

Description

The IDT8SLVP1104I is a high-performance differential LVPECL fanout buffer. The device is designed for the fanout of high-frequency, very low additive phase-noise clock and data signals. The IDT8SLVP1104I is characterized to operate from a 3.3V or 2.5V power supply.

Guaranteed output-to-output and part-to-part skew characteristics make the IDT8SLVP1104I ideal for those clock distribution applications demanding well-defined performance and repeatability. Four low skew outputs are available. The integrated bias voltage reference enables easy interfacing of single-ended signals to the device inputs. The device is optimized for low power consumption and low additive phase noise.

Features

- Four low skew, low additive jitter LVPECL differential output pairs
- Differential LVPECL input pair can accept the following differential input levels: LVDS, LVPECL, CML
- Differential PCLKx pairs can also accept single-ended LVCMOS levels. See the Applications section Writing the Differential Input Levels to Accept Single-ended Levels (Figures 1 and 2)
- Maximum input clock frequency: 2GHz
- LVCMOS interface levels for the control input (input select)
- Output skew: 5ps (typical)
- Propagation delay: 320ps (maximum)
- Low additive phase jitter, RMS; $f_{REF} = 156.25\text{MHz}$, $V_{PP} = 1\text{V}$, 12kHz - 20MHz: 40fs (maximum)
- Maximum device current consumption (I_{EE}): 60mA (maximum)
- Full 3.3V or 2.5V supply voltage
- Lead-free (RoHS 6) packaging
- -40°C to 85°C ambient operating temperature

Pin Descriptions and Characteristics

Table 1. Pin Descriptions

| Number | Name | Type | | Description |
|--------|------------------|--------|---------------------|--|
| 1 | V _{EE} | Power | | Negative supply pin. |
| 2 | nc | Unused | | Do not connect. |
| 3 | nc | Unused | | Do not connect. |
| 4 | nc | Unused | | Do not connect. |
| 5 | V _{CC} | Power | | Power supply pin. |
| 6 | PCLK | Input | Pulldown | Non-inverting differential LVPECL clock/data input. |
| 7 | nPCLK | Input | Pullup/ Pulldown | Inverting differential LVPECL clock/data input. V _{CC} /2 default when left floating. |
| 8 | V _{REF} | Output | | Bias voltage reference for the PCLK inputs. |
| 9, 10 | Q0, nQ0 | Output | | Differential output pair 0. LVPECL interface levels. |
| 11, 12 | Q1, nQ1 | Output | | Differential output pair 1. LVPECL interface levels. |
| 13, 14 | Q2, nQ2 | Output | | Differential output pair 2. LVPECL interface levels. |
| 15, 16 | Q3, nQ3 | Output | | Differential output pair 3. LVPECL interface levels. |

NOTE: *Pulldown* and *Pullup* refers to an internal input resistors. See Table 2, *Pin Characteristics*, for typical values.

Table 2. Pin Characteristics

| Symbol | Parameter | Test Conditions | Minimum | Typical | Maximum | Units |
|-----------------------|-------------------------|-----------------|---------|---------|---------|-------|
| C _{IN} | Input Capacitance | | | 2 | | pF |
| R _{PULLDOWN} | Input Pulldown Resistor | | | 51 | | kΩ |
| R _{PULLUP} | Input Pullup Resistor | | | 51 | | kΩ |

Absolute Maximum Ratings

NOTE: Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These ratings are stress specifications only. Functional operation of product at these conditions or any conditions beyond those listed in the *DC Characteristics* or *AC Characteristics* is not implied. Exposure to absolute maximum rating conditions for extended periods may affect product reliability.

| Item | Rating |
|--|--------------------------|
| Supply Voltage, V_{CC} | 4.6V |
| Inputs, V_I | -0.5V to $V_{CC} + 0.5V$ |
| Outputs, I_O (LVPECL) Continuous Current Surge Current | 50mA 100mA |
| Input Sink/Source, I_{REF} | $\pm 2mA$ |
| Maximum Junction Temperature, $T_{J,MAX}$ | 125°C |

NOTE: Electrical parameters are guaranteed over the specified ambient operating temperature range, which is established when the device is mounted in a test socket with maintained transverse airflow greater than 500 lfm. The device will meet specifications after thermal equilibrium has been reached under these conditions.

NOTE 1: Measured from the differential input crossing point to the differential output crossing point.

NOTE 2: Defined as skew between outputs at the same supply voltage and with equal load conditions. Measured at the differential crosspoints.

NOTE 3: This parameter is defined in accordance with JEDEC Standard 65.

NOTES continued on next page.

NOTE 4: Defined as skew between outputs on different devices operating at the same supply voltage, same frequency, same temperature and with equal load conditions. Using the same type of inputs on each device, the outputs are measured at the differential cross points.

NOTE 5: For single-ended LVCMOS input applications, refer to the Applications section *Writing the Differential Input Levels to Accept Single-ended Levels* (Figures 1 and 2).

NOTE 6: V_{IL} should not be less than -0.3V.

NOTE 7: Common mode input voltage is defined as the crosspoint.

Additive Phase Jitter

The spectral purity in a band at a specific offset from the fundamental compared to the power of the fundamental is called the **dBc Phase Noise**. This value is normally expressed using a Phase noise plot and is most often the specified plot in many applications. Phase noise is defined as the ratio of the noise power present in a 1Hz band at a specified offset from the fundamental frequency to the power value of the fundamental. This ratio is expressed in decibels (dBm) or a ratio

of the power in the 1Hz band to the power in the fundamental. When the required offset is specified, the phase noise is called a **dBc** value, which simply means dBm at a specified offset from the fundamental. By investigating jitter in the frequency domain, we get a better understanding of its effects on the desired application over the entire time record of the signal. It is mathematically possible to calculate an expected bit error rate given a phase noise plot.

As with most timing specifications, phase noise measurements has issues relating to the limitations of the equipment. Often the noise floor of the equipment is higher than the noise floor of the device. This is illustrated above. The device meets the noise floor of what is shown, but can actually be lower. The phase noise is dependent on the input source and measurement equipment.

Measured using a Wenzel 156.25MHz Oscillator as the input source.

Applications Information

Wiring the Differential Input to Accept Single-Ended Levels

The IDT8SLVP1104I inputs can be interfaced to LVPECL, LVDS, CML or LVCMOS drivers. *Figure 1A* illustrates how to dc couple a single LVCMOS input to the IDT8SLVP1104I. The value of the series resistance R_S is calculated as the difference between the transmission line impedance and the driver output impedance. This resistor should be placed close to the LVCMOS driver. To avoid cross-coupling of single-ended LVCMOS signals, apply the LVCMOS signals to no more than one PCLK input.

A practical method to implement V_{th} is shown in *Figure 1B* below. The reference voltage $V_{th} = V_1 = V_{CC}/2$, is generated by the bias resistors R_1 and R_2 . The bypass capacitor (C_1) is used to help filter noise on the DC bias. This bias circuit should be located as close to the input pin as possible.

The ratio of R_1 and R_2 might need to be adjusted to position the V_1 in the center of the input voltage swing. For example, if the input clock swing is 2.5V and $V_{CC} = 3.3V$, R_1 and R_2 value should be adjusted to set V_1 at 1.25V. The values below apply when both the single-ended swing and V_{CC} are at the same voltage.

Figure 1A. DC-Coupling a Single LVCMOS Input to the IDT8SLVP1104I

When using single-ended signaling, the noise rejection benefits of differential signaling are reduced. Even though the differential input can handle full rail LVCMOS signaling, it is recommended that the amplitude be reduced, particularly if both input references are LVCMOS to minimize cross talk. The datasheet specifies a lower differential amplitude, however this only applies to differential signals. For single-ended applications, the swing can be larger, however V_{IL} cannot be less than $-0.3V$ and V_{IH} cannot be more than $V_{CC} + 0.3V$.

Figure 1B shows a way to attenuate the PCLK input level by a factor of two as well as matching the transmission line between the LVCMOS driver and the IDT8SLVP1104I at both the source and the

load. This configuration requires that the sum of the output impedance of the driver (R_o) and the series resistance (R_s) equals the transmission line impedance. R_3 and R_4 in parallel should equal the transmission line impedance; for most 50Ω applications, R_3 and R_4 will be 100Ω . The values of the resistors can be increased to reduce the loading for slower and weaker LVCMOS driver.

Though some of the recommended components of *Figure 1B* might not be used, the pads should be placed in the layout so that they can be utilized for debugging purposes. The datasheet specifications are characterized and guaranteed by using a differential signal.

Figure 1B. Alternative DC Coupling a Single LVCMOS Input to the IDT8SLVP1104I

3.3V LVPECL Clock Input Interface

The PCLK/nPCLK accepts LVPECL, LVDS, CML and other differential signals. Both signals must meet the V_{PP} and V_{CMR} input requirements. Figures 2A to 2E show interface examples for the PCLK/nPCLK input driven by the most common driver types. The

input interfaces suggested here are examples only. If the driver is from another vendor, use their termination recommendation. Please consult with the vendor of the driver component to confirm the driver termination requirements.

Recommendations for Unused Output Pins

Outputs:

LVPECL Outputs

All unused LVPECL outputs can be left floating. We recommend that there is no trace attached. Both sides of the differential output pair should either be left floating or terminated.

VFQFPN EPAD Thermal Release Path

In order to maximize both the removal of heat from the package and the electrical performance, a land pattern must be incorporated on the Printed Circuit Board (PCB) within the footprint of the package corresponding to the exposed metal pad or exposed heat slug on the package, as shown in *Figure 4*. The solderable area on the PCB, as defined by the solder mask, should be at least the same size/shape as the exposed pad/slug area on the package to maximize the thermal/electrical performance. Sufficient clearance should be designed on the PCB between the outer edges of the land pattern and the inner edges of pad pattern for the leads to avoid any shorts.

While the land pattern on the PCB provides a means of heat transfer and electrical grounding from the package to the board through a solder joint, thermal vias are necessary to effectively conduct from the surface of the PCB to the ground plane(s). The land pattern must be connected to ground through these vias. The vias act as “heat pipes”. The number of vias (i.e. “heat pipes”) are application specific

and dependent upon the package power dissipation as well as electrical conductivity requirements. Thus, thermal and electrical analysis and/or testing are recommended to determine the minimum number needed. Maximum thermal and electrical performance is achieved when an array of vias is incorporated in the land pattern. It is recommended to use as many vias connected to ground as possible. It is also recommended that the via diameter should be 12 to 13mils (0.30 to 0.33mm) with 1oz copper via barrel plating. This is desirable to avoid any solder wicking inside the via during the soldering process which may result in voids in solder between the exposed pad/slug and the thermal land. Precautions should be taken to eliminate any solder voids between the exposed heat slug and the land pattern. Note: These recommendations are to be used as a guideline only. For further information, please refer to the Application Note on the Surface Mount Assembly of Amkor’s Thermally/ Electrically Enhance Leadframe Base Package, Amkor Technology.

Figure 4. P.C. Assembly for Exposed Pad Thermal Release Path – Side View (drawing not to scale)

Termination for 3.3V LVPECL Outputs

The clock layout topology shown below is a typical termination for LVPECL outputs. The two different layouts mentioned are recommended only as guidelines.

The differential outputs are a low impedance follower output that generate ECL/LVPECL compatible outputs. Therefore, terminating resistors (DC current path to ground) or current sources must be used for functionality. These outputs are designed to drive 50Ω

transmission lines. Matched impedance techniques should be used to maximize operating frequency and minimize signal distortion.

Figures 5A and 5B show two different layouts which are recommended only as guidelines. Other suitable clock layouts may exist and it would be recommended that the board designers simulate to guarantee compatibility across all printed circuit and clock component process variations.

Figure 5A. 3.3V LVPECL Output Termination

Figure 5B. 3.3V LVPECL Output Termination

Termination for 2.5V LVPECL Outputs

Figure 6A and Figure 6B show examples of termination for 2.5V LVPECL driver. These terminations are equivalent to terminating 50Ω to $V_{CC} - 2V$. For $V_{CC} = 2.5V$, the $V_{CC} - 2V$ is very close to ground

level. The R3 in Figure 6B can be eliminated and the termination is shown in Figure 6C.

Figure 6C. 2.5V LVPECL Driver Termination Example

Power Considerations

This section provides information on power dissipation and junction temperature for the IDT8SLVP1104I. Equations and example calculations are also provided.

1. Power Dissipation.

The total power dissipation for the IDT8SLVP1104I is the sum of the core power plus the power dissipated due to loading. The following is the power dissipation for $V_{CC} = 3.465V$, which gives worst case results.

NOTE: Please refer to Section 3 for details on calculating power dissipated due to loading.

The maximum current at 85° is as follows:

$$I_{EE_MAX} = 60mA$$

- Power (core)_{MAX} = $V_{CC_MAX} * I_{EE_MAX} = 3.465V * 60mA = 207.9mW$
- Power (outputs)_{MAX} = **33.2mW/Loaded Output pair**
If all outputs are loaded, the total power is $4 * 33.2mW = 132.8mW$

$$\text{Total Power}_{_MAX} (3.465V, \text{ with all outputs switching}) = 207.9mW + 132.8mW = 340.7mW$$

2. Junction Temperature.

Junction temperature, T_j , is the temperature at the junction of the bond wire and bond pad directly affects the reliability of the device. The maximum recommended junction temperature is 125°C. Limiting the internal transistor junction temperature, T_j , to 125°C ensures that the bond wire and bond pad temperature remains below 125°C.

The equation for T_j is as follows: $T_j = \theta_{JA} * Pd_total + T_A$

T_j = Junction Temperature

θ_{JA} = Junction-to-Ambient Thermal Resistance

Pd_total = Total Device Power Dissipation (example calculation is in section 1 above)

T_A = Ambient Temperature

In order to calculate junction temperature, the appropriate junction-to-ambient thermal resistance θ_{JA} must be used. Assuming no air flow and a multi-layer board, the appropriate value is 74.7°C/W per Table 5 below.

Therefore, T_j for an ambient temperature of 85°C with all outputs switching is:

$$85^\circ C + 0.341W * 74.7^\circ C/W = 110.5^\circ C. \text{ This is below the limit of } 125^\circ C.$$

This calculation is only an example. T_j will obviously vary depending on the number of loaded outputs, supply voltage, air flow and the type of board (multi-layer).

Table 5. Thermal Resistance θ_{JA} for 16-Lead VFQFPN, Forced Convection

| Meters per Second | θ_{JA} by Velocity | | |
|---|---------------------------|----------|----------|
| | 0 | 1 | 2.5 |
| Multi-Layer PCB, JEDEC Standard Test Boards | 74.7°C/W | 65.3°C/W | 58.5°C/W |

3. Calculations and Equations.

The purpose of this section is to calculate the power dissipation for the LVPECL output pair.

LVPECL output driver circuit and termination are shown in *Figure 7*.

Figure 7. LVPECL Driver Circuit and Termination

To calculate power dissipation due to loading, use the following equations which assume a 50Ω load, and a termination voltage of V_{CC} - 2V. These are typical calculations.

- For logic high, V_{OUT} = V_{OH_MAX} = V_{CC_MAX} - 0.7V
(V_{CC_MAX} - V_{OH_MAX}) = 0.7V
- For logic low, V_{OUT} = V_{OL_MAX} = V_{CC_MAX} - 1.5V
(V_{CC_MAX} - V_{OL_MAX}) = 1.5V

Pd_H is power dissipation when the output drives high.

Pd_L is the power dissipation when the output drives low.

$$Pd_H = [(V_{OH_MAX} - (V_{CC_MAX} - 2V))/R_L] * (V_{CC_MAX} - V_{OH_MAX}) = [(2V - (V_{CC_MAX} - V_{OH_MAX}))/R_L] * (V_{CC_MAX} - V_{OH_MAX}) = [(2V - 0.7V)/50\Omega] * 0.7V = \mathbf{18.2mW}$$

$$Pd_L = [(V_{OL_MAX} - (V_{CC_MAX} - 2V))/R_L] * (V_{CC_MAX} - V_{OL_MAX}) = [(2V - (V_{CC_MAX} - V_{OL_MAX}))/R_L] * (V_{CC_MAX} - V_{OL_MAX}) = [(2V - 1.5V)/50\Omega] * 1.5V = \mathbf{15mW}$$

$$\text{Total Power Dissipation per output pair} = Pd_H + Pd_L = \mathbf{33.2mW}$$

Reliability Information

Table 6. θ_{JA} vs. Air Flow Table for a 16-Lead VFQFPN

| θ_{JA} at 0 Air Flow | | | |
|---|----------|----------|----------|
| Meters per Second | 0 | 1 | 2.5 |
| Multi-Layer PCB, JEDEC Standard Test Boards | 74.7°C/W | 65.3°C/W | 58.5°C/W |

Transistor Count

The transistor count for the IDT8SLVP1104I is: 258
