

Description

The 9DMV0131B/9DMV0141B are 1.8V members of IDT's full-featured PCIe clock family. The 9DMV0131B uses external series resistors for maximum flexibility, while the 9DMV0141B integrates output terminations for direct connection to 100Ω transmission lines. An OE# pin provides optimal system control and power management. The parts provide asynchronous or glitch-free switching modes.

PCIe Clocking Architectures

- Common Clocked (CC)
- Independent Reference (IR) with and without spread spectrum

Typical Applications

- Servers
- nVME drives
- Embedded systems/Industrial control
- High-performance computing
- Accelerators

Key Specifications

- Additive cycle-to-cycle jitter < 5ps
- Additive PCIe Gen5 phase jitter < 38fs RMS
- 156.25MHz additive phase jitter 130fs RMS typical (12kHz to 20MHz)

Features

- Direct connection to 100Ω loads saves 4 resistors (9DMV0141B)
- External series resistors allow use in 85Ω or 100Ω systems (9DMV0131B)
- 1.8V operation; 12mW typical power consumption
- Selectable asynchronous or glitch-free switching; allows the mux to be selected at power up even if both inputs are not running, then transition to glitch-free switching mode
- OE# pin for flexible power sequencing
- HCSL differential inputs
- Spread spectrum tolerant; allows reduction of EMI
- 1MHz to 200MHz operating frequency
- Configuration accomplished with strapping pins, no SMBus needed
- Space-saving 3 × 3 mm 16-VFQFPN; minimal board space

Output Features

- 1 Low-Power HCSL (LP-HCSL) DIF pair

 v prefix indicates internal 120kOhm pull-down resistor

Note: Paddle may be connected to ground for thermal purposes. It is not required electrically.

Pin Descriptions

Table 1. Pin Descriptions

Number	Name	Type	Description
1	GNDR	GND	Analog ground pin for the differential input (receiver).
2	VDDR1.8	Power	Power supply for differential input clock (receiver). This V _{DD} should be treated as an analog power rail and filtered appropriately. Nominally 1.8V.
3	VDDR1.8	Power	Power supply for differential input clock (receiver). This V _{DD} should be treated as an analog power rail and filtered appropriately. Nominally 1.8V.
4	GNDR	GND	Analog ground pin for the differential input (receiver).
5	DIF_INB	Input	True input of differential clock.
6	DIF_INB#	Input	Complement input of differential clock.
7	vSW_MODE	Input	Switch Mode. This pin selects either asynchronous or glitch-free switching of the mux. Use asynchronous mode if 0 or 1 of the input clocks is running. Use glitch-free mode if both input clocks are running. This pin has an internal pull down resistor of ~s. 0 = asynchronous mode, 1 = glitch-free mode.
8	^OE0#	Input	Active low input for enabling output 0. This pin has an internal pull-up resistor. 1 = disable output, 0 = enable output.
9	DIF0	Output	Differential true clock output.
10	DIF0#	Output	Differential complementary clock output.
11	GND	GND	Ground pin.

Absolute Maximum Ratings

The absolute maximum ratings are stress ratings only. Stresses greater than those listed below can cause permanent damage to the device. Functional operation of the 9DMV0131B/9DMV0141B at absolute maximum ratings is not implied. Exposure to absolute maximum rating conditions may affect device reliability.

Table 4. Absolute Maximum Ratings

Symbol	Parameter	Conditions	Minimum	Typical	Maximum	Units	Notes
V_{DDxx}	Supply Voltage	Applies to all V_{DD} pins.	-0.5		2.5	V	1,2

¹ Guaranteed by design and characterization, not 100% tested in production.

² Slew rate measured through $\pm 75mV$ window centered around differential zero.

Table 8. DIF Low-Power HCSL Outputs

Symbol	Parameter	Conditions	Minimum	Typical	Maximum	Units	Notes
T_{RF}	Slew Rate	Scope averaging on, 9DMV0141B	2	2.9	4.0	V/ns	1,2,3
ΔT_{RF}	Slew Rate Matching	Slew rate matching, scope averaging on.		3	20	%	1,4
V_{HIGH}	Voltage High	Statistical measurement on single-ended signal using oscilloscope math function (scope averaging on).	660	783	850	mV	
V_{LOW}	Voltage Low		-150	26	150		
V_{MAX}	Max Voltage	Measurement on single ended signal using absolute value (scope averaging off).		790	1150	mV	
V_{MIN}	Min Voltage		-300	9			
V_{CROSS_ABS}	Crossing Voltage (abs)	Scope averaging off.	250	393	550	mV	1,5
$\Delta-V_{CROSS}$	Crossing Voltage (var)	Scope averaging off.		12	140	mV	1,6

¹ Guaranteed by design and characterization, not 100% tested in production.

² Measured from differential waveform.

³ Slew rate is measured through the V_{SWING} voltage range centered around differential 0V. This results in a $\pm 150mV$ window around differential 0V.

⁴ Matching applies to rising edge rate for Clock and falling edge rate for Clock#. It is measured using a $\pm 75mV$ window centered on the average cross point where Clock rising meets Clock# falling. The median cross point is used to calculate the voltage thresholds the oscilloscope is to use for the edge rate calculations.

⁵ V_{CROSS} is defined as voltage where Clock = Clock# measured on a component test board and only applies to the differential rising edge (i.e. Clock rising and Clock# falling).

⁶ The total variation of all V_{CROSS} measurements in any particular system. Note that this is a subset of $V_{CROSS-MIN/MAX}$ (V_{CROSS} absolute) allowed. The intent is to limit V_{CROSS} induced modulation by setting $\Delta-V_{CROSS}$ to be smaller than V_{CROSS} absolute.

t _{j_{cyc-cyc}}	Jitter, Cycle to Cycle	Additive Jitter.			5	ps	1,2

¹ Guaranteed by design and characterization, not 100% tested in production.

² Measured from differential waveform.

³ Duty cycle distortion is the difference in duty cycle between the output and the input clock.

¹ The Refclk jitter is measured after applying the filter functions found in PCI Express Base Specification 5.0, Revision 1.0. See the [Test Loads](#) section of the data sheet for the exact measurement setup. The worst case results for each data rate are summarized in this table. Equipment noise is removed from all measurements.

² Jitter measurements shall be made with a capture of at least 100,000 clock cycles captured by a real-time oscilloscope (RTO) with a sample rate of 20 GS/s or greater. Broadband oscilloscope noise must be minimized in the measurement. The measured PP jitter is used (no extrapolation) for RTO measurements. Alternately - Jitter measurements may be used with a Phase Noise Analyzer (PNA) extending (flat) and integrating and folding the frequency content up to an offset from the carrier frequency of at least 200 MHz (at 300 MHz absolute frequency) below the Nyquist frequency. For PNA measurements for the 2.5 GT/s data rate, the RMS jitter is converted to peak-to-peak jitter using a multiplication factor of 8.83.

- ³ SSC spurs from the fundamental and harmonics are removed up to a cutoff frequency of 2 MHz taking care to minimize removal of any non-SSC content.
- ⁴ The PCI Express Base Specification 5.0, Revision 1.0 provides the filters necessary to calculate SRIS jitter values; it does not provide specification limits, hence the n/a in the Limit column. SRIS values are informative only. A common practice is to split the common clock budget in half. For 16GT/s data rates and above, the user must choose whether to use the output jitter specification, or the input jitter specification, which includes an allocation for the jitter added by the channel. Using 32GT/s, the Refclk jitter budget is 150fs RMS. One half of the Refclk jitter budget is 106fs RMS. At the clock input, the system must deliver 250fs RMS. One half of this value is 177fs RMS. If the clock is placed next to the PCIe device in an SRIS system, the channel is very short and the user may choose to use this more relaxed value as the jitter limit.
- ⁵ The RMS sum of the source jitter and the additive jitter must be less than the jitter specification listed for the clock generator operating mode.
- ⁶ Note that 0.7 ps RMS is to be used in channel simulations to account for additional noise in a real system.
- ⁷ Note that 0.25 ps RMS is to be used in channel simulations to account for additional noise in a real system.

Table 12. Non-PCIe Additive Phase Jitter

T_{AMB} = over the specified operating range. Supply Voltages per normal operation conditions. See [Test Loads](#) for loading conditions

Parameter	Symbol	Conditions	Minimum	Typical	Maximum	Units
Additive Phase Jitter ^[1]	t _{jph12k-20Madd}	12kHz to 20MHz integration range, 156.25MHz carrier. ^[2]	—	130	—	fs RMS

¹ Additive jitter for RMS values is calculated by solving for b, where $[b = \sqrt{c^2 - a^2}]$, "a" is rms input jitter and "c" is rms total jitter.

² Driven by SMA100B source.
