology Corporation, and Renesas Electronics Corporation took over all the business of both companies. Therefore, although the old company name remains in this document, it is a valid Renesas Electronics document. We appreciate your understanding.

Renesas Electronics website: http://www.renesas.com

April 1st, 2010
Renesas Electronics Corporation

Issued by: Renesas Electronics Corporation (http://www.renesas.com)
Send any inquiries to http://www.renesas.com/inquiry.
**Notice**

1. All information included in this document is current as of the date this document is issued. Such information, however, is subject to change without any prior notice. Before purchasing or using any Renesas Electronics products listed herein, please confirm the latest product information with a Renesas Electronics sales office. Also, please pay regular and careful attention to additional and different information to be disclosed by Renesas Electronics such as that disclosed through our website.

2. Renesas Electronics does not assume any liability for infringement of patents, copyrights, or other intellectual property rights of third parties by or arising from the use of Renesas Electronics products or technical information described in this document. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.

3. You should not alter, modify, copy, or otherwise misappropriate any Renesas Electronics product, whether in whole or in part.

4. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation of these circuits, software, and information in the design of your equipment. Renesas Electronics assumes no responsibility for any losses incurred by you or third parties arising from the use of these circuits, software, or information.

5. When exporting the products or technology described in this document, you should comply with the applicable export control laws and regulations and follow the procedures required by such laws and regulations. You should not use Renesas Electronics products or the technology described in this document for any purpose relating to military applications or use by the military, including but not limited to the development of weapons of mass destruction. Renesas Electronics products and technology may not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations.

6. Renesas Electronics has used reasonable care in preparing the information included in this document, but Renesas Electronics does not warrant that such information is error free. Renesas Electronics assumes no liability whatsoever for any damages incurred by you resulting from errors in or omissions from the information included herein.

7. Renesas Electronics products are classified according to the following three quality grades: “Standard”, “High Quality”, and “Specific”. The recommended applications for each Renesas Electronics product depend on the product’s quality grade, as indicated below. You must check the quality grade of each Renesas Electronics product before using it in a particular application. You may not use any Renesas Electronics product for any application categorized as “Specific” without the prior written consent of Renesas Electronics. Further, you may not use any Renesas Electronics product for any application for which it is not intended without the prior written consent of Renesas Electronics. Renesas Electronics shall not be in any way liable for any damages or losses incurred by you or third parties arising from the use of any Renesas Electronics product for an application categorized as “Specific” or for which the product is not intended where you have failed to obtain the prior written consent of Renesas Electronics. The quality grade of each Renesas Electronics product is “Standard” unless otherwise expressly specified in a Renesas Electronics data sheets or data books, etc.

   - **“Standard”**: Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; and industrial robots.
   - **“High Quality”**: Transportation equipment (automobiles, trains, ships, etc.); traffic control systems; anti-disaster systems; anti-crime systems; safety equipment; and medical equipment not specifically designed for life support.
   - **“Specific”**: Aircraft; aerospace equipment; submersible repeaters; nuclear reactor control systems; medical equipment or systems for life support (e.g. artificial life support devices or systems), surgical implantations, or healthcare intervention (e.g. excision, etc.), and any other applications or purposes that pose a direct threat to human life.

8. You should use the Renesas Electronics products described in this document within the range specified by Renesas Electronics, especially with respect to the maximum rating, operating supply voltage range, movement power voltage range, heat radiation characteristics, installation and other product characteristics. Renesas Electronics shall have no liability for malfunctions or damages arising out of the use of Renesas Electronics products beyond such specified ranges.

9. Although Renesas Electronics endeavors to improve the quality and reliability of its products, semiconductor products have specific characteristics such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Further, Renesas Electronics products are not subject to radiation resistance design. Please be sure to implement safety measures to guard them against the possibility of physical injury, and injury or damage caused by fire in the event of the failure of a Renesas Electronics product, such as safety design for hardware and software including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult, please evaluate the safety of the final products or system manufactured by you.

10. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. Please use Renesas Electronics products in compliance with all applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive. Renesas Electronics assumes no liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.

11. This document may not be reproduced or duplicated, in any form, in whole or in part, without prior written consent of Renesas Electronics.

12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products, or if you have any other inquiries.

**(Note 1)** “Renesas Electronics” as used in this document means Renesas Electronics Corporation and also includes its majority-owned subsidiaries.

**(Note 2)** “Renesas Electronics product(s)” means any product developed or manufactured by or for Renesas Electronics.
H8/300L SLP Series
Implementation of I²C (Port) to Three I²C Devices (3I2Cport)

Introduction
This application note provides an overview of the I²C bus interface. It also demonstrates how to integrate and interface multiple I²C devices to the H8/38024 SLP series through software control of its two general I/O pins:

- Microchip 24AA16 16-Kbytes I²C Serial EEPROM (read/write)
- Maxim MAX6626 12-bit Temperature Sensor (read/write)
- MAX6953EPL 2-wire Interfaced 4-digit 5 × 7 Matrix LED Display Driver (write only)

Target Device
H8/38024

1. I²C™ Interface Overview

The I²C bus uses a two-wire interface consisting of a serial data line (SDA) and a serial clock line (SCL) to exchange information between devices connected to the bus. Each device on the bus has its own unique address and can operate as a transmitter or receiver (depending on its particular function). Devices are further categorized as masters or slaves. A master is defined as a device that initiates, controls (generates all framing and clock signals), and terminates a transfer whereas a slave is any device addressed by the master.

It is noted that different I²C devices will have slightly different protocols. This application note describes an I²C interface comprising of a bus master (the H8/38024 SLP MCU) and three slave devices (Microchip 24AA16 16-Kbytes I²C Serial EEPROM, Maxim MAX6626 12-bit temperature sensor and MAX6953EPL 2-wire interfaced 4-digit 5 × 7 Matrix LED Display Driver). In this simple interface, the temperature converted from the MAX6626 will be displayed and can also be stored in the EEPROM. Note that the I²C interface is simulated using software to control two general I/O pins (P70 → SDA & P80 → SCL) of the H8/38024 SLP MCU. The SDA and SCL pins of these devices are directly connected to P70 and P80 of the MCU respectively. Figure 1 shows the system block diagram.

![System Block Diagram](image)

The address of each device is summarized in table 1 (This discussion is limited to the I²C 7-bit addressing mode). Each device has a unique 7-bit I²C address so that the master knows which device it is communicating with. Typically, the upper address lines are fixed while the lower address lines are set by hardware. For the case of three lower address lines (A2, A1, A0), there are up to eight different combinations. Therefore, up to a maximum of eight identical devices can be interfaced on the same bus. To interface another I²C device, the SDA and SCL pins must be connected to the bus with a unique address assigned to it.

The features of these three slave devices and the software description together with the hardware design will be covered in the following sections.
2. Microchip 24AA16 E²PROM

The diagram below will illustrate the read data when 0x0D (RETURN) is send at various baud rates.

![Block Diagram](image)

**Figure 2 Microchip 24AA16 E²PROM Block Diagram**

2.1 Bus Protocol

Transferring data on the I²C bus is controlled (and framed) via two unique bus states generated by the bus master. These bus states are the start and stop bit conditions. When the bus is free, both lines are high.

The start condition is defined the high-to-low level transition on the SDA while the SCL line is high. The stop condition is defined as the low-to-high level transition on the SDA while the SCL line is high. Data must always be valid (stable) on the SDA line while the SCL is high. The SDA line is only allowed to change during the low period of SCL. One data bit is transmitted per the SCL clock pulse.

Following the start condition, the first 8 bit (1 byte) sent in a bus message is a 7-bit slave address field along with a data direction or R/W bit. The data direction bit (the least significant bit) controls whether the master transmits (0 = write) or receives (1 = read) data from the addressed slave.

The acknowledge bit is a low-level signal placed on the SDA line by the receiving device (master or slave) during the master-transmitted acknowledge clock pulse (the ninth high SCL clock pulse of the byte transmission). If the slave is busy and unable to receive data or the master needs to signal the end of data transfer, a non-acknowledge is sent (the SDA is high during the ninth high SCL clock pulse time).

Following the start and slave address transmission, data is exchanged between the master and receiver as required. Upon exchange of the final byte and its acknowledge, the master issues the stop condition to end bus usage.
2.1.1 Device Addressing

A control byte is the first byte received following the start condition from the master device. For the 24AA16, the first four bits of the control code are set to 1010 binary for both read and write operations. The next three bits are the block select bits (B2, B1, B0), used by the master device to select which 256-word block of memory to be accessed. These bits are in effect the three most significant bits of the word address. It should be noted that the protocol limits the size of the memory to eight blocks of 256 words; therefore the protocol can support only one 24AA16 per system. The last bit of the control byte defines the operation to be performed. When setting to ‘1’, a read operation is selected. When setting to ‘0’, a write operation is selected. Following the start condition, the 24AA16 monitors the SDA bus to check the device type identifier being transmitted. Upon reception of the 1010 code, the slave device outputs an acknowledge signal on the SDA line. Depending on the state of the R/W bit, the 24AA16 will select the read or write operation.

2.1.2 Bit Transfer and Data Validity

The number of data bytes, transferred from the transmitter to the receiver between the start and stop conditions, is determined by the master. Each byte (eight bits) is transferred serially with the most significant bit first followed by an acknowledge bit. The state of the data line represents valid data when, after the start condition, the data line is stable for the duration of the high period of the clock signal. The data on the line must be changed during the low period of the clock signal. There is one clock pulse per bit of data.
2.1.3 Acknowledge
Each receiving device, when addressed, is obliged to generate acknowledge after the reception of each byte. The master device must generate an extra clock pulse associated with this acknowledge bit. For the 24AA16, it does not generate any acknowledge bits if an internal programming cycle is in progress.

2.2 Write Operation
Write operations are initiated when the R/W bit of the slave address is set to ‘0’. There are two types of write operations, byte and page writes.

2.2.1 Byte Write
Byte operations allow a random EEPROM address to be written. Byte-write operations require the following transmissions:
- Start condition (Master)
- EEPROM device address with R/W = 0 (master)
- Acknowledge bit (EEPROM)
- Target EEPROM word address to be written (master)
- Acknowledge bit (EEPROM)
- Data byte to be written (master)
- Acknowledge bit (EEPROM)
- Stop condition (master)

![Figure 5 Byte Write](image)

2.2.2 Page Write
Page write operations allow up to 16 bytes to be written to the EEPROM. During these page writes, the EEPROM automatically increments its internal address pointer between bytes.

![Figure 6 Page Write](image)
2.3 Read Operation

Three types of read operations are supported: Current address, random, and sequential read. Read operations begin just like write operations, except that the R/W bit is set to 1 for the device address byte.

2.3.1 Current Address Read

In the current address read mode, the data is read from the location of the most recent access. This read transmission type sequence appears as follows:

- Start condition (master)
- EEPROM device address with R/W = 1 (master)
- Acknowledge bit (EEPROM)
- Data byte to be read (EEPROM bytes sent from the addressed slave’s most recent pointed-to memory location incremented by 1)
- Non-acknowledge bit (master)
- Stop condition (master)

![Figure 7 Current Address Read](image)

2.3.2 Random Read

The random read mode is begun with a dummy byte write cycle (the master sends a start condition followed by the device address and target word address) followed by the current address read mode cycle as described previously.

![Figure 8 Random Read](image)
2.3.3 Sequential Read

The sequential read mode is initiated with a random read. Instead of the master terminating the read after a single byte exchange (with non-acknowledge), the master responds with valid acknowledge after each received data byte. The acknowledge instructs the slave EEPROM to continue the read operation and transmit out the next data byte. The sequential reads continue until terminated by the master via issuance of non-acknowledge on the most recent byte read followed by the stop condition.

![Figure 9 Sequential Read](image-url)
3. **I²C Temperature Sensor**

The MAX6626 comprises a temperature sensor, programmable over-temperature alarm, and an I²C-compatible serial interface. The temperature of the die is converted into digital values using the internal A/D converter. The converted result is stored in a temperature register, which is readable at any time through the serial interface. A dedicated alarm output (OT) is activated if the conversion result exceeds the value in the programmable high-temperature register. It also comes with a programmable fault queue, which sets the number of faults that must occur, before the alarm activates. This prevents spurious alarms in noisy environments. The device functions as a slave and supports byte/word-read/write commands. The functional block diagram is shown in figure 10.

![Figure 10 Block Diagram of Temperature Sensor](image)

### 3.1 Addressing

Four separate addresses can be configured with the ADD pin, allowing up to four MAX6626s to be connected on the same bus. The table summarizes the different address selection. In this interface, the ADD pin is connected to GND and the address is set to 90 (hexadecimal).

<table>
<thead>

Figures 12 and 13 show the timing diagrams for a read from and write to the configuration register respectively.

**Figure 12 Read from Configuration Register**

**Figure 13 Write to Configuration Register**

(1) The **High-Temperature** (T\text{HIGH}) register is a 9-bit read/write register which contains the value that triggers the over-temperature alarm. The **Low-Temperature** (T\text{LOW}) register is a 9-bit read/write register. It contains the value to which the temperature must fall before the over-temperature alarm is de-asserted in comparator mode. Refer to table 6 for the bit structure of these two registers. The timing diagrams for reading from and writing to are shown in figures 11 and 14 respectively.

Notes: 1. D15: MSB is the sign bit
2. D6 to D0: will read all zeros and cannot be written
3. LSB = 0.5°C
3.3 Temperature Conversion

An on-chip bandgap reference produces a signal proportional to absolute temperature (PTAT), as well as the temperature-stable reference voltage necessary for the A/D conversion. The resolution of the digitized PTAT signal is 0.0625°C with the rate of conversion at 133 ms. The temperature register contains the value of the most recently completed conversion.

3.4 Over-Temperature Alarm

The polarity and modes (interrupt and comparator) of the dedicated over-temperature output pin (OT) are programmable through the configuration register. The fault queue depth defines the alarm activity.

- The programmable fault queue eliminates spurious alarm activity in noisy environments by setting the number of consecutive out-of-tolerance temperature readings that must occur before the OT alarm is triggered. The out-of-tolerance refers to the temperature reading above \( T_{\text{HIGH}} \) or below \( T_{\text{LOW}} \).

- In the comparator mode, the OT is asserted when the number of consecutive conversions exceeding the value of the \( T_{\text{HIGH}} \) register is equal to the fault queue depth. The OT will be de-asserted when the number of consecutive conversions below \( T_{\text{LOW}} \) is equal to the fault queue depth. For example, \( T_{\text{HIGH}} \), \( T_{\text{LOW}} \), and the fault queue depth are set to +75°C, +50°C, and 4 respectively. The OT will not assert until four consecutive conversions exceed +75°C. Similarly, the OT will not be de-asserted until four consecutive conversions are below +50°C. The Comparator mode allows autonomous clearing of the OT fault without the intervention of master and is ideal for driving a cooling fan.

- In the interrupt mode, the OT pin asserts an alarm for the under-temperature fault as well as the over-temperature fault, depending on certain conditions. If the fault queue is cleared at power-up, the IC looks for a \( T_{\text{HIGH}} \) fault after which it will then monitor for a \( T_{\text{LOW}} \) fault. After the \( T_{\text{LOW}} \) fault, it will then monitor for the \( T_{\text{HIGH}} \) fault. This process will be repeated if the OT is properly de-asserted each time. Once either fault has occurred, it remains active until de-asserted by a read of any register. The device will then monitor for a fault of the opposite type. For example, \( T_{\text{HIGH}}, T_{\text{LOW}} \) and fault queue depth are set to +75°C, +50°C and 4 respectively. The OT will not assert until four consecutive conversions exceed +75°C. The OT will then de-assert upon reading the temperature register. The OT will then assert again after four consecutive conversions below +50°C.

3.5 Shutdown

In the shutdown mode, the temperature register is set to H'8000 and the A/D converter is turned off (reducing the device current to 1 \( \mu \)A). Upon exiting from shutdown, the value of the temperature register is H’8000 until the completion of the first temperature conversion.
4. **I²C 4-Digit 5 × 7 Matrix LED Display Driver**

The MAX6953 is a serially interfaced display driver that can drive four digits of $5 \times 7$ cathode-row dot-matrix displays. It includes an ASCII 104-character font, multiplex scan circuitry, column and row drivers, static RAM to store each digit as well as font data for 24 user-definable characters. The segment current for the LEDs is set by an internal digit-by-digit digital brightness control. It also features a low-power shutdown mode, segment blinking, and a test mode that forces all LEDs to be on. Figure 15 shows the functional block diagram for the LED driver.

![Figure 15 Block Diagram for the MAX6953](image)

#### 4.1 Serial Addressing

The MAX6953 operates as a slave that sends and receives data through an I²C-compatible 2-wire interface. The serial data (SDA) and clock (SCL) lines are used to achieve bi-directional communication between the master (the H8/38024) and the slave (the MAX6953). The master initiates all data transfers to and from the MAX6953, and also generates the SCL clock for the synchronization of data transfer.

#### 4.2 Start and Stop Conditions

Both the SCL and SDA remain high when the interface is not busy. The master signals the beginning of transmission with the start (S) condition by the high to low transition on the SDA while the SCL is high. When the master has finished communicating with the slave, it issues the stop (P) condition by the low to high transition on the SDA while the SCL is high. Another bus transmission can then begin.
4.3 Bit Transfer

One data bit is transferred during each clock pulse. The data on the SDA line must remain stable while the SCL is high.

4.4 Acknowledge

The acknowledge bit is a clocked 9th bit that the recipient uses to handshake receipt of each data byte. Refer to figure 18. Thus, each transferred byte effectively requires 9 bits. The master generates the 9th clock pulse, and the recipient pulls down the SDA such that the SDA line is stable low during the high period of the acknowledge clock pulse. When the master is transmitting to the MAX6953, the acknowledge bit is generated by the MAX6953. When the MAX6953 is transmitting to the master, the master generates the acknowledge bit because the master is the recipient.
4.5 Slave Address

The MAX6953 has a 7-bit slave address. The 8th bit following the 7-bit slave address is the R/W bit. It is low for a write command and high for a read command. The first 3 bits (A6, A5, & A4) of the MAX6953 slave address are always 101. The address input pins AD1 and AD0 determine the slave address bits A3, A2, A1, and A0. These two input pins can be connected to GND, V+, SDA or SCL. Table 7 lists all the possible connections for AD1 and AD0 and the correspondingly addresses assigned to the MAX6953. Note that addresses A0 to AE (hexadecimal) have already been assigned to the EEPROM, the address B0 is allocated to the MAX6953.

Figure 19 Slave Address
4.6 Writing Message Format

A write to the MAX6953 comprises the transmission of the slave address with the R/W set to zero followed by at least one byte of information. The first byte of information is the command byte, which determines the register to be written to by the next byte. If the stop condition is detected after the command byte is received, then no further action other than the storage of the command byte is taken (figure 20).

![Figure 20 Command Byte Received](image)

All bytes received after the command byte are data bytes. The first data byte goes into the internal register of the MAX6953 selected by the command byte (figure 21).

![Figure 21 Command and Single Data Byte Received](image)

If multiple data bytes are transmitted before the stop condition is detected, these bytes are generally stored in the subsequent MAX6953 internal registers because the command byte address generally auto-increments (refer to table 8 and figure 22).

![Figure 22 n Data Bytes Received](image)
### 4.7 Reading Message Format

The MAX6953 is read using the MAX6953’s internally stored command byte as an address pointer, the same way the stored command byte is used as an address pointer for a write. The pointer generally auto-increments after each data byte is read using the same rules described in table 8. Thus, the read is initiated by performing the write (figure 20). The master can now read n consecutive bytes from the MAX6953, with the first data byte being read from the register addressed by the initialized command byte (figure 22).

</tbody>
</table>

The MAX6953 is read using the MAX6953’s internally stored command byte as an address pointer, the same way the stored command byte is used as an address pointer for a write. The pointer generally auto-increments after each data byte is read using the same rules described in table 8. Thus, the read is initiated by performing the write (figure 20). The master can now read n consecutive bytes from the MAX6953, with the first data byte being read from the register addressed by the initialized command byte (figure 22).
5. Code Listing

The functions are listed in these two C source files:

- **I2C.c**
  - Contains the main function
  - Performs initialization of the Serial Communication Interface (SCI) and temperature sensor
  - Tests the EEPROM, temperature sensor, and the LED driver

- **RW.c**
  - Contains the general functions to emulate the SDA and SCL

The flowchart of the main function is shown in figure 23. The following steps are performed:

1. Initialization of the SCI (2400 bps, 1 stop bit, parity disabled), temperature sensor, and LED driver.
2. Test EEPROM: Perform byte write, byte read, page write, read from current, and sequential addresses. The test results are transmitted to the PC via the SCI.
3. Read temperature, transmit to PC via the SCI, and then display on digits 1, 2, and 3.
4. Display ‘0’ to ‘9’ on digit 0.
5. Repeat steps 2 to 4.

/****************************************************************************

Since Microchip devices such as 24AA16 will not acknowledge during
the internal write cycle, this can be used to determined when this
cycle is complete so that the master can proceed with next operation.

Acknowledge Polling
a. Send write command
b. Send stop condition to initiate write cycle
c. Send start bit
d. Send control byte with r/w_n = 0
e. If device acknowledge, goto f. Else go to c
f. Ready for next operation

Note that (c) to (e) - internal write cycle

Keep safety first in your circuit designs!

1. Renesas Technology Corp. puts the maximum effort into making semiconductor products better and more reliable, but there is always the possibility that trouble may occur with them. Trouble with semiconductors may lead to personal injury, fire or property damage. Remember to give due consideration to safety when making your circuit designs, with appropriate measures such as (i) placement of substitutive, auxiliary circuits, (ii) use of nonflammable material or (iii) prevention against any malfunction or mishap.

Notes regarding these materials

1. These materials are intended as a reference to assist our customers in the selection of the Renesas Technology Corp. product best suited to the customer's application; they do not convey any license under any intellectual property rights, or any other rights, belonging to Renesas Technology Corp. or a third party.

2. Renesas Technology Corp. assumes no responsibility for any damage, or infringement of any third-party's rights, originating in the use of any product data, diagrams, charts, programs, algorithms, or circuit application examples contained in these materials.

3. All information contained in these materials, including product data, diagrams, charts, programs and algorithms represents information on products at the time of publication of these materials, and are subject to change by Renesas Technology Corp. without notice due to product improvements or other reasons. It is therefore recommended that customers contact Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor for the latest product information before purchasing a product listed herein. The information described here may contain technical inaccuracies or typographical errors. Renesas Technology Corp. assumes no responsibility for any damage, liability, or other loss rising from these inaccuracies or errors. Please also pay attention to information published by Renesas Technology Corp. by various means, including the Renesas Technology Corp. Semiconductor home page (http://www.renesas.com).

4. When using any or all of the information contained in these materials, including product data, diagrams, charts, programs, and algorithms, please be sure to evaluate all information as a total system before making a final decision on the applicability of the information and products. Renesas Technology Corp. assumes no responsibility for any damage, liability or other loss resulting from the information contained herein.

5. Renesas Technology Corp. semiconductors are not designed or manufactured for use in a device or system that is used under circumstances in which human life is potentially at stake. Please contact Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor when considering the use of a product contained herein for any specific purposes, such as apparatus or systems for transportation, vehicular, medical, aerospace, nuclear, or undersea repeater use.

6. The prior written approval of Renesas Technology Corp. is necessary to reprint or reproduce in whole or in part these materials.

7. If these products or technologies are subject to the Japanese export control restrictions, they must be exported under a license from the Japanese government and cannot be imported into a country other than the approved destination. Any diversion or reexport contrary to the export control laws and regulations of Japan and/or the country of destination is prohibited.

8. Please contact Renesas Technology Corp. for further details on these materials or the products contained therein.
