

Features

- ◆ 128K x 36 memory configuration, pipelined outputs
- ◆ Supports high performance system speed - 133 MHz (4.2 ns Clock-to-Data Access)
- ◆ ZBT™ Feature - No dead cycles between write and read cycles
- ◆ Internally synchronized registered outputs eliminate the need to control  $\overline{OE}$
- ◆ Single R/W (READ/WRITE) control pin
- ◆ Positive clock-edge triggered address, data, and control signal registers for fully pipelined applications
- ◆ 4-word burst capability (interleaved or linear)
- ◆ Individual byte write ( $\overline{BW1}$  -  $\overline{BW4}$ ) control (May tie active)
- ◆ Three chip enables for simple depth expansion
- ◆ Single 3.3V power supply ( $\pm 5\%$ )
- ◆ Packaged in a JEDEC standard 100-pin TQFP package
- ◆ Green parts available, see Ordering Information

## Description

The IDT71V546 is a 3.3V high-speed 4,718,592-bit (4.5 Megabit) synchronous SRAM organized as 128K x 36 bits. It is designed to eliminate dead bus cycles when turning the bus around between reads and writes, or writes and reads. Thus it has been given the name ZBT™, or Zero Bus Turn-around.

Address and control signals are applied to the SRAM during one clock cycle, and two cycles later its associated data cycle occurs, be it read or write.

The IDT71V546 contains data I/O, address and control signal registers. Output enable is the only asynchronous signal and can be used to disable the outputs at any given time.

A Clock Enable ( $\overline{CEN}$ ) pin allows operation of the IDT71V546 to be suspended as long as necessary. All synchronous inputs are ignored when  $\overline{CEN}$  is high and the internal device registers will hold their previous values.

There are three chip enable pins ( $\overline{CE1}$ ,  $CE2$ ,  $\overline{CE2}$ ) that allow the user to deselect the device when desired. If any one of these three is not active when  $ADV/\overline{LD}$  is low, no new memory operation can be initiated and any burst that was in progress is stopped. However, any pending data transfers (reads or writes) will be completed. The data bus will tri-state two cycles after the chip is deselected or a write initiated.

The IDT71V546 has an on-chip burst counter. In the burst mode, the IDT71V546 can provide four cycles of data for a single address presented to the SRAM. The order of the burst sequence is defined by the  $\overline{LBO}$  input pin. The  $\overline{LBO}$  pin selects between linear and interleaved burst sequence. The  $ADV/\overline{LD}$  signal is used to load a new external address ( $ADV/\overline{LD} = \text{LOW}$ ) or increment the internal burst counter ( $ADV/\overline{LD} = \text{HIGH}$ ).

The IDT71V546 SRAM utilizes a high-performance, high-volume 3.3V CMOS process, and is packaged in a JEDEC standard 14mm x 20mm 100-pin thin plastic quad flatpack (TQFP) for high board density.

## Pin Definitions<sup>(1)</sup>

Symbol	Pin Function	I/O	Active	Description
A <sub>0</sub> - A <sub>16</sub>	Address Inputs	I	N/A	Synchronous Address inputs. The address register is triggered by a combination of the rising edge of CLK and ADV/LD Low, CEN Low and true chip enables.
ADV/LD	Address/Load	I	N/A	ADV/LD is a synchronous input that is used to load the internal registers with new address and control when it is sampled low at the rising edge of clock with the chip selected. When ADV/LD is low with the chip deselected, any burst in progress is terminated. When ADV/LD is sampled high then the internal burst counter is advanced for any burst that was in progress. The external addresses are ignored when ADV/LD is sampled high.
R/W	Read/Write	I	N/A	R/W signal is a synchronous input that identified whether the current load cycle initiated is a Read or Write access to the memory array. The data bus activity for the current cycle takes place two clock cycles later.
CEN	Clock Enable	I	LOW	Synchronous Clock Enable Input. When CEN is sampled high, all other synchronous inputs, including clock are ignored and outputs remain unchanged. The effect of CEN sampled high on the device outputs is as if the low to high clock transition did not occur. For normal operation, CEN must be sampled low at rising edge of clock.
BW <sub>1</sub> - BW <sub>4</sub>	Individual Byte Write Enables	I	LOW	Synchronous byte write enables. Enable 9-bit byte has its own active low byte write enable. On load write cycles (When R/W and ADV/LD are sampled low) the appropriate byte write signal (BW <sub>1</sub> - BW <sub>4</sub> ) must be valid. The byte write signal must also be valid on each cycle of a burst write. Byte Write signals are ignored when R/W is sampled high. The appropriate byte(s) of data are written into the device two cycles later. BW <sub>1</sub> - BW <sub>4</sub> can all be tied low if always doing write to the entire 36-bit word.
CE <sub>1</sub> , CE <sub>2</sub>	Chip Enables	I	LOW	Synchronous active low chip enable. CE <sub>1</sub> and CE <sub>2</sub> are used with CE <sub>2</sub> to enable the IDT71V546. (CE <sub>1</sub> or CE <sub>2</sub> sampled high or CE <sub>2</sub> sampled low) and ADV/LD low at the rising edge of clock, initiates a deselect cycle. the ZBT™ has a two cycle deselect, i.e., the data bus will tri-state two clock cycles after deselect is initiated.
CE2	Chip Enable	I	HIGH	Synchronout active high chip enable. CE <sub>2</sub> is used with CE <sub>1</sub> and CE <sub>2</sub> to enable the chip. CE <sub>2</sub> has inverted polarity but otherwise identical to CE <sub>1</sub> and CE <sub>2</sub> .
CLK	Clock	I	N/A	This is the clock input to the IDT71V546. Except for OE, all timing references for the device are made with respect to the rising edge of CLK.
I/O <sub>0</sub> - I/O <sub>31</sub> I/OP <sub>1</sub> - I/OP <sub>4</sub>	Data Input/Output	I/O	N/A	Synchronous data input/output (I/O) pins. Both the data input path and data output path are registered and triggered by the rising edge of CLK.
LBO	Linear Burst Order	I	LOW	Burst order selection input. When LBO is high the Interleaved burst sequence is selected. When LBO is low the Linear burst sequence is selected. LBO is a static DC input.
OE	Output Enable	I	LOW	Asynchronous output enable. OE must be low to read data from the 71V546. When OE is high the I/O pins are in a high-impedance state. OE does not need to be actively controlled for read and write cycles. In normal operation, OE can be tied low.
V <sub>DD</sub>	Power Supply	N/A	N/A	3.3V power supply input.
V <sub>SS</sub>	Ground	N/A	N/A	Ground pin.

**NOTE:**

1. All synchronous inputs must meet specified setup and hold times with respect to CLK.

T <sub>STG</sub>	Storage Temperature	-55 to +125	°C
P <sub>T</sub>	Power Dissipation	2.0	W
I <sub>OUT</sub>	DC Output Current	50	mA

**NOTES:**

- Stresses greater than those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.
- V<sub>DD</sub> and Input terminals only.
- I/O terminals.
- During production testing, the case temperature equals the ambient temperature.

**NOTE:**

- This parameter is guaranteed by device characterization, but not production tested.

### Recommended DC Operating Conditions

Symbol	Parameter	Min.	Typ.	Max.	Unit
V <sub>DD</sub> <sup>(3)</sup>	Supply Voltage	3.135	3.3	3.465	V
V <sub>SS</sub>	Ground	0	0	0	V
V <sub>IH</sub>	Input High Voltage - Inputs	2.0	—	4.6	V
V <sub>IH</sub>	Input High Voltage - I/O	2.0	—	V <sub>DD</sub> +0.3 <sup>(2)</sup>	V
V <sub>IL</sub>	Input Low Voltage	-0.5 <sup>(1)</sup>	—	0.8	V

3821 tbl 04

**NOTES:**

- V<sub>IL</sub> (min.) = -1.0V for pulse width less than t<sub>CYC2</sub>, once per cycle.
- V<sub>IH</sub> (max.) = +6.0V for pulse width less than t<sub>CYC2</sub>, once per cycle.
- V<sub>DD</sub> needs to be ramped up smoothly to the operating level. If there are any glitches on V<sub>DD</sub> that cause the voltage level to drop below 2.0 volts then the device needs to be reset by holding V<sub>DD</sub> to 0.0 volts for a minimum of 100 ms.

3821 tbl 07

**NOTES:**

- L = V<sub>IL</sub>, H = V<sub>IH</sub>, X = Don't Care.
- When ADV/ $\overline{LD}$  signal is sampled high, the internal burst counter is incremented. The  $\overline{R/W}$  signal is ignored when the counter is advanced. Therefore the nature of the burst cycle (Read or Write) is determined by the status of the R/ $\overline{W}$  signal when the first address is loaded at the beginning of the burst cycle.
- Deselect cycle is initiated when either ( $\overline{CE}_1$ , or  $\overline{CE}_2$  is sampled high or CE2 is sampled low) and ADV/ $\overline{LD}$  is sampled low at rising edge of clock. The data bus will tri-state two cycles after deselect is initiated.
- When  $\overline{CEN}$  is sampled high at the rising edge of clock, that clock edge is blocked from propagating through the part. The state of all the internal registers and the I/Os remains unchanged.
- To select the chip requires  $\overline{CE}_1 = L$ ,  $\overline{CE}_2 = L$ , CE2 = H on these chip enables. Chip is deselected if either one of the chip enables is false.
- Device Outputs are ensured to be in High-Z after the first rising edge of clock upon power-up.
- Q - Data read from the device, D - data written to the device.

1. This assumes  $\overline{\text{CEN}}$ ,  $\overline{\text{CE1}}$ ,  $\text{CE2}$ ,  $\overline{\text{CE2}}$  are all true.
2. All Address, Control and Data\_In are only required to meet set-up and hold time with respect to the rising edge of clock. Data\_Out is valid after a clock-to-data delay from the rising edge of clock.

**NOTES:**

- t<sub>F</sub> = 1/t<sub>cyc</sub>.
- Measured as HIGH above 2.0V and LOW below 0.8V.
- Transition is measured ±200mV from steady-state.
- These parameters are guaranteed with the AC load (Figure 1) by device characterization. They are not production tested.
- To avoid bus contention, the output buffers are designed such that t<sub>CHZ</sub> (device turn-off) is about 2 ns faster than t<sub>CLZ</sub> (device turn-on) at a given temperature and voltage. The specs as shown do not imply bus contention because t<sub>CLZ</sub> is a Min. parameter that is worse case at totally different test conditions (0 deg. C, 3.465V) than t<sub>CHZ</sub>, which is a Max. parameter (worse case at 70 deg. C, 3.135V).

### Timing Waveform of Read Cycle<sup>(1,2,3,4)</sup>

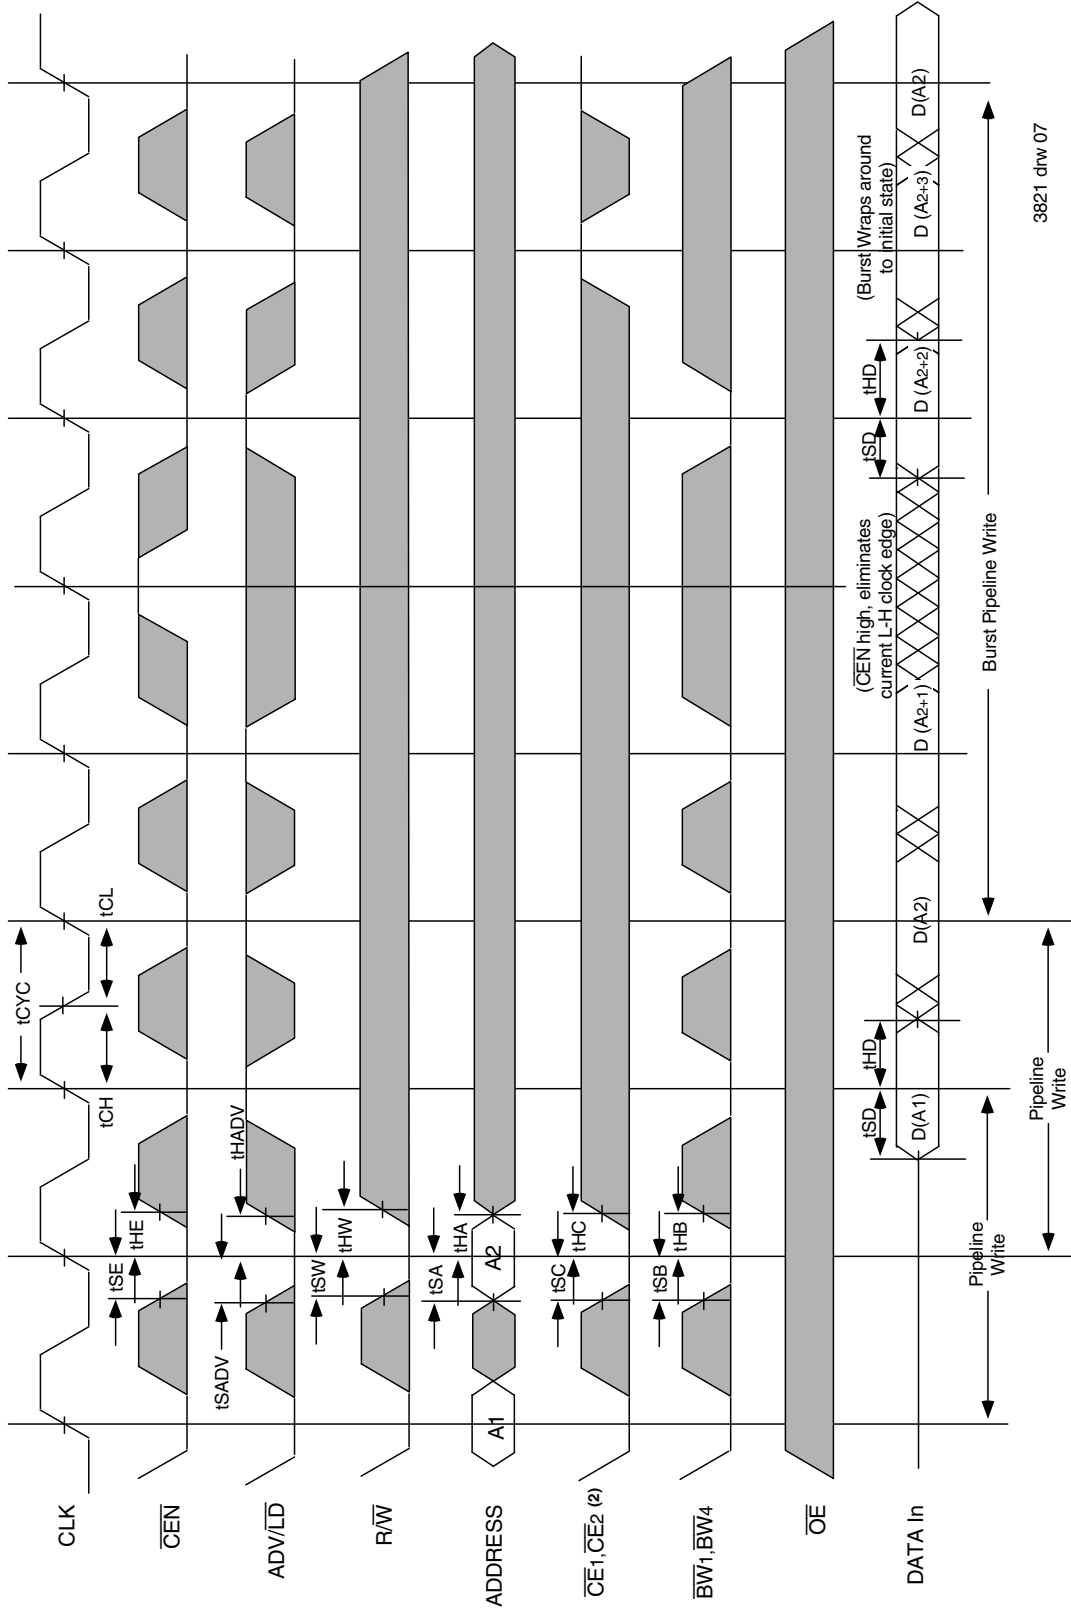

3821 drw 06

**NOTES:**

1. Q (A1) represents the first output from the external address A1. Q (A2) represents the first output from the external address A2. Q (A2+1) represents the next output data in the burst sequence of the base address A2, etc. where address bits A0 and A1 are advancing for the four word burst in the sequence defined by the state of the  $\overline{LBO}$  input.
2. CE2 timing transitions are identical but inverted to the  $\overline{CE1}$  and  $\overline{CE2}$  signals. For example, when  $\overline{CE1}$  and  $\overline{CE2}$  are LOW on this waveform, CE2 is HIGH.
3. Burst ends when new address and control are loaded into the SRAM by sampling ADV/LD LOW.
4.  $\overline{RW}$  is don't care when the SRAM is bursting (ADV/LD sampled HIGH). The nature of the burst access (Read or Write) is fixed by the state of the  $\overline{RW}$  signal when new address and control are loaded into the SRAM.

## Timing Waveform of Write Cycles<sup>(1,2,3,4,5)</sup>

3821 drw 07

### NOTES:

1. D (A1) represents the first input to the external address A1. D (A2) represents the first input to the external address A2. D (A2+) represents the next input data in the burst sequence of the base address A2, etc. where address bits A0 and A1 are advancing for the four word burst in the sequence defined by the state of the LBO input.
2. CE2 timing transitions are identical but inverted to the CE1 and CE2 signals. For example, when CE1 and CE2 are LOW on this waveform, CE2 is HIGH.
3. Burst ends when new address and control are loaded into the SRAM by sampling ADV/LD LOW.
4. RW is don't care when the SRAM is bursting (ADV/LD sampled HIGH). The nature of the burst access (Read or Write) is fixed by the state of the RW signal when new address and control are loaded into the SRAM.
5. Individual Byte Write signals (BWx) must be valid on all write and burst-write cycles. A write cycle is initiated when RW signal is sampled LOW. The byte write information comes in two cycles before the actual data is presented to the SRAM.

Timing Waveform of Combined Read and Write Cycles<sup>(1,2,3)</sup>

3821 drw 08

NOTES:

1. Q(A1) represents the first output from the external address A1. D(A2) represents the input data to the SRAM corresponding to address A2.
2. CE2 timing transitions are identical but inverted to the CE1 and CE2 signals. For example, when CE1 and CE2 are LOW on this waveform, CE2 is HIGH.
3. Individual Byte Write signals (BWx) must be valid on all write and burst-write cycles. A write cycle is initiated when RW signal is sampled LOW. The byte write information comes in two cycles before the actual data is presented to the SRAM.

### Timing Waveform of **CEN** Operation<sup>(1,2,3,4)</sup>

3821 drw 09

**NOTES:**

1. Q (A1) represents the first output from the external address A1. D (A2) represents the input data to the SRAM corresponding to address A2.
2. CE2 timing transitions are identical but inverted to the CE1 and CE2 signals. For example, when CE1 and CE2 are LOW on this waveform, CE2 is HIGH.
3. CEN when sampled high on the rising edge of clock will block that L-H transition of the clock from propagating into the SRAM. The part will behave as if the L-H clock transition did not occur. All internal registers in the SRAM will retain their previous state.
4. Individual Byte Write signals (BWx) must be valid on all write and burst-write cycles. A write cycle is initiated when RW signal is sampled LOW. The byte write information comes in two cycles before the actual data is presented to the SRAM.

### Timing Waveform of $\overline{CS}$ Operation<sup>(1,2,3,4)</sup>

3821 drw 10

**NOTES:**

1. Q (A1) represents the first output from the external address A1. D (A3) represents the input data to the SRAM corresponding to address A3 etc.
2.  $\overline{CE2}$  timing transitions are identical but inverted to the  $\overline{CE1}$  and  $\overline{CE2}$  signals. For example, when  $\overline{CE1}$  and  $\overline{CE2}$  are LOW on this waveform,  $\overline{CE2}$  is HIGH.
3. When either one of the Chip enables ( $\overline{CE1}$ ,  $\overline{CE2}$ ,  $\overline{CE2}$ ) is sampled inactive at the rising clock edge, a deselect cycle is initiated. The data-bus tri-states two cycles after the initiation of the deselect cycle. This allows for any pending data transfers (reads or writes) to be completed.
4. Individual Byte Write signals ( $\overline{BWx}$ ) must be valid on all write and burst-write cycles. A write cycle is initiated when  $\overline{R/W}$  signal is sampled LOW. The byte write information comes in two cycles before the actual data is presented to the SRAM.
