Renesas RA Family

Securing Data at Rest Utilizing the Renesas Security MPU

Introduction

This application project discusses the considerations for securing Data at Rest in an embedded system and provides guidelines on how to use the Security MPU hardware feature of the RA Family MCUs to implement a secure Data at Rest solution. Securing Data at Rest refers to the features and services provided to protect sensitive data residing on a device which may or may not be modifiable. At the time of release of this Application Project, the group of RA Family MCUs that include the Security MPU are RA6M3, RA6M2, RA6M1, RA6T1, RA4M1, RA4W1, RA2L1, and RA2A1.

Note: In the following sections within this application note, “RA MCUs” refers to above mentioned MCU Groups.

RA MCUs offer data encryption, authentication schemes, and read/write and write-once access protection from CPU and bus masters for secure Data at Rest designs. In addition, RA MCUs provide security functions that disable control of certain security-related peripherals from non-secure software access.

For internal flash applications, this application project provides usage examples for sensitive data read protection, write protection, read/write protection, write-once protection, and write-once with read protection. For internal SRAM usage, this application project provides usage examples for read and write protection.

Upon completion of this guide, you will be able to use the secure Data at Rest features and solutions provided by RA MCUs in your own design, configure the secure components correctly for the target application, and write code using the included application example code as a reference. This guide provides a step-by-step operational flow for setting up the memory access features to efficiently use the security features of the RA MCU. More detailed hardware feature and API descriptions are available in the hardware user manual and the Flexible Software Package (FSP) User’s Manual (see References section).

Required Resources

Development tools and software

- The e² studio ISDE v2022-10
- Renesas Flex Software Package (FSP) v4.1.0
- SEGGER J-link® USB driver
  
  The above three software components: the FSP, J-Link USB drivers, and e² studio are bundled in a downloadable platform installer available on the FSP webpage at renesas.com/ra/fsp

Other tools

- SEGGER J-Link V7.80c or later (segger.com/downloads/jlink/)

Hardware

- EK-RA6M3, Evaluation Kit for RA6M3 MCU Group (renesas.com/ra/ek-ra6m3)
- Workstation running Windows® 10; the Tera Term console, or similar application
- Two USB device cables (type-A male to micro-B male)

Prerequisites and Intended Audience

This application project assumes you have some experience with the Renesas e² studio ISDE and FSP. Before you perform the procedures in this application note, follow the procedure in the EK-RA6M3 Quick Start Guide to build and run the Out of Box program. Doing so enables you to become familiar with e² studio and the FSP and validates that the debug connection to your board functions properly. In addition, this
application project assumes you have some knowledge on RA6M3 flash memory organization and customizing the e² studio linker script.

The intended audience are users who are interested in developing secure Data at Rest solutions with RA MCUs.

1. Secure Data Overview

With the expanse of AI, IoT, and Cloud connectivity, digital data security has become the number one priority when protecting trade secrets and personal privacy.

Secure data technology includes **Data in Transit** and **Data at Rest**. **Data in Transit**, or data in motion is data actively moving from one location to another, such as across the internet or through a private network. **Data in Transit protection** is the protection of data while it is traveling from network to network or being transferred from a local storage device to a cloud storage device. **Data at Rest** is data that is not actively moving from device to device or network to network, such as data stored on a hard drive, laptop, flash drive, embedded memory, or archived/stored in some other way. **Data at Rest protection** aims to secure inactive data stored on any device or network. This application project focuses on **Data at Rest design** in an embedded environment using an RA MCU.

**Data at Rest protection** uses **Data Encryption** and **Data Access Control** as major security measures. This application project provides detailed steps to establish the Write Once and Read/Write Access Control for an RA MCU as well as guidelines for applying these security features to a wide range of secure **Data at Rest** applications. Data Encryption is not covered in this release and may be provided in later releases.

When considering securing **Data at Rest**, one should consider the impact of using a secure boot solution to the overall application design.

1.1 Sensitive Data at Rest Topology

In an embedded system, secure data can reside in volatile data storage (MCU’s internal SRAM or external SDRAM) or non-volatile data storage (such as MCU’s internal flash storage, external QSPI storage, and external EEPROM storage.) As part of the application security design, one must consider the topology of the data based on its use case. As an example, in a medical device, some data (like blood pressure measured every 5 minutes) can be stored in volatile memory while other types of data (daily blood pressure averages) may need to be stored in non-volatile memory for future use. One should consider the nature of the data and therefore determine its topology before beginning the design as this decision will have an impact on securing the data.

With the first release of this application project, example code will be available to demonstrate how to secure data that resides in an internal SRAM or internal flash storage. The follow-on release of this application project will describe the methodology and provide sample projects to secure data in external storage (QSPI, EEPROM, and so forth.)

1.2 Data at Rest Security Measures

**Encryption** and **Access Control** are two of the main secure Data at Rest protection schemes that will be discussed in this application project. These two schemes apply to both volatile and non-volatile storage types including internal and external storage. With the first release of this application project, access control for internal storage (both volatile and non-volatile) will be covered with example projects.

1.2.1 Data Encryption

Data Encryption is widely used in both secure **Data at Rest** and **Data in Transit**.

Securing internal data through encryption is increasingly becoming a necessity for small Arm® Cortex MCUs, as these devices are used more in networking and communication applications. Secure Data at Rest almost always means the data is encrypted or certain protocols exist that include encryption to protect the data from unauthorized access. The SCE (Secure Crypto Engine) feature of RA MCUs are, for example, used to generate encrypted private keys.

An example use of encryption of Data at Rest is encryption of data in external storage. An embedded system could use an AES key to encrypt sensitive data and code that resides on the external storage. Upon successful authentication, the external code data can be decrypted and used.

1.2.2 Data Access Control

Increased demands for device connectivity as well as increased complexity in embedded systems result in more potential attack surfaces exposed. Controlled access to the secure data effectively reduces the attack surface, thus increasing system security. The following is a brief introduction to possible use cases where access controls provided in RA MCUs can be applied.
1.2.2.1 Read Protection
Sensitive data and code residing in flash and SRAM can have read protection properties set such that only software granted with read permission can access them. RA MCUs have a Security MPU, which can help establish sensitive regions with read protection.

- Section 2.2 introduces the Security MPU’s functionality.
- Section 3.2 provides the configuration methods for the Security MPU.
- Section 4.1 explains the operational flow of establishing read protection using the Security MPU.

1.2.2.2 Write Protection
It is important to protect sensitive data from being maliciously modified or erased. Volatile and non-volatile data can be write-protected to avoid unauthorized writes by using the memory options setting in RA MCUs.

There are two ways to establish flash write protection:
- The RA MCU Security MPU can disable the flash erase and write access from non-secure software access. See section 2.2 for details.
- The RA MCU Flash Access Window (FAW) can protect sensitive flash data from being modified by secure and non-secure software.
  — Section 2.3 introduces the FAW functionality.
  — Section 3.3 provides the configuration methods for the FAW.
  — Section 4.2 explains the operational flow of establishing write protection using the FAW.

1.2.2.3 Read/Write Protection
Read/write protection reduces the attack surface from malware and IP theft. For internal flash data, similar to write protection, there are two ways RA MCUs can provide read/write protection:

- The RA Security MPU can disable read and write access to the security MPU flash and SRAM regions from non-secure software.
- When the Security MPU and FAW are used together, the sensitive data in flash can be read and write protected from both secure and non-secure software. An example project for this use case is provided in this release.
  — Section 4.3 explains the operational flow of establishing read and write protection using the Security MPU and FAW.

1.2.2.4 Write-Once Protection
In some use cases, sensitive Data at Rest needs to be protected from access or alteration for the lifetime of the device. For example, a secure bootloader must be immutable for the lifetime of the product. For use cases where the data resides on internal flash, FAW settings can be programmed to provide write-once protection.

It is important to note the implication of using a secure boot manager in your design. If your end application uses a secure bootloader, then special consideration must be taken to include the write-once data memory regions for the application with the regions that the secure bootloader reserves for its own. This must be done because setting the Flash Access Window (FAW) properties to implement the write once policy can only be done once for the lifetime of the device. In other words, once the FAW policies are programmed, they cannot be changed.

- Section 4.4 explains the operational flow of establishing write-once secure data and program usage.

1.2.2.5 Write-Once and Read Protection
Write-once protected data can be optionally read protected. When handling sensitive data, read protection can be provided to the write-once protected flash data such that only secure software can read the contents. For RA MCUs, this is realized by using both the Security MPU and FAW.

- Section 4.5 explains the operational flow of establishing write-once and read protection for RA MCUs.
1.3 Data at Rest Risk Profile and Attack Surface Analysis

To fully consider and design for secure Data at Rest in an embedded environment, one should thoroughly consider the following topics:

1. Consider who will have access to the sensitive data in the embedded system.
2. Consider if the CPU bus can access the sensitive data.
3. Consider if other bus masters can access the sensitive data. If so, determine which peripheral the bus master connects to, and what entity this peripheral communicates with.
4. Consider if the debugger can access the sensitive data.
5. Consider the robustness of the application design such that there are measures taken against the application itself to accidently damage the sensitive data by overwriting the security policies and measures in place.

Reducing the attack surface helps in all of the above situations. Securing the entire MCU’s memory may not effectively enhance the overall data security, since a larger attack surface translates to a higher chance that hackers will find a weak point. A good guideline for securing sensitive data is to design the application such that only the minimum amount of data is secured, and access is controlled through strategic interfaces.

The analysis of a system’s risk profile and attack surface is outside of the scope of this application note; however, the security measures offered by RA MCUs will be introduced to help in reducing the attack surface and minimizing the system’s risk profile.

1.4 Secure Data at Rest with and without Secure Bootloader

Whether your system will or will not use a secure bootloader solution will have an impact on how to implement secure Data at Rest.

As mentioned before in section 1.2.2 Data Access Control, there may be a need for the application to protect sensitive data for the lifetime of the device and a secure boot manager is being used. In this case, one must consider the setting of FAW (Flash Access Window) properties appropriately to ensure that the application-specific sensitive data can be allocated in the region unmodifiable by FAW and programmed onto the MCU at the same time the secure boot manager is programmed during the manufacturing provisioning process. In addition, if the application must protect sensitive data with read protection only, the Security MPU region needs to be appropriately considered to ensure that the application-specific read-protected sensitive data can be allocated within the Security MPU region.

It is worth noting that RA MCUs allocate the Security MPU setting in the first block of the user flash (which is a block of 8 KB flash). As a result, if there is a need to permanently lock the Security MPU settings, the first 8 KB of internal flash needs to be part of the write-once flash region.

2. RA MCU Features for Secure Data at Rest

RA MCUs provide a rich set of hardware features to address secure Data at Rest needs. From a high level, RA MCUs support the following data protection features:

- Write Once access control for internal flash
- Read/write access control for internal flash
- Read/write access control for internal SRAM
- Data access protection from bus masters and debuggers
- Hardware data encryption support for both volatile and non-volatile, internal and external storage
- Security functions to disable certain peripherals from being accessed by a non-secure program

This chapter will introduce the hardware features that can support the above security features without getting into the operational details. Details on the configurations of these hardware components are provided in section 3.

Integration of the MCU internal data access control with encryption support for external data provides a consistent level of security support for the entire embedded system.
2.1 Overview of RA MCU Security Elements

Following is a list of security elements on the RA MCUs:

- Security MPU
- Flash Access Window (FAW)
- Secure Crypto Engine (SCE)
- Debug Protection with OSIS

Table 1 summarizes the availability of the secure elements on the RA MCUs.

**Note:** * Refer to section 2.6.1 for details on the SCE support for RA MCU families. The RA2A1 MCU hardware user manual named the Security and Encryption hardware block differently compared with the other MCUs.

This section also explains how the Arm® MPU, bus master MPU, and bus slave MPU operation relate to Data at Rest from a high level.

2.2 Security MPU

The Security MPU feature of RA MCUs implements a set of versatile data security policies by creating isolation between different software and hardware components. Identification of secure and non-secure program and data is based on address location.

The Security MPU settings are read and applied before the reset vector is fetched, and therefore take effect before any code is executed.

2.2.1 Secure Data Regions

Figure 1 describes the available secure data regions and secure program regions provided by the Security MPU. Each region is defined by a pair of start and end addresses and an enable bit.

![Figure 1. Security MPU Secure Regions](image-url)
The Security MPU provides four secure data regions, as shown in Figure 1.

- One secure flash data region (located in the MCU’s code flash region). Note that in terms of Security MPU usage, the secure flash data region can contain both secure flash data and secure flash program.

- One secure SRAM data region. Note that in terms of Security MPU usage, secure SRAM data region can contain both secure SRAM data and secure SRAM program.

- Two security function regions:
  - Security function region for the SCE (Secure Crypto Engine): address 0x400C0000 to 0x400DFFFF
    - This region maps to the RA MCU’s internal peripheral bus 7.
    - When this security function is enabled, the SCE cannot be controlled from a non-secure program.
  - Security function for the flash (code and data) erase and program (E/P): address 0x40100000 to 0x407FFFFF
    - This region maps to the RA MCU’s internal peripheral bus 9.
    - When this security function is enabled, the flash cannot be put in erase and program mode from a non-secure program.
    - Note that this security function does not control TSN even though it is in the same memory space.
2.2.1.1 Secure Program

The Security MPU provides two secure program regions, each defined by a pair of start and end Program Counter (PC) addresses and an enable bit. There can be one secure flash program region and one secure SRAM program region. For security purpose, it is recommended that the secure program regions are located within the secure flash and secure SRAM data region respectively as shown in Figure 1.

Note: The secure program region can reside outside of the secure flash and secure SRAM region; however, in this case, there is a security hole. The secure program in Flash and SRAM can be read by non-secure software.

Non-secure program and secure program can make function calls into each secure and non-secure region, which provides efficiency in embedded system design.

2.2.1.2 Secure Access Monitor and Protection

- The Security MPU monitors and protects secure flash and secure SRAM data regions (Region 0 and Region 1) from unauthorized CPU read from the D Code bus (Data access), as shown in Figure 5. The I Code bus (Instruction access) is not monitored. This allows secure instructions to be accessed by the non-secure program.
- The Security MPU monitors and protects secure SRAM data and security function regions from system bus access (such as debugger access), as shown in Figure 5.
- The Security MPU monitors and protects all four secure data regions from access from the three bus master groups. See the hardware user’s manual for definition of the bus master groups.

Figure 5. Data Protection for Security MPU Regions

The table in Figure 6 describes the details of CPU access and debugger access to the secure and non-secure regions.

- ✔️ indicates that the bus master on the left is granted access to the region on the top
- ✗ indicates that the bus master on the left is not granted access to the region on the top

Note: The secure program located in the SRAM region other than the SRAMHS region cannot be fetched by a non-secure program as marked by the red box shown in Figure 6.

Configuration details of the Security MPU are described in section 3.2.

![Figure 6. CPU and Debugger Access Summary](image-url)
2.3 Flash Access Window (FAW)

The Flash Access Window (FAW) defines one contiguous flash region within the MCU flash space. Within this region, the flash erase and write operation is allowed from both secure and non-secure program. The access window is only valid in the program flash area. The access window provides protection in self-programming mode, serial programming mode, and on-chip debug mode.

The FAW region setting uses flash block boundaries as the start and end addresses of the flash access window. There is one bit (FSPR) in the FAW control register that, when cleared, disables any possible update to the flash access window setting for the lifetime of the device. The internal flash write-once protection uses this bit to implement the write-once protection.

Refer to section 3.3 for configuration details on the FAW.

2.3.1 Using the Security MPU and FAW for Code Flash Write Protection

As explained in section 1.2.2, there are two ways to establish flash region write protection. In this application project, the FAW is used to establish flash write protection. Figure 8 summarizes the code flash read, erase, and programming access control when the Security MPU is used in conjunction with the FAW, and the security function is not enabled.
Case A: Flash Erase/Program Security function not enabled. FAW enabled and but not locked down.

- Flash can never be erased and reprogrammed by secure and non-secure program unless FAW region is cleared
- Flash can be read by secure and non-secure program
- Flash can be read and written by secure and non-secure program
- FAW region: Flash can be erased and reprogrammed by secure and non-secure program
- Flash cannot be erased and reprogrammed by secure and non-secure program unless FAW region is cleared

Secure flash data region: Flash can be read by secure program only

Case B: Flash Erase/Program Security function not enabled. FAW enabled and locked down.

- Flash can never be erased and reprogrammed by secure and non-secure program
- Flash can be read by secure and non-secure program
- Flash can be read and written by secure and non-secure program
- FAW region: Flash can be erased and reprogrammed by secure and non-secure program
- Flash can never be erased and reprogrammed by secure and non-secure program

Secure flash data region: Flash can be read by secure program only

Case C: Flash Erase/Program Security function not enabled. No FAW region established.

- Flash can be read and written by secure and non-secure program
- Flash can be read by secure program only
- Flash can be erased and reprogrammed by secure and non-secure program

Secure flash Data region

Figure 8. Code Flash Read, Erase, and Program Control when Security Function is not Enabled
2.4 Debugging Security Considerations
The RA MCUs provide OCD/serial programmer ID code protection with the OSIS register. The OSIS register stores the ID for ID code protection of the OCD/serial programmer. Once the OSIS register ID code is set for the MCU, the user must provide the matching ID code when connecting an OCD/serial programmer. If the ID code matches, debugging is allowed; otherwise, the debugging process is not allowed. Configuration of the OSIS ID code protection is described in section 3.5.

2.5 Notes on Arm MPU, Bus Master MPU, Bus Slave MPU
This section explains how the MPU, Bus Master MPU, and Bus Slave MPU relate to Data at Rest design. Refer to the Arm® Cortex technical user manual to understand the definition and settings of the Arm MPU. Refer to RA MCUs hardware user’s manuals to understand the definition and settings of the Bus Master and Bus Slave MPUs.

While these three MPUs intend to catch inadvertent accesses to the regions defined by these MPUs, they do not provide protection of reading and updating the register settings from non-secure program. The register settings of these MPUs are not protected from reading by a debugger nor by non-secure programs. Secure and non-secure programs can follow correct procedures to update the registers.

In addition, the MPU regions defined by these three MPUs do not provide the same level of security compared to the protection provided by the Security MPU:
- A debugger can access the protected regions.
- A read-protected region (without write protection) can be written by secure and non-secure code.
- A write-protected region (without read protection) can be read by secure and non-secure code.
- A read/write-protected region cannot be read nor written by either secure or non-secure code.

2.6 Other Security Elements

2.6.1 Secure Crypto Engine (SCE)
The Secure Crypto Engine (SCE) hardware block on RA MCUs provides data encryption and authentication capability. Following are the encryption and authentication algorithms supported.

2.6.1.1 Security Algorithms
- Symmetric algorithms: AES
- Asymmetric algorithms: RSA and ECC
- MCU support status:
  - RA6M3, RA6M2, and RA6M1 MCU Groups support all the above symmetric and asymmetric algorithms.
  - RA4M1, RA4W1, and RA2A1 support only symmetric algorithms.

Configuration details of the SCE is outside the scope of this application project. Refer to the hardware user manual and FSP user manual for operational details.

2.6.1.2 Other Crypto Security Features
- TRNG (True Random Number Generator)
- Hash value generation: SHA1, SHA224, SHA256, GHASH
- 128-bit unique ID
- MCU support:
  - RA6M3, RA6M2, and RA6M1 support this entire group of features.
  - RA4M1, RA4W1 supports AES, TRNG and GHASH.
  - RA2A1 supports AES and TRNG.
3. Configuring the Security Elements

This section explains the detailed process to set up the Security MPU, FAW, and the OSIS ID register to provide the desired security level for Data at Rest security design. It also explains how to undo the security feature settings in the development stage. In addition, steps needed to lock the security features in the MCU are provided.

3.1 Overview of RA MCU Option-Setting Memory

The Security MPU and the FAW registers are in the MCU Option-Setting Memory, as shown below. The option-setting memory is in the flash user area. Setting these registers requires different procedures compared to erasing and programming the other part of the code and data flash area. Figure 9 is an example location of the option-setting memory based on RA6M3. Other MCUs can have the FAW register located at a different location. Refer to the hardware user’s manual for the exact location for the MCU involved.

As we can see from Figure 9, the Security MPU registers are allocated in the first sector of the program flash area. The FAW register and OSIS register settings are allocated in the configuration setting area.

We recommend using the following methods to set up the Security MPU and FAW registers:

- Use the RA MCU configurator to define the Security MPU registers. Section 3.2.1 describes this method.
- Use the FSP flash driver API to configure the FAW register when locking the register settings is not required. Use the factory bootloader to lock the FAW register setting. Section 3.3 describes this method.

Other methods of setting the Security MPU and FAW registers include:

- Using a J-Link script.
- Using a serial port to communicate with the MCU’s factory bootloader and use the factory bootloader’s utilities. (Section 3.4 describes using this method to clear the locking bit, FSPR, and hence permanently lock the FAW register setting).
3.2 Configuring the Security MPU

This section describes the steps needed to set up and reset the Security MPU registers.

3.2.1 Setting up the Security MPU Registers

Through the RA MCU configurator FSP BSP tab, users can define and enable the four secure data regions and the two secure program regions.

![Figure 10. Security MPU Configuration](image)

The following list describes all the regions defined by the above property fields (in bold).

- **Secure flash program**
  - **PC0 Start** and **PC0 End**: Program counter region for the secure flash program.
  - **Enable or disable PC Region 0**: Enable or disable the secure flash program.

- **Secure SRAM program**
  - **PC1 Start** and **PC1 End**: Program counter region for the secure SRAM program.
  - **Enable or disable PC Region 1**: Enable or disable the secure SRAM program.

- **Secure flash data region**
  - **Memory Region 0 Start** and **Memory Region 0 End**: Secure flash data region start and end addresses.
  - **Enable or disable Memory Region 0**: Enable or disable the secure flash data region.

- **Secure SRAM data region**
  - **Memory Region 1 Start** and **Memory Region 1 End**: Secure SRAM data region start and end addresses.
  - **Enable or disable Memory Region 1**: Enable or disable the secure SRAM data region.

- **Security Function Region 1**
  - **Memory Region 2 Start** and **Memory Region 2 End**: Security function 1 start and end addresses (must be the address space for internal peripheral bus 7 or 9, see description that follows).
  - **Enable or disable Memory Region 2**: Enable or disable the security function 1.

- **Security Function Region 2**
  - **Memory Region 3 Start** and **Memory Region 3 End**: Security function 2 start and end addresses (must be the address space for internal peripheral bus 7 or 9, see description that follows).
  - **Enable or disable Memory Region 3**: Enable or disable the security function 2.

See section 4.1 for the operational flow of using the Security MPU in an application project.
3.2.2 Locating Secure Code/Data to a Specific Memory Region

In addition to setting up the Security MPU registers, one must allocate the secure code and secure data to the intended memory region. This is achieved by customizing the linker script. When you have regions of secure and non-secure program, the default linker is not sufficient. When designing with the Security MPU, you must define multiple flash and/or SRAM regions in the linker script.

Refer to section 5.1.2 for an example of locating secure code/data to a specific memory region.

3.2.3 Resetting the Security MPU registers

Resetting the Security MPU registers is possible if the Security MPU registers are located in the FAW region, or if they are located outside the FAW region, but the FAW region is not permanently locked down.

Resetting the Security MPU requires a flash erase operation for the first block of the MCU flash. Below are the steps to reset the Security MPU setting with an RA MCU e² studio project:

1. Create an SRAM project to execute from an SRAM region other than SRAMHS.
2. Open the flash HAL driver.
3. If the Security MPU flash region is not part of the FAW region, clear the FAW register setting first. See section 3.3.2 to understand how to clear the FAW region.
4. Erase the first flash block using the flash HAL driver.
5. Close the flash HAL driver.

Refer to the example e² studio project secure_data_at_rest_ek_ra6m3 described in section 5.2 for the implementation of these steps.

3.3 Configuring the FAW

This section describes the steps to set up and clear the FAW regions, and to permanently lock the FAW setting.

3.3.1 Setting up the FAW Region

Call the following FSP FAW API to set up the FAW:

```c
err = R_FLASH_HP_AccessWindowSet(&g_flash0_ctrl, FAW_START, FAW_END);
```

- `g_flash0_ctrl` is the instance of this flash HAL driver.
- `FAW_START` is the start address of the FAW window.
- `FAW_END` is the address of the next block acceptable for programming and erasure defined by the access window.

**Note:** If the FAW is permanently locked prior to running this API, the FAW region cannot be updated using this API.

3.3.2 Clearing the FAW Regions

Call the following FSP FAW API to clear the FAW setting:

```c
err = R_FLASH_HP_AccessWindowClear(g_flash0.p_ctrl);
```

The `R_FLASH_HP_AccessWindowClear` API clears the FAW window setting, essentially disabling the FAW control by setting the start address and end address to 0. This routine will work only if the FAW is not permanently locked.

Follow the steps below to clear the FAW setting in the development stage (prior to clearing FSPR) in an RA MCU e² studio project:

1. Create an SRAM project to execute from an SRAM region other than SRAMHS.
2. Open the flash HAL driver.
3. Clear the FAW setting using `R_FLASH_HP_AccessWindowClear`.
4. Close the flash HAL driver.
3.4 Permanent Locking of the FAW Region

Permanently locking the FAW region prevents a user from updating the FAW region. This step is needed to establish the write-once flash region.

There are two use cases when a user may want to consider permanently locking the FAW region:

- To lock critical runtime data in real time when the device is deployed to the field (the use case without secure bootloader).
- To lock critical data/code during the manufacturing stage (the use case with secure bootloader).

For manufacturing usage, to permanently lock the FAW register, we can use the factory bootloader routines, which implement the FAW register setting and clearing procedure. This application project provides an example PC application `final_programInstaller` to program the application and permanently lock the FAW.

![Figure 11. Permanently Locking the FAW](image)

3.5 Setting up the Security Control for Debugging

The OCD/Serial Programming ID Setting Register (OSIS) stores the ID code protection for the OCD/serial programmer. Upon connection, an OCD/serial programmer must provide an ID value so that the MCU can determine whether to permit the connection.

- **OSIS**
  - 128-bit register holds the ID for authenticating the debugger/programmer.
  - SCI/USB boot mode programming also uses this ID code.
The following table is from the RA2E1 Hardware User’s Manual, which is applicable to all the MCU Groups mentioned in the Table 1. Note that not all relevant Hardware User’s Manuals have been updated to this table yet, that will be taken care of in future releases.

<table>
<thead>
<tr>
<th>Operating mode on boot up</th>
<th>ID code</th>
<th>State of protection</th>
<th>Operations on connection with the programmer or on-chip debugger</th>
</tr>
</thead>
<tbody>
<tr>
<td>Serial programming mode (SCI boot mode)</td>
<td>0xFF, ..., 0xFF (all bytes 0xFF)</td>
<td>Protection disabled</td>
<td>The ID code is not checked, the ID code always matches, and the connection to the serial programmer or on-chip debugger is permitted.</td>
</tr>
<tr>
<td>On-chip debug mode (SWD boot mode)</td>
<td>Bit [127] = 1, bit [126] = 1, and at least one of all 16 bytes is not 0xFF</td>
<td>Protection enabled</td>
<td>Matching ID code indicates that authentication is complete and connection to the serial programmer or on-chip debugger is permitted. Mismatching ID code indicates transition to the ID code protection wait state. When the ID code sent from the serial programmer or the on-chip debugger is ALeeRASE in ASCII code (0x414C_6552_4153_45FF_FFFF_FFFF_FFFF_FFFF), the content of the user flash area is erased and all bits in the OSIS register are 1. However, when the AWS.FSPR bit is 0 or security MPU is enabled, the content of the user flash area is not erased.</td>
</tr>
<tr>
<td></td>
<td>Bit [127] = 1 and bit [126] = 0</td>
<td>Protection enabled</td>
<td>Matching ID code indicates that authentication is complete and connection to the serial programmer or on-chip debugger is permitted. Mismatching ID code indicates transition to the ID code protection wait state.</td>
</tr>
<tr>
<td></td>
<td>Bit [127] = 0</td>
<td>Protection enabled</td>
<td>The ID code is not checked, the ID code is always mismatching, the connection to the serial programmer or the on-chip debugger is prohibited. When the ID code sent from the on-chip debugger is ALeeRASE in ASCII code (0x414C_6552_4153_45FF_FFFF_FFFF_FFFF_FFFF), the content of the user flash area is erased and all bits in the OSIS register are 1. However, when the AWS.FSPR bit is 0 or security MPU is enabled, the content of the user flash area is not erased.</td>
</tr>
</tbody>
</table>

Figure 12. Specifications for ID Code Protection

There are multiple ways the user can set up the OSIS ID code:

- Use the RA MCU Configurator with the support of the J-Link debugger.
- Use Renesas Flash Programming Tool (RFP).
  — See the Reference section for the RFP download link.
- Use a J-Link script.
- Use the factory bootloader.
- Use the flash HAL driver to program the OSIS ID.
3.5.1 Methods of Setting the OSIS ID Code

3.5.1.1 Using the RA MCU Configurator and J-Link Debugger

The RA MCU configurator allows the user to set up the OSIS ID code through the FSP property setting shown in Figure 13.

- During development stage, it is recommended to choose “Locked with All Erase support” for the ID Code Mode selection. Section 5.5 provides an example a J-Link script which erases the entire flash to reset the ID code setting to all FFs.
- When “Locked” is selected for the ID Code Mode, the device will be disabled from debugging and factory programming.

3.5.1.2 Using a J-Link Script

The J-Link script SEGGER can set up the OSIS ID. This application project does not provide an example script for this usage.

3.5.1.3 Using the Factory Bootloader

The factory bootloader has capability of setting up the OSIS ID. This application project does not provide an example for this functionality.

3.5.1.4 Using the Flash Driver

FSP has the capability of setting up the OSIS ID using the flash driver.

```c
err = R_FLASH_HP_IdCodeSet(&g_flash0_ctrl, id_bytes, FLASH_ID_CODE_MODE);
```

- `g_flash0_ctrl` is the instance of this flash HAL driver.
- `id_bytes` is the ID code to set.
- `FLASH_ID_CODE_MODE` has three options.
  - `FLASH_ID_CODE_MODE_UNLOCKED`: ID code is ignored.
  - `FLASH_ID_CODE_MODE_LOCKED_WITH_ALL_ERASE_SUPPORT`: ID code is checked. All erase is available.
  - `FLASH_ID_CODE_MODE_LOCKED`: ID code is checked.

This application project does not provide an example using this API.
3.5.2 Method of Setting up the OSIS ID Code for Debugging
With e² studio, a user can set up the ID code using this interface.

![Figure 14. Setting up the ID Code with e² studio](image)

3.5.3 Method of Resetting the OSIS ID code
Following are the methods of resetting the OSIS ID code.

3.5.3.1 Using J-Link Script
This application project includes an example J-Link script to reset the OSIS ID code by erasing the entire flash. Refer to section 5.5 for details on the operation.

3.5.3.2 Using Factory Bootloader
User can use the RFP routine to reset the OSIS ID.

3.5.3.3 Self-programming
Supported by FSP Flash driver.

4. Operational Flow using Security MPU and FAW
This section describes the operational flow for designing a secure application using the RA MCU Security MPU and FAW.

4.1 Internal Flash and SRAM Read Protection
When the Security MPU enables the secure flash data and secure SRAM data regions, these regions gain read protection:

- Secure SRAM regions are read and write protected from non-secure flash and SRAM programs.
- Secure flash regions are read protected from non-secure flash and non-secure SRAM programs.
- The bus master and debuggers are disabled from access to the secure region.

The high-level operational flow of establishing the Security MPU regions is described by the flow diagram in Figure 14. See Figure 8 for examples of internal flash read protection.
Figure 15. Operational Flow for Using the Security MPU

The following is a summary of setting up the Security MPU for the MCU:

- Use the configurator BSP tab to define secure regions.
- Use the linker script to define the secure regions and non-secure regions.
- Establish the secure and non-secure functions.
- Copy the secure SRAM function (if defined) from the secure flash region to the secure SRAM region.
- Test the system.

Note: Once the Security MPU is enabled, the MCU needs to run the reset routine (refer to section 5.2) whenever a new program needs to be programmed on the device.

4.2 Internal Flash Write Protection

As described in section 4.1, the internal SRAM region gains write protection when the Security MPU is enabled for the secure SRAM region. The internal flash region can gain write protection through two methods:

- Set up the FAW region such that it does not include the secure flash region. The entire region (whether it is part of the secure flash region or non-secure flash region) that is not included in the FAW region will have erase and write protection from secure and non-secure program. See Figure 8 for an example of internal flash write protection.
- When the Security Function for internal peripheral bus 9 is enabled, the entire flash region, including secure and non-secure flash regions, is protected from erasing and programming by non-secure flash and non-secure SRAM program.

In this application project, only the first method is described. See section 5.1 for an example of the implementation.
4.2.1 Operational Flow

The FSP API, R_FLASH_HP_AccessWindowSet (see section 3.3.1) must be called from the user application to set up the erase and write enabled region. The rest of the flash region will be disabled for erase and write from both secure and non-secure programs.

![Diagram](image)

**Figure 16. Establish Write Protected Internal Flash Region**

4.3 Internal Flash and SRAM Read/Write Protection

When the Security MPU is enabled for the secure SRAM region, the secure SRAM gains read/write protection from non-secure flash and non-secure SRAM programs.

If the write-protected flash region is part of the secure flash region, this secure flash region is read and write protected from non-secure program and write protected from secure program. See Figure 8 for an example of internal flash read and write protection.

4.3.1 Operational Flow

When the internal SRAM region gains read protection by setting up the secure SRAM region, it also gains write protection by the same process. Refer to section 4.1 for details on the operational flow.

If the write protected internal flash region is set up through the FAW, and it is also part of the secure flash data region, this section of the secure flash region is erased and write protected from the secure and non-secure programs. The entire secure flash region is read protected from the non-secure program.

Refer to section 5.1 for an example of the implementation of internal SRAM and flash read and write protection.

![Diagram](image)

**Figure 17. Establish Read/write Protected Internal Flash Region**
4.4 Internal Flash Write-Once Protection

When the FSPR bit is cleared in the FAW register, the internal flash region that is not included in the FAW window becomes write-once protected from the secure and non-secure programs. The content within this write-once protected region cannot be altered for the lifetime of the device. See Figure 8 for an example of the internal flash write-once protection.

4.4.1 Operational Flow

Before performing the write-once protection:

- Fully test the critical data and/or code that the application intends to lock down.
- Ensure that no other critical data and/or code needs to be assigned to the write-once protected region.

Figure 17 is the operational flow when operating in a manufacturing stage. Refer to section 5.3 for an implementation of the write-once protection.

![Figure 18. Write-once Protection](image)

As explained in section 3.4, runtime write-once protection by locking the FAW register is not supported by FSP.

4.5 Internal Flash Write-Once and Read Protection

The write-once and read protection can be achieved for secure flash program and data. When a secure flash region gains read/write protection by setting up the Security MPU and FAW region, a user can permanently lock the FAW window such that the corresponding region can never be erased and programmed by any tools, and it is read protected from non-secure software. Erasing and programming this flash region is not possible through the factory bootloader, J-Link script, or self-programming.

Region 8 in Figure 8 is an example of write-once and read protected internal flash region.

4.5.1 Operational Flow

For internal secure flash applications, a user can follow these operational steps to set up regions that are write-once from secure and non-secure program and read protected from non-secure program.

![Figure 19. Write-once and Read Protection](image)

Refer to section 5.3 for an example implementation of locking down the FAW region.
4.6 Operation Notes

4.6.1 Memory Allocation

4.6.1.1 Space between Secure and Non-secure Instructions

An address space of greater than 12 bytes is required between the last instruction of a non-secure program and the first instruction of a secure program. If a secure program is stored in the area following the non-secure program without the gap, the secure program might be fetched as non-secure program. See hardware user manual for details.

4.6.1.2 Do Not Assign the Memory Mirror Region to the Secure Region

Setting of the memory mirror space (for example, 0200 0000h to 027F FFFFh for RA6M3) for secure region is prohibited.

4.6.1.3 Startup Area of Security MPU Regions

The start address area of the secure flash data region cannot be set at the vector table area.

The start address of the secure SRAM data region cannot be set at the stack area or the vector table area.

4.6.2 Limitations on Programming the Option-Setting Memory

Refer to the hardware user manual section “Changing the option-setting memory by self-programming” and “Debugging through an OCD or programming by a flash writer” to understand the limitations on programming the Option-Setting Memory for flash access window setup and OSIS ID setup.

The application code included in this application project follows the guidelines provided in the user manual.

4.6.3 Factory Bootloader Accessibility

If the Security MPU is enabled, the factory bootloader is not available anymore. Reset of the Security MPU register settings is needed to re-enable the factory bootloader. Refer to section 5.2 for a Security MPU reset example implementation.

4.6.4 Access Secure Function from Non-Secure Functions

Secure functions can be called from non-secure functions (see Figure 6 in 2.2).

The application project implemented in this release calls the secure function directly from the non-secure function.

Special considerations are needed when accessing secure functions located in a secure bootloader:

- Define a group of secure function entry points (function pointers) in the secure flash data region.
- Access the secure function from a function pointer stored in the secure function table.

4.6.5 Debugger Access to the Security MPU Regions

When the debugger is operating in debug mode, viewing of the Security MPU flash and secure SRAM region contents is disabled. With e² studio, when the secure region is viewed from the ‘memory’ view, the values are shown as “0”.

5. Security Application e² studio Projects: Internal Flash and SRAM

This section introduces the example projects for using the Security MPU and FAW as follows:

- Access secure flash and secure SRAM data from secure flash and secure SRAM code
- Access secure flash and secure SRAM data from non-secure flash

There are two example projects included for the internal flash and SRAM secure Data at Rest application:

- **Project 1**: e² studio RA MCU project (\embedded\secure_data_at_rest_ek_ra6m3) that demonstrates:
  - Secure flash data read protection
  - Secure and non-secure flash data write protection
  - Secure SRAM read and write protection

- **Project 2**: PC-based Visual Studio application (programInstaller.sln) that downloads the application created from project 1 and provides the option to permanently lock the FAW using the factory bootloader on the MCU, thus realizing the write-once protection of the regions not included in the FAW.
In addition, there are several example J-Link scripts included in this application project, which perform the Security MPU, FAW, and OSIS ID code resetting.

Section 5.4 explains a J-Link script that resets the FAW and Security MPU registers before the FAW region is permanently locked down.

Section 5.5 explains the procedures for setting up the OSIS ID with an e² studio auto-generated blinky project and the usage of the J-Link scripts to reset the OSIS ID. The reset OSIS ID script is used in conjunction with the blinky project to demonstrate an end-to-end development for debugging security handling with the RA MCUs.

5.1 Project 1: e² studio project - Internal Flash and SRAM Read Write Protection

5.1.1 Software Architecture Overview
Project 1: This project implements four groups of the software components that demonstrate the flash and SRAM read and write protection:
- J-Link RTT Viewer User Interface code
- Secure flash code
- Secure SRAM code
- Non-secure flash code

The J-Link RTT user code runs in the non-secure flash region. It monitors user input from the J-Link RTT Viewer and activates the corresponding secure flash/SRAM and non-secure flash application code. See Figure 20.

5.1.2 Memory Allocation Arrangement
The SRAM and Flash memory regions of the system are controlled by the linker script `secure_data_at_rest_ek_ra6m3\script\ra6m3.ld`.

The Security MPU regions are defined by the configuration settings under the BSP tab in the RA Smart Configurator as shown in Figure 10.
The FAW region is defined by the following two macros in `src/DAR_utilities.h`:

- `#define FAW_START (0x100000)
- `#define FAW_END (0x200000)

It is important to note that the RTT Viewer message output included in this application project is based on the default project settings for the SRAM, Flash memory regions, Security MPU regions, and default FAW setting as shown below. If these configurations are changed, different outputs are expected. These are not covered in the provided screen shots as the result varies based on the configurations.

The software uses macros defined in `secure_definitions.h` to allocate the different secure and non-secure code.

Figure 21 shows the flash memory allocation based on the flash software components.

![Figure 21. Project 1 Internal Flash](image)

In this example project, the FAW window does not include any Secure MPU defined secure flash region. By setting up the FAW window like this, the Security MPU Registers as well as the secure flash data region are protected from modification from both secure and non-secure code.

If the user wishes to have a portion of the secure flash data region inside the FAW window, they can update the `FAW_START` macro definition to adjust the FAW window location.

Note that it is always recommended to exclude the Secure MPU Register settings outside the FAW window, so the Security MPU settings can be protected from modification and thus enhance the security of the system.
Figure 22 shows the SRAM memory allocation based on the different SRAM software components.

![Figure 22. Project 1 Internal SRAM](image)

Following are the memory regions defined by the linker script (`\script\fsp_app.ld`):

<table>
<thead>
<tr>
<th>Regions</th>
<th>Start Address</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>VECTOR_TABLE (rx)</td>
<td>0x00000000</td>
<td>0x00000400</td>
</tr>
<tr>
<td>SECURE_PROGRAM (rx)</td>
<td>0x000000400</td>
<td>0x0007FC00</td>
</tr>
<tr>
<td>SECURE_DATA (rw)</td>
<td>0x00080000</td>
<td>0x00080000</td>
</tr>
<tr>
<td>SECURE_RAM_PROGRAM (rwx)</td>
<td>0x1FFE0000</td>
<td>0x00010000</td>
</tr>
<tr>
<td>SECURE_RAM (rw)</td>
<td>0x1FFF0000</td>
<td>0x00040000</td>
</tr>
</tbody>
</table>

Following are the memory assignment macros used by the secure software and data sections defined by `secure_definitions.h`:

```c
#define SECURE_PROGRAM __attribute__((section (".secure_text")))
#define SECURE_CONST __attribute__((section (".secure_rodata")))
#define SECURE_DATA __attribute__((section (".secure_data")))
#define SECURE_BSS __attribute__((section (".secure_bss")))
#define SECURE_SRAM_PROGRAM __attribute__((section (".secure_sram_program")))
```

Following are the test variables that are used to demonstrate the protection on secure flash data and secure SRAM data. Global variables are used to allow read and write directly from non-secure program to simulate reading and writing to the secure data area.
### Table 3. Test Variables

<table>
<thead>
<tr>

<td>Uninitialized</td>
<td>Write to this variable from non-secure flash program and show the write is not valid.</td>
</tr>
</tbody>
</table>

### 5.1.3 Functionality Description

#### 5.1.3.1 J-Link RTT Viewer User Interface

This section of code takes user input from the RTT Viewer, activates the operation, and prints the test results on the RTT Viewer.

#### 5.1.3.2 Secure Flash Program

- Read and write from the secure flash program to the secure SRAM and non-secure SRAM region.
  - Show access to all SRAM regions are granted.
- Read from the secure flash program to the secure flash data region and non-secure flash data region.
  - Show access to all flash regions are granted.

#### 5.1.3.3 Secure SRAM Program

- Read and write from the secure SRAM program to the secure SRAM and non-secure SRAM region.
  - Show access to all SRAM regions are granted.
- Read and write from the secure SRAM program to the secure flash and non-secure flash region.
  - Show access to all flash regions are granted.

#### 5.1.3.4 Non-secure Flash Program

- Read and write from the non-secure flash program to the secure SRAM and non-secure SRAM region.
  - Show access to the non-secure SRAM region is granted.
  - Show access to the secure SRAM region is not granted.
- Read and write from the non-secure flash program to the secure and non-secure flash region.
  - Show that before the FAW is set up, write access to all flash regions is granted. This is an example of internal flash read protection (see section 4.1).
  - Show that after the FAW is set up, write access to the non-FAW region is not granted. This is an example of internal flash write protection (see section 4.2).
    - If this non-FAW region is part of the Security MPU region, this is an example of internal flash read and write protection (see section 4.3).
    - If we lock the FAW setting (by clearing the FSPR bit):
      - The above flash write-protected region becomes a write-once region (see section 4.4).
      - The above flash read/write protected region becomes a write-once and read protected region (see section 4.5).

Special Note on the macro definition for `SECURE_PADDING`: This macro inserts the gap between secure and non-secure code execution as requested by the Security MPU architecture as described in section 4.6.1.1.
Figure 23 shows the source files grouped by functionality.

![Source Code Diagram]

Note that the non-secure functions defined in the above source files may call secure subroutines and secure functions defined above may call non-secure subroutines. The Security MPU allows cross-domain function calls between secure and non-secure domain.

Care should be taken such that the secure information does not leak to the non-secure region through the stack area. Whenever it is possible, design the secure function such that the stack area is not used to store local variables.

5.1.4 Establishing and Running Software from Secure SRAM Region

Running secure programs from the secure SRAM region involves the following actions:

- Set up the secure SRAM region from the linker script, as shown in section 5.1.2.
- Relocate the secure SRAM application code (.secure_sram_program region) from the secure flash region to the secure SRAM region in the linker script.

```c
/* Secure application SRAM code and secure flash driver code are stored in this section. */

.secure_sram_program :
    . = ALIGN(8);
    secure_sram_program_start : KEEP("(secure_sram_program*)")
    Code_In_RAM_Start : KEEP("(code_in_ram*)")
    _Code_In_RAM_Start = ;
    _secure_sram_program_end = ;

} > SECURE_RAM_PROGRAM AT>SECURE_PROGRAM
```

Figure 24. Allocate Code to Secure SRAM

- Copy the secure SRAM code from the secure flash region to the secure SRAM region using application code. Refer to the secure_sram_section_copy function (in secure_flash_functions.c) for implementation
- The .code_in_ram FSP code section relocates the flash writing routine to RAM. In this application project, we allocated this section of the code in the secure SRAM section as shown above.

5.1.5 Importing and Building the Project

Create a new workspace and import the "\embedded\secure_data_at_rest_ek_ra6m3" project into e2 studio, build, and run the project. Note that once this program is run, the Security MPU is set up, user must
run the Reset Script (using section 5.3) prior to programming a new application or program an updated version of this secure_data_at_rest_ek_ra6m3 application.

5.1.6 Hardware Setup
Connect J10 using the micro-USB cable to the workstation to provide power and debugging capability using the on-board debugger.

5.1.7 Verifying the Secure Functionalities
Launch ‘J-Link RTT Viewer’ V6.52b or later.

![Launch J-Link RTT Viewer](image)

**Figure 25. Launch J-Link RTT Viewer**

Select ‘USB’ as connection type. Click on the ‘ ‘ button to select ‘R7FA6M3AH’ as the device.

If the host PC has more than one J-Link debugger connected to the PC, set the ‘Serial No’ (by default Serial No is set to 0).

Click ‘Next’ to establish the connection.

![Launch SEGGER RTT Viewer](image)

**Figure 26. Launch SEGGER RTT Viewer**

**Step 1:** The main menu items are printed on the RTT Viewer Terminal 0.

![Main Menu](image)

**Figure 27. Main Menu**
**Step 2:** Input ‘1’ on RTT Viewer Terminal 0 and view the default Security MPU and FAW settings (Function `read_secure_settings` performs this task).

![Security MPU settings](image)

**Figure 28. Security Setting**

**Step 3:** Input ‘2’ on RTT Viewer Terminal 0 to view the secure flash functions (functions running in secure flash region).

![Secure Flash Program Operation Menu](image)

**Figure 29. Secure Flash Program Operation Menu**

Input ‘a’ to read the secure flash, secure SRAM, non-secure flash, non-secure SRAM region from the secure flash functions and confirm that read accesses are granted. Function `secure_code_read()` verifies this functionality.

![Secure Flash Program Read](image)

**Figure 30. Secure Flash Program Read**
Input ‘b’ to perform writing of the secure SRAM, non-secure SRAM regions from the secure flash functions and confirm the write accesses are granted. Function `secure_code_write()` performs this function.

Figure 31. Secure Flash Program Writes

Input ‘c’ to set up the FAW. Figure 31 shows the default FAW region set up by the example project. Input ‘1’ to confirm FAW is set up.

Figure 32. Set up the FAW (from 0x100000 to 0x1FFFFF)
Input ‘2’ and then ‘d’ to reset the FAW from secure flash program.

```
Choose an option from the below menu for secure flash operation
Press a to read
Press b to write
Press c to setup faw
Press d to reset faw
**************************************************************************
Enter r to go back to the main menu
**************************************************************************
Reset Flash Access Window...running from flash
PASS secure program => faw is reset
**************************************************************************
Enter r to go back to the main menu
```

**Figure 33. Reset the FAW**

Input ‘1’ to confirm the FAW region is disabled.

```
Security MPU settings
PC Region 0: enabled [0x 500 | 0x 7FFF]
PC Region 1: enabled [0x1FFE0000 | 0x1FFEFFF]
Secure Region 0: enabled [0x 400 | 0x DFFF]
Secure Region 1: enabled [0x1FFE0000 | 0x2002FFFF]
Secure Region 2: disabled
Secure Region 3: disabled
Access Window: disabled
Enter r to go back to the main menu
```

**Figure 34. Confirm FAW is Disabled**

**Step 4:** Input ‘3’ to view the secure SRAM functions (functions running out of the secure SRAM region).

```
Choose an option from the below menu for secure sram operation
Press g to read
Press h to write
**************************************************************************
Enter r to go back to the main menu
```

**Figure 35. Secure SRAM Program**
Input ‘g’ to read the secure flash, secure SRAM, non-secure flash, non-secure SRAM region from the secure SRAM functions and confirm read accesses are granted. Function `secure_sram_code_read` performs this function.

![Secure SRAM Program Read](image1.png)

**Figure 36. Secure SRAM Program Read**

Input ‘h’ to write to the secure flash, secure SRAM, non-secure flash, non-secure SRAM regions from the secure SRAM functions with FAW region enabled from 0x100000 to 0x1FFFFF. Function `secure_sram_code_write` performs this function.

```c
// Secure sram code writes...running from secure sram
// Access Window: enabled [0x A0000 | 0x 200000]
// PASS! secure sram program can write secure sram data
// PASS! secure sram program can write non-secure sram data
// PASS! secure sram program can write to secure flash FLASH_WRITE_TEST_BLOCK1
// which is modifiable based on FAM setting.
// PASS! secure sram program can write to non-secure flash FLASH_WRITE_TEST_BLOCK2
// which is modifiable based on FAM setting.
Enter r to go back to the main menu
```

![Secure SRAM Program Write](image2.png)

**Figure 37. Secure SRAM Program Write**
Step 5: Input ‘r’ then ‘4’ to view the non-secure flash functions (functions running out of non-secure flash region).

![Figure 38. Non-secure Flash Program Functions](image)

Input ‘m’ to read the secure flash, secure SRAM, non-secure flash, non-secure SRAM region from the non-secure flash functions and confirm that reading secure memory is not valid. Function `non_secure_code_read` performs this function.

![Figure 39. Read Operation from Non-secure Flash Program](image)

Input ‘n’ to write the secure flash, secure SRAM, non-secure flash, non-secure SRAM regions from non-secure flash program with FAW region enabled from 0x100000 to 0x1FFFFF and show that secure flash memory should be protected with FAW to prevent non-secure code writing. Function `non_secure_code_write` performs this function.
Figure 40. Write Operation from Non-secure Flash Program

Step 6: Input ‘d’ to reset the FAW setting and verify the operation by inputting ‘1’.

```
> **************
> non-secure flash code tests...running from non-secure flash
> Access Window: enabled [0x 180000 | 0x 200000]
> PASS! non-secure flash program cannot write secure sram data
> PASS! non-secure flash program can write to non-secure sram data
> PASS! non-secure flash program cannot write to secure flash region FLASH_WRITE_TEST_BLOCK1
> which is unmodifiable based on FAW setting.
> PASS! non-secure flash program can write to non-secure flash region FLASH_WRITE_TEST_BLOCK2
> which is modifiable based on FAW setting.
> r Enter r to go back to the main menu
```

Figure 41. Reset FAW and Confirm FAW is Reset

Note that once this program is run, the Security MPU is set up. The user must run the Reset Script (using section 5.3) prior to programming a new application or programming an updated version of this secure_data_rest_ek_ra6m3 application.
5.1.7.1 Summary of the Functionalities Provided in this Application Project:

- Establish read/write protection to the secure flash and secure SRAM regions using Security MPU and FAW setting.
- Shield secure data from the debugger. For demonstration, try to view the memory of the secure data region from the debugger, value “0” is presented. The protection from debugger is effective after first power recycle.

![Figure 42. Secure Data Region is not Viewable from Debugger](image)

5.1.8 Migrating to Other RA MCUs

Each MCU group and each MCU within a group may have different internal flash and SRAM size.

Follow these steps to migrate this application:

1. Modify the BSP Security MPU region settings to fit the memory size.
2. Copy over the RA6M3.ld and rename to confirm to the new RA MCU.
3. Modify the linker script to take care of the new secure flash and SRAM regions defined in the BSP tab.
4. Modify the FAW region range if needed in the application code based on the flash size of the new MCU.
5. The entire application code size is about 22 kB flash and 5 kB of SRAM. Use these numbers as reference when migrating to other RA MCU devices. No application code update is needed when migrating to RA6M1 and RA6M2.

5.2 Project 2: PC Application to Permanently Lock the FAW

The workstation utility that permanently locks the FAW uses the MCU’s factory loader as shown in Figure 11.

**Factory Boot Loader Mode:**

Connect Jumper J12 to 2 and 3 to enable USB FS Device mode of the RA6M3 MCU. Connect J10 to the PC using the micro USB cable.

Connect jumper J16 and power cycle the board. The RA6M3 boots with the factory bootloader in USB program mode, which enables you to load a program directly to the internal microcontroller flash through the USB device interface (CDC Class).
To use this tool, follow the steps below:

**Step 1:** Exercise the default evaluation content, which programs the default program to the EK-RA6M3. The default `programInstaller.exe` under `\pc\program\final_program_installer_script` _does not_ lock down the FAW. It does set up the FAW region.

1. Put the RA MCU in factory bootloader mode.
2. Open the device manager and find the enumerated COM port number for “USB Serial Device”.
3. Run the `deploy_app.bat` file and provide the enumerated COM port number as the argument. See example output in Figure 43.

C:\MyProjects\RA\Data at Rest Repo\ra_solutions\Data-at-Rest-Dev\pc\program\final_program_installer_script>deploy_app.bat 12

C:\MyProjects\RA\Data at Rest Repo\ra_solutions\iotsg-2712-secure-data-at-rest-dev\pc\program\final_program_installer_script>deploy_app.bat 12

C:\MyProjects\RA\Data at Rest Repo\ra_solutions\iotsg-2712-secure-data-at-rest-dev\pc\program\final_program_installer_script>REM script to download application and setup FAW

Parsed SREC file: secure_data_at_rest_ek_ra6m3.srec (0x0..0x103513)
Initialising flash programming connection to port COM12
Established flash programming connection
Disabling flash access window (0x0..0xFFFFFFF)
Flash access window is now disabled
Erasing flash
Flash erased OK
Writing flash for secure_data_at_rest_ek_ra6m3.srec region (bufferOffset=0x0, 0x103513 bytes)
Flash region written OK
Flash Access Window configured for start=0x100000, end=0x1ffffff
Completed OK

**Figure 43. Program the Application without Locking the FAW Region (needs update)**

**Note:** Every time before reprogramming the application, the reset routine must be performed successfully.

**Step 2:** Proceed with locking the FAW region, if needed, by performing the following steps:

1. Open the Visual Studio project `program_installer.sln` (`\pc\program\final_program_installer_script\pc\apps\programInstaller\programInstaller.sln`).
2. Open the project properties. Under C/C++\Preprocessor, add a Preprocessor definition for `ACTIVATE_THE_FSPR`.

**Figure 44. Set up the FAW Locking**
3. Compile Program Installer project.
   If you are using Visual Studio 2017 professional or enterprise version, you will run into following error message.

![Error List Image]

Figure 45. Compiling the Program Installer

To resolve this error message, right-click on the project and select Retarget Projects. Then choose the SDK version you are using. Proceed to compiling.

![Retarget Projects Image]

Figure 46. Retarget the Solution

4. Compile the application Project 1 \embedded\secure_data_at_rest_ek_ra6m3 with ID code region removed. This is a limitation of this tool. If you do not change secure_data_at_rest_ek_ra6m3, there is no need to take this action as there is a copy of the default.srec file included in the script folder.

5. Put the generated secure_data_at_rest_ek_ra6m3.srec and newly built programInstaller.exe in the same folder as the deploy_app.bat file (\pc program\final_program_installer_script).

6. Proceed to use the same steps from 1 to 3 in Step 1 in this section to program the final application.

Warning: The unmodifiable flash region will be permanently locked down with the current image (from 0x0 to 0xFFFFF).

Writing flash for secure_data_at_rest_ek_ra6m3.srec region (bufferOffset=0x0, 0x10BBE8 bytes)
Flash region written OK
Flash Access Window configured for start=0x10000, end=0x1fffffff
Completed OK

Figure 47. Lock the FAW Region

5.3 Example Reset J-Link Script for the Security MPU and FAW

In the \reset_scripts folder, there is the Security MPU and FAW region reset J-Link Script under smpu_aws_reset_script. This script resets the Security MPU and FAW settings before the FSPR bit is cleared (that is, the FAW region is permanently locked down). Under smpu_aws_reset_script, there are two files (Figure 48).
Figure 48. Security MPU and FAW Reset Script

Open RA6M3_ERASE_SMPU_AWS.bat and update the SEGGER J-Link version to match your J-Link version by updating the folder name.

Figure 49. Update the SEGGER J-Link Version

The script performs the following functions:

1. Reset the device.
2. Reprogram the Flash Access Window configuration area (0x0100A160 for RA6M3) to all FFs.
3. Reset the device.
4. Erase the first block of code flash.
5. Reset the device.

To run the reset script, put RA6M3 into Normal Boot mode and open a command line window, navigate to the location of the .bat file, and run the RA6M3_ERASE_SMPU_AWS.bat. The last portion of the output from running this script is included below:

Normal Boot: Remove jumper J16 and power cycle the board. The RA6M3 starts execution from internal flash (ROM). This is the normal mode of operation.
J-Link Command File read successfully.

Figure 50. Running the Security MPU and FAW Reset Script

5.4 J-Link Scripts for Resetting OSIS ID code for RA6M3

Under \reset_scripts\osis_id_resetting_script, there are three files:

- ID_Code_ERASEALL_RA6M3.bat
- IDCode_ALeRASE_RV40_ph2.jlinkscript
- RA6M3_connect.jlink

Follow the steps below to exercise these reset scripts.

Step 1: If you do not have the SEGGER tools installed, go to https://www.segger.com/downloads/J-Link/ and download and install the latest J-Link software.

Step 2: Create a blinky project using e² studio.
Figure 51. Create a Blinky Project

Step 3: Setup the ID code in the “Property” field under the BSP tab. Note bit 127 and bit 126 are both set to 1.

Figure 52. Setup ID Code in Configurator

Step 4: Click *Generate Project Content* and compile the project.

Step 5: Open the debug configuration *Debugger > Connection Settings* and input the OSIS ID below. Click *Apply > Debug*.

Figure 53. Setup Matching ID Code in Debug Configuration

Step 6: Debug the project. If the debugging is happening, it is a proof that the ID code matched up.

Step 7: Stop the project.

The next steps shows how to reset the OSIS ID code using the script included.

Step 8: Open a command prompt and navigate to the folder where you extracted the script files.

Step 9: Set the path to the version of J-Link that you are using for the RA projects:

```
set PATH=%PATH%;"C:\Program Files (x86)\SEGGER\JLink"
```
Step 10: Run the batch file `ID_Code_ERASEALL_RA6M3.bat`. You should see output similar to Figure 54.

![Image of Figure 54: Erase Entire Flash and Reset the OSIS ID Code](image-url)
The following two steps confirm the OSIS ID reset is successfully done.

**Step 11:** Reset the OSIS ID to all FFs in the configurator for the blinky project (see Figure 52) and compile the project.

**Step 12:** Reset the OSIS ID for the debugger configuration to all FFs (see Figure 53) and confirm the debugging works.

6. Secure Data at Rest Next Steps

6.1 Secure Data Encryption and Authentication

A future release of this application project will cover secure data encryption and authentication.

6.2 External Storage Secure Data at Rest

A future release of this application project will cover external storage data encryption and authentication as well as access control.

6.3 Example using the Security MPU Security Functions

As explained in section 2.2, there are two security functions that can be controlled by the Security MPU. One security function controls the access to the Secure Crypto Engine (SCE). When this security function is enabled, only secure program can access the SCE.

The other security function controls the access to the code and data flash Erase and Programming (E/P). When this security function is enabled, only secure program can perform internal flash E/P.

This application project does not provide an example of using these security functions.
