The MCU drives the RSPCKn, MOSIn, SSLn1, and SSLn2 signals when the SSLn0 input level is high. When the SSLn0 input level is low, the MCU detects a mode fault error, sets RSPCKn, MOSIn, SSLn1, and SSLn2 to Hi-Z, and releases the SPI bus directly to the other master. Of the SPI slaves 1 and 2, the slave that receives low-level input into the SSL input drives the MISO signal.

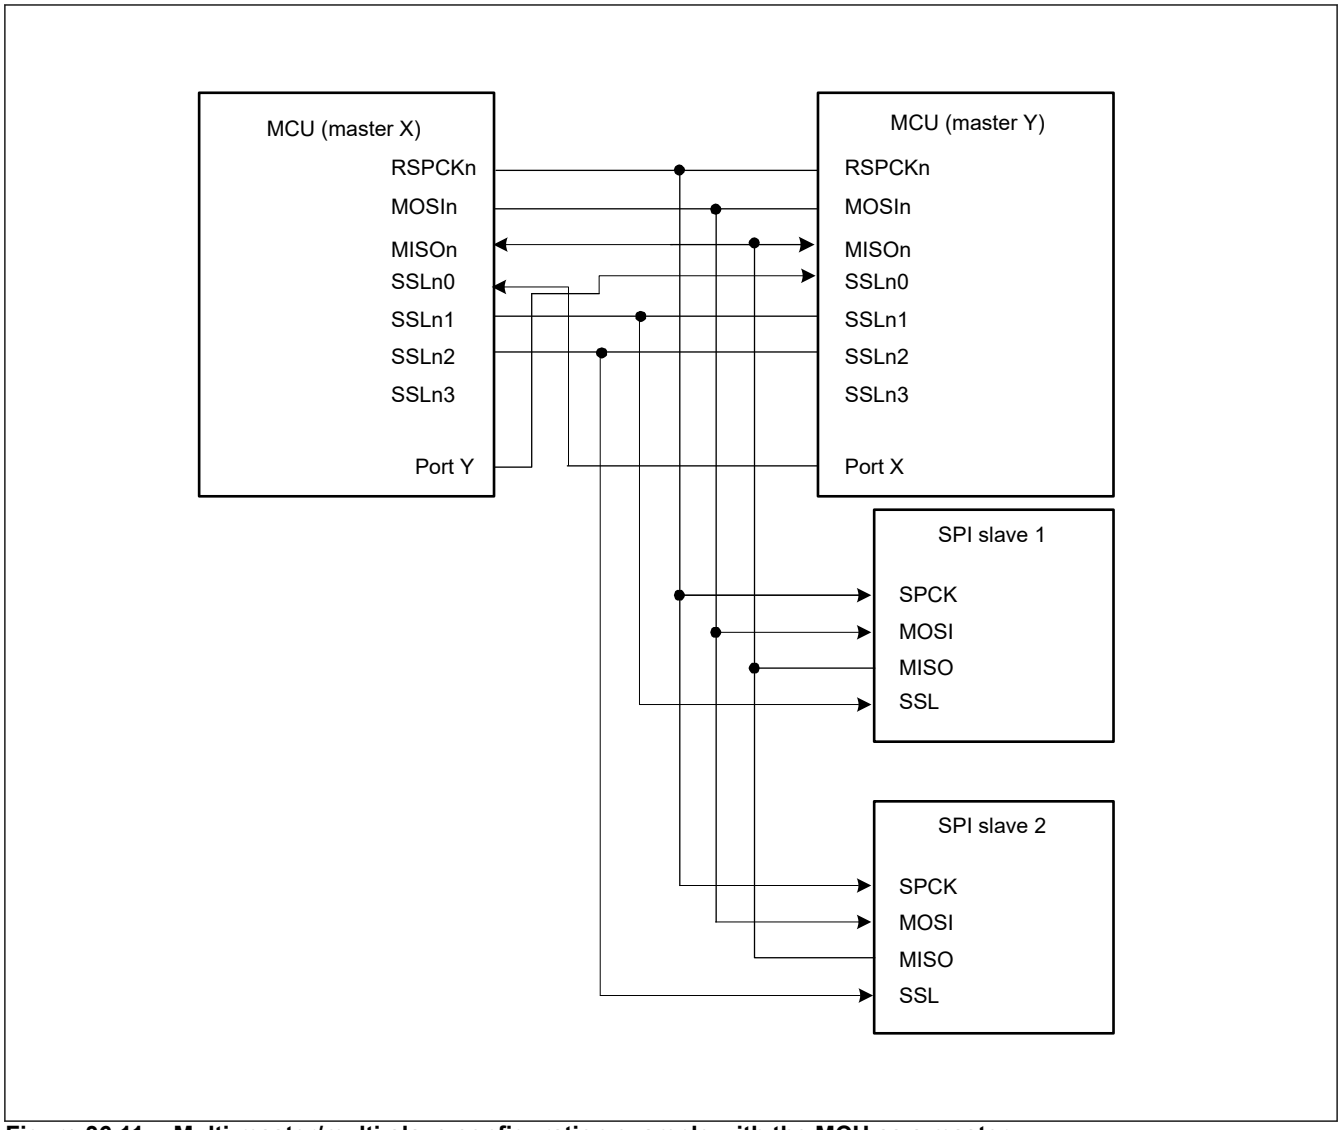

Figure 36.11 Multi-master/multi-slave configuration example with the MCU as a master

When setting TI SSP, enter the following levels for port X and port Y.

- Start of communication: the value of SPCR3.SSL0P of the other master.
- End of communication: the inverted value of SPCR3.SSL0P of the other master.

36.3.3.6 Master and slave in clock synchronous mode with the MCU configured as a master

Figure 36.12 shows a master and slave in clock synchronous mode configuration example where the MCU is used as a master. In this configuration, SSLni of the MCU (master) are not used.

The MCU (master) drives the RSPCKn and MOSIn signals. The SPI slave drives the MISO signal.

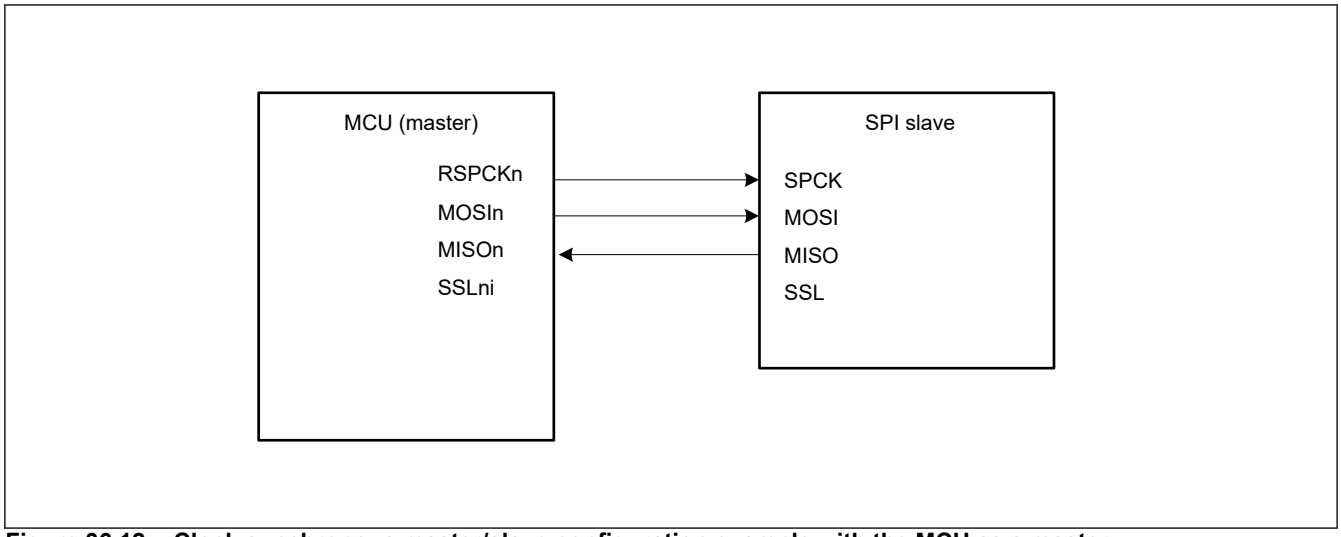

Figure 36.12 Clock synchronous master/slave configuration example with the MCU as a master

36.3.3.7 Master and slave in clock synchronous mode with the MCU as a slave

Figure 36.13 shows a master and slave in clock synchronous mode configuration example where the MCU is used as a slave. When the MCU operates as a slave (clock synchronous operation), the MCU (slave) drives the MISOn signal and the SPI master drives the SPCK and MOSI signals. In addition, SSLn0 to SSLn3 of the MCU (slave) are not used.

The MCU (slave) can only execute serial transfers in the single-slave configuration when the SPCMDm.CPHA bit is set to 1.

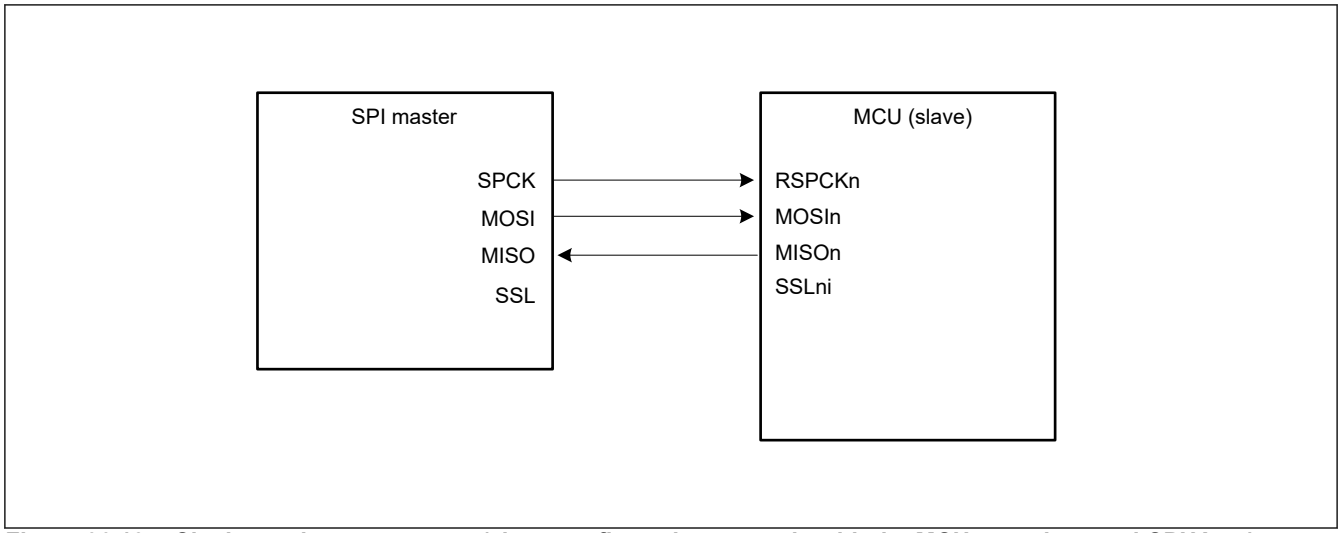

Figure 36.13 Clock synchronous master/slave configuration example with the MCU as a slave and CPHA = 1

36.3.4 Data Formats

The data format of the SPI depends on the settings in SPI Command Register m (SPCMDm) and the parity enable bit in SPI Control Register (SPCR.SPPE). Regardless of whether the MSB or LSB is first, the SPI treats the range from the LSB bit in the SPI Data Register (SPDR) to the bit associated with the selected data length, as transfer data.

This section shows the format of one frame of data before or after transfer.

Data format with parity disabled

When parity is disabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register m (SPCMDm.SPB[4:0]).

Data format with parity enabled

When parity is enabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register m (SPCMDm.SPB[4:0]). In this case, however, the last bit is a parity bit.

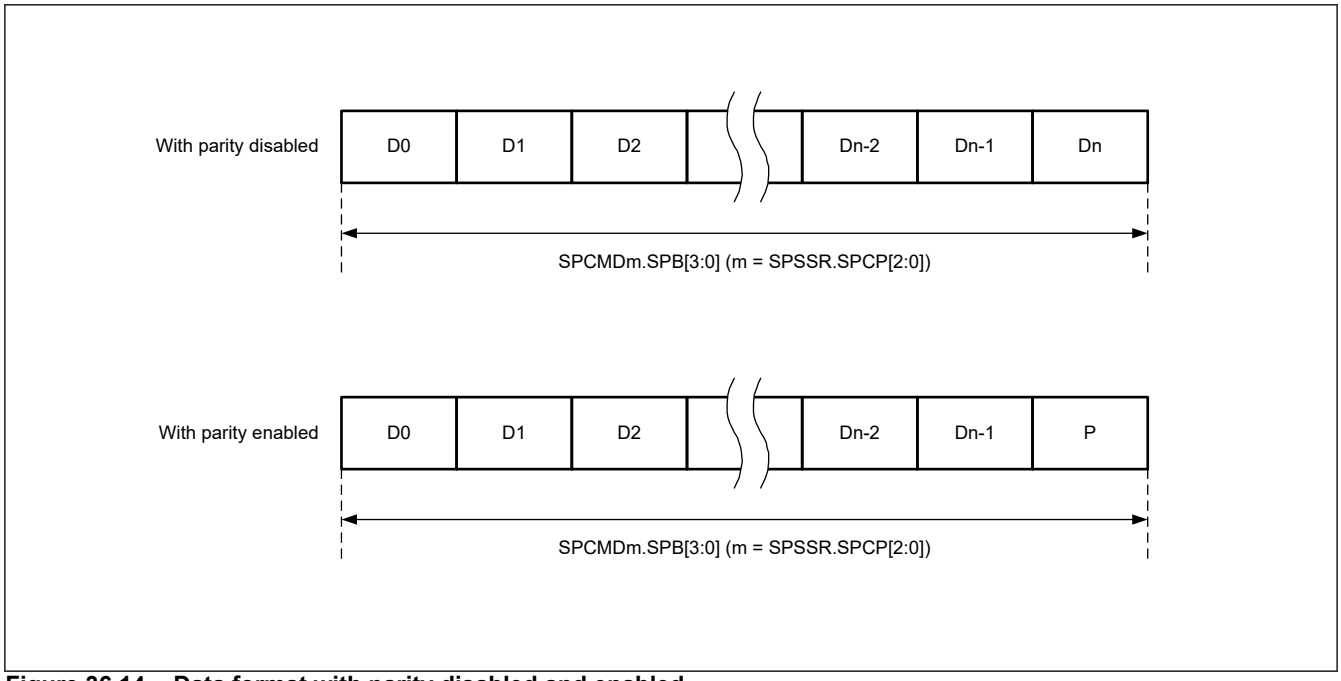

Figure 36.14 Data format with parity disabled and enabled

36.3.4.1 Operation when parity is disabled (SPCR.SPPE = 0)

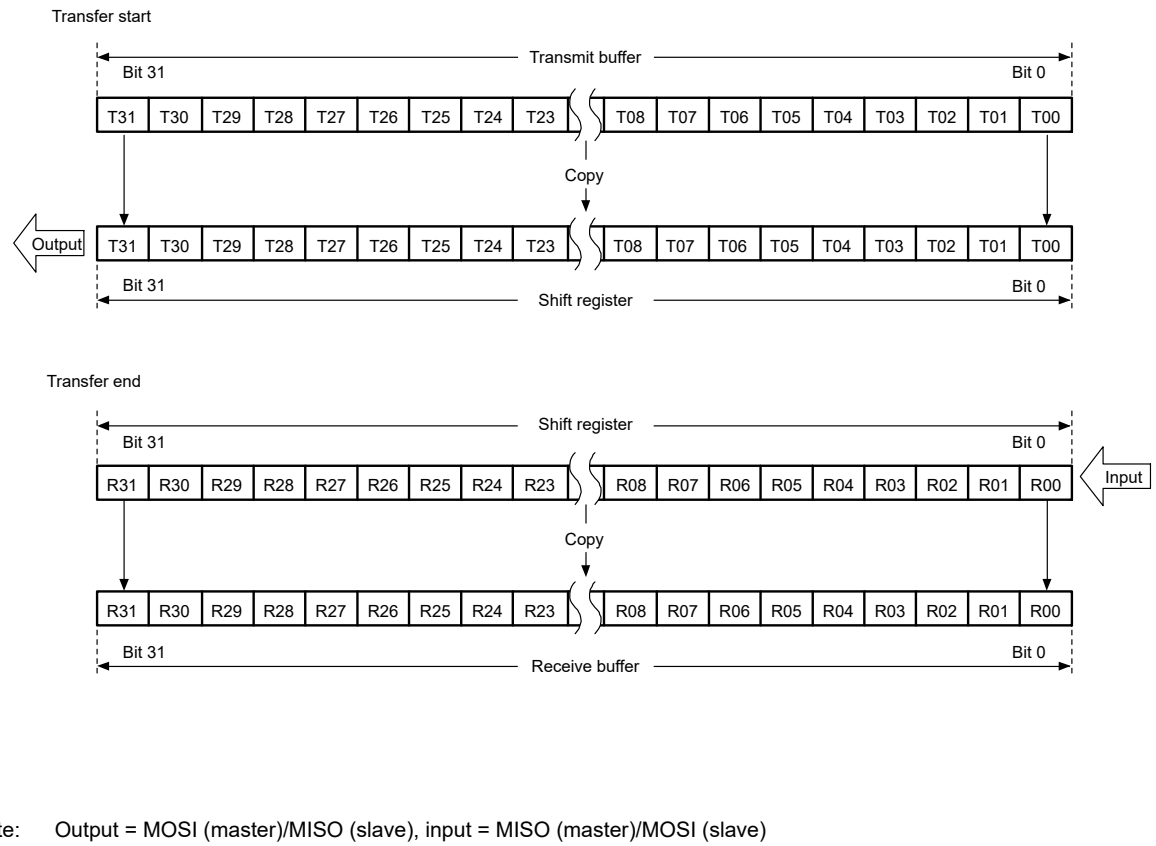
When parity is disabled, data for transmission is copied to the shift register with no pre-processing. This section describes the connection between the SPI Data Register (SPDR) and the shift register in terms of the combination of MSB- or LSB-first order and data length.

(1) MSB-first transfer with 32-bit data

Figure 36.15 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, a SPI data length of 32 bits, and MSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T31 to T30, and continuing to T00.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R31 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

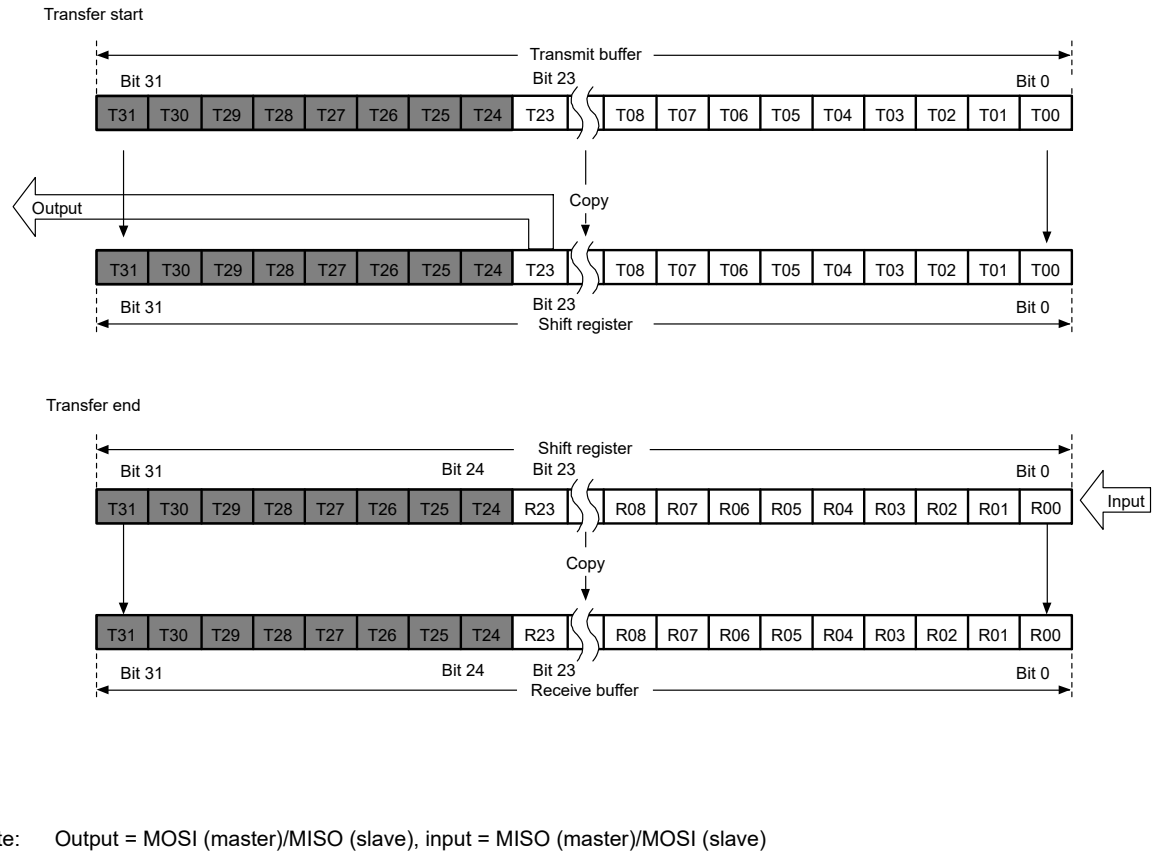
Figure 36.15 MSB-first transfer with 32-bit data and parity disabled

(2) MSB-first transfer with 24-bit data

Figure 36.16 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 24 bits for an example that is not 32 bits, and MSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T23 to T22, and continuing to T00.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R23 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 36.16 MSB-first transfer with 24-bit data and parity disabled

(3) LSB-first transfer with 32-bit data

Figure 36.17 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 32 bits, and LSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are reordered bit-by-bit to obtain the order T00 to T31 for copying to the shift register. Data for transmission is shifted out from the shift register in order from T00 to T01, and continuing to T31.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R00 to R31 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

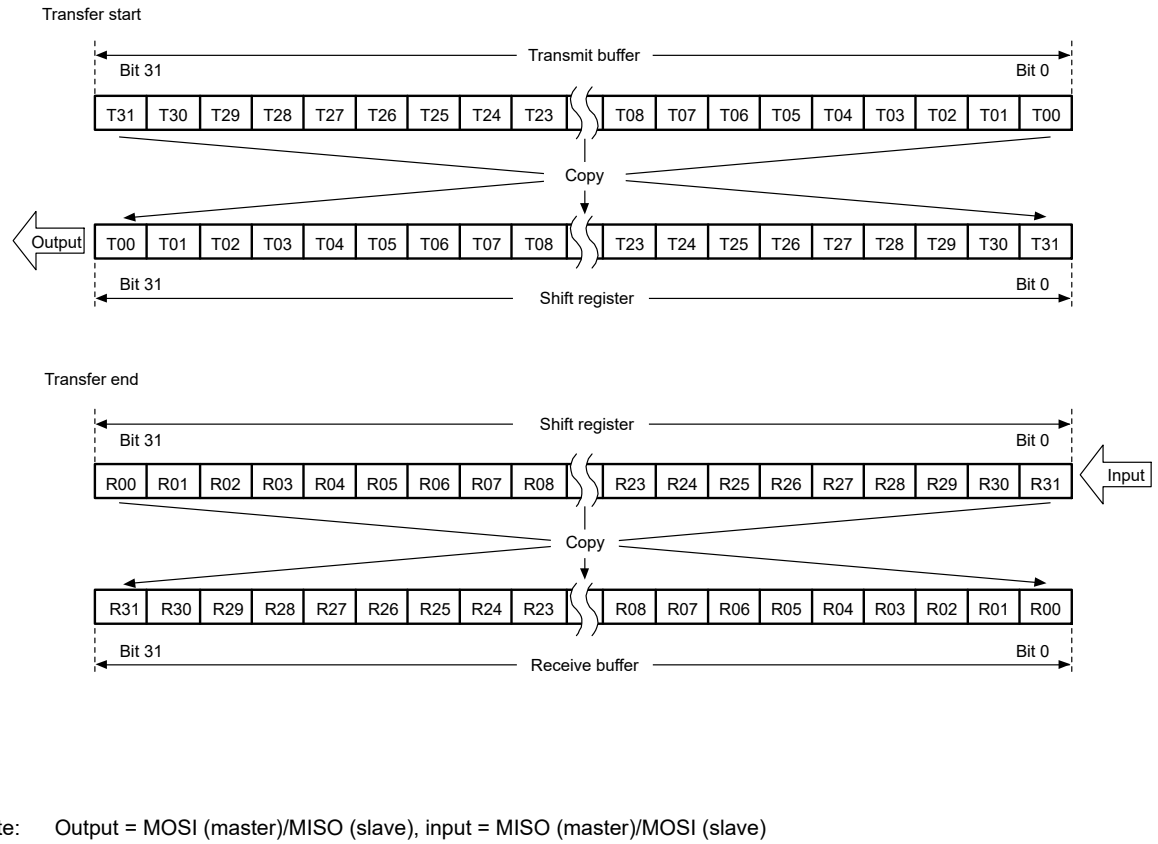


Figure 36.17 LSB-first transfer with 32-bit data and parity disabled

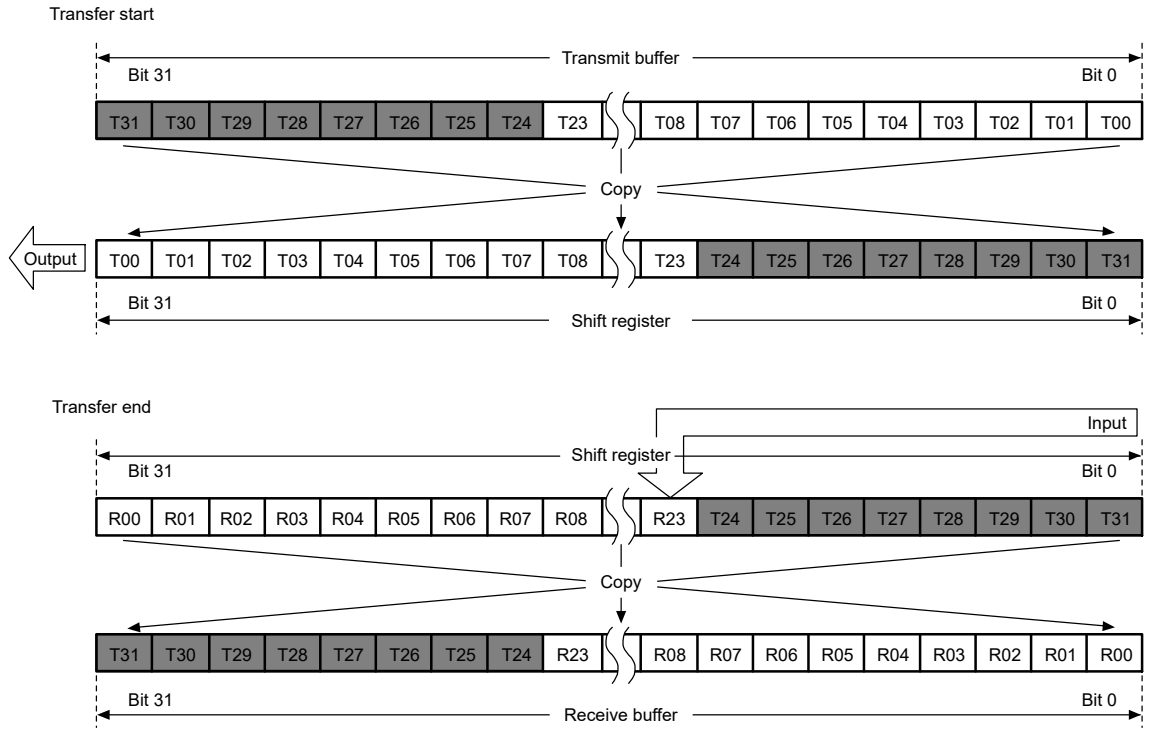
(4) LSB-first transfer with 24-bit data

Figure 36.18 shows the operation of the SPI Data Register (SPDR) and the shift register in transfers with parity disabled, an SPI data length of 24 bits for an example that is not 32, and LSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are reordered bit-by-bit to obtain the order T00 to T23 for copying to the shift register. Data for transmission is shifted out from the shift register from T00 to T01, and continuing to T23.

In reception, received data is shifted in bit-by-bit through bit[8] of the shift register. When the R00 to R23 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 36.18 LSB-first transfer with 24-bit data and parity disabled

36.3.4.2 Operation when parity is enabled (SPCR.SPPE = 1)

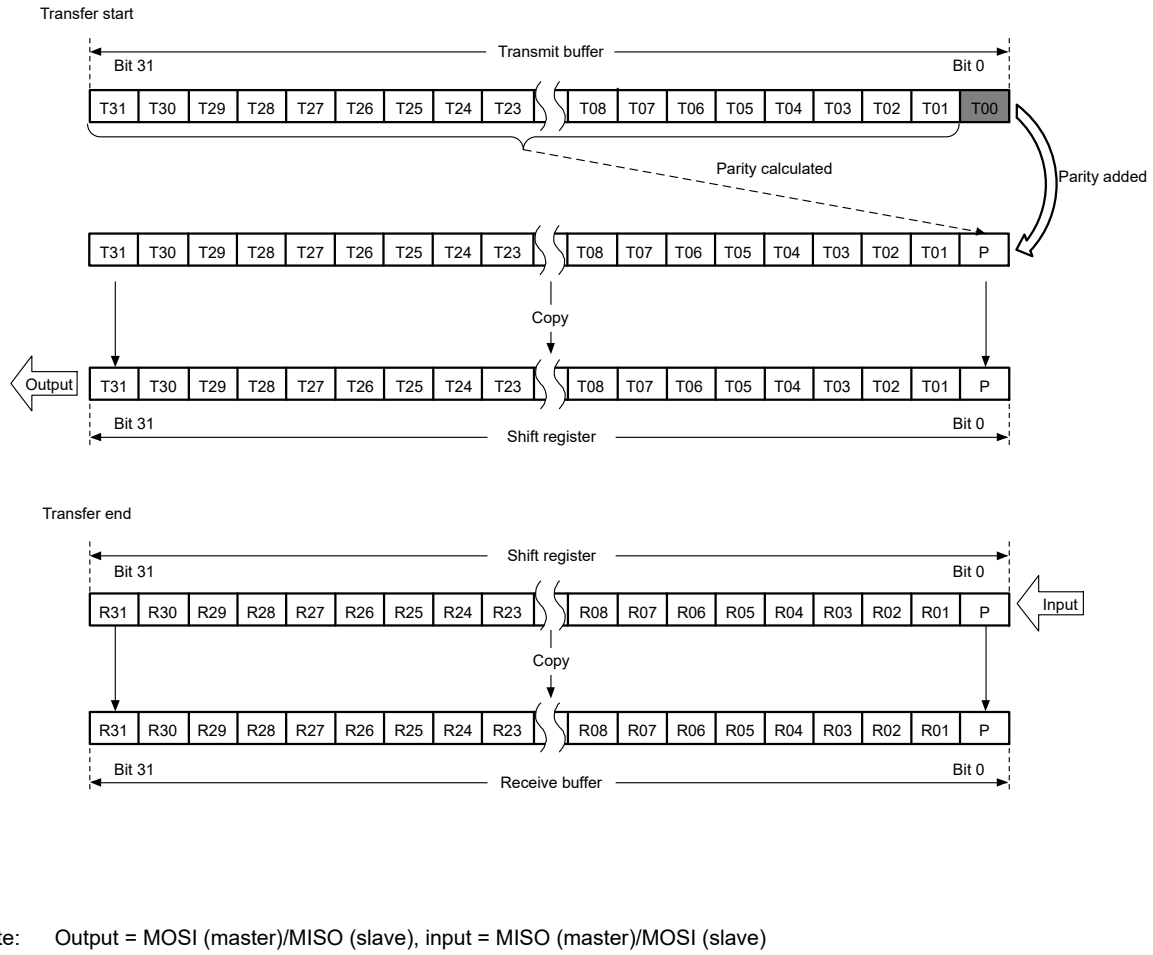
When parity is enabled, the lowest-order bit of the data for transmission becomes a parity bit. Hardware calculates the value of the parity bit.

(1) MSB-first transfer with 32-bit data

Figure 36.19 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 32 bits, and MSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T31 to T01. This replaces the final bit, T00, and the whole value is copied to the shift register. Data is transmitted in the order T31, T30, …, T01, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R31 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R31 to P is checked for parity.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

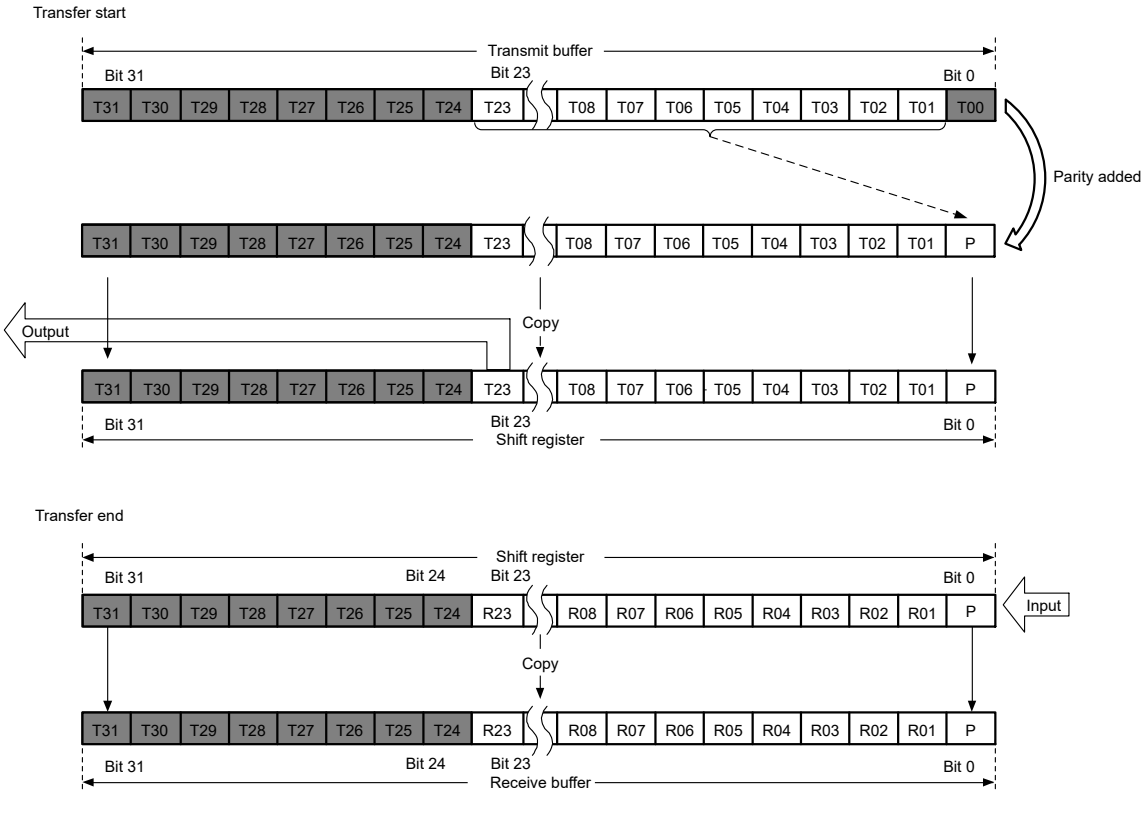
Figure 36.19 MSB-first transfer with 32-bit data and parity enabled

(2) MSB-first transfer with 24-bit data

Figure 36.20 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, a SPI data length of 24 bits, and MSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T23 to T01. This replaces the final bit, T00, and the whole value is copied to the shift register. Data is transmitted in the order T23, T22, …, T01, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R23 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R23 to P is checked for parity.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

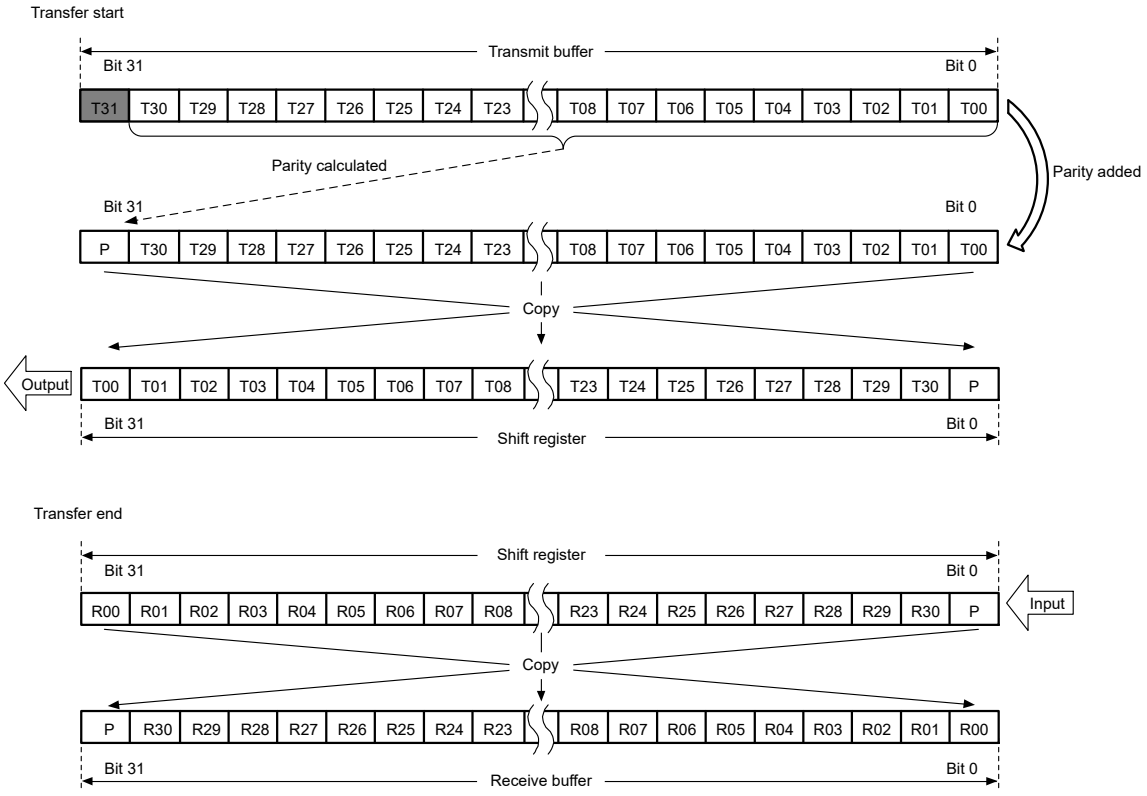
Figure 36.20 MSB-first transfer with 24-bit data and parity enabled

(3) LSB-first transfer with 32-bit data

Figure 36.21 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 32 bits, and LSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T30 to T00. This replaces the final bit, T31, and the whole value is copied to the shift register. Data is transmitted in the order T00, T01, …, T30, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R00 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P is checked for parity.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

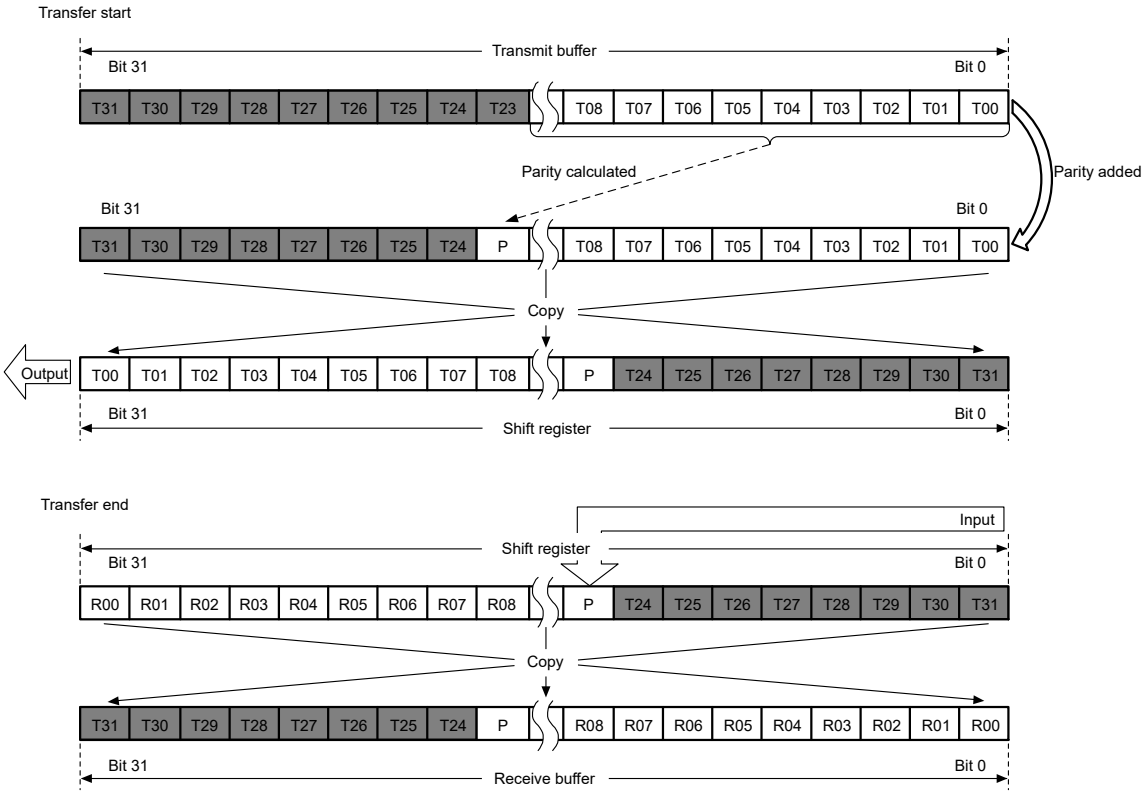
Figure 36.21 LSB-first transfer with 32-bit data and parity enabled

(4) LSB-first transfer with 24-bit data

Figure 36.22 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, a SPI data length of 24 bits, and LSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T22 to T00. This replaces the final bit, T23, and the whole value is copied to the shift register. Data is transmitted in the order T00, T01, …, T22, and P.

In reception, received data is shifted in bit-by-bit through bit[8] of the shift register. When the R00 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P is checked for parity.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 36.22 LSB-first transfer with 24-bit data and parity enabled

36.3.4.3 Byte Swap Transmission

When byte swapping is enabled, the data in the transmission buffer, swapped in 8-bit units, is copied to the shift register. Figure 36.23 shows the relationship between the SPDR (transmit buffer) and the shift register when transferring data with a 32-bit data length, using a combination of MSB / LSB first and with / without byte swap.

(1) MSB-first transfer. (When the byte swap is disabled.)

Data (Byte3 [T31 to T24] to Byte0 [T07 to T00]) in the transmit buffer are copied to the shift register.

Bit values in the shift register are shifted and transmitted in the order of T31 → T30 → … → T00 as transmit data.

(2) MSB-first transfer. (When the byte swap is enabled.)

Byte values of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte0 [T07 to T00] to Byte3 [T31 to T24].

Bit values in the shift register are shifted and transmitted in the order of T07 → T06 → … → T00 → T15 → T14 → … → T08 → T23 → T22 → … → T16 → T31 → T30 → … → T24 as transmit data.

(3) LSB-first transfer. (When the byte swap is disabled.)

Bit values of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte0 [T00 to T07] to Byte3 [T24 to T31].

Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T31 as transmit data.

(4) LSB-first transfer. (When the byte swap is enabled.)

Bit values of each byte of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte3 [T24 to T31] to Byte0 [T00 to T07].

Bit values in the shift register are shifted and transmitted in the order of T24 → T25 → … → T31 → T16 → T17 → … → T23 → T08 → T09 → … → T15 → T00 → T01 → … → T07 as transmit data.

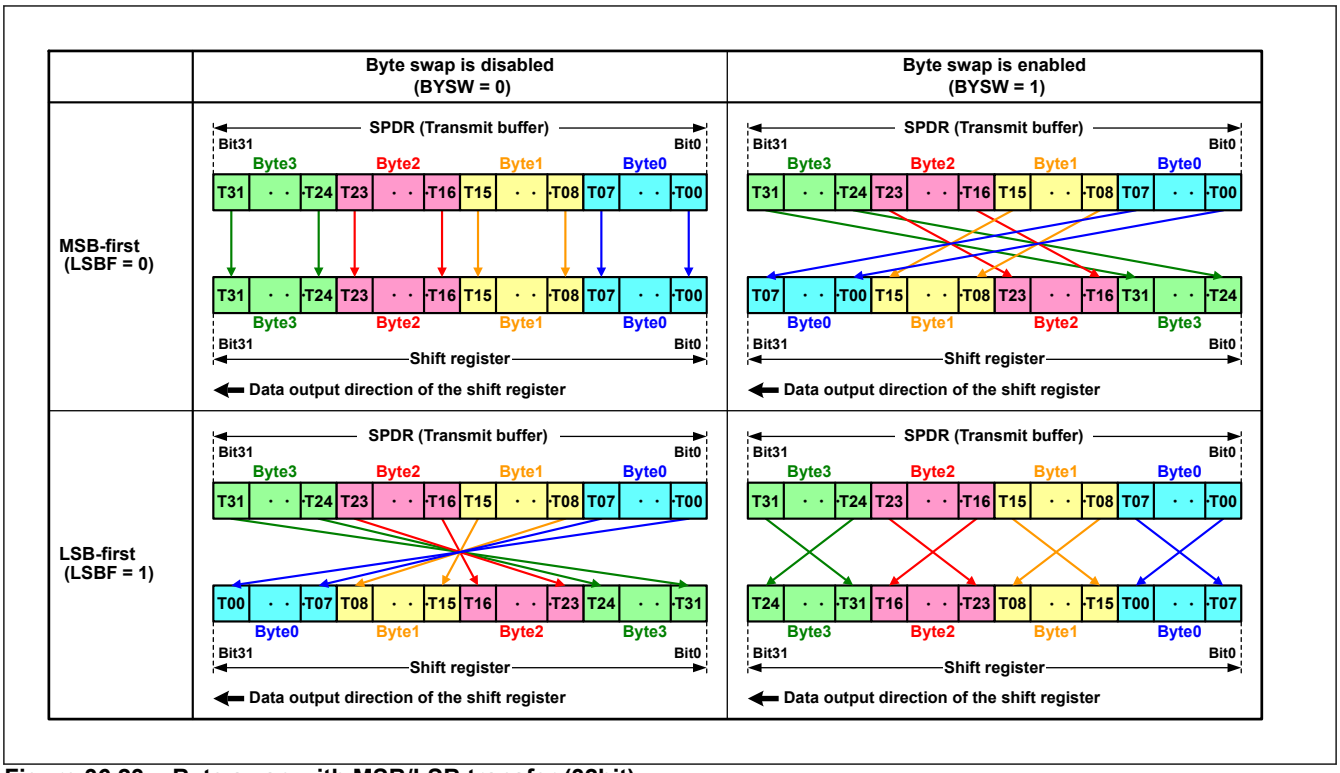


Figure 36.23 Byte swap with MSB/LSB transfer (32bit)

Figure 36.24 shows the relationship between the SPDR (transmit buffer) and the shift register when transferring data with a 16-bit data length, using a combination of MSB / LSB first and with / without byte swap.

1. MSB-first transfer. (When the byte swap is disabled.)
   Data (Byte1 [T15 to T08] to Byte0 [T07 to T00]) in the transmit buffer are copied to the shift register in the order of Byte1 [T15 to T08] to Byte0 [T07 to T00], Byte1 [T15 to T08] to Byte0 [T07 to T00]. Bit values in the shift register are shifted and transmitted in the order of T15 → T14 → … T00 as transmit data.
2. MSB-first transfer. (When the byte swap is enabled.)
   Byte values of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte0 [T07to T00] to Byte1 [T15 to T08], Byte0 [T07 to T00] to Byte1 [T15 to T08]. Bit values in the shift register are shifted and transmitted in the order of T07 → T06 → … T00 → T15 → T14 → … T08 as transmit data.
3. LSB-first transfer. (When the byte swap is disabled.)
   Bit values of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte0 [T00 to T07] to Byte1 [T08 to T15], Byte0 [T00 to T07] to Byte1 [T08 to T15]. Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … T15 as transmit data.
4. LSB-first transfer. (When the byte swap is enabled.)
   Bit values of each byte of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte1 [T08 to T15] to Byte0 [T00 to T07], Byte1 [T08 to T15] to Byte0 [T00 to T07]. Bit values in the shift register are shifted and transmitted in the order of T08 → T09 → … T15 → T00 → T01 → … T07 as transmit data.

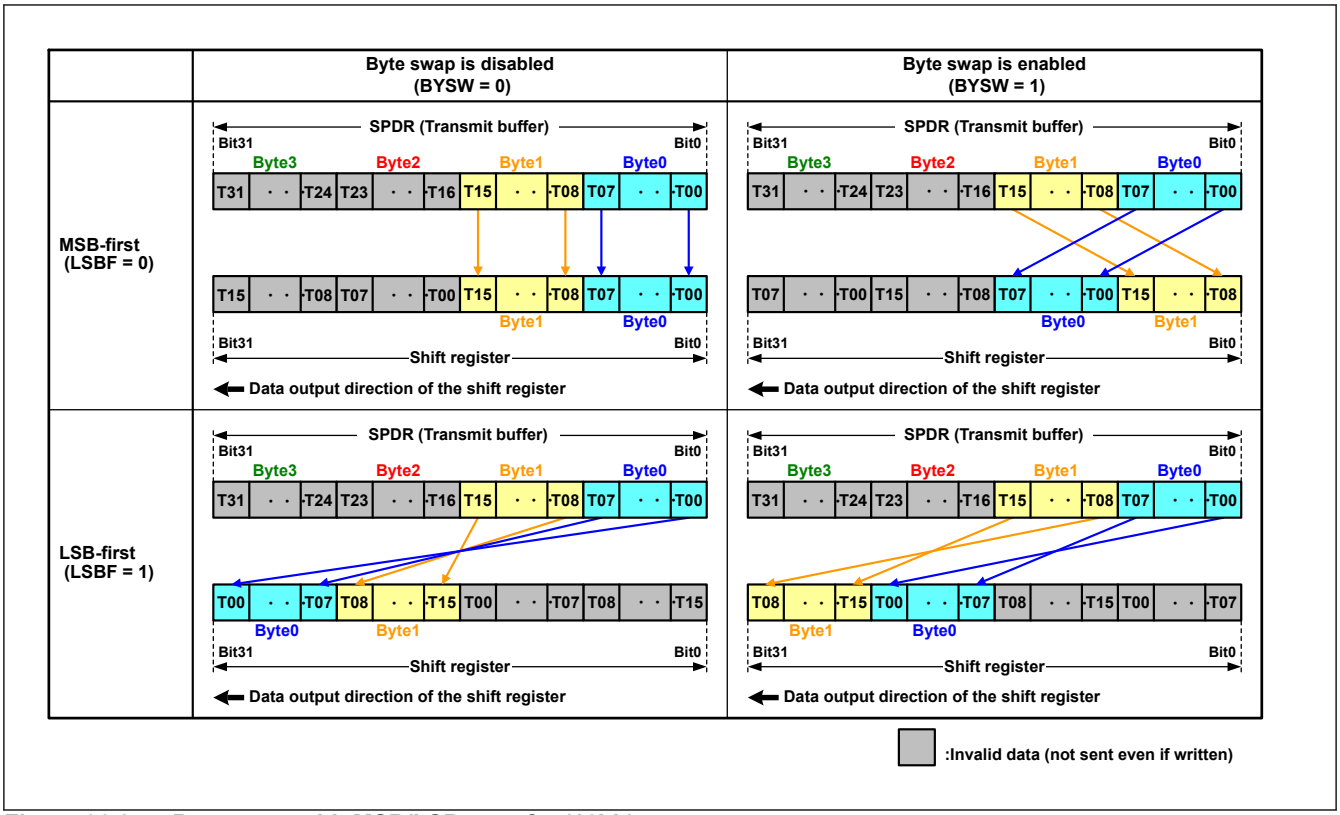

Figure 36.24 Byte swap with MSB/LSB transfer (16bit)

Note: 1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMDm.SPB[4:0] setting). If setting the other length, the behavior is not guaranteed.
2. When the byte swap is valid, set the parity function as invalid (SPCR.SPPE bit = 0). If setting the parity function as valid (SPPE bit = 1), the behavior is not guaranteed.
3. Set SPDCR.BYSW bit, when SPCR.SPE bit is 0. If rewriting BYSW bit, when SPE bit is 1, the behavior after it is not guaranteed.

36.3.4.4 Byte Swap Reception

When byte swap is enabled, the data in the shift register, swapped in 8-bit units, is copied to the receive buffer. Figure 36.25 shows the relationship between the shift register and SPDR (reception buffer) when transferring data with a 32-bit data length, using a combination of MSB / LSB first and with / without byte swap.

(1) MSB-first transfer (When the byte swap is disabled)

The first received data (R31) is stored in bit 0 of the shift register, and received data is shifted in the order of R31 → R30 → … → R00.

When necessary RSPCK cycles are input and data is stored from Byte3 [R31 to R24] to Byte0 [R07 to R00], the shift register value is copied to the receive buffer.

(2) MSB-first transfer (When the byte swap is enabled)

The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → … → R00 → R15 → R14 → … → R08 → R23 → R22 → … → R16 → R31 → R30 → … → R24.

When necessary RSPCK cycles are input and data is stored from Byte0 [R07 to R00] to Byte3 [R31 to R24], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

(3) LSB-first transfer (When the byte swap is disabled)

The first received data (R00) is stored in bit 0 of the shift register, and received data is shifted in the order of R00 → R01 → … → R31.

When necessary RSPCK cycles are input and data is stored from Byte0 [R00 to R07] to Byte3 [R24 to R31], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

(4) LSB-first transfer (When the byte swap is enabled)

The first received data (R24) is stored in bit 0 of the shift register, and received data is shifted in the order of R24 → R25 → … → R31 → R16 → R17 → … → R23 → R08 → R09 → … → R15 → R00 → R01 → … → R07.

When necessary RSPCK cycles are input and data is stored from Byte3 [R24 to R31] to Byte0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

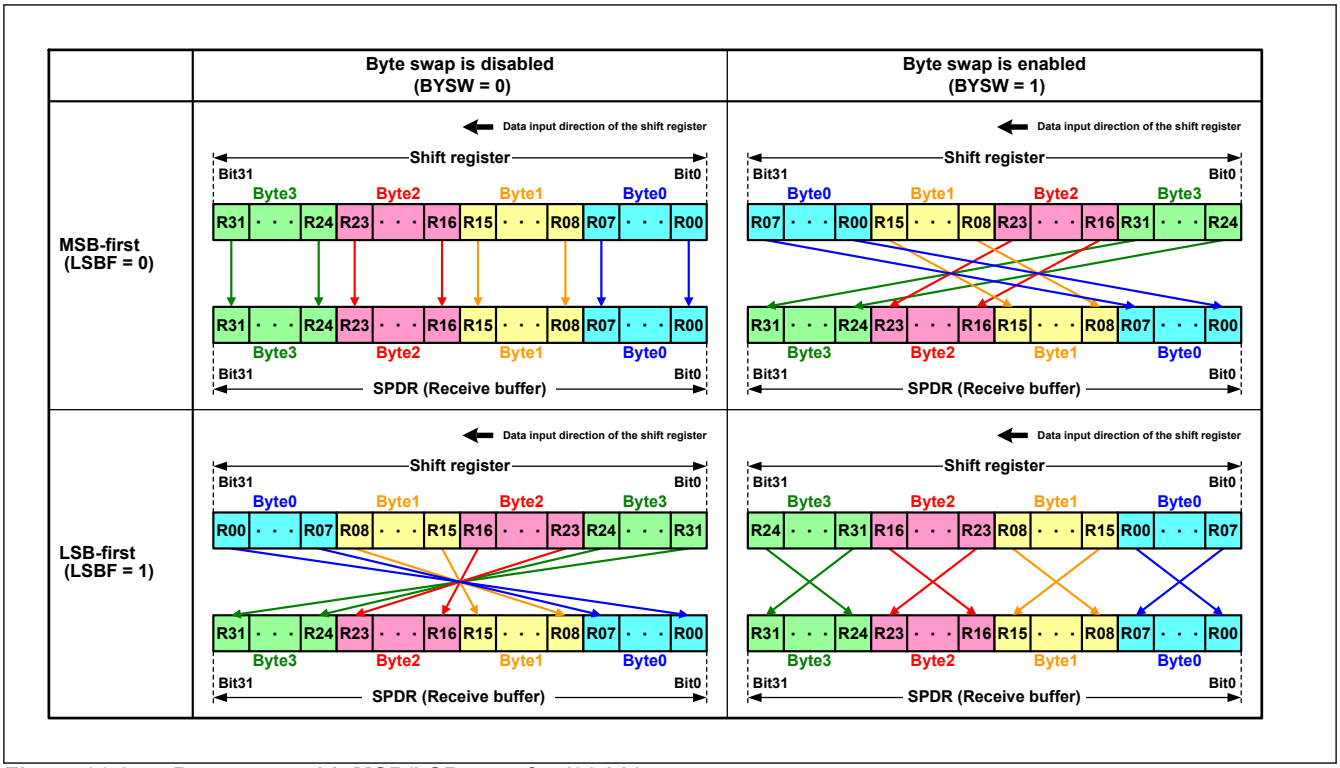

Figure 36.25 Byte swap with MSB/LSB transfer (32-bit)

Figure 36.26 shows the relationship between the shift register and SPDR (reception buffer) when transferring data with a 16-bit data length, using a combination of MSB / LSB first and with / without byte swap.

1. MSB-first transfer (when the byte swap is disabled)
   The first received data (R15) is stored in bit 0 of the shift register, and received data is shifted in the order of R15 → R14 → … R00. When necessary RSPCK cycles are input and data is stored from Byte3 [R31 to R24] to Byte0 [R07 to R00], the shift register value is copied to the receive buffer.
2. MSB-first transfer (when the byte swap is enabled)
   The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → … R00 → R15 → R14 → … R08. When necessary RSPCK cycles are input and data is stored from Byte0 [R07 to R00] to Byte1 [R15 to R08], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].
3. LSB-first transfer (when the byte swap is disabled)
   The first received data (R00) is stored in bit 15 of the shift register, and received data is shifted in the order of R00 → R01 → … R07 → R08 → R09 → … R15. When necessary RSPCK cycles are input and data is stored from Byte0 [R00 to R07] to Byte1 [R08 to R15], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07-R00].
4. LSB-first transfer (when the byte swap is enabled)
   The first received data (R08) is stored in bit 15 of the shift register, and received data is shifted in the order of R08 → R09 → … R15 → R00 → R01 → … R07. When necessary RSPCK cycles are input and data is stored from Byte1 [R08

to R15] to Byte0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

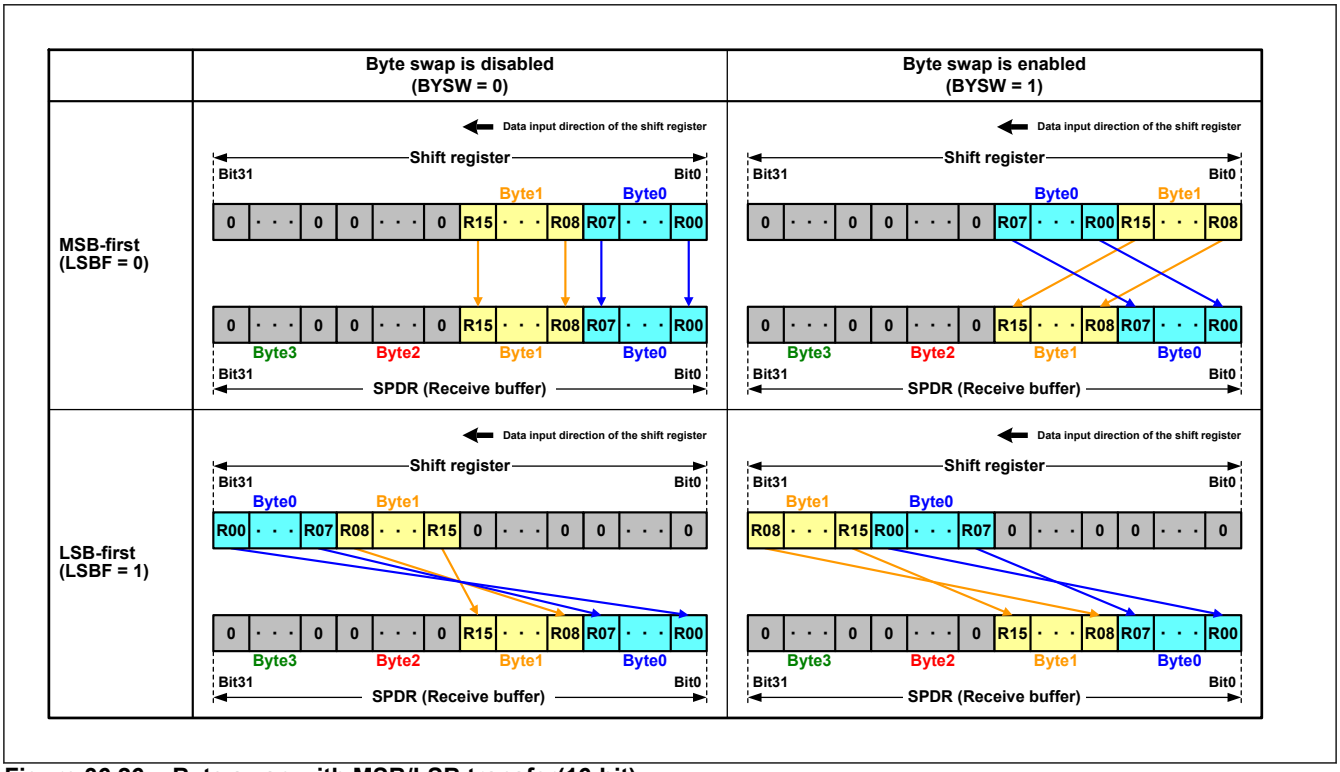

Figure 36.26 Byte swap with MSB/LSB transfer(16-bit)

Note: 1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMDm.SPB[4:0] setting). If setting the other length, the behavior is not guaranteed.
2. When the byte swap is valid, set the parity function as invalid (SPCR.SPPE bit = 0). If setting the parity function as valid (SPPE bit = 1), the behavior is not guaranteed.
3. Set SPDCR.BYSW bit, when SPCR.SPE bit is 0. If rewriting BYSW bit, when SPE bit is 1, the behavior after it is not guaranteed.

36.3.5 Transfer Formats

36.3.5.1 When CPHA = 0

Figure 36.27 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 0. Do not perform clock synchronous operation (SPCR.SPMS = 1) when the SPI operates in slave mode (SPCR.MSTR = 0) and the CPHA bit is 0. In Figure 36.27, RSPCKn (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0, and RSPCKn (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI settings. For details, see section 36.3.2. Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 0, the driving of valid data to the MOSIn and MISOn signals begins at an SSLni signal assertion. The first RSPCKn signal change that occurs after the SSLni signal assertion becomes the first transfer data fetch. After this, data is sampled every 1 RSPCKn cycle. The change timing for MOSIn and MISOn signals is 1/2 RSPCK cycles after the transfer data fetch timing. The CPOL bit setting does not affect the RSPCKn signal operation timing as it only affects the signal polarity.

t1 denotes the RSPCK delay, the period from an SSLni signal assertion to RSPCKn oscillation. t2 denotes the SSL negation delay, the period from the termination of RSPCKn oscillation to an SSLni signal negation. t3 denotes the next-access delay, the period in which SSLni signal assertion is suppressed for the next transfer after the end of serial transfer. t1, t2, and t3 are controlled by a master device running on the SPI system. For a description of t1, t2, and t3 when the SPI is in master mode, see section 36.3.12.1. Master mode operation.

[In the Motorola-SPI case]

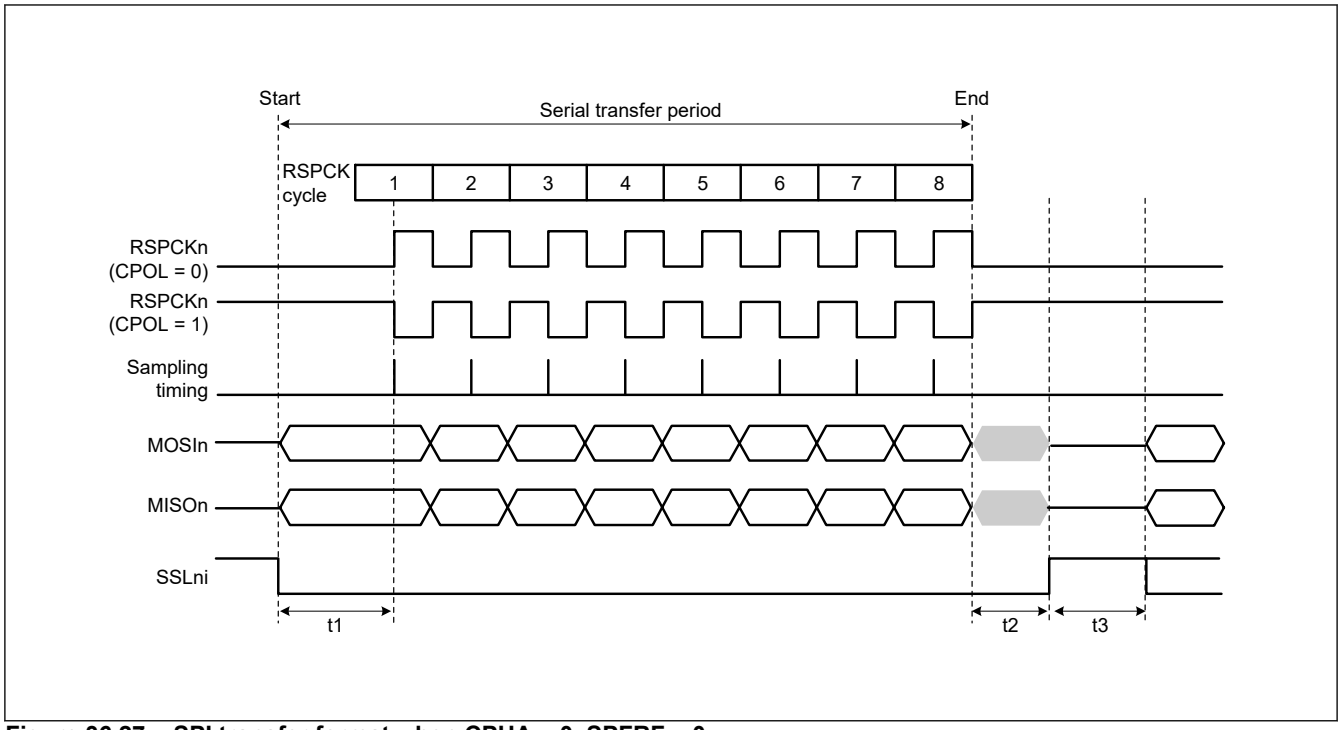

Figure 36.27 SPI transfer format when CPHA = 0, SPFRF = 0

[In TI-SSP case]

Not supported in CPHA = 0

36.3.5.2 When CPHA = 1

Figure 36.28 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 1. However, when the SPCR.SPMS bit is 1, the SSLni signals are not used, and only the three signals RSPCKn, MOSIn, and MISOn handle communications. In Figure 36.28, RSPCKn (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0 and RSPCKn (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI mode (master or slave mode). For details, see section 36.3.2. Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 1, the driving of invalid data to the MISOn signal begins at an SSLni signal assertion. The output of valid data to the MOSIn and MISOn signals begins at the first RSPCKn signal change that occurs after the SSLni signal assertion. After this, data is updated every 1 RSPCK cycle. The transfer data fetch timing is 1/2 RSPCK cycles after the data update timing. The SPCMDm.CPOL bit setting does not affect the RSPCKn signal operation timing. It only affects the signal polarity.

t1, t2, and t3 are the same as those when CPHA = 0. For a description of t1, t2, and t3 when the SPI of the MCU is in master mode, see section 36.3.12.1. Master mode operation.

[In the Motorola-SPI case]

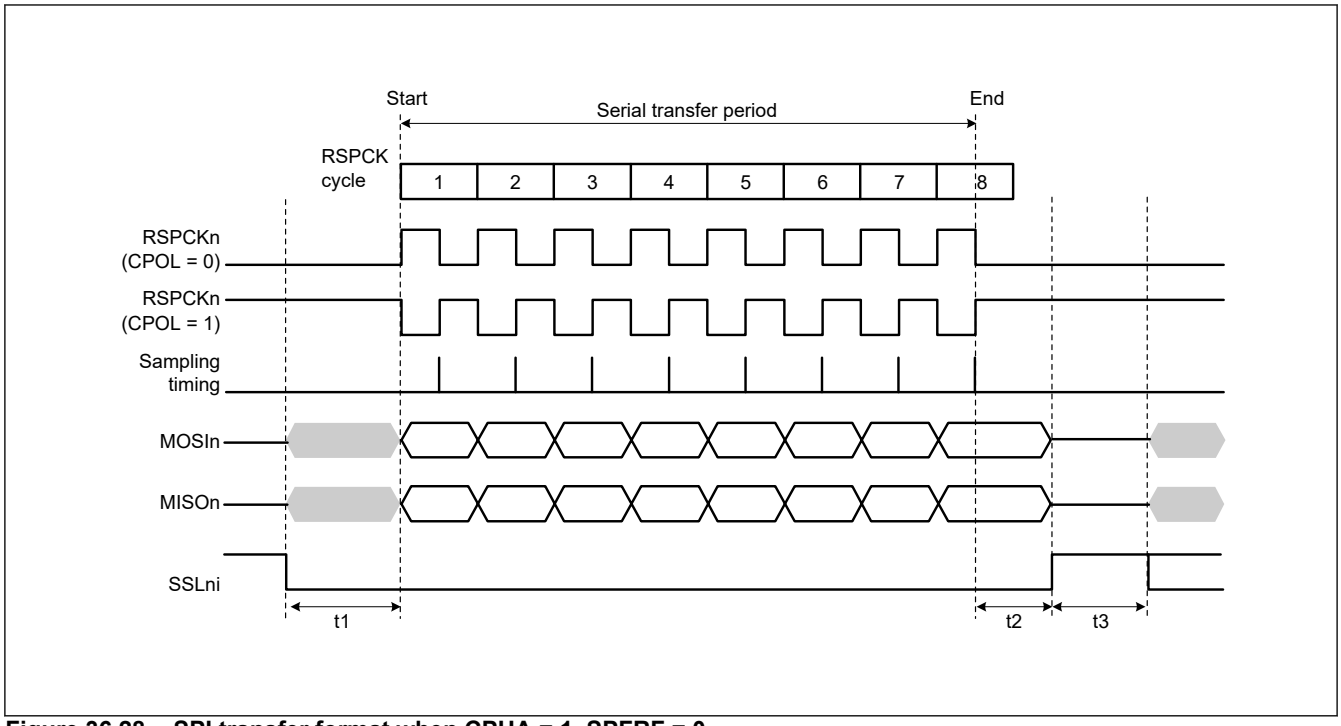

Figure 36.28 SPI transfer format when CPHA = 1, SPFRF = 0

[In the TI-SSP case]

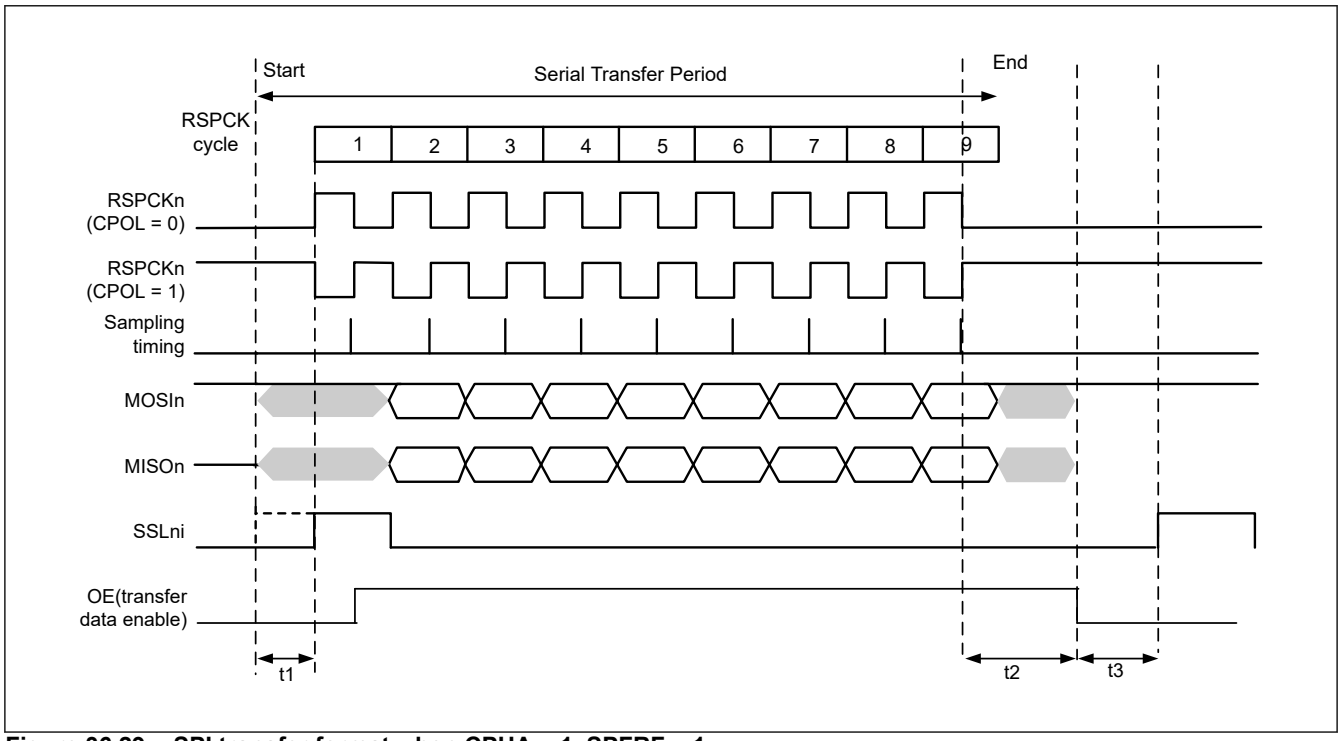

Figure 36.29 SPI transfer format when CPHA = 1, SPFRF = 1

36.3.6 Communication Operating Mode

Transmit-Receive serial communication, transmit-only operation, and Receive-only operation are selected by setting the Communication Mode Select bits (TXMD [1:0]) of the SPI control register (SPCR).

SPDR access described in Figure 36.30, Figure 36.31, Figure 36.32 shows an access to the SPI data register (SPDR). W shows a write cycle.

36.3.6.1 Transmit-Receive Serial Communication (TXMD[1:0] = 00b)

Figure 36.30 shows an example of operation when the communication mode select bit (TXMD[1:0]) in the SPI control register (SPCR) is set to 00b. In the example, the SPI performs an 8-bit serial transfer when the SPDCR2.TTRG is 0, the SPDCR2.RTRG is FIFO stage - 1, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

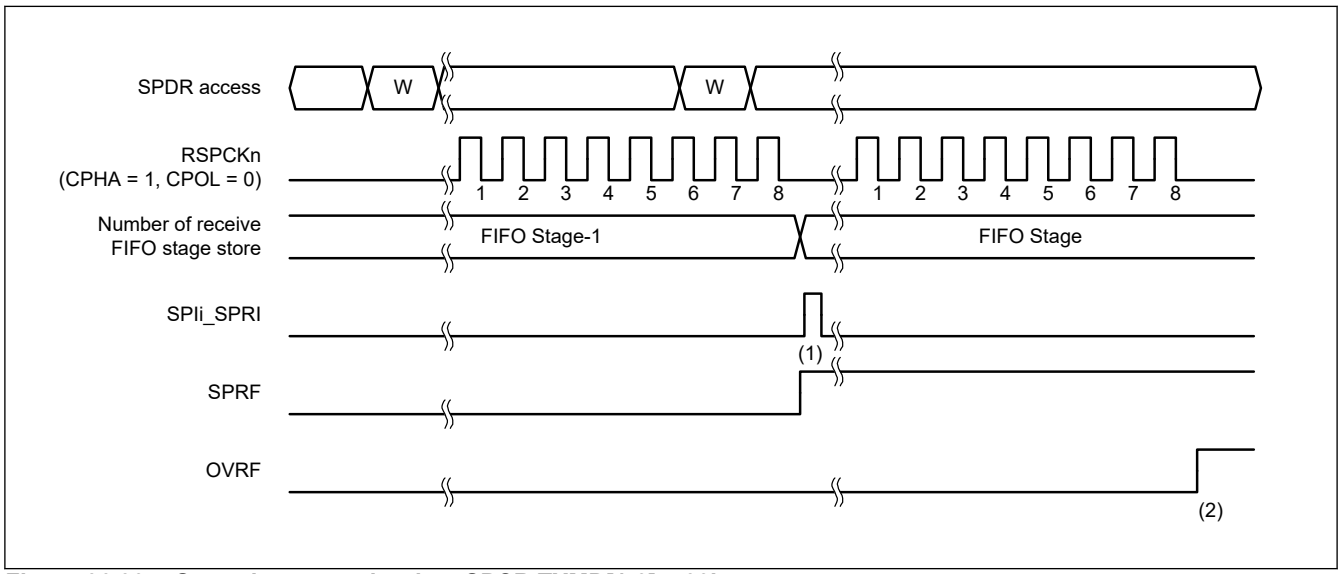

Figure 36.30 Operation example when SPCR.TXMD[1:0] = 00b

The operation of the flags at timings (1) and (2) in Figure 36.30 is as follows:

1. When serial transfer ends while the number of SPDR receive buffer store matches the number of frames set in SPDCR2.RTRG, the SPI generates a receive buffer full interrupt request (SPIi_SPRI), the SPI sets the SPSR.SPRF flag to 1, and copies the received data in the shift register to the receive buffer.
2. When serial transfer ends with data for the number of FIFO stages stored in the SPDR receive buffer, the SPI sets the SPSR.OVRF flag to 1, and discards the received data in the shift register. For details about the operation of the SPSR.OVRF flag, see section 36.3.10.1. Overrun errors.

In Transmit-Receive serial communication (TXMD[1:0] = 00b), transmit data is transmitted and receive data is received. Therefore, the SPRF flag and the OVRF flag are set to 1 at timings (1) and (2) respectively.

36.3.6.2 Transmit-Only Serial Communications (TXMD[1:0] = 01b)

Figure 36.31 shows an example of operation when the communication mode select bit (TXMD[1:0]) in the SPI control register (SPCR) is set to 01b. In this example, the SPI performs an 8-bit serial transfer when the SPDCR2.TTRG is 0, the SPDCR2.RTRG is 0, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

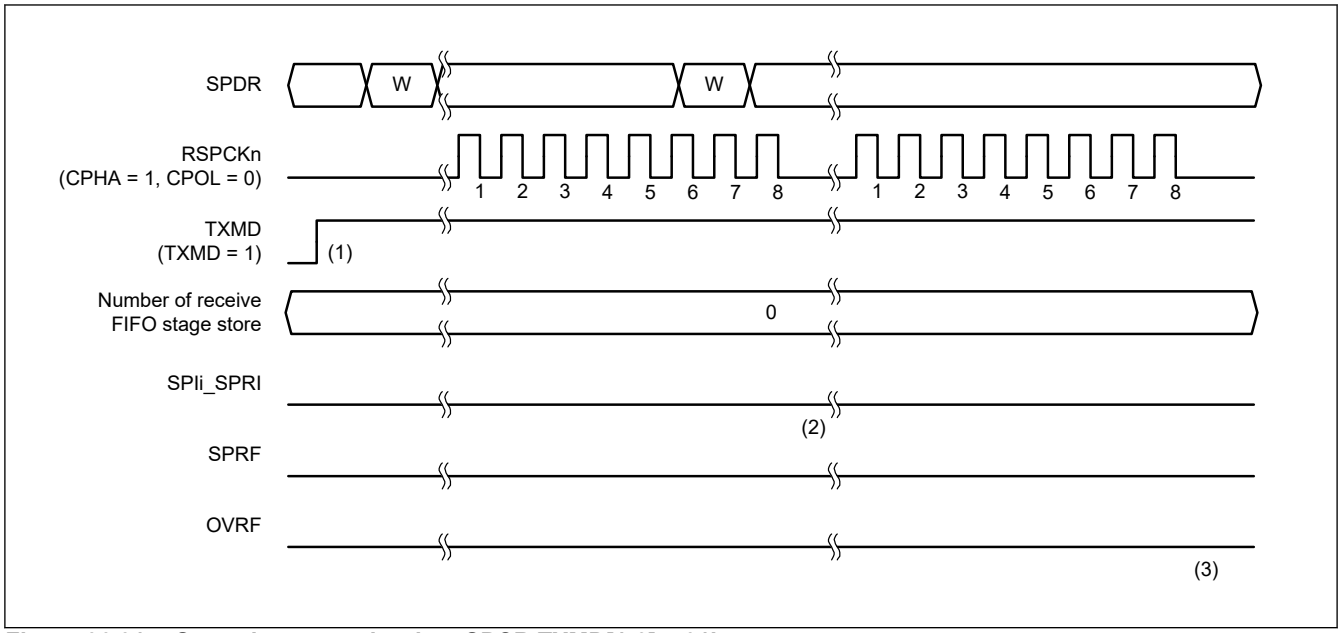

Figure 36.31 Operation example when SPCR.TXMD[1:0] = 01b

The operation of the flags at timings (1) to (3) in Figure 36.31 is as follows:

1. Make sure there is no data left in the receive buffer (the SPSR.SPRF flag is 0) and the SPSR.OVRF flag is 0 before entering transmit-only mode (SPCR.TXMD[1:0] = 01b).
2. When a serial transfer ends without receiving data in the receiving FIFO of SPDR, if the transmit-only mode is selected (SPCR.TXMD[1:0] = 01b), the SPSR.SPRF flag retains the value of 0, and the SPI does not copy the data in the shift register to the receive buffer.
3. Because the receive buffer of SPDR does not hold data that was received in the previous serial transfer, even when a serial transfer ends, the SPSR.OVRF flag retains the value of 0, and the data in the shift register is not copied to the receive buffer.

In transmit-only mode (SPCR.TXMD[1:0] = 01b), the SPI transmits data but does not receive data. Therefore, the SPSR.SPRF and SPSR.OVRF flags remain 0 at timings (1) to (3).

36.3.6.3 Receive-Only Serial Communication (TXMD[1:0] = 10b)

Figure 36.32 shows an example of operation when the communication mode select bit (TXMD[1]) in the SPI control register (SPCR) is set to 1. In this example, the SPI performs an 8-bit serial transfer when the SPDCR2.TTRG is FIFO stage - 1, the SPDCR2.RTRG is 0, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

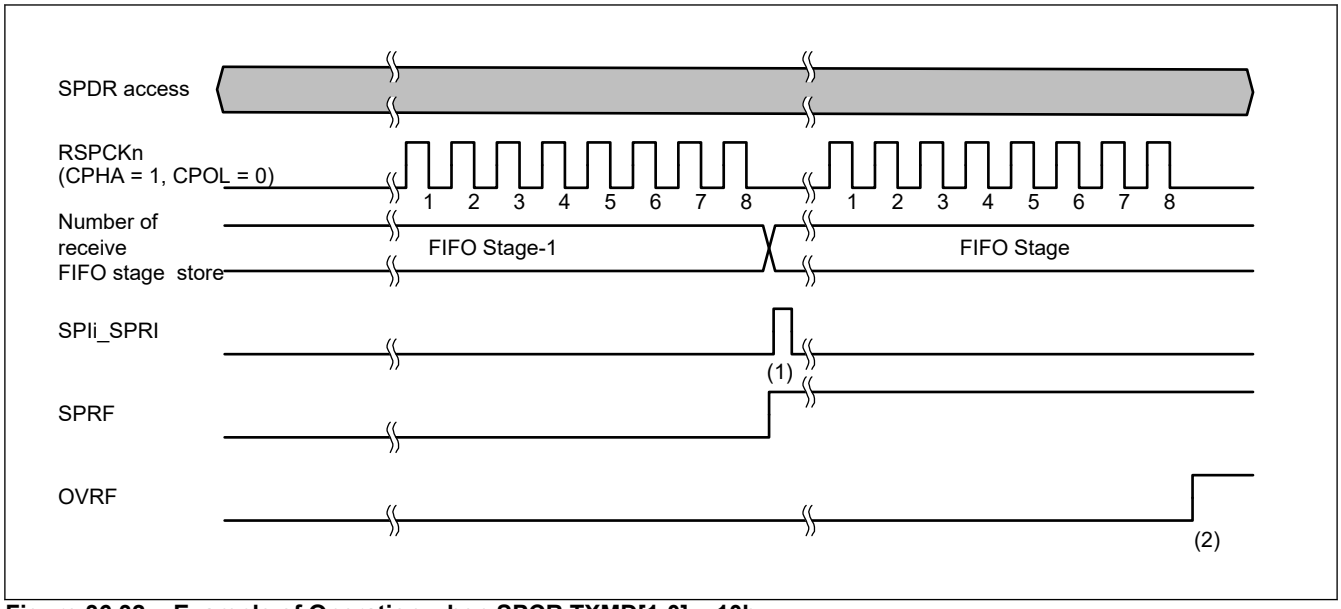

Figure 36.32 Example of Operation when SPCR.TXMD[1:0] = 10b

The following describes operation of flags at timings (1) and (2) in the figure above.

1. When serial transfer ends while the number of SPDR receive buffer store matches the number of frames set in SPDCR2.RTRG, the SPI generates a receive buffer full interrupt request (SPIi_SPRI), the SPI sets the SPSR.SPRF flag to 1, and copies the received data in the shift register to the receive buffer
2. When serial transfer ends with data for the number of FIFO stages stored in the SPDR receive buffer, the SPI sets the SPSR.OVRF flag to 1 and discards the received data in the shift register.

36.3.7 Transmit Buffer Empty and Receive Buffer Full Interrupts

Figure 36.33 show examples of operation of the transmit buffer empty interrupt (SPIi_SPTI (i = 0, 1)) and the receive buffer full interrupt (SPIi_SPRI). The SPDR register accesses shown in these figures indicate the conditions of access to the register, where W denotes a write cycle and R a read cycle. In Figure 36.33, the SPI performs an 8-bit serial transfer when SPCR.TXMD[1:0] bits are 00b, the SPDCR2.TTRG bit is 0, the SPDCR2.RTRG bit is 0, the SPCMDm.CPHA bit is 0, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

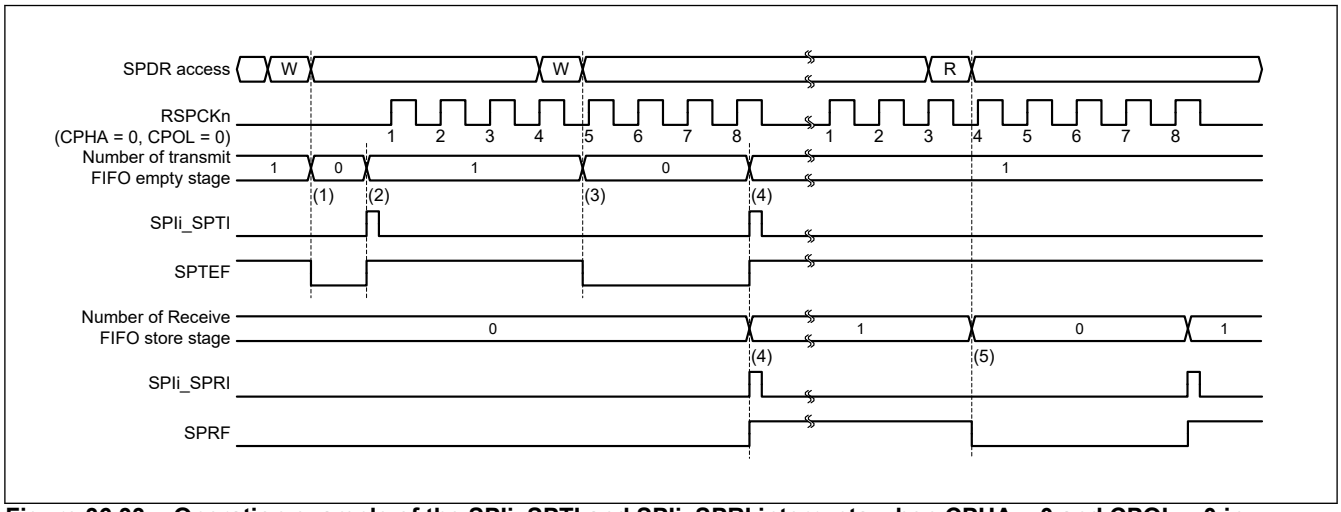

Figure 36.33 Operation example of the SPIi_SPTI and SPIi_SPRI interrupts when CPHA = 0 and CPOL = 0 in master mode

The operation of the SPI at timings (1) to (5) in Figure 36.33 is as follows:

1. When transmit data is written to SPDR with the transmit buffer of SPDR is before the next transfer data is set, the SPI writes data to the transmit buffer. When transmit data is written to SPDR in one processing routine using DTC / DMAC, the SPSR.SPTEF flag is cleared to 0 at the last access.
2. If the shift register is empty, the SPI copies the data in the transmit buffer to the shift register. At this time, if transmit FIFO empty stage number > TTRG value, then the SPI generates a transmit buffer empty interrupt request (SPIi_SPTI), and sets the SPSR.SPTEF flag to 1. How a serial transfer is started depends on the SPI mode. For details, see section 36.3. Operation, and section 36.3.13. Clock Synchronous Operation.
3. When transmit data is written to SPDR either by the transmit buffer empty interrupt routine, or by the processing of the transmit buffer empty using the SPTEF flag, the SPI writes data to the transmit buffer. When the transmit data is written to SPDR in one processing routine using DTC / DMAC, the SPTEF flag is cleared to 0 at the last access. Because the data being transferred serially is stored in the shift register, the SPI does not copy the data in the transmit buffer to the shift register.
4. When the serial transfer ends with the receive buffer of SPDR > FIFO stage number, the SPI copies the receive data in the shift register to the receive buffer, generates a receive buffer full interrupt request (SPIi_SPRI), and sets the SPRF flag to 1. Because the shift register becomes empty on completion of the serial transfer, if the next transfer data is set in the transmit FIFO before the serial transfer ended, the SPI sets the SPTEF flag to 1 and copies data in the transmit buffer to the shift register. Even when received data is not copied from the shift register to the receive buffer in an overrun error status, on completion of the serial transfer, the SPI determines that the shift register is empty, so data transfer from the transmit buffer to the shift register is enabled.
5. When SPDR is read either by the receive buffer full interrupt routine or processing of the receive buffer full interrupt using the SPRF flag, the receive data can be read. If the received data is read from SPDR in one processing routine using DTC / DMAC, the SPRF flag is cleared to 0 at the last access.

When transmit data is written to the SPDR register while no empty stages in the transmit FIFO, the SPI does not update data in the transmit buffer. When writing to SPDR, always use either a transmit buffer empty interrupt request or check the empty or processing of the transmit buffer empty interrupt using the SPTEF flag. To use a transmit buffer empty interrupt, set the SPTIE bit in SPCR to 1. If the SPI function is disabled (the SPCR.SPE bit is 0), set the SPTIE bit to 0.

When serial transfer ends while data is stored in the receive FIFO for the number of FIFO stages, the SPI does not copy data from the shift register to the receive buffer, and it detects an overrun error (see section 36.3.10. Error Detection). To prevent a receive data overrun error, read the received data using a receive buffer full interrupt request before the next serial transfer ends. To use an SPI receive buffer full interrupt, set the SPCR.SPRIE bit to 1.

Transmission and reception interrupts or the associated IELSRn.IR flags (where n is the interrupt vector number) in the ICU can be used to confirm the states of the transmit and receive buffers.

Similarly, the SPTEF and SPRF flags can be used to confirm the states of the transmit and receive buffers. See section 13, Interrupt Controller Unit (ICU) for the interrupt vector numbers.

36.3.8 Idle Interrupt

When the SPCP[2:0] of the SPI status register (SPSR) becomes 000b (start of sequence control), the IDLNF flag in the SPI status register (SPSR) is set to 1 and an idle interrupt request is made during master mode operation. An interrupt request is also made by clearing the SPCR.SPE bit to 0.

[In the Motorola-SPI case]

Figure 36.34 shows an example of idle interrupt operation during normal operation.

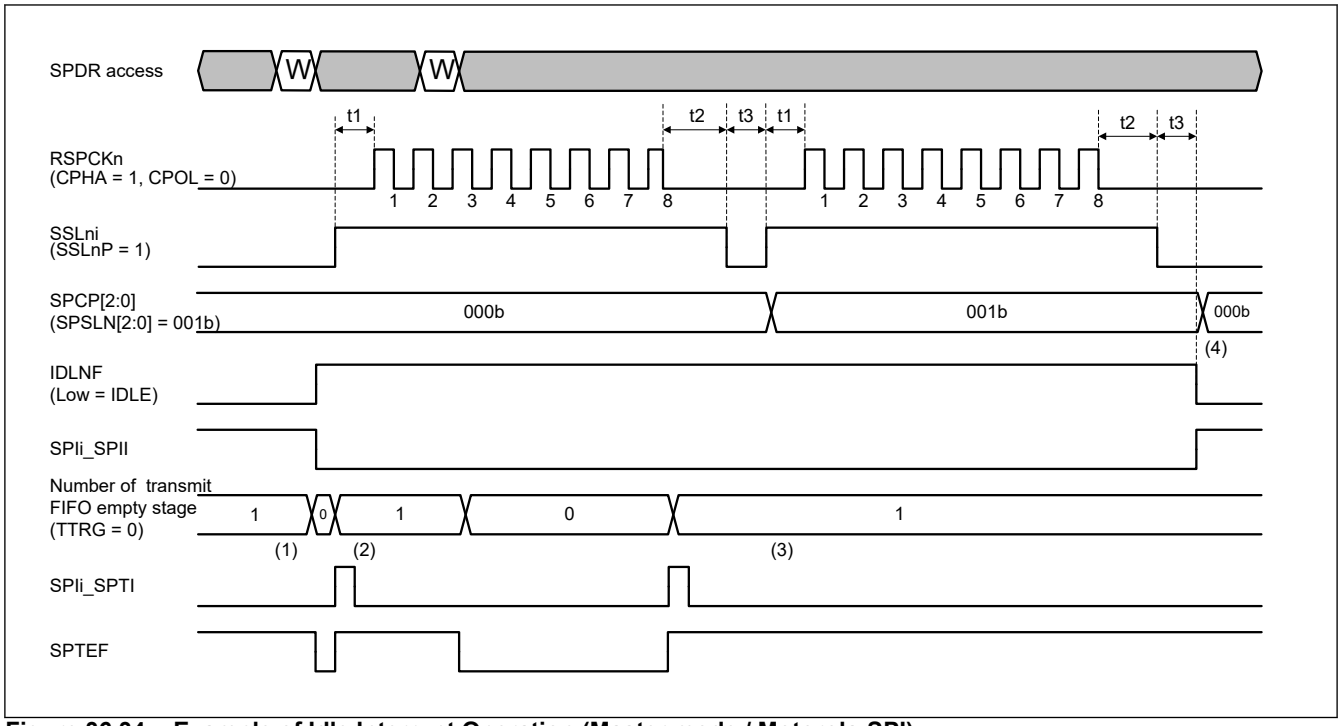

Figure 36.34 Example of Idle Interrupt Operation (Master mode / Motorola-SPI)

1. At the start of transmission, if the next transfer data is not set in the transmission buffer, the IDLNF flag is 0 (IDLE). Writing transmit data sets the IDLNF flag to 1 (BUSY). When the SPIIE bit in the SPI control register (SPCR) is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPIIE bit to 0 before starting transmission.
2. After transmission has started, the IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.
3. The SPCP[2:0] bits change the command to the next command at the end of t3 cycle. When the next command is not 000b, the IDLNF flag remains unchanged even when the next transmit data has not been written.
4. The IDLNF flag is cleared to 0 (IDLE) at the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPIIE bit is 1 currently, an SPIi_SPII (i = 0, 1) interrupt is output.

[In the TI-SSP case]

Figure 36.35 shows an example of idle interrupt operation during normal operation.

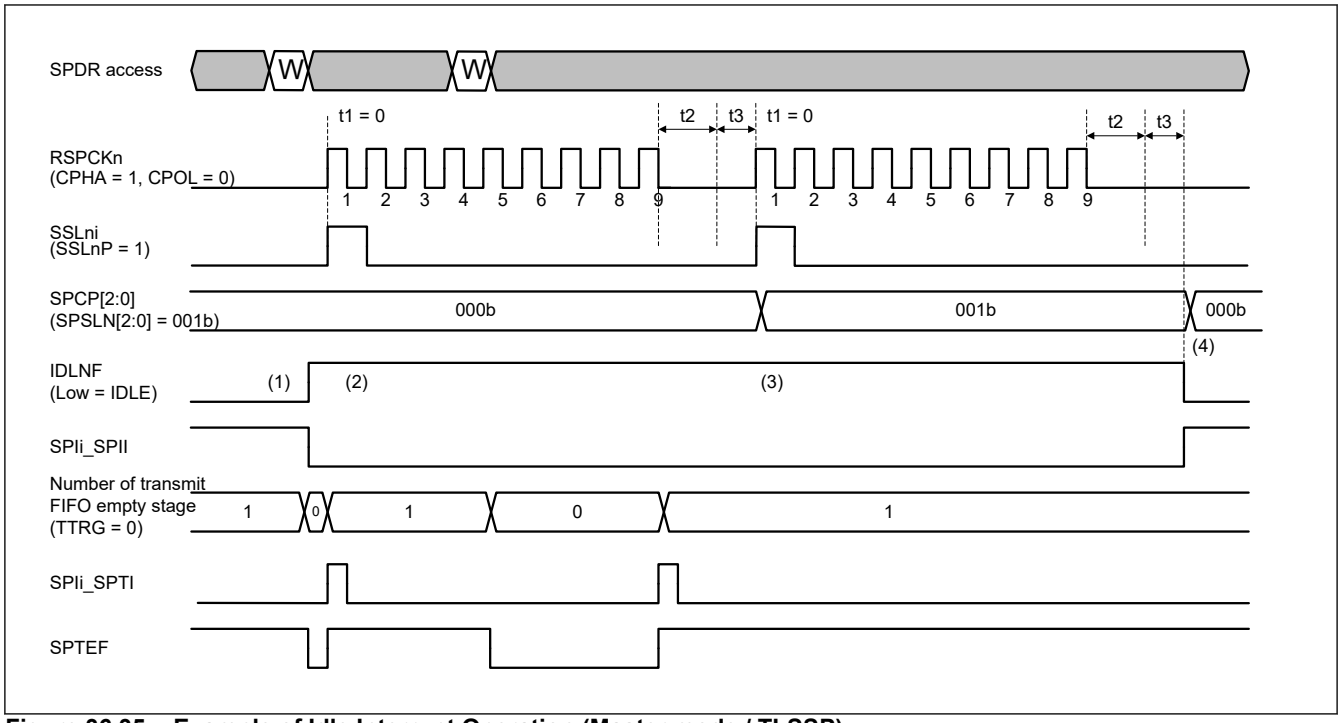

Figure 36.35 Example of Idle Interrupt Operation (Master mode / TI-SSP)

1. At the start of transmission, if the next transfer data is not set in the transmission buffer, the IDLNF flag is 0 (IDLE). Writing transmit data makes sets the IDLNF flag to 1 (BUSY). When the SPIIE bit in the SPI control register (SPCR) is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPIIE bit to 0 before starting transmission.
2. After transmission has started, the IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.
3. The SPCP[2:0] bits change the command to the next command at the end of t3 cycle. When the next command is not 000b, the IDLNF flag remains unchanged even when the next transmit data has not been written.
4. The IDLNF flag is cleared to 0 (IDLE) at the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPIIE bit is 1 currently, an SPIi_SPII interrupt is output.

36.3.9 Communication End Interrupt

36.3.9.1 Transmit-Receive/Transmit in Master Mode

See the description of the CENDF bit in section 36.2.9. SPSR : SPI Status Register for the setting / clearing conditions of the communication completion flag during Transmit-Receive/Transmit-only in Master Mode.

[In the Motorola-SPI case]

Figure 36.36 shows an example of communication end interrupt operation during transmit-receive/transmit master mode.

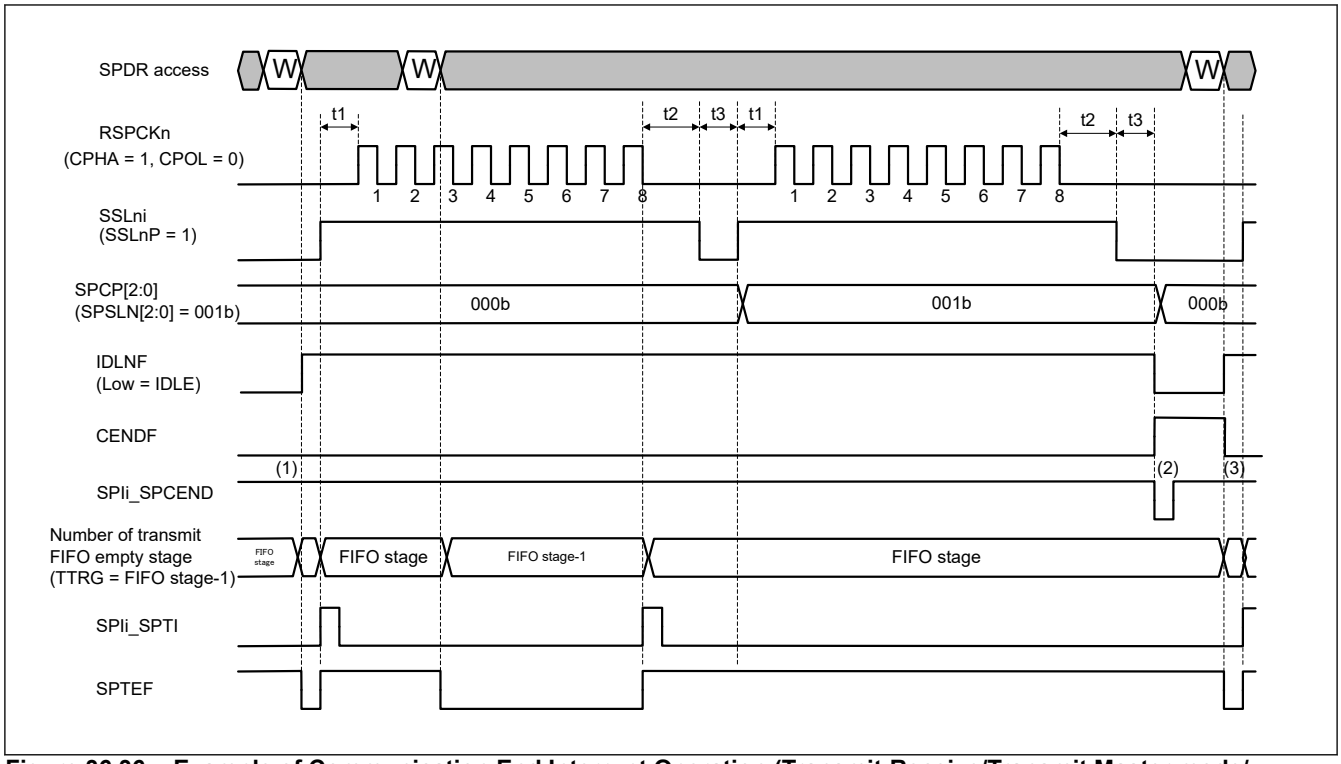

Figure 36.36 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Master mode/ Motorola-SPI)

1. The CENDF flag is 0 and the level of SPIi_SPCEND (i = 0, 1) is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle because the next command is 000b and there is no next transmit data, and then the SPIi_SPCEND interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

[In the TI-SSP case]

Figure 36.37 shows an example of communication end interrupt operation during transmit-receive/transmit-only master mode.

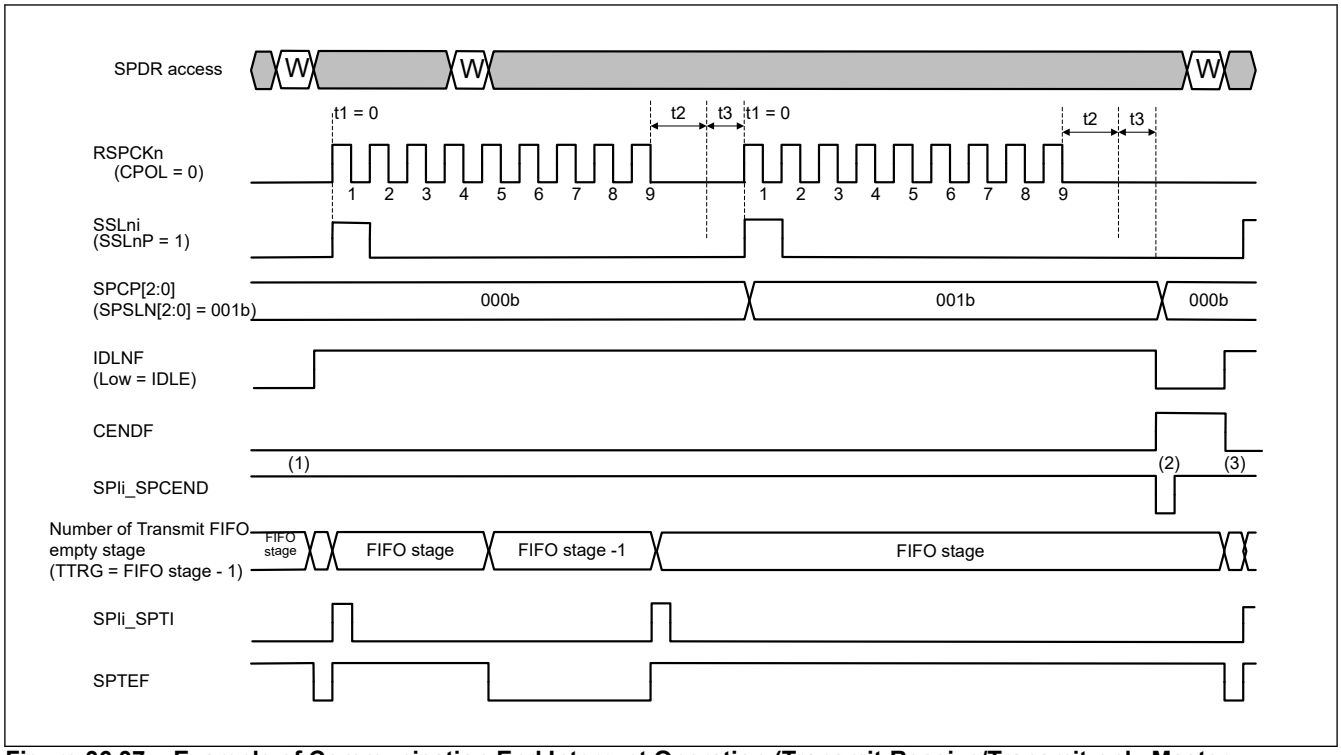

Figure 36.37 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit-only Master mode/TI-SSP)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle because the next command is 000b and there is no next transmit data, and then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

In slave mode operation, the output timing of the communication end interrupt is deferent due to the value of the SPCR.SPMS bit (SPI mode select bit), and the clear timing of the communication end interrupt is deferent due to the communication mode (transmit-receive or transmit-only or receive-only).

36.3.9.2 Receive-only in Master Mode

See the description of the CENDF bit in section 36.2.9. SPSR : SPI Status Register for the setting / clearing conditions of the communication completion flag during Receive-only in Master Mode.

Figure 36.38 shows an example of communication end interrupt operation during receive-only master mode at RMFM[4:0] = 0.

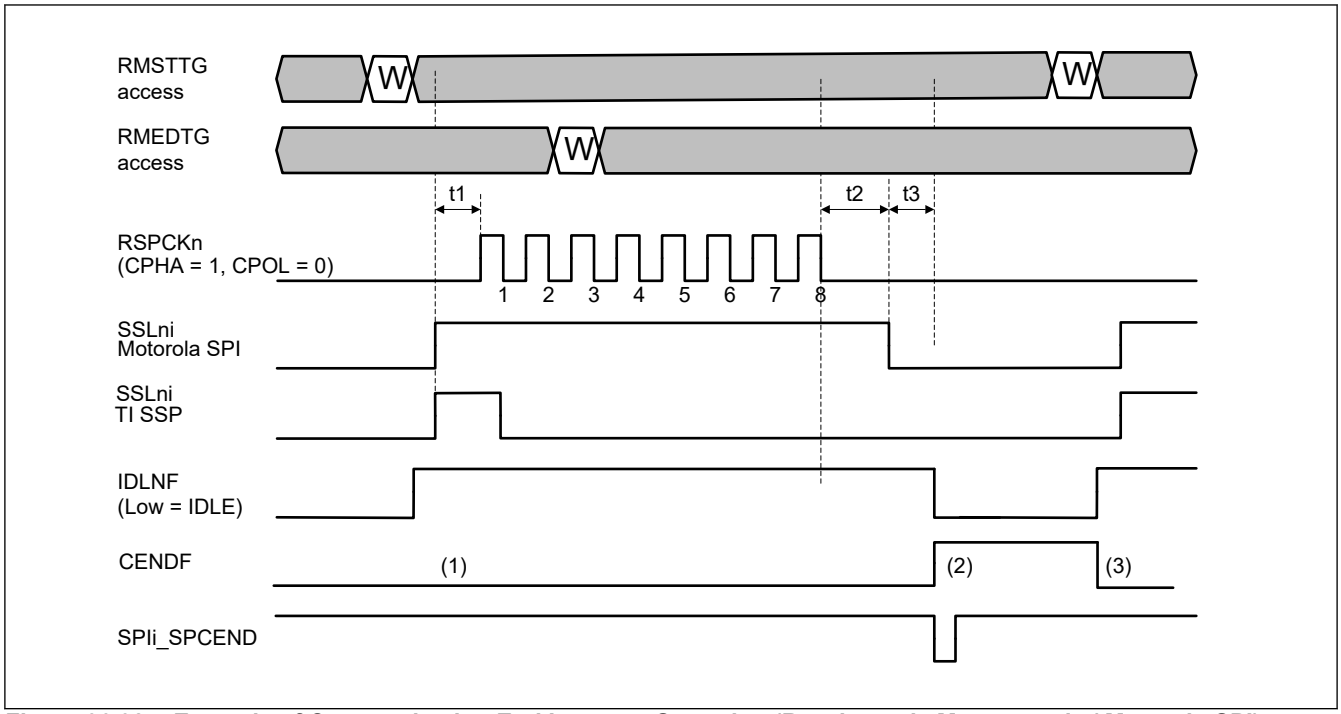

Figure 36.38 Example of Communication End Interrupt Operation (Receive-only Master mode / Motorola-SPI) at RMFM [4:0] = 0

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start. These have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle by writing 1 to RMEDTG during the communication frame. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when writing 1 to RMSTTG. Also when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

Figure 36.39 shows an example of communication end interrupt operation during receive-only master mode at RMFM[4:0] ≠ 0.

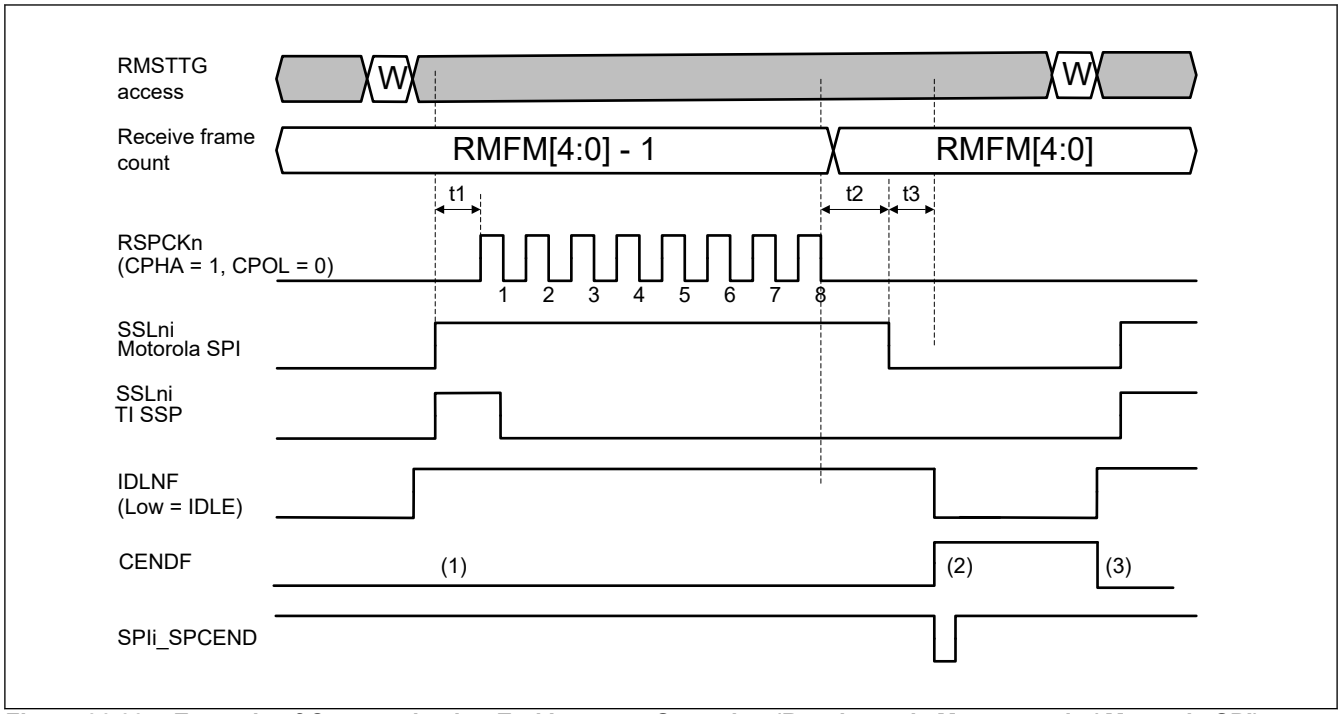

Figure 36.39 Example of Communication End Interrupt Operation (Receive-only Master mode / Motorola-SPI) at RMFM [4:0] ≠ 0

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start. These have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle after receiving the number of frames set by RMFM[4:0]. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when writing 1 to RMSTTG. Also when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

36.3.9.3 Transmit-Receive/Transmit in Slave Mode on SPI Operation (4-wire)

See the description of the CENDF bit in section 36.2.9. SPSR : SPI Status Register for the setting / clearing conditions of the communication completion flag during Transmit-Receive/Transmit-only in Slave Mode (4-wire).

[In the Motorola-SPI case]

Figure 36.40 shows an example of communication end interrupt operation during transmit-receive/transmit slave mode on SPI operation.

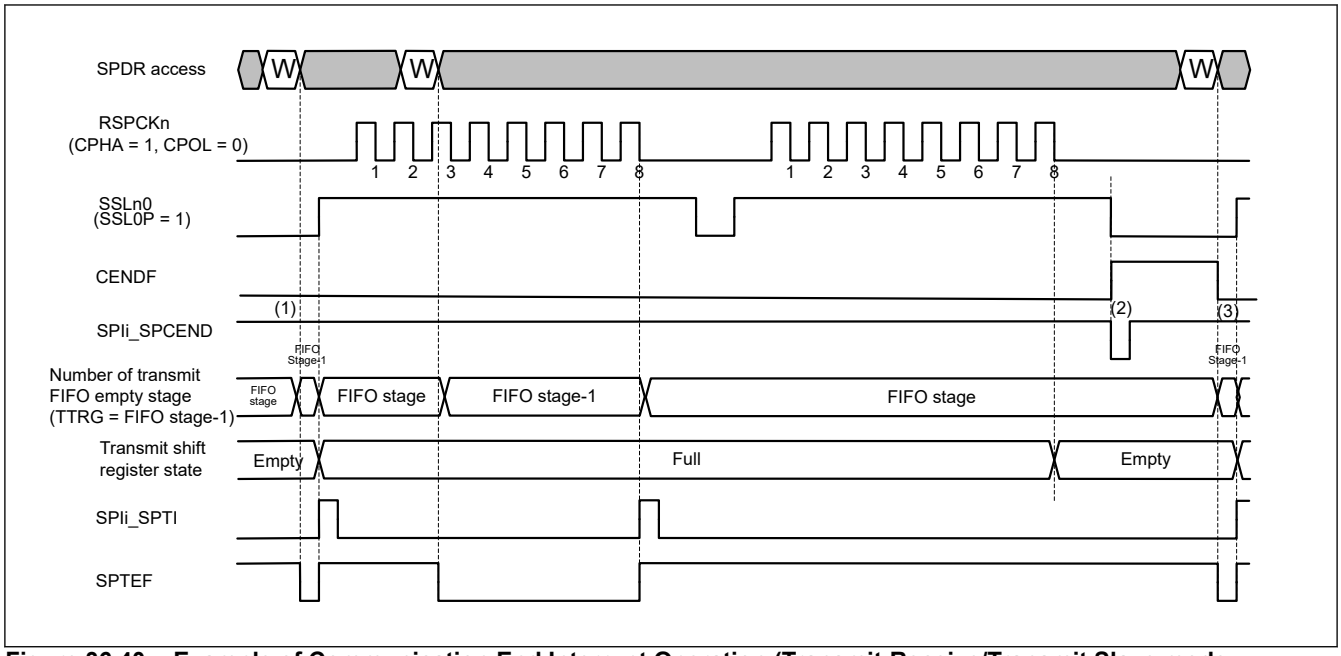

Figure 36.40 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Slave mode on SPI Operation/Motorola-SPI)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the timing of SSLn0 negate when the next transfer data is not set in the transmit FIFO and the transmit shift register is empty. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

[In the TI-SSP case]

Figure 36.41 shows an example of communication end interrupt operation during transmit-receive/transmit-only slave mode on SPI operation.

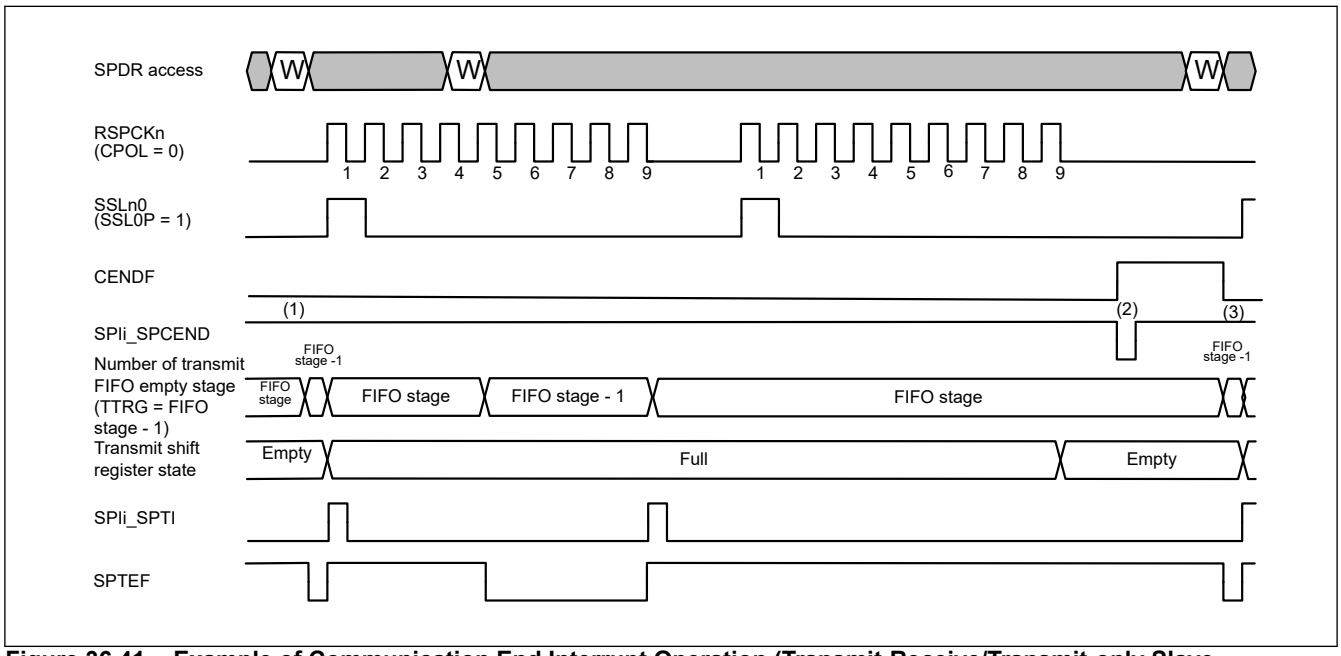

Figure 36.41 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit-only Slave mode on SPI Operation / TI-SSP)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the RSPCKn last data bit sampling when the next transfer data is not set in the transmit FIFO and the transmit shift register is empty. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

36.3.9.4 Receive Only in Slave Mode on SPI Operation (4-wire)

See the description of the CENDF bit in section 36.2.9. SPSR : SPI Status Register for the setting / clearing conditions of the communication completion flag during Receive-only in Slave Mode (4-wire).

[In the Motorola-SPI case]

Figure 36.42 shows an example of communication end interrupt operation during receive only slave mode on SPI operation (4-wire).

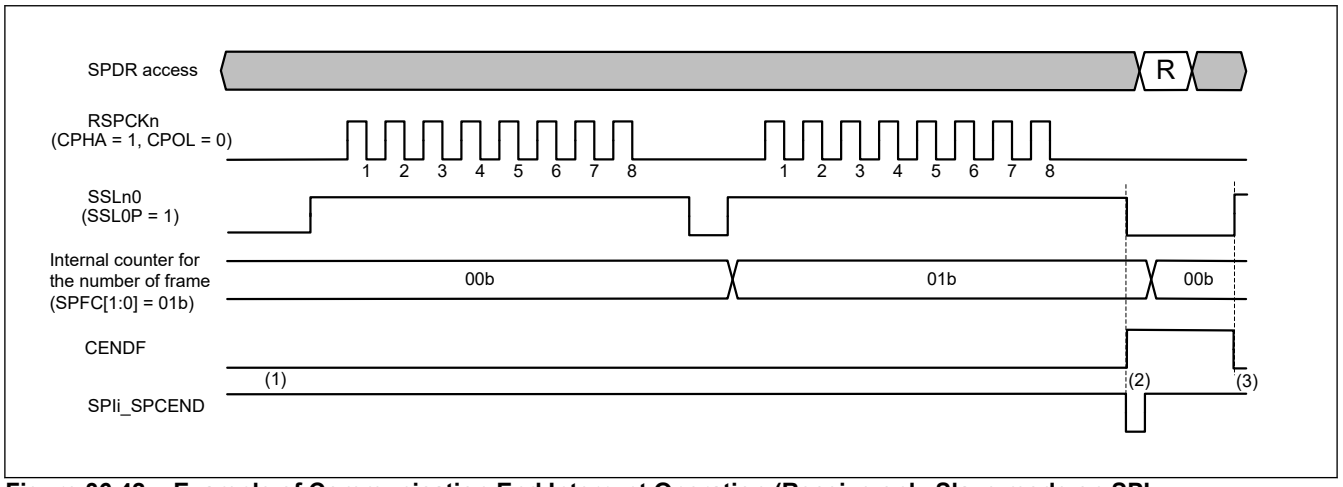

Figure 36.42 Example of Communication End Interrupt Operation (Receive only Slave mode on SPI Operation / Motorola-SPI)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.
2. After the frames for SPFC set value in the SPI data control register (SPDCR) are stored in the receive buffer, the CENDF flag becomes 1 (communication completed) at the timing of SSLn0 negation. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared at the SSLn0 assert when the next transmission start. Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

[In the TI-SSP case]

Figure 36.43 shows an example of communication end interrupt operation during receive only slave mode on SPI operation (4-wire).

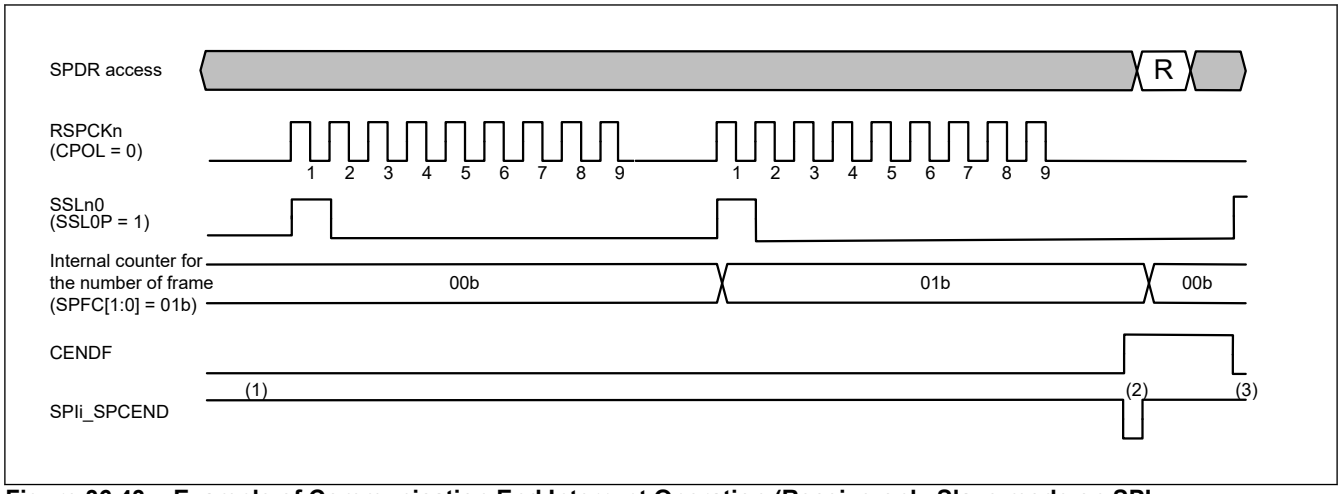

Figure 36.43 Example of Communication End Interrupt Operation (Receive-only Slave mode on SPI Operation / TI-SSP)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the RSPCK last data bit sampling when the last frame transmission ends. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared at the SSLn0 assert when the next transmission start. Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

36.3.9.5 Transmit-Receive/Transmit in Slave Mode on Clock Synchronous Operation (3-wire)

See the description of the CENDF bit in section 36.2.9. SPSR : SPI Status Register for the setting / clearing conditions of the communication completion flag during Transmit-Receive/Transmit-only in Slave Mode on Clock Synchronous (3-wire).

Figure 36.44 shows an example of communication end interrupt operation during transmit-receive/transmit slave mode on clock synchronous operation (3-wire).

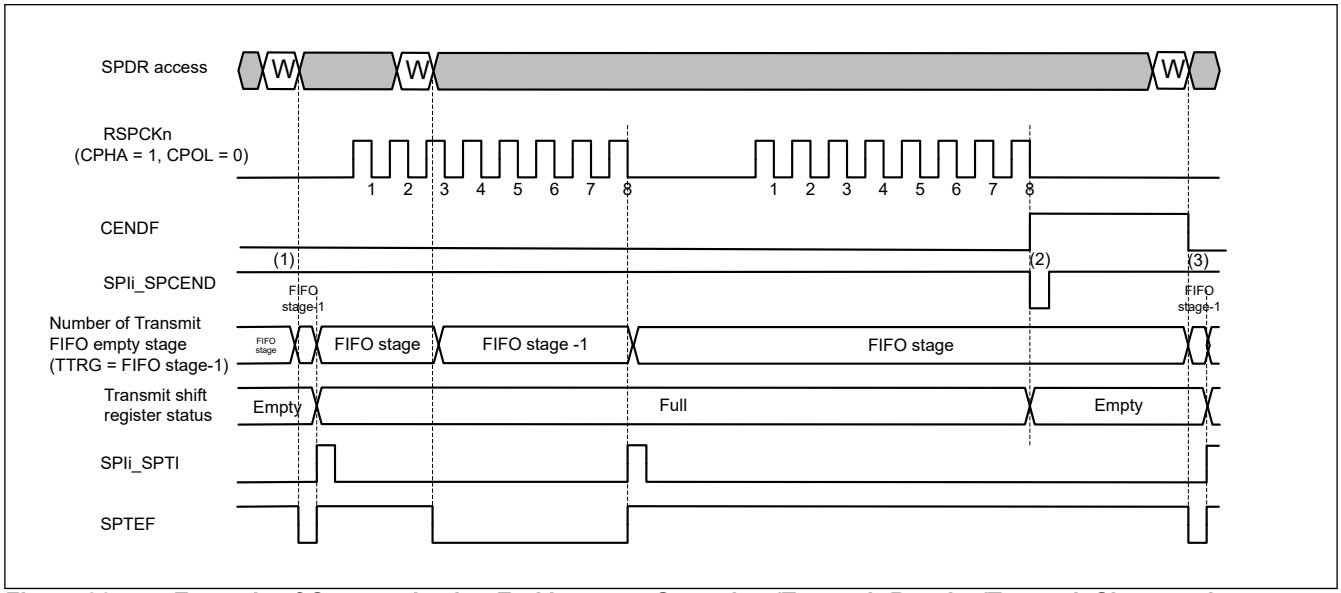

Figure 36.44 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Slave mode on Clock Synchronous Operation)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.

2. When the next transfer data is not set in the transmit FIFO and the transmit shift register is empty, then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

36.3.9.6 Receive Only in Slave Mode on Clock Synchronous Operation (3-wire)

See the description of the CENDF bit in section 36.2.9. SPSR : SPI Status Register for the setting / clearing conditions of the communication completion flag during Receive -only in Slave Mode on Clock Synchronous (3-wire).

Figure 36.45 shows an example of communication end interrupt operation during receive only slave mode on clock synchronous operation.

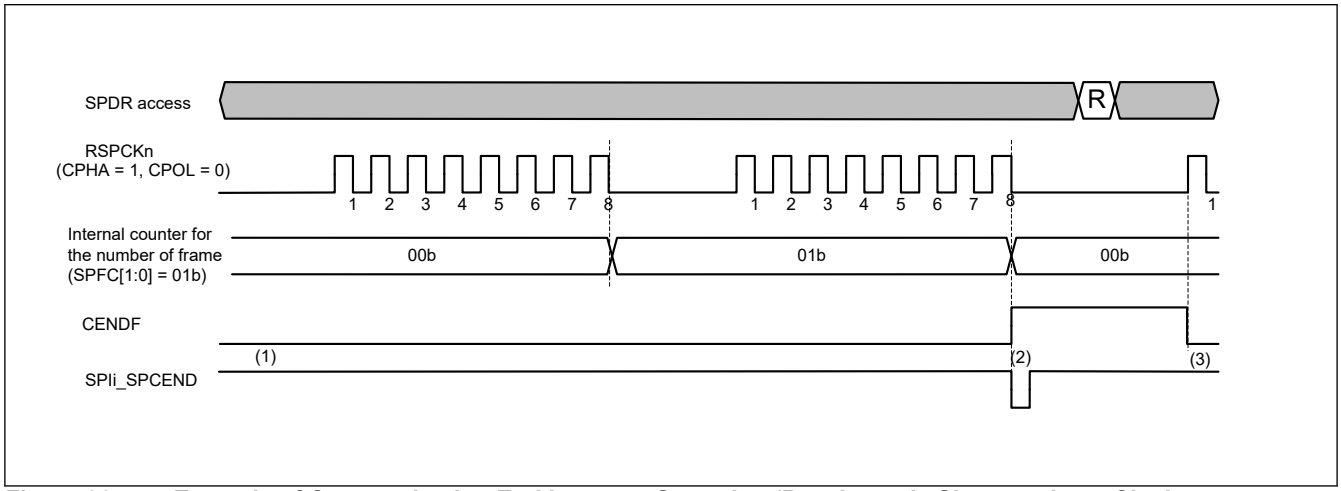

Figure 36.45 Example of Communication End Interrupt Operation (Receive-only Slave mode on Clock Synchronous Operation)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.
2. The CENDF flag is set to 1 (communication completed) at the timing of the last data bit sampling of RSPCKn in the last frame communication when the last frame of the SPI data control register (SPDCR) SPFC set value is received. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared at the first edge of RSPCKn for the next transmission. Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

36.3.9.7 Common Operation

In this chapter, the operation common to each mode / area option communication in section 36.3.9.1. Transmit-Receive/ Transmit in Master Mode to section 36.3.9.6. Receive Only in Slave Mode on Clock Synchronous Operation (3-wire) is explained. When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, a flag of communication end (CENDF) is set and an event of communication end is output, but no interrupt is output. However, if the enable of communication end interrupt (CENDIE) is set to 1 before clearing the flag of communication end (CENDF) while the enable of SPI function (SPE) is 1, the communication end interrupt (SPIi_SPCEND) is output.

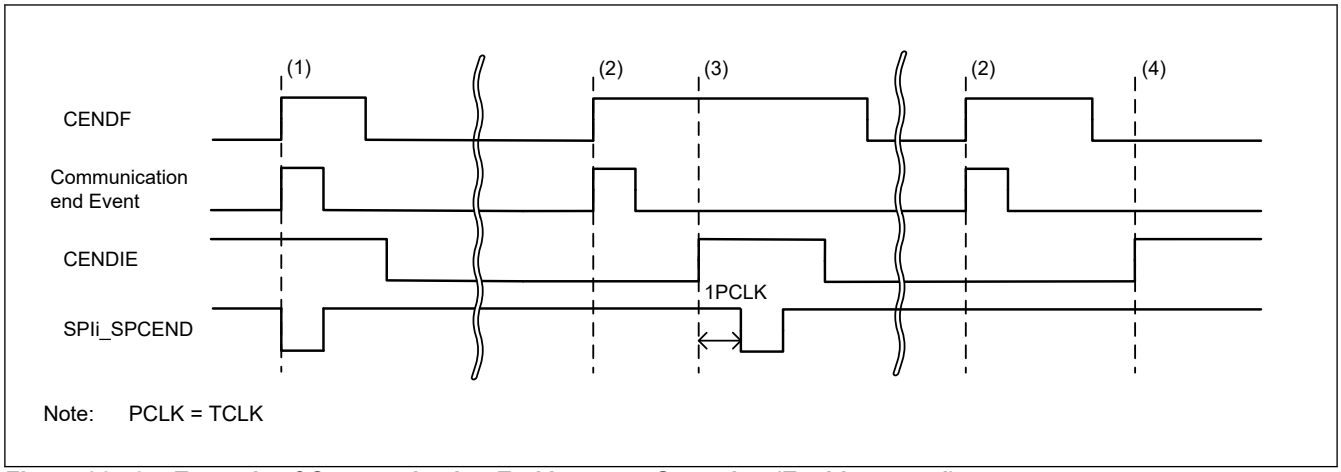

Figure 36.46 Example of Communication End Interrupt Operation (Enable control)

1. When the enable of SPI communication end interrupt (CENDIE) is 1, at the time of communication completion, the following three are the same timing.
   - A flag of communication end (CENDF)
   - An event of communication end
   - The communication end interrupt (SPIi_SPCEND)
2. When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, the following two are the same timing, but no interrupt.
   - A flag of communication end (CENDF)
   - An event of communication end
3. After (2), if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) and the flag of communication end (CENDF) are 1, the communication end interrupt (SPIi_SPCEND) is output after 1 TCLK.
4. After (2), even if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) or the flag of communication end (CENDF) is 0, the communication end interrupt (SPIi_SPCEND) is not output.

36.3.10 Error Detection

In normal SPI serial transfers, data written to the transmit buffer of SPDR is transmitted, and received data can be read from the receive buffer of SPDR. If access is made to SPDR, an abnormal transfer might occur, depending on the status of the transmit or receive buffer or the status of the SPI at the beginning or end of serial transfer.

If an abnormal transfer occurs, the SPI detects the event as an underrun error, overrun error, parity error, or mode fault error. Table 36.9 lists the relationship between non-normal transfer operations and the SPI error detection function.

Table 36.9 Relationship between non-normal transfer operations and SPI error detection (1 of 2)

Operation	Occurrence condition	SPI operation	Error detection
1	SPDR is written while no empty stages in the transmit FIFO.	• The contents of the transmit buffer are kept • Write data is missing	None
2	SPDR is read while no data stored in receive FIFO.	The contents of the receive buffer and previously received data are output.	None
3	Serial transfer is started in slave mode when the SPI is not able to transmit data.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the MISOn output signal is stopped • SPI function is disabled	Underrun error
4	Serial transfer ends when data is stored in the receive FIFO for the number of FIFO stages.	• Keeps the contents of the receive FIFO • Missing receive data	Overrun error

Table 36.9 Relationship between non-normal transfer operations and SPI error detection (2 of 2)

Operation	Occurrence condition	SPI operation	Error detection
5	An incorrect parity bit is received during full-duplex synchronous serial communication with the parity function enabled in following mode: • Transmit-receive master mode • Receive-only master mode • Transmit-receive slave mode • Receive-only slave mode	The parity error flag is asserted	Parity error
6	The SSLn0 input signal is asserted when the serial transfer is idle in multi-master mode.	• Driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals is stopped • SPI function is disabled	Mode fault error
7	The SSLn0 input signal is asserted during serial transfer in multi-master mode.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals is stopped • SPI function is disabled	Mode fault error
8	[In the Motorola-SPI case] The SSLn0 input signal is negated during serial transfer in slave mode.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the MISOn output signal is stopped • SPI function is disabled	Mode fault error
9	[In the TI-SSP case] The SSLn0 input signal is asserted during serial transfer in slave mode.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the MISOn output signal is stopped • SPI function is disabled	Mode fault error
10	After data is stored in the receive FIFO with SPDRES = 1, the number of stored data is less than the threshold value and no receive data is written for the set value of SPDRC [7:0]	Assert the receive data ready flag	Receive data ready

In operation 1 described in Table 36.9, the SPI does not detect an error. To prevent data omission during writes to SPDR, the writes to SPDR must be executed using a transmit buffer empty interrupt request (when the SPSR.SPTEF flag is 1).

Similarly, the SPI does not detect an error in operation 2. To prevent extraneous data from being read, SPDR read must be executed with an SPI receive buffer full interrupt request (when the SPSR.SPRF flag is 1).

For information on the other errors, see the following sections:

- Underrun error, indicated in operation 3, see section 36.3.10.4. Underrun errors
- Overrun error, indicated in operation 4, see section 36.3.10.1. Overrun errors
- Parity error, indicated in operation 5, see section 36.3.10.2. Parity errors
- Mode fault error, indicated in operations 6 to 9, see section 36.3.10.3. Mode fault errors
- For the transmit and receive interrupts, see section 36.3.7. Transmit Buffer Empty and Receive Buffer Full Interrupts.
- For the reception data ready in operations 10, see section 36.3.10.5. Received data ready.

36.3.10.1 Overrun errors

If a serial transfer ends when the receive buffer of SPDR is full, the SPI detects an overrun error and sets the SPSR.OVRF flag to 1. When the OVRF flag is 1, the SPI does not copy data from the shift register to the receive buffer, so the data prior to the error occurrence is retained in the receive buffer. To set the OVRF flag to 0, issue a system reset or 1 is written to the SPSRC.OVRFC bit.

Figure 36.47 shows an example of operation of the OVRF and SPRF flags. The SPSRC and SPDR accesses shown in Figure 36.47 indicate the condition of accesses to the SPSRC and SPDR register, where W denotes a write cycle, and R a read cycle. In this example, the SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

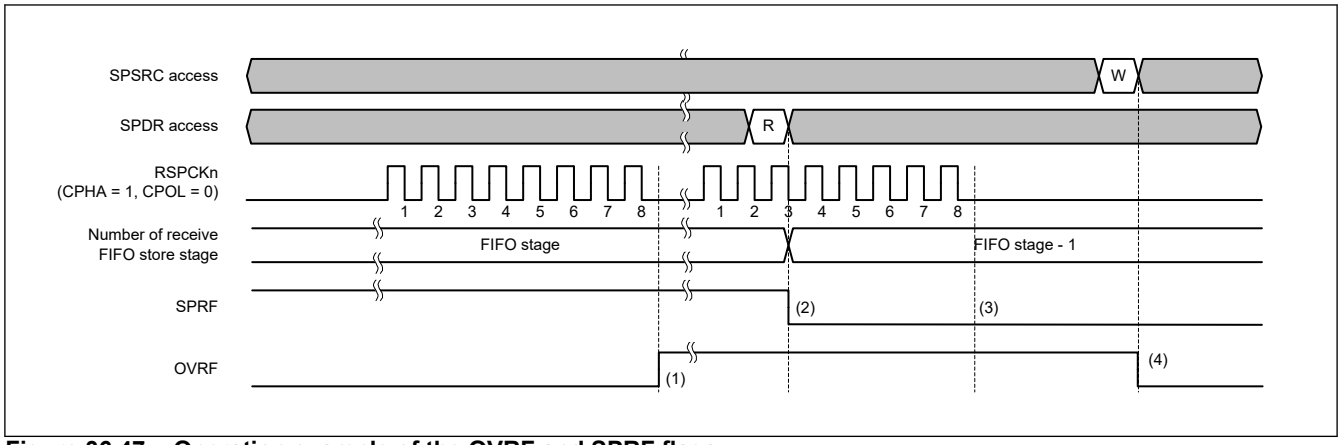

Figure 36.47 Operation example of the OVRF and SPRF flags

The operation of the flags at timings (1) to (4) in Figure 36.47 is as follows:

1. When serial transfer ends while data is stored for the number of FIFO stages, the SPI detects an overrun error and sets the OVRF flag to 1. The SPI does not copy shift register data to the receive buffer. The SPI does not detect a parity error even when SPPE = 1. In master mode, the SPI copies the value of pointer to the SPI command register (SPCMDm) to the SPECM[2:0] bits in the SPI status register (SPSR).
2. When SPDR is read, the SPI outputs the data in the receive buffer. At this time, the SPRF flag is cleared to 0 at the last access when the received data is read from SPDR in one processing routine using DTC / DMAC.
3. If the serial transfer ends with the OVRF flag set to 1 (overrun error occurred), the SPI does not copy data in the shift register to the receive buffer (the SPRF flag does not set to 1). A receive buffer full interrupt is not generated. Even when the SPPE bit is 1, parity errors are not detected. In an overrun error state when the SPI does not copy the received data from the shift register to the receive buffer, on termination of the serial transfer, the SPI determines that the shift register is empty. This enables data transfer from the transmit buffer to the shift register.
4. When 1 is written to the SPSRC.OVRFC bit, the SPSR.OVRF flag is cleared.

The occurrence of an overrun can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. When executing a serial transfer, you must ensure that overrun errors are detected early, for example by reading SPSR immediately after SPDR is read.

If an overrun error occurs and the OVRF flag sets to 1, normal reception operations cannot be performed until the OVRF flag is set to 0.

When the RSPCK auto-stop function is enabled (SPCR.SCKASE = 1) in master mode, an overrun error does not occur. Figure 36.48 and Figure 36.49 show the clock stop waveform when a serial transfer continues while the receive buffer is full in master mode.

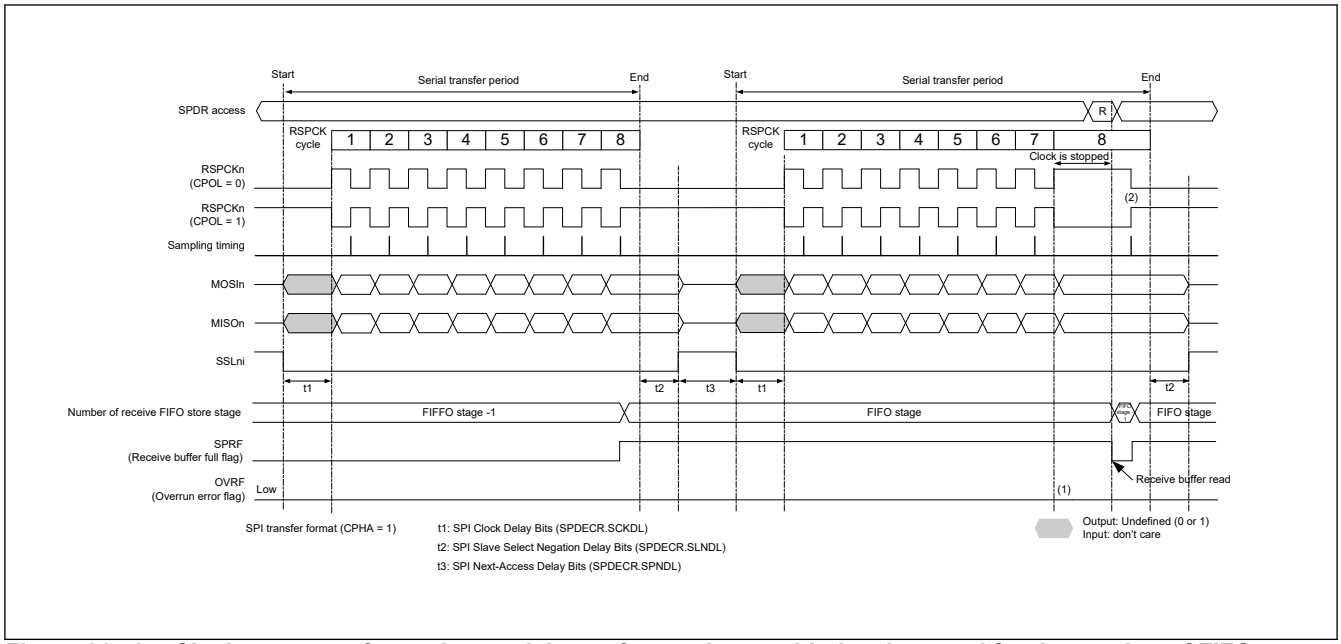

Figure 36.48 Clock stop waveform when serial transfer continues with data is stored for the number of FIFO stages in master mode (CPHA = 1)

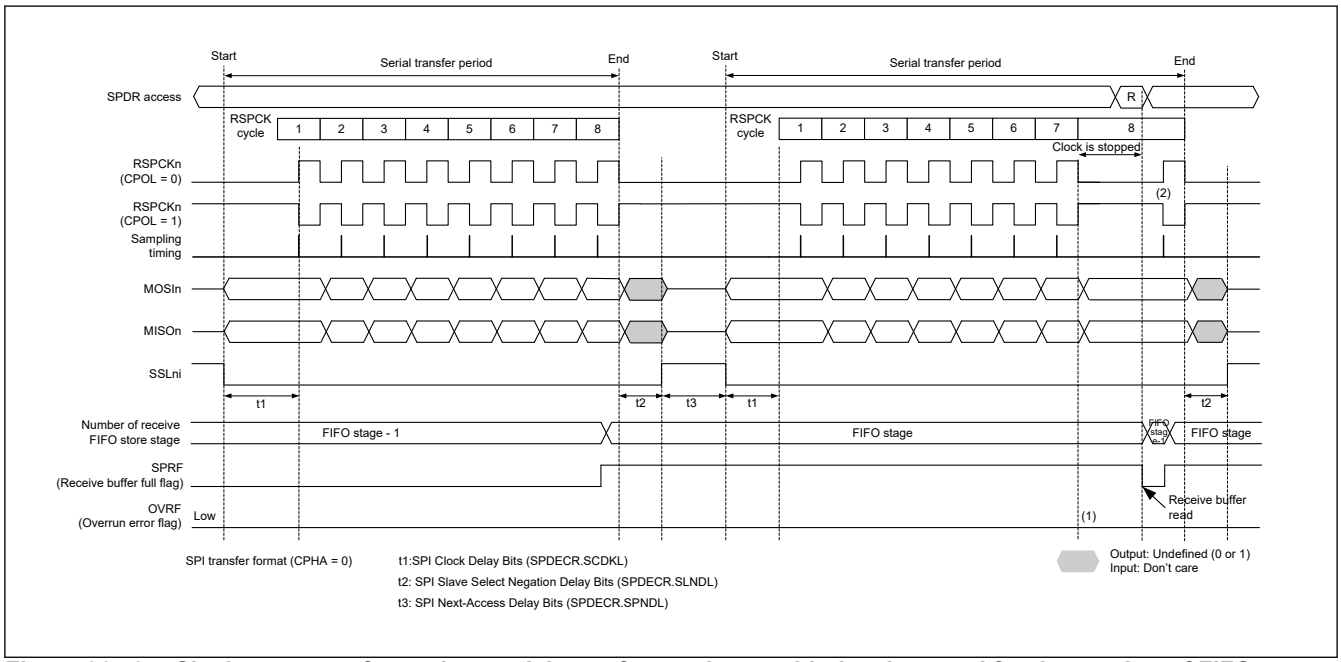

Figure 36.49 Clock stop waveform when serial transfer continues with data is stored for the number of FIFO stages in master mode (CPHA = 0)

The operation of the flags at timings (1) and (2) in Figure 36.48 and Figure 36.49 is as follows:

1. While data is stored in the receive FIFO for the number of FIFO stages, the RSPCK clock is deactivated and no overrun error occurs.
2. If SPDR is read while the clock is stopped, data in the receive buffer can be read. The RSPCK clock restarts.

Overrun error does not occur when RSPCK automatic stop function is enabled for transfer with no delay of between frames during burst transfer in master mode. Figure 36.50 and Figure 36.51 show the clock stop waveform, when there is no delay between frames at burst transfer and the serial transfer continues in the data is stored in the receive FIFO for the number of FIFO stages.

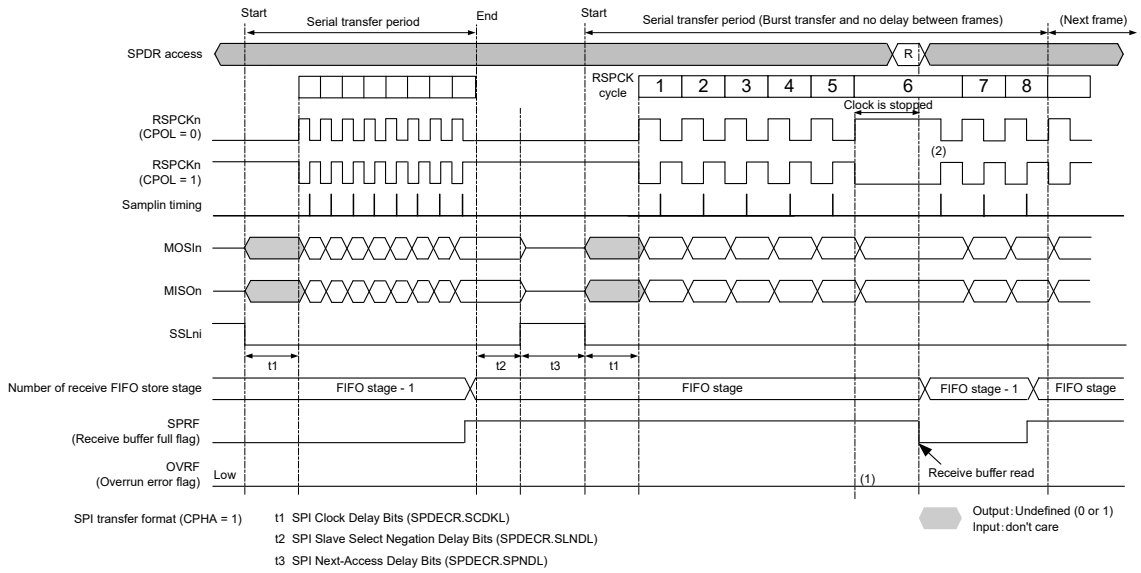

Figure 36.50 Clock Stop Waveform when Serial Transfer Continues in the Receive Buffer Full with data is stored for the number of FIFO stages (at burst transfer and no delay between frames CPHA = 1)

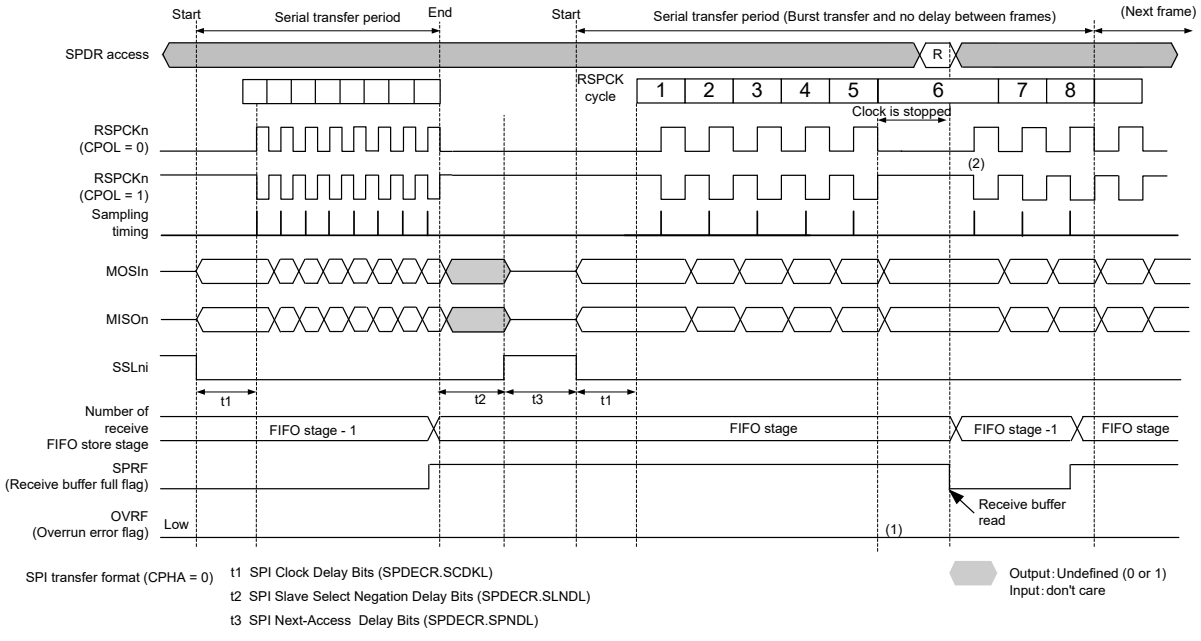

Figure 36.51 Clock Stop Waveform when Serial Transfer Continues with data is stored for the number of FIFO stages in Master Mode (at burst transfer and no delay between frames CPHA = 0)

The following describes operation of flags at timings (1) and (2) in the figure above.

1. While the data is stored for the number of FIFO stages, the RSPCK clock is deactivated and no overrun error occurs.
2. Receive buffer data can be read by reading SPDR during clock stop. After the receive buffer data has been read the RSPCK clock restarts.

36.3.10.2 Parity errors

After transfer in transmit-receive or receive-only master mode, transmit-receive slave mode or receive only slave mode while the SPPE bit in the SPI control register (SPCR) is 1, the SPI checks occurrence of a parity error. When the SPI detects a parity error in received data, the PERF flag in the SPI status register (SPSR) is set to 1. While the OVRF flag is 1, the SPI does not copy shift register data to the receive buffer. Therefore, parity error in received data is not detected. To clear the PERF flag in SPSR to 0, issue a system reset or 1 is written to the SPSRC.PERFC bit.

Figure 36.52 shows an example of operation of the OVRF and PERF flags. The SPSR access shown in Figure 36.52 indicates the condition of access to the register, where W denotes a write cycle, and R a read cycle. In this example, full-duplex serial communication is performed while the SPCR.SPPE bit is 1. The SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

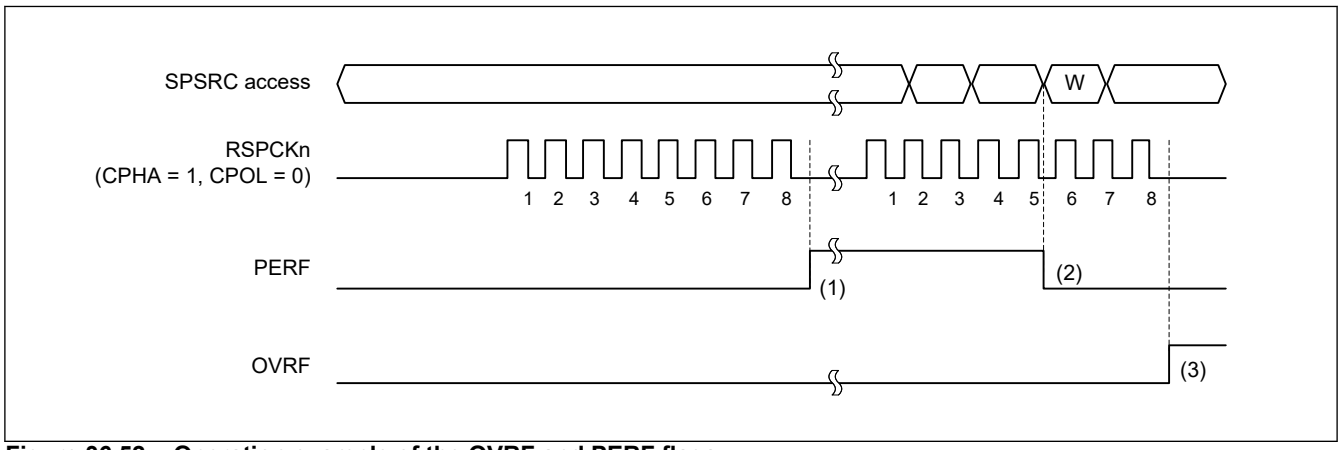

Figure 36.52 Operation example of the OVRF and PERF flags

The operation of the flags at timings (1) to (3) in Figure 36.52 is as follows:

1. When the SPI does not detect an overrun error and terminates the serial transfer, the SPI copies shift register data to the receive buffer. When the SPI checks the received data and detects a parity error at this time, the PERF flag is set to 1. In master mode, the SPI copies the value of pointer to the SPI command register (SPCMDm) to the SPECM[2:0] bits in the SPI Data control register 2 (SPDCR2).
2. When 1 is written to the SPSRC.PERFC bit, then clear the PERF flag.
3. When the SPI detects an overrun error and serial transfer is terminated, the data in the shift register is not copied to the receive buffer. The SPI does not perform parity error detection at this time.

Parity errors can be checked for by either reading the SPSR register or using an SPI error interrupt and reading the SPSR register. When executing a serial transfer, such checks are required to ensure early detection of parity errors. When the SPI is used in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPDCR2.SPECM[2:0] bits.

36.3.10.3 Mode fault errors

The SPI operates in multi-master mode when the SPCR.MSTR bit is 1, the SPCR.SPMS bit is 0, and the SPCR.MODFEN bit is 1.

If the active level is input for the SSLn0 input signal of the SPI in multi-master mode, the SPI detects a mode fault error regardless of the status of the serial transfer, and sets the SPSR.MODF flag to 1.

On detecting the mode fault error, the SPI copies the value of the pointer to SPCMD to the SPECM[2:0] bits.

The active level of the SSLn0 signal is determined by the SPCR3.SSL0P bit.

When the MSTR bit is 0, the SPI operates in slave mode.

When the SPCR.MODFEN bit = 1 and the SPMS bit = 0 in slave mode, if the SSLn0 input signal is negated during the serial transfer period (from valid data drive start to final valid data latch), the SPI detects a mode fault error, while any of the following 2 conditions is met.

[In the Motorola-SPI case]

When the SSLn0 input signal is negated while serial data transfer.

[In the TI-SSP case]

When the SSLn0 input signal is asserted while serial data transfer. However, during burst transfer, no error is detected even if the SSLn0 input signal is asserted during the last bit of frame.

When the SPI detects a mode fault error, it stops driving output signals and clears the SPE bit in the SPCR register. When the SPE bit is cleared, the SPI function is disabled (as described in section 36.3.12. SPI Operation). In a multi-master configuration, the mastership can be released by stopping driving output signals and disabling the SPI function by using a mode fault error.

Whether a mode fault error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR. To detect a mode fault error without using an SPI error interrupt, poll SPSR. When the SPI is used in master mode, the pointer value to SPCMD when an error is present can be checked by reading the SPECM[2:0] bits in SPSR.

While the MODF flag = 1, the SPI ignores writing 1 to the SPE bit. To enable the SPI function after a mode fault error is detected, clear the MODF flag to 0 without fail.

36.3.10.4 Underrun errors

While the SPI is operating in slave mode (SPCR.MSTR bit = 0) and the communication mode select bit (TXMD[1:0]) in the SPI control register (SPCR) is set to 00b or 01b, if serial transfer is started before transmit data output is ready with the SPCR.SPE bit set to 1 (SPI function enabled), the SPI detects an underrun error and sets the SPSR.MODF and SPSR.UDRF flags to 1.

On detecting an underrun error, the SPI stops the driving of output signals and clears the SPCR.SPE bit to 0 (see section 36.3.11. Initializing the SPI).

The occurrence of underrun errors can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. Detecting underrun errors without using the SPI error interrupt requires polling of SPSR.

When the MODF flag is 1, writing 1 to the SPE bit is ignored by the SPI. To enable the SPI function after the detection of an underrun error, the MODF flag must be set to 0.

36.3.10.5 Received data ready

When SPCR.TXMD[1:0] = 00b, 01b, or 11b, and SPCR2.SPDRC[7:0] ≠ 0x00, after receiving data in the receive FIFO during communication (SPE = 1), SPSR.SPDRF flag is set to 1 when the received data is not stored even after the number of received FIFOs is equal to or less than ≤ the threshold value and the value set in SPDRC[7:0] has elapsed.

When the receive data ready is detected, the interrupt and event link output can be selected as SPIi_SPRI or SPIi_SPEI with the SPCR.SPDRES bit.

Figure 36.53 shows an example of reception data ready detection operation.

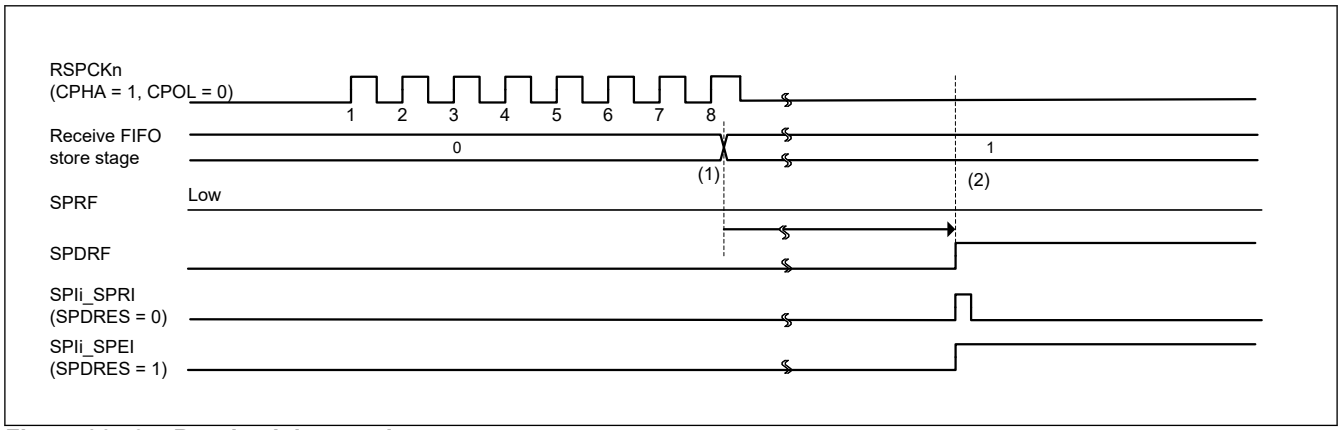

Figure 36.53 Received data ready

The following describes the operation at the timings indicated by (1) and (2) in the figure.

(1) Store the received data in the receive FIFO. SPRF is 0, because receive FIFO store stage ≤ number of frames set by SPDCR2.RTRG[1:0] .

(2) Set SPDRF and assert SPIi_SPRI or SPIi_SPEI because there is no writing to the receive FIFO for the amount of SPDRFC [7:0] set from above (1).

36.3.11 Initializing the SPI

If 0 is written to the SPCR.SPE bit or if the SPI sets the SPE bit to 0 because it detected a mode fault error or an underrun error, the SPI disables the SPI function and initializes some of the module functions. When a system reset is generated, the SPI initializes all of the module functions. This section describes initialization by clearing of the SPCR.SPE bit and by a system reset.

36.3.11.1 Initialization by clearing of the SPCR.SPE bit

When the SPCR.SPE bit is set to 0, the SPI initializes by:

- Suspending any serial transfer that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state of the SPI
- Initializing the transmit buffer of the SPI (the SPSR.SPTEF flag sets to 1)

Initialization by clearing of the SPE bit does not initialize the control bits of the SPI. For this reason, the SPI can be started in the same transfer mode in use prior to initialization when the SPE bit is set to 1 again.

The SPSR.CENDF, SPSR.SPRF, SPSR.OVRF, SPSR.MODF, SPSR.PERF, and SPSR.UDRF flags are not initialized, and the value of the SPDCR2.SPECM[2:0] and SPDCR2.SPCP[2:0] bits are not initialized. Therefore, even after the SPI is initialized, data from the receive buffer can be read to check the communication completion status and the error status during an SPI transfer.

The transmit buffer is initialized to an empty state (the SPSR.SPTEF flag sets to 1). Therefore, if the SPCR.SPTIE bit is set to 1 after SPI initialization, a transmit buffer empty interrupt is generated. To disable any transmit buffer empty interrupts when the SPI is initialized, write 0 to the SPTIE bit simultaneously while writing 0 to the SPE bit.

36.3.11.2 Initialization by system reset

A system reset completely initializes the SPI by initializing all SPI control bits, status bits, and data registers, in addition to the requirements described in section 36.3.11.1. Initialization by clearing of the SPCR.SPE bit.

36.3.12 SPI Operation

36.3.12.1 Master mode operation

The only difference between single- and multi-master mode operation is the use of mode fault error detection (see section 36.3.10. Error Detection). In single-master mode, the SPI does not detect mode fault errors whereas in multi-master mode, it does. This section explains operations that are common to both modes.

(1) Starting a serial transfer

When data is written to the SPI data register (SPDR) while the next transfer data is not set in the transmit FIFO, the SPI updates the transmit buffer (SPTXn, n = 0 to 3) data in SPDR. When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR, the SPI copies data from the transmit buffer to the shift register and starts serial transfer. On copying transmit data to the shift register, the SPI changes the status of the shift register to full. On termination of the serial transfer, it changes the status of the shift register to empty. The status of the shift register cannot be referenced.

The polarity of the SSLni output pins depends on the SPCR3.SSLnP (n = 0 to 3) bits settings. For details on the SPI transfer format, see section 36.3.5. Transfer Formats.

(2) Terminating a serial transfer

[Except Receive-only in Master Mode]

After the SPI detects the RSPCKn edge corresponding to the final sampling timing regardless of the CPHA bit value in the SPI command register (SPCMD), the SPI terminates serial transfer. When the number of data stored in the receive FIFO is

less than the number of FIFO stages, data is copied from the shift register to the receive buffer in the SPI data register (SPDR) after serial transfer.

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[4:0] bit settings. The polarity of the SSLni output pin depends on the SPCR3.SSLnP (n = 0 to 3) bits settings. For details on the SPI transfer format, see section 36.3.5. Transfer Formats.

[Receive-only in Master Mode]

When any of the following 2 conditions is met, then SPI terminating the serial transfer.

- After the SPI detects the RSPCKn edge corresponding to the final sampling timing regardless of the CPHA bit value in the SPI command register (SPCMD), the SPI terminates serial transfer.
- When writing SPCR2.RMEDTG = 1 during the serial transfer period, SPI terminating the serial transfer.

When the number of data stored in the receive FIFO is less than the number of FIFO stages, data is copied from the shift register to the receive buffer in the SPI data register (SPDR) after serial transfer.

The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in master mode depends on the set value of the SPB[4:0] bits in the SPI command register (SPCMD). The SSLni output signal polarity depends on the set SPI SSLi signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value. For details about the SPI transfer format, see section 36.3.5. Transfer Formats.

(3) Sequence control

The transfer format in master mode is determined as follows.

The transfer format used in master mode is determined by the SPCR3, SPCMDm, and SPDECR registers.

The SPCR3.SPSLN[2:0] bits determine the sequence configuration for serial transfers that are executed by the SPI in master mode. The following items are set in the SPCMDm register:

- SSLni pin output signal value
- MSB- or LSB-first
- Data length
- Some of the bit rate settings
- RSPCKn polarity and phase
- Whether SPDECR.SCKDL is to be referenced
- Whether SPDECR.SLNDL is to be referenced
- Whether SPDECR.SPNDL is to be referenced

SPCR3.SPBR holds some of the bit rate settings, including SPDECR.SCKDL (SPI clock delay), SPDECR.SLNDL (SSL negation delay), and SPDECR.SPNDL (next-access delay).

Based on the sequence length assigned in SPCR3.SPSLN, the SPI makes up a sequence comprised of a part or all of the SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPDCR2.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command in the sequence, the SPI sets the pointer to SPCMD0, and in this way the sequence is executed repeatedly.

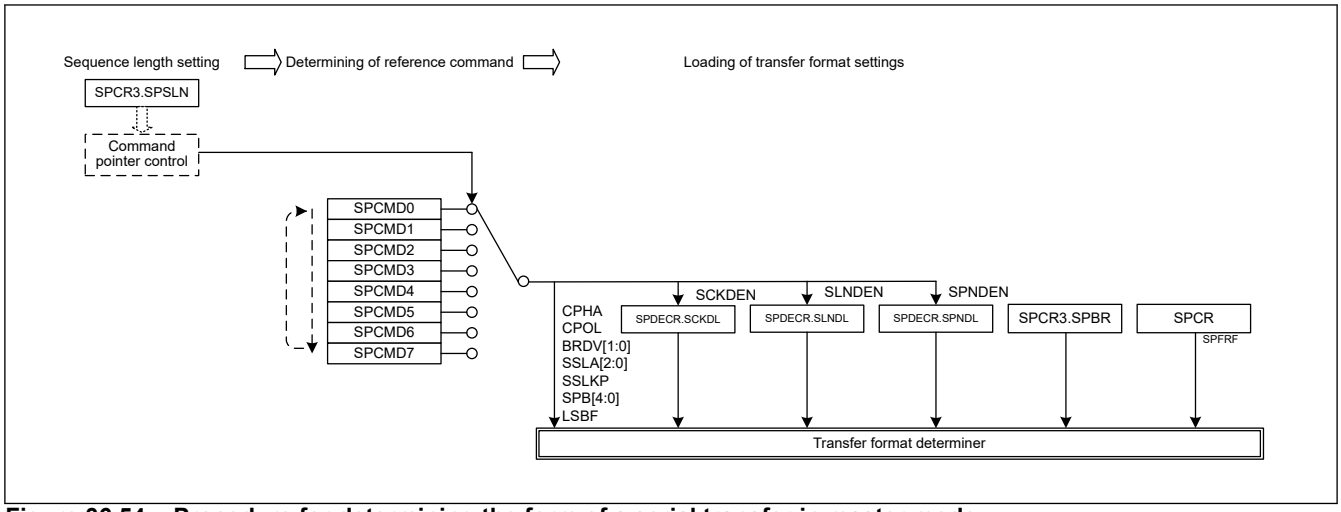

Figure 36.54 Procedure for determining the form of a serial transfer in master mode

In this section, a frame is the combination of the data in SPDR and the settings in SPCMDm.

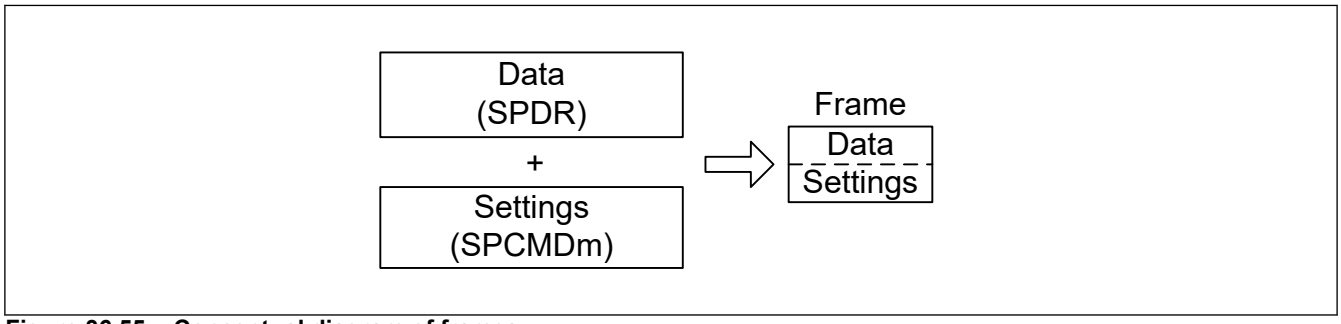

Figure 36.55 Conceptual diagram of frames

Figure 36.56 shows the correspondence between the commands and the transmit and receive buffers in the sequence of operations specified by the settings.

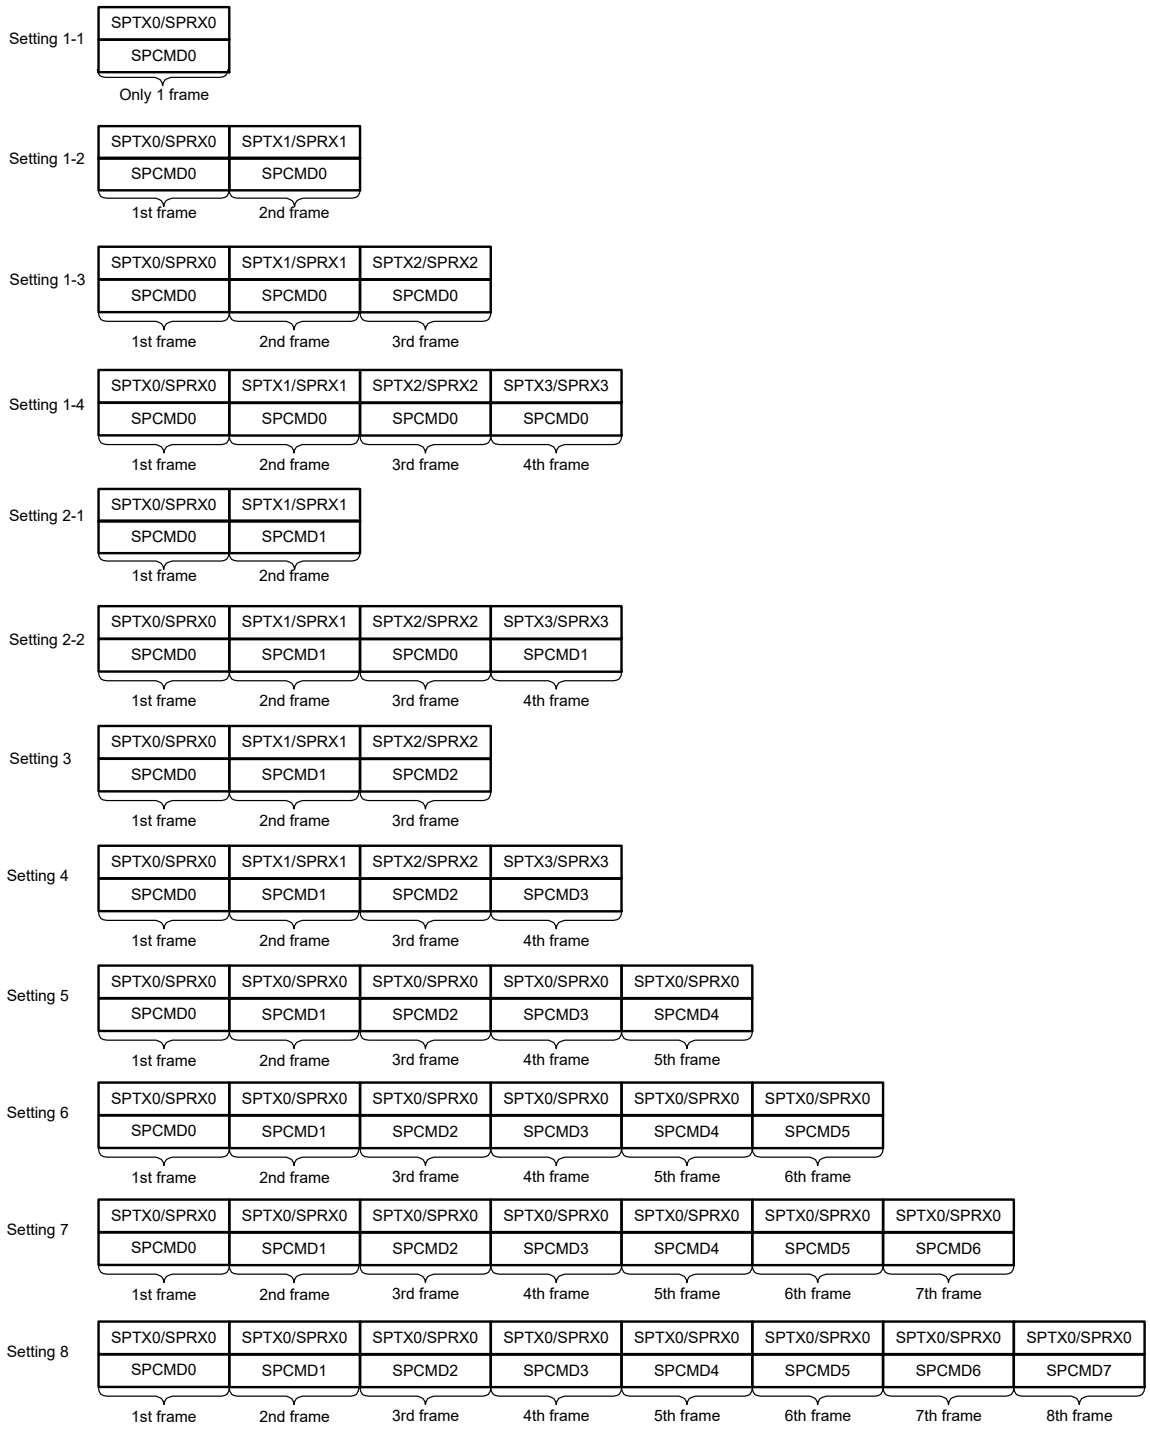

Figure 36.56 Correspondence between SPI Command Register and transmit and receive buffers in sequence operations

(4) Burst transfers

This section describes burst transfer during transmit-receive/transmit-only operation.

[In the Motorola-SPI case]

If the SPCMDm.SSLKP bit that the SPI references during the current serial transfer is 1, the SPI maintains the SSLni signal level during the serial transfer until the beginning of the SSLni signal assertion for the next serial transfer. If the SSLni signal level for the next serial transfer is the same as the SSLni signal level for the current serial transfer, the SPI can execute continuous serial transfers while keeping the SSLni signal assertion status (burst transfer).

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register (SPCR) is 0.

Figure 36.57 shows an example of an SSLni signal operation for a burst transfer that is implemented using the SPCMD0 and SPCMD1 register settings. This section describes SPI operations (1) to (8) shown in Figure 36.57.

Note: The polarity of the SSLni output signal depends on the SPCR3.SSLnP (n = 0 to 3) bits settings.

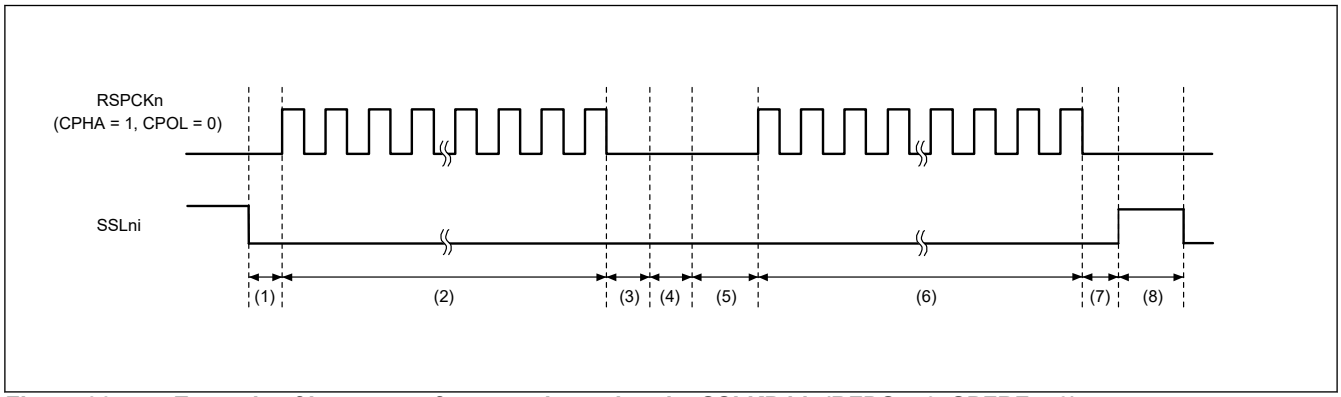

Figure 36.57 Example of burst transfer operation using the SSLKP bit (BFDS = 0, SPFRF = 0)

The SPI operation at times (1) to (8) in the figure is as follows:

1. Based on the SPCMD0 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
2. The SPI executes serial transfers in accordance with the SPCMD0 settings.
3. The SPI inserts an SSL negation delay.
4. Because the SPCMD0.SSLKP bit is 1, the SPI keeps the SSLni signal value specified in SPCMD0. This period additionally continues for 5 TCLK cycles (at minimum) that is the same as the next-access delay time of SPCMD0. If the shift register is empty after the passage of the minimum period, this period is sustained until the transmit data is stored in the shift register for the next transfer.
5. Based on the SPCMD1 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
6. The SPI executes serial transfers in accordance with the SPCMD1 settings.
7. Insert SSL negate delay.
8. Because the SPCMD1.SSLKP bit is 0, the SPI negates the SSLni signal. In addition, a next-access delay is inserted in accordance with SPCMD1.

If the SSLni signal output settings in the SPCMDm register where 1 is assigned to the SSLKP bit are different from the SSLni signal output settings in the SPCMDm register to be used in the next transfer, the SPI switches the SSLni signal status to SSLni signal assertion as shown in (5) in Figure 36.57. This corresponds to the command for the next transfer.

Note: If such an SSLni signal switching occurs, the slaves that drive the MISOn signal compete, and collision of signal levels might occur.

The SPI in master mode references the SSLni signal operation within the module when the SSLKP bit is not used. When the SPCMDm.CPHA bit is 0, the SPI can accurately start serial transfers by using the SSLni signal assertion for the next transfer that is detected internally.

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register (SPCR) is 1.

Figure 36.58 shows an example of SSLni signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in Figure 36.58. The SSLni output signal polarity depends on the set SPCR3.SSLnP (n = 0 to 3) value.

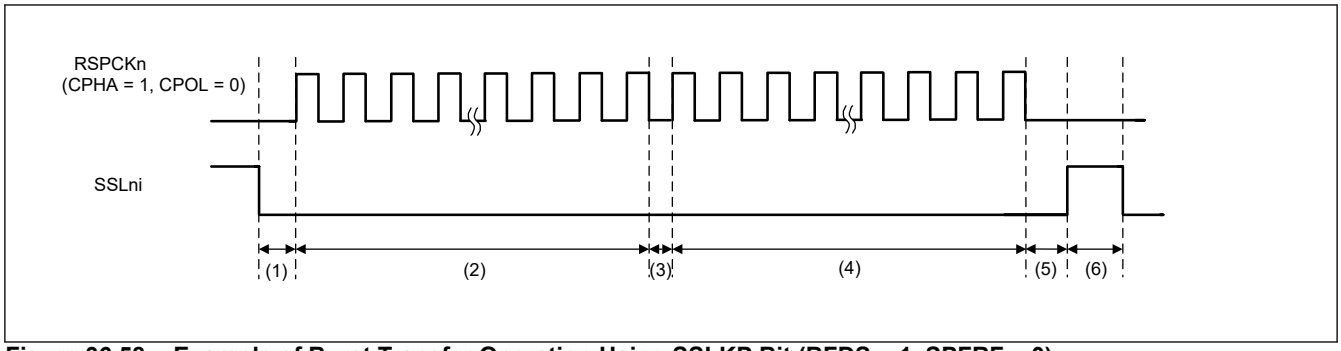

Figure 36.58 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 1, SPFRF = 0)

1. Assert the SSLni signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmission.
2. Perform serial transfer according to SPCMD0. Wait last clock until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.
3. The value of SSLni signal according to SPCMD0 was hold, because the SPCMD0.SSLKP bit is 1. RSPCK negate period between frames is 0.5RSPCK, if the shift register is not empty.
4. Perform serial transfer according to SPCMD1.
5. Insert SSLni negate delay for the last frame.
6. The SSLni signal is negated because the SSLKP bit in SPCMD1 is 0. Furthermore, the next-access delay is inserted according to SPCMD1.

[In the TI-SSP case]

SPI asserts the SSLni signal for one cycle at the start of serial transfer.

Serial transfer can be executed continuously by asserting the SSLni signal for one cycle at the start of the next serial transfer (burst transfer).

- When the SSLni signal level holding bit (SSLKP) of the SPI command register (SPCMD) is 1 and the burst transfer frame delay selection bit (BFDS) of the SPI control register (SPCR) is 1, SPCMD0 to SPCMD1 are shown in Figure 36.59. The following shows an example of SSLni signal operation and serial data MISOn/MOSIn when burst transfer is realized using the settings. The SSLni output signal polarity depends on the set SPI SSLi signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value.

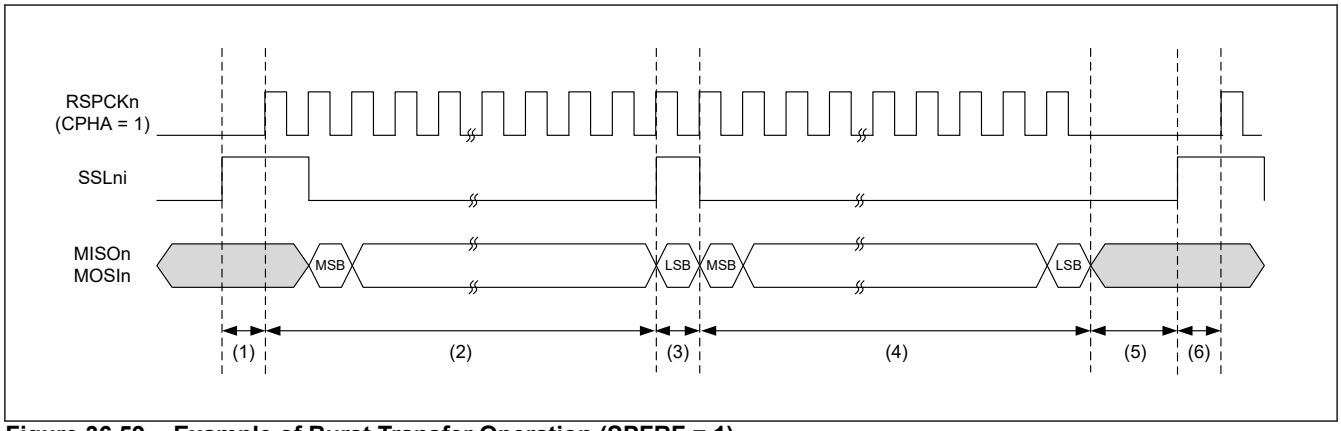

Figure 36.59 Example of Burst Transfer Operation (SPFRF = 1)

1. Assert the SSLni signal and insert an RSPCK delay according to SPCMD0.
   The RSPCK delay is inserted only the first frame of burst transmission.
2. Perform serial transfer according to SPCMD0.
3. Final data transfer and SSLni assertion are performed simultaneously. If the shift register is empty during the RSPCK negation period between frames, wait for the output of the last clock until the transmission data for the next transfer is stored in the shift register.

4. Perform serial transfer according to SPCMD1.
5. Insert OE negate delay for the last frame.
6. Insert the next access delay according to SPCMD1.

If the SSLni signal output setting in SPCMD with the SSLKP bit set to 1 differs from the SSLni signal output setting in SPCMD to be used for the next transfer, the SPI changes the SSLni signal state when the SSLni signal corresponding to the next-transfer command is asserted ((5)). Note that, if an SSLni signal change like this takes place, slaves that drive the MISOn signal may conflict with each other, which may cause collision of signal level.

This section describes burst transfer during receive-only operation.

[In the Motorola-SPI case]

When the SSLKP bit in the SPI command register (SPCMD), which the SPI references in the current serial transfer, is 1, the SPI retains the SSLni signal level during serial transfer until the SSLni signal assertion of the next serial transfer starts. When the SSLni signal level in the next serial transfer is the same as the SSLni signal level in the current serial transfer, the SPI can continuously perform serial transfer while holding the SSLni signal assertion status (burst transfer).

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register (SPCR) is 0.

Figure 36.60 shows an example of SSLni signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (8) shown in Figure 36.60. The SSLni output signal polarity depends on the set SPI SSLni signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value.

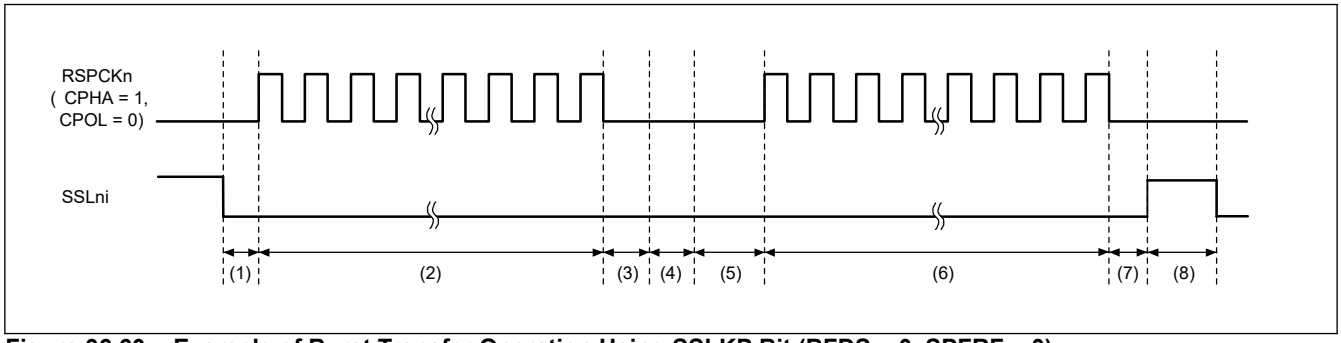

Figure 36.60 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 0, SPFRF = 0)

1. Assert the SSLni signal and insert an RSPCK delay according to SPCMD0.
2. Perform serial transfer according to SPCMD0.
3. Insert an SSLni negation delay.
4. The SSLni signal value in SPCMD0 is retained because the SSLKP bit in SPCMD0 is 1. This period additionally continues for 5 TCLK cycles (at minimum) that is the same as the next-access delay time of SPCMD0.
5. Assert the SSLni signal and insert an RSPCK delay according to SPCMD1.
6. Perform serial transfer according to SPCMD1.
7. Insert SSLni negate delay.
8. The SSLni signal is negated because the SSLKP bit in SPCMD1 is 0. Furthermore, the next-access delay is inserted according to SPCMD1.

If the SSLni signal output setting and the SSLni signal output setting between SPCMDs used for burst transfer are different, SPI switches the SSLni signal state when the SSLni signal corresponding to the next transfer command is asserted (5). Note that, if an SSLni signal change like this takes place, slaves that drive the MISOn signal may conflict with each other, which may cause collision of signal level.

The SPI in master mode references the SSLni signal operation in the module when SSLKP is not used.

Even when the CPHA bit in SPCMD is 0, the SPI can accurately start serial transfer by using the next transfer SSLni signal assertion detected internally. For this reason, burst transfer in master mode is enabled regardless of the set CPHA bit value. (See section 36.3.11. Initializing the SPI.)

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register (SPCR) is 1.

Figure 36.61 shows an example of SSLni signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in Figure 36.61. The SSLni output signal polarity depends on the set SPI SSLi signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value.

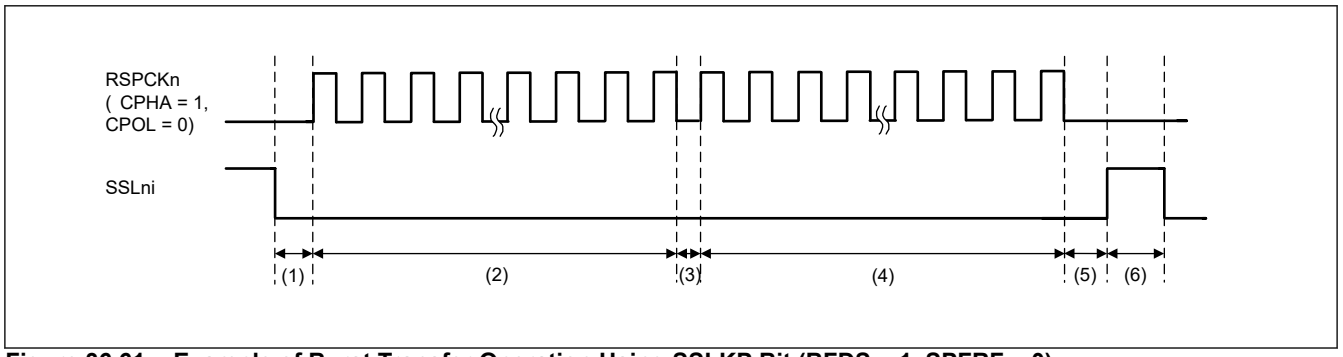

Figure 36.61 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 1, SPFRF = 0)

1. Assert the SSLni signal and insert an RSPCK delay according to SPCMD0.
   The RSPCK delay is inserted only the first frame of burst transmission.
2. Perform serial transfer according to SPCMD0.
3. Since it is not the last frame, the SSLni signal value at SPCMD0 is retained. RSPCKn negation between frames is 0.5 RSPCKn for the next frame.
4. Perform serial transfer according to SPCMD1.
5. Insert SSLni negate delay for the last frame.
6. The SSLni signal is negated. Furthermore, the next-access delay is inserted according to SPCMD1.

Note: Last frame: Frame set by RMFM[4:0] bits when SPCR2.RMFM[4:0] ≠ 0x00
Or, a frame in which SPCR2.RMEDTG = 1 has been accepted.

[In the TI-SSP case]

SPI asserts the SSLni signal for one cycle at the start of serial transfer.

Serial transfer can be executed continuously by asserting the SSLni signal for one cycle at the start of the next serial transfer (burst transfer).

- When the SSLni signal level holding bit (SSLKP) of the SPI command register (SPCMD) is 1 and the burst transfer frame delay selection bit (BFDS) of the SPI control register (SPCR) is 1, SPCMD0 to SPCMD1 are shown in Figure 36.62. The following shows an example of SSLni signal operation and serial data MISOn / MOSIn when burst transfer is realized using the settings. The SSLni output signal polarity depends on the set SPI SSLi signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value.

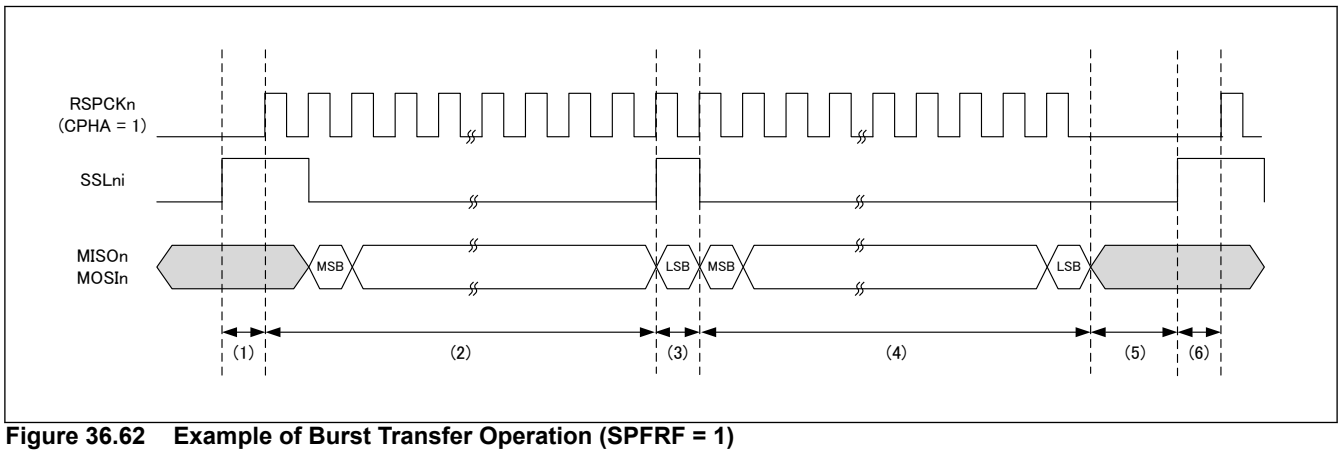

Figure 36.62 Example of Burst Transfer Operation (SPFRF = 1)

1. Assert the SSLni signal and insert an RSPCK delay according to SPCMD0.
   The RSPCK delay is inserted only the first frame of burst transmission.

2. Perform serial transfer according to SPCMD0.
3. Final data transfer and SSLni assertion are performed simultaneously.
4. Perform serial transfer according to SPCMD1.
5. Insert OE negate delay for the last frame.
6. Insert the next access delay according to SPCMD1.

Note: Last frame: Frame set by RMFM[4:0] bits when SPCR2.RMFM[4:0] ≠ 0x00
Or, a frame in which SPCR2.RMEDTG = 1 has been accepted.

If the SSLni signal output setting between the SPCMDs used for burst transfer differs from the SSLni signal output setting, SPI switches the SSLni signal state when the SSLni signal corresponding to the next transfer command is asserted (5). Note that, if an SSLni signal change like this takes place, slaves that drive the MISOn signal may conflict with each other, which may cause collision of signal level.

(5) RSPCK delay (t1)

The RSPCK delay value of the SPI in master mode depends on the SPCMDm.SCKDEN bit setting and the SPDECR.SCKDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during a serial transfer by pointer control, and determines an RSPCK delay using the SPCMDm.SCKDEN bit and SPDECR.SCKDL[2:0] bits, as listed in Table 36.10. For a definition of RSPCK delay, see section 36.3.5. Transfer Formats.

RSPCK delay insert to only the first frame of burst transmission, when transmit without “Between Burst Transfer Frames Delay”. (The SPCMD.SSLKP bit is 1 and the SPCR.BFDS bit is 1.)

Table 36.10 Relationship between the SPCMDm.SCKDEN bit, SPDECR.SCKDL[2:0] bits, and RSPCK delay

SPCMDm.SCKDEN bit	SPDECR.SCKDL[2:0] bits	RSPCK delay	
		Motorola-SPI	TI-SSP
0	000b to 111b	1 RSPCK	0 RSPCK
1	000b	1 RSPCK	1 RSPCK
	001b	2 RSPCK	2 RSPCK
	010b	3 RSPCK	3 RSPCK
	011b	4 RSPCK	4 RSPCK
	100b	5 RSPCK	5 RSPCK
	101b	6 RSPCK	6 RSPCK
	110b	7 RSPCK	7 RSPCK
	111b	8 RSPCK	8 RSPCK

(6) SSL negation delay (t2)

The SSL negation delay value of the SPI in master mode depends on the SPCMDm.SLNDEN bit setting and the SPDECR.SLNDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced by pointer control during a serial transfer, and determines an SSL negation delay using the SPCMDm.SLNDEN bit and SPDECR.SLNDL[2:0] bits, as listed in Table 36.11. For a definition of SSL negation delay, see section 36.3.5. Transfer Formats.

An SSL negation delay is inserted to only the last frame of the burst transmission, that is, transmit without between burst transfer frames delay. (SPCMD.SSLKP bit is 1 and SPCR.BFDS bit is 1).

Table 36.11 Relationship between the SPCMDm.SLNDEN bit, SPDECR.SLNDL[2:0] bits, and SSL negation delay (1 of 2)

SPCMDm.SLNDEN bit	SPDECR.SLNDL[2:0] bits	SSL negation delay
0	000b to 111b	1 RSPCK

Table 36.11 Relationship between the SPCMDm.SLNDEN bit, SPDECR.SLNDL[2:0] bits, and SSL negation delay (2 of 2)

SPCMDm.SLNDEN bit	SPDECR.SLNDL[2:0] bits	SSL negation delay
1	000b	1 RSPCK
	001b	2 RSPCK
	010b	3 RSPCK
	011b	4 RSPCK
	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(7) Next-access delay (t3)

The next-access delay value of the SPI in master mode depends on the SPCMDm.SPNDEN bit setting and the SPDECR.SPNDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and then determines a next-access delay during serial transfer using the SPCMDm.SPNDEN bit and SPDECR.SPNDL[2:0] bits, as listed in Table 36.12. For a definition of next-access delay, see section 36.3.5. Transfer Formats.

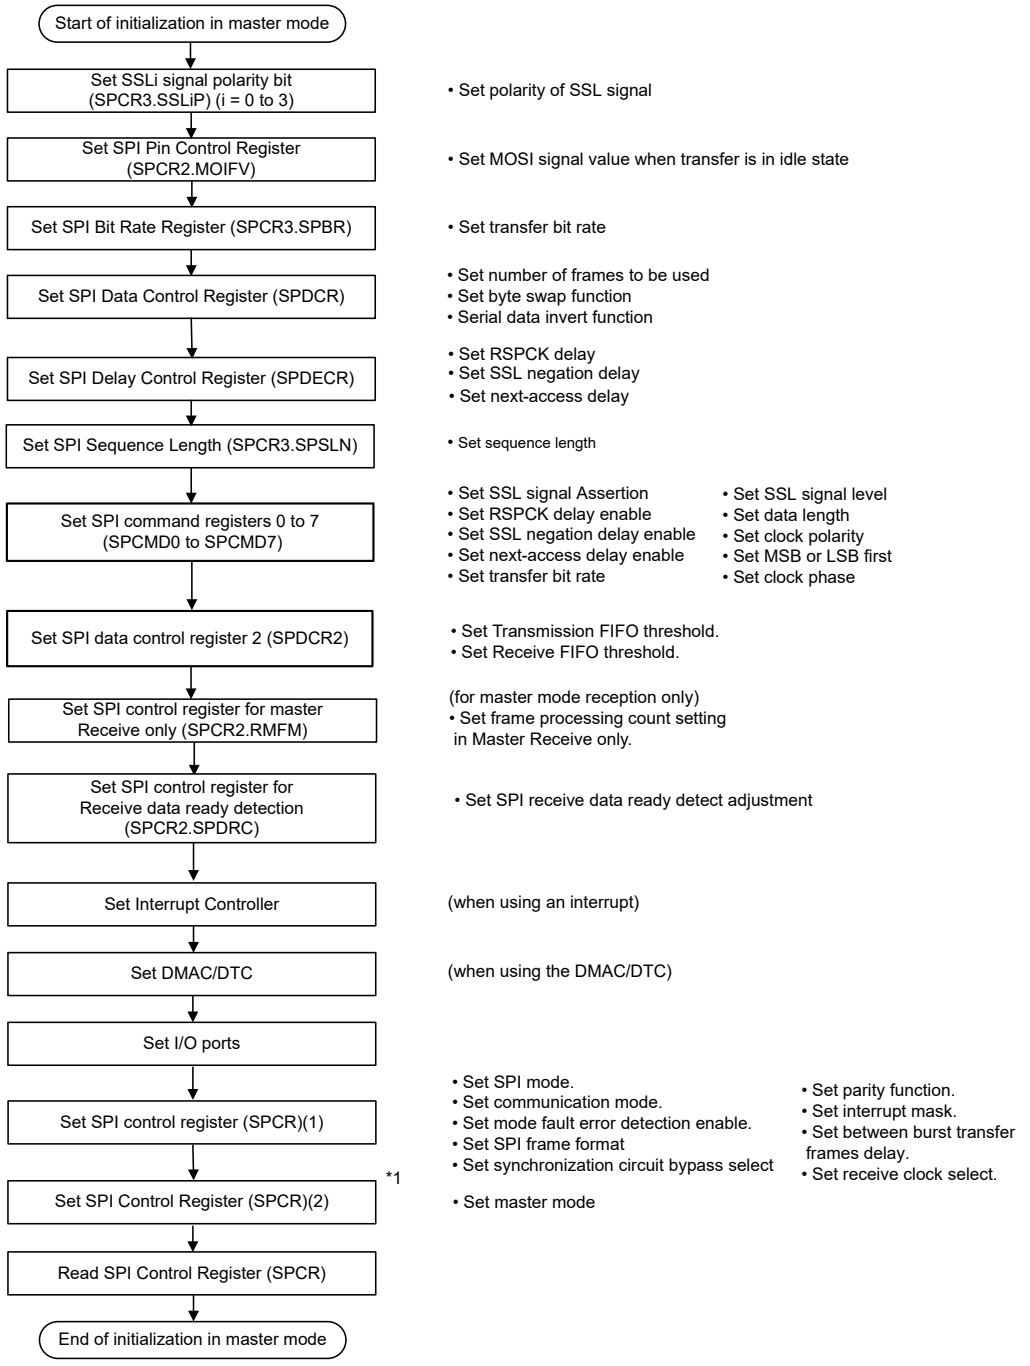
A next-Access delay is inserted to only the last frame of the burst transmission, that is, transmit without between burst transfer frames delay. (SPCMD.SSLKP bit is 1 and SPCR.BFDS bit is 1).

Table 36.12 Relationship between the SPCMDm.SPNDEN bit, SPDECR.SPNDL[2:0] bits, and next-access delay

SPCMDm.SPNDEN bit	SPDECR.SPNDL[2:0] bits	Next-access delay
0	000b to 111b	1 RSPCK + 5 TCLK
1	000b	1 RSPCK + 5 TCLK
	001b	2 RSPCK + 5 TCLK
	010b	3 RSPCK + 5 TCLK
	011b	4 RSPCK + 5 TCLK
	100b	5 RSPCK + 5 TCLK
	101b	6 RSPCK + 5 TCLK
	110b	7 RSPCK + 5 TCLK
	111b	8 RSPCK + 5 TCLK

(8) Initialization flow

Figure 36.63 shows an example of SPI initialization flow when the SPI is in master mode. For information on how to set up the Interrupt Controller Unit (ICU), DMAC or DTC, and I/O ports, see the descriptions given in the individual blocks.



Note 1. Regarding the setting of the SPI control register (SPCR), leave an interval of 1TCLK between setting (1) (initial setting other than MSTR bit) and setting (2) (MSTR setting).

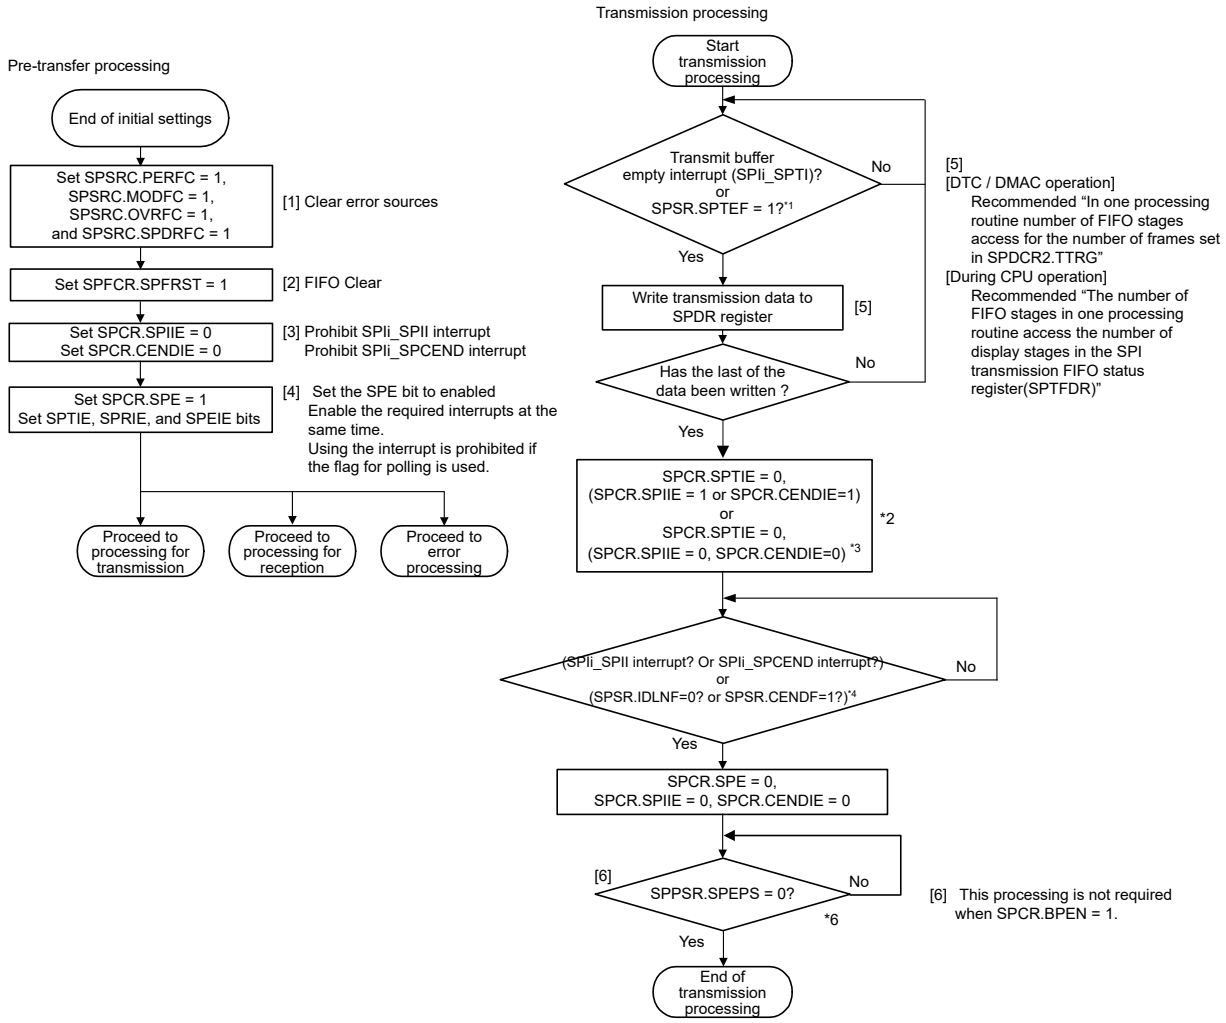
Figure 36.63 Example of initialization flow in master mode for SPI operation

(9) Software processing flow

Figure 36.64 to Figure 36.67 show examples of the software processing flow.

Transmit processing flow

When transmitting data, with the SPIi_SPII or SPIi_SPCEND interrupt enabled, the CPU is notified of the completion of data transmission after the last data write for transmission.

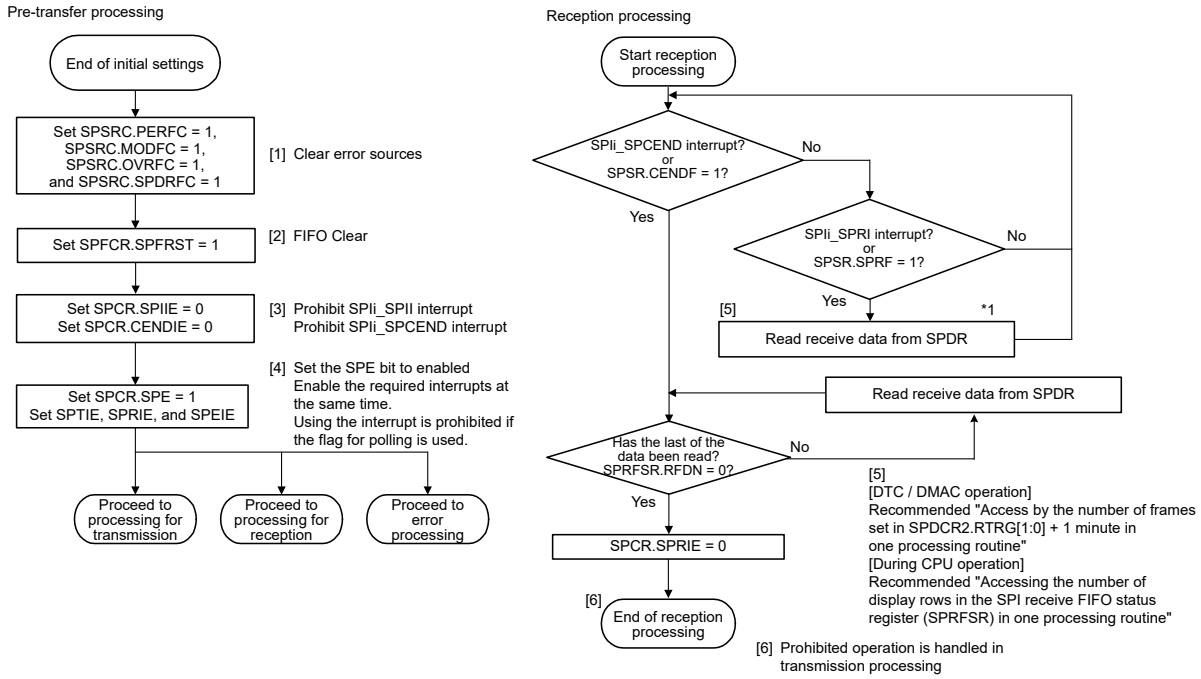


Note 1. Proceed to process of writing data for transmission after reading SPSR.SPTEF flag is 1, if the user uses the flag for polling.
Note 2. The user can know the communication end by SPIi_SPII interrupt (IDLNF flag) or SPIi_SPCEND interrupt (CENDF flag). Use either SPIi_SPII interrupt (IDLNF flag) or SPIi_SPCEND interrupt (CENDF flag).
Note 3. Set SPIi_SPII interrupt prohibited (SPCR.SPIIE = 0) and SPIi_SPCEND interrupt prohibited (SPCR.CENDIE = 0), if the user uses the flag for polling.
Note 4. Wait more than 1 PCLK, after writing data for transmission to SPDR, and before starting polling of SPSR.IDLNF or SPSR.CENDF, if the user uses the flag for polling.
Note 5. During CPU operation, Write 1 to SPI transmit buffer empty flag clear bit (SPSRC.SPTEFC) after one processing routine.
Note 6. When setting to 0 in slave mode and SPCR.BPEN = 0, check that SPPSR.SPEPS has become 0. (Not required when BPEN = 1.)

Figure 36.64 Transmission flow in master mode

Receive processing flow

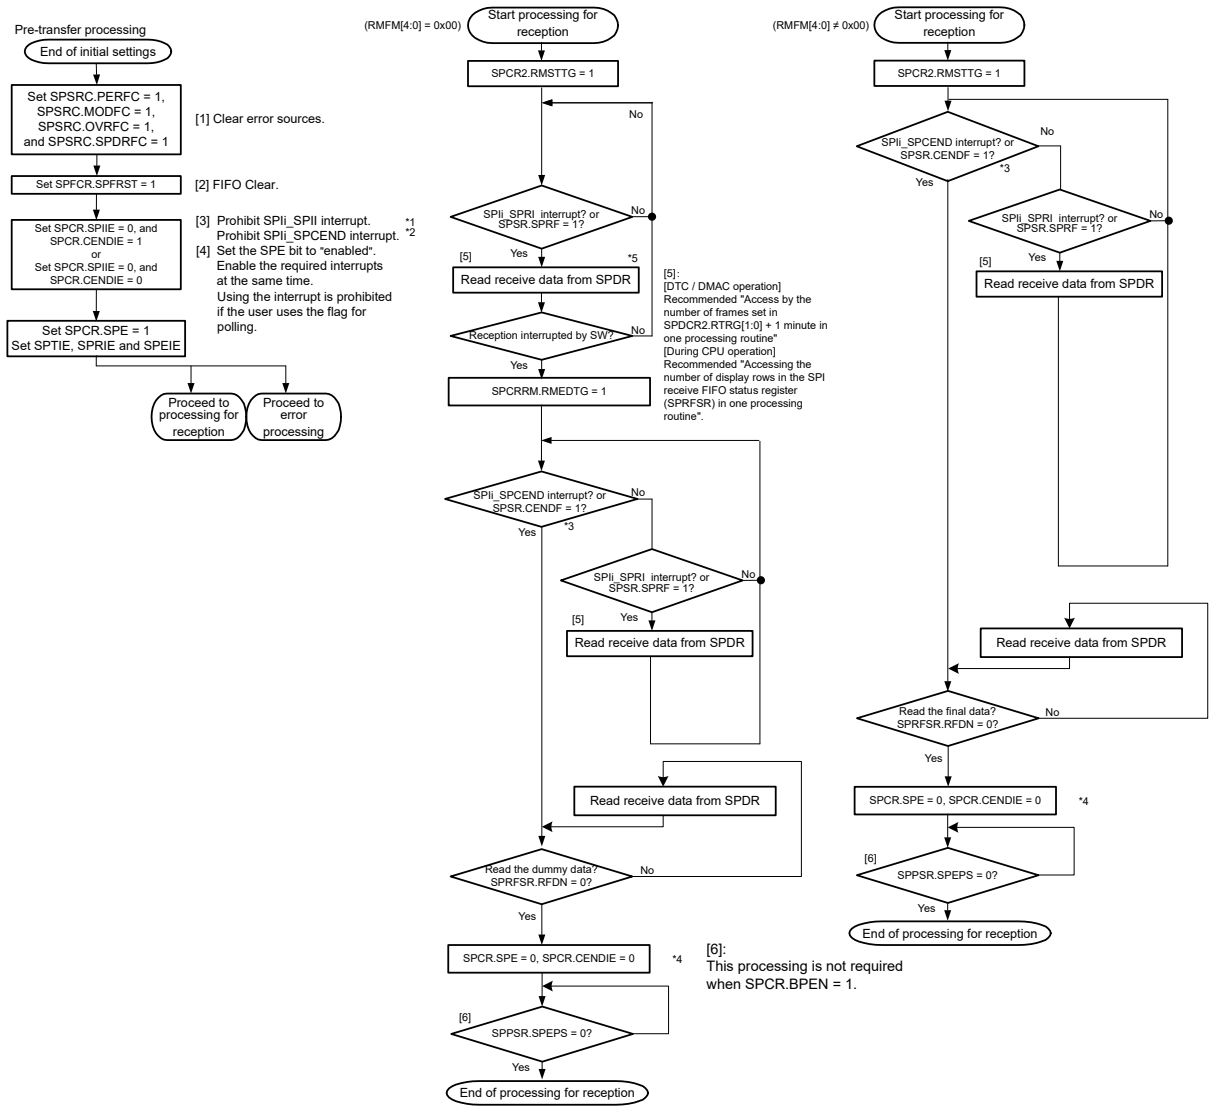
The SPI has receive only operation in slave mode.



Note 1. During CPU operation, write 1 to the SPSRC.SPRFC bit (SPI receive buffer full flag clear bit) after one processing routine.

Figure 36.65 Reception flow in master mode

Receive only processing flow in master mode



Note 1. The end of communication can be determined by the SPIi_SPCEND interrupt (CENDF flag). Use the SPIi_SPCEND interrupt (CENDF flag).
Note 2. Disable SPIi_SPCEND interrupt (SPCR.CENDIE = 0) during flag polling.
Note 3. A communication completion interrupt at reception only operation (Master) occurs at a predetermined timing under any of the following conditions.
- Frame number processing set by RMFM completed (RMFM[4:0] ≠ 0x00)
- RMEDTG = 1, when processing of the number of frames set by RMFM is not completed (including RMFM[4:0] = 0x00)

Note 4. Internal trigger is also cleared.
Note 5. During CPU operation, write 1 to the SPI receive buffer full flag clear bit (SPSRC.SPRFC) after one processing routine.

Figure 36.66 Software Processing Flowchart in Master Mode (Reception-only)

Error processing flow

The SPI detects the following errors:

- Mode fault error
- Underrun error
- Overrun error
- Parity error

When a mode fault error is generated, the SPCR.SPE bit is automatically cleared, stopping operations for transmission and reception. For errors from other sources, the SPCR.SPE bit is not cleared and operations for transmission and reception continue. Therefore, Renesas recommends clearing the SPCR.SPE bit to stop operations for errors other than mode fault errors. Not doing so leads to updating of the SPDCR2.SPECM[2:0] bits.

When an error is detected using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi_SPTI or SPIi_SPRI interrupt request. If the SPIi_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

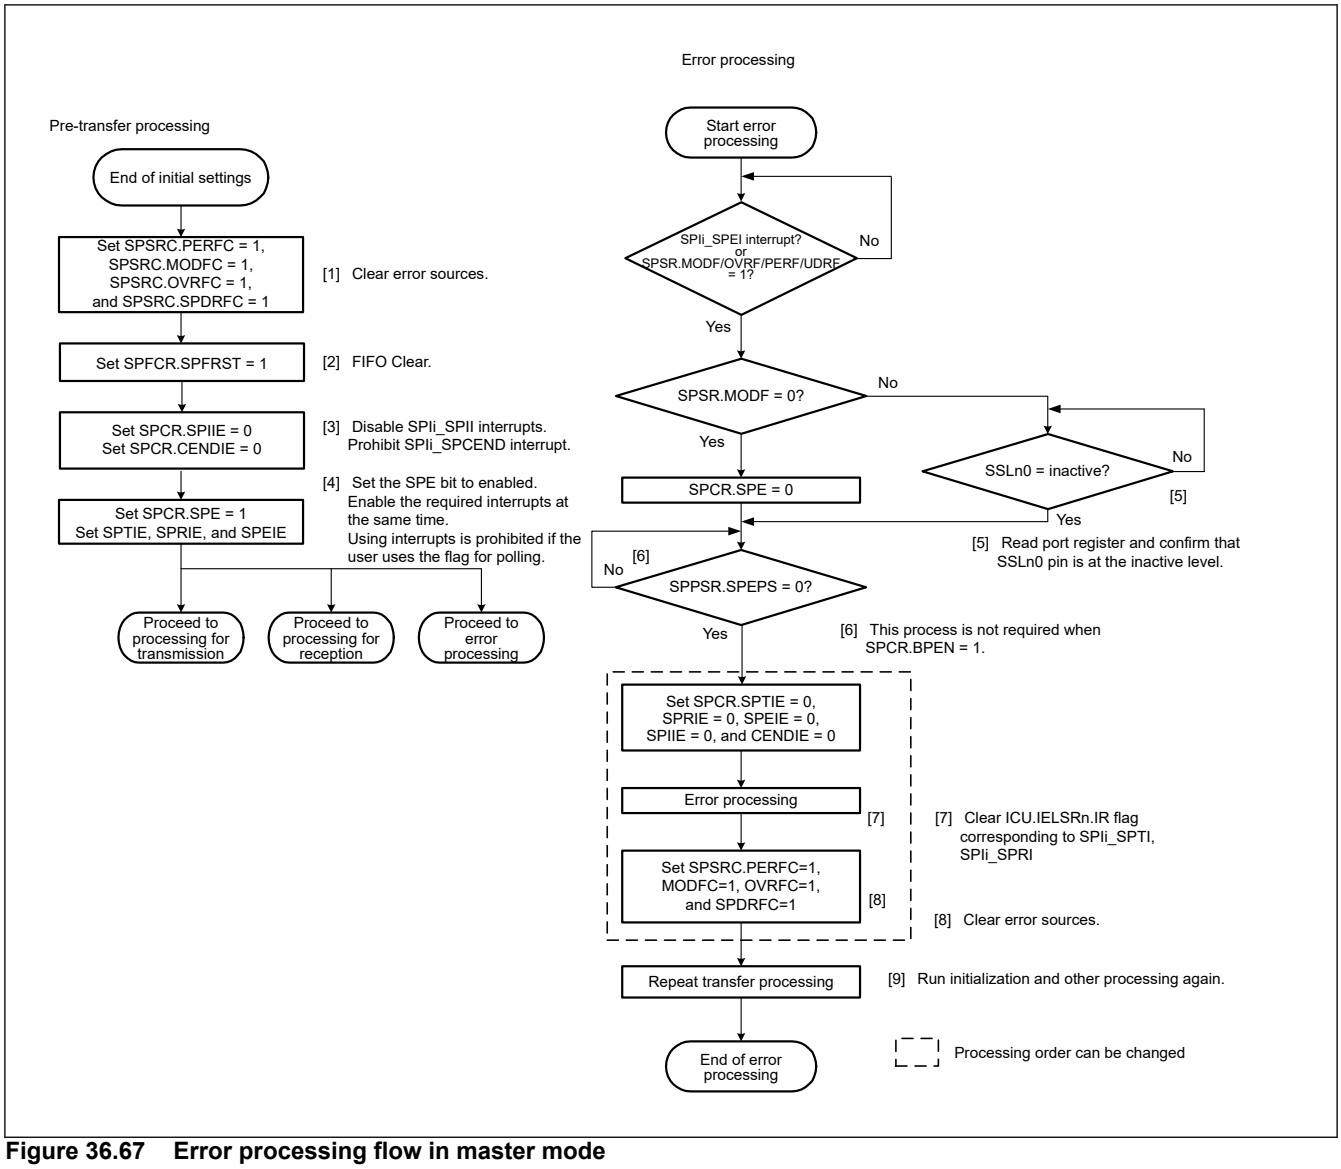


Figure 36.67 Error processing flow in master mode

36.3.12.2 Slave mode operation

(1) Starting a serial transfer

When the SPCMD0.CPHA bit is 0, if the SPI detects an SSLn0 input signal assertion, it must drive valid data to the MISOn output signal. For this reason, when the CPHA bit is 0, the assertion of the SSLn0 input signal triggers the start of a serial transfer.

When the CPHA bit is 1, if the SPI detects the first RSPCKn edge in an SSLn0 signal asserted condition, it must drive valid data to the MISOn output signal. For this reason, when the CPHA bit is 1, the first RSPCKn edge in an SSLn0 signal asserted condition triggers the start of a serial transfer.

Regardless of the CPHA bit setting, the SPI drives the MISOn output signal on SSLn0 signal assertion. The data that is output by the SPI is either valid or invalid, depending on the CPHA bit setting.

For details on the SPI transfer format, see section 36.3.5. Transfer Formats. The polarity of the SSLn0 input signal depends on the SPCR3.SSL0P setting.

(2) Terminating a serial transfer

Regardless of the SPCMD0.CPHA bit setting, the SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When the number of data stored in the receive FIFO is less than the number of FIFO stages, on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR register. On termination of a serial transfer, the SPI changes the status of the shift register to empty, regardless of the receive buffer state. A mode fault error occurs if the SPI detects an SSLn0 input signal negation from the beginning of serial transfer to the end of serial transfer (see section 36.3.10. Error Detection).

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length is determined by the SPCMD0.SPB[4:0] bits setting. The polarity of the SSLn0 input signal is determined by the SPCR3.SSL0P bit setting. For details on the SPI transfer format, see section 36.3.5. Transfer Formats.

(3) Notes on single-slave operations

[In the Motorola-SPI case]

If the SPCMD0.CPHA bit is 0, the SPI starts serial transfers when it detects the assertion edge for an SSLn0 input signal. In the configuration shown in Figure 36.8, if the SPI is used in single-slave mode, the SSLn0 signal is fixed at an active state. Therefore, when the CPHA bit is set to 0, the SPI cannot correctly start a serial transfer. For the SPI to correctly execute transmit and receive operations in slave mode when the SSLn0 input signal is fixed at an active state, the CPHA bit must be set to 1. Do not fix the SSLn0 input signal if there is a requirement for setting the CPHA bit to 0.

[In the TI-SSP case]

When SPI is used as a single slave in the configuration shown in the Figure 36.8, the SSLn0 input signal is always fixed to the inactive state, so the SPI cannot start the serial transfer.

When using a single slave, use the configuration shown in the example in Figure 36.7.

(4) Burst transfer

[In the Motorola-SPI case]

If the SPCMD0.CPHA bit is 1, continuous serial transfer (burst transfer) can be executed while retaining the assertion state for the SSLn0 input signal. When the CPHA bit is 1, the serial transfer period is the period from the first RSPCKn edge to the sampling timing for the reception of the final bit in an SSLn0 signal active state. Even when the SSLn0 input signal remains at the active level, the SPI can accommodate burst transfers, because it can detect the start of an access.

When the CPHA bit is 0, the second and subsequent serial transfers during burst transfer cannot be executed correctly.

[In the TI-SSP case]

In serial transfer, data transfer starts after the SSLn0 input signal is asserted for RSPCK 1 cycle. Since frame transfer starts from the SSLn0 input signal, SSLn0 must be asserted between frames.

(5) Initialization flow

Figure 36.68 shows an example of initialization flow for SPI operation when the SPI is in slave mode. For a description of how to set up the ICU, DMAC or DTC, and I/O ports, see the descriptions given in the individual blocks.

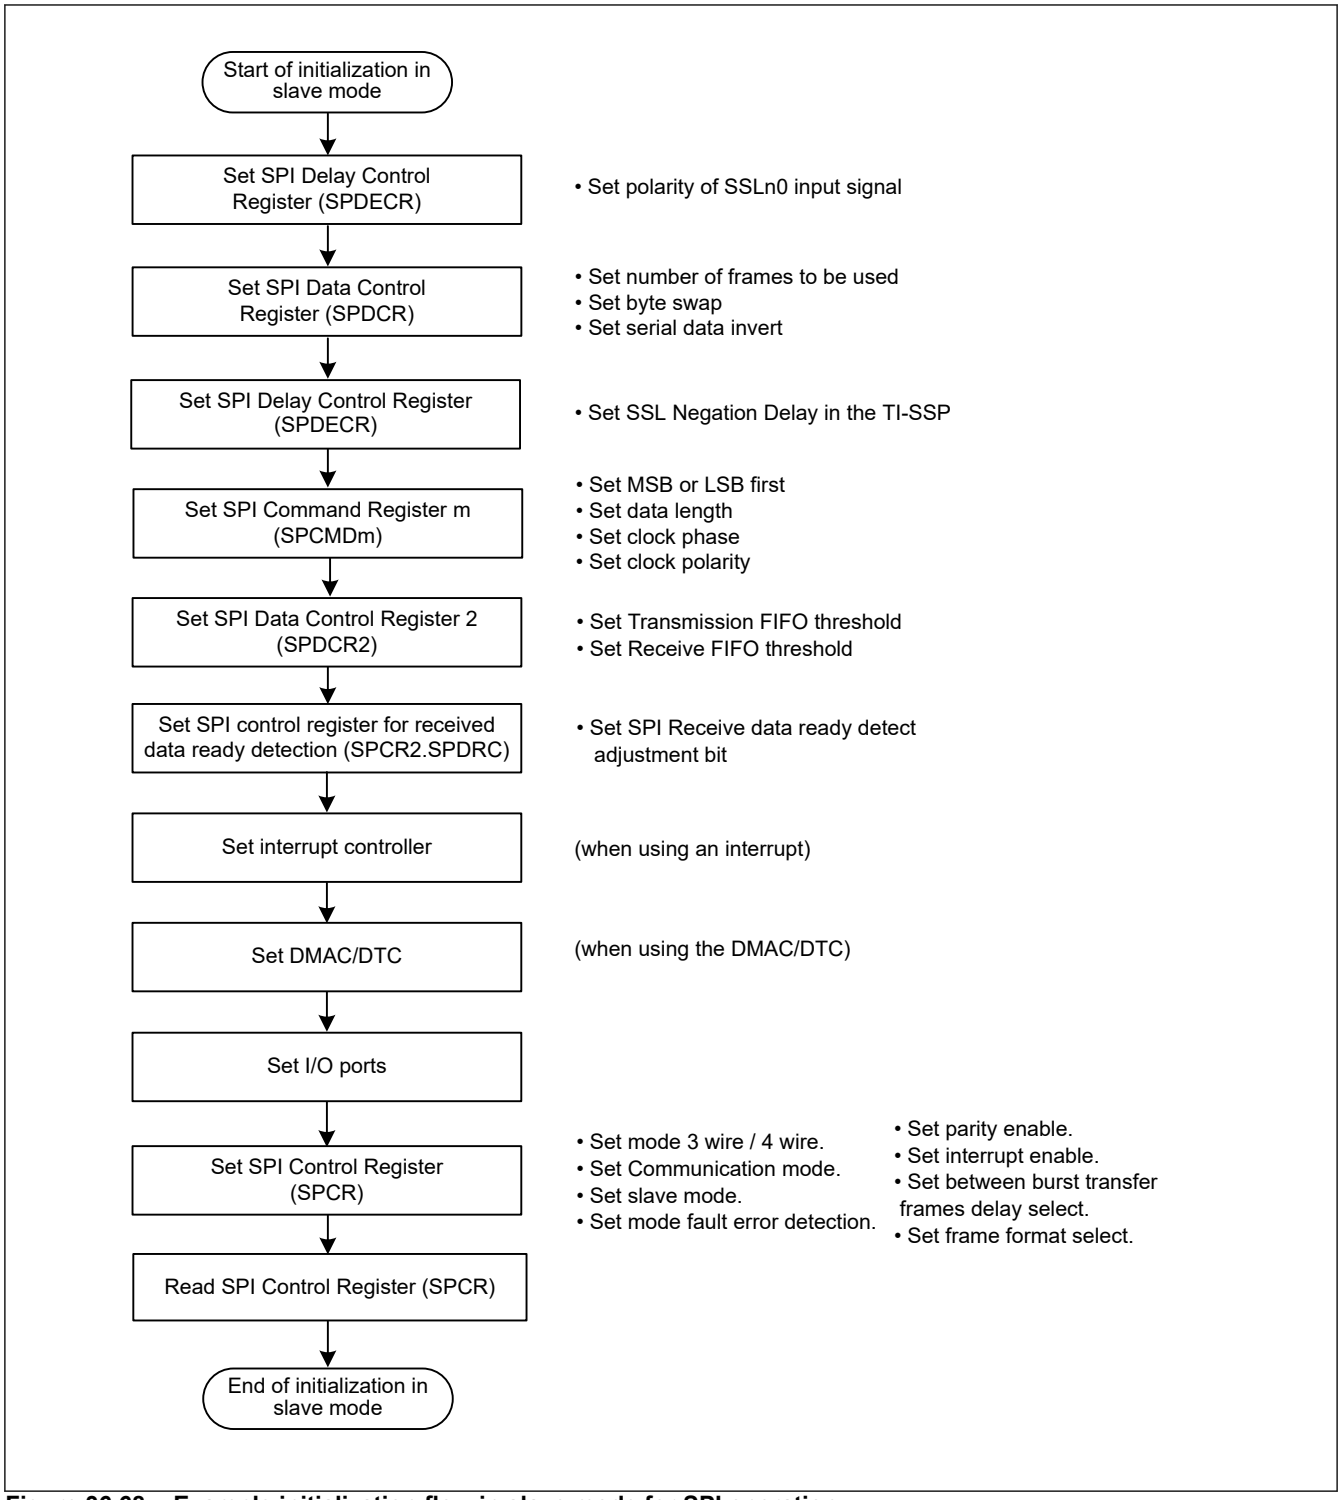

Figure 36.68 Example initialization flow in slave mode for SPI operation

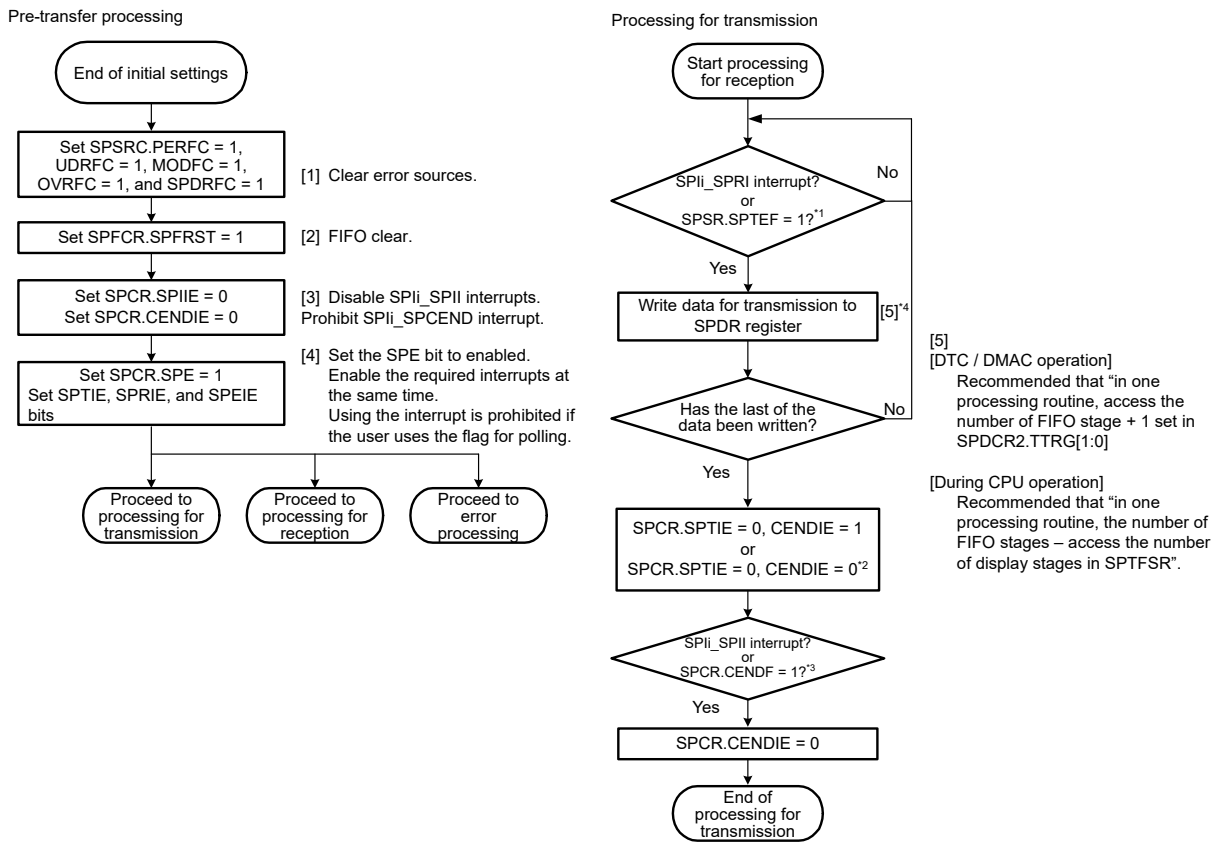
(6) Software processing flow

Figure 36.69 to Figure 36.72 show examples of the flow of software processing.

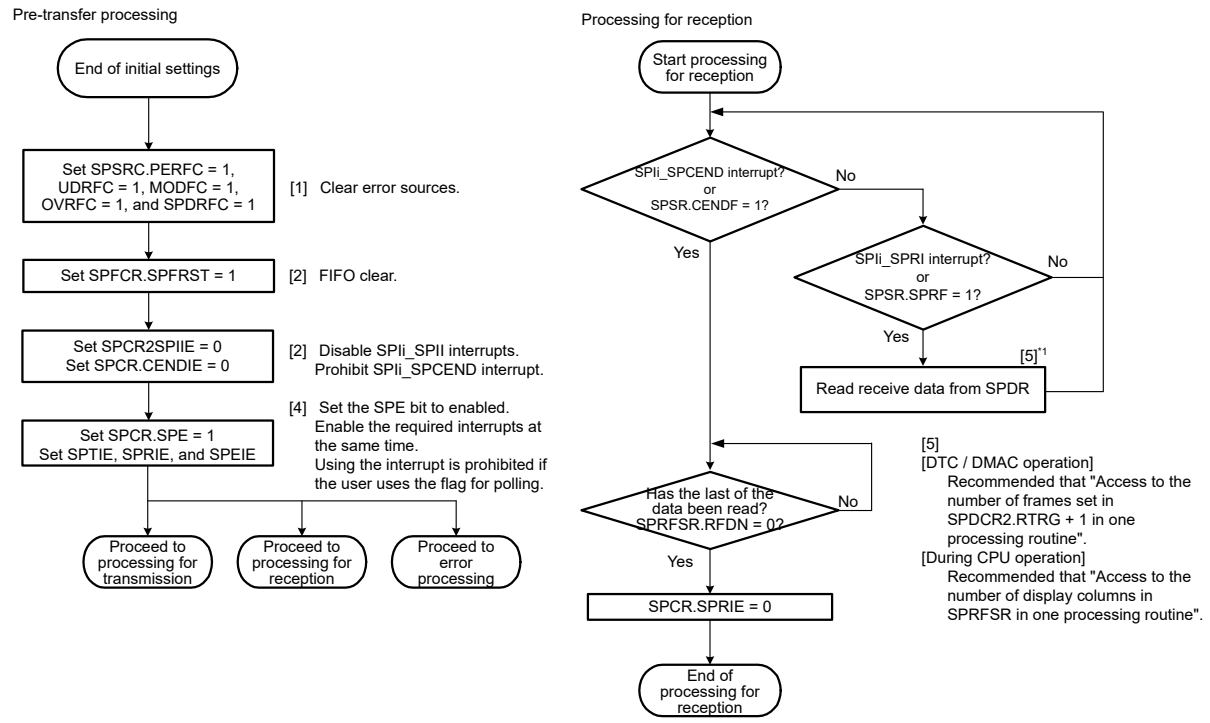
Transmit processing flow



Note 1. Before writing data for transmission to SPDR register, check the transmit buffer empty interrupt by reading SPSR.SPTEF flag, if the flag for polling is used.
Note 2. Set SPIi_SPCEND interrupt prohibited (SPCR.CENDIE = 0), if the user uses the flag for polling.
Note 3. Wait more than 1 PCLK, after writing data for transmission to SPDR, and before starting polling of SPSR.IDLNF or SPSR.CENDF, if the user uses the flag for polling.
Note 4. During CPU operation, write 1 to SPI transmit buffer empty flag clear bit (SPSRC.SPTEFC) after one processing routine.

Figure 36.69 Transmission flow in slave mode

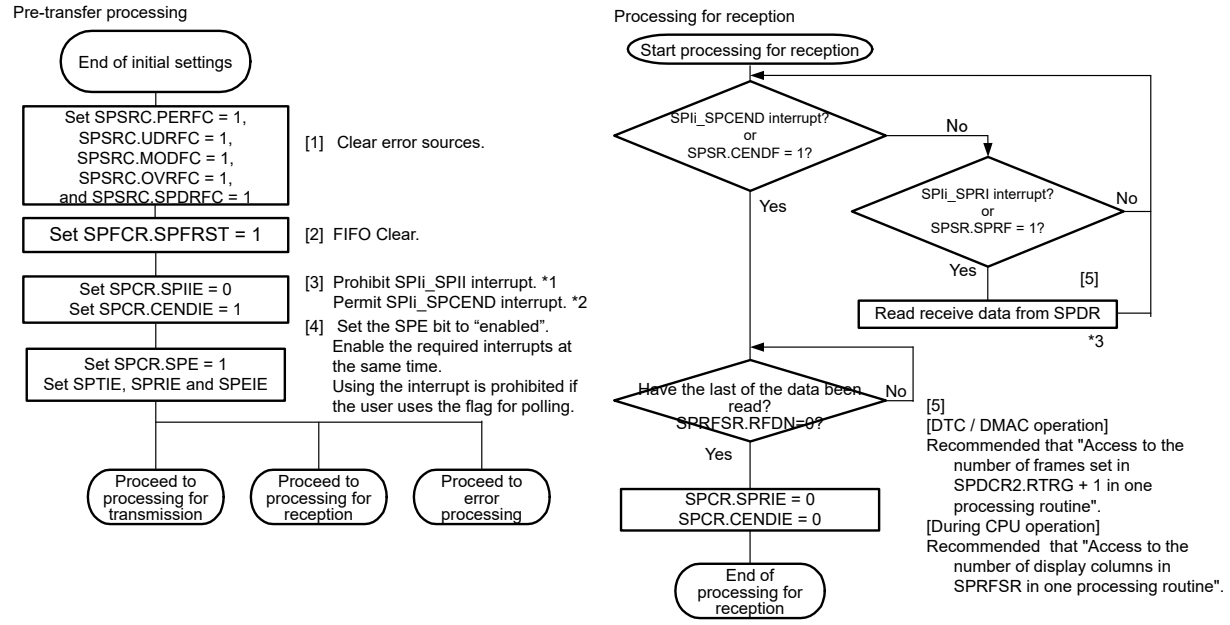
Receive processing flow



Note 1. During CPU operation, write 1 to the SPI receive buffer full flag clear bit (SPSRC.SPTEFC) after one processing routine.

Figure 36.70 Reception flow in slave mode

Master Reception-only processing flow



Note 1. The end of communication can be determined by the SPIi_SPCEND interrupt (CENDF flag). Use the SPIi_SPCEND interrupt (CENDF flag).
Note 2. Disable the SPIi_SPCEND interrupt (SPCR.CENDIE = 0) during flag polling.
Note 3. During CPU operation, write 1 to the SPI receive buffer full flag clear bit (SPSRC.SPTEFC) after one processing routine.

Figure 36.71 Software Processing Flowchart in Master Mode (Reception-only)

Error processing flow

In slave mode operation, even when a mode fault error is generated, the SPSR.MODF flag can be cleared regardless of the state of the SSLn0 pin.

When an error is detected by using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi_SPTI or SPIi_SPRI interrupt request. If the SPIi_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

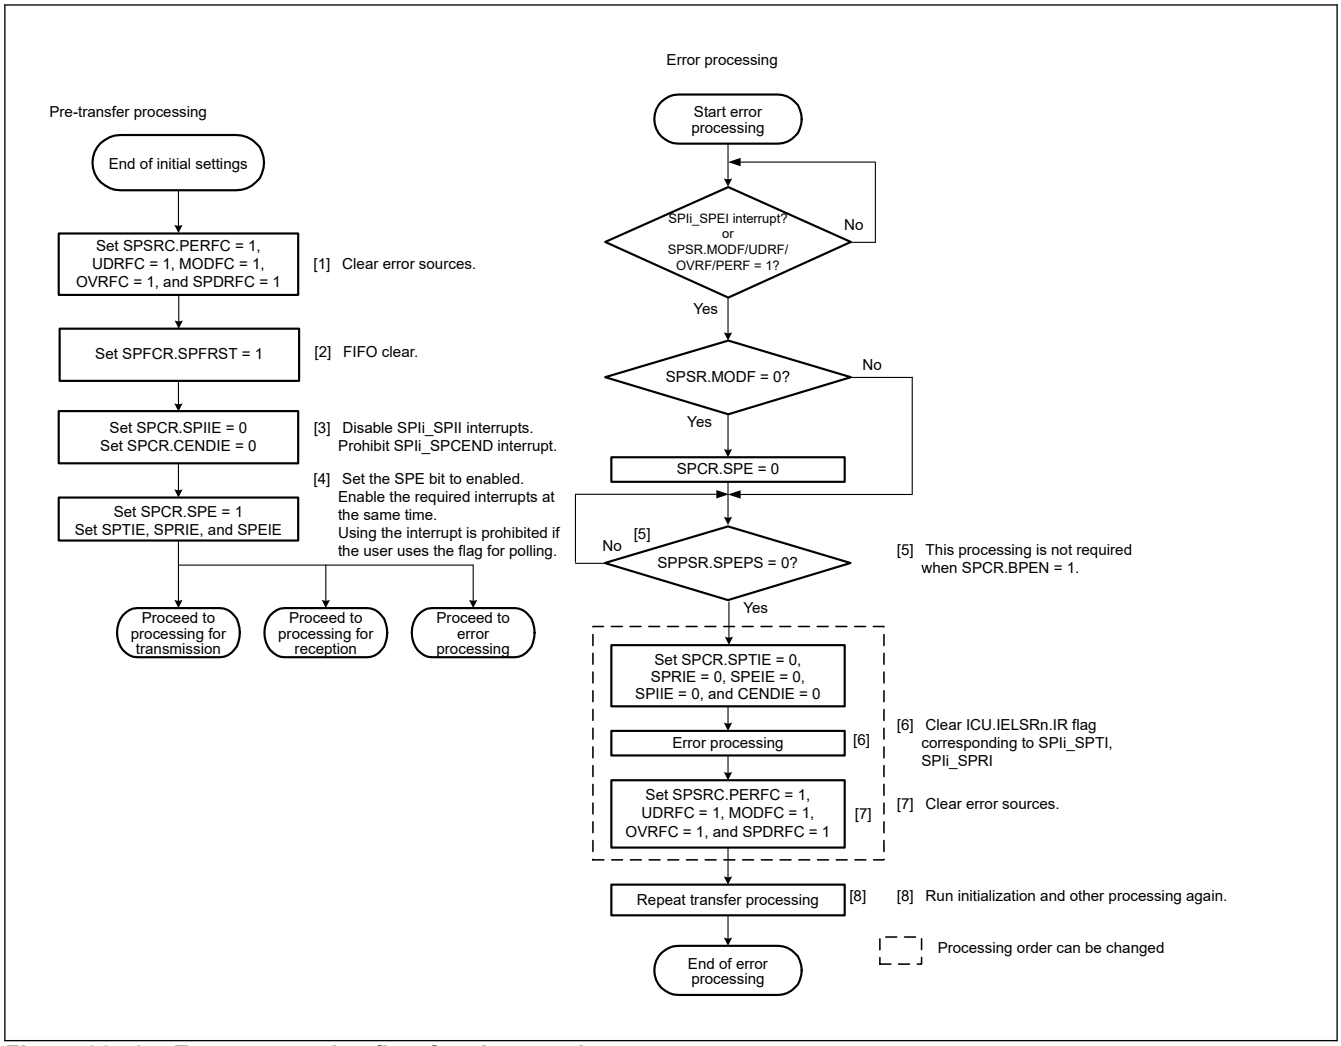


Figure 36.72 Error processing flow for slave mode

36.3.13 Clock Synchronous Operation

Setting the SPCR.SPMS bit to 1 selects clock synchronous operation of the SPI. In clock synchronous operation, the SSLni pin is not used, and the RSPCKn, MOSIn, and MISOn pins handle communications. All SSLni pins are available as I/O port pins.

Although clock synchronous operation does not require the use of the SSLni pin, operation of the module is the same as in SPI operation. In both master mode and slave mode operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected, because the SSLni pin is not used.

Additionally, do not perform operation if clock synchronous operation is enabled when the SPCMDm.CPHA bit is set to 0 in slave mode (SPCR.MSTR = 0).

36.3.13.1 Master mode operation

(1) Starting serial transfer

When data is written to the SPI data register (SPDR) while the next transfer data is not set in the transmit FIFO, the SPI updates the transmit buffer (SPTXn, n = 0 to 3) data in SPDR.While the shift register is empty, the SPI copies transmit buffer data to the shift register to start serial transfer. After the SPI copies transmit data to the shift register, it changes the shift register status to full. Upon completion of serial transfer, the SPI changes the shift register status to empty. The shift register status cannot be monitored.

For details about the SPI transfer format, see section 36.3.5. Transfer Formats. In clock synchronous operation, however, the SSLn0 output signal is not used for communication.

(2) Terminating serial transfer

The SPI terminates the serial transfer after transmitting an RSPCKn edge corresponding to the sampling timing. If the number of data stored in the receive FIFO < the number of FIFO stages, on termination of serial transfer, the SPI copies data from the shift register to the receive buffer of the SPI Data Register (SPDR).

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[4:0] bits setting. Transfer in clock synchronous operation is conducted without the SSLn0 output signal. For details on the SPI transfer format, see section 36.3.5. Transfer Formats.

(3) Sequence control

The transfer format used in master mode is determined by the SPCR3, SPCMDm, and SPDECR registers. Although the SSLni signals are not output in clock synchronous operation, these settings are valid.

The SPCR3.SPSLN[2:0] bits determine the sequence configuration for serial transfers that are executed by the SPI in master mode. The following parameters are specified in the SPCMDm register:

- SSLni output signal value
- MSB or LSB first
- Data length
- Some of the bit rate settings
- RSPCKn polarity and phase
- Whether SPDECR.SCKDL is to be referenced
- Whether SPDECR.SLNDL is to be referenced
- Whether SPDECR.SPNDL is to be referenced

SPCR3.SPBR holds some of the bit rate settings such as SPDECR.SCKDL, an SPI clock delay value, SPDECR.SLNDL, an SSL negation delay, and SPDECR.SPNDL, a next-access delay value.

Based on the sequence length that is assigned to SPCR3, the SPI makes up a sequence comprised of a part or all of SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPDCR2.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command comprising the sequence, the SPI sets the pointer to the SPCMD0 register, and in this manner the sequence is executed repeatedly.

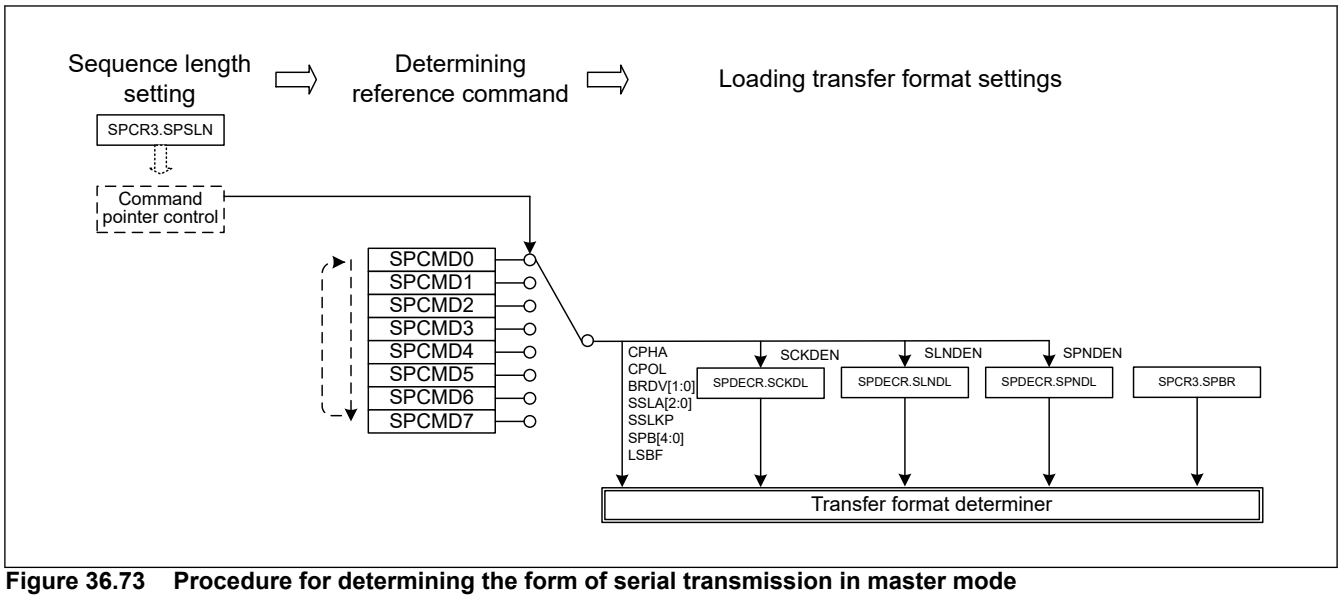

Figure 36.73 Procedure for determining the form of serial transmission in master mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

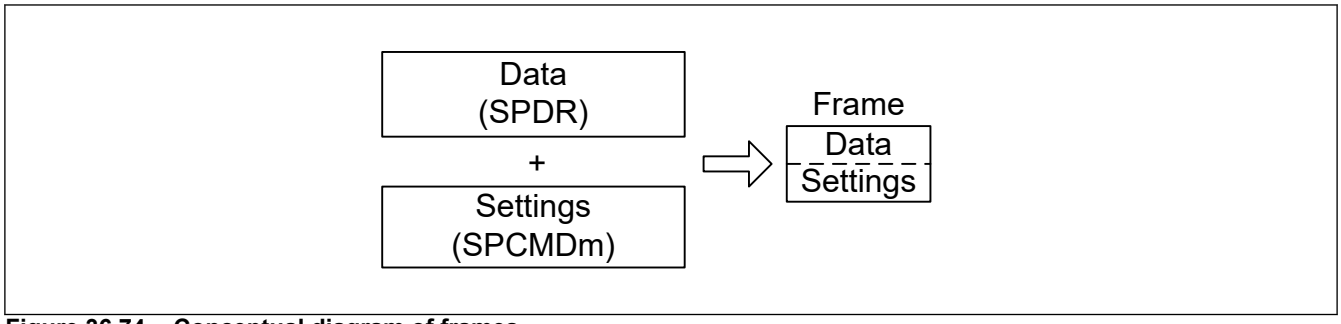

Figure 36.74 Conceptual diagram of frames

Figure 36.75 shows the relationship between the command and the transmit and receive buffers in the sequence of operations specified by the settings.

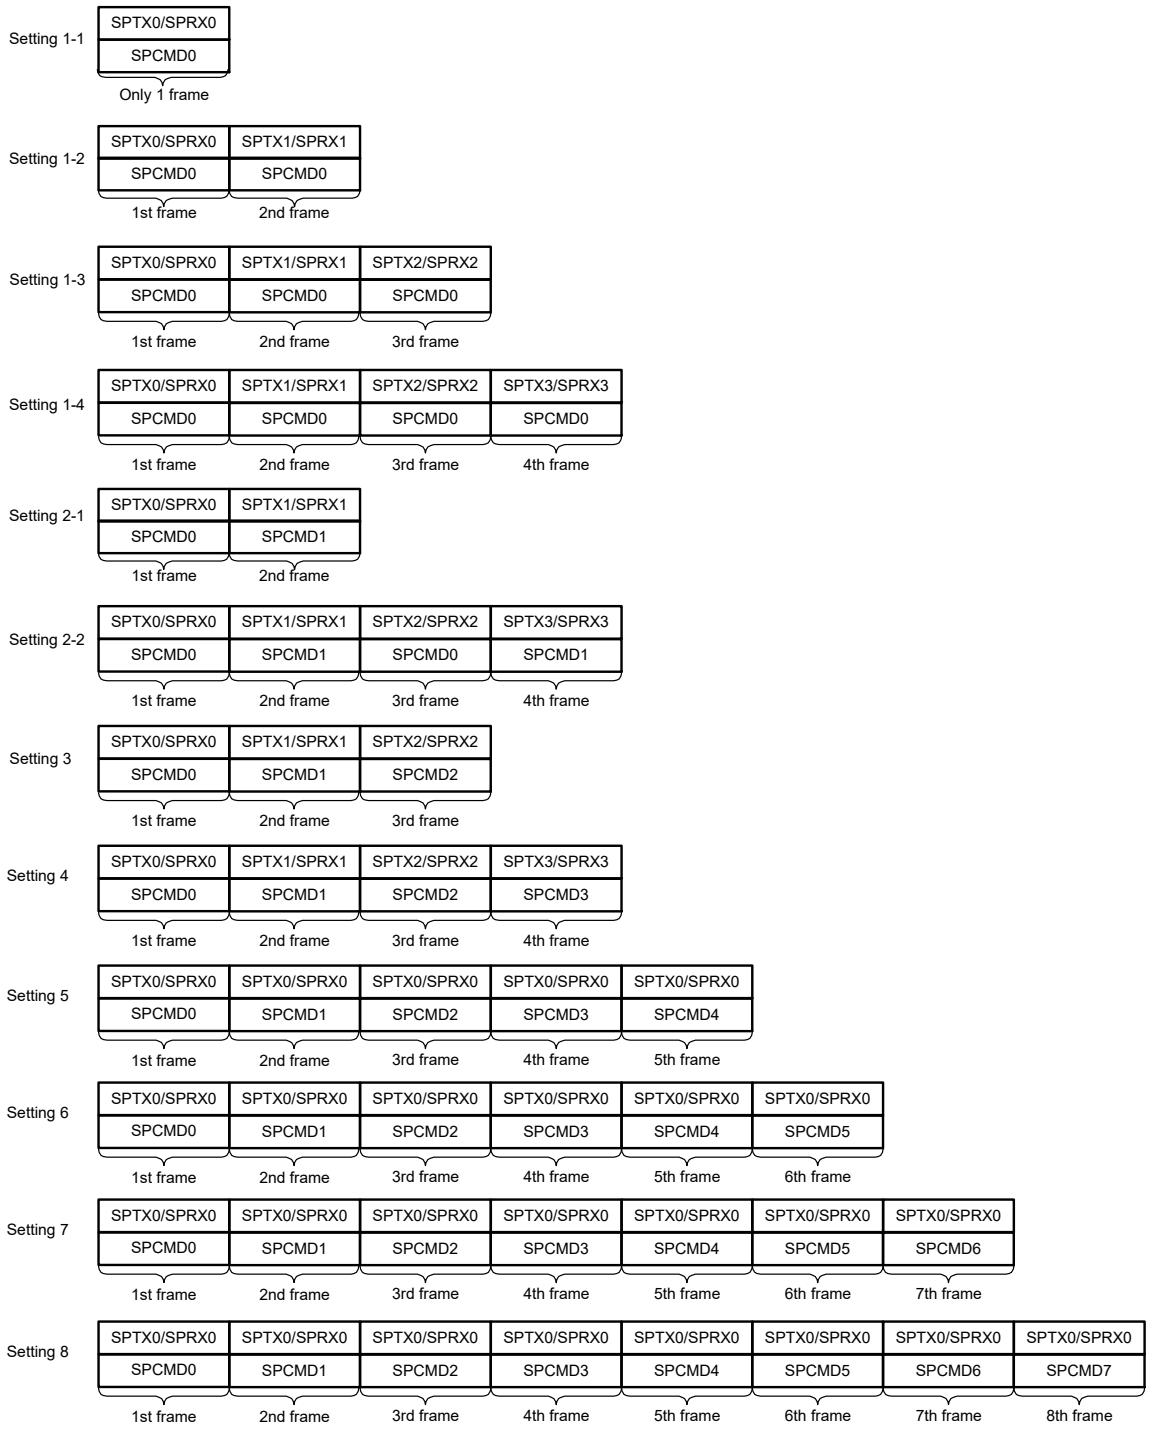

Figure 36.75 Correspondence between SPI Command Register and transmit and receive buffers in sequence operations

(4) Initialization flow

Figure 36.76 shows an example of initialization flow for clock synchronous operation when the SPI is used in master mode. For information on how to set up the ICU, DMAC or DTC, and I/O ports, see the descriptions given in the individual blocks.

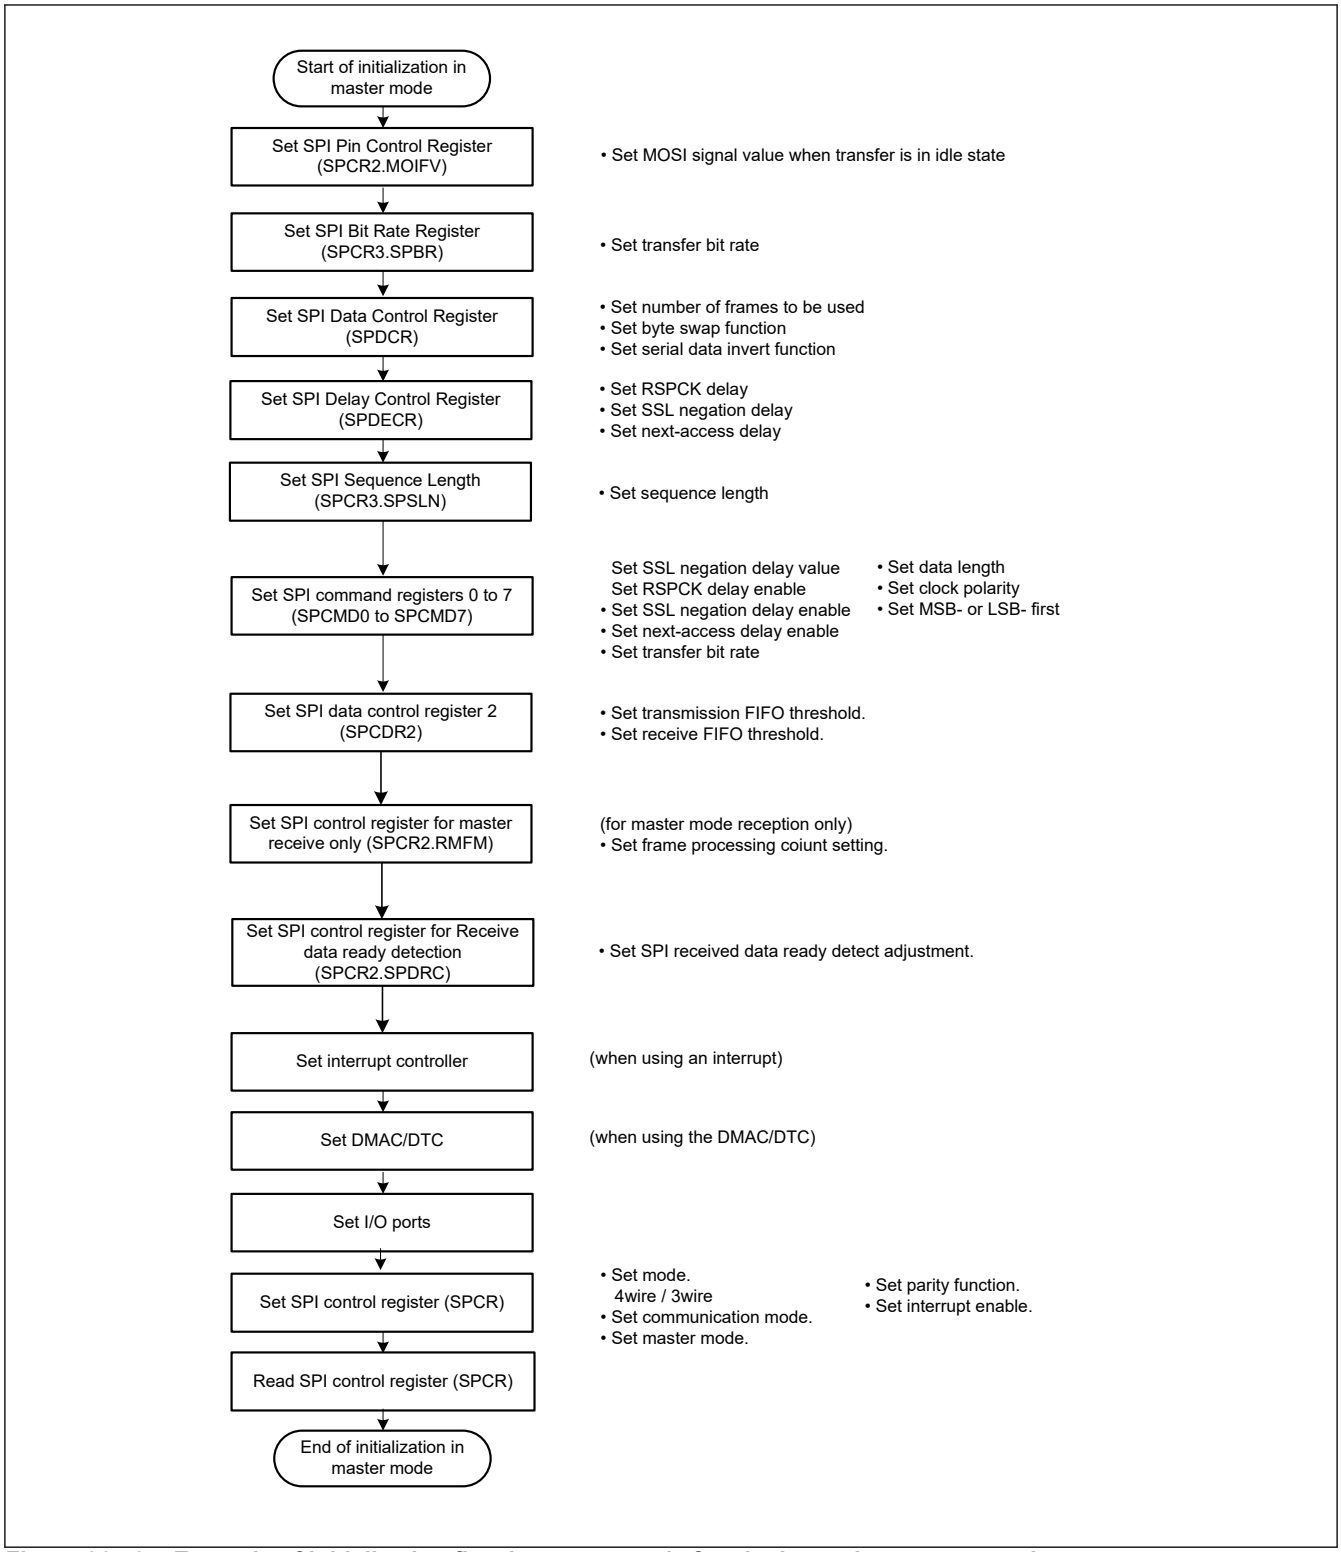

Figure 36.76 Example of initialization flow in master mode for clock synchronous operation

(5) Software processing flow

Software processing during clock synchronous master operation is the same as that for SPI master operation. For details, see (9) Software processing flow in section 36.3.12.1. Master mode operation. Mode fault errors do not occur in clock synchronous operation.

36.3.13.2 Slave mode operation

(1) Starting serial transfer

When the SPCR.SPMS bit is 1, the first RSPCKn edge triggers the start of a serial transfer in the SPI, and the SPI drives the MISOn output signal. The SSLn0 input signal is not used in clock synchronous operation. For details on the SPI transfer format, see section 36.3.5. Transfer Formats.

(2) Terminating serial transfer

The SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When the number of data stored in the receive FIFO < the number of FIFO stages, on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR register. On termination of a serial transfer, the SPI changes the status of the shift register to empty regardless of the receive buffer.

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length depends on the SPCMD0.SPB[4:0] bits setting. For details on the SPI transfer format, see section 36.3.5. Transfer Formats.

(3) Initialization flow

Figure 36.77 shows an example of initialization flow for clock synchronous operation when the SPI is used in slave mode. For a description of how to set up the ICU, DMAC or DTC, and I/O ports, see the descriptions given in the individual blocks.

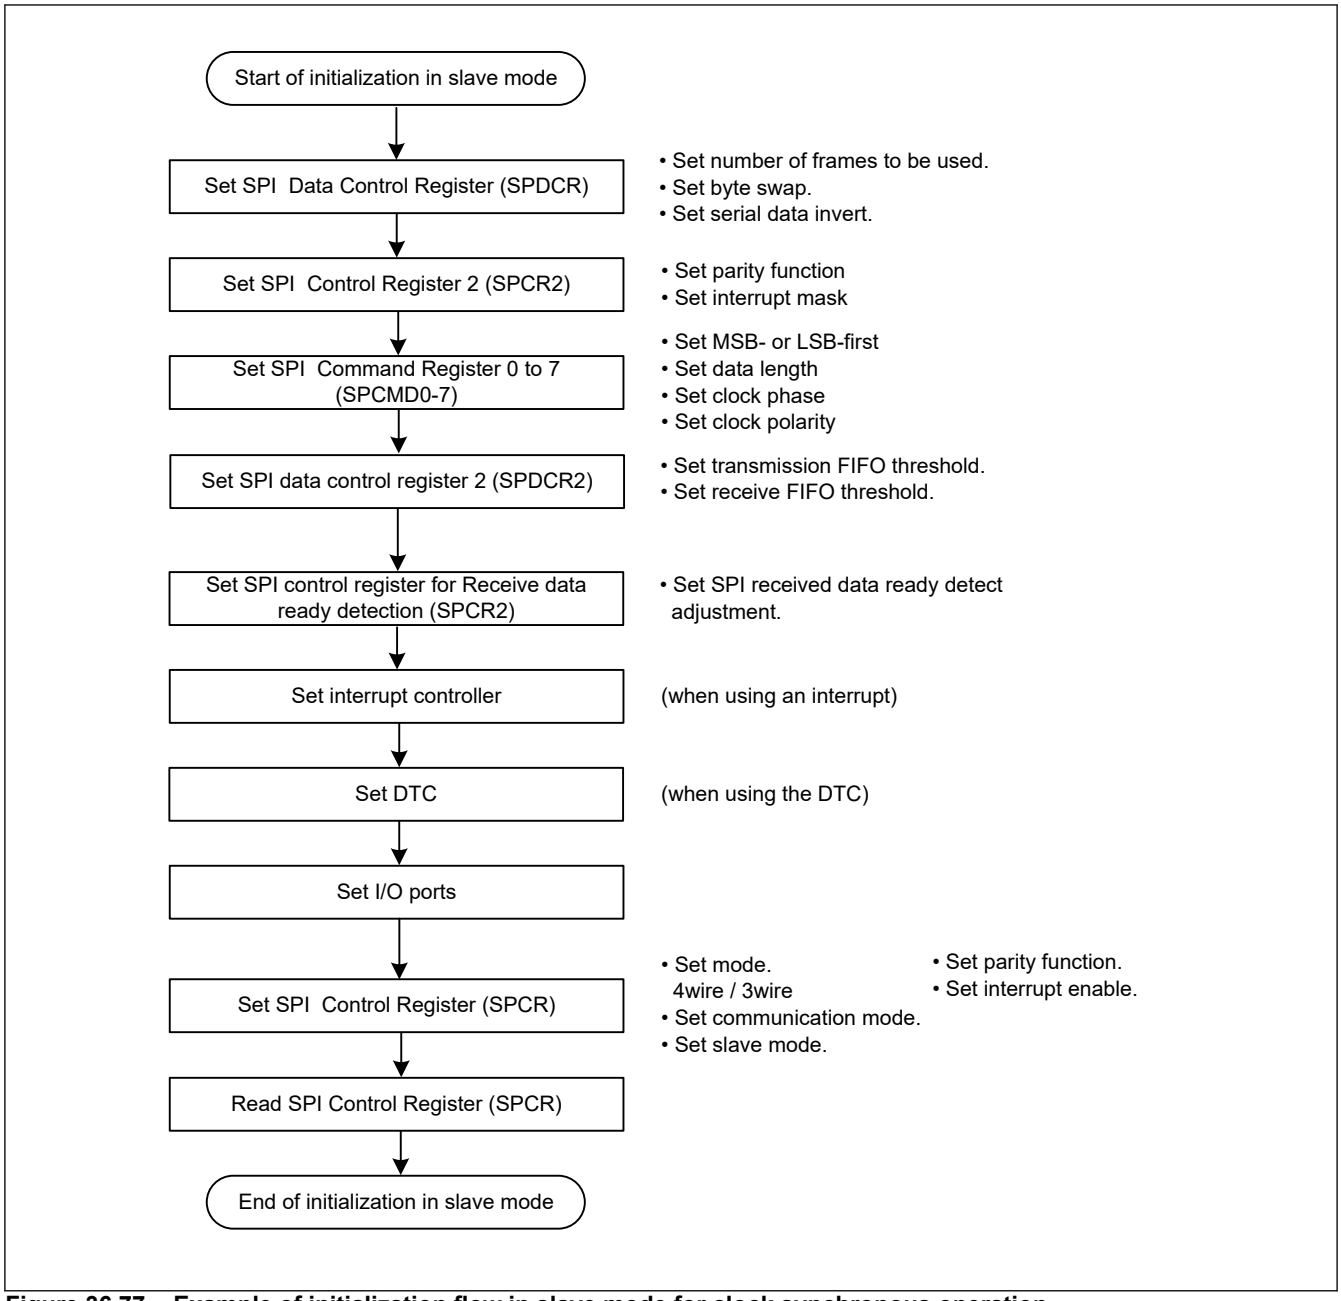

Figure 36.77 Example of initialization flow in slave mode for clock synchronous operation

(4) Software processing flow

Software processing during clock synchronous slave operation is the same as that for SPI slave operation. For details, see (6)Software processing flow. Mode fault errors do not occur in clock synchronous mode.

36.3.14 Loopback Mode

When 1 is written to the SPCR2.SPLP2 bit or SPCR2.SPLP bit, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, or between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0, and connects the input and output paths of the shift register, establishing a loopback mode. The SPI does not shut off the path between the MOSIn pin and the shift register if the SPCR.MSTR bit is 1, or between the MISOn pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data for the SPI or the reversed transmit data becomes the received data for the SPI.

Table 36.13 lists the relationship between the SPLP2 and SPLP bits and the received data. Figure 36.78 shows the configuration of the shift register I/O paths when the SPI in master mode is set to loopback mode (SPCR2.SPLP2 = 0, SPCR2.SPLP = 1).

Table 36.13 SPLP2 and SPLP bit settings and received data

SPCR2.SPLP2 bit	SPCR2.SPLP bit	Received data
0	0	Input data from the MOSIn pin or MISOn pin
0	1	Inverted transmit data
1	0	Transmit data
1	1	Transmit data

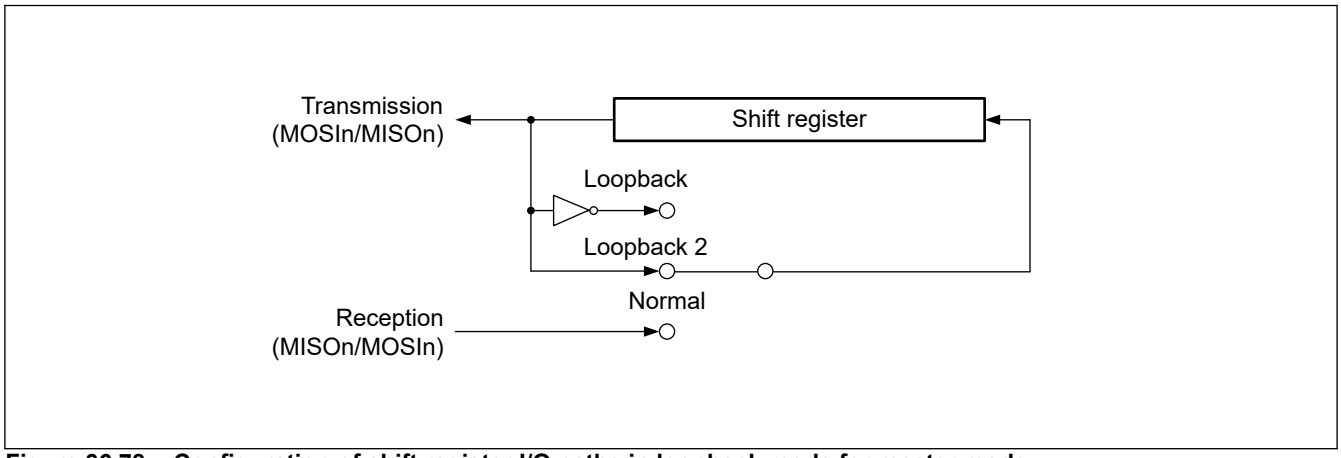

Figure 36.78 Configuration of shift register I/O paths in loopback mode for master mode

36.3.15 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. To detect defects in the parity bit adding unit and error detecting unit, the parity circuit performs self-diagnosis as shown in Figure 36.79.

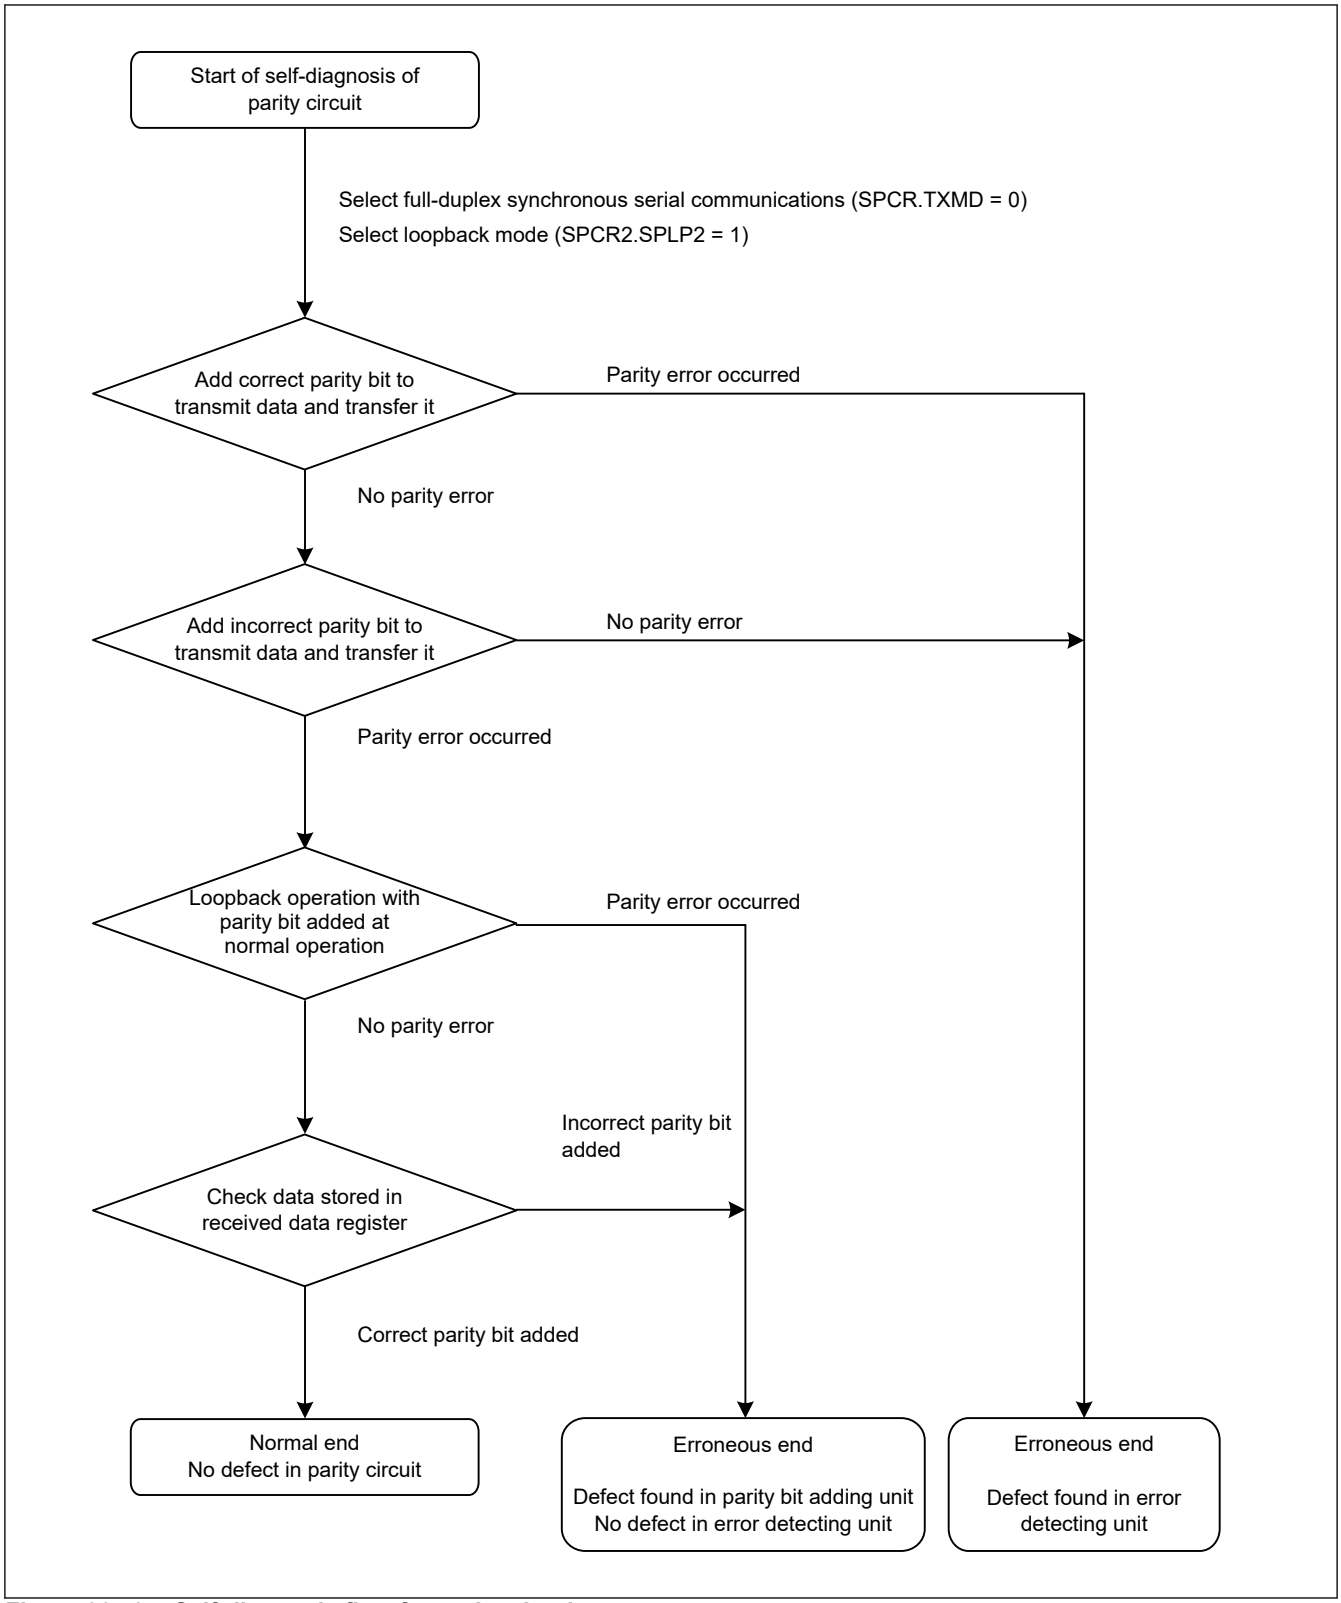

Figure 36.79 Self-diagnosis flow for parity circuit

36.3.16 Interrupt Sources

The SPI has the following interrupt sources:

- Receive buffer full
- Transmit buffer empty

- SPI error (mode-fault, underrun, overrun, or parity error)
- SPI idle
- Communication-end

The DMAC or DTC can be activated by the receive buffer full or transmit buffer empty interrupt to perform data transfer.

Because the vector address for the SPIi_SPEI (SPI error interrupt) is allocated to interrupt requests on mode-fault, underrun, overrun, and parity errors, the actual interrupt source must be determined from the flags. Interrupt sources for the SPI are listed in Table 36.14. An interrupt is generated on satisfaction of one of the interrupt conditions in Table 36.14. Clear the receive buffer full and transmit buffer empty sources through a data transfer.

When using the DMAC or DTC to perform data transmission and reception, you must first set up the DMAC or DTC to be in a transfer-enabled status before setting the SPI. For information on setting up the DMAC or DTC, see section 16, DMA Controller (DMAC) and section 17, Data Transfer Controller (DTC).

If the conditions for generating a transmit buffer empty or receive buffer full interrupt occur while the ICU.IELSRn.IR flag is 1, the interrupt is not output as a request for the ICU but is retained internally (the capacity for retention is one request per source). A retained interrupt request is output when the ICU.IELSRn.IR flag becomes 0. A retained interrupt request is automatically discarded when it is output as an actual interrupt request. The interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) for an internally retained interrupt request can also be set to 0.

Table 36.14 SPI interrupt sources

Interrupt source	Symbol	Interrupt condition	DTC/DMAC activation
Receive buffer full	SPIi_SPRI	The receive buffer becomes full (SPSR.SPRF flag is 1) while the SPCR.SPRIE bit is 1 or The receive data become ready (SPSR.SPDRF flag is 1) while the SPCR.SPDRES bit is 0	Possible
Transmit buffer empty	SPIi_SPTI	The transmit buffer becomes empty (SPSR.SPTEF flag is 1) while the SPCR.SPTIE bit is 1	Possible
SPI error (mode-fault, underrun, overrun, or parity error)	SPIi_SPEI	The SPSR.MODF, OVRF,or PERF flag sets to 1, or the SPSR.SPDRES and SPDRF flag set to 1 while the SPCR.SPEIE bit is 1	Impossible
SPI idle	SPIi_SPII	The SPSR.IDLNF flag sets to 0 while the SPCR.SPIIE bit is 1	Impossible
Communication-end	SPIi_SPCEND	CENDIE = 1 and CENDF = 1	Impossible

36.4 Event Link Controller Event Output

The Event Link Controller (ELC) can produce the following event output signals:

- Receive buffer full event output
- Transmit buffer empty event output
- Mode-fault, underrun, overrun, or parity error event output
- SPI idle event output
- Transmission-completed event output

The event link output signal is output regardless of the interrupt enable bit setting.

36.4.1 Receive Buffer Full Event Output

When the number of data stored in the receive FIFO > the threshold value, or when the number of data stored in the receive FIFO ≤ the threshold value and SPDRES = 0 has elapsed after writing to the receive FIFO, and the SPDRC [7:0] has elapsed outputs an event.

36.4.2 Transmit Buffer Empty Event Output

An event is output when the number of empty transmission FIFO stage > the threshold or when the SPCR.SPE bit changes from 0 to 1.

36.4.3 Mode-Fault, Underrun, Overrun, Parity Error, or received data ready Event Output

This event signal is output when mode-fault, underrun, overrun, or parity error is detected. See section 36.5.4. Constraints on Mode-Fault, Underrun, Overrun, Parity Error, or Receive Data Ready Event Output if using this event signal.

(1) Mode-fault

Table 36.15 lists the conditions for occurrence of a mode-fault event.

Table 36.15 Conditions for mode-fault occurrence

SPI mode	SPCR.MODFEN bit	SSLn0 pin	Remarks
SPI operation (SPMS = 0) Slave (SPCR.MSTR = 0) Motorola-SPI (SPCR.SPFRF = 0)	1	Not active	Event is output only when the SSLn0 pin is deactivated during transmission
SPI operation (SPMS = 0) Slave (SPCR.MSTR = 0) TI-SSP (SPCR.SPFRF = 1)	1	active	Event is output only when the SSLn0 pin is activated during transmission

(2) Underrun

This event signal is output in response to an underrun when a serial transfer starts while the transmission data is not ready, and the value of the SPCR.MSTR bit is 0 and the SPCR.SPE bit is 1. Under these conditions, the MODF and UDRF flags are set to 1.

(3) Overrun

This event signal is output in response to an overrun when a serial transfer completes while the receive buffer contains unread data and the value of the SPCR.TXMD[1:0] bits are 00b or 10b. Under these conditions, the OVRF flag is set to 1.

(4) Parity error

This event signal is output in response to a parity error detected on completion of a serial transfer while the value of the SPPE bit in SPCR is 1.

(5) Receive Data Ready

When TXMD[1:0] of SPCR = 00b or 10b and SPDRES = 1 as the receive data ready event output condition, the number of data stored in the receive FIFO is received after writing the receive FIFO. An event will be output when the set value of SPDRC[7:0] has elapsed while the number is less than the FIFO threshold.

36.4.4 SPI Idle Event Output

(1) In master mode

In Transmit-Receive / Transmit-only master mode, an event is output when the IDLNF flag in SPSR changes from 1 to 0.

The IDLNF flag changes from 1 to 0 only when either of the conditions 1) and 2) below is met.

1. The SPE bit in SPCR is cleared to 0 (SPI initialized) during transmission.
2. All of the following three conditions are met.
   - The transmit buffer (SPTXn, n = 0 to 3) is empty (next transfer data has not been set).
   - The SPCP [2:0] bits in SPSR are 000b (at the start of sequence control).
   - Operation completed by the next access delay (when the master main state machine transitions to the idle state).

In receive only master mode

Any of the following 2 conditions is met.

1. SPE bit of SPCR is 0 (SPI initialization)
2. When any of the following is met
   - When RMFM [4:0] = 0x00, after writing 1 to RMEDTG, operation completed by the next access delay (when the master main state machine transitions to the idle state).

- When RMFM [4:0] ≠ 0x00, after writing 1 to RMEDTG, operation completed by the next access delay (when the master main state machine transitions to the idle state).
- When RMFM [4:0] ≠ 0x00, the SPI internal sequencer transitions to the idle state after operation completed by the next access delay (when the master main state machine transitions to the idle state).

(2) In slave mode

In slave mode, an event is output when the SPCR.SPE bit is set to 0 (SPI is initialized).

36.4.5 Communication End Event Output

In master mode, an event is output when the IDLNF flag (SPI idle flag) changes from 1 to 0. In slave mode, an event occurs with conditions shown in Table 36.16 and Table 36.17

Table 36.16 Communication End Event Generating Conditions (transmit-receive/transmit slave mode)

	Transmit Buffer Status	Shift Register Status	Others
SPI operation (SPMS = 0, SPFRF = 0)	Empty	Empty	SSLn0 input is negated
SPI operation (SPMS = 0, SPFRF = 1)	Empty	Empty	SSL negation delay completed
Clock synchronous operation (SPMS = 1)	Empty	Empty	The last even edge of RSPCK of last data was detected (CPHA = 1)

Table 36.17 Communication End Event Generating Conditions (receive only slave mode)

	Others
SPI operation (SPMS = 0, SPFRF = 0)	After storing the frames corresponding to the SPFC setting value in the receive buffer, negate SSLn0 input.
SPI operation (SPMS = 0, SPFRF = 1)	After storing the frames corresponding to the SPFC setting value in the receive buffer, SSL negation delay completed
Clock synchronous operation (SPMS = 1)	RSPCK last even edge detection when receiving the last frame for the SPFC set value (CPHA = 1)

Regardless of master mode or slave mode, no event is output when 0 is written to the SPCR.SPE bit during transmission or when the SPCR.SPE bit is cleared due to a mode fault error or an underrun error.

A communication end event is output at the following timing. The communication end event output timing in master operation is omitted because it is output at the same timing as an idle event.

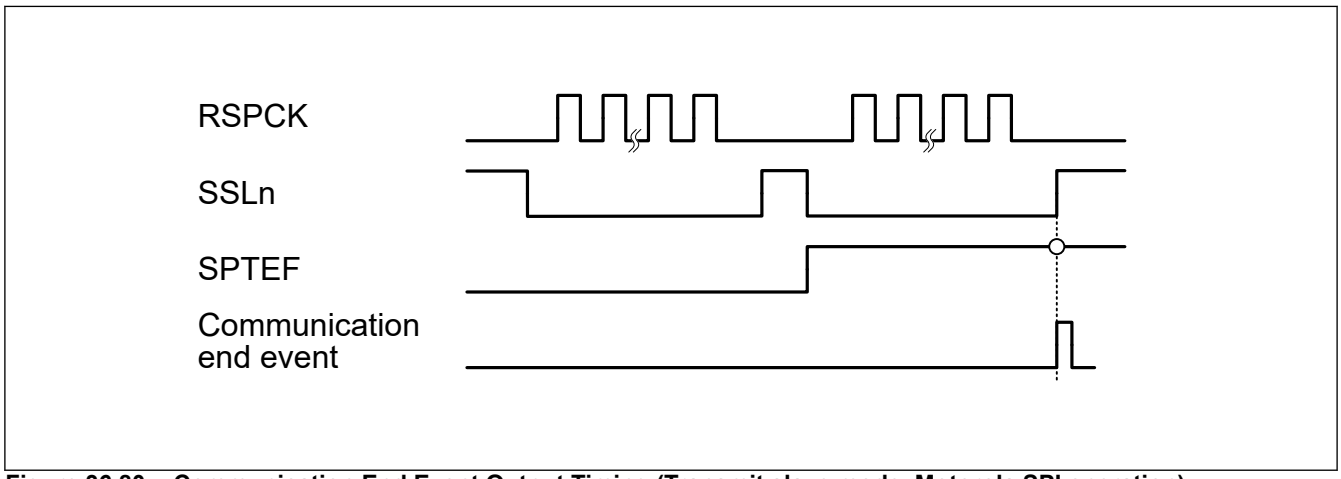

Figure 36.80 Communication End Event Output Timing (Transmit slave mode, Motorola SPI operation)

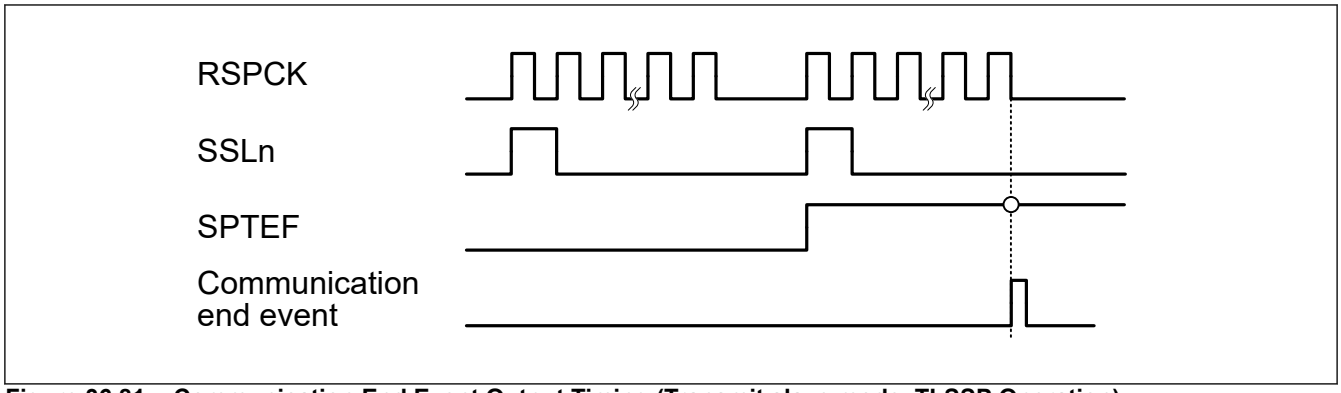

Figure 36.81 Communication End Event Output Timing (Transmit slave mode, TI-SSP Operation)

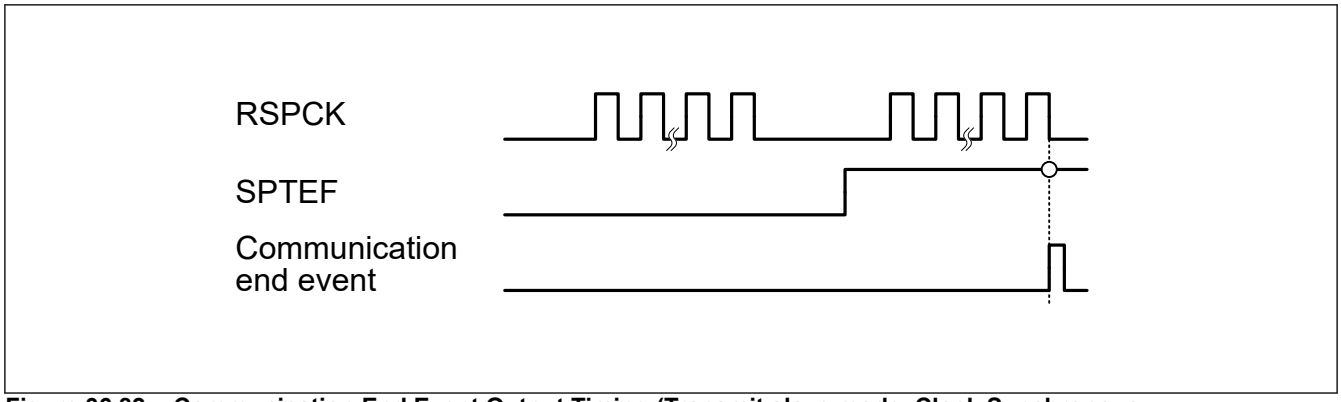

Figure 36.82 Communication End Event Output Timing (Transmit slave mode, Clock Synchronous Operation)

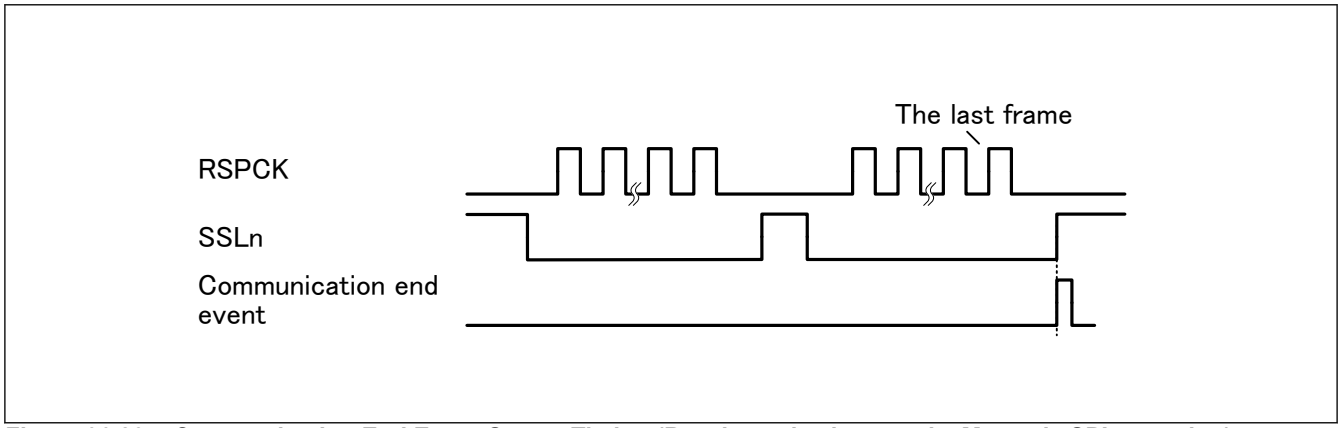

Figure 36.83 Communication End Event Output Timing (Receive only slave mode, Motorola SPI operation)

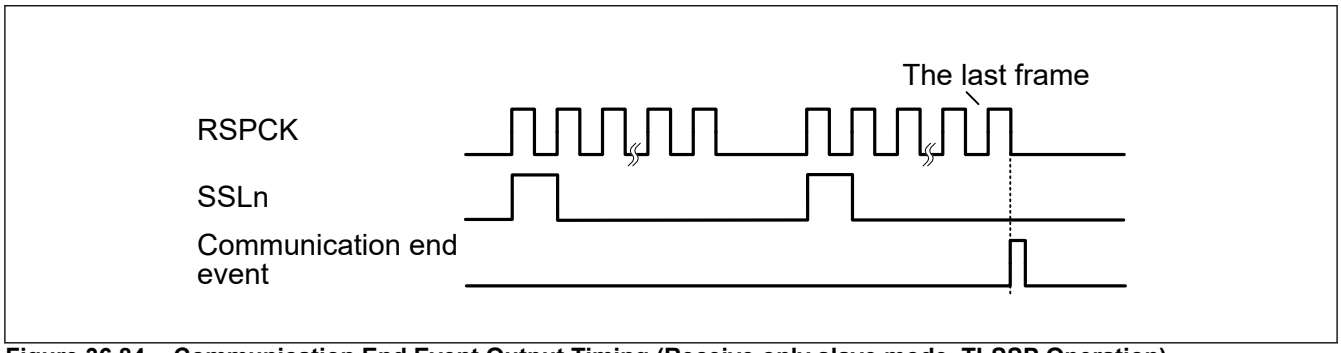

Figure 36.84 Communication End Event Output Timing (Receive only slave mode, TI-SSP Operation)

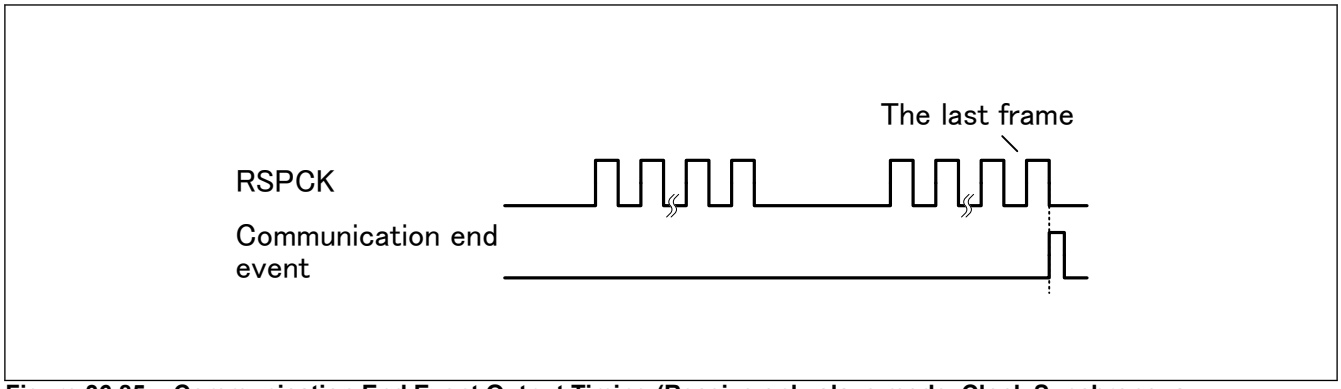

Figure 36.85 Communication End Event Output Timing (Receive only slave mode, Clock Synchronous Operation)

36.4.6 Synchronization bypass function

SPI has an internal clock (PCLK) and an operation clock (TCLK), and each has its own operation circuit. Therefore, a synchronization circuit is inserted between the signals between different clocks, and a signal delay between different clocks requires a synchronization delay time.

However, the synchronization circuit can be bypassed by the BPEN = 1 of the SPI control register (SPCR) only when the same clock is input as the internal bus clock and the operation clock. In this case, the synchronization delay time is excluded, and responsiveness is improved.

In addition, SPI has a synchronization circuit between the communication clock (RSPCK) and the operation clock (TCLK), but this synchronization circuit cannot be bypassed.

36.5 Usage Notes

36.5.1 Settings for the Module-Stop State

The Module Stop Control Register B (MSTPCRB) can enable or disable the SPI operation. The SPI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details on the Module Stop Control Register B, see section 10, Low Power Modes.

36.5.2 Constraint on Low-Power Functions

When using the module-stop function and entering a low-power mode other than CPU Sleep mode or CPU Deep Sleep mode, set the SPCR.SPE bit to 0 before completing communication.

36.5.3 Constraints on Starting Transfer

If the ICU.IELSRn.IR flag is 1 when transfer starts, the interrupt request is internally retained, which can lead to unanticipated behavior of the ICU.IELSRn.IR flag.

To prevent this, use the following procedure to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1):

1. Confirm that transfer stopped (the SPCR.SPE bit is 0).
2. Set the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0.
3. Read the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) and confirm that its value is 0.
4. Set the ICU.IELSRn.IR flag to 0.

36.5.4 Constraints on Mode-Fault, Underrun, Overrun, Parity Error, or Receive Data Ready Event Output

Using the mode-fault, underrun, overrun, parity error, or receive data ready event is prohibited if the SPI is in multi-master mode (when the SPCR.SPMS bit is 0, the SPCR.MSTR bit is 1, and the SPCR.MODFEN bit is 1).

36.5.5 Constraints on the SPSR.SPRF and SPSR.SPTEF Flags

If the polling flags, SPRF and SPTEF, are used, using the interrupts is prohibited, and you must set the SPCR.SPRIE and SPCR.SPTIE bits to 0. Either the interrupts or the flags can be used, but not both.

37. Octal Serial Peripheral Interface (OSPI)

This is the OSPI_B version of the OSPI peripheral module.

OSPI_B is referred to as OSPI in this chapter.

37.1 Overview

The xSPI (eXpanded Serial Peripheral Interface) protocol specifies the interface for Non-Volatile Memory Devices, which provides high data throughput, low signal count, and limited backward compatibility with legacy SPI devices. The electrical interface can deliver up to 200 Mbytes per second raw data throughput. The OSPI is compliant with JEDEC standard JESD251(Profile 1.0 and 2.0), JESD251-1 and JESD252.

JESD251 specifies two interface profiles where profile 1.0 is Octal SPI and profile 2.0 is HyperBus™

Table 37.1 lists the OSPI specifications, Figure 37.1 shows a block diagram, and Table 37.2 lists the I/O pins.

Table 37.1 OSPI Specifications

Item	Description
Protocol	Compliant with the xSPI protocol
Data transmission and reception	Issue the transaction for up to 2 Slave as Master Only one of the memory devices can operate at a time.
Transfer speed	Support the transfer at xSPI200
Mode	• Support Protocol modes below – 1/4/8pin with SDR/DDR (1S-1S-1S, 4S-4D-4D, 8D-8D-8D) – 2/4pin with SDR (1S-2S-2S, 2S-2S-2S, 1S-4S-4S, 4S-4S-4S) • Configurable address length • Configurable initial access latency cycle • Support XiP mode
OSPI function	• Support Write Data Mask • Support In-band Reset • Memory-mapping – Support up to 256 MB address space each CS – Prefetch function for burst-read with low latency – Outstanding buffer for burst-write with high throughput • Manual command – Configurable up to 4 commands – Status Register Polling function • Input Strobe port timing shift
Transfer target	• ch1 : GLCDC1 bus master • ch0 : Other bus master
Decryption function	Decryption on the fly is available for memory map read
Interrupt source	Error interrupt Completion interrupt
Module-stop function	Module-stop state can be set to reduce power consumption
Trust Zone Filter	Security attribution can be set for IO register area External address space is defined as Non-secure

OM_SIO5	I/O	Data 5 input/output
OM_SIO6	I/O	Data 6 input/output
OM_SIO7	I/O	Data 7 input/output
OM_RESET	Output	Master reset status for slave0,1
OM_RSTO1	Input	Slave reset status for slave1
OM_ECSINT1	Input	Interrupt for slave1 / Error Correction Status for slave1
OM_WP1	Output	Write Protect for slave1

Note: For OM_SIO7-0, OM_SCLK, OM_SCKN and OM_DQS pins, 36Ω±5% resistor need to be put on the board to comply with JESD251 I/O driver definition. It is recommended for the operation with proper signal quality.

37.2 Register Descriptions

37.2.1 OSPI Configuration Registers

These registers configure xSPI Master function. These registers should be configured in the initialization phase before issuing xSPI transaction.

37.2.1.1 WRAPCFG : OSPI Wrapper Configuration Register

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	DSSFTCS1[4:0]					—	—	—	—	—	—	—	—	—	—	—	DSSFTCS0[4:0]					—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
12:8	DSSFTCS0[4:0]	OM_DQS shift for slave0 This field configures the number of delay cell for a OM_DQS port. It is used to adjust the OM_DQS sampling timing. When automatic calibration is enabled, it could be updated automatically. In this case, it shall not be written by user. 0x00: No shift 0x01: Add a delay of 1 cell ⋮ 0x1E: Add a delay of 30 cells 0x1F: Add a delay of 31 cells	R/W
23:13	—	These bits are read as 0. The write value should be 0.	R/W
28:24	DSSFTCS1[4:0]	OM_DQS shift for slave1 The function is same as one of slave0.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to configure xSPI Master function.

37.2.1.2 COMCFG : OSPI Common Configuration Register

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OENEGEX	OEASTEX	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ARBMD[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	ARBMD[1:0]	Channel arbitration mode This field selects the behavior when system bus accesses from ch0 and ch1 to slave devices occurred simultaneously. It is used only for memory-mapping mode. 0 0: Round-Robbin (ch0-ch1-ch0-ch1…)*1 0 1: Always ch0 win 1 0: Always ch1 win*1 1 1: Reserved	R/W
15:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
16	OEASTEX	Output Enable Asserting extension This bit extends 1 cycle output enable of OM_SIO7-0 and OM_DQS during output enable asserting. When set to 1, OM_CSn (n = 0, 1) asserting should be extended (LIOCFGCSn.CSASTEX = 1 (n = 0, 1)). This bit shall not be used in case of no latency cycle. Because OSPI output data could be conflicted with OSPI input data. 0: No extend 1 cycle Output enable 1: Extend 1 cycle Output enable	R/W
17	OENEGEX	Output Enable Negating extension This bit extends 1 cycle output enable of OM_SIO7-0 and OM_DQS during output enable negating. This bit should not be used in case of no latency cycle. Because OSPI output data could be conflicted with OSPI input data. 0: No extend 1 cycle Output enable 1: Extend 1 cycle Output enable	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. ch1 can only be used for GLCDC1 bus master.

This register has functions to configure xSPI Master function.

37.2.1.3 BMCFGCHn : OSPI Bridge Map Configuration Register chn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x008 + 0x004 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CMBTIM[7:0]								—	—	—	—	—	—	—	PREEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MWRSIZE[7:0]								MWRCOMB	—	—	—	—	—	—	WRMD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	WRMD	System bus Write Response mode This bit selects the timing of System bus write response in memory-mapping mode. When set to 1, it returns the response after transmitting a frame on xSPI bus. When enabled this mode, Memory Write Combination mode must be disabled. 0: Return response after storing to Internal Write Buffer 1: Return response after issuing write transaction to xSPI bus	R/W
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	MWRCOMB	Memory Write Combination mode This bit selects to combine the OSPI data in write access of memory-mapping mode. When set to 0, OSPI data size depends on system bus's burst type and size. When this field is set to "1", the data size depends on MWRSIZE[7:0] field.*1 When set to 1, any write transaction could be held in this xSPI master temporarily. 0: Disable combination mode 1: Enable combination mode	R/W

Bit	Symbol	Function	R/W
15:8	MWRSIZE[7:0]	Memory Write Size These bits select the size to combine incremental address in memory-mapping mode. It transmits an xSPI frame with the data combined up to the configured size while the address is incremental. When detected non-incremental address or a read transaction before reaching to the target size, it transmits the pending data into xSPI bus. 0x00: Combine incremental address up to 4 bytes 0x01: Combine incremental address up to 8 bytes ⋮ 0x0E: Combine incremental address up to 60 bytes 0x0F: Combine incremental address up to 64 bytes 0xFF: Combine incremental address up to 2 bytes Others: Setting prohibited	R/W
16	PREEN	Prefetch enable This bit enables prefetch function for read transaction in memory-mapping mode. It could reduce the latency for read transaction with incremental address. 0: Disable prefetch function 1: Enable prefetch function	R/W
23:17	—	These bits are read as 0. The write value should be 0.	R/W
31:24	CMBTIM[7:0]	Combination timer This field specifies expiration period of combination timer. This timer is counted by PCLKA. 0x00 means disabling the combination timer. When the timer is expired, the data in the combination buffer is pushed to memory device.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Writing to OSPI memory space other than 64 bit is prohibited during combination mode.

This register has functions to configure xSPI Master function.

37.2.1.4 CMCFG0CSn : OSPI Command Map Configuration Register 0 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x010 + 0x010 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ADDRPCD[7:0]								ADDRPEN[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	ARYAMD	WPBSTMD	ADDSIZE[1:0]		FFMT[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	FFMT[1:0]	Frame format These bits configure xSPI frame format in memory-mapping mode. Please see Table 37.7 for detail. 0 0: Normal format: Command 1 byte, Address ADDSIZE, Data up to system bus transaction. 0 1: 8D-8D-8D profile 1.0 format: Command 2 bytes, Address ADDSIZE, Data up to system bus transaction 1 0: 8D-8D-8D profile 2.0 Command Modifier format: Command & Modifier 6 bytes, Data up to system bus transaction 1 1: 8D-8D-8D profile 2.0 Commands with Extended Command Modifier format: Command & Modifier 6 bytes, Data up to system bus transaction	R/W

Bit	Symbol	Function	R/W
3:2	ADDSIZE[1:0]	Address size These bits configure the number of address byte in memory-mapping mode. In case of 8D-8D-8D profile 2.0, it should be configured to 4 bytes. 0 0: 1 byte (256-byte address space) 0 1: 2 bytes (64 KB address space) 1 0: 3 bytes (16 MB address space) 1 1: 4 bytes (4 GB address space)	R/W
4	WPBSTMD	Wrapping burst mode When this field is set to 1, the wrapping boundary between system bus access and xSPI memory shall be mached. 0: Separate xSPI transfer at the wrapping address boundary 1: Not separate xSPI transfer at the wrapping address boundary	R/W
5	ARYAMD	Array address mode When this field is set to 1, address for memory is mapped as {A[25:10], A[9:4], 6{RSV}, A[3:0]} where A[25:0] is normal address, and RSV is reserved value(0b). This field is effective only when FFMT=1d. 0: Normal address mode 1: Array address mode	R/W
15:6	—	These bits are read as 0. The write value should be 0.	R/W
23:16	ADDRPEN[7:0]	Address Replace Enable These bits select the bits to replace for MSByte of System bus address in memory-mapping mode. 0: No replacement (xSPI frame address field is same as System bus address) 1: Replacement	R/W
31:24	ADDRPCD[7:0]	Address Replace Code These bits configure the code to replace the MSByte of System bus address in memory-mapping mode. It replaces the corresponding bits when Address Replace Enable bit is set to 1.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to configure xSPI Master function.

37.2.1.5 CMCFG1CSn : OSPI Command Map Configuration Register 1 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x014 + 0x010 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	RDLATE[4:0]					RDCMD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RDCMD[15:0]	Read command These bits configure the command field of read transaction in memory-mapping mode. Normal format and 8D-8D-8D profile 2.0 format use only upper 1 byte. 8D-8D-8D profile 1.0 format uses 2 bytes.	R/W
20:16	RDLATE[4:0]	Read latency cycle These bits configure the latency cycle of read transaction in memory-mapping mode. 0x00: No latency 0x01: 1 cycle ⋮ 0x08: 8 cycle (default) ⋮ 0x1E: 30 cycles 0x1F: 31 cycles Others: Setting prohibited	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to configure xSPI Master function.

37.2.1.6 CMCFG2CSn : OSPI Command Map Configuration Register 2 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x018 + 0x010 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	16	15	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	WRLATE[4:0]		WRCMD[15:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	WRCMD[15:0]	Write command These bits configure the command field of write transaction in memory-mapping mode. Normal format and 8D-8D-8D profile 2.0 format use only upper 1 byte. 8D-8D-8D profile 1.0 format uses 2 bytes.	R/W
20:16	WRLATE[4:0]	Write latency cycle These bits configure the latency cycle of write transaction in memory-mapping mode. 0x00: No latency 0x01: 1 cycle ⋮ 0x08: 8 cycle (default) ⋮ 0x1E: 30 cycles 0x1F: 31 cycles Others: Setting prohibited	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to configure xSPI Master function.

37.2.1.7 LIOCFGCSn : OSPI Link I/O Configuration Register CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x050 + 0x004 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DDRSMPEX[3:0]				SDRSMPSFT[3:0]				SDRSMPMD	SDRDRV	CSNEGEX	CSASTEX	CSMIN[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	WRMSKMD	LATEMD	PRTMD[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

<table>
<tr><th>Bit</th><th>Symbol</th><th>Function</th><th>R/W</th></tr>
<tr><td>9:0</td><td>PRTMD[9:0]</td><td>Protocol mode
These bits configure the protocol mode and the pin to sample data inputs.
In case of using not SPI clock but Data strobe for sampling in SDR mode, it is required to set PRTMD[9] to 1.
0x000: 1S-1S-1S
0x3B2: 4S-4D-4D
0x3FF: 8D-8D-8D
0x048: 1S-2S-2S
0x049: 2S-2S-2S
0x090: 1S-4S-4S
0x092: 4S-4S-4S
Others: Setting prohibited</td><td>R/W</td></tr>
<tr><td>10</td><td>LATEMD</td><td>Latency mode
This bit selects the behavior of initial access latency phase for both direct-manual mode and memory-mapping mode. When set to 0, the latency cycle is equal to each configured cycle from transmitting address field. When set to 1, the latency cycle is incremented from the last byte-pair of Address field and is extended 2 times of each configured cycle depending on OM_DQS port.
It is used only for profile 2.0 frame format of 8D-8D-8D protocol mode with 6 bytes command/address field. Please refer to xSPI protocol for detail.
<table>
<tr><th>Value: Function</th><th>Frame format</th><th>Usage</th></tr>
<tr><td rowspan="2">0: Configurable latency</td><td>profile 2.0</td><td>The configurable latency cycle should be set as minus 1.</td></tr>
<tr><td>Others</td><td>Latency cycle increments after address field.</td></tr>
<tr><td rowspan="2">1: Variable latency</td><td>profile 2.0</td><td>Latency cycle increments from address [23:16]. And it should not be set to 1.</td></tr>
<tr><td>Others</td><td>Not support</td></tr>
</table></td><td>R/W</td></tr>
<tr><td>11</td><td>WRMSKMD</td><td>Write mask mode
This bit selects to use OM_DQS port as write data mask. It could be useful for write access of odd byte.
It is used only for 8D-8D-8D protocol mode.
0: Write mask disable
1: Write mask enable</td><td>R/W</td></tr>
<tr><td>15:12</td><td>—</td><td>These bits are read as 0. The write value should be 0.</td><td>R/W</td></tr>
<tr><td>19:16</td><td>CSMIN[3:0]</td><td>CS minimum idle term
This bit configures the minimum cycle between xSPI frames.
0x0: 1 cycle
0x1: 2 cycles
⋮
0x7: 8 cycles (default)
⋮
0xE: 15 cycles
0xF: 16 cycles
Others: Setting prohibited</td><td>R/W</td></tr>
<tr><td>20</td><td>CSASTEX</td><td>CS asserting extension
This bit extends 1 cycle chip select pins when asserting.
0: No extension
1: Extend 1 cycle</td><td>R/W</td></tr>

This bit extends 1 cycle chip select pins when negating.
0: No extension
1: Extend 1 cycle</td><td>R/W</td></tr>
<tr><td>22</td><td>SDRDRV</td><td>SDR driving timing
This bit configures the timing of data output in SDR.
This bit should not be set to 1 in case of no latency cycle. Because OSPI output data could be conflicted with OSPI input data.
0: Drive at 1/2 cycle before CK rising-edge
1: Drive at CK rising-edge</td><td>R/W</td></tr>
</table>

Bit	Symbol	Function	R/W
23	SDRSMPMD	SDR Sampling mode This bit selects the edge of sampling in SDR. In DDR, regardless of this setting, it samples OM_SIOn (n = 0 to 7) ports with both edges of OM_DQS. When set to 1, it samples at rising-edge before falling-edge. 0: Samples data input at falling-edge 1: Samples data input at rising-edge	R/W
27:24	SDRSMPSFT[3:0]	SDR Sampling window shift These bits shift the timing of CK sampling in SDR. In case of using OM_DQS in SDR, there is no influence on the behavior. In case of DDR or using OM_DQS in SDR, it should be set to 0. 0x0: Sample without delay 0x1: Sample at 1 cycle delay ⋮ 0x6: Sample at 6 cycle delay 0x7: Sample at 7 cycle delay Others: Setting prohibited	R/W
31:28	DDRSMPEX[3:0]	DDR sampling window extend These bits configure the cycle of extending the sampling window in DDR. In DDR, the input data is sampled during the expected cycle soon after latency cycle. The input data out of range is ignored. It can be configured depending on OM_DQS propagation delay. 0x0: Expand no cycle 0x1: Expand 1 cycle ⋮ 0x6: Expand 6 cycles 0x7: Expand 7 cycles Others: Setting prohibited	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to configure xSPI Master function.

37.2.2 OSPI Control Registers

These registers control xSPI Master function.

37.2.2.1 BMCTL0 : OSPI Bridge Map Control Register 0

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x060

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	CH1CS1ACC[1:0]		CH1CS0ACC[1:0]		CH0CS1ACC[1:0]		CH0CS0ACC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
1:0	CH0CS0ACC[1:0]	System bus ch0 to slave0 memory area access enable This field enables the access from ch0 to CS0 memory. 0 0: Read/Write disable 0 1: Read enable, Write disable 1 0: Read disable, Write enable 1 1: Read/Write enable	R/W

Bit	Symbol	Function	R/W
3:2	CH0CS1ACC[1:0]	System bus ch0 to slave1 memory area access enable This field enables the access from ch0 to CS1 memory. 0 0: Read/Write disable 0 1: Read enable, Write disable 1 0: Read disable, Write enable 1 1: Read/Write enable	R/W
5:4	CH1CS0ACC[1:0]	System bus ch1 to slave0 memory area access enable This field enables the access from ch1 to CS0 memory.*1 0 0: Read/Write disable 0 1: Read enable, Write disable 1 0: Read disable, Write enable 1 1: Read/Write enable	R/W
7:6	CH1CS1ACC[1:0]	System bus ch1 to slave1 memory area access enable This field enables the access from ch1 to CS1 memory.*1 0 0: Read/Write disable 0 1: Read enable, Write disable 1 0: Read disable, Write enable 1 1: Read/Write enable	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. ch1 can only be used for GLCDC1 bus master.

This register has functions to control xSPI Master function.

This register shall be configured in the initialization phase. When setting is needed to be changed after beginning xSPI transaction, please stop all communication, see section 37.3.7.2. Flow of Communication Stop before changing the value of BMCTL0.

37.2.2.2 BMCTL1 : OSPI Bridge Map Control Register 1

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x064

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	PBUFCLRCH1	PBUFCLRCH0	MWRPUSHCH1	MWRPUSHCH0	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	The write value should be 0.	W
8	MWRPUSHCH0	Memory Write Data Push for ch0 This field requests to push the pending data in combination mode.*1 0: No command 1: Push request	W
9	MWRPUSHCH1	Memory Write Data Push for ch1*2 The function is same as one of ch0.*1	W
10	PBUFCLRCH0	Prefetch Buffer clear for ch0 This field requests to clear the prefetch buffer when the prefetch function is enabled.*1 It should not be set during memory access (COMSTT.MEMACCCH0 = 1). 0: No command 1: Clear request	W

Bit	Symbol	Function	R/W
11	PBUFCLRCH1	Prefetch Buffer clear for ch1*2 This function is same as one of ch0.*1	W
31:12	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3
Note 1. Prefetch/Combination behavior is not defined when cycle base race condition between asserting these bits and system bus access is occurred.
Note 2. ch1 can only be used for GLCDC1 bus master

This register has functions to control xSPI Master function.

37.2.2.3 CMCTLCHn : OSPI Command Map Control register chn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x0068 + 0x004 × n (n = 0, 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	XIPEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	XIPEXCODE[7:0]								XIPENCODE[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	XIPENCODE[7:0]	XiP mode enter code These bits configure the code to enter XiP mode in memory-mapping mode.	R/W
15:8	XIPEXCODE[7:0]	XiP mode exit code These bits configure the code to exit XiP mode in memory-mapping mode.	R/W
16	XIPEN	XiP mode enable This bit enables XiP mode in memory-mapping mode. When set to 1, XiP enter code is inserted in the latency field, and the command field in next transaction is omitted. When set to 0, XiP exit code is inserted in the latency field. And it is set to 0 automatically when transmitting XiP disable pattern. It should not be used for 8D-8D-8D protocol mode profile 2.0 frame format. 0: Disable XiP mode 1: Enable XiP mode	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.4 CDCTL0 : OSPI Command Manual Control Register 0

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x070

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	PEREP[3:0]				—	—	—	PERITV[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	TRNUM[1:0]		CSSEL	—	PERMD	TRREQ
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TRREQ	Transaction request This bit requests to issue the transaction of manual-command. When set to 1, it starts the transaction. It is cleared to 0 when the transaction completed. The transaction is canceled by clearing to 0 while the transaction is ongoing. 0: No transaction 1: Request transaction	R/W
1	PERMD	Periodic mode This bit enables the periodic transaction mode. When set to 1, it repeats a transaction periodically and compares the read value with the expected value. It alternates the status polling operation for external memory. 0: Direct manual-command mode 1: Periodic manual-command mode	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	CSSEL	Chip select This bit selects a target memory to issue manual-command. 0: CS0 1: CS1	R/W
5:4	TRNUM[1:0]	Transaction number These bits configure the number of transactions in normal manual-command mode. In periodic manual-command, regardless of this setting, the read data of last command is compared. 0 0: Issue 1 command (using command buffer 0) 0 1: Issue 2 commands (using command buffer 0-1) 1 0: Issue 3 commands (using command buffer 0-2) 1 1: Issue 4 commands (using command buffer 0-3)	R/W
15:6	—	These bits are read as 0. The write value should be 0.	R/W
20:16	PERITV[4:0]	Periodic transaction interval These bits configure the interval of transaction in periodic manual-command mode. Too short interval compared with CPU bus cycle could result in no store into command buffer0. The interval should be longer than 4 times of CPU bus cycle. 0x00: 2 (= 2^1) cycles 0x01: 4 (= 2^2) cycles ⋮ 0x1E: 2,147,483,648 (= 2^{31}) cycles 0x1F: 4,294,967,296 (= 2^{32}) cycles	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
27:24	PEREP[3:0]	Periodic transaction repeat These bits configure the number of transaction repetitions in periodic manual-command mode. 0x0: 1 (= 2^0) time 0x1: 2 (= 2^1) times ⋮ 0xE: 16384 (= 2^{14}) times 0xF: 32768 (= 2^{15}) times	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

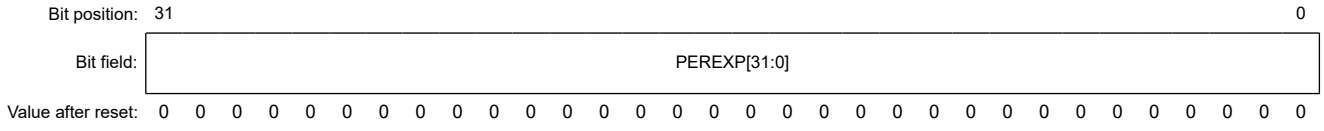
Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.5 CDCTL1 : OSPI Command Manual Control Register 1

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x074



Bit	Symbol	Function	R/W
31:0	PEREXP[31:0]	Periodic transaction expected value These bits configure the expected value to compare with the read value in periodic manual-command mode. For example, in case of comparing 1 byte, the lower byte should be configured.	R/W

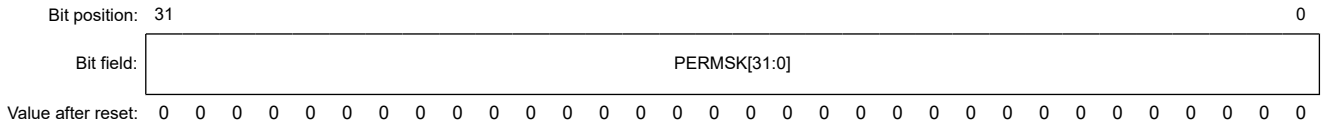
Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.6 CDCTL2 : OSPI Command Manual Control Register 2

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x078



Bit	Symbol	Function	R/W
31:0	PERMSK[31:0]	Periodic transaction masked value These bits configure the masked value for the expected value in periodic manual-command mode. When set 1 to any bit, the corresponding bit configured as expected value (CDCTL1.PEREXP[31:0]) is ignored. In 8D-8D-8D, the data bytes are transferred only in byte pairs on xSPI bus. It means the dummy read data could be stored. It should be masked for unused bits. For example, in case of read lower 1 byte, it should be configured to 0xFFFFFF00.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.7 CDTBUFn : OSPI Command Manual Type Buf n (n = 0 to 3)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x080 + 0x010 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CMD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TRTYPE	—	LATE[4:0]					DATASIZE[3:0]				ADDSIZE[2:0]			CMDSIZE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CMDSIZE[1:0]	Command Size These bits configure the size of command field. In case of 8D-8D-8D, it should be fixed to 10b. It should not be configured both command size and address size to zero. 0 0: 0 bytes (No command phase) 0 1: 1 byte 1 0: 2 bytes Others: Setting prohibited	R/W
4:2	ADDSIZE[2:0]	Address size These bits configure the size of address field. 0 0 0: 0 bytes (No address phase) 0 0 1: 1 byte 0 1 0: 2 bytes 0 1 1: 3 bytes 1 0 0: 4 bytes Others: Setting prohibited	R/W
8:5	DATASIZE[3:0]	Write/Read Data Size These bits configure the size of data field. In 8D-8D-8D, the data bytes are transferred only in byte pairs on xSPI bus. For example, even if configuring 1 byte for read, 2 bytes data is received. The last byte should be ignored. The 0 bytes must not configured for read transaction. 0x0: 0 bytes (No data phase) 0x1: 1 byte ⋮ 0x7: 7 bytes 0x8: 8 bytes Others: Setting prohibited	R/W
13:9	LATE[4:0]	Latency cycle These bits configure the latency cycle in manual-command mode. 0x0: No latency 0x1: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
14	—	This bit is read as 0. The write value should be 0.	R/W
15	TRTYPE	Transaction Type This bit selects the type of transaction. 0: Read transaction (Readout data from slave device) 1: Not read transaction	R/W

Bit	Symbol	Function	R/W
31:16	CMD[15:0]	Command (1-2 bytes) These bits configure the command field in manual-command mode. The number of bytes configured in Command Size bit is transferred. 1S-1S-1S, 4S-4D-4D: CMD[15:8] is command field, CMD[7:0] is not used. 8D-8D-8D profile 1.0: CMD[15:8] is command field, CMD[7:0] is extension field. 8D-8D-8D profile 2.0: CMD[15:0] is upper 2 bytes of command & modifier field. (bit 47-32 in xSPI protocol)	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.8 CDABUFn : OSPI Command Manual Address Buf n (n = 0 to 3)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x084 + 0x10 × n

Bit position:	31																												0
Bit field:	ADD[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ADD[31:0]	Address These bits configure the address field in manual-command mode. 1S-1S-1S, 4S-4D-4D, 8D-8D-8D profile 1.0: It is address field. 8D-8D-8D profile 2.0: It is lower 4 bytes of command & modifier field. (bit 31-0 in xSPI protocol)	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.9 CDD0BUFn : OSPI Command Manual Data 0 Buf n (n = 0 to 3)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x088 + 0x10 × n

Bit position:	31																												0
Bit field:	DATA[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DATA[31:0]	Write/Read Data These bits configure the data field in manual-command mode. In case of write transaction, the write data should be configured. In case of read transaction, the read data is stored.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.10 CDD1BUFn : OSPI Command Manual Data 1 Buf n (n = 0 to 3)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x08C + 0x10 × n

Bit position:	31																												0
Bit field:	DATA[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DATA[31:0]	Write/Read Data These bits configure the data field in manual-command mode. In case of write transaction, the write data should be configured. In case of read transaction, the read data is stored.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.11 LPCTL0 : OSPI Link Pattern Control Register 0

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x100

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	XD2VAL	—	—	XD2LEN[4:0]					XD1VAL	—	—	XD1LEN[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	XDPIN[1:0]		CSSEL	—	—	PATREQ
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PATREQ	Pattern request This bit requests to issue the pattern. When set to 1, it starts the pattern. It is cleared to 0 when the pattern completed. 0: No request XiP Disable pattern 1: Request XiP Disable pattern	R/W
2:1	—	These bits are read as 0. The write value should be 0.	R/W
3	CSSEL	Chip select This bit selects a target memory to issue a pattern. 0: slave0 (CS0) 1: slave1 (CS1)	R/W
5:4	XDPIN[1:0]	XiP Disable pattern pin These bits select the data output pins to transmit XiP Disable pattern. 0 0: 1 pin 0 1: 2 pins 1 0: 4 pins 1 1: 8 pins	R/W
15:6	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
20:16	XD1LEN[4:0]	XiP Disable pattern 1st phase length These bits select the length of 1st phase in XiP disable pattern. The pattern with zero-length both 1st phase and 2nd phase should not be configured. 0x0: 0 cycles 0x1: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
22:21	—	These bits are read as 0. The write value should be 0.	R/W
23	XD1VAL	XiP Disable pattern 1st phase value This bit selects the value of 1st phase in XiP disable pattern. 0: Low drive 1: High drive	R/W
28:24	XD2LEN[4:0]	XiP Disable pattern 2nd phase length These bits select the length of 2nd phase in XiP disable pattern. 0x00: 0 cycles 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
30:29	—	These bits are read as 0. The write value should be 0.	R/W
31	XD2VAL	XiP Disable pattern 2nd phase value This bit selects the value of 2nd phase in XiP disable pattern. 0: Low drive 1: High drive	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.12 LPCTL1 : OSPI Link Pattern Control Register 1

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x104

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	RSTSU[2:0]			—	RSTWID[2:0]			—	—	RSTREP[1:0]		CSSEL	—	PATREQ[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PATREQ[1:0]	Pattern request These bits request to issue the pattern. When set to 01b or 10b, it starts the pattern. It is cleared to 00b when the pattern completed. 0 0: No request 0 1: Request Reset pattern 1 0: Request CS only pattern 1 1: Setting prohibited	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	CSSEL	Chip select This bit selects a target memory to issue a pattern. 0: slave0 (CS0) 1: slave1 (CS1)	R/W

Bit	Symbol	Function	R/W
5:4	RSTREP[1:0]	Reset pattern repeat These bits select the repeating time to toggle CS from LOW to HIGH. 0 0: 4 times (Specified on Reset Signaling Protocol) 0 1: 5 times 1 0: 6 times 1 1: 7 times	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
10:8	RSTWID[2:0]	Reset pattern width These bits configure the width of cycle in reset pattern and CS only pattern. It toggles CS with the configured cycle. 0 0 0: 2 (= 2^1) cycles 0 0 1: 4 (= 2^2) cycles ⋮ 1 1 0: 128 (= 2^7) cycles 1 1 1: 256 (= 2^8) cycles	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
14:12	RSTSU[2:0]	Reset pattern data output setup time These bits configure the number of setup cycle for data output based on the edge of CS in reset pattern. It needs enough setup time because xSPI slave samples any data at the rising edge of CS. This cycle of setup time should be less than the cycle of reset pattern width (RSTWID[2:0]). 0 0 0: 1 cycle 0 0 1: 2 cycles ⋮ 1 1 0: 7 cycles 1 1 1: 8 cycles	R/W
31:15	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.13 LIOCTL : OSPI Link I/O Control Register

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x108

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RSTCS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WPCS1	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
0	—	This bit is read as 1. The write value should be 1.	R/W
1	WPCS1	WP drive for slave1 This bit controls the value of OM_WP1 port. It can be useful only for xSPI slave with write protect port. 0: Drive Low level 1: Drive High level	R/W
15:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
16	RSTCS0	Reset drive This bit controls the value of OM_RESET port. It could be useful only for xSPI slave with reset port. 0: Drive Low level 1: Drive High level	R/W
17	—	This bit is read as 1. The write value should be 1.	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.14 CCCTL0CSn : OSPI Command Calibration Control Register 0 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x130 + 0x020 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	CASFTEND[4:0]					—	—	—	CASFTSTA[4:0]				
Value after reset:	0	0	0	1	1	1	1	1	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	CAITV[4:0]					—	—	—	—	—	—	CANOWR	CAEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CAEN	Automatic Calibration Enable This bit enables the automatic calibration. When set to 1, it transmits the calibration sequence periodically and adjusts the value of phase shift. When set to 0 during the calibration sequence, it stops after completed ongoing calibration sequence, and then this bit is cleared. 0: Disable automatic calibration 1: Enable automatic calibration	R/W
1	CANOWR	Calibration no write mode This bit selects to omit write command in calibration sequence. It can be used for any slave device with fixed calibration pattern data. 0: Calibration sequence with write command 1: Calibration sequence without write command	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
12:8	CAITV[4:0]	Calibration interval These bits configure the interval between calibration patterns. 0x00: 2 (= 2^1) cycle wait 0x01: 4 (= 2^2) cycle wait ⋮ 0x1E: 2,147,483,648 (= 2^{31}) cycle wait 0x1F: 4,294,967,296 (= 2^{32}) cycle wait	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
20:16	CASFTSTA[4:0]	Calibration OM_DQS shift start value These bits configure the start value of OM_DQS shift.	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
28:24	CASFTEND[4:0]	Calibration OM_DQS shift end value These bits configure the end value of OM_DQS shift. It should be equal or more than the start value (CASFTSTA[4:0]).	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.15 CCCTL1CSn : OSPI Command Calibration Control Register 1 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x134 + 0x020 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	CARDLATE[4:0]					—	—	—	CAWRLATE[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CADATASIZE[3:0]				CAADDSIZE[2:0]			CACMDSIZE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CACMDSIZE[1:0]	Command Size These bits configure the size of command field. In case of 8D-8D-8D, it should be fixed to 10b. It should not be configured both command size and address size to zero. 0 0: 0 bytes (No command phase) 0 1: 1 byte 1 0: 2 bytes 1 1: Setting prohibited	R/W
4:2	CAADDSIZE[2:0]	Address size These bits configure the size of address field. 0 0 0: 0 bytes (No address phase) 0 0 1: 1 byte 0 1 0: 2 bytes 0 1 1: 3 bytes 1 0 0: 4 bytes Others: Setting prohibited	R/W
8:5	CADATASIZE[3:0]	Write/Read Data Size These bits configure the size of data field. In 8D-8D-8D, it should be configured with even byte. 0x0: 1 byte 0x1: 2 bytes ⋮ 0xE: 15 bytes 0xF: 16 bytes	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
20:16	CAWRLATE[4:0]	Write Latency cycle These bits configure the latency cycle in calibration frame. 0x00: No latency 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
28:24	CARDLATE[4:0]	Read Latency cycle These bits configure the latency cycle in calibration frame. 0x00: No latency 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

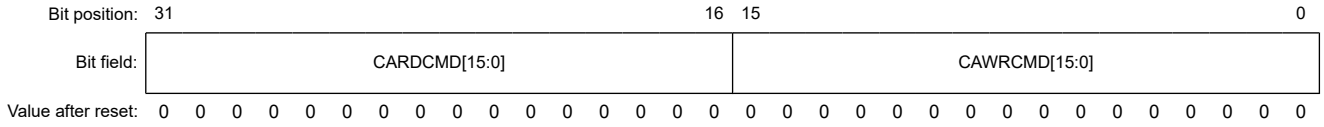
Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.2.2.16 CCCTL2CSn : OSPI Command Calibration Control Register 2 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x138 + 0x020 × n



Bit	Symbol	Function	R/W
15:0	CAWRCMD[15:0]	Calibration pattern write command These bits configure the calibration pattern write command.	R/W
31:16	CARDCMD[15:0]	Calibration pattern read command These bits configure the calibration pattern read command.	R/W

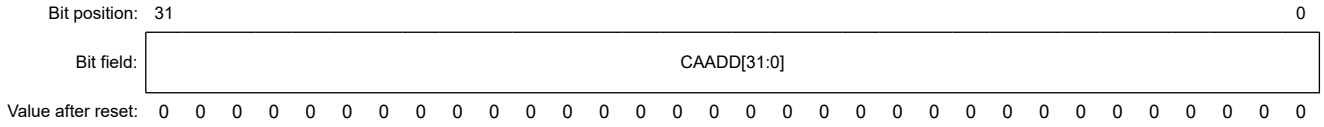
Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.2.2.17 CCCTL3CSn : OSPI Command Calibration Control Register 3 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x13C + 0x020 × n



Bit	Symbol	Function	R/W
31:0	CAADD[31:0]	Calibration pattern address These bits configure the calibration pattern address.	R/W

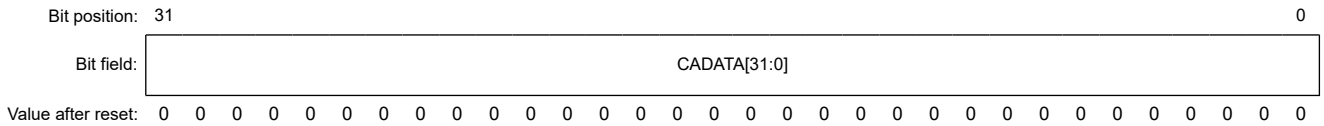
Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.2.2.18 CCCTL4CSn : OSPI Command Calibration Control Register 4 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x140 + 0x020 × n



Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

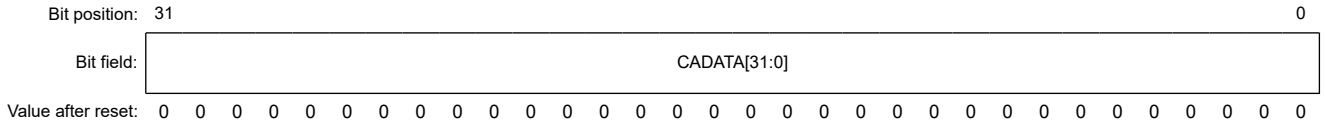
Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.2.2.19 CCCTL5CSn : OSPI Command Calibration Control Register 5 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x144 + 0x020 × n



Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

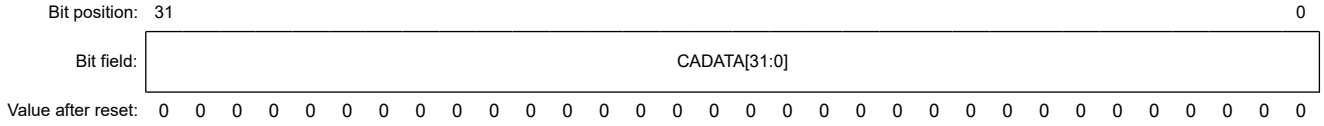
Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.2.2.20 CCCTL6CSn : OSPI Command Calibration Control Register 6 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x148 + 0x020 × n



Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

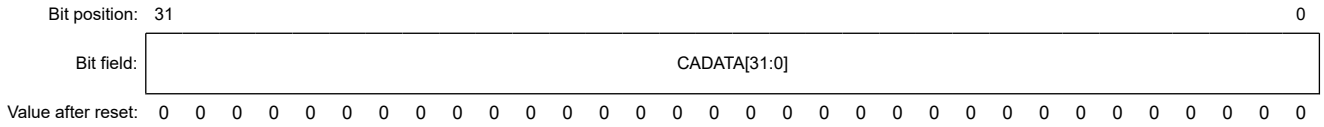
Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.2.2.21 CCCTL7CSn : OSPI Command Calibration Control Register 7 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x14C + 0x020 × n



Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.2.3 OSPI Status Registers

These registers monitor the status of xSPI Master.

37.2.3.1 COMSTT : OSPI Common Status Register

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x184

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	RSTOCS1	INTCS1	ECSCS1	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	WRBUFNECH1	WRBUFNECH0	PBUFNECH1	PBUFNECH0	—	—	MEMACCCH1	MEMACCCH0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MEMACCCH0	Memory access ongoing from ch0 This bit is only valid in the section 37.3.7.2. Flow of Communication Stop and section 37.3.7.6. Flow of Memory-mapping Stop flows. 0: System bus bridge ch0 is not accessing to memory. 1: System bus bridge ch0 is accessing to memory.	R
1	MEMACCCH1	Memory access ongoing from ch1*1 This function is same as ch0.	R
3:2	—	These bits are read as 0.	R
4	PBUFNECH0	Prefetch Buffer Not Empty for ch0 0: Empty 1: Not empty	R
5	PBUFNECH1	Prefetch Buffer Not Empty for ch1*1 This function is same as ch0.	R
6	WRBUFNECH0	Write Buffer Not Empty for ch0 This bit is only valid in the section 37.3.7.2. Flow of Communication Stop and section 37.3.7.6. Flow of Memory-mapping Stop flows. 0: Empty 1: Not empty	R
7	WRBUFNECH1	Write Buffer Not Empty for ch1*1 This function is same as ch0.	R
19:8	—	These bits are read as 0.	R
20	ECSCS1	ECS monitor for slave1 This bit indicates the value of OM_ECSINT1 port. 0: Low level 1: High level	R
21	INTCS1	INT monitor for slave1 This bit indicates the value of OM_ECSINT1 port. 0: Low level 1: High level	R
22	RSTOCS1	RSTO monitor for slave1 This bit indicates the value of OM_RSTO1 port. 0: Low level 1: High level	R
31:23	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3
Note 1. ch1 can only be used for GLCDC1 bus master.

This register indicates the status of xSPI Master.

37.2.3.2 CASTTCSn : OSPI Calibration Status Register CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x188 + 0x004 × n

Bit position:	31																												0
Bit field:	CASUC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CASUC[31:0]	Calibration Success These bits indicate the calibration success for each OM_DQS shift value. It is updated when completed each calibration sequence. CASUC[x] indicates calibration success in OM_DQS shift value = x.	R

Note: S-TYPE-3, P-TYPE-3

This register indicates the status of xSPI Master.

37.2.4 OSPI Interrupt Registers

These registers control the interrupt function of xSPI Master.

37.2.4.1 INTS : OSPI Interrupt Status Register

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x190

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CASUCCS1	CASUCCS0	CAFAILCS1	CAFAILCS0	—	—	—	—	—	—	BUSERRCH1	BUSERRCH0	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	INTCS1	—	—	—	ECSCS1	—	—	—	DSTOCS1	DSTOCS0	PERTO	—	PATCMP	CMDCMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMDCMP	Command Completed This bit is set to 1 when completed the requested manual-command. In direct manual-command, it means all transactions completed. In periodic manual-command, it means the read data matches with the expected data. 0: No detection 1: Detection	R
1	PATCMP	Pattern Completed This bit is set to 1 when completed the requested pattern. 0: No detection 1: Detection	R
2	—	This bit is read as 0.	R
3	PERTO	Periodic transaction timeout This bit is set to 1 when the read value does not match with the expected value in periodic manual-command mode. 0: No detection 1: Detection	R

Bit	Symbol	Function	R/W
4	DSTOCS0	OM_DQS timeout for slave0 This bit is set to 1 when lost OM_DQS in read transaction with using OM_DQS. It means not receiving the data during expected read phase. In this case, xSPI master stops the read transaction and the following transaction. This error may issue error response to system bus. 0: No detection 1: Detection	R
5	DSTOCS1	OM_DQS timeout for slave1 This function is same as DSTOCS0. 0: No detection 1: Detection	R
8:6	—	These bits are read as 0.	R
9	ECSCS1	ECC error detection for slave1 This bit is set to 1 when detected the falling edge on OM_ECSINT1 port. It can be useful only for xSPI slave with ECC detection function. 0: No detection 1: Detection	R
12:10	—	These bits are read as 0.	R
13	INTCS1	Interrupt detection for slave1 This bit is set to 1 when detected the falling edge on OM_ECSINT1 port. It can be useful only for xSPI slave with interrupt function. 0: No detection 1: Detection	R
19:14	—	These bits are read as 0.	R
20	BUSERRCH0	System bus error for ch0 This bit is set to 1 when an error response occurs on system bus channel0.	R
21	BUSERRCH1	System bus error for ch1[*1] This function is same as CH0.	R
27:22	—	These bits are read as 0.	R
28	CAFAILCS0	Calibration failed for slave0 This bit is set to 1 when failed calibration. 0: No detection 1: Detection	R
29	CAFAILCS1	Calibration failed for slave1 This function is same as CAFAILCS0. 0: No detection 1: Detection	R
30	CASUCCS0	Calibration success for slave0 This bit is set to 1 when success calibration. 0: No detection 1: Detection	R
31	CASUCCS1	Calibration success for slave1 This function is same as CASUCCS0. 0: No detection 1: Detection	R

Note: S-TYPE-3, P-TYPE-3
Note 1. ch1 can only be used for GLCDC1 bus master.

This register indicates the status of interrupt. The bits in this register are cleared to 0 when writing 1 on the corresponding bit of INTC register.

37.2.4.2 INTC : OSPI Interrupt Clear Register

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x194

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CASUCCS1C	CASUCCS0C	CAFAILCS1C	CAFAILCS0C	—	—	—	—	—	—	BUSERRCH1C	BUSERRCH0C	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	INTCS1C	—	—	—	ECSCS1C	—	—	—	DSTOCS1C	DSTOCS0C	PERTOC	—	PATCMPC	CMDCMPC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMDCMPC	Command Completed interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
1	PATCMPC	Pattern Completed interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
2	—	The write value should be 0.	W
3	PERTOC	Periodic transaction timeout interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
4	DSTOCS0C	OM_DQS timeout for slave0 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
5	DSTOCS1C	OM_DQS timeout for slave1 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
8:6	—	The write value should be 0.	W
9	ECSCS1C	ECC error detection for slave1 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
12:10	—	The write value should be 0.	W
13	INTCS1C	Interrupt detection for slave1 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
19:14	—	The write value should be 0.	W
20	BUSERRCH0C	System bus error for ch0 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
21	BUSERRCH1C	System bus error for ch1 interrupt clear*1 0: No change interrupt status 1: Clear interrupt status	W
27:22	—	The write value should be 0.	W
28	CAFAILCS0C	Calibration failed for slave0 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
29	CAFAILCS1C	Calibration failed for slave1 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W

Bit	Symbol	Function	R/W
30	CASUCCS0C	Calibration success for slave0 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
31	CASUCCS1C	Calibration success for slave1 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W

Note: S-TYPE-3, P-TYPE-3
Note 1. ch1 can only be used for GLCDC1 bus master.

This register clears the status of interrupt.

37.2.4.3 INTE : OSPI Interrupt Enable Register

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x198

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CASUCCS1E	CASUCCS0E	CAFAILCS1E	CAFAILCS0E	—	—	—	—	—	—	BUSERRCH1E	BUSERRCH0E	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	INTCS1E	—	—	—	ECSCS1E	—	—	—	DSTOCS1E	DSTOCS0E	PERTOE	—	PATCMPE	CMDCMPE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMDCMPE	Command Completed interrupt enable 0: Disabled 1: Enabled	R/W
1	PATCMPE	Pattern Completed interrupt enable 0: Disabled 1: Enabled	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	PERTOE	Periodic transaction timeout interrupt enable 0: Disabled 1: Enabled	R/W
4	DSTOCS0E	OM_DQS timeout for slave0 interrupt enable 0: Disabled 1: Enabled	R/W
5	DSTOCS1E	OM_DQS timeout for slave1 interrupt enable 0: Disabled 1: Enabled	R/W
8:6	—	These bits are read as 0. The write value should be 0.	R/W
9	ECSCS1E	ECC error detection for slave1 interrupt enable 0: Disabled 1: Enabled	R/W
12:10	—	These bits are read as 0. The write value should be 0.	R/W
13	INTCS1E	Interrupt detection for slave1 interrupt enable 0: Disabled 1: Enabled	R/W
19:14	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
20	BUSERRCH0E	System bus error for ch0 interrupt enable 0: Disabled 1: Enabled	R/W
21	BUSERRCH1E	System bus error for ch1 interrupt enable*1 0: Disabled 1: Enabled	R/W
27:22	—	These bits are read as 0. The write value should be 0.	R/W
28	CAFAILCS0E	Calibration failed for slave0 interrupt enable 0: Disabled 1: Enabled	R/W
29	CAFAILCS1E	Calibration failed for slave1 interrupt enable 0: Disabled 1: Enabled	R/W
30	CASUCCS0E	Calibration success for slave0 interrupt enable 0: Disabled 1: Enabled	R/W
31	CASUCCS1E	Calibration success for slave1 interrupt enable 0: Disabled 1: Enabled	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. ch1 can only be used for GLCDC1 bus master.

This register enables the interrupt.

37.3 Operation

xSPI Master interface has the functions to issue the transaction for external memory with xSPI Slave interface. It allows to write to registers in external memory or read from it.

This xSPI Master mainly has two modes to issue the transaction. One is a manual-command mode; Software configures all fields of xSPI frame and starts the transaction by software request. The other is a memory-mapping mode; it automatically converts system bus for pre-configured memory area into xSPI transaction. It enables to access from system bus to external memory area outside of chip via xSPI bus.

This section describes the xSPI bus operation, the direct control of xSPI frame (manual-command), the control of memory access (memory-mapping), the error operation, and the flow to operation.

37.3.1 xSPI Bus

This section describes the xSPI bus operation.

Figure 37.2 shows an example of connections between OSPI and memory devices.

In this case, OM_CS0 should be connected to the RAM device and OM_CS1 should be connected to the Flash device.

Pull-up resistors should be specified according to the instructions for each device.

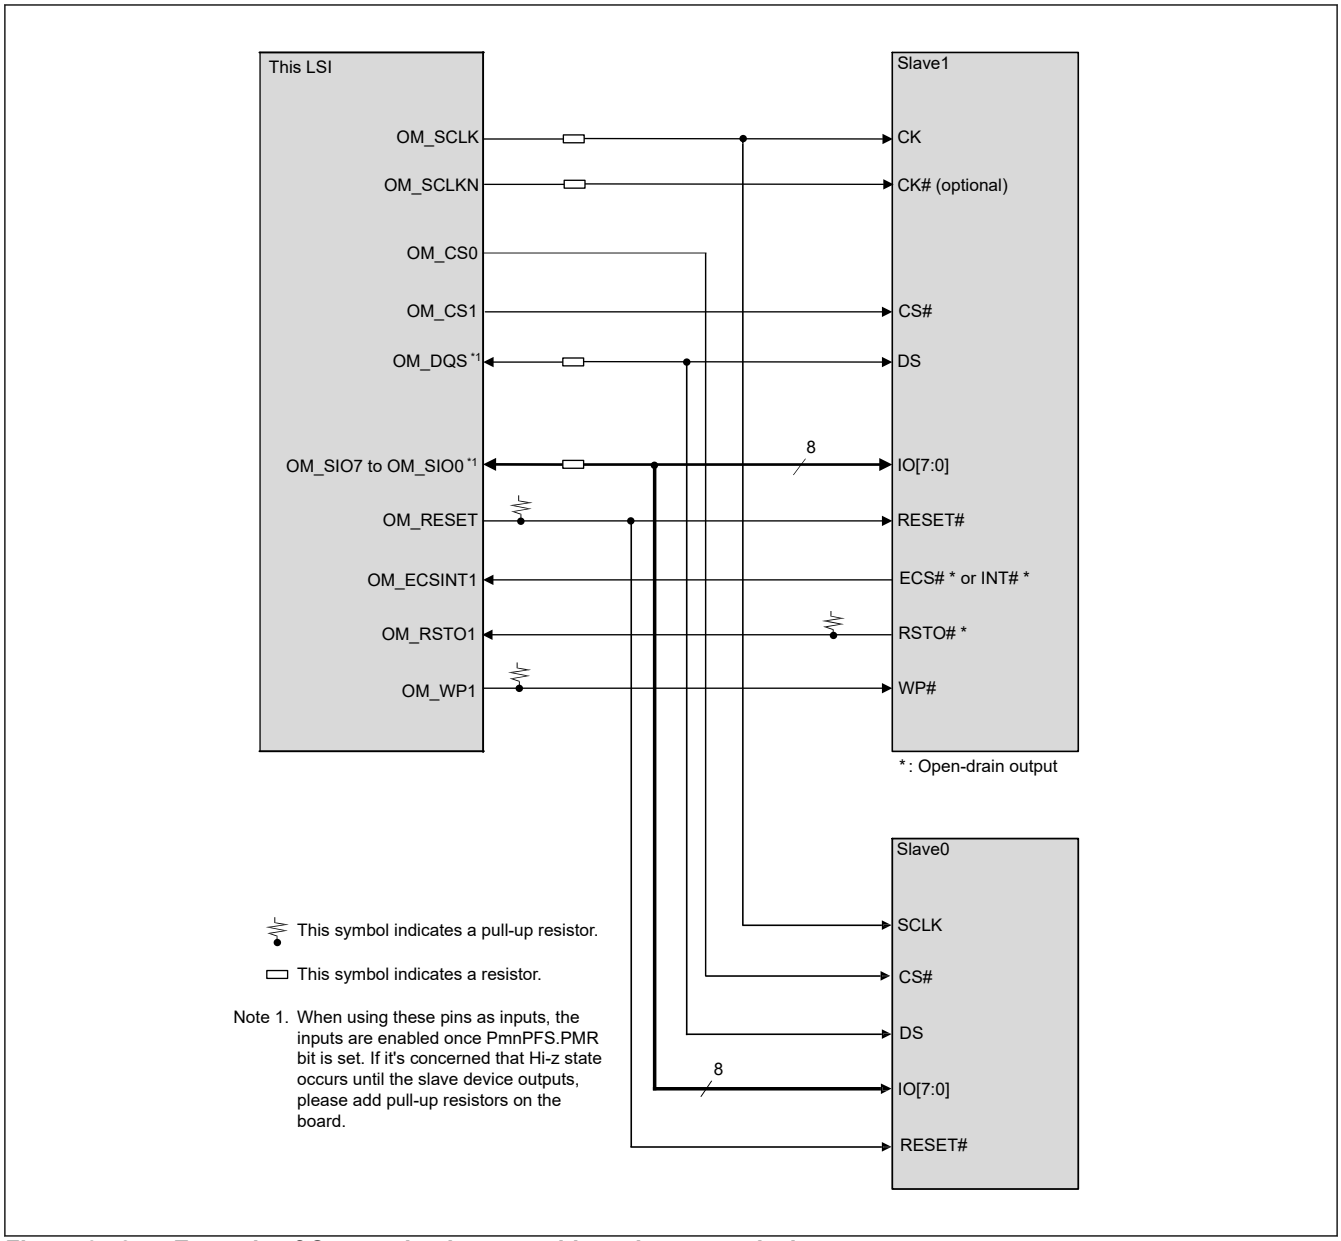


Figure 37.2 Example of Connection between this and memory devices

37.3.1.1 Supported Protocol Mode

This xSPI Master supports various protocol modes. It is configured by Protocol mode bits (LIOCFGCSn.PRTMD[9:0]). Table 37.3 shows the summary of protocol modes.

Table 37.3 Supported protocol mode (1 of 2)

Protocol mode	Function	PRTMD[9:0]	Note
1S-1S-1S	Command, Address and Data field are transferred at SDR with using 1 data input pin and 1 data output pin. Read data is sampled with CK.	0x000	Specified by xSPI protocol
4S-4D-4D	Command field is transferred at SDR with using 4 data pins. Address and Data fields are transferred at DDR with using 4 data pins. Read data is sampled with OM_DQS.	0x3B2	Specified by xSPI protocol
8D-8D-8D	Command, Address and Data fields are transferred at DDR with using 8 data pins. Read data is sampled with OM_DQS.	0x3FF	Specified by xSPI protocol
1S-2S-2S	Command field is transferred at SDR with using 1 data pin. Address and Data fields are transferred at SDR with using 2 data pins. Read data is sampled with CK.	0x048	—

Table 37.3 Supported protocol mode (2 of 2)

Protocol mode	Function	PRTMD[9:0]	Note
2S-2S-2S	Command, Address and Data fields are transferred at SDR with using 2 data pins. Read data is sampled with CK.	0x049	—
1S-4S-4S	Command field is transferred at SDR with using 1 data pin. Address and Data fields are transferred at SDR with using 4 data pins. Read data is sampled with CK.	0x090	—
4S-4S-4S	Command, Address, and Data fields are transferred at SDR with using 4 data pins. Read data is sampled with CK.	0x092	—

Note: In case of XiP mode enable, XiP code is inserted in Latency field. It is valid only for memory-mapping mode.

The bytes of Command and Address fields are transferred in highest order to lowest order sequence. The sequential bytes of Data field are transferred in lowest address to highest address order. In case of using multiple pins, the least significant bit of each byte is placed on OM_SIO0 with each higher order bit on the successively higher numbered OM_SIOn (n = 1 to 7) signals.

Figure 37.3 shows timing-chart for 1S-1S-1S protocol mode. The OM_SIO0 signal is used for output data and the OM_SIO1 signal is used for input data.

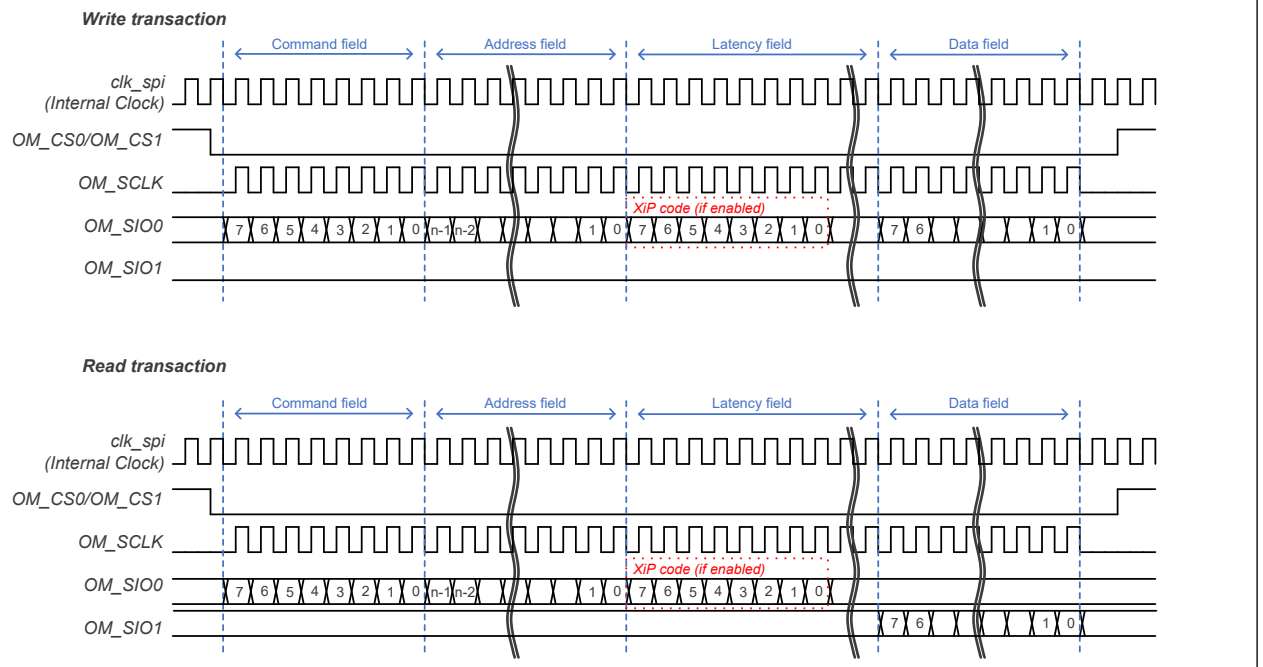

Figure 37.3 1S-1S-1S timing-chart

Figure 37.4 shows timing-chart for 1S-2S-2S protocol mode.

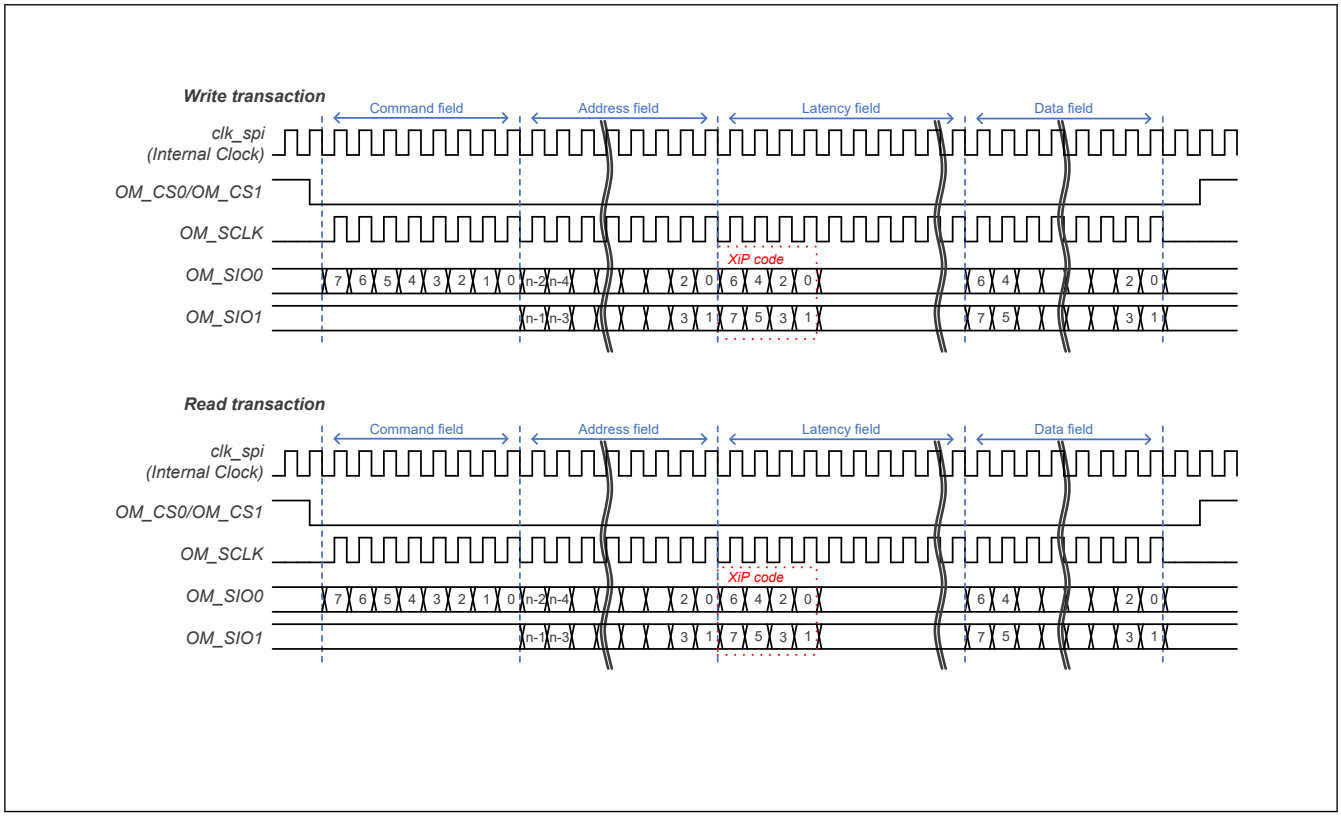

Figure 37.4 1S-2S-2S timing-chart

Figure 37.5 shows timing-chart for 4S-4D-4D protocol mode.

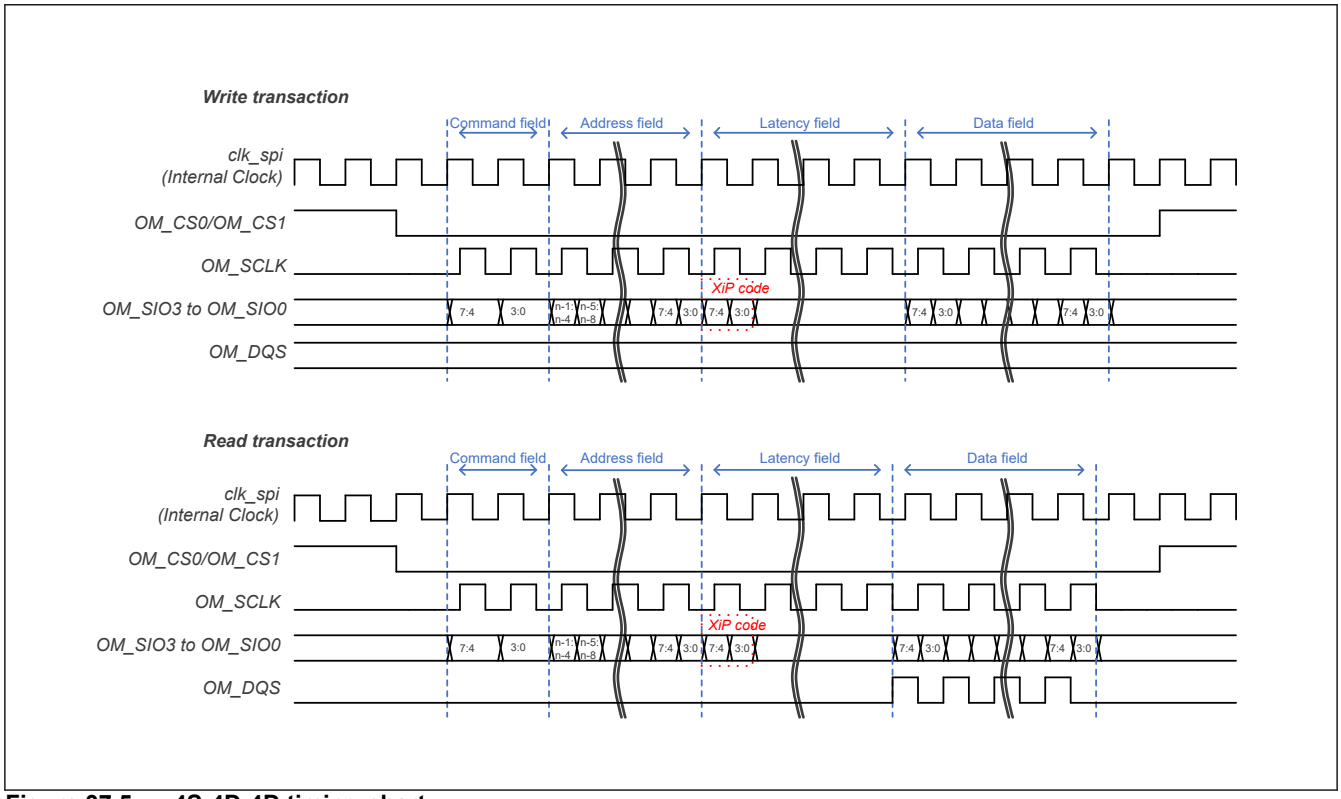

Figure 37.5 4S-4D-4D timing-chart

Figure 37.6 shows timing-chart for 8D-8D-8D profile 1.0 protocol mode. In 8D-8D-8D, the data is always transmitted with byte-pair. In case each field is odd byte, last one byte is padded with invalid data.

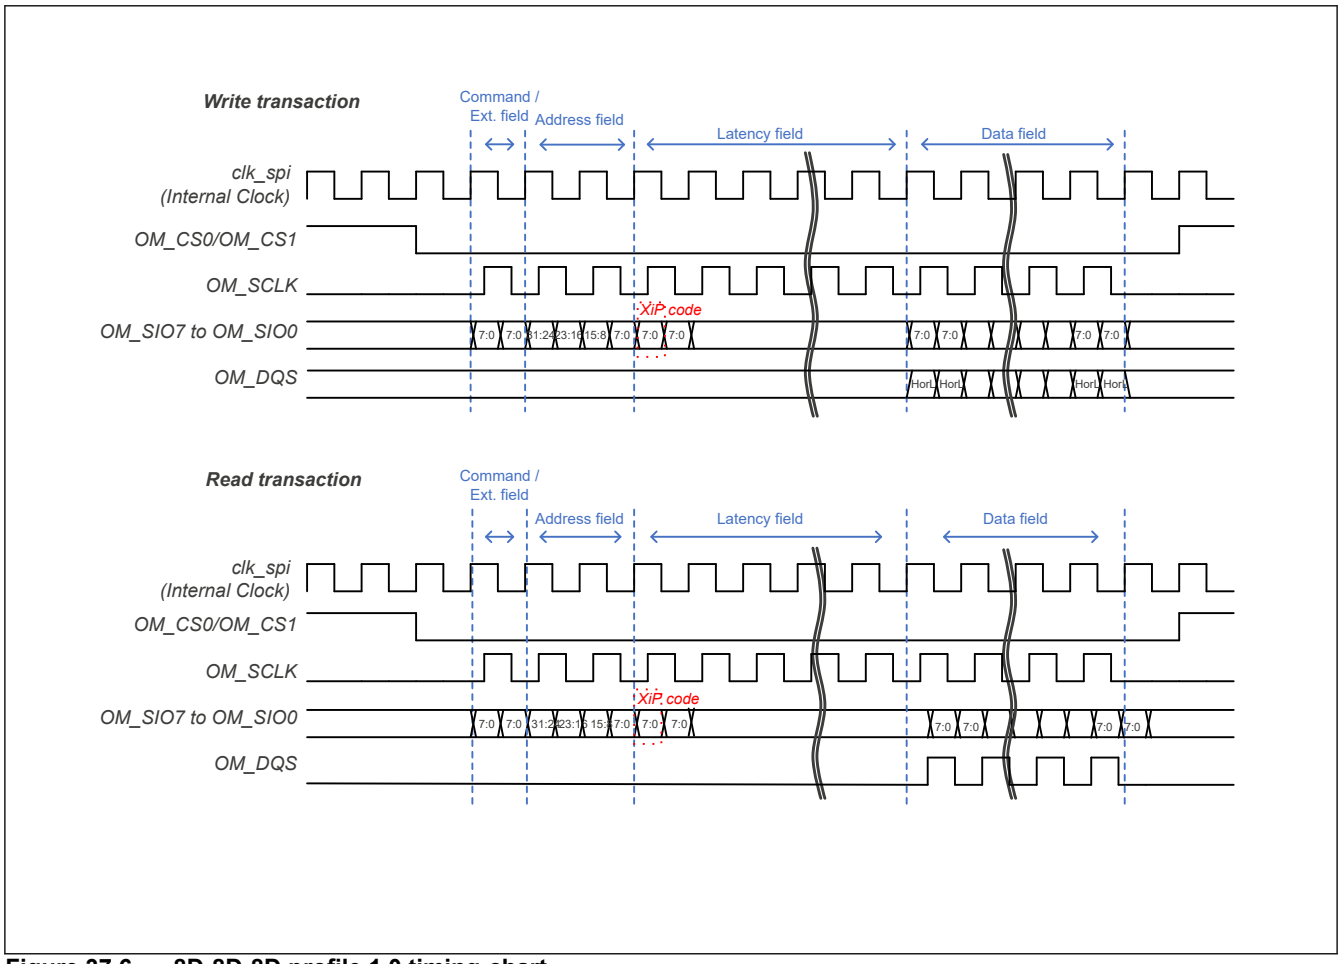

Figure 37.6 8D-8D-8D profile 1.0 timing-chart

Figure 37.7 shows timing-chart for 8D-8D-8D profile 2.0 protocol mode. In 8D-8D-8D, the data is always transmitted with byte-pair. In case each field is odd byte, last one byte is padded with invalid data.

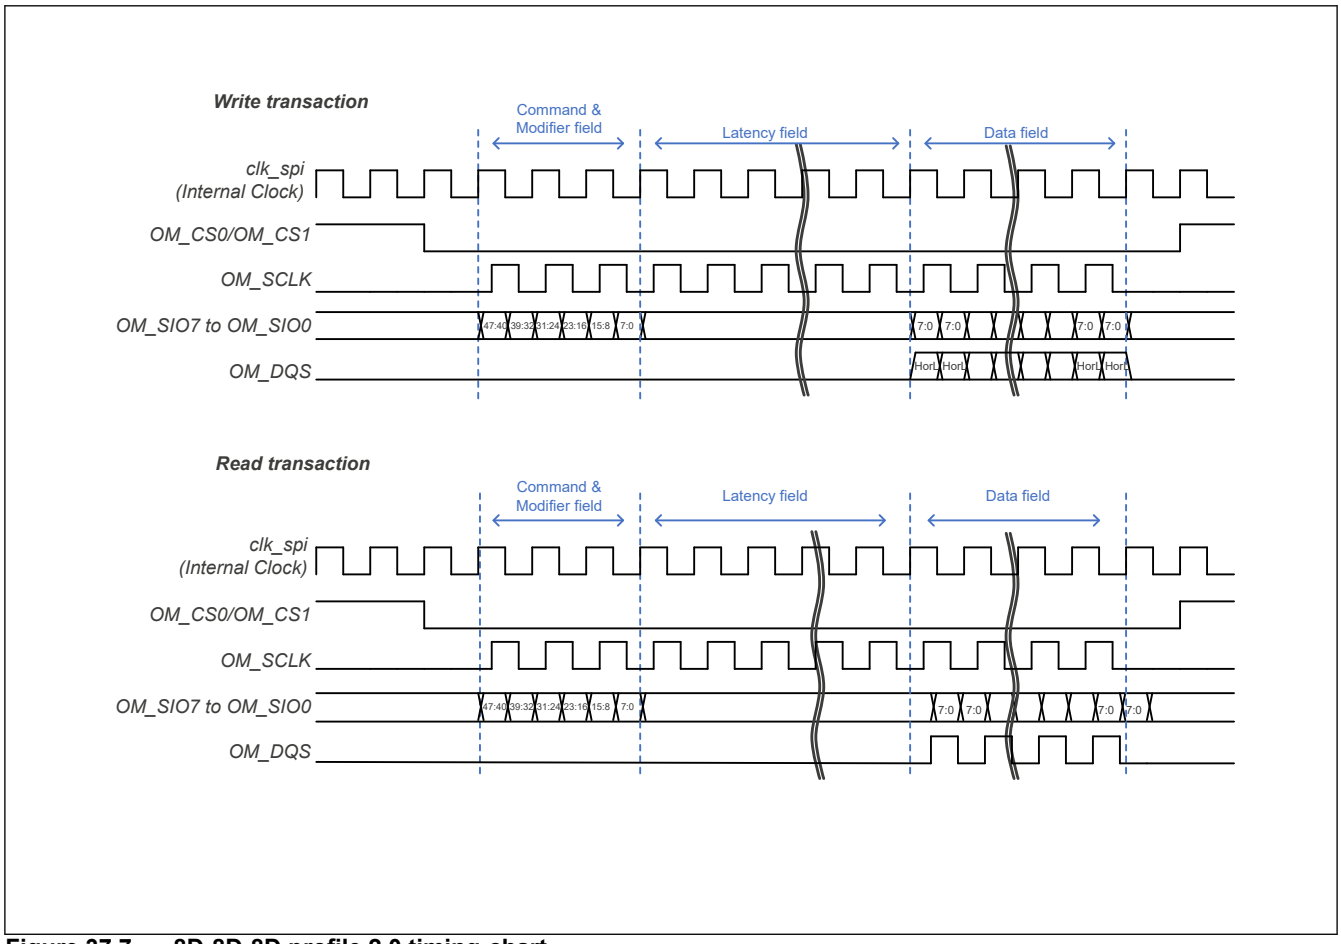

Figure 37.7 8D-8D-8D profile 2.0 timing-chart

37.3.1.2 xSPI Frame Interval

The interval between xSPI frames is configured with CS minimum idle term bits (LIOCFGCSn.CSMIN[3:0]). It depends on the specification of xSPI slave device.

37.3.1.3 OSPI Signals Timing Control

This xSPI Master supports both SDR and DDR. It is possible to sample input data with Data-Strobe (OM_DQS) signal at SDR. For various modes and easy implementation, this xSPI Master could adjust the timing to drive/sample xSPI interface signals statically. Table 37.4 shows the summary of xSPI Interface signal timing control.

Table 37.4 Summary of OSPI signals timing control (1 of 2)

Signal	Mode	Default operation	Timing control (n = 0, 1)
OM_CS0, OM_CS1 drive	—	Asserting 1 cycle before the rising-edge of first OM_SCLK	1 cycle extension for asserting with LIOCFGCSn.CSASTEX bit
		Negating 1.5 cycle after the falling-edge of last OM_SCLK	1 cycle extension for negating with LIOCFGCSn.CSNEGEX bit
OM_SCLK drive	SDR without OM_DQS SDR with OM_DQS	Reference point	—
	DDR with OM_DQS	Reference point	—

Table 37.4 Summary of OSPI signals timing control (2 of 2)

Signal	Mode	Default operation	Timing control (n = 0, 1)
OM_SIOn (n = 0 to 7) output drive	SDR without OM_DQS SDR with OM_DQS	Falling edge of clk_spi (Internal Clock)	0 or 0.5 cycle shift with LIOCFGCSn.SDRDRV bit
	DDR with OM_DQS	Both edges of clk_spi (Internal Clock)	—
OM_SIOn (n = 0 to 7) input sample	SDR without OM_DQS	Falling edge of OM_SCLK on expected data size	0 to 7 cycle shift (1 cycle unit) with LIOCFGCSn.SDRSMPSFT[3:0] bits 0 or 0.5 cycle shift with LIOCFGCSn.SDRSMPMD bit
	SDR with OM_DQS	Falling edge of OM_DQS signal on expected data size	Sample at rising edge with LIOCFGCSn.SDRSMPMD bit 0 to 1 cycle phase shift with WRAPCFG.DSSFTCSn[4:0] bits 0 to 7 cycle extension with LIOCFGCSn.DDRSMPEX[3:0] bits
	DDR with OM_DQS	Both edges of OM_DQS signal on expected data size	0 to 1 cycle phase shift with WRAPCFG.DSSFTCSn[4:0] bits 0 to 7 cycle extension with LIOCFGCSn.DDRSMPEX[3:0] bits

Note: In DDR on xSPI protocol, OM_DQS should be aligned for center of data. It means to shift the phase by 0.25 cycle (90 degrees). This xSPI master supports to adjust this phase depending on the usage conditions.

Figure 37.8 shows the default operation and timing control for SDR without OM_DQS.

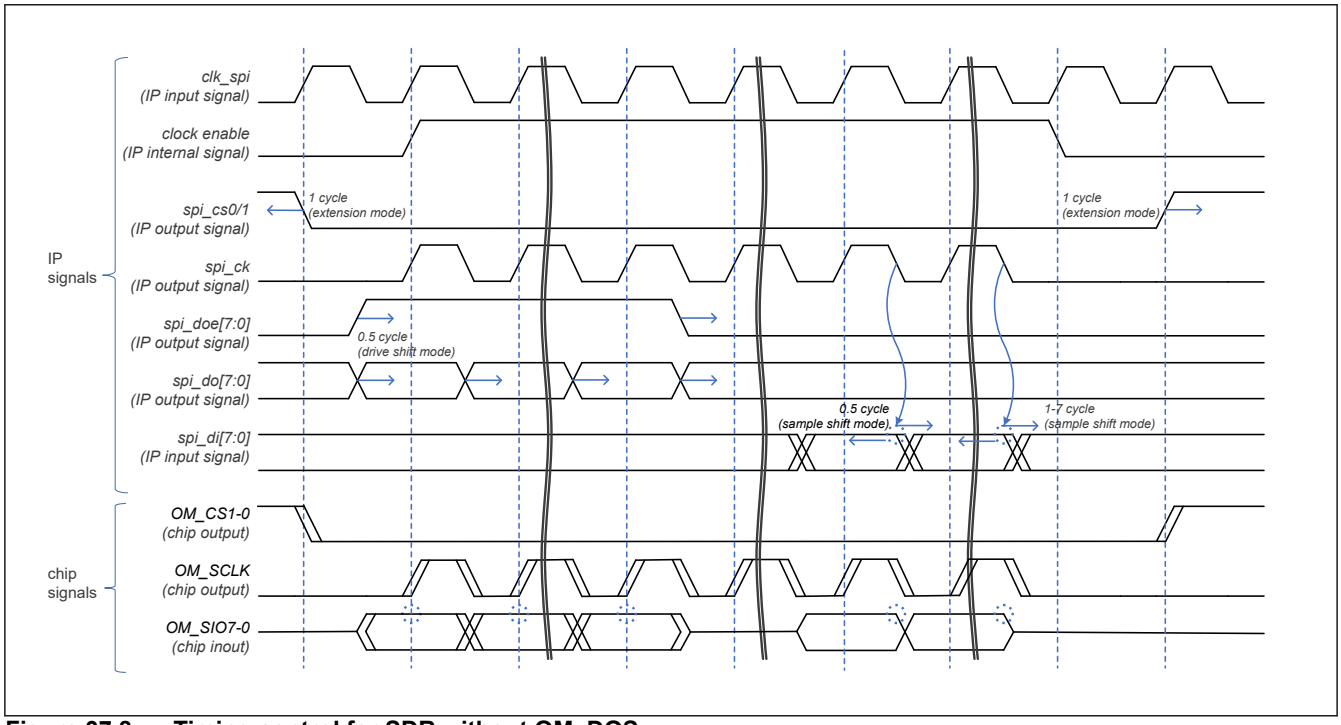

Figure 37.8 Timing control for SDR without OM_DQS

Figure 37.9 shows the default operation and timing control for SDR with OM_DQS.

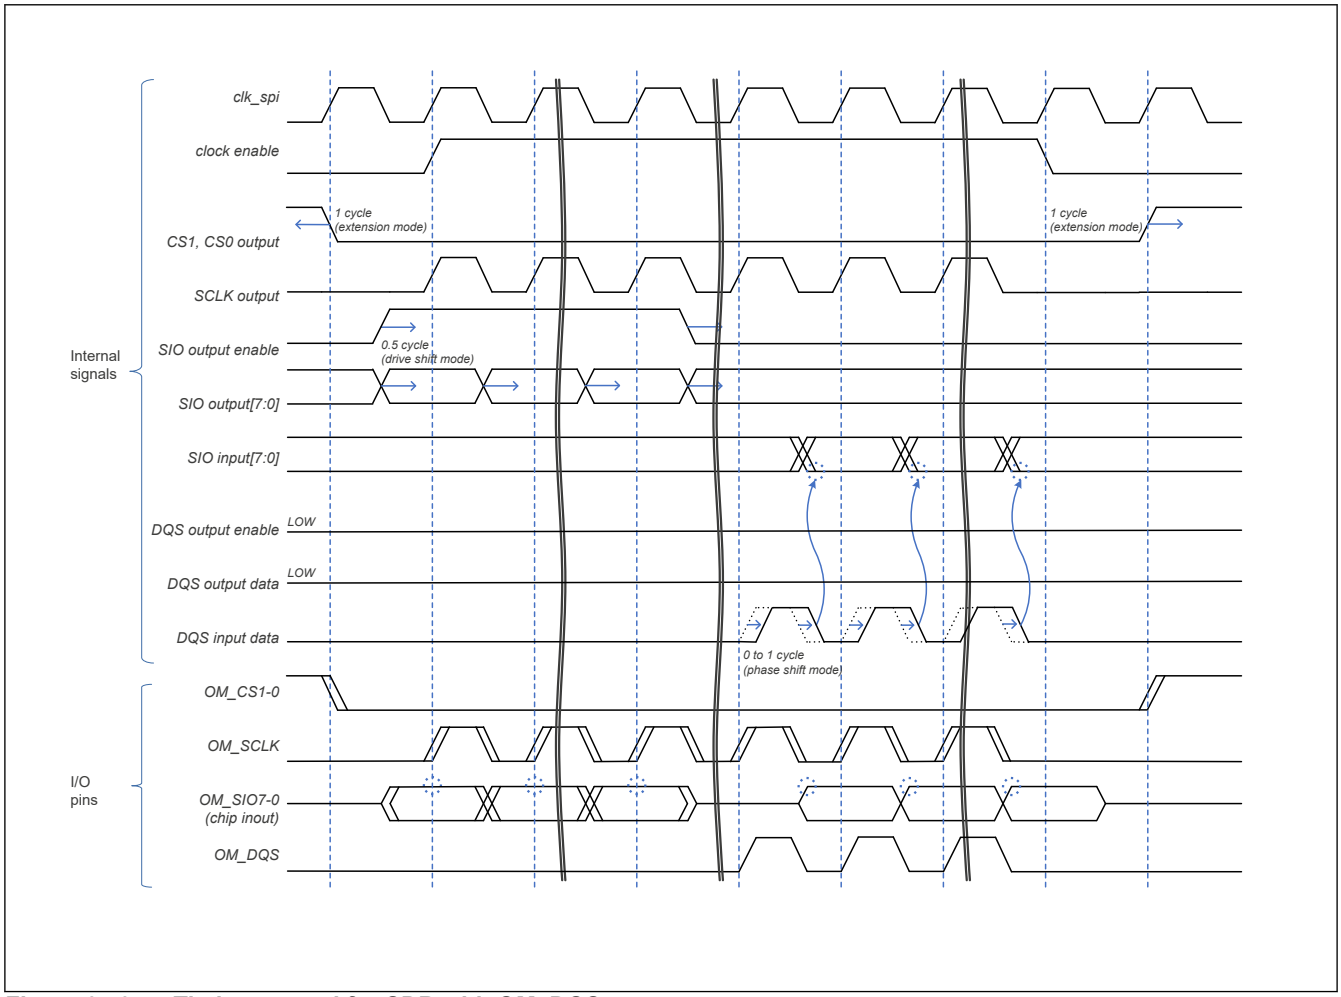

Figure 37.9 Timing control for SDR with OM_DQS

Figure 37.10 shows the default operation and timing control for DDR with OM_DQS.

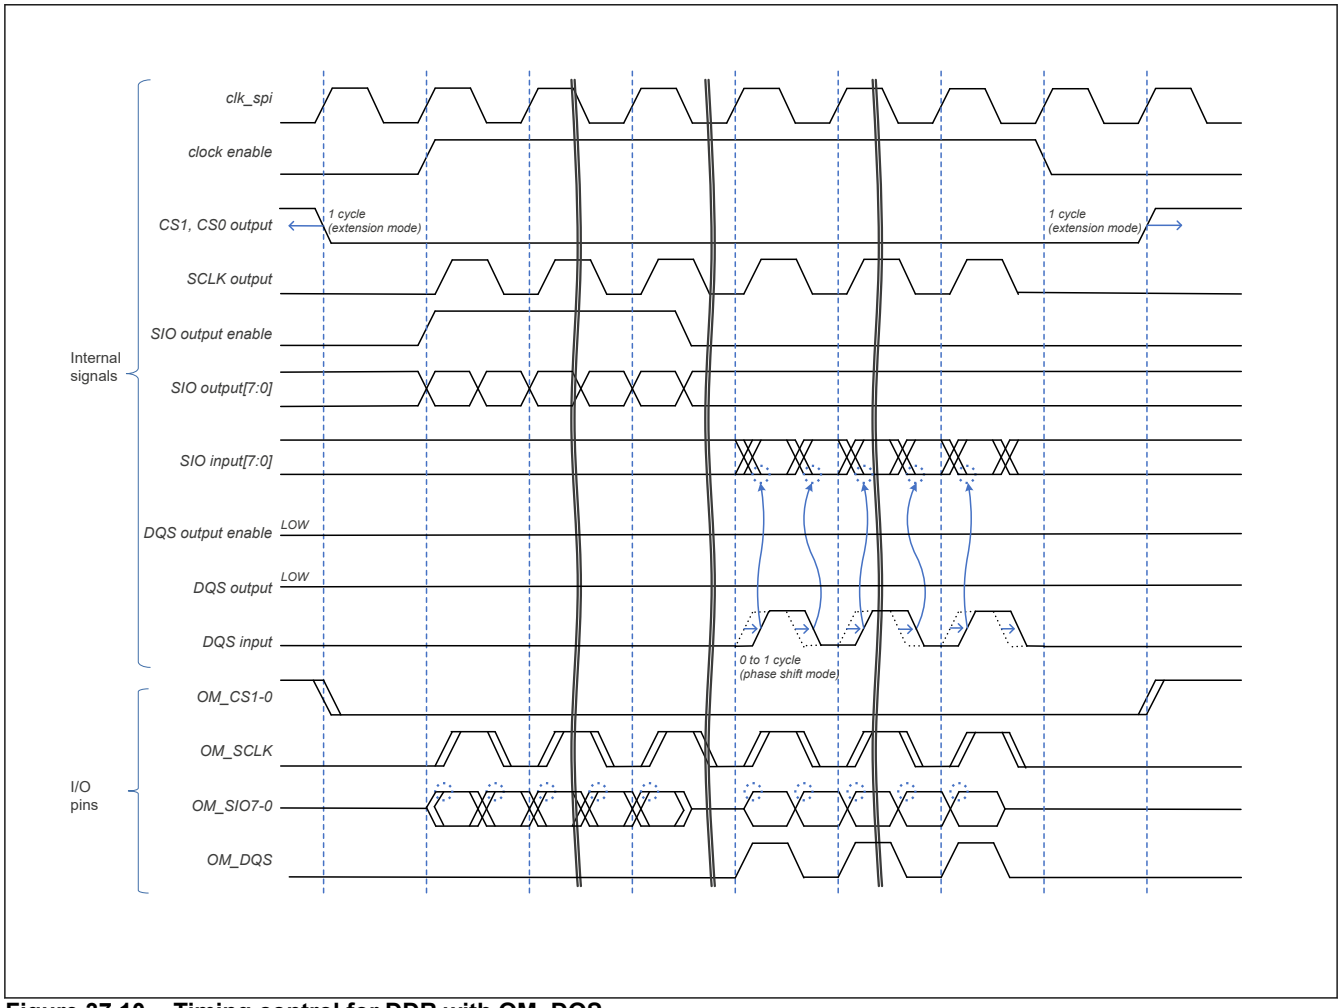

Figure 37.10 Timing control for DDR with OM_DQS

37.3.1.4 Automatic calibration

This xSPI master supports the function to adjust OM_DQS shift value (WRAPCFG.DSSFTCSn (n = 0, 1)) automatically. When this function is enabled (CCCTL0CSn.CAEN = 1), this xSPI master transmits the calibration sequence periodically and adjusts the value of phase shift.

When all read compare is mismatched in read transaction during the calibration sequence, the calibration fail bit (INTS.CAFAILCSn = 1 (n = 0, 1)) is asserted and OM_DQS shift value is not updated. When at least one read compare is matched, the calibration success bit (INTS.CASUCCSn = 1 (n = 0, 1)) is asserted and OM_DQS shift value is updated. The result of each OM_DQS shift value is monitored by Calibration Status register (CASTTCSn). Figure 37.11 shows automatic calibration.

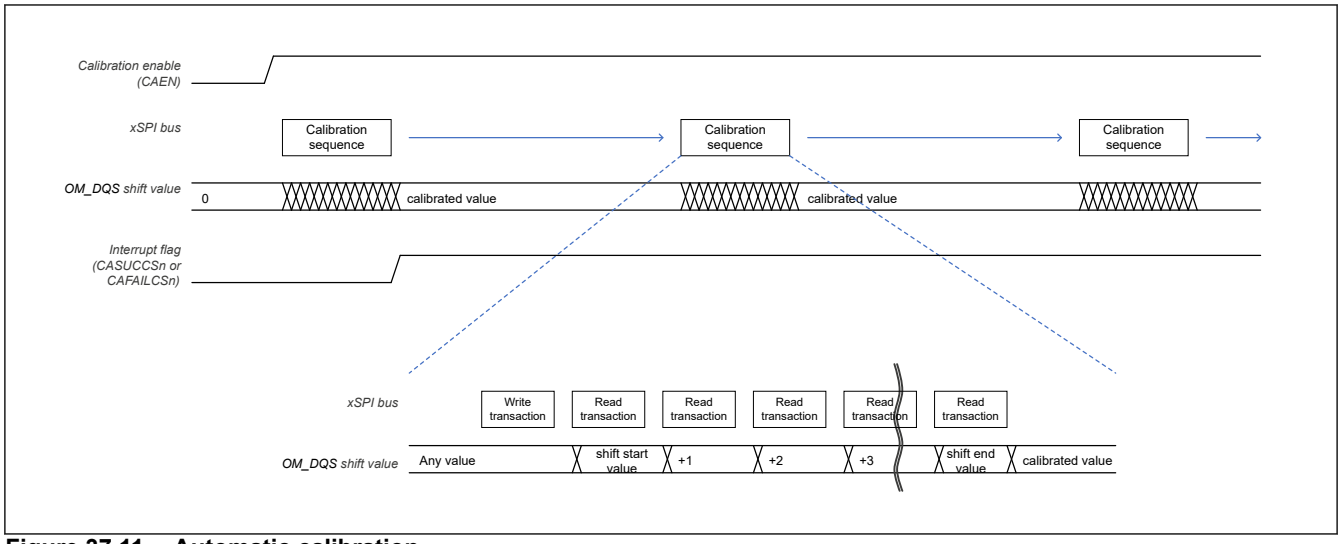

Figure 37.11 Automatic calibration

37.3.2 Manual-command

This section describes the manual-command mode. The manual-command has two functional modes: direct mode and periodic mode.

37.3.2.1 Direct Mode

This mode sequentially can issue up to four xSPI transactions configured and requested by Software. A series of transaction can be issued by a transaction request (CDCTL0.TRREQ = 1 with PERMD = 0). The number of transactions (CDCTL0.TRNUM[1:0]) can be configured up to 4. It can be used to change the mode or read the status of xSPI slave device.

Table 37.5 shows the configured register bits for direct manual-command. The operating flow is illustrated in Figure 37.25.

Table 37.5 Manual-command configuration for direct mode

Transaction	Transaction type	Command	Command size	Address	Address size	Data (x = 0, 1)	Data size	Latency cycle
1st Transaction	CDTBUF0.TRTYPE	CDTBUF0.CMD[15:0]	CDTBUF0.CMDSIZE[1:0]	CDABUF0.ADD[31:0]	CDTBUF0.ADDSIZE[2:0]	CDDxBUF0.DATA[31:0]	CDTBUF0.DATASIZE[3:0]	CDTBUF0.LATE[4:0]
2nd Transaction	CDTBUF1.TRTYPE	CDTBUF1.CMD[15:0]	CDTBUF1.CMDSIZE[1:0]	CDABUF1.ADD[31:0]	CDTBUF1.ADDSIZE[2:0]	CDDxBUF1.DATA[31:0]	CDTBUF1.DATASIZE[3:0]	CDTBUF1.LATE[4:0]
3rd Transaction	CDTBUF2.TRTYPE	CDTBUF2.CMD[15:0]	CDTBUF2.CMDSIZE[1:0]	CDABUF2.ADD[31:0]	CDTBUF2.ADDSIZE[2:0]	CDDxBUF2.DATA[31:0]	CDTBUF2.DATASIZE[3:0]	CDTBUF2.LATE[4:0]
4th Transaction	CDTBUF3.TRTYPE	CDTBUF3.CMD[15:0]	CDTBUF3.CMDSIZE[1:0]	CDABUF3.ADD[31:0]	CDTBUF3.ADDSIZE[2:0]	CDDxBUF3.DATA[31:0]	CDTBUF3.DATASIZE[3:0]	CDTBUF3.LATE[4:0]

37.3.2.2 Periodic Mode

This mode periodically issues an xSPI read transaction configured and requested by Software. And it can compare the read value up to 4 bytes with expected value. The transaction is issued by a transaction request (CDCTL0.TRREQ = 1 with PERMD = 1). It can be used to alternate the status polling operation of xSPI slave device.

The periodic term is configured in Periodic transaction interval bits (CDCTL0.PERITV[4:0]). The expected value is configured in Periodic transaction expected and masked value bits (CDCTL1.PEREXP[31:0] and CDCTL2.PERMSK[31:0]). Table 37.6 shows the configured register bits for periodic manual-command. The operating flow is illustrated in Figure 37.26.

Table 37.6 Manual-command configuration for periodic mode

Transaction	Transaction type	Command	Command size	Address	Address size	Data (x = 0, 1)	Data size	Latency cycle
Read Transaction	CDTBUF0.TRTYPE	CDTBUF0.CMD[15:0]	CDTBUF0.CMDSIZE[1:0]	CDABUF0.ADD[31:0]	CDTBUF0.ADDSIZE[2:0]	CDDxBUF0.DATA[31:0]	CDTBUF0.DATASIZE[3:0]	CDTBUF0.LATE[4:0]

37.3.3 Memory-mapping

This section describes the memory-mapping mode. This mode automatically converts system bus access for pre-configured memory area into xSPI transaction.

37.3.3.1 Configuration

In this operation, the payload of address and data field are delivered from system bus signals. The information of command field and size are delivered from the configured register bits. Table 37.7 shows the register bits configured for memory-mapping.

Table 37.7 Memory-mapping configuration for memory area access (n = 0, 1)

System bus Transaction	Format Change mode	Command	Command size	Address	Address size	Data	Data size	Latency cycle
Write for slave n memory area	Normal	CMCFG2CSn.WRCMD[15:8]	1 byte	SAWADDR[x:0]	CMCFG0CSn.ADDSIZE[1:0]	SWDATA	Up to SAWLEN and SAWSIZE	CMCFG2CSn.WRLATE[4:0]
	8D-8D-8D profile 1.0	CMCFG2CSn.WRCMD[15:0]	2 bytes					
	8D-8D-8D profile 2.0 Command Modifier	CMCFG2CSn.WRCMD[15:8]	1 byte	{SAWADDR[27:4], 0000000000000b, SAWADDR[3:1]}	5 bytes			
	8D-8D-8D profile 2.0 Extended Command Modifier	CMCFG2CSn.WRCMD[15:13]	3 bits	{0b, SAWADDR[31:4], 0000000000000b, SAWADDR[3:1]	45 bits			
Read for slave n memory area	Normal	CMCFG1CSn.RDCMD[15:8]	1 byte	SARADDR[x:0]	CMCFG0CSn.ADDSIZE[1:0]	SRDATA	Up to SARLEN and SARSIZE	CMCFG1CSn.RDLATE[4:0]
	8D-8D-8D profile 1.0	CMCFG1CSn.RDCMD[15:0]	2 bytes					
	8D-8D-8D profile 2.0 Command Modifier	CMCFG1CSn.RDCMD[15:8]	1 byte	{SARADDR[27:4], 0000000000000b, SARADDR[3:1]}	5 bytes			
	8D-8D-8D profile 2.0 Extended Command Modifier	CMCFG1CSn.RDCMD[15:13]	3 bits	{0b, SARADDR[31:4], 0000000000000b, SARADDR[3:1]}	45 bits			

Note: The MSByte of Address can be replaced with Address Replace Enable and Code bits (CMCFG0CSn.ADDRPEN[7:0] / ADDRPCD[7:0]).

37.3.3.2 Write Access Operation

At accepting write access for memory area from system bus, this xSPI Master stores all payload data in internal bridge buffer and then issues a write transaction into xSPI slave. Figure 37.12 shows the operation summary.

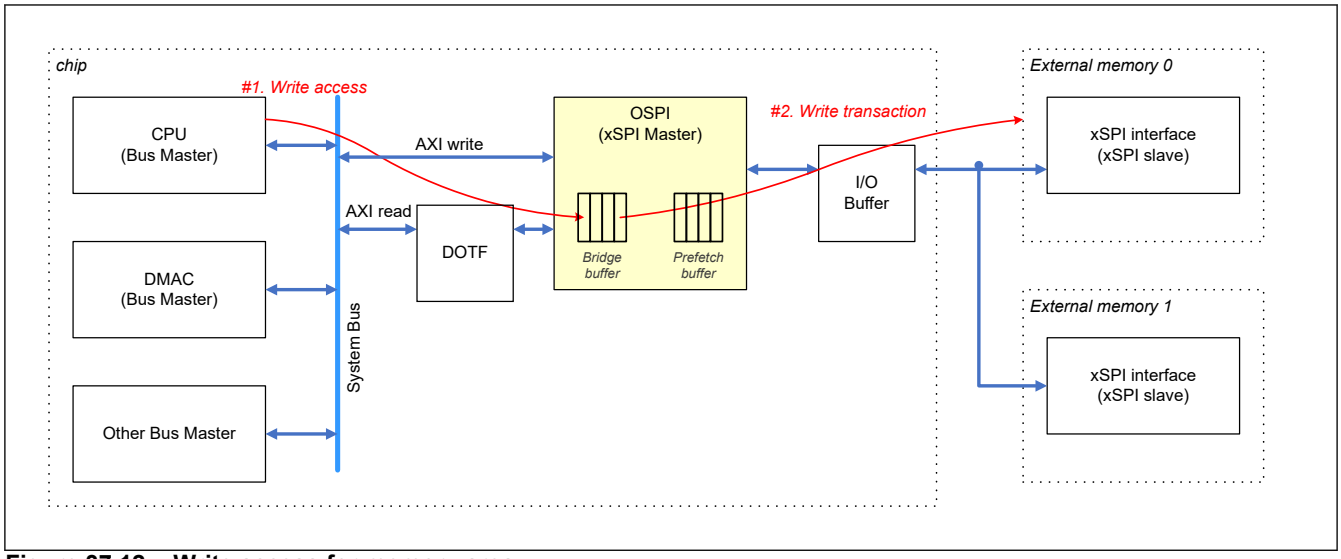

Figure 37.12 Write access for memory area

The operation of xSPI bus changes depending on system bus's burst type. When the burst type is single type or incremental type, one system bus transaction triggers for one xSPI frame. When the burst type is wrap type and the CMCFG0CSn.WPBSTMD is 0, one system bus transaction triggers two xSPI frames. Figure 37.13 shows the relationship between AXI and xSPI frames.

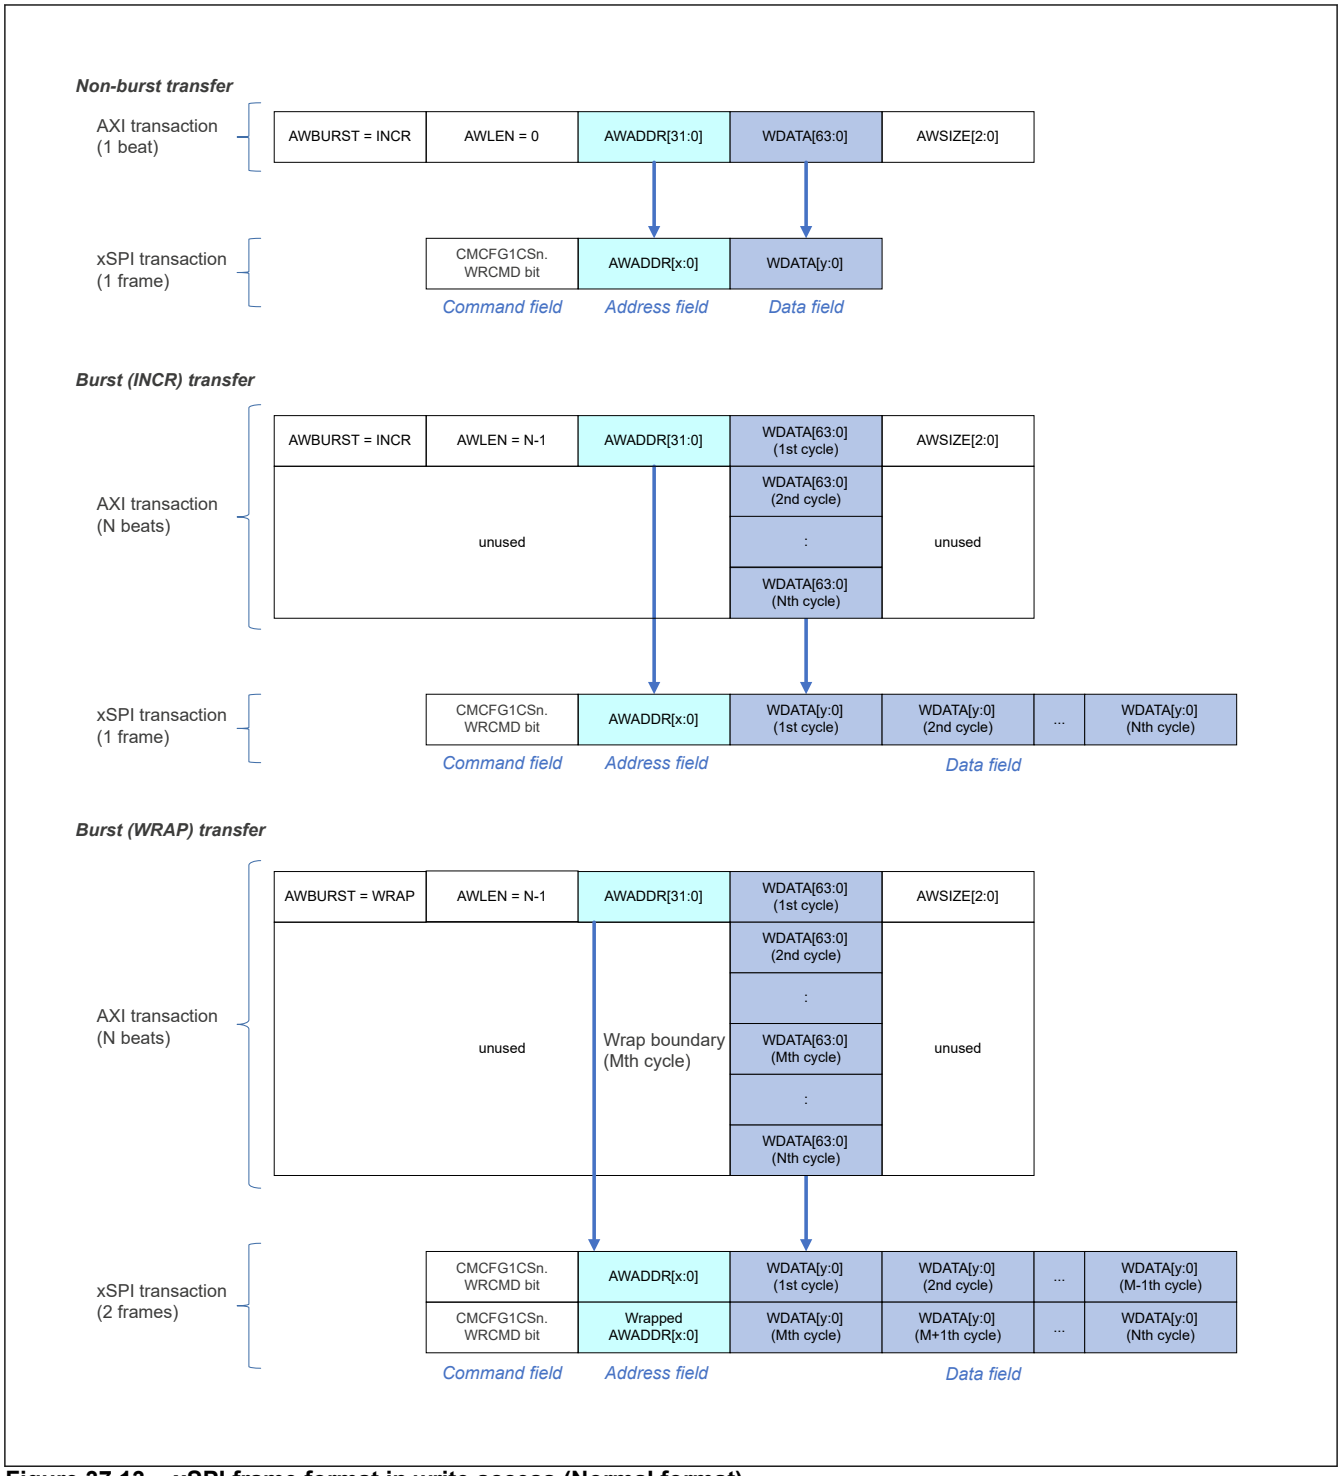

Figure 37.13 xSPI frame format in write access (Normal format)

37.3.3.3 Combination Function

At the system bus write access for memory area, this xSPI master has the function to combinate the write data for high throughput on xSPI bus. When this function is enabled (BMCFGCHn.MWRCOMB = 1), this xSPI master transmits a xSPI frame with the selected size while the sequential address is incremental[*1]. When one of the below conditions is detected, even though not reaching to the target size (BMCFGCHn.MWRSIZE[7:0]), this xSPI master transmits the pending data into xSPI bus.

- Non-incremental address is detected.
- Different burst type is detected.

- Read transaction is detected.
- Access for different slave is detected.
- Memory Write Data Push bit (BMCTL1.MWRPUSHCHn (n = 0, 1)) is set.

This function could be useful for any slave device to request a chunk of data at a time. In the case, system bus master shall continue to provide the fixed data size with incremental address. e.g. there is any device to request to write in page unit.

Figure 37.14 shows the operation when enable the combination function.

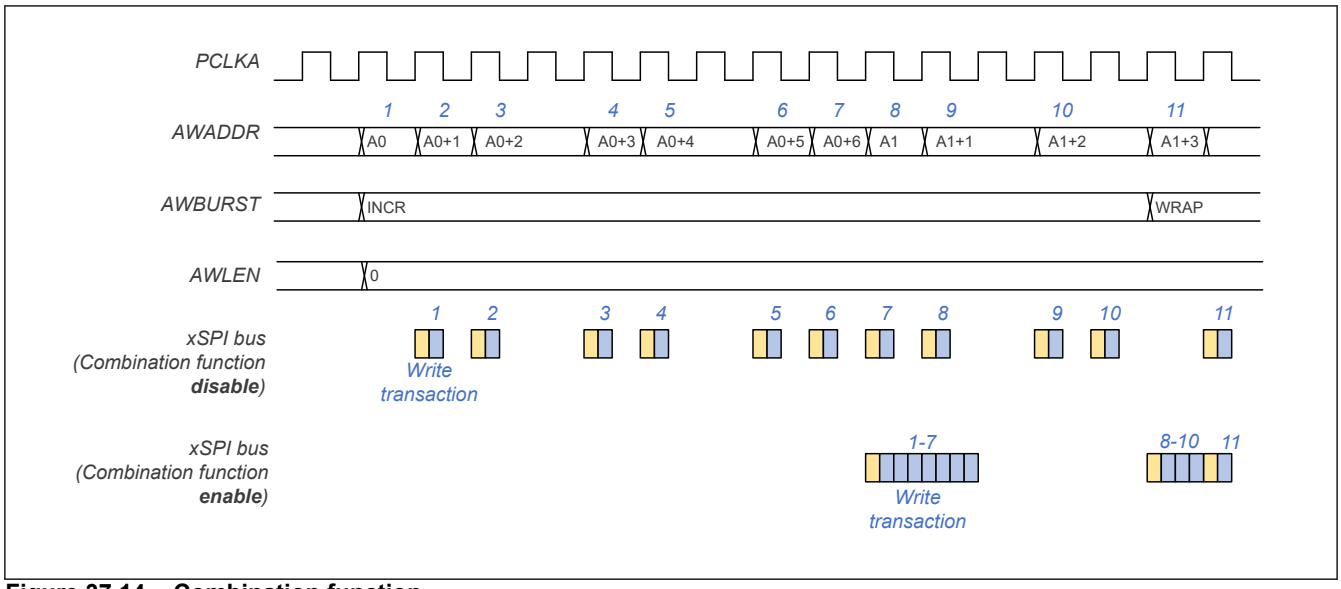

Figure 37.14 Combination function

Note 1. The access which comply all below condition is considered as incremental address.

- Transaction type is INCR.
- The access's start address is continuous to the previous last write address.
  - The access's start position of WSTRB is treated as start address.
  - Previous access's last WSTRB is treated last write address.

Figure 37.15 shows data combined example with AXI access.

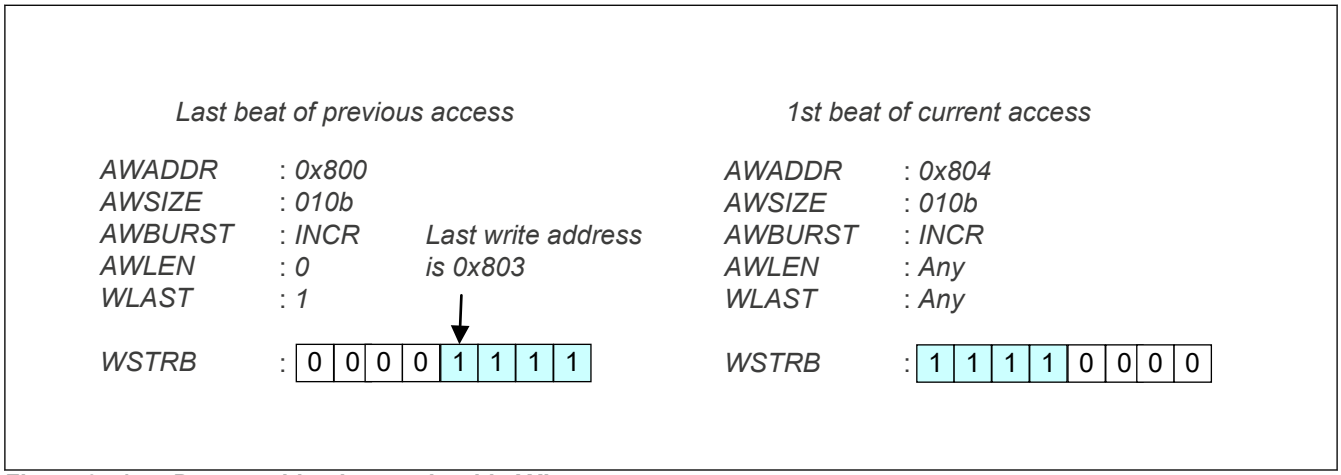

Figure 37.15 Data combined example with AXI access

37.3.3.4 Read Access Operation

At the read access for memory area, soon after detected the read access, this xSPI Master issues a read transaction into xSPI slave. Figure 37.16 shows the operation summary.

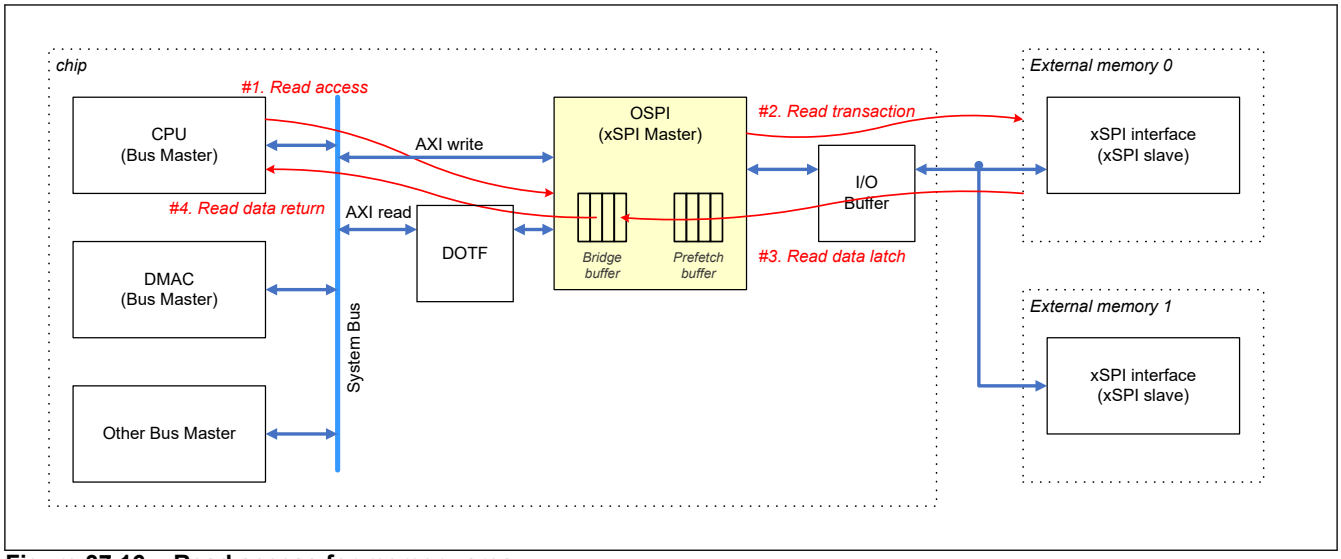

Figure 37.16 Read access for memory area

The operation of xSPI bus changes depending on burst type. When the type is single or increment type, one system bus's read transaction triggers one xSPI frame. When the type is wrap type and the CMCFG0CSn.WPBSTMD is 0, one system bus read transactions triggers two xSPI frames. Figure 37.17 shows the relationship between AXI and xSPI frames.

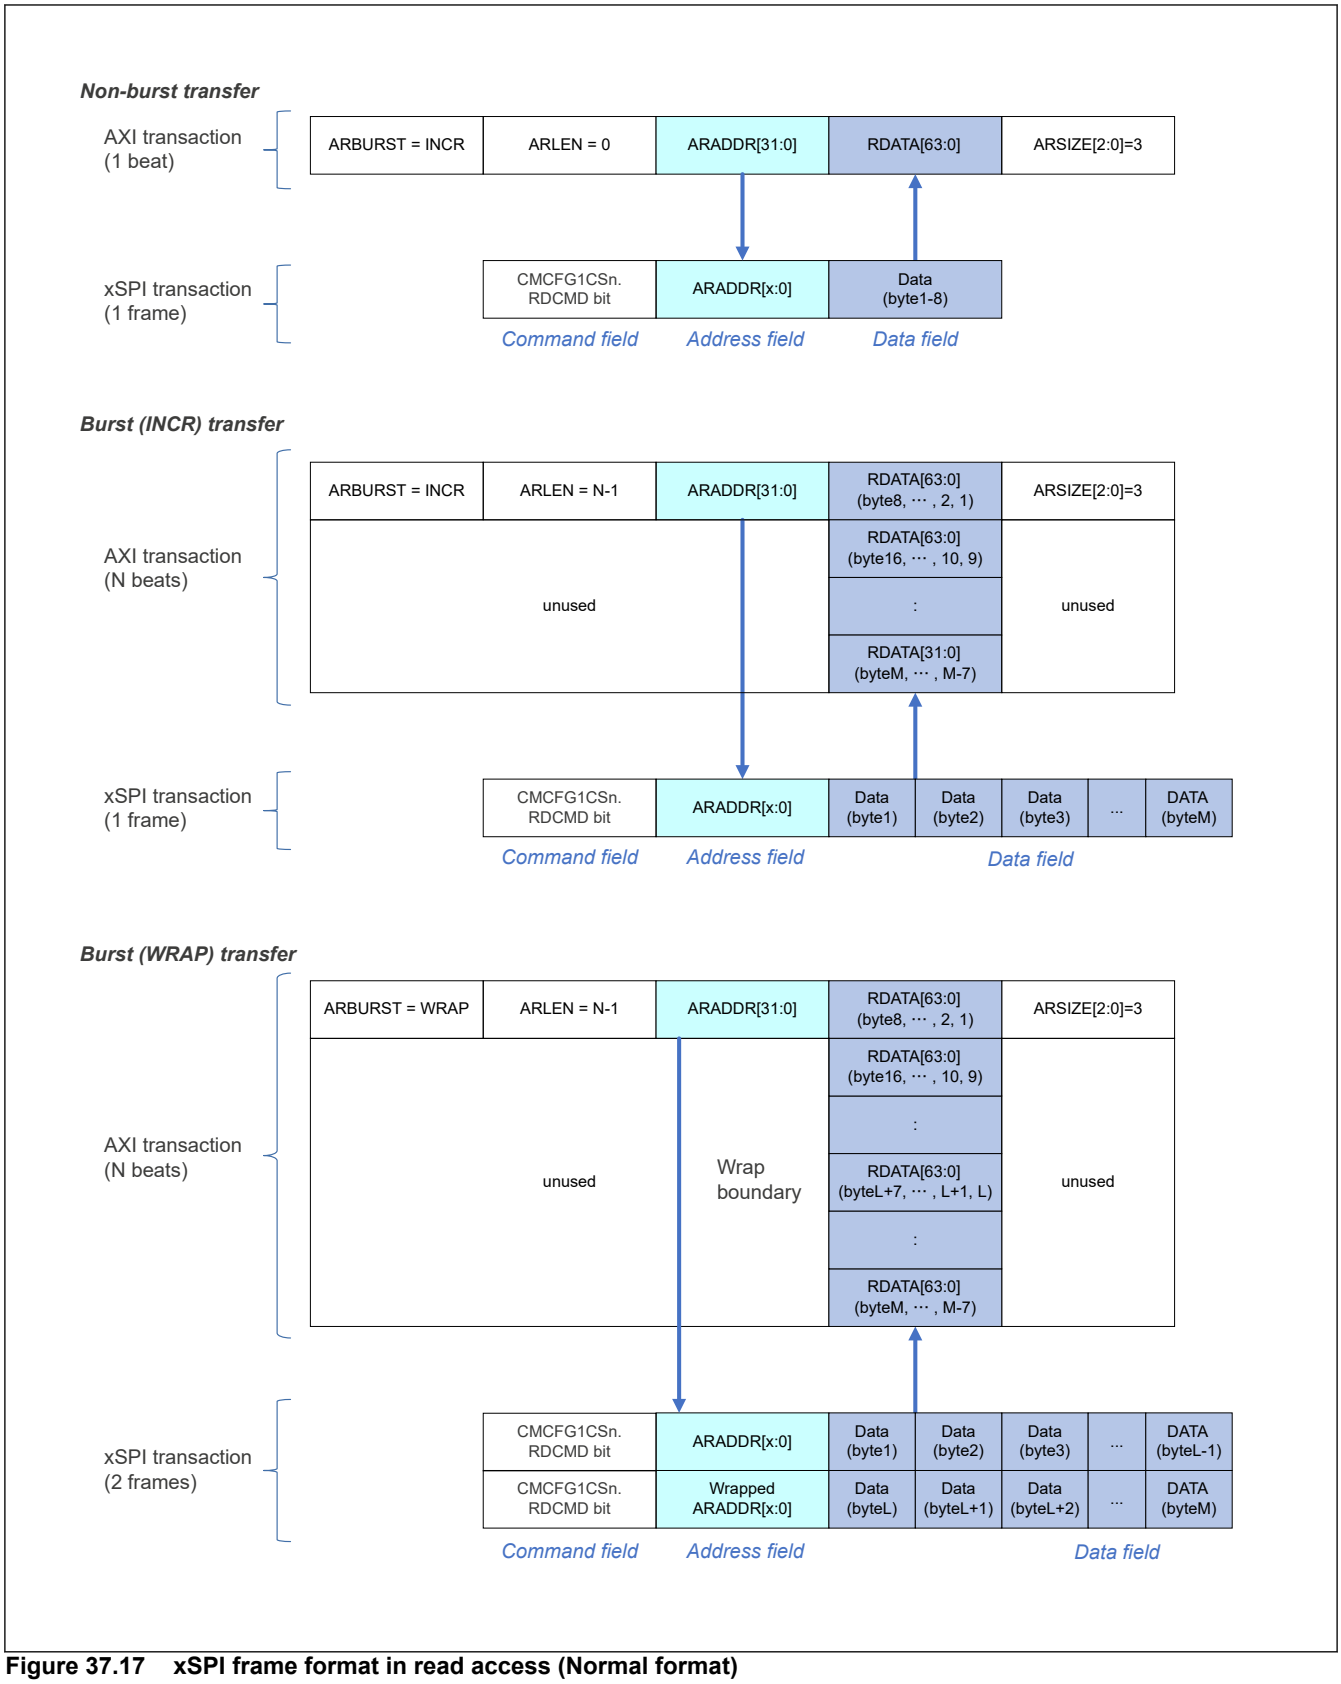

Figure 37.17 xSPI frame format in read access (Normal format)

37.3.3.5 Prefetch Function

At the read access for memory area from system bus, this xSPI Master has the function to prefetch the read data for reducing the latency. When enabled this function (BMCFGCHn.PREEN = 1), this xSPI Master continues to read the incremental address and store the read data from xSPI slave in internal prefetch buffer. And this xSPI master searches in

prefetch buffer for the following read access from system bus. If found the target read data in prefetch buffer, this xSPI Master returns the data from prefetch buffer. If not found, this xSPI Master clears prefetch buffer and newly issues a read transaction into xSPI slave. This function is effective in application such as the consecutive read addresses are close. But it is not effective in application such as the consecutive read addresses are not incremental because xSPI read frame for prefetch uses xSPI bus. Figure 37.18 shows the operation summary.

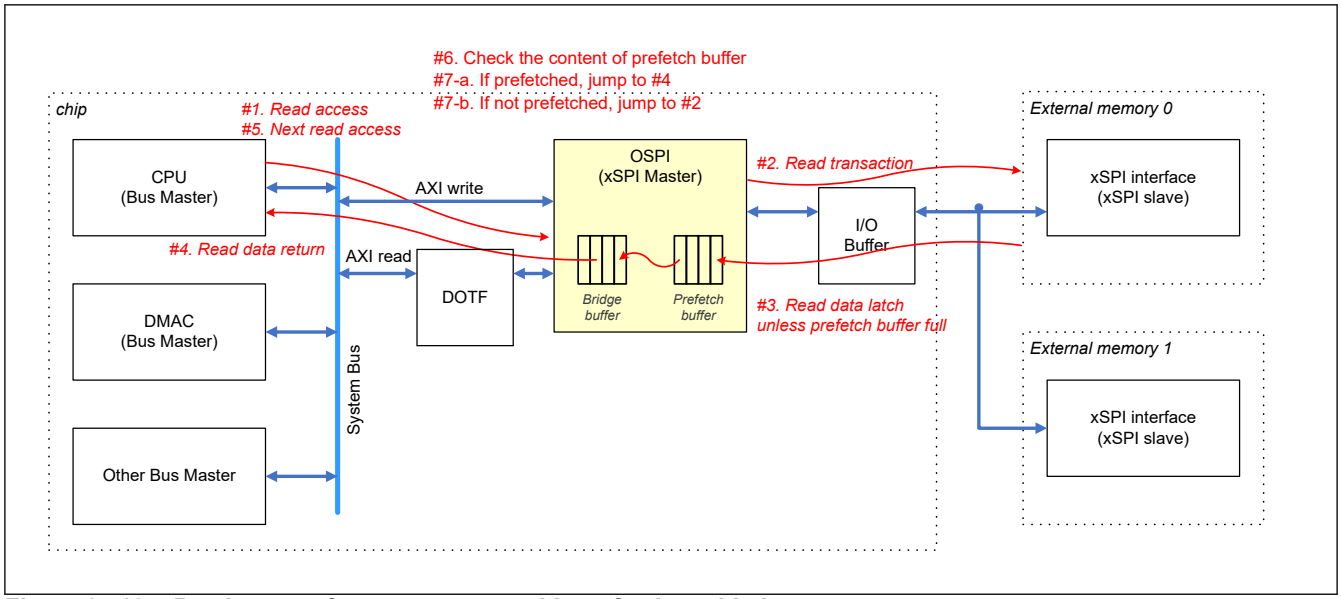

Figure 37.18 Read access for memory area with prefetch enabled

Note: When enabled this prefetch function, Bus Master could read from not a slave device but the internal prefetch buffer. When accessed to the same address from multiple Bus Masters, this xSPI Master does not guarantee to read the latest data. If Bus Master wish to read the latest data from a slave device, it should read after cleared the prefetch buffer (BMCTL1.PBUFCLRCHn (n = 0, 1)).

Note: Prefetch buffer is implemented as FIFO-based, and when read access is issued, the data before the access address is discarded from the buffer. And when next access is issued to the region which is discarded at previous access, this module issues the xSPI read access again to fill the prefetch buffer.

Note: OSPI has the 1line buffer which keeps the last 8Byte read data from prefetch buffer. When read access is issued to the same address to the data in 1line buffer, OSPI returns read data from 1line buffer.

37.3.3.6 XiP Mode

Some slave devices have a mode (XiP mode) in which the command phase is not required for lower latency. While in this mode, the xSPI master skips sending the command and the slave device implicitly performs the command that was executed in the previous transaction. When enabled XiP mode bit (CMCTLCHn.XIPEN = 1), this xSPI master inserts XiP enter code (CMCTLCHn.XIPENCODE[7:0]) in latency field. When disabled XiP mode bit (CMCTLCHn.XIPEN = 0), this xSPI master inserts XiP exit code (CMCTLCHn.XIPEXCODE[7:0]) in latency field. This function is available only for memory-mapping mode.

And when this xSPI master transmits XiP disable pattern, this master clears XiP mode bit and disables XiP mode configured for both channels. Note that it is not possible to disable XiP mode for only one channel by transmitting XiP disable pattern.

Note: When enough latency cycle does not exist for XiP code, this xSPI Master could not insert XiP code.

Note: XiP mode could be used only for unidirectional access to a slave. The write transaction and read transaction should be separated.

Note: The XiP exit code is inserted once when disabled. More details, See Figure 37.30.

37.3.4 Pattern Control

This xSPI Master has the function to transmit 3 type of patterns which is not xSPI frame format. The pattern is triggered by setting trigger bit (LPCTL0-1.PATREQ).

37.3.4.1 XiP Disable Pattern

XiP Disable pattern transmits any pattern with the configured length and value (LPCTL0.XD1LEN[4:0] / XD1VAL / XD2LEN[4:0] / XD2VAL). It uses OM_SCLK, OM_SIO7-0 signals. The number of output pin can be configured by XiP Disable pattern pin bits (LPCTL0.XDPIN[1:0]). It may be used to disable XiP mode for legacy SPI. Figure 37.19 shows the timing-chart.

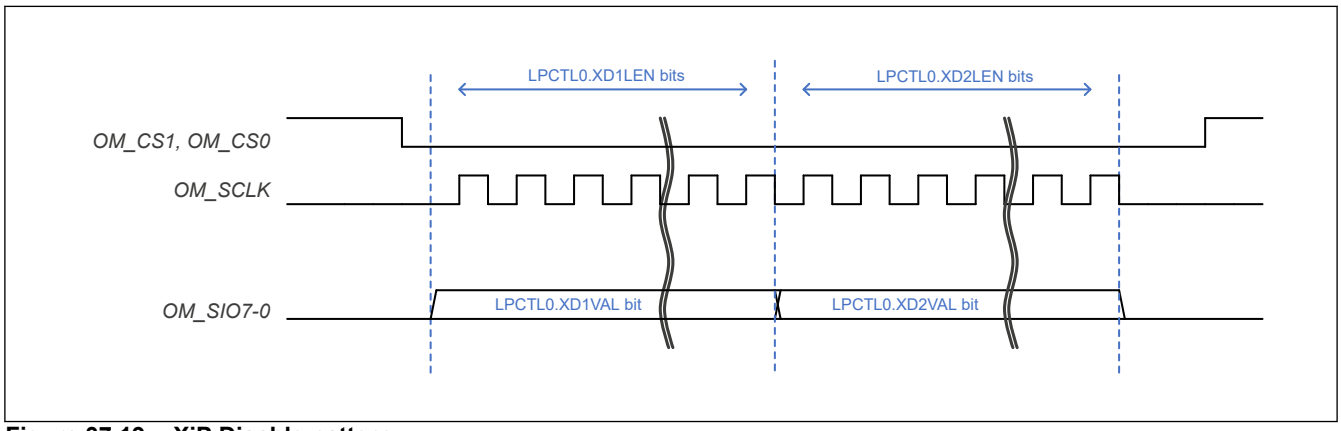

Figure 37.19 XiP Disable pattern

37.3.4.2 Reset Pattern

Reset pattern transmits the pattern specified in Serial Flash Reset Signaling Protocol. Figure 37.20 shows the timing chart.

CS Low/High width is configured with Reset Pattern Length bits (LPCTL1.RSTWID[2:0]). xSPI slave will sample the data input at the rising edge of CS. Setup time for data output is configured with Reset pattern data output setup time bits (LPCTL1.RSTSU[2:0]). The setup time should be less than Reset pattern width always.

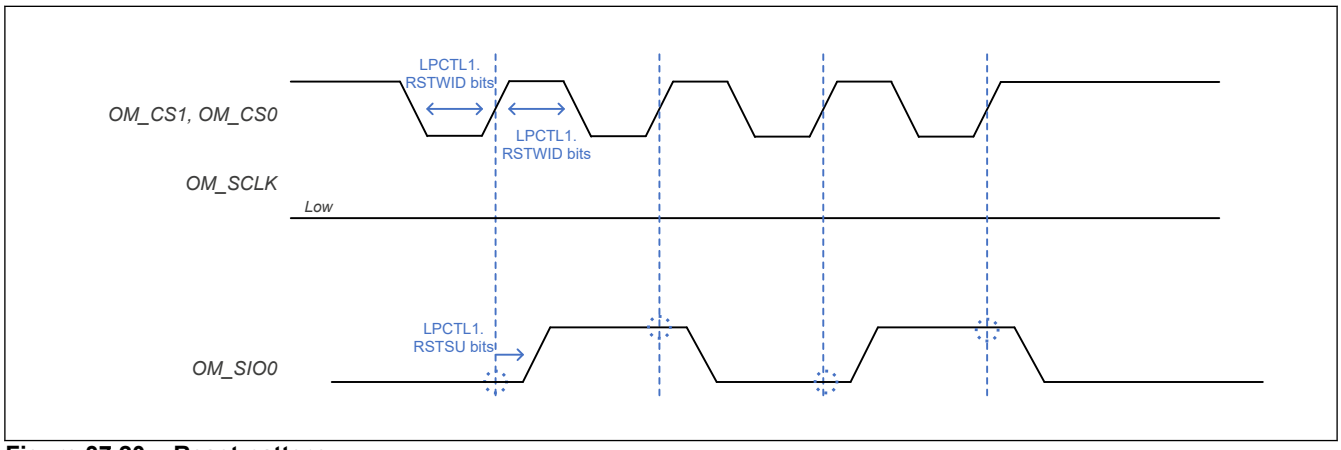

Figure 37.20 Reset pattern

Note: In the protocol, CS Low/High width is defined as minimum 500 ns and Setup time is defined as minimum 6 ns.

37.3.4.3 CS Only Pattern

CS Only pattern activates CS port with the configured length bits (LPCTL1.RSTWID[2:0]). It may be used to resume from Deep Power Down state. Figure 37.21 shows the timing-chart.

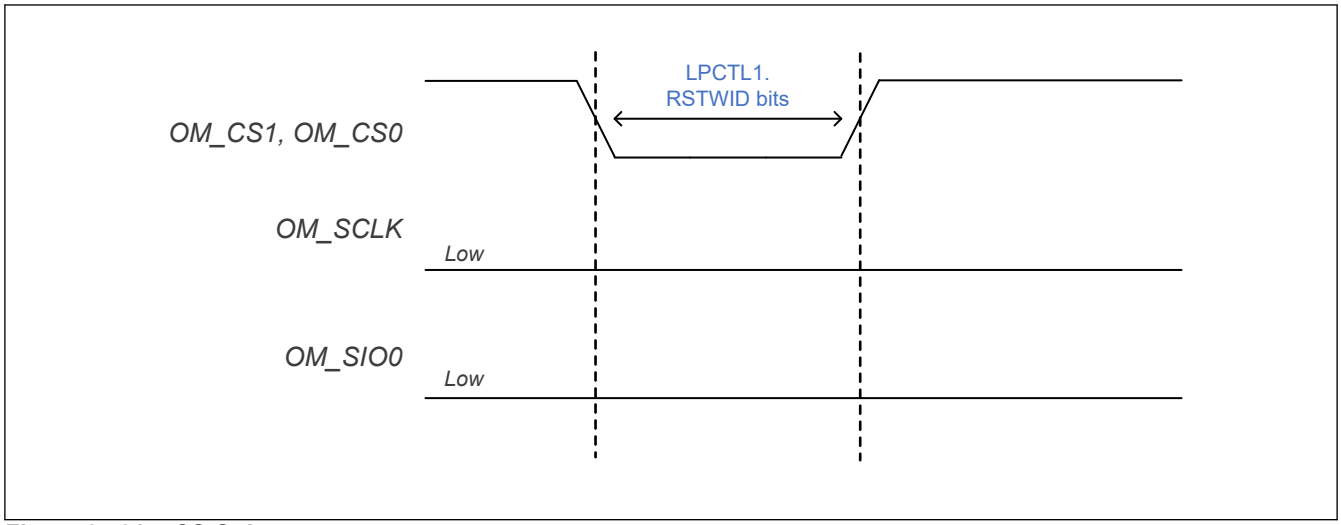

Figure 37.21 CS Only pattern

37.3.5 Integrity Checking

This xSPI Master can detect some errors. Table 37.8 shows the error list and the detail behavior.

Table 37.8 Error list (n = 0, 1)

Error type	Event	Flag bit	Note (action)
Calibration failed	When the read data did not match the expected value during automatic calibration.	INTS.CAFAILCSn	It results in writing unexpected data to xSPI slave.
System bus error	When an error response occurred on AXI slave interface for memory-mapping.	INTS.BUSERRCHn	This xSPI master shall be reset for fatal error.
ECC error detection	When detected the falling edge on OM_ECSINT1 port. It can be useful only for xSPI slave with ECC detection function.	INTS.ECSCS1	Only notify the error event of xSPI slave.
OM_DQS timeout	When OM_DQS does not toggle in read transaction with using OM_DQS.	INTS.DSTOCSn	Both xSPI master and xSPI slave should be reset for fatal error.
Periodic transaction timeout	When the read value does not match with the expected value in periodic manual-command mode.	INTS.PERTO	Depending on the status of function.

37.3.6 Interrupts

This xSPI Master has an interrupt port.

It can monitor with Interrupt Status Register (INTS). In case of initialization phase, it can be programmable with Interrupt Enable register (INTE). Table 37.9 shows OSPI interrupt sources, and Table 37.10 shows the related register bit.

Note: Interrupt pulse port signal is not asserted when the corresponding bit of INTE is set after the interrupt event is detected.

Table 37.9 OSPI interrupt sources

Name	Interrupt sources	DMAC activation
OSPI0_ERR	Error	Not possible
OSPI0_CMP	Complete	Not possible

Table 37.10 Interrupt register bit (1 of 2)

Flag bit	Enable bit	Clear bit	Interrupt sources
CASUCCS1	CASUCCS1E	CASUCCS1C	OSPI0_CMP
CASUCCS0	CASUCCS0E	CASUCCS0C	

Table 37.10 Interrupt register bit (2 of 2)

Flag bit	Enable bit	Clear bit	Interrupt sources
CAFAILCS1	CAFAILCS1E	CAFAILCS1C	OSPI0_ERR
CAFAILCS0	CAFAILCS0E	CAFAILCS0C	
BUSERRCH1	BUSERRCH1E	BUSERRCH1C	OSPI0_ERR
BUSERRCH0	BUSERRCH0E	BUSERRCH0C	
INTCS1	INTCS1E	INTCS1C	OSPI0_ERR
ECSCS1	ECSCS1E	ECSCS1C	OSPI0_ERR
DSTOCS1	DSTOCS1E	DSTOCS1C	OSPI0_ERR
DSTOCS0	DSTOCS0E	DSTOCS0C	
PERTO	PERTOE	PERTOC	OSPI0_ERR
PATCMP	PATCMPE	PATCMPC	OSPI0_CMP
CMDCMP	CMDCMPE	CMDCMPC	OSPI0_CMP

37.3.7 Flows of Operations

37.3.7.1 Flow of Configuration

Figure 37.22 shows flow of configuration.

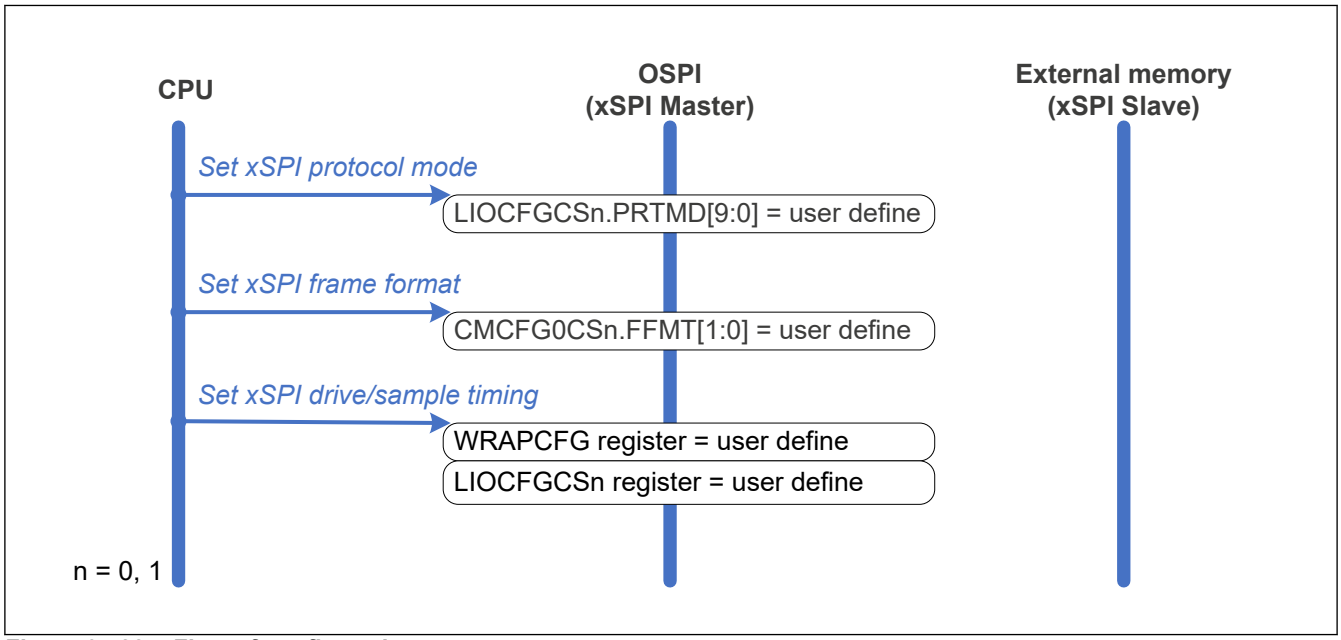

Figure 37.22 Flow of configuration

37.3.7.2 Flow of Communication Stop

Figure 37.23 shows flow of communication stop.

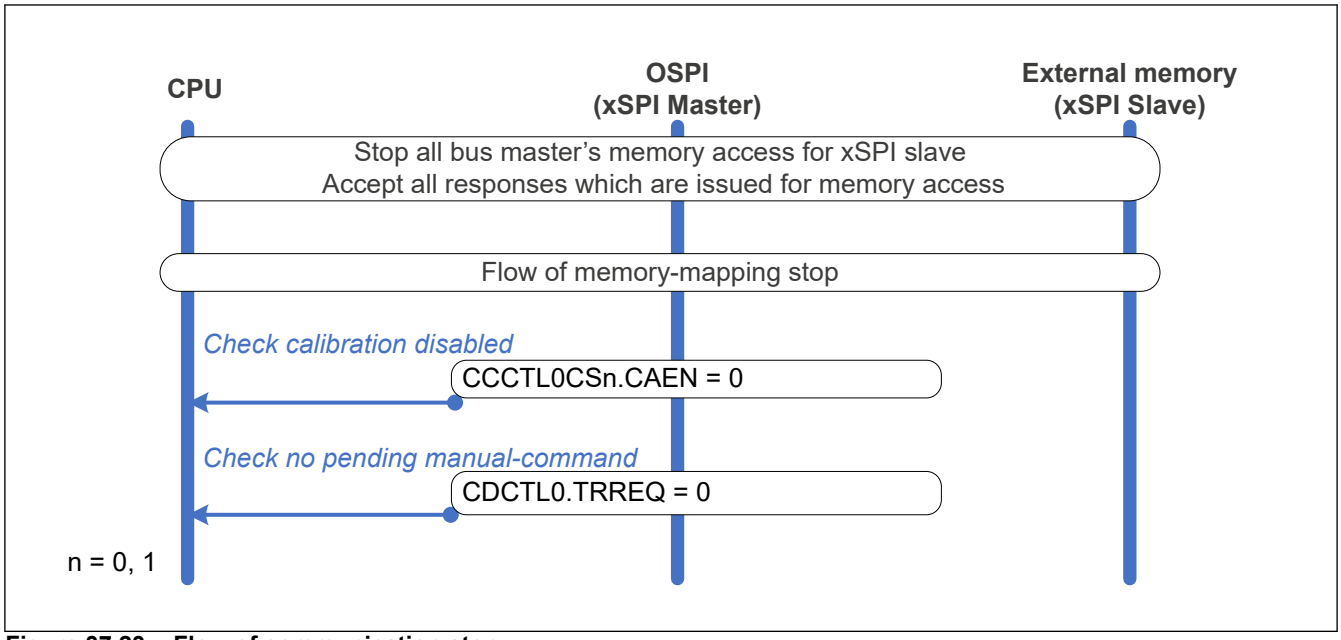

Figure 37.23 Flow of communication stop

Note: In case of re-config of any configuration register, all communication with xSPI slave shall be stopped surely to avoid race condition between register setting and memory access. It means that the automatic calibration is disabled, and there is no pending manual-command and memory-mapping access.

37.3.7.3 Flow of Automatic Calibration

Figure 37.24 shows flow of automatic calibration.

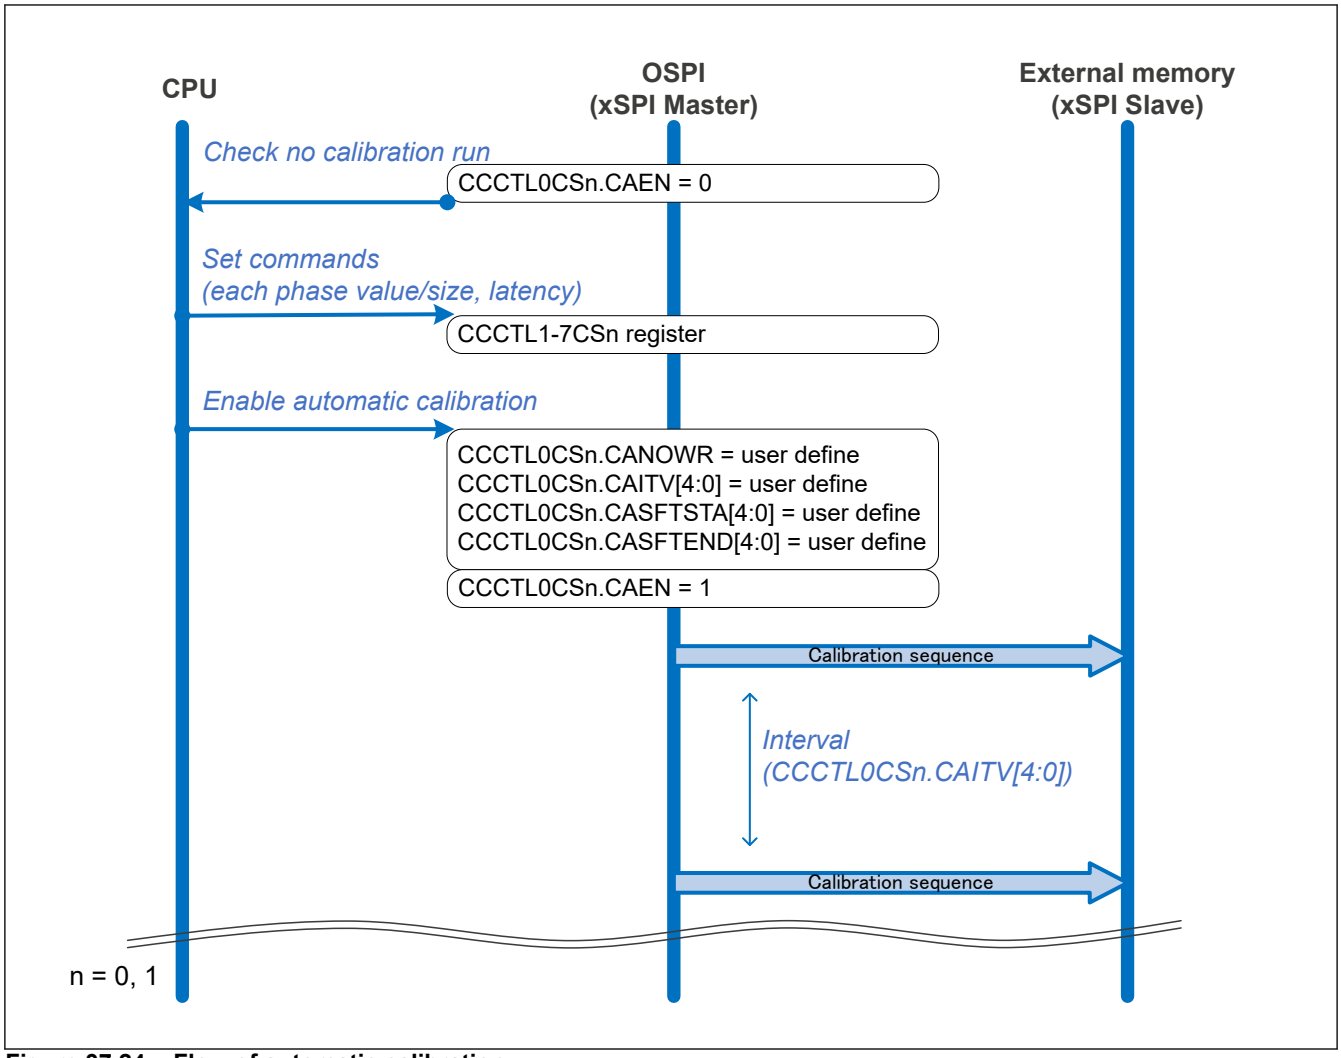

Figure 37.24 Flow of automatic calibration

37.3.7.4 Flow of Manual-command Procedure

Figure 37.25 shows manual-command procedure for direct mode.

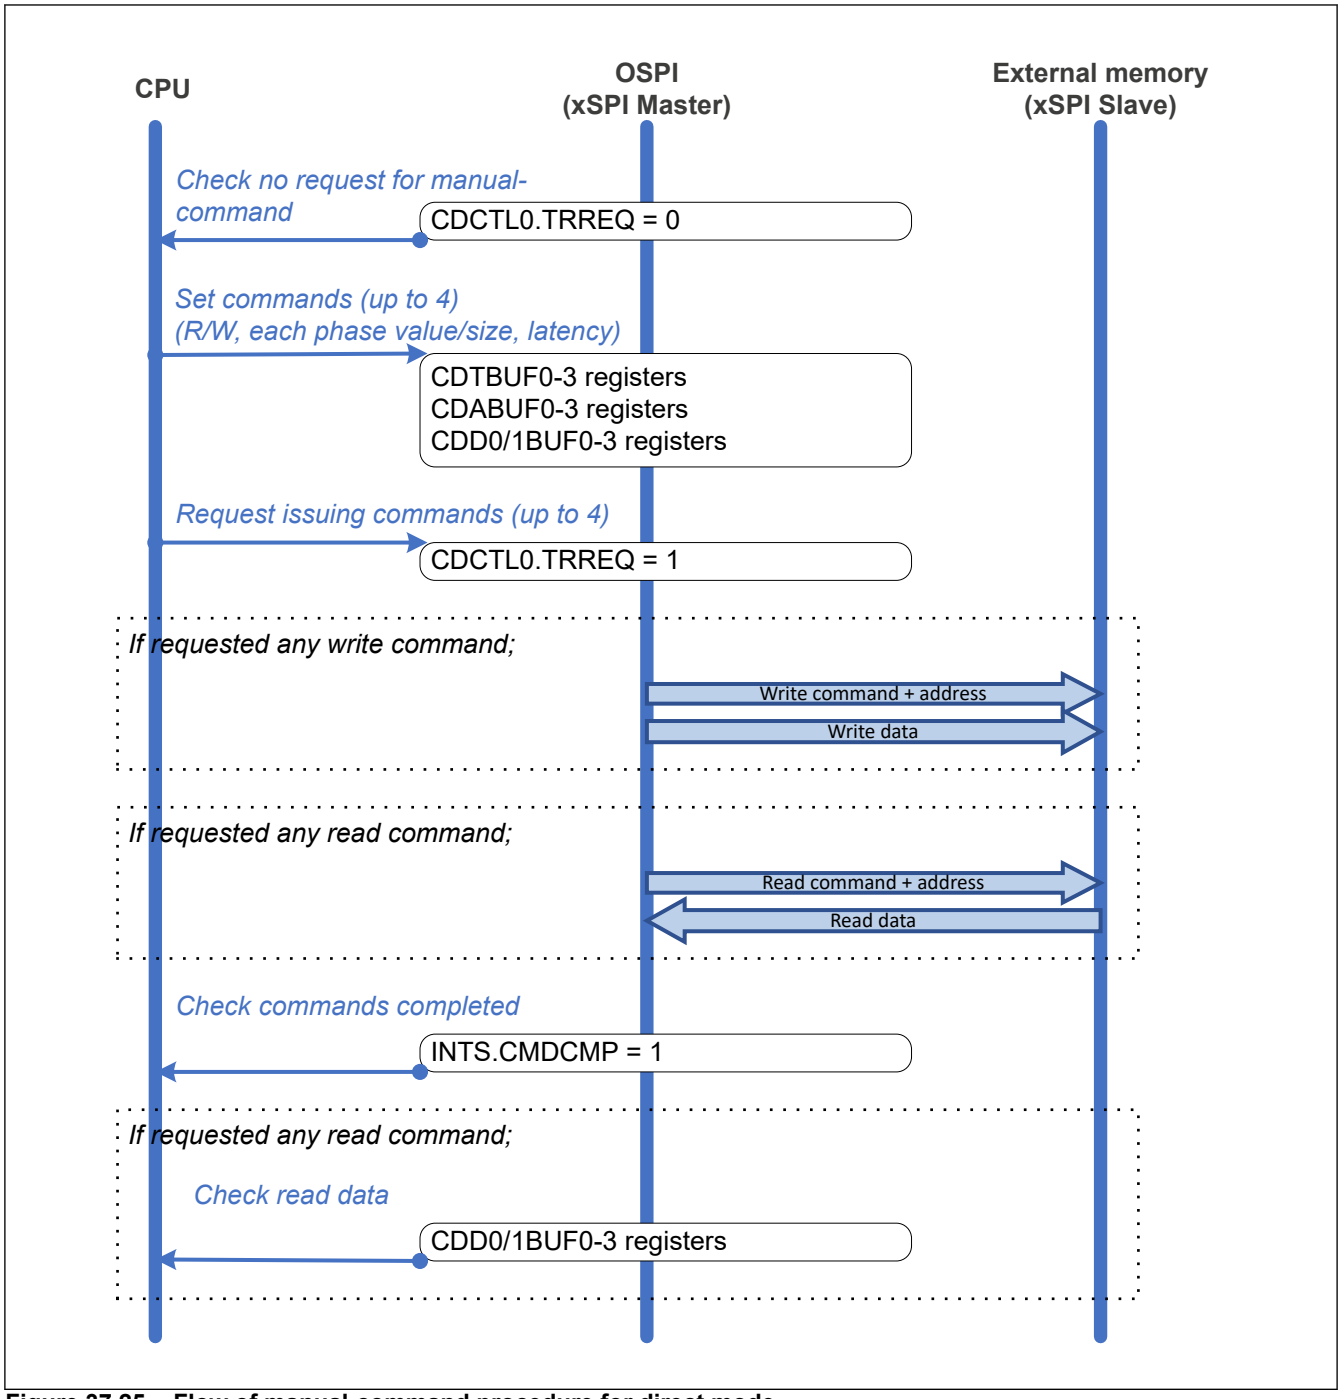

Figure 37.25 Flow of manual-command procedure for direct mode

Figure 37.26 shows manual-command procedure for periodic mode.

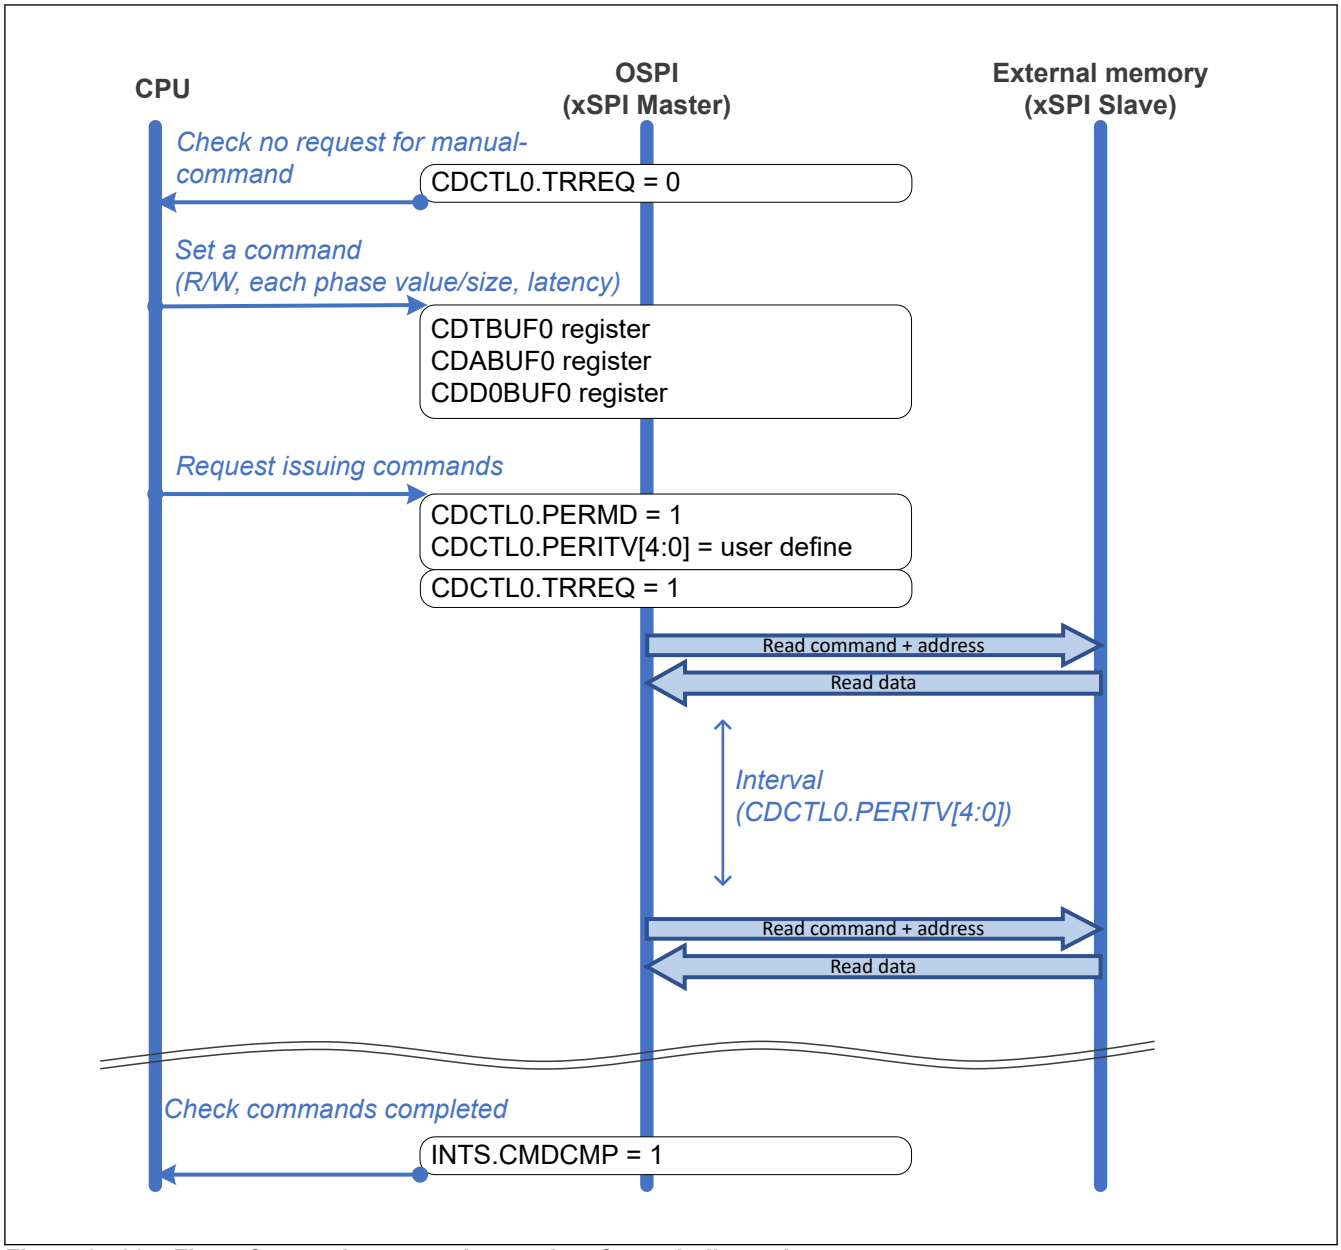

Figure 37.26 Flow of manual-command procedure for periodic mode

37.3.7.5 Flow of Memory-mapping

Figure 37.27 shows flow of memory-mapping.

Figure 37.30 shows flow of XiP mode enable/disable.

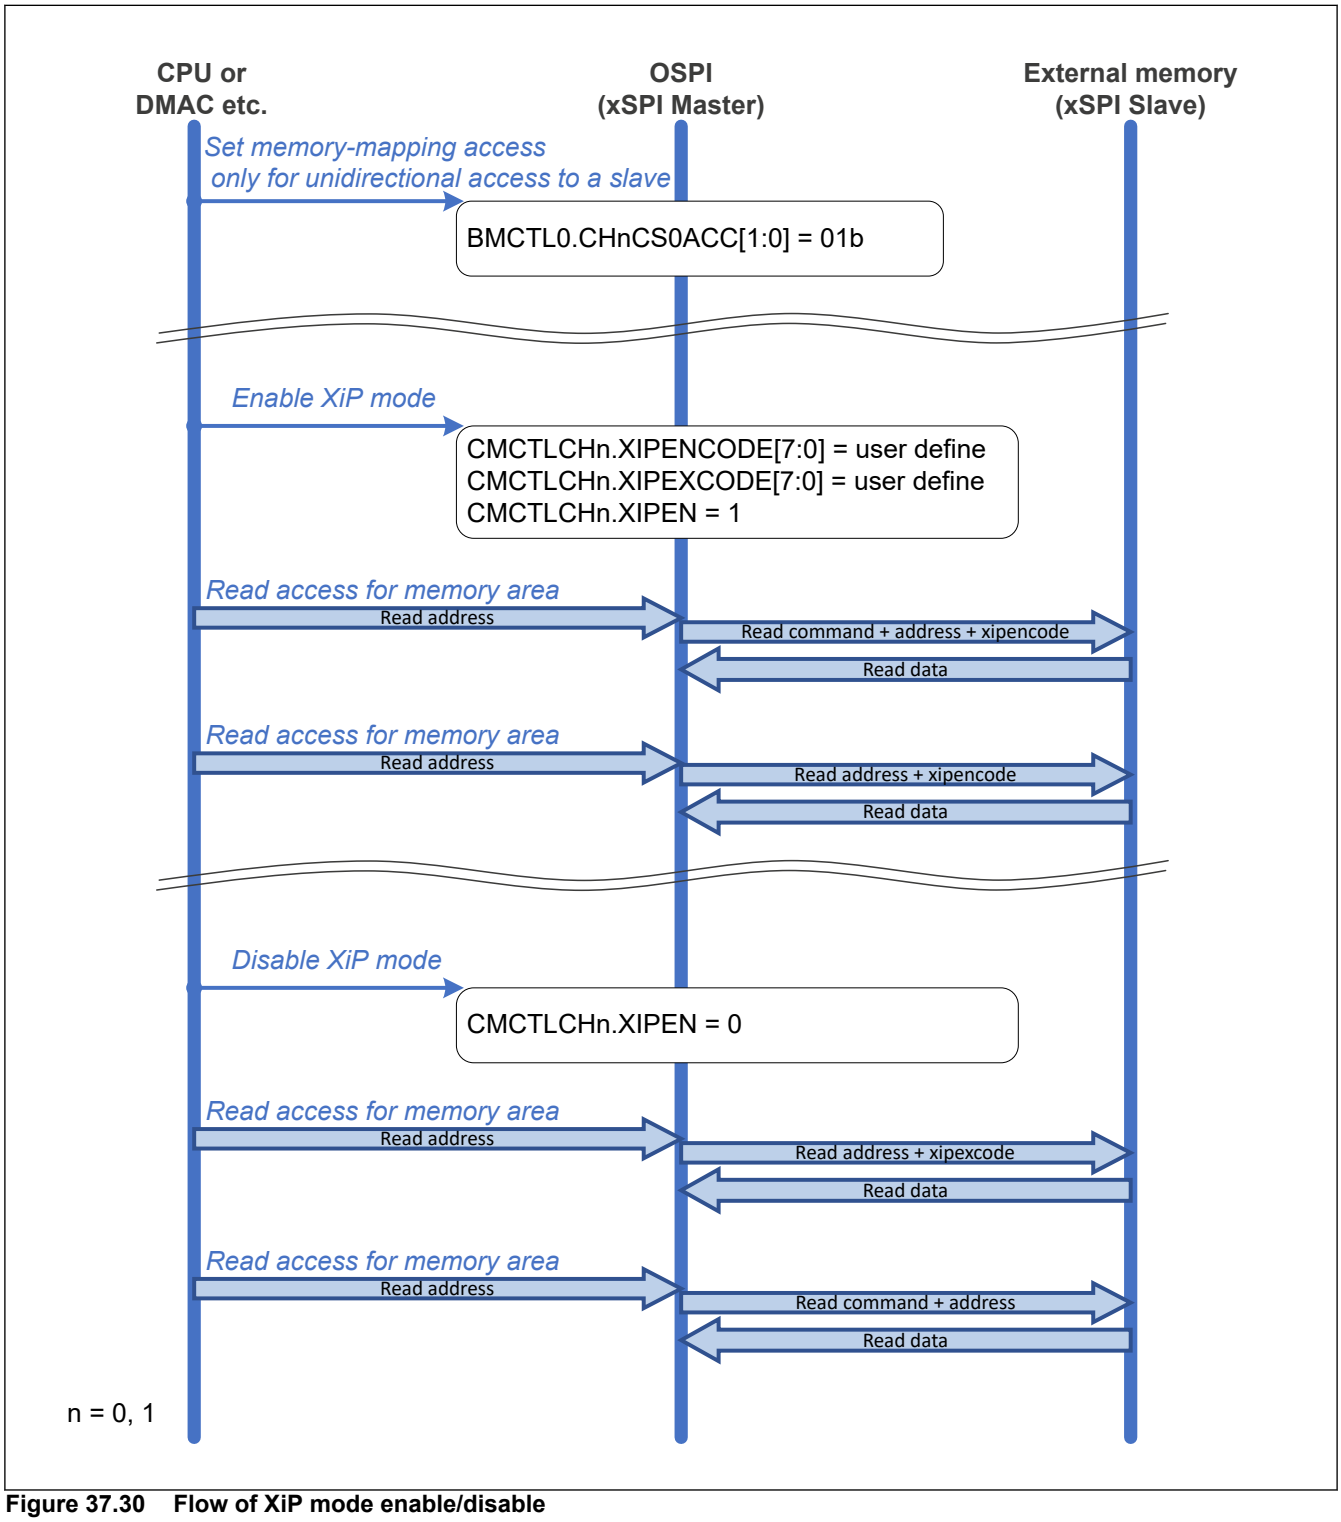

Figure 37.30 Flow of XiP mode enable/disable

37.3.8 Usage Notes

37.3.8.1 Constraint on Memory Access

The memory access has the following constraints:

- Prohibit to access last 128 byte area of memory support area.
- Not using prefetch function if application access to the last 128 byte area

37.3.8.2 Constraint on Burst Length

AXI bus master must have a Burst Length of 16 or less.

37.3.8.3 Memory Write Combination Mode

When BMCFGCHn.MWRCOMB is 1, memory write combination mode is enabled. However, combination does not work if the bus master is CPU, and OSPI data is under 32bit. Table 37.11 shows the possibility of data write for each bus master.

Table 37.11 Data write possibility for each bus master

Bus Master	Combination Enable	Combination Disable
CPU under 32 bit Access	Not possible	Possible
CPU 64 bit Access	Possible	Possible
DMAC/DTC	Possible	Possible
EDMAC	Possible	Possible
CEU	Possible	Possible
DRW	Possible	Possible

37.3.8.4 Module-stop function

OSPI operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The OSPI module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

37.3.8.5 Restriction in 8D-8D-8D profile 1.0 format

"When read or write access to the Octal Serial Peripheral Interface (OSPI) is performed from the following bus masters with 8-bit wide, access to odd addresses is prohibited as it will not be worked correctly. See Table 37.12 for the applicable conditions and their workarounds for each bus master"

Table 37.12 Workaround for the restriction in 8D-8D-8D profile 1.0 format

Bus master		Conditions that require workaround	Workaround
CPU	Normal memory	Debugger is connected	Access only even addresses.
	Device memory	Always	Access only even addresses.
DMAC/DTC	DMAC	DMTMD.SZ[1:0] = 00b	Access only even addresses.
	DTC	MRA.SZ[1:0] = 00b	Access only even addresses.
DRW		Settings of CONTROL2.WRITEFORMAT[1:0] bits and ORIGIN register	Set CONTROL2.WRITEFORMAT[1:0] only in 16 bpp or 32 bpp, and set even addresses only in the ORIGIN register.

38. Decryption On The Fly (DOTF)

38.1 Overview

DOTF has a function to decode read data of the AXI bus using AES core.

Table 38.1 lists the DOTF specifications and for a system using DOTF, see section 37.1. Overview.

Table 38.1 DOTF Specification

Item	Description
Clock Source	Register clock : PCLKB AES core clock : PCLKA
AES core function	• Utilize for on-the-fly decryption of encrypted software stored in external memory. • Block size: 128-bit • Key size: 128-bit, 192-bit, 256-bit • Support the following block cipher mode. − Counter (CTR) mode following NIST SP800-38A • Support side channel counter measure function. • Supports self-test function.
Tamper Resistance	Countermeasures available for side-channel attacks, including SPA/DPA and timing attacks
Module-stop function	Module-stop state can be set to reduce power consumption. same as OSPI module stop
Trust Zone Filter	Security and Privilege attribution can be set for each channel. same as TZF of OSPI

38.2 Block Diagram

The block diagram of DOTF is shown in Figure 38.1. See Figure 37.1 for a diagram including the OSPI.

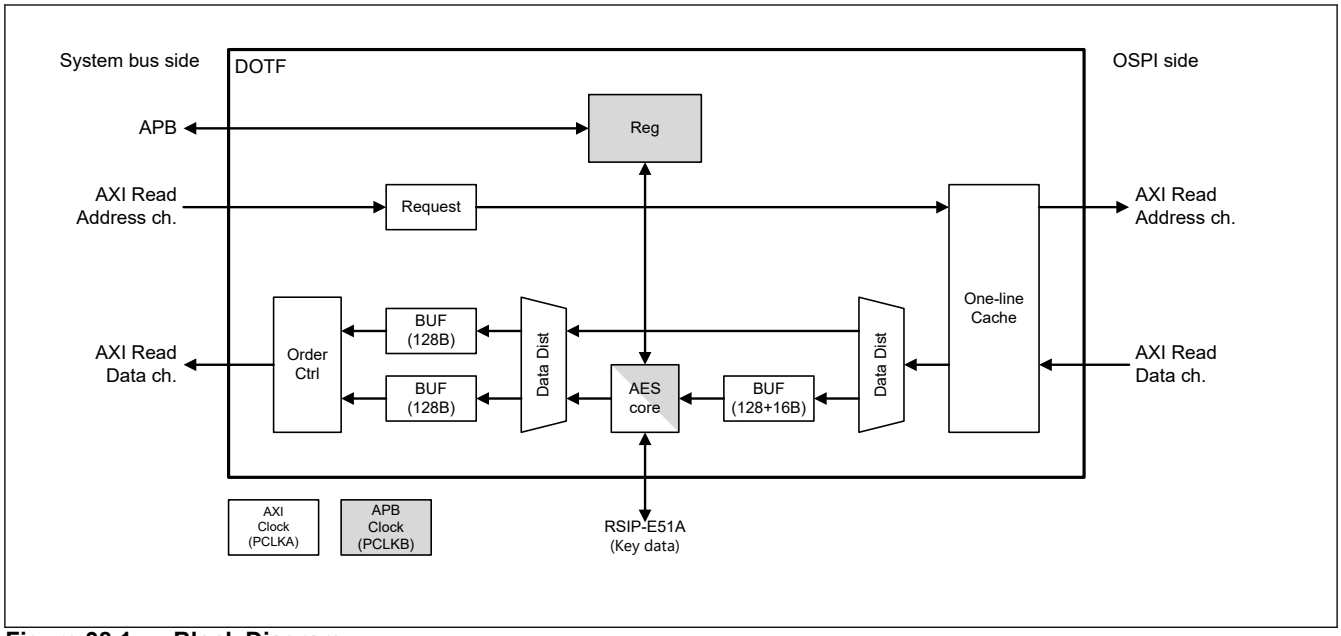

Figure 38.1 Block Diagram

38.3 Register Descriptions

DOTF allows the entire area to be an accessible area, but the area where decryption processing is performed can be specified as the entire area or one contiguous area. The region can be specified by setting the start and end addresses to the CONVAREAST and CONAREAED registers, respectively.

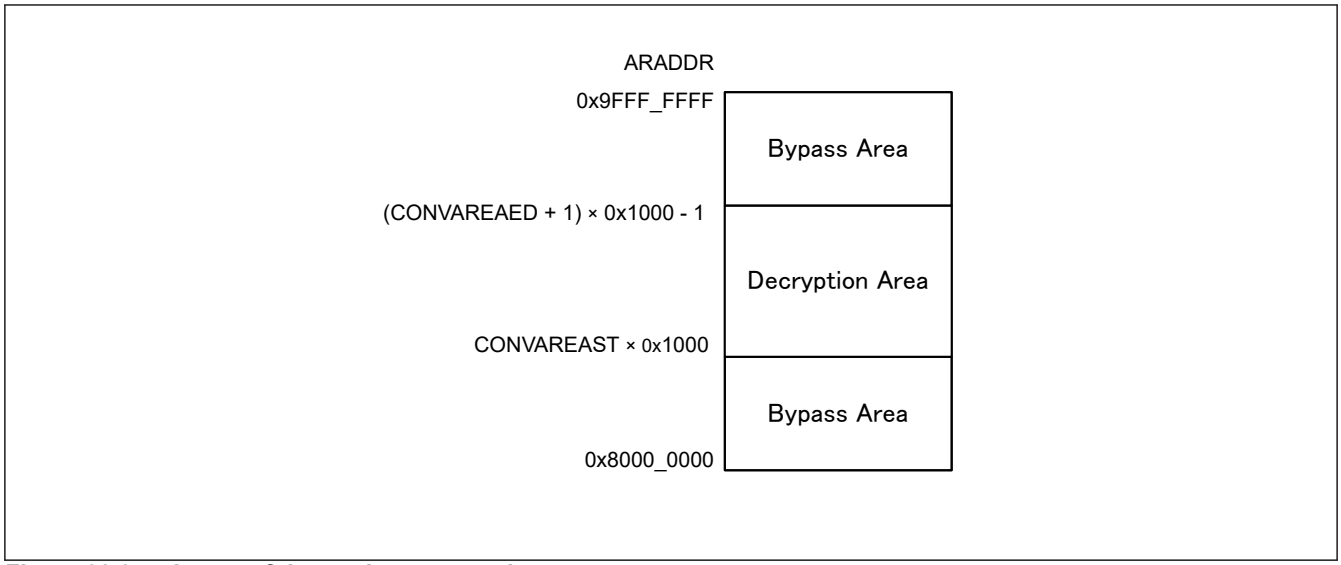

Figure 38.2 Image of decryption area setting

38.3.1 CONVAREAST : DOTF Conversion Area Start Address Register

Base address: DOTF0 = 0x4026_8800
DOTF0_NS = 0x5026_8800

Offset address: 0x00

Bit position:	31																		12											0
Bit field:	CONVAREAST[31:12]																		—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	—	These bits are read as 0.	R/W
31:12	CONVAREAST[31:12]	The first address of the decryption processing area. The actual address is CONVAREAST[31:12] × 0x1000.	R/W

Note: S-TYPE-3, P-TYPE-3

Specify the first address of the decryption processing area. Set before the AXI transfer request and do not make any further changes. Setting CONVAREAST[31:12] > CONVAREAED[31:12] is prohibited.

38.3.2 CONVAREAD : DOTF Conversion Area End Address Register

Base address: DOTF0 = 0x4026_8800
DOTF0_NS = 0x5026_8800

Offset address: 0x04

Bit position:	31																		12											0
Bit field:	CONVAREAED[31:12]																		—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	—	These bits are read as 0.	R/W
31:12	CONVAREAED[31:12]	The end address of the decryption processing area. The actual address is CONVAREAED[31:12] ×0x1000.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Setting CONVAREAST[31:12] > CONVAREAED[31:12] is prohibited.

Specify the tail address of the decryption processing area. Set before the AXI transfer request and do not make any further changes. Setting CONVAREAST[31:12] > CONVAREAED[31:12] is prohibited.

38.4 Operation

DOTF has one AXI Read Slave Interface and one AXI Read Master Interface.

An AXI transfer request received on the AXI Slave Address channel is issued to the AXI Master's Read Address channel, and the Slave data is received from the Master's AXI Read data channel and sent to the AXI Slave Read data channel.

At this time, the necessity of decryption is determined by the requested address area, and the decrypted data is transmitted through AES core if necessary. When decryption is not required, the received response is sent without conversion.

38.5 System flow

The initialization flow after HW reset is shown in Figure 38.3.

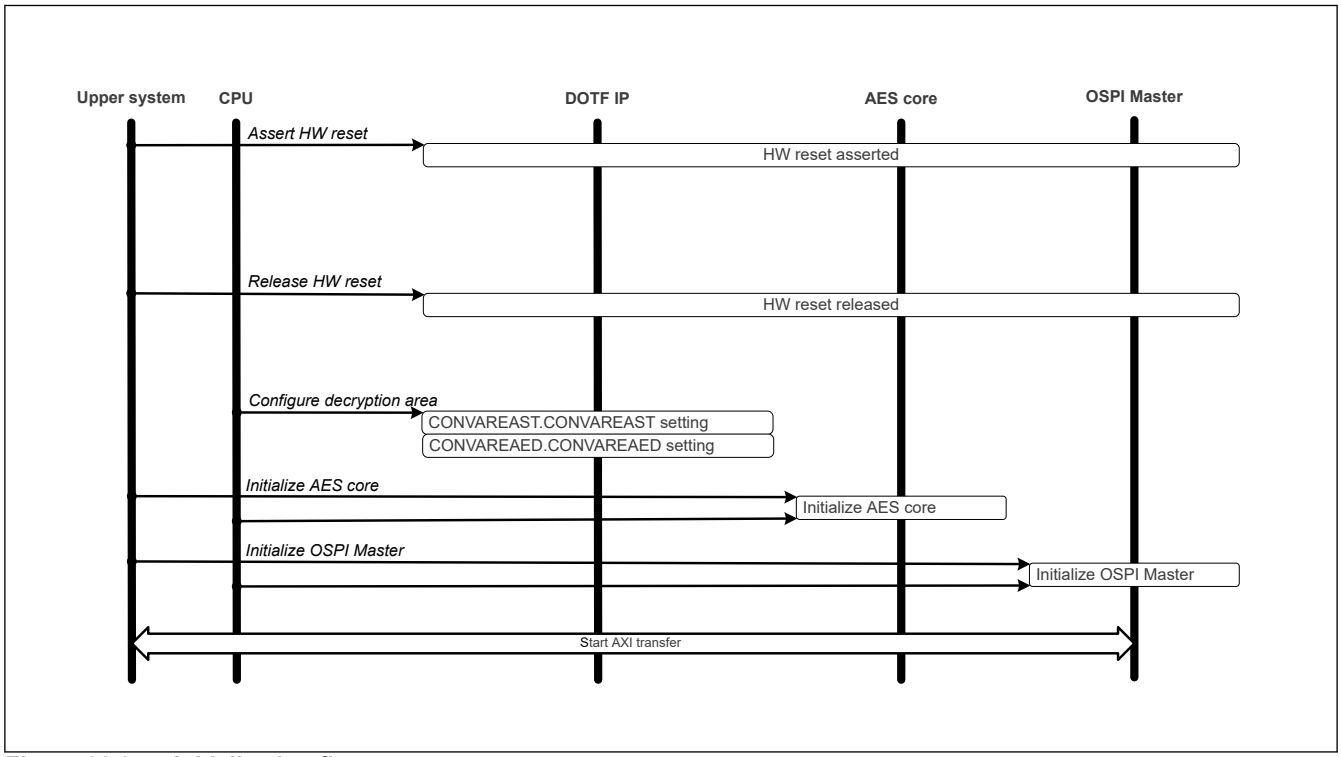

Figure 38.3 Initialization flow

38.6 Usage notes

38.6.1 Module-stop function

DOTF operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The DOTF module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

39. Serial Sound Interface Enhanced (SSIE)

39.1 Overview

The Serial Sound Interface Enhanced (SSIE) can transmit and receive audio data to and from various devices that support any of audio data formats, such as I^2S, monaural, and TDM.

Table 39.1 lists the SSIE specifications, Figure 39.3, Figure 39.4 and Figure 39.5 show a block diagram of SSIE, and Table 39.4 lists the I/O pins.

Table 39.1 SSIE specifications

Item		Description
Number of channels		Two channels, SSIE0 and SSIE1
Communication mode		• Master/slave • Transmission/reception (SSIE0:full duplex communication, SSIE1:half-duplex communication)
Communication format		• I^2S format • Monaural format • TDM format
Serial data		• MSB first • Data can be left-justified or right-justified. • Data delay (1 clock cycle) or no delay selectable for the period from SSILRCKn/SSIFSn (n = 0, 1) to SSITXD0/SSIRXD0/SSIDATA1 • System word length: 8, 16, 24, 32, 48, 64, 128, or 256 bits • Data word length: 8, 16, 18, 20, 22, 24, or 32 bits • Padding polarity: Low or high
Bit clock (SSIBCKn (n = 0, 1))	In master mode	• Two clock sources available (AUDIO_CLK/GPT output (GTIOC2A)) • Clock source division ratio: 1/1, 1/2, 1/4, 1/6, 1/8, 1/12, 1/16, 1/24, 1/32, 1/48, 1/64, 1/96, and 1/128. • Supply/stop is selectable while communication is halted.
	In master/slave mode	• Polarity (rising edge or falling edge) selectable
LR clock/frame synchronization (SSILRCKn/SSIFSn (n = 0, 1))	In master mode	• Polarity (low level or high level) selectable • Supply/stop is selectable while communication is halted.
Transmit data (SSITXD0/SSIDATA1) and receive data (SSIRXD0/SSIDATA1)	Transmission	• Muting method (transmission of transmit FIFO data or transmission of data fixed to 0) selectable
FIFO	Capacity	• Transmit FIFO/receive FIFO: 4 bytes × 32 stages
	Data alignment	• Data alignment method (left-justification or right-justification) selectable for the data transfer between FIFO and shift register
Interrupt	Interrupt output	• Communication error/idle mode • Receive data full • Transmit data empty
Low power consumption function		• Whether to supply the audio clock selectable in master mode
Module stop function		Module stop state can be set for each channels to reduce power consumption.
TrustZone Filter		Security and Privilege attribution can be set for each channels.

The following table lists and defines the terms used for the communication formats SSIE can use:

Table 39.2 Definition of terms (1 of 2)

Term	Definition
Start trigger	First edge of the signal on the SSILRCKn/SSIFSn (n = 0, 1) pin when the signal is set to the value specified in LRCKP to enable communication

Table 39.2 Definition of terms (2 of 2)

Term	Definition
Frame boundary	Point where SSIE starts transferring the first data of a frame or the point where SSIE ends transferring the last data of the frame
Frame word number	Number of sound channels per frame
System word length	Number of bits per channel
Data word length	Number of significant bits per channel
Control bits for communication formats	• SSICR register: FRM, DWL, SWL, LRCKP, SPDP, SDTA, PDTA, and DEL bits • SSIFCR register: BSW bit • SSIOFR register: OMOD bit • SSISCR register: TDES[4:0] and RDFS[4:0] bits

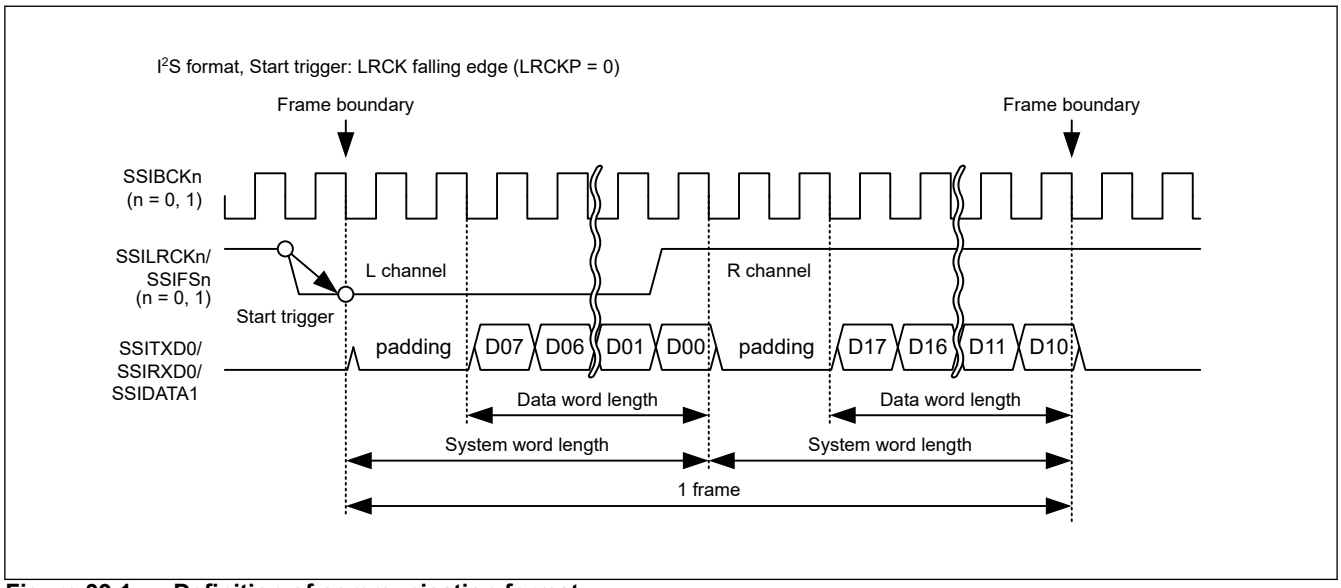

Figure 39.1 Definition of communication format

Figure 39.2 and Figure 39.3 shows a block diagram of SSIE.

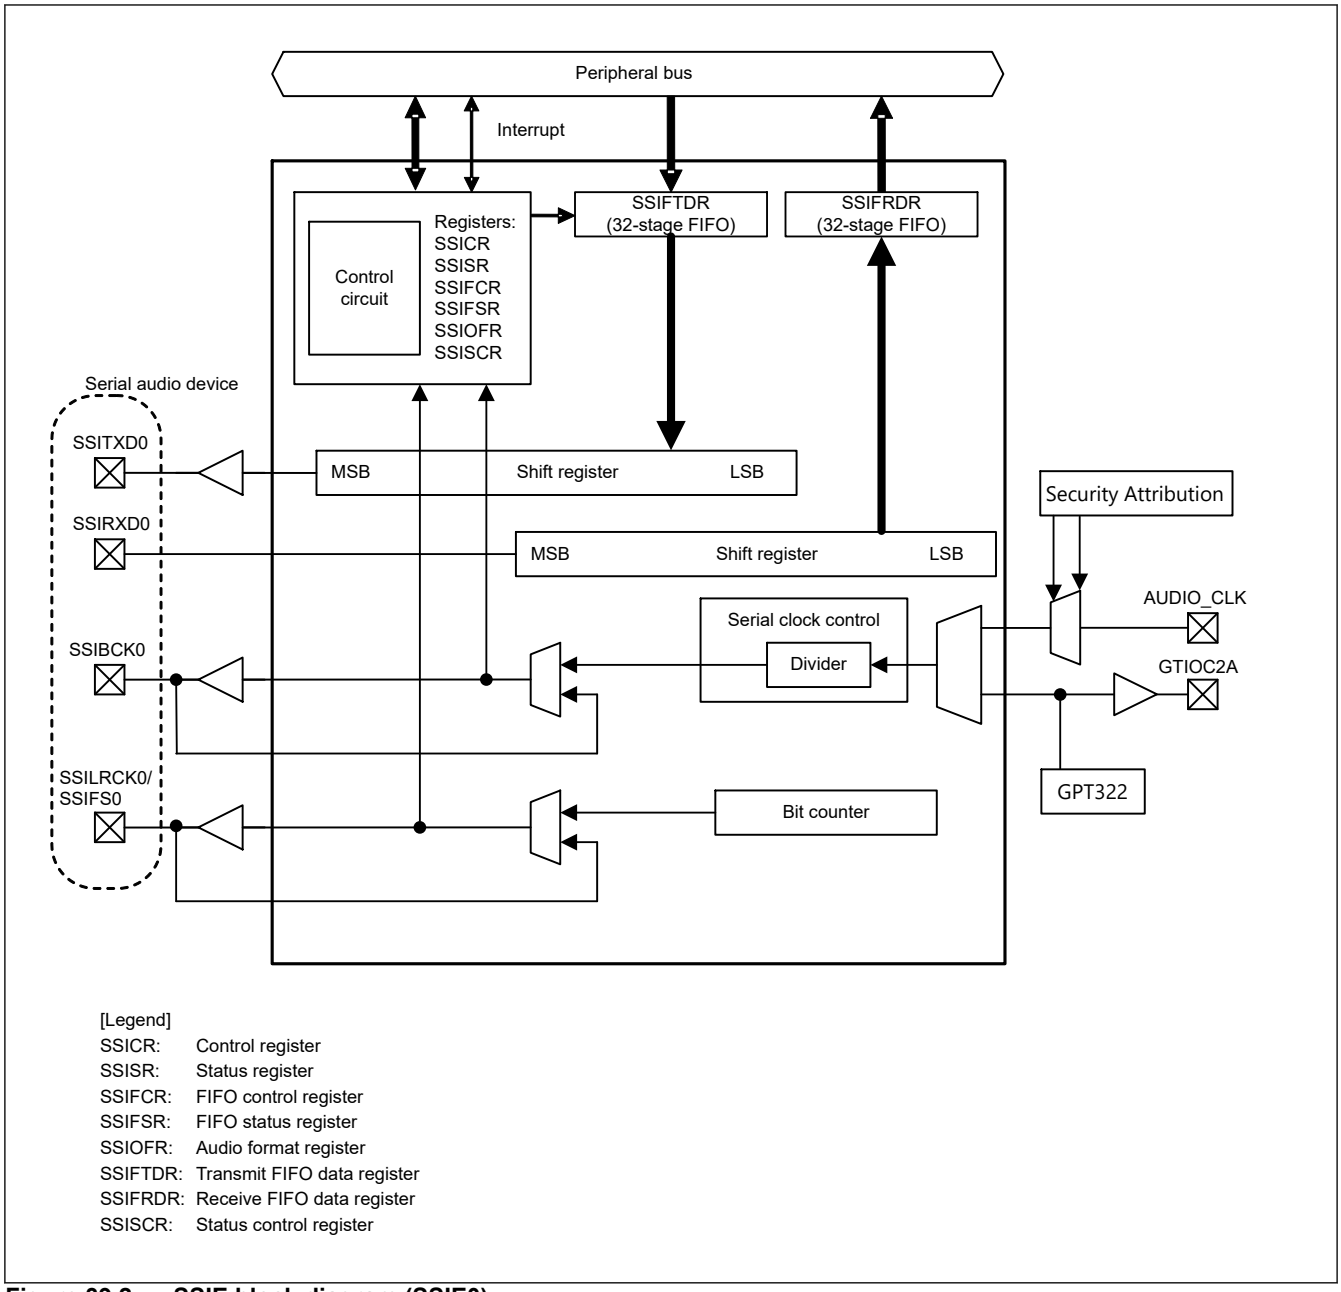

Figure 39.2 SSIE block diagram (SSIE0)

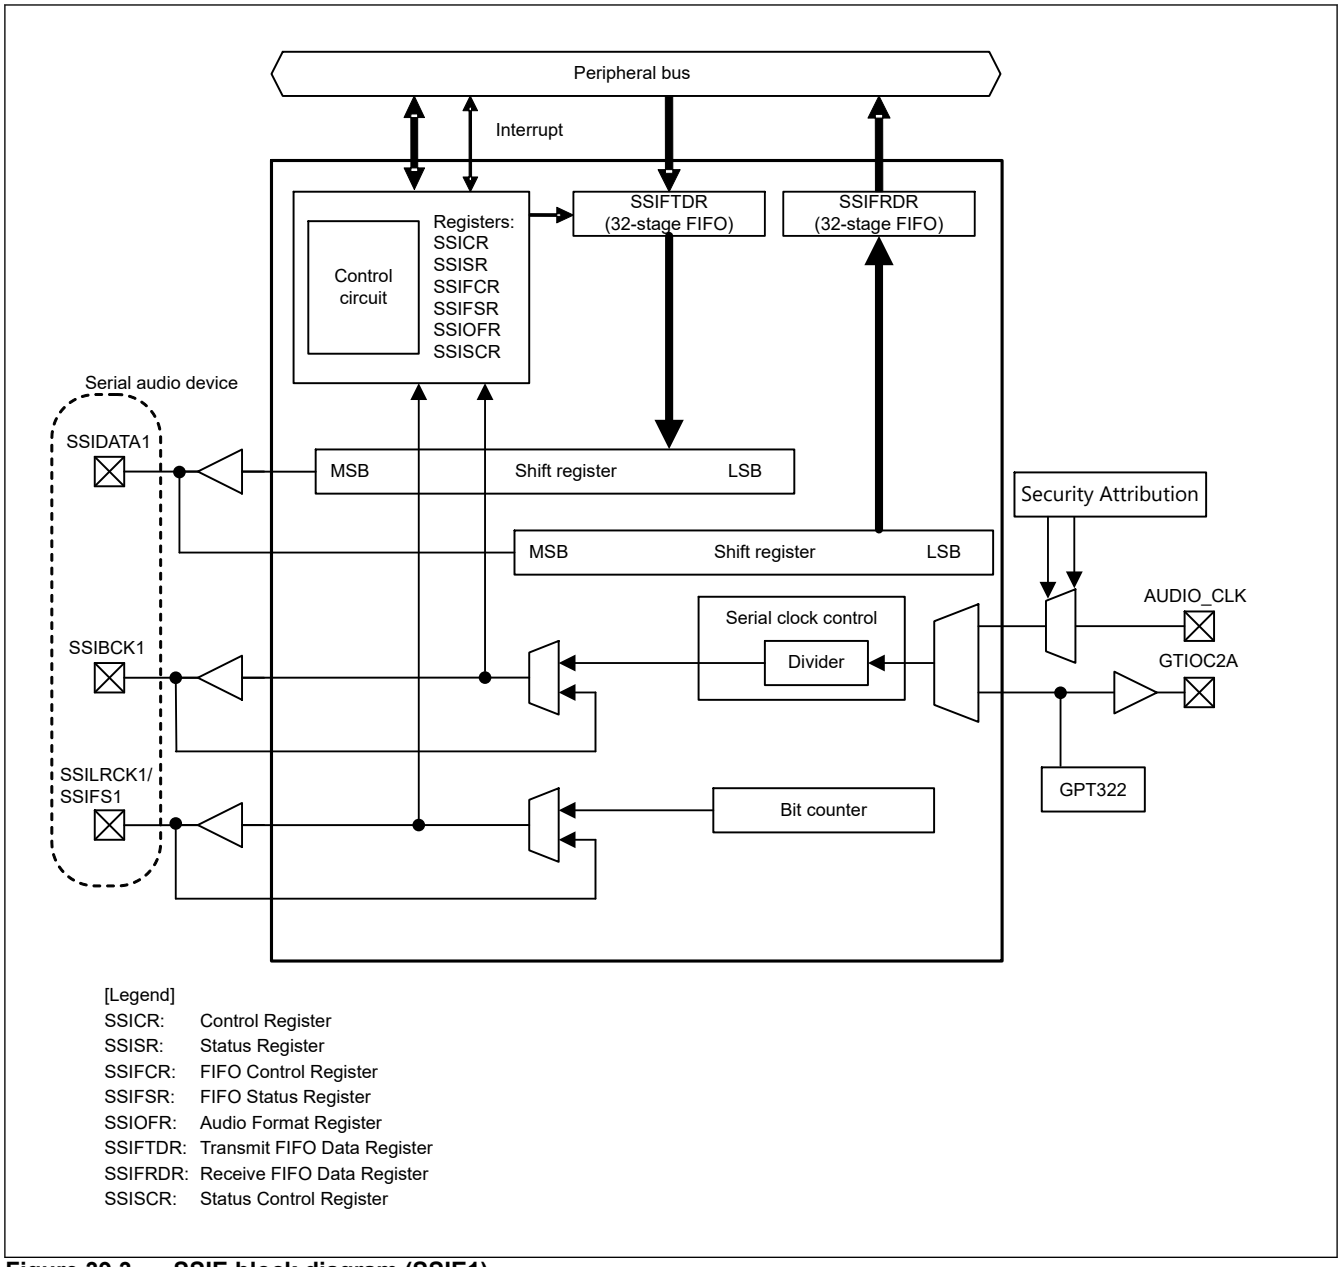

Figure 39.3 SSIE block diagram (SSIE1)

Figure 39.4 shows the clock configuration of SSIE.

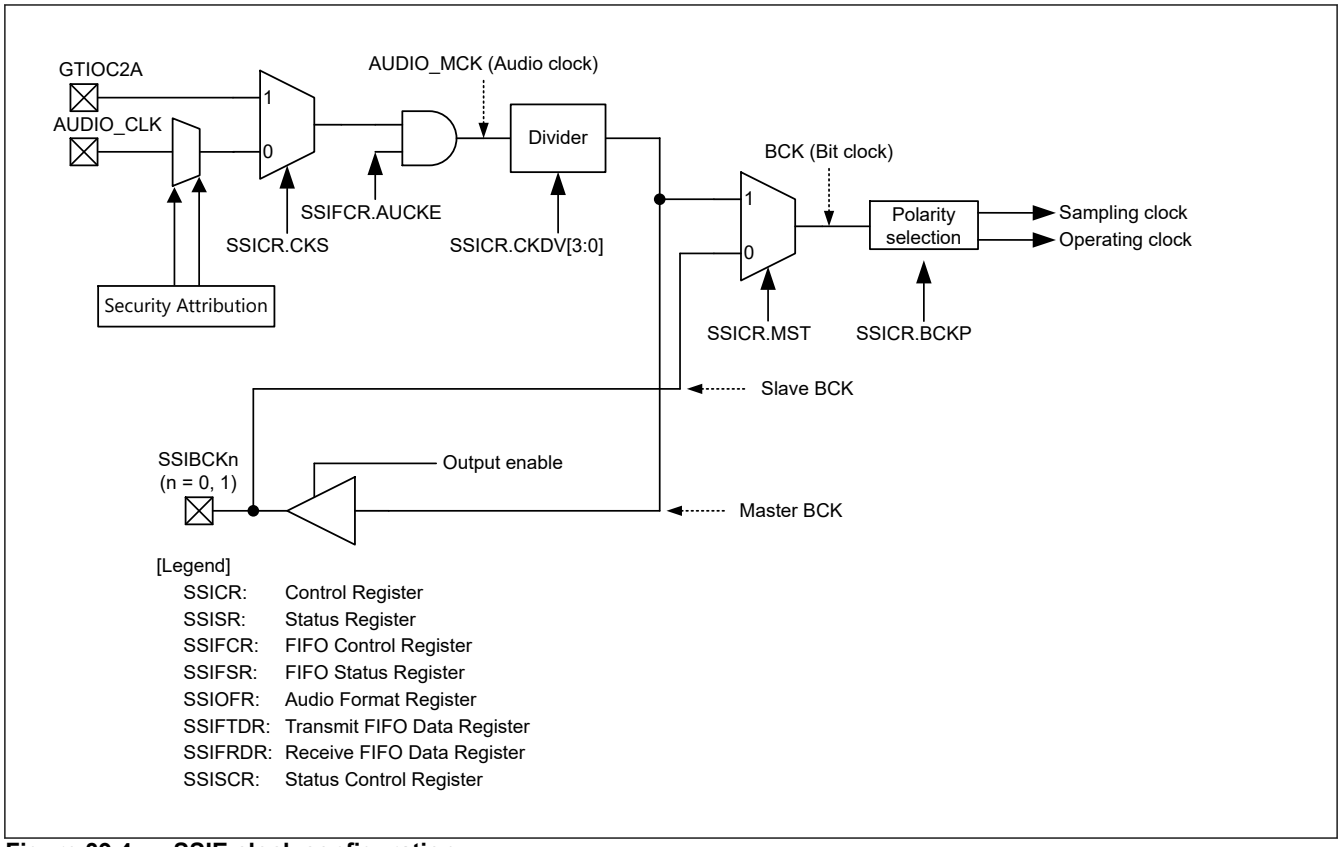

Figure 39.4 SSIE clock configuration

The AUDIO_CLK can be input according to the security attribution of Port and SSIE and SSICR.CKS bit setting as shown in the Table 39.3.

Table 39.3 The input condition of AUDIO_CLK by the security setting

PORT Security Attribution (PmSAR (m = 0 - 9, A, B))	SSIE0 Security Attribution (PSARm (B - E))	SSIE0's SSICR.CKS	SSIE1 Security Attribution (PSARm (B - E))	SSIE1's SSICR.CKS	AUDIO_CLK pin input
0 (secure)	0 (secure)	0 (AUDIO_CLK)	Don't care		AUDIO_CLK input enable
	Don't care		0 (secure)	0 (AUDIO_CLK)	
1 (non-secure)	1 (non-secure)	Don't care	0 (secure)	1 (GTIOC2A)	
			1 (non-secure)	Don't care	
	0 (secure)	1 (GTIOC2A)	1 (non-secure)	Don't care	
	1 (non-secure)	Don't care			
other than above					AUDIO_CLK input disable

Table 39.4 lists the I/O pins.

Table 39.4 SSIE I/O pins

Channel	Pin name	I/O	Function
Common	SSIBLKn	Input	Serial bit clock pins
	AUDIO_CLK	Input	External clock pin for audio (input oversampling clock)
	SSILRCKn/SSIFSn	Output	LR clock/frame synchronization pins
SSIE0	SSIRXD0	Input	Serial data input pin
	SSITXD0	Output	Serial data output pin
SSIE1	SSIDATA1	I/O	Serial data input/output pin

Note: n = 0, 1

39.2 Register Descriptions

39.2.1 SSICR : Control Register

Base address: SSIEn = 0x4025_D000 + 0x0100 × n (n = 0, 1)
SSIEn_NS = 0x5025_D000 + 0x0100 × n (n = 0, 1)

Offset address: 0x00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	CKS	TUIEN	TOIEN	RUIEN	ROIEN	IIEN	—	FRM[1:0]		DWL[2:0]			SWL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	MST	BCKP	LRCKP	SPDP	SDTA	PDTA	DEL	CKDV[3:0]				MUEN	—	TEN	REN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	REN	Reception Enable*2 0: Disables reception 1: Enables reception (starts reception)	R/W
1	TEN	Transmission Enable*2 0: Disables transmission 1: Enables transmission (starts transmission)	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	MUEN	Mute Enable 0: Disables muting on the next frame boundary 1: Enables muting on the next frame boundary	R/W
7:4	CKDV[3:0]	Selects Bit Clock Division Ratio*1 0x0: AUDIO_MCK 0x1: AUDIO_MCK/2 0x2: AUDIO_MCK/4 0x3: AUDIO_MCK/8 0x4: AUDIO_MCK/16 0x5: AUDIO_MCK/32 0x6: AUDIO_MCK/64 0x7: AUDIO_MCK/128 0x8: AUDIO_MCK/6 0x9: AUDIO_MCK/12 0xA: AUDIO_MCK/24 0xB: AUDIO_MCK/48 0xC: AUDIO_MCK/96 Others: Setting prohibited	R/W
8	DEL	Selects Serial Data Delay*1 In the monaural format, this bit controls the waveform of SSILRCKn/SSIFSn (n = 0, 1). For details, see section 39.3.2. Monaural Format. 0: Delay of 1 cycle of SSIBCKn (n = 0, 1) between SSILRCKn/SSIFSn (n = 0, 1) and SSITXD0/SSIRXD0/SSIDATA1 1: No delay between SSILRCKn/SSIFSn (n = 0, 1) and SSITXD0/SSIRXD0/ SSIDATA1	R/W
9	PDTA	Selects Placement Data Alignment*1 0: Left-justifies placement data (SSIFTDR, SSIFRDR) 1: Right-justifies placement data (SSIFTDR, SSIFRDR)	R/W
10	SDTA	Selects Serial Data Alignment*1 0: Transmits and receives serial data first and then padding bits 1: Transmit and receives padding bits first and then serial data	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If the value of these bits is changed by rewriting, subsequent operation is unpredictable.

Note 2. If the TEN bit or REN bit is rewritten, make sure that the SSISR.IIRQ bit is in the desired status. If the value of the TEN or REN bit is changed by rewriting, subsequent operation is unpredictable. For example, when transmission or reception is enabled, check that SSISR.IIRQ is 0; when transmission or reception is disabled, check that SSISR.IIRQ is 1.

With this register, select an audio clock, control interrupt requests, select data formats, and set an operation mode.

TEN and REN bits (Transmission and Reception Enable)

The TEN and REN bits enable/disable transmission and reception. When 1 is written to one of these bits, the corresponding communication operation starts in synchronization with a start trigger by the SSILRCKn/SSIFSn (n = 0, 1) signal. For details, see section 39.6.2. Transmission to section 39.6.4. Transmission and Reception. When 0 is written to this bit, the current communication operation stops at the next frame boundary. To use SSIE for both transmission and reception, always write 1 to these bits together. When stopping the communication using SSIE, always disable both transmission and reception (write 0 to the TEN and REN bits).

If you want to stop SSIE before a frame boundary is reached, perform a software reset procedure.

MUEN bit (Mute Enable)

The MUEN bit sets/clears the mute function for the data output from the SSITXD0/SSIDATA1 pin. When this bit is set to 1 in the middle of a frame, the SSITXD0/SSIDATA1 output changes to 0 at the next frame boundary. When this bit is set to 0 in the middle of a frame, the SSITXD0/SSIDATA1 output changes to the data of transmit FIFO data register at the next frame boundary. Note that this bit controls data only. Status flags and interrupt signals are normally generated.

Changing the value of this bit must be performed only after setting the communication format to be used.

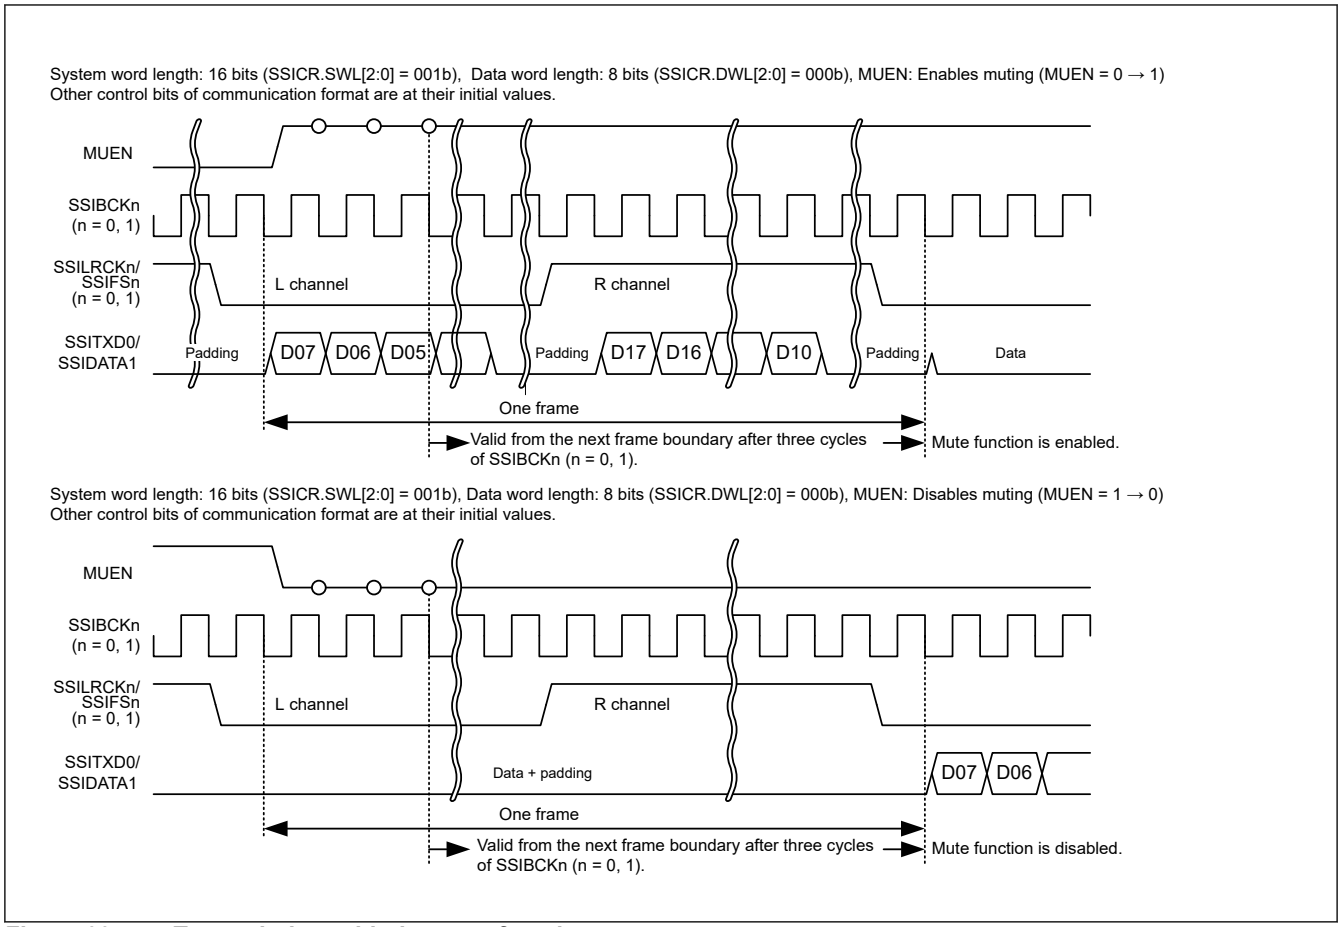

Figure 39.5 Transmit data with the mute function set

CKDV[3:0] bits (Selects Bit Clock Division Ratio)

The CKDV[3:0] bits set the division ratio of the bit clock based on AUDIO_MCK in master-mode communication (MST= 1). In slave-mode communication (MST = 0), setting of these bits are invalid.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in section 39.2.3. SSIFCR : FIFO Control Register.

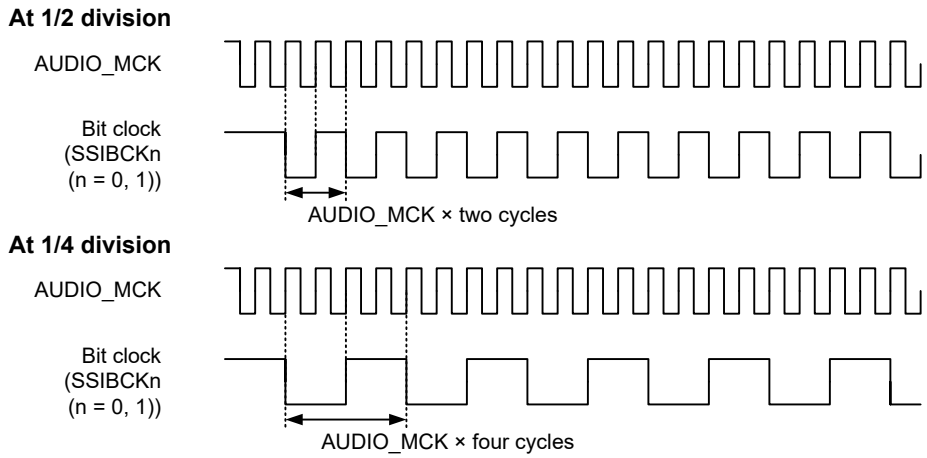

Figure 39.6 Sampling frequencies in master-mode communication

DEL bit (Selects Serial Data Delay)

The DEL bit sets whether or not there will be a delay between SSILRCKn/SSIFSn (n = 0, 1) and SSITXD0/SSIRXD0/ SSIDATA1.

For the I^2S or TDM format, set the DEL bit to 0. When the monaural format is used, setting of this bit changes the high period width of SSILRCKn/SSIFSn (n = 0, 1). For details, see section 39.3.2. Monaural Format. When using a compatible communication format, specify a setting of this bit that enables communication.

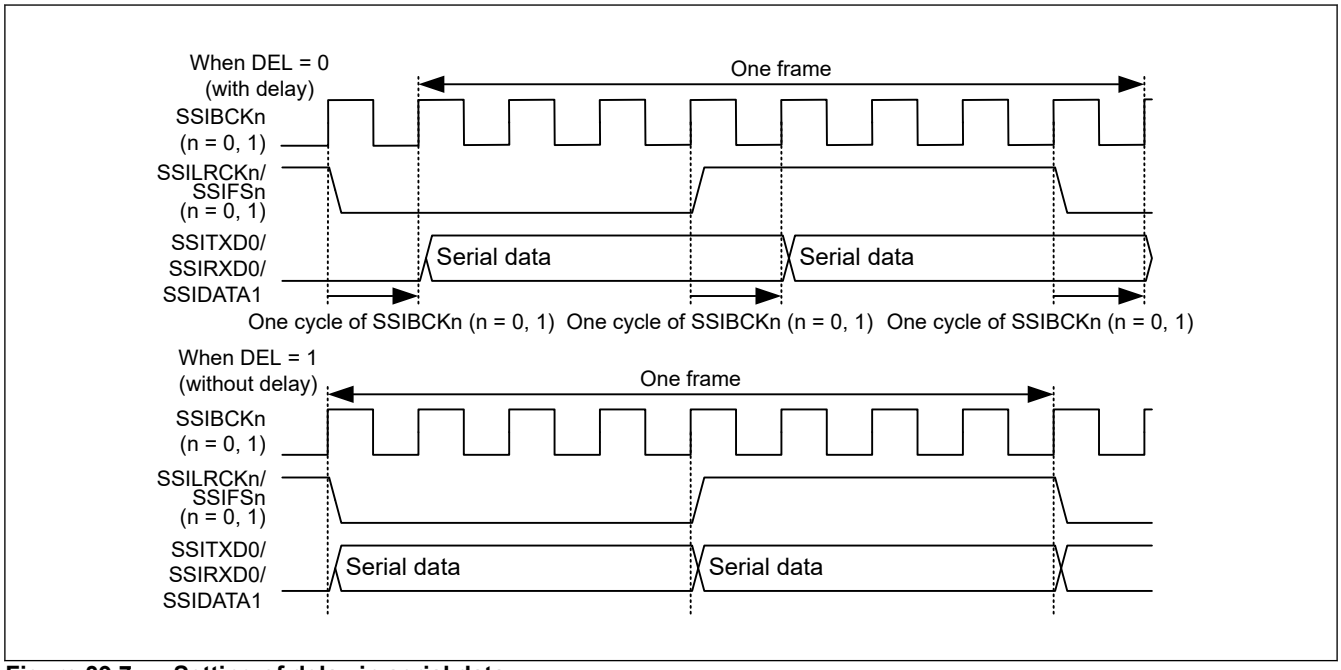

Figure 39.7 Setting of delay in serial data

PDTA bit (Selects Placement Data Alignment)

The PDTA bit sets how to align placement data. With the setting of data word length as 32 bits (SSICR.DWL[2:0] = 110b), this bit is invalid.

At transmission, see Figure 39.8.

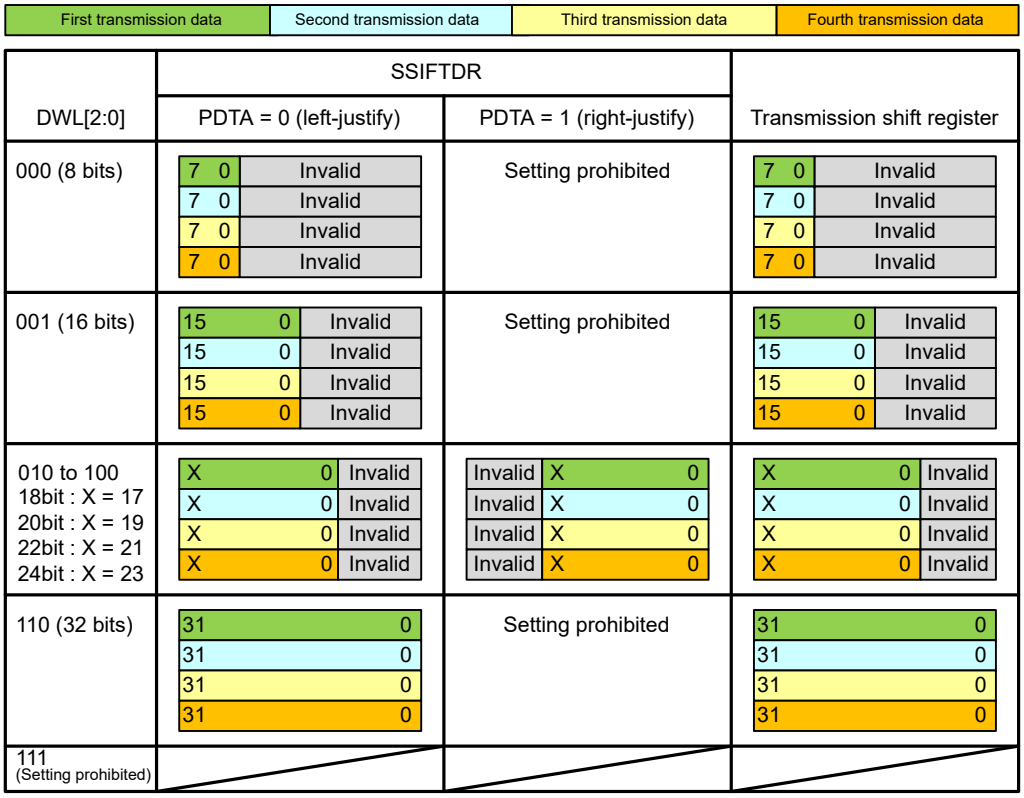

Figure 39.8 Alignment of placement data at transmission

At reception, see Figure 39.9.

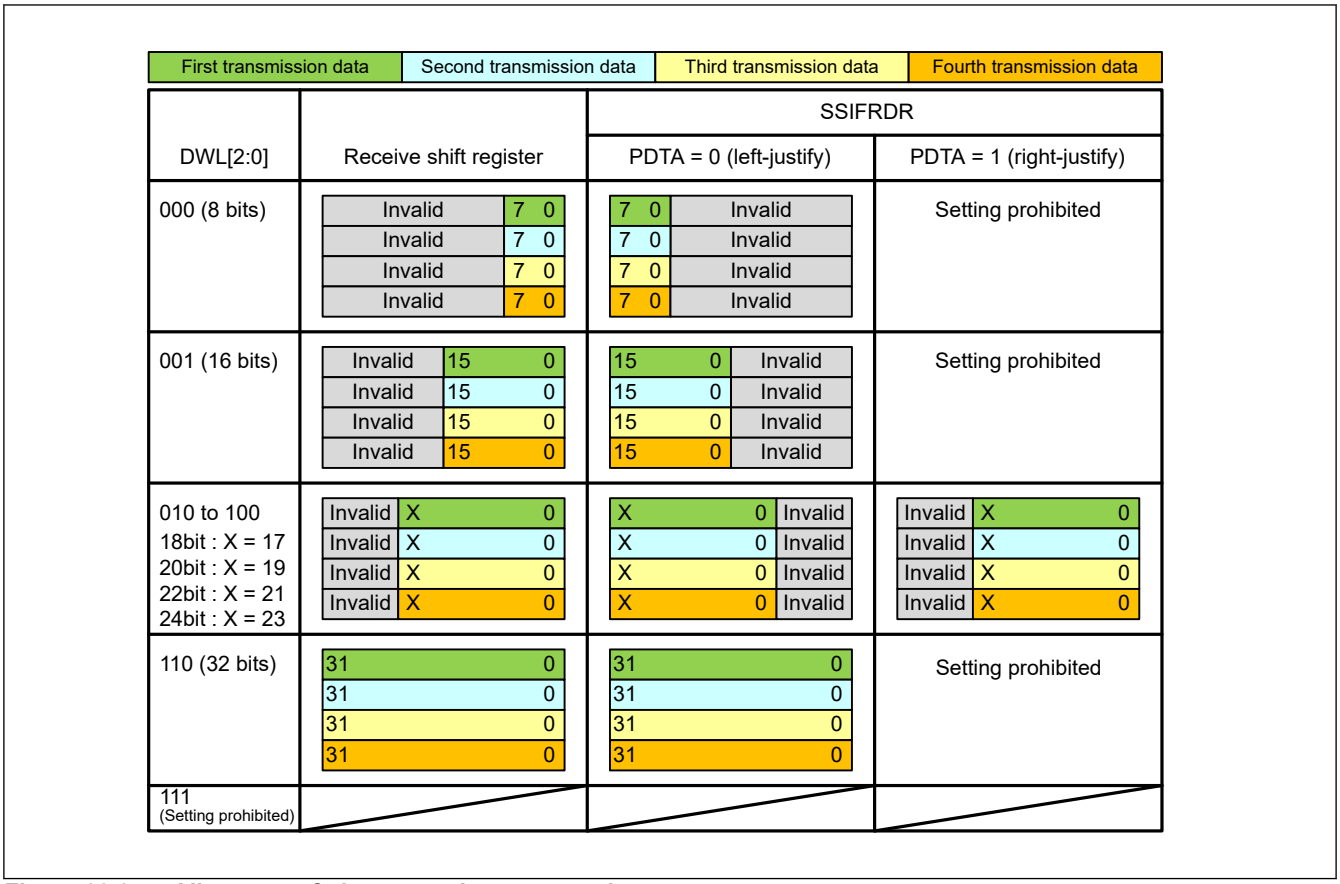

Figure 39.9 Alignment of placement data at reception

SDTA bit (Selects Serial Data Delay)

The SDTA bit sets how to align serial data and padding bits. For communication without padding bits, this bit is invalid.

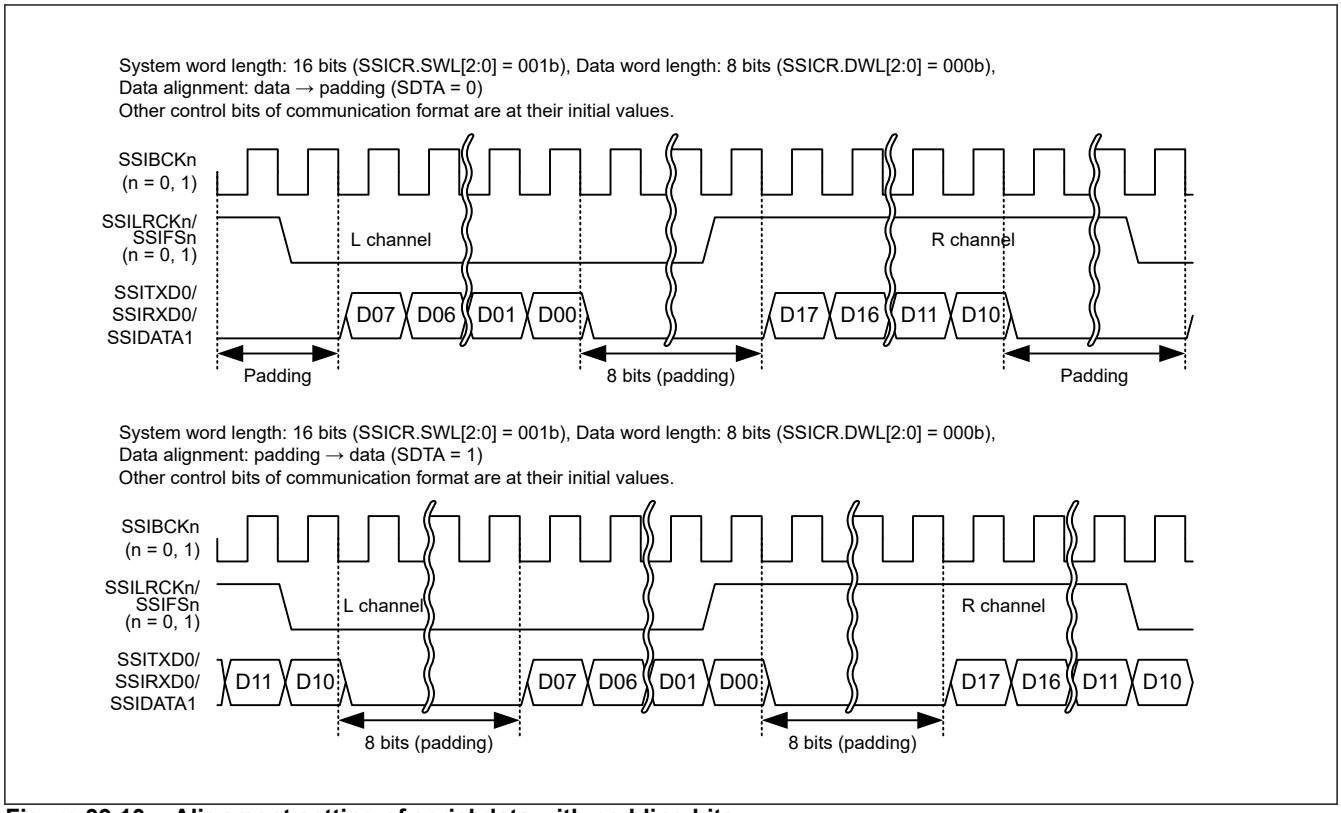

Figure 39.10 Alignment setting of serial data with padding bits

SPDP bit (Selects Serial Padding Polarity)

The SPDP bit sets polarity of padding bits.

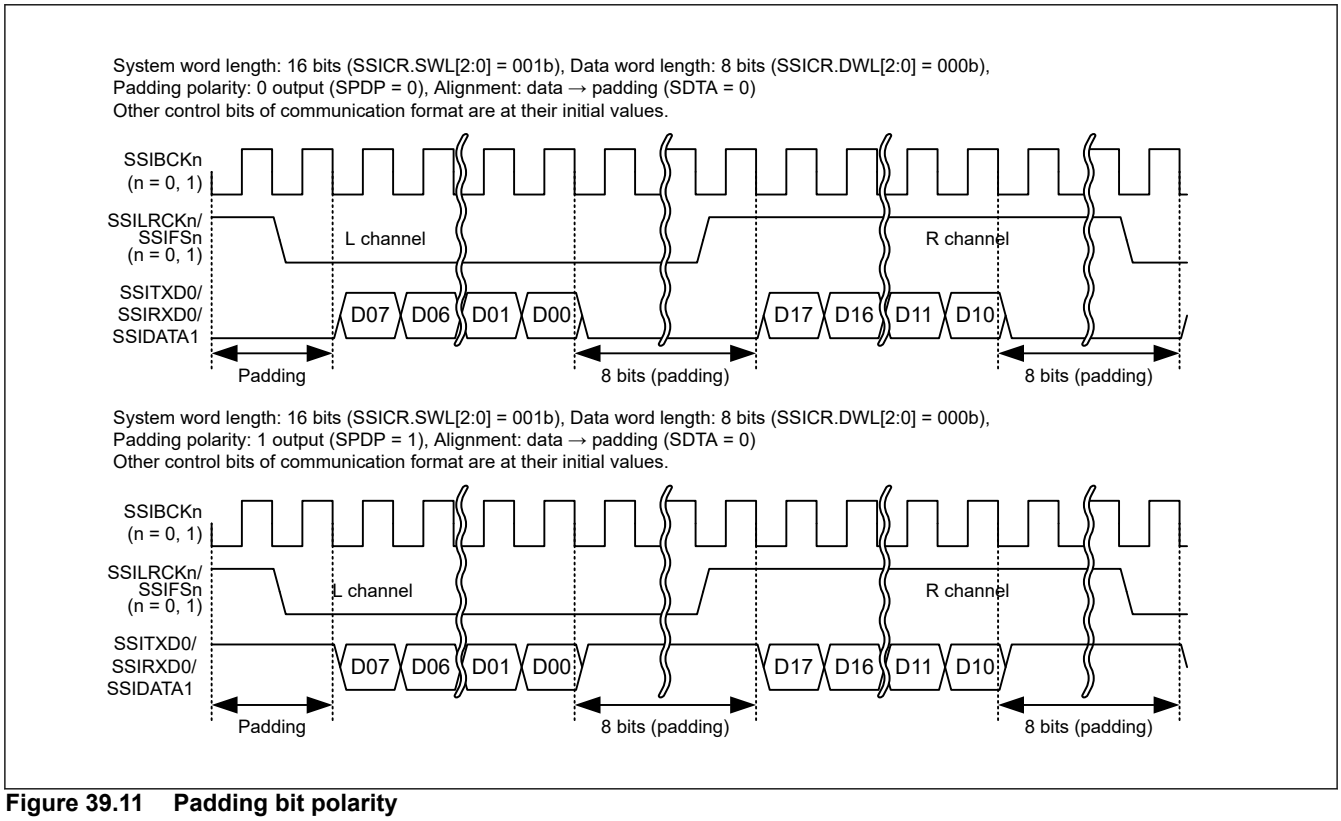

Figure 39.11 Padding bit polarity

LRCKP bit (Selects the Initial Value and Polarity of LR Clock/Frame Synchronization Signal)

The LRCKP bit sets the initial value and polarity of SSILRCKn/SSIFSn (n = 0, 1). Set this bit according to the communication format to be used in SSIE. See Table 39.5 Initial output value and polarity of SSILRCKn/SSIFSn (n = 0, 1) pin. For the slave-mode communication (MST = 0), only the start trigger is used.

Writing to these bits must be performed when the LR clock supply to the SSILRCKn/SSIFSn (n = 0, 1) pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in section 39.2.7. SSIOFR : Audio Format Register.

Table 39.5 Initial output value and polarity of SSILRCKn/SSIFSn (n = 0, 1) pin

Communication Format	Expected Initial State	Setting Value of LRCKP
I^2S	High	0
Monaural	Low	1
TDM	Low	1

Note: When the format to be used is compatible with the I^2S, monaural, or TDM format, specify settings to enable communication with the respective formats.

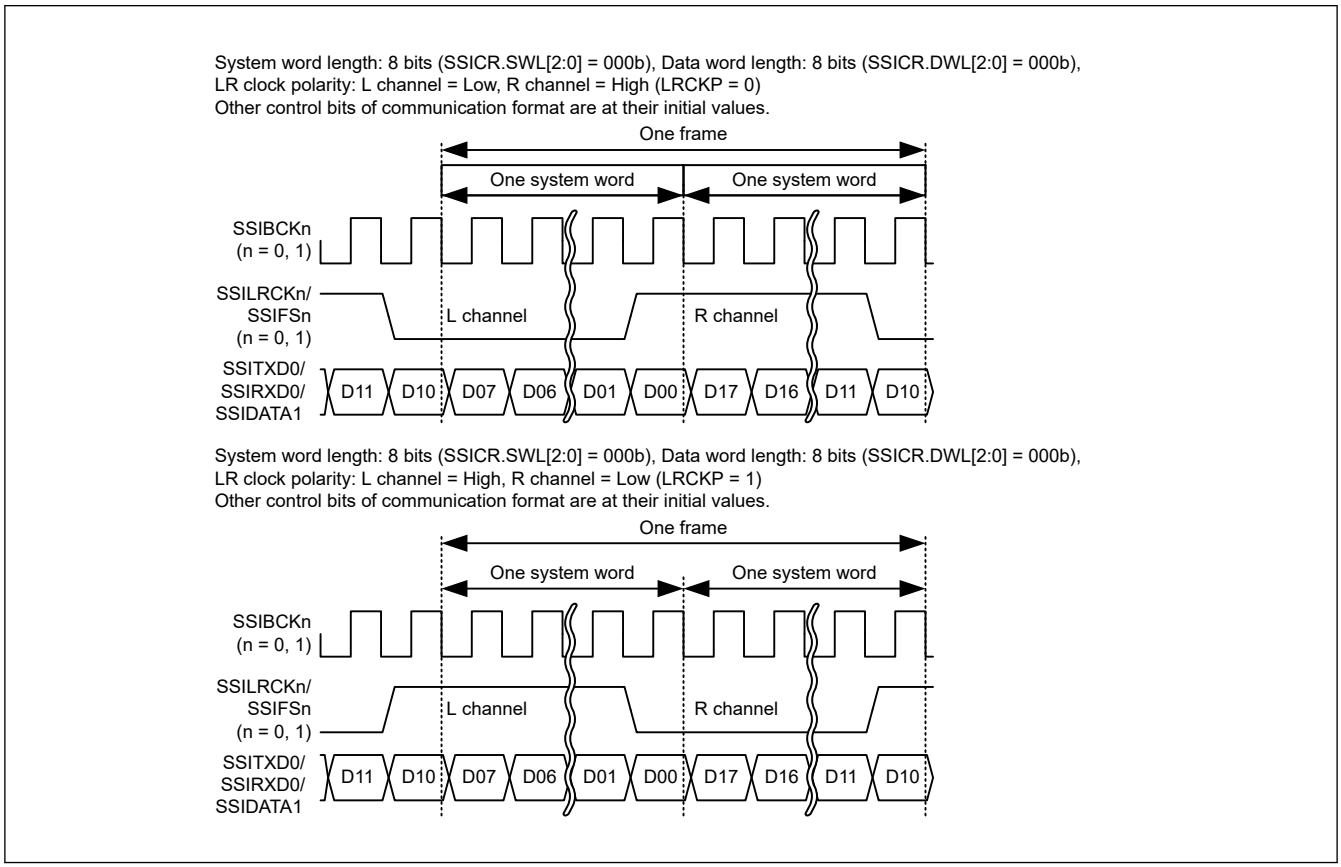

Figure 39.12 LR clock/frame synchronization polarity setting

BCKP bit (Selects Bit Clock Polarity)

The BCKP bit sets the bit clock polarity.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in section 39.2.3. SSIFCR : FIFO Control Register.

Table 39.6 Bit clock polarity

Communication	Master/Slave	Timing	BCKP = 0	BCKP = 1
Reception	Slave	At SSILRCKn/SSIFSn (n = 0, 1) sampling	SSIBCKn (n = 0, 1) rising edge	SSIBCKn (n = 0, 1) falling edge
	Master/slave	At SSIRXD0/SSIDATA1 sampling	SSIBCKn (n = 0, 1) rising edge	SSIBCKn (n = 0, 1) falling edge
Transmission	Master	At change of SSILRCKn/SSIFSn (n = 0, 1) output	SSIBCKn (n = 0, 1) falling edge	SSIBCKn (n = 0, 1) rising edge
	Master/slave	At change of SSITXD0/SSIDATA1 output	SSIBCKn (n = 0, 1) falling edge	SSIBCKn (n = 0, 1) rising edge

MST bit (Master Enable)

The MST bit sets master-/slave-mode communication.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in section 39.2.3. SSIFCR : FIFO Control Register.

SWL[2:0] bits (Selects System Word Length)

The SWL[2:0] bits set the number of bits in one system word. Padding bits are sent and received in relation with one data word set with DWL[2:0]. See Table 39.13 for details.

Writing to these bits must be performed when the LR clock supply to the SSILRCKn/SSIFSn (n = 0, 1) pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in section 39.2.7. SSIOFR : Audio Format Register.

DWL[2:0] bits (Selects Data Word Length)

The DWL[2:0] bits set the number of bits in one data word. The data word length (number of bits per data word) must not exceed the system word length (number of bits per system word). For details, see Table 39.13.

FRM[1:0] bits (Selects Frame Word Number)

The FRM[1:0] bits set the frame word number in individual communication formats.

Writing to these bits must be performed when the LR clock supply to the SSILRCKn/SSIFSn (n = 0, 1) pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in section 39.2.7. SSIOFR : Audio Format Register.

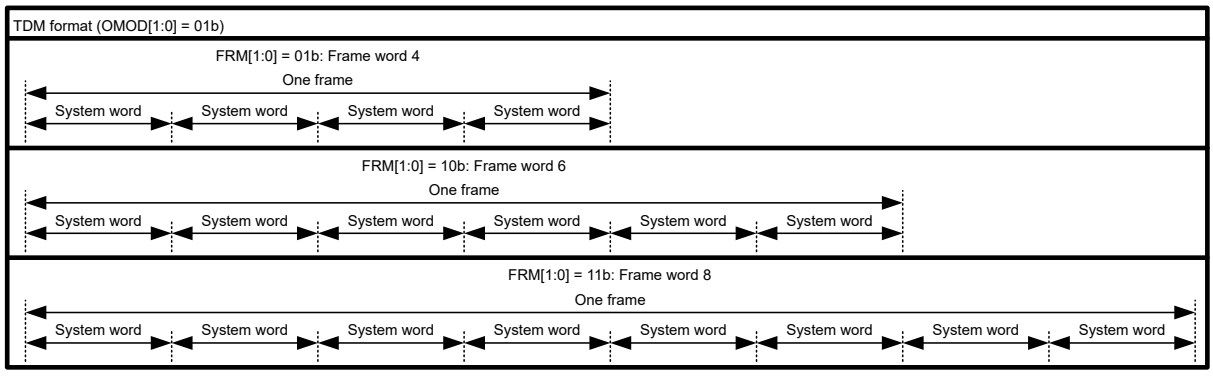

Figure 39.13 Frame word number

IIEN bit (Idle Mode Interrupt Output Enable)

The IIEN bit enables/disables output of idle mode interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.IIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.IIRQ = 1.

ROIEN bit (Receive Overflow Interrupt Output Enable)

The ROIEN bit enables/disables output of receive overflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.ROIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.ROIRQ = 1.

RUIEN bit (Receive Underflow Interrupt Output Enable)

The RUIEN bit enables/disables output of receive underflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.RUIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.RUIRQ = 1.

TOIEN bit (Transmit Overflow Interrupt Output Enable)

The TOIEN bit enables/disables output of transmit overflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.TOIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.TOIRQ = 1.

TUIEN bit (Transmit Underflow Interrupt Output Enable)

The TUIEN bit enables/disables output of transmit underflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.TUIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.TUIRQ = 1.

CKS bit (Selects an Audio Clock for Master-mode Communication)

The CKS bit sets the audio clock in master-mode communication (MST = 1). In slave-mode communication (MST = 0), setting of this bit is invalid.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in section 39.2.3. SSIFCR : FIFO Control Register.

39.2.2 SSISR : Status Register

Base address: SSIEn = 0x4025_D000 + 0x0100 × n (n = 0, 1)
SSIEn_NS = 0x5025_D000 + 0x0100 × n (n = 0, 1)

28	TOIRQ	Transmit Overflow Error Status Flag 0: No transmit overflow error is generated. 1: A transmit overflow error is generated.	R/W

Bit	Symbol	Function	R/W
29	TUIRQ	Transmit Underflow Error Status flag 0: No transmit underflow error is generated. 1: A transmit underflow error is generated.	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register is configured with status flags that indicate SSIE operational state.

IIRQ flag (Idle Mode Status Flag)

The IIRQ flag is a status flag that indicates the idle state. It indicates whether SSIE is in the idle state or communication state.

For details, see Figure 39.14 and Figure 39.15.

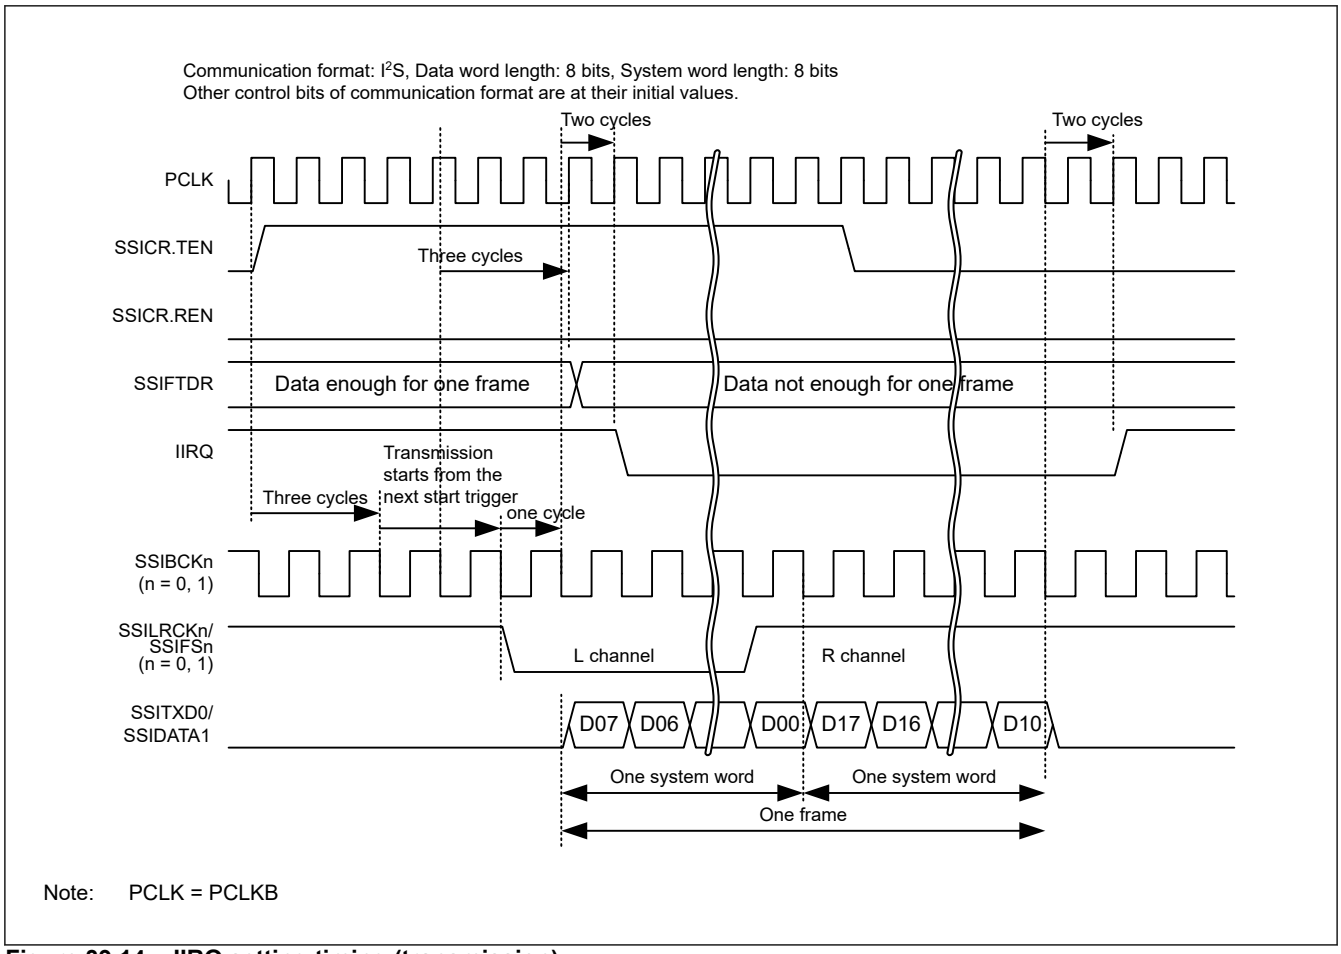

Figure 39.14 IIRQ setting timing (transmission)

- Transmitter (dedicated to transmission)

[Clearing condition]

While transmission was enabled (SSICR.TEN = 1 and SSICR.REN = 0), the transmit data for a transmission frame was written to the SSIFTDR register, and a start trigger was generated by the SSILRCKn/SSIFSn (n = 0, 1) signal.

[Clearing timing]

1 SSIBCKn (n = 0, 1) cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), transmission of one frame was complete.

[Setting timing]

2 PCLKB cycles after the end of transmission (at a frame boundary) that is the setting condition.

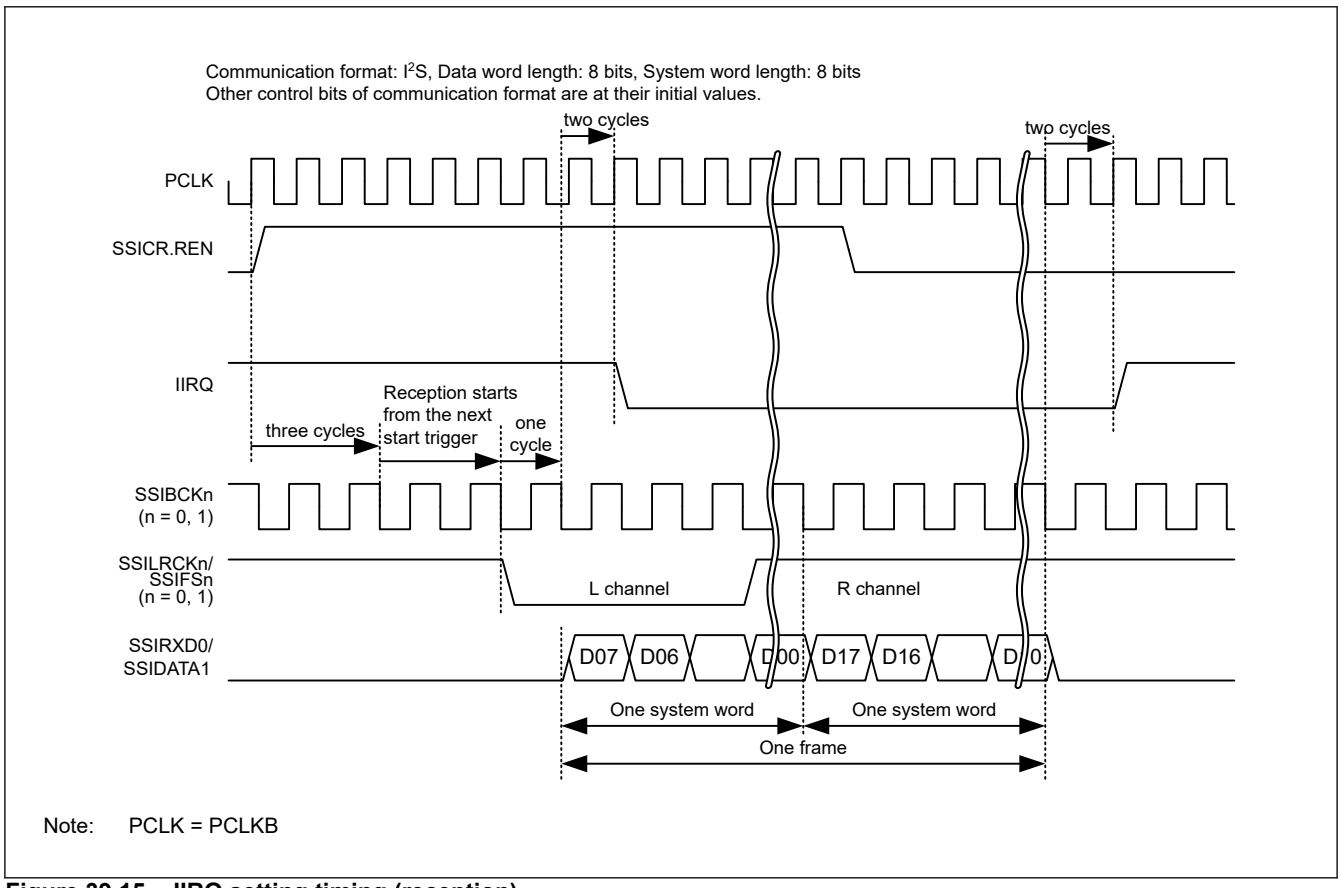

Figure 39.15 IIRQ setting timing (reception)

- Receiver (dedicated to reception)

[Clearing condition]

While reception was enabled (SSICR.TEN = 0 and SSICR.REN = 1, a start trigger was generated by the SSILRCKn/ SSIFSn (n = 0, 1) signal.

[Clearing timing]

1 SSIBCKn (n = 0, 1) cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), reception of one frame was complete.

[Setting timing]

2 PCLKB cycles after the end of reception (at a frame boundary) that is the setting condition.

- Transceiver (transmission and reception)

[Clearing condition]

While transmission and reception were enabled (SSICR.TEN = 1 and SSICR.REN = 1), the transmit data for a transmission frame was written to the SSIFTDR register, and a start trigger is generated by the SSILRCKn/SSIFSn (n = 0, 1) signal.

[Clearing timing]

1 SSIBCKn (n = 0, 1) cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), transmission of one frame was complete.

[Setting timing]

2 PCLKB cycles after the end of transmission (at a frame boundary) that is the setting condition.

ROIRQ flag (Receive Overflow Error Status Flag)

The ROIRQ flag is a status flag that indicates a receive overflow error. This flags is set by automatic determination but it must be cleared by register access. This flag indicates that received data is supplied at a higher rate than requested. Data is not transferred from the receive shift register to SSIFRDR where a receive overflow error is generated. For the procedure to recover from the overflow error, see section 39.6.6. Error Handling. This flag is not cleared by a receive FIFO data register reset (SSIFCR.RFRST).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.REN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition:

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 39.19)
2. 1 PCLKB cycle after writing 1 to SSICR.REN.*3

[Setting condition]
At completion of receiving new data while SSIFRDR is full.

[Setting timing]
3 cycles of PCLKB after reception is completed.

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:
- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- 1 PCLKB cycle passes after 1 has been written to SSICR.REN.

Note 3. After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

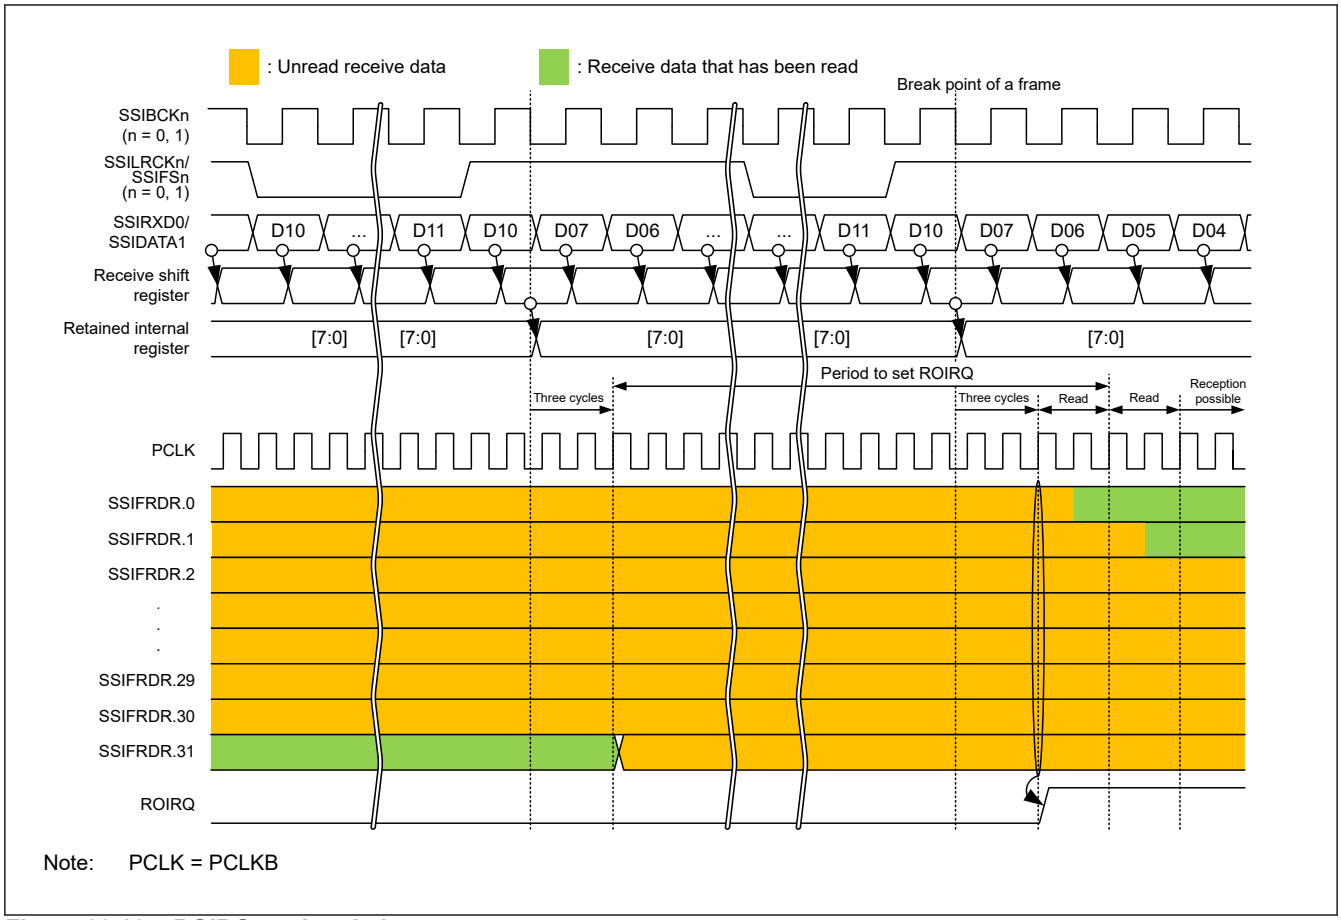

Figure 39.16 ROIRQ setting timing

RUIRQ flag (Receive Underflow Error Status Flag)

The RUIRQ flag is a status flag that indicates a receive underflow error. This flags is set by automatic determination but it must be cleared by register access. This flag indicates that SSIFRDR is read while it is empty. Data read from SSIFRDR where a receive underflow error is generated is invalid. See section 39.6.6. Error Handling for the error recovery procedure. This flag is not cleared by a receive FIFO data register reset (SSIFCR.RFRST). Note, however, that this flag is not set even if the SSIFRDR register is read while the receive FIFO data register is reset (by setting SSIFCR.RFRST to 1).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.REN from 0 to 1).

[Clearing timing]
Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 39.19)
2. 1 PCLKB cycle after writing 1 to SSICR.REN.*3

[Setting condition]

Reading from SSIFRDR while it is empty.

[Setting timing]

At completion of reading from SSIFRDR. See Figure 39.17.

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:

- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- 1 PCLKB cycle passes after 1 has been written to SSICR.REN.

Note 3. After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

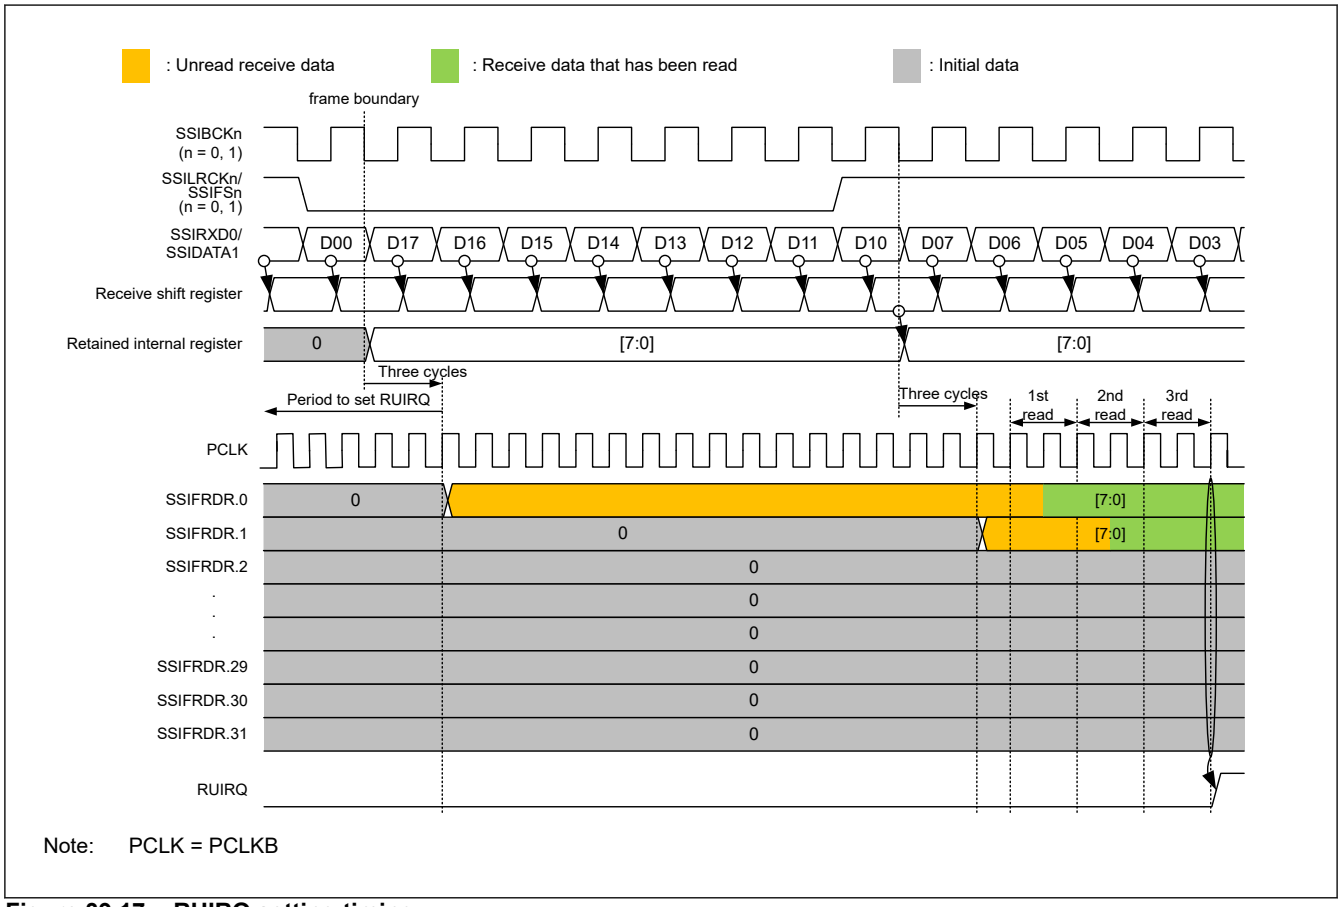

Figure 39.17 RUIRQ setting timing

TOIRQ flag (Transmit Overflow Error Status Flag)

The TOIRQ flag is a status flag that indicates a transmit overflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that an attempt has been made to write data to the SSIFTDR register when the register is full of data. The data writing that causes a transmit overflow is ignored. For the procedure to recover from the overflow error, see section 39.6.6. Error Handling. This flag is not cleared by a transmit FIFO data register reset (SSIFCR.TFRST).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.TEN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 39.19)
2. 1 PCLKB cycle after writing 1 to SSICR.TEN.*3

[Setting condition]

An attempt was made to write data to the SSIFTDR register when the register is full of data.

[Setting timing]

At completion of writing to SSIFTDR. For details, see Figure 39.18.

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:
- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- 1 PCLKB cycle passes after 1 has been written to SSICR.TEN.

Note 3. After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

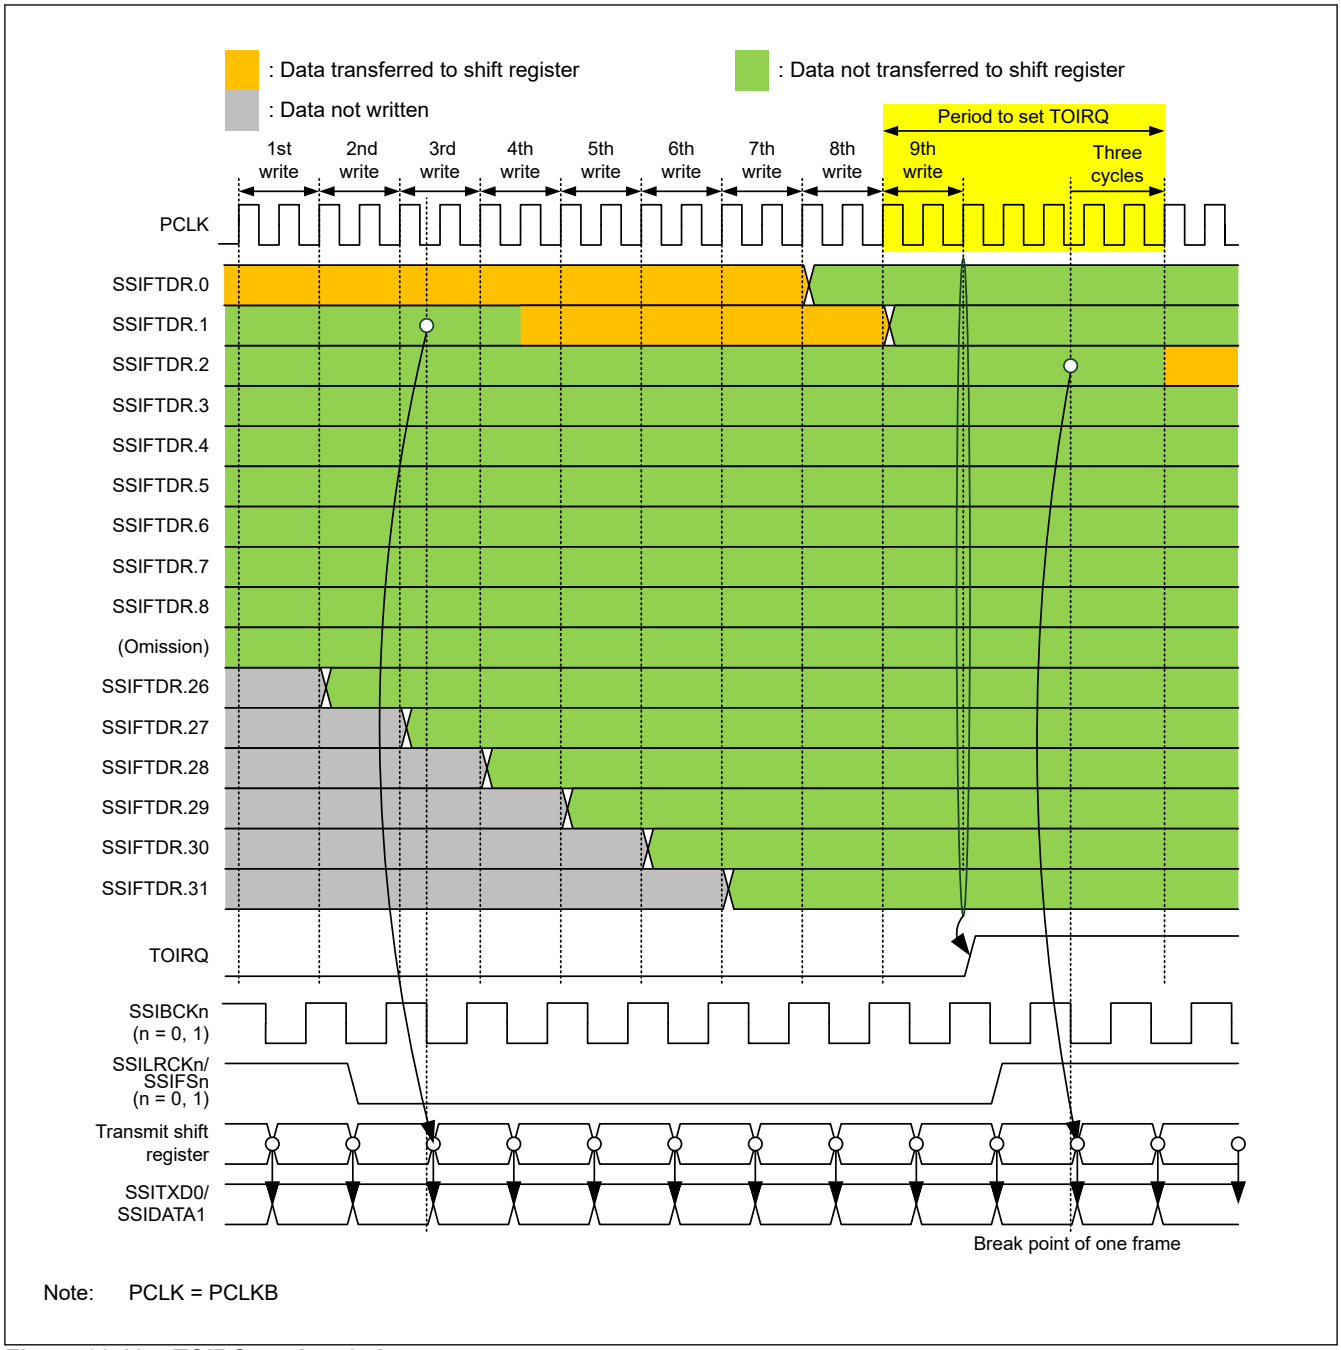

Figure 39.18 TOIRQ setting timing

TUIRQ flag (Transmit Underflow Error Status flag)

The TUIRQ flag is a status flag that indicates a transmit underflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that writing the serial data required for a frame to SSIFTDR did not catch up with transmission of the frame. Even if this flag is cleared after it has been set, the SSITXD0/SSIDATA1 output remains to be 0. To output the data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0/SSIDATA1 pin, follow the communication stop procedure in Figure 39.56 and error-handling procedure in Figure 39.57. For the procedure to recover from an error, see section 39.6.6. Error Handling. This flag is not cleared by a reset of transmit FIFO data register (by the SSIFCR.TFRST signal).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.TEN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit
2. 1 PCLKB cycle after writing 1 to SSICR.TEN.*3

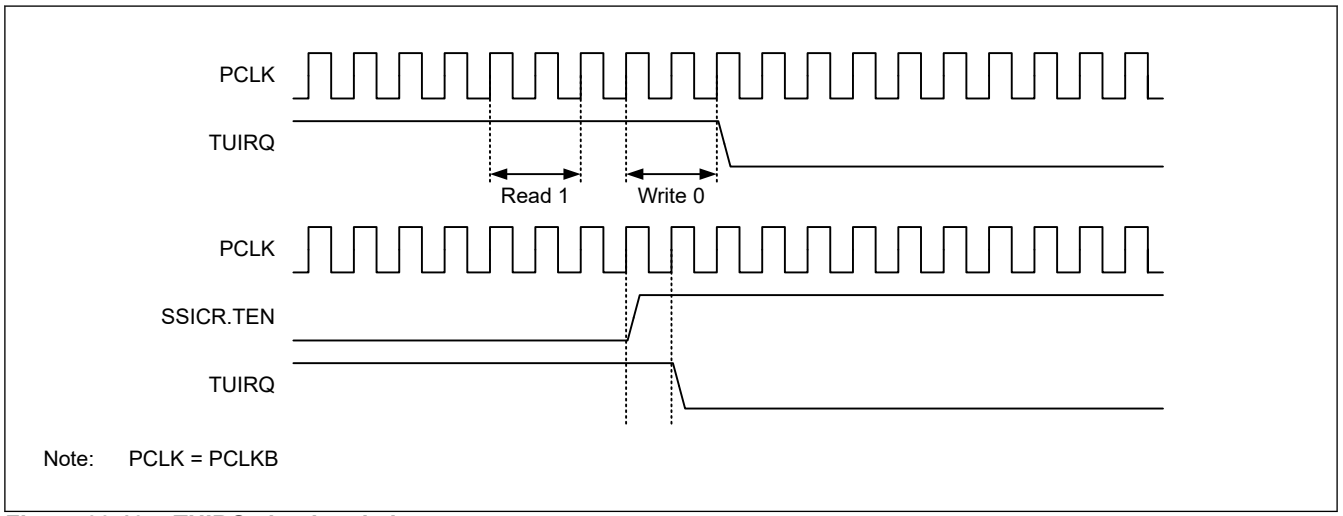

Figure 39.19 TUIRQ clearing timing

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:
- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- 1 PCLKB cycle passes after 1 has been written to SSICR.TEN.

Note 3. After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

[Setting condition]

When communication continues over a frame boundary, the transmit data required for the next frame has not been written to SSIFTDR. For details, see Figure 39.20 and Figure 39.21.

[Setting timing]

3 PCLKB cycles after the frame boundary. For details, see Figure 39.20.

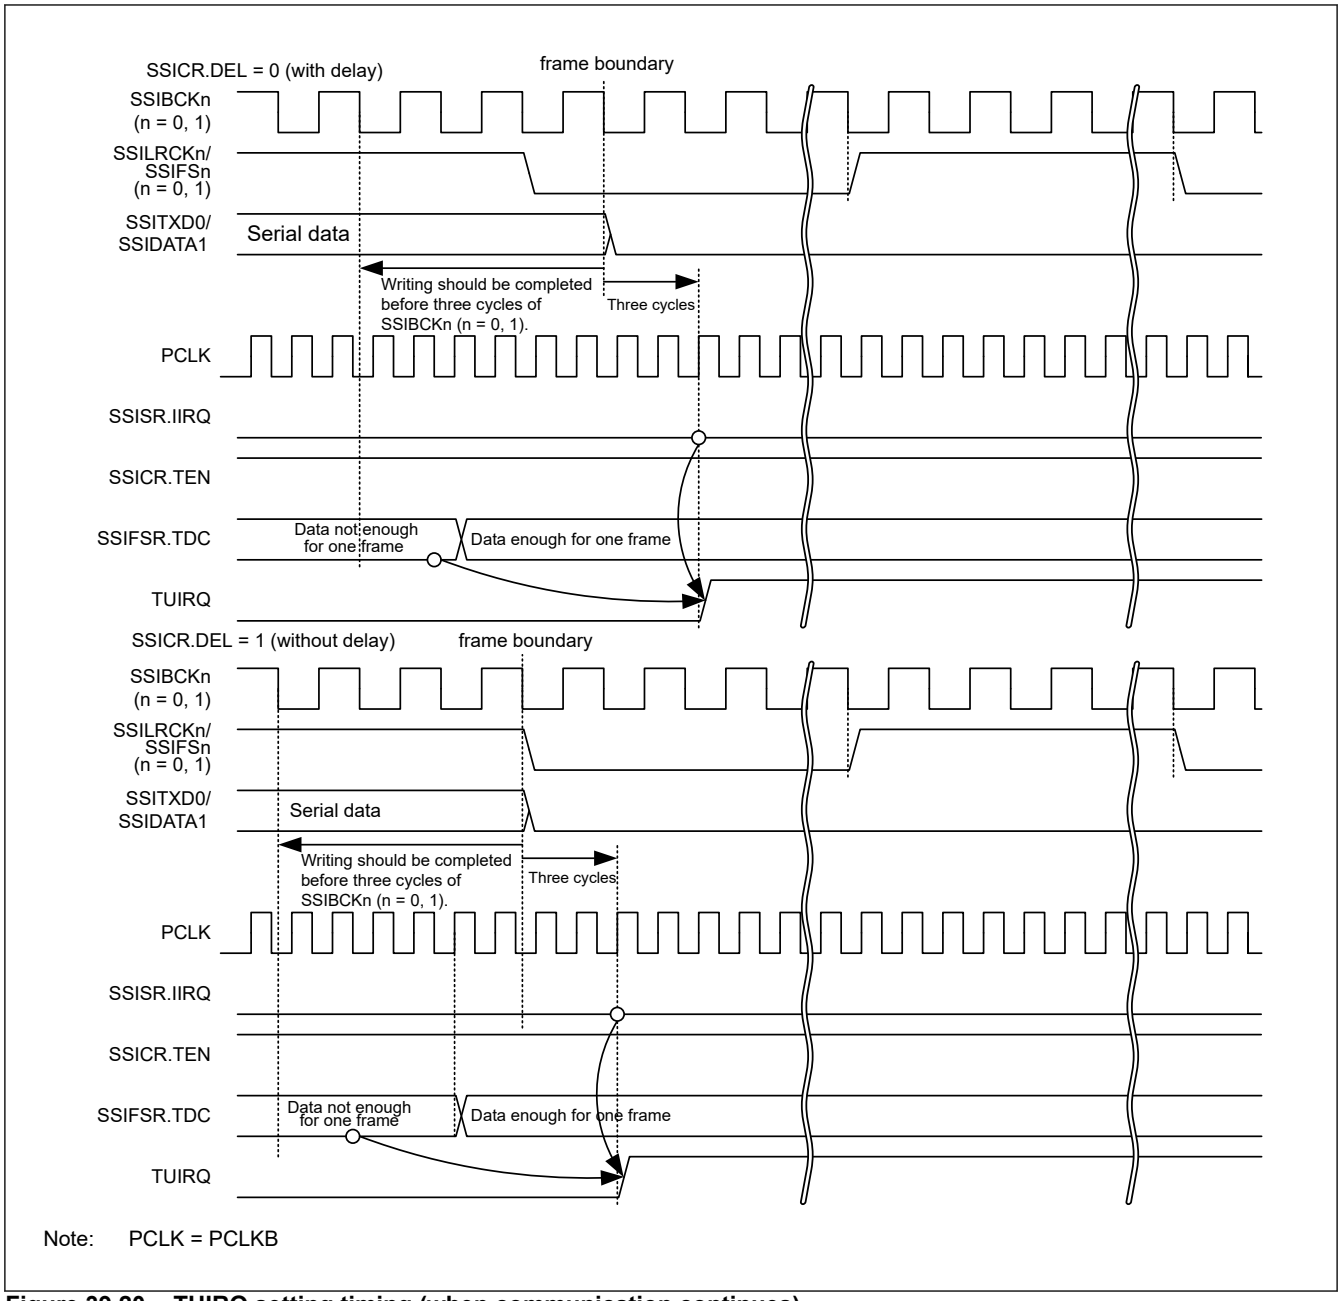

Figure 39.20 TUIRQ setting timing (when communication continues)

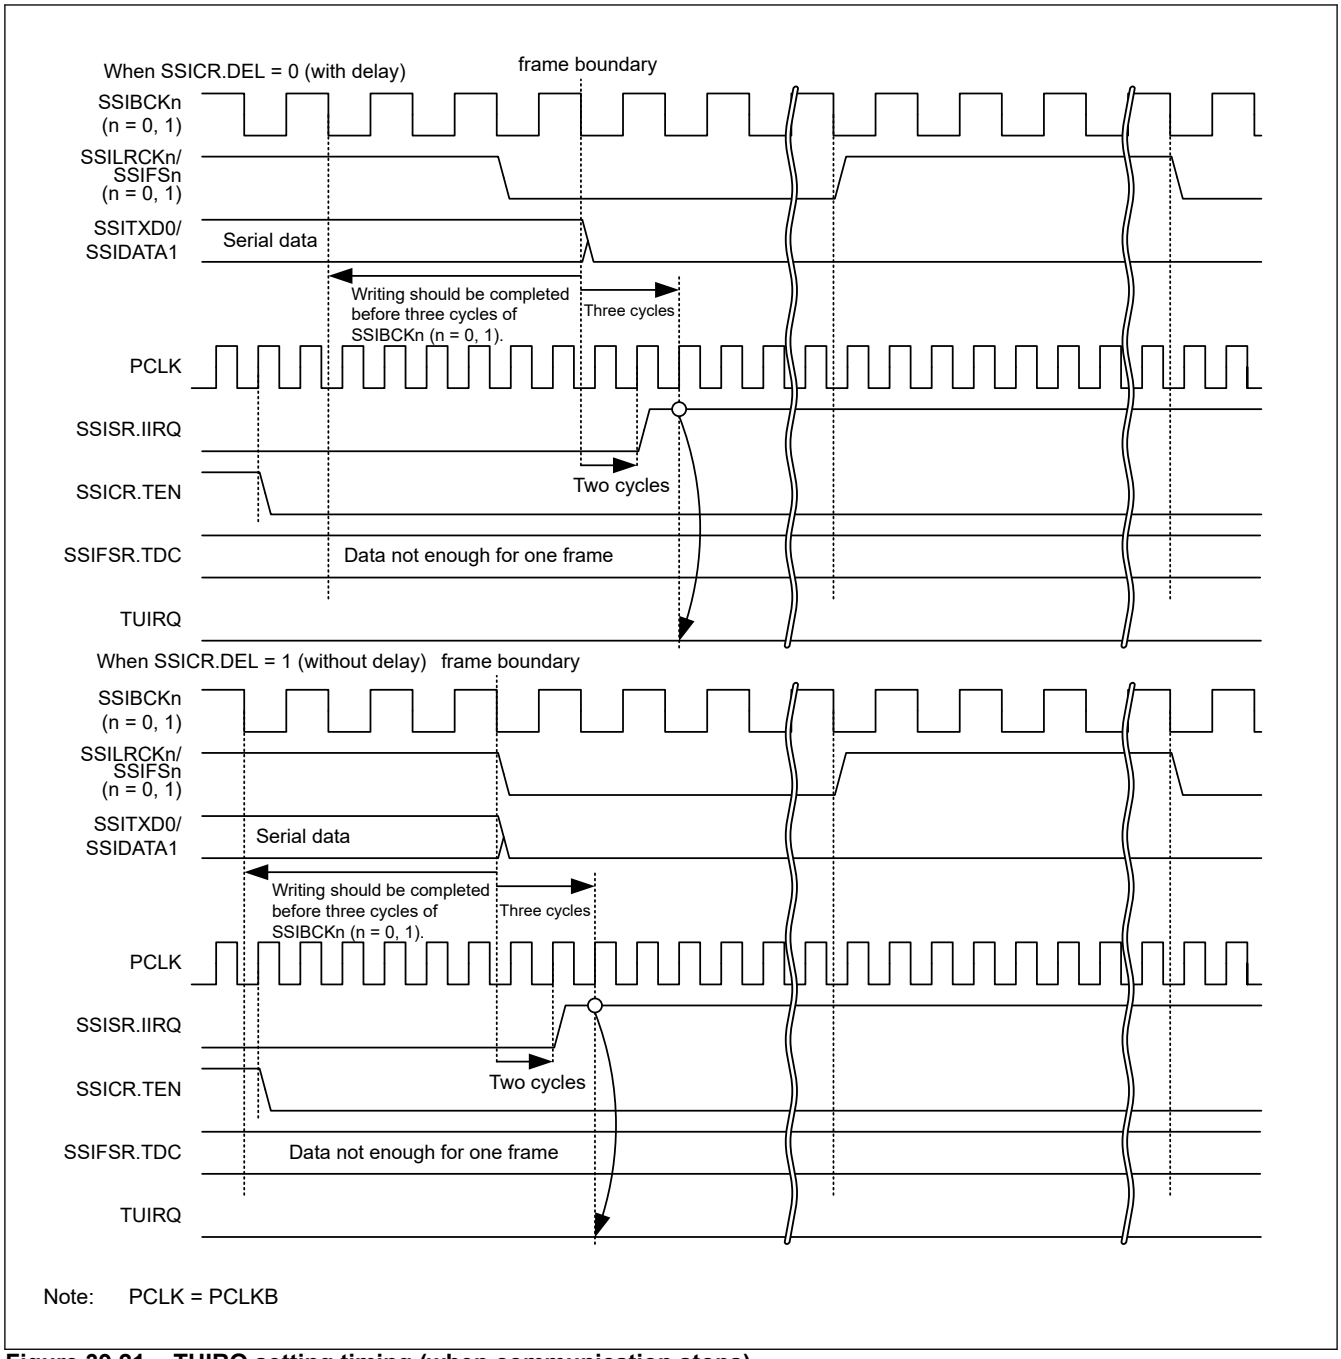

Figure 39.21 TUIRQ setting timing (when communication stops)

39.2.3 SSIFCR : FIFO Control Register

Base address: SSIEn = 0x4025_D000 + 0x0100 × n (n = 0, 1)
SSIEn_NS = 0x5025_D000 + 0x0100 × n (n = 0, 1)

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15:12	—	These bits are read as 0. The write value should be 0.	R/W
16	SSIRST	Software Reset 0: Clears a software reset condition 1: Sets a software reset condition	R/W
30:17	—	These bits are read as 0. The write value should be 0.	R/W
31	AUCKE	AUDIO_MCK Enable in Mastermode Communication*1 0: Disables supply of AUDIO_MCK 1: Enables supply of AUDIO_MCK	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If the value of these bits is changed by rewriting, subsequent operation is unpredictable.

This register sets a software reset, byte swap, and enable/disable of interrupt requests.

RFRST bit (Receive FIFO Data Register Reset)

The RFRST bit sets a software reset of the receive FIFO data register (SSIFRDR). Writing 1 to this bit initializes the internal state related to SSIFRDR. The register bits subject to the software reset triggered by this bit are indicated by shading in Table 39.7. Because this bit is not automatically cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

This bit is subject to the software reset by the SSIRST bit. Because the software reset by the SSIRST bit has priority over the reset by this bit, setting this bit is ignored when the SSIRST bit is set.

TFRST bit (Transmit FIFO Data Register Reset)

The TFRST bit sets a software reset of the transmit FIFO data register (SSIFTDR). Writing 1 to this bit initializes the internal state related to SSIFTDR. The register bits subject to the software reset triggered by this bit are indicated by shading in Table 39.8. Because this bit is not automatically cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

This bit is subject to the software reset by the SSIRST bit. Because the software reset by the SSIRST bit has priority over the reset by this bit, setting this bit is ignored when the SSIRST bit is set.

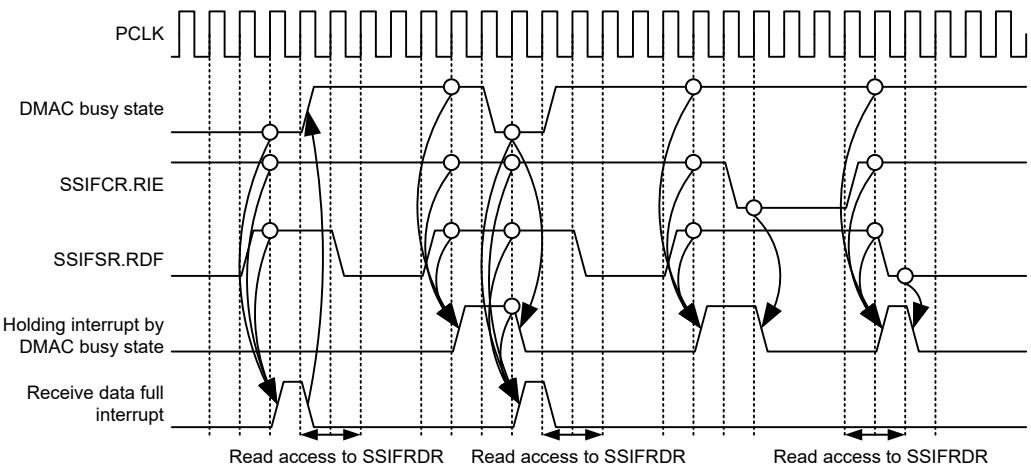
RIE bit (Receive Data Full Interrupt Output Enable)

The RIE bit enables/disables output of receive data full interrupts. Use a receive data full interrupt as an interrupt to trigger data reading from the receive FIFO data register. Write 1 to this bit after specifying the setting condition for receive data full interrupt (by using the SSISCR.RDFS bit). Figure 39.22 shows the timing of generating the receive data full interrupt.

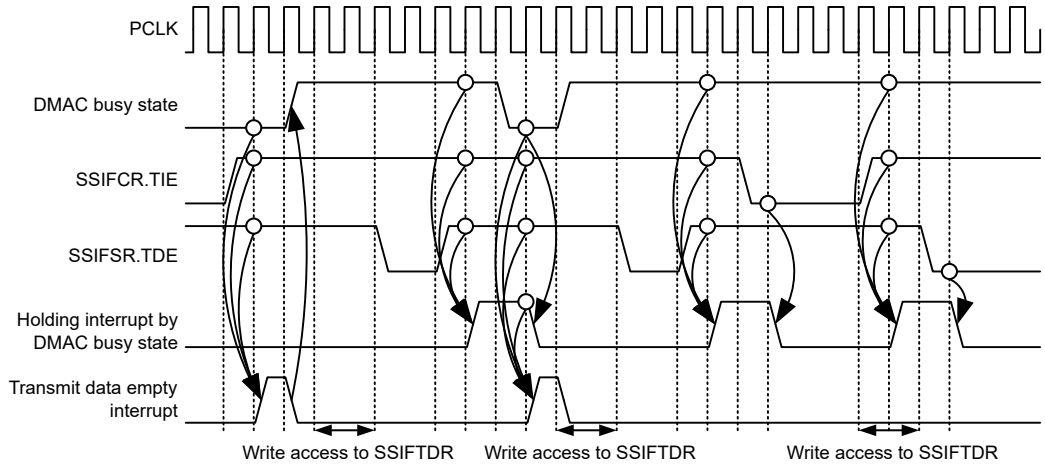


Note: PCLK = PCLKB

Figure 39.22 Timing of receive data full interrupt

TIE bit (Transmit Data Empty Interrupt Output Enable)

The TIE bit enables/disables output of transmit data empty interrupts. Use a transmit data empty interrupt as an interrupt to trigger data writing to the transmit FIFO data register. Write 1 to this bit after specifying the setting condition for transmit data empty interrupt (by using the SSISCR.TDES bit). Figure 39.23 shows the timing of generating the transmit data empty interrupt.



Note: PCLK = PCLKB

Figure 39.23 Timing of transmit data empty interrupt

BSW bit (Byte Swap Enable)

The BSW bit enables/disables byte swap of register access for the transmit FIFO data register (SSIFTDR) and the receive FIFO data register (SSIFRDR). This bit is valid only with 16-bit access or 32-bit access to SSIFTDR and SSIFRDR. For details, see Figure 39.24.

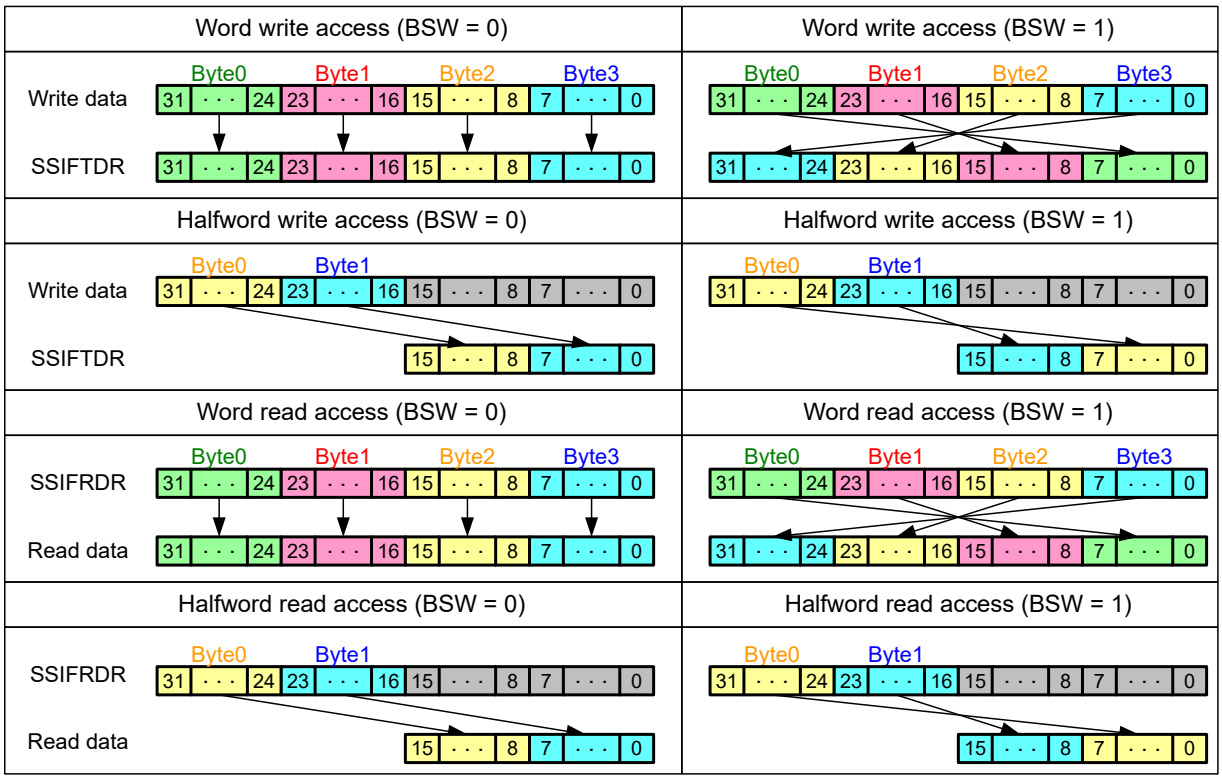


Figure 39.24 Operation example of byte swap

SSIRST bit (Software Reset)

The SSIRST bit sets a software reset of SSIE. Writing 1 to this bit initializes the internal state of SSIE. The register bits subject to the software reset triggered by this bit are indicated by shading in Table 39.9. Because this bit is not automatically

cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

To stop communication of SSIE immediately, after turning off the peripheral functions, write 1 to this bit. Initialization by a software reset is performed without any relation with the bit clock.

Table 39.9 Bits subject to software reset by the SSIRST bit

AUCKE bit (AUDIO_MCK Enable in Mastermode Communication)

The AUCKE bit enables/disables supply to AUDIO_MCK while in master-mode communication (MST = 1).

Changing the value of this bit must be performed only after specifying the settings related to AUDIO_MCK (by using the CKS, MST, BCKP, and CKDV bits in the SSICR register).

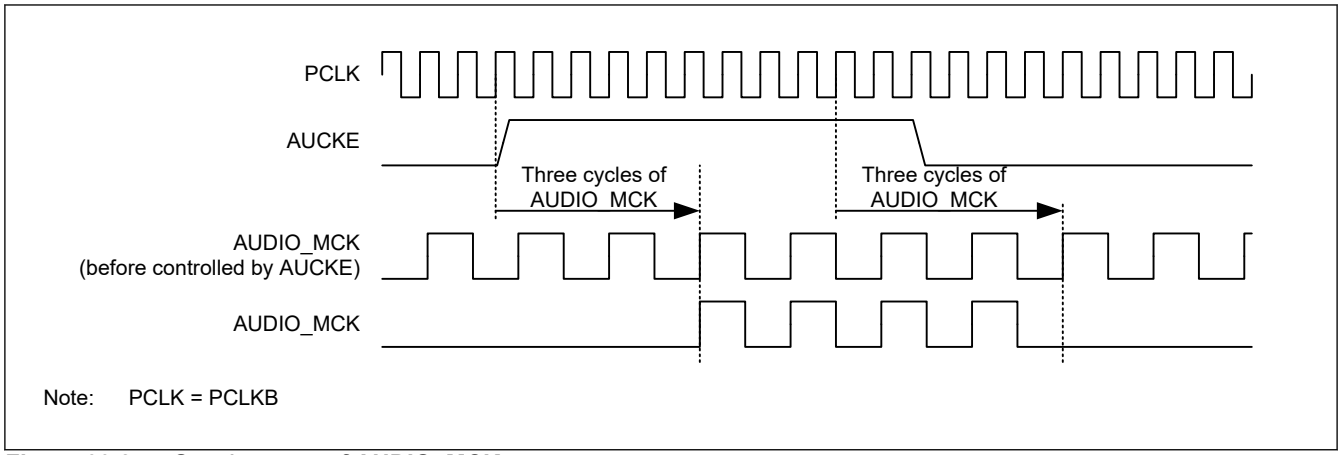

Figure 39.25 Stop/resume of AUDIO_MCK

Note: In slave-mode communication (SSICR.MST = 0), SSIE needs supply of SSIBCKn (n = 0, 1). To stop BCK on the master side, make sure that SSIE is in the idle state (SSISR.IIRQ = 1). If BCK is stopped before SSIE becomes idle, take the procedure to start communication in Figure 39.52 or wait for an idle state by taking the procedure to resume communication in Figure 39.58.

In master-mode communication (SSICR.MST = 1), SSIE operates with the audio clock (AUDIO_MCK). To stop SSIE completely, make sure that SSIE is in the idle state (SSISR.IIRQ = 1) and then write 0 to SSIFCR.AUCKE. If 0 is written to SSIFCR.AUCKE before SSIE becomes idle, take the procedure to start communication in Figure 39.52.

Figure 39.26 and Figure 39.27 show the timings of signal operation in the period from setting this bit to 1 to the output to the SSIBCKn (n = 0, 1) pin.

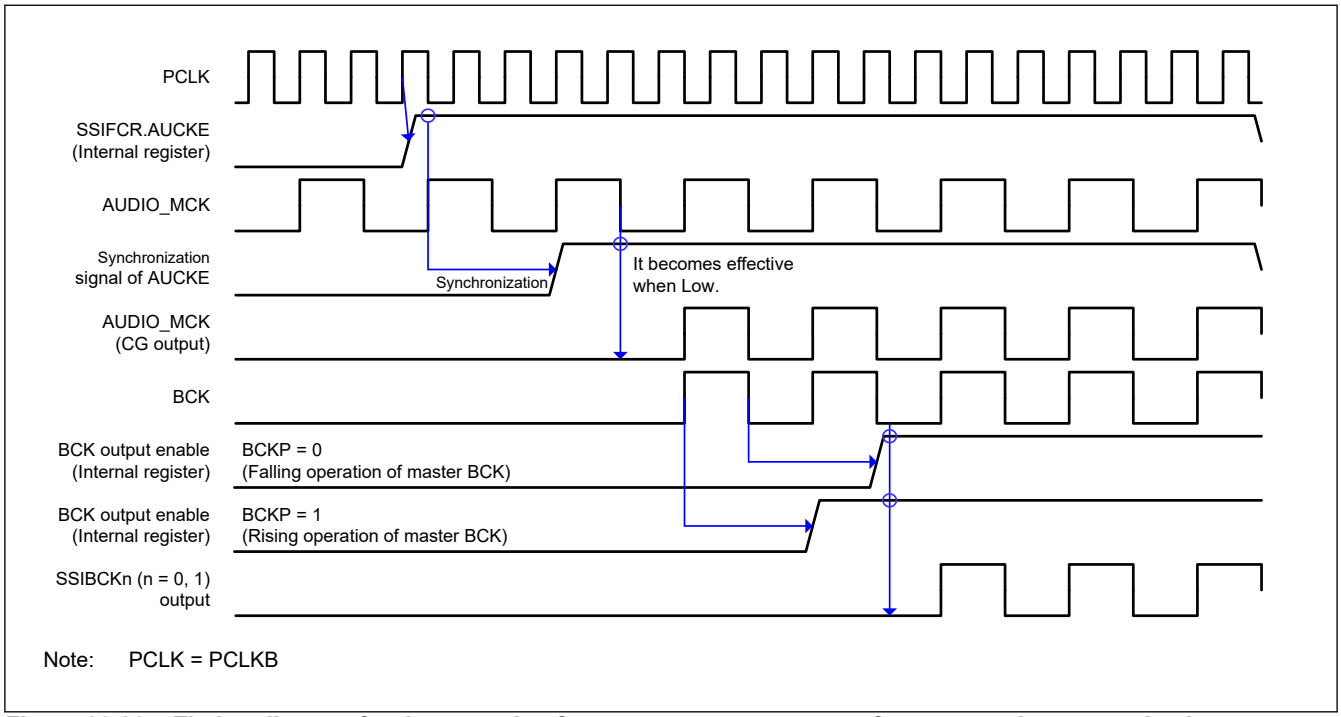

Figure 39.26 Timing diagram for the operation from system reset to start of master-mode communication

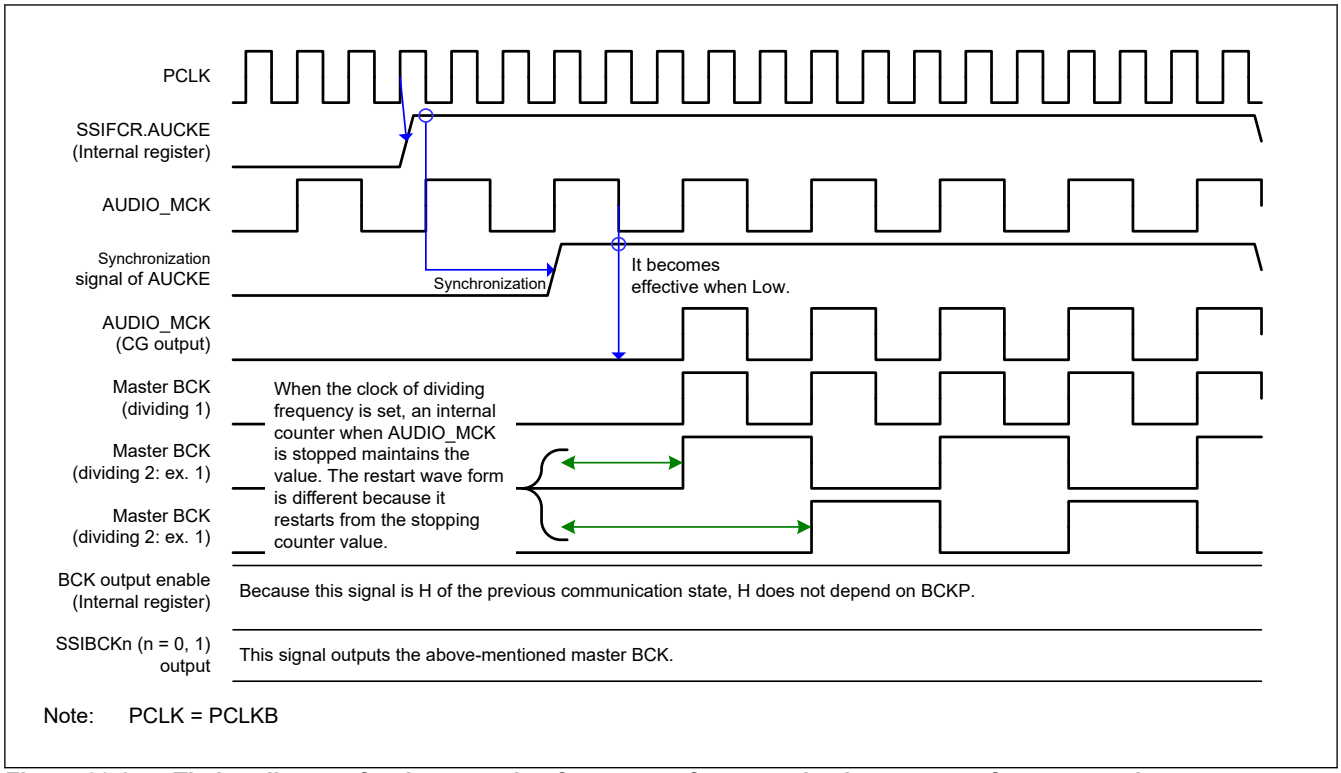

Figure 39.27 Timing diagram for the operation from stop of communication to start of master-mode communication

Note: If the supply of AUDIO_MCK stops, the value of the SSIBCKn (n = 0, 1) pin is held. Therefore, the SSIBCKn (n = 0, 1) signal might stop in the H (high level) state.

39.2.4 SSIFSR : FIFO Status Register

Base address: SSIEn = 0x4025_D000 + 0x0100 × n (n = 0, 1)
SSIEn_NS = 0x5025_D000 + 0x0100 × n (n = 0, 1)

Offset address: 0x14

23:17	—	These bits are read as 0. The write value should be 0.	R/W
29:24	TDC[5:0]	Number of Transmit FIFO Data Indication Flag Number of transmit FIFO data indication flag	R
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register is configured with status flags that indicate the status of the transmit FIFO data register and the receive FIFO data register.

RDF flag (Receive Data Full Flag)

The RDF flag indicates that the receive FIFO data register (SSIFRDR) has unread received data not less than the amount set with the SSISCR.RDFS bit plus one. This flag is set by automatic determination but it must be cleared by register access.

[Priority order for setting and clearing]

Clearing is prioritized.

[Clearing condition]

Either of the following two:*1

1. Writing 0 to this bit after reading 1 from this bit (CPU operation)*2
2. Last access (DTC/DMAC operation) to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 39.19)
2. After the PCLKB cycle in which the last access instruction is issued to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

[Setting condition]

SSIFTDR has free space not less than the amount set with the SSIFCR.TTRG bit plus one.

[Setting timing]

At completion of transfer from the shift register that results in SSIFRDR having data not less than the amount set with the SSISCR.RDFS bit plus one.

Note 1. These bits are cleared by a software reset (SSIFCR.SSIRST = 1) and receive FIFO data register reset (SSIFCR.RFRST = 1). Reset conditions available for these bits are the software reset and receive FIFO data register reset as well as the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following four conditions is met:
- A software reset is done (SSIFCR.SSIRST = 1).
- A receive FIFO data register reset is done (SSIFCR.RFRST = 1).
- After 1 has been read, writing of 0 is complete.
- Last access is performed to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

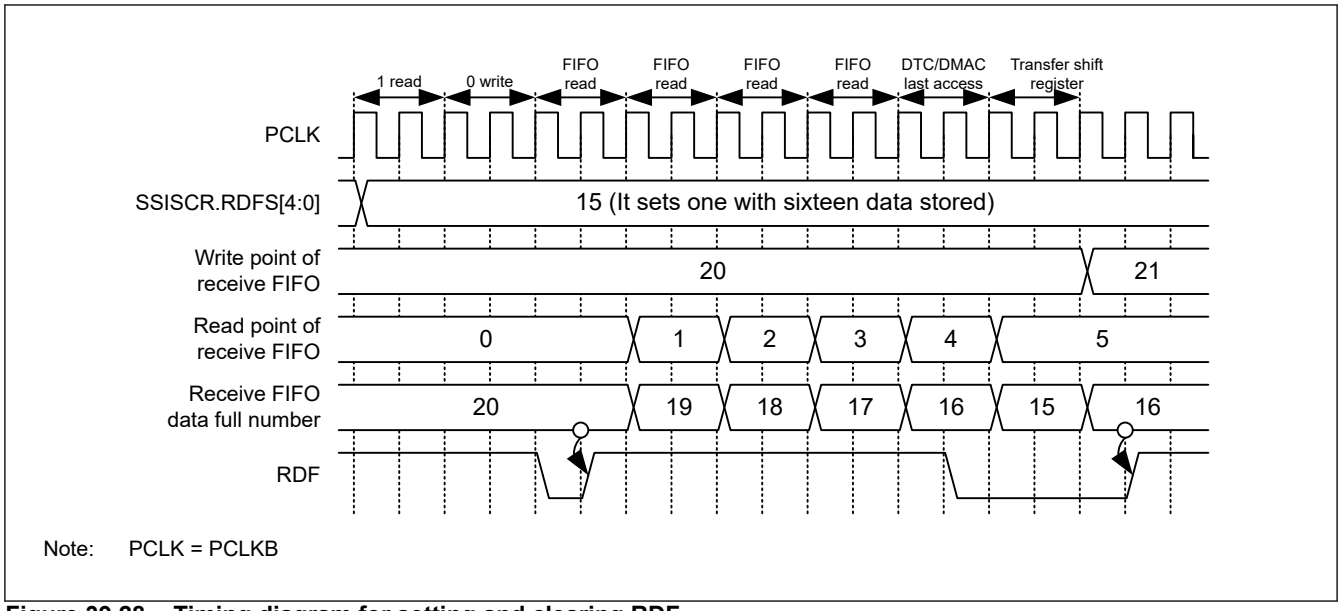

Figure 39.28 Timing diagram for setting and clearing RDF

RDC[5:0] flags (Number of Receive FIFO Data Indication Flag)

The RDC[5:0] flags indicate the number of valid data that are stored in the receive FIFO data register (SSIFRDR). With this flag as 0x00, there is no received data. With 0x20, the register is filled with received data and there is no free space.

TDE flag (Transmit Data Empty Flag)

The TDE flag indicates that the transmit FIFO data register (SSIFTDR) has free space not less than the amount set with the SSIFCR.TTRG bit plus one. This flag is set by automatic determination but it must be cleared by register access.

[Priority order for setting and clearing]

Clearing is prioritized.*1

[Clearing condition]

Either of the following two:

1. Writing 0 to this bit after reading 1 from this bit (CPU operation)*2
2. Last access (DTC/DMAC operation) to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 39.19)
2. Last access (DTC/DMAC operation) to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

[Setting condition]

SSIFTDR has free space not less than the amount set with the SSIFCR.TTRG bit plus one.

[Setting timing]

While operating on PCLKB, SSIFTDR is found to have free space not less than “size set in the SSISCR.TDES bits + 1.”

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1) and transmit FIFO data register reset (SSIFCR.TFRST = 1). The software reset and transmit FIFO data register reset have priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following four conditions is met:
- A software reset is done (SSIFCR.SSIRST = 1).
- A transmit FIFO data register reset is done (SSIFCR.TFRST = 1).
- After 1 has been read, writing of 0 is complete.
- Last access is performed to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

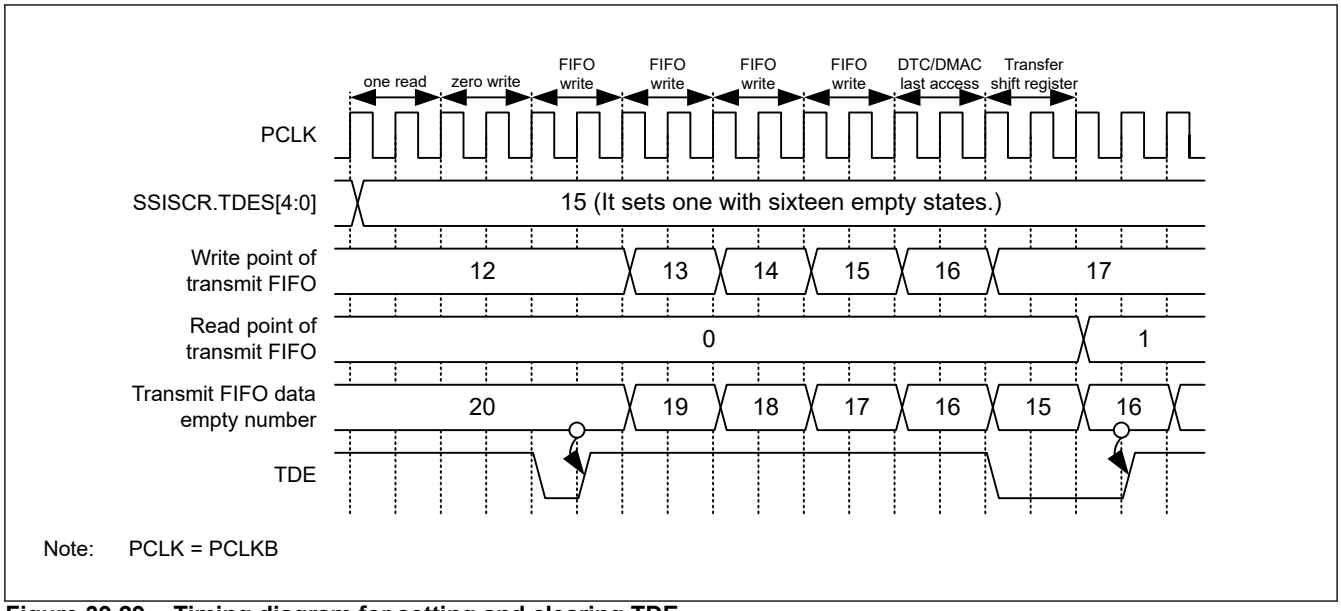

Figure 39.29 Timing diagram for setting and clearing TDE

TDC[5:0] flags (Number of Transmit FIFO Data Indication Flag)

The TDC[5:0] flags indicate the number of valid data that are stored in the transmit FIFO data register (SSIFTDR). With this flag as 0x00, there is no data to be transmitted. With 0x20, there is no space to write data.

39.2.5 SSIFTDR : Transmit FIFO Data Register

Base address: SSIEn = 0x4025_D000 + 0x0100 × n (n = 0, 1)
SSIEn_NS = 0x5025_D000 + 0x0100 × n (n = 0, 1)

Offset address: 0x18

9	BCKASTP	Whether to Enable Stopping BCK Output When SSIE is in Idle Status*1 *2 0: Always outputs BCK to the SSIBCKn (n = 0, 1) pin 1: Automatically controls output of BCK to the SSIBCKn (n = 0, 1) pin	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. This bit is valid only in master-mode communication (SSICR.MST = 1). The setting is invalid in slave-mode communication (SSICR.MST = 0).
Note 2. The BCKASTP and LRCONT bits must not be set to 1 together.
Note 3. While SSIE is communicating (SSISR.IIRQ = 0), writing to these bits is prohibited. If the value of these bits is changed by writing, subsequent operation is unpredictable.
Note 4. If the communication format of other-party device is compatible with a communication format of SSIE, specify and use the communication format that enables communication with the other-party device.

This register is used to set an audio format (which involves the settings of communication format, LR clock/frame synchronization continuation mode, and BCK output stop).

OMOD[1:0] bits (Audio Format Select)

The OMOD[1:0] bits set an audio format. Writing to these bits must be performed when the LR clock supply to the SSILRCKn/SSIFSn (n = 0, 1) pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in section 39.2.7. SSIOFR : Audio Format Register.

LRCONT bit (Whether to Enable LRCK/FS Continuation)

The LRCONT bit enables or disables the output from SSILRCKn/SSIFSn (n = 0, 1) pin when the communication mode is master-mode communication (SSICR.MST = 1) and SSIE is in the idle state (SSISR.IIRQ = 1).

Even in the idle state, a signal can output from the SSILRCKn/SSIFSn (n = 0, 1) pin when this bit is set to 1 (to enable LR clock/frame synchronization continuation) in master mode (SSICR.MST = 1).

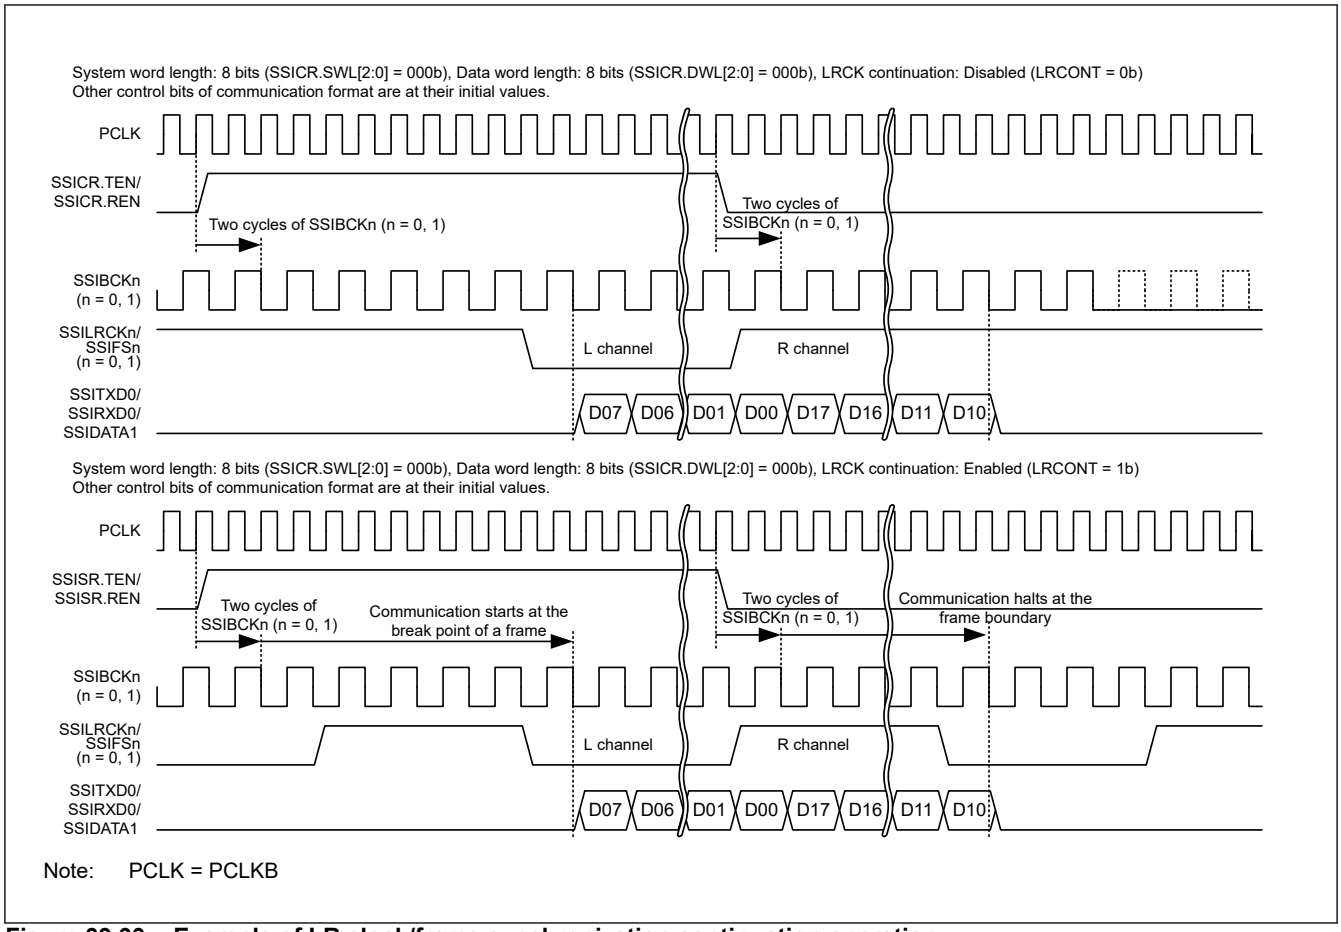

Figure 39.33 Example of LR clock/frame synchronization continuation operation

BCKASTP bit (Whether to Enable Stopping BCK Output When SSIE is in Idle Status)

The BCKASTP bit turns on or off the function to output BCK to the SSIBCKn (n = 0, 1) pin according to the communication shown in Figure 39.34 and Figure 39.35 in master-mode communication (SSICR.MST = 1).

Changing the value of this bit must be performed only after setting the communication format to be used.

This bit must be used in the following way:

Write 0 to the BCKASTP bit, and then start communication. During the communication, write 1 to the BCKASTP bit. By this operation, the bit clock output to the SSIBCKn (n = 0, 1) pin stops automatically when the communication stops. To resume the communication, set SSIE to the idle state (SSICR.IIRQ = 1), enable the supply of AUDIO_MCK (SSIFCR.AUCKE = 1), and then write 0 to the BCKASTP bit.

When the communication mode is master-mode communication (SSICR.MST = 1) and SSIE is in the idle state (SSICR.IIRQ = 1):

Table 39.11 BCKASTP bit status and SSIBCKn (n = 0, 1) pin output

BCKASTP Bit	SSIBCKn (n = 0, 1) Pin Output Status
0	Output
1	Stopped

Note: The BCKASTP bit cannot be used when the other-party device (which is a slave) requires the clock output from the SSIBCKn (n = 0, 1) pin before and during communication. In such a case, use the BCKASTP bit to stop the clock only after communication. For the timing of enabling the clock stop function, see Figure 39.34.

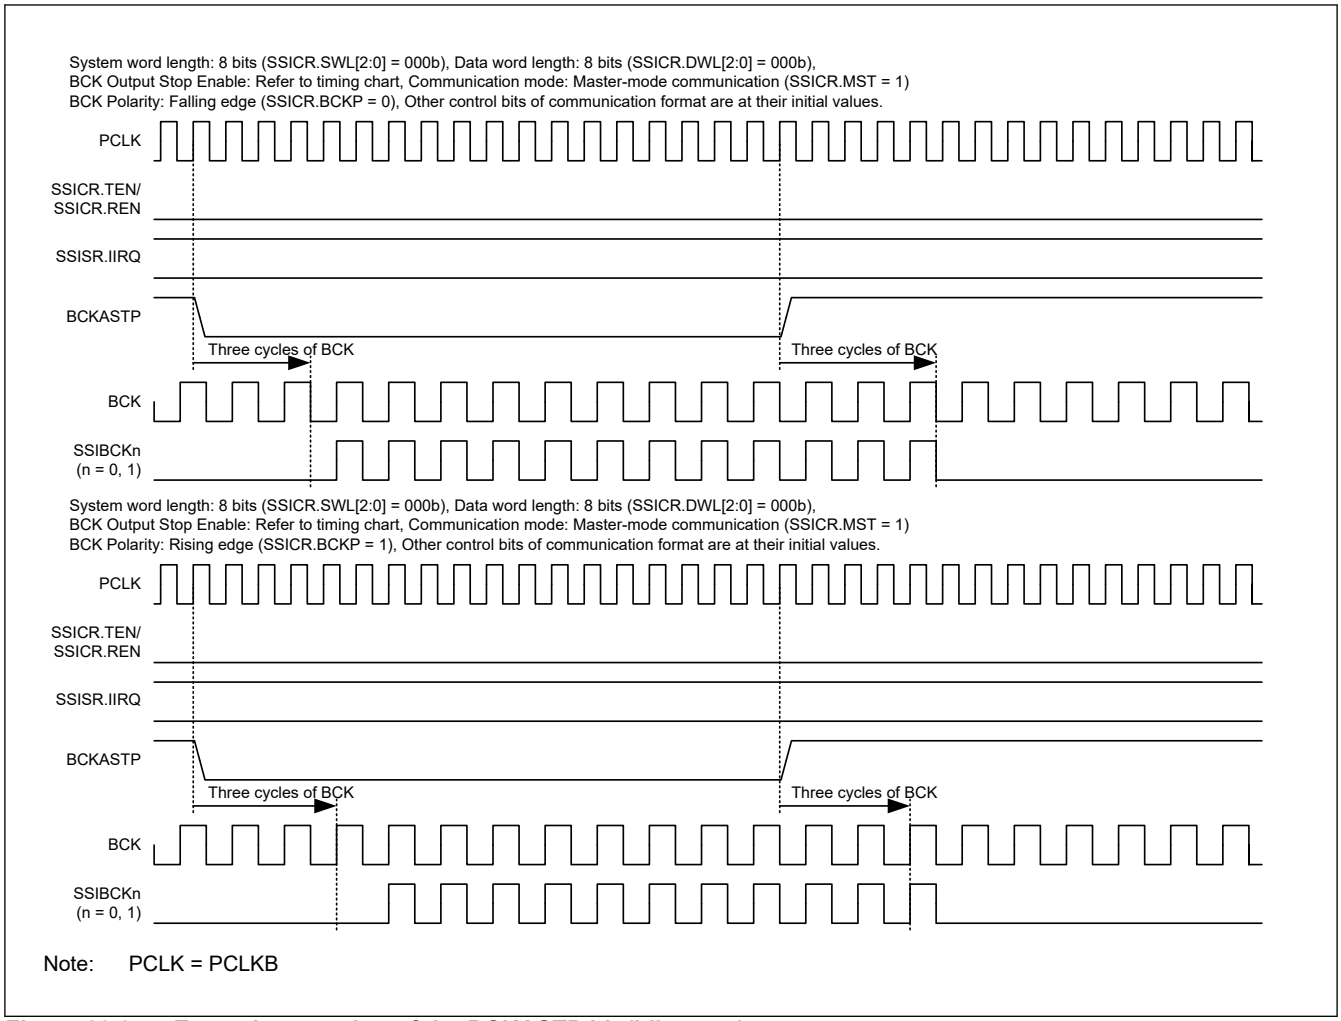

Figure 39.34 Example operation of the BCKASTP bit (idle state)

When the communication mode is master-mode communication (SSICR.MST = 1) and the BCK output stop function is enabled (BCKASTP = 1):

Details of the BCK output to the SSIBCKn (n = 0, 1) pin are as follows:

Output start timing: BCK is output in appropriate timing so that a valid edge is generated when the LR clock/frame synchronization signal shifts to a valid value.

Output stop timing: 1 to 1.5 clock cycles after a frame boundary.

For details about the timings, see the timing diagram in Figure 39.35.

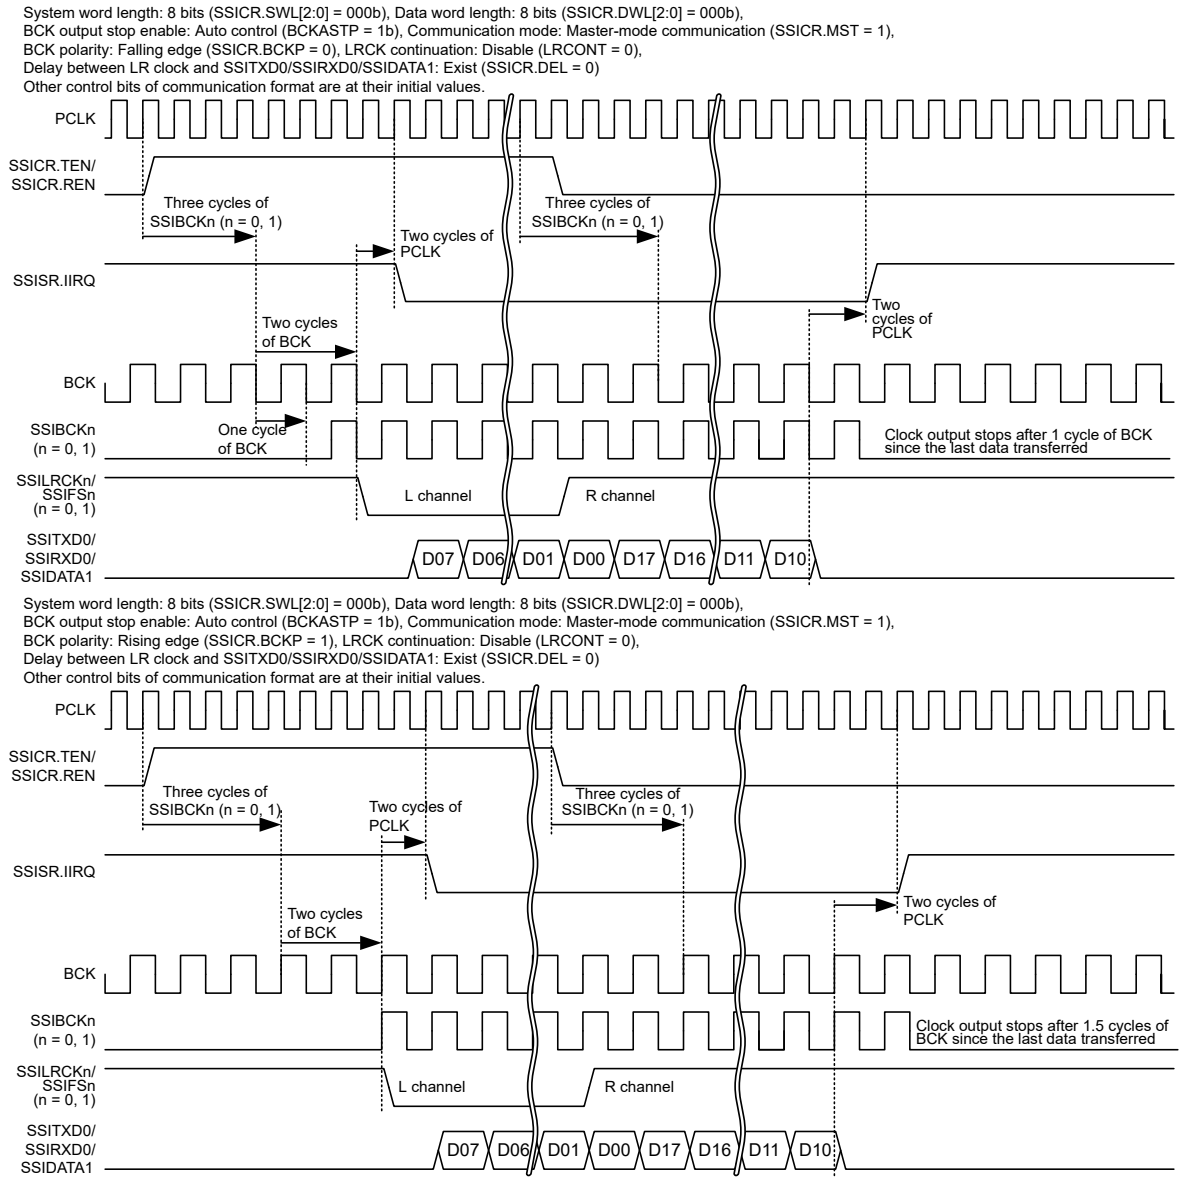

Figure 39.35 Example operation of the BCKASTP bit (communication operation with BCKASTP = 1)

39.2.8 SSISCR : Status Control Register

Base address: SSIEn = 0x4025_D000 + 0x0100 × n (n = 0, 1)
SSIEn_NS = 0x5025_D000 + 0x0100 × n (n = 0, 1)

Bit	Symbol	Function	R/W
4:0	RDFS[4:0]	RDF Setting Condition Select*1 0x00: SSIFRDR has one stage or more data size. 0x01: SSIFRDR has two stages or more data size. ⋮ 0x1E: SSIFRDR has thirty-one stages or more data size. 0x1F: SSIFRDR has thirty-two stages or more data size.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
12:8	TDES[4:0]	TDE Setting Condition Select*1 0x00: SSIFTDR has one stage or more free space. 0x01: SSIFTDR has two stages or more free space. ⋮ 0x1E: SSIFTDR has thirty-one stages or more free space. 0x1F: SSIFTDR has thirty-two stages or more free space.	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If written, the operation performed immediately after writing is not guaranteed.

RDFS[4:0] bits (RDF Setting Condition Select)

The RDFS[4:0] bits set the setting condition of the receive data full flag (RDF).

TDES[4:0] bits (TDE Setting Condition Select)

The TDES[4:0] bits set the setting condition of the transmit data empty flag (TDE).

39.3 Communication Formats

SSIE supports three communication formats. Table 39.12 shows supported communication formats.

Table 39.12 Supported communication formats

Communication Format	SSIOFR.OMOD[1:0]
I²S format	00
TDM format	01
Monaural format	10

The following describes the serial data structure shared by communication formats. A serial data structure is defined by the system word length (set in SSICR.SWL[2:0]) and the data word length (set in SSICR.DWL[2:0]). If the data word length is shorter than the system word length, padding bits are transferred in the serial data. For details, see Figure 39.36.

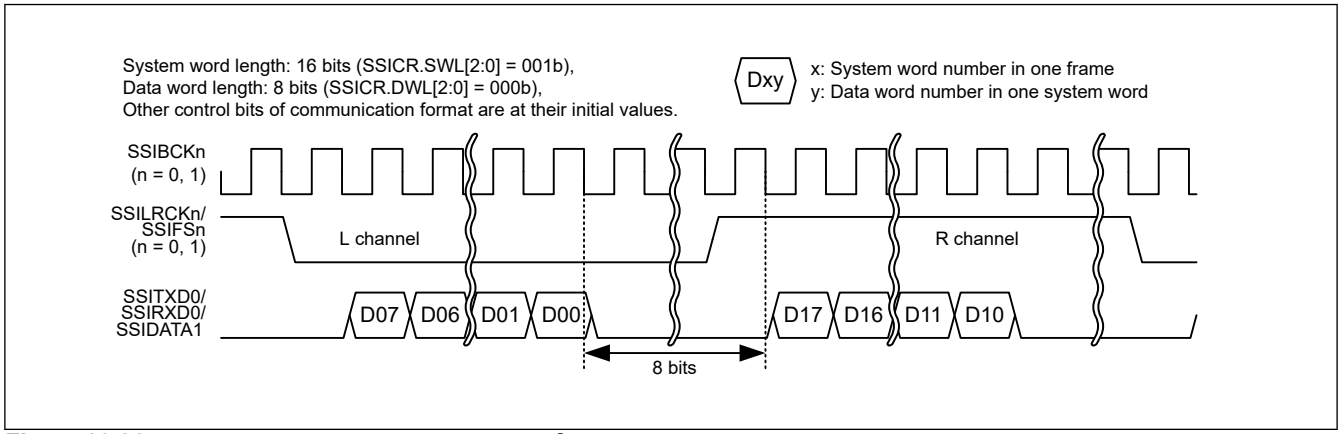

Figure 39.36 Example of padding bit transfer (I²S format: system word length > data word length)

Table 39.13 lists the number of padding bits to be transferred with each combination of system word length (SSICR.SWL[2:0]) and data word length (SSICR.DWL[2:0]). "-" indicates that the setting is prohibited.

Table 39.13 Number of padding bits

	SSICR.DWL[2:0]	000b	001b	010b	011b	100b	101b	110b	111b
SSICR.SWL[2:0]	System Word Length	8	16	18	20	22	24	32	Setting prohibited
000b	8	0	—	—	—	—	—	—	—
001b	16	8	0	—	—	—	—	—	—
010b	24	16	8	6	4	2	0	—	—
011b	32	24	16	14	12	10	8	0	—
100b	48	40	32	30	28	26	24	16	—
101b	64	56	48	46	44	42	40	32	—
110b	128	120	112	110	108	106	104	96	—
111b	256	248	240	238	236	234	232	224	—

39.3.1 I²S Format

The I²S format is a communication format used for connection with I²S-compatible serial devices. With this format setting (SSIOFR.OMOD[1:0] = 00b), one frame is configured with two system words, one for the channel L and the other for channel R. The SSILRCKn/SSIFSn (n = 0, 1) signals are at a low level for the channel L and at a high level for the channel R. Set the polarity of the signals with the SSICR.LRCKP bit. Figure 39.37 shows the I²S format without padding. See Figure 39.36 for the format with padding.

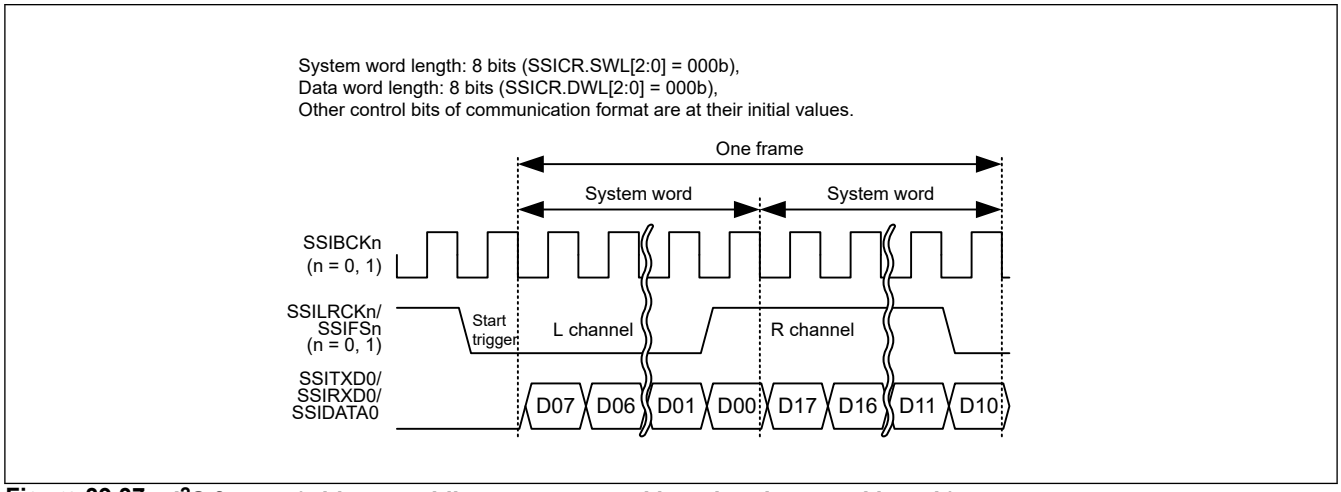

Figure 39.37 I²S format (without padding: system word length = data word length)

For the state of external pins when SSIE is in the idle state, see section 39.5.1. Idle State.

Note: SSIE has the SSILRCKn/SSIFSn (n = 0, 1) pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCKn/SSIFSn (n = 0, 1) pin only as a trigger to start communication.

39.3.2 Monaural Format

The monaural format is a communication format used for connection with monaural-compatible serial devices. When the monaural format is specified (SSIOFR.OMOD[1:0] = 10b) for use, one frame consists of one system word. Also, a rising edge of the SSILRCKn/SSIFSn (n = 0, 1) signal indicates a communication start trigger. Figure 39.38 and Figure 39.39 respectively show the monaural formats without and with padding.

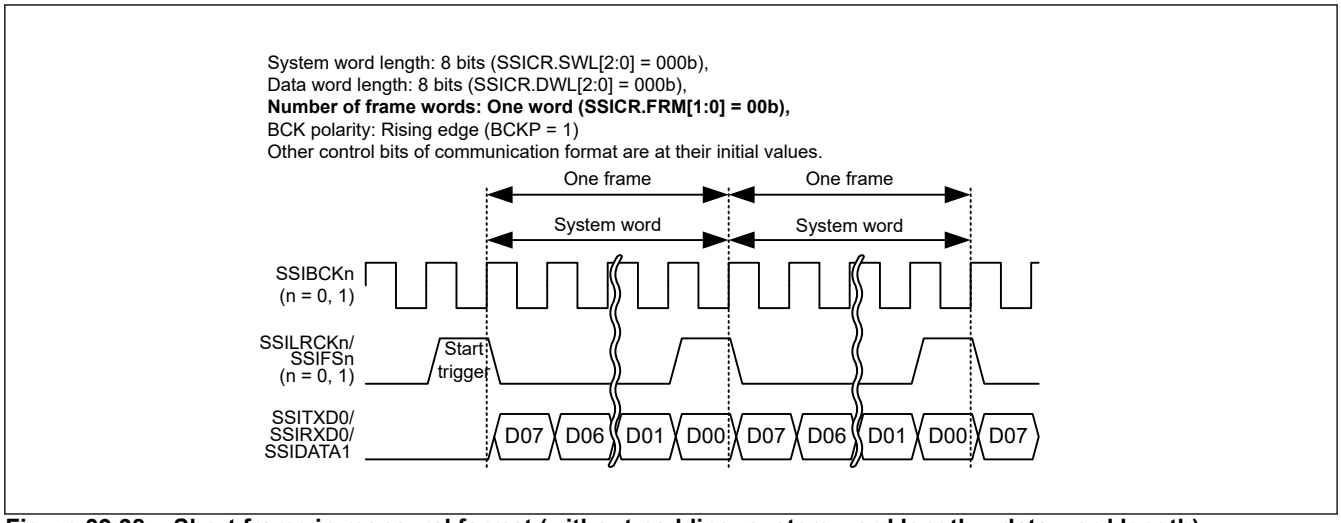

Figure 39.38 Short frame in monaural format (without padding: system word length = data word length)

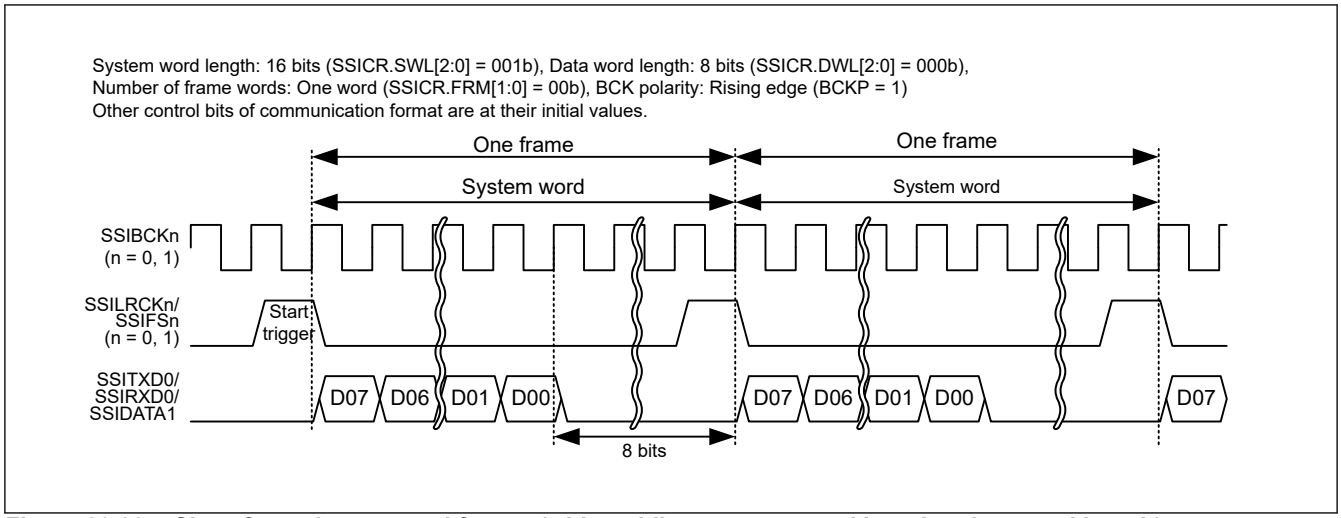

Figure 39.39 Short frame in monaural format (with padding: system word length > data word length)

The monaural formats supported by SSIE consist of short frames and long frames. See section 39.3.2.1. Short frame and section 39.3.2.2. Long frame for the difference between these two frames.

For the state of external pins state when SSIE is in the idle state, see section 39.5.1. Idle State.

Note: SSIE has the SSILRCKn/SSIFSn (n = 0, 1) pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCKn/SSIFSn (n = 0, 1) pin only as a trigger to start communication.

39.3.2.1 Short frame

When a short frame is used (SSICR.DEL = 0), the SSILRCKn/SSIFSn (n = 0, 1) signal indicating the start of serial data is set to high level only for 1 cycle of SSIBCKn (n = 0, 1). Data transfer starts at the falling edge of the signal.

39.3.2.2 Long frame

When a long frame is used (SSICR.DEL = 1), the SSILRCKn/SSIFSn (n = 0, 1) signal indicating the start of serial data is set to high level only for 2 cycles of SSIBCKn (n = 0, 1). See Figure 39.40. Data transfer starts at the rising edge of the signal.

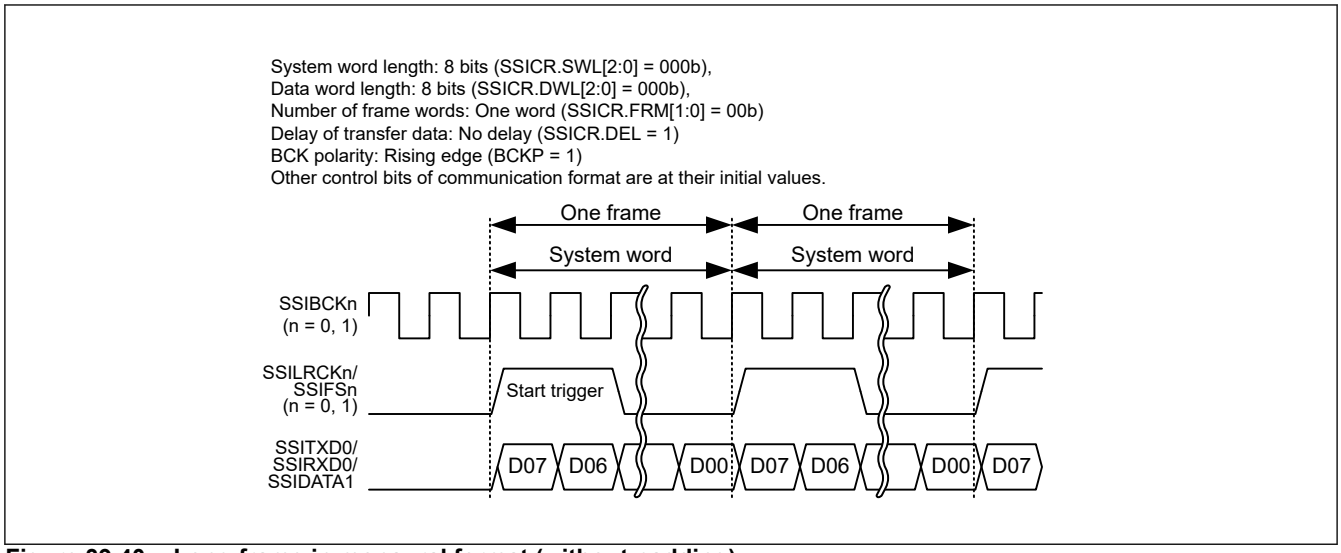

Figure 39.40 Long frame in monaural format (without padding)

39.3.3 TDM Format

The TDM format is a communication format used for connection with TDM-compatible multi-channel devices. With this format setting (SSIOFR.OMOD[1:0] = 01b), one frame is configured with four to eight system words set with the SSICR.FRM[1:0] bits. With this format, the SSILRCKn/SSIFSn (n = 0, 1) signal is at a high level for the first one system word and at a low level for the rest. The pulse generated on the SSILRCKn/SSIFSn (n = 0, 1) signal is defined as the SYNC pulse and its rising edge means a start of one frame. Figure 39.41 and Figure 39.42 respectively show the TDM formats without and with padding.

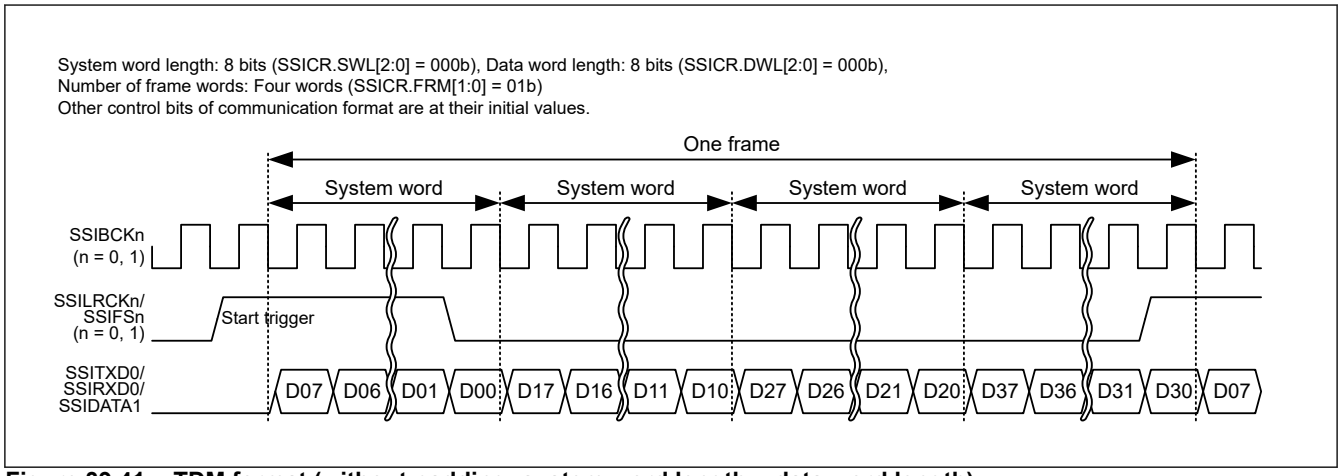

Figure 39.41 TDM format (without padding: system word length = data word length)

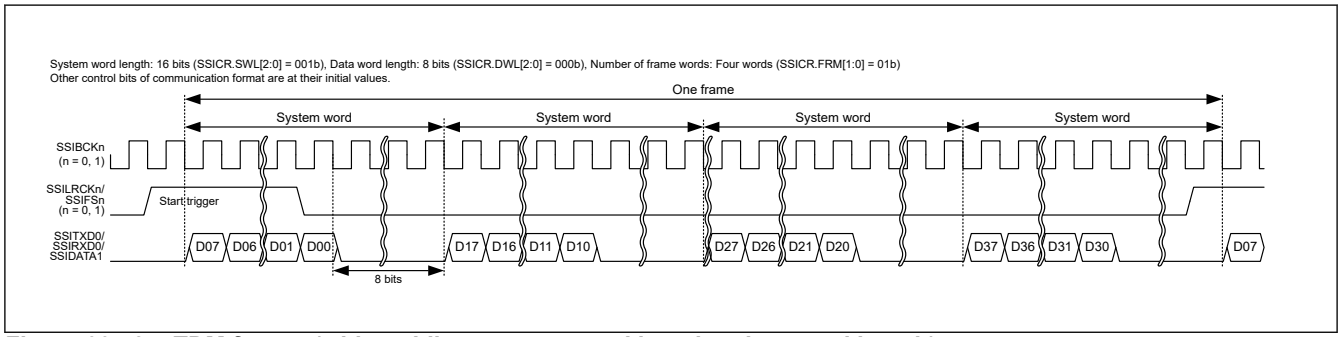

Figure 39.42 TDM format (with padding: system word length > data word length)

For the state of external pins when SSIE is in the idle state, see section 39.5.1. Idle State.

Note: SSIE has the SSILRCKn/SSIFSn (n = 0, 1) pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCKn/SSIFSn (n = 0, 1) pin only as a trigger to start communication.

39.4 Communication Modes

SSIE supports the following communication modes. Table 39.15 lists the control bits that are not available with each communication mode. See section 39.4.1. Slave-mode Communication to section 39.4.5. Transmission and Reception for details of these communication modes.

Table 39.14 Communication modes

Communication Mode	SSICR.MST Bit	SSICR.REN Bit	SSICR.TEN Bit
Slave-mode transmission	0	0	1
Slave-mode reception	0	1	0
Slave-mode transmission and reception	0	1	1
Master-mode transmission	1	0	1
Master-mode reception	1	1	0
Master-mode transmission and reception	1	1	1

Table 39.15 Control bits that cannot be used in each communication mode

Control Bit	Slave-mode Reception	Slave-mode Transmission	Slave-mode Transmission and Reception	Master-mode Reception	Master-mode Transmission	Master-mode Transmission and Reception
SSICR.CKS	Invalid	Invalid	Invalid	Available	Available	Available
SSICR.CKDV	Invalid	Invalid	Invalid	Available	Available	Available
SSICR.MUEN	Invalid	Available	Available	Invalid	Available	Available
SSICR.TEN	Invalid	Available	Available	Invalid	Available	Available
SSICR.REN	Available	Invalid	Available	Available	Invalid	Available
SSIFCR.AUCKEN	Invalid	Invalid	Invalid	Available	Available	Available
SSIFCR.TIE	Invalid	Available	Available	Invalid	Available	Available
SSIFCR.RIE	Available	Invalid	Available	Available	Invalid	Available
SSIFCR.TFRST	Invalid	Available	Available	Invalid	Available	Available
SSIFCR.RFRST	Available	Invalid	Available	Available	Invalid	Available
SSIOFR.BCKASTP	Invalid	Invalid	Invalid	Available	Available	Available
SSIOFR.LRCONT	Invalid	Invalid	Invalid	Available	Available	Available
SSIOFR.OMOD	Available	Available	Available	Available	Available	Available
SSISCR.TDES	Invalid	Available	Available	Invalid	Available	Available
SSISCR.RDFS	Available	Invalid	Available	Available	Invalid	Available

“Invalid” means it has no effect on operation. Writing is possible.

39.4.1 Slave-mode Communication

SSIE operates in slave mode with SSICR.MST = 0. The SSIBCKn (n = 0, 1) and SSILRCKn/SSIFSn (n = 0, 1) signals to be used for serial-data communication must be supplied from an external device. If these signals do not match the communication format set for SSIE, operation is not guaranteed.

39.4.2 Master-mode Communication

SSIE operates in master mode with SSICR.MST = 1. The SSIBCKn (n = 0, 1) and SSILRCKn/SSIFSn (n = 0, 1) signals to be used for serial data communication must be internally generated from the audio clock. These signals use the format according to the setting of SSIE. If the communication format the slave device uses does not match the communication format set for SSIE, the operation is unpredictable.

39.4.3 Transmission

SSIE transmits serial data to the other-party device when the SSICR.TEN bit is 1 and the SSICR.REN bit is 0. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

39.4.4 Reception

SSIE receives serial data from the other-party device when the SSICR.TEN bit is 0 and the SSICR.REN bit is 1. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

39.4.5 Transmission and Reception

SSIE transmits and receives serial data to and from the other-party device when the SSICR.TEN bit is 1 and the SSICR.REN bit is 1. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

39.5 Operation

SSIE has the following two main operation states Figure 39.43 shows SSIE state transition.

- Idle state (SSISR.IIRQ = 1)
- Communication state (SSISR.IIRQ = 0).

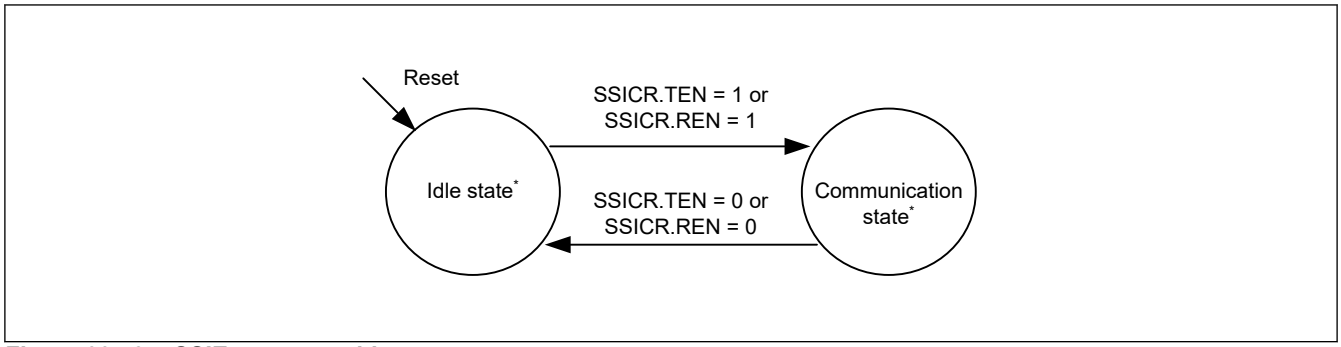

Figure 39.43 SSIE state transition

Note: See section 39.6.1. Start Communication for details of the idle state.
See section 39.6.2. Transmission for details of the communication state.

39.5.1 Idle State

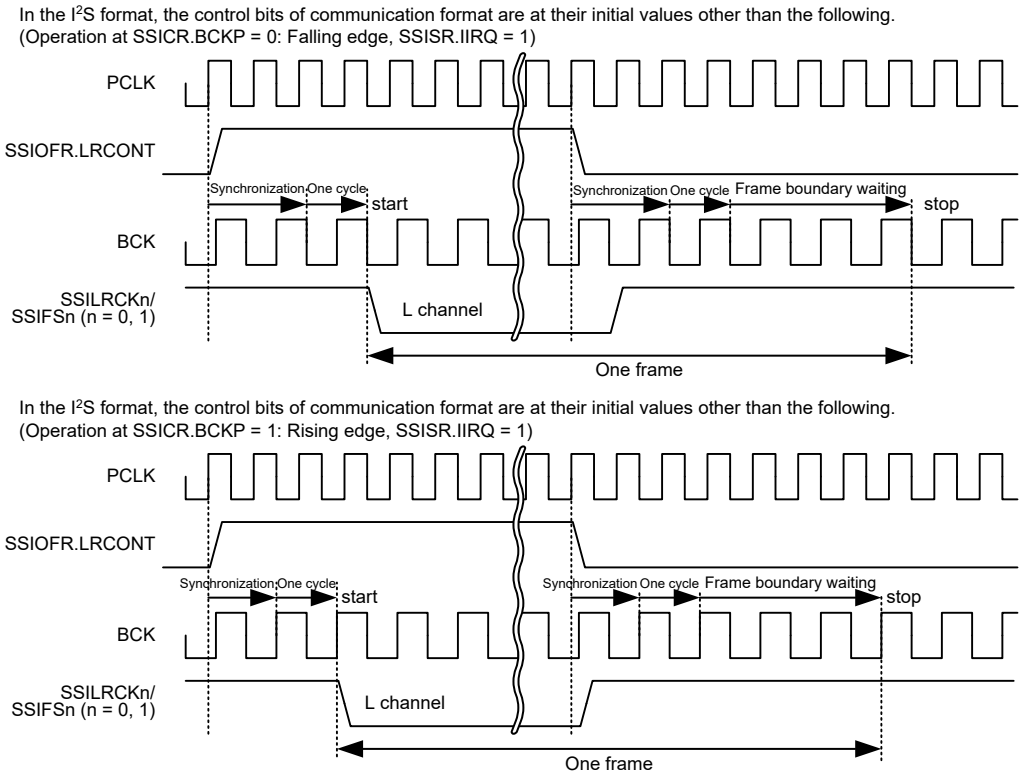
In this state, communication of SSIE is halted. If, however, the SSICR.MST bit is 1, output of the BCK and LR clock/frame synchronization signals to external pins can be controlled according to the settings of SSIOFR.BCKASTP and SSIOFR.LRCONT bits. This function is common to all formats. For details, see Table 39.16.

Table 39.16 Output from external pins in the idle state (1 of 2)

SSICR.MST	SSIOFR.BCKASTP	SSIOFR.LRCONT	Output from Pins		
			SSIBCKn (n = 0, 1)	SSILRCKn/SSIFSn (n = 0, 1)	SSITXD0/SSIDATA1
0	—	—	Stop	Stop	Stop

Table 39.16 Output from external pins in the idle state (2 of 2)

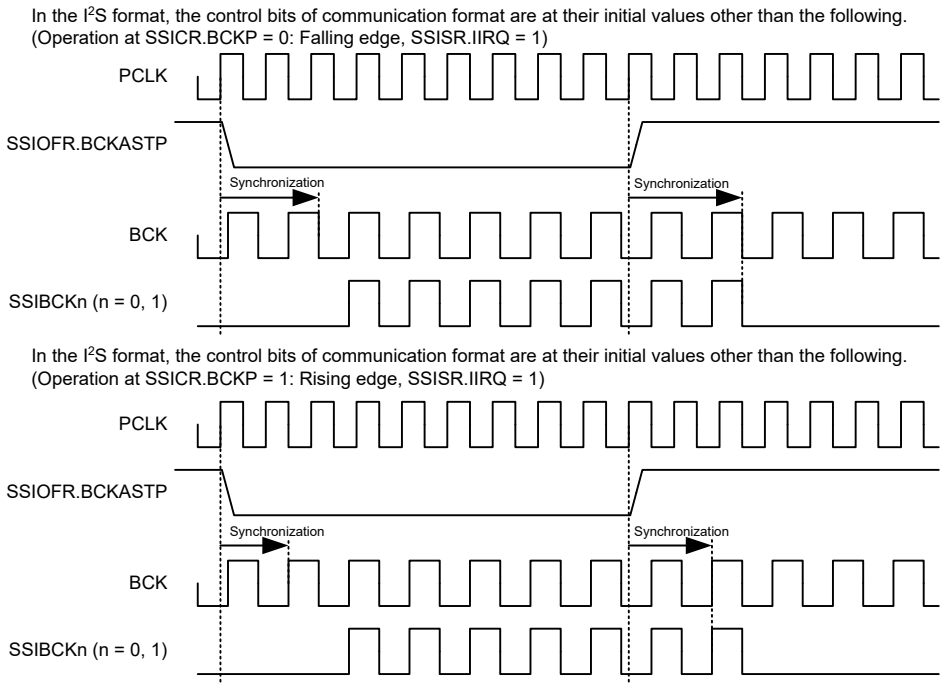
SSICR.MST	SSIOFR.BCKASTP	SSIOFR.LRCONT	Output from Pins		
			SSIBCKn (n = 0, 1)	SSILRCKn/SSIFSn (n = 0, 1)	SSITXD0/SSIDATA1
1	0	0	Supply	Stop	Stop
1	0	1	Supply	Supply	Stop
1	1	0	Stop	Stop	Stop
1	1	1	Stop	Supply	Stop



Note: PCLK = PCLKB

Figure 39.44 Example of disabling LR clock/frame synchronization continuation by SSIOFR.LRCONT

Note: To stop the output to the SSILRCKn/SSIFSn (n = 0, 1) pin with SSIOFR.LRCONT when SSIE is in the idle state in master-mode communication (SSICR.MST = 1), note the following: The output stops when the value of the SSIOFR.LRCONT bit is changed from 1 to 0. Make sure that the other-party device is not affected.



Note: PCLK = PCLKB

Figure 39.45 Example of stopping SSIBCKn (n = 0, 1) with SSIOFR.BCKASTP

Note: To stop the output to the SSIBCKn (n = 0, 1) pin with SSIOFR.BCKASTP in master-mode communication (SSICR.MST = 1) and while SSIE is in the idle state, note the following: The output stops when the value of the SSIOFR.BCKASTP bit is changed from 0 to 1. So, make sure that the other-party device is not affected.

39.5.2 Communication States

In this state, SSIE is during communication. Figure 39.46 shows transitions of communication states and Table 39.17 lists the conditions for transition. If the transition condition is not satisfied, the state does not transit.

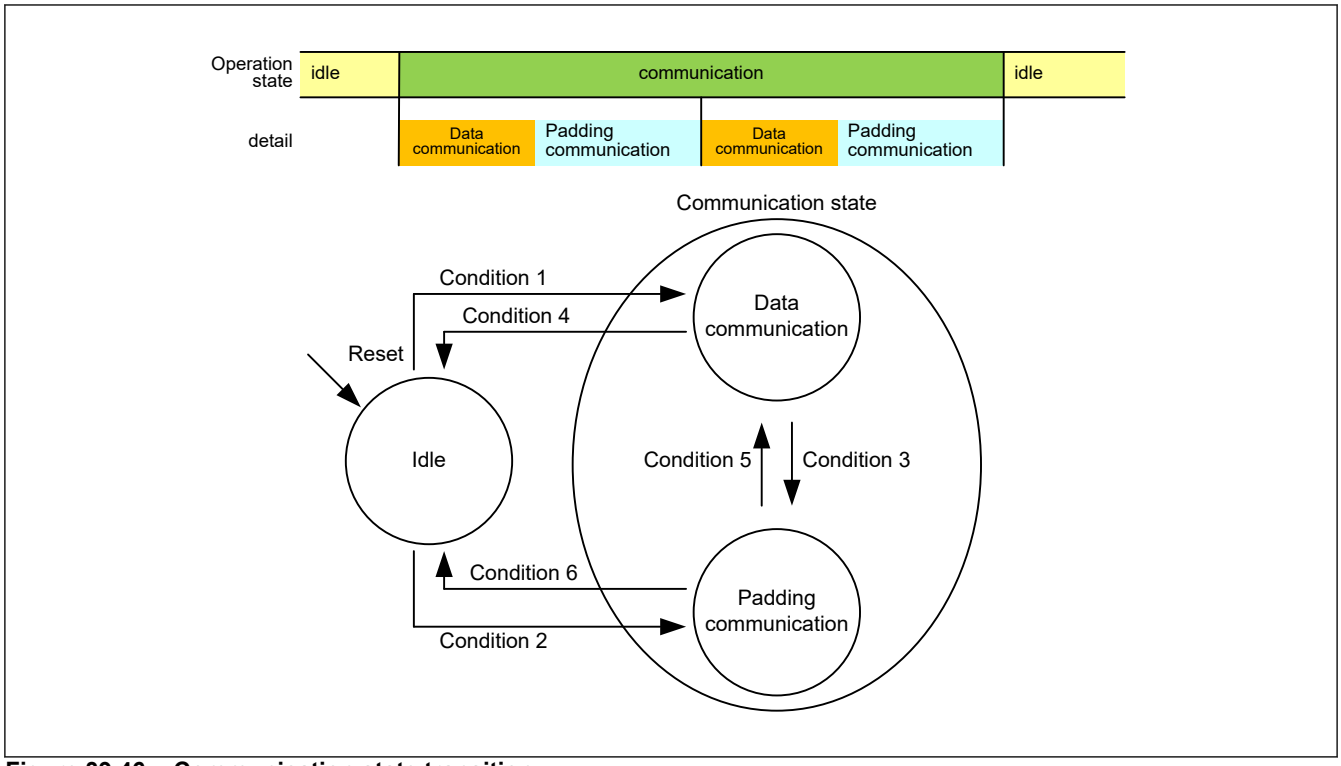


Figure 39.46 Communication state transition

Table 39.17 Condition for communication state transition

Condition Number	Condition for Transition
1	Writing SSICR.TEN = 1 or SSICR.REN = 1 while SSICR.SDTA = 0 or in the setting without padding bits.
2	Writing SSICR.TEN = 1 or SSICR.REN = 1 while SSICR.SDTA = 1 and in the setting with padding bits.
3	The following three conditions are all met: ● SSICR.TEN = 1 or SSICR.REN = 1 ● In the setting with padding bits ● The last bit of the data words has been transferred.
4	Both the following two conditions are met: ● SSICR.SDTA = 1 or without padding bits ● While SSICR.TEN = 0 and SSICR.REN = 0, the last bit of the data words in a frame has been transferred.
5	Transfer of the last padding bit is completed while SSICR.TEN = 1 or SSICR.REN = 1
6	Both the following two conditions are met: ● SSICR.SDTA = 0 and with padding bits ● While SSICR.TEN = 0 and SSICR.REN = 0, the last padding bit has been transferred.

See Table 39.13 for the setting with/without padding bits.

39.5.2.1 Data communication state

In this state, SSIE is during communication. Data of the data word length set with the SSICR.DWL[2:0] bits is transmitted, received, or transmitted and received.

- State Transition in the Setting without Padding Bits

During communication (SSISR.IIRQ = 0), SSIE is during data communication for all the time. By disabling transmission and reception (SSICR.TEN = 0, SSICR.REN = 0), SSIE transits to the idle state. For details, see Figure 39.47 and Figure 39.48.

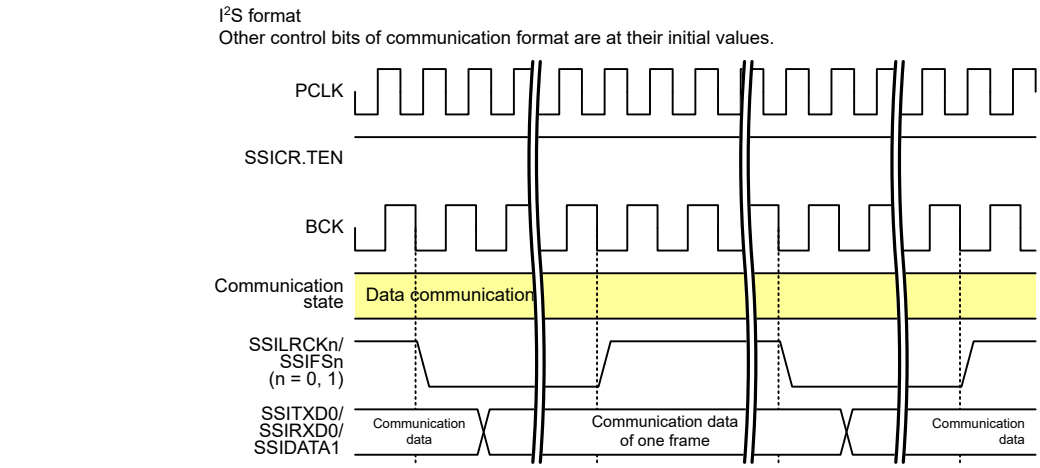

Figure 39.47 Continuation of the data communication

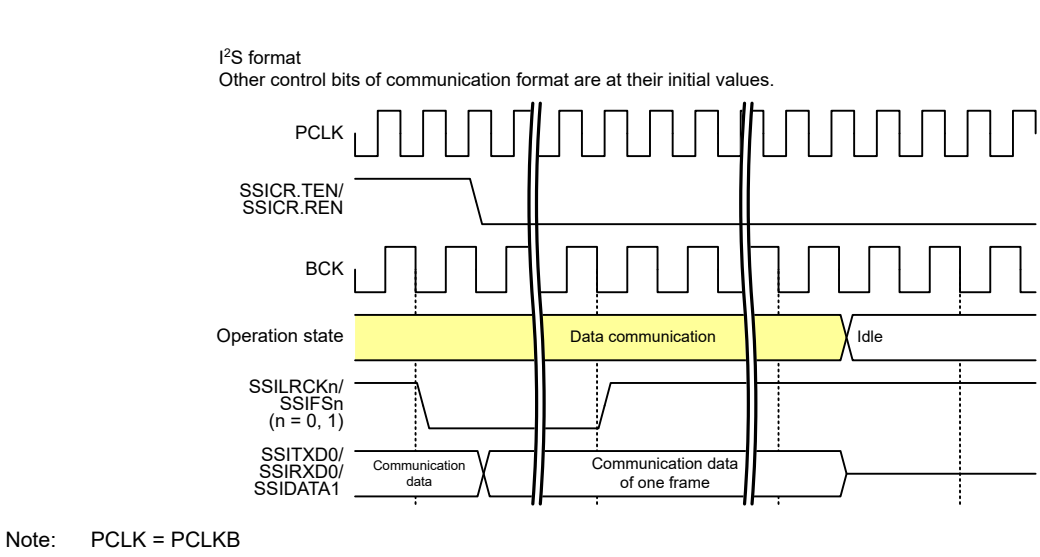

Figure 39.48 Halt from the data communication (without padding bits)

- State Transition in the Setting with Padding Bits

When SSIE ends transfer of the last bit of a data word during communication (SSISR.IIRQ = 0), SSIE transitions from the data communication state to the padding communication state in Figure 39.49. Except in the status with SSICR.SDTA = 1 and transmission and reception disabled (SSICR.TEN = 0 and SSICR.REN = 0), SSIE transitions from the data communication state to the idle state when it stops communication in Figure 39.51.

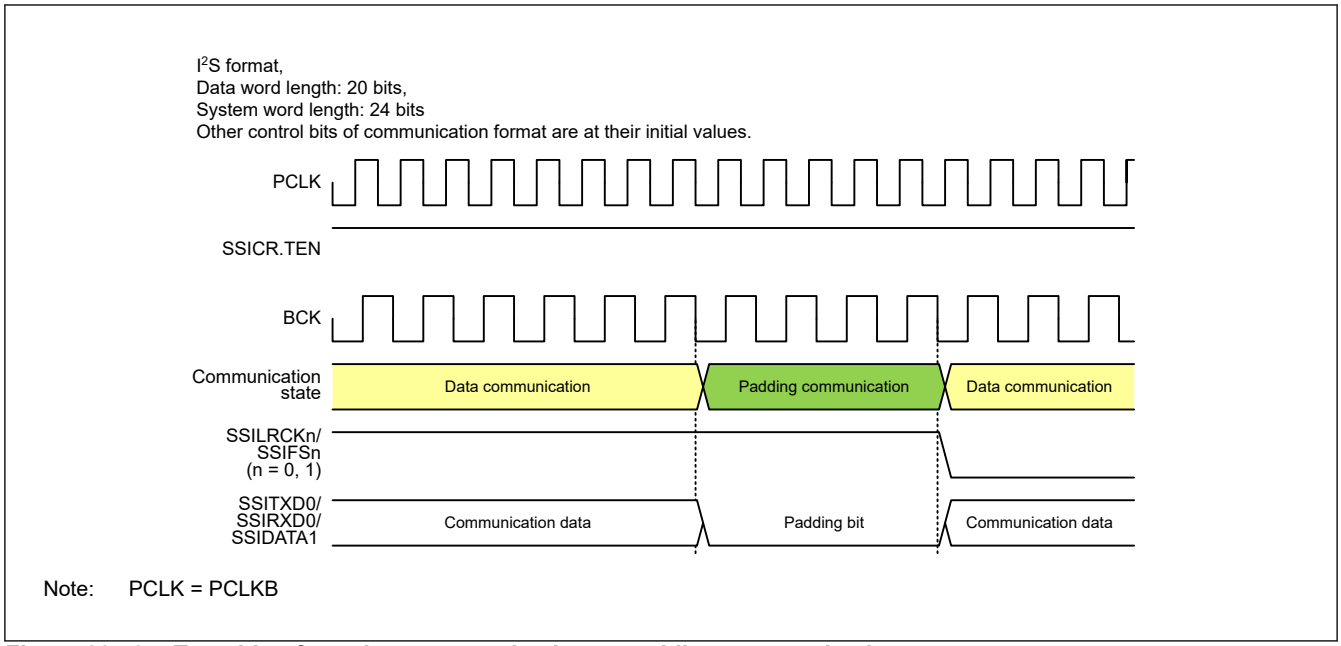

Figure 39.49 Transition from data communication to padding communication

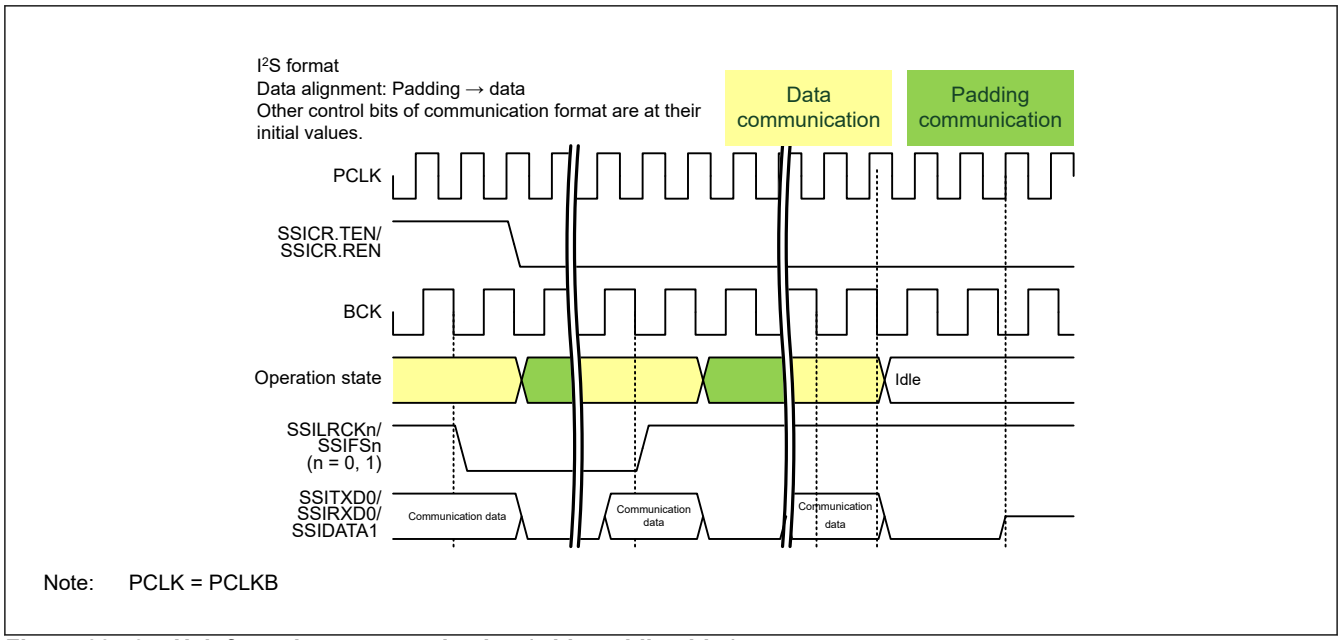

Figure 39.50 Halt from data communication (with padding bits)

39.5.2.2 Padding communication

In this state, SSIE is during communication. The padding bits set with the SSICR.SWL[2:0] bits and SSICR.DWL[2:0] bits are transmitted, received, or transmitted and received.

- State Transition in the Setting with Padding Bits

When SSIE ends transfer of the last padding bit during communication (SSISR.IIRQ = 0), SSIE transitions to the data communication state in Figure 39.49. If SSIE is in the status with SSICR.SDTA = 0 and transmission and reception disabled (SSICR.TEN = 0 and SSICR.REN = 0), SSIE transitions from the padding communication state to the idle state when it stops communication in Figure 39.51.

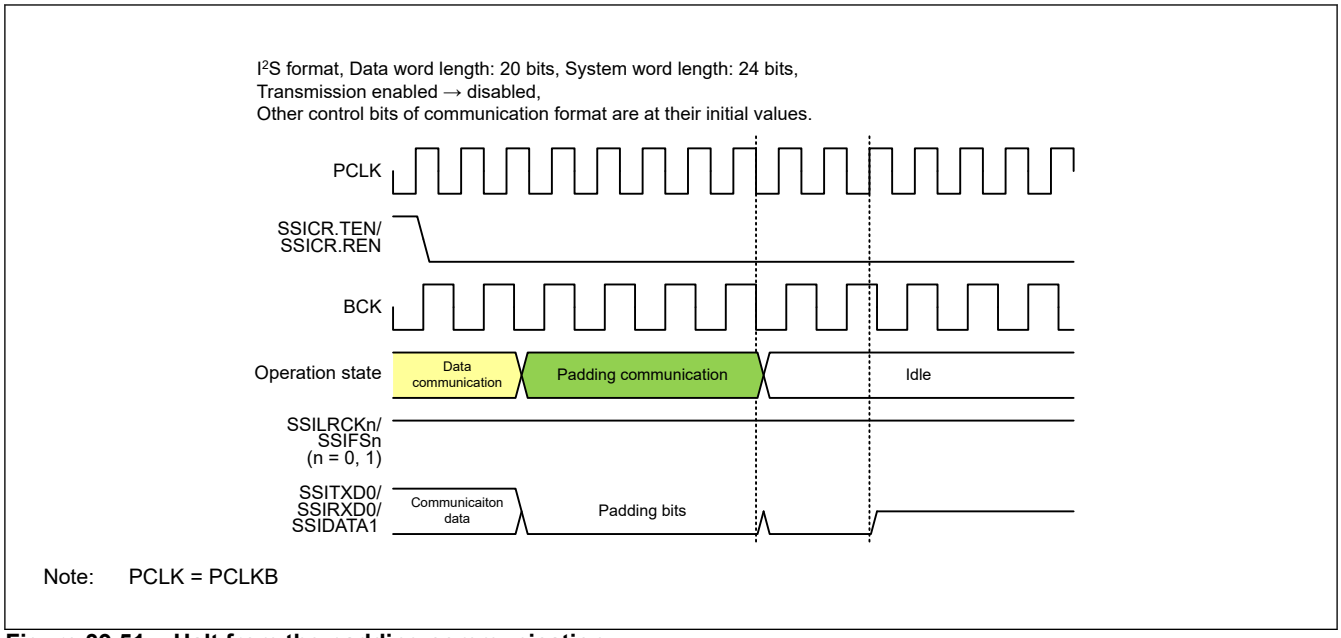

Figure 39.51 Halt from the padding communication

39.6 Communication Operation

Figure 39.52 shows the communication flow of SSIE.

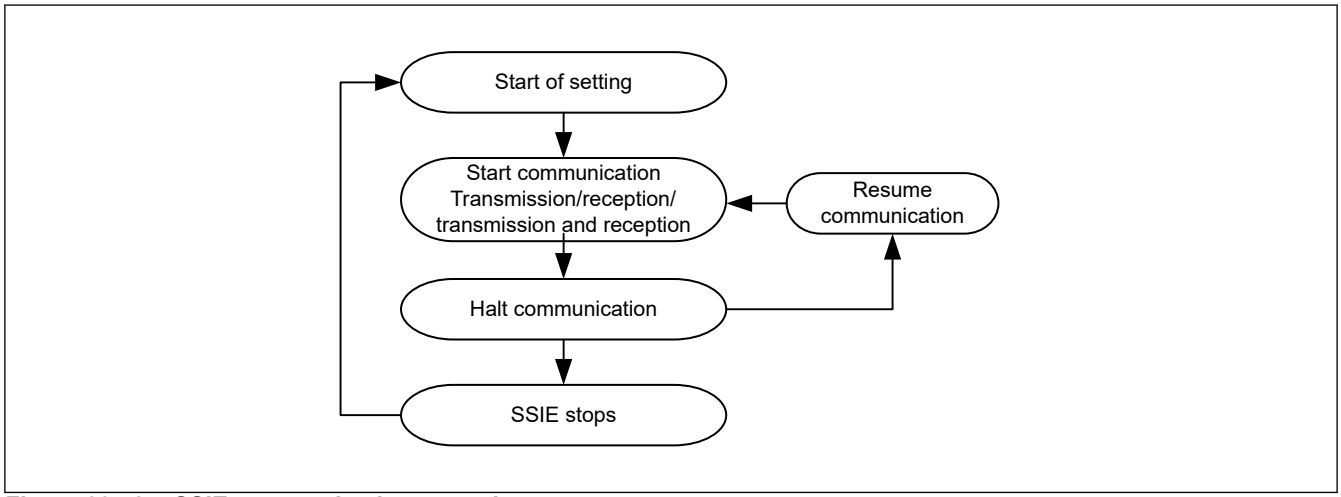

Figure 39.52 SSIE communication operation

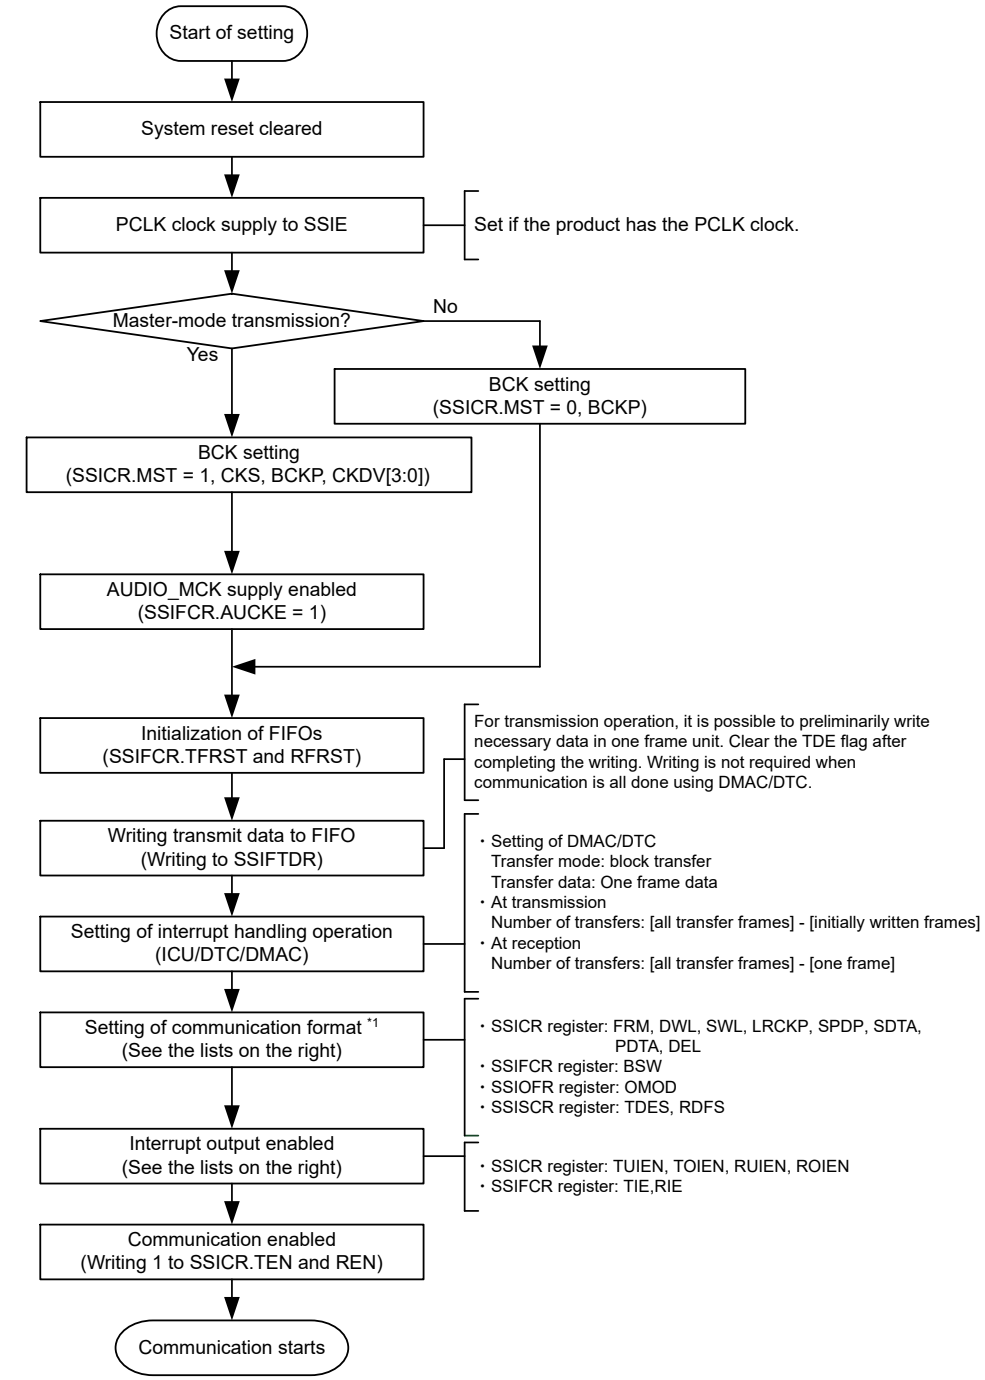
The procedure of each operation is described from section 39.6.1. Start Communication to section 39.6.7. Resume Communication.

39.6.1 Start Communication

This section describes how to start communication of SSIE. Figure 39.53 shows the procedure to start communication. Be sure to follow the procedure. See section 39.6.2. Transmission for transmission operation and section 39.6.3. Reception for reception operation.



Note: PCLK = PCLKB
Note 1. Set SSICR.MUEN, SSIOFR.BCKASTP, and SSIOFR.LRCONT after completing the setting of the communication format.

Figure 39.53 Procedure to start communication (CPU operation procedure)

SSIE can perform continuous communication based on interrupts by the DTC/DMAC. For transmission, write 1 to SSIFCR.TIE, SSICR.TUIEN, and SSICR.TOIEN. For reception, write 1 to SSIFCR.RIE, SSICR.RUIEN, and SSICR.ROIEN.

39.6.2 Transmission

The transmission procedure in Figure 39.54 must be followed throughout a transmission operation.

After transmission is enabled (SSICR.TEN = 1 and SSICR.REN = 0), SSIE starts transmission when a start trigger is generated by SSILRCKn/SSIFSn (n = 0, 1) with the serial data for at least a frame contained in the transmit FIFO data

register (SSIFTDR). SSIE outputs a transmit data empty interrupt to the DTC/DMAC according to the TDE setting condition (SSISCR.TDES) and the status of transmit data empty interrupt enable (SSIFCR.TIE) bit specified in the communication start procedure. This interrupt requests writing to the transmit FIFO data register (SSIFTDR). In the communication start procedure, specify writing to the transmit FIFO data register (SSIFTDR) as the DTC/DMAC operation in response to the transmit data empty interrupt. With this setting, SSIE can continuously transmit data not through the CPU. The transmit data empty interrupt is generated when the free space size of transmit FIFO data register reaches the value set in SSISCR.TDES. The number of times of writing must be specified in accordance with the free space size of the transmit FIFO data register indicated by the transmit data empty interrupt. If an error occurs, perform the error-handling procedure as instructed in the communication stop procedure.

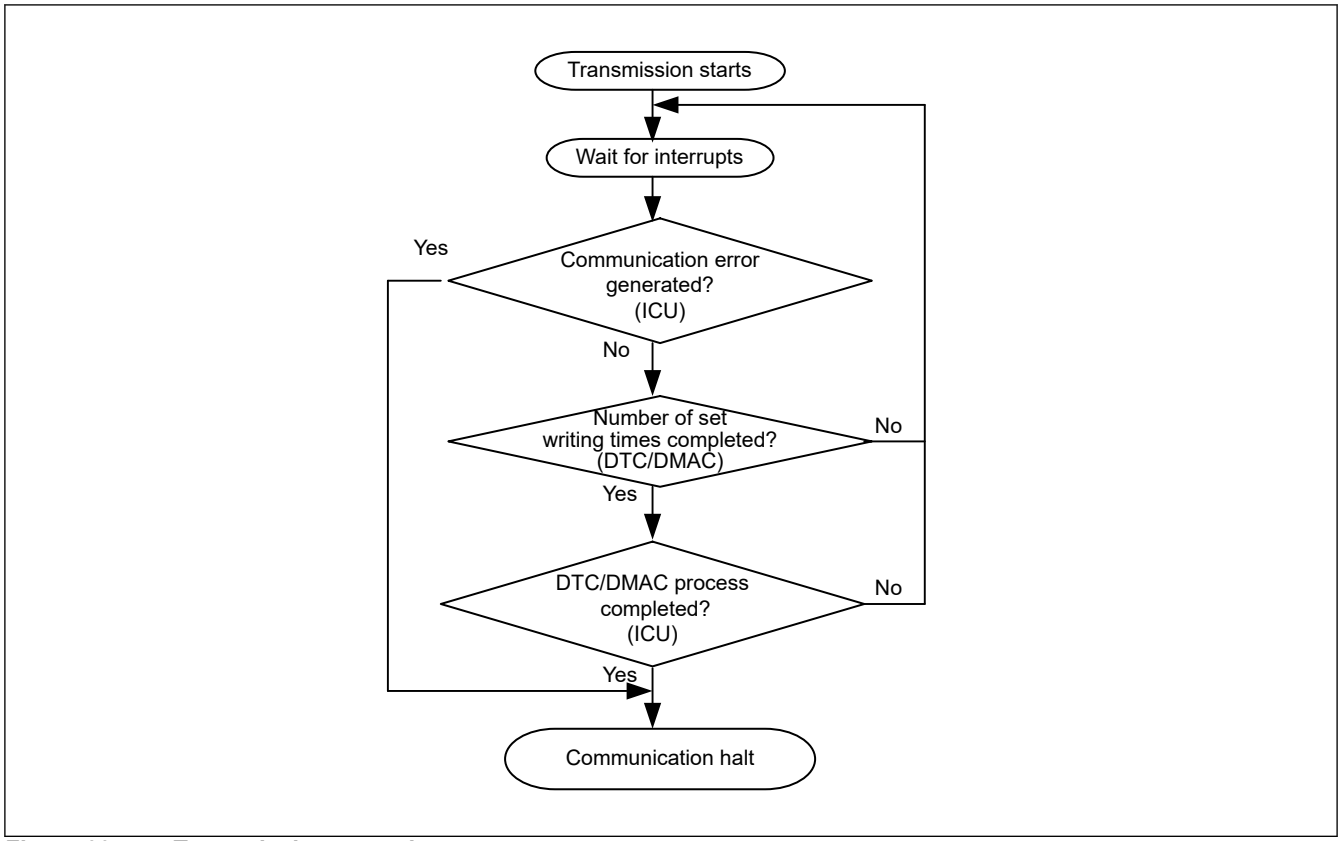


Figure 39.54 Transmission procedure

Note: The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.TDE to write data to SSIFTDR. The number of times of writing data to SSIFTDR by detecting the value 1 of SSIFSR.TDE must be in accordance with the free space size of the transmit FIFO data register specified by SSISCR.TDES. After as much transmit data as the free space size is written to SSIFTDR, the SSIFSR.TDE flag must be cleared. Continuous transmission is enabled by repeating data writing. If the SSIFSR.TDE flag is not cleared, the flag is not cleared automatically.

39.6.3 Reception

The reception procedure in Figure 39.55 must be followed throughout a reception operation.

After reception is enabled (SSICR.TEN = 0 and SSICR.REN = 1), SSIE starts reception when a start trigger is generated by SSILRCKn/SSIFSn (n = 0, 1). SSIE outputs a receive data full interrupt to the DTC/DMAC according to the RDF setting condition (SSISCR.RDFS) and the status of receive data full interrupt enable (SSIFCR.RIE) bit specified in the communication start procedure. This interrupt requests data reading from the receive FIFO data register (SSIFRDR). In the communication start procedure, specify reading from the receive FIFO data register (SSIFRDR) as the DTC/DMAC operation in response to the receive data full interrupt. With this setting, SSIE can continuously read data not through the CPU. The receive data full interrupt is generated when data as much as the capacity of receive FIFO data register has been stored. The number of times of reading must be specified in accordance with the data size of the receive FIFO data register indicated by the receive data full interrupt. If an error occurs, perform the error-handling procedure as instructed in the communication stop procedure.

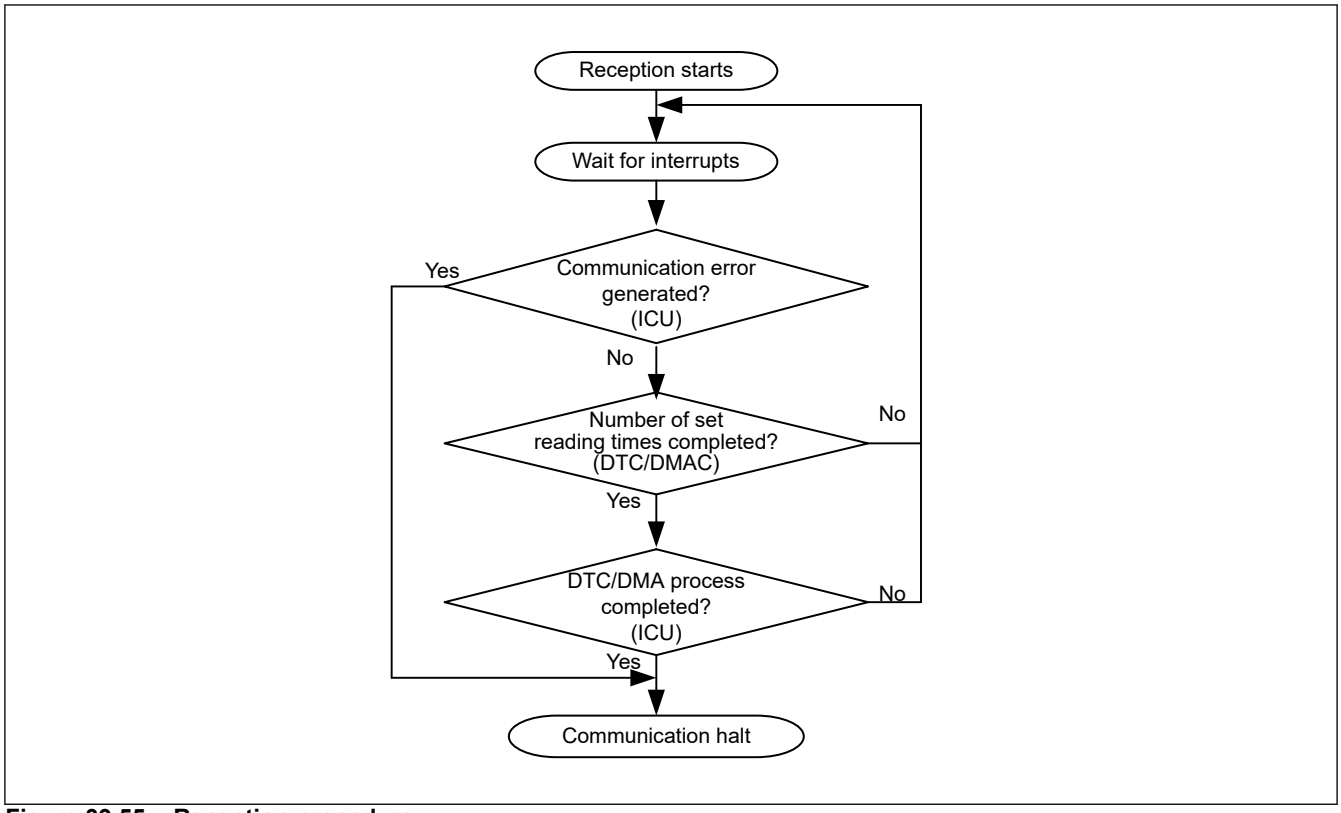

Figure 39.55 Reception procedure

Note: The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.RDF to read data from SSIFRDR. The number of times of reading data from SSIFRDR by detecting the value 1 of SSIFSR.RDF must be in accordance with the receive data storage capacity of the receive FIFO data register specified by SSISCR.RDFS. After received data is read from SSIFRDR, the SSIFSR.RDF flag must be cleared. Continuous reception is enabled by repeating data reading. If the SSIFSR.RDF flag is not cleared, the flag is not cleared automatically.

39.6.4 Transmission and Reception

After transmission and reception are enabled (SSICR.TEN = 1 and SSICR.REN = 1), SSIE starts transmission and reception when a start trigger is generated by SSILRCKn/SSIFSn (n = 0, 1) with the serial data for at least a frame contained in the transmit FIFO data register (SSIFTDR). SSIE can continuously transmit and receive data by performing the procedures described in section 39.6.2. Transmission and section 39.6.3. Reception, respectively. For how to stop transmission and reception, see section 39.6.5. Halt Communication.

39.6.5 Halt Communication

This section describes how to halt communication of SSIE. Figure 39.56 shows the procedure to halt communication. Be sure to follow the procedure.

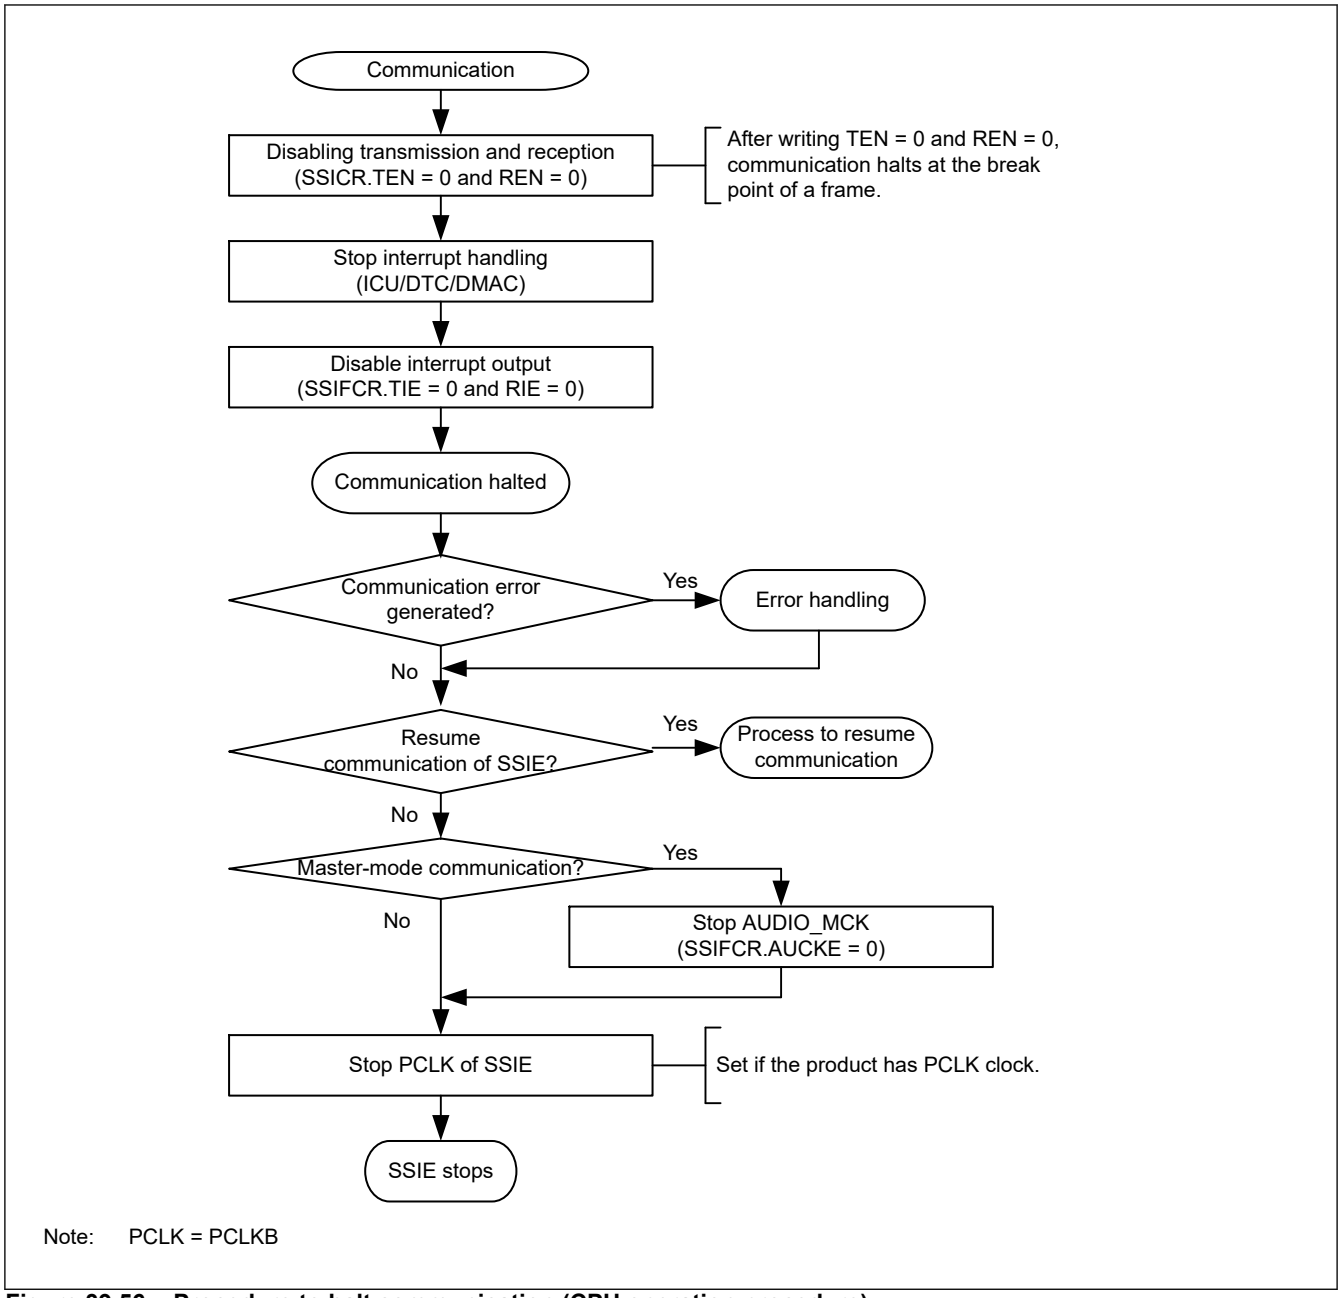

Figure 39.56 Procedure to halt communication (CPU operation procedure)

To halt the communication of SSIE, supply of the following clocks are required until the SSISR.IIRQ bit indicates an idle state.

- Input clock from the SSIBCKn (n = 0, 1) pin when SSICR.MST = 0
- AUDIO_MCK when SSICR.MST = 1
  To resume communication of SSIE in the previous setting, see section 39.6.7. Resume Communication.

Note: When communication of SSIE is halted according to the procedure to halt communication in Figure 39.56, resume communication according to the procedure to resume communication in Figure 39.58.

39.6.6 Error Handling

SSIE has the following four errors.

- Transmit underflow error
- Transmit overflow error
- Receive underflow error

- Receive overflow error.

When an underflow error or overflow error is generated, SSIE need to be restarted. Follow the procedure to halt communication in Figure 39.56 and error-handling procedure in Figure 39.57.

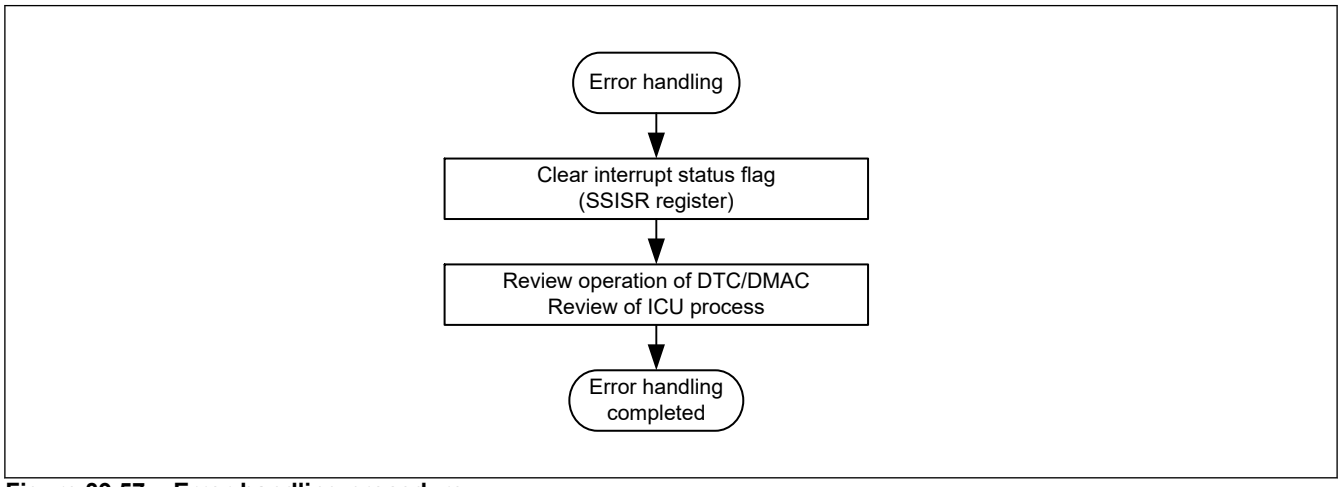

Figure 39.57 Error-handling procedure

Four error operations are described as follows. When the interrupt output enable bit of the SSICR register is enabled and error flags are set, an error interrupt is generated. See section 39.2.2. SSISR : Status Register for the setting conditions of error flags.

(1) Transmit Underflow Error

If a transmit underflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to a transmit data empty interrupt. After a transmit underflow error occurs, SSIE outputs 0s as data. To normally output the serial data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0/SSIDATA1 pin, follow the procedure to halt communication in Figure 39.56 and error-handling procedure in Figure 39.57. After this error occurs, serial data is consumed as usual. If you resume communication, write the serial data from the beginning.

(2) Transmit Overflow Error

If a transmit overflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to transmit data empty interrupts. The serial data written to the transmit FIFO data register (SSIFTDR) that caused the transmit overflow error becomes invalid. This error can occur regardless of whether a transmission operation is being done. To recover from the error, follow the procedure to halt communication in Figure 39.56 and error-handling procedure in Figure 39.57. When you resume communication, deal with the invalid serial data appropriately.

(3) Receive Underflow Error

If a receive underflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The values read from the receive FIFO data register (SSIFRDR) that caused the receive underflow error are undefined. This error can occur regardless of whether a reception operation is being done. To recover from the error, follow the procedure to halt communication in Figure 39.56 and error-handling procedure in Figure 39.57.

(4) Receive Overflow Error

If a receive overflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The receive data that caused the receive overflow error cannot be stored in the receive FIFO data register (SSIFRDR). To recover from the error, follow the procedure to halt communication in Figure 39.56 and error-handling procedure in Figure 39.57.

39.6.7 Resume Communication

When you resume the communication using SSIE, follow the communication resume procedure in Figure 39.58. The communication resume procedure is designed on the assumption that you resume the communication stopped by the

communication stop procedure without changing any settings. If you want to change clock and slave/master settings, use and follow the communication start procedure in Figure 39.53. For details about the transmission operation and reception operation after starting communication, see section 39.6.2. Transmission and section 39.6.3. Reception, respectively.

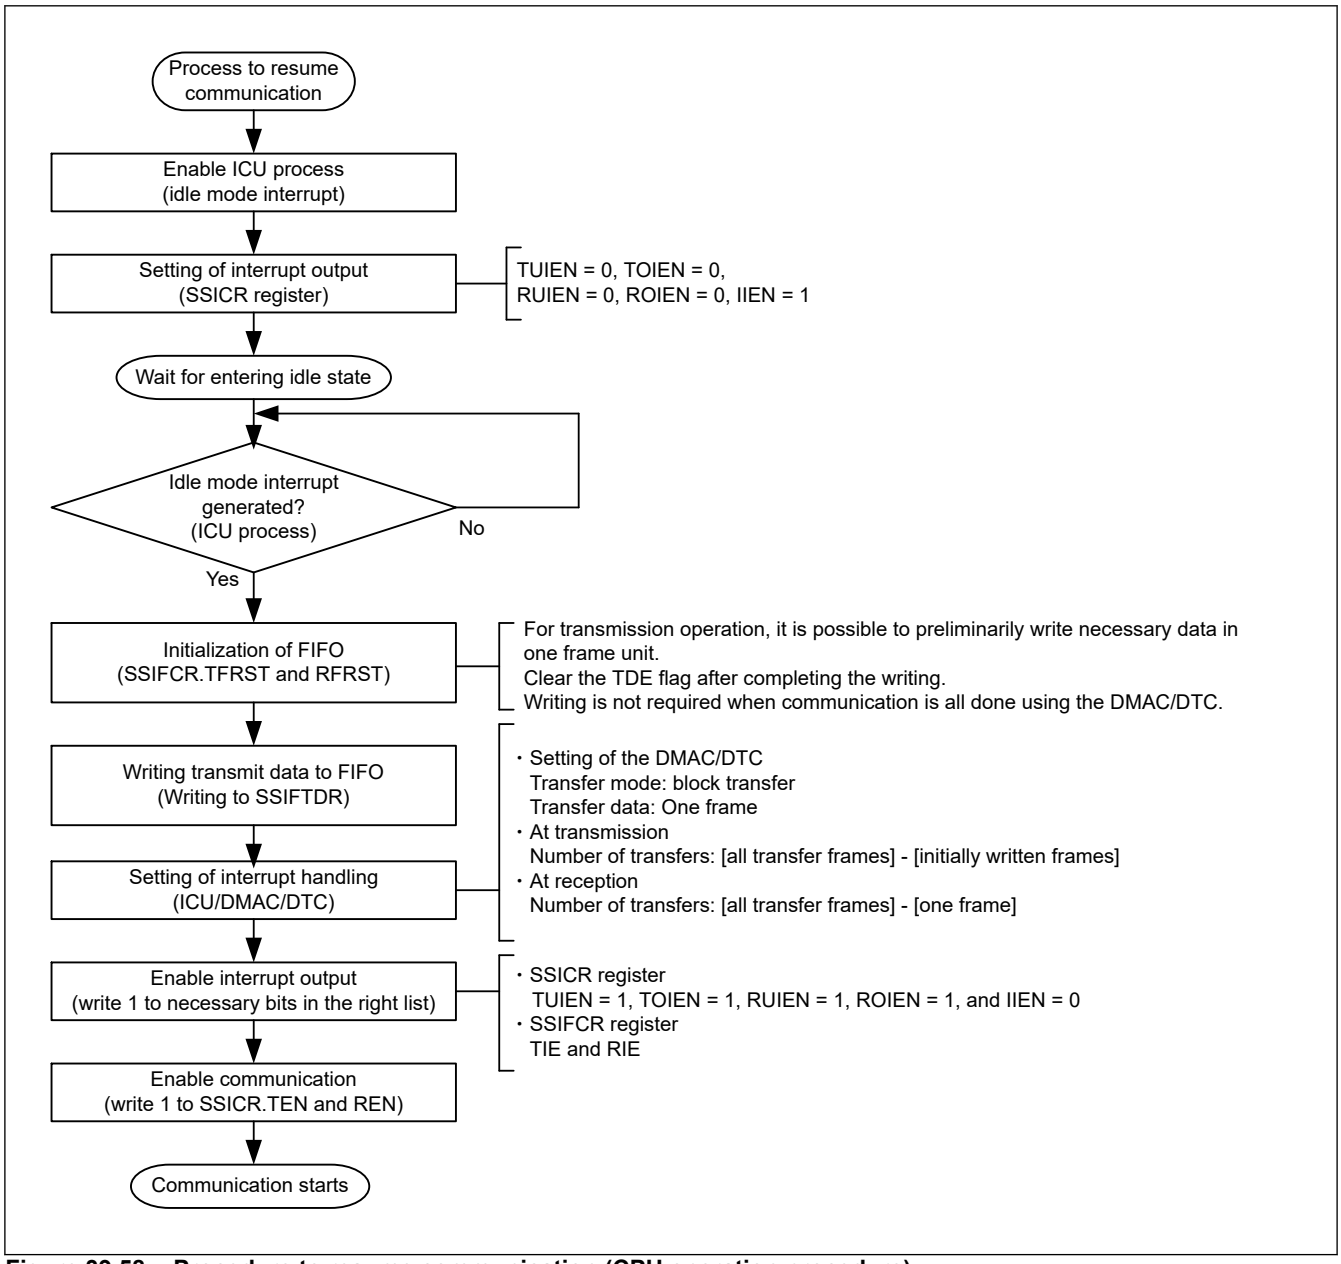

Figure 39.58 Procedure to resume communication (CPU operation procedure)

39.7 Interrupts

Table 39.18 lists the interrupt sources. Set enable/disable of interrupt output of each source with the TUIEN, TOIEN, RUIEN, ROIEN, and IIEN bits in the SSICR register and the TIE and RIE bits in the SSIFCR register.

Table 39.18 SSIE interrupt sources

Channel	Interrupt source	Description	Interrupt flag	DMAC/DTC activation
SSIE0	SSIE0_SSIF	• Transmit underflow interrupt • Transmit overflow interrupt • Receive underflow interrupt • Receive overflow interrupt • Idle interrupt	SSISR.TUIRQ SSISR.TOIRQ SSISR.RUIRQ SSISR.ROIRQ SSISR.IIRQ	Not possible
	SSIE0_SSIRXI	Receive data full interrupt	SSIFSR.RDF	Possible
	SSIE0_SSITXI	Transmit data empty interrupt	SSIFSR.TDE	Possible
SSIE1	SSIE1_SSIF	• Transmit underflow interrupt • Transmit overflow interrupt • Receive underflow interrupt • Receive overflow interrupt • Idle interrupt	SSISR.TUIRQ SSISR.TOIRQ SSISR.RUIRQ SSISR.ROIRQ SSISR.IIRQ	Not possible
	SSIE1_SSIRT	• Receive data full interrupt • Transmit data empty interrupt	SSIFSR.RDF SSIFSR.TDE	Possible

39.7.1 SSIEn_SSIF Interrupt (n = 0, 1)

This interrupt source combines five interrupts. Enable output of necessary interrupts before using SSIE. The five interrupts are operated by using the flags assigned to individual interrupts and interrupt output enable bits. To clear an interrupt, set the interrupt enable to 0 or clear the interrupt flag to 0.

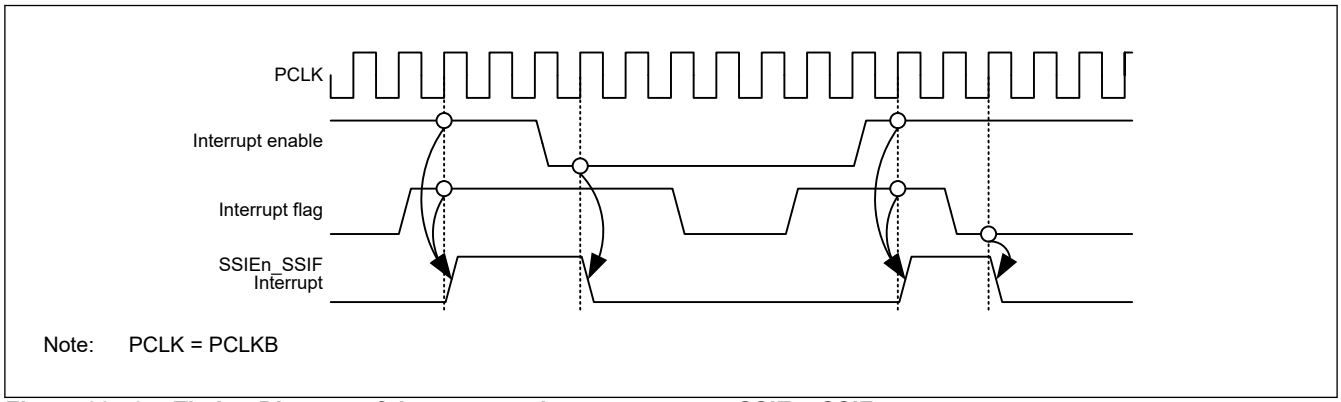

Figure 39.59 Timing Diagram of the common interrupt source, SSIEn_SSIF

- Transmit underflow interrupt

As the transmit underflow interrupt, SSISR.TUIRQ is output while SSICR.TUIEN = 1. When you use SSIE for transmission, enable the output of this interrupt (SSICR.TUIRQ = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in Figure 39.56 and error-handling procedure in Figure 39.57.

- Transmit overflow interrupt

As the transmit overflow interrupt, SSISR.TOIRQ is output while SSICR.TOIRQ = 1. When you use SSIE for transmission, enable the output of this interrupt (SSICR.TOIRQ = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in Figure 39.56 and error-handling procedure in Figure 39.57.

- Receive underflow interrupt

As the receive underflow interrupt, SSISR.RUIRQ is output while SSICR.RUIRQ = 1. When you use SSIE for reception, enable the output of this interrupt (SSICR.RUIRQ = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in Figure 39.56 and error-handling procedure in Figure 39.57.

- Receive overflow interrupt

As the receive overflow interrupt, SSISR.ROIRQ is output while SSICR.ROIRQ = 1. When you use SSIE for reception, enable the output of this interrupt (SSICR.ROIRQ = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in Figure 39.56 and error-handling procedure in Figure 39.57.

- Idle mode interrupt

As the idle mode interrupt, SSISR.IIRQ is output while SSICR.IIEN = 1. This interrupt is used to make sure that communication has stopped fully.

39.7.2 SSIE0_SSITXI Interrupt [Full-duplex communication]

The transmit data empty interrupt is a pulse interrupt that is output when the following condition is met:

- SSIFCR.TIE = 1 and SSIFSR.TDE = 1
  SSIE operation: When the value of SSIFSR.TDE changes from 0 to 1 while the value of SSIFCR.TIE is 1
  CPU instruction: When the value of SSIFCR.TIE changes from 0 to 1 while the value of SSIFSR.TDE is 1

This interrupt is subject to the interrupt suppression function. If an interrupt condition for this interrupt occurs when the DTC/DMAC is busy (when the DTC/DMAC cannot accept interrupts), the interrupt suppression function holds the output of this interrupt. The held interrupt will be output after the DTC/DMAC is enabled to accept interrupts. For details, see Figure 39.60.

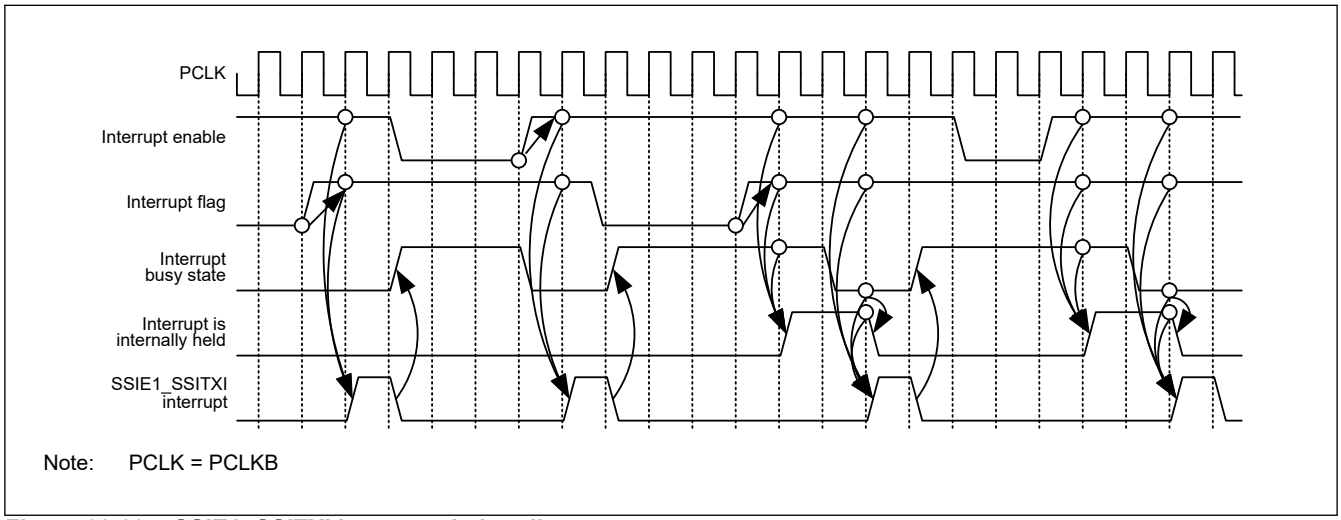

Figure 39.60 SSIE1_SSITXI interrupt timing diagram

39.7.3 SSIE0_SSIRXI Interrupt [Full-duplex communication]

The receive data full interrupt is a pulse interrupt that is output when the following condition is met:

- SSIFCR.RIE = 1 and SSIFSR.RDF = 1.
  SSIE operation: When the value of SSIFSR.RDF changes from 0 to 1 while the value of SSIFCR.RIE is 1
  CPU instruction: When the value of SSIFCR.RIE changes from 0 to 1 while the value of SSIFSR.RDE is 1

This interrupt is subject to the interrupt suppression function. If an interrupt condition for this interrupt occurs when the DTC/DMAC is busy (when the DTC/DMAC cannot accept interrupts), the interrupt suppression function holds the output of this interrupt. The held interrupt will be output after the DTC/DMAC is enabled to accept interrupts. The behavior of this interrupt is the same as the behavior shown in Figure 39.60.

39.7.4 SSIE1_SSIRT Interrupt [Half-duplex communication]

This interrupt is output by two sources, transmit data empty interrupt and receive data full interrupt. When this interrupt is generated, read the interrupt flag and specify the interrupt source.

This interrupt is subject to the interrupt suppression function. If an interrupt condition for this interrupt occurs when the DTC/DMAC is busy (when the DTC/DMAC cannot accept interrupts), the interrupt suppression function holds the output of this interrupt. The held interrupt will be output after the DTC/DMAC is enabled to accept interrupts. For details, see Figure 39.61.

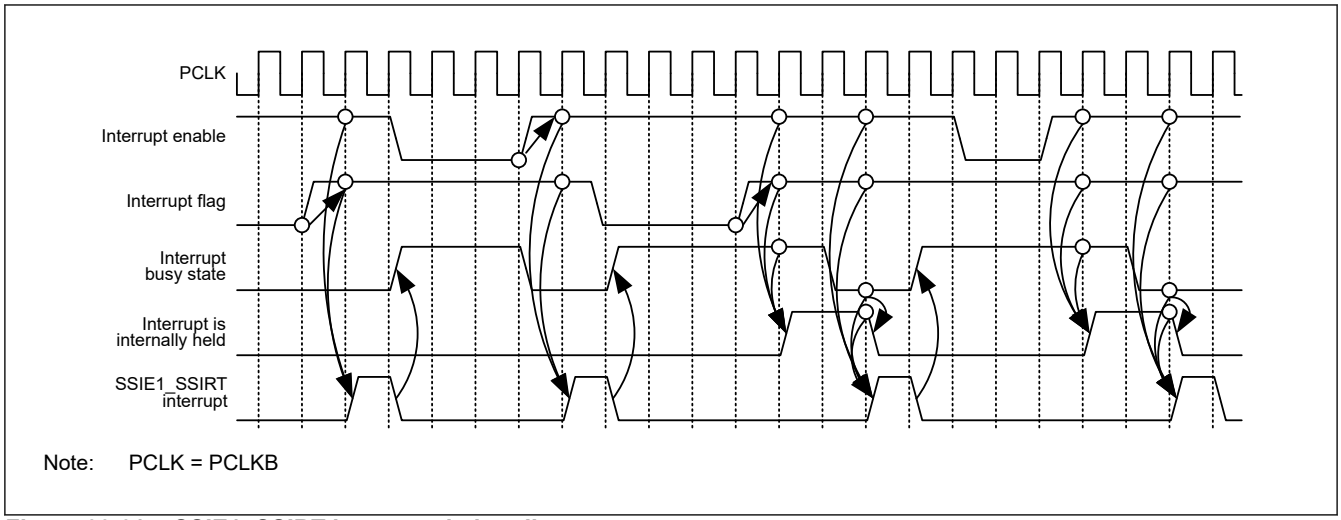

Figure 39.61 SSIE1_SSIRT interrupt timing diagram

39.8 Software Resets

SSIE has three software reset bits to reset its states.

- SSIE software reset (SSIFCR.SSIRST)
- Transmit FIFO data register reset (SSIFCR.TFRST)
- Receive FIFO data register reset (SSIFCR.RFRST).

This section describes the procedures for the three types of software resets.

39.8.1 Software Reset Procedure

(1) SSIE Software Reset

For the SSIE software reset bit (SSIFCR.SSIRST), follow the procedure shown in Figure 39.62. After a reset, the same setting is applied when it is resumed. To change the settings of clocks and slave/master mode, follow the procedure to start communication in Figure 39.53. See section 39.6.2. Transmission and section 39.6.3. Reception respectively for transmission and reception after communication is resumed.

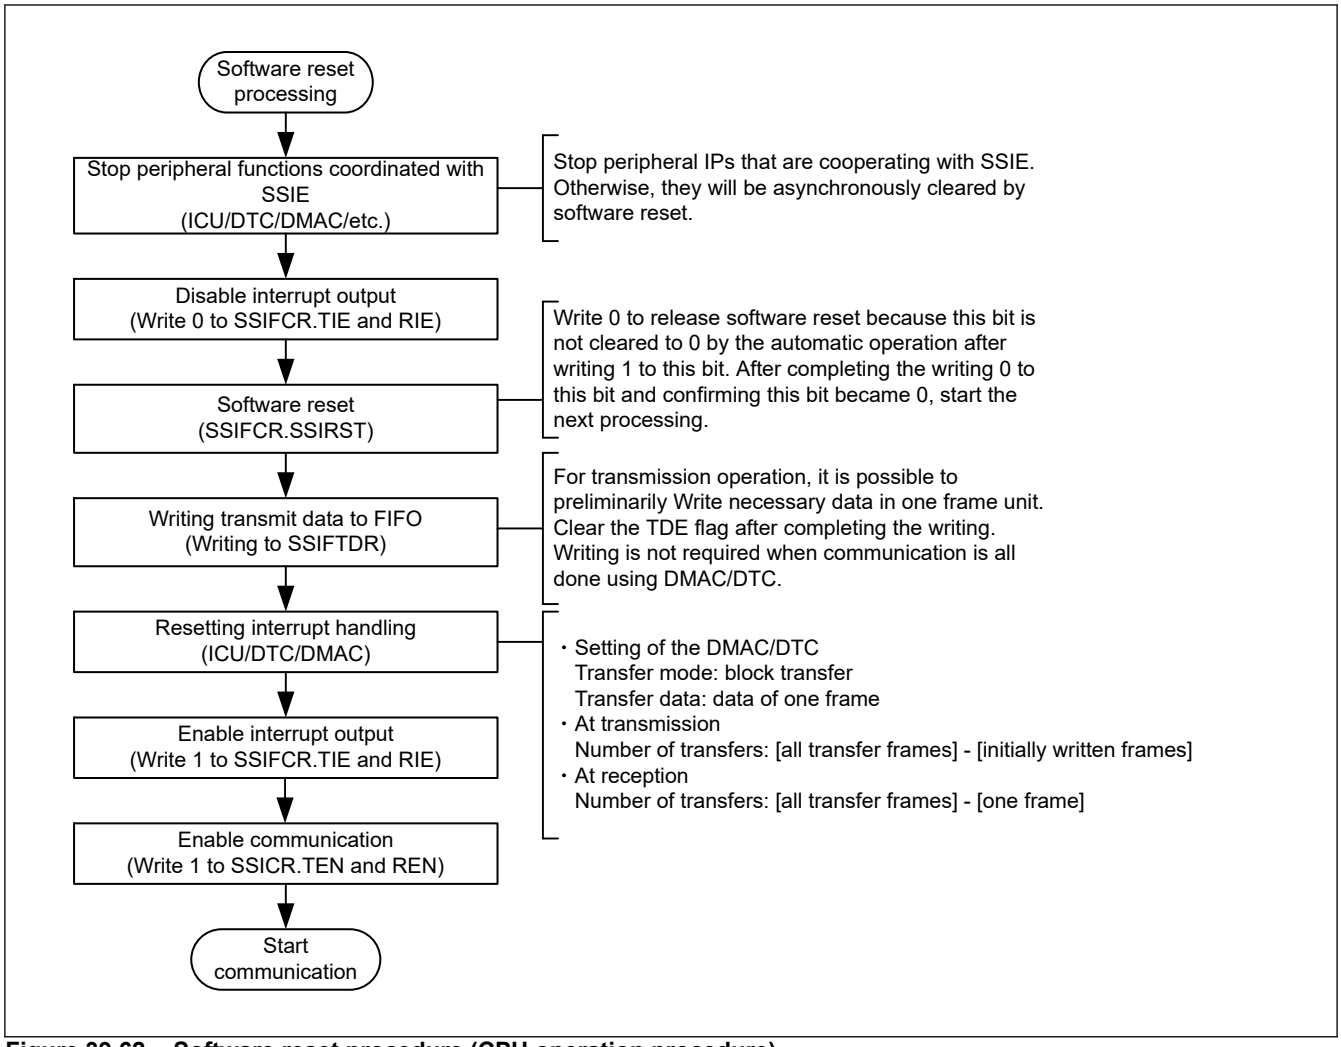

Figure 39.62 Software reset procedure (CPU operation procedure)

(2) Transmit FIFO data register reset

To perform a transmit FIFO data register reset, follow instructions in the procedure to start communication in Figure 39.53 and procedure to resume communication in Figure 39.58.

(3) Receive FIFO data register reset

To perform a receive FIFO data register reset, follow instructions in the procedure to start communication in Figure 39.53 and procedure to resume communication in Figure 39.58.

39.9 Usage Notes

39.9.1 Notes for Slave-mode Communication

39.9.1.1 SSIBCKn (n = 0, 1) control

In slave-mode communication (SSICR.MST = 0), SSIE needs supply of SSIBCKn (n = 0, 1). To stop BCK on the master side, make sure that SSIE is in the idle state (SSISR.IIRQ = 1). If BCK is stopped before SSIE becomes idle, take the procedure to start communication in Figure 39.53 or wait for an idle state by taking the procedure to resume communication in Figure 39.58.

39.9.1.2 SSILRCKn/SSIFSn (n = 0, 1) pin

SSIE has the SSILRCKn/SSIFSn (n = 0, 1) pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCKn/SSIFSn (n = 0, 1) pin only as a trigger to start communication.

39.9.2 Notes for Master-mode Communication

39.9.2.1 AUCKE control

In master-mode communication (SSICR.MST = 1), SSIE operates with the audio clock (AUDIO_MCK). To stop SSIE completely, make sure that SSIE is in the idle state (SSISR.IIRQ = 1) and then write 0 to SSIFCR.AUCKE.

39.9.2.2 LRCONT control

To stop the output to the SSILRCKn/SSIFSn (n = 0, 1) pin with SSIOFR.LRCONT when SSIE is in the idle state in master-mode communication (SSICR.MST = 1), note the following: The output stops when the value of the SSIOFR.LRCONT bit is changed from 1 to 0. Make sure that the other-party device is not affected. For details, see Figure 39.44.

39.9.2.3 BCKASTP control

To stop the output to the SSIBCKn (n = 0, 1) pin with SSIOFR.BCKASTP in master-mode communication (SSICR.MST = 1) and while SSIE is in the idle state, note the following: The output stops when the value of the SSIOFR.BCKASTP bit is changed from 0 to 1. So, make sure that the other-party device is not affected. For details, see Figure 39.45.

The BCKASTP bit cannot be used when the other-party device (which is a slave) requires the clock output from the SSIBCKn (n = 0, 1) pin before and during communication.

39.9.3 Notes for Communication Flow

39.9.3.1 When an error interrupt is generated

SSIE has the following four errors.

- Transmit underflow error
- Transmit overflow error
- Receive underflow error
- Receive overflow error

When an underflow error or overflow error is generated, SSIE need to be restarted. Follow the procedure to halt communication in Figure 39.56 and error-handling procedure in Figure 39.57.

(1) Transmit Underflow Error

If a transmit underflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to a transmit data empty interrupt. After a transmit underflow error occurs, SSIE outputs 0s as data. To normally output the serial data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0/SSIDATA1 pin, follow the procedure to halt communication in Figure 39.56 and error-handling procedure in Figure 39.57. After this error occurs, serial data is consumed as usual. If you resume communication, write the serial data from the beginning.

(2) Transmit Overflow Error

If a transmit overflow error occurs, review the number of times of writing data to the Transmit FIFO Data Register (SSIFTDR) in response to transmit data empty interrupts. The serial data written to the Transmit FIFO Data Register (SSIFTDR) that caused the transmit overflow error becomes invalid. This error can occur regardless of whether a transmission operation is being done. To recover from the error, follow the procedure to halt communication in Figure 39.56 and error-handling procedure in Figure 39.57. When you resume communication, deal with the invalid serial data appropriately.

(3) Receive Underflow Error

If a receive underflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The values read from the receive FIFO data register (SSIFRDR) that caused the receive underflow error are undefined. This error can occur regardless of whether a reception operation is being done. To recover from the error, follow the procedure to halt communication in Figure 39.56 and error-handling procedure in Figure 39.57.

(4) Receive Overflow Error

If a receive overflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The receive data that caused the receive overflow error cannot be stored in the receive FIFO data register (SSIFRDR). To recover from the error, follow the procedure to halt communication in Figure 39.56 and error-handling procedure in Figure 39.57.

39.9.3.2 Transmit data empty interrupt

The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.TDE to write data to SSIFTDR. The number of times of writing data to SSIFTDR by detecting the value 1 of SSIFSR.TDE must be in accordance with the free space size of the transmit FIFO data register specified by SSISCR.TDES. After as much transmit data as the free space size is written to SSIFTDR, the SSIFSR.TDE flag must be cleared. Continuous transmission is enabled by repeating data writing. If the SSIFSR.TDE flag is not cleared, the flag is not cleared automatically.

39.9.3.3 Receive data full interrupt

The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.RDF to read data from SSIFRDR. The number of times of reading data from SSIFRDR by detecting the value 1 of SSIFSR.RDF must be in accordance with the receive data storage capacity of the receive FIFO data register specified by SSISCR.RDFS. After received data is read from SSIFRDR, the SSIFSR.RDF flag must be cleared. Continuous reception is enabled by repeating data reading. If the SSIFSR.RDF flag is not cleared, the flag is not cleared automatically.

39.9.3.4 Switching transfer modes

1. For state transition from transmission, reception, and transmission and reception, disable transmission and reception (SSICR.TEN = 0, SSICR.REN = 0).
2. Confirm it is in the idle state (SSISR.IIRQ = 1).
3. In the idle state, set the SSICR.TEN bit or the SSICR.REN bit again and resume transfer.

39.9.3.5 Resume communication after halting SSIE

When communication of SSIE is halted according to the procedure to halt communication in Figure 39.56, resume communication according to the procedure to resume communication in Figure 39.58.

39.9.4 Write Access Restriction

39.9.4.1 SSICR register

If the TEN bit or REN bit is rewritten, make sure that the SSISR.IIRQ bit is in the desired status. If the value of the TEN or REN bit is changed by rewriting, subsequent operation is unpredictable. For example, when transmission or reception is enabled, check that SSISR.IIRQ is 0; when transmission or reception is disabled, check that SSISR.IIRQ is 1.

(1) TEN Bit and REN Bit

These bits enable/disable transmission and reception. When 1 is written to one of these bits, the corresponding communication operation starts in synchronization with a start trigger by the SSILRCKn/SSIFSn (n = 0, 1) signal. For details, see section 39.6.2. Transmission, section 39.6.3. Reception, and section 39.6.4. Transmission and Reception. When 0 is written to this bit, the current communication operation stops at the next frame boundary. To use SSIE for both transmission and reception, always write 1 to these bits together. When stopping the communication using SSIE, always disable both transmission and reception (write 0 to the TEN and REN bits).

39.9.4.2 SSISR register

(1) Clearing TUIRQ and TOIRQ

After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

(2) Clearing RUIRQ and ROIRQ

After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

39.9.4.3 Communication state

Writing to the bits with orange-shaded area in Table 39.19 is prohibited. If written, the operation performed immediately after writing is not guaranteed.

Table 39.19 Bits protected from writing during communication

Symbol	Address (BASE+)		+0								+1							
			31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

39.9.5 Module-stop function

SSIE operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The SSIE module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

40. SD/MMC Host Interface (SDHI)

40.1 Overview

The Secure Digital Host Interface (SDHI) and MultiMediaCard (MMC) Interface provide the functionality required to connect a variety of external memory cards with the MCU. The SDHI supports both 1- and 4-bit buses for connecting different memory cards that support SD, SDHC, and SDXC formats. When developing host devices that are compliant with the SD Specifications, you must comply with the SD Host/Ancillary Product License Agreement (SD HALA).

The MMC interface supports 1-bit, 4-bit, and 8-bit MMC buses that provide eMMC 4.51 (JEDEC Standard JESD 84- B451) device access. This interface also provides backward compatibility and supports for high-speed SDR transfer modes.

Table 40.1 lists the SD/MMC Host Interface specifications and Figure 40.1 shows a block diagram.

Table 40.1 SD/MMC Host Interface specifications

Interface	Parameter	Specifications
SD	SD bus interface	• Compatible with SD memory card and SDIO card • Transfer bus mode selectable from 4-bit wide bus mode or 1-bit default bus mode • Compatible with SD, SDHC, and SDXC formats
	Transfer modes	Default Speed mode, High Speed mode, SDR12 or SDR25
SD and MMC shared	SDHI clock frequency	The SDHI clock is generated by dividing PCLKB by 2^n (n = 0 to 9)
	Error check functions	CRC7 (command/response), CRC16 (transfer data)
	Interrupt sources	Card access interrupt (SDHI_MMCn_ACCS), SDIO access interrupt (SDHI_MMCn_SDIO), Card detection interrupt (SDHI_MMCn_CARD) (n = 0, 1)
	DMA transfer sources	DMAC and DTC triggerable by the DMA transfer requests (SDHI_MMCn_ODMSDBREQ (n = 0, 1)) interrupt SD buffer is read and write accessible using the DMAC
	Other functions	• Card detect function • Write protect support
MMC	MMC bus interface	Transfer bus mode selectable from 1-bit, 4-bit, or 8-bit
	Transfer modes	Backward compatible mode or high-speed SDR mode selectable
	Other functions	e.MMC device access supported
Module-stop function	Module-stop state can be set for each channel to reduce power consumption.	
TrustZone Filter	Security and Privilege attribution can be set for each channel.	

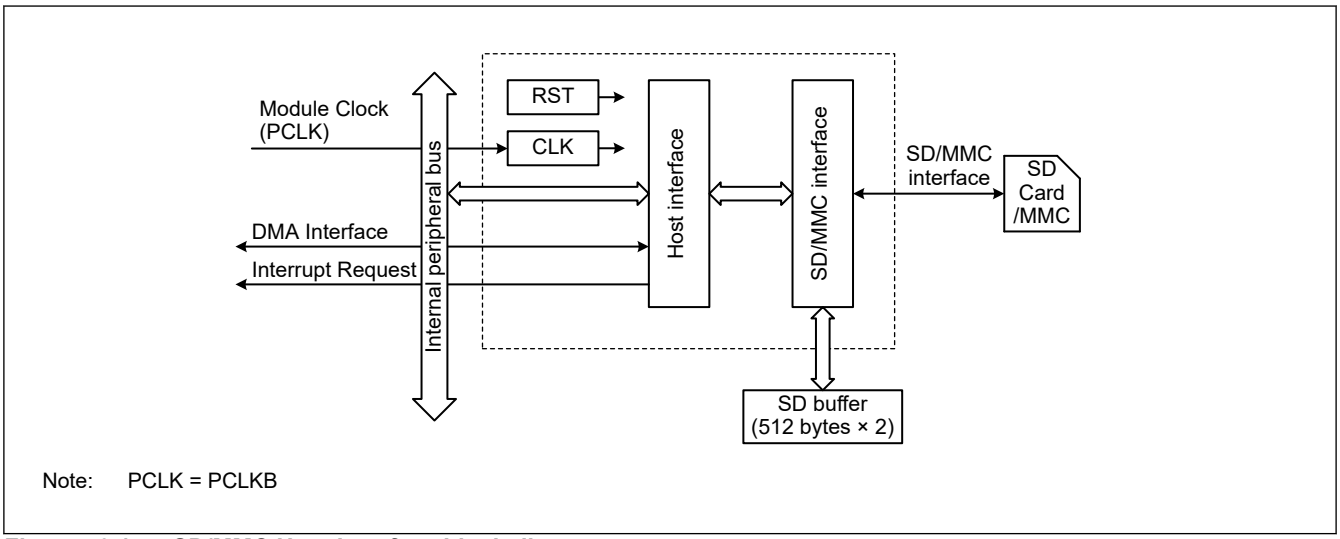

Figure 40.1 SD/MMC Host Interface block diagram

Table 40.2 SDHI I/O pins (n = 0, 1)

Channel	Pin name	I/O	Description
Ch n	SDnCLK	Output	SDHI clock
	SDnCMD	I/O	Command output, response input
	SDnDAT0	I/O	Data 0 (DAT0)
	SDnDAT1	I/O	Data 1 (DAT1), SDIO interrupt
	SDnDAT2	I/O	Data 2 (DAT2), SDIO Read wait
	SDnDAT3	I/O	Data 3 (DAT3), SD Card detect
	SDnDAT4	I/O	MMC Data 4 (DAT4)
	SDnDAT5	I/O	MMC Data 5 (DAT5)
	SDnDAT6	I/O	MMC Data 6 (DAT6)
	SDnDAT7	I/O	MMC Data 7 (DAT7)
	SDnCD	Input	SD card detection
	SDnWP	Input	SD card write protection

40.2 Register Descriptions

40.2.1 SD_CMD : Command Type Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMD12AT[1:0]		TRSTP	CMDRW	CMDTP	RSPTP[2:0]			ACMD[1:0]		CMDIDX[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CMDIDX[5:0]	Command Index Field Value Select These bits configure the command index field value. The examples shown include the bit values for the ACMD[1:0] bits. 0x06: CMD6 0x12: CMD18 0x4D: ACMD13	R/W
7:6	ACMD[1:0]	Command Type Select 0 0: CMD 0 1: ACMD Others: Setting prohibited	R/W
10:8	RSPTP[2:0]	Response Type Select*1 0 0 0: Normal mode Depending on the command, the response type and transfer method are selected in the ACMD[1:0] and CMDIDX[5:0] bits. At this time, the values for bits 15 to 11 in this register are invalid. 0 1 1: Extended mode and no response 1 0 0: Extended mode and R1, R5, R6, or R7 response 1 0 1: Extended mode and R1b response 1 1 0: Extended mode and R2 response 1 1 1: Extended mode and R3 or R4 response Others: Setting prohibited	R/W

Bit	Symbol	Function	R/W
11	CMDTP	Data Transfer Select*2 0: Do not include data transfer (bc, bcr, or ac) in command 1: Include data transfer (adtc) in command	R/W
12	CMDRW	Data Transfer Direction Select*3 0: Write (SD/MMC Host Interface → SD card/MMC) 1: Read (SD/MMC Host Interface ← SD card/MMC)	R/W
13	TRSTP	Block Transfer Select*3 0: Single block transfer 1: Multiple blocks transfer	R/W
15:14	CMD12AT[1:0]	CMD12 Automatic Issue Select*4 0 0: Automatically issue CMD12 during multiblock transfer 0 1: Do not automatically issue CMD12 during multiblock transfer Others: Setting prohibited	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Some commands cannot be used in normal mode.
Note 2. The CMDTP bit is only valid when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b.
Note 3. Bits CMDRW and TRSTP are only valid when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b, and the CMDTP bit is 1.
Note 4. The CMD12AT[1:0] bits are only valid when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b, and the TRSTP bit is 1.

The command type and response type are set in the SD_CMD register. The command type and transfer mode must be set when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b. The sequence starts when a value is written to this register. See Table 40.8 and Table 40.9 for setting examples. Do not write to the SD_CMD register when the SD_INFO2.CBSY flag is 1.

40.2.2 SD_ARG : SD Command Argument Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	—	These bits specify command format[39:8] (argument).	R/W

Note: S-TYPE-3, P-TYPE-3

The SD_ARG register is used for setting the argument field value. Set the SD_ARG register before setting the SD_CMD register. The argument field value of the automatically issued CMD12 is 0x0000_0000 regardless of the SD_ARG register value.

40.2.3 SD_ARG1 : SD Command Argument Register 1

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x00C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits specify command format[39:24] (argument).	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The SD_ARG1 register is used for setting the argument field value. Set the SD_ARG1 register before setting the SD_CMD register. The argument field value of the automatically issued CMD12 is 0x0000_0000 regardless of the SD_ARG1 register value.

40.2.4 SD_STOP : Data Stop Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SEC	—	—	—	—	—	—	—	STP
Value after reset:	0	0	0	0	0	0	0	0*1	0	0	0	0	0	0	0	0*1

Bit	Symbol	Function	R/W
0	STP	Transfer Stop Data transfer stops when this bit is set to 1.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	SEC	Block Count Register Value Select*2 0: Disable SD_SECCNT register value 1: Enable SD_SECCNT register value	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. Do not rewrite this bit when the SD_INFO2.CBSY flag is 1.

The SD_STOP register stops data transfer. During a multiblock transfer sequence, the SD_SECCNT register value (number of blocks to be transferred) can be set to valid or invalid by setting the SD_STOP register.

STP bit (Transfer Stop)

When the STP bit is set to 1 during multiple block transfer, CMD12 is issued to halt the transfer through the SDHI. However, if a command sequence is halted because of a communications error or timeout, CMD12 is not issued. Although continued buffer access is possible even after STP is set to 1, the buffer access error bit (ILR or ILW) in SD_INFO2 is set accordingly.

When STP is set to 1 during transfer for single block write, the access end flag sets when SD_BUF becomes empty, and CMD12 is not issued. If SD_BUF does contain data, the access end flag sets on completion of reception of the busy state without CMD12 being issued.

When STP is set to 1 during transfer for single block read, the access end flag sets immediately after the STP bit is set, and CMD12 is not issued.

When STP is set to 1 during reception of the busy state after an R1b response, the access end flag sets on completion of reception of the busy state without CMD12 being issued.

When STP is set to 1 after a command sequence is completed, CMD12 is not issued and the access end flag does not set.

Set STP to 1 after the response end flag sets.

Set STP to 0 after the access end flag sets.

SEC bit (Block Count Register Value Select)

When SD_CMD is set in the following section to start the command sequence while the SEC bit is set to 1, CMD12 is automatically issued to stop multiblock transfer with the number of blocks set in SD_SECCNT.

CMD18 or CMD25 in normal mode (SD_CMD[10:8] = 000b)

SD_CMD[15:13] = 001b in extended mode (CMD12 is automatically issued, multiple block transfer)

When the command sequence is halted because of a communications error or timeout, CMD12 is not automatically issued.

40.2.5 SD_SECCNT : Block Count Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	—	These bits set the number of blocks to be transferred.	R/W

Note: S-TYPE-3, P-TYPE-3

When performing a multiblock transfer, SD_SECCNT is a read/write register used to set the number of blocks to be transferred. For example, when the register value is 0x0000_0001, 1 block is transferred. When the register value is 0x0000_FFFF, 65,535 blocks are transferred and when the register value is 0xFFFF_FFFF, 4,294,967,295 blocks are transferred. Do not set this register to 0x0000_0000. Do not rewrite the SD_SECCNT register when the SD_INFO2.CBSY flag is 1.

40.2.6 SD_RSPi : SD Card Response Register i (i = 10, 32, 54)

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x018 (SD_RSP10)
0x020 (SD_RSP32)
0x028 (SD_RSP54)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	—	These bits store the response from the SD card/MMC.	R

Note: S-TYPE-3, P-TYPE-3

40.2.7 SD_RSPj : SD Card Response Register j (j = 1, 3, 5)

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x01C (SD_RSP1)
0x024 (SD_RSP3)
0x02C (SD_RSP5)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits store the response from the SD card/MMC.	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

40.2.8 SD_RSP76 : SD Card Response Register 76

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x030

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	SD_RSP76[23:16]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SD_RSP76[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
23:0	SD_RSP76[23:0]	These bits store the response from the SD card/MMC.	R
31:24	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

40.2.9 SD_RSP7 : SD Card Response Register 7

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x034

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	SD_RSP7[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	SD_RSP7[7:0]	These bits store the response from the SD card/MMC.	R
31:8	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

SD_RSP10, SD_RSP32, SD_RSP54, SD_RSP1, SD_RSP3, SD_RSP5, SD_RSP76, and SD_RSP7 are read-only registers that store the response from the SD card/MMC. Depending on the type of response from the SD card/MMC, the SD/MMC Host Interface divides and stores the response among the four registers.

Table 40.3 lists the correspondence between the response type and its storage destination.

Table 40.3 Correspondence between response type and storage destination (1 of 2)

Response type	SD_RSP10 register	SD_RSP32 register	SD_RSP54 register	SD_RSP1 register	SD_RSP3 register	SD_RSP5 register	SD_RSP76 register	SD_RSP7 register
R1	[39:8]	—	[39:8]*1	—	—	—	—	—
R1b	[39:8]	—	[39:8]*1	—	—	—	—	—
R2	[39:8]	[71:40]	[103:72]	—	—	—	[127:104]	—
R3	[39:8]	—	—	—	—	—	—	—
R4	[39:8]	—	—	—	—	—	—	—

Table 40.3 Correspondence between response type and storage destination (2 of 2)

Response type	SD_RSP10 register	SD_RSP32 register	SD_RSP54 register	SD_RSP1 register	SD_RSP3 register	SD_RSP5 register	SD_RSP76 register	SD_RSP7 register
R5	[39:8]	—	—	—	—	—	—	—
R6	[39:8]	—	—	—	—	—	—	—
R7	[39:8]	—	—	—	—	—	—	—

Note 1. The responses for CMD18 and CMD25 are stored in registers SD_RSP10 and SD_RSP54. Therefore, even if the SD_RSP10 register is overwritten with the response for the automatically issued CMD12, the response for CMD18 or CMD25 can be confirmed by reading the SD_RSP54 register.

40.2.10 SD_INFO1 : SD Card Interrupt Flag Register 1

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x038

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SDD3MON	SDD3IN	SDD3RM	SDWPMON	—	SDCDMON	SDCDIN	SDCDRM	ACEND	—	RSPEND
Value after reset:	0	0	0	0	0	x	0	0	x	0	x	0	0	0*1	0	0*1

Bit	Symbol	Function	R/W
0	RSPEND	Response End Detection Flag 0: Response end not detected 1: Response end detected	R/(W)*2
1	—	This bit is read as 0. The write value should be 0.	R/W
2	ACEND	Access End Detection Flag 0: Access end not detected 1: Access end detected	R/(W)*2
3	SDCDRM	SDnCD Removal Flag 0: SD card/MMC removal not detected by the SDnCD pin 1: SD card/MMC removal detected by the SDnCD pin	R/(W)*2
4	SDCDIN	SDnCD Insertion Flag 0: SD card/MMC insertion not detected by the SDnCD pin 1: SD card/MMC insertion detected by the SDnCD pin	R/(W)*2
5	SDCDMON	SDnCD Pin Monitor Flag 0: SDnCD pin level is high*3 1: SDnCD pin level is low*3	R
6	—	This bit is read as 0. The write value should be 0.	R/W
7	SDWPMON	SDnWP Pin Monitor Flag 0: SDnWP pin level is high 1: SDnWP pin level is low	R
8	SDD3RM	SDnDAT3 Removal Flag 0: SD card/MMC removal not detected by the SDnDAT3 pin 1: SD card/MMC removal detected by the SDnDAT3 pin	R/(W)*2
9	SDD3IN	SDnDAT3 Insertion Flag 0: SD card/MMC insertion not detected by the SDnDAT3 pin 1: SD card/MMC insertion detected by the SDnDAT3 pin	R/(W)*2
10	SDD3MON	SDnDAT3 Pin Monitor Flag 0: SDnDAT3 pin level is low 1: SDnDAT3 pin level is high	R

Bit	Symbol	Function	R/W
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. The flag does not change even if set to 1. Writing 0 changes the flag value to 0.
Note 3. The flag changes when the pin level continues for the period set in the SD_OPTION.CTOP[3:0] bits or longer.

The SD_INFO1 register indicates the detection of a response end or access end for a command sequence. The SD_INFO1 register also indicates the detection SD card/MMC insertion/removal and the write protection status.

During a multiblock transfer sequence, if CMD12 or CMD52 (SDIO abort) is issued, the ACEND flag sets to 1, but the RSPEND flag remains set to 0.

If the command sequence is stopped because of a communication error or timeout, the ACEND flag or RSPEND flag sets to 1.

After a reset is canceled, the SDD3MON bit, SDD3IN flag, and SDD3RM flag values are changed in accordance with the status of the SDnDAT3 (n = 0, 1) pin, and their values are changed when data is being transferred in wide bus mode. These 3 bits are used only for SD card. Set flags to be cleared to 0. Set flags that are not being cleared to 1.

RSPEND flag (Response End Detection Flag)

The RSPEND flag indicates that a response end was detected.

[Setting conditions]

- When reception of the response is completed
- When transmission of a command without response is completed
- When reception of the busy state after R1b response is completed
- When reception of the response to CMD52 that was issued by setting the C52PUB bit to 1 is completed for transfer of multiple block read
- When reception of the response to CMD52 that was issued by setting the C52PUB bit to 1 is completed for transfer of multiple block write
- This bit is set when a command sequence is halted because of a communications error or timeout.

[Clearing conditions]

- When 0 is written to RSPEND
- When a command without data is issued.

Note: When a command is issued in absence of data transfer, the RSPEND flag becomes 1 after the command sequence ends.

ACEND flag (Access End Detection Flag)

The ACEND flag indicates that an access end was detected.

[Setting conditions]

- When read access to the buffer is completed for transfer of single block read
- When read access to the buffer for the last block of data is completed for transfer of multiple block read
- When read access to the buffer and reception of the response to CMD12 are completed for transfer of multiple block read with automatic issuing of CMD12
- When reception of the busy state after reception of the CRC status is completed for transfer of single block write
- When reception of the busy state after reception of the CRC status of the last block of data is completed for transfer of multiple block write
- When reception of the response busy state for CMD12 is completed for transfer of multiple block write with automatic issuing of CMD12
- When reception of the response to CMD12 that was issued by setting the STP bit to1 is completed for transfer of multiple block read

- When reception of the response busy state for CMD12 that was issued by setting the STP bit to1 is completed for transfer of multiple block write
- When reception of the response to CMD52 that was issued by setting the IOABT bit to 1 is completed for transfer of multiple block read
- When reception of the response to CMD52 that was issued by setting the IOABT bit to1 is completed for transfer of multiple block write
- This bit is set when a command sequence is halted because of a communications error or timeout.

[Clearing conditions]

- When 0 is written to ACEND
- When the access end bit is set to 1.

Note: The ACEND flag becomes 1 after the command sequence ends.

SDCDRM flag (SDnCD Removal Flag)

The SDCDRM flag indicates that SDnCD was removed.

[Setting condition]

- After a change in SDnCD from 0 to 1, Mcycle elapsed with SDnCD held at 1.

[Clearing conditions]

- When 0 is written to SDCDRM.

Note: Mcycle is set in bits [3:0] in SD_OPTION.

SDCDIN flag (SDnCD Insertion Flag)

The SDCDIN flag indicates that SDnCD was inserted.

[Setting condition]

- After a change in SDnCD from 1 to 0, Mcycle elapsed with SDnCD held at 0.

[Clearing conditions]

- When 0 is written to SDCDIN.

Note: Mcycle is set in bits [3:0] in SD_OPTION.

SDD3RM flag (SDnDAT3 Removal Flag)

The SDD3RM flag indicates that SDnDAT3 was removed.

[Setting condition]

- After a change in SDnDAT3 from 1 to 0, two cycles of PCLKB elapsed with SDnDAT3 held at 0.

[Clearing condition]

- When 0 is written to SDD3RM.

SDD3IN flag (SDnDAT3 Insertion Flag)

The SDD3IN flag indicates that SDnDAT3 was inserted.

[Setting condition]

- After a change in SDnDAT3 from 0 to 1, two cycles of PCLKB elapsed with SDnDAT3 held at 1.

[Clearing condition]

- When 0 is written to SDD3IN.

40.2.11 SD_INFO2 : SD Card Interrupt Flag Register 2

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x03C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

6	RSPTO	Response Timeout Detection Flag 0: Response timeout not detected 1: Response timeout detected	R/W*2
7	SDD0MON	SDnDAT0 Pin Status Flag 0: SDnDAT0 pin is low 1: SDnDAT0 pin is high	R
8	BRE	SD_BUF0 Read Enable Flag 0: Disable read access to the SD_BUF0 register 1: Enable read access to the SD_BUF0 register	R/W*2
9	BWE	SD_BUF0 Write Enable Flag 0: Disable write access to the SD_BUF0 register 1: Enable write access to the SD_BUF0 register	R/W*2
10	—	This bit is read as 0. The write value should be 0.	R/W
11	—	The read value is undefined. The write value should be 1.	R/W
12	—	This bit is read as 0. The write value should be 0.	R/W
13	SD_CLK_CTRLEN	SD_CLK_CTRL Write Enable Flag 0: SD/MMC bus (CMD and DAT lines) is busy, so write access to the SD_CLK_CTRL.CLKEN and CLKSEL[7:0] bits is disabled 1: SD/MMC bus (CMD and DAT lines) is not busy, so write access to the SD_CLK_CTRL.CLKEN and CLKSEL[7:0] bits is enabled	R

Bit	Symbol	Function	R/W
14	CBSY	Command Sequence Status Flag 0: Command sequence complete 1: Command sequence in progress (busy)	R
15	ILA	Illegal Access Error Detection Flag 0: Illegal access error not detected 1: Illegal access error detected	R/W*2
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. The flag does not change even if set to 1. Writing 0 changes the flag value to 0.

The SD_INFO2 register indicates the status of the SD buffer and the status of the SD card/MMC. Set flags to be cleared to 0. Set flags that are not being cleared to 1.

CMDE flag (Command Error Detection Flag)

The CMDE flag indicates that a command error was detected. The command sequence stops when a command error occurs. When the SDIO_MODE.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence is not completed. Perform the error processing shown in section 40.3.12. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read) or section 40.3.13. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Write), and complete the command sequence.

[Setting conditions]

- The command index of the transmitted command differs from the command index of the received response.
- The command index of a command issued within a command sequence differs from the command index of the received response.

[Clearing condition]

- When 0 is written to CMDE.

CRCE flag (CRC Error Detection Flag)

The CRCE flag indicates that a CRC error was detected. The command sequence stops when a CRC error occurs. When the SDIO_MODE.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence is not completed. Perform the error processing shown in section 40.3.12. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read) or section 40.3.13. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Write), and complete the command sequence.

[Setting conditions]

- When an error occurs in the CRC status.
- When a CRC error occurs in the read data.
- When a CRC error occurs in the response.
- A CRC error in the response to a command issued within a command sequence.

[Clearing condition]

- When 0 is written to CRCE.

ENDE flag (End Bit Error Detection Flag)

The ENDE flag indicates that an end bit error was detected. The command sequence is stopped when an end bit error occurs. When the SDIO_MODE.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence is not completed. Perform the error processing shown in section 40.3.12. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read) or section 40.3.13. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Write), and complete the command sequence.

[Setting conditions]

- When an error occurs in the response length (and the end bit is not detected).
- When an error occurs in the read data length (and the end bit is not detected among the valid bits).

- When an error occurs in the CRC status length (and the end bit is not detected).
- An error in the length of a response to a command issued within a command sequence, for example when the end bit is not detected.

[Clearing condition]

- When 0 is written to ENDE.

DTO flag (Data Timeout Detection Flag)

The DTO flag indicates that a data timeout was detected. The command sequence stops when a data timeout occurs.

[Setting conditions]

- After R1b response, the busy state (SDnDAT0 = 0) continues for longer than Ncycle.
- After CRC status, the busy state (SDnDAT0 = 0) continues for longer than Ncycle.
- After write data, the CRC status is not received though Ncycle has elapsed.
- After read command, read data is not received though a time longer than Ncycle has elapsed.
- After CMD12 is issued within a command sequence, the busy state (SDnDAT0 = 0) for longer than Ncycle continues.
- After the reception of read data, read data for the next block are not received though a time longer than Ncycle has elapsed.
- After release of the read wait state, read data for the next block are not received though a time longer than Ncycle has elapsed.

Note: Ncycle is set in bits [7:4] in SD_OPTION.

[Clearing condition]

- When 0 is written to DTO.

ILW flag (SD_BUF0 Illegal Write Access Detection Flag)

The ILW flag indicates that an SD_BUF0 illegal write access was detected.

[Setting conditions]

- When data is written to SD_BUF0 while it is not in the data read/write command state.
- When data is written to SD_BUF0 while SD_BUF is full.
- When data is written to SD_BUF0 while an error occurs in the CRC status or CRC status length.
- When data is written to SD_BUF0 while a busy state after the CRC status continues for longer than Ncycle.

Note: Ncycle is set in bits [7:4] in SD_OPTION.

[Clearing condition]

- When 0 is written to ILW.

ILR flag (SD_BUF0 Illegal Read Access Detection Flag)

The ILR flag indicates that an SD_BUF0 illegal read access was detected.

[Setting conditions]

- When SD_BUF is empty while SD_BUF0 is read.
- When data with a CRC error or END error is read from SD_BUF0.

[Clearing condition]

- When 0 is written to ILR.

RSPTO flag (Response Timeout Detection Flag)

The RSPTO flag indicates that a response timeout was detected. The command sequence is stopped when a response timeout occurs. When the SDIOMD.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or

response timeout occurs, the command sequence is not completed. Perform the error processing shown in section 40.3.12. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read) or section 40.3.13. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Write), and complete the command sequence.

[Setting condition]

- When a response is not received though a time longer than 640 cycles of SD/MMC clock has elapsed (including a response to a command issued within a command sequence).

[Clearing condition]

- When 0 is written to RSPTO.

SDD0MON flag (SDnDAT0 Pin Status Flag)

The SDD0MON flag indicates the status of the SDnDAT0 pin. If the data timeout (DTO) is set but the response timeout (RSPTO) is not set after the Erase command is issued, the end of the Erase sequence (SDD0MON = 1) is confirmed by polling DAT0.

If a communication error or timeout occurs during a write sequence, the DAT0 bit might retain the value 0.

While the SD/MMC clock is stopped, the DAT0 bit retains the value before the clock is stopped.

BRE flag (SD_BUF0 Read Enable Flag)

The BRE flag indicates that SD_BUF0 is enabled for reading.

[Setting conditions]

- When data set in SD_SIZE is stored in SD_BUF0 at single block transfer.
- When data set in SD_SIZE is stored in either bank 1 or bank 2 of SD_BUF0 at multiple block transfer.

[Clearing conditions]

- When 0 is written to BRE
- Reading of a block of data from SD_BUF0 by DMA transfer

When data is read from SD_BUF0 by the CPU, clear BRE then read the amount of data specified in SD_SIZE.

Even if a CRC error or an END error occurs while block data is read, data is stored in SD_BUF0 and BRE is set.

BWE flag (SD_BUF0 Write Enable Flag)

The BWE flag indicates that SD_BUF0 is enabled for writing.

[Setting conditions]

- When SD_BUF0 is empty at single block transfer.
- When either bank 1 or bank 2 of SD_BUF0 is empty at multiple block transfer.

[Clearing conditions]

- When 0 is written to BWE.
- Writing of a block of data to SD_BUF0 by DMA transfer.

When data is written to SD_BUF0 by the CPU, clear BWE and then write the amount of data specified in SD_SIZE.

SD_CLK_CTRLEN flag (SD_CLK_CTRL Write Enable Flag)

When a command sequence is started by writing to SD_CMD, the CBSY bit is set to 1 and, at the same time, the SD_CLK_CTRLEN bit is set to 0. The SD_CLK_CTRLEN bit is set to 1 after 8 cycles of SDCLK have elapsed after the CBSY bit clears to 0 on completion of the command sequence.

ILA flag (Illegal Access Error Detection Flag)

The ILA flag indicates that an illegal access error was detected.

[Setting conditions]

- Writing of data to SD_CMD within a command sequence (CBSY = 1).

- When SD_CMD[11] = 1 (command with data transfer) and SD_CMD[7:0] = 0000 1100b (CMD12) are set in SD_CMD.

[Clearing condition]

- When 0 is written to ILA.

40.2.12 SD_INFO1_MASK : SD INFO1 Interrupt Mask Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x040

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SDD3INM	SDD3RMM	—	—	—	SDCDINM	SDCDRMM	ACENDM	—	RSPENDM
Value after reset:	0	0	0	0	0	0	1	1	0	0	0	1	1	1	0	1

Bit	Symbol	Function	R/W
0	RSPENDM	Response End Interrupt Request Mask 0: Do not mask response end interrupt request 1: Mask response end interrupt request	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
2	ACENDM	Access End Interrupt Request Mask 0: Do not mask access end interrupt request 1: Mask access end interrupt request	R/W
3	SDCDRMM	SDnCD Removal Interrupt Request Mask 0: Do not mask SD card/MMC removal interrupt request by the SDnCD pin 1: Mask SD card/MMC removal interrupt request by the SDnCD pin	R/W
4	SDCDINM	SDnCD Insertion Interrupt Request Mask 0: Do not mask SD card/MMC insertion interrupt request by the SDnCD pin 1: Mask SD card/MMC insertion interrupt request by the SDnCD pin	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	SDD3RMM	SDnDAT3 Removal Interrupt Request Mask 0: Do not mask SD card/MMC removal interrupt request by the SDnDAT3 pin 1: Mask SD card/MMC removal interrupt request by the SDnDAT3 pin	R/W
9	SDD3INM	SDnDAT3 Insertion Interrupt Request Mask 0: Do not mask SD card/MMC insertion interrupt request by the SDnDAT3 pin 1: Mask SD card/MMC insertion interrupt request by the SDnDAT3 pin	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The SD_INFO1_MASK register enables or disables interrupt requests from the status flags in the SD_INFO1 register. See Table 40.5, for details on the relationship between the status flags and the requested interrupt source.

40.2.13 SD_INFO2_MASK : SD INFO2 Interrupt Mask Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x044

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ILAM	—	—	—	—	—	BWEM	BREM	—	RSPTOM	ILRM	ILWM	DTOM	ENDEM	CRCEM	CMDEM
Value after reset:	1	0	0	0	1	0	1	1	0	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
0	CMDEM	Command Error Interrupt Request Mask 0: Do not mask command error interrupt request 1: Mask command error interrupt request	R/W
1	CRCEM	CRC Error Interrupt Request Mask 0: Do not mask CRC error interrupt request 1: Mask CRC error interrupt request	R/W
2	ENDEM	End Bit Error Interrupt Request Mask 0: Do not mask end bit detection error interrupt request 1: Mask end bit detection error interrupt request	R/W
3	DTOM	Data Timeout Interrupt Request Mask 0: Do not mask data timeout interrupt request 1: Mask data timeout interrupt request	R/W
4	ILWM	SD_BUF0 Register Illegal Write Interrupt Request Mask 0: Do not mask illegal write detection interrupt request for the SD_BUF0 register 1: Mask illegal write detection interrupt request for the SD_BUF0 register	R/W
5	ILRM	SD_BUF0 Register Illegal Read Interrupt Request Mask 0: Do not mask illegal read detection interrupt request for the SD_BUF0 register 1: Mask illegal read detection interrupt request for the SD_BUF0 register	R/W
6	RSPTOM	Response Timeout Interrupt Request Mask 0: Do not mask response timeout interrupt request 1: Mask response timeout interrupt request	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
8	BREM*1	BRE Interrupt Request Mask 0: Do not mask read enable interrupt request for the SD buffer 1: Mask read enable interrupt request for the SD buffer	R/W
9	BWEM*1	BWE Interrupt Request Mask 0: Do not mask write enable interrupt request for the SD_BUF0 register 1: Mask write enable interrupt request for the SD_BUF0 register	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	—	This bit is read as 1.The write value should be 1.	R/W
14:12	—	These bits are read as 0. The write value should be 0.	R/W
15	ILAM	Illegal Access Error Interrupt Request Mask 0: Do not mask illegal access error interrupt request 1: Mask illegal access error interrupt request	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. When the SD_INFO2_MASK.BWEM bit is 0 or the SD_INFO2_MASK.BREM bit is 0, set the SD_DMAEN.DMAEN bit to 0. When the SD_DMAEN.DMAEN bit is 1, set the SD_INFO2_MASK.BWEM bit to 1 and the SD_INFO2_MASK.BREM bit to 1.

The SD_INFO2_MASK register enables or disables interrupt requests from the status flags in the SD_INFO2 register. See Table 40.5 for details on the relationship between the status flags and the requested interrupt source.

40.2.14 SD_CLK_CTRL : SD Clock Control Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x048

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CLKCTRLEN	CLKEN	CLKSEL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0*1	0	0	1	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CLKSEL[7:0]	SDHI Clock Frequency Select*2 0xFF PCLKB 0x00: PCLKB/2 0x01: PCLKB/4 0x02: PCLKB/8 0x04: PCLKB/16 0x08: PCLKB/32 0x10: PCLKB/64 0x20: PCLKB/128 0x40: PCLKB/256 0x80: PCLKB/512 Others: Setting prohibited	R/W
8	CLKEN	SD/MMC Clock Output Control*2 0: Disable SD/MMC clock output (fix SDnCLK signal low) 1: Enable SD/MMC clock output	R/W
9	CLKCTRLEN	SD/MMC Clock Output Automatic Control Select 0: Disable automatic control of SD/MMC clock output 1: Enable automatic control of SD/MMC clock output	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. Bits CLKSEL[7:0] and CLKEN cannot be write accessed when the SD_INFO2.SD_CLK_CTRLEN flag is 0.

The SD_CLK_CTRL register controls the SD/MMC clock frequency settings and output. Set the CLKEN bit to 1 before writing to the SD_CMD register to start a command sequence. Do not write to the SD_CLK_CTRL register when the SD_INFO2.SD_CLK_CTRLEN flag is 0.

CLKCTRLEN bit (SD/MMC Clock Output Automatic Control Select)

The CLKCTRLEN bit enables or disables the automatic control function for SD/MMC clock output, which causes the SD/MMC clock to output only within a command sequence.

The timing with which SD/MMC clock output starts and stops is as follows:

- SD/MMC clock output starts after writing to SD_CMD
- SD/MMC clock output stops when 8 cycles of SD/MMC clock have elapsed after the end of the command sequence.

In addition, SD/MMC clock is fixed to 0 while SCLKEN of SD_CLK_CTRL is 0, regardless of the value of this bit.

40.2.15 SD_SIZE : Transfer Data Length Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x04C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	LEN[9:0]									
Value after reset:	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	LEN[9:0]	Transfer Data Size Setting These bits specify the transfer data size.*1	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Do not rewrite these bits when the SD_INFO2.CBSY flag is 1.

The SD_SIZE register sets the transfer data size.

LEN[9:0] bits (Transfer Data Size Setting)

When using single block transfer, the transfer data size can be set in the LEN[9:0] bits from 1 byte to 512 bytes. When CMD12 is automatically issued during a multiblock transfer sequence (CMD18 and CMD25), the transfer data size can only be set to 512 bytes. When CMD12 is not automatically issued during a multiblock transfer sequence, the transfer data size can be set to 32, 64, 128, 256, or 512 bytes. However, a 32, 64, 128, or 256 bytes multiblock read transfer can only be performed during an SDIO multiblock transfer (CMD53). Do not set these bits to 0 when using a command that includes data transfer.

40.2.16 SD_OPTION : SD Card Access Control Option Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x050

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WIDTH	—	WIDTH8	—	—	—	—	TOUTMASK	TOP[3:0]				CTOP[3:0]			
Value after reset:	0*1	1	0*1	0	0	0	0	0*1	1*1	1*1	1*1	0*1	1*1	1*1	1*1	0*1

Bit	Symbol	Function	R/W
3:0	CTOP[3:0]	Card Detection Time Counter*2 0x0: PCLKB × 2^{10} 0x1: PCLKB × 2^{11} 0x2: PCLKB × 2^{12} 0x3: PCLKB × 2^{13} 0x4: PCLKB × 2^{14} 0x5: PCLKB × 2^{15} 0x6: PCLKB × 2^{16} 0x7: PCLKB × 2^{17} 0x8: PCLKB × 2^{18} 0x9: PCLKB × 2^{19} 0xA: PCLKB × 2^{20} 0xB: PCLKB × 2^{21} 0xC: PCLKB × 2^{22} 0xD: PCLKB × 2^{23} 0xE: PCLKB × 2^{24} 0xF: Setting prohibited	R/W
7:4	TOP[3:0]	Timeout Counter*2 0x0: SDHI clock × 2^{13} 0x1: SDHI clock × 2^{14} 0x2: SDHI clock × 2^{15} 0x3: SDHI clock × 2^{16} 0x4: SDHI clock × 2^{17} 0x5: SDHI clock × 2^{18} 0x6: SDHI clock × 2^{19} 0x7: SDHI clock × 2^{20} 0x8: SDHI clock × 2^{21} 0x9: SDHI clock × 2^{22} 0xA: SDHI clock × 2^{23} 0xB: SDHI clock × 2^{24} 0xC: SDHI clock × 2^{25} 0xD: SDHI clock × 2^{26} 0xE: SDHI clock × 2^{27} 0xF: Setting prohibited	R/W
8	TOUTMASK	Timeout Mask 0: Activate timeout 1: Inactivate timeout (do not set RSPTO and DTO bits of SD_INFO2 or CRCBSYTO, CRCTO, RDTO, BSYTO1, BSYTO0, RSPTO1 and RSPTO0 bits of SD_ERR_STS2) When timeout occurs because of an inactivated timeout, execute a software reset to terminate the command sequence.	R/W
12:9	—	These bits are read as 0. The write value should be 0.	R/W
13	WIDTH8	Bus Width*2 See bit 15 WIDTH bit.	R/W
14	—	This bit is read as 1. The write value should be 1.	R/W
15	WIDTH	Bus Width*2 **WIDTH / WIDTH8 / Bus Width** 0 / 1 / 8-bit width 0 / 0 / 4-bit width 1 / 0 / 1-bit width 1 / 1 / 1-bit width For 1-byte write transfers, set 4-bit or 1-bit width. Do not set 8-bit width.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.

Note 2. Do not rewrite these bits when the SD_INFO2.CBSY flag is 1.

The SD bus width and timeout counter are set in the SD_OPTION register.

40.2.17 SD_ERR_STS1 : SD Error Status Register 1

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x058

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	CRCTK[2:0]			CRCTKE	RDCRCE	RSPCRCE1	RSPCRCE0	—	—	CRCLENE	RDLENE	RSPLENE1	RSPLENE0	CMDE1	CMDE0
Value after reset:	0	0*1	1*1	0*1	0*1	0*1	0*1	0*1	0	0	0*1	0*1	0*1	0*1	0*1	0*1

Bit	Symbol	Function	R/W
0	CMDE0	Command Error Flag 0 0: No error exists in command index field value of a command*2 response 1: Error exists in command index field value of a command*2 response	R
1	CMDE1	Command Error Flag 1 0: No error exists in command index field value of a command*3 response 1: Error exists in command index field value of a command*3 response (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the CMDE0 flag)	R
2	RSPLENE0	Response Length Error Flag 0 0: No error exists in command*2 response length 1: Error exists in command*2 response length	R
3	RSPLENE1	Response Length Error Flag 1 0: No error exists in command*3 response length 1: Error exists in command*3 response length (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the RSPLENE0 flag)	R
4	RDLENE	Read Data Length Error Flag 0: No read data length error occurred 1: Read data length error occurred	R
5	CRCLENE	CRC Status Token Length Error Flag 0: No CRC status token length error occurred 1: CRC status token length error occurred	R
7:6	—	These bits are read as 0.	R
8	RSPCRCE0	Response CRC Error Flag 0 0: No CRC error detected in command*2 response 1: CRC error detected in command*2 response	R
9	RSPCRCE1	Response CRC Error Flag 1 0: No CRC error detected in command*3 response (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the RSPCRCE0 flag) 1: CRC error detected in command*3 response	R
10	RDCRCE	Read Data CRC Error Flag 0: No CRC error detected in read data 1: CRC error detected in read data	R
11	CRCTKE	CRC Status Token Error Flag 0: No error detected in CRC status token 1: Error detected in CRC status token	R

Bit	Symbol	Function	R/W
14:12	CRCTK[2:0]	CRC Status Token These bits store the CRC status token value (normal value is 010b).	R
31:15	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 3. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

The SD_ERR_STS1 register indicates the CRC status token, CRC error, end bit error, and command error.

40.2.18 SD_ERR_STS2 : SD Error Status Register 2

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x05C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	CRCBSYTO	CRCTO	RDTO	BSYTO1	BSYTO0	RSPTO1	RSPTO0
Value after reset:	0	0	0	0	0	0	0	0	0	0*1	0*1	0*1	0*1	0*1	0*1	0*1

Bit	Symbol	Function	R/W
0	RSPTO0	Response Timeout Flag 0 0: After command*2 was issued, response was received in less than 640 cycles of the SD/MMC clock 1: After command*2 was issued, response was not received in 640 or more cycles of the SD/MMC clock	R
1	RSPTO1	Response Timeout Flag 1 0: After command*3 was issued, response was received in less than 640 cycles of the SD/MMC clock 1: After command*3 was issued, response was not received after 640 or more cycles of the SD/MMC clock (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the RSPTO0 flag)	R
2	BSYTO0	Busy Timeout Flag 0 0: After R1b response was received, SD/MMC was released from the busy state during the specified period*4 1: After R1b response was received, SD/MMC was in the busy state after the specified period*4 elapsed	R
3	BSYTO1	Busy Timeout Flag 1 0: After CMD12 was automatically issued, SD/MMC was released from the busy state during the specified period*4 1: After CMD12 was automatically issued, SD/MMC was in the busy state after the specified period*4 elapsed (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the BSYTO0 flag)	R
4	RDTO	Read Data Timeout Flag When a read command is issued, this flag sets to 1 when read data is not received after the specified period*4 elapses. When read data is received, this flag sets to 1 when the next block of read data is not received after the specified period*4 elapses. When the SD/MMC exits the read wait state, this flag sets to 1 when the next block of read data is not received after the specified period*4 elapses.	R

Bit	Symbol	Function	R/W
5	CRCTO	CRC Status Token Timeout Flag 0: After CRC data was written to the SD card/MMC, a CRC status token was received during the specified period*4 1: After CRC data was written to the SD card/MMC, a CRC status token was not received after the specified period*4 elapsed	R
6	CRCBSYTO	CRC Status Token Busy Timeout Flag 0: After a CRC status token was received, the SD/MMC was released from the busy state during the specified period*4 1: After a CRC status token was received, the SD/MMC was in the busy state after the specified period*4 elapsed	R
31:7	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 3. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 4. Set the SD_OPTION.TOP[3:0] bits to select the number of *n* cycles.

The SD_ERR_STS2 register indicates the timeout status.

40.2.19 SD_BUF0 : SD Buffer Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x060

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:																
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
31:0	n/a	When writing to the SD card, the write data is written to this register. When reading from the SD card, the read data is read from this register.	R/W

This register is internally connected to two 512-byte buffers.

If both buffers are not empty when executing multiple block read, the SD card/MMC clock is stopped to suspend receiving data. When one of the buffers is empty, the SD card/MMC clock is supplied to resume receiving data.

40.2.20 SDIO_MODE : SDIO Mode Control Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x068

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	C52PUB	IOABT	—	—	—	—	—	RWREQ	—	INTEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	INTEN	SDIO Interrupt Acceptance Enable*1 0: Disable SDIO interrupt acceptance 1: Enable SDIO interrupt acceptance	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
2	RWREQ	Read Wait Request 0: Allow SD/MMC to exit read wait state 1: Request for SD/MMC to enter read wait state	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
8	IOABT	SDIO Abort If this bit is set to 1 during multiblock transfer triggered by CMD53, CMD52 is immediately issued, and the command sequence is aborted.	R/W
9	C52PUB	SDIO None Abort If this bit is set to 1 during multiblock transfer triggered by CMD53, CMD52 is issued after the transfer process is complete, and the command sequence is completed.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Do not rewrite this bit when the SD_INFO2.CBSY flag is 1.

The SDIO_MODE register controls reception of the SDIO interrupt, CMD52 issuance during multiblock transfer, and read wait request. Do not set bits C52PUB and IOABT to 1 at the same time.

RWREQ bit (Read Wait Request)

When RWREQ is set to 1 in the CMD53 (multiple block) read sequence, the block transfer enters the read wait state between blocks.

[Read wait state releasing]

- The read wait state is released, when RWREQ is cleared to 0 in the read wait state.
- When IOABT is set to 1 in the read wait state, RWREQ is automatically cleared to 0 after CMD52 is issued, and then the read wait state is released.
- When C52PUB and RWREQ are set to 1 simultaneously in the CMD53 (multiple block) read sequence, the read wait state is not automatically released. Therefore, after the CMD52 response is received, clear RWREQ. You must set RWREQ and C52PUB simultaneously.

When RWREQ is set to 1 while the last block in the CMD53 (multiple block) read sequence is transferred, the read wait state is not entered and RWREQ is automatically cleared to 0 by setting access end. Set RWREQ to 1 after the response end flag sets.

IOABT bit (SDIO Abort)

When the IOABT bit is set to 1 in a CMD53 (multiple block) sequence, the CMD53 sequence is halted and CMD52 is issued. However, if a command sequence is halted because of a communication error or timeout, CMD52 is not issued.

Although continued buffer access is possible even after IOABT is set to 1, the buffer access error bit (ILR or ILW) in SD_INFO2 is set accordingly. Set SD_ARG before setting IOABT to 1.

When IOABT is set to 1 during transfer for a single block write, the access end flag sets when SD_BUF0 becomes empty, and CMD52 is not issued. If SD_BUF0 contains data, the access end flag sets on completion of reception of the busy state without CMD52 being issued.

When IOABT is set to 1 during transfer for single block read, the access end flag sets immediately after IOABT is set, and CMD52 is not issued.

When IOABT is set to 1 during reception of the busy state after an R1b response, the access end flag sets on completion of reception of the busy state without CMD52 being issued.

When IOABT is set to 1 after a command sequence is completed, CMD52 is not issued and the access end flag does not set.

Set IOABT to 1 after the response end flag sets.

Set IOABT to 0 after the access end flag sets.

C52PUB bit (SDIO None Abort)

When the C52PUB bit is set to 1 in the CMD53 (multiple block) write sequence, CMD52 is automatically issued between blocks if SD_BUF0 becomes empty. C52PUB is automatically cleared to 0 after reception of the response to CMD52 is completed. Additionally, if C52PUB is set to 1 while the last block is being transferred, CMD52 is not issued. In this case, C52PUB is automatically cleared to 0 after the access end flag sets to 1.

When C52PUB and RWREQ are set to 1 in the CMD53 (multiple block) read sequence, the block transfer enters the read wait state between blocks and CMD52 is automatically issued. C52PUB is automatically cleared to 0 after reception of the response to CMD52 is completed. Additionally, if C52PUB is set to 1 while the last block is being transferred, CMD52 is not issued. In this case, C52PUB is automatically cleared to 0 after the access end flag sets to 1.

If C52PUB is set to 1 in the CMD53 (multiple block) read sequence, you must set RWREQ to 1 in addition to C52PUB.

Set SD_ARG before setting C52PUB to 1.

Set C52PUB to 1 after the response end flag sets.

40.2.21 SDIO_INFO1 : SDIO Interrupt Flag Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x06C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EXWT	EXPUB52	—	—	—	—	—	—	—	—	—	—	—	—	—	IOIRQ
Value after reset:	0*1	0*1	0	0	0	0	0	0	0	0	0	0	0	x	x	0*1

Bit	Symbol	Function	R/W
0	IOIRQ	SDIO Interrupt Status Flag 0: No SDIO interrupt detected 1: SDIO interrupt detected	R/(W)*2
2:1	—	The read values are undefined. The write value should be 1.	R/W
13:3	—	These bits are read as 0. The write value should be 0.	R/W
14	EXPUB52	EXPUB52 Status Flag Indicates the status of the EXPUB52.	R/(W)*2
15	EXWT	EXWT Status Flag Indicates the status of the EXWT.	R/(W)*2

Bit	Symbol	Function	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. Only 0 can be written to clear the bit.

The SDIO_INFO1 register indicates the status of the SDIO card access. Set flags to be cleared to 0. Set flags that are not being cleared to 1.

IOIRQ flag (SDIO Interrupt Status Flag)

The IOIRQ flag indicates that an SDIO interrupt occurred.

[Setting condition]

- When SDIO interrupt from an SDIO card is received while INTEN in SDIO_MODE is set to 1.

[Clearing condition]

- When 0 is written to IOIRQ.*1

Note 1. Before clearing this bit, access the SDIO card to negate the SDIO interrupt signal from the SDIO card. If the interrupt signal is not negated, this bit can be set again.

EXPUB52 flag (EXPUB52 Status Flag)

The EXPUB52 flag indicates the EXPUB52 status.

[Setting conditions]

- While the last block in the CMD53 (multiple block) sequence is transferred, C52PUB in SDIO_MODE is set to 1.
- While C52PUB is set to 1 in the CMD53 (multiple block) write sequence, the last block is transferred.

[Clearing condition]

- When 0 is written to EXPUB52.

EXWT flag (EXWT Status Flag)

The EXWT flag indicates the EXWT status.

[Setting condition]

- While the last block in the CMD53 (multiple block) read sequence is transferred, RWREQ in SDIO_MODE is set to 1.

[Clearing condition]

- When 0 is written to EXWT.

40.2.22 SDIO_INFO1_MASK : SDIO INFO1 Interrupt Mask Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x070

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EXWTM	EXPUB52M	—	—	—	—	—	—	—	—	—	—	—	—	—	IOIRQM
Value after reset:	1	1	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Function	R/W
0	IOIRQM	IOIRQ Interrupt Mask Control 0: Do not mask IOIRQ interrupts 1: Mask IOIRQ interrupts	R/W
2:1	—	These bits are read as 1.The write value should be 1.	R/W
13:3	—	These bits are read as 0. The write value should be 0.	R/W
14	EXPUB52M	EXPUB52 Interrupt Request Mask Control 0: Do not mask EXPUB52 interrupt requests 1: Mask EXPUB52 interrupt requests	R/W
15	EXWTM	EXWT Interrupt Request Mask Control 0: Do not mask EXWT interrupt requests 1: Mask EXWT interrupt requests	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The SDIO_INFO1_MASK register enables or disables interrupt requests from the status flags in the SDIO_INFO1 register. See Table 40.5 for details on the relationship between the status flags and the requested interrupt source.

40.2.23 SD_DMAEN : DMA Mode Enable Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x1B0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DMAEN	—
Value after reset:	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	DMAEN	DMA Transfer Enable*1 *2 0: Disable use of DMA transfer to access SD_BUF0 register 1: Enable use of DMA transfer to access SD_BUF0 register	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	—	This bit is read as 1. The write value should be 1.	R/W
11:5	—	These bits are read as 0. The write value should be 0.	R/W
12	—	This bit is read as 1. The write value should be 1.	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Do not rewrite this bit when the SD_INFO2.CBSY bit is 1.
Note 2. When the SD_INFO2_MASK.BWEM bit is 0 or the SD_INFO2_MASK.BREM bit is 0, set the SD_DMAEN.DMAEN bit to 0. When the SD_DMAEN.DMAEN bit is 1, set the SD_INFO2_MASK.BWEM bit to 1 and the SD_INFO2_MASK.BREM bit to 1.

The SD_DMAEN register enables or disables DMA transfers.

DMAEN bit (DMA Transfer Enable)

When using DMA transfer to access the SD buffer, set the DMAEN bit to 1 before setting the SD_CMD register.

40.2.24 SOFT_RST : Software Reset Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x1C0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SDRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Function	R/W
0	SDRST	Software Reset Control 0: Reset SD/MMC Host Interface software 1: Cancel reset of SD/MMC Host Interface software	R/W
2:1	—	These bits are read as 1. The write value should be 1.	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Table 40.4 lists the bits and flags initialized by SD/MMC Host Interface software reset.

Table 40.4 Bits and flags initialized by SD/MMC Host Interface software reset

Register	Bit/flag
SD_STOP	SEC, STP
SD_INFO1	RSPEND, ACEND
SD_INFO2	CMDE, CRCE, ENDE, DTO, ILW, ILR, RSPTO, BRE, BWE, SD_CLK_CTRLEN, CBSY, ILA
SD_CLK_CTRL	CLKEN
SD_OPTION	CTOP[3:0], TOP[3:0], TOUTMASK, WIDTH8, WIDTH
SD_ERR_STS1	CMDE0, CMDE1, RSPLENE0, RSPLENE1, RDLENE, CRCLENE, RSPCRCE0, RSPCRCE1, RDCRCE, CRCTKE, CRCTK[2:0]
SD_ERR_STS2	RSPTO0, RSPTO1, BSYTO0, BSYTO1, RDTO, CRCTO, CRCBSYTO
SDIO_INFO1	IOIRQ, EXPUB52, EXWT
SDIF_MODE	NOCHKCR

40.2.25 SDIF_MODE : SD Interface Mode Setting Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x1CC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	NOCHKCR	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0*1	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	NOCHKCR	CRC Check Mask CRC check mask bit for MMC test commands. Set when CRC16 or CRC status value check is not executed. 0: Enable CRC check 1: Disable CRC Check (ignore CRC16 valued when reading and ignore CRC status value when writing)	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.

NOCHKCR bit (CRC Check Mask)

The NOCHKCR bit is used for MMC test commands. This bit is set when CRC16 or CRC status value check is not executed.

40.2.26 EXT_SWAP : Swap Control Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x1E0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	BRSWP	BWSWP	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	BWSWP	SD_BUF0 Swap Write*1 0: Normal write operation 1: Swap the byte endian order before writing to SD_BUF0 register	R/W
7	BRSWP	SD_BUF0 Swap Read*1 0: Normal read operation 1: Swap the byte endian order before reading SD_BUF0 register	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Do not rewrite this bit when the SD_INFO2.CBSY flag is 1.

The EXT_SWAP register selects whether or not the byte endian order is swapped when accessing the SD_BUF0 register. See section 40.3.1. SD/MMC Interface for details on the differences in accessing the SD_BUF0 register based on the EXT_SWAP register value.

40.3 Operation

40.3.1 SD/MMC Interface

When data is read from the SD card/MMC, the process is as follows:

1. The SD/MMC Host Interface receives data from the SD card/MMC through the SDnDAT signal (see Figure 40.2 and Figure 40.3).
2. The received data is stored in SD_BUF of the MMC Host Interface (see Figure 40.4).

3. The data stored in SD_BUF is read from SD_BUF0 (see Figure 40.5).

When data is written to the SD card/MMC, the specified procedure is reversed.

When accessing SD_BUF0, pay attention to the transfer order in SDnDAT and the store order in SD_BUF. If required, you can change the byte endian of the data read from or written to SD_BUF0 using the SDSWAP register. See Figure 40.6.

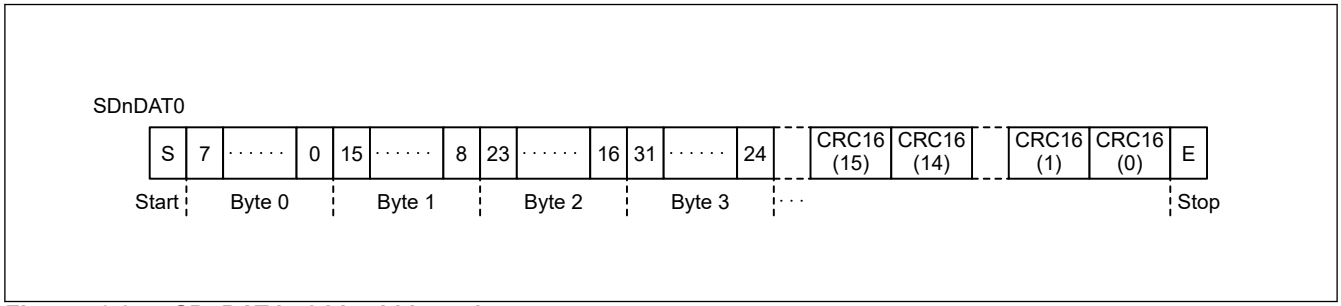

Figure 40.2 SDnDAT in 1-bit width mode

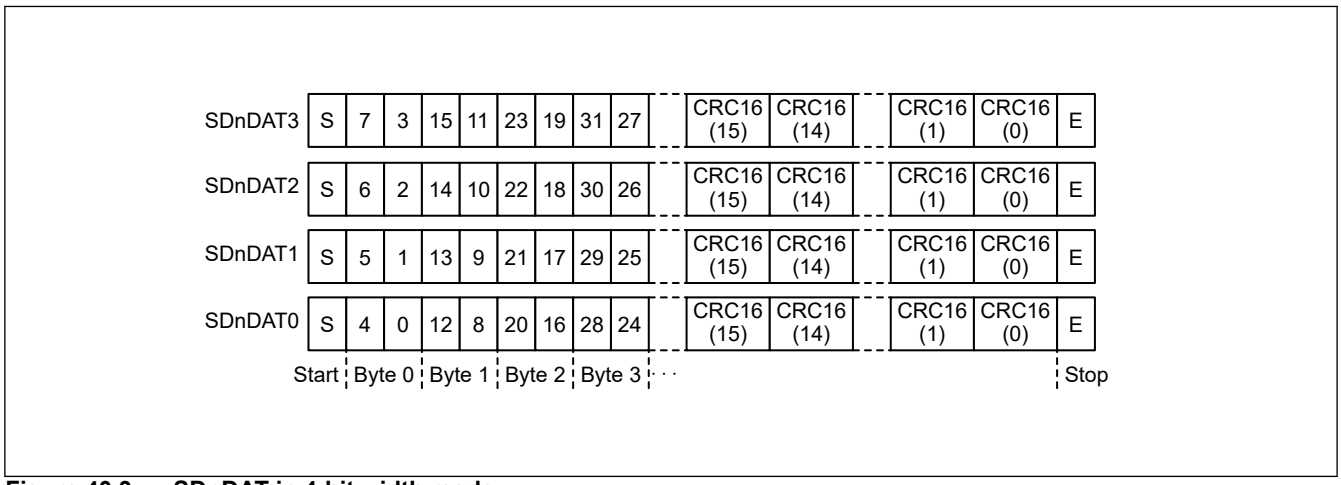

Figure 40.3 SDnDAT in 4-bit width mode

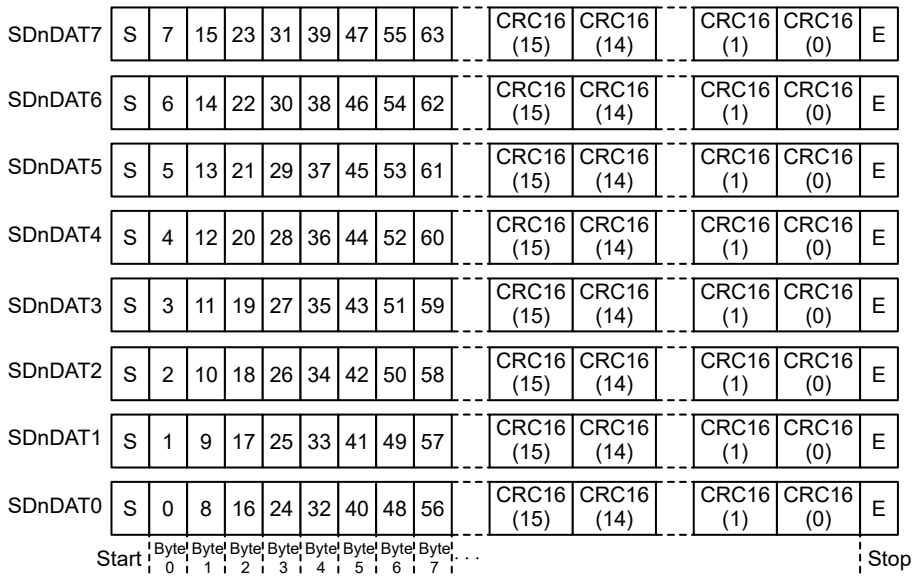

Figure 40.4 SDnDAT in 8-bit width mode

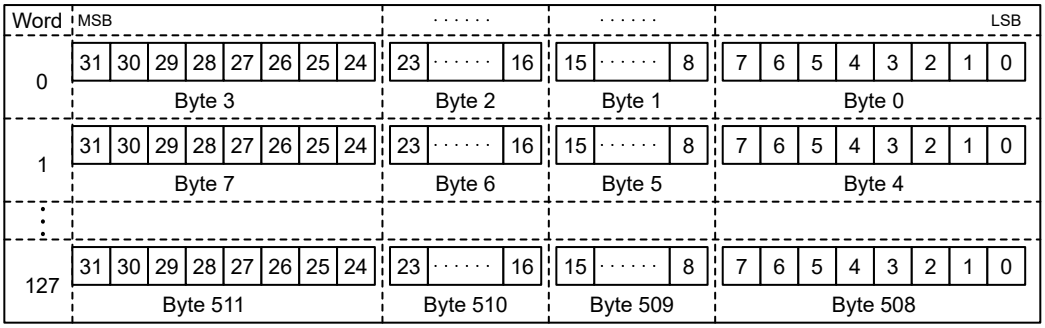

Figure 40.5 SD_BUF store data

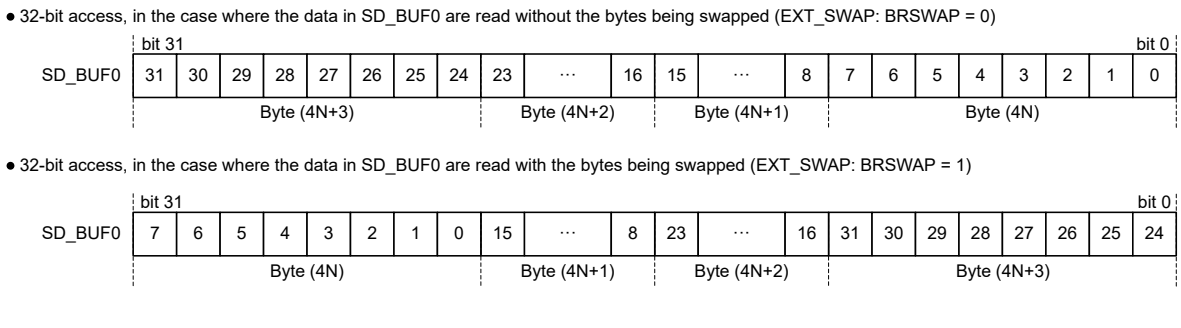

Figure 40.6 Read from SD_BUF0

40.3.2 Card Detect/Write Protect

40.3.2.1 Card detect

The SD/MMC Host Interface has two types of card detect functions.

(1) Card detect with SDnCD (n = 0, 1)

Figure 40.7 shows the timing for card detect using SDnCD. SDnCD is connected to the card socket and pulled up on the host device. The resistance of the pull-up resistor is determined by the specification of the SD/MMC host device.

(2) Card insertion

SDnCD is pulled down when a card is inserted. At this point, if SDnCD is pulled down for the Mcycle period (set in SD_OPTION), SDCDIN in SD_INFO1 is set to 1. It is cleared by writing 0.

(3) Card removal

SDnCD is pulled up when a card is removed. At this point, if SDnCD is pulled up for the Mcycle period (set in SD_OPTION), SDCDRM in SD_INFO1 is set to 1. It is cleared by writing 0.

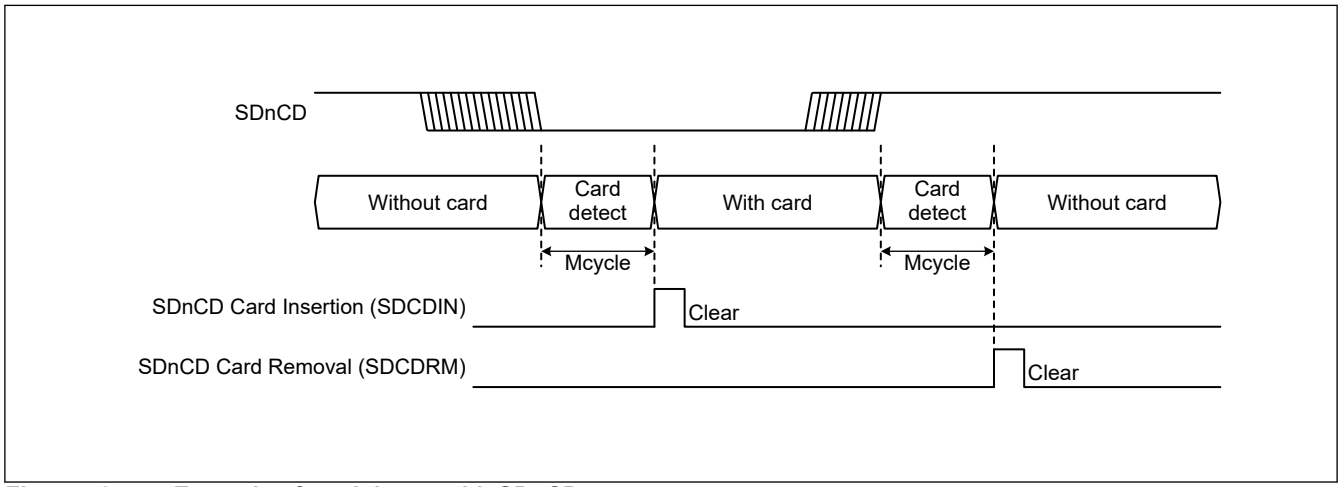

Figure 40.7 Example of card detect with SDnCD

(4) SD card detect with SDnDAT3 (n = 0, 1)

Figure 40.8 shows the timing when the SD card is detected with SDnDAT3. In addition, SDnDAT3 is pulled down by the host device, and the resistance value for pulling down is determined by the specification of the SD host device.

(5) Card insertion

When an SD card is inserted, SDnDAT3 is pulled up and SDD3IN in SD_INFO1 is set to 1. It is cleared by writing 0.

(6) Card removal

When an SD card is removed, SDnDAT3 is pulled down and SDD3RM in SD_INFO1 is set to 1. It is cleared by writing 0.

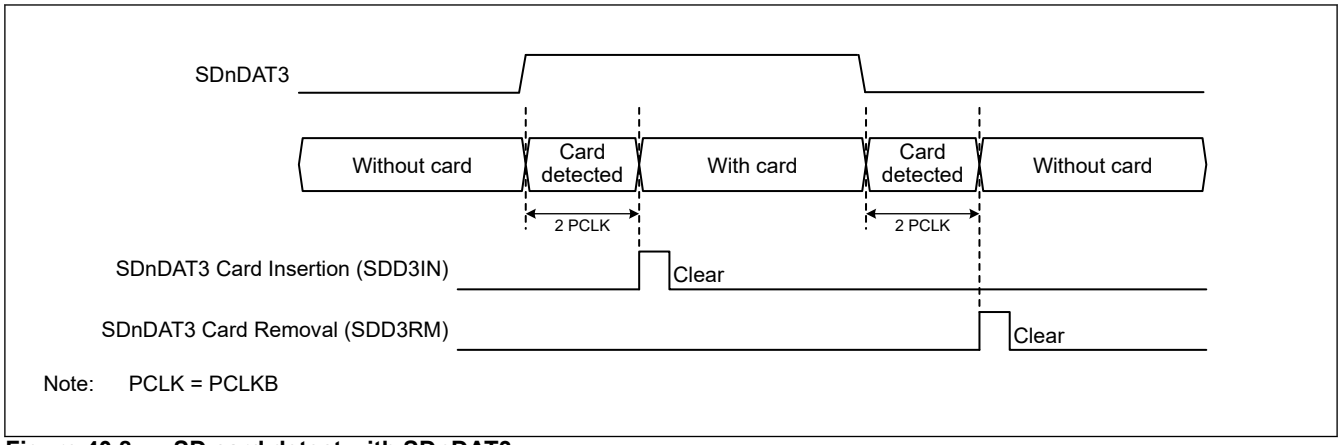

Figure 40.8 SD card detect with SDnDAT3

40.3.2.2 Write protect

The SD/MMC Host Interface has two types of write protect functions.

(1) Write protect with SDnWP (n = 0, 1)

SDnWP is connected to the card socket and pulled up or pulled down by the card insertion. The selection of pulling up or pulling down and the resistance value is determined by the specification of the SD host device. When the SDnWP state is reflected to SDWPMON in SD_INFO1, the write protect state is set after the SD card is inserted.

(2) Write protect with command

The internal write protection of the card and the lock/unlock operation of the card are realized by the command.

40.3.3 Interrupt Request and DMA Transfer Request

40.3.3.1 Interrupts

Table 40.5 lists the SDHI interrupt sources. The SDHI requests an interrupt when:

- The status flags in registers SD_INFO1, SD_INFO2, and SDIO_INFO1 set to 1.
- The associated bits in the SD_INFO1_MASK, SD_INFO2_MASK, and SDIO_INFO1_MASK registers are 0.

When clearing the status flags in registers SD_INFO1, SD_INFO2, and SDIO_INFO1, write 0 to the status flags to be cleared and write 1 to the status flags that are not being cleared.

Table 40.5 Interrupt sources

Interrupt sources	Status flag register		Interrupt mask register		Interrupt name
	Register symbol	Bit symbol	Register symbol	Bit symbol	Ch n (n = 0, 1)
Card Access Interrupt (CACI)	SD_INFO1	ACEND	SD_INFO1_MASK	ACENDM	SDHI_MMCn_ACCS
		RSPEND		RSPENDM	
	SD_INFO2	ILA	SD_INFO2_MASK	ILAM	
		BWE		BWEM	
		BRE		BREM	
		RSPTO		RSPTOM	
		ILR		ILRM	
		ILW		ILWM	
		DTO		DTOM	
		ENDE		ENDEM	
		CRCE		CRCEM	
		CMDE		CMDEM	
SDIO Access Interrupt (SDACI)	SDIO_INFO1	EXWT	SDIO_INFO1_MASK	EXWTM	SDHI_MMCn_SDIO
		EXPUB52		EXPUB52M	
		IOIRQ		IOIRQM	
Card Detect Interrupt (CDETI)	SD_INFO1	SDD3IN	SD_INFO1_MASK	SDD3INM	SDHI_MMCn_CARD
		SDD3RM		SDD3RMM	
		SDCDIN		SDCDINM	
		SDCDRM		SDCDRMM	

40.3.3.2 DMA transfer requests (SDHI_MMCn_ODMSDBREQ, n = 0, 1)

The SD/MMC Host Interface has two types of DMA transfer requests.

(1) SD_BUF write DMA transfer request

- When the BWE bit in SD_INFO2 is set to 1 while the DMAEN bit in SD_DMAEN is set to 1, the SD_BUF write DMA transfer request is asserted.
- The SD_BUF write DMA transfer request is negated when the last data in one block (based on the transfer data size set in SD_SIZE) is transferred. The SD_BUF write DMA transfer request is also negated by clearing the SDRST bit in SOFT_RST to 0 or setting the STP bit in SD_STOP to 1. However, if a communications error or timeout occurs at the DMA transfer, the SD_BUF write DMA transfer request is not negated.
- The BWE bit in SD_INFO2 is cleared after transfer of the last data in one block following a request for writing to SD_BUF by DMA transfer.
- The number of DMA transfers must be n × one block. (n = integer, one block = the transfer data size set in SD_SIZE)
- When the IOABT bit in SDIO_MODE is set to 1, the SD_BUF write DMA transfer request is negated.
- The DMA transfer request is also negated by clearing the DMAEN bit to 0. However, the DMA transfer request is asserted again when the DMAEN bit is set to 1 before writing to SD_CMD.
- Because the BWE bit in SD_INFO2 is not cleared in response to setting the STP/IOABT bit, or to a communications error or timeout, clear the bit to 0 before issuing the next command. The next request to write to SD_BUF by DMA transfer is not issued while the BWE bit is set.

(2) SD_BUF read DMA transfer request

- When the BRE bit in SD_INFO2 is set to 1 while the DMAEN bit in the SD_DMAEN register is set to 1, the SD_BUF read DMA transfer request is asserted.

- The SD_BUF read DMA transfer request is negated when the last data in one block (based on the transfer data size set in SD_SIZE) is transferred. The SD_BUF read DMA transfer request is also negated by clearing the SDRST bit in SOFT_RST to 0 or setting the STP bit in SD_STOP to 1. However, if a communications error or timeout occurs at the DMA transfer, the SD_BUF read DMA transfer request is not negated.
- The BRE bit in SD_INFO2 is cleared after transfer of the last data in one block following a request to write to SD_BUF by DMA transfer.
- The number of DMA transfers must be n × one block. (n = integer, one block = the transfer data size set in SD_SIZE)
- When the IOABT bit in SDIO_MODE is set to 1, the SD_BUF read DMA transfer request is negated.
- The DMA transfer request is also negated by clearing the DMAEN bit to 0. However, the DMA transfer request is asserted again when the DMAEN bit is set to 1 before writing to SD_CMD.
- Because the BRE bit in SD_INFO2 is not cleared in response to setting the STP/IOABT bit or in response to a communications error or timeout, clear the bit to 0 before issuing the next command. The next request to write to SD_BUF by DMA transfer is not issued while the BRE bit is set.

40.3.4 Communication Errors and Timeouts

When a communication error or timeout error occurs, depending on the type of error, the associated status flag in the SD_INFO2 register sets to 1. Also, depending on the source of the error, the associated flag in the SD_ERR_STS1 or SD_ERR_STS2 register sets to 1.

The status flags in registers SD_ERR_STS1 and SD_ERR_STS2 clear to 0 by writing to the SD_CMD register, or by setting the SOFT_RST.SDRST bit to 0.

Table 40.6 Communication errors

Communication error	Interrupt flag register		Error status register		This occurs when…
	Register symbol	Bit symbol	Register symbol	Bit symbol	
End bit error	SD_INFO2	ENDE	SD_ERR_STS1	CRCLENE	The CRC status token length is in error
				RDLENE	The read data length is in error
				RSPLENE1	The response length is in error*1
				RSPLENE0	The response length is in error*2
CRC error		CRCE		CRCTKE	The CRC status token is in error
				RDCRCE	There is a CRC error in the read data
				RSPCRCE1	There is a CRC error in the response*1
				RSPCRCE0	There is a CRC error in the response*2
Command error		CMDE		CMDE1	The command index field value for the transmitted command and received response do not match*1
				CMDE0	The command index field value for the transmitted command and received response do not match*2

Note 1. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

Table 40.7 Timeouts

Timeout	Interrupt flag register		Error status register		This occurs when…
	Register symbol	Bit symbol	Register symbol	Bit symbol	
Response timeout	SD_INFO2	RSPTO	SD_ERR_STS2	RSPTO1	A response is not received even after a minimum of 640 SDHI clock cycles elapse*1
				RSPTO0	A response is not received even after a minimum of 640 SDHI clock cycles elapse*2
Data timeout (excluding response timeout)		DTO		CRCBSYTO	After the CRC status token is received, the SDHI is busy for at least the period set*3
				CRCTO	After the write data is transmitted, the CRC status token is not received even after at least the period set*3 elapses
				RDTO	After the read command is issued, the read data is not received even after at least the period set*3 elapses
					After the read data is received, the next block read data is not received even after at least the period set*3 elapses
					After the SDHI exits the read wait state, the next block read data is not received even after at least the period set*3 elapses
				BSYTO1	After CMD12 is issued during the command sequence, the SDHI is busy for at least the period set*3
				BSYTO0	After the R1b response is received, the SDHI is busy for at least the period set*3 (a command other than CMD12 is issued during the command sequence)

Note 1. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP bit is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 3. The period is set in the SD_OPTION.TOP[3:0] bits.

40.3.5 Command without Data Transfer (SD/MMC)

The following legend is used for description of register read/write.

W (register name, value): Write to register

R (register name): Read from register

Figure 40.9 and Figure 40.10 show example flows.

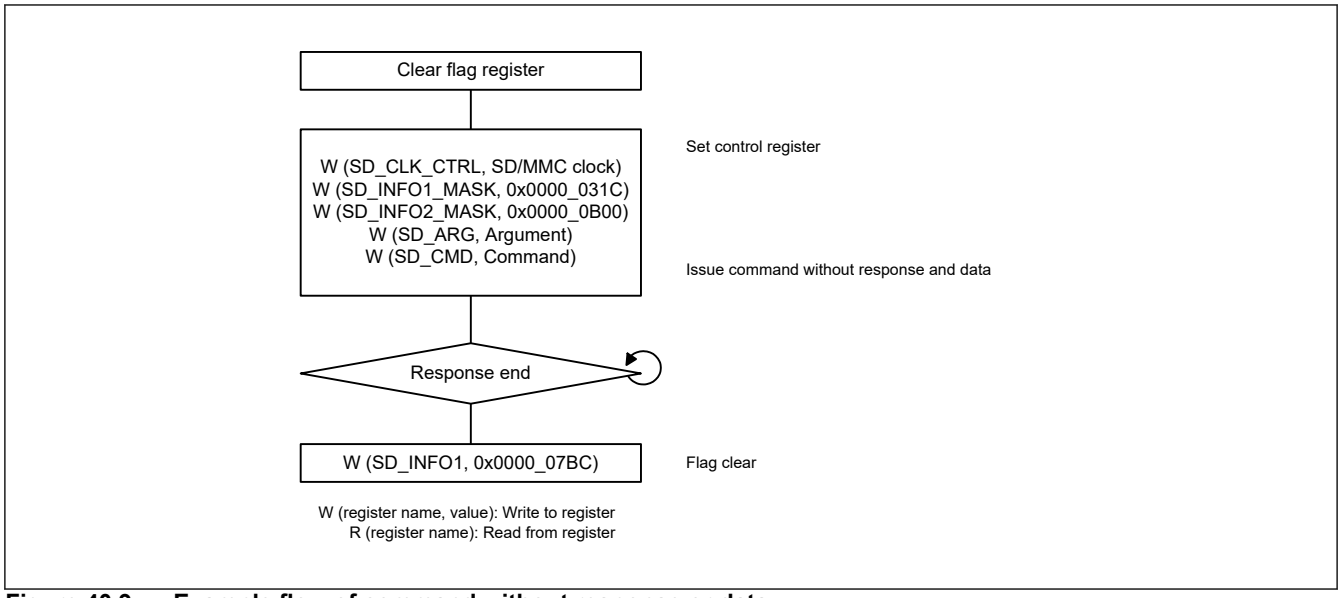

Figure 40.9 Example flow of command without response or data

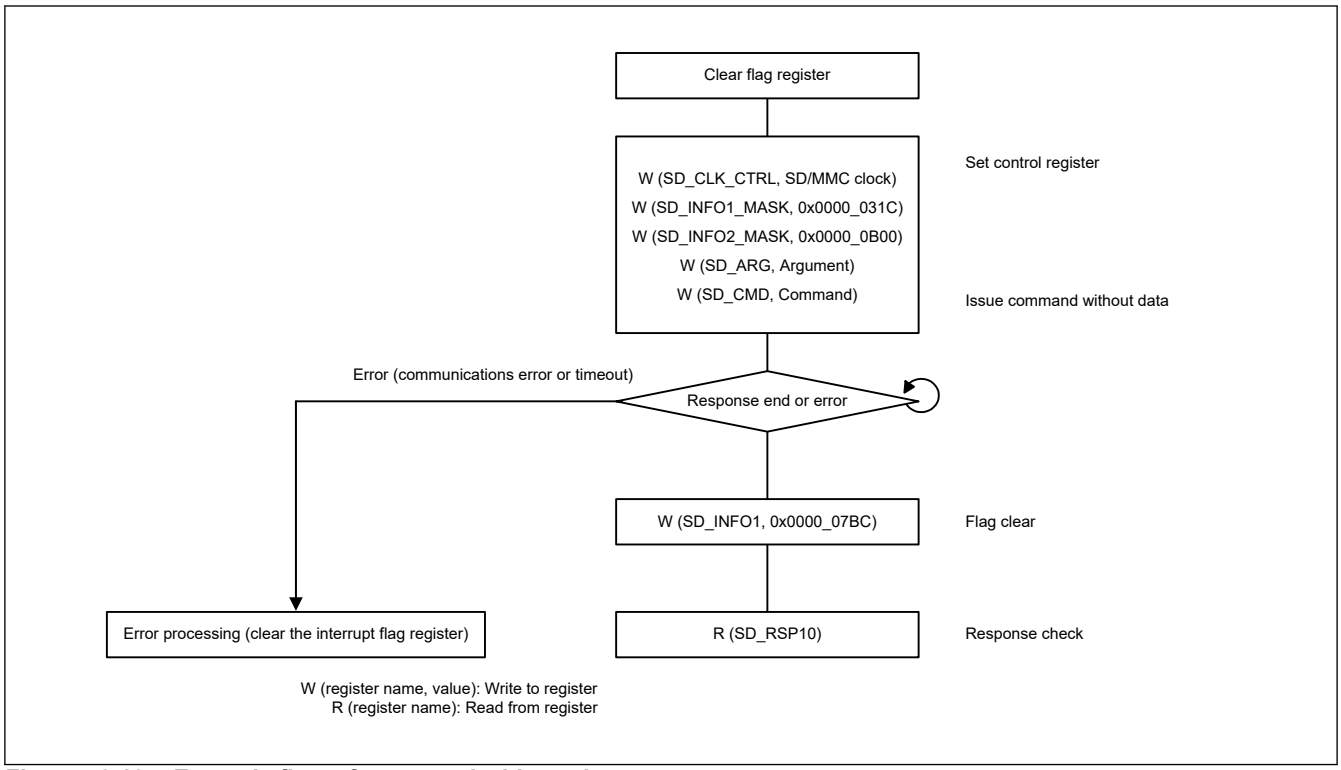

Figure 40.10 Example flow of command without data

40.3.5.1 Operation for command without data transfer

The operation is described in the following section.

(1) Command without response and data

a. Flag register clear
First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)

b. Control register set
Set the SD/MMC clock and interrupt masking. (SD_CLK_CTRL, SD_INFO1_MASK, and SD_INFO2_MASK)

c. Command issue
Set CMD argument in SD_ARG and write to SD_CMD.

Accordingly, CMD is issued, and the operation is started.

d. Flag clear
When transmission of a command is completed, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0.

(2) Command without data

a. Flag register clear
First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)

b. Control register set
Set the SD/MMC clock and interrupt masking. (SD_CLK_CTRL, SD_INFO1_MASK, and SD_INFO2_MASK)

c. Command issue
Set CMD argument in SD_ARG and write to the SD_CMD.
Accordingly, CMD is issued, and the operation is started.

d. Flag clear
When a response is received, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0.

e. Read a response from SD_RSP10. Additionally, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

40.3.6 Single Block Read (SD/MMC)

Figure 40.11 shows an example flow of a single block read operation.

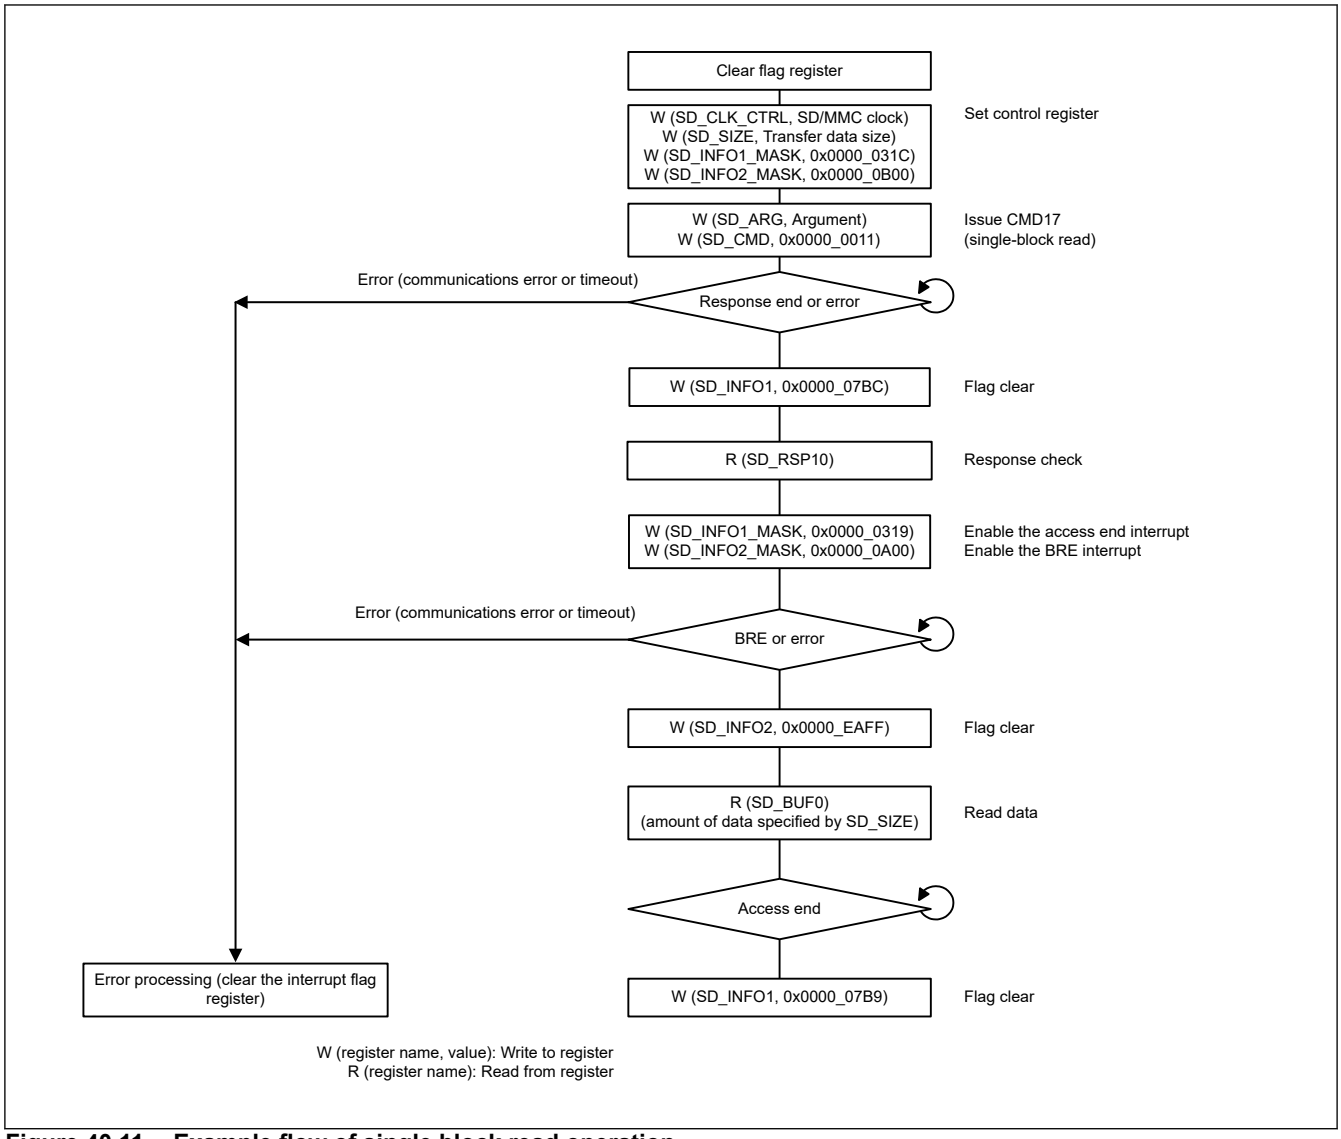

Figure 40.11 Example flow of single block read operation

40.3.6.1 Single block read operation

The operation of the single block read is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set
Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).

c. Command issue (CMD17)
Set CMD17 argument in SD_ARG and write 0x0000_0011 to SD_CMD. CMD17 is issued and the single block read operation is started.

d. Response check
On receiving the response, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0 and read the response from SD_RSP10. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP or the IOABT bit in SDIO_MODE to 1. In addition, this causes CMD12 and CMD52 to not be issued. If the ACEND bit (access end) in SD_INFO1 is set, halting the command sequence also leads to the generation of an interrupt.

e. Data receive from SD card/MMC and data read

Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_0A00 to SD_INFO2_MASK to enable the BRE interrupt. When the data received from the SD card/MMC is completed, the BRE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BRE bit to 0 and read the amount of data specified in SD_SIZE from SD_BUF0.
A communication error or timeout might be generated if data is being received while reading of SD_BUF0 is in progress.

f. Operation complete
When the data read from SD_BUF0 is completed, ACEND (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear ACEND to 0 to end the single block read operation.
Additionally, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

40.3.7 Single Block Write (SD/MMC)

Figure 40.12 shows an example flow of a single block write operation.

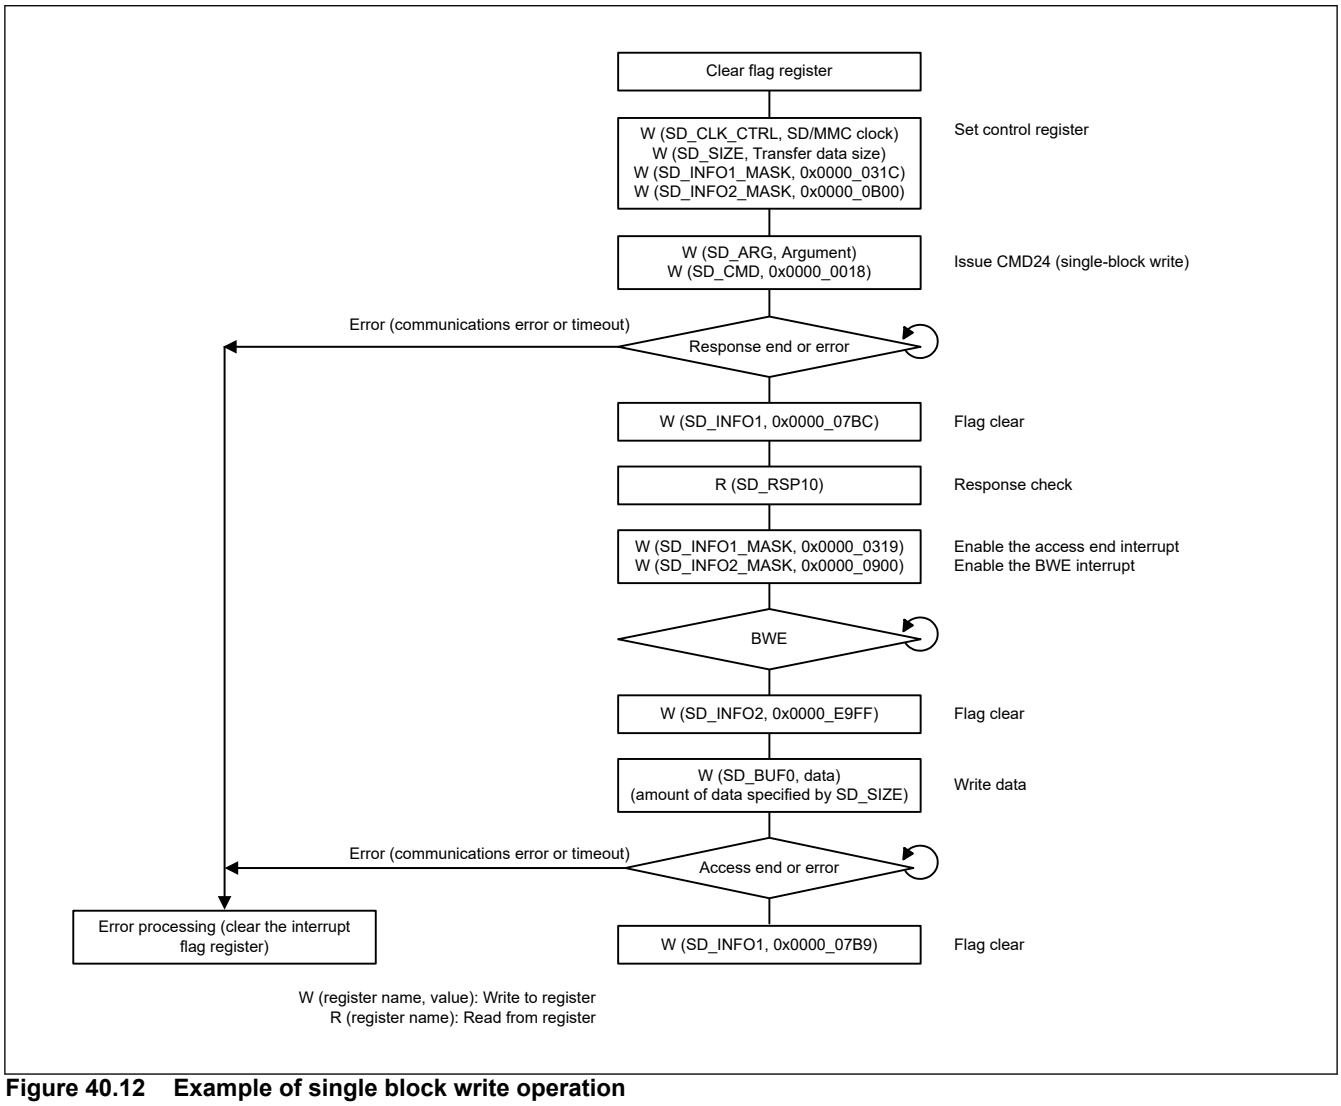

Figure 40.12 Example of single block write operation

40.3.7.1 Single block write operation

The operation of the single block write is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set

Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).

c. Command issue (CMD24)
Set CMD24 argument in SD_ARG and write 0x0000_0018 to SD_CMD. CMD24 is issued and the single block write operation is started.

d. Response check
On receiving the response, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0 and read the response from SD_RSP10. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP or the IOABT bit in SDIO_MODE to 1. In addition, this causes CMD12 and CMD52 to not be issued. If the ACEND bit (access end) in SD_INFO is set, halting the command sequence also leads to the generation of an interrupt.

e. Data write and data transmit to SD card/MMC
Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_0900 to SD_INFO2_MASK to enable the BWE interrupt. When SD_BUF0 is ready for the data to be written, the BWE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified in SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card. Then, the CRC status and busy state are received from the SD card/MMC.
However, a communications error or timeout might be generated if data is being transmitted after writing to SD_BUF0.

f. Operation complete
When the CRC status and busy state are received from the SD card/MMC, ACEND (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the ACEND bit to 0 to end the single block write operation.
In addition, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

40.3.8 Multiple Block Read (SD/MMC)

Figure 40.13 shows an example flow of a multiple block read operation.

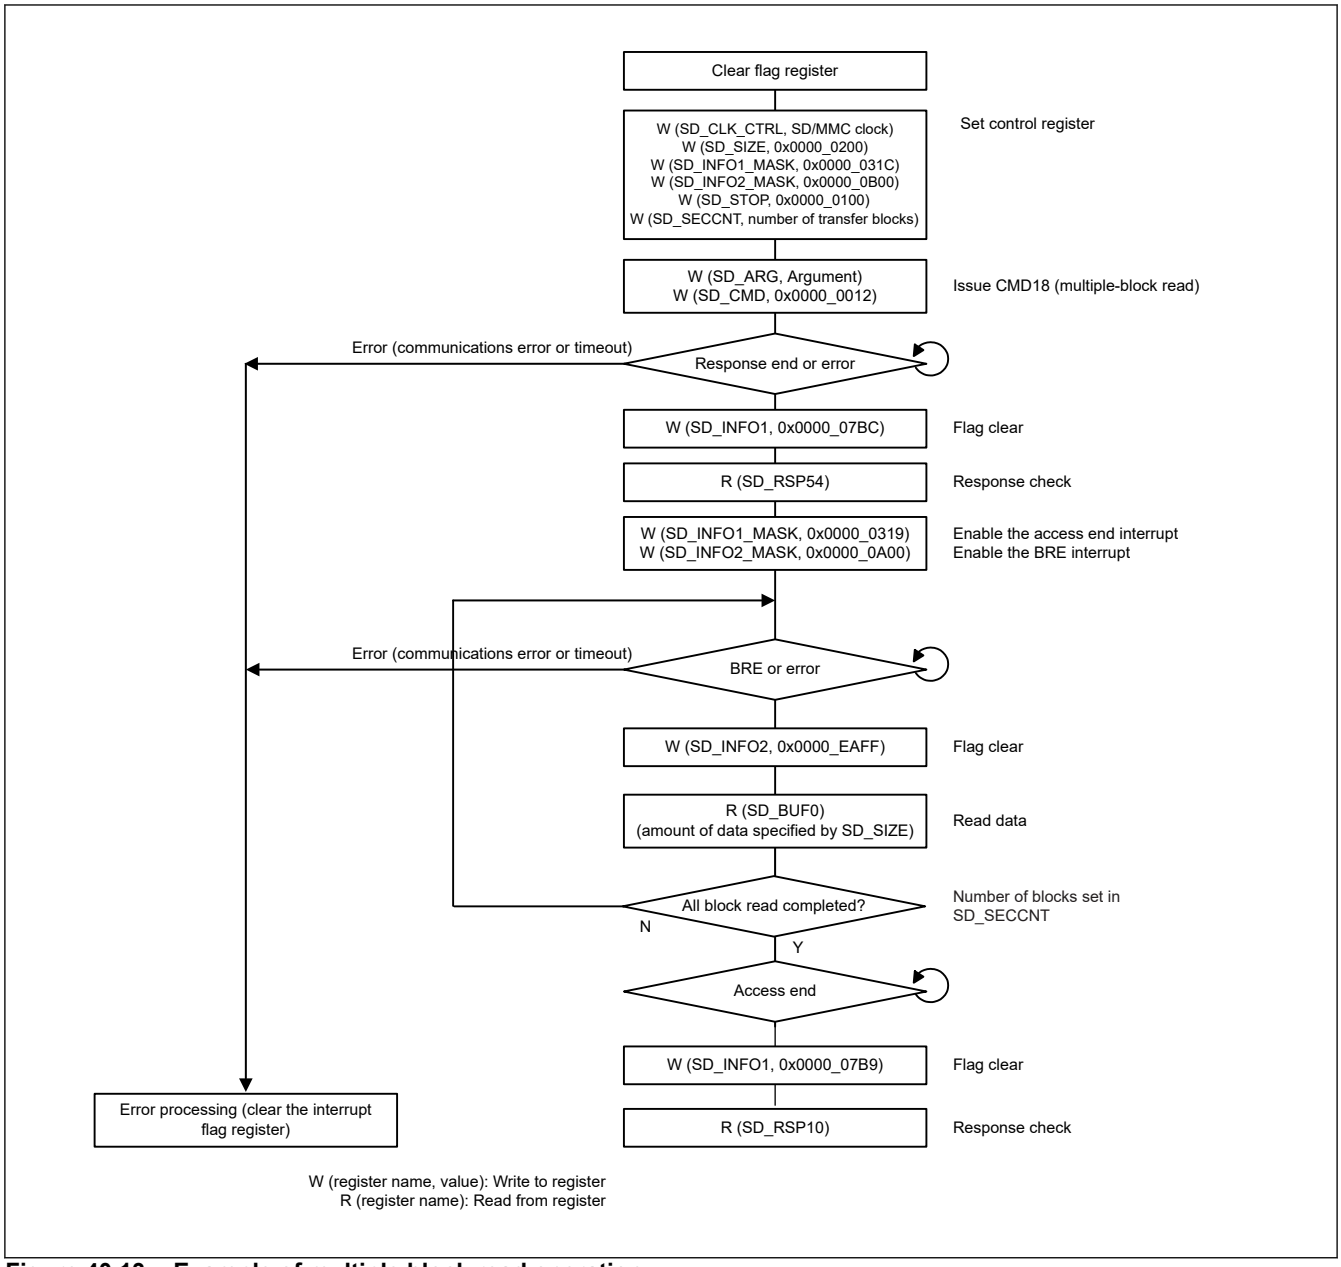

Figure 40.13 Example of multiple block read operation

40.3.8.1 Multiple block read operation

The operation of the multiple block read is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set
Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).
Set SEC in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.

c. Command issue (CMD18)
Set CMD18 argument in SD_ARG and write 0x0000_0012 to SD_CMD. CMD18 is issued and the multiple block read operation is started.

d. Response check
On receiving the response, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0 and read the response from SD_RSP54. If the result of response decoding is an error, the command sequence can be

halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued and the response received. If the command sequence is halted because the access end interrupt is enabled, an interrupt is generated when the ACEND bit (access end) bit in SD_INFO1 sets to 1 on completion of response reception. Clear the ACEND bit to 0 and read the response.

e. Data receive from SD card/MMC and data read
Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_0A00 to SD_INFO2_MASK to enable the BRE interrupt. When one-block data received from the SD card/MMC is completed, the BRE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BRE bit to 0 and read the amount of data specified in SD_SIZE from SD_BUF0. Doing this repeats transfer of the number of blocks set in SD_SECCNT. However, a communication error or timeout might be generated if data is being received while reading of SD_BUF0 is in progress. CMD12 is automatically issued to stop multiblock transfer with the number of blocks that is set to SD_SECCNT and the response is received. At this point, CMD12 argument is automatically set to 0x0000_0000.

f. Operation complete
When all-block data read and the CMD12 response received are completed, ACEND (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear ACEND to 0 to read the response. This is the end of multiple block read operation. In addition, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

40.3.9 Multiple Block Write (SD/MMC Using Internal Timer)

Figure 40.14 shows an example flow of a multiple block write using internal timer.

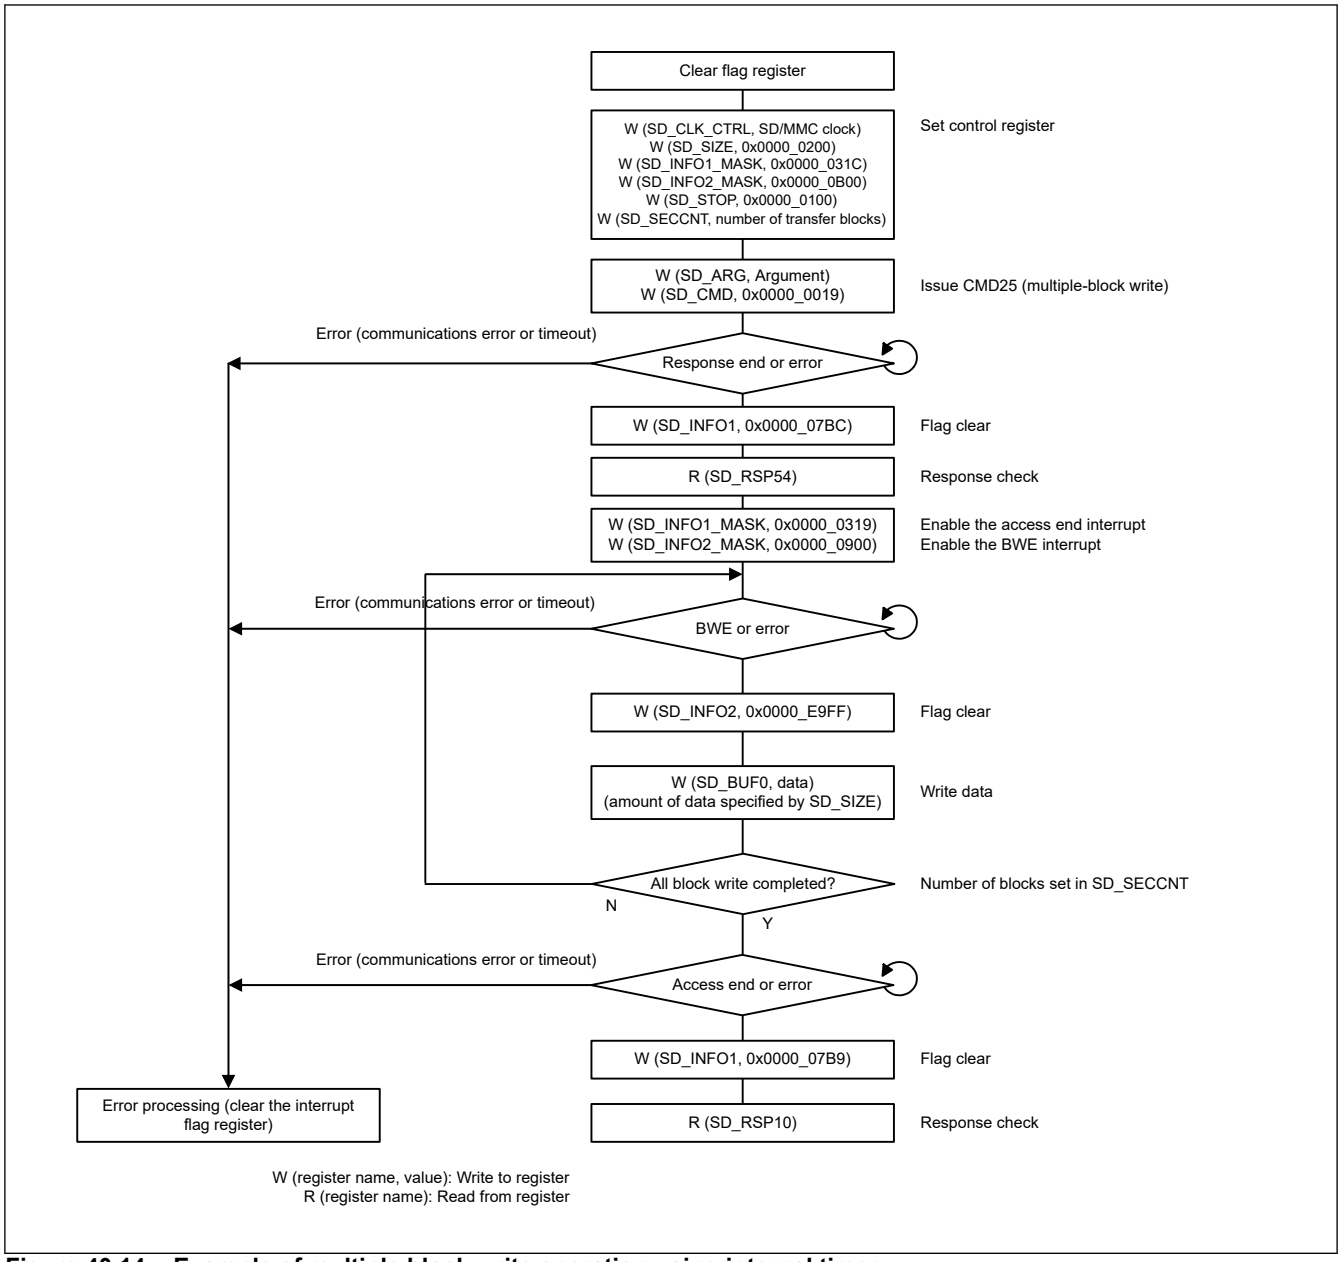

Figure 40.14 Example of multiple block write operation using internal timer

40.3.9.1 Multiple block write operation using internal timer

The operation of the multiple block write is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set
Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).
Set the SEC bit in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.

c. Command issue (CMD25)
Set CMD25 argument in SD_ARG and write 0x0000_0019 to SD_CMD. CMD25 is issued and the multiple block write operation is started.

d. Response check
On receiving the response, the RSPEND bit (response end) in SD_INFO1 is set to 1 to generate an interrupt.
Clear the RSPEND bit to 0 and read the response from SD_RSP54. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to

be issued and the response received. If the command sequence is halted because the access end interrupt is enabled, an interrupt is generated by when the ACEND bit (access end) bit in SD_INFO1 sets to 1 on completion of response reception. Clear the ACEND bit to 0 and read the response.

e. Data write and data transmit to SD card/MMC
Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_0900 to SD_INFO2_MASK to enable the BWE interrupt. When SD_BUF0 is ready for the data to be written, the BWE bit in the SD_INFO2 resister is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified in SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card/MMC. The CRC status and busy state are received from the SD card/MMC. This repeats transfer of the number of blocks set in SD_SECCNT. However, a communication error or timeout might be generated if data is being received while writing to SD_BUF0 is in progress. CMD12 is automatically issued to stop multiblock transfer with the number of blocks which is set to SD_SECCNT and the response is received. At this point, CMD12 argument is automatically set to 0x0000_0000.

f. Operation complete
When all-block data transmit and the CRC status receive are completed, the ACEND bit (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the ACEND bit to 0 to read the response. This is the end of multiple block write operation. Additionally, perform error processing (clear the interrupt flag register) if a communications error or timeout occurs.

40.3.10 Multiple Block Write (MMC using external timer)

Figure 40.15 shows an example flow of a multiple block write using an external timer.

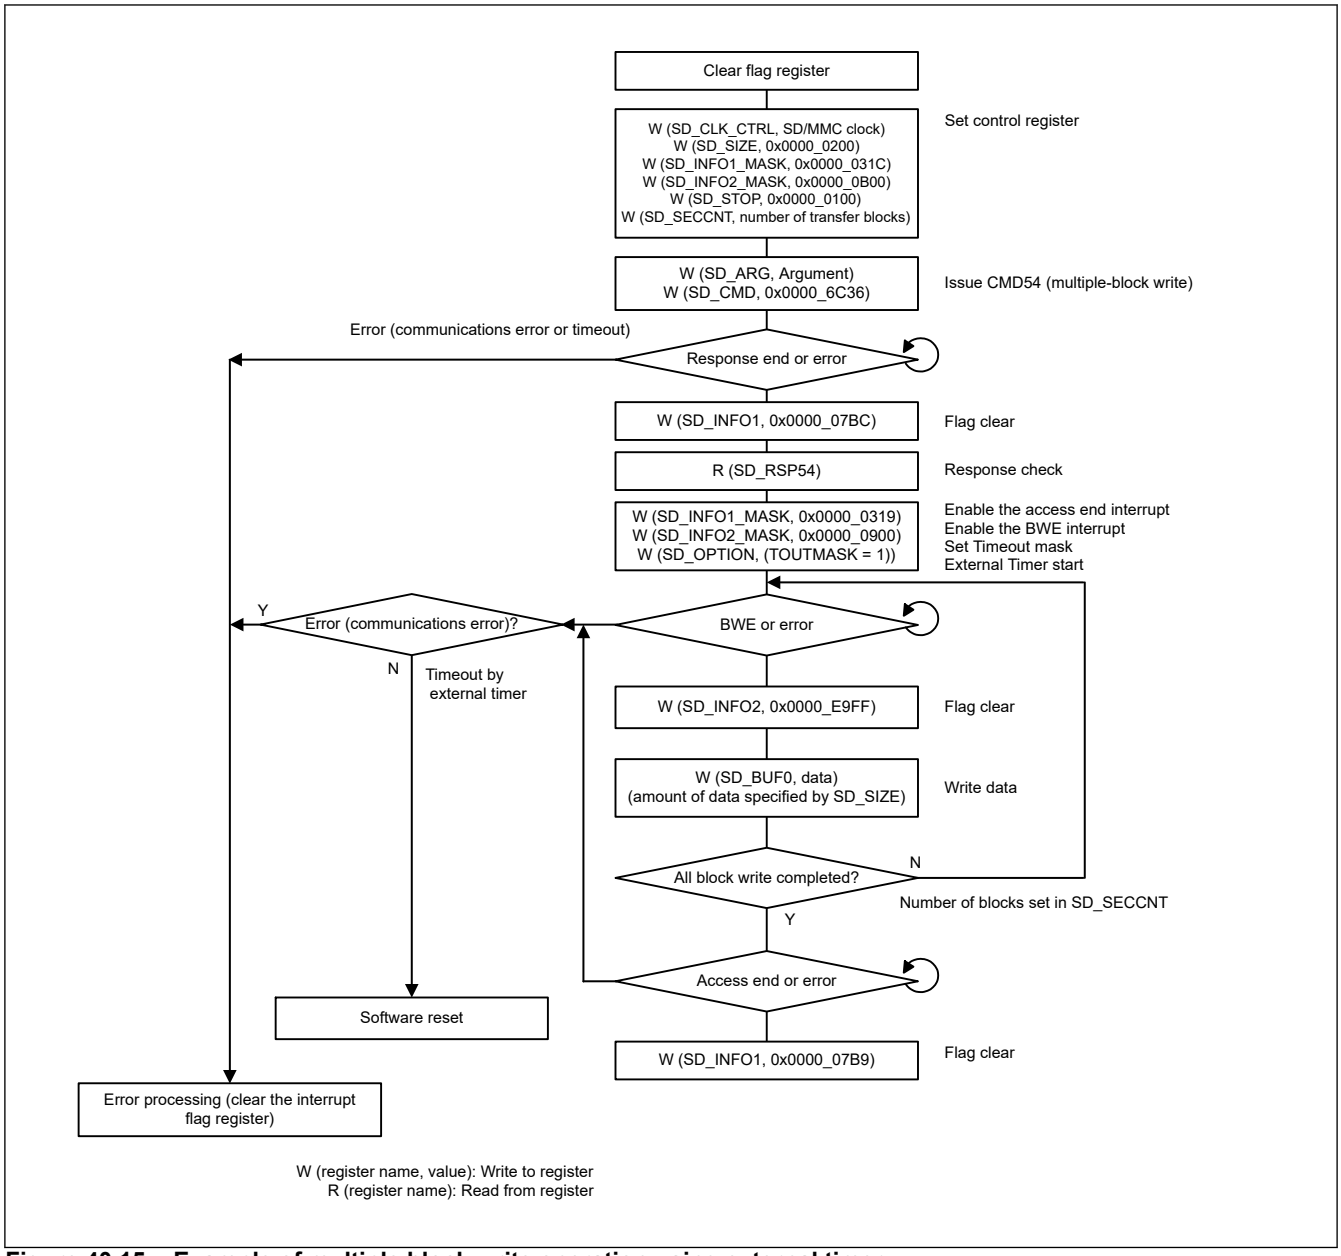

Figure 40.15 Example of multiple block write operation using external timer

40.3.10.1 Multiple block write operation using external timer

The operation of the multiple block write is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set
Set the MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).
Set the SEC bit in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.

c. Command issue (CMD54)
Set CMD54 Argument in SD_ARG and write 0x0000_6C36 to SD_CMD. CMD54 is issued and the multiple block write operation is started.

d. Response check
On receiving the response, the RSPEND bit (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the RSPEND bit to 0 and read the response from SD_RSP54. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued

and the response received. If the command sequence is halted because the access end interrupt is enabled, an interrupt is generated by when the ACEND bit (access end) bit in SD_INFO1 sets to 1 on completion of response reception. Clear the ACEND bit to 0 and read the response.

e. Data write and data transmit to MMC
Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt, write 0x0000_0900 to SD_INFO2_MASK to enable the BWE interrupt and set 1 to TOUTMASK of SD_OPTION to inactivate timeout. In addition, start external timer. When SD_BUF0 is ready for the data to be written, the BWE bit in the SD_INFO2 resister is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified in SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the MMC. The CRC status and busy state are received from the MMC. Doing this repeats transfer of the number of blocks set in SD_SECCNT. However, a communication error or timeout might be generated if data is being received while writing to SD_BUF0 is in progress.

f. Operation complete
When all-block data transmit and the CRC status receive are completed, the ACEND bit (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the ACEND bit to 0 to read the response. This is the end of multiple block write operation. Additionally, perform error processing (clear the interrupt flag register) if a communications error or timeout occurs when receiving response. Execute software reset if a timeout by external timer occurs when transmitting data.

40.3.11 IO_RW_DIRECT Command (SD: CMD52)

Figure 40.16 shows an example flow of an IO_DIRECT command (CMD52) operation.

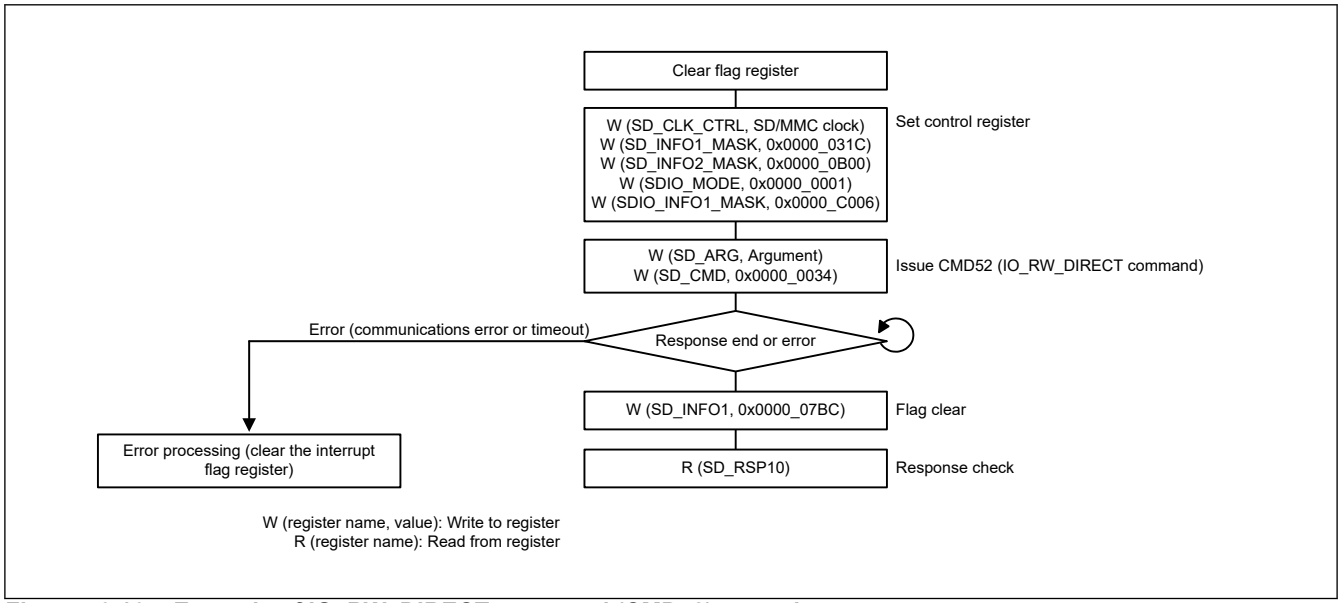

Figure 40.16 Example of IO_RW_DIRECT command (CMD52) operation

40.3.12 IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read)

40.4 Usage Notes

40.4.1 SD_BUF Illegal Write Access (SD/MMC)

When writing data to SD_BUF0 after the single block write or multi block write command is issued, the data of the size specified in SD_SIZE must be written.

If the data exceeds the size specified in SD_SIZE is written, the ERR4 bit in SD_INFO2 is set to 1. In addition, the data written to SD_BUF0 might not be transmitted and the SD_CLK_CTRLEN bit in SD_INFO2 is held at the value of 0. If this occurs, clearing the SDRST bit in SOFT_RST to 0 and then restoring its value to 1 clears the SD_CLK_CTRLEN bit to 1.

However, this does not apply to the single byte or three bytes when the SD_SIZE setting is odd, or to the fraction of bytes when the SD_SIZE setting is even (the 2 bytes that are not in a 4-byte unit), because the portion of dummy data writing is regarded as excess data and ignored.

40.4.2 Block Number Constraint for Multiple Block Read (SD)

When performing a multiple block read of one or two blocks, depending on the timing with which the SD card response register is read, the response value might not be read properly. To prevent this, do one of the following:

1. When receiving one or two blocks of data, use single block reading.
2. Read the response to CMD18 from SD_RSP54.

40.4.2.1 Mechanism of incorrect reading

Figure 40.25 shows the processing flows of the SDHI (hardware) operation and software operation when a multiple block read is performed on two blocks. As shown in the incorrect operation in Figure 40.25, when an interrupt is generated on reception of the CMD18 response and the timing with which the SD card response register (SD_RSP10) is read by the interrupt is delayed, the data during the CMD12 response reception or the CMD12 response might be read. This problem does not occur for multiple block reads of three or more blocks, because CMD12 is not issued until the block of data is read. The problem also does not occur for multiple block writes, because the CMD25 response is read before the block of data is sent.

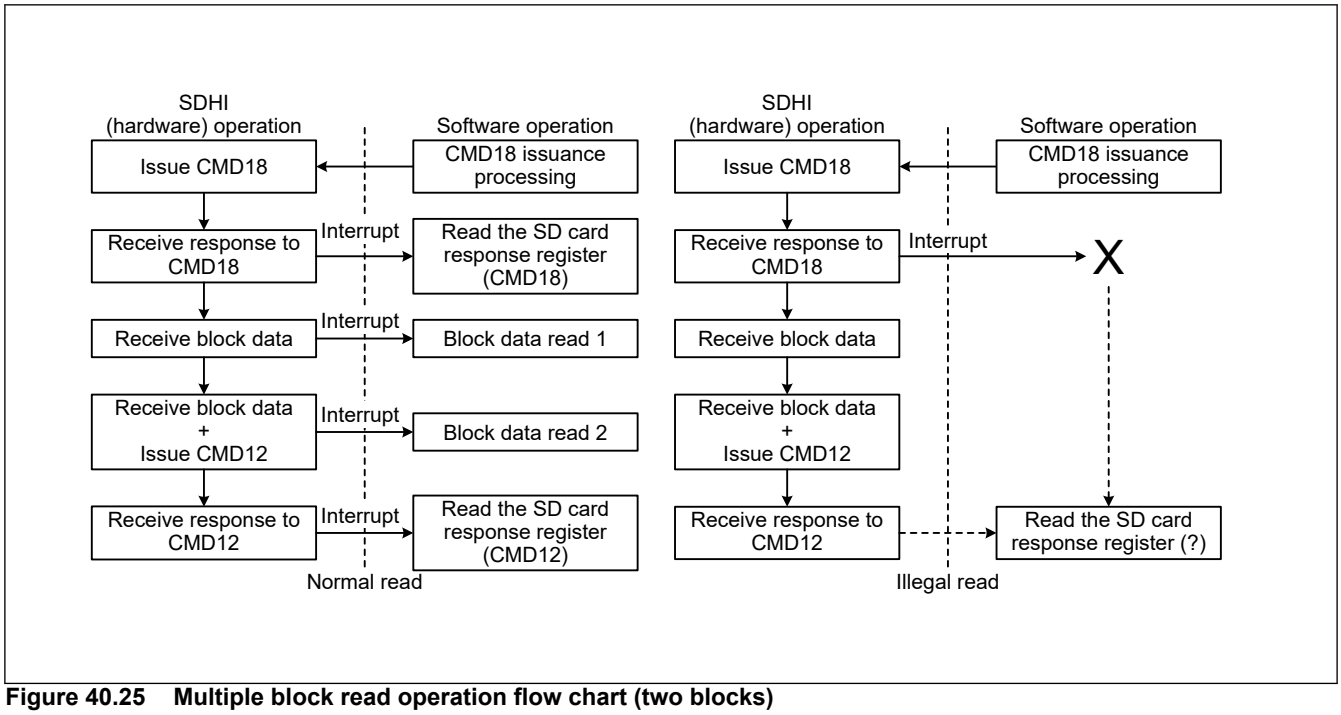

Figure 40.25 Multiple block read operation flow chart (two blocks)

40.4.3 Automatic Control of SD/MMC Clock Output (SD/MMC)

In the SD Card/MMC standard, 74 cycles of SD/MMC clock must be output before initialization of the card. For this reason, use automatic control of SD/MMC clock output after 74 cycles of SD/MMC clock are output. In addition, if

automatic control of SD/MMC clock output was in use, SD/MMC clock output is stopped on completion of the sequence for a communications error or timeout. When state transitions within the SD card/MMC are necessary after completion of the sequence, release automatic control of SD/MMC clock output and restart supply of the SD/MMC clock to the SD card/MMC.

40.4.4 Control of the C52PUB Setting for Multiple Block Write (SD)

If the C52PUB bit in SDIO_MODE is set to 1 during a sequence of multiple block write because of CMD53, CMD52 is not issued until SD_BUF becomes empty. For this reason, set the C52PUB bit after suspending writing to SD_BUF by using one of the following procedures, as appropriate:

(a) When DMA transfer is not in use

1. Before setting the C52PUB bit, suspend writing to SD_BUF by making the setting in SD_INFO2 to disable BWE interrupts.
2. Set the C52PUB bit in SDIO_MODE to 1 (so that CMD52 is issued when SD_BUF becomes empty).
3. After the RSPEND interrupt processing in SD_INFO1 because the issuing of CMD52 is completed, restart writing to SD_BUF by making the setting in SD_INFO2 to enable BWE interrupts.

(b) When DMA transfer is in use

1. Every time DMA transfer of the value set in SD_SIZE × n blocks (where n = 1, 2,…) proceeds, suspend writing to SD_BUF by DMA transfer before the C52PUB bit is set.
2. Set the C52PUB bit in SDIO_MODE to 1 (so that CMD52 is issued when SD_BUF becomes empty).
3. After the RSPEND interrupt processing in SD_INFO1 because the issuing of CMD52 is completed, restart writing to SD_BUF by DMA transfer.

40.4.5 Notes on SD_CLK_CTRL Register Settings (SD/MMC)

When the SD_CLK_CTRLEN bit in SD_INFO2 is 0, SD_CLK_CTRL cannot be written to. Before writing to SD_CLK_CTRL, you must check that the SD_CLK_CTRLEN bit in SD_INFO2 is 1.

40.4.6 Specification Limitations

1. The Suspend/Resume operation of the SDIO is not supported.
2. The SPI bus is not supported. (SD/MMC)
3. The shared bus and 8-bit SD bus of the embedded SDIO are not supported.
4. Stream transfer of MMC is not supported.
5. High Priority Interrupt (HPI) of MMC is not supported.
6. Boot Operation/Alternative Boot Operation of MMC is not supported.
7. Open-ended multiple block transfer of MMC is not supported.

40.4.7 STP Bit Setting during Multiple Block Read (SD/MMC)

During execution of multiple block read with automatic CMD12 execution by setting the SEC bit in SD_STOP to 1, even if the STP bit in SD_STOP is set to 1 to forcibly stop the execution, the command sequence might not stop depending on the timing of setting the STP bit.

To avoid this, when setting the STP bit in SD_STOP to 1 during multiple block transfer, clear the SEC bit in SD_STOP to 0 at the same time. (Even when the SD_CLK_CTRLEN bit in SD_INFO2 is 0, change the SEC bit from 1 to 0.)

When the command sequence does not stop because the SEC bit was not cleared to 0, the command sequence can be stopped by clearing the SDRST bit in SOFT_RST to 0.

When forcibly terminating the CMD53 multiple block transfer through the IOABT bit in SDIO_MODE, you must leave the SEC bit in SD_STOP as 1.

40.4.8 Register Setting Notes

1. All registers in section 40.2. Register Descriptions are accessed in 32-bit access-only.
2. When setting registers, set them after the I/O Port Register setting.

40.4.9 Module-stop function

SDHI operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The SDHI module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

41. Cyclic Redundancy Check (CRC)

41.1 Overview

The Cyclic Redundancy Check (CRC) calculator generates CRC codes to detect errors in the data. The bit order of CRC calculation results can be switched for LSB-first or MSB-first communication. Additionally, various CRC-generation polynomials are available. The snoop function allows monitoring reads from and writes to specific addresses. This function is useful in applications that require CRC code to be generated automatically in certain events, such as monitoring writes to the serial transmit buffer and reads from the serial receive buffer.

Table 41.1 lists the CRC calculator specifications and Figure 41.1 shows a block diagram.

Table 41.1 CRC calculator specifications

Item	Description	
Data size	8-bit	32-bit
Data for CRC calculation*1	CRC code generated for data in 8n-bit units (where n is a natural number)	CRC code generated for data in 32n-bit units (where n is a natural number)
CRC processor unit	Operation executed on 8 bits in parallel	Operation executed on 32 bits in parallel
CRC generating polynomial	One of three generating polynomials that is selectable: [8-bit CRC] • $X^8 + X^2 + X + 1$ (CRC-8) [16-bit CRC] • $X^{16} + X^{15} + X^2 + 1$ (CRC-16) • $X^{16} + X^{12} + X^5 + 1$ (CRC-CCITT)	One of two generating polynomials that is selectable: [32-bit CRC] • $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$ (CRC-32) • $X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$ (CRC-32C)
CRC calculation switching	The bit order of CRC calculation results can be switched for LSB-first or MSB-first communication	
Module-stop function	Module-stop state can be set to reduce power consumption	
CRC snoop	Monitor reads from and writes to a certain register address	
TrustZone Filter	Security and Privilege attribution can be set	

Note 1. This function cannot divide data used in CRC calculations. Write data in 8-bit or 32-bit units.

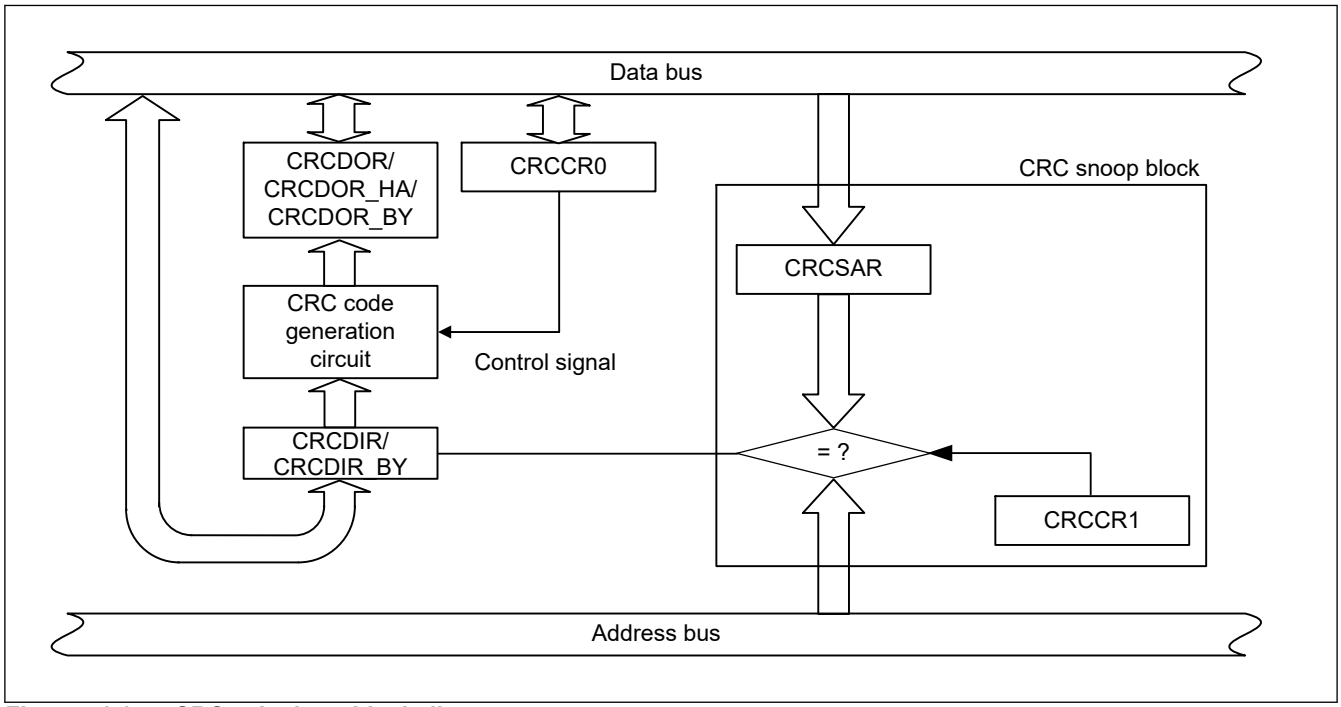

Figure 41.1 CRC calculator block diagram

41.2 Register Descriptions

41.2.1 CRCCR0 : CRC Control Register 0

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DORCLR	LMS	—	—	—	GPS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	GPS[2:0]	CRC Generating Polynomial Switching 0 0 1: 8-bit CRC-8 ($X^8 + X^2 + X + 1$) 0 1 0: 16-bit CRC-16 ($X^{16} + X^{15} + X^2 + 1$) 0 1 1: 16-bit CRC-CCITT ($X^{16} + X^{12} + X^5 + 1$) 1 0 0: 32-bit CRC-32 ($X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$) 1 0 1: 32-bit CRC-32C ($X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$) Others: No calculation is executed	R/W
5:3	—	These bits are read as 0. The write value should be 0.	R/W
6	LMS	CRC Calculation Switching 0: Generate CRC code for LSB-first communication 1: Generate CRC code for MSB-first communication	R/W
7	DORCLR	CRCDOR/CRCDOR_HA/CRCDOR_BY Register Clear 0: No effect 1: Clear the CRCDOR/CRCDOR_HA/CRCDOR_BY register	W

Note: S-TYPE3, P-TYPE3

GPS[2:0] bits (CRC Generating Polynomial Switching)

The GPS[2:0] bits select the CRC generating polynomial.

LMS bit (CRC Calculation Switching)

The LMS bit selects the bit order of generated CRC code. Transmit the lower byte of the CRC code first for LSB-first communication and the upper byte first for MSB-first communication. For details on transmitting and receiving CRC code, see section 41.3. Operation.

DORCLR bit (CRCDOR/CRCDOR_HA/CRCDOR_BY Register Clear)

Write 1 to the DORCLR bit to set the CRCDOR/CRCDOR_HA/CRCDOR_BY register to 0x00000000. This bit is read as 0. Only 1 can be written to it.

41.2.2 CRCCR1 : CRC Control Register 1

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x01

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CRCSEN	CRCSWR	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	CRCSWR	Snoop-On-Write/Read Switch 0: Snoop-on-read 1: Snoop-on-write	R/W
7	CRCSEN	Snoop Enable 0: Disabled 1: Enabled	R/W

Note: S-TYPE3, P-TYPE3

CRCSWR bit (Snoop-On-Write/Read Switch)

The CRCSWR bit selects the direction of access in the CRC snoop function.

When this bit is set to 0 (initial value), the CRC snoop operation to read a specific register is enabled. Similarly, when this bit is set to 1, the CRC snoop operation to write a specific register is enabled.

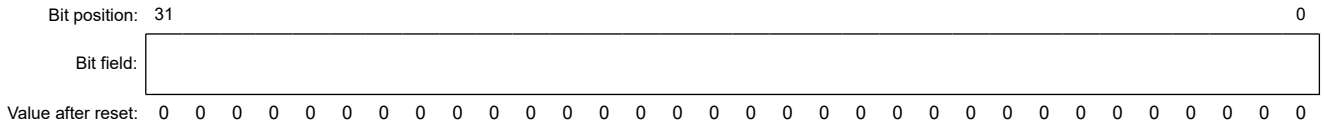
CRCSEN bit (Snoop Enable)

When the CRCSEN bit is set to 1, the CRC snoop operation is enabled. When this bit is set to 0, the CRC snoop operation is disabled.

41.2.3 CRCDIR/CRCDIR_BY : CRC Data Input Register

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x04



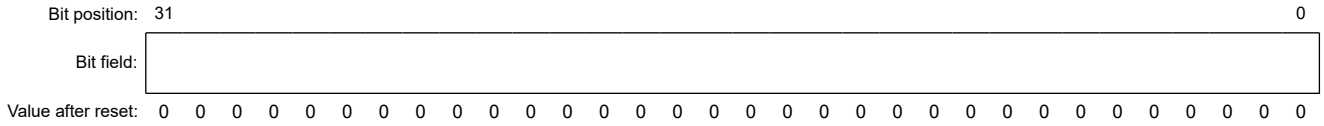
Bit	Symbol	Function	R/W
31:0	n/a	CRC input data The CRCDIR register is a 32-bit read/write register to write data for CRC-32 or CRC-32C calculation. The CRCDIR_BY (CRCDIR[31:24]) is an 8-bit read/write register to write data for CRC-8, CRC-16, or CRC-CCITT calculation.	R/W

Note: S-TYPE3, P-TYPE3

41.2.4 CRCDOR/CRCDOR_HA/CRCDOR_BY : CRC Data Output Register

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x08



Bit	Symbol	Function	R/W
31:0	n/a	CRC output data The CRCDOR register is a 32-bit read/write register for CRC-32 or CRC-32C calculation. The CRCDOR_HA (CRCDOR[31:16]) register is a 16-bit read/write register for CRC-16 or CRC-CCITT calculation. The CRCDOR_BY (CRCDOR[31:24]) register is an 8-bit read/write register for CRC-8 calculation. Because its initial value is 0x00000000, rewrite the CRCDOR/CRCDOR_HA/ CRCDOR_BY register to perform the calculations using a value other than the initial value. Data written to the CRCDIR/CRCDIR_BY register is CRC calculated and the result is stored in the CRCDOR/CRCDOR_HA/CRCDOR_BY register. If the CRC code is calculated following the transferred data and the result is 0x00000000, there is no CRC error.	R/W

Note: S-TYPE3, P-TYPE3

41.2.5 CRCSAR : Snoop Address Register

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x0C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	CRCSA[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
13:0	CRCSA[13:0]	Register Snoop Address These bits store the TDR or RDR address in the SCI module to snoop	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

CRCSA[13:0] bits (Register Snoop Address)

The CRCSA[13:0] bits specify the lower address 14 bits of the register monitored by the CRC snoop operation.

Only the following addresses can be used for the CRCSA[13:0] bits:

[secure region address]

- 0x4035_8004: SCI0.TDR, 0x4035_8000: SCI0.RDR
- 0x4035_8104: SCI1.TDR, 0x4035_8100: SCI1.RDR
- 0x4035_8204: SCI2.TDR, 0x4035_8200: SCI2.RDR
- 0x4035_8304: SCI3.TDR, 0x4035_8300: SCI3.RDR
- 0x4035_8404: SCI4.TDR, 0x4035_8400: SCI4.RDR
- 0x4035_8904: SCI9.TDR, 0x4035_8900: SCI9.RDR

[non-secure region address]

- 0x5035_8004: SCI0.TDR, 0x5035_8000: SCI0.RDR
- 0x5035_8104: SCI1.TDR, 0x5035_8100: SCI1.RDR
- 0x5035_8204: SCI2.TDR, 0x5035_8200: SCI2.RDR
- 0x5035_8304: SCI3.TDR, 0x5035_8300: SCI3.RDR
- 0x5035_8404: SCI4.TDR, 0x5035_8400: SCI4.RDR
- 0x5035_8904: SCI9.TDR, 0x5035_8900: SCI9.RDR

41.3 Operation

41.3.1 Basic Operation

The CRC calculator generates CRC codes for use in LSB-first or MSB-first transfer.

The following examples show CRC code generation for input data (0xF0) using the 16-bit CRC-CCITT generating polynomial ($X^{16} + X^{12} + X^5 + 1$). In these examples, the value of the CRC Data Output Register (CRCDOR_HA) is cleared before CRC calculation.

When an 8-bit CRC (with the polynomial $X^8 + X^2 + X + 1$) is in use, the valid bits of the CRC code are obtained in CRCDOR_BY. When a 32-bit CRC is in use, the valid bits of the CRC code are obtained in CRCDOR.

Figure 41.2 and Figure 41.3 show the LSB-first and MSB-first data transmission examples respectively. Figure 41.4 and Figure 41.5 show the LSB-first and MSB-first data reception examples.

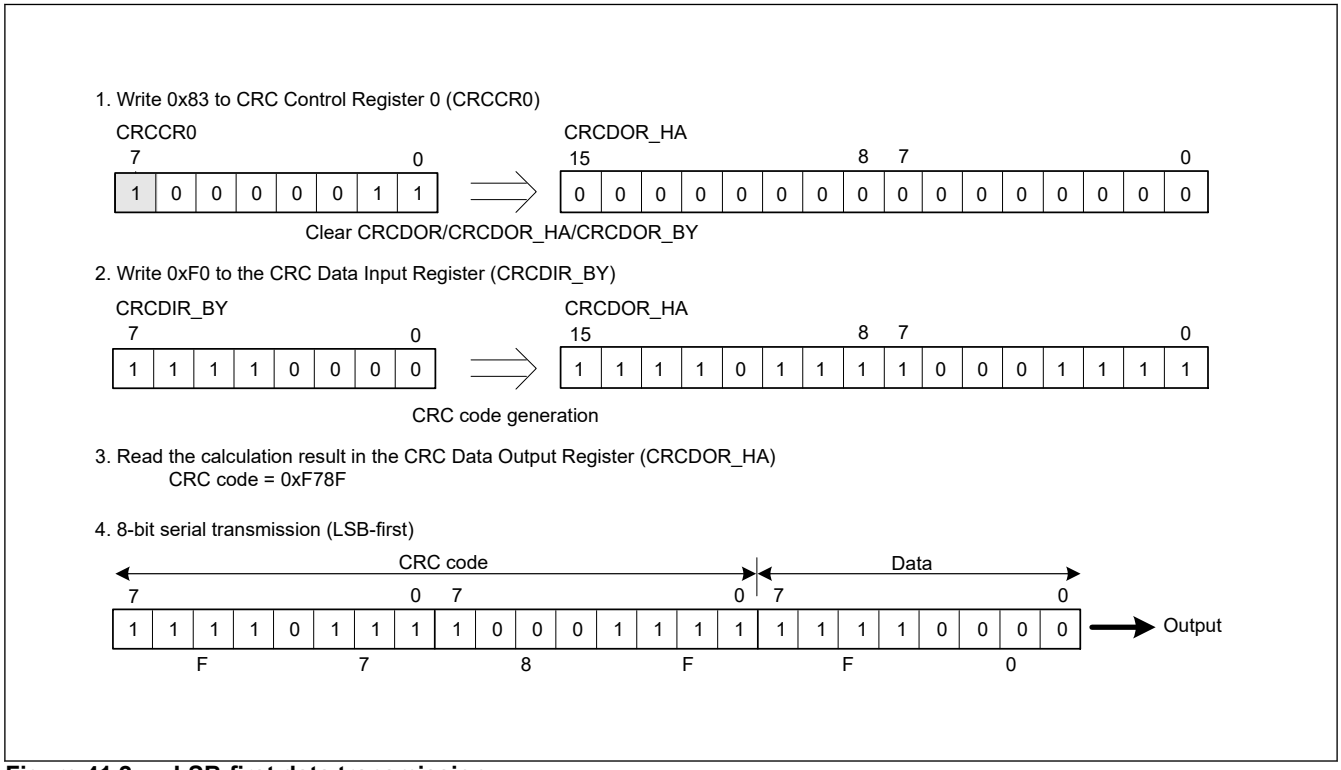


Figure 41.2 LSB-first data transmission

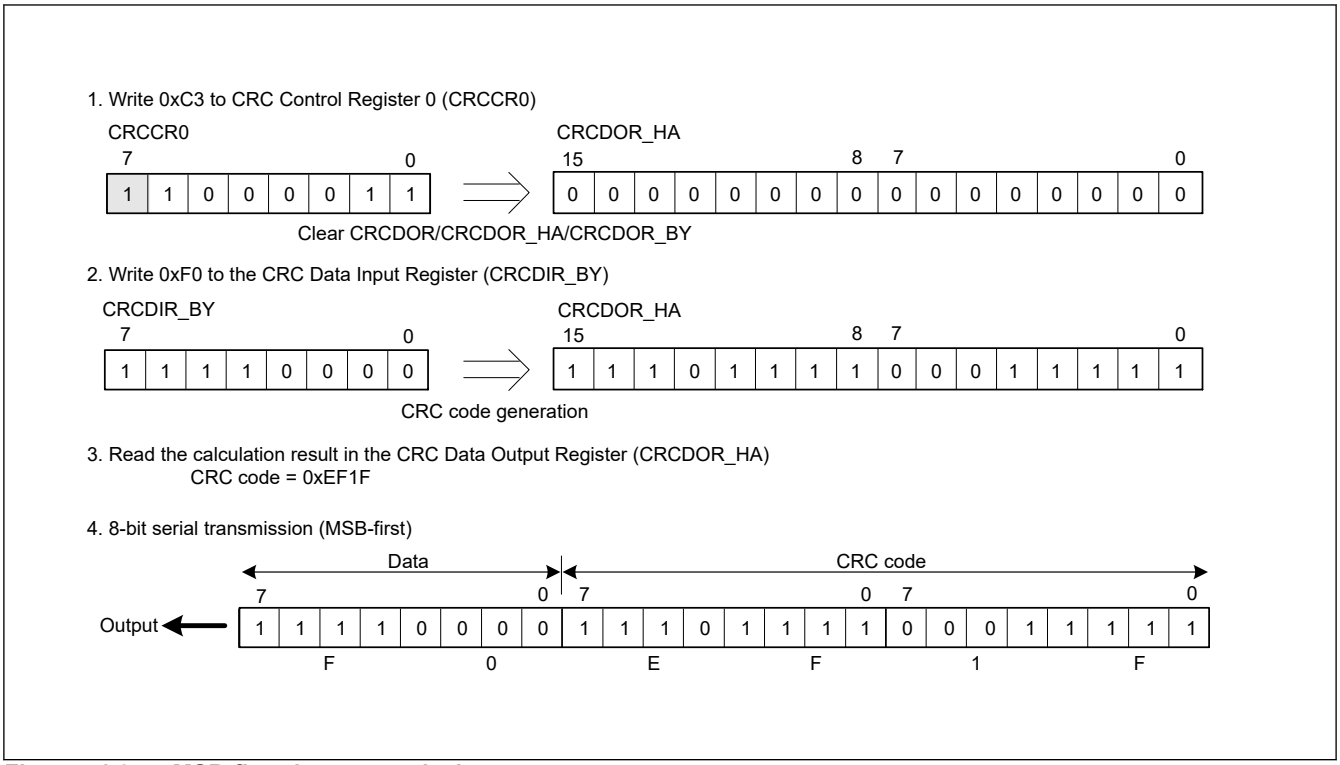

Figure 41.3 MSB-first data transmission

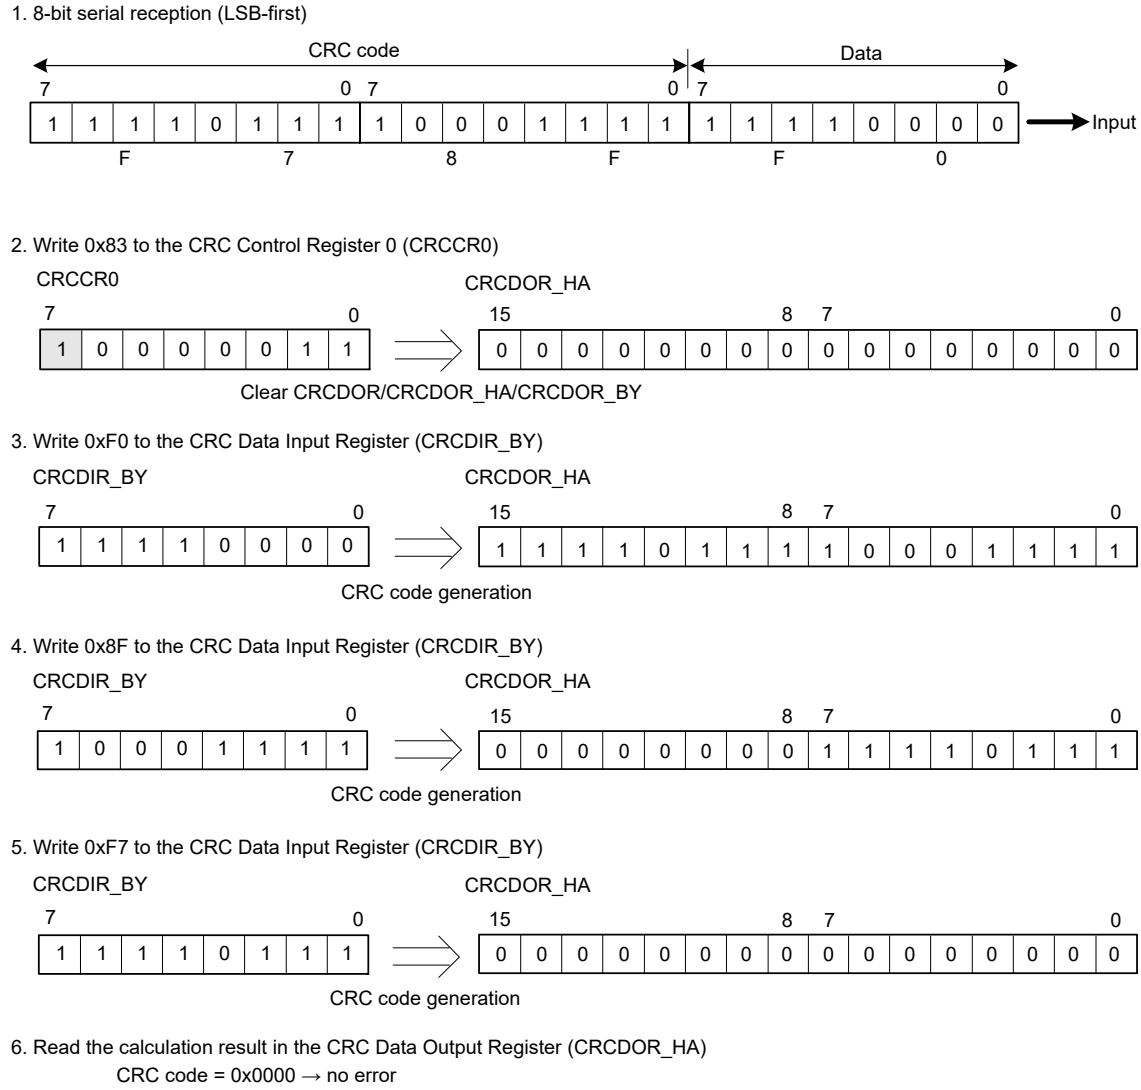

Figure 41.4 LSB-first data reception

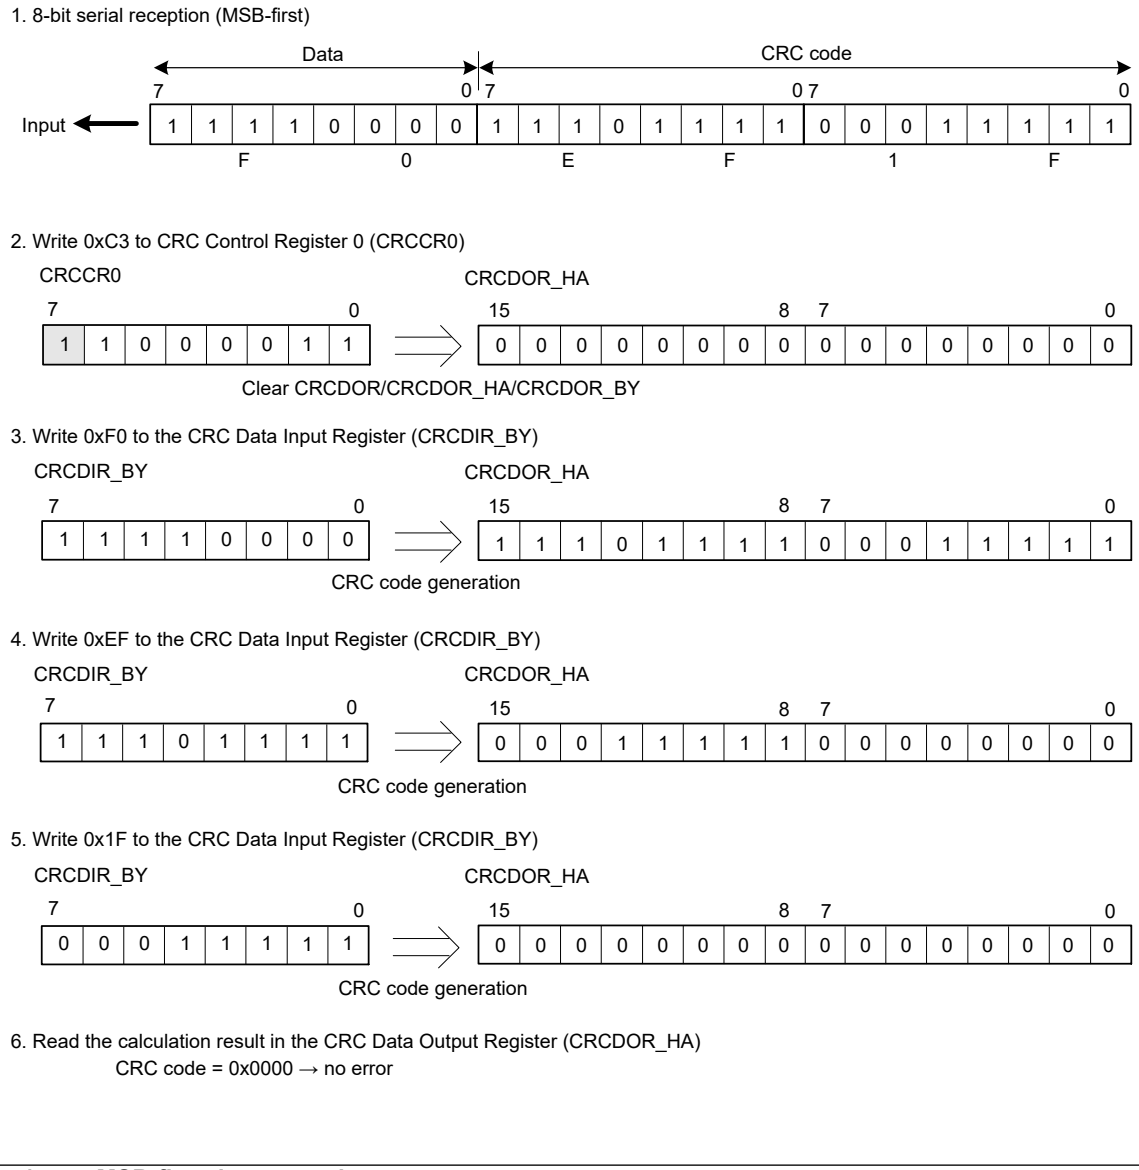

Figure 41.5 MSB-first data reception

41.3.2 CRC Snoop Function

The CRC snoop function monitors reads from and writes to a specific register and performs CRC calculation on the monitored data automatically. Because the CRC snoop function recognizes writes to and reads from a specific register address as a trigger to automatically perform CRC calculation, there is no need to write data to the CRCDIR register. All I/O register specified in the section 41.2.5. CRCSAR : Snoop Address Register are subject to the CRC snoop. The CRC snoop is useful in monitoring writes to the SCIn.TDR (n = 0 to 4, 9) register, and reads from the SCIn.RDR (n = 0 to 4, 9) register.

To use this function, write the lower address 14 bits of a specific register to bits CRCSA13 to CRCSA0 in the CRCSAR register, and set CRCSEN bit in the CRCCR1 register to 1. Then, set the CRCSWR bit in the CRCCR1 register to 1 to enable snooping on writes to the target register, or set the CRCSWR bit in the CRCCR1 register to 0 to enable snooping on reads from the target register. It is possible that access to a target I/O register may be executed before the CRCSWR bit write completed. In this case, the data is not stored in the CRCDIR register. To avoid this issue, before accessing I/O register, read back the CRCSWR bit that was written to confirm that the write completed.

When both the CRCSEN and CRCSWR bits are set to 1, and data is written to a target register in a bus master module such as the CPU, DMAC, and DTC, the CRC calculator stores the data in the CRCDIR register and performs CRC calculation. Similarly, when the CRCSEN bit is set to 1, CRCSWR bit to 0, and data is read from a target register in a bus master

module such as the CPU, DMAC, and DTC, the CRC calculator stores the data in the CRCDIR register and performs CRC calculations.

When the CRC code is generated by using CRC-8, CRC-16, and CRC-CCITT generating polynomial, the target register is accessed in 1 byte (8 bits). RDR_BY and TDR_LL should be used to access RDR and TDR. Similarly, when the CRC code is generated by using CRC-32 and CRC-32C generating polynomial, the target register is accessed in words (32 bits). Note that for RDR and TDR, CRC codes are generated that contain data other than RDAT and TDAT.

When CRC is marked as secure by PSARC.PSARC1 bit, the CRC snoop function is available for secure access to the specified I/O registers. When CRC is marked as non-secure by PSARC.PSARC1 bit, the CRC snoop function is available for non-secure access to the specified I/O registers.

41.4 Usage Notes

41.4.1 Settings for the Module-Stop State

The Module Stop Control Register C (MSTPCRC) can enable or disable CRC calculator operation. The CRC calculator is initially stopped after a reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

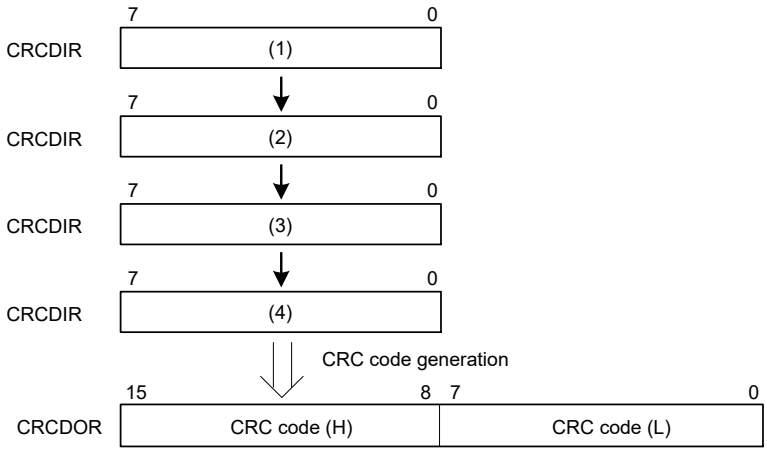
41.4.2 Note on Transmission

The transmission sequence for the CRC code differs based on whether the transmission is LSB-first or MSB-first. Figure 41.6 shows an LSB-first and MSB-first data transmission.

When transmitting 32-bit data (for operation executed on 8 bits in parallel)

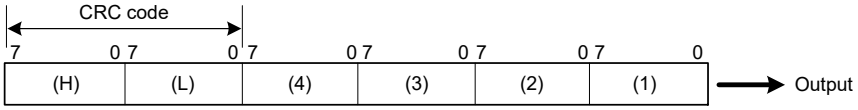
1. CRC code

After specifying the method for generation calculation, write data to CRCDIR in order of (1), (2), (3), and (4).



2. Transmit data

(i) When transmission is LSB-first



(ii) When transmission is MSB-first

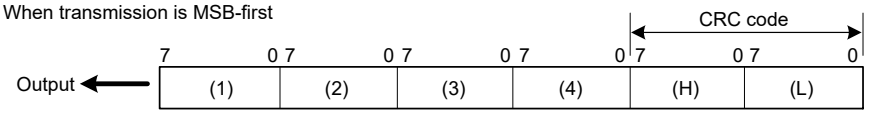


Figure 41.6 LSB-first and MSB-first data transmission

42. Boundary Scan

42.1 Overview

The boundary scan function provides a serial I/O interface based on the JTAG (Joint Test Action Group), IEEE Std.1149.1, and IEEE Standard Test Access Port and Boundary Scan Architecture. Table 42.1 lists the boundary scan specifications, Figure 42.1 shows a block diagram, and Table 42.2 lists the I/O pins.

Table 42.1 Boundary scan specifications

Parameter	Specifications
Execution condition	Boundary scan must be executed when the RES pin is driven low.
Test modes	• BYPASS mode • EXTEST mode • SAMPLE/PRELOAD mode • CLAMP mode • HIGHZ mode • IDCODE mode

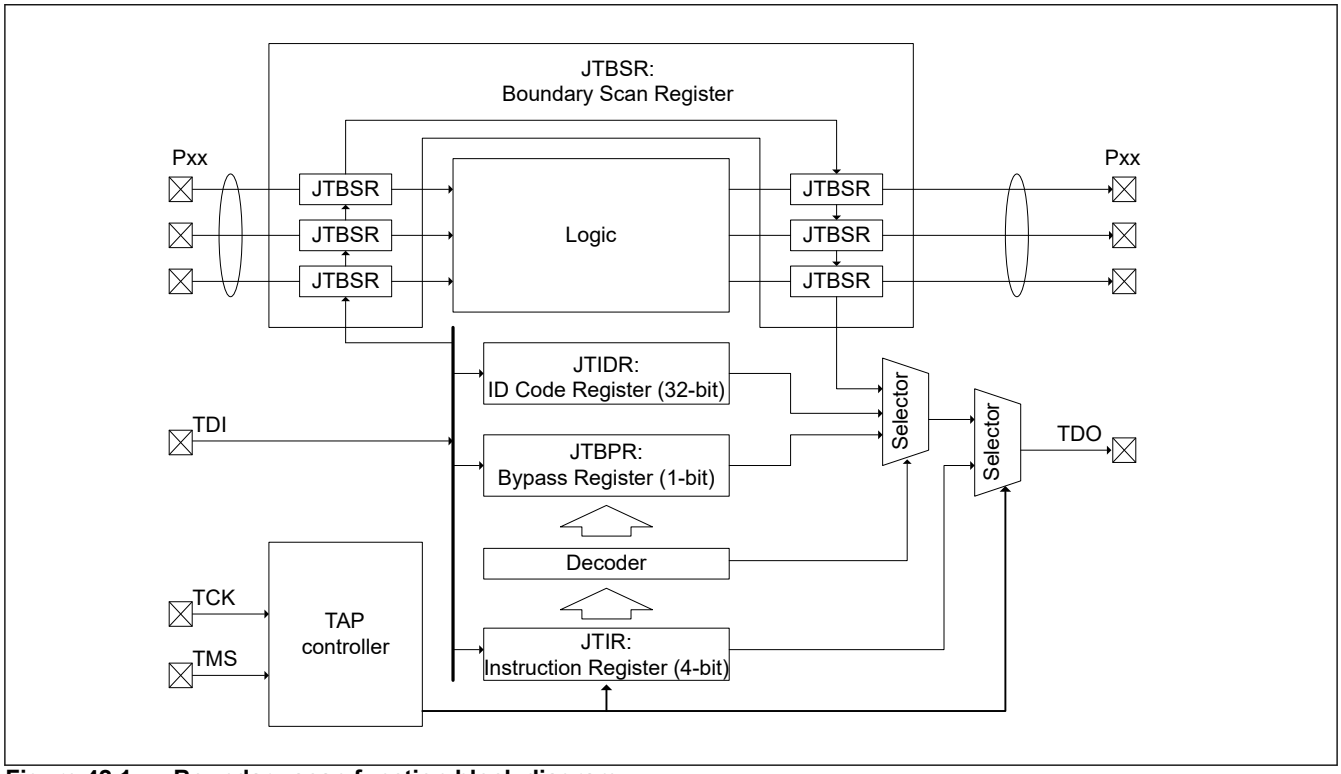

Figure 42.1 Boundary scan function block diagram

Table 42.2 Boundary scan I/O pins

Pin name	I/O	Description
TCK	Input	Test clock input pin Clock signal for boundary scan. The input clock duty cycle is 50% when the boundary scan function is used.
TMS	Input	Test mode select pin
TDI	Input	Test data input pin
TDO	Output	Test data output pin

Note: This device does not support the TRST pin for the JTAG interface.

42.2 Register Descriptions

Table 42.3 lists the boundary scan registers.

Table 42.3 Boundary scan registers

Register name	Symbol	Value after reset
Instruction Register	JTIR	0xE
ID Code Register	JTIDR	0x0841_9447
Bypass Register	JTBPR	Undefined
Boundary Scan Register	JTBSR	Undefined

Usage notes for the boundary scan registers:

- Instructions can be input to the Instruction Register (JTIR) through the TDI pin by serial transfer.
- The Bypass Register (JTBPR), which is a 1-bit register, is connected between the TDI and TDO pins in BYPASS mode.
- The Boundary Scan Register (JTBSR), which is configured according to the BSDL description, is connected between the TDI and TDO pins when test data is being shifted in.

Table 42.4 shows the availability of serial transfer for the registers.

Table 42.4 Serial transfer for registers

Register name	Serial input	Serial output
Instruction Register (JTIR)	Available	Available
ID Code Register (JTIDR)	Available	Available
Bypass Register (JTBPR)	Available	Available
Boundary Scan Register (JTBSR)	Available	Available

42.2.1 JTIR : Instruction Register

Bit position:	3	2	1	0
Bit field:	TS[3:0]			
Value after reset:	1	1	1	0

Bit	Symbol	Function	R/W
3:0	TS[3:0]	Test Bit Set The command configuration for these bits	—

TS[3:0]	Instruction
0x0	EXTEST
0x1	SAMPLE/PRELOAD
0x3	IDCODE (Renesas code)
0x5	CLAMP
0x6	HIGHZ
0xF	BYPASS
Others	Reserved

JTAG instructions can be transferred to the JTIR register by serial input from the TDI pin. The JTIR register is initialized when a power-on reset occurs, or when the TAP controller is in the Test-Logic-Reset state.

42.2.2 JTIDR : ID Code Register

Bit position:	31																												0
Bit field:	DID[31:0]																												
Value after reset:	0	0	0	0	1	0	0	0	0	1	0	0	0	0	0	1	1	0	0	1	0	1	0	0	0	1	0	0	0	1	1	1

Bit	Symbol	Function	R/W
31:0	DID[31:0]	Device ID These bits store the fixed value that indicates the device IDCODE (0x0841_9447).	—

The JTIDR register data is output from the TDO pin when the IDCODE instruction is executed. After a reset release, the DID[31:0] of JTIDR changes into the Arm® debug code. See the *Arm® CoreSight™ SoC-400 Technical Reference Manual* (ARM DDI 0480F).

42.2.3 JTBPR : Bypass Register

The JTBPR register is a 1-bit register and is connected between the TDI and TDO pins when the JTIR register is set to BYPASS mode. The JTBPR register cannot be read from or written to by the CPU.

42.2.4 JTBSR : Boundary Scan Register

The JTBSR register is a shift register for controlling the external input and output pins of this device, and is distributed across the pads. To apply the JTBSR register in boundary-scan testing, issue the EXTEST, SAMPLE/PRELOAD, CLAMP and HIGHZ instructions. The BSDL file describes the associations between the JTBSR register bits and the pins of this device. The value after reset is undefined.

42.3 Operation

During a reset, the JTAG ports, TCK, TMS, TDI and TDO are assigned as default pin functions. The TCK, TMS and TDI pins are pulled up by the pull-up resistors. Boundary scan testing can be executed after the setup time elapses when POR is negated and RES is driven low.

42.3.1 TAP Controller

Figure 42.2 shows the state transition diagram of the TAP controller. All transitions are controlled by the TMS signal.

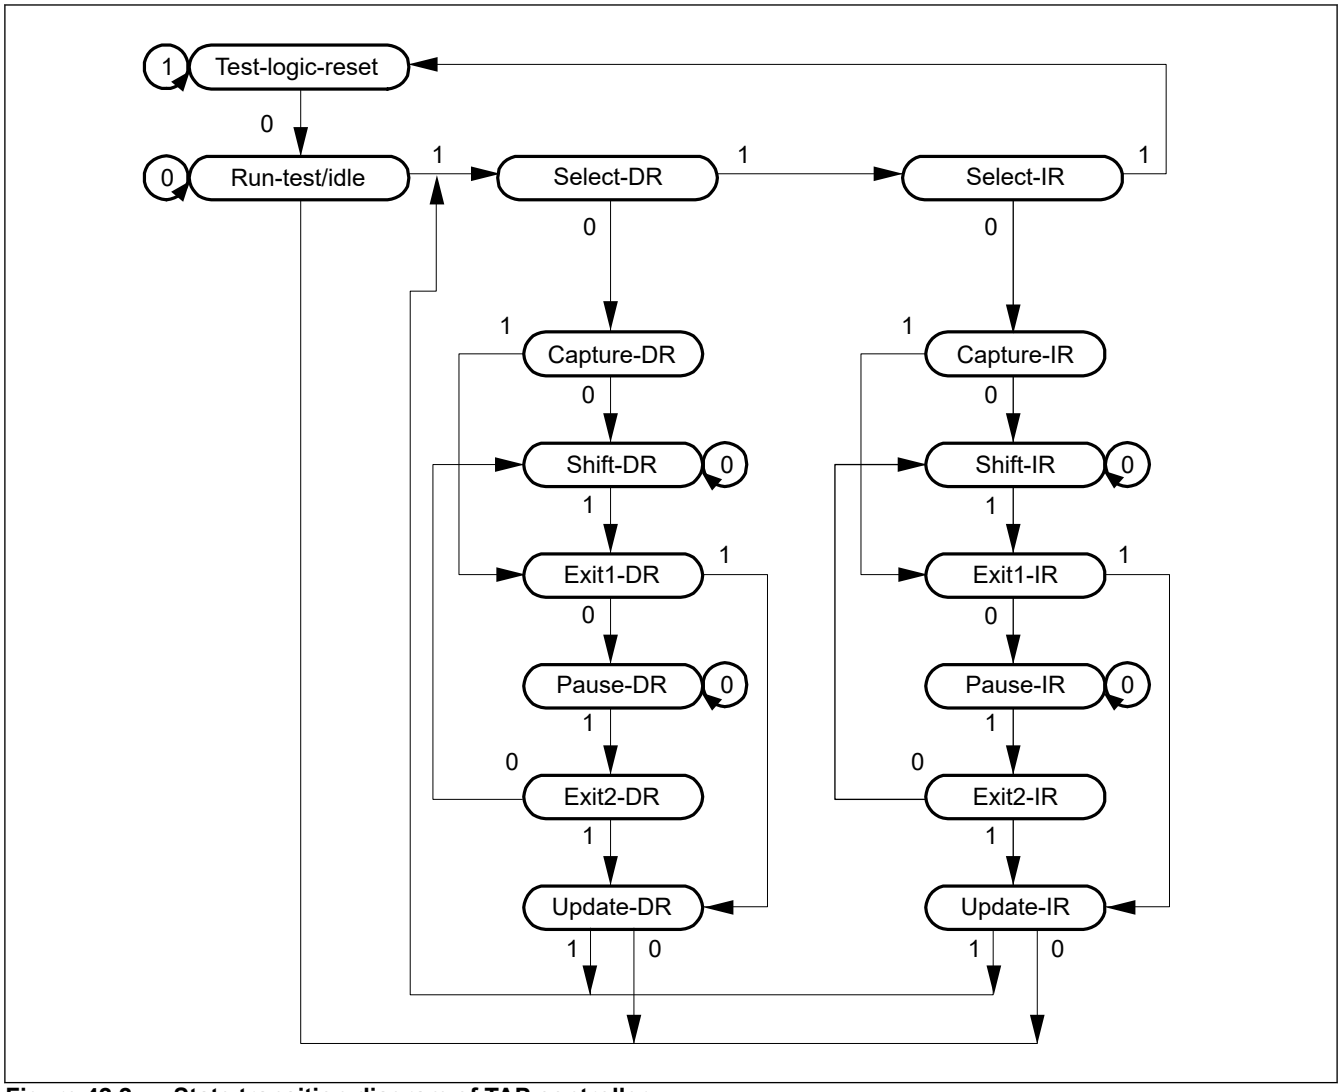

Figure 42.2 State transition diagram of TAP controller

42.3.2 Commands

(1) BYPASS

The BYPASS instruction drives the Bypass Register (JTBPR). This instruction shortens the shift path, facilitating the transfer of serial data to other LSIs on a printed circuit board at higher speeds. While this instruction is being executed, the test circuit has no effect on the system circuits.

The JTBPR register is connected between the TDI and TDO pins. Bypass operation is initiated from the Shift-DR operation. The TDO is low in the first clock cycle in the Shift-DR state. In the subsequent clock cycles, values input to the TDI pin are output from the TDO pin.

(2) EXTEST

The EXTEST instruction is used to test external circuits when this device is installed on the printed circuit board. If this instruction is executed, output pins are used to output test data (specified in the SAMPLE/PRELOAD instruction) from the Boundary Scan Register (JTBSR) to the other devices, and input pins are used to input the test result.

(3) SAMPLE/PRELOAD

The SAMPLE/PRELOAD instruction is used to input data from the internal circuits of this device to the JTBSR register, output data from the scan path, and reload the data to the scan path. While this instruction is executed, input signals are directly input to this device and output signals are also directly output to the external circuits. This device system circuit is not affected by this instruction.

In SAMPLE operation, the JTBSR register latches a snapshot of the data transferred from the input pins to the internal circuit or data transferred from the internal circuit to the output pins. The latched data is read from the scan path. The JTBSR register latches the data snapshot on the rising edge of the TCK pin in the Capture-DR state. The data snapshot is only transferred from the internal circuit to the output pins during a reset.

In PRELOAD operation, the initial value is written from the scan path to the parallel output latch of the JTBSR register prior to the EXTEST instruction execution. If EXTEST is executed without executing this PRELOAD operation, undefined values are output from the beginning to the end (transfer to the output latch) of the EXTEST sequence. (In the EXTEST instruction, output parallel latches are always output to the output pins.)

(4) IDCODE

When the IDCODE instruction is selected, the ID Code Register (JTIDR) value is output to the TDO pin in the Shift-DR state of the TAP controller. In this case, the JTIDR register value is output LSB-first. During this instruction execution, the test circuit does not affect the system circuit.

(5) CLAMP

When the CLAMP instruction is selected, output pins output the JTBSR register value that was specified in the SAMPLE/PRELOAD instruction in advance. While the CLAMP instruction is selected, the status of the JTBSR register is maintained regardless of the TAP controller state.

The JTBPR register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

(6) HIGHZ

When the HIGHZ instruction is selected, all output pins enter high-impedance state. While the HIGHZ instruction is selected, the JTBSR register is maintained regardless of the state of the TAP controller.

The JTBPR register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

42.4 Usage Notes

The boundary scan function is subject to the following constraints:

- The boundary scan must be executed when the RES pin is driven low
- Serial data input/output is in LSB order, as shown in Figure 42.3

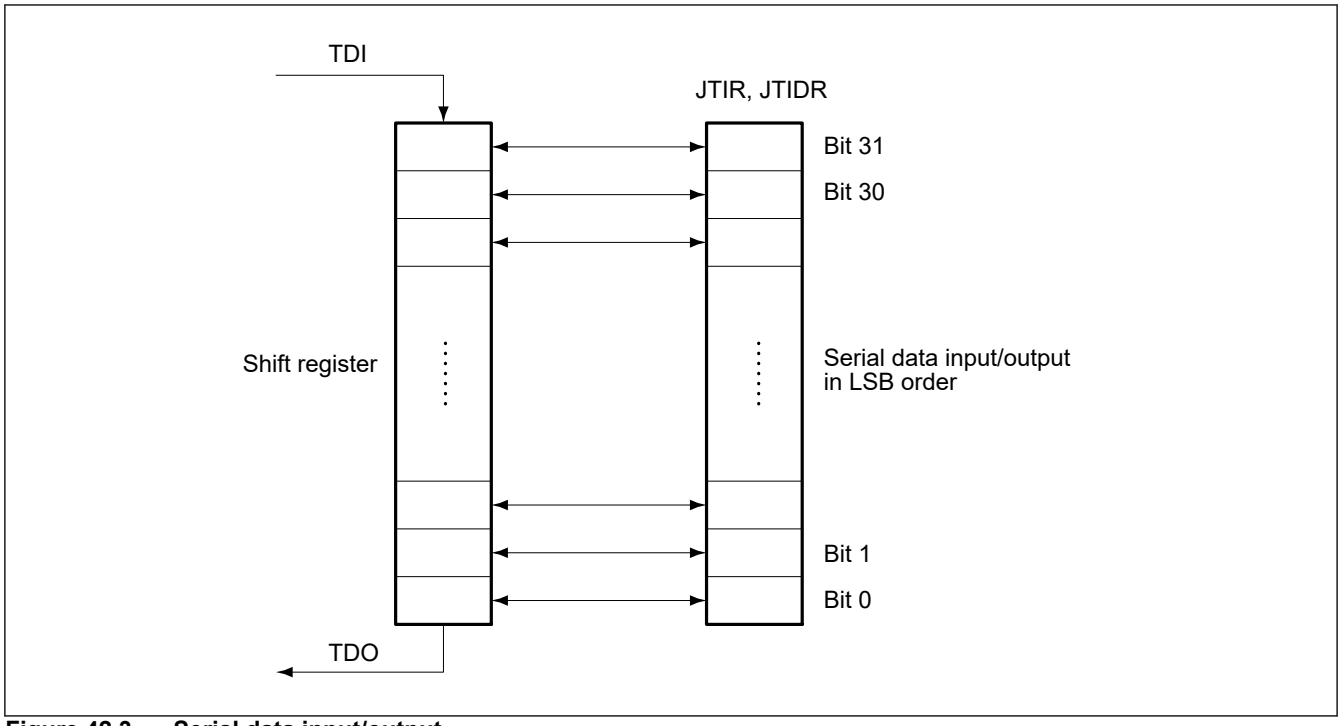

Figure 42.3 Serial data input/output

The following pins cannot be boundary-scanned:

- Power supply pins (VCC, VCC2, VCC_DCDC, VCL, VSS, VSS_DCDC, VBATT, AVCC0, AVSS0, VCC_USB, VSS_USB, VSS1_USBHS, VSS2_USBHS, AVCC_MIPI, VCC18_MIPI and VSS_MIPI)
- Analog reference pins (VREFH0, VREFL0, VREFH, VREFL)
- Clock pins (EXTAL, XTAL, XCIN, and XCOUT)
- Reset pin (RES)
- USBHS-dedicated pins (USBHS_DP, USBHS_DM)
- USBFS pin (USB_DP, USB_DM)
- The boundary-scan pins (TCK, TMS, TDI, and TDO).
- MIPI-dedicated pins (MIPI_CL_N, MIPI_CL_P, MIPI_DL0_N, MIPI_DL0_P, MIPI_DL1_N, MIPI_DL1_P)
- The switching regulator pin (VLO)

43. Security Features

43.1 Features

- Armv8-M TrustZone Technology
  - Implementation Defined Attribution Unit (IDAU) is implemented
  - Security Attribution Unit (SAU) is implemented
    - 8 regions
  - Master Security Attribution Unit (MSAU) is implemented (IDAU for master other than CPU)
  - Code flash
    - Up to 2 regions (secure/non-secure) in linear mode
    - Up to 4 regions (2 secure regions/2 non-secure regions) in dual mode
  - Data flash
    - Up to 2 regions (secure/non-secure)
  - SRAM
    - Up to 2 regions (secure/non-secure) per SRAM
  - Standby SRAM
    - Up to 2 regions (secure/non-secure)
  - VBATT backup registers
    - Up to 2 regions (secure/non-secure)
  - Peripheral
    - Security attributes can be set individually for each unit/channel
  - CSC[*1]
    - CSC region is defined as non-secure
  - SDRAM[*1]
    - SDRAM region is defined as non-secure
  - OSPI[*1]
    - OSPI region is defined as non-secure
- Privileged control
  - Access permissions for memory except Standby SRAM and VBATT backup register are controlled by MPU managed by the privileged code
  - Privilege attributes of Standby SRAM and VBATT backup register are controlled by the registers of each controller
  - Individual privileged or Unprivileged attribution for each peripheral.
- Device lifecycle management
- Three debug levels
  - AL2: Non-secure and secure debug functions are enabled and accessible from the debugger
  - AL1: Only non-secure debug functions is enabled, and the debugger can access only defined non-secure debug accessible regions
  - AL0: No debug functions are available.
- Key injection
- Secure factory programming
  - Supports image programming in ciphertext format in an untrusted factory
- Secure boot

  - Verify the integrity and authenticity of image to be programmed
  - Verify the integrity and authenticity of the executable image by the immutable (ROM) First Stage Bootloader (FSBL) prior to executing the image.
- Cryptographic accelerator
  - See section 44, Renesas Secure IP (RSIP-E51A).
- Secure pin multiplexing
  - All I/O port pins can be configured individually as secure or non-secure
  - Peripheral pin function is valid when the security attribute of peripheral and I/O port match. See section 19, I/O Ports.

Note 1. There is no TrustZone filter in the external RAM and external device area. Therefore, even if these regions are marked as secure in the SAU settings, non-secure masters except the CPU can access them.

43.2 Tamper Detection

The device is provided with I/O ports capable of detecting an external tamper attempt. In the case of a tamper event:

- Timestamping
  The RTC can take a timestamp to log the event, and an interrupt can be generated. See section 24, Realtime Clock (RTC).
- VBATT backup registers
  VBATT backup registers are zeroized (set to zero) following detection of a tamper event. Seesection 11, Battery Backup Function.

43.3 Arm Security Features

43.3.1 Arm TrustZone Technology

Arm TrustZone technology divides the system and the application into secure and non-secure domains. A secure application can issue both secure and non-secure transactions, but a non-secure application can only issue non-secure transactions. Secure transactions can only access secure memory and resources, and non-secure transactions can only access non-secure memory and resources. Secure transactions can be issued only using secure region addresses and non-secure transactions can be issued only using non-secure region addresses. Figure 43.1shows the security attributes of transactions that can be issued by each master.

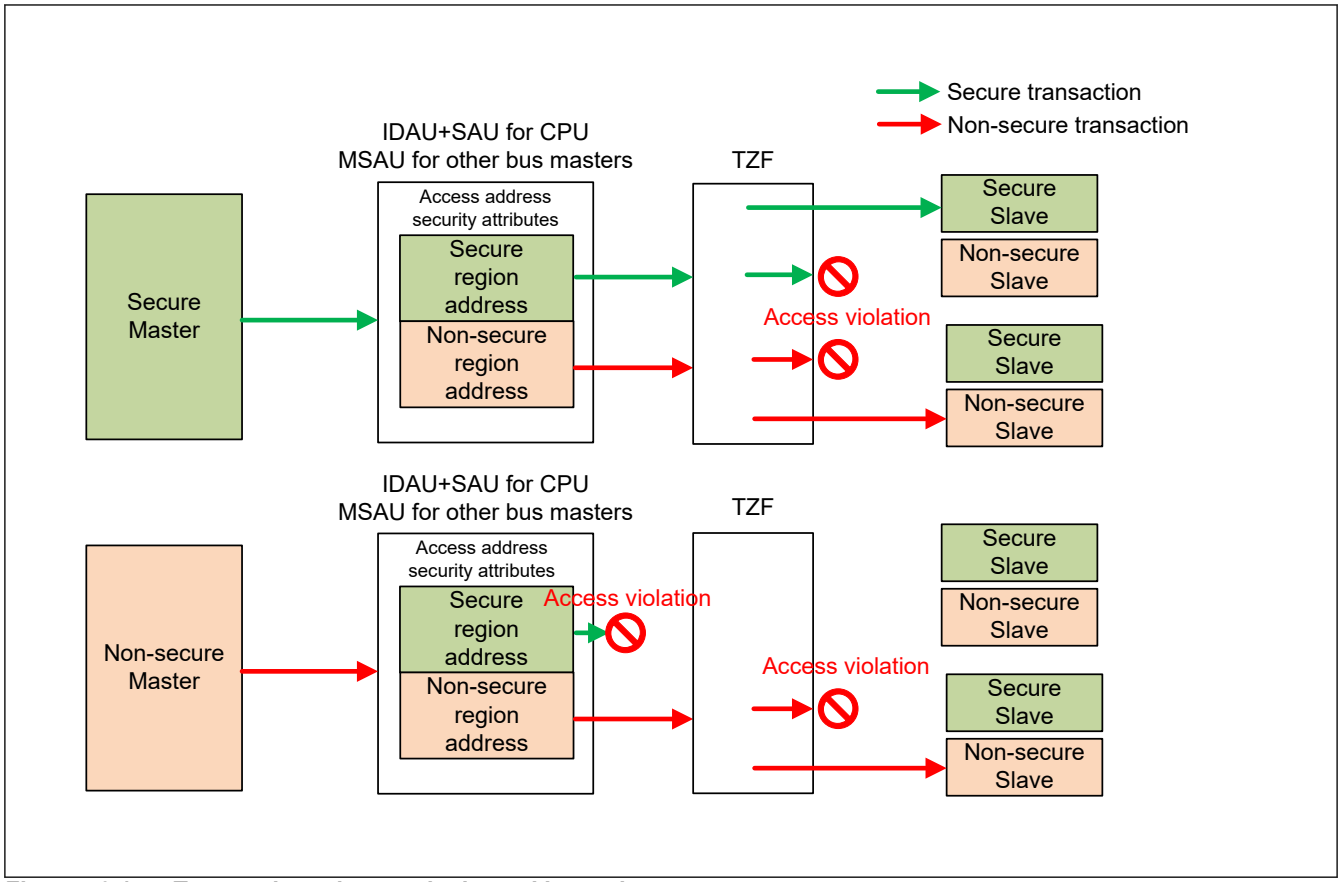

Figure 43.1 Transactions that can be issued by each master

For more details, see the *Arm® v8-M Architecture Reference Manual and Arm® Platform Security Architecture Trusted Base System Architecture for Arm®v8-M 1.0*.

43.3.2 Privileged Control

Systems and applications are divided into privileged and unprivileged domains. The CPU can limit or exclude access to some resources by executing code in privileged or unprivileged mode. Privileged mode can access both privileged and unprivileged domains, but unprivileged mode can access only the unprivileged domain.

For more details, see the *Arm® v8-M Architecture Reference Manual and Arm® Platform Security Architecture Trusted Base System Architecture for Arm®v8-M 1.0*.

43.3.3 Security Attribution

The TrustZone for Armv8.1-M implementation consists of the Security Attribution Unit (SAU) and Implementation Defined Attribution Unit (IDAU). The 4GB memory space is partitioned into Secure (S) and Non-secure (NS) memory regions. The Secure memory space is further divided into two types, Non-secure Callable (NSC) and Secure.

Note:
- S = Secure addresses are used for memory and peripherals that are only accessible by secure software or secure masters.
- NSC = A special type of secure location. This type of memory is the only type in which an Armv8.1-M processor permits to hold a Secure Gateway (SG) instruction that enables software to transition from Non-secure to Secure state.
- NS = Non-secure addresses are used for memory and peripherals accessible by all software running on the device.

43.3.3.1 Implementation Defined Attribution Unit (IDAU)

The IDAU defines the code, SRAM and peripheral region into the secure alias region and the non-secure alias region by the address bit [28]. The secure code region and secure SRAM region are assigned the NSC security attributes. The security map defined by IDAU is fixed in hardware and cannot be changed by software.

43.3.3.2 Master Security Attribution Unit (MSAU)

MSAU is IDAU that defines system-specific security address map for masters other than CPU. The MSAU defines secure and non-secure alias regions but does not define the Non-secure Callable (NSC) and region number. Masters other than the CPU can issue a security transaction using the secure alias address defined by MSAU. However, non-secure masters are prohibited from issuing secure transactions using an address in the secure alias region. Figure 43.2 shows the defined security map of IDAU and MSAU. The security map defined by MSAU is fixed in hardware and cannot be changed by software.

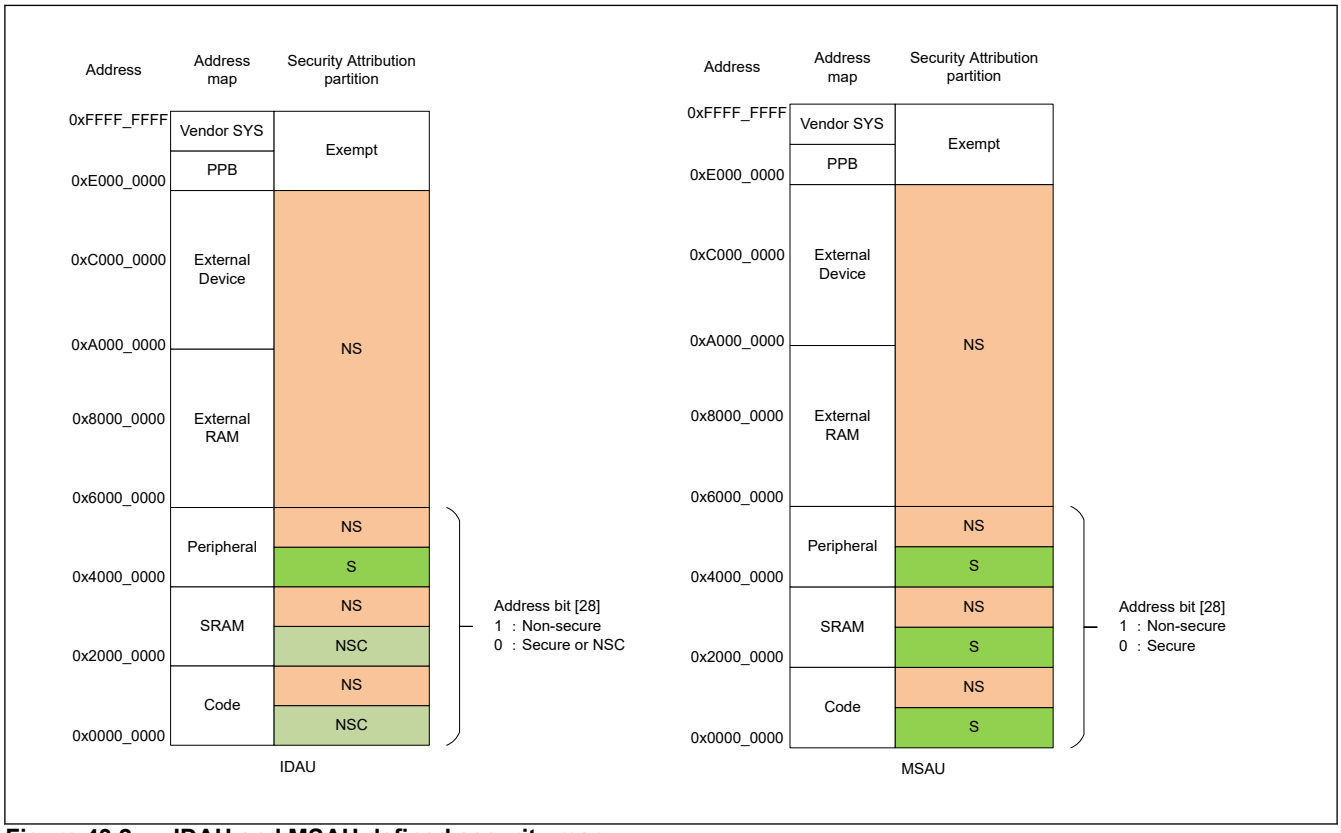

Figure 43.2 IDAU and MSAU defined security map

43.3.3.3 Secure Attribution Unit (SAU)

The SAU is a programmable unit that determines the security of an address. The SAU is programmable in the Secure state and has a programmers' model similar to the MPU. If an address maps to regions defined by both IDAU and SAU, the region of the highest security level is selected. Secure master can issue secure and non-secure transactions using the address of each security alias region. Non-secure master cannot issue secure transactions using the address of the secure alias region. Figure 43.3 shows the final determination of the address map security level.

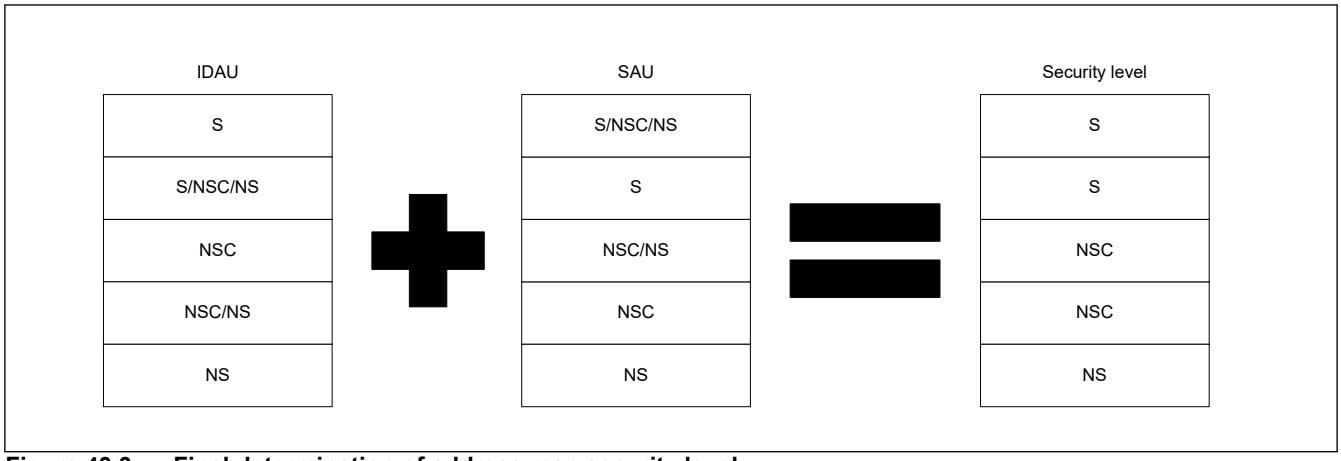

Figure 43.3 Final determination of address map security level

When using TrustZone to perform secure and non-secure region separation, SAU MUST be set according to the following.

The regions set as NS attribute in IDAU MUST be set to NS in the SAU as well. The regions set to NS attribute in IDAU are:

0x1000_0000 to 0x1FFF_FFFF (SAU Region 1 in Figure 43.4)

0x3000_0000 to 0x3FFF_FFFF (SAU Region 3 in Figure 43.4)

0x5000_0000 to 0xDFFF_FFFF (SAU Region 3 in Figure 43.4)

At least one NSC region MUST be created within any region defined as NSC by the IDAU. The regions set to NSC attribute by the IDAU are:

0x0000_0000 to 0x0FFF_FFFF (SAU Region 0 in Figure 43.4)

0x2000_0000 to 0x2FFF_FFFF (SAU Region 2 in Figure 43.4)

If you do not wish to define any isolation by means of using TrustZone, do not change SAU_CTRL.ALLNS = 0 and SAU_CTRL.ENABLE = 0 (initial value).

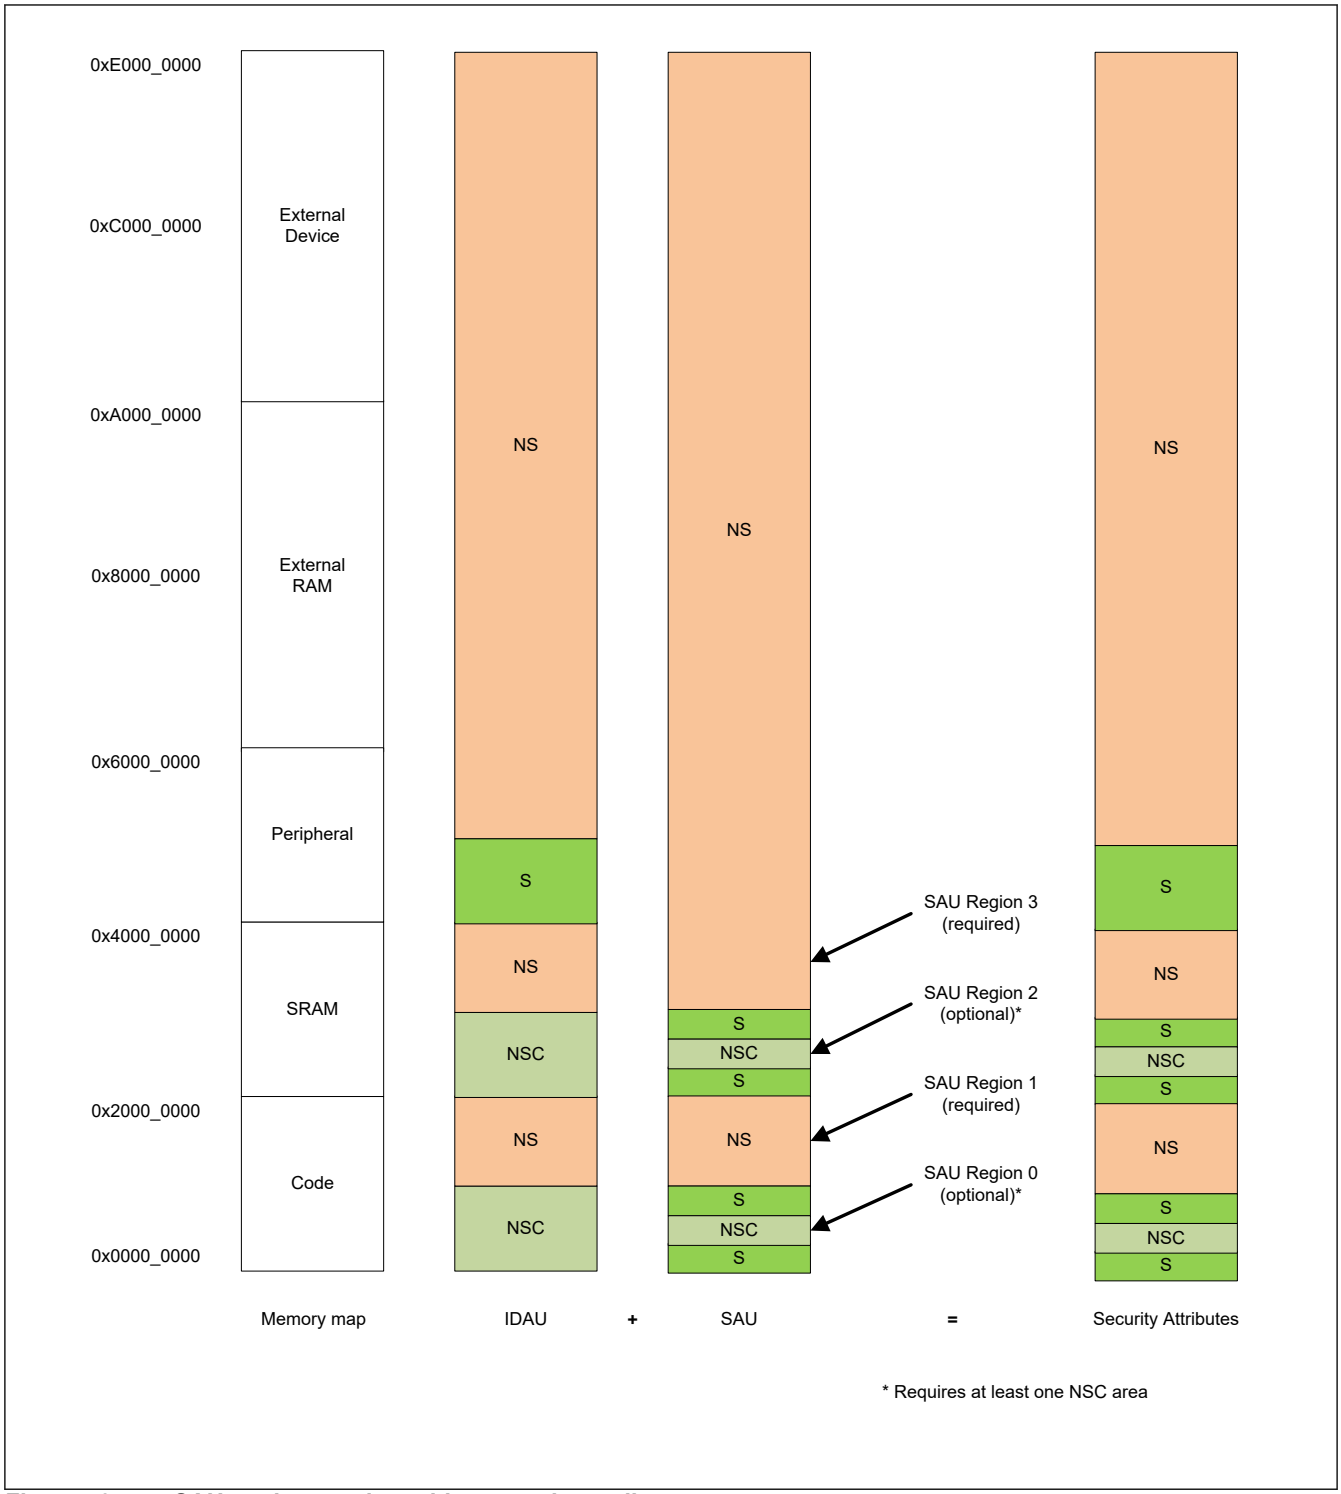

Figure 43.4 SAU settings and resulting security attributes

43.3.3.4 Region Number

The SAU and IDAU also define region numbers for each of the memory regions and security attributes. This region number is used by software to determine if a contiguous range of memory shares common security attributes. Figure 43.5 shows the defined region number of IDAU.

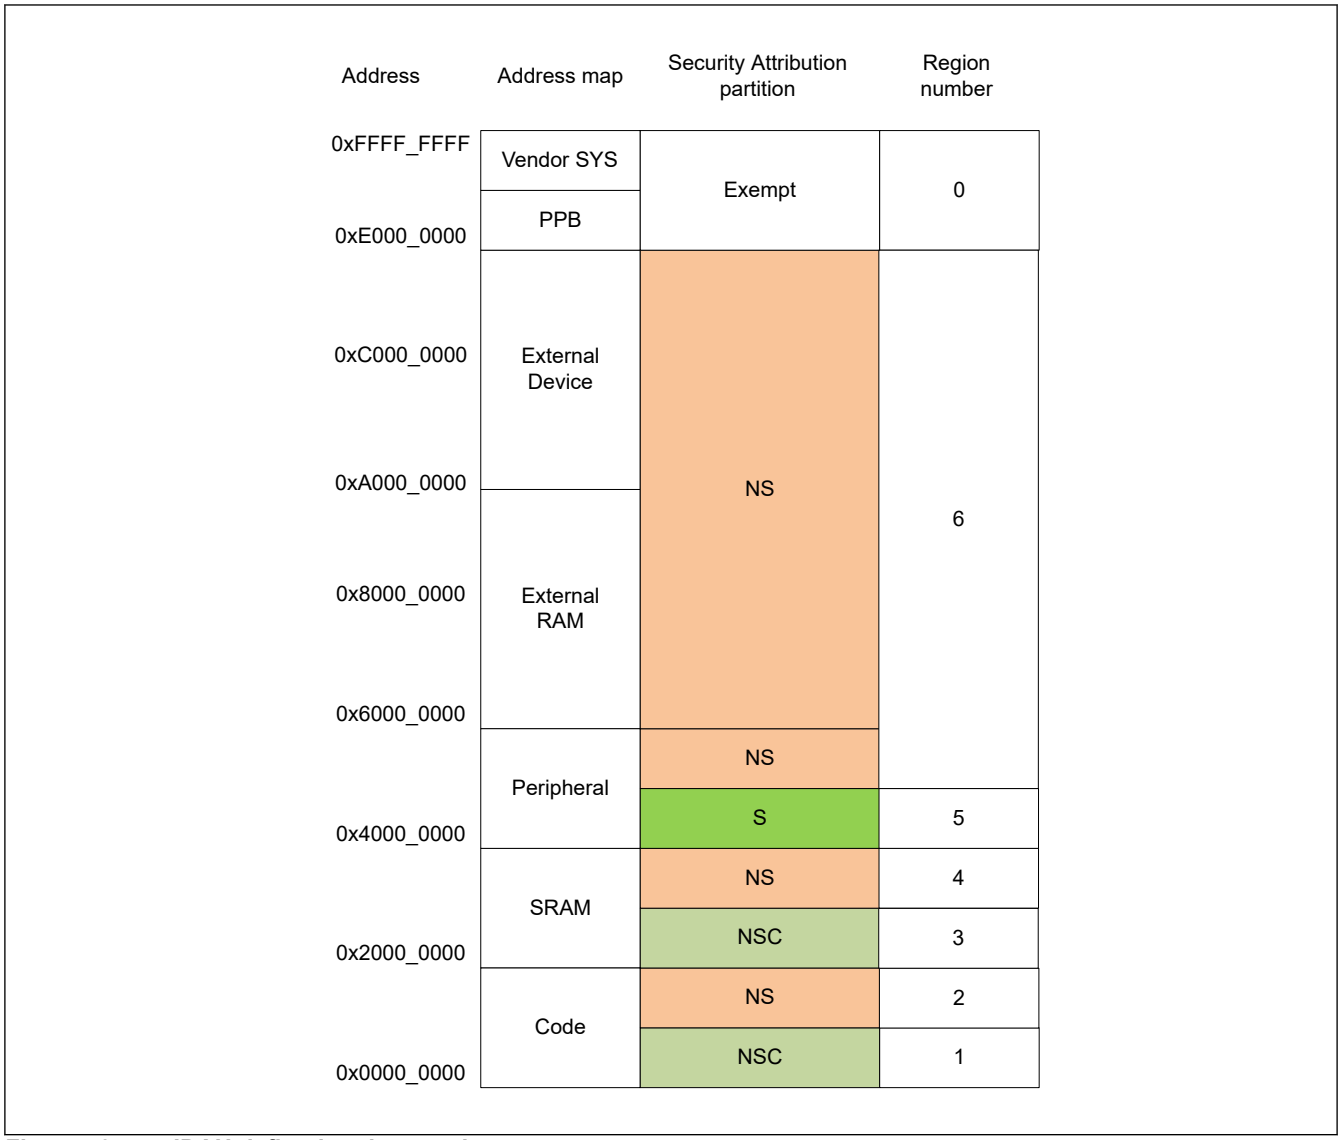

Figure 43.5 IDAU defined region numbers

43.3.3.5 Memory Security Attribution of TrustZone filter

The memories are divided into S and NS regions. The memory security attribution of code flash and data flash is stored into nonvolatile memory by a boot firmware command when the device lifecycle is in the OEM state and the authentication level is AL2. These memory security attributions are applied before application execution. They cannot be updated by the application but are readable using dedicated registers. The memory security attributions of SRAM, standby SRAM, and VBATT backup registers are set by a dedicated security attribution register writable only by secure access.

The code flash can be divided in up to two regions in linear mode and four regions in dual mode. The partitioning is the same between bank0 and bank1 in the dual mode. The data flash can be divided in up to two regions. SRAM, standby SRAM, and VBATT backup registers can be divided in up to two regions. Figure 43.6 shows the memory mapping. Table 43.1 shows size of the memory region and Table 43.2 shows access permission of the memory region.

It is prohibited to place Secure or Non-secure Callable regions in a block swappable area in linear mode because the secure application would be placed in the non-secure region after block swapping.

The contents in Secure or Non-secure Callable regions must be the same in both bank0 and bank1 in the dual mode. Otherwise, the contents of secure or non-secure regions may not be consistent after a field update. See section 43.8. Field Updating in Dual Mode.

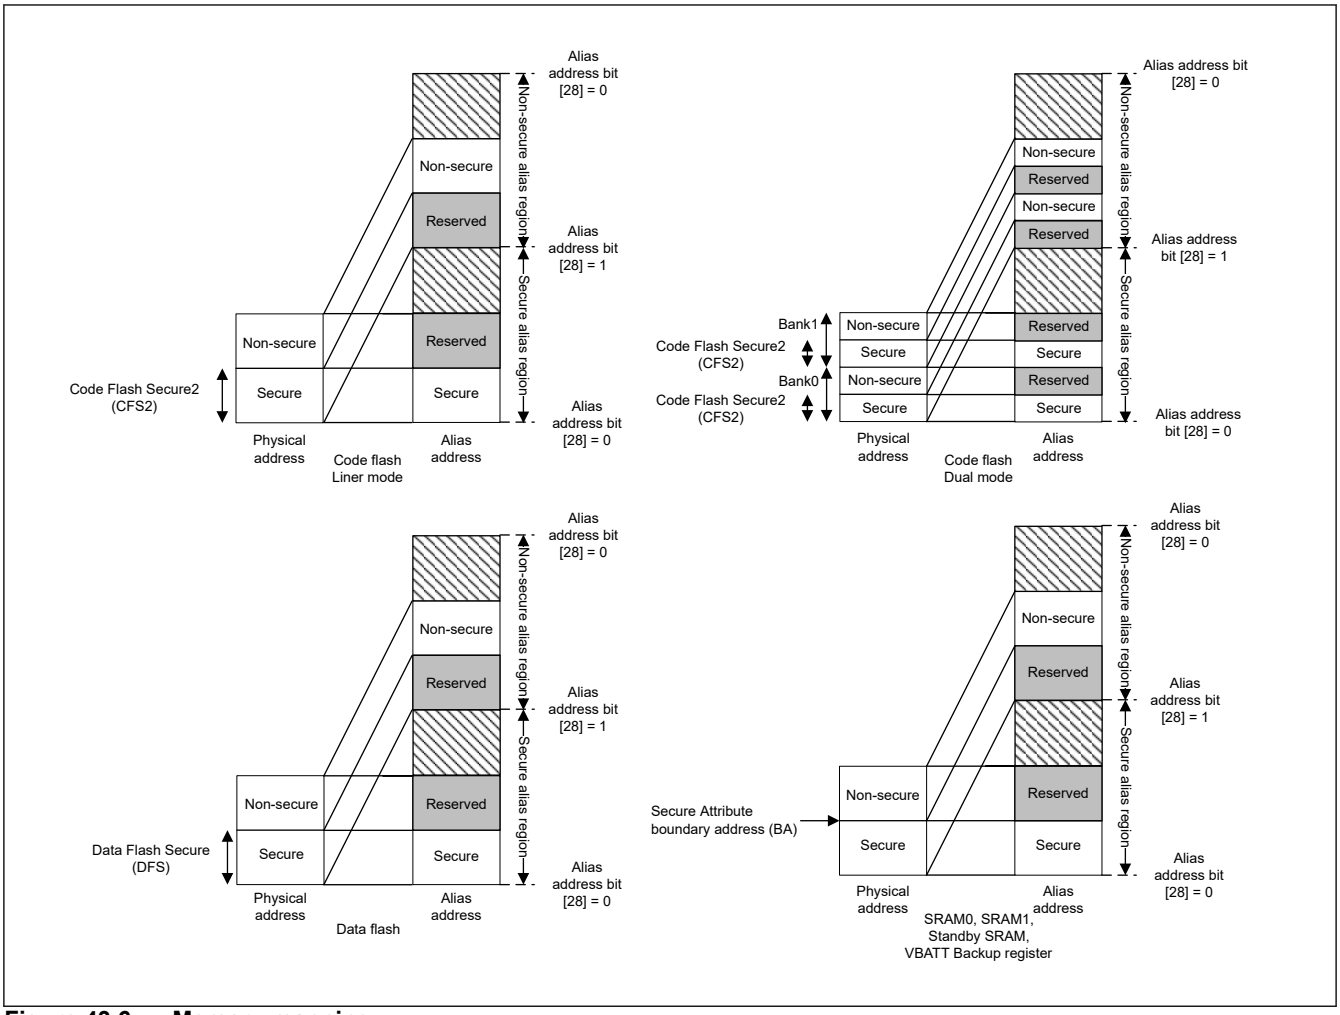

Figure 43.6 Memory mapping

Table 43.1 Size of memory region

Memory region		Start address	Size
Linear mode	Code flash secure	0x0200_0000	CFS2 size (32 KB)
	Code flash non-secure	0x1200_0000 + CFS2 size (32 KB)	Code flash size - CFS2 size (32 KB)
Dual mode	Code flash bank0 secure	0x0200_0000	CFS2 size (32 KB)
	Code flash bank0 non-secure	0x1200_0000 + CFS2 size (32 KB)	Code flash size/2 - CFS2 size (32 KB)
	Code flash bank1 secure	0x0220_0000	CFS2 size (32 KB)
	Code flash bank1 non-secure	0x1220_0000 + CFS2 size (32 KB)	Code flash size/2 - CFS2 size (32 KB)
Data flash secure		0x2700_0000	DFS size (1 KB)
Data flash non-secure		0x3700_0000 + DFS size (1 KB)	Data flash size - DFS size (1 KB)
SRAM0 secure		0x2200_0000	BA (8 KB)
SRAM0 non-secure		0x3200_0000 + BA (8 KB)	SRAM0 size - BA (8 KB)
SRAM1 secure		0x2206_0000	BA (8 KB)
SRAM1 non-secure		0x3206_0000 + BA (8 KB)	SRAM1 size - BA (8 KB)
Standby SRAM secure		0x2600_0000	BA (128 bytes)
Standby SRAM non-secure		0x3600_0000 + BA (128 bytes)	Standby SRAM size - BA (128 bytes)
VBATT backup register secure		0x4001_ED00	BA (32 bytes)
VBATT backup register non-secure		0x5001_ED00 + BA (32 bytes)	Backup register size - BA (32 bytes)

Note: The number in parentheses indicates the smallest unit that can be set by the user.

Note: BA is the setting value of the security attribution boundary address register for each memory region.

Table 43.2 Access permission of the memory region

Memory region	Secure transaction	Non-secure transaction
Each memory region configured as S or NSC	Allowed	Write ignored/Read ignored TrustZone access error is generated
Each memory region configured as NS	Write ignored/Read ignored TrustZone access error is generated	Allowed

43.3.3.6 Peripheral Security Attribution of TrustZone filter

Each peripheral can be configured as secure or non-secure. Peripherals are divided into two types.

Type1 peripheral has one security attribution and access to all registers is controlled by one security attribution. Type1 peripheral security attribution is set to the PSARx (x = B to E) register by the secure application.

Type2 peripheral has the security attribution for each register or for each bit and access to each register or bit field is controlled according to these security attributions. Type2 peripheral security attribution is set to the Security Attribution register in each module by the secure application. For details on the Security Attribution register, see each section.

Table 43.3 shows the classification of peripheral type.

Table 43.3 Classification of peripheral type

Type1	Type2
SCI, SPI, OSPI, DOTF, ETHERC, EDMAC, USBHS, USBFS, IIC, I3C,RSIP-E51A, CANFD, CEU, DRW, GLCDC, MIPI-DSI, DOC, SDHI, SSIE, CRC, CAC, ACMPHS, TSN, ADC12, DAC12, POEG, AGT, GPT, ULPT, RTC, IWDT, and WDT	System control (Resets, PVD, Clock Generation Circuit, Low Power Modes, Battery Backup Function), Flash memory controller, Flash cache, SRAM controller, CPU cache, DMAC, DTC, ICU, MPU, BUS, Security setting, ELC, and I/O ports

Table 43.4 shows the access permission of type1 peripherals. The access permission of type2 peripherals is different by peripherals. See the register description of each peripherals for details.

Table 43.4 Access permission of type1 peripherals

	Secure access	Non-secure access
Peripheral configured as S	Allowed	Write ignored/Read ignored TrustZone Access error is generated
Peripheral configured as NS	Write ignored/Read ignored TrustZone access error is generated	Allowed

43.3.4 TrustZone Access Error

Table 43.5 shows the behavior when TrustZone access error occurs. The behavior varies depending on the master or the slave area to be accessed.

Table 43.5 Behavior of TrustZone access error

DAP	CPU	DMAC/DTC	EDMAC	DRW	MIPI	GLCDC/CEU
• Only error response is returned*1	• IDAU/SAU detects SecureFault exception • TrustZone filter detects BusFault exception • Can issue a reset*2	• Stop transfer • Issue NMI or reset*2 • Generate interrupt (DMA0_TRANSERR)	• Issue NMI or reset*2 • Generate interrupt (ETHER_EINT0)*3	• Stop next transfer • Issue NMI or reset*2 • Generate interrupt (DRW_IRQ)*4	• Stop next transfer • Issue NMI or reset*2 • Generate interrupt (DSI_SEQ0, DSI_SEQ1)*5	• Issue NMI or reset*2

Note: This behavior is not applicable for bufferable write access. For more information on when a bufferable write access error is detected, see section 14.7.2. Operations When a Bus Error Occurs.

Note 1. When a TrustZone access error occurs by a debugger access, exception, NMI, or reset does not occur. Only the error response is returned.

Note 2. The operation after error detection is selected by the BUSOAD.SRERROAD bit.

Note 3. Address Error flag in EESR.ADE bit is set. The interrupt occurs when it is enabled in EESIPR.ADEIP bit.

Note 4. Access error flag in STATUS.BUSIRQ is set. The interrupt occurs when it is enabled in IRQCTL.BUSIRQEN bit.
Note 5. Access error flag in SQCH0SR.TXIBERR, SQCH1SR.TXIBERR is set. The interrupt occurs when it is enabled in SQCH0IER.TXIBERR, or SQCH1IER.TXIBERR bits.

43.4 Device Lifecycle Management

Device Lifecycle Management (DLM) identifies the current development/production/deployment phase of the device and controls the capabilities of the debug function, the serial programming interface, and Renesas test mode. Figure 43.7 shows the available device lifecycle states and Table 43.6 shows the lifecycle state definitions and capabilities in each state.

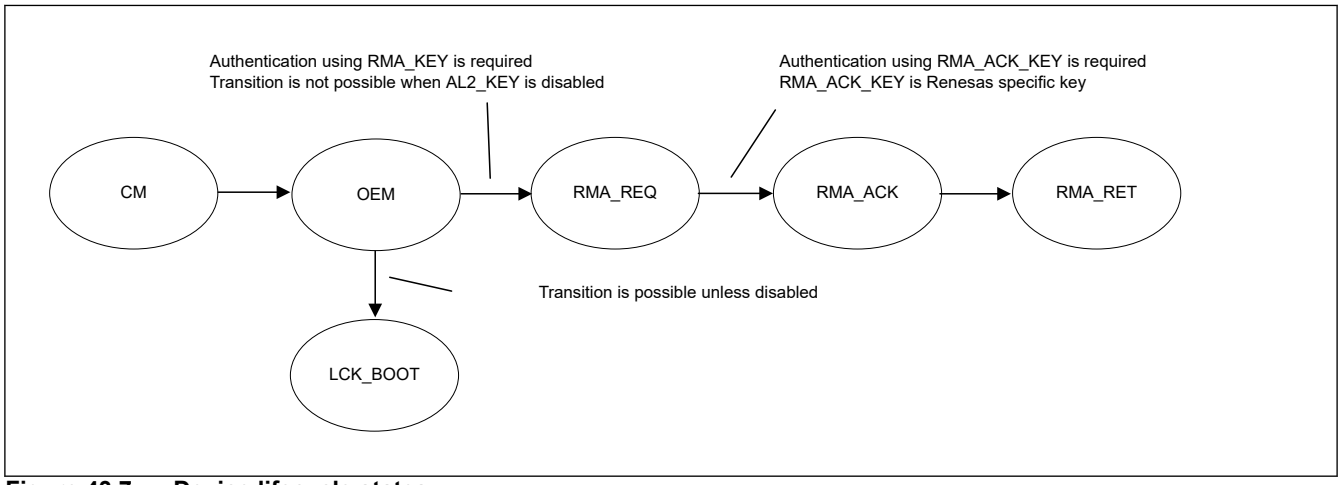

Figure 43.7 Device lifecycle states

Table 43.6 Lifecycle state definition and capabilities in each state

Lifecycle	Definition	Protection level	Debug function	Serial programming	Renesas test mode
CM	“Chip Manufacturing” The device is out of Renesas factory. The customer receives the device in this state.	PL2	Available in the secure and non-secure debug	Available Cannot access code/data flash area	Not available
OEM	“Original Equipment Manufacturer” The device is owned by the customer.	PL2 or PL1 or PL0	Depend on the authentication level		Not available
LCK_BOOT	“LoCKed BOOT interface” The debug interface and the serial programming interface are permanently disabled.	PL0	Not available	Not available	Not available
RMA_REQ	“Return Material Authorization REQuest” Request for RMA. The customer must send the device to Renesas in this state.	PL0	Not available	Available Cannot access code/data flash area	Not available
RMA_ACK	“Return Material Authorization ACKnowledged” Failure analysis in Renesas	PL2	Available in the secure and non-secure debug	Available Cannot access code/data flash area	Available
RMA_RET	“Return Material Authorization RETurn” The device is back to the customer. The device does not boot.	PL0	Not available	Not available	Not available

43.4.1 Changing the Lifecycle State

Use the boot firmware commands to change the device lifecycle state. These commands are available via the boot firmware's UART and USB interfaces, plus SWD/JTAG. See the boot firmware application note for details of the command. The lifecycle state cannot be updated by an application, but the current lifecycle state can be read through the dedicated registers.

As shown in Figure 43.7, each transition is one-way and the state cannot be regressed.

Transition from OEM to RMA_REQ requires key authentication using the RMA_KEY which must have been previously injected by the customer. The key length of the RMA_KEY is 128 bits. Inject the RMA_KEY as shown in section 43.5. Secure Key Injection. RMA_KEY can be injected in AL2.

The key authentication uses a challenge and response authentication or authentication using the MCU's unique ID. The response (challenge and response authentication) or the authentication code (using the MCU's unique ID) can be calculated as follows:

Response = AES-128 CMAC (RMA_KEY, 128-bit challenge)

Authentication code = AES-128 CMAC (RMA_KEY, 128-bit MCU unique ID)

The contents of the flash memory except permanently locked blocks or registers are erased when transitioning to RMA_REQ. The contents of the permanently locked blocks or registers can be read by Renesas at failure analysis. A flash block can permanently locked by setting the PBPS/PBPS_SEC and BPS_SEL registers to permanently disable programming and erasure of the block. The SAS register can be permanently locked by the FSPR bit, permanently disabling programming and erasure of the register. Transition to RMA_REQ is not possible if the AL2_KEY is disabled. The MCU does not respond after changing the device lifecycle state to RMA_REQ. To continue to use boot firmware commands, you must enter boot mode again after a reset. See the boot firmware application note for details.

Transition from OEM to LCK_BOOT is possible unless that transition has been explicitly disabled. Use the parameter setting command in AL2 or AL1 to prohibit the transition to LCK_BOOT. The LCK_BOOT transition prohibition is a permanent setting and cannot be undone. The debug interface and serial programming interface are permanently disabled in LCK_BOOT.

43.4.2 Protection and Authentication Level

The protection level (PL) and the authentication level (AL) determine the availability of the debug function and the serial programming interface. PL and AL are fixed except in the OEM state. For PL and for AL, three levels can be set for each in the OEM state. AL indicates a temporary authentication status and is initialized to PL after an MCU power-on reset. Both PL and AL can be changed only by the boot firmware and cannot be changed by the application. Figure 43.8 shows the available Protection Level and Authentication Level states and transitions. Table 43.7 shows the availability of the debug function and the serial programming interface in each level.

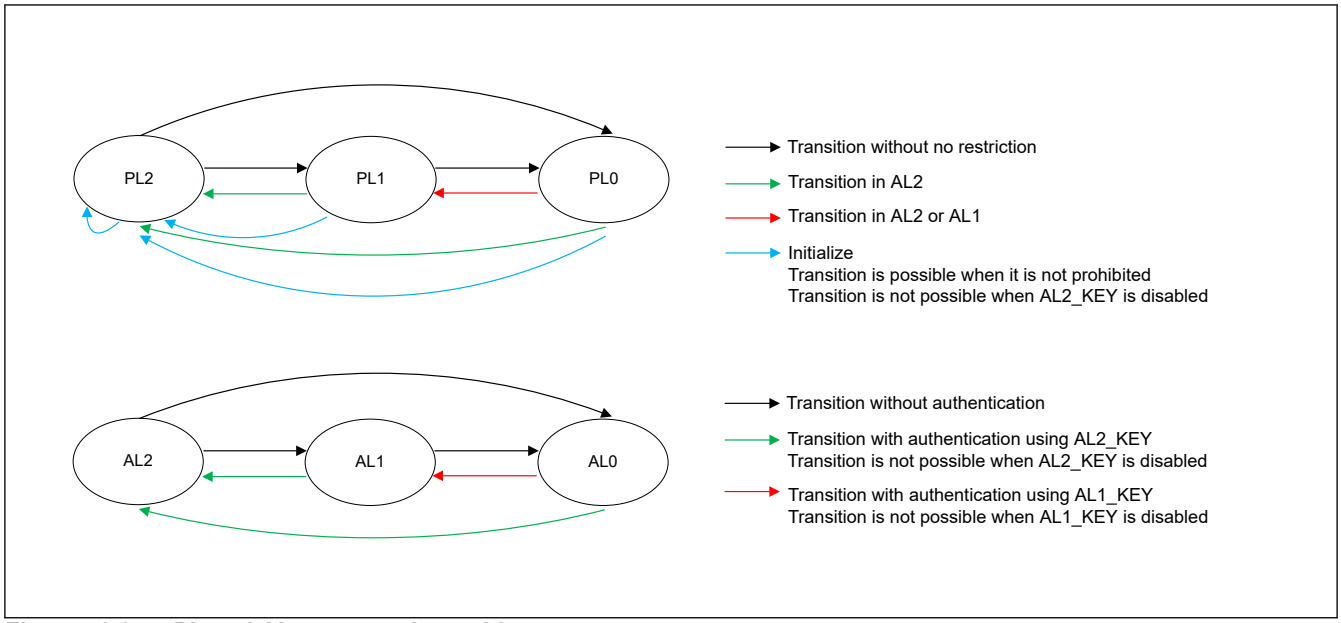

Figure 43.8 PL and AL states and transitions

Table 43.7 Availability of the debug function and the serial programming interface in each authentication level (1 of 2)

AL	Debug function	Serial programming interface
AL2	Non-secure and Secure debug functions are enabled and accessible from the debugger	All functions are available

Table 43.7 Availability of the debug function and the serial programming interface in each authentication level (2 of 2)

AL	Debug function	Serial programming interface
AL1	Only non-secure debug function is enabled, and debugger can access only defined non-secure debug accessible regions	Available but cannot program, erase, or read secure code or data flash area
AL0	No debug functions are available	Available but cannot access code or data flash area

Use the boot firmware commands to change PL and AL. See the boot firmware application note for details of the command.

Changing to a lower PL can be done with no restriction. Changing to a higher PL requires that the MCU be at that AL or higher. For example, when the current AL is AL1, changing to PL1 is possible but changing to PL2 is impossible. PL can be reset by the Initialize command unless the command itself is disabled. The Initialize command will set the PL to PL2 and the content in the flash memory will be erased. If there are any permanently locked blocks or registers, the Initialize command does not execute. In other words, when all the bits of the PBPS and PBPS_SEC registers are 1 and the FSPR bit is 1, the Initialize command is executable. The Initialize command can be disabled permanently in all AL states by the parameter setting command to prevent users from erasing the contents of flash memory. The Initialize command is disabled also when AL2_KEY is disabled. The MCU does not respond after executing the Initialize command. To continue to use the boot firmware commands, enter boot mode again after a reset. See the boot firmware application note for details.

Changing to a lower AL can be done without authentication. Changing to a higher AL requires key authentication using AL2_KEY or AL1_KEY, as appropriate. These keys are 128-bit keys. Injection of AL2_KEY or AL1_KEY is performed as shown in section 43.5. Secure Key Injection. AL2_KEY can be injected in AL2, AL1_KEY can be injected in AL2 or AL1. The key authentication uses a challenge and response authentication. The response can be calculated as follows:

Response = AES-128 CMAC (KEY, 128 bits challenge)

AL2_KEY can be disabled permanently in AL2 by parameter setting command. AL1_KEY can be disabled permanently in AL2 or AL1 by parameter setting command.

43.4.3 Serial Programming

Whether a serial programmer can be connected and the range of flash memory that can be accessed depends on the device lifecycle state and AL as shown in Table 43.6 and Table 43.7. In addition, the accepted serial programming commands differ depending on the device lifecycle state and AL. See the boot firmware application note for details of the commands.

43.4.4 Device Lifecycle State and PL Change Example

The following section describes a typical device lifecycle state and PL change example.

- Secure developer
  - Change the device lifecycle state from CM to OEM using the boot firmware command
  - Set the memory security attribution of the code flash and data flash using the boot firmware command
  - Program and debug the secure application. Debug is possible if the lifecycle is CM, but it is not possible to set the memory security attribution in CM state. If the memory security attribution is not set, all area of the code flash and data flash is secure. Inject application AES, RSA, ECC, HMAC keys listed in Table 43.8 (if required)
  - If the AL2_KEY and RMA_KEY are required, inject them using the boot firmware commands.
  - Prepare the MCU for the Non-secure developer
    - If the Non-secure Developer will not be permitted to use the Initialize command, disable it using the boot firmware command.
    - If the AL2_KEY will not be used and the Non-secure Developer will not be permitted to use the Initialize function,disable the AL2_KEY using the boot firmware command.
    - Change the PL from PL2 to PL1 using the boot firmware command
- Non-secure developer
  - Program and debug the non-secure application. Inject application AES, RSA, ECC, HMAC keys listed in Table 43.8 (if required)
  - If the AL1_KEY is required, inject it using the boot firmware command.

– Prepare the MCU for end-product deployment
  - Disable the Initialize command using the boot firmware command (if required)
  - If the AL1_KEY will not be used, disable the AL1_KEY using the boot firmware command.
  - Change the PL from PL1 to PL0 using the boot firmware command

43.4.5 Failure Analysis

If the customer requests failure analysis by Renesas, it is necessary to send the device after changing the device lifecycle state to RMA_REQ. If the device lifecycle state is not RMA_REQ, Renesas cannot perform the failure analysis. After failure analysis, Renesas changes the lifecycle to RMA_RET and returns the device to the customer.

Note: RMA_KEY is required to change the device lifecycle state to RMA_REQ or the MCU's Unique ID must be used as part of an authentication code. See section 43.4.1. Changing the Lifecycle State for details.

43.5 Secure Key Injection

To inject a user key into the MCU, perform the following steps.

Renesas provides the Security Key Management Tool, available on the Renesas web site, to assist with key injection preparation.

1. Create a 256-bit installation key.
   This key is called the User Factory Programming Key (UFPK) and is used to wrap a user key
2. Get the wrapped version (W-UFPK) of the UFPK through the Renesas Key Wrapping Service.
3. Wrap the user key using the UFPK.
4. Send the W-UFPK and the wrapped user key to the MCU using a boot firmware interface.
   The user key is unwrapped, wrapped with the MCU's hardware unique key, and stored in nonvolatile memory. DLM keys are stored in upmapped flash. Application keys are stored at the address specified with the key injection command.

Figure 43.9 shows an example of key injection and Table 43.8 shows the keys that can be injected.

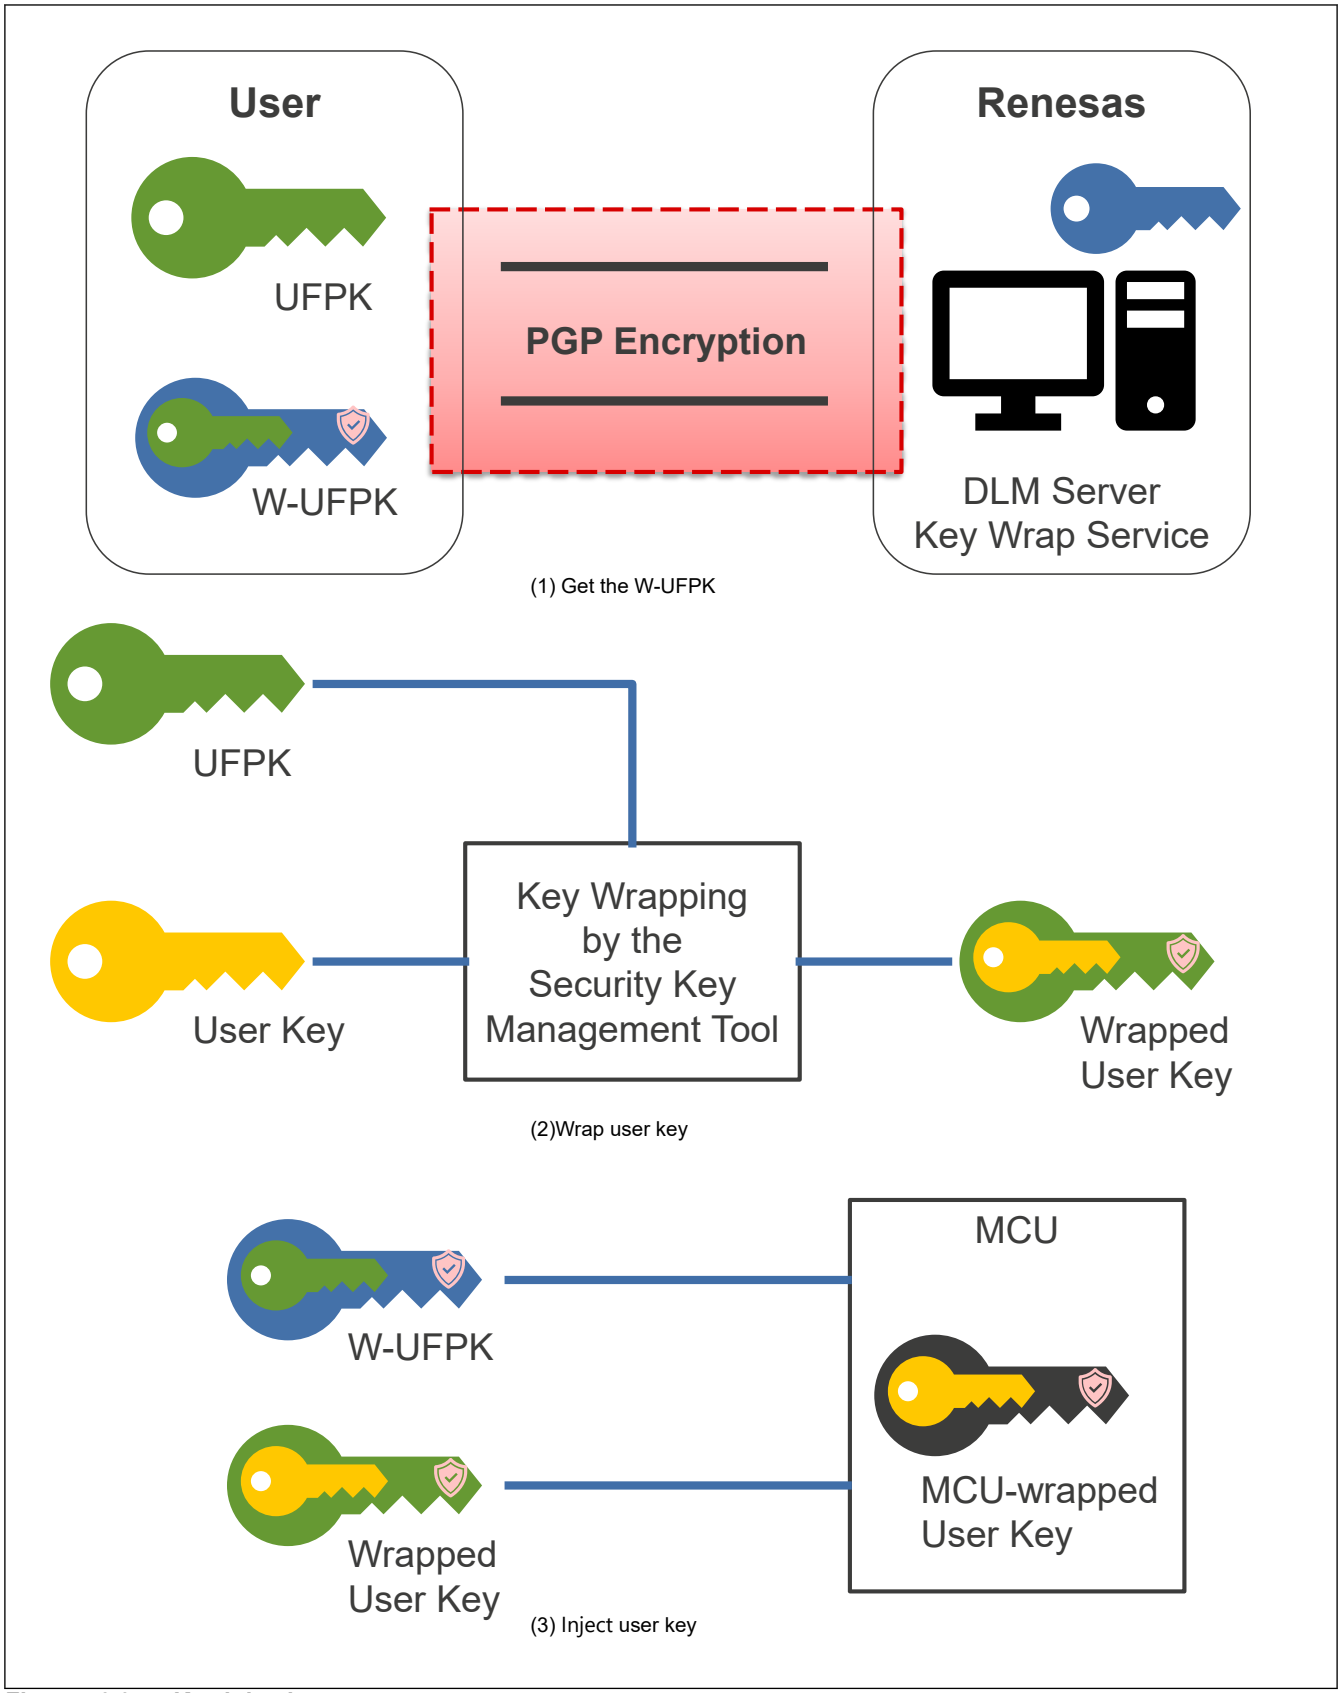

Figure 43.9 Key injection

Table 43.8 Keys that can be injected

DLM transition	AL transition	AES	RSA	ECC	HMAC	EdDSA	Secure boot	Other
RMA_KEY	AL2_KEY, AL1_KEY	AES-128, AES-192, AES-256, AES-XTS-128, AES-XTS-256	RSA-1024, RSA-2048, RSA-3072, RSA-4096 (Public and Private) RSA-2048 Public Key for TLS	secp192r1, secp224r1, secp256r1, secp384r1, secp521r1, Brainpool P256r1, Brainpool P384r1, Brainpool P521r1, Koblitz secp256k1 (Public and Private)	HMAC-SHA224, HMAC-SHA256, HMAC-SHA384, HMAC-SHA512, HMAC-SHA512/224, HMAC-SHA512/256	Ed25519 (Public and Private)	OEM_ROOT_PK	Key-Update Key

43.6 Secure Factory Programming

In addition to secure key injection support for injecting user keys (DLM, debug authentication, application, and secure boot keys), the MCU supports the programming of a firmware image in ciphertext format to prevent assets from being leaked during production programming. This enables secure factory programming in a non-secure environment. Secure factory programming is supported by the boot firmware. Figure 43.10 shows an example of secure factory programming of an encrypted firmware image. The customer wraps the Image Encryption Key with the UFPK and encrypts the image with the Image Encryption Key using AES128-CCM. When the customer sends the W-UFPK, the wrapped Image Encryption Key, and encrypted image to the MCU through the serial programming interface, the MCU decrypts and programs the firmware image.

To further support secure factory programming in a non-secure environment, the DLM state, Protection Level, and Authentication Keys can all be set via a single boot firmware command. Points to note about this boot firmware command include:

- Encrypted firmware programming can be performed only when the MCU is in the OEM state.
- This command will change the Protection Level of the MCU. The initial PL must be PL2. The final PL must be PL0.
- If the DLM state will remain in the OEM state, AL2 key must be injected. AL1 key can optionally also be injected.
- The MCU can be transitioned to the LCK_BOOT state. In this case, AL keys cannot be injected.
- AL keys must be wrapped with the same UFPK as the Image Encryption Key.
- This command will erase all code and data flash area except option-setting memory before programming encrypted firmware image. If there are any permanently locked blocks, this command can not be executed.
- This command will not be executed if the current register setting or write value to the registers related to startup area selection and startup bank selection are other than the following.
  - SAS.BTFLG = 1b
  - BANKSEL.BANKSWP[2:0] = 111b
  - BANKSEL_SEC.BANKSWP[2:0] = 111b
- All option-setting memory values must be included in the encrypted firmware image, including settings that are not used with default values. However, if the following areas are write-protected, the write data in these areas should not be included in the image. If included, this command will terminate with an error.
  - SAS register
  - Lockable Area 0 to 2 in the data flash option setting memory

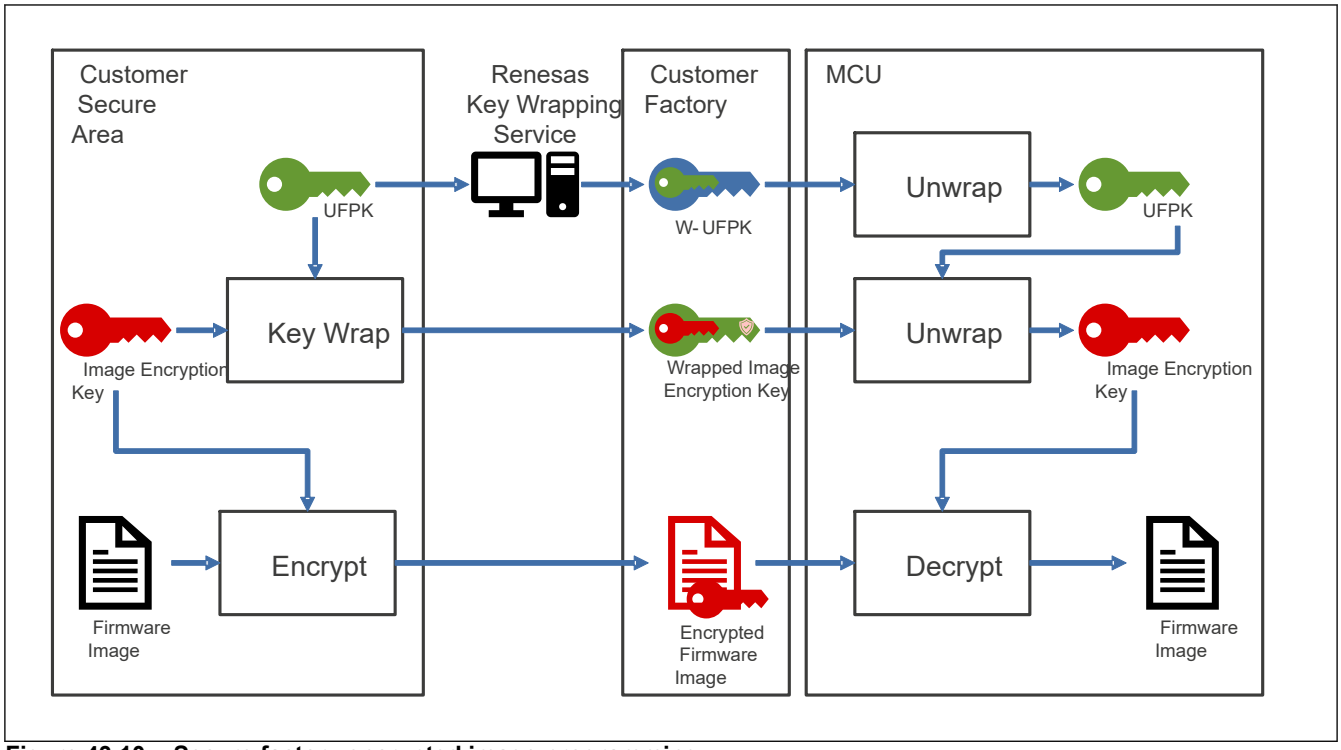

Figure 43.10 Secure factory encrypted image programming

43.7 Secure Boot

Secure boot verifies the integrity and authenticity of an OEM boot loader (called OEM_BL) starting at the beginning of application executable memory.

The OEM_BL is verified when it is initially programmed and prior to execution.

OEM_BL is verified when it is programmed using the boot firmware. Two certificates are used for validation. One is the key certificate, which is used to certify the OEM_BL verification key (called the OEM_BL_PK, the public part of the OEM_BL verification key pair). The key certificate is signed by the secret part of OEM_BL verification root key pair (called OEM_ROOT_SK). The public part of OEM_BL verification root key pair (called OEM_ROOT_PK) is registered with the MCU as the root of trust key using secure key injection as described in section 43.5. Secure Key Injection. The OEM_ROOT_SK and OEM_ROOT_PK are a 256-bit ECC (secp256r1 curve) key pair. The SHA2-256 hash of the OEM_ROOT_PK is stored during the secure key injection process.

The other certificate for validation during programming is the code certificate, which is used to certify the OEM_BL. The code certificate is signed by the secret part of OEM_BL verification key pair (called OEM_BL_SK). After successful validation of the OEM_BL, the HMAC value of OEM_BL and the code certificate (called OEM_BL_digest) is generated and programmed to flash. HMAC SHA2-256 is used to generate the HMAC value. A derived key from the HUK is used as the HMAC key, so the HMAC value is unique in each MCU.

In single-chip mode, the immutable first stage boot loader (called FSBL) in ROM is executed after reset when the FSBL is enabled in the FSBLCTRL0 register. When secure boot is selected in FSBLCTRL1 register, the FSBL generates the HMAC value of the OEM_BL and the code certificate, and compares it to the expected HMAC value. When the HMAC value is the same, the FSBL jumps to the OEM_BL. When CRC boot is selected in the FSBLCTRL1 register, the FSBL calculates the CRC of the OEM_BL and compares it to the expected CRC value, which is located in the code certificate. If the CRC values match, the FSBL jumps to the OEM_BL.

The Code certificate must be programmed into flash, and its location in flash must be programmed into the SACC0 register or SACC1 register. The SACC0 register specifies the start address of the code certificate when BANKSWP[2:0] = 111b in dual mode or when BTFLG = 1 in linear mode. The SACC1 register specifies the start address of the code certificate when BANKSWP[2:0] = 000b in dual mode or when BTFLG = 0 in linear mode.

When measurement reporting is enabled in the FSBLCTRL1 register, the FSBL stores the measurement report to the SRAM address specified by the SAMR register.

FSBL execution can be skipped after a software reset or deep software standby reset, as configured by the FSBLCTRL0 register.

If the generated HMAC or CRC value is different from the expected value, the high level is output to the port set by the FSBLCTRL2 register and the MCU goes to CPU Sleep mode.

Programming the hash of OEM_ROOT_PK and FSBL related registers can be permanently locked. It is strongly recommended to lock these items during production programming.

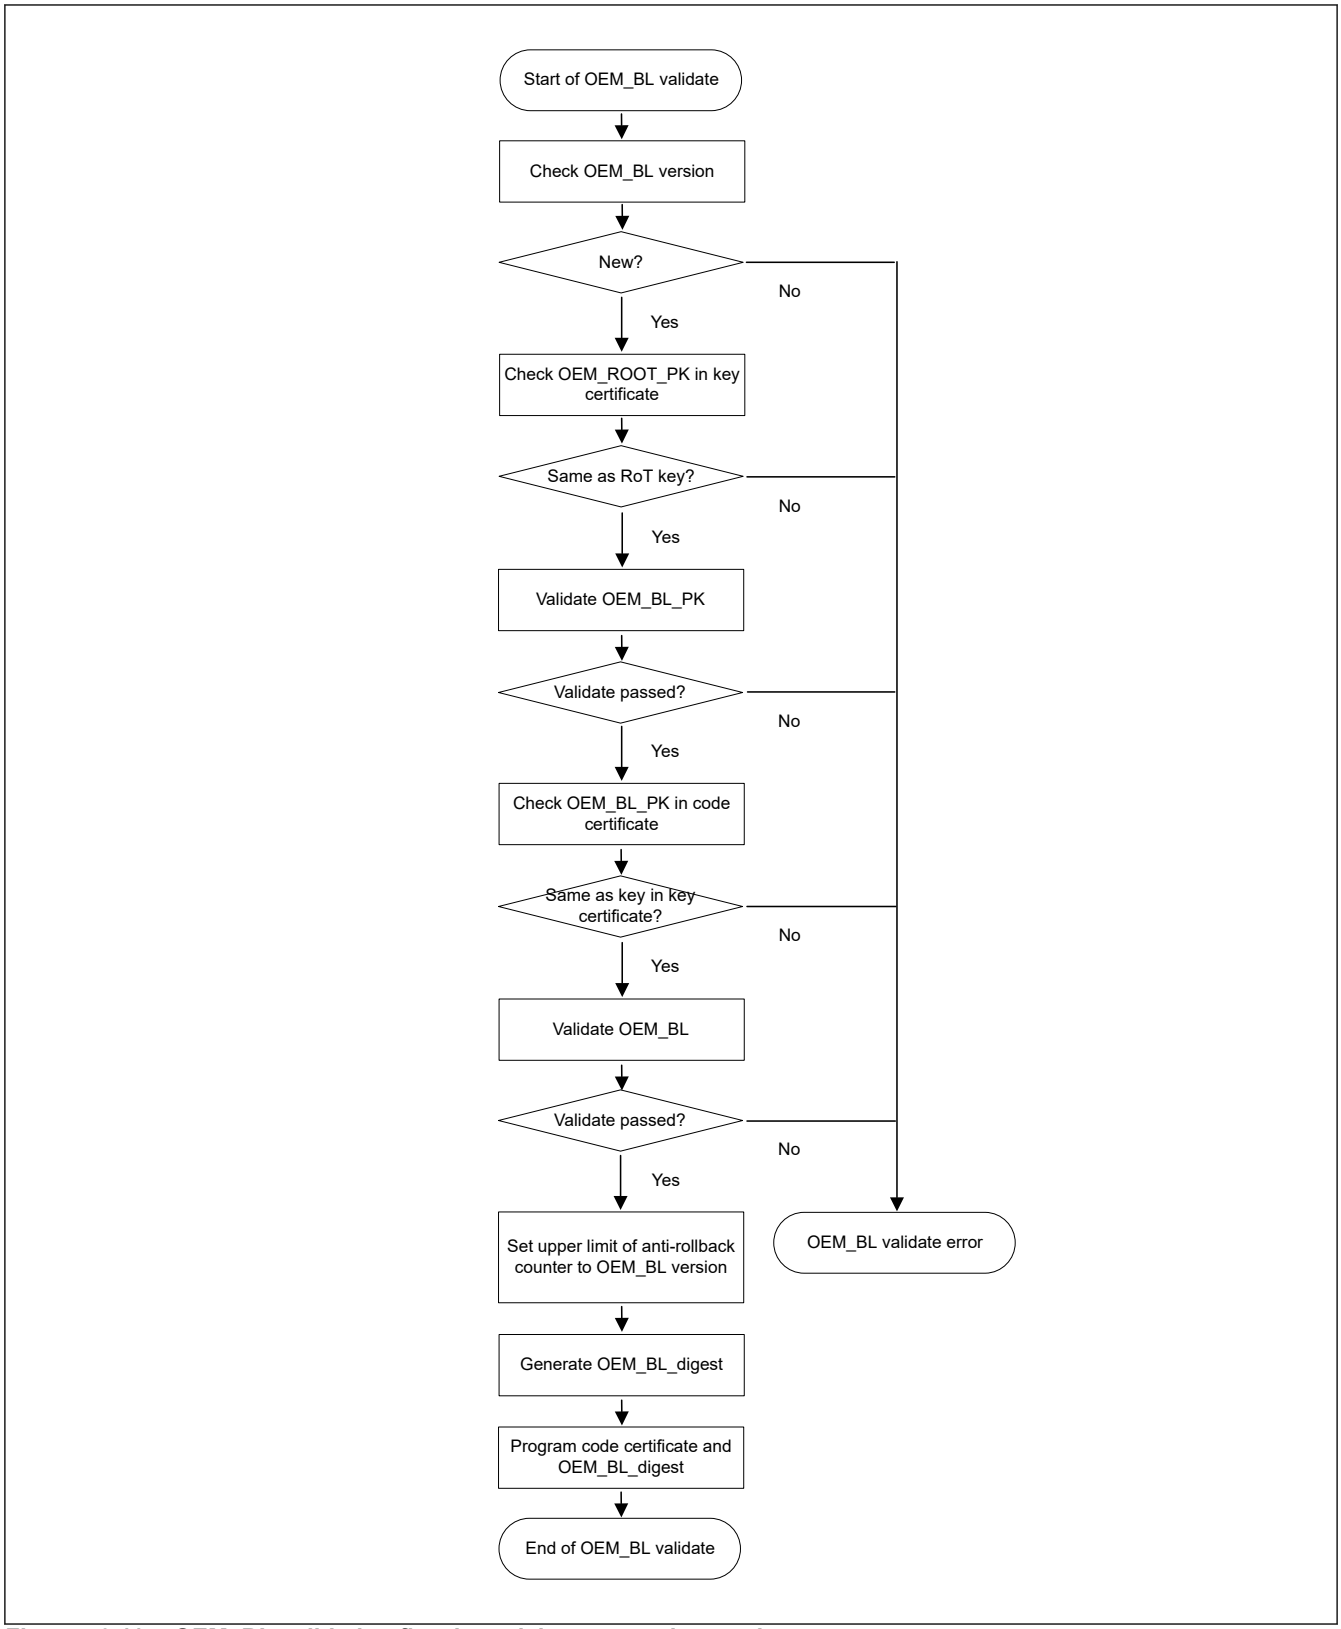

Figure 43.11 OEM_BL validation flow in serial programming mode

Field		Size [byte]	Description
TLV EXPECTED_MAC	Type & Length	4	Fixed value 0x30184008
	Value	32	Unique OEM_BL_digest in each MCU

Note: OEM_BL_digest should be programmed in the area contiguous with the code certificate.

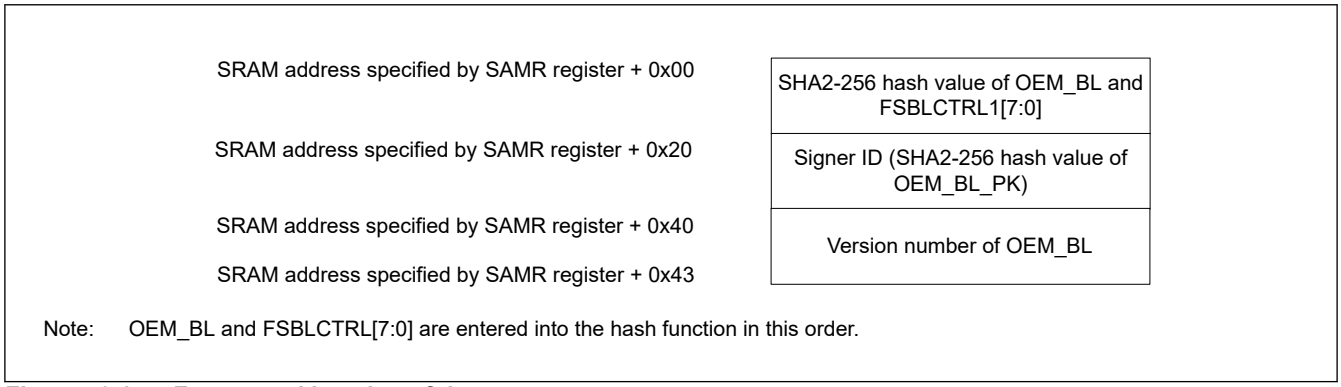

Figure 43.14 Format and location of the measurement report

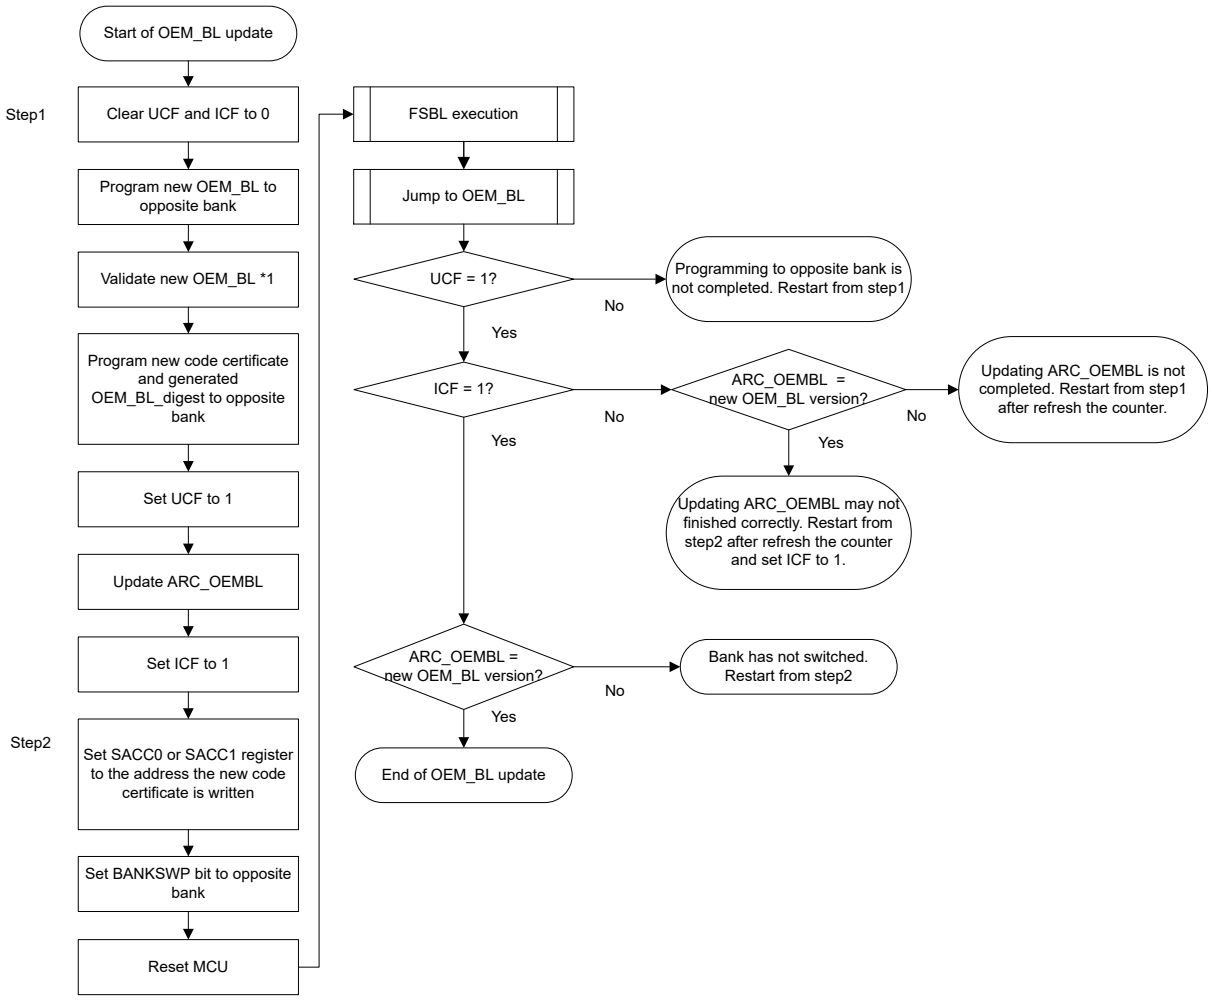
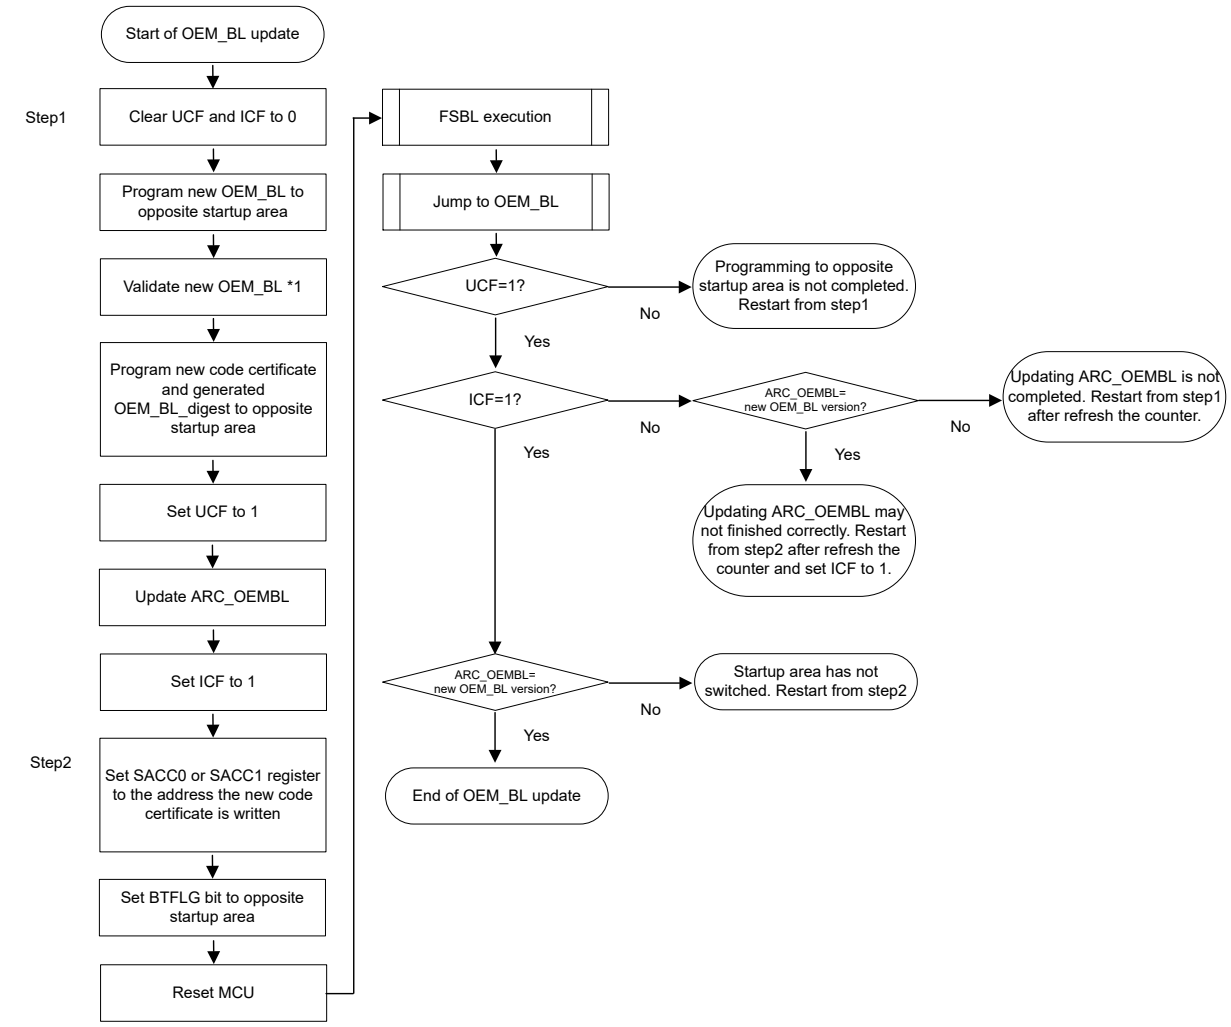
OEM_BL can be updated by application code. In this case, the application code must validate the updated bootloader, generate the OEM_BL_digest, and store it immediately after the new code certificate, as per the flow described by Figure 43.11.Figure 43.15 and Figure 43.16 show the OEM_BL update flow in dual mode or linear mode. When using linear mode, if the total size of OEM_BL, code certificate, and OEM_BL_digest is larger than the startup area size of 8 KB, you cannot use this update flow. It is recommended to use dual mode.

The implementation of the OEM_BL is user defined and application specific. However, it is recommended to implement status flags such as Update Complete Flag (UCF) and Increment Complete Flag (ICF) in the user lockable area of the data flash option-setting memory as a countermeasure against update errors due to unexpected power failure. If an update error occurs, it can be recovered as shown in the following figures. If an update error occurs, the current OEM_BL is executed after FSBL execution. Note that the update error determination program is required for both the current OEM_BL and the new OEM_BL.



Note 1. Validate new OEM_BL the same way as Figure 43.11.

Figure 43.15 OEM_BL update flow in dual mode



Note 1. Validate new OEM_BL the same way as Figure 43.11.

Figure 43.16 OEM_BL update flow in linear mode

43.8 Field Updating in Dual Mode

Be careful when performing in-field firmware update to keep the contents of secure (S or NSC) or Non-secure (NS) regions after bank swapping in the dual mode. Figure 43.17 and Figure 43.18 show the performing in-field update of information flow of secure or non-secure regions in the dual mode.

Figure 43.17 and Figure 43.18 show updating the Secure and the Non-secure regions respectively when operating in dual bank mode. Initially, BANK0 contains Version 1 of the firmware, and BANK1 is blank. As shown in Figure 43.17, to update the S or NSC firmware to Version 2, first copy the Version 1 NS firmware in BANK0 to BANK1, update the S or NSC to Version 2, and then execute the bank swap.

As shown in Figure 43.18, to update the NS firmware to Version 2, first copy the Version 1 S and NSC firmware from BANK0 to BANK1. Note that this process must be done by a secure service. After that, non-secure users should update the NS firmware to Version 2 and execute the bank swap.

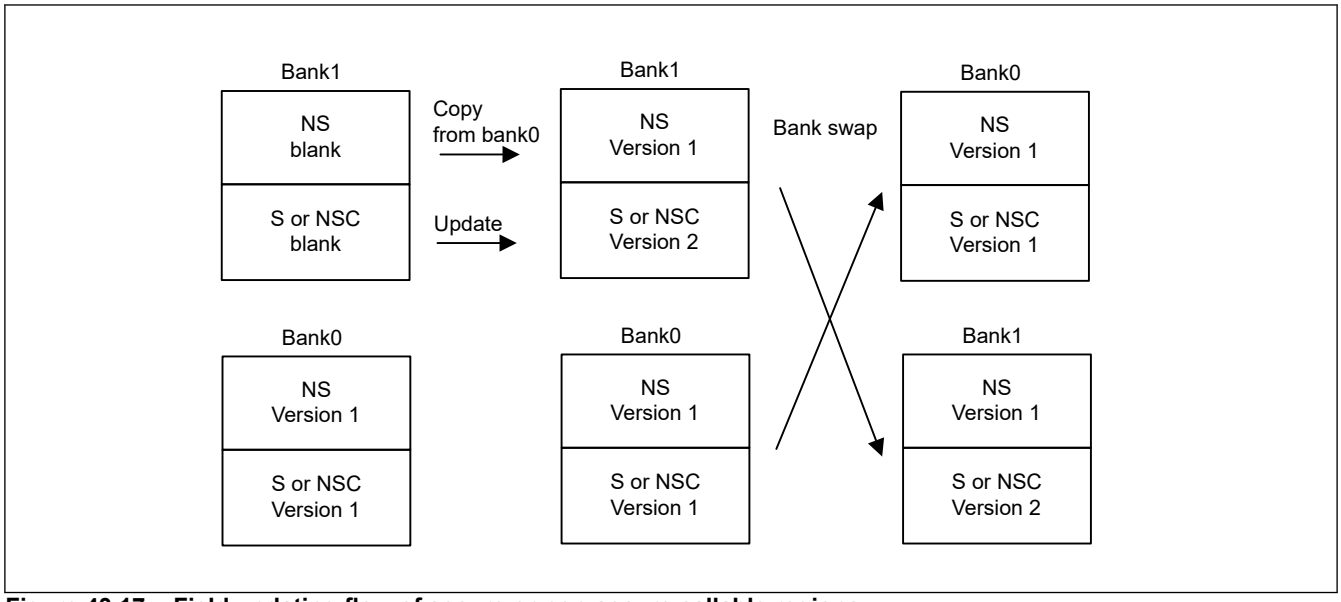


Figure 43.17 Field updating flow of secure or non-secure callable regions

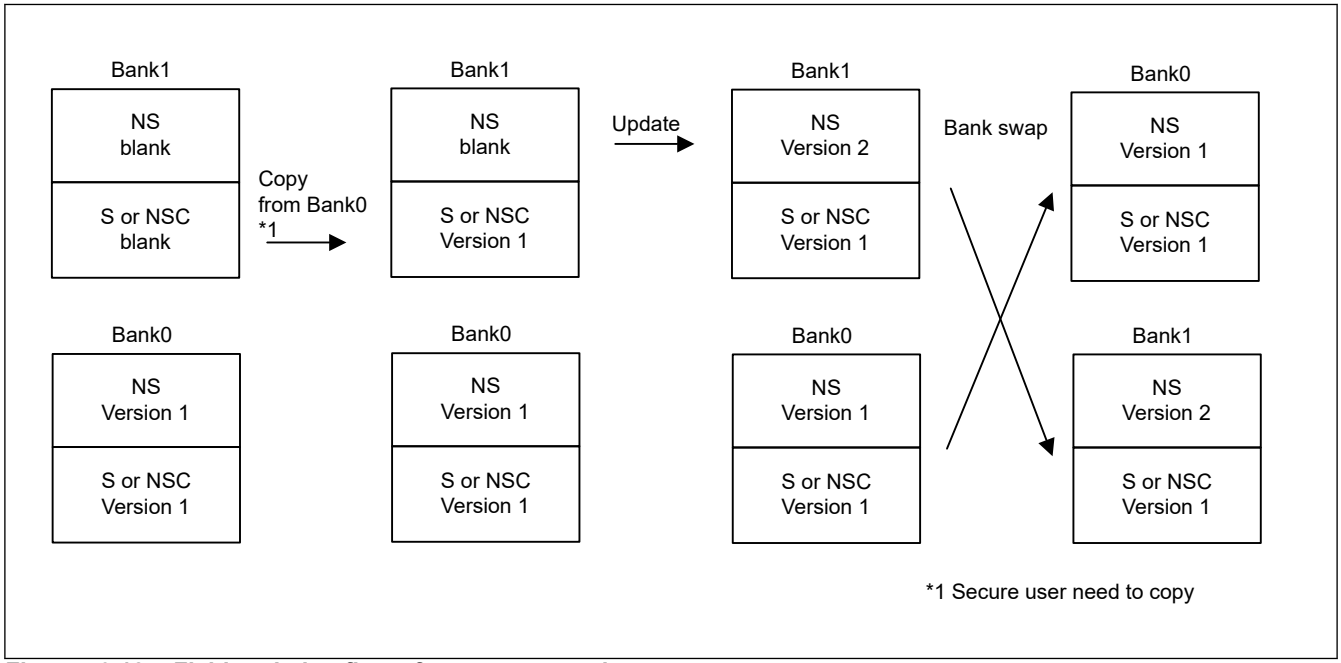

Figure 43.18 Field updating flow of non-secure region

43.9 Register Description

43.9.1 PSARB : Peripheral Security Attribution Register B

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PSARB31	PSARB30	PSARB29	PSARB28	PSARB27	—	—	—	—	PSARB22	—	—	PSARB19	PSARB18	—	PSARB16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PSARB15	—	—	PSARB12	PSARB11	—	PSARB9	PSARB8	—	—	—	PSARB4	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	PSARB4	I3C Bus Interface Security Attribution Target module: I3C and the MSTPCRB.MSTPB4 bit 0: Secure 1: Non-secure	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	PSARB8	I2C Bus Interface 1 Security Attribution Target module: IIC1 and the MSTPCRB.MSTPB8 bit 0: Secure 1: Non-secure	R/W
9	PSARB9	I2C Bus Interface 0 Security Attribution Target module: IIC0 and the MSTPCRB.MSTPB9 bit 0: Secure 1: Non-secure	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	PSARB11	Universal Serial Bus 2.0 FS Interface 0 Security Attribution Target module: USBFS0 and the MSTPCRB.MSTPB11 bit 0: Secure 1: Non-secure	R/W
12	PSARB12	Universal Serial Bus 2.0 HS Interface Security Attribution Target module: USBHS and the MSTPCRB.MSTPB12 bit 0: Secure 1: Non-secure	R/W
14:13	—	These bits are read as 0. The write value should be 0.	R/W
15	PSARB15	ETHERC/EDMAC Controller Security Attribution Target module: ETHERC/EDMAC, the MSTPCRB.MSTPB15 bit, and the PFENET.PHYMODE0 bit 0: Secure 1: Non-secure	R/W
16	PSARB16	Octa Memory Controller Security Attribution Target module: OSPI (+DOTF) and the MSTPCRB.MSTPB16 bit 0: Secure 1: Non-secure	R/W
17	—	This bit is read as 0. The write value should be 0.	R/W
18	PSARB18	Serial Peripheral Interface 1 Security Attribution Target module: RSPI1 and the MSTPCRB.MSTPB18 bit 0: Secure 1: Non-secure	R/W

Bit	Symbol	Function	R/W
19	PSARB19	Serial Peripheral Interface 0 Security Attribution Target module: RSPI0 and the MSTPCRB.MSTPB19 bit 0: Secure 1: Non-secure	R/W
21:20	—	These bits are read as 0. The write value should be 0.	R/W
22	PSARB22	Serial Communication Interface 9 Security Attribution Target module: SCI9 and the MSTPCRB.MSTPB22 bit 0: Secure 1: Non-secure	R/W
26:23	—	These bits are read as 0. The write value should be 0.	R/W
27	PSARB27	Serial Communication Interface 4 Security Attribution Target module: SCI4 and the MSTPCRB.MSTPB27 bit 0: Secure 1: Non-secure	R/W
28	PSARB28	Serial Communication Interface 3 Security Attribution Target module: SCI3 and the MSTPCRB.MSTPB28 bit 0: Secure 1: Non-secure	R/W
29	PSARB29	Serial Communication Interface 2 Security Attribution Target module: SCI2 and the MSTPCRB.MSTPB29 bit 0: Secure 1: Non-secure	R/W
30	PSARB30	Serial Communication Interface 1 Security Attribution Target module: SCI1 and the MSTPCRB.MSTPB30 bit 0: Secure 1: Non-secure	R/W
31	PSARB31	Serial Communication Interface 0 Security Attribution Target module: SCI0 and the MSTPCRB.MSTPB31 bit 0: Secure 1: Non-secure	R/W

Note: S-TYPE-1, P-TYPE-1.

The PSARB register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

43.9.2 PSARC : Peripheral Security Attribution Register C

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PSARC31	—	—	—	PSARC27	PSARC26	—	—	—	—	—	—	—	—	—	PSARC16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PSARC15	—	PSARC13	PSARC12	PSARC11	—	—	PSARC8	PSARC7	—	—	—	—	—	PSARC1	PSARC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PSARC0	Clock Frequency Accuracy Measurement Circuit Security Attribution register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register. Target module: CAC and the MSTPCRC.MSTPC0 bit 0: Secure 1: Non-secure	R/W

Bit	Symbol	Function	R/W
1	PSARC1	Cyclic Redundancy Check Calculator Security Attribution Target module: CRC and the MSTPCRC.MSTPC1 bit 0: Secure 1: Non-secure	R/W
6:2	—	These bits are read as 0. The write value should be 0.	R/W
7	PSARC7	Serial Sound Interface Enhanced (channel 1) Security Attribution Target module: SSIE1 and the MSTPCRC.MSTPC7 bit 0: Secure 1: Non-secure	R/W
8	PSARC8	Serial Sound Interface Enhanced (channel 0) Security Attribution Target module: SSIE0 and the MSTPCRC.MSTPC8 bit 0: Secure 1: Non-secure	R/W
10:9	—	These bits are read as 0. The write value should be 0.	R/W
11	PSARC11	Secure Digital Host IF 1 Security Attribution Target module: SDHI1 and the MSTPCRC.MSTPC11 bit 0: Secure 1: Non-secure	R/W
12	PSARC12	Secure Digital Host IF 0 Security Attribution Target module: SDHI0 and the MSTPCRC.MSTPC12 bit 0: Secure 1: Non-secure	R/W
13	PSARC13	Data Operation Circuit Security Attribution Target module: DOC and the MSTPCRC.MSTPC13 bit 0: Secure 1: Non-secure	R/W
14	—	This bit is read as 0. The write value should be 0.	R/W
15	PSARC15	Graphic (GLCDC, MIPI-DSI, DRW) Security Attribution Target module: GLCDC, MIPI-DSI, DRW and the MSTPCRC.MSTPC4, MSTPCRC.MSTPC6, MSTPCRC.MSTPC10 bits 0: Secure 1: Non-secure	R/W
16	PSARC16	CEU Security Attribution Target module: CEU and the MSTPCRC.MSTPC16 bit 0: Secure 1: Non-secure	R/W
25:17	—	These bits are read as 0. The write value should be 0.	R/W
26	PSARC26	Controller Area Network with Flexible Data-Rate 1 Security Attribution Target module: CANFD1 and the MSTPCRC.MSTPC26 bit 0: Secure 1: Non-secure	R/W
27	PSARC27	Controller Area Network with Flexible Data-Rate 0 Security Attribution Target module: CANFD0 and the MSTPCRC.MSTPC27 bit 0: Secure 1: Non-secure	R/W
30:28	—	These bits are read as 0. The write value should be 0.	R/W
31	PSARC31	RSIP-E51A Security Attribution Target module:RSIP-E51A and the MSTPCRC.MSTPC31 bit 0: Secure 1: Non-secure	R/W

Note: S-TYPE-1, P-TYPE-1.

The PSARC register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

43.9.3 PSARD : Peripheral Security Attribution Register D

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x0C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	PSARD28	PSARD27	—	—	—	—	PSARD22	—	PSARD20	—	—	—	PSARD16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PSARD15	PSARD14	PSARD13	PSARD12	PSARD11	—	—	—	—	—	PSARD5	PSARD4	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	PSARD4	Asynchronous General Purpose Timer 1 Security Attribution Target module: AGT1 and the MSTPCRD.MSTPD4 bit 0: Secure 1: Non-secure	R/W
5	PSARD5	Asynchronous General Purpose Timer 0 Security Attribution Target module: AGT0 and the MSTPCRD.MSTPD5 bit 0: Secure 1: Non-secure	R/W
10:6	—	These bits are read as 0. The write value should be 0.	R/W
11	PSARD11	Port Output Enable for GPT Group 3 Security Attribution Target module: POEG Group D and the MSTPCRD.MSTPD11 bit 0: Secure 1: Non-secure	R/W
12	PSARD12	Port Output Enable for GPT Group 2 Security Attribution Target module: POEG Group C and the MSTPCRD.MSTPD12 bit 0: Secure 1: Non-secure	R/W
13	PSARD13	Port Output Enable for GPT Group 1 Security Attribution Target module: POEG Group B and the MSTPCRD.MSTPD13 bit 0: Secure 1: Non-secure	R/W
14	PSARD14	Port Output Enable for GPT Group 0 Security Attribution Target module: POEG Group A and the MSTPCRD.MSTPD14 bit 0: Secure 1: Non-secure	R/W
15	PSARD15	12-Bit A/D 1 Converter Security Attribution Target module: ADC12_1 and the MSTPCRD.MSTPD15 bit 0: Secure 1: Non-secure	R/W
16	PSARD16	12-Bit A/D 0 Converter Security Attribution Target module: ADC12_0 and the MSTPCRD.MSTPD16 bit 0: Secure 1: Non-secure	R/W
19:17	—	These bits are read as 0. The write value should be 0.	R/W
20	PSARD20	12-Bit D/A Converter Security Attribution Target module: DAC12 and the MSTPCRD.MSTPD20 bit 0: Secure 1: Non-secure	R/W
21	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
22	PSARD22	Temperature Sensor Security Attribution Target module: TSN and the MSTPCRD.MSTPD22 bit 0: Secure 1: Non-secure	R/W
26:23	—	These bits are read as 0. The write value should be 0.	R/W
27	PSARD27	High Speed Analog Comparator 1 Security Attribution Target module: ACMPHS1 and the MSTPCRD.MSTPD27 bit 0: Secure 1: Non-secure	R/W
28	PSARD28	High Speed Analog Comparator 0 Security Attribution Target module: ACMPHS0 and the MSTPCRD.MSTPD28 bit 0: Secure 1: Non-secure	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-1, P-TYPE-1.

The PSARD register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

43.9.4 PSARE : Peripheral Security Attribution Register E

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PSARE31	PSARE30	PSARE29	PSARE28	PSARE27	PSARE26	PSARE25	PSARE24	PSARE23	PSARE22	PSARE21	PSARE20	PSARE19	PSARE18	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PSARE9	PSARE8	—	—	—	—	PSARE3	PSARE2	PSARE1	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	PSARE1	WDT Security Attribution Target module: WDT 0: Secure 1: Non-secure	R/W
2	PSARE2	IWDT Security Attribution Target module: IWDT 0: Secure 1: Non-secure	R/W
3	PSARE3	Real Time Clock Security Attribution Target module: RTC 0: Secure 1: Non-secure	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
8	PSARE8	ULPT1 Security Attribution Target module: ULPT1 and the MSTPCRE.MSTPE8 bit 0: Secure 1: Non-secure	R/W

Bit	Symbol	Function	R/W
9	PSARE9	ULPT0 Security Attribution Target module: ULPT0 and the MSTPCRE.MSTPE9 bit 0: Secure 1: Non-secure	R/W
17:10	—	These bits are read as 0. The write value should be 0.	R/W
18	PSARE18	General PWM Timer Channel 13 Security Attribution Target module: GPT13 and the MSTPCRE.MSTPE18 bit 0: Secure 1: Non-secure	R/W
19	PSARE19	General PWM Timer Channel 12 Security Attribution Target module: GPT12 and the MSTPCRE.MSTPE19 bit 0: Secure 1: Non-secure	R/W
20	PSARE20	General PWM Timer Channel 11 Security Attribution Target module: GPT11 and the MSTPCRE.MSTPE20 bit 0: Secure 1: Non-secure	R/W
21	PSARE21	General PWM Timer Channel 10 Security Attribution Target module: GPT10 and the MSTPCRE.MSTPE21 bit 0: Secure 1: Non-secure	R/W
22	PSARE22	General PWM Timer Channel 9 Security Attribution Target module: GPT9 and the MSTPCRE.MSTPE22 bit 0: Secure 1: Non-secure	R/W
23	PSARE23	General PWM Timer Channel 8 Security Attribution Target module: GPT8 and the MSTPCRE.MSTPE23 bit 0: Secure 1: Non-secure	R/W
24	PSARE24	General PWM Timer Channel 7 Security Attribution Target module: GPT7 and the MSTPCRE.MSTPE24 bit 0: Secure 1: Non-secure	R/W
25	PSARE25	General PWM Timer Channel 6 Security Attribution Target module: GPT6 and the MSTPCRE.MSTPE25 bit 0: Secure 1: Non-secure	R/W
26	PSARE26	General PWM Timer Channel 5 Security Attribution Target module: GPT5 and the MSTPCRE.MSTPE26 bit 0: Secure 1: Non-secure	R/W
27	PSARE27	General PWM Timer Channel 4 Security Attribution Target module: GPT4 and the MSTPCRE.MSTPE27 bit 0: Secure 1: Non-secure	R/W
28	PSARE28	General PWM Timer Channel 3 Security Attribution Target module: GPT3 and the MSTPCRE.MSTPE28 bit 0: Secure 1: Non-secure	R/W
29	PSARE29	General PWM Timer Channel 2 Security Attribution Target module: GPT2 and the MSTPCRE.MSTPE29 bit 0: Secure 1: Non-secure	R/W
30	PSARE30	General PWM Timer Channel 1 Security Attribution Target module: GPT1 and the MSTPCRE.MSTPE30 bit 0: Secure 1: Non-secure	R/W

Bit	Symbol	Function	R/W
31	PSARE31	General PWM Timer Channel 0 Security Attribution Target module: GPT0, GPT_OPS and the MSTPCRE.MSTPE31 bit 0: Secure 1: Non-secure	R/W

Note: S-TYPE-1, P-TYPE-1.

The PSARE register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

43.9.5 MSSAR : Module Stop Security Attribution Register

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x14

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MSSAR31	—	—	—	—	—	—	—	—	MSSAR22	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MSSAR15	—	—	—	—	—	—	—	—	—	—	—	—	—	MSSAR1	MSSAR0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MSSAR0	SRAM0 Clock Stop Security Attribution Target module: the MSTPCRA.MSTPA0 bit 0: Secure 1: Non-secure	R/W
1	MSSAR1	SRAM1 Clock Stop Security Attribution Target module: the MSTPCRA.MSTPA1 bit 0: Secure 1: Non-secure	R/W
14:2	—	These bits are read as 0. The write value should be 0.	R/W
15	MSSAR15	Standby RAM Clock Stop Security Attribution Target module: the MSTPCRA.MSTPA15 bit 0: Secure 1: Non-secure	R/W
21:16	—	These bits are read as 0. The write value should be 0.	R/W
22	MSSAR22	DMAC/DTC Clock Stop Security Attribution Target module: the MSTPCRA.MSTPA22 bit 0: Secure 1: Non-secure	R/W
30:23	—	These bits are read as 0. The write value should be 0.	R/W
31	MSSAR31	ELC Clock Stop Security Attribution Target module: the MSTPCRC.MSTPC14 bit 0: Secure 1: Non-secure	R/W

Note: S-TYPE-1, P-TYPE-1.

The MSSAR register specifies the security attribution for the corresponding bit in Module Stop Control Register.

43.9.6 PPARB : Peripheral Privilege Attribution Register B

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x1C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PPARB31	PPARB30	PPARB29	PPARB28	PPARB27	—	—	—	—	PPARB22	—	—	PPARB19	PPARB18	—	PPARB16
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PPARB15	—	—	PPARB12	PPARB11	—	PPARB9	PPARB8	—	—	—	PPARB4	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 1. The write value should be 1.	R/W
4	PPARB4	I3C Bus Interface Privilege Attribution Target module: I3C and the MSTPCRB.MSTPB4 bit 0: Privileged 1: UnPrivileged	R/W
7:5	—	These bits are read as 1. The write value should be 1.	R/W
8	PPARB8	I2C Bus Interface 1 Privilege Attribution Target module: IIC1 and the MSTPCRB.MSTPB8 bit 0: Privileged 1: UnPrivileged	R/W
9	PPARB9	I2C Bus Interface 0 Privilege Attribution Target module: IIC0 and the MSTPCRB.MSTPB9 bit 0: Privileged 1: UnPrivileged	R/W
10	—	This bit is read as 1. The write value should be 1.	R/W
11	PPARB11	Universal Serial Bus 2.0 FS Interface 0 Privilege Attribution Target module: USBFS0 and the MSTPCRB.MSTPB11 bit 0: Privileged 1: UnPrivileged	R/W
12	PPARB12	Universal Serial Bus 2.0 HS Interface 0 Privilege Attribution Target module: USBHS and the MSTPCRB.MSTPB12 bit 0: Privileged 1: UnPrivileged	R/W
14:13	—	These bits are read as 1. The write value should be 1.	R/W
15	PPARB15	ETHERC/EDMAC Controller Privilege Attribution Target module: ETHERC/EDMAC, the MSTPCRB.MSTPB15 bit, and the PFENET.PHYMODE0 bit 0: Privileged 1: UnPrivileged	R/W
16	PPARB16	Octa Memory Controller Privilege Attribution Target module: OSPI (+DOTF) and the MSTPCRB.MSTPB16 bit 0: Privileged 1: UnPrivileged	R/W
17	—	This bit is read as 1. The write value should be 1.	R/W
18	PPARB18	Serial Peripheral Interface 1 Privilege Attribution Target module: RSPI1 and the MSTPCRB.MSTPB18 bit 0: Privileged 1: UnPrivileged	R/W

Bit	Symbol	Function	R/W
19	PPARB19	Serial Peripheral Interface 0 Privilege Attribution Target module: RSPI0 and the MSTPCRB.MSTPB19 bit 0: Privileged 1: UnPrivileged	R/W
21:20	—	These bits are read as 1. The write value should be 1.	R/W
22	PPARB22	Serial Communication Interface 9 Privilege Attribution Target module: SCI9 and the MSTPCRB.MSTPB22 bit 0: Privileged 1: UnPrivileged	R/W
26:23	—	These bits are read as 1. The write value should be 1.	R/W
27	PPARB27	Serial Communication Interface 4 Privilege Attribution Target module: SCI4 and the MSTPCRB.MSTPB27 bit 0: Privileged 1: UnPrivileged	R/W
28	PPARB28	Serial Communication Interface 3 Privilege Attribution Target module: SCI3 and the MSTPCRB.MSTPB28 bit 0: Privileged 1: UnPrivileged	R/W
29	PPARB29	Serial Communication Interface 2 Privilege Attribution Target module: SCI2 and the MSTPCRB.MSTPB29 bit 0: Privileged 1: UnPrivileged	R/W
30	PPARB30	Serial Communication Interface 1 Privilege Attribution Target module: SCI1 and the MSTPCRB.MSTPB30 bit 0: Privileged 1: UnPrivileged	R/W
31	PPARB31	Serial Communication Interface 0 Privilege Attribution Target module: SCI0 and the MSTPCRB.MSTPB31 bit 0: Privileged 1: UnPrivileged	R/W

Note: S-TYPE-2, P-TYPE-1.

The PPARB register specifies the privilege attribution for each module and the corresponding bit in Module Stop Control Register.

43.9.7 PPARC : Peripheral Privilege Attribution Register C

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PPARC31	—	—	—	PPARC27	PPARC26	—	—	—	—	—	—	—	—	—	PPARC16
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PPARC15	—	PPARC13	PPARC12	PPARC11	—	—	PPARC8	PPARC7	—	—	—	—	—	PPARC1	PPARC0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
0	PPARC0	Clock Frequency Accuracy Measurement Circuit Privilege Attribution Target module: CAC and the MSTPCRC.MSTPC0 bit 0: Privileged 1: UnPrivileged	R/W

Bit	Symbol	Function	R/W
1	PPARC1	Cyclic Redundancy Check Calculator Privilege Attribution Target module: CRC and the MSTPCRC.MSTPC1 bit 0: Privileged 1: UnPrivileged	R/W
6:2	—	These bits are read as 1. The write value should be 1.	R/W
7	PPARC7	Serial Sound Interface Enhanced (Channel 1) Privilege Attribution Target module: SSIE1 and the MSTPCRC.MSTPC7 bit 0: Privileged 1: UnPrivileged	R/W
8	PPARC8	Serial Sound Interface Enhanced (Channel 0) Privilege Attribution Target module: SSIE0 and the MSTPCRC.MSTPC8 bit 0: Privileged 1: UnPrivileged	R/W
10:9	—	These bits are read as 1. The write value should be 1.	R/W
11	PPARC11	Secure Digital Host IF 1 Privilege Attribution Target module: SDHI1 and the MSTPCRC.MSTPC11 bit 0: Privileged 1: UnPrivileged	R/W
12	PPARC12	Secure Digital Host IF 0 Privilege Attribution Target module: SDHI0 and the MSTPCRC.MSTPC12 bit 0: Privileged 1: UnPrivileged	R/W
13	PPARC13	Data Operation Circuit Privilege Attribution Target module: DOC and the MSTPCRC.MSTPC13 bit 0: Privileged 1: UnPrivileged	R/W
14	—	This bit is read as 1. The write value should be 1.	R/W
15	PPARC15	Graphic (GLCDC, MIPI-DSI, DRW) Privilege Attribution Target module: GLCDC, MIPI-DSI, DRW and the MSTPCRC.MSTPC4, MSTPCRC.MSTPC6, MSTPCRC.MSTPC10 bits 0: Privileged 1: UnPrivileged	R/W
16	PPARC16	CEU Privilege Attribution Target module: CEU and the MSTPCRC.MSTPC16 bit 0: Privileged 1: UnPrivileged	R/W
25:17	—	These bits are read as 1. The write value should be 1.	R/W
26	PPARC26	Controller Area Network with Flexible Data-Rate 1 Privilege Attribution Target module: CANFD1 and the MSTPCRC.MSTPC26 bit 0: Privileged 1: UnPrivileged	R/W
27	PPARC27	Controller Area Network with Flexible Data-Rate 0 Privilege Attribution Target module: CANFD0 and the MSTPCRC.MSTPC27 bit 0: Privileged 1: UnPrivileged	R/W
30:28	—	These bits are read as 1. The write value should be 1.	R/W
31	PPARC31	RSIP-E51A Privilege Attribution Target module: RSIP-E51A and the MSTPCRC.MSTPC31 bit 0: Privileged 1: UnPrivileged	R/W

Note: S-TYPE-2, P-TYPE-1.

The PPARC register specifies the privilege attribution for each module and the corresponding bit in Module Stop Control Register.

43.9.8 PPARD : Peripheral Privilege Attribution Register D

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x24

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	PPARD28	PPARD27	—	—	—	—	PPARD22	—	PPARD20	—	—	—	PPARD16
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PPARD15	PPARD14	PPARD13	PPARD12	PPARD11	—	—	—	—	—	PPARD5	PPARD4	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 1. The write value should be 1.	R/W
4	PPARD4	Asynchronous General Purpose Timer 1 Privilege Attribution Target module: AGT1 and the MSTPCRD.MSTPD4 bit 0: Privileged 1: UnPrivileged	R/W
5	PPARD5	Asynchronous General Purpose Timer 0 Privilege Attribution Target module: AGT0 and the MSTPCRD.MSTPD5 bit 0: Privileged 1: UnPrivileged	R/W
10:6	—	These bits are read as 1. The write value should be 1.	R/W
11	PPARD11	Port Output Enable for GPT Group 3 Privilege Attribution Target module: POEG Group D and the MSTPCRD.MSTPD11 bit 0: Privileged 1: UnPrivileged	R/W
12	PPARD12	Port Output Enable for GPT Group 2 Privilege Attribution Target module: POEG Group C and the MSTPCRD.MSTPD12 bit 0: Privileged 1: UnPrivileged	R/W
13	PPARD13	Port Output Enable for GPT Group 1 Privilege Attribution Target module: POEG Group B and the MSTPCRD.MSTPD13 bit 0: Privileged 1: UnPrivileged	R/W
14	PPARD14	Port Output Enable for GPT Group 0 Privilege Attribution Target module: POEG Group A and the MSTPCRD.MSTPD14 bit 0: Privileged 1: UnPrivileged	R/W
15	PPARD15	12-Bit A/D 1 Converter Privilege Attribution Target module: ADC12_1 and the MSTPCRD.MSTPD15 bit 0: Privileged 1: UnPrivileged	R/W
16	PPARD16	12-Bit A/D 0 Converter Privilege Attribution Target module: ADC12_0 and the MSTPCRD.MSTPD16 bit 0: Privileged 1: UnPrivileged	R/W
19:17	—	These bits are read as 1. The write value should be 1.	R/W
20	PPARD20	12-Bit D/A Converter Privilege Attribution Target module: DAC12 and the MSTPCRD.MSTPD20 bit 0: Privileged 1: UnPrivileged	R/W
21	—	This bit is read as 1. The write value should be 1.	R/W

Bit	Symbol	Function	R/W
22	PPARD22	Temperature Sensor Privilege Attribution Target module: TSN and the MSTPCRD.MSTPD22 bit 0: Privileged 1: UnPrivileged	R/W
26:23	—	These bits are read as 1. The write value should be 1.	R/W
27	PPARD27	High speed analog Comparator 1 Privilege Attribution Target module: ACMPHS1 and the MSTPCRD.MSTPD27 bit 0: Privileged 1: UnPrivileged	R/W
28	PPARD28	High speed analog Comparator 0 Privilege Attribution Target module: ACMPHS0 and the MSTPCRD.MSTPD28 bit 0: Privileged 1: UnPrivileged	R/W
31:29	—	These bits are read as 1. The write value should be 1.	R/W

Note: S-TYPE-2, P-TYPE-1.

The PPARD register specifies the privilege attribution for each module and the corresponding bit in Module Stop Control Register.

43.9.9 PPARE : Peripheral Privilege Attribution Register E

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x28

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PPARE31	PPARE30	PPARE29	PPARE28	PPARE27	PPARE26	PPARE25	PPARE24	PPARE23	PPARE22	PPARE21	PPARE20	PPARE19	PPARE18	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PPARE9	PPARE8	—	—	—	—	PPARE3	PPARE2	PPARE1	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
0	—	This bit is read as 1. The write value should be 1.	R/W
1	PPARE1	WDT Privilege Attribution Target module: WDT 0: Privileged 1: UnPrivileged	R/W
2	PPARE2	IWDT Privilege Attribution Target module: IWDT 0: Privileged 1: UnPrivileged	R/W
3	PPARE3	Real Time Clock Privilege Attribution Target module: RTC 0: Privileged 1: UnPrivileged	R/W
7:4	—	These bits are read as 1. The write value should be 1.	R/W
8	PPARE8	ULPT1 Privilege Attribution Target module: ULPT1 and the MSTPCRE.MSTPE8 bit 0: Privileged 1: UnPrivileged	R/W

Bit	Symbol	Function	R/W
9	PPARE9	ULPT0 Privilege Attribution Target module: ULPT0 and the MSTPCRE.MSTPE9 bit 0: Privileged 1: UnPrivileged	R/W
17:10	—	These bits are read as 1. The write value should be 1.	R/W
18	PPARE18	General PWM Timer Channel 13 Privilege Attribution Target module: : GPT13 and the MSTPCRE.MSTPE18 bit 0: Privileged 1: UnPrivileged	R/W
19	PPARE19	General PWM Timer Channel 12 Privilege Attribution Target module: : GPT12 and the MSTPCRE.MSTPE19 bit 0: Privileged 1: UnPrivileged	R/W
20	PPARE20	General PWM Timer Channel 11 Privilege Attribution Target module: : GPT11 and the MSTPCRE.MSTPE20 bit 0: Privileged 1: UnPrivileged	R/W
21	PPARE21	General PWM Timer Channel 10 Privilege Attribution Target module: : GPT10 and the MSTPCRE.MSTPE21 bit 0: Privileged 1: UnPrivileged	R/W
22	PPARE22	General PWM Timer Channel 9 Privilege Attribution Target module: : GPT9 and the MSTPCRE.MSTPE22 bit 0: Privileged 1: UnPrivileged	R/W
23	PPARE23	General PWM Timer Channel 8 Privilege Attribution Target module: : GPT8 and the MSTPCRE.MSTPE23 bit 0: Privileged 1: UnPrivileged	R/W
24	PPARE24	General PWM Timer Channel 7 Privilege Attribution Target module: : GPT7 and the MSTPCRE.MSTPE24 bit 0: Privileged 1: UnPrivileged	R/W
25	PPARE25	General PWM Timer Channel 6 Privilege Attribution Target module: : GPT6 and the MSTPCRE.MSTPE25 bit 0: Privileged 1: UnPrivileged	R/W
26	PPARE26	General PWM Timer Channel 5 Privilege Attribution Target module: : GPT5 and the MSTPCRE.MSTPE26 bit 0: Privileged 1: UnPrivileged	R/W
27	PPARE27	General PWM Timer Channel 4 Privilege Attribution Target module: : GPT4 and the MSTPCRE.MSTPE27 bit 0: Privileged 1: UnPrivileged	R/W
28	PPARE28	General PWM Timer Channel 3 Privilege Attribution Target module: : GPT3 and the MSTPCRE.MSTPE28 bit 0: Privileged 1: UnPrivileged	R/W
29	PPARE29	General PWM Timer Channel 2 Privilege Attribution Target module: : GPT2 and the MSTPCRE.MSTPE29 bit 0: Privileged 1: UnPrivileged	R/W
30	PPARE30	General PWM Timer Channel 1 Privilege Attribution Target module: : GPT1 and the MSTPCRE.MSTPE30 bit 0: Privileged 1: UnPrivileged	R/W

Bit	Symbol	Function	R/W
31	PPARE31	General PWM Timer Channel 0 Privilege Attribution Target module: : GPT0 and the MSTPCRE.MSTPE31 bit 0: Privileged 1: UnPrivileged	R/W

Note: S-TYPE-2, P-TYPE-1.

The PPARE register specifies the privilege attribution for each module and the corresponding bit in Module Stop Control Register.

43.9.10 MSPAR : Module Stop Privilege Attribution Register

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x2C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MSPAR31	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
30:0	—	These bits are read as 1. The write value should be 1.	R/W
31	MSPAR31	ELC Clock Stop Privilege Attribution Target module: the MSTPCRC.MSTPC14 bit 0: Privileged 1: UnPrivileged	R/W

Note: S-TYPE-2, P-TYPE-1.

The MSPAR register specifies the privilege attribution for the corresponding bit in the Module Stop Control Register.

43.9.11 CFSAMONA : Code Flash Security Attribution Monitor Register A

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x30

Bit position:	31								23								15								0
Bit field:	—	—	—	—	—	—	—	—	CFS2[8:0]								—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	*1	*1	*1	*1	*1	*1	*1	*1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note 1. The value in a blank product is 0x1FF. It is set to the value written by your application.

Bit	Symbol	Function	R/W
14:0	—	These bits are read as 0.	R
23:15	CFS2[8:0]	Code Flash Secure Area Indicate the area of secure region for code flash.	R
31:24	—	These bits are read as 0.	R

Note: S-TYPE-5, P-TYPE-5.

43.9.12 DFSAMON : Data Flash Security Attribution Monitor Register

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x34

Bit position:	31																15						10									0

31:4	—	These bits are read as 0.	R

Note: S-TYPE-5, P-TYPE-5.

43.9.14 MSAOAD : Master Security Attribution Operation After Detection Register

Base address: BUS = 0x4000_3000

Offset address: 0x1010

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OAD	Operation after detection 0: NMI 1: Reset	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code These bits enable or disable writing of the OAD bit.	W

Note: S-TYPE-6, P-TYPE-2.

OAD bit (Operation after detection)

The OAD bit specifies operation when the access violation is detected. When OAD = 0, error response is returned and NMI is generated. When OAD = 1, reset request is generated. When writing to the OAD bit, write 0xA5 simultaneously to the KEY[7:0] bits using halfword access.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits enable or disable writing to the OAD bit. When writing to the OAD bit, write 0xA5 simultaneously to the KEY[7:0] bits. If this value is not written to the KEY[7:0] bits, the OAD bit is not updated.

43.9.15 MSAPT : Master Security Attribution Protect Register

Base address: BUS = 0x4000_3000

Offset address: 0x1014

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	PROTECT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PROTECT	Protection of register 0: MSAOAD register writing is possible. 1: MSAOAD register writing is protected. Read is possible.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code These bits enable or disable writing of the PROTECT bit.	W

Note: S-TYPE-6, P-TYPE-2.

PROTECT bit (Protection of register)

The PROTECT bit enables or disables writes to the associated registers to be protected.

MSAPT.PROTECT controls the MSAOAD register.

When the PROTECT bit is set simultaneously, write 0xA5 to the KEY[7:0] bits using half word access.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits enable or disable writing to the PROTECT bit. When writing to the PROTECT bit, write 0xA5 simultaneously to the KEY[7:0] bits. If this value is not written to the KEY[7:0] bits, the PROTECT bit is not updated.

43.10 Usage Note

43.10.1 Security or Privilege Bit Write Timing

When writing a security or privilege attribution bit, confirm that the write is complete by reading the security or privilege register until it matches the value written. The protection is not effective until the write to the security or privilege register is complete.

44. Renesas Secure IP (RSIP-E51A)

44.1 Overview

This security engine consists of an isolated subsystem comprising an access management circuit, storage area, encryption/decryption circuit, and random number generation circuit. In combination with the RSIP library, the security engine can prevent eavesdropping (to maintain confidentiality), falsification of information (to ensure integrity), and impersonation (to verify authenticity).

Because key information required for encryption and decryption is stored only in the security engine and all accesses from the outside can be blocked, the security engine enables building a more robust security system.

Table 44.1 lists the security engine specifications. Figure 44.1 shows the security engine block diagram.

Table 44.1 Security engine specifications (1 of 2)

Parameter	Specifications
Access control	Access management circuit ● In case of irregular access to the security engine due to a tampered program or CPU runaway, this circuit blocks all subsequent accesses and stops data output from the security engine
Symmetric cryptography	AES: Compliant with NIST FIPS PUB 197 ● Key length: 128, 192, or 256 bits ● Data block size: 128 bits ● AES supports following block cipher mode ECB, CBC, CTR: Compliant with NIST SP 800-38A CCM: Compliant with NIST SP 800-38C GCM: Compliant with NIST SP 800-38D XTS: Compliant with IEEE 1619-2007 ● AES supports following authentication algorithm CMAC: Compliant with NIST SP 800-38B GMAC: Compliant with NIST SP 800-38D ● AES does not support the KEY size of 192-bit in CCM, GCM, XTS, CMAC and GMAC.
Random number generation	128-bit true random number generation circuit
Asymmetric cryptography	RSA ● Maximum number of operable bits: 4224 bits ● Supported key sizes: 1024-bit, 2048-bit, 3072-bit, and 4096-bit ● Signature generation, signature verification, public-key encryption, private-key decryption ECC ● Maximum number of operable bits: 576 bits ● Support for curve – NIST P-192, P-224, P-256, P-384 and P-521 – Brainpool P256r1, P384r1, and P512r1 – Ed25519 – secp256k1 ● Signature generation, signature verification, key generation
Message digest computation	HASH ● Block size: 512-bit(SHA-224, SHA-256) 1024-bit(SHA-512/224, SHA-512/256, SHA-384, SHA-512) ● Key size: 512-bit or less ● HASH supports following secure hash algorithms SHA-224, SHA-256, SHA-512/224, SHA-512/256, SHA-384 and SHA-512: Compliant with FIPS PUB 180-4 ● HASH supports following message authentication algorithm HMAC: Compliant with FIPS PUB 198

Table 44.1 Security engine specifications (2 of 2)

Parameter	Specifications
Hardware Unique Key	• A read-only, 256-bit Hardware Unique Key (HUK) is exclusively accessible by the security engine access management circuit through a dedicated bus. • Key derivation functions (KDFs) combine the Hardware Unique Key with the key generation information. The derived keys implement the key wrapping for user key secure storage. • The HUK uniqueness prevents the illicit cloning and copying of keys to another MCU of the MCU group. • The HUK itself is stored in wrapped (encrypted, non-plain) format in an isolated memory area. Therefore, it is protected from illicit access and copy.
Application Key Management	• Wrapped keys are only valid within the security engine.
Unique ID	• A read-only, 128-bit ID unique to an MCU (Unique ID) is accessible from the access management circuit. • Key derivation functions (KDFs) combine the Unique ID with the key generation information. Such derived keys are used to unwrap the HUK within the security engine boundary.
OEM boot loader version	• The security engine outputs OEM boot loader version (OEM BL Ver.). • Flash sequencer supports Anti-Rollback Counter Protection using the OEM boot loader version, which is protected by the security engine.
Decryption-on-the-fly	The security engine outputs the key data of the decryption-on-the-fly IP (DOTF) through a dedicated bus
Tamper Resistance	Countermeasures available for side-channel attacks, including SPA/DPA and timing attacks.
Module-stop function	Module-stop state can be set to reduce power consumption
TrustZone Filter	Security and Privilege attribution can be set

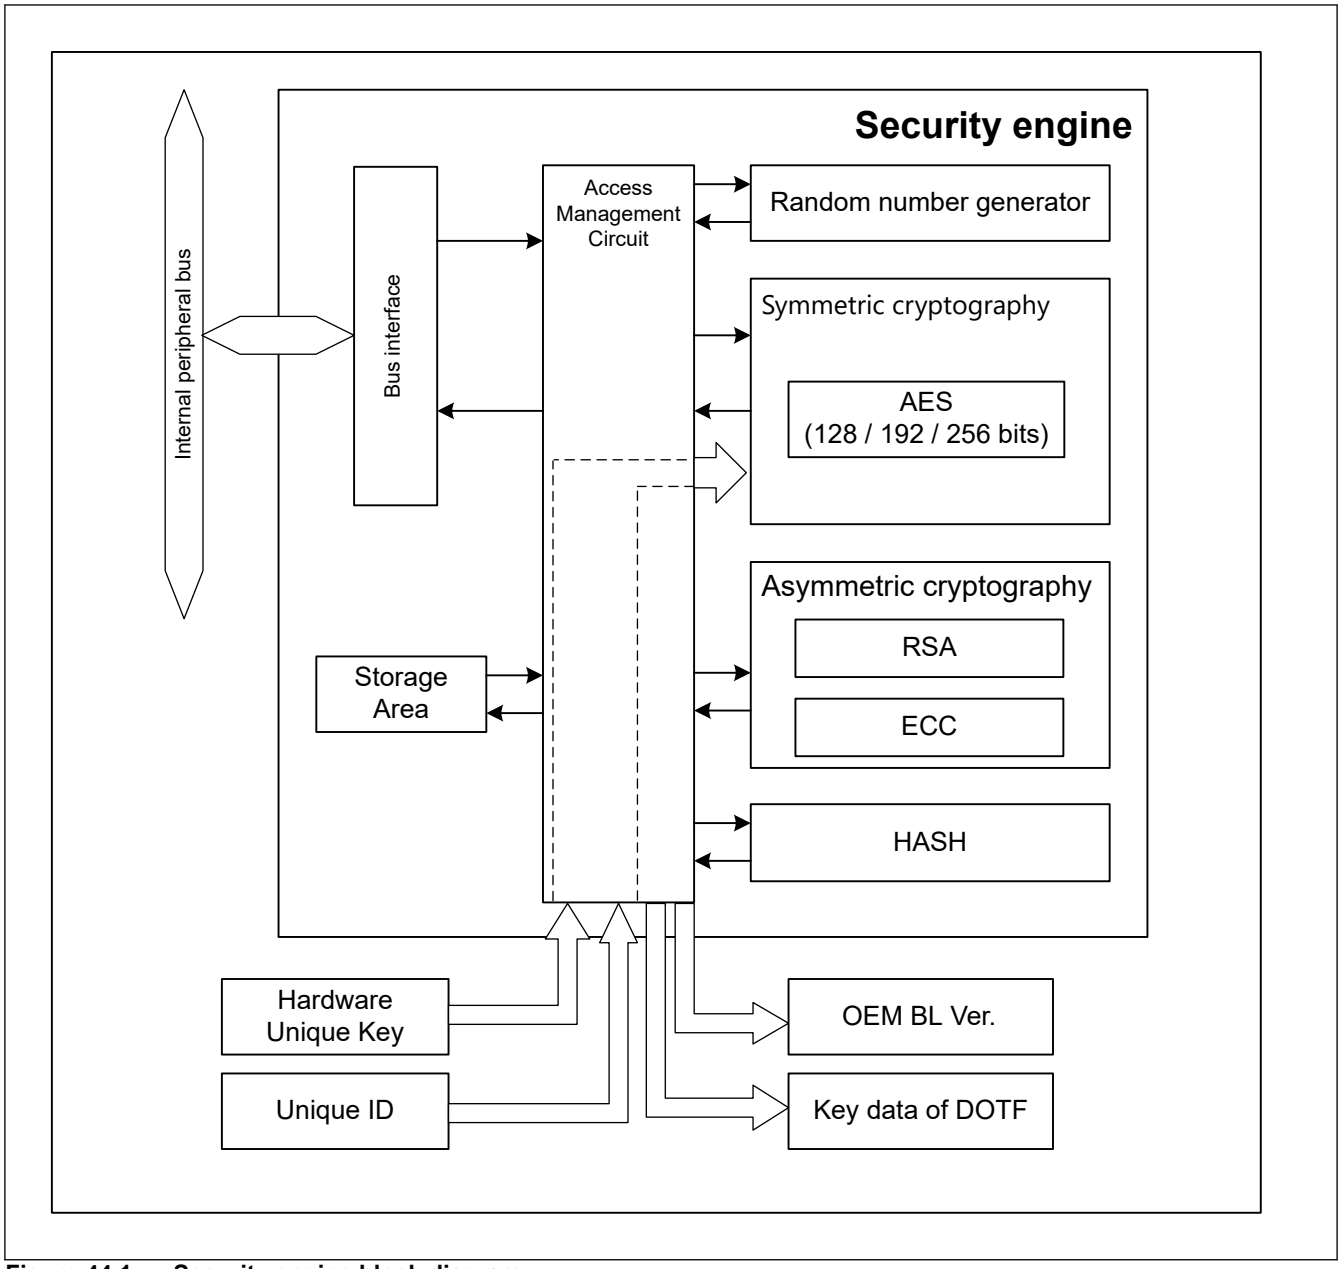

Figure 44.1 Security engine block diagram

44.2 Operation

44.2.1 Symmetric cryptography

Figure 44.2 shows conceptual block diagram of the symmetric cryptography installed in the security engine.

The symmetric cryptography uses the input key information and converts the plaintext data to ciphertext or ciphertext data to plaintext through the hardware.

The encryption/decryption process can be completed without exposing the key data and the process's intermediate data outside of the security engine. This process is performed by the encryption/decryption circuit and storage area of the security engine internally.

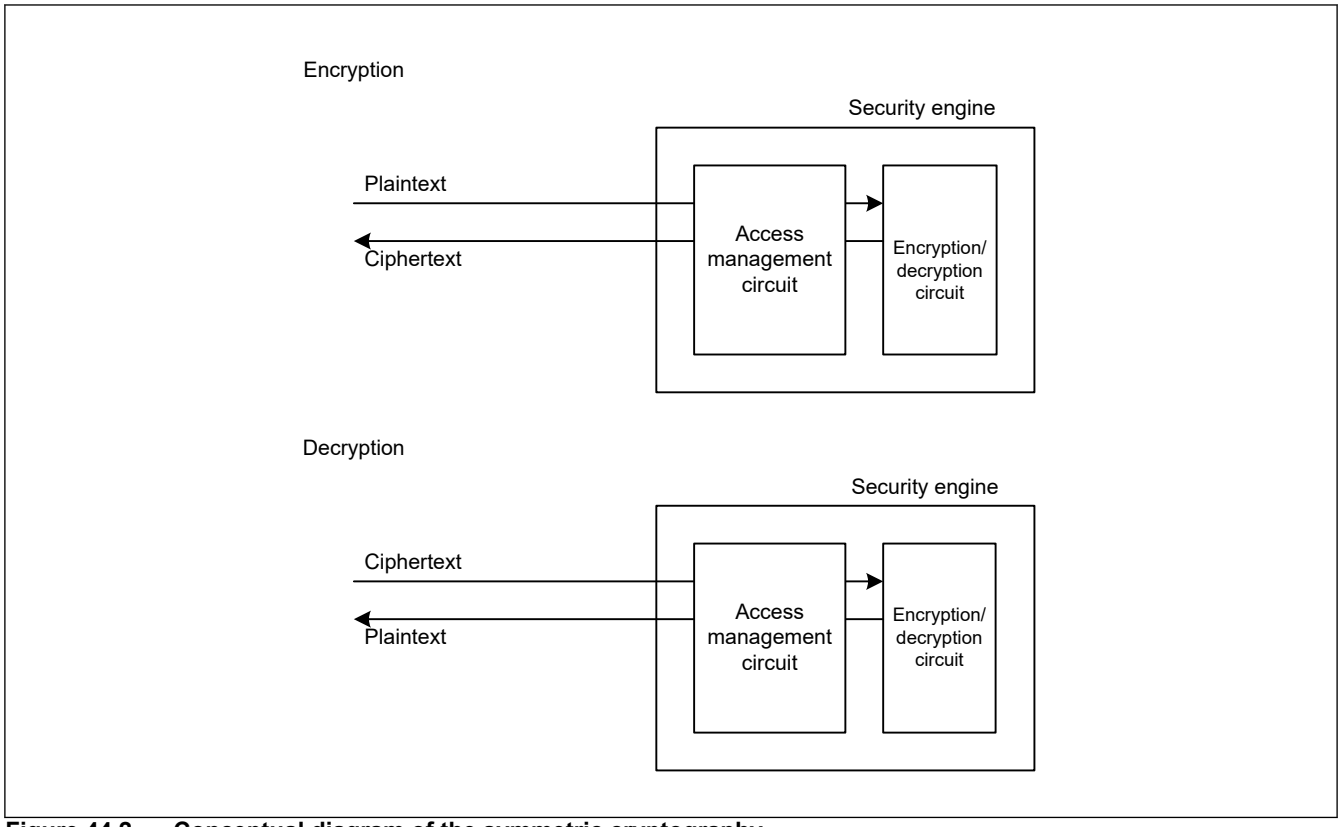

Figure 44.2 Conceptual diagram of the symmetric cryptography

44.2.2 Asymmetric Cryptography

Figure 44.3 shows conceptual block diagram of the asymmetric cryptography installed in the security engine.

The asymmetric cryptography uses the input key information and converts the plaintext data to ciphertext or ciphertext data to plaintext or generates/verifies the signature.

The encryption/decryption or signature generation/verification process can be completed without exposing the key data and the process's intermediate data outside of the security engine. This process is performed by the cryptographic circuit and storage area of the security engine internally.

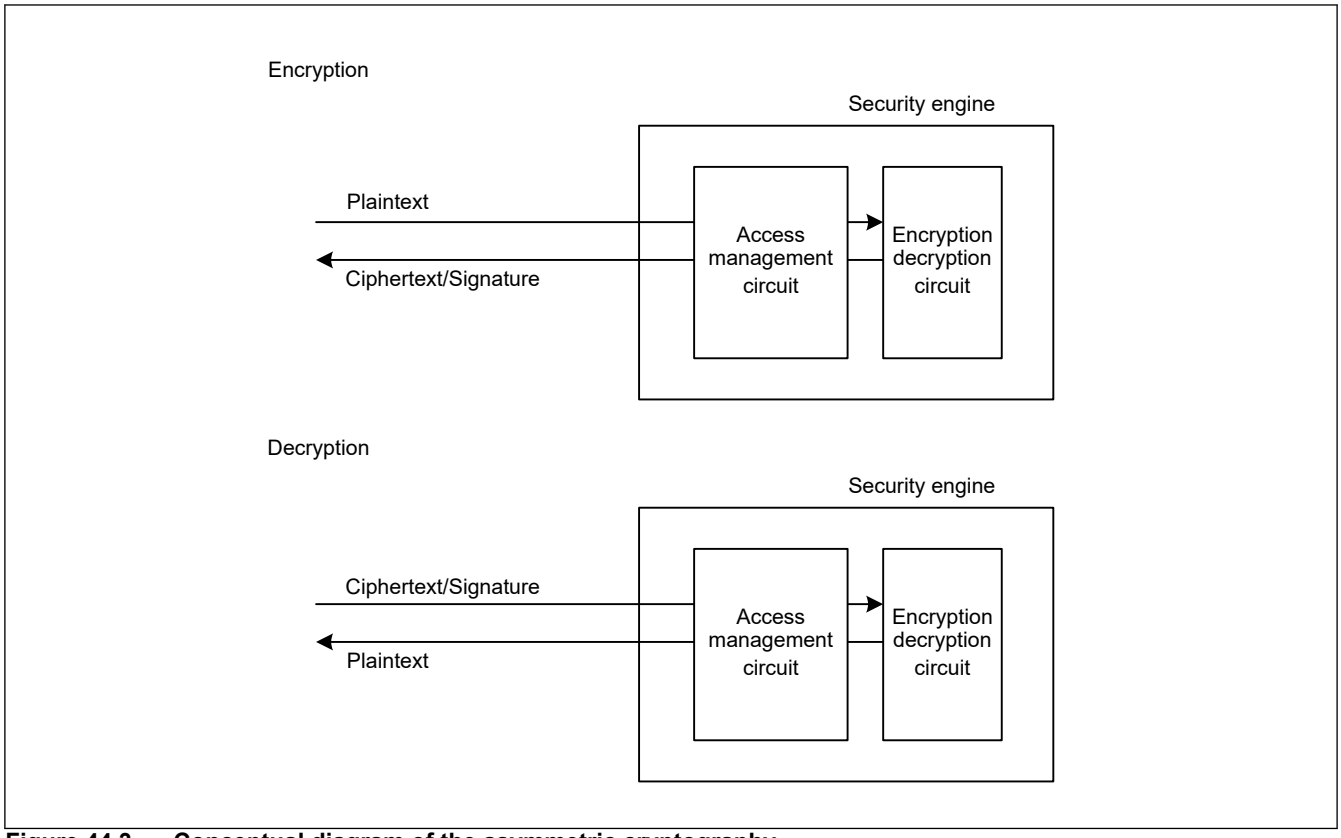

Figure 44.3 Conceptual diagram of the asymmetric cryptography

44.2.3 Hash generator

Figure 44.4 shows conceptual block diagram of the hash generator installed in the security engine.

The hash generator generates uses the input key information (if required for the hash calculation) and generates the message digest or tag.

The calculation process can be completed without exposing any key data and the process's intermediate data outside of the security engine. This process is performed by the hash circuit and storage area of the security engine internally.

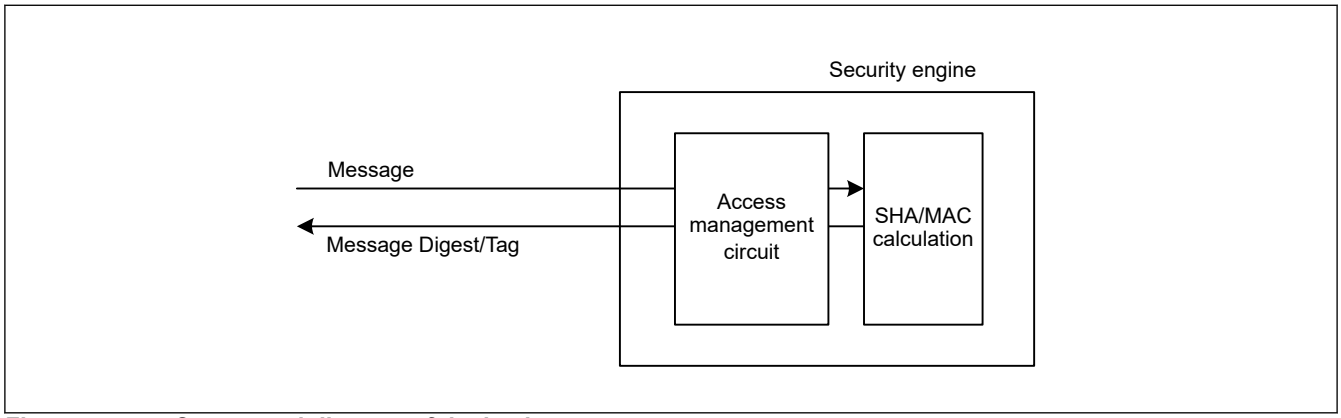

Figure 44.4 Conceptual diagram of the hash generator

44.2.4 Encryption and Decryption

Follow the procedure below to encrypt and decrypt the data:

1. Input the key information to the security engine.
2. Input the target data to the security engine. Plaintext data is converted to ciphertext and ciphertext data to plaintext.
3. Read the converted data.

The encryption/decryption circuit has input and output buffers, and can perform encryption/decryption in parallel with data input/output. Figure 44.5 shows the encryption engine timing.

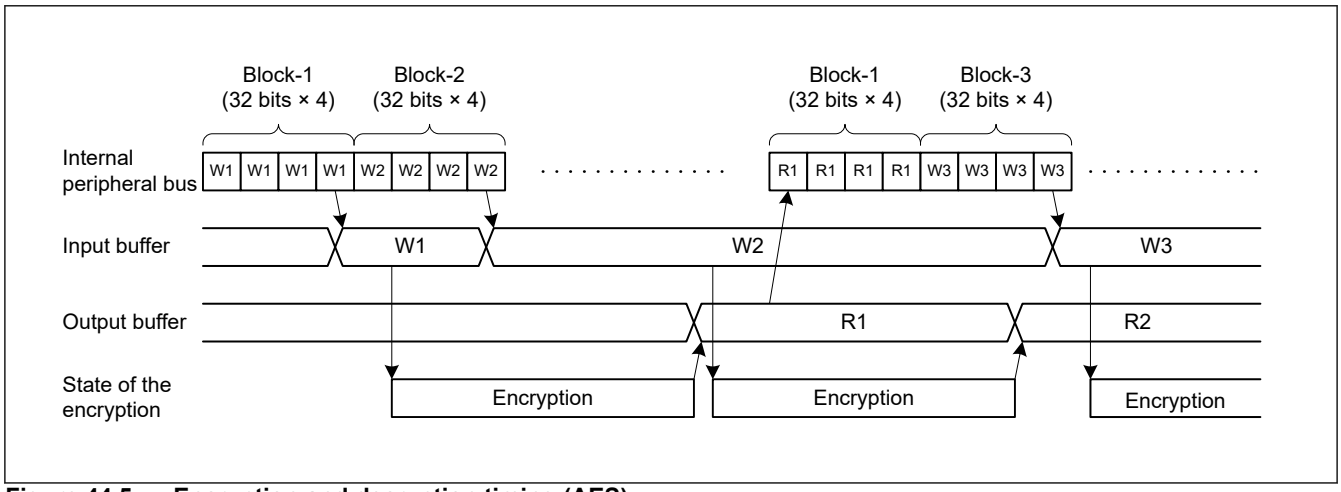

Figure 44.5 Encryption and decryption timing (AES)

44.3 Usage Notes

44.3.1 Software Standby Mode

When Software Standby mode is entered while the security engine is in process, proper processing cannot be resumed after cancelling Software Standby mode. Software Standby mode should therefore be entered while the security engine is not running.

44.3.2 Module-Stop Function Setting

The security engine operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The security engine module is initially stopped after reset. Releasing the module-stop state enables access to the registers.

44.3.3 SPA/DPA Protections

SPA/DPA protections can optionally be enabled for encryption/decryption processing.

44.3.4 Restrictions on Open process

While open process of security engine's API (R_RSIP_Open) is running, the following restrictions is applied.

- Available CPU frequency is up to 240MHz
- Do not change frequency of CPUCLK, ICLK and PCLKn (n = A to E)
- Do not change MSTPCRn registers (n = A to E)
- Do not transition to CPU Sleep mode, CPU Deep Sleep mode, Software Standby mode and Deep Software Standby mode 1/2/3."

45. 12-Bit A/D Converter (ADC12)

45.1 Overview

The MCU includes 12-bit successive approximation A/D converter (ADC12) units. In unit 0, up to 12 analog input channels are selectable. In unit 1, up to 13 analog input channels, temperature sensor output, internal reference voltage, VBATT 1/3 voltage monitor output can be selected for conversion in respective units.

The A/D conversion accuracy is selectable from 12-bit, 10-bit, 8-bit conversion, making it possible to optimize the trade-off between speed and resolution in generating a digital value.

The ADC12 supports the following operating modes:

- Single scan mode to convert analog inputs of selected channels in ascending order of channel number
- Continuous scan mode to convert analog inputs of selected channels continuously in ascending order of channel number
- Group scan mode to divide analog inputs of channels into two groups (group A and B) and convert the analog inputs of selected channels for each group in ascending order of channel number.

In group scan mode, select two groups (group A and B). You can individually select the scan start conditions for each group (group A, B) and start scanning of each group at different times. In addition, when group A priority control operation is set, the ADC12 accepts group A scan start during group B A/D conversion, suspending group B conversion. This allows you to assign higher priority to A/D conversion start for group A.

In double trigger mode, the analog input of a selected channel is converted in single scan mode or group scan mode (group A), and data converted by the first and second A/D conversion start triggers are stored in different registers, providing duplexing of A/D converted data.

Self-diagnosis is performed once at the beginning of each scan, and one of the three reference voltage values generated in ADC12 is A/D converted.

The temperature sensor output and the internal reference voltage is selectable at the same time as the analog input of the channel. First A/D conversion is performed for the analog input of the channel, next the temperature sensor output and then for the internal reference voltage.

The ADC12 also provides a compare function (window A and window B). The compare function specifies the upper reference value for window A and lower reference value for window B, and outputs an interrupt when the A/D converted value of the selected channel meets the comparison conditions.

The A/D data storage buffer is a ring buffer consisting of 16 buffers to sequentially store A/D converted data.

Table 45.1lists the ADC12 specifications and Table 45.2 list the functions. Figure 45.1 shows a block diagram of ADC12 and Table 45.3 lists the I/O pins.

Table 45.1 ADC12 specifications (1 of 3)

Parameter	Specifications
Number of units	two units
Input channels	Up to 25 channels (AN000 to AN002, AN004 to AN008, AN016 to AN019, AN100 to AN102, AN104 to AN106, AN116 to AN122)
Analog function	Temperature sensor output, internal reference voltage, VBATT 1/3 voltage monitor output
Conversion method	Successive approximation method
Resolution	12-bit, 10-bit, 8-bit
Conversion time	0.4 µs/channel (when 12-bit A/D conversion clock PCLKC (ADCLK) is operating at 60 MHz)
A/D conversion clock	Peripheral module clock PCLKA and A/D conversion clock PCLKC (ADCLK) can be set with the following division ratios: PCLKA to PCLKC (ADCLK) frequency ratio = 1:1, 2:1, 4:1, 8:1, 1:2, 1:4

Table 45.1 ADC12 specifications (2 of 3)

Parameter	Specifications
Data registers[*1]	• 25 registers for analog input • One register for A/D-converted data duplication in double trigger mode • Two registers for A/D-converted data duplication during extended operation in double trigger mode • One register for temperature sensor output • One register for internal reference voltage • One register for VBATT 1/3 voltage monitor output • One register for self-diagnosis • A/D conversion results are stored in A/D data registers • 12-bit, 10-bit, 8-bit accuracy for A/D conversion results • A/D-converted value addition mode, in which the sum of all A/D-converted results is stored in the A/D data registers as a value with the conversion accuracy bit count + extended bits • Double-trigger mode (selectable in single scan and group scan modes): – The first unit of A/D-converted analog input data on one selected channel is stored in the data register for the channel, and the second unit is stored in the duplication register. • Extended operation in double trigger mode (available for specific triggers): – A/D-converted analog input data on one selected channel is stored in the duplication register provided for the associated trigger.
Operating modes[*2]	• Single scan mode: – A/D conversion is performed only once on the analog inputs of arbitrarily selected channels , on the temperature sensor output, on the internal reference voltage. • Continuous scan mode: A/D conversion is performed repeatedly on the analog inputs of the selected channels on the temperature sensor output, and on the internal reference voltage. • Group scan mode: – Analog inputs of selected channels, the temperature sensor output, and the internal reference voltage are divided into groups A and B. Then A/D conversion of the analog inputs selected on a group basis is performed once. – The scan start conditions can be independently selected for group A, B, allowing A/D conversion of group A, B to be started independently. • Group scan mode (when group priority operation is selected): – If a priority group trigger is input during scanning of a lower-priority group, the scanning of the lower-priority group is stopped and then scanning of the priority group is started. The order of priority is group A > group B. – It is possible to select whether to restart scanning (rescan) of the lower-priority group upon completion of the priority group scan. It is also possible to specify rescanning to be started from the first channel of the selected channels or from the channel for which A/D conversion has not been completed.
Conditions for A/D conversion start	• Software trigger • Synchronous triggers from the Event Link Controller (ELC) and GPT • Asynchronous triggering by the external trigger pins, ADTRG0 (unit 0) and ADTRG1 (unit 1)
Functions	• Dedicated sample-and-hold function with optional constant sampling and 3 channels in unit 0 • Variable sampling state count • Self-diagnosis of A/D converter • Selectable A/D-converted value addition mode or average mode • Analog input disconnection detection function (discharge and precharge functions) • Double-trigger mode (duplication of A/D conversion data) • Automatic clear function for A/D data registers • Digital comparison of values in the comparison register and data register, and comparison between values in the data registers • Ring buffer

Table 45.1 ADC12 specifications (3 of 3)

Parameter	Specifications
Interrupt sources	• In single scan mode (double trigger deselected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) can be generated on completion of single scan. – A compare interrupt request (ADC12i_CMPAI (i = 0, 1)/ADC12i_CMPBI (i = 0, 1)) can be generated in response to a match with a digital comparison condition. – A window compare ELC event signal (ADC12i_WCMPM (i = 0, 1)) can be generated in response to a match with a digital comparison condition. – A window compare ELC event signal (ADC12i_WCMPUM (i = 0, 1)) can be generated in response to a mismatch with a digital comparison condition. • In single scan mode (double trigger selected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of two scans. • In continuous scan mode, an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of all the selected channel scans. • In group scan mode (double trigger deselected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of group A scan, and an A/D scan end interrupt request for group B (ADC12i_GBADI (i = 0, 1)) can be generated on completion of group B scan. • In group scan mode (double trigger selected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of two group A scans, and an A/D scan end interrupt request for group B (ADC12i_GBADI (i = 0, 1)) can be generated on completion of group B scan. • ADC12i_ADI (i = 0, 1), ADC12i_GBADI (i = 0, 1), ADC12i_WCMPM (i = 0, 1), and ADC12i_WCMPUM (i = 0, 1) can activate the Data Transfer Controller (DTC).
ELC interface	• An event is generated upon completion of group A scan in group-scan mode. • An event is generated upon completion of group B scan in group-scan mode. • An event is generated when all scans complete. • Scan can be started by a trigger from the ELC. • An event is generated according to conditions of the compare function window in single-scan mode.
Reference voltage	• Unit 0: VREFH0 is the analog reference voltage. VREFL0 is the analog reference ground. • Unit 1: VREFH is the analog reference voltage. VREFL is the analog reference ground.
Analog channel input SA judgement function	Input channels of analog can be valid only when the security attribution of ADC12n (n = 0, 1) match the security attribution of PORT (PmSAR). When the security attribution of ADC12n (n = 0, 1) does not match the PORT security attribution, the conversion result of ADC input channel will be unexpected. Internal reference voltage, Temperature sensor output and VBATT 1/3 voltage monitor output have no Security Attribution judgement function.
Module-stop function	Module-stop state can be set to for each units reduce power consumption.*3
TrustZone Filter	Security and Privilege attribution can be set for each units

Note 1. Changing the A/D conversion accuracy also changes the A/D conversion time. For details, see section 45.3.6. Analog Input Sampling and Scan Conversion Time.
Note 2. When selectingthe temperature sensor output, the internal reference voltage, do not use continuous scan mode or group scan mode.
Note 3. For details, see section 10, Low Power Modes.

Table 45.2 ADC12 functions (1 of 2)

Parameter	function
Analog input channel	AN000 to AN002, AN004 to AN008, AN016 to AN019(unit 0), AN100 to AN102, AN104 to AN106, AN116 to AN122(unit 1) Internal reference voltage Temperature sensor output VBATT 1/3 voltage monitor output

Table 45.2 ADC12 functions (2 of 2)

Parameter			function
Conditions for A/D conversion starts	Software	Software trigger	Enabled
	Asynchronous trigger (external trigger)	Trigger input pin	ADTRGn (n = 0, 1)
	Synchronous trigger (trigger from ELC)	ELC trigger	ELC_AD00 (unit 0) and ELC_AD10 (unit 1), ELC_AD01 (unit 0) and ELC_AD11 (unit 1)
		GPT trigger	GTCIADAm, GTCIADBm (unit 0) (m = 0 to 3) GTCIADAn, GTCIADBn (unit 1) (n = 4 to 7)
Channel-dedicated sample-and-hold function Target channel			AN000 to AN002 (unit 0)
Interrupt			ADC12i_ADI (i = 0, 1) ADC12i_GBADI (i = 0, 1) ADC12i_CMPAI (i = 0, 1) ADC12i_CMPBI (i = 0, 1)
Output to ELC			ADC12i_ADI (i = 0, 1) ADC12i_WCMPM (i = 0, 1) ADC12i_WCMPUM (i = 0, 1)
Module-stop function settings*1 *2			MSTPCRD.MSTPD16 bit (unit 0) , MSTPCRD.MSTPD15 bit (unit 1)

Note 1. For details, see section 10, Low Power Modes.
Note 2. Wait 1 µs or longer to start A/D conversion after release from the module-stop state.

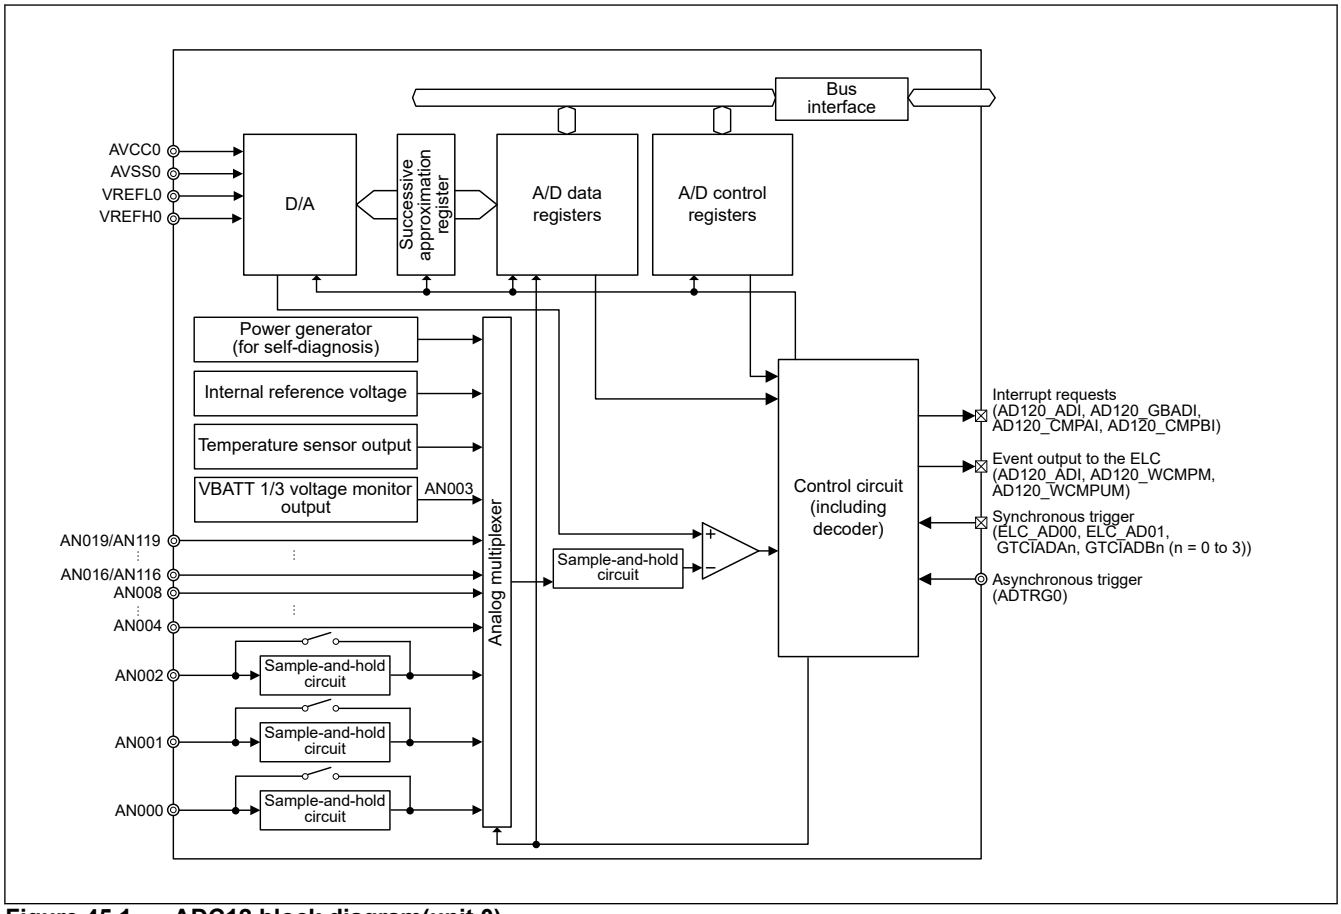

Figure 45.1 ADC12 block diagram(unit 0)

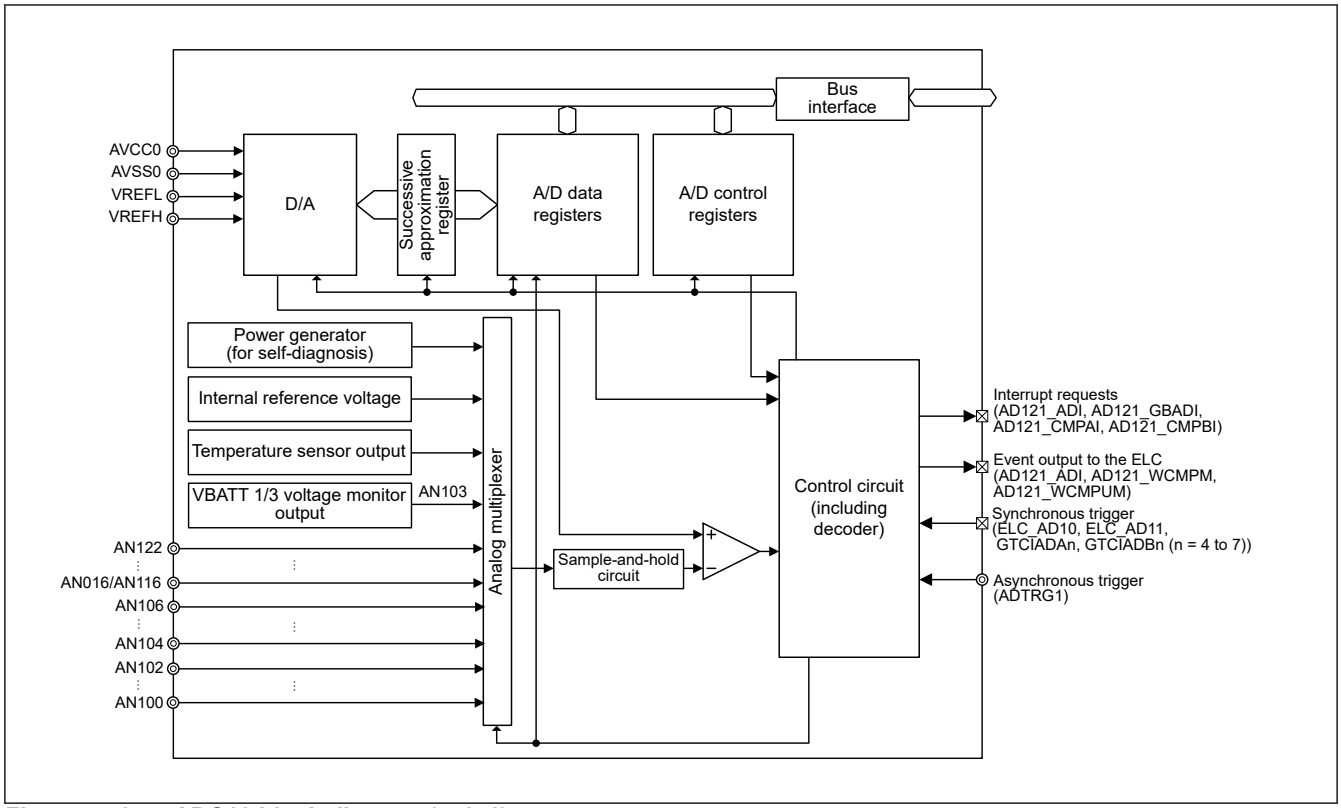

Figure 45.2 ADC12 block diagram (unit 1)

Table 45.3 lists the ADC12 I/O pins.

Table 45.3 ADC12 I/O pins (unit 0)

Pin name	I/O	Function
AVCC0	Input	Analog block power supply pin (Connect to VCC when ADC12/DAC12 is not used.)
AVSS0	Input	Analog block power supply ground pin (Connect to VSS when ADC12/DAC12 is not used.)
VREFH0	Input	Analog reference voltage supply pin
VREFL0	Input	Analog reference ground pin
AN000 to AN002, AN004 to AN008, AN016 to AN019	Input	Analog input pins 0 to 2, 4 to 8, 16 to 19
ADTRG0	Input	External trigger input pin for starting A/D conversion

Table 45.4 ADC12 I/O pins (unit 1)

Pin name	I/O	Function
AVCC0	Input	Analog block power supply pin
AVSS0	Input	Analog block power supply ground pin
VREFH	Input	Analog reference voltage supply pin
VREFL	Input	Analog reference ground pin
AN100 to AN102, AN104 to AN106, AN116 to AN122	Input	Analog input pins 0 to 2, 4 to 6, 16 to 22
ADTRG1	Input	External trigger input pin for starting A/D conversion

45.2 Register Descriptions

45.2.1 ADDRn : A/D Data Registers n

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x020 + 0x2 × n (n = 0 to 8, 16 to 19, m = 0)
0x020 + 0x2 × n (n = 0 to 6, 16 to 22, m = 1)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 45.5 and Table 45.6.	R

Note: S-TYPE-3, P-TYPE-3

ADDRn registers are 16-bit read-only registers to store A/D conversion results.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 45.5 shows the example of bit assignment for 12-bit accuracy.

Table 45.5 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, these registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 45.6 shows example of the bit assignment for 12-bit accuracy.

Table 45.6 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

45.2.2 ADDBLDR : A/D Data Duplexing Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x018

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADDBLDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADDBLDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 45.7 and Table 45.8.	R

Note: S-TYPE-3, P-TYPE-3

ADDBLDR register is a 16-bit read-only register to store A/D conversion results in response to a second trigger in double-trigger mode.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 45.7 shows the example of bit assignment for 12-bit accuracy.

Table 45.7 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 45.8 shows example of the bit assignment for 12-bit accuracy.

Table 45.8 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

45.2.3 ADDBLDRn : A/D Data Duplexing Register n (n = A, B)

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x084 (n = A)
0x086 (n = B)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADDBLDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADDBLDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 45.9 and Table 45.10.	R

Note: S-TYPE-3, P-TYPE-3

ADDBLDRn registers are 16-bit read-only registers to store A/D conversion results in response to respective triggers during extended operation in double-trigger mode.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)

- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 45.9 shows the example of bit assignment for 12-bit accuracy.

Table 45.9 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, these registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 45.10 shows example of the bit assignment for 12-bit accuracy.

Table 45.10 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

45.2.4 ADTSDR : A/D Temperature Sensor Data Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x01A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADTSDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADTSDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 45.11 and Table 45.12.	R

Note: S-TYPE-3, P-TYPE-3

ADTSDR register is a 16-bit read-only register to store A/D conversion result of the temperature sensor output.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 45.11 shows the example of bit assignment for 12-bit accuracy.

Table 45.11 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 45.12 shows example of the bit assignment for 12-bit accuracy.

Table 45.12 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

45.2.5 ADOCDR : A/D Internal Reference Voltage Data Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x01C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADOCDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADOCDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 45.13 and Table 45.14.	R

Note: S-TYPE-3, P-TYPE-3

ADOCDR register is a 16-bit read-only register to store A/D conversion result of the internal reference voltage.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 45.13 shows the example of bit assignment for 12-bit accuracy.

Table 45.13 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a

specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 45.14 shows example of the bit assignment for 12-bit accuracy.

Table 45.14 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

45.2.6 ADVMDR : A/D VBATT monitor Data Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x026

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADDR[15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 45.15 and Table 45.16	R

Note: S-TYPE-3, P-TYPE-3

ADVMDR register is a 16-bit read-only register to store A/D conversion result of the VBATT 1/3 voltage. For VBATT 1/3 voltage measurement, VBATTMNSELR.VBTMNSEL need to be set. For more information, seesection 11, Battery Backup Function. ADVMDR register is an alias for the ADDR3 register.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 45.15 shows the example of bit assignment for 12-bit accuracy.

Table 45.15 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 45.16 shows example of the bit assignment for 12-bit accuracy.

Table 45.16 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.	Added Value 13 to 0: 14-bit sum of A/D conversion results														
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

45.2.7 ADRD : A/D Self-Diagnosis Data Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x01E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DIAGST[1:0]		—	—	AD[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	AD[11:0]	Converted Value 11 to 0 12-bit A/D-converted value	R
13:12	—	These bits are read as 0.	R
15:14	DIAGST[1:0]	Self-Diagnosis Status For details on self-diagnosis, see section 45.2.16. ADCER : A/D Control Extended Register. 0 0: Self-diagnosis not executed after power-on. 0 1: Self-diagnosis was executed using the 0 V voltage. 1 0: Self-diagnosis was executed using the reference voltage*1 × 1/2. 1 1: Self-diagnosis was executed using the reference voltage *1.	R

Note: S-TYPE-3, P-TYPE-3
Note: The example of the bit assignment for the right-justified data with 12-bit accuracy is indicated.
Note 1. The reference voltage refers to VREFH0 for unit 0 and to VREFH for unit 1.

ADRD is a 16-bit read-only register that holds the A/D conversion results based on the self-diagnosis of the ADC12. In addition to the AD[11:0] bits indicating the A/D-converted value, it includes the Self-Diagnosis Status bit (DIAGST[1:0]).

The settings of the A/D data register format and the A/D conversion accuracy determines the formats for data in this register.

The A/D-converted value addition and average modes cannot be applied to the A/D self-diagnosis function. For details on self-diagnosis, see section 45.2.16. ADCER : A/D Control Extended Register.

This section describes the data formats for each condition. The register diagram and the register bit table shown in this section indicate example of the bit assignment for the left and right-justified data with 12-bit accuracy.

Table 45.17 Bit assignment for each right-justified accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	DIAGST[1:0]		—		AD[11:0]

45.2.8 ADCSR : A/D Control Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x000

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADST	ADCS[1:0]		—	—	—	TRGE	EXTRG	DBLE	GBADIE	—	DBLANS[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	DBLANS[4:0]	Double Trigger Channel Select These bits select one analog input channel for double-trigger operation. The setting is only valid in double-trigger mode.	R/W
5	—	This bit is read as 0. The write value should be 0.	R/W
6	GBADIE	Group B Scan End Interrupt and ELC Event Enable Group B scan only works in group scan mode. 0: Disable ADC12i_GBADI (i = 0, 1) interrupt generation on group B scan completion. 1: Enable ADC12i_GBADI (i = 0, 1) interrupt generation on group B scan completion.	R/W

Bit	Symbol	Function	R/W
7	DBLE	Double Trigger Mode Select 0: Deselect double-trigger mode. 1: Select double-trigger mode.	R/W
8	EXTRG	Trigger Select*1 0: Start A/D conversion by the synchronous trigger (GPT, ELC). 1: Start A/D conversion by the asynchronous trigger (ADTRGn*2).	R/W
9	TRGE	Trigger Start Enable 0: Disable A/D conversion to be started by the synchronous or asynchronous trigger 1: Enable A/D conversion to be started by the synchronous or asynchronous trigger	R/W
12:10	—	These bits are read as 0. The write value should be 0.	R/W
14:13	ADCS[1:0]	Scan Mode Select 0 0: Single scan mode 0 1: Group scan mode 1 0: Continuous scan mode 1 1: Setting prohibited	R/W
15	ADST	A/D Conversion Start 0: Stop A/D conversion process. 1: Start A/D conversion process.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. To start A/D conversion using an external pin (asynchronous trigger):
After a high-level signal is input to the external pin (ADTRGn), write 1 to both the TRGE and EXTRG bits in the ADCSR register and drive the ADTRGn pin low. With these settings, the scan conversion process starts on detection of the falling edge of ADTRGn. The pulse width of the low-level input must be at least PCLKA 1.5 clock cycles.
Note 2. n = 0 (unit 0), 1 (unit 1)

The ADCSR register sets double-trigger mode and A/D conversion start trigger, enables or disables scan end interrupt, selects the scan mode, and starts or stops A/D conversion.

DBLANS[4:0] bits (Double Trigger Channel Select)

The DBLANS[4:0] bits select one channel for A/D conversion data duplication in double-trigger mode. This can be selected by setting the binary value of the channel number to be duplicated. The A/D conversion results of the analog input of the channel selected in the DBLANS[4:0] bits are stored in A/D Data Register y when conversion is started by the first trigger, and stored in the A/D Data Duplexing Register when conversion is started by the second trigger.

In double-trigger mode, the channels selected in the ADANSA0 and ADANSA1 registers, are invalid, and the channel selected in the DBLANS[4:0] bits is A/D converted instead.

When double-trigger mode is used in group scan mode, double-trigger control is only applied to group A and not to group B.

Also, in double trigger mode, the analog inputs of multiple channels, temperature sensor outputs, or internal reference voltage cannot be selected for group A, but can be selected for groups B.

Only set the DBLANS[4:0] bits when the ADST bit is 0. Do not set the DBLANS[4:0] bits at the same time that you write 1 to the ADST bit.

To enter A/D-converted value addition/average mode when in double-trigger mode, set the same channel in the ADADS0 and ADADS1 registers as the channel selected in the DBLANS[4:0] bits.

A/D-converted data from the self-diagnosis function temperature sensor output and internal reference voltage cannot be used in double-trigger mode.

GBADIE bit (Group B Scan End Interrupt and ELC Event Enable)

The GBADIE bit enables or disables group B scan end interrupt (ADC12i_GBADI (i = 0, 1)) in group scan mode.

DBLE bit (Double Trigger Mode Select)

The DBLE bit selects or deselects double-trigger mode. Double-trigger mode can only be operated by the synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSA[5:0] bits.

Double-trigger operation is as follows:

1. The ADC12i_ADI (i = 0, 1) interrupt is not output on completion of the first conversion but on completion of the second conversion.
2. The A/D conversion results from the duplication channel (selected in DBLANS[4:0]) started by the first trigger are stored in A/D Data Register y and those started by the second trigger are stored in the A/D Data Duplexing Register.

When the DBLE bit is set (double-trigger mode is selected), the channels specified in the ADANSA0 and ADANSA1 registers are invalid. Double-trigger mode is deselected by setting DBLE to 0. Setting DBLE to 1 again enables the same double-trigger operation described in 1. and 2. for first time scanning with the first trigger.

Do not select double-trigger mode in continuous scan mode. When using double trigger mode in group scan mode, A/D conversion of the temperature sensor output and internal reference voltage should not be selected for group A. Software triggering cannot be used in double-trigger mode. Always set the ADST bit to 0 before setting the DBLE bit. Do not set the DBLE bit at that same time as writing 1 to the ADST bit.

EXTRG bit (Trigger Select)

The EXTRG bit selects the synchronous or asynchronous trigger as the trigger for starting A/D conversion.

In group scan mode, the setting of this bit takes effect on the trigger selected for group A. For group B, A/D conversion is started by the selected synchronous trigger regardless of this bit setting.

TRGE bit (Trigger Start Enable)

The TRGE bit enables or disables A/D conversion by the synchronous and asynchronous triggers. In group scan mode, set this bit to 1.

ADCS[1:0] bits (Scan Mode Select)

The ADCS[1:0] bits select the scan mode.

In single scan mode, A/D conversion is performed for the analog inputs of the channels selected in the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, the scan conversion stops.

In continuous scan mode, when the ADCSR.ADST bit is 1, A/D conversion is performed for the analog inputs of the channels selected with the ADANSA0 and ADANSA1 registers , in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion repeats from the first channel. If the ADCSR.ADST bit is set to 0 during continuous scan, A/D conversion stops even if scanning is in progress.

In group scan mode:

- Group A scanning is started by the synchronous trigger (GPT, ELC) selected in the TRSA[5:0] bits in the ADSTRGR register. A/D conversion is performed on group A analog inputs of the channels selected in the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.
- Group B scanning is started by the synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSB[5:0] bits. A/D conversion is performed on group B analog inputs of the channels selected in the ADANSB0 and ADANSB1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.

If the conversion processes in group A and group B occur at the same time, those conversions cannot be controlled separately. In this case, set group A Priority Control Setting bit (ADGSPCR.PGS) in the A/D Group Scan Priority Control Register (ADGSPCR) to 1 to assign a priority to group A conversion.

In group scan mode, select different channels and triggers for group A and group B.

Only set the ADCS[1:0] bits when the ADST bit is 0. Do not set the ADCS[1:0] bits at the same time that you write 1 to the ADST bit.

Table 45.19 Selectable targets for A/D conversion depending on scan and double-trigger mode settings

Scan mode setting	Double-trigger mode setting	Targets for A/D conversion				
		Self-diagnosis	Analog input (group A)	Analog input (group B)	Temperature sensor output	Internal reference voltage
Single scan	DBLE = 0	✓	✓	—	✓	✓
	DBLE = 1	—	✓ (1 ch only)	—	—	—
Continuous scan	DBLE = 0	✓	✓	—	✓	✓
	DBLE = 1	—	—	—	—	—
Group scan	DBLE = 0	✓	✓	✓	✓	✓
	DBLE = 1	—	✓ (1 ch only)	✓	✓	✓

Note: ✓: Selectable, —: Not selectable

ADST bit (A/D Conversion Start)

The ADST bit starts or stops the A/D conversion process. Before the ADST bit is set to 1, set the A/D conversion clock, the conversion mode, and the conversion target analog input.

[Setting conditions]

- 1 is written.
- The synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSA[5:0] bits is detected when ADCSR.EXTRG is 0 and ADCSR.TRGE is 1.
- The synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSB[5:0] bits is detected when ADCSR.TRGE is set to 1 in group scan mode.
- The asynchronous trigger is detected when the ADCSR.TRGE and ADCSR.EXTRG bits are set to 1 and the ADSTRGR.TRSA[5:0] bits are set to 0x00.
- When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADGSPCR.GBRP bit is set to 1, and each time A/D conversion on the group with the lowest priority is started.

[Clearing conditions]

- 0 is written.
- The A/D conversion of all the selected channels, the temperature sensor output the internal reference voltage completes in single scan mode.
- Group A scan completes in group scan mode.
- Group B scan completes in group scan mode.
- When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADGSPCR.GBRSCN bit is set to 1, and A/D conversion on the group with the lowest priority started by trigger completes.

Note: When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), do not set the ADST bit to 1.

Note: When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), do not set the ADST bit to 0. When forcing A/D conversion to terminate, follow the procedure for clearing the ADST bit.

45.2.9 ADANSA0 : A/D Channel Select Register A0

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x004

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADS15 to ADS00[*1]	A/D-Converted Value Addition/Average Channel Select Bit 15 (ADS15) is associated with ANm15 and bit 0 (ADS00) is associated with ANm00. 0: Do not select associated input channel. 1: Select associated input channel.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.
Note 1. 00 to 08 (unit 0), 00 to 06 (unit 1) is available.

ADSn bits (A/D-Converted Value Addition/Average Channel Select)

The ADSn bits determine which A/D-converted channels are subject to A/D-converted value addition/averaging. When an ADSn bit associated with a channel selected for A/D conversion is set to 1, A/D conversion of the analog input of the respective channel is performed successively 1, 2, 3, 4, or 16 times, as specified in the ADC[2:0] bits in the ADADC register.

When the ADADC.AVEE bit is 0, the value obtained by addition is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition is stored in the A/D data register.

The ADSn bits apply only to channels that are selected for A/D conversion in:

- The ANSAn bits in the ADANSA0 register or the DBLANS[4:0] bits in the ADCSR register
- The ANSBn bits in the ADANSB0 register

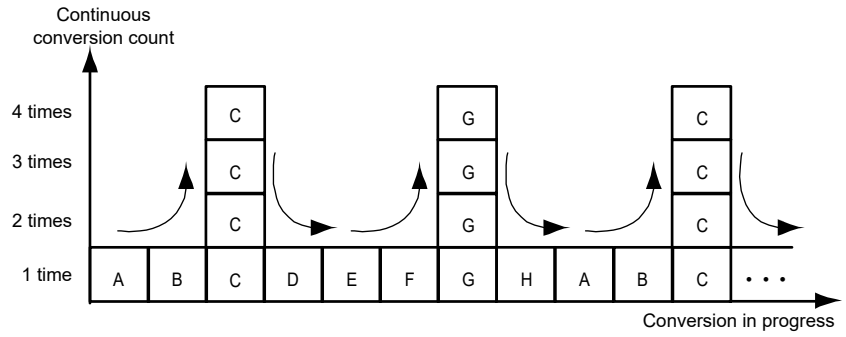
For channels on which the A/D conversion is performed and for which addition/average mode is not selected, a normal 1-time conversion is executed, and the conversion result is stored in the A/D data register.

Only set ADADS0 register bits when the ADCSR.ADST bit is 0.

Figure 45.3 shows a scanning operation sequence in which the ADADS0 register bits (channel c and g) are set to 1. In this figure:

- Addition mode is selected (ADADC.AVEE = 0)
- The number of conversions is set to 4 (ADADC.ADC[1:0] = 11b)
- The analog input channels (a to h) are selected by ADANSA0 register in continuous scan mode (ADCSR.ADCS[1:0] = 10b).

The conversion process begins with analog input A (channel a). The analog input C (channel c) conversion is performed successively 4 times and the added value is returned to A/D Data Register c (ADDRc). Next, the analog input D (channel d) conversion process is started. The analog input G (channel g) is performed successively 4 times and the added value is returned to A/D Data Register g (ADDRg). After conversion of analog input H (channel h), the conversion operation repeats in the same sequence starting with analog input A (channel a).



Note: A to H are analog inputs (channel a to h)

Figure 45.3 Scan conversion sequence with ADADC.ADC[2:0] = 011b, set 1 for analog inputs C and G by ADADS0/1

45.2.14 ADADS1 : A/D-Converted Value Addition/Average Channel Select Register 1

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x00A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADS31 to ADS16*1	A/D-Converted Value Addition/Average Channel Select Bit 15 (ADS31) is associated with ANm31 and bit 0 (ADS16) is associated with ANm16. 0: Do not select associated input channel. 1: Select associated input channel.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.
Note 1. 16 to 19 (unit 0), 16 to 22 (unit 1) is available.

ADSn bits (A/D-Converted Value Addition/Average Channel Select)

The ADSn bits determine which A/D-converted channels are subject to A/D-converted value addition/averaging. When an ADSn bit associated with a channel selected for A/D conversion is set to 1, A/D conversion of the analog input of the respective channel is performed successively 1, 2, 3, 4, or 16 times, as specified in the ADC[2:0] bits in the ADADC register.

When the ADADC.AVEE bit is 0, the value obtained by addition is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition is stored in the A/D data register.

The ADSn bits apply only to channels that are selected for A/D conversion in:

- The ANSAn bits in the ADANSA1 register or the DBLANS[4:0] bits in the ADCSR register
- The ANSBn bits in the ADANSB1 register.

For channels on which the A/D conversion is performed and for which addition/average mode is not selected, a normal 1-time conversion is executed, and the conversion result is stored in the A/D data register.

Only set ADADS1 register when the ADCSR.ADST bit is 0.

45.2.15 ADADC : A/D-Converted Value Addition/Average Count Select Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)

Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	ADC[2:0]	Addition/Average Count Select 0 0 0: 1-time conversion (no addition, same as normal conversion) 0 0 1: 2-time conversion (1 addition) 0 1 0: 3-time conversion (2 additions) 0 1 1: 4-time conversion (3 additions) 1 0 1: 16-time conversion (15 additions) Others: Setting prohibited	R/W
6:3	—	These bits are read as 0. The write value should be 0.	R/W
7	AVEE	Average Mode Select 0: Enable addition mode 1: Enable average mode	R/W

Note: S-TYPE-3, P-TYPE-3

ADADC sets the addition or average mode and addition count for A/D conversion. Table 45.20 lists the settable combinations of ADADC register.

Table 45.20 Settable combinations of ADADC register

Mode select	Resolution	Conversion time				
		1-time	2-time	3-time	4-time	16-time
Addition mode (AVEE = 0)	8-bit	✓	✓	✓	✓	—
	10-bit	✓	✓	✓	✓	—
	12-bit	✓	✓	✓	✓	✓
Average mode (AVEE = 1)	8, 10, 12 bits	—	✓	—	✓	—

Note: ✓: Selectable, —: Not selectable

ADC[2:0] bits (Addition/Average Count Select)

The ADC[2:0] bits set the addition count in all channels for which A/D conversion and addition/average mode are selected, including the channel selected in double trigger mode with the ADCSR.DBLANS[4:0] bits. The count also applies to A/D conversion of the temperature sensor output and the internal reference voltage.
When self-diagnosis is executed (ADCER.DIAGM = 1), do not set the ADC[2:0] bits to any value other than 000b.

AVEE bit (Average Mode Select)

The AVEE bit selects addition or average mode in all channels for which A/D conversion and addition/average mode are selected, including the channels selected in double-trigger mode in the ADCSR.DBLANS[4:0] bits, temperature sensor output, internal reference voltage.

45.2.16 ADCER : A/D Control Extended Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x00E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADRFMT	—	—	—	DIAGM	DIAGLD	DIAGVAL[1:0]		—	—	ACE	—	—	ADPRC[1:0]		—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
2:1	ADPRC[1:0]	A/D Conversion Accuracy Specify 0 0: 12-bit accuracy 0 1: 10-bit accuracy 1 0: 8-bit accuracy 1 1: Setting prohibited	R/W
4:3	—	These bits are read as 0. The write value should be 0.	R/W
5	ACE	A/D Data Register Automatic Clearing Enable 0: Disable automatic clearing 1: Enable automatic clearing	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
9:8	DIAGVAL[1:0]	Self-Diagnosis Conversion Voltage Select 0 0: Setting prohibited when self-diagnosis is enabled 0 1: 0 volts 1 0: Reference voltage*1 × 1/2 1 1: Reference voltage*1	R/W
10	DIAGLD	Self-Diagnosis Mode Select 0: Select rotation mode for self-diagnosis voltage 1: Select mixed mode for self-diagnosis voltage	R/W

Bit	Symbol	Function	R/W
11	DIAGM	Self-Diagnosis Enable 0: Disable ADC12 self-diagnosis 1: Enable ADC12 self-diagnosis	R/W
14:12	—	These bits are read as 0. The write value should be 0.	R/W
15	ADRFMT	A/D Data Register Format Select 0: Select right-justified for the A/D data register format 1: Select left-justified for the A/D data register format	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The reference voltage refers to VREFH0 for unit 0 and to VREFH for unit 1.

ADPRC[1:0] bit (A/D Conversion Accuracy Specify)

The ADPRC[1:0] bits set the A/D conversion accuracy. Changing the A/D conversion accuracy also changes the bit width of valid data stored in the result register and the A/D conversion time. For details, see section 45.3.6. Analog Input Sampling and Scan Conversion Time. Only set the ADPRC[1:0] bits while the ADCSR.ADST bit is 0.

ACE bit (A/D Data Register Automatic Clearing Enable)

The ACE bit enables or disables automatic clearing (all 0) of the ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR or ADVMDR register after any of these registers is read by the CPU or DTC. Automatic clearing of the A/D data registers enables detection of failures that are not updated in the A/D data registers. For details, see section 45.3.7. Usage Example of A/D Data Register Automatic Clearing Function.

DIAGVAL[1:0] bits (Self-Diagnosis Conversion Voltage Select)

The DIAGVAL[1:0] bits select the voltage value used in self-diagnosis fixed voltage mode. For details, see the DIAGLD bit description.

Do not execute self-diagnosis by setting the DIAGLD bit to 1 when the DIAGVAL[1:0] bits are set to 00b.

DIAGLD bit (Self-Diagnosis Mode Select)

The DIAGLD bit selects whether the three voltage values are rotated, or the fixed voltage is used in self-diagnosis.

Setting the DIAGLD bit to 0 selects conversion of the voltages in rotation mode, where 0 V, the reference voltage × 1/2, and the reference voltage are converted, in that order. After reset and when self-diagnosis voltage rotation mode is selected, self-diagnosis is executed from 0 V. The self-diagnosis voltage value does not return to 0 V when scan conversion completes. When scan conversion is restarted, rotation starts at the voltage value following the previous value.

Setting the DIAGLD bit to 1 selects fixed voltage, in which the fixed voltage specified in the ADCER.DIAGVAL[1:0] bits is converted. If fixed mode is switched to rotation mode, rotation starts at the fixed voltage value.

Only set the DIAGLD bit when the ADCSR.ADST bit is 0.

DIAGM bit (Self-Diagnosis Enable)

The DIAGM bit enables or disables self-diagnosis.

Self-diagnosis is used to detect a failure of the ADC12. In self-diagnosis mode, one of the three voltage values (0 V, the reference voltage × 1/2, or the reference voltage) is converted. When conversion completes, information on the converted voltage and the conversion result is stored into the A/D Self-Diagnosis Data Register (ADRD). The ADRD register can be read to determine whether the conversion result falls within the normal or abnormal range.

Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages is converted. In double trigger mode (ADCSR.DBLE = 1), self-diagnosis (DIAGM = 0) is deselected. When self-diagnosis is selected in group scan mode, self-diagnosis is executed separately for group A and group B.

Only set the DIAGM bit when the ADCSR.ADST bit is 0.

ADRFMT bit (A/D Data Register Format Select)

The ADRFMT bit specifies flush-right or flush-left for data to be stored in the ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADVMDR, ADCMPDR0/1, ADWINLLB, ADWINULB, or ADRD register.

Only set the ADRFMT bit when the ADCSR.ADST bit is 0.

45.2.17 ADSTRGR : A/D Conversion Start Trigger Select Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x010

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	TRSA[5:0]						—	—	TRSB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	TRSB[5:0]	A/D Conversion Start Trigger Select for Group B Select the A/D conversion start trigger for group B in group scan mode.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
13:8	TRSA[5:0]	A/D Conversion Start Trigger Select Select the A/D conversion start trigger in single scan mode and continuous scan mode. In group scan mode, the A/D conversion start trigger for group A is selected.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

TRSB[5:0] bits (A/D Conversion Start Trigger Select for Group B)

The TRSB[5:0] bits select the trigger to start scanning of the analog input selected in group B. The TRSB[5:0] bits must only be set in group scan mode and are not used in any other scan mode. For the scan conversion start trigger for group B, setting a software trigger or an asynchronous trigger is prohibited. In group scan mode, set the TRSB[5:0] bits to a value other than 0x00 and set the ADCSR.TRGE bit to 1.

When group A is given priority in group scan mode, setting the ADGSPCR.GBRP bit to 1 allows group B to continuously operate in single scan mode. When setting the ADGSPCR.GBRP bit to 1, set the TRSB[5:0] bits to 0x3F. The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time (t_{SCAN}). If the issuance period is less than t_{SCAN}, A/D conversion by the trigger might have no effect.

When the GPT module is selected as an A/D conversion start trigger, a delay for synchronization processing occurs. For details, see section 45.3.6. Analog Input Sampling and Scan Conversion Time.

Table 45.21 lists the A/D conversion startup sources selected in the TRSB[5:0] bits.

Table 45.21 Selection of A/D conversion start sources in the TRSB[5:0] bits (1 of 2)

Source	Remarks	TRSB[5]	TRSB[4]	TRSB[3]	TRSB[2]	TRSB[1]	TRSB[0]

TRSA[5:0] bits (A/D Conversion Start Trigger Select)

The TRSA[5:0] bits select the trigger to start A/D conversion in single scan mode and continuous scan mode, or the trigger to start scanning of group A analog inputs in group scan mode. When scanning is executed in group scan mode or double trigger mode, software trigger or asynchronous trigger is prohibited.

- When using a synchronous trigger (GPT, ELC), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 0.
- When using the asynchronous trigger (ADTRGn (n = 0, 1), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 1.
- Software trigger (ADCSR.ADST) is enabled regardless of the settings of the ADCSR.TRGE bit, the ADCSR.EXTRG bit, or the TRSA[5:0] bits.

The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time (tSCAN). If the issuance period is less than tSCAN, A/D conversion by a trigger might have no effect.

When the GPT module is selected as an A/D conversion start trigger, a delay for synchronization processing occurs. For details, see section 45.3.6. Analog Input Sampling and Scan Conversion Time.

Table 45.22 lists the A/D conversion start sources selected in the TRSA[5:0] bits.

Table 45.22 Selection of A/D activation sources in the TRSA[5:0] bits (1 of 2)

Source	Remarks	TRSA[5]	TRSA[4]	TRSA[3]	TRSA[2]	TRSA[1]	TRSA[0]

45.2.18 ADEXICR : A/D Conversion Extended Input Control Registers

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x012

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	OCSB	TSSB	OCSA	TSSA	—	—	—	—	—	—	OCSAD	TSSAD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TSSAD	Temperature Sensor Output A/D-Converted Value Addition/Average Mode Select 0: Do not select addition/average mode for temperature sensor output. 1: Select addition/average mode for temperature sensor output.	R/W
1	OCSAD	Internal Reference Voltage A/D-Converted Value Addition/Average Mode Select 0: Do not select addition/average mode for internal reference voltage. 1: Select addition/average mode for internal reference voltage.	R/W

Bit	Symbol	Function	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	TSSA	Temperature Sensor Output A/D Conversion Select 0: Disable A/D conversion of temperature sensor output 1: Enable A/D conversion of temperature sensor output	R/W
9	OCSA	Internal Reference Voltage A/D Conversion Select 0: Disable A/D conversion of internal reference voltage 1: Enable A/D conversion of internal reference voltage	R/W
10	TSSB	Temperature Sensor Output A/D Conversion Select for Group B 0: Disable A/D conversion of temperature sensor output 1: Enable A/D conversion of temperature sensor output	R/W
11	OCSB	Internal Reference Voltage A/D Conversion Select for Group B 0: Disable A/D conversion of internal reference voltage 1: Enable A/D conversion of internal reference voltage	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

TSSAD bit (Temperature Sensor Output A/D-Converted Value Addition/Average Mode Select)

When the TSSAD bit is set to 1, A/D conversion of the temperature sensor output is selected and performed successively the number of times specified in the ADC[2:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D Temperature Sensor Data Register (ADTSDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADTSDR.

Only set the TSSAD bit while the ADCSR.ADST bit is 0.

OCSAD bit (Internal Reference Voltage A/D-Converted Value Addition/Average Mode Select)

When the OCSAD bit is set to 1, A/D conversion of the internal reference voltage is selected and performed successively the number of times specified in the ADC[2:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D Internal Reference Voltage Data Register (ADOCDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADOCDR.

Only set the OCSAD bit while the ADCSR.ADST bit is 0.

TSSA bit (Temperature Sensor Output A/D Conversion Select)

The TSSA bit selects A/D conversion of the temperature sensor output for group A in single scan mode, continuous scan mode, or group scan mode. When A/D conversion of the temperature sensor output is selected and performed, set the ADCSR.DBLE bit to 0.

Only set the TSSA bit while the ADCSR.ADST bit is 0.

OCSA bit (Internal Reference Voltage A/D Conversion Select)

The OCSA bit selects A/D conversion of the internal reference voltage for group A in single scan mode, continuous scan mode, or group scan mode. When A/D conversion of the internal reference voltage is selected and performed, set the ADCSR.DBLE bit to 0.

Only set the OCSA bit while the ADCSR.ADST bit is 0. In addition, wait for 400 ns or more after the OCSA bit is set to 1 before starting A/D conversion.

TSSB bit (Temperature Sensor Output A/D Conversion Select for Group B)

The TSSB bit selects A/D conversion of the temperature sensor output for group B in group scan mode. Only set the TSSB bit while the ADCSR.ADST bit is 0. Do not set the TSSB bit to 1 while the TSSA bit is 1.

OCSB bit (Internal Reference Voltage A/D Conversion Select for Group B)

The OCSB bit selects A/D conversion of the internal reference voltage for group B in group scan mode. Only set the OCSB bit while the ADCSR.ADST bit is 0. Do not set the OCSB bit to 1 while the OCSA bit is 1. Moreover, start the A/D conversion after waiting for 400 ns or more after the OCSB bit is set to 1.

45.2.19 ADSSTRn/ADSSTRL/ADSSTRT/ADSSTRO/ADSSTRV: A/D Sampling State Register (n = 0 to 8)

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0E0 + 0x1 × n (n = 0 to 8, m = 0)
0x0E0 + 0x1 × n (n = 0 to 6, m = 1)
0x0DD (ADSSTRL)
0x0DE (ADSSTRT)
0x0DF (ADSSTRO)
0x0E3 (ADSSTRV)

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SST[7:0]							
Value after reset:	0	0	0	0	1	0	1	1

Bit	Symbol	Function	R/W
7:0	SST[7:0]	Sampling Time Setting These bits set the sampling time in the range from 5 to 255 states.	R/W

Note: S-TYPE-3, P-TYPE-3

The ADSSTRn register sets the sampling time for analog input.

The sampling time can be adjusted if the impedance of the analog input signal source is too high to secure sufficient sampling time, or if the ADCLK clock is slow. The set value indicates the time for one ADCLK cycle, and the required sampling time is specified by the voltage conditions. For details, see section 60.6. ADC12 Characteristics.

ADSSTRV register is an alias for the ADSSTR3 register.

The lower limit of the sampling time setting depends on the frequency ratio:

- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:1, 2:1, 4:1, or 8:1 the sampling time must be set to a value of more than 5 states
- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:2 or 1:4, the sampling time must be set to a value of more than 6 states.

Table 45.23 shows the relationship between the A/D Sampling State Register and the associated channels. For details, see section 45.3.6. Analog Input Sampling and Scan Conversion Time.

Only set the SST[7:0] bits when the ADCSR.ADST bit is 0.

Table 45.23 Relationship between A/D sampling state register and associated channels

Bit name	Associated channels
ADSSTRn.SST[7:0] bits (n = 0 to 8(unit 0), 0 to 6(unit 1))*1	AN000 to AN008, AN100 to AN106
ADSSTRL.SST[7:0] bits	AN016 to AN019, AN116 to AN122
ADSSTRT.SST[7:0] bits	Temperature sensor output
ADSSTRO.SST[7:0] bits	Internal reference voltage
ADSSTRV.SST[7:0] bits	VBATT 1/3 voltage monitor output*2

Note 1. When the self-diagnosis function is selected, the sampling time set in the ADSSTR0.SST[7:0] bits is applied.
Note 2. For the stabilization time,see section 11, Battery Backup Function.

45.2.20 ADSHCR : A/D Sample and Hold Circuit Control Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0)

Offset address: 0x066

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SHANS[2:0]			SSTSH[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0

Bit	Symbol	Function	R/W
7:0	SSTSH[7:0]	Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting Sampling time (4 to 255 states).	R/W
10:8	SHANS[2:0]	Channel-Dedicated Sample-and-Hold Circuit Bypass Select Select whether to use or bypass channel-dedicated sample-and-hold circuits for AN000 to AN002 (unit 0). 0: Bypass the circuits 1: Use the circuits	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SSTSH[7:0] bits (Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting)

The SSTSH[7:0] bits set the sampling time for the channel-dedicated sample-and-hold circuits. If one state is 1 ADCLK (A/D conversion clock) cycle and the ADCLK clock is 60 MHz, one state is 16.7 ns. The initial value is 24 states. The sampling time can be adjusted if the impedance of the analog input signal source is too high to secure sufficient sampling time, or if the ADCLK clock is slow.

Only set the SSTSH[7:0] bits while the ADCSR.ADST bit is 0. The sampling time must be set to a value that is 4 states or more and 255 or less.

SHANS[2:0] bits (Channel-Dedicated Sample-and-Hold Circuit Bypass Select)

The SHANS[2:0] bits select whether to use or bypass the channel-dedicated sample-and-hold circuits for AN000 to AN002 (unit 0). In unit 0, the SHANS[0] bit is associated with AN000, the SHANS[1] bit with AN001, and the SHANS[2] bit with AN002.

If any channel from among AN000 to AN002 (unit 0) is selected for group B while operation is in group scan mode under group A priority control, use this setting to bypass the dedicated sample-and-hold circuit of the channel.

Only set the SHANS[2:0] bits while the ADCSR.ADST bit is 0 and the ADSHMSR.SHMD bit is 0.

45.2.21 ADSHMSR : A/D Sample and Hold Operation Mode Selection Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0)

Offset address: 0x07C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SHMD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SHMD	Sampling Operation Selection 0: Sampling Operation Selection 1: Enable continuous sampling function	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SHMD bit (Sampling Operation Selection)

Setting SHMD to 1 enables the constant sampling function of the channel-dedicated sample-and-hold selected in the ADSHCR.SHANS[2:0] bits. Only set the SHMD bit while the ADCSR.ADST bit is 0.

When the sampling function is enabled, the sample-and-hold circuit operates sampling while the ADC12 is not operating, and it operates holding while the ADC12 is operating.

Note: The ADCSR.ADST bit must become 1 after a time of 400 ns or more elapses after the SHMD bit is set to 1 (when the permissible signal source impedance is 1 kΩ). The sampling period of the sample-and-hold circuit must be 400 ns or more (when the permissible signal source impedance is 1 kΩ).

45.2.22 ADDISCR : A/D Disconnection Detection Control Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x07A

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	PCHG	ADNDIS[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	ADNDIS[3:0]	Disconnection Detection Assist Setting 0x0: The disconnection detection assist function is disabled 0x1: Setting prohibited Others: The number of states for the discharge or precharge period.	R/W
4	PCHG	Precharge/discharge select 0: Discharge 1: Precharge	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The ADDISCR register selects either precharge or discharge, and the period of precharge or discharge for the A/D disconnection detection assist function. Only set the ADDISCR register when the ADCSR.ADST bit is 0. When the temperature sensor output or internal reference voltage is converted, the A/D converter executes discharge automatically.

Disable the disconnection detection assist function if any of the following functions are used:

- The temperature sensor
- The internal reference voltage
- A/D self-diagnosis
- VBATT 1/3 voltage monitor

ADNDIS[3:0] bits (Disconnection Detection Assist Setting)

The ADNDIS[3:0] bits specify the period of precharge or discharge. When ADNDIS[3:0] = 0000b, the disconnection detection assist function is disabled. Setting the ADNDIS[3:0] bits to 0001b is prohibited. Except when ADNDIS[3:0] = 0000b or 0001b, the specified value indicates the number of states for the period of precharge or discharge. When the ADNDIS[3:0] bits are set to any values other than 0000b or 0001b, the disconnection detection assistance function is enabled.The ADNDIS[4:0] should be set while the ADCSR.ADST bit is 0. When the ADNDIS[3:0] bits are set to any values other than 0000b, and the disconnection detection assistance is enabled, the disconnection detection assistance for the channel-dedicated sample-and-hold circuit used for analog inputs are also enabled. When the temperature sensor output or internal reference voltage is converted or self-diagnosis is used, the disconnection detection assistance cannot be used. In that case, the ADNDIS[3:0] bits should be set to 0000b.

PCHG bit (Precharge/discharge select)

The PCHG bit selects either precharge or discharge.

45.2.23 ADGSPCR : A/D Group Scan Priority Control Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x080

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GBRP	LGRRS	—	—	—	—	—	—	—	—	—	—	—	—	GBRSCN	PGS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PGS	Group Priority Operation Setting*1 0: Operate without group priority control. 1: Operate with group priority control.	R/W
1	GBRSCN	Lower-Priority Group Restart Setting (enabled only when PGS = 1 and reserved when PGS = 0.) 0: Disable rescanning of the group that was stopped in group priority operation 1: Enable rescanning of the group that was stopped in group priority operation.	R/W
13:2	—	These bits are read as 0. The write value should be 0.	R/W
14	LGRRS	Restart Channel Select Enabled only when PGS = 1 and GBRSCN = 1. 0: Start rescanning from the first channel for scanning 1: Start rescanning from the channel for which A/D conversion is not completed.	R/W
15	GBRP	Single Scan Continuous Start*2 (enabled only when PGS = 1 and reserved when PGS = 0.) 0: Single scan is not continuously activated. 1: Single scan for the group with the lower-priority is continuously activated.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting PGS to 1. Operation is not guaranteed if these bits are set to any other value.
Note 2. When the GBRP bit is set to 1, single scan is performed continuously for the group with the lower-priority regardless of the setting in the GBRSCN bit.

PGS bit (Group Priority Operation Setting)

The PGS bit controls group priority operation in group scan mode. Set the PGS bit to 1 to enable group priority operation.

The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting the PGS bit to 1. Operation is not guaranteed if the bits are set to any other value.

When the PGS bit is set to 0, a clear operation must be performed by software as described in section 45.6.3. Constraints on Stopping A/D Conversion. When the PGS bit is set to 1, use the settings described in section 45.3.4.3. Group Priority Operation.

GBRSCN bit (Lower-Priority Group Restart Setting)

The GBRSCN bit controls the restarting of scan operation in group priority operation.

When the GBRSCN bit is set to 1, if the scan operation of a lower-priority group is stopped by a trigger input of a priority group, the lower-priority group scanning is restarted on completion of the priority group scanning. If a trigger of a lower-priority group is input during scanning of the priority group, the lower-priority group scanning is started on completion of the priority group scanning.

When the GBRSCN bit is set to 0, triggers input during scanning are ignored. Set the GBRSCN bit while the ADCSR.ADST bit is 0.

LGRRS bit (Restart Channel Select)

This bit sets the channel from which rescanning is to be started in group priority operation. The setting of the LGRRS bit is valid when the PGS and GBRSCN bits are 1.

If the LGRRS bit is 0, scanning of a lower-priority group that was stopped in group priority operation is restarted from the first channel after scanning of the priority group completes.

If the LGRRS bit is 1, scanning of a lower-priority group that was stopped in group priority operation is restarted (upon completion of scanning of the priority group) from the channel for which A/D conversion is not complete. If A/D conversion of the addition setting channel was not completed the specified number of times when scanning stopped, A/D conversion of the addition setting channel is performed again the specified number of times when scanning restarts.

Set the LGRRS bit while the ADCSR.ADST bit is 0.

GBRP bit (Single Scan Continuous Start)

The GBRP bit is set when a single scan operation is to be performed continuously on the group with the lower-priority.

Setting the GBRP bit to 1 starts a single scan of the group with the lower-priority. On completion of the scan, another single scan of the group with the lower-priority is started automatically. If scanning has been stopped during group priority operation, single scan of the group with the lower-priority is automatically restarted on completion of the A/D conversion of the priority group.

Before setting the GBRP bit to 1, disable input of a trigger for the lower-priority group. If the GBRP bit is set to 1, rescanning is performed only on the group with the lower-priority even if the GBRSCN bit is set to 0.

45.2.24 ADCMPCR : A/D Compare Function Control Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x090

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPAIE	WCMPE	CMPBIE	—	CMPAE	—	CMPBE	—	—	—	—	—	—	—	CMPAB[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CMPAB[1:0]	Window A/B Composite Conditions Setting These bits are valid when both window A and window B are enabled (CMPAE = 1 and CMPBE = 1). 0 0: Output ADC12i_WCMPM (i = 0, 1) when window A OR window B comparison conditions are met. Otherwise, output ADC12i_WCMPUM (i = 0, 1). 0 1: Output ADC12i_WCMPM (i = 0, 1) when window A EXOR window B comparison conditions are met. Otherwise, output ADC12i_WCMPUM (i = 0, 1). 1 0: Output ADC12i_WCMPM (i = 0, 1) when window A AND window B comparison conditions are met. Otherwise, output ADC12i_WCMPUM (i = 0, 1). 1 1: Setting prohibited.	R/W
8:2	—	These bits are read as 0. The write value should be 0.	R/W
9	CMPBE	Compare Window B Operation Enable 0: Disable compare window B operation. Disable ADC12i_WCMPM (i = 0, 1) and ADC12i_WCMPUM (i = 0, 1) outputs. 1: Enable compare window B operation.	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	CMPAE	Compare Window A Operation Enable 0: Disable compare window A operation. Disable ADC12i_WCMPM (i = 0, 1) and ADC12i_WCMPUM (i = 0, 1) outputs. 1: Enable compare window A operation.	R/W
12	—	This bit is read as 0. The write value should be 0.	R/W
13	CMPBIE	Compare B Interrupt Enable 0: Disable ADC12i_CMPBI (i = 0, 1) interrupt when comparison conditions (window B) are met. 1: Enable ADC12i_CMPBI (i = 0, 1) interrupt when comparison conditions (window B) are met.	R/W

Bit	Symbol	Function	R/W
14	WCMPE	Window Function Setting 0: Disable window function Window A and window B operate as a comparator to compare the single value on the lower side with the A/D conversion result. 1: Enable window function Window A and window B operate as a comparator to compare the two values on the upper and lower sides with the A/D conversion result.	R/W
15	CMPAIE	Compare A Interrupt Enable 0: Disable ADC12i_CMPAI (i = 0, 1) interrupt when comparison conditions (window A) are met. 1: Enable ADC12i_CMPAI (i = 0, 1) interrupt when comparison conditions (window A) are met.	R/W

Note: S-TYPE-3, P-TYPE-3

CMPAB[1:0] bits (Window A/B Composite Conditions Setting)

The CMPAB[1:0] bits are valid when both window A and window B are enabled (CMPAE = 1 and CMPBE = 1) in single scan mode. These bits specify the compare function match/mismatch event output conditions and monitoring conditions of ADWINMON.MONCOMB. Only set the CMPAB[1:0] bits while the ADCSR.ADST bit is 0.

CMPBE bit (Compare Window B Operation Enable)

The CMPBE bit enables or disables the compare window B operation. Set the CMPBE bit while the ADCSR.ADST bit is 0.

Set this bit to 0 before setting the following registers:

- A/D Channel Select Registers A0, A1, B0, B1 (ADANSA0, ADANSA1, ADANSB0, ADANSB1)
- OCSB, TSSB, OCSA, or TSSA bits in the A/D Conversion Extended Input Control Register (ADEXICR)
- CMPCHB[5:0] bits in the Window B Channel Select Register (ADCMPBNSR)

CMPAE bit (Compare Window A Operation Enable)

The CMPAE bit enables or disables the compare window A operation. Set the CMPAE bit while the ADCSR.ADST bit is 0.

Set this bit to 0 before setting the following registers:

- A/D Channel Select Registers A0, A1, B0, B1 (ADANSA0, ADANSA1, ADANSB0, ADANSB1)
- OCSB, TSSB, OCSA, or TSSA bits in the A/D Conversion Extended Input Control Register (ADEXICR)
- Window A Channel Select Registers 0 and 1 (ADCMPANSR0 and ADCMPANSR1)
- Window A Extended Input Select Register (ADCMPANSER)

CMPBIE bit (Compare B Interrupt Enable)

The CMPBIE bit enables or disables the ADC12i_CMPBI (i = 0, 1) interrupt output when the comparison conditions (window B) are met.

WCMPE bit (Window Function Setting)

The WCMPE bit enables or disables the window function. Set the WCMPE bit while the ADCSR.ADST bit is 0.

CMPAIE bit (Compare A Interrupt Enable)

The CMPAIE bit enables or disables the ADC12i_CMPAI (i = 0, 1) interrupt output when the comparison conditions (window A) are met.

45.2.25 ADCMPANSR0 : A/D Compare Function Window A Channel Select Register 0

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x094

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPCHA15	CMPCHA14	CMPCHA13	CMPCHA12	CMPCHA11	CMPCHA10	CMPCHA09	CMPCHA08	CMPCHA07	CMPCHA06	CMPCHA05	CMPCHA04	CMPCHA03	CMPCHA02	CMPCHA01	CMPCHA00

Bit	Symbol	Function	R/W
15:0	CMPCHA15 to CMPCHA00*1	Compare Window A Channel Select Bit 15 (CMPCHA15) is associated with ANm15 and bit 0 (CMPCHA00) is associated with ANm00. 0: Disable compare function for associated input channel 1: Enable compare function for associated input channel	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.
Note 1. 00 to 08 (unit 0), 00 to 06 (unit 1) is available.

CMPCHAn bits (Compare Window A Channel Select)

The compare function is enabled by writing 1 to the CMPCHAn bits with the same number as the A/D conversion channel selected in the ADANSA0.ANSAn bits and the ADANSB0.ANSBn bits.

Set the CMPCHAn bits while the ADCSR.ADST bit is 0.

45.2.26 ADCMPANSR1 : A/D Compare Function Window A Channel Select Register 1

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Note: S-TYPE-3, P-TYPE-3
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.
Note 1. 16 to 19 (unit 0), 16 to 22 (unit 1) is available.

CMPCHAn bits (Compare Window A Channel Select)

The compare function is enabled by writing 1 to the CMPCHAn bits with the same number as the A/D conversion channel selected in the ADANSA1.ANSA bits and the ADANSB1.ANSB bits.

Set the CMPCHAn bits while the ADCSR.ADST bit is 0.

45.2.27 ADCMPANSER : A/D Compare Function Window A Extended Input Select Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x092

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CMPOCA	CMPTSA
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMPTSA	Temperature Sensor Output Compare Select 0: Exclude the temperature sensor output from the compare Window A target range. 1: Include the temperature sensor output in the compare Window A target range.	R/W
1	CMPOCA	Internal Reference Voltage Compare Select 0: Exclude the internal reference voltage from the compare Window A target range. 1: Include the internal reference voltage in the compare Window A target range.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CMPTSA bit (Temperature Sensor Output Compare Select)

The compare Window A function is enabled by setting the CMPTSA bit to 1 while the ADEXICR.TSSA bit or the ADEXICR.TSSB bit is 1. Set the CMPTSA bit while the ADCSR.ADST bit is 0.

CMPOCA bit (Internal Reference Voltage Compare Select)

The compare window A function is enabled by setting the CMPOCA bit to 1 when the ADEXICR.OCSA and ADEXICR.OCSB bit is 1. Set the CMPOCA bit when the ADCSR.ADST bit is 0.

45.2.28 ADCMPLR0 : A/D Compare Function Window A Comparison Condition Setting Register 0

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x098

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPLCHA15 to CMPLCHA00*1	Compare Window A Comparison Condition Select These bits set comparison conditions for channels to which Window A comparison conditions are applied. Bit 15 (CMPLCHA15) is associated with ANm15 and bit 0 (CMPLCHA00) is associated with ANm00. Comparison conditions are shown in Figure 45.4. 0: When window function is disabled (ADCMPCR.WCMPE = 0): ADCMPDR0 value > A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): A/D-converted value < ADCMPDR0 value, or ADCMPDR1 value < A/D-converted value 1: When window function is disabled (ADCMPCR.WCMPE = 0): ADCMPDR0 value < A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): ADCMPDR0 value < A/D-converted value < ADCMPDR1 value	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.
Note 1. 00 to 08 (unit 0), 00 to 06 (unit 1) is available.

CMPLCHAn bits (Compare Window A Comparison Condition Select)

The CMPLCHAn bits specify the comparison conditions for channels to which Window A comparison conditions are applied. These bits can be set for each analog input to be compared. When the comparison result of each analog input meets the set condition, the ADCMPSR0.CMPSTCHAn flag sets to 1 and a compare interrupt (ADC12i_CMPAI (i = 0, 1)) is generated.

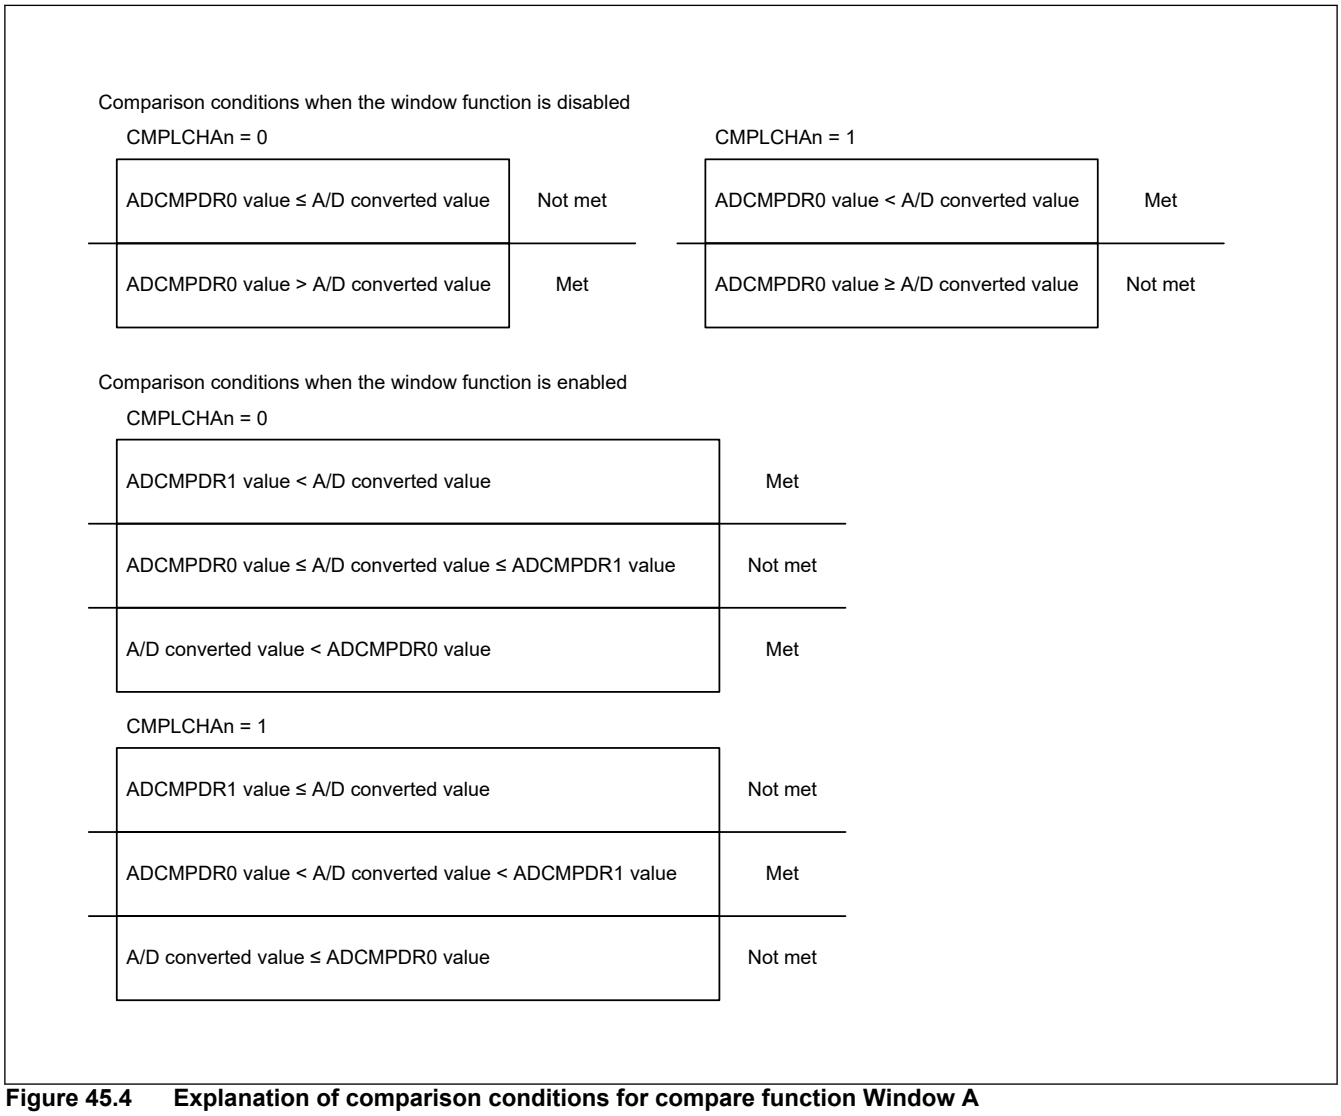

Figure 45.4 Explanation of comparison conditions for compare function Window A

45.2.29 ADCMPLR1 : A/D Compare Function Window A Comparison Condition Setting Register 1

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)

7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CMPLTSA bit (Compare Window A Temperature Sensor Output Comparison Condition Select)

The CMPLTSA bit specifies comparison conditions when the temperature sensor output is the target for the Window A comparison condition. When the temperature sensor output comparison result meets the set condition, the ADCMPSER.CMPSTTSA flag sets to 1 and a compare interrupt (ADC12i_CMPAI (i = 0, 1)) is generated.

CMPLOCA bit (Compare Window A Internal Reference Voltage Comparison Condition Select)

The CMPLOCA bit specifies comparison conditions when the internal reference voltage is the target for the Window A comparison condition. When the internal reference voltage comparison result meets the set condition, the ADCMPSER.CMPSTOCA flag sets to 1 and a compare interrupt (ADC12i_CMPAI (i = 0, 1)) is generated.

45.2.31 ADCMPDRn : A/D Compare Function Window A Lower-Side/Upper-Side Level Setting Register (n = 0, 1)

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x09C + (0x2 × n)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: S-TYPE-3, P-TYPE-3

The ADCMPDRy (y = 0, 1) register specifies the reference data when the compare window A function is used. ADCMPDR0 sets the lower reference for window A, and ADCMPDR1 sets the upper reference for window A.

ADCMPDRy are read/write registers.

ADCMPDRy are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion*1.

Set these registers so that the upper reference is not less than the lower reference (ADCMPDR1 ≥ ADCMPDR0). ADCMPDR1 are not used when the window function is disabled.

Note 1. The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after rewrite), and the lower reference (before rewrite) with the A/D conversion result. See Figure 45.5. If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the target Compare Window Operation Enable bit (ADCMPCR.CMPAE or ADCMPCR.CMPBE) are 0.

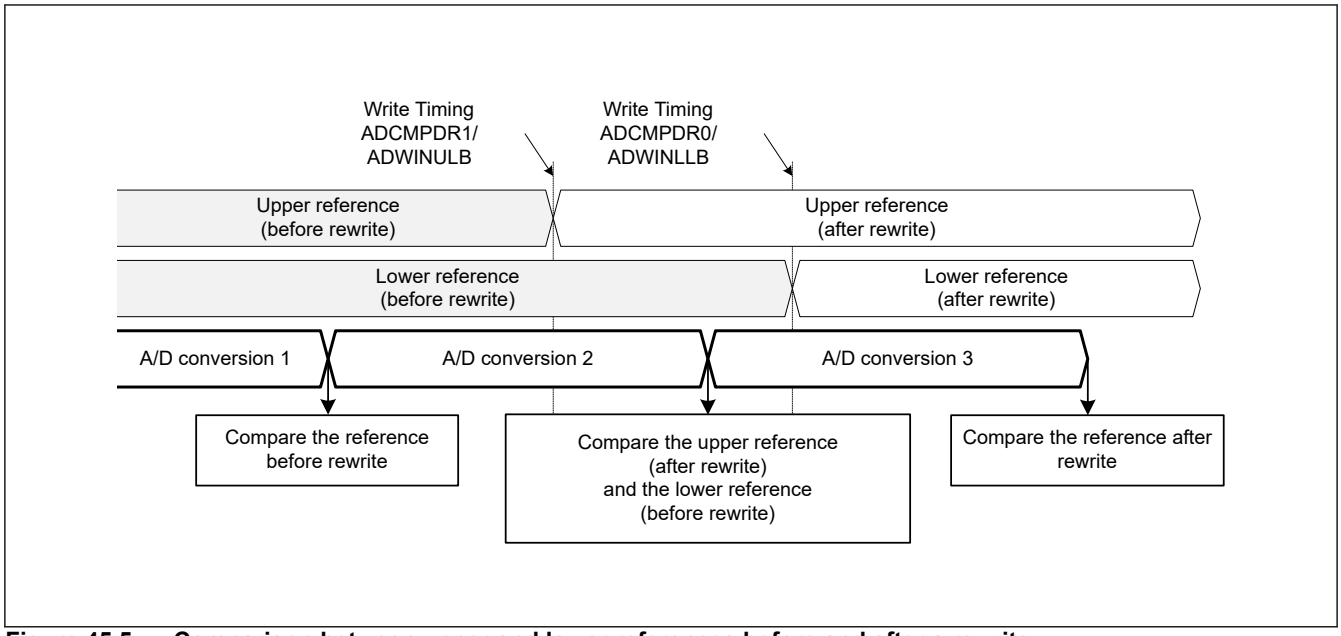

Figure 45.5 Comparison between upper and lower references before and after a rewrite

The ADCMPDRy registers use different formats depending on the following conditions:

- The value of A/D Data Register Format Select bit (flush-right or flush-left)
- The value of the A/D Conversion Accuracy Select bit (12-bit, 10-bit, 8-bit)
- The value of A/D-Converted Value Addition/Average Channel Select bits (A/D-converted value addition mode selected or not selected).

The data formats for each condition are shown as follows:

1. When A/D-converted value addition mode is not selected
   - Flush-right data with 12-bit accuracy — Lower 12 bits ([11:0]) are valid
   - Flush-right data with 10-bit accuracy — Lower 10 bits ([9:0]) are valid
   - Flush-right data with 8-bit accuracy — Lower 8 bits ([7:0]) are valid
   - Flush-left data with 12-bit accuracy — Upper 12 bits ([15:4]) are valid
   - Flush-left data with 10-bit accuracy — Upper 10 bits ([15:6]) are valid
   - Flush-left data with 8-bit accuracy — Upper 8 bits ([15:8]) are valid
2. When A/D-converted value addition mode is selected
   - Flush-right data with 12-bit accuracy — Lower 14 bits ([13:0]) are valid
   - Flush-right data with 10-bit accuracy — Lower 12 bits ([11:0]) are valid
   - Flush-right data with 8-bit accuracy — Lower 10 bits ([9:0]) are valid
   - Flush-left data with 12-bit accuracy — Upper 14 bits ([15:2]) are valid
   - Flush-left data with 10-bit accuracy — Upper 12 bits ([15:4]) are valid
   - Flush-left data with 8-bit accuracy — Upper 10 bits ([15:6]) are valid

45.2.32 ADWINnLB : A/D Compare Function Window B Lower-Side/Upper-Side Level Setting Register (n = L, U)

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0A8 (n = L)
0x0AA (n = U)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: S-TYPE-3, P-TYPE-3

The ADWINULB and ADWINLLB registers specify the reference data when the compare window B function is used. ADWINLLB sets the lower reference for window B, and ADWINULB sets the upper reference for window B.

ADWINnLB are read/write registers.

ADWINnLB are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion*1.

Set these registers so that the upper reference is not less than the lower reference (ADWINULB ≥ ADWINLLB). ADWINULB are not used when the window function is disabled.

Note 1. The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after rewrite), and the lower reference (before rewrite) with the A/D conversion result. See Figure 45.6. If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the target Compare Window Operation Enable bit (ADCMPCR.CMPAE or ADCMPCR.CMPBE) are 0.

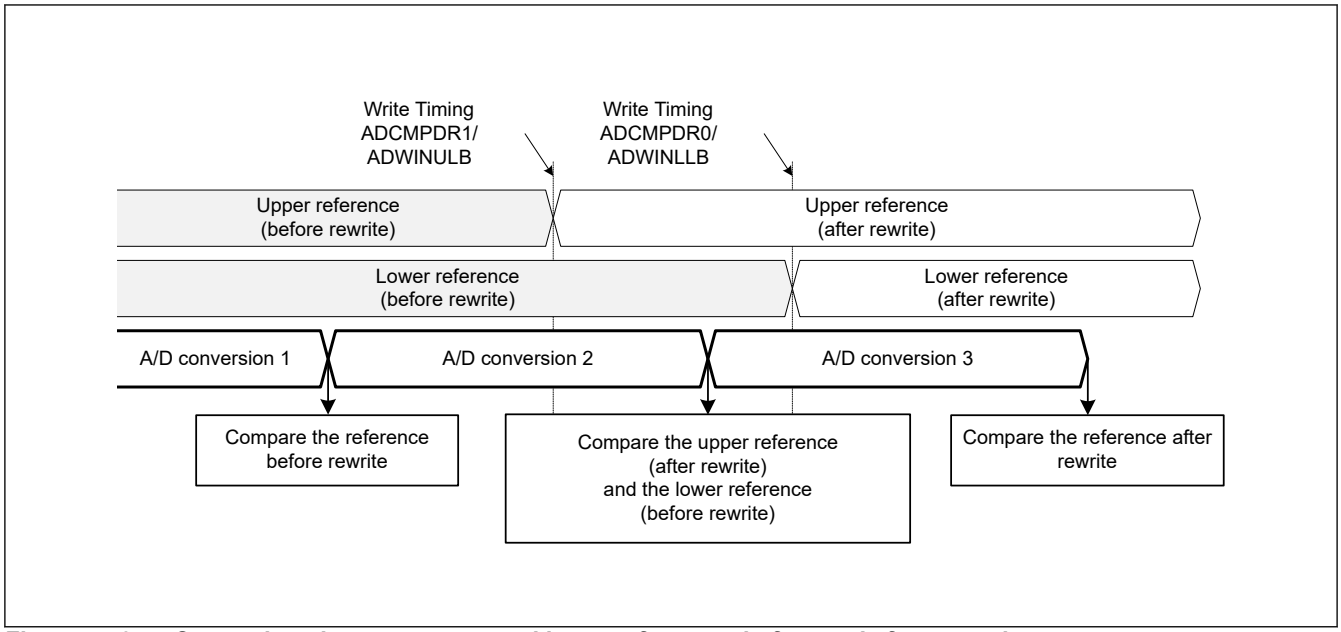

Figure 45.6 Comparison between upper and lower references before and after a rewrite

The ADWINnLB registers use different formats depending on the following conditions:

- The value of A/D Data Register Format Select bit (flush-right or flush-left)
- The value of the A/D Conversion Accuracy Select bit (12-bit, 10-bit, 8-bit)
- The value of A/D-Converted Value Addition/Average Channel Select bits (A/D-converted value addition mode selected or not selected).

The data formats for each condition are shown as follows:

1. When A/D-converted value addition mode is not selected
   - Flush-right data with 12-bit accuracy — Lower 12 bits ([11:0]) are valid
   - Flush-right data with 10-bit accuracy — Lower 10 bits ([9:0]) are valid
   - Flush-right data with 8-bit accuracy — Lower 8 bits ([7:0]) are valid
   - Flush-left data with 12-bit accuracy — Upper 12 bits ([15:4]) are valid
   - Flush-left data with 10-bit accuracy — Upper 10 bits ([15:6]) are valid
   - Flush-left data with 8-bit accuracy — Upper 8 bits ([15:8]) are valid
2. When A/D-converted value addition mode is selected
   - Flush-right data with 12-bit accuracy — Lower 14 bits ([13:0]) are valid
   - Flush-right data with 10-bit accuracy — Lower 12 bits ([11:0]) are valid
   - Flush-right data with 8-bit accuracy — Lower 10 bits ([9:0]) are valid
   - Flush-left data with 12-bit accuracy — Upper 14 bits ([15:2]) are valid
   - Flush-left data with 10-bit accuracy — Upper 12 bits ([15:4]) are valid
   - Flush-left data with 8-bit accuracy — Upper 10 bits ([15:6]) are valid

45.2.33 ADCMPSR0 : A/D Compare Function Window A Channel Status Register 0

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0A0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPSTCHA15	CMPSTCHA14	CMPSTCHA13	CMPSTCHA12	CMPSTCHA11	CMPSTCHA10	CMPSTCHA09	CMPSTCHA08	CMPSTCHA07	CMPSTCHA06	CMPSTCHA05	CMPSTCHA04	CMPSTCHA03	CMPSTCHA02	CMPSTCHA01	CMPSTCHA00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPSTCHA15 to CMPSTCHA00*1	Compare Window A Flag When Window A operation is enabled (ADCMPCR.CMPAE = 1b), these bits indicate the comparison result of channels to which Window A comparison conditions are applied. Bit 15 (CMPSTCHA15) is associated with ANm15 and bit 0 (CMPSTCHA00) is associated with ANm00. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.
Note 1. 00 to 08 (unit 0), 00 to 06 (unit 1) is available.

CMPSTCHAn flags (Compare Window A Flag)

The CMPSTCHAn flags indicate the comparison results for channels to which Window A comparison conditions are applied. When a comparison condition set in ADCMPLR0.CMPLCHA is met at the end of A/D conversion, the associated CMPSTCHAn flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTCHAn flags is invalid.

[Setting condition]

- The condition set in ADCMPLR0.CMPLCHA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

45.2.34 ADCMPSR1 : A/D Compare Function Window A Channel Status Register1

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0A2

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPSTCHA31	CMPSTCHA30	CMPSTCHA29	CMPSTCHA28	CMPSTCHA27	CMPSTCHA26	CMPSTCHA25	CMPSTCHA24	CMPSTCHA23	CMPSTCHA22	CMPSTCHA21	CMPSTCHA20	CMPSTCHA19	CMPSTCHA18	CMPSTCHA17	CMPSTCHA16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPSTCHA31 to CMPSTCHA16*1	Compare Window A Flag When Window A operation is enabled (ADCMPCR.CMPAE = 1), these bits indicate the comparison result of channels to which Window A comparison conditions are applied. Bit 15 (CMPSTCHA31) is associated with ANm31 and bit 0 (CMPSTCHA16) is associated with ANm16. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.
Note 1. 16 to 19 (unit 0), 16 to 22 (unit 1) is available.

CMPSTCHAn flags (Compare Window A Flag)

The CMPSTCHAn flags indicate the comparison results for channels to which Window A comparison conditions are applied. When the comparison condition set in ADCMPLR1.CMPLCHA is met at the end of A/D conversion, the associated CMPSTCHAn flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTCHAn flags is invalid.

[Setting condition]

- The condition set in ADCMPLR1.CMPLCHA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

45.2.35 ADCMPSER : A/D Compare Function Window A Extended Input Channel Status Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0A4

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CMPSTOCA	CMPSTTSA
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMPSTTSA	Compare Window A Temperature Sensor Output Compare Flag When Window A operation is enabled (ADCMPCR.CMPAE = 1), this bit indicates the temperature sensor output comparison result. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W

Bit	Symbol	Function	R/W
1	CMPSTOCA	Compare Window A Internal Reference Voltage Compare Flag When Window A operation is enabled (ADCMPCR.CMPAE = 1), this bit indicates the internal reference voltage comparison result. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The ADCMPSER register stores compare results of compare function window A.

CMPSTTSA flag (Compare Window A Temperature Sensor Output Compare Flag)

The CMPSTTSA flag indicates the temperature sensor output comparison result. When the comparison condition set in ADCMPLER.CMPLTSA is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTTSA flag is invalid.

[Setting condition]

- The condition set in ADCMPLER.CMPLTSA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

CMPSTOCA flag (Compare Window A Internal Reference Voltage Compare Flag)

The CMPSTOCA flag indicates the internal reference voltage comparison result. When the comparison condition set in ADCMPLER.CMPLOCA is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTOCA flag is invalid.

[Setting condition]

- The condition set in ADCMPLER.CMPLOCA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

45.2.36 ADCMPBNSR : A/D Compare Function Window B Channel Select Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0A6

Bit position:	7	6	5	4	3	2	1	0

This bit sets comparison conditions for channels for Window B. The comparison conditions are shown in Figure 45.7.
0: When window function is disabled (ADCMPCR.WCMPE = 0):
ADWINLLB value > A/D-converted value
When window function is enabled (ADCMPCR.WCMPE = 1):
A/D-converted value < ADWINLLB value, or ADWINULB value < A/D-converted value
1: When window function is disabled (ADCMPCR.WCMPE = 0):
ADWINLLB value < A/D-converted value
When window function is enabled (ADCMPCR.WCMPE = 1):
ADWINLLB value < A/D-converted value < ADWINULB value</td><td>R/W</td></tr>
</table>

Note: S-TYPE-3, P-TYPE-3

CMPCHB[5:0] bits (Compare Window B Channel Select)

The CMPCHB[5:0] bits specify the channels to be compared with the compare Window B conditions from AN000 to AN002, AN004 to AN008, AN016 to AN019, AN100 to AN102, AN104 to AN106, AN116 to AN122, the temperature sensor, the internal reference voltage and the VBATT 1/3 voltage monitor output. The compare Window B function is enabled by specifying the hexadecimal number of the A/D conversion channel selected in the ADANSA0, ADANSA1, ADANSB0, ADANSB1 registers.

Set the CMPCHB[5:0] bits while the ADCSR.ADST bit is 0.

CMPLB bit (Compare Window B Comparison Condition Setting)

The CMPLB bit specifies the comparison conditions for channels for Window B. When the comparison result of an analog input meets the set condition, the associated ADCMPBSR.CMPSTB flag sets to 1 and a compare interrupt request (ADC12i_CMPBI (i = 0, 1)) is generated.

Compare conditions when the window function is disabled

CMPLB = 0

ADWINLLB value ≤ A/D converted value	Not met
ADWINLLB value > A/D converted value	Met

CMPLB = 1

ADWINLLB value < A/D converted value	Met
ADWINLLB value ≥ A/D converted value	Not met

Compare conditions when the window function is enabled

CMPLB = 0

A/D converted value > ADWINULB value	Met
ADWINLLB value ≤ A/D converted value ≤ ADWINULB value	Not met
A/D converted value < ADWINLLB value	Met

CMPLB = 1

A/D converted value ≥ ADWINULB value	Not met
ADWINLLB value <A/D converted value < ADWINULB value	Met
A/D converted value ≤ ADWINLLB value	Not met

Figure 45.7 Explanation of compare conditions for compare function Window B

45.2.37 ADCMPBSR : A/D Compare Function Window B Status Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0AC

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CMPSTB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMPSTB	Compare Window B Flag When Window B operation is enabled (ADCMPCR.CMPBE = 1), this bit indicates the comparison result of channels to which Window B comparison conditions are applied,temperature sensor output, internal reference voltage. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CMPSTB flag (Compare Window B Flag)

The CMPSTB flag indicates the comparison result of channels to which Window B comparison conditions are applied, the temperature sensor output, internal reference voltage. When the comparison condition set in ADCMPBNSR.CMPLB is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPBIE bit is 1, a compare interrupt request (ADC12i_CMPBI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTB flag is invalid.

[Setting condition]

- The condition set in ADCMPBNSR.CMPLB is met when ADCMPCR.CMPBE = 1.

[Clearing condition]

- Writing 0 after reading 1.

45.2.38 ADWINMON : A/D Compare Function Window A/B Status Monitor Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x08C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	MONCMPB	MONCMPA	—	—	—	MONCOMB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MONCOMB	Combination Result Monitor This bit indicates the combination result. This bit is valid when both Window A and Window B operations are enabled. 0: Window A/B composite conditions are not met. 1: Window A/B composite conditions are met.	R
3:1	—	These bits are read as 0.	R
4	MONCMPA	Comparison Result Monitor A 0: Window A comparison conditions are not met. 1: Window A comparison conditions are met.	R
5	MONCMPB	Comparison Result Monitor B 0: Window B comparison conditions are not met. 1: Window B comparison conditions are met.	R
7:6	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

MONCOMB bit (Combination Result Monitor)

The read-only MONCOMB bit indicates the combined result of comparison condition results A and B based on the combination condition set in the ADCMPCR.CMPAB[1:0] bits.

[Setting condition]

- The combined result meets the combination condition set in the ADCMPCR.CMPAB[1:0] bits when ADCMPCR.CMPAE = 1 and ADCMPCR.CMPBE = 1.

[Clearing conditions]

- The combined result does not meet the combination condition set in the ADCMPCR.CMPAB[1:0] bits.
- ADCMPCR.CMPAE = 0 or ADCMPCR.CMPBE = 0.

MONCMPA bit (Comparison Result Monitor A)

The read-only MONCMPA bit is read as 1 when the A/D-converted value of the Window A target channel meets the condition set in ADCMPLR0/ADCMPLR1 and ADCMPLER. Otherwise, it is read as 0.

[Setting condition]

- The A/D-converted value meets the condition set in the ADCMPLR0/ADCMPLR1 and ADCMPLER registers when ADCMPCR.CMPAE = 1.

[Clearing conditions]

- The A/D-converted value does not meet the condition set in the ADCMPLR0/ADCMPLR1 and ADCMPLER registers when ADCMPCR.CMPAE = 1.
- ADCMPCR.CMPAE = 0 (automatically cleared when the ADCMPCR.CMPAE value changes from 1 to 0).

MONCMPB bit (Comparison Result Monitor B)

The read-only MONCMPB bit is read as 1 when the A/D-converted value of the Window B target channel meets the condition set in the ADCMPBNSR.CMPLB bit. Otherwise, it is read as 0.

[Setting condition]

- The A/D-converted value meets the condition set in ADCMPBNSR.CMPLB when ADCMPCR.CMPBE = 1.

[Clearing conditions]

- The A/D-converted value does not meet the condition set in ADCMPBNSR.CMPLB when ADCMPCR.CMPBE = 1.
- ADCMPCR.CMPBE = 0 (automatically cleared when the ADCMPCR.CMPBE value changes from 1 to 0).

45.2.39 ADBUFEN : A/D Data Buffer Enable Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0D0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	BUFEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BUFEN	Data Buffer Enable 0: The data buffer is not used. 1: The data buffer is used.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The ADBUFEN register sets whether to enable the data buffer.

BUFEN bit (Data Buffer Enable)

This bit enables the use of the data buffer.

When BUFEN = 1b, A/D conversion result (addition result) other than self-diagnosis result is stored in ADBUFn.

Disable the data storage operation (BUFEN = 0b) before reading ADBUFPTR.

Do not use the data buffer for data duplexing, or group scan.

45.2.40 ADBUFPTR : A/D Data Buffer Pointer Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0D2

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	PTROVF	BUFPTR[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	BUFPTR[3:0]	Data Buffer Pointer These bits indicate the number of data buffer to which the next A/D converted data is transferred.	R/W
4	PTROVF	Pointer Overflow Flag 0: The data buffer pointer has not overflowed. 1: The data buffer pointer has overflowed.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

ADBUFPTR is a register that indicates the data buffer pointer and overflow status.

BUFPTR[3:0] bit (Data Buffer Pointer)

These bits indicate the number of data buffer to which the next A/D converted data is transferred.

When data has been transferred to data buffer 15, the pointer value becomes 0000b and the PTROVF bit is set to 1.

When the next data has been transferred, the data in data buffer 0 is overwritten.

Writing 0x00 to this register clears the value of these bits. Writing a value other than 0x00 is disabled.

PTROVF bit (Pointer Overflow Flag)

This bit indicates whether the data buffer pointer has overflowed. This bit is set to 1 when the pointer value becomes 0000b (overflow).

Writing 0x00 to this register clears this bit value. Writing a value other than 0x00 is disabled.

45.2.41 ADBUFn : A/D Data Buffer Registers n (n = 0 to 15)

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0B0 + 0x2 × n (n = 0 to 15))

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADBUF[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADBUF[15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 45.24 and Table 45.25.	R

Note: S-TYPE-3, P-TYPE-3

ADBUFn registers are 16-bit read-only registers that sequentially store all A/D conversion results. The automatic clear function is not applied to these registers.

ADBUFn settings are the same as the A/D data register format settings.

The following conditions determine the formats for data in the ADBUFn registers:

- Setting of the Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 45.24 shows the bit assignment for each accuracy.

Table 45.24 Bit assignment for each accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, This register indicatesThese registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicatesthese registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 45.25 shows the bit assignment for each accuracy.

Table 45.25 Bit assignment for each accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

45.3 Operation

45.3.1 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.

Scan conversion is performed in any of the three operating modes:

- Single scan mode
- Continuous scan mode
- Group scan mode

In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until software sets the ADCSR.ADST bit to 0. In group scan mode, the selected channels in group A, B are scanned once after scan starts in response to the respective synchronous trigger.

In single scan mode and continuous scan mode, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n. In group scan mode, A/D conversion is performed for the ANn channels in group A selected in the ADANSA0 and ADANSA1 registers, and for the ANn channels in group B selected in the ADANSB0 and ADANSB1 registers, starting from the channel with the smallest number n.

When self-diagnosis is selected, it is executed once at the beginning of each scan and one of the three reference voltages is converted.

The temperature sensor output and internal reference voltage can be selected at the same time as the analog input of the channels, and A/D conversion is performed on the analog input of channels, temperature sensor output, and internal reference voltage, in that order.

Double trigger mode can be used with single scan mode or group scan mode. With double trigger mode enabled (ADCSR.DBLE = 1), A/D conversion data of a channel selected in the ADCSR.DBLANS[4:0] bits is duplicated only if the conversion is started by the synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSA[5:0] bits. In group scan mode, only group A can use double trigger mode.

In the extended operation of double trigger mode, the A/D conversion operation is generated from the synchronous trigger combination selected in the ADSTRGR.TRSA[5:0] bits. In addition to normal double trigger mode operation, A/D conversion data with odd number trigger (ELC_AD00 (unit 0), ELC_AD10 (unit 1), GTCIADAn (Unit0) and GTCIADAm (Unit1) (n = 0 to 3, m = 4 to 7)) is stored in A/D Data Duplexing Register A (ADDBLDRA), and A/D conversion data with even number trigger (ELC_AD01 (unit 0), ELC_AD11 (unit1), GTCIADBn (Unit0) and GTCIADBm (Unit1) (n = 0 to 3, m = 4 to 7)) is stored in A/D Data Duplexing Register B (ADDBLDRB). In the extended operation of double trigger mode, when one of the trigger combinations occurs at the same time, the data duplexing register settings for the specified triggers do not work, and A/D conversion data is stored in A/D Data Duplexing Register B (ADDBLDRB).

The ADC12 ignores a synchronous trigger that occurs during the A/D conversion started by another synchronous trigger.

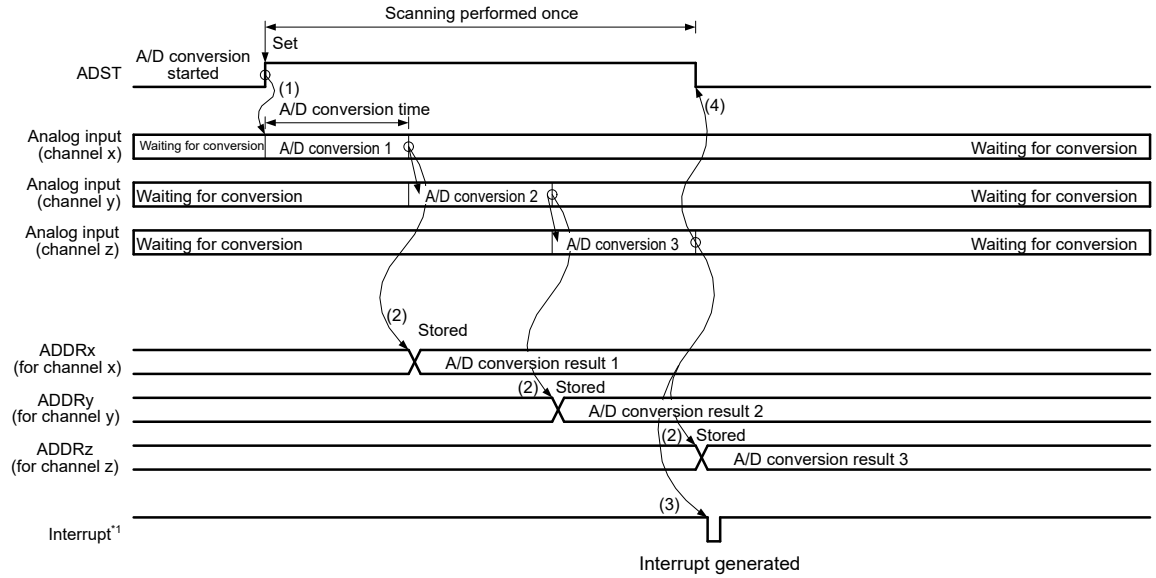
When any of the channels AN000 to AN002 (unit 0) are set as a channel-dedicated sample-and-hold circuit in the SHANS[2:0] bits in ADSHCR, the target analog input specified is sampled and held before the first A/D conversion of each scan.

45.3.2 Single Scan Mode

45.3.2.1 Basic Operation (Without Channel-Dedicated Sample-and-Hold Circuits)

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (GPT, ELC), or an asynchronous trigger input, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D data register (ADDRy).
3. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated .
4. The ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion of all the selected channels is completed. The ADC12 then enters a wait state.



Note: x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1.
Note 1. ADC12i_ADI (i = 0, 1)

Figure 45.8 Example basic operation in single scan mode when the analog inputs (channel x to z) are selected

45.3.2.2 Basic operation (With channel-dedicated sample-and-hold circuits and continuous sampling disabled)

When the channel-dedicated sample-and-hold circuit is used, sample-and-hold operation is first performed, and then A/D conversion is performed on the analog input of all the specified channels once. The channels whose dedicated sampleand-hold circuit is to be used can be selected in the SHANS[2:0] bits in ADSHCR.

The operation is as follows:

1. Analog input sampling of all channels whose dedicated sample-and-hold circuit is to be used starts when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (GPT, ELC), or asynchronous trigger input.
2. After the sample-and-hold operation, A/D conversion is performed on the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D data register (ADDRy).
4. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting).
5. The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state.

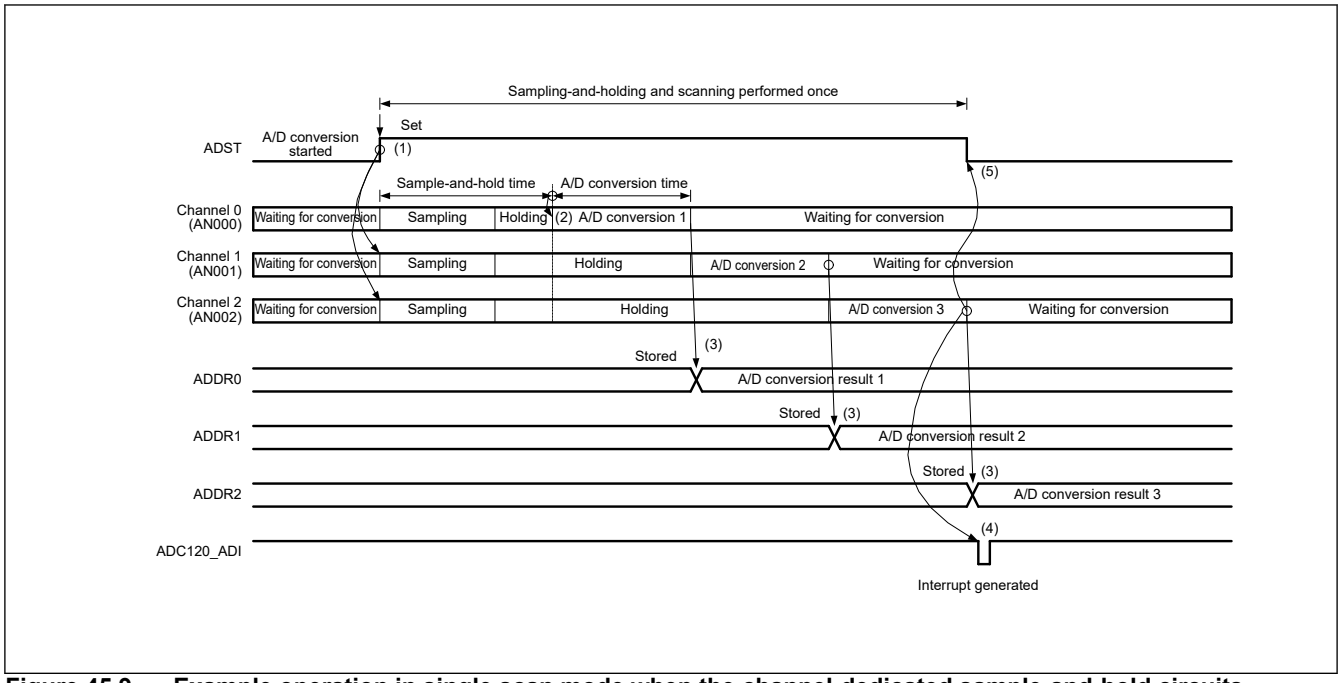


Figure 45.9 Example operation in single scan mode when the channel-dedicated sample-and-hold circuits are used and AN000 to AN002 are selected

45.3.2.3 Basic operation (With channel-dedicated sample-and-hold circuits and continuous sampling enabled)

When a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, followed by A/D conversion on the analog inputs on all selected channels, once. The ADSHCR.SHANS[2:0] bits specify the channels for which the channel-dedicated sample-and-hold circuits are to be used.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all the channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (GPT, ELC), or input of an asynchronous trigger.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion is performed on the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D data register (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting).
6. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state. If this is followed by single scanning, set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).
7. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.

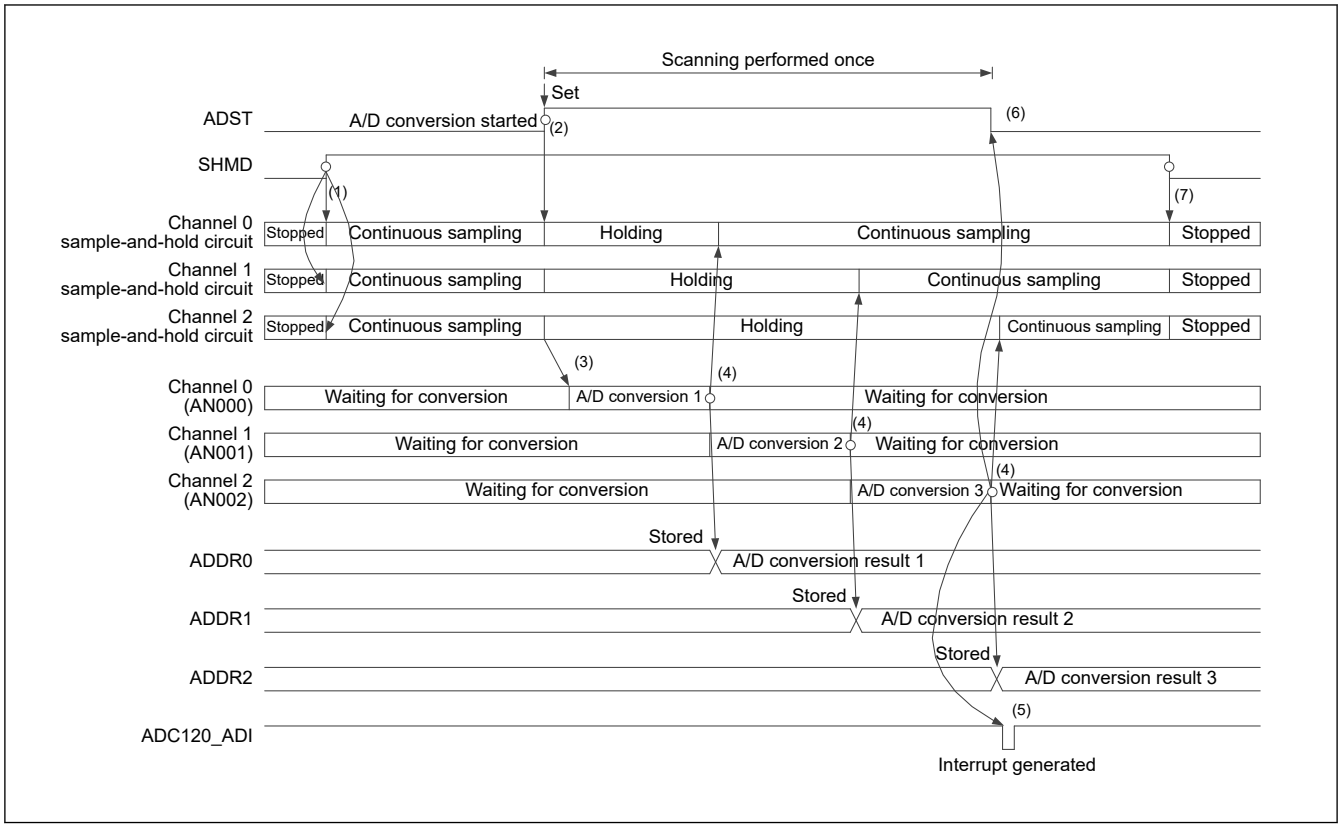

Figure 45.10 Example operation in single scan mode when channel-dedicated sample-and-hold circuits are used, AN000 to AN002 are selected, and continuous sampling is enabled

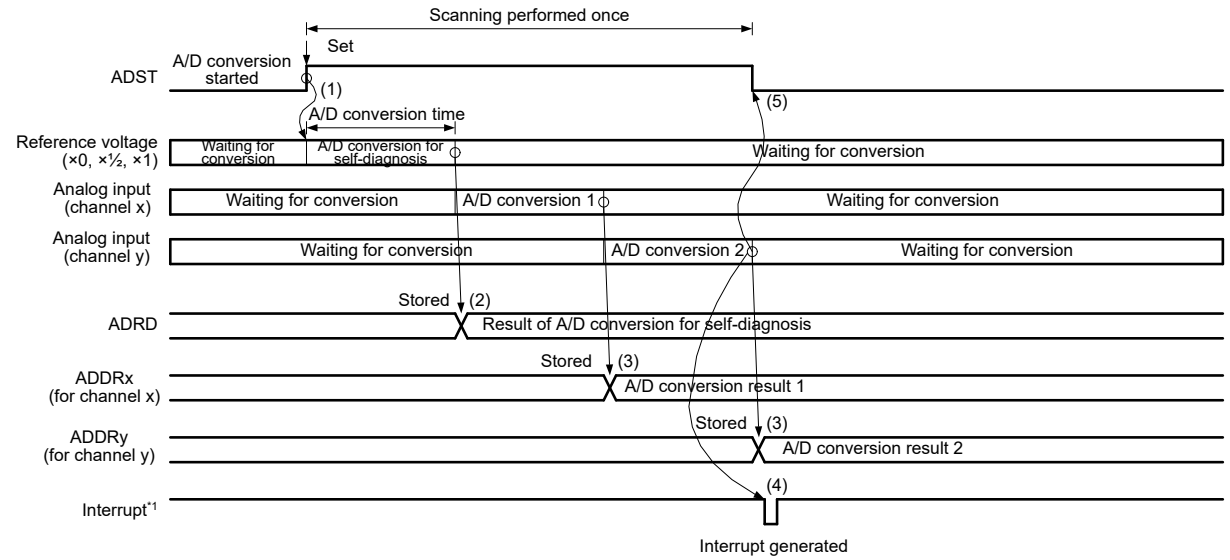
45.3.2.4 Channel Selection and Self-Diagnosis (Without Channel-Dedicated Sample-and-Hold Circuits)

When channels and self-diagnosis are selected, A/D conversion is first performed for the reference voltage VREFH0, VREFH (×0, ×1/2, or ×1) , then A/D conversion is performed once on the analog input of the selected channels as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger input, a synchronous trigger input (GPT, ELC), or an asynchronous trigger input.
2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D data register (ADDRy).
4. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated .
5. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion of all the selected channels is completed. The ADC12 then enters a wait state.



Note: x and y (x < y) are the selected channel numbers by ADANSA0/1.
Note 1. ADC12i_ADI (i = 0, 1)

Figure 45.11 Example basic operation in single scan mode when the analog inputs (channel x and y) are selected with self- diagnosis

45.3.2.5 Channel selection and self-diagnosis with channel-dedicated sample-and-hold circuits and continuous sampling disabled

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is disabled, the sample-and-hold operation is performed first, and then A/D conversion is performed once for the reference voltage VREFH0 (unit 0) (×0, ×1/2, or ×1) supplied to the ADC12. After that, A/D conversion is performed only once on the analog input of the selected channels.

The operation is as follows:

1. Analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (GPT, ELC), or asynchronous trigger input.
2. After the sample-and-hold operation, A/D conversion for self-diagnosis starts.
3. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting).
6. The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state.

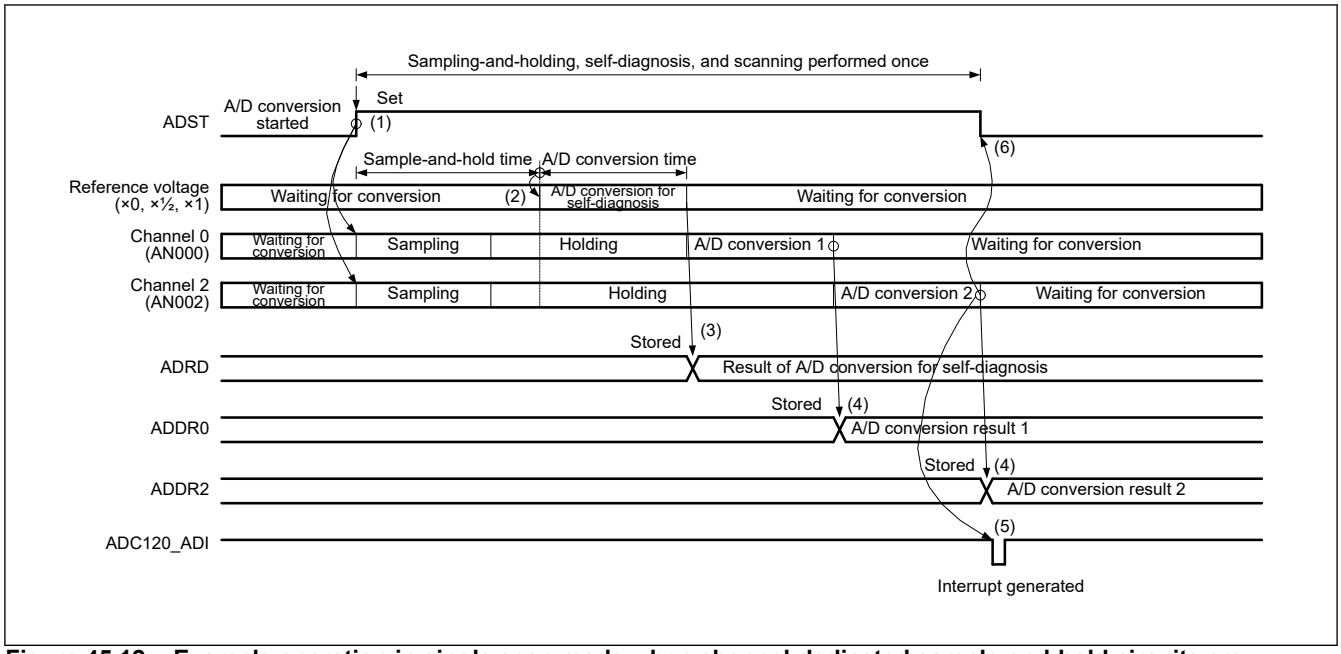


Figure 45.12 Example operation in single scan mode when channel-dedicated sample-and-hold circuits are used, AN000 and AN002 are selected with self-diagnosis, and continuous sampling is disabled

45.3.2.6 Channel selection and self-diagnosis with channel-dedicated sample-and-hold circuits and continuous sampling enabled

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, followed by A/D conversion of the reference voltage VREFH0 (unit 0) supplied to the ADC12. After that, A/D conversion is performed only once on the analog input of the selected channels.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all the channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (GPT, ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 kΩ) elapse after the ADSHMSR.SHMD bit is set to 1..
3. After the stabilization time of the sample-and-hold circuits elapse, A/D conversion for self-diagnosis starts.
4. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
5. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
6. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting).
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state. If this is followed by single scanning, set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).
8. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.

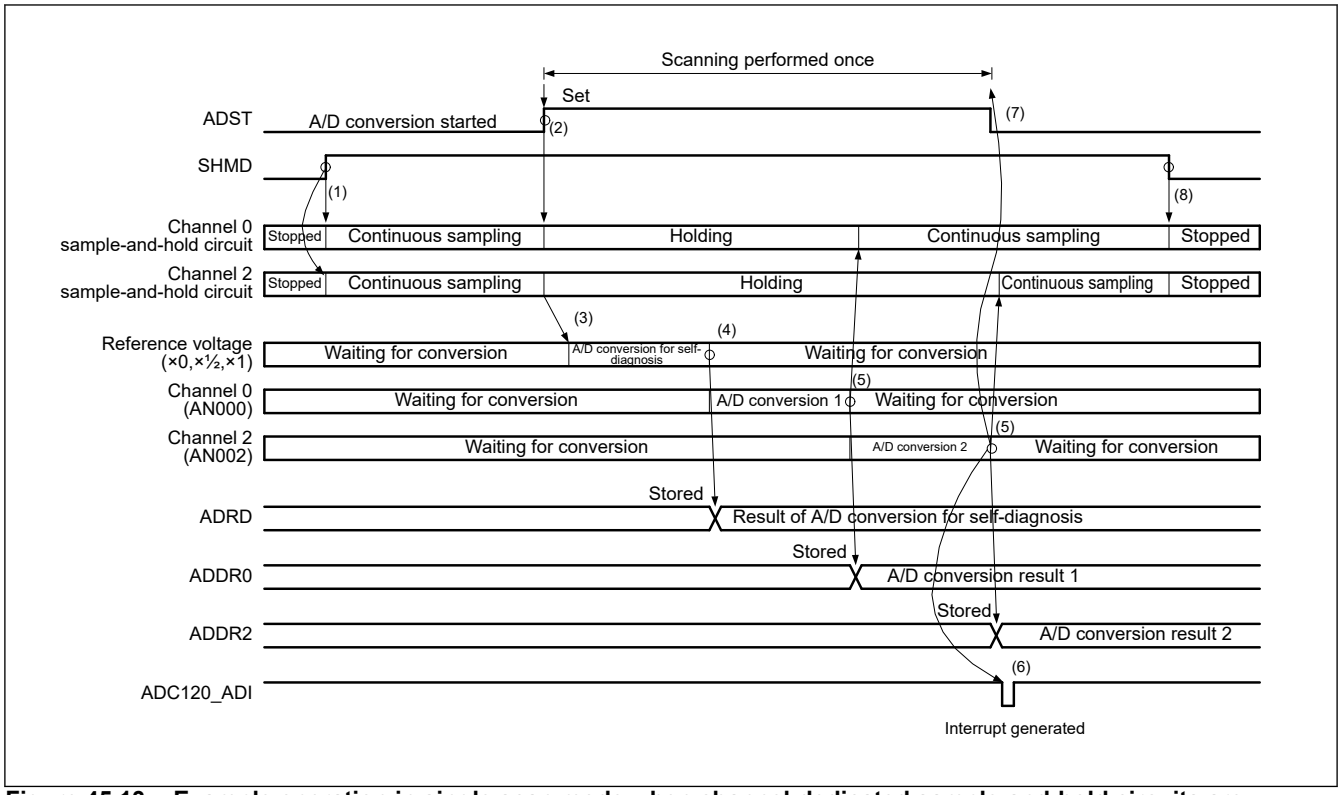

Figure 45.13 Example operation in single scan mode when channel-dedicated sample-and-hold circuits are used, AN000 to AN002 are selected with self-diagnosis, and continuous sampling is enabled

45.3.2.7 A/D Conversion of Temperature Sensor Output or Internal Reference Voltage

When the channels and temperature sensor output or internal reference voltage are selected at the same time, A/D conversion is performed first on the analog input of the selected channels, and once on the temperature sensor output or internal reference voltage. When both temperature sensor output and internal reference voltage are selected, A/D conversion of the temperature sensor output and internal reference voltage is performed, in that order. With the channels deselected, selecting only the temperature sensor output or internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (GPT, ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of the temperature sensor output starts.
3. On completion of A/D conversion of the temperature sensor output, the result is stored in the associated A/D Temperature Sensor Data Register (ADTSDR), and then A/D conversion of the internal reference voltage starts.
4. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
5. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 on completion of A/D conversion. Then, the ADC12 enters a wait state.

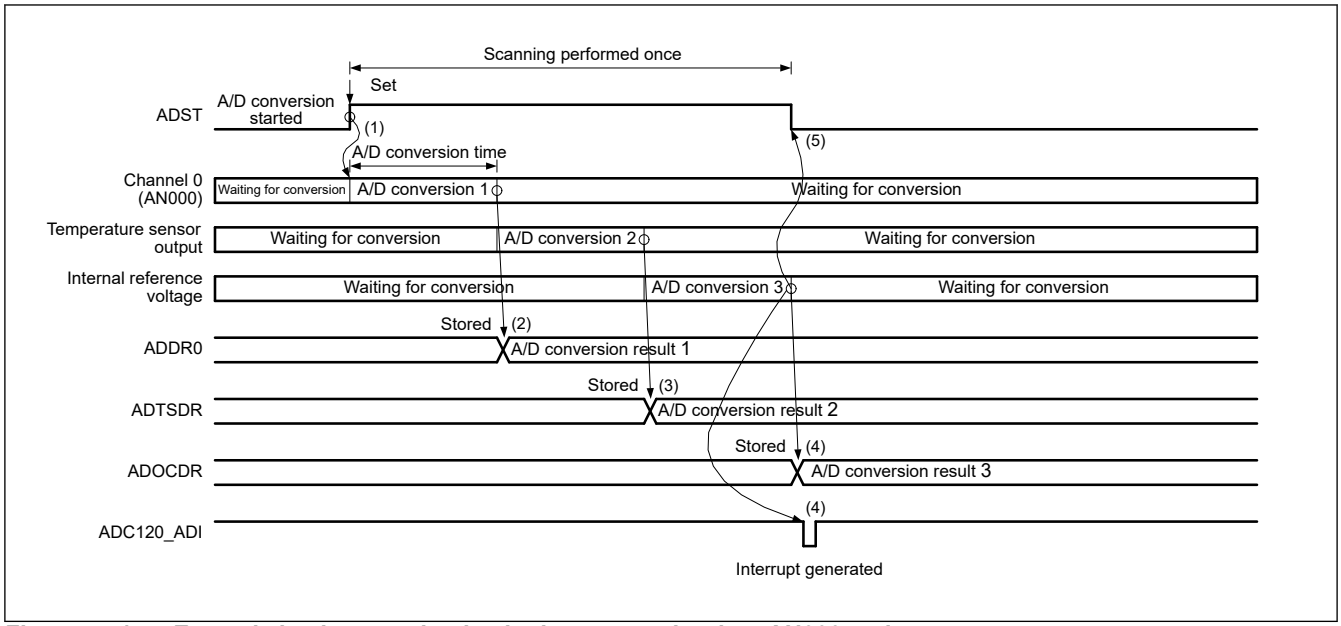

Figure 45.14 Example basic operation in single scan mode when AN000 and temperature sensor output or internal reference voltage are selected

45.3.2.8 A/D conversion in double-trigger mode

When double trigger mode is selected in single scan mode, two rounds of single scan operation started by a synchronous trigger (GPT, ELC) are performed in sequence.

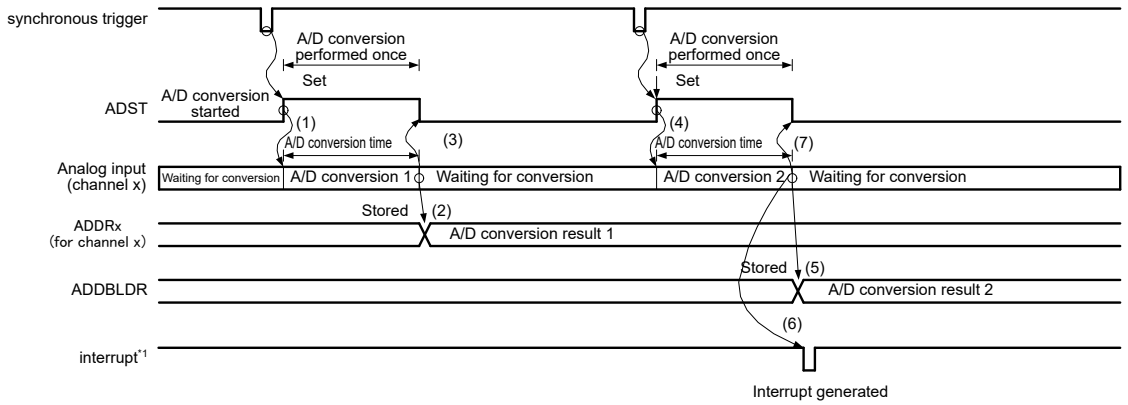
Deselect self-diagnosis and set the temperature sensor output A/D conversion select bit (ADEXICR.TSSA and ADEXICR.TSSB) and the internal reference voltage A/D conversion select bit (ADEXICR.OCSA and ADEXICR.OCSB) to 0.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

In double trigger mode, select a synchronous trigger (GPT, ELC) with the ADSTRGR.TRSA[5:0] bits. Additionally, set the ADCSR.EXTRG bit to 0 and the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input (GPT, ELC), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC12i_ADI (i = 0, 1) interrupt request is not generated .
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger input, A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion is completed, the result is stored in the A/D Data Duplexing Register (ADDBLDR), which is exclusively used in double-trigger mode.
6. An ADC12i_ADI (i = 0, 1) interrupt request is generated.
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion is completed. Then the ADC12 enters a wait state.



Note: x is the selected channel number by ADCSR.DBLANS[4:0].
Note 1. ADC12i_ADI (i = 0, 1)

Figure 45.15 Example operation in single scan mode when double-trigger mode is selected and the analog input (channel x) is duplicated

45.3.2.9 Extended operations when double-trigger mode is selected

When double trigger mode is selected in single scan mode, and a synchronous trigger (ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1), GTCIADA0 (Unit0) and GTCIADA4 (Unit1) / GTCIADB0 (Unit0) and GTCIADB4 (Unit1), GTCIADA1 (Unit0) and GTCIADA5 (Unit1) / GTCIADB1 (Unit0) and GTCIADB5 (Unit1), GTCIADA2 (Unit0) and GTCIADA6 (Unit1) / GTCIADB2 (Unit0) and GTCIADB6 (Unit1) or GTCIADA3 (Unit0) and GTCIADA7 (Unit1) / GTCIADB3 (Unit0) and GTCIADB7 (Unit1)) is selected as the trigger for the start of A/D conversion, two rounds of single scan operation are performed.

Deselect self-diagnosis and set the temperature sensor output A/D conversion select bit (ADEXICR.TSSA and ADEXICR.TSSB), and the internal reference voltage A/D conversion select bit (ADEXICR.OCSA and ADEXICR.OCSB) to 0.

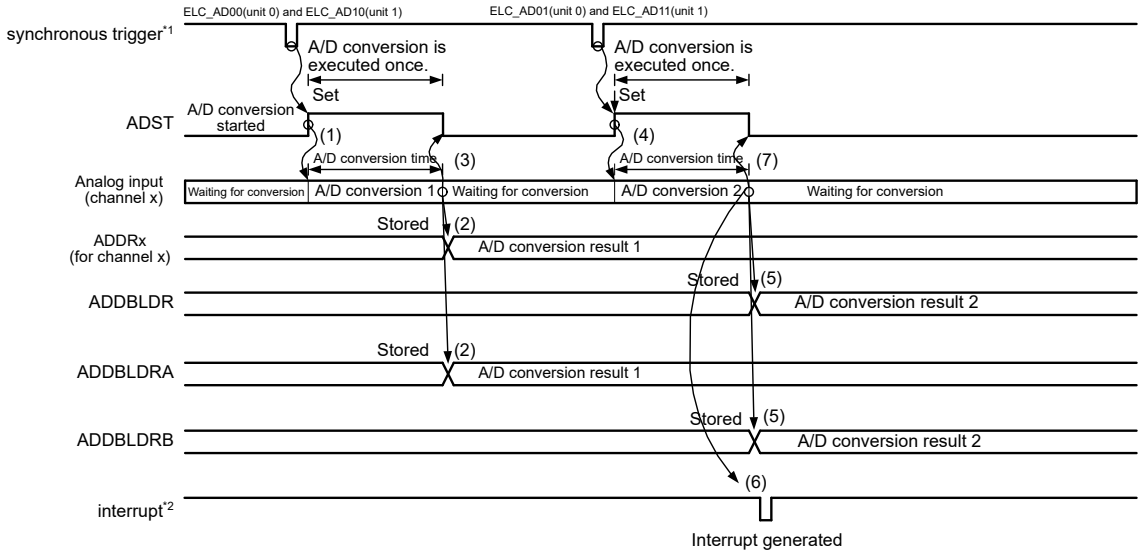
Duplication of A/D conversion data is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

In extended double trigger mode, select a synchronous trigger combination by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, set the ADCSR.EXTRG bit to 0, and set the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input, A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. When A/D conversion completes, the A/D conversion result is stored in the associated A/D Data Register (ADDRy) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the ELC_ADi0 or ELC_ADi1 trigger is input respectively (i = 0, 1).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC12i_ADI (i = 0, 1) interrupt request is not generated.
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger (ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1)), A/ D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion completes, the A/D conversion result is stored in the A/D Data Duplexing Register (ADDBLDR) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the ELC_ADi0 or ELC_ADi1 trigger is input respectively (i = 0, 1).
6. An ADC12i_ADI (i = 0, 1) interrupt request is generated.

7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion completes. The ADC12 then enters a wait state.



Note: x is the selected channel number by ADANSA0/1.
Note 1. ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1)
Note 2. ADC12i_ADI (i = 0, 1)

Figure 45.16 Example extended operation in double trigger mode with duplication selected for the analog input (channel x) and ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1)

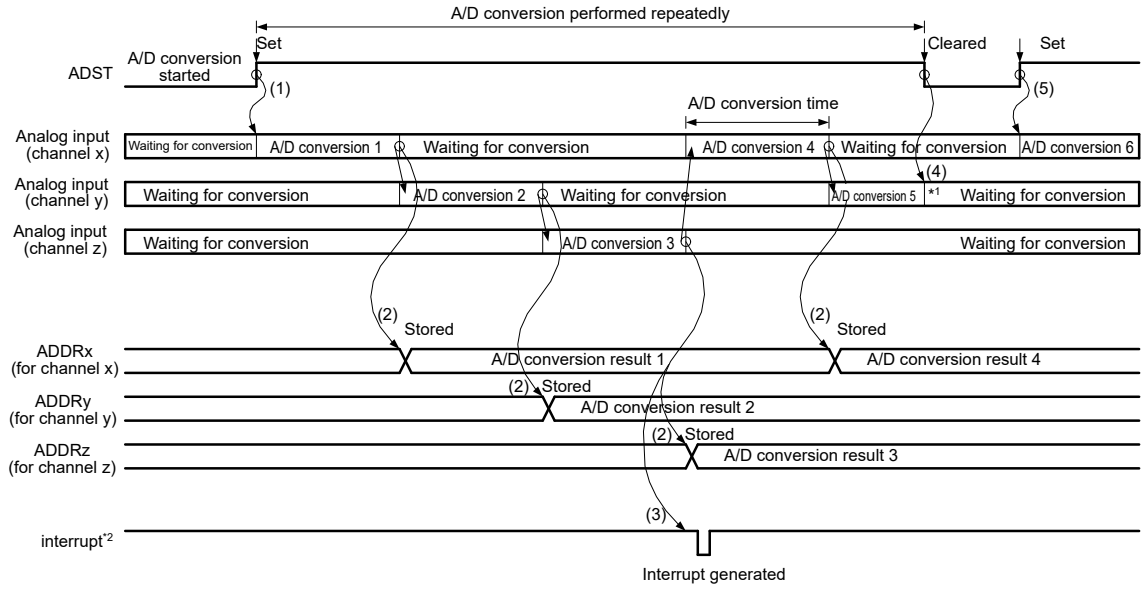
45.3.3 Continuous Scan Mode

45.3.3.1 Basic Operation (Without Channel-Dedicated Sample-and-Hold Circuits)

In continuous scan mode, A/D conversion is performed repeatedly on the analog input of the specified channels.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (GPT, ELC), or an asynchronous trigger input, A/D conversion is performed for ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register (ADDRy).
3. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated. The ADC12 sequentially starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. The ADCSR.ADST bit is not automatically cleared, and steps 2. and 3. are repeated as long as ADCSR.ADST remains 1 (A/ D conversion start). When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
5. When the ADCSR.ADST bit is later set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.



Note: x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1.
Note 1. Data for A/D conversion 5 is ignored.
Note 2. ADC12i_ADI (i = 0, 1)

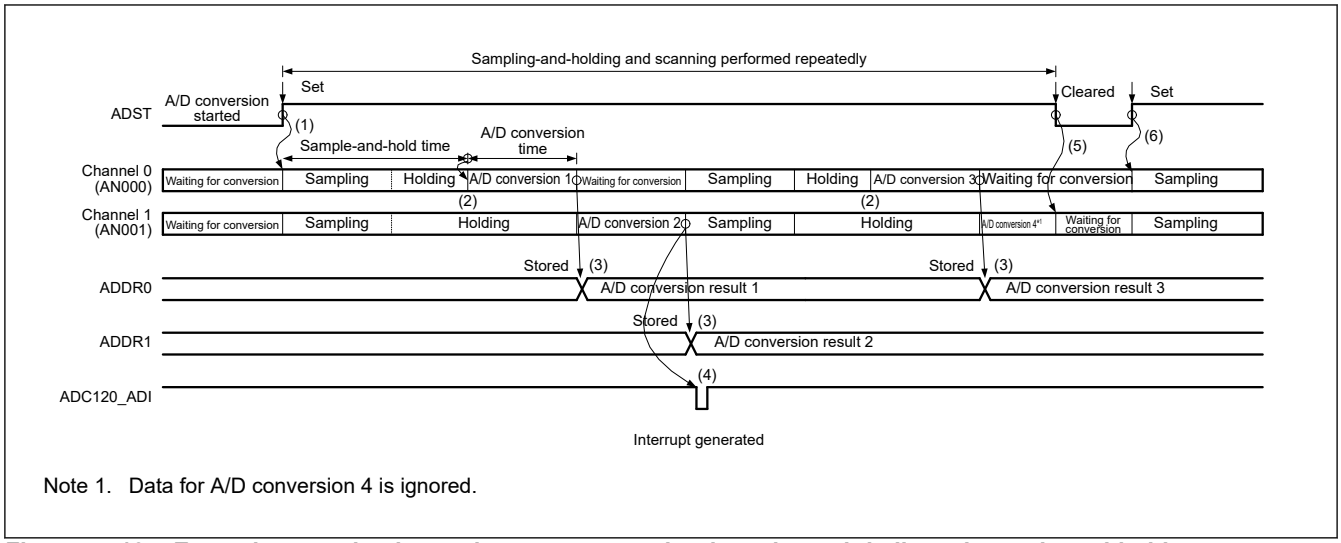
Figure 45.17 Example basic operation in continuous scan mode when the analog inputs (channel x to z) are selected

45.3.3.2 Basic operation (With channel-dedicated sample-and-hold circuits and continuous sampling disabled)

When the channel-dedicated sample-and-hold circuit is used with the continuous sampling disabled, sample-and-hold operation is performed first, and then A/D conversion is repeated on the analog input of all the specified channels. The channels whose dedicated sample-and-hold circuit is to be used can be selected in the SHANS[2:0] bits in ADSHCR.

The operation is as follows:

1. Analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (GPT, ELC), or asynchronous trigger input.
2. After the sample-and-hold operation, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
4. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting). At the same time, analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used.
5. The ADST bit is not automatically cleared, and steps 2 to 4 are repeated as long as the bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADST bit is then set to 1 (A/D conversion start), analog input sampling starts again for all the channels whose dedicated sample-and-hold circuit is to be used.



Note 1. Data for A/D conversion 4 is ignored.

Figure 45.18 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used and AN000 and AN001 are selected

45.3.3.3 Basic operation (With channel-dedicated sample-and-hold circuits and continuous sampling enabled)

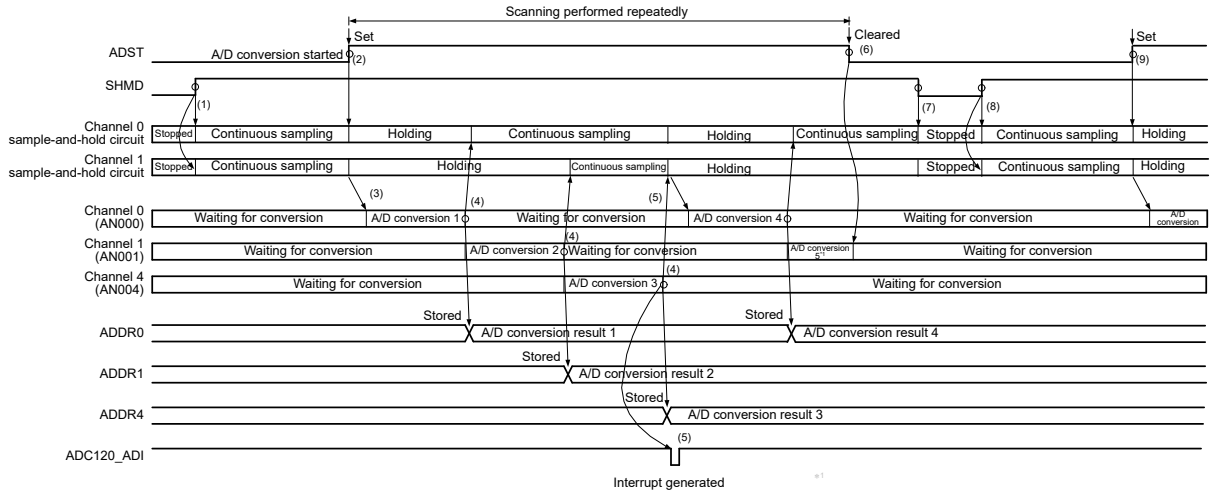
When a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, after which the analog inputs on all the selected channels are A/D-converted as described in this section. The channels for which the channel-dedicated sample-and-hold circuits are to be used can be selected in the ADSHCR.SHANS[2:0] bits.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (GPT, ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 kΩ) elapse after the ADSHMSR.SHMD bit is set to 1.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting). Also, analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.
6. The ADCSR.ADST bit is not automatically cleared, and steps 3 to 5 are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
7. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.
8. When the ADSHMSR.SHMD bit is then set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
9. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.

Note: If continuous scanning is performed when only those channels with the sample-and-hold circuits are selected, time for continuous sampling cannot be secured in the second and subsequent continuous scans. When continuous sampling by the channel-dedicated sample-and-hold circuits is enabled for continuous scanning, select one or more channels among AN003 to AN008 and AN016 to AN019, temperature sensor output, internal reference voltage and VBATT 1/3 voltage monitor output for unit 0, and AN100 to AN106 and AN116 to AN122, temperature sensor output,

internal reference voltage and VBATT 1/3 voltage monitor output for unit 1, and set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).



Note 1. Data for A/D conversion 5 is ignored.

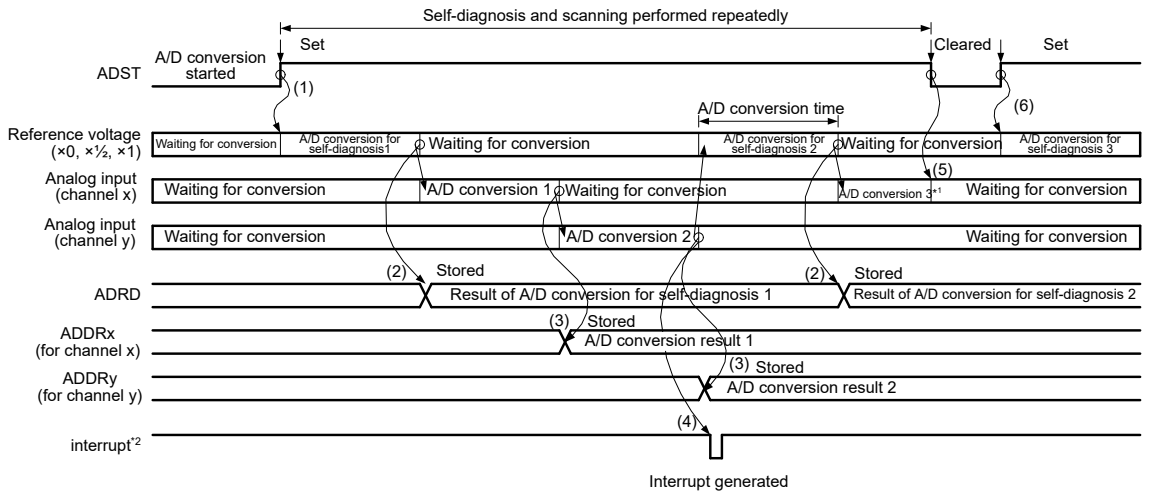
Figure 45.19 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used, AN000, AN001, and AN004 are selected, and continuous sampling is enabled

45.3.3.4 Channel Selection and Self-Diagnosis (Without Channel-Dedicated Sample-and-Hold Circuits)

When channels and self-diagnosis are selected at the same time, A/D conversion is first performed for the reference voltage VREFH0, VREFH (×0, ×1/2, or ×1) supplied to the ADC12, and A/D conversion is performed on the analog input of the selected channels. This sequence is repeated as described in the section that follows.

The operation is as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger input, a synchronous trigger input (GPT, ELC), or an asynchronous trigger input.
2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the corresponding A/D Data Register (ADDRy).
4. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated. At the same time, the ADC12 starts A/D conversion for self-diagnosis and then on the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
5. The ADCSR.ADST bit is not automatically cleared, and steps 2. to 4. are repeated as long as the ADCSR.ADST bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADST bit is later set to 1 (A/D conversion start), the A/D conversion for self-diagnosis is started again.



Note: x and y (x < y) are the selected channel numbers by ADANSA0/1.
Note 1. Data for A/D conversion 3 is ignored.
Note 2. ADC12i_ADI (i = 0, 1)

Figure 45.20 Example basic operation in continuous scan mode when the analog inputs (channel x and y) are selected with self-diagnosis

45.3.3.5 Channel selection and self-diagnosis with channel-dedicated sample-and-hold circuits and continuous sampling disabled

When the channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is disabled, sample-and- hold operation is performed first, and then A/D conversion is performed for the reference voltage VREFH0 (unit 0) (×0, ×1/2, or ×1) supplied to the ADC12, and then A/D conversion is performed on the analog input of the selected channels, and this sequence is repeated.

The operation is as follows:

1. Analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (GPT, ELC), or asynchronous trigger input.
2. After the sample-and-hold operation, A/D conversion for self-diagnosis starts.
3. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D data register (ADDRy).
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting). At the same time, analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used.
6. The ADST bit is not automatically cleared, and steps 2 to 5 are repeated as long as the bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
7. When the ADST bit is then set to 1 (A/D conversion start), analog input sampling starts again for all the channels whose dedicated sample-and-hold circuits are to be used.

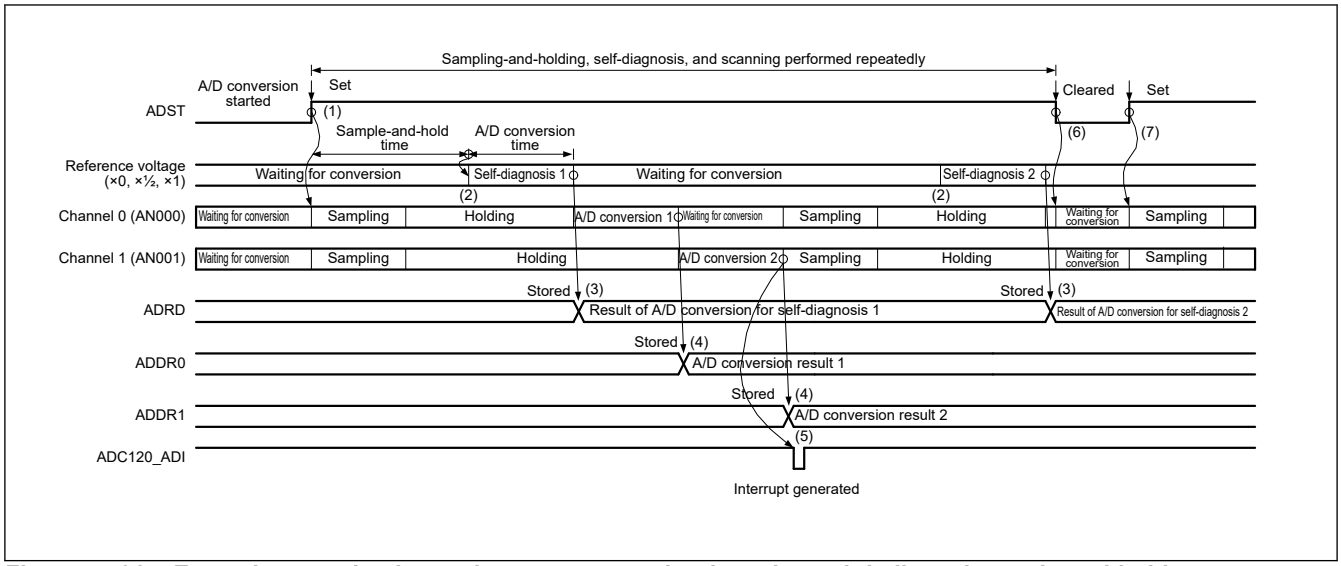


Figure 45.21 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used and AN000 and AN001 are selected with self-diagnosis

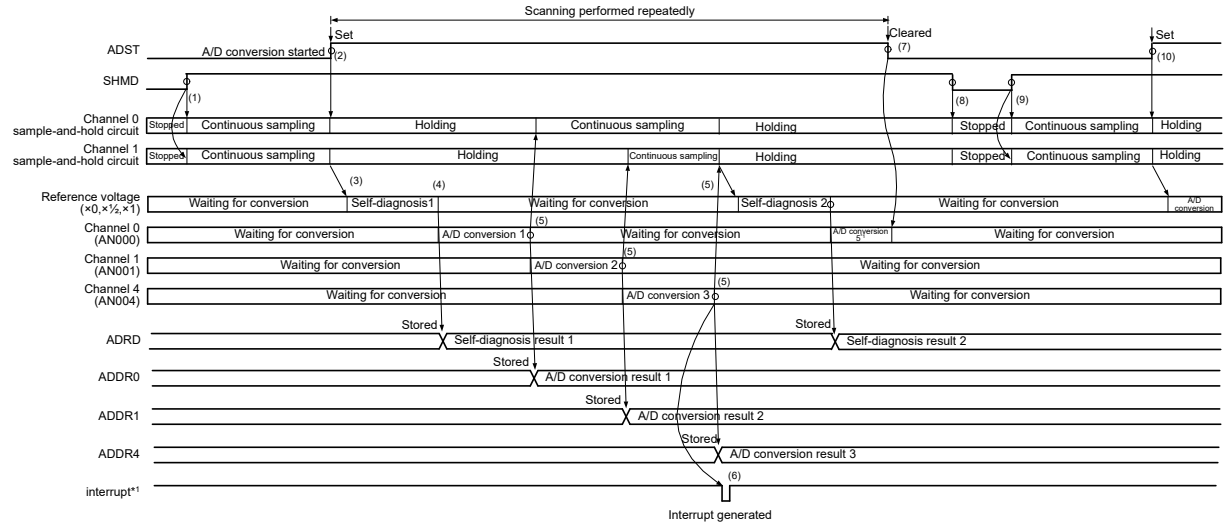
45.3.3.6 Channel selection and self-diagnosis with channel-dedicated sample-and-hold circuits and continuous sampling enabled

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, the sample-and-hold operation is performed first, and followed by A/D conversion of the reference voltage VREFH0 (unit 0) (×0, ×1/2, or ×1) supplied to the ADC12. After that, A/D conversion is performed on the analog input of the selected channels, and this sequence is repeated.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (GPT, ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 kΩ) elapse after the ADSHMSR.SHMD bit is set to 1.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion for self-diagnosis starts.
4. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
5. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
6. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting). Also, analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.
7. The ADCSR.ADST bit is not automatically cleared, and steps 3 to 6 are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
8. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.
9. When the ADSHMSR.SHMD bit is then set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
10. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.



Note: Data for A/D conversion 5 is ignored.
Note 1. ADC12i_ADI (i = 0)

Figure 45.22 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used, AN000, AN001, and AN004 are selected with self-diagnosis, and continuous sampling is enabled

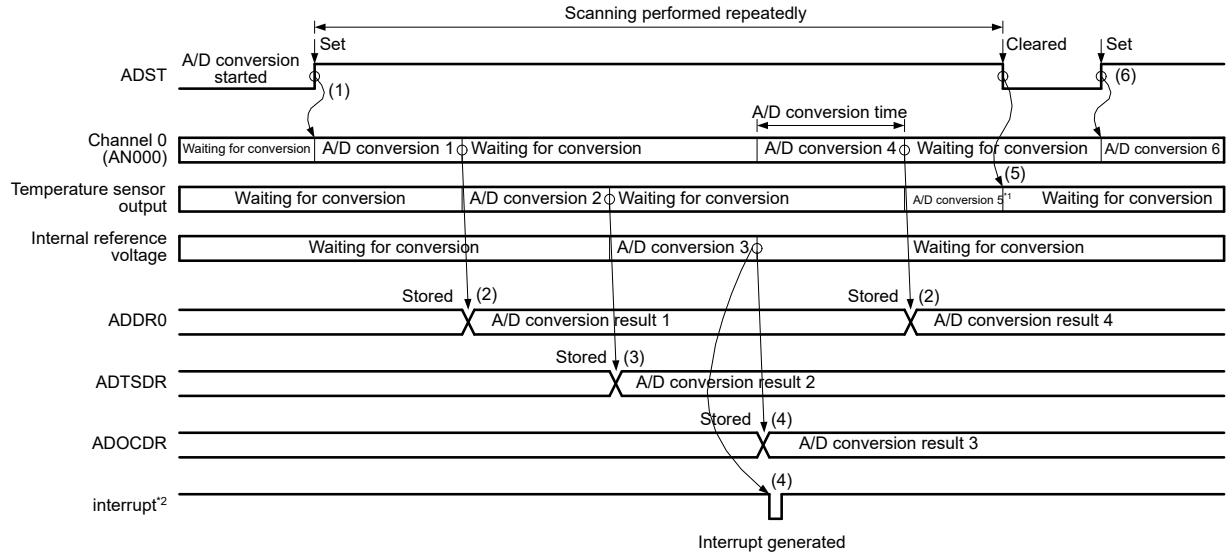
45.3.3.7 A/D Conversion of Temperature Sensor Output or Internal Reference Voltage

When the channels and temperature sensor output or internal reference voltage are selected at the same time, A/D conversion is first performed on the analog input of the selected channels, and then the A/D conversion of the temperature sensor output or internal reference voltage is repeated. When both the temperature sensor output and internal reference voltage are selected, A/D conversion of the temperature sensor output and internal reference voltage is performed, in that order.

With the channels deselected, selecting only the temperature sensor output or internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (GPT, ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of temperature sensor output starts.
3. On completion of A/D conversion of the temperature sensor output, the result is stored in the associated A/D Temperature Sensor Data Register (ADTSDR), and then A/D conversion of the internal reference voltage starts.
4. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC12i_ADI (i = 0, 1) interrupt request is generated. In addition, the ADC12 continuously starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the lowest number n.
5. The ADCSR.ADST bit is not cleared automatically, and steps 2 to 4 are repeated as long as this bit remains set to 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the lowest number n.



Note 1. Data for A/D conversion 5 is ignored.
Note 2. ADC12i_ADI (i = 0, 1)

Figure 45.23 Example basic operation in continuous scan mode when AN000 and temperature sensor output or internal reference voltage are selected

45.3.4 Group Scan Mode

45.3.4.1 Basic Operation

In group scan mode, A/D conversion is performed once on the analog input of all the specified channels in group A and B after scanning is started by a synchronous trigger (GPT, ELC). The scan operation of each group is similar to the scan operation in single scan mode.

The synchronous triggers can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for group A and B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger.

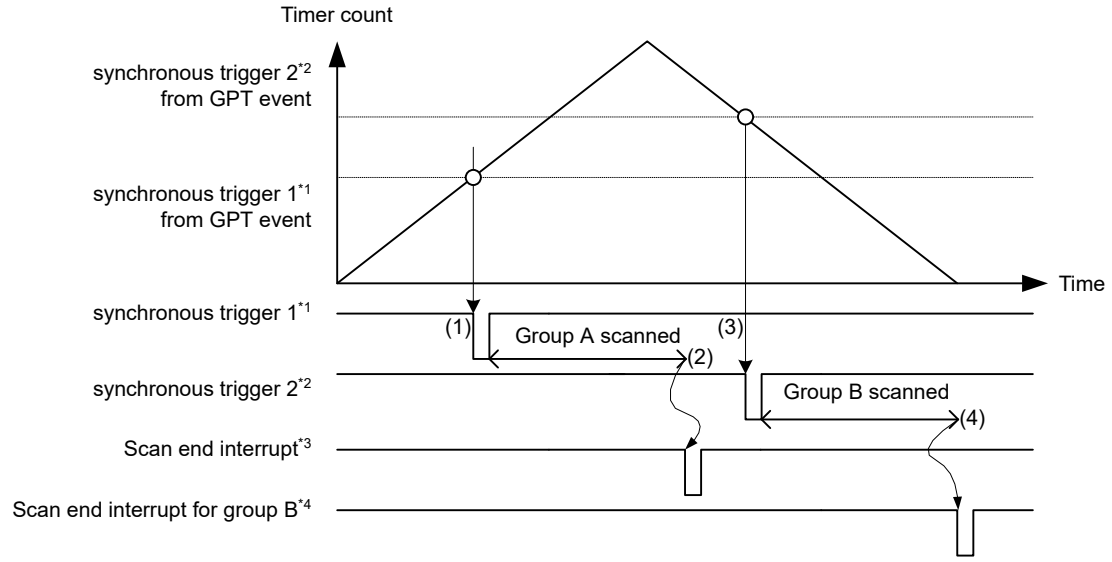
The group A channels to be A/D-converted are selected using the ADANSA0 and ADANSA1 registers and the ADEXICR.TSSA and OCSA bits. The group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers and the ADEXICR.TSSB and OCSB bits. Group A and B cannot use the same channels.

When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed for Group A and B.

The following sequence describes operation in group scan mode using a synchronous trigger from the ELC. In this example, the ELC_AD00 (unit 0) and ELC_AD10 (unit 1) trigger from the ELC is used to start conversion of group A and the ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger from the ELC is used to start conversion of group B. In addition, ELC_AD00 (unit 0) and ELC_AD10 (unit 1) and ELC_AD01 (unit 0) and ELC_AD11 (unit 1) are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group A is started by ELC_AD00 (unit 0) and ELC_AD10 (unit 1).
2. When group A scanning completes, an ADC12i_ADI (i = 0, 1) interrupt is generated (no register setting).
3. Scanning of group B is started by ELC_AD01 (unit 0) and ELC_AD11 (unit 1).
4. When group B scanning completes, an ADC12i_GBADI (i = 0, 1) interrupt is generated if the ADCSR.GBADIE bit is 1 (ADC12i_GBADI (i = 0, 1) interrupt when scanning completion is enabled).



Note 1. ELC_AD00 (unit 0) and ELC_AD10 (unit 1)
Note 2. ELC_AD01 (unit 0) and ELC_AD11 (unit 1)
Note 3. ADC12i_ADI (i = 0, 1)
Note 4. ADC12i_GBADI (i = 0, 1)

Figure 45.24 Example basic operation in group scan mode when synchronous triggers from the ELC are used

45.3.4.2 A/D Conversion in Double-Trigger Mode

When double trigger mode is selected in group scan mode, two rounds of single scan operation started by a synchronous trigger (GPT, ELC) are performed as a sequence for group A. For group B, single scan operation started by a synchronous trigger (GPT, ELC) is performed once.

In group scan mode, the synchronous trigger can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for groupA, B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger or an asynchronous trigger.

When an ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1) is selected as group A synchronous triggers by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, operation proceeds in extended double trigger mode.

The group A channel to be A/D-converted is selected using the DBLANS[4:0] bits in the ADCSR register, while the group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers. Group A, B cannot use the same channels.

When double-trigger mode is selected in group scan mode, set the A/D conversion select bits for both the temperature sensor output (ADEXICR.TSSA) and the internal reference voltage (ADEXICR.OCSA) to 0 (deselected).

Self-diagnosis cannot be selected when double trigger mode is selected in group scan mode.

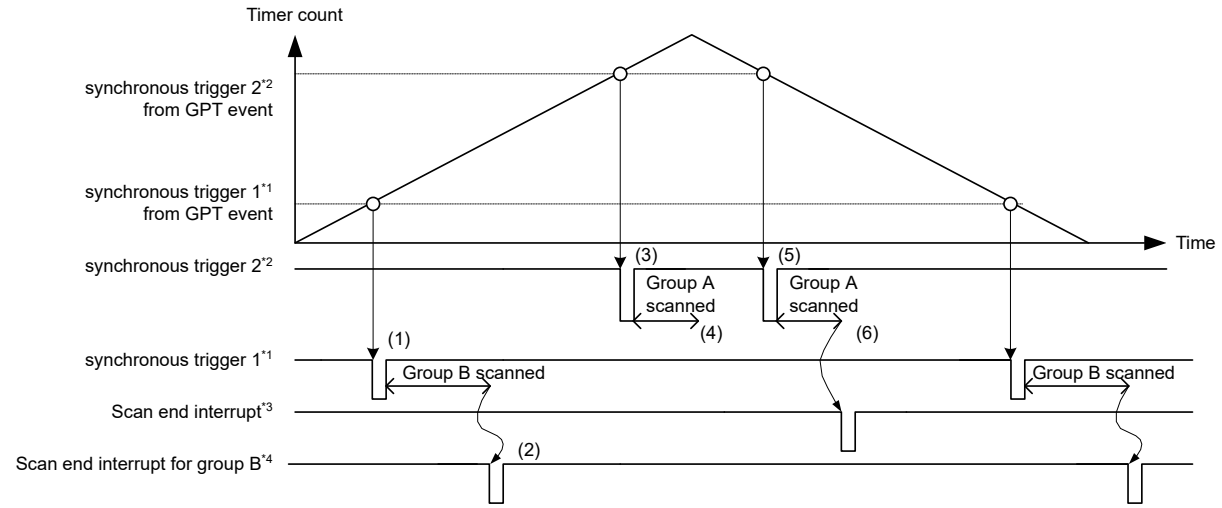
Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1.

The following sequence describes operation in group scan mode with double trigger mode selected and using a synchronous trigger from the ELC. In this example, the ELC_AD00 (unit 0) and ELC_AD10 (unit 1) trigger is used to start conversion of group A and the ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger is used to start conversion of group B. In addition, ELC_AD00 (unit 0) and ELC_AD10 (unit 1) and ELC_AD01 (unit 0) and ELC_AD11 (unit 1) are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group B is started by the ELC_AD00 (unit 0) and ELC_AD10 (unit 1) trigger from the ELC.

2. When group B scanning completes, an ADC12i_GBADI (i = 0, 1) interrupt is generated if the GBADIE bit in ADCSR is 1 (ADC12i_GBADI (i = 0, 1) interrupt when scanning completion is enabled).
3. The first scan of group A is started by the first ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger.
4. When the first scan of group A completes, the conversion result is stored in the associated A/D Data Register y (ADDRy); an ADC12i_ADI (i = 0, 1) interrupt request is not generated.
5. The second scan of group A is started by the second ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger.
6. When the second scan of group A completes, the conversion result is stored in ADDBLDR. An ADC12i_ADI (i = 0, 1) interrupt is generated.



Note 1. ELC_AD00 (unit 0) and ELC_AD10 (unit 1)
Note 2. ELC_AD01 (unit 0) and ELC_AD11 (unit 1)
Note 3. ADC12i_ADI (i = 0, 1)
Note 4. ADC12i_GBADI (i = 0, 1)

Figure 45.25 Example basic operation in group scan mode with double-trigger mode when synchronous triggers from the ELC are used

45.3.4.3 Group Priority Operation

Group priority operation is performed by setting the ADGSPCR.PGS bit to 1 in group-scan mode. The priority of groups is group A > group B.

When setting the PGS bit in the ADGSPCR register to 1, follow the procedure described in Figure 45.26. If the procedure is not followed, A/D conversion operation and stored data are not guaranteed.

As the basic operation in group-scan mode, a trigger input generated during A/D conversion of group A, B is ignored, and the A/D conversion operation of each group is similar to the operation in single-scan mode.

In group priority operation, if a trigger for a priority group is input during scanning of a lower-priority group, A/D conversion for the lower-priority group is stopped and A/D conversion for the priority group is performed.

If the setting of the ADGSPCR.GBRSCN bit is 0, the lower-priority group enters a wait state when A/D conversion for the priority group completes. A trigger input of the lower-priority group generated during A/D conversion is ignored.

If the setting of the ADGSPCR.GBRSCN bit is 1, A/D conversion for the lower-priority group automatically restarts upon completion of A/D conversion for the priority group. A trigger input of the lower-priority group generated during A/D conversion on the priority group takes effect, and A/D conversion for the lower-priority group is automatically performed upon completion of A/D conversion on the priority group.

If the ADGSPCR.GBRSCN bit is 1 and the ADGSPCR.LGRRS bit is 0, A/D conversion for the lower-priority group is restarted from the first channel. If the setting of the ADGSPCR.LGRRS bit is 1, A/D conversion for the lower-priority group is restarted from the channel for which the conversion stopped. However, if the self-diagnosis function is used, the A/D conversion is restarted from the channel for which the conversion stopped after self-diagnosis completed.

Table 45.26 summarizes operations in response to the input of a trigger during A/D conversion with the settings of the ADGSPCR.GBRSCN bit.

If the setting of the ADGSPCR.GBRP bit is 1, A/D conversion operation for the lowest-priority group is to continuously perform single scans.

For the trigger settings in group-scan mode, select a synchronous trigger for group A by using the ADSTRGR.TRSA[5:0] bits, a synchronous trigger for group B by using the ADSTRGR.TRSB[5:0] bits. Each trigger must be different from each other. Set the ADSTRGR.TRSB[5:0] bits to 0x3F when setting the ADGSPCR.GBRP bit to 1.

The channels to be scanned must be selected in the registers shown in section 45.3.4. Group Scan Mode.

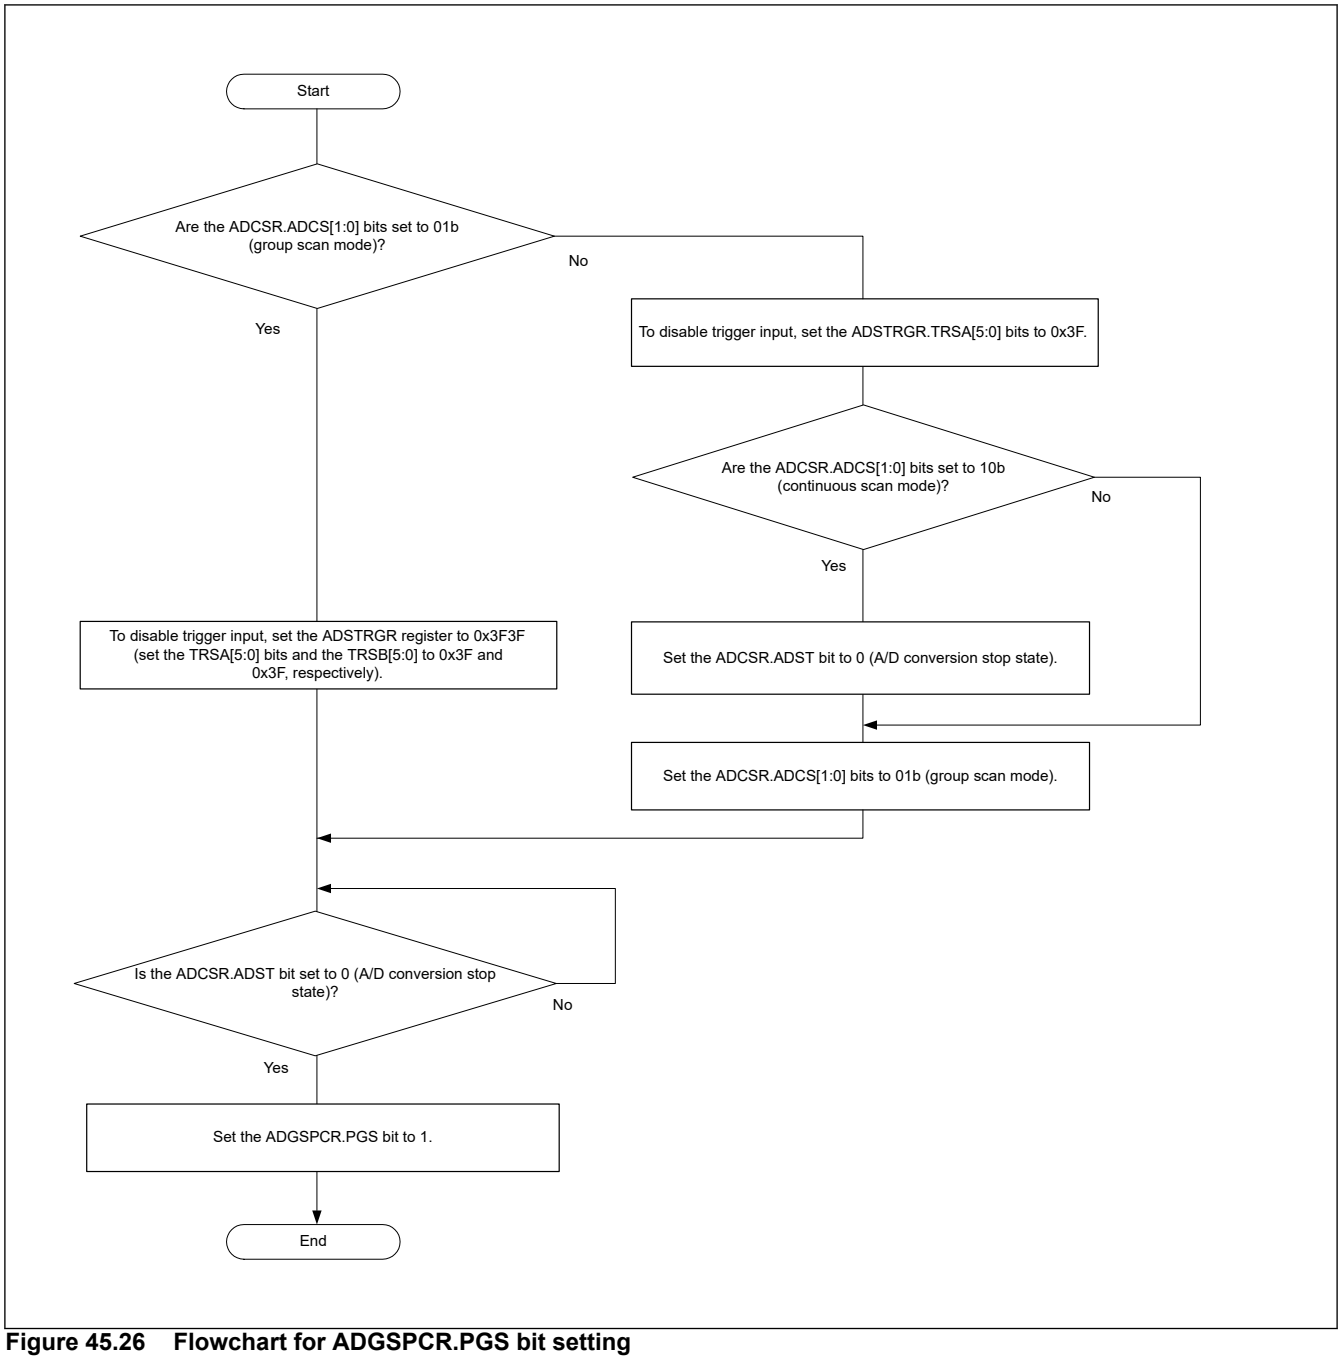


Figure 45.26 Flowchart for ADGSPCR.PGS bit setting

Table 45.26 Control of A/D conversion operations according to ADGSPCR.GBRSCN bit setting

A/D conversion operation	Trigger input	ADGSPCR.GBRSCN = 0	ADGSPCR.GBRSCN = 1
When A/D conversion for group A is in progress	Input of trigger for group A	Trigger input is ineffective.	Trigger input is ineffective.
	Input of trigger for group B	Trigger input is ineffective.	A/D conversion for group B is performed after A/D conversion for group A completes.
When A/D conversion for group B is in progress	Input of trigger for group A	A/D conversion for group B is discontinued and A/D conversion for group A starts.	• A/D conversion for group B is discontinued and A/D conversion for group A starts. • A/D conversion for group B starts after A/D conversion for group A completes.
	Input of trigger for group B	Trigger input is ineffective.	Trigger input is ineffective.

To use group priority operation mode, select the operation mode to be implemented and set the registers according to the following table.

Table 45.27 Group priority operation setting and operation mode for two groups (ADGSPCR.PGS = 1)

ADGSPCR			Operation category
GBRSCN	LGRRS	GBRP	
0	x	0	Group priority operation for two groups (groups A and B) • When a trigger of group A is input, A/D conversion for group B is terminated (and will not be restarted).
1	0	0	Group priority operation for two groups (groups A and B) • After A/D conversion for group B stopped, when A/D conversion for group A completes, A/D conversion for the group B channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order of smaller channel number.
1	1	0	Group priority operation for two groups (groups A and B) • After A/D conversion for group B stopped, when A/D conversion for group A completes, A/D conversion for the group B channels selected in the ADANSB0/1 register restarts according to the conversion order of smaller channel number, beginning from the channel for which A/D conversion stopped.*1
x	0	1	Group priority operation for two groups (groups A and B) • Single scanning for group B is continuously performed without a start trigger input. After A/D conversion for group B stopped, when A/D conversion for group A completes, single scanning for the channels selected in the ADANSB0/1 register restarts according to the conversion order of smaller channel number.
1	1	1	Group priority operation for two groups (groups A and B) • Single scanning for group B is continuously performed without a start trigger input. After A/D conversion for group B stopped, when A/D conversion for group A completes, single scanning for the channels selected in the ADANSB0/1 register restarts according to the conversion order of smaller channel number, beginning from the channel for which A/D conversion stopped.*1

Note: x: Don't care.
Note 1. When the self-diagnosis function is enabled (ADCER.DIAGM = 1), A/D conversion for the channel that has been stopped is started after self-diagnosis is performed.

(1) Group priority operation for two groups (when ADGSPCR.PGS = 1)

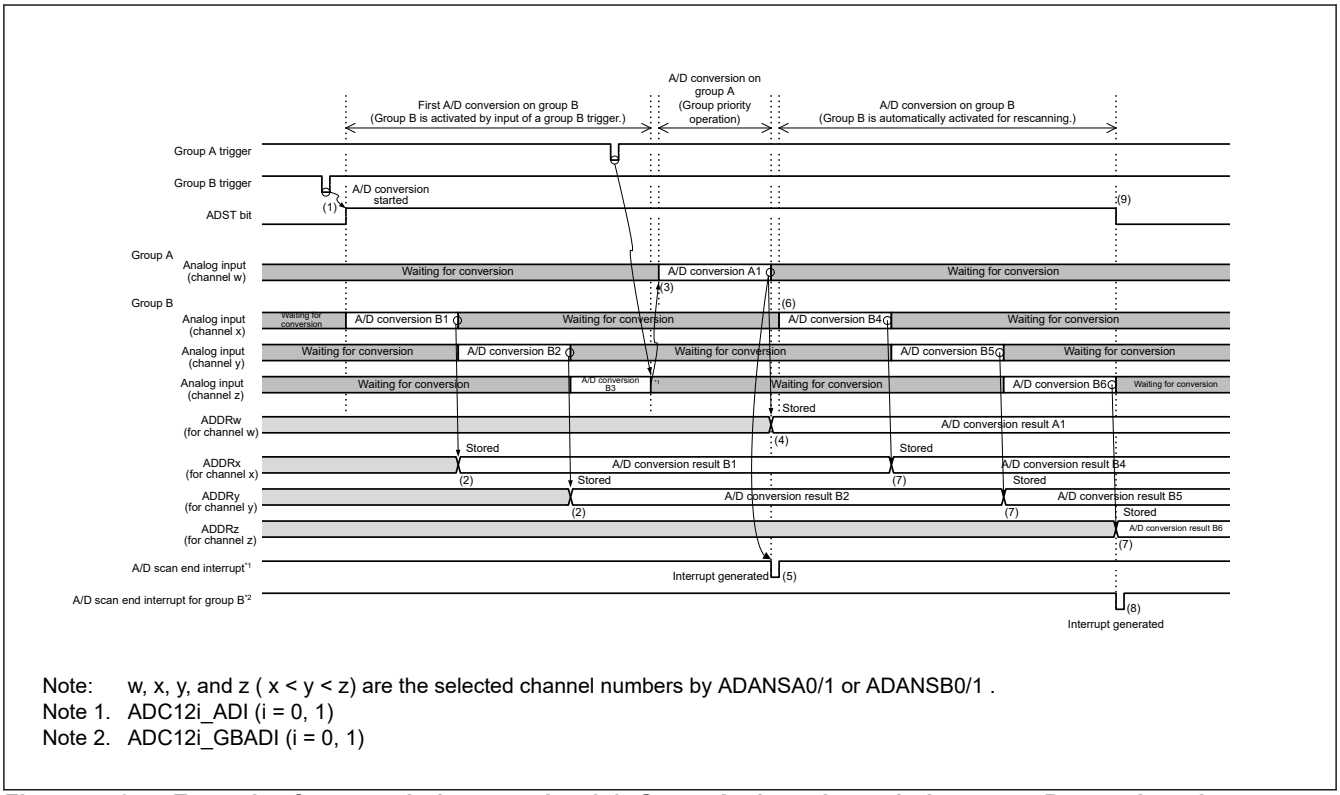
Operation examples 1-1 to 1-3 show group priority operations in group-scan mode (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0).

Operation example 1-1: "Group A trigger input during group B scan" when rescanning is enabled

1. When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1. Then A/D conversion for the group A analog input channels selected in the ADANSA0

and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).

4. On completion of A/D conversion on the channels, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. An ADC120_ADI interrupt request is generated.
6. If the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning of the group that was stopped in group priority operation), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1.
7. On completion of A/D conversion on the channels, the result is stored in the corresponding A/D Data Register y (ADDRy).
8. If the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan), a group B scan end interrupt request is generated.
9. When A/D conversion for all the channels completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state.



Note: w, x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1 .
Note 1. ADC12i_ADI (i = 0, 1)
Note 2. ADC12i_GBADI (i = 0, 1)

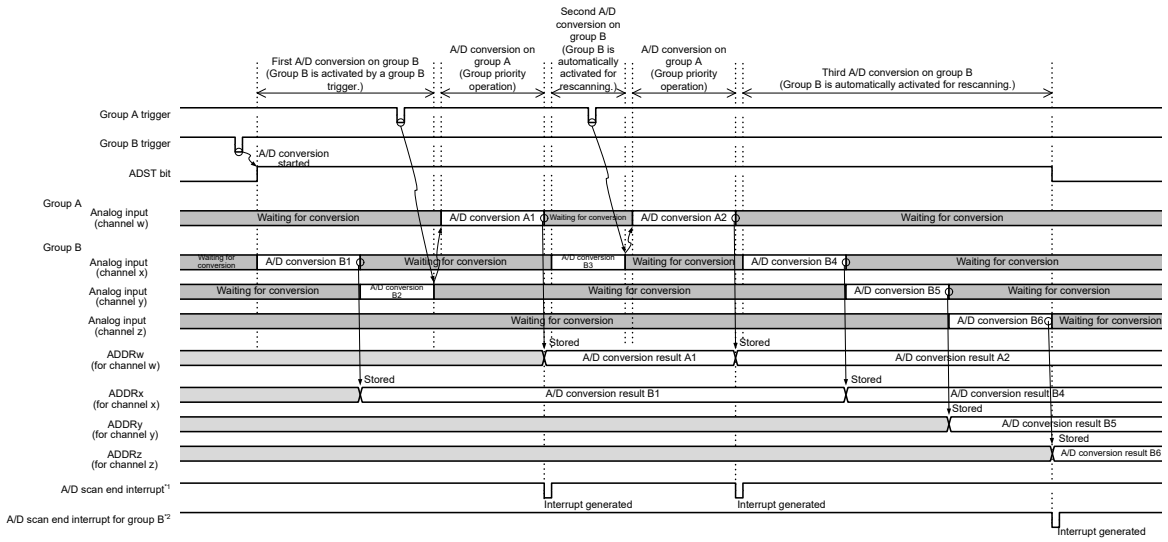
Figure 45.27 Example of group priority operation 1-1: Group A trigger input during group B scanning when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-2: “Group A trigger input during rescanning of group B” when rescanning is enabled

Figure 45.28 shows the operation when a group A trigger is input during rescanning operation for group B.

Even during rescanning operation, when a trigger for group A is input, A/D conversion on group B stops and A/D conversion for group A starts. A/D conversion for group B starts after A/D conversion for group A completes.

Operations for setting the ADCSR.ADST bit, storing the A/D conversion result in the corresponding A/D Data Register y (ADDRy), and generating interrupt requests are the same as those in operation example 1-1.



Note: w, x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1.
Note 1. ADC12i_ADI (i = 0, 1)
Note 2. ADC12i_GBADI (i = 0, 1)

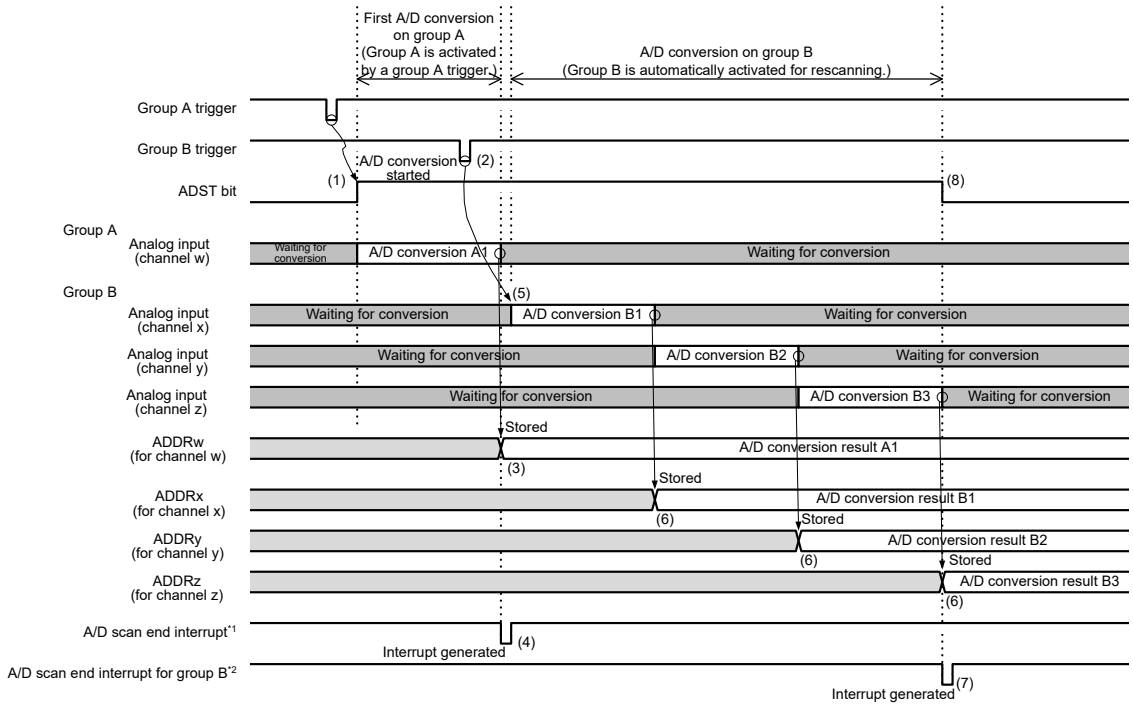
Figure 45.28 Example of group priority operation 1-2: Group A trigger input during rescanning of group B when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-3: “Group B trigger input during group A scan” when rescanning is enabled

The following describes the operation when the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning of the group that was stopped in group priority operation) and a trigger for group B is input during scanning operation for group A.

If the setting of the ADGSPCR.GBRSCN bit is 0, any trigger for group B that is input during scanning operation for group A is invalid.

1. When input of a trigger for group A sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n.
2. When a trigger for group B is input during A/D conversion for group A, group B is ready for A/D conversion.
3. On completion of A/D conversion for each channel in group A, the result is stored in the corresponding A/D Data Register y (ADDRy).
4. An ADC120_ADI interrupt request is generated.
5. When A/D conversion for group A completes, while the ADCSR.ADST bit remains 1, A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
   (As with the case of operation example 1-1, if a trigger for group A is input during A/D conversion for group B, A/D conversion for group A starts. Then A/D conversion for group B starts upon completion of A/D conversion for group A.)
6. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
7. Upon completion of A/D conversion for group B, a group B scan end interrupt request is generated if the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan).
8. When A/D conversion for all the channels completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state.



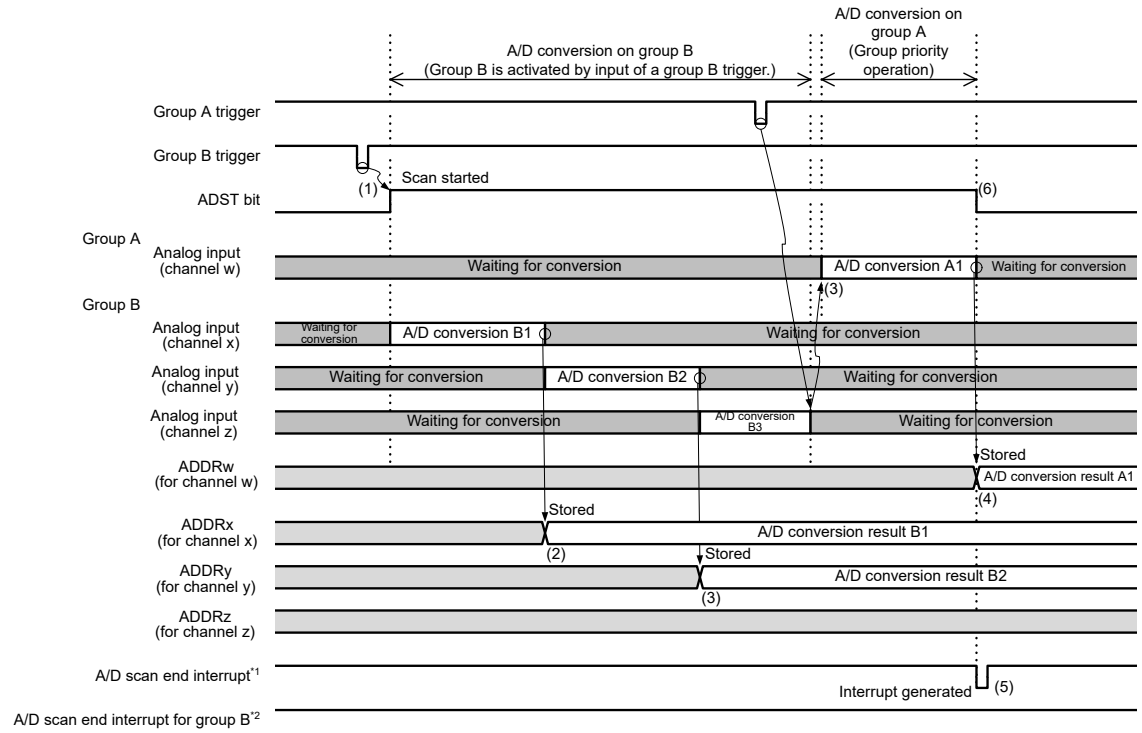
Note: w, x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1.
Note 1. ADC12i_ADI (i = 0, 1)
Note 2. ADC12i_GBADI (i = 0, 1)

Figure 45.29 Example of group priority operation 1-3: Group B trigger input during group A scan when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-4 shows the group priority operation in group-scan mode (when ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0).

Operation example 1-4: “Group A trigger input during group B scan” when rescanning is disabled

1. When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1, and then A/D conversion for the group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).
4. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. On completion of A/D conversion for group A, an ADC120_ADI interrupt request is generated.
6. When A/D conversion for group A completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state. A/D conversion for group B is not performed until a trigger for group B is input the next time.



Note: w, x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1.
Note 1. ADC12i_ADI (i = 0, 1)
Note 2. ADC12i_GBADI (i = 0, 1)

Figure 45.30 Group priority operation example 1-4: "Group A trigger is input during group B scan" when rescanning is disabled (when ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

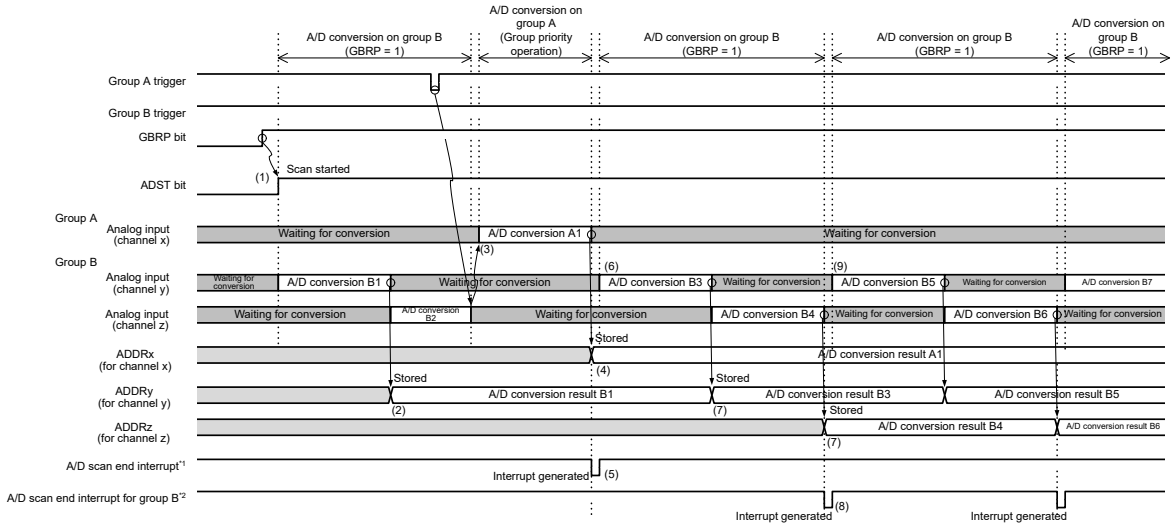
Operation example 1-5 shows the group priority operation in group-scan mode (when ADGSPCR.GBRP = 1, and ADGSPCR.LGRRS = 0).

Operation example 1-5: Continuously activating single-scan operation for group B

1. When ADGSPCR.GBRP = 1 is set, the ADCSR.ADST bit is set to 1 (starting A/D conversion) and A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1, and then A/D conversion for group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).
4. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. On completion of A/D conversion for group A, an ADC120_ADI interrupt request is generated.
6. If ADGSPCR.GBRP = 1 is set (performing single scan continuously), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1 (starting A/D conversion).
7. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).

8. If the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan), a group B scan end interrupt request is generated.
9. If ADGSPCR.GBRP = 1 is set (performing single scan continuously), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1 (starting A/D conversion).

Steps 6 to 9 are repeated as long as the ADGSPCR.GBRP bit remains 1. Do not clear the ADCSR.ADST bit as long as the ADGSPCR.GBRP bit is 1. To forcibly stop A/D conversion while ADGSPCR.GBRP = 1, follow the procedure shown in Figure 45.43.



Note: x, y, and z (y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1.
Note 1. ADC12i_ADI (i = 0, 1)
Note 2. ADC12i_GBADI (i = 0, 1)

Figure 45.31 Group priority operation example 1-5: Continuously activating single scan for group B (when ADGSPCR.GBRP = 1 , ADGSPCR.LGRRS = 0)

Note: To continuously activate single-scan operation for group B, disable group B trigger input.

45.3.5 Compare Function for Windows A and B

45.3.5.1 Compare Function Windows A and B

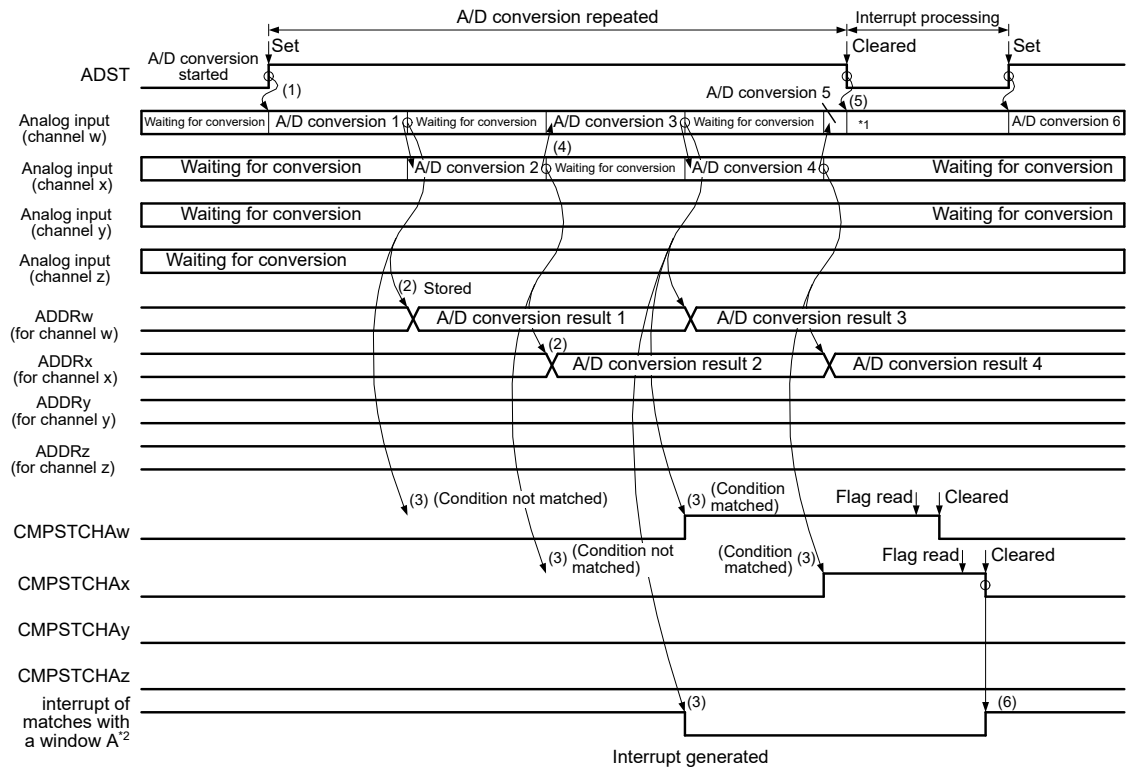
The compare function compares a reference value with the A/D conversion result. The reference value can be set for Window A and Window B independently. When the compare function is in use, the self-diagnosis function and double trigger mode cannot be used. The main differences between Window A and Window B are their different interrupt output signals and the constraint on Window B of only one selectable channel.

This section provides an example operation that combines continuous scan mode and the compare function.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, a synchronous trigger (GPT, ELC) or an asynchronous trigger, A/D conversion starts in the order of the selected channels , temperature sensor, and internal reference voltage.
2. On completion of A/D conversion, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy, ADTSDR, or ADOCDR). When ADCMPCR.CMPAE = 1, if bits in the ADCMPANSRy register or the ADCMPANSER register are set for Window A, the A/D conversion result is compared with the set ADCMPDR0/1 register value. When ADCMPCR.CMPBE = 1, if bits in the ADCMPBNSR register are set for Window B, the A/D conversion result is compared with the ADWINULB/ADWINLLB register setting.

3. As a result of the comparison, when Window A meets the condition set in ADCMPLR0/1 or ADCMPLER, the Compare Window A Flag (ADCMPSR0.CMPSTCHAn, ADCMPSR1.CMPSTCHAn, ADCMPSER.CMPSTTSA or ADCMPSER.CMPSTOCA) sets 1. At this time, if the ADCMPCR.CMPAIE bit is 1, an ADC12i_CMPAI (i = 0, 1) interrupt request is generated. In the same way, when Window B meets the condition set in ADCMPBNSR.CMPLB, the Compare Window B Flag (ADCMPBSR.CMPSTB) sets to 1. At this time, if the ADCMPCR.CMPBIE bit is 1, an ADC12i_CMPBI (i = 0, 1) interrupt request is generated.
4. On completion of all selected A/D conversions and comparisons, scan restarts.
5. After the ADC12i_CMPAI (i = 0, 1) and ADC12i_CMPBI (i = 0, 1) interrupts are accepted, the ADCSR.ADST bit is set to 0 (A/D conversion stop) and processing is performed for channels for which the compare flag is set to 1.
6. When all compare flags of Window A are cleared, the ADC12i_CMPAI (i = 0, 1) interrupt request is canceled. In the same way, when all compare flags of Window B are cleared, the ADC12i_CMPBI (i = 0, 1) interrupt request is reset. To perform comparison again, restart the A/D conversion.



Note: w, x, y, and z (w < x < y < z) are the selected channel numbers by ADANSA0/1.
Note 1. Data on conversion is ignored.
Note 2. ADC12i_CMPAI (i = 0, 1)

Figure 45.32 Example of compare function operation, when the analog inputs (channel w to z) are compared

45.3.5.2 Event output of compare function

The event output of the compare function specifies the upper-side reference voltage value and the lower-side reference voltage value for window A and window B, respectively. The output compares the A/D converted value of the selected channel with the upper and lower side reference voltage value and outputs events (ADC12i_WCMPM (i = 0, 1)/ ADC12i_WCMPUM (i = 0, 1)) based on event conditions (A or B, A and B, A xor B) and comparison result of window A and window B.

If more than one channel is selected for window A, and even when one channel in window A meets the comparison condition, the comparison result of window A is met. When using this function, perform A/D conversion in single scan mode.

Any channels from analog input, internal reference voltage, temperature sensor output and VBATT 1/3 voltage monitor output are selectable for window A.

One channel from analog input, internal reference voltage, temperature sensor output and VBATT 1/3 voltage monitor output is selectable for window B.

The following sequence is an example of how to set up and use the event output of the compare function:

1. Confirm that the value in the ADCSR.ADCS bits is 00b (single scan mode).
2. Select the channel for window A in the ADCMPANSR0/1 and ADCMPANSER registers. Set the window comparison conditions in the ADCMPLR0/1 and ADCMPLER registers. Set the upper-side and lower-side reference values in the ADCMPDR0/1 registers.
3. Select the channel and comparison conditions for Window B in the ADCMPBNSR register, and set the upper and lower reference values in the ADWINULB and ADWINLLB registers.
4. Set the composite conditions for window A/B, window A/B operation enable, and interrupt output enable in the ADCMPCR register.

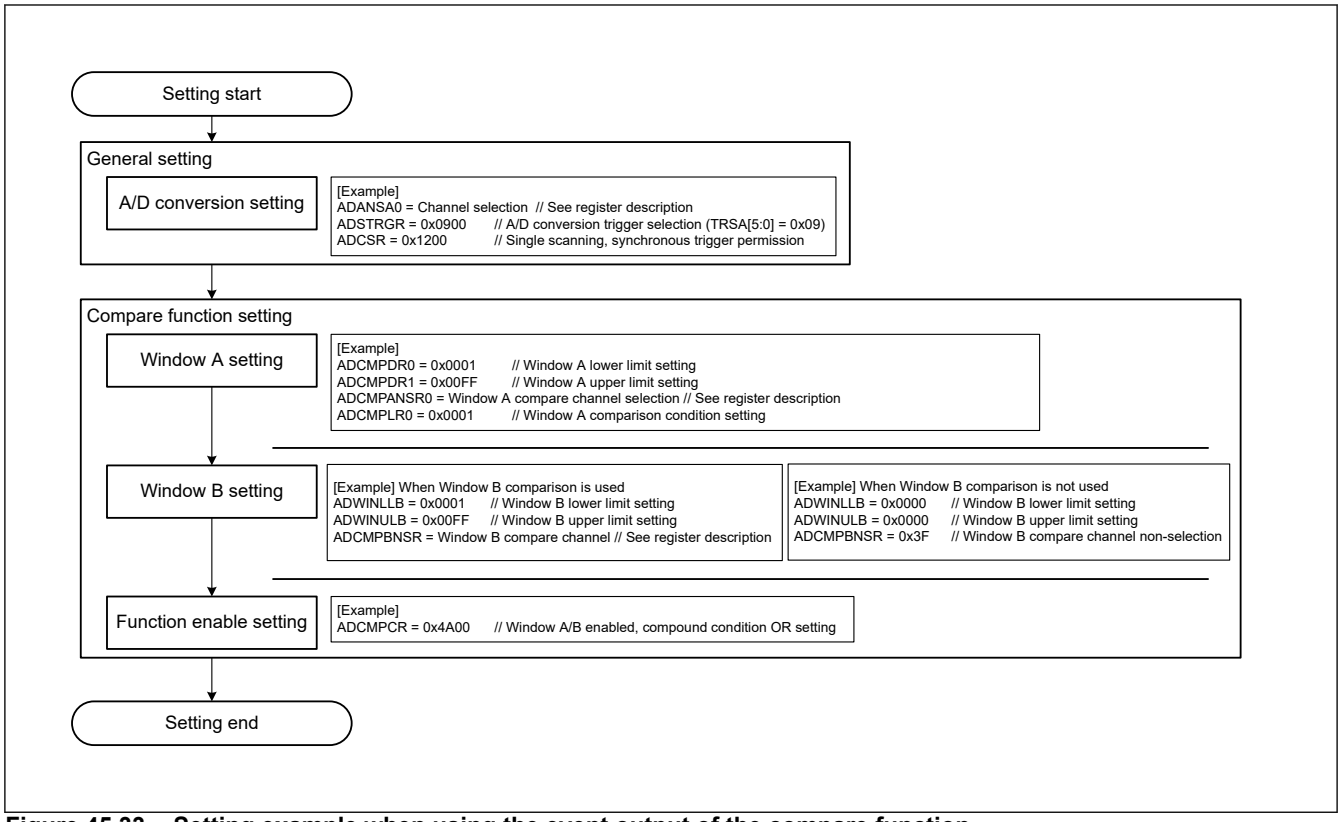


Figure 45.33 Setting example when using the event output of the compare function

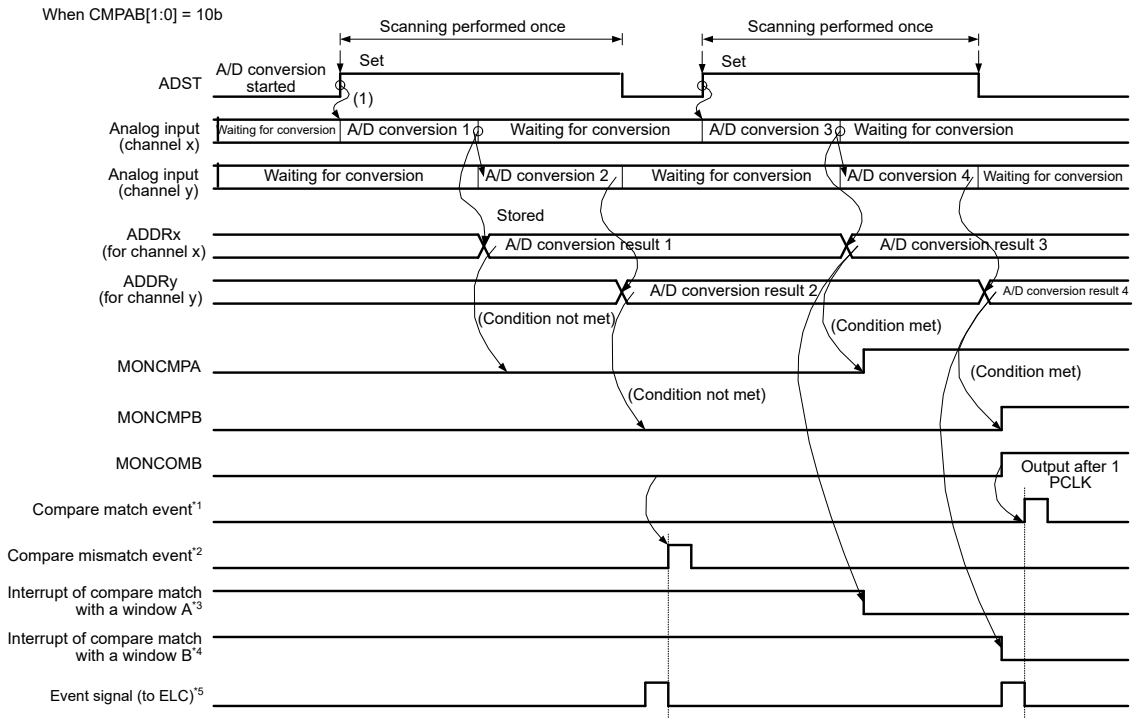
For event output usage when using only window A for the compare function, note the following:

- Enable both Window A and Window B (ADCMPCR.CMPAE = 1, ADCMPCR.CMPBE = 1)
- Set the compound condition of Window A and Window B to “OR condition” (ADCMPCR.CMPAB[1:0] = 00b)
- Set the compared channel of Window B to “No selection” (ADCMPBNSR.CMPCHB[5:0] = 0x3F)
- Set the compare condition of Window B to “0 < results < 0 always means mismatch”. (ADCMPCR.WCMPE = 1, ADWINLLB[15:0] = ADWINULB[15:0] = 0x0000, and ADCMPBNSR.CMPLB = 1)

Figure 45.34 shows the event output operation example of compare function.

A scan end event (ADC12i_ADI (i = 0, 1)) is output with the same timing as single scan completion. A match or mismatch event (ADC12i_WCMPM (i = 0, 1)/ADC12i_WCMPUM (i = 0, 1)) is output with 1 PCLKA cycle delay depending on the ADCMPCR.CMPAB[1:0] settings.

Note: The match and mismatch events are exclusive, so both events are never output simultaneously.



Note: x, and y (x < y) are the selected channel numbers by ADANSA0/1.
Note 1. ADC12i_WCMPM (i = 0, 1)
Note 2. ADC12i_WCMPUM (i = 0, 1)
Note 3. ADC12i_CMPAI (i = 0, 1)
Note 4. ADC12i_CMPBI (i = 0, 1)
Note 5. ADC12i_ADI (i = 0, 1)

Figure 45.34 Example operation of the compare function event output, when the analog inputs (channel x and y) are compared

Note: Event output of compare function outputs match/mismatch from the comparison results of Window A and Window B, based on the ADCMPCR.CMPAB[1:0] settings.

Note: The comparison result of Window A is the logical addition of the comparison results of the comparison target channels of Window A. The comparison results of Window A and Window B are updated by each A/D conversion, and are kept even when single scan ends. Set ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0 to clear the comparison results to 0.

45.3.5.3 Restrictions on Compare Function

The following constraints apply for the compare function:

- The compare function cannot be used together with the self-diagnosis function or double-trigger mode. (The compare function is not available for ADRD, ADDBLDR, ADDBLDRA, and ADDBLDRB.)
- Specify single scan mode when using match/mismatch event outputs.
- When the temperature sensor output, internal reference voltage is selected for Window A, Window B operations are prohibited.
- When the temperature sensor output, internal reference voltage is selected for Window B, Window A operations are prohibited.
- Setting the same channel for Window A and Window B is prohibited.
- Specify single scan mode when using the buffer function. It is prohibited to use double trigger mode together.
- Set the reference voltage values so that the high-potential reference voltage value is equal to or larger than the low potential reference voltage value.

45.3.6 Analog Input Sampling and Scan Conversion Time

Scan conversion can be activated either by a software trigger, a synchronous trigger (GPT, ELC), or an asynchronous trigger (ADTRGn (n = 0, 1)). After the start-of-scanning-delay time (t_D) has elapsed, processing by the channel-dedicated sample-and-hold circuits, processing for disconnection detection assistance, and processing of conversion for self-diagnosis all proceed, followed by processing for A/D conversion.

Figure 45.35 shows the scan conversion timing, in which scan conversion is activated by a software trigger or a synchronous trigger (GPT, ELC). Figure 45.36 shows the scan conversion timing, in which scan conversion is activated by an asynchronous trigger (ADTRGn (n = 0, 1)). The scan conversion time (t_{SCAN}) includes the start-of-scanning-delay time (t_D), channel-dedicated sample-and-hold circuit processing time (tSPLSH)*1, disconnection detection assistance processing time (t_{DIS})*2, self-diagnosis A/D conversion processing time (t_{DIAG} and t_{DSD})*3, A/D conversion processing time (t_{CONV} and t_{DSD}), channel-dedicated sample-and-hold circuit end time (tSHED)*4 and end-of-scanning-delay time (t_{ED}).

The A/D conversion processing time (t_{CONV}) consists of input sampling time (t_{SPL}) and time for conversion by successive approximation (t_{SAM}). The sampling time (t_{SPL}) is used to charge sample-and-hold circuits in the A/D converter. If there is not sufficient sampling time due to the high impedance of an analog input signal source, or if the A/ D conversion clock (ADCLK) is slow, sampling time can be adjusted using the ADSSTRn register.

The time for conversion by successive approximation (t_{SAM}) is the following

- 13 ADCLK states with 12-bit accuracy selected.
- 11 ADCLK states with 10-bit accuracy selected.
- 9 ADCLK states with 8-bit accuracy selected.

Table 45.28 shows the time for conversion by successive approximation (t_{SAM}).

The scan conversion time (t_{SCAN}) in single scan mode for which the number of selected channels is n can be determined as follows:

$$t_{SCAN} = t_D + t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + t_{ED} + (t_{CONV} \times n) + t_{ED}$$ *5

The scan conversion time for the first cycle in continuous scan mode is t_{SCAN} for single scan minus t_{ED} . The scan conversion time for the second and subsequent cycles in continuous scan mode is fixed in the following:

$$t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + t_{DSD} + t_{SHED} + (t_{CONV} \times n) + t_{SHED}$$ *5

Note 1. When no channel-dedicated sample-and-hold circuits are used, tSPLSH = 0.
Note 2. When disconnection detection assistance is not selected, t_{DIS} = 0.

Only when the temperature sensor or internal reference voltage is A/D-converted, the auto-discharge period of 15 ADCLK states is inserted.

Note 3. When the self-diagnosis function is not used, t_{DIAG} = 0, t_{DSD} = 0.
Note 4. When no channel-dedicated sample-and-hold circuits are used, t_{SHED} = 0, assuming continuous scan mode is active. In single scan mode and group scan mode, t_{SHED} is included in the end-of-scanning-delay (t_{ED}).
Note 5. When input sampling times (t_{SPL}) of all selected channels are the same, this element equals t_{CONV} × n. If each channel has a different sampling time, this element equals that of t_{SPL} and t_{SAM} set to each selected channel.

Table 45.28 shows the times for conversion during scanning.

Table 45.28 Conversion times during scanning (in numbers of cycles of ADCLK and PCLKA)

Item			Symbol		Type/Conditions			Unit
					Synchronous trigger*4	Asynchronous trigger	Software trigger	
Scan start processing time*1 *2	A/D conversion on group A under group A priority control.	Group B is to be stopped (Group A is activated after group B is stopped by of an A/D conversion source from group A).	t_D		3 PCLKA + 6 ADCLK 5 PCLKA + 3 ADCLK*5	—	—	Cycles
		Group B is not to be stopped (activation by an A/D conversion source from group A).			2 PCLKA + 4 ADCLK	—	—	
	A/D conversion when self-diagnosis is enabled.	A/D conversion for self-diagnosis is to be started.			2 PCLKA + 6 ADCLK	4 PCLKA + 6 ADCLK	6 ADCLK	
	All other				2 PCLKA + 4 ADCLK	2 PCLKA + 4 ADCLK	4 ADCLK	
Channel-dedicated sample-and-hold processing time*1	Sampling time		t_{SPLSH}	t_{SH}	Without continuous sampling: setting in ADSHCR.SSTSH[7:0] (initial value = 18h × ADCLK) With continuous sampling: 0			
	Wait time between sampling and A/D Conversion			t_W	12			
Disconnection detection assistance processing time			t_{DIS}		Setting in ADNDIS[3:0] (initial value = 0x0) × ADCLK			
Self-diagnosis conversion processing time*1	Sampling time		t_{DIAG}	t_{SPL}	Setting in ADSSTR00 (initial value = 0x0B) × ADCLK*3	—	—	
	Time for conversion by successive approximation	12-bit conversion accuracy		t_{SAM}	15 ADCLK	—	—	
		10-bit conversion accuracy			13 ADCLK	—	—	
		8-bit conversion accuracy			11 ADCLK	—	—	
	Wait time between self-diagnosis conversion end and analog channel sampling start.			t_{DED}	2 ADCLK			
	Wait time between last channel conversion end and self-diagnosis sampling start in continuous scan mode.		t_{DSD}		2 ADCLK			
A/D conversion processing time*1	Sampling time		t_{CONV}	t_{SPL}	Setting in ADSSTRn (n = 0 to 8(unit 0), 0 to 6(unit 1), L, T, O, V) (initial value = 0x0B) × ADCLK + 0.5 ADCLK			
	Time for conversion by successive approximation	12-bit conversion accuracy		t_{SAM}	13 ADCLK			
		10-bit conversion accuracy			11 ADCLK			
		8-bit conversion accuracy			9 ADCLK			
Channel-dedicated sample-and-hold end processing time			t_{SHED}		2 ADCLK			
Scan end processing time*1			t_{ED}		1 PCLKA + 3 ADCLK 2 PCLKA + 3 ADCLK*5			

Note 1. See Figure 45.35 and Figure 45.36 for an illustration of times t_D, t_{SPLSH}, t_{DIAG}, t_{CONV}, and t_{ED}.
Note 2. This is the maximum time required from software writing or trigger input to A/D conversion start.
Note 3. The sampling time setting must satisfy the electrical characteristics.
Note 4. This does not include the time consumed in the path from timer output to trigger input.
Note 5. If ADCLK is faster than PCLKA (PCLKA to ADCLK frequency ratio = 1:2 or 1:4), the scan end processing time changes.

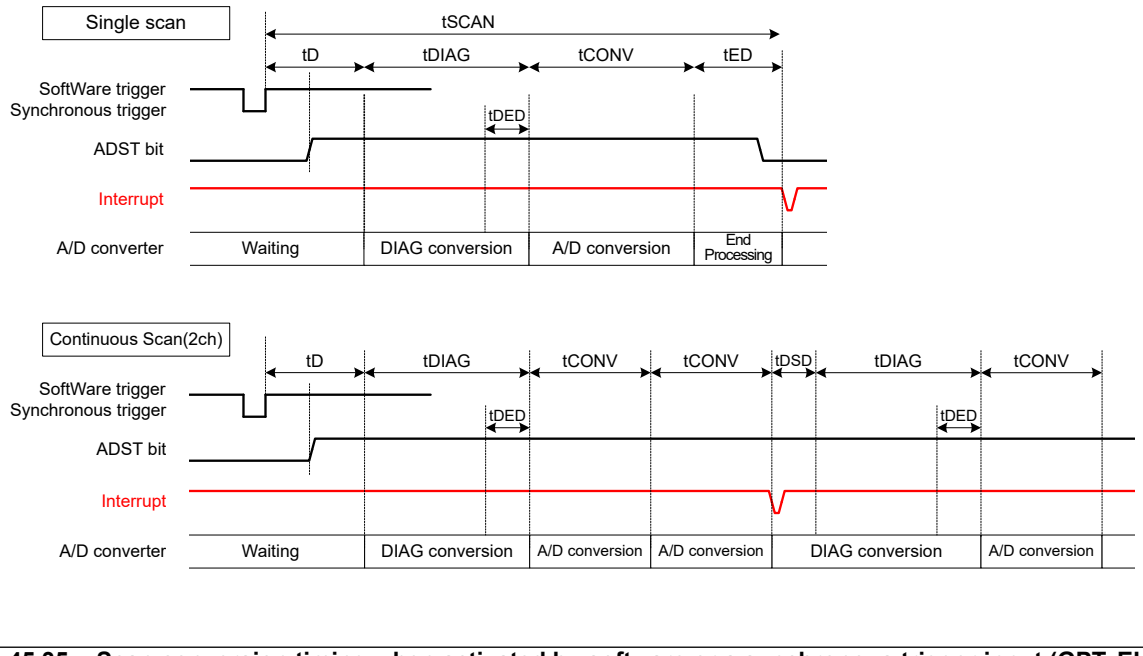


Figure 45.35 Scan conversion timing when activated by software or a synchronous trigger input (GPT, ELC)

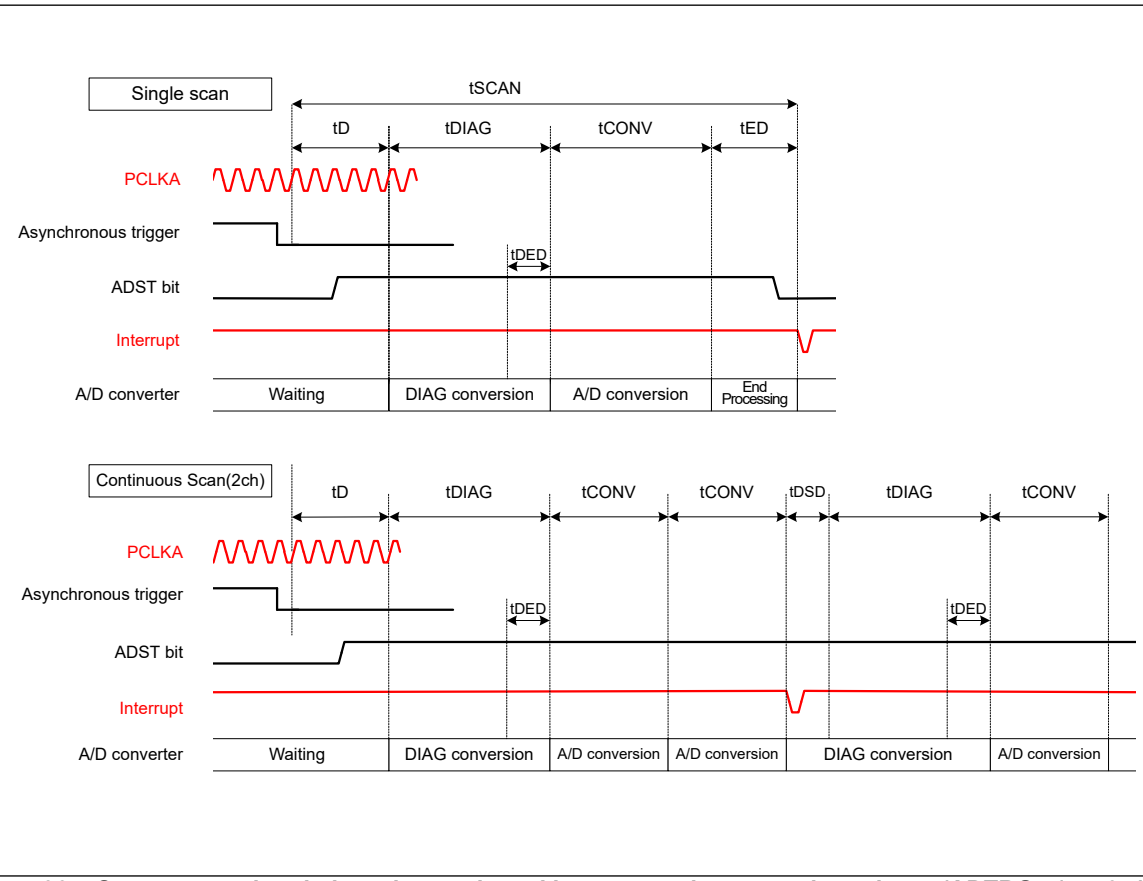

Figure 45.36 Scan conversion timing when activated by an asynchronous trigger input (ADTRGn (n = 0, 1))

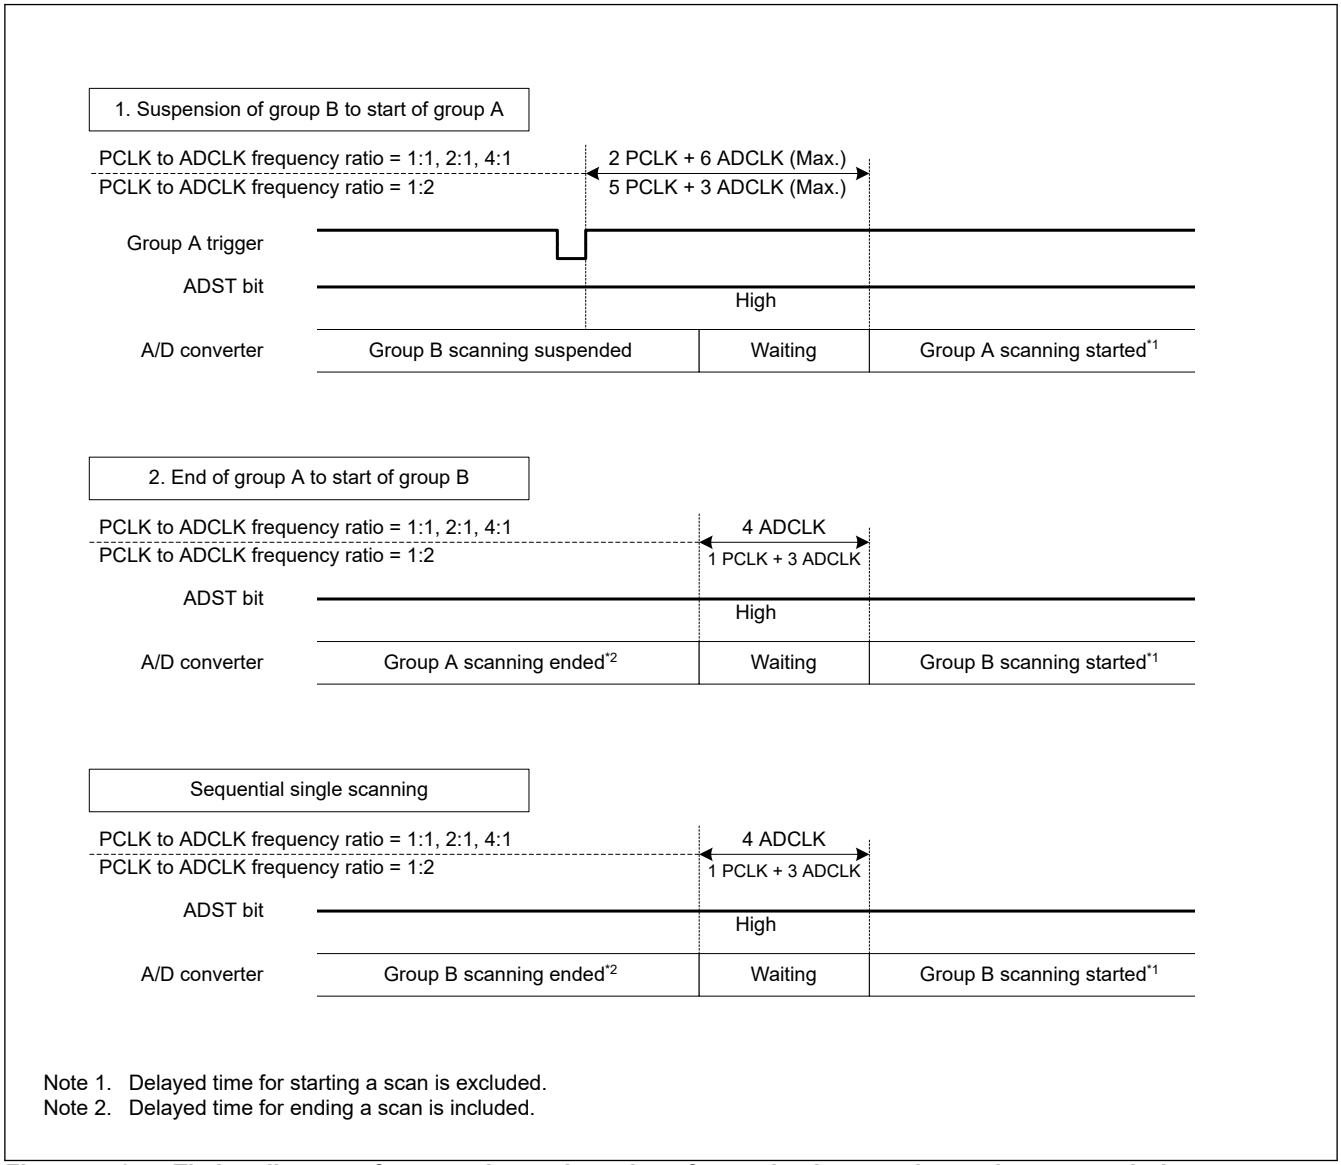
45.3.6.1 Timing of Suspension and Starting of Scanning in Operation under Group Priority Control

The timings for suspension and starting of scanning in operation under group priority control that must considered are listed below.

1. The timing for suspending a scan of a group with a lower-priority and the timing for starting a scan of a group with a higher-priority.
2. The time at which scanning by the group with a lower-priority is resumed on completion of scanning by the higherpriority group when the trigger for scanning by the lower-priority group is accepted during scanning by the higherpriority group.
3. The timing for performing sequential single scans by a lower-priority group.

Figure 1.37 shows the timing diagram of each of the above cases.



Note 1. Delayed time for starting a scan is excluded.
Note 2. Delayed time for ending a scan is included.

Figure 45.37 Timing diagram of suspension and starting of scanning in operation under group priority control

45.3.7 Usage Example of A/D Data Register Automatic Clearing Function

Setting the ADCER.ACE bit to 1 automatically clears the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADVMDR) to 0x0000 when the A/D data registers are read by the CPU or DTC or DMAC.

This function enables detection of update failures of the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADVMDR). This section describes examples in which the function to automatically clear the ADDRy register is enabled and disabled.

- If the ADCER.ACE bit is 0 (automatic clearing is disabled) and for some reason, if the A/D conversion result (0x0222) is not written to the ADDRy register, the ADDRy value retains the old data (0x0111). In addition, if this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, the old data (0x0111) can be saved in the general-purpose register. When checking whether there is an update failure, it is necessary to frequently save the old data in SRAM or in a general-purpose register.
- If the ADCER.ACE bit is 1 (automatic clearing is enabled), when ADDRy = 0x0111 is read by the CPU or DTC or DMAC, ADDRy is automatically set to 0x0000. Next, if the A/D conversion result of 0x0222 cannot be transferred to ADDRy for some reason, the cleared data (0x0000) remains as the ADDRy value. If this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, 0x0000 is saved in the general-purpose register. Occurrence of an ADDRy update failure can be determined by checking that the read data value is 0x0000.

45.3.8 A/D-Converted Value Addition/Average Mode

A/D-converted value addition/average mode can be used when A/D conversion of the analog input of the selected channels, the temperature sensor output, the internal reference voltage and VBATT 1/3 voltage monitor output is selected.

In A/D-converted value addition mode, the same channel is A/D-converted 1, 2, 3, 4, or 16 consecutive times, and the sum of the converted values is stored in the data register. The conversion count of the addition function can be set to 16 only when 12-bit accuracy is selected. In A/D-converted value average mode, the same channel is A/D-converted 2 or 4 consecutive times, and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that are present. This function, however, cannot always guarantee an improvement in A/D conversion accuracy.

The A/D-converted value addition/average function can be used when A/D conversion of the analog inputs of the selected channels or A/D conversion of the temperature sensor output or A/D conversion of the internal reference voltage or A/D conversion of the VBATT 1/3 voltage monitori output is selected. The A/D-converted value addition/average function can also be used for channels for which the double-trigger function is selected.

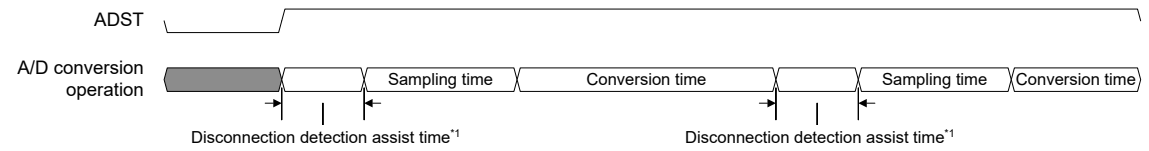
The addition function for self-diagnosis is not provided.

45.3.9 Disconnection Detection Assist Function

The ADC12 incorporates a function to fix the charge for sampling capacitance to the specified state (VREFH0 or VREFL0 for unit 0, VREFH or VREFL for unit 1) before the start of A/D conversion. This function enables disconnection detection in wiring of analog inputs.

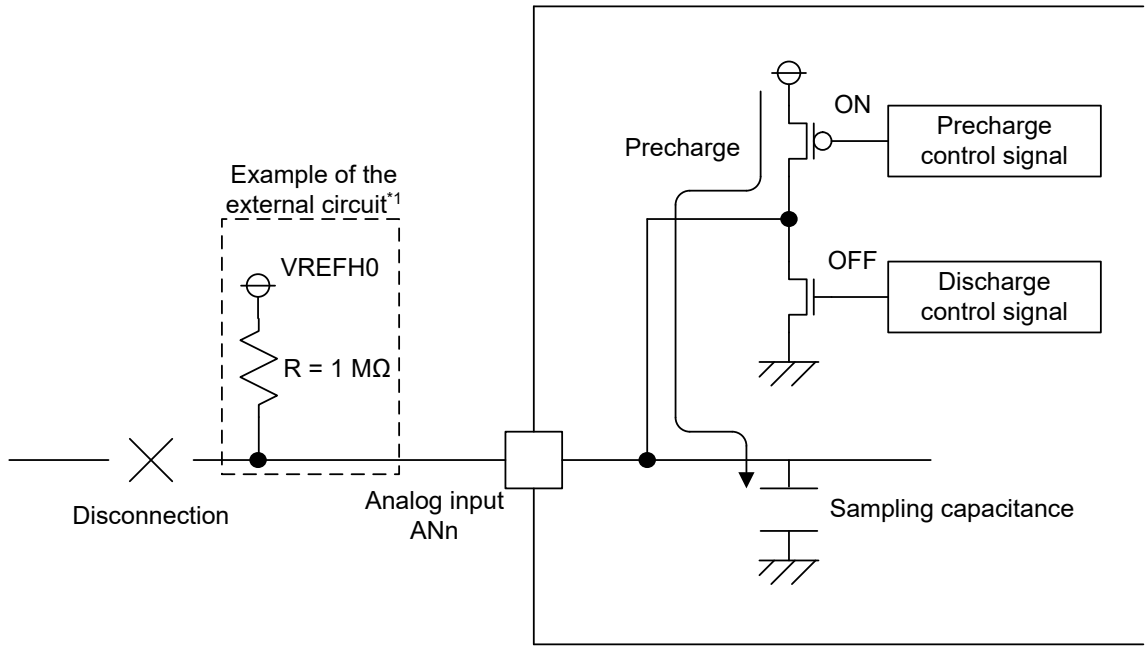
When using the disconnection detection assist function for the channel-dedicated sample-and-hold circuit, set the ADSHMSR.SHMD bit to 0 (select disable continuous sampling function).

Figure 45.38 shows the A/D conversion operation when the disconnection detection assist function is used. Figure 45.39 shows an example of disconnection detection when precharge is selected. Figure 45.40 shows an example of disconnection detection when discharge is selected.



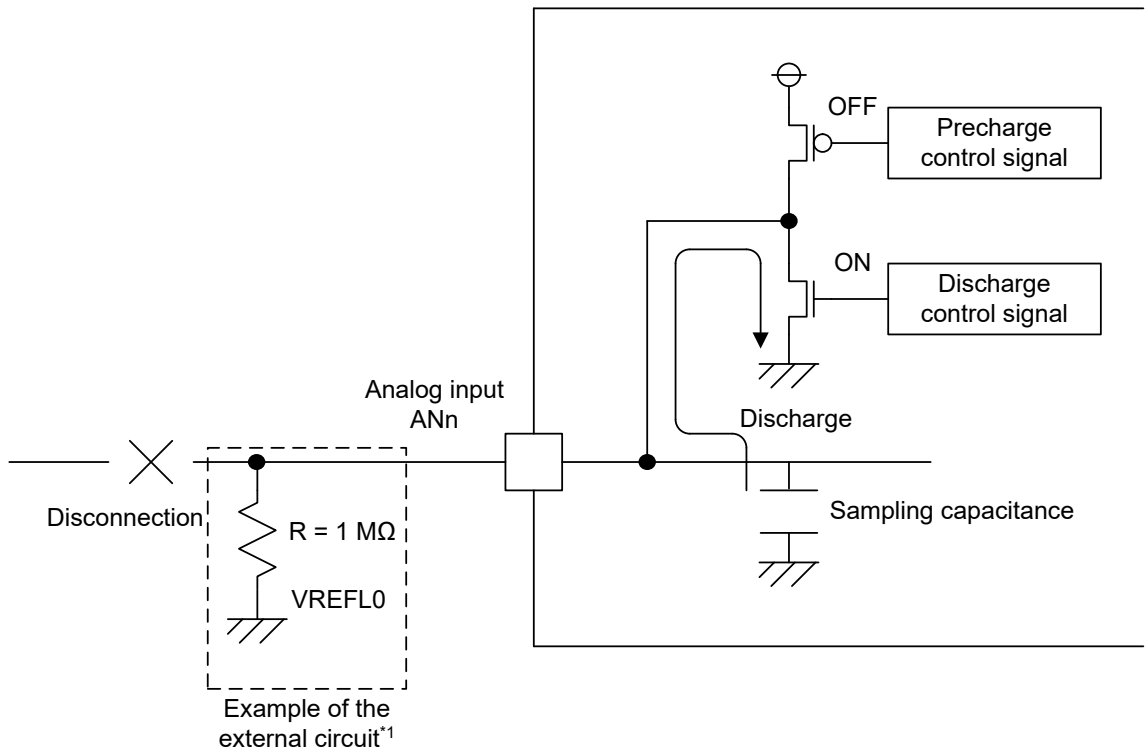
Note 1. 0 to 15 cycles of ADCLK

Figure 45.38 Operation of A/D conversion when disconnection detection assist function is used



Note 1. The converted result should be used after it is fully evaluated because the result data when disconnection occurs varies depending on the external circuit.

Figure 45.39 Example of disconnection detection when precharge is selected



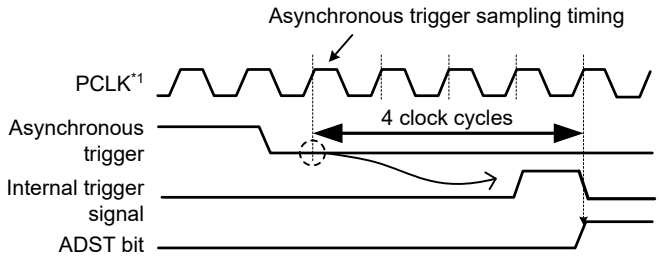
Note 1. The converted result should be used after it is fully evaluated because the result data when disconnection occurs varies depending on the external circuit.

Figure 45.40 Example of disconnection detection when discharge is selected

45.3.10 Starting A/D Conversion with an Asynchronous Trigger

A/D conversion can be started by the input of an asynchronous trigger. To start A/D conversion by an asynchronous trigger, set the pin function in the PmnPFS register, set the A/D Conversion Start Trigger Select bits (ADSTRGR.TRSA[5:0]) to 0x00, then input a high-level signal to the asynchronous trigger (ADTRGn (n = 0, 1) pin). Finally, set both the ADCSR.TRGE and ADCSR.EXTRG bits to 1. Figure 45.41 shows timing of the asynchronous trigger input.

An asynchronous trigger cannot be selected in the A/D conversion start trigger for group B used in group scan mode. For details on setting the pin function, see section 19, I/O Ports.



Note 1. PCLKA

Figure 45.41 Asynchronous trigger input timing

45.3.11 Starting A/D Conversion with a Synchronous Trigger from a Peripheral Module

A/D conversion can be started by a synchronous trigger (GPT, ELC). To do this, set the ADCSR.TRGE bit to 1 and the ADCSR.EXTRG bit to 0, and select the relevant sources in the ADSTRGR.TRSA[5:0] bits and ADSTRGR.TRSB[5:0] bits.

45.3.12 Security Attribution between ADCn (n = 0, 1) and PORT (PmSAR (m = 0 to 9, A, B))

Only when the security attribution of ADC12n (n = 0, 1) match the security attribution of PORT (PmSAR), the correspond analog input channel can be set for ADC conversion. Otherwise the conversion result is unexpected.

Table 45.29 shows the condition of ADC for each Security Attribution setting.

Table 45.29 Analog input pin conditions by security settings

Security Attribution setting*1		ADC input channel select	
ADC12n (n = 0, 1) security setting PSARD	PORT security setting PmSAR	ADANSA0/ADANSA1 ADANSB0/ADANSB1	Setting Combination result
0 (Secure)	0 (Secure)	1 (channel correspond bit)	Input Valid
1 (Non-secure)	1 (Non-secure)	1 (channel correspond bit)	Input Valid
1 (Non-secure)	0 (Secure)	1 (channel correspond bit)	Input invalid and the conversion result is unexpected
0 (Secure)	1 (Non-secure)	1 (channel correspond bit)	Input invalid and the conversion result is unexpected

Note 1. VBATT 1/3 voltage monitor output do not have the Security Attribution judgement function.

45.3.13 Using Data Buffers

A ring buffer function consisting of 16 A/D data buffers is available. This function sequentially stores A/D conversion results other than self-diagnosis result (including addition/average results) in data buffers (ADBUFn, n = 0 to 15).

Each conversion result is stored at the timing when the A/D conversion result is stored in the data register, and most recent 16 conversion result data are retained.

The figure-below shows the schematic of data buffers, pointer, and overflow flag operations. When the BUFEN bit is set to 1, the A/D conversion result is transferred at each end of A/D conversion. The pointer indicates the number of data buffer to which the next transferred data is to be written. When data is written to up to buffer 15, the pointer is reset to 0000b and the overflow flag is set to 1. Subsequently transferred data overwrites the previously written data.

The overflow flag is reset to the initial value by writing 0x00 to the ADBUFPTR register.

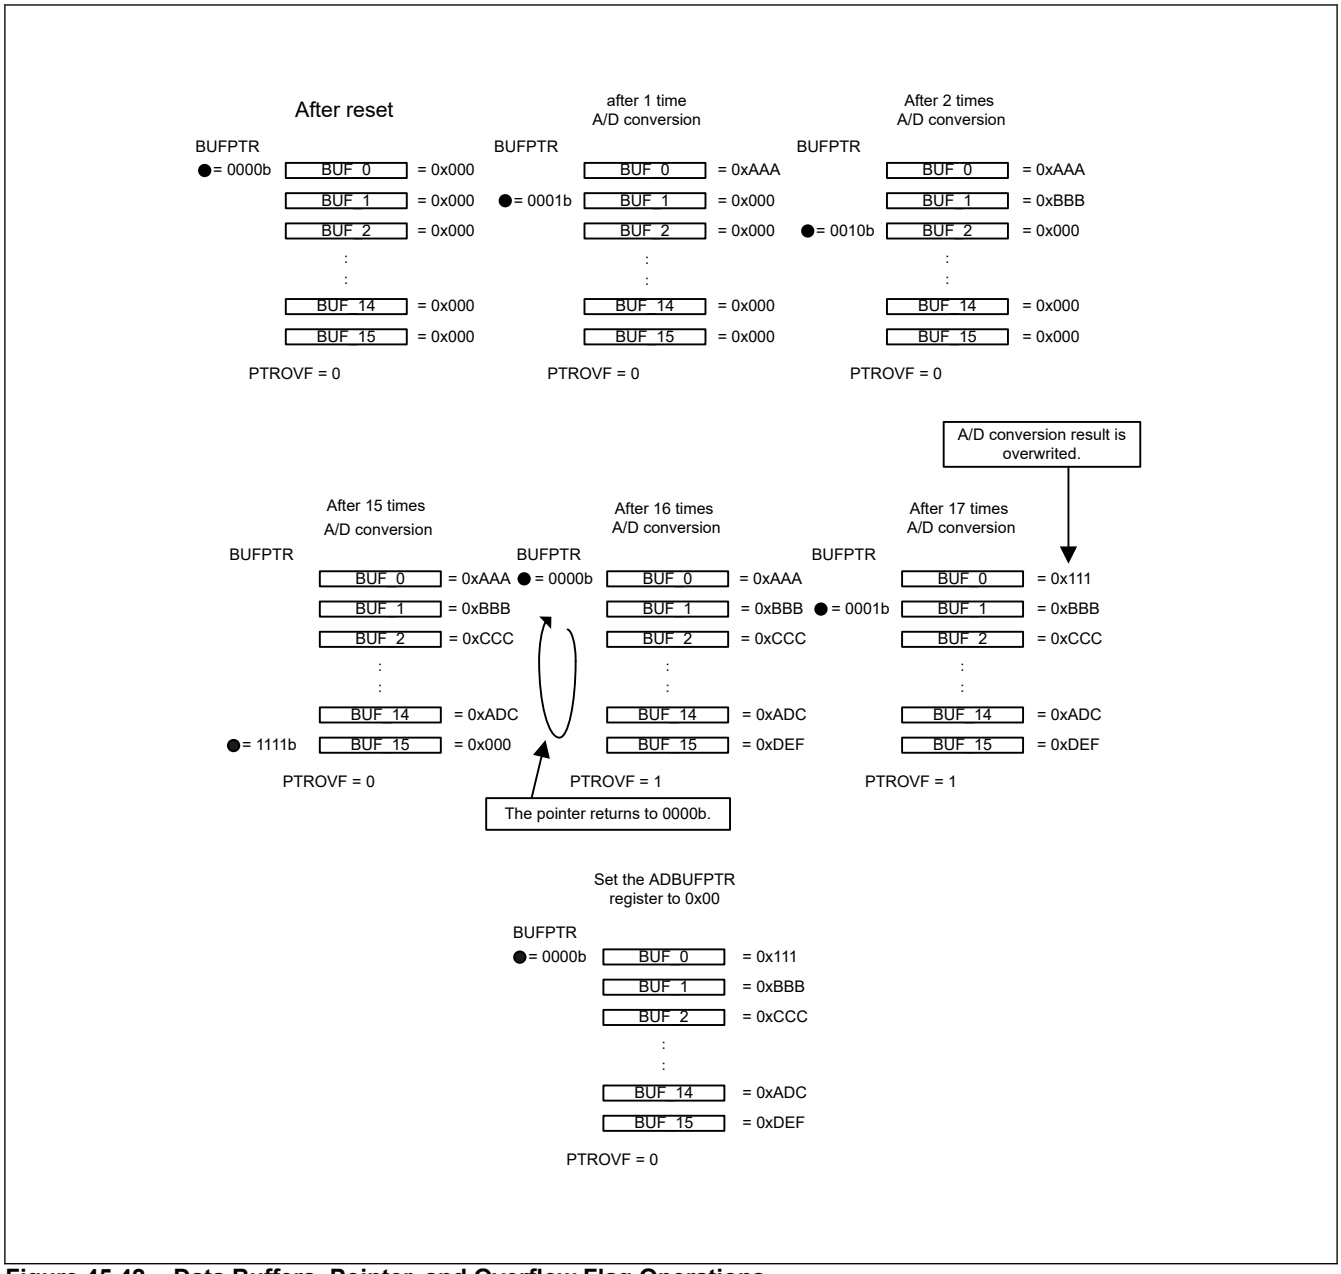


Figure 45.42 Data Buffers, Pointer, and Overflow Flag Operations

45.4 Interrupt Sources and DTC, DMAC Transfer Requests

45.4.1 Interrupt Requests

The ADC12 can send scan end interrupt requests ADC12i_ADI (i = 0, 1) and ADC12i_GBADI (i = 0, 1) to the CPU. The ADC12 also generates the ADC12i_CMPAI (i = 0, 1)/ADC12i_CMPBI (i = 0, 1) interrupt for the CPU in response to matches with a condition for comparison.

An ADC12i_ADI (i = 0, 1) interrupt is always generated. An ADC12i_GBADI (i = 0, 1) interrupt can be generated by setting the ADCSR.GBADIE bit to 1. Similarly, ADC12i_CMPAI (i = 0, 1) and ADC12i_CMPBI (i = 0, 1) interrupts can be generated by setting the ADCMPCR.CMPAIE and ADCMPCR.CMPBIE bit to 1.

In addition, the DTC or DMAC can be started when an ADC12i_ADI (i = 0, 1) or an ADC12i_GBADI (i = 0, 1) interrupt is generated. Using an ADC12i_ADI (i = 0, 1) or ADC12i_GBADI (i = 0, 1) interrupt to activate the DTC or DMAC to read the converted data enables continuous conversion without a burden on software.

Table 45.30 describes the interrupt sources and ELC events available for the ADC12.

Table 45.30 The interrupt source and ELC event of ADC12 (1 of 2)

Operation			Interrupt request or ELC event	Interrupt request	DTC or DMAC activation	ELC event request	Function
Scan mode	Double trigger mode	Compare function Window A/B					
Single scan mode	Deselected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of single scan
		Selected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of single scan
			ADC12i_CMPAI (i = 0, 1)	✓	—	—	ADC12i_CMPAI (i = 0, 1) generated on a match comparison condition of Window A
			ADC12i_CMPBI (i = 0, 1)	✓	—	—	ADC12i_CMPBI (i = 0, 1) generated on a match comparison condition of Window B
			ADC12i_WCMPM (i = 0, 1)	—	✓	✓	ADC12i_WCMPM (i = 0, 1) generated on a match condition of the Window A/B compare function
			ADC12i_WCMPUM (i = 0, 1)	—	✓	✓	ADC12i_WCMPUM (i = 0, 1) generated on a mismatch condition of the Window A/B compare function
	Selected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of scans in the even numbered times
Continuous scan mode	Deselected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of scan of all selected channels
		Selected	ADC12i_CMPAI (i = 0, 1)	✓	—	—	ADC12i_CMPAI (i = 0, 1) generated on a match comparison condition of Window A
			ADC12i_CMPBI (i = 0, 1)	✓	—	—	ADC12i_CMPBI (i = 0, 1) generated on a match comparison condition of Window B

Table 45.30 The interrupt source and ELC event of ADC12 (2 of 2)

Operation			Interrupt request or ELC event	Interrupt request	DTC or DMAC activation	ELC event request	Function
Scan mode	Double trigger mode	Compare function Window A/B					
Group scan mode	Deselected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of group A scan
			ADC12i_GBADI (i = 0, 1)	✓	✓	—	ADC12i_GBADI (i = 0, 1) dedicated to group B generated at the end of group B scan
		Selected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of group A scan
			ADC12i_GBADI (i = 0, 1)	✓	✓	—	ADC12i_GBADI (i = 0, 1) dedicated to group B generated at the end of group B scan
			ADC12i_CMPAI (i = 0, 1)	✓	—	—	ADC12i_CMPAI (i = 0, 1) generated on a match comparison condition of Window A
			ADC12i_CMPBI (i = 0, 1)	✓	—	—	ADC12i_CMPBI (i = 0, 1) generated on a match comparison condition of Window B
	Selected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of group A scans in the even-numbered times
			ADC12i_GBADI (i = 0, 1)	✓	✓	—	ADC12i_GBADI (i = 0, 1) dedicated to group B generated at the end of group B scan

Note: ✓ available
—: unavailable

For details on DTC settings, see section 17, Data Transfer Controller (DTC).

45.5 Event Link Function

45.5.1 Event Output to the ELC

The ELC uses the ADC12i_ADI (i = 0, 1) interrupt request signal as an event signal ADC12i_ADI (i = 0, 1), enabling link operation for the preset module. The ADC12i_GBADI (i = 0, 1) interrupt and ADC12i_CMPAI (i = 0, 1)/ADC12i_CMPBI (i = 0, 1) interrupts cannot be used as an event signal. For details, see Table 45.30.

An event signal can be output regardless of the settings of the corresponding interrupt request enable bits. For the scan end event(ADC12i_ADI (i = 0, 1)), a high-level pulse for one PCLKA cycle is output at the same output timing as the interrupt output (ADC12i_ADI (i = 0, 1)) shown in Table 45.30. For a compare function match (ADC12i_WCMPM (i = 0, 1)) and mismatch event (ADC12i_WCMPUM (i = 0, 1)) to the ELC, a high-level pulse for one PCLKA cycle is output at the timing delayed by one cycle (PCLKA) from the interrupt output (ADC12i_ADI (i = 0, 1)) shown in Table 45.30.

To use compare function match (ADC12i_WCMPM (i = 0, 1)) or mismatch event (ADC12i_WCMPUM (i = 0, 1)) to the ELC, specify single-scan mode.

45.5.2 ADC12 Operation through an Event from the ELC

The ADC12 can start A/D conversion by the preset event specified in the ELSRn settings for the ELC as follows:

- Select the ELC_AD00 (unit 0) signal in the ELC.ELSR8 register
- Select the ELC_AD01 (unit 0) signal in the ELC.ELSR9 register

- Select the ELC_AD10 (unit 1) signal in the ELC.ELSR10 register
- Select the ELC_AD11 (unit 1) signal in the ELC.ELSR11 register.

If an ELC event occurs during A/D conversion, the event is disabled.

45.6 Usage Notes

45.6.1 Constraints on Setting the Registers

Set each register while the ADCSR.ADST bit is 0.

45.6.2 Constraints on Reading the Data Registers

The following registers must be read in halfword units:

- A/D Data Registers
- A/D Data Duplexing Register
- A/D Data Duplexing Register A
- A/D Data Duplexing Register B
- A/D Temperature Sensor Data Register
- A/D Internal Reference Voltage Register
- A/D VBATT monitor Data Register
- A/D Self-Diagnosis Data Register
- A/D Data Buffer Registers n (N = 0 to 15)

If a register is read twice in byte units, that is, the upper byte and lower byte are read separately, the A/D-converted value read initially might disagree with the A/D-converted value read subsequently. To prevent this, never read the data registers in byte units.

45.6.3 Constraints on Stopping A/D Conversion

(1) A/D Conversion Stop Procedure

To stop A/D conversion when an asynchronous trigger or a synchronous trigger is selected as the condition for starting A/D conversion, follow the procedure shown in Figure 45.43.

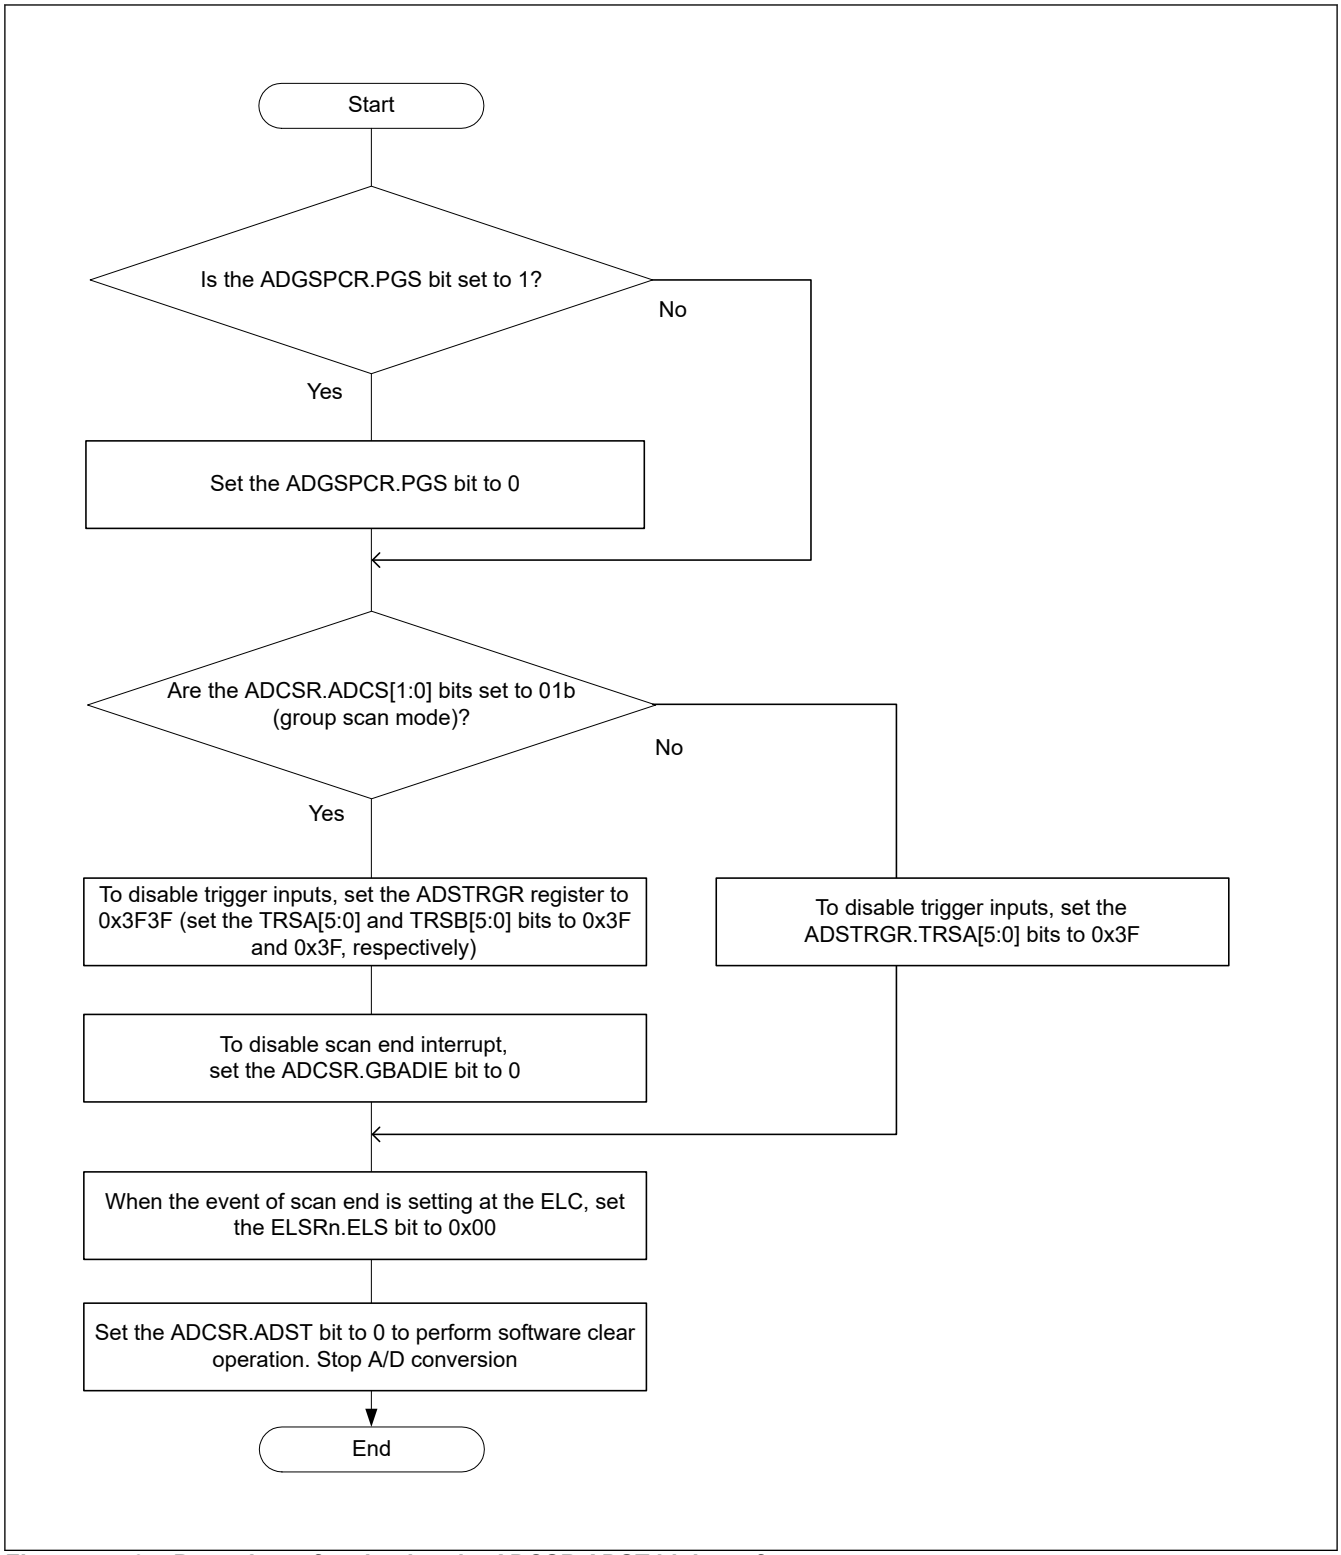

Figure 45.43 Procedures for clearing the ADCSR.ADST bit by software

To specify the following settings after performing the clear operation by software, provide a wait period for at least two ADCLK cycles.

- Enabling scan end interrupts
- Enabling scan end events for the event link controller
- Starting A/D conversion by software
- Enabling trigger input

(2) Notes on Modes and Status Bits

If necessary, individually initialize or set again the voltage status for self-diagnosis, the judgment of the even number or odd number specified for double-trigger mode, and the monitor flags of the compare function.

- To set again the voltage status for self-diagnosis, set the ADCER.DIAGLD bit to 1 and then set a desired value in the ADCER.DIAGVAL[1:0] bits.
- If the setting of the ADCSR.DBLE bit is changed from 0 to 1, the double-trigger mode operation starts from the first scanning.
- To initialize the monitor flags of the compare function (MONCMPA, MONCMPB, and MONCOMB), set the ADCMPCR.CMPAE and ADCMPCR.CMPBE bits to 0.
- To initialize the data storage buffer pointer, set the ADBUFPTR register to "0x00".
- To initialize the continuous sampling function (ADSHMSR.SHMD = 1), set ADSHMSR.SHMD to "0". To use the continuous sampling function again after initialization, set ADSHMSR.SHMD to "1" after waiting for 1 cycle of ADCLK or longer.

45.6.4 A/D Conversion Restart and Termination Timing

A maximum of 6 ADCLK cycles is required for the idle analog unit of the ADC12 to restart on setting the ADCSR.ADST bit to 1. A maximum of 2 ADCLK cycles is required for the operating analog unit of the ADC12 to terminate on setting the ADCSR.ADST bit to 0. A maximum of 1 PCLKA + 1 ADCLK cycles is required for the operating analog unit of the ADC12 to terminate on setting the ADCSR.ADST bit to 0 when PCLKA to ADCLK frequency ratio is 1:2 or 1:4.

45.6.5 Constraints on Scan End Interrupt Handling

When scanning the same analog input twice using any trigger, the first A/D-converted data is overwritten with the second A/D-converted data. This occurs when the CPU does not complete the reading of the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated.

45.6.6 Settings for the Module-Stop Function

The Module Stop Control Register can enable or disable ADC12 operation. The ADC12 is initially stopped after a reset. The registers become accessible on release from the module-stop state. After release from the module-stop state, wait for at least 1 µs before starting A/D conversion. For details, see section 10, Low Power Modes.

45.6.7 Notes on Entering the Low-Power States

Before entering the module-stop state or Software Standby mode, be sure to stop A/D conversion. Set the ADCSR.ADST bit to 0 and secure certain period until the analog unit of the ADC12 stops. Follow the procedure shown in Figure 45.43 to clear the ADCSR.ADST bit with software. Then, wait for 2 clock cycles of ADCLK before entering the module-stop state or Software Standby mode.

45.6.8 Notes on Canceling Software Standby Mode

After software standby mode is canceled, wait at least 1 µs after the stabilization time for the oscillator elapses and before starting A/D conversion. For details, see section 10, Low Power Modes

45.6.9 Error in Absolute Accuracy When Disconnection Detection Assistance Is in Use

Using disconnection detection assistance leads to an error in absolute accuracy of the ADC12. This error arises because an erroneous voltage is input to the analog input pins due to the resistive voltage division between the pull-up or pull- down resistor (Rp) and the resistance of the signal source (Rs). This error in absolute accuracy is calculated from the following formula:

$$\text{Maximum error in absolute accuracy (LSB)} = \left(2^{\text{Resolution}} - 1\right) \times \text{Rs} / \left(\text{Rs} + \text{Rp}\right)$$

Only use disconnection detection assistance after thorough evaluation.

45.6.10 Constraints on Operating Modes and Status Bits

Initialize or set again individually, if necessary, the voltage values in self-diagnosis, the value of the first scan or second scan in double trigger mode, the data buffer pointer, and status monitor in the compare function.

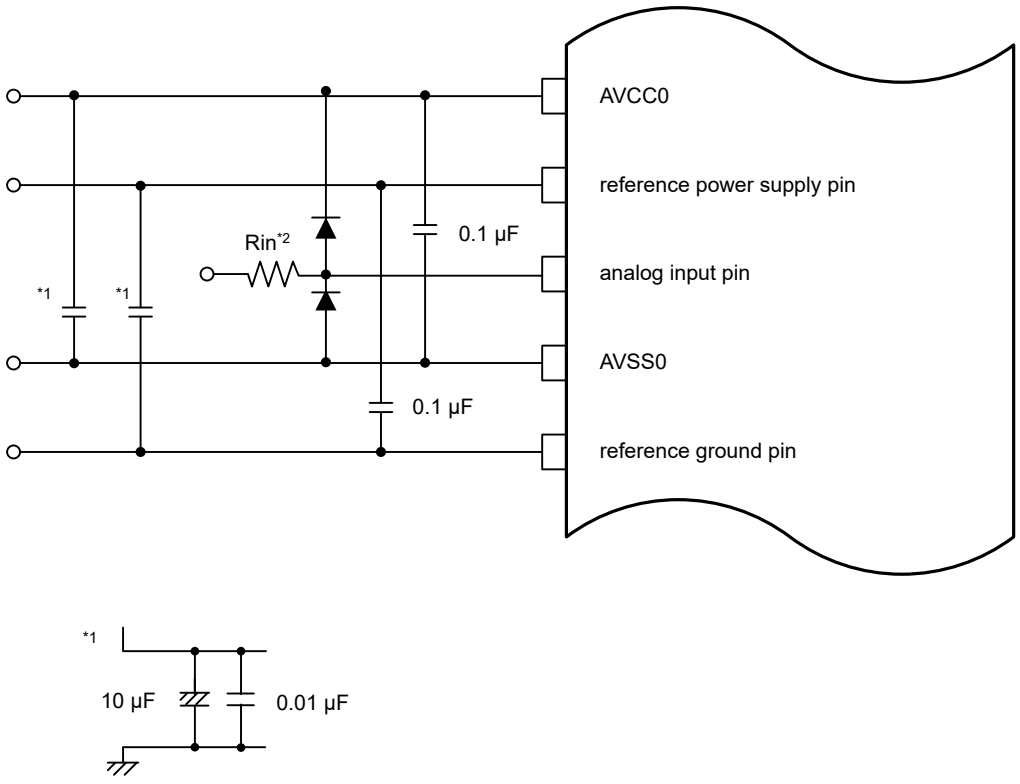
- Select the voltage values in self-diagnosis (ADCER.DIAGVAL[1:0]) after setting ADCER.DIAGLD to 1.
- Double-trigger mode operates as the first scan after setting ADCSR.DBLE from 0 to 1.
- The status monitor bits (MONCMPA, MONCMPB, MONCOMB) in the compare function are initialized after setting ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0.

45.6.11 Notes on Board Design

The board should be designed so that digital circuits and analog circuits are separated from each other as far as possible. In addition, digital circuit signal lines and analog circuit signal lines should not intersect or be placed near each other. If these rules are not followed, noise can occur on analog signals and A/D conversion accuracy is affected. The analog input pins, reference power supply pin (VREFH0, VREFH), reference ground pin (VREFL0, VREFL), and analog power supply (AVCC0) should be separated from digital circuits using the analog ground (AVSS0). The analog ground (AVSS0) should be connected to a stable digital ground (VSS) on the board (single-point ground plane connection).

45.6.12 Constraints on Noise Prevention

To prevent the analog input pins from being destroyed by abnormal voltage such as excessive surge, insert a capacitor between AVCC0 and AVSS0 and between VREFH0 and VREFL0 and between VREFH and VREFL. Additionally, connect a protection circuit to protect the analog input pins as shown in Figure 45.44.



Note 1. The values shown here are reference values.
Note 2. Rin: Signal source impedance

Figure 45.44 Example protection circuit for analog inputs

45.6.13 Port Settings When Using the ADC12 Input

When using the high-precision channels, do not use PORT0 as general I/O. Renesas recommends that you do not use the digital output that is also used as the AD analog input if normal-precision channel is used. If the digital output that is also used as the AD analog input is used for output signals, perform A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results.

45.6.14 Relationship between ADC12 Units 0 and 1 and the ACMPHS

For the A/D conversion targets in Table 45.31, unit 0 and 1 cannot perform A/D conversion at the same time.

Table 45.31 A/D conversion targets that are mutually exclusive with each other

A/D conversion target	
Unit0	**Unit1**
Temperature sensor	
Internal reference voltage	
VBATT 1/3 voltage monitor output	
AN016	AN116
AN017	AN117
AN018	AN118
AN019	AN119

The A/D conversion targets in Table 45.32 should not be selected as ACMPHS input during A/D conversion, because these pins are multiplexed with the ADC12 and ACMPHS.

Table 45.32 A/D conversion targets that are mutually exclusive with ACMPHS

A/D conversion target		
Unit0	**Unit1**	**ACMPHS**
AN000	-	ACMPHS0.IVCMP2
AN002	-	ACMPHS0.IVCMP3
AN005	-	ACMPHS0.IVCMP0
AN007/DA0	-	ACMPHS0.IVREF3
AN016	AN116	ACMPHS1.IVCMP0
Internal reference voltage	-	ACMPHS0.IVREF2
-	AN100	ACMPHS1.IVCMP2
-	AN101	ACMPHS1.IVREF0
-	AN102	ACMPHS1.IVCMP3
-	AN104	ACMPHS1.IVREF1
-	AN105/DA1	ACMPHS1.IVCMP1
-	Internal reference voltage	ACMPHS1.IVREF2

45.6.15 Calculation for Sampling Time

The sampling time can be easily estimated by the following figure and formula. This is the time to reach the voltage within 1/4 LSB.

$$t_{SPL} = (R_{EXT} + R_{AD}) \times (C_{EXT} + C_{AD}) \times \ln (C_{AD} / (C_{EXT} + C_{AD}) \times 2^{N+2})$$

R_{EXT} shows external signal source impedance
C_{EXT} shows external capacitance (pin capacitance*1 + PCB parasitic capacitance)
N = 12, 10 or 8 (conversion resolution)
C_{AD} = 5 pF (internal capacitance)
R_{AD} = 1.0 kΩ (internal resistance, case of high-speed channels)
R_{AD} = 2.0 kΩ (internal resistance, case of normal-speed channels)

Note 1. Typical value of analog input pin is 5 pF

For example, if R_{EXT} is 1 kΩ, C_{EXT} is 10 pF and N is 12 bits, t_{SPL} of high-speed channel is 258 ns.

This formula simplifies the general use case. This formula is not guaranteed and should be used only for estimation.

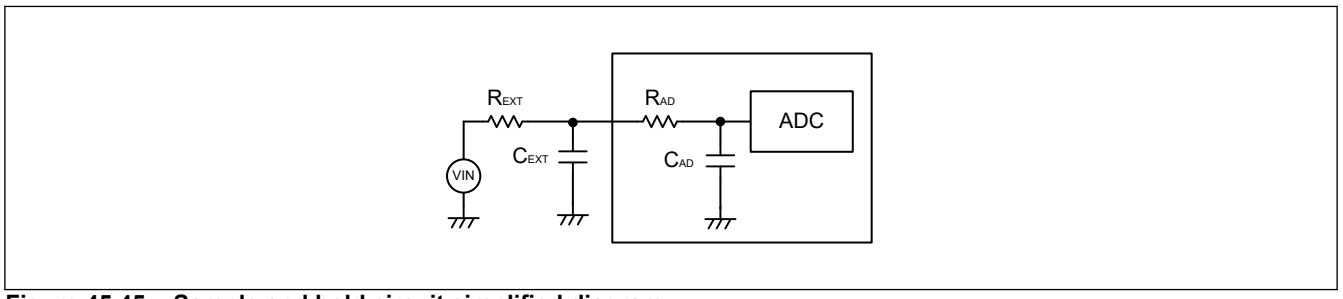


Figure 45.45 Sample and hold circuit simplified diagram

45.6.16 Notes on simultaneous operation with other modules

The following combinations may degrade the ADC accuracy depending on the specific timing of operation.

1. AN000 without channel-dedicated sample-and-hold and AN104 mutually.
2. AN007 and AN105 mutually.
3. Normal-precision channel of unit 0 and 1 mutually when these pins are adjacent or one pin apart.
4. AN000 to AN002 using channel-dedicated sample-and-hold when ADC unit 1, DAC12 or ACMPHS is operated.
5. High-precision channels of ADC unit1 when AN000 to AN002 using channel-dedicated sample-and-hold are operated.
6. AN019 when DAC12 or ACMPHS is operated.
7. AN119 to AN122 when DAC12 is operated in DCDC mode.
8. All channels of ADC unit 1 when ACMPHS is operated.
9. All channels of ADC unit 1 when DAC12 is operated.

To mitigate deterioration, it is recommended to take following measures.

- Performing A/D conversion with average mode.
- For even better results, performing A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results. (For the condition No.4, only performing average mode may not be effective depending on the noise. Eliminating the maximum and minimum is recommended.)
- For the condition No.9, using DA AD synchronous conversion set by DAADSCR.DAADST and DAADUSR.AMADSEL1 bits of DAC12.

Depending on the environment, ADC accuracy may be deteriorated even under conditions not listed here.

46. 12-Bit D/A Converter (DAC12)

46.1 Overview

The MCU provides a 12-bit D/A Converter (DAC12) with an output amplifier. Table 46.1 lists the DAC12 specifications, Figure 46.1 shows a block diagram, and Table 46.2 lists the I/O pins.

Table 46.1 DAC12 specifications

Parameter	Specifications
Resolution	12 bits
Output channels	2 channels
Interference reduction between analog modules	Methods provided to minimize interference between D/A and A/D conversion: • D/A converted data update timing is controlled by the synchronous D/A conversion enable input signal from the ADC12 (unit 1) • Degradation of A/D conversion accuracy caused by interference is reduced by controlling the DAC12 inrush current generation timing with the enable signal.
Module-stop function	Module-stop state can be set to reduce power consumption
Event link function (input)	The DA0 and DA1 conversion can be started on input of an event signal
D/A output amplifier control function	Controls whether the output amplifier (for both amplifier-through and amplifier-bias controls) is used
Destination of D/A output control function	Controls whether the output to the external pin or to the internal modules (ACMPHS) is used
TrustZone Filter	Security and Privilege attribution can be set

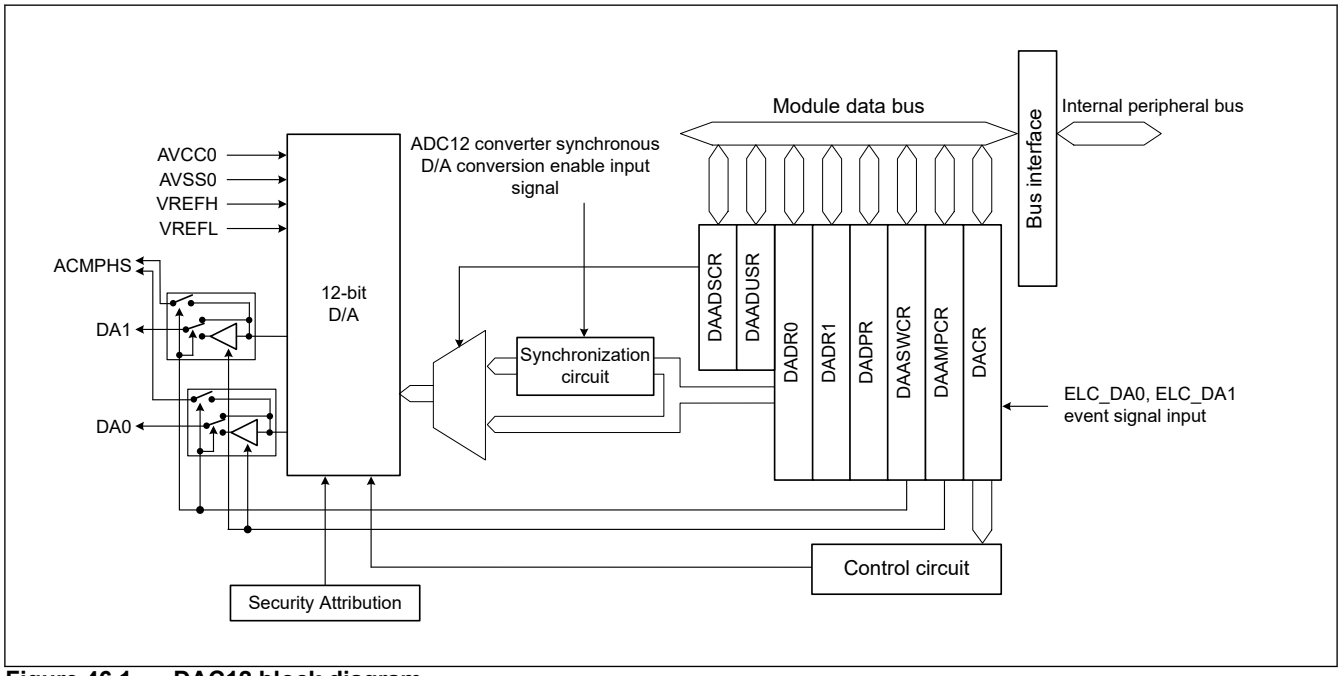

Figure 46.1 DAC12 block diagram

Table 46.2 lists the pin configuration of the DAC12.

Table 46.2 DAC12 I/O pins (1 of 2)

Pin name	I/O	Function
AVCC0	Input	• Analog power and analog reference top voltage supply pin for ADC12 and DAC12. • Connect to VCC when these modules are not used.
AVSS0	Input	• Analog ground and analog reference ground supply pin for ADC12 and DAC12. • Connect to VSS when these modules are not used.
VREFH	Input	Analog reference top voltage supply pin for the ADC12 (unit 1) and the DAC12

Table 46.2 DAC12 I/O pins (2 of 2)

Pin name	I/O	Function
VREFL	Input	Analog reference ground pin for the ADC12 (unit 1) and the DAC12
DA0	Output	Channel 0 output pin for the analog signals processed by the DAC12
DA1	Output	Channel 1 output pin for the analog signals processed by the DAC12

46.2 Register Descriptions

46.2.1 DADRn : D/A Data Register n (n = 0, 1)

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x00 + 0x02 × n

Bit position:	15															0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: S-TYPE-3, P-TYPE-3

DADRn register is 16-bit read/write registers that store data for D/A conversion. When an analog output is enabled, the values in DADRn are converted and output to the analog output pins.

12-bit data can be formatted as left- or right-justified in the DADPR.DPSEL bit setting. In right-justified format (DADPR.DPSEL = 0), the lower 12 bits, [11:0], are valid. In left-justified format (DADPR.DPSEL = 1), the upper 12 bits, [15:4], are valid.

46.2.2 DACR : D/A Control Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DAOE1	DAOE0	DAE	—	—	—	—	—
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Function	R/W
4:0	—	These bits are read as 1. The write value should be 1.	R/W
5	DAE*1	D/A Enable 0: Control D/A conversion of channels 0 and 1 individually 1: Control D/A conversion of channels 0 and 1 collectively	R/W
6	DAOE0	D/A Output Enable 0 0: Disable analog output of channel 0 (DA0) 1: Enable D/A conversion of channel 0 (DA0)	R/W
7	DAOE1	D/A Output Enable 1 0: Disable analog output of channel 1 (DA1) 1: Enable D/A conversion of channel 1 (DA1)	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. This bit controls D/A conversion in combination with the DAOEi bit (i = 0, 1), which controls the output of the conversion results. For details, see Table 46.3.

Table 46.3 D/A conversion controls

DAE	DAOE1	DAOE0	Description
0	0	0	Disable D/A conversion and analog output pins (DA0, DA1)*1
		1	• Enable D/A conversion of channel 0 and disable D/A conversion of channel 1 • Enable analog output of channel 0 (DA0) and disable analog output of channel 1 (DA1)*1
	1	0	• Disable D/A conversion of channel 0 and enable D/A conversion of channel 1 • Disable analog output of channel 0 (DA0)*1 and enable analog output of channel 1 (DA1)
		1	• Enable D/A conversion of channels 0 and 1 • Enable analog output of channels 0 and 1 (DA0, DA1)
1	x	x	• Enable D/A conversion of channels 0 and 1 • Collective enable analog output of channels 0 and 1 (DA0, DA1)

Note: x: Don't care
Note 1. When analog output is disabled, the analog output signal is placed in the Hi-Z state.

Only set this register while the ADC12 is halted when the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled). Only set DACR while the ADCSR.ADST bit is 0 and after selecting the software trigger, for the ADC12 trigger to securely stop the ADC12. This MCU only supports ADC12 (unit 1).

DAE bit (D/A Enable)

The DAE bit controls D/A conversion, amplifier operation, and analog output in combination with the DAOEi bit (i = 0, 1) , the DAAMPCR.DAAMPi bit (i = 0, 1) and the DAASWCR.DAASWi bit (i = 0, 1). See Table 46.4.

When interference reduction between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the ADCSR.ADST bit of the ADC12 (unit 1) to 0. Then, select the software trigger for the ADC12 (unit 1) trigger to securely stop the ADC12 (unit 1).

DAOEi bit (D/A Output Enable i)

The DAOEi bit (i = 0, 1) controls D/A conversion, amplifier operation, and analog output in combination with the DAE bit, DAAMPCR.DAAMPi bit (i = 0, 1) and the DAASWCR.DAASWi bit (i = 0, 1). See Table 46.4.

When both the DAOEi bit (i = 0, 1) and DAE bit are 0, D/A conversion of channel i (i = 0, 1) is not processed, and no conversion result is output.

When interference reduction between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the DAOEi bit while the ADCSR.ADST bit of the ADC12 (unit 1) is set to 0. Then, select the software trigger for the ADC12 (unit 1) trigger to securely stop the ADC12 (unit 1).

The event link function can be used to set the DAOEi bit to 1. The DAOE0 bit is set to 1 when the event specified in the ELSR12 register of the ELC (ELC_DA0 event) occurs, and output of the D/A conversion results starts. The DAOE1 bit is set to 1 when the event specified in the ELSR13 register of the ELC (ELC_DA1 event) occurs, and output of the D/A conversion results starts.

Table 46.4 D/A conversion and analog output control

DACR		DAAMPCR	DAASWCR	Channel i operation	Amplifier operation of channel i	Analog external output of channel i*1	Analog internal output of channel i*2
DAE	DAOEi	DAAMPi	DAASWi				
0	0	x	x	Stop	Stop	Hi-Z	Hi-Z
0	1	0	0	Run	Stop	Amplifier-through	Hi-Z
0	1	0	1	Run	Stop	Hi-Z	Amplifier-through
0	1	1	0	Run	Run	Amplifier output	Hi-Z
0	1	1	1	Run	Run	Hi-Z	Hi-Z
1	x	0	0	Run	Stop	Amplifier-through	Hi-Z
1	x	0	1	Run	Stop	Hi-Z	Amplifier-through
1	x	1	0	Run	Run	Amplifier output	Hi-Z
1	x	1	1	Run	Run	Hi-Z	Hi-Z

Note: x : Don't care
Note 1. output to pin
Note 2. output to ACMPHS

46.2.3 DADPR : DADRn Format Select Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DPSEL	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0. The write value should be 0.	R/W
7	DPSEL	DADRn Format Select 0: Right-justified format 1: Left-justified format	R/W

Note: S-TYPE-3, P-TYPE-3

46.2.4 DAADSCR : D/A A/D Synchronous Start Control Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x06

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DAADST	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0. The write value should be 0.	R/W
7	DAADST	D/A A/D Synchronous Conversion 0: Do not synchronize DAC12 with ADC12 (unit 1) operation (disable interference reduction between D/A and A/D conversion). 1: Synchronize DAC12 with ADC12 (unit 1) operation (enable interference reduction between D/A and A/D conversion).	R/W

Note: S-TYPE-3, P-TYPE-3

To minimize interference between D/A and A/D conversion, the DAADSCR register enables synchronization of the start timing of D/A conversion with the ADC12 synchronous D/A conversion enable input signal.

Only set this register while the ADC12 (unit 1) is halted, that is, while the ADCSR.ADST bit is 0 after selecting the software trigger as the ADC12 (unit 1) trigger.

Select unit 1 as the target ADC12 unit before setting the DAADST bit to 1. Set DAADUSR.AMADSEL1 bit to 1 to select unit 1. This MCU only supports ADC12 unit 1.

DAADST bit (D/A A/D Synchronous Conversion)

Setting the DAADST bit to 0 allows the DADRn register value to be converted into analog data at any time. Setting the DAADST bit to 1 allows synchronization of D/A conversion with the synchronous D/A conversion enable input signal from the ADC12 (unit 1). With this bit set, D/A conversion does not start until the ADC12 (unit 1) completes A/D conversion, even when the DADRn register is changed.

Set this bit while the ADCSR.ADST bit is set to 0. Then, select the software trigger for the ADC12 (unit 1) trigger to securely stop the ADC12 (unit 1). Set the DAADUSR.AMADSEL1 bit to 1 before setting the DAADST bit to 1.

The event link function cannot be used when the DAADST bit is set to 1. Stop the event link function by setting the ELSR12 and ELSR13 registers of the ELC. The setting of the DAADST bit is shared by channels 0 and 1 of the DAC12.

46.2.5 DAAMPCR : D/A Output Amplifier Control Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DAAMP1	DAAMP0	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	DAAMP0	Amplifier Control 0 0: Do not use channel 0 output amplifier 1: Use channel 0 output amplifier	R/W
7	DAAMP1	Amplifier Control 1 0: Do not use channel 1 output amplifier 1: Use channel 1 output amplifier	R/W

Note: S-TYPE-3, P-TYPE-3

The DAAMPCR register selects D/A output with or without using the amplifier.

DAAMP0 bit (Amplifier Control 0)

When the DAAMP0 bit is 0, analog values are output for D/A output of channel 0 without using the amplifier. When the DAAMP0 bit is 1, analog values are output for D/A output of channel 0 through the amplifier.

When both the DACR.DAE and DACR.DAOE0 bits are 0, the amplifier is not used regardless of the setting of the DAAMP0 bit. See Table 46.4 for details.

DAAMP1 bit (Amplifier Control 1)

When the DAAMP1 bit is 0, analog values are output for D/A output of channel 1 without using the amplifier. When the DAAMP1 bit is 1, analog values are output for D/A output of channel 1 through the amplifier.

When both the DACR.DAE and DACR.DAOE1 bits are 0, the amplifier is not used regardless of the setting of the DAAMP1 bit. See Table 46.4 for details.

46.2.6 DAASWCR : D/A Amplifier Stabilization Wait Control Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x1C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DAASW1	DAASW0	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	DAASW0	D/A Amplifier Stabilization Wait 0 and D/A internal output control 0: For output to external pin: Amplifier stabilization wait off (output) for channel 0 For output to internal module: Disable output for channel 0 1: For output to external pin: Amplifier stabilization wait on (high-Z) for channel 0 For output to internal module: Enable output for channel 0	R/W

Bit	Symbol	Function	R/W
7	DAASW1	D/A Amplifier Stabilization Wait 1 and D/A internal output control 0: For output to external pin: Amplifier stabilization wait off (output) for channel 1 For output to internal module: Disable output for channel 1 1: For output to external pin: Amplifier stabilization wait on (high-Z) for channel 1 For output to internal module: Enable output for channel 1	R/W

Note: S-TYPE-3, P-TYPE-3

The DAASWCR register controls D/A output with the output amplifier or D/A output for internal modules. This register is used in the initialization procedure to wait for stabilization of the D/A output amplifier. Each bit in DAASWCR should be set to 1 when both the DACR.DAE bit and the DACR.DAOEi (i = 0, 1) bit are 0. See section 46.7.5. Initialization Procedure with the Output Amplifier.

DAASW0 bit (D/A Amplifier Stabilization Wait 0)

Set the DAASW0 bit to 1 in the initialization procedure to wait for the stabilization of the D/A channel 0 output amplifier. When DAASW0 is set to 1, D/A conversion operates, but the conversion result of D/A is not output from channel 0 to the DA0 pin. When the DAASW0 bit is 0, the stabilization wait time stops, and the D/A conversion result of channel 0 is output through the output amplifier to the DA0 pin. When the amplifier is not used (DAAMPCR.DAAMP0 bit is 0) and DAASW0 is set to 1, D/A conversion result of channel 0 is output to the internal modules.

DAASW1 bit (D/A Amplifier Stabilization Wait 1)

Set the DAASW1 bit to 1 in the initialization procedure to wait for the stabilization of the D/A channel 1 output amplifier. When DAASW1 is set to 1, D/A conversion operates, but the conversion result of D/A is not output from channel 1 to the DA1 pin. When the DAASW1 bit is 0, the stabilization wait time stops, and the D/A conversion result of channel 1 is output through the output amplifier to the DA1 pin. When the amplifier is not used (DAAMPCR.DAAMP1 bit is 0) and DAASW1 is set to 1, D/A conversion result of channel 1 is output to the internal modules.

46.2.7 DAADUSR : D/A A/D Synchronous Unit Select Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x10C0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	AMADSEL1	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	AMADSEL1	A/D Unit 1 Select 0: Do not select unit 1 1: Select unit 1	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The DAADUSR register selects the target ADC12 unit for D/A and A/D synchronous conversions. Set the AMADSEL1 bit to 1 to select unit 1 as the target synchronous unit for the MCU. When setting the DAADSCR.DAADST bit to 1 for synchronous conversions, select the target unit in this register in advance.

Only set the DAADUSR register while the ADCSR.ADST bit of the ADC12 is set to 0 and the DAADSCR.DAADST bit is set to 0.

46.3 Operation

The DAC12 includes D/A conversion circuits for two channles, each of which can operate independently. When the DAOEn bit (n = 0, 1) in DACR is set to 1, DAC12 is enabled and the conversion result is output.

This following example shows D/A conversion on channel 0. Figure 46.2 shows the timing of this operation.

To process D/A conversion on channel 0:

1. Set the data for D/A conversion in the DADR0 register and the data format in the DADPR.DPSEL bit.
2. Set the DACR.DAOE0 bit to 1 to start D/A conversion. The conversion result is output from the analog output pin DA0 after the conversion time t_{DCONV} elapses. The conversion result continues to be output until DADR0 is written to again or the DAOE0 bit is set to 0. The output value (reference) is expressed by the following formula:

$$\frac{\text{Setting in DADR0}}{4096} \times \text{VREFH}$$

3. To start conversion again, write another value to DADR0. The conversion result is output after the conversion time t_{DCONV} elapses.
   When the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled), a maximum of one A/D conversion time is required for D/A conversion to start. When ADCLK is faster than the peripheral clock, a longer time might be required.
4. To disable analog output, set the DAOE0 bit to 0.

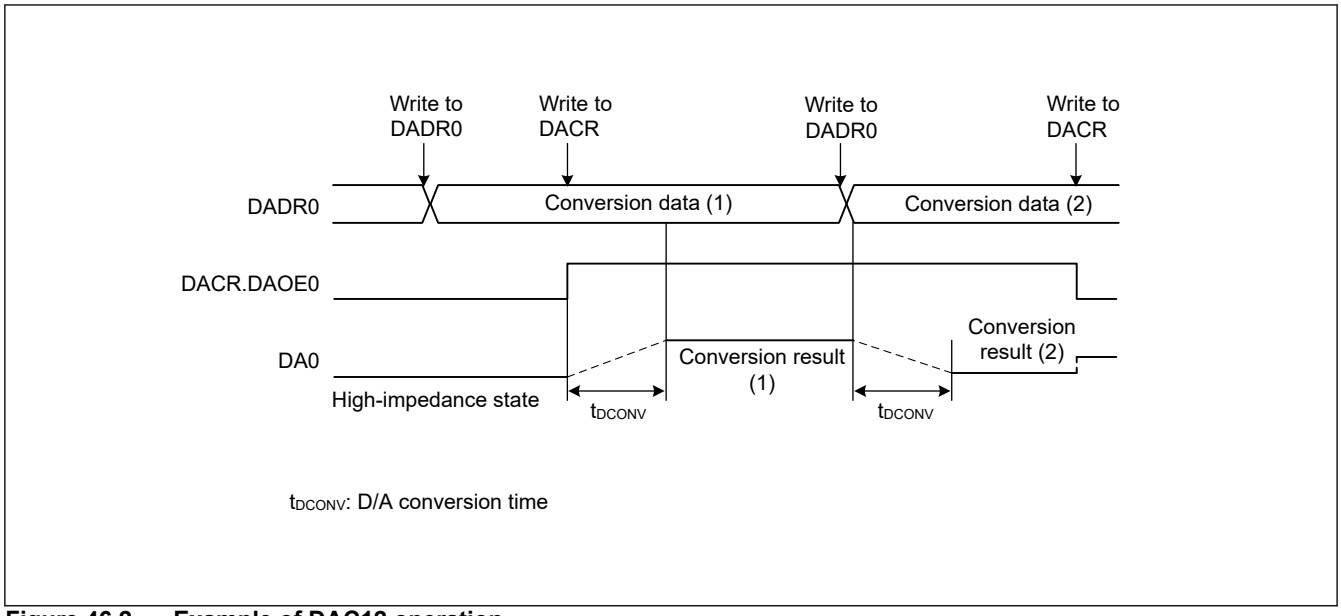

Figure 46.2 Example of DAC12 operation

46.3.1 Reducing Interference between D/A and A/D Conversion

When D/A conversion starts, the DAC12 generates inrush current. Because the DAC12 and ADC12 (unit 1) share the same analog power supply, the generated inrush current can interfere with ADC12 (unit 1) operation.

While the DAADSCR.DAADST bit is 1, D/A conversion does not start immediately on updating the DADRm register. Instead:

- If the DADRm register data is modified while the ADC12 is halted, D/A conversion starts in 1 PCLKA cycle.
- If the DADRm register data is modified while the ADC12 is performing a 12-bit A/D conversion, D/A conversion starts on A/D conversion completion. Therefore, it takes up to one A/D conversion time period for the DADRm register data update to be reflected as the D/A conversion circuit output. Until the D/A conversion completes, the DADRm register value does not correspond to the analog output value.

When the DAADSCR.DAADST bit is 1, it is not possible to check through software whether the DADRm register value was D/A-converted.

The following sequence provides an example of channel 0 D/A conversion, in which the DAC12 is synchronized with the ADC12 (unit 1). Figure 46.3 shows the timing of this operation.

To perform D/A conversion on channel 0 in synchronization with the ADC12 (unit 1):

1. Confirm that the ADC12 (unit 1) is halted and set the DAADUSR.AMADSEL1 bit to 1.

2. Confirm that the ADC12 (unit 1) is halted and set the DAADSCR.DAADST bit to 1.
3. Confirm that the ADC12 (unit 1) is halted and set the DACR.DAOE0 bit to 1.
4. Set the DADR0 register. If ADCLK is faster than the peripheral clock, D/A conversion might be delayed for longer than one A/D conversion time.
   - If the ADC12 (unit 1) is halted (ADCSR.ADST = 0) when the DADR0 register is modified, D/A conversion starts in 1 PCLKA cycle.
   - If the 12-bit A/D conversion is in progress (ADCSR.ADST = 1) when the DADR0 register is modified, D/A conversion starts on A/D conversion completion. If the DADR0 register is modified twice during A/D conversion, the first update might not be converted.

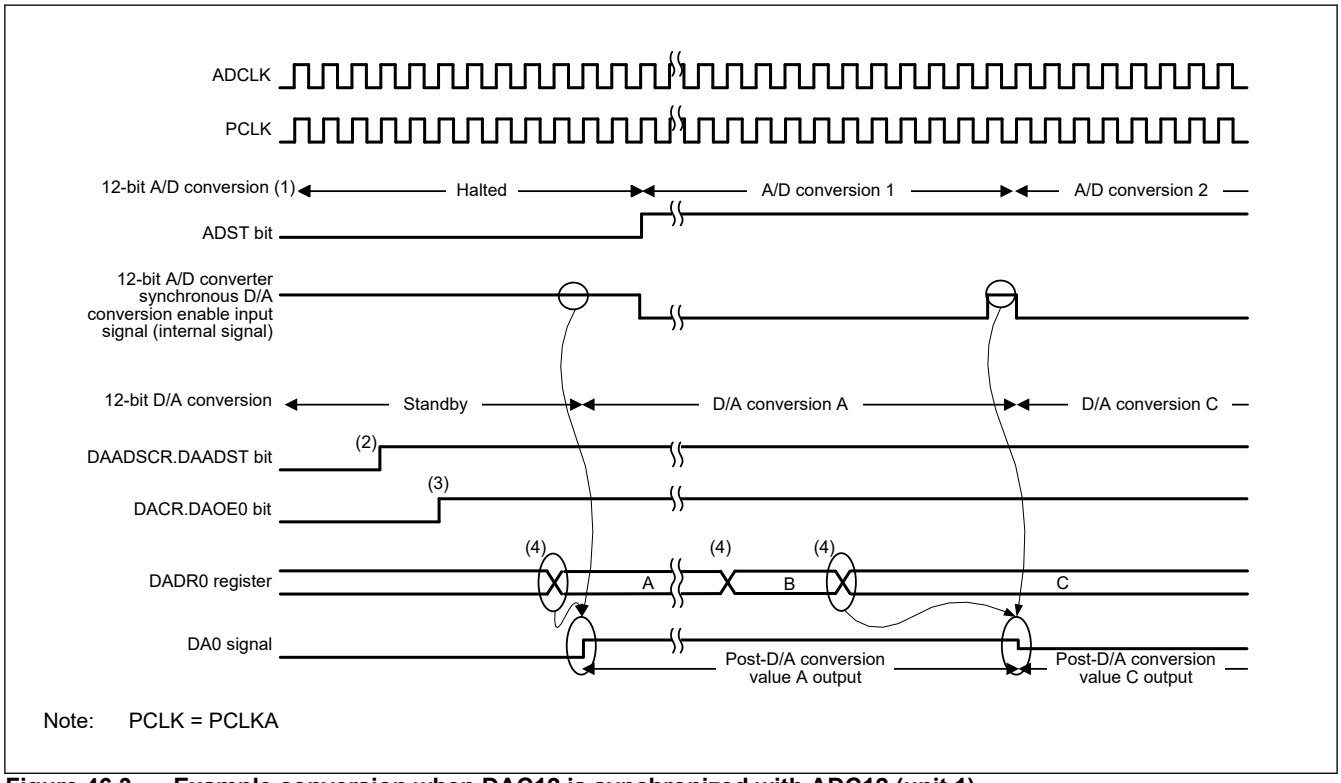

Figure 46.3 Example conversion when DAC12 is synchronized with ADC12 (unit 1)

When ADCLK is faster than PCLKA, the DAC12 might not be able to capture the synchronous D/A conversion enable input signal from the ADC12 (unit 1) during the 1 ADCLK cycle that is output between A/D conversion 1 and A/D conversion 2, as shown in Figure 46.4. In this case, post-D/A conversion value A is continuously output as the DA0 signal.

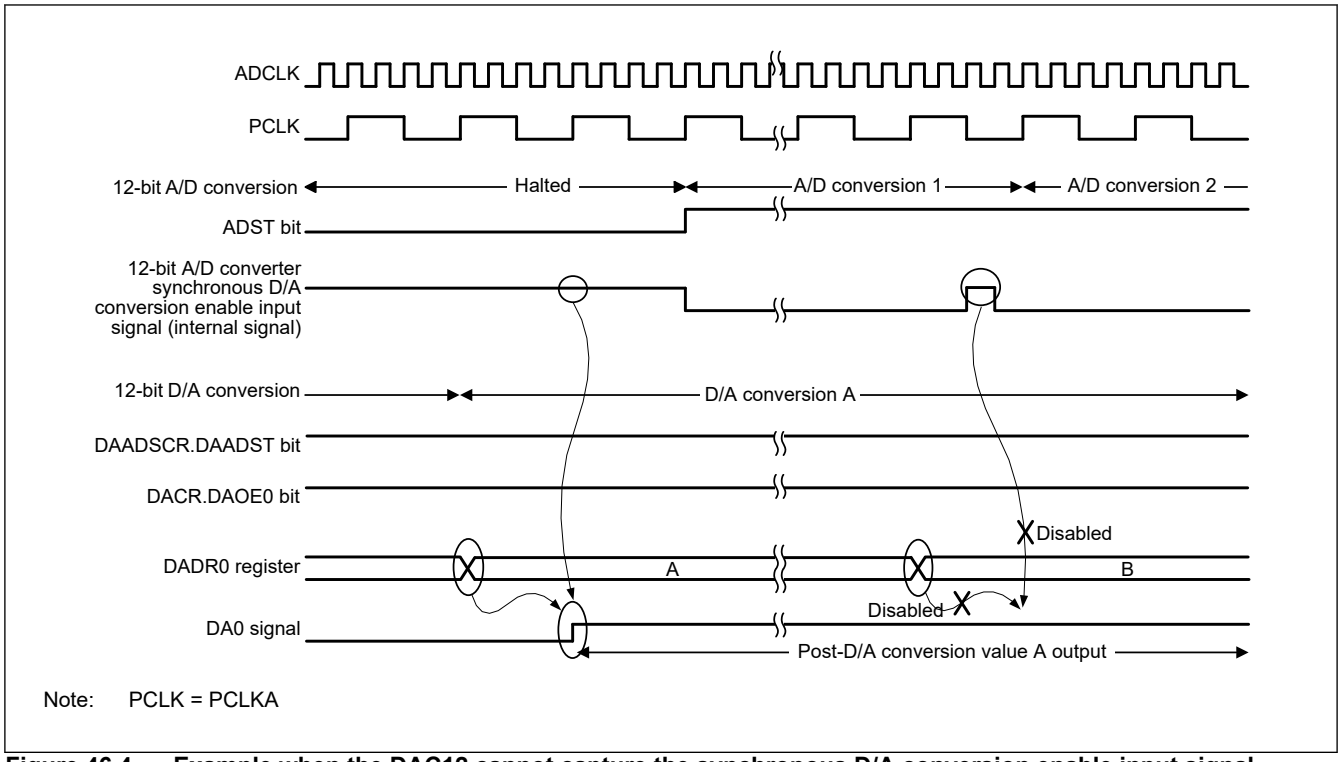

Figure 46.4 Example when the DAC12 cannot capture the synchronous D/A conversion enable input signal from the ADC12 (unit 1)

46.4 Event Link Operation Setting Procedure

This section describes the procedures used in event link operation.

46.4.1 DA0 Event Link Operation Setting Procedure

To set up DA0 event link operation:

1. Set the DADPR.DPSEL bit and the data for D/A conversion in the DADR0 register.
2. Set the ELC_DA0 event signal to be linked to each peripheral module in the ELSR12 register.
3. Set the ELCR.ELCON bit to 1. This enables event link operation for all modules with the event link function selected.
4. Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE0 bit becomes 1, and D/A conversion starts on channel 0.
5. Set the ELSR12 register to 0x0000 to stop event link operation of DAC12 channel 0. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

46.4.2 DA1 Event Link Operation Setting Procedure

To set up DA1 event link operation:

1. Set the DADPR.DPSEL bit and set the data for D/A conversion in the DADR1 register.
2. Set the ELC_DA1 event signal to be linked to each peripheral module in the ELSR13 register.
3. Set the ELCR.ELCON bit to 1. This enables the event link operation for all modules with the event link function selected.
4. Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE1 bit is becomes 1, and D/A conversion starts on channel 1.
5. Set the ELSR13 register to 0x0000 to stop event link operation on DAC12 channel 1. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

46.5 Analog Output Control by Security Attribution

Analog output to DA0/DA1 pin is controlled by the security attribution of Port and DAC12 as shown in Table 46.5.

Analog output to ACMPHS is not controlled by the security attribution.

Table 46.5 Analog output control by security attribution

Security Attribution			Analog Output	
DAC12 (PSARD)	P014 (PmSAR (m = 0~9, A, B))	P015 (PmSAR (m = 0~9, A,B))	P014 pin output	P015 pin output
0 (secure)	1 (non-secure)	1 (non-secure)	enable	enable
0 (secure)	1 (non-secure)	0 (secure)	enable	enable
0 (secure)	0 (secure)	1 (non-secure)	enable	enable
0 (secure)	0 (secure)	0 (secure)	enable	enable
1 (non-secure)	1 (non-secure)	1 (non-secure)	enable	enable
1 (non-secure)	1 (non-secure)	0 (secure)	enable	disable
1 (non-secure)	0 (secure)	1 (non-secure)	disable	enable
1 (non-secure)	0 (secure)	0 (secure)	disable	disable

46.6 Usage Notes on Event Link Operation

- When the event link function is used, do not use the amplifier output function.
- When the event link function is used, set the DACR.DAE bit to 0.
- When the event specified for the ELC_DA0 event signal is generated while a write to the DACR.DAOE0 bit is performed, the write cycle is stopped, and the generated event takes precedence in setting the bit to 1.
- When the event specified for the ELC_DA1 event signal is generated while a write to the DACR.DAOE1 bit is performed, the write cycle is stopped, and the generated event takes precedence in setting the bit to 1.
- Use of the event link function is prohibited when the DAADSCR.DAADST bit is set to 1 to reduce interference between D/A and A/D conversions.

46.7 Usage Notes

46.7.1 Settings for the Module-Stop Function

DAC12 operation can be disabled or enabled using the Module Stop Control Register. The DAC12 is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

46.7.2 DAC12 Operation in the Module-Stop State

When the MCU enters the module-stop state with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in the module-stop state, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

46.7.3 DAC12 Operation in Software Standby Mode

When the MCU enters Software Standby mode with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in Software Standby mode, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

46.7.4 Constraint on Entering Deep Software Standby Mode

When the MCU enters Deep Software Standby mode with D/A conversion enabled, the outputs of the DAC12 are placed in a high impedance state.

46.7.5 Initialization Procedure with the Output Amplifier

Use the following initialization procedures with the output amplifier. The example shows the case for channel 0.

To initialize the DAC12 with the output amplifier:

1. Write 0x0000 to the DADR0 register.
2. Set the DAASWCR.DAASW0 bit to 1.
3. Set the DAAMPCR.DAAMP0 bit to 1.
4. Set the DACR.DAE bit or the DACR.DAOE0 bit to 1 to start operation of the amplifier.
5. Clear the DAASWCR.DAASW0 bit to 0 after waiting for the duration of D/A conversion time t_{DCONV}.
6. Write the value to be converted in the DADR0 register.

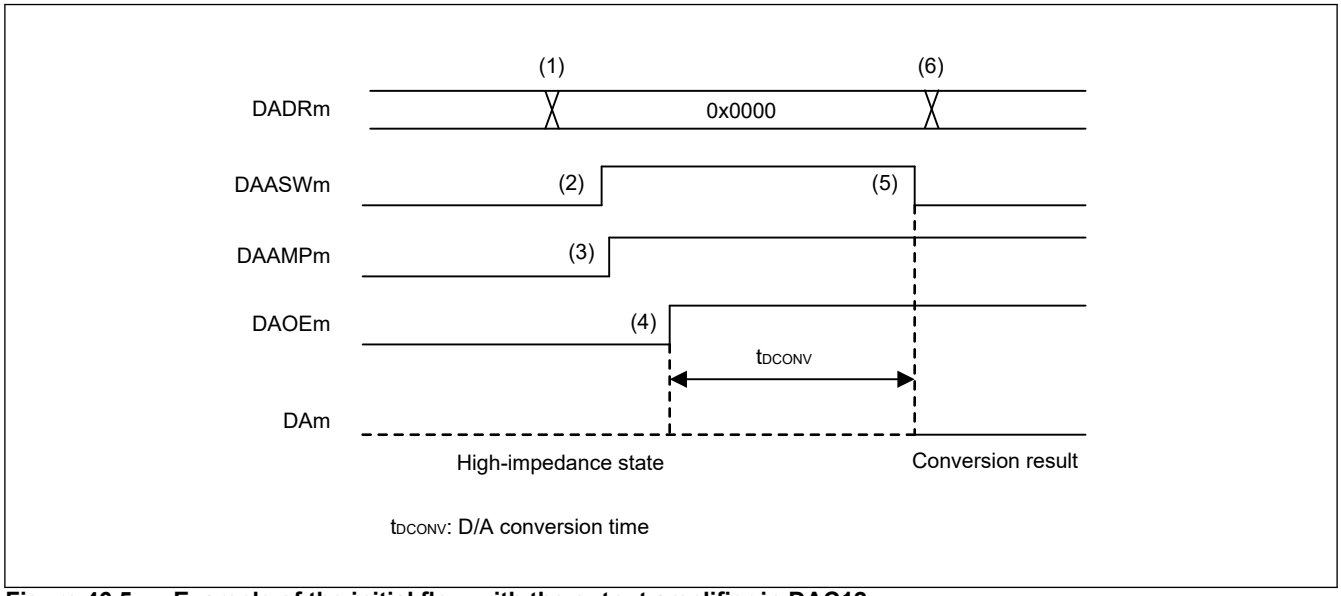

Figure 46.5 Example of the initial flow with the output amplifier in DAC12

While the amplifier is running, clearing the DACR.DAE and DACR.DAOE0 bits to 0 allows the amplifier to stop operation. To use the amplifier again, repeat steps 1 to 6.

46.7.6 Initialization Procedure of the Output to internal modules

Use the following initialization procedures for the output to internal modules.

The example shows the case for channel 0.

1. Set the DAASWCR.DAASW0 bit to 1.
2. Set the DACR.DAE bit or the DACR.DAOE0 bit to 1.
3. Write the value to be converted in the DADR0 register.

When you stop output of the DAC12, set DAASWCR.DAASWi to 0 after setting DACR.DAE to 0 or DACR.DAOEi to 0.

46.7.7 Constraint on Usage When Interference Reduction between D/A and A/D Conversion Is Enabled

When the DAADSCR.DAADST bit is 1, enabling interference reduction between D/A and A/D conversion, do not place the ADC12 in the module-stop state. Doing so can halt D/A conversion in addition to A/D conversion.

47. Temperature Sensor (TSN)

47.1 Overview

The on-chip Temperature Sensor (TSN) determines and monitors the die temperature for reliable operation of the device. The sensor outputs a voltage directly proportional to the die temperature, and the relationship between the die temperature and the output voltage is fairly linear. The output voltage is provided to the ADC12 for conversion and can be further used by the end application.

Table 47.1 lists the TSN specifications, and Figure 47.1 shows a block diagram.

Table 47.1 TSN specifications

Item	Description
Temperature sensor voltage output	Temperature sensor outputs a voltage to the 12-bit A/D converter
Module-stop function	Module-stop state can be set to reduce power consumption
Temperature sensor calibration data	Reference data measured for each chip at factory shipment is stored in a register
TrustZone Filter	Security and Privilege attribution can be set

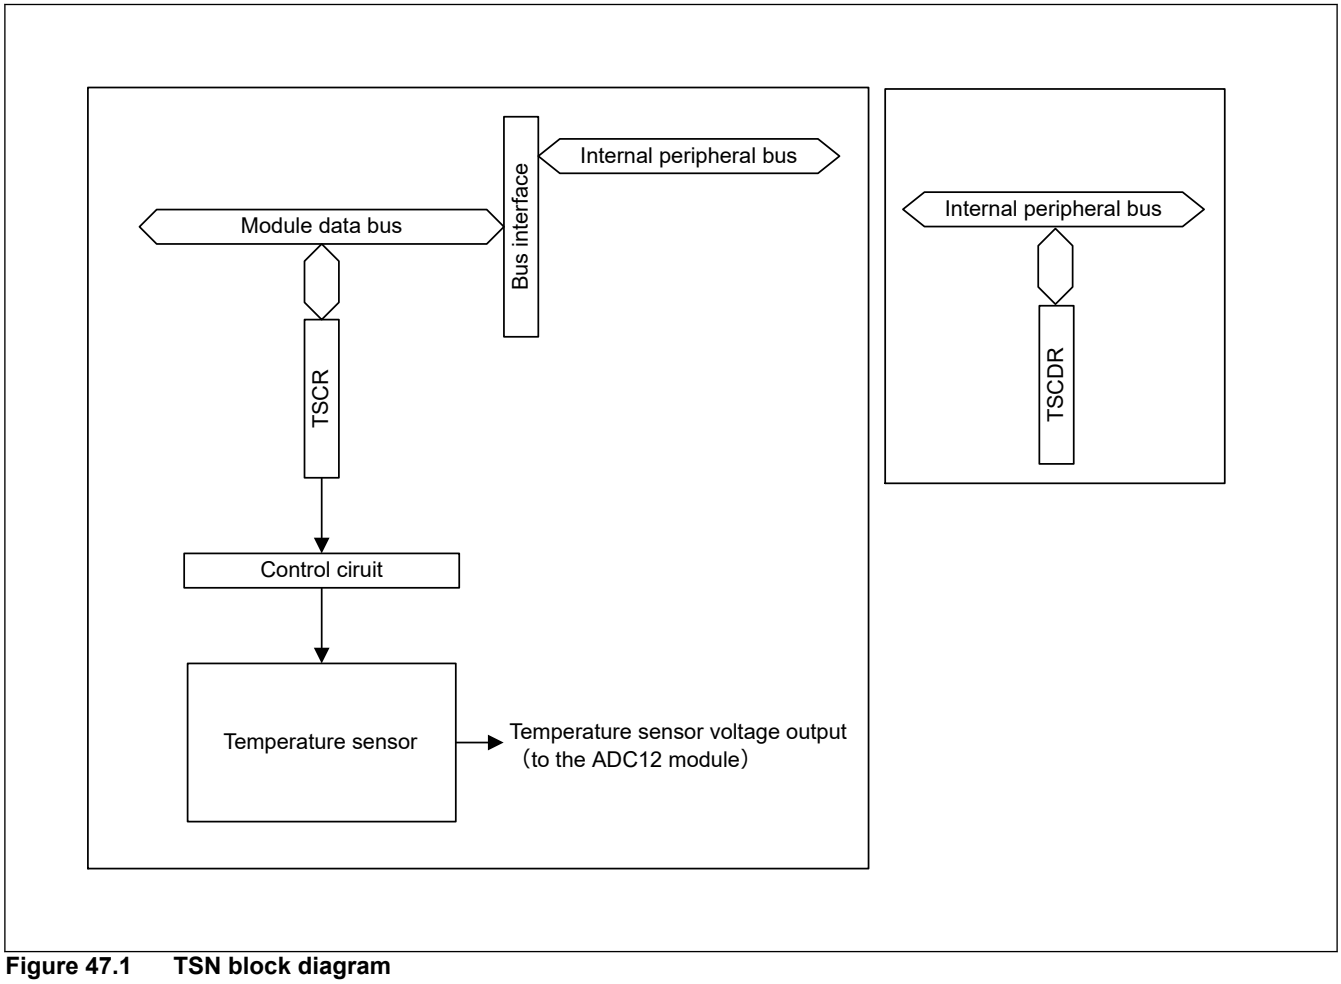

Figure 47.1 TSN block diagram

47.2 Register Descriptions

47.2.1 TSCR : Temperature Sensor Control Register

Base address: TSN = 0x4023_5000
TSN_NS = 0x5023_5000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TSEN	—	—	TSOE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	TSOE	Temperature Sensor Output Enable 0: Disable output from the temperature sensor to the ADC12 1: Enable output from the temperature sensor to the ADC12	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	TSEN	Temperature Sensor Enable 0: Stop the temperature sensor 1: Start the temperature sensor.	R/W

Note: S-TYPE3, P-TYPE3

The TSCR is a register which controls the temperature sensor. The timing constraints shown in Figure 47.3 apply to the settings of the TSCR register.

TSOE bit (Temperature Sensor Output Enable)

The TSOE bit enables or disables the temperature sensor output to ADC12.

TSEN bit (Temperature Sensor Enable)

The TSEN bit starts or stops the temperature sensor.

47.2.2 TSCDR : Temperature Sensor Calibration Data Register

Base address: TSD = 0x4011_B000
TSD_NS = 0x5011_B000

Offset Address: 0x017C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TSCDR[15:0]															
Value after reset:	Chip-specific value															

Bit	Symbol	Function	R/W
15:0	TSCDR[15:0]	Temperature Sensor Calibration Data Chip-specific value	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE5, P-TYPE5

The TSCDR register stores temperature sensor calibration data measured for each chip at factory shipment.

Temperature sensor calibration data is the output voltage of the temperature sensor under the conditions Tj = 125°C and AVCC0 = VREFH0 = 3.3 V converted to a digital value by the 12-bit A/D converter.

The TSCDR register is a read-only 32-bit register. Read from this register in 32-bit units.

Temperature sensor calibration data is stored in the lower 12 bits of the TSCDR register.

47.3 Using the Temperature Sensor

The temperature sensor outputs a voltage that varies with the temperature. This voltage is converted to a digital value by the 12-bit A/D converter. To obtain the die temperature, convert this value into the temperature.

47.3.1 Preparation for Using the Temperature Sensor

The ambient temperature (T) is proportional to the temperature sensor voltage output (Vs), so ambient temperature is calculated with the following formula:

T = (Vs - V1) / slope + T1

- T: Ambient temperature of MCU as calculation result (°C)
- Vs: Voltage output by the temperature sensor on temperature measurement (V)
- T1: Temperature experimentally measured at one point (°C)
- V1: Voltage output by the temperature sensor on measurement of T1 (V)
- T2: Temperature experimentally measured at a second point (°C)
- V2: Voltage output by the temperature sensor on measurement of T2 (V)
- Slope: Temperature gradient of the temperature sensor (V / °C), slope = (V2 - V1) / (T2 -T1)

Characteristics vary between sensors, so Renesas recommends measuring two different sample temperatures as follows:

1. Use the 12-bit A/D converter to measure the voltage V1 output by the temperature sensor at temperature T1.
2. Again use the 12-bit A/D converter to measure the voltage V2 output by the temperature sensor at a different temperature T2.
3. Obtain the temperature gradient (slope = (V2 - V1) / (T2 - T1)) from these results.
4. Subsequently, obtain temperatures by substituting the slope into the formula for the temperature characteristic (T = (Vs - V1) / slope + T1).

In order to make the temperature Ta and Tj as close as possible, perform the measurement with the power consumption of the MCU as low as possible.

If you are using the temperature gradient given in section 60, Electrical Characteristics, use the A/D converter to measure the voltage V1 output by the temperature sensor at temperature T1, then calculate the temperature characteristic using the following formula:

T = (Vs - V1) / slope + T1

Note: This method produces less accurate temperatures than measurement at two points.

In this MCU, the TSCDR register stores the temperature value (CAL125) of the temperature sensor measured under the condition Ta = Tj = 125°C and AVCC0 = VREFH0 = 3.3 V. If you use this value as the sample measurement result at the first point, you can omit the preparation before using the temperature sensor.

V1 is calculated from CAL125:

V1 = 3.3 × CAL125 / 4096 [V] (In case of 12 bit accuracy)

Using this value, the measured temperature can be calculated according to the following formula:

T = (Vs - V1) / slope + 125 [°C]

- T: Ambient temperature of MCU as calculation result (°C)
- Vs: Voltage output by the temperature sensor when the temperature is measured (V)
- V1: Voltage output by the temperature sensor when Ta = Tj = 125°C and AVCC0 = VREFH0 = 3.3 V (V)

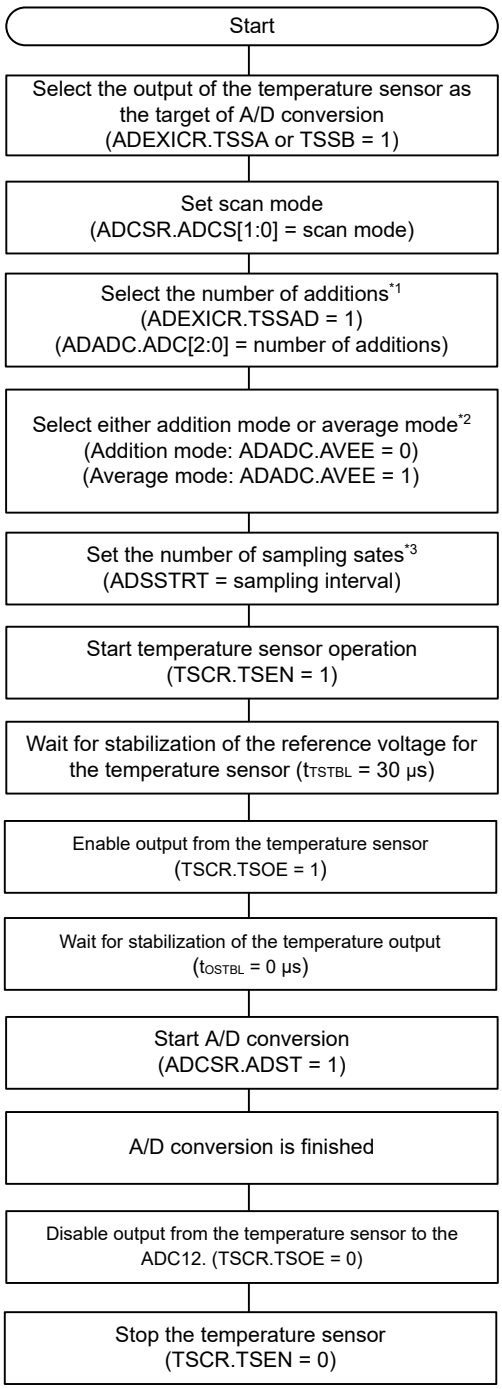
- Slope: Temperature gradient of the temperature sensor*1 / 1000 (V/°C)

Note 1. See section 60, Electrical Characteristics

47.3.2 Procedures for Using the Temperature Sensor

Figure 47.2 shows the procedure for using the TSN.

For details, see section 45, 12-Bit A/D Converter (ADC12).



Note 1. This setting is not required if addition/average mode is not set.
Note 2. The ADADC.ADC[2:0] setting is limited to some values in additions/average mode. For details on the available ADADC.ADC[2:0] settings in additions/average mode, see section 45, 12-Bit A/D Converter (ADC12).
Note 3. Set the sampling time to more than the value described in section 60, Electrical Characteristics.

Figure 47.2 Procedure example for using the TSN

Figure 47.3 shows the timing from the start of temperature sensor operation until the completion of A/D conversion when the ADC12 is in single scan mode (the conversion target is the temperature sensor output only). The times shown in the figure are described in Table 47.2

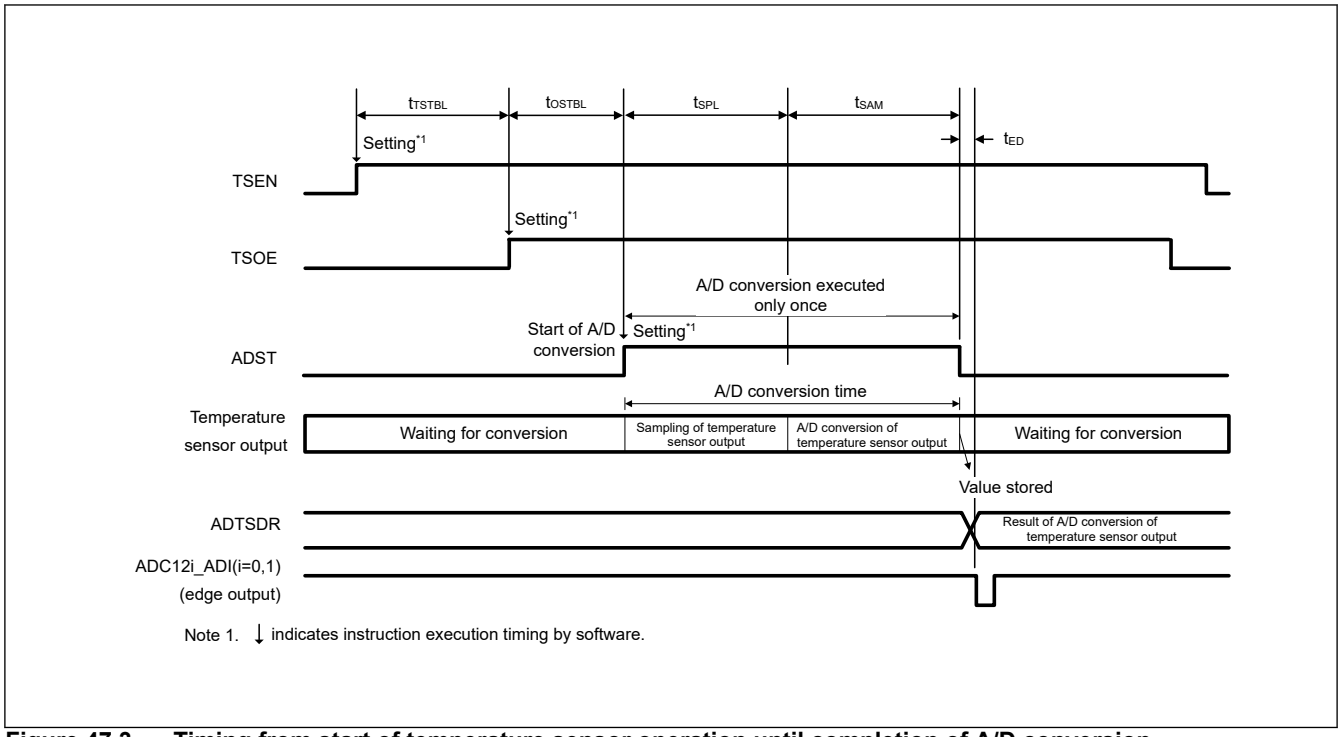


Figure 47.3 Timing from start of temperature sensor operation until completion of A/D conversion

Table 47.2 Time until completion of A/D conversion after start of temperature sensor operation

Parameter	Symbol	Time
Wait time for temperature sensor reference voltage stabilization	t_{TSTBL}	30 µs (min)
Wait time for temperature sensor output stabilization	t_{OSTBL}	0 µs (min)
A/D converter input sampling time	t_{SPL}	ADSSTRn setting × ADCLK period
A/D conversion time	t_{SAM}	See the table in section 45.3.6. Analog Input Sampling and Scan Conversion Time.
Scan conversion end delay	t_{ED}	

47.4 Usage Notes

47.4.1 Settings for the Module-Stop Function

TSN operation can be disabled or enabled using the associated bit in Module Stop Control Register D (MSTPCRD). The TSN is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

47.4.2 Settings for the Software Standby Mode

Before entering Software Standby Mode, set TSCR.TSOE bit to 0 after stopping A/D conversion, then set TSCR.TSEN bit to 0 to stop the TSN.

48. High-Speed Analog Comparator (ACMPHS)

48.1 Overview

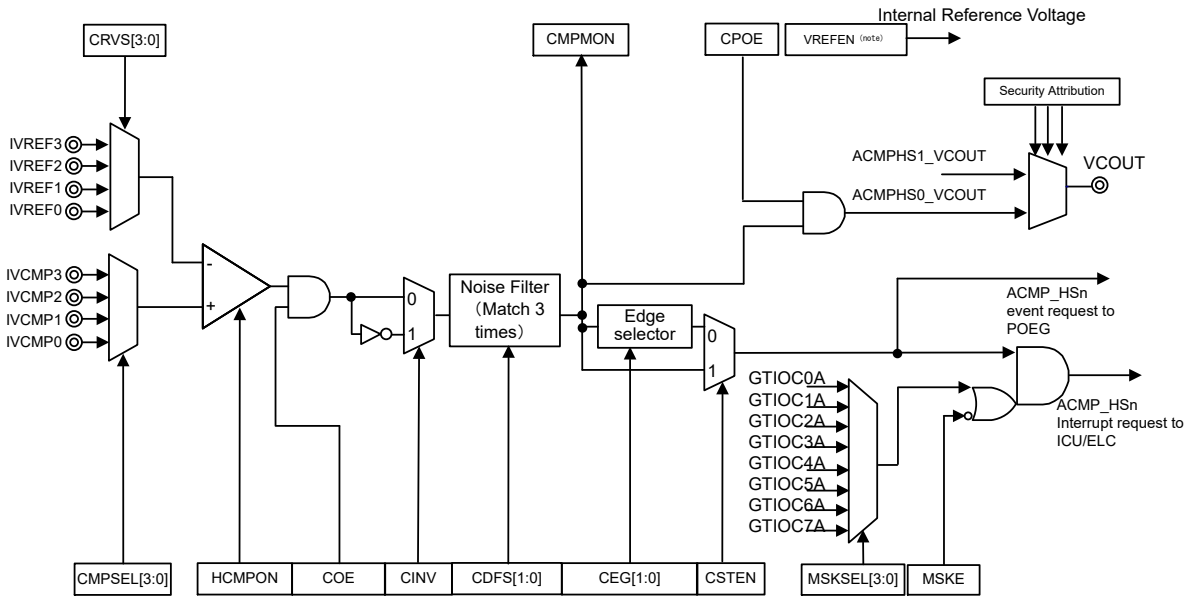
The High-Speed Analog Comparator (ACMPHS) can be used to compare an analog input voltage with a reference voltage and to provide a digital output based on the result of conversion. Both the analog input voltage and the reference voltage can be provided to the ACMPHS from internal sources (D/A converter output or internal reference voltage) and an external source. Such flexibility is useful in applications that require go/no-go comparisons to be performed between analog signals without necessarily requiring A/D conversion.

Table 48.1 lists the ACMPHS specifications, Figure 48.1 shows a block diagram, and Table 48.2 shows the input source configurations.

Table 48.1 ACMPHS specifications

Parameter	Specifications
Number of channels	2 channels: ACMPHSn (n = 0, 1)
Analog input voltage	• Output from internal D/A conveter • Input from an external source (compatible with internal A/D converter input pin (one selectable))
Reference voltage	• Internal reference voltage (Vref) • Output from internal D/A converter • Input from an external source (compatible with internal A/D converter input pin (one selectable))
ACMPHS output	• Comparison result output to terminal PIN • Generation of ELC event output • Monitor output from register • Generation of interrupt request output
Interrupt request signal	• Interrupt request generated on valid edge detection from comparison result (when CMPCTL.CSTEN = 0[*1]) • Selectable to rising edge, falling edge, or both edges (when CMPCTL.CSTEN = 0[*1]) • Rising edge only (when CMPCTL.CSTEN = 1[*1])
Digital filter function	• Selectable to one of three sampling frequencies • Not using the filter function is selectable
Module-stop function	Module-stop state can be set for each groups to reduce power consumption.
TrustZone Filter	Security and Privilege attribution can be set for each group

Note 1. Interrupt request signal selection restriction detail refers to section 48.5. ACMPHS Interrupts and section 48.6. ACMPHS Output to the Event Link Controller (ELC).



n = 0～1

CMPSEL[3:0] : bits in ACMPHSn.CMPSEL0 register
CRVS[3:0] : bits in ACMPHSn.CMPSEL1 register
CPOE, VREFEN : bits in ACMPHSn.CPIOC register
CMPMON : bits in ACMPHSn.CMPMON register
HCMPON, COE, CINV, CDFS[1:0], CEG[1:0], CSTEN : bits in ACMPHSn.CMPCTL register
MSKSEL[3:0] : bits in ACMPHSn.CMPSKCTL register
MSKE : bits in ACMPHSn.CMPINTCTL register

Note : VREFEN exists only in ACMPHS0.

Figure 48.1 ACMPHS block diagram

Table 48.2 Input source configuration of the ACMPHS

Comparator	Reference voltage input source				Analog voltage input source				Output pin
	IVREF3	IVREF2	IVREF1	IVREF0	IVCMP3	IVCMP2	IVCMP1	IVCMP0	
ACMPHS0	DA0*3	Vref*1	AN104	AN101	AN002	AN000	DA1*4	AN005	VCOUT*2
ACMPHS1	DA0*3	Vref*1	AN104	AN101	AN102	AN100	DA1*4	AN016/ AN116	

Note 1. Internal voltage reference.
Note 2. ACMPHS0 to ACMPHS1 compare outputs are bundled with the VCOUT pin.
Note 3. When D/A converter 0 output is not used, the signal can be used as AN007 analog input.
Note 4. When D/A converter 1 output is not used, the signal can be used as AN105 analog input.

48.2 Register Descriptions

48.2.1 CMPCTL : Comparator Control Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x000

Bit position:	7	6	5	4	3	2	1	0
Bit field:	HCMPON	CDFS[1:0]		CEG[1:0]		CSTEN	COE	CINV
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CINV	Comparator Output Polarity Selection*1 *2 0: Do not invert comparator output 1: Invert comparator output	R/W
1	COE	Comparator Output Enable 0: Disable comparator output (output signal is low level) 1: Enable comparator output	R/W
2	CSTEN	Interrupt Select*3 0: Output through the edge selector 1: Output directly	R/W
4:3	CEG[1:0]	Selection of Valid Edge (Edge Selector) 0 0: Do not detect edge 0 1: Detect rising edge 1 0: Detect falling edge 1 1: Detect both edges	R/W
6:5	CDFS[1:0]	Noise Filter Selection *1 *2 *3 *4 0 0: Do not use noise filter 0 1: Use noise filter sampling frequency of PCLKB/2^3 1 0: Use noise filter sampling frequency of PCLKB/2^4 1 1: Use noise filter sampling frequency of PCLKB/2^5	R/W
7	HCMPON	Comparator Operation Control*5 0: Stop operation (comparator outputs a low-level signal) 1: Enable operation (enables input to the comparator pins)	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Disable the ACMPHS output (COE= 0) before changing the CDFS[1:0] and CINV bits.
Note 2. If the CDFS[1:0] and CINV bits are changed, an ACMPHS interrupt request and an ELC event might be generated. Before changing these bits, set the ELSRn register to 0 (the ACMPHS output is not linked). After changing these bits, clear the IR flag in the IELSRn register to 0 to clear the interrupt status.
Note 3. Set the CSTEN bit to 1 and the CDFS[1:0] bits to 00b if the ACMPHS interrupt causes release of Software Standby mode. CSTEN is supported only by the ACMPHS0. ACMPHS1.CMPCTL.CSTEN must be set to 0.
Note 4. If the CDFS[1:0] bits are changed from 00b (noise filter not used) to a value other than 00b (noise filter used), perform sampling four times and update the filter output, and then use the ACMPHS interrupt request or the ELC event.
Note 5. A stabilization wait time is required to permit ACMPHS operation after enabling it (HCMPON = 1). The operation stabilization wait time for ACMPHS modules 0 to 1 is 300 ns.

Note: Set this register before setting registers in the POEG when using comparator output as a POEG source.

The CMPCTL register controls the ACMPHS operation, enables or disables the ACMPHS output, selects the noise filter, selects the valid edge of the interrupt signal, and selects the interrupt.

48.2.2 CMPSEL0 : Comparator Input Select Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x004

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	CMPSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CMPSEL[3:0]	Comparator Input Selection*1 *2 *3 0x00: Do not input 0x01: Select IVCMP0 0x02: Select IVCMP1 0x04: Select IVCMP2 0x08: Select IVCMP3 Others: Setting prohibited	R/W

Bit	Symbol	Function	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Use the following procedure to change the CMPSEL[3:0] bits. Writing a value other than 0x00 while the value of the CMPSEL0 register is not 0x00 is invalid. Writing 1 to two or more bits is also invalid. In both cases, the previous value is retained.
To change the CMPSEL[3:0] bits:
1. Set the CMPCTL.COE bit to 0.
2. Set the CMPSEL0 register to 0x00.
3. Set a new value in the CMPSEL[3:0] bits, with 1 set in only one of the bits.
4. Wait for the input switching stabilization wait time (200 ns).
5. Set the CMPCTL.COE bit to 1.
6. Clear the IR flag in the IELSRn register to clear the interrupt status.

Note 2. For details, see Table 48.2.
Note 3. If ACMPHSn level detection signal is used as a POEG source, write access to these bits after the setting of any register in the POEG may generate a POEG source.

48.2.3 CMPSEL1 : Comparator Reference Voltage Select Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x008

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	CRVS[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CRVS[3:0]	Reference Voltage Selection*1*2*3*4 0x00: Do not input 0x01: Select IVREF0 0x02: Select IVREF1 0x04: Select IVREF2 0x08: Select IVREF3 Others: Setting prohibited	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Use the following procedure to change the CRVS[3:0] bits. Writing a value other than 0x00 while the value of the CMPSEL1 register is not 0x00 is invalid. Writing 1 to two or more bits is also invalid. In both cases, the previous value is retained.
To change the CRVS[3:0] bits:
1. Set the CMPCTL.COE bit to 0.
2. Set the CMPSEL1 register to 0x00.
3. Set a new value to the CRVS[3:0] bits, with 1 set in only one of the bits.
4. Wait for the input switching stabilization wait time (200 ns)
5. Set the CMPCTL.COE bit to 1.
6. Clear the IR flag in the IELSRn register to clear the interrupt status.

Note 2. For details, see Table 48.2.
Note 3. When the on-chip D/A converter output voltage is used, set the D/A converter to generate comparator C reference voltage before enabling comparator operation (CMPCTL.HCMPON bit = 1). For details on setting the D/A converter, see section 46, 12-Bit D/A Converter (DAC12).
Note 4. If ACMPHSn level detection signal is used as a POEG source, write access to these bits after the setting of any register in the POEG may generate a POEG source.

48.2.4 CMPMON : Comparator Output Monitor Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x00C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	COMPMON
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	COMPMON	Comparator Output Monitor*1 0: Comparator output is low 1: Comparator output is high	R
7:1	—	These bits are read as 0. The write value should be 0.	R

Note: S-TYPE-3, P-TYPE-3
Note 1. When ACMPHS operation is enabled (CMPCTL.HCMPON = 1 and CMPCTL.COE = 1) but the noise filter is not in use (CDFS[1:0] = 00b), design the software so that the COMPMON bit is read twice and the values are only used after the two consecutive values match.

48.2.5 CPIOC : Comparator Output Control Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x010

Bit position:	7	6	5	4	3	2	1	0
Bit field:	VREFEN	—	—	—	—	—	—	CPOE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CPOE	External Pin Output Enable Comparison result by the comparator is output to an external pin. 0: Output to the comparator external pin is disabled (the output signal is fixed to low) 1: Output to the comparator external pin is enabled	R/W
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	VREFEN	Internal Vref Enable*1 0: Disable internal Vref 1: Enable internal Vref	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. For ACMPHS modules 0 to 1, VREFEN exists only in ACMPHS0.CPIOC. When using the internal Vref in ACMPHS0 to ACMPHS1, set the VREFEN bit in ACMPHS0.CPIOC to 1. Bit [7] in ACMPHS1.CPIOC should be 0 regardless of whether or not the internal Vref is used.

48.2.6 CPINTCTL : Comparator Interrupt Control Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x040

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	MSKE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MSKE	Comparator Interrupt Periodic Mask Enable 0: Disable interrupt masking (Default) 1: Enable interrupt masking by GPT output signal selected by CPMSKCTL.MSKSEL[2:0]	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register controls the interrupt to ICU/ELC, while the event to POEG(Port Output Enable) is not controlled by this register.

48.2.7 CPMSKCTL : Comparator Interrupt Mask Control Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x044

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	MSKSEL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	MSKSEL[2:0]	Comparator Interrupt Periodic Mask Selection 0 0 0: Enable interrupt masking by GTIOC0A output signal 0 0 1: Enable interrupt masking by GTIOC1A output signal 0 1 0: Enable interrupt masking by GTIOC2A output signal 0 1 1: Enable interrupt masking by GTIOC3A output signal 1 0 0: Enable interrupt masking by GTIOC4A output signal 1 0 1: Enable interrupt masking by GTIOC5A output signal 1 1 0: Enable interrupt masking by GTIOC6A output signal 1 1 1: Enable interrupt masking by GTIOC7A output signal	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register controls the interrupt to ICU/ELC, while the event to POEG(Port Output Enable) is not controlled by this register.

48.3 Operation

The ACMPHS compares a reference voltage to an analog input voltage. Operation is not guaranteed when the values of registers are changed during ACMPHS operation. Table 48.3 shows the procedures for setting the registers associated with ACMPHS.

Table 48.3 Procedure for setting registers associated with ACMPHSn (n = 0, 1) (1 of 2)

Step	Register	Bit	Setting
1	Associated MSTPCRD register	MSTPD28 to MSTPD27	0: Input clock supply.
2	Associated pin function control register (PFS)	ASEL	1: Select the function of pins IVREF and IVCMP.
3	ACMPHSn.CPIOC	VREFEN	1: When using the internal Vref.
4	Associated D/A convertor		When using the D/A convertor, select in the register.
5	CMPSEL0, CMPSEL1	CMPSEL[3:0] CRVS[3:0]	Select the ACMPHSn input, with 1 set in only one of the bits.
6	CMPCTL	CDFS[1:0], CEG[1:0], and CINV	Set up ACMPHSn control.
		HCMPON	1: Enable ACMPHSn operation.
7	CMPSKCTL	MSKCTL[2:0]	Select the interrupt mask source signal (from GPT)

Table 48.3 Procedure for setting registers associated with ACMPHSn (n = 0, 1) (2 of 2)

Step	Register	Bit	Setting
8	CPINT	MSKE	1: Enable interrupt mask function if need
9	Waiting for the ACMPHS stabilization time (minimum 300 ns).		
10	CMPCTL	COE	1: Enable ACMPHSn output.
11	CPIOC	CPOE	Set the VCOUT output
	Associated pin function control register (PFS)	PSEL, PMR	Select the VCOUT port function.
12	IELSRn	IR, IELS[8:0]	When using an interrupt, select the interrupt status flag and the ICU event link.*1
13	ELSRn	ELS[8:0]	When using an ELC, select the event link*2.
14	Operation started		
15	CMPCTL	COE	0: When changing IVREF or IVCMP, to disable ACMPHSn output.
16	CMPSEL1	CRVS[3:0]	Change the CMPSEL1 bits as follows: 1. Set bits CMPSEL1 to 0000 0000b. 2. Set a new value to the CMPSEL1 bits, with 1 set in only one of the bits.
	CMPSEL0	CMPSEL[3:0]	Change the CMPSEL0 bits as follows: 1. Set bits CMPSEL0 to 0000 0000b. 2. Set a new value to the CMPSEL0 bits, with 1 set in only one of the bits.
17	Waiting for the ACMPHS switching stabilization time (minimum 200 ns).		
18	CMPCTL	COE	1: Enable ACMPHSn output.
19	Operation restarted		

Note 1. After ACMPHSn is set, an unnecessary interrupt might occur until operation becomes stable, so initialize the interrupt flag.
Note 2. After ACMPHSn is set, an unnecessary interrupt might occur until operation becomes stable, so initialize the event link select.

Figure 48.2 and Figure 48.3 show an example of ACMPHS operation. The VCOUT output becomes 1 when the analog input voltage is higher than the ACMPHS reference input voltage, and the VCOUT output becomes 0 when the analog input voltage is lower than the reference voltage. When the ACMPHS output changes, an interrupt request and an ELC event are output.

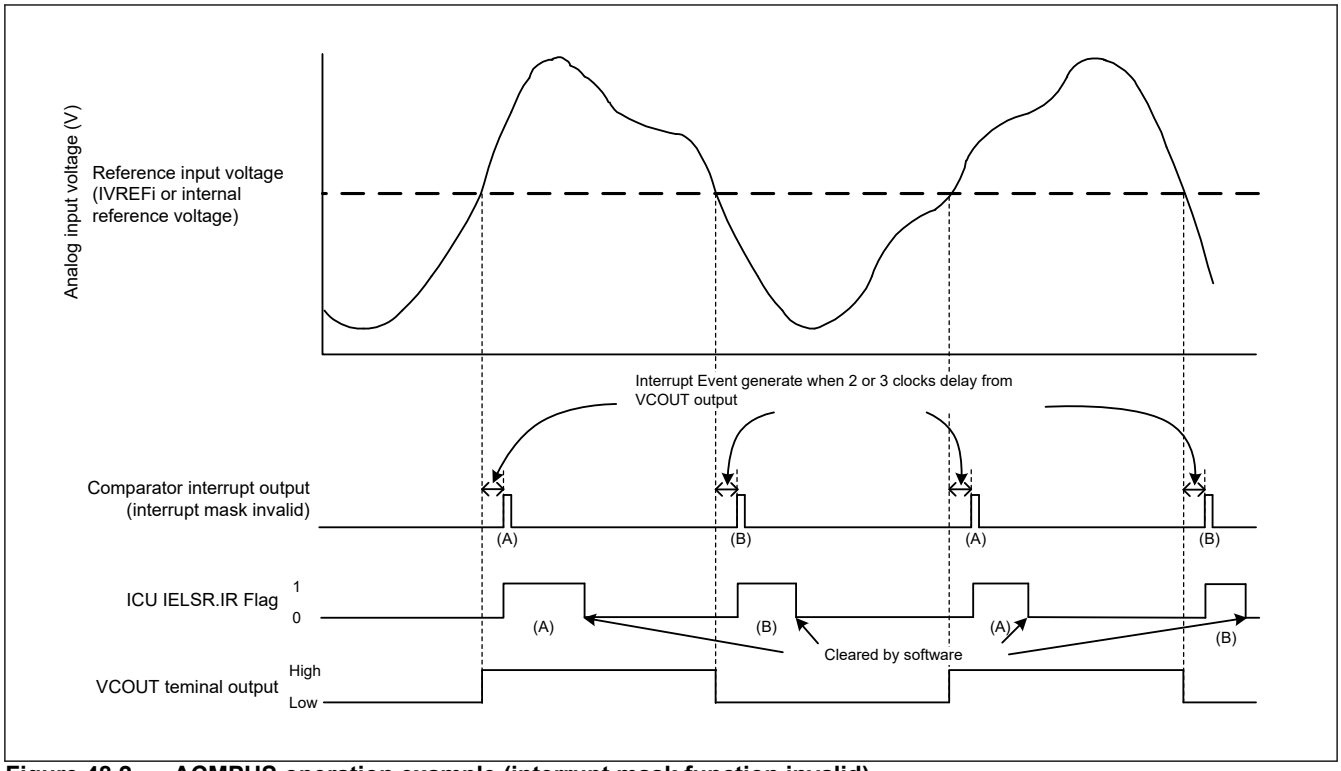


Figure 48.2 ACMPHS operation example (interrupt mask function invalid)

Figure 48.2 applies when CPOE = 1 (pin output enabled), CDFS[1:0] = 00b (filter not used), and CEG[1:0] = 11b (both-edge detection selected). When CINV = 0, CEG[1:0] = 01b (rising-edge detection selected for non-inversion output signal from the ACMPHS), the IELSR.IR flag changes as shown by (A) only. When CINV = 0, CEG[1:0] = 10b (falling-edge detection selected for non-inversion output signal from the ACMPHS), the IR flag changes as shown by (B) only. When CPOE = 1, VCOUT directly outputs.

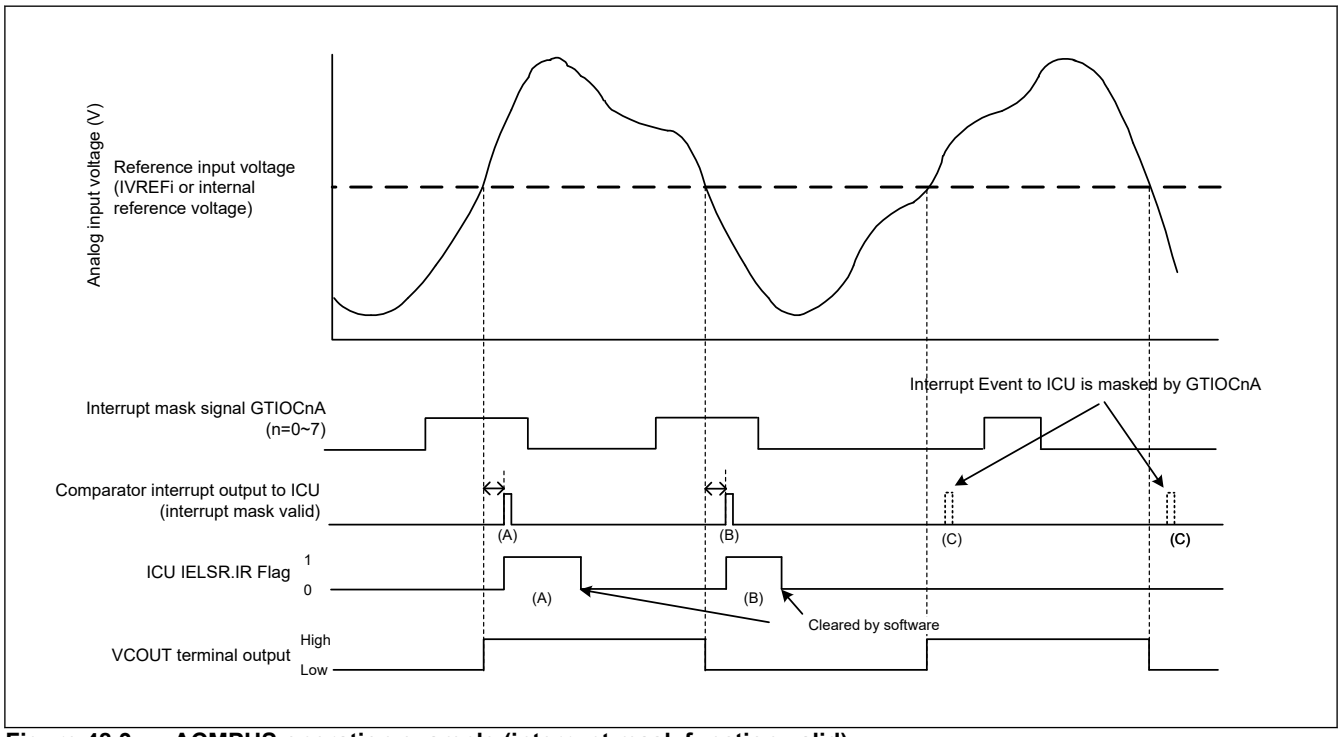

Figure 48.3 ACMPHS operation example (interrupt mask function valid)

Figure 48.3 applies when CPOE = 1 (pin output enabled), CDFS[1:0] = 00b (filter not used), CEG[1:0] = 11b (both-edge detection selected). When CINV = 0, CEG[1:0] = 01b (rising-edge detection selected for non-inversion output signal from

the ACMPHS), the IELSR.IR flag changes as shown by (A) only. When CINV = 0, CEG[1:0] = 10b (falling-edge detection selected for non-inversion output signal from the ACMPHS), the IR flag changes as shown by (B) only.

When MSKE = 1 and MSKSEL[2:0] = 000b, the interrupt signal output to ICU is masked by GTIOC0A when GTIOC0A = low level as shown by (C), while it passes through when GTIOC0A = high level.

When CPOE = 1, VCOUT directly outputs, regardless of the MSKE setting.

48.4 Noise Filter

The ACMPHS contains a noise filter. The sampling clock can be selected in the CMPCTL.CDFS[1:0] bits. The comparator output signal is sampled every sampling clock, and if the same value is sampled three times, the noise filter output at the next sampling clock cycle is used as the ACMPHS output.

Figure 48.4 shows the configuration of the noise filter and edge detector, and Figure 48.5 shows an example of noise filter and interrupt operation.

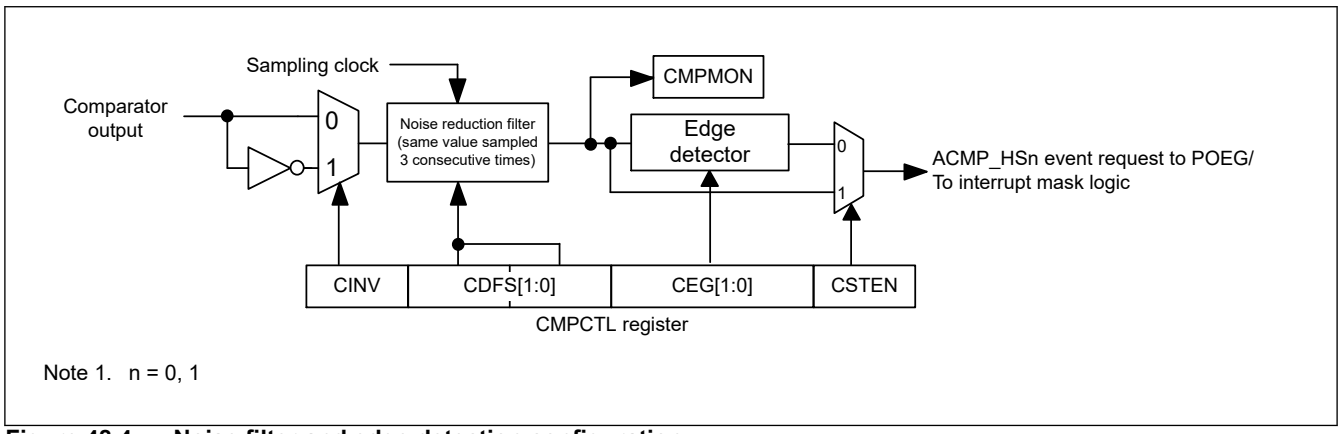

Figure 48.4 Noise filter and edge detection configuration

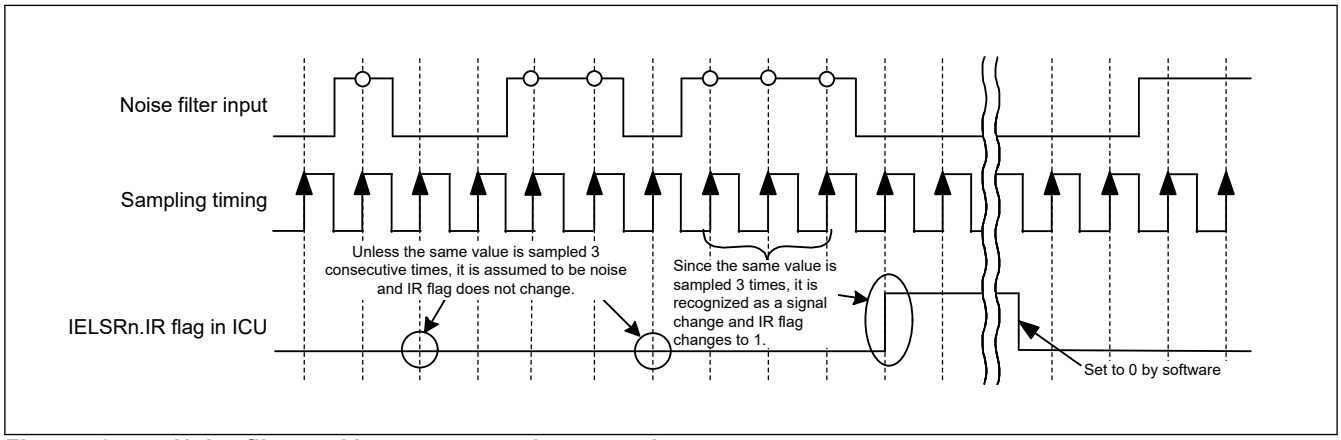

Figure 48.5 Noise filter and interrupt operation example

The operation example in Figure 48.5 applies when the CMPCTL.CDFS[1:0] bits are 01b, 10b, or 11b (noise filter used).

48.5 ACMPHS Interrupts

The ACMPHS generates two interrupt requests from sources ACMPHSn (n = 0, 1). To use an ACMPHS interrupt, select it in the IELSR register in the Interrupt Controller Unit (ICU). Select the interrupt request in the CMPCTL.CSTEN bit either through the edge selector, or not.

Interrupt event to ICU/ELC can be masked by GPT output (GTIOCnA (n = 0 to 7)), it's controlled by CPINTCTL.MSKE bit and CPMSKCTL.MSKSEL[2:0] bits. Detail refer to Figure 48.3.

Event to POEG can't be masked by GPT output (GTIOCnA (n = 0 to 7)), it's not controlled by CPINTCTL.MSKE bit and CPMSKCTL.MSKSEL[2:0] bits.

When using the ACMPHS interrupt through the edge selector, set at least one of the CMPCTL.CEG[1:0] bits to 1 (to a value other than 00b for no edge selection). Set the CMPCTL.CSTEN bit to 0 (output through the edge selector) in Normal mode, CPU Sleep mode, and CPU Deep Sleep mode.

To use the ACMPHS interrupt in Software Standby mode, set the CMPCTL.CSTEN bit to 1 (direct output), set the CMPCTL.CDFS[1:0] bit to 00b (digital noise filter not used), and set CMPCTL.CINV as follows:

- When detecting compare result 0 to 1, set CMPCTL.CINV to 0 (comparator output not inverted)
- When detecting compare result 1 to 0, set CMPCTL.CINV to 1 (comparator output inverted).

An ACMPHS0 interrupt request can be used to release Software Standby mode. ACMPHS1 cannot be used.

ACMPHS0/ACMPHS1 both can not be used in Deep Software Standby mode.

For details on the register settings related to ACMPHS interrupt requests, see section 48.2.1. CMPCTL : Comparator Control Register, section 48.2.6. CPINTCTL : Comparator Interrupt Control Register and section 48.2.7. CPMSKCTL : Comparator Interrupt Mask Control Register.

48.6 ACMPHS Output to the Event Link Controller (ELC)

The ELC uses the ACMPHS interrupt request signal as an ELC event signal, enabling link operation for the preset module. To use the ACMPHS ELC event, select them in the ELSR register in the ELC. When using the ELC event request, set the CMPCTL.CSTEN bit to 0 (output through the edge selector). Also set at least one of the CMPCTL.CEG[1:0] bits to 1 (to a value other than 00b for no edge selection).

Interrupt event to ELC can be masked by GPT output (GTIOCnA (n = 0 to 7)), it's controlled by CPINTCTL.MSKE bit and CPMSKCTL.MSKSEL[2:0] bits.

48.7 ACMPHS Pin Output

The comparison result from the ACMPHS can be output to external pins. Use the CMPCTL.CINV and CPIOC.CPOE bits to set the output polarity (non-inverted or inverted output) and enable or disable output. To output the ACMPHS comparison result to the VCOUT output pin, set the associated port mn pin function control register (PmnPFS) in the I/O register.

Only when the security attribution of Port and ACMPHS match, the ACMPHS comparison result is output to the VCOUT pin as shown in the Table 48.4.

Table 48.4 The output condition of VCOUT pin by the security setting

PORT Security Attribution (PmSAR (m = 0 to 9, A, B))	ACMPHS0 Security Attribution PSARD	ACMPHS1 Security Attribution PSARD	VCOUT pin output
0 (secure)	0 (secure)	0 (secure)	both ACMPHS0/1 output enable
1 (non-secure)	0 (secure)	0 (secure)	both ACMPHS0/1 output disable
0 (secure)	0 (secure)	1 (non-secure)	ACMPHS0_VCOUT output enable ACMPHS1_VCOUT output disable
1 (non-secure)	0 (secure)	1 (non-secure)	ACMPHS0_VCOUT output disable ACMPHS1_VCOUT output enable
0 (secure)	1 (non-secure)	0 (secure)	ACMPHS0_VCOUT output disable ACMPHS1_VCOUT output enable
1 (non-secure)	1 (non-secure)	0 (secure)	ACMPHS0_VCOUT output enable ACMPHS1_VCOUT output disable
0 (secure)	1 (non-secure)	1 (non-secure)	both ACMPHS0/1 output disable
1 (non-secure)	1 (non-secure)	1 (non-secure)	both ACMPHS0/1 output enable

48.8 Usage Notes

48.8.1 Settings for the Module-Stop Function

ACMPHS operation can be disabled or enabled using the Module Stop Control Register. The ACMPHS is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

48.8.2 Settings for the DAC12

ACMPHS is connected to the internal module output of the D/A converter. For details, see section 46, 12-Bit D/A Converter (DAC12).

48.8.3 Relationship with the ADC12

Constraints apply on the simultaneous use of ACMPHS analog input and ADC12 analog input. For details, see section 45.6.14. Relationship between ADC12 Units 0 and 1 and the ACMPHS.

48.8.4 ACMPHS Operation in Module-Stop State

When the module-stop state is entered while ACMPHS is operating, analog circuits in the ACMPHS are not stopped and the analog power supply current is the same as that when ACMPHS is being used. If the analog power supply current needs to be reduced in the module-stop state, set the CMPCTL.HCMPON bit to 0 to stop the ACMPHS.

48.8.5 ACMPHS Operation in Software Standby Mode

When Software Standby mode is entered while ACMPHS is operating, analog circuits in the ACMPHS are not stopped and the analog power supply current is the same as that when ACMPHS is being used. If the analog power supply current needs to be reduced in Software Standby mode, set the CMPCTL.HCMPON bit to 0 to stop the ACMPHS.

48.8.6 Setting the D/A Converter for Generating Reference Voltage

Set the D/A converter to generate reference voltage and wait for the D/A converter output settling time before enabling the comparator. Similarly, before making any changes to the settings of the D/A converter, stop the comparator temporarily. After the changes are made, wait for the D/A converter output settling time before enabling the comparator.

49. Data Operation Circuit (DOC)

This is the DOC_B version of the DOC peripheral module.

DOC_B is referred to as DOC in this chapter.

49.1 Overview

The data operation circuit (DOC) is used to compare, add, and subtract 16 or 32-bit data. An interrupt can be generated when the following conditions apply.

- When the 16 or 32-bit compared values match the detection condition
- When the result of 16 or 32-bit data addition overflows
- When the result of 16 or 32-bit data subtraction underflows

Table 49.1 lists the data operation circuit specifications and Figure 49.1 shows a block diagram of the data operation circuit.

Table 49.1 DOC specifications

Item	Description
Data operation function	• 16 or 32-bit data comparison, comparison to detect data above or below thresholds, and window comparison • 16 or 32-bit data addition, and subtraction
Module-stop function	The module-stop state can be set to reduce power consumption.
Interrupts	• The compared values match the detection condition • The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1) • The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)
Event link function (output)	• The result of data comparison is consistent with detection condition • The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1) • The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)
TrustZone Filter	Security and Privilege attribution can be set

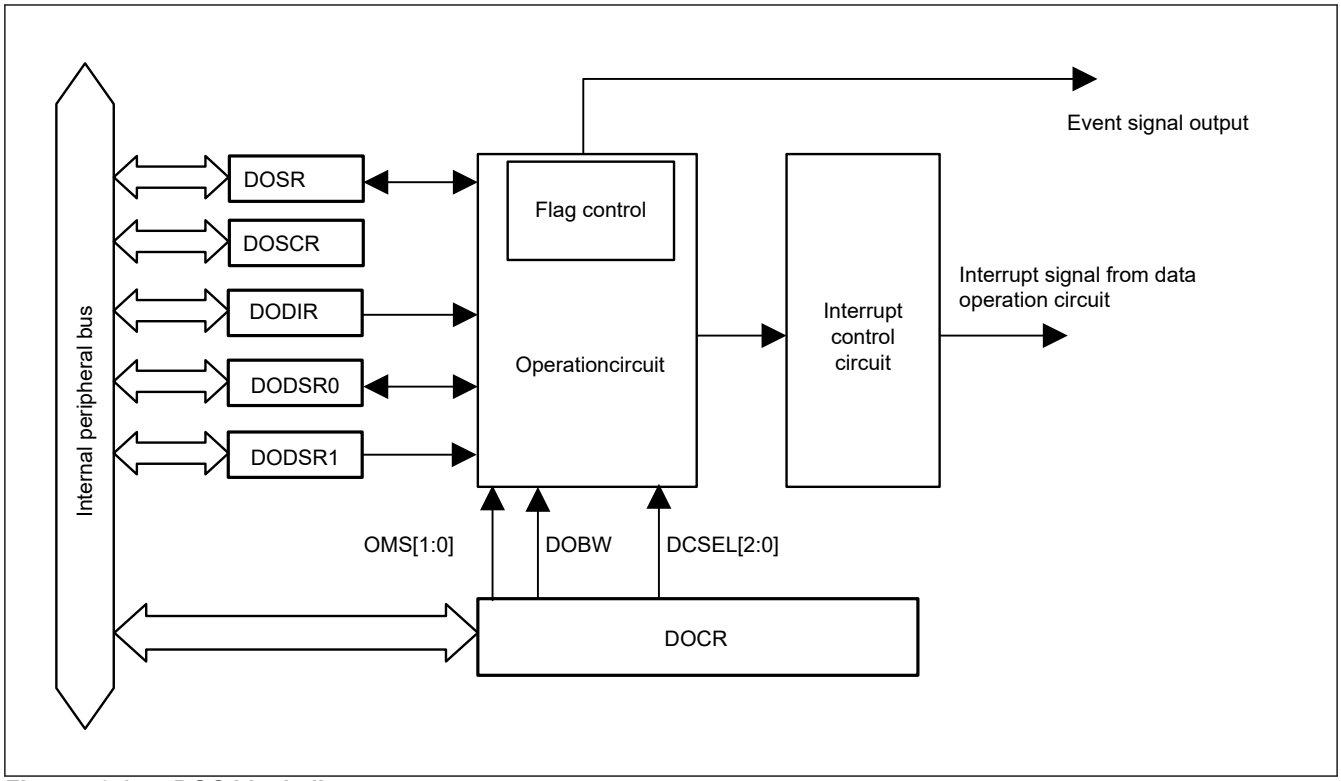

Figure 49.1 DOC block diagram

49.2 DOC Register Descriptions

49.2.1 DOCR : DOC Control Register

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	DCSEL[2:0]			DOBW	—	OMS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

1:0	OMS[1:0]	Operating Mode Select 0 0: Data comparison mode 0 1: Data addition mode 1 0: Data subtraction mode 1 1: Setting prohibited	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	DOBW	Data Operation Bit Width Select 0: 16-bit 1: 32-bit	R/W
6:4	DCSEL[2:0]*1	Detection Condition Select 0 0 0: Mismatch (DODSR0 ≠ DODIR) 0 0 1: Match (DODSR0 = DODIR) 0 1 0: Lower (DODSR0 > DODIR) 0 1 1: Upper (DODSR0 < DODIR) 1 0 0: Inside window (DODSR0 < DODIR < DODSR1) 1 0 1: Outside window (DODIR < DODSR0, DODSR1 < DODIR) Others: Setting prohibited	R/W

Bit	Symbol	Function	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. Valid only when data comparison mode is selected.

The DOCR is a register which can set the operation mode of data operation circuit and interrupt enable/disable.

OMS[1:0] bits (Operating Mode Select)

These bits select the operating mode of the data operation circuit.

DOBW bit (Data Operation Bit Width Select)

This bit selects the bit width of data operation.

DCSEL[2:0] bits (Detection Condition Select)

These bits are valid only when data comparison mode is selected.

These bits select the condition for detection in data comparison mode.

49.2.2 DOSR : DOC Flag Status Register

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	DOPCF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DOPCF	Data Operation Circuit Flag Indicates the result of an operation.	R
7:1	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3

The DOSR register indicates the status of the data operation.

DOPCF flag (Data Operation Circuit Flag)

[Setting conditions]

- DOCR.OMS[1:0] bits = 00b (Data comparison mode): The compared value matches the detection condition selected by DOCR.DCSEL[2:0] bits
- DOCR.OMS[1:0] bits = 01b (Data addition mode): The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1)
- DOCR.OMS[1:0] bits = 10b (Data subtraction mode): The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)

[Clearing condition]

- Writing 1 to the DOSCR.DOPCFCL bit

49.2.3 DOSCR : DOC Flag Status Clear Register

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	DOPCFCL
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DOPCFCL	DOPCF Clear 0: Maintains the DOPCF flag state. 1: Clears the DOPCF flag.	W
7:1	—	The write value should be 0.	W

Note: S-TYPE3, P-TYPE3

The DOSCR is a register which can clear the status of data operation. This register is read as 0x00.

DOPCFCL bit (DOPCF Clear)

Setting this bit to 1 clears the DOPCF flag.

49.2.4 DODIR : DOC Data Input Register

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x0C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	It stores data used in the operations. Access the DODIR with the bit width of data operation selected by the DOCR.DOBW bit.	R/W

Note: S-TYPE3, P-TYPE3

49.2.5 DODSR0 : DOC Data Setting Register 0

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	Access the DODSR0 with the bit width of data operation selected by the DOCR.DOBW bit. This register stores data for use as a reference in data comparison mode. When selecting window comparison (DOCR.DCSEL[2:0] = 100b, 101b), set a value less than DODSR1 (DODSR1 > DODSR0). This register also stores the results of operations in data addition and data subtraction modes.	R/W

Note: S-TYPE3, P-TYPE3

49.2.6 DODSR1 : DOC Data Setting Register 1

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x14

Bit position:	31																												0
Bit field:																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	Access the DODSR1 with the bit width of data operation selected by the DOCR.DOBW bit. This register stores data for use as a reference in data comparison mode. When selecting window comparison (DOCR.DCSEL[2:0] = 100b, 101b), set a value greater than DODSR0 (DODSR1 > DODSR0). This register is only used for window comparisons.	R/W

Note: S-TYPE3, P-TYPE3

49.3 Operation

49.3.1 Data Comparison Mode

Figure 49.2 to Figure 49.7 shows an example of the steps involved in data comparison mode operation by the data operation circuit.

The following is an example of operation when the bit width of data operation is 32-bit.

1. Writing 00b to the DOCR.OMS[1:0] bits selects data comparison mode, and setting the DOCR.DCSEL[2:0] to selects detection condition.
2. The 32-bit reference data is set in DODSR0 and DODSR1.*1
3. 32-bit data for comparison is written to DODIR.
4. If a value written to DODIR match the detection condition set by DOCR.DCSEL[2:0], the DOCR.DOPCF flag is set to 1 and an ELC event and a data operation circuit interrupt are generated.

Note: The comparison operation is executed only by writing to the DODIR

Note 1. The DODSR1 register setting is required only when window comparison is selected. Set a value greater than DODSR0 (DODSR1 > DODSR0).

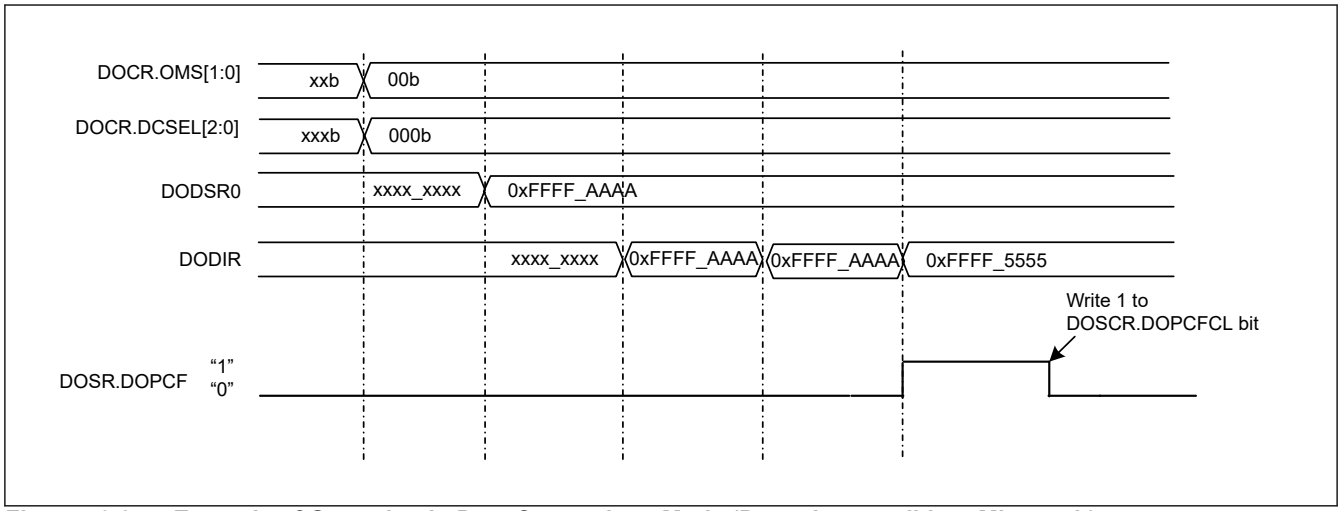

Figure 49.2 Example of Operation in Data Comparison Mode (Detection condition: Mismatch)

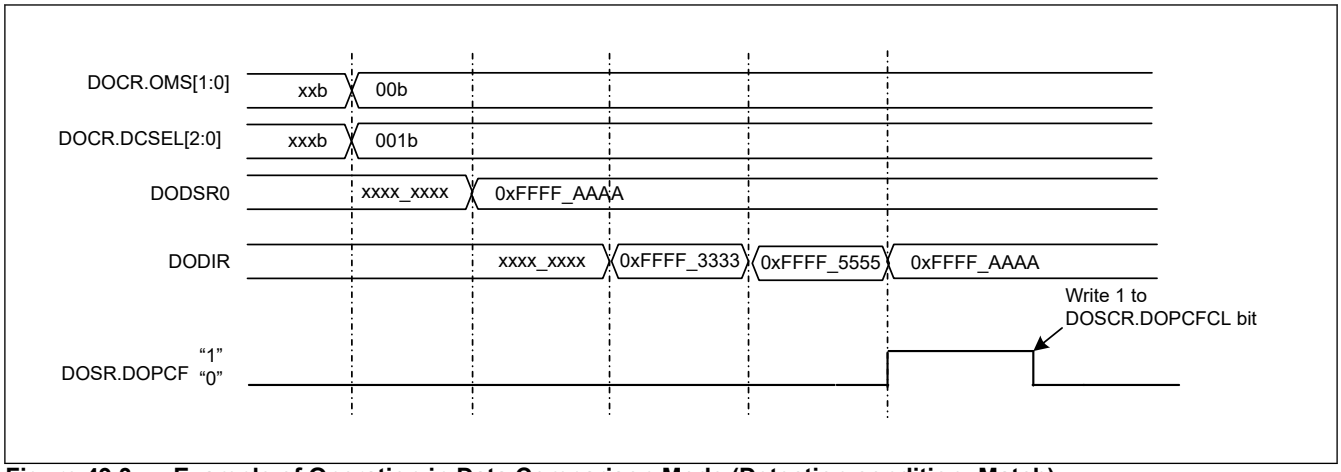

Figure 49.3 Example of Operation in Data Comparison Mode (Detection condition: Match)

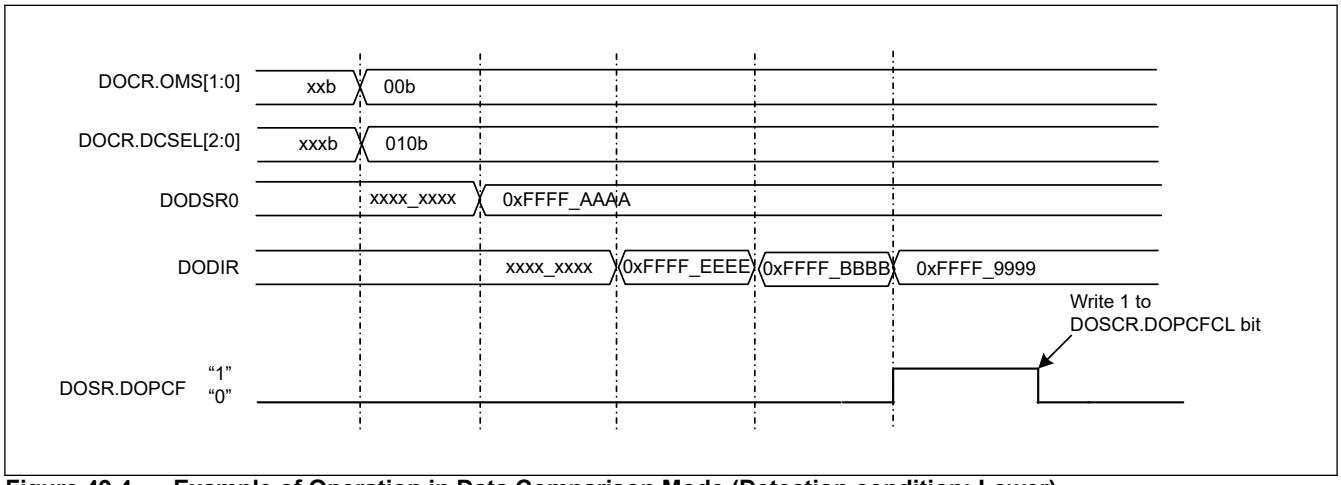

Figure 49.4 Example of Operation in Data Comparison Mode (Detection condition: Lower)

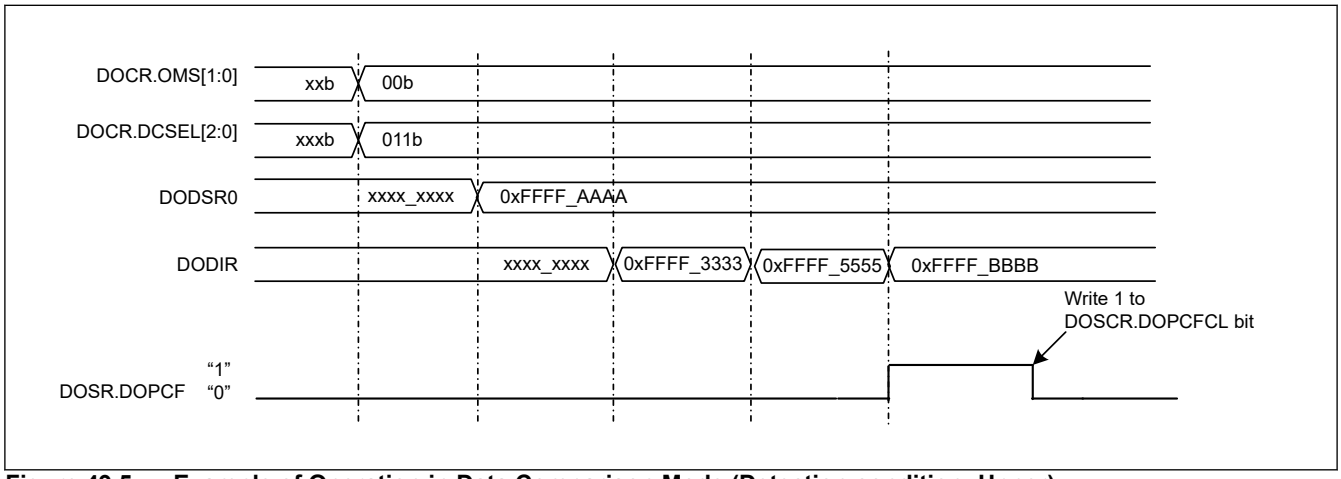

Figure 49.5 Example of Operation in Data Comparison Mode (Detection condition: Upper)

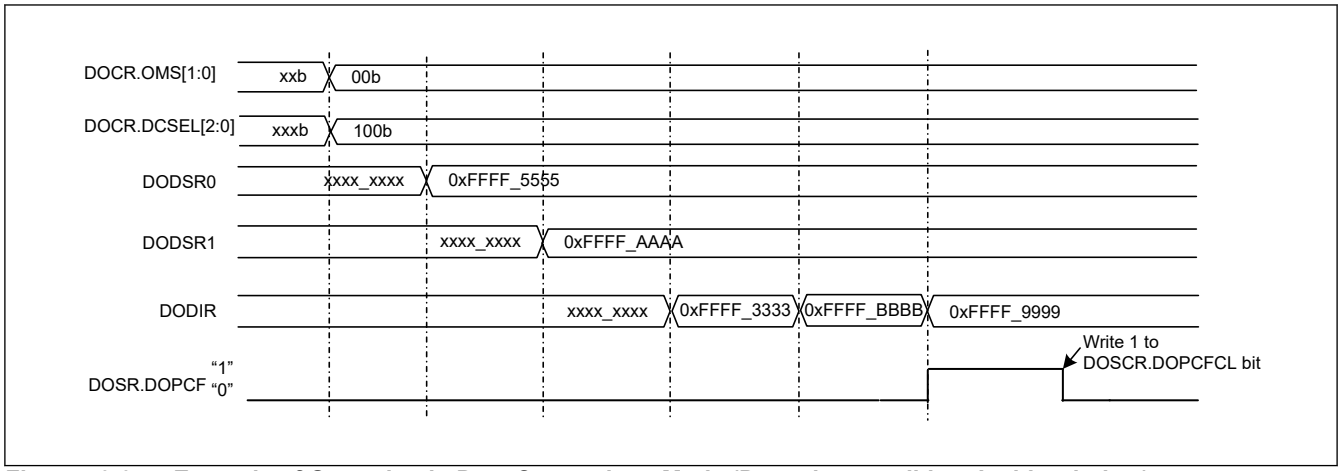

Figure 49.6 Example of Operation in Data Comparison Mode (Detection condition: Inside window)

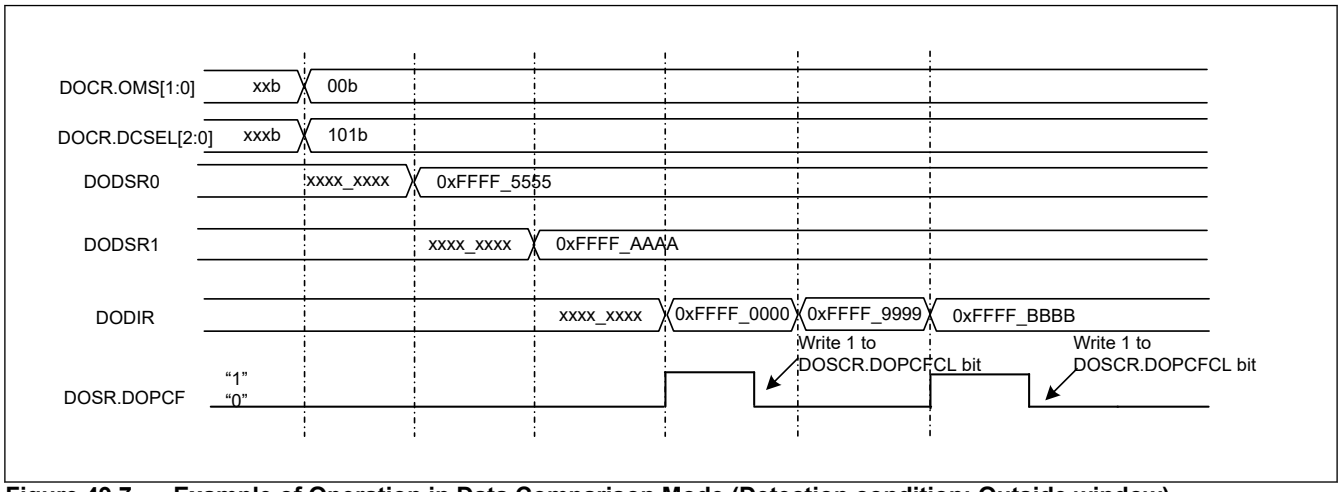

Figure 49.7 Example of Operation in Data Comparison Mode (Detection condition: Outside window)

49.3.2 Data Addition Mode

Figure 49.8 shows an example of the steps involved in data addition mode [*1] operation by the data operation circuit.

The following is an example of operation when the bit width of data operation is 32-bit.

1. Writing 01b to the DOCR.OMS[1:0] bits selects data addition mode.
2. 32-bit data is set in the DODSR0 register as the initial value.
3. 32-bit data to be added is written to DODIR. The result of the operation is stored in DODSR0.
4. Writing of 32-bit data continues until all data for addition have been written to DODIR.
5. If the result of an operation is greater than 0xFFFF_FFFF, the DOSR.DOPCF flag is set to 1 and an ELC event and a data operation circuit interrupt are generated.

Note 1. Addition is executed only by writing to the DODIR.

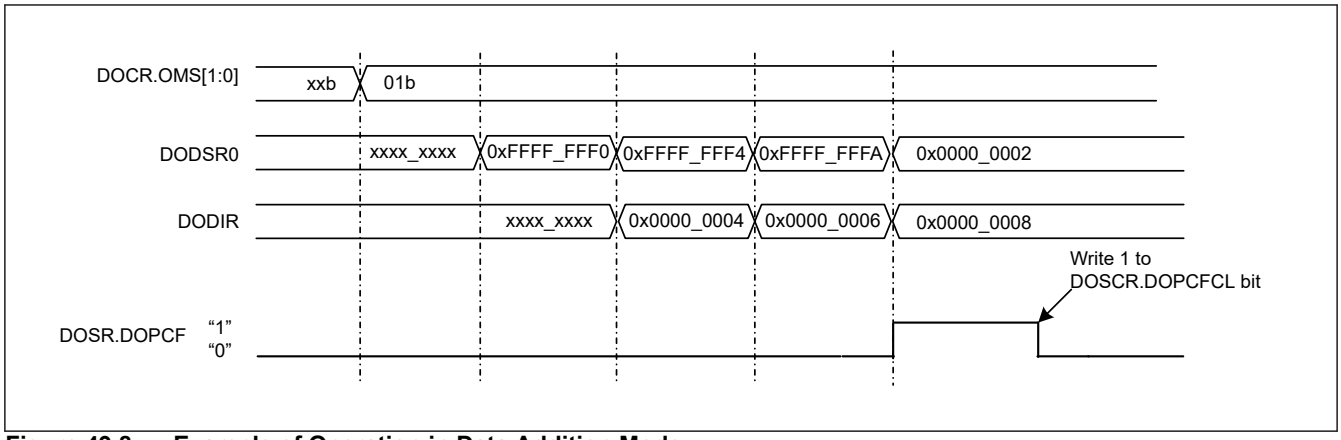

Figure 49.8 Example of Operation in Data Addition Mode

49.3.3 Data Subtraction Mode

Figure 49.9 shows an example of the steps involved in data subtraction mode *1 operation by the data operation circuit.

The following is an example of operation when the bit width of data operation is 32-bit.

1. Writing 10b to the DOCR.OMS[1:0] bits selects data subtraction mode.
2. 32-bit data is set in the DODSR0 register as the initial value.
3. 32-bit data to be subtracted is written to DODIR. The result of the operation is stored in DODSR0.
4. Writing of 32-bit data continues until all data for subtraction have been written to DODIR.
5. If the result of an operation is less than 0x0000_0000, the DOSR.DOPCF flag is set to 1 and an ELC event and a data operation circuit interrupt are generated.

Note 1. Subtraction is executed only by writing to the DODIR.

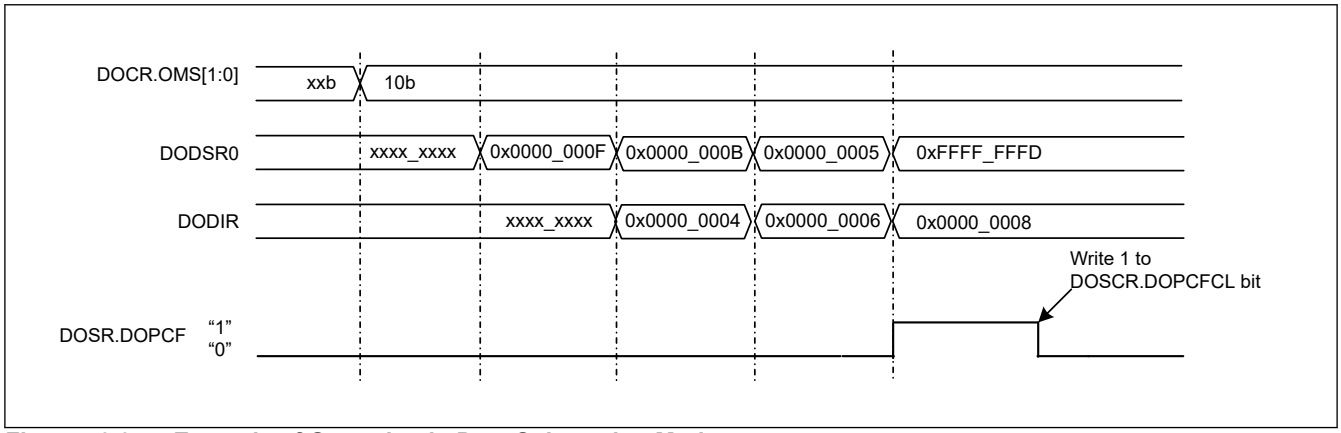

Figure 49.9 Example of Operation in Data Subtraction Mode

49.4 Interrupt Source

The data operation circuit generates the data operation circuit interrupt (DOC_DOPCI) as an interrupt request. When an interrupt source is generated, the data operation circuit flag corresponding to the interrupt is set to 1, and then interrupt request signal is generated. Table 49.2 describes the interrupt request.

Table 49.2 Interrupt request from DOC

Interrupt request	Status flag	Interrupt source
DOC interrupt	DOPCF	• The compared values match the detection condition. • The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1). • The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1).

49.5 Event Link Output

The DOC outputs event signals for the event link controller (ELC) under the following conditions, and these can be used to initiate operations by other modules selected in advance.

- The compared values match the detection condition
- The data addition result is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1)
- The data subtraction result is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)

49.6 Interrupt Handling and Event Linking

The DOC has a bit to enable or disable interrupts. An interrupt request signal is output for the CPU when an interrupt source is generated while the corresponding enable bit is enabled.

In contrast, an event link output signal is sent to other modules as an event signal via the ELC when an interrupt source is generated, regardless of the setting of the corresponding interrupt enable bit.

49.7 Usage Notes

49.7.1 Settings for the Module-Stop State

The module Stop Control Register C (MSTPCRC) can enable or disable DOC operation. The DOC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

50. SRAM

50.1 Overview

The MCU provides an on-chip, high-density SRAM module with either parity-bit checking or Error Correction Code (ECC). SRAM0 is ECC. SRAM1 is Parity check.

Table 50.1 lists the SRAM specifications.

Table 50.1 SRAM specifications

Parameter	SRAM0	SRAM1
SRAM capacity	384 KB	512 KB
SRAM address	0x2200_0000 to 0x2205_FFFF (Secure alias), 0x3200_0000 to 0x3205_FFFF (Non-secure alias)	0x2206_0000 to 0x220D_FFFF (Secure alias), 0x3206_0000 to 0x320D_FFFF (Non-secure alias)
Access	Wait states are inserted into the read cycle by default. If the ICLK frequency is higher than 120 MHz, a wait state is required. If the ICLK frequency is 120 MHz or less, a wait state is not required.	
Data retention function	Not available in Deep Software Standby mode	
Module-stop function	Module-stop state can be set to reduce power consumption	
Error checking	SEC-DED (Single-Error Correction and Double-Error Detection Code)	Even-parity (Data: 8 bits, Parity: 1 bit)
Security	TrustZone Filter is integrated for memory access and SFR access. Access to the memory space is controlled by setting the memory Security Attribution (SA). And access to I/O space (SFR) space is controlled by setting the register SA. See section 50.3.6. TrustZone Filter function.	

50.2 Register Descriptions

50.2.1 SRAMSABARn : SRAM Security Attribute Boundary Address Register (n = 0, 1)

Base address: CPSCU = 0x4000_8000
CPSCU_NS = 0x5000_8000

Offset address: 0x400 + 0x04 × n

Bit position:	31																												0
Bit field:	n/a																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	Boundary address between Secure and Non-secure. (Start address of Non-secure region)	R/W

Note: S-TYPE-1, P-TYPE-1
Note: This register is write-protected by PRCR_S.PRC4 register.

SRAMSABARn specifies the boundary address between the Secure and Non-secure regions of each SRAM. Write the absolute address to the SRAMSABARn. When writing to SRAMSABARn, writing from b31 to b21 is ignored and the value written from b12 to b0 should be 0.

The region lower than the boundary address is marked as Secure, and higher than or equal to the boundary address is marked as Non-secure.

The boundary address is as follow.

0x2200_0000 + SRAMSABARn (Secure alias)

0x3200_0000 + SRAMSABARn (Non-secure alias)

For SRAMSABAR0

When the boundary address is 0x00000000, whole SRAM0 is marked as Non-secure.

When the boundary address is 0x00060000 or large, whole SRAM0 is marked as Secure.

For SRAMSABAR1

When the boundary address is 0x00060000 or less, whole SRAM1 is marked as Non-secure.

When the boundary address is 0x000E0000 or large, whole SRAM1 is marked as Secure.

50.2.2 SRAMSAR : SRAM Security Attribution Register

Base address: CPSCU = 0x4000_8000
CPSCU_NS = 0x5000_8000

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SRAMWTSA	STBRAMSA	—	—	—	—	—	SRAMSA1	SRAMSA0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SRAMSA0	SRAM0 Register Security Attribution 0: Secure 1: Non-secure	R/W
1	SRAMSA1	SRAM1 Register Security Attribution 0: Secure 1: Non-secure	R/W
6:2	—	These bits are read as 0. The write value should be 0.	R/W
7	STBRAMSA	Standby SRAM Register Security Attribution 0: Secure 1: Non-secure	R/W
8	SRAMWTSA	SRAMWTSC Security Attribution 0: Secure 1: Non-secure	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-1, P-TYPE-1
Note: Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.
Note: This register is write-protected by PRCR_S.PRC4 register.

SRAMSA0 bit (SRAM0 Register Security Attribution)

The SRAMSA0 bit specifies security attributes of SRAMCR0, SRAMECCRGN0, SRAMESCLR.CLR00, and SRAMESCLR.CLR01.

SRAMSA1 bit (SRAM1 Register Security Attribution)

The SRAMSA1 bit specifies security attributes of SRAMCR1 and SRAMESCLR.CLR1.

STBRAMSA bit (Standby SRAM Register Security Attribution)

The STBRAMSA bit specifies security attributes of STBRAMCR and SRAMESCLR.CLRS.

SRAMWTSA bit (SRAMWTSC Security Attribution)

The SRAMWTSA bit specifies security attributes of SRAMWTSC.

50.2.3 SRAMPRCR_S : SRAM Protection Control Register for Secure

Base address: SRAM = 0x4000_2000

Offset address: 0x00

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KW[7:0]								—	—	—	—	—	—	—	PR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PR	Register Write Control 0: Writing to registers are disabled 1: Writing to registers are enabled	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KW[7:0]	Write Key Code Key code protection to the PR bit	R/W

Note: S-TYPE-6, P-TYPE-2

Note: It is necessary to write by half word access.
Byte write access is prohibited. When byte write access is executed, operation is not guaranteed.

PR bit (Register Write Control)

The PR bit controls the write mode of the SRAMWTSC, SRAMCR0, SRAMCR1, SRAMECCRGN0, and STBRAMCR registers that are marked as Secure by SRAMSAR register. When this bit is set to 1, writing to the SRAMWTSC, SRAMCR0, SRAMCR1, SRAMECCRGN0, and STBRAMCR marked as Secure is enabled.

While writing to this register it is necessary to write 0xA5 to the KW[7:0] bits simultaneously.

KW[7:0] bits (Write Key Code)

The KW[7:0] bits enable or disable writing to the PR bit. When you write to the PR bit, write 0xA5 to the KW[7:0] bits simultaneously. When a value other than 0xA5 is written to KW[7:0], the PR bit is not updated. The KW[7:0] bits are always read as 0x00.

50.2.4 SRAMPRCR_NS : SRAM Protection Control Register for Non-secure

Base address: SRAM_NS = 0x5000_2000

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KW[7:0]								—	—	—	—	—	—	—	PR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PR	Register Write Control 0: Writing to registers are disabled 1: Writing to registers are enabled	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KW[7:0]	Write Key Code Key code protection to the PR bit	R/W

Note: S-TYPE-7, P-TYPE-2

Note: It is necessary to write by half word access.
Byte write access is prohibited. When byte write access is executed, operation is not guaranteed.

PR bit (Register Write Control)

The PR bit controls the write mode of the SRAMWTSC, SRAMCR0, SRAMCR1, SRAMECCRGN0, and STBRAMCR registers that are marked as Non-secure by SRAMSAR register. When this bit is set to 1, writing to the SRAMWTSC, SRAMCR0, SRAMCR1, SRAMECCRGN0, and STBRAMCR marked as Non-secure is enabled.

While writing to this register it is necessary to write 0xA5 to the KW[7:0] bits simultaneously.

KW[7:0] bits (Write Key Code)

The KW[7:0] bits enable or disable writing to the PR bit. When you write to the PR bit, write 0xA5 to the KW[7:0] bits simultaneously. When a value other than 0xA5 is written to KW[7:0], the PR bit is not updated. The KW[7:0] bits are always read as 0x00.

50.2.5 SRAMWTSC : SRAM Wait State Control Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	WTEN
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	WTEN	SRAM Wait Enable 0: No wait 1: Add wait state in read access cycle to SRAMs	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3 (SRAMSAR.SRAMWTSA), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

WTEN bit (SRAM Wait Enable)

The WTEN bit sets the wait cycle insertion to the access cycle of SRAM. When 1 is set to the WTEN bit, 1 wait cycle is inserted to the read access cycle of SRAM. Also when the WTEN bit is 1, the access to the same region*1 and the same mat*2 is continuous and 1 wait cycle is inserted to the second access cycle. When the access frequency is more than 120 MHz, it is necessary to set 1 wait cycle to the WTEN bit.

Note 1. The region of SRAM is divided into 128 KB units.
Note 2. The mat is divided into 0x0 to 0x7 and 0x8 to 0xF in the lower 4 bits of the address.

For example, the same region and the same mat is 6 areas of SRAM0, and 8 areas of SRAM1 in the figure below. If 1 area is accessed continuously, 1 wait cycle is inserted. If ECC function is enabled or bypass is enabled, ECC region is accessed, and so if access to the same mat continues, 1 wait cycle is inserted.

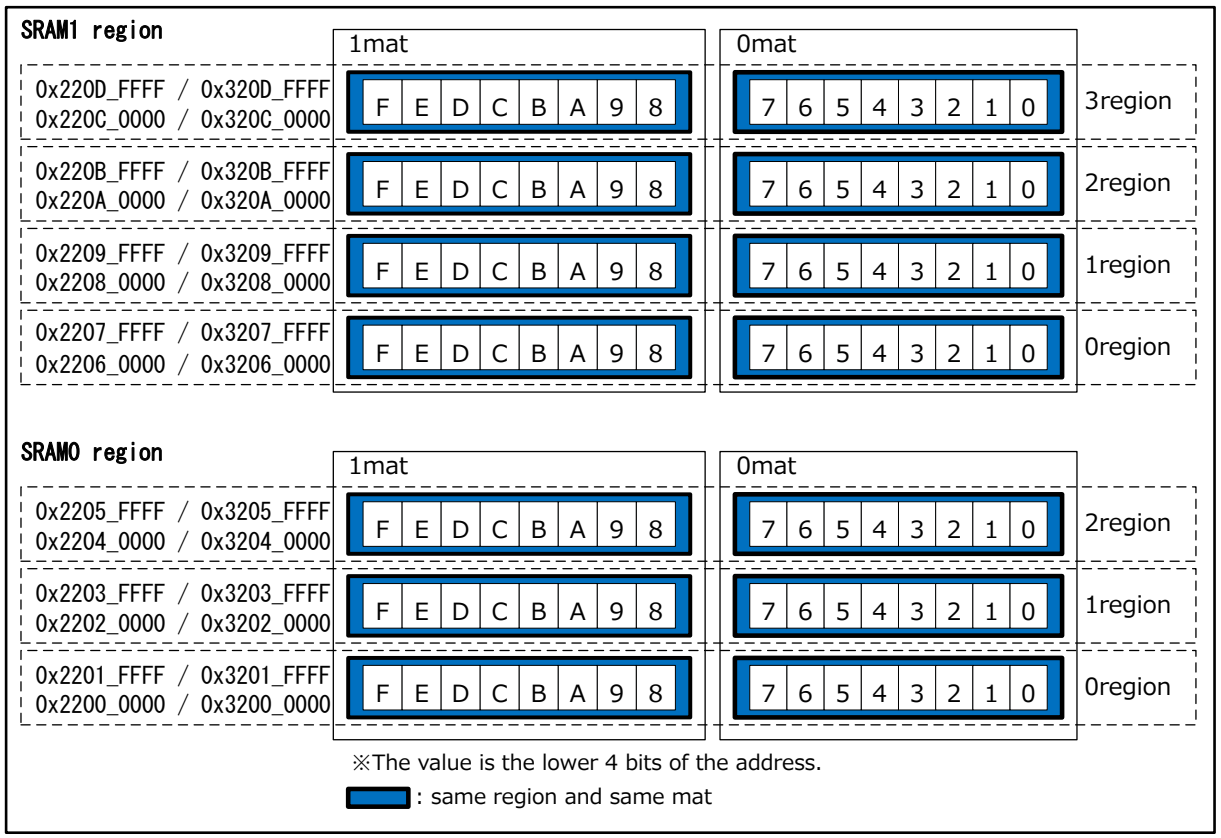

Figure 50.1 Mat configuration of each SRAM

50.2.6 SRAMCR0 : SRAM Control Register 0

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x10

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TSTBYP	—	—	E1STSEN	ECCMOD[1:0]		—	OAD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OAD	Operation after Detection for ECC Error Detection 0: Non-maskable interrupt 1: Reset.	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
3:2	ECCMOD[1:0]	ECC Operating Mode Select 0 0: Disable ECC function 0 1: Setting prohibited 1 0: Enable ECC function without error checking 1 1: Enable ECC function with error checking	R/W
4	E1STSEN	ECC 1-Bit Error Information Update Enable 0: Disable updating of 1-bit ECC error information 1: Enable updating of 1-bit ECC error information	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
7	TSTBYP	ECC Bypass Select 0: Disable ECC bypass 1: Enable ECC bypass	R/W

Note: S-TYPE-3 (SRAMSAR.SRAMSA0), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

Do not write to this register while access to SRAM is in progress. See section 50.4.2. Note of write to SRAMCR0, SRAMCR1 and SRAMECCRGN0 registers for writing to this register.

OAD bit (Operation after Detection for ECC Error Detection)

The OAD bit selects a reset or non-maskable interrupt when a ECC error is detected.

ECCMOD[1:0] bits (ECC Operating Mode Select)

The ECCMOD[1:0] bits set the access mode to the ECC area.

E1STSEN bit (ECC 1-Bit Error Information Update Enable)

The E1STSEN bit enables or disables updating of the ECC 1-bit error status bit in the SRAMESR in response to a 1-bit error. This bit also functions as an interrupt or a reset mask.

TSTBYP bit (ECC Bypass Select)

The TSTBYP bit enables direct access to ECC code by bypassing the ECC function. The ECC Bypass function is used along with setting the ECCMOD[1:0] bits in the same register as 00b. The ECC must be accessed the same address. The ECC code is assigned to the lower 8 bits. When writing the ECC code, the bits above the ECC bits are ignored. When reading the ECC code, the bits above the ECC bits are undefined.

For details of ECC test, see section 50.3.4. ECC Decoder Testing.

50.2.7 SRAMCR1 : SRAM Control Register 1

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x14

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OAD	Operation after Detection for Parity Error Detection 0: Non-maskable interrupt 1: Reset.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3 (SRAMSAR.SRAMSA1), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

Do not write to this register while access to SRAM is in progress. See section 50.4.2. Note of write to SRAMCR0, SRAMCR1 and SRAMECCRGN0 registers for writing to this register.

OAD bit (Operation after Detection for Parity Error Detection)

The OAD bit selects a reset or non-maskable interrupt when a parity error is detected.

50.2.8 SRAMECCRGN0 : SRAM0 ECC Region Control Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x30

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	ECCRGN[1:0]	
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
1:0	ECCRGN[1:0]	ECC Region Control ECC region selection 0 0: No ECC Region 0 1: 0x2200_0000 – 0x2201_FFFF / 0x3200_0000 – 0x3201_FFFF (128 KB) 1 0: 0x2200_0000 – 0x2203_FFFF / 0x3200_0000 – 0x3203_FFFF (256 KB) 1 1: 0x2200_0000 – 0x2205_FFFF / 0x3200_0000 – 0x3205_FFFF (384 KB) The ECC area selected by this register can be controlled by SRAMCR0.	R/W
7:2	—	These bits are read as 1. The write value should be 1.	R/W

Note: S-TYPE-3 (SRAMSAR.SRAMSA0), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

Do not write to this register while access to SRAM is in progress. See section 50.4.2. Note of write to SRAMCR0, SRAMCR1 and SRAMECCRGN0 registers for writing to this register.

ECCRGN[1:0] bits (ECC Region Control)

The ECCRGN[1:0] bits select ECC area in SRAM0.

50.2.9 SRAMESR : SRAM Error Status Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x40

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	ERRS	—	—	—	—	—	—	—	—	—	—	—	ERR1	ERR01	ERR00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ERR00	SRAM0 1-bit ECC Error Status 0: 1-bit ECC error has not occurred. 1: 1-bit ECC error has occurred.	R
1	ERR01	SRAM0 2-bit ECC Error Status 0: 2-bit ECC error has not occurred. 1: 2-bit ECC error has occurred.	R
2	ERR1	SRAM1 Parity Error Status 0: Parity error has not occurred. 1: Parity error has occurred.	R
13:3	—	These bits are read as 0.	R
14	ERRS	Standby SRAM Parity Error status 0: Parity error has not occurred. 1: Parity error has occurred.	R
15	—	This bit is read as 0.	R

Note: S-TYPE-5, P-TYPE-2

This register is cleared by the corresponding bit in the SRAMESCLR register or resets other than Bus Error Reset and Memory Error Reset. If error and clear occur at the same time, clear has priority. Also updating register stops during accessing from debugger.

ERR00 bit (SRAM0 1-bit ECC Error Status)

The ERR00 bit shows whether there is a 1-bit ECC error in SRAM0.

When ECC operations are enabled, error correction is selected and updating of the 1-bit error information is enabled. The ERR00 bit is set to 1 if there is a 1-bit error.

When the ERR00 bit is set to 1, a reset or non-maskable interrupt request is generated according to the SRAMCR0.OAD.

ERR01 bit (SRAM0 2-bit ECC Error Status)

The ERR01 bit shows whether there is a 2-bit ECC error in SRAM0.

When ECC operations are enabled, error correction is selected. The ERR01 bit is set to 1 if there is a 2-bit error.

When the ERR01 bit is set to 1, a reset or non-maskable interrupt request is generated according to the SRAMCR0.OAD.

ERR1 bit (SRAM1 Parity Error Status)

The ERR1 bit shows whether there is a parity error or not in the SRAM1.

The ERR1 bit is set if a parity error is detected.

When the ERR1 bit is set to 1, a reset or non-maskable interrupt request is generated according to the SRAMCR1.OAD.

ERRS bit (Standby SRAM Parity Error status)

The ERRS bit shows whether there is a parity error or not in the Standby SRAM.

The ERRS bit is set to 1 if there is an error.

When the ERRS bit is set to 1, a reset or non-maskable interrupt request is generated according to the STBRAMCR.OAD.

50.2.10 SRAMESCLR : SRAM Error Status Clear Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x48

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	CLRS	—	—	—	—	—	—	—	—	—	—	—	CLR1	CLR01	CLR00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CLR00	SRAM0 1-bit ECC Error Status Clear Writing to the CLR00 clears SRAMESR.ERR00. 1: Clear 1-bit ECC error. Read value is always 0.	R/W*1
1	CLR01	SRAM0 2-bit ECC Error Status Clear Writing to the CLR01 clears SRAMESR.ERR01. 1: Clear 2-bit ECC error. Read value is always 0.	R/W*1
2	CLR1	SRAM1 Parity Error Status Clear Writing to the CLR1 clears SRAMESR.ERR1. 1: Clear Parity error. Read value is always 0.	R/W*1
13:3	—	These bits are read as 0. The write value should be 0.	R/W
14	CLRS	Standby SRAM Parity Error Status Clear Writing to the CLRS clears SRAMESR. ERRS. 1: Clear Parity error. Read value is always 0.	R/W*1

Bit	Symbol	Function	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-4 (SRAMSAR.SRAMSAn,STBRAMSA), P-TYPE-2
Note 1. For each bit, only 1 can be written to clear the error status.

CLR00 bit (SRAM0 1-bit ECC Error Status Clear)

The CLR00 bit can clear the SRAM0 1-bit ECC error status bit in the SRAMESR. If error and clear occur at the same time, clear has priority.

The SRAMESR.ERR00 bit can be cleared when writing 1 to CLR00.

CLR01 bit (SRAM0 2-bit ECC Error Status Clear)

The CLR01 bit can clear the SRAM0 2-bit ECC error status bit in the SRAMESR. If error and clear occur at the same time, clear has priority.

The SRAMESR.ERR01 bit can be cleared when writing 1 to CLR01.

CLR1 bit (SRAM1 Parity Error Status Clear)

The CLR1 bit can clear the SRAM1 parity error status bit in the SRAMESR. If error and clear occur at the same time, clear has priority.

The SRAMESR.ERR1 bit can be cleared when writing 1 to CLR1.

CLRS bits (Standby SRAM Parity Error Status Clear)

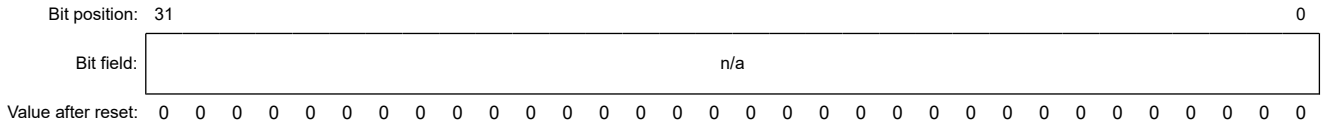
The CLRS bits can clear the Standby SRAM Parity error bit in the SRAMESR. If error and clear occur at the same time, clear has priority.

The SRAMESR.ERRS bit can be cleared when writing 1 to CLRS.

50.2.11 SRAMEARn : SRAM Error Address Register (n = 0 to 2)

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x50 + 0x04 × n



Bit	Symbol	Function	R/W
31:0	n/a	When an SRAM error occurs, it stores an error address.	R

Note: S-TYPE-5, P-TYPE-2

This register is cleared by the corresponding bit in the SRAMESCLR register or resets other than Bus Error Reset and Memory Error Reset. If error and clear occur at the same time, clear has priority. Also updating register stops during accessing from debugger.

The error address is as follow.

0x2200_0000 + SRAMEARn (Secure alias)

0x3200_0000 + SRAMEARn (Non-secure alias)

For SRAMEAR0

This register stores the error address where 1-bit ECC error is detected. These bits hold the error address that occurred first. These bits are cleared by clearing 1-bit ECC error from SRAMESCLR.

For SRAMEAR1

This register stores the error address where 2-bit ECC error is detected. These bits hold the error address that occurred first. These bits are cleared by clearing 2-bit ECC error from SRAMESCLR.

For SRAMEAR2

This register stores the error address where parity error is detected. These bits hold the error address that occurred first. These bits are cleared by clearing parity error from SRAMESCLR.

50.3 Operation

50.3.1 Module Stop Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to SRAM.

SRAMn (n = 0 ,1) is controlled by SRAMn bit in MSTPCRA register and, in the case of 1, SRAMn becomes the clock stop state.

The SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The SRAM operates after a reset.

SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to SRAM is in progress.

Access to the SRAM in the module-stop state is prohibited. If access is attempted, correct operation is not guaranteed.

For details on the MSTPCRA register, see section 10, Low Power Modes.

50.3.2 Correction of ECC errors

Enabling and disabling of ECC error correction can be selected through the setting by ECCMOD[1:0] bits of SRAMCR0 register. In the initial state, ECC error correction is disabled. The ECC check type is SEC-DED (Single-Error Correction and Double-Error Detection Code).

When ECC function is enabled, 8-bit check bits are appended to 64-bit data for writing. For reading, 72-bit (data: 64 bits, check bits: 8 bits) data is read out from the SRAM (ECC area) .

When ECC function and error checking are enabled, error correction is done if a 1-bit error occurs and the ERR00 bit in the SRAMESR register is set to 1 if the E1STSEN bit in the SRAMCR0 register is 1. If a 2-bit error occurs, error detection is done and the ERR01 bit in the SRAMESR register is set to 1, though error correction is not performed.

When ECC function is enabled and the error checking is disable, error correction is done if a 1-bit error occurs but ERR00 bit in the SRAMESR register is not updated although E1STSEN bit in the SRAMCR0 register is 1. If a 2-bit error occurs, this error is detected but the ERR01 bit in the SRAMESR register is not updated, and error correction is not performed.

When ECC function is disable, neither error correction nor error detection is done although 1-bit or 2-bit error occur.

So ERR00 and ERR01 bits are not updated.

When updating all the data after the occurrence of an error, the only support of 64 bit data writing.

Since the SRAM data is undefined after power on and release from Deep Software Standby mode, accessing the SRAM when ECC function is enabled and error checking is selected causes an ECC error to occur. Therefore, before using ECC function, initial writing with 64-bit data size, or initial writing with ECC function is enabled and the error checking is disabled, to the area to be used in the SRAM should be done.

When a read access is executed in a row after a write access, read access may be executed with priority. Therefore, during initialization, please do not perform the read access in a row after the write access.

50.3.3 ECC Error Interrupt Function

When ECC function is enabled, error checking is possible in the SRAM0. In the case of a 2-bit error, the ERR01 bit in the SRAMESR register set to 1. In the case of a 1-bit error, the ERR00 bit in the SRAMESR register set to 1 when SRAMCR0.E1STSEN bit is 1.

When the ECC 1-bit error is to be masked, it is necessary to set the SRAMCR0.E1STSEN bit to 0 to disable updating of the ERR00 bit to 1. An ECC error will not be generated while ECC function is disabled or when ECC function is enabled but error checking is not selected using the SRAMCR0.ECCMOD[1:0] bits.

ECC error may result in non-maskable interrupt or reset. When the OAD bit in the SRAMCR0 register is 1, ECC error is outputted to the Reset function. When it is 0, ECC Error interrupt is outputted to the ICU as a non-maskable interrupt.

ECC Error interrupt occurs when one flag in the SRAMESR register is set. ECC Error interrupt continues to occur until the SRAMESR register flag is cleared.

50.3.4 ECC Decoder Testing

ECC decoder testing should be done in the following order.

1. Executes the DMB instruction.
2. Write 0xA501 to the SRAMPRCR_S or SRAMPRCR_NS and enable writes to the SRAM-related registers.
3. Write 0x08 to the SRAMCR0 and enable the ECC function without error checking and disable the ECC bypass.
4. Executes the DMB instruction.
5. Write 8-bytes data to the target address. The 8-bits ECC code is automatically updated.
6. Executes the DMB instruction.
7. Write 0x80 to the SRAMCR0 and enable the ECC bypass.
8. Executes the DMB instruction.
9. Read target address to get 8-bits-ECC code.
10. To generate 1-bit/2-bit ECC error, reverse 1-bit/2-bit of the data read in the previous process and write the data back to the target address.
11. Executes the DMB instruction.
12. Write 0x1C to the SRAMCR0, disable the ECC bypass and enable the updating of 1-bit ECC error information and enable the ECC function with error checking.
13. Executes the DMB instruction.
14. Read the target address.
15. Executes the DMB instruction.
16. Confirm the generation of the ECC error by the SRAMESR.

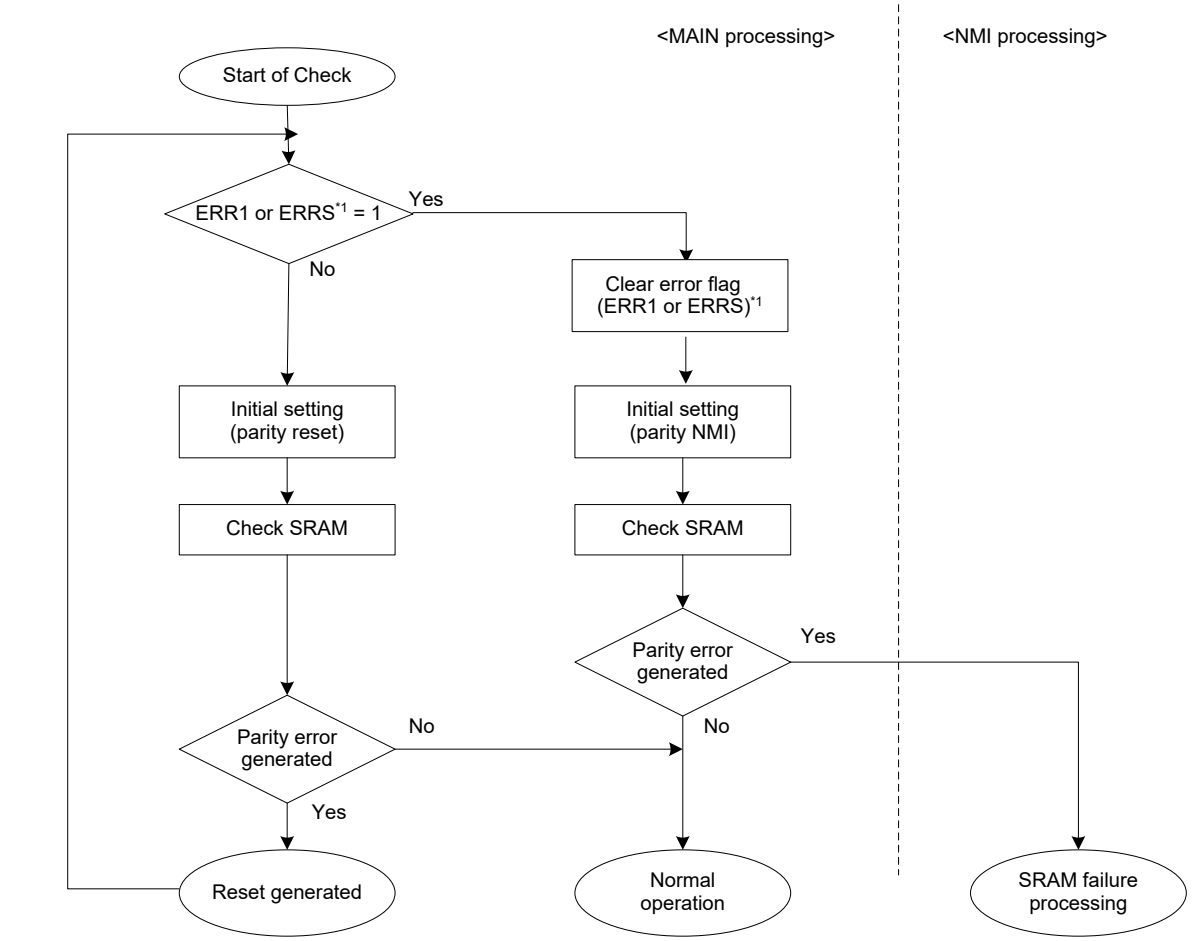
50.3.5 Parity Calculation Function

The IEC60730 standard requires the checking of SRAM data. When data is written, a parity bit is added to every 8-bit data in the SRAM, and when data is read, the parity is checked. When a parity error occurs, a parity-error notification is generated. This function can also be used to trigger a reset.

The parity-error notification can be specified as a non-maskable interrupt or a reset in the OAD bit of the SRAMCR1 register. When the OAD bit is set to 1, a parity error is output to the reset function. When the OAD bit is set to 0, a parity error is output to the ICU as a non-maskable interrupt.

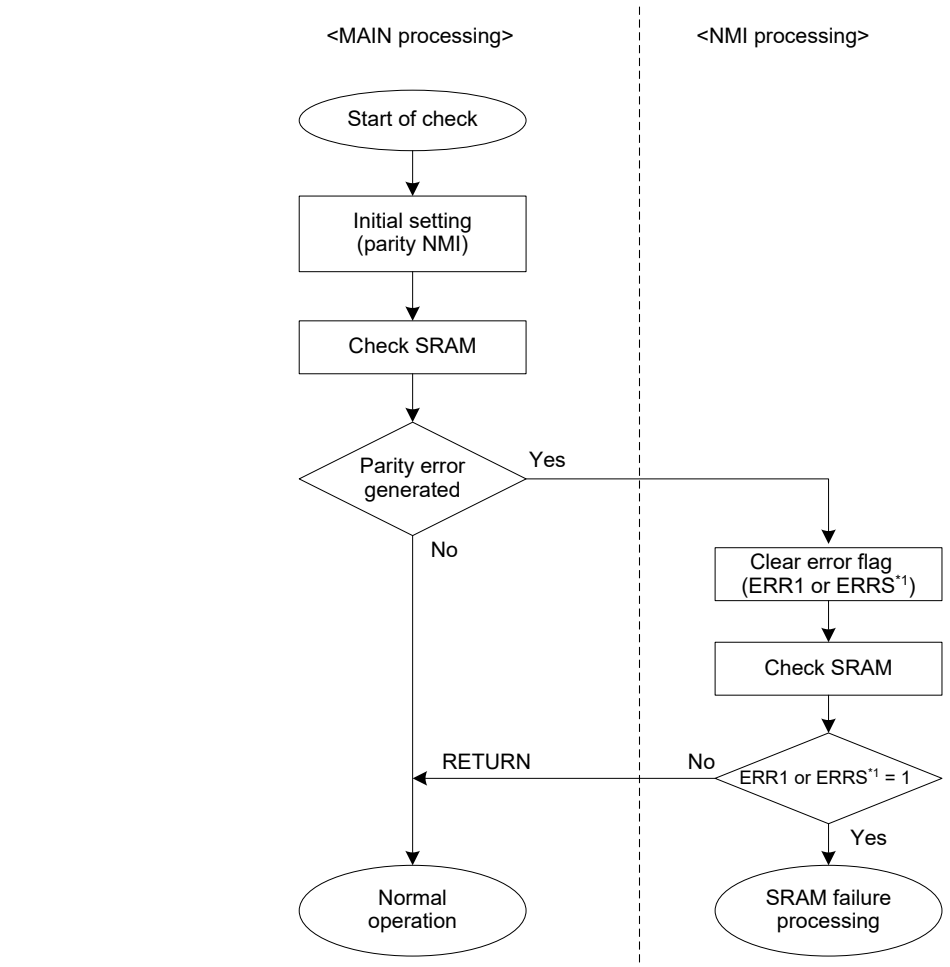
Parity Error often occurs due to noise. It is possible to confirm whether the parity error is caused by noise or destruction of data by following the parity operation flowchart. Figure 50.2 and Figure 50.3 shows flowcharts of SRAM parity check operation..

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, do not perform the read access in a row after the write access.



Note 1. ERR1 or ERRS: SRAM error status (SRAMESR.ERR1, ERRS bit)

Figure 50.2 Flow of SRAM parity check when SRAM parity reset is enabled



Note 1. ERR1 or ERRS: SRAM error status (SRAMESR.ERR1, ERRS bit)

Figure 50.3 Flow of SRAM parity check when SRAM parity interrupt is enabled

50.3.6 TrustZone Filter function

50.3.6.1 TrustZone Filter for SRAM Registers

SRAM registers can be protected with a Security Attribution (SA) from Non-secure or Secure transaction. When SA indicates that SRAM registers are Secure status, Non-secure transaction cannot access them because TrustZone Filter detects an error and protects the access. When SA indicates that SRAM registers are Non-secure status, Secure transaction cannot access them because Trust Zone Filter detects an error and protects the access. SA for SRAM registers is just one to be used commonly among SRAM registers.

In the case of a failed access due to TrustZone error, error response is generated.

Table 50.2 Register protection (1 of 2)

SA	Transaction	Write access	Read access
Secure	Secure	Permitted	Permitted
	Non-secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)

Table 50.2 Register protection (2 of 2)

SA	Transaction	Write access	Read access
Non-secure	Secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
	Non-secure	Permitted	Permitted

50.3.6.2 TrustZone Filter for SRAM Memory Regions

SRAM0, SRAM1 regions can be divided into Secure and Non-secure independently. The access permissions for these regions are as below.

Table 50.3 Memory protection

SA	Transaction	Write access	Read access
Secure	Secure	Permitted	Permit
	Non-secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
Non-secure	Secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
	Non-secure	Permitted	Permitted

TrustZone filter error for SRAM memory generates an error notification.

50.3.7 Interrupt Source

The SRAM interrupt source includes an ECC error, Parity error and TrustZone filter error. ECC error and Parity error can choose non-maskable interrupt or reset by SRAMCR0.OAD or SRAMCR1.OAD bit. The SRAM interrupt occurs when one error status in the SRAMESR register is set to 1, the SRAM interrupt continues to occur until the SRAMESR register flag is cleared. When Common memory error occur (NMISR.CMST=1 or RSTSR1.CMSR=1), please read SRAMESR and check SRAM interrupt source. When the access from debugger, the error is detected and corrected, but no error flag is set, reset and non-maskable interrupt are maskable. For details on the debug mode, see section 2, CPU.

Table 50.4 SRAM Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
ECCERR	ECC error (SRAMs with ECC)	Not possible	Not possible
PARITYERR	Parity error (SRAMs with parity)	Not possible	Not possible
TZFLT	TrustZone filter error	Not possible	Not possible

50.3.8 Wait state

When ICLK frequencies is higher than 120 MHz, do not set 0x00 in wait enable bit for the SRAMWTSC register, in order to insert a wait cycle. When the wait is not inserted, the operation is not guaranteed.

Depending on the operating frequency of ICLK, the WAIT setting for SRAM access has the following conditions.

[ICLK frequency]:

- 240 MHz ≥ ICLK > 120 MHz = 1 wait
- 120 MHz ≥ ICLK = No-wait

50.4 Usage Note

50.4.1 Instruction fetch from SRAM area

When using SRAM to operate a program, initialize the SRAM area so that the CPU can correctly prefetch data. A parity or ECC error might occur if the CPU prefetches from an area that is not initialized. Initialize the additional 12-byte area from the end address of the program with the 8-byte boundary. Renesas recommends using the NOP instruction for data initialization.

50.4.2 Note of write to SRAMCR0, SRAMCR1 and SRAMECCRGN0 registers

This chapter provides examples of how to configure SRAMCR0, SRAMCR1 and SRAMECCRGN0.

All of the followings have to be satisfied:

1. CPU does not execute program stored in SRAM
2. All bus masters other than CPU does not access SRAM
3. SRAMCR0, SRAMCR1 and SRAMECCRGN0 are Device-nGnRnE set by MPU
4. SRAMCR0, SRAMCR1 and SRAMECCRGN0 have to be configured with the following procedure:
   1. DMB instruction
   2. Write to SRAMCR0, SRAMCR1 and SRAMECCRGN0 registers
   3. DMB instruction

50.4.3 Notes on Using Error Checking of SRAM

Data in SRAM are undefined when the power is turned on. Therefore, parity check errors or ECC errors occur if the data are read before initialization. The SRAM are read in 8-byte (64-bit) units. Initialize them on 8-byte boundaries.

51. Standby SRAM

51.1 Overview

An on-chip SRAM is provided to retain data in Deep Software Standby mode. Table 51.1 lists the Standby SRAM specifications.

Table 51.1 Standby SRAM specifications

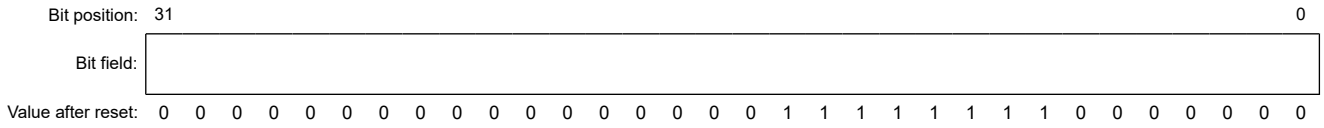
Item	Description
SRAM capacity	1 KB
SRAM address	0x2600_0000 to 0x2600_03FF (Secure alias), 0x3600_0000 to 0x3600_03FF (Non-secure alias)
Access	Wait states are inserted into the access cycle by default. If the ICLK frequency is higher than 120 MHz, a wait state is required. If the ICLK frequency is 120 MHz or less, a wait state is not required.
Data retention function	Data can be retained in Deep Software Standby mode 1. In Deep Software Standby mode 2 and 3, data cannot be retained. See section 51.3.1. Data Retention for details.
parity	Even parity (data: 8 bits, parity: 1 bit)
Module-stop function	Module-stop state can be set to reduce power consumption. See section 51.3.2. Module-stop Function for details.
Security	Permits the read and write operations to Standby RAM following TrustZone Filter function. See section 51.3.4. TrustZone Filter function for details.

51.2 Register Descriptions

51.2.1 STBRAMSABAR : Standby SRAM Security Attribute Boundary Address Register

Base address: CPSCU = 0x4000_8000
CPSCU_NS = 0x5000_8000

Offset address: 0x420



Bit	Symbol	Function	R/W
31:0	n/a	Boundary address between Secure and Non-secure.	R/W

Note: S-TYPE-1, P-TYPE-1
Note: This register is write-protected by PRCR_S.PRC4 register.

STBRAMSABAR specifies the boundary address between the Secure and Non-secure regions of Standby SRAM. Write the absolute address to the STBRAMSABAR. When writing to STBRAMSABAR, writing from b31 to b15 is ignored and the value written from b6 to b0 should be 0.

The region lower than the boundary address is marked as Secure, and higher than or equal to the boundary address is marked as Non-secure. Therefore, when the boundary address is 0x00000000, whole Standby SRAM is marked as Non-secure, and when the boundary address is 0x00000400 or large, whole Standby SRAM is marked as Secure.

The boundary address is as follow.

- 0x2600_0000 + STBRAMSABAR (Secure alias)
- 0x3600_0000 + STBRAMSABAR (Non-secure alias)

51.2.2 STBRAMPABAR_NS : Standby SRAM Privilege Attribute Boundary Address Register for Non-secure

Base address: CPSCU_NS = 0x5000_8000

Offset address: 0x490

Bit position:	31																												0
Bit field:	n/a																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	Boundary address between Privileged and Unprivileged.	R/W

Note: S-TYPE-7, P-TYPE-2
Note: This register is write-protected by PRCR_NS.PRC4 register.

STBRAMPABAR_NS specifies the boundary address between the Privileged and Unprivileged regions of Standby SRAM Non-secure regions set by STBRAMSABAR. Write the absolute address to the STBRAMPABAR_NS. When writing to STBRAMPABAR_NS, writing from b31 to b15 is ignored and the value written from b6 to b0 should be 0.

The region lower than the boundary address is marked as Privileged, and higher than or equal to the boundary address is marked as Unprivileged. Therefore, when the boundary address is 0x00000000, or less than or equal to start address of Standby SRAM Non-secure regions set by STBRAMSABAR, whole Standby SRAM is marked as Unprivileged, and when the boundary address is 0x00000400 or large, or higher than or equal to end address of Standby SRAM Non-secure regions set by STBRAMSABAR, whole Standby SRAM is marked as Privileged.

The boundary address is as follow.

- 0x3600_0000 + STBRAMPABAR_NS (Non-secure alias)

51.2.3 STBRAMPABAR_S : Standby SRAM Privilege Attribute Boundary Address Register for Secure

Base address: CPSCU = 0x4000_8000

Offset address: 0x494

Bit position:	31																												0
Bit field:	n/a																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	Boundary address between Privileged and Unprivileged.	R/W

Note: S-TYPE-6, P-TYPE-2
Note: This register is write-protected by PRCR_S.PRC4 register.

STBRAMPABAR_S specifies the boundary address between the Privileged and Unprivileged regions of Standby SRAM Secure regions set by STBRAMSABAR. Write the absolute address to the STBRAMPABAR_S. When writing to STBRAMPABAR_S, writing from b31 to b15 is ignored and the value written from b6 to b0 should be 0.

The region lower than the boundary address is marked as Privileged, and higher than or equal to the boundary address is marked as Unprivileged. Therefore, when the boundary address is 0x00000000, or less than or equal to start address of Standby SRAM Secure regions set by STBRAMSABAR, whole Standby SRAM is marked as Unprivileged, and when the boundary address is 0x00000400 or large, or higher than or equal to end address of Standby SRAM Secure regions set by STBRAMSABAR, whole Standby SRAM is marked as Privileged.

The boundary address is as follow.

- 0x2600_0000 + STBRAMPABAR_S (Secure alias)

51.2.4 STBRAMCR : Standby SRAM Control Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x110

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OAD	Operation after detection 0: Non-maskable interrupt. 1: Reset.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3 (SRAMSAR.STBRAMSA), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

Do not write to this register while access to Standby SRAM is in progress.

OAD bit (Operation after detection)

This bit is specified to generate either reset or non-maskable interrupt when parity error is detected.

51.2.5 STBRAMEAR : Standby SRAM Error Address Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x150

Bit position:	31	0
Bit field:	n/a	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	n/a	When an SRAM error occurs, it stores an error address.	R

Note: S-TYPE-5, P-TYPE-2

This register is cleared by the corresponding bit in SRAMESCLR register, or resets other than Bus Error Reset and Memory Error Reset. If error and clear occur at the same time, clear has priority. Also during accessing from debugger it is to stop updating register.

The error address is as follow.

- 0x2600_0000 + STBRAMEAR (Secure alias)
- 0x3600_0000 + STBRAMEAR (Non-secure alias)

This register stores the error address where parity error is detected. These bits hold the error address that occurred first. These bits are cleared by clearing parity error from SRAMESCLR.

51.3 Operation

51.3.1 Data Retention

The power supply to the Standby SRAM in Deep Software Standby mode is enabled by the DPSBYCR.SRKEEP bit. If the DPSBYCR.SRKEEP bit are set to 1b, data in the Standby SRAM is retained in Deep Software Standby mode 1. For details on the DPSBYCR.SRKEEP bit, see section 10, Low Power Modes.

51.3.2 Module-stop Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to SRAM.

If the Standby SRAM bit in MSTPCRA is set to 1, supply of the clock signal to the Standby SRAM is stopped.

The Standby SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The Standby SRAM operates after a reset.

The Standby SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to the standby SRAM is in progress.

Access to the Standby SRAM in the module-stop state is prohibited. If access is attempted, correct operation is not guaranteed.

For details on the MSTPCRA register, see section 10, Low Power Modes.

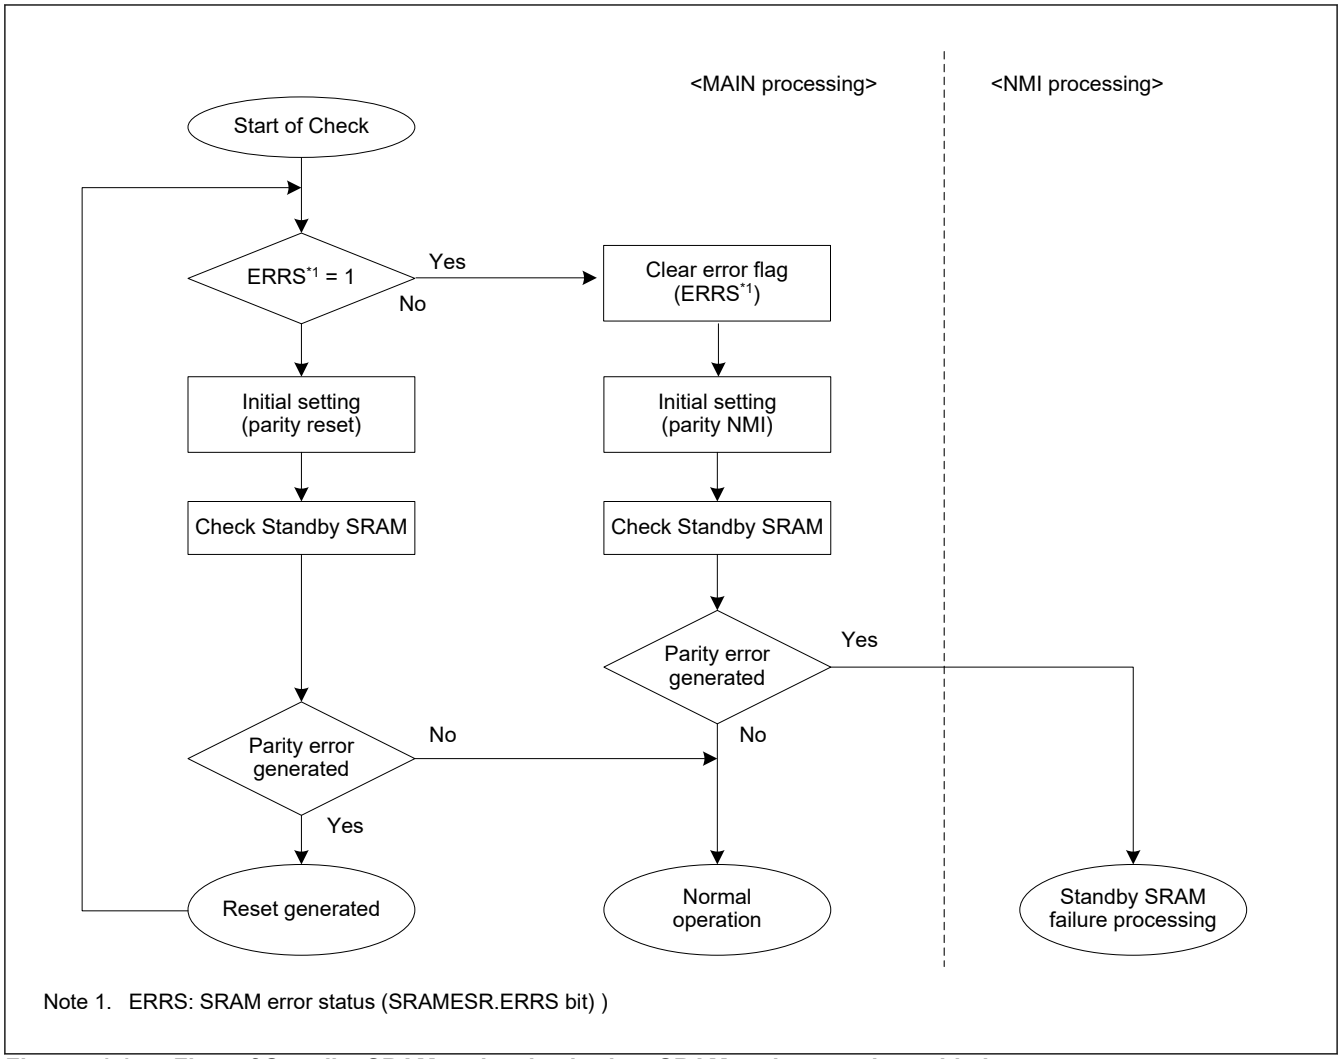
51.3.3 Parity Calculation Function

The IEC60730 standard requires the checking of STBRAMCR data. When data is written, a parity bit is added to every 8-bit data in the Standby SRAM which has 32-bit data width, and when data is read, the parity is checked. When a parity error occurs, a parity error notification is generated. This function can also be used to trigger a reset.

The parity-error notification can be specified as a non-maskable interrupt or a reset in the OAD bit of the STBRAMCR register. When the OAD bit is set to 1, a parity error is output to the reset function. When the OAD bit is set to 0, a parity error is output to the ICU as a non-maskable interrupt.

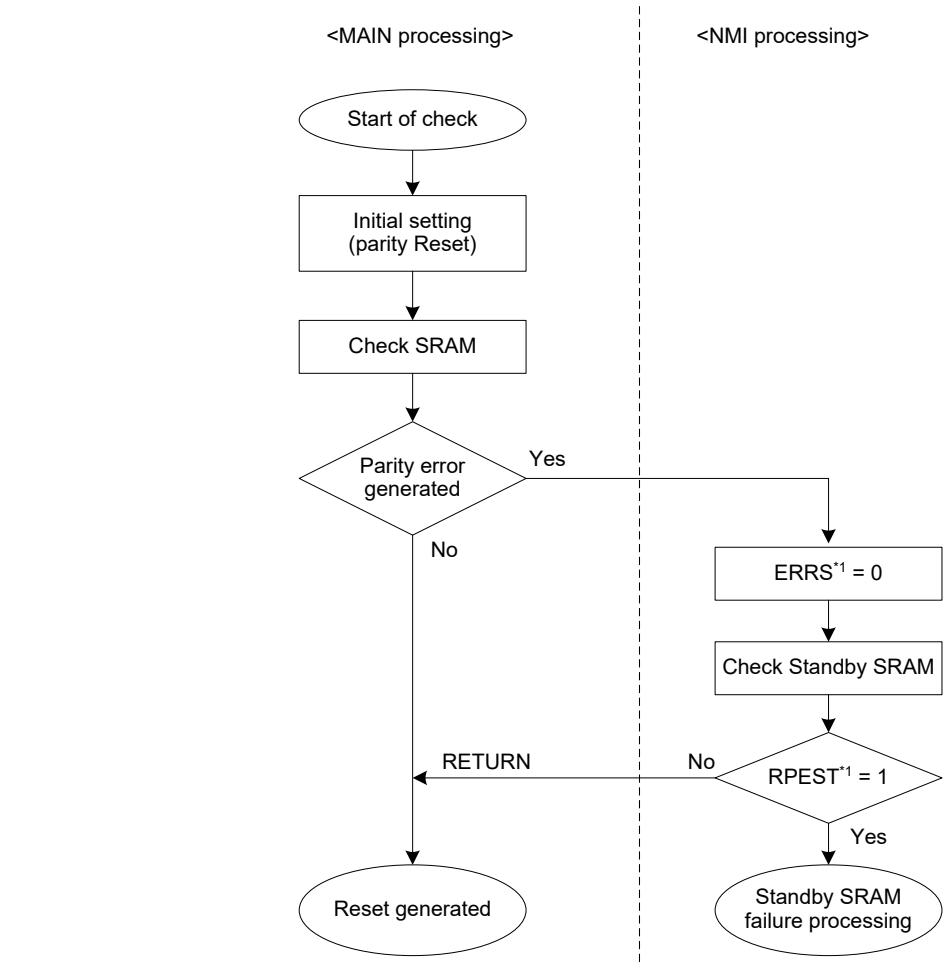
Parity errors often occur because of noise. To confirm whether the cause of the parity error is noise or corruption, follow the parity check flows shown in Figure 51.1 and Figure 51.2.

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, do not perform the read access in a row after the write access.



Note 1. ERRS: SRAM error status (SRAMESR.ERRS bit))

Figure 51.1 Flow of Standby SRAM parity check when SRAM parity reset is enabled



Note 1. ERRS: SRAM error status (SRAMESR.ERRS bit)

Figure 51.2 Flow of Standby SRAM parity check when SRAM parity interrupt is enabled

51.3.4 TrustZone Filter function

51.3.4.1 TrustZone Filter for Standby SRAM registers

Standby SRAM registers can be protected with a Security Attribution (SA) from Non-secure or Secure transaction. When SA indicates that Standby SRAM registers are Secure status, Non-secure transaction can not access them because TrustZone Filter detects finds an error and protects the access. When SA indicates that SRAM registers are Non-secure status, Secure transaction can not access them because Trust Zone Filter detects finds an error and protects the access. SA for Standby SRAM registers is just one to be used commonly among Standby SRAM registers.

In the case of a failed access due to TrustZone error, error response is generated.

Table 51.2 Standby SRAM register protection

SA	Transaction	Write access	Read access
Secure	Secure	Permitted	Permitted
	Non-secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
Non-secure	Secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
	Non-secure	Permitted	Permitted

51.3.4.2 TrustZone Filter for Standby SRAM memory regions

Standby SRAM regions can be divided into Secure and Non-secure. The access permissions for these regions are as below.

Table 51.3 Standby SRAM memory protection by Security Attribution

SA	Transaction	Write access	Read access
Secure	Secure	Permitted	Permitted
	Non-secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
Non-secure	Secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
	Non-secure	Permitted	Permitted

Standby SRAM regions can be divided into Privileged and Unprivileged. The access permissions for these regions are as below.

Table 51.4 Standby SRAM memory protection by Privilege Attribution

PA	Transaction	Write access	Read access
Privileged	Privileged	Permitted	Permitted
	Unprivileged	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
Unprivileged	Privileged	Permitted	Permitted
	Unprivileged	Permitted	Permitted

TrustZone Filter error for Standby SRAM memory generates an error notification.

For details, see section 43, Security Features .

51.3.5 Interrupt Source

The Standby SRAM interrupt source includes a Parity error and TrustZone filter error.

Parity error can choose non-maskable interrupt or reset by STBRAMCR.OAD bit.

The Standby SRAM interrupt occurs when the SRAMESR.ERRS is set to 1. the Standby SRAM interrupt continues to occur until the SRAMESR.ERRS is cleared.

When Common memory error occur(NMISR.CMST=1 or RSTSR1.CMSR=1), please read SRAMESR and check SRAM interrupt source. When the access from debugger, no error flag is set, reset and non-maskable interrupt are maskable.

For more detail on the debug mode, see section 2, CPU.

Table 51.5 Standby SRAM Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
PARITYERR	Parity error	Not possible	Not possible
TZFLT	TrustZone filter error	Not possible	Not possible

51.3.6 Wait state

When ICLK frequencies is higher than 120 MHz, do not set 0x00 in wait enable bit for the SRAMWTSC register, in order to insert a wait cycle. When the wait is not inserted, the operation is not guaranteed.

Depending on the operating frequency of ICLK, the WAIT setting for Standby SRAM access has the following conditions.

[ICLK frequency]:

- 240 MHz ≥ ICLK > 120 MHz = 1 wait
- 120 MHz ≥ ICLK = No-wait

51.4 Usage Notes

51.4.1 Instruction Fetch from the Standby SRAM Area

When using Standby SRAM to operate a program, initialize the Standby SRAM area so that the CPU can correctly prefetch data. A parity error might occur if the CPU prefetches from an area that is not initialized. Initialize the additional 12-byte area from the end address of the program with the 4-byte boundary. Renesas recommends using the NOP instruction for data initialization.

51.4.2 Notes on Self-Diagnosis of the Standby SRAM

A write buffer is mounted for the Standby Standby SRAM. When the same address is read after a write operation, data in the write buffer, rather than in the memory cell of the Standby SRAM may be read. When the Standby SRAM is self-diagnosed, confirm that the data have been written by following the procedure below so that data will not be read from the write buffer.

1. Write data to the address targeted for diagnosis.
2. Write data to an address which is at least 4 addresses away from the that in step1.
3. Read the data from the address in step1.

52. Flash Memory

This MCU incorporates code flash memory, data flash memory, and option-setting memory. The code flash memory stores instructions and operands, and the data flash memory stores data. For option-setting memory, see section 6, Option-Setting Memory.

52.1 Overview

Table 52.1 lists the specifications of the flash memory, and Figure 52.1 is block diagrams of the flash memory related modules.

The I/O pins used in boot mode, see Table 52.37.

The FCU (flash control unit) controls programming and erasure of the flash memory. The FACI (flash application command interface) controls the FCU according to the specified FACI commands.

Regarding the configuration of the code flash memory, see Figure 52.2 to Figure 52.3, and for the configuration of the data flash memory, see Figure 52.4.

Table 52.1 Specifications of flash memory (1 of 2)

Item	Code flash memory	Data flash memory
Memory capacity	User area: 2 Mbytes max	Data area: 12 Kbytes
Value after erasure	0xFF	Undefined
Programming/erasing method	• Programming and erasing the code flash memory and data flash memory, and programming the option-setting memory are handled by the FACI commands specified in the FACI command issuing area (Secure: 0x4010_0000, Non-secure: 0x5010_0000) (self-programming). • Programming/erasure through transfer by a serial-programmer via a serial interface (serial programming)	
Protection	Protects against erroneous rewriting of the flash memory	
Dual bank function	The dual-bank structure makes a safe update possible in cases where programming is suspended. • Linear mode: the code flash memory is used as one area. • Dual mode: the code flash memory is divided into two areas.	Not available
Block swap function	The block swap structure makes a safe update for a part of Non-secure application possible in case where programming is suspended.	Not available
Background operations (BGOs)	• The code flash memory can be read while the code flash memory is being programmed or erased. • The data flash memory can be read while the code flash memory is being programmed or erased. • The code flash memory can be read while the data flash memory is being programmed or erased.	
Units of programming and erasure	• Units of programming for the user area: 128 bytes • Units of erasure for the user area: Block units	• Unit of programming for the data area:4/8/16 bytes • Unit of erasure for the data area:64/128/256 bytes
Other functions	Interrupts can be accepted during self-programming. In the initial settings of this MCU, an expansion area of the option-setting memory can be set.	
On-board programming (four types)	Programming/erasure in boot mode (for the SCI interface) • The asynchronous serial interface (SCI9) is used. • The transfer rate is adjusted automatically. Programming/erasure in boot mode (for the USB interface) • USBFS is used. • Dedicated hardware is not required, so direct connection to a PC is possible. Programming/erasure in On-chip debug mode • JTAG or SWD interface is used Programming and erasure by self-programming • This allows code flash memory programming/erasure without resetting the system.	

Table 52.1 Specifications of flash memory (2 of 2)

Item	Code flash memory	Data flash memory
Unique ID	A 16-byte ID code provided for each MCU	
FACI command	Program : 128 bytes Block erase: 1 block (8 KB or 32 KB) P/E suspend P/E resume Forced Stop Status Clear Configuration set (16 bytes)	Program: 4/8/16 bytes Block Erase: 1 block (64 bytes) Multi Block Erase: 64/128/256 bytes P/E suspend P/E resume Forced Stop Blank Check: 4 bytes to data flash memory capacity Status Clear Configuration set (4/16 Bytes) Increment Counter: 1bit Refresh Counter Read Counter: 8 Bytes
Security function	Protects against illicit tampering with or reading out of data in flash memory Startup area select setting protection ● BTFLG and FSUACR registers are protected by the FSPR bit. Permanent block protect setting protection ● Code flash memory is permanently protected from programming/erasure operation by the permanent block protect function. Flash memory protection for TrustZone ● Protection for flash memory area (P/E) ● Protection for flash memory area (read) ● Protection for register ● Protection during FACI command operation. ● Code flash P/E mode entry protection ● Data flash configuration area protection ● Anti-rollback Counter	
Safety function	Software protection ● FACI command protection by FENTRYR register. ● Flash memory is protected by FWEPROR register ● The user area is protected by the block protect setting Error protection ● Error is detected when unintended commands or prohibited settings occur. The FACI command is not accepted after an error detection. Boot area protection ● The start-up area select function allows customer to safely update the boot firmware. The size of the start-up area is 8 KB.	
Interrupt request	● FRDYI (flash sequencer ready (processing end)) : Enabled by FRDYIE bit. ● FIFERR (flash sequencer error) : Enabled by CFAEIE/CMDLKIE/DFAEIE bits	
Address conversion	Start-up area select function is supported in linear mode Dual mode and Linear mode ● Bank swap function is supported in dual mode ● Block swap function is supported in linear mode	

Figure 52.1 shows how modules related to flash memory can be configured. The flash sequencer is configured with the FCU and FACI. The FCU executes basic control for rewriting of the flash memory. The FACI receives FACI commands using peripheral bus, and controls FCU operations accordingly.

In response to a reset, the FACI transfers data from the flash memory to the option byte storage registers.

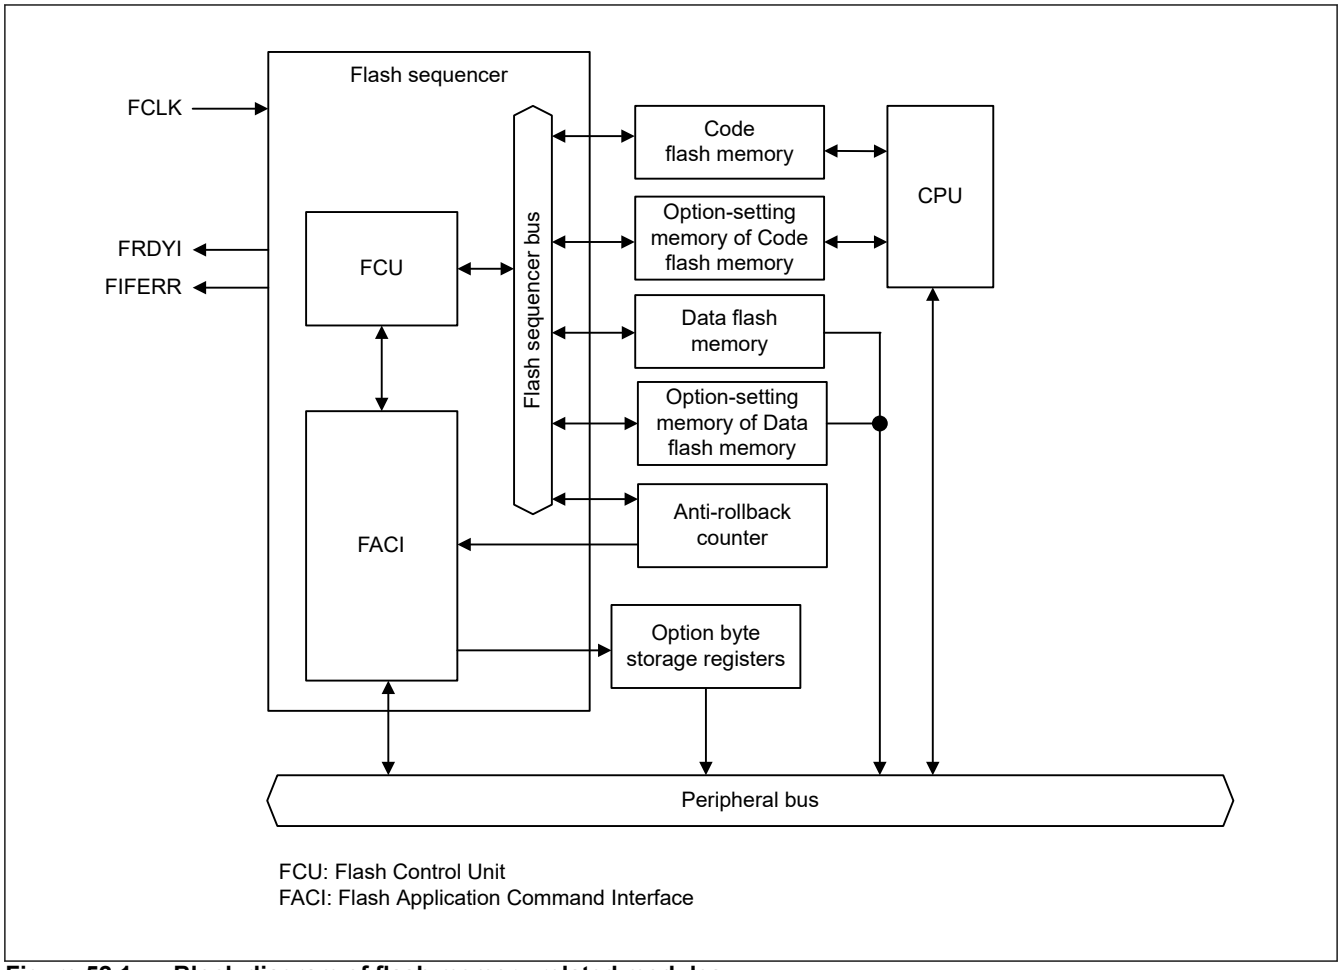


Figure 52.1 Block diagram of flash memory-related modules

52.2 Structure of Memory

Figure 52.2 shows the memory map of code flash memory in linear mode. Figure 52.3 shows the memory map of code flash memory in dual mode. This MCU can use the code flash memory as 2 bank areas by using the dual bank function. This dual-bank structure allows a safe update of a program while a user program is running.

The user area of the code flash memory in this MCU is divided into 8 KB and 32 KB blocks, which serve as the units of erasure.

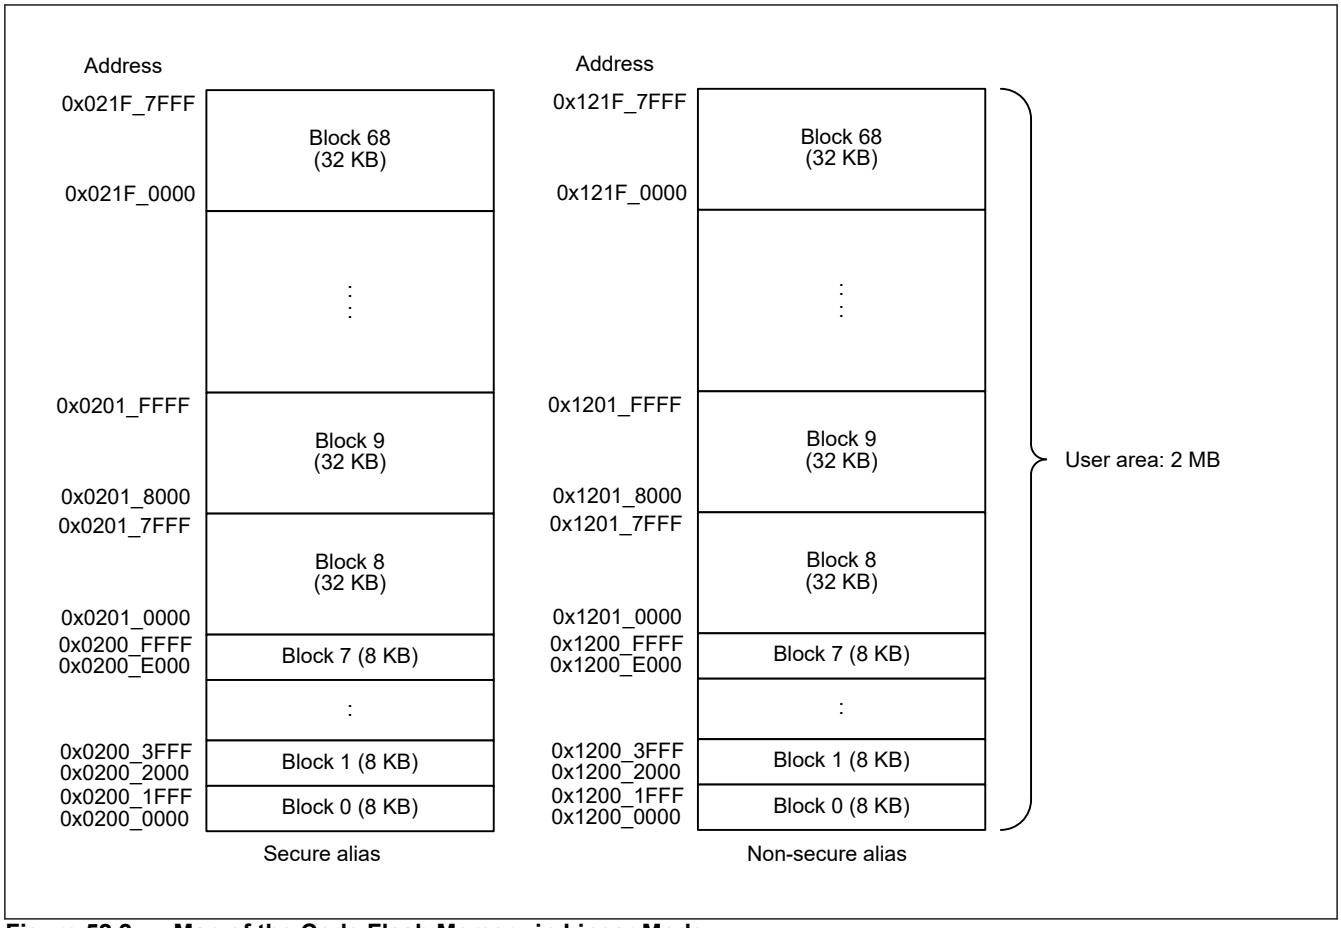

Figure 52.2 Map of the Code Flash Memory in Linear Mode

Table 52.2 Read and programming/erasure address by product for the code flash memory in Linear Mode

Product	Address	Number of blocks
2 MB product	Secure alias : 0x0200_0000 to 0x021F_7FFF Non-secure alias : 0x1200_0000 to 0x121F_7FFF	0 to 68
1 MB product	Secure alias : 0x0200_0000 to 0x020F_FFFF Non-secure alias : 0x1200_0000 to 0x120F_FFFF	0 to 37

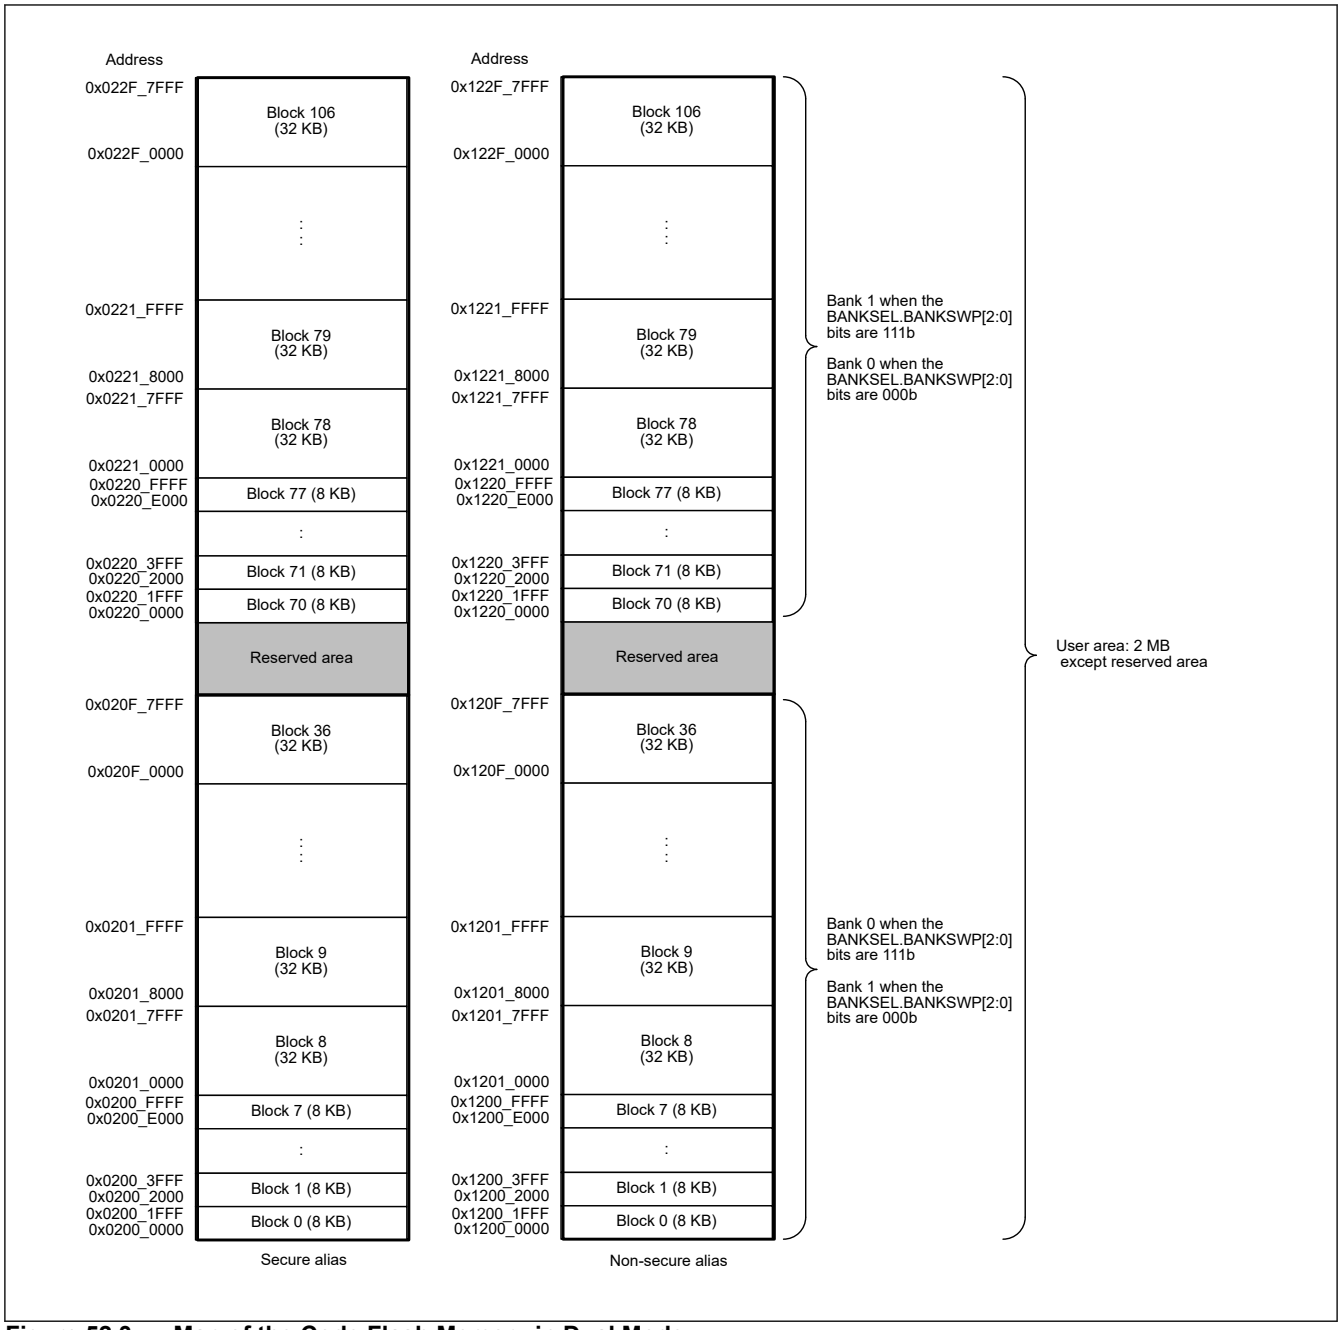

Figure 52.3 Map of the Code Flash Memory in Dual Mode

Table 52.3 Read and programming/erasure address by product for the code flash memory in Dual Mode

Product	Address	Number of blocks
2 MB product, lower side bank	Secure alias : 0x0200_0000 to 0x020F_7FFF Non-secure alias : 0x1200_0000 to 0x120F_7FFF	0 to 36
2 MB product, upper side bank	Secure alias : 0x0220_0000 to 0x022F_7FFF Non-secure alias : 0x1220_0000 to 0x122F_7FFF	70 to 106
1 MB product, lower side bank	Secure alias : 0x0200_0000 to 0x0207_FFFF Non-secure alias : 0x1200_0000 to 0x1207_FFFF	0 to 21
1 MB product, upper side bank	Secure alias : 0x0220_0000 to 0x0227_FFFF Non-secure alias : 0x1220_0000 to 0x1227_FFFF	70 to 91

The data area of the data flash memory in this MCU is divided into 64 byte blocks, with each being a unit for erasure. Figure 52.4 shows the mapping of the data flash memory.

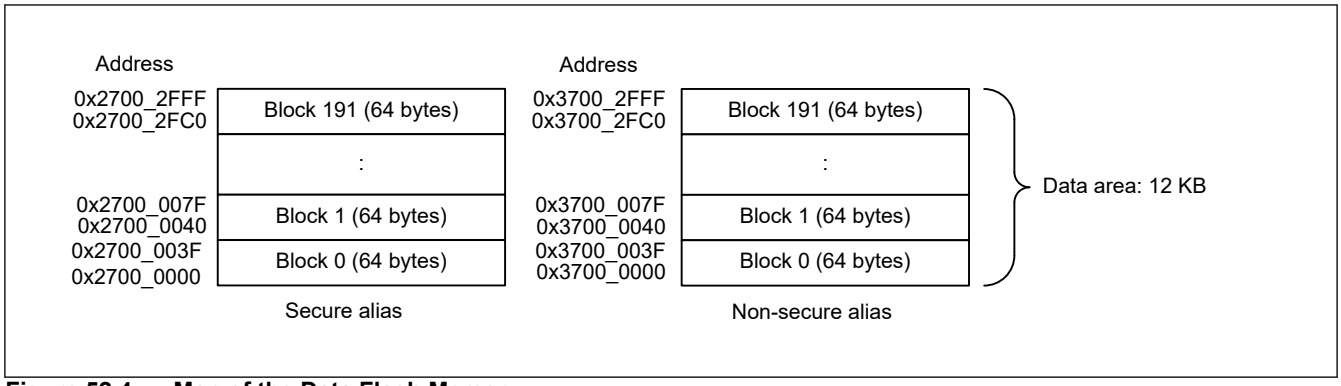

Figure 52.4 Map of the Data Flash Memory

52.3 Address Space

Using the hardware interface with flash memory requires access to all registers of the hardware, which is for issuing FACI commands. Table 52.4 provides information about the hardware interface.

Table 52.4 Information on the hardware interface area

Area	Address	Capacity
Area containing various registers of the hardware	See section 52.4. Register Descriptions.	See section 52.4. Register Descriptions.
FACI command-issuing area	Secure alias : 0x4010_0000 Non-secure alias : 0x5010_0000	4 bytes

For the address information of the flash memory, see Figure 52.2.

52.4 Register Descriptions

52.4.1 FCACHEE : Flash Cache Enable Register

Base address: FCACHE = 0x4001_C100
FCACHE_NS = 0x5001_C100

Offset address: 0x000

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FCACHEEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FCACHEEN	Flash Cache Enable 0: FCACHE is disabled 1: FCACHE is enabled	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register.

FCACHEEN bit (Flash Cache Enable)

FCACHEE.FCACHEEN bit enable and disables the function of Flash Cache of FCACHE1, FCACHE2 and FLPF.

FCACHEE.FCACHEEN bit dose not influence for FCACHEIV.FCACHEIV.

When FCACHE is enabled, it works for accesses marked as cacheable.

It is prohibited to disable FCACHE after enabling.

52.4.2 FCACHEIV : Flash Cache Invalidate Register

Base address: FCACHE = 0x4001_C100
FCACHE_NS = 0x5001_C100

Offset address: 0x004

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FCACHEIV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FCACHEIV	Flash Cache Invalidate 0: Read: Do not invalidate. Write: The setting is ignored. 1: Invalidate FCACHE is invalidated.	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-5, P-TYPE-2

This register is not controlled by any security attribute register.

FCACHEIV bit (Flash Cache Invalidate)

When 1 is written to FCACHEIV.FCACHEIV bit, the Flash cache data of FCACHE1, FCACHE2 and FLPF is invalidated.

Invalidate FCACHE with keeping FCACHE enabled after programming or erasing the code flash or the option setting memory.

52.4.3 FLWT : Flash Wait Cycle Register

Base address: FCACHE = 0x4001_C100
FCACHE_NS = 0x5001_C100

Offset address: 0x01C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	FLWT[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	FLWT[2:0]	Flash Wait Cycle 0 0 0: 0 wait (ICLK ≤ 48 MHz) 0 0 1: 1 wait (48 MHz < ICLK ≤ 96 MHz) 0 1 0: 2 wait (96 MHz < ICLK ≤144 MHz) 0 1 1: 3 wait (144 MHz <ICLK ≤ 192 MHz) 1 0 0: 4 wait (192 MHz < ICLK ≤ 240 MHz) Others: Setting prohibited	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register.

FLWT[2:0] bits (Flash Wait Cycle)

The Flash Wait Cycle Register (FLWT) sets the access wait count for the flash memory.

For faster clock frequencies, set FLWT.FLWT before changing the clock frequency. For slower clock frequencies, set FLWT.FLWT after changing the clock frequency.

For information on the frequency setting, see section 8, Clock Generation Circuit.

52.4.4 FSAR : Flash Security Attribution Register

Base address: FCACHE = 0x4001_C100
FCACHE_NS = 0x5001_C100

Offset address: 0x040

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	FACICMRSA	FACICMISA	FCKMHZSA	—	—	—	—	—	—	FCACHESA	FLWTSA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FLWTSA	FLWT Security Attribution Target register : FLWT 0: Secure 1: Non-secure	R/W
1	FCACHESA	FCHACHEEN Security Attribution Target register : FCHACHEEN 0: Secure 1: Non-secure	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	FCKMHZSA	FCKMHZ Security Attribution Target register : FCKMHZ 0: Secure 1: Non-secure	R/W
9	FACICMISA	FACI command Issuing Security Attribution Target area : Flash access area 0: Secure 1: Non-secure	R/W
10	FACICMRSA	FACI command Registers Security Attribution Target registers : FASTAT, FAEINT, FRDYIE, FSADDR, FEADDR, FBPROT1, FSTATR, FENTRYR, FSUINITR, FCMDR, FBCCNT, FBCSTAT, FPSADDR, FSUASMON, FCPSR, FPCKAR, FWEPROR 0: Secure 1: Non-secure	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-1, P-TYPE-1
Note: Set the PRCR.PRC4 bit to 1 (write enabled) before rewriting this register.

FLWTSA bit (FLWT Security Attribution)

This bit sets the security attribute of FLWT.

FCACHESA bit (FCHACHEEN Security Attribution)

This bit sets the security attribute of FCHACHEEN.

FCKMHZSA bit (FCKMHZ Security Attribution)

This bit sets the security attribute of Flash access area.

FACICMISA bit (FACI command Issuing Security Attribution)

This bit sets the security attribute of Flash access area.

FACICMRSA bit (FACI command Registers Security Attribution)

This bit sets the security attribute of FACI command security registers.

52.4.5 UIDRn : Unique ID Registers n (n = 0 to 3)

Address: 0x0300_8190 + n × 4

Bit position:	31	0
Bit field:	UID	
Value after reset:	Unique value for each chip	

Bit	Symbol	Function	R/W
31:0	UID	Unique ID	R

Note: S-TYPE-5, P-TYPE-5

The UIDRn is a read-only register that stores a 16-byte ID code (unique ID) for identifying the individual MCU. The UIDRn register should be read in 32-bit units. When reading by the signature request command of the serial programming interface, the data is read in order from the data with the large address. That is, the data in 0x0300_819F is read first, and in 0x0300_8190 is read last.

52.4.6 PNRn : Part Numbering Register n (n = 0 to 3)

Address: 0x0300_80F0 + n × 4

Bit position:	31	0
Bit field:	PNR	
Value after reset:	Unique value for each chip	

Bit	Symbol	Function	R/W
31:0	PNR	Part Number	R

Note: S-TYPE-5, P-TYPE-5

The PNRn is a read-only register that stores a 16-byte part numbering. The PNRn register should be read in 32-bit units. Each byte corresponds to the ASCII code representation of the product part number as detailed in . The first character ("R", 0x52 in ASCII code) of the part number is stored in the byte with the smallest address (0x0300_80F0). When reading by the signature request command of the serial programming interface, the data is read in order from the data with the small address. That is, the data in 0x0300_80F0 is read first, and in 0x0300_80FF is read last.

52.4.7 MCUVER : MCU Version Register

Address: 0x0300_81B0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	MCUVE							
Value after reset:	Value depend on the chip							

Bit	Symbol	Function	R/W
7:0	MCUVE	MCU Version	R

Note: S-TYPE-5, P-TYPE-5

The MCUVER is a read-only register that stores a MCU version. The MCUVER register should be read in 8-bit units.

52.4.8 FWEPROR : Flash P/E Protect Register

Base address: SYSC = 0x4001_E000
SYSC_NS = 0x5001_E000

Offset address: 0xA54

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	FLWE[1:0]	
Value after reset:	0	0	0	0	0	0	1	0

Bit	Symbol	Function	R/W
1:0	FLWE[1:0]	Flash Programming and Erasure 0 0: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing. 0 1: Permits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing. 1 0: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing. 1 1: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2

It is possible that Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing are prohibited by software.

The FWEPROR register is initialized by a reset from the following:

- All reset source except for VBATT_POR reset
- Transition to Deep Software Standby mode
- Transition to Software Standby mode.

FLWE[1:0] bits (Flash Programming and Erasure)

The FLWE[1:0] bits are used to set the flash P/E protection. The value after reset is 10b.

If these bits are set to other than 01b that does not allow programming and erasure of the flash memory, the following commands cannot be executed. Issuing any of the following commands leads to setting of the FLWEERR bit in the FSTATR register to 1.

Program / Block Erase / Multi Block Erase / Blank Check / Configuration set command

52.4.9 FASTAT : Flash Access Status Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x10

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CFAE	—	—	CMDLK	DFAE	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	—	These bits are read as 0. The write value should be 0.	R/W
3	DFAE	Data Flash Memory Access Violation Flag 0: No data flash memory access violation has occurred 1: A data flash memory access violation has occurred.	R/W*1

Bit	Symbol	Function	R/W
4	CMDLK	Command Lock Flag 0: The flash sequencer is not in the command-locked state 1: The flash sequencer is in the command-locked state.	R
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	CFAE	Code Flash Memory Access Violation Flag 0: No code flash memory access violation has occurred 1: A code flash memory access violation has occurred.	R/W*1

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register
Note 1. Only 0 can be written to clear the flag after 1 is read.

The FASTAT register indicates whether a code flash or data flash memory access violation has occurred. If any of the CFAE, CMDLK, and DFAE bits is set to 1, the flash sequencer enters the command-locked state (see section 52.11.2. Error Protection). To release it from the command-locked state, issue a status clear command or Forced Stop command to the flash sequencer.

DFAE bit (Data Flash Memory Access Violation Flag)

The DFAE bit indicates whether a data flash memory access violation occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

[Setting conditions]

FACI commands issued in the data flash P/E mode are as follows:

- The setting of the FSADDR or FEADDR register is the reserved portion of the data area
- The Configuration set command is issued while the setting of the FSADDR register is out of 0x2703_0050 to 0x2703_03FF.
- FACI command is issued to data flash memory with the wrong security attribution.

[Clearing conditions]

- When this bit is written as 0 after it is set to 1
- When the flash sequencer starts to process the Status Clear or Forced Stop command.

CMDLK bit (Command Lock Flag)

The CMDLK bit indicates that the flash sequencer is in the command-locked state.

[Setting conditions]

- The flash sequencer detects an error and enters the command-locked state.

[Clearing conditions]

- When the flash sequencer starts to process the Status Clear or Forced Stop command.

CFAE bit (Code Flash Memory Access Violation Flag)

The CFAE bit indicates whether a code flash memory access violation has occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

[Setting conditions]

FACI commands issued in the code flash P/E mode are as follows:

- The setting of the FSADDR register is the reserved portion of the user area
- The Configuration set command is issued while the setting of the FSADDR register is from 0x0200_A100 to 0x0200_A2F0 in self-programming mode
- FACI command is issued to code flash memory with the wrong security attribution.

[Clearing conditions]

- When this bit is written as 0 after it is set to 1

- When the flash sequencer starts to process the Status Clear or Forced Stop command.

52.4.10 FAEINT : Flash Access Error Interrupt Enable Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x14

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CFAEIE	—	—	CMDLKIE	DFAEIE	—	—	—
Value after reset:	1	0	0	1	1	0	0	0

Bit	Symbol	Function	R/W
2:0	—	These bits are read as 0. The write value should be 0.	R/W
3	DFAEIE	Data Flash Memory Access Violation Interrupt Enable 0: Generation of an FIFERR interrupt request is disabled when FASTAT.DFAE is set to 1 1: Generation of an FIFERR interrupt request is enabled when FASTAT.DFAE is set to 1.	R/W
4	CMDLKIE	Command Lock Interrupt Enable 0: Generation of an FIFERR interrupt request is disabled when FASTAT.CMDLK is set to 1 1: Generation of an FIFERR interrupt request is enabled when FASTAT.CMDLK is set to 1.	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	CFAEIE	Code Flash Memory Access Violation Interrupt Enable 0: Generation of an FIFERR interrupt request is disabled when FASTAT.CFAE is set to 1 1: Generation of an FIFERR interrupt request is enabled when FASTAT.CFAE is set to 1.	R/W

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. Seesection 52.4.4. FSAR : Flash Security Attribution Register

The FAEINT register enables or disables generation of a flash access error (FIFERR) interrupt request.

DFAEIE bit (Data Flash Memory Access Violation Interrupt Enable)

The DFAEIE bit enables or disables generation of an FIFERR interrupt request when a data flash memory access violation occurs, setting the DFAE bit in the FASTAT register to 1.

CMDLKIE bit (Command Lock Interrupt Enable)

The CMDLKIE bit enables or disables generation of an FIFERR interrupt request when the flash sequencer enters the command-locked state, setting the CMDLK bit in the FASTAT register to 1.

CFAEIE bit (Code Flash Memory Access Violation Interrupt Enable)

The CFAEIE bit enables or disables generation of an FIFERR interrupt request when a code flash memory access violation occur, setting the CFAE bit in the FASTAT register to 1.

52.4.11 FRDYIE : Flash Ready Interrupt Enable Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x18

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	FRDYIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FRDYIE	Flash Ready Interrupt Enable 0: Generation of an FRDY interrupt request is disabled 1: Generation of an FRDY interrupt request is enabled.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register

The FRDYIE register enables or disables generation of a flash ready (FRDY) interrupt request.

FRDYIE bit (Flash Ready Interrupt Enable)

The FRDYIE bit enables or disables generation of an FRDY interrupt request when the FRDY bit in the FSTATR register is changed from 0 to 1 on completion of processing by the flash sequencer of the Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command.

52.4.12 FSADDR : FACI Command Start Address Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x30

Bit position:	31																												0
Bit field:	FSADDR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FSADDR[31:0]	Start Address for FACI Command Processing	R/W*1

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register
Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0. Note that b0 and b1 are read-only.

Table 52.5 FACI command address boundary

Command	Address Boundary
Program (code flash memory)	128 byte
Program (data flash memory)	4, 8, 16 byte
Block Erase (code flash memory)	8 KB or 32 KB
Block Erase (data flash memory)	64 byte
Multi Block Erase (data flash memory)	64 byte
Blank Check (data flash memory)	4 byte
For code flash configuration set	16 byte
For data flash configuration set	4, 16 byte

The FSADDR register specifies the address where the target area for command processing starts when the FACI command for Program, Block Erase, Multi Block Erase, Blank Check, or Configuration set is issued.

The FSADDR value is initialized when the SUINIT bit in the FSUINITR register is set to 1. It is also initialized by a reset.

FSADDR[31:0] bits (Start Address for FACI Command Processing)

The FSADDR[31:0] bits specify the start address for FACI command processing. Bits [31:29] and [27:24] are ignored in FACI command processing for the code flash memory. Bits [31:29] and [27:13] are ignored in FACI command processing for the data flash memory. Bit [28] is used the security alias for flash sequencer command. When bit [28] is "0", flash sequencer can update secure region with secure access. When bit [28] is "1", flash sequencer can update non-security region with secure and non-secure access. Bits associated with the address bits of lower order than the address boundary listed in Table 52.5 are also ignored.

For information on the addresses of the code flash memory and the data flash memory, see section 52.2. Structure of Memory.

For information on the addresses of the configuration setting, see section 52.9.3.15. Configuration Set Command.

52.4.13 FEADDR : FACI Command End Address Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x34

Bit position:	31																												0
Bit field:	FEADDR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FEADDR[31:0]	End Address for FACI Command Processing	R/W*1

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register
Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0. Note that bit [0] and bit [1] are read-only.

The FEADDR register specifies the end address of the target area for Multi Block Erase and Blank Check command processing. When incremental mode is selected as the addressing mode for Blank Checking (when FBCCNT.BCDIR = 0), the address specified in the FSADDR register should be equal to or smaller than the address in the FEADDR register. Conversely, the address in the FSADDR register should be equal to or larger than the address in the FEADDR register when decremental mode is selected as the addressing mode for Blank Check (i.e. when FBCCNT.BCDIR = 1). If the BCDIR, FSADDR, and FEADDR bit settings are inconsistent with the specified rules, the flash sequencer enters the command-locked state (see section 52.11.2. Error Protection).

The FEADDR value is initialized when the SUINIT bit in the FSUINITR register is set to 1. It is also initialized by a reset.

FEADDR[31:0] bits (End Address for FACI Command Processing)

The FEADDR[31:0] bits specify the end address for Multi Block Erase and Blank Check command processing. In command processing, bits 31 to 17 and any bits that do not reach the address boundaries listed in the section 52.4.12. FSADDR : FACI Command Start Address Register are ignored.

For information on the addresses of the flash memory, see section 52.2. Structure of Memory.

52.4.14 FMEPROT : Flash P/E Mode Entry Protection Register

Base address: FACI = 0x4011_E000

Offset address: 0x44

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	CEPROT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	x	1

Bit	Symbol	Function	R/W
0	CEPROT	Code Flash P/E Mode Entry Protection 0: FENTRYC bit is not protected 1: FENTRYC bit is protected.	R/W*1 *2 *4
1	—	The read value is undefined. The write value should be 0.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W*3

Note: S-TYPE-6, P-TYPE-2

Note 1. Writing to this bit is only possible when the FRDY bit in the FSTATR register is 1. Writing to this bit while the FRDY bit = 0 is ignored.
Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY bits is 0xD9.
Note 3. Written values are not retained by these bits (always read as 0x00).
Note 4. Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is not generated.

CEPROT bit (Code Flash P/E Mode Entry Protection)

The CEPROT bit specifies the protection setting of the FRNTRYC bit in the FENTRYR register.

[Setting condition]

- 1 being written to the CEPROT bit while writing to FMEPROT is enabled.

[Clearing condition]

- 0 being written to the CEPROT bit while writing to FMEPROT is enabled.

52.4.15 FCNTSELR : Flash Counter Select Register

Base address: FACI = 0x4011_E000

Offset address: 0x048

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	CNTSEL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CNTSEL[2:0]	Counter Select 0 0 0: Anti-rollback counter is not selected 0 0 1: ARC_SEC is selected. Counter size is 64 bits. 0 1 0: ARC_OEMBL is selected. Counter size is 64 bits. 0 1 1: Anti-rollback counter is not selected. 1 x x: ARC_NSEC is selected. Counter configuration is 64 or 256 bits. See ,Table 52.6 Table 52.7 and Table 52.8 in details counter select condition. Others: Setting prohibited	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-6, P-TYPE-2
Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

CNTSEL[2:0] bits (Counter Select)

FCNTSELR specifies 3 types of anti-rollback counter (ARC_SEC, ARC_NSEC, or ARC_OEMBL) in "Increment Counter", "Refresh Counter", or "Read Counter" command.

FCNTSELR value is initialized when SUINIT bit in FSUINITR is set to "1"

Note: This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.

Before using the ARC_NSEC counter, it is necessary to set whether the counter is to be used with 4line x 64 bits or 1line x 256 bits using the Data Flash configuration set command. The bits to be set are CNF_ARCNS0 and CNF_ARCNS1. If the CNF_ARCNS1 bit is set to 1, the ARC_NSEC counter cannot be used. Once the counter type is decided, it cannot be changed.

Table 52.6 Select condition of ARC_NSEC (64 bits) in Increment/Refresh/Read Counter Command

FCNTSELR[2:0]	Target Counter	Counter Configuration
100	ARC_NSEC[63:0]	Counter number is 4. Counter size is 64bit.
101	ARC_NSEC[127:64]	
110	ARC_NSEC[191:128]	
111	ARC_NSEC[255:192]	

Table 52.7 Select condition of ARC_NSEC (256 bits) in Increment/Refresh Counter Command

FCNTSELR[2:0]	Target Counter	Counter Configuration
100	ARC_NSEC[255:0]]	Counter number is 1. Counter size is 256bit.
101		
110		
111		

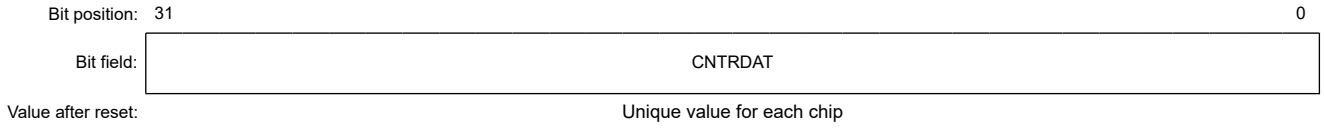
Table 52.8 Select condition of ARC_NSEC (256 bits) in Read Counter Command

FCNTSELR[2:0]	Target Counter	Counter Configuration
100	ARC_NSEC[63:0]	Counter number is 1. Counter size is 256bit.
101	ARC_NSEC[127:64]	
110	ARC_NSEC[191:128]	
111	ARC_NSEC[255:192]	

52.4.16 FCNTDATARn : Flash Counter Data Register n (n = 0, 1)

Base address: FACI = 0x4011_E000

Offset address: 0x04C + 0x004 × n (n = 0 ,1)



Bit	Symbol	Function	R/W
31:0	CNTRDAT	Counter Read Data Reading data of 32 bits (LSB side of counter values) is output to FCNTDATAR0. Reading data of 32 bits (MSB side of counter values) is output to FCNTDATAR1. .	R

Note: S-TYPE-6, P-TYPE-2

FCNTDATAR0 and FCNTDATAR1 indicate anti-rollback counter values (64bits) that read by "Read Counter" command.

CNTRDAT bit (Counter Read Data)

[Setting condition]

- FACI has accepted "Read Counter" command.

[Clearing condition]

- FACI has accepted flash sequencer command except for "Read Counter" command.
- Flash sequencer enters "Command Lock" state

52.4.17 FBPROT0 : Flash Block Protection Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x78

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	BPCN0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BPCN0	Block Protection for Non-secure Cancel 0: Block protection is enabled 1: Block protection is disabled.	R/W*1 *2
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W*3

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register
Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.
Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x78.
Note 3. Written values are not retained by these bits (always read as 0x00).

The FBPROT0 register is used to disable the block protect function for Non-secure. When the block protect setting is locked by the permanent block setting, it cannot be disabled by this register.

The FBPROT0 value is initialized when the SUINIT bit in the FSUINITR is set to 1, because the FENTRYR value is initialized to 0x0000. It is also initialized by a reset.

BPCN0 bit (Block Protection for Non-secure Cancel)

The BPCN0 bit disables the block protect setting for Non-secure function.

[Setting condition]

- When the write-enabling conditions are satisfied and the FENTRYR is not 0x0000, write 1 to this bit.

[Clearing conditions]

- 8 bits being written to FBPROT0 while the FRDY bit is 1.
- A value other than 0x78 specified in the KEY bits and 16 bits are written to FBPROT0 while the FRDY bit is 1.
- 0 being written to the BPCN0 bit while writing to FBPROT0 is enabled.
- The FENTRYR register value is 0x0000.

52.4.18 FBPROT1 : Flash Block Protection for Secure Register

Base address: FACI = 0x4011_E000

Offset address: 0x7C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	BPCN1
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BPCN1	Block Protection for Secure Cancel 0: Block protection is enabled 1: Block protection is disabled.	R/W*1 *2
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15:8	KEY[7:0]	Key Code	W*3

Note: S-TYPE-6, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register
Note 1. Writing to this bit is only possible when the FRDY bit in the FSTATR register is 1. Writing to this bit while FRDY bit = 0 is ignored.
Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0xB1.
Note 3. Written values are not retained by these bits (always read as 0x00).

The FBPROT1 register is used to disable the block protect function for Secure developer. When the block protect setting is locked by the permanent block setting, it cannot be disabled by this register.

The FBPROT1 value is initialized when the SUINIT bit in the FSUINITR is set to 1, because the FENTRYR value is initialized to 0x0000. It is also initialized by a reset.

BPCN1 bit (Block Protection for Secure Cancel)

The BPCN1 bit disables the block protect setting for Secure function.

[Setting condition]

- When the write-enabling conditions are satisfied and the FENTRYR is not 0x0000, write 1 to BPCN1.

[Clearing conditions]

- 8 bits being written to FBPROT1 while the FRDY bit is 1.
- A value other than 0xB1 specified in the KEY bits and 16 bits are written to FBPROT1 while the FRDY bit is 1.
- 0 being written to the BPCN1 bit while writing to FBPROT1 is enabled.
- The FENTRYR register value is 0x0000.

52.4.19 FSTATR : Flash Status Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x80

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	ILGCOMERR	FESETERR	SECERR	OTERR	TZFERR	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FRDY	ILGLERR	ERSERR	PRGERR	SUSRDY	DBFULL	ERSSPD	PRGSPD	—	FLWEERR	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0.	R
6	FLWEERR	Flash Write/Erase Protect Error Flag 0: An error has not occurred 1: An error has occurred.	R
7	—	This bit is read as 0.	R
8	PRGSPD	Programming Suspend Status Flag 0: The flash sequencer is not in the programming suspension processing state or programming suspended state 1: The flash sequencer is in the programming suspension processing state or programming suspended state.	R
9	ERSSPD	Erasure Suspend Status Flag 0: The flash sequencer is not in the erasure suspension processing state or the erasure suspended state 1: The flash sequencer is in the erasure suspension processing state or the erasure suspended state.	R

Bit	Symbol	Function	R/W
10	DBFULL	Data Buffer Full Flag 0: The data buffer is empty 1: The data buffer is full.	R
11	SUSRDY	Suspend Ready Flag 0: The flash sequencer cannot receive P/E suspend commands 1: The flash sequencer can receive P/E suspend commands.	R
12	PRGERR	Programming Error Flag 0: Programming has completed successfully 1: An error has occurred during programming.	R
13	ERSERR	Erasure Error Flag 0: Erasure has completed successfully 1: An error has occurred during erasure.	R
14	ILGLERR	Illegal Command Error Flag 0: The flash sequencer has not detected an illegal FACI command or illegal flash memory access 1: The flash sequencer has detected an illegal FACI command or illegal flash memory access.	R
15	FRDY	Flash Ready Flag 0: Program, Block Erase, Multi Block Erase, P/E suspend, P/E resume, Forced Stop, Blank Check, Configuration set, Increment counter, Refresh counter, or Read counter command processing is in progress. 1: None of the above is in progress.	R
18:16	—	These bits are read as 0.	R
19	TZFERR	TrustZone Filter Error 0: A TrustZone filter error has not been detected. 1: A TrustZone filter error has been detected.	R
20	OTERR	Other Error 0: An error has not been detected. 1: An error has been detected.	R
21	SECERR	Security Error 0: A write protection error against MSUASMON.FSPR bit has not been detected. 1: A write protection error against MSUASMON.FSPR bit has been detected.	R
22	FESETERR	FENTRY Setting Error 0: A setting error in the FENTRYR register has not been detected. 1: A setting error in the FENTRYR register has been detected.	R
23	ILGCOMERR	Illegal Command Error 0: An illegal FACI command error has not been detected. 1: An illegal FACI command error has been detected.	R
31:24	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register

The FSTATR register indicates the state of the flash sequencer.

FLWEERR flag (Flash Write/Erase Protect Error Flag)

The FLWEERR flag indicates a violation of the flash memory overwrite protection setting in the FWEPROR register. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The flash sequencer starts processing the Forced Stop command.

PRGSPD flag (Programming Suspend Status Flag)

The PRGSPD flag indicates that the flash sequencer is in the programming suspension processing state or programming suspended state.

[Setting condition]

- The flash sequencer starts processing in response to the programming suspend command.

[Clearing conditions]

- Reception of the P/E resume command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- The flash sequencer starts processing the Forced Stop command.

ERSSPD flag (Erasure Suspend Status Flag)

The ERSSPD flag indicates that the flash sequencer is in the erasure suspension processing state or erasure suspended state.

[Setting condition]

- The flash sequencer starts processing in response to an erasure suspend command.

[Clearing condition]

- Reception of the P/E resume command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- The flash sequencer starts processing of the Forced Stop command.

DBFULL flag (Data Buffer Full Flag)

The DBFULL flag indicates the state of the data buffer when the program command is issued. The flash sequencer incorporates a buffer for write data (data buffer). When data for writing to the flash memory are written to the FACI command-issuing area while the data buffer is full, the flash sequencer inserts a wait cycle in the peripheral bus.

[Setting condition]

- The data buffer becomes full while program commands are issued.

[Clearing condition]

- The data buffer becomes empty.

SUSRDY flag (Suspend Ready Flag)

The SUSRDY flag indicates whether the flash sequencer can receive a P/E suspend command.

[Setting condition]

- After starting programming/erasure processing, the flash sequencer enters a state in which P/E suspend commands can be received.

[Clearing conditions]

- Reception of the P/E suspend command or Forced Stop command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- During programming or erasure, the flash sequencer enters the command-locked state
- Programming or erasure has completed.

PRGERR flag (Programming Error Flag)

The PRGERR flag indicates the result of programming of the flash memory. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred during programming.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

ERSERR flag (Erasure Error Flag)

The ERSERR flag indicates the result of erasure of the flash memory. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred during erasure.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

ILGLERR flag (Illegal Command Error Flag)

The ILGLERR flag indicates that the flash sequencer has detected an illegal FACI command or flash memory access. If this flag is 1, the flash sequencer is in the command-locked state.

[Setting conditions]

- See section 52.11.2. Error Protection.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

FRDY flag (Flash Ready Flag)

The FRDY flag indicates the command processing state of the flash sequencer.

[Setting conditions]

- The flash sequencer completes command processing
- The flash sequencer receives a P/E suspend command and suspends programming of the flash memory
- The flash sequencer received the Forced Stop command and ended command processing.

Note: In the case of program command processing, the FRDY flag might be set to 1 even if the flash sequencer does not complete command processing. For details, see section 52.9.3.7. Program Command.

[Clearing conditions]

- The flash sequencer received an FACI command
- For Program and Configuration setting, the first write access to the FACI command-issuing area
- For other commands, the last write access to the FACI command-issuing area.

TZFERR flag (TrustZone Filter Error)

This flag indicates the TrustZone protection error in the FACI command.
See Table 52.30. When this bit is "1", flash sequencer enters "Command Lock" state.

[Setting conditions]

- An error has been detected.

[Clearing conditions]

- Status Clear or Forced Stop command processing is completed.

OTERR flag (Other Error)

This flag indicates that an FACI command has been issued when the condition of accepting commands is not satisfied.
See Table 52.30. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

SECERR flag (Security Error)

This flag indicates that write protection by the MSUASMON.FSPR bit is violated.
See Table 52.30. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

FESETERR flag (FENTRY Setting Error)

This flag indicates that a value of 0xAA81 is written in the FENTRYR register or the value in the FENTRYR register differs when P/E is suspended and resumed.
See Table 52.30. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

ILGCOMERR flag (Illegal Command Error)

This flag indicates that the flash sequencer has detected an illegal FACI command.
See Table 52.30. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

52.4.20 FENTRYR : Flash P/E Mode Entry Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x84

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								FENTRYD	—	—	—	—	—	—	FENTRYC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FENTRYC	Code Flash P/E Mode Entry 0: Code flash is in read mode 1: Code flash is in P/E mode.	R/W*1*2
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	FENTRYD	Data Flash P/E Mode Entry 0: Data flash is in read mode 1: Data flash is in P/E mode.	R/W*1*2
15:8	KEY[7:0]	Key Code	W*3

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register
Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0.
Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0xAA.
Note 3. Written values are not retained by these bits (always read 0x00).

FENTRYR is used to specify code flash P/E mode or data flash P/E mode. To specify the code flash P/E mode or data flash P/E mode so that the flash sequencer can receive FACI commands, set either the FENTRYD or FENTRYC bit to 1 to place the flash sequencer in P/E mode.

FENTRYR is initialized when the SUINIT bit in FSUINITR is set to 1. It is also initialized by a reset.

Note: Writing a value of 0XAA81 to this register causes the ILGLERR bit in the FSTATR register to be set to 1, resulting in the flash sequencer being placed in the command-locked state.

FENTRYC bit (Code Flash P/E Mode Entry)

The FENTRYC bit specifies P/E mode for the code flash memory.

[Setting condition]

- Write 1 to the FENTRYC bit while writing to FENTRYR is enabled and FENTRYR is 0x0000.

[Clearing conditions]

- Write 8 bits to FENTRYR while the FRDY bit is 1
- A value other than 0xAA is specified in the KEY[7:0] bits and 16 bits are written to FENTRYR while the FRDY bit is 1
- Write 0 to the FENTRYC bit while writing to FENTRYR is enabled
- Write to FENTRYR while writing is enabled and its value is other than 0x0000
- The protection of FMEPROT register is enabled.

FENTRYD bit (Data Flash P/E Mode Entry)

The FENTRYD bit specifies P/E mode for the data flash memory.

[Setting condition]

- Write 1 to the FENTRYD bit while writing to FENTRYR is enabled and FENTRYR is 0x0000.

[Clearing conditions]

- Write 8 bits to FENTRYR while the FRDY bit is 1
- Writing of 16 bits to FENTRYR with a value other than 0xAA specified for the KEY[7:0] bits while the FRDY bit is 1
- Write 0 to the FENTRYD bit while writing to FENTRYR is enabled
- Write to FENTRYR while writing is enabled and its value is other than 0x0000.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the FENTRYD or FENTRYC bits.

52.4.21 FSUINITR : Flash Sequencer Setup Initialization Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x8C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	SUINIT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SUINIT	Set-Up Initialization 0: The FSADDR, FEADDR, FBPROT0, FBPROT1, FENTRYR, FBCCNT, FCPSR, and FCNTSELR flash sequencer setup registers keep their current values 1: The FSADDR, FEADDR, FBPROT0, FBRPOT1, FENTRYR, FBCCNT, FCPSR, and FCNTSELR flash sequencer setup registers are initialized.	R/W*1*2
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15:8	KEY[7:0]	Key Code	W*3

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register
Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.
Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x2D.
Note 3. Written values are not retained by these bits (always read 0x00).

FSUINITR is used for initialization of the flash sequencer setup.

SUINIT bit (Set-Up Initialization)

The SUINIT bit initializes the following flash sequencer setup registers:

- FSADDR
- FEADDR
- FBPROT0
- FBPROT1
- FENTRYR
- FBCCNT
- FCPSR
- FCNTSELR

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the SUINIT bit.

52.4.22 FCMDR : FACI Command Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0xA0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMDR[7:0]								PCMDR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	PCMDR[7:0]	Pre-command Flag The command just before the latest command is stored.	R
15:8	CMDR[7:0]	Command Flag The latest command is stored.	R

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register

FCMDR records the two most recent commands accepted by the flash sequencer.

PCMDR[7:0] bits (Pre-command Flag)

The PCMDR[7:0] bits indicate the command received immediately before the latest command received by the flash sequencer.

CMDR[7:0] bits (Command Flag)

The CMDR[7:0] bits indicate the latest command received by the flash sequencer.

Table 52.9 States of FCMDR after receiving commands

Command	CMDR	PCMDR
Program	0xE8	Previous command
Block erase	0xD0	0x20
Multi block erase	0xD0	0x21
P/E suspend	0xB0	Previous command
P/E resume	0xD0	Previous command
Status Clear	0x50	Previous command
Forced Stop	0xB3	Previous command
Blank Check	0xD0	0x71
Configuration set	0x40	Previous command
Increment Counter	0xD0	0x35
Refresh Counter	0xD0	0x37
Read Counter	0xD0	0x39

52.4.23 FBCCNT : Blank Check Control Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0xD0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	BCDIR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BCDIR	Blank Check Direction 0: Blank checking is executed from the lower addresses to the higher addresses (incremental mode) 1: Blank checking is executed from the higher addresses to the lower addresses (decremental mode).	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register

FBCCNT specifies the addressing mode in processing the Blank Check command. FBCCNT is initialized when the SUINIT bit in FSUINITR is set to 1. It is also initialized by a reset.

BCDIR bit (Blank Check Direction)

The BCDIR bit specifies the addressing mode for Blank Check.

52.4.24 FBCSTAT : Blank Check Status Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0xD4

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	BCST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BCST	Blank Check Status Flag 0: The target area is in the non-programmed state, that is, the area has been erased but has not yet been reprogrammed 1: The target area has been programmed with 0s or 1s.	R
7:1	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register

FBCSTAT stores the results of checking in response to the Blank Check command.

BCST flag (Blank Check Status Flag)

The BCST flag indicates the results of checking in response to the Blank Check command.

52.4.25 FPSADDR : Data Flash Programming Start Address Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0xD8

Bit position:	31															16															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PSADR[16:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
16:0	PSADR[16:0]	Programmed Area Start Address The address of the first programmed area	R
31:17	—	These bits are read as 0. The write value should be 0.	R

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register

FPSADDR indicates the address of the first programmed area found in processing of the Blank Check command.

PSADR[16:0] bits (Programmed Area Start Address)

The PSADR[16:0] bits indicate the address of the first programmed area found in processing of the Blank Check command. The address is an offset from the address where the data flash memory starts. The setting of these bits is only valid if the BCST bit in the FBCSTAT register is 1 and while the FRDY bit in the FSTATR register is 1. When the BCST bit in the FBCSTAT register is 0, the PSADR[16:0] bits hold the address produced by the previous check.

52.4.26 FSUASMON : Flash Startup Area Select Monitor Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0xDC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	BTFLG	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0/1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FSPR	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0/1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
14:0	—	These bits are read as 0. The write value should be 0.	R
15	FSPR	Protection Programming Flag to set Boot Flag and Startup Area Control 0: Protected state 1: Non-protected state.	R
30:16	—	These bits are read as 0. The write value should be 0.	R
31	BTFLG	Flag of Startup Area Select for Boot Swap 0: The startup area is the alternate block (block 1) 1: The startup area is the default block (block 0).	R

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register.

FSPR bit (Protection Programming Flag to set Boot Flag and Startup Area Control)

The FSPR bit indicates the protection state against the configuration set command for the BTFLG bit, and FSUACR Register.

In response to a reset or configuration set command, the FACI transfers data from flash memory to this register.

BTFLG bit (Flag of Startup Area Select for Boot Swap)

The BTFLG bit indicates whether the address of the startup area is exchanged for the boot swap function or not.

In response to a reset or configuration set command, the FACI transfers data from flash memory to this register.

52.4.27 FCPSR : Flash Sequencer Processing Switching Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0xE0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ESUSPMD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ESUSPMD	Erasure Suspend Mode 0: Suspension priority mode 1: Erasure priority mode.	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register

FCPSR selects the erasure suspension mode. FCPSR is initialized when the SUINIT bit in FSUINITR is set to 1. It is also initialized by a reset.

ESUSPMD bit (Erasure Suspend Mode)

The ESUSPMD bit selects the erasure suspension mode when a P/E suspend command is issued while the flash sequencer is executing erasure processing (see section 52.9.3.10. P/E Suspend Command). This bit should be set before issuing Block Erase or Multi Block Erase command.

52.4.28 FPCKAR : Flash Sequencer Processing Clock Notification Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0xE4

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								PCKA[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0	0

Bit	Symbol	Function	R/W
7:0	PCKA[7:0]	Flash Sequencer Operating Clock Notification These bits are used to set the operating frequency of the flash sequencer while processing FACI commands.	R/W*1*2
15:8	KEY[7:0]	Key Code	W*3

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 52.4.4. FSAR : Flash Security Attribution Register
Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.
Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x1E.
Note 3. Written values are not retained by these bits (always read 0x00).

FPCKAR specifies the operating frequency of the flash sequencer while processing FACI commands. The highest operating frequency for the given product is set as the initial value.

PCKA[7:0] bits (Flash Sequencer Operating Clock Notification)

The PCKA[7:0] bits specify the operating frequency of the flash sequencer while processing FACI commands. Set the desired frequency for these bits before issuing an FACI command. Specifically, convert the frequency in MHz to a binary number and set it for these bits.

Example:

Frequency is 35.9 MHz (PCKA = 0x24)

Round up the first decimal place of 35.9 MHz to a whole number (= 36) and convert it into a binary number.

If the value set in these bits is smaller than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics cannot be guaranteed. If the value set in these bits is greater than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics can be guaranteed but the FACI command processing time such as the time programming/erasure takes will increase. The minimum FACI command processing time is obtained when the operating frequency of the flash sequencer is the same as the PCKA value.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the PCKA bit.

52.4.29 FSUACR : Flash Startup Area Control Register

Base address: FACI = 0x4011_E000

Offset address: 0xE8

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	SAS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	SAS[1:0]	Startup Area Select 0 0: Startup area is selected by BTFLG bit 0 1: Startup area is selected by BTFLG bit 1 0: Startup area is temporarily switched to the default area (block 0) 1 1: Startup area is temporarily switched to the alternate area (block 1).	R/W*1 *3
7:2	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W*2

Note: S-TYPE-6, P-TYPE-2
Note 1. Following described the write condition of these bits (these conditions are required at the same time).
1. Access size to this register is 16 bits
2. The value of KEY[7:0] is 0x66
3. The FSPR bit is 1.

Note 2. Written values are not retained by these bits (always read 0x00).
Note 3. Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is not generated.

FSUACR sets the startup area for the boot swap function. Do not use this register in dual mode (the DUALSEL.BANKMD[2:0] bits are 000b). In dual mode, starting up proceeds from startup area 0.

SAS[1:0] bits (Startup Area Select)

The SAS[1:0] bits select the startup area. Three methods are available for changing the startup area.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the SAS [1:0] bits.

52.4.30 FCKMHZ : Data Flash Access Frequency Register

Base address: FLAD = 0x4011_C000
FLAD_NS = 0x5011_C000

Offset address: 0x40

Bit position:	7	6	5	4	3	2	1	0
Bit field:	FCKMHZ[7:0]							
Value after reset:	0	0	1	1	1	1	0	0

Bit	Symbol	Function	R/W
7:0	FCKMHZ[7:0]	Data Flash Access Frequency Register These bits optimize the speed of reading the data flash memory.	R/W

Note: S-TYPE-3, P-TYPE-2
Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

This register optimizes the speed of reading the data flash memory.

Set the frequency of the peripheral module clock (FCLK) of internal peripheral bus which is the clock for access to the data flash memory, in MHz units. For example, 35.9 MHz should be rounded up and set the frequency to 36. Number of cycles required for access to the data flash memory are inserted according to the frequency. When changing the frequency of the FCLK, follow the procedure below to modify the value of the data flash access frequency register (FCKMHZ) in either of the following ways according to whether operation is at a lower frequency before or after the change.

- When changing the speed from low to high: Modify FCKMHZ. After confirming the change by reading FCKMHZ, change the frequency.
- When changing the speed from high to low: Change the frequency. After the frequency is changed, modify FCKMHZ.

52.5 Flash Cache

52.5.1 Feature of flash cache

The FCACHE (Flash Cache) speeds up read access from bus master to the flash memory. The FCACHE includes:

- FCACHE1, for CPU instruction fetches
- FCACHE2, for CPU operand access and access from EDMAC
- FLPF, for the prefetch access in CPU instruction fetches

Table 52.10 Flash Cache 1 (FCACHE1) overview

Cache Target Region	Secure alias : 0x0200_0000 - 0x021F_7FFF Non-secure alias : 0x1200_0000 - 0x121F_7FFF
Target Bus Master	CPU instruction Fetch
Capacity	256 Bytes
Associativity	8WAY set associative
	128 bits/entry (128 bit aligned data), 2 entries/way
Access Cycle	Cache Hit : 0 wait Cache Miss : wait number of Flash Wait Cycle Register

Table 52.11 Flash Cache 2 (FCACHE2) overview

Cache Target Region	Secure alias : 0x0200_0000 - 0x021F_7FFF Non-secure alias : 0x1200_0000 - 0x121F_7FFF
Target Bus Master	CPU Operand Access and Access from other than CPU
Capacity	16 Bytes
Associativity	Full Associative
	128 bits/entry (128 bit aligned data), 1 entry
Access Cycle	Cache Hit : 0 wait Cache Miss : wait number of Flash Wait Cycle Register

Table 52.12 Prefetch Buffer (FLPF) overview

Cache Target Region	Secure alias : 0x0200_0000 - 0x021F_7FFF Non-secure alias : 0x1200_0000 - 0x121F_7FFF
Capacity	32 Bytes
Associativity	Full Associative
	128 bits/entry (128 bit aligned data), 2 entries
Request Address	Next address of previous CPU Instruction
Access Cycle	Cache Hit : 0 wait Cache Miss : wait number of Flash Wait Cycle Register

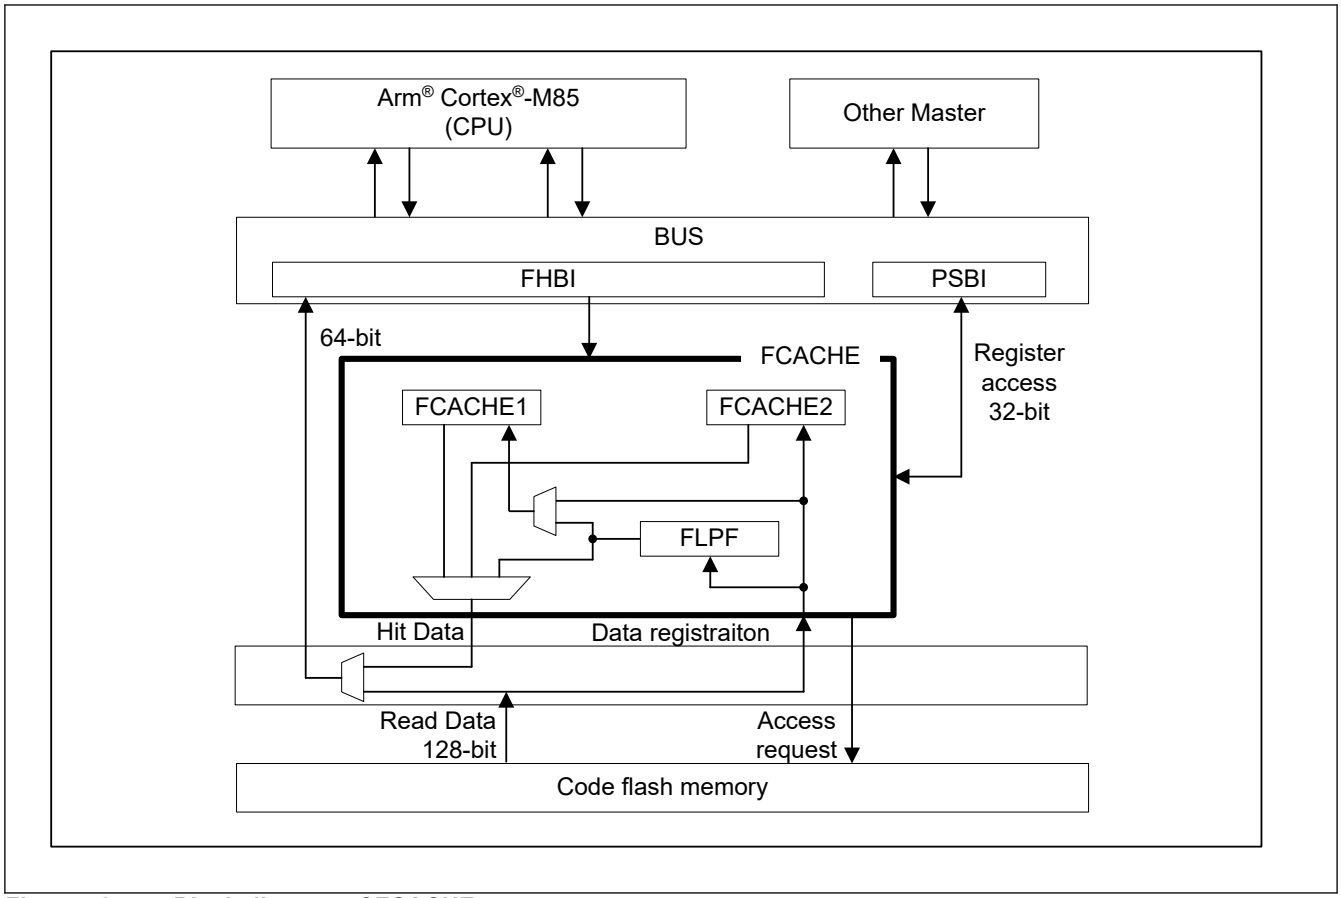


Figure 52.5 Block diagram of FCACHE

52.6 Operating Modes Associated with Flash Memory

Figure 52.6 is a diagram of the mode transitions associated with the flash memory. For the procedures for setting the modes, see section 6, Option-Setting Memory.

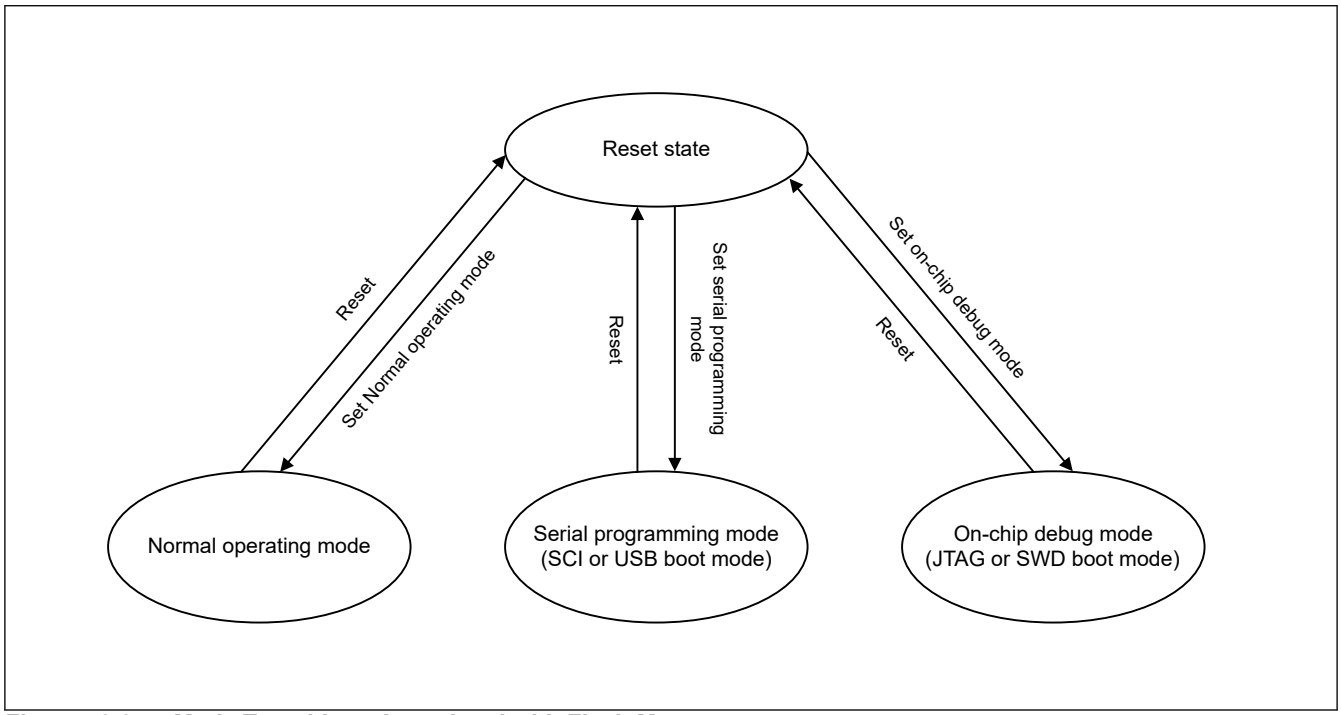

Figure 52.6 Mode Transitions Associated with Flash Memory

The flash memory area where programming and erasure are permitted and the boot program after a reset are different according to each mode. The differences between modes are listed in Table 52.13.

Table 52.13 Differences between Modes

Parameter	Normal operating mode	Serial programming mode (SCI or USB boot mode)	On-chip debug mode (JTAG or SWD boot mode)
Programmable and erasable areas	• Code flash memory • Data flash memory • Option setting memory (programming only)	• Code flash memory • Data flash memory • Option-setting memory (programming only)	• Code flash memory • Data flash memory • Option setting memory (programming only)
Erasure in block units	Possible	Possible	Possible
Boot program at a reset	User area program	Embedded program for serial programming	Depends on debug command

52.7 Overview of Functions

By using a dedicated flash-memory programmer to program the flash memory through a serial interface (serial programming) or JTAG/SWD interface (on-chip debug mode), the device can be rewritten regardless of whether this is before or after it is mounted on the target system.

Furthermore, security functions to prohibit rewriting or reading of the user program written to the flash memory are incorporated, and this can prevent falsification and illicit reading of the programs by third parties.

Programming by the user program (self-programming) is available to suit applications where the application on the target system may require updating after manufacturing or shipment. Protection features for the safe rewriting of the flash memory are also incorporated. Furthermore, interrupt processing during self-programming is supported, so programming can proceed at the same time as processing for external communications, etc., and this is the case in various situations. Table 52.14 lists the overview of the methods of programming and the corresponding operating modes.

Table 52.14 Programming methods

Programming method	Functional overview	Operating mode
Serial programming	A dedicated flash-memory programmer through the SCI or USBFS interface enables on-board programming of the flash memory after the device is mounted on the target system.	Serial programming mode
	A dedicated flash-memory programmer through the SCI or USBFS interface and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system.	
Self-programming	A user program written to memory in advance of serial programming execution can also program the flash memory. The background operation capability makes it possible to fetch instructions or otherwise read data from the code flash memory while the data flash memory is programmed. As a result, a program resident in the code flash memory is able to program the data flash memory. For background operations that are not possible, instructions in the code flash memory cannot be fetched and data cannot be accessed while the code flash memory is being programmed by self-programming. In such cases, a program for programming from the internal SRAM or external memory must be transferred in advance and executed.	Normal operating mode
JTAG or SWD programming	A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD enables on-board programming of the flash memory after the device is mounted on the target system. A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system.	On-chip debug mode

Table 52.15 lists the functions of the flash memory. Serial programmer commands realize each function of serial programming, while reading of the flash memory by an FACI command or the user program realizes each function of self-programming.

Table 52.15 Basic Functions

Function	Functional overview	Availability	
		Serial programming	Self-programming
Blank check	Checks a specified block to ensure that writing to it has not already proceeded. Results of reading from data flash memory to which nothing is written after erasure are not guaranteed, so use blank checking to confirm that writing to memory has not proceeded after erasure.	Not supported	Supported (data flash programming only)
Block erasure	Erases the memory contents in the specified block	Supported	Supported
Programming	Writes to the specified address	Supported	Supported
CRC	Calculates the CRC in the specified range of the flash memory and transfers it to the flash programmer	Supported	Not supported
Read	Reads data programmed in the flash memory	Supported	Not supported (read by user program is possible)
Start-up program protection functions	Configures the start-up program protection functions	Supported	Supported
Option function selection	Selects the option function, and modifies the initial setting of this MCU	Supported	Supported
Dual bank function	Switches different modes (linear or dual)	Supported	Supported
Block swap function	Setting block swap functions	Supported	Supported
Block protection	Setting block protection	Supported	Supported
Device lifecycle transition	Transitions the device lifecycle	Supported	Not supported
Memory security attribution	Setting the memory security attribution	Supported	Not supported
Key	Injects key	Supported	Supported (except the key related to device lifecycle transition)
All erasure	Erase the flash memory to the state after shipment	Supported	Not supported

The flash memory supports various security functions.

Table 52.16 lists the security functions supported by the flash memory.

Table 52.16 Lists of Security Functions

Function	Description
Security flag for Start-up area select	Start-up area selection can be protected by setting of security flag (FSPR).
Permanently block protection	Programming or erasure of each block of code flash memory can be protected permanently.
Protection for TrustZone	Programming or erasure area, readable area, register access, and FACI command operation are protected by ARM TrustZone security.
Data flash configuration area protection	When target area of configuration set command includes protection area by lock bit, flash sequencer detects an error and enters command lock state.
Anti-rollback Counter	Anti-rollback counter used only by Secure applications for firmware updates.
Programming or erasure mode protection	Only Secure developer can enter the programming or erasure mode for code flash.

52.8 Operating Modes of the Flash Sequencer

The flash sequencer has three operating modes as shown in Figure 52.7. Transitions between modes are initiated by changing the value of the FENTRYR register.

When the value of the FENTRYR register is 0x0000, the flash sequencer is in read mode. In this mode, it does not receive FACI commands. The code flash memory and data flash memory are both readable.

When the value of the FENTRYR register is 0x0001, the flash sequencer is in code flash P/E mode where the code flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is readable. In addition, the code flash memory is not readable if background operation (BGO) is disabled. If BGO is enabled, the code flash memory

that is not selected by FSADDR register is readable when the FRDY bit in the FSTATR register is 0. As for the condition for enabling BGO, see section 52.15.2. Background Operation.

When the value of the FENTRYR register is 0x0080, the flash sequencer is in data flash P/E mode where the data flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is not readable. However, the code flash memory is readable.

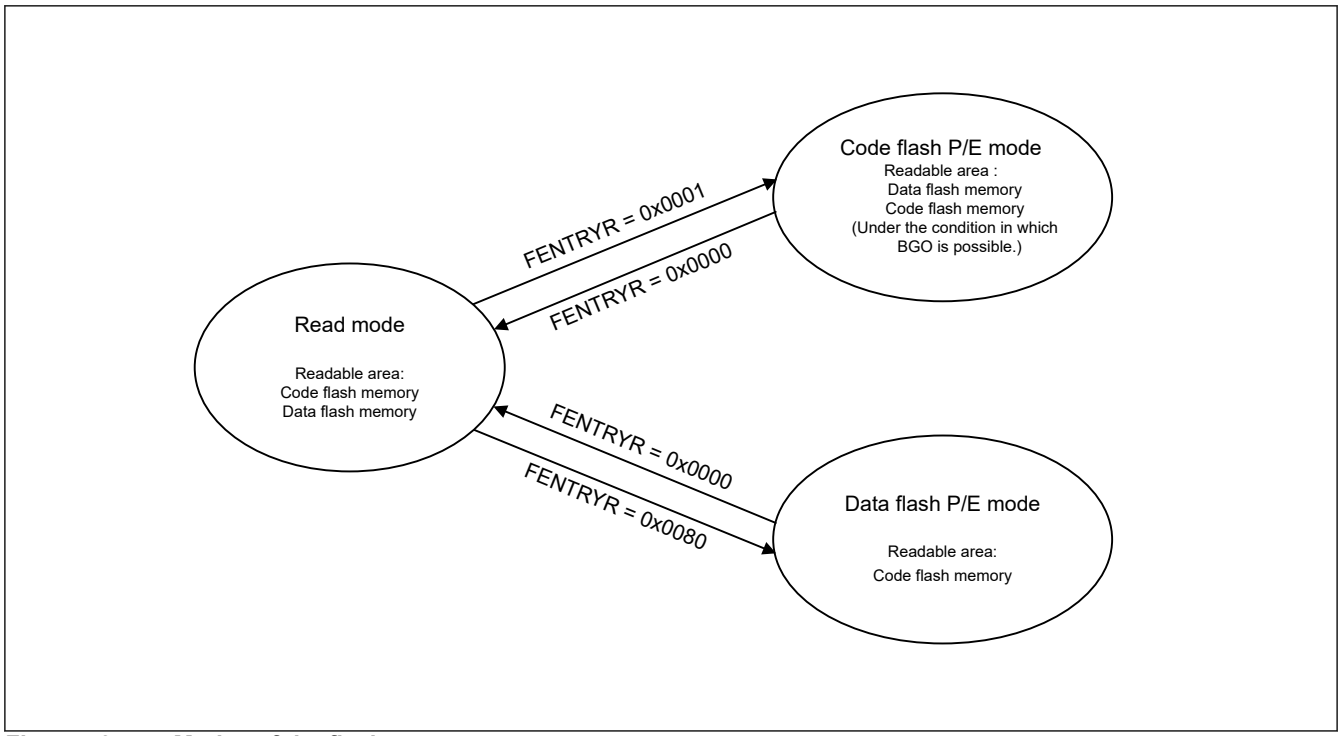

Figure 52.7 Modes of the flash sequencer

52.9 FACI Commands

52.9.1 List of FACI Commands

The FACI controls the FCU according to the specified FACI commands.

This section describes information about the FACI commands and Table 52.17 lists the FACI commands.

Table 52.17 FACI commands (1 of 2)

FACI command	Function
Program	Programs the user area and data area. Units of programming are 128 bytes for the user area and 4, 8, or 16 bytes for the data area.
Block erase	Erases user area and data area. The erase unit is 8 KB or 32 KB for user area, and 64 bytes for data flash.
Multi block erase	Erases data area. The erase unit is 64, 128, 256 bytes for data flash.
P/E suspend	Suspends programming or erasure processing.
P/E resume	Resumes suspended programming or erasure processing.
Status clear	Initializes the ILGLERR, ERSERR, PRGERR, ILGCOMERR, FESETERR, SECERR, and OTERR bits in the FSTATR register and the CMDLK, CFAE, OTERR and TZFERR bits in the FASTAT register, and the flash sequencer released from command-locked state.

Table 52.17 FACI commands (2 of 2)

FACI command	Function
Forced stop	Forcibly stops processing of FACI commands and initializes the FSTATR and FASTAT registers.
Blank check	Checks if data areas are blank. Units of Blank Check: 4 bytes to data flash memory capacity (specified in 4-byte units).
Configuration set	Sets the option-setting memory. Units of setting: 16 bytes.
Increment Counter (Secure access only)	Increments Anti-rollback counter value . The target of counter is selected by FCNTSELR register. Update data unit is 1bit.
Refresh Counter recovery flow (Secure access only)	This is used to anti-rollback counter recovery flow. The target of counter is selected by FCNTSELR register. This command can refresh anti-rollback counter area without increasing counter value.
Read Counter (Secure access only)	Read Anti-rollback counter value. The target of counter is selected by FCNTSELR register. Reading data is output to FCNTDATAR0 and FCNTDATAR1 registers. Read unit is 64bit.

The FACI commands are issued by writing to the FACI command-issuing area (see Table 52.4). When write access as shown in Table 52.18 proceeds in the specified state, the flash sequencer executes the processing associated with the given command (see section 52.9.2. Relationship between the Flash Sequencer State and FACI Commands).

Table 52.18 FACI command formats

FACI commands	Number of write access	Write data to the FACI command-issuing area			
		1st access	2nd access	3rd to (N+2)th access	(N+3)th access
Program (user area) N = 64	67	0xE8	0x40 (=N)	WD1 to WD64	0xD0
Program (data area) 4-byte programming: N = 2 8-byte programming: N = 4 16-byte programming: N = 8	N+3	0xE8	0x02 (=N) 0x04 (=N) 0x08 (=N)	WD1 to WDN	0xD0
Block Erase (user area 8K/32K Bytes)	2	0x20	0xD0	—	—
Block Erase (data area 64 bytes)	2	0x20	0xD0	—	—
Multi block erase (data area 64/128/256 bytes)	2	0x21	0xD0	—	—
P/E suspend	1	0xB0	—	—	—
P/E resume	1	0xD0	—	—	—
Status Clear	1	0x50	—	—	—
Forced Stop	1	0xB3	—	—	—
Blank Check	2	0x71	0xD0	—	—
Configuration set (Code flash memory) N = 8	11	0x40	0x08 (=N)	WD1 to WD8	0xD0
Configuration set (Data flash memory) N = 2 (4 Bytes) N = 8 (16 Bytes)	N+3	0x40	0x02 (=N) 0x08 (=N)	WD1 to WDn	0xD0
Increment Counter	2	0x35	0xD0	—	—
Refresh Counter	2	0x37	0xD0	—	—
Read Counter	2	0x39	0xD0	—	—

Note: WDN (N = 1, 2, …): Nth 16-bit data to be programmed.

The flash sequencer clears the FSTATR.FRDY bit to 0 at the start of a command processing other than the Status Clear command, and sets this bit to 1 on completion.

If the FRDYIE.FRDYIE bit setting is 1, a flash ready (FRDY) interrupt is generated when the FSTATR.FRDY bit is set to 1.

52.9.2 Relationship between the Flash Sequencer State and FACI Commands

The FACI commands are accepted according to the mode/state of the flash sequencer. FACI commands should be issued after transitioning of the flash sequencer to the code flash P/E mode or data flash P/E mode and after checking the state of the flash sequencer.

Use the FSTATR and FASTAT registers to check the state of the flash sequencer. In addition, the occurrence of errors in general can be checked by reading the CMDLK bit in the FASTAT register. The value of the CMDLK bit is the logical OR of the following bits in the FSTATR register:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- TZFERR
- ERSERR
- PRGERR
- FLWEERR.

Table 52.19 lists the available FACI commands in each operating mode.

Table 52.19 Operating mode and available FACI commands

Operating mode	FENTRYR	Available FACI commands
Read mode	0x0000	None
Code flash P/E mode	0x0001	Program Block erase P/E suspend P/E resume Status Clear Forced Stop Configuration set
Data flash P/E mode	0x0080	Program Block erase Multi block erase P/E suspend P/E resume Status Clear Forced Stop Blank Check Configuration set Increment Counter Refresh Counter Read Counter

Table 52.20 shows the state of the flash sequencer and acceptable FACI commands. An appropriate mode is assumed to have been set before the commands are executed.

Table 52.20 Acceptable FACI commands and state of the flash sequencer

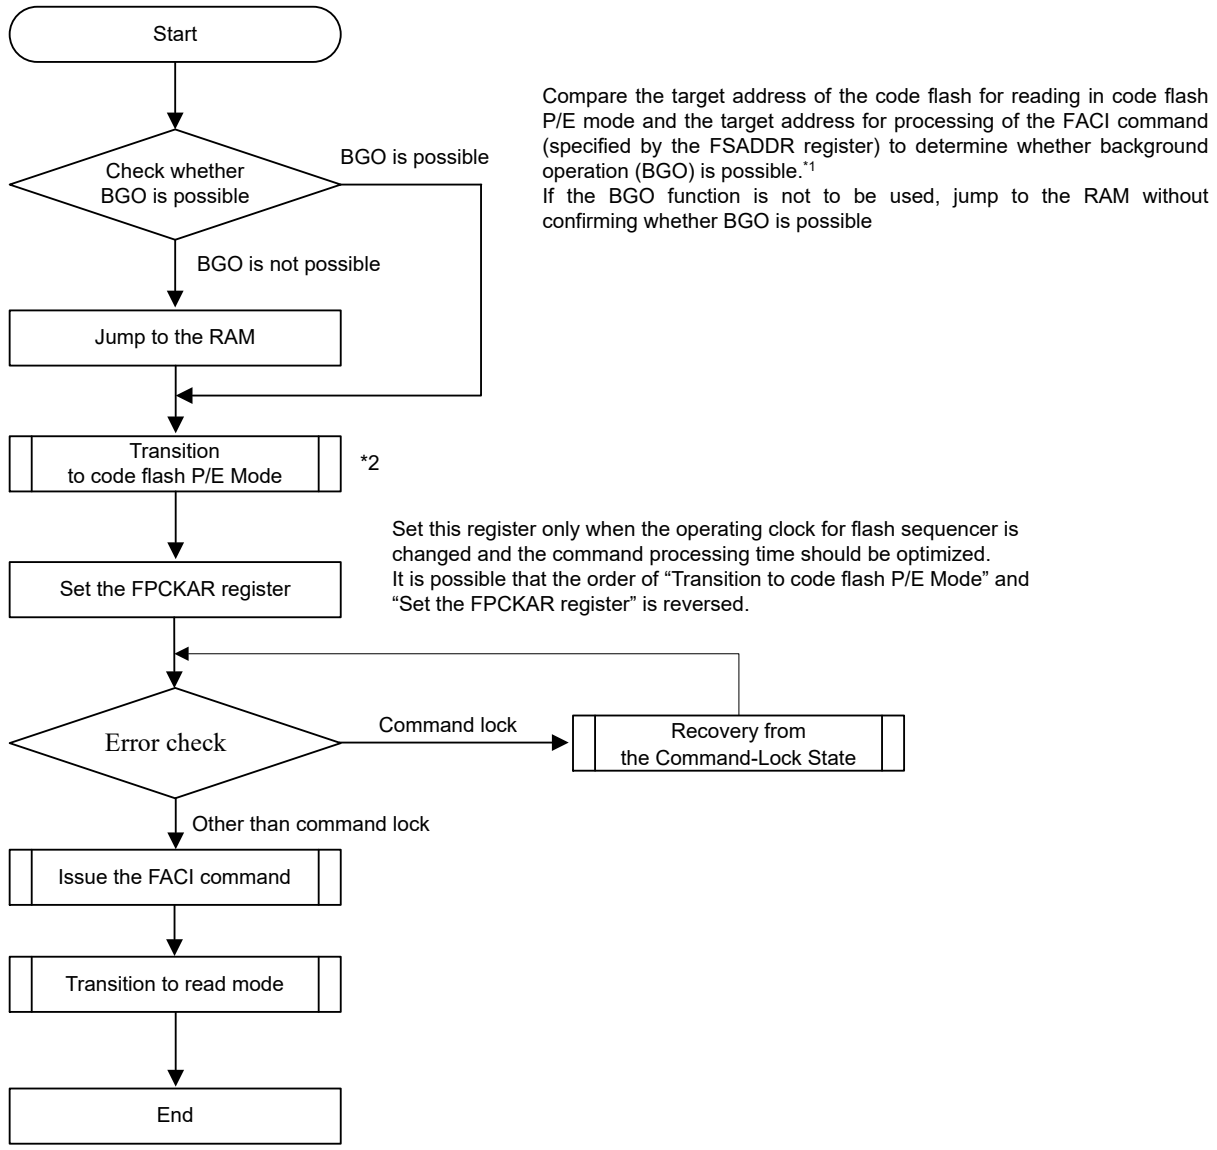
	Program, block erase or multi block erase command processing	Configuration set, configuration clear,increment counter, refresh counter or read counter command processing	Program, block erase or multi block erase command suspension processing	Blank check command processing	Programming suspended	Erasure suspended	Programming while erasure is suspended	Command-locked state (FRDY = 1)	Command-locked state (FRDY = 0)	Processing of forced stop command	Other state
FRDY bit	0	0	0	0	1	1	0	1	0	0	1
SUSRDY bit	1	0	0	0	0	0	0	0	0	0	0
ERSSPD bit	0	0	0/1	0/1	0	1	1	0/1	0/1	0	0
PRGSPD bit	0	0	0/1	0/1	1	0	0	0/1	0/1	0	0
CMDLK bit	0	0	0	0	0	0	0	1	1	0	0
Program	X	X*3	X	X	X	O*2	X	X	X	X	O
Block erase or multi block erase	X	X*3	X	X	X	X	X	X	X	X	O
P/E suspend	O	X*3	X	X	X	X	X	—	X	X	—
P/E resume	X	X*3	X	X	O	O	X	X	X	X	X
Status clear	X	X*3	X	X	O	O	X	O	X	X	O
Forced stop	O	O*3	O	O	O	O	O	O	O	O	O
Blank check	X	X*3	X	X	O*1	O*1	X	X	X	X	O*1
Configuration set	X	X*3	X	X	X	X	X	X	X	X	O
Increment Counter	X	X*3	X	X	X	X	X	X	X	X	O*1
Refresh Counter	X	X*3	X	X	X	X	X	X	X	X	O*1
Read Counter	X	X*3	X	X	X	X	X	X	X	X	O*1

Note: O: Acceptable
X: Not acceptable (places the sequencer in the command-locked state)
—: Ignored
Note 1. Only acceptable in data flash P/E mode.
Note 2. Acceptable when programming area is other than erase suspending block.
Note 3. When configuration set is processing and when FSTATR.DBFULL bit is 1, do not issue this command.

52.9.3 Usage of FACI Commands

52.9.3.1 Overview of Command Usage in Code Flash P/E Mode

Figure 52.8 show an overview of FACI command usage in code flash P/E mode. For the available commands in code flash P/E mode, see Table 52.19.

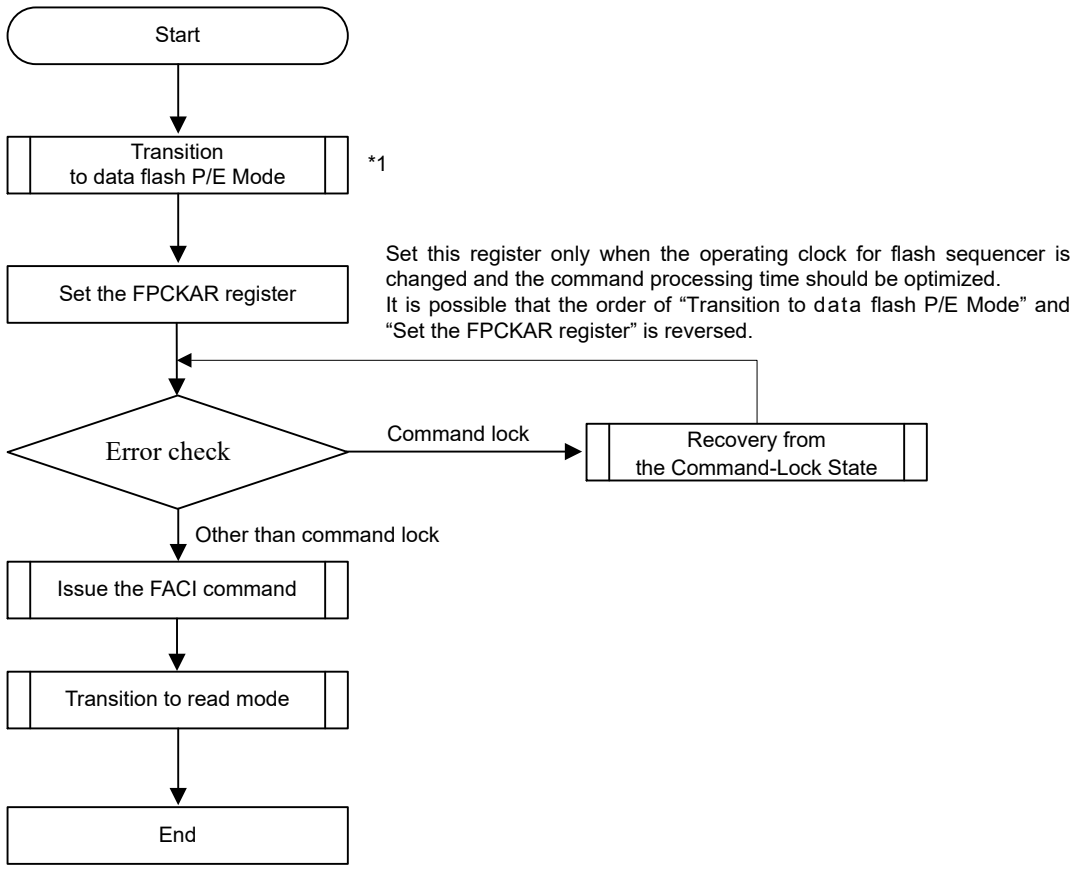


Note 1. See section 52.15.2. Background Operation
Note 2. For the condition in which BGO is possible, see section 52.9.3.3. Transition to Code Flash P/E Mode

Figure 52.8 Overview of command usage in code flash P/E mode

52.9.3.2 Overview of Command Usage in Data Flash P/E Mode

Figure 52.9 shows an overview of FACI command usage in data flash P/E and Table 52.19 lists the available commands in data flash P/E mode.



Note 1. See section 52.9.3.4. Transition to Data Flash P/E Mode

Figure 52.9 Overview of command usage in data flash P/E mode

52.9.3.3 Transition to Code Flash P/E Mode

To issue FACI commands for the code flash memory, a transition to code flash P/E mode is required by setting the FENTRYC bit in the FENTRYR register to 1.

Figure 52.10 shows the procedure to transition to code flash P/E mode.

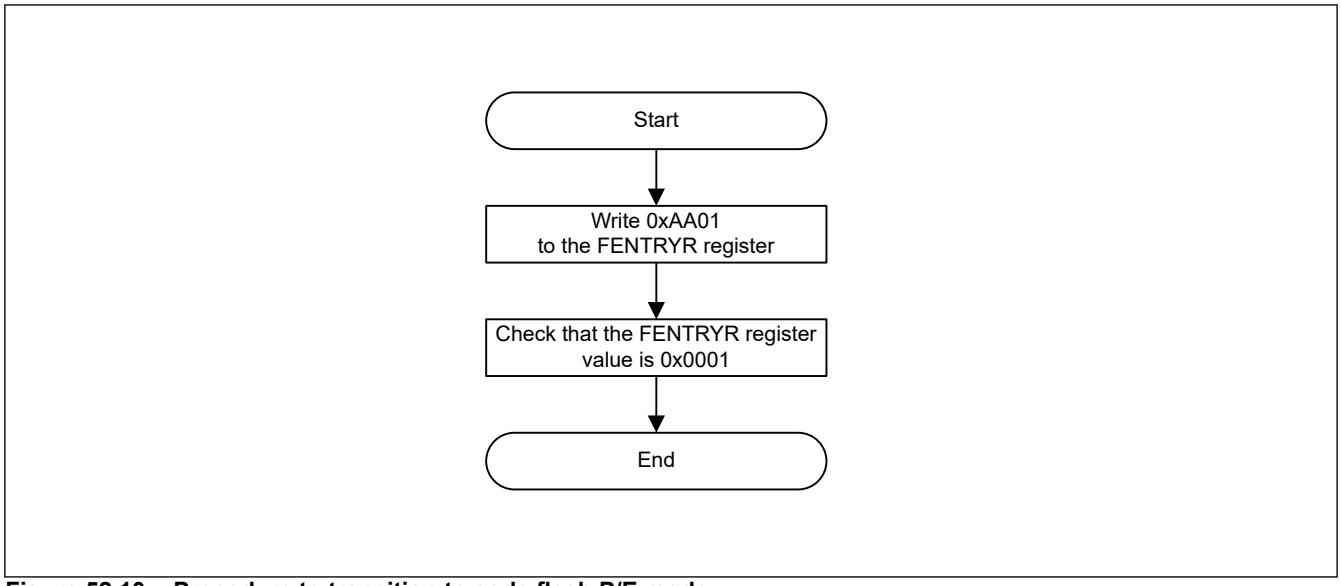


Figure 52.10 Procedure to transition to code flash P/E mode

52.9.3.4 Transition to Data Flash P/E Mode

To issue FACI commands for the data flash memory, a transition to data flash P/E mode is required by setting the FENTRYD bit in the FENTRYR register to 1.

Figure 52.11 shows the procedure to transition to data flash P/E mode.

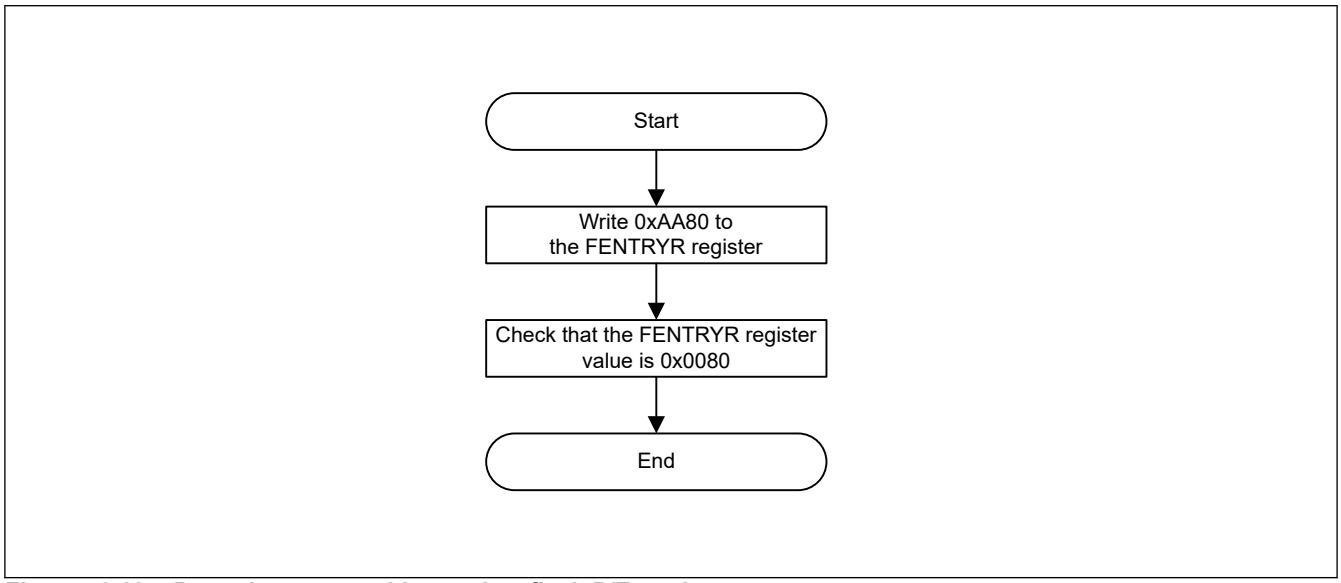

Figure 52.11 Procedure to transition to data flash P/E mode

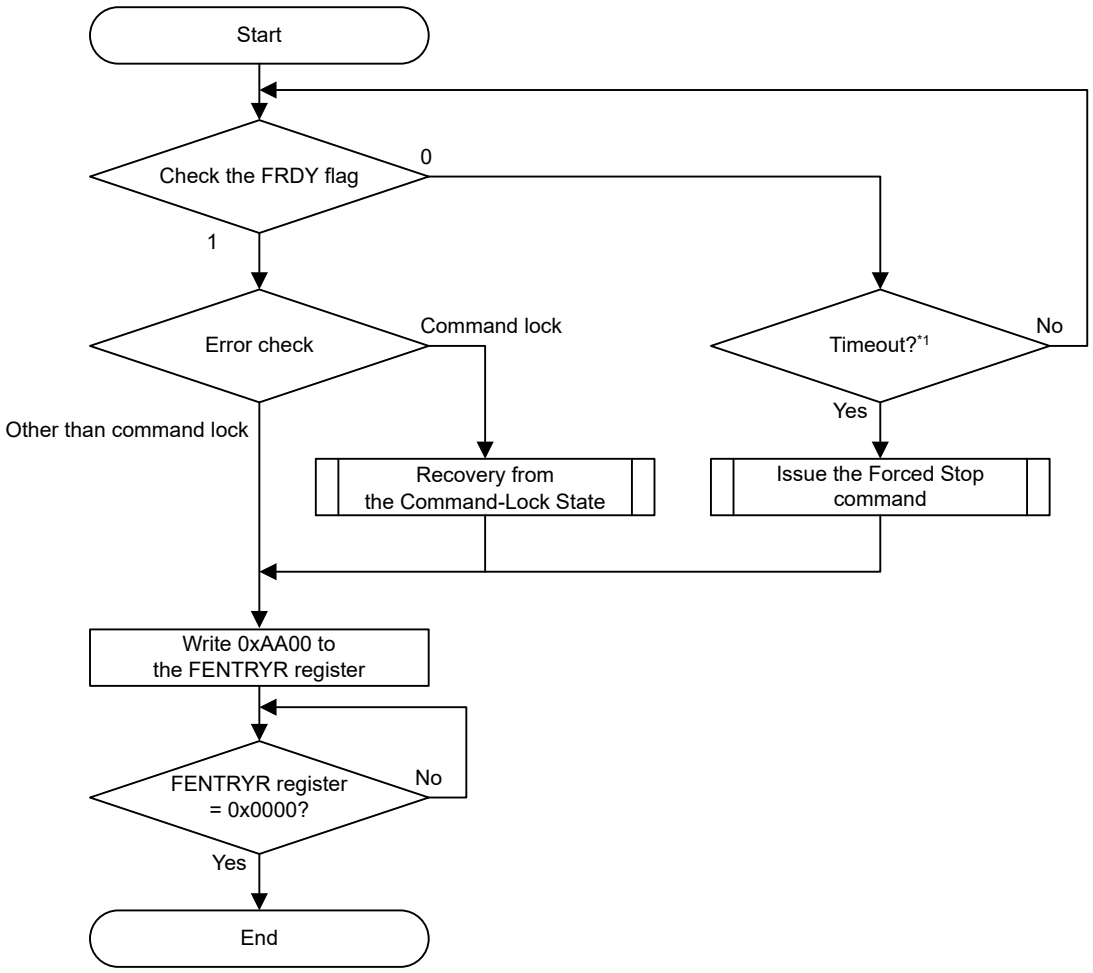
52.9.3.5 Transition to Read Mode

To read the flash memory, a transition to read mode is required by setting the FENTRYR register to 0x0000. The transition to read mode should be made after the flash sequencer completes the processing and while operation is not in the command-locked state.

Figure 52.12 shows the procedure to transition to read mode.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for processing of the FACI command that is in progress (see section 60, Electrical Characteristics)

Figure 52.12 Procedure to transition to read mode

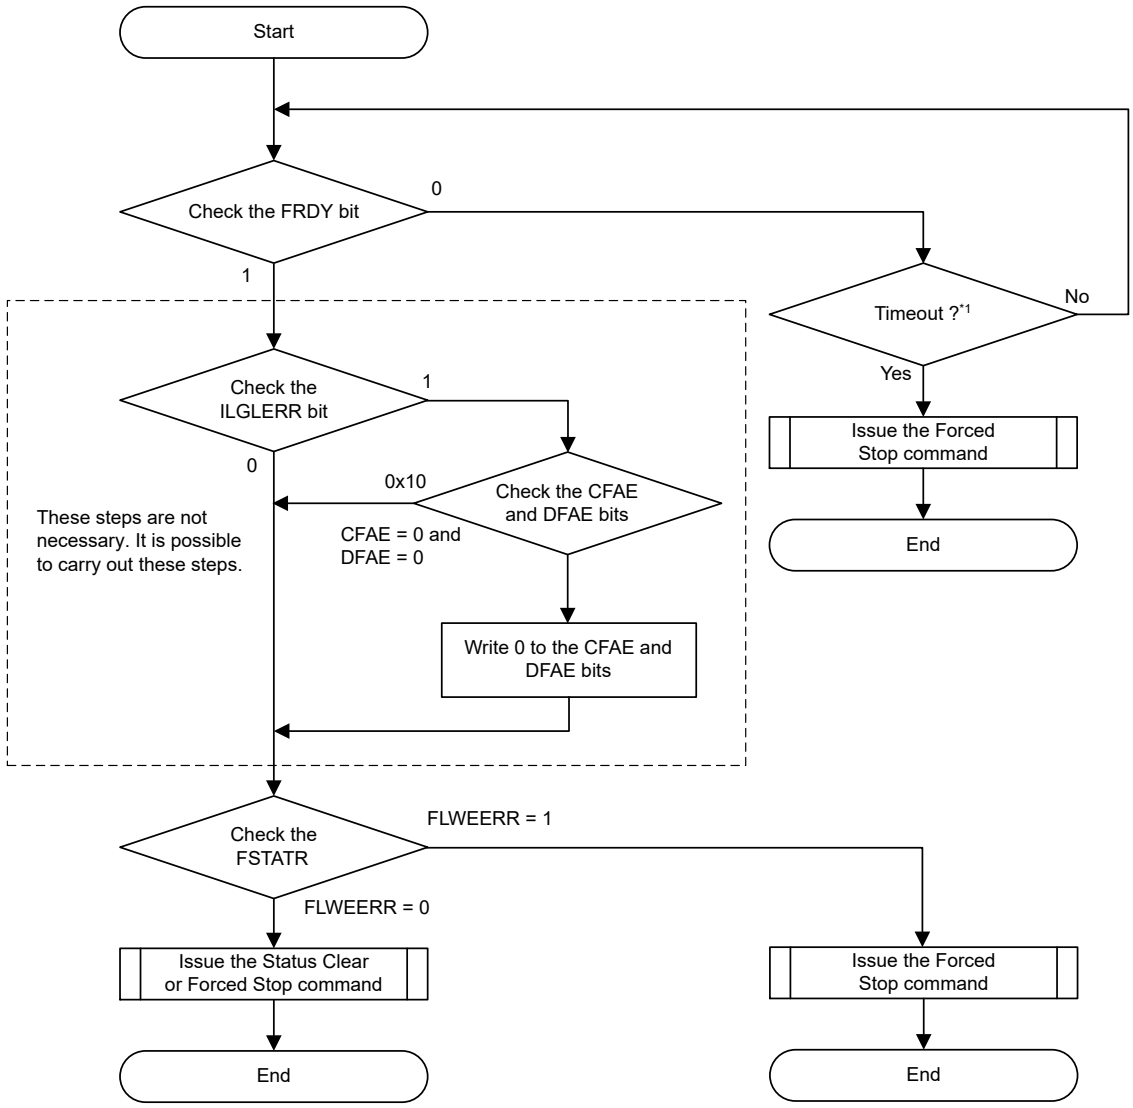
52.9.3.6 Recovery from the Command-Locked State

When the flash sequencer enters the command-locked state, FACI commands cannot be accepted. To release the sequencer from the command-locked state, use the status clear command, forced stop command, or FASTAT register.

When the command-locked state is detected by checking for an error before issuing the P/E suspend command, the FRDY bit in the FSTATR register might be 0 even though command processing has not completed. If processing is not complete by the maximum programming/erasure time specified in the electrical characteristics, this is a timeout and the flash sequencer must be stopped with the forced stop command.

The FLWEERR bit in the FSTATR register does not change from 1 to 0 with the status clear command. When these bits are set to 1, use the forced stop command to release from the command-locked state. Bits other than FRDY and FLWEERR in FSTATR register that indicate the command-locked state can be changed from 1 to 0 with the status clear or forced stop command.

Figure 52.13 shows the recovery flow from the command-locked state.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for processing of the FACI command that is in progress (see section 60, Electrical Characteristics)

Figure 52.13 Recovery flow from the command-locked state

52.9.3.7 Program Command

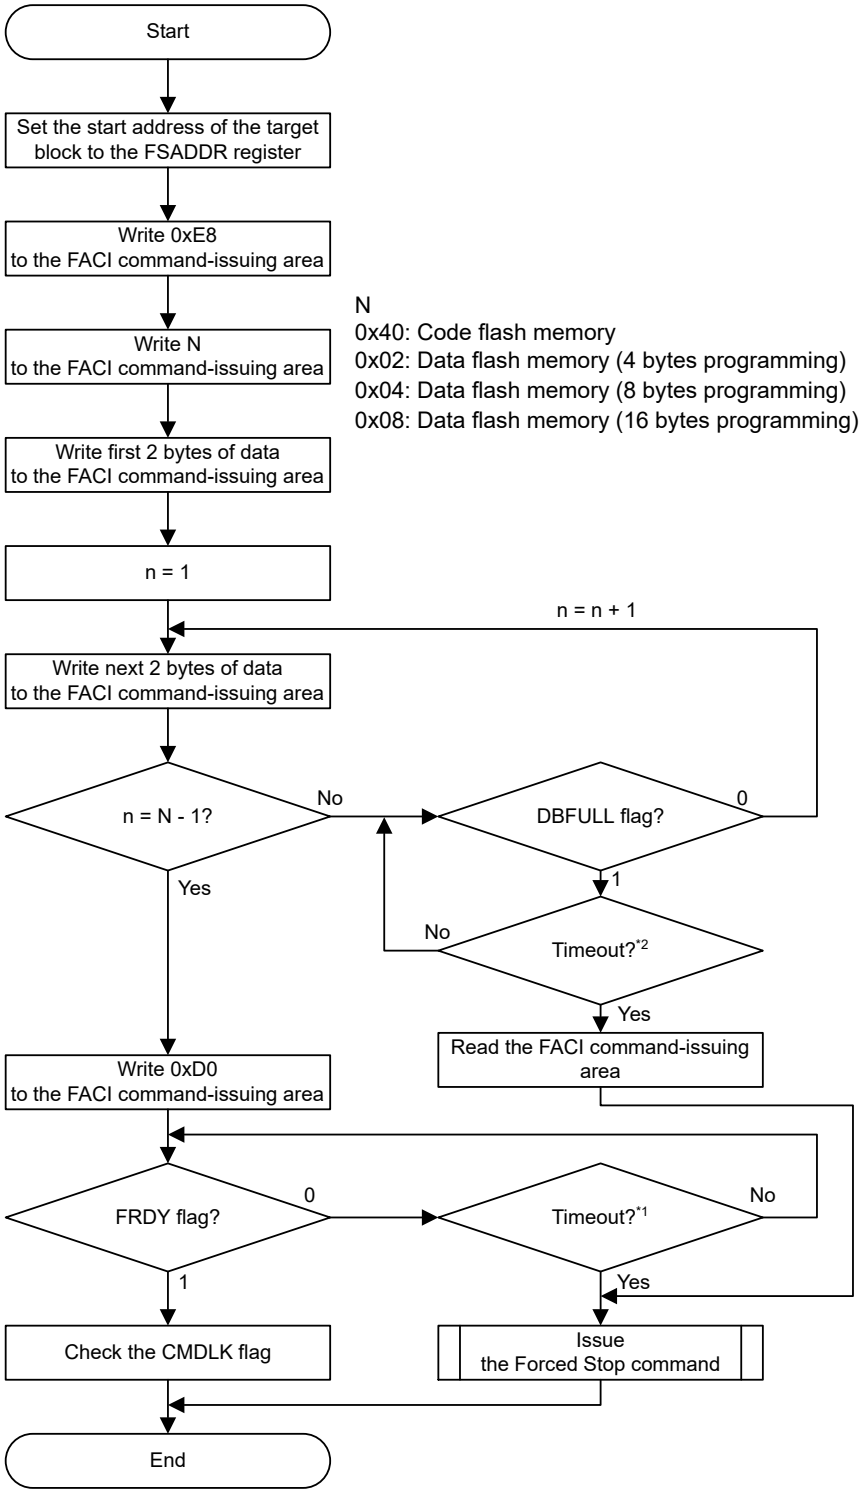
Program commands are used to write to the user and data areas. Before issuing the FACI program command, set the first address of the target block in the FSADDR register.

Program processing is started by writing the last 16 bits of program data (WD64 for code flash and WD2, WD4, and WD8 for data flash in Table 52.18) to the FACI command-issuing area before 0xD0, the final value of the FACI command, is written. Therefore, if it takes time from writing the last 16 bits of program data to writing the final FACI command value 0xD0 (for example, due to interrupt processing), the FSTATR.FRDY bit is set to 1 when program processing is completed even if 0xD0 has not been written. In this case, the program processing has been completed, but the FACI command reception has not been completed. If a subsequent FACI command is issued in this state, an illegal command error will occur. To avoid illegal command errors, disable interrupts with processing that issues FACI commands while program commands are issued (from writing 0xE8 to writing 0xD0).

If the target area for program command processing includes an area that is not for writing, write 0xFFFF to the corresponding area. If a program command is issued while the FACI internal data buffer is full, a wait period may occur on

the peripheral bus, which may affect the communication performance of other peripheral modules. To avoid the occurrence of a waiting period, set the DBFULL bit in the FSTATR register to 0 when issuing a FACI command. Writing to the data area will not cause the data buffer to become full.

Figure 52.14 shows the usage of the program command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of programming. See section 60, Electrical Characteristics about those time

Note 2. 1.4 µs (f_{FCLK} ≥ 20 MHz)

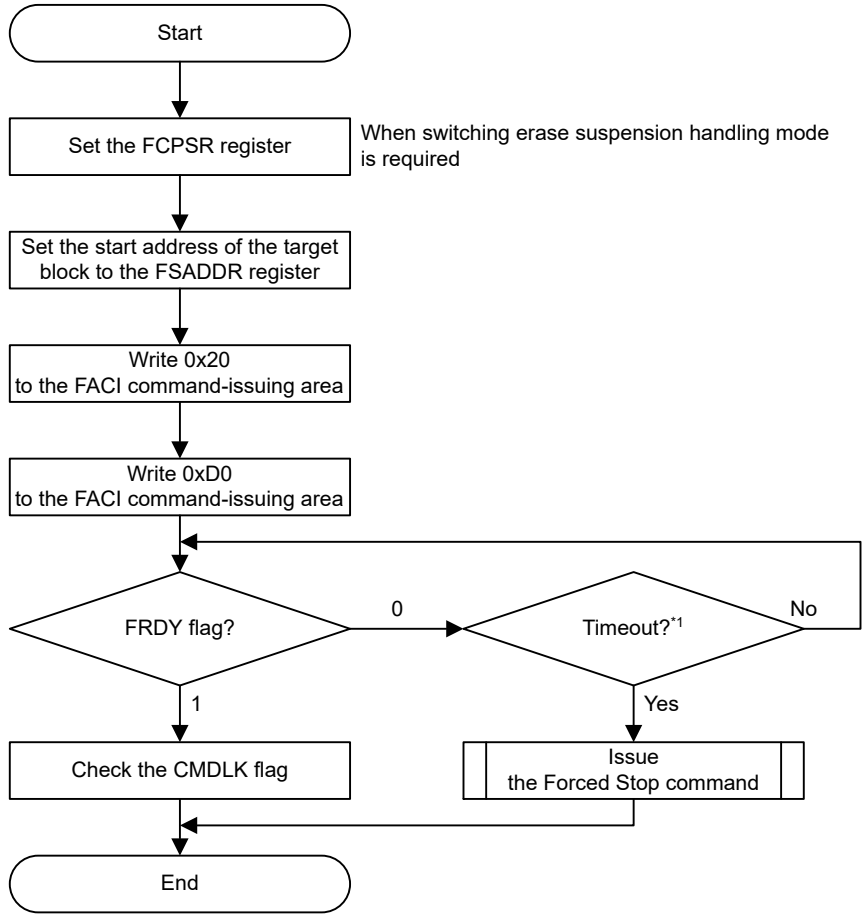
Figure 52.14 Usage flow of the program command

52.9.3.8 Block Erase Command

The block erase command is used for erasing user area or data area. The erase unit is one block. Before issuing a block erase command, set the first address of the target block to FSADDR register. Writing 0xD0 at the second write access of the FACI command triggers the FACI to start the block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Set the FCPSR registers before issuing the block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

Figure 52.15 shows the usage of the block erase command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of erasure. See section 60, Electrical Characteristics.

Figure 52.15 Usage flow of the block erase command

52.9.3.9 Multi Block Erase Command

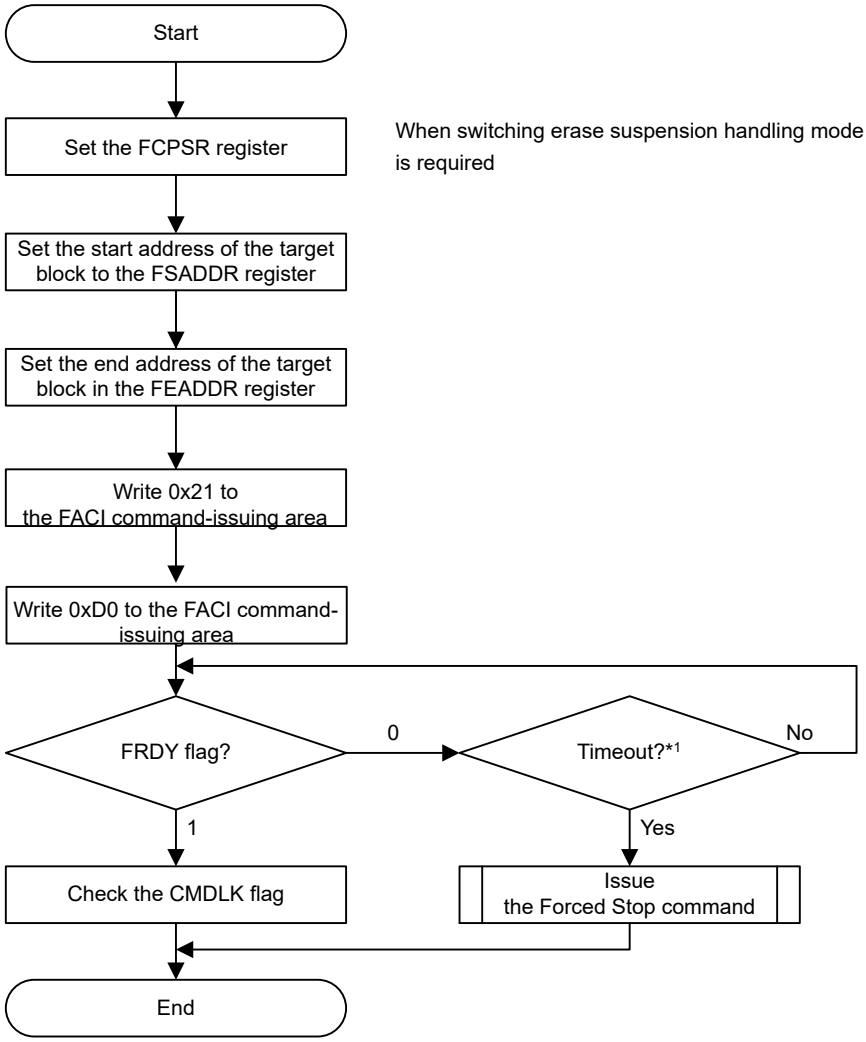
The multi block erase command is used for erasing data area. The erase unit is 64, 128, or 256 bytes. Before issuing the multi block erase command, set the start address to FSADDR register and the end address to FEADDR register. Writing 0xD0 at the second write access of the FACI command triggers FACI to start the multi block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Set the FCPSR registers before issuing the multi block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

The erase size is specified by both the FSADDR and FEADDR settings. Table 52.21 describes how to set the FSADDR and FEADDR.

Table 52.21 Settings for the erase size

Erase size	FSADDR	FEADDR
64 bytes	FSA0 to FSA5 = 0 (64 byte-boundary)	FSADDR + 0x3C
128 bytes	FSA0 to FSA6 = 0 (128 byte-boundary)	FSADDR + 0x7C
256 bytes	FSA0 to FSA7 = 0 (256 byte-boundary)	FSADDR + 0xFC



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of erasure. See section 60, Electrical Characteristics.

Figure 52.16 Usage flow of the multi block command

52.9.3.10 P/E Suspend Command

The P/E suspend command is used to suspend programming/erasure. Before issuing a P/E suspend command, check that the CMDLK bit in the FASTAT register is 0, and that the execution of programming/erasure is performed normally. To confirm that the P/E suspend command can be received, check that the SUSRDY bit in the FSTATR register is 1. After issuing a P/E suspend command, read the CMDLK bit to confirm that no error occurs.

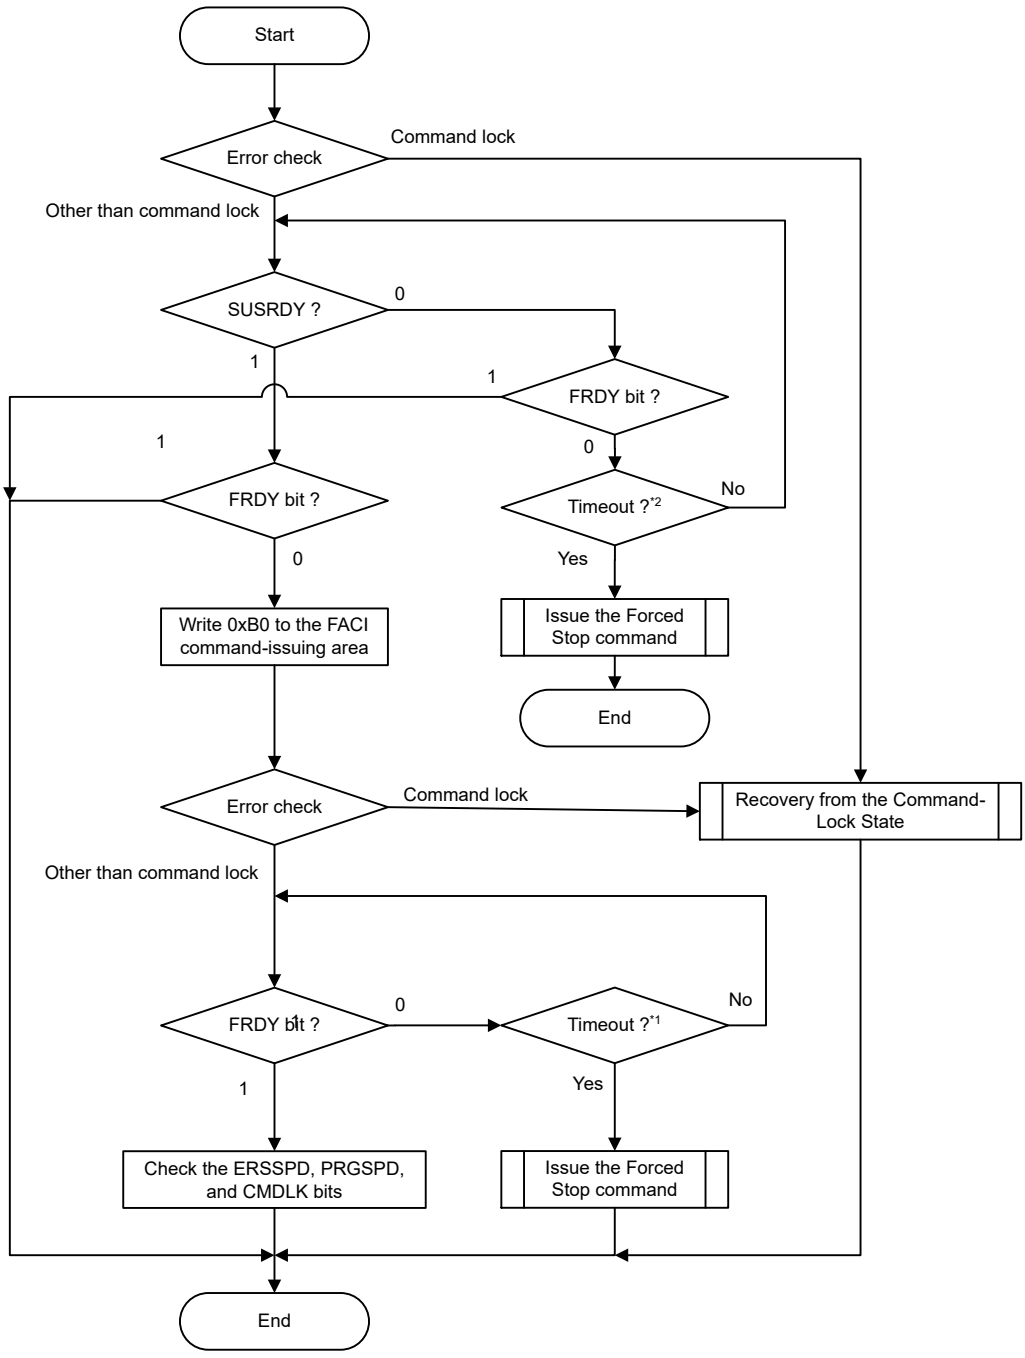
If an error occurs during programming/erasure, the CMDLK bit is set to 1. When programming/erasure processing has finished from the time when the SUSRDY bit is 1 to when the P/E suspend command is received, no error occurs and the

suspended state is not entered (the FRDY bit in the FSTATR register is 1 and the ERSSPD and PRGSPD bits in FSTATR are 0).

When a P/E suspend command is received and the programming/erasure suspend processing finishes normally, the flash sequencer enters the suspended state, the FRDY bit is set to 1, and the ERSSPD or PRGSPD bit is 1. After issuing a P/E suspend command, check that the ERSSPD or PRGSPD bit is 1 and the suspended state is entered, then proceed with the subsequent flow. If a P/E resume command is issued in the subsequent flow even when the suspended state is not entered, an illegal command error occurs and the flash sequencer shifts to the command-locked state (see section 52.11.2. Error Protection).

If the erasure suspended state is entered, programming to blocks other than an erasure target block can be performed. Additionally, the programming and erasure suspended states can shift to read mode by clearing the FENTRYR register.

Figure 52.17 shows the usage of the P/E suspend command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of suspend delay during erasure for both code flash and data flash.
See section 60, Electrical Characteristics.
Note 2. 4.4µs (f_{FCLK} >= 20MHz)

Figure 52.17 Usage flow of the P/E suspend command

(1) Suspension during Programming

When issuing a P/E suspend command during flash memory programming, the flash sequencer suspends programming processing. Figure 52.18 shows the suspend programming operation. When receiving programming-related command, the flash sequencer clears the FRDY bit in the FSTATR register to 0 to start programming. If the flash sequencer enters the state

in which the P/E suspend command can be received after programming starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0. If the flash sequencer receives a P/E suspend command while a programming pulse is applied, the flash sequencer continues with the pulse. After the specified pulse application time, the flash sequencer finishes pulse application, starts the programming suspend processing, and sets the PRGSPD bit in the FSTATR register to 1.

When a suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the programming suspended state. When receiving a P/E resume command in the programming suspended state, the flash sequencer clears the FRDY and PRGSPD bits to 0 and resumes programming.

Figure 52.18 shows the timing for suspension during programming.

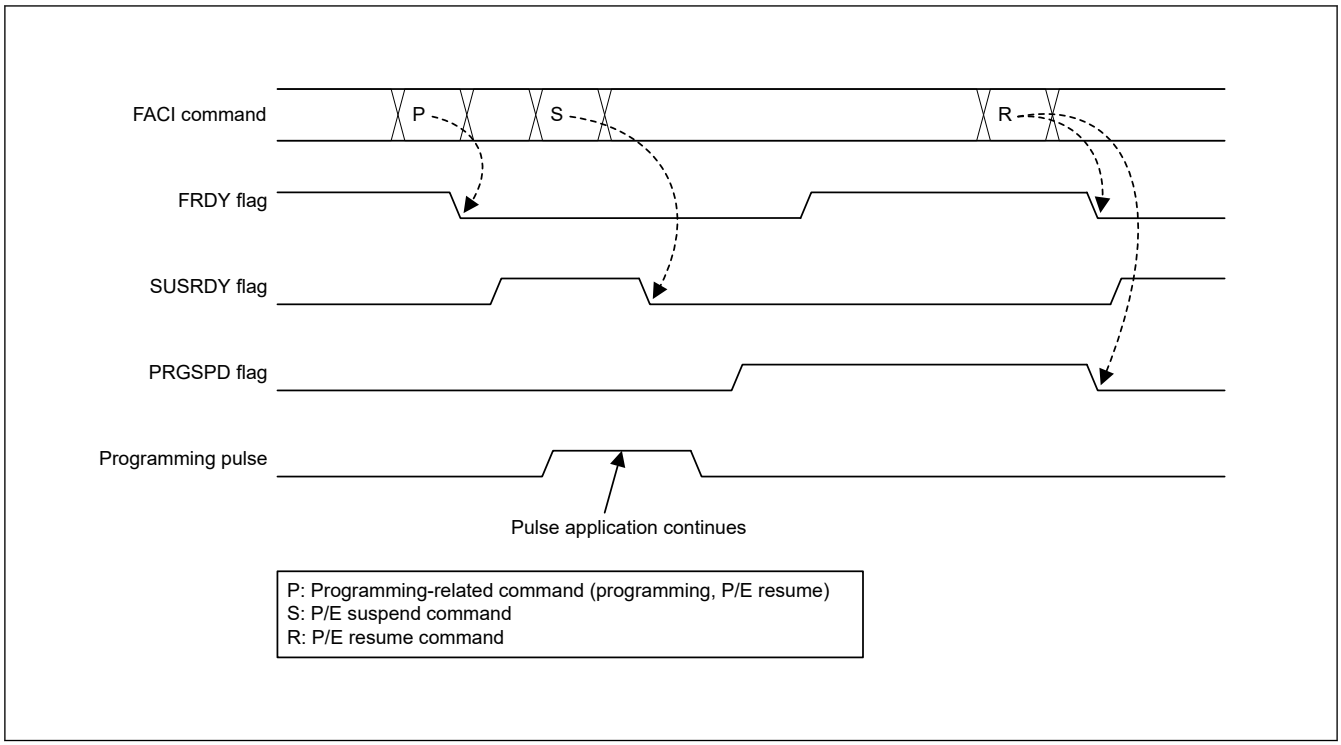


Figure 52.18 Suspension during programming

(2) Suspension during Erasure (Suspension Priority Mode)

The flash sequencer has a suspension priority mode for the suspension of erasure. Figure 52.19 shows the suspend operation of erasure when the erasure suspend mode is set to the suspension priority mode (the ESUSPMD bit in the FCPSR register is 0).

When receiving an erasure-related command, the flash sequencer clears the FRDY bit in the FSTATR register to 0 to start erasure. If the flash sequencer enters the state in which the P/E suspend command can be received after erasure starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0.

When receiving a suspend command during erasure, the flash sequencer starts the suspend processing and sets the ERSSPD bit in the FSTATR register to 1 even when it is applying an erasure pulse. When the suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the erasure suspended state. When receiving a P/E resume command in the erasure suspended state, the flash sequencer clears the FRDY and ERSSPD bits to 0 and resumes erasure. Operations of the FRDY, SUSRDY, and ERSSPD bits at the suspension and resumption of erasure are the same, regardless of the erasure suspend mode.

The setting of the erasure suspend mode affects the control method of erasure pulses. In suspension priority mode, when receiving a P/E suspend command while erasure pulse A that has not been previously suspended is being applied, the flash sequencer suspends the application of erasure pulse A and enters the erasure suspended state. When receiving a P/E suspend command while reapplying erasure pulse A after erasure is resumed with a P/E resume command, the flash sequencer

continues to apply erasure pulse A. After the specified pulse application time, the flash sequencer finishes erasure pulse application and enters the erasure suspended state.

When the flash sequencer receives a P/E resume command next and erasure pulse B is being applied, the flash sequencer receives a P/E suspend command again, and the application of erasure pulse B is then suspended. In suspension priority mode, delays due to suspension can be minimized because the application of an erasure pulse is suspended once per pulse, and priority is given to the suspend processing.

If the interval of suspension after resume is longer than t_{REST1} (Resume time: priority on suspension, resume after the 1st suspend for the same pulse), suspend delay will be always t_{SESD1} (Suspend delay: priority on suspension, the 1st suspend for the same pulse).

If the interval of suspension after resume is shorter than t_{REST1}, suspend delay becomes either t_{SESD1} or t_{SESD2} (Suspend delay: priority on suspension, the 2nd suspend for the same pulse).

(The value of t_{REST1} / t_{SESD1} / t_{SESD2}, see section 60, Electrical Characteristics.)

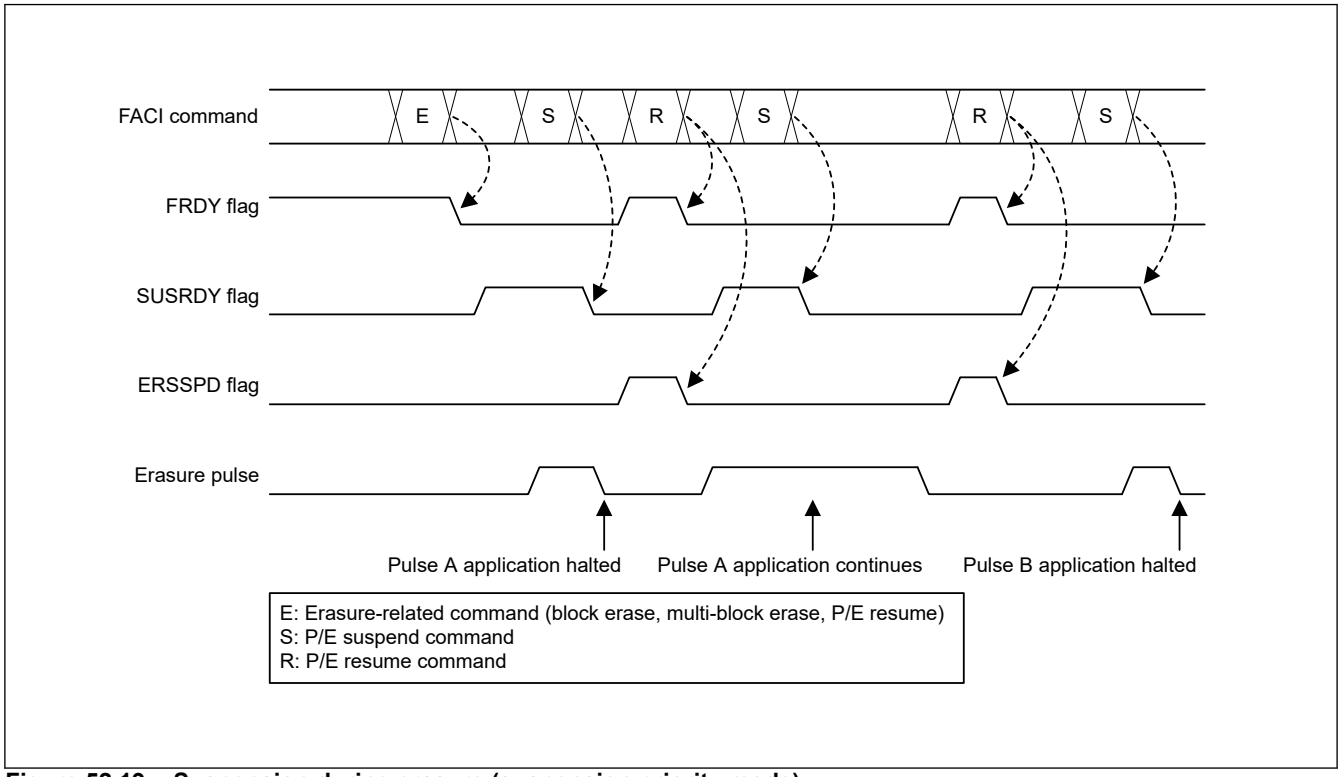

Figure 52.19 Suspension during erasure (suspension priority mode)

(3) Suspension during Erasure (Erasure Priority Mode)

The flash sequencer has an erasure priority mode for the suspension of erasure. Figure 52.20 shows the suspend operation of erasure when the erasure suspend mode is set to the erasure priority mode (the ESUSPMD bit in the FCPSR register is 1). The control method of erasure pulses in erasure priority mode is the same as that of programming pulses for the programming suspend processing.

If the flash sequencer receives a P/E suspend command while an erasure pulse is applied, the flash sequencer continues to apply the pulse. In this mode, the required time for the erasure processing can be reduced compared to the suspension priority mode because the re-application of erasure pulses does not occur when a P/E resume command is issued.

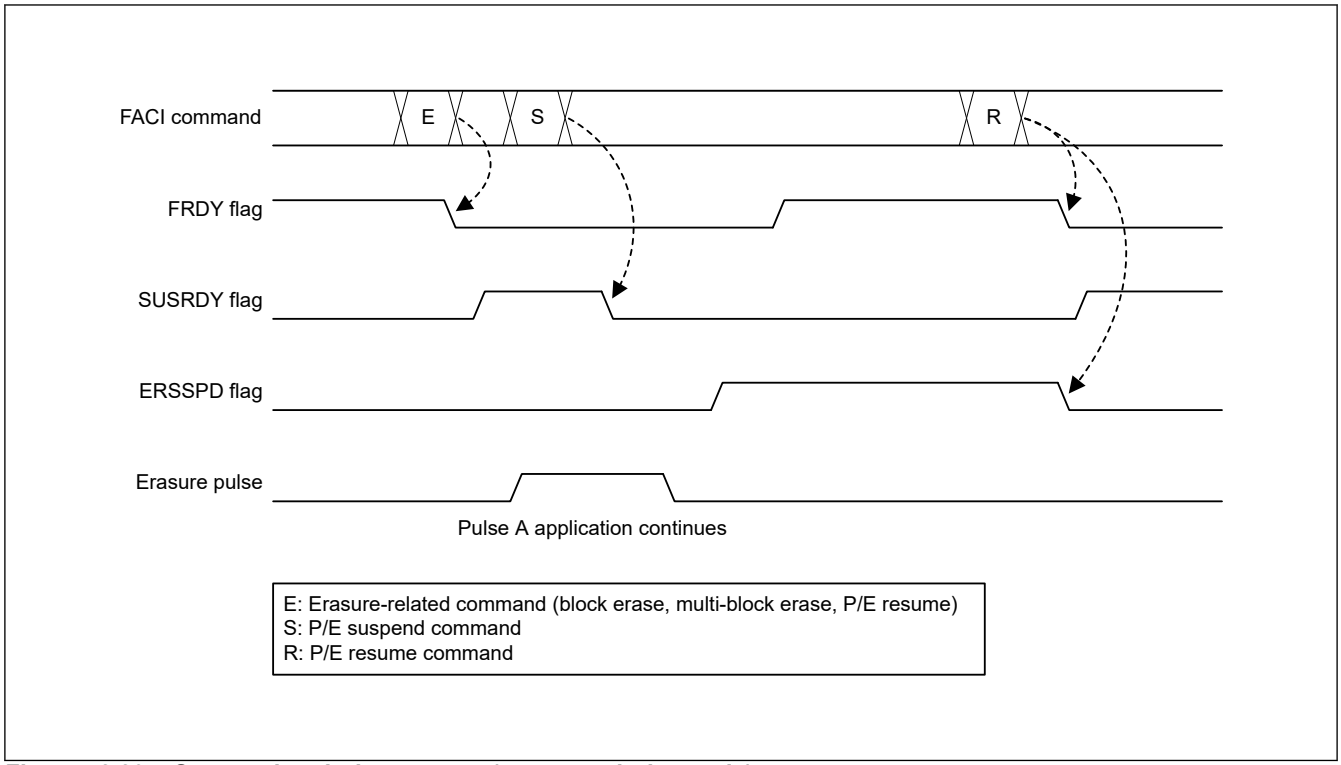

Figure 52.20 Suspension during erasure (erasure priority mode)

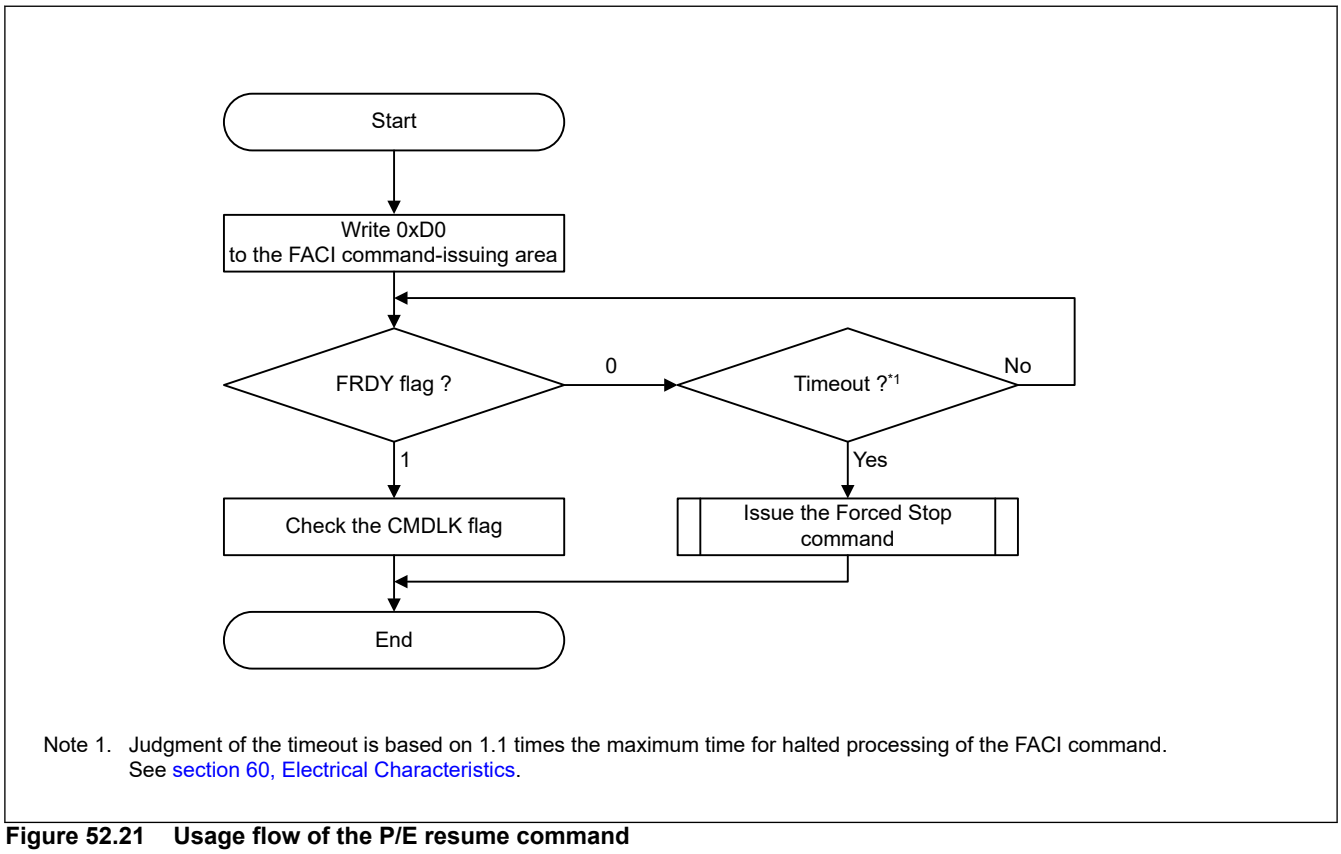
52.9.3.11 P/E Resume Command

The P/E resume command is used to resume suspended programming or erasure. If the FENTRYR setting has been modified during suspension, issue a P/E resume command only after resetting FENTRYR to the previous value that was held before the P/E suspend command was issued. Figure 52.21 shows usage of the P/E resume command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for halted processing of the FACI command. See section 60, Electrical Characteristics.

Figure 52.21 Usage flow of the P/E resume command

52.9.3.12 Status Clear Command

The status clear command is used to clear the command-locked state (see section 52.9.3.6. Recovery from the Command-Locked State).

You can use the status clear command to clear the following bits in the FSTATR register in the command-locked state:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR
- TZFERR

Figure 52.22 shows usage of the status clear command.

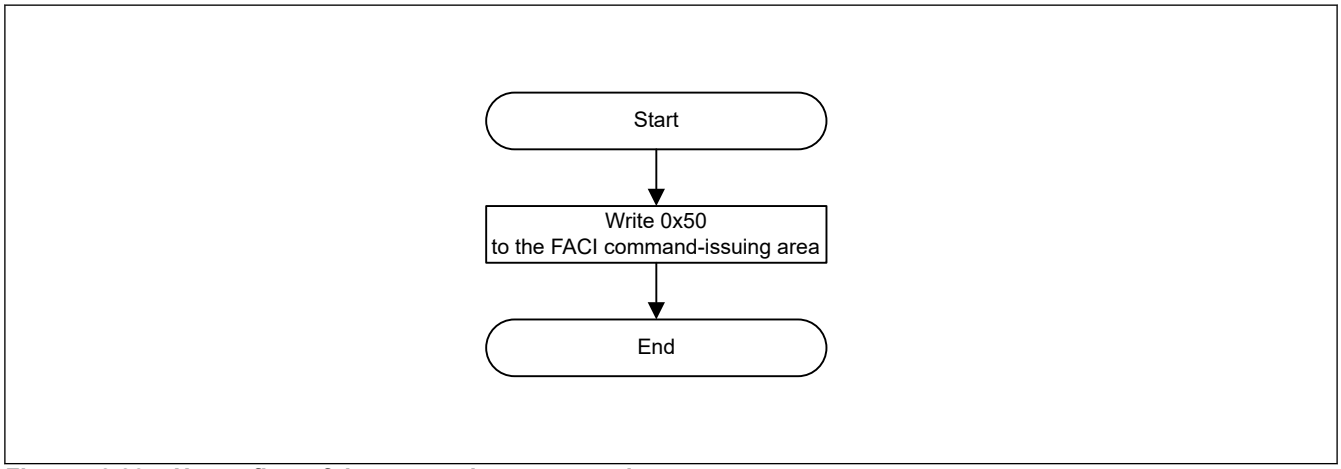


Figure 52.22 Usage flow of the status clear command

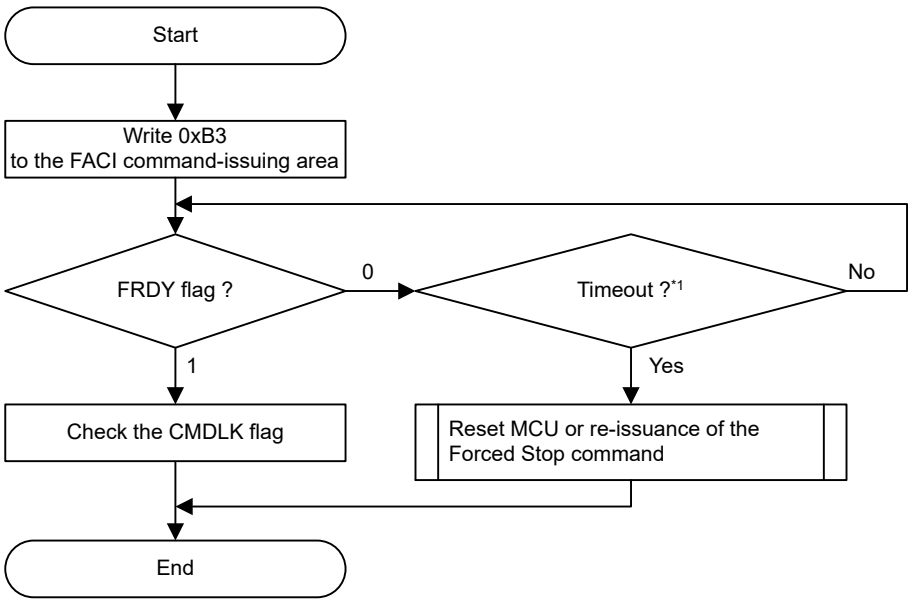
52.9.3.13 Forced Stop Command

The forced stop command is used to forcibly end command processing by the flash sequencer. Although this command halts command processing more quickly than the P/E suspension command, values from the programming or erasure that are in progress are not guaranteed. Additionally, resumption of processing is not possible. Processing of programming or erasure that is halted by the forced stop command is also defined as one programming round.

Executing the forced stop command also initializes part of the FACI, the whole FCU, the FSTATR and FASTAT registers. This command can be used in the procedure for recovery from the command-locked state and for processing in response to a timeout of the flash sequencer (see section 52.9.3.6. Recovery from the Command-Locked State).

Figure 52.23 shows usage of the forced stop command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of the Forced Stop command latency. See section 60, Electrical Characteristics.

Figure 52.23 Usage flow of the forced stop command

(1) Notes on Using the Forced Stop Command during Command Issue

When using the forced stop command at the timeout occurrence by DBFULL bit of the program command, writing in the FACI command-issuing area is sometimes processed as writing in data of the program command. See Table 52.4 in section 52.3. Address Space for information on the FACI command-issuing area to force a command lock. Then issue a forced stop command with return method from the command lock status (see Figure 52.14). Locking commands is possible in any case where the unit for reading the FACI command issuing area is 8, 16, or 32 bits.

52.9.3.14 Blank Check Command

The blank check command is used to confirm that an area is in the non-programmed state. Values read from the data flash memory that have been erased but not yet programmed again that is in the non-programmed state, are undefined.

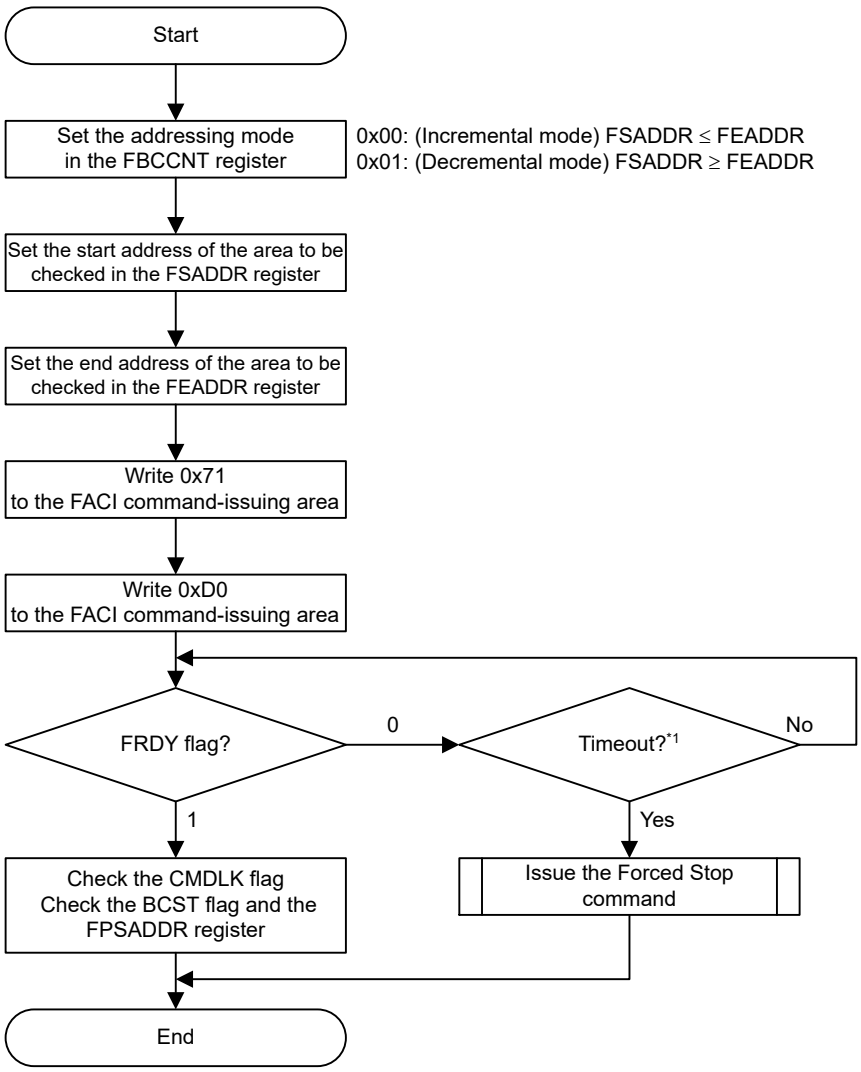
Before issuing the Blank Check command, set addressing mode, start address, and end address of the target area for Blank Check to the FBCCNT, FSADDR, and FEADDR registers. When Blank Check addressing mode is set to decremental mode (i.e. FBCCNT.BCDIR = 1), address specified in FSADDR should be equal to or larger than address in FEADDR.

On the other hand, the address in FSADDR should be equal to or smaller than address in FEADDR when Blank Check addressing mode is set to incremental mode (i.e. FBCCNT.BCDIR = 0).

If the settings of the BCDIR bit, FSADDR, and FEADDR are inconsistent, the flash sequencer enters the command-locked state. The size of the target area for Blank Check is in the range from 4 bytes to the data flash memory capacity and is set in units of 4 bytes.

Write 0x71 and 0xD0 to the FACI command-issuing area to start Blank Check. Completion of processing can be confirmed by the FRDY bit of the FSTATR register. At the end of processing, the result of Blank Check is stored in the BCST bit in the FBCSTAT register. If non-programmed data exists within the target area for Blank Check, flash sequencer stops Blank Check command operation. In this case, address of non-programmed data is indicated to FPSADDR register.

Figure 52.24 shows usage of the blank check command.



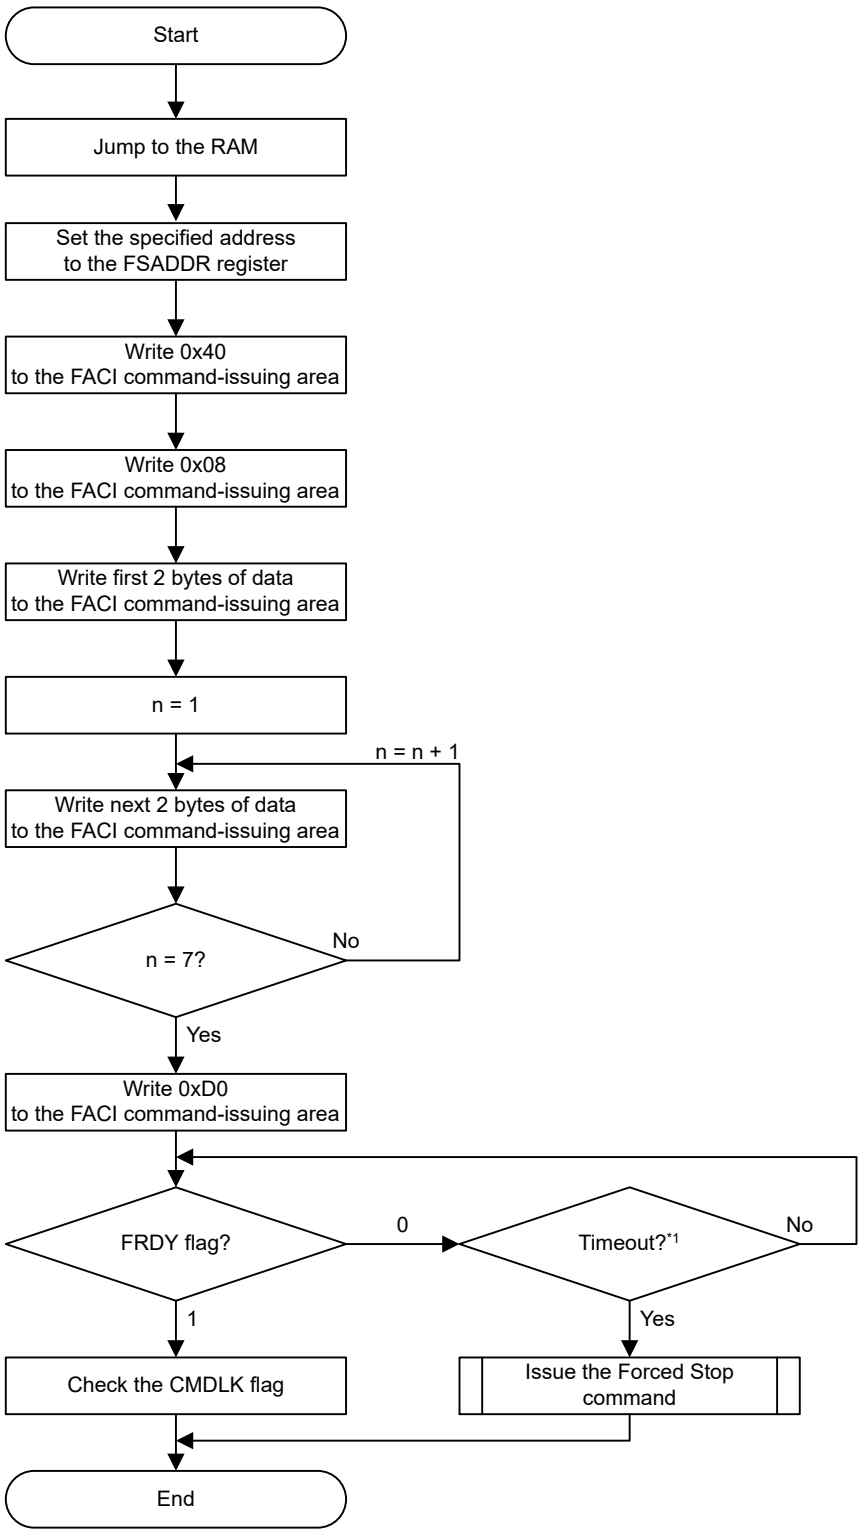
Note 1. Judgment of the timeout is based on 1.1 times the maximum time of Blank Checking for the whole target range. See section 60, Electrical Characteristics.

Figure 52.24 Usage flow of the blank check command

52.9.3.15 Configuration Set Command

The Configuration set command is used to set option-setting memory. Before issuing the Configuration set command, set the specified address (shown in Table 52.22) in the FSADDR register. Writing 0xD0 to the FACI command-issuing area in the final access for issuing the FACI command starts FACI processing of the Configuration set command.

Figure 52.25 shows usage of the configuration set command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of programing in option-setting memory. See section 60, Electrical Characteristics.

Figure 52.25 Usage flow of the configuration set command

The correspondence between the possible target data for configuration setting and the address value set in the FSADDR register is shown in Table 52.22. For details, see section 52.4.12. FSADDR : FACI Command Start Address Register.

Table 52.22 Address Used by Configuration Set Command for Secure alias (Code flash memory)

Address	FSADDR Register Value	Setting Data	Operation of additional writing		Timing when the Setting is Enabled
			SAS.FSPR bit is 1	SAS.FSPR bit is 0	
0x0300_A100	0x0300_A100	Option Function Select Register 0 (OFS0)	Writable	Writable	At a reset
0x0300_A104		Option Function Select Register 2 (OFS2)			
0x0300_A110	0x0300_A110	Dual Mode Select Register (DUALSEL)	Writable	Writable	At a reset
0x0300_A134	0x0300_A130	Start-up Area Setting Register (SAS)	Writable	Not writable*1	When a reset or command is executed
0x1300_A180	0x1300_A180	Option Function Select Register 1 (OFS1)	Writable	Writable	At a reset
0x1300_A190	0x1300_A190	Bank Select Register (BANKSEL)	Writable	Writable	At a reset
0x1300_A1C0	0x1300_A1C0	Block Protect Setting Register (BPS)	Writable*2	Writable*2	When a reset or command is executed
0x1300_A1E0	0x1300_A1E0	Permanent Block Protect Setting Register (PBPS)	Writable*3 (from 1 to 0 only)	Writable*3 (from 1 to 0 only)	When a reset or command is executed
0x0300_A200	0x0300_A200	Option Function Select Register 1 Secure (OFS1_SEC)	Writable	Writable	At a reset
0x0300_A210	0x0300_A210	Bank Select Register Secure (BANKSEL_SEC)	Writable	Writable	At a reset
0x0300_A240	0x0300_A240	Block Protect Setting Register Secure (BPS_SEC)	Writable*4	Writable*4	When a reset or command is executed
0x0300_A260	0x0300_A260	Permanent Block Protect Setting Register Secure (PBPS_SEC)	Writable*5 (from 1 to 0 only)	Writable*5 (from 1 to 0 only)	When a reset or command is executed
0x0300_A280	0x0300_A280	Option Function Select Register 1 Select (OFS1_SEL)*6	Writable	Writable	At a reset
0x0300_A290	0x0300_A290	Bank Select Register Select (BANKSEL_SEL)	Writable	Writable	At a reset
0x0300_A2C0	0x0300_A2C0	Block Protect Setting Register Select (BPS_SEL)	Writable*6	Writable*6	At a reset

Note 1. The SAS.FSPR bit cannot be restored to 1 by using the Configuration set command once it is set to 0. Therefore, setting the start-up area select flags again becomes impossible. (when the Configuration set command is issued to the address of 0x0100A134, the command is locked.) Exercise extra caution when handling the SAS.FSPRbit.
Note 2. Once PBPS[n] bit is set to 0, the BPS[n] bit cannot be restored to 1 by using the Configuration set command.
Note 3. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration set command. The PBPS[n] bit cannot be set to 0 by using the Configuration set command when the BPS[n] bit is 1.
Note 4. Once PBPS_SEC[n] bit is set to 0, the BPS_SEC[n] bit cannot be restored to 1 by using the Configuration set command.
Note 5. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration set command. The PBPS_SEC[n] bit cannot be set to 0 by using the Configuration set command when the BPS_SEC[n] bit is 1.
Note 6. When the Permanent Block Protect bit is enabled, Block protect setting register cannot be written.

Table 52.23 Address Used by Configuration Set Command for Secure alias (Data flash memory) (1 of 2)

Address	FSADDR	Setting Data	Operation of additional writing		Timing when the Setting is Enabled
	Register Value		Lock bit is 1	Lock bit is 0	
0x2703_0080~ 0x2703_017C	0x2703_0080~ 0x2703_017C	Lockable Configuration Data Area 0 (LK_CD_A0)	Writable*1	Not Writable*1	At a reset
0x2703_0180~ 0x2703_027C	0x2703_0180~ 0x2703_027C	Lockable Configuration Data Area 1 (LK_CD_A1)	Writable*1	Not Writable*1	At a reset
0x2703_0280~ 0x2703_037C	0x2703_0280~ 0x2703_037C	Lockable Configuration Data Area 2 (LK_CD_A2)	Writable*1	Not Writable*1	At a reset

Table 52.23 Address Used by Configuration Set Command for Secure alias (Data flash memory) (2 of 2)

Address	FSADDR	Setting Data	Operation of additional writing		Timing when the Setting is Enabled
	Register Value		Lock bit is 1	Lock bit is 0	
0x2703_0380~ 0x2703_0384	0x2703_0380~ 0x2703_0384	Configuration Data Lock Bit Area 0 (CD0_LK)	Writable	Writable	When a reset or command is executed
0x2703_0388~ 0x2703_038C	0x2703_0380~ 0x2703_0384	Configuration Data Lock Bit Area 1 (CD1_LK)	Writable (from 1 to 0 only)	Writable (from 1 to 0 only)	When a reset or command is executed
0x2703_0390~ 0x2703_0391	0x2703_0380~ 0x2703_0384	Configuration Data Lock Bit Area 2 (CD2_LK)	Writable (from 1 to 0 only)	Writable (from 1 to 0 only)	When a reset or command is executed
0x2703_03C0	0x2703_03C0	Anti-Rollback Counter Lock Setting (ARCLS)	Writable (from 1 to 0 only)	Writable (from 1 to 0 only)	When a reset or command is executed
0x2703_03C2		Anti-Rollback Counter Configuration Setting for ARC_NSEC (ARCCS)	Writable*2	Writable*2	When a reset or command is executed

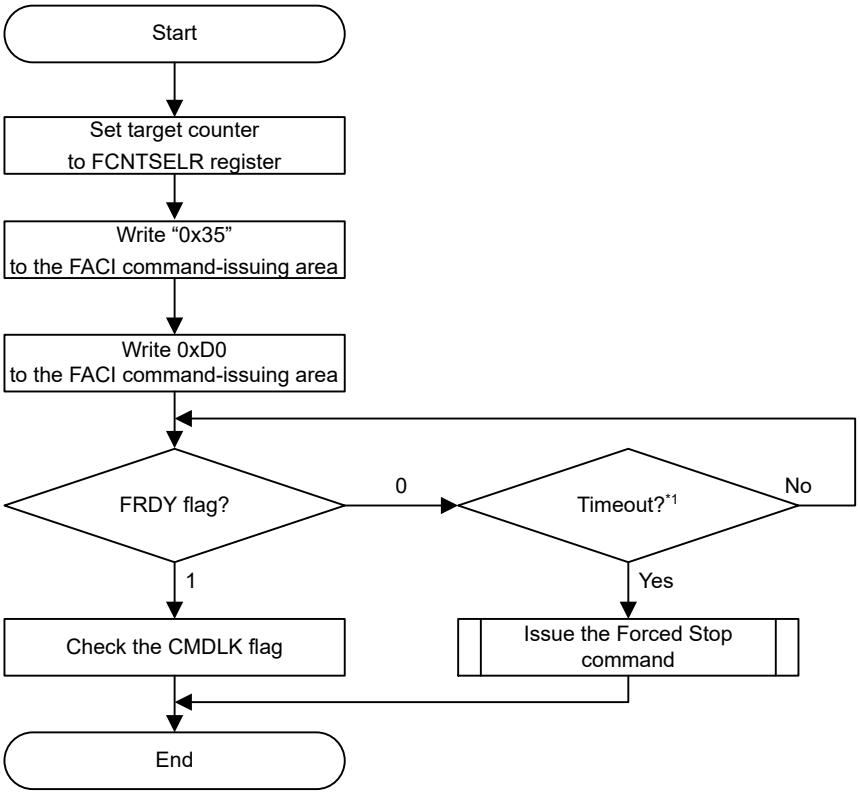
Note 1. For details of relation of write-protection area and lock bit, see section 52.12.4. Data Flash Configuration Area Protection.
Note 2. The ARC_NSEC counter selection bit cannot be changed after set to 00b or 01b. When using the ARC_NSEC counter, this counter can be selected either of 4 lines of 64 bits (00b setting) or 1 line of 256 bits (01b setting).

52.9.3.16 Increment Counter Command

The Increment Counter command is used to security function, safety function. "Increment Counter" command is used for updating 3 types of anti-rollback counter (ARC_SEC, ARC_NSEC, and ARC_OEMBL). The counter update is executed increment processing and cannot be decrement processing.

Writing "0xD0" at 2nd write access of flash sequencer command triggers FACI to start “Increment Counter” command processing. Completion of command processing can be confirmed by FRDY bit of FSTATR register.

If "Command Lock" status occurs during command execution, refresh the counter with "Refresh Counter" command after "Command Lock" state is released.



Note 1. 50msec(FCLK>=20MHz)

Figure 52.26 Usage of the Increment Counter Command

Anti-rollback counter value is not increased the following conditions by “Increment Counter” command.

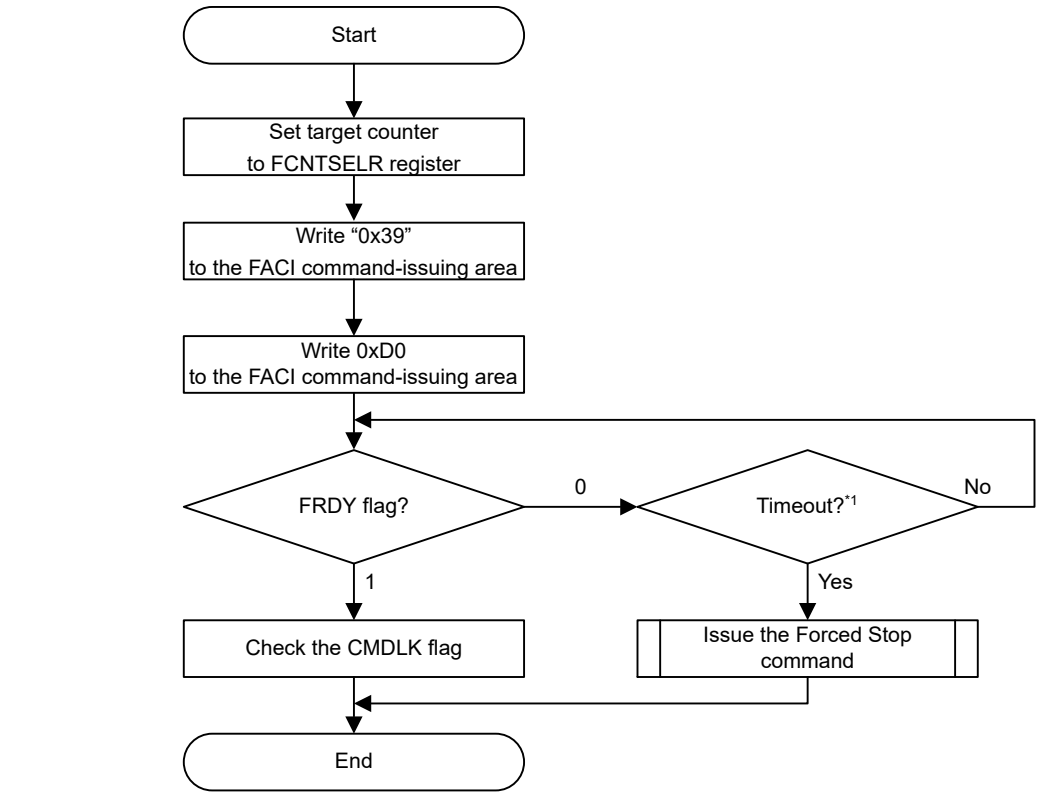
- Target counter is protected by ARCSEC_LK, ARCNSEC_LK0~3, or ARCOEMBL_LK.
- The previous command is not "Read Counter" command against ARC_OEMBL when target counter is ARC_OEMBL.
- The anti-rollback counter for OEM_BL cannot be incremented more than OEM_BL version number specified in the image version of the header of the code certificate. After updated the OEM_BL, the anti-rollback counter for OEM_BL cannot be incremented. For details, see section 43, Security Features .
- Target counter value is maximum. (Error does not occur)
- Target counter is ARC_NSEC when CNF_ARCNSEC0~1 is invalid setting.

52.9.3.17 Refresh Counter Command

The Refresh Counter command is used to security function, safety function. "Refresh Counter" command is used for update of anti-rollback counter when power failure is occurred while “Increment Counter” command processing. Counter value is not changed by "Refresh Counter" command.

Writing "0xD0" at 2nd write access of flash sequencer command triggers FACI to start “Increment Counter” command processing. Completion of command processing can be confirmed by FRDY bit of FSTATR register.

If "Command Lock" status occurs during command execution, refresh the counter with "Refresh Counter" command after "Command Lock" state is released.



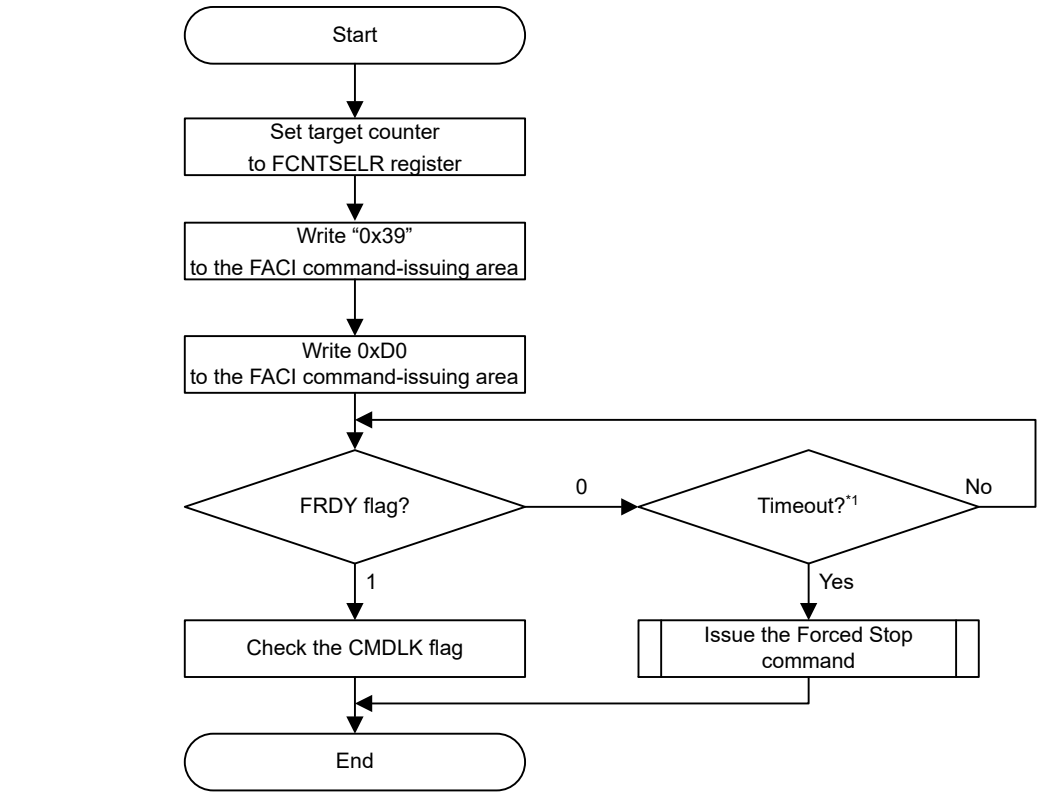
Note 1. 50msec(FCLK>=20MHz)

Figure 52.27 Usage of the Refresh Counter Command

52.9.3.18 Read Counter Command

The Read Counter command is used to security function, safety function. "Read Counter" command is used for reading 3 types of anti-rollback counter (ARC_SEC, ARC_NSEC, and ARC_OEMBL). Flash sequencer automatically judges valid area of anti-rollback counter, reads 64 bits data, and stores to FCNTDATAR0 and FCNTDATAR1 registers.

Writing "0xD0" at 2nd write access of flash sequencer command triggers FACI to start “Read Counter” command processing. Completion of command processing can be confirmed by FRDY bit of FSTATR register.



Note 1. 50msec(FCLK>=20MHz)

Figure 52.28 Usage of the Read Counter Command

52.10 Suspend Operation

Reading from the flash memory is not possible during programming or erasure if the conditions for background operation given in Table 52.39 are not satisfied. When a P/E suspend command is issued to suspend the programming or erasure of the flash memory, reading from the flash memory is enabled. Regarding P/E suspend commands, there are one suspend command mode for programming and two suspend command modes for erasure (suspension priority mode and erasure priority mode). To resume suspended programming or erasure, the P/E resume command is available. For details on the suspend operation, see Figure 52.17.

52.11 Protection Function

52.11.1 Software Protection

Software protection disables programming and erasure of the code flash memory through the settings of control registers and block protect setting in the user area. If an attempt is made to issue an FACI command against software protection, the flash sequencer enters the command-locked state.

52.11.1.1 Protection through FWEPROR

Unless the FWEPROR.FLWE[1:0] bits are set to 01b, programming cannot proceed in any mode.

52.11.1.2 Protection by FENTRYR

When the FENTRYR register is set to 0x0000, the flash sequencer enters read mode. In read mode, FACI commands cannot be accepted. If an attempt is made to issue an FACI command in read mode, the flash sequencer enters the command-locked state.

52.11.1.3 Protection by Block Protect Setting

Each block in user area has the block protect setting (BPS or BPS_SEC). When the FBPROT0 or FBPROT1 register is 0x0000 and the block protect bit is 0, issuing the Program or Block Erase command to user area of the code flash causes the command-locked state. To program or erase the block whose block protect bit is 0, set the FBPROT0 or FBPROT1 register to 0x0001.

The block protect setting can be locked by the permanent block protect setting (PBPS or PBPS_SEC). When the permanent block protect setting and the block protect setting are 0, issuing a Program or Block erase command to user area of the code flash causes the flash sequencer to enter the command-locked state regardless of the FBPROT0 and FBPROT1 register settings.

Valid block protect setting (BPS or BPS_SEC) depends on the Block Protect Select bit (BPS_SEL).

See section 52.12.2. Permanent Block Protect Setting for details of the block protect setting and permanent block protect setting. See section 52.4.17. FBPROT0 : Flash Block Protection Register and section 52.4.18. FBPROT1 : Flash Block Protection for Secure Register for more information.

For details of block protect setting (BPS or BPS_SEC) and block protect select (BPS_SEL), see section 6, Option-Setting Memory.

The protected area by the block protect setting is always determined by the address of the FSADDR register setting regardless of the address swapping function setting (the startup area select, the block swap in linear mode, and the startup bank select in dual mode). Table 52.24 to Table 52.29 show the relation of user area and the block protect setting in each function setting.

(1) In case of the linear mode

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned to the block of user area (for example, address is 0x00_0000 to the last block address).
- BPS[0]/BPS_SEC[0] and BPS[1]/BPS_SEC[1] are assigned to the block of user area depending on the startup area select setting (SAS.BTFLG bit). (See section 52.11.3. Start-Up Program Protection).
- The second half of FLI user area is assigned to block protect setting depending on the block swap select setting (BANKSEL.BLCKSWP[6:0] bits). See section 52.11.5. Block Swap Function.

Table 52.24 shows the block protect setting when the startup area select is disabled (not swapping).

Table 52.25 and later show example of the block protect setting when the address conversion function is used.

Table 52.24 Example of Block Protect setting when SAS.BTFLG is 1

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes
The last block address	32 KB	BPS[n] or BPS_SEC[n]	Block n	—
⋮	⋮	⋮	⋮	—
0x01_8000 to 0x01_FFFF	32 KB	BPS[9] or BPS_SEC[9]	Block 9	—
0x01_0000 to 0x01_7FFF	32 KB	BPS[8] or BPS_SEC[8]	Block 8	—
0x00_E000 to 0x00_FFFF	8 KB	BPS[7] or BPS_SEC[7]	Block 7	—
0x00_C000 to 0x00_DFFF	8 KB	BPS[6] or BPS_SEC[6]	Block 6	—
⋮	⋮	⋮	⋮	—
0x00_2000 to 0x00_3FFF	8 KB	BPS[1] or BPS_SEC[1]	Block 1	Not swap block 0 and block 1 in this startup area select setting
0x00_0000 to 0x00_1FFF	8 KB	BPS[0] or BPS_SEC[0]	Block 0	Not swap block 0 and block 1 in this startup area select setting

Table 52.25 Example of Block Protect setting when SAS.BTFLG is 0

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes
The last block address	32 KB	BPS[n] or BPS_SEC[n]	Block n	—
⋮	⋮	⋮	⋮	—
0x01_8000 to 0x01_FFFF	32 KB	BPS[9] or BPS_SEC[9]	Block 9	—
0x01_0000 to 0x01_7FFF	32 KB	BPS[8] or BPS_SEC[8]	Block 8	—
0x00_E000 to 0x00_FFFF	8 KB	BPS[7] or BPS_SEC[7]	Block 7	—

⋮	⋮	⋮	⋮	—
0x00_2000 to 0x00_3FFF	8 KB	BPS[1] or BPS_SEC[1]	Block 1	—
0x00_0000 to 0x00_1FFF	8 KB	BPS[0] or BPS_SEC[0]	Block 0	—

(2) In case of the dual mode (DUALSEL.BANKMD[2:0] = 000b)

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned the block of bank 0 user area (for example, address is 0x00000000 to the last block address in the lower side bank).
- BPS[70] to BPS[70 + n] or BPS_SEC[70] to BPS_SEC[70 + n] are assigned to the block of bank 1 user area (for example, address is 0x00200000 to the last block address in the upper side bank).

Bank0 is upper side bank (BANKSEL.BANKSWP[2:0] = 000b)

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned to the block of bank1 user area (e.g. Address is 0x00_0000 to The last block address in lower side bank).
- BPS[70] to BPS[70+n] or BPS_SEC[70] to BPS_SEC[70+n] are assigned to the block of bank0 user area (e.g. Address is 0x20_0000 to The last block address in upper side bank).

Table 52.28 and Table 52.29 show example of the block protect setting in the dual mode. See section 52.11.4. Dual Bank Function for details of dual bank function (DUALSEL.BANKMD[2:0] and BANKSEL.BANKSWP[2:0] bits).

Table 52.28 Example of Block Protect setting when BANKSEL.BANKSWP[2:0] is 111b (1 of 2)

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes
The last block address in upper side bank	32 KB	BPS[70 + n] or BPS_SEC[70 + n]	Block 70 + n	Not swap bank 0 and bank 1 in this startup bank switch setting

52.11.2 Error Protection

Error protection detects the issuing of illegal FACI commands, illegal access, and flash sequencer malfunction. FACI command acceptance is disabled (command-locked state) in response to the detection of these errors. The flash memory cannot be programmed or erased while the flash sequencer is in the command-locked state. For release from the command-locked state, issue the Status Clear or Forced Stop command. The Status Clear command can only be used while the FRDY bit in the FSTATR register is 1. The Forced Stop command can be used regardless of the value of the FRDY bit. While the CMDLKIE bit in the FAEINT register is 1, a flash access error (FIFERR) interrupt is generated if the flash sequencer enters the command-locked state (the CMDLK bit in the FASTAT register is set to 1).

If the flash sequencer enters the command-locked state in response to a command other than the P/E suspend command during programming or erasure processing, the flash sequencer continues the processing for programming or erasure. In this

state, the P/E suspend command cannot be used to suspend the processing for programming or erasure. If a command is issued in the command-locked state, the ILGLERR bit becomes 1 and the other bits retain the values set from previous error detection.

Table 52.30 shows the error protection types and status bit values after error detections.

Table 52.30 Error protection type (1 of 3)

Error type	Description	ILGCOMERR	FESETERR	SECERR	OTERR	TZFERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE
FENTRYR setting error	The value set in FENTRYR is not 0x0000, 0x0001, or 0x0080	0	1	0	0	0	1	0	0	0	0	0
	The FENTRYR setting at suspension is different from that at resumption	0	1	0	0	0	1	0	0	0	0	0
Illegal command error	An undefined size is specified in the first cycle of the command. (not byte-write)	1	0	0	0	0	1	0	0	0	0	0
	An undefined code is written in the first access of the FACI command	1	0	0	0	0	1	0	0	0	0	0
	The value specified in the last access of the multiple-access FACI command is not 0xD0	1	0	0	0	0	1	0	0	0	0	0
	The value (N) specified in the second write access of the FACI command in the program or configuration set command is wrong	1	0	0	0	0	1	0	0	0	0	0
	Blank Check command is issued with inconsistent BCDIR, FSADDR, and FEADDR settings (see section 52.4.13. FEADDR : FACI Command End Address Register)	1	0	0	0	0	1	0	0	0	0	0/1 *1
	A multi block erase command is issued with inconsistent FSADDR and FEADDR settings. ● FSADDR > FEADDR ● FEADDR is set to reserved area.	1	0	0	0	0	1	0	0	0	0	0/1 *1
	Increment Counter, Refresh Counter, or Read Counter command is issued with inconsistent FCNTSELR[2:0] setting. (Include CNF_ARCNS0,1 setting is the mismatch.)	1	0	0	0	0	1	0	0	0	0	0
	An FACI command not acceptable in each mode is issued (see Table 52.19)	1	0	0	0	0	1	0	0	0	0	0
	An FACI command is issued when command acceptance conditions are not satisfied (see Table 52.20)	0/1	0/1	0/1	0/1	0	1	0/1	0/1	0/1	0/1	0/1
	A program, block erase or multi block erase command is issued against the area protected by the block protect setting (see section 52.11.1.3. Protection by Block Protect Setting)	1	0	0	0	0	1	0	0	0	0	0

Table 52.30 Error protection type (2 of 3)

Error type	Description	ILGCOMERR	FESETERR	SECERR	OTERR	TZFERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE
Illegal command error	Configuration set command is issued against Data flash configuration area protected by lock bit setting	1	0	0	0	0	1	0	0	0	0	0
	Increment Counter or Refresh Counter command is issued against anti-rollback area protected by lock bit setting	1	0	0	0	0	1	0	0	0	0	0
	A program command is issued against the erase area in erase suspend	1	0	0	0	0	1	0	0	0	0	0
	Increment counter command against ARC_OEMBL is issued when the RSIP-E51A register setting is same or smaller than ARC_OEMBL value. (see section 52.12.5. Anti-Rollback Counter)	1	0	0	0	0	1	0	0	0	0	0
	Increment counter command against ARC_OEMBL is issued when previous command is not read counter command against ARC_OEMBL.	1	0	0	0	0	1	0	0	0	0	0
	A command is issued against flash sequencer command illegal status(see Table 52.17).	0/1	0/1	0/1	0/1	0	1	0/1	0/1	0/1	0/1	0/1
Erasure error	An error occurs during erasure	0	0	0	0	0	0	1	0	0	0	0
Programming error	An error occurs during programming	0	0	0	0	0	0	0	1	0	0	0
Code flash memory access violation	An FACI command is issued to the reserved portion of the user area in code flash P/E mode	0	0	0	0	0	1	0	0	0	1	0
	Configuration set command is issued to the reserved configuration area in code flash P/E mode.	0/1	0	0	0	0	1	0	0	0	1	0
	Program, block erase, or configuration set command is issued to TrustZone protection area in code flash P/E mode.	0/1	0	0	0	1	1	0	0	0	1	0
Data flash memory access violation	A program or block erase command is issued to the reserved data area in data flash P/E mode	0	0	0	0	0	1	0	0	0	0	1
	A multi block erase command is issued to the reserved data area in data flash P/E mode. (FSADDR is set to reserved data area).	1	0	0	0	0	1	0	0	0	0	1
	Blank Check command is issued to reserved data area in data flash P/E mode. (FSADDR is set to reserved data area).	1	0	0	0	0	1	0	0	0	0	1
	Configuration set command has been issued to reserved configuration area in data flash P/E mode.	0/1	0	0	0	0	1	0	0	0	0	1
	A program, block erase, multi block erase, blank check, configuration set, increment counter, refresh counter, or read counter command is issued to TrustZone protection area in data flash P/E mode.	0	0	0	0	0	1	0	0	0	0	1

Table 52.30 Error protection type (3 of 3)

Error type	Description	ILGCOMERR	FESETERR	SECERR	OTERR	TZFERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE
Security error	Configuration set command for the SAS.BTFLG bit setting is issued when the SAS.FSPR bit is 0 (see section 52.9.3.15. Configuration Set Command)	0	0	1	0	0	1	0	0	0	0	0
Others	An FACI command-issuing area is accessed in read mode	0	0	0	1	0	1	0	0	0	0	0
	An FACI command-issuing area is read in code flash P/E mode or data flash P/E mode	0	0	0	1	0	1	0	0	0	0	0
Flash write erase protection error	A flash memory write protection error is detected by the FWEPROR register setting*2 during command processing by the flash sequencer	0	0	0	0	0	0	0/1	0/1	1	0	0

Note 1. DFAE value depends on the FSADDR setting.
Note 2. For details on the FWEPROR register, see section 52.4.8. FWEPROR : Flash P/E Protect Register.

52.11.3 Start-Up Program Protection

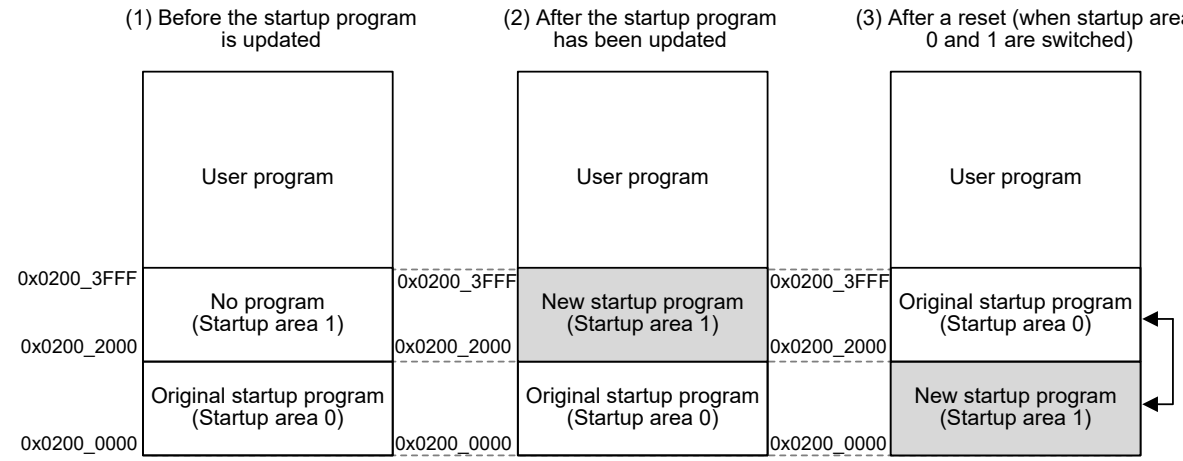
Protection of the startup program is for protection of the program to be started after a reset (the startup program). This function provides a way to safely update the startup program when rewriting is suspended during a reset.

The startup area is 8 Kbytes in size and is assigned to the user area in the code flash memory. This function uses the values of the SAS.BTFLG bit and the FSUACR.SAS[1:0] bits to change the area where the startup program is stored in block units (see Figure 52.29 to Figure 52.32).

In protection of the startup program, the state of the selection of the startup area can be fixed by the FSPR bit. However, the SAS.FSPR bit never be restored to 1 once the flag is set to 0. Exercise extra caution when handling the SAS.FSPR bit.

In addition, this protection cannot be used when dual mode is selected by the bank mode switching function (when the BANKMD[2:0] bits are 000b).

For details of SAS.FSPR bit and DUALSEL.BANKMD[2:0] bits, see section 6, Option-Setting Memory.



Note: The addresses are used for reading, programming, and erasure. Startup area 0 is erased when Block Erase command is issued for the address 0x0200_0000 with allocation shown under 3.

1. Before the startup program is updated
   When the SAS.BTFLG bit is 1 and the FSUACR.SAS[1:0] bits are 0xb, the address range from 0x0100_2000 to 0x0200_3FFF is selected as startup area 1 and the address range from 0x0200_0000 to 0x0200_1FFF is selected as startup area 0.
2. After the startup program has been updated
   A new startup program can be written to startup area 1. At this time, startup area 0 will still contain the previous startup program, so rewriting by starting up from startup area 0 remains possible if rewriting to the startup area 1 fails.
3. After a reset (when startup areas 0 and 1 are switched)
   When rewriting startup area 1 is successfully completed, switch the assignment of startup areas 0 and 1 by rewriting the startup area selection bit (the SAS.BTFLG bit) with Configuration set command. Afterwards, the program is started up from startup area 1 after a reset.

Figure 52.29 Concept of Protection of the Startup Program for Secure alias

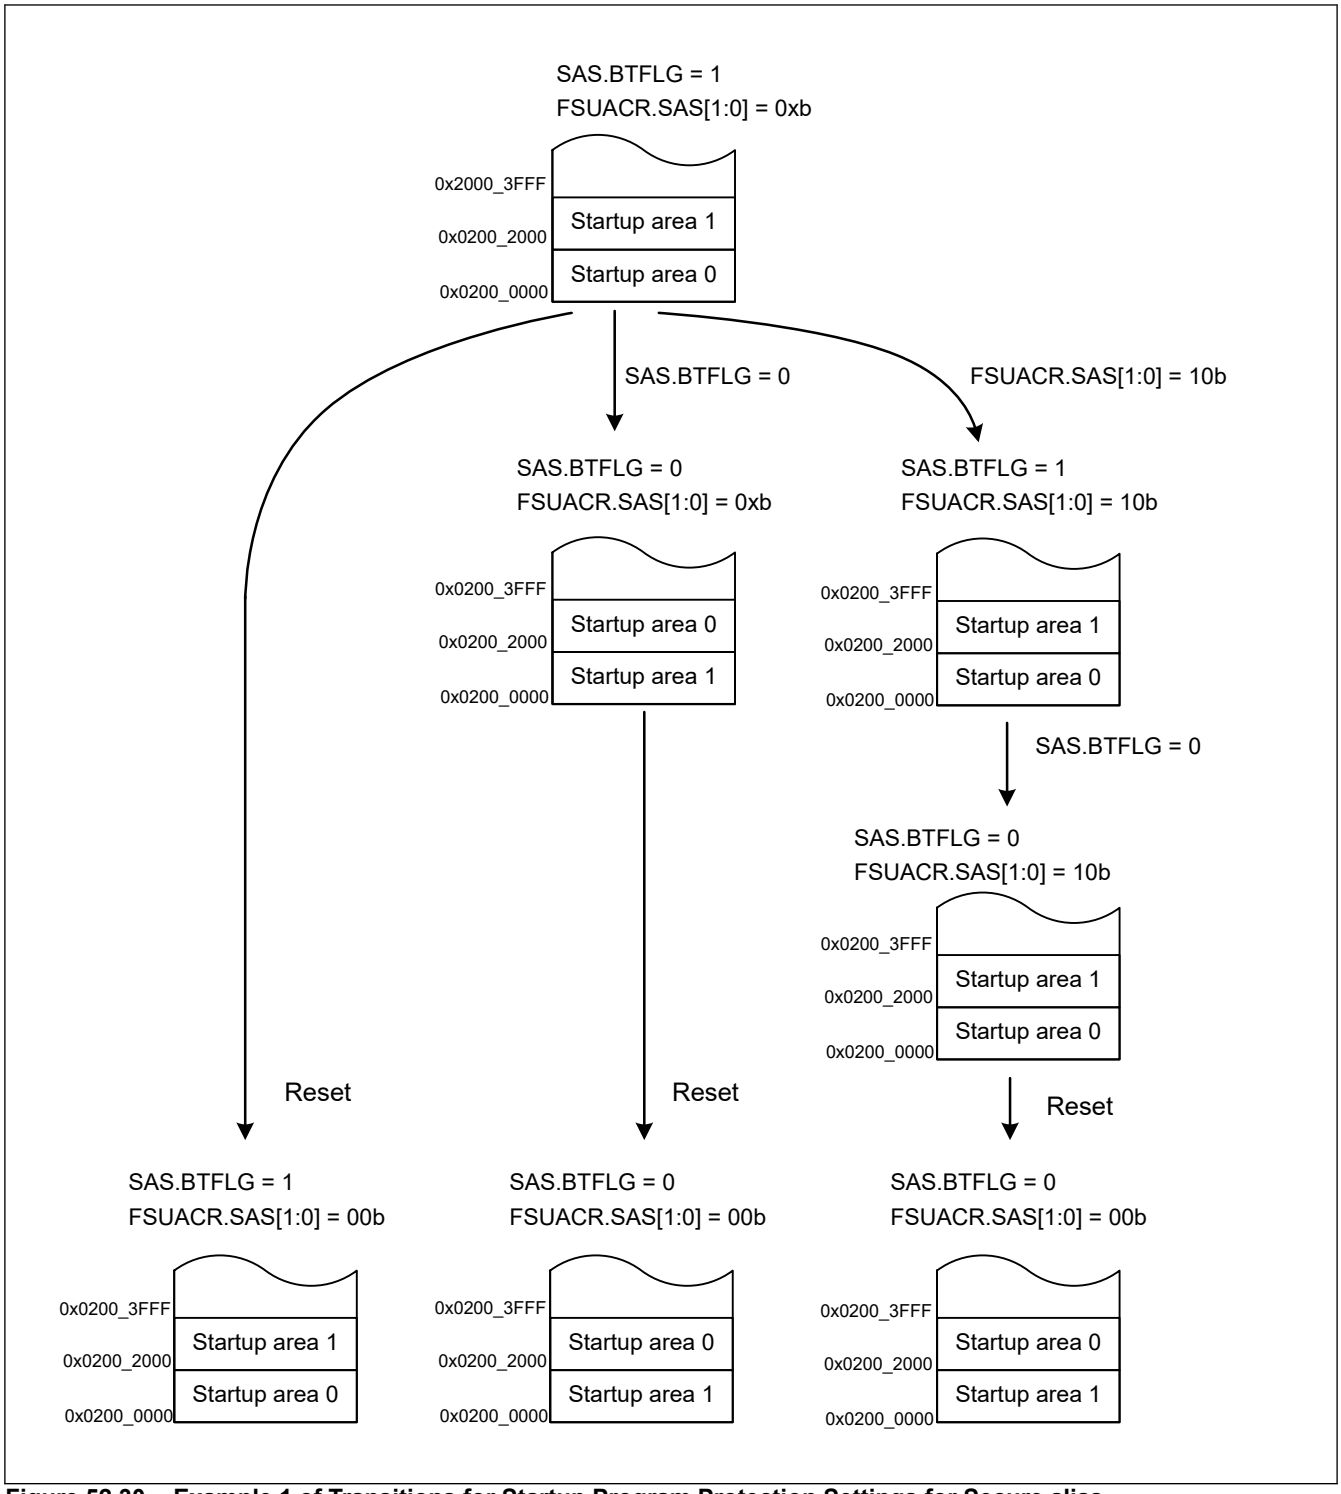


Figure 52.30 Example 1 of Transitions for Startup Program Protection Settings for Secure alias

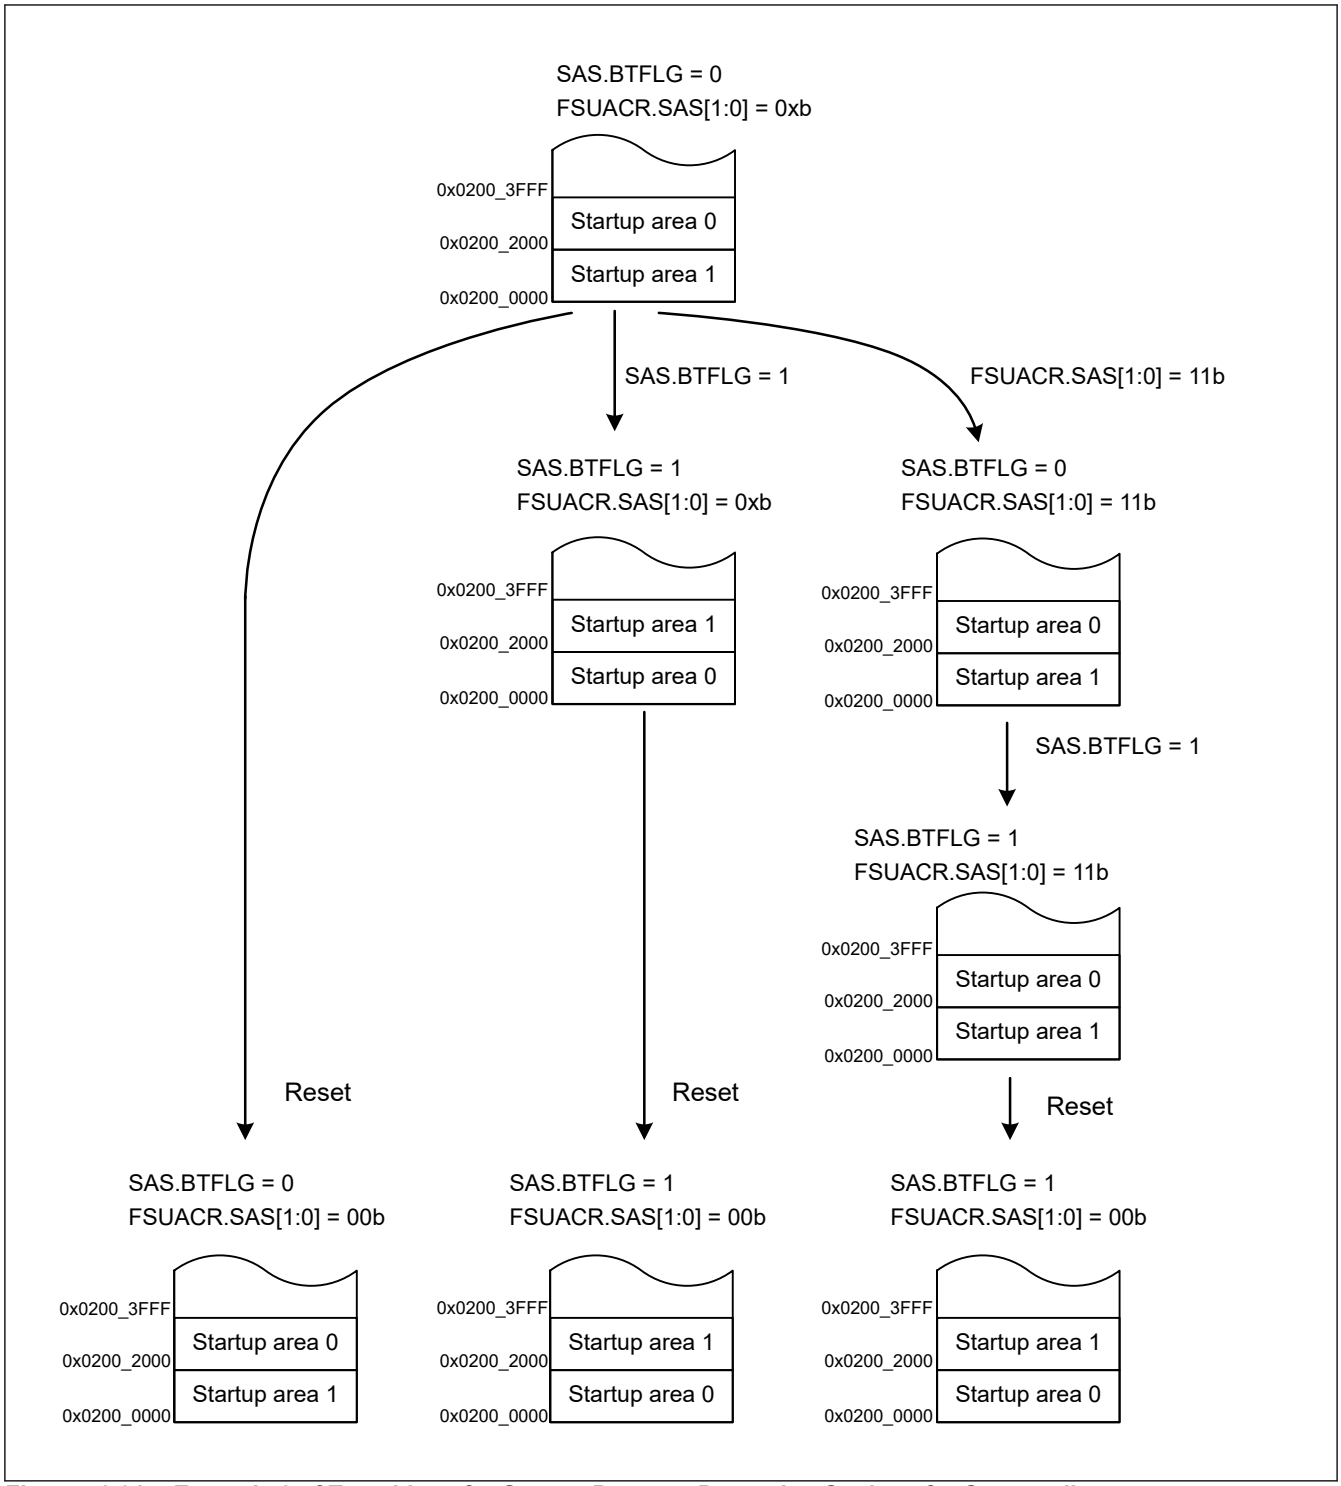

Figure 52.31 Example 2 of Transitions for Startup Program Protection Settings for Secure alias

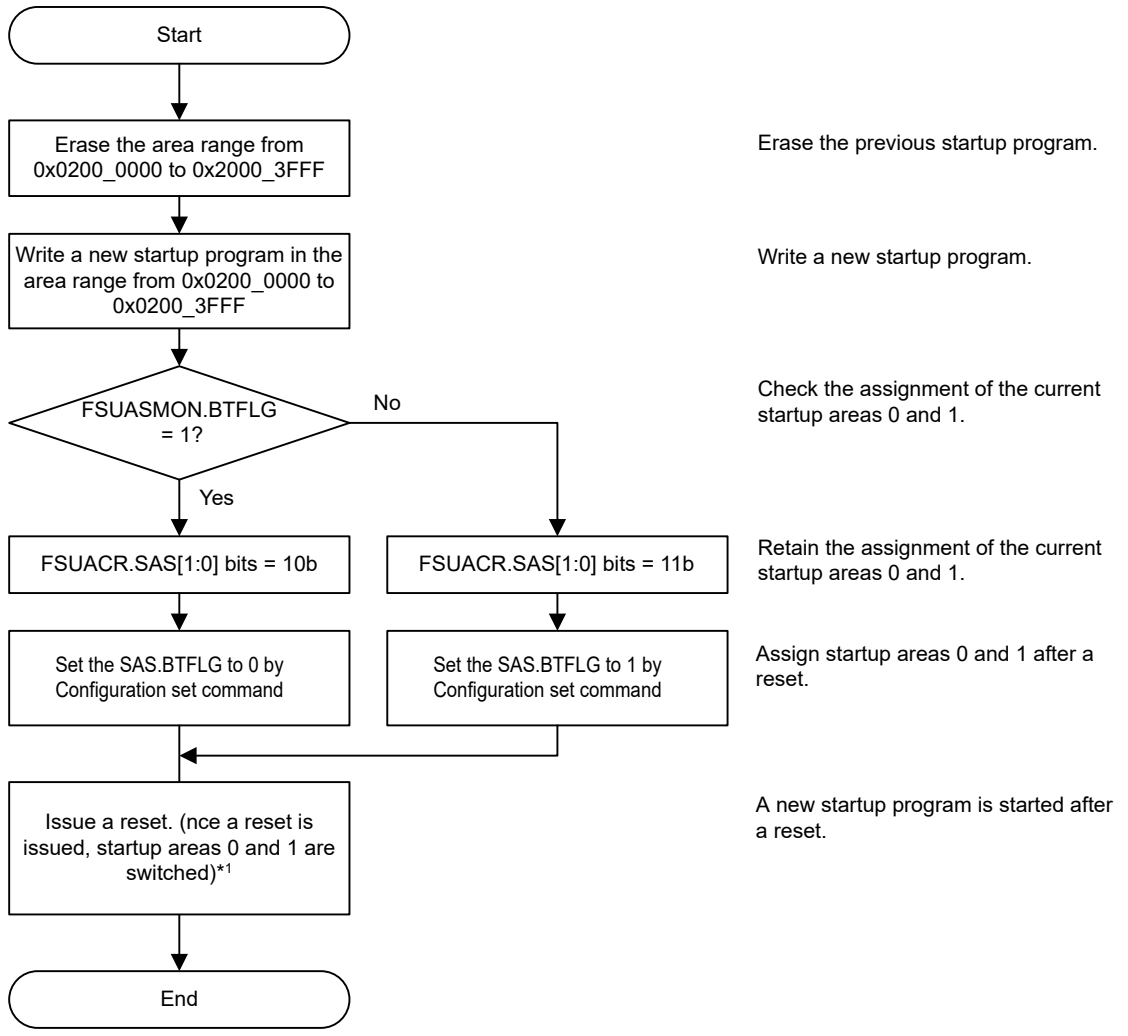

Note 1. For details, see Figure 52.30 and Figure 52.31.

Figure 52.32 Concept of Protection of the Startup Program for Secure alias

52.11.4 Dual Bank Function

This protection uses the functions of bank mode switching and startup bank selection to update a program while a user program is running and to provide a safe method of updating in cases where programming is suspended during a reset.

52.11.4.1 Switching Bank Modes

The bank mode switching function selects either linear mode in which the user area in the code flash memory is used as one area, or dual mode in which the user area is divided into two bank areas. Figure 52.33 shows an example of flow of switching bank modes. A reset after setting the DUALSEL.BANKMD[2:0] bits in the option setting memory determines the mode of the bank mode switching function. Selecting dual mode enables the startup bank selection function.

When dual mode is selected by bank mode switching function (the DUALSEL.BANKMD[2:0] bits are 000b), start-up program protection function cannot be used.

For details of DUALSEL.BANKMD[2:0] bits, see section 6, Option-Setting Memory.

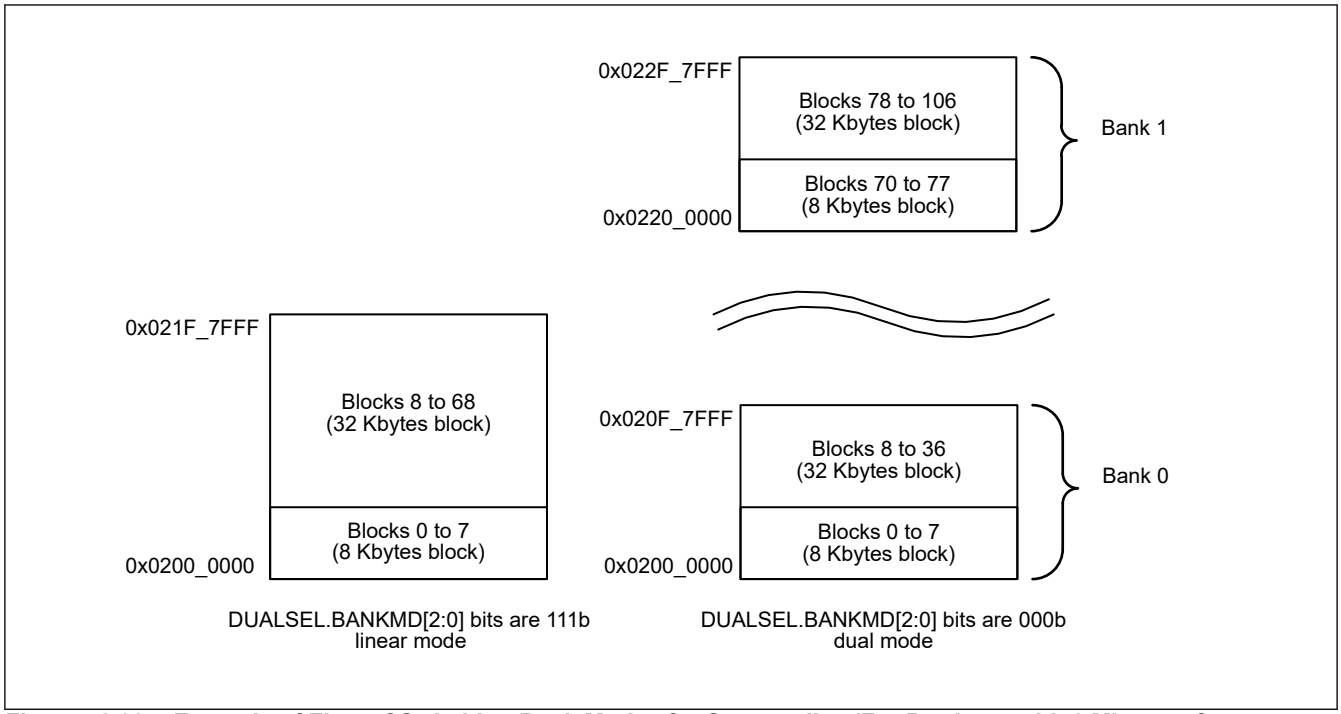

Figure 52.33 Example of Flow of Switching Bank Modes for Secure alias (For Products with 2 Mbytes of Code Flash Memory)

52.11.4.2 Selecting the Startup Bank

Startup bank selection provides a way to safely update the program by selecting a bank area to be started in dual mode (when the DUALSEL.BANKMD[2:0] bits are 000b) when programming is suspended during a reset. Figure 52.34 is a schematic view of startup bank selection and Table 52.31 shows an example of the flow of startup bank selection. A reset after setting the value of the BANKSEL.BANKSWP[2:0] bits in the option-setting memory changes the addresses of banks 0 and 1 and booting up a program proceeds from the updated area. When the address is switched by using startup bank selection, the programming/erasure target for the FACI commands is also switched. This function is invalid in linear mode.

For details of DUALSEL.BANKMD[2:0] bits and BANKSEL.BANKSWP[2:0] bits, see section 6, Option-Setting Memory.

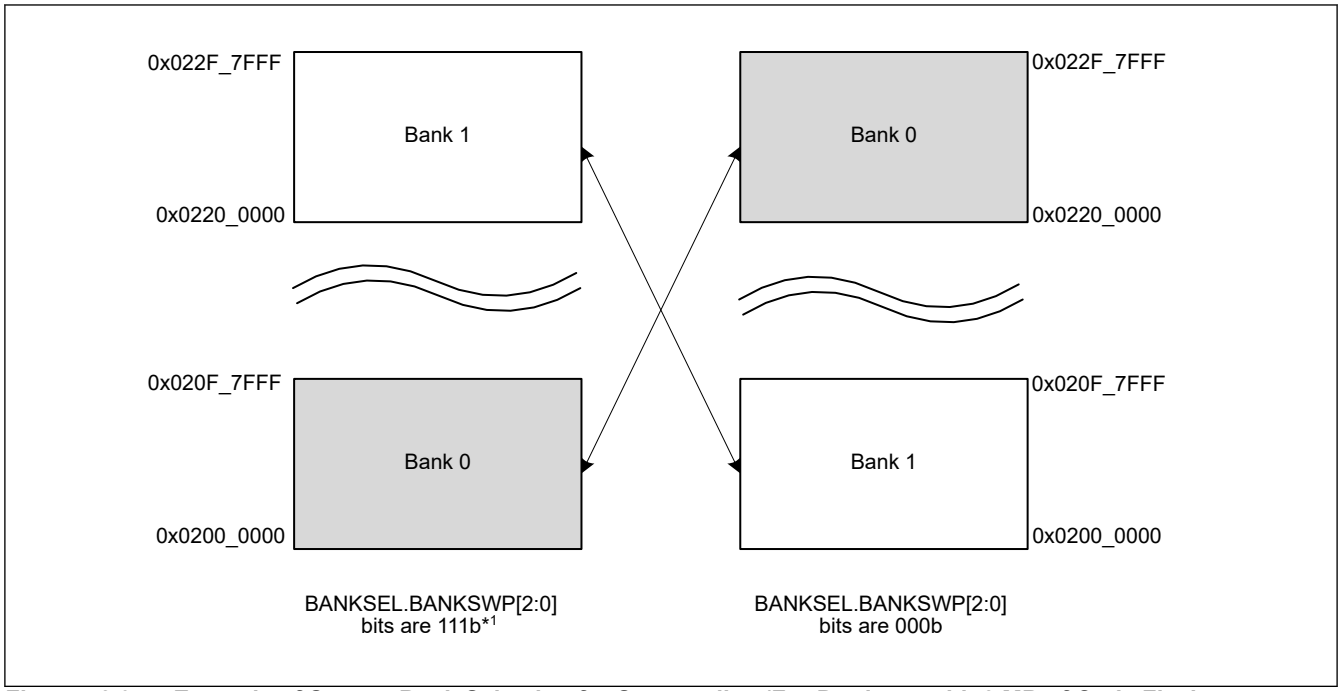

Figure 52.34 Example of Startup Bank Selection for Secure alias (For Products with 2 MB of Code Flash Memory)

Table 52.31 Example of Startup Bank Selection Flow for Secure alias (For Products with 2 MB of Code Flash Memory)

No.	Step Name	Description
1	Erase block	Erase blocks to be programed in the address range from 0x0220_0000 to 0x022F_7FFF
2	Program a new software	Program a new software in the address range from 0x0220_0000 to 0x022F_7FFF
3	Read the value	Read the value of the BANKSEL.BANKSWP[2:0] bits.
4	Write an inverted value	Write an inverted value in the BANKSEL.BANKSWP[2:0] bits*1.
5	Issue a reset	Issue a reset (A reset switches the banks.)

Note 1. Set the inverse of the read value of the BANKSEL.BANKSWP[2:0] bits (000b or 111b).

52.11.5 Block Swap Function

This protection uses the functions of block swap selection to update a program while a user program is running and to provide a safe method of updating in cases where programming is suspended during a reset.

52.11.5.1 Selecting the Block Swap

Block swap selection provides a way to safely update the program when programming is suspended during a reset. Figure 52.35 is a schematic view of block swap selection and Figure 52.36 shows an example of the flow of block swap selection. A reset after setting the value of the BANKSEL.BLCKSWP bit in the option-setting memory changes the addresses of block A and B. When the address is switched, the Programming/erasure target for the FACI commands is also switched.

In addition, this protection cannot be used when dual mode is selected by the bank mode switching function (when the DUALSEL.BANKMD[2:0] bits are 000b).

For details of DUALSEL.BANKMD[2:0] bits and BANKSEL.BLCKSWP bit, see section 6, Option-Setting Memory.

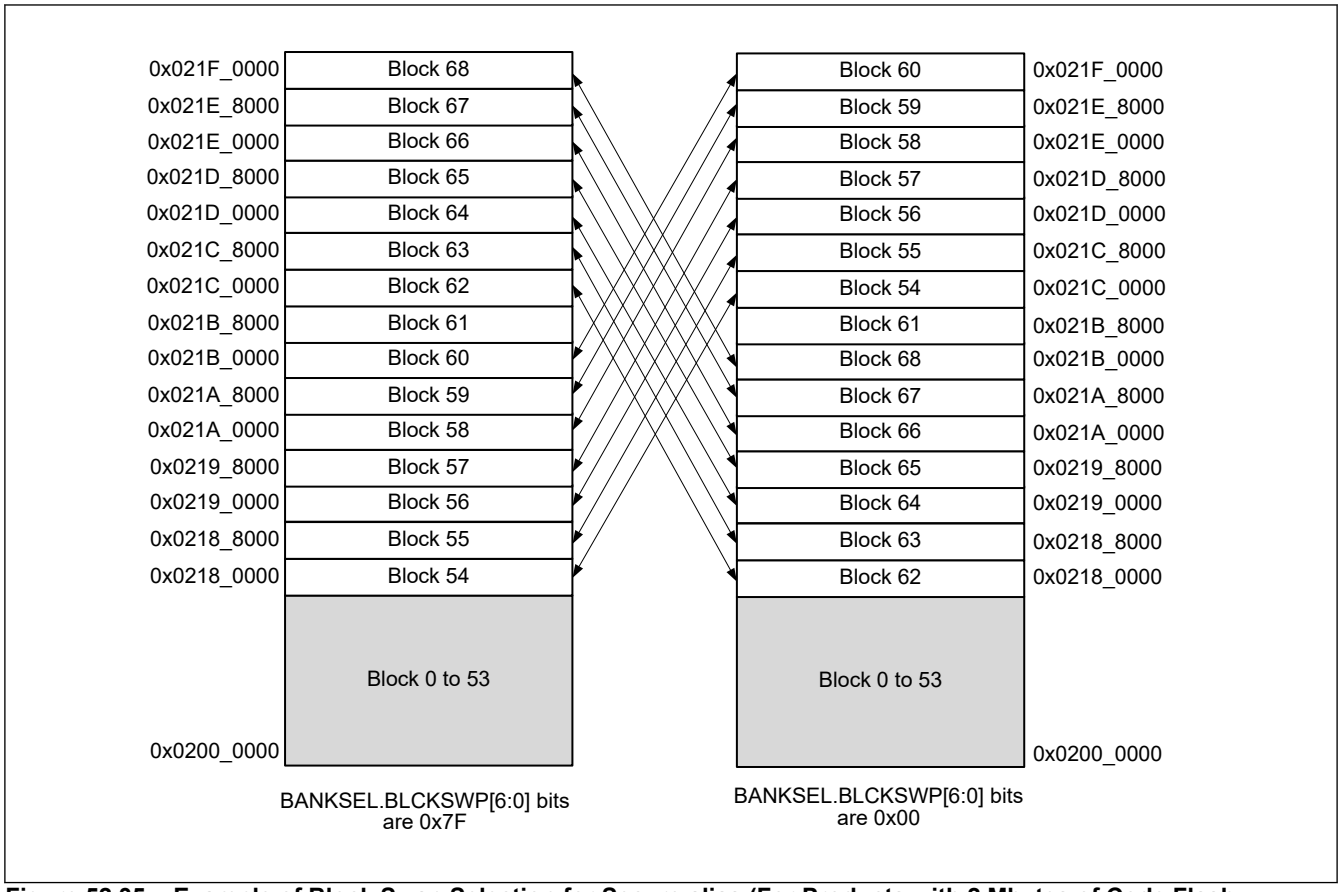

Figure 52.35 Example of Block Swap Selection for Secure alias (For Products with 2 Mbytes of Code Flash Memory)

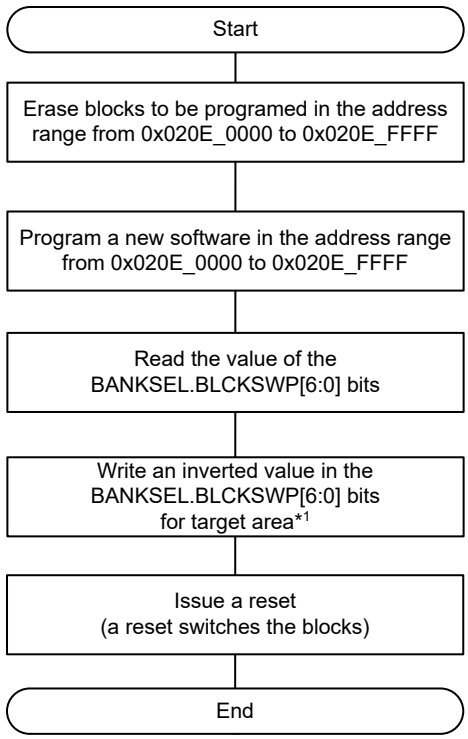

Note 1. See Table 6.2 for the correspondence between the target region and the BANKSEL.BLCKSWP[6:0] bits.

Figure 52.36 Example of Block Swap Selection Flow for Secure alias (For Products with 2 Mbytes of Code Flash Memory)

52.12 Security Function

The flash sequencer supports the following security functions:

- Security flag for startup area
- Permanent block protect setting
- Flash memory protection for TrustZone
- Code Flash P/E mode Entry Protection
- Data flash configuration area protection
- Anti-rollback Counter

52.12.1 Security Flag for Startup Area Select

The security flag (SAS.FSPR) for the startup area is located in the option-setting memory.

When the SAS.FSPR bit is 0, issuing the configuration set command to change the SAS.BTFLG bit causes the flash sequencer to be in the command-locked state. Also, when the SAS.FSPR bit is 0, it is invalid to write to the Startup Area Select bits SAS[1:0] in the FSUACR register. The SAS.FSPR bit enables protection.

52.12.2 Permanent Block Protect Setting

The permanent block protect setting is the clear protection for the block protection setting. User area cannot be permanently updated by the FACI command when the permanent block protect setting is enabled. See section 52.11.1.3. Protection by Block Protect Setting for more details.

The block protect setting and the permanent block protect setting have the write/clear protection against the configuration set command. The flash sequencer does not detect an error when the configuration set command is issued to the write/clear protected settings.

Figure 52.37 and Table 52.32 show the write/clear protection against the block protect setting (BPS[n]) and the permanent protect setting (PBPS[n]). Figure 52.38 and Table 52.33 show the write/clear protection against the block protect setting for Secure (BPS_SEC[n]) and permanent protect setting for Secure (PBPS_SEC[n]).

Effective permanent block protect setting (PBPS or PBPS_SEC) depends on block protect select (BPS_SEL). For details of permanent block protect setting (PBPS or PBPS_SEC) and block protect select (BPS_SEL), see section 6, Option-Setting Memory.

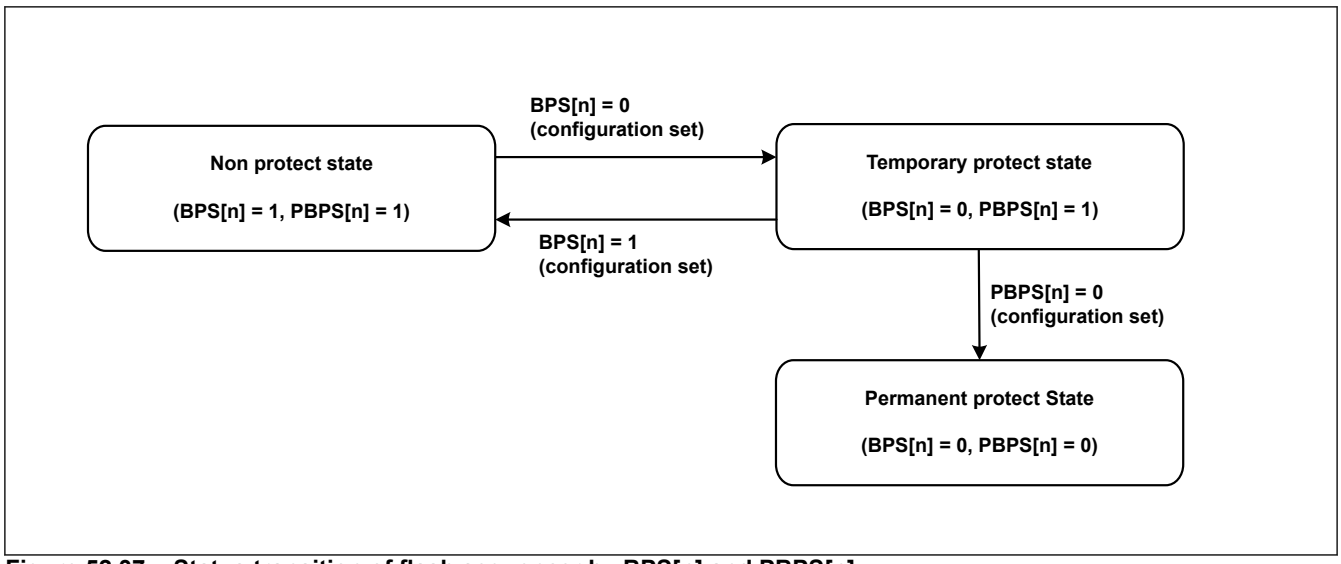

Figure 52.37 Status transition of flash sequencer by BPS[n] and PBPS[n]

Table 52.32 Write/clear protection of BPS[n] , PBPS[n] and BPS_SEL[n]

Current state		Updatable state by configuration set command				
BPS[n]	PBPS[n]	BPS[n] = 1	BPS[n] = 0	PBPS[n] = 1	PBPS[n] = 0	BPS_SEL[n] = 1
1	1	✓	✓	✓	X	✓
1	0	—	—	—	—	—
0	1	✓	✓	✓	✓	✓
0	0	X	✓	X	✓	X

Note:
- ✓ indicates updatable by configuration set command.
- X indicates not updatable by configuration set command (error does not occur).
- — indicates not reaching to this state.

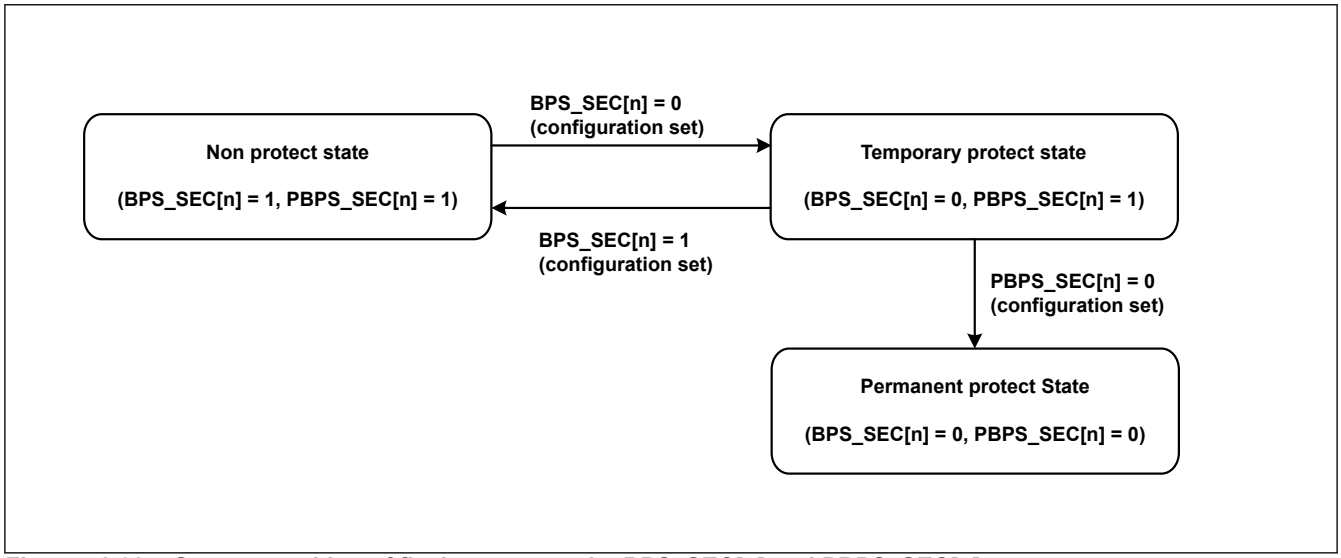

Figure 52.38 Status transition of flash sequencer by BPS_SEC[n] and PBPS_SEC[n]

Table 52.33 Write/clear protection of BPS_SEC[n], PBPS_SEC[n] and BPS_SEL[n]

Current state		Updatable state by configuration set command				
BPS_SEC[n]	PBPS_SEC[n]	BPS_SEC[n] = 1	BPS_SEC[n] = 0	PBPS_SEC[n] = 1	PBPS_SEC[n] = 0	BPS_SEL[n] = 0
1	1	✓	✓	✓	X	✓
1	0	—	—	—	—	—
0	1	✓	✓	✓	✓	✓
0	0	X	✓	X	✓	X

Note:
- ✓ indicates updatable by configuration set command.
- X indicates not updatable by configuration set command (error does not occur).
- — indicates not reaching to this state.

52.12.3 Flash Memory Protection for TrustZone

Information in this section focuses on the flash sequencer operation.

The flash memory provides the following types of protect function against Non-secure access:

- Protection for flash memory area (P/E)
- Protection for flash memory area (read)
- Protection for registers
- Code flash P/E mode entry protection

52.12.3.1 Protection for Flash Memory Area (P/E)

This function protects the Secure region of the code flash and data flash from FACI commands of Non-secure access. The condition of protection depends on the FACI command, the access attribution, and the memory boundary setting.

For details of Secure region, see section 43, Security Features .

See Table 52.34 for information on protection of the flash memory area (P/E).

Table 52.34 Protection for the flash memory area (P/E) (1 of 2)

FACI command	Target area			Issuing FACI command by Non-secure access	Issuing FACI command by Secure access
Program Block Erase	Code flash memory	User area (Non-secure area)	Secure alias*1	X	X
			Non-secure alias*2	✓	✓
		User area (Secure area)	Secure alias*1	X	✓
			Non-secure alias*2	X	X
	Data flash memory	Data area (Non-secure area)	Secure*1 alias	X	X
			Non-secure alias*2	✓	✓
		Data area (Secure area)	Secure alias*1	X	✓
			Non-secure alias*2	X	X

Table 52.34 Protection for the flash memory area (P/E) (2 of 2)

FACI command	Target area			Issuing FACI command by Non-secure access	Issuing FACI command by Secure access
Multi Block Erase Blank Check	Data flash memory	Data area (Non-secure area)	Secure alias*3	X	X
			Non-secure alias*4	✓	✓
		Data area (Secure area)	Secure alias*3	X	✓
			Non-secure alias*4	X	X
Configuration set	Code flash memory	Configuration area (Non-secure area)	Secure alias*1	X	X
			Non-secure alias*2	✓	✓
		Configuration area (Secure area)	Secure alias*1	X	✓
			Non-secure alias*2	X	X
	Data flash memory	Configuration area (Secure area only)	Secure alias*1	X	✓
			Non-secure alias*2	X	X
Increment Counter Refresh Counter Read Counter	Data flash memory	Anti-rollback counter area(Secure area only)	-	X	✓

Note:
- ✓ indicates FACI command operation is not prohibited.
- X indicates FACI command operation is prohibited. Error occurs when the area is selected, and the FACI command is executed.

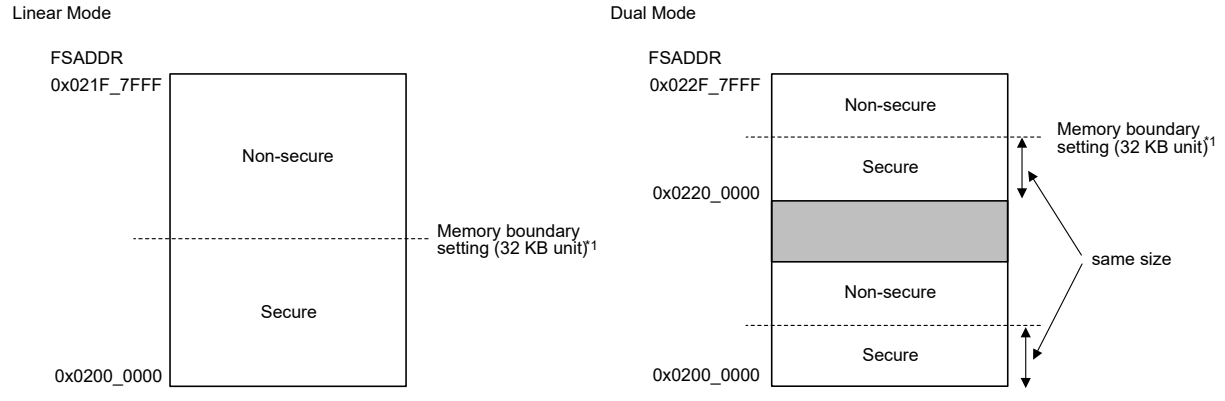
Note 1. The Secure alias is judged when the address of FSADDR[28] is 0.
Note 2. The Non-secure alias is judged when the address of FSADDR[28] is 1.
Note 3. The Secure alias is judged when the address of FSADDR[28] and FEADDR[28] are 0.
Note 4. The Non-secure alias is judged when the address of FSADDR[28] and FEADDR[28] are 1.

When the target area of FACI command is the user area of code flash, the flash sequencer compares the FSADDR register setting with the memory boundary setting of the code flash and determines whether the target area is in the Secure region.

In linear mode, the memory boundary can be set to 0x0200_0000 to 0x021F_0000 in 32 KB unit.

In dual mode, the memory boundary can be set to 0x0200_0000 to 0x0220_0000 in 32 KB unit. When the memory boundary is set to 0x0220_0000 or greater in the dual mode, the entire user area is defined as the Secure region.

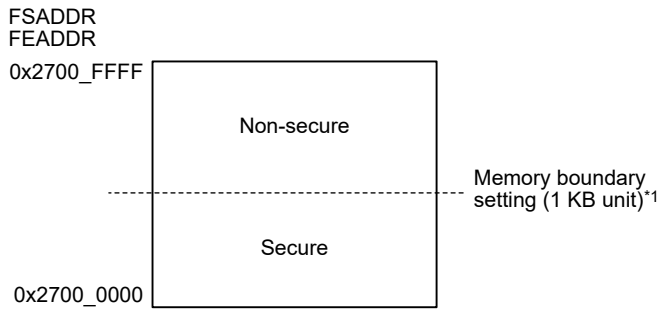
Figure 52.39 shows details of the Secure and Non-secure attribute of user area in the code flash.



Note 1. Comparing FSADDR with memory boundary setting of user area and judges whether the target area is in Secure area.

Figure 52.39 Secure and Non-secure region in user area for Secure alias

When the target area of the issuing FACI command is the data area of data flash, the flash sequencer compares the FSADDR/FEADDR register setting with the memory boundary setting of the data flash and determines whether the target area is in Secure region. The memory boundary can be set to 0x0270_0000 to 0x0270_FC00 in 1 KB unit. Figure 52.40 shows details of the Secure and Non-secure attribute of data area in the data flash.



Note 1. Comparing FSADDR/FEADDR with memory boundary setting of data area and judges whether the target area is in Secure area.

Figure 52.40 Secure and Non-secure region in data area for Secure alias

See Figure 52.41 in the details of Secure and Non-secure region of option-setting memory. The flash sequencer judges that target area is Secure region from the FSADDR register setting.

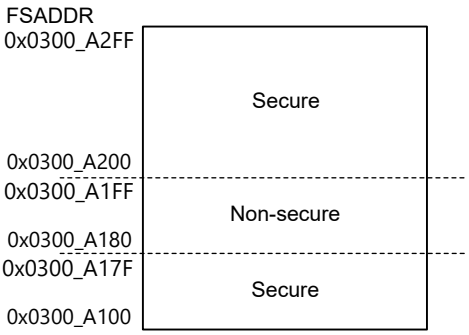


Figure 52.41 Secure and Non-secure region in option-setting memory for Secure alias

52.12.3.2 Protection for Flash Memory Area (Read)

This function protects the Secure region of code flash and data flash from Non-secure bus access.

For details of Secure region, see section 43, Security Features .

52.12.3.3 Protection for Register

The flash sequencer registers have write-access protection against Non-secure access. Table 52.35 shows details of the protected registers of the flash sequencer.

Table 52.35 Protected registers of the flash sequencer for TrustZone (1 of 2)

Protection target register	Security attribute setting	Notes
FCKMHZ register	SA register setting (FSAR.FCKMHZSA)	For details of section 52.4.4. FSAR : Flash Security Attribution Register
Flash Access area	SA register setting (FSAR.FACICMISA)	For details of section 52.4.4. FSAR : Flash Security Attribution Register
FACI registers*1 and FWEPROR registers	SA register setting (FSAR.FACICMRSA)	For details of section 52.4.4. FSAR : Flash Security Attribution Register

Table 52.35 Protected registers of the flash sequencer for TrustZone (2 of 2)

Protection target register	Security attribute setting	Notes
FCTRCNTR, FCTRLSR FCTRADDR, and FCTRSTATR registers	SA register setting (FSAR.FACITRSA)	For details of section 52.4.4. FSAR : Flash Security Attribution Register
FMEPROT, FCNTSELR, FCNTDATAR0 to 1, FBPROT1 and FSUACR registers	Always Secure	—

Note 1. The target FACI registers are FASTAT, FAEINT, FRDYIE, FSADDR, FEADDR, FBPROT0, FSTATR, FENTRYR, FSUINITR, FCMDR, FBCCNT, FBCSTAT, FPSADDR, FSUASMON, FCPSR, and FPCKAR.

52.12.3.4 Code Flash P/E Mode Entry Protection

The flash sequencer has protection function of code flash P/E by the FMEPROT register for the Secure developer. Secure function can prevent disturbance of reading code flash memory by this protection function. See section 52.4.14. FMEPROT : Flash P/E Mode Entry Protection Register.

For applications that do not require Non-secure region programming/erasure other than from Secure function, it is recommended to always disable Non-secure function of code flash programming/erasure by enabling the protection function of FMEPROT register.

For details, see Figure 52.42 of the code flash P/E sequence example by Non-secure function.

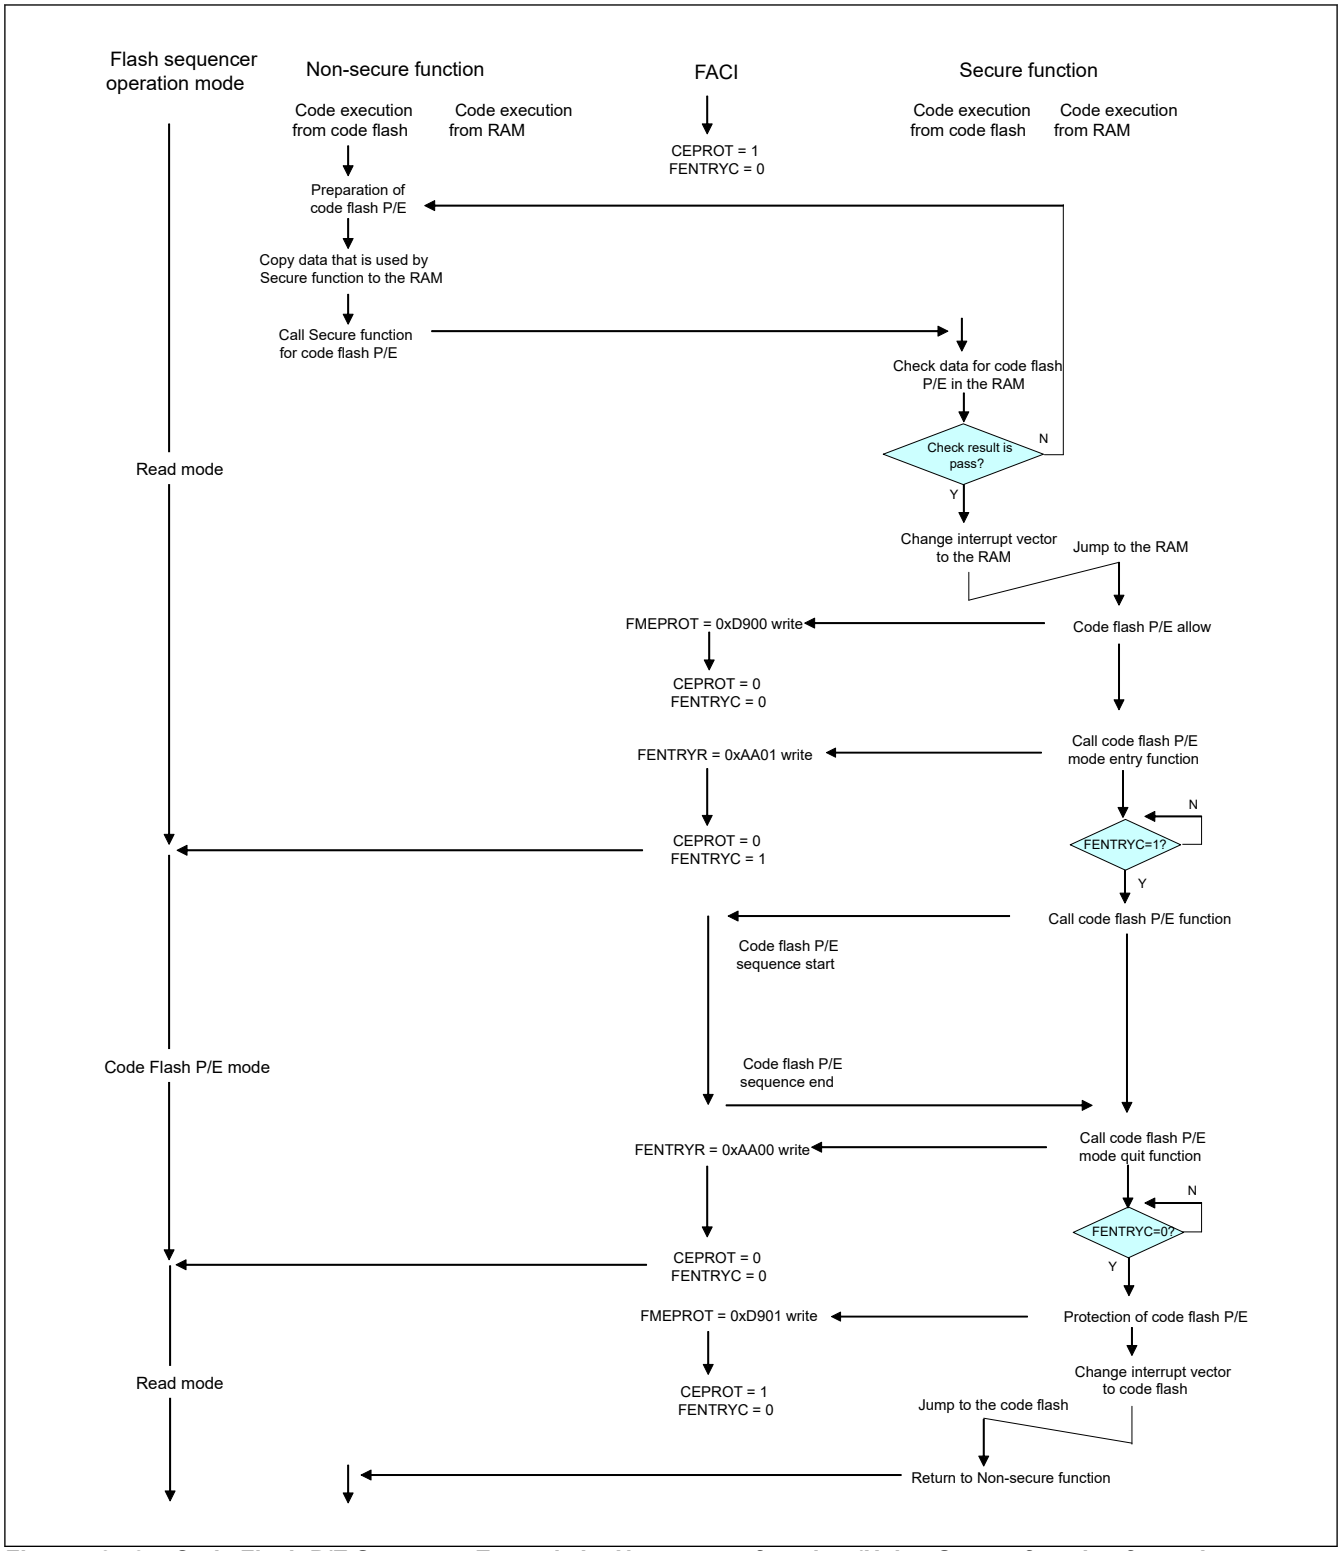

Figure 52.42 Code Flash P/E Sequence Example by Non-secure function (Using Secure function for code flash P/E)

52.12.4 Data Flash Configuration Area Protection

Data flash configuration area has 3 types of lockable area (LK_CD_A0, LK_CD_A1, and LK_CD_A2) by lock bit. When target area of “Configuration set” command includes protection area by lock bit, flash sequencer detects an error and enters "Command Lock" state.

LK_CD_A0 and LK_CD_A1 are protected 4 bytes data by 1 lock bit.

LK_CD_A2 are protected 16 bytes data by 1 lock bit, and 32 bytes (0x2703_0360 ~ 0x2703_037F) in LK_CD_A2 have writing protection that cannot update except for serial programing mode. See in details of protection for flash memory area (P/E). See Table 52.36 in detail of protection condition of lockable area in data flash configuration area.

Table x-1 Protection Condition of Lockable area in Data Flash Configuration Area

Table 52.36 Protection Condition of Lockable area in Data Flash Configuration Area for Secure alias

Lockable Area		Protection Size	Lock Bit	Remarks
Area Name	address			
LK_CD_A0	0x2703_0080 ~ 0x2703_0083	4 bytes	CD0_LK0	In the case of the 16-byte Configuration set command, data cannot be updated if any of the lock bits corresponding to the update address is 0.
	0x2703_0084 ~ 0x2703_ 0087	4 bytes	CD0_LK1	
	:	:	:	
	0x2703_0170 ~ 0x2703_0177	4 bytes	CD0_LK60	
	0x2703_0174 ~ 0x2703_0177	4 bytes	CD0_LK61	
	0x2703_0178 ~ 0x2703_017B	4 bytes	CD0_LK62	
	0x2703_017C ~ 0x2703_017F	4 bytes	CD0_LK63	
LK_CD_A1	0x2703_0180 ~ 0x2703_0183	4 bytes	CD1_LK0	
	0x2703_0184 ~ 0x2703_0187	4 bytes	CD1_LK1	
	:	:	:	
	0x2703_0270 ~ 0x2703_0277	4 bytes	CD1_LK60	
	0x2703_0274 ~ 0x2703_0277	4 bytes	CD1_LK61	
	0x2703_0278 ~ 0x2703_027B	4 bytes	CD1_LK62	
	0x2703_027C ~ 0x2703_027F	4 bytes	CD1_LK63	
LK_CD_A2	0x2703_0280 ~ 0x2703_028F	16 bytes	CD2_LK0	
	0x2703_0290 ~ 0x2703_029F	16 bytes	CD2_LK1	
	:	:	:	
	0x2703_0340 ~ 0x2703_034F	16 bytes	CD2_LK12	
	0x2703_0350 ~ 0x2703_035F	16 bytes	CD2_LK13	
	0x2703_0360 ~ 0x2703_036F	16 bytes	CD2_LK14	This lockable area and lock bit cannot be updated except for serial programing mode.
	0x2703_0370 ~ 0x2703_037F	16 bytes	CD2_LK15	

52.12.5 Anti-Rollback Counter

See section 6.2.21. ARCLS : Anti-Rollback Counter Lock Setting to section 6.2.25. ARC_OEMBLn : Anti-Rollback Counter for OEMBL (n = 0, 1) for Anti-rollback counter related Option flash memory.

Anti-rollback counter cannot be decremented and is used in the firmware update. Only Secure applications are available. Anti-rollback counter shifts one bit to the left with the increment counter command from the initial value of 0. The least significant bit (bit 0) is set to 1. When anti-rollback counter is maximum value, flash sequencer does not change counter by Increment Counter command (does not occur error).

There are three commands that control the counters. For details, see section 52.9.3.16. Increment Counter Command, section 52.9.3.17. Refresh Counter Command, and section 52.9.3.18. Read Counter Command.

Figure 52.43 shows anti-rollback counter increment image when increment counter command is issued.

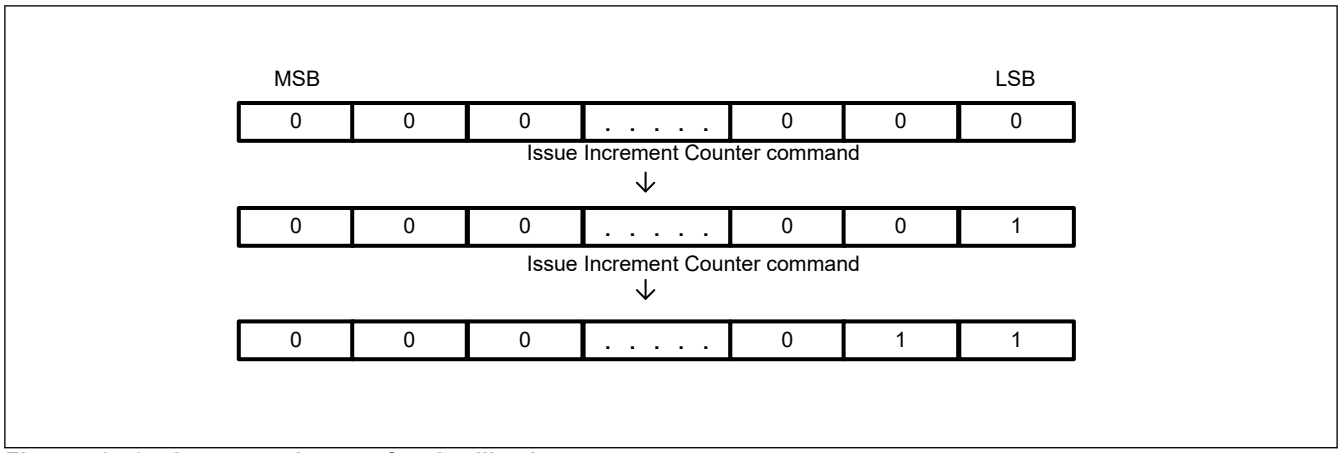

Figure 52.43 Increment image of anti-rollback counter

Anti-rollback counter has 3 types of counters (ARC_SEC, ARC_NSEC, and ARC_OEMBL) and lock bit (ARCSEC_LK, ARCNSEC_LK0 to 3, ARCOEMBL_LK) for protection each counter.

ARC_NSEC can be configured as 1 × 256 or 4 × 64 bits by configuration area setting (CNF_ARCNS0 and CNF_ARCNS0) and cannot be updated in invalid setting.

ARC_OEMBL can be protected by RSIP-E51A register setting. It cannot be updated when RSIP-E51A register setting is same or less than FCNTDATAR0 to 1 register value. For details of RSIP-E51A's register, see section 44, Renesas Secure IP (RSIP-E51A).

52.12.5.1 Anti-Rollback Counter Recovery Flow

Figure 52.44, Figure 52.45 and Figure 52.46-4 shows the recovery flow in the case of OEM_BL anti-rollback counter. The recovery flow for rest anti-rollback counter should be considered necessary processing to depend on customer's application by Secure software developer. As an example, the flow in dual mode is shown. In linear mode, the same operation can be performed using start-up area select, but application size that be managed by anti-rollback counter should be limited to 8 KB.

Example Operation: Update from Bank0 selected in Dual mode

Notation

UCF: Update Complete Flag set/clear by Secure software.
ICF: Increment Complete Flag set/clear by Secure software.
Set status: Indicate that update processing is completed.
Clear status: Indicate that the update processing is not completed.

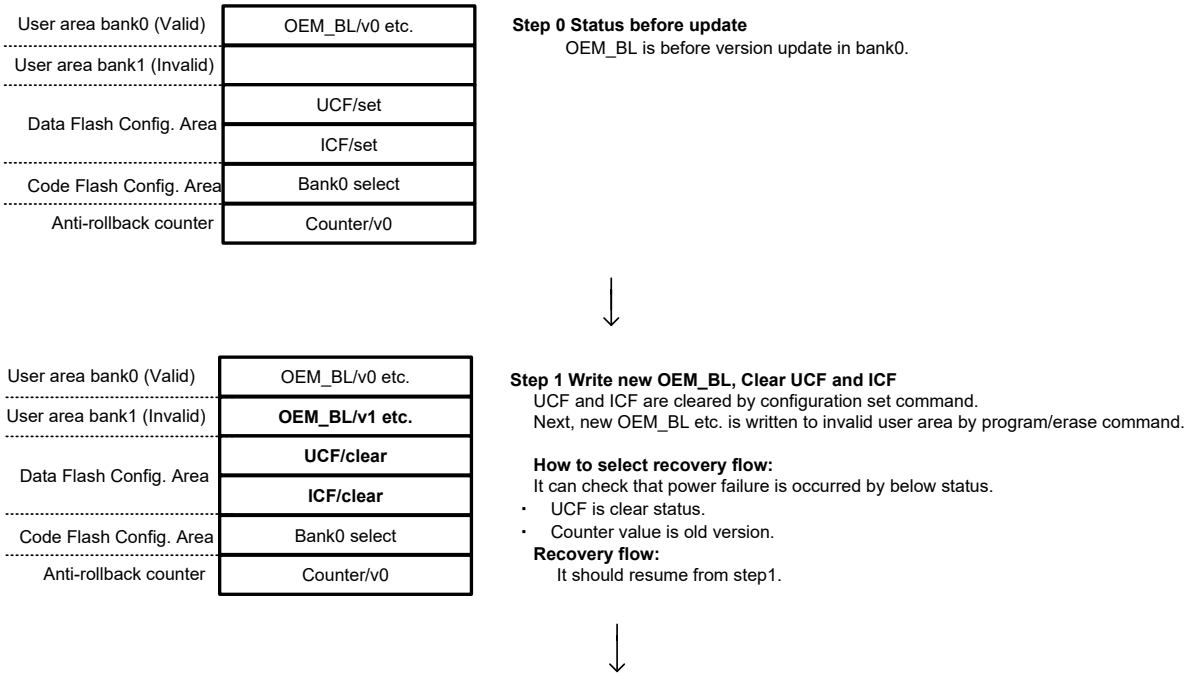

Figure 52.44 Recovery flow of OEM_BL update in Dual mode at power failure (1/3)

Example Operation: Update from Bank0 selected in Dual mode

Notation

UCF: Update Complete Flag set/clear by Secure software.
ICF: Increment Complete Flag set/clear by Secure software.
Set status: Indicate that update processing is completed.
Clear status: Indicate that the update processing is not completed.

User area bank0 (Valid)	OEM_BL/v0 etc.
User area bank1 (Invalid)	OEM_BL/v1 etc.
Data Flash Config. Area	**UCF/set**
	ICF/clear
Code Flash Config. Area	Bank0 select
Anti-rollback counter	Counter/v0

Step 2 Set UCF
UCF is set by configuration set command.

How to select recovery flow:
Same as step1.
Recovery flow:
Same as step1.

↓

User area bank0 (Valid)	OEM_BL/v0 etc.
User area bank1 (Invalid)	OEM_BL/v1 etc.
Data Flash Config. Area	UCF/set
	ICF/set
Code Flash Config. Area	Bank0 select
Anti-rollback counter	**Counter/v1**

Step 3 Update counter version, Set ICF
OEM_BL version counter is update by increment counter command. Next, ICF is set by configuration set command.

How to select recovery flow(a):
It can check that power failure is occurred by below status.
- UCF is set status.
- ICF is clear status.
- Counter value is old version.

Recovery flow(a):
It should issue refresh counter command. Next, after clearing UCF, it should resume from step1.

How to select recovery flow(b):
It can check that power failure is occurred by below status.
- UCF is set status.
- ICF is clear status.
- Counter value is new version.

Recovery flow(b):
It should issue refresh counter command and set ICF. Next, it should resume from step4.

↓

User area bank0 (Valid)	OEM_BL/v0 etc.
User area bank1 (Invalid)	OEM_BL/v1 etc.
Data Flash Config. Area	UCF/clear
	ICF/clear
Code Flash Config. Area	**Bank1 select**
Anti-rollback counter	Counter/v1

Step 4 Update bank selection
BANKSWP[2:0] bits are changed to bank1 selection by configuration set command.

How to select recovery flow:
It can check that power failure is occurred by below status.
- UCF is set status.
- ICF is set status.
- Counter value is new version.
- BANKSWP[2:0] bits are bank0 selection.

Recovery flow:
It should resume from step4.

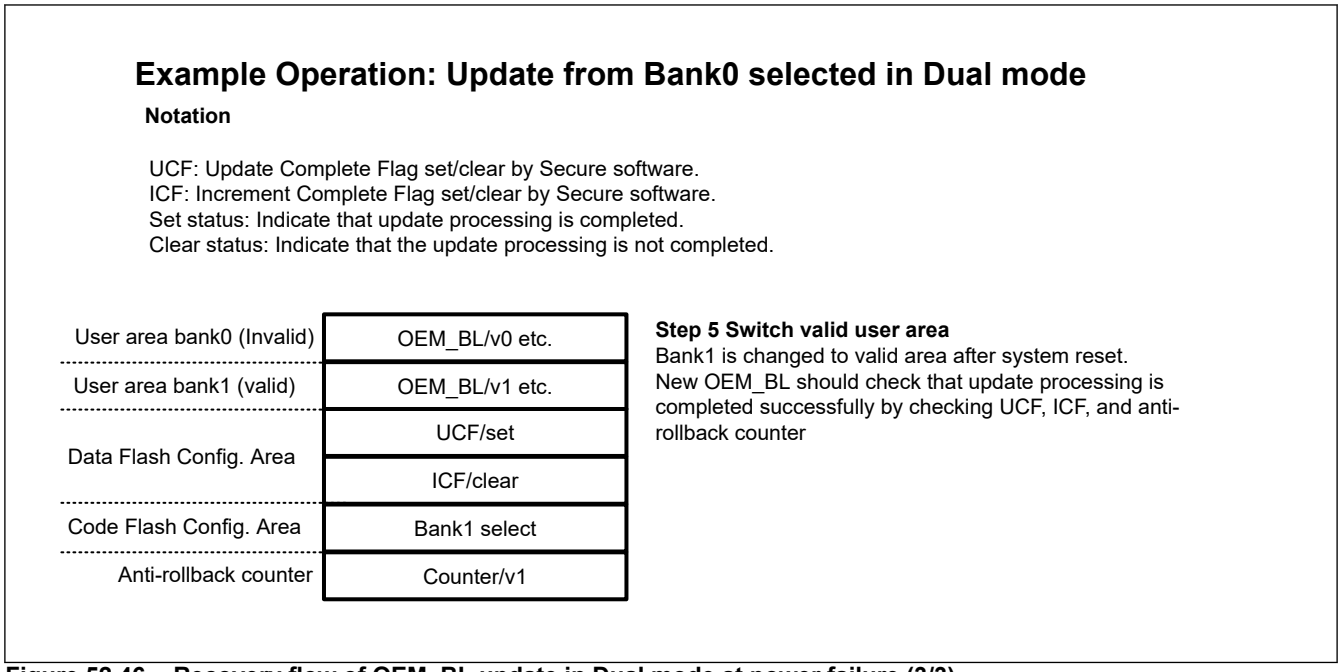

Figure 52.46 Recovery flow of OEM_BL update in Dual mode at power failure (3/3)

52.13 Boot Mode

There are two serial programming modes; the boot mode (for the SCI interface) with SCI9 and the boot mode (for the USB interface) with USBFS. Table 52.37 lists the I/O pins used in boot mode. Table 52.38 lists the available communication interface used in the boot mode.

Table 52.37 I/O Pins Used in Boot Mode

Pin Name	I/O	Mode to be Used	Use
MD	Input	Boot mode (for the SCI interface) Boot mode (for the USB interface) Boot mode (for the JTAG interface) Boot mode (for the SWD interface)	Selection of operating mode
P208/RXD9	Input	Boot mode(for the SCI interface)	For host communication (to receive data through SCI)
P209/TXD9	Output		For host communication (to transmit data through SCI)
USB_DP, USB_DM	I/O	Boot mode(for the USB interface)	Data input/output of USB
USB_VBUS	Input		Detection of connection and disconnection of USB cables
P211/TCK	Input	Boot mode (for the JTAG interface)	Clock pin of JTAG
P210/TMS	Input		Mode Select pin of JTAG
P208/TDI	Input		Data In pin of JTAG
P209TDO	Output		Data Out pin of JTAG
P211/SWCLK	Input	Boot mode (for the SWD interface)	Clock pin of SWD
P210/SWDIO	I/O		Data In-Out pin of SWD

Table 52.38 Available Communication Interface Used in Boot Mode (1 of 2)

Main clock oscillator or external clock is connected	Yes	No	No
Sub clockoscillator is connected*1	Yes or No	Yes	No
Available interface	JTAG, SWD, SCI or USB	JTAG, SWD, SCI or USB	JTAG, SWD or SCI

Table 52.38 Available Communication Interface Used in Boot Mode (2 of 2)

Tool connection time*2	Up to 1 second	Up to 2 seconds	Up to 3 seconds

Note 1. The drive capability of the sub clock oscillator is set to standard by SOMCR.SODRV bit. Note that if you use the crystal corresponding the low drive capability on your board, the crystal may not oscillate in the boot mode.
Note 2. See the boot firmware manual for the detail connection time.

52.13.1 Boot Mode (for the SCI Interface)

In boot mode (for the SCI interface), the host sends control commands and data for programming, and the flash memory is programmed or erased accordingly. An on-chip SCI handles transfer between the host and this MCU in asynchronous mode. Tools for transmission of control commands and the data for programming must be prepared in the host.

When this MCU is activated in boot mode (for the SCI interface), the program on the dedicated area the MCU is executed. The boot program automatically adjusts the bit rate of the SCI and controls programming/erasure by receiving control commands from the host.

Figure 52.47 shows the system configuration for operations in boot mode (for the SCI interface).

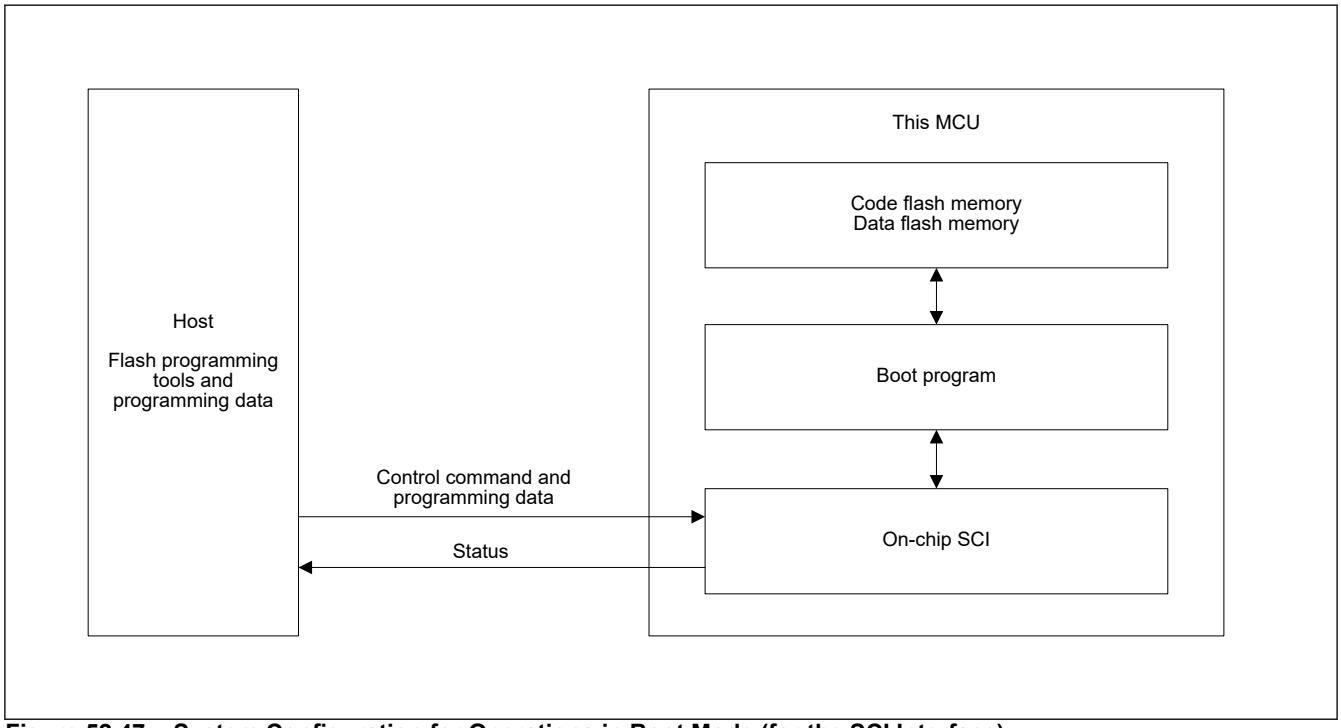

Figure 52.47 System Configuration for Operations in Boot Mode (for the SCI Interface)

52.13.2 Boot Mode (for the USB Interface)

In boot mode (with the USB interface), the flash memory can be programmed or erased by sending control commands and program data from the host. An on-chip USB is used for communications between the host and this MCU. The host requires tools for sending control commands and data for programming. Figure 52.48 shows the configuration of a system for use in boot mode (for the USB interface). The USB cable must be connected on reset release.

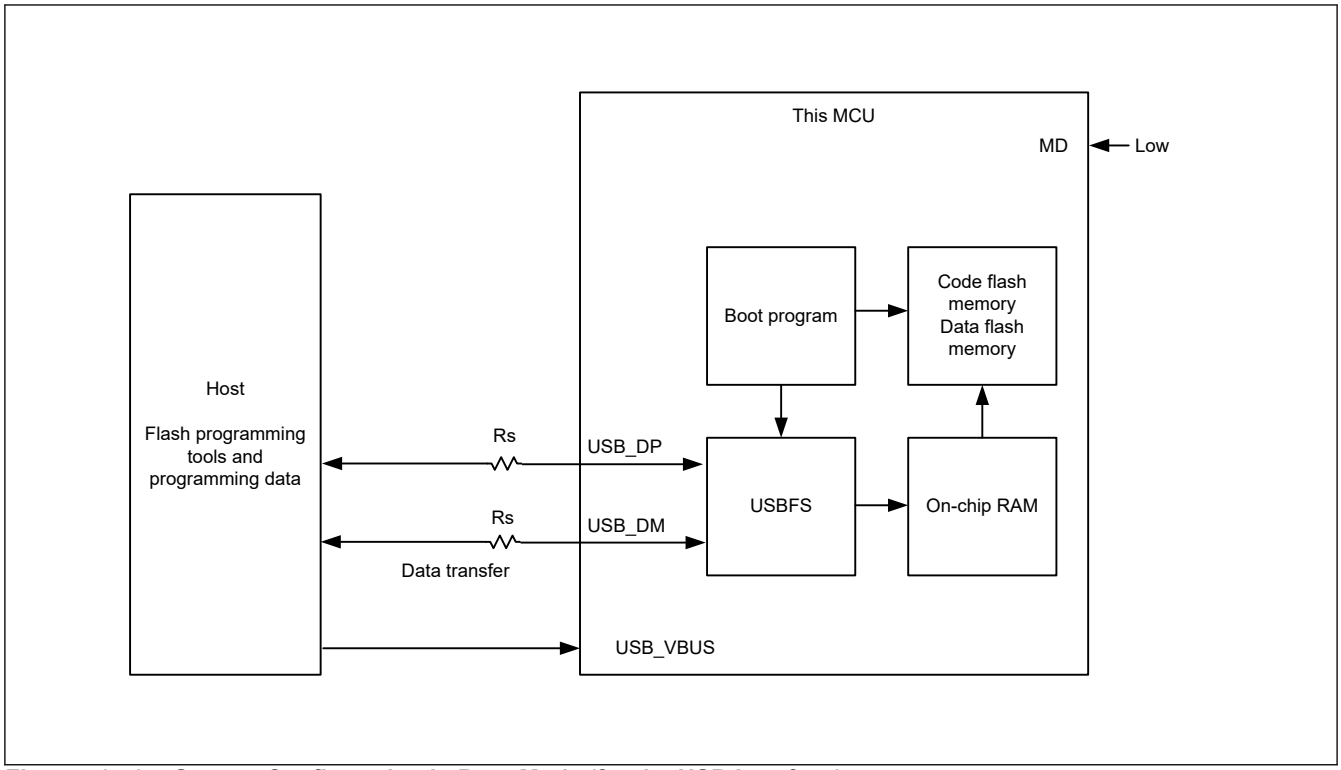

Figure 52.48 System Configuration in Boot Mode (for the USB Interface)

52.14 Using the Serial Programmer for Rewriting

A serial programmer can be used to rewrite flash memory in boot mode.

(1) Serial Programming

This MCU is mounted on the system board at the time of serial programming. Providing a connector to the board enables rewriting of this MCU by the serial programmer to proceed.

52.14.1 Environments for Serial Programming

The recommended environments for rewriting the flash memory of the MCU with data are described below.

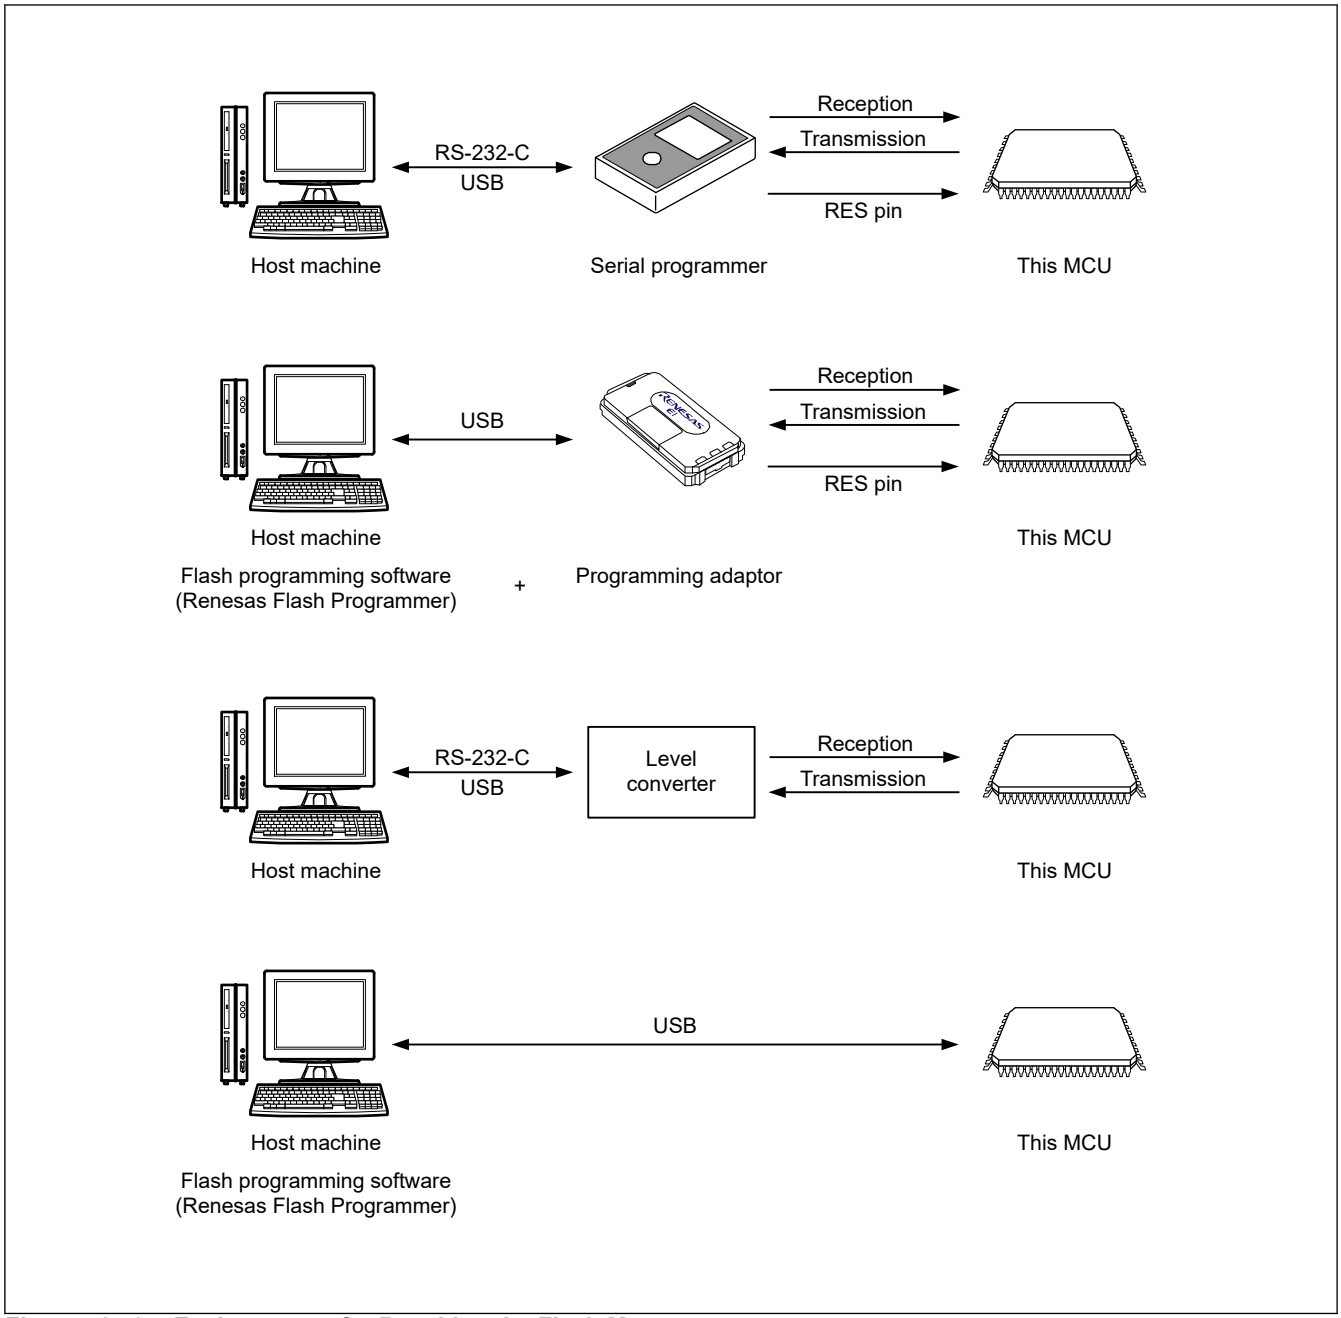

Figure 52.49 Environments for Rewriting the Flash Memory

52.15 Programming through Self-Programming

52.15.1 Overview

This MCU supports programming of the flash memory by the user program itself. The FACI commands can be used with user programs for writing to the flash memory. This allows upgrading of user programs and rewriting of constant data fields.

The program for rewriting must be transferred to the internal RAM or external memory in advance when the BGO is not available or when rewriting the option-setting memory.

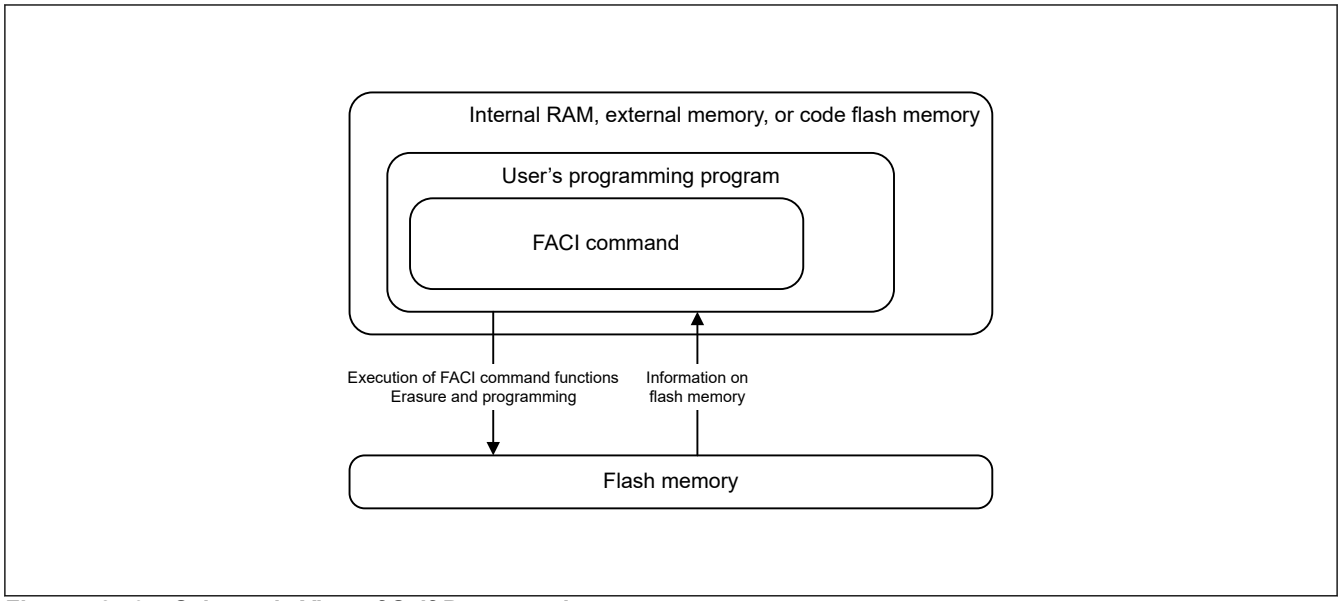

Figure 52.50 Schematic View of Self-Programming

For comprehensive information on the self-programming, see section 52.9. FACI Commands.

52.15.2 Background Operation

The background operation (BGO) can be used to execute the flash rewrite routine on the code flash memory when the data flash memory or other area of code flash memory is rewritten.

Background operations can be used when the combination of the flash memory for rewriting and the flash memory for reading is any of those listed below.

Table 52.39 Conditions under which Background Operation is Usable (1 of 2)

		Range for rewriting	Range for reading
Common to linear and dual modes		Code flash memory	Data flash memory
		Data flash memory	Code flash memory
Liner mode	Products with 2 Mbytes of code flash memory	First half (1 Mbytes) of the code flash memory addresses Secure alias: 0x0200_0000 to 0x020F_FFFF Non-secure alias: 0x1200_0000 to 0x120F_FFFF	Second half (1 Mbytes) of the code flash memory addresses Secure alias: 0x0210_0000 to 0x021F_7FFF Non-secure alias: 0x1210_0000 to 0x121F_7FFF
		Second half (1 Mbytes) of the code flash memory addresses Secure alias: 0x0210_0000 to 0x021F_7FFF Non-secure alias: 0x1210_0000 to 0x121F_7FFF	First half (1 Mbytes) of the code flash memory addresses Secure alias: 0x0200_0000 to 0x020F_FFFF Non-secure alias: 0x1200_0000 to 0x120F_FFFF
	Products with 1 Mbytes of code flash memory	First half (0.5 Mbytes) of the code flash memory addresses Secure alias: 0x0200_0000 to 0x0207_FFFF Non-secure alias: 0x1200_0000 to 0x1207_FFFF	Second half (0.5 Mbytes) of the code flash memory addresses Secure alias: 0x0208_0000 to 0x020F_FFFF Non-secure alias: 0x1208_0000 to 0x120F_FFFF
		Second half (0.5 Mbytes) of the code flash memory addresses Secure alias: 0x0208_0000 to 0x020F_FFFF Non-secure alias: 0x1208_0000 to 0x120F_FFFF	First half (0.5 Mbytes) of the code flash memory addresses Secure alias: 0x0200_0000 to 0x0207_FFFF Non-secure alias: 0x1200_0000 to 0x1207_FFFF

Table 52.39 Conditions under which Background Operation is Usable (2 of 2)

		Range for rewriting	Range for reading
Dual mode	When the BANKSEL_SEC.BANKSWP[2:0] or BANKSEL.BANKSWP[2:0] bits are 111b	Bank 1 area of the code flash memory	Bank 0 area of the code flash memory
	When the BANKSEL_SEC.BANKSWP[2:0] or BANKSEL.BANKSWP[2:0] bits are 000b	Bank 0 area of the code flash memory	Bank 1 area of the code flash memory

52.16 Reading Flash Memory

52.16.1 Reading Code Flash Memory

Special settings are not required to read code flash memory after release from the reset state. Data can simply be read out through access to addresses in the code flash memory.

When reading code flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state), all bits are read as 1.

52.16.2 Reading Data Flash Memory

Special settings are not required to read data flash memory after release from the reset state. Data can simply be read out through access to addresses in the data flash memory.

Values read from data flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state) are undefined. Use blank checking when you need to confirm that an area is in the non-programmed state.

52.17 Usage Notes

(1) Reading Area Where Programming/Erasure was Interrupted and Area Targeted for Suspension

The data stored in the area where programming or erasure has been suspended or the area where programming or erasure has been suspended by using the suspend command are undefined. To avoid faulty operation caused by reading undefined data, take care not to fetch instructions or read data from areas where programming or erasure was suspended and where programming or erasure was suspended by using the suspend command.

(2) Suspension During Programming/Erasure

When processing of programming/erasure is stopped by issuing the P/E suspend command, the programming/erasure processing can be resumed by issuing the P/E resume command. If the flash sequencer enters the command-locked state for any reason and issues the forced stop command after the suspended processing is normally completed and the ERSSPD flag or PRGSPD flag is set to 1, the suspended processing cannot be resumed. In addition, the values in the area where the processing was suspended are not guaranteed. Erase that area

(3) Prohibition of Additional Programming

Programming a given area of the code flash memory or data flash memory twice is not possible. To program the code flash memory or data flash memory where has been programed, erase the target area. Programming can be added to the option-setting memory.

(4) Resets During Programming/Erasure, or Blank Checking

In the case of a reset due to the signal on the RES pin during programming/erasure, or blank checking of the flash memory, wait for at least t_{RESW} (see section 60, Electrical Characteristics) of the reset input period once the operating voltage is within the range stipulated in the electrical characteristics, then release the device from the reset state.

(5) Allocation of Vectors for Interrupts and Other Exceptions During Programming/Erasure

Generation of an interrupt or other exception during programming/erasure may lead to fetching of the vector from the code flash memory. Under conditions where BGO cannot be used, set the address of the vector to an address that is not in the code flash memory. Alternatively, make sure that no handling of interrupts or exceptions proceeds during programming/erasure.

(6) Items Prohibited During Programming/Erasure, or Blank Checking

High voltage is applied to the flash memory during programming/erasure, or blank checking. To prevent damage to the flash memory, do not perform the following operations.

- Have the operating voltage from the power supply go beyond the permitted range.
- Change the FWEPROR.FLWE[1:0]bits.
- Change the OPCCR.OPCM[2:0] bits.
- Change the SCKDIVCR.FCK[2:0]bits.
- Change the SCKSCR.CKSEL[2:0]bits.
- Transition to the software standby mode, or Deep Software Standby mode.

(7) Programming/Erasure in Low-Speed Modes

Do not programming/erasure the flash memory when low-speed mode is selected with the operating power control register (OPCCR).

(8) Setting dual bank mode and programming in Boot Mode

The initial mode of the MCU shipped from Renesas is linear mode. In customer's factory when programming dual bank mode and customer's applications on MCU set in linear mode, it is recommended that only area1 in Figure 52.51 is programed in boot mode and area2 is kept blank. After reset, MCU starts in dual mode and the application is in bank0. Use self-programming when programming area2 for updating in the field. See section 43.8. Field Updating in Dual Mode for details

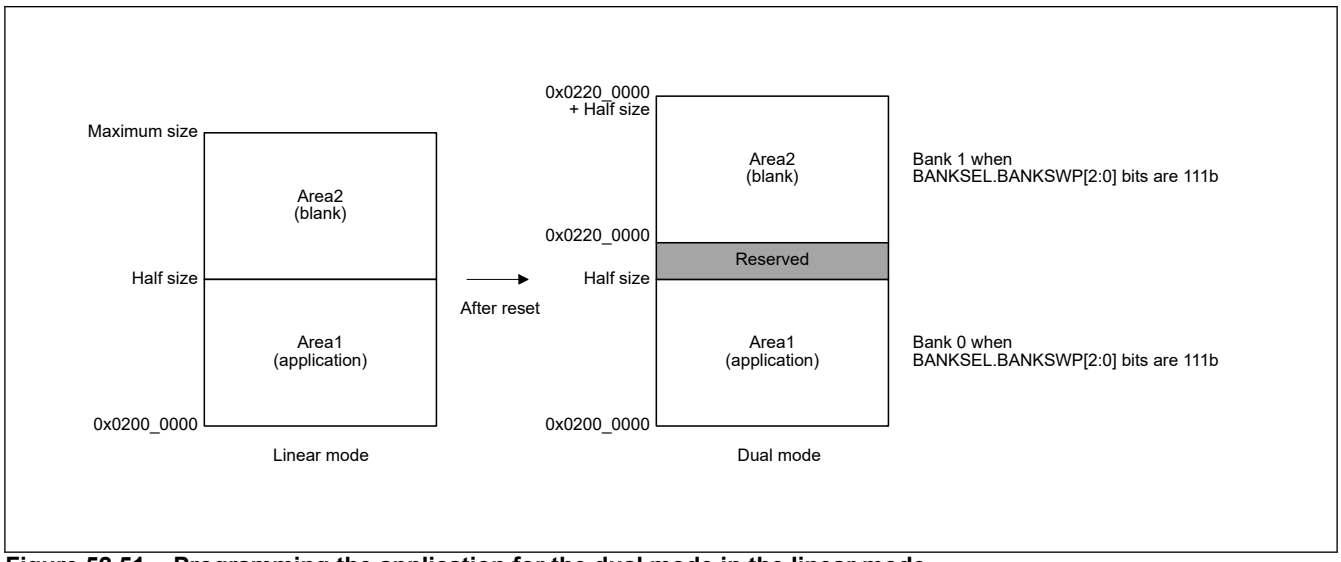

Figure 52.51 Programming the application for the dual mode in the linear mode

(9) Emulator Connection

Renesas provides the emulator which supports both debugging using SWD or JTAG communication and serial programming using SCI communication.

Table 52.40 shows the pinout of 10 pin or 20 pin socket pinouts when using this emulator. The pinout of SWD and JTAG is ARM standard, and MD, TXD, RXD pins are added for the serial programming using SCI communication.

Table 52.40 Pin assign for emulator (1 of 2)

Pin No.	SWD	JTAG	Serial Programming using SCI
1	VCC	VCC	VCC
2	P210/SWDIO	P210/TMS	NC
4	P211/SWCLK	P211/TCK	P201/MD

Table 52.40 Pin assign for emulator (2 of 2)

Pin No.	SWD	JTAG	Serial Programming using SCI
6	P209/SWO	P209/TDO	P209/TXD9

53. Capture Engine Unit (CEU)

53.1 Overview

The Capture Engine Unit (CEU) is a capture module that fetches image data externally input and transfers it to the memory. The CEU is connected to the system bus via bus bridge modules.

Lists the features of CEU as follows.

(1) Image data fetch

- Captures an image output from an external module and writes YCbCr data to the memory with it separated into Y data and CbCr data.
- Fetches image data other than YCbCr data, for example, JPEG data, RGB565, from an externally connected module, such as a camera, and sequentially writes the image data to the memory.
- Fetches an interlace source image in both-field units or one-field units and writes it to the memory. In both-field capture, an image can be stored in the memory as a frame image.

(2) Filter processing

- Performs scale-down and removal of high-frequency components (only in the horizontal direction) for an image using internal filters. Note that the scaled-down image must not exceed VGA. The filter processing can be applied to only YCbCr input data.

(3) Format conversion

- Converts image data input in the YCbCr422 format into the YCbCr420 format and writes it to the memory. Note that the conversion algorithm is simple thinning in which the chrominance component (CbCr) of the evennumbered lines is thinned.

The functional overview of the CEU is shown in Table 53.1 and the main functions and their details are shown in Table 53.2.

Table 53.1 Functional overview of CEU (1 of 2)

Classification	Item	Function	Description	Note
Connectable camera	Size*1	5 megapixels	2,560 pixels × 1,920 lines	Image capture mode or data synchronous fetch mode Horizontal : 8-pixel units Vertical : 4-line units Data enable fetch mode 32-byte units The range of the image size that can be input is as follows. Horizontal: 2,560 pixels to 128 pixels Vertical: 1,920 pixels lines to 96 lines
		3 megapixels	2,048 pixels × 1,536 lines	
		2 megapixels	1,632 pixels × 1,224 lines	
		UXGA	1,600 pixels × 1,200 lines	
		SXGA (1)	1,280 pixels × 1,024 lines	
		SXGA (2)	1,280 pixels × 960 lines	
		WXGA	1,280 pixels × 768 lines	
		XGA	1,024 pixels × 768 lines	
		SVGA	800 pixels × 600 lines	
		WVGA	800 pixels × 480 lines	
		VGA	640 pixels × 480 lines	
		CIF	352 pixels × 288 lines	
		WQVGA	480 pixels × 240 lines	
		QVGA	320 pixels × 240 lines, 240 pixels × 320 lines	
		QCIF	176 pixels × 144 lines	
		QQVGA	160 pixels × 120 lines	
		Sub-QCIF	128 pixels × 96 lines	
	Input format	YCbCr422 8 bits	Cb_0, Y_0, Cr_0, Y_1…	Supports clock ratio of 1:1
			Cr_0, Y_0, Cb_0, Y_1…	
			Y_0, Cb_0, Y_1, Cr_0…	
			Y_0, Cr_0, Y_1, Cb_0…	
		YCbCr422 16 bits	{Y_0, Cb_0}, {Y_1, Cr_0}, …	
			{Y_0, Cr_0}, {Y_1, Cb_0}, …	
		Binary data	Specified amount to be fetched on edges of the sync signal	Written sequentially
			Data is fetched with the horizontal sync signal as an enable signal	
	Horizontal and vertical sync signal polarities	Arbitrary	High-active and low-active	
	Capture start location	Arbitrary	Can be specified in camera input clock units	Horizontal: 1-cycle units Vertical: 1-HD (horizontal sync signal) units
	Number of captured pixels	Arbitrary	Can be specified in 8-pixel units horizontally and in 4-line units vertically	
	Interlace	Both-field capture	Stored as a field image	Capture: 2-VD (vertical sync signal) units
			Stored as a frame image	
		One-field capture	Top field or bottom field can be specified	Capture: 1-VD units
Memory write	Output format	YCbCr422 YCbCr420	YCbCr420 is realized by simple thinning	

Table 53.1 Functional overview of CEU (2 of 2)

Classification	Item	Function	Description	Note
Filter function	No scaling or scale-down	Scale-down of captured display	Desired scaling factor from 1/16 to 1 (scaled-down display must not exceed VGA)	
	Low-pass filter		Removal of high-frequency components	Only in the horizontal direction
Module-stop function	Module-stop state can be set to reduce power consumption.			
TrustZone Filter	Security and Privilege attribution can be set.			

Note 1. The range of the image size that can be input depends on the AC characteristics and the frame rate of the connected device, and the transfer speed to the destination RAM.

Table 53.2 Main functions of CEU and their details

Main function	Detailed description
Image data fetch	• Captures an image output from an external module and writes YCbCr data to the memory with it separated into Y data and CbCr data. • Fetches image data other than YCbCr data, e.g. JPEG data, from an externally connected module, such as a camera, and sequentially writes the image data to the memory. • Fetches an interlace source image in both-field units or one-field units and writes it to the memory. In both-field capture, an image can be stored in the memory as a frame image.
Filter processing	Performs scale-down and removal of high-frequency components (only in the horizontal direction) for an image using internal filters. Note that the scaled-down image must not exceed VGA. The filter processing can be applied to only YCbCr input data.
Format conversion	Converts image data input in the YCbCr422 format into the YCbCr420 format and writes it to the memory. Note that the conversion algorithm is simple thinning in which the chrominance component (CbCr) of the even-numbered lines is thinned.

Figure 53.1 shows a block diagram of the CEU.

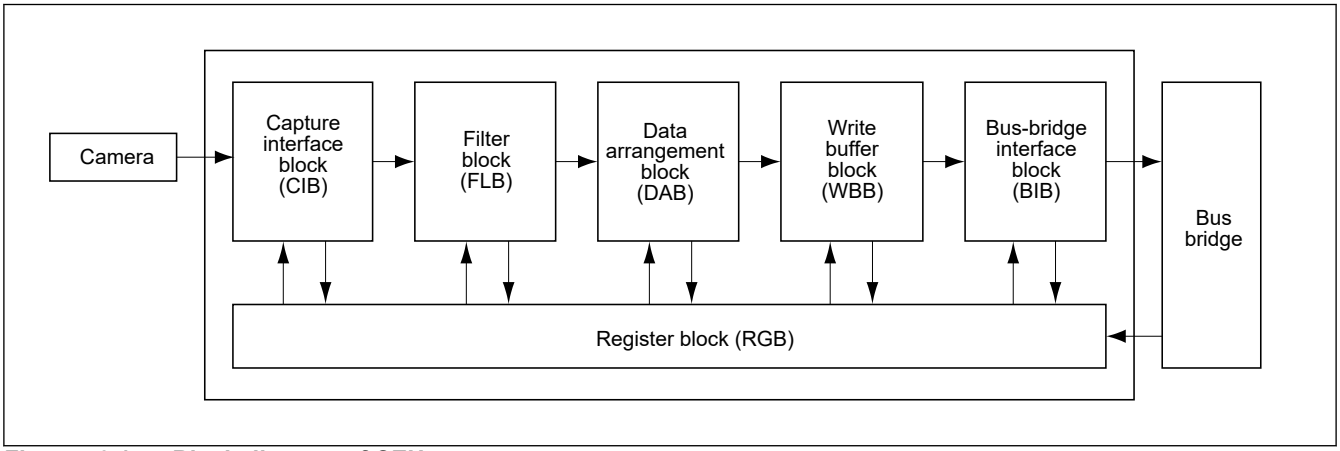

Figure 53.1 Block diagram of CEU

The pin configuration of the CEU is shown in Table 53.3.

Table 53.3 Pin configuration of CEU (1 of 2)

Pin name	Function	I/O	Description
VIO_D15 to VIO_D0*1	CEU data bus	Input	Camera image data input to the CEU
VIO_CLK	CEU clock	Input	Camera clock input to the CEU
VIO_VD	CEU vertical sync	Input	Camera vertical sync signal input to the CEU

Table 53.3 Pin configuration of CEU (2 of 2)

Pin name	Function	I/O	Description
VIO_HD	CEU horizontal sync	Input	Camera horizontal sync signal input to the CEU
VIO_FLD*2	Field signal	Input	Field identification signal to the CEU

Note 1. When the distinction according to the bus width for the data bus is not needed, VIO_D is used in this manual. Otherwise, VIO_D15 to VIO_D0 are used.
Note 2. The VIO_FLD pin is valid only in interlace input mode (CAIFR.IFS=1).

53.2 Register Descriptions

The register configuration of the CEU is shown in Table 53.4.

Most CEU registers have a 2-plane configuration (plane A and plane B). The CEU switches the planes when using these 2-plane registers. A mirror address, which is an address that can always access the register on the unused plane, is provided for each 2-plane register. Figure 53.2 shows the timing to switch the register planes. The CEU switches the register planes at the same time a VD interrupt is asserted.

In the following register descriptions, "during operation" indicates the period that begins when the CEU is activated by the CE bit in the capture start register (CAPSR) and ends when a capture end interrupt (CPE) of the capture event flag clear register (CETCR) occurs. In the read-only bits in each register, the write value should always be 0. If a value other than 0 is written to any of these bits, correct operation cannot be guaranteed.

Table 53.4 Register configuration of CEU (1 of 2)

Register name	Abbr.	R/W	Addresses			Access size
			Address (Plane A)	Address (Plane B)	Mirror Address	
Capture Start Register	CAPSR	R/W	0x4034_8000	—	—	32

CEU Bufferable Write Enable Register	CBWER	R/W	0x4034_80A0	—	—	32

Note: The address shown in this table are Secure region. The address corresponding to the Non-secure region is when b28 of address is set to 1.

Note 1. After changing the setting of a register (CAMCR or CMCYR) that is determined by the external module characteristics, do not start capture until at least 10 external input clock cycles have elapsed.

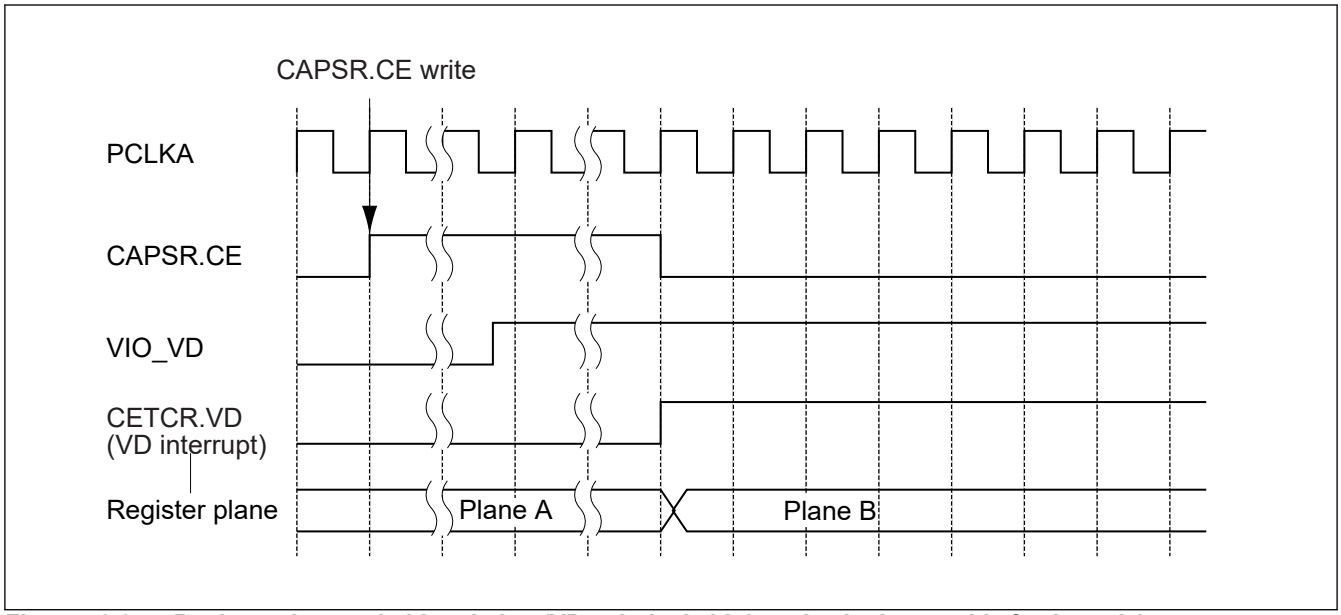

Figure 53.2 Register plane switching timing (VD polarity is high-active in data enable fetch mode)

53.2.1 CAPSR : Capture Start Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CPKIL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CE	Capture enable ● Single-capture This bit reserves capturing of the next frame. When 1 is written to this bit, the capture of one frame starts from the next VD input, and stops when the one-frame capture end interrupt (CPE bit in CETCR) is asserted (Figure 53.7). To perform capture again, write 1 to this bit. After the VD or HD polarity is changed, do not write 1 to this bit until the next VD interrupt is asserted. As this bit indicates the capture reserve state, this bit is read as 1 after it is set to 1 and until VD is input. When VD is input, this bit returns to 0 and so is read as 0. The capture end is determined by the one-frame capture end interrupt (CPE bit). This is similar in data fetch mode. Registers should be set before the VD interrupt of the frame where capture starts next. The new register settings take effect at the next VD input. When registers are modified during capturing, the register settings take effect from the capture operations of the next VD input. If a setting register to which writing during capturing is prohibited is modified during capturing, an interrupt source (IGRW bit in CETCR) is generated. For details on the interrupt source, see the description on CETCR. ● Continuous capture When this bit is set to 1 while the CTNCP bit in CAPCR is set to 1, continuous capture starts from the next frame (Figure 53.8). Note that this bit is not cleared to 0 but remains as 1. To stop capturing, clear this bit to 0; capturing stops after the current frame is completed. Continuous capture operations are possible in only image capture mode. The start address of the memory to which the captured data is written to must be set for each frame. 0: Stops capturing 1: Starts capturing	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W
16	CPKIL	Software reset of capturing Write 1 to this bit to perform a software reset of capturing. At a software reset, capturing ends immediately without completing capture operation until the end of a frame. Clear the CE bit to 0 when writing 1 to this bit. Processing of the capture software reset is indicated by this bit being set to 1. When CPKIL = 1, do not start capturing since reset processing is in progress. When restarting capture operations, after referring to the CPTON bit in CSTSR to ensure that the CEU is halted (in the idle state), wait until this bit is cleared to 0. The timing of restarting capture operations is shown in Figure 53.6. When a software reset is generated by this bit, a capture end interrupt (CPE bit in CETCR) may be output immediately after the software reset. However, such kind of interrupt should be ignored. Also, even if the capture end interrupt is not output, the interrupt source (CPE bit) must be cleared before capturing of the next frame. 0: Normal state 1: Software reset of capturing	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CAPSR captures data input to the CEU from an external module.

When both the VD (vertical sync signal) and HD (horizontal sync signal) polarities are high-active, one frame is defined as a period from a VD rising edge to the next VD rising edge, and one line as a period from an HD rising edge to the next HD rising edge. Figure 53.3 shows the timing of one frame (when both the VD and HD polarities are high-active).

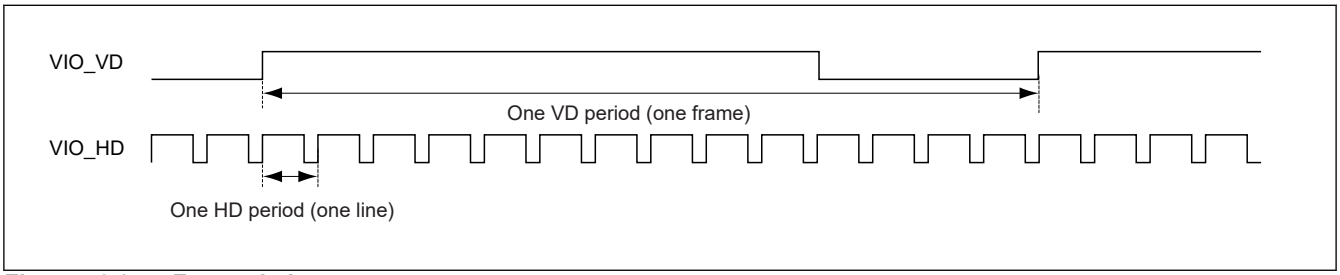

Figure 53.3 Frame timing

When both the VD and HD polarities are high-active, similar to one frame, one field is defined as follows:

- Period from a VD rising edge to the next VD rising edge
- One line is a period from an HD rising edge to the next HD rising edge

The field identification signal FLD should be fixed for at least 1-HD period from a VD input. Figure 53.4 shows the timing of one field (when both the VD and HD polarities are high-active).

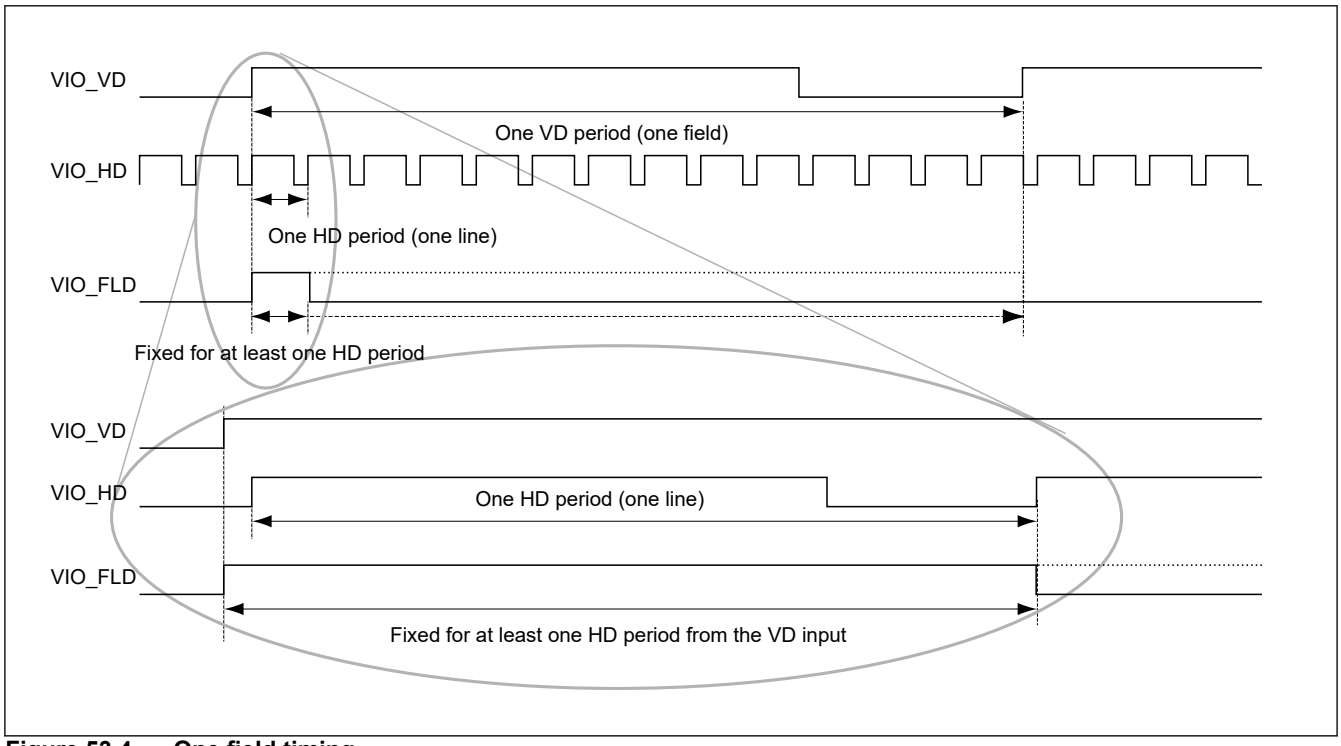

Figure 53.4 One field timing

In data enable fetch, one frame is defined as a period from a VD rising edge to the VD falling edge. With the HD as an enable signal (positive polarity), data of a cycle in which the HD is asserted is fetched while the VD is high. Figure 53.5 shows the timing of one frame for data enable fetch.

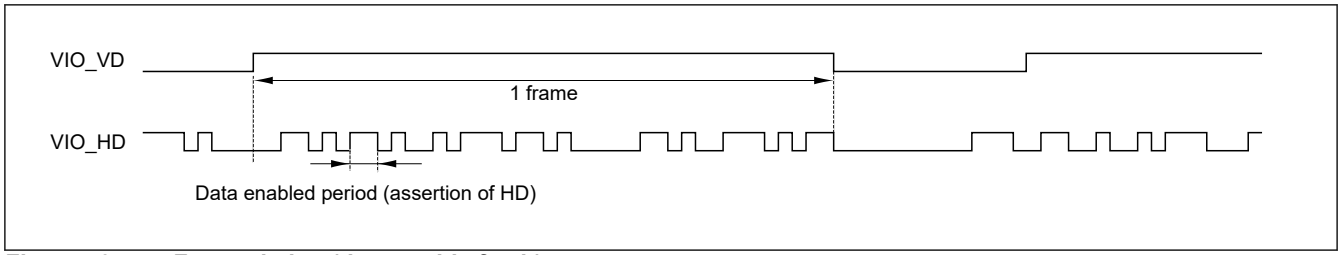

Figure 53.5 Frame timing (data enable fetch)

53.2.2 CAPCR : Capture Control Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	FDRP[7:0]								—	—	MTCM[1:0]		—	—	—	CTNCP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W
16	CTNCP	Continuous capture When capturing is started with this bit set to 1, capturing continues until the CE bit in CAPSR is cleared to 0 or a software reset is initiated by the CPKIL bit in CAPSR (see Figure 53.8). Continuous capture must be set before capturing is started. This bit is modified only after 0 is written to the CE bit to stop capturing. If this bit is modified during capturing, correct operation cannot be guaranteed. In data fetch mode, clear this bit to 0. 0: One-frame capture when CAPSR.CE = 1 1: Continuous capture until CAPSR.CE = 0	R/W
19:17	—	These bits are read as 0. The write value should be 0.	R/W
21:20	MTCM[1:0]	Specify the unit for transferring data to a bus bridge module. The efficiency of writing image data can be improved by continuously accessing the addresses. To improve the write efficiency, set these bits to 11. The setting of these bits appear to be unchanged from the outside. 0 0: Image capture: Y data and C data are transferred in 32-byte units Data fetch : Data is transferred in 32-byte units 0 1: Image capture: Y data and C data are transferred in 64-byte units Data fetch : Data is transferred in 64-byte 1 0: Image capture: Y data and C data are transferred in 128-byte units Data fetch : Data is transferred in 128-byte 1 1: Image capture: Y data and C data are transferred in 256-byte units Data fetch : Data is transferred in 256-byte	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
31:24	FDRP[7:0]	Set the frame drop interval in continuous-frame capture. When these bits are cleared to 0, frame drop is not performed, and all frames are captured. Figure 53.9 shows the value set in these bits and the timing of captured frames. The frame drop interval unit differs according to the capture setting. Table 53.5 shows the relationship between the capture setting and frame drop interval unit. The image of the frame drop timing for each capture setting when these bits are set to 2 is shown in Figure 53.10. In both-field capture, capturing is performed continuously for 2-VD periods, regardless of whether the second field is the top field or bottom field. In addition, in both-field capture, the frame drop counter is incremented when the first field has been identified as the top field or bottom field, regardless of whether the second field is the top field or bottom field. When 0 is written to the CE bit in CAPSR, capturing terminates after the current frame has been captured for a capture frame. However, for a drop frame, capturing is forcibly terminated in the CEU so no capture end interrupt (CPE bit in CETCR) is output. While CAPSR.CE = 1, do not change the setting of these bits. Note: Do not change the setting of these bits during continuous capture operations. To change the setting of these bits, stop continuous capture (CAPSR.CE = 0), clear the CTNCP bit (continuous capture) in CAPCR to 0, and then restart continuous capture. Continuous capture is performed during the period of CAPSR.CE = 1 shown in Figure 53.9.	R/W

Note: S-TYPE-3, P-TYPE-3

CAPCR sets continuous-frame capture and the frame drop intervals.

Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to 1.

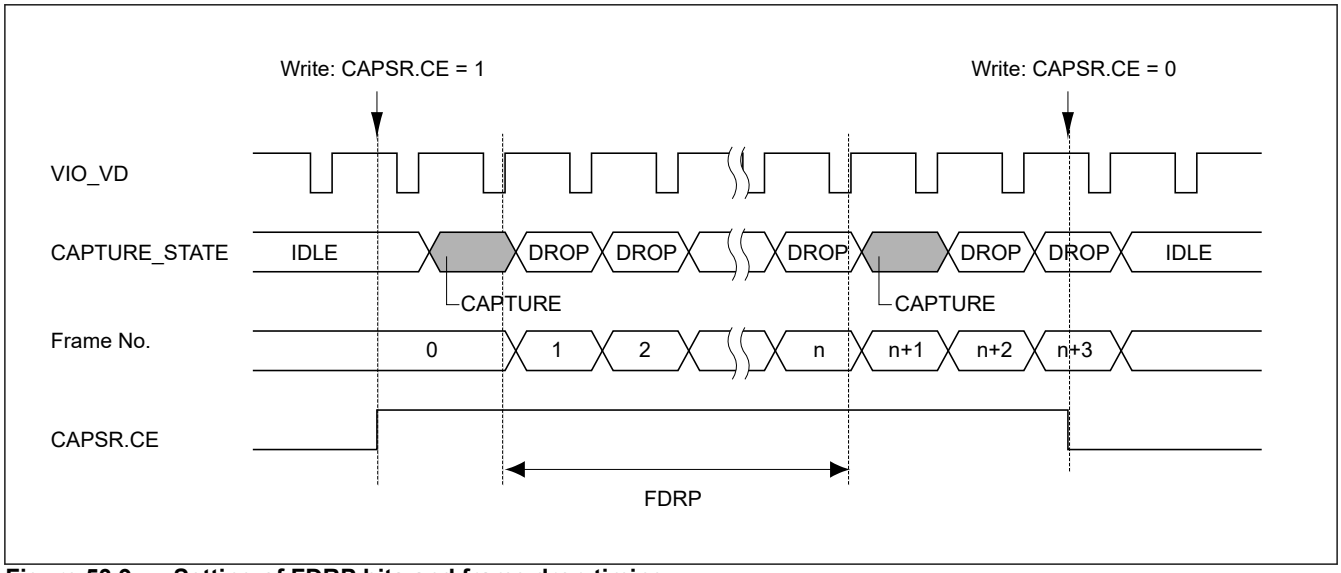

Figure 53.9 Setting of FDRP bits and frame drop timing

Table 53.5 Relationship between capture setting and frame drop interval unit

Input Mode	Captured Image	First Captured Image	Frame Drop Interval Unit	Capture Setting
Progressive	Frame	Frame immediately after capture start	Frame	A
Interlace	Both-field (2-VD capture)	Field immediately after capture start	2 fields (first capture field count)	B

Bit field:	—	—	—	DTIF	—	—	DTARY[1:0]		—	—	JPG[1:0]		—	—	VDPOL	HDPOL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	HDPOL	Sets the polarity for detection of the horizontal sync signal (HD) input from an external module. Figure 53.16 shows the relationship between the HD and HD interrupt when high-active is selected. Since an HD interrupt may occur when this bit value is modified, the HD bit in CETCR must always be cleared to 0 when this bit value is changed. In data enable fetch mode, set this bit to 0. 0: Horizontal sync signal (HD) from an external module is detected as high active 1: Horizontal sync signal (HD) from an external module is detected as low active	R/W
1	VDPOL	Sets the polarity for detection of the vertical sync signal (VD) input from an external module. Figure 53.14 and Figure 53.15 show the relationship between the VD, HD and VD interrupt when high-active is selected. Since a VD interrupt may occur when this bit value is modified, the VD bit in CETCR must always be cleared to 0 when this bit value is changed. In data enable fetch mode, this bit is not used and the sense for detection is always active high. 0: Vertical sync signal (VD) from an external module is detected as high active 1: Vertical sync signal (VD) from an external module is detected as low active	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
5:4	JPG[1:0]	These bits select the fetched data type. 0 0: Image capture mode (input data are separated into the luminance component data (Y) and the chrominance component data (CbCr) for output to the memory) 0 1: Data synchronous fetch mode (specified size of input data are output to the specified memory addresses in order of input and in synchronization with the sync signal) 1 0: Data enable fetch mode (input data are fetched with HD as an enable signal and output to the specified addresses in memory in order of input) 1 1: Setting prohibited	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
9:8	DTARY[1:0]	Set the input order of the luminance component and chrominance component. The order in which Y and CbCr are input from an external module differs among modules. The CEU supports the input orders shown in Figure 53.12. Set the corresponding value in these bits. In data fetch mode, set these bits to 00. 0 0: 8-bit interface: Image input data is fetched in the order of Cb_0, Y_0, Cr_0, and Y_1 16-bit interface: Image input data is fetched in the order of {Cb_0, Y_0} and {Cr_0, Y_1} 0 1: 8-bit interface: Image input data is fetched in the order of Cr_0, Y_0, Cb_0, and Y_1 16-bit interface: Image input data is fetched in the order of {Cr_0, Y_0} and {Cb_0, Y_1} 1 0: 8-bit interface: Image input data is fetched in the order of Y_0, Cb_0, Y_1, and Cr_0 16-bit interface: Image input data is fetched in the order of {Y_0, Cb_0} and {Y_1, Cr_0} 1 1: 8-bit interface: Image input data is fetched in the order of Y_0, Cr_0, Y_1, and Cb_0 16-bit interface: Image input data is fetched in the order of {Y_0, Cr_0} and {Y_1, Cb_0}	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
12	DTIF	Sets the digital image input pins from which data is to be captured. 0: Data input to 8-bit digital image input pins is captured 1: Data input to 16-bit digital image input pins is captured	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
16	FLDPOL	Sets the polarity of the field identification signal (FLD) from an external module. 0: When the FLD signal is high-active, the field is detected as the top field and when low-active, the field is detected as the bottom field. 1: When the FLD signal is low-active, the field is detected as the top field and when high-active, the field is detected as the bottom field.	R/W
23:17	—	These bits are read as 0. The write value should be 0.	R/W
24	DSEL	Sets the edge for fetching the image data (D15 to D0) from an external module. 0: D15 to D0 are fetched at the rising edge of the camera clock. 1: D15 to D0 are fetched at the falling edge of the camera clock.	R/W
25	FLDSEL	Sets the edge for capturing FLD from an external module. 0: FLD is captured at the rising edge of the camera clock. 1: FLD is captured at the falling edge of the camera clock.	R/W
26	HDSEL	Sets the edge for capturing HD from an external module. 0: HD is captured at the rising edge of the camera clock. 1: HD is captured at the falling edge of the camera clock.	R/W
27	VDSEL	Sets the edge for capturing VD from an external module. 0: VD is captured at the rising edge of the camera clock. 1: VD is captured at the falling edge of the camera clock.	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CAMCR sets the capture interface.

The following items are set by CAMCR.

- Selection between the rising edge or falling edge of the camera clock for signal capture or data fetch operation
- Selection between image capture operation or data fetch operation
- Polarities of the vertical and horizontal sync signals
- Input order of image data components (Y, Cb, and Cr) (only for image capture mode)
- Selection of digital image input pins (8 bits or 16 bits)

- Polarity of the field identification signal

CAMCR must be set according to the module connected. In data fetch mode, set the DTARY bits to 0. Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to 1.

Note: After changing the setting of this register, do not start capture until at least 10 external input clock cycles have elapsed.

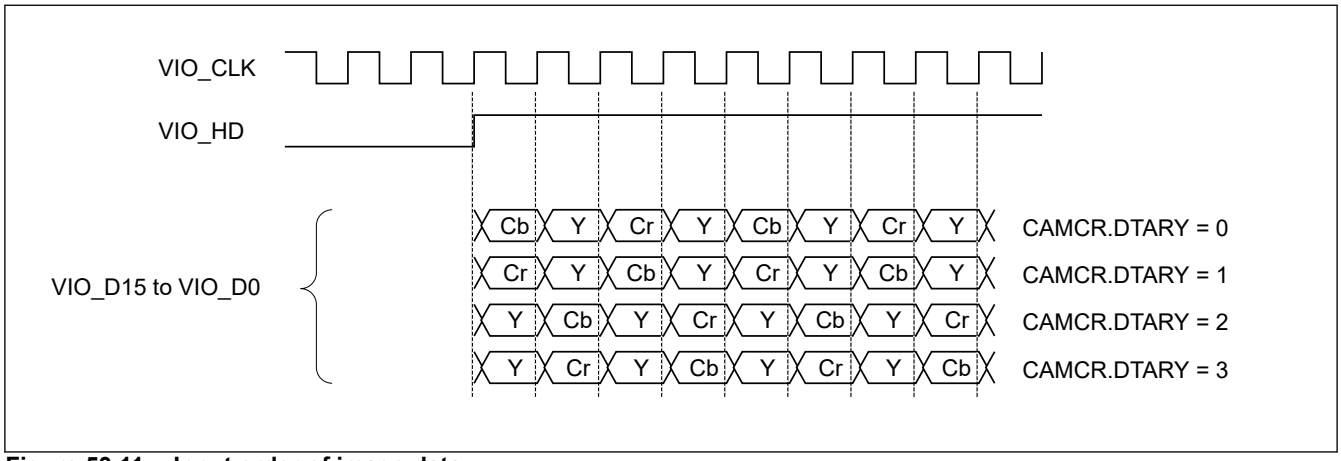

Figure 53.11 Input order of image data

The JPG bit in CAMCR selects whether digital image data is fetched or data such as JPEG is fetched. In addition, when data such as JPEG is fetched, select whether the specified amount of data is continuously fetched in synchronization with the sync signal or data is fetched while the horizontal sync signal is enabled.

In data enable fetch mode, one frame is defined as a period from the rising edge to the falling edge of the vertical sync signal (VD) for data fetching. The horizontal sync signal (HD) is enabled only when the VD is high and treated as an enable signal. Data input in the cycle in which the HD is asserted (high) is fetched and output to the memory continuously.

This module starts fetching data at the rising edge of the VD and stops fetching data at the falling edge of the VD in data enable fetch mode. Thus, if the VD remains high and does not go low, end processing does not start. In addition, if the VD remains high and the HD also remains asserted, data continues to be fetched.

Figure 53.12 and Figure 53.13 show the interface timing in data enable fetch mode.

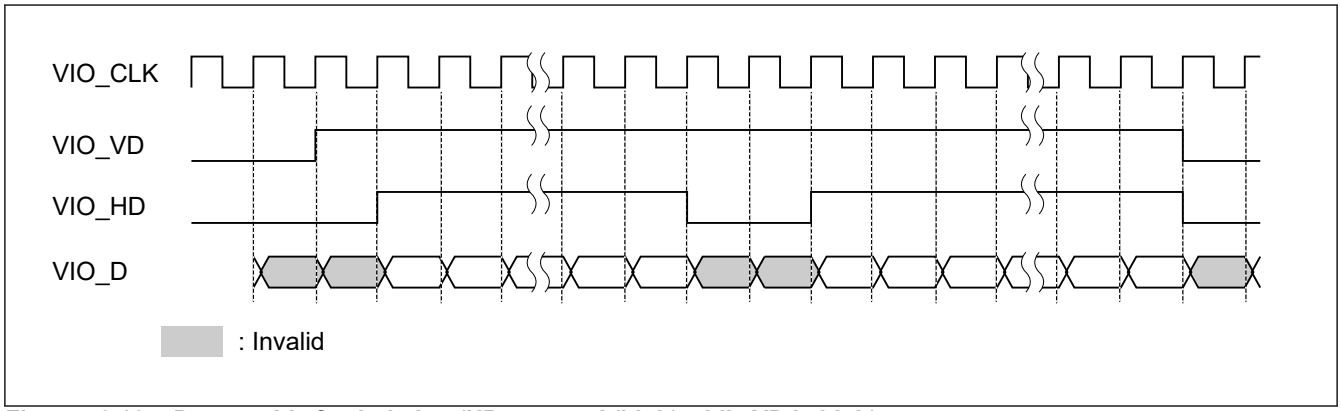

Figure 53.12 Data enable fetch timing (HD asserted (high) while VD is high)

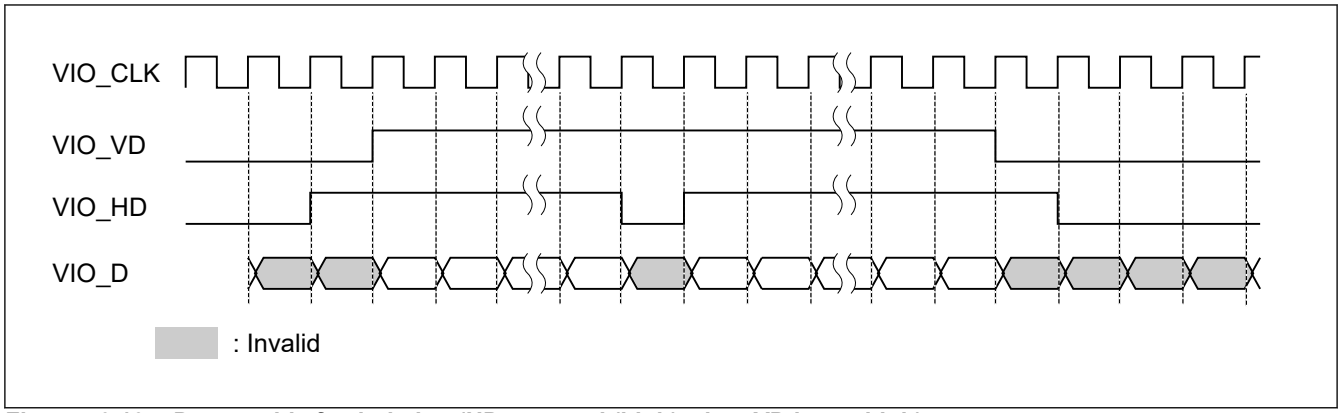

Figure 53.13 Data enable fetch timing (HD asserted (high) when VD is not high)

In data enable fetch mode, this module generates a VD interrupt in response to detection of the active level of VD. In image capture mode and data synchronous fetch mode, this module generates a VD interrupt in response to the first detection of the active level of HD following detection of the active level of VD. Note that, when VD and HD are asserted and detected at the same time, this module generates a VD interrupt at that time.

Figure 53.14 to Figure 53.16 show the relationships between the VIO_VD signal and the VD interrupt, the VIO_VD and VIO_HD signals and the VD interrupt, and the VIO_HD signal and the HD interrupt.

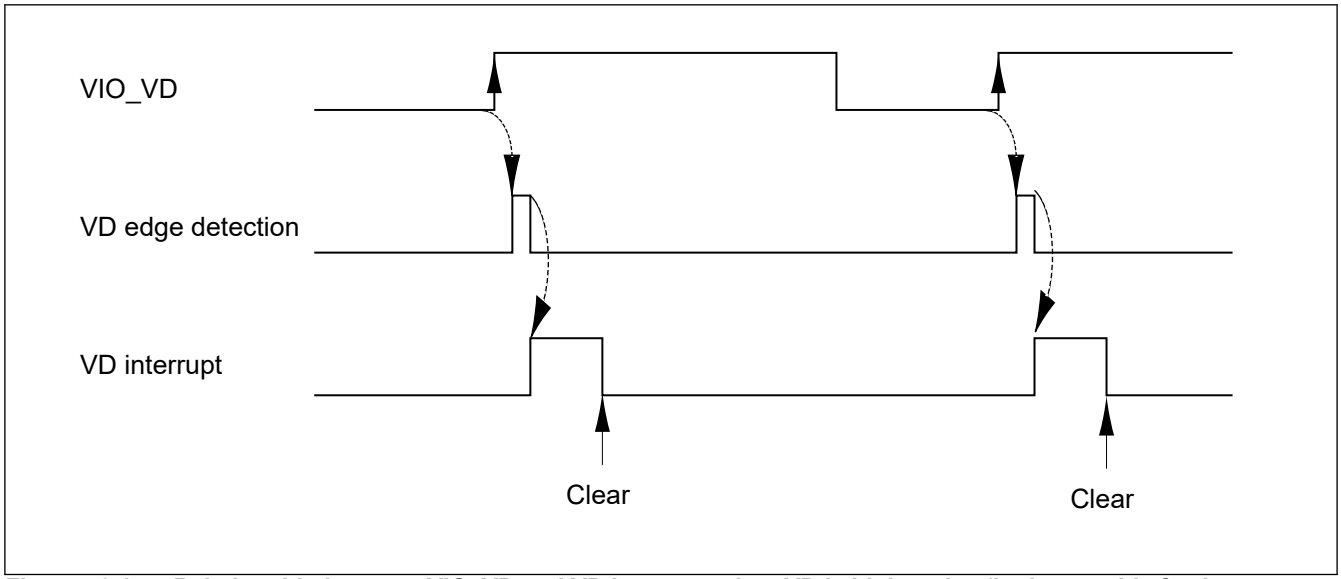

Figure 53.14 Relationship between VIO_VD and VD interrupt when VD is high-active (in data enable fetch mode)

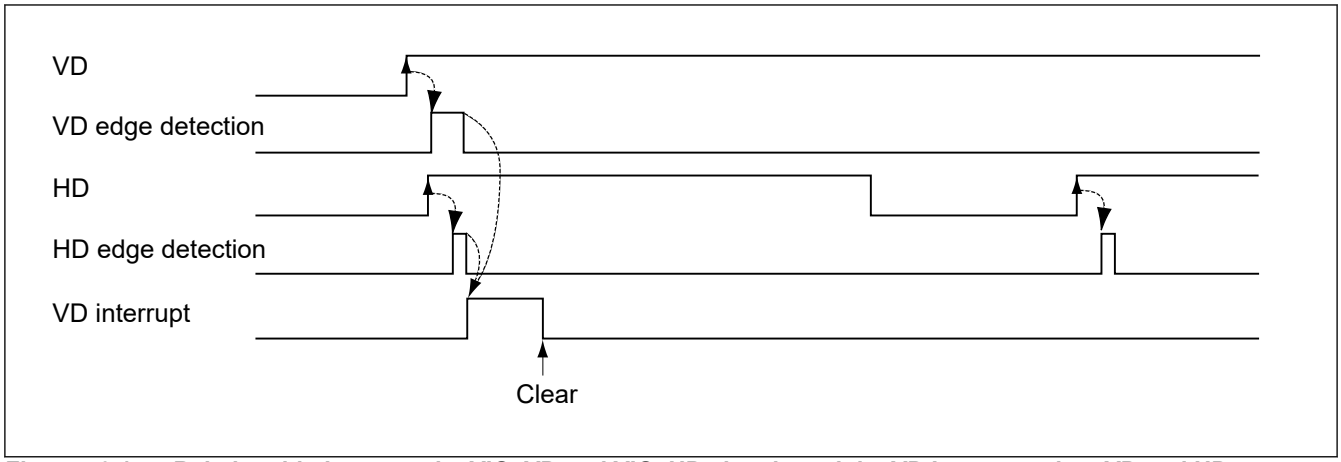

Figure 53.15 Relationship between the VIO_VD and VIO_HD signals and the VD Interrupt when VD and HD are high-active (in Image capture mode or data synchronous fetch mode)

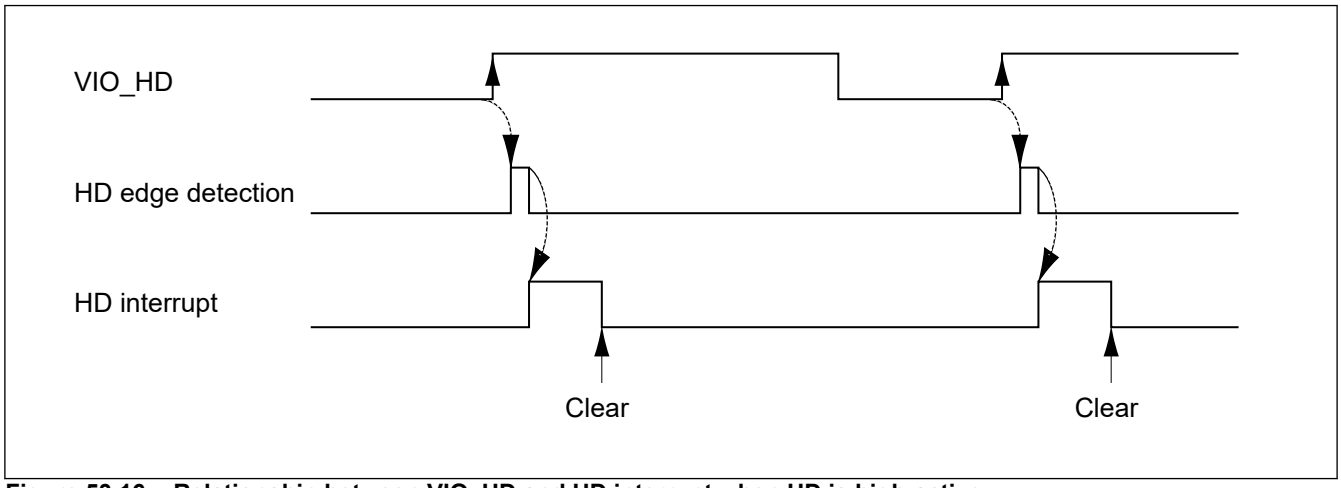

Figure 53.16 Relationship between VIO_HD and HD interrupt when HD is high-active

53.2.4 CMCYR : Capture Interface Cycle Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x000C

Bit position:	31	29														16		13													0
Bit field:	—	—	VCYL[13:0]														—	—	HCYL[13:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
13:0	HCYL[13:0]	Horizontal Cycle Count of External Module These bits set the number of HD cycles of an external module. The interrupt source bit IGHS in CETCR is set to 1 when the actual number of HD cycles input from the external module differs from this setting. Set these bits for detecting an illegal HD. When these bits are all cleared to 0, the interrupt source bit IGHS in CETCR is not set to 1. Though the interrupt source bit IGHS in CETCR may be set to 1 after the HDPOL bit (HD polarity) in CAMCR is changed, this interrupt should be ignored.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
29:16	VCYL[13:0]	Vertical HD Count of External Module These bits set the number of VD cycles of an external module with the number of HD inputs. The interrupt source bit IGVS in CETCR is set to 1 when the actual number of VD cycles input from the external module differs from this setting. Set these bits for detecting an illegal VD. When these bits are all cleared to 0, the interrupt source bit IGVS in CETCR is not set to 1. Though the interrupt source bit IGVS in CETCR may be set to 1 after the VDPOL bit (VD polarity) in CAMCR is changed, this interrupt should be ignored.	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CMCYR is used to detect an illegal VD and an illegal HD. For HD, the number of cycles from a rising edge of HD to the next rising edge is set (falling edges when low-active is selected for HD). For VD, the number of HD inputs from a rising edge of VD to the next rising edge is set (falling edges when low-active is selected for VD).

Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to 1.

Set 0 in all bits of this register, during data enable fetch mode.

Note: After changing the setting of this register, do not start capture until at least 10 external input clock cycles have elapsed.

53.2.5 CAMOR, CAMOR_x : Capture Interface Offset Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0010 (CAMOR)
0x1010 (CAMOR_B)
0x2010 (CAMOR_M)

Bit position:	31															27														16			12																				0
Bit field:	—				—				VOFST[11:0]																—				HOFST[12:0]																								
Value after reset:	0				0				0																0				0																								

Bit	Symbol	Function	R/W
12:0	HOFST[12:0]	Specify the capture start location in terms of the number of clock cycles from a horizontal sync signal (1-cycle units). The blanking period from a horizontal sync signal differs among external modules. Therefore, the horizontal capture start location must be specified by these bits in terms of external input clock cycles from a horizontal sync signal so that an image can be captured from the valid image area. This is similar in data synchronous fetch mode (see Figure 53.19). Some external modules output a horizontal sync signal as a data enable signal. In this case, there is no blanking period so these bits must be cleared to 0 (see Figure 53.20). Note: The first HD (horizontal sync signal) being input simultaneously or after the first VD (vertical sync signal) is the operating condition of the CEU. These inputs are affected by the polarities (set by the VDPOL and HDPOL bits in CAMCR).	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
27:16	VOFST[11:0]	Specify the capture start location in terms of the HD count from a vertical sync signal (1-HD units). The blanking period from a vertical sync signal differs among external modules. Therefore, the vertical capture start location must be specified by these bits in terms of the HD count from a vertical sync signal so that an image can be captured from the valid image area (see Figure 53.17). Some external modules output a vertical sync signal as a data enable signal. In this case, there is no blanking period so these bits must be cleared to 0 (see Figure 53.18).	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CAMOR sets the location to start capturing when capturing images.

Since the number of HD (horizontal sync signal) inputs from a VD (vertical sync signal) input to the start of a valid image period, and the number of clock cycles from an HD input to the start of a valid image period differ among external modules, these must be set in CAMOR. By setting a value greater than the valid image area, part of the image can be clipped for capture. In data synchronous fetch mode, the setting of this register becomes the number of cycles (HD count) up to the start of a valid data period.

This register is not used, during data enable fetch mode.

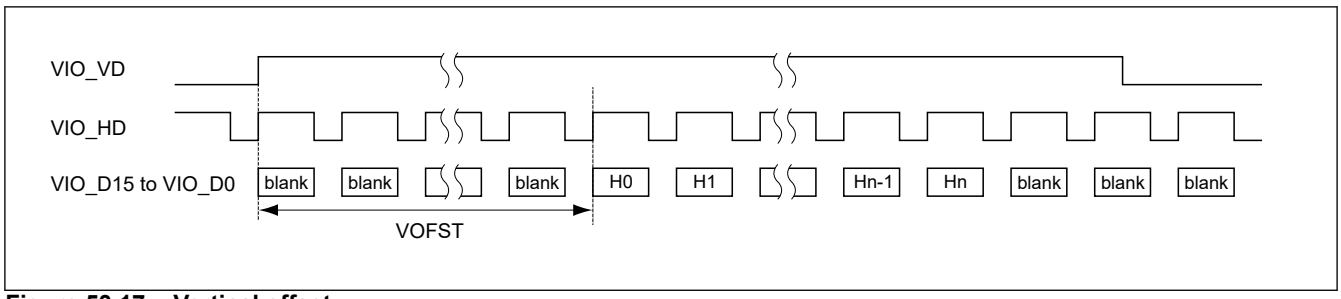

Figure 53.17 Vertical offset

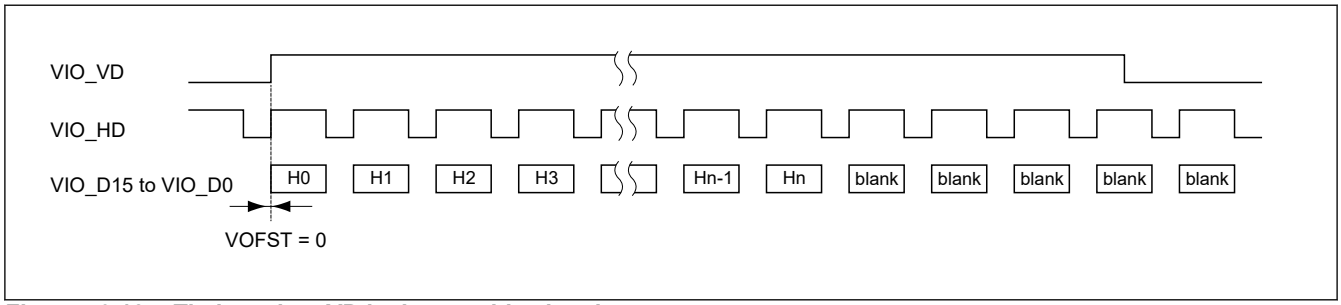

Figure 53.18 Timing when VD is data enable signal

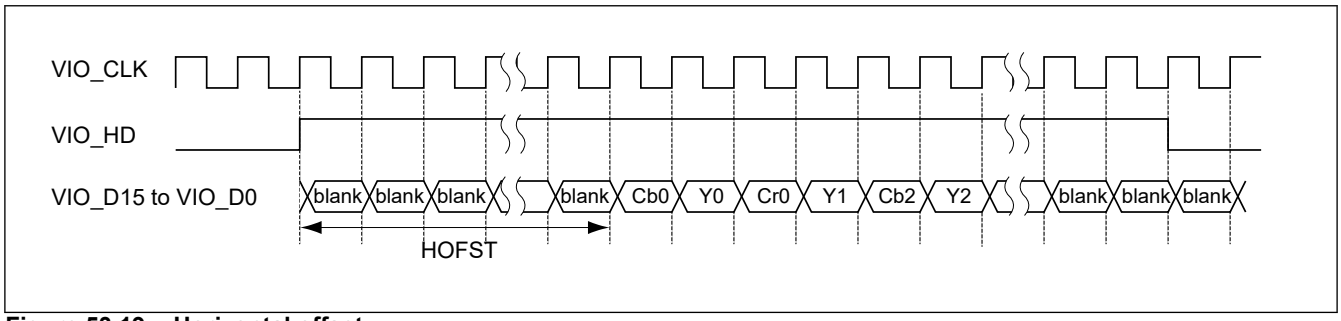

Figure 53.19 Horizontal offset

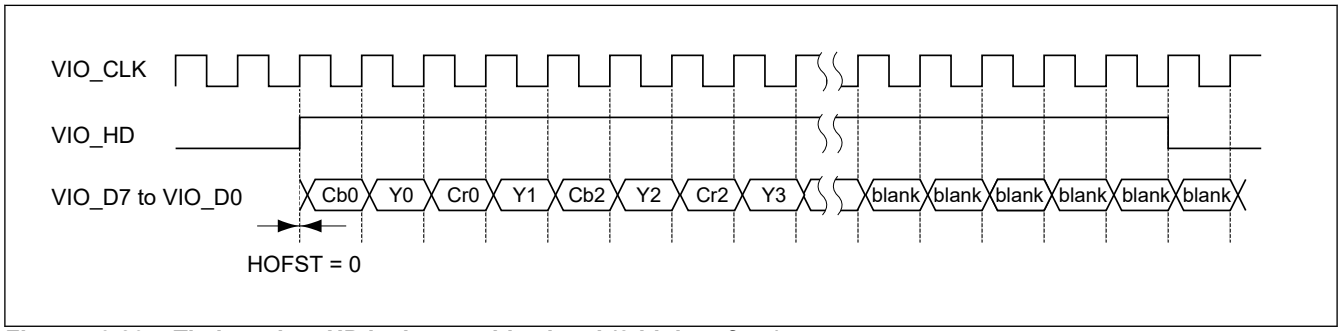

Figure 53.20 Timing when HD is data enable signal (8-bit interface)

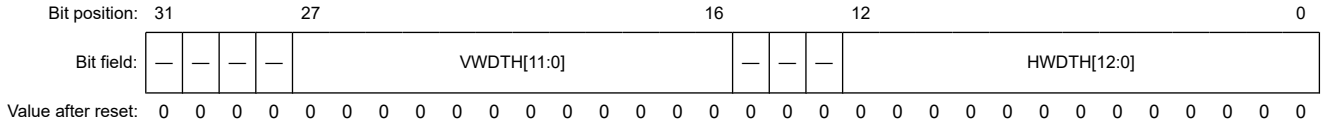
53.2.6 CAPWR, CAPWR_x : Capture Interface Width Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0014 (CAPWR)
0x1014 (CAPWR_B)
0x2014 (CAPWR_M)



Bit	Symbol	Function	R/W
12:0	HWDTH[12:0]	Specify the horizontal capture period. Specify the number of cycles to be captured from the location specified by the HOFST bits. Figure 53.22 shows the timing when the horizontal blanking period is 0. The CEU captures for only the number of cycles specified by these bits in the horizontal direction. Make a similar setting for data synchronous fetch. The maximum value to be set is as follows: ● 8-bit interface Image capture (16-cycle units) : 5,120 cycles (2,560 pixels) Data synchronous fetch (8-cycle units) : 2,560 cycles (2,560 bytes) ● 16-bit interface Image capture (8-cycle units) : 2,560 cycles (2,560 pixels) Data synchronous fetch (4-cycle units) : 1,280 cycles (2,560 bytes) The lower 2 bits should be written 0. Note: In data synchronous fetch mode, set CFSZR and CDWDR according to the values set in this register. For details, see the descriptions on CFSZR and CDWDR.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
27:16	VWDTH[11:0]	Specify the vertical capture period (4-HD units). Specify the number of lines (HD count) to be captured from the location specified by the VOFST bits in CAMOR. Figure 53.21 shows the timing when the vertical blanking period is 0. The CEU captures only the number of lines (HD count) specified by these bits in the vertical direction. Make a setting in the same way to obtain data synchronization. The maximum value to be set is 1,920 HD (5 megapixels). The value of writing are ignored on the lower 2 bits, so write 0 to the lower 2 bits.	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CAPWR sets the fetch (capture) cycle width when capturing images.

The cycle width unit differs according to the interface and the data type to be captured. For each setting unit, see Table 53.6.

This register is not used, during data enable fetch mode.

Table 53.6 Unit for setting fetch (capture) cycle width

	Vertical Direction		Horizontal Direction	
Interface	Image Capture	Data Synchronous Fetch	Image Capture	Data Synchronous Fetch
8-bit interface	4 HD	4 HD	16 cycles	8 cycles
16-bit interface	4 HD	4 HD	8 cycles	4 cycles

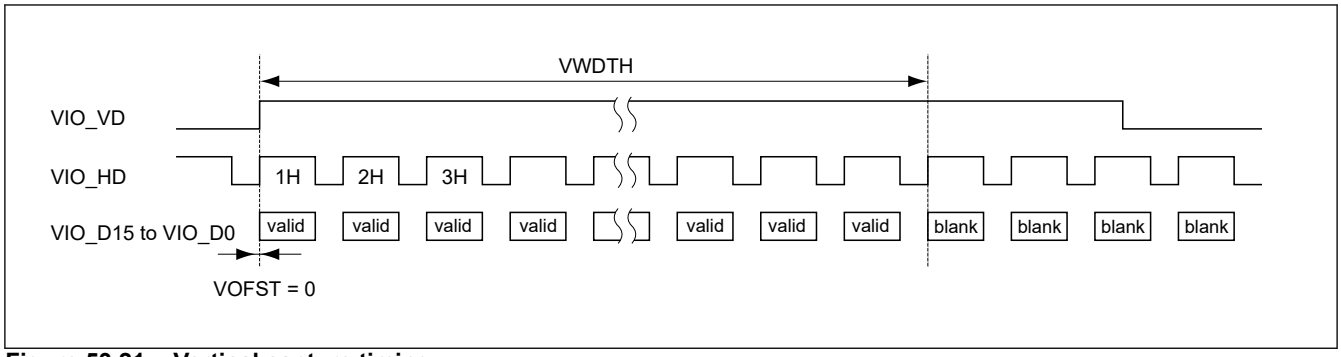


Figure 53.21 Vertical capture timing

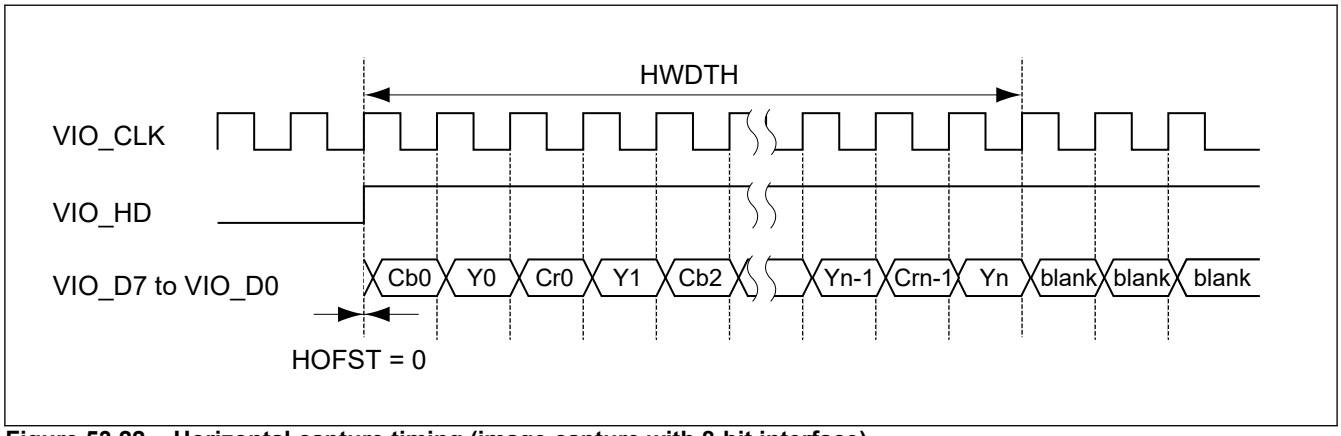

Figure 53.22 Horizontal capture timing (image capture with 8-bit interface)

53.2.7 CAIFR : Capture Interface Input Format Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0018

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	IFS	—	—	—	CIM	—	—	FCI[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	FCI[1:0]	Set the timing to start capturing. The timing to start capturing is set by specifying the image to be captured first. Set these bits to 00 when the input mode is progressive. 0 0: Capture starts from the VD input immediately after the CEU activation regardless of it being a top or bottom field 0 1: After the CEU activation, input of a top-field image is waited, and then capture starts from the top field 1 0: After the CEU activation, input of a bottom-field image is waited, and then capture starts from the bottom field 1 1: Setting prohibited	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
4	CIM	Sets the images to be captured. Clear this bit to 0 when the input mode for image capture is progressive (frame image) or when the input mode for image capture is interlace for continuous capture of both the top and bottom fields. Set this bit to 1 when the input mode for image capture is interlace for capture of only a one-field image. 0: Capture of frame image (1 VD) or both-field image (2 VD) 1: Capture of one-field image (1 VD)	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	IFS	Sets the input mode for capturing images. 0: Progressive 1: Interlace	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CAIFR sets the input mode (progressive or interlace) for capturing images, the images to be captured (frame, both-field, or one-field), the image from which capturing starts (top field or bottom field), etc. CAIFR is not used in data fetch mode.

Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to 1.

The items set by CAIFR are listed in Table 53.7.

Table 53.7 CAIFR Setting Items

Input Mode	IFS Bit	Captured Image	CIM Bit	Image to Start Capture	FCI Bits
Progressive	0	Frame	0	Frame immediately after activation	00
Interlace	1	Both-field (2-VD capture)	0	Field immediately after activation	00
				Top field	01
				Bottom field	10
				Setting prohibited	11
		One-field (1-VD capture)	1	Field immediately after activation	00
				Top field	01
				Bottom field	10
				Setting prohibited	11

In frame image capture and one-field image capture, a one-frame capture end interrupt occurs when capture for 1 VD finishes. In both-field image capture, a one-field capture end interrupt occurs when capture for 1 VD finishes and a oneframe capture end interrupt occurs when capture for 2 VD finishes. At this time, a one-field capture end interrupt occurs simultaneously with a one-frame capture end interrupt. Figure 53.23 shows the timing of a one-frame capture end interrupt and one-field capture end interrupt in both-field image capture.

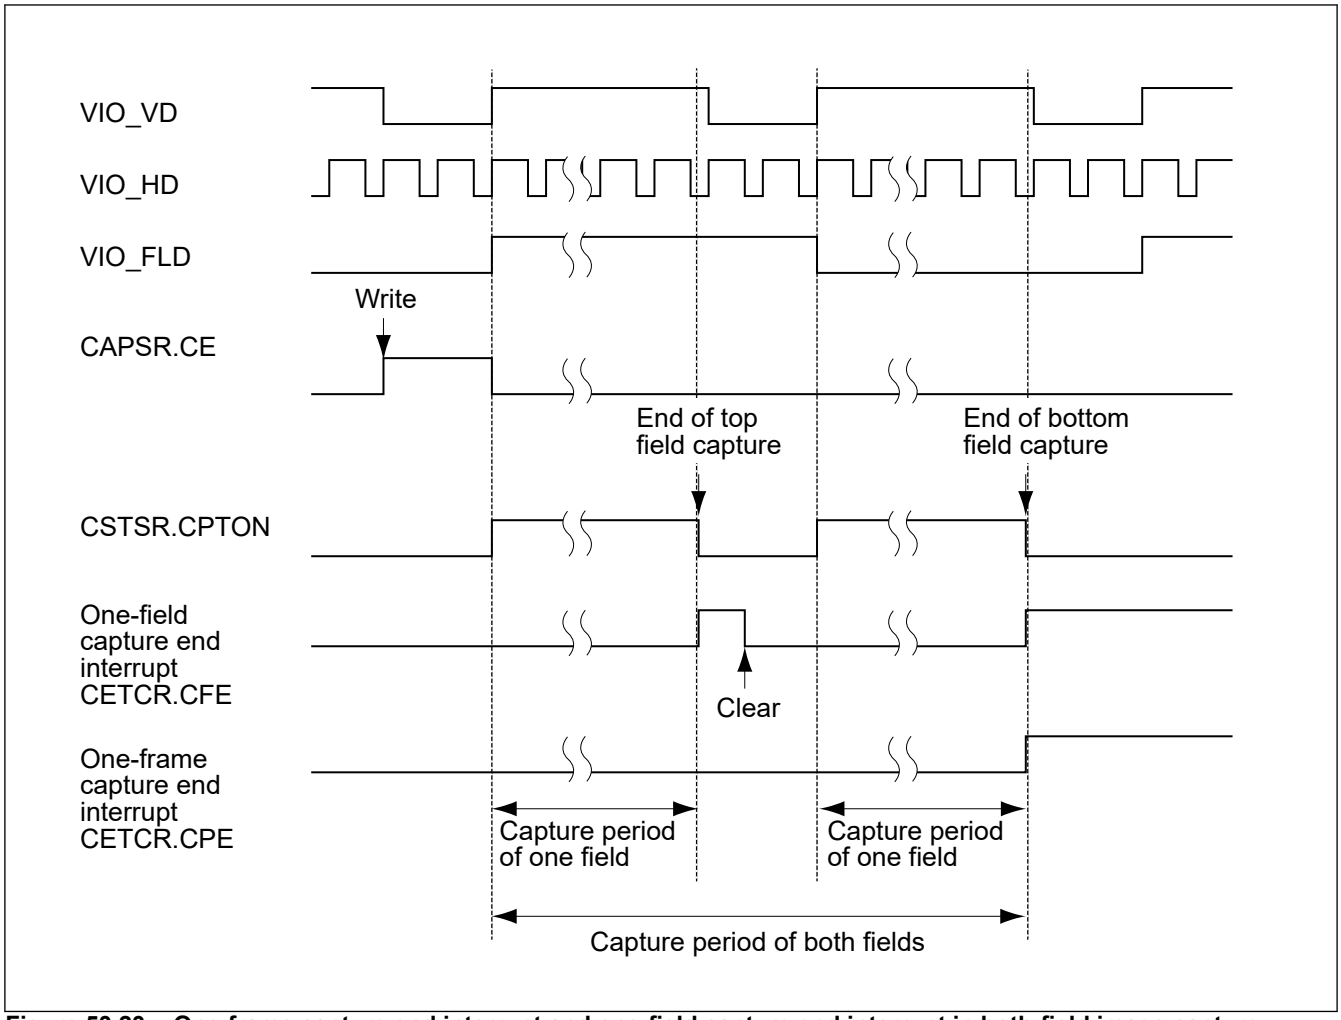

Figure 53.23 One-frame capture end interrupt and one-field capture end interrupt in both-field image capture

A captured frame image or captured one-field image is stored in the memory from the addresses set in CDAYR and CDACR (Figure 53.24). Captured both-field images are stored in different memory areas depending on whether it is a top-field or bottom-field image. A top-field image is stored in the memory from the addresses set in CDAYR and CDACR whereas a bottom-field image is stored in the memory from the addresses set in CDBYR and CDBCR (Figure 53.25).

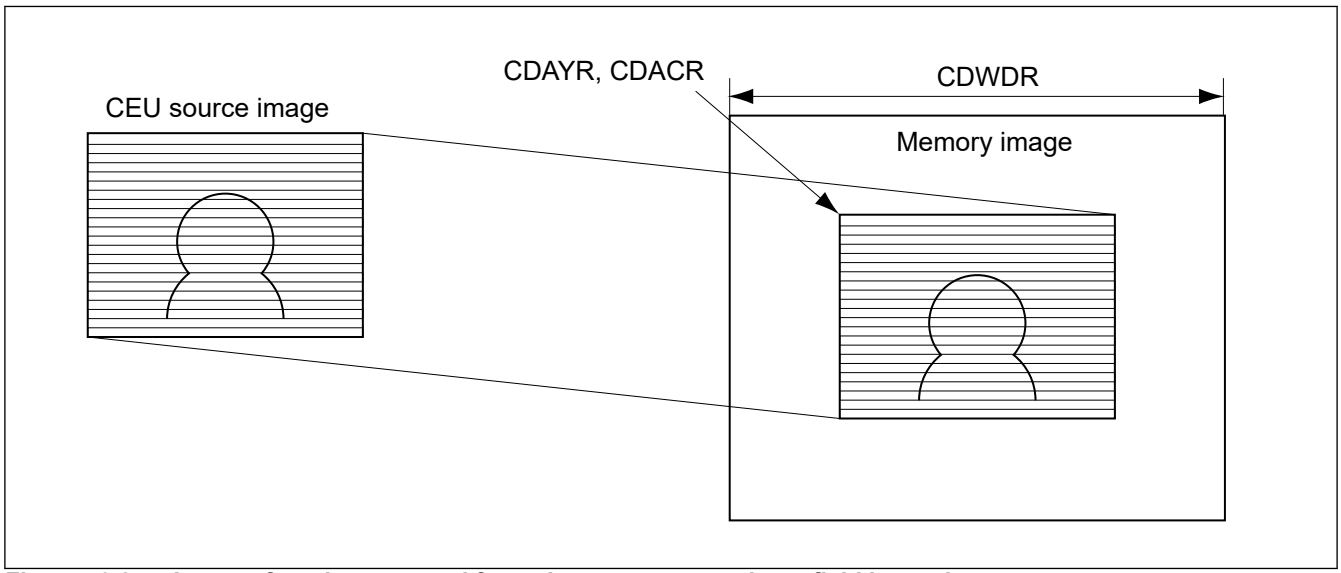

Figure 53.24 Image of storing captured frame image or captured one-field image in memory

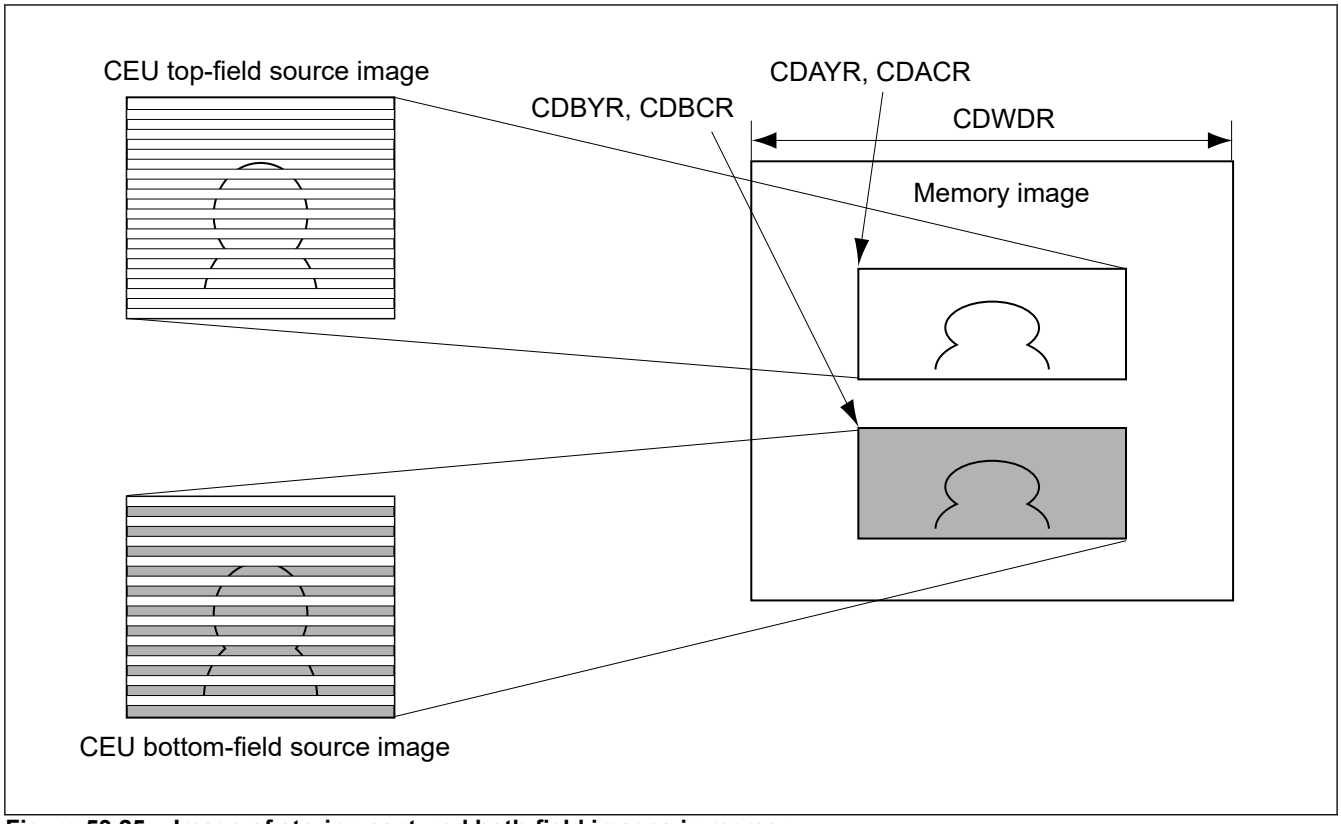

Figure 53.25 Image of storing captured both-field images in memory

If the FCI bits are set to 00b for continuous capture in interlace input mode, images are continuously captured for 2 VD with the first captured field as the reference in both-field image capture (Figure 53.26). In one-field image capture, only the first captured field is continuously captured for 1 VD (Figure 53.27).

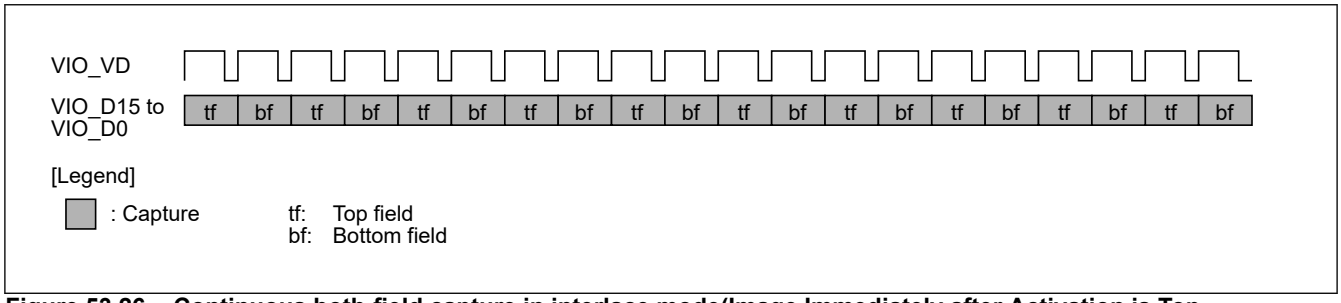

Figure 53.26 Continuous both-field capture in interlace mode(Image Immediately after Activation is Top Field (FCI[1:0] = 00b))

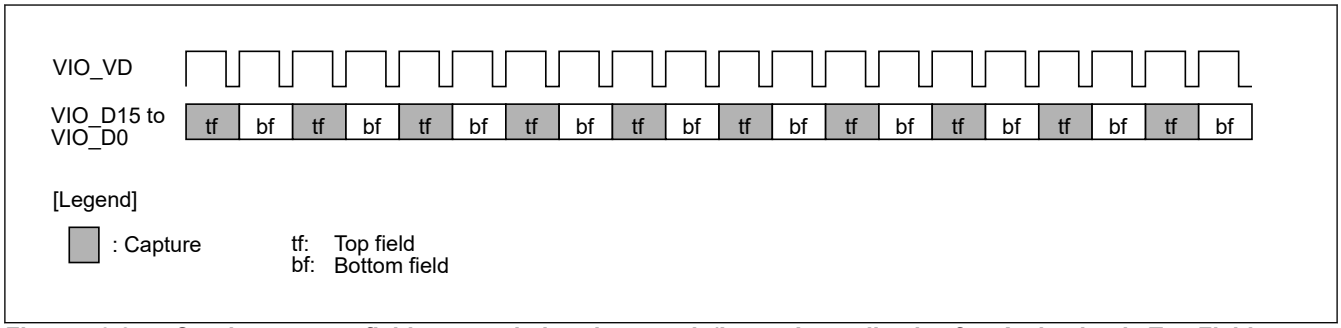

Figure 53.27 Continuous one-field capture in interlace mode(Image Immediately after Activation is Top Field (FCI[1:0] = 00b))

(1) Storage of Interlace Input as Frame Image

The CEU can store an interlace source image in the memory as a frame image. To store an interlace source image as a frame image, make the following register settings:

Input mode: Interlace (IFS = 1)

Capture image: Both-field (CIM = 0)

Image to start capture: Any setting other than the prohibited setting (FCI[1:0] = as desired)

Figure 53.28 shows a memory image of capturing both fields of an interlace input and storing it as a frame image in the memory. Set the start addresses of the memory destination for the captured top-field image in CDAYR and CDACR, and the start addresses of the memory destination for the captured bottom-field image in CDBYR and CDBCR. When storing an interlace image as a frame image in the memory, set the horizontal image size of the memory area in CDWDR with the top-field image and bottom-field image placed next to each other as shown in Figure 53.28. In addition, set the number of captured lines of the field image in the VWDTH bits in CAPWR.

A memory image of folding the horizontal image size of the memory area in Figure 53.28 at CDWDR/2 is shown in Figure 53.29. Setting the registers to form the image in Figure 53.28 enables an interlace image to be stored as a frame image in the memory as shown in Figure 53.29.

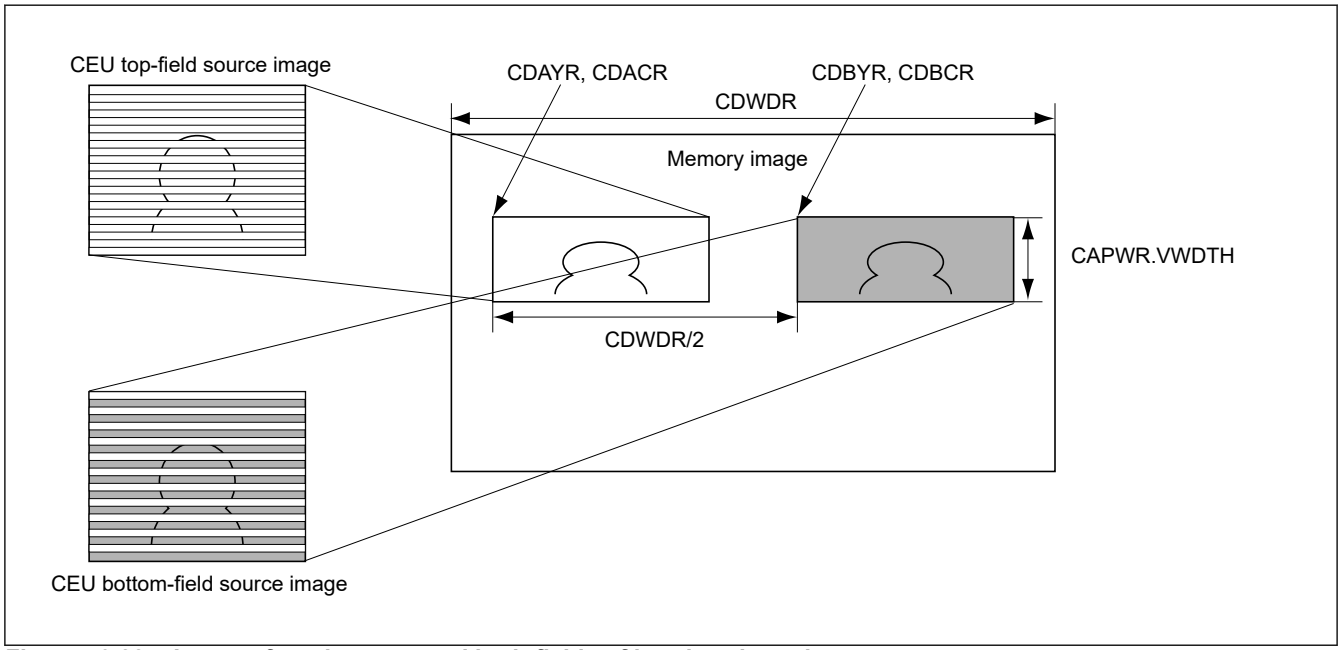

Figure 53.28 Image of storing captured both-fields of interlace input in memory

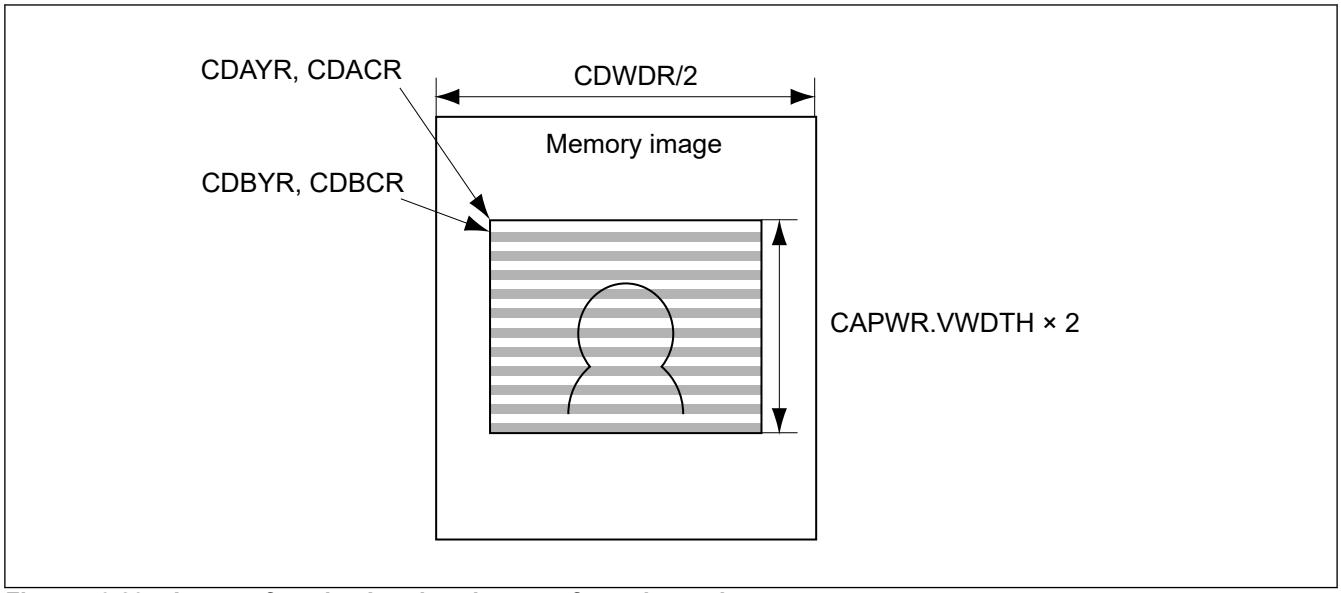

Figure 53.29 Image of storing Interlace input as frame image in memory

53.2.8 CRCNTR : CEU Register Control Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0028

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	RVS	—	—	RS	RC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RC	Specifies switching of the register plane used by the CEU in synchronization with VD. If the register plane is not switched, the register plane specified by the RS bit is used. 0: Uses the specified register plane in synchronization with VD 1: Switches the register plane in synchronization with VD	R/W
1	RS	Specifies which register plane is used by the CEU in synchronization with VD. The setting of this bit is valid only when RC = 0. 0: Uses plane A of the register 1: Uses plane B of the register	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	RVS	Sets the timing to switch the register plane in both-field capture. The setting of this bit is valid only when RC = 1 in both-field capture. 0: Switches the register plane every 2 VD 1: Switches the register plane every 1 VD	R/W
31:5	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CRCNTR controls switching of the planes of registers with a 2-plane configuration.

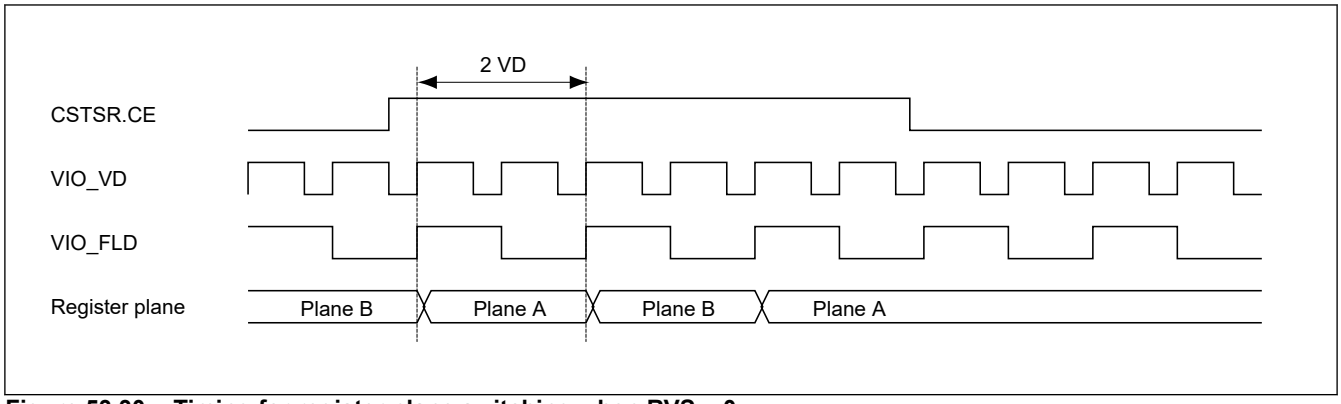

Figure 53.30 Timing for register plane switching when RVS = 0

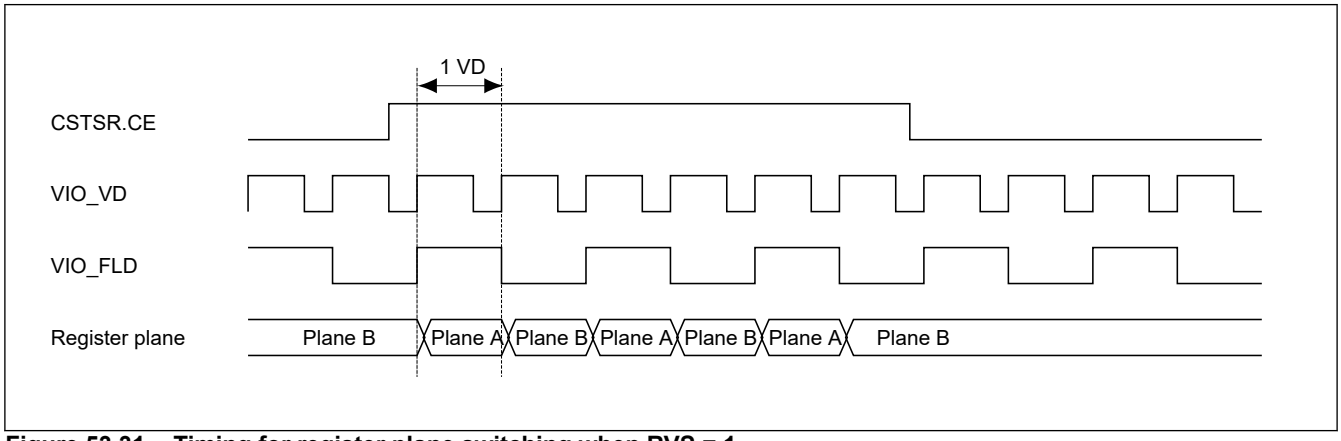

Figure 53.31 Timing for register plane switching when RVS = 1

53.2.9 CRCMPR : CEU Register Forcible Control Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x002C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RA	Indicates the register plane currently specified. This register value automatically changes in synchronization with VD for starting capture. To start capture with plane A of the register when a setting to switch the register plane in synchronization with VD has been made (CRCNTR.RC = 1), specify plane B of the register using this bit. 0: Specifies plane A of the register 1: Specifies plane B of the register	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CRCMPR forcibly controls switching of the planes of registers with a 2-plane configuration. Setting this register enables direct control of register plane switching.

Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to 1.

53.2.10 CFLCR, CFLCR_x : Capture Filter Control Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0030 (CFLCR)
0x1030 (CFLCR_B)
0x2030 (CFLCR_M)

Bit position:	31 28	27 16	15 12	11 0
Bit field:	VMANT[3:0]	VFRAC[11:0]	HMANT[3:0]	HFRAC[11:0]
Value after reset:	0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
11:0	HFRAC[11:0]	Fraction Part of Horizontal Scale-Down Factor The specifiable range is 0x000 to 0xFF8. The fraction of the scale-down factor that cannot be set with only the HMANT bits must be specified with these bits. The value of writing are ignored on the lower 3 bits, so write 0 to the lower 3 bits.	R/W
15:12	HMANT[3:0]	Mantissa Part of Horizontal Scale-Down Factor The specifiable range is 0x0 to 0xF. When 0x0 is set for the HMANT bits and 0x000 is set for the HFRAC bits, the scale-down filter is not used.	R/W
27:16	VFRAC[11:0]	Fraction Part of Vertical Scale-Down Factor The specifiable range is 0x000 to 0xFF8. The fraction of the scale-down factor that cannot be set with only the VMANT bits must be set with these bits. The value of writing are ignored on the lower 3 bits, so write 0 to the lower 3 bits.	R/W
31:28	VMANT[3:0]	Mantissa Part of Vertical Scale-Down Factor The specifiable range is 0x0 to 0xF. When 0x0 is set for the VMANT bits and 0x000 is set for the VFRAC bits, the scale-down filter is not used.	R/W

Note: S-TYPE-3, P-TYPE-3

CFLCR sets the scale-down factor for the filter to scale images down.

The CEU has an image scale-down filter which can be used to scale down the captured images before storing them in the memory. Set CFLCR to 0 when not performing scale-down (same size output). If a value other than 0 is set in CFLCR, scale-down is performed. In data fetch mode, set CFLCR to 0.

When handling an interlace source image as a frame image, set CFLCR to 0 not to use the filter.

An image scale-down filter is installed in the CEU, and the captured images can be scaled down and stored in the memory.

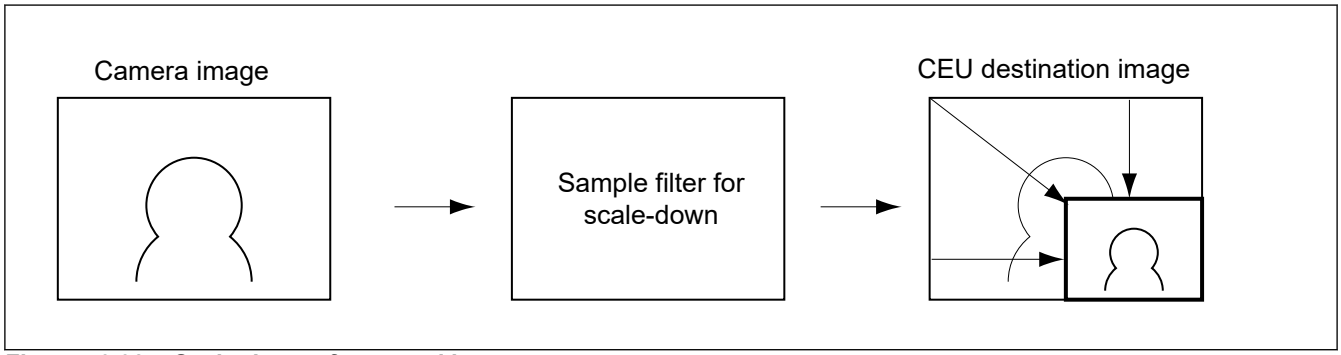

Figure 53.32 Scale-down of captured image

The formulas for obtaining the MANT (VMANT or HMANT) and FRAC (VFRAC or HFRAC) values from the input pixel count and output pixel count of the filter are shown below. Set the MANT and FRAC bits in order to obtain the desired output pixel count from the number of pixels input to the CEU.

First, calculate preliminary MANT and FRAC values. The parameters needed for calculation are defined as follows:

$$\alpha = \mathrm{MANT} \times 4096 + \mathrm{FRAC} \quad \text{...Formula 1}$$

$$\mathrm{SCL\ (scaling\ factor)} = \frac{4096}{\alpha} \quad \text{...Formula 2}$$

Assuming an operator ⌊x⌋ which discards fractions of an integer x, the MANT and FRAC values can be temporarily set as follows, according to formula 1 and formula 2.

$$\mathrm{MANT} = \left\lfloor \frac{1}{\mathrm{SCL}} \right\rfloor, \mathrm{FRAC} = \left\lfloor 512 \times \left(\frac{1}{\mathrm{SCL}} - \mathrm{MANT} \right) \right\rfloor \times 8$$

Here, the scaled-down filter output size ($SIZE_D$) can be calculated using the input image size S_{in} (8-bit interface: half of the CAPWR setting, 16-bit interface: CAPWR setting) in the following formula.

$$\mathrm{SIZE}_D = \left\lfloor 1 + \left(\left\lfloor \frac{1}{2} + \frac{S_{\mathrm{in}} - 1}{\mathrm{MANT}_{\mathrm{pre}}} \right\rfloor - 1 \right) \times \frac{\mathrm{MANT}_{\mathrm{pre}} \times 4096}{\alpha} \right\rfloor \quad \text{...Formula 3}$$

$$\begin{bmatrix} \mathrm{MANT}_{\mathrm{pre}} = 1 \rightarrow (0 \leq \mathrm{MANT} < 2) \\ \mathrm{MANT}_{\mathrm{pre}} = 2 \rightarrow (2 \leq \mathrm{MANT} < 4) \\ \mathrm{MANT}_{\mathrm{pre}} = 4 \rightarrow (4 \leq \mathrm{MANT} < 8) \\ \mathrm{MANT}_{\mathrm{pre}} = 8 \rightarrow (8 \leq \mathrm{MANT}) \end{bmatrix}$$

The number of output pixels can be obtained by substituting the temporarily calculated MANT, FRAC, and input image size into these formulas. If the calculated number of output pixels is smaller than the number of output pixels used to obtain the preliminary MANT and FRAC values, recalculate with a smaller FRAC (α) value, and set the MANT and FRAC values in this register so that a pixel value greater than the desired number of output pixels can be obtained.

Example: Scale down 640 pixels to 480 pixels

SCL = 480/640 = 3/4, and the preliminary settings of MANT = 1, MANTpre = 1, and FRAC = 0x550 are made. Substituting these in the following formula results in an output pixel count of 479.

$$\mathrm{SIZE}_D = \left\lfloor 1 + \left(\left\lfloor \frac{1}{2} + \frac{S_{\mathrm{in}} - 1}{\mathrm{MANT}_{\mathrm{pre}}} \right\rfloor - 1 \right) \times \frac{\mathrm{MANT}_{\mathrm{pre}} \times 4096}{\alpha} \right\rfloor \quad \text{...Formula 3}$$

Since this output pixel count is smaller than the desired output pixel count of 480, the formula is recalculated with a FRAC value of 0x548, a value eight less than the previous time. The obtained result of output pixel count = 480 is equal to the desired output pixel count of 480, so this register is set as MANT = 1 and FRAC = 0x548.

Table 53.8 Setting examples for each scale-down filter factor

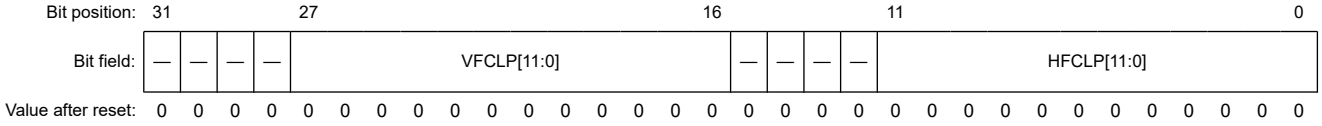
Scale-down factor	FRAC		MANT	Input pixel count	Output pixel count	Clipping size (CFSZR)
	Decimal	Hexadecimal				
7/8	576	0x240	1	640	560	560
3/4	1352	0x548	1	640	480	480
5/8	2448	0x990	1	640	400	400
1/2	0	0x0	2	640	320	320
3/8	2728	0xAA8	2	640	240	240
1/3	0.0	0x0	3	640	213	212
1/4	0.0	0x0	4	640	160	160
1/5	0.0	0x0	5	640	128	128
1/6	0.0	0x0	6	640	107	104
1/7	0.0	0x0	7	640	91	88
1/8	0.0	0x0	8	640	80	80
1/16	4088	0xFF8	15	640	40	40

Note: This scale-down filter uses a VGA-size line memory for scale-down. Therefore, when an image larger than the VGA size is input for scale-down, settings must be made so that the output image size is equal to or larger than the SubQCIF size and equal to or smaller than the VGA size. When an image is not scaled down (same size output), this restriction does not apply.

53.2.11 CFSZR, CFSZR_x : Capture Filter Size Clip Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0034 (CFSZR)
0x1034 (CFSZR_B)
0x2034 (CFSZR_M)



Bit	Symbol	Function	R/W
11:0	HFCLP[11:0]	Specify the horizontal clipping value of the filter output size (8-pixel units). The lower 3 bits should be written 0.	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
27:16	VFCLP[11:0]	Specify the vertical clipping value of the filter output size (4-pixel units). The value of writing are ignored on the lower 2 bits, so write 0 to the lower 2 bits.	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CFSZR sets the clipping size for fine adjustment of the image size output from the filter, and must be set in combination with CFLCR. When clipping the output size of the filter, set the clipping size as a number of pixels, and the setting unit should be four pixels. CFSZR must be set even when scale-down is not performed (same size output).

This register is not used, during data enable fetch mode.

In data synchronous fetch mode, set CFSZR according to the setting of CAPWR.

The scale-down filter in the CEU may output an odd number of pixels or lines depending on the settings. To adjust the output size of the filter, the CEU clips the destination image by using the number of pixels specified in CFSZR, as shown in Figure 53.33. The clipping size must be specified vertically in 4-pixel units and horizontally in 8-pixel units.

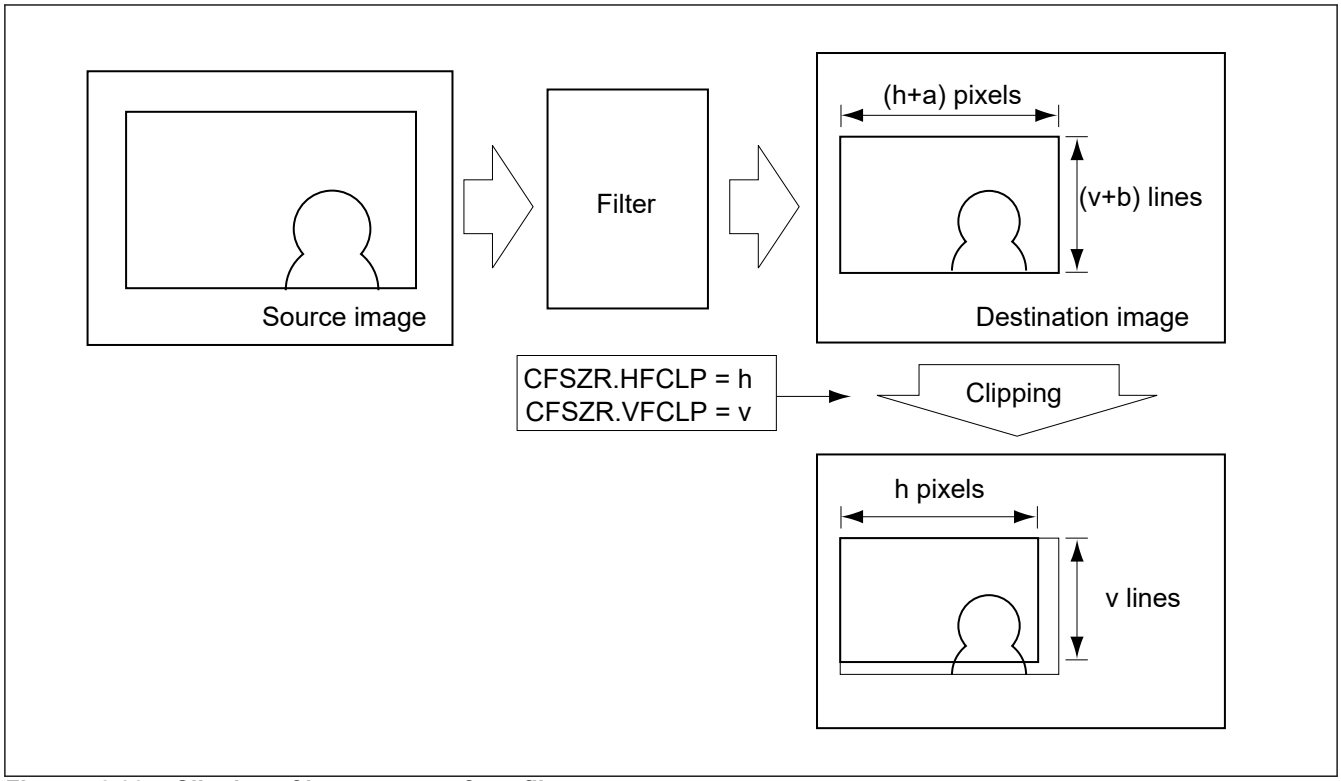


Figure 53.33 Clipping of image output from filter

The pixels to be clipped are counted from the top-left corner of a display. The pixels located to the right of the specified number of pixels or below the specified number of lines are discarded by the clipping function. If the number of pixels specified in CFSZR is larger than that output from the filter, correct operation cannot be guaranteed. To avoid this, the clipping size specified in CFSZR must be equal to or smaller than the number of pixels output from the filter.

Note: In data synchronous fetch mode, the following settings are required. Data cannot be fetched correctly unless the following settings are made.

- 8-bit interface:
  VFCLP = CAPWR.VWDTH
  HFCLP = CAPWR.HWDTH/2
- 16-bit interface:
  VFCLP = CAPWR.VWDTH
  HFCLP = CAPWR.HWDTH

53.2.12 CDWDR, CDWDR_x : Capture Destination Width Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0038 (CDWDR)
0x1038 (CDWDR_B)
0x2038 (CDWDR_M)

Bit position:	31															12														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CHDW[12:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	CHDW[12:0]	Specify the horizontal image size in the memory area where the captured image is to be stored (8-byte units). The image data captured by the CEU is stored in the memory. In data synchronous fetch mode, set as follows: 8-bit interface: CHDW = CAPWR.HWDTH 16-bit interface: CHDW = CAPWR.HWDTH × 2 The lower 3 bits should be written 0.	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDWDR sets the horizontal image size in the memory area where the captured image is to be output in 8-byte units (8-pixel units).

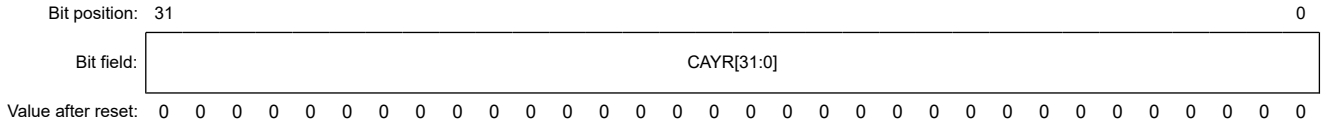
In data synchronous fetch mode, set CDWDR according to the setting of CAPWR.

This register is not used, during data enable fetch mode.

53.2.13 CDAYR, CDAYR_x : Capture Data Address Y Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x003C (CDAYR)
0x103C (CDAYR_B)
0x203C (CDAYR_M)



Bit	Symbol	Function	R/W
31:0	CAYR[31:0]	Capture Data Address Y ● Frame image capture: These bits set the address for storing the luminance component data of the captured data (8-pixel units). ● One-field image capture: These bits set the address for storing the luminance component data of the captured data (8-pixel units). ● Both-field image capture: These bits set the address for storing the luminance component data of the captured top-field data (8-pixel units). ● Data fetch: These bits set the address for storing data (8-byte units). ● Data enable fetch bundle write: These bits set the address for storing data (32-byte units). The lower 3 bits should be written 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDAYR specifies the address where the luminance component of the captured data is to be stored in frame image capture or one-field image capture, the address where the luminance component of the captured top field is to be stored in both-field image capture, and the address where the fetched data is to be stored in data fetch. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or one-field image capture, set the start address of the memory area where the luminance component of the captured data is to be stored by CDAYR. In both-field image capture, set the start address of the memory area where the luminance component of the captured top-field image is to be stored by CDAYR. In data fetch, set the start address of the memory area where data is to be stored by CDAYR.

Because the address must be specified in 32 bits, the address set by CDAYR must be in longword units.

Set the address of the starting point of the memory area where the fetched data is to be stored in this register, as shown in Figure 53.34.

- Frame image capture: Set the address of the starting point of the memory area where the luminance component of the captured image is to be stored.
- One-field image capture: Set the address of the starting point of the memory area where the luminance component of the captured image is to be stored.

- Both-field image capture: Set the address of the starting point of the memory area where the luminance component of the captured top-field image is to be stored.
- Data fetch: Set the address of the starting point of the memory area where the fetched data is to be stored. In data fetch mode, the data is simply stuffed in order from the start address so the end address becomes as follows:
  End address = CDAYR + number of fetched bytes
- Data enable fetch bundle write: Set the address in 32-byte units.

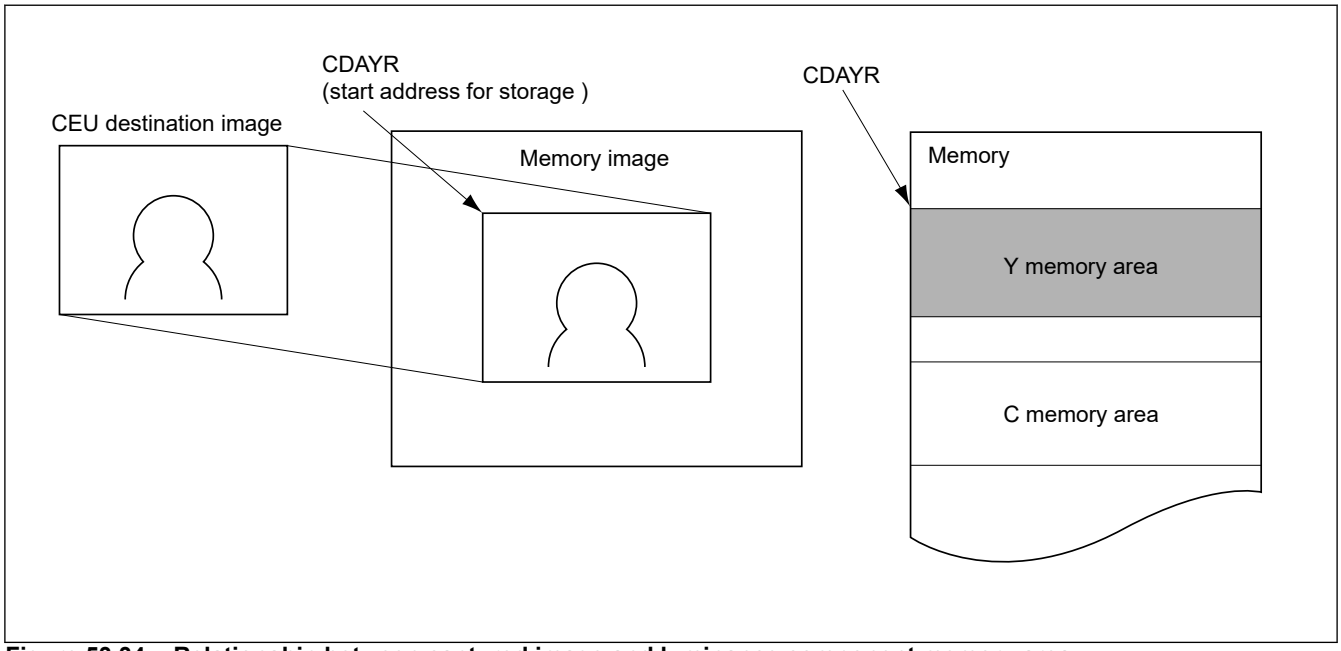


Figure 53.34 Relationship between captured image and luminance component memory area

53.2.14 CDACR, CDACR_x : Capture Data Address C Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0040 (CDACR)
0x1040 (CDACR_B)
0x2040 (CDACR_M)

Bit position:	31																														0
Bit field:	CACR[31:0]																														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CACR[31:0]	Capture Data Address C • Frame image capture: These bits set the address for storing the chrominance component data of the captured data (8-pixel units). • One-field image capture: These bits set the address for storing the chrominance component data of the captured data (8-pixel units). • Both-field image capture: These bits set the address for storing the chrominance component data of the captured top-field data (8-pixel units). The lower 3 bits should be written 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDACR specifies the address where the chrominance component of the captured data is to be stored in frame image capture or one-field image capture, and the address where the chrominance component of the captured top field is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or onefield image capture, set the start address of the memory area where the chrominance component of the captured data is to be stored by

CDACR. In both-field image capture, set the start address of the memory area where the chrominance component of the captured top-field image is to be stored by CDACR. CDACR is not used in data fetch.

Because the address must be specified in 32 bits, the address set by CDACR must be in longword units.

Set the address of the starting point of the memory area where the chrominance component of the captured image is to be stored in this register, as shown in Figure 53.35. The chrominance component has an output data format like that in Figure 53.36, and is saved in the memory in this format.

- Frame image capture: Set the address of the starting point of the memory area where the chrominance component of the captured image is to be stored.
- One-field image capture: Set the address of the starting point of the memory area where the chrominance component of the captured image is to be stored.
- Both-field image capture: Set the address of the starting point of the memory area where the chrominance component of the captured top-field image is to be stored.

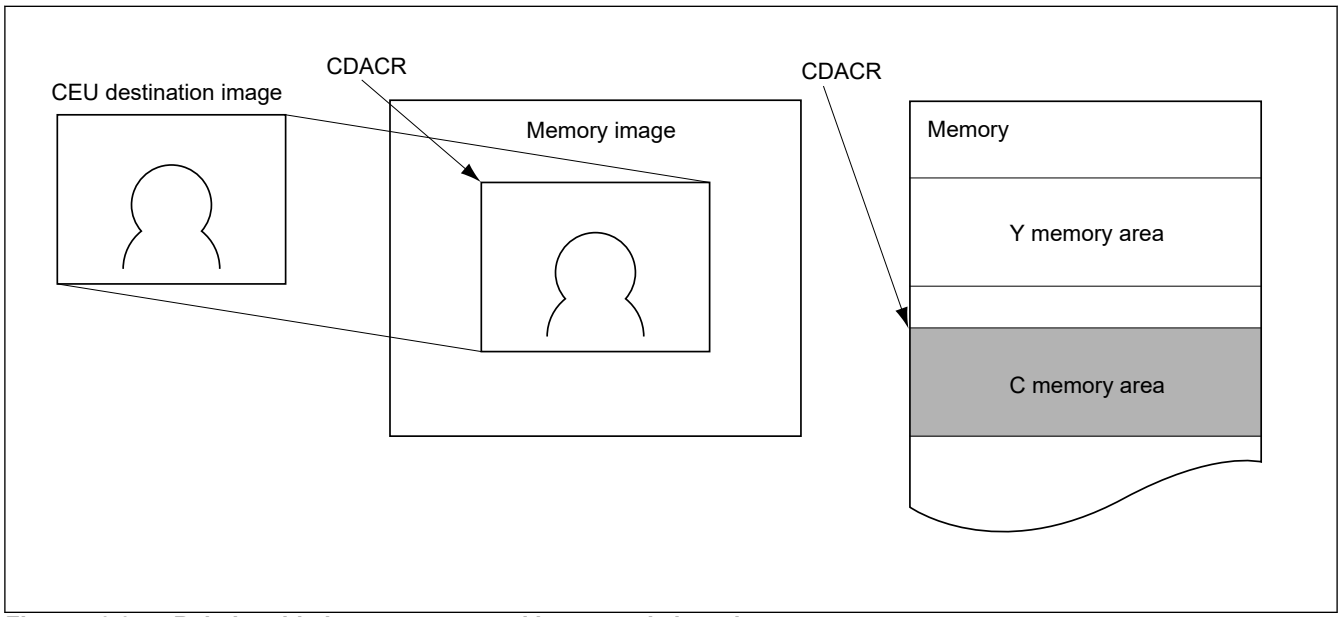

Figure 53.35 Relationship between captured image and chrominance component memory area

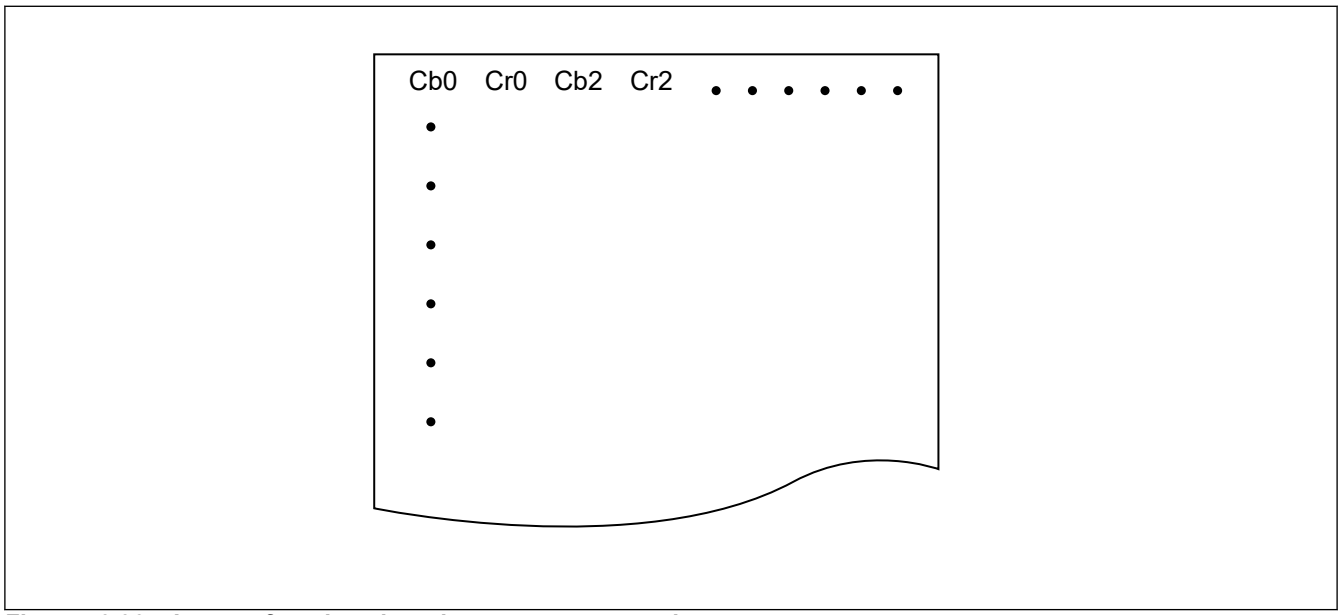

Figure 53.36 Image of storing chrominance components in memory

53.2.15 CDBYR, CDBYR_x : Capture Data Bottom-Field Address Y Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0044 (CDBYR)
0x1044 (CDBYR_B)
0x2044 (CDBYR_M)

Bit position:	31																												0
Bit field:	CBYR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CBYR[31:0]	Set the address for storing the luminance component data of the captured bottom-field data (8-pixel units). The lower 3 bits should be written 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDBYR specifies the address where the luminance component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the luminance component of the captured bottom-field image is to be stored by CDBYR. CDBYR is not used in frame image capture, one-field image capture, or data fetch.

Because the address must be specified in 32 bits, the address set by CDBYR must be in longword units.

Set the address of the starting point of the memory area where the luminance component of the captured bottom-field image is to be stored in this register, as shown in Figure 53.37.

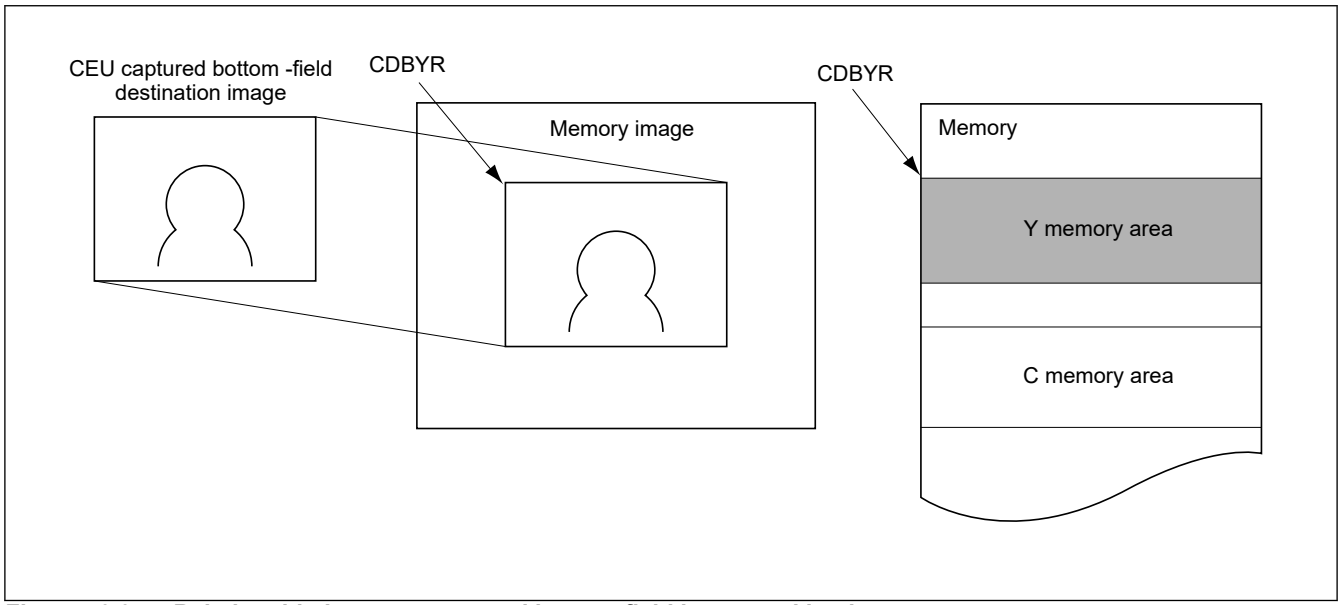

Figure 53.37 Relationship between captured bottom-field image and luminance component memory area

53.2.16 CDBCR, CDBCR_x : Capture Data Bottom-Field Address C Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0048 (CDBCR)
0x1048 (CDBCR_B)
0x2048 (CDBCR_M)

Bit position:	31																													0
Bit field:	CBCR[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CBCR[31:0]	Set the address for storing the chrominance component data of the captured bottom-field data (8-pixel units). The lower 3 bits should be written 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDBCR specifies the address where the chrominance component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the chrominance component of the captured bottom-field image is to be stored by CDBCR. CDBCR is not used in frame image capture, one-field image capture, or data fetch.

Because the address must be specified in 32 bits, the address set by CDBCR must be in longword units.

Set the address of the starting point of the memory area where the chrominance component of the captured bottom-field image is to be stored in this register, as shown in Figure 53.38. The chrominance component has an output data format like that in Figure 53.39, and is saved in the memory in this format.

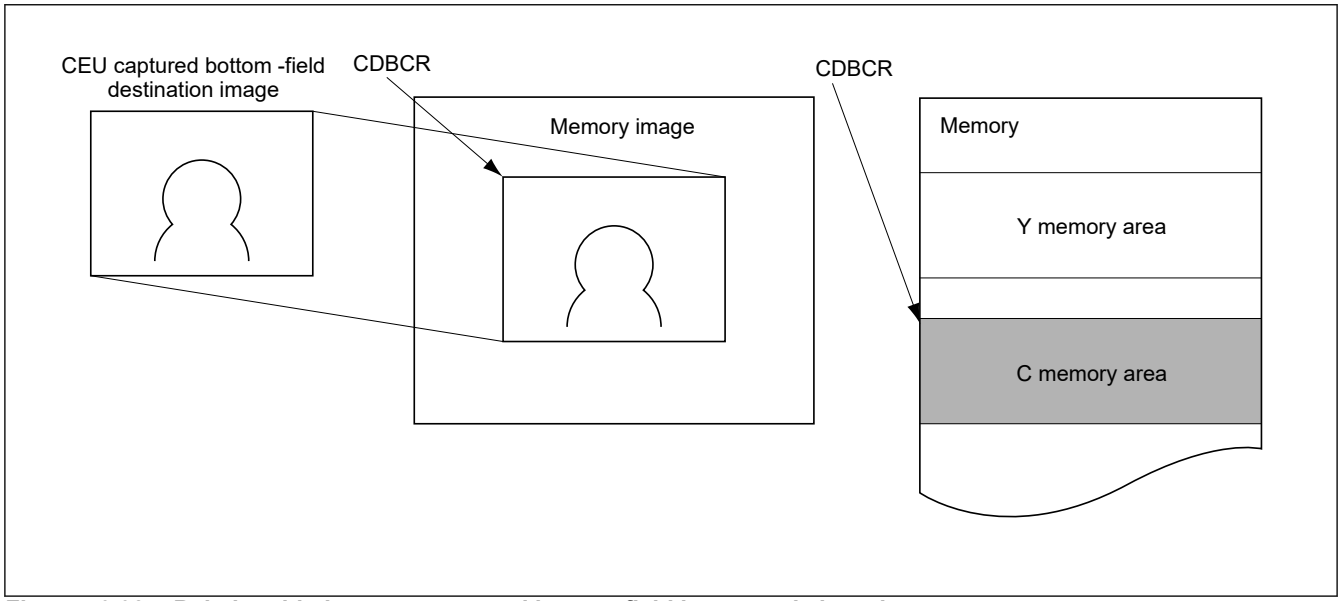

Figure 53.38 Relationship between captured bottom-field image and chrominance component memory area

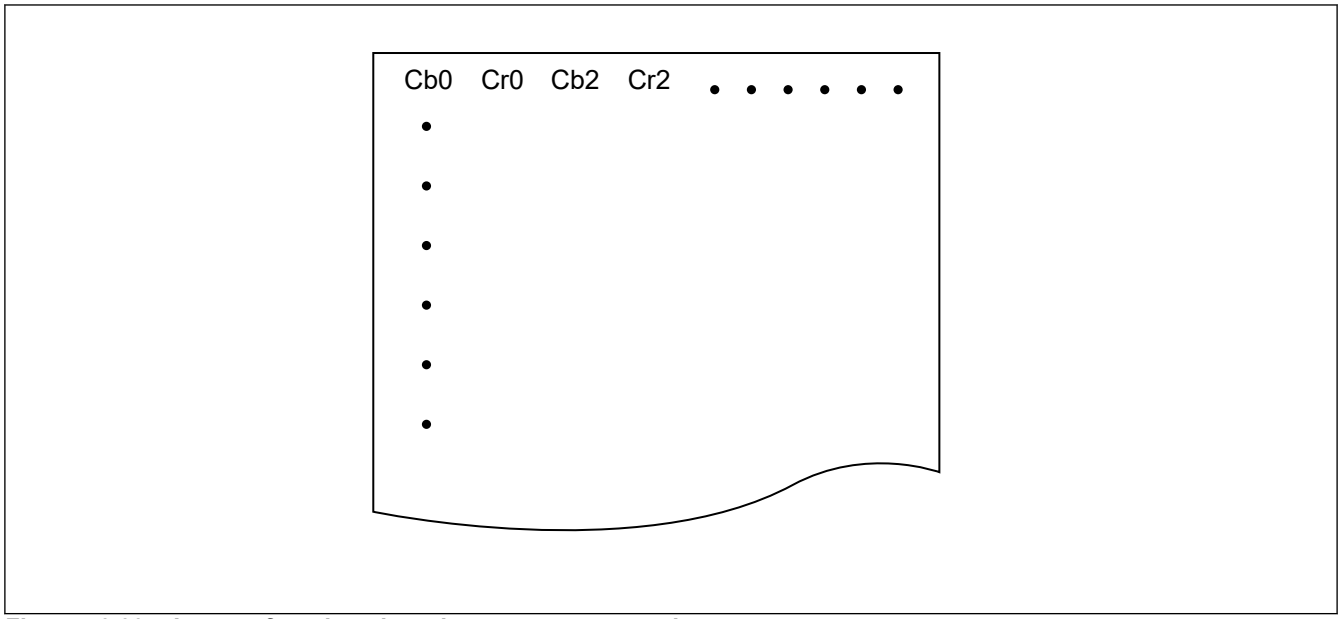

Figure 53.39 Image of storing chrominance components in memory

53.2.17 CBDSR, CBDSR_x : Capture Bundle Destination Size Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x004C (CBDSR)
0x104C (CBDSR_B)
0x204C (CBDSR_M)

Bit position:	31									22																				0
Bit field:	—	—	—	—	—	—	—	—	—	CBVS[22:0]																				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
22:0	CBVS[22:0]	Select the number of lines or number of bytes for output to the memory in a bundle write. Image capture and data synchronous fetch: Number of lines for output to the memory in a bundle write. Unit: 8 lines, min.: 8 lines, max.: 1,920 lines (0x780) Data enable fetch: Number of bytes for output to the memory in a bundle write. Unit: 32 bytes, min.: 512 bytes, max.: 6291456 bytes (0x600000) The value of writing are ignored on the lower 3 bits, so write 0 to the lower 3 bits.	R/W
31:23	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CBDSR sets the size of output to memory in a bundle write. The number of output lines should be specified for image capture or data synchronous fetch. The number of bytes should be specified for data enable fetch.

(a) Image capture and data synchronous fetch

Set the number of lines of captured data to be written to the memory by a bundle write as a multiple of eight. This register is valid only when CDOCR.CBE = 1. When CDOCR.CBE = 1 and this register cleared to 0, this module operates with the number of lines of captured data to be written to the memory as eight. The maximum number of lines that can be set is 1,920 (0x780). Only bits CBVS[11:3] are valid.

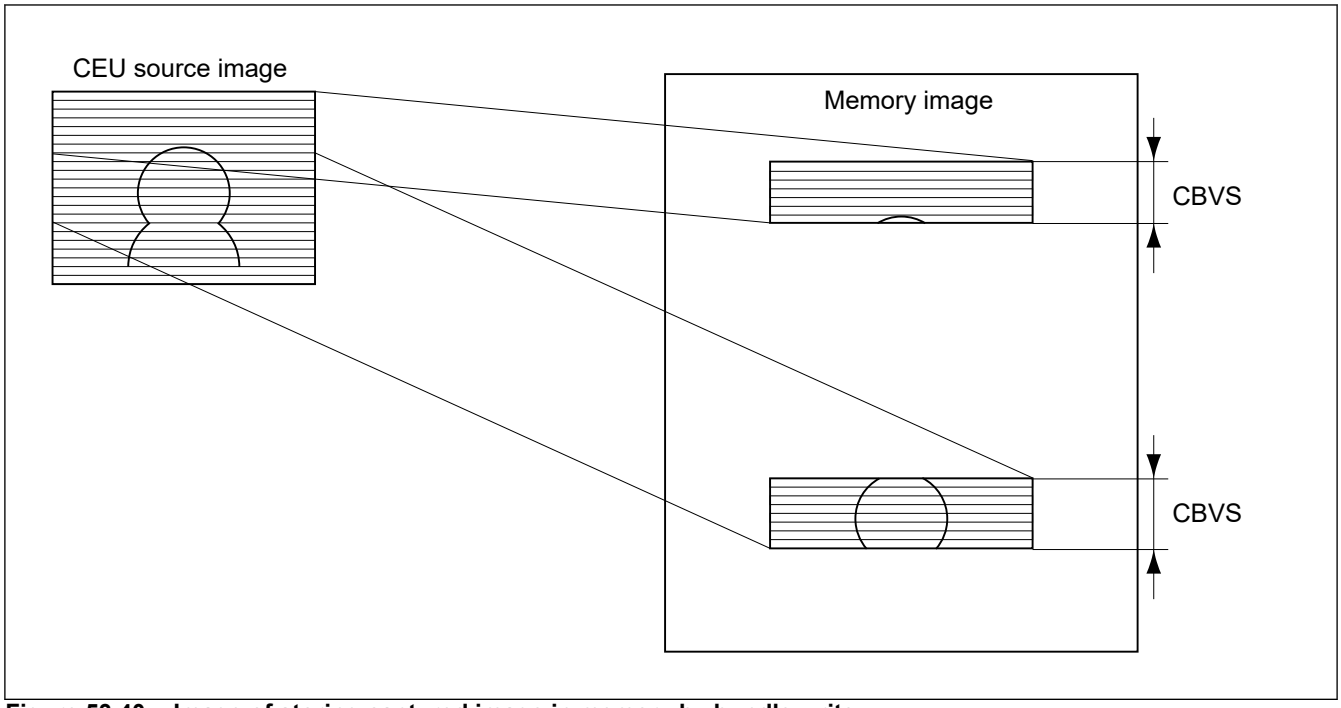

Figure 53.40 Image of storing captured image in memory by bundle write

(b) Data enable fetch

Set the number of bytes of captured data to be written to the memory by a bundle write as a multiple of 32. This register is valid only when CDOCR.CBE = 1. The minimum settable size is 512 bytes. When a number smaller than 512 bytes is specified, operation is not guaranteed.

53.2.18 CFWCR : Firewall Operation Control Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x005C

Bit position:	31																							5					0
Bit field:	FWV[26:0]																							—	—	—	—	FWE	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FWE	Firewall Operation With the setting of FWE = 1, when a write address exceeds the value set with FWV, the address is retained and an interrupt source FWF is set. After this, the address is not incremented and data is overwritten on the upper limit address. 0: Firewall is not activated. 1: Firewall is activated.	R/W
4:1	—	These bits are read as 0. The write value should be 0.	R/W
31:5	FWV[26:0]	Specify the upper limit of a write address. Specify the upper 27 bits of the 32-bit address. The upper limit of an address is FWV[26:0]<<5 + 0x1F.	R/W

Note: S-TYPE-3, P-TYPE-3

CFWCR specifies the upper limit of a write address in data enable fetch. When the VD input from an external module dose not go low and end notification is not given, this register can prevent writing to memory from being out of control.

This register is enabled only in data enable fetch.

53.2.19 CLFCR, CLFCR_x : Capture Low-Pass Filter Control Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0060 (CLFCR)
0x1060 (CLFCR_B)
0x2060 (CLFCR_M)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LPF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	LPF	Enables or disables operation of the low-pass filter. The low-pass filter removes high-frequency components from the destination image in the horizontal direction. Clear this bit to 0 in data fetch mode. 0: Low-pass filter not used 1: Low-pass filter used (only in the horizontal direction)	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CLFCR specifies whether or not to operate the low-pass filter. In data fetch mode, clear the LPF bit to 0.

The characteristic of the low-pass filter installed in the CEU causes the phase location of the image processed by the low-pass filter to be shifted right by one pixel compared to the raw image.

53.2.20 CDOCR, CDOCR_x : Capture Data Output Control Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0064 (CDOCR)
0x1064 (CDOCR_B)
0x2064 (CDOCR_M)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CBE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	CDS	—	COLS	COWS	COBS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	COBS	Controls swapping in 8-bit units for data output from the CEU. 0: Data is not swapped in 8-bit units 1: Data is swapped in 8-bit units	R/W
1	COWS	Controls swapping in 16-bit units for data output from the CEU. 0: Data is not swapped in 16-bit units 1: Data is swapped in 16-bit units	R/W
2	COLS	Controls swapping in 32-bit units for data output from the CEU. 0: Data is not swapped in 32-bit units 1: Data is swapped in 32-bit units	R/W

Bit	Symbol	Function	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
4	CDS	Sets the image format when outputting the image data captured in the YCbCr422 format to the memory. When 0 is written to this bit, only the luminance component (Y) is output and no chrominance components (Cb and Cr) are output for the odd-numbered lines. With an interlace source image, similarly only the luminance component (Y) is output and no chrominance components (Cb and Cr) are output for the odd-numbered lines of the field. In data fetch mode, set this bit to 1. 0: Converts the YCbCr422 format to the YCbCr420 format before outputting data to the memory 1: Outputs data in the YCbCr422 format to the memory without conversion	R/W
15:5	—	These bits are read as 0. The write value should be 0.	R/W
16	CBE	Controls the number of lines of captured data to be written to the memory. ● Image capture This bit controls the number of lines of captured data to be written to the memory. When bundle write is set by this register, captured data is written in line units specified by CBDSR to the addresses specified by CDAYR and CDACR, and CDAYR2 and CDACR2 (CDBYR and CDBCR, and CDBYR2 and CDBCR2 for the bottom field in both-field capture) alternately (Figure 53.41). When captured data has been written for the number of lines set by CBDSR, a write end interrupt corresponding to each address setting register occurs. However, after write for one-frame (one-field) capture ends, a bundle write end interrupt does not occur even when bundle write has finished. ● Data synchronous fetch This bit controls the number of lines of captured data to be written to the memory. When bundle write is set by this register, captured data is written in line units specified by CBDSR to the addresses specified by CDAYR and CDAYR2 alternately. When captured data has been written for the number of lines set by CBDSR, a write end interrupt corresponding to each address setting register occurs. However, after write for one-frame capture ends, a bundle write end interrupt does not occur even when bundle write has finished. ● Data enable fetch This bit controls the number of bytes of captured data to be written to the memory. When bundle write is set by this register, captured data is written in byte units specified by CBDSR to the addresses specified by CDAYR and CDAYR2 alternately. When captured data has been written for the number of bytes set by CBDSR, a write end interrupt corresponding to each address setting register occurs. Also, only in data enable fetch, a bundle write end interrupt occurs when bundle write has finished after write for one-frame capture ends. Table 53.9 shows the correspondence between address setting registers and write end interrupt sources. Figure 53.42 shows the timing of write end interrupts in image capture and data synchronous fetch. Figure 53.43 shows the timing of write end interrupts in data enable fetch. 0: Normal write 1: Bundle write	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDOCR sets the format for outputting captured data to the memory. In data fetch mode, set the CDS bit to 1.

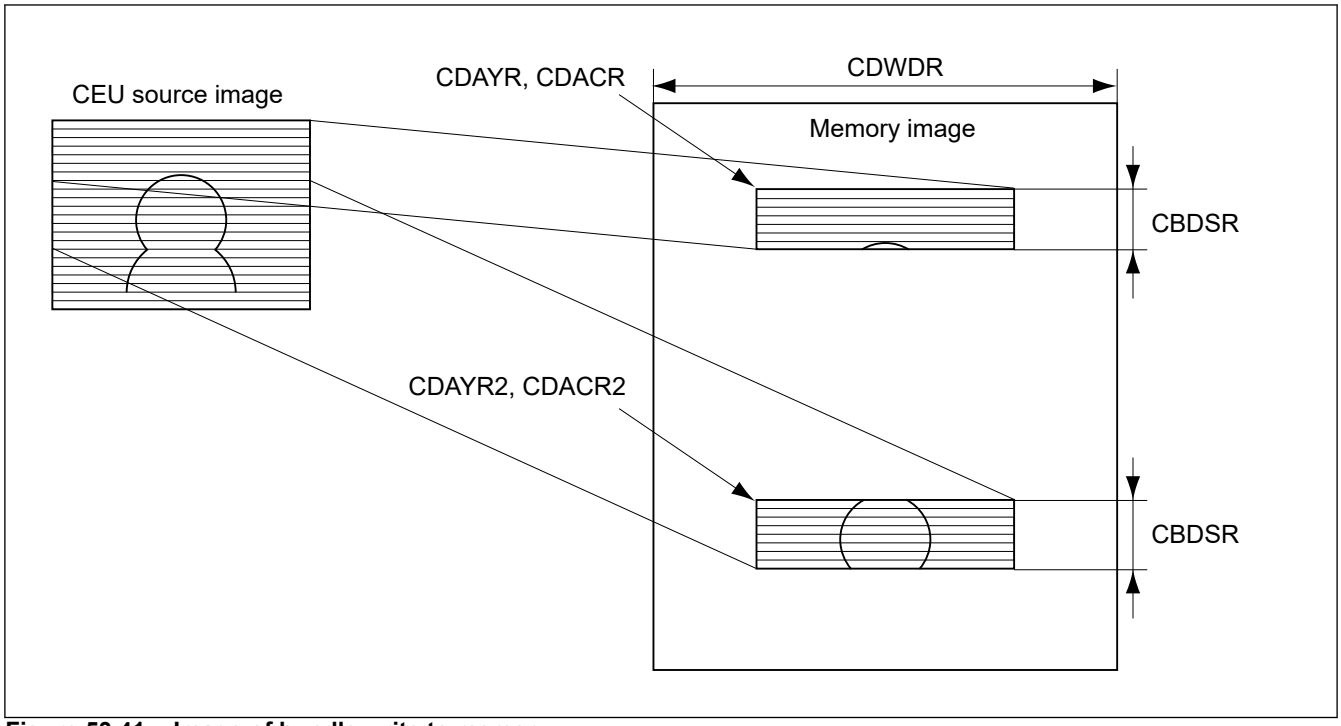

Figure 53.41 Image of bundle write to memory

Table 53.9 Correspondence between address setting registers and write end interrupt sources

Address setting registers	Bundle write end interrupt source
CDAYR, CDACR	CPBE1 bit in CETCR
CDAYR2, CDACR2	CPBE2 bit in CETCR
CDBYR, CDBCR	CPBE3 bit in CETCR
CDBYR2, CDBCR2	CPBE4 bit in CETCR

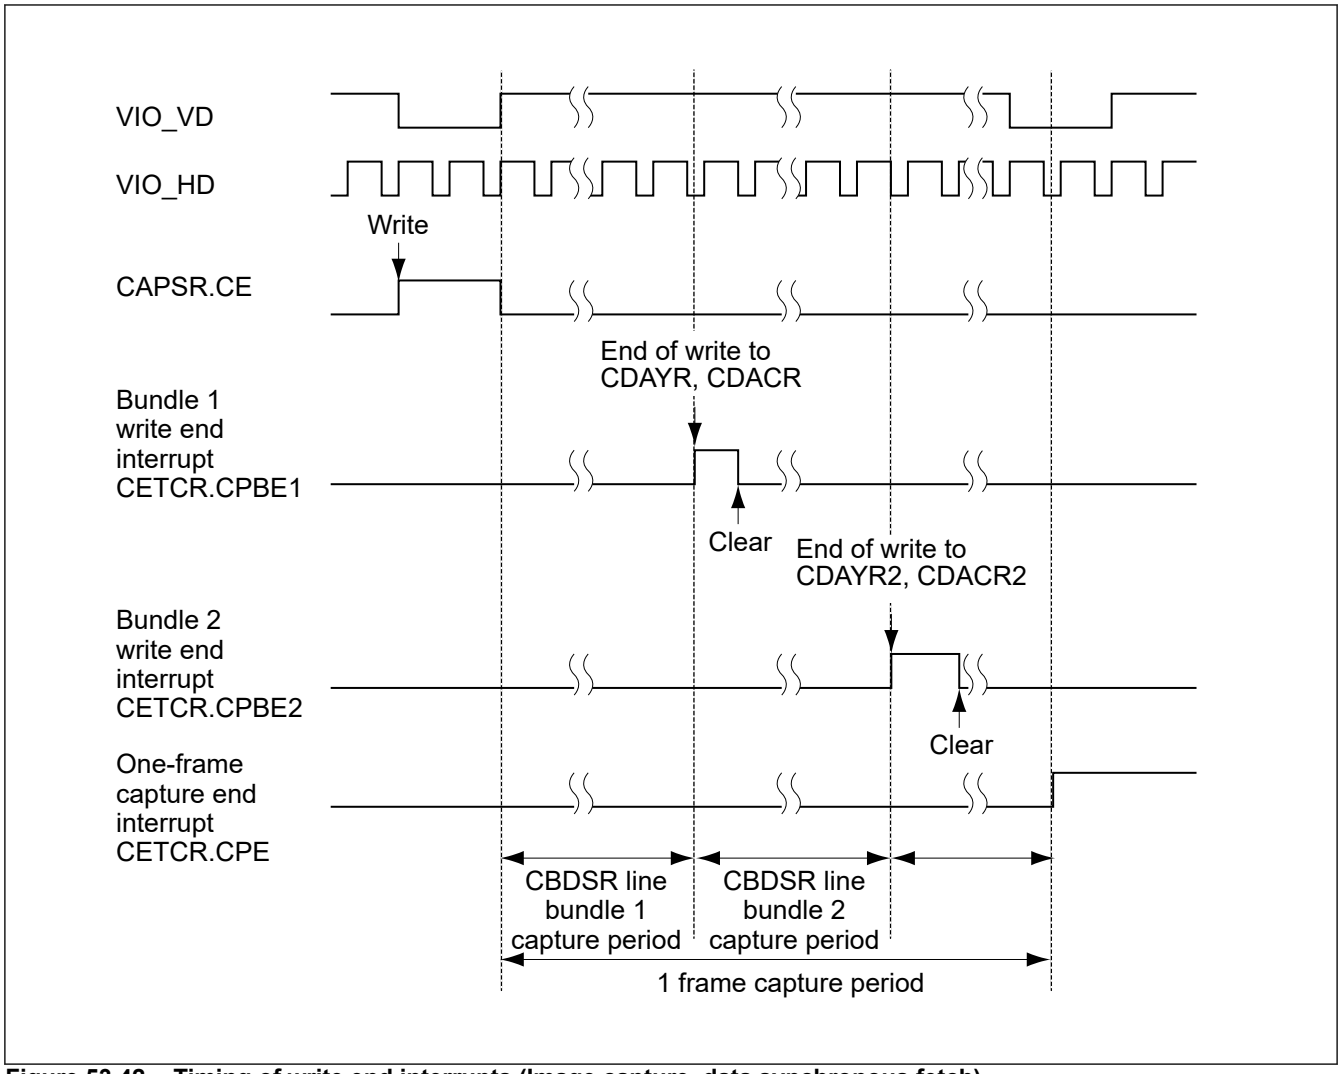

Figure 53.42 Timing of write end interrupts (Image capture, data synchronous fetch)

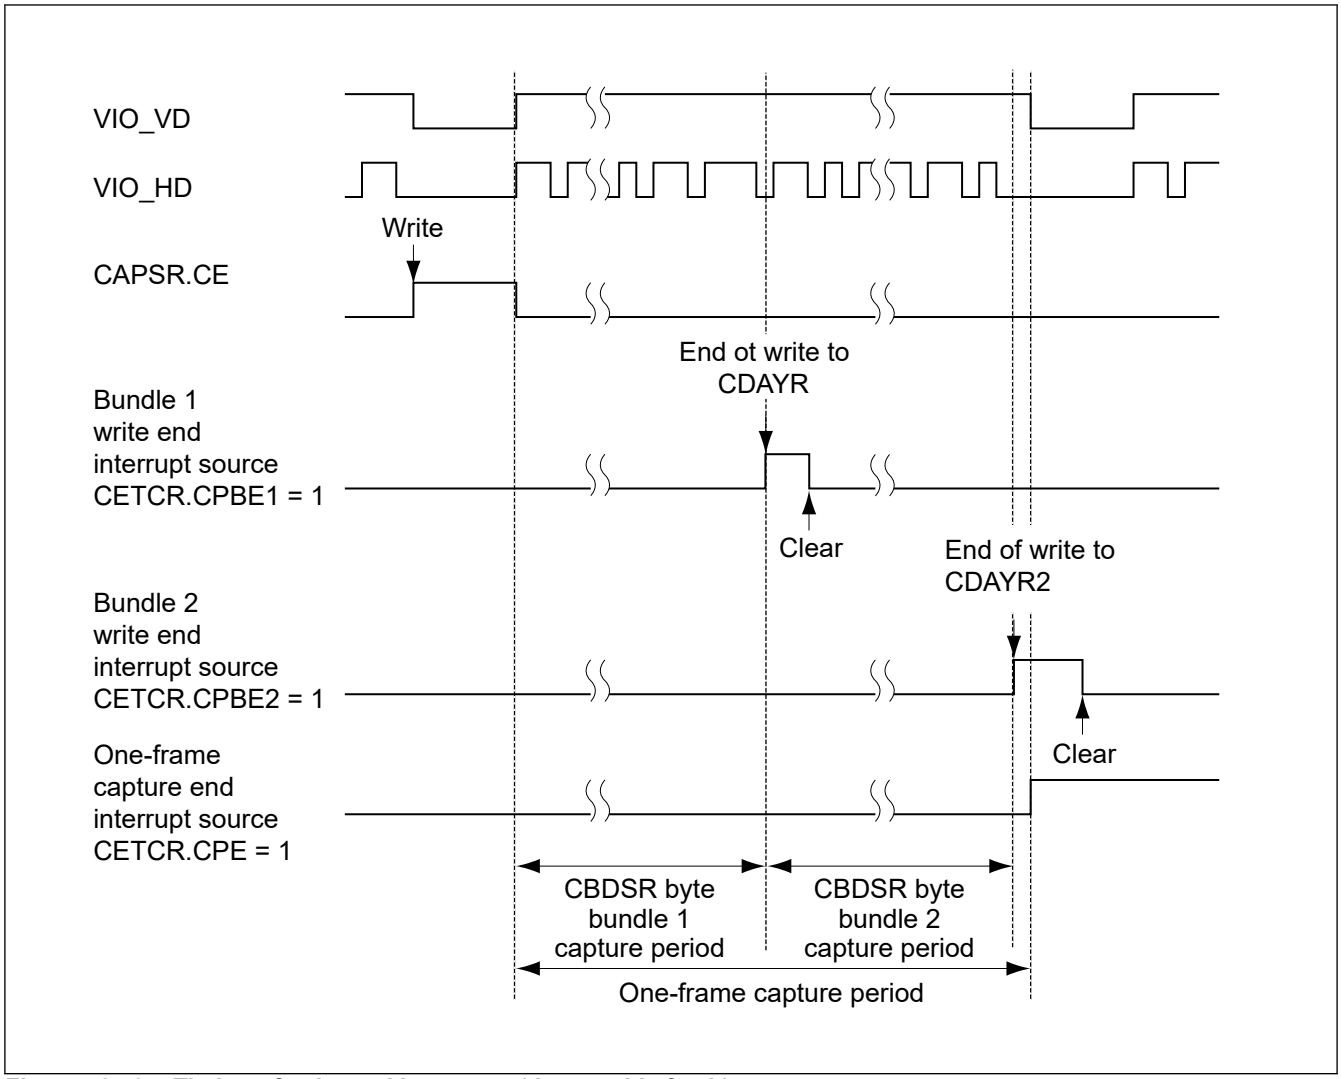

Figure 53.43 Timing of write end interrupts (data enable fetch)

For data output from the CEU, the COLS, COWS, and COBS bits control swapping in 32-bit, 16-bit, and 8-bit units, respectively. Set these bits when data is misaligned because of a difference in endian. The data swapping bits are shown below. These bits can be set similarly in data fetch mode.

Data can be swapped in 8-bit, 16-bit, 32-bit units, or in 32 bits, 16 bits and 8 bits, as shown in Figure 53.44. To enable data swapping, set the corresponding control bit to 1.

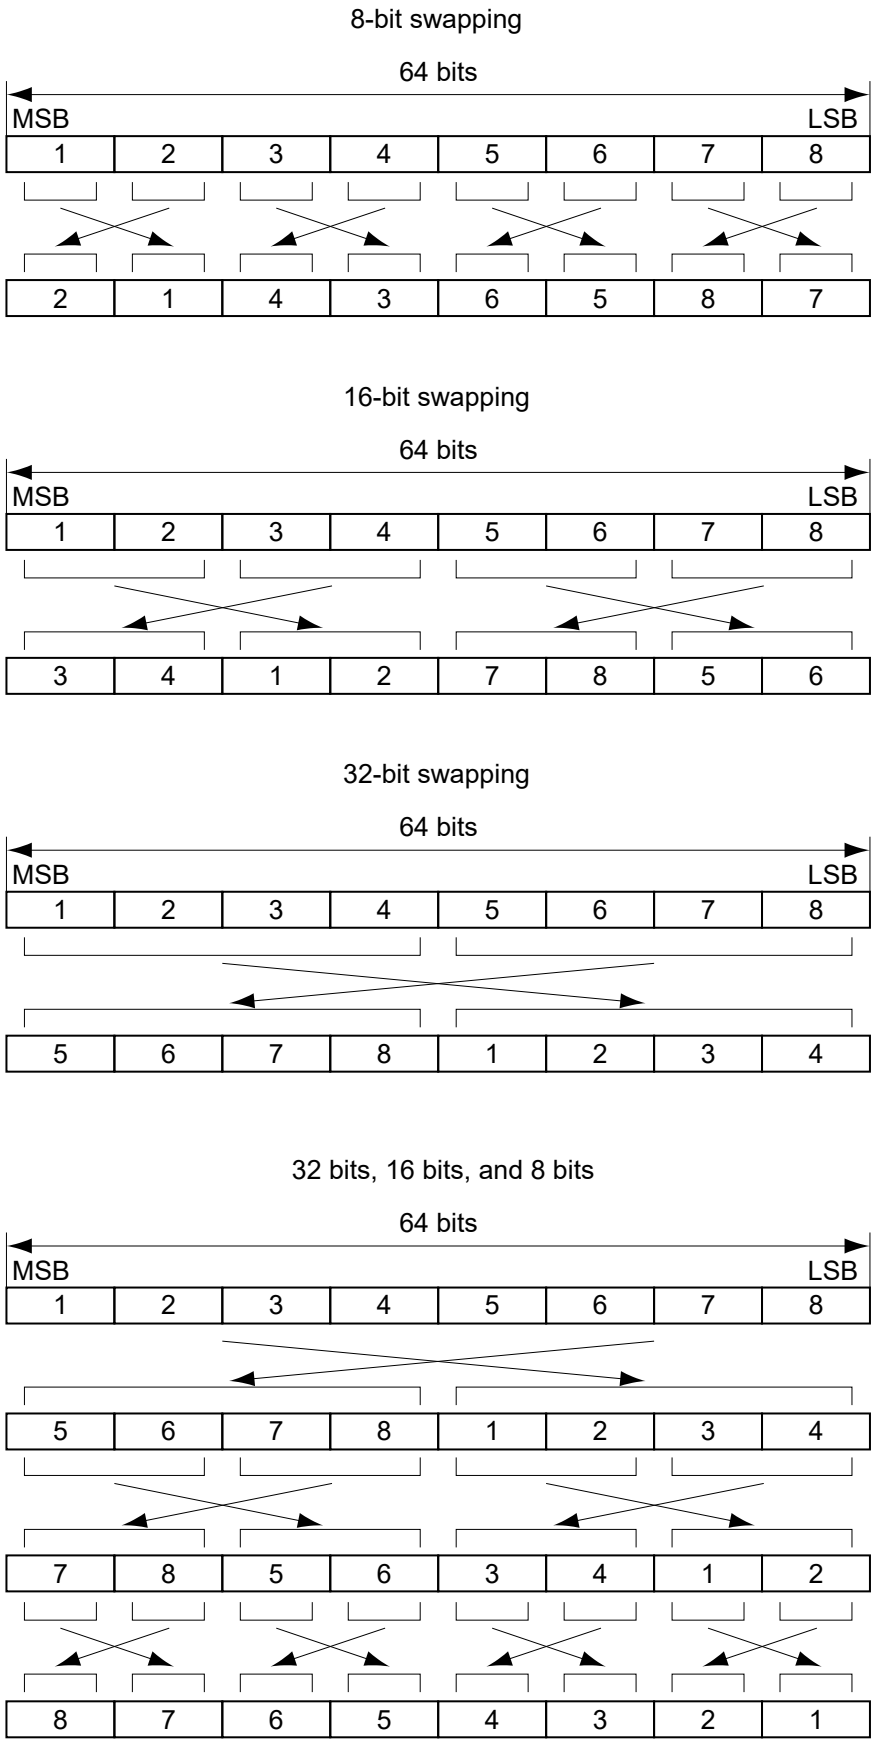

Figure 53.44 Data swapping by data aligner

53.2.21 CEIER : Capture Event Interrupt Enable Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0070

23	FWFIE	FWF Interrupt Enable 0: Disables a FWF interrupt 1: Enables a FWF interrupt	R/W
24	NHDIE	Non-HD Interrupt Enable Disable this interrupt (NHDIE = 0) for data enable fetch. 0: Disables a non-HD interrupt 1: Enables a non-HD interrupt	R/W
25	NVDIE	Non-VD Interrupt Enable Disable this interrupt (NVDIE = 0) for data enable fetch. 0: Disables a non-VD interrupt 1: Enables a non-VD interrupt	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CEIER enables or disables interrupts of the event flag register that generates CEU interrupts.

53.2.22 CETCR : Capture Event Flag Clear Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0074

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	NVD	NHD	FWF	—	—	VBP	—	IGVS	IGHS	CDTOF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CPBE4	CPBE3	CPBE2	CPBE1	—	—	VD	HD	—	—	—	IGRW	—	—	CFE	CPE
Value after reset:	0	0	0	0	0	0	x	x	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CPE	An interrupt indicating that capturing of one frame from an external module has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next VD input. This interrupt indicates that capturing of one frame has finished. This bit is set to 1 when the image of the size set in CAPWR is captured and the last data transfer to the bus finished (see Figure 53.46).	R/W
1	CFE	An interrupt indicating that capturing of one field from an external module has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next VD input (see Figure 53.45). This interrupt occurs only in both-field capture mode.	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	IGRW	An interrupt indicating that during capturing, access was attempted to a register to which writing during operation is prohibited. Among the CEU registers, writing during capturing is prohibited for some registers. Table 53.10 shows which registers can/cannot be written to during capturing. This bit is set to 1 when a register to which writing during capturing is prohibited has been written to.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
8	HD	An interrupt indicating that HD (horizontal sync signal) was input from an external module. This bit is set to 1 when an HD input from an external module is detected. Immediately after the HDPOL bit in CAMCR is modified, a pseudo HD is input and this bit is set to 1. The HD interrupt after the HDPOL bit is modified should be ignored.	R/W
9	VD	An interrupt indicating that VD (vertical sync signal) was input from an external module. In data enable fetch mode, this bit is set to 1 when a VD input from an external module is detected. In image capture mode and data synchronous fetch mode, this module generates a VD interrupt in response to the first detection of the active level of HD following detection of the active level of VD from an external module. Note that, when VD and HD are asserted and detected at the same time, this module generates a VD interrupt at that time. Immediately after the VDPOL bit in CAMCR is modified, a pseudo VD is input and this bit is set to 1. The VD interrupt after the VDPOL bit is modified should be ignored.	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
12	CPBE1	An interrupt indicating that writing to CDAYR and CDACR in a bundle write has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next HD input. This bit is set to 1 when data for the number of lines (number of bytes in data enable fetch) set in CBDSR has been captured and the last data transfer to the bus has completed. However, in image capture or data synchronous fetch, this interrupt does not occur when the last captured data in a bundle write is the last captured data of a frame (field).	R/W
13	CPBE2	An interrupt indicating that writing to CDAYR2 and CDACR2 in a bundle write has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next HD input. This bit is set to 1 when data for the number of lines (number of bytes in data enable fetch) set in CBDSR has been captured and the last data transfer to the bus has completed. However, in image capture or data synchronous fetch, this interrupt does not occur when the last captured data in a bundle write is the last captured data of a frame (field).	R/W
14	CPBE3	An interrupt indicating that writing to CDBYR and CDBCR in a bundle write has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next HD input. This bit is set to 1 when data for the number of lines set in CBDSR has been captured and the last data transfer to the bus has completed. However, this interrupt does not occur when the last captured data in a bundle write is the last captured data of a frame (field).	R/W
15	CPBE4	An interrupt indicating that writing to CDBYR2 and CDBCR2 in a bundle write has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next HD input. This bit is set to 1 when data for the number of lines set in CBDSR has been captured and the last data transfer to the bus has completed. However, this interrupt does not occur when the last captured data in a bundle write is the last captured data of a frame (field).	R/W
16	CDTOF	An interrupt indicating that data overflowed in the CRAM of the write buffer Since data is input at realtime from an external module in capture operations, the frame image is overwritten unless the captured data is transferred from the CEU internal buffer to the memory at a certain or higher transfer rate. This bit is set to 1 when writing the data in the CRAM of the CEU internal write buffer to the bus is not performed within time and data has overflowed.	R/W
17	IGHS	An interrupt generated when the number of HD cycles set in CMCYR differ from the number of HD cycles input from an external module. This bit is set to 1 when there is an illegal HD input from an external module. This bit is set to 1 when the number of clock cycles for the HD input to the CEU differs from the value set in the HCYL bits in CMCYR. Note however that when the HCYL bits are cleared to 0, this interrupt does not occur.	R/W
18	IGVS	An interrupt generated when the number of VD cycles set in CMCYR differ from the number of VD cycles input from an external module. This bit is set to 1 when there is an illegal VD input from an external module. This bit is set to 1 when the number of HD cycles for the VD input to the CEU differs from the value set in the VCYL bits in CMCYR. Note however that when the VCYL bits are cleared to 0, this interrupt does not occur.	R/W
19	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
20	VBP	An interrupt indicating that VD has been input while the CEU holds data (insufficient vertical-sync front porch). The conditions for a VBP interrupt to occur are as follows: ● Condition 1 VD is input when there is captured data within the CEU ● Condition 2 The last transfer data cannot be internally detected due to a write buffer overflow or an illegal HD so that the end timing is unclear until the next VD (By generating a VBP interrupt at the VD input timing, capture fail can be announced.) When a VBP interrupt occurs, a capture end interrupt (CPE bit in CETCR) does not occur and the image of that frame is not captured correctly. Though a capture end interrupt (CPE bit) will occur on rare occasions, it should be ignored in this case. Capturing cannot be performed until the next VD (even if the CE bit (capture reservation signal) in CAPSR is 1, capturing does not start). In the case of condition 2, instead of waiting for a VBP interrupt to occur, execute a software reset (CPKIL bit in CAPSR) to stop capturing and then restart capturing. In this case, since capture operation is terminated without waiting for the next VD, a VBP interrupt does not occur and capturing can be performed from the next VD.	R/W
22:21	—	These bits are read as 0. The write value should be 0.	R/W
23	FWF	The interrupt is generated when data is written to the address that exceeds the value specified with CFWCR.FMV. This bit is set to 1 when data is written to the address that exceeds the value specified with CFWCR.FMV while CFWCR.FWE = 1.	R/W
24	NHD	An interrupt indicating that no HD was input. The timing for a non-HD interrupt to occur differs depending on the bit width of the digital image input pins. 8-bit digital image input pins: Occurs when the 11-bit internal counter that is incremented every eight cycles becomes full. Accordingly, this bit is set to 1 when no HD has been input for at least 16,376 cycles since the last HD was input. 16-bit digital image input pins: Occurs when the 12-bit internal counter that is incremented every four cycles becomes full. Accordingly, this bit is set to 1 when no HD has been input for at least 16,380 cycles since the last HD was input. When connecting a camera whose HD is fixed low when VD is low, this bit may be set to 1. Ignore this interrupt during data enable fetch.	R/W
25	NVD	An interrupt indicating that no VD was input. A non-VD interrupt occurs when the 14-bit internal counter becomes full. Accordingly, this bit is set to 1 when no VD has been input for at least 16,383 lines since the last VD was input.	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CETCR notifies the CPU of the source of an interrupt that is generated in the CEU. The flags of CETCR can be used as interrupt signals. When the corresponding interrupt is enabled, an interrupt (CEU_CEUI) is generated. To clear the interrupt, clear the bit corresponding to the interrupt source to 0. After several cycles have passed after modifying the bit, the interrupt is cleared.

To clear the bit corresponding to the interrupt source to be cleared to 0 and retain that state, write 1 to that bit. For example, to clear only the CPE bit to 0, write 0xFFFFFFFE to CETCR.

In CETCR, only bits to which 0 is written are cleared. Bits to which 1 is written retain their current values. To clear an interrupt source, write 0 only to the bit corresponding to the interrupt source to be cleared, and 1 to the other bits.

Note: Since the CETCR value becomes undefined in the following cases, clear all bits in CETCR to 0.
- VD and HD bits immediately after system reset or Software Standby mode is entered.
- VD and HD bits after the polarities of the capture interface sync signals are changed.

53.2.23 CSTSR : Capture Status Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x007C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	CRST	—	—	—	—	—	—	—	CPFLD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CPTON
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CPTON	Indicates that the CEU is operating. This bit retains 1 during the period that starts from the internal VD at capture start and ends when a one-frame capture end interrupt occurs. Figure 53.47 shows the CEU operating period.	R
15:1	—	These bits are read as 0.	R
16	CPFLD	Indicates which field is being captured. 0: Bottom field is being captured 1: Top field is being captured	R
23:17	—	These bits are read as 0.	R
24	CRST	Indicates which register plane is currently used. 0: Plane A of the register is being used 1: Plane B of the register is being used	R
31:25	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

CSTSR indicates the internal status of the CEU. CSTSR differs from CETCR in that no interrupt is generated for the events indicated in CSTSR.

The CEU operating/halt state can be confirmed using CSTSR. To confirm the halt state of the CEU, make sure that the status bit (bit 0) indicating that the CEU is operating is cleared to 0 for sure.

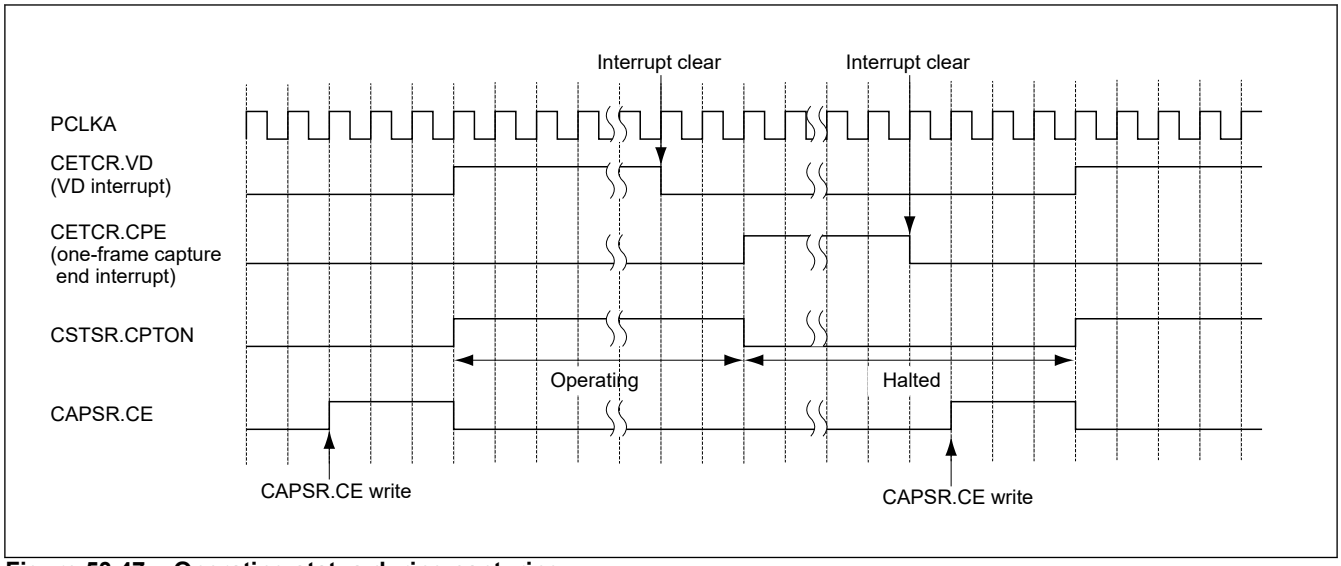

Figure 53.47 Operating status during capturing

53.2.24 CDSSR : Capture Data Size Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0084

Bit position:	31																												0
Bit field:	CDSS[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CDSS[31:0]	Indicate the size of data written to the memory in data enable fetch. In a bundle write, size of data written to the selected address at the end of one-frame capture is indicated. In a bundle write, as soon as the number of bytes specified by CBDSR is transferred to the bus, address to which data is written is switched. Therefore, if one-frame capture is completed at the same time as a bundle write is completed, this register indicates 0x00000000. Figure 53.48 and Figure 53.49 show the overall timing of the CDSSR operation in a bundle write.	R

Note: S-TYPE-3, P-TYPE-3

CDSSR indicates the size of data written to the memory in data enable fetch. As this register indicates a correct value at the end of capture, confirm this register when capture is completed.

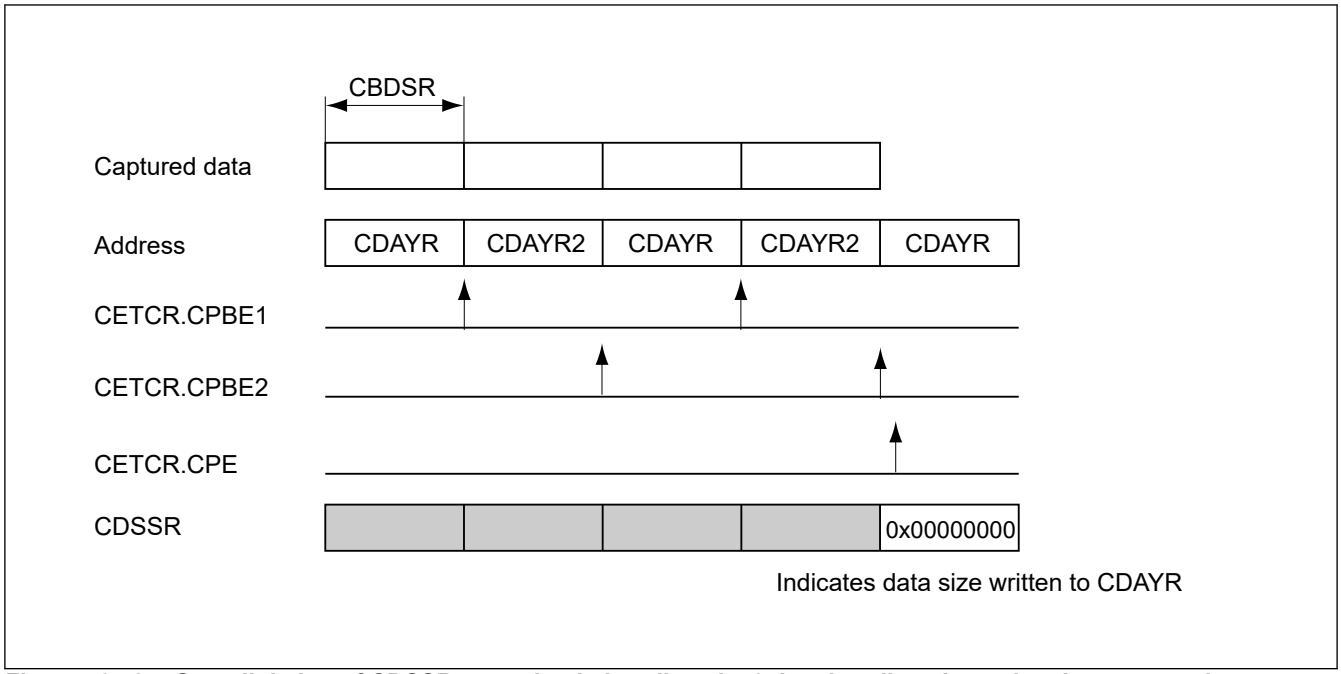

Figure 53.48 Overall timing of CDSSR operation in bundle write (when bundle write end and capture end coincide)

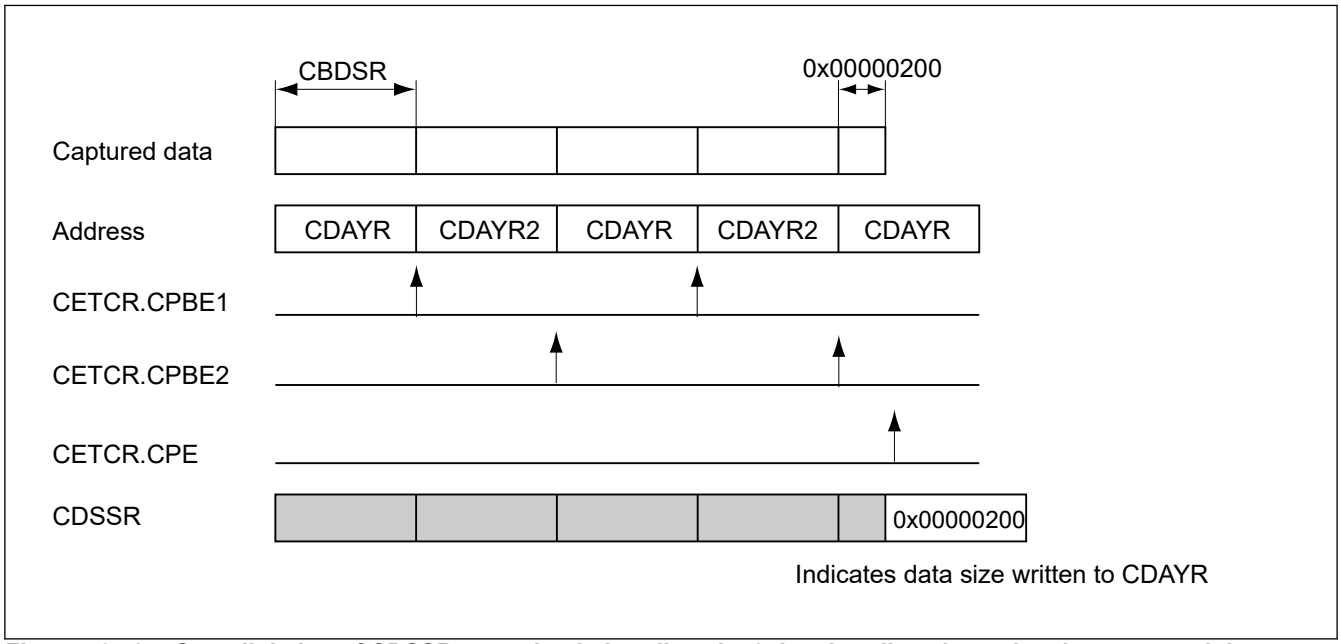

Figure 53.49 Overall timing of CDSSR operation in bundle write (when bundle write end and capture end do not coincide)

53.2.25 CDAYR2, CDAYR2_x : Capture Data Address Y Register 2 (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0090 (CDAYR2)
0x1090 (CDAYR2_B)
0x2090 (CDAYR2_M)

Bit position:	31																													0
Bit field:	CAYR2[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CAYR2[31:0]	Capture Data Address Y Frame image capture: These bits set the address for storing the luminance component data of the captured data (8-pixel units). ● One-field image capture: These bits set the address for storing the luminance component data of the captured data (8-pixel units). ● Both-field image capture: These bits set the address for storing the luminance component data of the captured top-field data (8-pixel units). ● Data synchronous fetch: These bits set the address for storing data (8-byte units). ● Data enable fetch: These bits set the address for storing data (32-byte units). The lower 3 bits should be written 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDAYR2 specifies the address for the luminance component used in a bundle write and the address for data storage in a bundle write in data fetch. CDAYR2 is used only in a bundle write.

CDAYR2 specifies the address where the luminance component of the captured data is to be stored in frame image capture or one-field image capture, the address where the luminance component of the captured top field is to be stored in both-field image capture, and the address where data is to be stored in data fetch. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or one-field image capture, set the start address of the memory area where the luminance component of the captured data is to be stored by CDAYR2. In both-field image capture, set the start address of the memory area where the luminance component of the captured top-field image is to be stored by CDAYR2. In data fetch, set the start address of the memory area to be used for data storage.

The address specified by this register must be in 32-bit units.

Set the address of the starting point of the memory area where the luminance component of the captured image is to be stored in this register, as shown in Figure 53.50.

- Frame image capture: Set the address of the starting point of the memory area where the luminance component of the captured image is to be stored.
- One-field image capture: Set the address of the starting point of the memory area where the luminance component of the captured image is to be stored.
- Both-field image capture: Set the address of the starting point of the memory area where the luminance component of the captured top-field image is to be stored.
- Data synchronous fetch: Set the address of the starting point of the memory area where the captured data is to be stored.
- Data enable fetch: Set the address of the starting point of the memory area where the captured data is to be stored in 32-byte units.

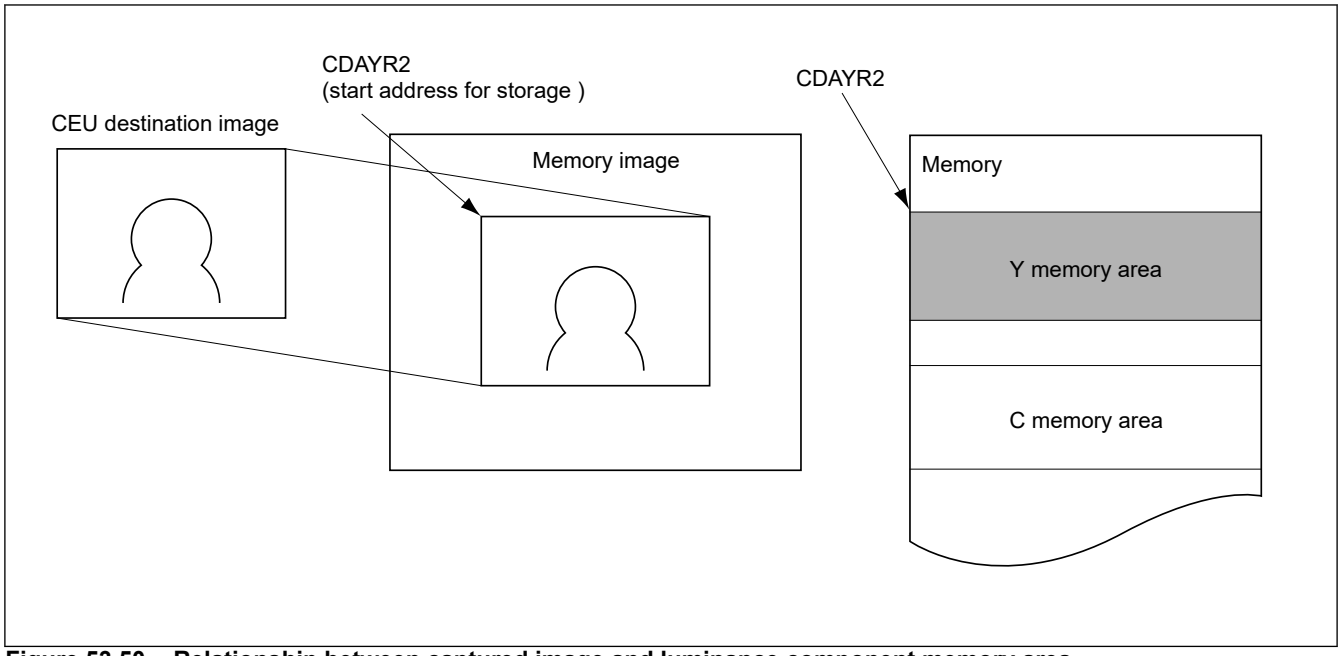

Figure 53.50 Relationship between captured image and luminance component memory area

53.2.26 CDACR2, CDACR2_x : Capture Data Address C Register 2 (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0094 (CDACR2)
0x1094 (CDACR2_B)
0x2094 (CDACR2_M)

Bit position:	31																												0
Bit field:	CACR2[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CACR2[31:0]	Capture Data Address C • Frame image capture: These bits set the address for storing the chrominance component data of the captured data (8-pixel units). • One-field image capture: These bits set the address for storing the chrominance component data of the captured data (8-pixel units). • Both-field image capture: These bits set the address for storing the chrominance component data of the captured top-field data (8-pixel units). The lower 3 bits should be written 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDACR2 specifies the address for the chrominance component used in a bundle write. CDACR2 is used only in a bundle write.

CDACR2 specifies the address where the chrominance component of the captured data is to be stored in frame image capture or one-field image capture, and the address where the chrominance component of the captured top field is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or one-field image capture, set the start address of the memory area where the chrominance component of the captured data is to be stored by CDACR2. In bothfield image capture, set the start address of the memory area where the chrominance component of the captured top-field image is to be stored by CDACR2. CDACR2 is not used in data fetch.

The address specified by this register must be in 32-bit units.

In this register, set the address of the starting point of the memory area where the captured data is to be stored in a bundle write, as shown in Figure 53.51.

- Frame image capture: Set the address of the starting point of the memory area where the chrominance component of the captured image is to be stored.
- One-field image capture: Set the address of the starting point of the memory area where the chrominance component of the captured image is to be stored.
- Both-field image capture: Set the address of the starting point of the memory area where the chrominance component of the captured top-field image is to be stored.

The chrominance component has an output data format as shown in Figure 53.52, and is saved in the memory in this format.

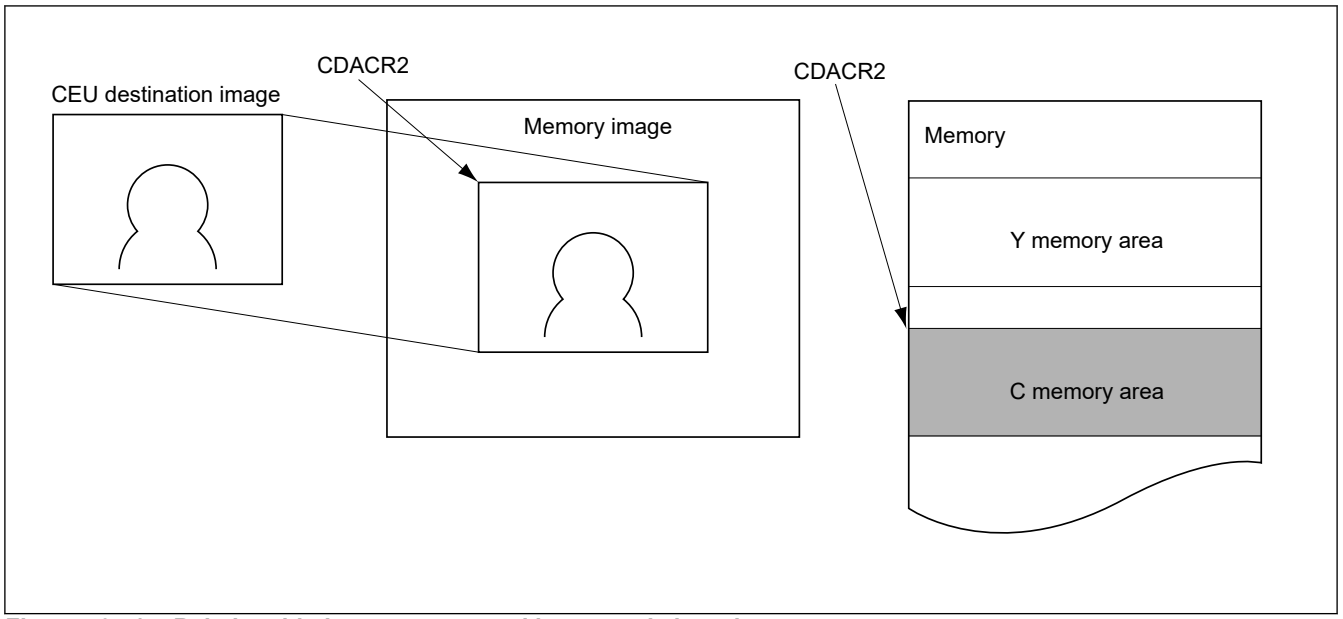

Figure 53.51 Relationship between captured image and chrominance component memory area

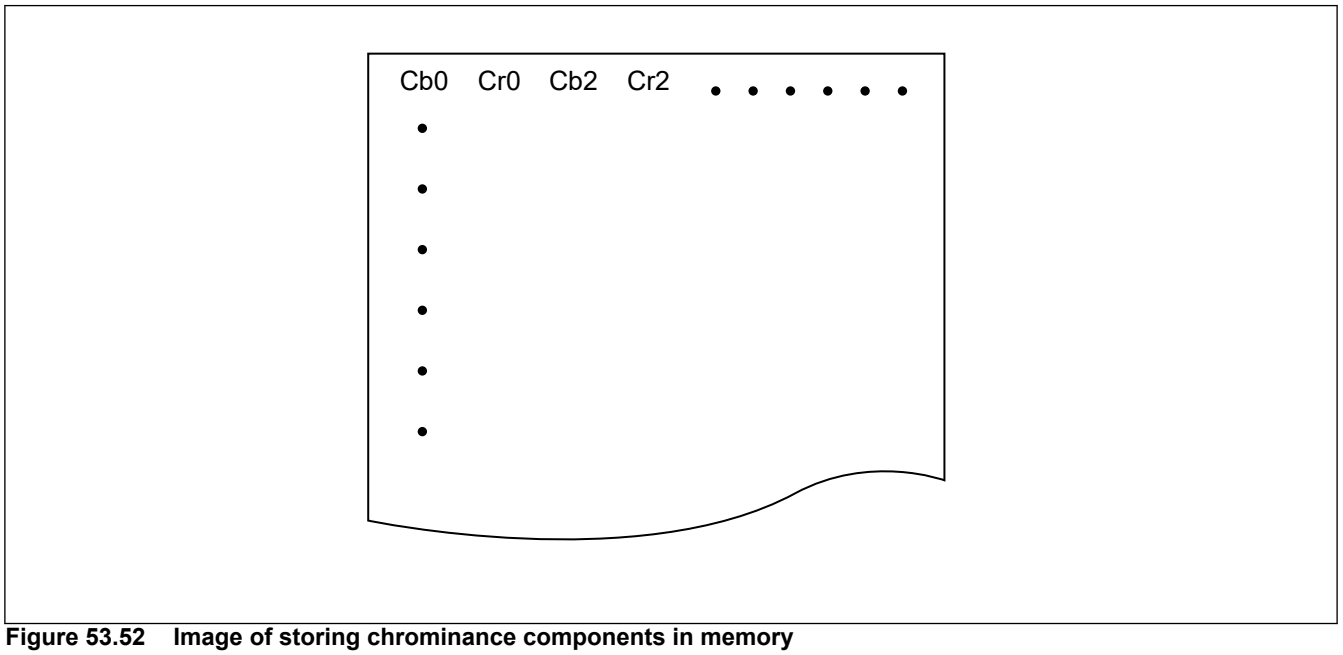

Figure 53.52 Image of storing chrominance components in memory

53.2.27 CDBYR2, CDBYR2_x : Capture Data Bottom-Field Address Y Register 2 (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0098 (CDBYR2)
0x1098 (CDBYR2_B)
0x2098 (CDBYR2_M)

Bit position:	31																												0
Bit field:	CBYR2[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CBYR2[31:0]	Set the address for storing the luminance component data of the captured bottom-field data (8-pixel units). The lower 3 bits should be written 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDBYR2 specifies the address for the luminance component of the bottom field used in a bundle write. CDBYR2 is used only in a bundle write.

CDBYR2 specifies the address where the luminance component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the luminance component of the bottom-field image captured in both-field image capture is to be stored by CDBYR2. CDBYR2 is not used in frame image capture, one-field image capture, or data fetch.

The address specified by this register must be in 32-bit units.

In this register, set the address of the starting point of the memory area where the luminance component of the captured bottomfield image is to be stored in a bundle write, as shown in Figure 53.53.

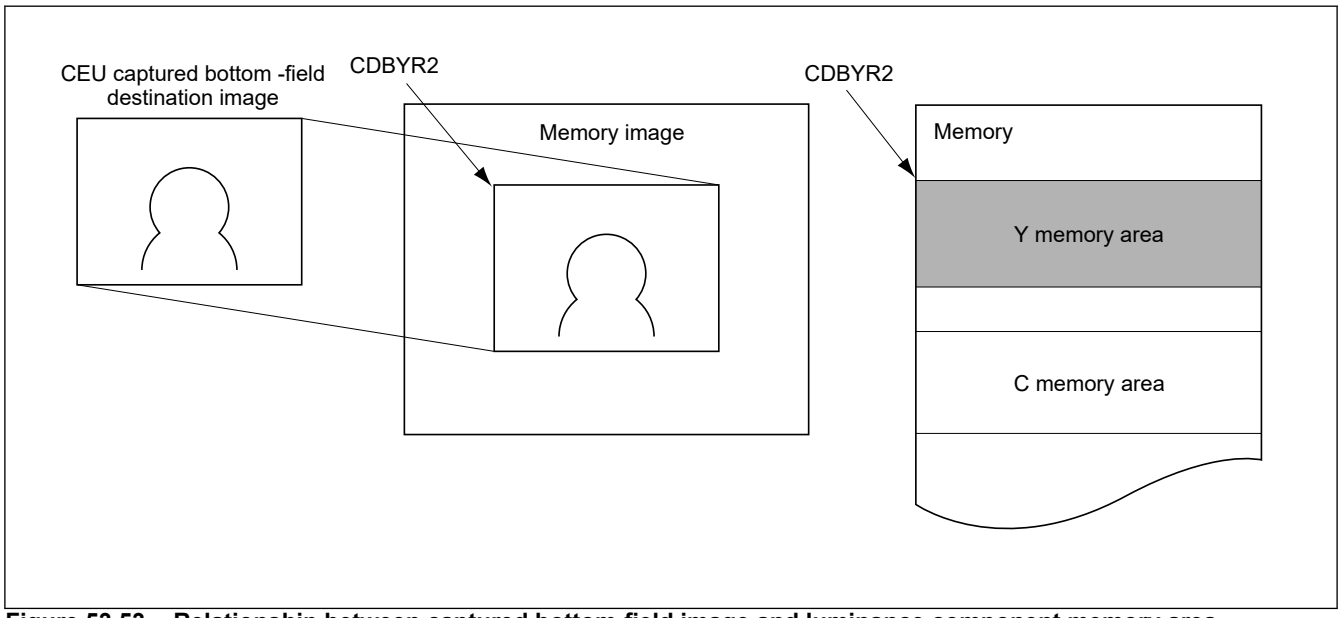

Figure 53.53 Relationship between captured bottom-field image and luminance component memory area

53.2.28 CDBCR2, CDBCR2_x : Capture Data Bottom-Field Address C Register 2 (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x009C (CDBCR2)
0x109C (CDBCR2_B)
0x209C (CDBCR2_M)

Bit position:	31																												0
Bit field:	CBCR2[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CBCR2[31:0]	Set the address for storing the chrominance component data of the captured bottom-field data (8-pixel units). The lower 3 bits should be written 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDBCR2 specifies the address for the chrominance component of the bottom field used in a bundle write. CDBCR2 is used only in a bundle write.

CDBCR2 specifies the address where the chrominance component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the chrominance component of the bottom-field image captured in both-field image capture is to be stored by CDBCR2. CDBCR2 is not used in frame image capture, one-field image capture, or data fetch.

The address specified by this register must be in 32-bit units.

In this register, set the address of the starting point of the memory area where the chrominance component of the captured bottomfield image is to be stored in a bundle write, as shown in Figure 53.54. The chrominance component has an output data format as shown in Figure 53.55, and is saved in the memory in this format.

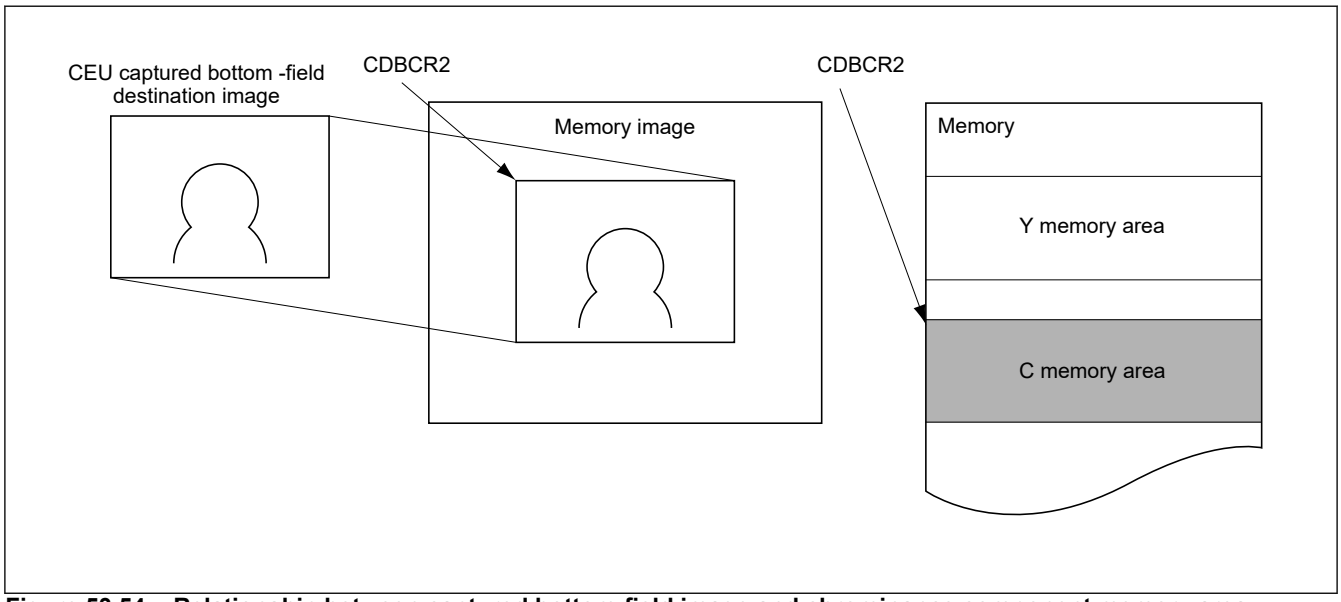

Figure 53.54 Relationship between captured bottom-field image and chrominance component memory area

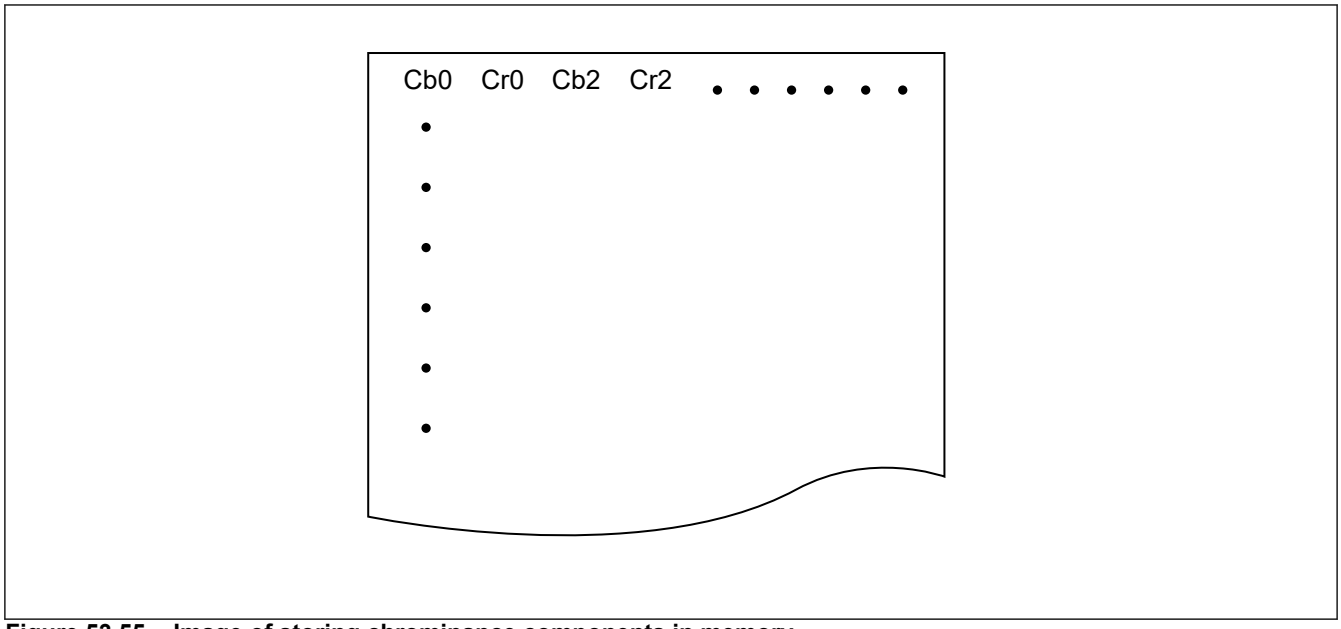

Figure 53.55 Image of storing chrominance components in memory

53.2.29 CBWER : CEU Bufferable Write Enable Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x00A0

Bit position:	31																														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BWE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BWE	Bufferable Write Enable 0: Disables Bufferable Write 1: Enables Bufferable Write	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

BWE bit (Bufferable Write Enable)

BWE bit indicates bufferable write is either enabled or disabled.

Note that if this bit is 1, even if the write access as CEU is completed, the actual slave write may not have ended.

Note: When this bit is 1, it requests an early response by writing write data to the temporary buffer if possible to the slave. Therefore, even if write access as CEU is completed, the actual slave write may not be finished. For details on slave groups that support bufferable writes, see section 14.7.2. Operations When a Bus Error Occurs and respective module sections.

53.3 Usage Notes

53.3.1 Settings for the Module-Stop Function

CEU operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The CEU is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

53.3.2 Conditions for Connection to an External Module

(1) Clock Frequency

The external input clock (VIO_CLK) should have a frequency at most the same as the CEU operating clock (PCLKA) frequency, with jitter on both sides included.

$$PCLKA \geq VIO\_CLK$$

(2) Blanking Period

The period from the last valid pixel in each line to the next horizontal sync signal HD must be at least 20 cycles.

(3) Fixed Period of Field Identification Signal

The field identification signal FLD should be fixed for at least 1-HD period since a VD input

53.3.3 Restrictions on Input/Output Functions

Table 53.11 lists the restrictions regarding the CEU input/output functions.

Table 53.11 Restrictions on CEU Input/Output Functions

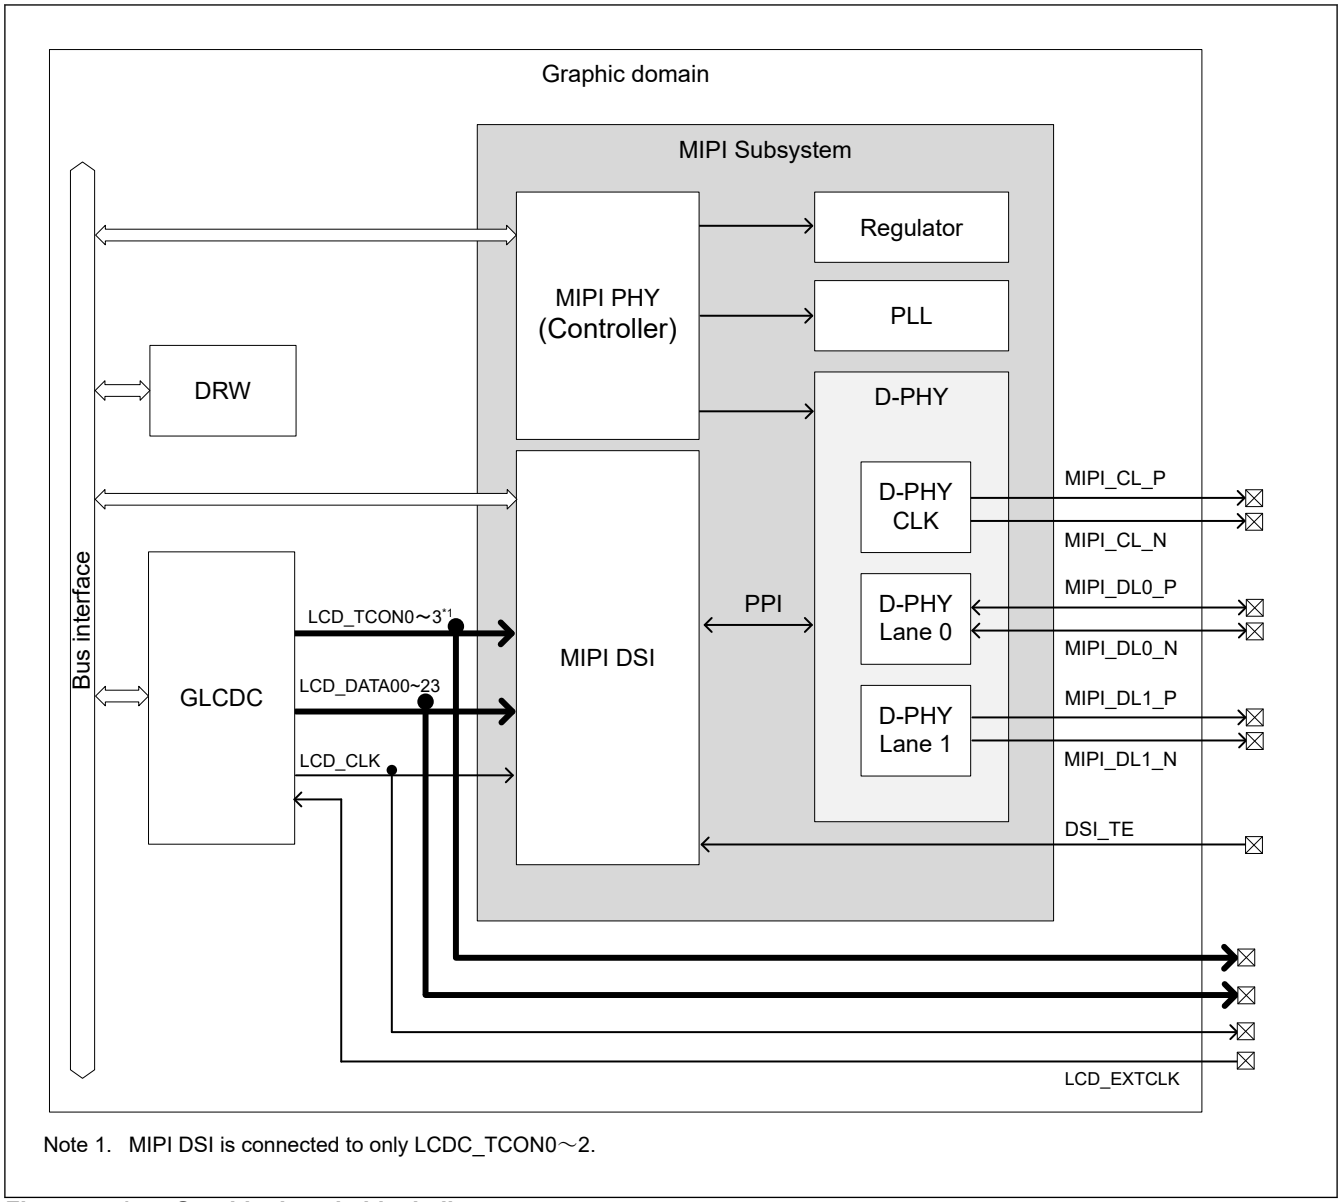
Item	Restrictions
External module interface	The operating clock of the external module (VIO_CLK) should always have a frequency at most the same as that of the CEU operating (PCLKA), with jitter on both sides included.
	Selecting the interface, or modifying the frequency of the external module operating clock or HD/VD polarity must be done when capture operations are halted for sure.
	The capture horizontal size in image capture must be specified as follows: 8-bit interface: 16-cycle units 16-bit interface: 8-cycle units
	The capture horizontal size in data fetch must be specified as follows: 8-bit interface: 8-cycle units 16-bit interface: 4-cycle units
	The capture vertical size must be specified in 4-line units.
	The maximum number of cycles in the horizontal sync signal period should be 16,375 cycles of external input clock for 8-bit digital image input pins, or 16,379 cycles of external input clock for 16-bit digital image input pins.
	The maximum number of lines (HD count) in the vertical sync signal should be 16,382 lines.
	The minimum number of captured pixels should be sub-QCIF (128 × 96).
	The maximum number of captured pixels should be 5 megapixels (2,560 × 1,920).
	The capture size in data enable fetch must be controlled by VD and HD in 4-byte units. The range of the capture size in data enable fetch that can be input is as follows. Maximum: 6 MB (2,048 × 1,536 × 2) Minimum: 16 bytes
Memory output	The output address must be specified in 32-bit units.
	The horizontal size of the destination image (memory) must be specified in 8-pixel units.
	The number of horizontal output pixels (= horizontal clipping size) must be specified in 8-pixel units.
	The number of vertical output lines (HD) (= vertical clipping size) must be specified in 4-line (HD) units.
	In data enable fetch bundle write, the output address must be specified in 32-byte units.
Internal processing	The filter clipping size must be specified as a value equal to or lower than the actual output size of the filter.

54. Graphics Subsystem

54.1 Graphics Overview

The graphic domain has the following features.

- Graphics LCD Controller (GLCDC): 8/16/18/24-bit RGB LCD interface supported.
- 2D Drawing Engine (DRW): Raster and vector graphics supported.
- MIPI D-PHY controller (MIPI PHY): Used for MIPI DSI
- MIPI Display Serial Interface (MIPI DSI): Display Serial interface 2 supported.



Note 1. MIPI DSI is connected to only LCDC_TCON0～2.

Figure 54.1 Graphic domain block diagram

Table 54.1 MIPI subsystem I/O pins (1 of 2)

Pin name	I/O	Function
MIPI_CL_P	Output	DSI Clock Lane positive pin
MIPI_CL_N	Output	DSI Clock Lane negative pin
MIPI_DL0_P	I/O	DSI Data Lane 0 positive pin

Table 54.1 MIPI subsystem I/O pins (2 of 2)

Pin name	I/O	Function
MIPI_DL0_N	I/O	DSI Data Lane 0 negative pin
MIPI_DL1_P	Output	DSI Data Lane 1 positive pin
MIPI_DL1_N	Output	DSI Data Lane 1 negative pin
DSI_TE	Input	DSI Tearing Effect pin
AVCC_MIPI	Power	D-PHY Analog Power Connect this pin to VSS_MIPI by a 0.1-µF capacitor. The capacitor should be placed close to the pin.
VCC18_MIPI	Power	D-PHY I/O Power Connect this pin to VSS_MIPI by a 0.1-µF capacitor. The capacitor should be placed close to the pin.
VSS_MIPI	Power	D-PHY GND

54.1.1 Start and stop MIPI DSI

It is recommended that the settings for starting and stopping MIPI DSI be performed in the order shown in Table 54.2 below.

Table 54.2 List of Operation

Function	Item	No	Description
MIPI DSI	Start Setting	1	See section 56.3.1. Overall Control
		2	See section 57.3.1. D-PHY Start-up Procedure
		3	See section 58.3.3. Start of HS Clock
	Stop Setting	1	See section 58.3.4. Stop of HS Clock
		2	See section 57.3.2. D-PHY Stop Procedure
		3	See Stopping and restarting in normal operation or stopping and restarting in abnormal operation in section 56.3.1. Overall Control

55. 2D Drawing Engine (DRW)

55.1 Overview

This MCU incorporates a 2D drawing engine (DRW). Table 55.1 lists the DRW specifications.

Table 55.1 DRW Specifications

Item		Descriptions
Vector drawing engine		Extended rendering primitives supported in hardware ● Lines ● Polygons ● Circles and ellipses ● Quadratic Béziers ● Texture mapping
BitBLT function		Types of BitBLT operations ● Fill ● Copy ● Stretch BitBLT ● Rotate and scale ● Alpha blending ● Bilinear filtering ● Color conversion ● Subpixel exact placement
Color format	Frame buffer	Four types ● A (8) ● RGB (565) ● ARGB (4444) ● ARGB (8888)
	Texture	11 types ● CLUT (1)/I (1) ● CLUT (2)/I (2) ● CLUT (4)/I (4) ● CLUT (8)/I (8) ● A (8) ● ACLUT (44) ● RGB (565) ● ARGB (4444) ● ARGB (1555) ● RGB (888) ● ARGB (8888)
Texture		● Run-length encoding (RLE) unit ● 256-entry color look-up table (CLUT) ● Color keying unit
Render		Two modes for rendering process ● Register mode ● Display list mode
Data arrangement		Little endian
Performance counter		● Two independent 32-bit counters ● Trigger is selectable from 14 events
Interrupt sources		Three interrupt sources ● 2D Drawing Engine bus error interrupt (DRWBUSIRQ) ● Current render process finished interrupt (DRWENUMIRQ) ● Display list interrupt (DRWDLISTIRQ)
Module-stop function		Module-stop state can be set to reduce power consumption
TrustZone Filter		Security and Privilege attribution can be set

The 2D Drawing Engine provides two inputs (texture read and frame buffer read) and one output (frame buffer write). The internal color format is always ARGB (8888). The color formats from the inputs are converted to the internal format on read and converted back on write.

The 2D Drawing Engine also supports a display list mode, which makes it possible to decouple the CPU and graphics controller efficiently and perform rendering in parallel with other CPU activities.

Figure 55.1 shows examples of objects that can be drawn in hardware with the 2D Drawing Engine, Figure 55.2 shows a simplified rendering pipeline setup, and Figure 55.3 shows a block diagram of the module.

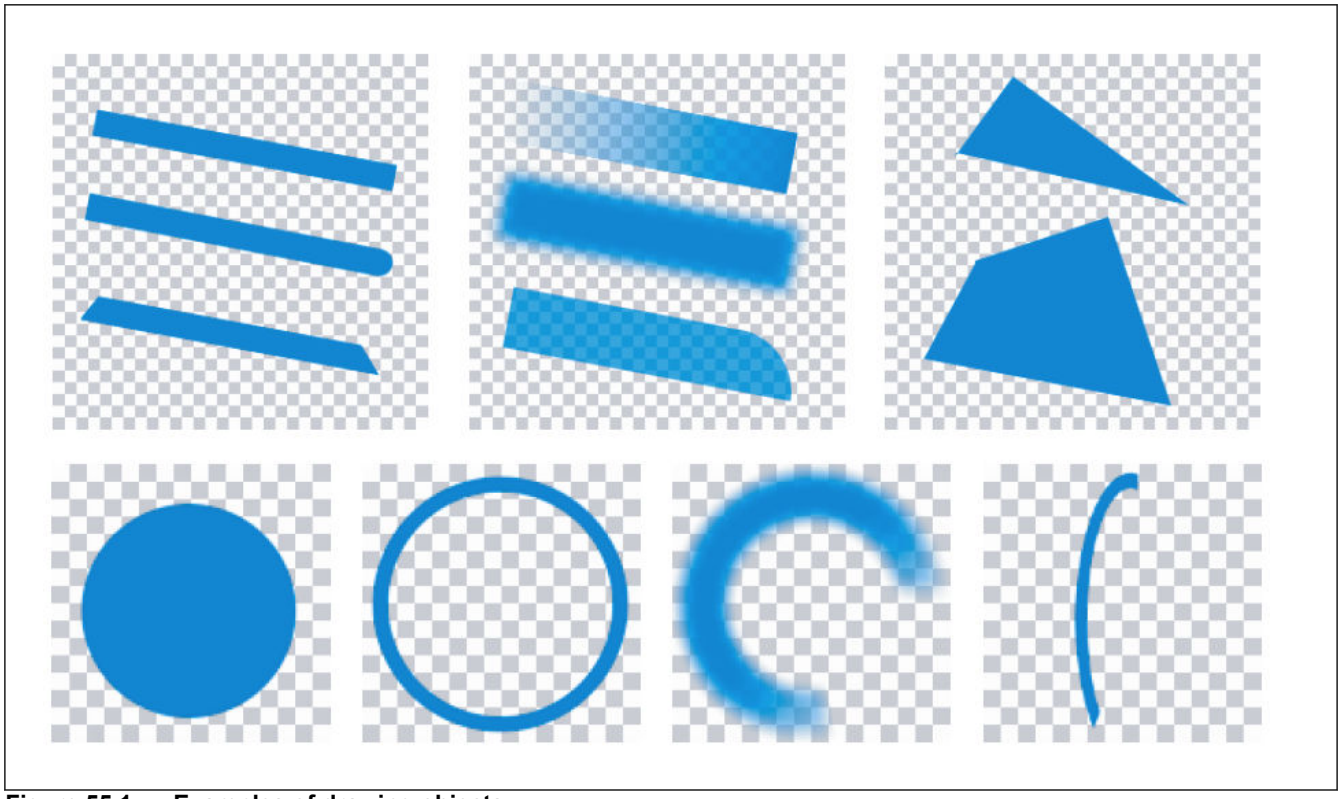


Figure 55.1 Examples of drawing objects

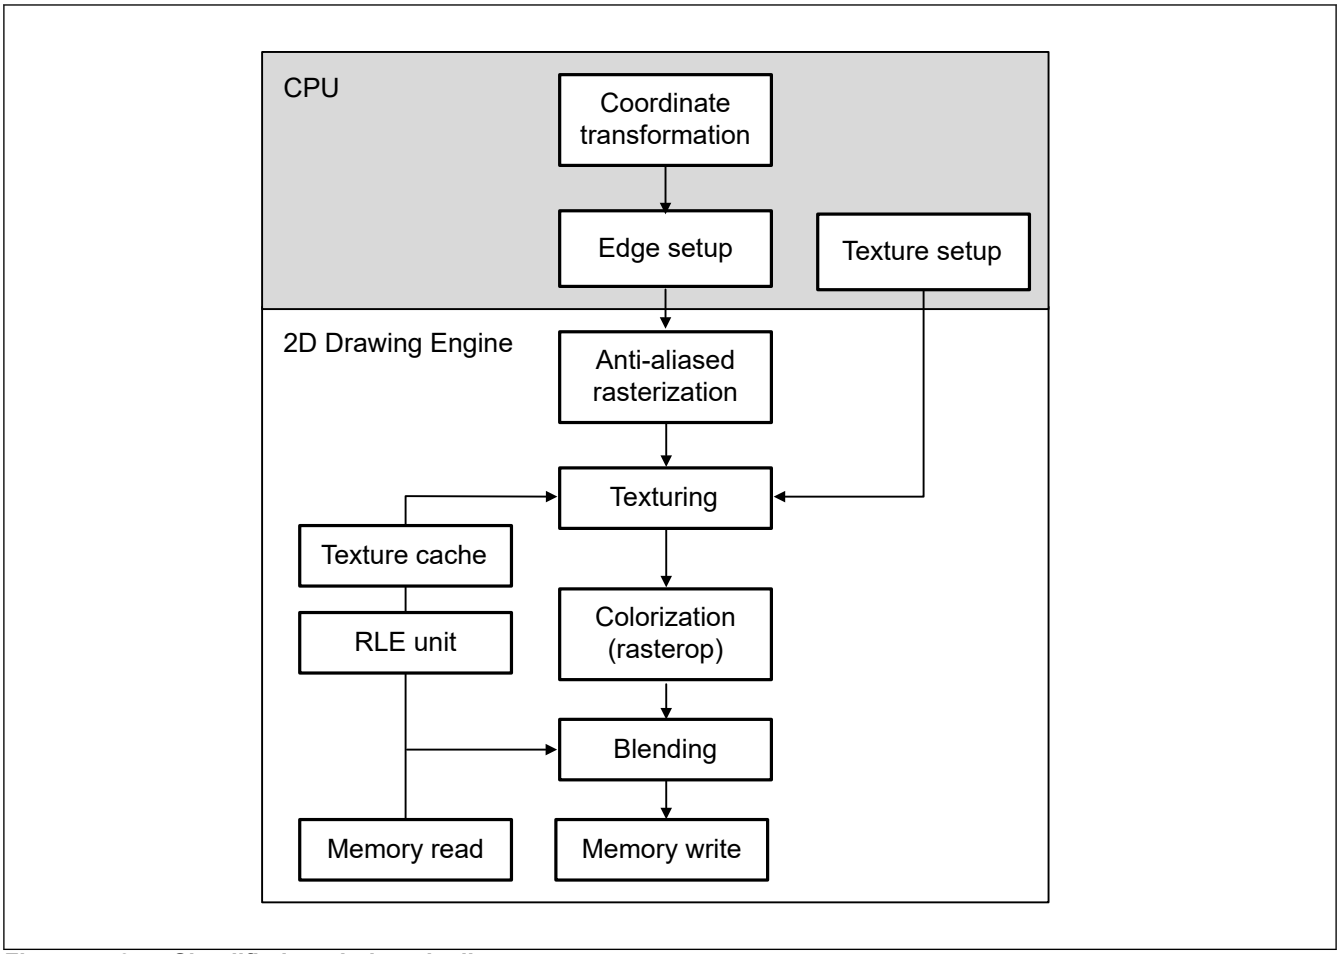

Figure 55.2 Simplified rendering pipeline setup

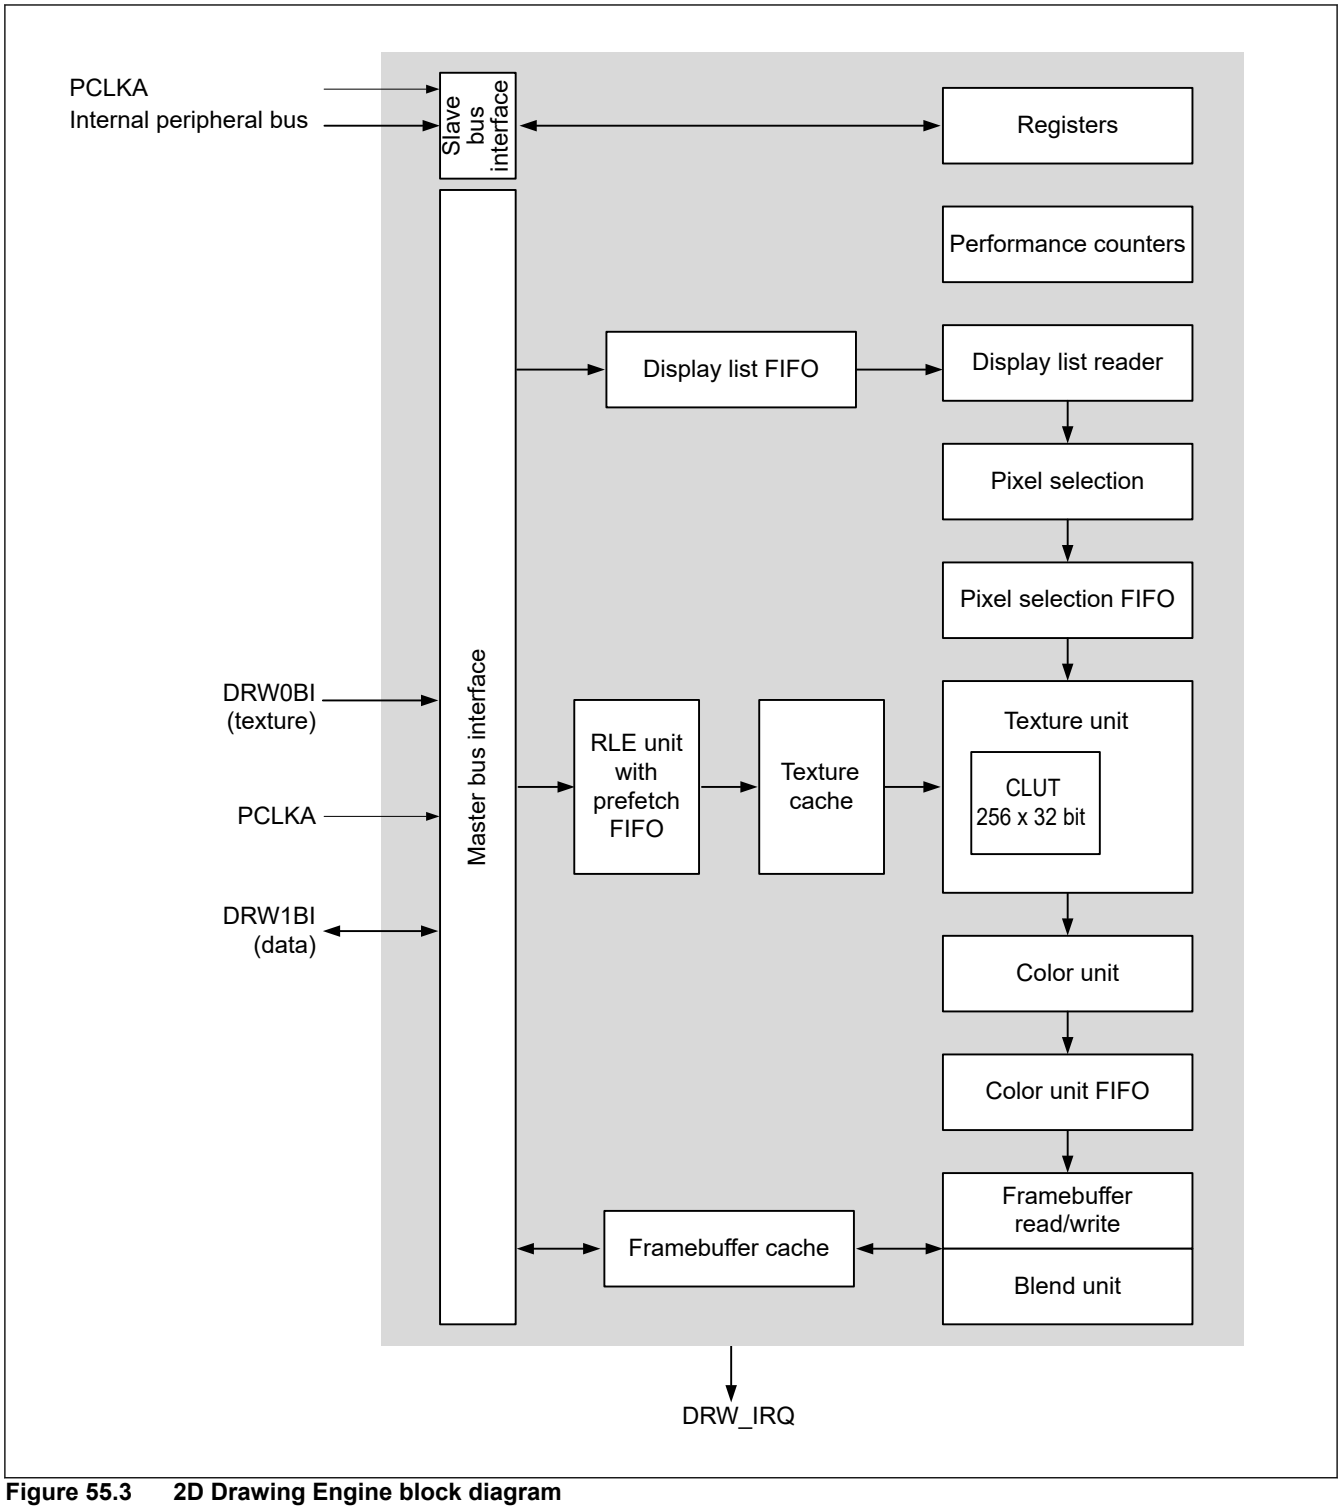

Figure 55.3 2D Drawing Engine block diagram

The 2D Drawing Engine accesses the DRW bus as a bus master through separate caches for:

- Reading and writing pixel data from and to the framebuffer
- Reading textures
- Reading display lists.

The control registers are accessed through the internal peripheral bus interface.

55.2 Register Descriptions

55.2.1 CONTROL : Geometry Control Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TEXTURECLAMPY	TEXTURECLAMPX	BC2	BDI	BSI	BDF	BSF	WRITEFORMAT2	BDFA	BSFA	READFORMAT_H[3:2]		USEACB	PATTERNSOURCEL5	TEXTUREENABLE	PATTERNENABLE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PATTERNENABLE	Pattern Color Enable for Pixel Source Pixel source is a pattern color (blend of COLOR1 and COLOR2 depending on PATTERN and pattern index). When patterns are used to fill a primitive index into the pattern, bit mask is generated for each pixel with the U limiter. Depending on the pattern bits, the color is selected from COLOR1 and COLOR2 registers. Fractional indices can be interpolated between those two values using TEXTUREFILTERX = 1. The pattern can be wrapped using TEXTURECLAMPX = 0, and the mask must be set in the TEXMASK register using the mask for U limiter. 0: Disable pattern 1: Enable pattern.	W
1	TEXTUREENABLE	Texture Enable for Pixel Source Pixel source is read from texture and used as an alpha to blend between COLOR1 and COLOR2. 0: Disable texture 1: Enable texture.	W
2	PATTERNSOURCEL5	Limiter 5 Enable for Pattern Index Limiter 5 is used as a pattern index instead of the default U limiter. Limiter 5 can be combined with limiter 6 to form a quadratic limiter that can be used to make quadratic pattern functions to draw radial patterns.	W
3	USEACB	Alpha Blend Mode 0: Use WRITEALPHA[1:0] mode 1: Use full alpha channel blending mode.	W
5:4	READFORMAT_H[3:2]	Texture Format Descriptor Bits [3] and [2] of the texture buffer format. See the detailed description of the READFORMAT[1:0] bit in this section.	W
6	BSFA	Blend Source Factor for Alpha Channel Valid in alpha channel blending mode (USEACB = 1). 0: Use 1.0 as blend source factor for alpha channel 1: Use alpha as blend source factor for alpha channel.	W
7	BDFA	Blend Destination Factor for Alpha Channel Valid in alpha channel blending mode (USEACB = 1). 0: Use 1.0 as blend destination factor for alpha channel 1: Use alpha as blend destination factor for alpha channel.	W
8	WRITEFORMAT2	Writeback Framebuffer Format Bit [2] of framebuffer pixel format. See the description of WRITEFORMAT[1:0] in this section.	W
9	BSF	Blend Source Factor Source factor is alpha (factor is 1 per default). 0: Use 1.0 as blend source factor 1: Use alpha as blend source factor.	W
10	BDF	Blend Destination Factor Destination factor is alpha (factor is 1 per default). 0: Use 1.0 as blend destination factor 1: Use alpha as blend destination factor.	W
11	BSI	Blend Source Factor Inverted Source factor is inverted (meaning 1-a or 1-1 depending on BSF). 0: Use blend factor as specified through BSF 1: Invert blend source factor (1-x).	W
12	BDI	Blend Destination Factor Inverted Destination factor is inverted (meaning 1-a or 1-1 depending on BDF). 0: Use blend factor as specified through BDF 1: Invert blend destination factor (1-x).	W
13	BC2	Blend color 2 Select of blend color 2 instead of framebuffer pixel. 0: Use pixel from framebuffer as destination (DST) 1: Use color 2 as destination (DST).	W

<table>

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	CFLUSHTX	CENABLETX	CFLUSHFX	CENABLEFX
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CENABLEFX	Framebuffer Cache Enable 0: Disable the framebuffer cache 1: Enable the framebuffer cache.	W
1	CFLUSHFX	Flush Framebuffer Cache 0: Do not flush the framebuffer cache 1: Flush the framebuffer cache.	W
2	CENABLETX	Texture Cache Enable 0: Disable the texture cache 1: Enable the texture cache.	W
3	CFLUSHTX	Flush Texture Cache 0: Do not flush the texture cache 1: Flush the texture cache.	W
31:4	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

55.2.5 STATUS : Status Control Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	BUSERRMDL	BUSERRMTXMRL	BUSERRMFB	—	BUSIRQ	DLISTIRQ	ENUMIRQ	DLISTACTIVE	CACHEDIRTY	BUSYWRITE	BUSYENUM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BUSYENUM	Enumeration Unit Status 0: Enumeration unit idle 1: Enumeration unit is busy, new primitive cannot be started.	R
1	BUSYWRITE	Framebuffer Writeback Status 0: Framebuffer writeback finished 1: Framebuffer writeback busy, framebuffer type cannot be changed.	R
2	CACHEDIRTY	Framebuffer Cache Status 0: Framebuffer cache is not dirty 1: Framebuffer cache is dirty, and frame should not be flipped.	R
3	DLISTACTIVE	Display List Reader Status 0: Display list reader is idle 1: Display list reader is busy, and no direct write access to registers allowed.	R
4	ENUMIRQ	Enumeration Interrupt Triggered 0: Enumeration not finished or interrupt disabled 1: Enumeration finished interrupt triggered.	R
5	DLISTIRQ	Display List Interrupt Triggered 0: Display list not finished or interrupt disabled 1: Display list finished interrupt triggered.	R
6	BUSIRQ	Bus Error Interrupt Triggered 0: No bus error occurred or interrupt disabled 1: Bus error interrupt triggered.	R
7	—	This bit is read as 0.	R
8	BUSERRMFB	Framebuffer Bus Error Interrupt Triggered 0: No framebuffer bus error occurred or interrupt disabled 1: Framebuffer bus error interrupt triggered.	R
9	BUSERRMTXMRL	Texture Bus Error Interrupt Triggered*1 0: No texture bus error occurred or interrupt disabled 1: Texture bus error interrupt triggered.	R
10	BUSERRMDL	Display List Bus Error Interrupt Triggered 0: No display list bus error occurred or interrupt disabled 1: Display list bus error interrupt triggered.	R
31:11	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3
Note 1. Because the RLE unit is also reading data through the texture bus, an error during RLE data access is also reflected in this bit.

55.2.6 HWREVISION : Hardware Version and Feature Set ID Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	1	1	1

Bit	Symbol	Function	R/W
11:0	REV[11:0]	Revision Number of DRW is stored.	R
16:12	—	These bits are read as 0.	R
17	DLR	Display List Reader Available 0: No display list reader 1: Display list reader is available	R
18	FBCACHE	Framebuffer Cache Available 0: No framebuffer cache 1: Framebuffer cache is available	R
19	TXCACHE	Texture Cache Available 0: No texture cache 1: Texture cache is available	R
20	PERFCOUNT	Two Performance Counter Available 0: No performance counter 1: Tow performance counters available	R
21	TEXCLUT	Texture CLUT Available 0: No texture CLUT 1: Texture CLUT is available	R
22	—	This bit is read as 0.	R
23	RLEUNIT	RLE Unit Available 0: No RLE unit 1: RLE unit is available	R
24	TEXCLUT256	Texture CLUT size 0: Texture CLUT size is 16 entries 1: Texture CLUT size is 256 entries	R
25	COLORKEY	Color Key Available 0: No color key 1: Color key is available	R
26	—	This bit is read as 1.	R
27	ACBLEND	Alpha Channel Blending Available 0: Full alpha channel blending is not available 1: Full alpha channel blending is available	R
31:28	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

55.2.7 COLOR1 : Base Color Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x64

Bit position:	31							24	23							16	15							8	7							0
Bit field:	COLOR1A[7:0]								COLOR1R[7:0]								COLOR1G[7:0]								COLOR1B[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	COLOR1B[7:0]	Blue Channel of Color 1 Specifies blue channel of color 1.	W
15:8	COLOR1G[7:0]	Green Channel of Color 1	W
23:16	COLOR1R[7:0]	Red Channel of Color 1	W
31:24	COLOR1A[7:0]	Alpha Channel of Color 1 Specifies alpha channel of color 1. 0x00: Transparent ⋮ 0xFF: Opaque.	W

Note: S-TYPE-3, P-TYPE-3

55.2.8 COLOR2 : Secondary Color Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x68

Bit position:	31							24	23							16	15							8	7							0
Bit field:	COLOR2A[7:0]								COLOR2R[7:0]								COLOR2G[7:0]								COLOR2B[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

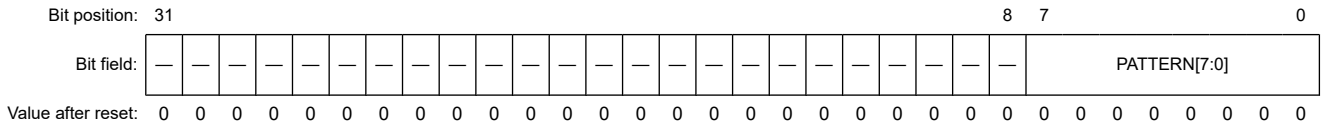
Bit	Symbol	Function	R/W
7:0	COLOR2B[7:0]	Blue Channel of Color 2 Specifies blue channel of color 2.	W
15:8	COLOR2G[7:0]	Green Channel of Color 2 Specifies green channel of color 2.	W
23:16	COLOR2R[7:0]	Red Channel of Color 2 Specifies red channel of color 2.	W
31:24	COLOR2A[7:0]	Alpha Channel of Color 2 Specifies alpha channel of color 2. 0x00: Transparent ⋮ 0xFF: Opaque.	W

Note: S-TYPE-3, P-TYPE-3

55.2.9 PATTERN : Pattern Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x74



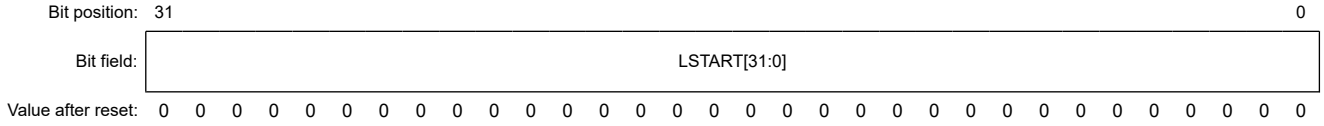
Bit	Symbol	Function	R/W
7:0	PATTERN[7:0]	Bitmap of the Pattern Specifies bitmap of the pattern.	W
31:8	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

55.2.10 LnSTART : Limiter n Start Value Register (n = 1 to 6)

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x10 + 0x4 × (n - 1)



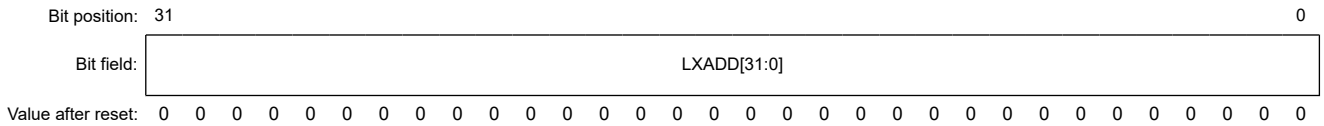
Bit	Symbol	Function	R/W
31:0	LSTART[31:0]	Start Value of the nth Limiter Specifies start value of the nth limiter.	W

Note: S-TYPE-3, P-TYPE-3

55.2.11 LnXADD : Limiter n X-Axis Increment Register(n = 1 to 6)

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x28 + 0x4 × (n - 1)



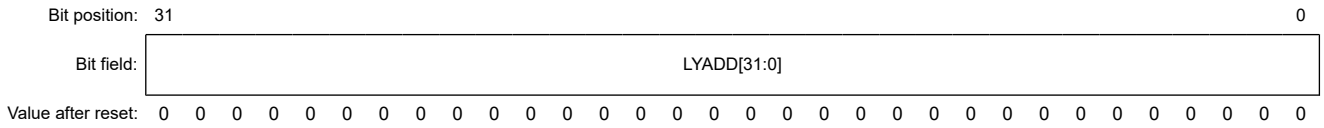
Bit	Symbol	Function	R/W
31:0	LXADD[31:0]	X-Axis Increment Specifies x-axis increment.	W

Note: S-TYPE-3, P-TYPE-3

55.2.12 LnYADD : Limiter n Y-Axis Increment Register(n = 1 to 6)

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x40 + 0x4 × (n - 1)



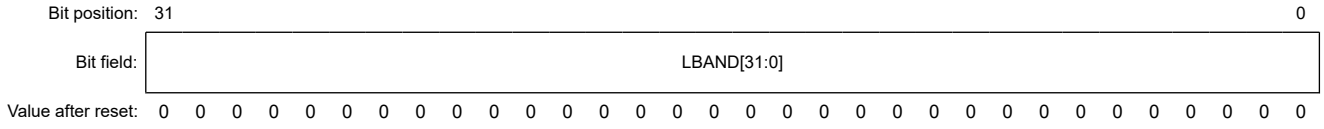
Bit	Symbol	Function	R/W
31:0	LYADD[31:0]	Y-Axis Increment Specifies y-axis increment.	W

Note: S-TYPE-3, P-TYPE-3

55.2.13 LmBAND : Limiter m Band Width Parameter Register(n = 1, 2)

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x58 + 0x4



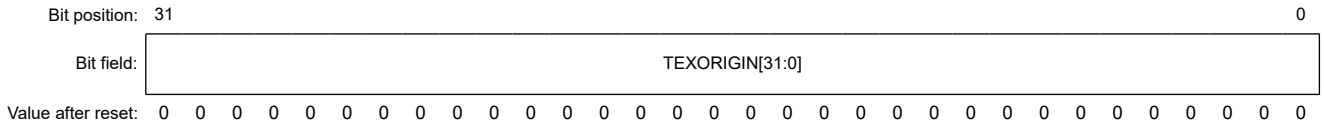
Bit	Symbol	Function	R/W
31:0	LBAND[31:0]	Limiter m Band Width Parameter Specifies limiter m band width parameter.	W

Note: S-TYPE-3, P-TYPE-3

55.2.14 TEXORIGIN : Texture Base Address Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xBC



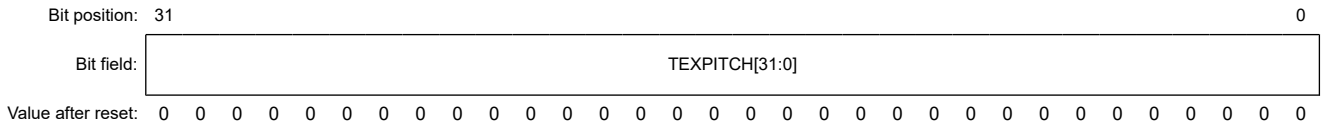
Bit	Symbol	Function	R/W
31:0	TEXORIGIN[31:0]	Texture Base Address Specifies texture base address.	W

Note: S-TYPE-3, P-TYPE-3

55.2.15 TEXPITCH : Texels Per Texture Line Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xB4



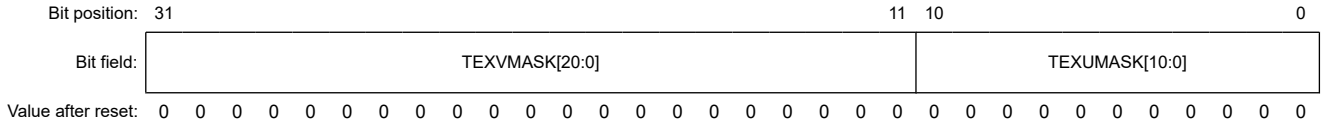
Bit	Symbol	Function	R/W
31:0	TEXPITCH[31:0]	Texels Per Texture Line Specifies texels per texture line. Valid range is from 0 to 2048.	W

Note: S-TYPE-3, P-TYPE-3

55.2.16 TEXMASK : Texture Size or Texture Address Mask Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xB8



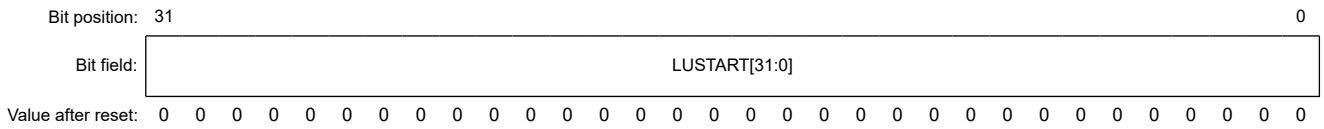
Bit	Symbol	Function	R/W
10:0	TEXUMASK[10:0]	U Mask in Texture Mode Specifies the U mask. Set to texture_width -1. ● In texture wrapping mode (CONTROL2.TEXTURECLAMPX = 0): Texture_width must be a power of 2 ● In texture clamping mode (CONTROL2.TEXTURECLAMPX = 1): All widths up to 2048 are allowed.	W
31:11	TEXVMASK[20:0]	V Mask in Texture Mode Specifies the V mask. Set to DRWTEXPITCH (texture_height - 1). ● In texture wrapping mode (CONTROL2.TEXTURECLAMPY = 0): Texture_height must be a power of 2 ● In texture clamping mode (CONTROL2.TEXTURECLAMPY = 1): All heights up to 1024 are allowed.	W

Note: S-TYPE-3, P-TYPE-3

55.2.17 LUSTART : U Limiter Start Value Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x90



Bit	Symbol	Function	R/W
31:0	LUSTART[31:0]	U Limiter Start Value Specifies U limiter start value.	W

Note: S-TYPE-3, P-TYPE-3

55.2.18 LUXADD : U Limiter X-Axis Increment Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x94

Bit position:	31																												0
Bit field:	LUXADD[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	LUXADD[31:0]	U Limiter X-Axis Increment Specifies U limiter x-axis increment.	W

Note: S-TYPE-3, P-TYPE-3

55.2.19 LUYADD : U Limiter Y-Axis Increment Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x98

Bit position:	31																												0
Bit field:	LUYADD[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	LUYADD[31:0]	U Limiter Y-Axis Increment Specifies U limiter y-axis increment.	W

Note: S-TYPE-3, P-TYPE-3

55.2.20 LVSTARTI : V Limiter Start Value Integer Part Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x9C

Bit position:	31																												0
Bit field:	LVSTARTI[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

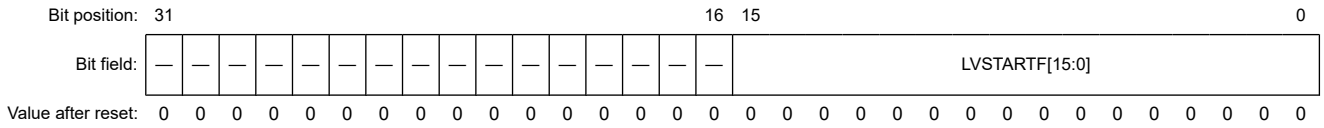
Bit	Symbol	Function	R/W
0	LVSTARTI[31:0]	V Limiter Start Value Integer Part Specifies integer part of V limiter start value.	W

Note: S-TYPE-3, P-TYPE-3

55.2.21 LVSTARTF : V Limiter Start Value Fractional Part Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xA0



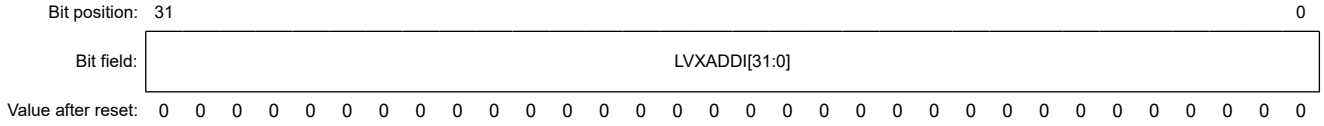
Bit	Symbol	Function	R/W
15:0	LVSTARTF[15:0]	V Limiter Start Value Fractional Part Specifies fractional part of V limiter start value.	W
31:16	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

55.2.22 LVXADDI : V Limiter X-Axis Increment Integer Part Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xA4



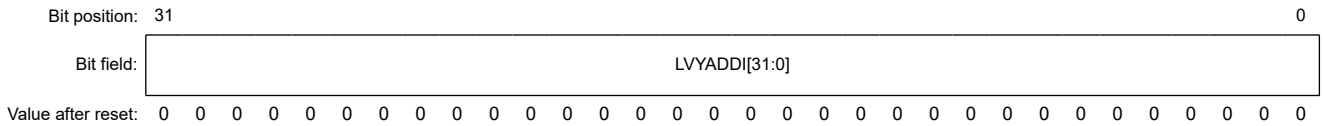
Bit	Symbol	Function	R/W
31:0	LVXADDI[31:0]	V Limiter X-Axis Increment Integer Part Specifies integer part of V limiter x-axis increment.	W

Note: S-TYPE-3, P-TYPE-3

55.2.23 LVYADDI : V Limiter Y-Axis Increment Integer Part Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xA8



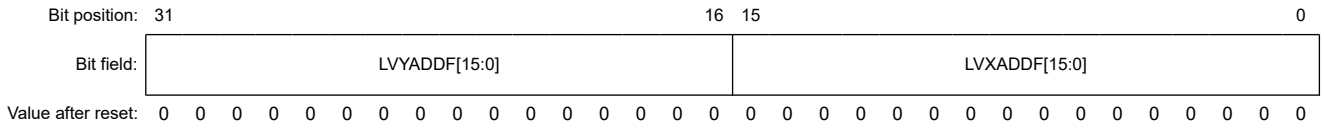
Bit	Symbol	Function	R/W
31:0	LVYADDI[31:0]	V Limiter Y-Axis Increment Integer Part Specifies integer part of V limiter y-axis increment.	W

Note: S-TYPE-3, P-TYPE-3

55.2.24 LVYXADDF : V Limiter Increment Fractional Parts Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xAC



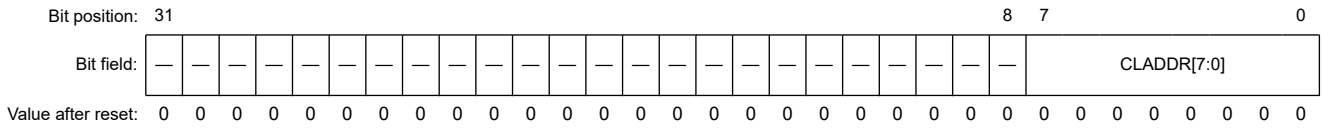
Bit	Symbol	Function	R/W
15:0	LVXADDF[15:0]	V Limiter X-Axis Increment Fractional Part Specifies fractional part of V limiter x-axis increment.	W
31:16	LVYADDF[15:0]	V Limiter Y-Axis Increment Fractional Part Specifies fractional part of V limiter y-axis increment.	W

Note: S-TYPE-3, P-TYPE-3

55.2.25 TEXCLADDR : CLUT Start Address Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xDC



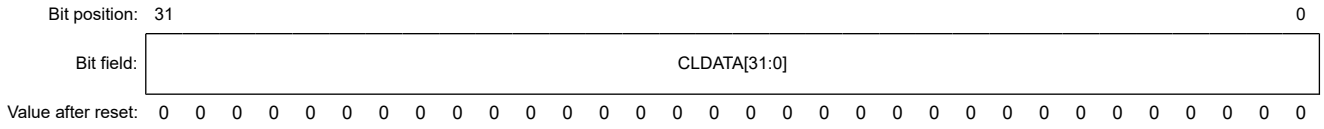
Bit	Symbol	Function	R/W
7:0	CLADDR[7:0]	Texture CLUT Start Address Specifies texture CLUT start address.	W
31:8	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

55.2.26 TEXCLDATA : CLUT Data Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xE0



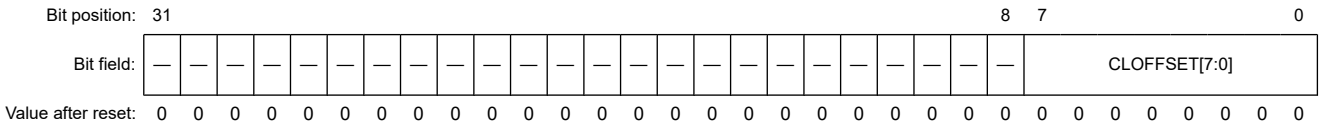
Bit	Symbol	Function	R/W
31:0	CLDATA[31:0]	Texture CLUT Data Specifies texture CLUT data.	W

Note: S-TYPE-3, P-TYPE-3

55.2.27 TEXCLOFFSET : CLUT Offset Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xE4



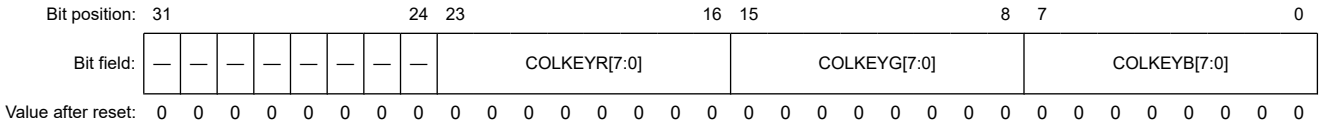
Bit	Symbol	Function	R/W
7:0	CLOFFSET[7:0]	Texture CLUT Offset Specifies texture CLUT offset. CLOFFSET[7:0] is OR gated with the original index.	W
31:8	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

55.2.28 COLKEY : Color Key Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xE8



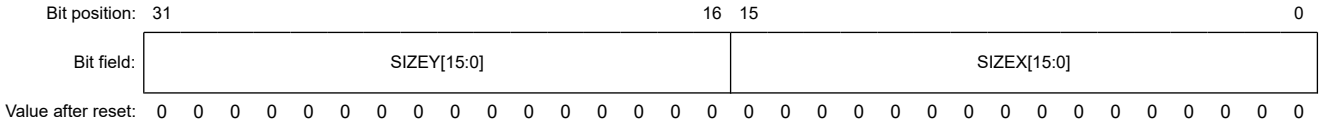
Bit	Symbol	Function	R/W
7:0	COLKEYB[7:0]	Blue Channel of Color Key Specifies blue channel of color key.	W
15:8	COLKEYG[7:0]	Green Channel of Color Key Specifies green channel of color key.	W
23:16	COLKEYR[7:0]	Red Channel of Color Key Specifies red channel of color key.	W
31:24	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

55.2.29 SIZE : Bounding Box Dimension Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x78



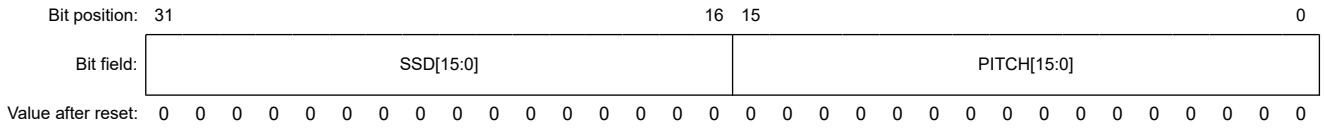
Bit	Symbol	Function	R/W
15:0	SIZEX[15:0]	Bounding Box Width Specifies the width of bounding box in pixels. Valid range is 0 to 1024.	W
31:16	SIZEY[15:0]	Bounding Box Height Specifies the height of bounding box in pixels. Valid range is 0 to 1024.	W

Note: S-TYPE-3, P-TYPE-3

55.2.30 PITCH : Framebuffer Pitch And Spanstore Delay Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x7C



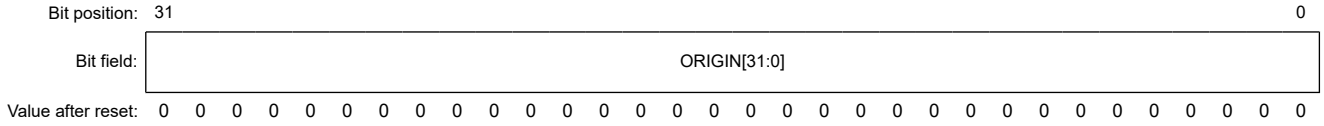
Bit	Symbol	Function	R/W
15:0	PITCH[15:0]	Pitch of the Framebuffer A negative width can be used to render bottom-up instead of top-down.	W
31:16	SSD[15:0]	Spanstore Delay Specifies the number of scan lines to delay spanstore operations.	W

Note: S-TYPE-3, P-TYPE-3

55.2.31 ORIGIN : Framebuffer Base Address Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x80



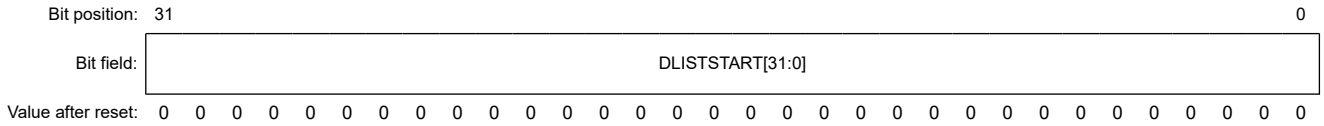
Bit	Symbol	Function	R/W
31:0	ORIGIN[31:0]	Address of the First Pixel in Framebuffer Writing to ORIGIN[31:0] triggers the start of rendering.	W

Note: S-TYPE-3, P-TYPE-3

55.2.32 DLISTSTART : Display List Start Address Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xC8



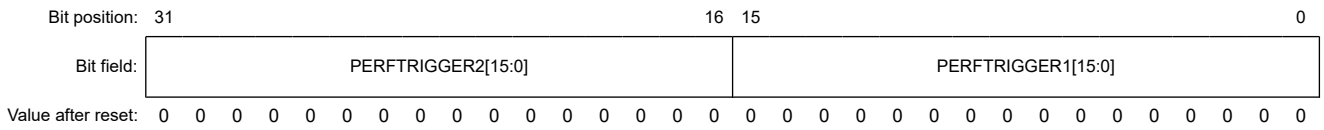
Bit	Symbol	Function	R/W
31:0	DLISTSTART[31:0]	Display List Start Address Setting a new display list base address triggers execution of the new display list. Execution stops only when a new list is set or the current list terminates.	W

Note: S-TYPE-3, P-TYPE-3

55.2.33 PERFTRIGGER : Performance Counters Control Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xD4



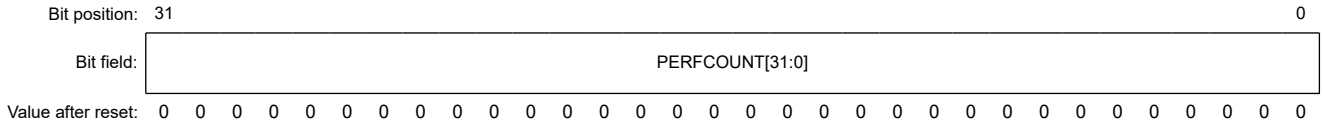
Bit	Symbol	Function	R/W
15:0	PERFTRIGGER1[15:0]	Trigger of Performance Counter 1 Select the internal event that increments the PERFCOUNT1 register. 0x0000: Disable performance counter 0x0001: Select 2D Drawing Engine active cycles 0x0002: Select framebuffer read access 0x0003: Select framebuffer write access 0x0004: Select texture read access 0x0005: Select invisible pixels (enumerated but selected with alpha 0%) 0x0006: Select invisible pixels while internal FIFO is empty (lost cycles) 0x0007: Select display list reader active cycles 0x0008: Select framebuffer read hits 0x0009: Select framebuffer read misses 0x000A: Select framebuffer write hits 0x000B: Select framebuffer write misses 0x000C: Select texture read hits 0x000D: Select texture read misses 0x001F: Select every clock cycle (for use as timer). Others: Setting prohibited.	W
31:16	PERFTRIGGER2[15:0]	Trigger of Performance Counter 2 Select the internal event that increments the PERFCOUNT2 register. See the above settings for performance counter 2.	W

Note: S-TYPE-3, P-TYPE-3

55.2.34 PERFCOUNTk : Performance Counter k (k = 1, 2)

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xCC (PERFCOUNT1)
0xD0 (PERFCOUNT2)



Bit	Symbol	Function	R/W
31:0	PERFCOUNT[31:0]	Performance Counter k Value Specifies counter k value. The counter is reset by writing PERFCOUNTk = 0x0000_0000.	R/W

Note: S-TYPE-3, P-TYPE-3

55.3 Drawing Features

55.3.1 Drawing Features Summary

55.3.1.1 Color formats

Supported color formats are:

(1) Framebuffer formats

- 8-bit: A (8)
- 16-bit: RGB (565), ARGB (4444)
- 32-bit: ARGB (8888).

(2) Texture formats

- 1-bit: CLUT (1)/I (1)
- 2-bit: CLUT (2)/I (2)
- 4-bit: CLUT (4)/I (4)
- 8-bit: A (8), CLUT (8)/I (8), ACLUT (44)
- 16-bit: ARGB (4444), ARGB (1555), RGB (565)
- 24-bit: RGB (888) (run length encoded (RLE) unit)
- 32-bit: ARGB (8888).

CLUT formats use a 256-entry color Lookup table.

55.3.1.2 BitBLT features

The 2D Drawing Engine supports the BitBLT features using its vector drawing function to draw a rectangle and texture it based on the selected BitBLT function. This approach results in the following BitBLT features:

- Fill
- Copy
- Stretch BitBLT
- Rotate and scale
- Alpha blending
- Bilinear filtering
- Color conversion
- Subpixel exact placement.

55.3.1.3 Vector drawing features

The vector 2D Drawing Engine uses a half-plane rendering approach, which simplifies implementation of edge antialiasing and blurring features without much overhead. When combining some of its functional units, the module can draw not only linear primitives such as lines or polygons, but also quadratic equation-based primitives such as circles and ellipsoids. The following primitives are supported:

- Lines
- Polygons
- Circles and ellipses
- Quadratic curves (software driver support)

- 2D texture mapping
- Bilinear filtering of the textures.

55.3.2 Vector Drawing

For a detailed explanation of the algorithms, see section 55.6. Rendering Pipeline. Supported vector drawing includes:

(1) Lines

- Arbitrary width
- Round endpoints
- Truncated endpoints
- Alpha gradients
- Soft edges (blurring)
- Render attribute: color, pattern, or texture.

(2) Polygons

- Triangles and quadrangles (complex polygons are tessellated by software)
- Alpha gradients
- Soft edges (blurring)
- Per edge controls for anti-aliasing
- Render attribute: color, pattern, or texture.

(3) Circles and ellipses

- All conic sections
- Filled or with arbitrary width
- Arcs of 0° to 360°
- Soft edges
- Alpha gradients
- Render attribute: color, pattern, or texture.

(4) Quadratic Bézier

- Approximated by circle arcs
- Arbitrary width
- Round or truncated endpoints
- Outlines, blurring
- Alpha gradients
- Render attribute: color.

(5) Texture mapping

- 2D array of pixels that can be mapped implicitly or explicitly on all primitives provided by the 2D Drawing Engine
- Translation, rotation, and scaling/shearing
- Bilinear filtering of the textures
- 3D-like texturing accomplished with line-by-line mapping, if constant in one axis.

55.3.3 BitBLT

A dedicated BitBLT unit is not required in the 2D Drawing Engine. The rendering pipeline described for vector drawing is used as the BitBLT unit and already provides a 1 pixel/cycle throughput. For details, see section 55.6. Rendering Pipeline.

55.3.3.1 Fill

A rectangle in the framebuffer can be filled with any value. Possible color formats are 8-, 16-, or 32-bpp format. The driver optimizes the fill to gain the full benefit of 32-bit parallel rasterization. If the selected color format is less than 32 bpp, the driver corrects the alignment and fills 32 bits per clock, resulting in 2 to 4 times faster fill performance for 8- and 16-bpp formats.

55.3.3.2 Copy

A rectangle in the framebuffer can be filled with any rectangular data from the texture input. When the texture input points to the framebuffer, copying from framebuffer to framebuffer is possible. To avoid copy problems because of overlapping source and destination areas, the copy start point can be selected from top left to bottom right. Possible color formats are 8-, 16-, or 32-bpp format.

The driver optimizes the copy to gain the full benefit of 32-bit parallel rasterization. If the selected color format is less than 32 bpp, the driver corrects the alignment and copies 32 bits per clock, resulting in 2 to 4 times faster copy performance for 8- and 16-bpp formats.

55.3.3.3 Stretch BitBLT

This is similar to the normal copy operation. Because the copy is done as a type of texture mapping, the full texture mapping feature set can be used. Any scaling ratios in the x and y directions is selectable, and filtering can be enabled independently for each axis.

55.3.3.4 Rotate and scale

This is similar to the normal copy operation. Because the copy is done as a type of texture mapping, the full texture mapping feature set can be used. Any scaling ratios in the x and y direction and any rotation angle is selectable. The x and y directions can be rotated and scaled independently, and filtering for the scalers can be enabled independently for each axis.

55.3.3.5 Alpha blending

Alpha blending is a fundamental block in the rendering pipeline, so the full alpha blend feature set is available for any BitBLT operation. It is possible to copy an area and blend it over the destination by using any constant global alpha value (register value) or by using an alpha mask. The alpha mask is part of the texture data and can be either a per-pixel value together with a pixel color (ARGB formats) or an alpha-only format using a register color.

In addition to the color channels, the alpha channel can be blended. The formula for the alpha channel can be set independently from the formula for the color channels.

55.3.3.6 Bilinear filtering

The texture unit can be used to scale, rotate, or shear images. The texturing result can be filtered in the x and y directions independently. When selecting both filters, the result is a bilinear filtered texture. Using the unit twice with two independent textures would generate trilinear filtered bitmaps, improving the visual impression for high dynamic scale ratios.

55.3.3.7 Color conversion

Color conversion is required when using different texture formats than the framebuffer format. To save texture memory, several formats are supported with less bpp than the framebuffer normally has. The 2D Drawing Engine always operates internally with 32-bpp ARGB (8888). All input data is converted into 32 bpp, and is finally converted back into the framebuffer format.

55.4 Input and Output Data Formats

55.4.1 Source and Destination Data

There are two possible inputs, the framebuffer and the texture or pattern input. The output is always the framebuffer.

Every drawing operation is internally rendered in 32 bpp ARGB (8888). If the input color does not provide an alpha channel, the blue channel is taken as the alpha channel. This alpha can be substituted with any alpha (for example, by an external constant) during the colorization step in the 2D Drawing Engine.

55.4.2 Framebuffer Color Formats

Table 55.2 shows the supported framebuffer color formats.

Table 55.2 Framebuffer color formats

Framebuffer memory occupation	Format	Remarks
8 bpp	A (8)	This color format uses 1 byte per pixel. The alpha channel is internally replicated on the red, blue, and green channels and can be substituted with any color during the color step in the 2D Drawing Engine.
16 bpp	RGB (565)	This color format uses 2 bytes per pixel with 5 bits for red and blue and 6 bits for green. The blue color is taken as the alpha channel during color conversion. The alpha can be substituted with any alpha during the colorization step in the 2D Drawing Engine.
	ARGB (4444)	This color format uses 2 bytes per pixel with 4 bits for each color and alpha channel.
32 bpp	ARGB (8888)	This color format uses 4 bytes per pixel with 8 bits for each color and alpha channel.

The framebuffer color format is selected in the Surface Control Register with the CONTROL2.READFORMAT[2:0] bits.

55.4.3 Texture Color Formats

Table 55.3 shows the supported texture color formats.

Table 55.3 Texture color formats

Texture memory occupation	Format	Remarks
1 bpp	CLUT (1)/I (1)	In this mode, a 1-bit index is used to address one of 256 predefined colors in the color lookup table. If the CLUT is not used, the index is taken as a luminance value.
2 bpp	CLUT (2)/I (2)	In this mode, a 2-bit index is used to address one of 256 predefined colors in the color lookup table. If the CLUT is not used, the index is taken as a luminance value.
4 bpp	CLUT (4)/I (4)	In this mode, a 4-bit index is used to address one of 256 predefined colors in the color lookup table. If the CLUT is not used, the index is taken as a luminance value.
8 bpp	CLUT (8)/I (8)	In this mode, an 8-bit index is used to address one of 256 predefined colors in the color lookup table. If the CLUT is not used, the index is taken as a luminance value.
	A (8)	This color format uses 1 byte per pixel. The alpha channel is internally replicated on the red, blue, and green channels and can be substituted with any color during the colorization step in the 2D Drawing Engine.
	ACLUT (44)	This color format uses 1 byte per pixel. 4 bits are used as an alpha value and 4 bits are used as an index to a color palette. This approach saves space if 16 colors are sufficient to describe the image, because the next bigger alpha format would be 2-byte ARGB (4444).
16 bpp	RGB(565)	This color format uses 2 bytes per pixel with 5 bits for red and blue and 6 bits for green. The blue color is taken as the alpha channel during color conversion. The alpha can be substituted with any alpha during the colorization step in the 2D Drawing Engine.
	ARGB (4444)	This color format uses 2 bytes per pixel with 4 bits for each color and alpha channel.
	ARGB (1555)	This color format uses 2 bytes per pixel. Every color channel has 5 bits and the topmost single bit is taken as an alpha value. This can be used to hold an image with a transparency mask.
24 bpp	RGB (888)	This color format uses 3 bytes per pixel with 8 bits for each color channel. This format is only available as run length encoded data (RLE compression).
32 bpp	ARGB (8888)	This color format uses 4 bytes per pixel with 8 bits for each color and alpha channel.

The texture color format is selected in the Surface Control Register with the CONTROL2.WRITEFORMAT[3:0] bits.

55.5 Texture Data Processing

Figure 55.4 shows the processing of texture data.

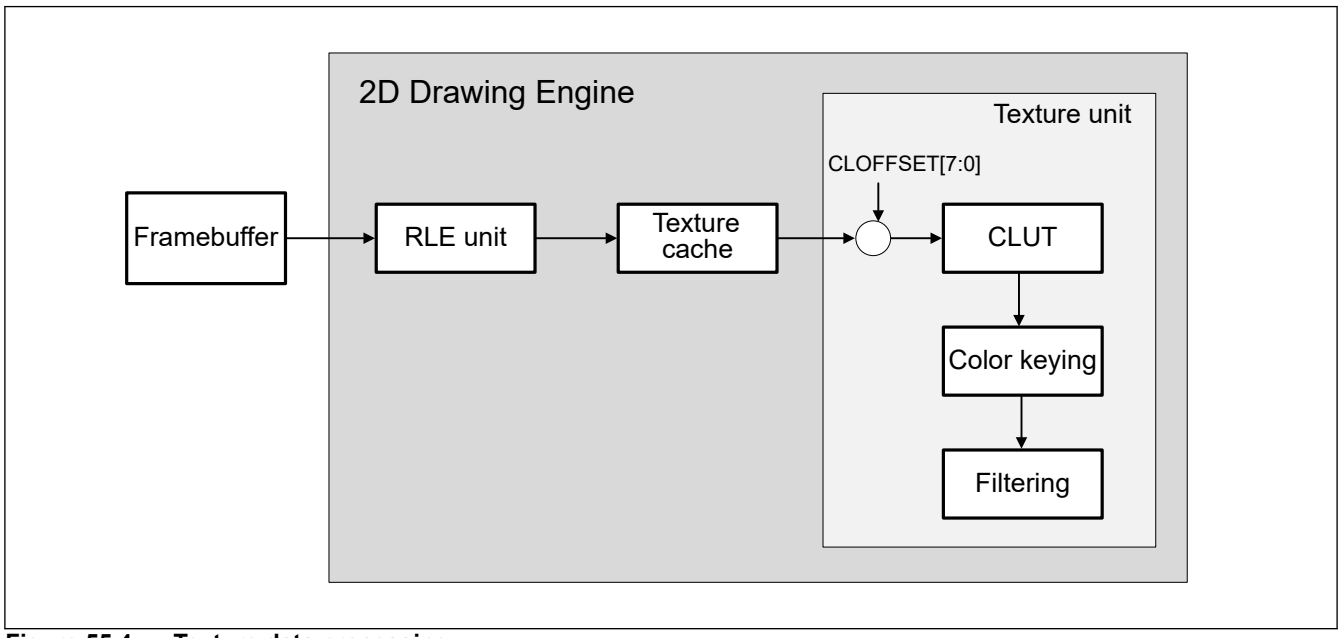


Figure 55.4 Texture data processing

55.5.1 Texture Color Format

Table 55.4 shows the supported texture data formats.

Table 55.4 Texture color formats

Texel bit width	Texel format
32 bits	ARGB (8888)
24 bits	RGB (888)
16 bits	ARGB (4444), ARGB (1555), RGB (565)
8 bits	CLUT (8)I (8), A (8), ACLUT (44)
4 bits	CLUT (4)/I (4)
2 bits	CLUT (2)/I (2)
1 bit	CLUT (1)/I (1)

55.5.2 Run Length Encoded (RLE) Unit

The RLE unit decompresses Targa-like compressed textures and hands the decompressed texel data over to the texture unit. The key features are:

- Support for Targa format
- Avoid the additional Targa limitation to scan lines
- Support for clipping of compressed images, in which the 2D Drawing Engine is allowed to copy only a portion of a larger original texture
- Control of the RLE unit in drawing list operation
- Bypassing of the RLE unit logic if uncompressed textures are fetched from the framebuffer.

(1) Texture cache

The RLE unit feeds the texture cache. The texture cache can be disabled by setting CACHECTL.CENABLETX = 0.

Caution: A texture cache flush operation (CACHECTL.CFLUSHTX = 1) is necessary at the beginning and end of every new RLE texture.

The texture cache and the RLE unit can be bypassed by setting CONTROL2.RLEENABLE = 0.

55.5.2.1 RLE Texel formats

Table 55.5 lists the data formats supported by the RLE unit.

Table 55.5 Texel formats supported by the RLE unit

Memory texel format	RLE parameters	RLE coded unit format (CONTROL2.RLEPIXELWIDTH[1:0])	Delivered format
32-bit ARGB (8888)	Included in Targa and RLE formats	32 bits*1 (11b)	32 bits
24-bit RGB (888)		24 bits (10b)	32 bits
16-bit ARGB (4444), ARGB (1555), RGB (565)		16 bits (01b)	16 bits
8-bit CLUT (8)I (8), A (8), ACLUT (44)		8 bits (00b)	8 bits
4-bit CLUT (4)/I (4)	Optional for RLE*2	8 = 2 x 4 bits	4 + 4 bits
2-bit CLUT (2)/I (2)	No RLE		
1-bit CLUT (1)/I (1)			

Note 1. 24-bit RGB (888) encoded texels are delivered as ARGB (8888) with Alpha set to 1.
Note 2. Encoding of textures with 4 bits per texel is not defined by the Targa specification but can be done by:

- Combining two 4-bit texels to one byte
- Padding with four 0-bit at the end of the file, if the number of texels is odd
- Encoding as with 8-bit texels.

(1) Texel addressing for RLE textures

The address of a texel is the byte address of the first byte of the texel. The origin of the texture is given by the register TEXORIGIN.

Note: The RLE code must begin at a word boundary of the memory.

Caution: When the FIFO is filled, there is no provision to inhibit read access beyond the end of the RLE code. To avoid memory access violations, the RLE code must be padded by 32 memory words, where every bit of each word is set to 1.

55.5.2.2 Targa RLE format

Run-length encoded (RLE) images include two types of data elements:

- Run-length packets
- Raw packets.

The first field (1 byte) of each packet is called the repetition count field. The second field is called the pixel value field (1, 2, 3. or 4 bytes). For run-length packets, the pixel value field contains a single pixel value. For raw packets, the field is a variable number of pixel values.

The highest order bit of the repetition count indicates whether the packet is a raw packet or a run-length packet, as follows:

- If bit [7] of the repetition count is set to 1, the packet is a run-length packet
- If bit [7] of the repetition count is set to zero, the packet is a raw packet.

The lower 7 bits of the repetition count specify how many pixel values are represented by the packet. For a run-length packet, this count indicates how many successive pixels have the pixel value specified in the pixel value field. For raw packets, this count specifies how many pixel values are actually contained in the next field. This 7-bit value is actually encoded as 1 less than the number of pixels in the packet (a value of 0 implies 1 pixel while a value of 0x7F implies 128 pixels).

(1) Run-length packet

Run-length packets are composed of two parts. The first is a repetition count and the second is the pixel value to repeat.

Table 55.6 Run-length packet

Field name	Field size
Packet type (must be 1 for run-length)	1 bit
Pixel count (number of pixels encoded in this packet - 1)	7 bits
Pixel data (the shared pixel value to be used)	Pixel depth (field 5.5)

(2) Raw packet

The raw packet always includes two fields. The first field is the repetition count and the second field is the pixel data field.

Table 55.7 Raw packet

Field name	Field size
Packet type (must be 0 for raw packet)	1 bit
Pixel count (number of pixels encoded by this packet - 1)	7 bits
Pixel data	Pixel depth x pixel count - 1

55.5.3 Color Lookup Table (CLUT)

The color lookup table receives an index that addresses one out of the 256 predefined colors.

The predefined color format can be selected as:

- CONTROL2.CLUTFORMAT = 0: ARGB (8888)
- CONTROL2.CLUTFORMAT = 1: RGB (565).

The CLUT is filled by the use of two registers:

- TEXCLDATA
  The ARGB (8888) color definition is written to this register, while the CLUT address is taken from TEXCLADDR.
- TEXCLADDR.
  This is set to the first address of the CLUT to write to and is automatically incremented after each write to TEXCLDATA.

An offset for indexed formats (CLUT (1), CLUT (2), CLUT (4), and CLUT (8)) can be set up in the TEXCLOFFSET register to allow selecting an offset part of the CLUT. The CLUT index is calculated by CLUT (x) or TEXCLOFFSET.CLOFFSET[7:0].

55.5.3.1 CLUT/I pixel data formats

(1) CLUT (1)/I (1) format

The CLUT (1)/I (1) format expresses 1 pixel by using a total of 1 bit.

Memory byte	Pixel
7 (MSB)	P7
6	P6
5	P5
4	P4
3	P3
2	P2
1	P1
0 (LSB)	P0

The left-most pixel is stored at the lowest bit of the memory byte.

(2) CLUT (2)/I (2) format

The CLUT (2)/I (2) format expresses 1 pixel by using a total of 2 bits.

Memory byte	Pixel
7 (MSB)	P3
6	
5	P2
4	
3	P1
2	
1	P0
0 (LSB)	

The left-most pixel is stored at lowest 2 bits of the memory byte.

(3) CLUT (4)/I (4) format

The CLUT (4)/I (4) format expresses 1 pixel by using a total of 4 bits.

Memory byte	Pixel
7 (MSB)	P1
6	
5	
4	
3	P0
2	
1	
0 (LSB)	

The left-most pixel is stored at lowest 4 bits of the memory byte.

55.5.4 Color Keying

The 2D Drawing Engine provides a color keying unit in front of the texture unit. It operates as follows:

1. If enabled, the incoming color is compared with a transparent color, defined by COLKEY.
2. If the value matches, the alpha and color values are set to 0 to mark the color as transparent and handle it as if alpha was pre-multiplied.
3. If the value does not match, then alpha is set to 1.
4. Additional operations such as alpha_in × alpha_const are still possible.

With this approach, an object such as a round icon can be cut out from a rectangular texture and still can be faded by a constant alpha over the background.

55.6 Rendering Pipeline

55.6.1 Coordinate Transformation

Coordinate transformation such as rotation, translation, projection, and scaling must be done on the application side. This is not part of the 2D Drawing Engine hardware or driver. Because all coordinates fed into the 2D Drawing Engine are in fixed point format, these calculations can be made in fixed point format and do not require a floating point unit.

55.6.2 Rasterization

During rasterization, the vector data of the object must be converted to pixel data. To convert the data, the program sets up the edge interpolation hardware, called a limiter, for each edge of the object that calculates a decision value. The limiter determines which side of the edge the pixel is positioned on. The 2D Drawing Engine includes six internal hardware limiters. In principle, the limiter registers contain the distance between the pixel being processed and the edge.

In the linear setup, a limiter describes a half plane. The intersection of all half planes is the object. If three half planes intersect, a triangle is created as shown in Figure 55.5.

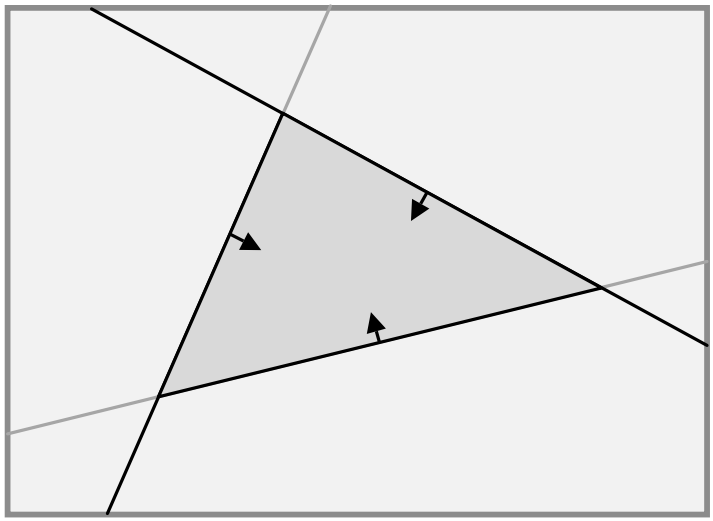

Figure 55.5 Intersection of half planes

The limiter output is clamped to an interval of [0:1]. In limiters 1 and 2 it is possible to apply a band filter before the clamping operation. In this case, the limiter is not describing a half plane but a small band. With this approach, a single limiter can describe a thick line of infinite length.

The output of the different limiters can be combined by the combiner units with a maximum or minimum operation. Maximum operation describes the union of both half planes, and minimum operation describes the intersection of both half planes. The final output is then used as an alpha value. Edge anti-aliasing can be done with no additional effort with this hardware.

To calculate the decision value for each possible pixel with a limiter, the bounding box of the object must be calculated. Then, the decision value for the top left corner of the bounding box must be calculated for each edge. Finally, the increments for a step in the x direction and a step in the y direction must be calculated. This is done by the CPU in the driver.

With this information, the 2D Drawing Engine scans the whole bounding box and calculates the decision value for every pixel incrementally. For a block diagram of the entire rasterization unit, see section 55.1. Overview.

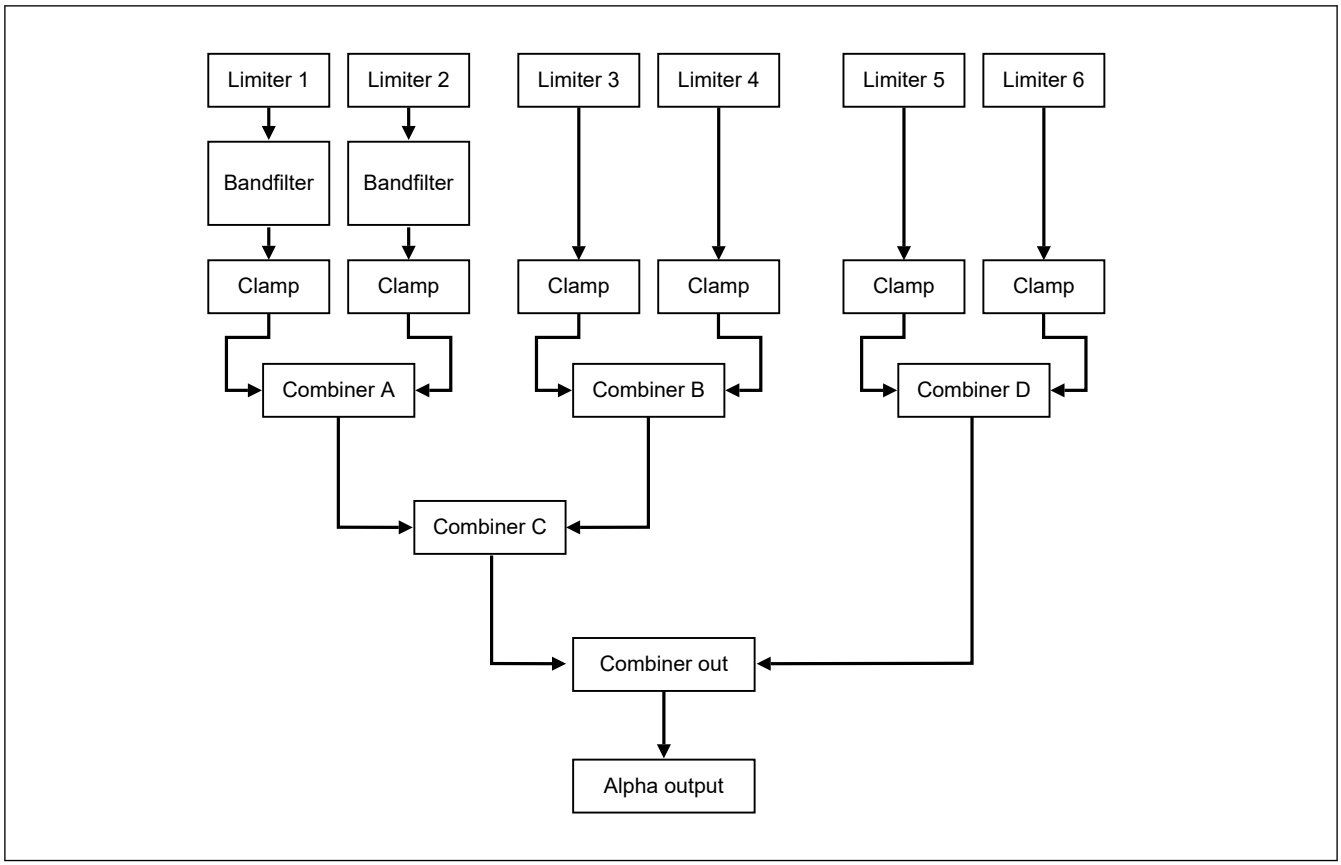

Figure 55.6 Block diagram of rasterization unit

The limiters calculate distances and the combiner units combine them to an alpha value. The combiner units define the conditions for whether or not a pixel is in the bounding box. The alpha value must be greater than 0.

Note: It is possible to have all limiters switched off.

55.6.2.1 Edge setup linear case

(1) Mathematical background

To setup a linear edge, consider the line equation in the classical form.

This can be written as:

$y = \widetilde{a}x + \widetilde{b}$

This can be rewritten as:

$0 = f(x,y) = \widetilde{a}x - y + \widetilde{b} = \mathrm{ax} + \mathrm{by} + c$

with $a = \widetilde{a}$, $b = -1$, $c = \widetilde{b}$

This is a more general form. Consider a vector form of this equation:

$\vec{p} = \begin{pmatrix} x \\ y \end{pmatrix}, \vec{n} = \begin{pmatrix} a \\ b \end{pmatrix} \Rightarrow f(x,y) = \mathrm{ax} + \mathrm{by} + c = \vec{p} \cdot \vec{n} + c$

If a point $\vec{p}_0$ is on the line:

$0 = f(x,y) = \vec{p}_0 \cdot \vec{n} + c \Rightarrow c = -\vec{p}_0 \cdot \vec{n}$

Rewriting the constant, the equation becomes:

$c = -\vec{p}_0 \cdot \vec{n} \Rightarrow f(x,y) = \left(\vec{p} - \vec{p}_0\right) \cdot \vec{n}$

The vector $\vec{n}$ is called the normal vector and is perpendicular to the line. The setup can be seen in Figure 55.7.

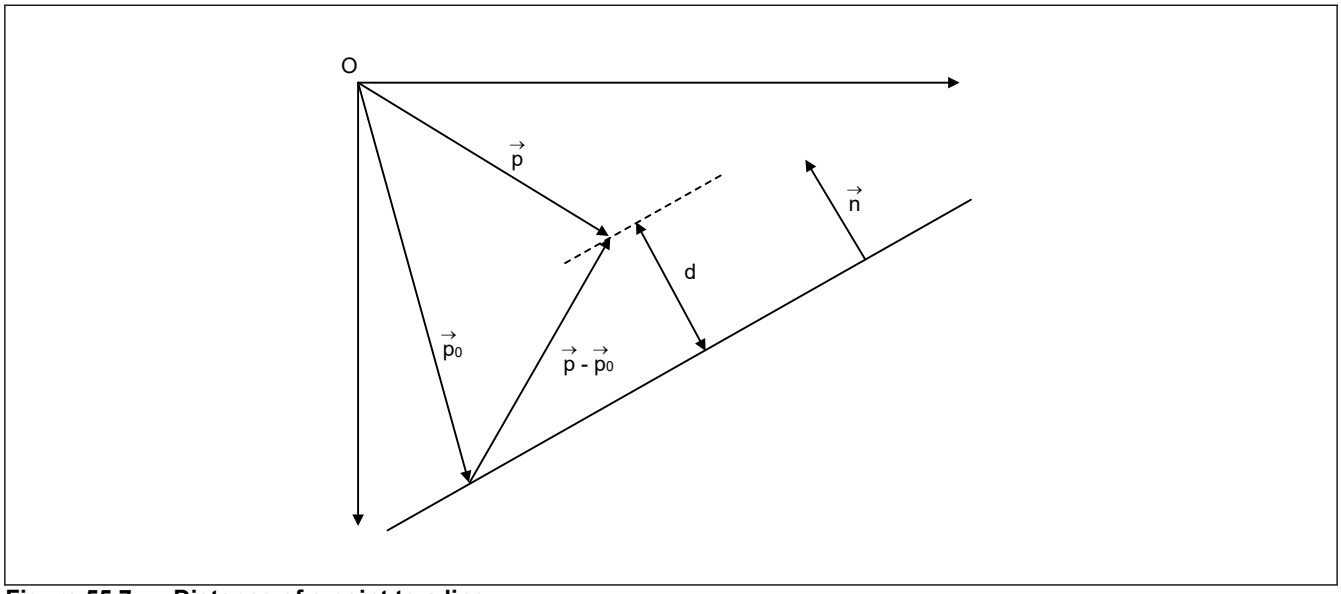

Figure 55.7 Distance of a point to a line

The projection of $\vec{p} - \vec{p}_0$ to $\vec{n}$ is the distance d of the point P to the line. In this case, f (x, y) describes the distance to the line of the pixel with coordinates (x, y).

To calculate the distance of every pixel of the bounding box incrementally, first the distance to the line at origin must be calculated:

$f(0,0) = -\vec{p}_0 \cdot \vec{n} = c$

Next the increments for a step in the x direction and a step in the y direction must be calculated:

$f\left(\vec{p} + \vec{e}_x\right) = \left(\vec{p} + \vec{e}_x - \vec{p}_0\right) \cdot \vec{n} = f\left(\vec{p}\right) + \vec{e}_x \cdot \vec{n} = f\left(\vec{p}\right) + a$

$f\left(\vec{p} + \vec{e}_y\right) = \left(\vec{p} + \vec{e}_y - \vec{p}_0\right) \cdot \vec{n} = f\left(\vec{p}\right) + \vec{e}_y \cdot \vec{n} = f\left(\vec{p}\right) + b$

with $\vec{e}_x = \begin{pmatrix}1\\0\end{pmatrix}, \vec{e}_y = \begin{pmatrix}0\\1\end{pmatrix}$

Consequently, the new distance can be calculated from the old distance with the increments a and b. A step in the x direction changes the distance by a, and a step in the y direction changes the distance by b. The distance of the origin to the line is c.

With this information, the entire bounding box can be scanned. If the bounding box top left corner is not at the origin, an offset must be added.

(2) Limiter operation

The 2D Drawing Engine contains six limiters. Each limiter contains three registers:

- LnSTART
- LnXADD
- LnYADD.

See Figure 55.8 for details. It is possible to drive the limiters in a threshold mode, in which all values above 0.5 are set to 1, and all values below or equal to 0.5 are set to 0. This feature is used when anti-aliasing is not wanted.

Note: In Figure 55.8, the following abbreviations are used:

start = LnSTART
xadd = LnXADD
yadd = LnYADD

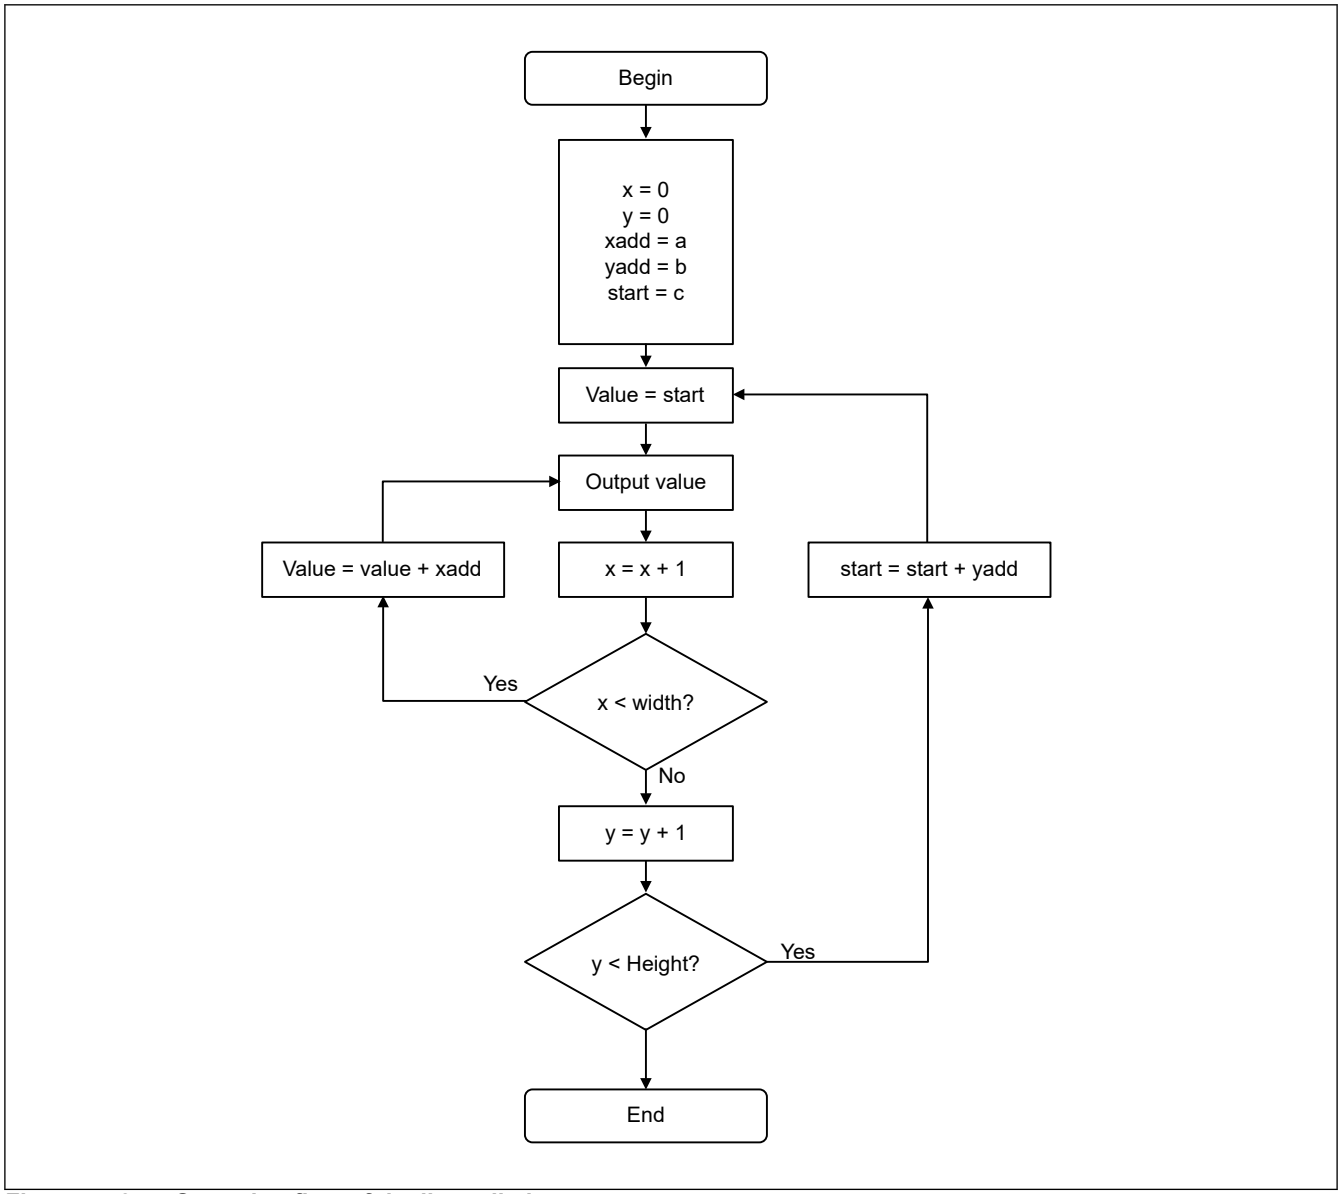

Figure 55.8 Operation flow of the linear limiter

(3) Example

If a straight line is given by the points P0 and P1, then the values are calculated as follows:

$$\Delta\vec{p} = \vec{p}_1 - \vec{p}_0 = \begin{pmatrix} x_1 - x_0 \\ y_1 - y_0 \end{pmatrix} = \begin{pmatrix} \Delta x \\ \Delta y \end{pmatrix}$$

The normal vector (perpendicular but not unit size) is then:

$$\vec{n} = \begin{pmatrix} -\Delta y \\ \Delta x \end{pmatrix}$$

The not normalized distance between edge and origin is then:

$$\vec{p}_0 \cdot \vec{n} = -x_0\Delta y + y_0\Delta x$$

The limiter parameters would be:

$\text{start} = -x_0\Delta y + y_0\Delta x$

$\text{xadd} = -\Delta y$

$\text{yadd} = \Delta x$

In the normalized case, the normal vector is:

$$\vec{n} = \begin{pmatrix} -\Delta y \\ \Delta x \end{pmatrix} \cdot \frac{1}{\sqrt{\Delta x^2 + \Delta y^2}}$$

The distance between edge and origin is:

$$\vec{p}_0 \cdot \vec{n} = \left(-x_0 \cdot \Delta y + y_0 \cdot \Delta x\right) \cdot \frac{1}{\sqrt{\Delta x^2 + \Delta y^2}}$$

The limiter parameters would be:

$$\text{start} = \left(-x_0\Delta y + y_0\Delta x\right) \cdot \frac{1}{\sqrt{\Delta x^2 + \Delta y^2}}$$

$$\text{xadd} = -\Delta y \cdot \frac{1}{\sqrt{\Delta x^2 + \Delta y^2}}$$

$$\text{yadd} = \Delta x \cdot \frac{1}{\sqrt{\Delta x^2 + \Delta y^2}}$$

Normalization is only required if anti-aliasing is used. The driver contains an optimized inverse square root function to speed up the normalization process.

55.6.2.2 Edge setup quadratic case

(1) Mathematical background

It is also possible to set up the limiters to incrementally calculate the following equation:

$f(x,y) = ax^2 + by^2 + cx + dy + f$

At the origin, the value is:

$f(0,0) = f$

The step in the x direction is:

$f(x+1,y)$

$= a(x+1)^2 + by^2 + c(x+1) + dy + f$

$= ax^2 + 2ax + a + by^2 + cx + c + dy + f$

$= f(x,y) + 2ax + c + a$

$dx(x) = f(x+1,y) - f(x,y) = 2ax + c + a$

The step in the y direction is:

$f(x,y+1)$

$= ax^2 + b(y+1)^2 + cx + d(y+1) + f$

$= ax^2 + by^2 + 2by + b + cx + d(y+1) + f$

$= f(x,y) + 2by + d + b$

$dy(y) = f(x,y+1) - f(x,y) = 2by + d + b$

In the quadratic case, the increments dx and dy depend on x and y and are not constant. They can be calculated incrementally:

$d^2x = dx(x+1) - dx(x) = 2a(x+1) + c + a - (2ax + c + a) = 2a$

$d^2y = dy(y+1) - dy(y) = 2b(y+1) + d + b - (2by + d + b) = 2b$

At the origin, the increments are:

$\mathrm{dx}(0) = c + a$ and $\mathrm{dy}(0) = d + b$

By incrementing the value by dx and dy for every step in the x and y direction and incrementing dx, dy by d^2x, and d^2y for every step in the x and y direction, the quadratic equation can be easily calculated for the whole bounding box.

(2) Limiter operation

In the quadratic case, two linear limiters are combined to operate as one quadratic limiter, called limiter 1 and limiter 2. The registers are:

- L1START, L1XADD, L1YADD
- L2START, L2XADD, L2YADD.

See Figure 55.9 for details. The gray box is an addition that performs a different operation, as in the linear setup. It is possible to drive the limiters in a threshold mode, in which all values above 0.5 are set to 1, and all values below or equal to 0.5 are set to 0. This feature is used when anti-aliasing is not needed.

Note: In Figure 55.9, the following abbreviations are used:

- start1 = L1START, start2 = L2START
- xadd1 = L1XADD, xadd2 = L2XADD
- yadd1 = L1YADD, yadd2 = L2YADD.

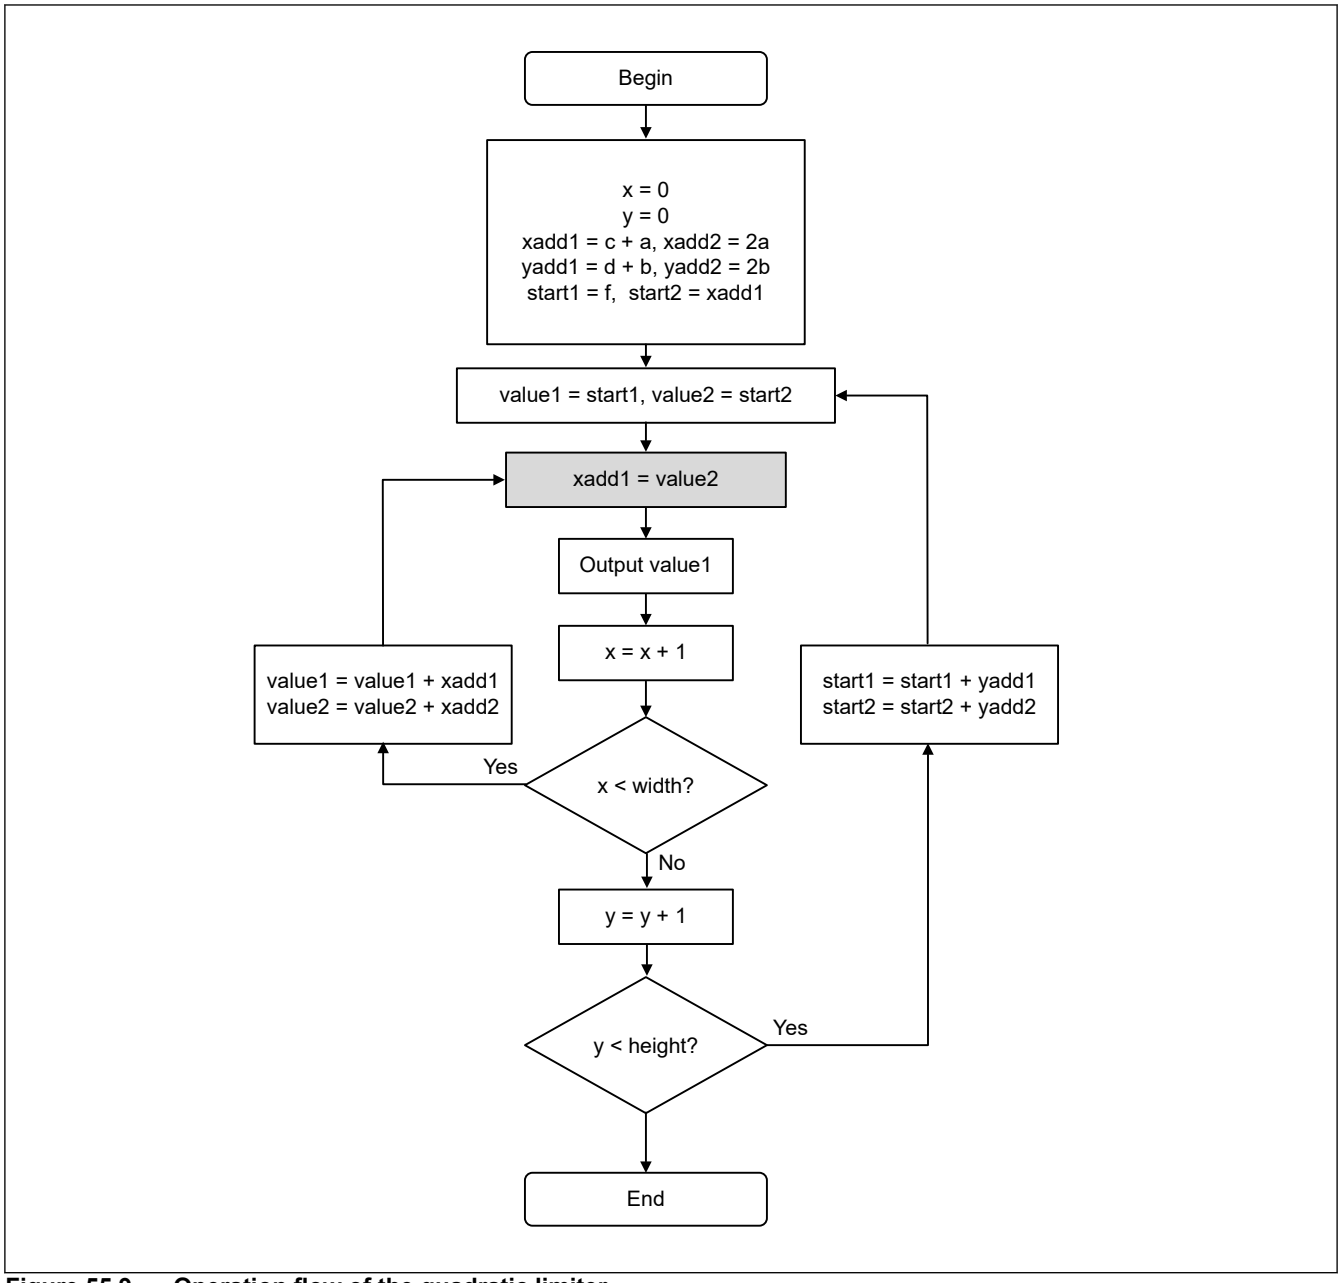

Figure 55.9 Operation flow of the quadratic limiter

(3) Example

Consider the equation for a circle with the center at $\vec{c} = \begin{pmatrix} s \\ t \end{pmatrix}$ and radius r:

$0 = f(x,y) = (x-s)^2 + (y-t)^2 - r^2$

This equation can be rewritten as:

$f(x,y) = x^2 - 2\mathrm{xs} + s^2 + y^2 - 2\mathrm{yt} + t^2 - r^2$

This can be sorted to fit to the original equation:

$f(x,y) = x^2 + y^2 - 2\mathrm{sx} - 2\mathrm{ty} + \left(s^2 + t^2 - r^2\right)$

With the following assignments, the circle equation can be calculated incrementally:

$a = 1$

$b = 1$

$c = -2s$

$d = -2t$

$f = s^2 + t^2 - r^2$

For the limiters with the results calculated in (1)Mathematical background, this would result in:

$\text{start1} = f = s^2 + t^2 - r^2$

$\text{xadd1} = c + a = -2s + 1$

$\text{yadd1} = d + b = -2t + 1$

$\text{start2} = \text{xadd1}$

$\text{xadd2} = 2a = 2$

$\text{yadd2} = 2b = 2$

55.6.2.3 Band filter

The output of limiter 1 and 2 can be modified to use a band filter. The band filter has a single filter parameter w.

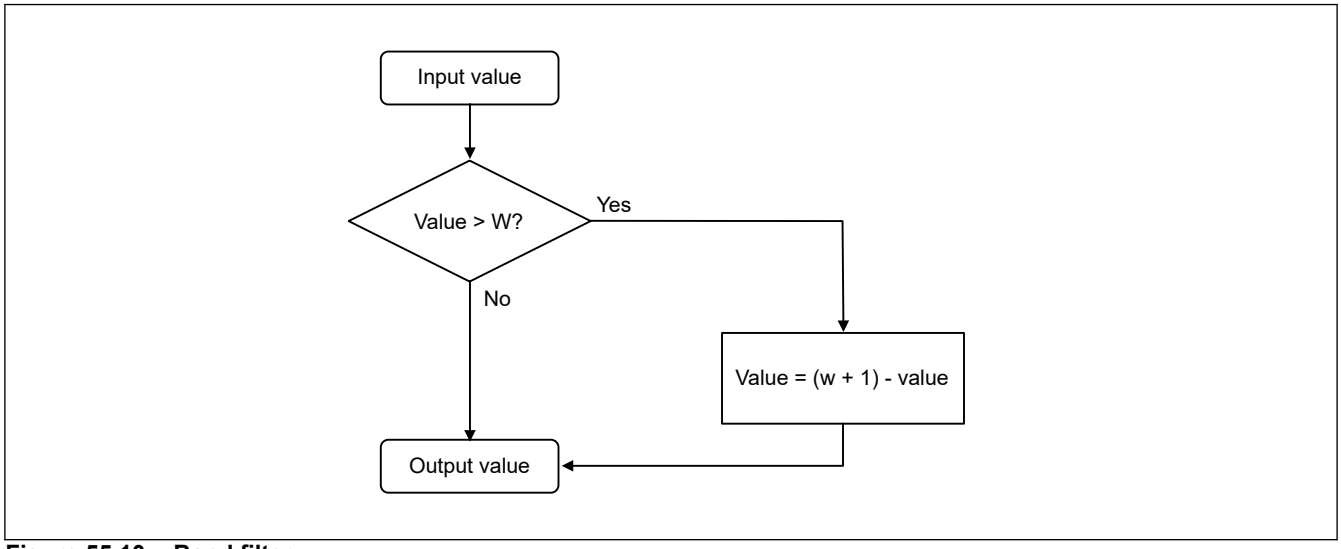

Figure 55.10 Band filter

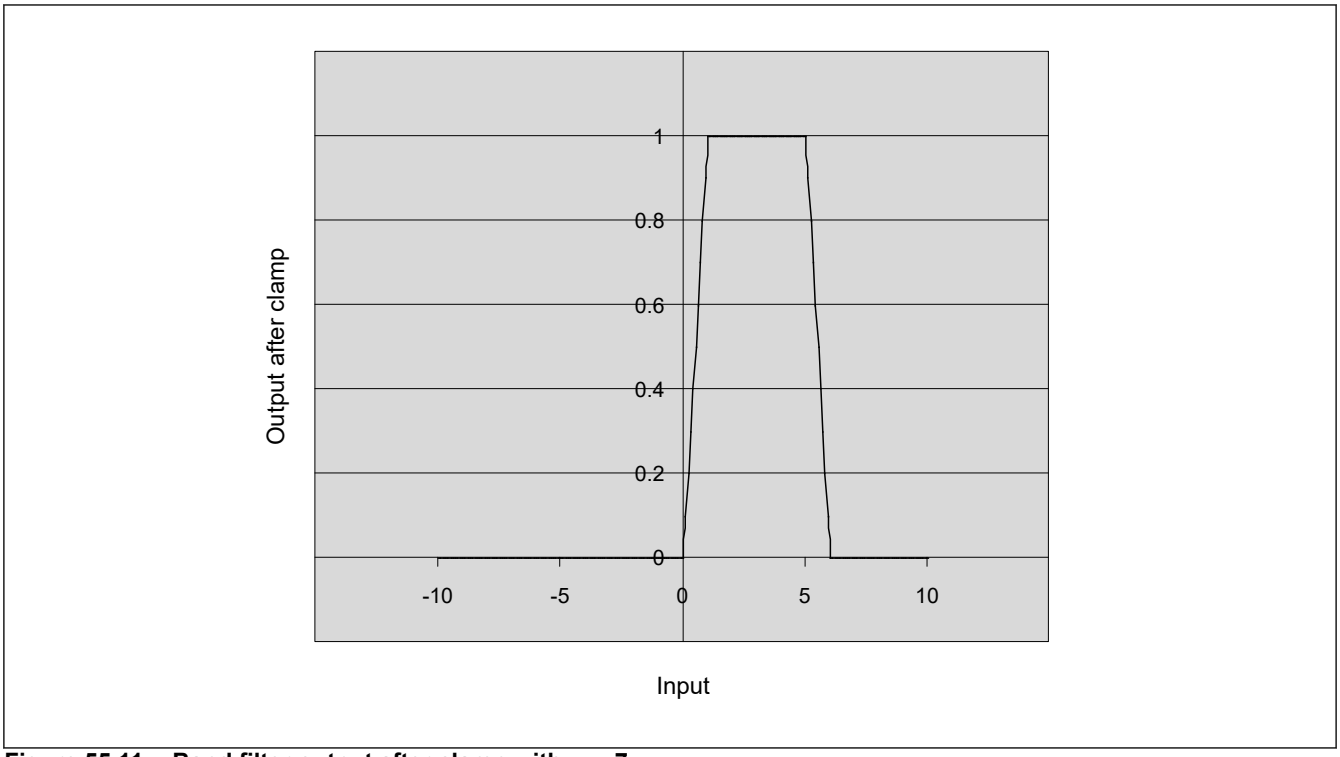

Figure 55.11 Band filter output after clamp with w = 7

55.6.2.4 Clamping unit

The clamping unit cuts the limiter output to the interval [0:1].

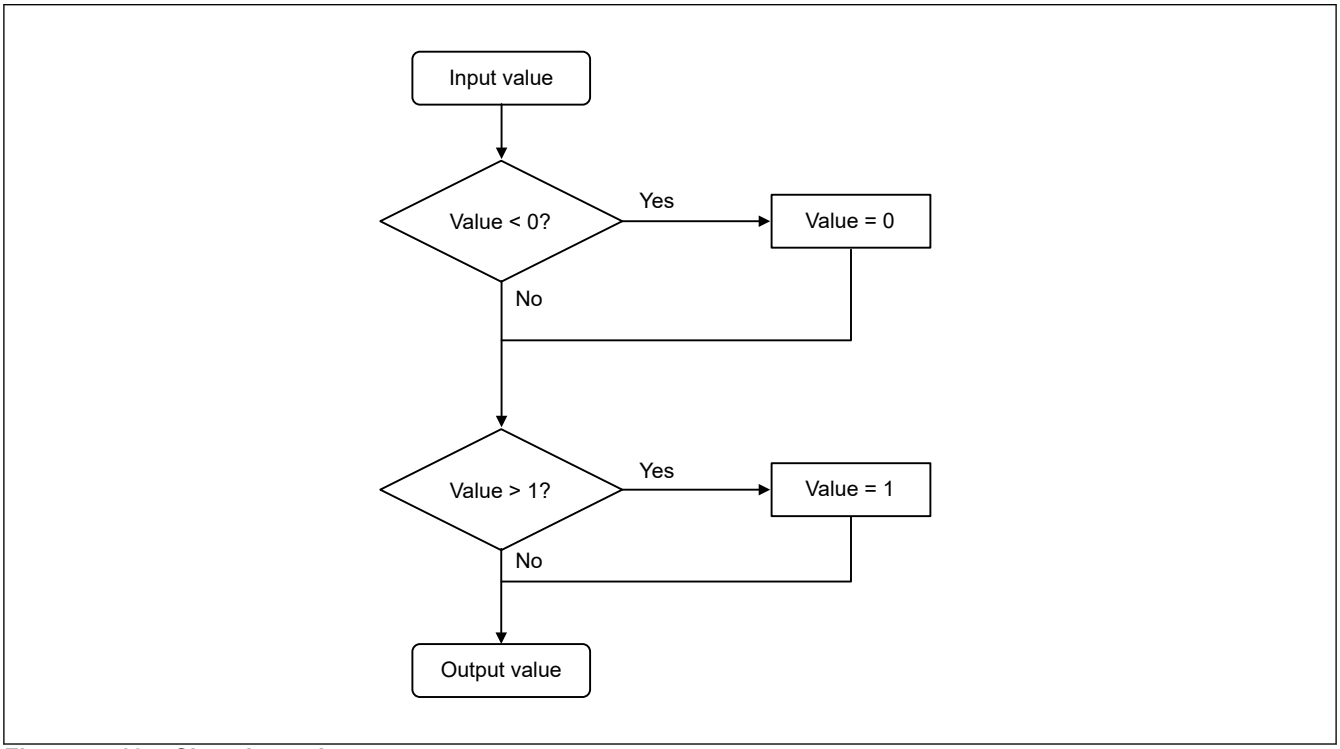

Figure 55.12 Clamping unit

The clamping unit can be put into threshold mode, in which all values greater than 0.5 are set to 1, and all values below or equal to 0.5 are set to 0. This feature is used when anti-aliasing is not needed, such as for shared edges.

55.6.2.5 Combiner unit

The combiner unit can be operated in minimum mode and in maximum mode. In minimum mode the smaller value is output, and in maximum mode the larger value is output. The minimum mode represents the intersection, and the maximum mode represents the union of the two regions.

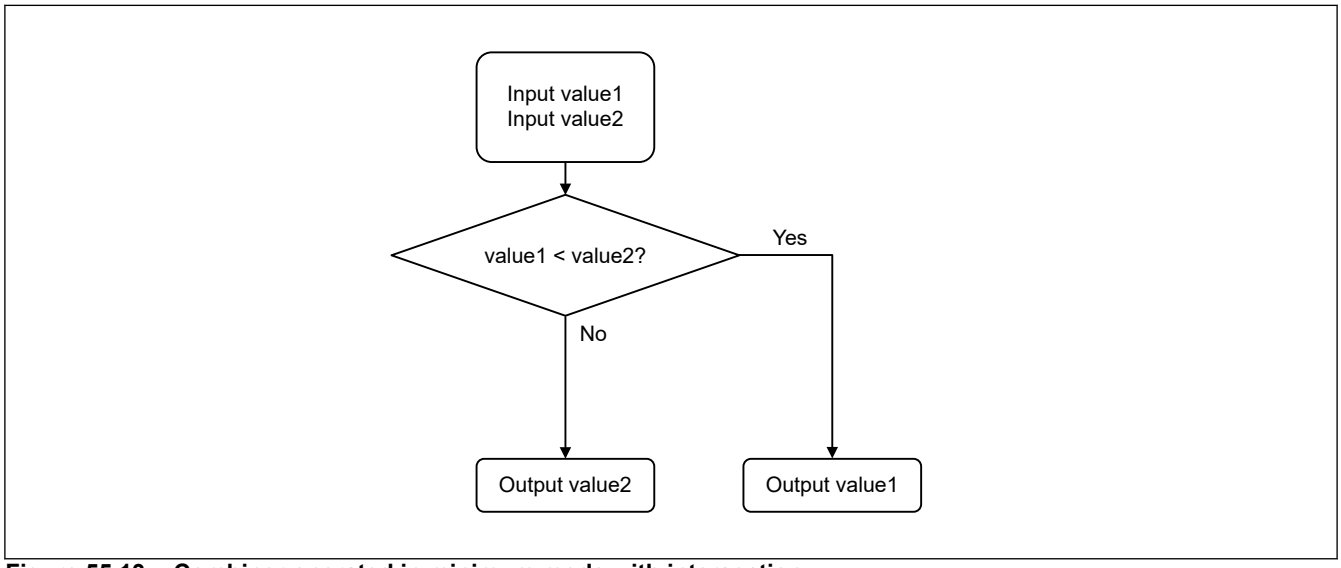

Figure 55.13 Combiner operated in minimum mode with intersection

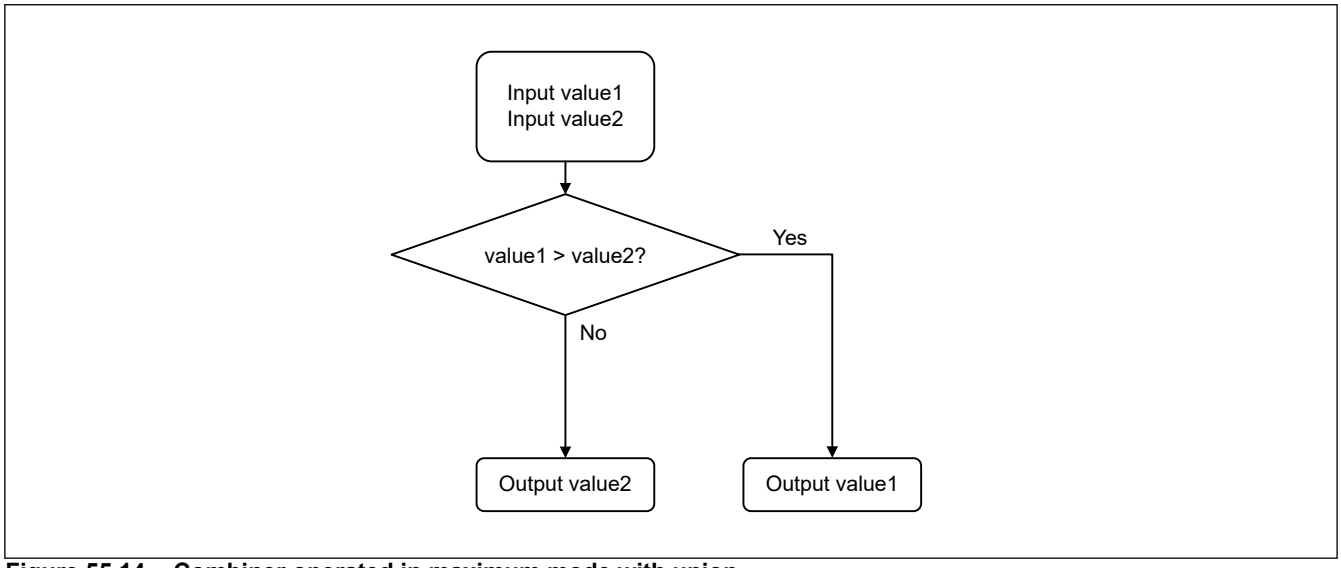

Figure 55.14 Combiner operated in maximum mode with union

55.6.2.6 Rasterization optimization

During rasterization, it is necessary to step through the whole bounding box one pixel at a time. This requirement can lead to an unnecessary number of steps for pixels that are not drawn. The 2D Drawing Engine provides optimization methods designed to reduce the number of steps required during rasterization. One optimization relies on the fact that any convex primitive can have only one span per line (a span is a contiguous horizontal line). This form of optimization detects a span start and saves the information for the next line. Another optimization is to detect a span end and stop rasterization for the current line.

(1) Spanstore

Consider the case in Figure 55.15.

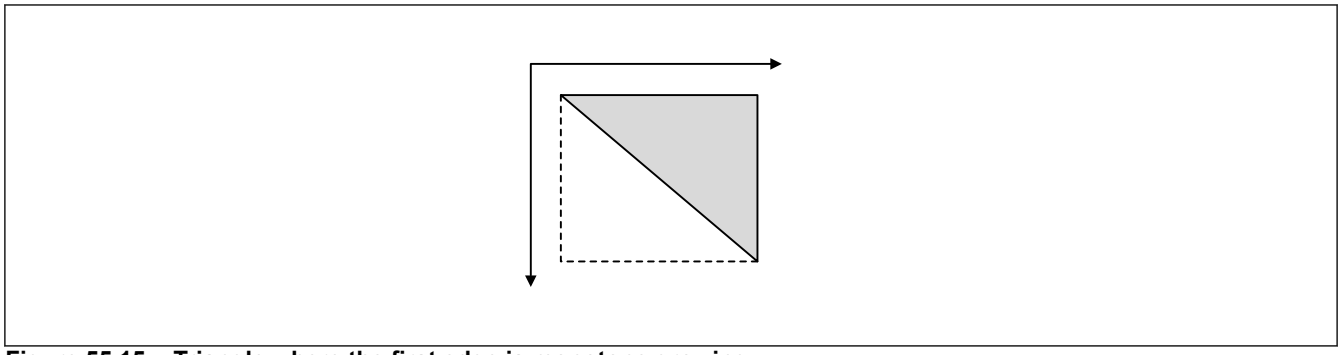

Figure 55.15 Triangle where the first edge is monotone growing

If the gray triangle must be rendered, half of the pixels processed by the rendering engine in the dotted bounding box would not be drawn. This situation can be optimized with the spanstore operation. When spanstore is activated and a span start is detected, the x position of the span start is detected.

In the next line the rendering starts with the stored x position. This only works if the edge is monotonically increasing ($y1 > y2 \Rightarrow x1 \geq x2$).

Consider the case in Figure 55.16.

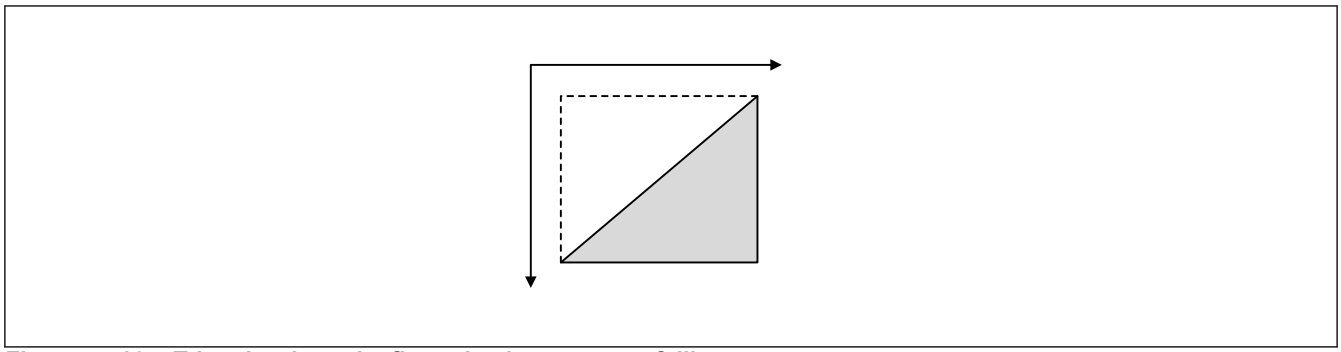

Figure 55.16 Triangle where the first edge is monotone falling

In this case, the normal spanstore operation cannot be performed. For this, the y direction of the rendering is reversed, and spanstore can operate again.

Consider the last case in Figure 55.17.

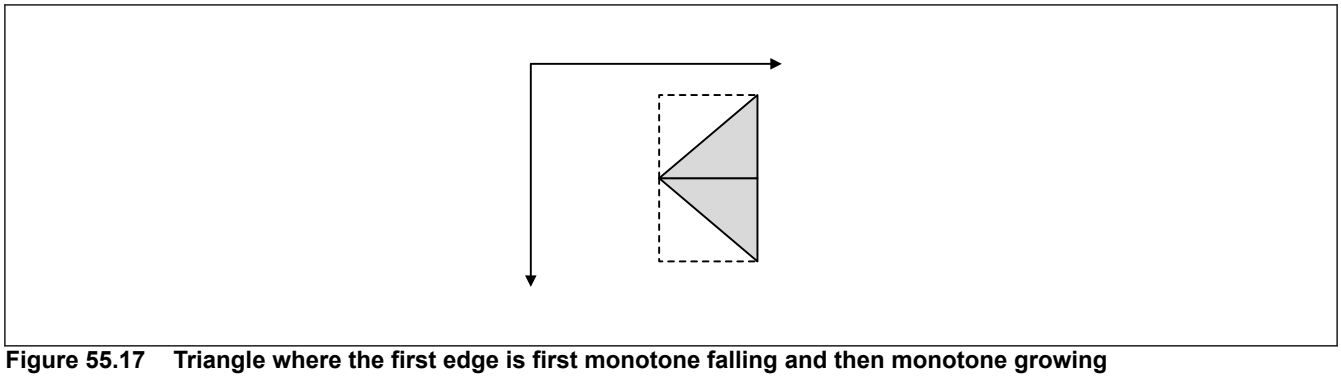

Figure 55.17 Triangle where the first edge is first monotone falling and then monotone growing

In this case, the triangle must be split and rendered as two parts for the spanstore optimization to work.

It is also possible to delay spanstore activation for a number of lines. This approach is used for rasterizing circles, as shown in Figure 55.18.

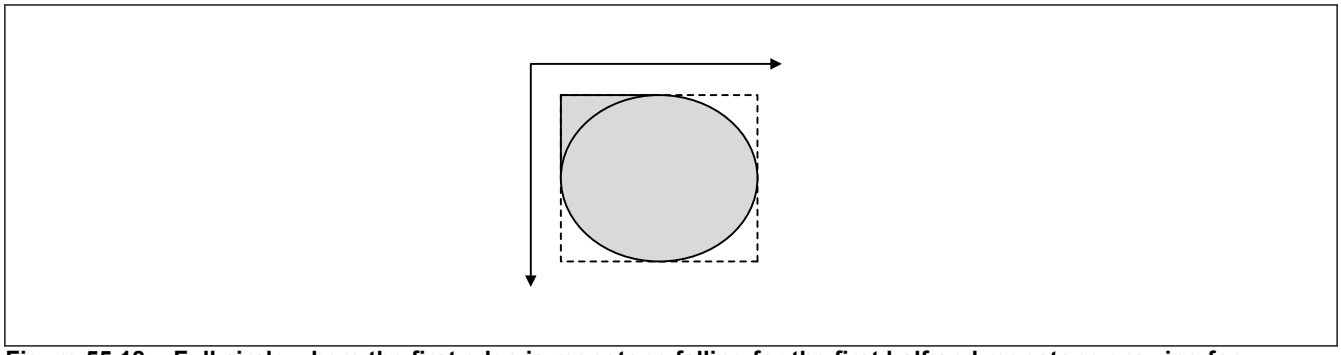

Figure 55.18 Full circle where the first edge is monotone falling for the first half and monotone growing for the second half

In this case, spanstore cannot be activated in the top left corner but can be activated in the bottom left corner. The empty corners in the top right and the bottom right cannot be rasterized because of the spanabort optimization.

(2) Spanabort

The second optimization assumes that the object that must be drawn is convex, which means there is only one span per scan line to be drawn. A non-convex object includes an object such as a triangle that is not filled and only consists of a thick border.

For a convex object, the rasterization can be stopped when the end of the first span is detected. No other constraints apply to this optimization for convex objects.

(3) Optimization efficiency

The efficiency of the optimizations can be seen for a typical case in Figure 55.19. In this case, the triangle is always rendered as single piece and is not separated into multiple triangles for higher optimizations. For this, the spanstore delay is used.

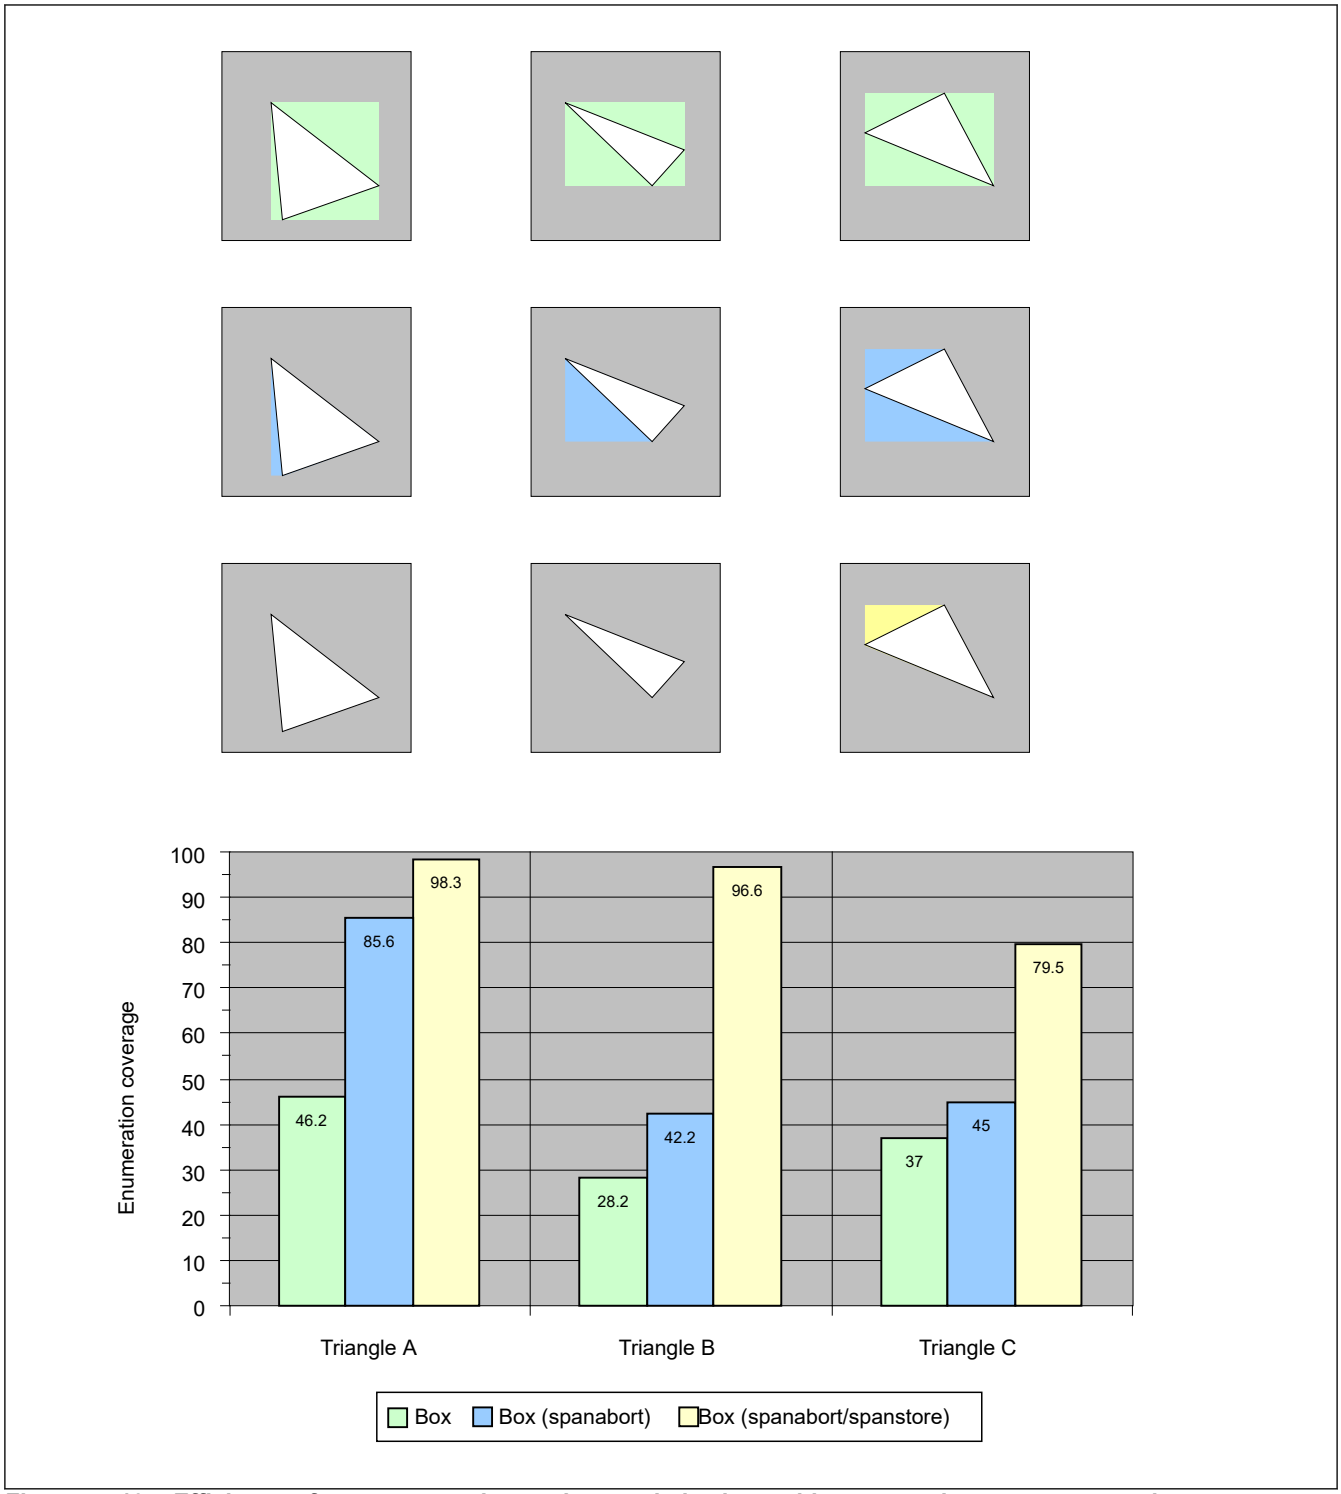

Figure 55.19 Efficiency of spanstore and spanabort optimizations with enumeration coverage equal to pixels of primitive/pixels of bounding box

55.6.3 Texturing

The texture unit can cover any primitive with a picture. The picture can be stretched, sheared, rotated, and translated in one step. To avoid aliasing, the result can be filtered bilinear in the u and v directions.

55.6.3.1 Mathematical background

The arbitrary mapping problem is completely determined by a mapping from 3 points in the object space (x, y) to 3 points in the texture space (u, v).

Consider the following mapping:

$$\vec{p}_0 = \begin{pmatrix} x_0 \\ y_0 \end{pmatrix} \Rightarrow \left(\widetilde{\vec{p}_0}\right) = \begin{pmatrix} u_0 \\ v_0 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

$$\vec{p}_1 = \begin{pmatrix} x_1 \\ y_1 \end{pmatrix} \Rightarrow \left(\widetilde{\vec{p}_1}\right) = \begin{pmatrix} u_1 \\ v_1 \end{pmatrix} = \begin{pmatrix} w \\ 0 \end{pmatrix}$$

$$\vec{p}_2 = \begin{pmatrix} x_2 \\ y_2 \end{pmatrix} \Rightarrow \left(\widetilde{\vec{p}_2}\right) = \begin{pmatrix} u_2 \\ v_2 \end{pmatrix} = \begin{pmatrix} 0 \\ h \end{pmatrix}$$

where w is the width of the texture and h is the height of the texture.

Examine Figure 55.20 in the object space. To simplify calculations the difference vectors are taken as calculations:

$$\vec{d}_1 = \vec{p}_1 - \vec{p}_0$$

$$\vec{d}_2 = \vec{p}_2 - \vec{p}_0$$

This is equivalent to transforming from coordinate system O to coordinate system O'.

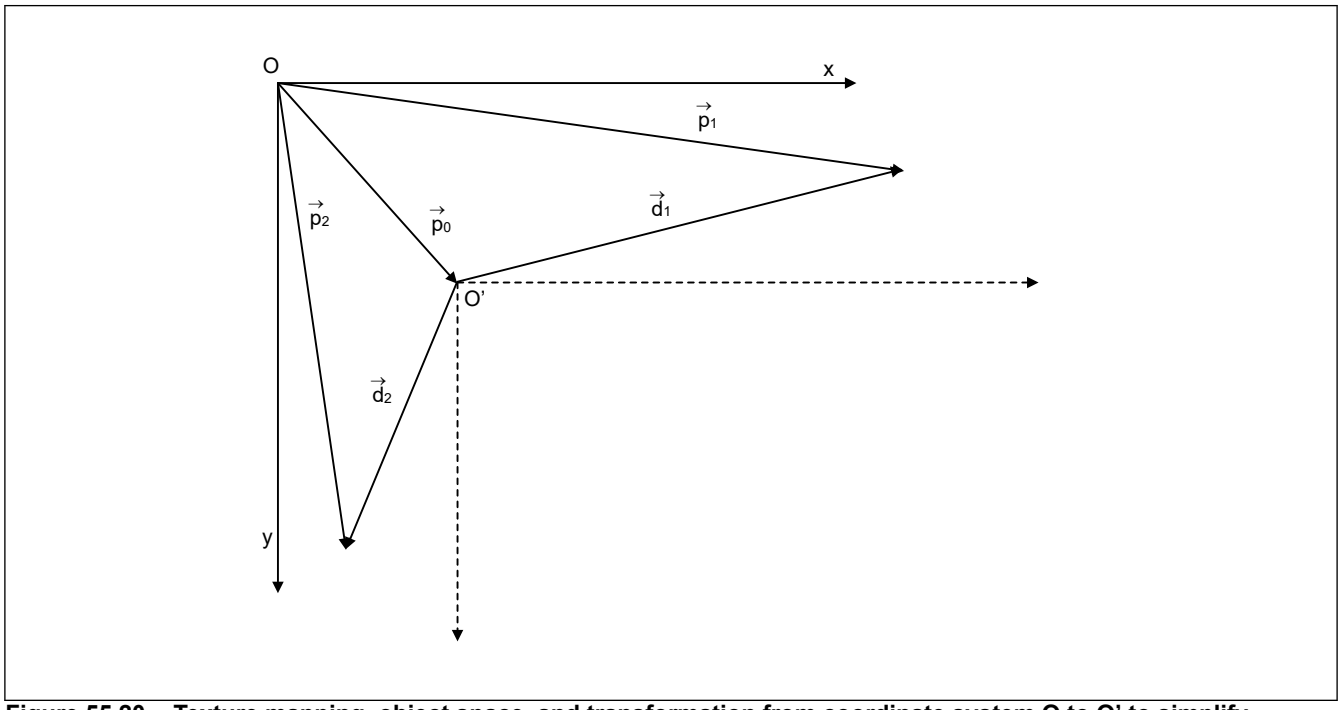

Figure 55.20 Texture mapping, object space, and transformation from coordinate system O to O' to simplify calculations

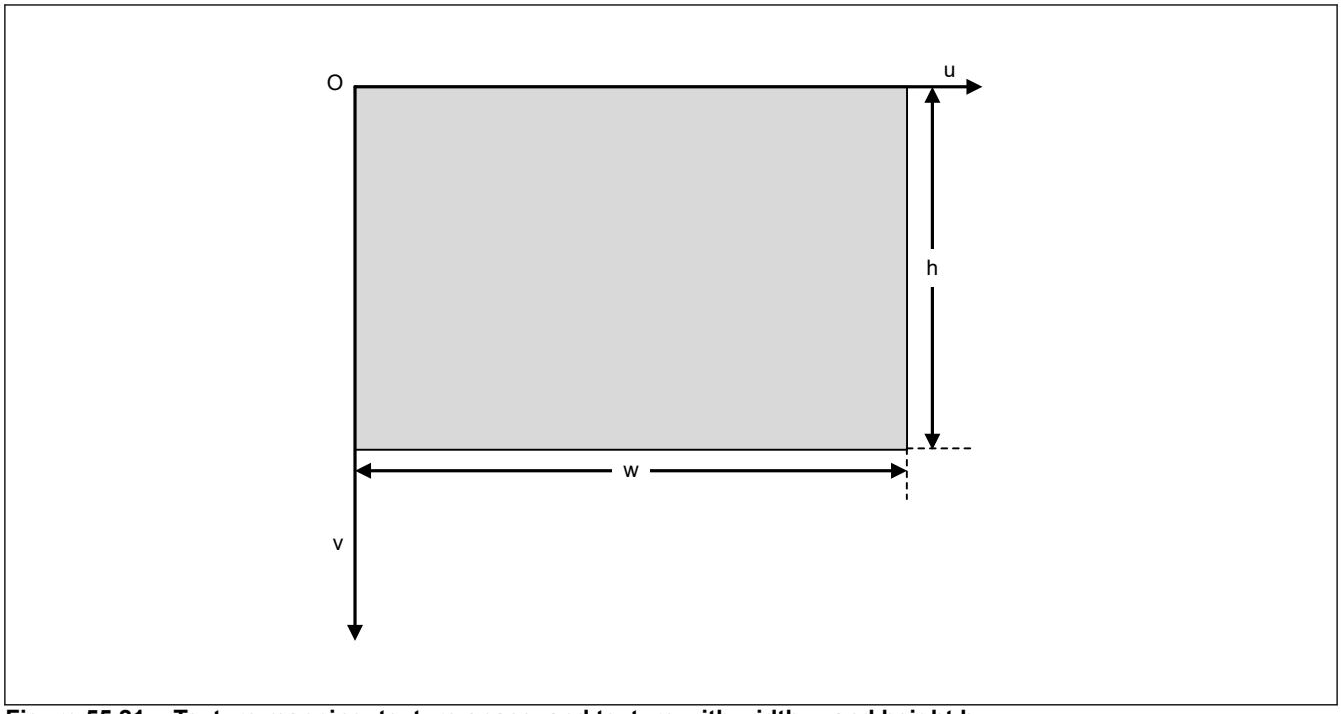

Figure 55.21 Texture mapping, texture space, and texture with width w and height h

In O', the mapping is:

$$\overrightarrow{\mathrm{p}'}_0 = \begin{pmatrix}0\\0\end{pmatrix} \Rightarrow \left(\widetilde{\overrightarrow{p}}_0\right) = \begin{pmatrix}u_0\\v_0\end{pmatrix} = \begin{pmatrix}0\\0\end{pmatrix}$$

$$\overrightarrow{d}_1 = \begin{pmatrix}\mathrm{dx}_1\\\mathrm{dy}_1\end{pmatrix} \Rightarrow \left(\widetilde{\overrightarrow{p}}_1\right) = \begin{pmatrix}u_1\\v_1\end{pmatrix} = \begin{pmatrix}w\\0\end{pmatrix}$$

$$\overrightarrow{d}_2 = \begin{pmatrix}\mathrm{dx}_2\\\mathrm{dy}_2\end{pmatrix} \Rightarrow \left(\widetilde{\overrightarrow{p}}_2\right) = \begin{pmatrix}u_2\\v_2\end{pmatrix} = \begin{pmatrix}0\\h\end{pmatrix}$$

This is a linear mapping that can be described by a 2 x 2 matrix.

$$\left(\widetilde{\overrightarrow{p}}\right) = M \cdot \overrightarrow{\mathrm{p}'} = \begin{bmatrix}m_{11} & m_{12}\\m_{21} & m_{22}\end{bmatrix} \cdot \overrightarrow{\mathrm{p}'}$$

$$\Rightarrow \begin{pmatrix}\mathrm{w}\\0\end{pmatrix} = M \cdot \overrightarrow{d}_1 \wedge \begin{pmatrix}0\\h\end{pmatrix} = M \cdot \overrightarrow{d}_2$$

If the equations are expanded and sorted, the result is two equation systems each with two unknowns. These can be described more easily with a new matrix.

Let A = $\begin{bmatrix}\mathrm{dx}_1 & \mathrm{dy}_1\\\mathrm{dx}_2 & \mathrm{dy}_2\end{bmatrix}$ then the equation can be rewritten as:

$$\begin{pmatrix}\mathrm{w}\\0\end{pmatrix} = A \cdot \begin{pmatrix}m_{11}\\m_{12}\end{pmatrix} \wedge \begin{pmatrix}0\\h\end{pmatrix} = A \cdot \begin{pmatrix}m_{21}\\m_{22}\end{pmatrix}$$

This can be easily solved with determinants.

Let c = $\frac{1}{\mathrm{detA}} = \frac{1}{\mathrm{dx}_1 \cdot \mathrm{dy}_2 - \mathrm{dx}_2 \cdot \mathrm{dy}_1}$

The resulting constants are:

$$m_{11} = c \cdot w \cdot \mathrm{dy}_2 = \frac{\mathrm{du}}{\mathrm{dx}}$$

$$m_{12} = -\mathrm{c} \cdot w \cdot \mathrm{dx}_2 = \frac{\mathrm{du}}{\mathrm{dy}}$$

$m_{21} = -\mathrm{c} \cdot h \cdot \mathrm{dy}_1 = \frac{\mathrm{dv}}{\mathrm{dx}}$

$m_{22} = c \cdot h \cdot \mathrm{dx}_1 = \frac{\mathrm{dv}}{\mathrm{dy}}$

To calculate the start values for u and v at the top of the bounding box, the transformation from O' to O must be reversed. Let U_s and V_s be the start values, then:

$$\begin{pmatrix} U_s \\ V_s \end{pmatrix} = M \cdot \left(-\vec{p}_0 \right) = c \cdot \begin{pmatrix} -\mathrm{w} \cdot (x_0 \cdot \mathrm{dy}_2 - y_0 \cdot \mathrm{dx}_2) \\ h \cdot (x_0 \cdot \mathrm{dy}_1 - y_0 \cdot \mathrm{dx}_1) \end{pmatrix}$$

(1) Examples

U and v are in the texture space. Enter the following into any case:

- Copy case
  $\mathrm{dx}_1 = 1, \mathrm{dx}_2 = 0, \mathrm{dy}_1 = 0, \mathrm{dy}_2 = 1$
- Scaling case x scaling copy case
  $\mathrm{dx}_1 = f, \mathrm{dx}_2 = 0, \mathrm{dy}_1 = 0, \mathrm{dy}_2 = 1$
  with f being the scaling factor in the x direction similar for the y direction.
- Rotation case
  $\mathrm{dx}_1 = \mathrm{cosa}, \mathrm{dx}_2 = -\mathrm{sina}, \mathrm{dy}_1 = \mathrm{sina}, \mathrm{dy}_2 = \mathrm{cosa}$
  with the angle between d1 and the x axis in the clockwise direction.

55.6.3.2 Limiter operation

The texture limiters operate exactly the same as the spatial limiters shown in Figure 55.8

The register layout for the u limiter is the same.

- LUSTART = U_s
- LUXADD = du/dx
- LUYADD = du/dy.

The register layout for the v limiter is slightly different. TEXPITCH is multiplied to save one hardware multiplier.

- LVSTARTI = floor (V_s) • TEXPITCH
  Contains the integer part of the start value.
- LVSTARTF = (V_s - floor (V_s)) • TEXPITCH
  Contains the fractional part of the start value.
- LVXADDI = floor (dv/dx) • TEXPITCH
  Contains the integer part of dv/dz.
- LVYADD = floor (dv/dy) • TEXPITCH
  Contains the integer part of dv/dy.
- LVYXADDF = (dv/dy - floor (dv/dy)) • TEXPITCH ((dv/dx - floor (dv/dx)) • TEXPITCH)
  Contains the fractional part of dv/dy and dv/dx combined in one register.
- TEXMASK
  Contains a mask for u and v separately to wrap around values of u and v. This is useful for staying inside the limits of the texture or repeat a texture. Wrap around textures have to have a size multiple of 2.
- TEXPITCH
  Contains the width of the texture in pixels in framebuffer memory. This information is required to calculate the new address if stepping to a new line.
- TEXORIGIN
  Contains the base address of the texture.

55.6.4 Colorization

After a pixel is found to be part of the geometry, its color is calculated. The 2D Drawing Engine supports a very general color calculation scheme, allowing support for several color modes. This color scheme uses an interpolation between two color registers, COLOR1 and COLOR2. See Figure 55.22 for details. COLOR1 and COLOR2 are marked as A, B in the figure for clarity.

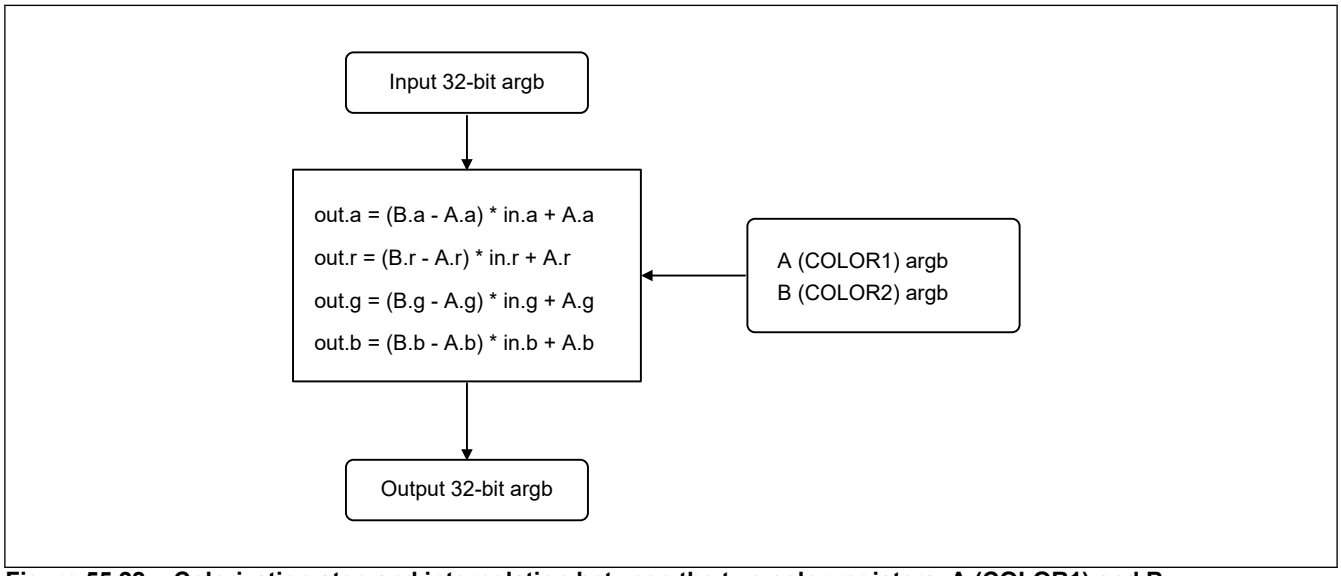

Figure 55.22 Colorization step and interpolation between the two color registers, A (COLOR1) and B (COLOR2)

This general approach can be used to support several different color modes that can be individually applied to any color or alpha channel of the input.

Table 55.8 Colorization operations

Operation	Settings for A and B*1
Copy	A = 0, B = 0xff
Replace with a constant value v	A = v, B = v
Multiply by a constant value v	A = 0, B = v
Colorize an alpha texture with the RGB value v	A.a = 0, A.r = B.r, A.g = B.g, A.b = B.b, B.a = 0xff, B.r = v.r, B.g = v.g, B.b = v.b
Invert a channel	A = 0xff, B = 0
Invert multiply with v	A = v, B = 0
Interpolate between color v and color u	A = v, B = u

Note 1. A = COLOR1, B = COLOR2

55.6.5 Blending

55.6.5.1 Color channel blending

The last step before the pixel is written to the framebuffer is to blend the pixel with the data that is already written to the framebuffer. If blending is activated, the framebuffer, referred to as DST, must be read. SRC is the output from the colorization unit.

The following color blend modes are supported:

- SRC_ZERO
- SRC_ONE
- SRC_ALPHA

- SRC_ONE_MINUS_ALPHA
- DST_ZERO
- DST_ONE
- DST_ALPHA
- DST_ONE_MINUS_ALPHA.

The selection of the color channel blend modes is performed with the following flags:

- BSF: blend source factor is alpha
- BSI: blend source factor invert
- BDF: blend destination factor is alpha
- BDI: blend destination factor invert.

The formula for the blending is:

$dst = src \cdot f_S + dst \cdot f_D$

where:

$BSF = 0, BSI = 0 \Rightarrow f_S = 1$

$BSF = 1, BSI = 0 \Rightarrow f_S = \alpha$

$BSF = 0, BSI = 1 \Rightarrow f_S = 0$

$BSF = 1, BSI = 1 \Rightarrow f_S = 1 - \alpha$

$BDF = 0, BDI = 0 \Rightarrow f_D = 1$

$BDF = 1, BDI = 0 \Rightarrow f_D = \alpha$

$BDF = 0, BDI = 1 \Rightarrow f_D = 0$

$BDF = 1, BDI = 1 \Rightarrow f_D = 1 - \alpha$

Table 55.9 lists all possible color channel blend modes.

Table 55.9 Color channel blend modes

Mode	BSF	BSI	BDF	BDI	Blend equation
SRC_ONE DST_ONE	0	0	0	0	SRC + DST
SRC_ONE	0	0	0	1	SRC
SRC_ONE DST_ALPHA	0	0	1	0	SRC + DST × ALPHA
SRC_ONE DST_ONE_MINUS_ALPHA	0	0	1	1	SRC + DST × (1 - ALPHA)
SRC_ZERO DST_ONE	0	1	0	0	DST
SRC_ZERO DST_ZERO	0	1	0	1	0
SRC_ZERO DST_ALPHA	0	1	1	0	DST × ALPHA
SRC_ZERO DST_ONE_MINUS_ALPHA	0	1	1	1	DST × (1 - ALPHA)
SRC_ALPHA DST_ONE	1	0	0	0	SRC × ALPHA + DST
SRC_ALPHA	1	0	0	1	SRC × ALPHA
SRC_ALPHA DST_ALPHA	1	0	1	0	SRC × ALPHA + DST × ALPHA
SRC_ALPHA DST_ONE_MINUS_ALPHA	1	0	1	1	SRC × ALPHA + DST × (1 - ALPHA)
SRC_ONE_MINUS_ALPHA DST_ONE	1	1	0	0	SRC × (1 - ALPHA) + DST
SRC_ONE_MINUS_ALPHA	1	1	0	1	SRC × (1 - ALPHA)
SRC_ONE_MINUS_ALPHA DST_ALPHA	1	1	1	0	SRC × (1 - ALPHA) + DST × ALPHA
SRC_ONE_MINUS_ALPHA DST_ONE_MINUS_ALPHA	1	1	1	1	SRC × (1 - ALPHA) + DST × (1 - ALPHA)

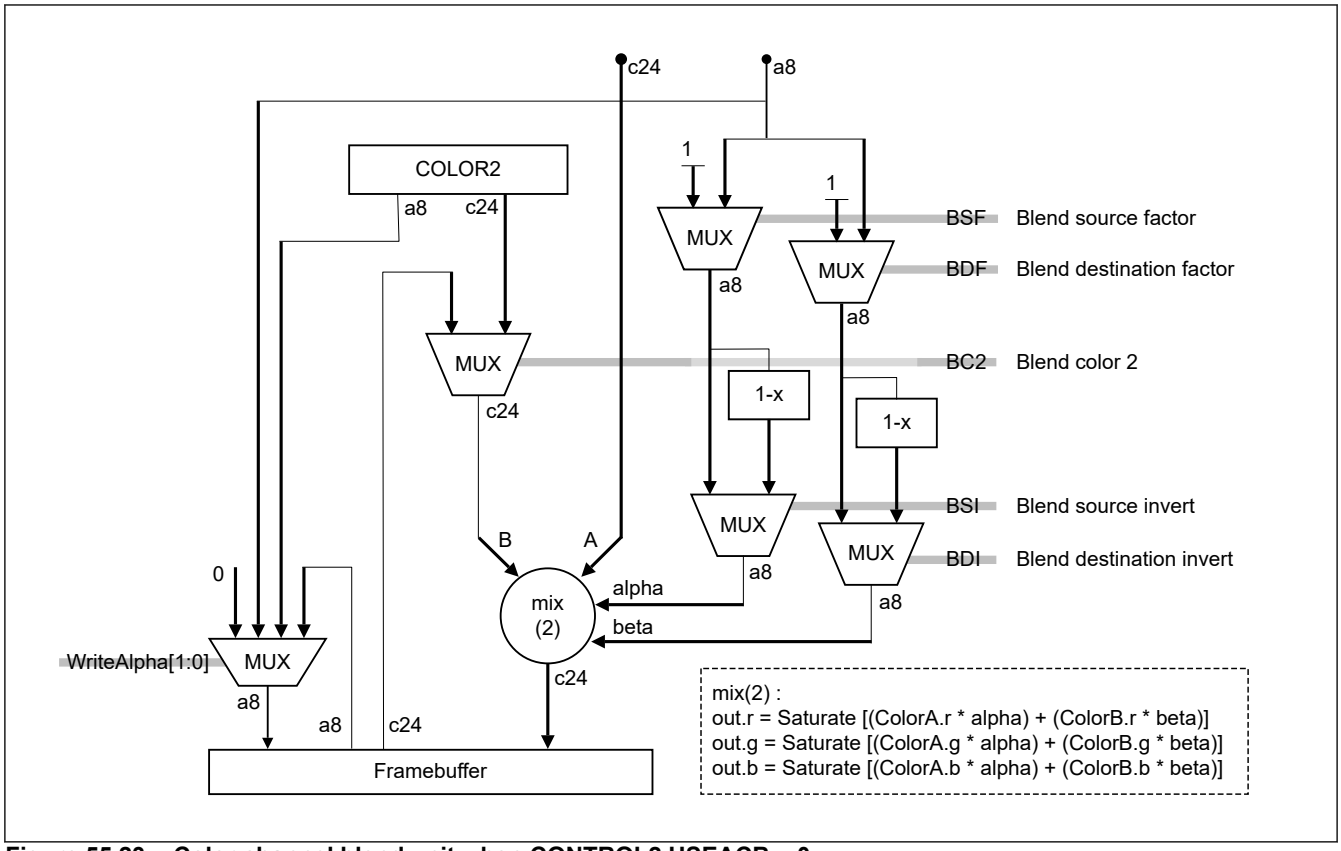

Figure 55.23 Color channel blend unit when CONTROL2.USEACB = 0

55.6.5.2 Alpha channel blending

The alpha channel can be blended in addition to the color channels. Alpha channel blending is enabled by setting CONTROL2.USEACB = 1. Alpha channel blending uses the same formulas and same blend modes as for the color channels. The alpha channel formulas can be set independently from the color channels.

The following alpha channel blend modes are supported:

- SRC_A_ZERO
- SRC_A_ONE
- SRC_A_SRC_A
- SRC_A_ONE_MINUS_SRC_A
- DST_A_ZERO
- DST_A_ONE
- DST_A_SRC_A
- DST_A_ONE_MINUS_SRC_A.

The alpha channel blend modes selected with the following flags:

- BSFA: blend source factor is SRC_A
- BSIA: blend source factor invert
- BDFA: blend destination factor is SRC_A
- BDIA: blend destination factor invert.

The formula for the blending is:

$dst\_alpha = src\_a \cdot f_{S\_a} + dst\_a \cdot f_{D\_a}$

where:

BSFA = 0, BSIA = 0 ⇒ $f_{S\_a} = 1$

BSFA = 1, BSIA = 0 ⇒ $f_{S\_a} = src\_a$

BSFA = 0, BSIA = 1 ⇒ $f_{S\_a} = 0$

BSFA = 1, BSIA = 1 ⇒ $f_{S\_a} = 1 - src\_a$

BDFA = 0, BDIA = 0 ⇒ $f_{D\_a} = 1$

BDFA = 1, BDIA = 0 ⇒ $f_{D\_a} = src\_a$

BDFA = 0, BDIA = 1 ⇒ $f_{D\_a} = 0$

BDFA = 1, BDIA = 1 ⇒ $f_{D\_a} = 1 - src\_a$

Table 55.10 lists all possible alpha channel blend modes.

Table 55.10 Alpha channel blend modes

Mode	BSF	BSI	BDF	BDI	Blend equation
SRC_A_ONE DST_A_ONE	0	0	0	0	SRC_A + DST_A
SRC_A_ONE	0	0	0	1	SRC_A
SRC_A_ONE DST_A_SRC_A	0	0	1	0	SRC_A + DST_A × SRC_A
SRC_A_ONE DST_A_ONE_MINUS_SRC_A	0	0	1	1	SRC_A + DST_A × (1 - SRC_A)
SRC_A_ZERO DST_A_ONE	0	1	0	0	DST_A
SRC_A_ZERO DST_A_ZERO	0	1	0	1	0
SRC_A_ZERO DST_A_SRC_A	0	1	1	0	DST_A × SRC_A
SRC_A_ZERO DST_A_ONE_MINUS_SRC_A	0	1	1	1	DST_A × (1 - SRC_A)
SRC_A_SRC_A DST_A_ONE	1	0	0	0	SRC_A × SRC_A + DST_A
SRC_A_SRC_A	1	0	0	1	SRC_A × SRC_A
SRC_A_SRC_A DST_A_SRC_A	1	0	1	0	SRC_A × SRC_A + DST_A × SRC_A
SRC_A_SRC_A DST_A_ONE_MINUS_SRC_A	1	0	1	1	SRC_A × SRC_A + DST_A × (1 - SRC_A)
SRC_A_ONE_MINUS_SRC_A DST_A_ONE	1	1	0	0	SRC_A × (1 - SRC_A) + DST_A
SRC_A_ONE_MINUS_SRC_A	1	1	0	1	SRC_A × (1 - SRC_A)

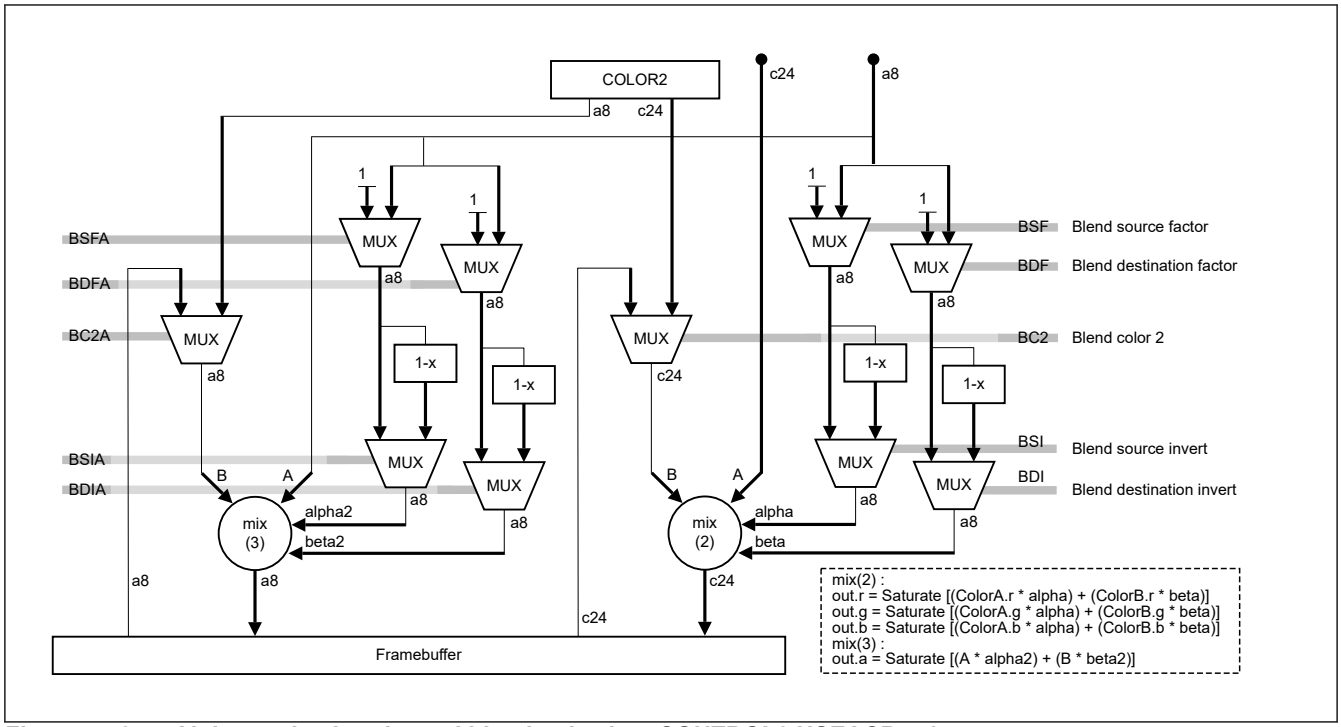

Figure 55.24 Alpha- and color-channel blend unit when CONTROL2.USEACB = 1

55.7 Rendering Modes

The rendering process can be performed in two different modes, register mode and display list mode.

55.7.1 Register Mode

In register mode, when operation is based on register settings, the host CPU configures and initiates each render process separately. To start a new render process, the host CPU must wait until the previous one is completed. In this mode, the host CPU is heavily engaged throughout the entire drawing procedure and is consequently to a large extent unavailable for other tasks.

The host CPU must set up all registers for performing a certain drawing operation before it can start the rendering process. A new register setup can only be started when the previous render process has completed. Before starting a new register setup, make sure that:

- STATUS.DLISTACTIVE = 0: Display list reader is idle
- STATUS.BUSENUM = 0: Pixel selection unit is idle.

Lastly, write the framebuffer start address to the ORIGIN register. This write triggers the 2D Drawing Engine to start rendering.

55.7.2 Display List Mode

In display list mode, the host CPU creates a display list in memory prior to starting the 2D Drawing Engine. Such a display contains a bundle of render operations. When started, the 2D Drawing Engine executes the display list autonomously in parallel with the host CPU, which is not involved with drawing operations most of the time. Use of a display list allows a fully asynchronous operation of the host CPU and the 2D Drawing Engine and offers the best possible system performance.

In this mode, the display list reader reads a memory block containing instructions on how to set the 2D Drawing Engine control registers and executes these control register writes accordingly.

(1) Display list start

To start execution of a display list, which already resides in memory, the start address of the display list is written to the display list start address register DLISTSTART. Because rewriting DLISTSTART also stops any ongoing display list execution, make sure that the previous display list process is completed by either of the following two methods:

- Check that STATUS.DLISTACTIVE = 0, which indicates idle status of the display list reader

- Wait for the display list interrupt DRWDLISTIRQ, which indicates completion of the previous display list process.

Caution: Direct writing to 2D Drawing Engine registers while the display list mode is active (STATUS.DLISTACTIVE = 1) might lead to a 2D Drawing Engine hang-up. To prevent this, always check that the display list reader is idle ((STATUS.DLISTACTIVE = 0) before writing to any 2D Drawing Engine register.

(2) Display list format

Display lists are stored using direct register-to-value mappings, which means that the display list contains a one byte index that addresses a certain register and the value to be written to the register. The register index is derived from the address offset of the register address and can be calculated by dividing the address offset by 4. For the index of each register, see section 55.2. Register Descriptions.

As the 2D Drawing Engine registers are always 32 bits wide, each data unit (called a data word) to be written to a register is of the same size. An address word that contains the indices of the register to be written is stored in a packed notation with up to four indices stored in one 32-bit address word.

A display list command always starts with an address word, followed by up to four data words, one for each register. The indices are read and interpreted from LSB to MSB, so the register of the low byte index is written first.

(3) Example

In the following example:

- DWORD 0x201A_1930 // start of list address word
- DWORD 0x0000_0013 // data word 1 (for register 0x30)
- DWORD 0xFFFF_FFAA // data word 2 (for register 0x19)
- DWORD 0x4033_6480 // data word 3 (for register 0x1A)
- DWORD 0x0001_0000 // data word 4 (for register 0x20)
- DWORD... // next address word.

This stream of dwords updates the DRW registers as follows:

- Write 0x0000_0013 to register 0x30 = 48, which is IRQCTL
- Write 0xFFFF_FFAA to register 0x19 = 25, which is COLOR1
- Write 0x4033_6480 to register 0x1A = 26, which is COLOR2
- Write 0x0001_0000 to register 0x20 = 32, which is ORIGIN.

(4) Address word indices

Besides referencing a register, the indices of an address word can also have other meanings, depending on their value.

Table 55.11 Address indices function (1 of 2)

Index	Function	
0x00 to 0x7F	Register indices Two register indices trigger additional actions:	
	0x20 = 32:	A write to ORIGIN to set a new frame buffer address is delayed until the ongoing frame buffer write-back is complete, when STATUS.BUSYWRITE = 0.
	0x32 = 50:	A write to DLISTSTART sets a new display list start address stops the current display list and starts the new one.
0x80	Gap index, which is used to fill unused bytes of an address word. For example, if fewer than four indices are required, the remaining bytes are filled with 0x80. In this case, the number of the subsequent data words must be reduced accordingly.	

Table 55.11 Address indices function (2 of 2)

Index	Function	
0xFF	If the first index of an address word contains the special index 0xFF, the subsequent (second) index is interpreted as follows:	
	Bit [0] set:	Display list end.
	Bit [1] set:	Issue a full pipeline flush and wait (necessary before flip).
	Bit [2] set:	Wait for writeback complete (necessary before framebuffer format change).
	Bits [3:7]	Set all to 0s.
	Bit [1] and [2] settings are mutually exclusive. All indices after the special index 0xFF are ignored, and the next address word is read, if no display list end (bit [0] = 1) was set.	
	The remaining two indices must be set to 0x00.	

Caution : Gap indices 0x80 must not be placed between other indices, for example as “index1 - 0x80 - index3 - index4”. Always fill all indices after 0x80 with the gap index.

Caution : If any of the special indices 0x80 and 0xFF are used, no register index can follow after them in the same address word.

Table 55.12 2D Drawing Engine registers overview (1 of 2)

Register function	Symbol	Index
Control registers:		
Geometry control 0	CONTROL	0
Surface control	CONTROL2	1
Interrupt control	IRQCTL	48

Secondary color	COLOR2	26
Pattern	PATTERN	29
Limiter registers:		
Limiter 1 start value	L1START	4
Limiter 2 start value	L2START	5
Limiter 3 start value	L3START	6
	L4START	7
Limiter 5 start value	L5START	8
Limiter 6 start value	L6START	9
Limiter 1 x-axis increment	L1XADD	10
Limiter 2 x-axis increment	L2XADD	11
Limiter 3 x-axis increment	L3XADD	12
Limiter 4 x-axis increment	L4XADD	13
Limiter 5 x-axis increment	L5XADD	14
Limiter 6 x-axis increment	L6XADD	15
Limiter 1 y-axis increment	L1YADD	16
Limiter 2 y-axis increment	L2YADD	17
Limiter 3 y-axis increment	L3YADD	18

Table 55.12 2D Drawing Engine registers overview (2 of 2)

Register function	Symbol	Index
Limiter 4 y-axis increment	L4YADD	19
Limiter 5 y-axis increment	L5YADD	20
Limiter 6 y-axis increment	L6YADD	21
Limiter 1 band width parameter	L1BAND	22
Limiter 2 band width parameter	L2BAND	23
Texture registers:		
Texture base address	TEXORIGIN	47
Texels per texture line	TEXPITCH	45
Texture size or texture address mask	TEXMASK	46
U limiter start value	LUSTART	36
U limiter x-axis increment	LUXADD	37
U limiter y-axis increment	LUYADD	38
V limiter start value integer part	LVSTARTI	39
V limiter start value fractional part	LVSTARTF	40
V limiter x-axis increment integer part	LVXADDI	41
V limiter y-axis increment integer part	LVYADDI	42
V limiter increment fractional parts	LVYXADDF	43
Color lookup table start address	TEXCLADDR	55
Write Data to DRWTEXCLADDR; after each data write, DRWTEXCLADDR is incremented by 1.	TEXCLDATA	56
Offset to the index for the indexed texture formats i8, i4, i2, and i1	TEXCLOFFSET	57
Compare value for R,G, B components of internal texel color representation.	COLKEY	58
Miscellaneous registers:		
Bounding box dimension	SIZE	30
Framebuffer pitch and spanstore delay	PITCH	31
Address of the first pixel in framebuffer	ORIGIN	32
Display list start address	DLISTSTART	50
Performance counters control	PERFTRIGGER	53
Performance counter 1	PERFCOUNT1	51
Performance counter 2	PERFCOUNT2	52

Note 1. These registers are read-only and cannot be accessed in display list mode, and they therefore have no index.

55.7.3 Stopping the Render Process

Stopping an ongoing render process requires a specific procedure, which is described in section 55.10. Stopping the 2D Drawing Engine Render Process.

55.8 Interrupts

The 2D Drawing Engine generates three interrupts:

- DRWBUSIRQ
- DRWENUMIRQ
- DRWDLISTIRQ.

55.8.1 Interrupt sources

(1) DRWBUSIRQ

This is the 2D Drawing Engine bus error interrupt. It occurs when the 2D Drawing Engine attempts to access an undefined address range through the following registers:

- Framebuffer Base Address Register ORIGIN
- Texture Base Address Register TEXORIGIN
- Display List Start Address Register (DLISTSTART).

The bus error interrupt DRWBUSIRQ is then generated. The bus error interrupt only serves for debugging purposes. The interrupt source can be determined by the BUSERRMFB, BUSERRMTXMRL, and BUSERRMDL bits of the STATUS register.

Note: After a DRWBUSIRQ occurrence, you must apply a system reset.

(2) DRWENUMIRQ

This is the current render process finished interrupt.

(3) DRWDLISTIRQ

This is the display list interrupt. It is asserted on completion of a display list process. DRWDLISTIRQ is activated if one of the following conditions is true:

- The entire display list is complete
- The display list processing stops because a new display list start is triggered by a write to the Display List Start Address Register (DLISTSTART).

55.8.2 Interrupt Control

The three 2D Drawing Engine interrupts are combined into a single shared interrupt, DRW_IRQ, to the CPU. Each interrupt can be masked (disabled), or unmasked (enabled) by setting its associated enable bit in the Interrupt Control Register (IRQCTL).

The occurrence of an enabled interrupt (one with its mask bit set to 1 in IRQCTL) is monitored in the Status Control Register (STATUS) with its associated interrupt status bit is set to 1. The shared 2D Drawing Engine interrupt DRW_IRQ is then generated.

To clear the interrupt, the host CPU must write 1 to the interrupt clear bit in IRQCTL. The interrupt clear bit returns to 0 automatically.

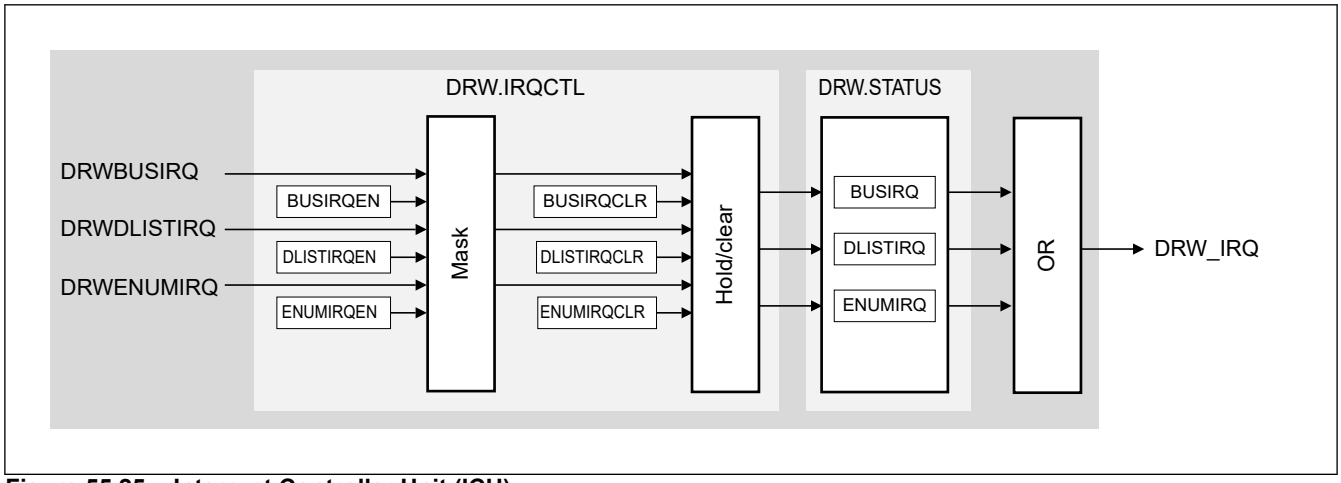

Figure 55.25 Interrupt Controller Unit (ICU)

55.9 Performance Counters

The 2D Drawing Engine features two independent 32-bit performance counter registers (PERFCOUNTk (k = 1, 2)) to count the number of occurrences of a certain event. The events to be counted can be set up independently for each performance counter register with the Performance Counter Control Registers, PERFTRIGGER.PERFTRIGGER2 for PERFCOUNT2 and PERFTRIGGER.PERFTRIGGER1 for PERFCOUNT1.

Table 55.13 lists the performance counter trigger events that can be selected.

Table 55.13 Performance counter trigger events

PERFTRIGGER.PERFTRIGGERk	Event
0	Disable performance counter
1	2D Drawing Engine active cycles
2	Framebuffer read access
3	Framebuffer write access
4	Texture read access
5	Invisible pixels (enumerated but selected with alpha 0%)
6	Invisible pixels while internal FIFO is empty (lost cycles)
7	Display list reader active cycles
8	Framebuffer read hits
9	Framebuffer read misses
10	Framebuffer write hits
11	Framebuffer write misses
12	Texture read hits
13	Texture read misses
31	Every clock cycle (for use as timer)

55.10 Stopping the 2D Drawing Engine Render Process

If a render process has started either in register or display list mode, the 2D Drawing Engine processes the data autonomously until the render process is finished. Depending on the rendering, this process might take several milliseconds.

If the 2D Drawing Engine is to be disabled because, for example, the MCU enters a low power mode, proceed as follows to stop the ongoing rendering:

1. Set the following registers as follows:
   SIZE = 0x00010001
   Set bounding box dimensions to 1 pixel x 1 line.
   CONTROL2 = 0x00000000
   Color format A (8), no texture, CLUT.
   ORIGIN = UnmappedAddress
   The UnmappedAddress is an address that is not available for 2D Drawing Engine access.
   The recommended UnmappedAddress is given here under the key word “UnmappedAddress”.
   Alternatively do the same in display list mode:
   DWORD 0x8020011E // start of “address word” list
   DWORD 0x00010001 // SIZE = 0x00010001
   DWORD 0x00000000 // CONTROL2 = 0x00000000
   DWORD UnmappedAddress // ORIGIN = UnmappedAddress
2. Wait for the Bus Error corresponding to the unmapped address violation, which indicates access to an unmapped address and the stop of the render process.
   UnmappedAddress = 0xFFFFFFF0
3. Disable the 2D Drawing Engine, if wanted.

55.11 MathML sample

#1

$y = \widetilde{a}x + \widetilde{b}$

#2

$0 = f(x,y) = \widetilde{a}x - y + \widetilde{b} = \mathrm{ax} + \mathrm{by} + c$

with $a = \widetilde{a}$, $b = -1$, $c = \widetilde{b}$

#3

$\overrightarrow{p} = \begin{pmatrix} x \\ y \end{pmatrix}, \overrightarrow{n} = \begin{pmatrix} a \\ b \end{pmatrix} \Rightarrow f(x,y) = \mathrm{ax} + \mathrm{by} + c = \overrightarrow{p} \cdot \overrightarrow{n} + c$

#4

The projection of $\overrightarrow{p} - \overrightarrow{p}_0$ to $\overrightarrow{n}$ is the distance d of the point P to the line. In this case, f (x, y) describes the distance to the line of the pixel with coordinates (x, y).

#5

$\Delta\overrightarrow{p} = \overrightarrow{p}_1 - \overrightarrow{p}_0 = \begin{pmatrix} x_1 - x_0 \\ y_1 - y_0 \end{pmatrix} = \begin{pmatrix} \Delta\mathrm{x} \\ \Delta\mathrm{y} \end{pmatrix}$

#6

Consider the equation for a circle with the center at $\overrightarrow{c} = \begin{pmatrix} s \\ t \end{pmatrix}$ and radius r:

#7

$0 = f(x,y) = (x-s)^2 + (y-t)^2 - r^2$

#8

$0 = f(x,y) = \overrightarrow{p}_0 \cdot \overrightarrow{n} + c \Rightarrow c = -\overrightarrow{p}_0 \cdot \overrightarrow{n}$

#9 OLD

$\overrightarrow{p}_0 = \begin{pmatrix} x_0 \\ y_0 \end{pmatrix} \Rightarrow \widetilde{(\overrightarrow{p}_0)} = \begin{pmatrix} u_0 \\ v_0 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$

#9 NEW

$\overrightarrow{p}_0 = \begin{pmatrix} x_0 \\ y_0 \end{pmatrix} \Rightarrow \left(\widetilde{\overrightarrow{p}_0}\right) = \begin{pmatrix} u_0 \\ v_0 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$

#10 OLD

$\overrightarrow{n} = \begin{pmatrix} -\Delta\mathrm{y} \\ \Delta\mathrm{x} \end{pmatrix} / \left(\sqrt{\Delta x^2 + \Delta y^2}\right)$

#10 NEW

$\overrightarrow{n} = \begin{pmatrix} -\Delta\mathrm{y} \\ \Delta\mathrm{x} \end{pmatrix} \cdot \frac{1}{\sqrt{\Delta x^2 + \Delta y^2}}$

#11

$\begin{bmatrix} a & b \\ c & d \end{bmatrix}$

#11-2

$\begin{bmatrix} m_{11} & m_{12} \\ m_{21} & m_{22} \end{bmatrix}$

#12

$\mathrm{start2} = \mathrm{xadd1}$

#13

$f(x+1, y)$

#14

$$\begin{pmatrix} \mathrm{w} \\ 0 \end{pmatrix} = A \cdot \begin{pmatrix} m_{11} \\ m_{12} \end{pmatrix} \wedge \begin{pmatrix} 0 \\ h \end{pmatrix} = A \cdot \begin{pmatrix} m_{21} \\ m_{22} \end{pmatrix}$$

#15

$$\mathrm{sqrt}\left(x^2 + y^2\right) = \frac{\sqrt{x^2 + y^2}}{k}$$

#16

$$k = \prod_{i=0}^{\infty} \frac{1}{\sqrt{1 + 2^{-2i}}} \fallingdotseq 0.607252935008881256169 4$$

55.12 Usage notes

55.12.1 Module-stop function

DRW operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The DRW module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

55.12.2 Restriction for OSPI

There is a restriction to using OSPI, see section 37.3.8.5. Restriction in 8D-8D-8D profile 1.0 format.

56. Graphics LCD Controller (GLCDC)

56.1 Overview

The multifunctional Graphics LCD Controller (GLCDC) supports multiple data formats and panels. Key GLCDC features include:

- GLCDC0 and GLCDC1 bus master function for accessing graphics data
- Superimposition of three planes (single color background plane, graphics 1 plane, and graphics 2 plane)
- Supports many types of 32- and 16-bit/pixel graphics data and 8-, 4-, and 1-bit LUT data formats
- Digital interface signal output supporting the video image size up to WXGA(1280 x 800).

Figure 56.1 shows a block diagram of the GLCDC.

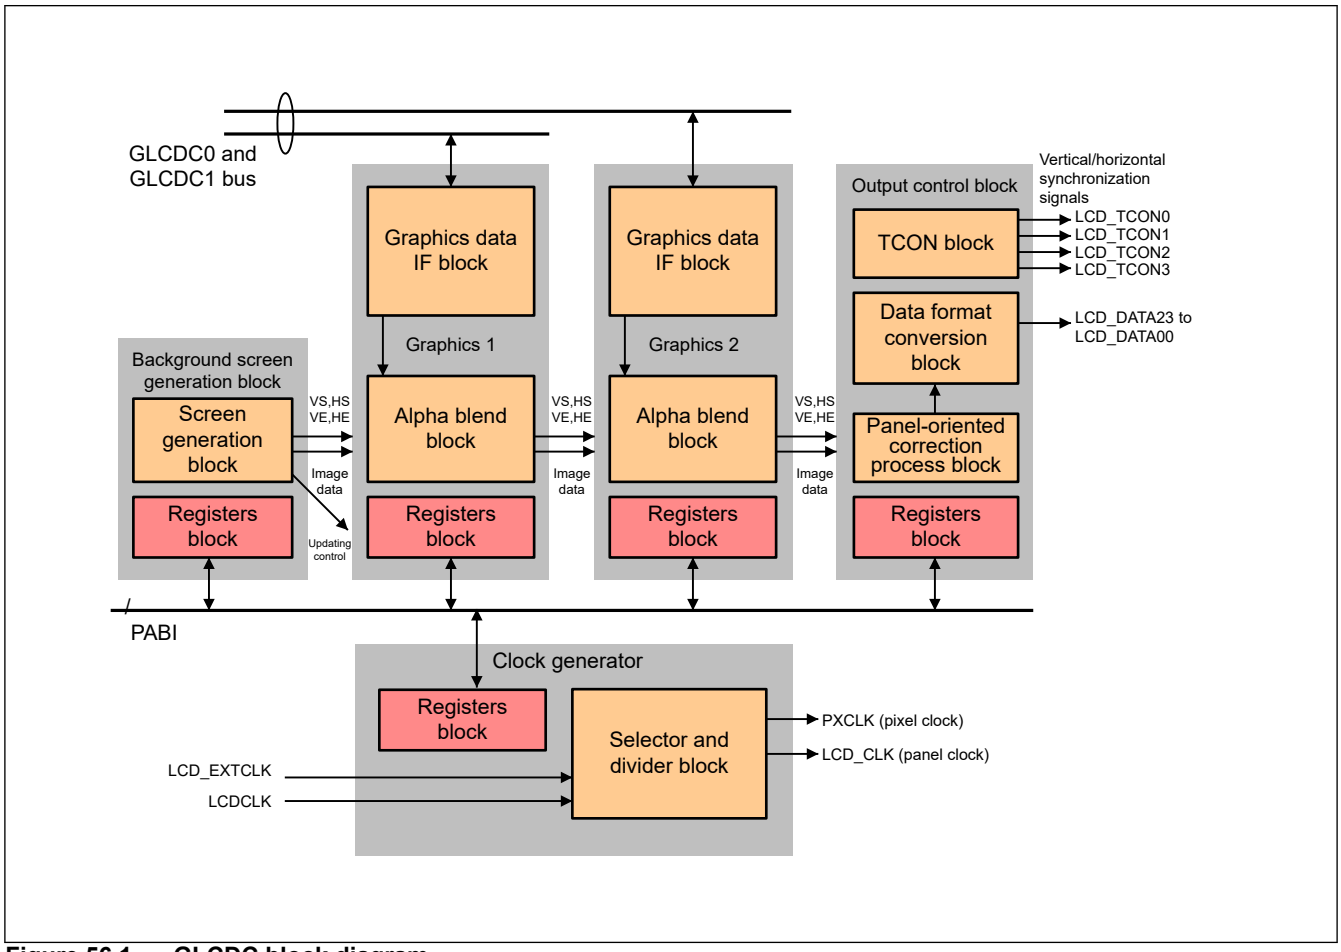

Figure 56.1 GLCDC block diagram

Table 56.1 GLCDC I/O pins

Function	Pin name	I/O	Description
GLCDC	LCD_EXTCLK	Input	Panel clock source input pin
	LCD_CLK	Output	Panel clock output pin
	LCD_DATA23 to LCD_DATA00	Output	LCD signal output pins RGB888 signal R/G/B: 8 bits each (unsigned) RGB666 signal R/G/B: 6 bits each (unsigned) RGB565 signal R/B: 5 bits each (unsigned) G: 6 bits (unsigned) Serial RGB signal R/G/B/-: 8 bits (unsigned)
	LCD_TCON3	Output	LCD_TCON3 output signal pin
	LCD_TCON2	Output	LCD_TCON2 output signal pin
	LCD_TCON1	Output	LCD_TCON1 output signal pin
	LCD_TCON0	Output	LCD_TCON0 output signal pin

Table 56.2 provides a functional overview of GLCDC.

Table 56.2 Functional overview of GLCDC (1 of 2)

Parameter		Function
Graphics	Graphics planes	• Single color background (lowest layer) and two graphics planes • Graphics planes can be alpha-blended with the lower-layer plane
	Pixel format	• RGB-888 progressive format (-: 8 bits, R: 8 bits, G: 8 bits, B: 8 bits; 32 bits in total) • ARGB8888 progressive format (A: 8 bits, R: 8 bits, G: 8 bits, B: 8 bits; 32 bits in total) • RGB565 progressive format (A: None, R: 5 bits, G: 6 bits, B: 5 bits; 16 bits in total) • ARGB1555 progressive format (CLUT: 1 bit, R: 5 bits, G: 5 bits, B: 5 bits; 16 bits in total) • ARGB4444 progressive format (A: 4 bits, R: 4 bits, G: 4 bits, B: 4 bits; 16 bits in total) • CLUT8 progressive format (color palette address: 8 bits) • CLUT4 progressive format (color palette address: 4 bits) • CLUT1 progressive format (color palette address: 1 bit) • CLUT memory: 512 words × 32 bits per graphics plane (ARGB8888)
	Frame buffer control	The following parameters can be set for the frame buffer: • Base address: Start address of the frame buffer, aligned with a 64-byte boundary (burst transfer size) • Macro line offset: Offset address from the start address to the next macro line, aligned with a 64-byte boundary (burst transfer size) • Frame offset: Offset address from the start address to the next frame, aligned with a 64-byte boundary (burst transfer size) • Number of data transfers: Number of data transfers of a macro line • Number of macro lines: Number of macro lines in a single frame
	Alpha blending	• Alpha blending in rectangular area (blending ratio: 256 gradation levels) • Alpha blending in pixel units (blending ratio: 256 gradation levels) • RGB-index chroma key (replaced with the specified color when the object color agrees with the preset value)
Internal video image format		• Total number of vertical lines: Up to 2048 lines • Number of valid vertical lines: 16 to 2044 lines (resolution: 1 line) • Vertical front porch: 2 lines (minimum) • Vertical back porch: 1 line (minimum) • Vertical pulse width: 1 line • Total number of horizontal pixels: Up to 2048 pixels • Number of valid horizontal pixels: 16 to 2040 pixels (resolution: 2 pixels) • Horizontal front porch: 3 pixels (minimum) (preliminary) • Horizontal back porch: 1 pixel (minimum) (preliminary) • Horizontal pulse width: 4 pixels

Table 56.2 Functional overview of GLCDC (2 of 2)

Parameter		Function
Data format conversion	Output video image size	• From 16 lines × 16 pixels to 2044 lines × 2040 pixels
	Data format	• RGB888 (parallel 24 bits) • RGB666 (parallel 18 bits) • RGB565 (parallel 16 bits) • RGB888 (serial 8 bits); clock cycle is four times the pixel clock • Bit endian order change and B/R signal swap
	Dither processing	• Reduces 10-bit signals (output after panel-oriented correction) to 8-, 6-, or 5-bit signals (output data format) • Supports the following modes: – Truncate mode – Round-off mode – 2 × 2 pattern dither mode
Timing control signal	Signal generation	5 timing signals (STVA, STVB, STHA, STHB, and DE) can be generated from HS / VS: • Vertical synchronization signal (variable) • Horizontal synchronization signal (variable) • Data enable signal
	Signal select	• Signals generated by the signal generation circuit can be output from LCD_TCONn pins (n = 0 to 3)
Output control panel-oriented correction processing	Brightness and contrast	• 10-bit internal processing; the sequence of this processing and gamma correction can be swapped. • Brightness: DC value adjustment range: from -512[LSB] to +512[LSB] • Contrast: gain value adjustment range: from 0 to 2 times (from 0/128 to 255/128)
	Gamma correction	• Sixteen areas; input/output: 10 bits • Gain value adjustment range in the area: From 0 to 2 times (from 0/1024 to 2047/1024)
Interrupts		• Number of specified lines interrupt (GLCDC_VPOS) • Graphics 1 buffer underflow interrupt (GLCDC_L1UNDF) • Graphics 2 buffer underflow interrupt (GLCDC_L2UNDF)
Module-stop function		Module-stop state can be set to reduce power consumption.
TrustZone Filter		Security and Privilege attribution can be set.

56.1.1 GLCDC Configuration

Figure 56.2 shows the configuration of the GLCDC.

The GLCDC includes the following blocks:

- Background screen generation block: Generates the background screen (including the blanking interval), selects the background color, and generates the synchronization signals for controlling the screens.
- Graphics data interface blocks (2 blocks): Convert the graphics data/CLUT data read through the GLCDC0 and GLCDC1 bus into ARGB (8888) data for internal processing, and transfer the clocks (PCLKA → PXCLK).
- Alpha blending blocks (2 blocks): Superimpose graphics data on the lower-layer screen and perform alpha blending based on the register settings and the alpha blending values for the current screen graphics data.
- TCON block: Generates the vertical and horizontal synchronization and enable signals suited for the specifications of the connected panel, from the internal vertical and horizontal synchronization signals.
- Data format conversion block: Processes data into the specific internal RGB888 format into the data of the specific format suited for the specifications of the panel with dither correction for output image data length.
- Panel-oriented correction processing block: Corrects brightness and contrast, and performs gamma correction suited for the characteristics of the connected panel, allowing either brightness and contrast correction or gamma correction to be performed first.
- Clock generator block: Generates the pixel and the panel clocks on a specific frequency from either LCD_EXTCLK or LCDCLK.

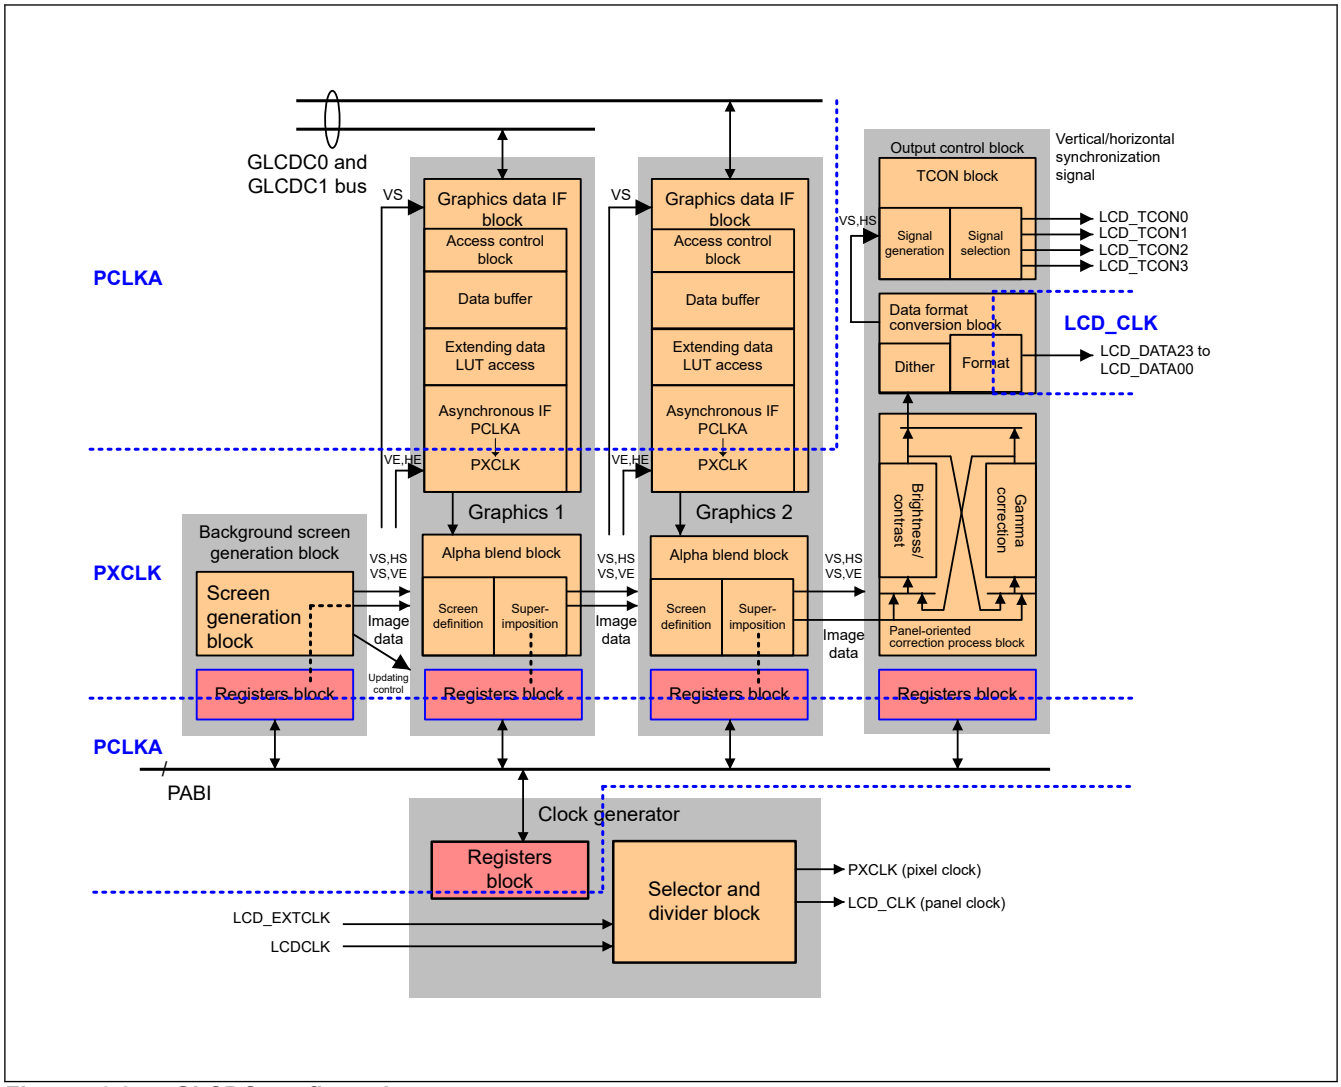

Figure 56.2 GLCDC configuration

56.1.2 Screen Format

Figure 56.3 shows the screen format overview of the GLCDC.

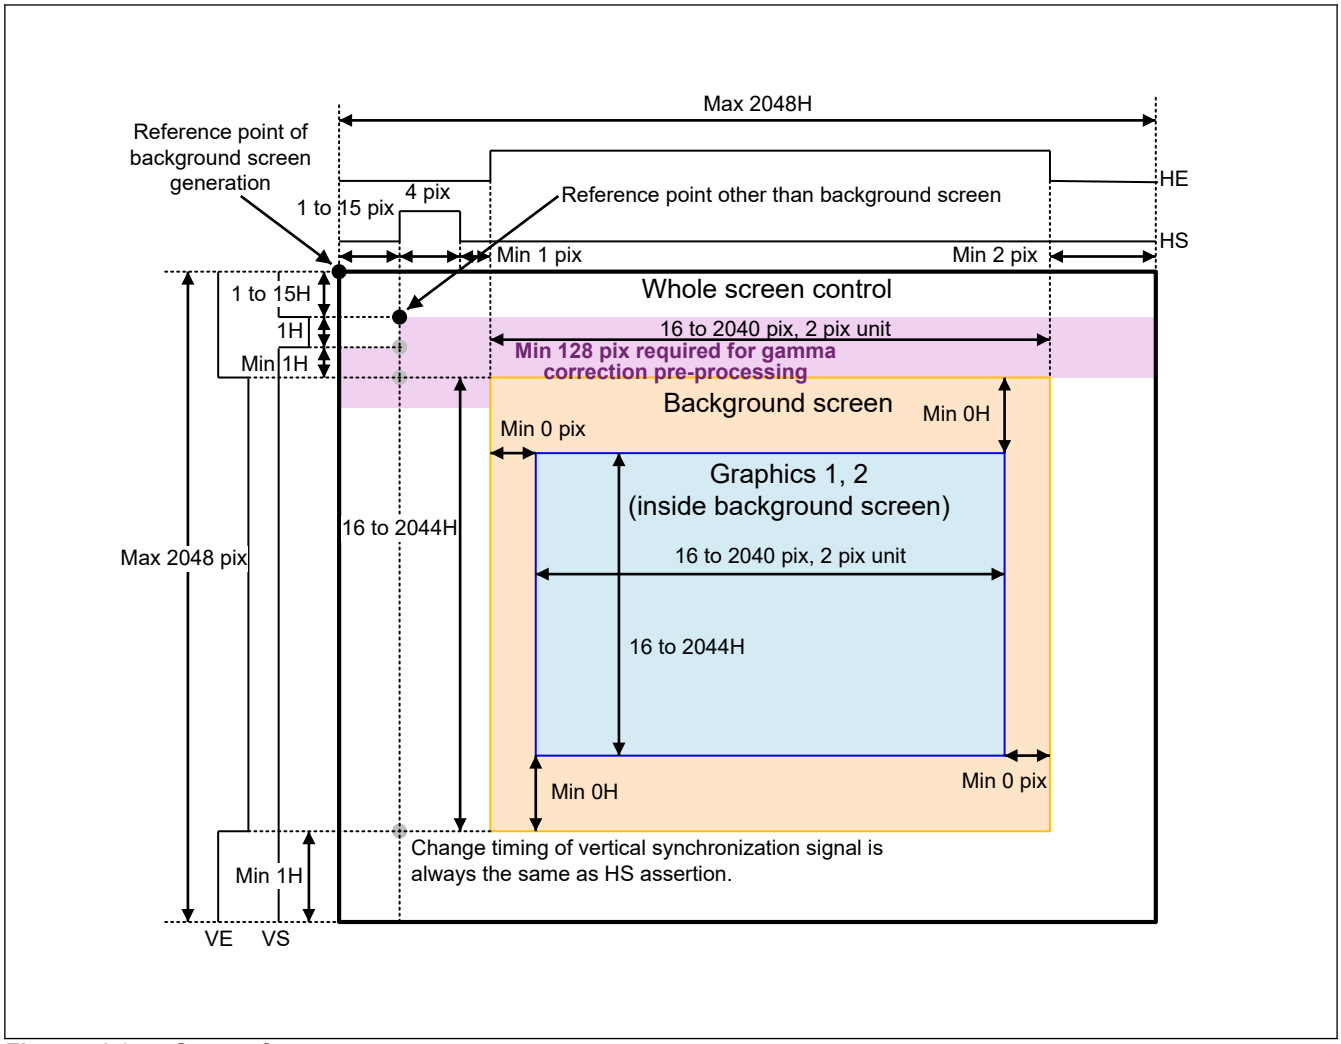

Figure 56.3 Screen format

The background screen generation block generates the essential timing signals for operations in the module as a whole. The graphics data interface blocks, alpha blending blocks, gamma correction block, output control block, and TCON block operate based on the synchronization and enable signals, which are sequentially transferred from the background screen generation block.

56.1.3 Graphics and Color Palette (CLUT) Data Formats

The GLCDC handles three display screens, one of which is a background screen. For the background screen, frame data is RGB888 graphics data stored in the registers, and for the other two screens, frame data is stored in the memory connected to the GLCDC0 and GLCDC1 bus as 32- or 16-bit/pixel graphics data or 8-, 4-, or 1-bit/pixel color palette (CLUT) data. The frame data of the relevant screen is read by the graphics data interface block, read into the GLCDC, and extended (converted) into ARGB8888 data for superimposition and blending. Figure 56.4 shows the frame data formats.

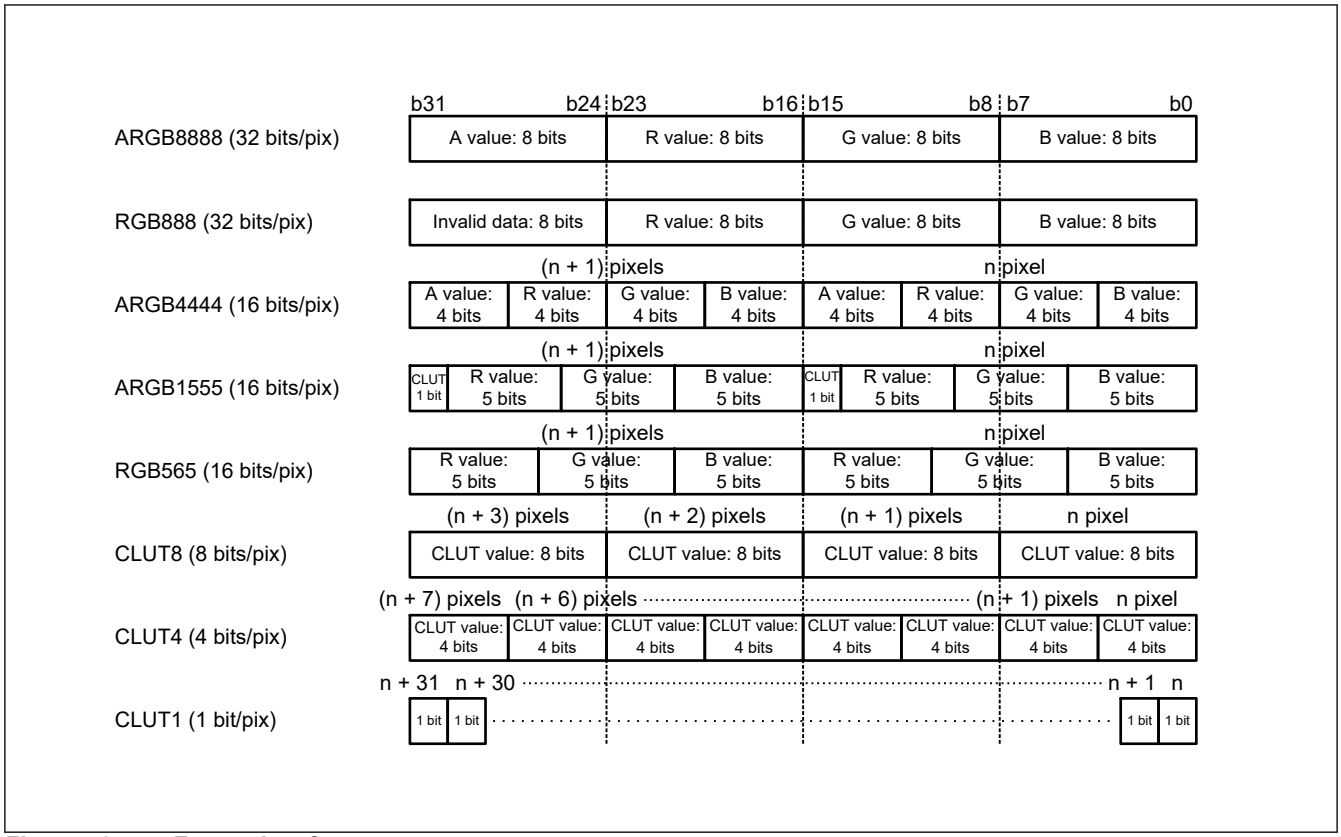

Figure 56.4 Frame data format

The A value (alpha blending value) represents the blending ratio of pixel data for displaying the lower-layer and current graphics screens after superimposition. The blending process is performed in accordance with the equations given in section 56.1.7. Graphics Data Interface. The CLUT value represents the color palette memory address (plane 0 or 1 is selected in the registers), and the data in the color palette is ARGB8888 (32 bits/pixel) graphics data. Addresses 0x01/0x00 are accessed with CLUT1, 0x0F to 0x00 with CLUT4, and 0xFF to 0x00 with CLUT8. Addresses 0x80/0x00 are accessed with ARGB1555 data.

56.1.4 Output Control for Data Format

The GLCDC can output data in accordance with the following formats and register settings:

- Data formats
  - Parallel: RGB888, RGB666, and RGB565
  - Serial: RGB888
  - Lower bits are processed in one of the following modes when 10-bit signals are reduced to 8-, 6-, and 5- bit signals:
    - Truncate mode
    - Round-off mode
    - 2×2 pattern dither processing + truncate mode
- Pixel arrangement
  - RGB
  - BGR
- Scan direction select for serial RGB888
  - Forward scan
  - Reverse scan
- Data output delay of serial RGB888

  - 0 to 3 clock cycles.

- Pin assignment
  - Little endian
  - Big endian

For details on dither processing, see section 56.2.48. OUT_PDTHA : Output Control Block Panel Dither Correction Register.

Bit assignment of LCD signals for parallel RGB888 format

Table 56.3 shows RGB signal inputs assigned to the LCD signal outputs for the parallel RGB888 output format.

Table 56.3 Bit assignment of RGB signal inputs for parallel RGB888 format

Pin assignment	Pixel arrangement

56.1.5 Output Control for Panel-Oriented Correction Process

The following panel-oriented correction processes are provided:

- Brightness correction
- Contrast correction
- RGB gamma correction

Brightness correction always precedes contrast correction, but RGB gamma correction can either precede or follow brightness and contrast correction, based on the register settings. In panel-oriented correction, 10-bit RGB data obtained by extending 8-bit RGB data output from graphics 2 is used, and 10-bit RGB data is also output to the output control (data format conversion) block. Figure 56.6 shows the configuration of the panel-oriented correction circuit.

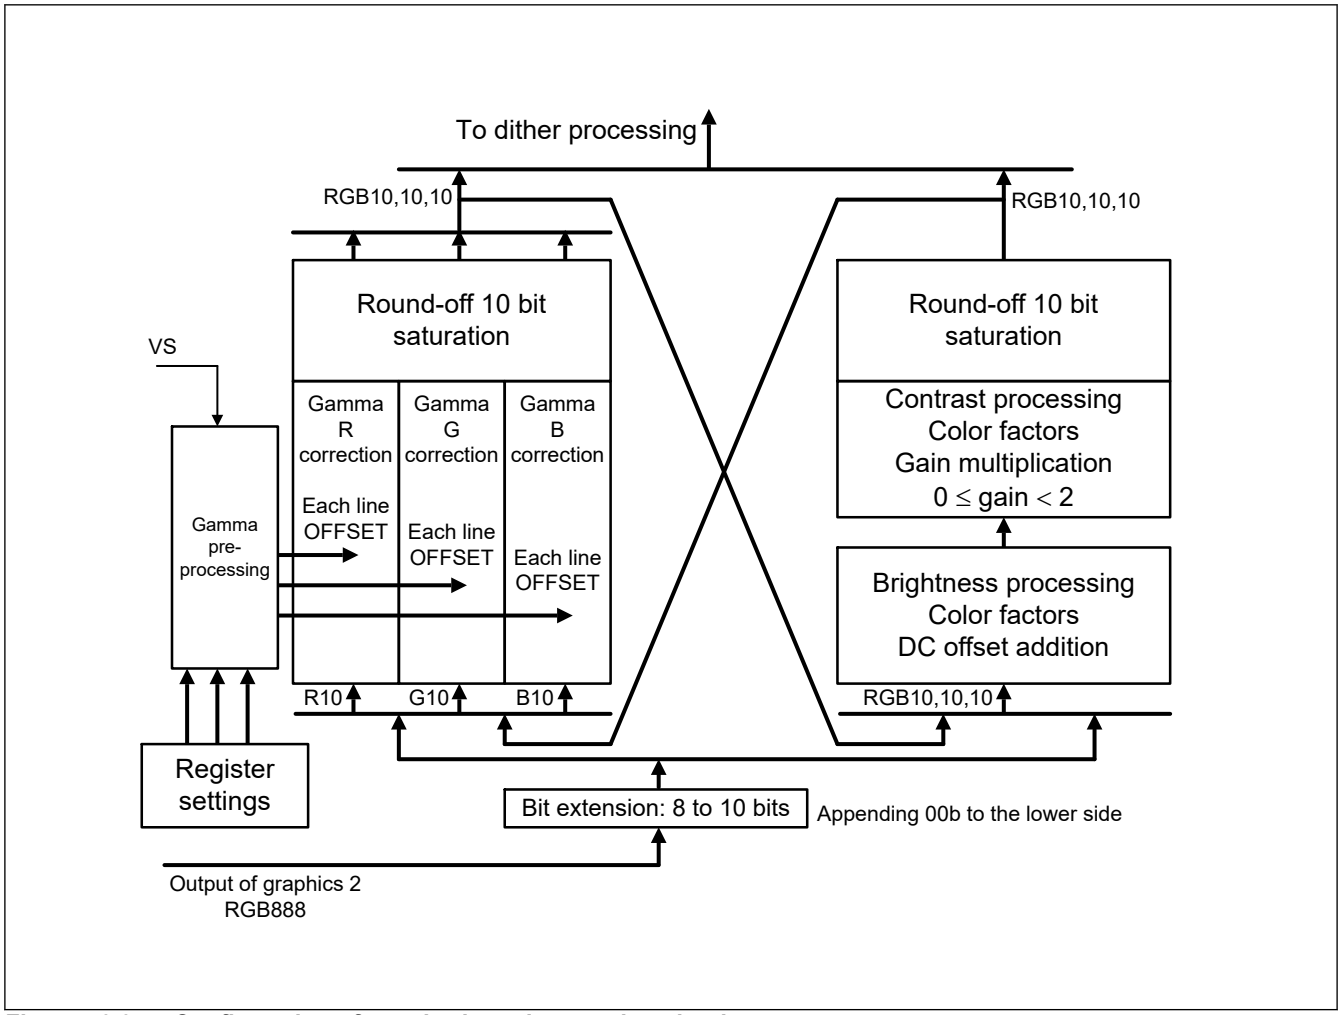

Figure 56.6 Configuration of panel-oriented correction circuit

56.1.6 Output Control for TCON

Any of the four signals generated from the internal vertical and horizontal synchronization signals (STVA, STVB, STHA, and STHB) that have passed through the data format conversion block can be selected for output on four pins, LCD_TCON0, LCD_TCON1, LCD_TCON2, and LCD_TCON3. The generated signals are completely independent of the image data. They are not affected by the output image format or any internal data process, and no register settings for signal generation affect the output image format or any internal data process. The data enable signal DE, which is to be generated by the TCON block, is the logical AND of the two signals STVB and STHB, which were previously generated by the TCON block. Consequently, three signals in total can actually be generated if DE is to be output.

56.1.7 Graphics Data Interface

Two circuit systems are provided for reading graphics data (graphics 1 and 2), each of which incorporates an access control block, data buffer, CLUT memory, data extension block, and asynchronous interface block.

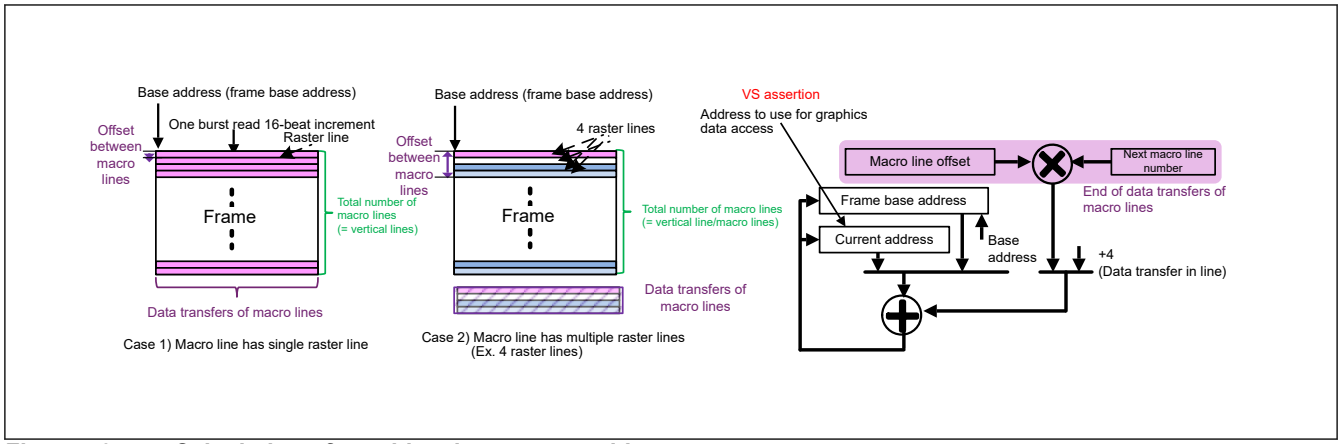

Figure 56.7 Calculation of graphics data access address

Graphics (or CLUT) data is accessed and output to the pixel operation block as ARGB8888 data (32 bits/pixel).

The GLCDC0 and GLCDC1 bus is accessed in word (32-bit) units in 16-beat increment burst reads, in accordance with the preset parameters in the two-dimensional addressing mode, in which the macro line structure is accounted for as shown in Figure 56.7, and data is stored in the data buffer. Even if invalid data is at the raster line end, all the data is stored in the data buffer, and the invalid data is skipped when data is read internally. Regardless of the format of the graphics data, data is extended to ARGB8888 data before being output to the alpha blending blocks.

56.1.8 Blending

The following processes are performed for the graphics areas specified in the registers. The lower-layer graphics plane is output without any processing to the display area outside the graphics area.

- Display plane selection
- RGB-index chroma-key
- Alpha blending

Figure 56.8 shows the relationship between the graphics display selection and rectangular alpha blending area.

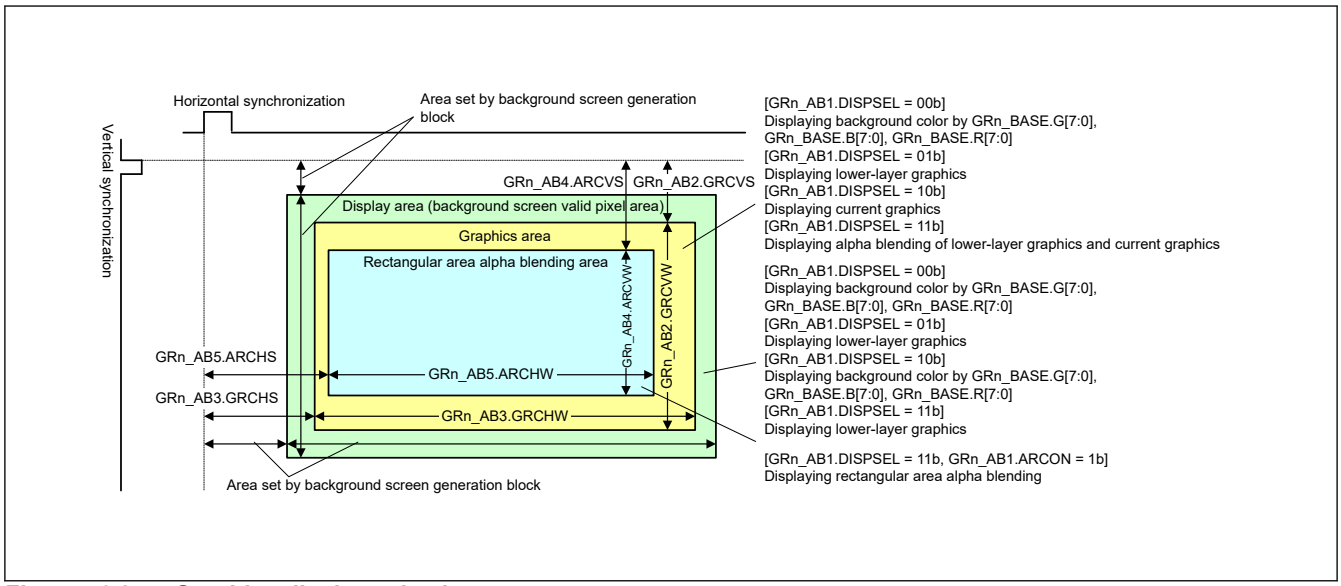

Figure 56.8 Graphics display selection

(1) Display plane selection

Based on the register settings, the following data is output to the graphics area:

- Background color:
  - RGB data specified in the registers.

- Lower-layer graphics:
  - RGB data input from the previous module
  - Output from the background screen generation block for graphics 1
  - Output from graphics 1 for graphics 2
- Current graphics:
  - RGB data obtained by the graphics data interface block extending the graphics data read by the graphics 1 or 2 module through the GLCDC0 and GLCDC1 bus or CLUT data to ARGB8888 format data.
- Blending:
  - RGB data obtained by blending the lower-layer graphics data and current graphics data obtained by the graphics data interface block extension to ARGB8888 format data, based on the alpha blending values or the register settings.

It is possible to modify the register values related to these functions while display operation is in progress, and to allow reflection of the updates to the internal operations when the VS (vertical synchronization signal) is asserted, if reflection of the register settings to the internal operations on vertical synchronization is enabled.

(2) RGB-index chroma-key

If the RGB value of the ARGB8888 data input from the graphics data interface block agrees with the value set in the GRn_AB8 register, the ARGB8888 data is entirely replaced with the value preset in the GRn_AB9 register. All the ARGB8888 data input from the graphics data interface block is subject to this process. If your application excludes CLUT memory output from this process, you must disable the corresponding process in GRn_AB7.CKON.

(3) Alpha blending

If blending is selected in the selected display plane, lower-layer graphics and current graphics are alpha-blended based on the register settings using either of the following two functions.

Alpha-blending in a rectangular area

The following process is performed for the rectangular area (in the graphics area) preset in the registers:

1. Lower-layer graphics and current graphics planes are blended in accordance with the A value set in the registers.
2. After the number of frames set in the registers passes, the A value is updated to the A value + Δ (register setting).
3. The lower-layer graphics and current graphics planes are blended in accordance with this updated A value.
4. The process of updating the A value after the number of frames set in the registers passes is repeated (A value: min/max value saturation).

Alpha-blending in pixel units

The lower-layer graphics and current graphics planes are blended in accordance with the A value of the ARGB8888 data input from the graphics data interface block.

Figure 56.9 shows the update of the alpha blending value in the rectangular alpha blending area.

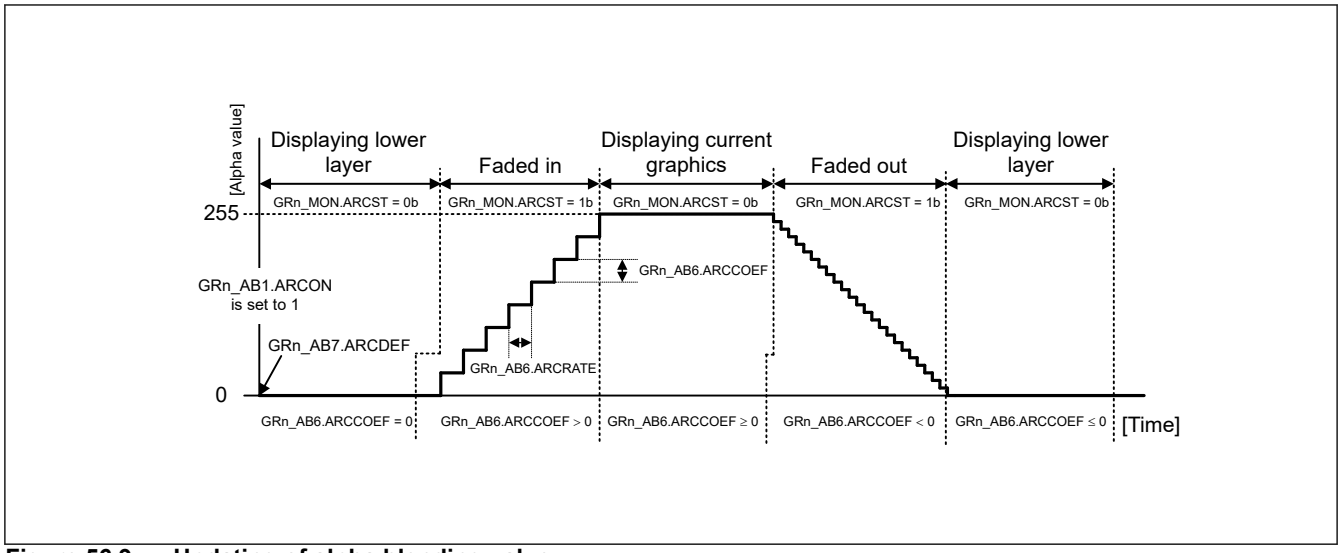

Figure 56.9 Updating of alpha blending value

Alpha blending is based on the following formulas:

When A value = 255

Rout/Gout/Bout = current graphics data

When A value ≠ 255

Rout = (Rin1 × A + Rin0 × (256 - A))/256

Gout = (Gin1 × A + Gin0 × (256 - A))/256

Bout = (Bin1 × A + Bin0 × (256 - A))/256

where,

A: alpha blending value

Rin1/Gin1/Bin1: current graphics data

Rin0/Gin0/Bin0: lower-layer graphics data

56.2 Register Descriptions

56.2.1 GRm_CLUTn[y] : Color Palette (m = 1 to 2, n = 0 to 1, y = 0 to 255)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x0+0x4 × y (GR1_CLUT0[y])
0x0400+0x4 × y (GR1_CLUT1[y])
0x0800+0x4 × y (GR2_CLUT0[y])
0x0C00+0x4 × y (GR2_CLUT1[y])

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	A[7:0]								R[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	G[7:0]								B[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	B[7:0]	B Value of Color Palette n Plane for Graphics m Plane B value of color palette n plane for graphics m plane. Unsigned 8-bit integer.	R/W

Bit	Symbol	Function	R/W
15:8	G[7:0]	G Value of Color Palette n Plane for Graphics m Plane G value of color palette n plane for graphics m plane. Unsigned 8-bit integer.	R/W
23:16	R[7:0]	R Value of Color Palette n Plane for Graphics m Plane R value of color palette n plane for graphics m plane. Unsigned 8-bit integer.	R/W
31:24	A[7:0]	Alpha Blending Value of Color Palette n Plane for Graphics m Plane Alpha blending value of color palette n plane for graphics m plane. Unsigned 8-bit integer.	R/W

Note: S-TYPE-3, P-TYPE-3

B[7:0] bits (B Value of Color Palette n Plane for Graphics m Plane)

The B[7:0] bits set the B value when this color palette is used.

G[7:0] bits (G Value of Color Palette n Plane for Graphics m Plane)

The G[7:0] bits set the G value when this color palette is used.

R[7:0] bits (R Value of Color Palette n Plane for Graphics m Plane)

The R[7:0] bits set the R value when this color palette is used.

A[7:0] bits (Alpha Blending Value of Color Palette n Plane for Graphics m Plane)

The A[7:0] bits set the alpha blending value when this color palette is used.

All the planes can always be accessed through the register access bus (PABI), regardless of the plane specified to be used by the graphics data access block. The updates are reflected to the internal operations directly, not in synchronization with the vertical synchronization signal. To keep reflection of the CLUT memory contents to the internal operations in synchronization with the vertical synchronization signal, first write data through the register access bus to the plane that is not being used for internal operations, and then modify the GRn_CLUTINT.SEL bit for controlling the plane that is to be used.

56.2.2 BG_EN : Background Plane Setting Operation Control Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SWRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	VEN	—	—	—	—	—	—	—	EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EN	Background Plane Operation Enable 0: Disable background plane operation 1: Enable background plane operation	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	VEN	Control of GLCDC Internal Register Value Reflection to Internal Operations This bit is set to 0 by an internal source. 0: Disable GLCDC register values from being reflected in internal operations at start of screen generation 1: Enable GLCDC register values to be reflected in internal operations at start of screen generation	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
16	SWRST	Software Reset Control 0: Place entire module in software reset state 1: Release entire module from software reset state	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

EN bit (Background Plane Operation Enable)

The EN bit enables or disables the operation of the background plane generation module. When the operation is stopped (this bit is cleared to 0) after the operation is enabled (set to 1), the operation is stopped at the end of screen generation, unlike when a software reset occurs.

When setting this bit to 1, set the BG_EN.VEN bit to 1 simultaneously to enable register value reflection to internal operations. When clearing this bit to 0, also clear the BG_EN.VEN bit to 0 simultaneously. Before clearing this bit to 0, confirm that the BG_MON.VEN bit is cleared to 0, to make sure that the signal for controlling reflection of the register values to internal operations is negated. Operation is not guaranteed if this bit and the BG_EN.VEN bit are set to 1, or if the settings in other registers are modified before the BG_MON.EN bit is cleared to 0.

VEN bit (Control of GLCDC Internal Register Value Reflection to Internal Operations)

The VEN bit enables or disables reflection of the GLCDC internal register to the GLCDC internal operation on assertion of the vertical synchronization signal (input). When this bit is set to 1, the signal of GLCDC internal register values reflection control is set to 1 at the immediate start of the screen, and are automatically cleared to 0 at the end of the vertical valid pixel of the same screen. Set this bit to 1 only when 0. Operation is not guaranteed if this bit is set to 1 when 1. Also, while this bit is 1, do not modify any register whose value is reflected to the internal operations at the start of the screen in the GLCDC or on assertion of the vertical synchronization signal (input). Otherwise, operation is not guaranteed.

SWRST bit (Software Reset Control)

The SWRST bit controls a software reset of the entire GLCDC, not only the background plane generation module. When this bit is cleared to 0, the GLCDC enters the reset state from any operation state. This bit must be set to 1 before the registers are set or operation enabled. Although the registers (except the CLUT memory and the some of the operation control registers) can be set while this bit is set to 1 (immediately after), before accessing the CLUT memory, enabling operation, or reflecting the register values to the internal operation by the vertical synchronization signal, confirm that PXCLK/LCD_CLK and PCLKA are supplied and that the BG_MON.SWRST bit, which monitors the entire module software reset state, is set to 1. Operation is not guaranteed if the software accesses CLUT memory, enables operation, or reflects the register vales to the internal operation on the vertical synchronization signal while PXCLK/LCD_CLK and PCLKA are not supplied or the BG_MON.SWRST bit is not set to 1. The peripheral bus clock (PCLKA) must be supplied to the GLCDC when this bit is used to apply or cancel a software reset. If PCLKA is not supplied, writing to this bit is impossible.

The bits in this register control the GLCDC states. The internal states can be read from the associated bits in the status monitor registers and BG_EN.VEN (this register). Because the GLCDC, which operates on multiple clock signals, requires a certain period for state transition, you must confirm that the internal state has stabilized (state transition is complete) when settings are modified. Operation is not guaranteed if settings are modified again before the internal state stabilizes (state transition is complete). However, clearing a software reset to 0 immediately makes the whole GLCDC reset, setting it to 1 releases the reset state. These operations do not require the clock supply of PXCLK.

56.2.3 BG_PERI : Background Plane Setting Free-Running Period Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	FV[10:0]

Bit	Symbol	Function	R/W
10:0	FH[10:0]	Background Plane Horizontal Synchronization Signal Period Period based on pixel clocks (PXCLK). The valid range is 0x17 to 0x7FF. 0x017: 24 cycles (pixels) 0x3FF: 1024 cycles (pixels) 0x7FF: 2048 cycles (pixels)	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	FV[10:0]	Background Plane Vertical Synchronization Signal Period Period based on lines. The valid range is 0x013 to 0x7FF. 0x013: 20 lines 0x3FF: 1024 lines 0x7FF: 2048 lines	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

FH[10:0] bits (Background Plane Horizontal Synchronization Signal Period)

The FH[10:0] bits set the horizontal synchronization signal period of the background plane. This field contains 11 bits and can be set to any number from 0x000 to 0x7FF. However, the valid range is 0x017 to 0x7FF.

FV[10:0] bits (Background Plane Vertical Synchronization Signal Period)

The FV[10:0] bits set the vertical synchronization signal period of the background plane. This field contains 11 bits and can be set to any number from 0x000 to 0x7FF. However, the valid range is 0x013 to 0x7FF.

56.2.4 BG_SYNC : Background Plane Setting Synchronization Position Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	VP[3:0]>			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	HP[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
3:0	HP[3:0]	Background Plane Horizontal Synchronization Signal Assertion Position Position based on pixel clocks (PXCLK). 0x0: Setting prohibited Others: HPth cycle (pixel)	R/W
15:4	—	These bits are read as 0. The write value should be 0.	R/W
19:16	VP[3:0]	Background Plane Vertical Synchronization Assertion Position Position based on lines. 0x0: Setting prohibited Others: VPth line	R/W
31:20	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

HP[3:0] bits (Background Plane Horizontal Synchronization Signal Assertion Position)

The HP[3:0] bits set the horizontal synchronization signal assertion position of the background plane. The signal is held asserted for a 4-pixel clock width.

VP[3:0] bits (Background Plane Vertical Synchronization Assertion Position)

The VP[3:0] bits set the vertical synchronization signal assertion position of the background plane. The signal is held asserted for a 1H width, and the assertion timing within a single horizontal line is specified in BG_SYNC.HP[3:0].

56.2.5 BG_VSIZE : Background Plane Setting Full Image Vertical Size Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x100C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	VP[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	VW[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
10:0	VW[10:0]	Background Plane Vertical Valid Pixel Width Width based on lines. 0x010: 16 lines ⋮ 0x7FC: 2044 lines Others: Setting prohibited	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	VP[10:0]	Background Plane Vertical Valid Pixel Start Position Position based on of lines. 0x003: 3rd line ⋮ 0x7EF: 2031 lines Others: Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

VW[10:0] bits (Background Plane Vertical Valid Pixel Width)

The VW[10:0] bits set the vertical valid pixel width of the background plane. This field contains 11 bits and can be set to any number from 0x000 to 0x7FF. However, the valid range is 0x010 to 0x7FC. Operation is not guaranteed if a value outside the valid range is set.

VP[10:0] bits (Background Plane Vertical Valid Pixel Start Position)

The VP[10:0] bits set the vertical valid pixel start position of the background plane. This field contains 11 bits and can be set to any number from 0x000 to 0x7FF. However, the valid range is 0x003 to 0x7EF. Operation is not guaranteed if a value outside the valid range is set.

Specify the vertical valid pixel area between the assertion position of the vertical synchronization signal + 2 and the (background plane end - 1)th line. Operation is not guaranteed if the area is specified outside this range.

56.2.6 BG_HSIZE : Background Plane Setting Full Image Horizontal Size Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	HP[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	HW[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
10:0	HW[10:0]	Background Plane Horizontal Valid Pixel Width Width based on pixel clocks (PXCLK). 0x010: 16 cycles ⋮ 0x7F8: 2040 cycles Others: Setting prohibited	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	HP[10:0]	Background Plane Horizontal Valid Pixel Start Position Position based on pixel clocks (PXCLK). 0x006: 6th cycle (pixel) ⋮ 0x7EE: 2030 cycles Others: Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

HW[10:0] bits (Background Plane Horizontal Valid Pixel Width)

The HW[10:0] bits set the horizontal valid pixel width of the background plane. This field contains 11 bits and can be set to any number from 0x000 to 0x7FF. However, the valid range is 0x010 to 0x7F8. Operation is not guaranteed if a value outside the valid range is set. When serial RGB is selected as the output format for the output control block, add two to the horizontal valid pixel width and set the resulting value to these bits.

HP[10:0] bits (Background Plane Horizontal Valid Pixel Start Position)

The HP[10:0] bits set the horizontal valid pixel start position of the background plane. This field contains 11 bits and can be set to any number from 0x000 to 0x7FF. However, the valid range is 0x006 to 0x7EE. Operation is not guaranteed if a value outside the valid range is set.

Specify the horizontal valid pixel area between the assertion position of the horizontal synchronization signal + 5 and pixel number (line end – 2). Operation is not guaranteed if the area is specified outside this range.

The background plane generation module outputs the values that are specified in the Background Color Register (BG_BGC) for the area defined by the Full Image Vertical Size Register (BG_VSIZE) and Full Image Horizontal Size Register (BG_HSIZE), and it outputs 0x00 as the RGB values for the blanking interval area.

56.2.7 BG_BGC : Background Plane Setting Background Color Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	R[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	G[7:0]								B[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	B[7:0]	Background Plane Valid Pixel Area B Value B value for background plane valid pixel area. Unsigned 8-bit integer.	R/W
15:8	G[7:0]	Background Plane Valid Pixel Area G Value G value for background plane valid pixel area. Unsigned 8-bit integer.	R/W
23:16	R[7:0]	Background Plane Valid Pixel Area R Value R value for background plane valid pixel area. Unsigned 8-bit integer.	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

B[7:0] bits (Background Plane Valid Pixel Area B Value)

The B[7:0] bits set the B value of image data to be output to the valid pixel area of the background plane.

G[7:0] bits (Background Plane Valid Pixel Area G Value)

The G[7:0] bits set the G value of image data to be output to the valid pixel area of the background plane.

R[7:0] bits (Background Plane Valid Pixel Area R Value)

The R[7:0] bits set the R value of image data to be output to the valid pixel area of the background plane.

56.2.8 BG_MON : Background Plane Setting Status Monitor Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1018

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SWRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	VEN	—	—	—	—	—	—	—	EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EN	Background Plane Operation Monitor 0: Operation is stopped 1: Operation is in progress	R
7:1	—	These bits are read as 0. The write value should be 0.	R
8	VEN	Entire Module Internal Operation Reflection Control Signal Monitor 0: Signal for controlling reflection of the register values to internal operations on assertion of vertical synchronization signal is negated 1: Signal for controlling reflection of the register values to internal operations on assertion of vertical synchronization signal is asserted	R
15:9	—	These bits are read as 0.	R
16	SWRST	Entire Module SW Reset State Monitor 0: Entire module is in software reset state 1: Entire module is released from software reset state	R
31:17	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

EN bit (Background Plane Operation Monitor)

The EN bit indicates whether the background plane generation module is operating or not. To stop the operation of the background plane generation module by clearing BG_EN.EN to 0, read this bit to confirm that the operation of the background plane is complete. Clearing BG_EN.EN to 0 does not stop the operation until completion of the background plane, unlike when BG_EN.SWRST is cleared to 0.

VEN bit (Entire Module Internal Operation Reflection Control Signal Monitor)

The VEN bit indicates the value of the signal for controlling reflection of the GLCDC internal register values to the internal operations. This signal is asserted at the start of a screen immediately after setting BG_EN.VEN to 1 and negated at the VE negate timing output from the background screen generation block.

SWRST bit (Entire Module SW Reset State Monitor)

The SWRST bit indicates the software reset state of the entire module when PXCLK is supplied. This bit value indicates the result of the peripheral module clock A (PCLKA) resampling the result of the pixel clock (PXCLK) sampling the BG_EN.SWRST bit. Even if PXCLK is not supplied, clearing the BG_EN.SWRST to 0 clears this bit to 0.

56.2.9 GRn_VEN : Graphics n Register Update Control Register (n = 1 to 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1100 + 0x100 × (n-1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PVEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PVEN	Control of Graphics n Register Value Reflection to Internal Pixel Operations This bit is cleared to 0 by an internal source. 0: Disable reflection of register values to internal operations on assertion of vertical synchronization signal (VS) 1: Enable reflection of register values to internal operations on assertion of the vertical synchronization signal (VS)	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

PVEN bit (Control of Graphics n Register Value Reflection to Internal Pixel Operations)

The PVEN bit enables or disables reflection of the register values to the internal operations of the pixel operation circuit on assertion of the vertical synchronization signal (input). When this bit is set to 1, the register values are immediately reflected to the internal operations on assertion of the vertical synchronization signal (input), and are automatically cleared to 0. Set this bit to 1 only when 0. Operation is not guaranteed if this bit is set to 1 when 1. Also, if the signal output is asserted from the background plane generation module that controls reflection of the register values to the internal operations of all the modules, the register values are always reflected to the internal operations on assertion of the vertical synchronization signal (input), regardless of the value of this bit. While this bit is 1, do not modify any register whose value is reflected to the internal operations on assertion of the vertical synchronization signal (input) in this block. Otherwise, operation is not guaranteed.

This bit must not be 1 at the same time as the BG_EN.VEN bit (control of background plane register value reflection to internal operations) in the Operation Control Register (BG_EN), one of the background plane setting registers. Otherwise, operation is not guaranteed.

56.2.10 GRn_FLMRD : Graphics n Frame Buffer Read Control Register (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1104 + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RENB
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RENB	Graphics Data Read Enable Graphics data is the frame buffer data. 0: Disable reading 1: Enable reading	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

RENB bit (Graphics Data Read Enable)

The RENB bit enables or disables reading of the graphics data (frame buffer data in memory connected through the GLCDC0 and GLCDC1 bus). If the current graphics data is required, data read must be enabled (GRn_FLMRD.RENB = 1) before the background panel operation is enabled, register value internal operation reflection control is enabled, or the register value internal operation reflection control of graphics 1 and 2 is enabled.

If the current graphics data is not required, data read must be disabled (GRn_FLMRD.RENB = 0) before the background panel operation is enabled, register value internal operation reflection control is enabled, or the register value internal operation reflection control of graphics 1 and 2 is enabled.

56.2.11 GRn_FLM1 : Graphics n Frame Buffer Control Register 1 (n = 1 to 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1108 + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BSTMD[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
1:0	BSTMD[1:0]	Burst Transfer Control for Graphics Data Access Graphics data is the frame buffer data. 1 1: 16-beat increment burst transfer (64-byte boundary) Others: Setting prohibited	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

BSTMD[1:0] bits (Burst Transfer Control for Graphics Data Access)

The BSTMD[1:0] bits control burst transfers for accessing the graphics data (frame buffer data in memory connected to memory through the GLCDC0 and GLCDC1 bus). In this GLCDC, these bits are fixed to 11b. Operation is not guaranteed if these bits are set to any other value.

56.2.12 GRn_FLM2 : Graphics n Frame Buffer Control Register 2 (n = 1 to 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x110C + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	BASE[31:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BASE[31:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	BASE[31:0]	Base Address for Accessing Graphics Data Start address in the frame buffer where graphics data is to be stored. Fix GRn_FLM2.BASE[5:0] to 0 during 64-byte burst transfer.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

BASE[31:0] bits (Base Address for Accessing Graphics Data)

The BASE[31:0] bits specify the base address (start address in the first frame buffer) for graphics data access. Because the GLCDC only supports the 16-beat increment burst transfer mode, in which data is aligned with a 64-byte boundary, the lower 6 bits (GRn_FLM2.BASE[5:0]) must be fixed to 0.

56.2.13 GRn_FLM3 : Graphics n Frame Buffer Control Register 3 (n = 1 to 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1110 + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	LNOFF[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W
31:16	LNOFF[15:0]	Macro Line Offset Address for Accessing Graphics Data Macro line offset address for accessing graphics data (frame buffer data). Signed, 16-bit integer.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

LNOFF[15:0] bits (Macro Line Offset Address for Accessing Graphics Data)

The LNOFF[15:0] bits specify the macro line offset address for accessing graphics data (offset to be added to the current address at the macro line end for calculating the start address of the next macro line). Because the GLCDC only supports the 16-beat increment burst transfer mode, in which data is aligned with a 64-byte boundary, the lower 6 bits (GRn_FLM3.LNOFF[5:0]) must be fixed to 0.

56.2.14 GRn_FLM5 : Graphics n Frame Buffer Control Register 5 (n = 1 to 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1118 + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	LNNUM[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DATANUM[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DATANUM[15:0]	Number of Data Transfer Times Per Line for Accessing Graphics Data Number of data transfers per macro line for accessing graphics data (frame buffer data), where one transfer is defined as 16-beat burst access (64-byte boundary). 0x0000 Once : ⋮ 0xFFFF 65536 times :	R/W
26:16	LNNUM[10:0]	Number of Lines Per Frame for Accessing Graphics Data Number of macro lines per frame for accessing graphics data (frame buffer data). 0x000: 1 macro line ⋮ 0x7FB: 2044 macro lines Others: Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

DATANUM[15:0] bits (Number of Data Transfer Times Per Line for Accessing Graphics Data)

The DATANUM[15:0] bits specify the number of data transfers per macro line for accessing graphics data, where one transfer is defined as a 16-beat burst access through the GLCDC0 and GLCDC1 bus. For all the data transfers, at least 2 bytes of valid pixel data are required (16 pixels in LUT1 format and 16 pixels or more in the other formats). If the number of bytes per macro line cannot be divided by 64 (4 bytes × 16-beat), DATANUM is obtained by rounding up to the whole number.

LNNUM[10:0] bits (Number of Lines Per Frame for Accessing Graphics Data)

The LNNUM[10:0] bits specify the number of lines per frame for accessing graphics data. When graphics data for the number of lines set to these bits is read, it signals the end of the frame and the base address is loaded.

The following are two use cases for macro lines. In these use cases, the frame size is 480 pixels × 272 lines and the pixel format is RGB565 (16 bpp).

Case 1) One macro line is configured to be equivalent to the frame raster width. The number of macro lines is equivalent to the number of vertical lines.

DATANUM: 0x000E (15 times = 16 × 480 / 512)

LNNUM: 0x10F (272 macro lines = 272 / 1)

Case 2) One macro line is configured to be repeated during the display frame. The number of macro lines is not equivalent to the number of vertical lines. In the example, one macro line has 16 times the raster width.

DATANUM: 0x00EF (240 times = 16 × 480 / 512 × 16)

LNNUM: 0x010 (17 macro lines = 272 / 16)

56.2.15 GRn_FLM6 : Graphics n Frame Buffer Control Register 6 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x111C + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	FORMAT[2:0]			—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
27:0	—	These bits are read as 0. The write value should be 0.	R/W
30:28	FORMAT[2:0]	Data Format for Accessing Graphics Data Data format for accessing graphics data (frame buffer data). 0 0 0: RGB565 (16 bits/pixel) 0 0 1: RGB888 (32 bits/pixel, 8 bits on the MSB side are invalid) 0 1 0: ARGB1555 (16 bits/pixel, 1 bit of A is LUT data) 0 1 1: ARGB4444 (16 bits/pixel) 1 0 0: ARGB8888 (32 bits/pixel) 1 0 1: CLUT8 (8 bits/pixel) 1 1 0: CLUT4 (4 bits/pixel) 1 1 1: CLUT1 (1 bit/pixel)	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

FORMAT[2:0] bits (Data Format for Accessing Graphics Data)

The FORMAT[2:0] bits specify the data format for accessing graphics data. CLUT1, CLUT4, CLUT8 contain the addresses 0x01 or 0x00, 0x0F to 0x00, and 0xFF to 0x00, respectively, for accessing the color palette. ARGB1555 contains the address for accessing the color palette (0x80 or 0x00) in the MSB and RGB data in the other bits. ARGB8888 and ARGB4444 contain the upper 8-bit or 4-bit alpha blending values and RGB data. RGB888 and RGB565 contain RGB data only.

56.2.16 GRn_AB1 : Graphics n Alpha Blending Control Register 1 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1120 + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	ARCON	—	—	—	ARCDISPON	—	—	—	GRCDISPON	—	—	DISPSEL[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	DISPSEL[1:0]	Graphics Display Plane Control 0 0: Background color display (value set in the GRn_BASE register) 0 1: Lower-layer graphics display 1 0: Current graphics display 1 1: Blended display of lower-layer graphics (input image from the previous stage) and current graphics (data read from the GLCDC0 and GLCDC1 bus)	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	GRCDISPON	Graphics Image Area Border Display Control 0: Turn display off 1: Turn display on	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	ARCDISPON	Image Area Border Display Control for Rectangular Area Alpha Blending 0: Turn display off 1: Turn display on	R/W
11:9	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
12	ARCON	Rectangular Area Alpha Blending Control 0: Turn blending off 1: Turn blending on	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

DISPSEL[1:0] bits (Graphics Display Plane Control)

The DISPSEL[1:0] bits control the graphics display plane. When the plane is selected as the lower-layer graphics, the image input from the previous stage is displayed (the background plane for GR1, and output from GR1 for GR2); as the background color, the background color specified in the GLCDC registers is displayed; and as the current graphics, the ARGB8888 data obtained by expanding the graphics data read by the GLCDC from the GLCDC0 and GLCDC1 bus is displayed. When the current graphics display is selected (these bits are set to 10b), RGB888 data is displayed, regardless of the alpha blending value in the pixel. Table 56.8 and Figure 56.10 show the relationship between the register setting and display area.

GRCDISPON bit (Graphics Image Area Border Display Control)

The GRCDISPON bit turns on or off the border display for the graphics image area. When the display is turned on (this bit is set to 1), the graphics image area is bordered with the preset color. The border is 1 pixel wide on the outermost periphery of the area with the display data set as 0xFF for each RGB color.

ARCDISPON bit (Image Area Border Display Control for Rectangular Area Alpha Blending)

The ARCDISPON bit turns on or off the border display for the image area where rectangular area alpha blending is performed. When the display is turned on (this bit is set to 1), the image area for the rectangular alpha blending is bordered with the preset color. The border is 1 pixel wide on the outermost periphery of the area and the display data set as 0xFF for each RGB color.

ARCON bit (Rectangular Area Alpha Blending Control)

The ARCON bit turns on or off alpha blending in a rectangular area. When alpha blending is turned on (this bit is set to 1), pixels are processed in accordance with the alpha blending control specified in the relevant registers for the specified rectangular area, not in accordance with the alpha value input from the graphics data interface for each pixel. In the areas outside the rectangular area in the graphics area, pixels are processed in accordance with the alpha value input from the graphics data interface for each pixel.

Table 56.8 Display selections

GRn_AB1. DISPSEL[1:0] (display plane)	GRn_AB1. ARCON (rectangular)	GRn_AB7. CKON (chroma key)	Within rectangular alpha blending area	Outside rectangular alpha blending area within graphics area	Outside graphics area within display area	Outside display area
00b	0	0	—	Background color	Background color	Lower layer R = G = B = 0x00
01b	0	0	—	Lower layer	Lower layer	Lower layer R = G = B = 0x00
10b	0	0	—	Current	Background color	Lower layer R = G = B = 0x00
11b	0	0	—	Current + alpha blending in pixel units	Lower layer	Lower layer R = G = B = 0x00
11b	0	1	—	Current + RGB-index chroma key + alpha blending in pixel units	Lower layer	Lower layer R = G = B = 0x00
11b	1	0	Current + rectangular alpha blending	Current + alpha blending in pixel units	Lower layer	Lower layer R = G = B = 0x00
11b	1	1	Current + rectangular alpha blending	Current + RGB-index chroma key + alpha blending in pixel units	Lower layer	Lower layer R = G = B = 0x00

Note: Operation is not guaranteed when any other value is set.

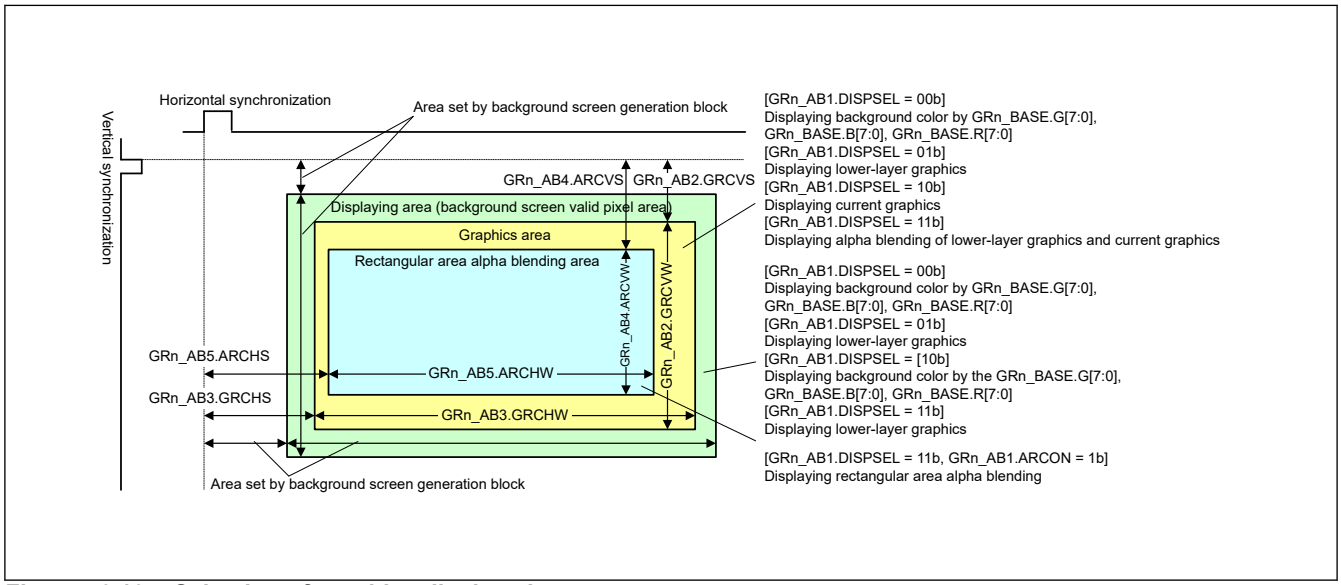

Figure 56.10 Selection of graphics display plane

56.2.17 GRn_AB2 : Graphics n Alpha Blending Control Register 2 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1124 + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	GRCVS[10:0]

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	GRCVW[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
10:0	GRCVW[10:0]	Vertical Width of Graphics Image Area Width in lines. 0x010: 16 lines ⋮ 0x7FC: 2044 lines Others: Setting prohibited	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	GRCVS[10:0]	Vertical Start Position of Graphics Image Area Position in lines. 0x002: 2nd line ⋮ 0x7EE: 2030th line Others: Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GRCVW[10:0] bits (Vertical Width of Graphics Image Area)

The GRCVW[10:0] bits specify the vertical width of the graphics image area.

GRCVS[10:0] bits (Vertical Start Position of Graphics Image Area)

The GRCVS[10:0] bits specify the vertical start position of the graphics image area, in reference to assertion of the vertical synchronization signal (VS). For the relationship with the graphics display plane, see Figure 56.10.

56.2.18 GRn_AB3 : Graphics n Alpha Blending Control Register 3 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1128 + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	GRCHS[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	GRCHW[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
10:0	GRCHW[10:0]	Horizontal Width of Graphics Image Area Width in pixels. 0x010: 16 pixels ⋮ 0x7F8: 2040 pixels Others: Setting prohibited	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/(W)
26:16	GRCHS[10:0]	Horizontal Start Position of Graphics Image Area Position in pixels. 0x005: 5th pixel ⋮ 0x7ED: 2029th pixel Others: Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GRCHW[10:0] bits (Horizontal Width of Graphics Image Area)

The GRCHW[10:0] bits specify the horizontal width of the graphics image area.

GRCHS[10:0] bits (Horizontal Start Position of Graphics Image Area)

The GRCHS[10:0] bits specify the horizontal start position of the graphics image area, in reference to assertion of the horizontal synchronization signal (VS). For the relationship with the graphics display plane, see Figure 56.10.

56.2.19 GRn_AB4 : Graphics n Alpha Blending Control Register 4 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x112C + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	ARCVS[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	ARCVW[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
10:0	ARCVW[10:0]	Vertical Width of Rectangular Area Alpha Blending Image Area Width in lines. 0x001: 1 line ⋮ 0x7FC: 2044 lines Others: Setting prohibited	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	ARCVS[10:0]	Vertical Start Position of Rectangular Area Alpha Blending Image Area Position in lines. 0x002: 2nd line ⋮ 0x7EE: 2030th line Others: Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

ARCVW[10:0] bits (Vertical Width of Rectangular Area Alpha Blending Image Area)

The ARCVW[10:0] bits specify the vertical width of the rectangular area alpha blending image area.

ARCVS[10:0] bits (Vertical Start Position of Rectangular Area Alpha Blending Image Area)

The ARCVS[10:0] bits specify the vertical start position of the rectangular area alpha blending image area, in reference to assertion of the vertical synchronization signal (VS). For the relationship with the graphics display plane, see Figure 56.10.

56.2.20 GRn_AB5 : Graphics n Alpha Blending Control Register 5 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1130 + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	ARCHS[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	ARCHW[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
10:0	ARCHW[10:0]	Horizontal Width of Rectangular Area Alpha Blending Image Area Width in pixels. 0x001: 1 pixel ⋮ 0x7F8: 2040 pixels Others: Setting prohibited	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	ARCHS[10:0]	Horizontal Start Position of Rectangular Area Alpha Blending Image Area Position in pixels. 0x005: 5th pixel ⋮ 0x7ED: 2029th pixel Others: Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

ARCHW[10:0] bits (Horizontal Width of Rectangular Area Alpha Blending Image Area)

The ARCHW[10:0] bits specify the horizontal width of the rectangular area alpha blending image area.

ARCHS[10:0] bits (Horizontal Start Position of Rectangular Area Alpha Blending Image Area)

The ARCHS[10:0] bits specify the horizontal start position of the rectangular area alpha blending image area, in reference to assertion of the horizontal synchronization signal (HS). For the relationship with the graphics display plane, see Figure 56.10.

56.2.21 GRn_AB6 : Graphics n Alpha Blending Control Register 6 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1134 + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	ARCCOEF[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	ARCRATE[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	ARCRATE[7:0]	Frame Rate for Alpha Blending in Rectangular Area 0x00: 1 frame ⋮ 0xFF: 256 frames	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W
24:16	ARCCOEF[8:0]	Alpha Coefficient for Alpha Blending in Rectangular Area Valid settings: -255 to 255. Bit [8]: Sign 0: Add 1: Subtract Bits [7:0]: Variation, as an absolute value	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

ARCRATE[7:0] bits (Frame Rate for Alpha Blending in Rectangular Area)

The ARCRATE[7:0] bits specify the frame rate for alpha blending in a rectangular area.

ARCCOEF[8:0] bits (Alpha Coefficient for Alpha Blending in Rectangular Area)

The ARCCOEF[8:0] bits specify the alpha coefficient for alpha blending in a rectangular area.

In alpha blending in a rectangular area, current graphics are faded in or out with the GRn_AB7.ARCDEF[7:0], GRn_AB6.ARCCOEF[8:0], and GRn_AB6.ARCRATE[7:0] settings. If the alpha value is set in the GR_ARC_DEF[7:0] bits, the GR_ARC_DEF[7:0] bits and the alpha blending in a rectangular area are turned on. Each time the vertical synchronization signal (VS) rises the number of times set in the GR_ARC_RATE[7:0] bits, the value in GR_ARC_COEF[8:0] is added to or subtracted from the alpha value. Figure 56.11 shows change in the alpha value.

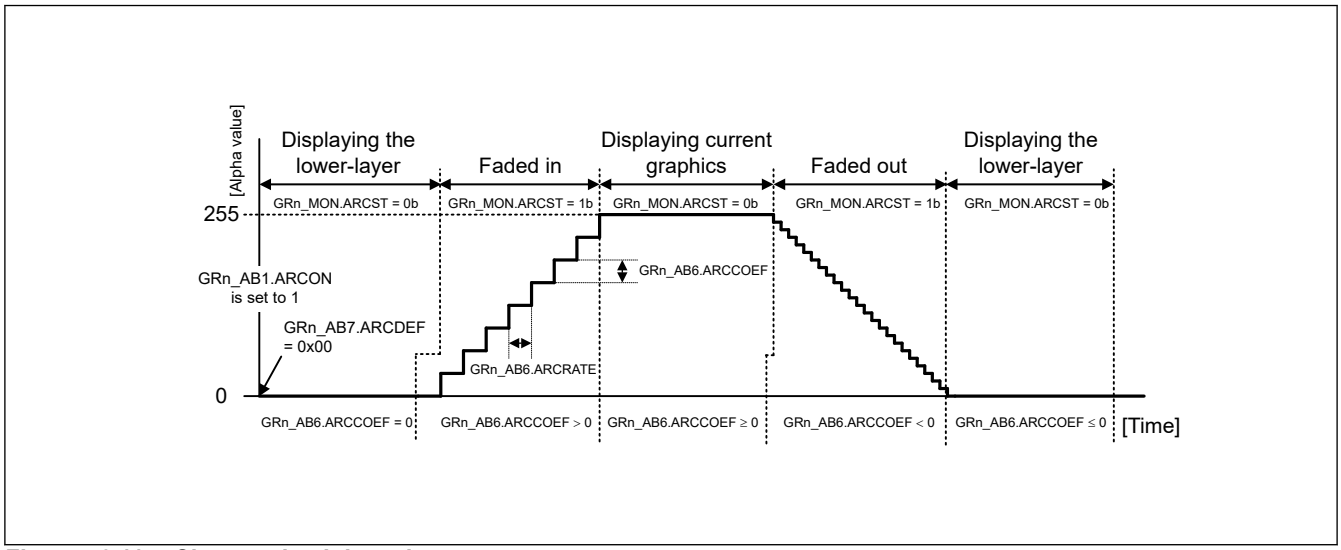

Figure 56.11 Changes in alpha value

56.2.22 GRn_AB7 : Graphics n Alpha Blending Control Register 7 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1138 + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	ARCDEF[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CKON
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CKON	RGB-Index Chroma-Key Processing Control 0: Disable chroma-key processing 1: Enable chroma-key processing	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W
23:16	ARCDEF[7:0]	Initial Alpha Value for Alpha Blending in Rectangular Area	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

CKON bit (RGB-Index Chroma-Key Processing Control)

The CKON bit turns RGB-index chroma-key processing on or off. This function is enabled only if this bit is 1 when the graphics display plane is the blended display (GRn_AB1.DISPSEL[1:0] = 11b). And it is reflected to the graphics area except alpha blending in a rectangular area. For details, see Table 56.8.

ARCDEF[7:0] bits (Initial Alpha Value for Alpha Blending in Rectangular Area)

The ARCDEF[7:0] bits specify the initial alpha value for alpha blending in a rectangular area. For changes in the alpha value during fade-in or fade-out of the current graphics using this bit, see Figure 56.11.

56.2.23 GRn_AB8 : Graphics n Alpha Blending Control Register 8 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x113C + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	CKKG[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CKKB[7:0]								CKKR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CKKR[7:0]	R Signal for RGB-Index Chroma-Key Processing R signal for RGB-index chroma-key processing. Unsigned 8-bit value.	R/W
15:8	CKKB[7:0]	B Signal for RGB-Index Chroma-Key Processing B signal for RGB-index chroma-key processing. Unsigned 8-bit value.	R/W
23:16	CKKG[7:0]	G Signal for RGB-Index Chroma-Key Processing G signal for RGB-index chroma-key processing. Unsigned 8-bit value.	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

If RGB-index chroma-key processing is enabled when the RGB values of the current bit graphics agree with the values of the associated chroma-key bits, the image data of the current graphics (ARGB8888, including the alpha blending values) is replaced by the values in the GRn_AB9 register. In alpha blending in pixel units at later stages, the latest alpha values are used.

CKKR[7:0] bits (R Signal for RGB-Index Chroma-Key Processing)

The CKKR[7:0] bits specify the value to be compared with the R value of the current graphics in the RGB-index chromakey processing.

CKKB[7:0] bits (B Signal for RGB-Index Chroma-Key Processing)

The CKKB[7:0] bits specify the value to be compared with the B value of the current graphics in the RGB-index chromakey processing.

CKKG[7:0] bits (G Signal for RGB-Index Chroma-Key Processing)

The CKKG[7:0] bits specify the value to be compared with the G value of the current graphics in the RGB-index chroma-key processing.

56.2.24 GRn_AB9 : Graphics n Alpha Blending Control Register 9 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1140 + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CKA[7:0]								CKG[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CKB[7:0]								CKR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CKR[7:0]	R Value after RGB-Index Chroma-Key Processing Replacement R value after RGB-index chroma-key processing replacement. Unsigned 8-bit value.	R/W
15:8	CKB[7:0]	B Value after RGB-Index Chroma-Key Processing Replacement B value after RGB-index chroma-key processing replacement. Unsigned 8-bit value.	R/W
23:16	CKG[7:0]	G Value after RGB-Index Chroma-Key Processing Replacement G value after RGB-index chroma-key processing replacement. Unsigned 8-bit value.	R/W
31:24	CKA[7:0]	A Value after RGB-Index Chroma-Key Processing Replacement A value after RGB-index chroma-key processing replacement.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

If the RGB-index chroma-key processing is enabled and the pixel data is to be replaced (the RGB values of the current graphics agree with the GRn_AB8 values), alpha blending in pixel units is performed in later stages in accordance with this image data.

CKR[7:0] bits (R Value after RGB-Index Chroma-Key Processing Replacement)

The CKR[7:0] bits specify the R value after RGB-index chroma-key processing replacement.

CKB[7:0] bits (B Value after RGB-Index Chroma-Key Processing Replacement)

The CKB[7:0] bits specify the B value after RGB-index chroma-key processing replacement.

CKG[7:0] bits (G Value after RGB-Index Chroma-Key Processing Replacement)

The CKG[7:0] bits specify the G value after RGB-index chroma-key processing replacement.

CKA[7:0] bits (A Value after RGB-Index Chroma-Key Processing Replacement)

The CKA[7:0] bits specify the A value after RGB-index chroma-key processing replacement.

56.2.25 GRn_BASE : Graphics n Background Color Control Register (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x114C + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	G[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	B[7:0]								R[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	R[7:0]	Background Color R Value Background color R value. Unsigned 8-bit value.	R/W
15:8	B[7:0]	Background Color B Value Background color B value. Unsigned 8-bit value.	R/W
23:16	G[7:0]	Background Color G Value Background color G value. Unsigned 8-bit value.	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

When the background color is selected in the display selection (GRn_AB1.DISPSEL[1:0] = 00b), this RGB data is output to the entire display image area. When the current graphics setting is selected (GRn_AB1.DISPSEL[1:0] = 10b), the RGB data is output to the outside of the graphics image area within the display image area.

R[7:0] bits (Background Color R Value)

The R[7:0] bits specify the background color R value.

B[7:0] bits (Background Color B Value)

The B[7:0] bits specify the background color B value.

G[7:0] bits (Background Color G Value)

The G[7:0] bits specify the background color G value.

56.2.26 GRn_CLUTINT : Graphics n CLUT Table Interrupt Control Register (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1150 + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SEL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	LINE[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	LINE[10:0]	Number of Detection Lines 0x000: 1 line ⋮ 0x7FF: 2048 lines	R/W
15:11	—	These bits are read as 0. The write value should be 0./	R/W
16	SEL	CLUT Table Control 0: Select CLUT table 0 1: Select CLUT table 1	R/W
31:17	—	These bits are read as 0. The write value should be 0./	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

LINE[10:0] bits (Number of Detection Lines)

The LINE[10:0] bits specify the number of lines to be detected. When the number of lines specified in this bit are detected, the event is recognized outside the module on the HS assertion. To retain the status of the recognized event and assert the GLCDC interrupt request signal, set the prescribed value to the State Detection Control Register (SYSCNT_DTCTEN) and Interrupt Request Enable Control Register (SYSCNT_INTEN), which are system control registers. Although this function is provided to both graphics 1 and 2, it is only enabled in graphics 2 in this GLCDC.

SEL bit (CLUT Table Control)

The SEL bit controls the CLUT plane to be used for internal operations. Access to the color palette (CLUT) through the register access bus is always valid for both planes 0 and 1, regardless of the setting in this bit, and the written value is immediately reflected to the internal operations (not in synchronization with the vertical synchronization signal).

To keep reflection of the CLUT memory contents to the internal operations in synchronization with the vertical synchronization signal, first write data through the register access bus to the plane that is not being used for the internal operations, and then modify the bits intended for controlling the plane that is to be used for the internal operations.

56.2.27 GRn_MON : Graphics n Status Monitor Register (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1154 + 0x100 × (n -1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	UNDFLST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ARCST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ARCST	Status Monitor for Alpha Blending in Rectangular Area 0: Fade-in/fade-out not in progress 1: Fade-in/fade-out in progress	R
15:1	—	These bits are read as 0.	R
16	UNDFLST	Underflow Status Monitor 0: No underflow occurred in internal operations 1: Underflow occurred in internal operations	R
31:17	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

ARCST bit (Status Monitor for Alpha Blending in Rectangular Area)

The ARCST bit indicates whether or not alpha blending (fade-in/fade-out) in a rectangular area is in progress. When alpha blending in a rectangular area is turned on (GRn_AB1.ARCON is set to 1) and the register value is to be reflected to the internal operations on assertion of the vertical synchronization signal (VS), this bit sets to 1 immediately on assertion of the vertical synchronization signal. When alpha blending in a rectangular area is turned off (GRn_AB1.ARCON cleared to 0) or when the alpha blending (fade-in/fade-out) in a rectangular area is complete (alpha blended value reaches the minimum or maximum value), this bit clears to 0. If the alpha coefficient for the alpha blending in a rectangular area (GRn_AB6.ARCCOEF[8:0]) is set to 0x000 and the initial alpha value for alpha blending in a rectangular area (GRn_AB7.ARCDEF[7:0]) is set to any value other than 0xFF or 0x00, the alpha blending value does not reach the minimum or maximum value, and this bit remains 1 (no timeout processing is performed).

UNDFLST bit (Underflow Status Monitor)

The UNDFLST bit indicates whether or not an underflow has occurred in the internal operations. The underflow interrupt request flag sets when an underflow occurs, and retains its value until it is cleared by software. However, this bit monitors the internal status, and so the flag automatically clears to 0 when the graphics data bus interface initializes on assertion of the vertical synchronization signal. Even when the current graphics data is not required (GRn_AB1.DISPSEL[1:0] = 0xb), this bit sets to 1 during the period from the graphics image valid area start to the next frame vertical synchronization signal (VS) assertion timing set in the registers.

56.2.28 GAMn_LATCH : Gamma n Register Update Control Register (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1300 (GAMG_LATCH)
0x1340 (GAMB_LATCH)
0x1380 (GAMR_LATCH)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	VEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	VEN	Control of Gamma Correction × Module Register Value Reflection to Internal Operations 0: Disable reflection of register values to internal operations on assertion of vertical synchronization signal (VS) 1: Enable reflection of register values to internal operations on assertion of the vertical synchronization signal (VS)	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

VEN bit (Control of Gamma Correction × Module Register Value Reflection to Internal Operations)

The VEN bit enables or disables reflection of the register values to the internal operations in the gamma correction circuit on assertion of the vertical synchronization signal (input). When this bit is set to 1, the register values are immediately reflected to the internal operations on assertion of the vertical synchronization signal (input), and then this bit automatically clears to 0. Also, if the signal is asserted that controls reflection of the register values to the internal operations of all the modules output from the background plane generation module, the register values are reflected to the internal operations on assertion of the vertical synchronization signal (input), regardless of the value of this bit. While this bit is 1, do not modify any register whose value is reflected to the internal operations on assertion of the vertical synchronization signal (input) in the GLCDC. Otherwise, operation is not guaranteed.

This bit must not be 1 at the same time as the BG_EN.VEN bit (control of background plane register value reflection to internal operations) in the Operation Control Register (BG_EN), one of the background plane setting registers. Otherwise, operation is not guaranteed.

Although there are three VEN bits, one for each G, R, and B color, only the GAMG_LATCH.VEN bit controls the gamma correction with the reflection of the GAM_SW.GAMON bit. To enable gamma correction, set the GAMG_LATCH.VEN bit once after setting the GAM_SW.GAMON bit.

The VEN bit is set to 1 by writing 1, and automatically clears to 0 immediately on assertion of the vertical synchronization signal.

56.2.29 GAM_SW : Gamma Correction Block Function Switch Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1304

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	GAMON
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	GAMON	Gamma Correction On/Off Control 0: Turn off gamma correction 1: Turn on gamma correction	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMG_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GAMON bit (Gamma Correction On/Off Control)

The GAMON bit turns on or off gamma correction.

56.2.30 GAMn_LUT1 : Gamma n Correction Block Table Setting Register 1 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1308 (GAMG_LUT1)
0x1348 (GAMB_LUT1)
0x1388 (GAMR_LUT1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	GAIN00[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	GAIN01[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	GAIN01[10:0]	Gain Value of Area 1 Unsigned 11-bit fixed point value. 0x000: 0.000 (0/1024) ⋮ 0x400: 1.000 (1024/1024) ⋮ 0x7FF: 1.999 (2047/1024)	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	GAIN00[10:0]	Gain Value of Area 0 0x000: 0.000 (0/1024) ⋮ 0x400: 1.000 (1024/1024) ⋮ 0x7FF: 1.999 (2047/1024)	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

Gamma correction for each color is carried out as follows:

- Din (input signal): 10 bits. To correct the output of graphics 2, 00b is appended as the lower 2 bits for extension
- Dout (output signal): 10 bits
- TH (threshold): 10 bits (register setting); up to 15 can be set
- GAIN (gain): 0/1024 to 2047/1024 for each area (register setting), can be set for up to 16 areas
- OFFSET (offset value): 21 bits (result of internal calculation; calculation of up to 15 points)

The following is automatically calculated from the assertion of the vertical synchronization signal (VS) to the start of valid pixel data internally:

- $D_{out} = ((D_{in} - TH(n)) \times GAIN(n) + OFFSET(n))$
- $OFFSET(n) = OFFSET(n-1) + (TH(n) - TH(n-1)) \times GAIN(n-1),\ \text{where}\ OFFSET(n) = 0$

Note: Because the gain is a positive number (≥ 0), the correction line shows a monotonic increase.

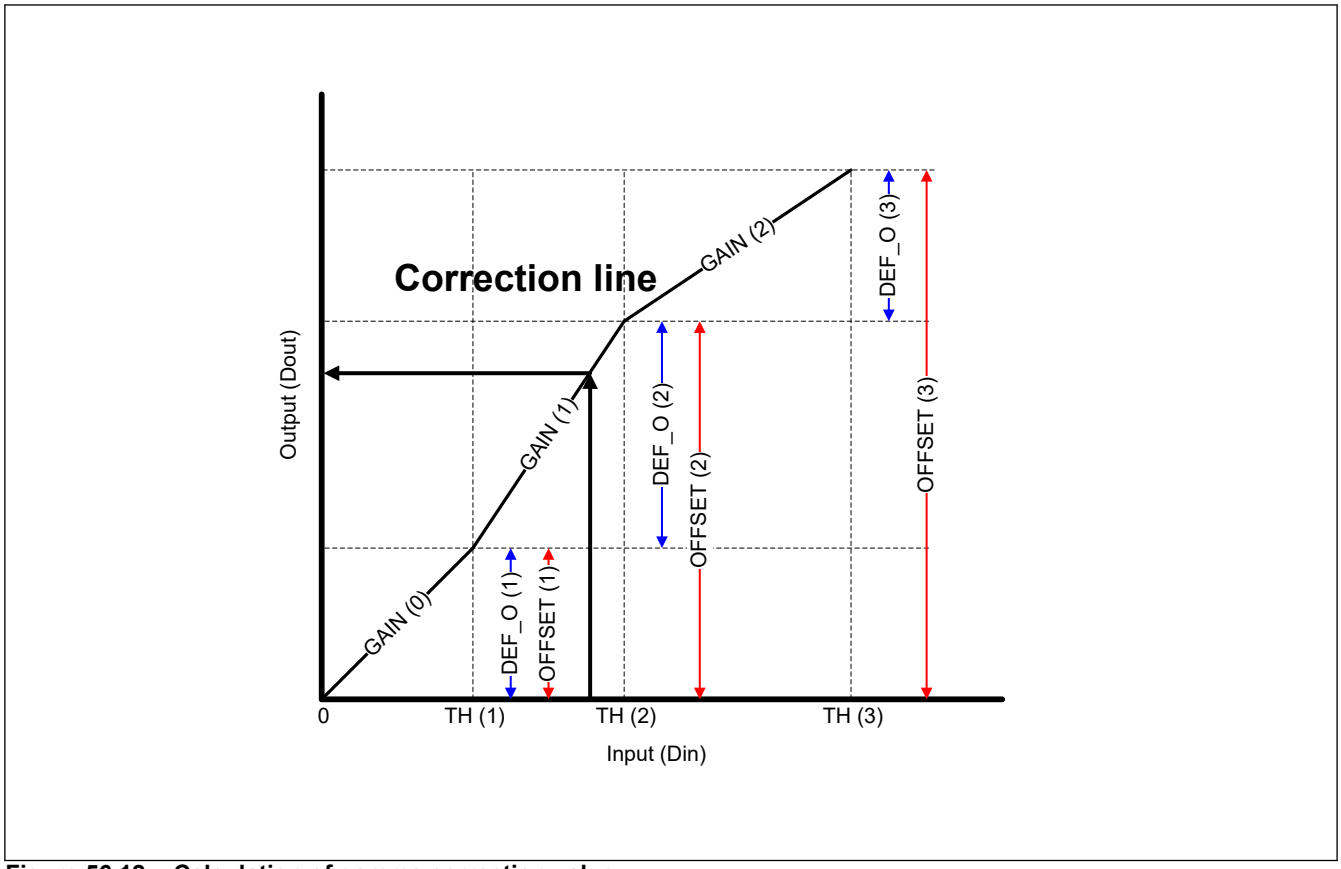

Figure 56.12 Calculation of gamma correction value

GAIN01[10:0] bits (Gain Value of Area 1)

The GAIN01[10:0] bits specify the gain value of area 1 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN00[10:0] bits (Gain Value of Area 0)

The GAIN00[10:0] bits specify the gain value of area 0 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

56.2.31 GAMn_LUT2 : Gamma n Correction Block Table Setting Register 2 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x130C (GAMG_LUT2)
0x134C (GAMB_LUT2)
0x138C (GAMR_LUT2)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GAIN03[10:0] bits (Gain Value of Area 3)

The GAIN03[10:0] bits specify the gain value of area 3 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN02[10:0] bits (Gain Value of Area 2)

The GAIN02[10:0] bits specify the gain value of area 2 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

56.2.32 GAMn_LUT3 : Gamma n Correction Block Table Setting Register 3 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1310 (GAMG_LUT3)
0x1350 (GAMB_LUT3)
0x1390 (GAMR_LUT3)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GAIN05[10:0] bits (Gain Value of Area 5)

The GAIN05[10:0] bits specify the gain value of area 5 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN04[10:0] bits (Gain Value of Area 4)

The GAIN04[10:0] bits specify the gain value of area 4 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

56.2.33 GAMn_LUT4 : Gamma n Correction Block Table Setting Register 4 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1314 (GAMG_LUT4)
0x1354 (GAMB_LUT4)
0x1394 (GAMR_LUT4)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GAIN07[10:0] bits (Gain Value of Area 7)

The GAIN07[10:0] bits specify the gain value of area 7 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN06[10:0] bits (Gain Value of Area 6)

The GAIN06[10:0] bits specify the gain value of area 6 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

56.2.34 GAMn_LUT5 : Gamma n Correction Block Table Setting Register 5 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1318 (GAMG_LUT5)
0x1358 (GAMB_LUT5)
0x1398 (GAMR_LUT5)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	GAIN08[10:0]

31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GAIN09[10:0] bits (Gain Value of Area 9)

The GAIN09[10:0] bits specify the gain value of area 9 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN08[10:0] bits (Gain Value of Area 8)

The GAIN08[10:0] bits specify the gain value of area 8 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

56.2.35 GAMn_LUT6 : Gamma n Correction Block Table Setting Register 6 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x131C (GAMG_LUT6)
0x135C (GAMB_LUT6)
0x139C (GAMR_LUT6)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	GAIN10[10:0]

31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GAIN11[10:0] bits (Gain Value of Area 11)

The GAIN11[10:0] bits specify the gain value of area 11 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN10[10:0] bits (Gain Value of Area 10)

The GAIN10[10:0] bits specify the gain value of area 10 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

56.2.36 GAMn_LUT7 : Gamma n Correction Block Table Setting Register 7 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1320 (GAMG_LUT7)
0x1360 (GAMB_LUT7)
0x13A0 (GAMR_LUT7)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GAIN13[10:0] bits (Gain Value of Area 13)

The GAIN13[10:0] bits specify the gain value of area 13 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN012[10:0] bits (Gain Value of Area 12)

The GAIN012[10:0] bits specify the gain value of area 12 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

56.2.37 GAMn_LUT8 : Gamma n Correction Block Table Setting Register 8 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1324 (GAMG_LUT8)
0x1364 (GAMB_LUT8)
0x13A4 (GAMR_LUT8)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	GAIN14[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	GAIN15[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	GAIN15[10:0]	Gain Value of Area 15 Unsigned 11-bit fixed point value. 0x000: 0.000 (0/1024) ⋮ 0x400: 1.000 (1024/1024) ⋮ 0x7FF: 1.999 (2047/1024)	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W

31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GAIN15[10:0] bits (Gain Value of Area 15)

The GAIN15[10:0] bits specify the gain value of area 15 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN14[10:0] bits (Gain Value of Area 14)

The GAIN14[10:0] bits specify the gain value of area 14 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

56.2.38 GAMn_AREA1 : Gamma n Correction Block Area Setting Register 1 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1328 (GAMG_AREA1)
0x1368 (GAMB_AREA1)
0x13A8 (GAMR_AREA1)

Bit position:	31	29	20	19	10	9	0
Bit field:	—	—	TH01[9:0]	TH02[9:0]	TH03[9:0]		
Value after reset:	0 0	0 0 0 0 0 0 0 0 0 0		0 0 0 0 0 0 0 0 0 0		0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
9:0	TH03[9:0]	Start Threshold of Area 3 Unsigned 10-bit integer.	R/W
19:10	TH02[9:0]	Start Threshold of Area 2 Unsigned 10-bit integer.	R/W
29:20	TH01[9:0]	Start Threshold of Area 1 Unsigned 10-bit integer.	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

Set the start threshold TH (n) of area n (n = 0 to 15) to satisfy the following conditions. Otherwise, operation is not guaranteed.

TH (n) < TH (n + 1)

n = 0 to 15 and TH (0) = 0x000, TH (16) = 0x3FF

TH (n) = TH (n + 1) is valid only if TH (n) = 0x3FF.

For details on calculation of the gamma correction value, see section 56.2.30. GAMn_LUT1 : Gamma n Correction Block Table Setting Register 1 (n = G, B, R) and Figure 56.12

TH03[9:0] bits (Start Threshold of Area 3)

The TH03[9:0] bits specify the start threshold of area 3 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH02[9:0] bits (Start Threshold of Area 2)

The TH02[9:0] bits specify the start threshold of area 2 to be used for gamma correction in terms of an unsigned 10-bit integer.

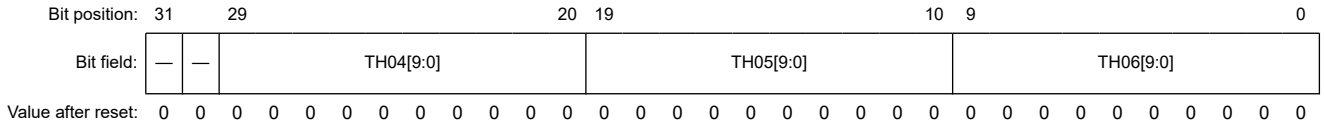
TH01[9:0] bits (Start Threshold of Area 1)

The TH01[9:0] bits specify the start threshold of area 1 to be used for gamma correction in terms of an unsigned 10-bit integer.

56.2.39 GAMn_AREA2 : Gamma n Correction Block Area Setting Register 2 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x132C (GAMG_AREA2)
0x136C (GAMB_AREA2)
0x13AC (GAMR_AREA2)



Bit	Symbol	Function	R/W
9:0	TH06[9:0]	Start Threshold of Area 6 Unsigned 10-bit integer.	R/W
19:10	TH05[9:0]	Start Threshold of Area 5 Unsigned 10-bit integer.	R/W
29:20	TH04[9:0]	Start Threshold of Area 4 Unsigned 10-bit integer.	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

TH06[9:0] bits (Start Threshold of Area 6)

The TH06[9:0] bits specify the start threshold of area 6 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH05[9:0] bits (Start Threshold of Area 5)

The TH05[9:0] bits specify the start threshold of area 5 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH04[9:0] bits (Start Threshold of Area 4)

The TH04[9:0] bits specify the start threshold of area 4 to be used for gamma correction in terms of an unsigned 10-bit integer.

56.2.40 GAMn_AREA3 : Gamma n Correction Block Area Setting Register 3 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1330 (GAMG_AREA3)
0x1370 (GAMB_AREA3)
0x13B0 (GAMR_AREA3)

Bit position:	31	30	29 ... 20	19 ... 10	9 ... 0
Bit field:	—	—	TH07[9:0]	TH08[9:0]	TH09[9:0]
Value after reset:	0	0	0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
9:0	TH09[9:0]	Start Threshold of Area 9 Unsigned 10-bit integer.	R/W
19:10	TH08[9:0]	Start Threshold of Area 8 Unsigned 10-bit integer.	R/W
29:20	TH07[9:0]	Start Threshold of Area 7 Unsigned 10-bit integer.	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

TH09[9:0] bits (Start Threshold of Area 9)

The TH09[9:0] bits specify the start threshold of area 9 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH08[9:0] bits (Start Threshold of Area 8)

The TH08[9:0] bits specify the start threshold of area 8 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH07[9:0] bits (Start Threshold of Area 7)

The TH07[9:0] bits specify the start threshold of area 7 to be used for gamma correction in terms of an unsigned 10-bit integer.

56.2.41 GAMn_AREA4 : Gamma n Correction Block Area Setting Register 4 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1334 (GAMG_AREA4)
0x1374 (GAMB_AREA4)
0x13B4 (GAMR_AREA4)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	TH10[9:0]										TH11[9:0]										TH12[9:0]

Bit	Symbol	Function	R/W
9:0	TH12[9:0]	Start Threshold of Area 12 Unsigned 10-bit integer.	R/W
19:10	TH11[9:0]	Start Threshold of Area 11 Unsigned 10-bit integer.	R/W
29:20	TH10[9:0]	Start Threshold of Area 10 Unsigned 10-bit integer.	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

TH12[9:0] bits (Start Threshold of Area 12)

The TH12[9:0] bits specify the start threshold of area 12 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH11[9:0] bits (Start Threshold of Area 11)

The TH11[9:0] bits specify the start threshold of area 11 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH10[9:0] bits (Start Threshold of Area 10)

The TH10[9:0] bits specify the start threshold of area 10 to be used for gamma correction in terms of an unsigned 10-bit integer.

56.2.42 GAMn_AREA5 : Gamma n Correction Block Area Setting Register 5 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1338 (GAMG_AREA5)
0x1378 (GAMB_AREA5)
0x13B8 (GAMR_AREA5)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	TH13[9:0]										TH14[9:0]										TH15[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	TH15[9:0]	Start Threshold of Area 15 Unsigned 10-bit integer.	R/W

29:20	TH13[9:0]	Start Threshold of Area 13 Unsigned 10-bit integer.	R/W

Bit	Symbol	Function	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

TH15[9:0] bits (Start Threshold of Area 15)

The TH15[9:0] bits specify the start threshold of area 15 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH14[9:0] bits (Start Threshold of Area 14)

The TH14[9:0] bits specify the start threshold of area 14 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH13[9:0] bits (Start Threshold of Area 13)

The TH13[9:0] bits specify the start threshold of area 13 to be used for gamma correction in terms of an unsigned 10-bit integer.

56.2.43 OUT_VLATCH : Output Control Block Register Update Control Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x13C0

Bit position:	31																													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	VEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	VEN	Control of Output Control Module Register Value Reflection to Internal Operations 0: Disable reflection of register values to internal operations on assertion of vertical synchronization signal (VS) 1: Enable reflection of register values to internal operations on assertion of vertical synchronization signal (VS).	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

VEN bit (Control of Output Control Module Register Value Reflection to Internal Operations)

The VEN bit enables or disables reflection of the register values to the internal operations in the output control circuit on assertion of the vertical synchronization signal (input). When this bit is set to 1, the register values are immediately reflected to the internal operations on assertion of the vertical synchronization signal (input), and then this bit automatically clears to 0. Also, if the signal is asserted that controls reflection of the register values to the internal operations of all the modules output from the ground plane generation module, the register values are reflected to the internal operations on assertion of the vertical synchronization signal (input), regardless of the value of this bit. While this bit is 1, do not modify any register whose value is reflected to the internal operations on assertion of the vertical synchronization signal (input) in the GLCDC. Otherwise, operation is not guaranteed.

This bit must not be 1 at the same time as the BG_EN.VEN bit (control of background plane register value reflection to internal operations) in the Operation Control Register (BG_EN), or one of the background plane setting registers. Otherwise, operation is not guaranteed.

56.2.44 OUT_SET : Output Control Block Output Interface Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x13C4

Bit position:	31			28				24											13	12			9	8				4			1	0

24	SWAPON	Pixel Order Control 0: RGB order 1: BGR order	R/W
27:25	—	These bits are read as 0. The write value should be 0.	R/W
28	ENDIANON	Bit Endian Control 0: Descending order (little endian) 1: Ascending order (big endian)	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Rewriting these bits is prohibited during operation. Set the settings before operation is enabled. Operation is not guaranteed if the bit is rewritten during operation.

For details on assignment of pixel data to the output pins (LCD_DATA23 to LCD_DATA00) by setting these bits (except for OUT_SET.FRQSEL[1:0]), see Figure 56.3 to Figure 56.6.

PHASE[1:0] bits (Data Output Delay Control in Serial RGB Format)

The PHASE[1:0] bits control data output delay in serial RGB format. When the delay is 0 cycle (these bits are 00b), pixel data (R, B, or invalid data, depending on the setting in this register) is output one pixel clock (PXCLK) cycle after the horizontal data enable signal (HE). When any value other than 00b is set to OUT_SET.PHASE[1:0], pixel data output is delayed for a preset number of LCD_CLK cycles.

DIRSEL bit (Scan Direction Select of Serial RGB Format)

The DIRSEL bit controls the data arrangement of the serial RGB format. When this bit is set to 1, the serial RGB data is arranged in reverse direction, and when it is 0, the serial RGB is arranged in forward direction.

FRQSEL[1:0] bits (Clock Frequency Division Control)

The FRQSEL[1:0] bits control clock frequency division of LCD_CLK (panel output clock) and PXCLK (pixel clock for internal operations). Set these bits to 10b only for the serial RGB format (OUT_SET.FORMAT[1:0] = 11b), so that PXCLK has a 1/4 frequency of the LCD_CLK frequency and synchronizes with LCD_CLK. Set these bits to 00b for the parallel RGB format (OUT_SET.FORMAT[1:0] = 10b, 01b, or 00b), so that PXCLK has the same frequency as the LCD_CLK frequency and synchronizes with LCD_CLK. Otherwise, operation is not guaranteed.

FORMAT[1:0] bits (Output Format Select)

The FORMAT[1:0] bits select the output format of RGB data. Set these bits in accordance with the output format select bits in the Panel Dither Correction Register (OUT_PDTHA.FORM[1:0]). For serial RGB format (these bits are 11b), set OUT_PDTHA.FORM[1:0] to 00b. Otherwise, operation is not guaranteed.

SWAPON bit (Pixel Order Control)

The SWAPON bit controls the pixel order of RGB data output. When this bit is set to 1, internally processed data is assigned to the output pins in BGR order, and when this bit is 0, data is assigned in the RGB order. Data is assigned to the output pins (LCD_DATA23 to LCD_DATA00) with the MSB first for the RGB parallel format, and serially for the RGB serial format.

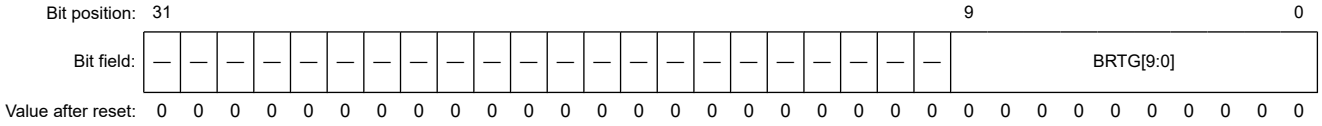
ENDIANON bit (Bit Endian Control)

The ENDIANON bit controls the bit order of RGB data output. When this bit is set to 1, internally processed data is assigned to the output pins in ascending order (big endian), and when this bit is 0, data is assigned in descending order (little endian).

56.2.45 OUT_BRIGHT1 : Output Control Block Brightness Correction Register 1

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x13C8



Bit	Symbol	Function	R/W
9:0	BRTG[9:0]	Brightness Adjustment of G Signal Brightness (DC) adjustment of G signal. Unsigned 10-bit integer, +512 with offset.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when OUT_VLATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

BRTG[9:0] bits (Brightness Adjustment of G Signal)

The BRTG[9:0] bits specify the brightness (DC) adjustment of the G signal.

Brightness correction of the G signal is performed as follows:

- Gout: Output of brightness correction (input of contrast correction). Unsigned 10 bits
- Gin: Input of brightness correction. Unsigned 10 bits
- BRTG: Setting in this bit
- Gout = Gin + BRTG - 512.

56.2.46 OUT_BRIGHT2 : Output Control Block Brightness Correction Register 2

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x13CC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	BRTB[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	BRTR[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	BRTR[9:0]	Brightness Adjustment of R Signal Brightness (DC) adjustment of R signal. Unsigned 10-bit integer, +512 with offset.	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
25:16	BRTB[9:0]	Brightness Adjustment of B Signal Brightness (DC) adjustment of B signal. Unsigned 10-bit integer, +512 with offset.	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when OUT_VLATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

BRTR[9:0] bits (Brightness Adjustment of R Signal)

The BRTR[9:0] bits specify the brightness (DC) adjustment of the R signal.

Brightness correction of the R signal is performed as follows:

- Rout: Output of brightness correction (input of contrast correction), unsigned, 10 bits
- BRTR: Setting in this bit
- Rout = Rin + BRTR - 512.

BRTB[9:0] bits (Brightness Adjustment of B Signal)

The BRTB[9:0] bits specify the brightness (DC) adjustment of the B signal.

Brightness correction of the B signal is performed as follows:

- Bout: Output of brightness correction (input of contrast correction), unsigned, 10 bits
- Bin: Input of brightness correction, unsigned, 10 bits
- BRTB: Setting in this bit
- Bout = Bin + BRTB - 512.

56.2.47 OUT_CONTRAST : Output Control Block Contrast Correction Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x13D0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	CONTG[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CONTB[7:0]								CONTR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CONTR[7:0]	Contrast Adjustment of R Signal Unsigned 8-bit fixed point value adjusting GAIN on R signal. 0x00: 0/128 = 0.000 ⋮ 0x80: 128/128 = 1.000 ⋮ 0xFF: 255/128 = 1.992	R/W
15:8	CONTB[7:0]	Contrast Adjustment of B Signal Unsigned 8-bit fixed point value adjusting GAIN on B signal. 0x00: 0/128 = 0.000 ⋮ 0x80: 128/128 = 1.000 ⋮ 0xFF: 255/128 = 1.992	R/W
23:16	CONTG[7:0]	Contrast Adjustment of G Signal Unsigned 8-bit fixed point value adjusting GAIN on G signal. 0x00: 0/128 = 0.000 ⋮ 0x80: 128/128 = 1.000 ⋮ 0xFF: 255/128 = 1.992	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when OUT_VLATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

CONTR[7:0] bits (Contrast Adjustment of R Signal)

The CONTR[7:0] bits specify the contrast (GAIN) adjustment of R signal. The location of the decimal point is between bits [7] and [6].

CONTB[7:0] bits (Contrast Adjustment of B Signal)

The CONTB[7:0] bits specify the contrast (GAIN) adjustment of B signal. The location of the decimal point is between bits [7] and [6].

CONTG[7:0] bits (Contrast Adjustment of G Signal)

The CONTG[7:0] bits specify the contrast (GAIN) adjustment of G signal. The location of the decimal point is between bits [7] and [6].

Contrast correction of each pixel is performed as follows (x = R, G, B):

- Dxout: Output of contrast correction, unsigned, 10 bits
- Dxin: Input of contrast correction (output of brightness correction), unsigned, 10 bits
- CONTx: Setting in this bit

- Dxout = Dxin × CONTx.

56.2.48 OUT_PDTHA : Output Control Block Panel Dither Correction Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x13D4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	SEL[1:0]		—	—	FORM[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	PA[1:0]		—	—	PB[1:0]		—	—	PC[1:0]		—	—	PD[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PD[1:0]	Pattern Value (D) of 2×2 Pattern Dither Unsigned 2-bit integer.	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
5:4	PC[1:0]	Pattern Value (C) of 2×2 Pattern Dither Unsigned 2-bit integer.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
9:8	PB[1:0]	Pattern Value (B) of 2×2 Pattern Dither Unsigned 2-bit integer.	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
13:12	PA[1:0]	Pattern Value (A) of 2×2 Pattern Dither Unsigned 2-bit integer.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
17:16	FORM[1:0]	Output Format Select 0 0: RGB888; select RGB888 or serial RGB as output interface format 0 1: RGB666; select RGB666 as output interface format 1 0: RGB565; select RGB565 as output interface format 1 1: Setting prohibited Select output interface format in OUT_SET.FORMAT[1:0].	R/W
19:18	—	These bits are read as 0. The write value should be 0.	R/W
21:20	SEL[1:0]	Operation Mode 0 0: Truncate 0 1: Round-off 1 0: 2×2 pattern dither 1 1: Setting prohibited	R/W
31:22	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when OUT_VLATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

PA[1:0], PB[1:0], PC[1:0], PD[1:0] bits (Pattern Value (A, B, C, D) of 2×2 Pattern Dither)

The PA[1:0], PB[1:0], PC[1:0], and PD[1:0] bits specify the pattern value A, B, C, and D of 2×2 pattern dither. Figure 56.13 shows the configuration of the dither correction block.

FORM[1:0] bits (Output Format Select)

The FORM[1:0] bits specify the output format of the dither process. These bits must be set in accordance with the OUT_SET.FORMAT[1:0] bits of the Output Interface Register. For serial RGB (OUT_SET.FORMAT[1:0] = 11b), set these bits to 00b. Otherwise, operation is not guaranteed.

SEL[1:0] bits (Operation Mode)

The SEL[1:0] bits specify the dither operation mode. The dither process is performed for the bits equal to or shorter than the pixel data length selected in the output format select bits (OUT_PDTHA.FORM[1:0]). OUT_PDTHA.PA[1:0], PB[1:0], PC[1:0], and PD[1:0] are used for 2×2 pattern dither.

Figure 56.13 shows the configuration of the dither correction block.

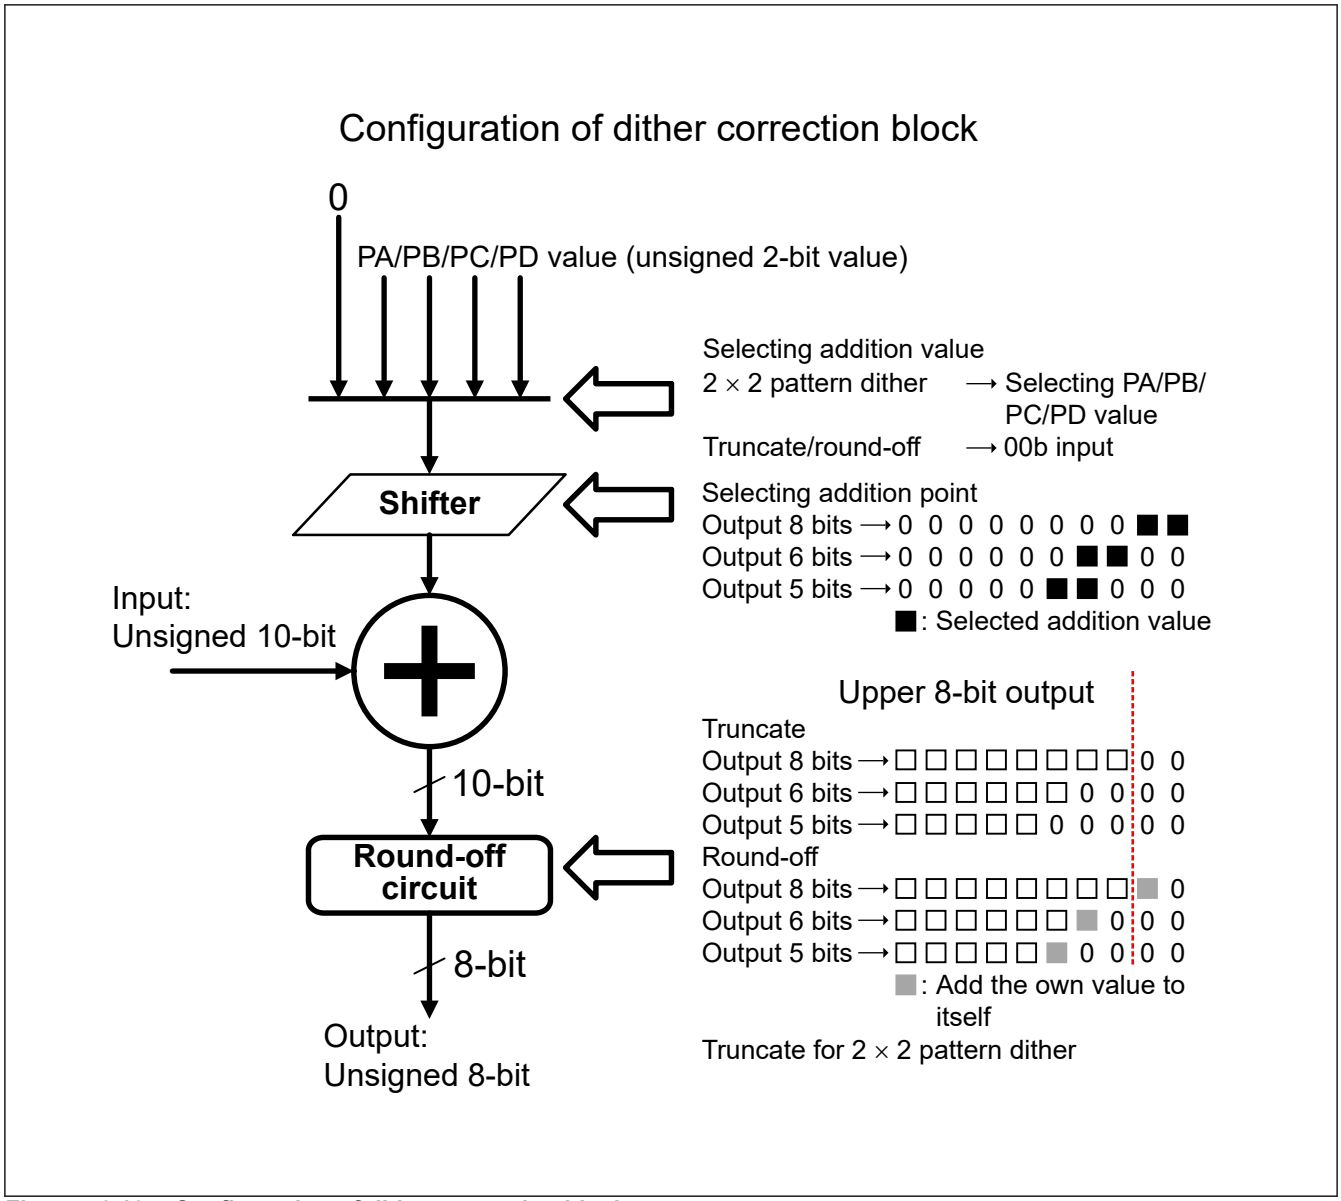


Figure 56.13 Configuration of dither correction block

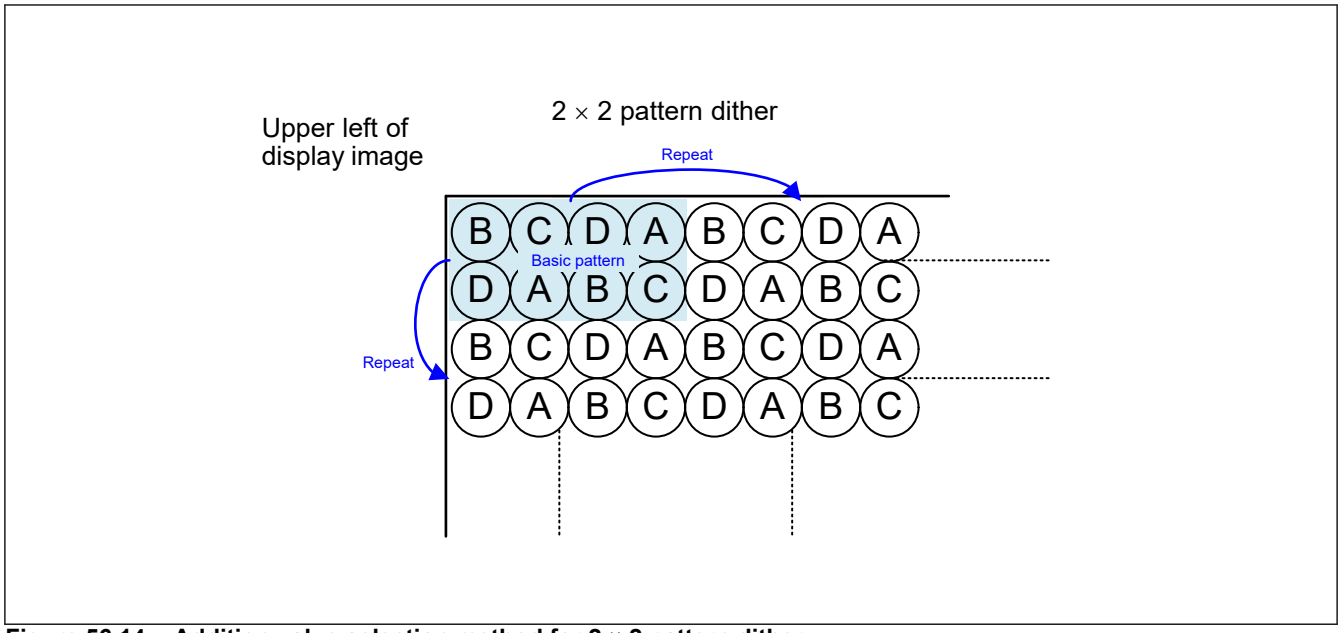

Figure 56.14 Addition value selection method for 2 × 2 pattern dither

A basic pattern is repeated as follows. Four frames constitute 1 cycle.

1st Frame	2nd Frame	3rd Frame	4th Frame	
BCDA DABC	→ CDAB → ABCD	→ DABC → BCDA	→ ABCD → CDAB	Shift to the left by one pixel Shift to the left by one pixel

- A: Value obtained after OUT_PDTHA.PA[1:0] bit value is shifted in accordance with the output format
- B: Value obtained after OUT_PDTHA.PB[1:0] bit value is shifted in accordance with the output format
- C: Value obtained after OUT_PDTHA.PC[1:0] bit value is shifted in accordance with the output format
- D: Value obtained after OUT_PDTHA.PD[1:0] bit value is shifted in accordance with the output format

Renesas recommends setting the bits as follows: PA[1:0] = 11b, PB[1:0] = 00b, PC[1:0] = 10b, PD[1:0] = 01b

When 2 × 2 pattern dither (OUT_PDTHA.SEL[1:0] = 10b) is to be set, the valid pixel area of the background plane must be an integer multiple of the basic pattern. If serial RGB is selected as the output format for the output control block, add two to the horizontal valid pixel width and set the resulting value to the background plane horizontal valid pixel width bits (BG_HSIZE.HW[10:0]).

56.2.49 OUT_CLKPHASE : Output Control Block Output Phase Control Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x13E4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	FRONTGAM	—	—	—	LCDEDGE	—	TCON0EDGE	TCON1EDGE	TCON2EDGE	TCON3EDGE	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	—	These bits are read as 0. The write value should be 0.	R/W
3	TCON3EDGE	LCD_TCON3 Output Phase Control 0: Synchronize output with rising edge of LCD_CLK 1: Synchronize output with falling edge of LCD_CLK	R/W
4	TCON2EDGE	LCD_TCON2 Output Phase Control 0: Synchronize output with rising edge of LCD_CLK 1: Synchronize output with falling edge of LCD_CLK	R/W
5	TCON1EDGE	LCD_TCON1 Output Phase Control 0: Synchronize output with rising edge of LCD_CLK 1: Synchronize output with falling edge of LCD_CLK	R/W
6	TCON0EDGE	LCD_TCON0 Output Phase Control 0: Synchronize output with rising edge of LCD_CLK 1: Synchronize output with falling edge of LCD_CLK	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
8	LCDEDGE	LCD_DATA Output Phase Control 0: Synchronize output with rising edge of LCD_CLK 1: Synchronize output with falling edge of LCD_CLK	R/W
11:9	—	These bits are read as 0. The write value should be 0.	R/W
12	FRONTGAM	Correction Control 0: Process brightness/contrast correction followed by gamma correction 1: Process gamma correction followed by brightness/contrast correction	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when OUT_VLATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

TCON3EDGE bit (LCD_TCON3 Output Phase Control)

The TCON3EDGE bit controls the output phase of LCD_TCON3. When this bit is set to 1, LCD_TCON3 is output in synchronization with the falling edge of LCD_CLK, and when it is set to 0, LCD_TCON3 is output in synchronization with the rising edge.

TCON2EDGE bit (LCD_TCON2 Output Phase Control)

The TCON2EDGE bit controls the output phase of LCD_TCON2. When this bit is set to 1, LCD_TCON2 is output in synchronization with the falling edge of LCD_CLK, and when it is set to 0, LCD_TCON2 is output in synchronization with the rising edge.

TCON1EDGE bit (LCD_TCON1 Output Phase Control)

The TCON1EDGE bit controls the output phase of LCD_TCON1. When this bit is set to 1, LCD_TCON1 is output in synchronization with the falling edge of LCD_CLK, and when it is set to 0, LCD_TCON1 is output in synchronization with the rising edge

TCON0EDGE bit (LCD_TCON0 Output Phase Control)

The TCON0EDGE bit controls the output phase of LCD_TCON0. When this bit is set to 1, LCD_ TCON0 is output in synchronization with the falling edge of LCD_CLK, and when it is cleared to 0, LCD_TCON0 is output in synchronization with the rising edge.

LCDEDGE bit (LCD_DATA Output Phase Control)

The LCDEDGE bit controls the output phase of the LCD_DATA pins (LCD_DATA23 to LCD_DATA00). When this bit is set to 1, the LCD_DATA pins are output in synchronization with the falling edge of LCD_CLK, and when it is set to 0, the LCD_DATA pins are output in synchronization with the rising edge.

FRONTGAM bit (Correction Control)

The FRONTGAM bit controls the correction sequence. When this bit is set to 1, gamma correction is followed by brightness and contrast correction, and when it is set to 0, gamma correction follows brightness and contrast correction. In both cases, each RGB data output from the graphics 2 module is extended from 8 bits to 10 bits (with 00b appended to the

lower side), and is input to the preceding stage of the correction circuit. The output is rounded to 10 bits and is input to the dither correction circuit. Although the sequence of RGB gamma correction and brightness/contrast correction can be reversed using this bit, brightness correction always precedes contrast correction.

56.2.50 TCON_TIM : TCON Reference Timing Setting Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1404

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	HALF[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	OFFSET[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	OFFSET[10:0]	Horizontal Synchronization Signal Generation Reference Timing Offset from the assertion of the internal horizontal synchronization signal in pixels. 0x000: 1 pixel ⋮ 0x7FF: 2048 pixels	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	HALF[10:0]	Vertical Synchronization Signal Generation Change Timing Delay from the assertion of the internal horizontal synchronization signal in pixels. 0x000: 1 pixel (no delay) ⋮ 0x7FF: 2048 pixels	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

OFFSET[10:0] bits (Horizontal Synchronization Signal Generation Reference Timing)

The OFFSET[10:0] bits specify the reference timing to be used when the horizontal synchronization signal is generated in the TCON. Set the offset from the assertion of the internal horizontal synchronization signal (HS) in terms of pixels. Figure 56.15 shows the horizontal synchronization signal generation reference timing in the TCON.

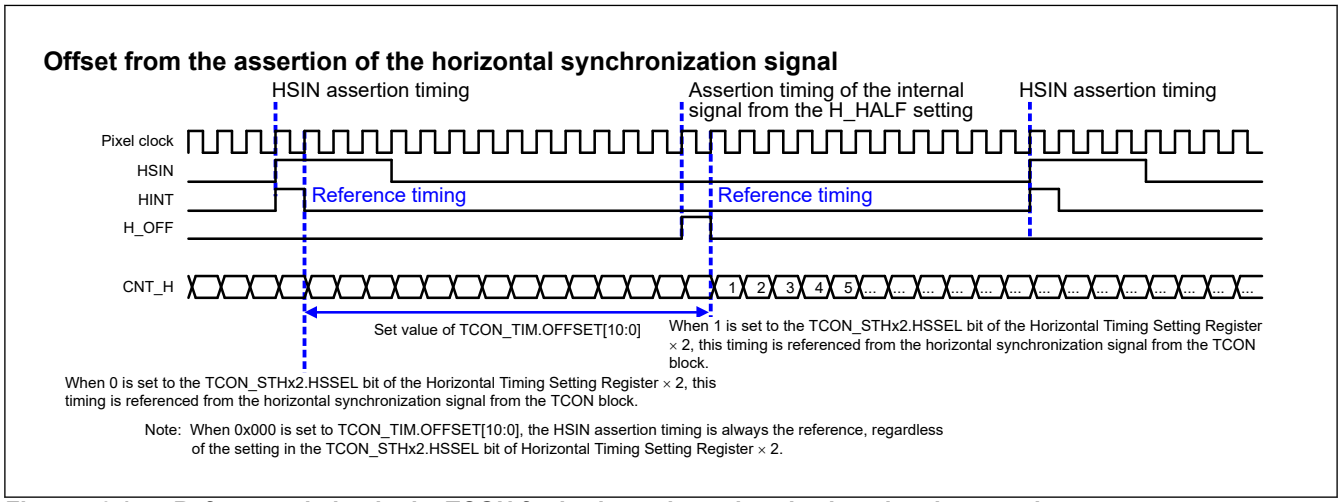

Figure 56.15 Reference timing in the TCON for horizontal synchronization signal generation

HALF[10:0] bits (Vertical Synchronization Signal Generation Change Timing)

The HALF[10:0] bits specify the vertical synchronization signal change timing when the signal is generated in the TCON. Set the change timing as a delay from the assertion of the internal horizontal synchronization signal (HS) in terms of pixels. Figure 56.16 shows the vertical synchronization signal change timing in the TCON.

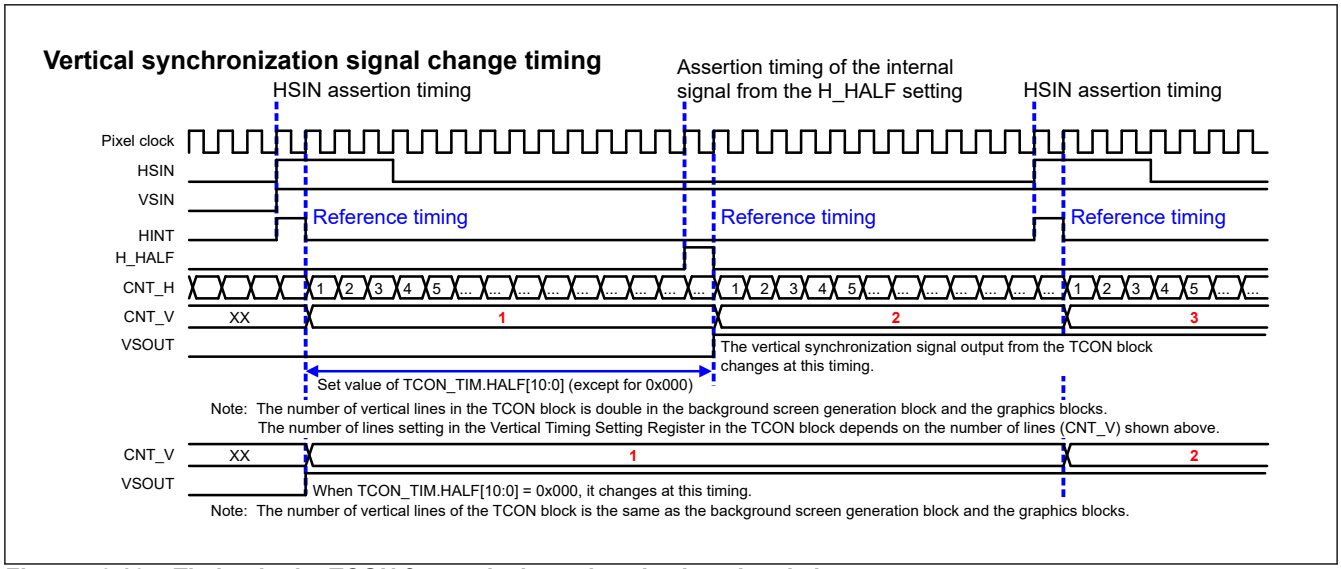

Figure 56.16 Timing in the TCON for vertical synchronization signal change

Also, Figure 56.17 shows the relationship between the TCON block and the output format block in the output control block. These blocks are based on shared control signals (same timing) and image data, and the internal delay is the same. The delay difference specified in the register settings is the source of the timing differences on the external pins.

- TCON block: 3 delay cycles of the pixel clock (PXCLK)
- Data format block:
  - Parallel RGB: 3 delay cycles of the pixel clock (PXCLK)
  - Serial RGB: 3 delay cycles of the pixel clock (PXCLK):
    - The delay of the pixel head data including invalid data
    - No delay of the serial RGB data.

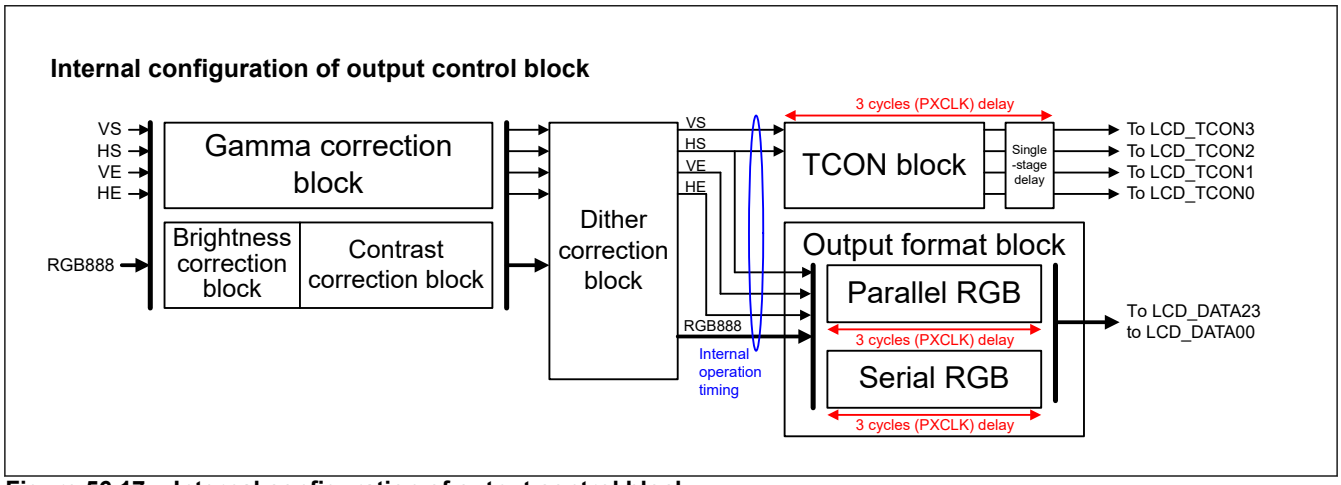

Figure 56.17 Internal configuration of output control block

56.2.51 TCON_STVx1 : TCON Vertical Timing Setting Register x1 (x = A, B)

Base address: GLCDC = 0x4034_2000

10:0	VW[10:0]	Vertical Synchronization Signal STVx1 Second Change Timing Signal assertion width in lines. 0x000: 0 line (no vertical synchronization signal assertion) ⋮ 0x7FF: 2047 lines.	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	VS[10:0]	Vertical Synchronization Signal STVx1 First Change Timing Signal delay in lines. 0x000: 0 line (no delay) ⋮ 0x7FF: 2047 lines	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

The vertical timing setting registers (TCON_STVA1/TCON_STVB1 and TCON_STVA2/TCON_STVB2) have the same configuration, and x is either A or B in the descriptions.

VW[10:0] bits (Vertical Synchronization Signal STVx1 Second Change Timing)

The VW[10:0] bits specify the second change (negation) timing of the vertical synchronization signal STVx1, which is generated in the TCON. Set the second change timing as a delay from the first change point in terms of lines. The change position in a horizontal line is defined in TCON_TIM.HALF[10:0] in the Reference Timing Setting Register (TCON_TIM), as is the first change timing.

VS[10:0] bits (Vertical Synchronization Signal STVx1 First Change Timing)

The VS[10:0] bits specify the first change (assertion) timing of the vertical synchronization signal STVx1, which is generated in the TCON. Set the change timing as a delay from the input vertical synchronization signal (VSIN) in terms of lines. The change position in a horizontal line is defined in TCON_TIM.HALF[10:0] in the Reference Timing Setting Register (TCON_TIM), as is the first change timing. Figure 56.18 shows the change timing of vertical synchronization signal to be generated.

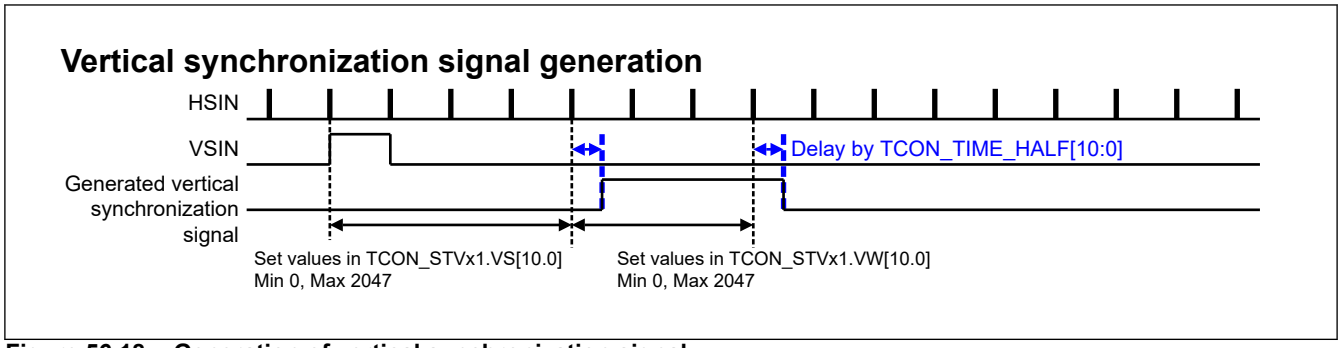

Figure 56.18 Generation of vertical synchronization signal

56.2.52 TCON_STVx2 : TCON Vertical Timing Setting Register x2 (x = A, B)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x140C (TCON_STVA2)
0x1414 (TCON_STVB2)

Note: S-TYPE-3, P-TYPE-3
Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

The vertical timing setting registers (TCON_STVA1/TCON_STVB1 and TCON_STVA2/TCON_STVB2) have the same configuration, and x is either A or B in the descriptions.

SEL[2:0] bits (Output Signal Select Control for VSOUT/VEOUT Pin)

The SEL[2:0] bits control output signal select for the LCD_TCON0/LCD_TCON1 pin. Figure 56.19 shows the configuration of the inversion control and output signal select.

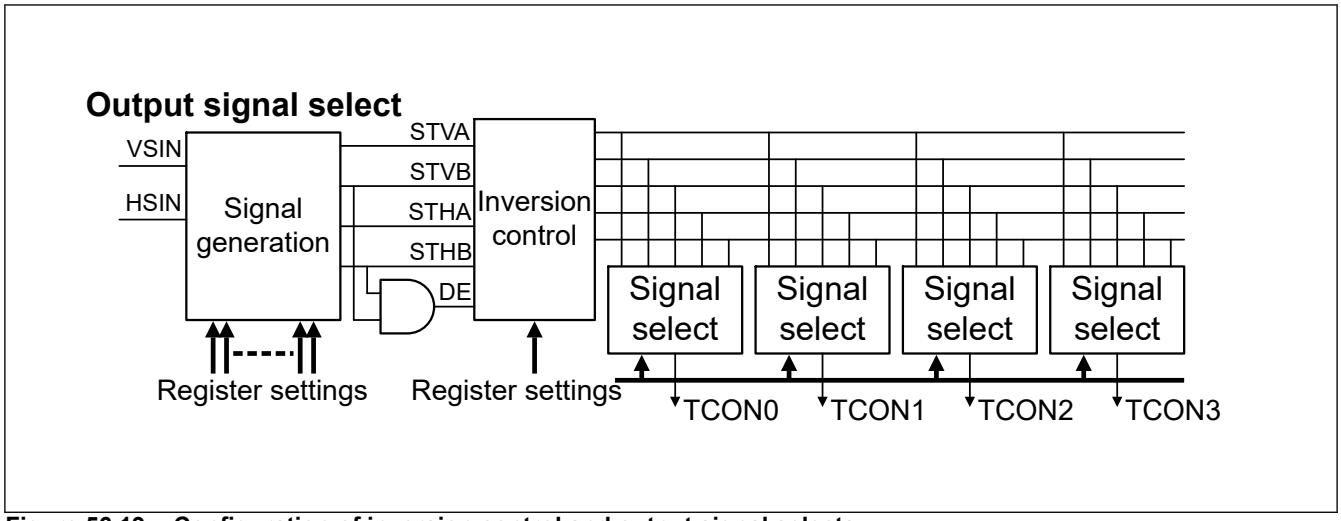

Figure 56.19 Configuration of inversion control and output signal selects

INV bit (Vertical Synchronization Signal STVx Polarity Inversion Control)

The INV bit controls polarity inversion of the vertical synchronization signal (STVx).

56.2.53 TCON_STHx1 : TCON Horizontal Timing Setting Register x1 (x = A, B)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1418 (TCON_STHA1)
0x1420 (TCON_STHB1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	HS[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	HW[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	HW[10:0]	Horizontal Synchronization Signal STHx1 Second Change Timing Signal assertion width in pixels. 0x000: 0 pixel (no horizontal synchronization signal assertion) ⋮ 0x7FF: 2047 pixels	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	HS[10:0]	Horizontal Synchronization Signal STHx1 First Change Timing Signal delay in pixels. 0x000: 0 pixel (no delay) ⋮ 0x7FF: 2047 pixels	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

The horizontal timing setting registers (TCON_STHA1/TCON_STHB1 and TCON_STHA2/TCON_STHB2) have the same configuration, and x is either A or B in the descriptions.

HW[10:0] bits (Horizontal Synchronization Signal STHx1 Second Change Timing)

The HW[10:0] bits specify the second change (negation) timing of the horizontal synchronization signal STHx1, which is generated in the TCON. Set the second change timing as a distance from the first change point in terms of pixels.

HS[10:0] bits (Horizontal Synchronization Signal STHx1 First Change Timing)

The HS[10:0] bits specify the first change (assertion) timing of the horizontal synchronization signal STHx1, which is generated in the TCON. Set the change timing as a distance from the input horizontal synchronization signal (HSIN) or the reference timing based on the offset specified in the TCON_TIM.OFFSET[10:0] bit (horizontal synchronization signal generation reference timing) in terms of pixels.

Figure 56.20 shows the horizontal synchronization signal generation timing if the input horizontal synchronization signal (HSIN) is based on the negated edge reference of the HINT signal. Figure 56.21 shows the horizontal synchronization signal generation timing after offset. By setting the TCON_TIM.OFFSET[10:0] bit (horizontal synchronization generation reference timing) and these horizontal synchronization bits appropriately, it is possible to generate a signal that is asserted before HSIN and negated after HSIN, where HSIN is the horizontal synchronization signal input to the TCON.

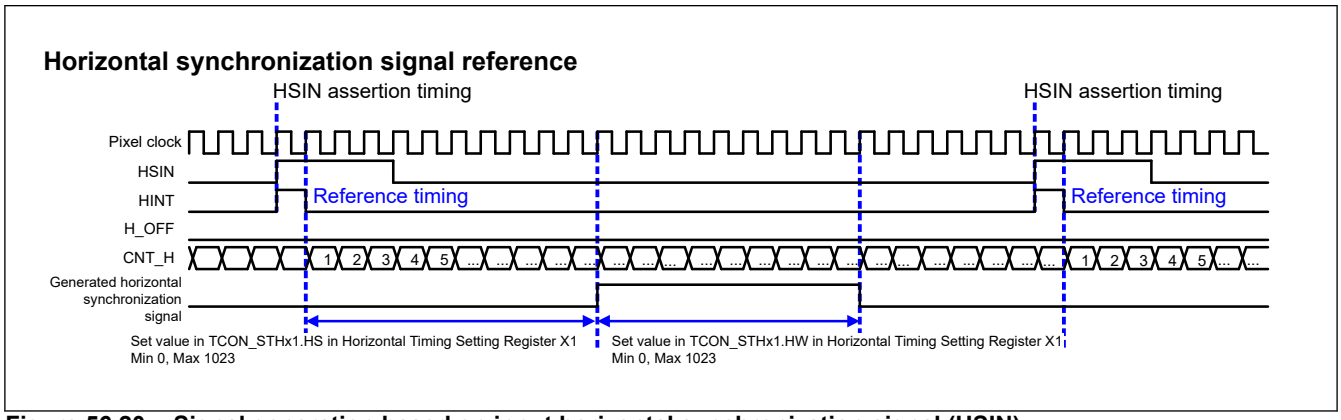

Figure 56.20 Signal generation based on input horizontal synchronization signal (HSIN)

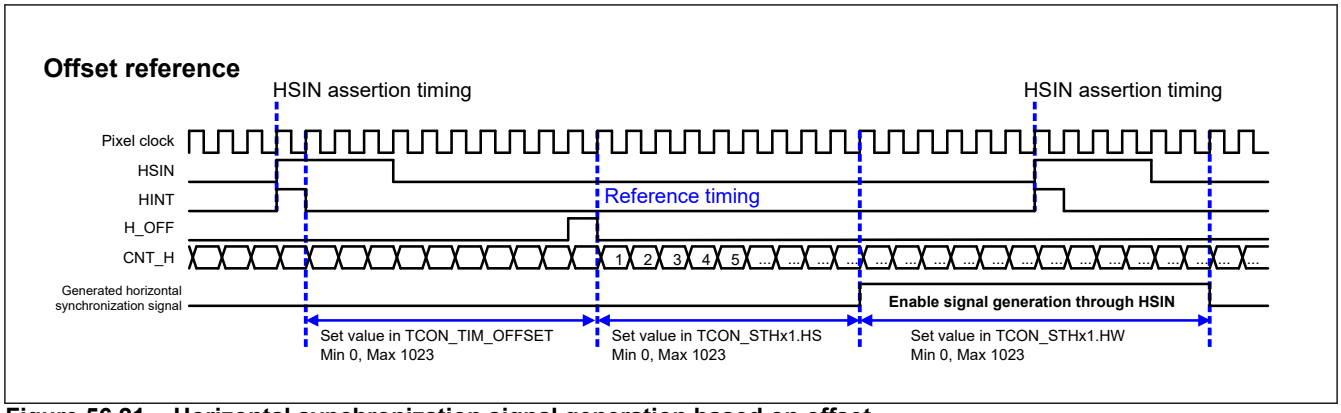

Figure 56.21 Horizontal synchronization signal generation based on offset

When generating the signal across HSIN on the offset reference, the horizontal synchronization signal of the last line of the frame spans the first line of the next frame. Even if the BG_EN.EN bit is cleared to 0 and the GLCDC operation is stopped, the horizontal synchronization signal across HSIN is not cleared at the frame end and retains the predetermined value until the second change timing set in the registers. If BG_EN.SWRST is cleared to 0, the signal returns to the initial state immediately.

56.2.54 TCON_STHx2 : TCON Horizontal Timing Setting Register x2 (x = A, B)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x141C (TCON_STHA2)
0x1424 (TCON_STHB2)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	HSSEL	—	—	—	INV	—	SEL[2:0]

8	HSSEL	Horizontal Synchronization Signal STHx Reference Timing Control 0: Select input horizontal synchronization signal (HSIN) as reference for signal generation 1: Select offset specified in TCON_TIM.OFFSET[10:0] (horizontal synchronization generation reference timing) as reference for signal generation	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

The horizontal timing setting registers (TCON_STHA1/TCON_STHB1 and TCON_STHA2/TCON_STHB2) have the same configuration, and x is either A or B in the descriptions.

SEL[2:0] bits (Output Signal Select Control for LCD_TCON2/LCD_TCON3 Pin)

The SEL[2:0] bits control the output signal select for the LCD_TCON2/LCD_TCON3 pins.

INV bit (Horizontal Synchronization Signal STHx Polarity Inversion Control)

The INV bit controls polarity inversion of the horizontal synchronization signal (STHx).

HSSEL bit (Horizontal Synchronization Signal STHx Reference Timing Control)

The HSSEL bit selects the reference timing for generating the horizontal synchronization signal STHx. For details on the signal to be generated, see Figure 56.20 and Figure 56.21. For the configuration of the inversion control and output signal select, see Figure 56.19.

56.2.55 TCON_DE : TCON Data Enable Polarity Setting Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1428

Bit position:	31																													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	INV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	INV	Data Enable Signal DE Polarity Inversion Control 0: Do not invert 1: Invert	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

INV bit (Data Enable Signal DE Polarity Inversion Control)

The INV bit controls polarity inversion of the data enable signal DE. The data enable signal DE generated in the TCON is the logical AND of the STVB and STHB signals.

56.2.56 SYSCNT_DTCTEN : System Control Block State Detection Control Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1440

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	L2UNDFDTC	L1UNDFDTC	VPOSDTC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	VPOSDTC	Specified Line Detection Control 0: Disable detection of specified line 1: Enable detection of specified line*1	R/W
1	L1UNDFDTC	Graphics 1 Underflow Detection Control 0: Disable detection of graphics 1 underflow 1: Enable detection of graphics 1 underflow*2	R/W
2	L2UNDFDTC	Graphics 2 Underflow Detection Control 0: Disable detection of graphics 2 underflow 1: Enable detection of graphics 2 underflow*2	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Set the VPOSDTC bit to 1 after setting the BG_EN.EN bit to 1.
Note 2. When setting the LnUNDFDTC (n = 1, 2) bit to 1 and when the BG_SYNC.VP[3:0] bits are set to a value greater than 0x5, an unexpected GLCDC_LnUNDF (n = 1, 2) interrupt is generated after the GLCDC starts.Therefore, set the SYSCNT_STCLR.LnUNDFCLR (n = 1, 2) bit to 1, then set the SYSCNT_STMON.LnUNDF (n = 1, 2) bit to 0 to clear the unexpected GLCDC_LnUNDF (n = 1, 2) interrupt.

VPOSDTC bit (Specified Line Detection Control)

The VPOSDTC bit enables or disables detection of the specified line. When this bit is set to 1, the associated bit in the SYSCNT_STMON register sets to 1 on event notification from graphics 2. When it is set to 0, the associated bit in the SYSCNT_STMON register does not set to 1 even on event notification from graphics 2.

L1UNDFDTC bit (Graphics 1 Underflow Detection Control)

The L1UNDFDTC bit enables or disables detection of the graphics 1 underflow. When this bit is set to 1, the associated bit in the SYSCNT_STMON register sets to 1 when an underflow occurs in graphics 1. When it is set to 0, the associated bit in the SYSCNT_STMON register does not set to 1 even when an underflow occurs in graphics 1. The underflow state in graphics 1 is automatically cleared on assertion of the vertical synchronization signal (VS) regardless of the value of this bit, and normal operation is recovered.

L2UNDFDTC bit (Graphics 2 Underflow Detection Control)

The L2UNDFDTC bit enables or disables detection of the graphics 2 underflow. When this bit is set to 1, the associated bit in the SYSCNT_STMON register sets to 1 when an underflow occurs in graphics 2. When it is set to 0, the associated bit in the SYSCNT_STMON register does not set to 1 even when an underflow occurs in graphics 2. The underflow state in graphics 2 is automatically cleared on assertion of the vertical synchronization signal (VS) regardless of the value of this bit, and normal operation is recovered.

56.2.57 SYSCNT_INTEN : System Control Block Interrupt Request Enable Control Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1444

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	L2UNDFINTEN	L1UNDFINTEN	VPOSINTEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	VPOSINTEN	Interrupt Request Signal GLCDC_VPOS Enable Control 0: Disable GLCDC_VPOS output 1: Enable GLCDC_VPOS output	R/W
1	L1UNDFINTEN	Interrupt Request Signal GLCDC_L1UNDF Enable Control 0: Disable GLCDC_L1UNDF output 1: Enable GLCDC_L1UNDF output	R/W
2	L2UNDFINTEN	Interrupt Request Signal GLCDC_L2UNDF Enable Control 0: Disable GLCDC_L2UNDF output 1: Enable GLCDC_L2UNDF output	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

VPOSINTEN bit (Interrupt Request Signal GLCDC_VPOS Enable Control)

The VPOSINTEN bit enables or disables the interrupt request signal GLCDC_VPOS. When this bit is set to 1, the interrupt request signal GLCDC_VPOS is asserted when the associated status monitor flag SYSCNT_STMON[0] sets. When it is cleared to 0, the interrupt request signal GLCDC_VPOS is not asserted even when the associated status monitor flag SYSCNT_STMON[0] sets. If this bit is cleared during GLCDC_VPOS assertion, the associated status monitor flag SYSCNT_STMON[0] does not change, but the interrupt request signal GLCDC_VPOS is negated.

L1UNDFINTEN bit (Interrupt Request Signal GLCDC_L1UNDF Enable Control)

The L1UNDFINTEN bit enables or disables the interrupt request signal GLCDC_L1UNDF. When this bit is set to 1, the interrupt request signal GLCDC_L1UNDF is asserted when the associated status monitor flag SYSCNT_STMON[1] sets. When it is cleared to 0, the interrupt request signal GLCDC_L1UNDF is not asserted even when the associated status monitor flag SYSCNT_STMON[1] sets. If this bit is cleared during GLCDC_L1UNDF assertion, the associated status monitor flag SYSCNT_STMON[1] does not change, but the interrupt request signal GLCDC_L1UNDF is negated.

L2UNDFINTEN bit (Interrupt Request Signal GLCDC_L2UNDF Enable Control)

The L2UNDFINTEN bit enables or disables the interrupt request signal GLCDC_L2UNDF. When this bit is set to 1, the interrupt request signal GLCDC_L2UNDF is asserted when the associated status monitor flag SYSCNT_STMON[2] sets. When it is cleared to 0, the interrupt request signal GLCDC_L2UNDF is not asserted even when the associated status monitor flag SYSCNT_STMON[2] sets. If this bit is cleared during GLCDC_L2UNDF assertion, the associated status monitor flag SYSCNT_STMON[2] does not change, but the interrupt request signal GLCDC_L2UNDF is negated.

56.2.58 SYSCNT_STCLR : System Control Block Status Clear Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1448

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	L2UNDFCLR	L1UNDFCLR	VPOSCLR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	VPOSCLR	Graphics 2 Specified Line Detection Flag Clear 0: No operation 1: Clear the graphics 2 specified line detection flag	R/W*1
1	L1UNDFCLR	Graphics 1 Underflow Detection Flag Clear 0: No operation 1: Clear the graphics 1 underflow detection flag	R/W*1
2	L2UNDFCLR	Graphics 2 Underflow Detection Flag Clear 0: No operation 1: Clears the graphics 2 underflow detection flag	R/W*1
31:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. These bits are read as 0.

VPOSCLR bit (Graphics 2 Specified Line Detection Flag Clear)

Writing 1 to the VPOSCLR bit clears the graphics 2 specified line detection flag. Clearance of the flag by this bit is only valid for the associated flag, and does not directly affect the other states and interrupt request signals. However, an interrupt request signal might be negated by clearing the detection flag.

L1UNDFCLR bit (Graphics 1 Underflow Detection Flag Clear)

Writing 1 to the L1UNDFCLR bit clears the graphics 1 underflow detection flag. Clearance of the flag by this bit is only valid for the associated flag, and does not directly affect the other states and interrupt request signals. However, an interrupt request signal might be negated by clearing the detection flag.

L2UNDFCLR bit (Graphics 2 Underflow Detection Flag Clear)

Writing 1 to the L2UNDFCLR bit clears the graphics 2 underflow detection flag. Clearance of the flag by this bit is only valid for the associated flag, and does not directly affect the other states and interrupt request signals. However, an interrupt request signal might be negated by clearing the detection flag.

56.2.59 SYSCNT_STMON : System Control Block Status Monitor Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x144C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	L2UNDF	L1UNDF	VPOS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	VPOS	Graphics 2 Specified Line Detection Flag 0: Specified line notification not detected in graphics 2 1: Specified line notification detected in graphics 2	R
1	L1UNDF	Graphics 1 Underflow Detection Flag 0: No underflow detected in graphics 1 1: Underflow detected in graphics 1	R
2	L2UNDF	Graphics 2 Underflow Detection Flag 0: No underflow detected in graphics 2 1: Underflow detected in graphics 2	R
31:3	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

VPOS flag (Graphics 2 Specified Line Detection Flag)

The VPOS flag indicates that the specified line notification was detected in graphics 2. When this flag is 1, it indicates that the specified line notification was detected in graphics 2 at some time in the past. It does not necessarily mean that graphics 2 is currently processing the specified line. When this flag is 0, it indicates that no specified line notification was detected after the module operation was enabled. When the interrupt request signal is enabled and is cleared while this flag is 1, the associated interrupt request signal GLCDC_VPOS is negated, but this does not affect the state of graphics 2.

L1UNDF flag (Graphics 1 Underflow Detection Flag)

The L1UNDF flag indicates that an underflow was detected in graphics 1. When this flag is 1, it indicates that an underflow was detected in graphics 1 at some time in the past. It does not necessarily mean that graphics 1 is currently in the underflow state. When this flag is 0, it indicates that no underflow was detected after the module operation was enabled. When the interrupt request signal is enabled and is cleared while this flag is 1, the associated interrupt request signal GLCDC_L1UNDF is negated, but this does not affect the state of graphics 1.

Even if the current graphics data is not required (GR1_AB1.DISPSEL[1:0] = 0xb), if the SYSCNT_DTCTEN.L1UNDFDTC flag (graphics 1 underflow detection control) is 1 and detection is enabled, this flag is set to 1 at the start of the graphics image valid area. To avoid unnecessary detection flag settings or interrupt request signal assertions, when the display does not require the current graphics data, set the SYSCNT_DTCTEN.L1UNDFDTC flag and the SYSCNT_INTEN.L1UNDFINTEN bit (interrupt request signal GLCDC_L1UNDF enable control) to 0.

L2UNDF flag (Graphics 2 Underflow Detection Flag)

The L2UNDF flag indicates that an underflow was detected in graphics 2. When this flag is 1, it indicates that an underflow was detected in graphics 2 at some time in the past. It does not necessarily mean that graphics 2 is currently in the underflow

state. When this flag is 0, it indicates that no underflow was detected after the module operation was enabled. When the interrupt request signal is enabled and is cleared while this flag is 1, the associated interrupt request signal GLCDC_L2UNDF is negated, but this does not affect the state of graphics 2.

Even if the current graphics data is not required (GR2_AB1.DISPSEL[1:0] = 0xb), if the SYSCNT_DTCTEN.L2UNDFDTC flag (graphics 2 underflow detection control) is 1 and detection is enabled, this flag is set to 1 at the start of the graphics image valid area. To avoid the unnecessary detection flag settings or interrupt request signal assertions, when the display does not require the current graphics data, set the SYSCNT_DTCTEN.L2UNDFDTC flag and the SYSCNT_INTEN.L2UNDFINTEN bit (interrupt request signal GLCDC_L2UNDF enable control) to 0.

56.2.60 SYSCNT_PANEL_CLK : System Control Block Version and Panel Clock Control Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1450

The configuration of the pixel and panel clock generator circuits are shown in section 8, Clock Generation Circuit.

DCDR[5:0] bits (Clock Division Ratio Setting Control)

The DCDR[5:0] bits control the setting of the panel clock division ratio. The division ratio bit can only be set to the values listed in Table 56.9. Operation is not guaranteed for values not listed.

Table 56.9 Input clock division (1 of 2)

DCDR[5:0]	Clock division ratio	CLKSEL = 0, LCD_EXTCLK (≤ 60 MHz)	CLKSEL = 1, LCDCLK (Up to 240 MHz)
000000b	1/2	LCD_EXTCLK/2	LCDCLK/2*1

Table 56.9 Input clock division (2 of 2)

DCDR[5:0]	Clock division ratio	CLKSEL = 0, LCD_EXTCLK (≤ 60 MHz)	CLKSEL = 1, LCDCLK (Up to 240 MHz)
000001b	1/1	LCD_EXTCLK*1	LCDCLK*1
000010b	1/2	LCD_EXTCLK/2	LCDCLK/2*1

010000b	1/16	LCD_EXTCLK/16	LCDCLK/16
011000b	1/24	LCD_EXTCLK/24	LCDCLK/24
100000b	1/32	LCD_EXTCLK/32	LCDCLK/32

Note 1. The panel clock is output as the LCD_CLK output clock. This setting may be prohibited because LCD_EXTCLK and LCD_CLK have limited frequencies. See section 60, Electrical Characteristics.

To set the panel clock:

1. After setting the input source of the panel clock in the CLKSEL bit, set the division ratio in the DCDR[5:0] bits and the pixel clock selection.
2. Set the CLKEN bit to 1.

CLKEN bit (Panel Clock Output Enable Control)

The CLKEN bit enables or disables the panel clock output. When enabling the panel clock output and operating the panel clock block, set this bit to 1. When changing the PIXSEL, CLKSEL, or DCDR bit, you must set this bit to 0 once and stop the panel clock output. Operation is not guaranteed if any setting is changed while the panel clock is being output.

CLKSEL bit (Panel Clock Supply Source Control)

The CLKSEL bit controls the selection of the panel clock supply source from either the external clock pin (LCD_EXTCLK) or LCDCLK. When the external clock is selected, set this bit to 0. When LCDCLK is selected, set this bit to 1.

PIXSEL bit (Pixel Clock Select Control)

The PIXSEL bit controls the selection of the pixel clock output. When selecting parallel RGB, set this bit to 0 to output the same frequency as the panel clock (no frequency division). When selecting serial RGB, set this bit to 1 to output the quarter frequency of the panel clock as the pixel clock.

This bit must be synchronized with the OUT_SET.FRQSEL[1:0] setting. You must set the same value as in FRQSEL[1]. Otherwise, operation is not guaranteed.

VER[15:0] bits (Version Information)

The VER[15:0] bits provide GLCDC version information.

56.3 Operation

56.3.1 Overall Control

The GLCDC consists of six modules as shown in Figure 56.22, each of which functions independently. The four modules handling image data are interconnected by the vertical and horizontal synchronization signals VS, HS, VE, and HE, and image data (RGB888), as shown in Figure 56.23. The processing of image data is carried out with the pixel clock (PXCLK). LCD_CLK synchronizes with PXCLK (also in phase with each other), and has the same or quadruple frequency (for serial RGB888 output). The registers controlling operation and setting parameters are connected with the PABI and operate on PCLKA. The circuits, including the data buffer and the CLUT memory, operate on PCLKA to read graphics data from the

GLCDC0 and GLCDC1 bus, access the color palette (CLUT) memory, and expand graphics data into the ARGB8888 format.

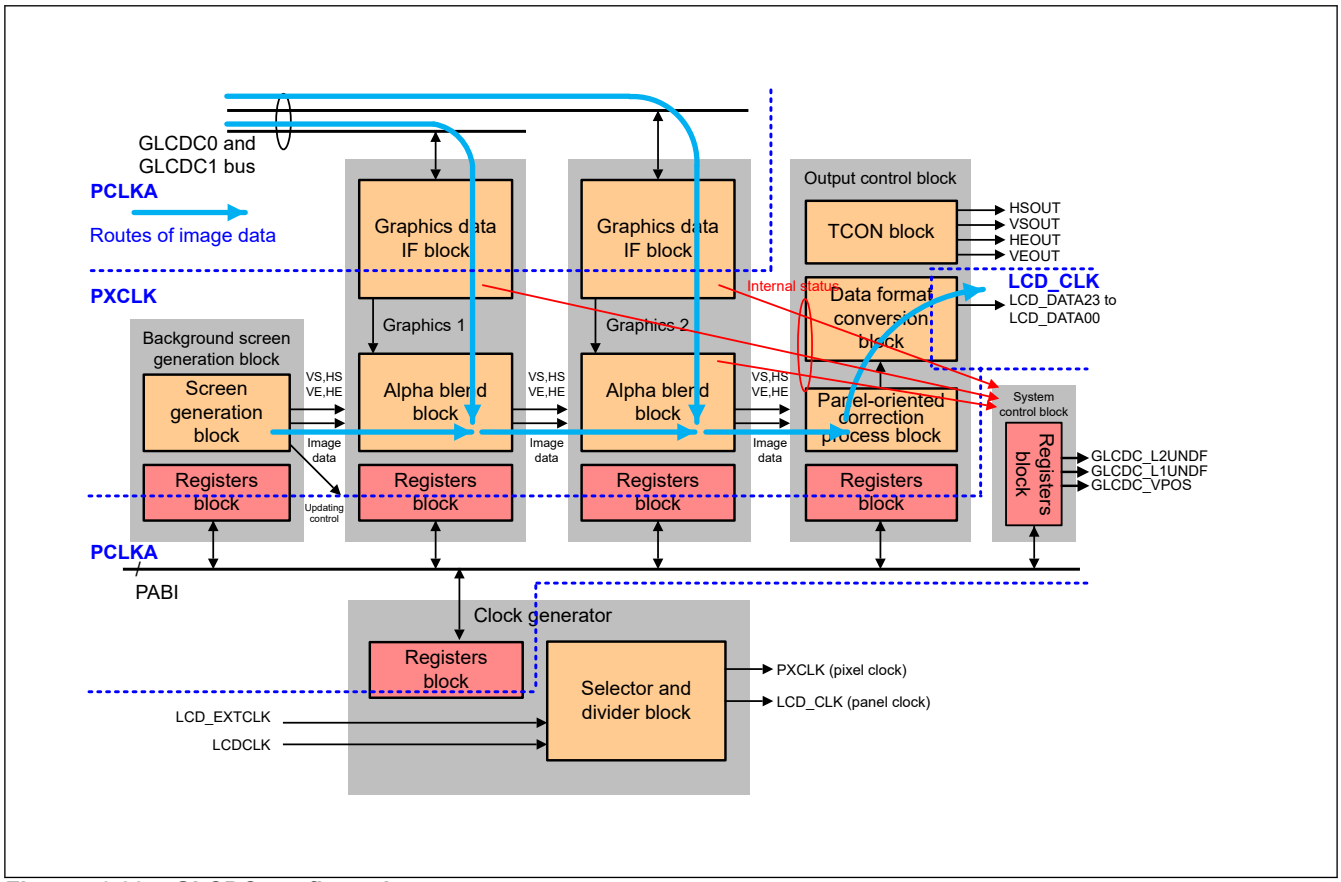

Figure 56.22 GLCDC configuration

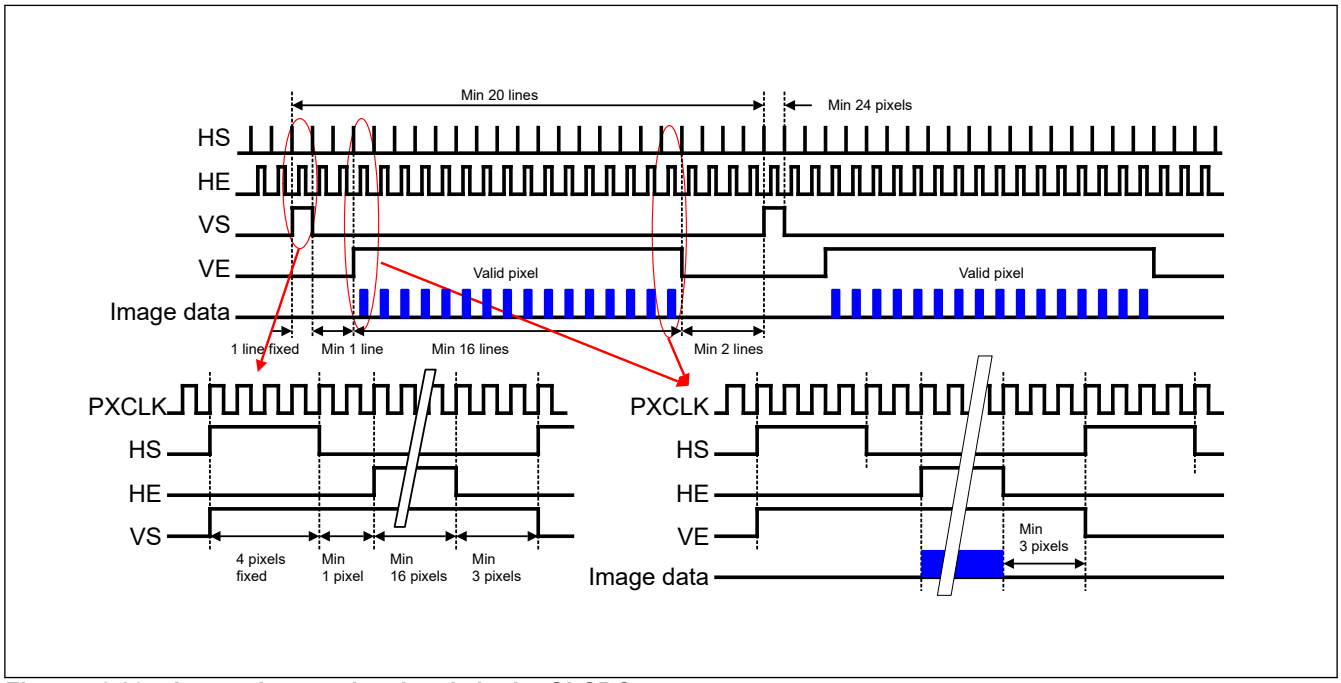

Figure 56.23 Image data carrier signals in the GLCDC

The graphics 1, graphics 2, and output control modules have no individual operation enable bits. By clearing the software reset state in the background screen generation module, these modules wait for vertical and horizontal synchronization signals VS, HS,VE, and HE, and image data (RGB888) to be input, detect assertion of the vertical synchronization signal

VS, and start operation for each frame based on the values preset in the registers. For the system control module, clearing the software reset state in the background screen generation module allows it to monitor the status of graphics 1 and 2 in accordance with the register settings and assert interrupt request signals. These status flags are intended for observing the internal status and exert no influence on the internal operation. The operation between startup and stop of the GLCDC is outlined in this section.

(1) Startup

To start GLCDC operation:

1. Confirm that PCLKA is supplied to the GLCDC and that the reset is negated. When setting LCD_CLK to the same frequency as PXCLK or LCD_CLK to the quadruple speed clock, the setting must be consistent with the value in the register specified in the subsequent stage. The quadruple speed clock is required only when the output format is serial RGB888. Operation is not guaranteed if the quadruple speed clock is supplied to LCD_CLK in other output formats than serial RGB888.
2. Set 1 to the BG_EN.SWRST bit to release the entire GLCDC from a software reset.
3. Set parameters necessary for operation in each register. Although registers of any module can be set first, while the BG_EN.VEN bit (control of GLCDC internal register value reflection to internal operations), BG_EN.EN bit (background plane operation enable) of the background screen generation module, and the VEN bit in the register update control register of each module remain cleared to 0, confirm that PCLKA and PXCLK/LCD_CLK are supplied and the BG_MON.SWRST bit (entire module software reset state monitor) is set to 1.
4. When displaying the graphics data read by graphics 1 and 2 through the GLCDC0 and GLCDC1 bus, set 1 to the GRn_FLMRD.RENB bit (graphics data read enable).
5. Write the color palette data of graphics 1 and 2 (0 and 1 planes) to the CLUT memory through the register access bus (PABI) as required. This is necessary for the LUT1, LUT4, LUT8, and ARGB1555 data formats. ARGB1555 uses addresses 0x80 and 0x00 on the two planes, LUT1 uses 0x01 and 0x00, LUT4 uses the addresses from 0x0F to 0x00, and LUT8 uses the addresses from 0xFF to 0x00.
6. Set 1 to the BG_EN.VEN bit (control of background plane register value reflection to internal operations) and the BG_EN.EN bit (background plane operation enable) of the background screen generation module at the same time. This setting allows output of the vertical and horizontal synchronization signals VS, HS, VE, and HE, and the image data (RGB888) from the background screen generation module. When the pixel data is valid (both VE and HE are 1), output from the background screen generation module uses the value in the BG_BGC register. The data value is 0x00000000 for pixels that are not valid.
7. Each module detects the assertion of the vertical synchronization signal (VS) output from its previous stage (background screen generation module for graphics 1, graphics 1 for graphics 2, and graphics 2 for the output control module) and starts operation in accordance with its register settings. All the modules control the operation in frame units. When the assertion of the vertical synchronization signal (VS) is detected, the current frame is taken as the frame head and the status is initialized. If necessary (when the VEN bits in the register update control registers are 1), the register values read through the register access bus are reflected to the internal operation.

(2) Changing parameters during operation

With the GLCDC, it is possible to update parameters of each module and reflect the updates to the internal operations during operation, without preventing graphics data to be read by the background screen generation module, graphics 1, or graphics 2. By setting 1 to the VEN bits of the modules, including the background screen generation module, almost all parameters are reflected to the internal operations at the start of the following frame (at the start of the control screen for the background screen generation module, and immediately after the VS assertion of the previous stage for the other modules). However, if the CLUT plane being used for internal operations (determined in the GRn_CLUTINT.SEL[1:0] bits) is modified, the updates are reflected to the internal operations immediately without waiting for the following VS assertion. To circumvent this immediate reflection of the CLUT plane modification to the internal operations, first write all the image data (ARGB8888) necessary for the CLUT plane that is not being used for internal operations, next modify the GRn_CLUTINT.SEL[1:0] bits, and finally set 1 to the VEN bit of the background screen generation module or the target module.

To modify parameters during operation:

1. Confirm that the VEN bit of each module is 0. Operation is not guaranteed if the target registers are modified when the VEN bit of the module to which the register values are to be reflected to the internal operations, or the VEN bit of the background screen generation module is 1.

2. Modify the value of the target registers.
3. If only a particular module is to be the target, set 1 to the VEN bit of the target module. If multiple modules or the background screen generation module are to be the targets, set 1 to the VEN bit of the background screen generation module. In this case, all the modules are included as targets, not only the background screen generation module.
4. Confirm that the VEN bit to which 1 was set is 0. If the bit is cleared to 0, the target register contents are reflected to the internal operations. If the bit remains 1, however, the target register contents might not yet be reflected to the internal operations. The VEN bit of each module is cleared to 0 immediately after the target register values are internally reflected. However, the VEN bit of the background screen generation module is not cleared to 0 until the module output VE is negated (with all the modules, sufficient delay is secured in reference to the VS assertion of the background screen generation module so that the register values are reflected to the internal operations for the same frame). Figure 56.24 shows the operation of the signals output by the background screen generation module and the monitor bits.

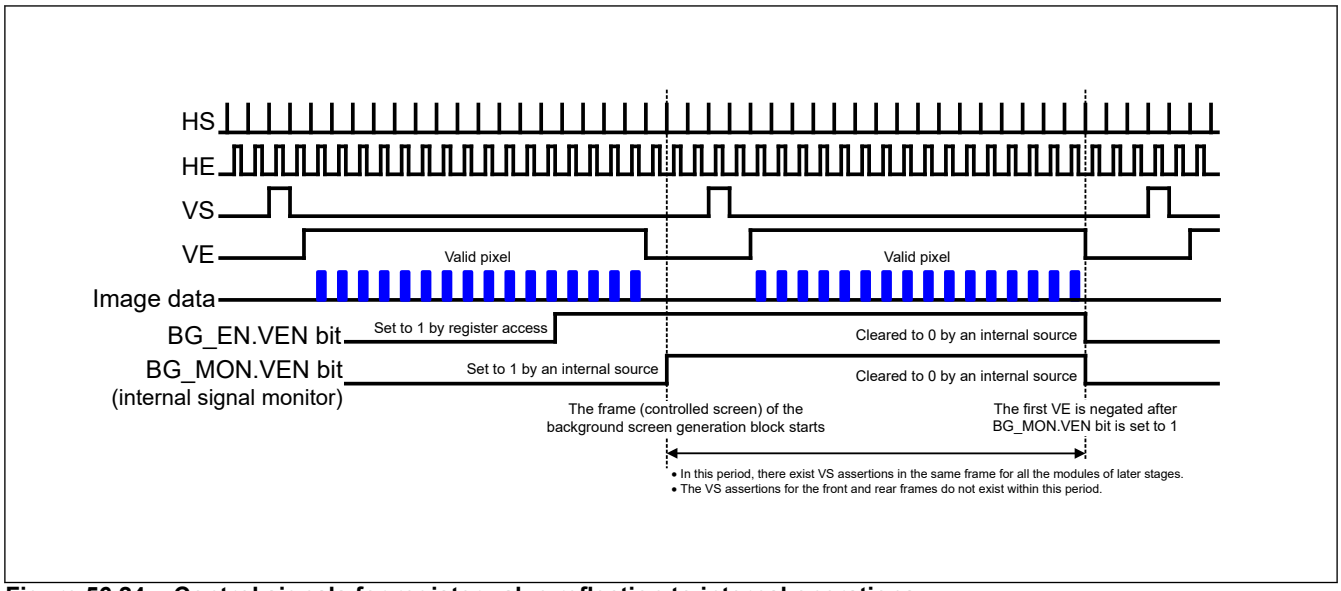

Figure 56.24 Control signals for register value reflection to internal operations

(3) Stopping and restarting in normal operation

To stop the GLCDC:

1. Confirm that the VEN bit of each module is cleared to 0.
2. Clear the BG_EN.EN bit (background plane operation enable) of the background screen generation module to 0.
3. Confirm that the BG_MON.EN bit (background plane operation monitor) of the background screen generation module has changed to 0. This bit is cleared to 0 only after operation has stopped. It is cleared at the frame end of the background screen generation module, not when the operations of all the modules are complete (not at the frame end of the output control module). If it is necessary to wait for all the modules to complete operations, a certain period (for example, a period equivalent to one line) is required.
4. Usually, a software reset can be safely applied (clearing of the BG_EN.SWRST bit) after confirming that the BG_MON.EN bit of the background screen generation module has changed to 0. (Even if the output signal returns to the initial value, no problems occur because the GLCDC has already entered the vertical blanking interval.)
5. When restarting the GLCDC by setting the relevant registers without applying a software reset, wait until sufficient time elapses after the BG_MON.EN bit becomes 0 (when the output control module output is the frame end) before starting the GLCDC. The GLCDC itself is not affected by this because the GLCDC starts operating after recognizing the assertion of the VS of the previous stage as the frame head. However, operation of some connected devices might be affected if a blanking interval or a period equivalent to one line is too short. For details, check the specifications of the connected device. When a software reset is applied, the register values are also initialized and almost all of the registers must be set again. Only the color palette data (CLUT memory content) is retained (only for a software reset after normal end).

Figure 56.25 shows the changes in signal lines and bits for the stop and restart in normal operation. Even if the background screen generation module is stopped by a clearing of the BG_EN.EN bit to 0, the GLCDC stops because of an abnormal

operation sequence, not normal operation, if the GLCDC0 and GLCDC1 bus access is not complete at the frame end because of an underflow in graphics 1 or 2, inappropriate setting of graphics data access, or other undesirable conditions.

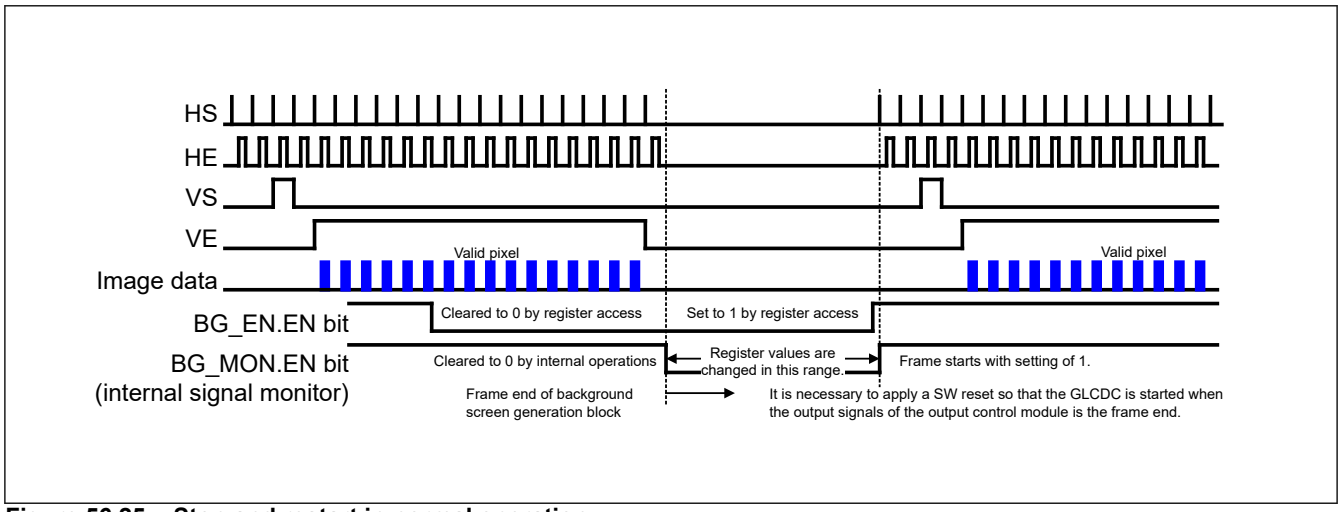

Figure 56.25 Stop and restart in normal operation

(4) Stopping and restarting in abnormal operation

Stop in abnormal operation occurs in the following cases:

- When during operation (BG_EN.EN or BG_MON.EN is set to 1), a software reset (BG_EN.SWRST bit is cleared to 0) or a reset is applied
- When unnecessary (unintended) access to the GLCDC0 and GLCDC1 bus occurs and a data cycle is not completed, even though the BG_EN.EN bit is cleared to 0 and so the BG_MON.EN bit is also cleared to 0

In both cases, the GLCDC is internally initialized and the register access bus can be accessed normally (except for a hardware reset). However, the GLCDC0 and GLCDC1 bus might write unintended graphics data to the GLCDC. Therefore, it is advisable to apply a software reset (clear the BG_EN.SWRST bit to 0) and confirm that there is no unintended access to the GLCDC0 and GLCDC1 bus, even after confirming that both the BG_EN.EN and BG_MON.EN bits are cleared to 0. Next release the GLCDC from the software reset (set the BG_EN.SWRST bit to 1), set the relevant registers, and set the BG_EN.En and BG_EN.VEN bits in the background screen generation module to 1 to restart the GLCDC. For the procedure for checking the GLCDC0 and GLCDC1 bus state, see the *ARM® AHB Specification*. Use this procedure even after a reset when the GLCDC0 and GLCDC1 bus, a target device, or a target controller is not initialized. If these are initialized on a reset assertion for the GLCDC, a normal startup procedure can be used without checking the GLCDC0 and GLCDC1 bus state.

56.3.2 Screen Definition

The essential signals for GLCDC operations are generated by the background screen generation module, and the graphics 1 and 2 modules and output control module operate based on the sequentially transferred vertical and horizontal synchronization signals (VS and HS) and vertical and horizontal pixel enable signals (VE and HE). The reference point (frame start point) of the background screen cannot be determined by the output signals. The point shown in the figures is virtual and provided only for register settings. The reference points (frame start points) of the graphics 1 and 2 modules and output control module are the assertion of the vertical synchronization signal (VS), which is input (output) from the previous stage. Each module defines the valid pixel display area and special processing area for pixel data (rectangular areas for graphics 1 and 2) according to the position and width based on this reference point. Figure 56.26 shows the definition of the background screen, and Figure 56.27 shows the definition of the graphics 1 and 2 screen. The output control module performs correction for the entire valid pixel area (when both VE and HE are 1) output from the previous stage (graphics 2). (No registers are provided in the output control module for setting the correction area.) TCON in the output control module generates the control signals to be output based on the internal vertical and horizontal synchronization signals (VS and HS), and the change timing of the output signals can be freely modified within the valid setting range specifiable in the registers.

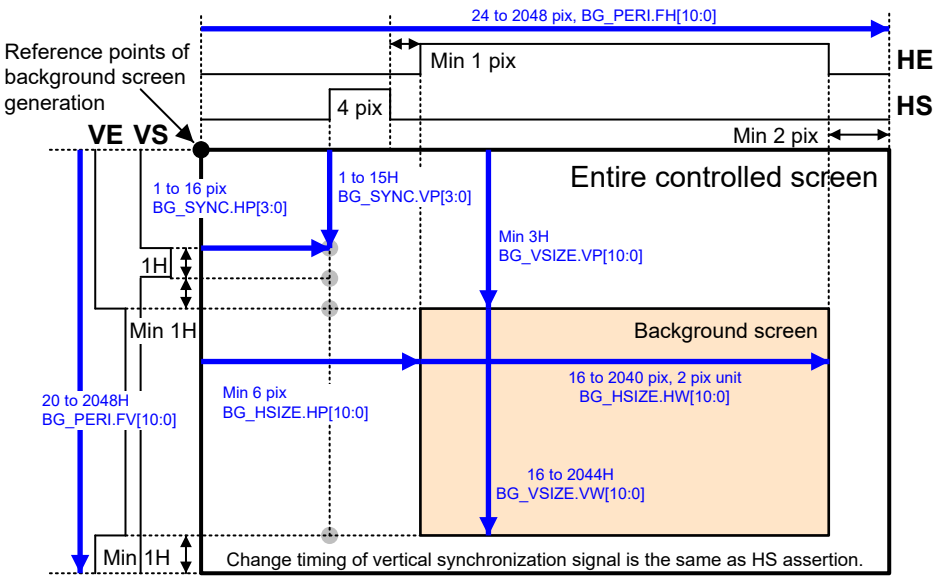

Figure 56.26 Definition of background screen

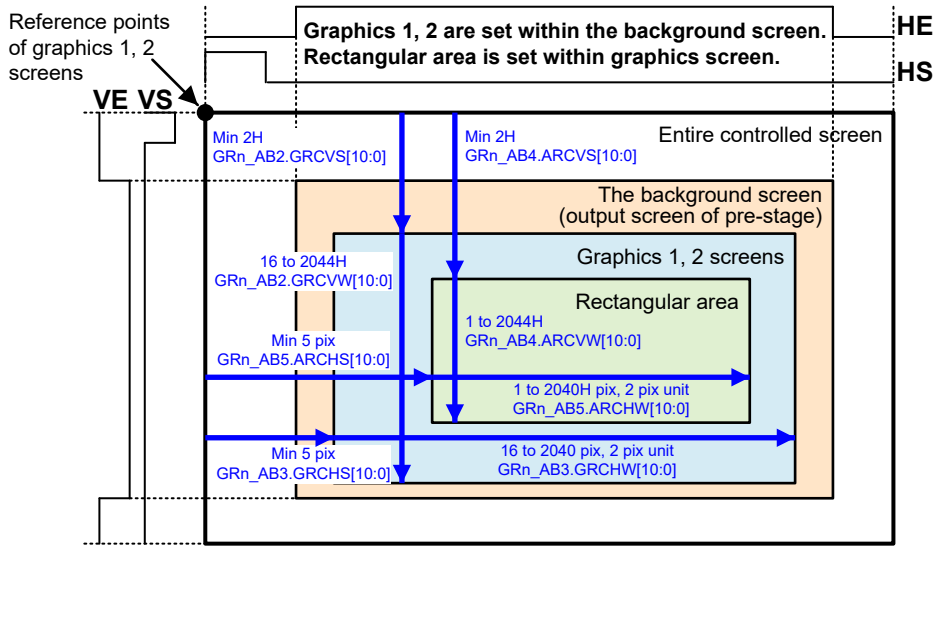

Figure 56.27 Definition of graphics 1 and 2 screens

56.3.3 Underflow and Interrupts

The GLCDC can detect the three types of status conditions described in this section. To detect each status condition, set the associated bit in the Status Detection Control Register (SYSCNT_DTCTEN) to 1.

56.3.3.1 Graphics 2 underflow detection

This function detects underflows in the graphics data interface block for graphics 2. The SYSCNT_STMON.L2UNDF flag sets to 1 if the graphics data cannot be read from the graphics data interface block (if valid data is not stored in the 4-stage ring buffer). The underflow is cleared as an internal state of graphics 2 on the VS (vertical synchronization) signal assertion of the previous stage. However, to clear the relevant bit in the Status Monitor Register of the system control block, the software must set the associated bit in the Status Clear Register to 1.

56.3.3.2 Graphics 1 underflow detection

This function detects underflows in the graphics data interface block for graphics 1. The SYSCNT_STMON.L1UNDF flag is set to 1 if the graphics data cannot be read from the graphics data interface block (if valid data is not stored in the 4-stage ring buffer). The underflow is cleared as an internal state of graphics 1 on the VS (vertical synchronization) signal assertion of the previous stage. However, to clear the relevant bit in the Status Monitor Register of the system control block, the software must set the associated bit in the Status Clear Register to 1.

56.3.3.3 Graphics 2 line detection

This function detects that the number of lines specified in the GR2_CLUTINT.LINE[10:0] bit was processed. The detection is performed on the HS (horizontal synchronization) signal assertion of the previous stage, not when valid pixels start to be processed. Each time the number of detected lines reach the value specified for graphics 2, the SYSCNT_STMON.VPOS flag sets to 1. As with underflow detection, to clear the relevant bit in the Status Monitor Register of the system control block, the software must set the associated bit in the Status Clear Register to 1.

56.3.3.4 Interrupts

The GLCDC provides three interrupt request output signals (GLCDC_L2UNDF, GLCDC_L1UNDF, and GLCDC_VPOS) that correspond to detection of the three status conditions. The GLCDC_L2UNDF, GLCDC_L1UNDF, and GLCDC_VPOS signals are associated with graphics 2 underflow detection, graphics 1 underflow detection, and graphics 2 line detection, respectively. Each of the interrupt request signals is asserted by setting the associated bit in the Interrupt Request Enable Register (SYSCNT_INTEN) to 1. Detecting the status and enabling the associated interrupt request can be controlled separately. Even if detection is enabled, the interrupt request signal is not asserted unless the interrupt request output signal is enabled. In addition, if the Status Monitor Register (SYSCNT_STMON) clears while the interrupt request output signal is asserted (the associated bit in the Status Clear Register (SYSCNT_STCLR) is set to 1), or if the associated bit in the Interrupt Request Enable Register (SYSCNT_INTEN) is cleared to 0, the interrupt request signal is negated. The interrupt request signal generation circuit is configured as shown in Figure 56.28. This circuit is glitch-free except for reset-induced glitches.

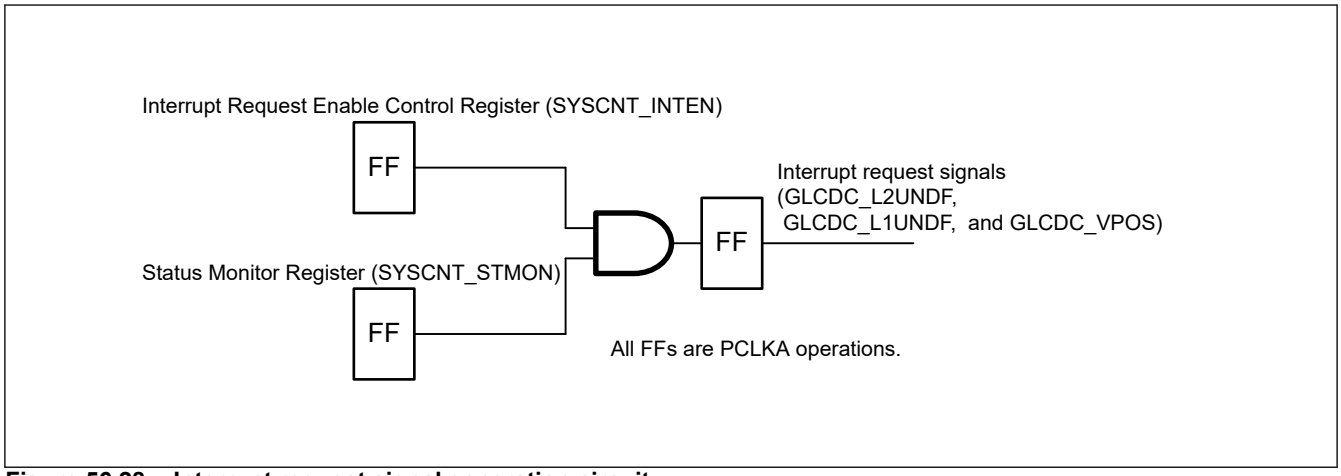

Figure 56.28 Interrupt request signal generation circuit

56.4 Usage notes

56.4.1 Module-stop function

GLCDC operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The GLCDC module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

57. MIPI PHY

57.1 Overview

This MIPI PHY is a MIPI D-PHY module.The D-PHY module supports MIPI Alliance Specification Version 2.1 for D-PHY Specification.

Table 57.1 MIPI DSI specifications

Parameter		Specifications
D-PHY	Number of lanes	Up to 2 Lanes
	Maximum rate	720 Mbps / Lane
MIPI PLL circuit	Input clock source	MOSC
	Input pulse frequency division ratio	Selectable from 1/2/3/4
	Input clock frequency	8 MHz to 48 MHz
	Input clock frequency (After DPHYPLFCR.IDIV[1:0] bits	5 MHz to 24 MHz *1
	Frequency multiplication ratio	Selectable from 20 to 180 (after the decimal point : 0/0.33/0.50/0.66)
	VCO frequency	160 MHz to 1440 MHz
	PLL Output clock	160 MHz to 1440 MHz

Note:
Note 1. . DPHYPLFCR.IDIV[1:0] must be set so that the frequency of the clock divided by DPHYPLFCR.IDIV[1:0] is within the range that is between 8 to 24 MHz. However, under the condition of 160 MHz ≤ PLL output clock (fDPHYPLL) < 320 MHz, the allowable frequency range of the clock divided by IDIV[1:0] is extended to 5 to 24 MHz.

The block diagram and I/O pins see Figure 54.1 and Table 54.1

57.2 Register Description

Access the following registers only in units of 32 bits.

57.2.1 DPHYREFCR : D-PHY Reference Clock Setting Register

Base address: MIPI_PHY0 = 0x4034_6C00
MIPI_PHY0_NS = 0x5034_6C00

Offset address: 0x000

Bit position:	31 … 7	6	5	4	3	2	1	0
Bit field:	—	RFREQ[7:0]						
Value after reset:	0 … 0	0	0	1	0	1	1	1	1

Bit	Symbol	Function	R/W
7:0	RFREQ[7:0]	Reference Clock Frequency Setting Set the frequency of the peripheral module clock (PCLKA).*1 PCLKA is used for the reference clock of the counter circuit which controls the internal timing of the D-PHY module. 0x27: 40 MHz*2 0x28: 41 MHz 0x29: 42 MHz ⋮ 0x75: 118 MHz 0x76: 119 MHz 0x77: 120 MHz Others: Settings prohibited.	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Remove digits after decimal point.
e.g.) PCLKA: 100.5 MHz → RFREQ[7:0] = 01100011b (100 MHz)
Note 2. Frequency of PCLKA must be 40 MHz or more to use MIPI DSI function. Therefore, when using the MIPI DSI function, the operating power control mode of the system must also be set to high-speed-mode (OPCCR.OPCM[1:0] = 00b).

RFREQ[7:0] bits (Reference Clock Frequency Setting)

Set the RFREQ[7:0] bits to the frequency of the peripheral module clock (PCLKA).*1

PCLKA is used for the reference clock of the counter circuit which controls the internal timing of the D-PHY module.

57.2.2 DPHYPLFCR : D-PHY PLL Frequency Control Register

Base address: MIPI_PHY0 = 0x4034_6C00
MIPI_PHY0_NS = 0x5034_6C00

Offset address: 0x004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	NMUL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1	1

Bit field:	—	—	—	—	—	—	NFMUL[1:0]		—	—	—	—	—	—	IDIV[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	IDIV[1:0]	D-PHY PLL Input Frequency Division Ratio Select 0 0: 1 0 1: 1/2 1 0: 1/3 1 1: 1/4	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
9:8	NFMUL[1:0]	D-PHY PLL Frequency Multiplication Factor Select (Fractional Part) 0 0: 0.00 0 1: 0.33 1 0: 0.66 1 1: 0.50	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
23:16	NMUL[7:0]	D-PHY PLL Frequency Multiplication Factor Select (Integer Part) 0x13: 20 0x14: 21 0x15: 22 ⋮ 0x62: 99 0x63: 100 0x64: 101 ⋮ 0xB1: 178 0xB2: 179 0xB3: 180 Others: Setting prohibited	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

IDIV[1:0] bits (D-PHY PLL Input Frequency Division Ratio Select)

The IDIV[1:0] bits control the input division ratio I for D-PHY PLL.*1*2*3

NFMUL[1:0] bits (D-PHY PLL Frequency Multiplication Factor Select (Fractional Part))

The NFMUL[1:0] bits control the fractional part NF of the multiplication factor for D-PHY PLL.*2*3

NMUL[7:0] bits (D-PHY PLL Frequency Multiplication Factor Select (Integer Part))

The NMUL[7:0] bits control the integer part N of the multiplication factor for D-PHY PLL. *2*3

The frequency of the PLL output clock ($f_{DPHYPLL}$) can be calculated by the following fomula.

$f_{DPHYPLL}$ [MHz] = f_{MAIN} [MHz] × I × (NF + N)

Where, f_{MAIN} is the frequency of Main clock oscillator.

The D-PHY High-Speed data transmission rate is determined by the following formula:

Line rate [Mbps] = $f_{DPHYPLL}$ [MHz] / 2

e.g.)

In the case of f_{MAIN} = 24.576 MHz, IDIV[1:0] = 01b, NFMUL[1:0] = 11b, NMUL[7:0] = 0x63

$f_{DPHYPLL}$ = 24.576 [MHz] × 1/2 × (0.50 + 100) = 1235 [MHz]

Line rate [Mbps] = $f_{DPHYPLL}$ / 2 = 1235 MHz / 2 = 617.47 Mbps

Note 1. IDIV[1:0] must be set so that the frequency of the clock divided by IDIV[1:0] is within the range that is between 8 to 24 MHz. However, under the condition of 160 MHz ≤ PLL output clock ($f_{DPHYPLL}$) < 320 MHz, the allowable frequency range of the clock divided by IDIV[1:0] is extended to 5 to 24 MHz.

Note 2. DPHYPLFCR must be set so that the frequency of the PLL output clock ($f_{DPHYPLL}$) is within the range that is between 160 MHz to 1.44 GHz.

Note 3. DPHYPLFCR must be set while D-PHY PLL operation is stopped (DPHYPLOCR. PLLSTP = 1).

57.2.3 DPHYPLOCR : D-PHY PLL Operation Control Register

Base address: MIPI_PHY0 = 0x4034_6C00
MIPI_PHY0_NS = 0x5034_6C00

Offset address: 0x008

Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PLLSTP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	PLLSTP	D-PHY PLL Operation Control 0: Operate the PLL 1: Stop the PLL	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

PLLSTP bit (D-PHY PLL Operation Control)

The PLLSTP bit controls the operation permission of the D-PHY PLL.

57.2.4 DPHYESCCR : D-PHY Escape Mode Clock Control Register

Base address: MIPI_PHY0 = 0x4034_6C00
MIPI_PHY0_NS = 0x5034_6C00

Offset address: 0x00C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ESCDIV[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	ESCDIV[4:0]	Escape Mode Transfer Clock Division Ratio 0x00: ×1/1 0x01: ×1/2 0x02: ×1/3 0x03: ×1/4 ⋮ 0x1D: ×1/30 0x1E: ×1/31 0x1F: ×1/32	R/W
31:5	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

ESCDIV[4:0] bits (Escape Mode Transfer Clock Division Ratio)

The ESCDIV[4:0] bits control the division ratio for Low-Power state clock which is use for Escape Mode Transfer.

The frequency of Low-Power state clock can be calculated by the following formula:

$f_{LPCLK} = f_{DPHYPLL} \times (1/16) \times (\text{division ratio set by ESCDIV[4:0]})^{*1*2*3}$

Note 1. These bits should be set so that the ratio of $T_{LPX\ (MASTER)}$/ $T_{LPX\ (SLAVE)}$ between this device and slave side is in the range of 2/3 to 3/2.

$T_{LPX\ (MASTER)} = 1 / f_{LPCLK}$

$T_{LPX\ (SLAVE)}$ is Transmitted length of any Low-Power state period on peripheral.

Note 2. These bits should be set so that the frequency of escape mode transfer clock (f_{LPX}) in this device is in the range of 2 to 17 MHz.

Note 3. These bits must be set while D-PHY PLL operation is stopped (DPHYPLOCR. PLLSTP = 1).

57.2.5 DPHYPWRCR : D-PHY Power Supplying Control Register

Base address: MIPI_PHY0 = 0x4034_6C00
MIPI_PHY0_NS = 0x5034_6C00

Offset address: 0x010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PWRSEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PWRSEN	D-PHY Power Supplying Control 0: Disable D-PHY LDO operation (stop supplying VDD_DPHY) 1: Enable D-PHY LDO operation (supply VDD_DPHY)	R/W

Bit	Symbol	Function	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

PWRSEN bit (D-PHY Power Supplying Control)

The PWRSEN bit controls the operation permission of the D-PHY LDO.

57.2.6 DPHYSFR : D-PHY Status Flag Register

Base address: MIPI_PHY0 = 0x4034_6C00
MIPI_PHY0_NS = 0x5034_6C00

Offset address: 0x01C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	PLLSF	—	—	—	—	—	—	—	PWRSF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PWRSF	D-PHY LDO Power-on Status Flag 0: D-PHY LDO is stopped or starting up 1: D-PHY LDO startup is completed (VDD_DPHY is stable)	R
7:1	—	These bits are read as 0.	R
8	PLLSF	D-PHY PLL Oscillation Stabilization Flag 0: D-PHY PLL clock is stopped or is not yet stable 1: D-PHY PLL clock is stable	R
31:9	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

PWRSF flag (D-PHY LDO Power-on Status Flag)

The PWRSF flag indicates whether the operation of the D-PHY LDO has stabilized or not.

PLLSF flag (D-PHY PLL Oscillation Stabilization Flag)

The PLLSF flag indicates whether the oscillation of the D-PHY PLL has stabilized or not.

57.2.7 DPHYOCR : D-PHY Operation Control Register

Base address: MIPI_PHY0 = 0x4034_6C00
MIPI_PHY0_NS = 0x5034_6C00

Offset address: 0x020

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DPHYEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DPHYEN	D-PHY Operation Control 0: Disable D-PHY operation 1: Enable D-PHY operation	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

DPHYEN bit (D-PHY Operation Control)

The DPHYEN bit controls the operation permission of the D-PHY.

57.2.8 DPHYTIM1 : D-PHY Timing Control Register 1

Base address: MIPI_PHY0 = 0x4034_6C00
MIPI_PHY0_NS = 0x5034_6C00

Offset address: 0x024

Bit position:	31													18													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	TINIT[18:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1	1	0	0	1	0	1	0	0	0	0	0	1

Bit	Symbol	Function	R/W
18:0	TINIT[18:0]	D-PHY T_INIT Parameter Setting Set the D-PHY TINIT parameter.	R/W
31:19	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

TINIT[18:0] bits (D-PHY T_INIT Parameter Setting)

The TINIT[18:0] bits specify the T_{INIT} parameter, which is the minimum duration of the TINIT state.

The time is calculated by the following formula:

T_{INIT} = (TINIT[18:0] + 1) × (period of the peripheral module clock (PCLKA))

When the frequency of PCLK is 120 MHz, the default value is below.

T_{INIT} = (72001 + 1) × 8.333 [ns] = 600 [µs]

57.2.9 DPHYTIM2 : D-PHY Timing Control Register 2

Base address: MIPI_PHY0 = 0x4034_6C00
MIPI_PHY0_NS = 0x5034_6C00

Offset address: 0x028

Bit position:	31																							7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TCLKPREP[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	1	0	0	0	0	0	0	0	0	1	0	0	0

Bit	Symbol	Function	R/W
7:0	TCLKPREP[7:0]	D-PHY T_CLK_PREPARE Parameter Setting Set the D-PHY $T_{CLK\text{-}PREPARE}$ parameter shown in Figure 57.1.	R/W
11:8	—	These bits are read as 0. The write value should be 0.	R/W
12	—	This bit is read as 1. The write value should be 1.	R/W
16:13	—	These bits are read as 0. The write value should be 0.	R/W
17	—	This bit is read as 1. The write value should be 1.	R/W

Bit	Symbol	Function	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

TCLKPREP[7:0] bits (D-PHY T_CLK_PREPARE Parameter Setting)

The TCLKPREP[7:0] bits specify the $T_{CLK\text{-}PREPARE}$ parameter, which is the duration of the LP-00 state (immediately before entry to the HS-0 state) in the clock lane. See Figure 57.1.

The time is calculated by the following formula:

$T_{CLK\text{-}PREPARE}$ = (TCLKPREP[7:0] + 1) × (period of the peripheral module clock (PCLKA))

When the frequency of PCLK is 120 MHz, the default value is below.

$T_{CLK\text{-}PREPARE}$ = (8 + 1) × 8.333 [ns] = 75 [ns]

57.2.10 DPHYTIM3 : D-PHY Timing Control Register 3

Base address: MIPI_PHY0 = 0x4034_6C00
MIPI_PHY0_NS = 0x5034_6C00

Offset address: 0x02C

Bit position:	31																						7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	THSPREP[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0

Bit	Symbol	Function	R/W
7:0	THSPREP[7:0]	D-PHY T_THS_PREPARE Parameter Setting Set the D-PHY $T_{HS\text{-}PREPARE}$ parameter shown in Figure 57.1.	R/W
11:8	—	These bits are read as 0. The write value should be 0.	R/W
12	—	This bit is read as 1. The write value should be 1.	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

THSPREP[7:0] bits (D-PHY T_THS_PREPARE Parameter Setting)

The THSPREP[7:0] bits specify the $T_{HS\text{-}PREPARE}$ parameter, which is the duration of the LP-00 state (immediately before entry to the HS-0 state) in the data lane. See Figure 57.1.

The time is calculated by the following formula:

$T_{HS\text{-}PREPARE}$ = (THSPREP[7:0] + 1) × (period of the peripheral module clock (PCLKA))

When the frequency of PCLK is 120 MHz, the default value is below.

$T_{HS\text{-}PREPARE}$ = (8 + 1) × 8.333 [ns] = 75 [ns]

57.2.11 DPHYTIM4 : D-PHY Timing Control Register 4

Base address: MIPI_PHY0 = 0x4034_6C00
MIPI_PHY0_NS = 0x5034_6C00

Offset address: 0x030

Bit position:	31							24	23							16	15							8	7						0
Bit field:	TCLKTRL[7:0]								TCLKPOST[7:0]								TCLKPRE[7:0]								TCLKZERO[7:0]							
Value after reset:	0	0	0	0	0	1	1	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	TCLKZERO[7:0]	D-PHY T_CLK_ZERO Parameter Setting Set the D-PHY $T_{CLK-ZERO}$ parameter shown in Figure 57.1.	R/W
15:8	TCLKPRE[7:0]	D-PHY T_TCLK_PRE Parameter Setting Set the D-PHY $T_{CLK-PRE}$ parameter shown in Figure 57.1.	R/W
23:16	TCLKPOST[7:0]	D-PHY T_TCLK_POST Parameter Setting Set the D-PHY $T_{CLK-POST}$ parameter shown in Figure 57.1.	R/W
31:24	TCLKTRL[7:0]	D-PHY T_TCLK_TRAIL Parameter Setting Set the D-PHY $T_{CLK-TRAIL}$ parameter shown in Figure 57.1.	R/W

Note: S-TYPE-3, P-TYPE-3

TCLKZERO[7:0] bits (D-PHY T_CLK_ZERO Parameter Setting)

The TCLKZERO[7:0] bits specify the $T_{CLK-ZERO}$ parameter. For details, see Figure 57.1.

The time is calculated by the following formula:

$T_{CLK-ZERO}$ = (TCLKZERO[7:0] + 1) × (period of the peripheral module clock (PCLKA))

When the frequency of PCLK is 120 MHz, the default value is below.

$T_{CLK-ZERO}$ = (31 + 1) × 8.333 [ns] = 267 [ns]

TCLKPRE[7:0] bits (D-PHY T_TCLK_PRE Parameter Setting)

The TCLKPRE[7:0] bits specify the $T_{CLK-PRE}$ parameter. For details, see Figure 57.1.

The time is calculated by the following formula:

$T_{CLK-PRE}$ = (TCLKPRE[7:0] + 1) × (period of the peripheral module clock (PCLKA))

When the frequency of PCLK is 120 MHz, the default value is below.

$T_{CLK-PRE}$ = (3 + 1) × 8.333 [ns] = 33 [ns]

TCLKPOST[7:0] bits (D-PHY T_TCLK_POST Parameter Setting)

The TCLKPOST[7:0] bits specify the $T_{CLK-POST}$ parameter. For details, see Figure 57.1.

The time is calculated by the following formula:

$T_{CLK-POST}$ = (TCLKPOST[7:0] + 1) × (period of the peripheral module clock (PCLKA))

When the frequency of PCLK is 120 MHz, the default value is below.

$T_{CLK-POST}$ = (32 + 1) × 8.333 [ns] = 275 [ns]

TCLKTRL[7:0] bits (D-PHY T_TCLK_TRAIL Parameter Setting)

The TCLKTRL[7:0] bits specify the $T_{CLK-POST}$ parameter. For details, see Figure 57.1.

The time is calculated by the following formula:

$T_{CLK-TRAIL}$ = (TCLKTRL[7:0] + 1) × (period of the peripheral module clock (PCLKA))

When the frequency of PCLK is 120 MHz, the default value is below.

$T_{CLK-TRAIL}$ = (6 + 1) × 8.333 [ns] = 58 [ns]

57.2.12 DPHYTIM5 : D-PHY Timing Control Register 5

Base address: MIPI_PHY0 = 0x4034_6C00
MIPI_PHY0_NS = 0x5034_6C00

Offset address: 0x034

Bit position:	31								23								16	15							8	7							0
Bit field:	—	—	—	—	—	—	—	—	THSEXIT[7:0]									THSTRL[7:0]								THSZERO[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1	1	1	1

Bit	Symbol	Function	R/W
7:0	THSZERO[7:0]	D-PHY T_THS_ZERO Parameter Setting Set the D-PHY $T_{HS-ZERO}$ parameter shown in Figure 57.1.	R/W
15:8	THSTRL[7:0]	D-PHY T_THS_TRAIL Parameter Setting Set the D-PHY $T_{HS-TRAIL}$ parameter shown in Figure 57.1.	R/W
23:16	THSEXIT[7:0]	D-PHY T_THS_EXIT Parameter Setting Set the D-PHY $T_{HS-EXIT}$ parameter shown in Figure 57.1.	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

THSZERO[7:0] bits (D-PHY T_THS_ZERO Parameter Setting)

The THSZERO[7:0] bits specify the $T_{HS-ZERO}$ parameter. For details, see Figure 57.1.

The time is calculated by the following formula:

$T_{HS-ZERO}$ = (THSZERO[7:0] + 1) × (period of the peripheral module clock (PCLKA))

When the frequency of PCLK is 120 MHz, the default value is below.

$T_{HS-ZERO}$ = (15 + 1) × 8.333 [ns] = 133 [ns]

THSTRL[7:0] bits (D-PHY T_THS_TRAIL Parameter Setting)

The THSTRL[7:0] bits specify the $T_{HS-TRAIL}$ parameter. For details, see Figure 57.1.

The time is calculated by the following formula:

$T_{HS-TRAIL}$ = (THSTRL[7:0] + 1) × (period of the peripheral module clock (PCLKA))

When the frequency of PCLK is 120 MHz, the default value is below.

$T_{HS-TRAIL}$ = (8 + 1) × 8.333 [ns] = 75 [ns]

THSEXIT[7:0] bits (D-PHY T_THS_EXIT Parameter Setting)

The THSEXIT[7:0] bits specify the $T_{HS-EXIT}$ parameter. For details, see Figure 57.1.

The time is calculated by the following formula:

$T_{HS-EXIT}$ = (THSEXIT[7:0] + 1) × (period of the peripheral module clock (PCLKA))

When the frequency of PCLK is 120 MHz, the default value is below.

$T_{HS-EXIT}$ = (12 + 1) × 8.333 [ns] = 108 [ns]

57.2.13 DPHYTIM6 : D-PHY Timing Control Register 6

Base address: MIPI_PHY0 = 0x4034_6C00
MIPI_PHY0_NS = 0x5034_6C00

Offset address: 0x038

Bit position:	31																							7						0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TLPX[7:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

Bit	Symbol	Function	R/W
7:0	TLPX[7:0]	D-PHY T_TLPX Parameter Setting Set the D-PHY T_{LPX} parameter shown in Figure 57.1.	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

TLPX[7:0] bits (D-PHY T_TLPX Parameter Setting)

The THSZERO[7:0] bits specify the T_{LPX} parameter. For details, see Figure 57.1.

The time is calculated by the following formula:

T_{LPX} = (TLPX[7:0] + 1) × (period of the peripheral module clock (PCLKA))

When the frequency of PCLK is 120 MHz, the default value is below.

T_{LPX} = (6 + 1) × 8.333 [ns] = 58 [ns]

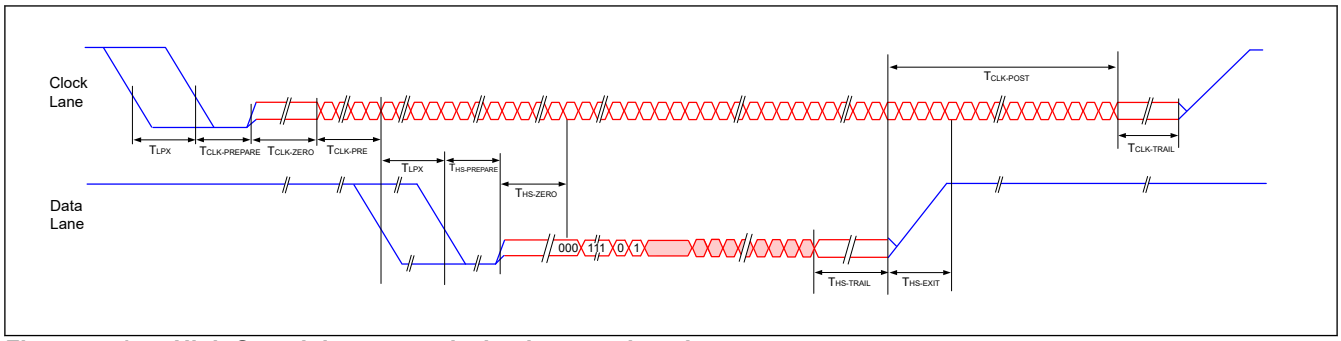

Figure 57.1 High-Speed data transmission in normal mode

Table 57.2 Recommended D-PHY timing setting for PCLKA = 120/100/80/75 [MHz] (1 of 6)

PCLKA 120MHz					
No.	Bit Name	Transmission Rate			
		80Mbps	125Mbps	250Mbps	Over 250Mbps

57.3 Operation

57.3.1 D-PHY Start-up Procedure

To use the MIPI DSI function, D-PHY must first be activated. The D-PHY has a dedicated regulator (D-PHY LDO) and PLL (D-PHY PLL), and these are activated when the D-PHY startup.

The startup procedure for the D-PHY is as follows:

Before executing the following flow, the basic register settings of GLCDC must be completed. Especially, SYSCNT_PANEL_CLK.CLKEN must be set to 1 to supply the panel clock to the DSI Host as the video clock.

1. Confirm that VDD_GD power domain is supplied power and PCLKA is supplied to the MIPI DSI subsystem.
2. Set the DPHYREFCR.RFREQ[7:0] bits for the frequency of PCLKA.
3. Set the DPHYPWRCR.PWRSEN bit to 1 to start operating the D-PHY LDO. (for supplying VDD_DPHY)
4. Wait for the start-up of VDD_DPHY while the DPHYSFR.PWRSF bit is 0.
5. Set the DPHYPLFCR register to determine the frequency of D-PHY PLL clock.
6. Set the DPHYESCCR.ESCDIV[4:0] bits to determine the frequency of the D-PHY escape mode clock.
7. Clear the DPHYPLOCR.PLLSTP bit to 0 to enable PLL operation.
8. Wait for the oscillation stabilization while the DPHYSFR.PLLSF bit is 0.
9. Set the following registers for the D-PHY timing parameters.
   (DPHYTIM1, DPHYTIM2, DPHYTIM3, DPHYTIM4, DPHYTIM5, DPHYTIM6)
10. Set the DPHYOCR.DPHYEN bit to 1 to enable D-PHY operation.

57.3.2 D-PHY Stop Procedure

To stop the D-PHY, follow the steps below.

And the D-PHY LDO is impossible to operate in the standby mode. Therefore, before going to standby mode, it is necessary to disable the D-PHY LDO operation according to follows.

1. Clear the DPHYOCR.DPHYEN bit to 0 to disable the D-PHY.
2. Set the DPHYPLOCR.PLLSTP bit to 1 to stop the PLL operation.
3. Clear the DPHYPWRCR.PWRSEN bit to 0 to disable the D-PHY LDO (Stop VDD_DPHY supply).

58. MIPI DSI

58.1 Overview

This MIPI DSI is a MIPI DSI-2 Host module.The DSI-2 Host module has a transmitter function for MIPI Alliance Specification for Display Serial Interface 2 (DSI-2). The DSI-2 Host supports MIPI Alliance Specification for Display Serial Interface 2 (DSI-2) Specification.

Table 58.1 MIPI DSI specifications

Parameter		Specifications
Compliant specification		• MIPI Alliance Specification for Display Serial Interface 2 Version 1.1 (with Errata 01) • MIPI Alliance Specification for D-PHY Version 2.1 (with Errata 01) (80 Mbps to 720 Mbps/Lane and up to 2 Lanes).
Video Mode Operation	Available input video format from GLCDC	• Parallel RGB888 (24 bits), little endian • Parallel RGB666 (18 bits), little endian • Parallel RGB565 (16 bits), little endian
	Available output format	• RGB (16 bits, 18 bits, 24 bits)
	Available video mode packet sequence	• Non-Burst Mode with Sync Pulse • Non-Burst Mode with Sync Event • Burst Mode
	Others	• Selectable Blanking Packet or LP-11 during each of blanking interval of HSA, HBP, and HFP
Command Mode Operation*1	Sequence Operation Channel-0	LP only packet generation and LP packet reception from descriptor list
	Sequence Operation Channel-1	HS or LP packet generation and LP packet reception from descriptor list
DSI Link support functions		• 1 and 2 Lane configurations • Unidirectional High-Speed mode transfer (HS-TX) • Bidirectional LP mode transfer/receipt (LP-TX / LP-RX) (Only Lane 0) • ECC/Checksum generation for Tx packet • ECC/Checksum verification and ECC error correction for Rx packet • Ultra-Low-Power mode (ULPS) • Automated power change to LP mode and return to HS mode • Automated clock stop and resume (non-continuous clock mode) • Assignment for Virtual Channel in video mode • Assignment for individual Virtual Channel for each packet in Command mode • Detection for PHY contention error and timeout error • Generation of scrambled packets • Input of TE signal
Module-stop function		Module-stop state can be set to reduce power consumption.
TrustZone Filter		Security and Privilege attribution can be set.

Note 1. Ch0 and Ch1 are exclusive.Cannot be used simultaneously.

The block diagram and I/O pins see Figure 54.1 and Table 54.1.

58.2 Register Description

Access the following registers only in units of 32 bits.

58.2.1 ISR : Interrupt Status Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	PPI	—	—	—	FERR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	RCV	—	—	—	VM	—	—	—	SQ1	—	—	—	SQ0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SQ0	Sequence Channel-0 Interrupt Flag 0: No interrupt detected 1: Sequence Operation Channel-0 interrupt detected	R
3:1	—	These bits are read as 0.	R
4	SQ1	Sequence Channel-1 Interrupt Flag 0: No interrupt detected 1: Sequence Operation Channel-1 interrupt detected	R
7:5	—	These bits are read as 0.	R
8	VM	Video Mode Interrupt Flag 0: No interrupt detected 1: Video Mode interrupt detected	R
11:9	—	These bits are read as 0.	R
12	RCV	Receive Interrupt Flag 0: No interrupt detected 1: Receive interrupt detected	R
15:13	—	These bits are read as 0.	R
16	FERR	Fatal Error Interrupt Flag 0: No interrupt detected 1: Fatal Error interrupt detected	R
19:17	—	These bits are read as 0.	R
20	PPI	PPI Interrupt Flag 0: No interrupt detected 1: PPI interrupt detected	R
31:21	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

SQ0 bit (Sequence Channel-0 Interrupt Flag)

The SQ0 flag indicates that the Sequence Operation Channel-0 interrupt is detected. The Sequence Operation Channel-0 interrupt is an interrupt shown in the SQCH0SR register.

The SQ0 flag is set to 1 when any one of the flags of the SQCH0SR register elements is set. For details, see section 58.2.54. SQCH0SR : Sequence Channel 0 Status Register.

SQ1 bit (Sequence Channel-1 Interrupt Flag)

The SQ1 flag indicates that the Sequence Operation Channel-1 interrupt is detected. The Sequence Operation Channel-1 interrupt is an interrupt shown in the SQCH1SR register.

The SQ1 flag is set to 1 when any one of the flags of the SQCH1SR register elements is set. For details, see section 58.2.58. SQCH1SR : Sequence Channel 1 Status Register.

VM bit (Video Mode Interrupt Flag)

The VM flag indicates that the Video Mode interrupt is detected. The Video Mode interrupt is an interrupt shown in the VMSR register.

The VM flag is set to 1 when any one of the flags of the VMSR register elements is set. For details, see section 58.2.45. VMSR : Video Mode Status Register.

RCV bit (Receive Interrupt Flag)

The RCV flag indicates that the Receive interrupt is detected. The Receive interrupt is an interrupt shown in the RXSR register.

The RCV flag is set to 1 when any one of the flags of the RXSR register elements is set. For details, see section 58.2.14. RXSR : Receive Status Register.

FERR bit (Fatal Error Interrupt Flag)

The FERR flag indicates that the Fatal Error interrupt is detected. The Fatal Error interrupt is an interrupt shown in the FERRSR register.

The FERR flag is set to 1 when any one of the flags of the FERRSR register elements is set. For details, see section 58.2.35. FERRSR : Fatal Error Status Register.

PPI bit (PPI Interrupt Flag)

The PPI flag indicates that the PPI interrupt is detected. The PPI interrupt is an interrupt shown in the PLSR register.

The PPI flag is set to 1 when any one of the flags of the PLSR register elements is set. For details, see section 58.2.40. PLSR : Physical Lane Status Register.

58.2.2 LINKSR : Link Status Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	LPBUSY	HSBUSY	—	—	—	VRUN	—	—	—	SQ1RUN	—	—	—	SQ0RUN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SQ0RUN	Sequence Channel-0 Running Flag 0: Sequence Operation Channel-0 stopped 1: Sequence Operation Channel-0 in operation	R
3:1	—	These bits are read as 0.	R
4	SQ1RUN	Sequence Channel-1 Running Flag 0: Sequence Operation Channel-1 stopped 1: Sequence Operation Channel-1 in operation	R
7:5	—	These bits are read as 0.	R
8	VRUN	Video Mode Operation Running Flag 0: Video mode stopped 1: Video mode in operation	R
11:9	—	These bits are read as 0.	R

Bit	Symbol	Function	R/W
12	HSBUSY	HS Operation Busy Flag 0: HS mode stopped 1: HS mode in operation	R
13	LPBUSY	LP Operation Busy Flag 0: LP mode stopped 1: LP mode in operation	R
15:14	—	These bits are read as 0.	R
20:16	—	The read values are undefined.	R
23:21	—	These bits are read as 0.	R
28:24	—	The read values are undefined.	R
31:29	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

SQ0RUN bit (Sequence Channel-0 Running Flag)

The SQ0RUN flag is a copy of the SQCH0SR.RUNNING flag. The meaning also is same. For details, see section 58.2.54. SQCH0SR : Sequence Channel 0 Status Register.

SQ1RUN bit (Sequence Channel-1 Running Flag)

The SQ1RUN flag is a copy of the SQCH1SR.RUNNING flag. The meaning also is the same. For details, see section 58.2.58. SQCH1SR : Sequence Channel 1 Status Register.

VRUN bit (Video Mode Operation Running Flag)

The VRUN flag is a copy of the VMSR.RUNNING bit. The meaning also is the same. For details, see section 58.2.45. VMSR : Video Mode Status Register.

HSBUSY bit (HS Operation Busy Flag)

The HSBUSY flag indicates that an operation related to HS mode is running.

LPBUSY bit (LP Operation Busy Flag)

The LPBUSY flag indicates that an operation related to LP mode is running.

58.2.3 TXSETR : Transmit Set Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x100

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	DLEN	CLEN	—	—	—	—	—	—	NUMLANE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
1:0	NUMLANE[1:0]	Number of Lane Set the number of lanes for use. 0 0: 1 Lane (Use of Lane-0) 0 1: 2 Lane (Use of Lane-0 and Lane-1) Others Setting prohibited	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
8	CLEN	Clock Lane Enable 0: Disable 1: Enable	R/W
9	DLEN	Data Lane Enable 0: Disable 1: Enable	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
16	—	This bit is read as 1. The write value should be 1.	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register can only be set to change during the initialization at initial startup or Software Reset process (section 58.3.2. Software Reset).

NUMLANE[1:0] bits (Number of Lane)

NUMLANE[1:0] bits control the number of lanes to be used. Set the number of lanes for use.

CLEN bit (Clock Lane Enable)

The CLEN bit controls a Clock Lane of D-PHY. Set the CLEN bit to 1 to enable the Clock Lane.

DLEN bit (Data Lane Enable)

The DLEN bit controls Data Lanes of D-PHY. When the DLEN bit is set to 1, the Data Lanes specified by the NUMLANE[1:0] bits are enabled.

58.2.4 HSCLKSETR : HS Clock Set Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x104

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	HSCLMD	HSCLST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	HSCLST	HS Clock Start 0: Stop HS transmission (keep LP state) 1: Start HS transmission	R/W
1	HSCLMD	HS Clock Running Mode 0: Non-continuous clock mode 1: Continuous clock mode	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

HSCLST bit (HS Clock Start)

The HSCLST bit controls the HS transmission from Clock Lane. When HSCLST = 1, the HS clock is transferred from the Clock Lane according to the setting of the HSCLMD bit.

It is prohibited to set the HSCLST bit to 1 when TXSETR.CLEN = 0.

HSCLMD bit (HS Clock Running Mode)

The HSCLMD bit controls the HS transmission mode from Clock Lane.

When HSCLMD = 0, the HS clock is transferred from the Clock Lane only when the HS transmit is requested (Non-continuous clock mode).

When HSCLMD = 1, the Clock Lane keeps the HS transmission (Continuous clock mode).

It is prohibited to change the setting of the HSCLMD bit when HSCLST = 1.

58.2.5 ULPSSETR : ULPS Set Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x108

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WKUP[7:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	WKUP[7:0]	ULPS Wakeup Period Set the T_{WAKEUP} period of ULPS.	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register can only be set to change during the initialization at initial startup or Software Reset process (section 58.3.2. Software Reset).

WKUP[7:0] bits (ULPS Wakeup Period)

The WKUP[7:0] bits control the T_{WAKEUP} period during which DSI Host drives a Mark-1 state prior to a Stop state in order to initiate an exit from ULPS.

This period is calculated by the following formula:

$T_{WAKEUP}[ms]^{*1} = WKUP[7:0] \times 128 \times (1 / f_{LPCLK}[MHz]^{*2}) / 1000$

Note 1. This period should be more than 1 ms.
Note 2. f_{LPCLK} is the frequency of the Low-Power mode clock (LPCLK).

58.2.6 ULPSCR : ULPS Control Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x10C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	DLEXIT	DLENT	—	—	CLEXIT	CLENT	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
23:0	—	These bits are read as 0. The write value should be 0.	W

Bit	Symbol	Function	R/W
24	CLENT	CL ULPS Enter 0: No operation 1: Transition Clock Lane to ULPS	W
25	CLEXIT	CL ULPS Exit 0: No operation 1: Clock Lane exits from ULPS	W
27:26	—	These bits are read as 0. The write value should be 0.	W
28	DLENT	DL ULPS Enter 0: No operation 1: Transition Data Lanes to ULPS	W
29	DLEXIT	DL ULPS Exit 0: No operation 1: Data Lanes exit from ULPS	W
31:30	—	These bits are read as 0. The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

CLENT bit (CL ULPS Enter)

The CLENT bit controls the transition of the Clock Lane to Ultra-low Power State (ULPS).

Set the CLENT bit to 1 during the period when the HSCLKSETR.HSCLST bit is 0.

It is prohibited to set the CLENT bit to 1 when Clock Lane is in ULPS.

CLEXIT bit (CL ULPS Exit)

The CLEXIT bit controls the exit of the Clock Lane from Ultra-low Power State (ULPS).

It is prohibited to set the CLEXIT bit to 1 when the Clock Lane is not in ULPS.

DLENT bit (DL ULPS Enter)

The DLENT bit controls the transition of the Data Lanes to Ultra-low Power State (ULPS).

It is prohibited to set the DLENT bit to 1 when the Data Lanes is in ULPS.

DLEXIT bit (DL ULPS Exit)

The DLEXIT bit controls the exit of the Data Lanes from Ultra-low Power State (ULPS).

It is prohibited to set the DLEXIT bit to 1 when the Data Lanes is not in ULPS.

58.2.7 RSTCR : Reset Control Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x110

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FTXSTP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SWRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SWRST	Software Reset 0: Complete the Software Reset 1: Request a Software Reset	R/W

Bit	Symbol	Function	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W
16	FTXSTP	Force Tx Stop Mode 0: Finish the Force Stop state 1: Force Data Lanes into transmit mode and generate Stop state	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SWRST bit (Software Reset)

The SWRST bit is used to request a software reset. See section 58.3.2. Software Reset for the software reset procedure.

FTXSTP bit (Force Tx Stop Mode)

When FTXSTP = 1, the Data Lanes immediately transitions into transmit mode and is forced into the Stop state.

It is prohibited to set the FTXSTP bit to 1 when SWRST = 0. The FTXSTP bit is set during the software reset procedure. See section 58.3.2. Software Reset for the software reset procedure.

58.2.8 RSTSR : Reset Status Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x114

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	DL0DIR	Data Lane-0 Direction 0: TX mode 1: RX mode	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

RSTHS bit (HS Software Reset Status)

The RSTHS bit indicates the state of the HS mode initialization process by software reset, which is caused by setting the RSTCR.SWRST bit to 1.

RSTLP bit (LP Software Reset Status)

The RSTLP bit indicates the state of the LP mode initialization process by software reset, which is caused by setting the RSTCR.SWRST bit to 1.

RSTAPB bit (APB Software Reset Status)

The RSTAPB bit indicates the state of the APB initialization process by software reset, which is caused by setting the RSTCR.SWRST bit to 1.

RSTAXI bit (AXI Software Reset Status)

The RSTAXI bit indicates the state of the AXI initialization process by software reset, which is caused by setting the RSTCR.SWRST bit to 1.

RSTV bit (Video Software Reset Status)

The RSTV bit indicates the state of the Video initialization process by software reset, which is caused by setting the RSTCR.SWRST bit to 1.

DL0STP bit (Data Lane-0 Stop Status)

The DL0STP bit indicates the Stop state of the Data Lane-0. The DL0STP bit is a copy of the PLSR.DL0STP bit. The meaning also is same. See section 58.2.40. PLSR : Physical Lane Status Register for details on the PLSR.DL0STP bit.

DL1STP bit (Data Lane-1 Stop Status)

The DL1STP bit indicates the Stop state of the Data Lane-1. The DL1STP bit is a copy of the PLSR.DL1STP bit. The meaning also is same. See section 58.2.40. PLSR : Physical Lane Status Register for details on the PLSR.DL1STP bit.

DL0DIR bit (Data Lane-0 Direction)

The DL0DIR bit indicates the direction of the Data Lane-0. The DL0DIR bit is a copy of the PLSR.DL0DIR bit. The meaning also is same. See section 58.2.40. PLSR : Physical Lane Status Register for details on the PLSR.DL0DIR bit.

58.2.9 DSISETR : DSI Set Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x120

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	EOTPEN	EXTEMD	SCREN	—	—	—	—	—	VC3CRCEN	VC2CRCEN	VC1CRCEN	VC0CRCEN	—	—	—	ECCEN
Value after reset:	1	0	0	0	0	0	0	0	1	1	1	1	0	0	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MRPSZ[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
15:0	MRPSZ[15:0]	Maximum Return Packet Size Set the maximum return packet size.	R/W
16	ECCEN	ECC Check Enable 0: Disable 1: Enable	R/W
19:17	—	These bits are read as 0. The write value should be 0.	R/W
20	VC0CRCEN	VC-0 CRC Check Enable 0: Disable 1: Enable	R/W
21	VC1CRCEN	VC-1 CRC Check Enable 0: Disable 1: Enable	R/W
22	VC2CRCEN	VC-2 CRC Check Enable 0: Disable 1: Enable	R/W
23	VC3CRCEN	VC-3 CRC Check Enable 0: Disable 1: Enable	R/W
28:24	—	These bits are read as 0. The write value should be 0.	R/W
29	SCREN	Data Scramble Enable 0: Disable 1: Enable	R/W
30	EXTEMD	External Tearing Effect Detection Sense Select 0: Rising edge 1: Falling edge	R/W
31	EOTPEN	HS Transfer EoTp Enable 0: Disable 1: Enable	R/W

Note: S-TYPE-3, P-TYPE-3

This register can only be set to change during the initialization at initial startup or Software Reset process (section 58.3.2. Software Reset).

MRPSZ[15:0] bits (Maximum Return Packet Size)

The MRPSZ[15:0] bits specify the maximum packet size to be received in LP-RX mode.

If the WC of the returned long packet exceeds the value of the MRPSZ[15:0] bits, Return Packet Size Error is occurred and the RXSR.RSIZEERR flag is set to 1. In this case, no data will be stored in the memory area.

It is prohibited to set the MMRPSZ[15:0] bits to 0.

ECCEN bit (ECC Check Enable)

The ECCEN bit controls the ECC check permission. To enable the ECC check, set the ECCEN bit to 1.

VC0CRCEN bit (VC-0 CRC Check Enable)

The VC0CRCEN bit controls the CRC check permission for Virtual Channel-0 (VC-0). To enable the CRC check for VC-0, set the VC0CRCEN bit to 1.

VC1CRCEN bit (VC-1 CRC Check Enable)

The VC1CRCEN bit controls the CRC check permission for Virtual Channel-1 (VC-1). To enable the CRC check for VC-1, set the VC1CRCEN bit to 1.

VC2CRCEN bit (VC-2 CRC Check Enable)

The VC2CRCEN bit controls the CRC check permission for Virtual Channel-2 (VC-2). To enable the CRC check for VC-2, set the VC2CRCEN bit to 1.

VC3CRCEN bit (VC-3 CRC Check Enable)

The VC3CRCEN bit controls the CRC check permission for Virtual Channel-3 (VC-3). To enable the CRC check for VC-3, set the VC3CRCEN bit to 1.

SCREN bit (Data Scramble Enable)

The SCREN bit controls the data scrambling permission. If the peripheral device does not have a scrambling function, do not set the SCREN bit to 1.

EXTEMD bit (External Tearing Effect Detection Sense Select)

The EXTEMD bit controls the detection edge of the External Tearing Effect (DSI_TE pin) input.

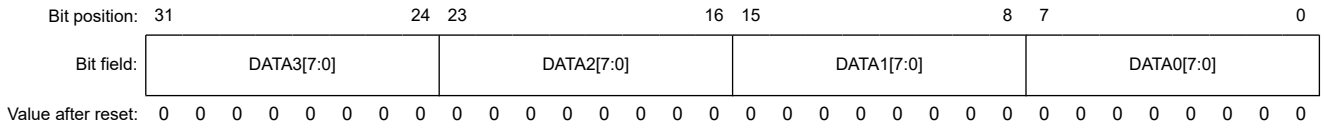
EOTPEN bit (HS Transfer EoTp Enable)

The EOTPEN bit controls the permission of the EoTp transfer in HS-TX mode. To enable to transfer EoTp, set the EOTPEN bit to 1. EoTp is always disabled in LP-TX mode.

58.2.10 TXPPD0R : Transmit Packet Payload Data 0 Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x160



Bit	Symbol	Function	R/W
7:0	DATA0[7:0]	Payload Data 0 Set the Long Packet Payload Data 0 to be transferred in Command mode.*1	R/W
15:8	DATA1[7:0]	Payload Data 1 Set the Long Packet Payload Data 1 to be transferred in Command mode.*1	R/W
23:16	DATA2[7:0]	Payload Data 2 Set the Long Packet Payload Data 2 to be transferred in Command mode.*1	R/W
31:24	DATA3[7:0]	Payload Data 3 Set the Long Packet Payload Data 3 to be transferred in Command mode.*1	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. These bits are valid when the SQCHnDSCmAR.FMT bit is set to 1 and the SQCHnDSCmBR.DTSEL[1:0] bits are set to 00b.

DATA0[7:0] bits (Payload Data 0)

TheDATA0[7:0] bits are used to store the Long Packet payload (Data 0) to be transferred in Command mode using Sequence operation.

DATA1[7:0] bits (Payload Data 1)

TheDATA1[7:0] bits are used to store the Long Packet payload (Data 1) to be transferred in Command mode using Sequence operation.

DATA2[7:0] bits (Payload Data 2)

TheDATA2[7:0] bits are used to store the Long Packet payload (Data 2) to be transferred in Command mode using Sequence operation

DATA3[7:0] bits (Payload Data 3)

TheDATA3[7:0] bits are used to store the Long Packet payload (Data 3) to be transferred in Command mode using Sequence operation.

58.2.11 TXPPD1R : Transmit Packet Payload Data 1 Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x164

Bit position:	31							24	23							16	15							8	7							0

Bit	Symbol	Function	R/W
23:16	DATA10[7:0]	Payload Data 10 Set the Long Packet Payload Data 10 to be transferred in Command mode.*1	R/W
31:24	DATA11[7:0]	Payload Data 11 Set the Long Packet Payload Data 11 to be transferred in Command mode.*1	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. These bits are valid when the SQCHnDSCmAR.FMT bit is set to 1 and the SQCHnDSCmBR.DTSEL[1:0] bits are set to 00b.

DATA8[7:0] bits (Payload Data 8)

The DATA8[7:0] bits are used to store the Long Packet payload (Data 8) to be transferred in Command mode using Sequence operation.

DATA9[7:0] bits (Payload Data 9)

The DATA9[7:0] bits are used to store the Long Packet payload (Data 9) to be transferred in Command mode using Sequence operation.

DATA10[7:0] bits (Payload Data 10)

The DATA10[7:0] bits are used to store the Long Packet payload (Data 10) to be transferred in Command mode using Sequence operation.

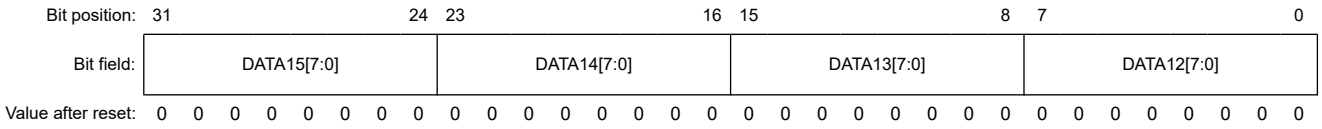
DATA11[7:0] bits (Payload Data 11)

The DATA11[7:0] bits are used to store the Long Packet payload (Data 11) to be transferred in Command mode using Sequence operation.

58.2.13 TXPPD3R : Transmit Packet Payload Data 3 Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x16C



Bit	Symbol	Function	R/W
7:0	DATA12[7:0]	Payload Data 12 Set the Long Packet Payload Data 12 to be transferred in Command mode.*1	R/W
15:8	DATA13[7:0]	Payload Data 13 Set the Long Packet Payload Data 13 to be transferred in Command mode.*1	R/W
23:16	DATA14[7:0]	Payload Data 14 Set the Long Packet Payload Data 14 to be transferred in Command mode.*1	R/W
31:24	DATA15[7:0]	Payload Data 15 Set the Long Packet Payload Data 15 to be transferred in Command mode.*1	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. These bits are valid when the SQCHnDSCmAR.FMT bit is set to 1 and the SQCHnDSCmBR.DTSEL[1:0] bits are set to 00b.

DATA12[7:0] bits (Payload Data 12)

The DATA12[7:0] bits are used to store the Long Packet payload (Data 12) to be transferred in Command mode using Sequence operation.

DATA13[7:0] bits (Payload Data 13)

The DATA13[7:0] bits are used to store the Long Packet payload (Data 13) to be transferred in Command mode using Sequence operation.

DATA14[7:0] bits (Payload Data 14)

The DATA14[7:0] bits are used to store the Long Packet payload (Data 14) to be transferred in Command mode using Sequence operation.

DATA15[7:0] bits (Payload Data 15)

The DATA15[7:0] bits are used to store the Long Packet payload (Data 15) to be transferred in Command mode using Sequence operation.

58.2.14 RXSR : Receive Status Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x200

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit field:	EXTEDET	RXACK	—	—	—	RXEOTP	—	RXRESP	—	—	—	—	—	TATO	LRXHTO	BTAREND
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BTAREND	BTA Request End Interrupt Flag 0: Not detected 1: BTA Completion detected	R
1	LRXHTO	LP-RX Host Processor Timeout Interrupt Flag 0: Not detected 1: LP-RX Host Processor Timeout (LRX-H_TO) detected	R
2	TATO	Turnaround Acknowledge Timeout Interrupt Flag 0: Not detected 1: Turnaround Acknowledge Timeout (TA_TO) detected	R
7:3	—	These bits are read as 0.	R
8	RXRESP	Response Packet Receive Interrupt Flag 0: No response received 1: Response packet received	R
9	—	This bit is read as 0.	R
10	RXEOTP	EoTp Receive Interrupt Flag 0: No received 1: EoTp received	R
13:11	—	These bits are read as 0.	R
14	RXACK	ACK Trigger Receive Interrupt Flag 0: No trigger received 1: ACK trigger received	R
15	EXTEDET	External Tearing Effect Detect Interrupt Flag 0: Not detected 1: External Tearing Effect detected	R
16	MLFERR	Malform Error Interrupt Flag 0: No error received 1: A packet of less than 4 bytes received	R
17	ECCERRM	Multi Bit ECC Error Interrupt Flag 0: No error detected 1: A multi-bit ECC error detected	R

Bit	Symbol	Function	R/W
18	UNEXERR	Unexpected Packet Error Interrupt Flag 0: No error 1: Unexpected packet received	R
19	—	This bit is read as 0.	R
20	WCERR	Word Count Error Interrupt Flag 0: No error detected 1: The length of the received packet is shorter than the WC indicated in the packet header.	R
21	CRCERR	CRC Error Interrupt Flag 0: No error detected 1: CRC error detected	R
22	IBERR	Internal Bus Error Interrupt Flag 0: No error detected 1: Internal AXI bus write failed	R
23	RXOVFERR	Receive Buffer Overflow Error Interrupt Flag 0: No error detected 1: A buffer overflow error detected on receiving long packets	R
24	PRTOERR	Peripheral Response Timeout Error Interrupt Flag 0: No error occurred 1: Peripheral response timeout occurred	R
25	NORESERR	No Response Error Interrupt Flag 0: No error occurred 1: No triggers or packets returned during BTA period	R
26	RSIZEERR	Return Packet Size Error Interrupt Flag 0: No error detected 1: Oversize error in a received long packet detected	R
27	—	This bit is read as 0.	R
28	ECCERRS	Single Bit ECC Error Interrupt Flag 0: No error detected 1: A single-bit ECC error detected	R
29	—	This bit is read as 0.	R
30	RXAKE	Acknowledge and Error Report Receive Interrupt Flag 0: No received 1: An Acknowledge and Error Report packet received	R
31	—	This bit is read as 0.	R

Note: S-TYPE-3, P-TYPE-3

BTAREND bit (BTA Request End Interrupt Flag)

The BTAREND flag indicates that the BTA request specified by the SQCHnDSCmAR.BTA[1:0] bits is completed.

For example, if the SQCHnDSCmAR.BTA[1:0] bits are set to 10b, the BTAREND flag is set to 1 after the reception of the response packet to read request following the BTA is completed.

The BTAREND flag is not cleared automatically, so set the RXSCR.BTAREND bit to 1 to clear the BTAREND flag.

LRXHTO bit (LP-RX Host Processor Timeout Interrupt Flag)

The LRXHTO flag indicates that a LP-RX Host Processor Timeout Interrupt Flag (LRX-H_TO) is detected.

The LRXHTO flag is not cleared automatically, so set the RXSCR.LRXHTO bit to 1 to clear the LRXHTO flag.

TATO bit (Turnaround Acknowledge Timeout Interrupt Flag)

The TATO flag indicates that a Turnaround Acknowledge Timeout (TA_TO) is detected.

The TATO flag is not cleared automatically, so set the RXSCR.TATO bit to 1 to clear the TATO flag.

RXRESP bit (Response Packet Receive Interrupt Flag)

The RXRESP flag indicates that a response packet is received.

The RXRESP flag is not cleared automatically, so set the RXSCR.RXRESP bit to 1 to clear the RXRESP flag.

RXEOTP bit (EoTp Receive Interrupt Flag)

The RXEOTP flag indicates that an EoTp is received.

The RXEOTP flag is not cleared automatically, so set the RXSCR.RXEOTP bit to 1 to clear the RXEOTP flag.

RXACK bit (ACK Trigger Receive Interrupt Flag)

The RXACK flag indicates that an ACK trigger is received.

The RXACK flag is not cleared automatically, so set the RXSCR.RXACK bit to 1 to clear the RXACK flag.

EXTEDET bit (External Tearing Effect Detect Interrupt Flag)

The EXTEDET flag indicates that External Tearing Effect from DSI_TE pin is detected.

The EXTEDET flag is not cleared automatically, so set the RXSCR.EXTEDET bit to 1 to clear the EXTEDET flag.

MLFERR bit (Malform Error Interrupt Flag)

The MLFERR flag indicates that a packet of less than 4 bytes is received.

The MLFERR flag is not cleared automatically, so set the RXSCR.MLFERR bit to 1 to clear the MLFERR flag.

ECCERRM bit (Multi Bit ECC Error Interrupt Flag)

The ECCERRM flag indicates that a multi-bit ECC error is detected in a received packet.

The ECCERRM flag is not cleared automatically, so set the RXSCR.ECCERRM bit to 1 to clear the ECCERRM flag.

UNEXERR bit (Unexpected Packet Error Interrupt Flag)

The UNEXERR flag indicates that an unexpected Data Type (DT) or unexpected response is received.

The UNEXERR flag is not cleared automatically, so set the RXSCR.UNEXERR bit to 1 to clear the UNEXERR flag.

WCERR bit (Word Count Error Interrupt Flag)

The WCERR flag indicates that the length of the received packet payload is shorter than the Word Count (WC) indicated in the packet header.

The WCERR flag is not cleared automatically, so set the RXSCR.WCERR bit to 1 to clear the WCERR flag.

CRCERR bit (CRC Error Interrupt Flag)

The CRCERR flag indicates that a CRC error is detected in a received packet.

The CRCERR flag is not cleared automatically, so set the RXSCR.CRCERR bit to 1 to clear the CRCERR flag.

IBERR bit (Internal Bus Error Interrupt Flag)

The IBERR flag is set to 1 when the internal AXI bus write failed.

The IBERR flag is not cleared automatically, so set the RXSCR.IBERR bit to 1 to clear the IBERR flag.

RXOVFERR bit (Receive Buffer Overflow Error Interrupt Flag)

The RXOVFERR flag is set to 1 when the receive buffer of Long Packet overflows.

The RXOVFERR flag is not cleared automatically, so set the RXSCR.RXOVFERR bit to 1 to clear the RXOVFERR flag.

PRTOERR bit (Peripheral Response Timeout Error Interrupt Flag)

The PRTOERR flag is set to 1 when the timeout for peripheral response expires after giving bus possession to the peripheral and entering in LP-RX mode. The timeout period is specified by the following registers depending on the type of Bus Turn-Around (BTA).

- PRESPTOBTASETR or
- PRESPTOLPSETR.LPRTO[15:0] or
- PRESPTOLPSETR.LPWTO[15:0] or
- PRESPTOHSSETR.HSRTO[15:0] or

- PRESPTOHSSETR.HSWTO[15:0]

The PRTOERR flag is not cleared automatically, so set the RXSCR.PRTOERR bit to 1 to clear the PRTOERR flag.

NORESERR bit (No Response Error Interrupt Flag)

The NORESERR flag is set to 1 when no trigger or packet is returned during BTA period.

The NORESERR flag is not cleared automatically, so set the RXSCR.NORESERR bit to 1 to clear the NORESERR flag.

RSIZEERR bit (Return Packet Size Error Interrupt Flag)

The RSIZEERR flag is set to 1 when the WC value of the received long packet is larger than the size set by the DSISETR.MRPSZ[15:0] bits.

The RSIZEERR flag is not cleared automatically, so set the RXSCR.RSIZEERR bit to 1 to clear the RSIZEERR flag.

ECCERRS bit (Single Bit ECC Error Interrupt Flag)

The ECCERRS flag indicates that a single-bit ECC error is detected and corrected in a received packet.

The ECCERRS flag is not cleared automatically, so set the RXSCR.ECCERRS bit to 1 to clear the ECCERRS flag.

RXAKE bit (Acknowledge and Error Report Receive Interrupt Flag)

The RXAKE flag indicates that the Acknowledge and Error Report packet is received from the peripheral.

The RXAKE flag is not cleared automatically, so set the RXSCR.RXAKE bit to 1 to clear the RXAKE flag.

58.2.15 RXSCR : Receive Status Clear Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Note: S-TYPE-3, P-TYPE-3

BTAREND bit (BTA Request End Interrupt Flag Clear)

Set the BTAREND bit to 1 to clear the RXSR.BTAREND flag.

LRXHTO bit (LP-RX Host Processor Timeout Interrupt Flag Clear)

Set the LRXHTO bit to 1 to clear the RXSR.LRXHTO flag.

TATO bit (Turnaround Acknowledge Timeout Interrupt Flag Clear)

Set the TATO bit to 1 to clear the RXSR.TATO flag.

RXRESP bit (Response Packet Receive Interrupt Flag Clear)

Set the RXRESP bit to 1 to clear the RXSR.RXRESP flag.

RXEOTP bit (EoTp Receive Interrupt Flag Clear)

Set the RXEOTP bit to 1 to clear the RXSR.RXEOTP flag.

RXACK bit (ACK Trigger Receive Interrupt Flag Clear)

Set the RXACK bit to 1 to clear the RXSR.RXACK flag.

EXTEDET bit (External Tearing Effect Detect Interrupt Flag Clear)

Set the EXTEDET bit to 1 to clear the RXSR.EXTEDET flag.

MLFERR bit (Malform Error Interrupt Flag Clear)

Set the MLFERR bit to 1 to clear the RXSR.MLFERR flag.

ECCERRM bit (Multi Bit ECC Error Interrupt Flag Clear)

Set the ECCERRM bit to 1 to clear the RXSR.ECCERRM flag.

UNEXERR bit (Unexpected Packet Error Interrupt Flag Clear)

Set the UNEXERR bit to 1 to clear the RXSR.UNEXERR flag.

WCERR bit (Word Count Error Interrupt Flag Clear)

Set the WCERR bit to 1 to clear the RXSR.WCERR flag.

CRCERR bit (CRC Error Interrupt Flag Clear)

Set the CRCERR bit to 1 to clear the RXSR.CRCERR flag.

IBERR bit (Internal Bus Error Interrupt Flag Clear)

Set the IBERR bit to 1 to clear the RXSR.IBERR flag.

RXOVFERR bit (Receive Buffer Overflow Error Interrupt Flag Clear)

Set the RXOVFERR bit to 1 to clear the RXSR.RXOVFERR flag.

PRTOERR bit (Peripheral Response Timeout Error Interrupt Flag Clear)

Set the PRTOERR bit to 1 to clear the RXSR.PRTOERR flag.

NORESERR bit (No Response Error Interrupt Flag Clear)

Set the NORESERR bit to 1 to clear the RXSR.NORESERR flag.

RSIZEERR bit (Return Packet Size Error Interrupt Flag Clear)

Set the RSIZEERR bit to 1 to clear the RXSR.RSIZEERR flag.

ECCERRS bit (Single Bit ECC Error Interrupt Flag Clear)

Set the ECCERRS bit to 1 to clear the RXSR.ECCERRS flag.

RXAKE bit (Acknowledge and Error Report Receive Interrupt Flag Clear)

Set the RXAKE bit to 1 to clear the RXSR.RXAKE flag.

30	RXAKE	Acknowledge and Error Report Receive Interrupt Enable 0: Disable 1: Enable	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

BTAREND bit (BTA Request End Interrupt Enable)

The BTAREND bit controls BTA Request End Interrupt permission. When a BTA Request End Interrupt occurs, the RXSR.BTAREND flag is set to 1.

To enable BTA Request End Interrupt, set the BTAREND bit to 1.

LRXHTO bit (LP-RX Host Processor Timeout Interrupt Enable)

The LRXHTO bit controls LP-RX Host Processor Timeout Interrupt permission. When an LP-RX Host Processor Timeout Interrupt occurs, the RXSR.LRXHTO flag is set to 1.

To enable LP-RX Host Processor Timeout Interrupt, set the LRXHTO bit to 1.

TATO bit (Turnaround Acknowledge Timeout Interrupt Enable)

The TATO bit controls Turnaround Acknowledge Timeout Interrupt permission. When a Turnaround Acknowledge Timeout Interrupt occurs, the RXSR.TATO flag is set to 1.

To enable Turnaround Acknowledge Timeout Interrupt, set the TATO bit to 1.

RXRESP bit (Response Packet Receive Interrupt Enable)

The RXRESP bit controls Response Packet Receive Interrupt permission. When a Response Packet Receive Interrupt occurs, the RXSR.RXRESP flag is set to 1.

To enable Response Packet Receive Interrupt, set the RXRESP bit to 1.

RXEOTP bit (EoTp Receive Interrupt Enable)

The RXEOTP bit controls EoTp Receive Interrupt permission. When an EoTp Receive Interrupt occurs, the RXSR.RXEOTP flag is set to 1.

To enable EoTp Receive Interrupt, set the RXEOTP bit to 1.

RXACK bit (ACK Trigger Receive Interrupt Enable)

The RXACK bit controls ACK Trigger Receive Interrupt permission. When an ACK Trigger Receive Interrupt occurs, the RXSR.RXACK flag is set to 1.

To enable ACK Trigger Receive Interrupt, set the RXACK bit to 1.

EXTEDET bit (External Tearing Effect Detect Interrupt Enable)

The EXTEDET bit controls External Tearing Effect Detect Interrupt permission. When an External Tearing Effect Detect Interrupt occurs, the RXSR.EXTEDET flag is set to 1.

To enable External Tearing Effect Detect Interrupt, set the EXTEDET bit to 1.

MLFERR bit (Malform Error Interrupt Enable)

The MLFERR bit controls Malform Error Interrupt permission. When a Malform Error Interrupt occurs, the RXSR.MLFERR flag is set to 1.

To enable Malform Error Interrupt, set the MLFERR bit to 1.

ECCERRM bit (Multi Bit ECC Error Interrupt Enable)

The ECCERRM bit controls Multi Bit ECC Error Interrupt permission. When a Multi Bit ECC Error Interrupt occurs, the RXSR.ECCERRM flag is set to 1.

To enable Multi Bit ECC Error Interrupt, set the ECCERRM bit to 1.

UNEXERR bit (Unexpected Packet Error Interrupt Enable)

The UNEXERR bit controls Unexpected Packet Error Interrupt permission. When an Unexpected Packet Error Interrupt occurs, the RXSR.UNEXERR flag is set to 1.

To enable Unexpected Packet Error Interrupt, set the UNEXERR bit to 1.

WCERR bit (Word Count Error Interrupt Enable)

The WCERR bit controls Word Count Error Interrupt permission. When a Word Count Error Interrupt occurs, the RXSR.WCERR flag is set to 1.

To enable Word Count Error Interrupt, set the WCERR bit to 1.

CRCERR bit (CRC Error Interrupt Enable)

The CRCERR bit controls CRC Error Interrupt permission. When a CRC Error Interrupt occurs, the RXSR.CRCERR flag is set to 1.

To enable CRC Error Interrupt, set the CRCERR bit to 1.

IBERR bit (Internal Bus Error Interrupt Enable)

The IBERR bit controls Internal Bus Error Interrupt permission. When an Internal Bus Error Interrupt occurs, the RXSR.IBERR flag is set to 1.

To enable Internal Bus Error Interrupt, set the IBERR bit to 1.

RXOVFERR bit (Receive Buffer Overflow Error Interrupt Enable)

The RXOVFERR bit controls Receive Buffer Overflow Error Interrupt permission. When a Receive Buffer Overflow Error Interrupt occurs, the RXSR.RXOVFERR flag is set to 1.

To enable Receive Buffer Overflow Error Interrupt, set the RXOVFERR bit to 1.

PRTOERR bit (Peripheral Response Timeout Error Interrupt Enable)

The PRTOERR bit controls Peripheral Response Timeout Error Interrupt permission. When a Peripheral Response Timeout Error Interrupt occurs, the RXSR.PRTOERR flag is set to 1.

To enable Peripheral Response Timeout Error Interrupt, set the PRTOERR bit to 1.

NORESERR bit (No Response Error Interrupt Enable)

The NORESERR bit controls No Response Error Interrupt permission. When an No Response Error Interrupt occurs, the RXSR.NORESERR flag is set to 1.

To enable No Response Error Interrupt, set the NORESERR bit to 1.

RSIZEERR bit (Return Packet Size Error Interrupt Enable)

The RSIZEERR bit controls Return Packet Size Error Interrupt permission. When a Return Packet Size Error Interrupt occurs, the RXSR.RSIZEERR flag is set to 1.

To enable Return Packet Size Error Interrupt, set the RSIZEERR bit to 1.

ECCERRS bit (Single Bit ECC Error Interrupt Enable)

The ECCERRS bit controls Single Bit ECC Error Interrupt permission. When a Single Bit ECC Error Interrupt occurs, the RXSR.ECCERRS flag is set to 1.

To enable Single Bit ECC Error Interrupt, set the ECCERRS bit to 1.

RXAKE bit (Acknowledge and Error Report Receive Interrupt Enable)

The RXAKE bit controls Acknowledge and Error Report Receive Interrupt permission. When an Acknowledge and Error Report Receive Interrupt occurs, the RXSR.RXAKE flag is set to 1.

To enable Acknowledge and Error Report Receive Interrupt, set the RXAKE bit to 1.

58.2.17 PRESPTOBTASETR : Peripheral Response Timeout BTA Set Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x210

Bit position:	31																												0
Bit field:	PRTBTA[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PRTBTA[31:0]	Peripheral Response Timeout Count Set the Peripheral Response Timeout value for Bus Turn-Around (BTA). If the setting value is 0, timeout is not detected.	R/W

Note: S-TYPE-3, P-TYPE-3

This register can only be set to change during the initialization at initial startup or Software Reset process (section 58.3.2. Software Reset).

The PRTBTA register defines the limit for waiting for a peripheral response after Bus Turn-Around (BTA) executed by settings SQCHnDSCmAR.BTA[1:0] = 11b.

Set the peripheral response timeout value from the time of entering LP-RX mode until the peripheral responds to a BTA.

The timeout value is calculated by the following formula:

Time [µs] = PRTBTA[31:0] × (1 / f_{LPCLK} [MHz]*1)

When a timeout is detected, the RXSR.PRTOERR bit is set to 1.

Note 1. f_{LPCLK} is frequency of Low-Power mode clock (LPCLK).

58.2.18 PRESPTOLPSETR : Peripheral Response Timeout LP Set Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x214

Bit position:	31															16	15													0
Bit field:	LPRTO[15:0]																LPWTO[15:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	LPWTO[15:0]	LPDT WRITE Request Timeout Set the Peripheral Response Timeout value for LPDT WRITE Request. If the setting value is 0, timeout is not detected.	R/W
31:16	LPRTO[15:0]	LPDT READ Request Timeout Set the Peripheral Response Timeout value for LPDT READ Request. If the setting value is 0, timeout is not detected.	R/W

Note: S-TYPE-3, P-TYPE-3

This register can only be set to change during the initialization at initial startup or Software Reset process (section 58.3.2. Software Reset).

LPWTO[15:0] bits (LPDT WRITE Request Timeout)

The LPWTO[15:0] bits define the limit for waiting for a peripheral response after Bus Turn-Around (BTA) executed by settings SQCHnDSCmAR.BTA[1:0] = 01b and SQCHnDSCmAR.SPD = 1.

Set the peripheral response timeout value from the time of entering LP-RX mode until the peripheral responds to a write request.

The timeout value is calculated by the following formula:

Time [µs] = LPWTO[15:0] × (1 / f_{LPCLK} [MHz]*1)

When a timeout is detected, the RXSR.PRTOERR bit is set to 1.

LPRTO[15:0] bits (LPDT READ Request Timeout)

The LPRTO[15:0] bits define the limit for waiting for a peripheral response after Bus Turn-Around (BTA) executed by settings SQCHnDSCmAR.BTA[1:0] = 10b and SQCHnDSCmAR.SPD = 1.

Set the peripheral response timeout value from the time of entering LP-RX mode until the peripheral responds to a read request.

The timeout value is calculated by the following formula:

Time [µs] = LPRTO[15:0] × (1 / f_{LPCLK} [MHz]*1)

When a timeout is detected, the RXSR.PRTOERR bit is set to 1.

Note 1. f_{LPCLK} is frequency of Low-Power mode clock (LPCLK).

58.2.19 PRESPTOHSSETR : Peripheral Response Timeout HS Set Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x218

Bit position:	31															16	15													0
Bit field:	HSRTO[15:0]																HSWTO[15:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	HSWTO[15:0]	HS WRITE Request Timeout Set the Peripheral Response Timeout value for HS WRITE Request. If the setting value is 0, timeout is not detected.	R/W
31:16	HSRTO[15:0]	HS READ Request Timeout Set the Peripheral Response Timeout value for HS READ Request. If the setting value is 0, timeout is not detected.	R/W

Note: S-TYPE-3, P-TYPE-3

This register can only be set to change during the initialization at initial startup or Software Reset process (section 58.3.2. Software Reset).

HSWTO[15:0] bits (HS WRITE Request Timeout)

The HSWTO[15:0] bits define the limit for waiting for a peripheral response after Bus Turn-Around (BTA) executed by settings SQCHnDSCmAR.BTA[1:0] = 01b and SQCHnDSCmAR.SPD = 0.

Set the peripheral response timeout value from the time of entering LP-RX mode until the peripheral responds to a write request.

The timeout value is calculated by the following formula:

Time [µs] = HSWTO[15:0] × (1 / f_{LPCLK} [MHz]*1)

When a timeout is detected, the RXSR.PRTOERR bit is set to 1.

HSRTO[15:0] bits (HS READ Request Timeout)

The HSRTO[15:0] bits define the limit for waiting for a peripheral response after Bus Turn-Around (BTA) executed by settings SQCHnDSCmAR.BTA[1:0] = 10b and SQCHnDSCmAR.SPD = 0.

Set the peripheral response timeout value from the time of entering LP-RX mode until the peripheral responds to a read request.

The timeout value is calculated by the following formula:

Time [µs] = HSRTO[15:0] × (1 / f_{LPCLK} [MHz]*1)

When a timeout is detected, the RXSR.PRTOERR bit is set to 1.

Note 1. f_{LPCLK} is frequency of Low-Power mode clock (LPCLK).

58.2.20 AKEPLATIR : Acknowledge and Error Report Packet Parameter Latest Info Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x220

Bit position:	31												19		16	15														0

Bit	Symbol	Function	R/W
15:0	EREP[15:0]	Error Report Received Error Report bits 15-0	R
19:16	VC[3:0]	Virtual Channel ID An Acknowledge and Error Report was received from the following Virtual Channel ID. 0x0: No Error Report received 0x1: From VC-0 0x2: From VC-1 0x4: From VC-2 0x8: From VC-3 Others: Reserved	R
31:20	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

EREP[15:0] bits (Error Report)

When an Acknowledge and Error Report packet is received from the peripheral device, the Error Report is stored in the EREP[15:0] bits.

VC[3:0] bits (Virtual Channel ID)

The VC[3:0] bits are indicated from which virtual channel the Error Report stored in the EREP[15:0] bits was received.

58.2.21 AKEPACMSR : Acknowledge and Error Report Packet Parameter Accumulate Status Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x224

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	AEREP[15:0]	Accumulated Error Report Accumulated Error Report bits 15-0	R
16	AVC0	Virtual Channel-0 Accumulated Information 0: No Error Report received from VC-0 1: Received an Acknowledge and Error Report from VC-0	R
17	AVC1	Virtual Channel-1 Accumulated Information 0: No Error Report received from VC-1 1: Received an Acknowledge and Error Report from VC-1	R
18	AVC2	Virtual Channel-2 Accumulated Information 0: No Error Report received from VC-2 1: Received an Acknowledge and Error Report from VC-2	R
19	AVC3	Virtual Channel-3 Accumulated Information 0: No Error Report received from VC-3 1: Received an Acknowledge and Error Report from VC-3	R
31:20	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

AEREP[15:0] bits (Accumulated Error Report)

The AKEPLATIR.EREP[15:0] bits contain the most recently received Error Report, while the AEREP[15:0] bits are the accumulated value of past Error Reports.

AVC0 bit (Virtual Channel-0 Accumulated Information)

The AKEPLATIR.VC[3:0] bits contain the virtual channel ID of the most recently received Error Report, while the AVC0 bit is the accumulated value received from Virtual Channel-0.

If the AVC0 bit is set to 1, it means that an Acknowledge and Error Report from Virtual Channel-0 has been received one or more times.

AVC1 bit (Virtual Channel-1 Accumulated Information)

The AKEPLATIR.VC[3:0] bits contain the virtual channel ID of the most recently received Error Report, while the AVC1 bit is the accumulated value received from Virtual Channel-1.

If the AVC1 bit is set to 1, it means that an Acknowledge and Error Report from Virtual Channel-1 has been received one or more times.

AVC2 bit (Virtual Channel-2 Accumulated Information)

The AKEPLATIR.VC[3:0] bits contain the virtual channel ID of the most recently received Error Report, while the AVC2 bit is the accumulated value received from Virtual Channel-2.

If the AVC2 bit is set to 1, it means that an Acknowledge and Error Report from Virtual Channel-2 has been received one or more times.

AVC3 bit (Virtual Channel-3 Accumulated Information)

The AKEPLATIR.VC[3:0] bits contain the virtual channel ID of the most recently received Error Report, while the AVC3 bit is the accumulated value received from Virtual Channel-3.

If the AVC3 bit is set to 1, it means that an Acknowledge and Error Report from Virtual Channel-3 has been received one or more times.

58.2.22 AKEPSCR : Acknowledge and Error Report Packet Parameter Status Clear Register

19	AVC3	Virtual Channel-3 Accumulated Information Clear 0: No operation 1: Clear the AKEPACMSR.AVC3 bit	W
31:20	—	These bits are read as 0. The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

AEREP[15:0] bits (Accumulated Error Report Clear)

Set the AEREP[15:0] bits to 1 to clear the AKEPACMSR.AEREP[15:0] bits.

Each of the AEREP[15:0] bits correspond to each of the AKEPACMSR.AEREP[15:0] bits to be cleared.

AVC0 bit (Virtual Channel-0 Accumulated Information Clear)

Set the AVC0 bit to 1 to clear the AKEPACMSR.AVC0 bit.

AVC1 bit (Virtual Channel-1 Accumulated Information Clear)

Set the AVC1 bit to 1 to clear the AKEPACMSR.AVC1 bit.

AVC2 bit (Virtual Channel-2 Accumulated Information Clear)

Set the AVC2 bit to 1 to clear the AKEPACMSR.AVC2 bit.

AVC3 bit (Virtual Channel-3 Accumulated Information Clear)

Set the AVC3 bit to 1 to clear the AKEPACMSR.AVC3 bit.

58.2.23 RXRSSR : Receive Result Saved Status Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x230

Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	SLT3VLD	SLT2VLD	SLT1VLD	SLT0VLD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SLT0VLD	Slot-0 Valid Flag 0: None received 1: Response packet is received and stored in the RXRSS0R register	R
1	SLT1VLD	Slot-1 Valid Flag 0: None received 1: Response packet is received and stored in the RXRSS1R register	R
2	SLT2VLD	Slot-2 Valid Flag 0: None received 1: Response packet is received and stored in the RXRSS2R register	R
3	SLT3VLD	Slot-3 Valid Flag 0: None received 1: Response packet is received and stored in the RXRSS3R register	R
31:4	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

SLT0VLD bit (Slot-0 Valid Flag)

The SLT0VLD flag indicates that the response packet is received and stored in the RXRSS0R register.

The SLT0VLD flag is set to 1 if a response packet is received when the SQCHnDSCmCR.ACTCODE[7:0] bits are set to 0x00b.

The SLT0VLD flag is not cleared automatically, so set the RXRSSCR.SLT0VLD bit to 1 to clear the SLT0VLD flag.

SLT1VLD bit (Slot-1 Valid Flag)

The SLT1VLD flag indicates that the response packet is received and stored in the RXRSS1R register.

The SLT1VLD flag is set to 1 if a response packet is received when the SQCHnDSCmCR.ACTCODE[7:0] bits are set to 0x01.

The SLT1VLD flag is not cleared automatically, so set the RXRSSCR.SLT1VLD bit to 1 to clear the SLT1VLD flag.

SLT2VLD bit (Slot-2 Valid Flag)

The SLT2VLD flag indicates that the response packet is received and stored in the RXRSS2R register.

The SLT2VLD flag is set to 1 if a response packet is received when the SQCHnDSCmCR.ACTCODE[7:0] bits are set to 0x02.

The SLT2VLD flag is not cleared automatically, so set the RXRSSCR.SLT2VLD bit to 1 to clear the SLT2VLD flag.

SLT3VLD bit (Slot-3 Valid Flag)

The SLT3VLD flag indicates that the response packet is received and stored in the RXRSS3R register.

The SLT3VLD flag is set to 1 if a response packet is received when the SQCHnDSCmCR.ACTCODE[7:0] bits are set to 0x03.

The SLT3VLD flag is not cleared automatically, so set the RXRSSCR.SLT3VLD bit to 1 to clear the SLT3VLD flag.

58.2.24 RXRSSCR : Receive Result Saved Status Clear Register

31	INFOOW	Information Overwrite 0: No update 1: This register information (RXRSSxR[30:0]) was overwritten	R

Note: S-TYPE-3, P-TYPE-3

DATA0[7:0] bits (Data 0)

Data0 of the received packet header are stored in the DATA0[7:0] bits.

When the received packet is Long Packet, the lower 8 bits of the word count are stored in the DATA0[7:0] bits.

The DATA0[7:0] bits are valid when the RXSUC bit is 1 and the DT[5:0] bits are not 0x00.

DATA1[7:0] bits (Data 1)

Data1 of the received packet header are stored in the DATA1[7:0] bits.

When the received packet is Long Packet, the upper 8 bits of the word count are stored in the DATA1[7:0] bits.

The DATA1[7:0] bits are valid when the RXSUC bit is 1 and the DT[5:0] bits are not 0x00.

DT[5:0] bits (Data Type)

The DT[5:0] bits indicate the Data Type of the received packet header.

When an ACK trigger is received, the DT[5:0] bits are set to 0x00.

The DT[5:0] bits are valid when the RXSUC bit is 1.

VC[1:0] bits (Virtual Channel)

The VC[1:0] bits indicate the Virtual Channel ID of the received packet header.

The VC[1:0] bits are valid when the RXSUC bit is 1 and the DT[5:0] bits are not 0x00.

FMT bit (Packet Format)

The FMT bit indicates the packet format of the received packet header.

The FMT bit is valid when the RXSUC bit is 1 and the DT[5:0] bits are not 0x00. It is also valid when the RXPFAIL bit is set to 1

RXSUC bit (Receive Success)

The RXSUC bit indicates that a response packet or ACK trigger is received.

The RXSR.RXRESP flag or the RXSR.RXACK flag is also set to 1.

RXFERR bit (Fatal Error)

The RXFERR bit indicates that a fatal timeout occurred during BTA.

The FERRSR.TATO flag or the FERRSR.LRXHTO flag is also set to 1.

RXFAIL bit (Receive Fail)

The RXFAIL bit indicates that an expected receive did not done.

One or more of the following flags are also set to 1.

- RXSR.PRTOERR
- RXSR.ECCERRM
- RXSR.MLFERR
- RXSR.NORESERR

RXPFAIL bit (Receive Packet Data Fail)

The RXPFAIL bit indicates that the packet header is saved correctly but payload data was not saved correctly.

One or more of the following flags are also set to 1.

- RXSR.CRCERR
- RXSR.WCERR
- RXSR.RSIZEERR
- RXSR.UNEXERR
- RXSR.RXOVFERR
- RXSR.IBERR

When the RXPFAIL bit and the RXSR.RXRESP bit are set to 1, it means that the packet received during BTA is redundant.

RXCERR bit (Receive Correctable Error)

The RXCERR bit indicates that the received packet has correctable error.

The RXSR.ECCERRS flag is also set to 1.

RXAKE bit (Receive Acknowledge and Error Report Packet)

The RXAKE bit indicates that an Acknowledge and Error Report packet is received.

The RXSR.RXAKE flag is also set to 1.

INFOOW bit (Information Overwrite)

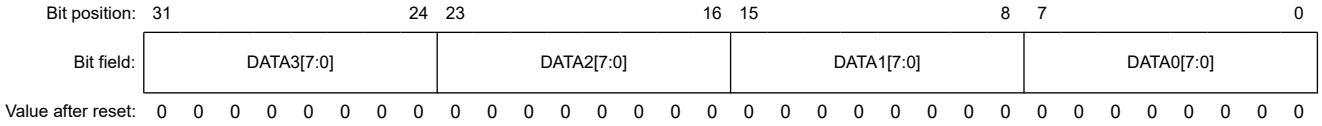
The INFOOW bit indicates that this register information (RXRSSxR[30:0]) are updated when RXRSSR.SLTxVLD = 1.

Set the RXRINFOOWSCR.SLxOW bit to 1 to clear the INFOOW bit.

58.2.28 RXPPD0R : Receive Packet Payload Data 0 Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x2C0



Bit	Symbol	Function	R/W
7:0	DATA0[7:0]	Payload Data 0 Long Packet Payload Data 0 received in Command mode*1	R
15:8	DATA1[7:0]	Payload Data 1 Long Packet Payload Data 1 received in Command mode*1	R
23:16	DATA2[7:0]	Payload Data 2 Long Packet Payload Data 2 received in Command mode*1	R
31:24	DATA3[7:0]	Payload Data 3 Long Packet Payload Data 3 received in Command mode*1	R

Note: S-TYPE-3, P-TYPE-3
Note 1. These bits are valid when SQCHnDSCmBR.DTSEL[1:0] = 00b.

DATA0[7:0] bits (Payload Data 0)

The DATA0[7:0] bits are used to store the Long Packet payload (Data 0) to be received in Command mode using Sequence operation.

DATA1[7:0] bits (Payload Data 1)

The DATA1[7:0] bits are used to store the Long Packet payload (Data 1) to be received in Command mode using Sequence operation.

DATA2[7:0] bits (Payload Data 2)

The DATA2[7:0] bits are used to store the Long Packet payload (Data 2) to be received in Command mode using Sequence operation.

DATA3[7:0] bits (Payload Data 3)

The DATA3[7:0] bits are used to store the Long Packet payload (Data 3) to be received in Command mode using Sequence operation.

58.2.29 RXPPD1R : Receive Packet Payload Data 1 Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x2C4

31:24	DATA15[7:0]	Payload Data 15 Long Packet Payload Data 15 received in Command mode*1	R

Note: S-TYPE-3, P-TYPE-3
Note 1. These bits are valid when SQCHnDSCmBR.DTSEL[1:0] = 00b.

DATA12[7:0] bits (Payload Data 12)

The DATA12[7:0] bits are used to store the Long Packet payload (Data 12) to be received in Command mode using Sequence operation.

DATA13[7:0] bits (Payload Data 13)

The DATA13[7:0] bits are used to store the Long Packet payload (Data 13) to be received in Command mode using Sequence operation.

DATA14[7:0] bits (Payload Data 14)

The DATA14[7:0] bits are used to store the Long Packet payload (Data 14) to be received in Command mode using Sequence operation.

DATA15[7:0] bits (Payload Data 15)

The DATA15[7:0] bits are used to store the Long Packet payload (Data 15) to be received in Command mode using Sequence operation.

58.2.32 HSTXTOSETR : HS TX Timeout Set Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x2E0

Bit position:	31																												0
Bit field:	HTXTO[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	HTXTO[31:0]	HS TX Timeout Count Set HS TX Timeout (HTX_TO) value.*1	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. If the setting value is 0, timeout is not detected.

This register can only be set to change during the initialization at initial startup or Software Reset process (section 58.3.2. Software Reset).

The HSTXTO register defines the limit for waiting for DSI Host own length of HS Transmission.

The timeout value is calculated by the following formula:

Time [µs] = HSTXTOSETR[31:0] × 32 × (period of High-Speed serial UI [ns]) / 1000

When a timeout is detected, the FERRSR.HTXTO bit is set to 1.

58.2.33 LRXHTOSETR : LRX-H Timeout Set Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x2E4

Bit position:	31																												0
Bit field:	LRXHTO[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	LRXHTO[31:0]	LP-RX Host Processor Timeout Set LP-RX Timeout (LRX-H_TO) value. If the setting value is 0, timeout is not detected.	R/W

Note: S-TYPE-3, P-TYPE-3

This register can only be set to change during the initialization at initial startup or Software Reset process (section 58.3.2. Software Reset).

The LRXHTO register defines the limit for waiting for transmission from the peripheral. If a LP TX-Peripheral timeout (LTX-P_TO) occurs on the peripheral side, then this LP-RX timeout will occur on DSI Host.

The timeout value is calculated by the following formula:

Time [µs] = LRXHTOSETR[31:0] × (1 / f_{LPCLK} [MHz]*1)

When a timeout is detected, the FERRSR.LRXHTO bit is set to 1.

Note 1. f_{LPCLK} is frequency of Low-Power mode clock (LPCLK).

58.2.34 TATOSETR : TA Timeout Set Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x2E8

Bit position:	31																												0
Bit field:	TATO[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TATO[31:0]	Turnaround Acknowledge Timeout Set Turnaround Acknowledge Timeout (TA_TO) value. If the setting value is 0, timeout is not detected.	R/W

Note: S-TYPE-3, P-TYPE-3

This register can only be set to change during the initialization at initial startup or Software Reset process (section 58.3.2. Software Reset).

The TATO register defines the limit for waiting for the data lane transition sequence processing after Bus Turn-Around (BTA) is issued.

The timeout value is calculated by the following formula:

Time [µs] = TATOSETR[31:0] × (1 / f_{LPCLK} [MHz]*1)

When a timeout is detected, the FERRSR.TATO bit is set to 1.

Note 1. f_{LPCLK} is frequency of Low-Power mode clock (LPCLK).

58.2.35 FERRSR : Fatal Error Status Register

Note: S-TYPE-3, P-TYPE-3

HTXTO flag (HS TX Timeout Interrupt Flag)

The HTXTO flag indicates that a HS TX Timeout (HTX_TO) is detected.

The HTXTO flag is set to 1 when the HS TX Timeout Timer expires. This timer monitors the DSI Host's own length of HS transmission.

The HTXTO flag is not cleared automatically, so set the FERRSCR.HTXTO bit to 1 to clear the HTXTO flag.

LRXHTO flag (LP-RX Host Processor Timeout Interrupt Flag)

The LRXHTO flag indicates that a LP-RX Host Processor Timeout (LRX-H_TO) is detected.

The LRXHTO flag is set to 1 when the Host Processor LP-RX Timer expires.

The LRXHTO flag is not cleared automatically, so set the FERRSCR.LRXHTO bit to 1 to clear the LRXHTO flag.

TATO flag (Turnaround Acknowledge Timeout Interrupt Flag)

The TATO flag indicates that a Turnaround Acknowledge Timeout (TA_TO) is detected.

The TATO flag is set to 1 when the timer TA_TO expires.

The TATO flag is not cleared automatically, so set the FERRSCR.TATO bit to 1 to clear the TATO flag.

ESCENT flag (Escape mode Entry Error Interrupt Flag)

The ESCENT flag indicates that an Escape mode Entry Error (ErrEsc) is detected.

The ESCENT flag is not cleared automatically, so set the FERRSCR.ESCENT bit to 1 to clear the ESCENT flag.

SYNCESC flag (LPDT Sync Error Interrupt Flag)

The SYNCESC flag indicates that a Low-Power Data Transmission Synchronization Error (ErrSyncEsc) is detected.

The SYNCESC flag is not cleared automatically, so set the FERRSCR.SYNCESC bit to 1 to clear the SYNCESC flag.

CTRL flag (Control Error Interrupt Flag)

The CTRL flag indicates that a Control Error (ErrControl) is detected.

The CTRL flag is not cleared automatically, so set the FERRSCR.CTRL bit to 1 to clear the CTRL flag.

CLP0 flag (LP0 Contention Error Interrupt Flag)

The CLP0 flag indicates that a LP0 Contention Error (ErrContentionLP0) is detected.

Once the CLP0S bit is detected to be 1, the CLP0 flag is set to 1.

The CLP0 flag is not cleared automatically, so set the FERRSCR.CLP0 bit to 1 to clear the CLP0 flag.

CLP1 flag (LP1 Contention Error Interrupt Flag)

The CLP1 flag indicates that a LP1 Contention Error (ErrContentionLP1) is detected.

Once the CLP1S bit is detected to be 1, the CLP1 flag is set to 1.

The CLP1 flag is not cleared automatically, so set the FERRSCR.CLP1 bit to 1 to clear the CLP1 flag.

CLP0S bit (LP0 Contention Error Status)

The CLP0S bit indicates the latest LP0 Contention Error state of the D-PHY.

The CLP0S bit is set to 1 when the D-PHY Lane module detects a contention situation on a line while trying to drive the line low.

CLP1S bit (LP1 Contention Error Status)

The CLP1S bit indicates the latest LP1 Contention Error state of the D-PHY.

The CLP1S bit is set to 1 when the D-PHY Lane module detects a contention situation on a line while trying to drive the line high.

58.2.36 FERRSCR : Fatal Error Status Clear Register

Base address: MIPI_DSI = 0x4034_6000

Note: S-TYPE-3, P-TYPE-3

HTXTO bit (HS TX Timeout Interrupt Flag Clear)

Set the HTXTO bit to 1 to clear the FERRSR.HTXTO flag.

LRXHTO bit (LP-RX Host Processor Timeout Interrupt Flag Clear)

Set the LRXHTO bit to 1 to clear the FERRSR.LRXHTO flag.

TATO bit (Turnaround Acknowledge Timeout Interrupt Flag Clear)

Set the TATO bit to 1 to clear the FERRSR.TATO flag.

ESCENT bit (Escape mode Entry Error Interrupt Flag Clear)

Set the ESCENT bit to 1 to clear the FERRSR.ESCENT flag.

SYNCESC bit (LPDT Sync Error Interrupt Flag Clear)

Set the SYNCESC bit to 1 to clear the FERRSR.SYNCESC flag.

CTRL bit (Control Error Interrupt Flag Clear)

Set the CTRL bit to 1 to clear the FERRSR.CTRL flag.

CLP0 bit (LP0 Contention Error Interrupt Flag Clear)

Set the CLP0 bit to 1 to clear the FERRSR.CLP0 flag.

CLP1 bit (LP1 Contention Error Interrupt Flag Clear)

Set the CLP1 bit to 1 to clear the FERRSR.CLP1 flag.

58.2.37 FERRIER : Fatal Error Interrupt Enable Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x308

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

20	CLP1	LP1 Contention Error Interrupt Enable 0: Disable 1: Enable	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

HTXTO bit (HS TX Timeout Interrupt Enable)

The HTXTO bit controls the HS TX Timeout (HTX_TO) Interrupt permission. When a HS TX Timeout Interrupt occurs, the FERRSR.HTXTO flag is set to 1.

To enable the HS TX Timeout Interrupt, set the HTXTO bit to 1.

LRXHTO bit (LP-RX Host Processor Timeout Interrupt Enable)

The LRXHTO bit controls the LP-RX Host Processor Timeout (LRX-H_TO) Interrupt permission. When a LP-RX Host Processor Timeout Interrupt occurs, the FERRSR.LRXHTO flag is set to 1.

To enable the LP-RX Host Processor Timeout Interrupt, set the LRXHTO bit to 1.

TATO bit (Turnaround Acknowledge Timeout Interrupt Enable)

The TATO bit controls the Turnaround Acknowledge Timeout (TA_TO) Interrupt permission. When a Turnaround Acknowledge Timeout Interrupt occurs, the FERRSR.TATO flag is set to 1.

To enable the Turnaround Acknowledge Timeout Interrupt, set the TATO bit to 1.

ESCENT bit (Escape mode Entry Error Interrupt Enable)

The ESCENT bit controls the Escape mode Entry Error (ErrEsc) Interrupt permission. When an Escape mode Entry Error Interrupt occurs, the FERRSR.ESCENT flag is set to 1.

To enable the Escape mode Entry Error Interrupt, set the ESCENT bit to 1.

SYNCESC bit (LPDT Sync Error Interrupt Enable)

The SYNCESC bit controls the Low-Power Data Transmission Synchronization Error (ErrSyncEsc) Interrupt permission. When a Low-Power Data Transmission Synchronization Error Interrupt occurs, the FERRSR.SYNCESC flag is set to 1.

To enable the Low-Power Data Transmission Synchronization Error Interrupt, set the SYNCESC bit to 1.

CTRL bit (Control Error Interrupt Enable)

The CTRL bit controls the Control Error (ErrControl) Interrupt permission. When a Control Error Interrupt occurs, the FERRSR.CTRL flag is set to 1.

To enable the Control Error Interrupt, set the CTRL bit to 1.

CLP0 bit (LP0 Contention Error Interrupt Enable)

The CLP0 bit controls the LP0 Contention Error (ErrContentionLP0) Interrupt permission. When an LP0 Contention Error Interrupt occurs, the FERRSR.CLP0 flag is set to 1.

To enable the LP0 Contention Error Interrupt, set the CLP0 bit to 1.

CLP1 bit (LP1 Contention Error Interrupt Enable)

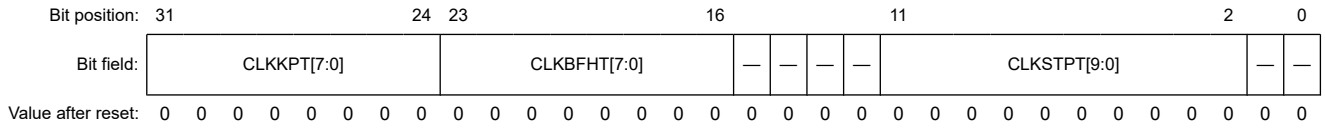
The CLP1 bit controls the LP1 Contention Error (ErrContentionLP1) Interrupt permission. When an LP1 Contention Error Interrupt occurs, the FERRSR.CLP1 flag is set to 1.

To enable the LP1 Contention Error Interrupt, set the CLP1 bit to 1.

58.2.38 CLSTPTSETR : Clock Lane Stop Time Set Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x314



Bit	Symbol	Function	R/W
1:0	—	These bits are read as 0. The write value should be 0.	R/W
11:2	CLKSTPT[9:0]	Clock Stop Time Set the CLKSTPT period shown in Figure 58.1.*1	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
23:16	CLKBFHT[7:0]	Clock Beforehand Time Set the CLKBFHT period shown in Figure 58.1.*2*3	R/W
31:24	CLKKPT[7:0]	Clock Keep Time Set the CLKKPT period shown in Figure 58.1.*2*3	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Set this bit to a value greater than or equal to the value of the calculated period rounded up plus 3.
Note 2. Set the appropriate value (non-zero) before setting the HSCLKSETR.HSCLST bit to 1.
Note 3. Set these bits to a value greater than the desired time.

This register can only be set to change during the initialization at initial startup or Software Reset process (section 58.3.2. Software Reset).

CLKSTPT[9:0] bits (Clock Stop Time)

The CLKSTPT[9:0] bits define the minimum period of time between the transition to LP mode and the return to HS mode on the Clock Lane.

This setting is used to stop the Clock Lane when no HS transfer is taking place in the non-continuous clock mode (HSCLKSETR.HSCLMD = 0).

If there is an interval of more than the period specified by the CLKSTPT[9:0] bits between HS transfers on the Clock Lane, an LP mode period is inserted on the Clock Lane.

When the HSCLKSETR.HSCLMD bit is set to 1 (Continuous clock mode), the setting of the CLKSTPT[9:0] bits is meaningless.

This period corresponds to the time specified in the MIPI D-PHY Specification ($T_{HS-TRAIL}$ + $T_{CLK-POST}$ + $T_{CLK-TRAIL}$

+ $T_{HS-EXIT}$ + T_{LPX} × 2 + $T_{LPX(For\ Clock\ Lane\ HS\ Entry)}$ + $T_{CLK-PREPARE}$ + $T_{CLK-ZERO}$ + $T_{CLK-PRE}$ + $T_{LPX(For\ Data\ Lane\ HS\ Entry)}$ + $T_{HS-PREPARE}$ + $T_{HS-ZERO}$ + $T_{HS-SYNC}$). See Figure 58.1.

The period is derived from the following formula:

CLKSTPT period [µs] = CLKSTPT[9:0] × (period of HS serial UI) [µs] × 32

e.g.)

In the case of CLKSTPT[9:0] = 0x3E8, HS rate = 720 Mbps

CLKSTPT period [µs] = 1000 × (1 / 720 Mbps) × 32 = 44.4 [µs]

For information about each parameter, refer to the D-PHY specification and Figure 3-1. Of these parameters, it is necessary to set the time set in CLKKPT for ($T_{HS-TRAIL}$+ $T_{CLK-POST}$) and that set in CLKBFHT for ($T_{LPX\ (For\ Clock\ Lane\ HS\ Entry)}$ + $T_{CLK-PREPARE}$ + $T_{CLK-ZERO}$ + $T_{CLK-PRE}$). Set the rounded-up value plus at least 3. Setting this field to 0 is prohibited.

$T_{LPX(For\ Clock\ Lane\ HS\ Entry)}$ means the period of LP-01 in the HS entry sequence of Clock Lane. $T_{LPX(For\ Data\ Lane\ HS\ Entry)}$ means the period of LP-01 in the HS entry sequence of Data Lane. If these periods are not the same as the standard T_{LPX} value of the host device (in the range of 67% to 150% of the T_{LPX} value of the peripheral device), use the actual periods for this calculation.

CLKBFHT[7:0] bits (Clock Beforehand Time)

The CLKBFHT[7:0] bits specify the period during which the Clock Lane returns to HS mode prior to the start of HS packet transfer.

If HS transfers are scheduled in LP mode, the Clock Lane will start HS transfer in advance according to this setting. See Figure 58.1.

The period is derived from the following formula:

CLKBFHT period [µs] = CLKBFHT[7:0] × (period of HS serial UI) [µs] × 32

e.g.)

In the case of CLKBFHT[7:0] = 0x64, HS rate = 720 Mbps

CLKBFHT period [µs] = 100 × (1 / 720 Mbps) × 32 = 4.4 [µs]

This time corresponds to the D-PHY specification ($T_{LPX\ (For\ Clock\ Lane\ HS\ Entry)}$ + $T_{CLK-PREPARE}$+ $T_{CLK-ZERO}$ + $T_{CLK-PRE}$). The value must be greater than the one calculated. Set an appropriate value (other than 0) before HSCLKSETR.HSCLST is set to 1.

$T_{LPX\ (For\ Clock\ Lane\ HS\ Entry)}$ means the period of LP-01 in the HS entry sequence of Clock Lane. If this period is not same as normal T_{LPX} value of host device (in the range of 67% to 150% of the T_{LPX} value of peripheral device), use the actual period for this calculation.

CLKKPT[7:0] bits (Clock Keep Time)

The CLKKPT[7:0] bits specify the period that the Clock Lane keeps the HS mode active after the last HS packet transfer. See Figure 58.1.

The period is derived from the following formula:

CLKKPT period [µs] = CLKKPT[7:0] × (period of HS serial UI) [µs] × 32

e.g.)

In the case of CLKKPT[7:0] = 0x64, HS rate = 720 Mbps

CLKKPT period [µs] = 100 × (1 / 720 Mbps) × 32 = 4.4 [µs]

This time corresponds to the D-PHY specification's ($T_{HS-TRAIL}$ + $T_{CLK-POST}$).

The value must be greater than the one calculated. Set an appropriate value (other than 0) before HSCLKSETR.HSCLST is set to "1".

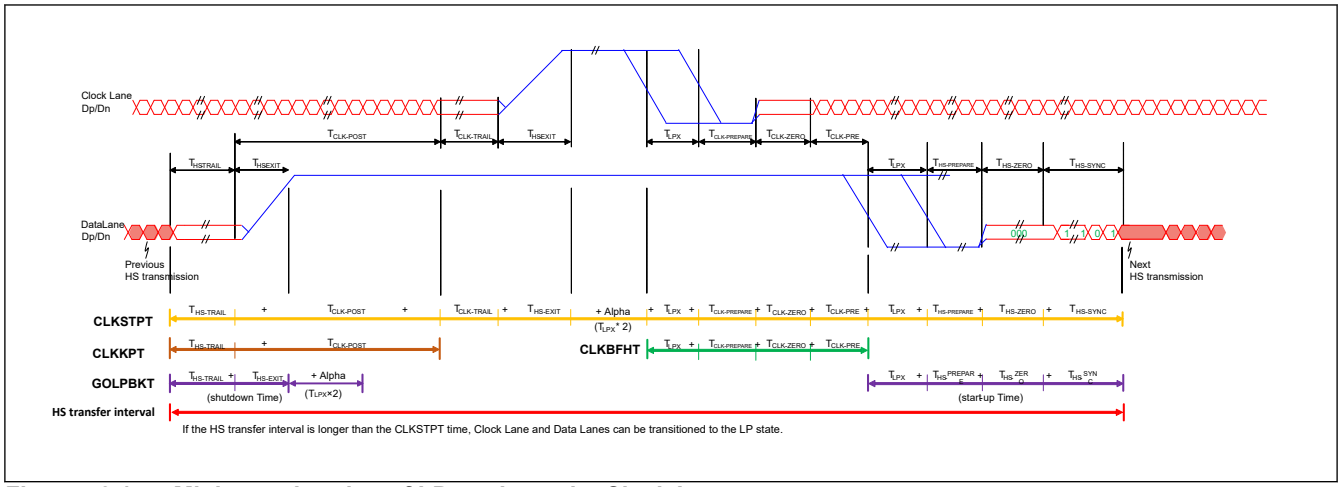


Figure 58.1 Minimum duration of LP mode on the Clock Lane

58.2.39 LPTRNSTSETR : LP Transition Time Set Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x318

Bit position:	31																		9											0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	GOLPBKT[9:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	GOLPBKT[9:0]	Go LP and Back Time Set the GOLPBKT period shown in Figure 58.2. Set this bit to a value greater than or equal to the value of the calculated period rounded up plus 3.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register can only be set to change during the initialization at initial startup or Software Reset process (section 58.3.2. Software Reset).

GOLPBKT[9:0] bits (Go LP and Back Time)

The GOLPBKT[9:0] bits indicate the minimum period of time between the transition to LP mode and the return to HS mode on the Data Lane.

This setting is used for the ability of the DSI Host to automatically transition the Data Lane from HS mode to LP mode during the HSA, HBP, and HFP periods. See section 58.3.6.5. Selection of Blanking Packets or LP-11 for HSA, HBP, and HFP.

If there is an interval of more than the period specified by the GOLPBKT[9:0] bits between HS transfers, an LP mode period is inserted on the Data Lane.

This period corresponds to the time specified in the MIPI D-PHY Specification ($T_{HS\text{-}TRAIL} + T_{HS\text{-}EXIT} + T_{LPX} \times 2 + T_{LPX}$ (For Data Lane HS Entry) $+ T_{HS\text{-}PREPARE} + T_{HS\text{-}ZERO} + T_{HS\text{-}SYNC}$). See Figure 58.2.

The period is derived from the following formula:

GOLPBKT period [µs] = GOLPBKT[9:0] × (period of HS serial 8UI) [µs]*1

e.g.)

In the case of GOLPBKT[9:0] = 0x3E8, HS rate = 720 Mbps

GOLPBKT period [µs] = 1000 × (1 / 720 Mbps) × 8 = 11.1 [µs]

The unit of this setting is 8 UIs, so if the result of this formula contains a fraction of less than 8 UIs, round it up. Set the rounded-up value plus at least 3. $T_{LPX\ (For\ Data\ Lane\ HS\ Entry)}$ means the period of LP-01 in the HS entry sequence of Data Lane. If this period is not the same as the standard T_{LPX} value of the host device (in the range of 67% to 150% of the TLPX value of the peripheral device), use the actual period for this calculation.

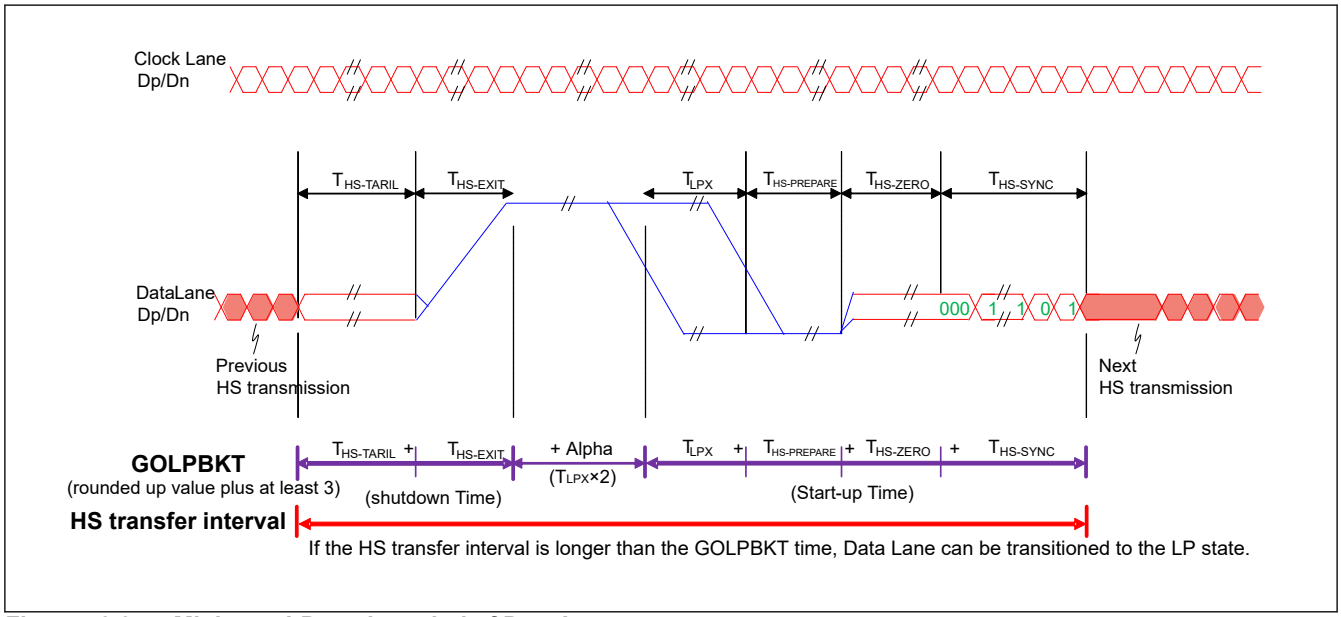

Figure 58.2 Minimum LP mode period of Data Lane

Note 1. The unit for this setting is 8UI, so if the result of this equation contains more than half of 8UI, round it up.

29	DLULPEXT	Data Lane ULPS Exit Interrupt Flag Data Lane transition from ULPS 0: Not detected 1: Detected	R
31:30	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

CLUAN bit (Clock Lane UlpsActiveNot Status)

The CLUAN bit indicates that the D-PHY Clock Lane is not in ULP State.*1

CLSTP bit (Clock Lane Stop Status)

The CLSTP bit indicates that the D-PHY Clock Lane module is currently in Stop state. *1

The CLSTP bit is used to indirectly determine if the PHY line levels are in the LP-11 state.

DL0RLE bit (Data Lane-0 RxLpdtEsc Status)

The DL0RLE bit indicates that the D-PHY Data Lane-0 module is in Low-Power data receive mode.*1

DL0RUE bit (Data Lane-0 RxUlpsEsc Status)

The DL0RUE bit indicates that the D-PHY Data Lane-0 module has entered the Ultra-Low Power State.*1

DL0UAN bit (Data Lane-0 UlpsActiveNot Status)

The DL0UAN bit indicates that the D-PHY Data Lane-0 is not in ULP State.*1

DL1UAN bit (Data Lane-1 UlpsActiveNot Status)

The DL1UAN bit indicates that the D-PHY Data Lane-1 is not in ULP State.*1

DL0STP bit (Data Lane-0 Stop Status)

The DL0STP bit indicates that the D-PHY Data Lane-0 module is currently in Stop state.*1

The DL0STP bit is used to indirectly determine if the PHY line levels are in the LP-11 state.

DL1STP bit (Data Lane-1 Stop Status)

The DL1STP bit indicates that the D-PHY Data Lane-1 module is currently in Stop state.*1

The DL1STP bit is used to indirectly determine if the PHY line levels are in the LP-11 state.

DL0RX2TX flag (Data Lane-0 RX to TX Transition Interrupt Flag)

The DL0RX2TX flag indicates that the D-PHY Data Lane-0 has transitioned from the receiver to the transmitter.

The DL0RX2TX flag is not cleared automatically, so set the PLSCR.DL0RX2TX bit to 1 to clear the DL0RX2TX flag.

DL0TX2RX flag (Data Lane-0 TX to RX Transition Interrupt Flag)

The DL0TX2RX flag indicates that the D-PHY Data Lane-0 has transitioned from the transmitter to the receiver.

The DL0TX2RX flag is not cleared automatically, so set the PLSCR.DL0TX2RX bit to 1 to clear the DL0TX2RX flag.

DL0DIR bit (Data Lane-0 Direction)

The DL0DIR bit indicates the status of the lane direction, whether the D-PHY Data Lane-0 is currently a transmitter or a receiver.*1

CLULPENT flag (Clock Lane ULPS Enter Interrupt Flag)

The CLULPENT flag indicates that the Clock Lane has entered ULPS.

The CLULPENT flag is not cleared automatically, so set the PLSCR.CLULPENT bit to 1 to clear the CLULPENT flag.

CLULPEXT flag (Clock Lane ULPS Exit Interrupt Flag)

The CLULPEXT flag indicates that the Clock Lane has exited from ULPS.

The CLULPEXT flag is not cleared automatically, so set the PLSCR.CLULPEXT bit to 1 to clear the CLULPEXT flag.

CLLP2HS flag (Clock Lane LP to HS Transition Interrupt Flag)

The CLLP2HS flag indicates that the Clock Lane has transitioned from LP mode to HS mode.

Ignore the CLLP2HS flag when the HSCLKSETR.HSCLMD bit is set to 0 (Non-continuous clock mode).

The CLLP2HS flag is not cleared automatically, so set the PLSCR.CLLP2HS bit to 1 to clear the CLLP2HS flag.

CLHS2LP flag (Clock Lane HS to LP Transition Interrupt Flag)

The CLHS2LP flag indicates that the Clock Lane has transitioned from HS mode to LP mode.

Ignore the CLHS2LP flag when the HSCLKSETR.HSCLMD bit is set to 0 (Non-continuous clock mode).

The CLHS2LP flag is not cleared automatically, so set the PLSCR.CLHS2LP bit to 1 to clear the CLHS2LP flag.

DLULPENT flag (Data Lane ULPS Enter Interrupt Flag)

The DLULPENT flag indicates that the Data Lanes specified by the TXSETR.NUMLANE[1:0] bits have transitioned from Stop state to ULPS by ULPS Enter.

The DLULPENT flag is not cleared automatically, so set the PLSCR.DLULPENT bit to 1 to clear the DLULPENT flag.

DLULPEXT flag (Data Lane ULPS Exit Interrupt Flag)

The DLULPEXT flag indicates that the Data Lanes specified by the TXSETR.NUMLANE[1:0] bits have transitioned from ULPS to Stop state by ULPS Exit.

The DLULPEXT flag is not cleared automatically, so set the PLSCR.DLULPEXT bit to 1 to clear the DLULPEXT flag.

Note 1. These bits are set after synchronization with LPCLK. Therefore, it takes time for the status to be refrected.

Note: S-TYPE-3, P-TYPE-3

DL0RX2TX bit (Data Lane-0 RX to TX Transition Interrupt Enable)

The DL0RX2TX bit controls the Data Lane-0 RX to TX Transition Interrupt permission.

When a Data Lane-0 RX to TX Transition Interrupt occurs, the PLSR.DL0RX2TX flag is set to 1.

To enable the Data Lane-0 RX to TX Transition Interrupt, set the DL0RX2TX bit to 1.

DL0TX2RX bit (Data Lane-0 TX to RX Transition Interrupt Enable)

The DL0TX2RX bit controls the Data Lane-0 TX to RX Transition Interrupt permission.

When a Data Lane-0 TX to RX Transition Interrupt occurs, the PLSR.DL0TX2RX flag is set to 1.

To enable the Data Lane-0 TX to RX Transition Interrupt, set the DL0TX2RX bit to 1.

CLULPENT bit (Clock Lane ULPS Enter Interrupt Enable)

The CLULPENT bit controls the Clock Lane ULPS Enter Interrupt permission.

When a Clock Lane ULPS Enter Interrupt occurs, the PLSR.CLULPENT flag is set to 1.

To enable the Clock Lane ULPS Enter Interrupt, set the CLULPENT bit to 1.

CLULPEXT bit (Clock Lane ULPS Exit Interrupt Enable)

The CLULPEXT bit controls the Clock Lane ULPS Exit Interrupt permission.

When a Clock Lane ULPS Exit Interrupt occurs, the PLSR.CLULPEXT flag is set to 1.

To enable the Clock Lane ULPS Exit Interrupt, set the CLULPEXT bit to 1.

CLLP2HS bit (Clock Lane LP to HS Transition Interrupt Enable)

The CLLP2HS bit controls the Clock Lane LP to HS Transition Interrupt permission.

When a Clock Lane LP to HS Transition Interrupt occurs, the PLSR.CLLP2HS flag is set to 1.

To enable the Clock Lane LP to HS Transition Interrupt, set the CLLP2HS bit to 1.

CLHS2LP bit (Clock Lane HS to LP Transition Interrupt Enable)

The CLHS2LP bit controls the Clock Lane HS to LP Transition Interrupt permission.

When a Clock Lane HS to LP Transition Interrupt occurs, the PLSR.CLHS2LP flag is set to 1.

To enable the Clock Lane HS to LP Transition Interrupt, set the CLHS2LP bit to 1.

DLULPENT bit (Data Lane ULPS Enter Interrupt Enable)

The DLULPENT bit controls the Data Lane ULPS Enter Interrupt permission.

When a Data Lane ULPS Enter Interrupt occurs, the PLSR.DLULPENT flag is set to 1.

To enable the Data Lane ULPS Enter Interrupt, set the DLULPENT bit to 1

DLULPEXT bit (Data Lane ULPS Exit Interrupt Enable)

The DLULPEXT bit controls the Data Lane ULPS Exit Interrupt permission.

When a Data Lane ULPS Exit Interrupt occurs, the PLSR.DLULPEXT flag is set to 1.

To enable the Data Lane ULPS Exit Interrupt, set the DLULPEXT bit to 1.

58.2.43 VMSET0R : Video Mode Set 0 Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x400

Bit	Symbol	Function	R/W
0	VSTART	Video Mode Operation Start 0: No operation 1: Start Video mode operation	W
1	VSTOP	Video Mode Operation Stop 0: No operation 1: Stop Video mode operation	W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	HSANOLP	HSA period No LP 0: Not suppressing the transition to LP during HSA period 1: Suppress the transition to LP during HSA period and keep HS	R/W
9	HBPNOLP	HBP period No LP 0: Not suppressing the transition to LP during HBP period 1: Suppress the transition to LP during HBP period and keep HS	R/W
10	HFPNOLP	HFP period No LP 0: Not suppressing the transition to LP during HFP period 1: Suppress the transition to LP during HFP period and keep HS	R/W
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

VSTART bit (Video Mode Operation Start)

The VSTART bit is start trigger for Video Mode operation.

Setting 1 to both the VSTART bit and the VSTOP bit is prohibited.

When the VMSR.RUNNING bit is set to 1, setting the VSTART bit to 1 is prohibited.

VSTOP bit (Video Mode Operation Stop)

The VSTOP bit is stop trigger for Video Mode operation.

The video mode operation is stopped at the end of video-frame. After the video mode operation is stopped, stop the GLCDC.

Setting 1 to both the VSTOP bit and the VSTART bit is prohibited.

When the VMSR.RUNNING bit is cleared to 0, setting the VSTOP bit to 1 is prohibited.

HSANOLP bit (HSA period No LP)

The HSANOLP bit controls whether to transition to LP during the HSA period.

When the HSANOLP bit is set to 1, the link does not transition to LP during HSA period and keep HS mode.

HS mode is kept by sending blanking packet.

HBPNOLP bit (HBP period No LP)

The HBPNOLP bit controls whether to transition to LP during the HBP period.

When the HBPNOLP bit is set to 1, the link does not transition to LP during HBP period and keep HS mode.

HS mode is kept by sending blanking packet.

HFPNOLP bit (HFP period No LP)

The HFPNOLP bit controls whether to transition to LP during the HFP period.

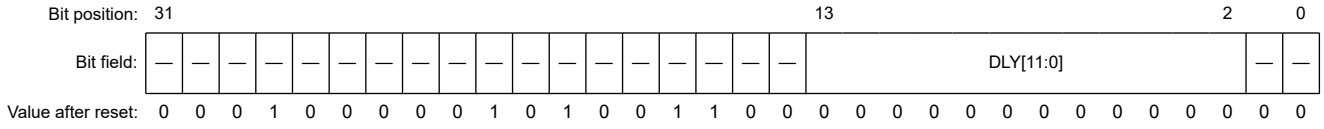
When the HFPNOLP bit is set to 1, the link does not transition to LP during HFP period and keep HS mode.

HS mode is kept by sending blanking packet.

58.2.44 VMSET1R : Video Mode Set 1 Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x404



Bit	Symbol	Function	R/W
1:0	—	These bits are read as 0. The write value should be 0.	R/W
13:2	DLY[11:0]	Delay Value Set the delay value inside DSI Host until the transfer begins.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
17:16	—	These bits are read as 1. The write value should be 1.	R/W
19:18	—	These bits are read as 0. The write value should be 0.	R/W
20	—	This bit is read as 1. The write value should be 1.	R/W
21	—	This bit is read as 0. The write value should be 0.	R/W
22	—	This bit is read as 1. The write value should be 1.	R/W
23	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
29:24	—	The read values are undefined. The write value should be 0.	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

DLY[11:0] bits (Delay Value)

The DLY[11:0] bits are for the control of the delay time inside DSI Host to avoid the underflow or the overflow of the video stream from GLCDC.

The delay time is derived from the following formula:

Delay time [µs] = DLY[11:0] × (period of HS serial UI) [µs] × 32

e.g.)

In the case of DLY[11:0] = 0x3E8, HS line rate = 720 Mbps

Delay time [µs] = 1000 × (1 / 720 Mbps) × 32 = 44.4 [µs]

For more details, see section 58.3.6.7. Delay Adjustment for Video Mode Operation.

It is prohibited to set the VMSET1R.DLY[11:0] bits to 0x000.

If the VMSET0R.HFPNOLP bit is set to 1, set the DLY[11:0] bits to more than HFP period.

If the VMSET0R.HBPNOLP bit is set to 1, set the DLY[11:0] bits to more than HBP period.

If the VMSET0R.HSANOLP bit is set to 1, set the DLY[11:0] bits to more than HSA period.

58.2.45 VMSR : Video Mode Status Register

Bit	Symbol	Function	R/W
21	—	This bit is read as 0.	R
22	VBUFUDF	Video Buffer Underflow Error Interrupt Flag 0: Data underflow is not occurred 1: Data underflow is occurred in the video buffer	R
23	VBUFOVF	Video Buffer Overflow Error Interrupt Flag 0: Data overflow is not occurred 1: Data overflow is occurred in the video buffer	R
31:24	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

START flag (Video Mode Operation Start Interrupt Flag)

The START flag indicates that the video mode operation has started.

The START flag is not cleared automatically, so set the VMSCR.START bit to 1 to clear the START flag.

STOP flag (Video Mode Operation Stop Interrupt Flag)

The STOP flag indicates that the video mode operation has stopped.

The STOP flag is not cleared automatically, so set the VMSCR.STOP bit to 1 to clear the STOP flag.

RUNNING bit (Video Mode Operation Running Status)

The RUNNING bit indicates the operating state of the video mode.

Changing the settings of VMSET0R, VMSET1R, VMPPSETR, VMVSSETR, VMVPSETR, VMHSSETR and VMHPSETR is prohibited while the RUNNING bit is 1.

VIRDY flag (Video Mode Operation Ready Interrupt Flag)

The VIRDY flag indicates that the video mode operation is ready to start working.

The VIRDY flag is not cleared automatically, so set the VMSCR.VIRDY bit to 1 to clear the VIRDY flag.

TIMERR flag (Timing Error Interrupt Flag)

The TIMERR flag indicates that the timing error is occurred during the video mode operation.

The TIMERR flag is not cleared automatically, so set the VMSCR.TIMERR bit to 1 to clear the TIMERR flag.

VBUFUDF flag (Video Buffer Underflow Error Interrupt Flag)

The VBUFUDF flag indicates that the data underflow is occurred in the video buffer.

The VBUFUDF flag is not cleared automatically, so set the VMSCR.VBUFUDF bit to 1 to clear the VBUFUDF flag.

VBUFOVF flag (Video Buffer Overflow Error Interrupt Flag)

The VBUFOVF flag indicates that the data overflow is occurred in the video buffer.

The VBUFOVF flag is not cleared automatically, so set the VMSCR.VBUFOVF bit to 1 to clear the VBUFOVF flag.

58.2.46 VMSCR : Video Mode Status Clear Register

22	VBUFUDF	Video Buffer Underflow Error Interrupt Enable 0: Disable 1: Enable	R/W
23	VBUFOVF	Video Buffer Overflow Error Interrupt Enable 0: Disable 1: Enable	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

START bit (Video Mode Operation Start Interrupt Enable)

The START bit controls the Video Mode Operation Start Interrupt permission.

When a Video Mode Operation Start Interrupt occurs, the VMSR.START flag is set to 1.

To enable the Video Mode Operation Start Interrupt, set the START bit to 1.

STOP bit (Video Mode Operation Stop Interrupt Enable)

The STOP bit controls the Video Mode Operation Stop Interrupt permission.

When a Video Mode Operation Stop Interrupt occurs, the VMSR.STOP flag is set to 1.

To enable the Video Mode Operation Stop Interrupt, set the STOP bit to 1.

VIRDY bit (Video Mode Operation Ready Interrupt Enable)

The VIRDY bit controls the Video Mode Operation Ready Interrupt permission.

When a Video Mode Operation Ready Interrupt occurs, the VMSR.VIRDY flag is set to 1.

To enable the Video Mode Operation Ready Interrupt, set the VIRDY bit to 1.

TIMERR bit (Timing Error Interrupt Enable)

The TIMERR bit controls the Timing Error Interrupt permission.

When a Timing Error Interrupt occurs, the VMSR.TIMERR flag is set to 1.

To enable the Timing Error Interrupt, set the TIMERR bit to 1.

VBUFUDF bit (Video Buffer Underflow Error Interrupt Enable)

The VBUFUDF bit controls the Video Buffer Underflow Error Interrupt permission.

When a Video Buffer Underflow Error Interrupt occurs, the VMSR.VBUFUDF flag is set to 1.

To enable the Video Buffer Underflow Error Interrupt, set the VBUFUDF bit to 1.

VBUFOVF bit (Video Buffer Overflow Error Interrupt Enable)

The VBUFOVF bit controls the Video Buffer Overflow Error Interrupt permission.

When a Video Buffer Overflow Error Interrupt occurs, the VMSR.VBUFOVF flag is set to 1.

To enable the Video Buffer Overflow Error Interrupt, set the VBUFOVF bit to 1.

58.2.48 VMPPSETR : Video Mode Pixel Packet Set Register

31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

TXESYNC bit (Transmit End of Sync Pulse)

0 setting is used for *Burst Mode* sequence or *Non-Burst Mode with Sync Events* sequence.

1 setting is used for *Non-Burst Mode with Sync Pulse* sequence.

DT[5:0] bits (Video Mode Data Type)

Set the same format as the input format from GLCDC.

VC[1:0] bits (Video Mode Virtual Channel)

Set a number between 00b to 11b as the virtual channel identifier.

58.2.49 VMVSSETR : Video Mode Vertical Size Set Register

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Bit	Symbol	Function	R/W
1:0	—	These bits are read as 0.	R
2	RUNNING	Sequence Operation Running Status 0: Sequence operation is stopped 1: Sequence operation is running	R
3	—	This bit is read as 0.	R
4	AACTFIN	All Actions Finish Interrupt Flag 0: All actions of a descriptor have not finished 1: All actions of a descriptor finished operations	R
7:5	—	These bits are read as 0.	R
8	ADESFIN	All-Descriptors Finish Interrupt Flag 0: All descriptors have not finished 1: All descriptors finished operations	R
23:9	—	These bits are read as 0.	R
24	TXIBERR	Tx Internal Bus Error Interrupt Flag 0: No error 1: Internal AXI bus read error occurred	R
25	—	This bit is read as 0.	R
26	RXFERR	Receive Fatal Error Interrupt Flag 0: No error 1: Fatal timeout occurred during BTA	R
27	RXFAIL	Receive Fail Interrupt Flag 0: No error 1: Expected receive did not take place	R
28	RXPFAIL	Receive Packet Data Fail Interrupt Flag 0: No error 1: Received packet data is not stored correctly	R
29	RXCORERR	Receive Correctable Error Interrupt Flag 0: No error 1: Received packets have correctable error	R
30	RXAKE	Receive Acknowledge and Error Report Packet Interrupt Flag 0: No error 1: Acknowledge and Error Report Packet is received	R
31	—	This bit is read as 0.	R

Note: S-TYPE-3, P-TYPE-3

RUNNING bit (Sequence Operation Running Status)

The RUNNING bit indicates the state of the sequence operation.

Changing the settings of the descriptor is prohibited while the RUNNING bit is 1.

AACTFIN flag (All Actions Finish Interrupt Flag)

The AACTFIN flag is set if this descriptor's all actions are finished with SQCHnDSCmCR.FINACT =1.

The AACTFIN flag is not cleared automatically, so set the SQCH0SCR.AACTFIN bit to 1 to clear the AACTFIN flag.

ADESFIN flag (All-Descriptors Finish Interrupt Flag)

The ADESFIN flag is set when all descriptors finish operations.

When Descriptor-m whose the SQCHnDSCmAR.NXACT[1:0] bits are set to 00b finishes the operation, the ADESFIN flag is set to 1.

The ADESFIN flag is not cleared automatically, so set the SQCH0SCR.ADESFIN bit to 1 to clear the ADESFIN flag.

TXIBERR flag (Tx Internal Bus Error Interrupt Flag)

The TXIBERR flag is set to 1 when the internal AXI bus read is failed.

The TXIBERR flag is not cleared automatically, so set the SQCH0SCR.TXIBERR bit to 1 to clear the TXIBERR flag.

RXFERR flag (Receive Fatal Error Interrupt Flag)

The RXFERR flag is set to 1 when the fatal timeout occurred during BTA.

The FERRSR.TATO flag or the FERRSR.LRXHTO flag is also set to 1.

The RXFERR flag is not cleared automatically, so set the SQCH0SCR.RXFERR bit to 1 to clear the RXFERR flag.

RXFAIL flag (Receive Fail Interrupt Flag)

The RXFAIL flag is set to 1 when the expected receive did not done.

The RXSR.PRTOERR flag, the RXSR.ECCERRM flag, the RXSR.MLFERR flag, or the RXSR.NORESERR flag is also set to 1.

The RXFAIL flag is not cleared automatically, so set the SQCH0SCR.RXFAIL bit to 1 to clear the RXFAIL flag.

RXPFAIL flag (Receive Packet Data Fail Interrupt Flag)

The RXPFAIL flag is set to 1 when the received packet header is stored correctly, but the packet data is not stored correctly.

The RXSR.CRCERR flag, the RXSR.WCERR flag, the RXSR.UNEXERR flag, the RXSR.RSIZEERR flag,

the RXSR.RXOVFERR flag, or the RXSR.IBERR flag is also set to 1.

The RXPFAIL flag is not cleared automatically, so set the SQCH0SCR.RXPFAIL bit to 1 to clear the RXPFAIL flag.

RXCORERR flag (Receive Correctable Error Interrupt Flag)

The RXCORERR flag is set to 1 when the received packet has correctable errors.

The RXSR.ECCERRS flag is also set to 1.

The RXCORERR flag is not cleared automatically, so set the SQCH0SCR.RXCORERR bit to 1 to clear the RXCORERR flag.

RXAKE flag (Receive Acknowledge and Error Report Packet Interrupt Flag)

The RXAKE flag is set to 1 when the Acknowledge and Error Report Packet is received.

The RXSR.RXAKE flag is also set to 1.

The RXAKE flag is not cleared automatically, so set the SQCH0SCR.RXAKE bit to 1 to clear the RXAKE flag.

58.2.55 SQCH0SCR : Sequence Channel 0 Status Clear Register

Note: S-TYPE-3, P-TYPE-3

AACTFIN bit (All Actions Finish Interrupt Flag Clear)

Set the AACTFIN bit to 1 to clear the SQCH0SR.AACTFIN flag.

ADESFIN bit (All-Descriptors Finish Interrupt Flag Clear)

Set the ADESFIN bit to 1 to clear the SQCH0SR.ADESFIN flag.

TXIBERR bit (Tx Internal Bus Error Interrupt Flag Clear)

Set the TXIBERR bit to 1 to clear the SQCH0SR.TXIBERR flag.

RXFERR bit (Receive Fatal Error Interrupt Flag Clear)

Set the RXFERR bit to 1 to clear the SQCH0SR.RXFERR flag.

RXFAIL bit (Receive Fail Interrupt Flag Clear)

Set the RXFAIL bit to 1 to clear the SQCH0SR.RXFAIL flag.

RXPFAIL bit (Receive Packet Data Fail Interrupt Flag Clear)

Set the RXPFAIL bit to 1 to clear the SQCH0SR.RXPFAIL flag.

RXCORERR bit (Receive Correctable Error Interrupt Flag Clear)

Set the RXCORERR bit to 1 to clear the SQCH0SR.RXCORERR flag.

RXAKE bit (Receive Acknowledge and Error Report Packet Interrupt Flag Clear)

Set the RXAKE bit to 1 to clear the SQCH0SR.RXAKE flag.

30	RXAKE	Receive Acknowledge and Error Report Packet Interrupt Enable 0: Disable 1: Enable	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

AACTFIN bit (All Actions Finish Interrupt Enable)

The AACTFIN bit controls the All Actions Finish Interrupt permission.

When an All Actions Finish Interrupt occurs, the SQCH0SR.AACTFIN flag is set to 1.

To enable the All Actions Finish Interrupt, set the AACTFIN bit to 1.

ADESFIN bit (All-Descriptors Finish Interrupt Enable)

The ADESFIN bit controls the All-Descriptors Finish Interrupt permission.

When an All-Descriptors Finish Interrupt occurs, the SQCH0SR.ADESFIN flag is set to 1.

To enable the All-Descriptors Finish Interrupt, set the ADESFIN bit to 1.

TXIBERR bit (Tx Internal Bus Error Interrupt Enable)

The TXIBERR bit controls the Tx Internal Bus Error Interrupt permission.

When a Tx Internal Bus Error Interrupt occurs, the SQCH0SR.TXIBERR flag is set to 1.

To enable the Tx Internal Bus Error Interrupt, set the TXIBERR bit to 1.

RXFERR bit (Receive Fatal Error Interrupt Enable)

The RXFERR bit controls the Receive Fatal Error Interrupt permission.

When a Receive Fatal Error Interrupt occurs, the SQCH0SR.RXFERR flag is set to 1.

To enable the Receive Fatal Error Interrupt, set the RXFERR bit to 1.

RXFAIL bit (Receive Fail Interrupt Enable)

The RXFAIL bit controls the Receive Fail Interrupt permission.

When a Receive Fail Interrupt occurs, the SQCH0SR.RXFAIL flag is set to 1.

To enable the Receive Fail Interrupt, set the RXFAIL bit to 1.

RXPFAIL bit (Receive Packet Data Fail Interrupt Enable)

The RXPFAIL bit controls the Receive Packet Data Fail Interrupt permission.

When a Receive Packet Data Fail Interrupt occurs, the SQCH0SR.RXPFAIL flag is set to 1.

To enable the Receive Packet Data Fail Interrupt, set the RXPFAIL bit to 1.

RXCORERR bit (Receive Correctable Error Interrupt Enable)

The RXCORERR bit controls the Receive Correctable Error Interrupt permission.

When a Receive Correctable Error Interrupt occurs, the SQCH0SR.RXCORERR flag is set to 1.

To enable the Receive Correctable Error Interrupt, set the RXCORERR bit to 1.

RXAKE bit (Receive Acknowledge and Error Report Packet Interrupt Enable)

The RXAKE bit controls the Receive Acknowledge and Error Report Packet Interrupt permission.

When a Receive Acknowledge and Error Report Packet Interrupt occurs, the SQCH0SR.RXAKE flag is set to 1.

To enable the Receive Acknowledge and Error Report Packet Interrupt, set the RXAKE bit to 1.

58.2.57 SQCH1SET0R : Sequence Channel 1 Set 0 Register

Base address: MIPI_DSI = 0x4034_6000

30	RXAKE	Receive Acknowledge and Error Report Packet Interrupt Flag 0: No error 1: Acknowledge and Error Report Packet is received	R
31	—	This bit is read as 0.	R

Note: S-TYPE-3, P-TYPE-3

RUNNING bit (Sequence Operation Running Status)

The RUNNING bit indicates the state of the sequence operation.

Changing the settings of the descriptor is prohibited while the RUNNING bit is 1.

AACTFIN flag (All Actions Finish Interrupt Flag)

The AACTFIN flag is set if this descriptor's all actions are finished with SQCHnDSCmCR.FINACT =1.

The AACTFIN flag is not cleared automatically, so set the SQCH1SCR.AACTFIN bit to 1 to clear the AACTFIN flag.

ADESFIN flag (All-Descriptors Finish Interrupt Flag)

The ADESFIN flag is set when all descriptors finish operations.

When Descriptor-m whose the SQCHnDSCmAR.NXACT[1:0] bits are set to 00b finishes the operation, the ADESFIN flag is set to 1.

The ADESFIN flag is not cleared automatically, so set the SQCH1SCR.ADESFIN bit to 1 to clear the ADESFIN flag.

SIZEERR flag (Packet Size Error Interrupt Flag)

The SQCH1SR.SIZEERR flag is set to 1 when the sequence packet is too large.

The SQCH1SR.SIZEERR flag is not cleared automatically, so set the SQCH1SCR.SIZEERR bit to 1 to clear the SQCH1SR.SIZEERR flag.

TXIBERR flag (Tx Internal Bus Error Interrupt Flag)

The TXIBERR flag is set to 1 when the internal AXI bus read is failed.

The TXIBERR flag is not cleared automatically, so set the SQCH1SCR.TXIBERR bit to 1 to clear the TXIBERR flag.

RXFERR flag (Receive Fatal Error Interrupt Flag)

The RXFERR flag is set to 1 when the fatal timeout occurred during BTA.

The FERRSR.TATO flag or the FERRSR.LRXHTO flag is also set to 1.

The RXFERR flag is not cleared automatically, so set the SQCH1SCR.RXFERR bit to 1 to clear the RXFERR flag.

RXFAIL flag (Receive Fail Interrupt Flag)

The RXFAIL flag is set to 1 when the expected receive did not done.

The RXSR.PRTOERR flag, the RXSR.ECCERRM flag, the RXSR.MLFERR flag, or the RXSR.NORESERR flag is also set to 1.

The RXFAIL flag is not cleared automatically, so set the SQCH1SCR.RXFAIL bit to 1 to clear the RXFAIL flag.

RXPFAIL flag (Receive Packet Data Fail Interrupt Flag)

The RXPFAIL flag is set to 1 when the received packet header is stored correctly, but the packet data is not stored correctly.

The RXSR.CRCERR flag, the RXSR.WCERR flag, the RXSR.UNEXERR flag, the RXSR.RSIZEERR flag, the RXSR.RXOVFERR flag, or the RXSR.IBERR flag is also set to 1.

The RXPFAIL flag is not cleared automatically, so set the SQCH1SCR.RXPFAIL bit to 1 to clear the RXPFAIL flag.

RXCORERR flag (Receive Correctable Error Interrupt Flag)

The RXCORERR flag is set to 1 when the received packet has correctable errors.

The RXSR.ECCERRS flag is also set to 1.

The RXCORERR flag is not cleared automatically, so set the SQCH1SCR.RXCORERR bit to 1 to clear the RXCORERR flag.

RXAKE flag (Receive Acknowledge and Error Report Packet Interrupt Flag)

The RXAKE flag is set to 1 when the Acknowledge and Error Report Packet is received.

The RXSR.RXAKE flag is also set to 1.

The RXAKE flag is not cleared automatically, so set the SQCH1SCR.RXAKE bit to 1 to clear the RXAKE flag.

Note: S-TYPE-3, P-TYPE-3

AACTFIN bit (All Actions Finish Interrupt Flag Clear)

Set the AACTFIN bit to 1 to clear the SQCH1SR.AACTFIN flag.

ADESFIN bit (All-Descriptors Finish Interrupt Flag Clear)

Set the ADESFIN bit to 1 to clear the SQCH1SR.ADESFIN flag.

SIZEERR bit (Packet Size Error Interrupt Flag Clear)

Set the SIZEERR bit to 1 to clear the SQCH1SR.SIZEERR flag.

TXIBERR bit (Tx Internal Bus Error Interrupt Flag Clear)

Set the TXIBERR bit to 1 to clear the SQCH1SR.TXIBERR flag.

RXFERR bit (Receive Fatal Error Interrupt Flag Clear)

Set the RXFERR bit to 1 to clear the SQCH1SR.RXFERR flag.

RXFAIL bit (Receive Fail Interrupt Flag Clear)

Set the RXFAIL bit to 1 to clear the SQCH1SR.RXFAIL flag.

RXPFAIL bit (Receive Packet Data Fail Interrupt Flag Clear)

Set the RXPFAIL bit to 1 to clear the SQCH1SR.RXPFAIL flag.

RXCORERR bit (Receive Correctable Error Interrupt Flag Clear)

Set the RXCORERR bit to 1 to clear the SQCH1SR.RXCORERR flag.

RXAKE bit (Receive Acknowledge and Error Report Packet Interrupt Flag Clear)

Set the RXAKE bit to 1 to clear the SQCH1SR.RXAKE flag.

31	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

AACTFIN bit (All Actions Finish Interrupt Enable)

The AACTFIN bit controls the All Actions Finish Interrupt permission.

When an All Actions Finish Interrupt occurs, the SQCH1SR.AACTFIN flag is set to 1.

To enable the All Actions Finish Interrupt, set the AACTFIN bit to 1.

ADESFIN bit (All-Descriptors Finish Interrupt Enable)

The ADESFIN bit controls the All-Descriptors Finish Interrupt permission.

When an All-Descriptors Finish Interrupt occurs, the SQCH1SR.ADESFIN flag is set to 1.

To enable the All-Descriptors Finish Interrupt, set the ADESFIN bit to 1.

SIZEERR bit (Packet Size Error Interrupt Enable)

The SIZEERR bit controls the Packet Size Error Interrupt permission.

When a Packet Size Error Interrupt occurs, the SQCH1SR.SIZEERR flag is set to 1.

To enable the Packet Size Error Interrupt, set the SIZEERR bit to 1.

TXIBERR bit (Tx Internal Bus Error Interrupt Enable)

The TXIBERR bit controls the Tx Internal Bus Error Interrupt permission.

When a Tx Internal Bus Error Interrupt occurs, the SQCH1SR.TXIBERR flag is set to 1.

To enable the Tx Internal Bus Error Interrupt, set the TXIBERR bit to 1.

RXFERR bit (Receive Fatal Error Interrupt Enable)

The RXFERR bit controls the Receive Fatal Error Interrupt permission.

When a Receive Fatal Error Interrupt occurs, the SQCH1SR.RXFERR flag is set to 1.

To enable the Receive Fatal Error Interrupt, set the RXFERR bit to 1.

RXFAIL bit (Receive Fail Interrupt Enable)

The RXFAIL bit controls the Receive Fail Interrupt permission.

When a Receive Fail Interrupt occurs, the SQCH1SR.RXFAIL flag is set to 1.

To enable the Receive Fail Interrupt, set the RXFAIL bit to 1.

RXPFAIL bit (Receive Packet Data Fail Interrupt Enable)

The RXPFAIL bit controls the Receive Packet Data Fail Interrupt permission.

When a Receive Packet Data Fail Interrupt occurs, the SQCH1SR.RXPFAIL flag is set to 1.

To enable the Receive Packet Data Fail Interrupt, set the RXPFAIL bit to 1.

RXCORERR bit (Receive Correctable Error Interrupt Enable)

The RXCORERR bit controls the Receive Correctable Error Interrupt permission.

When a Receive Correctable Error Interrupt occurs, the SQCH1SR.RXCORERR flag is set to 1.

To enable the Receive Correctable Error Interrupt, set the RXCORERR bit to 1.

RXAKE bit (Receive Acknowledge and Error Report Packet Interrupt Enable)

The RXAKE bit controls the Receive Acknowledge and Error Report Packet Interrupt permission.

When a Receive Acknowledge and Error Report Packet Interrupt occurs, the SQCH1SR.RXAKE flag is set to 1.

To enable the Receive Acknowledge and Error Report Packet Interrupt, set the RXAKE bit to 1.

58.2.61 SQCHnDSCmAR : Sequence Channel n Descriptor-m A Register (n = 0 to 1, m = 0 to 7)

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x780 + (0x10 × m) + (0x80 × n)

24	FMT	Format Set packet format of Tx Packet Header. 0: Short Packet 1: Long Packet	R/W
25	SPD	Speed Set the speed type for Tx request. 0: High Speed 1: Low Power	R/W
27:26	BTA[1:0]	Bus Turn Around Sets either Tx Request without Bus Turn-Around (BTA) or no-operation. Or else, sets Tx Request with BTA. 0 0: Tx Request without BTA or no-operation 0 1: Tx non-Read Request with BTA 1 0: Tx Read Request with BTA 1 1: BTA only	R/W
29:28	NXACT[1:0]	Next Action 0 0: Terminate the sequence operation after this descriptor processing is finished. 0 1: Start the next descriptor processing after this descriptor processing is finished. Others: Settings prohibited	R/W
31:30	—	The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The maximum size for Command Transfer mode Long Packet by using Packet Payload Data Register (SQCHnDSCmBR.DTSEL[1:0] = 00b and SQCHnDSCmAR.FMT = 1) is 16 bytes.

This register is not initialized by any reset. Therefore, if the user uses sequence operation, be sure to set the values according to the above description for the reserved area as well.

DATA0[7:0] bits (Data 0)

When Tx Packet format is Long Packet (FMT = 1), this value is lower 8 bits of the Word Count (WC).

DATA1[7:0] bits (Data 1)

When Tx Packet format is Long Packet (FMT = 1), this value is upper 8 bits of the Word Count (WC).

DT[5:0] bits (Data Type)

The DT[5:0] bits set the data type of Tx Packet Header.

VC[1:0] bits (Virtual Channel)

The VC[1:0] bits set the identifier of the virtual channel of Tx Packet Header.

FMT bit (Format)

The FMT bit set the packet format of Tx Packet Header. This field should be set by the data type.

SPD bit (Speed)

The SPD bit selects the speed type for Tx request. It is prohibited to set SPD bit to 1 during the Video Mode operation.

BTA[1:0] bits (Bus Turn Around)

The BTA[1:0] bits set either Tx Request without Bus Turn-Around (BTA) or no-operation. Or else, sets Tx Request with BTA.

NXACT[1:0] bits (Next Action)

The NXACT[1:0] bits select the next action after the Descriptor-m processing is finished.

When the SQCHnDSC7AR.NXACT[1:0] bits for Descriptor-7 are set to 01b (Start the next descriptor processing after this descriptor processing is finished), the next descriptor after Descriptor-7 is Descriptor-0.

58.2.62 SQCHnDSCmBR : Sequence Channel n Descriptor-m B Register (n = 0 to 1, m = 0 to 7)

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x784 + (0x10 × m) + (0x80 × n)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	DTSEL[1:0]		—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
23:0	—	The write value should be 0.	R/W
25:24	DTSEL[1:0]	Data Select Select the data buffer for Long Packet payload 0 0: Use Packet Payload Data Register (TXPPDxR, RXPPDxR) 0 1: Use Memory space Others Setting prohibited	R/W
31:26	—	The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register is not initialized by any reset. Therefore, if the user uses sequence operation, be sure to set the values according to the above description for the reserved area as well.

DTSEL[1:0] bits (Data Select)

The DTSEL[1:0] bits select the data source for Long Packet payload. Set the DTSEL[1:0] bits to 00b, in the case of the write request with the short packet.

When the SQCHnDSCmBR.DTSEL[1:0] bits are 00b, DSI Host uses Packet Payload Data Register (TXPPDxR and RXPPDxR, x = 0 to 3) for the Long Packet payload data buffer. In this setting, the Long Packet write request data size shall be same or lower than 16 bytes. When the read request data to save has over 16 bytes word count, it reports as error.

When the SQCHnDSCmBR.DTSEL[1:0] bits are 01b, DSI Host uses Memory space for the Long Packet payload data buffer. DSI Host transfer data stored in Memory space at the address specified in the SQCHnDSCmDR register at the write request. And stores data to Memory space at the address specified in the SQCHnDSCmDR register at the read request. The read header always saved to the RXRSSxR register.

58.2.63 SQCHnDSCmCR : Sequence Channel n Descriptor-m C Register (n = 0 to 1, m = 0 to 7)

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x788 + (0x10 × m) + (0x80 × n)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ACTCODE[7:0]								—	AUXOP	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FINACT
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
0	FINACT	Finish Action Select whether to set the SQCHnSR.AACTFIN bit to 1 when all actions of this Descriptor-m are finished. 0: Disable 1: Enable	R/W
21:1	—	The write value should be 0.	R/W
22	AUXOP	Auxiliary Operation 0: Not use auxiliary operation 1: Execute auxiliary operation*1	R/W
23	—	The write value should be 0.	R/W
31:24	ACTCODE[7:0]	Action Code When not use auxiliary operation (SQCHnDSCmCR.AUXOP = 0): Set the slot number for storing the received result during the BTA action.*2 0 0 0 0 0 0 0 0: Slot-0 (RXRSS0R) 0 0 0 0 0 0 0 1: Slot-1 (RXRSS1R) 0 0 0 0 0 0 1 0: Slot-2 (RXRSS2R) 0 0 0 0 0 0 1 1: Slot-3 (RXRSS3R) Other settings are prohibited. When execute auxiliary operation (SQCHnDSCmCR.AUXOP = 1): Select the action for the auxiliary operation. 0 0 0 0 0 0 0 0: Send Reset-Trigger 0 0 0 0 1 0 0 0: No-operation Other settings are prohibited.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. It is prohibited to set this bit to 1 during the Video mode operation is running.
Note 2. Setting the same slot number to the SQCHnDSCmCR.ACTCODE[7:0] bits of a different descriptor is prohibited.

This register is not initialized by any reset. Therefore, if the user uses sequence operation, be sure to set the values according to the above description for the reserved area as well.

FINACT bit (Finish Action)

The FINACT bit controls whether to set the SQCHnSR.AACTFIN bit to 1 when all actions of this Descriptor-m are finished. Since each descriptor's operation is not same, the descriptors may finish out of order. For example, Descriptor-1 may finish before Descriptor-0.

AUXOP bit (Auxiliary Operation)

The AUXOP bit selects whether executes the auxiliary operation or not. The action of the auxiliary operation is specified by the SQCHnDSCmCR.ACTCODE[7:0] bits. When this AUXOP bit is set to 1, the SQCHnDSCmAR.BTA[1:0] bits should be set to 00b.

ACTCODE[7:0] bits (Action Code)

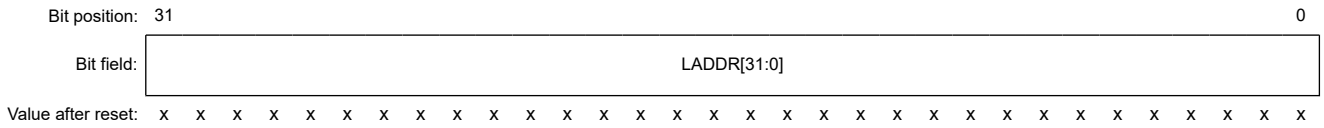
When not use auxiliary operation (SQCHnDSCmCR.AUXOP = 0), the ACTCODE[7:0] bits select the slot number for storing the received result during the BTA action. Set these bits to 0x00 for non-BTA action. Setting the same slot number to the SQCHnDSCmCR.ACTCODE[7:0] bits of a different descriptor is prohibited.

When execute the auxiliary operation (SQCHnDSCmCR.AUXOP = 1), the ACTCODE[7:0] bits select the action that can be taken as the auxiliary operation.

58.2.64 SQCHnDSCmDR : Sequence Channel n Descriptor-m D Register (n = 0 to 1, m = 0 to 7)

Base address: MIPI_DSI = 0x4034_6000
MIPI_DSI_NS = 0x5034_6000

Offset address: 0x78C + (0x10 × m) + (0x80 × n)



Bit	Symbol	Function	R/W
31:0	LADDR[31:0]	Lower Address Set the lower 32-bit address of Memory space to store the long packet payload data for Sequence Operation Channel-n Descriptor-m.	R/W

Note: S-TYPE-3, P-TYPE-3

The SQCHnDSCmDR register is not initialized by any reset. Therefore, if the user uses sequence operation, be sure to set all the bits.

LADDR[31:0] bits (Lower Address)

When the Memory space is selected for Long Packet payload (SQCHnDSCmBR.DTSEL[1:0] = 01b) and the Sequence Mode Operation Format is Long packet (SQCHnDSCmAR.FMT = 1), the DSI Host accesses Memory space at the address specified in this LADDR[31:0] bits. In the case of write operation, DSI Host transfer data stored in Memory space. In the case of read operation, DSI Host store data to Memory space.

58.3 Operation

58.3.1 Interrupt

Table 58.2 Interrupt Signals (1 of 3)

Interrupt Signal	Category	Interrupt Condition	Interrupt Source Register
DSI_SEQ0	Sequence Operation channel 0 interrupt	Receive Acknowledge and Error Report Packet	SQCH0SR.RXAKE
		Receive Correctable Error	SQCH0SR.RXCORERR
		Receive Packet Data Fail	SQCH0SR.RXPFAIL
		Receive Fail	SQCH0SR.RXFAIL
		Receive Fatal Error	SQCH0SR.RXFERR
		Tx Internal Bus Error	SQCH0SR.TXIBERR
		All-Descriptors Finish	SQCH0SR.ADESFIN
		All Actions Finish	SQCH0SR.AACTFIN

Table 58.2 Interrupt Signals (2 of 3)

Interrupt Signal	Category	Interrupt Condition	Interrupt Source Register
DSI_SEQ1	Sequence Operation channel 1 interrupt	Receive Acknowledge and Error Report Packet	SQCH1SR.RXAKE
		Receive Correctable Error	SQCH1SR.RXCORERR
		Receive Packet Data Fail	SQCH1SR.RXPFAIL

Table 58.2 Interrupt Signals (3 of 3)

Interrupt Signal	Category	Interrupt Condition	Interrupt Source Register
DSI_FERR	DSI Fatal Error interrupt	LP1 Contention Error	FERRSR.CLP1
		LP0 Contention Error	FERRSR.CLP0
		Control Error	FERRSR.CTRL
		LPDT Sync Error	FERRSR.SYNCESC
		Escape mode Entry Error	FERRSR.ESCENT
		Turnaround Acknowledge Timeout	FERRSR.TATO
		LP-RX Host Processor Timeout	FERRSR.LRXHTO
		HS TX Timeout Interrupt	FERRSR.HTXTO
DSI_PPI	DSI D-PHY PPI interrupt	Data Lane transition from ULPS	PLSR.DLULPEXT
		Data Lane transition to ULPS	PLSR.DLULPENT
		Clock Lane mode transition from HS to LP	PLSR.CLHS2LP
		Clock Lane mode transition from LP to HS	PLSR.CLLP2HS
		Clock Lane transition from ULPS	PLSR.CLULPEXT
		Clock Lane transition to ULPS	PLSR.CLULPENT
		Data Lane-0 direction transition from transmitter to receiver	PLSR.DL0TX2RX
		Data Lane-0 direction transition from receiver to transmitter	PLSR.DL0RX2TX

The relationship between Interrupt Signals and Interrupt Conditions is shown in Table 58.2

The interrupt signal consists of combinatorial logic shown in Figure 58.3. The interrupt signal from a Status register is enabled by the signal related Interrupt Enable register. These interrupt signals are bound by the OR logic. All interrupt signals are synchronized to pclk and the level signal, and are active-high.

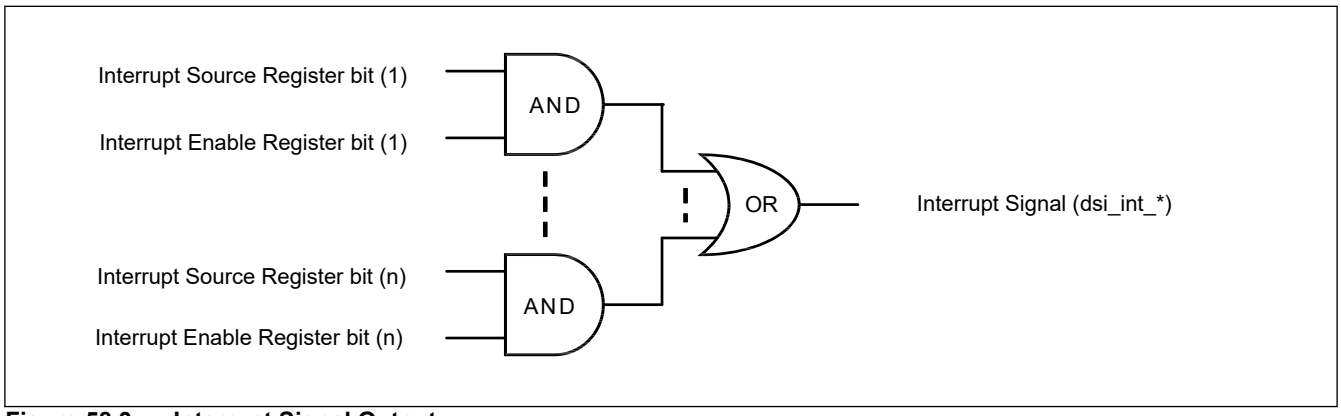

Figure 58.3 Interrupt Signal Output

58.3.2 Software Reset

The software reset is for the initialization of the DSI Host.*1

Initializing by the software reset is optional. To initialize the DSI Host using the software reset, follow the steps below.

1. Set the RSTCR.SWRST bit to 1 for the software reset.
2. Wait for the software reset process to start.
   Wait until the following bits are set to 1.
   (RSTSR.RSTHS, RSTSR.RSTLP, RSTSR.RSTAPB, RSTSR.RSTAXI, RSTSR.RSTV)
3. Set the following registers (optional)

(TXSETR, ULPSSETR, DSISETR, CLSTPTSETR, LPTRNSTSETR, PRESPTOBTASETR, PRESPTOLPSETR, PRESPTOHSSETR, HSTXTOSETR, LRXHTOSETR, TATOSETR)
These registers are allowed to be changed only during this process or initialization at initial startup.

4. Set the RSTCR.FTXSTP bit to 1 to transition to TX-Stop state (LP-11) for the data lane.
5. Wait for the valid data lane to transition to the stop state.
Wait until the RSTSR.DL0DIR bit is cleared to 0 and the RSTSR.DL1STP and DL0STP bits are set to 1 (RSTSR.DL1STP = 0 and RSTSR.DL0STP = 1 for a single lane)
6. Clear the RSTCR.FTXSTP bit to 0 to finish the operation of the transition to TX-Stop state.
7. Clear the RSTCR.SWRST bit to 0 to finish the software reset process.
8. Wait for the software reset process to end.
Wait until the following bits are cleared to 0.
(RSTSR.RSTHS, RSTSR.RSTLP, RSTSR.RSTAPB, RSTSR.RSTAXI, RSTSR.RSTV)

Note 1. The following registers are not initialized by the software reset.
- RSTCR
- RSTSR
- SQCHnDSCmAR (n = 0 to 1, m = 0 to 7)
- SQCHnDSCmBR (n = 0 to 1, m = 0 to 7)
- SQCHnDSCmCR (n = 0 to 1, m = 0 to 7)
- SQCHnDSCmDR (n = 0 to 1, m = 0 to 7)
- TXSETR
- ULPSSETR
- DSISETR
- CLSTPTSETR
- LPTRNSTSETR
- PRESPTOBTASETR
- PRESPTOLPSETR
- PRESPTOHSSETR
- HSTXTOSETR
- LRXHTOSETR
- TATOSETR

58.3.3 Start of HS Clock

HS clock is controlled by the software. Set the registers according to the following flow.

1. Set the TXSETR.CLEN bit to 1 to enable the D-PHY clock lane before starting the Video Mode operation or Sequence mode operation.
2. Set the HSCLKSETR.HSCLST bit to 1. At the same time, set the HSCLKSETR.HSCLMD bit to 1 when using the continuous clock mode.
In the continuous clock mode, the clock lane is always put the HS state.
In the non-continuous clock mode, the DSI Host automatically controls the transition between LP and HS states of the clock lane.
3. Wait until the PLSR.CLLP2HS bit is set 1. (only in the continuous clock mode)

58.3.4 Stop of HS Clock

1. Clear the HSCLKSETR.HSCLST bit to 0 to transition the clock lane to the LP state.
2. Wait until the PLSR.CLHS2LP bit is set 1. (only in the continuous clock mode)
The user can also check the status of the clock lane by reading the PLSR.CLSTP bit.

58.3.5 Command Mode Operation

The DSI Host supports two basic modes of operation: Command Mode and Video Mode. This section describes how to operate in Command Mode.

The Command Mode of this DSI Host is intended to be used for communication such as configuration settings for Peripheral before sending video signals.

In Command Mode, a descriptor list that describes the sending and receiving process in advance is used.

Processing using descriptors is referred to here as Sequence Operation.

The DSI Host has two channels for Sequence Operation (Sequence Operation Channel-n, n = 0 to 1).

Channel-0 supports only LP mode (LP-TX, LP-RX), while Channel-1 supports LP mode (LP-TX, LP-RX) and HS mode (HS-TX). There are 8 descriptors for each channel.

The Command Mode of this DSI Host supports only Sequence Operation using these descriptors.

Each descriptor has four control registers for Sequence Operation (SQCHnDSCmAR, SQCHnDSCmBR, SQCHnDSCmCR, SQCHnDSCmDR) that specify the transmit and receive operations.

The payload data for Long Packet is stored in Memory space or Packet Payload Data Register, which is shared among descriptors. Memory space for transfer is dedicated for Channel-0 and Channel-1, respectively. (Figure 58.4)

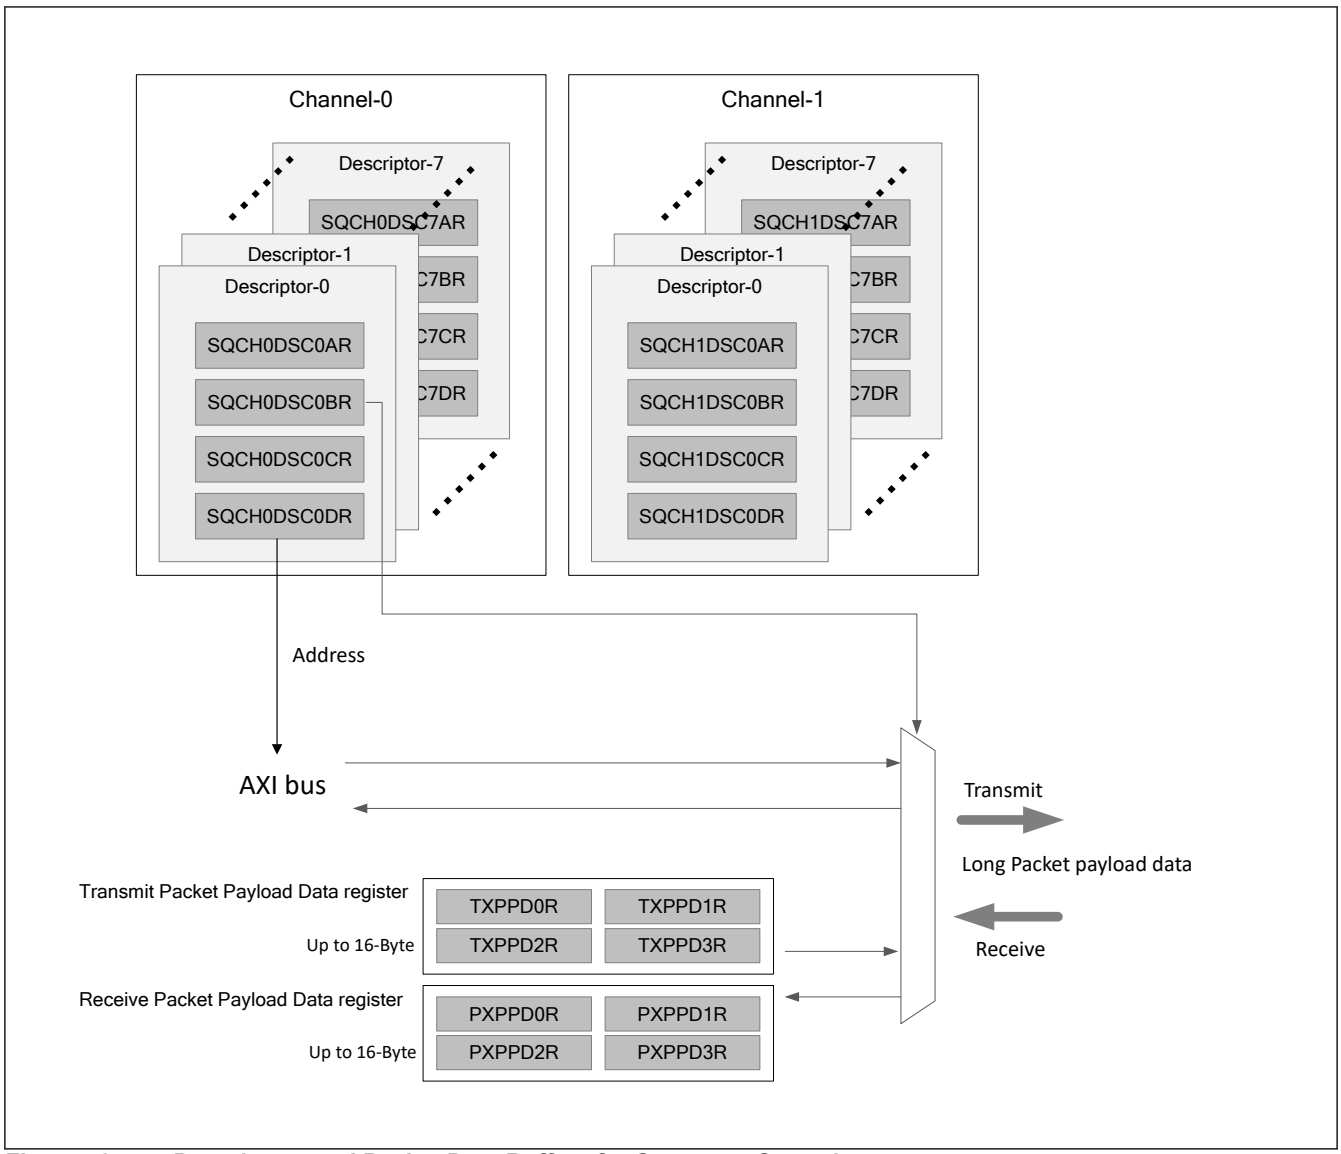

Figure 58.4 Descriptors and Packet Data Buffers for Sequence Operation

58.3.5.1 Basic Running Sequence

By setting the SQCHnSET0R.START bit to 1, the Sequence Operation Channel-n starts processing the descriptor. When the process of Descriptor-m which the SQCHnDSCmAR.NXACT[1:0] bits are set to 00b is completed, the sequence operations stop.

After setting the SQCHnSET0R.START bit to 1, the SQCHnSR.RUNNING bit is set to 1. Once the SQCHnSR.RUNNING bit is set to 1, it is prohibited to change the settings of the following registers until the sequence operation is stopped.

- SQCHnDSCmAR (n = 0 to 1, m = 0 to 7)

- SQCHnDSCmBR (n = 0 to 1, m = 0 to 7)
- SQCHnDSCmCR (n = 0 to 1, m = 0 to 7)
- SQCHnDSCmDR (n = 0 to 1, m = 0 to 7)

58.3.5.2 Single Packet Transmission

This section describes the transmission of the non-read packets in Command mode using Sequence operation.

In the non-read packet transmission, set the following registers before sending the packets.

- SQCHnDSCmAR.NXACT[1:0] : 00b
- SQCHnDSCmAR.FMT : 0 (Short Packet) or 1 (Long Packet)
- SQCHnDSCmAR.SPD : 0 (High Speed) or 1 (Low Speed)
- SQCHnDSCmAR.BTA[1:0] : 00b (without BTA) or 01b (with BTA)
- SQCHnDSCmAR.VC[1:0]
- SQCHnDSCmAR.DT[5:0]
- SQCHnDSCmAR.DATA0[7:0]
- SQCHnDSCmAR.DATA1[7:0]
- SQCHnDSCmBR.DTSEL[1:0] : Specify where to store the payload data for the non-read packets

  00b: TXPPDxR (x = 0 to 3). Payloads size is limited up to 16 bytes.

  01b: Memory space. Payloads size is limited up to 4KB.
- SQCHnDSCmCR.AUXOP : 0

When setting up a Long Packet (SQCHnDSCmAR.FMT = 1), the payload data should be in the format of little endian at the location specified by the SQCHnDSCmBR.DTSEL[1:0] bits.

When setting up a Short Packet (SQCHnDSCmAR.FMT = 0), no payload data is required.

After the above settings, send a non-read packet by setting the SQCHnSET0R.START bit to 1. When Single Packet Transmission is complete, the SQCHnSR.ADESFIN bit is set to 1.

When the SQCHnDSCmAR.BTA[1:0] bits are set to 01b, BTA will be taken place after sending a non-read packet. After DSI Host gives bus ownership to the peripheral, An ACK trigger Message or an Acknowledge and Error Report Packet may be returned from the peripheral.

The user can get a summary of the reception result by reading the RXRSSxR register with the number-x specified in the SQCHnDSCmCR.ACTCODE[7:0] bits, and can get the reception result details by reading the RXSR register.

58.3.5.3 Single Packet Reception

This section describes sending the read packets and receiving the response packets in Command mode using Sequence operation.

Since the read packet is a Short Packet, set the following registers before sending the packet.

- SQCHnDSCmAR.NXACT[1:0] : 00b
- SQCHnDSCmAR.FMT : 0 (Short Packet)
- SQCHnDSCmAR.SPD : 0 (High Speed) or 1 (Low Speed)
- SQCHnDSCmAR.BTA[1:0] : 10b (Read Request with BTA)
- SQCHnDSCmAR.VC[1:0]
- SQCHnDSCmAR.DT[5:0]
- SQCHnDSCmAR.DATA0[7:0]
- SQCHnDSCmAR.DATA1[7:0]
- SQCHnDSCmBR.DTSEL[1:0] : Specify where to store the payload data for response packets

00b : RXPPDxR (x = 0 to 3). Payloads size is limited up to 16 bytes.

01b : Memory space. Payloads size is limited up to 128 bytes.

- SQCHnDSCmCR.AUXOP : 0
- SQCHnDSCmCR.ACTCODE[7:0] : Received Result Save Slot number

When the SQCHnDSCmBR.DTSEL[1:0] bits are set to 00b, the payload data reception larger than 16 bytes is not supported. If there is a possibility of receiving the payload data larger than 16 bytes, set the SQCHnDSCmBR.DTSEL[1:0] bits to 01b.

After the above settings, send a read packet by setting the SQCHnSET0R.START bit to 1.

BTA takes place after sending the read packet. After DSI Host gives bus ownership to the peripheral, DSI Host receives a response packet. At this time, DSI Host may also receive an Acknowledge and Error Report Packet at the same time.

When Single Packet Reception is complete, the SQCHnSR.ADESFIN bit is set to 1.

The user can get a summary of the reception result by reading the RXRSSxR register with the number-x specified in the SQCHnDSCmCR.ACTCODE[7:0] bits, and can get the reception result details by reading the RXSR register.

If the response packet received is a Short Packet or Long Packet with WC = 0, the SQCHnDSCmBR.DTSEL[1:0] bits setting is not meaningful.

58.3.5.4 Reset Trigger Transmission

DSI Host can send the reset trigger in Command mode using Sequence operation.

Set the following registers before starting the sequence operation.

- SQCHnDSCmAR.NXACT[1:0] : 00b
- SQCHnDSCmCR.AUXOP : 1
- SQCHnDSCmCR.ACTCODE[7:0] : 0x00

After the above settings, send a reset trigger by setting the SQCHnSET0R.START bit to 1.

The SQCHnSR.ADESFIN bit is set to 1 when a reset trigger transmission is complete.

58.3.5.5 Execute Operation in Sequence

Explains the behavior of the descriptor in Command mode using Sequence operation.

By setting the SQCHnSET0R.START bit to 1, Sequence Operation Channel-n is enabled, and processing is performed from Descriptor-0.

Once Descriptor-m process is complete, the next process follows the value of the SQCHnDSCmAR.NXACT[1:0] bits.

When the SQCHnDSCmAR.NXACT[1:0] bits to be 00b:

After Descriptor-m processing is complete, Sequence Operation Channel-n stops.

When the SQCHnDSCmAR.NXACT[1:0] bits to be 01b:

After Descriptor-m processing is complete, Descriptor-(m + 1) processing begins.

58.3.5.6 Receiving EoTp

DSI Host can receive the End of Transmission Packet (EoTp). When DSI Host receives an EoTp, the RXSR.RXEOTP bit is set to be 1.

58.3.5.7 Acknowledge and Error Reporting Mechanism

The user can know the reliability of the serial bus by using Acknowledge and Error Reporting Mechanism.

If the peripheral detects an error on the serial bus in the peripheral-to-host transmission, the peripheral respond with Acknowledge and Error Report packet. When DSI Host receives this packet, it sets the RXRSSxR.RXAKE bit, the RXSR.RXAKE bit, and the SQCHnSR.RXAKE bit to 1. The virtual channel identifier and the error report for the latest received Acknowledge and Error Report packet is stored in the AKEPLATIR register and the accumulated information is displayed in the AKEPACMSR register.

58.3.6 Video Mode Operation

58.3.6.1 Start of Video Mode Operation

The procedure to start operating in video mode is as follows:

1. Set the video mode parameters (VMPPSETR, VMVSSETR, VMVPSETR, VMHSSETR, VMHPSETR)
2. Set the VMSET1R.DLY[11:0] bits.
3. Set the VMSET0R.VSTART bit to 1 with other VMSET0R setting values.
4. Wait until the VMSR.VIRDY bit is set to 1.
5. Set the BG_EN.VEN bit and GB_EN.EN bit to 1 at the same time for the GLCDC. By this setting, the output of the vertical and horizontal synchronization signals VSYNC, HSYNC, and DE, and the image data (RGB) from the GLCDC starts. (See section 58.5.1. GLCDC register setting when using Video Mode operation)

58.3.6.2 End of Video Mode Operation

The procedure to stop operating in video mode is as follows:

1. Set the VMSET0R.VSTOP bit to 1 to request that the video mode operation stops.
   When the DSI Host detects the start of the first frame after setting the VMSET0R.VSTOP bit to 1, it stops sending video mode packets and sets the VMSR.STOP flag to 1 and VMSR.RUNNING flag to 0.
2. Stop the GLCDC after checking that the VMSR.STOP flag is set to 1.
3. After Stopping the GLCDC, wait for the LINKSR.HSBUSY flag is set to 0.

58.3.6.3 Burst Mode

The DSI Host supports the burst mode. The burst mode is a mode for time-compression of pixel data.

Make the bandwidth of D-PHY wider than the bandwidth of the data stream from GLCDC to time compress the pixel data.

58.3.6.4 Non-Burst Mode

The DSI Host supports the non-burst mode.

Equalize the bandwidth of D-PHY with the bandwidth of the data stream from GLCDC.

58.3.6.5 Selection of Blanking Packets or LP-11 for HSA, HBP, and HFP

When both of the following two conditions are satisfied, the DSI Host automatically transitions the Data Lane from HS mode to LP mode during the HSA, HBP, and HFP periods respectively.

If the DSI Host does not transition from HS mode to LP mode, it sends the blanking packets with the same VC (Virtual Channel) as the VC of the previous packet to maintain HS mode.

1. There is time to transition from HS mode to LP mode and back to HS mode before the next HS transfer starts. (The minimum period required to transition to LP mode is specified by the LPTRNSTSETR.GOLPBKT[9:0] bits)
2. The following registers are set for each period of HSA, HBP, and HFP.
   HSA : VMSET0R.HSANOLP = 0
   HBP : VMSET0R.HBPNOLP = 0
   HFP : VMSET0R.HFPNOLP = 0

58.3.6.6 Non video packet action in Video Mode Operation

The DSI Host can send/receive packets using Sequence Operation (See section 58.3.5.2. Single Packet Transmission and section 58.3.5.3. Single Packet Reception) during Video Mode Operation.

Make sure that all Sequence Operation Channel's operations are finished before starting the Vide Mode Operation (before starting the process described in section 58.3.6.1. Start of Video Mode Operation).

During Video Mode Operation, Sequence Operation is used to send and receive packets after the HSE packet on the first horizontal line if the HSE transfer is permitted (VMPPSETR.TXESYNC = 1) and after the VSS packet if the HSE transfer is not permitted (VMPPSETR.TXESYNC = 0).

Also, sending packets using Sequence Operation is only possible with HS mode (SQCHnDSCmAR.SPD = 0). Transmission in LP mode (SQCHnDSCmAR.SPD = 1) is not supported.

Send and receive packets so that they are completed within the BLLP period of the first horizontal line.

Do not use any other functions of Sequence Operation.

If Sequence Operation is executed during Video Mode Operation, stop Video Mode Operation (section 58.3.6.2. End of Video Mode Operation) after confirming that Sequence Operation is completed.

The period of Video Mode Operation begins the moment the VMSET0R.VSTART bit is set to 1.

Note: The VMSR.RUNNING bit, which indicates that Vide Mode is operating, is reflected after a delay.

58.3.6.7 Delay Adjustment for Video Mode Operation

The DSI Host has a 4 KB video buffer to input video stream from GLCDC.

It is necessary to use the VMSET1R.DLY[11:0] bits to adjust the delay time for reading from the video buffer to prevent the video buffer from overflowing or underflowing during Video Mode operation.

The delay time is derived from the following formula:

Delay time [µs] = VMSET1R.DLY[11:0] × (period of HS serial UI) [µs] × 32

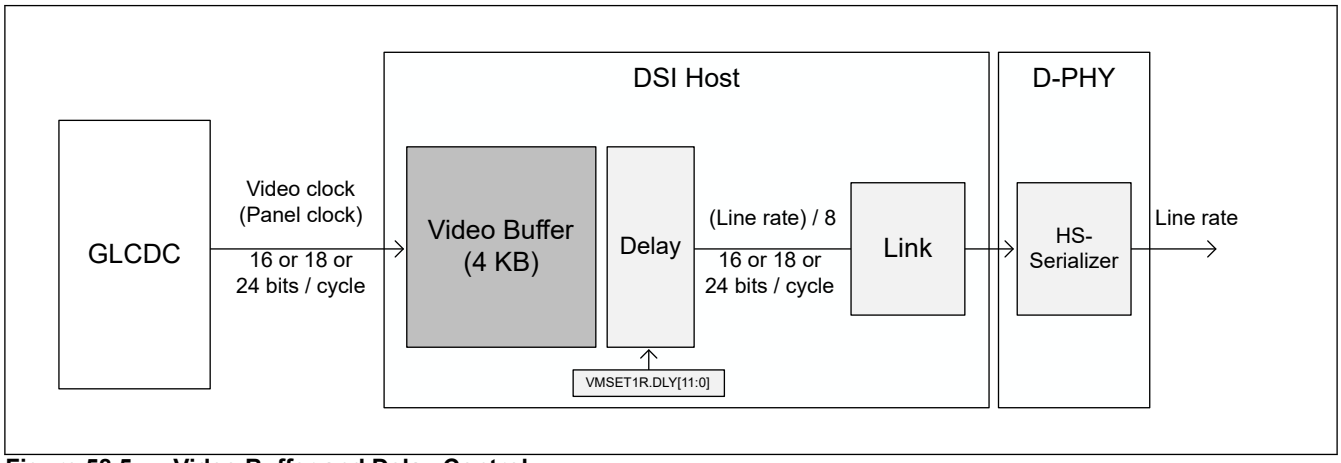

Figure 58.5 Video Buffer and Delay Control

58.3.7 Transition To/From ULPS

This section describes the sequence of transition to or return from ULPS.

The Clock Lane and Data Lanes (Lane-0 and Lane-1) can be transitioned to/from ULPS independently.

When the TXSETR.CLEN bit is set to 1, the Clock Lane can transition to ULPS. It is prohibited to change the TXSETR.CLEN bit to 0 while the Clock Lane is in ULPS.

When the TXSETR.DLEN bit is set to 1, the Data Lanes can transition to ULPS. It is prohibited to change the TXSETR.DLEN bit to 0 while the Data Lanes are in ULPS.

The transition to/from ULPS of the Data Lanes is performed simultaneously for the Data Lane specified by the TXSETR.NUMLANE[1:0] bits.

Only a specific Data Lane cannot be transitioned to ULPS.

When Data Lanes enter ULPS, another operation*1 which uses Data Lanes cannot be performed until exit from ULPS.

When Clock Lane enters ULPS, another operation*2 which uses Clock Lane cannot be performed until exit from ULPS.

Note that the High-Speed Transmit Word clock (HS mode clock) or Escape More Transmit clock (LP mode clock) might be stopped while Data Lanes and Clock Lane are in ULPS depending on the specifications of the system incorporating the DSI-Tx module.

To perform software reset processing (section1.3.2) in this state, restart the stopped clock before executing the software reset flow.

Note 1. Sequence Operation, Video mode Operation.
Note 2. HS Sequence Operation, Video mode Operation.

58.3.8 Error Handling

58.3.8.1 Error Detection by Peripheral

The peripheral notifies the DSI Host of errors it detects with the Acknowledge and Error Report packet.

When the DSI Host receives an Acknowledge and Error Report packet, it displays the latest result in the AKEPLATIR register and the accumulated result in the AKEPACMSR register.

If the user receives an Acknowledge and Error Report packet, review and change various settings as necessary.

58.3.8.2 Error Detection in D-PHY

When the D-PHY detects an error, the DSI Host sets the corresponding register flag.

The following errors are supported by the DSI Host. Refer to Annex A Logical PHY-Protocol Interface Description of MIPI Alliance Specification for D-PHY Version 2.1, Annex A Logical PHY-Protocol Interface Description.

- ErrEsc
- ErrSyncEsc
- ErrControl
- ErrContentionLP0
- ErrContentionLP1

If this error is detected, perform Software Reset (See section 58.3.2. Software Reset) and Reset Trigger Transmission (See section 58.3.5.4. Reset Trigger Transmission) as necessary.

When the ErrContentionLP0/ ErrContentionLP1 error occurs, be sure to execute Software Reset.

In this case, after writing 1 to the RSTCR.FTXSTP bit, wait for a time (equivalent to LRX-H_TO) after which Contention is resolved, and then write 0 to the RSTCR.FTXSTP bit. Also, if necessary, execute Reset Trigger Transmission.

For more information on recovery from contention, refer to 7.2 Contention Detection and Recovery in the MIPI Alliance Specification for Display Serial Interface 2 Version 1.1.

58.3.8.3 Timeout Error

The DSI Host has the timers defined in 7.2.2., Contention Recovery Using Timers in the DSI standard and additional timers.

Timers defined in MIPI DSI Specification

- HS TX Timeout Error (HTX_TO)
- LP-RX Host Processor Timeout Error (LRX-H_TO)
- Turnaround Acknowledge Timeout Error (TA_TO)

Additional Timers

- Peripheral Response Timeout Error

HS TX Timeout (HTX_TO) Error

If this error occurs, execute Software Reset (see section 58.3.2. Software Reset). In addition, if necessary, execute Reset Trigger Transmission (see section 58.3.5.4. Reset Trigger Transmission).

If this error is detected, the setting value of the HSTXTOSETR register may be too small.

Set the HSTXTOSETR register to a value greater than the HS transmission period.

LP-RX Host Processor Timeout (LRX-H_TO) Error

If this error occurs, execute Software Reset (see section 58.3.2. Software Reset). In addition, if necessary, execute Reset Trigger Transmission (see section 58.3.5.4. Reset Trigger Transmission).

If this error is detected, the setting value of the LRXHTOSETR register may be too small.

It is possible to receive multiple packets in one reception, such as a response packet and an Acknowledge and Error Report packet.

Set the LRXHTOSETR register to a value greater than the receive period.

Turnaround Acknowledge Timeout (TA_TO) Error

If this error occurs, if necessary, execute Software Reset (see section 58.3.2. Software Reset) and Reset Trigger Transmission (see section 58.3.5.4. Reset Trigger Transmission).

If this error is detected, the setting value of the TATOSETR register may be too small.

Check the specifications of the Peripheral, if the Peripheral does not support bidirectional communication, this error will also occur.

Peripheral Response Timeout Error

Refer to the description of Peripheral Response Timeout Error in section 58.3.8.4. Receive Related Error in Sequence Operation.

58.3.8.4 Receive Related Error in Sequence Operation

This section describes the errors in received packets detected by the DSI Host.

A maximum of one error is detected per packet.

Note: A single-bit ECC Error may occur at the same time as other errors.

Errors are determined in the following order:

1. Peripheral Response Timeout Error
2. Malformed Packet Error
3. ECC Error
4. Unexpected Packet Error
5. Word Count Error
6. CRC Error
7. No Response Error

Peripheral Response Timeout Error

If no packets or triggers are received within the time set in the register after the bus ownership has been changed from Host to Peripheral by the BTA, the RXSR.PRTOERR flag is set to 1.

When this error is detected, no packets or triggers will be received until the bus ownership shifts from Peripheral to Host.

Timeout Time Setting Registers

- Peripheral Response Timeout value for BTA is specified by the PRESPTOBTASETR register.
- Peripheral Response Timeout value for LP Read with BTA is specified by the PRESPTOLPSETR.LPRTO[15:0] bits.
- Peripheral Response Timeout value for LP Write with BTA is specified by the PRESPTOLPSETR.LPWTO[15:0] bits.
- Peripheral Response Timeout value for HS Read with BTA is specified by the PRESPTOHSSETR.HSRTO[15:0] bits.
- Peripheral Response Timeout value for HS Write with BTA is specified by the PRESPTOHSSETR.HSWTO[15:0] bits.

If this error is detected, the register setting value may be too small, so check the Peripheral specifications.

If this error occurs, perform the necessary processing, such as resending the previous command.

Malformed Packet Error

When a packet of less than 4 bytes is received, the RXSR.MLFERR flag is set to 1. Since there is an error in the received data, perform the necessary processing, such as resending the previous command.

ECC Error

ECC generation is mandatory for Peripherals that comply with the MIPI DSI-2 v1.1 standard. However, ECC generation is optional for "earlier revision of DSI Peripherals", so the DSI Host can control to enable the ECC check by the DSISETR.ECCEN bit.

When connecting to a Peripheral that does not support ECC generation, disable the ECC check by setting the DSISETR.ECCEN bit to 0.

Single Bit ECC Error

When a single-bit ECC error is detected, the RXSR.ECCERRS flag is set to 1, and single-bit ECC error correction is performed.

The DSI Host automatically corrects the error and restores the normal packet header, so that the subsequent packet reception process can continue.

Multi Bit ECC Error

When a multi-bit ECC error is detected, the RXSR.ECCERRM flag is set to 1, and the received packet is discarded.

When this error occurs, perform the necessary processing, such as resending the previous command.

Unexpected Packet Error

If an Unexpected Packet is received, the RXSR.UNEXERR flag is set to 1.

When this error occurs, the packet header is stored in the RXRSSxR register, and subsequent reception processing is stopped until the bus ownership shifts from Peripheral to Host.

The DSI Host judges the following packets as Unexpected Packet.

- Reception of a packet whose Data Type field in the packet header is defined as "Reserved" in Table 23 Data Types for Peripheral-Sourced Packets of the MIPI DSI-2 v1.1 standard.
- Reception of a packet other than Acknowledge and Error Report packet and EoTp after sending a BTA request when the SQCHnDSCmAR.BTA[1:0] bits are set to 01b.
- Reception of a packet other than Acknowledge and Error Report packet and EoTp after sending a BTA request when the SQCHnDSCmAR.BTA[1:0] bits are set to 11b.
- After receiving response packet after sending a read request following BTA when the SQCHnDSCmAR.BTA[1:0] bits are set to 10b, a response packet is received again.

Word Count Error

When the payload data of a long packet is shorter than the WC (Word Count) value, the RXSR.WCERR flag is set to 1.

When this error occurs, there is an error in the payload data length, but the payload data is not discarded, and the packet header is stored in the RXRSSxR register.

Since there is an error in the received data, perform the necessary processing, such as resending the previous command.

CRC Error

For the case of connecting to a Peripheral that does not support CRC generation, the DSI Host can select whether to enable or disable CRC checking for each Virtual Channel using the DSISETR.VCxCRCEN (x = 0 to 3) bit.

When connecting to a Peripheral that does not support CRC generation, disable the CRC check by setting the corresponding DSISETR.VCxCRCEN bit to 0.

When this error occurs, there is an error in the payload data, but the payload data is not discarded, and the packet header is stored in the RXRSSxR register.

If this error occurs, take the necessary action, such as resending the previous command.

No Response Error

After bus ownership is transferred from the host to the peripheral by BTA, if it is transferred back to the host without neither packet nor trigger being received, the RXSR.NORESERR flag is set to 1.

If this error occurs, take the necessary action such as resending the command.

If the error recurs, perform Software Reset (See section 58.3.2. Software Reset) or Reset Trigger Transmission (See section 58.3.5.4. Reset Trigger Transmission) as necessary.

Receive Long Packet Data Payload Related Error in Sequence Operation

Maximum Return Packet Size Error

If the WC (Word Count) value of the received long packet is greater than the value set in the DSISETR.MRPSZ[15:0] bits, the RXSR.RSIZEERR flag is set to 1.

When this error occurs, the packet header is stored in the RXRSSxR register and the payload data is discarded.

The payload data is discarded, but errors related to the payload data reception (WC Error, CRC Error) are detected.

If this error occurs, set the DSISETR.MRPSZ[15:0] bits to a value greater than or equal to the value set in the *Set Max Return Packet Size* command which limits the size of returning packets.

If this error occurs despite the correct settings, consider setting a larger value for the DSISETR.MRPSZ[15:0] bits, as Peripheral may be sending back large packets in violation of the DSI standard.

Internal Bus Error

If an error is detected in Internal AXI Bus Write, the RXSR.IBERR flag is set to 1.

Review the settings of the SQCHnDSCmDR.LADDR[31:0] bits and the DSISETR.MRPSZ[15:0] bits.

Receive Buffer Overflow Error

The RXSR.RXOVFERR flag is set to 1 when the following Receive Buffer Overflow Error is detected.

- In the case of using Packet Payload Data Register (SQCHnDSCmBR.DTSEL = 00b)
  The length of the received payload data is longer than 16 Bytes.
- In the case of using Memory space (SQCHnDSCmBR.DTSEL = 01b)
  Memory space overflows in LP-RX.

If this error occurs, do the following:

- In the case of using Packet Payload Data Register (SQCHnDSCmBR.DTSEL = 00b)
  - Change to use Memory space.
  - Change the maximum return packet size of peripheral device so that it does not exceed 16 bytes.
- In the case of using Memory space (SQCHnDSCmBR.DTSEL = 01b)
  - Reduce the maximum return packet size of peripheral device.

58.3.8.5 Transfer Packet Related Error in Sequence Operation

Internal Bus Error

When an error is detected in Internal AXI Bus Read, the SQCHnSR.TXIBERR flag is set to 1.

Review the settings of the SQCHnDSCmAR.DATA0[7:0] bits, the SQCHnDSCmAR.DATA1[7:0] bits, and the SQCHnDSCmDR.LADDR[31:0] bits.

Packet Size Error

If the packet of Sequence Operation is too large to be transmitted within the BLLP period of the first horizontal line of Video Mode operation, the SQCH1SR.SIZEERR bit will be set to 1.

When this error occurs, Sequence Operation packets will not be sent until the Video Mode operation is completed.

58.3.8.6 Error in Video Mode operation

Video Mode Buffer Overflow Error

The VMSR.VBUFOVF flag will be set to 1 if the video buffer overflows during the Video Mode operation.

If this error occurs, perform Software Reset (See section 58.3.2. Software Reset).

Also, take necessary measures such as increasing the line rate of the D-PHY or decreasing the value of the VMSET1R.DLY[11:0] bits.

In addition, perform Reset Trigger Transmission (See section 58.3.5.4. Reset Trigger Transmission) if necessary.

Video Mode Buffer Underflow Error

The VMSR.VBUFUDF flag will be set to 1 if the video buffer underflows during the Video Mode operation.

If this error occurs, perform Software Reset (See section 58.3.2. Software Reset).

Also, take necessary measures such as decreasing the line rate of the D-PHY or increasing the value of the VMSET1R.DLY[11:0] bits.

In addition, perform Reset Trigger Transmission (See section 58.3.5.4. Reset Trigger Transmission) if necessary.

Timing Error

The VMSR.TIMERR flag is set to 1 if a video packet (including Sync Event packet) is not sent at the intended timing during Video Mode operation.

If this error occurs, perform Software Reset (See section 58.3.2. Software Reset).

Also, take necessary measures such as reviewing the setting value of the LPTRNSTSETR.GOLPBKT[9:0] bits.

In addition, perform Reset Trigger Transmission (See section 58.3.5.4. Reset Trigger Transmission) if necessary.

58.4 Interface

58.4.1 Video mode Operation

58.4.1.1 Video mode Timing

Video mode Timing and Video mode Parameters are described in Figure 58.9 and Table 58.3.

In Table 58.3, the actual period of the following parameters depend on the specification of the D-PHY which is connected to the DSI-Tx module.

- Period for HS-LP-HS transition, period for HS-LP transition, and period for LP-HS transition.
- Period for BTA[host->peripheral].

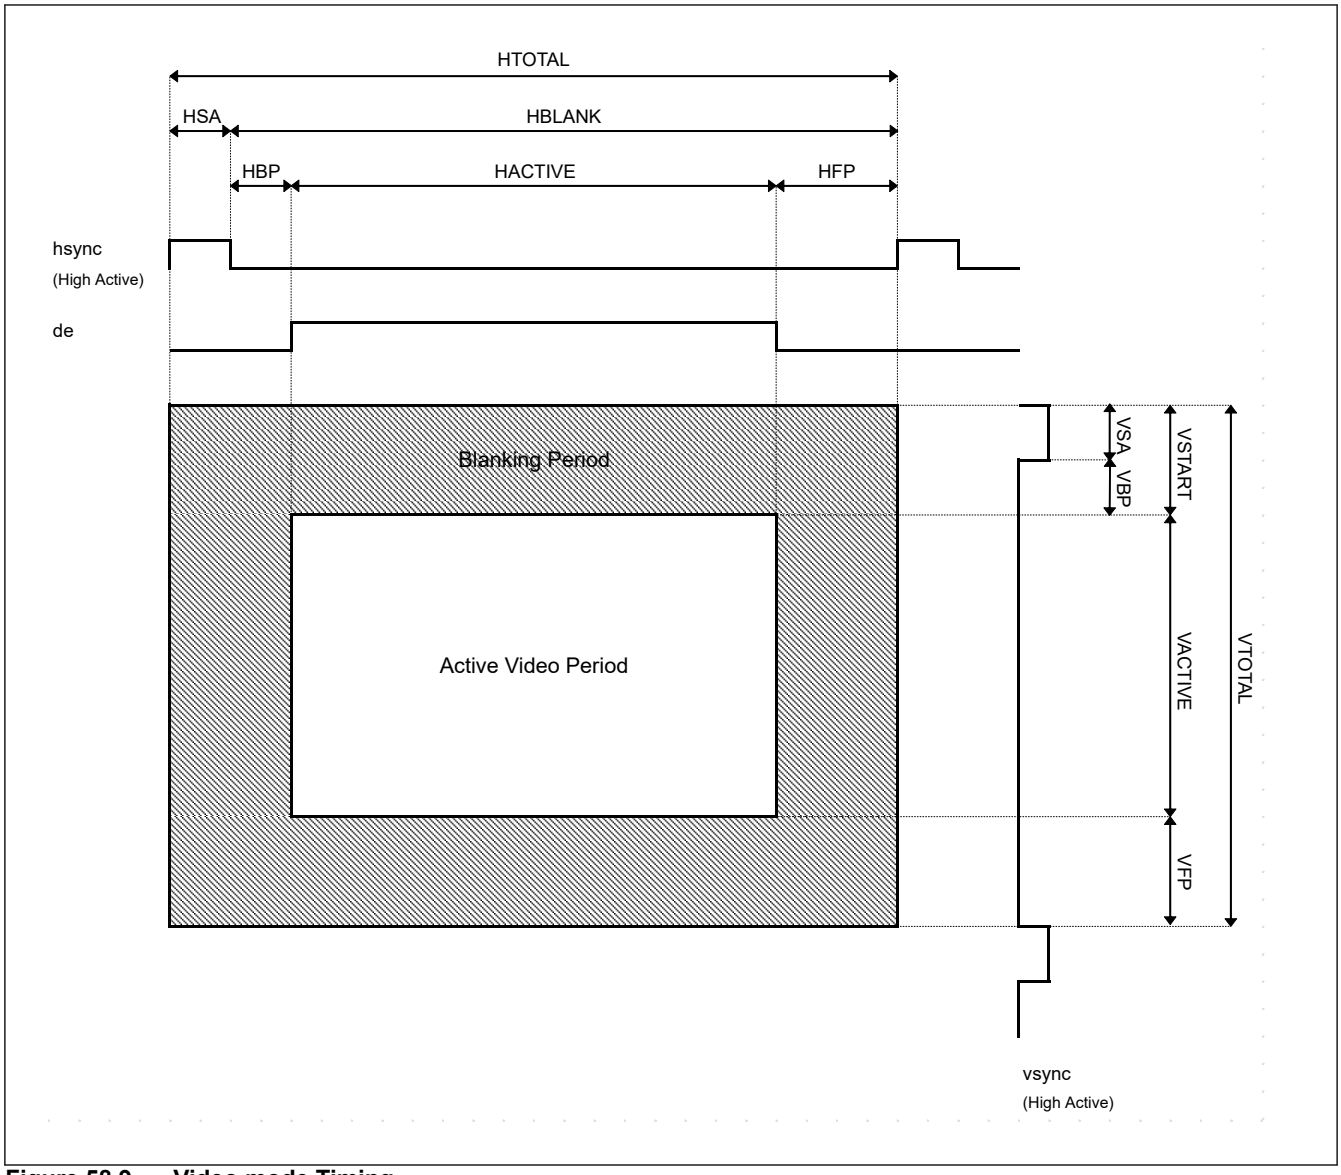

Figure 58.9 Video mode Timing

Table 58.3 Configurations for Video mode Interface (1 of 4)

Common Rules for All Modes		
Parameter	**Description**	
All	All parameters related to Input Video should be set to 1 or higher. Examples of the parameters: HSA, HBP, HACTIVE, HFP, VSA, VBP, VACTIVE, VFP	
Parameter	**VMPPSETR.DT**	**VMHSSETR.HACT**
HACTIVE	1Eh: Packed Pixel Stream, 18-bit RGB	This value should be a multiple of 4.
	2Ch: Packed Pixel Stream, 16-bit YCbCr 4: 2: 2 0Ch: Loosely Packed Pixel Stream, 20-bit YCbCr 4: 2: 2 1Ch: Packed Pixel Stream, 24-bit YCbCr 4: 2: 2	This value should be a multiple of 2.
	0Eh: Packed Pixel Stream, 16-bit RGB 2Eh: Loosely Packed Pixel Stream, 18-bit RGB 3Eh: Packed Pixel Stream, 24-bit RGB	No limitation
HFP	Rounddown (HFP*BPP/ 8, 0) >= 12, (12 = means Pixel Packet Header & footer 6 + Blanking Packet Header & footer 6)	

Table 58.3 Configurations for Video mode Interface (2 of 4)

Common Rules for All Modes		
Parameter	**Description**	
Parameter	**VMPPSETR.DT**	**VMHSSETR.HSA + VMHPSETR.HBP + VMHSSETR.HACT + VMHPSETR.HFP**
HTOTAL	1Eh: Packed Pixel Stream, 18-bit RGB	This value should be a multiple of 4.
	2Eh: Loosely Packed Pixel Stream, 18-bit RGB 0Ch: Loosely Packed Pixel Stream, 20-bit YCbCr 4: 2: 2 1Ch: Packed Pixel Stream, 24-bit YCbCr 4: 2: 2 2Ch: Packed Pixel Stream, 16-bit YCbCr 4: 2: 2 0Eh: Packed Pixel Stream, 16-bit RGB 3Eh: Packed Pixel Stream, 24-bit RGB	No limitation.

Table 58.3 Configurations for Video mode Interface (3 of 4)

Additional Rules for Non-burst Sync Pulse Mode	
Parameter	**Description**
Sequence Operation Packet	When a packet is transmitted by Sequence Operation during Video mode Operation (VMSR.RUNNING = 1), the period of (HBP+HACTIVE+HFP) should be longer than the sum of the following: ● Period for the Tx Sync Event packet (4 Bytes) ● Period for the packet sent by Sequence Operation ● Period for the Header and CRC of a Blanking packet (6 Bytes)
HBP + HACTIVE + HFP	HS-LP-HS transition is caused within the period between the current Sync Event packet and the next Sync Event packet, so the period of (HBP+HACTIVE+HFP) should be as follows. (HBP+HACTIVE+HFP) > (Period for the Tx Sync Event packet) + (Period for HS-LP-HS transition)
HSA	Blanking packet transmission is caused within the period between the current Sync Event packet and the next Sync Event packet, so the period of HSA should be as follows. (HSA*BPP)/8 >= 10 Note that HSA should not be less than the minimum value of the sum of (Period for the Tx Sync Event packet) + (Period for the Tx Blanking packet).
HBP	Blanking packet transmission is caused within the period between the current Sync Event packet and the next Sync Event packet, so the period of HBP should be as follows. (HBP*BPP)/8 >= 10 Note that HBP should not be less than the minimum value of the sum of (Period for the Tx Sync Event packet) + (Period for the Tx Blanking packet).

Table 58.3 Configurations for Video mode Interface (4 of 4)

Additional Rules for Non-burst Sync Event Mode and Burst Mode	
Parameter	**Description**
Sequence Operation Packet	When a packet is transmitted by Sequence Operation during Video mode Operation (VMSR.RUNNING = 1), the period of HTOTAL should be longer than the sum of the following: ● Period for the Tx Sync Event packet (4 Bytes) ● Period for the packet sent by Sequence Operation ● Period for the Header and CRC of a Blanking packet (6 Bytes)
HTOTAL	HS-LP-HS transition is caused within the period between the current Sync Event packet and the next Sync Event packet, so the period of HTOTAL should be as follows. HTOTAL > (Period for the Tx Sync Event packet) + (Period for HS-LP-HS transition)
HAS + HBP	Blanking packet transmission is caused within the period between the current Sync Event packet and the next Sync Event packet, so the period of (HSA+HBP) should be as follows. ((HSA+HBP)*BPP)/8 >= 10 Note that HSA+HBP should not be less than the minimum value of the sum of (Period for the Tx Sync Event packet) + (Period for the Tx Blanking packet). The minimum HSA+HBP value currently recognized is 8+8 and it is 32 even in the case of 16-bit RGB as the worst condition, which is not subject to this restriction. Therefore, this restriction is not presented up to the limit. Even if this condition is not satisfied, the result is Pixel-Packet is only slightly delayed.

58.5 Usage Notes

58.5.1 GLCDC register setting when using Video Mode operation

When using Video Mode operation, set the GLCDC registers as shown below to specify the video signals (VSYNC, HSYNC, DE, RGB) and supply a video clock.

Common

- SYSCNT_PANEL_CLK.CLKEN = 1 (Enable Panel Clock output)
- SYSCNT_PANEL_CLK.PIXSEL = 0 (Parallel RGB)
- TCON_STVA1 = Value to specify VSYNC signal
- TCON_STHA1 = Value to specify HSYNC signal
- TCON_STVB1 = Value to specify VE signal
- TCON_STHB1 = Value to specify HE signal
- TCON_STVA2.SEL[2:0] = 000b (Assign STVA signal to LCD_TCON0 output)
- TCON_STVB2.SEL[2:0] = 010b (Assign STHA signal to LCD_TCON1 output)
- TCON_STHA2.SEL[2:0] = 111b (Assign DE signal to LCD_TCON2 output)
- OUT_SET.FRQSEL[1:0] = 00b (Parallel RGB)
- OUT_SET.SWAPON = 0 (RGB order)
- OUT_SET.ENDIANON = 0 (little endian)

In the case of RGB888 (24-bit) format

- OUT_SET.FORMAT[1:0] = 00b (RGB888 format)

In the case of RGB666 (18-bit) format

- OUT_SET.FORMAT[1:0] = 01b (RGB666 format)

In the case of RGB565 (16-bit) format

- OUT_SET.FORMAT[1:0] = 10b (RGB565 format)

58.5.2 Module-stop function

MIPI DSI operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The MIPI DSI module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

59. Internal Voltage Regulator

59.1 Overview

The MCU supports two power supply providing for core voltage (VDD):

- Switching regulator (DCDC)
- External power supply from external power device (External VDD)

Table 59.1 shows the specifications of Internal voltage regulator.

DCDC or External VDD is selected with the OFS setting.

- When OFS2.DCDCEN is 1, DCDC is selected (DCDC mode)
- When OFS2.DCDCEN is 0, External VDD is selected (External VDD mode)

Table 59.1 Power supply selection

OFS setting (OFS2.DCDCEN)	Power mode
1	DCDC mode
0	External VDD mode

59.2 Operation

59.2.1 DCDC mode

Table 59.2 lists the DCDC mode pin settings, and Figure 59.1 shows the DCDC mode settings.

In DCDC mode, VDD is supplied from VCL through VLO output and an external inductor and capacitor.

Table 59.2 DCDC mode pin settings

Pins	Setting descriptions
All VCC and VCC2 pins	• Connect each pin to the system power supply. • Connect each pin to VSS through a 0.1 µF multilayer ceramic capacitor. Place the capacitor close to the pin.
VCC_DCDC pins	• Connect the pin to the system power supply. • Connect the pin to VSS_DCDC through a 22 µF and 0.1-µF multilayer ceramic capacitor in parallel. Place the capacitor close to the pin.
VCL pins	• Connect each pin to VSS through a 0.22 µF multilayer ceramic capacitor. Place the capacitor close to the pin. • Connect each pin to an external inductor and capacitor. Place the inductor and capacitor close to the pin.(see Figure 59.1.)
All VLO pins	Connect each pin to an external inductor and capacitor. Place the 2.2-µH inductor and 47 µF capacitor close to the pin. This capacitor must be grounded to VSS_DCDC

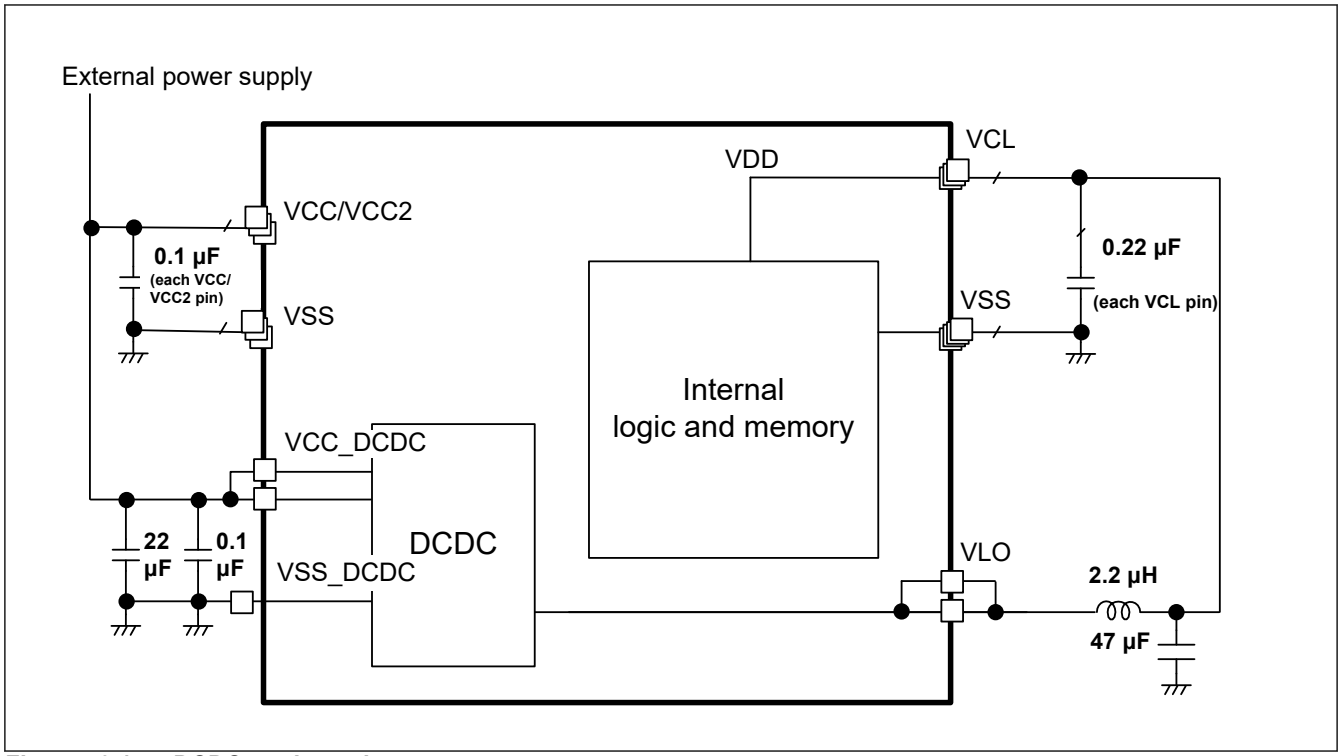

Figure 59.1 DCDC mode setting

59.2.2 External VDD mode

Table 59.3 lists the external VDD mode pin settings, and Figure 59.2 shows the external VDD mode settings.

VDD is supplied from VCL pins.

Note: Low-speed mode, Software Standby mode, Deep Software Standby mode 1, 2, 3 and Battery Backup Function are not supported in this mode.

Table 59.3 Setting Descriptions for external VDD mode

Pins	Setting descriptions
All VCC and VCC2 pins	• Connect each pin to the system power supply device for VCC. • Connect each pin to VSS through a 0.1 µF multilayer ceramic capacitor. Place the capacitor close to the pin.
VCC_DCDC pins	• Connect the pin to VSS_DCDC through 0.1 µF multilayer ceramic capacitor. Place the capacitor close to the pin.
VCL pins	• Connect each pin to the system power supply device for VDD. • Connect each pin to VSS through a 0.22 µF multilayer ceramic capacitor. Place the capacitor close to the pin.
All VLO pins	Keep pin open

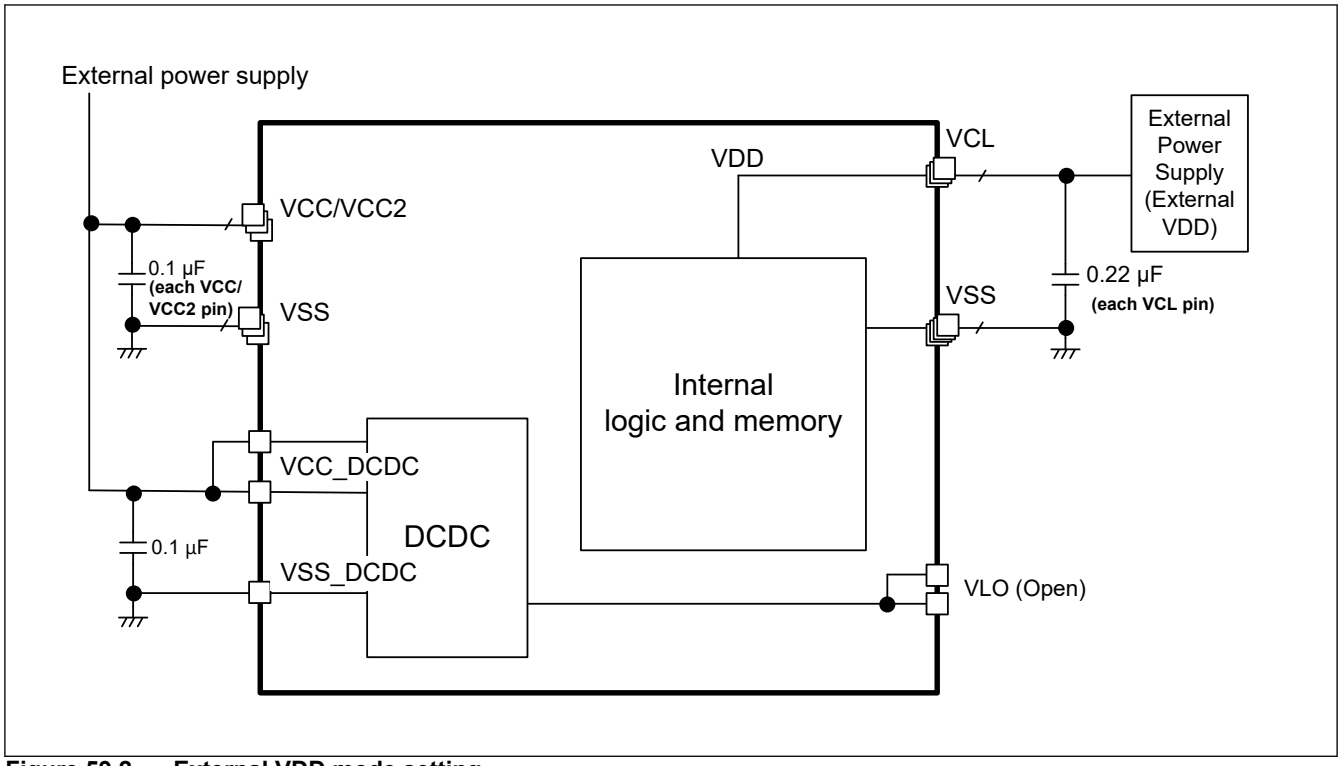

Figure 59.2 External VDD mode setting

In order to startup the device properly, use either of following procedure.

- VCL voltage must be raised 500 µs after VCC voltage is raised to minimum VCC voltage.
- Raise VCC voltage with RES pin is low, and release RES pin after 200 µs when VCL voltage is raised.

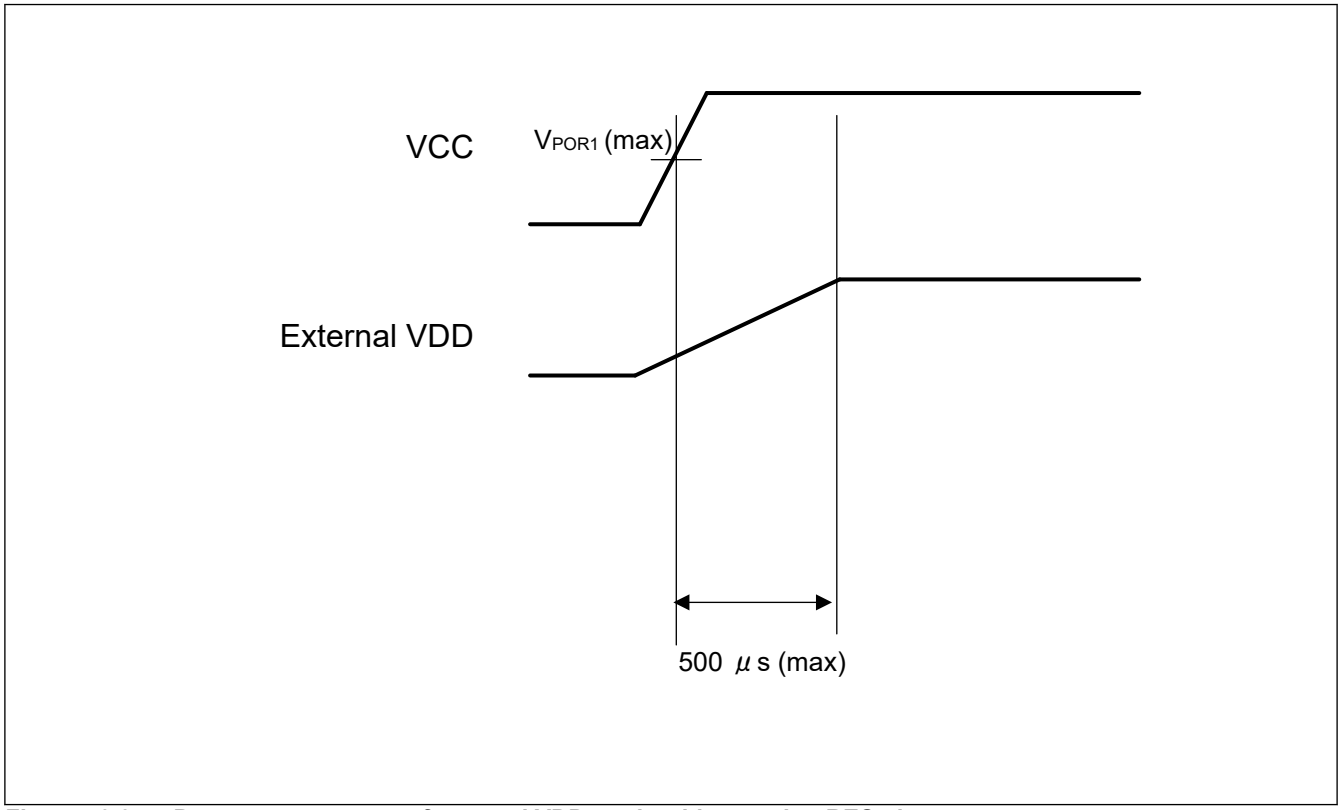

Figure 59.3 Power-up sequence of external VDD mode without using RES pin

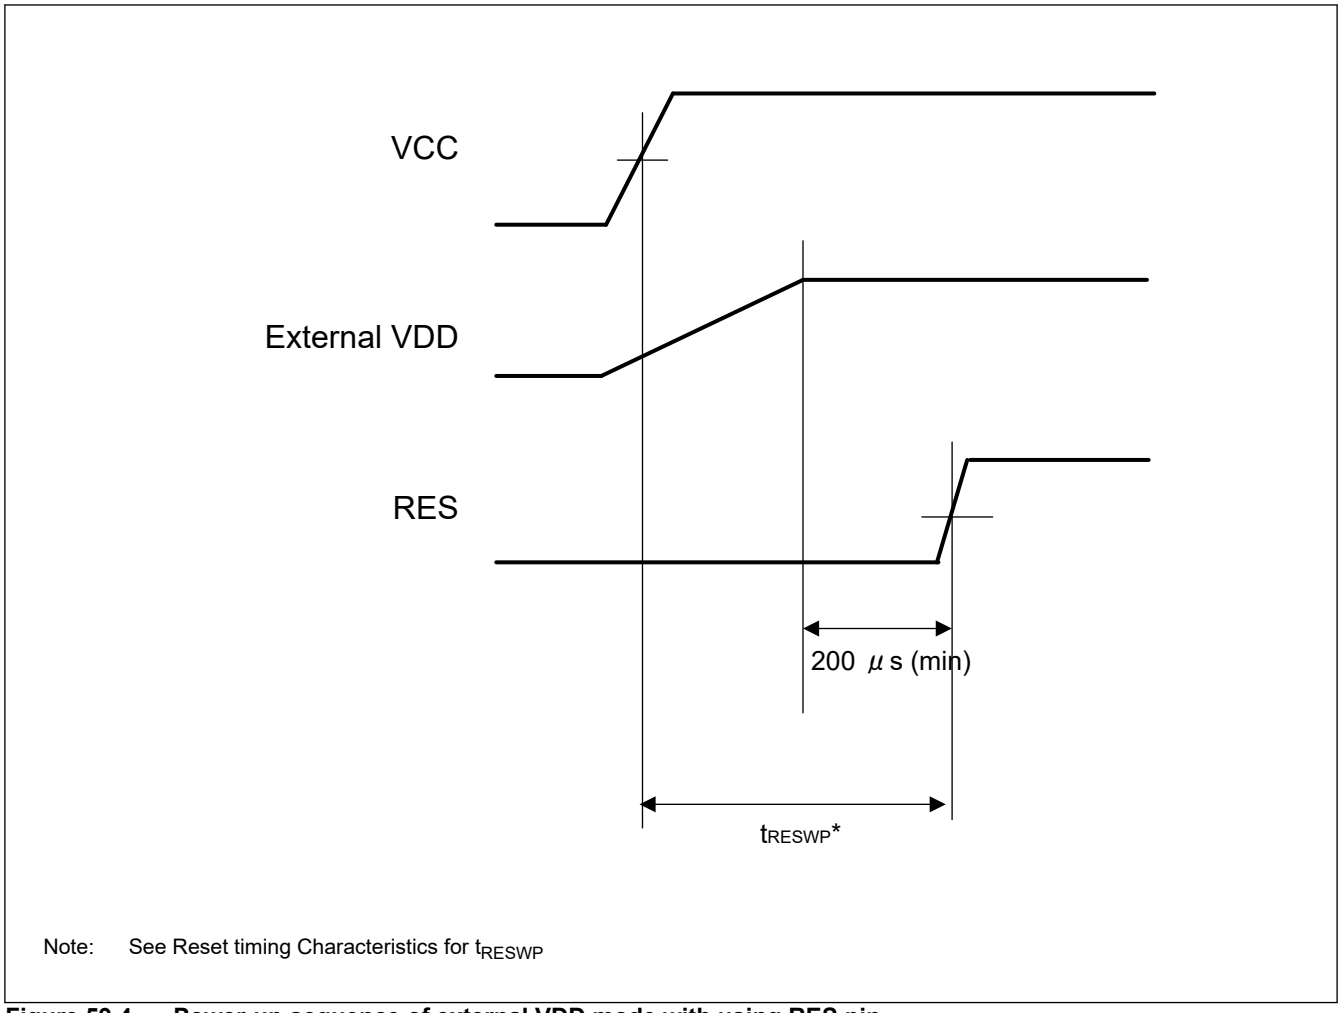

Figure 59.4 Power-up sequence of external VDD mode with using RES pin

59.3 Usage Notes

In DCDC mode, to minimize power loss and maximize efficiency, Renesas recommends using a 2.2-µH inductor with a DC resistance of 100 mΩ or less. Short VCC and VCC_DCDC.

In external VDD mode, the voltage of VDD should always be below the voltage of VCC including the power-on and power-off sequence. Refer to the chapter of electrical characteristics for more information.

60. Electrical Characteristics

Unless otherwise specified, minimum and maximum values are guaranteed by either design simulation, characterization results or test in production.

Supported peripheral functions and pins differ from one product name to another.

Unless otherwise specified, the electrical characteristics of the MCU are defined under the following conditions:

- VCC = VCC_DCDC = VCC_USB = VBATT = 1.68 to 3.6 V
- VCC2 = 1.65 to 3.6 V
- AVCC0 = 1.65 to 3.6 V
- VCC_USBHS = AVCC_USBHS = 3.0 to 3.6 V
- AVCC_MIPI = 3.0 to 3.6 V
- VREFH0 = 2.7 V to AVCC0
- VREFH = 1.65 V to AVCC0
- VCC18_MIPI = 1.7 to 1.9 V
- VSS = VSS_DCDC = AVSS0 = VREFL0 /VREFL = VSS_USB = VSS1_USBHS = VSS2_USBHS = VSS_MIPI = 0 V
- VCC voltage is lower than 2.7 V : LVOCR.LVO0E = 1, otherwise LVOCR.LVO0E = 0
- VCC2 voltage is lower than 2.7 V : LVOCR.LVO1E = 1, otherwise LVOCR.LVO1E = 0
- $T_j = T_{opj}$

When not specified otherwise, typical values are measured at room temperature of 25 °C and VCC = VCC_DCDC = VCC_USB = VBATT = VCC_USBHS = AVCC_USBHS = AVCC0 = AVCC_MIPI = VREFH0 = VREFH = 3.3V, VCC18_MIPI = 1.8V.

Figure 60.1 shows the timing conditions.

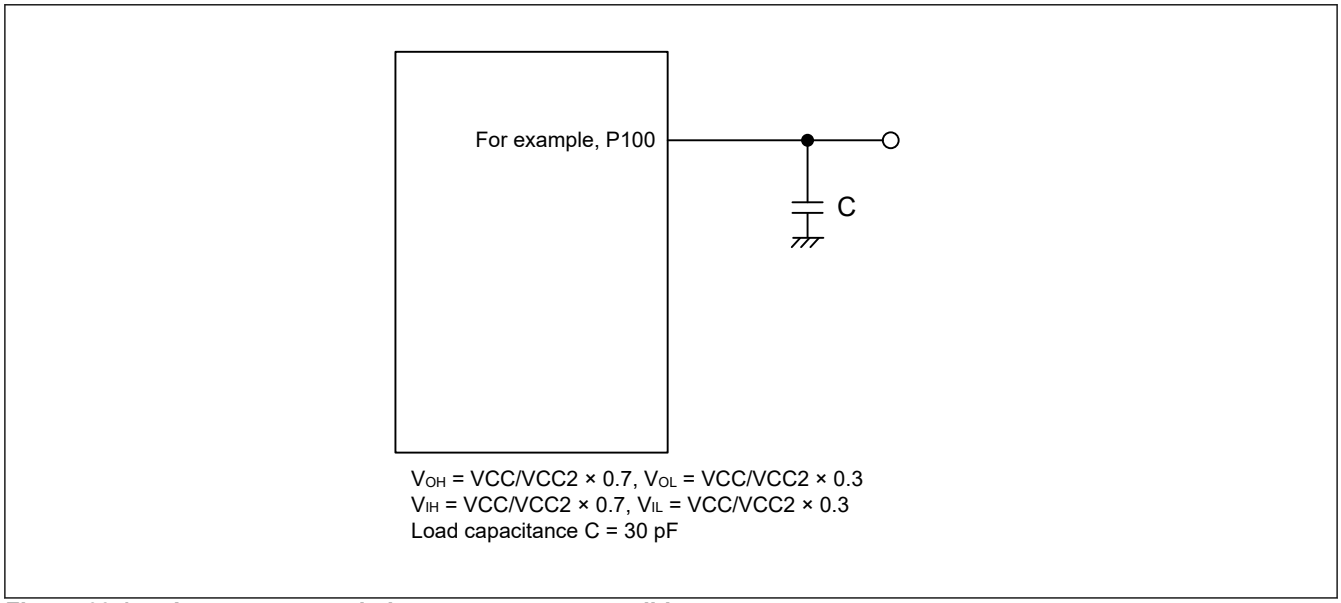

Figure 60.1 Input or output timing measurement conditions

The recommended measurement conditions for the timing specification of each peripheral provided are for the best peripheral operation. Make sure to adjust the driving abilities of each pin to meet your conditions.

60.1 Absolute Maximum Ratings

Table 60.1 Absolute maximum ratings

Parameter	Symbol	Value	Unit
Power supply voltage	VCC, VCC2, VCC_DCDC, VCC_USB*2	–0.3 to +4.0	V
External power supply voltage	VCL	–0.3 to +1.6	V
VBATT power supply voltage	VBATT	–0.3 to +4.0	V
Input voltage (except for 5 V-tolerant ports*1)	V_{in}	–0.3 to VCC + 0.3 or –0.3 to VCC2 + 0.3	V
Input voltage (5 V-tolerant ports*1)	V_{in}	–0.3 to + VCC + 4.0 (max. 5.8)	V
Reference power supply voltage	VREFH/VREFH0	–0.3 to AVCC0 + 0.3	V
USBHS power supply voltage	VCC_USBHS	–0.3 to +4.0	V
USBHS analog power supply voltage	AVCC_USBHS	–0.3 to +4.0	V
MIPI PHY analog power supply voltage	AVCC_MIPI	–0.3 to +4.0	V
MIPI PHY power supply voltage	VCC18_MIPI	–0.3 to +2.5	V
MIPI_DL0_P and MIPI_DL0_N input voltage	V_{PIN}	–0.5 to VCC18_MIPI + 0.5	V
Analog power supply voltage	AVCC0	–0.3 to +4.0	V
Analog input voltage	V_{AN}	–0.3 to AVCC0 + 0.3	V
Operating junction temperature*3 *4	T_{opj}	–40 to +125	°C
Storage temperature	T_{stg}	–55 to +125	°C

Note 1. Ports P205, P206, P402 to P404, P406 to P415, P511, P512, P709 to P715 and PB01 are 5 V tolerant.
Note 2. Connect VCC_DCDC and VCC_USB to VCC.
Note 3. See section 60.2.1. Tj/Ta Definition.
Note 4. Contact a Renesas Electronics sales office for information on derating operation when Tj = +105°C to +125°C. Derating is the systematic reduction of load for improved reliability.

Caution: Permanent damage to the MCU might result if absolute maximum ratings are exceeded.

Table 60.2 Recommended operating conditions (1 of 2)

Parameter	Symbol		Min	Typ	Max	Unit
Power supply voltages	VCC, VCC_DCDC	Other than the following	1.68	—	3.60	V
		When ETHERC/IIC Fast-mode + is used	2.70	—	3.60	V
		When USB/SDRAM is used	3.00	—	3.60	V
	VCC2		1.65	—	3.60	V
	VCL	When external VDD is used*2	1.20	—	1.25	V
		When DCDC is used (High-speed mode)	—	1.21	—	V
		When DCDC is used (Low-speed mode or Software Standby mode)	—	1.18	—	V
	VSS, VSS_DCDC		—	0	—	V
USB power supply voltages	VCC_USB, VCC_USBHS, AVCC_USBHS		—	VCC	—	V
	VSS_USB, VSS1_USBHS, VSS2_USBHS		—	0	—	V
MIPI PHY power supply voltages	VCC18_MIPI		1.70	1.80	1.90	V
	AVCC_MIPI		3.00	—	3.60	V
	VSS_MIPI		—	0	—	V
VBATT power supply voltage	VBATT		1.62	—	3.60	V

Table 60.2 Recommended operating conditions (2 of 2)

Parameter	Symbol		Min	Typ	Max	Unit
Analog power supply voltages	AVCC0*1	When ADC is not used	1.65	—	3.60	V
		When ADC is used	2.70	—	3.60	V
	AVSS0		—	0	—	V

Note 1. When the A/D converter, the D/A converter and the High-Speed Analog Comparator are not in use, do not leave the AVCC0, VREFH/VREFH0, AVSS0, and VREFL/VREFL0 pins open. Connect the AVCC0 and VREFH/VREFH0 pins to VCC, and the AVSS0 and VREFL/VREFL0 pins to VSS, respectively.
Note 2. VCL voltage must never be higher than VCC voltage.

60.2 DC Characteristics

60.2.1 Tj/Ta Definition

Table 60.3 DC characteristics

Parameter	Symbol	Typ	Max	Unit	Test conditions
Permissible operating junction temperature	T_j	—	125	°C	High-speed mode Low-speed mode

Note: Make sure that $T_j = T_a + \theta_{ja} \times$ total power consumption (W), where total power consumption = $(VCC - V_{OH}) \times \Sigma I_{OH} + V_{OL} \times \Sigma I_{OL} + (I_{CC}max + I_{CC\_DCDC}max) \times VCC$.
Note: Minimum Ambient Temperature(Ta) is -40℃

60.2.2 I/O V_{IH}, V_{IL}

Table 60.4 I/O V_{IH}, V_{IL} except for Schmitt trigger input pins

Parameter		VCC/VCC2/ AVCC0	Symbol	Min	Typ	Max	Unit
Peripheral function pins	EXTAL (external clock input), WAIT, SPI*1 (except RSPCK)	1.68 V or above	V_{IH}	VCC × 0.8	—	—	V
			V_{IL}	—	—	VCC × 0.2

Note 4. SD_A ch1
Note 5. MMC_A ch0, MMC_A ch1 and MMC_B ch1
Note 6. MMC_A ch1 (Up to 4-bit bus width)
Note 7. RES and peripheral function pins associated with P205, P206, P402 to P404, P406 to P415, P511, P512, P709 to P715, PB01 (total 26 pins).
Note 8. All input pins except for the peripheral function pins already described in the table. There is an item for each power supply voltage for each port. Refer to the IO chapter for the power supply of the port.
Note 9. P205, P206, P402 to P404, P406 to P415, P511, P512, P709 to P715, PB01 (total 25 pins).
Note 10. All input pins except for the ports already described in the table. There is an item for each power supply voltage for each port. Refer to the IO chapter for the power supply of the port.
Note 11. When VCC is less than 1.68 V, the input voltage of 5 V-tolerant ports should be less than 3.6 V, otherwise breakdown may occur because 5 V-tolerant ports are electrically controlled so as not to violate the break down voltage.

Table 60.5 I/O V_{IH}, V_{IL} of Schmitt trigger input pins

Parameter		VCC/VCC2/ AVCC0	Symbol	Min	Typ	Max	Unit
Peripheral function pins	IIC (except for SMBus)	1.68 V or above	V_{IH}	VCC × 0.7	—	VCC + 3.6 (max 5.8)	V
			V_{IL}	—	—	VCC × 0.3	
			ΔV_T	VCC × 0.05	—	—	
	I3C	1.68 V or above	V_{IH}	VCC × 0.7	—	VCC + 0.3	
			V_{IL}	—	—	VCC × 0.3	
			ΔV_T	VCC × 0.1	—	—	
	5 V-tolerant ports*7*11	1.68 V or above	V_{IH}	VCC × 0.8	—	VCC + 3.6 (max 5.8)	
			V_{IL}	—	—	VCC × 0.2	
			ΔV_T	VCC × 0.05	—	—	
	Other VCC input pins*8	1.68 V or above	V_{IH}	VCC × 0.8	—	—	
			V_{IL}	—	—	VCC × 0.2	
			ΔV_T	VCC × 0.05	—	—	
	Other VCC2 input pins*8	1.65 V or above	V_{IH}	VCC2 × 0.8	—	—	
			V_{IL}	—	—	VCC2 × 0.2	
			ΔV_T	VCC2 × 0.05	—	—	
	Other AVCC0 input pins*8	1.65 V or above	V_{IH}	AVCC0 × 0.8	—	—	
			V_{IL}	—	—	AVCC0 × 0.2	
			ΔV_T	AVCC0 × 0.05	—	—	
Ports	5 V-tolerant port*9*11	1.68 V or above	V_{IH}	VCC × 0.8	—	VCC + 3.6 (max 5.8)	V
			V_{IL}	—	—	VCC × 0.2	
	Other VCC input pins*10	1.68 V or above	V_{IH}	VCC × 0.8	—	—	
			V_{IL}	—	—	VCC × 0.2	
	Other VCC2 input pins*10	1.65 V or above	V_{IH}	VCC2 × 0.8	—	—	
			V_{IL}	—	—	VCC2 × 0.2	
	Other AVCC0 input pins*10	1.65 V or above	V_{IH}	AVCC0 × 0.8	—	—	
			V_{IL}	—	—	AVCC0 × 0.2	

Note 1. SPI0_A, SPI0_B, SPI0_C and SPI1_B
Note 2. SPI1_A
Note 3. SD_A ch0, SD_B ch1 and SD_B ch1
Note 4. SD_A ch1
Note 5. MMC_A ch0, MMC_A ch1 and MMC_B ch1
Note 6. MMC_A ch1 (Up to 4-bit bus width)

Note 7. RES and peripheral function pins associated with P205, P206, P402 to P404, P406 to P415, P511, P512, P709 to P715, PB01 (total 26 pins).
Note 8. All input pins except for the peripheral function pins already described in the table. There is an item for each power supply voltage for each port. Refer to the IO chapter for the power supply of the port.
Note 9. P205, P206, P402 to P404, P406 to P415, P511, P512, P709 to P715, PB01 (total 25 pins).
Note 10. All input pins except for the ports already described in the table. There is an item for each power supply voltage for each port. Refer to the IO chapter for the power supply of the port.
Note 11. When VCC is less than 1.68 V, the input voltage of 5 V-tolerant ports should be less than 3.6 V, otherwise breakdown may occur because 5 V-tolerant ports are electrically controlled so as not to violate the break down voltage.

60.2.3 I/O I_{OH}, I_{OL}

Table 60.6 I/O I_{OH}, I_{OL} (1 of 2)

Parameter			VCC/ VCC2/ AVCC0	Symbol	Min	Typ	Max	Unit
Permissible output current (average value per pin)	Ports P000 to P011, P014, P015, P201	—	—	I_{OH}	—	—	−2.0	mA
				I_{OL}	—	—	2.0	mA
	Ports P205, P206, P402 to P404, P406 to P408, P411 to P415, P709 to P715, PB01 (total 21 pins)	Low drive*1	—	I_{OH}	—	—	−2.0	mA
				I_{OL}	—	—	2.0	mA
		Middle drive*2	—	I_{OH}	—	—	−4.0	mA
				I_{OL}	—	—	4.0	mA
		High drive*3	—	I_{OH}	—	—	−20	mA
				I_{OL}	—	—	20.0	mA
	Ports P100 to P103, P304 to P308, P800 to P804, P808 to P810, PA09 (total 18 pins)	Low drive*1	—	I_{OH}	—	—	−2.0	mA
				I_{OL}	—	—	2.0	mA
		Middle drive*2	—	I_{OH}	—	—	−4.0	mA
				I_{OL}	—	—	4.0	mA
		High drive*3	—	I_{OH}	—	—	−16	mA
				I_{OL}	—	—	16.0	mA
		High-speed high drive*4	—	I_{OH}	—	—	−20	mA
				I_{OL}	—	—	20.0	mA
	Other output pins*5	Low drive*1	—	I_{OH}	—	—	−2.0	mA
				I_{OL}	—	—	2.0	mA
		Middle drive*2	—	I_{OH}	—	—	−4.0	mA
				I_{OL}	—	—	4.0	mA
		High drive*3	—	I_{OH}	—	—	−16	mA
				I_{OL}	—	—	16.0	mA

Table 60.6 I/O I_{OH}, I_{OL} (2 of 2)

Parameter			VCC/ VCC2/ AVCC0	Symbol	Min	Typ	Max	Unit
Permissible output current (max value per pin)	Ports P000 to P011, P014, P015, P201	—	—	I_{OH}	—	—	−4.0	mA
				I_{OL}	—	—	4.0	mA
	Ports P205, P206, P402 to P404, P406 to P408, P411 to P415, P709 to P715, PB01 (total 21 pins)	Low drive*1	—	I_{OH}	—	—	−4.0	mA
				I_{OL}	—	—	4.0	mA
		Middle drive*2	—	I_{OH}	—	—	−8.0	mA
				I_{OL}	—	—	8.0	mA
		High drive*3	—	I_{OH}	—	—	−40	mA
				I_{OL}	—	—	40.0	mA
	Ports P100 to P103, P304 to P308, P800 to P804, P808 to P810, PA09 (total 18 pins)	Low drive*1	—	I_{OH}	—	—	−4.0	mA
				I_{OL}	—	—	4.0	mA
		Middle drive*2	—	I_{OH}	—	—	−8.0	mA
				I_{OL}	—	—	8.0	mA
		High drive*3	—	I_{OH}	—	—	−32	mA
				I_{OL}	—	—	32.0	mA
		High-speed high drive*4	—	I_{OH}	—	—	−40	mA
				I_{OL}	—	—	40.0	mA
	Other output pins*5	Low drive*1	—	I_{OH}	—	—	−4.0	mA
				I_{OL}	—	—	4.0	mA
		Middle drive*2	—	I_{OH}	—	—	−8.0	mA
				I_{OL}	—	—	8.0	mA
		High drive*3	—	I_{OH}	—	—	−32	mA
				I_{OL}	—	—	32.0	mA
Permissible output current (max value of total of all pins)	Maximum of all output pins	VCC I/O	1.68 V or above	$\Sigma I_{OH\ (max)}$	—	—	−80	mA
		VCC2 I/O	1.65 V or above		—	—	−80	
		AVCC0 I/O	1.65 V or above		—	—	−33	
		VCC and VCC2 I/O	1.65 V or above	$\Sigma I_{OL\ (max)}$	—	—	80	mA
		AVCC0 I/O	1.65 V or above		—	—	33	

Note 1. This is the value when low driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability except for 400 and P401 is retained in Deep Software Standby mode.
Note 2. This is the value when middle driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability except for 400 and P401 is retained in Deep Software Standby mode.
Note 3. This is the value when high driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability except for 400 and P401 is retained in Deep Software Standby mode.
Note 4. This is the value when high-speed high driving ability is selected in the Port Drive Capability in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.
Note 5. Except for P200, which is an input port.

Caution: To protect the reliability of the MCU, the output current values should not exceed the values in this table. The average output current indicates the average value of current measured during 100 µs.

60.2.4 I/O V_{OH}, V_{OL}, and Other Characteristics

Table 60.7 I/O V_{OH}, V_{OL}, and other characteristics (1 of 3)

Parameter		VCC/VCC2/ AVCC0	Symbol	Min	Typ	Max	Unit	Test conditions
Output voltage	IIC	2.70 V or above	V_{OL}	—	—	0.4	V	I_{OL} = 3.0 mA
			V_{OL}	—	—	0.6		I_{OL} = 6.0 mA
		1.68 V or above	V_{OL}	—	—	VCC × 0.2		I_{OL} = 3.0 mA
			V_{OL}	—	—	0.6		I_{OL} = 6.0 mA
	IIC*1	2.70 V or above	V_{OL}	—	—	0.4		I_{OL} = 15.0 mA (ICFER.FMPE = 1)

		VCC_DCDC < 2.5 V	I_{CC_DCDC}*5	—	320	—		VCC_DCDC = 1.8 V
			I_{DD}	—	400*4	—		
	CPUCLK = 400 MHz	VCC_DCDC ≧ 2.5 V	I_{CC_DCDC}*5	—	267	307	mA	VCC_DCDC = 3.3 V CPUCLK = 400 MHz, ICLK = 200 MHz, PCLKA = 100 MHz, PCLKB = 50 MHz, PCLKC = 50 MHz, PCLKD = 100 MHz, PCLKE = 100 MHz, FCLK = 50 MHz, BCLK = 100 MHz
			I_{DD}*3	—	550	632		
		VCC_DCDC < 2.5 V	I_{CC_DCDC}*5	—	320	320		VCC_DCDC = 1.8 V
			I_{DD}	—	400*4	400*4		
	CPUCLK = 360 MHz	VCC_DCDC ≧ 2.5 V	I_{CC_DCDC}*5	—	257	297	mA	VCC_DCDC = 3.3 V CPUCLK = 360 MHz, ICLK = 120 MHz, PCLKA = 120 MHz, PCLKB = 60 MHz, PCLKC = 60 MHz, PCLKD = 120 MHz, PCLKE = 120 MHz, FCLK = 60 MHz, BCLK = 120 MHz
			I_{DD}*3	—	530	612		
		VCC_DCDC < 2.5 V	I_{CC_DCDC}*5	—	320	320		VCC_DCDC = 1.8 V
			I_{DD}	—	400*4	400*4		
	CPUCLK = 240 MHz	VCC_DCDC ≧ 2.5 V	I_{CC_DCDC}*5	—	224	264	mA	VCC_DCDC = 3.3 V CPUCLK = 240 MHz, ICLK = 240 MHz, PCLKA = 120 MHz, PCLKB = 60 MHz, PCLKC = 60 MHz, PCLKD = 120 MHz, PCLKE = 120 MHz, FCLK = 60 MHz, BCLK = 120 MHz
			I_{DD}*3	—	460	544		
		VCC_DCDC < 2.5 V	I_{CC_DCDC}*5	—	320	320		VCC_DCDC = 1.8 V
			I_{DD}	—	400*4	400*4		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. Measured with clocks supplied to the peripheral functions and peripherals being operated. This does not include the BGO operation.
Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.
I_{DD} Max. (105℃) = 0.68 × f CPUCLK + 0.51 × fICLK + 180 (unit : mA, fCPUCLK and fICLK are MHz)
I_{DD} Max. (125℃) = 0.68 × f CPUCLK + 0.51 × fICLK + 258 (unit : mA, fCPUCLK and fICLK are MHz)
Note 4. Do not actual consumption current during operation exceed the current value described here in VCC_DCDC < 2.5V.
Note 5. Typical DCDC efficiency is applied.

Table 60.9 Current of high-speed mode, maximum condition (External VDD mode)

Parameter	CPUCLK Frequency	Symbol	Typ	Max		Unit	Test conditions
				105℃	125℃		
Supply current*1 *2	—	I_{CC}	—	5.97	6.11	mA	
	CPUCLK = 480 MHz	I_{DD}*3	—	624	—	mA	CPUCLK = 480 MHz, ICLK = 240 MHz, PCLKA = 120 MHz, PCLKB = 60 MHz, PCLKC = 60 MHz, PCLKD = 120 MHz, PCLKE = 240 MHz, FCLK = 60 MHz, BCLK = 120 MHz
	CPUCLK = 400 MHz	I_{DD}*3	—	550	632	mA	CPUCLK = 400 MHz, ICLK = 200 MHz, PCLKA = 100 MHz, PCLKB = 50 MHz, PCLKC = 50 MHz, PCLKD = 100 MHz, PCLKE = 100 MHz, FCLK = 50 MHz, BCLK = 100 MHz

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. Measured with clocks supplied to the peripheral functions and peripherals being operated. This does not include the BGO operation.
Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.
I_{DD} Max. (105℃) = 0.68 × f CPUCLK + 0.51 × fICLK + 180 (unit : mA, fCPUCLK and fICLK are MHz)
I_{DD} Max. (125℃) = 0.68 × f CPUCLK + 0.51 × fICLK + 258 (unit : mA, fCPUCLK and fICLK are MHz)

Table 60.10 Current of high-speed mode, maximum data processing, peripheral clock ON (DCDC mode)

Parameter		Symbol	Typ	Max		Unit	Test conditions
				105℃	125℃		
Supply current*1*2	CPUCLK = 480 MHz	I_{CC_DCDC}*4	—	276	—	mA	VCC_DCDC = 3.3 V *5
		I_{DD}*3	—	568	—		
	CPUCLK = 400 MHz	I_{CC_DCDC}*4	—	246	286		
		I_{DD}*3	—	506	589		
	CPUCLK = 360 MHz	I_{CC_DCDC}*4	—	232	272		
		I_{DD}*3	—	478	561		
	CPUCLK = 240 MHz	I_{CC_DCDC}*4	—	198	239		
		I_{DD}*3	—	408	492		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. Measured with clocks supplied to the peripheral functions and peripherals being operated. This does not include the BGO operation.
Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.
I_{DD} Max. (105℃) = 0.67 × f CPUCLK + 0.30 × fICLK + 180 (unit : mA, fCPUCLK and fICLK are MHz)
I_{DD} Max. (125℃) = 0.67 × f CPUCLK + 0.30 × fICLK + 258 (unit : mA, fCPUCLK and fICLK are MHz)
Note 4. Typical DCDC efficiency is applied.
Note 5. Same frequency condition is applied as in the maximum condition.

Table 60.11 Current of high-speed mode, maximum data processing, peripheral clock ON (External VDD mode)

Parameter		Symbol	Typ	Max		Unit	Test conditions
				105℃	125℃		
Supply current*1*2	CPUCLK = 480 MHz	I_{DD}*3	—	568	—	mA	*4
	CPUCLK = 400 MHz	I_{DD}*3	—	506	589		
	CPUCLK = 360 MHz	I_{DD}*3	—	478	561		
	CPUCLK = 240 MHz	I_{DD}*3	—	408	492		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. Measured with clocks supplied to the peripheral functions and peripherals being operated. This does not include the BGO operation.
Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.
I_{DD} Max. (105℃) = 0.67 × f CPUCLK + 0.30 × fICLK + 180 (unit : mA, fCPUCLK and fICLK are MHz)
I_{DD} Max. (125℃) = 0.67 × f CPUCLK + 0.30 × fICLK + 258 (unit : mA, fCPUCLK and fICLK are MHz)
Note 4. Same frequency condition is applied as in the maximum condition.

Table 60.12 Current of high-speed mode, maximum data processing, peripheral clock OFF (DCDC mode)

Parameter		Symbol	Typ	Max		Unit	Test conditions
				105℃	125℃		
Supply current*1*2	CPUCLK = 480 MHz	I_{CC_DCDC}*4	—	263	—	mA	VCC_DCDC = 3.3 V *5
		I_{DD}*3	—	541	—		
	CPUCLK = 400 MHz	I_{CC_DCDC}*4	—	235	274		
		I_{DD}*3	—	483	565		
	CPUCLK = 360 MHz	I_{CC_DCDC}*4	—	219	259		
		I_{DD}*3	—	450	533		
	CPUCLK = 240 MHz	I_{CC_DCDC}*4	—	184	224		
		I_{DD}*3	—	378	462		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.
Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.
I_{DD} Max. (105℃) = 0.68 × f CPUCLK + 0.17 × fICLK + 180 (unit : mA, fCPUCLK and fICLK are MHz)
I_{DD} Max. (125℃) = 0.68 × f CPUCLK + 0.17 × fICLK + 258 (unit : mA, fCPUCLK and fICLK are MHz)
Note 4. Typical DCDC efficiency is applied.
Note 5. Same frequency condition is applied as in the maximum condition.

Table 60.13 Current of high-speed mode, maximum data processing, peripheral clock OFF (External VDD mode)

Parameter		Symbol	Typ	Max		Unit	Test conditions
				105℃	125℃		
Supply current*1*2	CPUCLK = 480 MHz	I_{DD}*3	—	541	—	mA	*4
	CPUCLK = 400 MHz	I_{DD}*3	—	483	565		
	CPUCLK = 360 MHz	I_{DD}*3	—	450	533		
	CPUCLK = 240 MHz	I_{DD}*3	—	378	462		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.
Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.
I_{DD} Max. (105℃) = 0.68 × f CPUCLK + 0.17 × fICLK + 180 (unit : mA, fCPUCLK and fICLK are MHz)
I_{DD} Max. (125℃) = 0.68 × f CPUCLK + 0.17 × fICLK + 226 (unit : mA, fCPUCLK and fICLK are MHz)
Note 4. Same frequency condition is applied as in the maximum condition.

Table 60.14 Current of high-speed mode, CPU Sleep mode (DCDC mode and External VDD mode)

Parameter		Symbol	Typ	Max		Unit	Test conditions
				105℃	125℃		
Supply current*1*3*4	CPUCLK = 240 MHz	I_{DD}*2	29	221	315	mA	—

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. I_{DD} depends on f (CPUCLK and ICLK) as follows.
I_{DD} Typ. (25℃) = 0.063 × f CPUCLK + 0.13 × fICLK + 17.6 (unit : mA, fCPUCLK and fICLK are MHz)
I_{DD} Max. (105℃) = 0.063 × f CPUCLK + 0.13 × fICLK + 180 (unit : mA, fCPUCLK and fICLK are MHz)
I_{DD} Max. (125℃) = 0.063 × f CPUCLK + 0.13 × fICLK + 258 (unit : mA, fCPUCLK and fICLK are MHz)
Note 3. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.
Note 4. ICLK, FCLK, BCLK, PCLKA, PCLKB, PCLKC, PCLKD and PCLKE are set to divided by 64.

Table 60.15 Current of high-speed mode, CPU Deep Sleep mode (DCDC mode and External VDD mode)

Parameter		Symbol	Typ	Max		Unit	Test conditions
				105℃	125℃		
Supply current*1*3*4	CPUCLK = 240 MHz	I_{DD}*2	12	90	117	mA	—

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. I_{DD} depends on f (ICLK) as follows.
I_{DD} Typ. (25℃) = 0.13 × fICLK + 5.3 (unit : mA, fCPUCLK and fICLK are MHz)
I_{DD} Max. (105℃) = 0.13 × fICLK + 72 (unit : mA, fCPUCLK and fICLK are MHz)
I_{DD} Max. (125℃) = 0.13 × fICLK + 101 (unit : mA, fCPUCLK and fICLK are MHz)
Note 3. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.
Note 4. ICLK, FCLK, BCLK, PCLKA, PCLKB, PCLKC, PCLKD and PCLKE are set to divided by 64.

Table 60.16 Increase during BGO operation (DCDC mode and External VDD mode)

Parameter		Symbol	Typ	Max		Unit	Test conditions
				105℃	125℃		
Supply current*1	Data flash P/E	I_{CC}	6	—	—	mA	—
	Code flash P/E		8	—	—		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Table 60.17 Current of Low-speed mode (DCDC mode)

Parameter	Symbol	Typ	Max		Unit	Test conditions
			105℃	125℃		
Supply current*1*2*3	I_{DD}	14.5	—	—	mA	CPUCLK = ICLK = 1MHz Graphics power domain is off

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.
Note 3. FCLK, BCLK, PCLKA, PCLKB, PCLKC, PCLKD and PCLKE are set to divided by 64 (15.6 kHz).

Table 60.18 Standby current (DCDC mode)

Parameter				Symbol	Typ	Max 125℃	Unit	Test conditions
Supply current*1		Software Standby mode*2		I_{CC}	0.02	0.94	mA	—
		Data of SRAM and TCM is retained		I_{CC_DCDC}	0.88	28.29		VCC_DCDC = 3.3 V PDRAMSCR0.RKEEPn = 1 (n = 0 to 6) PDRAMSCR1.RKEEP0 = 1
		Data of SRAM and TCM is not retained		I_{CC_DCDC}	0.83	26.64		VCC_DCDC = 3.3 V PDRAMSCR0.RKEEPn = 0 (n = 0 to 6) PDRAMSCR1.RKEEP0 = 0
		Deep Software Standby mode 1		I_{CC}	5.21	148	µA	—
				I_{CC_DCDC}	0.57	5.50		—
		Increase when the function is activated	Data of Standby SRAM is retained	I_{CC}	0.12	2.60		—
			PVD0, PVD1,PVD2 or Battery power supply switch		See Table 60.20			—
			When the LOCO is in use		3.10	—		—
			Crystal oscillator and RTC		See Table 60.21			—
			IWDT and ULPT(all units) are operating		0.07	—		—
		Deep Software Standby mode 2		I_{CC}	1.68	43.99		—
				I_{CC_DCDC}	0.57	5.50		—
		Increase when the function is activated	PVD0, PVD1,PVD2 or Battery power supply switch	I_{CC}	See Table 60.20			—
			Crystal oscillator and RTC		See Table 60.21			—
		Deep Software Standby mode 3		I_{CC}	0.99	42.90		—
				I_{CC_DCDC}	0.57	5.50		—
		Increase when the function is activated	Crystal oscillator and RTC		See Table 60.21			—
	RTC operating while VCC is off (with the battery backup function, only the RTC operate)	When a crystal oscillator with low power mode 3 is in use		I_{VBAT}	0.52	—		VBATT=1.8 V, VCC=0 V
					1.05	—		VBATT=3.3 V, VCC=0 V
		When a crystal oscillator with low power mode 2 is in use			0.56	—		VBATT=1.8 V, VCC=0 V
					1.10	—		VBATT=3.3 V, VCC=0 V
		When a crystal oscillator with low power mode 1 is in use			0.62	—		VBATT=1.8 V, VCC=0V
					1.17	—		VBATT=3.3 V, VCC=0 V
		When a crystal oscillator with standard mode is in use			0.93	—		VBATT=1.8 V, VCC=0 V
					1.50	—		VBATT=3.3 V, VCC=0 V
		When EXCIN is in use			0.37	—		VBATT=1.8 V, VCC=0 V
					0.86	—		VBATT=3.3 V, VCC=0 V
		Increase when the function is activated	Common circuit when using RTCICn (n = 0~2) input or EXCIN		0.04	—		VBATT=1.8 V, VCC=0 V
					0.04	—		VBATT=3.3 V, VCC=0 V
			RTCICn (n = 0～2) input is in use per channel		0.02	—		VBATT=1.8 V, VCC=0 V
					0.02	—		VBATT=3.3 V, VCC=0 V

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. When an external clock is used, EXTAL pin is pull-up or pull-down. In case clock is toggled, software standby mode current consumption is increased by 130µA at 48MHz under typical conditions.

Table 60.19 Coremark and normal mode current (DCDC and External power supply mode)

Parameter			Symbol	Typ	Max	Unit	Test conditions
Supply current*1*2	Coremark	Cache on	I_{DD}	318	—	µA/MHz	CPUCLK = 480 MHz ICLK = 240 MHz PCLKA = 7.5 MHz PCLKB = 7.5 MHz PCLKC = 7.5 MHz PCLKD = 7.5 MHz PCLKE = 7.5 MHz FCLK = 7.5 MHz BCLK = 7.5 MHz
		Cache off, executing from ITCM		281	—		
		Cache off, executing from SRAM		178	—		
		Cache off, executing from flash		169	—		
	Normal mode	All peripheral disabled, Cache on, while (1) code		223	—		
		All peripheral disabled, Cache off, while (1) code executing from flash		138	—		
	Coremark	Cache off, executing from flash		165	—	µA/MHz	CPUCLK = 360 MHz ICLK = 120 MHz PCLKA = 30 MHz PCLKB = 30 MHz PCLKC = 30 MHz PCLKD = 30 MHz PCLKE = 30 MHz FCLK = 30 MHz BCLK = 30 MHz
	Normal mode	All peripheral disabled, Cache off, while (1) code executing from flash		137	—		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.

Table 60.20 Increase when the PVD0, PVD1, PVD2 or Battery power supply switch is enabled in Deep Software Standby mode 1 and 2.

Parameter		Symbol	Typ	Max 125℃	Unit	Test conditions
Supply current	Common circuit when enabling PVDn (n = 0 to 2) or Battery power supply switch in Deep Software Standby mode 1	I_{CC}	4.51	—	µA	—
	Common circuit when enabling PVDn (n = 0 to 2) or Battery power supply switch in Deep Software Standby mode 2		4.97	—		—
	PVD0 enabled with OFS1(_SEC).PVDLPSEL = 1		2.16	—		—
	PVD1 enabled		2.16	—		—
	PVD2 enabled		2.16	—		—
	Battery power supply switch enabled with following conditions.*1 • Battery power supply switch enable (VBTBPCR1.BPWSWSTP = 0), voltage monitor 0 reset enable (OFS1(_SEC).PVDAS = 0) and low power consumption function of PVD0 disable (OFS1(_SEC).PVDLPSEL = 1). • Battery power supply switch enable (VBTBPCR1.BPWSWSTP=0) and voltage monitor 0 reset disable (OFS1(_SEC).PVDAS = 1).		2.16	—		—

Note 1. Consumption current is not increased in other condition.

Table 60.21 Increase when the sub-clock oscillator and RTC are enabled in Deep Software Standby mode 1, 2 and 3.

Parameter			Symbol	Typ	Max 125℃	Unit	Test conditions
Supply current	When a crystal oscillator is in use	Low Power mode 3	I_{CC}	0.22	—	µA	—
		Low Power mode 2		0.27	—		—
		Low Power mode 1		0.34	—		—
		Standard mode		0.67	—		—
	RTC is operating			0.33	—		—

Table 60.22 Inrush current

Parameter				Symbol	Typ	Max 125℃	Unit	Test conditions
Supply current	Inrush current on returning from deep software standby mode	Inrush current of VCC_DCDC*1	DPSBYCR.DCSSMODE = 0	I_{RUSH}	—	630	mA	—
			DPSBYCR.DCSSMODE = 1		—	1020		—

Note 1. Reference value

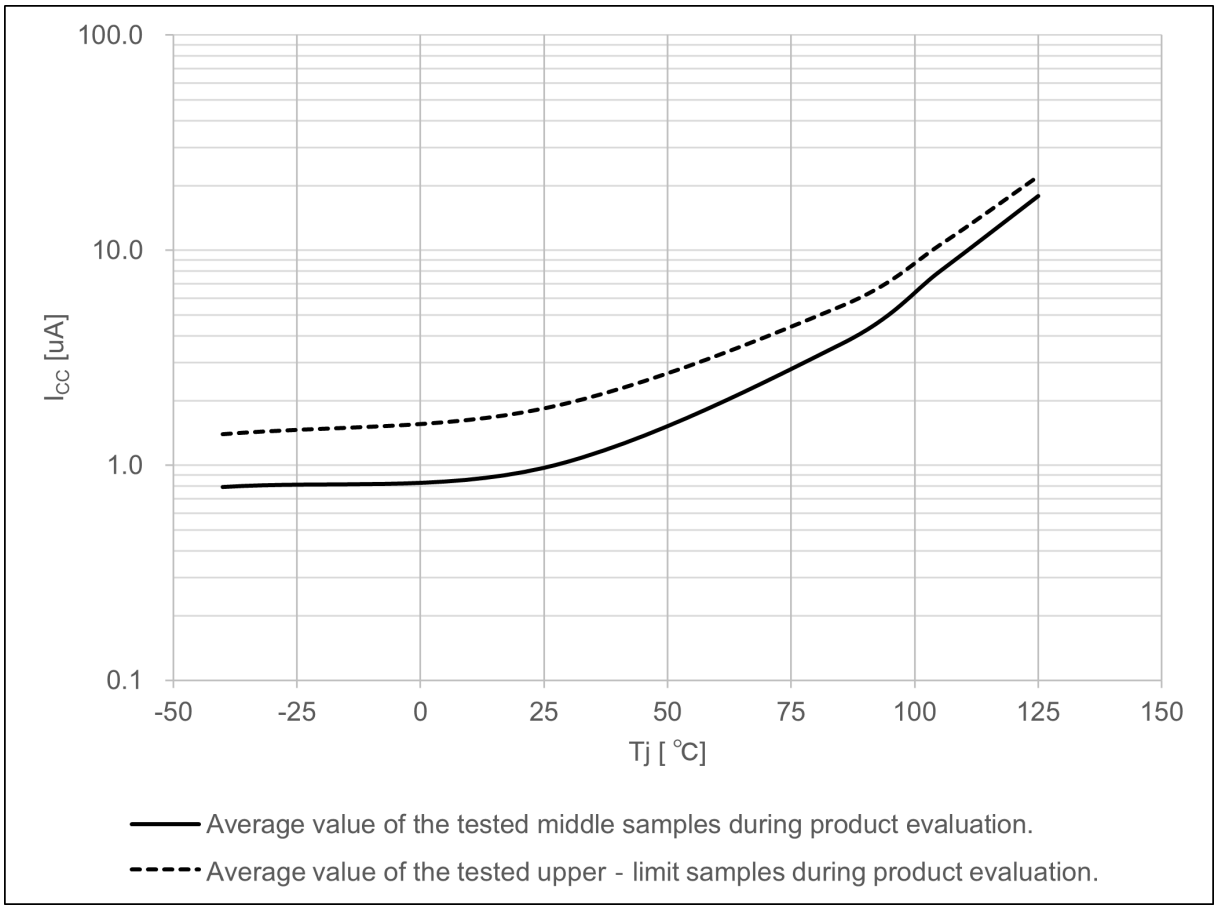

Figure 60.7 Temperature dependency in Deep Software Standby mode 3 (reference data)

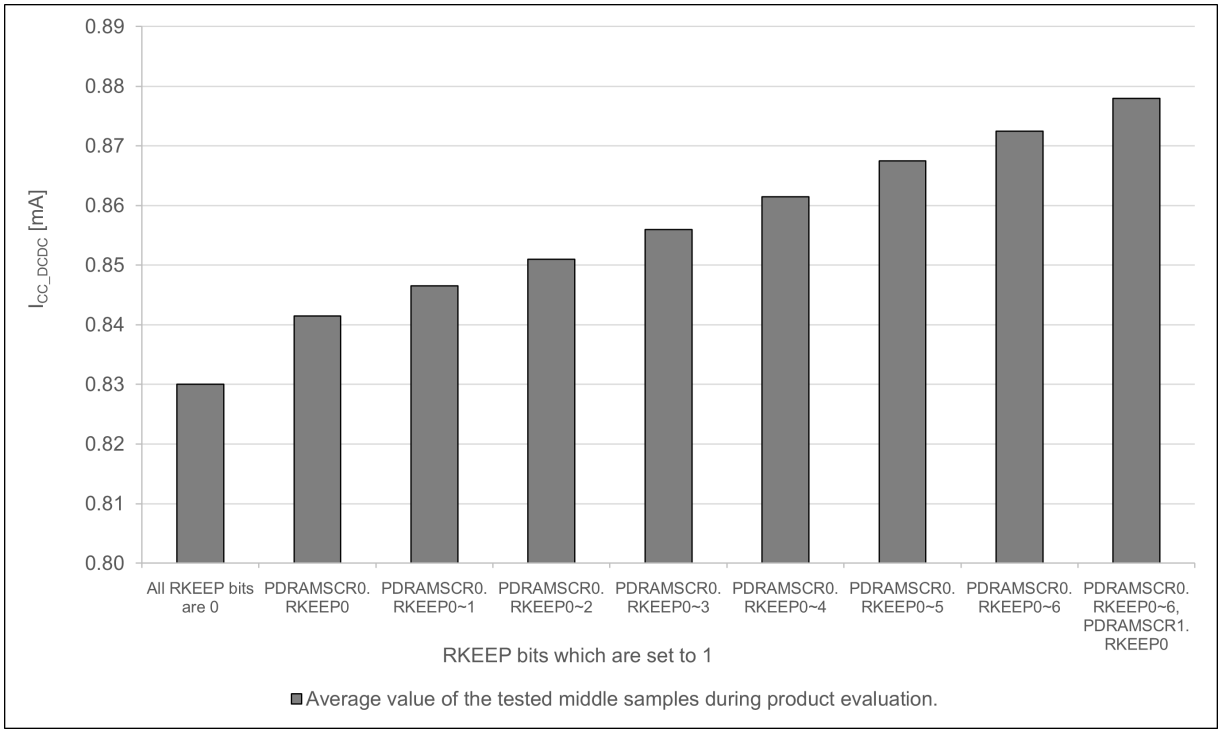

Figure 60.8 Software Standby current per SRAM state (reference data)

The more practical I_{CC_DCDC} value can be obtained with the following formula.

$I_{CC\_DCDC} = I_{DD} \times (VCL \div VCC) \div efficiency$

Where: VCL and VCC are the voltage of VCL pin and VCC pin respectively, and efficiency is shown in the following figures.

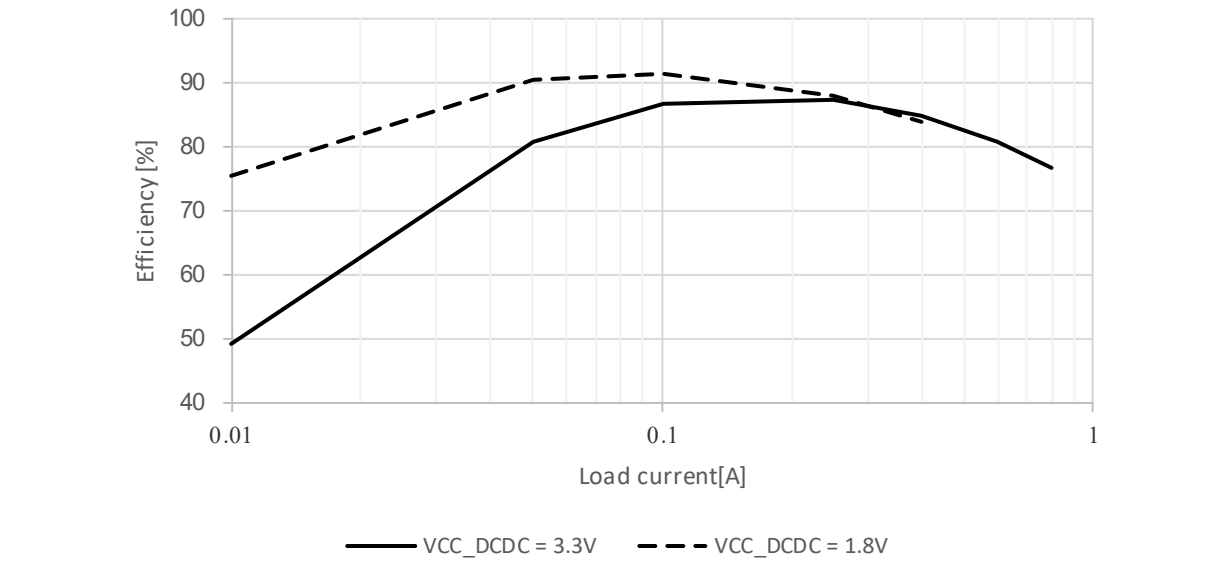

Figure 60.9 Typical DCDC efficiency (%) vs load current (A) in High-speed mode , Tj = 25°C

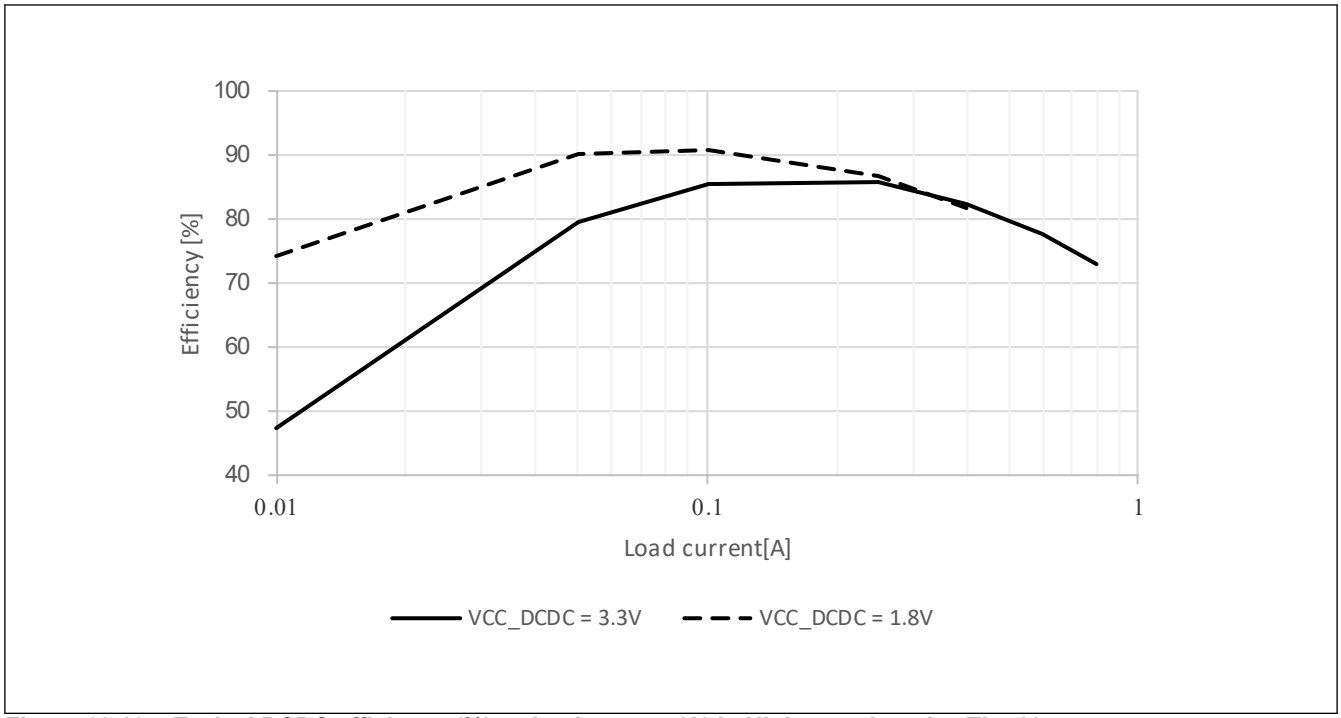

Figure 60.10 Typical DCDC efficiency (%) vs load current (A) in High-speed mode , Tj = 125℃

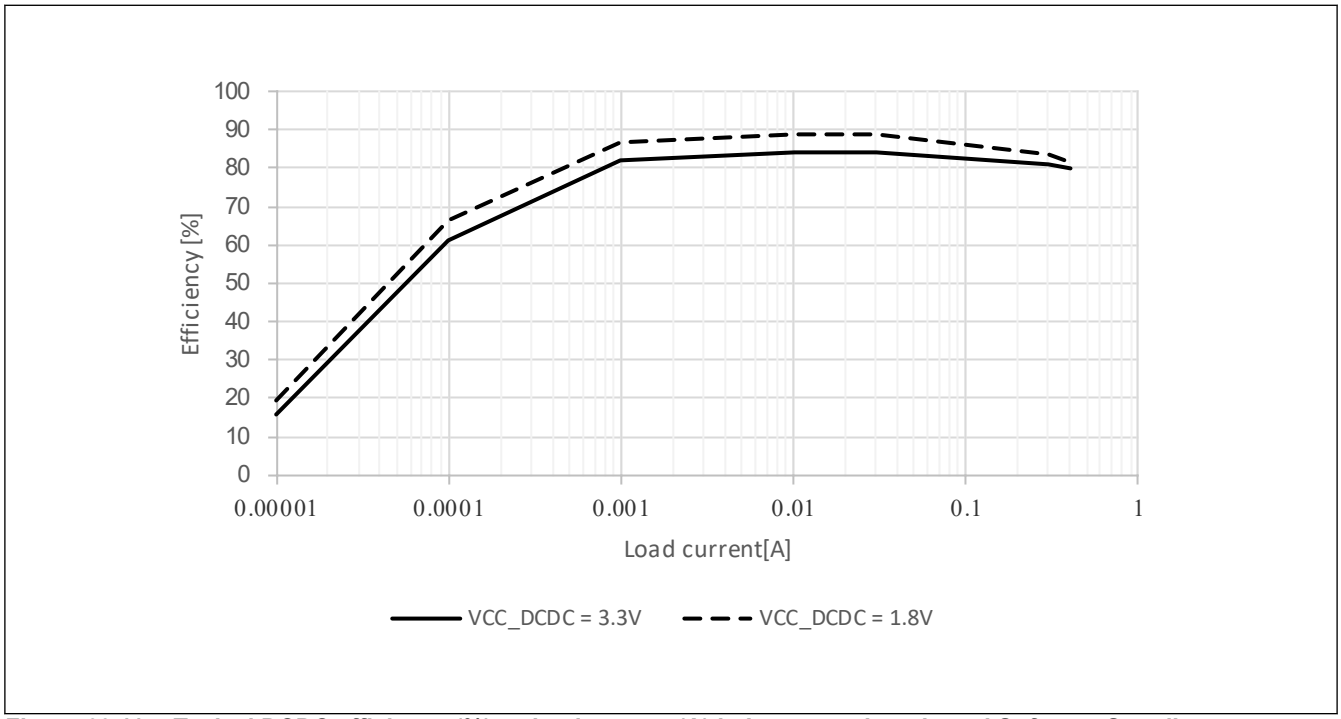

Figure 60.11 Typical DCDC efficiency (%) vs load current (A) in Low-speed mode and Software Standby mode, Tj = 25℃

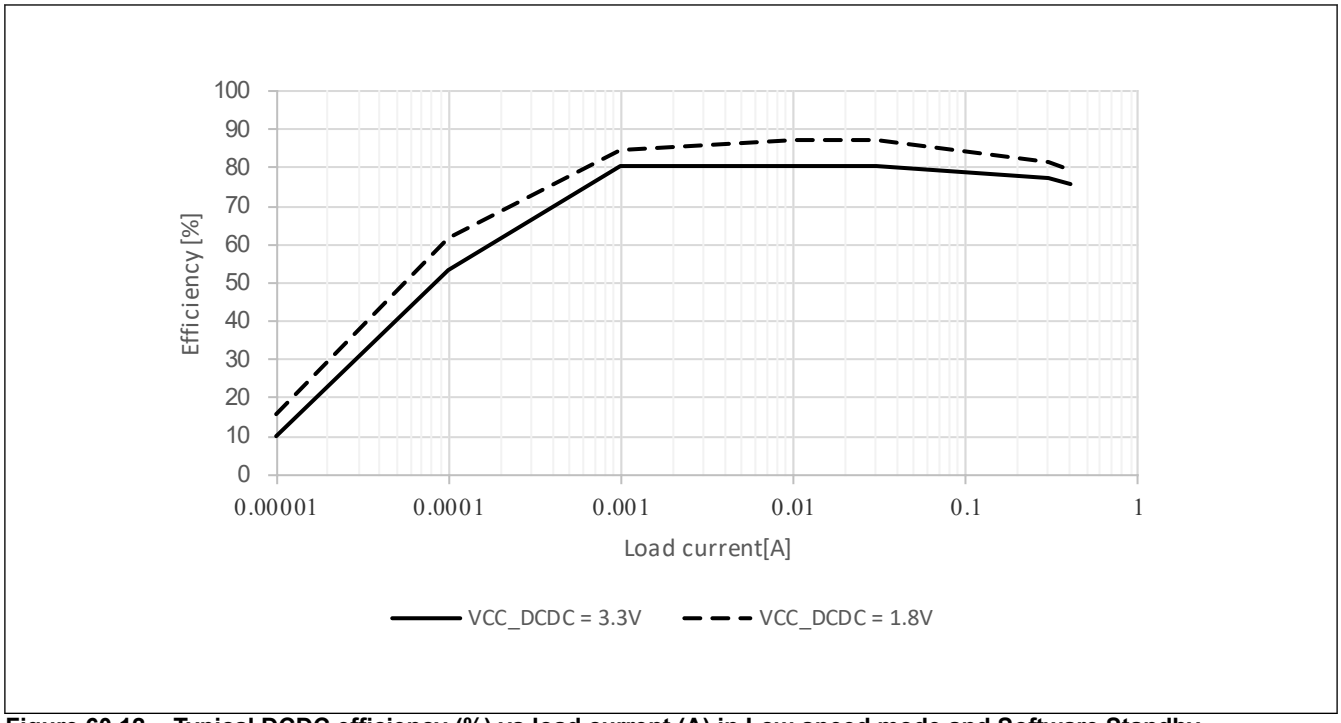

Figure 60.12 Typical DCDC efficiency (%) vs load current (A) in Low-speed mode and Software Standby mode, Tj = 125℃

Note: DCDC efficiency is obtained based on the VCC_DCDC current.

60.2.6 VCC Rise and Fall Gradient and Ripple Frequency

Table 60.24 VCC rise and fall gradient characteristics at power on/off

Parameter		Symbol	Min	Typ	Max	Unit	Test conditions
VCC rising gradient at power on*1		SrVCC	0.0084	—	20	ms/V	—
VCC falling gradient at power off	VBATT function is disabled*1	SfVCC1	0.0084	—	—	ms/V	—
	VBATT function is enabled	SfVCC2	1.0000	—	—		—

Note 1. In case the VCC voltage crosses V_{POR1}.

Table 60.25 VCC ripple frequency and gradient characteristics during operation

The ripple voltage must meet the allowable ripple frequency $f_{r(VCC)}$ within the range between the VCC upper limit (3.6 V) and lower limit (1.68 V). When the VCC change exceeds VCC ±10%, the allowable voltage change rising and falling gradient dt/dVCC must be met.

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions
Allowable ripple frequency	$f_{r\ (VCC)}$	—	—	10.0	kHz	Figure 60.13 $V_{r\ (VCC)} \leq VCC \times 0.2$
		—	—	1.0	MHz	Figure 60.13 $V_{r\ (VCC)} \leq VCC \times 0.08$
		—	—	10.0	MHz	Figure 60.13 $V_{r\ (VCC)} \leq VCC \times 0.06$
Allowable voltage change rising and falling gradient	dt/dVCC*1	1.0	—	—	ms/V	When VCC change exceeds VCC ±10%

Note 1. In case the VCC voltage does not cross V_{POR1}.

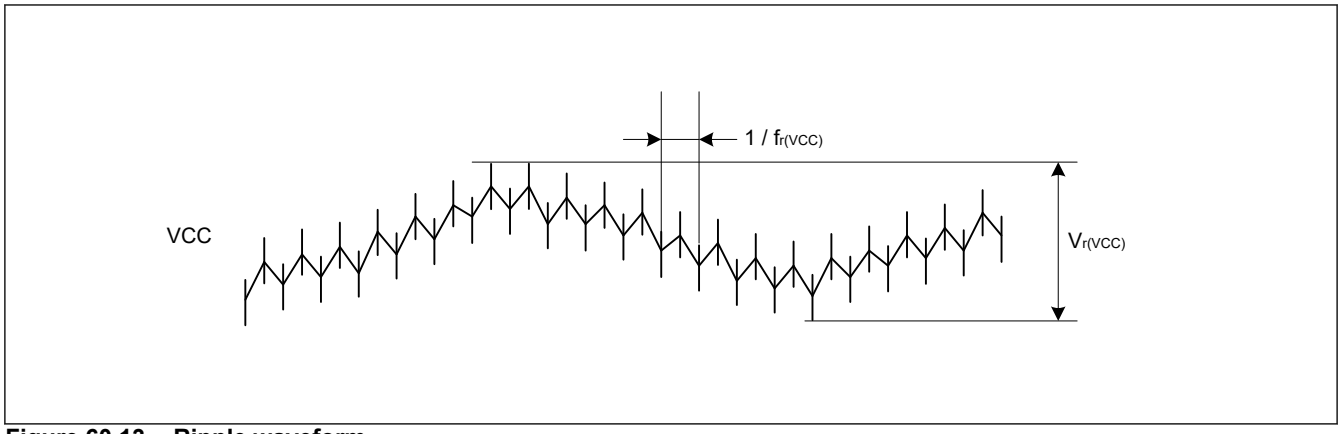

Figure 60.13 Ripple waveform

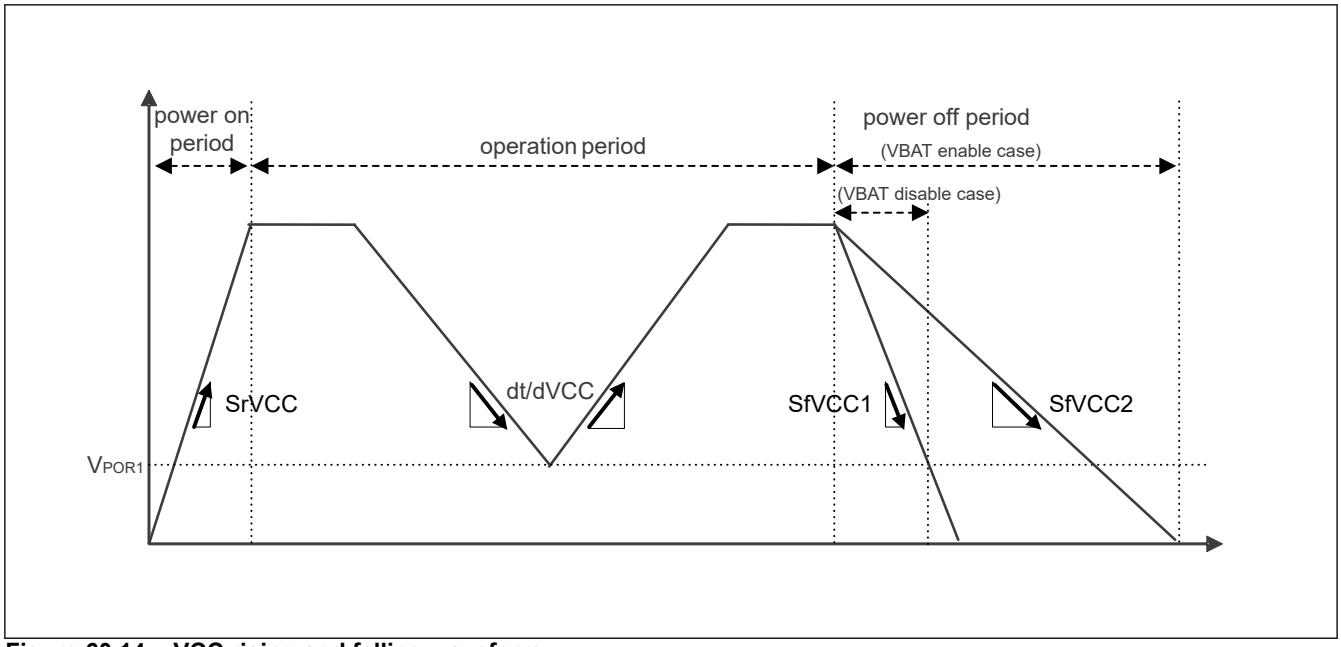

Figure 60.14 VCC rising and falling waveform

60.2.7 Thermal Characteristics

Maximum value of junction temperature (Tj) must not exceed the value of section 60.2.1. Tj/Ta Definition.

Tj is calculated by either of the following equations.

- Tj = Ta + θja × Total power consumption
- Tj = Tt + Ψjt × Total power consumption
  - Tj : Junction Temperature (°C)
  - Ta : Ambient Temperature (°C)
  - Tt : Top Center Case Temperature (°C)
  - θja : Thermal Resistance of “Junction”-to-“Ambient” (°C/W)
  - Ψjt : Thermal Resistance of “Junction”-to-“Top Center Case” (°C/W)
- Total power consumption = Voltage × (Leakage current + Dynamic current)
- Leakage current of IO = Σ (I_{OL} × V_{OL}) /Voltage + Σ (|I_{OH}| × |VCC – V_{OH}|) /Voltage
- Dynamic current of IO = Σ IO (C_{in} + C_{load}) × IO switching frequency × Voltage
  - C_{in}: Input capacitance
  - C_{load}: Output capacitance

Regarding θja and Ψjt, see Table 60.26.

Table 60.26 Thermal Resistance

Parameter	Package	Symbol	Value*1	Unit	Test conditions
Thermal Resistance	176-pin LQFP (PLQP0176KJ-A)	θja	32.0	°C/W	JESD 51-2 and 51-7 compliant
	224-pin BGA (PLBG0224GD-A)		21.5		JESD 51-2 and 51-9 compliant
	176-pin LQFP (PLQP0176KJ-A)	Ψjt	0.42	°C/W	JESD 51-2 and 51-7 compliant
	224-pin BGA (PLBG0224GD-A)		0.24		JESD 51-2 and 51-9 compliant

Note 1. The values are reference values when the 4-layer board is used. Thermal resistance depends on the number of layers or size of the board. For details, see the JEDEC standards.

60.2.7.1 Calculation guide of maximum current

Table 60.27 Power consumption of each unit (1 of 2)

Dynamic current/ Leakage current	MCU Domain	Category	Item	Symbol	Frequency [MHz]	Current [uA/MHz]	Current*1 [mA]	Condition
Leakage current	Analog	Regulator and Leak*1	Tj = 95°C	I_{CC}	—	—	0.54	—
			Tj = 105°C		—	—	0.64	
			Tj = 115°C		—	—	0.75	
			Tj = 125°C		—	—	0.85	
			Tj = 95°C	I_{CC_DCDC}	—	—	64	VCC_DCDC = 3.3V, High speed mode, PDCTRGD.PDDE = 0
			Tj = 105°C		—	—	77	
			Tj = 115°C		—	—	94	
			Tj = 125°C		—	—	111	
			Tj = 95°C		—	—	115	VCC_DCDC = 1.8V, High speed mode, PDCTRGD.PDDE = 0

	FSBL operation				240	—	93.4	—
					120	—	72.9	—

Note 1. Regulator and Leak are Internal voltage regulator's current and MCU's leakage current.
It is selected according to the temperature of Tj.
Note 2. To determine the current consumption per channel or unit, divide Current [mA] by the number of channels, groups or units.

Table 60.28 Outline of operation for each unit (1 of 2)

Peripheral	Outline of operation
RTC	RTC is operating with LOCO.
GPT	Operating modes is set to saw-wave PWM mode.
POEG	Only clear module stop bit.
AGT	AGT is operating with PCLKB.
ULPT	ULPT is operating with LOCO.

Table 60.28 Outline of operation for each unit (2 of 2)

Peripheral	Outline of operation
WDT	WDT is operating with PCLKB.
IWDT	IWDT is operating with IWDTCLK.
ETHERC	Operation modes is set to full-duplex mode. ETHERC is operating using Reduced Media Independent Interface (RMII).
USBFS	Transfer types is set to bulk transfer. USBFS is operating using Full-speed transfer (12 Mbps).
USBHS	Transfer types is set to bulk transfer. USBHS is operating using High-speed transfer.
SCI	SCI is transmitting data in clock synchronous mode.
IIC	Communication format is set to I2C-bus format. IIC is transmitting data in master mode.
I3C	Communication format is set to I3C SDR format. I3C is transmitting data in master mode (12.5MHz).
CANFD	CANFD is transmitting and receiving data in self-test mode 1.
SPI	SPI mode is set to SPI operation (4-wire method). SPI master/slave mode is set to master mode. SPI is transmitting 32-bit width data.
OSPI	OSPI is issuing memory write command to HyperRAM.
SSIE	Communication mode is set to Master. System word length is set to 32 bits. Data word length is set to 20 bits. SSIE is transmitting data using I2S format.
SDHI	Transfer bus mode is set to 8-bit wide bus mode. SDHI is issuing CMD24 (single-block write).
ADC	Resolution is set to 12-bit accuracy. Data registers is set to A/D-converted value addition mode. ADC12 is converting the analog input in continuous scan mode.
DAC12	DAC12 is outputting the conversion result while updating the value of data register.
TSN	TSN is operating.
ACMPHS	ACMPHS is operating.
GLCDC	GLCDC is operating after writing data to CLUT.
DRW	DRW is doing rendering operation after sending data from SDRAM.
MIPI DSI	MIPI DSI is operating with HS mode using 2-lane. Data is input via GLCDC.
CEU	CEU is capturing data and transferring to the SRAM.
ELC	Only clear module stop bit.
RSIP-E51A	RSIP is doing self-test operation.
DOTF	DOTF is doing decryption with AES.
CRC	CRC is generating CRC code using 32-bit CRC32-C polynomial.
DOC	DOC is operating in data comparison mode.
CAC	Measurement target clocks is set to PCLKB. Measurement reference clocks is set to PCLKB. CAC is measuring the clock frequency accuracy.
DMAC	Bit length of transfer data is set to 32 bits. Transfer mode is set to block transfer mode. DMAC is transferring data from SRAM0 to SRAM0.
DTC	Bit length of transfer data is set to 32 bits. Transfer mode is set to block transfer mode. DTC is transferring data from SRAM0 to SRAM0.

60.2.7.2 Example of Tj calculation

Assumption :

- Package 224-pin BGA : θja = 21.5 °C/W
- Ta = 80 °C
- $I_{CC} + I_{CC\_DCDC}$ = 240 mA
- VCC = 3.5 V (VCC = VCC2 = AVCC0 = AVCC_USBHS = VCC_USB = VCC_USBHS)
- I_{OH} = 1 mA, V_{OH} = VCC – 0.5 V, 12 Outputs

- I_{OL} = 20 mA, V_{OL} = 1.0 V, 8 Outputs
- I_{OL} = 1 mA, V_{OL} = 0.5 V, 12 Outputs
- C_{in} = 8 pF, 32 pins, Input frequency = 10 MHz
- C_{load} = 30 pF, 32 pins, Output frequency = 10 MHz

Static current of IO = Σ (VOL × IOL) / Voltage + Σ ((VCC - VOH) × IOH) / Voltage

= (20 mA × 1 V) × 8 / 3.5 V + (1 mA × 0.5 V) × 12 / 3.5 V + ((VCC - (VCC - 0.5 V)) × 1 mA) × 12 / 3.5 V

= 45.7 mA + 1.71 mA + 1.71 mA

= 49.1 mA

Dynamic current of IO = Σ IO (Cin + Cload) × IO switching frequency × Voltage

= ((8 pF × 32) × 10 MHz + (30 pF × 32) × 10 MHz) × 3.5 V

= 42.6 mA

Total power consumption = Voltage × (Static current + Dynamic current)

= (240 mA × 3.5 V) + (49.1 mA + 42.6 mA) × 3.5 V

= 1161 mW (1.161 W)

Tj = Ta + θja × Total power consumption

= 80 °C + 21.5 °C/W × 1.161W

= 105.0 °C

60.3 AC Characteristics

60.3.1 Frequency

Table 60.29 Operation frequency value in high-speed mode

Parameter			Symbol	Min	Typ	Max	Unit
Operation frequency	CPU clock (CPUCLK)*2	DCDC, BGA package, Tj ≤ 105℃*4	f	—	—	480	MHz
		DCDC, BGA package, Tj ≤ 125℃*4		—	—	400	
		External VDD, BGA package, Tj ≤ 105℃		—	—	480	
		External VDD, BGA package, Tj ≤ 125℃		—	—	400	
		DCDC, 176-pin LQFP package, Tj ≤ 125℃*4		—	—	400	
		External VDD, 176-pin LQFP package, Tj ≤ 125℃		—	—	400	
	System clock (ICLK)*2			—	—	240	
	Peripheral module clock (PCLKA)*2			—	—	120	
	Peripheral module clock (PCLKB)*2			—	—	60	
	Peripheral module clock (PCLKC)*2			—*3	—	60	
	Peripheral module clock (PCLKD)*2			—	—	120	
	Peripheral module clock (PCLKE)*2			—	—	240	
	Flash interface clock (FCLK)*2			—*1	—	60	
	External bus clock (BCLK)*2	VCC ≥ 2.7 V		—	—	120	
		VCC ≥ 1.68 V		—	—	60	
	EBCLK pin output	VCC ≥ 2.7 V		—	—	60	
		VCC ≥ 1.68 V		—	—	30	
	SDCLK pin output	VCC ≥ 3.0 V		—	—	120	
	SCI clock (SCICLK)			—	—	120	
	SPI clock (SPICLK)			—	—	120	
	Octal SPI clock (OCTACLK)			—	—	200	
	CANFD core clock (CANFDCLK)			—	—	80	
	LCD clock (LCDCLK)			—	—	240	
	USB clock (USBCLK)			—	—	48	
	USB clock (USB60CLK)			—	—	60	
	I3C clock (I3CCLK)			—	—	200	

Note 1. FCLK must run at a frequency of at least 4 MHz when programming or erasing the flash memory.
Note 2. See section 8, Clock Generation Circuit for the relationship between the CPUCLK, ICLK, PCLKA, PCLKB, PCLKC, PCLKD, PCLKE, FCLK, and BCLK frequencies.
Note 3. When the ADC12 is used, the PCLKC frequency must be at least 1 MHz.
Note 4. When DCDC is used with VCC_DCDC < 2.5V, I_{DD} current must be less than the value specified in operating current. Please see Table 60.8.

Table 60.30 Operation frequency value in low-speed mode

Parameter			Symbol	Min	Typ	Max	Unit
Operation frequency	CPU clock (CPUCLK)*2		f	—	—	1	MHz
	System clock (ICLK)*2			—	—	1	
	Peripheral module clock (PCLKA)*2			—	—	1	
	Peripheral module clock (PCLKB)*2			—	—	1	
	Peripheral module clock (PCLKC)*2			—*3	—	1	
	Peripheral module clock (PCLKD)*2			—	—	1	
	Peripheral module clock (PCLKE)*2			—	—	1	
	Flash interface clock (FCLK) *2			—*1	—	1	
	External bus clock (BCLK)*2			—	—	1	
	EBCLK pin output			—	—	1	
	SDCLK pin output	VCC ≥ 3.0 V		—	—	1	
	SCI clock (SCICLK)			—	—	1	
	SPI clock (SPICLK)			—	—	1	
	Octal SPI clock (OCTACLK)			—	—	1	
	CANFD core clock (CANFDCLK)			—	—	1	
	LCD clock (LCDCLK)			—	—	1	
	USB clock (USBCLK)			—	—	1	
	USB clock (USB60CLK)			—	—	1	
	I3C clock (I3CCLK)			—	—	1	

Note 1. Programming or erasing the flash memory is disabled in low-speed mode.
Note 2. See section 8, Clock Generation Circuit for the relationship between the CPUCLK, ICLK, PCLKA, PCLKB, PCLKC, PCLKD, PCLKE, FCLK, and BCLK frequencies.
Note 3. When the ADC12 is used, the PCLKC frequency must be at least 1 MHz.

60.3.2 Clock Timing

Table 60.31 Clock timing except for sub-clock oscillator (1 of 2)

Parameter		Symbol	Min	Typ	Max	Unit	Test conditions
EBCLK pin output cycle time	VCC = 2.70 V or above	t_{Bcyc}	16.6	—	—	ns	Figure 60.15
	VCC = 1.68 V or above		33.3	—	—		
EBCLK pin output high pulse width	VCC = 2.70 V or above	t_{CH}	3.3	—	—	ns	
	VCC = 1.68 V or above		9.6	—	—		
EBCLK pin output low pulse width	VCC = 2.70 V or above	t_{CL}	3.3	—	—	ns	
	VCC = 1.68 V or above		9.6	—	—		
EBCLK pin output rise time	VCC = 2.70 V or above	t_{Cr}	—	—	5.0	ns	
	VCC = 1.68 V or above		—	—	7.0		
EBCLK pin output fall time	VCC = 2.70 V or above	t_{Cf}	—	—	5.0	ns	
	VCC = 1.68 V or above		—	—	7.0		
SDCLK pin output cycle time		t_{SDcyc}	8.33	—	—	ns	
SDCLK pin output high pulse width		t_{CH}	1.0	—	—	ns	
SDCLK pin output low pulse width		t_{CL}	1.0	—	—	ns	
SDCLK pin output rise time		t_{Cr}	—	—	3.0	ns	
SDCLK pin output fall time		t_{Cf}	—	—	3.0	ns	

Table 60.31 Clock timing except for sub-clock oscillator (2 of 2)

Parameter		Symbol	Min	Typ	Max	Unit	Test conditions
EXTAL external clock input cycle time		t_{EXcyc}	20.80	—	—	ns	Figure 60.16

		f_{HOCO32}	31.55	32.00	32.45		
		f_{HOCO48}	47.33	48.00	48.67		
		f_{HOCO16}	15.71	16.00	16.29		–40 ≤ Tj ≤ –20 °C
		f_{HOCO18}	17.68	18.00	18.32		
		f_{HOCO20}	19.64	20.00	20.36		
		f_{HOCO32}	31.42	32.00	32.58		
		f_{HOCO48}	47.14	48.00	48.86		
	With FLL	f_{HOCO16}	15.960	16.000	16.040		–40 ≤ Tj ≤ 125 °C Sub-clock frequency accuracy is ±50 ppm.
		f_{HOCO18}	17.955	18.000	18.045		
		f_{HOCO20}	19.950	20.000	20.050		
		f_{HOCO32}	31.920	32.000	32.080		
		f_{HOCO48}	47.880	48.000	48.120		
HOCO clock oscillation stabilization wait time*2		t_{HOCOWT}	—	—	64.7	µs	—
HOCO stop width time		$t_{HOCOSTP}$	1	—	—	µs	Figure 60.21
HOCO period jitter		Jitter	-3	—	3	%	—
FLL stabilization wait time		t_{FLLWT}	—	—	1.8	ms	—
PLL1/PLL2 VCO frequency		f_{VCO}	640	—	1440.0	MHz	—
PLL1/PLL2 Output frequency for output clock P		t_{PLL}	40	—	480	MHz	—
PLL1/PLL2 Output frequency for output clock Q, R		t_{PLL}	71	—	480	MHz	—
PLL1/PLL2 clock oscillation stabilization wait time		t_{PLLWT}	—	—	40	µs	Figure 60.19
PLL1/PLL2 period jitter		—	—	—	±70	—	ps	—
PLL1/PLL2 long term jitter		—	—	—	±300	—	ps	Term: 1 µs, 10 µs

Note 1. When setting up the main clock oscillator, ask the oscillator manufacturer for an oscillation evaluation, and use the results as the recommended oscillation stabilization time. Set the MOSCWTCR register to a value equal to or greater than the recommended value.
After changing the setting in the MOSCCR.MOSTP bit to start main clock operation, read the OSCSF.MOSCSF flag to confirm that it is 1, and then start using the main clock oscillator.

Note 2. This is the time from release from reset state until the HOCO oscillation frequency (f_{HOCO}) reaches the range for guaranteed operation.

Table 60.32 Clock timing for the sub-clock oscillator

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions
Sub-clock frequency	f_{SUB}	—	32.768	—	kHz	—
Sub-clock oscillation stabilization wait time	$t_{SUBOSCWT}$	—	—	—*1	s	Figure 60.20

Note 1. When setting up the sub-clock oscillator, ask the oscillator manufacturer for an oscillation evaluation and use the results as the recommended oscillation stabilization time.
After changing the setting in the SOSCCR.SOSTP bit to start sub-clock operation, only start using the sub-clock oscillator after the sub-clock oscillation stabilization time elapses with an adequate margin. A value that is two times the value shown is recommended.

	System clock source is MOCO clock oscillator*8		Enabled	t_{SBYMO}*10	—	312	387	µs	

Table 60.34 Timing of recovery from low power modes (2 of 2)

Parameter			Fast return function*9	Symbol	Min	Typ	Max	Unit	Test conditions
Recovery time from Deep Software Standby mode	Deep Software Standby mode 1	Any of PVD0(OFS1(_SEC).PVDLPSEL=1), PVD1, PVD2, or Battery power supply switch is enabled	Standard	t_{DSBY}	—	0.68	1.20	ms	Figure 60.25
			Fast		—	0.29	0.62	ms	
		All of PVD0(OFS1(_SEC).PVDLPSEL=1), PVD1, PVD2, and Battery power supply switch are disabled	Standard			0.73	1.30		
			Fast			0.33	0.71		
	Deep Software Standby mode 2	DPSWCR.WSTS = 0x0B	Standard		—	0.73	1.10	ms	
			Fast		—	0.33	0.50	ms	
		DPSWCR.WSTS = 0x9A	Standard		—	1.60	2.00	ms	
			Fast		—	1.20	1.50	ms	
	Deep Software Standby mode 3		Standard		—	2.10	3.50	ms	
			Fast		—	1.70	2.90	ms	
Wait time after cancellation of Deep Software Standby mode			—	t_{DSBYWT}	47.7	—	64.6	µs	

Note 1. When the frequency of the crystal is 48 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 1.
Note 2. When the frequency of PLL1P is 480 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 8.
Note 3. When the frequency of the external clock is 48 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00) and the greatest value of the internal clock division setting is 1.
Note 4. When the frequency of PLL1P is 480 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00) and the greatest value of the internal clock division setting is 8.
Note 5. The Sub-clock oscillator frequency is 32.768 kHz and the greatest value of the internal clock division setting is 1.
Note 6. The HOCO frequency is 20 MHz and the greatest value of the internal clock division setting is 1.
Note 7. The PLL frequency is 480 MHz and the greatest value of the internal clock division setting is 8.
Note 8. The MOCO frequency is 8 MHz and the greatest value of the internal clock division setting is 1.
Note 9. For details, see SSCR1.SS1FR, DPSBYCR.DCSSMODE bits in the section 10, Low Power Modes.
Note 10. The recovery time can be calculated with the equation of t_{Common} + max(t_{OSCSTB}, t_{PG1}, t_{PGCK}) + max(t_{PG2}, t_{LPW}). And they can be determined with the following values and equations. For n, the greatest value is selected from among the internal clock(CPUCLK, ICLK, PCLKm, FCLK, BCLK and EBCLK) division settings (m = A to E).
t_{OSCSTB} in the table below means the time when each oscillator is active. When multiple oscillators are active, t_{OSCSTB} is determined by the longest t_{OSCSTB} among the active oscillators.
Note 11. The ICLK frequency is 240 MHz. This recovery time corresponds to t_{PG2}.

Table 60.35 Each element of recovery time

Wakeup time	Oscillation keep	Fast return function	Typ						Max						Unit
			t_{Common}	t_{OSCSTB} *1	t_{PG1}	t_{PGCK}	t_{PG2}	t_{LPW}	t_{Common}	t_{OSCSTB} *1	t_{PG1}	t_{PGCK}	t_{PG2}	t_{LPW}	
t_{SBYMC}	MOSC disabled	Enabled	52.667 + 4/ fICLK	$t_{MAINOSCWT}$	75.5	2.1 + 10.5/ fMOCO + 2.5n/ fMOCO + 2.5/ fSRCCLK + 2/ fICLK	1449/ fMOCO + 10/ fICLK	10 + 2/ fICLK + 2n/ fMAIN	82.369 + 4/ fICLK	$t_{MAINOSCWT}$ + 11/0.236	88.8	2.5 + 10.5/ fMOCO + 2.5n/ fMOCO + 2.5/ fSRCCLK + 2/ fICLK	1449/ fMOCO +10/ fICLK	10 + 2/ fICLK + 2n/ fMAIN	µs

60.3.5 NMI and IRQ Noise Filter

Table 60.36 NMI and IRQ noise filter

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions	
NMI pulse width	t_{NMIW}	200	—	—	ns	NMI digital filter disabled	$t_{Pcyc} \times 2 \leq 200$ ns
		$t_{Pcyc} \times 2$*1	—	—			$t_{Pcyc} \times 2 > 200$ ns
		200	—	—		NMI digital filter enabled	$t_{NMICK} \times 3 \leq 200$ ns
		$t_{NMICK} \times 3.5$*2	—	—			$t_{NMICK} \times 3 > 200$ ns
IRQ pulse width	t_{IRQW}	200	—	—	ns	IRQ digital filter disabled	$t_{Pcyc} \times 2 \leq 200$ ns
		$t_{Pcyc} \times 2$*1	—	—			$t_{Pcyc} \times 2 > 200$ ns
		200	—	—		IRQ digital filter enabled	$t_{IRQCK} \times 3 \leq 200$ ns
		$t_{IRQCK} \times 3.5$*3	—	—			$t_{IRQCK} \times 3 > 200$ ns

Note: 200 ns minimum in Software Standby mode.
Note: If the system clock source is switched, add 4 clock cycles of the switched source.
Note 1. t_{Pcyc} indicates the PCLKB cycle.
Note 2. t_{NMICK} indicates the cycle of the NMI digital filter sampling clock.
Note 3. t_{IRQCK} indicates the cycle of the IRQi digital filter sampling clock.

60.3.6 Bus Timing

Table 60.37 Bus timing (1 of 2)

Condition 1: When using the CS area controller (CSC).
VCC = VCC_DCDC = VCC_USB = VBATT = 1.68 V to 3.6 V, VCC2 = 1.65 V to 3.6 V
BCLK = 8 to 120 MHz, EBCLK = 8 to 60 MHz (When VCC = VCC_USB = VBATT = 2.70 to 3.6 V)
BCLK = 8 to 60 MHz, EBCLK = 8 to 30 MHz (When VCC = VCC_USB = VBATT = 1.68 to 3.6 V)
Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 30 pF
EBCLK: High drive output is selected in the port drive capability bit in the PmnPFS register.
Others: Middle drive output is selected in the port drive capability bit in the PmnPFS register.

Condition 2: When using the SDRAM area controller (SDRAMC).
BCLK = SDCLK = 8 to 120 MHz
VCC = VCC2 = VCC_DCDC = VCC_USB = VBATT = 3.0 to 3.6 V
Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 15 pF
SDCLK: High-speed high drive output is selected in the port drive capability bit in the PmnPFS register.
Others: High drive output is selected in the port drive capability bit in the PmnPFS register.

Condition 3: When using the SDRAM area controller (SDRAMC) and CS area controller (CSC) simultaneously.
BCLK = SDCLK = 8 to 60 MHz
VCC = VCC2 = VCC_DCDC = VCC_USB = VBATT = 3.0 to 3.6 V
Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 15 pF
EBCLK/SDCLK: High drive output is selected in the port drive capability bit in the PmnPFS register.
Others: Middle drive output is selected in the port drive capability bit in the PmnPFS register.

Parameter		Symbol	Min	Max	Unit	Test conditions
Address delay	2.70V or above	t_{AD}	1.0	12.5	ns	Figure 60.28 to Figure 60.34
	1.68V or above		1.0	12.5	ns

60.3.7 I/O Ports, POEG, GPT, AGT, ULPT and ADC12 Trigger Timing

Table 60.38 I/O ports, POEG, GPT, AGT, ULPT and ADC12 trigger timing (1 of 3)

GPT Conditions:
Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.
If GPT pins are specified across the VCC I/O and VCC2 I/O, characteristics below is guaranteed only when VCC = VCC2.
AGT Conditions:
Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	Min	Max	Unit	Test conditions
I/O ports	Input data pulse width	t_{PRW}	5.5	—	t_{Icyc}	Figure 60.42
	EXCIN input frequency	t_{EXCIN}	—	36	kHz	
	RTCICn (n = 0 to 2) input pulse width	t_{RTCICW}	13.89	—	μs	Figure 60.43
POEG	POEG input trigger pulse width	t_{POEW}	3	—	t_{Pcyc}	Figure 60.44

Table 60.38 I/O ports, POEG, GPT, AGT, ULPT and ADC12 trigger timing (2 of 3)

GPT Conditions:
Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.
If GPT pins are specified across the VCC I/O and VCC2 I/O, characteristics below is guaranteed only when VCC = VCC2.
AGT Conditions:
Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter			Symbol	Min	Max	Unit	Test conditions
GPT	Input capture pulse width (Cycle)	Single edge	t_{GTICW}*1	1.5	—	t_{PDcyc}	Figure 60.45
		Dual edge		2.5	—		
	Input capture pulse width (Time)	2.70V or above	t_{GTICW}*1	12.5	—	ns	
		1.68V or above (VCC) 1.65V or above (VCC2)		25.0	—

		1.68V or above (VCC) 1.65V or above (VCC2)		40	—		
	AGTIO, AGTO, AGTOA, AGTOB output cycle	2.70V or above	t_{ACYC2}	62.5	—	ns	
		1.68V or above (VCC) 1.65V or above (VCC2)		62.5	—		

Table 60.38 I/O ports, POEG, GPT, AGT, ULPT and ADC12 trigger timing (3 of 3)

GPT Conditions:
Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.
If GPT pins are specified across the VCC I/O and VCC2 I/O, characteristics below is guaranteed only when VCC = VCC2.
AGT Conditions:
Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter			Symbol	Min	Max	Unit	Test conditions
ULPT	ULPTEE, ULPTEVI input cycle	2.70V or above	t_{ULCYC}*3	32	-	μs	Figure 60.49
		1.68V or above (VCC) 1.65V or above (VCC2)		32	-		
	ULPTEE, ULPTVI input high width, low width	2.70V or above	t_{ULCKWH}, t_{ULCKWL}	12	-	μs	
		1.68V or above (VCC) 1.65V or above (VCC2)		12	-		
	ULPTO, ULPTOA, ULPTOB output cycle	2.70V or above	t_{ULCYC2}	64	-	μs	
		1.68V or above (VCC) 1.65V or above (VCC2)		64	-		
ADC12	ADC12 trigger input pulse width	2.70V or above	t_{TRGW}	1.5	—	t_{Pcyc}	Figure 60.50
		1.68V or above (VCC) 1.65V or above (VCC2)		3.0	—		

Note: t_{Icyc}: ICLK cycle, t_{Pcyc}: PCLKB cycle, t_{PDcyc}: PCLKD cycle, $t_{ULPTLCLK}$: ULPTLCLK cycle..
Note 1. For Cycle and Time, the longer time characteristics is applied.
Note 2. Constraints on input cycle:
When not switching the source clock: $t_{Pcyc} \times 2 < t_{ACYC}$ should be satisfied.
When switching the source clock: $t_{Pcyc} \times 6 < t_{ACYC}$ should be satisfied.
Note 3. Constraints on input cycle:
ULPTEVI : $t_{Pcyc} \times 2 < t_{ULCYC}$ should be satisfied.
ULPTEE: $t_{ULPTLCLK} \times 2 < t_{ULCYC}$ should be satisfied.

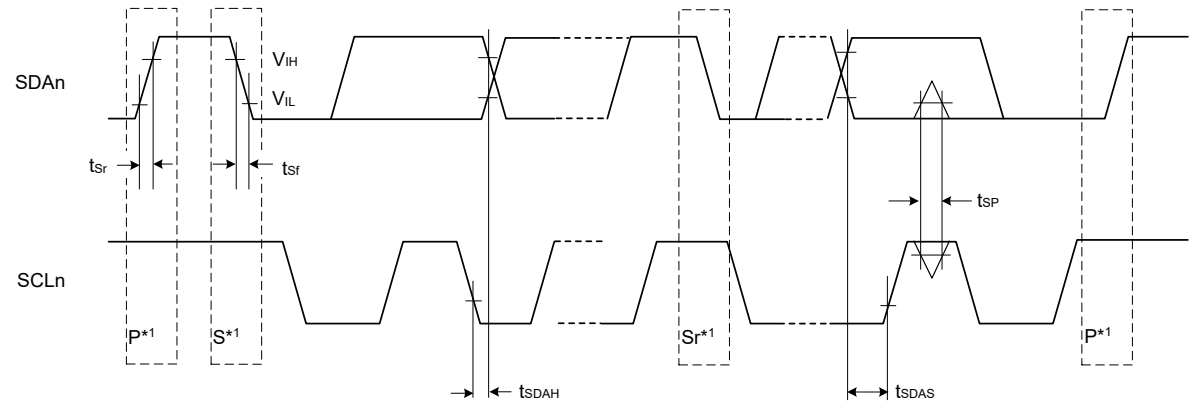
Table 60.43 SCI timing (Simple IIC mode)

Conditions: Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.
VCC: 1.68V or above, VCC2: 1.65V or above
If SCI pins are specified across the VCC I/O and VCC2 I/O, characteristics below is guaranteed only when VCC = VCC2.

Parameter		Symbol	Min	Max	Unit	Note
Simple IIC (Standard mode)	SCL, SDA input rise time	t_{Sr}	—	1000	ns	
	SCL, SDA input fall time	t_{Sf}	—	300	ns	
	SCL, SDA input spike pulse removal time	t_{SP}	0	4 × t_{Tcyc}	ns	
	Data input setup time	t_{SDAS}	250	—	ns	
	Data input hold time	t_{SDAH}	0	—	ns	
	SCL, SDA capacitive load	C_b *1	—	400	pF	
Simple IIC (Fast mode)	SCL, SDA input rise time	t_{Sr}	—	300	ns	
	SCL, SDA input fall time	t_{Sf}	—	300	ns	
	SCL, SDA input spike pulse removal time	t_{SP}	0	4 × t_{Tcyc}	ns	
	Data input setup time	t_{SDAS}	100	—	ns	
	Data input hold time	t_{SDAH}	0	—	ns	
	SCL, SDA capacitive load	C_b *1	—	400	pF	

Note: t_{Tcyc}: TCLK cycle.
Note 1. C_b indicates the total capacity of the bus line.



Test conditions:
V_{IH} = VCC × 0.7 or VCC2 × 0.7
V_{IL} = VCC × 0.3 or VCC2 × 0.3
V_{OL} = 0.6 V, I_{OL} = 6 mA

Note: n = 0 to 4, 9
Note 1. S, P, and Sr indicate the following conditions:
S: Start condition
P: Stop condition
Sr: Restart condition

			1.68 to 1.95 V				
	SCL, SDA fall time	t_{Sf}	2.70 V or above	20 × (external pullup voltage/5.5 V)*1	300	ns	
			1.68 to 1.95 V				
	SCL, SDA input spike pulse removal time	t_{SP}	2.70 V or above	0	1 (4) × t_{IICcyc}	ns	
			1.68 to 1.95 V				
	SDA input bus free time when wakeup function is disabled	t_{BUF}	2.70 V or above	3 (6) × t_{IICcyc} + 300	—	ns	
			1.68 to 1.95 V				
	SDA input bus free time when wakeup function is enabled	t_{BUF}	2.70 V or above	3 (6) × t_{IICcyc} + 4 × t_{Pcyc} + 300	—	ns	
			1.68 to 1.95 V				
	START condition input hold time when wakeup function is disabled	t_{STAH}	2.70 V or above	t_{IICcyc} + 300	—	ns	
			1.68 to 1.95 V				
	START condition input hold time when wakeup function is enabled	t_{STAH}	2.70 V or above	1 (5) × t_{IICcyc} + t_{Pcyc} + 300	—	ns	
			1.68 to 1.95 V				
	Repeated START condition input setup time	t_{STAS}	2.70 V or above	300	—	ns	
			1.68 to 1.95 V				
	STOP condition input setup time	t_{STOS}	2.70 V or above	300	—	ns	
			1.68 to 1.95 V				
	Data input setup time	t_{SDAS}	2.70 V or above	t_{IICcyc} + 50	—	ns	
			1.68 to 1.95 V				
	Data input hold time	t_{SDAH}	2.70 V or above	0	—	ns	
			1.68 to 1.95 V				
	SCL, SDA capacitive load	C_b	2.70 V or above	—	400	pF	
			1.68 to 1.95 V				

Note: t_{IICcyc}: IIC internal reference clock (IICφ) cycle, t_{Pcyc}: PCLKB cycle.
Note: Values in parentheses apply when ICMR3.NF[1:0] is set to 11b while the digital filter is enabled with ICFER.NFE set to 1.
Note: Must use pins that have a letter appended to their name, for instance "_A", "_B", to indicate group membership. For the IIC interface, the AC portion of the electrical characteristics is measured for each group.
Note 1. Only supported for SCL0_A, SDA0_A, SCL1_A, and SDA1_A.

Table 60.47 IIC timing (2)

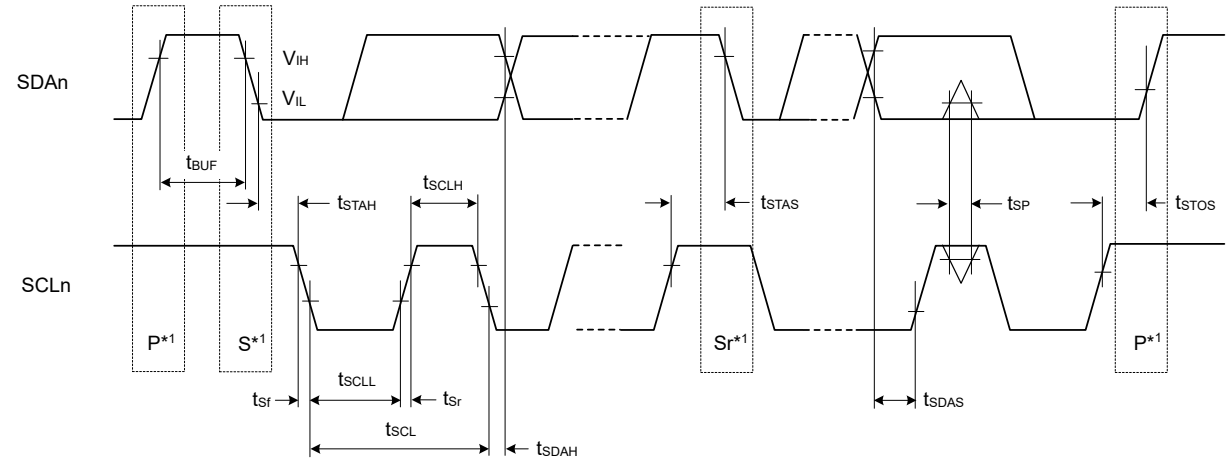
Setting of the SCL0_A, SDA0_A, SCL1_A, SDA1_A pins are not required with the port drive capability bit in the PmnPFS register.

Parameter		Symbol	VCC	Min	Max	Unit	Test conditions
IIC (Fast-mode+) ICFER.FMPE = 1	SCL input cycle time	t_{SCL}	2.70 V or above	6 (12) × t_{IICcyc} + 240	—	ns	Figure 60.71
	SCL input high pulse width	t_{SCLH}	2.70 V or above	3 (6) × t_{IICcyc} + 120	—	ns	
	SCL input low pulse width	t_{SCLL}	2.70 V or above	3 (6) × t_{IICcyc} + 120	—	ns	
	SCL, SDA rise time	t_{Sr}	2.70 V or above	—	120	ns	
	SCL, SDA fall time	t_{Sf}	2.70 V or above	20 × (external pullup voltage/ 5.5V)	120	ns	
	SCL, SDA input spike pulse removal time	t_{SP}	2.70 V or above	0	1 (4) × t_{IICcyc}	ns	
	SDA input bus free time when wakeup function is disabled	t_{BUF}	2.70 V or above	3 (6) × t_{IICcyc} + 120	—	ns	
	SDA input bus free time when wakeup function is enabled	t_{BUF}	2.70 V or above	3 (6) × t_{IICcyc} + 4 × t_{Pcyc} + 120	—	ns	
	Start condition input hold time when wakeup function is disabled	t_{STAH}	2.70 V or above	t_{IICcyc} + 120	—	ns	
	START condition input hold time when wakeup function is enabled	t_{STAH}	2.70 V or above	1 (5) × t_{IICcyc} + t_{Pcyc} + 120	—	ns	
	Restart condition input setup time	t_{STAS}	2.70 V or above	120	—	ns	
	Stop condition input setup time	t_{STOS}	2.70 V or above	120	—	ns	
	Data input setup time	t_{SDAS}	2.70 V or above	t_{IICcyc} + 30	—	ns	
	Data input hold time	t_{SDAH}	2.70 V or above	0	—	ns	
	SCL, SDA capacitive load	C_b*1	2.70 V or above	—	550	pF	

Note: t_{IICcyc}: IIC internal reference clock (IICφ) cycle, tPcyc: PCLKB cycle.

Note: Values in parentheses apply when ICMR3.NF[1:0] is set to 11b while the digital filter is enabled with ICFER.NFE set to 1.

Note 1. Cb indicates the total capacity of the bus line.



Note 1. S, P, and Sr indicate the following conditions:
S: Start condition
P: Stop condition
Sr: Restart condition

Figure 60.71 I²C bus interface input/output timing

60.3.13 I3C Timing

Table 60.48 IIC timing(1)-1

Setting of the I3C_SCL0, I3C_SDA0 pins are not required with the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	VCC	Min	Max	Unit
IIC (Standard mode, SMBus) BFCTL.FMPE = 0	SCL input cycle time	t_{SCL}	2.70 V or above, 1.68 to 1.95 V	10 (18) × t_{I3Ccyc} + 1300	—	ns

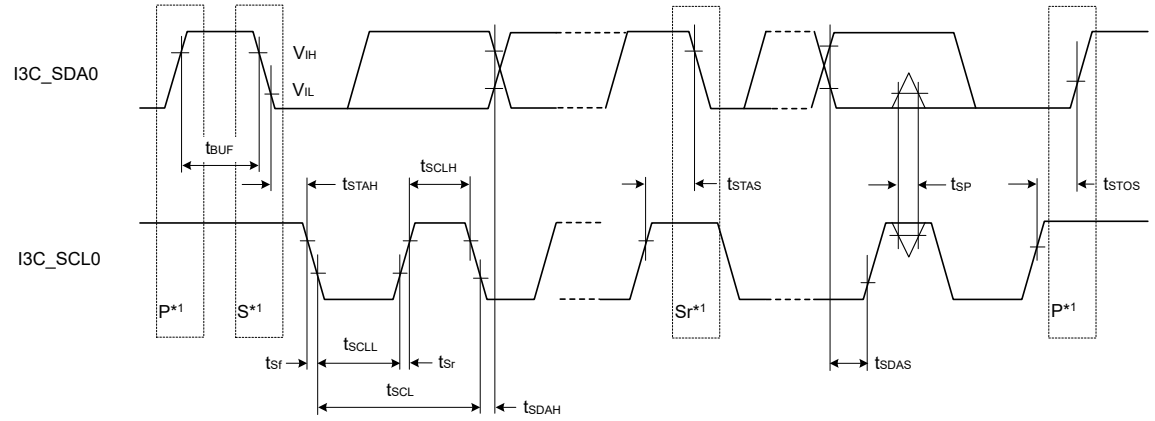
	SDA input bus free time when wakeup function is disabled	t_{BUF}	2.70 V or above	5 (9) × t_{I3Ccyc} + 120	—	ns
	SDA input bus free time when wakeup function is enabled			5(9) × t_{I3Ccyc} + 4 × t_{Tcyc} + 120		ns
	START condition input hold time when wakeup function is disabled	t_{STAH}	2.70 V or above	t_{I3Ccyc} + 120	—	ns
	START condition input hold time when wakeup function is enabled			1(5) × t_{I3Ccyc} + t_{Tcyc} + 120		ns
	Restart condition input setup time	t_{STAS}	2.70 V or above	120	—	ns
	Stop condition input setup time	t_{STOS}	2.70 V or above	120	—	ns
	Data input setup time	t_{SDAS}	2.70 V or above	t_{I3Ccyc} + 30	—	ns
	Data input hold time	t_{SDAH}	2.70 V or above	0	—	ns
	SCL, SDA capacitive load	C_b*1	2.70 V or above	—	550	pF

Note: t_{I3Ccyc}: I3C internal reference clock (I3Cφ) cycle. t_{Tcyc}: TCLK cycle.

Note: Values in parentheses apply when INCTL.DNFS[3:0] is set to 0011b while the digital filter is enabled with INCTL.DNFE set to 1.

Note 1. C_b indicates the total capacity of the bus line.



Test conditions:
V_{IH} = VCC × 0.7, V_{IL} = VCC × 0.3
V_{OL} = 0.6 V, I_{OL} = 6 mA (BFCTL.FMPE = 0)
V_{OL} = 0.4 V, I_{OL} = 15 mA (BFCTL.FMPE = 1)

Note 1. S, P, and Sr indicate the following conditions:
S: Start condition
P: Stop condition
Sr: Restart condition

Figure 60.72 I^2C bus interface input/output timing

Table 60.51 IIC timing(2)

Setting of the I3C_SCL0, I3C_SDA0 pins are not required with the Port Drive Capability bit in the PmnPFS register.

Parameter			Symbol	VCC	Min	Max	Unit
IIC (Hs-mode) BFCTL.HSME = 1	SCL input cycle time		t_{SCL}	3.00 V or above	47 (49) × t_{I3Ccyc}	—	ns
				1.68 to 1.95 V	48 (50) × t_{I3Ccyc}	—	
	SCL input high pulse width	Cb = 400 pF	t_{SCLH}	3.00 V or above	36 (37) × t_{I3Ccyc}	—	ns
				1.68 to 1.95 V	31 (32) × t_{I3Ccyc}	—	
		Cb = 100 pF		3.00 V or above	18 (19) × t_{I3Ccyc}	—	
				1.68 to 1.95 V	19 (20) × t_{I3Ccyc}	—	
	SCL input low pulse width	Cb = 400 pF	t_{SCLL}	3.00 V or above	61 (62) × t_{I3Ccyc}	—	ns
				1.68 to 1.95 V	61 (62) × t_{I3Ccyc}	—	
		Cb = 100 pF		3.00 V or above	29 (30) × t_{I3Ccyc}	—	
				1.68 to 1.95 V	29 (30) × t_{I3Ccyc}	—	
	SCL rise time	Cb = 400 pF	t_{SrCL}	3.00 V or above	—	80	ns

	Data input hold time	Cb = 400 pF	t_{SDAH}	3.00 V or above	0	150	ns
				1.68 to 1.95 V	0	150	
		Cb = 100 pF		3.00 V or above	0	70	
				1.68 to 1.95 V	0	70	
	SCL, SDA capacitive load		C_b*1	3.00 V or above	—	400	pF
				1.68 to 1.95 V	—	400	

Note: t_{I3Ccyc}: I3C internal reference clock (I3Cφ) cycle.
Note: Values in parentheses apply when INCTL.DNFS[3:0] is set to 0011b while the digital filter is enabled with INCTL.DNFE set to 1.
Note 1. C_b indicates the total capacity of the bus line.

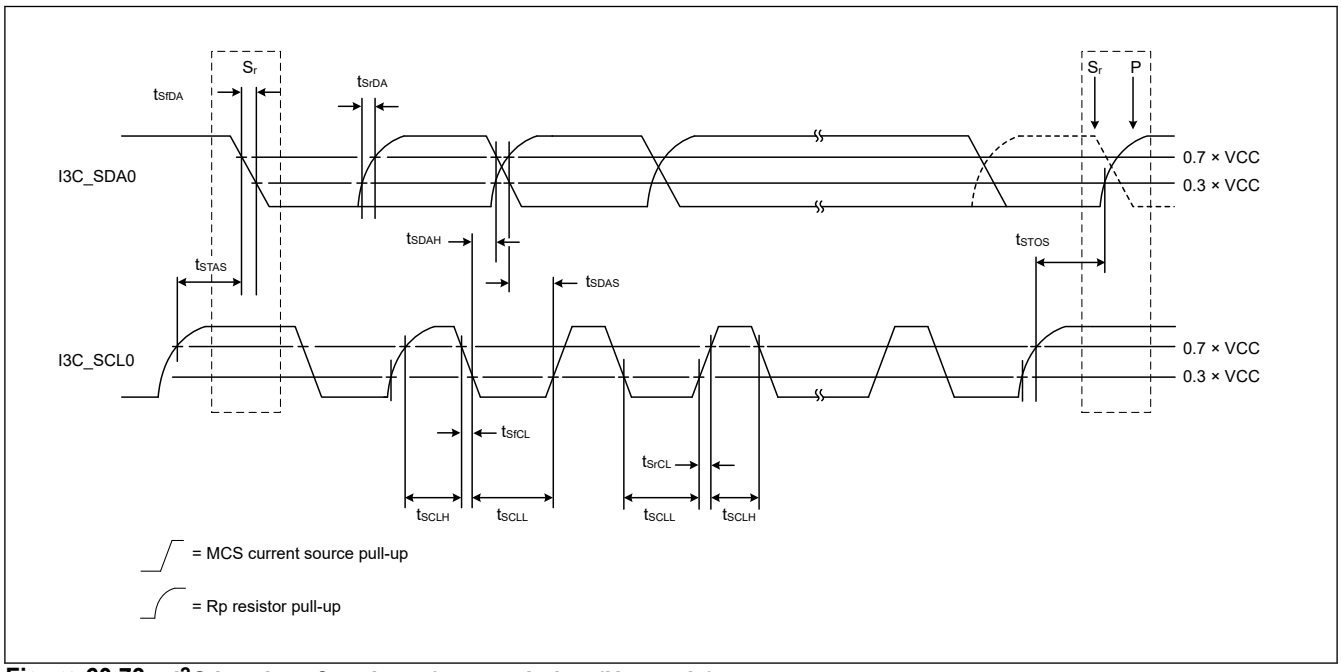

Figure 60.73 I²C bus interface input/output timing (Hs-mode)

Table 60.52 I3C timing (Open Drain Timing Parameters)

Setting of the I3C_SCL0, I3C_SDA0 pins are not required with the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	VCC	Min	Max	Unit	Test conditions
I3C Open Drain Timing Parameters	SCL Clock Low Period	t_{LOW_OD} *1 *2	3.00 V or above	200	—	ns	Figure 60.76
			1.68 to 1.95 V	200	—		
		$t_{DIG\_OD\_L}$	3.00 V or above	t_{LOW_ODmin} + t_{fDA_ODmin}	—	ns	Figure 60.76
			1.68 to 1.95 V	t_{LOW_ODmin} + t_{fDA_ODmin}	—		
	SCL Clock High Period	t_{HIGH} *3 *4	3.00 V or above	—	41	ns	Figure 60.74
			1.68 to 1.95 V	—	41		
		t_{DIG_H}	3.00 V or above	—	t_{HIGH} + t_{CF}	ns	Figure 60.74
			1.68 to 1.95 V	—	t_{HIGH} + t_{CF}		
	SDA Signal Fall Time	t_{fDA_OD}	3.00 V or above	t_{CF}	12	ns	Figure 60.76
			1.68 to 1.95 V	t_{CF}	12		
	SDA Data Setup Time Open Drain Mode	t_{SU_OD} *1	3.00 V or above	12	—	ns	Figure 60.75
			1.68 to 1.95 V	18	—		
	Clock After START (S) Condition	t_{CAS} *5 *6	3.00 V or above	38.4 nano	For ENAS0: 1 µ	seconds	Figure 60.76
					For ENAS1: 100 µ		
					For ENAS2: 2 milli		
					For ENAS3: 50 milli		
			1.68 to 1.95 V	38.4 nano	For ENAS0: 1 µ		
					For ENAS1: 100 µ		
					For ENAS2: 2 milli		
					For ENAS3: 50 milli		
	Clock Before STOP (P) Condition	t_{CBP}	3.00 V or above	t_{CASmin} / 2	—	seconds	Figure 60.77
			1.68 to 1.95 V	t_{CASmin} / 2	—		
	Current Master to Secondary Master Overlap time during handoff	$t_{MMOverlap}$	3.00 V or above	$t_{DIG\_OD\_Lmin}$	—	ns	Figure 60.83
			1.68 to 1.95 V	$t_{DIG\_OD\_Lmin}$	—		
	Bus Available Condition	t_{AVAL} *7	3.00 V or above	1	—	µs	—
			1.68 to 1.95 V	1	—		
	Bus Idle Condition	t_{IDLE}	3.00 V or above	1	—	ms	—
			1.68 to 1.95 V	1	—		
	Time Internal Where New Master Not Driving SDA Low	t_{MMLock}	3.00 V or above	$t_{AVALmin}$	—	µs	Figure 60.83
			1.68 to 1.95 V	$t_{AVALmin}$			

Note 1. This is approximately equal to t_{LOWmin} + t_{DS_ODmin} + t_{rDA_ODtyp} + t_{SU_Odmin}.

Note 2. The Master may use a shorter Low period if it knows that this is safe, i.e., that SDA is already above VIH

Note 3. Based on t_{SPIKE}, rise and fall times, and interconnect

Note 4. This maximum High period may be exceeded when the signals can be safely seen by Legacy I^2C Devices, and/or in consideration of the interconnect (e.g., a short Bus).
As a product specification, if this Max value cannot be guaranteed, change this Max value and specify that it cannot be used in the Mixed Bus.

Note 5. On a Legacy Bus where I^2C Devices need to see Start
Note 6. Slaves that do not support the optional ENTASx CCCs shall use the t_{CAS} Max value shown for ENTAS3
Note 7. On a Mixed Bus with Fm Legacy I^2C Devices, t_{AVAL} is 300 ns shorter than the Fm Bus Free Condition time (t_{BUF})

Table 60.53 I3C timing (Push-Pull Timing Parameters for SDR and HDR-DDR Modes)

Setting of the I3C_SCL0, I3C_SDA0 pins are not required with the Port Drive Capability bit in the PmnPFS register.

Parameter			Symbol	VCC	Min	Max	Unit	Test conditions
I3C Push-Pull Timing Parameters for SDR and HDR-DDR Modes	SCL Clock Frequency		f_{SCL} *1	3.00 V or above	0.01	12.5	MHz	—
				1.68 to 1.95 V	0.01	12.5		
	SCL Clock Low Period		t_{LOW}	3.00 V or above	27	—	ns	Figure 60.74
				1.68 to 1.95 V	32	—		
			t_{DIG_L} *2 *4	3.00 V or above	35	—	ns	Figure 60.74
				1.68 to 1.95 V	40	—		
	SCL Clock High Period for Mixed Bus		t_{HIGH_MIXED}	3.00 V or above	24	—	ns	Figure 60.74
				1.68 to 1.95 V	27	—		
			$t_{DIG\_H\_MIXED}$ *2 *3	3.00 V or above	32	45	ns	Figure 60.74
				1.68 to 1.95 V	35	45		
	SCL Clock High Period		t_{HIGH}	3.00 V or above	24	—	ns	Figure 60.74
				1.68 to 1.95 V	27	—		
			t_{DIG_H} *2	3.00 V or above	32	—	ns	Figure 60.74
				1.68 to 1.95 V	35	—		
	Clock in to Data Out for Slave		t_{SCO}	3.00 V or above	—	12	ns	Figure 60.79
				1.68 to 1.95 V	—	12		
	SCL Clock Rise Time		t_{CR}	3.00 V or above	—	150 × 1 / f_{SCL} (capped at 60)	ns	Figure 60.74
				1.68 to 1.95 V	—	150 × 1 / f_{SCL} (capped at 60)		
	SCL Clock Fall Time		t_{CF}	3.00 V or above	—	150 × 1 / f_{SCL} (capped at 60)	ns	Figure 60.74
				1.68 to 1.95 V	—	150 × 1 / f_{SCL} (capped at 60)		
	SDA Signal Data Hold in Push-Pull Mode	Master	t_{HD_PP} *4*5	3.00 V or above	t_{CR} + 3 and t_{CF} + 3	—	—	Figure 60.78
				1.68 to 1.95 V	t_{CR} + 3 and t_{CF} + 3	—		
		Slave	t_{HD_PP} *5	3.00 V or above	0	—	—	Figure 60.78
				1.68 to 1.95 V	0	—		
	SDA Signal Data Setup in Push-Pull Mode		t_{SU_PP}	3.00 V or above	12	N/A	ns	Figure 60.80
				1.68 to 1.95 V	18	N/A		
	Clock After Repeated START (Sr)		t_{CASr}	3.00 V or above	t_{CASmin}	N/A	ns	Figure 60.82
				1.68 to 1.95 V	t_{CASmin}	N/A		
	Clock Before Repeated START (Sr)		t_{CBSr}	3.00 V or above	t_{CASmin} / 2	N/A	ns	Figure 60.82
				1.68 to 1.95 V	t_{CASmin} / 2	N/A		
	Capacitive Load per Bus Line (SDA/SCL)		C_b	3.00 V or above	—	50	pF	—
				1.68 to 1.95 V	—	50		

Note 1. $f_{SCL} = 1 / (t_{DIG\_L} + t_{DIG\_H})$
Note 2. t_{DIG_L} and t_{DIG_H} are the clock Low and High periods as seen at the receiver end of the I3C Bus using V_{IL} and V_{IH}.
Note 3. When communicating with an I3C Device on a mixed Bus, the $t_{DIG\_H\_MIXED}$ period must be constrained in order to make sure that I^2C Devices do not interpret I3C signaling as valid I^2C signaling.
Note 4. As both edges are used, the hold time needs to be satisfied for the respective edges; i.e., t_{CF} + 3 for falling edge clocks, and t_{CR} + 3 for rising edge clocks.
Note 5. In SDR Mode the Hold time parameter is referred to as t_{HD_SDR}, and in DDR Mode it is referred to as t_{HD_DDR}.

Table 60.54 I3C timing (Push-Pull Timing Parameters for HDR-TSP and HDR-TSL Modes)

Setting of the I3C_SCL0, I3C_SDA0 pins are not required with the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	VCC	Min	Max	Unit	Test conditions
I3C Push-Pull Timing Parameters for HDR-TSP and HDR-TSL Modes	Edge-to-Edge Period	t_{EDGE} *1 *2	3.00 V or above	t_{DIG_H}	—	ns	Figure 60.74
			1.68 to 1.95 V	t_{DIG_H}	—		
	Allowed Difference Between Signals for 'Simultaneous' Change	t_{SKEW}	3.00 V or above	—	10	ns	
			1.68 to 1.95 V	—	10		
	Stable Condition Between Symbols	t_{EYE}	3.00 V or above	12	—	ns	
			1.68 to 1.95 V	12	—		
	Time Between Successive Symbols	t_{SYMBOL}	3.00 V or above	$t_{EDGE\ Min}$	—	ns	
			1.68 to 1.95 V	$t_{EDGE\ Min}$	—		
	Symbol Clock	t_{CLOCK}	3.00 V or above	1 / f_{SCL} (Max)	—	—	
			1.68 to 1.95 V	1 / f_{SCL} (Max)	—		

Note 1. Edges occur at the rate of 1 / (t_{EDGE} × 2)
Note 2. In a Mixed Bus, HDR-TSL shall respect the maximum $t_{DIG\_H\_MIXED}$ shown in Figure 60.77.

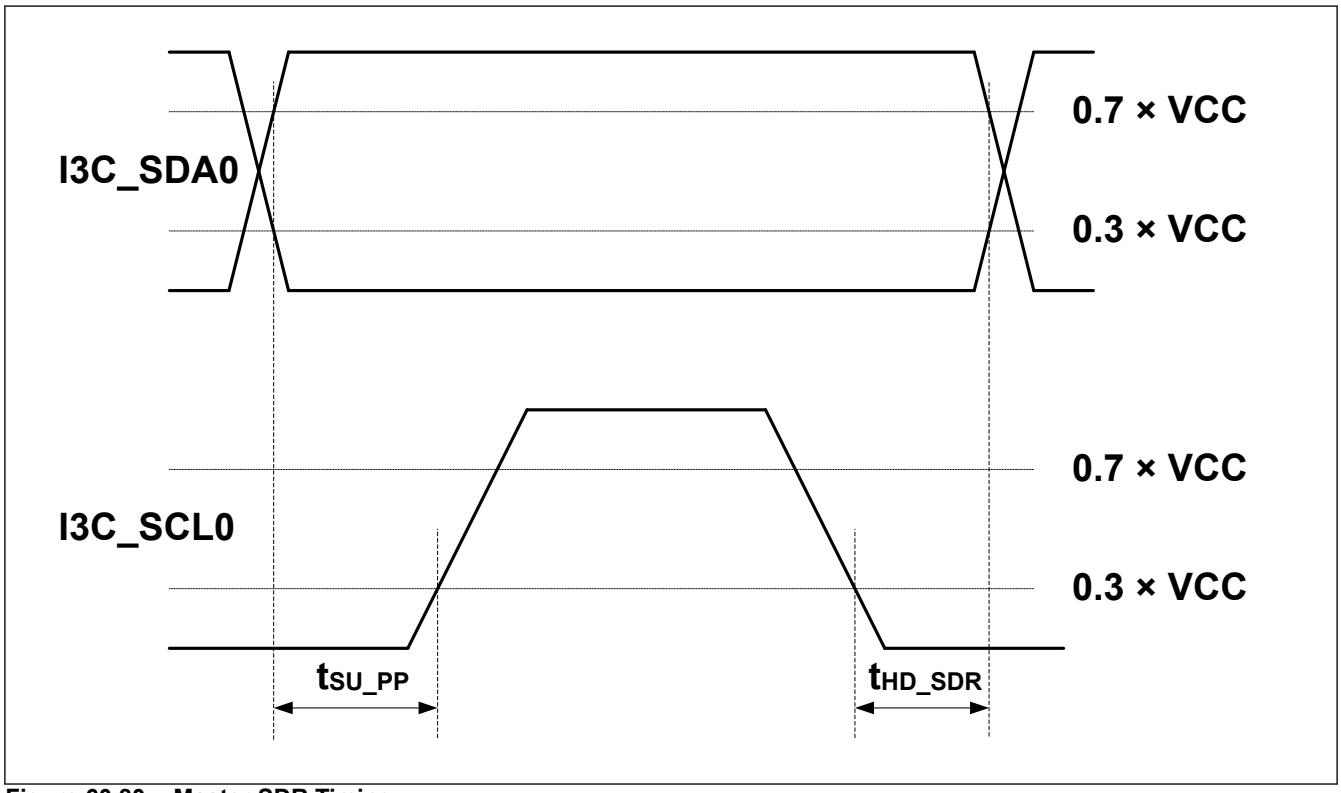

Figure 60.80 Master SDR Timing

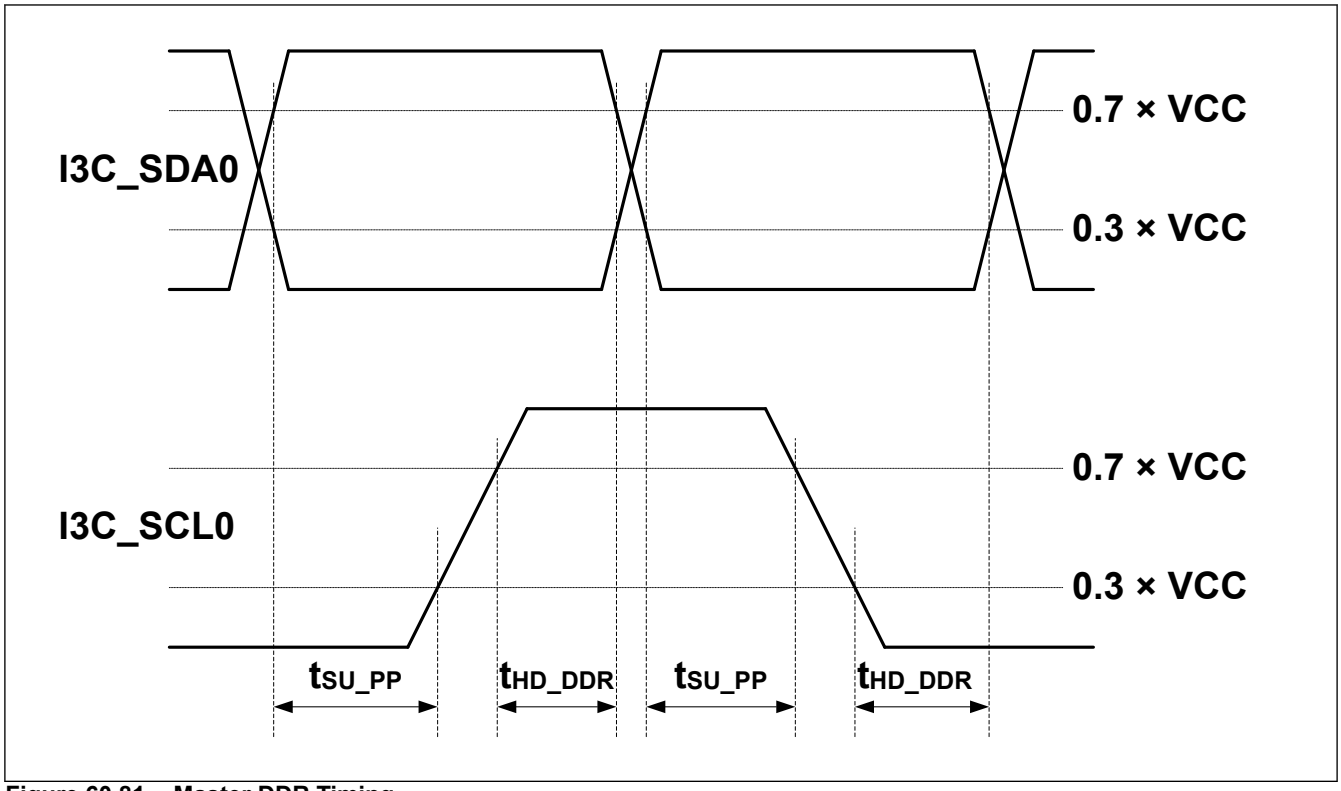

Figure 60.81 Master DDR Timing

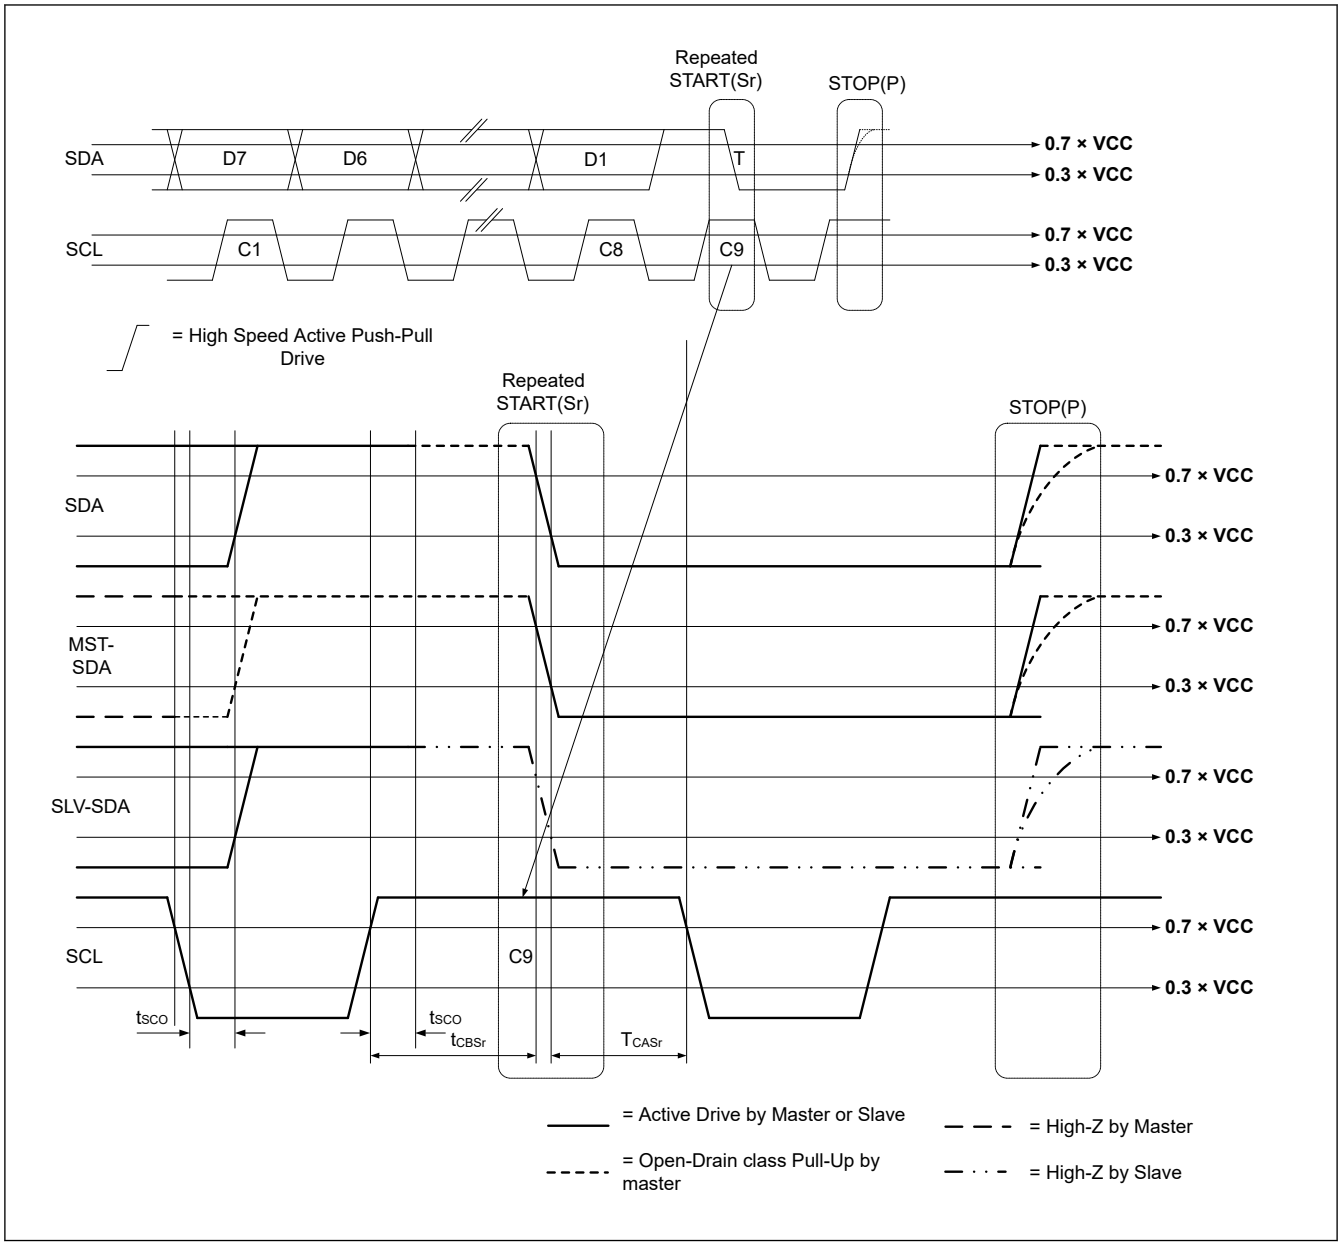

Figure 60.82 T-Bit When Master Ends Read with Repeated START and STOP

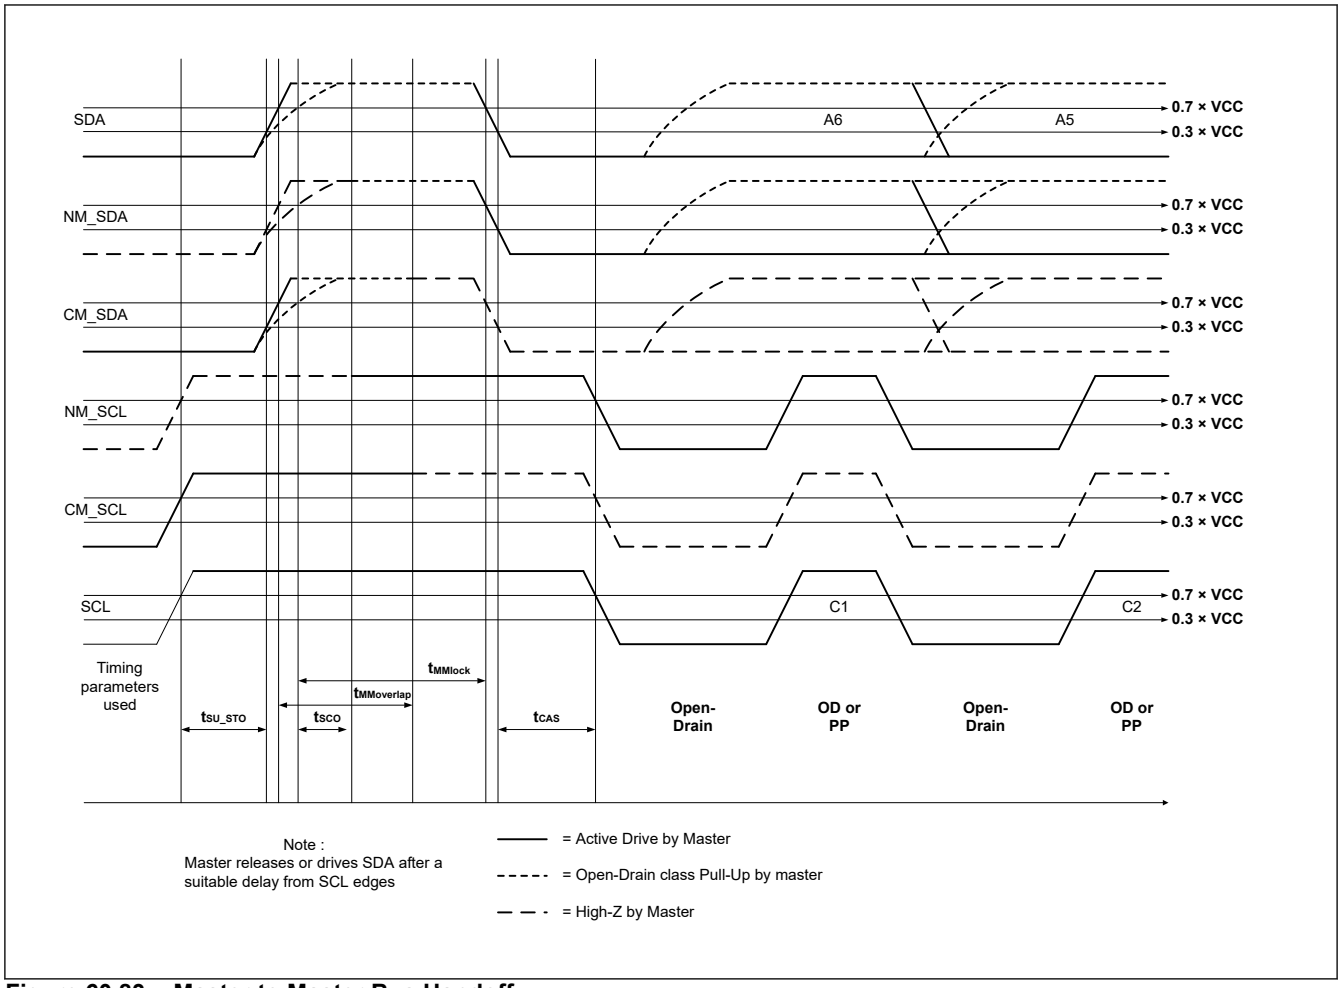

Figure 60.83 Master to Master Bus Handoff

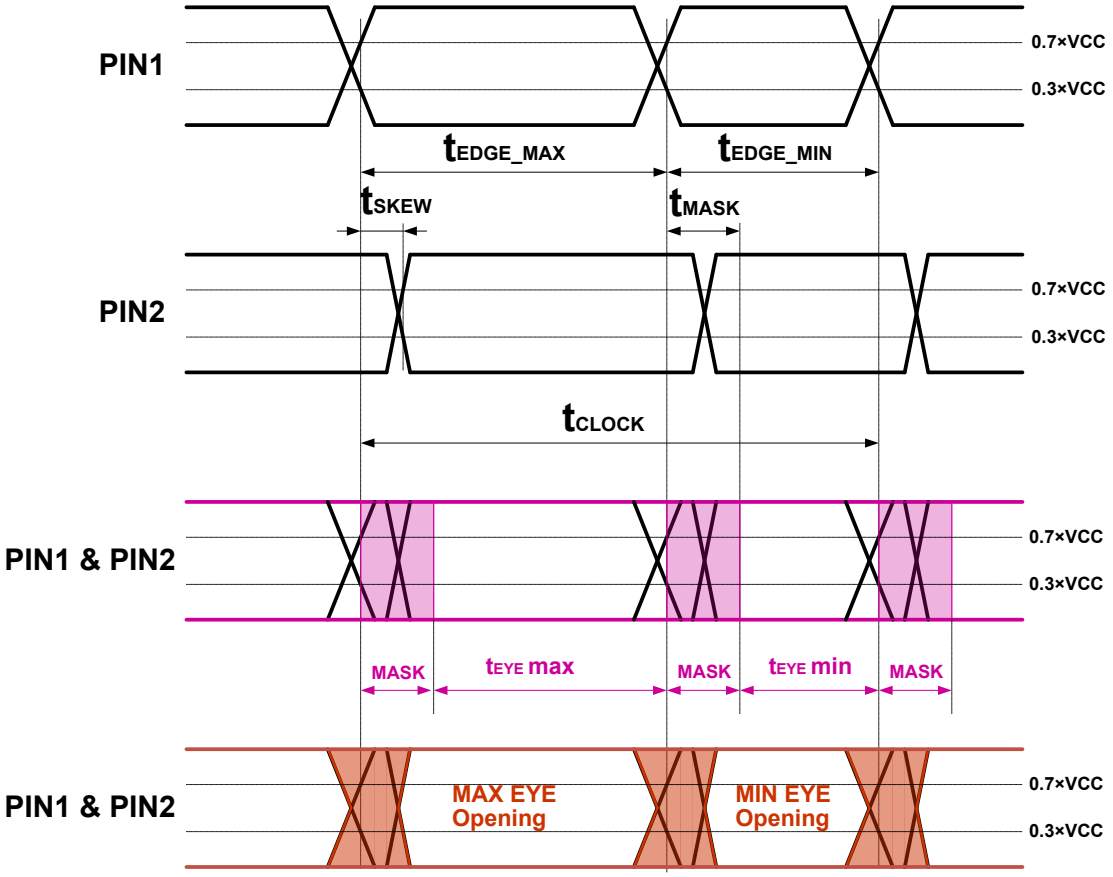

Design Conditions

1. The The differences of load magnitude and drive strength between the SDA and SCL lines result in different slopes, as shown
2. MASK period ≧ MAX t_{SKEW} + MAX rise/fall time between 0.3 × V_{DD} and 0.7 × V_{DD}, respectively, decreased by the time crossing the hysteresis window.

Simplifying Assumptions

1. t_{SKEW} is the same for both edges
2. Base CLOCK (e.g. 12.5MHz) is asymmetrical
3. Falling edges are equal rising edges
4. The MASK is shown as starting, from the last possible moment, whereas in reality it could be shifted left (towards the start point) delayed by the hysteresis window

Figure 60.84 Ternary Protocol Timing

60.3.14 SSIE Timing

Table 60.55 SSIE timing (1 of 2)

(1) High drive output is selected with the Port Drive Capability bit in the PmnPFS register.
(2) Use pins that have a letter appended to their names, for instance "_A" , "_B" or "_C" to indicate group membership. For the SSIE interface, the AC portion of the electrical characteristics is measured for each group.

Parameter			Symbol	VCC	Min.	Max.	Unit	Comments
SSIBCK	Cycle	Master	t_O	2.70V or above	80	—	ns	Figure 60.85
				1.68V or above	80	—		
		Slave	t_I	2.70V or above	80	—	ns	
				1.68V or above	80	—		
	High level/ low level	Master	t_{HC}/t_{LC}	2.70V or above	0.35	—	t_O	
				1.68V or above	0.35	—		
		Slave		2.70V or above	0.35	—	t_I	
				1.68V or above	0.35	—		
	Rising time/ falling time	Master	t_{RC}/t_{FC}	2.70V or above	—	0.15	t_O / t_I	
				1.68V or above	—	0.15		
		Slave		2.70V or above	—	0.15	t_O / t_I	
				1.68V or above	—	0.15		

Table 60.55 SSIE timing (2 of 2)

(1) High drive output is selected with the Port Drive Capability bit in the PmnPFS register.
(2) Use pins that have a letter appended to their names, for instance "_A" , "_B" or "_C" to indicate group membership. For the SSIE interface, the AC portion of the electrical characteristics is measured for each group.

Parameter			Symbol	VCC	Min.	Max.	Unit	Comments
SSILRCK0/ SSIFS0, SSITXD0, SSIRXD0	Input set up time	Master	t_{SR}	2.70V or above	12	—	ns	Figure 60.87, Figure 60.88
				1.68V or above	20	—		
		Slave		2.70V or above	12	—	ns	
				1.68V or above	12	—		
	Input hold time	Master	t_{HR}	2.70V or above	8	—	ns	
				1.68V or above	8	—		
		Slave		2.70V or above	15	—	ns	
				1.68V or above	15	—		
	Output delay time	Master	t_{DTR}	2.70V or above	-10	5	ns	
				1.68V or above	-10	7		
		Slave		2.70V or above	0	20	ns	
				1.68V or above	0	25		
	Output delay time from SSILRCK/ SSIFS change	Slave	t_{DTRW}	2.70V or above	—	20	ns	Figure 60.89
				1.68V or above	—	25		
GTIOC2A, AUDIO_CLK	Cycle		t_{EXcyc}	2.70V or above	20	—	ns	Figure 60.86*1
				1.68V or above	40	—		
	High level/ low level		t_{EXL}/t_{EXH}	2.70V or above	0.4	—	t_{EXcyc}	
				1.68V or above	0.4	—		
	Rising time/ falling time		t_{EXr}/t_{EXr}	2.70V or above	—	0.1*2	t_{EXcyc}	
				1.68V or above	—	0.1*2		

Note 1. For slave-mode transmission, SSIE has a path, through which the signal input from the SSILRCK/SSIFS pin is used to generate transmit data, and the transmit data is logically output to the SSITXD0 or SSIDATA1 pin.
Note 2. 1µs at the longest

60.3.15 SD/MMC Host Interface Timing

Table 60.56 SD/MMC Host Interface signal timing

Conditions: High drive output is selected in the Port Drive Capability bit in the PmnPFS register.
High-speed high drive output is selected in specific condition, please see note 1.
Clock duty ratio is 50%.

Parameter	Symbol	VCC/VCC2	Min	Max	Unit	Test conditions
SDCLK clock cycle	t_{SDCYC}	2.70V or above	20	—	ns	Figure 60.90
		1.70 to1.95V*1	20	—		
		1.70 to1.95V	40	—		
SDCLK clock high pulse width	t_{SDWH}	2.70V or above	6.5	—	ns	
		1.70 to1.95V*1	6.5	—		
		1.70 to1.95V	13.0	—		
SDCLK clock low pulse width	t_{SDWL}	2.70V or above	6.5	—	ns	
		1.70 to1.95V*1	6.5	—		
		1.70 to1.95V	13.0	—		
SDCLK clock rise time	t_{SDLH}	2.70V or above	—	3.0	ns	
		1.70 to1.95V*1	—	4.0		
		1.70 to1.95V	—	8.0		
SDCLK clock fall time	t_{SDHL}	2.70V or above	—	3.0	ns	
		1.70 to1.95V*1	—	4.0		
		1.70 to1.95V	—	8.0		
SDCMD/SDDAT output data delay	t_{SDODLY}	2.70V or above	–7.0	4.0	ns	
		1.70 to1.95V*1	–7.0	7.0		
		1.70 to1.95V	–15.0	15.0		
SDCMD/SDDAT input data setup	t_{SDIS}	2.70V or above	4.5	—	ns	
		1.70 to1.95V*1	4.5	—		
		1.70 to1.95V	20.0	—		
SDCMD/SDDAT input data hold	t_{SDIH}	2.70V or above	1.5	—	ns	
		1.70 to1.95V	1.5	—		

Note: Must use pins that have a letter appended to their name, for instance “_A”, “_B”, to indicate group membership. For the SD/MMC Host interface, the AC portion of the electrical characteristics is measured for each group.
Note: If SD1DAT4_A~SD1DAT7_A are used, characteristics above is guaranteed only when VCC = VCC2.
Note 1. Only supported for Ch0 group B ("SD0*_B") and Ch1 group A ("SD1*_A")
High-speed high drive output is selected in the port drive capability bit in the PmnPFS register for the following pins:
SD0CLK_B, SD1CLK_A

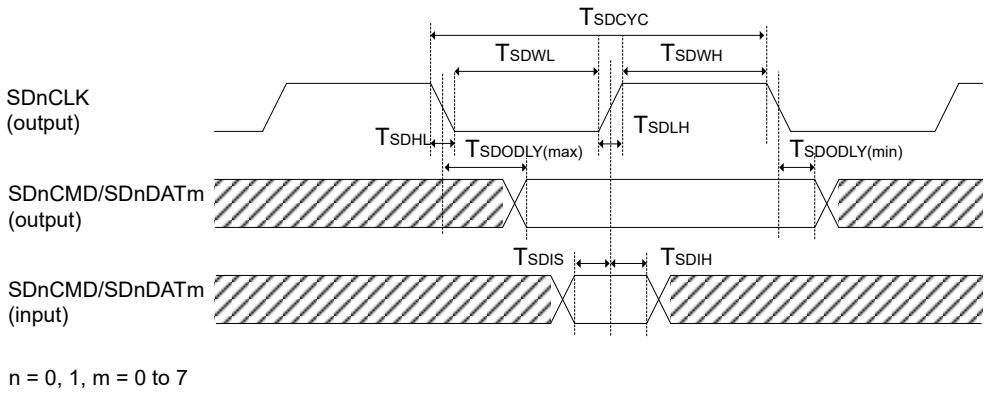

Figure 60.90 SD/MMC Host Interface signal timing

60.3.16 ETHERC Timing

Table 60.57 ETHERC timing

Conditions: ETHERC (RMII): Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register for the following pins: ET0_MDC, ET0_MDIO.
For other pins, high drive output is selected in the Port Drive Capability bit in the PmnPFS register.
ETHERC (MII): Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	VCC	Min	Max	Unit	Test conditions
ETHERC (RMII)	REF50CK0 cycle time	T_{ck}	2.70V or above	20	—	ns	Figure 60.91 to Figure 60.94

60.3.18 GLCDC Timing

Table 60.59 GLCDC Timing

Conditions:
LCD_CLK: High drive output is selected in the port drive capability bit in the PmnPFS register.
LCD_DATA: Middle drive output is selected in the port drive capability bit in the PmnPFS register.

Parameter		Symbol	VCC	Min	Max	Units	Test conditions
LCD_EXTCLK input clock frequency		t_{Ecyc}	2.70 V or above	—	60*1	MHz	Figure 60.103
			1.68 V or above	—	30		
LCD_EXTCLK input clock low pulse width		t_{WL}	2.70 V or above	0.45	—	t_{Ecyc}	
			1.68 V or above	0.45	—		
LCD_EXTCLK input clock high pulse width		t_{WH}	2.70 V or above	0.45	—		
			1.68 V or above	0.45	—		
LCD_CLK output clock frequency		$1/t_{Lcyc}$	2.70 V or above	—	60*1	MHz	Figure 60.104
			1.68 V or above	—	30		
LCD_CLK output clock low pulse width		t_{LOL}	2.70 V or above	0.4	0.6	t_{Lcyc}	
			1.68 V or above	0.4	0.6		
LCD_CLK output clock high pulse width		t_{LOH}	2.70 V or above	0.4	0.6	t_{Lcyc}	
			1.68 V or above	0.4	0.6		
LCD data output delay timing	_A or _B combinations*2	t_{DD}	2.70 V or above	-3.5	4.0	ns	Figure 60.105
			1.68 V or above	-5.5	6.0		
	_A and _B combinations*3		2.70 V or above	-5.0	5.5		
			1.68 V or above	-7.0	7.5		

Note 1. Parallel RGB888, 666, 565: Maximum 54 MHz
Serial RGB888: Maximum 60 MHz (4x speed)
Note 2. Use pins that have a letter appended to their names, for instance, "_A" or "_B", to indicate.
Note 3. Pins of group "_A" and "_B" combinations are used.

			—	±2.0	±7.5		BGA package AVCC0 = 2.7 to 3.6V VREFH0 = 2.7V to AVCC0
	DNL differential nonlinearity error		—	±0.5	±4.5	LSB	—
	INL integral nonlinearity error		—	±1.0	±5.5	LSB	—

Note: These specification values apply when only one A/D is operating and D/A and ACMPHS are not operating and there is no access to the external bus during A/D conversion.
If other A/D, D/A, or ACMPHS is operating or bus access occurs during A/D conversion, values might not fall within the indicated ranges.
The use of ports 0 as digital outputs is not allowed when the 12-Bit A/D converter is used.
The characteristics apply when AVCC0, AVSS0, VREFH0, VREFH, VREFL0, VREFL, and 12-bit A/D converter input voltage is stable.

Note 1. The conversion time includes the sampling and comparison times. The number of sampling states is indicated for the test conditions.

Note 2. Values in parentheses indicate the sampling time.

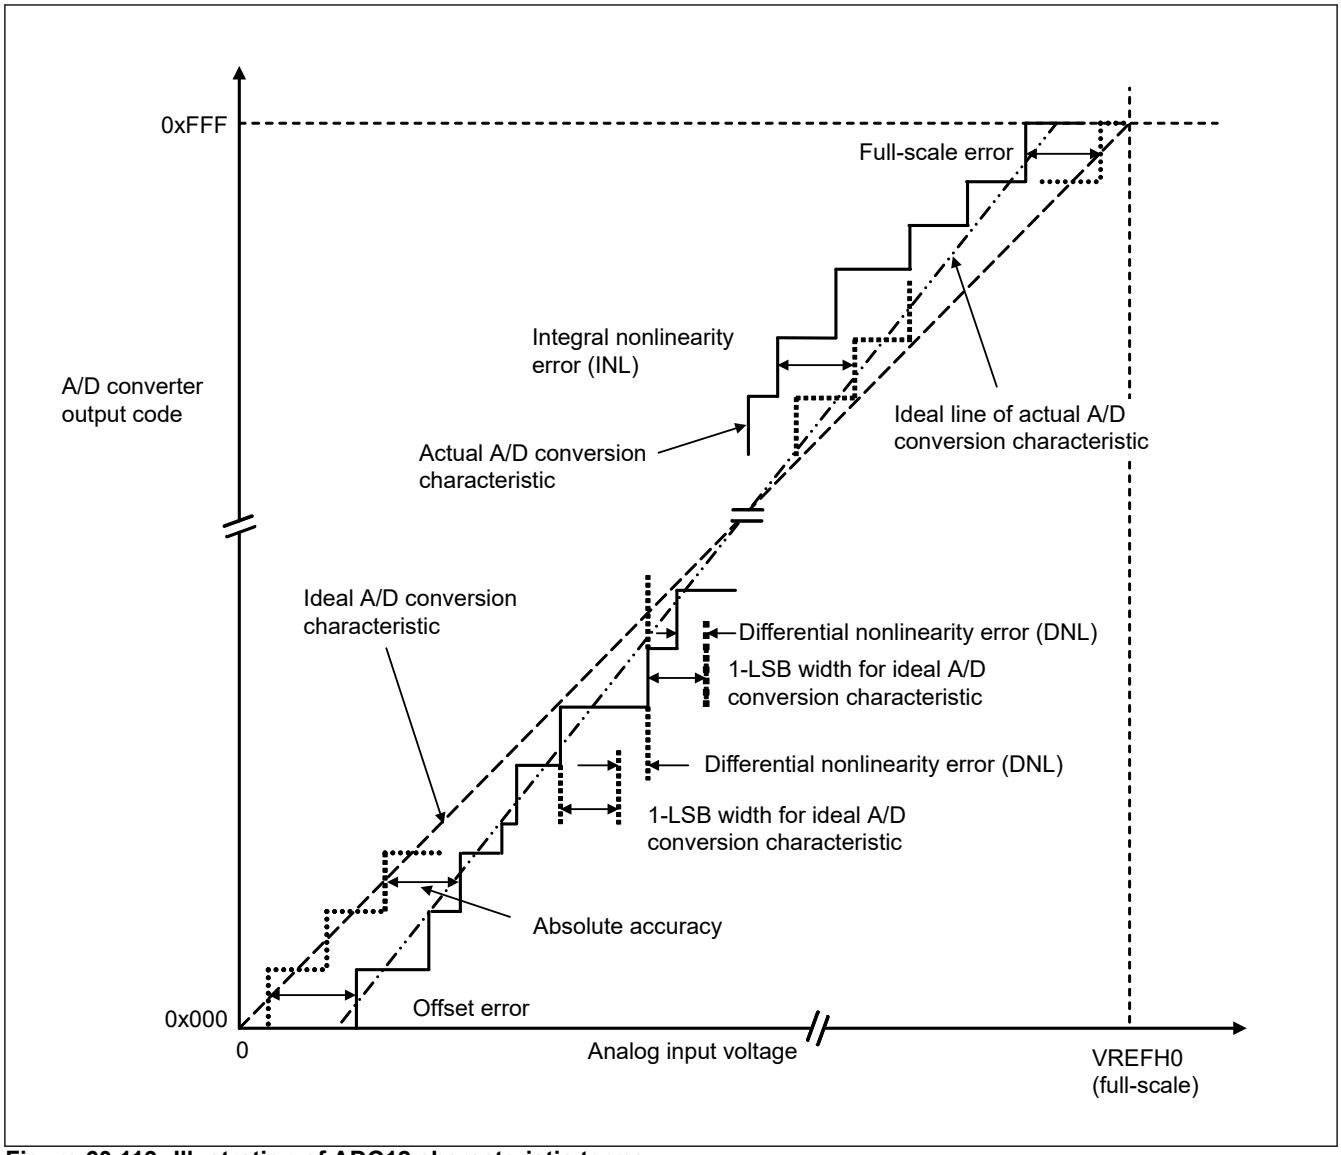

Figure 60.119 Illustration of ADC12 characteristic terms

Absolute accuracy

Absolute accuracy is the difference between output code based on the theoretical A/D conversion characteristics, and the actual A/D conversion result. When measuring absolute accuracy, the voltage at the midpoint of the width of the analog input voltage (1-LSB width), which can meet the expectation of outputting an equal code based on the theoretical A/D conversion characteristics, is used as an analog input voltage. For example, if 12-bit resolution is used and the reference voltage VREFH0 = 3.072 V, then the 1-LSB width becomes 0.75 mV, and 0 mV, 0.75 mV, and 1.5 mV are used as the analog input voltages. If the analog input voltage is 6 mV, an absolute accuracy of ±5 LSB means that the actual A/D conversion result is in the range of 0x003 to 0x00D, though an output code of 0x008 can be expected from the theoretical A/D conversion characteristics.

Integral nonlinearity error (INL)

Integral nonlinearity error is the maximum deviation between the ideal line when the measured offset and full-scale errors are zeroed, and the actual output code.

Differential nonlinearity error (DNL)

Differential nonlinearity error is the difference between the 1-LSB width based on the ideal A/D conversion characteristics and the width of the actual output code.

Offset error

Offset error is the difference between the transition point of the ideal first output code and the actual first output code.

Full-scale error

Full-scale error is the difference between the transition point of the ideal last output code and the actual last output code.

60.7 DAC12 Characteristics

VCC-off period for starting power supply switching*1 (Other than above)		200	—	—		
Backup domain power-down detection level	$V_{PDR\ (BATR)}$	1.45	1.50	1.60	V	Figure 60.125
Time delay in assertion of the reset signal for the backup domain*3	$t_{p\ (PDRL)}$	—	—	2000	µs	
Time delay in negation of the reset signal for the backup domain	$t_{p\ (PDRH)}$	—	—	3000		
VBATT monitor operation stabilization time (after VBATTMNSELR.VBTMNSEL is changed to 1)	t_{MONWT}	—	—	4.2	µs	—
VBATT voltage monitor level	$V_{MONBATT}$	—	VBATT / 3	—	V	—
VBATT current increase (when VBATTMNSELR.VBTMNSEL is 1 compared to the case that VBATTMNSELR.VBTMNSEL is 0)	$I_{VBATTSELB}$	—	1.50	2.35	µA	—
VCC current increase (when VBATTMNSELR.VBTMNSEL is 1 compared to the case that VBATTMNSELR.VBTMNSEL is 0)	$I_{VBATTSELC}$	—	330	577	µA	—

Note 1. The VCC-off period for starting power supply switching indicates the period in which VCC is below the minimum value of the voltage level for switching to battery backup ($V_{DETBATT}$).
In addition, this period indicates the time tVOFFP when VCC is below the minimum value of voltage detection levels V_{POR1}.
Note 2. Stable time when VBTBPCR2.VDETLVL is changed or VBTBPCR2.VDETLVL is changed from 0 to 1.
Note 3. When the VBATT_R recovers within this period, the backup domain reset signal may not be generated.

	8-KB	t_{P8K}	—	60	212	—	27	96	ms	
	32-KB	t_{P32K}	—	234	848	—	106	384	ms	
Erasure time N_{PEC} ≤ 100 times	8-KB	t_{E8K}	—	78	216	—	43	120	ms	
	32-KB	t_{E32K}	—	283	864	—	157	480	ms	
Erasure time N_{PEC} > 100 times	8-KB	t_{E8K}	—	94	260	—	52	144	ms	
	32-KB	t_{E32K}	—	341	1040	—	189	576	ms	
Reprogramming/erasure cycle*4		N_{PEC}	10000*1	—	—	10000*1	—	—	Times	
Suspend delay during programming		t_{SPD}	—	—	264	—	—	120	µs	
Programming resume time		t_{PRT}	—	—	110	—	—	50	µs	
First suspend delay during erasure in suspend priority mode		t_{SESD1}	—	—	216	—	—	120	µs	
Second suspend delay during erasure in suspend priority mode		t_{SESD2}	—	—	1.7	—	—	1.7	ms	
Suspend delay during erasure in erasure priority mode		t_{SEED}	—	—	1.7	—	—	1.7	ms	
First erasing resume time during erasure in suspend priority mode*5		t_{REST1}	—	—	1.7	—	—	1.7	ms	
Second erasing resume time during erasure in suspend priority mode		t_{REST2}	—	—	144	—	—	80	µs	
Erasing resume time during erasure in erasure priority mode		t_{REET}	—	—	144	—	—	80	µs	
Forced stop command		t_{FD}	—	—	32	—	—	20	µs	
Data hold time*2		t_{DRP}	10*2 *3	—	—	10*2 *3	—	—	Years	Tj = +125°C
			20*2 *3	—	—	20*2 *3	—	—		Tj = +105°C
			30*2 *3	—	—	30*2 *3	—	—		Tj = +85°C

Note 1. This is the minimum number of times to guarantee all the characteristics after reprogramming. The guaranteed range is from 1 to the minimum value.
Note 2. This indicates the minimum value of the characteristic when reprogramming is performed within the specified range.
Note 3. This result is obtained from reliability testing.
Note 4. The reprogram/erase cycle is the number of erasures for each block. When the reprogram/erase cycle is n times (n = 10,000), erasing can be performed n times for each block. For example, when 128-byte programming is performed 64 times for different addresses in 8-KB blocks, and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address several times as one erasure is not enabled. Overwriting is prohibited.
Note 5. Time for resumption includes time for reapplying the erasing pulse (up to one full pulse) that was cut off at the time of suspension.
Note 6. The reference value at VCC = 3.3V and room temperature.

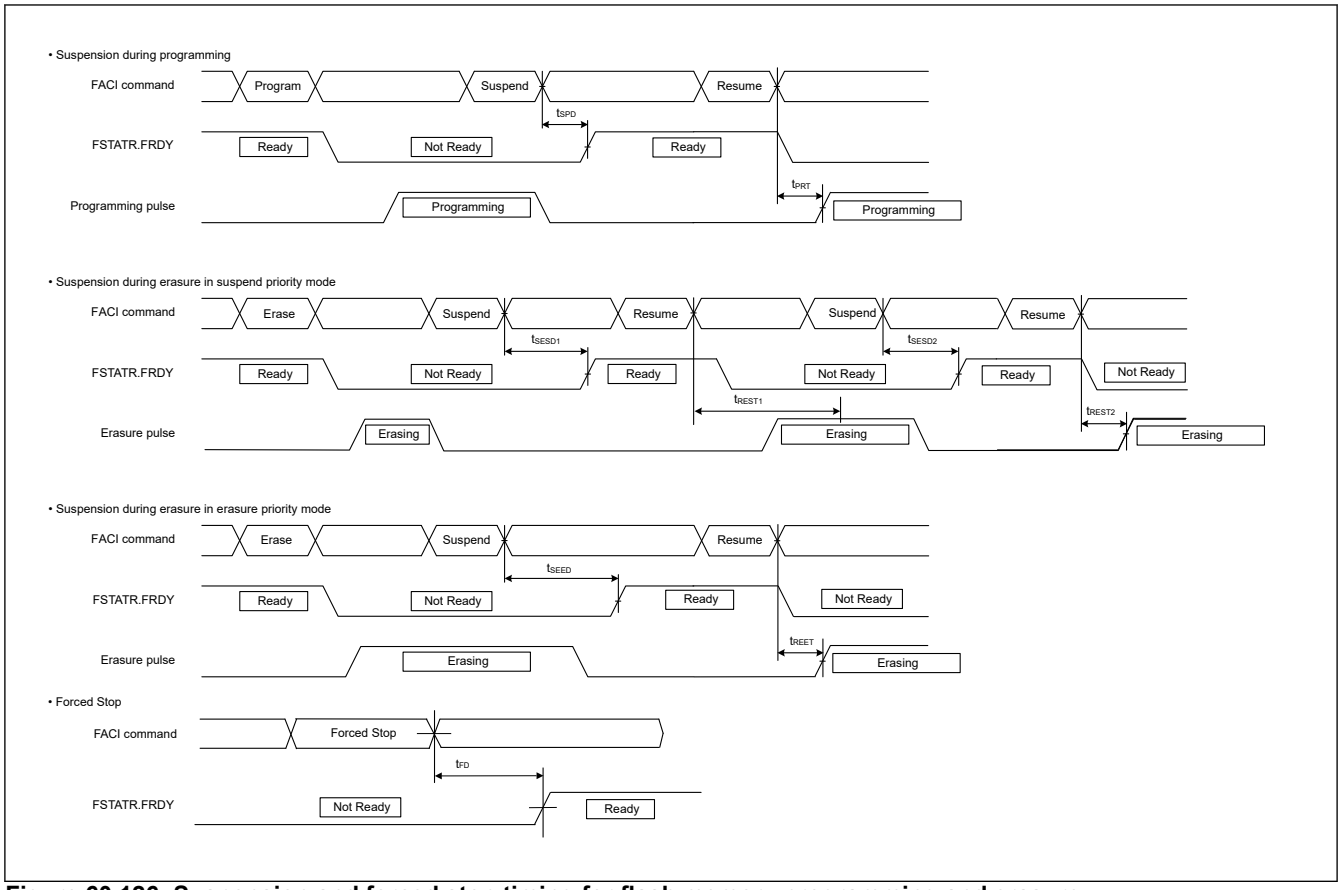

Figure 60.126 Suspension and forced stop timing for flash memory programming and erasure

60.13.2 Data Flash Memory Characteristics

Others	—	Hi-Z	Keep-O		Keep		Hi-Z	Keep

Note: Hi-Z: High-impedance
Keep-O: Output pins retain their previous values. Input pins go to high-impedance.
Keep-I: Pin states are retained same as during periods in Normal mode.
Keep: Pin states are retained same as during periods in Software Standby mode.
Note 1. Retains the I/O port state until the DPSBYCR.IOKEEP bit is cleared to 0.
Note 2. Input is enabled if the pin is specified as the Software Standby canceling source while it is used as an external interrupt pin.
Note 3. Input is enabled if the pin is specified as the Deep Software Standby canceling source.
Note 4. Input is enabled while the pin is used as an input pin.
Note 5. For host operation, set the USBHS.SYSCFG.DRPD bit to 1 to enable the USBHS_DP and USBHS_DM pull-down resistors.
For device operation, set the USBHS.SYSCFG.DPRPU bit to 1 to enable the DP pull-up resistor.

Appendix 2. Package Dimensions

Information on the latest version of the package dimensions or mountings is displayed in “Packages” on the Renesas Electronics Corporation website.

Appendix 3. I/O Registers

This appendix describes I/O register address and access cycles by function.

3.1 Peripheral Base Addresses

This section provides the base addresses for peripherals described in this manual. Table 3.1 shows the name, description, and the base address of each peripheral.

Table 3.1 Peripheral base address (1 of 3)

Description	Name of Secure registers	Base address of Secure registers in Secure alias region	Name of Non-secure registers	Base address of Non-secure registers in Non-secure alias region
Renesas Memory Protection Unit	RMPU	0x4000_0000	RMPU_NS	0x5000_0000
SRAM Control	SRAM	0x4000_2000	SRAM_NS	0x5000_2000
BUS Control	BUS	0x4000_3000	BUS_NS	0x5000_3000
Common Interrupt Controller	ICU_COMMON	0x4000_6000	ICU_COMMON_NS	0x5000_6000
CPU System Security Control Unit	CPSCU	0x4000_8000	CPSCU_NS	0x5000_8000
Direct memory access controller 00	DMAC00	0x4000_A000	DMAC00_NS	0x5000_A000
Direct memory access controller 01	DMAC01	0x4000_A040	DMAC01_NS	0x5000_A040
Direct memory access controller 02	DMAC02	0x4000_A080	DMAC02_NS	0x5000_A080
Direct memory access controller 03	DMAC03	0x4000_A0C0	DMAC03_NS	0x5000_A0C0
Direct memory access controller 04	DMAC04	0x4000_A100	DMAC04_NS	0x5000_A100
Direct memory access controller 05	DMAC05	0x4000_A140	DMAC05_NS	0x5000_A140

Description = Peripheral functionality
Base address = Lowest reserved address or address used by the peripheral

3.2 Access Cycles

This section provides access cycle information for the I/O registers described in this manual.

- Registers are grouped by associated module.
- The number of access cycles indicates the number of cycles based on the specified reference clock.
- In the internal I/O area, reserved addresses that are not allocated to registers must not be accessed, otherwise operations cannot be guaranteed.
- The number of I/O access cycles depends on bus cycles of the internal peripheral bus, divided clock synchronization cycles, and wait cycles of each module. Divided clock synchronization cycles differ depending on the frequency ratio between ICLK and PCLK.
- When the frequency of ICLK is equal to that of PCLK, the number of divided clock synchronization cycles is always constant.
- When the frequency of ICLK is greater than that of PCLK, at least 1 PCLK cycle is added to the number of divided clock synchronization cycles.
- The number of write access cycles indicates the number of cycles obtained by non-bufferable write access.

Note: This applies to the number of cycles when access from the CPU does not conflict with the instruction fetching to the external memory or bus access from other bus masters such as DTC or DMAC.

Table 3.2 Access cycles (1 of 3)

Peripheral base address symbol	Address*1		Number of access cycles				Cycle Unit	Related function
			ICLK = PCLK		ICLK > PCLK*2

RSIP-E51A	—	—	1 to 3	2	1 to 3	1 to 2	PCLKA	Renesas Security IP

Table 3.2 Access cycles (3 of 3)

Peripheral base address symbol	Address[*1]		Number of access cycles				Cycle Unit	Related function
			ICLK = FCLK		ICLK > FCLK[*2]			
	From	To	Read	Write	Read	Write		
FLAD, FACI	0x4011_C040	0x4011_EFFF	4	3	4	3	FCLK	Data Flash, Flash Application Command Interface

Note 1. This table only shows secure address. Access cycle of the non-secure address is the same as its secure address.
Note 2. If the number of PCLK or FCLK cycles is non-integer (for example 1.5), the minimum value is without the decimal point, and the maximum value is rounded up to the decimal point. For example, 1.5 to 2. 5 is 1 to 3.
Note 3. BWAIT is the number of waits (not cycles) described in the USBHS.BUSWAIT register.

Appendix 4. Note for Register R/W

- A secure bus master issues a "secure access" using an address marked as secure by IDAU/SAU or MSAU.
- A secure bus master issues a "non-secure access" using an address marked as non-secure by IDAU/SAU or MSAU.
- A non-secure bus master issues a "non-secure access" using an address marked as non-secure by IDAU/SAU or MSAU.

Table 4.1 Type of Register Notes(S-TYPE)

TYPE	UM Description
S-TYPE-1	Only Secure access can write to this register. Read access is always allowed. Non-secure write access is ignored, but TrustZone access error is not generated.
S-TYPE-2	Read access is always allowed If the security attribution is configured as Secure, ● Secure write access is allowed. ● Non-secure write access is ignored, but TrustZone access error is not generated.
	If the security attribution is configured as Non-secure, ● Secure write access is ignored, but TrustZone access error is not generated. ● Non-secure access is allowed.
S-TYPE-3	If the security attribution is configured as Secure, ● Secure access is allowed. ● Non-secure write access is ignored and Non-secure read access is read as 0, TrustZone access error is generated
	If the security attribution is configured as Non-secure, ● Secure write access is ignored and Secure read access is read as 0, TrustZone access error is generated. ● Non-secure access is allowed
S-TYPE-4	If the security attribution is configured as Secure, ● Secure access is allowed ● Non-secure write access is ignored and Non-secure read access is read as 0, but TrustZone access error is not generated.
	If the security attribution is configured as Non-secure, ● Secure write access is ignored and Secure read access is read as 0, but TrustZone access error is not generated. ● Non-secure access is allowed.
S-TYPE-5	No note required.
S-TYPE-6	Secure access is allowed. Non-secure write access is ignored, and Non-secure read access is read as 0, TrustZone access error is generated.
S-TYPE-7	Secure write access is ignored, and Secure read access is read as 0, TrustZone access error is generated. Non-secure access is allowed.

Note: A non-secure bus master does NOT issue any access using an address marked as secure by IDAU/SAU or MSAU.

Table 4.2 Type of Register Notes(P-TYPE)

TYPE	UM Description
P-TYPE-1	Privileged write access is allowed. Read access is always allowed. Unprivileged write access is ignored, but TrustZone access error is not generated.
P-TYPE-2	Privileged access is allowed. Unprivileged write access is ignored, and Unprivileged read access is read as 0, TrustZone access error is generated.
P-TYPE-3	If the privilege attribution is configured as Privileged, ● Privileged access is allowed. ● Unprivileged write access is ignored and Unprivileged read access is read as 0, TrustZone access error is generated.
	If the privilege attribution is configured as Unprivilege, ● Privileged access and Unprivileged access are allowed.
P-TYPE-4	If the privilege attribution is configured as Privileged, ● Privileged access is allowed. ● Unprivileged write access is ignored and Unprivileged read access is read as 0, TrustZone access error is not generated.
	If the privilege attribution is configured as Unprivilege, ● Privileged access and Unprivileged access are allowed.
P-TYPE-5	No note required.
