The ISL81801 is a true bidirectional 4-switch synchronous buck-boost controller with peak and average current sensing and monitoring at both ends. With wide input and output voltage ranges, the controller is suitable for industrial, telecommunication, and after-market automotive applications.

The ISL81801 uses a proprietary buck-boost control algorithm with valley current modulation for Boost mode and peak current modulation for Buck mode control.

The ISL81801 has four independent control loops for input and output voltages and currents. Inherent peak current sensing at both ends and cycle-by-cycle current limit of this family of products ensures high operational reliability by providing instant current limit in fast transient conditions at either end and in both directions. It also has two current monitoring pins at both input and output to facilitate Constant Current (CC) limit and other system management functions. CC operation down to low voltages avoids any runaway condition at over load or short-circuit conditions. In addition to multilayer overcurrent protection, it also provides full protection features such as OVP, UVP, OTP, average and peak current limit on both input and output to ensure high reliability in both unidirectional and bidirectional operation.

The IC is packaged in a space-conscious 32 LD 5mm x5mm TQFN package or easy to assemble 4.4mmx9.7mm 38 LD HTSSOP package. Both packages use an EPAD to improve thermal performance and noise immunity. Low pin count, fewer external components, and default internal values make the ISL81801 an ideal solution for time to market simple power supply designs. The unique DE/Burst mode at light-load dramatically lowers standby power consumption with consistent output ripple over different load levels.

### Features
- Single inductor 4-switch buck-boost controller
- On-the-fly bidirectional operation with independent control of voltage and current on both ends
- Proprietary algorithm for smoothest mode transition
- MOSFET drivers with adaptive shoot-through protection
- Wide input voltage range: 4.5V to 80V
- Wide output voltage range: 0.8V to 80V
- Supports startup into pre-biased rails
- Programmable frequency: 100kHz to 600kHz
- Supports parallel operation current sharing with cascade phase interleaving
- External sync with clock out or frequency dithering
- External bias for higher efficiency for 8V to 36V input
- Output and input current monitor
- Selectable PWM mode operation between PWM/DE/Burst modes
- Accurate EN/UVLO and PGOOD indicator
- Low shutdown current: 2.7µA
- Complete protection: OCP, SCP, OVP, OTP, and UVP
  - Dual-level OCP with average current and pulse-by-pulse peak current limit, also provides Short Circuit Protection (SCP)
  - Selectable OCP response with either hiccup or constant current mode
  - Negative pulse-by-pulse peak current limit

### Applications
- Battery backup
- UPS/storage systems
- Battery powered industrial applications
- Renewable energy
- Aftermarket automotive
- Redundant power supplies
- Robots and drones
- Medical equipment
- Building and industrial automation
- Security surveillance

**Notes:**
1. See TB347 for details about reel specifications.
2. These Pb-free plastic packaged products employ special Pb-free material sets, molding compounds/die attach materials, and 100% matte tin plate plus anneal (e3 termination finish, which is RoHS compliant and compatible with both SnPb and Pb-free soldering operations). Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J-STD-020.
3. For Moisture Sensitivity Level (MSL), see the ISL81801 device page. For more information about MSL, see TB363.

### Pin Information

<table>
<thead>
<tr>
<th>Pin # (TQFN)</th>
<th>Pin # (HTSSOP)</th>
<th>Pin Name</th>
<th>Function</th>
</tr>
</thead>
</table>
| 5           | 12            | RT/SYNC | A resistor from this pin to ground adjusts the default switching frequency from 100kHz to 600kHz. The default switching frequency of the PWM controller is determined by the resistor $R_T$ as shown in Equation 1.  

$$R_T = \left( \frac{34.7}{f_{SW}} - 4.78 \right) \cdot k\Omega$$  

where $f_{SW}$ is the switching frequency in MHz.  

When this pin is open or tied to VCC5V, $f_{SW}$ is set to 120kHz. When this pin is tied to GND, $f_{SW}$ is set to 575kHz.  

When an external clock signal is applied to this pin, the internal frequency is synchronized to the external clock frequency. |
| 6           | 13            | PLL_COMP | Compensation pin for the internal PLL circuit. A compensation network shown in the Figure 52 is required. $R_{PLL}$ (2.7kΩ), $C_{PLL1}$ (10nF), and $C_{PLL2}$ (820pF) are recommended. |
| 7           | 14            | CLKOUT/ DITHER | Dual function pin. When there is no capacitor connected to this pin, it provides a clock signal to synchronize the other ISL81901(s). The phase shift of the clock signal is set by the FB_IN and IMON_IN pin voltages.  

When a capacitor is connected to this pin, the clock out function is disabled and the frequency dither function is enabled before the soft-start. The capacitor is charged and discharged by internal current sources. As the voltage on the pin ramps up and down, the oscillator frequency is modulated between -15% and +15% of the nominal frequency set by the $R_T$ resistor. The frequency dither function is disabled in the external Sync mode or if the RT pin is open or shorted. |
| 8           | 15            | SS/TRK | Dual function pin. When used for soft-start control, a soft-start capacitor is connected from this pin to ground. A regulated 2μA current source charges up the soft-start capacitor. The value of the soft-start capacitor sets the output voltage ramp.  

When used for tracking control, an external supply rail is configured as the master, and the output voltage of the master supply is applied to this pin using a resistor divider. The output voltage tracks the master supply voltage. |
| 9           | 16            | COMP | Voltage error GM amplifier output. It sets the reference of the inner current loop. The feedback compensation network is connected between the COMP and SGND pins. When the COMP pin is pulled below 1V, the PWM duty cycle reduces to 0%. |
| 10          | 17            | FB_OUT | Output voltage feedback input. Connect FB_OUT to a resistive voltage divider between the output and SGND to adjust the output voltage. The FB_OUT pin voltage is regulated to the internal 0.8V reference. |
| 11          | 18            | IMON_OUT | Output current monitor. The current from this pin is proportional to the differential voltage between the ISEN+ and ISEN- pins. Connect a resistor and capacitor network between this pin and SGND to make the pin voltage proportional to the average output current. When the pin voltage reaches 1.2V, the internal average current limit loop reduces the output voltage to keep the output current constant when constant current OCP mode is set or the converter shuts down when hiccup OCP mode is set.  

In DE Burst mode, when this pin voltage is less than 850mV, the controller runs in Burst mode. When this pin voltage is higher than 880mV, the controller exits Burst mode. When a higher resistance on this pin sets its voltage higher than 880mV at no load condition, the controller runs in DE mode with no burst operation. |
<p>| 12          | 19            | OV | OVP comparator output signal. The pin is pulled low to GND by an internal 250k resistor in normal operation. It is pulled high when output OVP trips. The pull-up MOSFET $R_{DS(ON)}$ resistance is about 4.5k. Connect this pin with other OV pins in multi-chip parallel operation applications to sync all of the OV indicators of the chips together for the OVP reaction. |
| 13          | 20            | ISEN- | Output current sense signal negative input pin. |
| 14          | 21            | ISEN+ | Output current sense signal positive input pin. |
| 15          | 23            | PGOOD | Power Good open-drain logic output that indicates the status of output voltage. This pin is pulled low when the output is not within ±10% of the nominal voltage or the EN pin is pulled LOW. |
| 16          | 25            | UG2 | High-side MOSFET gate driver output controlled by the boost PWM signal. |
| 17          | 26            | PHASE2 | Phase node connection of the boost converter. This pin is connected to the junction of the upper MOSFET source, filter inductor, and lower MOSFET drain of the boost converter. |
| 18          | 27            | BOOT2 | Bootstrap pin to provide bias for the boost high-side driver. The positive terminal of the bootstrap capacitor connects to this pin. Connect a bootstrap diode between this pin and VDD to create the bias for the high-side driver. The BOOT2 to PHASE2 voltage is monitored internally. When the voltage drops to 5.95V at no switching condition, a minimum off-time pulse is issued to turn off UG2 and turn on LG2 to refresh the bootstrap capacitor and maintain the high-side driver bias voltage. |</p>

ISL81801 3. Specifications

FN8937 Rev.1.3
Jul 14, 2023
## 3. Specifications

Recommended operating conditions unless otherwise noted. See [Block Diagram](#) and [Typical Application Schematics](#). \( V_{IN} = 4.5 \text{V to 80V}, \) or \( V_{DD} = 8 \text{V} \pm 10\%, C_{VCC5V} = 4.7\mu F, T_A = -40^\circ \text{C to +125^\circ C}, \) Typical values are at \( T_A = +25^\circ \text{C}, \) unless otherwise specified. **Boldface limits** apply across the operating temperature range, \(-40^\circ \text{C to +125^\circ C}_.\) (Continued)

5. Functional Description

5.1 General Description

The ISL81801 implements complete buck-boost switching control with a PWM controller, internal drivers, references, protection circuitry, current and voltage control inputs, and monitor outputs. See Figure 6.

The ISL81801 is a current-mode controller. It uses a proprietary control algorithm to automatically switch between Buck and Boost modes as necessary to maintain a steady output voltage with changing input voltages and dynamic external loads. The controller integrates four control loops to regulate not only V\text{OUT} but also average I\text{OUT} and I\text{IN} for constant current control and V\text{IN} for reverse direction control.

The driver and protection circuits are also integrated to simplify the end design.

The part has an independent enable/disable control line (EN/UVLO pin), which provides flexible power-up sequencing and a simple V\text{IN} UVP implementation. The soft-start time is programmable by adjusting the soft-start capacitor on the SS/TRK pin.

5.2 Internal 8V Linear Regulator (VDD), External Bias Supply (EXTBIAS), and 5V Linear Regulator (VCC5V)

The ISL81801 provides two input pins, VIN and EXTBIAS, and two internal LDOs for the VDD gate driver supply. A third LDO generates VCC5V from VDD. VCC5V provides power to all internal functional circuits other than the gate drivers. Bypass the linear regulator outputs (VDD) with a 10µF capacitor to the power ground. Also, bypass the third linear regulator output (VCC5V) with a 10µF capacitor to the signal ground. VCC5V is monitored by a power-on-reset circuit, which disables all regulators when VCC5V falls below 3.5V.

Both LDOs from VIN and EXTBIAS can source over 75mA for VDD to power the buck and boost gate drivers. When driving large FETs at a high switching frequency, little or no regulator current may be available for external loads. The LDO from VDD to VCC5V can also source over 75mA to supply the IC internal circuit. Although the current consumed by the internal circuit is low, the current supplied by VCC5V to the external loads is limited by VDD. For example, a single large FET with 15nC total gate charge requires 15nC x 300kHz = 4.5mA (15nC x 600kHz = 9mA).

Also, at higher input voltages with larger FETs, the power dissipation across the internal 8V LDO increases. Excessive power dissipation across this regulator must be avoided to prevent junction temperature rise. Thermal protection is triggered if the die temperature increases above +160°C because excessive power dissipation.

When large MOSFETs or high input voltages are used, an external 8V bias voltage is applied to the EXTBIAS pin to alleviate excessive power dissipation. When the voltage at the EXTBIAS pin is higher than typical 7.38V, the LDO from EXTBIAS activates and the LDO from VIN is disconnected. The recommended maximum voltage at the EXTBIAS pin is 36V. For applications with V\text{OUT} significantly lower than VIN, EXTBIAS is usually back biased by V\text{OUT} to reduce the LDO power loss. EXTBIAS is allowed to activate only after soft-start is finished to avoid early activation during the V\text{OUT} rising stage. An external UVLO circuit might be necessary to ensure smooth soft-starting. Renesas recommends adding a 10µF capacitor on the EXTBIAS pin and using a diode to connect the EXTBIAS pin to V\text{OUT} to prevent the EXTBIAS pin voltage from being pulled low because a V\text{OUT} short-circuit condition.

The two VDD LDOs have an overcurrent limit for short-circuit protection. The VIN to VDD LDO current limit is set to typical 120mA. The EXTBIAS to VDD LDO current limit is set to a typical 160mA.

5.3 Enable (EN/UVLO) and Soft-Start Operation

Pulling the EN/UVLO pin high or low can enable or disable the controller. The EN/UVLO pin has an internal 5.6V voltage clamp that allows this pin to be connected through a resistor to a higher voltage, provided that the maximum current into the EN/UVLO pin does not exceed 100µA. When the EN/UVLO pin voltage is higher than 1.3V, the three LDOs are enabled. After the VCC5V reaches the POR threshold, the controller is powered up to initialize its internal circuit. When EN/UVLO is higher than the 1.8V accurate undervoltage-lockout (UVLO) threshold, the ISL81801 soft-start circuitry becomes active. An internal 2µA current source begins charging up the soft-start capacitor connected from the SS/TRK pin to GND. The voltage on the SS/TRK pin acts as the reference
for the voltage error amplifier during soft-start, until it reaches 0.8V. The output voltage thus rises from 0V to regulation as SS/TRK rises from 0V to 0.8V. Charging of the soft-start capacitor continues until the voltage on the SS/TRK pin reaches 3V.

Typical applications for ISL81801 use programmable analog soft-start or the SS/TRK pin for tracking. The soft-start time is set by the value of the soft-start capacitor connected from SS/TRK to GND. Inrush current during start-up is alleviated by adjusting the soft-starting time.

The typical soft-start time is set according to Equation 2:

\[
\text{\textbf{(EQ. 2)}} \quad t_{SS} = 0.8V\left(\frac{C_{SS}}{2\mu A}\right)
\]

When the soft-start time set by external \( C_{SS} \) or tracking is less than 1.7ms, an internal soft-start circuit of 1.7ms takes over the soft-start.

PGOOD toggles to high when the output voltage is in regulation.

Pulling the EN/UVLO lower than the EN falling threshold, \( V_{ENSS,\text{THF}} \) typical 0.9V, disables the PWM output and internal LDOs to achieve low standby current. The SS/TRK pin is also discharged to GND by an internal MOSFET with 70\( \Omega \) \( r_{DS(\text{ON})} \). For applications with a larger than 1\( \mu \)F capacitor on the SS/TRK pin, Renesas recommends adding a 100\( \Omega \) to 1k\( \Omega \) resistor in series with the capacitor to share the power loss at the discharge.

With use of the accurate UVLO threshold, an accurate \( V_{IN} \) Undervoltage Protection (UVP) feature is implemented by feeding the \( V_{IN} \) into the EN/UVLO pin using a voltage divider, \( R_{UV1} \) and \( R_{UV2} \), shown in Figure 42.

\[
\text{\textbf{Figure 42.} } V_{IN} \text{ Undervoltage Protection}
\]

The \( V_{IN} \) UVP rising threshold is calculated using Equation 3.

\[
\text{(EQ. 3)} \quad V_{\text{UVRISE}} = \frac{V_{\text{UVLO,THR}}(R_{UV1} + R_{UV2}) - 1.1x10^{-6} R_{UV1}R_{UV2}}{R_{UV2}}
\]

where \( V_{\text{UVLO,THR}} \) is the EN/UVLO pin UVLO rising threshold, typically 1.8V.

The \( V_{IN} \) UVP falling threshold is calculated using Equation 4.

\[
\text{(EQ. 4)} \quad V_{\text{UVFALL}} = \frac{V_{\text{UVLO,THR}}(R_{UV1} + R_{UV2}) - I_{\text{UVLO,HYST}} R_{UV1}R_{UV2}}{R_{UV2}}
\]

where \( I_{\text{UVLO,HYST}} \) is the UVLO hysteresis current, typically 4.2\( \mu \)A.

### 5.4 Tracking Operation

The ISL81801 can track an external supply. To implement tracking, connect a resistive divider between the external supply output and ground. Connect the center point of the divider to the SS/TRK pin of the ISL81801. The resistive divider ratio sets the ramping ratio between the two voltage rails. To implement coincident tracking, set the tracking...
resistive divider ratio the same as the ISL81801 output-resistive divider given by Equation 5. Make sure that the voltage at SS/TRK is greater than 0.8V when the master rail reaches regulation.

To minimize the impact of the 2µA soft-start current on the tracking function, Renesas recommends using resistors less than 10kΩ for the tracking resistive divider.

When the SS/TRK pin voltage is pulled down to less than 0.3V by the external tracking source, the prebias startup DE mode function is enabled again. The output voltage may not be able to be pull down if the load current is not high enough.

When Overcurrent Protection (OCP) is triggered, the internal minimum soft-start circuit determines the 50ms OCP soft-start hiccup off-time.

5.5 Control Loops

The ISL81801 is a current-mode controller that can provide an output voltage above, equal to, or below the input voltage. The Renesas proprietary control architecture uses a current sense resistor in series with the buck upper FET to sense the inductor current in Buck or Boost mode (see Figure 1 (Typical Application circuit) and Figure 6 (Block Diagram)). The inductor current is controlled by the voltage on the COMP pin, which is the lowest output of the error amplifiers Gm1 - Gm4. As the simplest example, when the output is regulated to a constant voltage, the FB_OUT pin receives the output feedback signal, which is compared to the internal reference by Gm1. Lower output voltage creates higher COMP voltage that leads to a higher PWM duty cycle to deliver more current to the output. Conversely, higher output voltage creates lower COMP voltage that leads to a lower PWM duty cycle to reduce the current delivered to the output.

The ISL81801 has four error amplifiers (Gm1-4) that can control output voltage (Gm1), input voltage (Gm2), input current (Gm3), and output current (Gm4). In a typical application, the output voltage is regulated by Gm1, and the remaining error amplifiers are monitoring for excessive input or output current or an input undervoltage condition. In other applications, such as a battery charger, the output current regulator (Gm4) implements constant current charging until a predetermined voltage is reached at which point the output voltage regulator (Gm1) takes control.

5.5.1 Output Voltage Regulation Loop

The ISL81801 provides a precision 0.8V internal reference voltage to set the output voltage. Based on this internal reference, the output voltage is set from 0.8V up to a level determined by the feedback voltage divider, as shown in Figure 43.

A resistive divider from the output to ground sets the output voltage. Connect the center point of the divider to the FB_OUT pin. The output voltage value is determined by Equation 5.

\[
V_{OUT} = 0.8V \left( \frac{R_{FBO1} + R_{FBO2}}{R_{FBO2}} \right)
\]

where \( R_{FBO1} \) is the top resistor of the feedback divider network and \( R_{FBO2} \) is the bottom resistor connected from FB_OUT to ground, shown in Figure 43.
As shown in Figure 43, the $R_{COMP}$, $C_{COMP1}$, and $C_{COMP2}$ network connected on the Gm1 regulator output COMP pin is needed to compensate the loop for stable operation. The loop stability is affected by many different factors such as $V_{IN}$, $V_{OUT}$, load current, switching frequency, inductor value, output capacitance and the compensation network on COMP pin. For most applications, 22nF is a good value for $C_{COMP1}$. A larger $C_{COMP1}$ makes the loop more stable by giving a larger phase margin, but the loop bandwidth is lower. $C_{COMP2}$ is typically 1/10th to 1/30th of $C_{COMP1}$ to filter high frequency noise. A good starting value for $R_{COMP}$ is 10k. Lower $R_{COMP}$ improves stability but slows the loop response. Optimize the final compensation network with a bench test.

### 5.5.2 Input Voltage Regulation Loop

As shown in Figure 44, the input voltage $V_{IN}$ is sensed by the FB_IN pin using a resistor divider $R_{FBIN1}/R_{FBIN2}$ and regulated by Gm2. When the FB_IN pin voltage falls below the 0.8V reference voltage, the COMP pin voltage is pulled low to reduce the PWM duty cycle and thus the input current. For applications with a high input source impedance, such as a solar panel, the input voltage regulation loop can prevent the input voltage from being pulled too low in high output load conditions. For applications with a low input source impedance, such as batteries, the $V_{IN}$ feedback loop can prevent the battery from being over-discharged. For DC back-up system applications, with loads on the VIN supply side and a backup battery or super capacitor on the output side, the input voltage regulation loop can reverse the power conversion direction and draw energy from the output side to regulate the VIN voltage. The regulated input voltage value is determined by Equation 6.

\[
V_{IN} = 0.8V \left( \frac{R_{FBIN1} + R_{FBIN2}}{R_{FBIN2}} \right)
\]

Figure 44. $V_{IN}$ Feedback Loop

FB_IN is a dual-function pin. It also sets the phase angle of the clock output signal on the CLKOUT/DITHER pin, shown in Table 2. The $V_{IN}$ feedback loop is disabled when the FB_IN pin voltage is below 0.3V or above 4.7V. The $V_{IN}$ feedback loop is also disabled in DE mode and during soft-start.
5.5.3 Input and Output Average Current Monitoring and Regulation Loops

As shown in Figure 45, the ISL81801 has two current sense amplifiers, A1 and A2, which monitor both input and output current. The voltage signals on the input and output current sense resistor $R_{\text{S,IN}}$ and $R_{\text{S,OUT}}$ are sent to the differential inputs of $CS^+$/CS- and $ISEN^+$/ISEN-, respectively, after the RC filters $R_{\text{S,IN1}}$/CS_IN1, $R_{\text{S,IN2}}$/CS_IN2, $R_{\text{S,OUT1}}$/CS_OUT1, and $R_{\text{S,OUT2}}$/CS_OUT2. Renesas recommends using a 1Ω value for $R_{\text{S,IN1}}, R_{\text{S,IN2}}, R_{\text{S,OUT1}},$ and $R_{\text{S,OUT2}},$ and a 10nF value for $CS_{\text{IN1}}, CS_{\text{IN2}}, CS_{\text{OUT1}},$ and $CS_{\text{OUT2}}$ to effectively damp the switching noise without delaying the current signal or introducing significant error because input bias current. The A1 and A2 amplifiers convert the current sense voltage signals to current signals $I_{\text{CS}}$ and $I_{\text{ISEN}}$.

\begin{align}
I_{\text{CS}} &= |I_{\text{IN}}| R_{\text{S,IN}} + V_{\text{CSOFFSET}} G_{\text{mCS}} \\
I_{\text{ISEN}} &= |I_{\text{OUT}}| R_{\text{S,OUT}} + V_{\text{ISENOFFSET}} G_{\text{mISEN}}
\end{align}

where:
- $I_{\text{IN}}$ is the input current in Q1 drain
- $V_{\text{CSOFFSET}}$ is the A1 input offset voltage
- $G_{\text{mCS}}$ is the gain of A1, typical 200μS
- $V_{\text{CSOFFSET}} G_{\text{mCS}} = I_{\text{CSOFFSET}}$

The typical value of $I_{\text{CSOFFSET}}$ is 19.5μA, then $V_{\text{CSOFFSET}}$ is 97.5mV.

where:
- $I_{\text{OUT}}$ is the output current in Q4 drain
- $V_{\text{ISENOFFSET}}$ is the A2 input offset voltage
- $G_{\text{mISEN}}$ is the gain of A2, typical 200μS
- $V_{\text{ISENOFFSET}} G_{\text{mISEN}} = I_{\text{ISENOFFSET}}$

The typical value of $I_{\text{ISENOFFSET}}$ is 20μA, then $V_{\text{ISENOFFSET}}$ is 100mV.

By connecting resistor $R_{\text{IM,IN}}$ and $R_{\text{IM,OUT}}$ on the IMON_IN and IMON_OUT pins, the $I_{\text{CS}}$ and $I_{\text{ISEN}}$ current signals are transferred to voltage signals. The RC networks on the IMON_IN and IMON_OUT pins

---

**Figure 45. Input and Output Average Current Monitoring and Regulation Loops**
RIM_IN1/CIM_IN1/CIM_IN2 and RIM_OUT1/CIM_OUT1/CIM_OUT2 are needed to remove the AC content in the ICS and ISEN signals and ensure stable loop operation. The average voltages at the IMON_IN and IMON_OUT pins are regulated to 1.2V by Gm3 and Gm4 for constant input and output current control.

The input constant current loop set point \( I_{INCC} \) is calculated using Equation 9. See \( V_{AVOCP,CS} \) in the Electrical Specifications table to estimate the set point tolerance.

\[
I_{INCC} = \frac{1.2 - I_{CSOFFSET} \times R_{IM\,IN}}{R_{IM\,IN} \times R_{S\,IN} \times GM_{CS}}
\]

The output constant current loop set point \( I_{OUTCC} \) is calculated using Equation 10. See \( V_{AVOCP,ISEN} \) in the Electrical Specifications table to estimate the set point tolerance.

\[
I_{OUTCC} = \frac{1.2 - I_{ISENOFFSET} \times R_{IM\,OUT}}{R_{IM\,OUT} \times R_{S\,OUT} \times GM_{ISEN}}
\]

The following is an example for output current accuracy calculation based on the \( V_{AVOCP,ISEN} \) value in the \( T_J = -40^\circ C \) to \(+125^\circ C \) condition.

With \( R_{IM\,OUT} = 40.2\,k \) and \( R_{S\,OUT} = 5\,m\Omega \), \( I_{OUTCC(TYP)} = 51mV/R_{S\,OUT} = 10.2A \), \( I_{OUTCC(MIN)} = 43mV/R_{S\,OUT} = 8.6A \), \( I_{OUTCC(MAX)} = 63mV/R_{S\,OUT} = 12.6A \). Therefore, the output current accuracy would be in the range of (-15.68% ~ +23.52%) in this condition.

Similar to the voltage control loops, the average current loop stability is affected by many different factors such as \( V_{IN}, V_{OUT} \), switching frequency, inductor value, output and input capacitance, and the RC network on the IMON_IN or IMON_OUT pin. Because the high AC content in ICS and ISEN, large CIM_IN1 and CIM_OUT1 are needed. Larger CIM_IN1 and CIM_OUT1 can also make the loop more stable by giving a larger phase margin, but the loop bandwidth is lower. For most applications 47nF is a good value for CIM_IN1 and CIM_OUT1. CIM_IN2 and CIM_OUT2 are typically 1/10th to 1/30th of CIM_IN1 and CIM_OUT1 to filter high frequency noise. RIM_IN1 and RIM_OUT1 are needed to boost the phase margin. A good starting value for RIM_IN1 and RIM_OUT1 is 5k. Optimize the final compensation network with iSim simulation and bench testing.

5.6 Buck-Boost Conversion Topology and Control Algorithm

The ISL81801 uses Renesas proprietary buck-boost control algorithm to achieve optimized power conversion performance. The buck-boost topology is shown in Figure 46. The ISL81801 controls the four power switches Q1, Q2, Q3, and Q4 to work in either Buck or Boost mode. When \( V_{IN} \) is far lower than \( V_{OUT} \), the converter works in Boost mode. When \( V_{IN} \) is far higher than \( V_{OUT} \), the converter works in Buck mode. When \( V_{IN} \) is equal or close to \( V_{OUT} \), the converter alternates between Buck and Boost mode as necessary to provide a regulated output voltage, which is called Buck-Boost mode. Figure 47 shows the relationship between the operation modes and \( V_{OUT} - V_{IN} \).

RS_IN is a current sense resistor to sense the inductor current during Q1 on-time. As shown in the Block Diagram, the sensed signal is fed into the CS+ and CS- pins and used for peak or valley current-mode control, DE mode control, input average current monitor, constant current control, and protections.
RS\_OUT is a current sense resistor to sense the inductor current during Q4 on-time. As shown in the Block Diagram, the sensed signal is fed into the ISEN+ and ISEN- pins and used for negative peak inductor current limit, output average current monitor, constant current control, and protections.

### 5.6.1 Buck Mode Operation (V\_IN > V\_OUT)

In Buck mode, Q4 is always on and Q3 is always off unless boot refresh or inductor negative peak current limit is tripped. Q1 and Q2 run in a normal peak current controlled sync buck operation mode. Q1 turns on by the clock. During Q1 on-time, the current sense amplifier (A1) senses the inductor current by the voltage on RS\_IN. Q1 turns off when the sensed signal combined with the slope compensation ramp is higher than the COMP pin voltage, which is the error signal from the upper voltage or current regulator. The equivalent circuit and operation waveforms are shown in Figure 48.

![Figure 48. Buck Mode Equivalent Circuit and Operation Waveforms](image)

In Buck mode, the Q1 duty cycle is given by: \( D_{Q1} = \frac{V_{OUT}}{V_{IN}} \times 100\% \).

As \( V_{IN} \) decreases to close to \( V_{OUT} \), \( D_{Q1} \) increases to close to its maximum value decided by its minimum off-time. When \( D_{Q1} \) reaches its maximum value, the converter moves to Buck-Boost mode.

When \( V_{IN} \) is much higher than \( V_{OUT} \), \( D_{Q1} \) decreases to close to its minimum duty cycle decided by its minimum on-time. To allow stable loop operation and avoid duty cycle jitter, Renesas recommends keeping the Q1 on-time always two to three times higher than the minimum on-time.

### 5.6.2 Boost Mode Operation (V\_IN < V\_OUT)

In Boost mode, Q1 is always on and Q2 is always off unless boot refresh or inductor negative peak current limit is tripped. Q3 and Q4 run in a normal valley current controlled sync boost operation mode. Q3 turns off by the clock. During Q3 off-time, current sense amplifier A1 senses the inductor current by the voltage on RS\_IN. Q3 turns on when the sensed signal combined with the slope compensation ramp is lower than the COMP pin voltage which is the error signal from the upper voltage or current regulator. The equivalent circuit and operation waveforms are shown in Figure 49.
In Boost mode, the $Q_3$ duty cycle is given by: $D_{Q3} = (1 - V_{IN}/V_{OUT}) \times 100\%$.

As $V_{IN}$ increases close to $V_{OUT}$, $D_{Q3}$ decreases close to its minimum value decided by its minimum on-time. When $D_{Q3}$ reaches its minimum value, the converter moves to Buck-Boost mode.

When $V_{IN}$ is much lower than $V_{OUT}$, $D_{Q3}$ increases close to its maximum duty cycle decided by its minimum off-time. To allow stable loop operation and avoid duty cycle jitter, Renesas recommends keeping the $Q_3$ off-time always two to three times higher than the minimum off-time.

### 5.6.3 Buck-Boost Mode Operation ($V_{IN} \approx V_{OUT}$)

In Buck-Boost mode, the converter runs in one cycle of Buck mode followed by one cycle of Boost mode operation mode. It takes two clock cycles to finish a full buck-boost period.

When $V_{IN}$ is higher than $V_{OUT}$, $Q_3$ runs in minimum duty in the Boost mode cycle. $Q_1$ duty cycle $D_{Q1}$ is modulated in the buck cycle to keep $V_{OUT}$ in regulation. As $V_{IN}$ increases, $D_{Q1}$ decreases. When $D_{Q1}$ decreases to less than 66.7% of the clock period, the converter moves to Buck mode.

When $V_{IN}$ is lower than $V_{OUT}$, $Q_3$ runs in maximum duty in the Buck mode cycle. $Q_3$ duty cycle $D_{Q3}$ is modulated in the Boost mode cycle to keep $V_{OUT}$ in regulation. As $V_{IN}$ decreases, $D_{Q3}$ increases. When $D_{Q3}$ increases to more than 33.3% of the clock period, the converter moves to Boost mode.
5.7 Light-Load Efficiency Enhancement

The ISL81801 is set to DE and Burst mode to improve light load efficiency. The dual functional LG1/PWM_MODE pin sets the DE or PWM mode operation in the initialization period before soft-start. During the initialization period, a typical 10µA current source I_MODELG1 from the LG1/PWM_MODE pin creates a voltage drop on the resistor R_LG1 connected between the LG1/PWM_MODE pin and GND. When the voltage is lower than typical 0.3V, PWM mode is set. Otherwise, DE mode is set. **Note:** DE or PWM mode can only be selected during the initialization period, and cannot be changed after initialization is complete.

To set for DE mode operation, select R_LG1 to meet:

\[
R_{LG1} \times I_{\text{MODELG1}} > 0.34 \text{V}
\]  

(EQ. 11)

When DE mode is set, the buck sync FET driven by LG1 and the boost sync FET driven by UG2 are all running in DE mode. The inductor current is not allowed to reverse (discontinuous operation) depending on the zero cross detection reference level V_CROSS1 for buck sync FET and V_CROSS2 for boost sync FET. At light load conditions, the converter goes into diode emulation. When the load current is less than the level set by V_{IMONOUTBSTEN} typical 0.85V on the IMON_OUT pin, the part enters Burst mode. **Equation 12** sets the Burst mode operation enter condition.

\[
R_{IM\_OUT} \times (I_{\text{SENOFFSET}} + I_{\text{OUT}} \times R_{\text{S\_OUT}} \times G_{\text{m\_ISEN}}) < V_{\text{IMONOUTBSTEN}}
\]  

(EQ. 12)

where (see **Figure 45**):

- I_{SENOFFSET} is the output current sense op amp internal offset current, typical 20µA
- G_{m\_ISEN} is the output current sense op amp Gm, typical 200µS.

The part exits Burst mode when the output current increases to higher than the level set by V_{IMONOUTBSTEX} typical 0.88V on the IMON_OUT pin. **Equation 13** sets the Burst mode operation exit condition.

\[
R_{IM\_OUT} \times (I_{\text{SENOFFSET}} + I_{\text{OUT}} \times R_{\text{S\_OUT}} \times G_{\text{m\_ISEN}}) > V_{\text{IMONOUTBSTEX}}
\]  

(EQ. 13)

When the part enters Burst mode, the BSTEN pin goes low. To fully avoid any enter/exit chattering, a 4-10MΩ resistor is added between the BSTEN and IMON_OUT pins to further expand the hysteresis.

In Burst mode, an internal window comparator takes control of the output voltage. The comparator monitors the FB_OUT pin voltage. When the FB_OUT pin voltage is higher than 0.82V, the controller enters Low Power Off
mode. Some unneeded internal circuits are powered off to further reduce power dissipation. When the FB_OUT pin voltage drops to 0.8V, the controller wakes up and runs in a fixed level peak current controlled D/(1-D) Buck-Boost mode when \( V_{IN} - V_{OUT} < 2V \) and Buck mode when \( V_{IN} - V_{OUT} > 2V \). In the D/(1-D) Buck-Boost mode, Q₁ and Q₃ conduct in \( D \cdot T \) period, where \( D \) is the duty cycle and \( T \) is the switching period. Q₂ and Q₄ conduct in \( (1-D) \cdot T \) period. Q₁ and Q₃ are turned on by the clock signal and turned off when the inductor current rises to the level that the input current sense amplifier input voltage reaches \( V_{BST-CS} \), typical 27mV. After Q₁ and Q₃ are turned off, Q₂ and Q₄ are turned on to pass the energy stored in the inductor to the output until the next cycle begins. The output voltage increases in the wake-up period. When the output reaches 0.82V again, the controller enters into Low Power Off mode again. When the load current increases, the Low Power Off mode period decreases. When the off mode period disappears and the load current further increases but still does not meet the Equation 13 exit condition, the output voltage drops. When the FB_OUT pin voltage drops to 0.78V, the controller exits Burst mode and runs in normal DE PWM mode. The voltage error amplifier takes control of the output voltage regulation.

In Low Power Off mode, the CLKEN pin goes low. By connecting the BSTEN and CLKEN pins in a multiple chip parallel system, the Burst mode enter/exit and burst on/off control are all synchronized.

Because \( V_{OUT} \) is controlled by a window comparator in Burst mode, higher than normal low-frequency voltage ripple appears on \( V_{OUT} \), which can generate audible noise if the inductor and output capacitors are not chosen properly. Also, the efficiency in D/(1-D) Buck-Boost mode is low. To avoid these drawbacks, disable the Burst mode by choosing a bigger \( R_{IM\_OUT} \) to set the IMON_OUT pin voltage higher than 0.88V at no load condition, shown in Equation 14. The part runs in DE mode only. Pulse Skipping mode can also be implemented to lower the light load power loss with much lower output voltage ripple as \( V_{OUT} \) is always controlled by the regulator Gm₁.

\[
R_{IM\_OUT} \times ISENOFFSET > V_{IMONOUTBSTEX}
\]

(R.14)

5.8 Prebiased Power-Up

The ISL81801 can soft-start with a prebiased output by running in forced DE mode during soft-start. The output voltage is not pulled down during prebiased start-up. The PWM mode is not active until the soft-start ramp reaches 90% of the output voltage times the resistive divider ratio. Forced DE mode is set again when the SS/TRK pin voltage is pulled to less than 0.3V by either an internal or external circuit.

The overvoltage protection function is still operational during soft-start in DE mode.

5.9 Frequency Selection

Switching frequency selection is a trade-off between efficiency and component size. Low switching frequency improves efficiency by reducing MOSFET switching loss. To meet the output ripple and load transient requirements, operation at a low switching frequency requires larger inductance and output capacitance. The switching frequency of the ISL81801 is set by a resistor connected from the RT/SYNC pin to GND according to Equation 1.

The frequency setting curve shown in Figure 51 assists in selecting the correct value for \( R_T \).
5.10 Phase Lock Loop (PLL)

The ISL81801 integrates a high-performance PLL. The PLL ensures a wide range of accurate clock frequency and phase setting. It also makes the internal clock easily synchronized to an external clock with the frequency either lower or higher than the internal setting.

As shown in Figure 52, an external compensation network of $R_{PLL}$, $C_{PLL1}$, and $C_{PLL2}$ is needed to connect to the PLL_COMP pin to ensure PLL stable operation. Renesas recommends choosing $2.7\,\text{k}\Omega$ for $R_{PLL}$, $10\,\text{nF}$ for $C_{PLL1}$, and $820\,\text{pF}$ for $C_{PLL2}$. With the recommended compensation network, the PLL stability is ensured in the full clock frequency range of 100kHz to 600kHz.

![Figure 52. PLL Compensation Network](image)

5.11 Frequency Synchronization and Dithering

The RT/SYNC pin can synchronize the ISL81801 to an external clock or the CLKOUT/DITHER pin of another ISL81801. When the RT/SYNC pin is connected to the CLKOUT/DITHER pin of another ISL81801, the two controllers operate in cascade synchronization with phase interleaving.

When the RT/SYNC pin is connected to an external clock, the ISL81801 synchronizes to this external clock frequency. The frequency set by the $R_T$ resistor is either lower or higher than, or equal to the external clock frequency.

The CLKOUT/DITHER pin outputs a clock signal with approximately $300\,\text{ns}$ pulse width. The signal frequency is the same as the frequency set by the resistor from the RT pin to ground or the external sync clock. The signal rising edge phase angle to the rising edge of the internal clock or the external clock to the RT/SYNC pin is set by the voltage applied to the FB_IN and IMON_IN pins. The phase interleaving is implemented by the cascade connecting of the upper chip CLKOUT/DITHER pin to the lower chip RT/SYNC pin in a parallel system. Table 2 shows the CLKOUT/DITHER phase settings with different FB_IN and IMON_IN pin voltages.
When the FB_IN is connected to 5V, the VIN feedback control loop is disabled. When IMON_IN is connected to 5V, the average input current control loop and input current hiccup OCP are disabled.

In multi-chip cascade parallel operation, the CLKOUT pin of the upstream chip is connected to the RT/SYNC pin of the downstream chip. The BSTEN, FB_IN, SS/TRK, COMP, FB_OUT, IMON_OUT, OV, EN/UVLO, IMON_IN, and CLKEN pins of all the paralleled chips should be tied together.

The CLKOUT/DITHER pin provides a dual function option. When a capacitor CDITHER is connected on the CLKOUT/DITHER pin, the internal circuit disables the CLKOUT function and enables the DITHER function. When the CLKOUT/DITHER pin voltage is lower than 1.05V, a typical 8µA current source IDITHERSO charges the capacitor on the pin. When the capacitor voltage is charged to more than 2.2V, a typical 10µA current source IDITHERSI discharges the capacitor on the pin. A sawtooth voltage waveform shown in Figure 53 is generated on the CLKOUT/DITHER pin. The internal clock frequency is modulated by the sawtooth voltage on the CLKOUT/DITHER pin. The clock frequency dither range is set to typically ±15% of the frequency set by the resistor on RT/SYNC pin. The dither function is lost when the chip is synchronized to an external clock.

The dither frequency FDITHER is calculated using Equation 15. Renesas recommends setting CDITHER between 10nF and 1µF. With a too low CDITHER, the part may not be able to set to Dither mode. With a higher CDITHER, the discharge power loss at disable or power off is higher, leading to a higher thermal stress to the internal discharge circuit. The recommended dither frequency is 1/10 of crossover frequency.

\[
F_{\text{DITHER}} = \frac{3.865 \times 10^{-6}}{C_{\text{DITHER}}}
\]  

### Table 2: CLKOUT Phase Shift vs FB_IN and IMON_IN Voltage

<table>
<thead>
<tr>
<th>CLKOUT Phase Shift</th>

Note: “1” means logic high 4.7V to 5V. “Active” means logic low 0V to 4.3V.
5.12 Parallel Operation Current Sharing

Multiple ISL81801 controlled buck-boost DC/DC converters are paralleled to each other in cascade as described in Frequency Synchronization and Dithering. The currents in the paralleled converters are shared by feeding the same connected COMP pin voltage signal to the reference of the current control loops in each IC. However, the current sharing accuracy is not ideal because the loose tolerance in RAMP and current sense circuit settings. To achieve an acceptable current sharing accuracy, an external active current sharing circuit is recommended, as shown in Figure 54.

---

**Figure 54. Current Sharing Circuit**

Figure 54 shows the connections between the two paralleled converters. Two external operational amplifiers (op amps) are added for active current sharing in each converter. The first op amp, U2B in Converter 1 or U4B in Converter 2, is a buffer to send the local output current signal from the IMON_OUT pin to the current sharing
circuit. The buffer output is connected to the iSh bus using R28 in Converter 1 and R61 in Converter 2 to create the reference signal. The voltage on the iSh bus, V_{iSh}, is calculated using Equation 16.

\[ V_{iSh} = \frac{V_{IMON\_OUT1} + V_{IMON\_OUT2}}{2} \]  

(EQ. 16)

where \( V_{IMON\_OUT1} \) is the Converter 1 IMON\_OUT pin voltage and \( V_{IMON\_OUT2} \) is the Converter 2 IMON\_OUT pin voltage.

The second op amp, U2A in Converter 1 or U4A in Converter 2 is a differential op amp to feed the current error signal to the IC FB\_OUT pin. The differential input signal is equal to \( V_{IMON\_OUT1} - V_{iSh} \) for U2A and \( V_{IMON\_OUT2} - V_{iSh} \) for U4A. The differential op amp gain and the value of the resistor between the op amp output and the FB\_OUT pin is defined based on the current sharing accuracy and the allowed maximum output voltage change caused by the current sharing loop, assuming the current sense circuit tolerance is ignored.

The maximum allowed current sharing error is represented by the maximum allowed differential op amp input. The differential op amp outputs a maximum voltage of 5V at its maximum differential input, assuming a rail-to-rail op amp is used. The differential op amp gain Ksh is calculated using Equation 17.

\[ Ksh = \frac{5}{\Delta V_{sh}} \]  

(EQ. 17)

where \( \Delta V_{sh} \) is the maximum allowed differential op amp input voltage, which is proportional to the output current sharing error \( \Delta I_{sh} = |I_{OUT1} - I_{OUT2}| / 2 \). \( I_{OUT1} \) and \( I_{OUT2} \) are the output currents of Converter 1 and 2, respectively.

\[ \Delta V_{sh} = \Delta I_{sh} \times R_{IM\_OUT} \times R_{S\_OUT} \times G_{m\_ISEN}, \]  

referring to the descriptions in Input and Output Average Current Monitoring and Regulation Loops.

As shown in Figure 54, \( Ksh = R_{23}/R_{27} \) for Converter 1 and \( Ksh = R_{56}/R_{58} \) for Converter 2.

The value Rsh of the resistor between the differential op amp output and the FB\_OUT pin is calculated using Equation 18.

\[ Rsh = \frac{5 \times R_{FBO1}}{\Delta V_{OUT}} \]  

(EQ. 18)

where \( \Delta V_{OUT} \) is the maximum allowed output voltage change caused by the current sharing loop, which is limited by the VOUT regulation tolerance.

\( R_{FBO1} \) is the resistance of the upper resistor of the VOUT voltage sense divider shown in Figure 43. As shown in Figure 54, \( Rsh = R_{29} + R_{30} \) for Converter 1 and \( Rsh = R_{64} + R_{65} \) for Converter 2. \( R_{FBO1} = R_{18} \) for Converter 1 and \( R_{FBO1} = R_{50} \) for Converter 2.

5.13 Gate Drivers

The ISL81801 integrates two almost identical high voltage driver pairs to drive both buck and boost MOSFET pairs. Each driver pair consists of a gate control logic circuit, a low-side driver, a level shifter, and a high-side driver.

The ISL81801 incorporates an adaptive dead time algorithm that optimizes operation with varying MOSFET conditions. This algorithm provides approximately 16ns dead time between the switching of the upper and lower MOSFETs. This dead time is adaptive and allows operation with different MOSFETs without having to externally adjust the dead time using a resistor or capacitor. During turn-off of the lower MOSFET, the LGATE voltage is monitored until it reaches a threshold of 1V, at which time the UGATE is released to rise. Adaptive dead time circuitry monitors the upper MOSFET gate voltage during UGATE turn-off. When the upper MOSFET gate-to-source voltage drops below a threshold of 1V, the LGATE is allowed to rise. Renesas recommends against using a resistor between the driver outputs and the respective MOSFET gates, because it can interfere with the dead time circuitry.

The low-side gate driver is supplied from VDD and provides a 3A peak sink and 2A peak source current. The high-side gate driver can also deliver peak 3A sink and 2A source current. Gate-drive voltage for the upper
N-channel MOSFET is generated by a flying capacitor boot circuit. A boot capacitor connected from the BOOT pin to the PHASE node provides power to the high-side MOSFET driver. As shown in Figure 55, the boot capacitor is charged up to VDD by an external Schottky diode during low-side MOSFET on-time (phase node low). To limit the peak current in the Schottky diode, an external resistor is placed between the BOOT pin and the boot capacitor. This small series resistor also damps any oscillations caused by the resonant tank of the parasitic inductances in the traces of the board and the FET’s input capacitance.

At start-up, the low-side MOSFET turns on first and forces PHASE to ground to charge the BOOT capacitor to 8V if the diode voltage drop is ignored. After the low-side MOSFET turns off, the high-side MOSFET is turned on by closing an internal switch between BOOT and UGATE. This provides the necessary gate-to-source voltage to turn on the upper MOSFET, an action that boosts the 8V gate drive signal above \( V_{\text{IN}} \). The current required to drive the upper MOSFET is drawn from the internal 8V regulator supplied from either VIN or EXTBIAS pin.

The BOOT to PHASE voltage is monitored internally. When the voltage drops to 5.95V at no switching condition, a minimum off-time pulse is issued to turn off the upper MOSFET and turn on the low-side MOSFET to refresh the bootstrap capacitor and maintain the upper driver bias voltage.

To optimize EMI performance or reduce phase node ringing, a small resistor is placed between the BOOT pin to the positive terminal of the bootstrap capacitor.

5.14 Power-Good Indicator

The power-good pin can monitor the status of the output voltage. PGOOD is true (open drain) 1.1ms after the FB_OUT pin is within ±10% of the reference voltage.

There is no extra delay when the PGOOD pin is pulled LOW.
6. Protection Circuits

The converter output and input are monitored and protected against overload, overvoltage, and undervoltage conditions.

6.1 Input Undervoltage Lockout (UVLO)

The ISL81801 includes input UVLO protection, which keeps the device in a reset condition until a proper operating voltage is applied. UVLO protection shuts down the ISL81801 if the input voltage drops below 3.2V. The controller is disabled when UVLO is asserted. When UVLO is asserted, PGOOD (Power Good) is valid and is deasserted. If the input voltage rises above 3.5V, UVLO is deasserted to allow the start-up operation.

6.2 VCC5V Power-On Reset (POR)

The ISL81801 sets its VCC5V POR rising threshold at 4V and falling threshold at 3.5V when supplied by V_IN. EXTBIAS can only be applied kick in only after VCC5V reaches its POR rising threshold.

6.3 Overcurrent Protection (OCP)

6.3.1 Input and Output Average Overcurrent Protection

As described in Input and Output Average Current Monitoring and Regulation Loops, the ISL81801 can regulate both input and output current with closed loop control. This provides a constant current type of overcurrent protection for both input and output average current. It is set to a hiccup type of protection by selecting a different value of the resistor connected between LG2/OC_MODE and GND.

The input and output constant or hiccup average OCP set points I_INCC and I_OUTCC are calculated using Equation 9 and Equation 10.

The average OCP mode is set by a resistor connected from the LG2/OC_MODE pin to ground during the initialization period before soft-start. During the initialization period, the LG2/OC_MODE pin sources out typical 10µA current IMODELG2 to set the voltage on the pin. If the pin voltage is less than typical 0.3V, the OCP is set to Constant Current-mode. Otherwise, the OCP is set to hiccup mode.

In hiccup OCP mode, after the average current is higher than the set point for 32 consecutive switching cycles the converter turns off for 50ms before a restart-up is issued.

6.3.2 First Level Pulse-by-Pulse Peak Current Limit

As shown in Figure 45 in Input and Output Average Current Monitoring and Regulation Loops, the inductor peak current is sensed by the shunt resistor R_S_IN and amplifier A1. When the voltage drop on R_S_IN reaches the set point V_OCSET-CS typical 82mV, Q1 is turned off in Buck mode or Q3 is turned off in Boost mode. The first level peak current limit set point IOCPP1 is calculated using Equation 19.

\[
I_{OCPP1} = \frac{V_{OCSET-CS}}{R_{S_{IN}}}
\]

(EQ. 19)

6.3.3 Second Level Hiccup Peak Current Protection

To avoid any false trip in peak current-mode operation, a minimum on or blanking time is set to the PWM signal. The first level pulse-by-pulse current limit circuit cannot further reduce the PWM duty cycle in the minimum on-time. In an output dead short condition, especially at high V_IN, the inductor current increases rapidly, even with the minimum on-time PWM duty cycle. The ISL81801 integrates a second level hiccup type of peak current protection. When the voltage drop on R_S_IN reaches the set point V_OCSET-CS-HIC (typical 100mV), the converter turns off by turning off all four switches Q1, Q2, Q3, and Q4 for 50ms before a re-start up is issued. The second level peak current protection set point IOCPP2 is calculated using Equation 20.

\[
I_{OCPP2} = \frac{V_{OCSET-CS-HIC}}{R_{S_{IN}}}
\]

(EQ. 20)
6.3.4 Pulse-by-Pulse Negative Peak Current Limit

In cases of reverse direction operation and OVP protection, the inductor current becomes negative. The negative current is sensed by the shunt resistor $R_{S\,\text{OUT}}$ and amplifier A2 as shown in Figure 45. When the voltage drop on $R_{S\,\text{OUT}}$ reaches the set point $V_{\text{OCSET-ISEN}}$ (typical -59mV), Q2 and Q4 are turned off and Q1 and Q3 are turned on. The negative peak current limit set point $I_{\text{OCPPN}}$ is calculated using Equation 21.

$$I_{\text{OCPPN}} = \frac{V_{\text{OCSET-ISEN}}}{R_{S\,\text{OUT}}} \quad \text{(EQ. 21)}$$

The device is damaged in negative peak current limit conditions. In these conditions, the energy flows from output to input. If the impedance of the input source or devices is not low enough, the $V_{\text{IN}}$ voltage increases. When $V_{\text{IN}}$ increases to higher than its maximum limit, the IC is damaged.

6.4 Overvoltage Protection (OVP)

The overvoltage set point is set at 114% of the nominal output voltage set by the feedback resistors. In the case of an overvoltage event, the IC attempts to bring the output voltage back into regulation by keeping Q1 and Q3 turned off and Q2 and Q4 turned on. If the OV condition continues, the inductor current goes negative to trip the negative peak current limit. The converter reverses direction to transfer energy from the output end to the input end. Input voltage is pushed high if the input source impedance is not low enough. The IC is damaged if the input voltage goes to higher than its maximum limit. If the overvoltage condition is corrected and the output voltage drops to the nominal voltage, the controller resumes normal PWM switching. The OV pin is pulled high when output OVP trips.

6.5 Over-Temperature Protection (OTP)

The ISL81801 incorporates an over-temperature protection circuit that shuts the IC down when a die temperature of +160°C is reached. Normal operation resumes when the die temperature drops below +145°C through the initiation of a full soft-start cycle. During OTP shutdown, the IC consumes only 100µA current. When the controller is disabled, thermal protection is inactive. This helps achieve a very low shutdown current of 5µA.
7. Layout Guidelines

Careful attention to layout requirements is necessary for successful implementation of an ISL81801 based DC/DC converter. The ISL81801 switches at a very high frequency, so the switching times are very short. At these switching frequencies, even the shortest trace has significant impedance. Also, the peak gate drive current rises significantly in an extremely short time. Transition speed of the current from one device to another causes voltage spikes across the interconnecting impedances and parasitic circuit elements. These voltage spikes can degrade efficiency, generate EMI, and increase device voltage stress and ringing. Careful component selection and proper Printed Circuit Board (PCB) layout minimize the magnitude of these voltage spikes.

The three sets of critical components in a DC/DC converter using the ISL81801 are the following:

- The controller
- The switching power components
- The small signal components

The switching power components are the most critical from a layout point of view because they switch a large amount of energy, which tends to generate a large amount of noise. The critical small signal components are those connected to sensitive nodes or those supplying critical bias currents. A multilayer PCB is recommended.

7.1 Layout Considerations

- Place the input capacitors, buck FETs, inductor, boost FETs, and output capacitor first. Isolate these power components on dedicated areas of the board with their ground terminals adjacent to one another. Place the input and output high frequency decoupling ceramic capacitors very close to the MOSFETs.

- If signal components and the IC are placed in a separate area to the power train, use full ground planes in the internal layers with shared SGND and PGND to simplify the layout design. Otherwise, use separate ground planes for the power ground and the small signal ground. Connect the SGND and PGND close to the IC. DO NOT connect them together anywhere else.

- Keep the loop formed by the input capacitor, the buck top FET, and the buck bottom FET as small as possible. Also, keep the loop formed by the output capacitor, the boost top FET, and the boost bottom FET as small as possible.

- Keep the current paths from the input capacitor to the buck FETs, the power inductor, the boost FETs, and the output capacitor as short as possible with maximum allowable trace widths.

- Place the PWM controller IC close to the lower FETs. The low-side FETs gate drive connections should be short and wide. Place the IC over a quiet ground area. Avoid switching ground loop currents in this area.

- Place the VDD bypass capacitor close to the VDD pin of the IC and connect its ground end to the PGND pin. Connect the PGND pin to the ground plane by a via. Do not directly connect the PGND pin to the SGND EPAD.

- Place the gate drive components (BOOT diodes and BOOT capacitors) together near the controller IC.

- Place the output capacitors as close to the load as possible. Use short, wide copper regions to connect output capacitors to load to avoid inductance and resistances.

- Use copper filled polygons or wide short traces to connect the junction of the buck or boost upper FET, buck or boost lower FET, and output inductor. Also, keep the buck and boost PHASE nodes connection to the IC short. DO NOT oversize the copper islands for the PHASE nodes. Because the phase nodes are subjected to very high dv/dt voltages, the stray capacitor formed between these islands and the surrounding circuitry tends to couple switching noise.

- Route all high speed switching nodes away from the control circuitry.

- Create a separate small analog ground plane near the IC. Connect the SGND pin to this plane. Connect a small signal grounding paths including feedback resistors, current monitoring resistors and capacitors, soft-starting capacitors, loop compensation capacitors and resistors, and EN pull-down resistors to this SGND plane.

- Use a pair of traces with minimum loop for the input or output current sensing connection.
• Keep the feedback connection to the output capacitor is short and direct.

### 7.2 General EPAD Design Considerations

Figure 56 shows how to use vias to remove heat from the IC.

![Figure 56. PCB Via Pattern](image)

Fill the thermal pad area with vias. A typical via array fills the thermal pad footprint so that their centers are three times the radius apart from each other. Keep the vias small but not so small that their inside diameter prevents solder wicking through during reflow.

Connect all vias to the ground plane. The vias must have a low thermal resistance for efficient heat transfer. Ensure a complete connection of the plated through hole to each plane.
8. Component Selection Guideline

8.1 MOSFET Considerations

The MOSFETs are chosen for optimum efficiency given the potentially wide input voltage range and output power requirement. Select these MOSFETs based upon $r_{DS(ON)}$, gate supply requirements, and thermal management considerations.

The buck maximum operation voltage of the MOSFETs is decided by the maximum $V_{IN}$ voltage, and the boost maximum operation voltage of the MOSFETs is decided by the maximum $V_{OUT}$ voltage. Choose the buck or boost MOSFETs based on their maximum operation voltage with sufficient margin for safe operation.

The MOSFET power dissipations are based on: conduction loss and switching loss. In Buck mode, the power loss of the buck upper and lower MOSFETs are calculated using Equation 22 and Equation 23. The conduction losses are the main source of power dissipation for the lower MOSFET. Only the upper MOSFET has significant switching losses, because the lower device turns on and off into near zero voltage. The equations assume linear voltage current transitions and do not model power loss because of the reverse recovery of the lower MOSFET body diode.

\[
P_{UPPERBUCK} = \frac{(I_{OUT})^2(r_{DS(ON)})(V_{OUT})}{V_{IN}} + \frac{(I_{OUT})(V_{IN})(t_{SW})}{2} \tag{EQ. 22}
\]

\[
P_{LOWERBUCK} = \frac{(I_{OUT})^2(r_{DS(ON)})(V_{IN} - V_{OUT})}{V_{IN}} \tag{EQ. 23}
\]

In Boost mode, there is only conduction loss on the buck upper MOSFET calculated using Equation 24.

\[
P_{UPPERBOOST} = \frac{(I_{OUT})^2(V_{OUT})^2}{V_{IN}^2} \cdot (r_{DS(ON)}) \tag{EQ. 24}
\]

In Boost mode, the power losses of the boost upper and lower MOSFETs are calculated using Equation 25 and Equation 26. The conduction losses are the main component of power dissipation for the upper MOSFET. Only the lower MOSFET has significant switching losses, because the upper device turns on and off into near zero voltage. The equations assume linear voltage current transitions and do not model power loss because the reverse recovery of the upper MOSFET body diode.

\[
P_{LOWERBOOST} = \frac{(I_{OUT})^2(V_{OUT})^2}{V_{IN}^2} \cdot \frac{V_{OUT} - V_{IN}}{V_{OUT}} \cdot (r_{DS(ON)}) + \frac{(I_{OUT})(V_{OUT})^2(t_{SW})}{2(V_{IN})} \tag{EQ. 25}
\]

\[
P_{UPPERBOOST} = \frac{(I_{OUT})^2(V_{OUT})}{V_{IN}} \tag{EQ. 26}
\]

In Buck mode, the conduction loss exists on the boost upper MOSFET calculated using Equation 27.

\[
P_{UPPERBOOST} = (I_{OUT})^2(r_{DS(ON)}) \tag{EQ. 27}
\]

A large gate-charge increases the switching time, $t_{SW}$, which increases the switching losses of the buck upper and boost lower MOSFETs. Ensure that all four MOSFETs are within their maximum junction temperature at high ambient temperature by calculating the temperature rise according to package thermal resistance specifications.
8.2 Inductor Selection

The inductor is selected to meet the output voltage ripple requirements. The inductor value determines the ripple current of the converter, and the ripple voltage is a function of the ripple current and the output capacitor(s) ESR. The ripple voltage expression is given in the capacitor selection section and the ripple current is approximated by Equation 28 for Buck mode and Equation 29 for Boost mode.

\[
\Delta I_{\text{Buck}} = \frac{(V_{\text{IN}} - V_{\text{OUT}})(V_{\text{OUT}})}{f_{\text{SW}} L (V_{\text{IN}})}
\]

(EQ. 28)

\[
\Delta I_{\text{Boost}} = \frac{(V_{\text{OUT}} - V_{\text{IN}})(V_{\text{IN}})}{f_{\text{SW}} L (V_{\text{OUT}})}
\]

(EQ. 29)

The ripple current ratio is usually 30% to 70% of the inductor average current at the full output load condition.

8.3 Output Capacitor Selection

In general, select the output capacitors to meet the dynamic regulation requirements including ripple voltage and load transients. Selection of output capacitors is also dependent on the inductor, so some inductor analysis is required to select the output capacitors.

One of the parameters limiting the converter’s response to a load transient is the time required for the inductor current to slew to its new level. The ISL81801 provides either 0% or maximum duty cycle in response to a load transient.

The response time is the time interval required to slew the inductor current from an initial current value to the load current level. During this interval, the difference between the inductor current and the transient current level must be supplied by the output capacitor(s). The output capacitance is minimized if faster loop compensation is used. Also, if the load transient rise time is slower than the inductor response time, as in a hard drive or CD drive, it reduces the requirement on the output capacitor.

The minimum capacitor value required to provide the full, rising step, transient load current during the response time of the inductor is shown in Equation 30 for Buck mode and Equation 31 for Boost mode:

\[
C_{\text{OUT Buck}} = \frac{(L)(I_{\text{TRAN}})^2}{2(V_{\text{IN}} - V_{\text{OUT}})(D\text{V}_{\text{OUT}})}
\]

(EQ. 30)

\[
C_{\text{OUT Boost}} = \frac{(L)(V_{\text{OUT}})(I_{\text{TRAN}})^2}{2(V_{\text{IN}}^2)(D\text{V}_{\text{OUT}})}
\]

(EQ. 31)

where \( C_{\text{OUT}} \) is the output capacitor(s) required, \( L \) is the inductor, \( I_{\text{TRAN}} \) is the transient load current step, \( V_{\text{IN}} \) is the input voltage, \( V_{\text{OUT}} \) is output voltage, and \( D\text{V}_{\text{OUT}} \) is the drop in output voltage allowed during the load transient.

High frequency capacitors initially supply the transient current and slow the load rate of change seen by the bulk capacitors. The bulk filter capacitor values are generally determined by the Equivalent Series Resistance (ESR), voltage rating requirements, and actual capacitance requirements.

In Buck mode, the output voltage ripple is because the inductor ripple current and the ESR of the output capacitors as defined by Equation 32:

\[
V_{\text{RIPPLE}} = \Delta I_{\text{Buck}}(\text{ESR})
\]

where \( \Delta I_{\text{Buck}} \) is calculated in Equation 28.
In Boost mode, the current to the output capacitor is not continuous. The output voltage ripple is much higher as defined by Equation 33:

\[ V_{\text{RIPPLE}} = \left( \frac{\left| I_{\text{OUT}} \right| V_{\text{OUT}}}{V_{\text{IN}}} + \frac{\Delta I_{\text{L,Boost}}}{2} \right) (\text{ESR}) \]

where \( \Delta I_{\text{L,Boost}} \) is calculated in Equation 29.

Place high frequency decoupling capacitors as close to the power pins of the load as physically possible. Be careful not to add inductance in the circuit board wiring that could cancel the usefulness of these low inductance components. Consult with the manufacturer of the load circuitry for specific decoupling requirements.

Use only specialized low-ESR capacitors intended for switching regulator applications for the bulk capacitors. In most cases, multiple small case electrolytic capacitors perform better than a single large case capacitor.

The stability requirement on the selection of the output capacitor is that the ESR zero \( f_z \) is between 2kHz and 60kHz. The ESR zero can help increase phase margin of the control loop.

This requirement is shown in Equation 34:

\[ C_{\text{OUT}} = \frac{1}{2\pi (\text{ESR})(f_z)} \]

In conclusion, the output capacitors must meet the following criteria:

- They must have sufficient bulk capacitance to sustain the output voltage during a load transient while the output inductor current is slewing to the value of the load transient.
- The ESR must be sufficiently low to meet the desired output voltage ripple because the supplied ripple current.
- The ESR zero should be placed in a large range to provide additional phase margin.

8.4 Input Capacitor Selection

The important parameters for the input capacitor(s) are the voltage rating and the RMS current rating. For reliable operation, select input capacitors with voltage and current ratings above the maximum input voltage and largest RMS current required by the circuit. The capacitor voltage rating should be at least 1.25 times greater than the maximum input voltage and 1.5 times is a conservative guideline. In Buck mode the AC RMS input current varies with the load giving in Equation 35:

\[ I_{\text{RMS}} = \sqrt{DC - DC^2} \times I_{\text{OUT}} \]

where DC is duty cycle.

The maximum RMS current supplied by the input capacitance occurs at \( V_{\text{IN}} = 2 \times V_{\text{OUT}}, DC = 50\% \) as shown in Equation 36:

\[ I_{\text{RMS}} = \frac{1}{2} \times I_{\text{OUT}} \]

In Boost mode, the input current is continuous. The RMS current supplied by the input capacitance is much smaller.

Use a mix of input bypass capacitors to control the voltage ripple across the MOSFETs. Use ceramic capacitors for the high frequency decoupling and bulk capacitors to supply the RMS current. Place small ceramic capacitors close to the MOSFETs to suppress the voltage induced in the parasitic circuit impedances.

Solid tantalum capacitors are used, but use caution with regard to the capacitor surge current rating. These capacitors must be capable of handling the surge current at power-up.

10. Package Outline Drawings

For the most recent package outline drawing, see L32.5x5A.

L32.5x5A
32 Lead Thin Quad Flat No-Lead Plastic Package
Rev 1, 5/17

NOTES:

1. Dimensions are in millimeters. Dimensions in ( ) for reference only.
2. Dimensioning and tolerancing conform to AMSE Y14.5m-1994.
3. Unless otherwise specified, tolerance: Decimal ±0.05
   Dimension applies to the metallized terminal and is measured between 0.15mm and 0.30mm from the terminal tip.
4. Tiebar shown (if present) is a non-functional feature.
5. The configuration of the pin #1 identifier is optional, but must be located within the zone indicated. The pin #1 identifier may be either a mold or mark feature.
For the most recent package outline drawing, see M38.173C.

M38.173C
38 Lead Heat-Sink Thin Shrink Small Outline Plastic Package (HTSSOP)
Rev 0, 4/10

NOTES:
1. Die thickness allowable is 0.279±0.0127 (0.0110±0.0005 inches).
3. Datum plane H located at mold parting line and coincident with lead where lead exits plastic body at bottom of parting line.
4. At reference datum and does not include mold flash or protrusions, and is measured at the bottom parting line. Mold flash or protrusions shall not exceed 0.15mm on the package ends and 0.25mm between the leads.
5. The lead width dimension does not include dambar protrusion. Allowable dambar protrusion shall be 0.07mm total in excess of the lead width dimension at maximum material condition. Dambar cannot be located on the lower radius or the foot. Minimum space between protrusions and an adjacent lead should be 0.08mm.
6. This part is compliant with JEDEC specification MO-153 variation BDT-1
