The **ISL85033** is a dual standard buck regulator capable of 3A per channel continuous output current. With an input range of 4.5V to 28V, it provides a high frequency power solution for a variety of point of load applications.

The PWM controller in the ISL85033 drives an internal switching N-Channel power MOSFET and requires an external Schottky diode to generate the output voltage. The integrated power switch is optimized for excellent thermal performance up to 3A of output current. The PWM regulator switches at a default frequency of 500kHz and it can be user programmed or synchronized from 300kHz to 2MHz. The ISL85033 utilizes peak current mode control to provide flexibility in component selection and minimize solution size. The protection features include overcurrent, UVLO and thermal overload protection.

The ISL85033 is available in a small 4mm x 4mm Thin Quad Flat No-Lead (TQFN) Pb-free package.

### Applications

- General purpose point-of-load DC/DC power conversion
- Set-top boxes
- FPGA power and STB power
- DVD and HDD drives
- LCD panels, TV power
- Cable modems

### Features

- Wide input voltage range from 4.5V to 28V
- Adjustable output voltage with continuous output current up to 3A
- Current mode control
- Adjustable switching frequency from 300kHz to 2MHz
- Independent power-good detection
- Selectable in-phase or out-of-phase PWM operation
- Independent, sequential, ratiometric or absolute tracking between outputs
- Internal 2ms soft-start time
- Overcurrent/short circuit protection, thermal overload protection, UVLO
- Boot undervoltage detection
- Pb-free (RoHS compliant)

**NOTES:**

1. See TB347 for details on reel specifications.
2. These Pb-free plastic packaged products employ special Pb-free material sets, molding compounds/die attach materials, and 100% matte tin plate plus anneal (e3 termination finish, which is RoHS compliant and compatible with both SnPb and Pb-free soldering operations). Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.
3. For Moisture Sensitivity Level (MSL), see the ISL85033 device page. For more information about MSL, see TB363.
Absolute Maximum Ratings

- VIN1/2 to GND: -0.3V to +30V
- PHASE1/2 to GND: -7V (<10ns) /-0.3V (DC) to +33V
- BOOT1/2 to PHASE1/2: -0.3V to +5.9V
- FS to GND: -0.3V to +5.9V
- SYNCIN to GND: -0.3V to +5.9V
- FB1/2 to GND: -0.3V to +2.95V
- EN1/2 to GND: -0.3V to +5.9V
- PGOOD1/2 to GND: -0.3V to +5.9V
- COMP1/2 to GND: -0.3V to +5.9V
- VCC to GND Short Maximum Duration: 1s
- SYNCOUT to GND: -0.3V to +5.9V
- SS1/2 to GND: -0.3V to +5.9V

ESD Rating

Detailed Description

The ISL85033 combines a standard buck PWM controller with integrated switching MOSFETs. The buck controller drives an internal N-Channel MOSFET and requires an external diode to deliver load current up to 3A. A Schottky diode is recommended for improved efficiency and performance over a standard diode. The standard buck regulator can operate from an unregulated DC source, such as a battery, with a voltage ranging from +4.5V to +28V. The converter output can be regulated to as low as 0.8V. These features make the ISL85033 ideally suited for FPGA, set-top boxes, LCD panels, DVD drives, and wireless chipset power applications.

The ISL85033 employs peak current-mode control loop, which simplifies feedback loop compensation and rejects input voltage variation. External feedback loop compensation allows flexibility in output filter component selection. The regulator switches at a default 500kHz and it can be adjusted from 300kHz to 2MHz with a resistor from FS to GND. The ISL85033 is synchronizable from 300kHz to 2MHz.

Operation Initialization

The power-on reset circuitry and enable inputs prevent false start-up of the PWM regulator output. Once all input criteria are met, the controller soft starts the output voltage to the programmed level.

Power-on Reset and Undervoltage Lockout

The ISL85033 automatically initializes upon receipt of input power supply. The power-on reset (POR) function continually monitors V_{IN1} voltage. While below the POR threshold, the controller inhibits switching of the internal power MOSFET. Once exceeded, the controller initializes the internal soft-start circuitry. If V_{IN1} supply drops below their falling POR threshold during soft-start or operation, the buck regulator is disabled until the input voltage returns.

Enable and Disable

When EN1 and EN2 are pulled low, the device enters shutdown mode and the supply current drops to a typical value of 20µA. All internal power devices are held in a high impedance state while in shutdown mode.

The EN pin enables the controller of the ISL85033. When the voltage on the EN pin exceeds its logic rising threshold, the controller initiates the 2ms soft-start function for the PWM regulator. If the voltage on the EN pin drops below the falling threshold, the buck regulator shuts down.

If EN1 and EN2 pins are driven by an external signal, the minimum off-time for EN1 and EN2 should be:

\[ EN_{x}T_{off} (\mu s) = 10\mu s \cdot CSS/2.2nF \]  

Where CSS is the soft-start pin capacitor (nF). The ISL85033 does not have debouncing to the EN1 and EN2 external signals.

Power-good

PG is the open-drain output of a window comparator that continuously monitors the buck regulator output voltage via the FB pin. PG is actively held low when EN is low and during the buck regulator soft-start period. After the soft-start period terminates, PG becomes high impedance as long as the output voltage (monitored on the FB pin) is above 90% of the nominal regulation voltage set by FB. When V\text{OUT} drops 10% below the nominal regulation voltage, the ISL85033 pulls PG low. Any fault condition forces PG low until the fault condition is cleared by attempts to soft-start. There is an internal 5MΩ internal pull-up resistor.

Output Voltage Selection

The regulator output voltage is easily programmed using an external resistor divider to scale V\text{OUT} relative to the internal reference voltage. The scaled voltage is applied to the inverting input of the error amplifier; refer to Figure 38.

The output voltage programming resistor, R2, depends on the value chosen for the feedback resistor, R3, and the desired output voltage, V\text{OUT}, of the regulator. Equation 2 describes the relationship between V\text{OUT} and resistor values. R3 is often chosen to be in the 1kΩ to 10kΩ range.

\[ R_2 = \left( V_{OUT} - 0.8 \right) \cdot R_3/0.8 \]  

If the desired output voltage is 0.8V, then R3 is left unpopulated and R2 is 0Ω.

![Figure 38. External Resistor Divider](image)

Output Tracking and Sequencing

The output tracking and sequencing between channels can be implemented by using the SS1 and SS2 pins. Figures 39, 40 and 41 show several configurations for output tracking/sequencing for a 2.5V and 1.8V application. Independent soft-start for each channel is shown in Figure 39 and measured in Figure 29. The output ramp-time for each channel (tSS) is set by the soft-start capacitor (CSS) as shown by Equation 3.

\[ CSS[\mu F] = 2.5 \cdot tSS[\mu s] \]  

The maximum CSS value is recommended not to exceed 100nF. Ratiometric tracking is achieved in Figure 40 by using the same value for the soft-start capacitor on each channel; it is measured in Figure 30.

By connecting a feedback network from V\text{OUT1} to the SS2 pin with the same ratio that sets V\text{OUT2} voltage, absolute tracking shown in Figure 41 is implemented. The measurement is shown in Figure 31. If the output of Channel 1 is shorted to GND, it will enter overcurrent hiccup mode, SS2 will be pulled low through the added resistor between V\text{OUT1} and SS2 and this will force Channel 2 into hiccup as well. If the output of Channel 2 is...
shorted to GND with \( V_{\text{OUT1}} \) in regulation, it will enter overcurrent hiccup mode with a very short hiccup waiting time. The reason is that \( V_{\text{OUT1}} \) is still in regulation and can pull up SS2 very quickly via the resistor added between \( V_{\text{OUT1}} \) and SS2.

Figure 42 illustrates output sequencing. When EN1 is high and EN2 is floating, OUT1 comes up first and OUT2 will not start until \( V_{\text{OUT1}} > 90\% \) of its regulation point. If EN1 is floating and EN2 is high, OUT2 comes up first and OUT1 will not start until \( V_{\text{OUT2}} > 90\% \) of its regulation point. If EN1 = EN2 = high, OUT1 and OUT2 come up at the same time. Please refer to Table 1 for conditions related to Figure 42 (Output Sequencing).

**Protection Features**

The ISL85033 limits the current in all on-chip power devices. Overcurrent protection limits the current on the two buck regulators and internal LDO for \( V_{\text{CC}} \).

**Buck Regulator Overcurrent Protection**

During PWM on-time, current through the internal switching MOSFET is sampled and scaled through an internal pilot device. The sampled current is compared to a nominal 5A overcurrent limit. If the sampled current exceeds the overcurrent limit reference level, an internal overcurrent fault counter is set to 1 and an internal flag is set. The internal power MOSFET is immediately turned off and will not be turned on again until the next switching cycle.

The protection circuitry continues to monitor the current and turns off the internal MOSFET as described. If the overcurrent condition persists for 17 sequential clock cycles, the overcurrent fault counter overflows indicating an overcurrent fault condition exists. The regulator is shutdown and power-good goes low.

The buck controller attempts to recover from the overcurrent condition after waiting 8 soft-start cycles. The internal overcurrent flag and counter are reset. A normal soft-start cycle
is attempted and normal operation continues if the fault condition has cleared. If the overcurrent fault counter overflows during soft-start, the converter shuts down and this hiccup mode operation repeats.

Thermal Overload Protection
Thermal overload protection limits maximum junction temperature in the ISL85033. When the junction temperature (TJ) exceeds +150 °C, a thermal sensor sends a signal to the fault monitor.

The fault monitor commands the buck regulator to shutdown. When the junction temperature has decreased by 20 °C, the regulator will attempt a normal soft-start sequence and return to normal operation. For continuous operation, the +125 °C junction temperature rating should not be exceeded.

BOOT Undervoltage Protection
If the BOOT capacitor voltage falls below 2.5V, the BOOT undervoltage protection circuit will pull the phase pin low through a 1Ω switch for 400ns to recharge the capacitor. This operation may arise during long periods of no switching as in no load situations.

Application Guidelines

Operating Frequency
The ISL85033 operates at a default switching frequency of 500kHz if FS is tied to VCC. Tie a resistor from FS to GND to program the switching frequency from 300kHz to 2MHz, as shown in Equation 4. [Minimum on-time of 150ns (typical) in conjunction with the input and output voltage should be considered when selecting the maximum operating frequency].

\[ R_{FS} \text{kΩ} = 122kΩ \times (t – 0.17 \mu s) \]  
\[ \text{EQ. 4} \]
Where t is the switching period in μs.

Synchronization Control
The frequency of operation can be synchronized up to 2MHz by an external signal applied to the SYNCIN pin. The falling edge on the SYNCIN triggers the rising edge of PHASE1/2. The switching frequency for each output is half of the SYNCIN frequency.

Output Inductor Selection
The inductor value determines the converter’s ripple current. Choosing an inductor current requires a somewhat arbitrary choice of ripple current, ΔI. A reasonable starting point is 30% of total load current. The inductor value can then be calculated using Equation 5:

\[ L = \frac{V_{IN} - V_{OUT}}{f_{SW} \times \Delta I} \times \frac{V_{OUT}}{V_{IN}} \]  
\[ \text{EQ. 5} \]

Increasing the value of inductance reduces the ripple current and thus ripple voltage. However, the larger inductance value may reduce the converter’s response time to a load transient. The inductor current rating should be such that it will not saturate in overcurrent conditions.

Buck Regulator Output Capacitor Selection
An output capacitor is required to filter the inductor current. The Output ripple voltage and transient response are 2 critical factors when considering output capacitance choice. The current mode control loop allows the usage of low ESR ceramic capacitors and thus smaller board layout. Electrolytic and polymer capacitors may also be used.

Additional consideration applies to ceramic capacitors. While they offer excellent overall performance and reliability, the actual in-circuit capacitance must be considered. Ceramic capacitors are rated using large peak-to-peak voltage swings and with no DC bias. In the DC/DC converter application, these conditions do not reflect reality. As a result, the actual capacitance may be considerably lower than the advertised value. Consult the manufacturers data sheet to determine the actual in-application capacitance. Most manufacturers publish capacitance vs DC bias so that this effect can be easily accommodated. The effects of AC voltage are not frequently published, but an assumption of ~20% further reduction will generally suffice. The result of these considerations can easily result in an effective capacitance 50% lower than the rated value. Nonetheless, they are a very good choice in many applications due to their reliability and extremely low ESR.

The following equations allow calculation of the required capacitance to meet a desired ripple voltage level. Additional capacitance may be used.

For the ceramic capacitors (low ESR):

\[ V_{OUT,ripple} = \frac{\Delta I}{8 \times f_{SW} \times C_{OUT}} \]  
\[ \text{EQ. 6} \]

Where ΔI is the inductor’s peak-to-peak ripple current, fSW is the switching frequency and COUT is the output capacitor.

If using electrolytic capacitors then:

\[ V_{OUT,ripple} = \Delta I \times ESR \]  
\[ \text{EQ. 7} \]
Regarding transient response needs, a good starting point is to determine the allowable overshoot in \( V_{OUT} \) if the load is suddenly removed. In this case, energy stored in the inductor will be transferred to \( C_{OUT} \) causing its voltage to rise. After calculating capacitance required for both ripple and transient needs, choose the larger of the calculated values. Equation 8 determines the required output capacitor value in order to achieve a desired overshoot relative to the regulated voltage.

\[
C_{OUT} = \frac{I_{OUT}^2 \cdot L}{V_{OUT}^2 \cdot (V_{OUTMAX}/V_{OUT})^2 - 1} \quad (EQ. 8)
\]

Where \( V_{OUTMAX}/V_{OUT} \) is the relative maximum overshoot allowed during the removal of the load. For an overshoot of 5%, the equation becomes Equation 9:

\[
C_{OUT} = \frac{I_{OUT}^2 \cdot L}{V_{OUT}^2 \cdot (0.05^2 - 1)} \quad (EQ. 9)
\]

Figure 44 shows the relationship of \( C_{OUT} \) and % overshoot at three different output voltages. \( L \) is assumed to be 7\( \mu \)H and \( I_{OUT} \) is 3A.

![Figure 44. C_{OUT} vs OVERSHOT V_{OUTMAX}/V_{OUT}](image)

### Current Sharing Configuration

In current sharing configuration, FB1 is connected to FB2, EN1 to EN2, COMP1 to COMP2 and \( V_{OUT1} \) to \( V_{OUT2} \) as shown in Figure 3 on page 5. As a result, the equivalent \( g_m \) doubles its single channel value. Since the two channels are out-of-phase, the frequency will be 2x the channel switching frequency. Ripple current cancellation will reduce the ripple current seen by the output capacitors and thus lower the ripple voltage. This results in the ability to use less capacitance than would be required by a single phase design of similar rating. Ripple current cancellation also reduces the ripple current seen at the input capacitors.

### Input Capacitor Selection

To reduce the resulting input voltage ripple and to minimize EMI by forcing the very high frequency switching current into a tight local loop, an input capacitor is required. The input capacitor must have adequate ripple current rating, which can be approximated by Equation 10. If capacitors other than MLCC are used, attention must be paid to ripple and surge current ratings.

\[
\frac{I_{RMS}}{I_o} = \sqrt{D - D^2} \quad (EQ. 10)
\]

Where \( D = V_o/V_IN \)

The input ripple current is graphically represented in Figure 45.

![Figure 45. I_{RMS}/I_o vs DUTY CYCLE](image)

A minimum of 10\( \mu \)F ceramic capacitance is required on each VIN pin. The capacitors must be as close to the IC as physically possible. Additional capacitance may be used.

### Loop Compensation Design

The ISL85033 uses a constant frequency current mode control architecture to achieve simplified loop compensation and fast loop transient response.

The compensator schematic is shown in Figure 47. As mentioned in the \( C_{OUT} \) selection, ISL85033 allows the usage of low ESR output capacitor. Choice of the loop bandwidth \( f_c \) is somewhat arbitrary but should not exceed 1/4 of the switching frequency. As a starting point, the lower of 100kHz or 1/6 of the switching frequency is reasonable. The following equations determine initial component values for the compensation, allowing the designer to make the selection with minimal effort. Further detail is provided in “Theory of Compensation” on page 20 to allow fine tuning of the compensator.

Compensation resistor \( R_1 \) is given by Equation 11:

\[
R_1 = \frac{2\pi f_c V_o C_o R_T}{g_m V_{FB}} \quad (EQ. 11)
\]

Which, when applied to the ISL85033 becomes:

\[
R_1[k\Omega] = 0.008247 \times f_c \times V_o \times C_o \quad (EQ. 12)
\]

Where \( C_o \) is the output capacitor value \([\mu F]\), \( f_c = \) loop bandwidth \([kHz]\) and \( V_o \) is the output voltage \([V]\).

Compensation capacitors \( C_1 \) \([nF]\), \( C_2 \) \([pF]\) are given by Equation 13:

\[
C_1 = \frac{C_o \times V_o \times (10)^3}{I_o \times R_1}, C_2 = \frac{C_o \times R_c \times (10)^6}{R_1} \quad (EQ. 13)
\]

Where \( I_o \) \([A]\) is the output load current, \( R_1 \) \([\Omega]\) and \( R_C \) \([\Omega]\) is the ESR of the output capacitor \( C_o \).
Example: $V_o = 5V$, $I_o = 3A$, $f_{SW} = 500kHz$, $f_c = 50kHz$, $C_0 = 47\mu F/R_c = 5\Omega$, then the compensation resistance $R_1 = 96k\Omega$.

The compensation capacitors are:

$C_1 = 815pF$, $C_2 = 2.5pF$ (There is approximately 3pF parasitic capacitance from $V_{COMP}$ to GND; therefore, $C_2$ is optional).

**Theory of Compensation**

The sensed current signal is injected into the voltage loop to achieve current mode control to simplify the loop compensation design. The inductor is not considered as a state variable for current mode control and the system becomes a single order system. It is much easier to design a compensator to stabilize the voltage loop than voltage mode control. Figure 46 shows the small signal model of the synchronous buck regulator.

**PWM Comparator Gain $F_m$**

The PWM comparator gain $F_m$ for peak current mode control is given by Equation 14:

$$F_m = \frac{\frac{d}{V_{COMP}}}{(Se + Sn)T_s}$$

(EQ. 14)

Where $Se$ is the slew rate of the slope compensation and $Sn$ is given by Equation 15.

$$Sn = \frac{VIN - VO}{RT}$$

(EQ. 15)

Where $RT$ is transresistance and is the product of the current sensing resistance and gain of the current amplifier in current loop.

**CURRENT SAMPLING TRANSFER FUNCTION $H_v(S)$**

In current loop, the current signal is sampled every switching cycle. Equation 16 shows the transfer function:

$$H_v(S) = \frac{S^2}{\omega_n^2 + \frac{S}{\omega_n Q_n} + 1}$$

(EQ. 16)

Where $Q_n$ and $\omega_n$ are given by $Q_n = \frac{2}{\pi} = \omega_n = \pi f_S$.

**Power Stage Transfer Functions**

Transfer function $F_2(S)$ from control to output voltage is calculated in Equation 17:

$$F_2(S) = \frac{V_{IN}}{\frac{1}{\omega \omega_p} \frac{1}{\omega P}}$$

(EQ. 17)

Where $\omega = \frac{1}{R_c C_0 Q_0} = R_0 \sqrt{\frac{C_0}{L}}$, $\omega = \frac{1}{\sqrt{LC_0}}$

Transfer function $F_2(S)$ from control to inductor current is given by Equation 18:

$$F_2(S) = \frac{\frac{1}{\omega \omega_p}}{S^2 + \frac{S}{\omega_n Q_p} + 1}$$

(EQ. 18)

Where $\omega = \frac{1}{R_c C_0}$

Current loop gain $T_i(S)$ is expressed as Equation 19:

$$T_i(S) = RT F_m F_2(S) H_v(S)$$

(EQ. 19)

The voltage loop gain with open current loop is calculated in Equation 20:

$$T_v(S) = K F_m F_1(S) A_v(S)$$

(EQ. 20)

The voltage loop gain with current loop closed is given by Equation 21:

$$L_v(S) = \frac{\frac{V_{FB}}{V_0}}{\frac{RT F_m F_1(S)}{1 + T_i(S)}}$$

(EQ. 21)

Where $K = \frac{V_{FB}}{V_0}$, $V_{FB}$ is the feedback voltage of the voltage error amplifier. If $T_i(S) >> 1$, then Equation 21 can be simplified as shown in Equation 22:

$$L_v(S) = \frac{V_{FB} R_0 + R_L}{\frac{1}{\omega P} H_v(S) \omega_p} + \frac{1}{R_0 C_0}$$

(EQ. 22)

Equation 22 shows that the system is a single order system, which has a single pole located at $\omega_p$ before the half switching frequency. Therefore, a simple type II compensator can be easily used to stabilize the system.
Figure 47 shows the type II compensator and its transfer function is expressed as Equation 23:

$$A_v(S) = \frac{v_{COMP}}{v_{FB}} = \frac{g_m}{C_1 + C_2} \left(1 + \frac{S}{\omega_{cz1}}\right) \left(1 + \frac{S}{\omega_{cz2}}\right) \left(1 + \frac{S}{\omega_{cp}}\right)$$

(EQ. 23)

Where:

$$\omega_{cz1} = \frac{1}{R_1C_1}, \quad \omega_{cz2} = \frac{1}{R_2C_2}, \quad \omega_{cp} = \frac{C_1 + C_2}{R_1C_1C_2}$$

(EQ. 24)

The compensator design goal is:
- High DC gain
- Loop bandwidth $f_c$: $\left(\frac{1}{4} to \frac{1}{10}\right) f_{SW}$
- Gain margin: $>10\text{dB}$
- Phase margin: $40^\circ$

The compensator design procedure is shown in Equation 25:

```
Put one compensator pole at zero frequency to achieve high DC gain, and put another compensator pole at either ESR zero or half switching frequency, whichever is lower.
```

Put the compensator zero at $6.6kHz$ ($\approx 1.5x C_0 R_3$), and put the compensator pole at ESR zero, which is $1.45MHz$. The compensator capacitors are:

$$C_1 = 470\text{pF}, \quad C_2 = 3\text{pF}$$

(There is approximately 3pF parasitic capacitance from VCOMP to GND; therefore, C2 is optional).

**Figure 48A** shows the simulated voltage loop gain. It is shown that it has 80kHz loop bandwidth with 69° phase margin and 15dB gain margin. Optional addition phase boost can be added to the overall loop response by using C3.

**Rectifier Selection**

Current circulates from ground to the junction of the external Schottky diode and the inductor when the high-side switch is off. As a consequence, the polarity of the switching node is negative with respect to ground. This voltage is approximately -0.5V (a Schottky diode drop) during the off-time. The rectifier’s rated reverse breakdown voltage must be at least equal to the maximum input voltage, preferably with a 20% derating factor.

The power dissipation when the Schottky diode conducts is expressed in Equation 28:

$$P_{D[W]} = I_{OUT} \cdot V_{D} \cdot \left[1 - \frac{V_{OUT}}{V_{IN}}\right]$$

(EQ. 28)

Where:

The $V_D$ is the voltage drop of the Schottky diode. Selection of the Schottky diode is critical in terms of the high temperature reverse bias leakage current, which is very dependent on $V_{IN}$ and exponentially increasing with temperature. Due to the nature of...
reverse bias leakage vs temperature, the diode should be carefully selected to operate in the worst case circuit conditions. Catastrophic failure is possible if the diode chosen experiences thermal runaway at elevated temperatures. See AN1574, AN1605, and AN1584 for diode selection on the application circuit on page 5.

**Power Derating Characteristics**

To prevent the ISL85033 from exceeding the maximum junction temperature, some thermal analysis is required. The temperature rise is given by Equation 29:

\[
T_{\text{RISE}} = (PD)(\theta_{JA})
\]  
\[\text{(EQ. 29)}\]

Where PD is the power dissipated by the regulator and \(\theta_{JA}\) is the thermal resistance from the junction of the die to the ambient temperature. The junction temperature, \(T_J\), is given by Equation 30:

\[
T_J = (T_A + T_{\text{RISE}})
\]  
\[\text{(EQ. 30)}\]

Where \(T_A\) is the ambient temperature. For the QFN package, the \(\theta_{JA}\) is +38 °C/W.

The actual junction temperature should not exceed the absolute maximum junction temperature of +125°C when considering the thermal design, (consider the thermal needs of the rectifier diode).

The ISL85033 delivers full current at ambient temperatures up to +85°C if the thermal impedance from the thermal pad maintains the junction temperature below the thermal shutdown level, depending on the Input Voltage/Output Voltage combination and the switching frequency. The device power dissipation must be reduced to maintain the junction temperature at or below the thermal shutdown level. Figure 49 illustrates the power derating versus ambient temperature for the ISL85033 evaluation kit. Note that the evaluation kit derating curve is based on total circuit dissipation, not IC dissipation alone.

![Power Derating Curve](image)

**Layout Considerations**

Layout is very important in high frequency switching converter designs. With power devices switching efficiently between 100kHz and 600kHz, the resulting current transitions from one device to another cause voltage spikes across the interconnecting impedances and parasitic circuit elements. These voltage spikes can degrade efficiency, radiate noise into the circuit, and lead to device overvoltage stress. Careful component layout and printed circuit board design minimizes these voltage spikes.

As an example, consider the turn-off transition of the upper MOSFET. Prior to turn-off, the MOSFET is carrying the full load current. During turn-off, current stops flowing in the MOSFET and is picked up by the Schottky diode. Any parasitic inductance in the switched current path generates a large voltage spike during the switching interval. Careful component selection, tight layout of the critical components and short, wide traces minimizes the magnitude of voltage spikes.

There are two sets of critical components in the ISL85033 switching converter. The switching components are the most critical because they switch large amounts of energy and therefore tend to generate large amounts of noise. Next are the small signal components which connect to sensitive nodes or supply critical bypass current and signal coupling.

A multilayer printed circuit board is recommended. Figure 50 shows the connections of the critical components in the converter. Note that capacitors \(C_{IN}\) and \(C_{OUT}\) could each represent numerous physical capacitors. Dedicate one solid layer, (usually a middle layer of the PC board) for a ground plane and make all critical component ground connections with vias to this layer. Dedicate another solid layer as a power plane and break this plane into smaller islands of common voltage levels. The metal runs from the PHASE terminals to the output inductor short. The power plane should support the input power and output power nodes. Use copper filled polygons on the top and bottom circuit layers for the phase nodes. Use the remaining printed circuit layers for small signal wiring.

In order to dissipate heat generated by the internal LDO and MOSFET, the ground pad should be connected to the internal ground plane through at least four vias. This allows the heat to move away from the IC and also ties the pad to the ground plane through a low impedance path.

The switching components should be placed close to the ISL85033 first. Minimize the length of the connections between the input capacitors, \(C_{IN}\), and the power switches by placing them nearby. Position both the ceramic and bulk input capacitors as close to the upper MOSFET drain as possible. Position the output inductor and output capacitors between the upper and Schottky diode and the load.

The critical small signal components include any bypass capacitors, feedback components, and compensation components. Place the PWM converter compensation components close to the FB and COMP pins. The feedback resistors should be located as close as possible to the FB pin with vias tied straight to the ground plane as required.

Page 2 in the pin table definition, please add the following sentence to the Pin 11 (VCC) description after “Output of the internal 5V linear regulator. Decouple to PGND with a minimum of 4.7 \( \mu \text{F} \) ceramic capacitor.”  
“This pin is provided only for internal bias of ISL85033 (not to be loaded with current over 10mA).”  
Page 8 all Absolute Max Ratings that are “5.5” should be changed to “5.9” |
| Oct 15, 2010 | 2.00 | Added the following sentence to the “SYNCIN” description in the “Pin Descriptions” table on page 4:  
“Set the internal switching frequency 20% lower than the external SYNC frequency applied to the SYNCIN pin.”  
Added the following sentence to “Synchronization Control” on page 18: “The switching frequency for each output is half of the SYNCIN frequency.”  
Revised tape and reel note in “Ordering Information” on page 7 from:  
“Add “-T” suffix for Tape and Reel. Please refer to TB347 for details on reel specifications”  
to:  
“Add “-T*” suffix for Tape and Reel. Please refer to TB347 for details on reel specifications”  
This is in order to delineate all tape and reel options.  
Corrected Eq. 2 on page 16 from:  
\[ R_3 = \frac{R_2 \times 0.8 \text{V}}{V_{\text{OUT}} - 0.8 \text{V}} \]  
to:  
\[ R_2 = \left( \frac{V_{\text{OUT}} - 0.8}{0.8} \right) \times R_3 / 0.8 \]  
Revised preceding paragraph from:  
“The output voltage programming resistor, \( R_3 \), depends on the value chosen for the feedback resistor, \( R_2 \), and the desired output voltage, \( V_{\text{OUT}} \), of the regulator. Equation 2 describes the relationship between \( V_{\text{OUT}} \) and resistor values. \( R_3 \) is often chosen to be in the 1kΩ to 10kΩ range.”  
to:  
“The output voltage programming resistor, \( R_3 \), depends on the value chosen for the feedback resistor, \( R_2 \), and the desired output voltage, \( V_{\text{OUT}} \), of the regulator. Equation 2 describes the relationship between \( V_{\text{OUT}} \) and resistor values. \( R_3 \) is often chosen to be in the 1kΩ to 10kΩ range.” |
| Jul 21, 2010 | 1.00 | Changed MIN/MAX for “Soft-start Charging Current” on page 8 from 1.5/2.5\( \mu \text{A} \) to 1.4/2.6\( \mu \text{A} \) |
| Jul 18, 2010 | 0.00 | Initial Release. |
Package Outline Drawing

L28.4x4
28 Lead Thin Quad Flat No-Lead Plastic Package
Rev 1, 6/15

For the most recent package outline drawing, see L28.4x4.

NOTES:
1. Controlling dimensions are in mm.
Dimensions in ( ) are for reference only.
2. Unless otherwise specified, tolerance: Decimal ±0.05
Angular ±2°
4. Bottom side Pin#1 ID is diepad chamfer as shown.
5. Tiebar shown (if present) is a non-functional feature.
