3.3V Phase-Lock Loop Clock Driver

General Description

The ICS2510C is a high performance, low skew, low jitter clock driver. It uses a phase lock loop (PLL) technology to align, in both phase and frequency, the CLKIN signal with the CLKOUT signal. It is specifically designed for use with synchronous SDRAMs. The **ICS2510C** operates at 3.3V VCC and drives up to ten clock loads.

One bank of ten outputs provide low-skew, low-jitter copies of CLKIN. Output signal duty cycles are adjusted to 50 percent, independent of the duty cycle at CLKIN. Outputs can be enabled or disabled via control (OE) inputs. When the OE inputs are high, the outputs align in phase and frequency with CLKIN; when the OE inputs are low, the outputs are disabled to the logic low state.

The **ICS2510C** does not require external RC filter components. The loop filter for the PLL is included on-chip, minimizing component count, board space, and cost. The test mode shuts off the PLL and connects the input directly to the output buffer. This test mode, the **ICS2510C** can be use as low skew fanout clock buffer device. The **ICS2510C** comes in 24 pin 173mil Thin Shrink Small-Outline package (TSSOP) package.

Features

- Meets or exceeds PC133 registered DIMM specification1.1
- Spread Spectrum Clock Compatible
- Distributes one clock input to one bank of ten outputs
- Operating frequency 25MHz to 175MHz
- External feedback input (FBIN) terminal is used to synchrionize the outputs to the clock input
- No external RC network required
- Operates at 3.3V Vcc
- Plastic 24-pin 173mil TSSOP package

Notes:

1. C_L includes probe and jig capacitance.
2. All input pulses are supplied by generators having the following characteristics: PRR ≤133 MHz, $Z_O = 50\Omega$, $T_r \leq 1.2$ ns, $T_f \leq 1.2$ ns.
3. The outputs are measured one at a time with one transition per measurement.

General Layout Precautions:
An ICS2509C is used as an example. It is similar to the ICS2510C. The same rules and methods apply.

1) Use copper flooded ground on the top signal layer under the clock buffer The area under U1 in figure 1 on the right is an example. Every ground pin goes to a ground via. The vias are not visible in figure 1.
2) Use power vias for power and ground. Vias 20 mil or larger in diameter have lower high frequency impedance. Vias for signals may be minimum drill size.
3) Make all power and ground traces are as wide as the via pad for lower inductance.
4) VAA for pin 23 has a low pass RC filter to decouple the digital and analog supplies. C9-12 may be replaced with a single low ESR (0.8 ohm or less) device with the same total capacitance. R2 may be replaced with a ferrite bead. The bead should have a DC resistance of at least 0.5 ohms. 1 ohm is better. It should have an impedance of at least 300 ohms at 100MHz. 600 ohms at 100MHz is better.
5) Notice that ground vias are never shared.
6) All VCC pins have a decoupling capacitor. Power is always routed from the plane connection via to the capacitor pad to the VCC pin on the clock buffer.
7) Component R1 is located at the clock source.
8) Component C1, if used, has the effect of adding delay.
9) Component C7 , if used, has the effect of subtracting delay. Delaying the FBIn clock will cause the output clocks to be earlier. A more effective method is to use the propagation time of a trace between FBOut and FBIn.
