b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The GTSECSR register selects an intended channel for updating an operation enable bit by the GTSECR register.
A bit position for the GTSECSR register indicates a channel number. The GTSECSR register of each channel is a common register, and writing 1 to a bit in the GTSECSR register in any channel and updating it changes a channel, related to the position of the bit written with 1 by the GTSECSR register, to be simultaneously controlled of the operation enable bit by the GTSECR register.
Access in 8-bit or 16-bit units to the GTSECSR register is prohibited, and it should be accessed in 32-bit units.

SECSELn Bit (Operation Enable Bit Simultaneous Control Channel Select) (n = 0 to 7)

This bit enables or disables the simultaneous control of operation enable in channel n.
When the bit is set to 1, the simultaneous control is enabled, and disabled when the bit is 0.

24.2.42 General PWM Timer Operation Enable Bit Simultaneous Control Register (GTSECR)

b31 to b26	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. When in complementary PWM mode, no matter which register of master channel/slave channel 1/slave channel 2 is written, three channels are written at the same time.

The GTSECR register simultaneously updates the value for operation enable bits of a channel set by the GTSECSR register.

Writing 1 to a bit in the GTSECR register in any channel and updating it updates an operation enable bit for all channels, related to the position of the bit written with 1 by the all GTSECR registers. Setting enable and disable bits for the same operation enable bit to 1 in the GTSECR is prohibited.

A bit written to 1 is automatically cleared. When the GTSECR is read, 0 is read.

Access in 8-bit or 16-bit units to the GTSECR register is prohibited, and it should be accessed in 32-bit units.

SBDCE Bit (GTCCR Register Buffer Operation Simultaneous Enable)

When 1 is written to this bit, 0 is simultaneously set to a GTBER.BD[0] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTCCRA, GTCCRC, and GTCCRD registers and using the GTCCRB, GTCCRE, and GTCCRF registers are enabled.
Simultaneous setting of SBDCE and SBDCD bits to 1 is prohibited.

SBDPE Bit (GTPR Register Buffer Operation Simultaneous Enable)

When 1 is written to this bit, 0 is simultaneously set to a GTBER.BD[1] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTPR, GTPBR, and GTPDBR registers are enabled.
Simultaneous setting of SBDPE and SBDPD bits to 1 is prohibited.

SBDAE Bit (GTADTR Register Buffer Operation Simultaneous Enable)

When 1 is written to this bit, 0 is simultaneously set to a GTBER.BD[2] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTADTRA, GTADTBRA, and GTADTDBRA registers and using the GTADTRB, GTADTBRB, and GTADTDBRB registers are enabled.
Simultaneous setting of SBDAE and SBDAD bits to 1 is prohibited.

SBDDE Bit (GTDV Register Buffer Operation Simultaneous Enable)

When 1 is written to this bit, 0 is simultaneously set to a GTBER.BD[3] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTDVU and GTDBU registers and using the GTDVD and GTDBD registers are enabled.
Simultaneous setting of SBDDE and SBDDD bits to 1 is prohibited.

SBDCD Bit (GTCCR Register Buffer Operation Simultaneous Disable)

When 1 is written to this bit, 1 is simultaneously set to a GTBER.BD[0] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTCCRA, GTCCRC, and GTCCRD registers and using the GTCCRB, GTCCRE, and GTCCRF registers are disabled.
Simultaneous setting of SBDCE and SBDCD bits to 1 is prohibited.

SBDPD Bit (GTPR Register Buffer Operation Simultaneous Disable)

When 1 is written to this bit, 1 is simultaneously set to a GTBER.BD[1] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTPR, GTPBR, and GTPDBR registers are disabled.
Simultaneous setting of SBDPE and SBDPD bits to 1 is prohibited.

SBDAD Bit (GTADTR Register Buffer Operation Simultaneous Disable)

When 1 is written to this bit, 1 is simultaneously set to a GTBER.BD[2] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTADTRA, GTADTBRA, and GTADTDBRA registers and using the GTADTRB, GTADTBRB, and GTADTDBRB registers are disabled.
Simultaneous setting of SBDAE and SBDAD bits to 1 is prohibited.

SBDDD Bit (GTDV Register Buffer Operation Simultaneous Disable)

When 1 is written to this bit, 1 is simultaneously set to a GTBER.BD[3] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTDVU and GTDBU registers and using the GTDVD and GTDBD registers are disabled.
Simultaneous setting of SBDDE and SBDDD bits to 1 is prohibited.

SPCE Bit (Cycle Count Function Simultaneous Enable)

Writing 1 to this bit simultaneously sets any GTPC.PCEN bits to 1 for channels with simultaneous control enabled by the setting 1 in the GTSECSR register and enables the cycle-counting function.
Simultaneous setting of SPCE and SPCD bits to 1 is prohibited.

SSCE Bit (Synchronous Set/Clear Simultaneous Enable)

Writing 1 to this bit simultaneously sets any GTCR.SSCEN bits to 1 for channels with simultaneous control enabled by the setting 1 in the GTSECSR register and enables the synchronous set/clear function.
Simultaneous setting of SSCE and SSCD bits to 1 is prohibited.

SPCD Bit (Cycle Count Function Simultaneous Disable)

Writing 1 to this bit simultaneously sets any GTPC.PCEN bits to 0 for channels with simultaneous control enabled by the setting 1 in the GTSECSR register and disables the cycle-counting function.
Simultaneous setting of SPCE and SPCD bits to 1 is prohibited.

SSCD Bit (Synchronous Set/Clear Simultaneous Disable)

Writing 1 to this bit simultaneously sets any GTCR.SSCEN bits to 0 for channels with simultaneous control enabled by the setting 1 in the GTSECSR register and disables the synchronous set/clear function.
Simultaneous setting of SSCE and SSCD bits to 1 is prohibited.

Note 1. Not available in GPTW3, GPTW7.

The GTBER2 register makes settings for buffer operation.
Set the CP3DB bit and OLTTm[1:0] (m = A, B) bits when the GTCNT counter is stopped.

CCTCm Bit (Counter Clear Source GTCCRm Register Buffer Transfer Disable) (m = A, B)

This bit disables buffer transfer by counter clear using the GTCCRm, GTCCRn, and GTCCRx registers together (m = A, B; n = C, E; x = D, F).
This bit is effective when the GTBER.BD[0] bit is 0 (buffer operation enabled) and the buffer operation is selected by the GTBER.CCRm[1:0] bits with sawtooth-waves.
The setting is invalid in triangle waves or complementary PWM mode. Even if the CCTCm bit is 0, buffer transfer is not performed by counter clear.
If there is a conflict with the CMTCm bit setting, the CCTCm bit setting has priority.
The setting is invalid during the event count operation.

CCTPR Bit (Counter Clear Source GTPR Register Buffer Transfer Disable)

This bit disables buffer transfer by counter clear using the GTPR, GTPBR, and GTPDBR registers together.
This bit is effective when the GTBER.BD[1] bit is 0 (buffer operation enabled) and the buffer operation is selected by the GTBER.PR[1:0] bits with sawtooth-waves.
The setting is invalid in triangle waves or complementary PWM mode. Even if the CCTPR bit is 0, buffer transfer is not performed by counter clear.
The setting is invalid during the event count operation.

b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The GTOLBR register is a buffer register for the GTIOR.GTIOA[4:0] bits and GTIOR.GTIOB[4:0] bits.

GTIOmB[4:0] Bits (GTIOm Buffer) (m = A, B)

These bits are buffer bits of GTIOR.GTIOm[4:0] bits.

These bits are transferred to the GTIOR.GTIOm[4:0] bits at the transfer timing selected by the GTBER2.OLTTm[1:0] (m = A, B) bits.

b31, b30	ICBGRP[1:0]	GTCCRB Input Capture Group Select	b31b30 0 0: Group A 0 1: Group B 1 0: Group D 1 1: Group D	R/W

The GTICCR register is a register that controls input capture by inter channel link.
For channels that perform input capture in cooperation, the input capture factor set in the GTICASR and GTICASR registers is invalid.

ICAFm Bit (Enable GTCCRm Register Compare Match/Input Capture as Source of Other Channel GTCCRA Input Capture) (m = A, B)

Enables/disables the use of compare match/input capture of GTCCRm register as the input capture source of other channel's GTCCRA register.

ICAFn Bit (Enable GTCCRn Register Compare Match as Source of Other Channel GTCCRA Input Capture) (n = C, D, E, F)

Enables/disables the use of compare match of GTCCRn register as the input capture source of other channel's GTCCRA register.

ICAFPO Bit (Enable Overflow as Source of Other Channel GTCCRA Input Capture)

Enable/disable to use the overflow of sawtooth-waves, the crest of triangle-waves or complementary PWM mode as the input capture source of other channel's GTCCRA register.

ICAFPU Bit (Enable Underflow as Source of Other Channel GTCCRA Input Capture)

Enable/disable to use the underflow of sawtooth-waves, the trough of triangle-waves or complementary PWM mode as the input capture source of other channel's GTCCRA register.

ICACLK Bit (Enable Count Clock as Source of Other Channel GTCCRA Input Capture)

Enable/disable to use count clock as the input capture source of other channel's GTCCRA register.

ICAGRP[1:0] Bits (GTCCRA Input Capture Group Select)

Select the group of input capture by inter channel cooperation for GTCCRA register.
For channels that accept input capture of the GTCCRA register due to input capture sources from other channels, set the GTICASR.ASOC bit to 1 and select the group of inter channel cooperation with the ICAGRP[1:0] bits.

ICBFm Bit (Enable GTCCRm Register Compare Match/Input Capture as Source of Other Channel GTCCRB Input Capture) (m = A, B)

Enables/disables the use of compare match/input capture of GTCCRm register as the input capture source of other channel's GTCCRB register.

ICBFn Bit (Enable GTCCRn Register Compare Match as Source of Other Channel GTCCRB Input Capture) (n = C, D, E, F)

Enables/disables the use of compare match of GTCCRn register as the input capture source of other channel's GTCCRB register.

ICBFPO Bit (Enable Overflow as Source of Other Channel GTCCRB Input Capture)

Enable/disable to use the overflow of sawtooth-waves, the crest of triangle-waves or complementary PWM mode as the input capture source of other channel's GTCCRB register.

ICBFPU Bit (Enable Underflow as Source of Other Channel GTCCRB Input Capture)

Enable/disable to use the underflow of sawtooth-waves, the trough of triangle-waves or complementary PWM mode as the input capture source of other channel's GTCCRB register.

ICBCLK Bit (Enable Count Clock as Source of Other Channel GTCCRB Input Capture)

Enable/disable to use count clock as the input capture source of other channel's GTCCRB register.

ICBGRP[1:0] Bits (GTCCRB Input Capture Group Select)

Select the group of input capture by inter channel cooperation for GTCCRB register.

For channels that accept input capture of the GTCCRB register due to input capture sources from other channels, set the GTICBSR.BSOC bit to 1 and select the group of inter channel cooperation with the ICBGRP[1:0] bits.

24.2.46 Output Phase Switching Control Register (OPSCR)

Address(es): GPTW.OPSCR 000C 2B00h

b29	NFEN	External Input Noise Filter Enable	0: The noise filter for the external input is disabled. 1: The noise filter for the external input is enabled.	R/W

Bit	Symbol	Bit Name	Description	R/W
b31, b30	NFCS[1:0]	External Input Noise Filter Clock Select	b31b30 0 0: PCLKC/1 0 1: PCLKC/4 1 0: PCLKC/16 1 1: PCLKC/64	R/W

Note 1. When the GODF bit is 1 and the signal value of the source selected by the GRP[1:0] bits becomes High, the EN bit is set to 0.

The OPSCR register sets the output of the signal waveform required for brushless DC motor control.

UF, VF, WF Bits (Input Phase Software Setting)

The UF, VF, and WF bits set the input phase from the software settings. When the FB bit is 1, these bits are valid. The set value of the UF, VF, and WF bit takes the place of the U, V, W external input.

U, V, W Bits (Input m-Phase Monitor) (m = U, V, W)

When the FB bit is 0, external inputs that are synchronized by PCLKC are monitored by these bits. When the FB bit is 1, the U, V, and W bits can read the UF, VF, and WF bits.

EN Bit (Output Phase Enable)

The EN bit controls the output enable signal of output phase (positive phase/negative phase).
When the EN bit is 1, the signal waveform is output.
When the EN bit is 0, first set FB, VF, and WF (software setting is selected), P, N, INV, RV, ALIGN, GRP[1:0], GODF, NFEN, and NFCS bits. Then, set this bit to 1. The EN bit should be set when output disable request doesn't occur from POEG. Also when GODF is 1 and the signal value selected in the GRP[1:0] bits are high, the EN bit is set to 0. And 1 by software to be written, the EN bit remains at 0.
For the return, after clearing the output disable request by software, set the EN bit to 1.

- EN bit priority order (conflict)

When 1 write by software and set to 0 by the output disable request has been conflicting for EN bit, set to 0 by the Output Disable Request is activated.

FB Bit (External Feedback Signal Enable)

The FB bit selects the input phase from the software settings (UF, VF, and WF bits) and external input such as a Hall element.

P Bit (Positive-Phase Output (P) Control)

The P bit selects one of the level signal output or PWM signal output for the positive-phase output (GTOUUP, GTOVUP and GTOWUP pins).

N Bit (Negative-Phase Output (N) Control)

The P bit selects one of the level signal output or PWM signal output for the negative-phase output (GTOULO, GTOVLO and GTOWLO pins).

INV Bit (Output Phase Invert Control)

The INV bit selects one of the positive logic (active-high) output or negative logic (active-low) output for the output phase.

RV Bit (Output Phase Rotation Direction Reversal Control)

The RV bit reverses the direction of rotation of the motor by inverting the input phase.

ALIGN Bit (Input Phase Alignment)

The ALIGN bit selects the PCLKC or PWM for the sampling of the input phase (input phase is specified in the FB bit).

When ALIGN bit is 0, input phase is aligned to PCLKC.

Note: When the chopping is performed, there are cases where the PWM width of output is shorter than the width of the PWM used to chop just before or after switching of output phase, depending on the phase difference between the phase output switch timing and the phase of PWM.

When ALIGN bit is 1, input phase is aligned with the falling edge of PWM.

GRP[1:0] Bits (Output Disabled Source Selection)

The GRP[1:0] bits select the output disable source.

When the GODF bit is 0, set the GRP[1:0] bits.

GODF Bit (Group Output Disable Function)

When the GODF bit is 1 and the signal value selected by the GRP[1:0] bits are high, the EN bit is set to 0.

When the GODF bit is 0, this bit is ignored.

Set the GODF bit while there is not output disable request from POEG.

NFEN Bit (External Input Noise Filter Enable)

The NFEN bit disables or enables the external input noise filter.

Note: Set this bit during the EN bit is 0 to avoid generation of unintentional internal edge caused by this bit switching.

NFCS[1:0] Bits (External Input Noise Filter Clock Select)

The NFCS[1:0] bits select the clock for the external input noise filter.

1. Set the NFCS[1:0] bits.
2. Wait for 2 cycles.
3. Set the EN bit to 1.

24.3 Operation

24.3.1 Basic Operation

The timer in each channel performs cycle count operation by count clock or hardware source. The GTCNT counter performs up-counting, or down-counting. The timer period is controlled by the GTPR or GTCCRm (m = A to F) registers. When the GTCNT counter value matches the values for GTCCRA or GTCCRB registers, the GTIOCnA or GTIOCnB pin outputs (n = 0 to 7) can be changed respectively. Also, the GTCCRA or GTCCRB registers can be used as the input capture registers by hardware source. The GTCCRC and GTCCRD registers can be performed as buffer registers for GTCCRA register, and the GTCCRE and GTCCRF registers can be performed as buffer registers for GTCCRB register.

24.3.1.1 Counter Operation

(1) Count Start/Count Stop

The counter in each channel starts counting operation when the corresponding GTCR.CST bit is set to 1, and stops counting when the bit is set to 0.
CST bit value can be changed by the following sources:

- Writing to the GTCR register
- Writing 1 to the bit corresponding to the channel number for the GTSTR register while the GTSSR.CSTRT bit is 1
- Writing 1 to the bit corresponding to the channel number for the GTSTP register while the GTPSR.CSTOP bit is 1
- Hardware source specified by the GTSSR register
- Hardware source specified by the GTPSR register
- Completion of the cycle count operation while the GTPC.ASTP bit is 1.

(2) Cycle Count Operation (In Up-Counting by the Count Clock)

The counter in each channel starts up-counting when the corresponding CST bit is set to 1 while the GTUPSR register and the GTDNSR register are 0000 0000h. When the value of the GTCNT counter changes from that of the GTPR register to 0000 0000h (an overflow) or the GTCCRm (m = A to F) value selected by the GTCSR.CSCMSC[2:0] bits to 0000 0000h in sawtooth-wave PWM mode 2 while the GTINTAD.GTINTPR[0] bit is 1, a GTCIV interrupt request is also issued. After GTCNT counter overflows, up-counting is resumed from 0000 0000h.
Figure 24.4 shows an example of cycle count operation in up-counting by count clock.

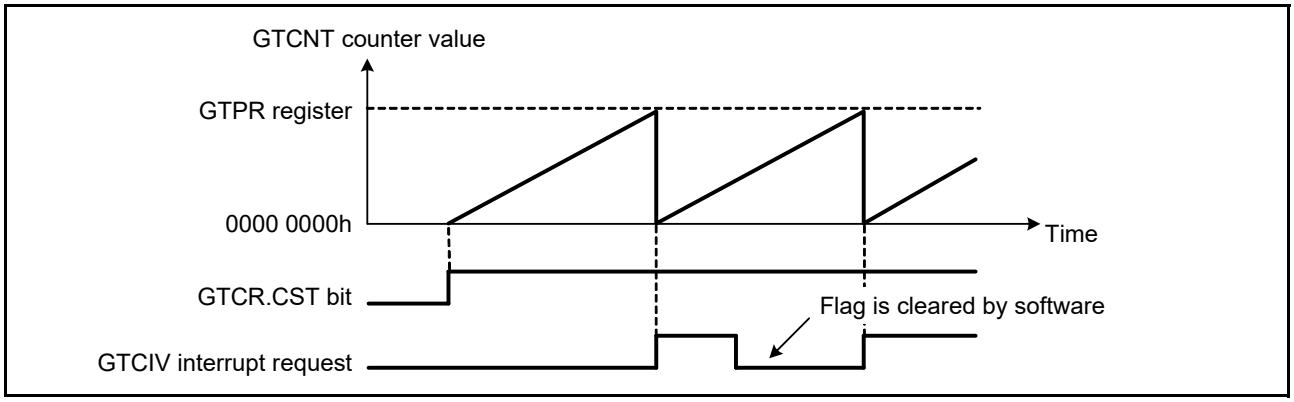

Figure 24.4 Example of Cycle Count Operation (In Up-Counting by the Count Clock)

Figure 24.5 shows an example for setting cycle count operation in up-counting.

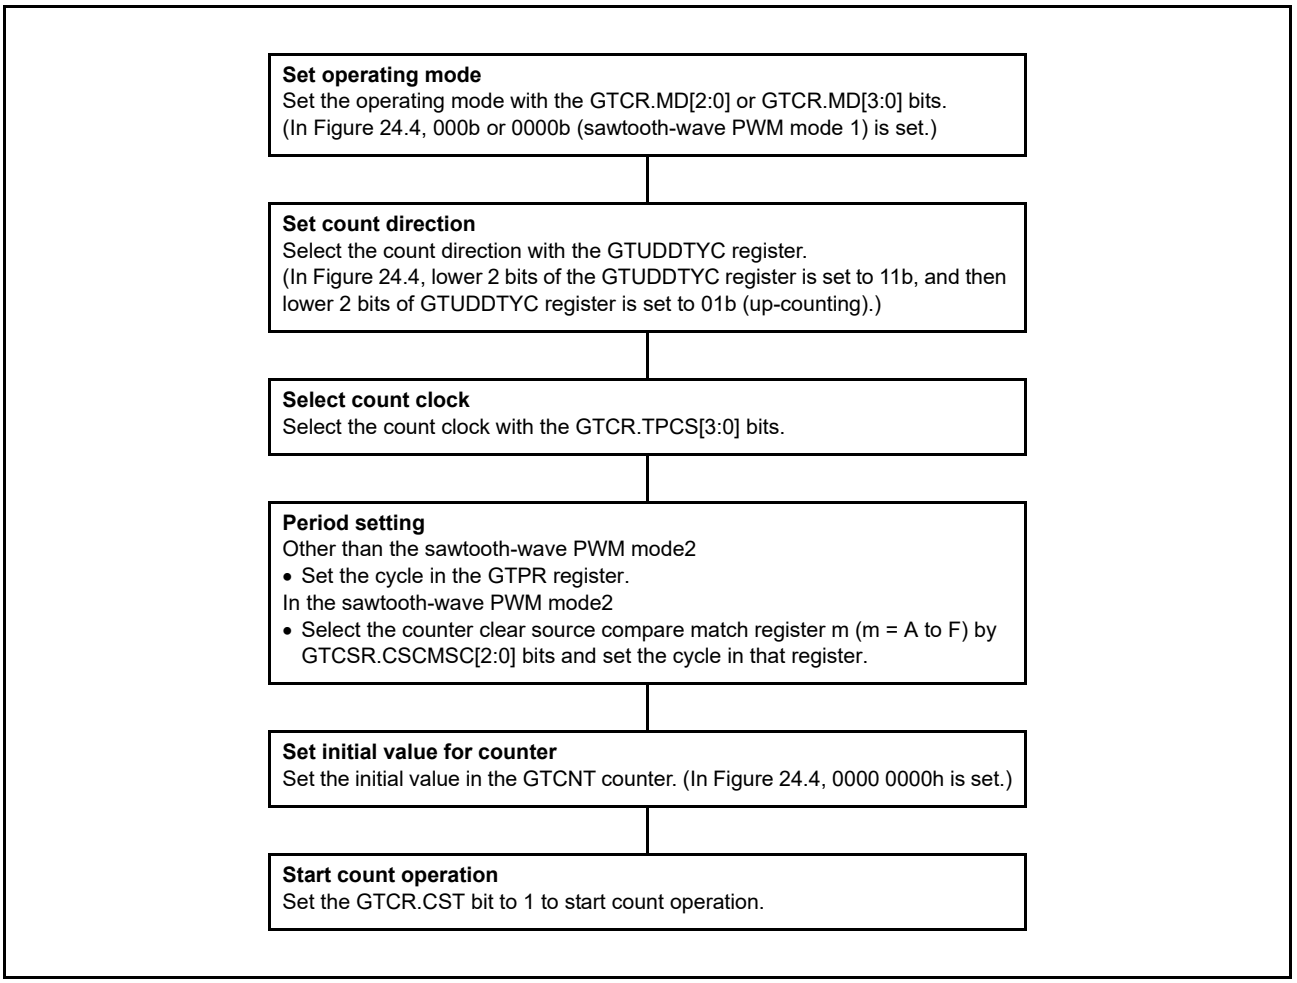

Figure 24.5 Example for Setting Cycle Count Operation (In Up-Counting by the Count Clock)

(3) Cycle Count Operation (In Down-Counting by the Count Clock)

The counter in each channel can start down-counting when the corresponding GTUDDTYC.UD bit is set in a state of the GTUPSR register and the GTDNSR register as 0000 0000h. When the value of the GTCNT counter changes from 0000 0000h to that of the GTPR register (an underflow) while the GTINTAD.GTINTPR[1] bit is 1, a GTCIU interrupt request is also issued. After the GTCNT counter underflows, down-counting is resumed from the GTPR register value.
Figure 24.6 shows an example of cycle count operation in down-counting by count clock.

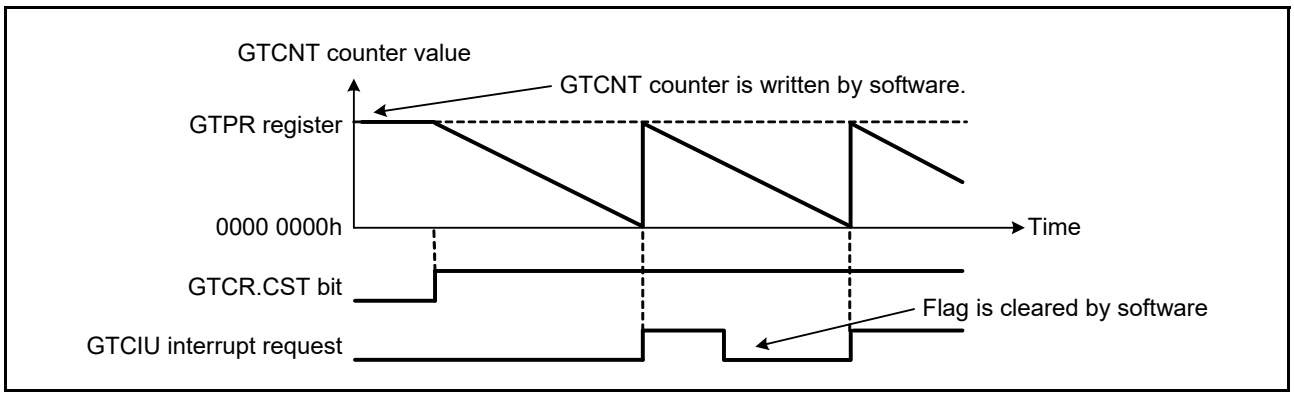

Figure 24.6 Example of Cycle Count Operation (In Down-Counting by the Count Clock)

Figure 24.7 shows an example for setting cycle count operation in down-counting by count clock.

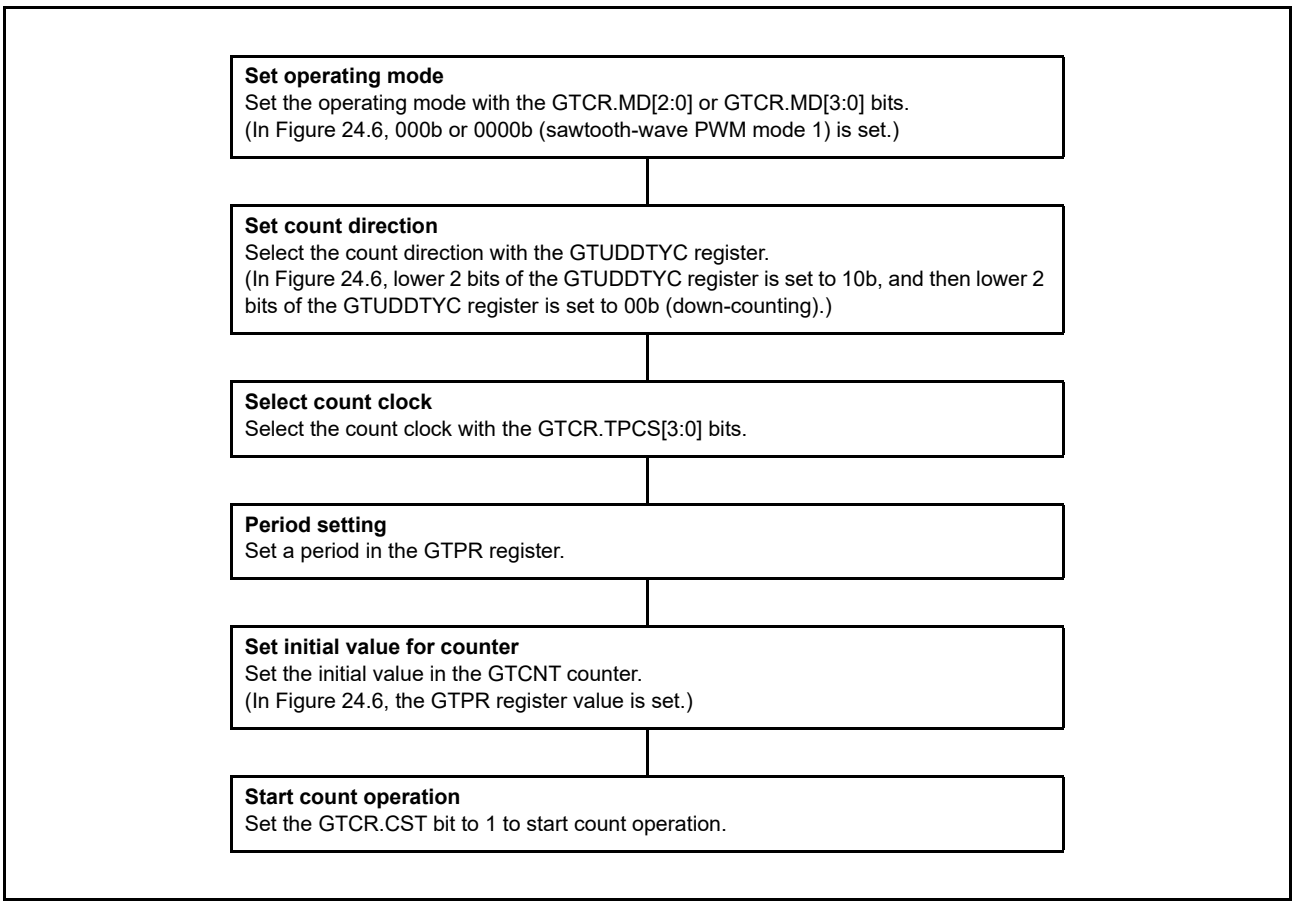

Figure 24.7 Example for Setting Cycle Count Operation (In Down-Counting by the Count Clock)

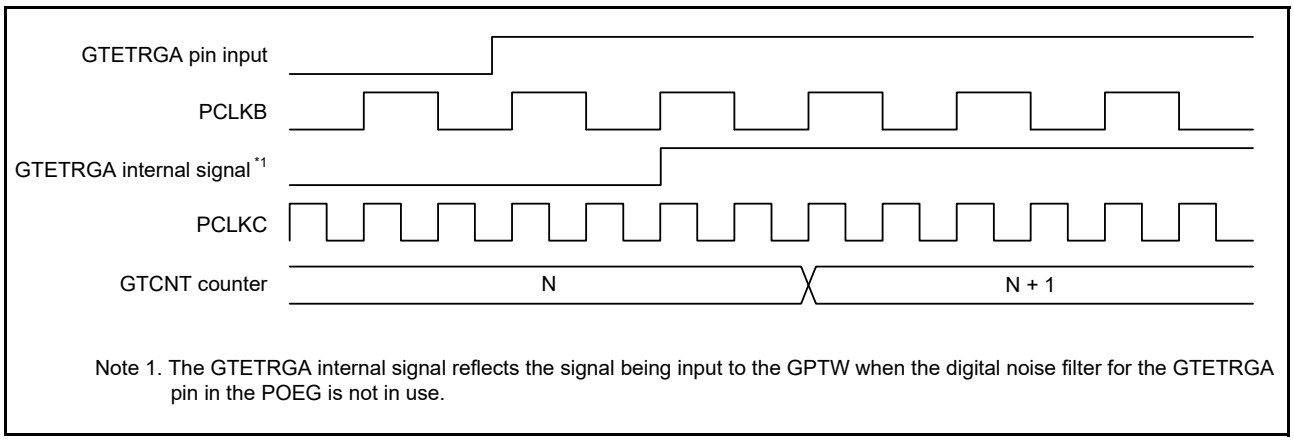
(4) Event Count Operation (In Up-Counting by Hardware Source)

The counter in each channel can start up-counting by hardware source by setting the GTUPSR register. When the GTUPSR register is set, the count clock selected by the GTCR.TPCS[3:0] bits and the count direction set by the GTUDDTYC.UD bit are invalid. If the hardware source in up-counting and the hardware source in down-counting are generated at the same time, the GTCNT counter value will not change.

Operation due to overflow in up-counting by hardware source is the same as the cycle count operation by the count clock.

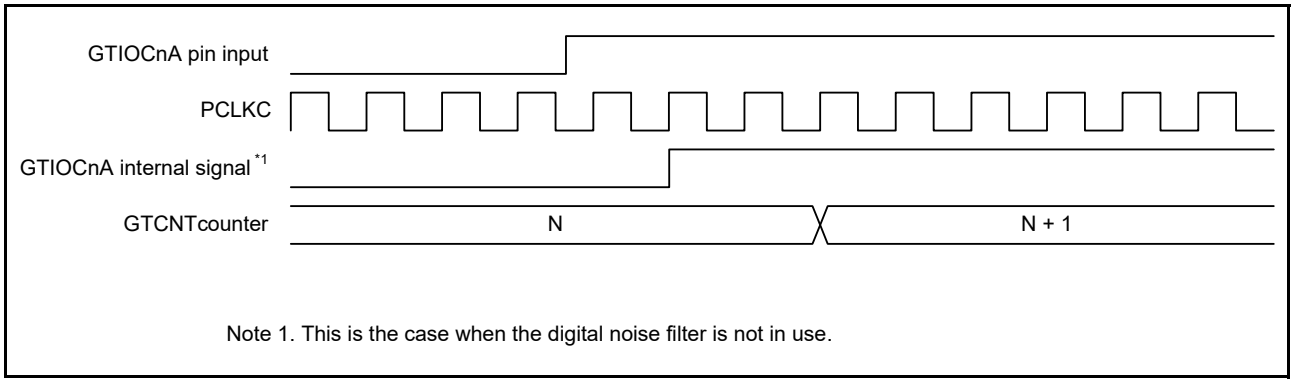
To perform up-counting by hardware source, start count operation by setting the GTCR.CST bit to 1. As the starting the count operation is synchronized with the count clock selected by TPCS[3:0] bits, set the CST bit to 1, and wait until the first cycle of the count clock elapses to start up-counting operation. To start up-counting after one PCLKC from setting the CST bit to 1, set the TPCS[3:0] bits to 0000b.

Figure 24.8 and Figure 24.9 show examples of up-counting operation by hardware source (edge of GTETRGA pin input and the rising edge of GTIOCnA pin input).



Note 1. The GTETRGA internal signal reflects the signal being input to the GPTW when the digital noise filter for the GTETRGA pin in the POEG is not in use.

Figure 24.8 Example of Event Count Operation (Up-Counting of Rising Edges of the Input on the GTETRGA Pin)



Note 1. This is the case when the digital noise filter is not in use.

Figure 24.9 Example of Event Count Operation (Up-Counting of Rising Edges of the Input on the GTIOCnA Pin)

Figure 24.10 shows an example of event counting by a hardware source (ELC event input).
This is an example when the ELC selectively outputs the event signal output to the ELC by the compare match to the GPTW0.GTCCRA register as the event factor A to the GPTW, and performs the event count operation of the GPTW1.GTCNT counter by the signal.
The GPTW0 compare match A signal synchronized with PCLKC is synchronized with PCLKB in ELC, and GPTW event factor A is output after 1 clock with PCLKB.

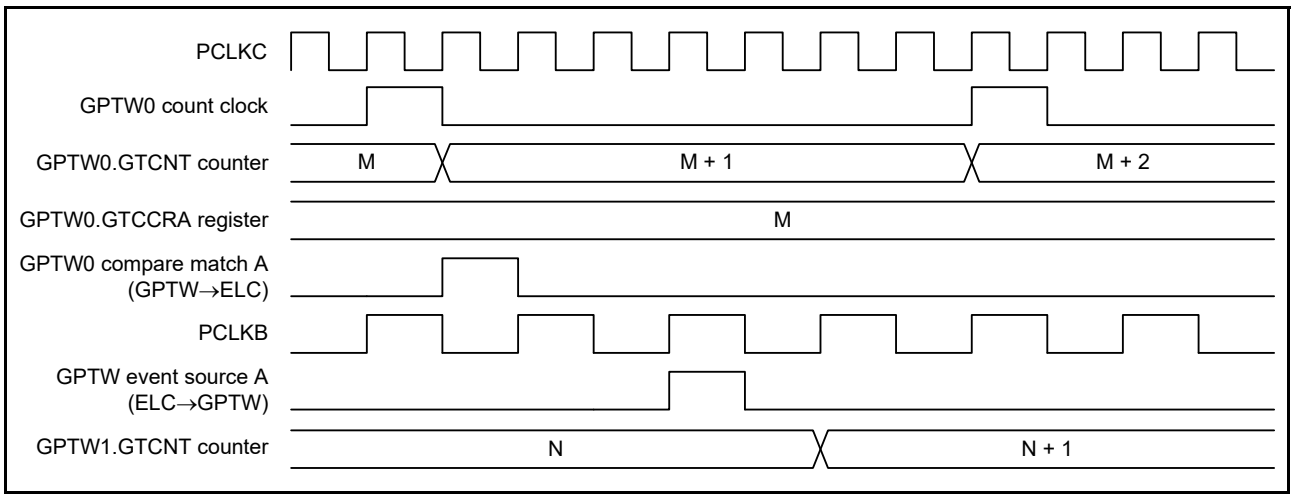


Figure 24.10 Example of Event Count Operation (Up-Counting the Number of Event Signals Input from the ELCA)

Figure 24.11 shows an example for setting cycle count operation in up-counting by hardware source.

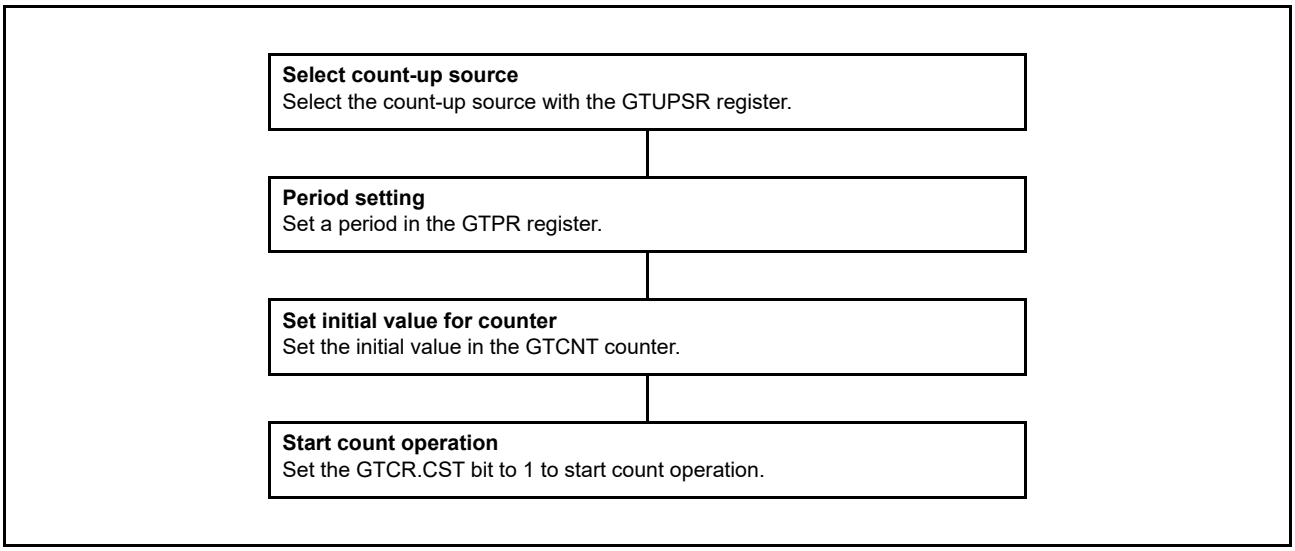

Figure 24.11 Example for Setting Event Count Operation (In Up-Counting by Hardware Source)

(5) Event Count Operation (In Down-Counting by Hardware Source)

The counter in each channel can start down-counting by hardware source by setting the GTDNSR register. When the GTDNSR register is set, the count clock selected by the GTCR.TPCS[3:0] bits and the count direction set by the GTUDDTYC.UD bit are invalid. If the hardware source in up-counting and the hardware source in down-counting are generated at the same time, the GTCNT counter value will not change.

Operation due to underflow in down-counting by hardware source is the same as the cycle count operation by the count clock.

To perform down-counting by hardware source, start count operation by setting the GTCR.CST bit to 1. As the starting the count operation is synchronized with the count clock selected by TPCS[3:0] bits, set the CST bit to 1, and wait until the first cycle of the count clock elapses to start down-counting operation. To start down-counting after one PCLKC from setting the CST bit to 1, set the TPCS[3:0] bits to 0000b.

Figure 24.12 shows an example of down-counting operation by hardware source.

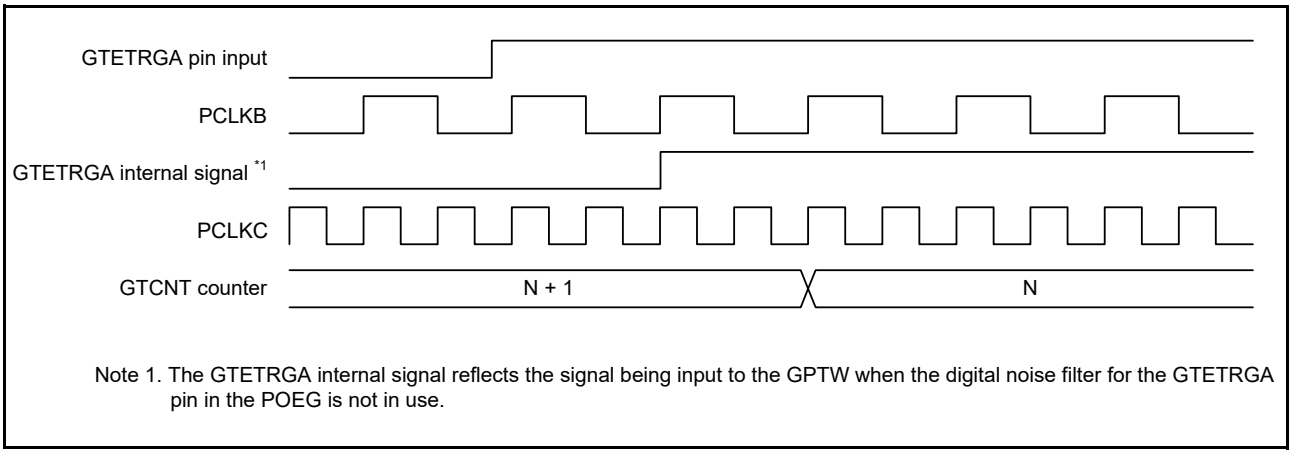

Figure 24.12 Example of Event Count Operation (Down-Counting of Rising Edges of the Input on the GTETRGA Pin)

Figure 24.13 shows an example for setting cycle count operation in down-counting by hardware source.

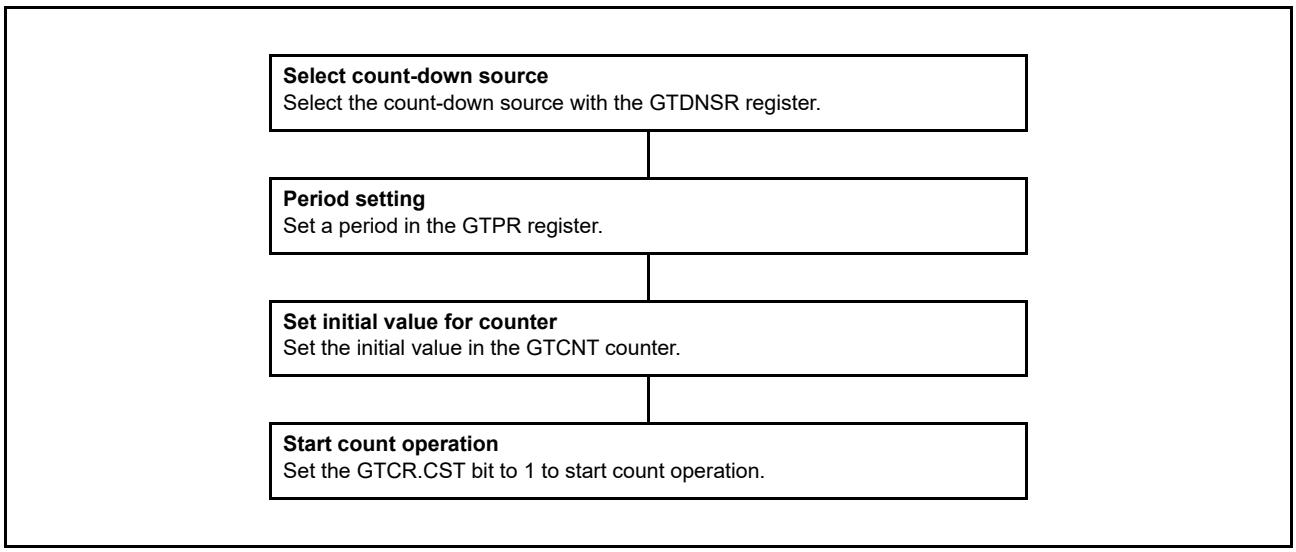

Figure 24.13 Example for Setting Event Count Operation (In Down-Counting by Hardware Source)

(6) Counter Clearing Operation

The counter in each channel can be cleared by the following sources:

- Writing to the GTCNT counter
- Writing 1 to the bit corresponding to the channel number for the GTCLR register while the GTCSR.CCLR bit is 1
- Hardware source specified by the GTCSR register

Write access during counting (when CST = 1) is disabled.
GTCLR register can be written to and cleared by hardware source whether the count operation is performed (GTCR.CST bit = 1) or is stopped (CST bit = 0). When the count direction flag is set as decrement (GTST.TUCF flag = 0) in sawtooth-wave mode (except sawtooth-wave PWM mode 2) selected with GTCR.MD[2:0] or GTCR.MD[3:0] bits, the GTCNT counter value for writing to the GTCLR register and for clearing by hardware source becomes the GTPR register value whether the counter is in operation or is stopped. The GTCNT counter value becomes 0000 0000h for other settings.
When the event count operation is set (at least one of bits for the GTUPSR or the GTDNSR register is set as 1), writing to the GTCLR register and clearing by hardware source are performed right after the clear source is generated (the operation is based on PCLKC). For other settings, clearing operation is synchronized with the count clock selected with the GTCR.TPCS[3:0] bits.

24.3.1.2 Waveform Output by Compare Match

Compare match refers to when the GTCNT counter value matches the GTCCRA or GTCCRB register value. The output of the corresponding GTIOCnA or GTIOCnB pin (n = 0 to 7) can be set to be driven low, high, or toggled in synchronization with the counter clock (including in the case of event counting) after the match.
In addition, the GTIOCnA or GTIOCnB pin output can be driven low, high, or toggled at the “end of the cycle” which is determined by the GTPR register or GTCCRm selected as a counter clear source by the GTCSR.CSCMSC[2:0] bits in sawtooth-wave PWM mode 2 (n = 0 to 7, m = A to F). The end of the cycle is as follows:

- For sawtooth waves (except sawtooth-wave PWM mode 2) in up-counting: When the GTCNT counter value changes from the GTPR register value to 0000 0000h (overflow)
- For sawtooth waves (except sawtooth-wave PWM mode 2) in down-counting: When the GTCNT counter value changes from 0000 0000h to the GTPR register value (underflow)
- For sawtooth-wave PWM mode 2 and GTCCRm register (m = A to F) selected as a counter clear source by the GTCSR.CSCMSC[2:0] bits. When the GTCNT counter value changes from the GTCCRm register value to 0000 0000h
- For sawtooth waves with the GTCNT counter clear
- For triangle waves: When the GTCNT counter value changes from 0000 0000h to 0000 0001h (trough)

(1) Low Output and High Output

Figure 24.14 shows an example of low output and high output operation by a compare match of the GTCNT counter and GTCCRA register and of the GTCNT counter and GTCCRB register.
In this example, the GPTW0.GTCNT counter performs up-counting, and settings have been made so that high is output from the GTIOC0A pin by a GPTW0.GTCCRA register compare match, and low is output from the GTIOC0B pin by a GPTW0.GTCCRB register compare match. The pin level does not change when the specified level and pin level match.

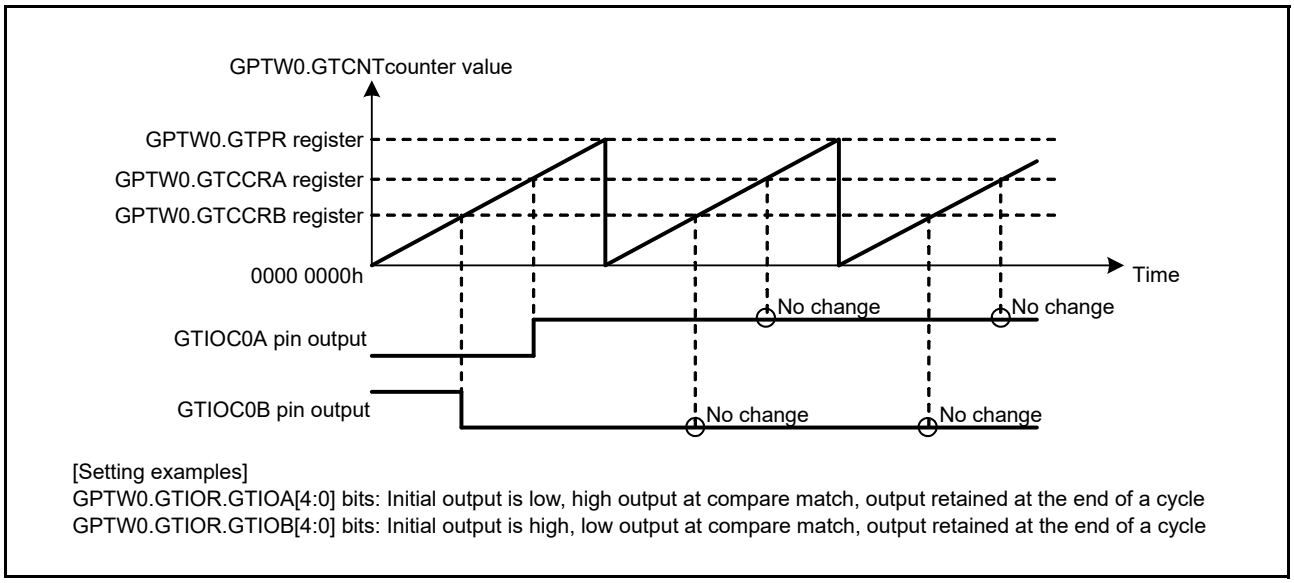

Figure 24.14 Example of Low Output and High Output Operation

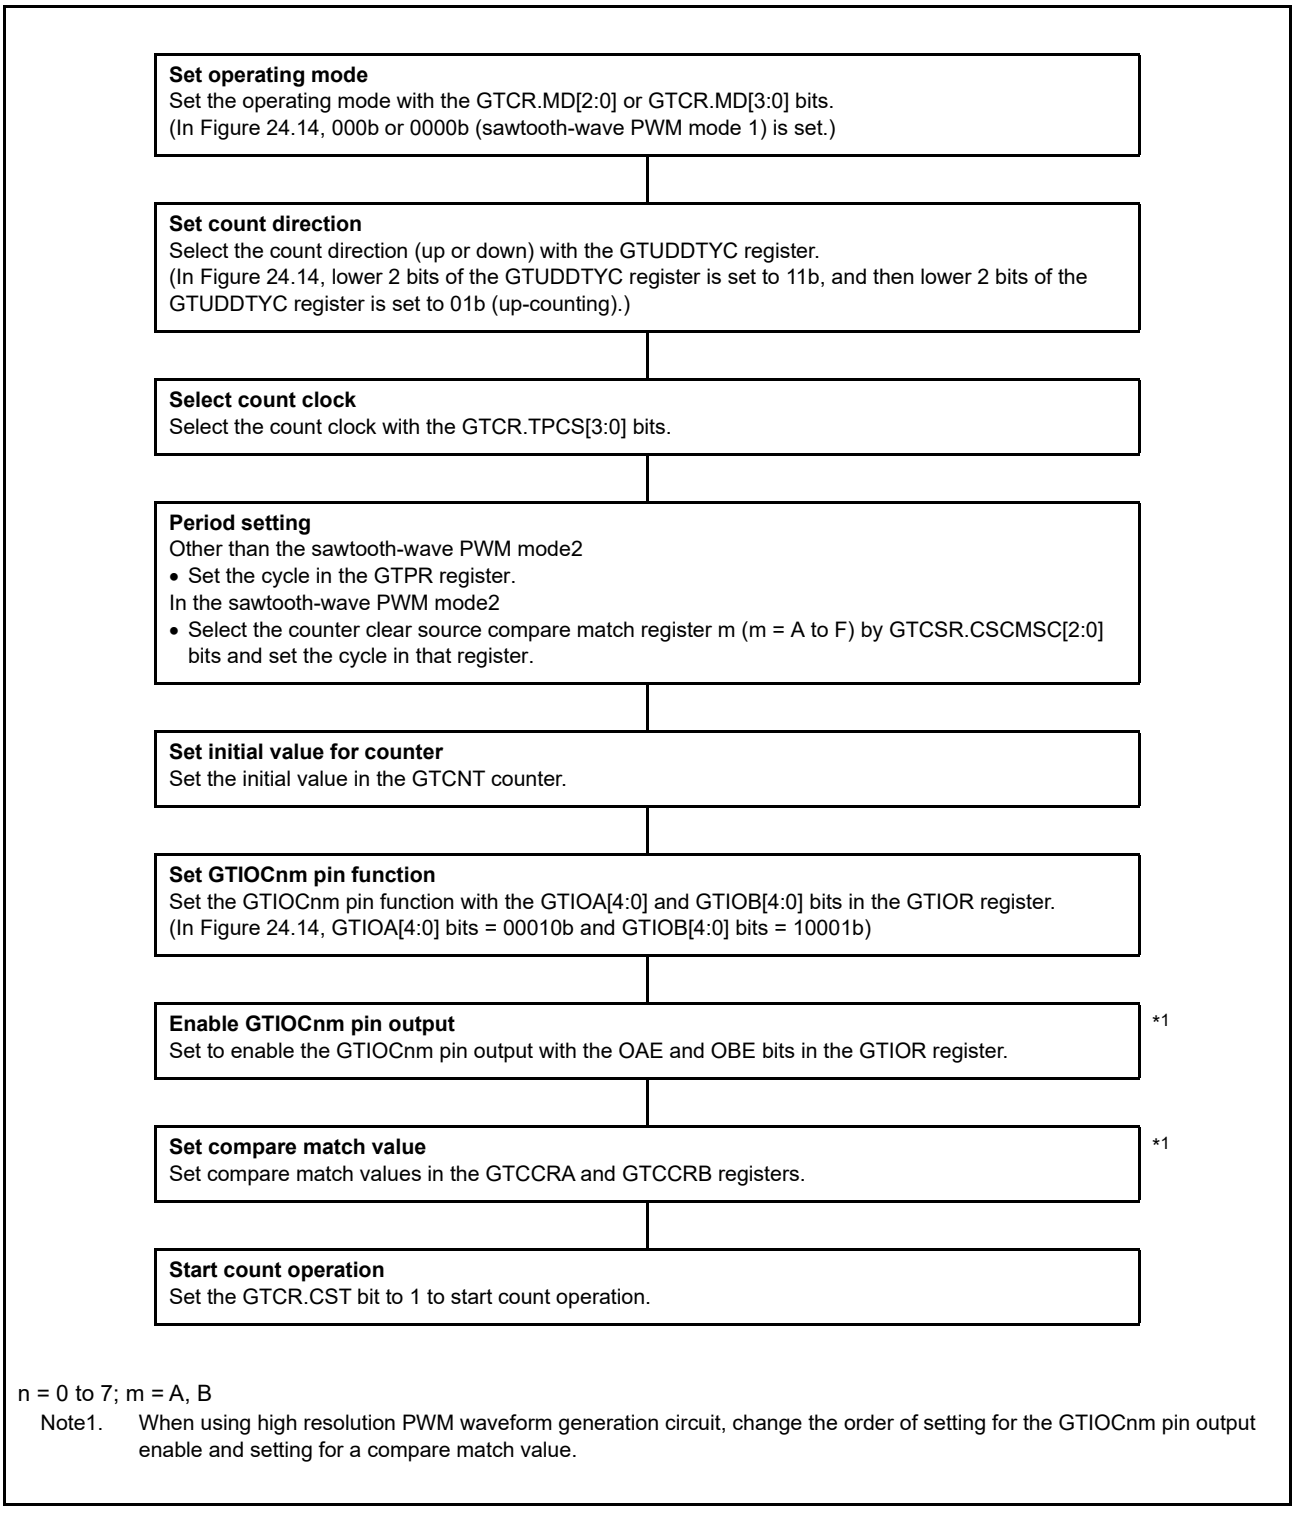
Figure 24.15 shows an example for setting Low/High output operation.



n = 0 to 7; m = A, B

Note1. When using high resolution PWM waveform generation circuit, change the order of setting for the GTIOCnm pin output enable and setting for a compare match value.

Figure 24.15 Example for Setting Low/High Output Operation

(2) Toggled Output

Figure 24.16 and Figure 24.17 show examples of toggle output operations by compare match between the GPTW0.GTCNT counter and the GTCCRA and GTCCRB registers.

In Figure 24.16, the GPTW0.GTCNT counter performs up-counting, and settings have been made so that the GTIOC0A pin output by a GPTW0.GTCCRA register compare match and GTIOC0B pin output by a GPTW0.GTCCRB register compare match are toggled.

In Figure 24.17, the GPTW0.GTCNT counter performs up-counting, and settings have been made so that the GTIOC0A pin output is toggled by a compare match of GPTW0.GTCCRA register and the GTIOC0B pin output is toggled at the end of the cycle.

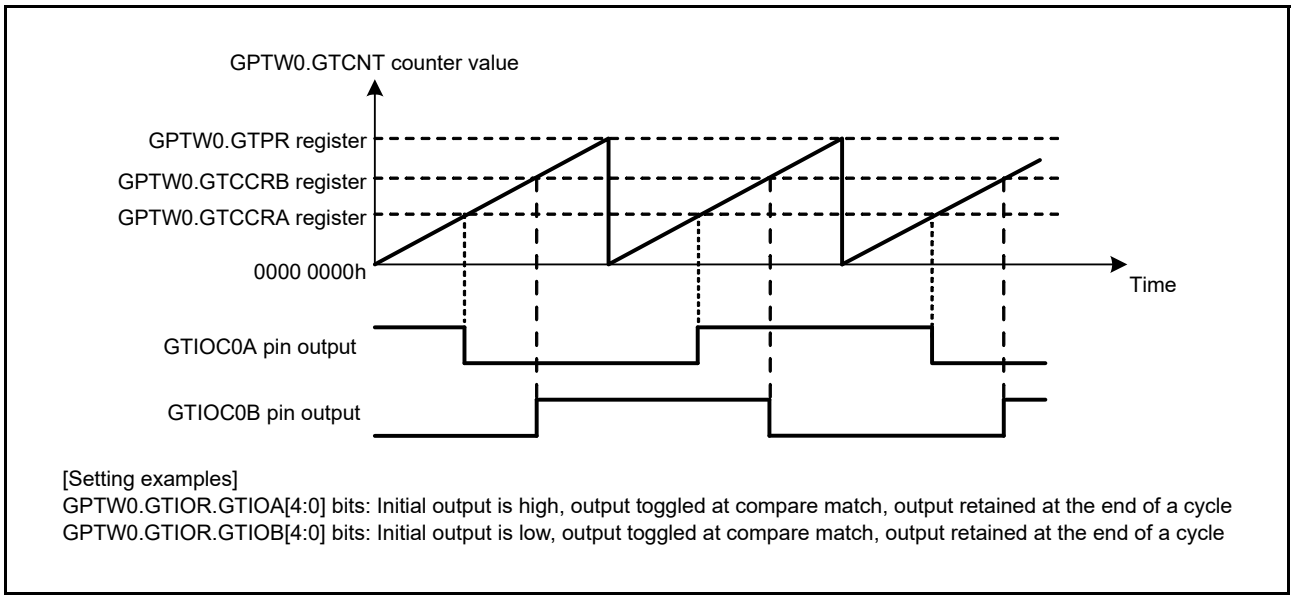


Figure 24.16 Example of Toggled Output Operation (1)

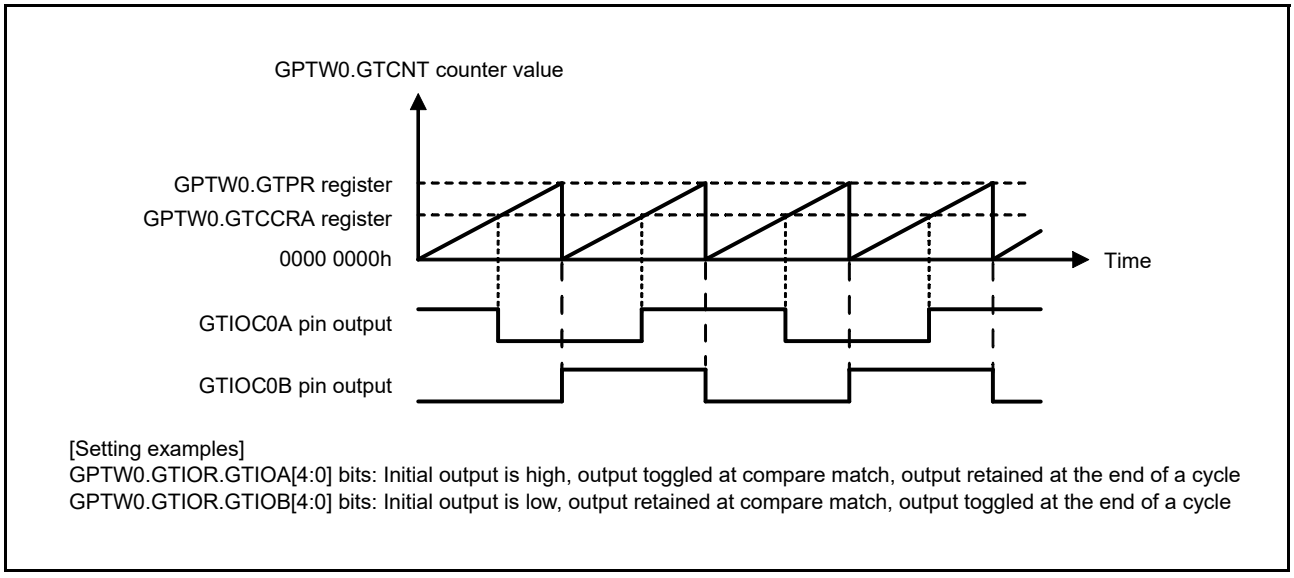

Figure 24.17 Example of Toggled Output Operation (2)

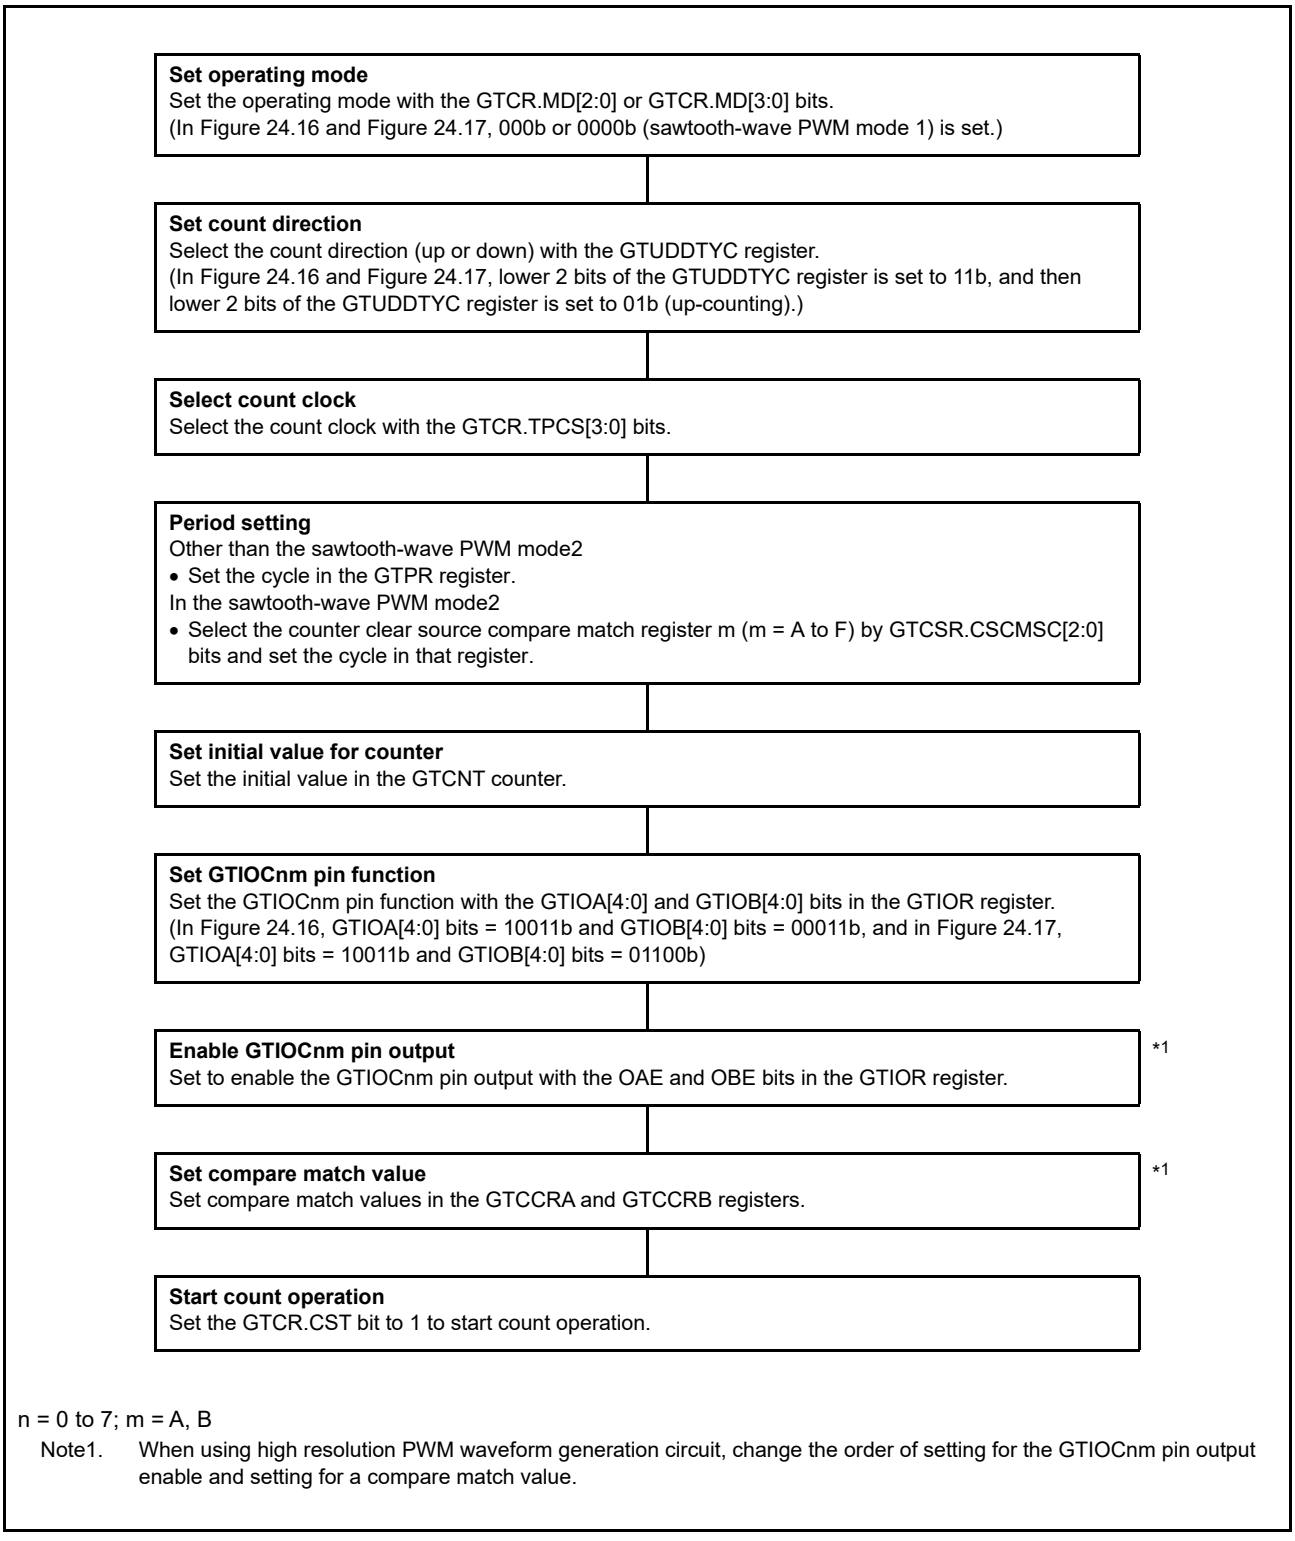
Figure 24.18 shows an example for setting toggled output operation.



n = 0 to 7; m = A, B

Note1. When using high resolution PWM waveform generation circuit, change the order of setting for the GTIOCnm pin output enable and setting for a compare match value.

Figure 24.18 Example for Setting Toggled Output Operation

24.3.1.3 Input Capture Function

Through detecting hardware sources selected by the GTICASR and GTICBSR registers, the GTCNT counter values can be transferred to the GTCCRA and GTCCRB registers respectively.

Figure 24.19 shows an example of input capture function operation.

In this example, the GPTW0.GTCNT counter performs up-counting, and settings have been made so that an input capture is performed at both edges of the GTIOC0A pin input and at the rising edge of the GTIOC0B pin input.

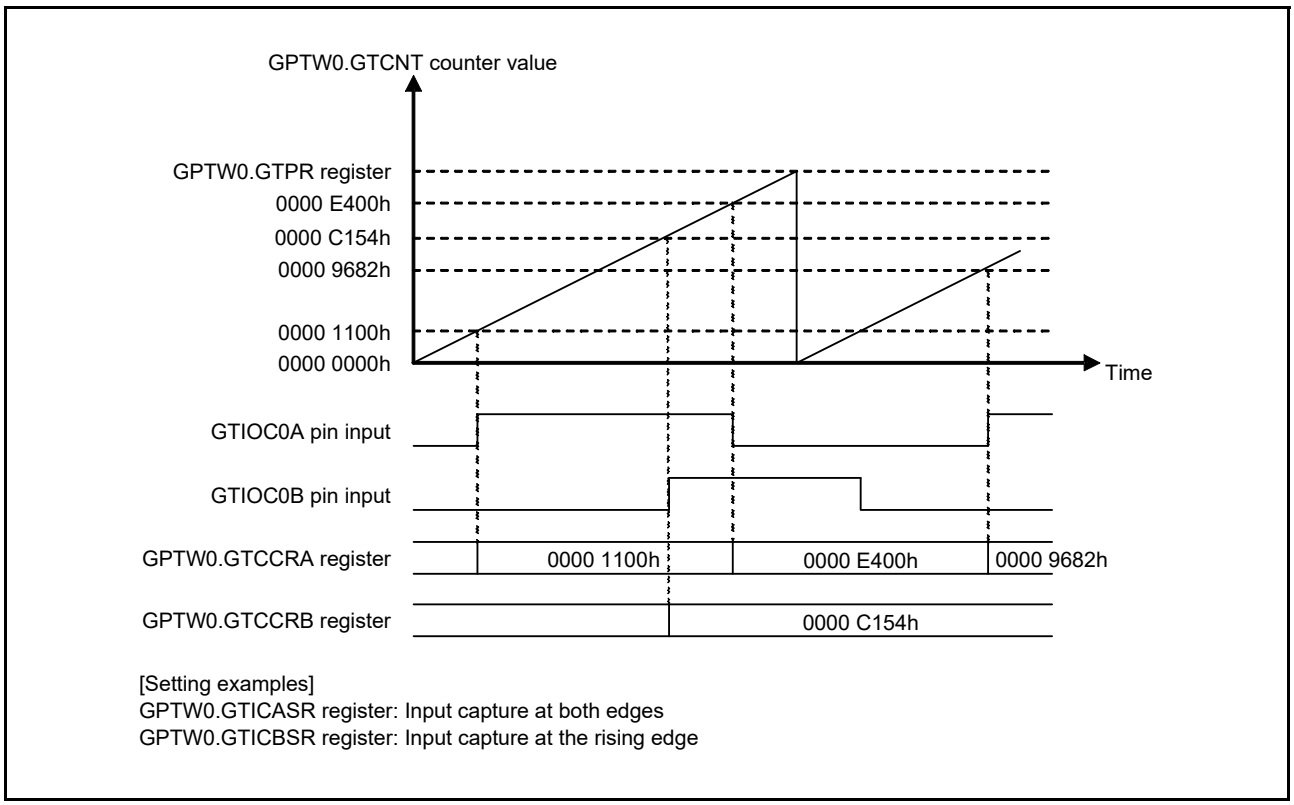


Figure 24.19 Example of Input Capture Operation

Figure 24.20 shows an example for setting input capture operation.

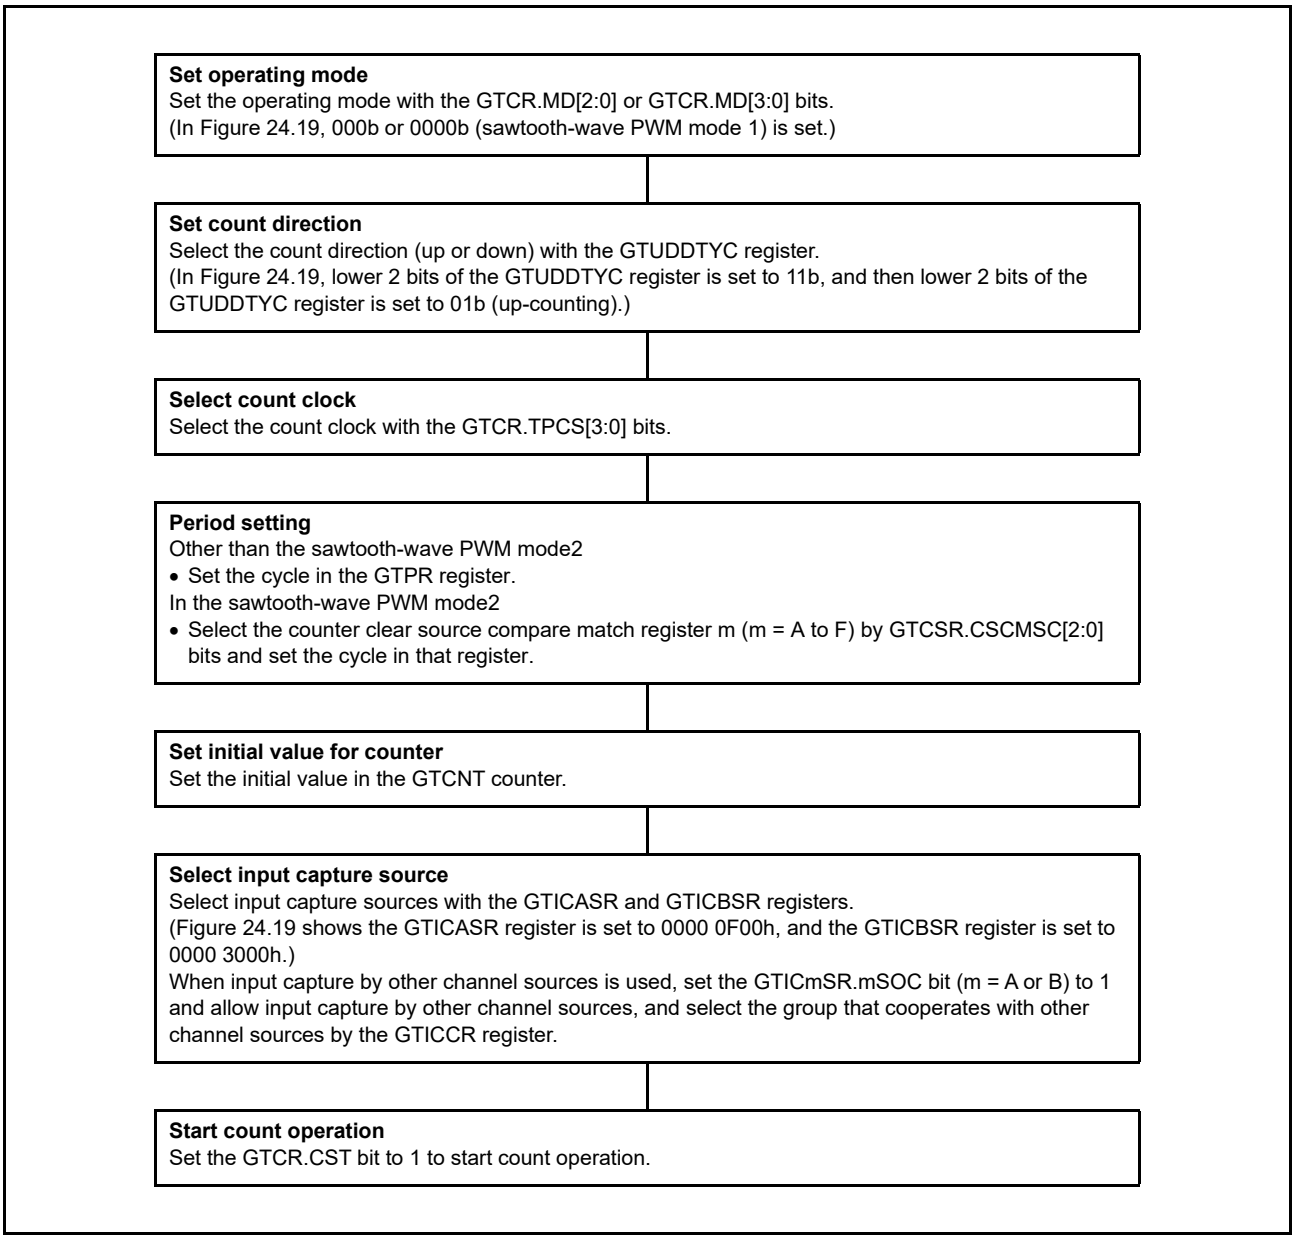

Figure 24.20 Example for Setting Input Capture Operation

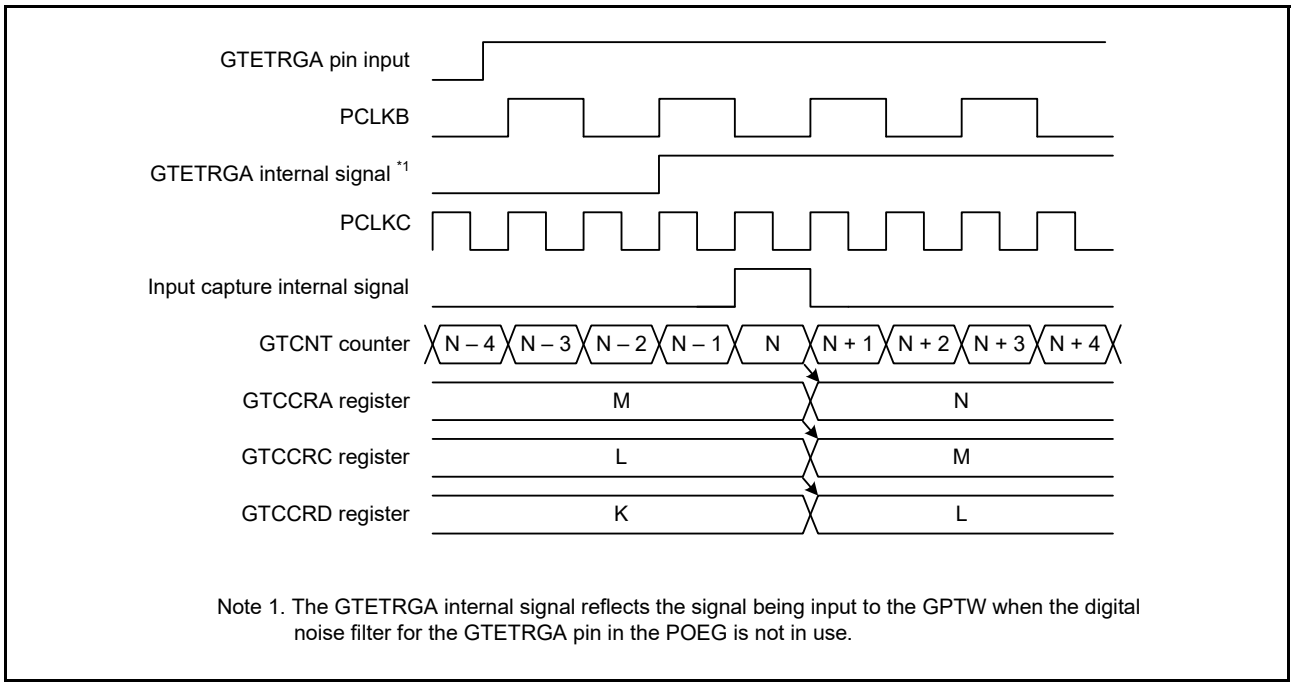
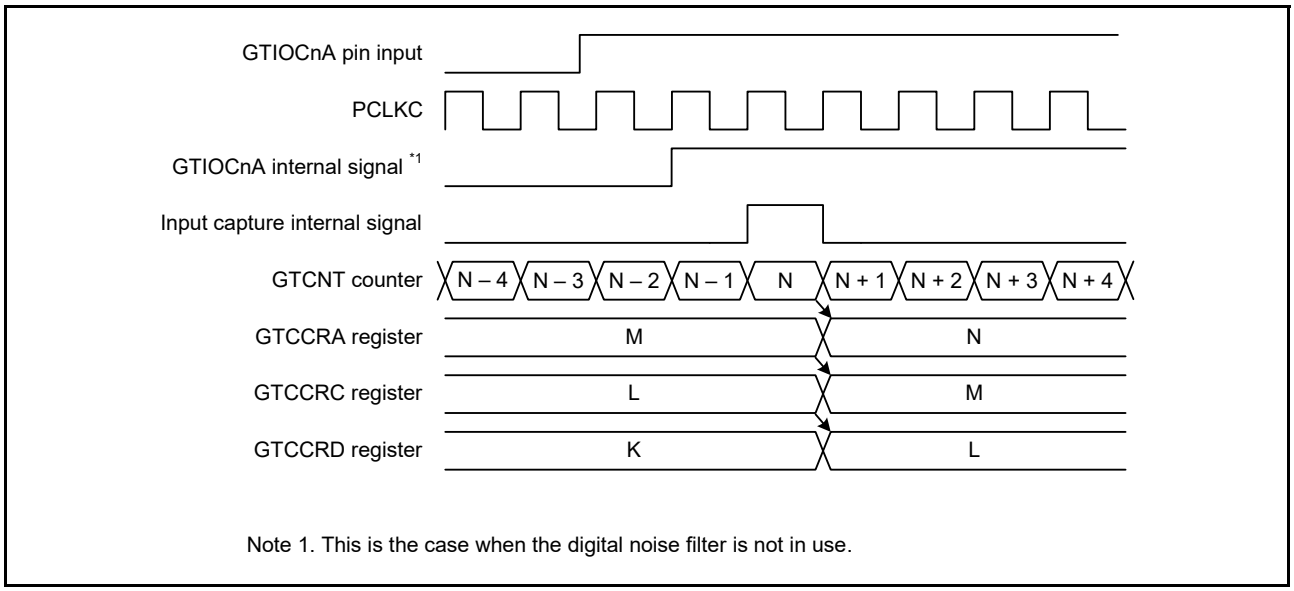
Figure 24.21 shows an example of the timing of input capture operation in response to a rising edge of the input on the GTETRGA pin.



Note 1. The GTETRGA internal signal reflects the signal being input to the GPTW when the digital noise filter for the GTETRGA pin in the POEG is not in use.

Figure 24.21 Example of the Timing of Input Capture Operation in Response to a Rising Edge of the Input on the GTETRGA Pin

Figure 24.22 shows an example of the timing of input capture operation in response to a rising edge of the input on the GTIOCnA pin.



Note 1. This is the case when the digital noise filter is not in use.

Figure 24.22 Example of the Timing of Input Capture Operation in Response to a Rising Edge of the Input on the GTIOCnA Pin

Figure 24.23 shows an example of the timing of operations for input capture in response to event input from the ELCA. This is an example of capture of the counter value by the GPTW1.GTCCRA register in response to an input signal. An event signal is output to the ELC after matches in comparison with the GPTW0.GTCCRA register. This is selected as a trigger for output to the GPTW by the ELC as event source A. The GPTW0 compare match A signal is synchronized with PCLKC. The ELC receives the signal in synchronization with PCLKB, and outputs the GPTW event source A signal after 1 cycle of PCLKB has elapsed.

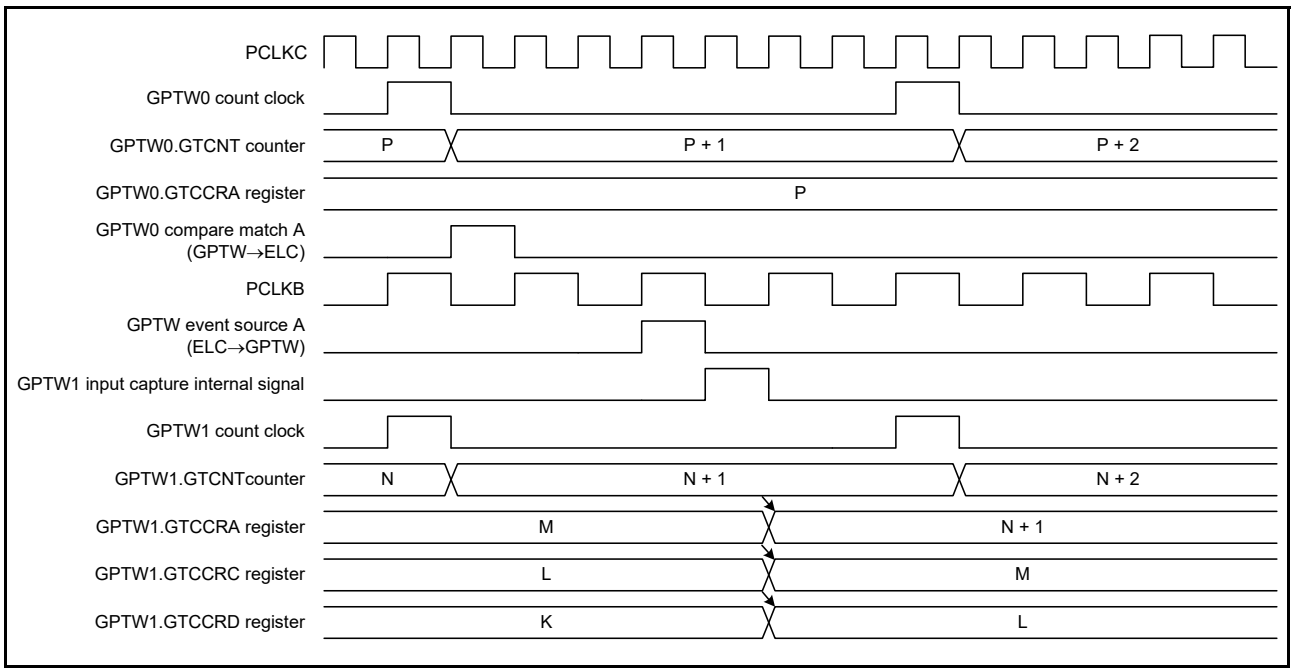


Figure 24.23 Example of the Timing of Operations for Input Capture in Response to Event Input from the ELCA

Figure 24.24 shows the input capture operation timing by the counter clock of other channels.

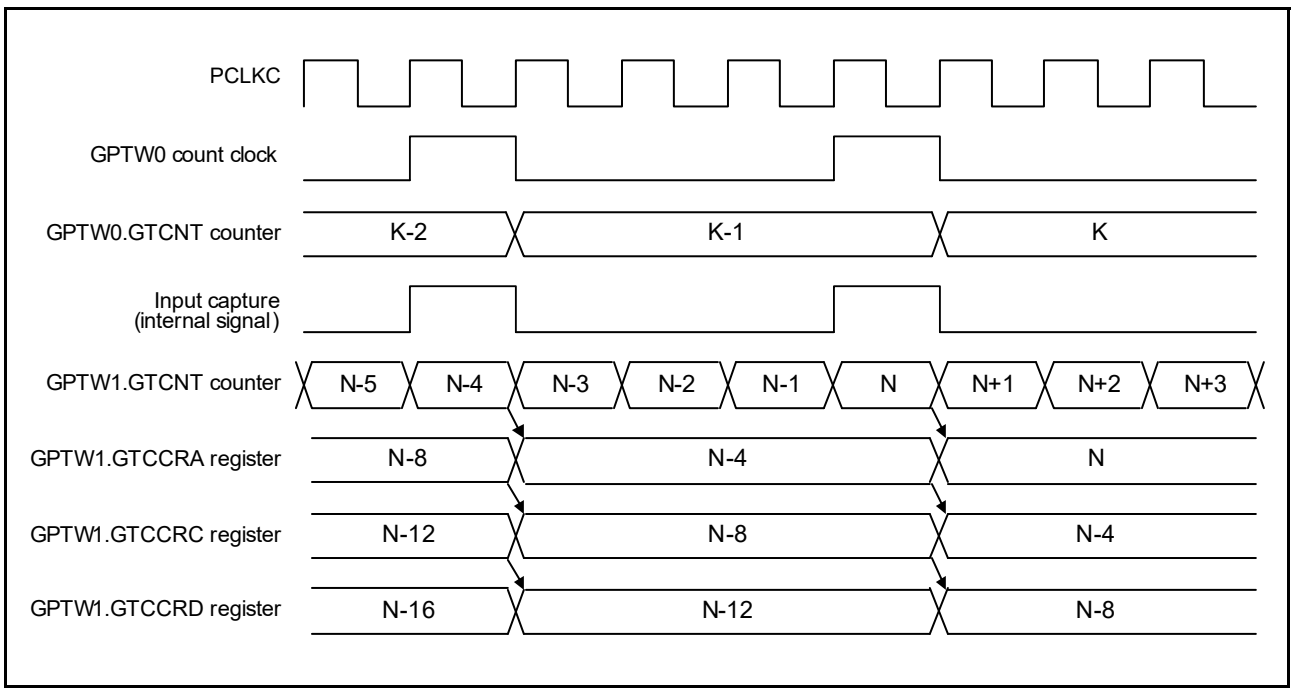

Figure 24.24 Example of the Timing of Input Capture Operation in Response to Count Clock from Other Channel

24.3.2 Buffer Operation

The following buffer operation can be set with the GTBER register.

- Buffer operation with the GTPR, GTPBR, and GTPDBR registers used together
- Buffer operation with the GTCCRA, GTCCRC, and GTCCRD registers used together
- Buffer operation with the GTCCRB, GTCCRE, and GTCCRF registers used together
- Buffer operation with the GTADTRA, GTADTBRA, and GTADTDBRA registers used together
- Buffer operation with the GTADTRB, GTADTBRB, and GTADTDBRB registers used together

The following buffer operation can be set with the GTDTCR register.

- Buffer operation with the GTDVU and GTDBU registers used together
- Buffer operation with the GTDVD and GTDBD registers used together

The following buffer operation can be set with the GTBER2 register.

- Buffer operation with the GTCCRA, GTCCRE, and GTCCRF registers (in complementary PWM mode 3, 4)
- Buffer operation with the GTOLBR.GTIOAB[4:0] bits and GTIOR.GTIOA[4:0] bits
- Buffer operation with the GTOLBR.GTIOBB[4:0] bits and GTIOR.GTIOB[4:0] bits

24.3.2.1 GTPR Register Buffer Operation

The GTPBR register can function as a buffer register for the GTPR register, and the GTPDBR register can function as a buffer register for the GTPBR register (double buffer register for the GTPR register).
In complementary PWM mode, the buffer transfer from the GTPDBR register to the temporary register P is performed only in the master channel (GPTWn). The temporary register P is transferred to each GTPBR register of master channel, slave channel 1 (GPTWn+1), and slave channel 2 (GPTWn+2). Transfer from the GTPBR register to the GTPR register is made concurrently in three channels. Therefore, the same value is stored in the same register of the three channels. The GTPR register of the master channel represents the GTCNT counter's (GTCNTn) period of the master channel. In the slave channels, periods are controlled using the GTPR register value and the GTDVU register value.
The setting is invalid in the sawtooth-wave PWM mode 2.
The buffer transfer is performed at an overflow (in up-counting) or underflow (in down-counting) in sawtooth-wave mode or in event counting, or at a trough in triangle-wave mode.
When in sawtooth-wave mode and in event counting, the buffer transfer is performed even when the counter clearing occurs during the count is in operation.

- Hardware source clearing

(Clear source selected with GTCSR.CSGTRGAR, CSGTRGAF, CSGTRGBR, CSGTRGBF, CSGTRGCR, CSGTRGCF, CSGTRGDR, CSGTRGDF, CSCARBL, CSCARBH, CSCAFBL, CSCAFBH, CSCBRAL, CSCBRAH, CSCBFAL, CSCBFAH, CSELCA, CSELCB, CSELCC, CSELCD, CSELCE, CSELCF, CSELCG, CSELCH, CSCMSC[2:0], or CP1CCE bit)

- Clearing by software

(When the GTCLR.CCLRn bit is written to 1 during the GTCSR.CCLR bit is set to 1) (n = 0 to 7)
In the case of sawtooth waves, the buffer transfer by clearing counter can by prohibited by the GTBER2.CCTPR bit.
Figure 24.10 shows the buffer transfer timing in the complementary PWM mode.

Table 24.11 The GTPR Buffer Transfer Timing in Complementary PWM Mode

Mode	Complementary PWM mode 1	Complementary PWM mode 2	Complementary PWM mode 3 Complementary PWM mode 4
GTPDBR register ↓ Temporary register P	After PCLKC 1 clock from the GTCCRD register write of slave channel 2 (GPTWn+2)	After PCLKC 1 clock from the GTCCRD register write of slave channel 2 (GPTWn+2)	After PCLKC 1 clock from the GTCCRD register write of slave channel 2 (GPTWn+2)
Temporary register P ↓ GTPBR register	When data is transferred to the temporary register P during up-counting middle • After PCLKC 1 clock from data transfer to the temporary register P When data is transferred to the temporary register P during a section other than up-counting middle • At the end of trough	When data is transferred to the temporary register P during down-counting middle • After PCLKC 1 clock from data transfer to the temporary register P When data is transferred to the temporary register P during a section other than down-counting middle • At the end of crest	When data is transferred to the temporary register P middle • After PCLKC 1 clock from data transfer to the temporary register P When data is transferred to the temporary register P during a section other than middle • At the end of crest/trough
GTPBR register ↓ GTPR register	At the end of crest • Counter clearing in an up-counting middle or crest section, including counter clearing enabled by setting the GTCSR.CP1CCE bit	At the end of trough • Counter clearing in a down-counting middle or trough section	At the end of crest At the end of trough • Counter clearing

To set the GTPR register to function as double buffer, set the GTBER.PR[1:0] bits to 10b or 11b. For single buffer operation, set 01b. Not to function as buffer, set 00b.
In complementary PWM mode, complementary PWM mode-specific buffer operation is performed regardless of the GTBER.PR[1:0] bit setting.
Figure 24.25 to Figure 24.27 show examples of the GTPR register buffer operation and Figure 24.31 shows an example for setting the GTPR register buffer operation.
For details of operation settings in complementary PWM mode, refer to section 24.3.3, PWM Output Operating Mode

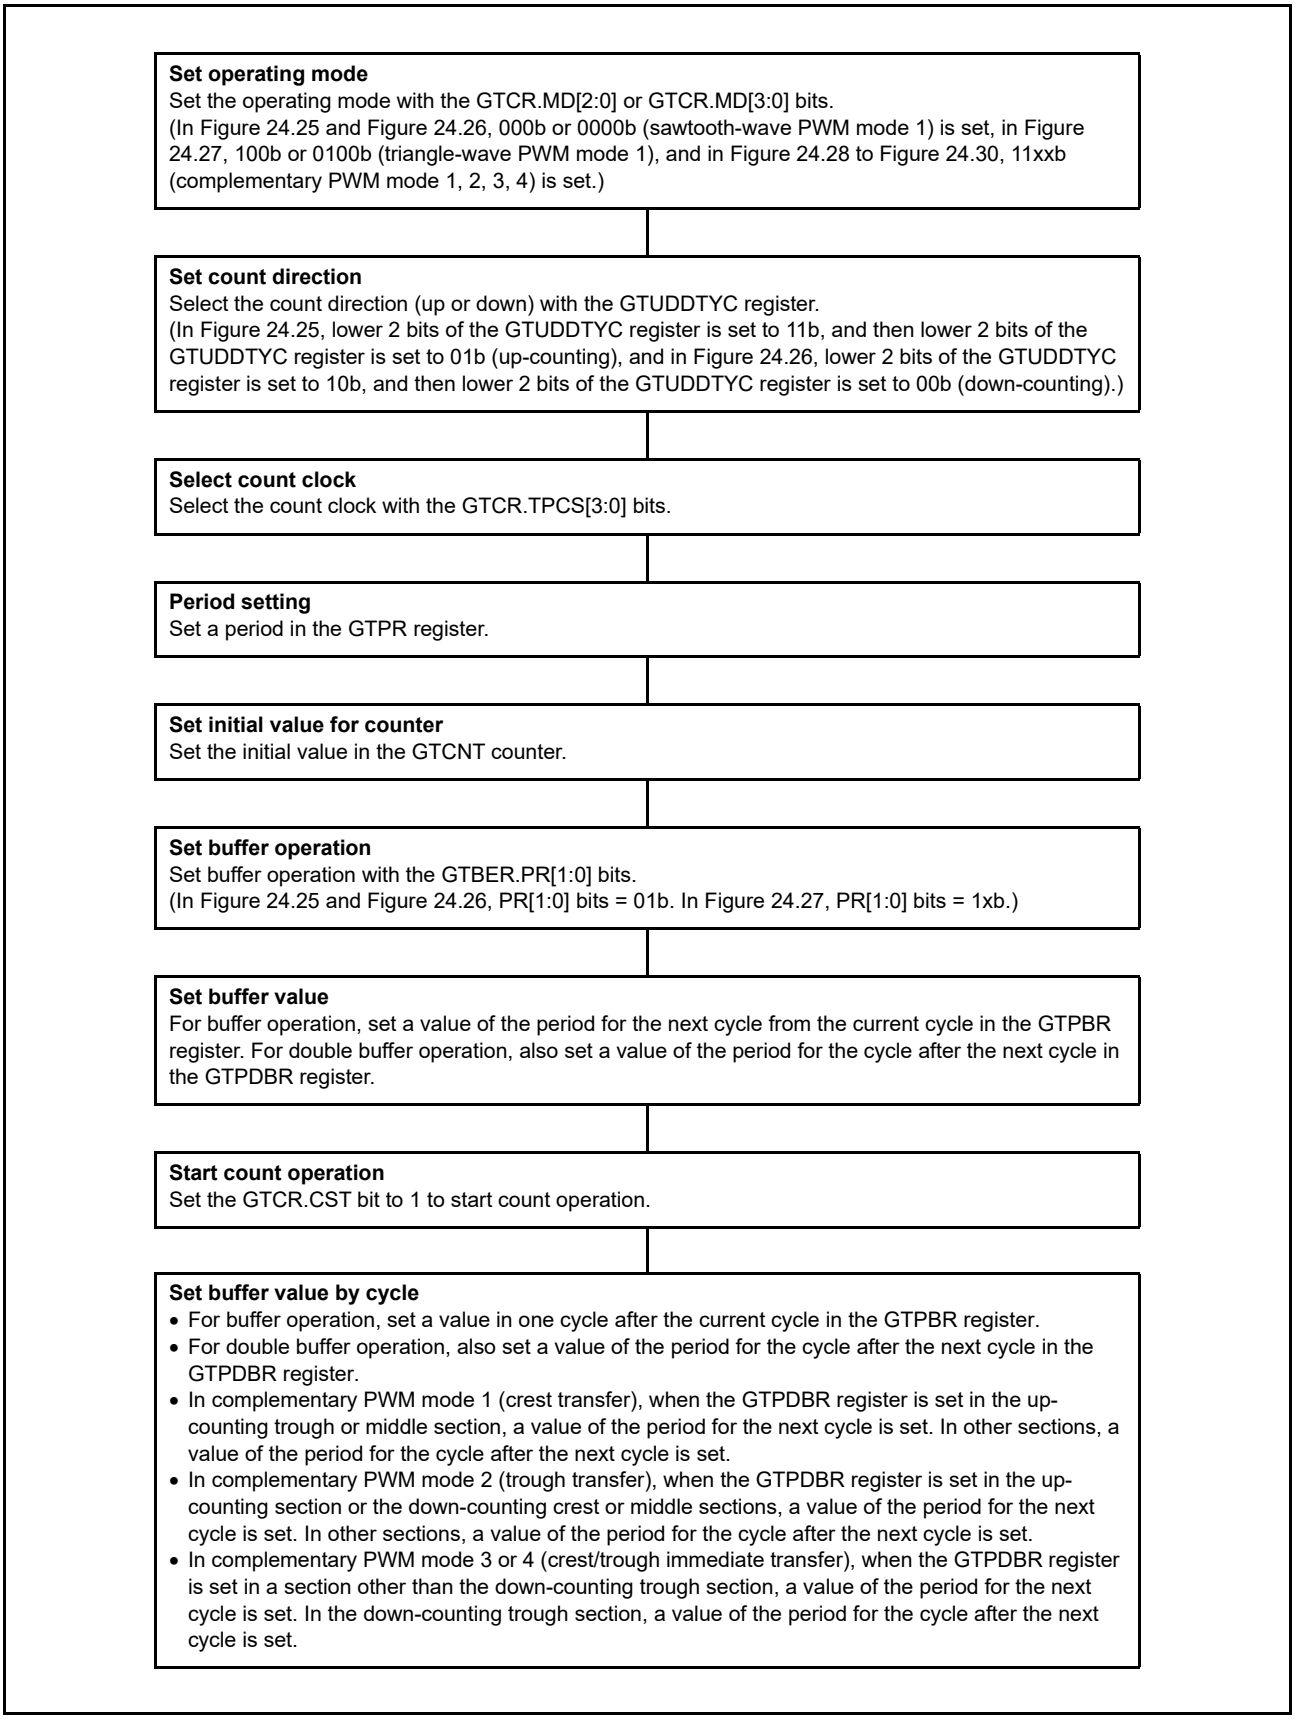

Figure 24.31 Example for Setting the GTPR Register Buffer Operation

24.3.2.2 Buffer Operation for the GTCCRA and GTCCRB Registers

The GTCCRC register can function as the GTCCRA buffer register and the GTCCRD register can function as the GTCCRC buffer register (double buffer register for the GTCCRA register). Similarly, the GTCCRE register can function as the GTCCRB buffer register and the GTCCRF register can function as the GTCCRE buffer register (double buffer register for the GTCCRB register).
To set the GTCCRA or GTCCRB register to function as a double buffer, set the GTBER.CCRA[1:0] or GTBER.CCRB[1:0] bits to 10b or 11b. For single buffer operation, set 01b. Not to function as buffer, set 00b.
The following describes buffer operation during output compare and input capture operation.
In sawtooth-wave one-shot pulse mode, triangle-wave PWM mode 3, complementary PWM mode, the buffer operations that specific each PWM output operation mode are performed regardless of the setting of GTBER.CCRA[1:0] bits and GTBER.CCRB[1:0] bits.

(1) When the GTCCRA or GTCCRB Register Functions as Output Compare Register

In sawtooth-wave one-shot pulse mode, triangle-wave PWM mode 3, complementary PWM mode, the buffer operations that specific each PWM output operation mode are performed regardless of the setting of GTBER.CCRA[1:0] bits and GTBER.CCRB[1:0] bits. For details, refer section 24.3.3, PWM Output Operating Mode. Other than above PWM output operation mode, buffer transfer is performed for the following three cases:

- Buffer transfer at an overflow (in up-counting) and underflow (in down-counting)
  Buffer transfer is performed at an overflow (in up-counting) or an underflow (in down-counting) in sawtooth-wave mode and in event counting, and at a trough (triangle-wave PWM mode 1) or at a crest/trough (triangle-wave PWM mode 2) in triangle-wave mode.
- Buffer transfer by counter clearing
  In sawtooth-wave mode and in event counting, the buffer transfer by similar counter clearing sources in counting operation and in section 24.3.2.1, GTPR Register Buffer Operation is performed in the same way at an overflow (in up-counting) or an underflow (in down-counting).
  In sawtooth-wave, the buffer transfer of GTCCRm register by counter clearing is possible to be disabled with GTBER2.CCTCm bit (m = A, B).
  In triangle-wave mode, buffer transfer by counter clearing is not performed.
- Buffer transfer by compare match
  In sawtooth-wave, the buffer transfer by the compare match of GTCCRm register enabled by GTBER2.CMTCm (m = A, B) bit is performed.
- Forcible buffer transfer
  In both sawtooth-wave mode and triangle-wave mode, buffer transfer of the GTCCRA and GTCCRB registers is forcibly performed by writing 1 to the GTBER.CCRSWT bit while the counting is stopped.
  In sawtooth-wave one-shot pulse mode and triangle-wave PWM mode 3, buffer transfer from the GTCCRD register to the temporary register A and from the GTCCRF register to the temporary register B is also performed using the forcible buffer operation.

When the setting of the GTBER.DBRTECm (m = A, B) bit is 1 in sawtooth-wave one-shot pulse mode or triangle-wave PWM mode 3, transfer from the intermediate buffers to the GTCCRm (m = A, B) registers is repeated on a cyclic basis even while buffer transfer is disabled by the setting of the GTBER.BD[0] bit or buffer transfer extended skipping function (function for repeated double-buffer operation while buffer transfer is disabled). For details, refer to section 24.8.2.2, Repeated Double-Buffered Operation When Disabling GTCCR Buffer Transfer.
Figure 24.32 to Figure 24.35 show examples of the GTCCRA and GTCCRB registers buffer operations, and Figure 24.36 shows an example for setting the GTCCRA and GTCCRB registers buffer operations.

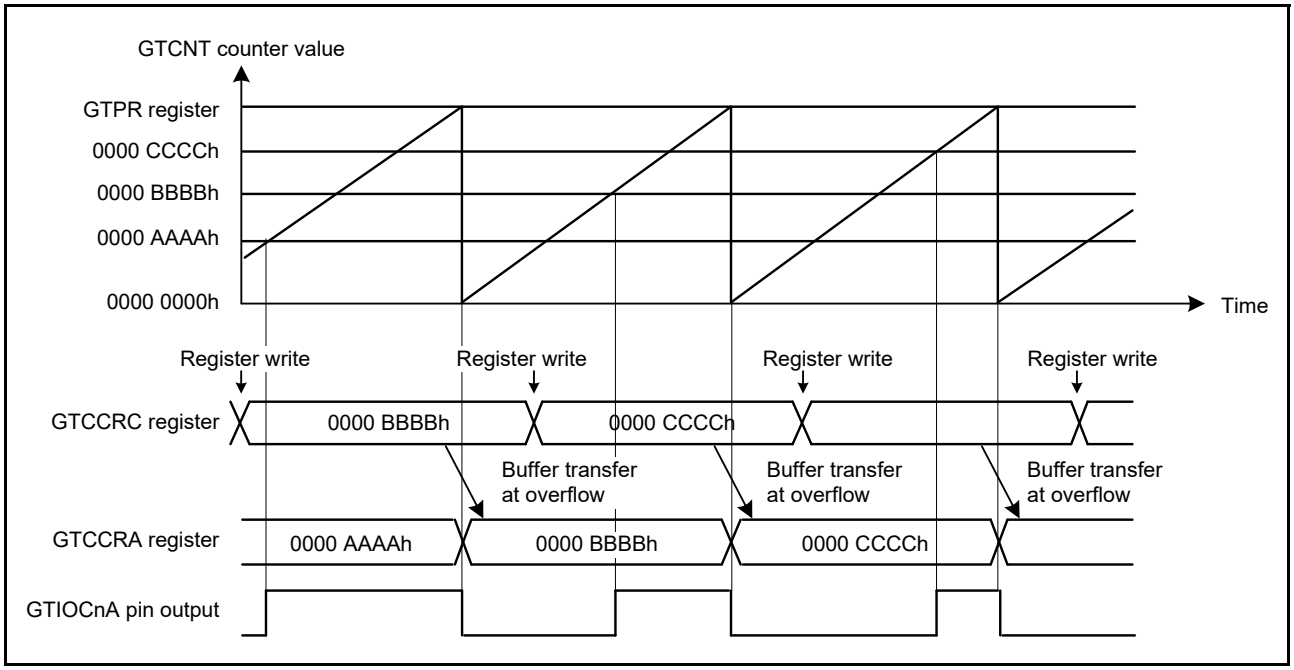

Figure 24.32 Example of GTCCRA and GTCCRB Registers Buffer Operation (Output Compare, Sawtooth-Waves, Sawtooth-Wave PWM mode 1 in Up-Counting, High Output at GTCCRA Register Compare Match, Low Output at the End of the Cycle) (n = 0 to 7)

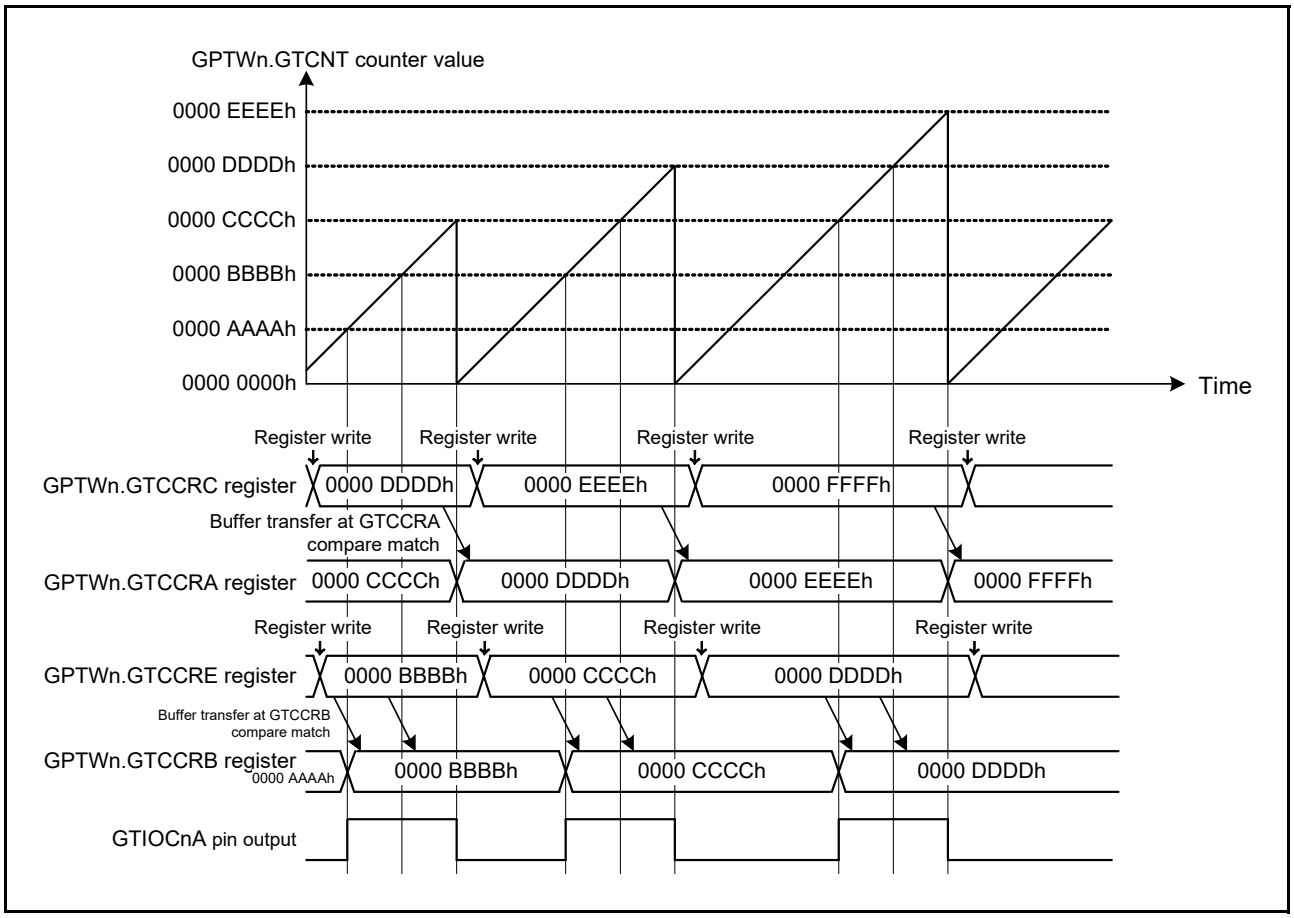

Figure 24.33 Example of GTCCRA and GTCCRB Registers Buffer Operation (Output Compare, Sawtooth-Wave PWM mode 2, Buffer Transfer at GTCCRA Register Compare Match, Counter Clearing, Low Output, Buffer Transfer at GTCCRB Register Compare Match, High Output) (n = 0 to 7)

n = 0 to 7; m = A, B

Note1. When using high resolution PWM waveform generation circuit, change the order of setting for the GTIOCnm pin output enable and setting for a compare match value.

Figure 24.36 Example for Setting Buffer Operation of the GTCCRA and GTCCRB Registers (for Output Compare)

(2) When the GTCCRA or GTCCRB Register Functions as Input Capture Register

The timing of transfer to the buffers is when an input capture is generated. When an input capture is generated, the GTCNT counter value is transferred to GTCCRA and GTCCRB registers and the stored GTCCRA and GTCCRB registers values are transferred to buffer registers. Buffer transfer by counter clearing is not performed at input capture. Figure 24.37 and Figure 24.38 show examples of buffer operation of the GTCCRA and GTCCRB registers, and Figure 24.39 shows an example for setting buffer operation of the GTCCRA and GTCCRB registers.

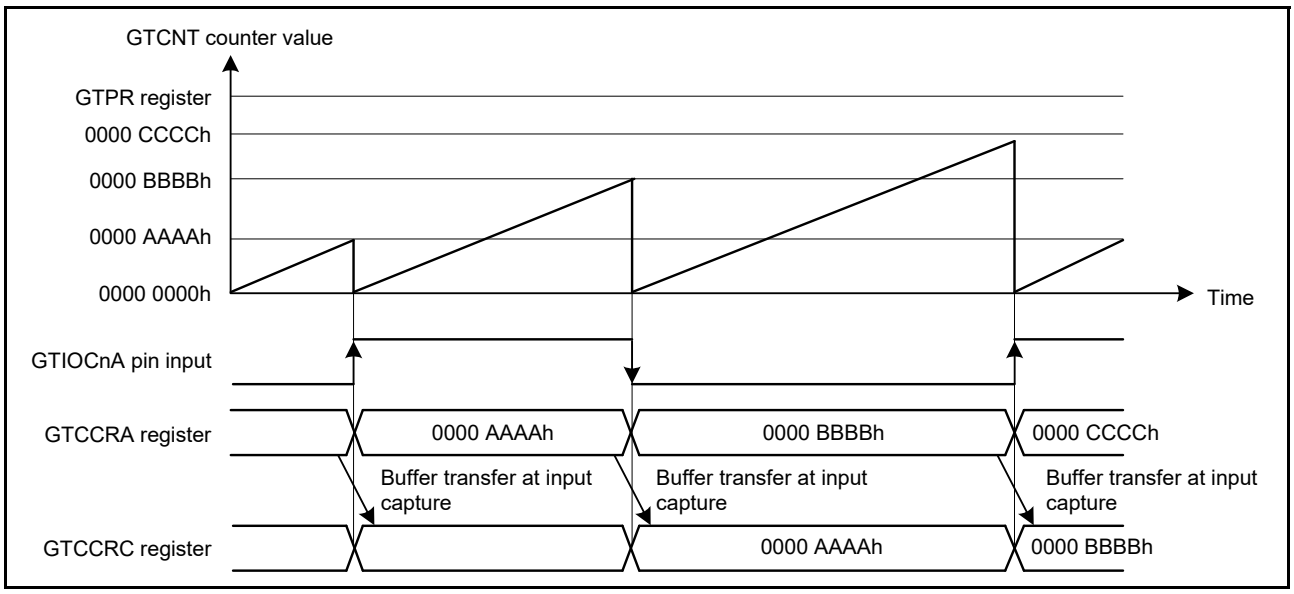

Figure 24.37 Example of Buffer Operation of the GTCCRA and GTCCRB Registers (Counting up to Produce a Sawtooth Wave, and Clearing the GTCNT Counter and Input Capture on Both Edges of the Input on the GTIOCnA Pin) (n = 0 to 7)

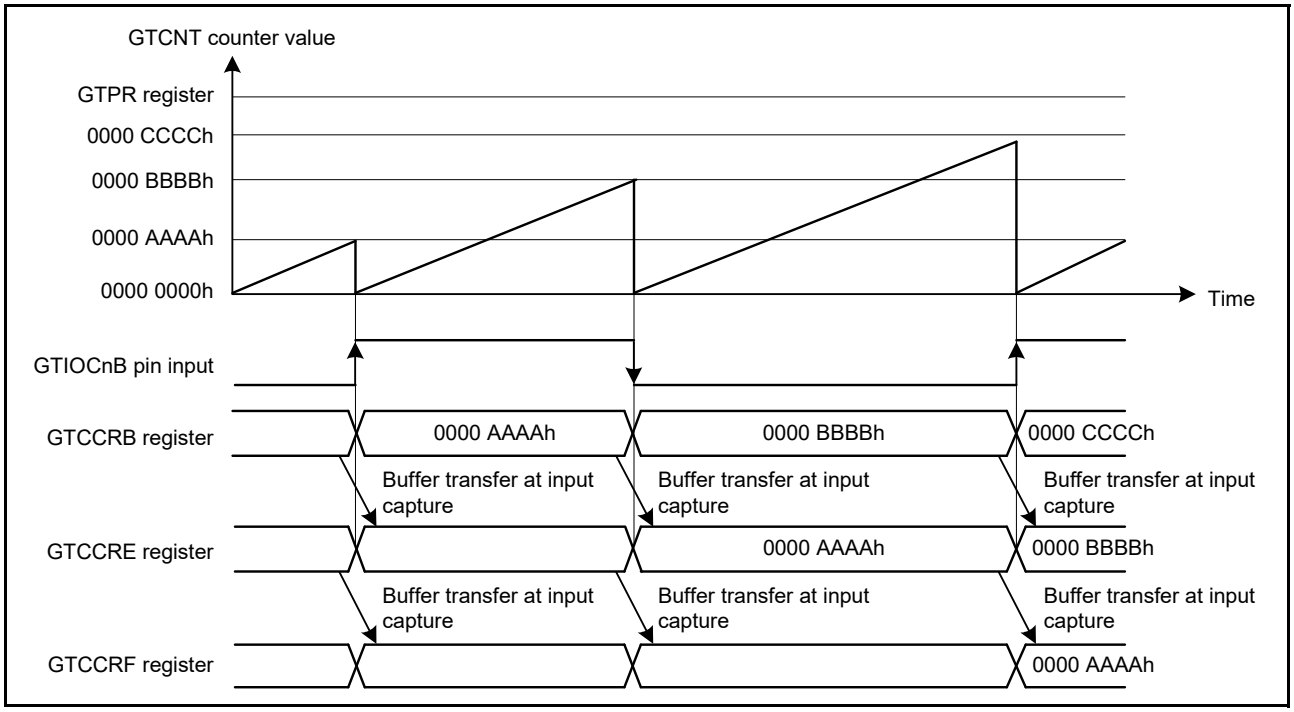

Figure 24.38 Example of Double Buffer Operation of the GTCCRA and GTCCRB Registers (Counting up to Produce a Sawtooth Wave, and Clearing the GTCNT Counter and Input Capture on Both Edges of the Input on the GTIOCnB Pin) (n = 0 to 7)

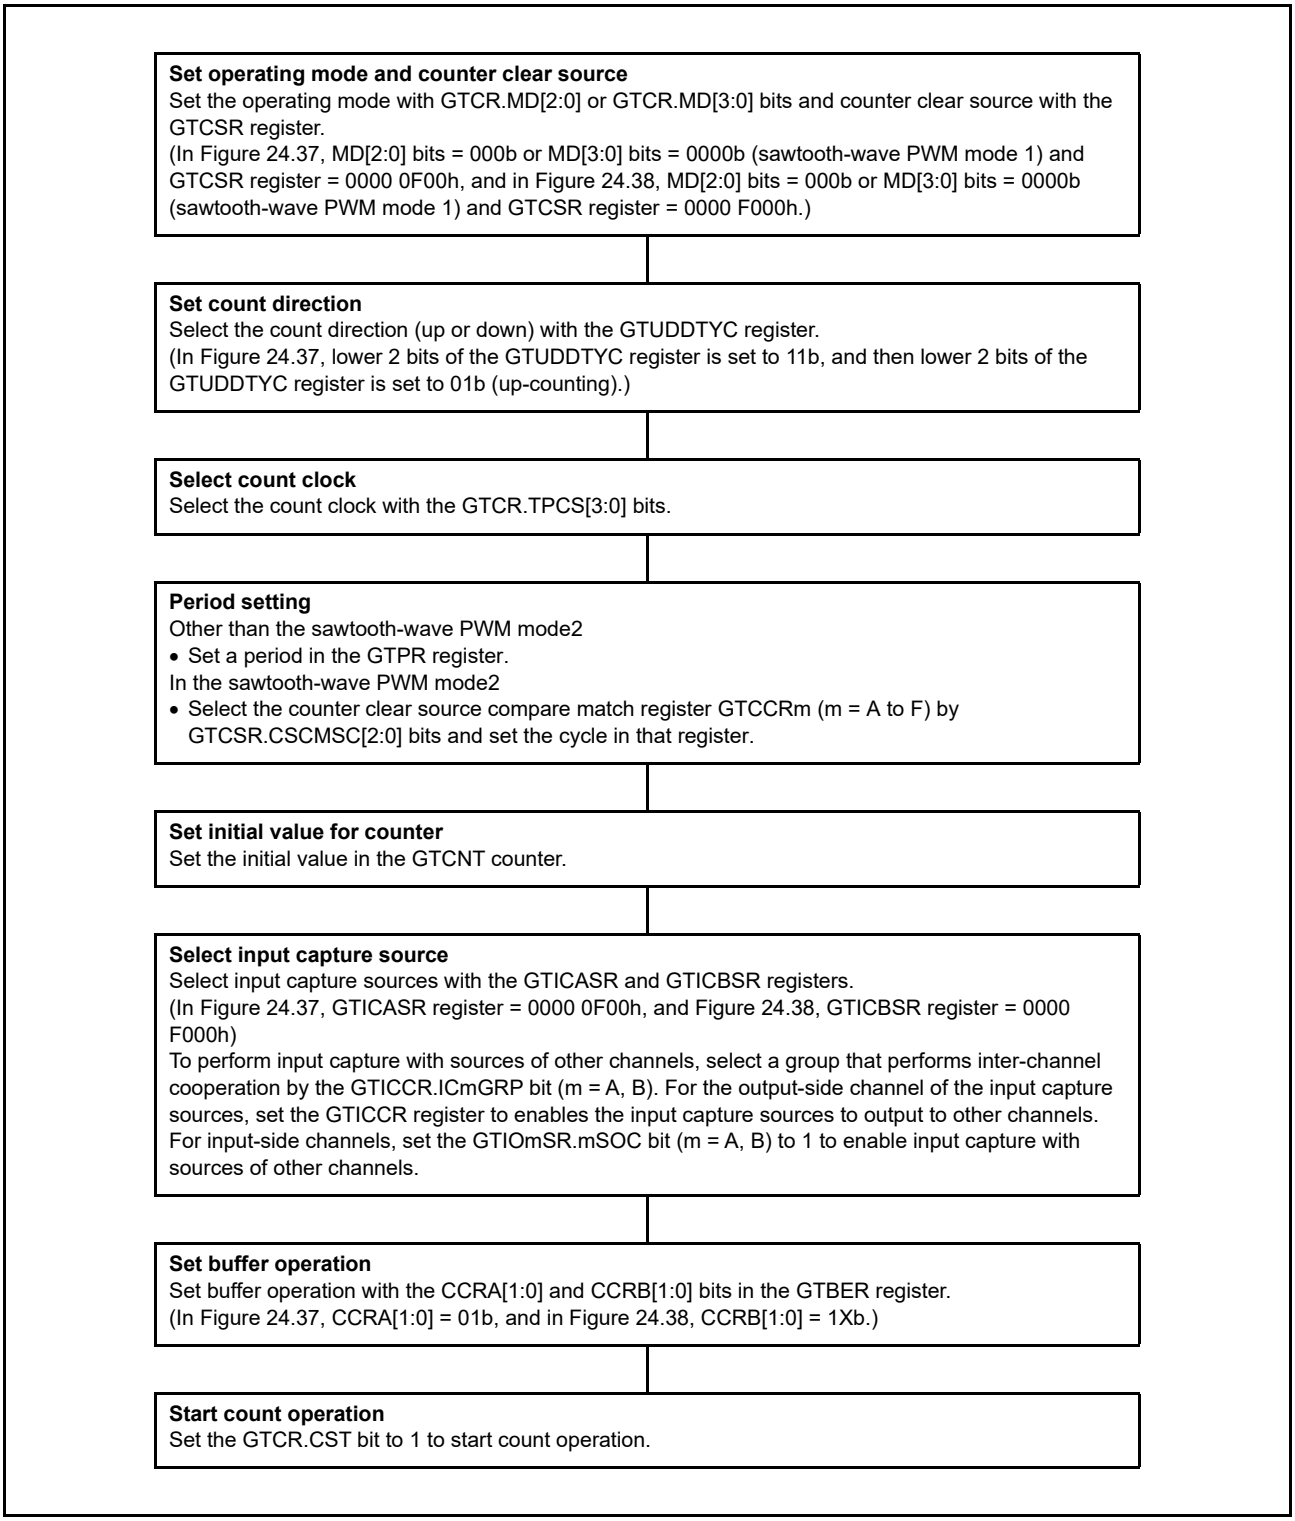

Figure 24.39 Example for Setting Buffer Operation of the GTCCRA and GTCCRB Registers (for Input Capture)

24.3.2.3 Buffer Operation for the GTADTRA and GTADTRB Registers

The GTADTBRA register can function as the GTADTRA buffer register and the GTADTDBRA register can function as the GTADTBRA buffer register (double buffer register for the GTADTRA register). Similarly, the GTADTBRB register can function as the GTADTRB buffer register and the GTADTDBRB register can function as the GTADTBRB buffer register (double buffer register for the GTADTRB register).

To set the GTADTRA or GTADTRB register to function as a double buffer, set the GTBER.ADTDA or ADTDB bit to 1. For single buffer operation, set 0. Not to function as buffer, set the GTBER.ADTTA[1:0] or ADTTB[1:0] bits to 00b.

The buffer transfer timing can be set with the ADTTA[1:0] and ADTTB[1:0] bits to an overflow (in up-counting) or an underflow (in down-counting) in sawtooth-wave mode, with ADTTA[1:0] and ADTTB[1:0] bits to 01b for a crest, to 10b for a trough, or to11b for both crest and trough in triangle-wave mode or complementary PWM mode.

In sawtooth-wave mode, when the ADTTA[1:0] and ADTTB[1:0] bits are set to value other than 00b and in count operation, the buffer transfer, by similar counter clearing sources in section 24.3.2.1, GTPR Register Buffer Operation, is performed in the same way at an overflow (in up-counting) or an underflow (in down-counting).

In complementary PWM mode, the buffer transfer is performed after one PCLK cycle from the GTCCRD register write of slave channel 2.

In sawtooth-wave mode, the buffer transfer of GTADTRm register by counter clearing can be disabled by GTBER2.CCTADm (m = A, B) bit setting.

In sawtooth-wave mode, the buffer transfer of GTADTRm register by its own compare match can be enabled by the GTBER2.CMTADm (m = A, B) bit setting.

Figure 24.40 to Figure 24.44 show examples of buffer operation of the GTADTRA and GTADTRB registers, and Figure 24.45 shows an example for setting buffer operation of the GTADTRA and GTADTRB registers.

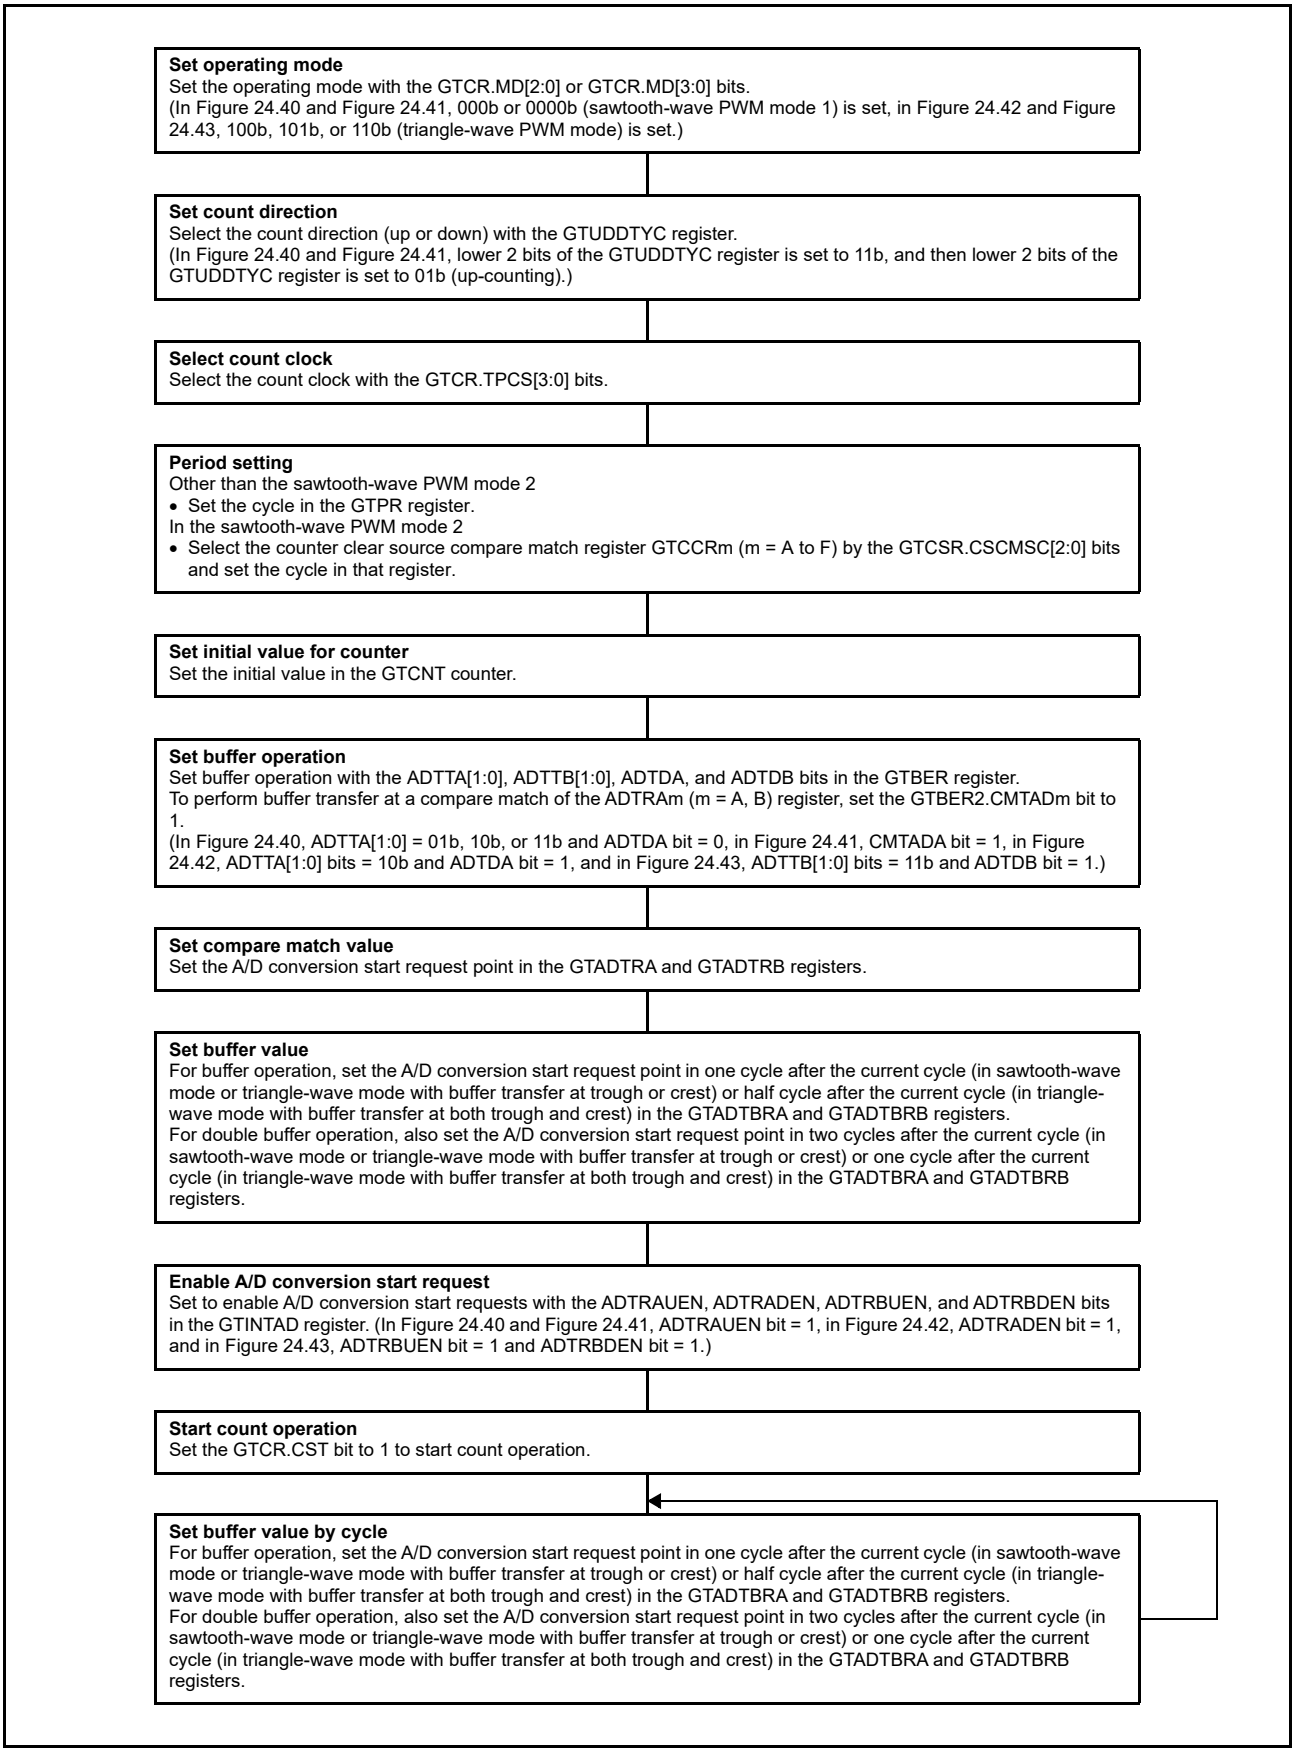

Figure 24.45 Example for Setting Buffer Operation of the GTADTRA and GTADTRB Registers

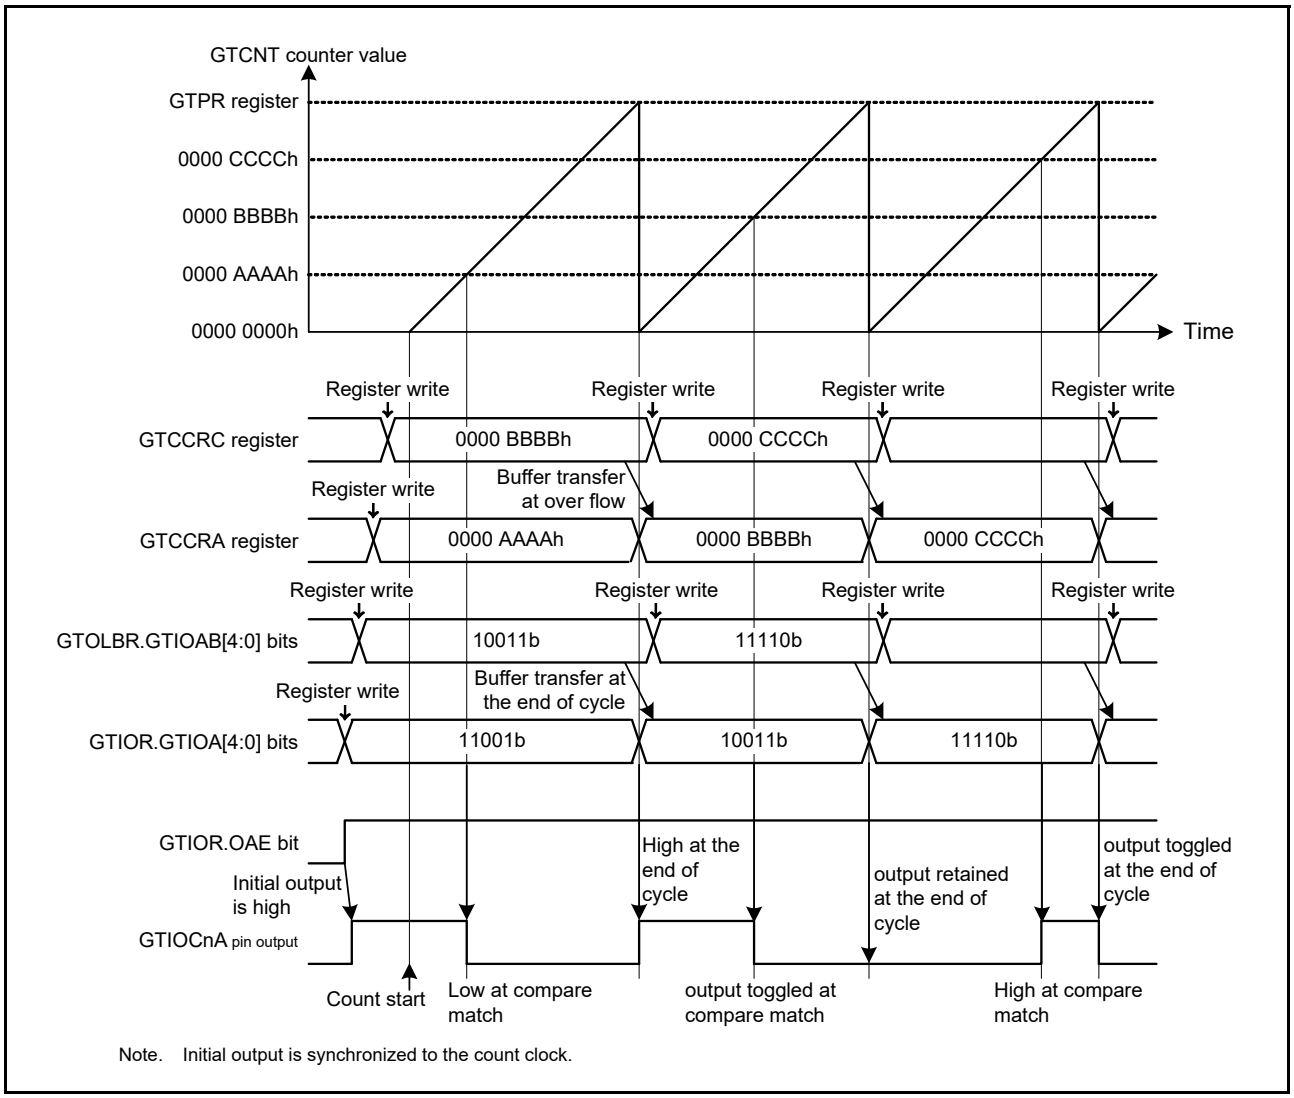
24.3.2.4 Buffer Operation for the GTIOA[4:0] and GTIOB[4:0] Bits

The GTOLBR.GTIOAB[4:0] bits can function as the buffer register of the GTIOR.GTIOA[4:0] bits and the GTOLBR.GTIOBB[4:0] bits can function as the buffer register of the GTIOR.GTIOB[4:0] bits.
Buffer transfer timing can be set with the GTBER2.OLTTm[1:0] bits (m = A, B). It can be selected from the end of cycle or GTCCR register compare match (in sawtooth-wave mode), from crest, trough, or both crest and trough (in triangle-wave mode and complementary PWM mode). In the case that the GTBER2.OLTTm[1:0] bits are 00b, buffer transfer is not performed.
In complementary PWM mode, it is prohibited to set the buffer transfer timing to overlap with the dead time. Therefore, when the buffer transfer timing is crest, set the GTCCRm (m = A, C, E) register to satisfy GTCCRm < GTPR. And when the buffer transfer timing is trough, set the GTCCRm register to satisfy GTDVU < GTCCRm.
Figure 24.46 to Figure 24.48 show examples of buffer operation of the GTIOR.GTIOA[4:0] and GTIOR.GTIOB[4:0] bits. Figure 24.49 shows an example for setting buffer operation of the GTIOR.GTIOA[4:0] and GTIOR.GTIOB[4:0] bits.



Note. Initial output is synchronized to the count clock.

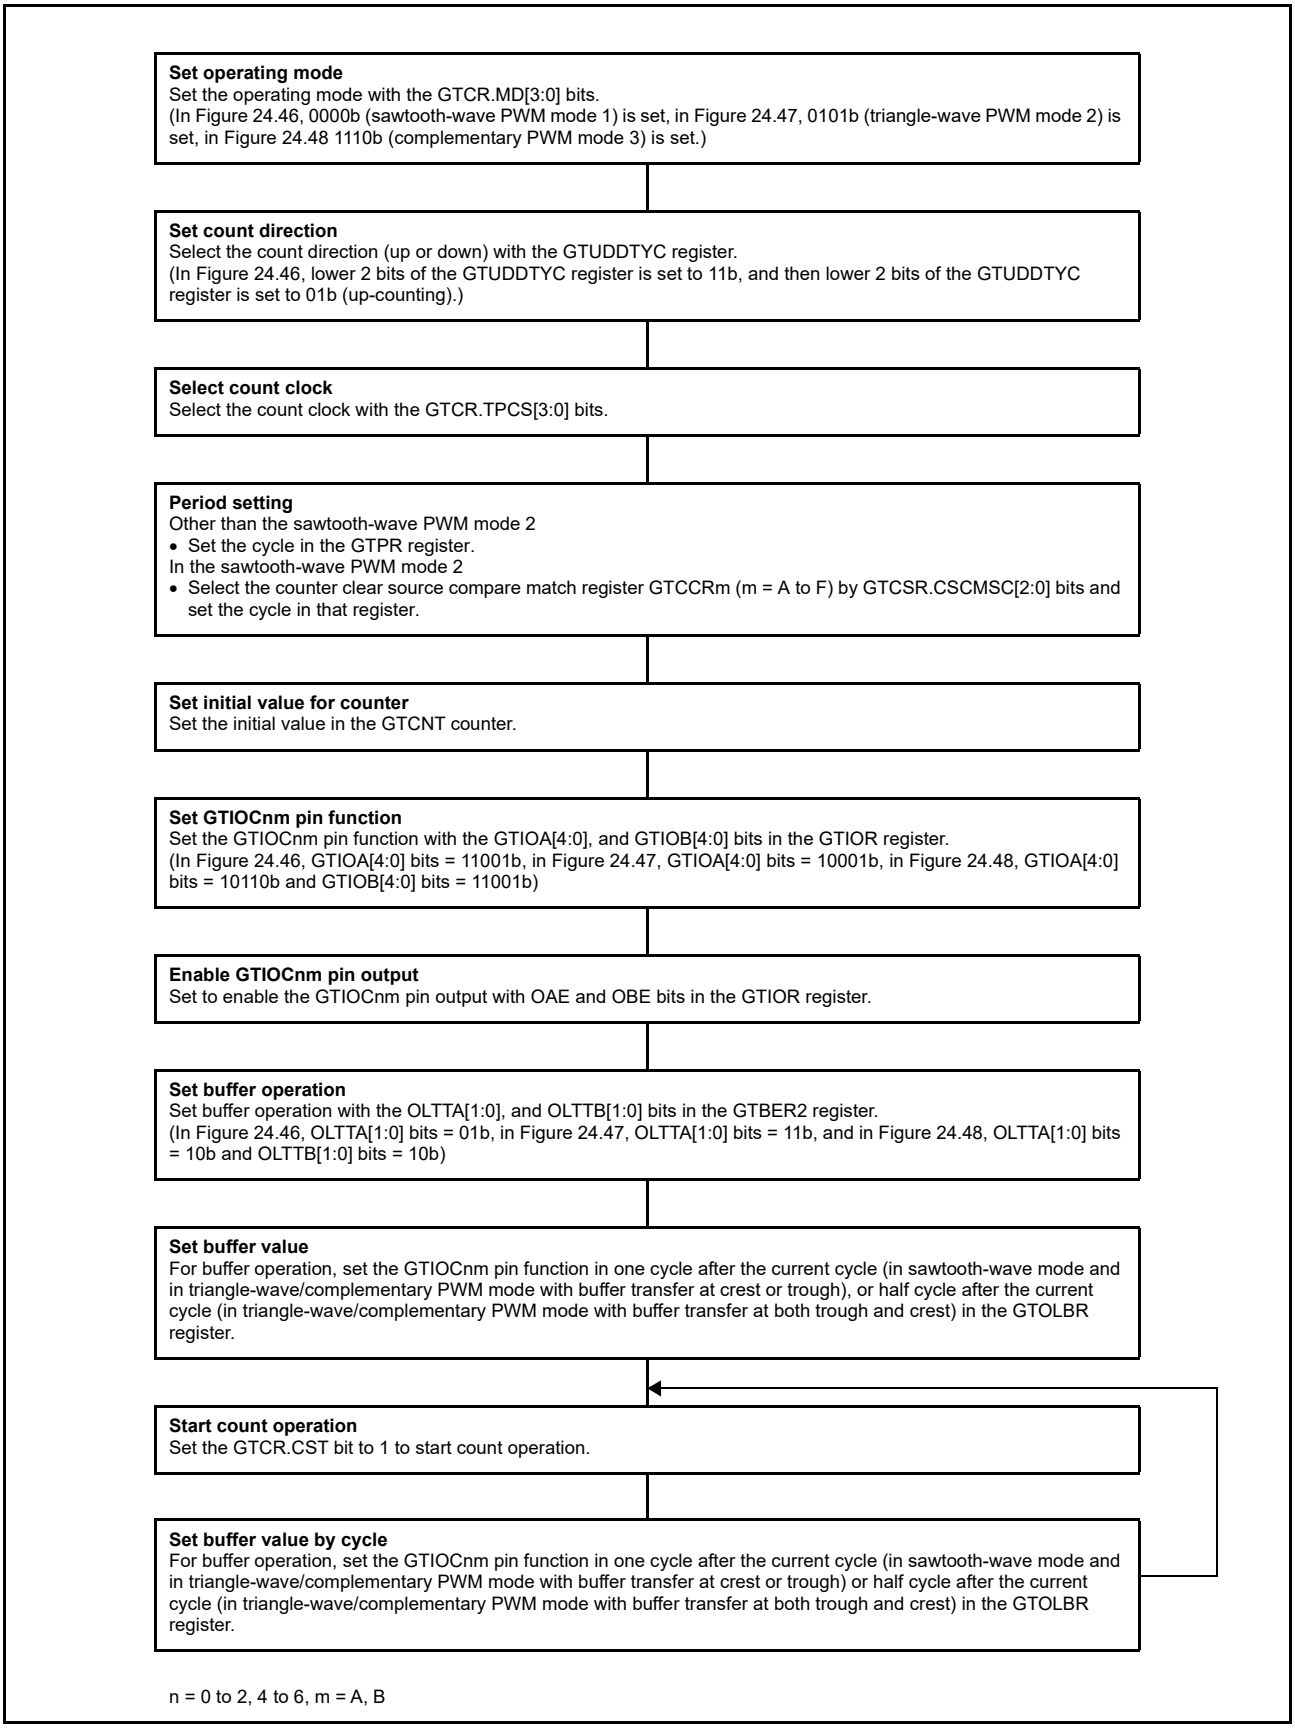

Figure 24.49 Example for Setting Buffer Operation of the GTIOA[4:0] and GTIOB[4:0] Bits

24.3.3 PWM Output Operating Mode

The GPTW can output PWM waveforms to the GTIOCnA pin or GTIOCnB pin (n = 0 to 7) by a compare match between the GTCNT counter and the GTCCRA or GTCCRB register.
By setting the GTDTCR, GTDVU, and GTDVD registers, the compare match value for a negative-phase waveform with dead time can automatically be set to the GTCCRB register.
In complementary PWM mode, it is possible to output PWM waveforms (positive phase, negative phase) with dead time that guarantees the linearity of the PWM output pulse width near 0% and 100% duty.
In sawtooth-wave mode other than sawtooth-wave PWM mode 2, or triangle-wave mode, or the master channel of complementary PWM mode, the signal synchronized with the PWM cycle can be output from the GTCPPOn output terminal by setting the GTIOR.PSYE bit to 1. The GTCPPOn output is toggled at the end of cycle in sawtooth-wave mode or at the timing of crest/trough/GTCNT counter clearing in triangle-wave mode or complementary PWM mode. The initial output of GTCPPOn is low, and it becomes high when the count starts.

(1) Sawtooth-Wave PWM Mode 1

In sawtooth-wave PWM mode 1, the GTCNT counter performs sawtooth-wave (half-wave) operation by setting the period in the GTPR register and a PWM waveform is output to the GTIOCnA or GTIOCnB pin when a GTCCRA or GTCCRB register compare match occurs. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the end of the cycle according to the GTIOR register setting.
When 0 is set in the GTIOR.OmEOCD (m = A, B) bit and the timing of the end of cycle and the timing of the GTCCRm register compare match are the same time, the output pin performs along the PWM output setting for the end of cycle set by the GTIOR.GTIOm[3:2] bits.
When 1 is set in the GTIOR.OmEOCD bit, GTIOCnm output is retained.
Figure 24.50 shows an example of sawtooth-wave PWM mode 1 operation, and Figure 24.51 shows an example for setting sawtooth-wave PWM mode 1.

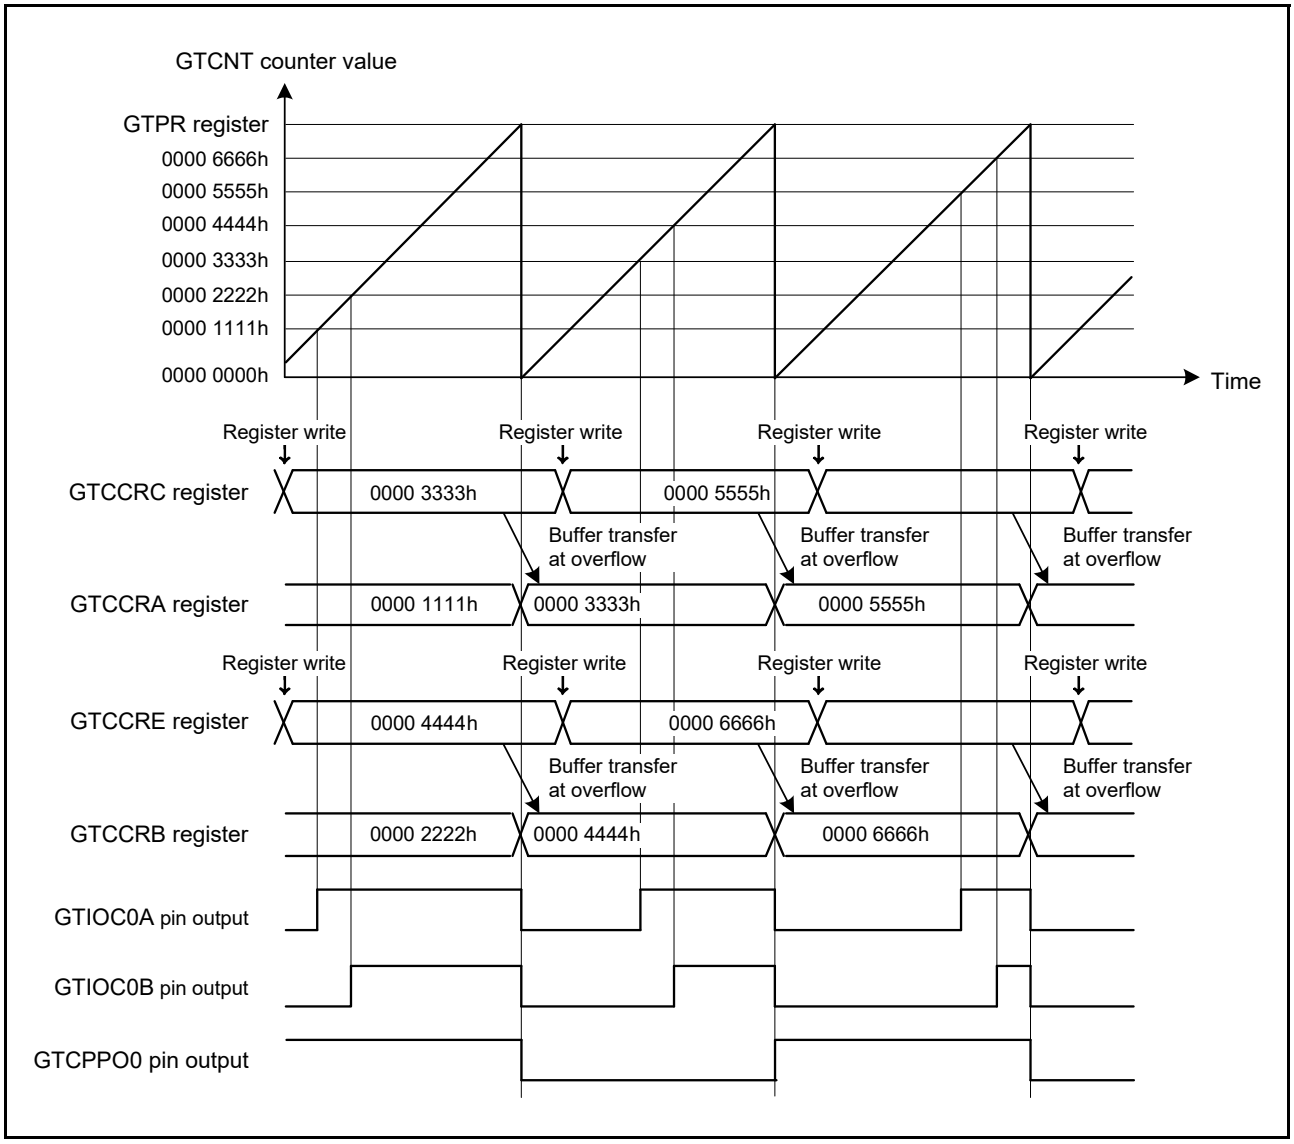

Figure 24.50 Example of Sawtooth-Wave PWM Mode Operation (Up-Counting, Buffer Operation, High Output at GTCCRA/GTCCRB Register Compare Match, Low Output at the End of the Cycle, GTIOR.PSYE = 1) (n = 0 to 7)

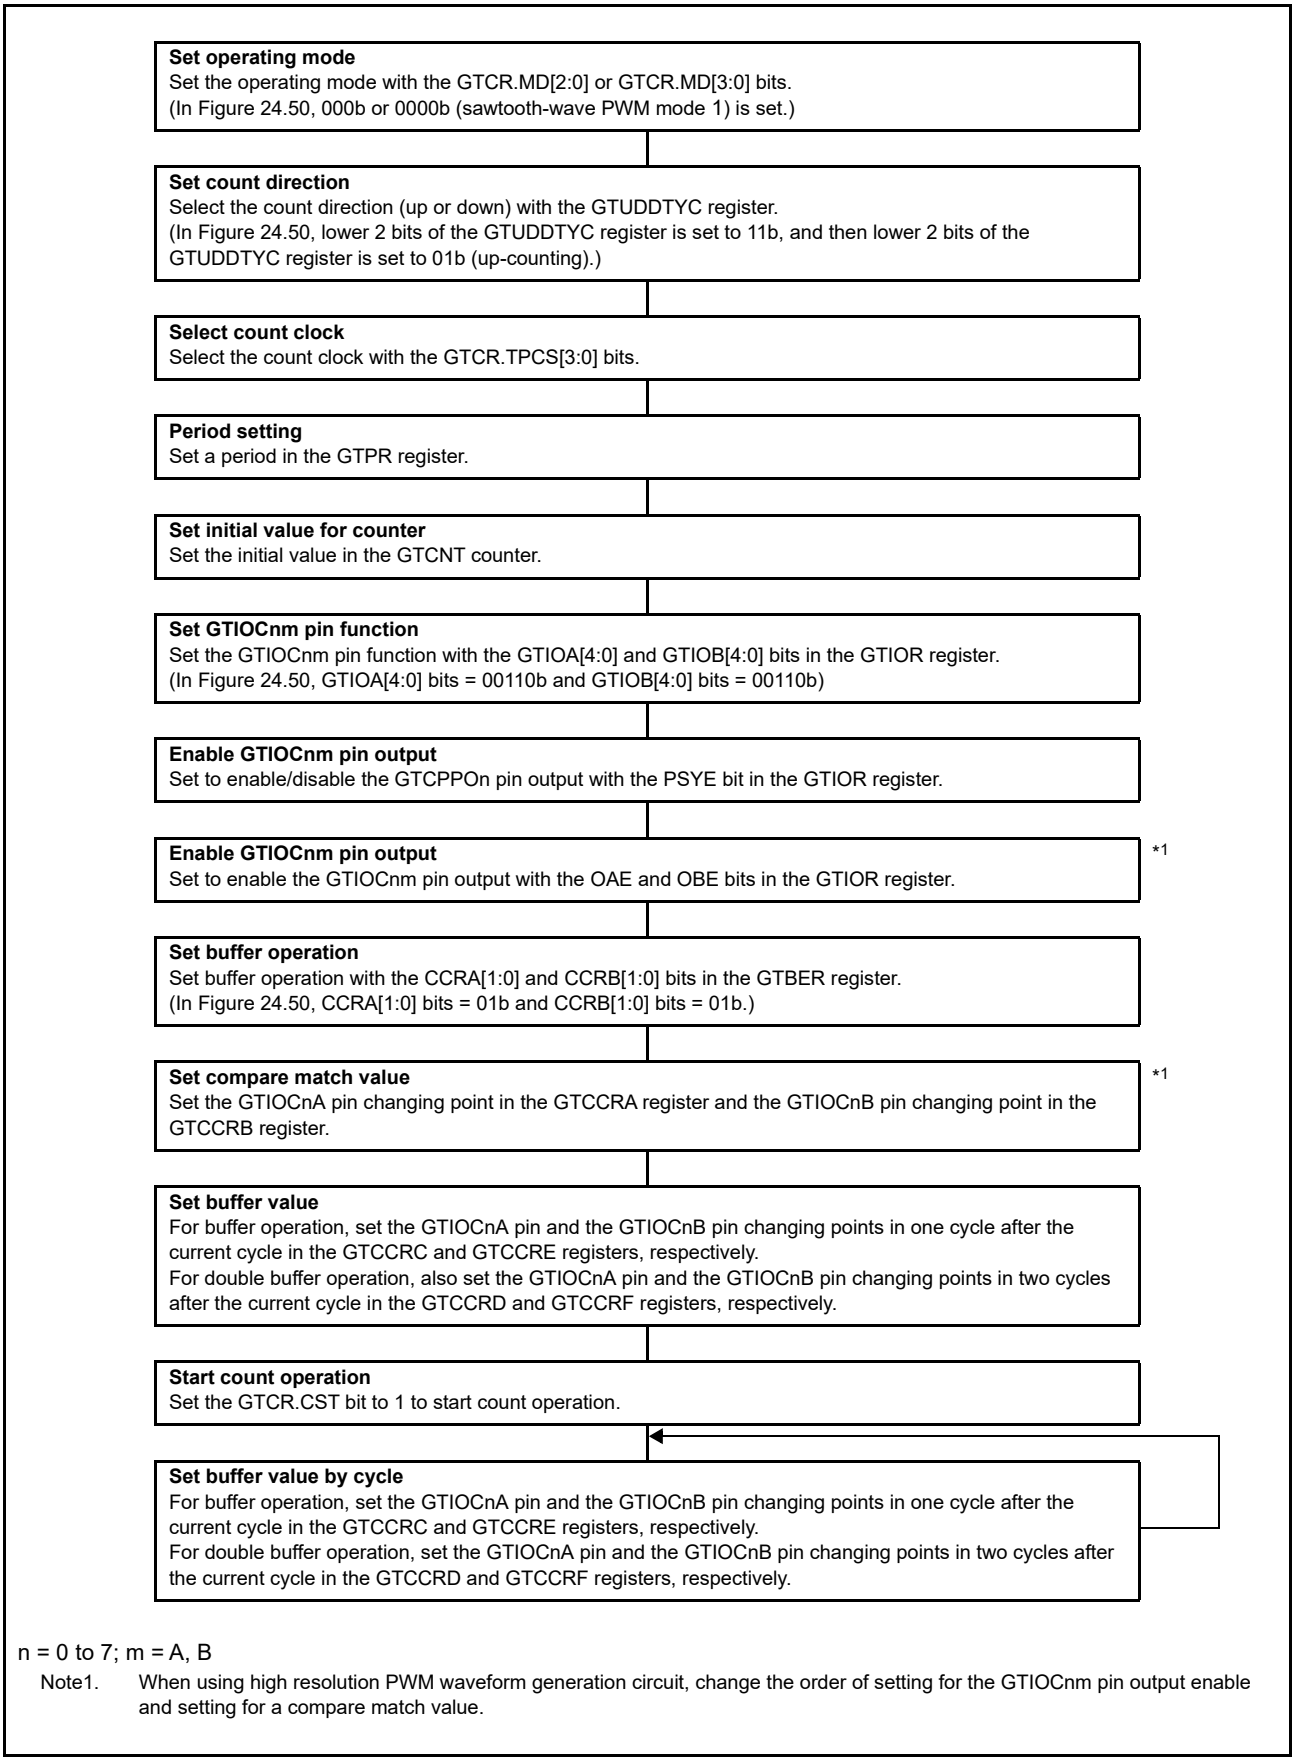

n = 0 to 7; m = A, B

Note1. When using high resolution PWM waveform generation circuit, change the order of setting for the GTIOCnm pin output enable and setting for a compare match value.

Figure 24.51 Example for Setting Sawtooth-Wave PWM Mode 1

(2) Sawtooth-Wave PWM Mode 2

The sawtooth-wave PWM mode 2 is a mode in which the GTCNT counter is operated as a sawtooth wave by up-counting without using the GTPR register, and the PWM waveform is output by the compare match of the GTCCRA and GTCCRB registers.

The pin output level can be selected from low output, high output, or toggle output separately for a compare match according to the GTIOR register setting.

The GTIOCnA (n = 0 to 2, 4 to 6) pin is used as an output pin. Use the GTIOR.GTIOB[1:0] bits for setting the GTIOCnA pin output at a compare match of the GTCCRB register.

When a counter clear occurs due to the GTCNT counter clearing source selected in the GTCSR register, this is handled at the end of cycle and PWM output operation at the end of the cycle selected with the GTIOR.GTIOA[3:2] bits is performed.

If a counter clear (at the end of cycle) conflicts with a PWM output change due to a GTCCRm (m = A, B) register compare match, PWM output operation is performed at the end of cycle (in the case of the GTIOR.OmEOCD bit = 0) or the PWM output is retained (in the case of GTIOR.OmEOCD bit = 1).

Figure 24.52 to Figure 24.54 show examples of sawtooth-wave PWM mode 2 operation. Figure 24.55 shows an example for setting sawtooth-wave PWM mode 2.

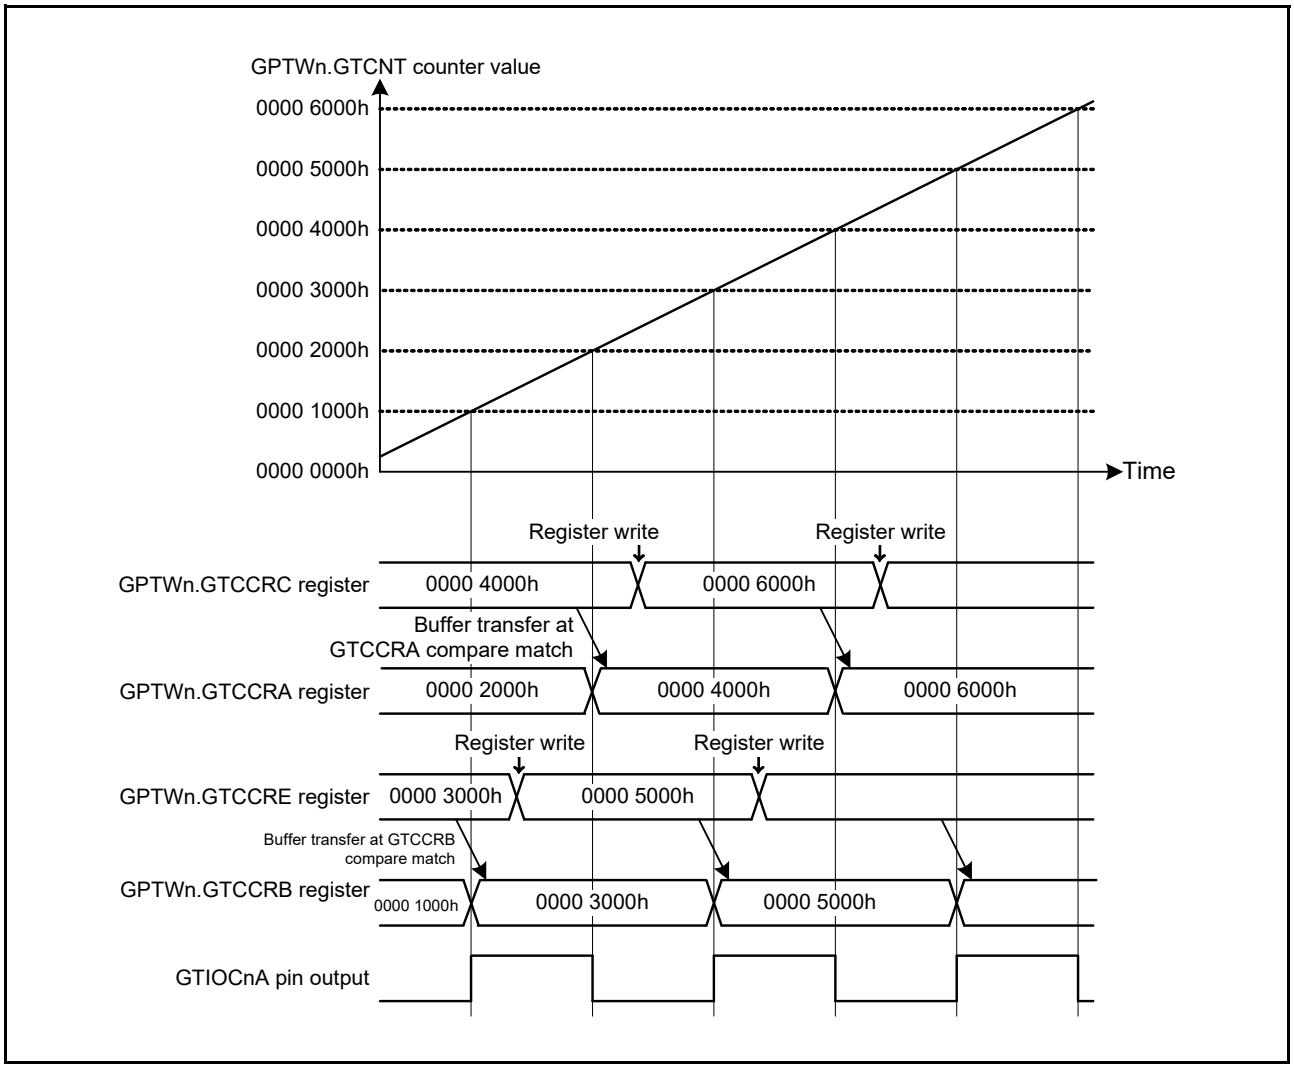

Figure 24.52 Example of Sawtooth-Wave PWM Mode 2 Operation (Low Output GTCCRA Register Compare Match, High Output at the GTCCRB Register Compare Match, Single Buffer Operation, and No Clear Setting) (n = 0 to 2, 4 to 6)

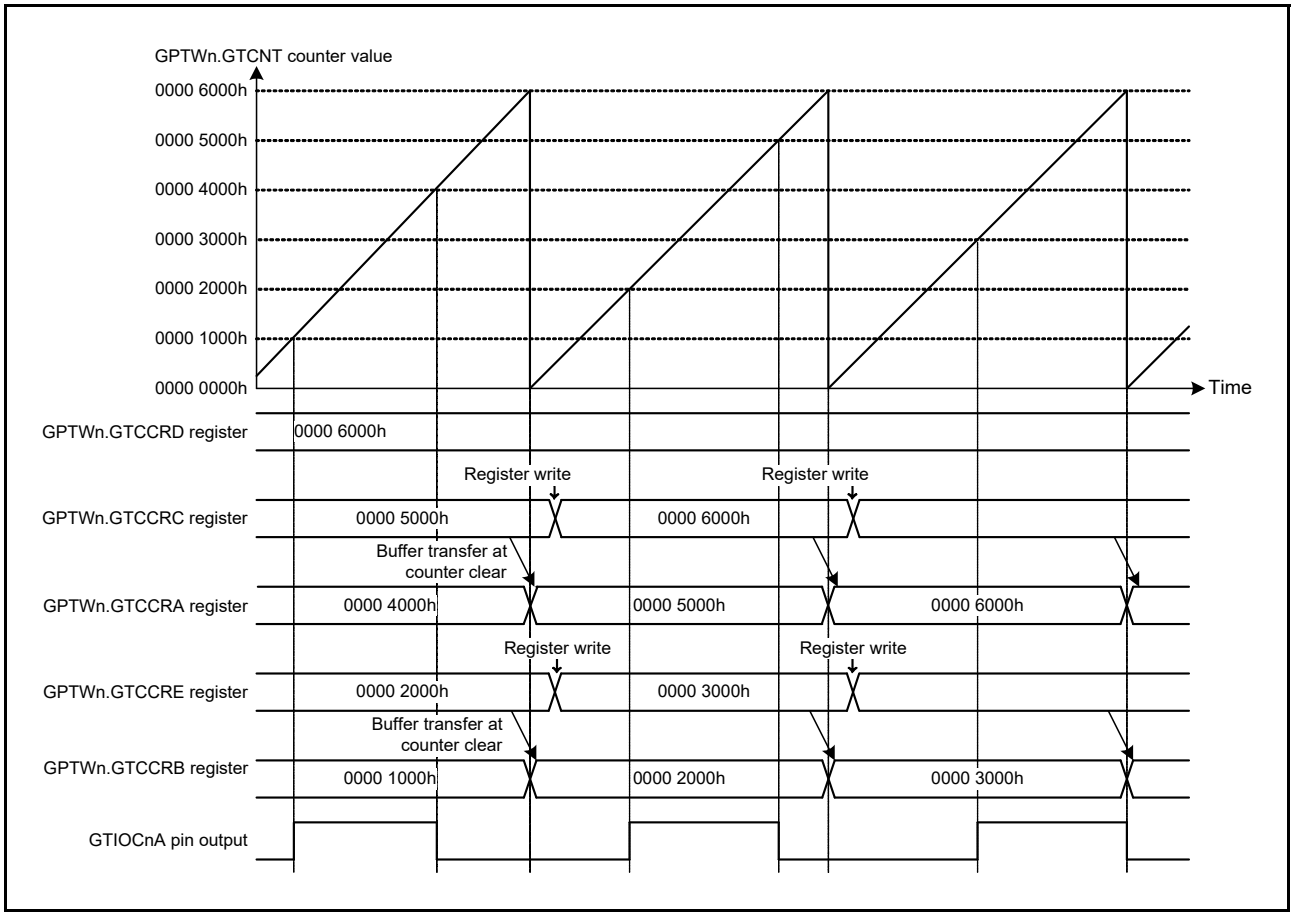

Figure 24.53 Example of Sawtooth-Wave PWM Mode 2 Operation (Low Output at the GTCCRA Register Compare Match, High Output at the GTCCRB Register Compare Match, Low Output at the End of the Cycle, Single Buffer Operation, Cleared at the GTCCRD Register Compare Match, and the GTIOR.OAEOCD Bit = 0) (n = 0 to 2, 4 to 6)

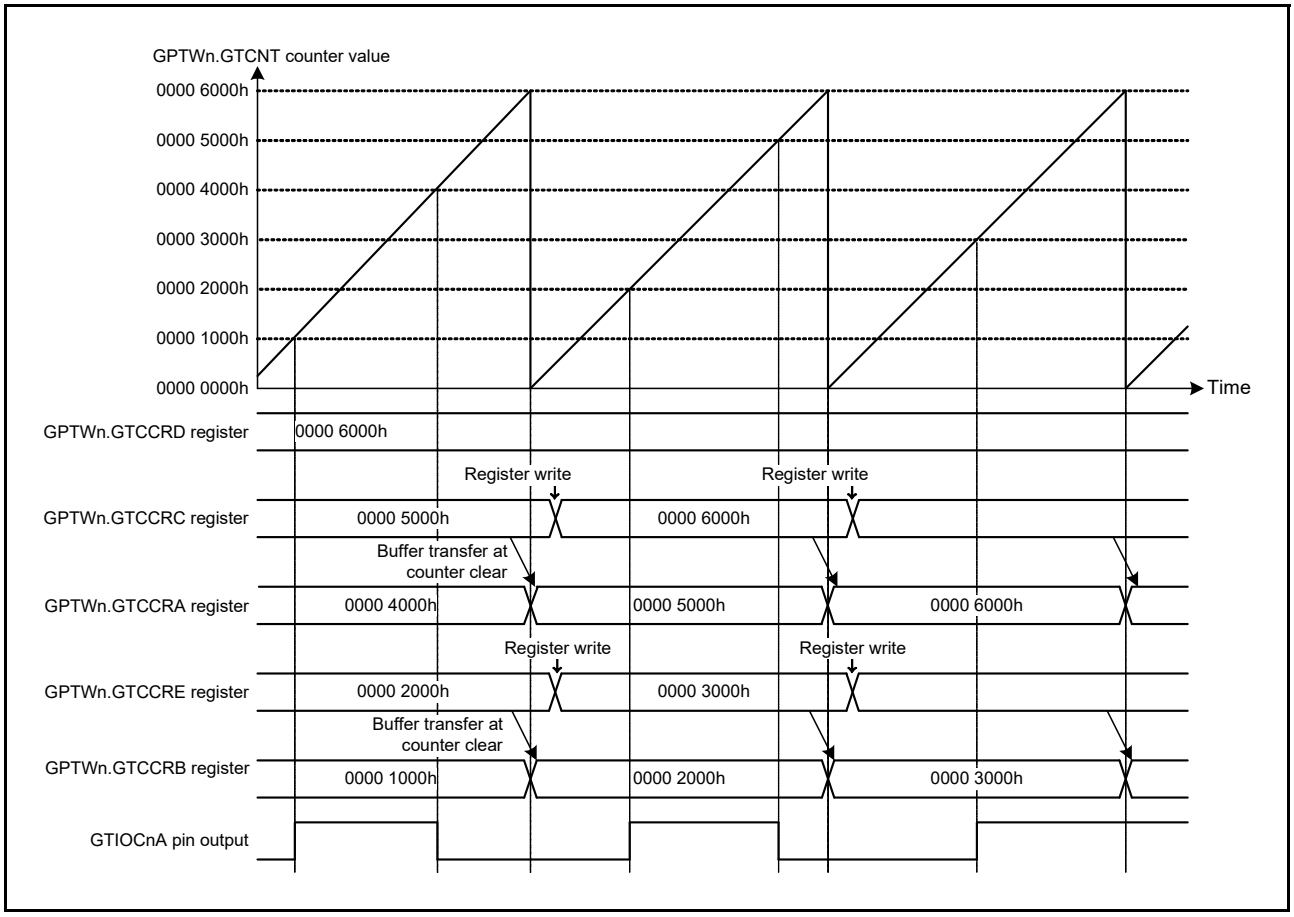

Figure 24.54 Example of Sawtooth-Wave PWM Mode 2 Operation (Low Output at the GTCCRA Register Compare Match, High Output at the GTCCRB Register Compare Match, Low Output at the End of Cycle, Single Buffer Operation, Cleared at the GTCCRD Register Compare Match, and GTIOR.OAEOCD Bit = 1) (n = 0 to 2, 4 to 6)

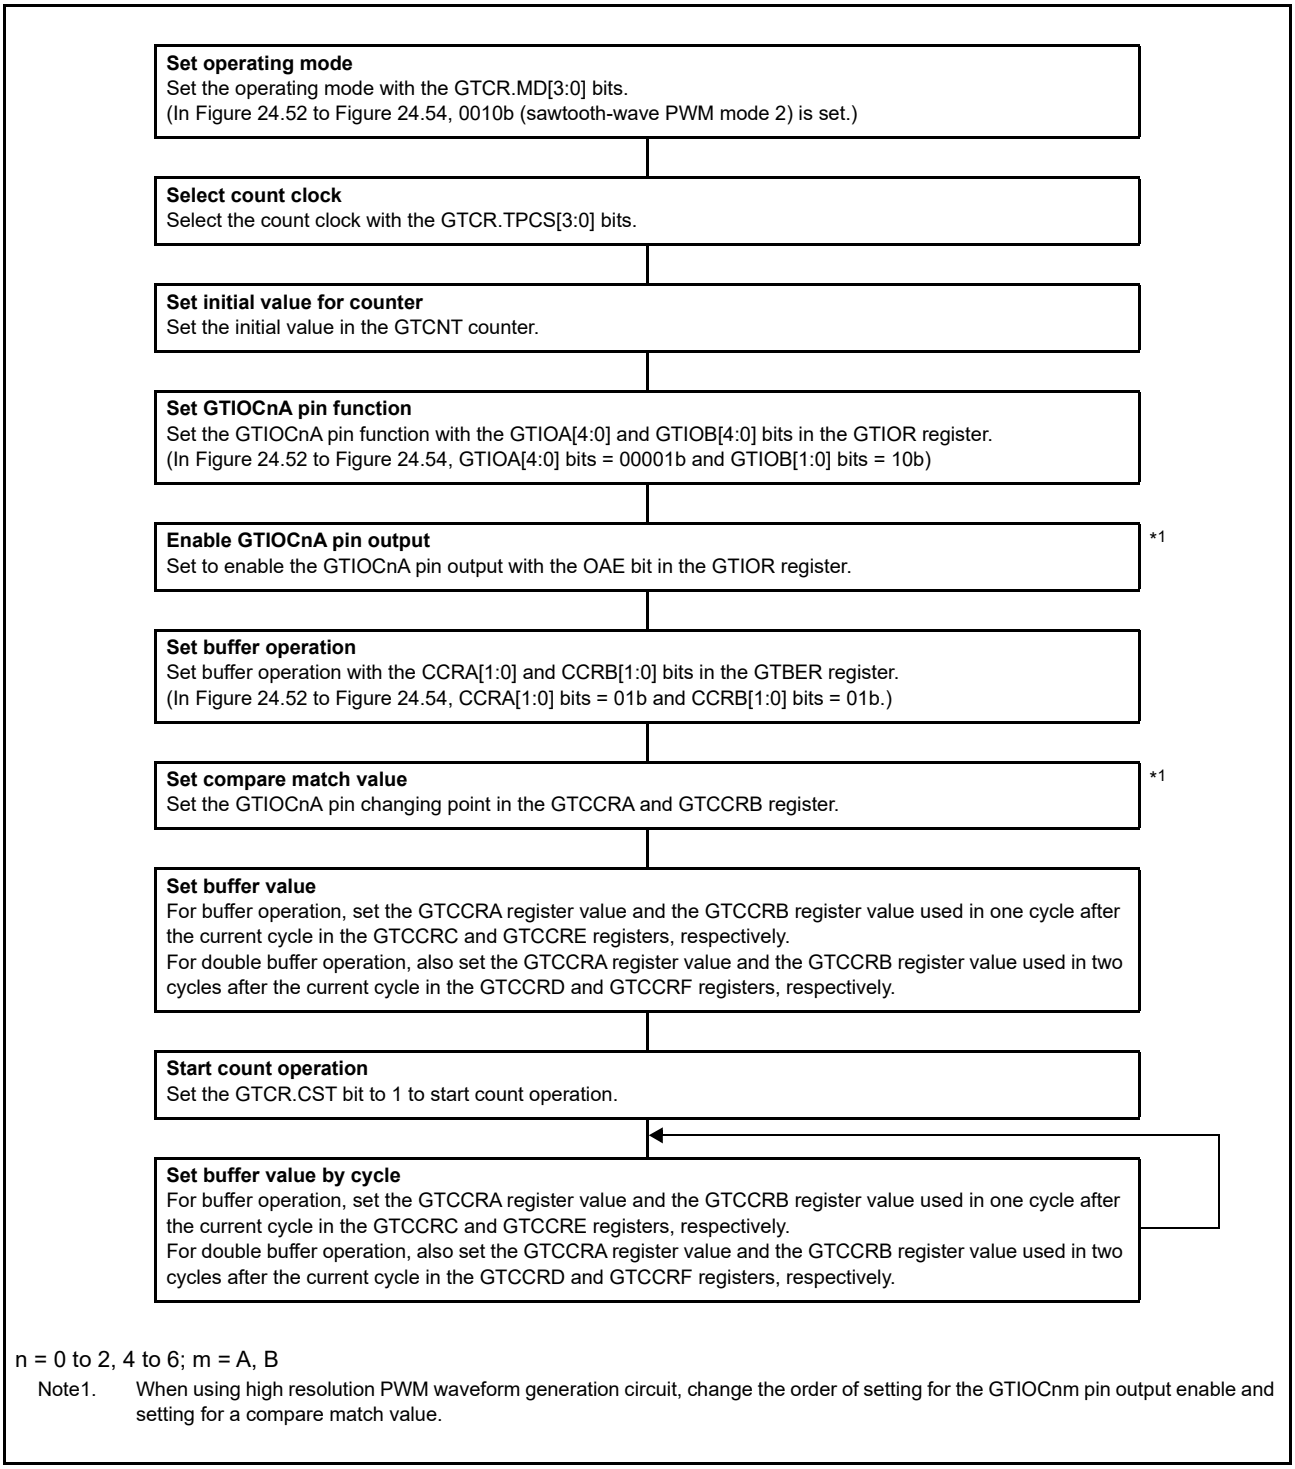

n = 0 to 2, 4 to 6; m = A, B

Note1. When using high resolution PWM waveform generation circuit, change the order of setting for the GTIOCnm pin output enable and setting for a compare match value.

Figure 24.55 Example for Setting Sawtooth-Wave PWM Mode 2

(3) Sawtooth-Wave One-Shot Pulse Mode

The sawtooth-wave one-shot pulse mode is a mode in which the period is set in the GTPR register, the GTCNT counter performs sawtooth-wave (half-wave) operation and a PWM waveform is output to the GTIOCnA or GTIOCnB pin at a compare match of the GTCCRA or GTCCRB register with buffer operation fixed (n = 0 to 7).

Buffer operation in sawtooth-wave one-shot pulse mode is different from the usual buffer operation. Buffer transfer is performed from the GTCCRC register to the GTCCRA register, from the GTCCRE register to the GTCCRB register, from the GTCCRD register to the temporary register A, and from the GTCCRF register to the temporary register B at the end of the cycle, and from the temporary register A to the GTCCRA register at a GTCCRA register compare match and from the temporary register B to the GTCCRB register at a GTCCRB register compare match. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and the end of the cycle according to the GTIOR register setting.

The temporary register A and the temporary register B can perform forcible buffer transfers from the GTCCRD register to the temporary register A and from the GTCCRF register to the temporary register B respectively by writing 1 to the GTBER.CCRSWT bit while the count is stopped.

By setting the GTDTCR, GTDVU, and GTDVD registers, a compare match value for a negative-phase waveform with dead time can automatically be set to the GTCCRB register.

When the GTBER.DBRTECm (m = A, B) bit is set to 1, transfer from an intermediate buffer to the GTCCRm (m = A, B) register is repeated on a cyclic basis with using the temporary register x (x = C, E) and temporary register m (m = A, B) which operate as intermediate buffers for the GTCCRx (x = C, E) and GTCCRm (m = A, B) registers, respectively, even while buffer transfer is disabled (repeated double buffer operation function during disabling of buffer transfer). For details, refer to section 24.8.2.2, Repeated Double-Buffered Operation When Disabling GTCCR Buffer Transfer.

Figure 24.56 shows an example of sawtooth-wave one-shot pulse mode operation, and Figure 24.57 shows an example for setting sawtooth-wave one-shot pulse mode.

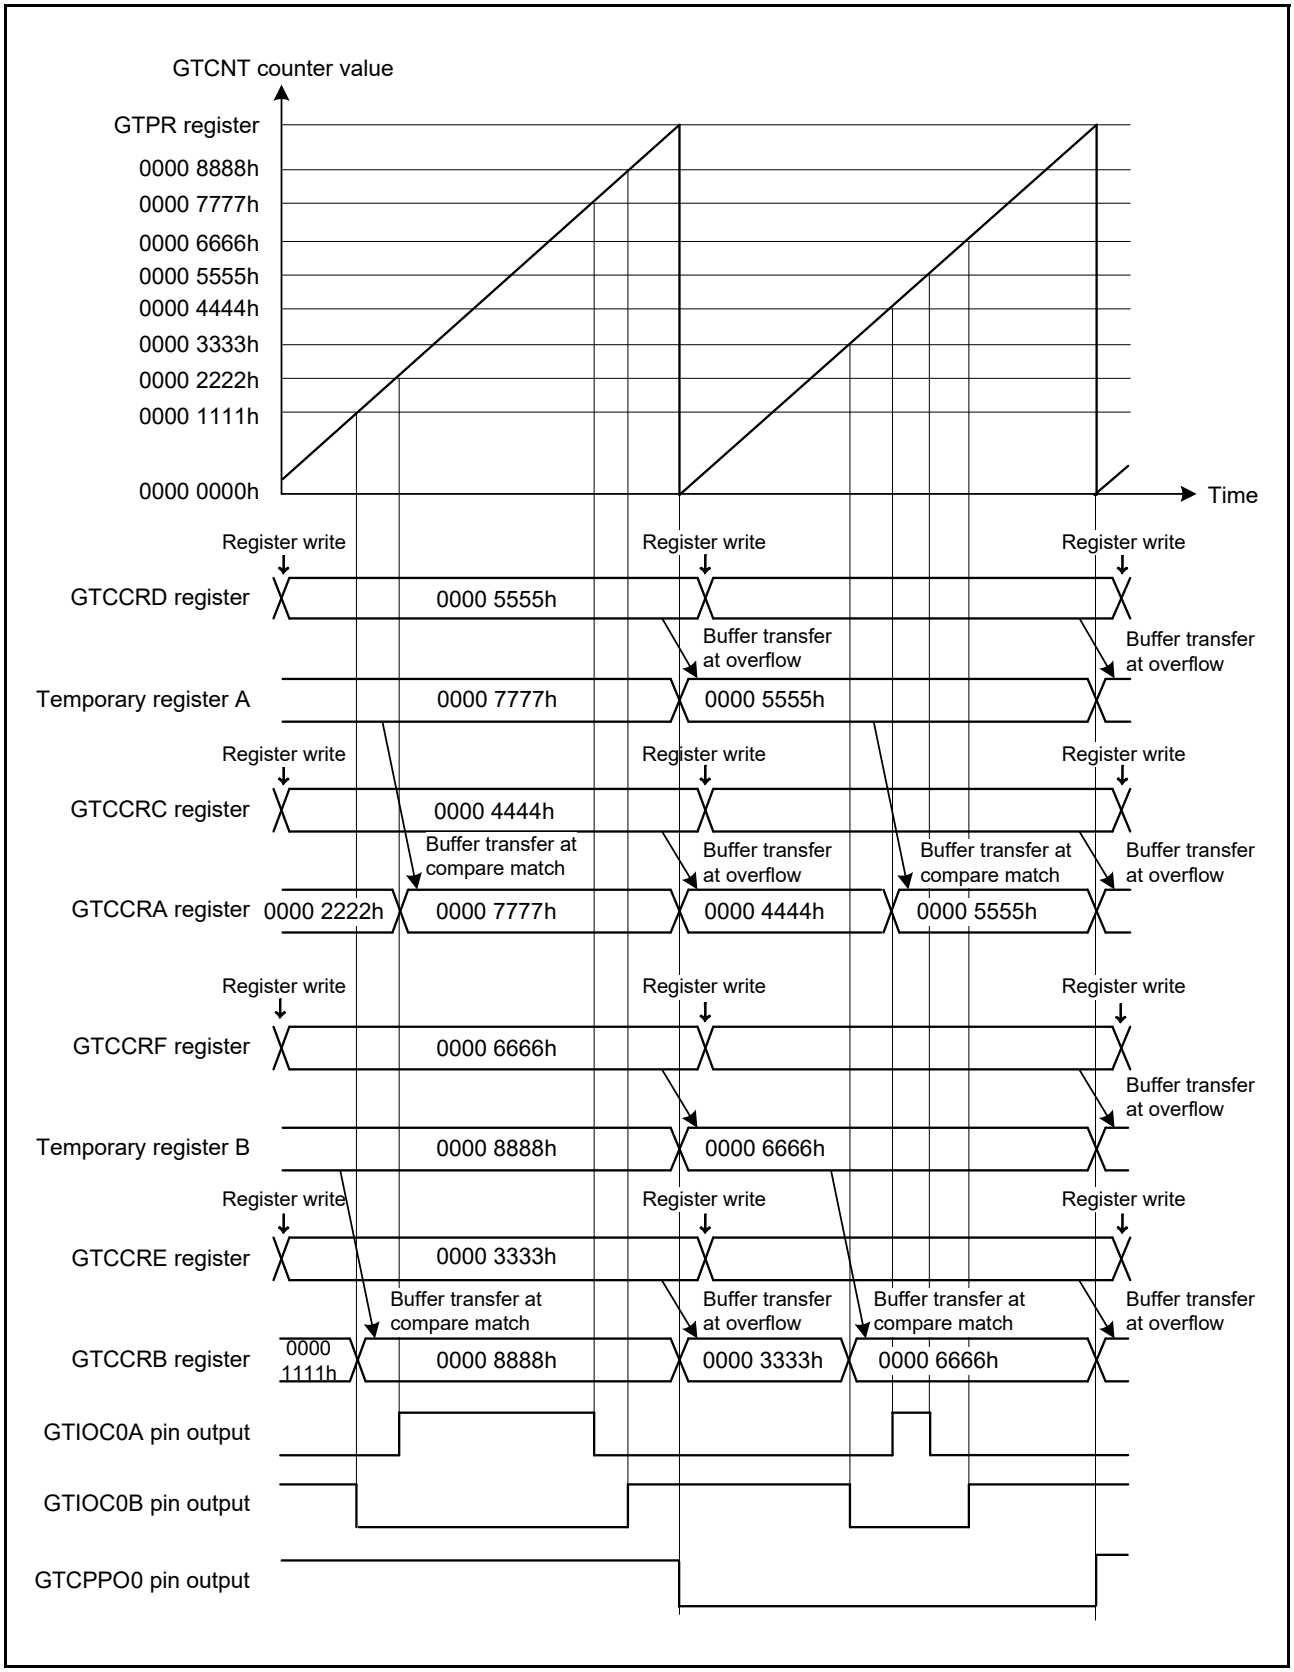

Figure 24.56 Example of Sawtooth-Wave One-Shot Pulse Mode Operation (Up-Counting, Low Output from the GTIOCnA Pin and High Output from the GTIOCnB Pin at Initial Output, Output Toggled at GTCCRA/GTCCRB Register Compare Match, Output Retained at the End of the Cycle, GTIOR.PSYE = 1) (n = 0 to 7)

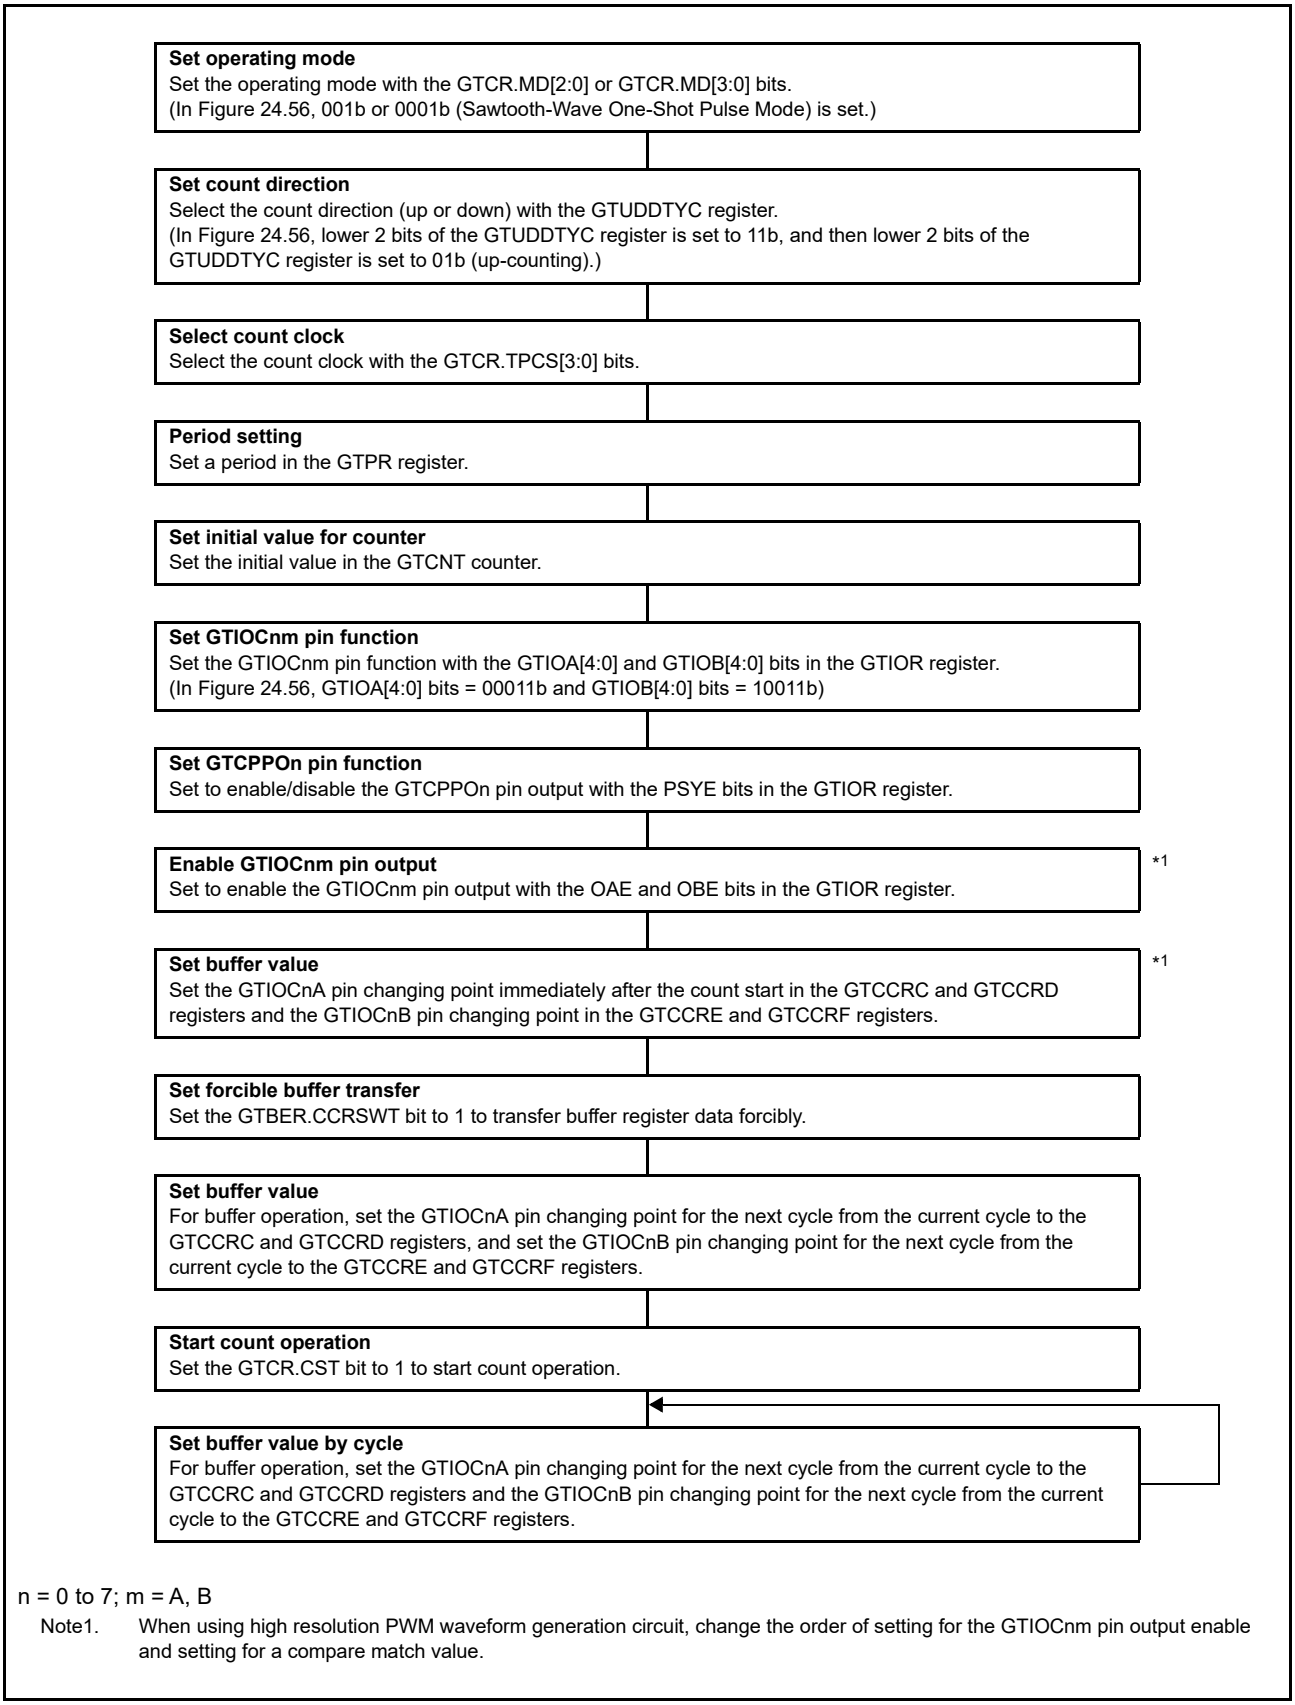

n = 0 to 7; m = A, B

Note1. When using high resolution PWM waveform generation circuit, change the order of setting for the GTIOCnm pin output enable and setting for a compare match value.

Figure 24.57 Example for Setting Sawtooth-Wave One-Shot Pulse Mode

(4) Triangle-Wave PWM Mode 1 (32-Bit Transfer at Trough)

The triangle-wave PWM mode 1 is a mode in which the period is set in the GTPR register, the GTCNT counter performs triangle-wave (full-wave) operation, and a PWM waveform is output to the GTIOCnA or GTIOCnB pin when a GTCCRA or GTCCRB register compare match occurs (n = 0 to 7).

Buffer transfer is performed at the trough. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the end of the cycle according to the GTIOR register setting.

By setting the GTDTCR, GTDVU, and GTDVD registers, a compare match value for a negative-phase waveform with dead time can automatically be set to the GTCCRB register.

Figure 24.58 shows an example of triangle-wave PWM mode 1 operation, and Figure 24.59 shows an example for setting triangle-wave PWM mode 1.

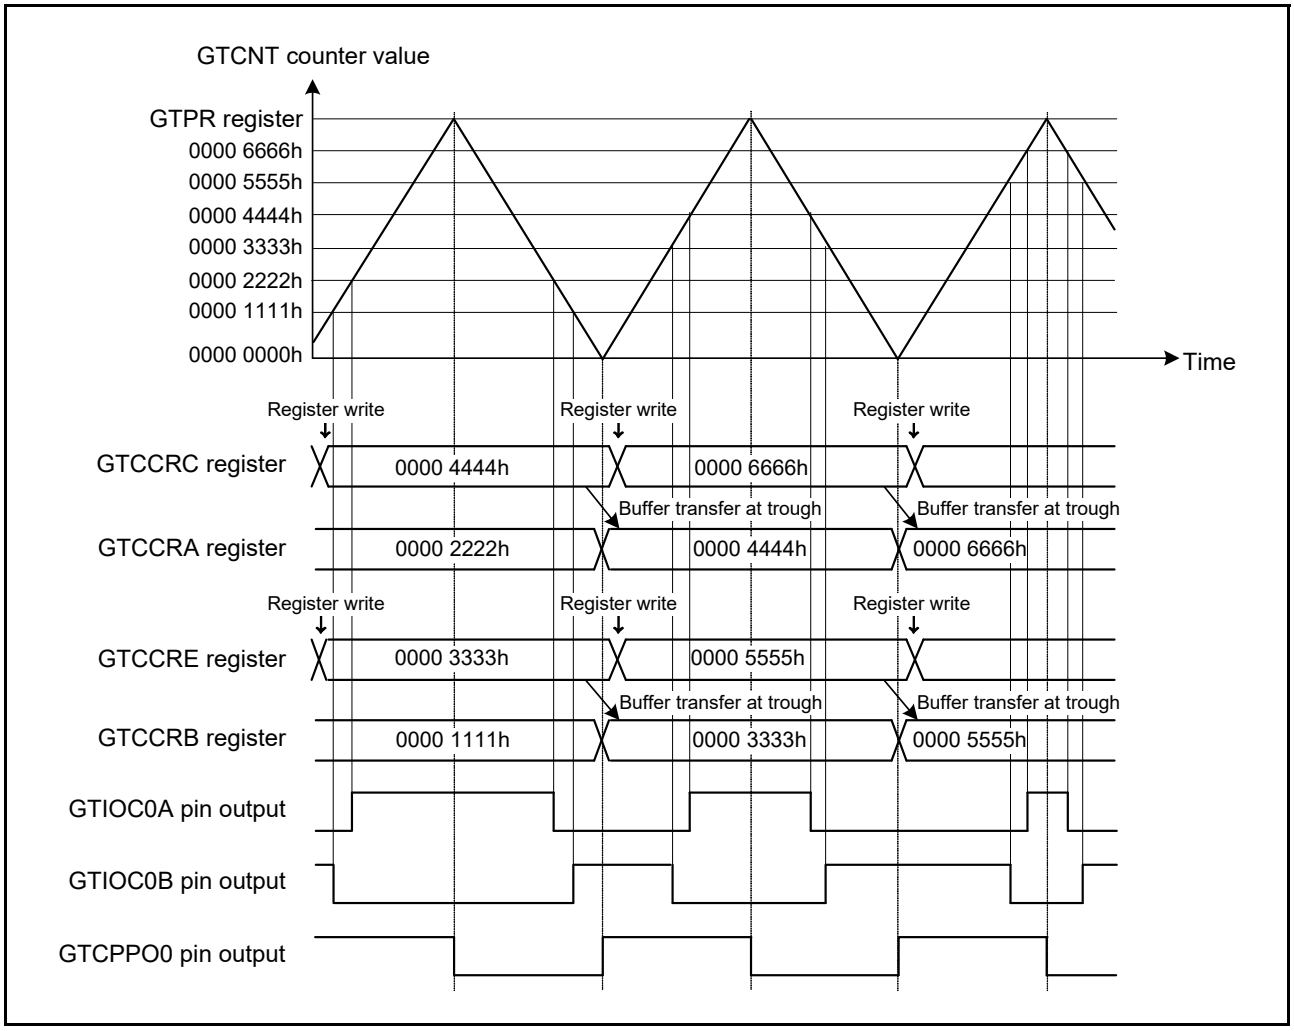

Figure 24.58 Example of Triangle-Wave PWM Mode 1 Operation (Buffer Operation, Low Output from the GTIOCnA Pin and High Output from the GTIOCnB Pin at Initial Output, Output Toggled at GTCCRA/GTCCRB Register Compare Match, Output Retained at the End of the Cycle, and GTIOR.PSYE = 1) (n = 0 to 7)

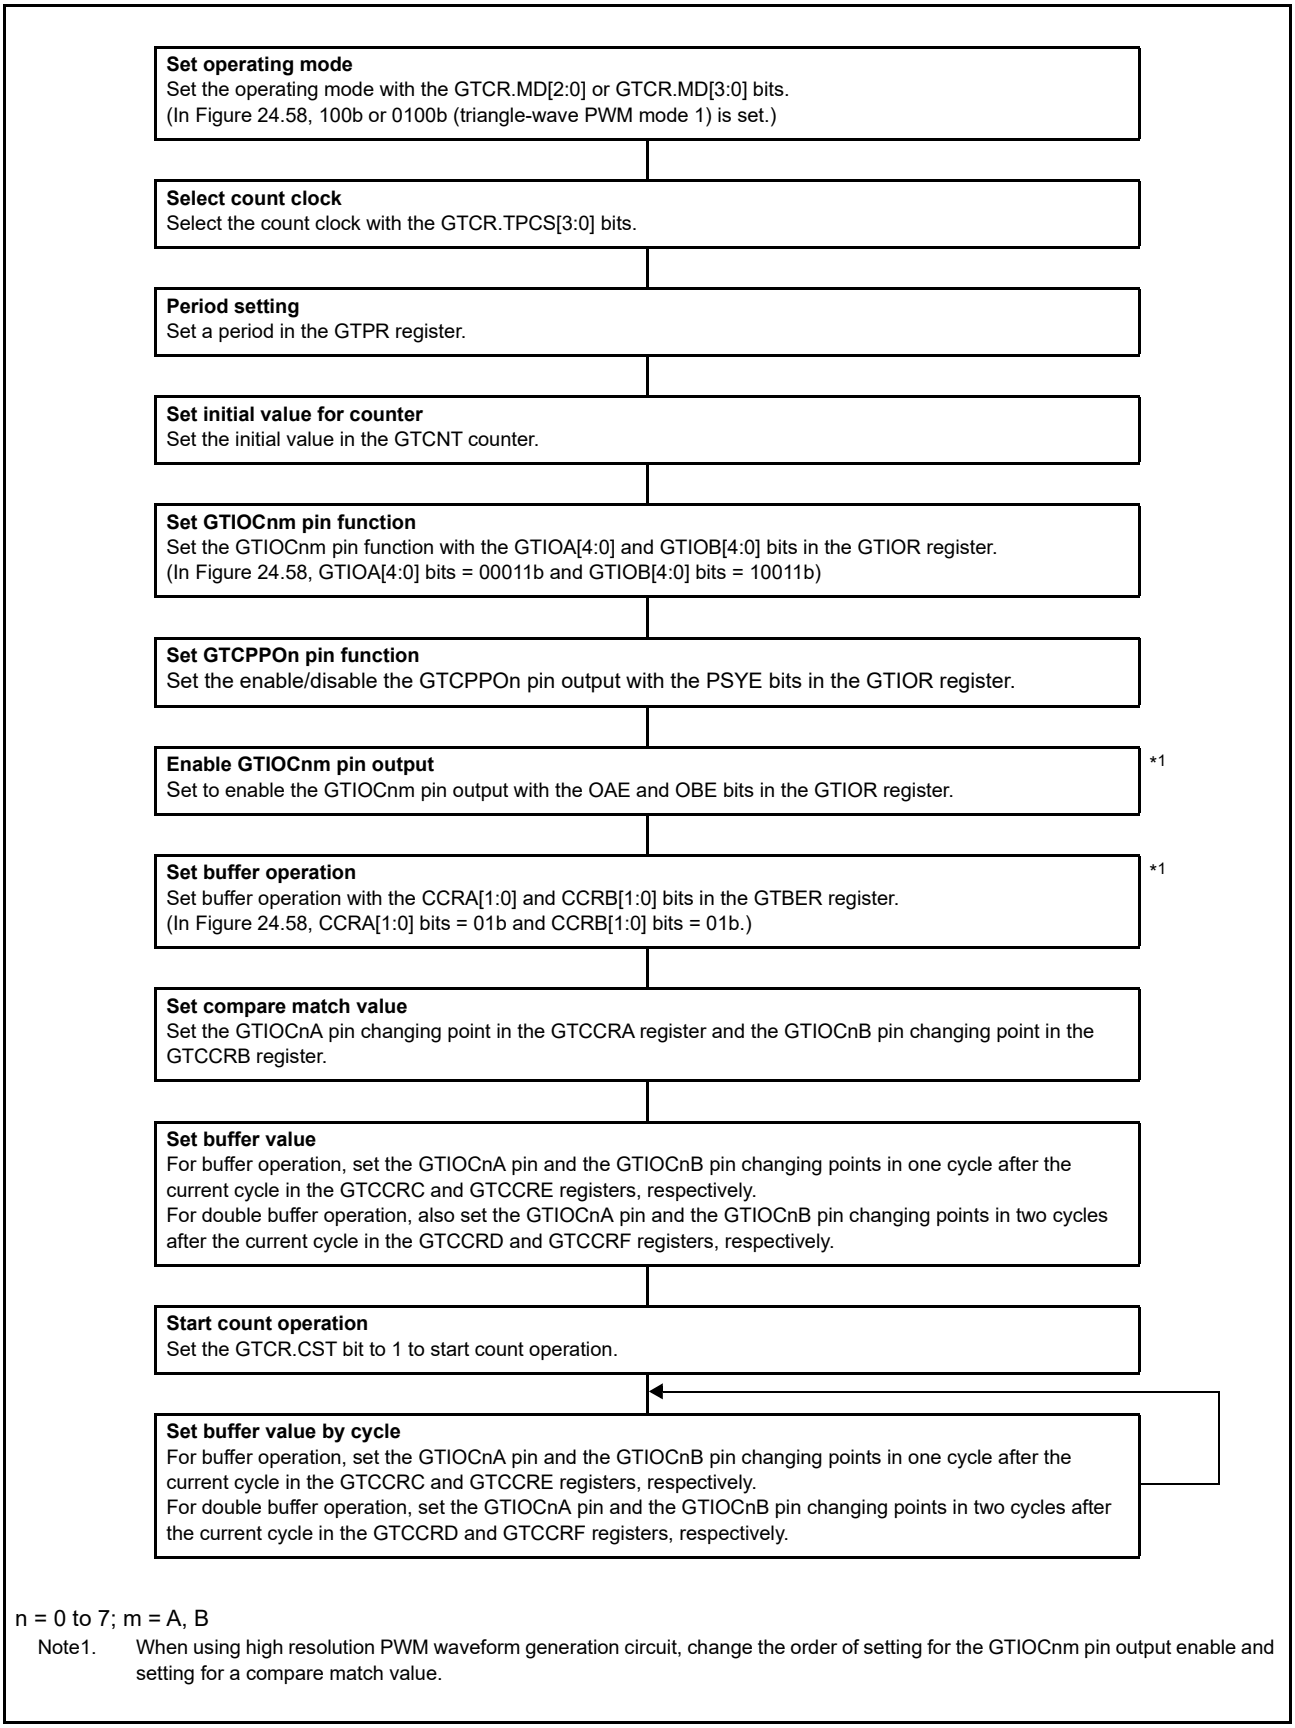

n = 0 to 7; m = A, B

Note1. When using high resolution PWM waveform generation circuit, change the order of setting for the GTIOCnm pin output enable and setting for a compare match value.

Figure 24.59 Example for Setting Triangle-Wave PWM Mode 1

(5) Triangle-Wave PWM Mode 2 (32-Bit Transfer at Crest and Trough)

Similarly to triangle-wave PWM mode 1, in triangle-wave PWM mode 2 the period is set in the GTPR register, the GTCNT counter performs triangle-wave (full-wave) operation, and a PWM waveform is output to the GTIOCnA or GTIOCnB pin when a GTCCRA or GTCCRB register compare match occurs (n = 0 to 7). The buffer transfer is performed at both crests and troughs. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the end of the cycle according to the GTIOR register setting.
By setting the GTDTCR, GTDVU, and GTDVD registers, a compare match value for a negative-phase waveform with dead time can automatically be set to the GTCCRB register.
Figure 24.60 shows an example of triangle-wave PWM mode 2 operation, and Figure 24.61 shows an example for setting triangle-wave PWM mode 2.

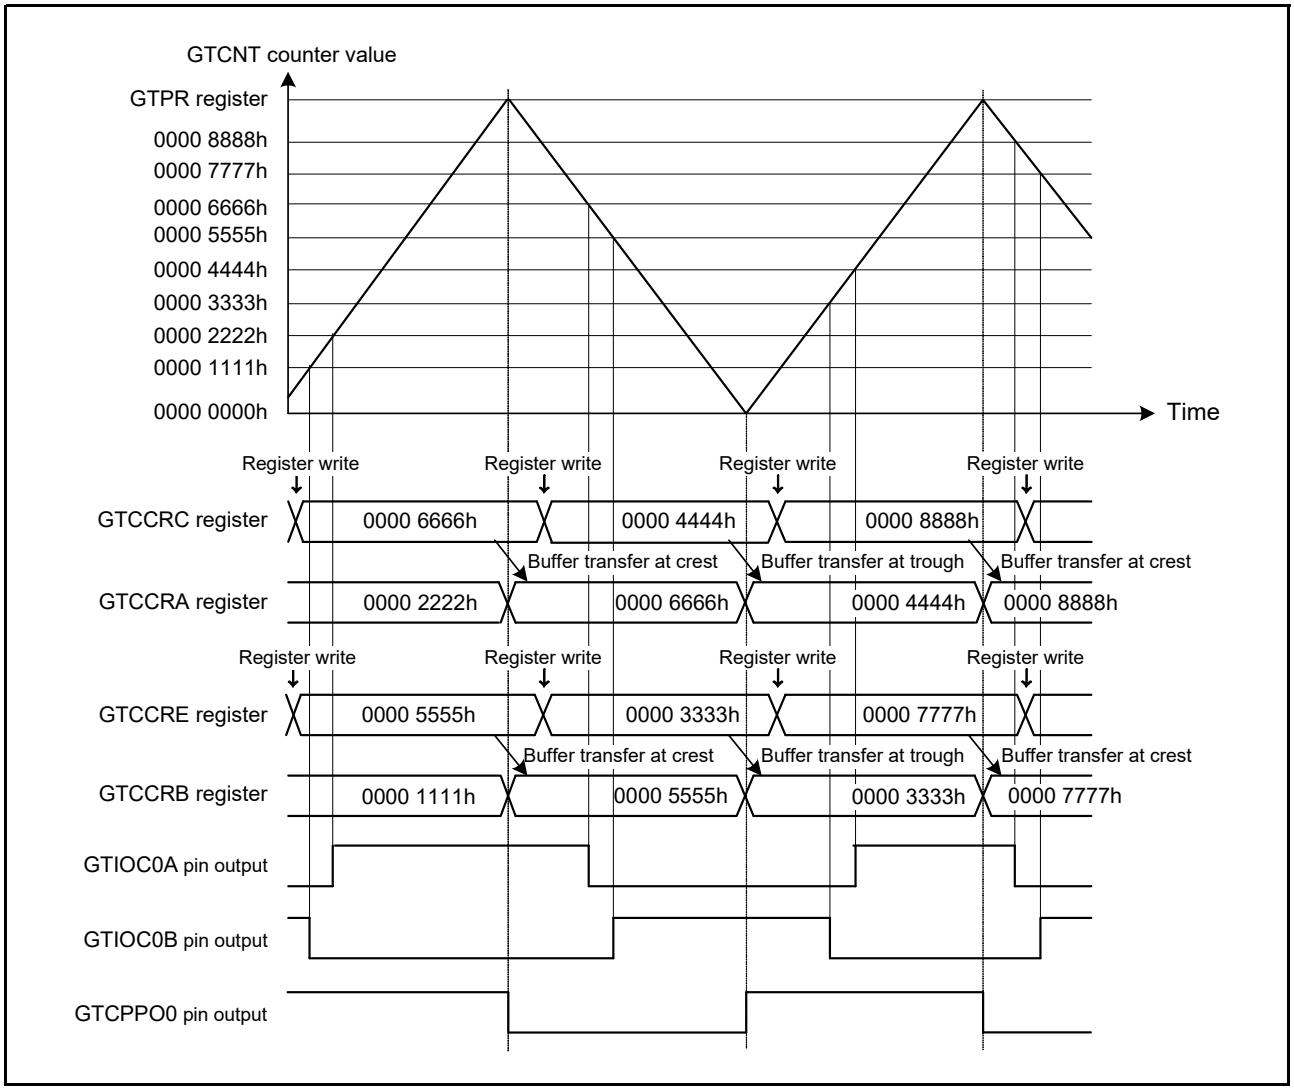

Figure 24.60 Example of Triangle-Wave PWM Mode 2 Operation (Buffer Operation, Low Output from the GTIOCnA Pin and High Output from the GTIOCnB Pin at Initial Output, Output Toggled at GTCCRA/GTCCRB Register Compare Match, Output Retained at the End of the Cycle, GTIOR.PSYE = 1) (n = 0 to 7)

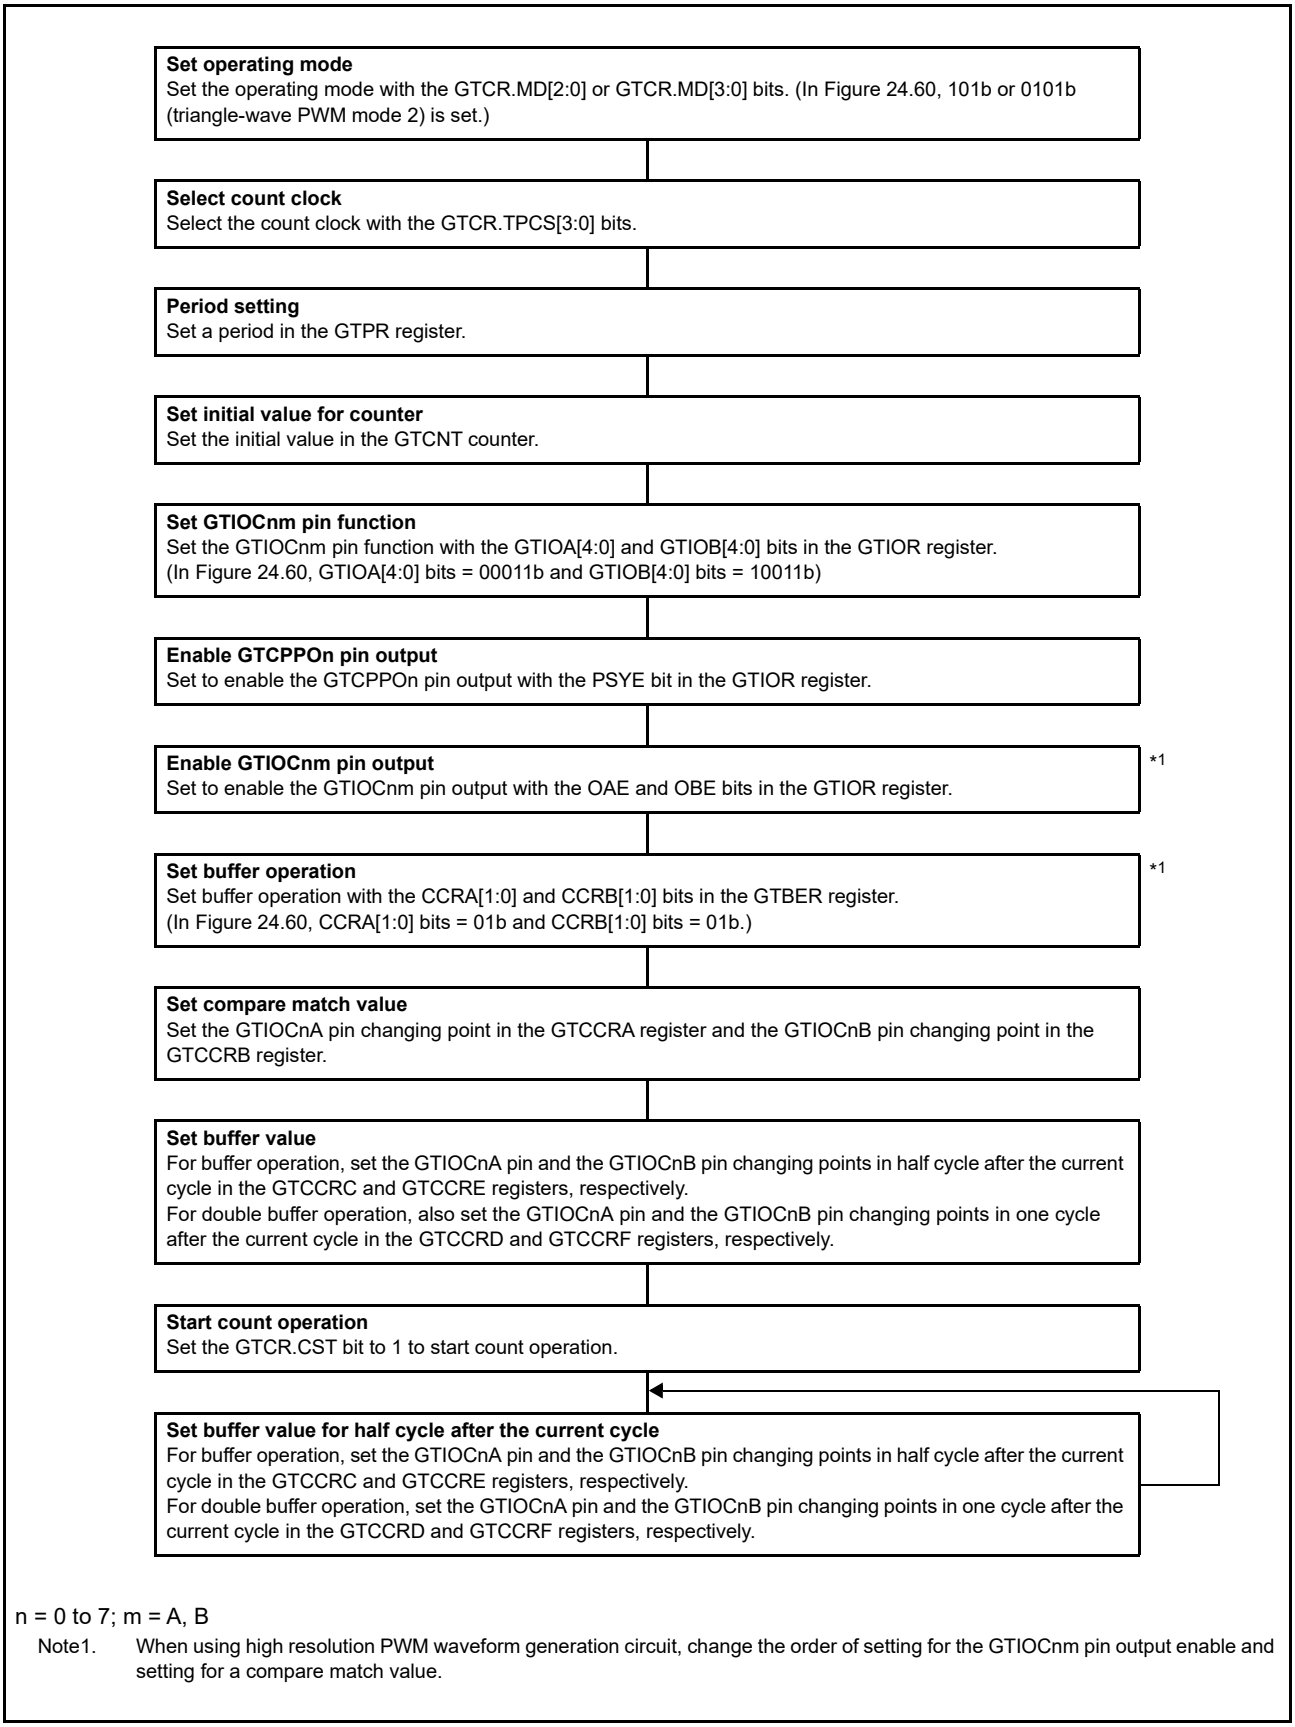

n = 0 to 7; m = A, B

Note1. When using high resolution PWM waveform generation circuit, change the order of setting for the GTIOCnm pin output enable and setting for a compare match value.

Figure 24.61 Example for Setting Triangle-Wave PWM Mode 2

(6) Triangle-Wave PWM Mode 3 (64-Bit Transfer at Trough)

The triangle-wave PWM mode 3 is a mode in which the period is set in the GTPR register, the GTCNT counter performs triangle-wave (full-wave) operation and a PWM waveform is output to the GTIOCnA or GTIOCnB pin at a compare match of the GTCCRA or GTCCRB register with buffer operation fixed (n = 0 to 7). Buffer operation in triangle-wave PWM mode 3 is different from the usual buffer operation. Buffer transfer is performed from the GTCCRC register to the GTCCRA register, from the GTCCRE register to the GTCCRB register, from the GTCCRD register to the temporary register A, and from the GTCCRF register to the temporary register B at the trough, and from the temporary register A to the GTCCRA register and from the temporary register B to the GTCCRB register at the crest. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the end of the cycle according to the GTIOR register setting.

By setting the GTDTCR, GTDVU, and GTDVD registers, a compare match value for a negative-phase waveform with dead time can automatically be set to the GTCCRB register.

When the GTBER.DBRTECm (m = A, B) bit is set to 1, transfer from an intermediate buffer to the GTCCRm (m = A, B) register is repeated on a cyclic basis with using the temporary register x (x = C, E) and temporary register m (m = A, B) which operate as intermediate buffers for the GTCCRx (x = C, E) and GTCCRm (m = A, B) registers, respectively, even while buffer transfer is disabled (repeated double buffer operation function during disabling of buffer transfer). For details, refer to section 24.8.2.2, Repeated Double-Buffered Operation When Disabling GTCCR Buffer Transfer.

Figure 24.62 shows an example of triangle-wave PWM mode 3 operation, and Figure 24.63 shows an example for setting triangle-wave PWM mode 3.

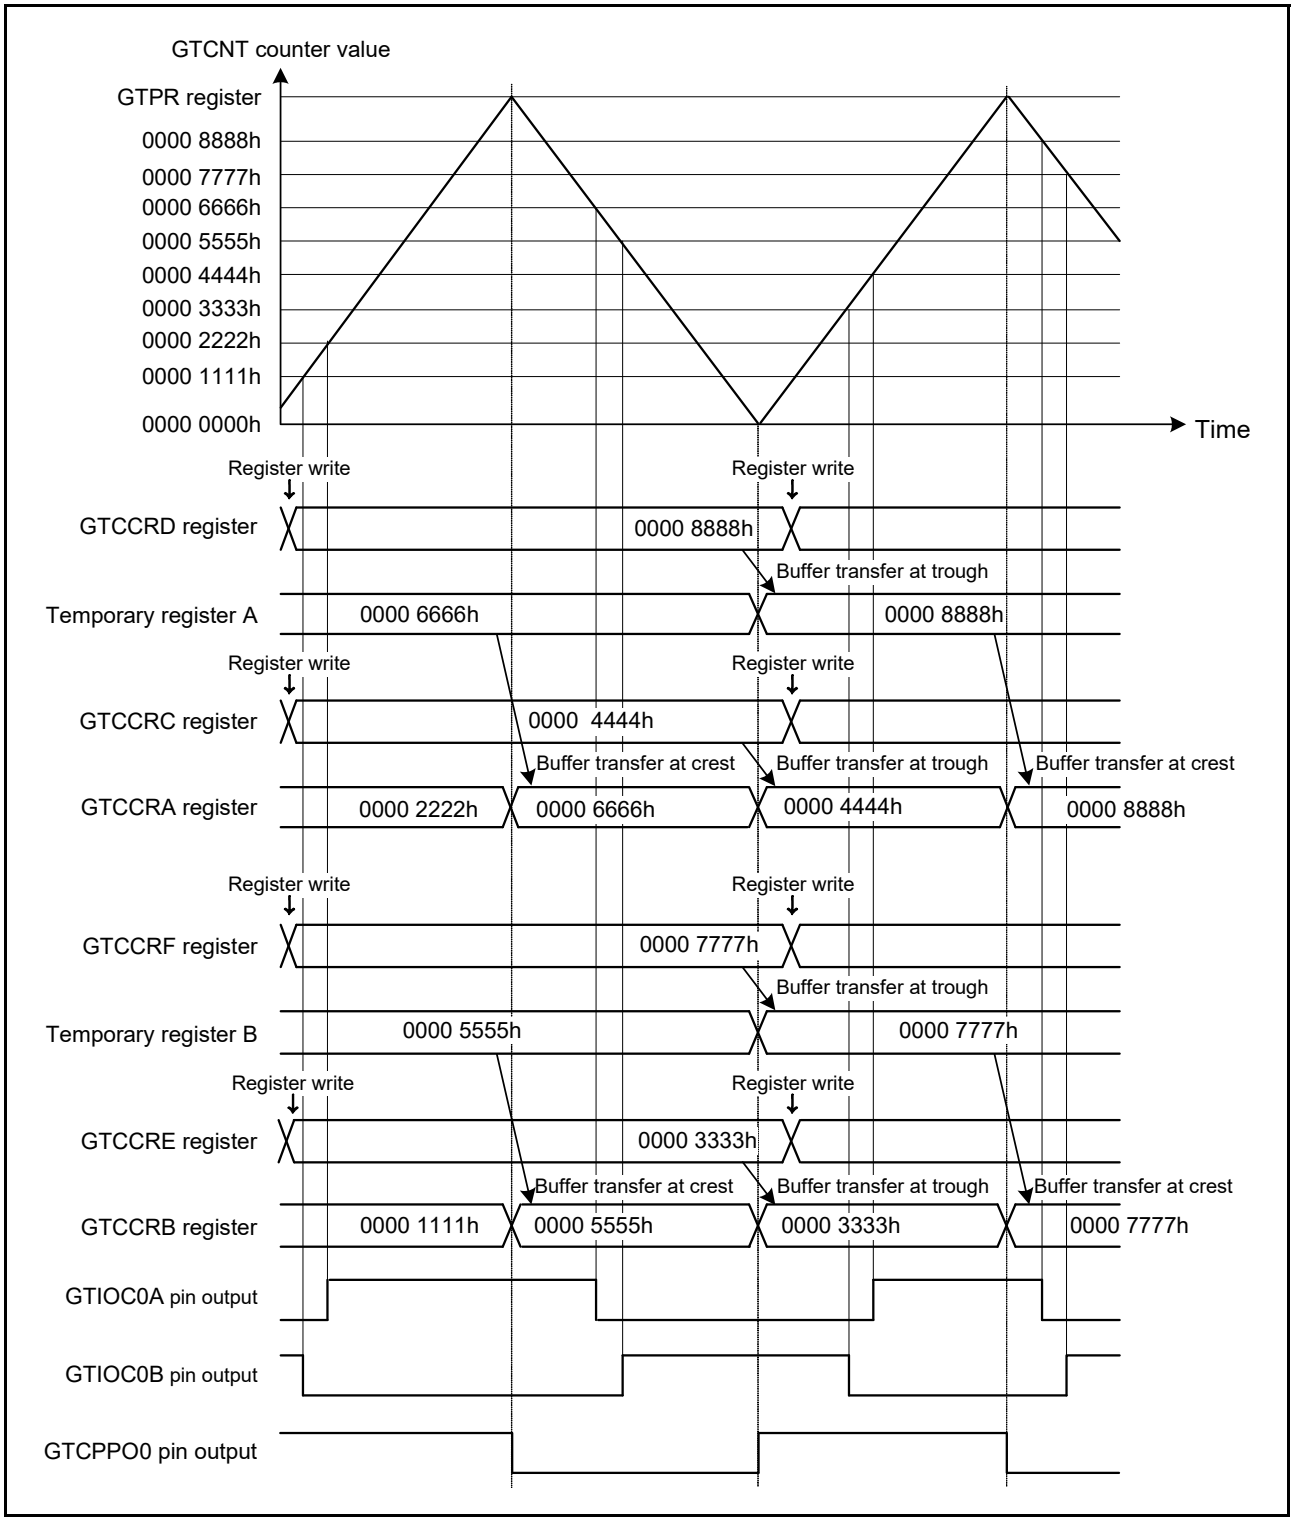

Figure 24.62 Example of Triangle-Wave PWM Mode 3 Operation (Low Output from the GTIOCnA Pin and High Output from the GTIOCnB Pin at Initial Output, Output Toggled at GTCCRA/GTCCRB Register Compare Match, Output Retained at the End of the Cycle, GTIOR.PSYE = 1) (n = 0 to 7)

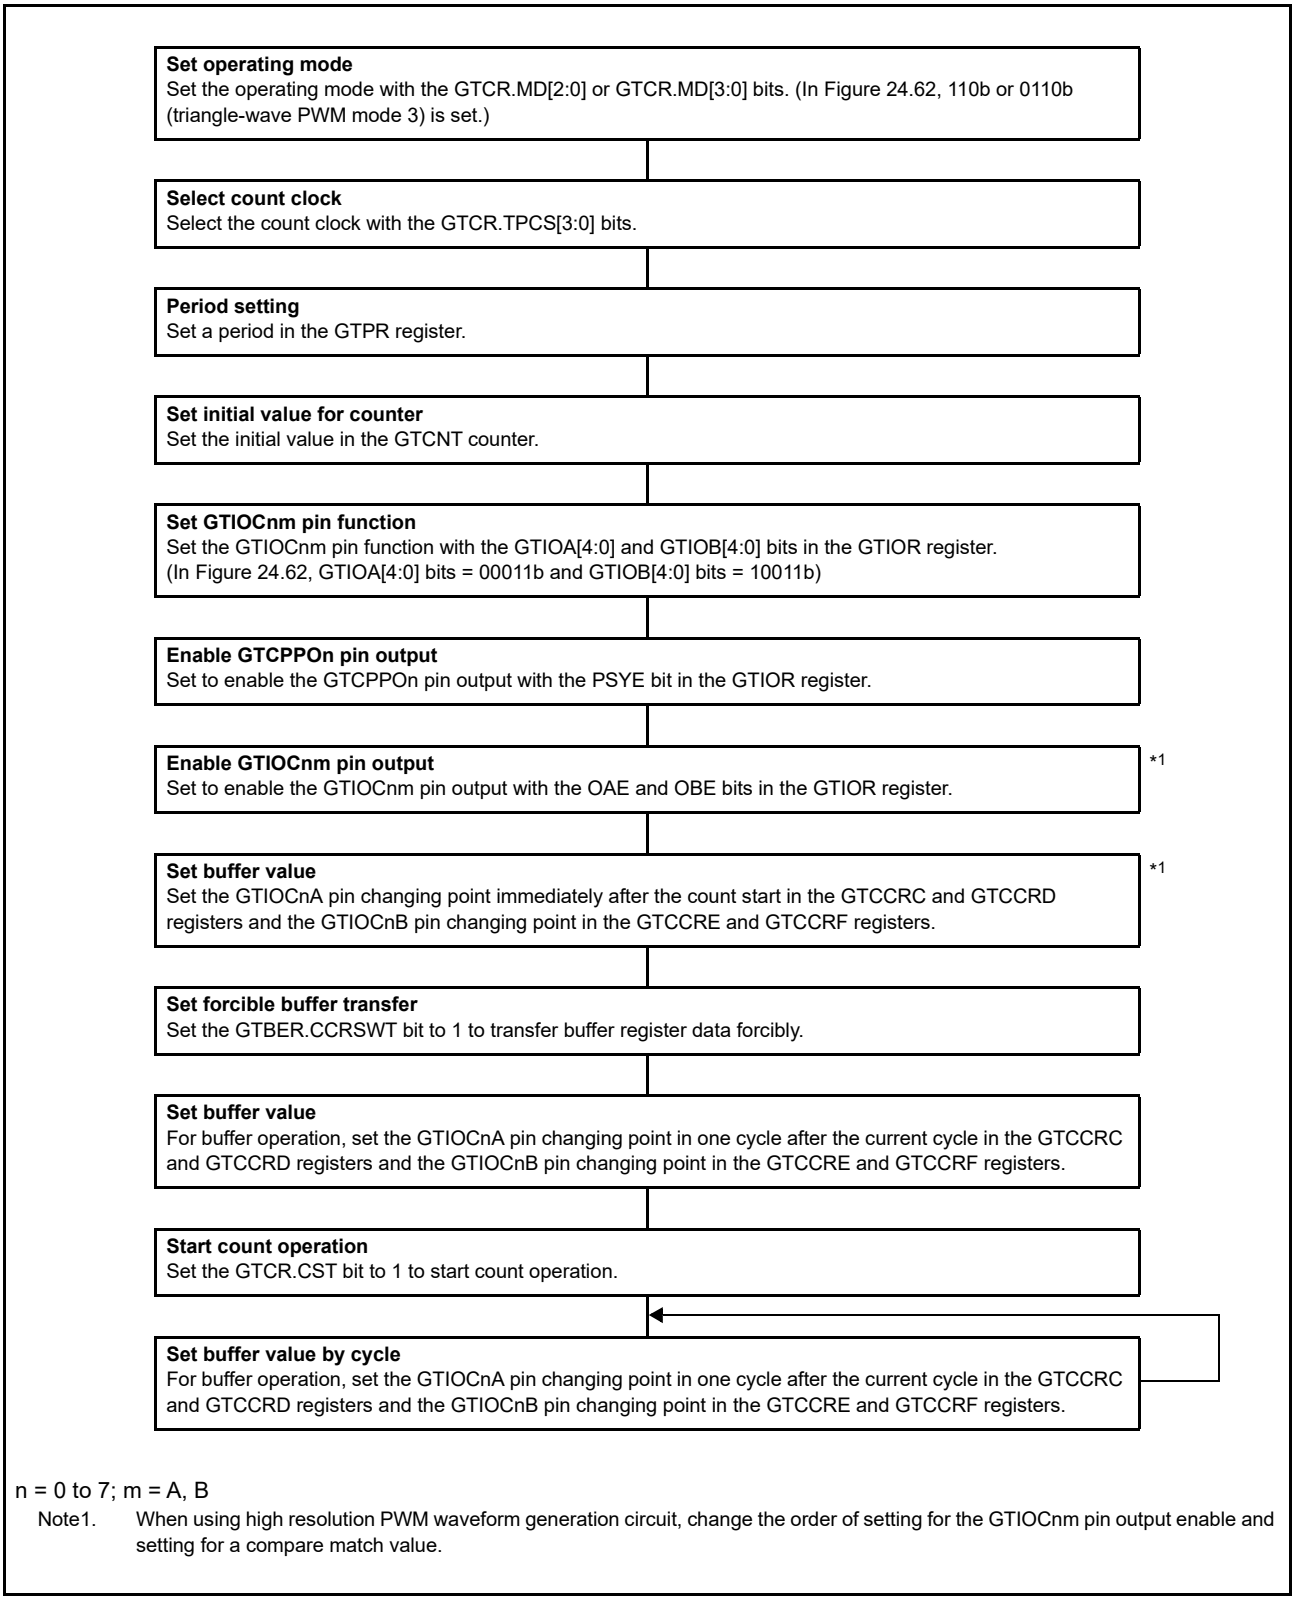

n = 0 to 7; m = A, B

Note1. When using high resolution PWM waveform generation circuit, change the order of setting for the GTIOCnm pin output enable and setting for a compare match value.

Figure 24.63 Example for Setting Triangle-Wave PWM Mode 3

(7) Complementary PWM mode 1, 2, 3

In complementary PWM mode, a three-phase PWM waveform with dead time that ensures the linearity in the vicinity of duty 0% and 100% can be output using the GTCNT counter of consecutive three channels. There are four modes depending on differences in buffer operation: (1) complementary PWM mode 1 (transfer at crests), (2) complementary PWM mode 2 (transfer at troughs), (3) complementary PWM mode 3 (transfer at crests and troughs), and (4) complementary PWM mode 4 (immediate transfer).

Figure 24.64 shows the block diagram in complementary PWM modes 1 to 3.

Among consecutive three channels, the lowest channel is referred to as master channel, and the adjacent upper two channels are referred to as slave channel 1 (lower) and slave channel 2 (upper).

The GTCNT counter of each channel performs individual count operation under the cycle operation by the master channel.

In each channel, compare match with the GTCCRA register is performed selecting one of the three GTCNT counters in each operation section, and a positive-phase waveform and a negative-phase waveform are output from the GTIOCn+iA pin (n = 0, 4; i = 0, 1, 2) and the GTIOCn+iB pin respectively with a non-overlapping section of the dead time value set in the GTDVU register of the master channel.

The GTCCRA register performs buffer operation by the GTCCRC register, temporary register A, and GTCCRD register. In complementary PWM mode 3, setting the GTBER2.CP3DB bit to 1 also enables buffer operation of the GTCCRA register by the GTCCRE register, temporary register B, and GTCCRF register, allowing double buffer operation.

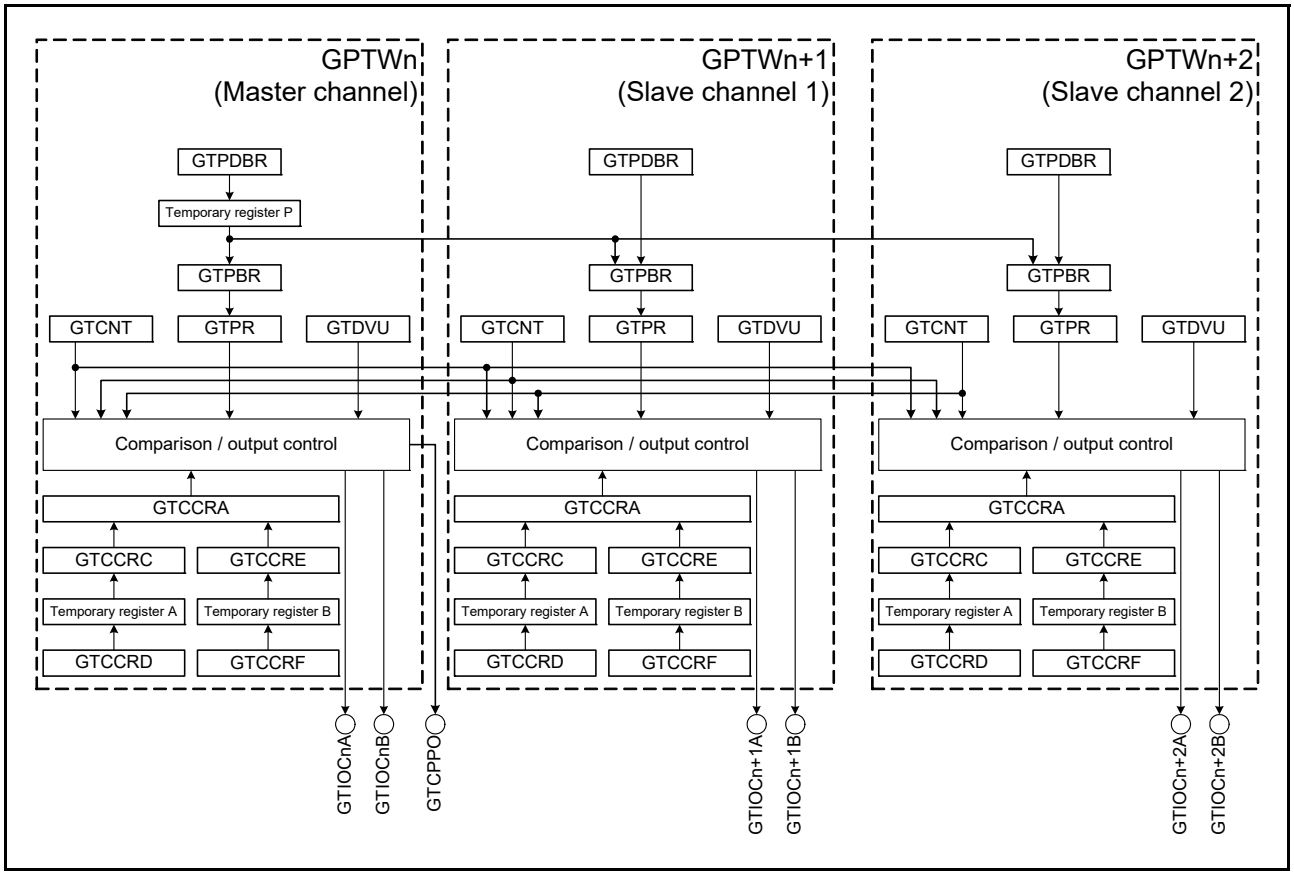

Figure 24.64 Block Diagram in Complementary PWM Mode 1, 2, 3 (n = 0, 4)

The GPTWn.GTCNT counter performs count operation for triangle waves using the GPTWn.GTPR register as a cycle register. A section where the GPTWn.GTCNT counter value is not larger than the dead time value is referred to as trough section.

The GPTWn+1.GTCNT counter performs count operation with the value (GPTWn.GTCNT counter value + dead time value set in the GPTWn.GTDVU register). A section where the GPTWn+1.GTCNT counter value is larger than the

GPTWn.GTPR register value is referred to as crest section.
Crest section and trough section are classified into up-counting crest section, down-counting crest section, up-counting trough section, and down-counting trough section according to counting direction. A section between trough section and crest section is referred to as up-counting middle section or down-counting middle section according to counting direction.
A section equivalent to the up-counting trough section after starting count operation is referred to as initial output section where operation differs partially from other up-counting trough sections.
The GPTWn+2.GTCNT counter functions as a counter to ensure the linearity in the vicinity of duty 0% and 100%. In a crest section, this counter performs count operation for a triangle wave (up-counting after down-counting) with the value (GPTWn.GTPR register value + dead time value) as an initial value and the GPTWn.GTPR register value as a trough. This counter is cleared to 0 at the end of the crest section, and then stops counting until the next trough section. In a trough section, this counter performs count operation for a triangle wave with an initial value of 0 and dead time value as a crest.
This counter becomes the value (GPTWn.GTPR register value + dead time value) at the end of the trough section, and then stops counting until the next crest section. In the initial output section, however, this counter counts up with an initial value of 0 until the dead time value, and then becomes the value (GPTWn.GTPR register value + dead time value).
If the counter stops and then restarts in complementary PWM mode, the counter of each channel returns to the initial value after starting count operation, and then starts counting from the initial output section.
Table 24.12 and Table 24.13 show count operation (counting direction/counting range) in each section. In these tables, registers with no channel identification indicate that the same value is stored in them of the master channel, slave channel 1, and slave channel 2.

Table 24.12 Count Operation in Complementary PWM Mode (1)

Counter	Initial Value	Initial Output Section (After Start)	Up-Counting Middle Section	Up-Counting Crest Section	Down-Counting Crest Section
GPTWn.GTCNT	0	Up-Counting 0 to GTDVU	Up-Counting GTDVU + 1 to GTPR – GTDVU	Up-Counting GTPR – GTDVU + 1 to GTPR	Down-Counting GTPR – 1 to GTPR – GTDVU
GPTWn+1.GTCNT	GTDVU	Up-Counting GTDVU to GTDVU × 2	Up-Counting GTDVU × 2 – 1 to GTPR	Up-Counting GTPR + 1 to GTPR + GTDVU	Down-Counting GTPR + GTDVU – 1 to GTPR
GPTWn+2.GTCNT	0	Up-Counting 0 to GTDVU	Stop GTPR + GTDVU	Down-Counting GTPR + GTDVU – 1 to GTPR	Up-Counting GTPR + 1 to GTPR + GPDVU

Table 24.13 Count Operation in Complementary PWM Mode (2)

Counter	Down-Counting Middle Section	Down-Counting Trough Section	Up-Counting Trough Section
GPTWn.GTCNT	Down-Counting GTPR – GTDVU – 1 to GTDVU	Down-Counting GTDVU – 1 to 0	Up-Counting 1 to GTDVU
GPTWn+1.GTCNT	Down-Counting GTPR – 1 to GTDVU × 2	Down-Counting GTDVU × 2 – 1 to GTDVU	Down-Counting GTDVU + 1 to GTDVU × 2
GPTWn+2.GTCNT	Stop 0	Up-Counting 1 to GTDVU	Down-Counting GTDVU – 1 to 0

In complementary PWM mode, the GTCCRA register buffer operation is different from normal buffer operation.
Data transfers from the GTCCRD register to the temporary register A and from the GTCCRF register to the temporary register B are performed at the same time in three channels by writing a value to the GTCCRD register of the GPTWn+2 channel.
Data transfers from the temporary register A and temporary register B to the GTCCRC and GTCCRE registers vary depending on the transfer timing to the temporary register A and temporary register B. Data transfers from the GTCCRC and GTCCRE registers to the GTCCRA register are performed according to each complementary PWM mode name (crest transfer, trough transfer, and crest/trough transfer).
Buffer operation of the GTPR register in complementary PWM mode is described in section 24.3.2.1, GTPR Register Buffer Operation. Do not perform buffer operation for the GTDVU register in complementary PWM mode.

Table 24.14 shows buffer transfer timing during single buffer operation in complementary PWM modes 1 to 3. Table 24.15 shows buffer transfer timing during double buffer operation in complementary PWM mode 3.

Table 24.14 Single Buffer Transfer Timing in Complementary PWM Mode 1, 2, 3

Buffer Transfer	Complementary PWM Mode 1	Complementary PWM Mode 2	Complementary PWM Mode 3
GTCCRD ↓ Temporary register A	After one PCLKC cycle from the GTCCRD register write of slave channel 2 (GPTWn+2)	After one PCLKC cycle from the GTCCRD register write of slave channel 2 (GPTWn+2)	After one PCLKC cycle from the GTCCRD register write of slave channel 2 (GPTWn+2)
Temporary register A ↓ GTCCRC	(1) When transferring to the temporary register A at the middle section of the up-count • After 1 PCLKC after for transferred to the temporary register A (2) When transferring to the temporary register A at other than the middle section of the up-count • The end of the trough	(1) When transferring to the temporary register A at the middle section of the down-count • After 1 PCLKC after for transferred to the temporary register A (2) When transferring to the temporary register A at other than the middle section of the down-count • The end of the crest	(1) When transferring to the temporary register A at the middle section • After 1 PCLKC after for transferred to the temporary register A (2) When transferring to the temporary register A at other than the middle section • The end of the crest/trough
GTCCRC ↓ GTCCRA	• The end of the trough • Counter clear in the up-count intermediate section and crest section	• The end of the trough section excluding the initial output section • Counter clear in the down-count intermediate section and trough section	• The end of the trough • The end of the trough section excluding the initial output section • Counter clear

Table 24.15 Double Buffer Transfer Timing in Complementary PWM Mode 3

Buffer Transfer	Transfer Timing
GTCCRD ↓ Temporary register A	After 1 PCLKC after slave channel 2 (GPTWn+2) writes to the GTCCRD register
Temporary register A ↓ GTCCRC	(1) When transferring data to the temporary register A at the middle section • After 1 PCLKC after data transfer to the temporary register A (2) When transferring data to the temporary register A at other than the middle section • At the end of crest and trough sections
GTCCRC ↓ GTCCRA	• The end of the crest • Counter clear

Buffer Transfer	Transfer Timing
GTCCRF ↓ Temporary register B	After 1 PCLKC after slave channel 2 (GPTWn+2) writes to the GTCCRD register
Temporary register B ↓ GTCCRE	(1) When transferring data to the temporary register B at the middle section • After 1 PCLKC after data transfer to the temporary register A (2) When transferring data to the temporary register B at other than the middle section • At the end of crest and trough sections
GTCCRE ↓ GTCCRA	• The end of the trough section excluding the initial output section

The change in the output level of the positive phase waveform output from the GTIOCn+mA pin (m = 0, 1, 2) and the negative phase waveform output from the GTIOCn+mB pin (m = 0, 1, 2) is determined by the compare match by the combination of the counter and register in each operation section. In the middle section, the compare match between the GPTWn.GTCNT counter and the GTCCRA register changes the positive phase waveform output level, and the compare match between the GPTWn+1.GTCNT counter and the GTCCRA register changes the negative phase waveform output level. The crest and trough sections use the GPTWn+2.GTCNT counter, GTCCRC register, and GTCCRE register to perform a compare match operation to ensure linearity near 0% and 100% duty.

When the comparison match value is greater than or equal to the GPTWn.GTPR register value, the duty is 0% (positive phase waveform OFF, negative phase waveform ON). When the comparison match value is 0, the duty is 100% (positive phase waveform ON, negative phase waveform OFF).

Table 24.16 shows the counter and register combinations used in the comparative match operation to generate a

positive-phase waveform and a negative-phase waveform in each operating section.

Table 24.16 Combinations of Counters and Registers for Compare Match Operation in Complementary PWM Mode

	Up-Counting Middle Section	Up-Counting Crest Section	Up-Counting Crest Section	Up-Counting Middle Section	Up-Counting Trough Section	Up-Counting Trough Section
Negative-Phase OFF	GPTWn+1.GTCNT	GPTWn+1.GTCNT	—	GPTWn+2.GTCNT*1	GPTWn+2.GTCNT	GPTWn+1.GTCNT

	—	GTCCRC	GTCCRC	GTCCRA	GTCCRA	GTCCRA

Note 1. Compare match is performed only at the time of final count in the target section, but is not performed at count values other than the final count.

In the case of normal complementary PWM mode waveform, a PWM waveform change occurs in the order of negative-phase OFF → positive-phase ON → positive-phase OFF → negative-phase ON. However, this order may vary depending on operation section and register values. In this case, OFF takes precedence in trough sections and ON takes precedence in crest sections (for negative-phase waveforms), and ON takes precedence in trough sections and OFF takes precedence in crest sections (for positive-phase waveforms). A lower-priority compare match that occurs at the same time or after a higher-priority compare match is ignored.

In the initial output section, the initial output set in the GTIOR register is retained. In the case that the GTCCRA register value is larger than the GTDVU register value at the end of the initial output section, negative phase is enabled. In the case that the GTCCRA register value is not larger than the GTDVU register value, positive phase is enabled.

As operation examples of normal complementary PWM mode waveform where compare match operation occurs in the middle section, Figure 24.65 and Figure 24.66 show complementary PWM mode 1, Figure 24.67 and Figure 24.68 show complementary PWM mode 2, Figure 24.69 and Figure 24.70 show single buffer complementary PWM mode 3, and Figure 24.71 and Figure 24.72 show double buffer complementary PWM mode 3.

Figure 24.73 to Figure 24.84 show complementary PWM mode waveforms where compare match operation occurs in crest sections and trough sections and differences due to compare match occurrence order.

Figure 24.85 and Figure 24.86 show examples of initial output operation according to the GTCCRA register value.

Figure 24.87 shows an example for setting complementary PWM modes 1 to 3.

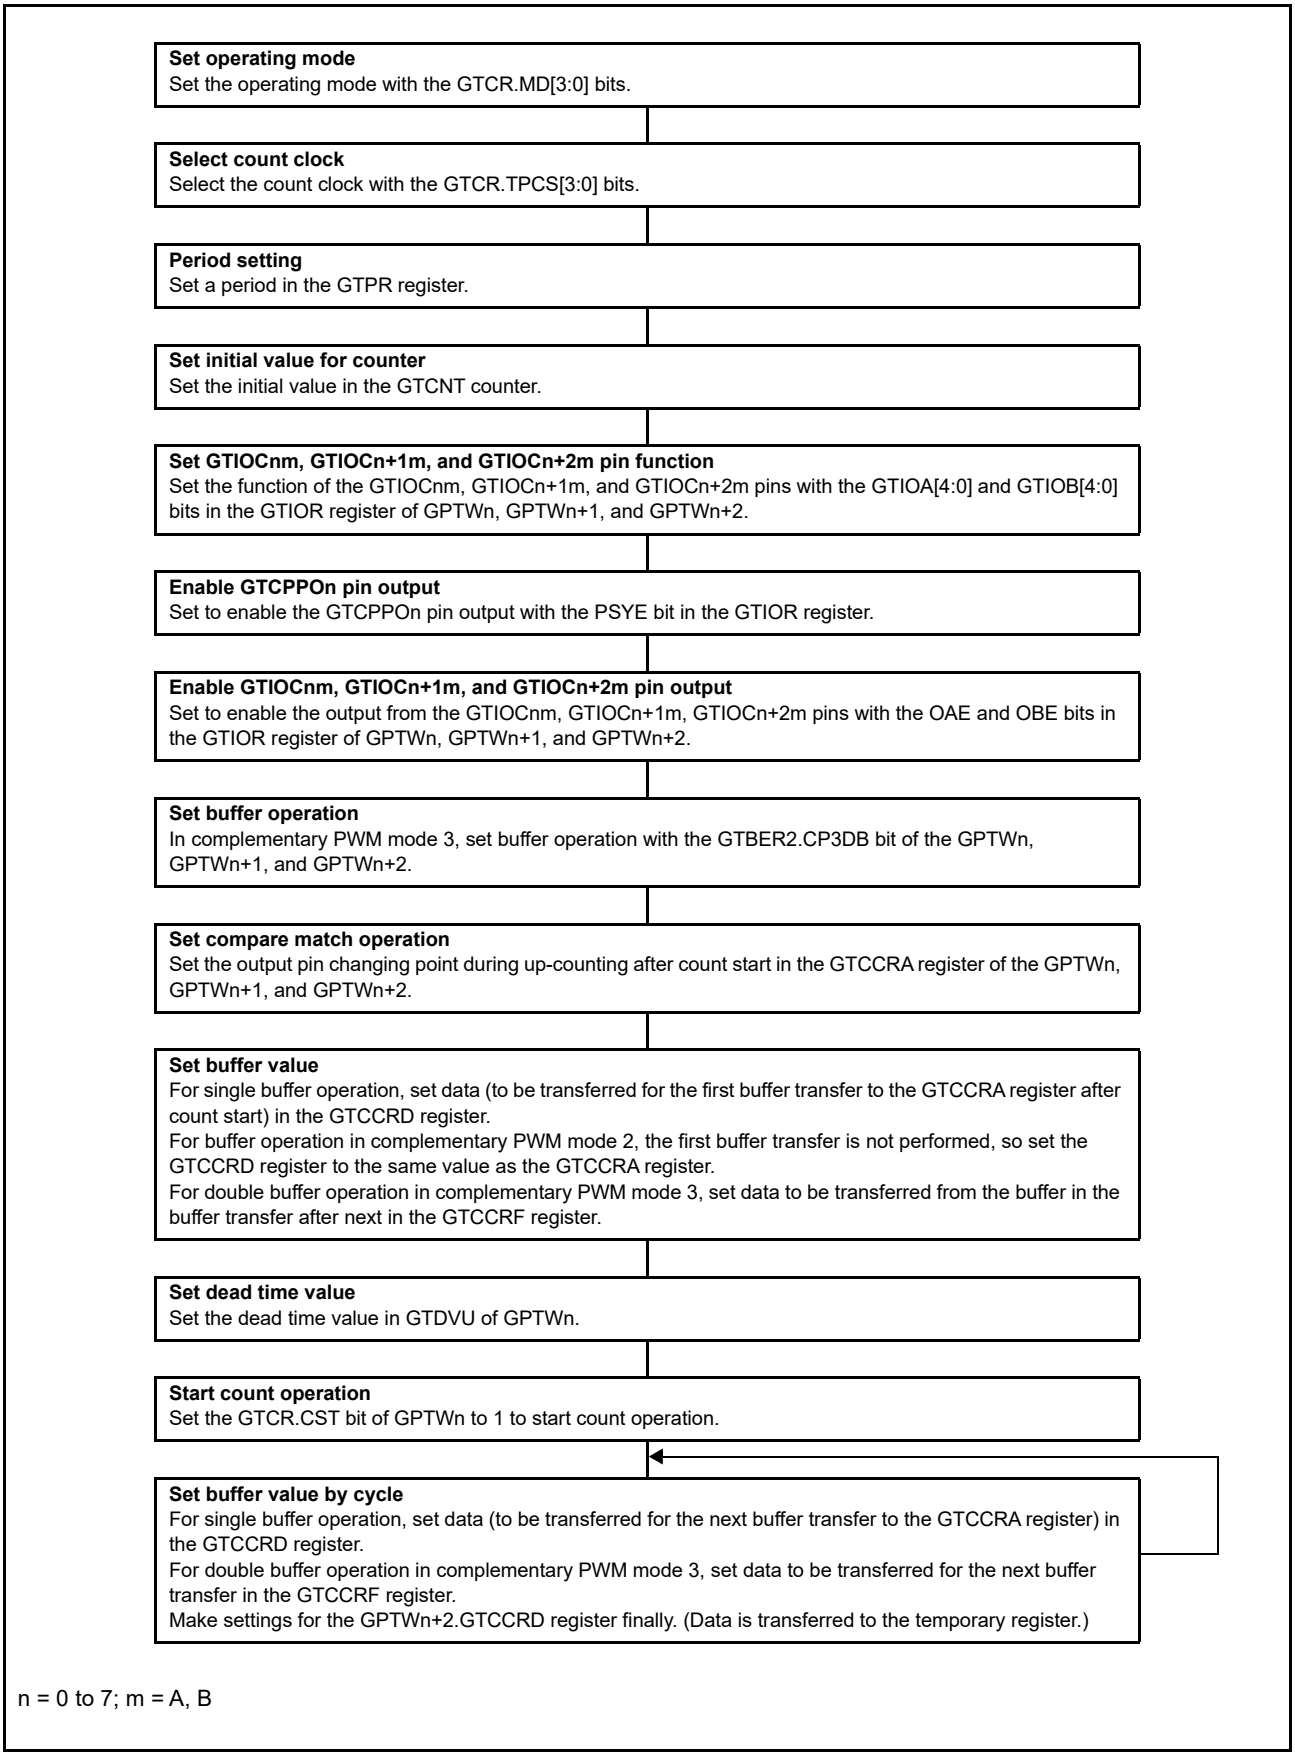

Figure 24.87 Example for Setting Complementary PWM Mode 1, 2, 3

(8) Complementary PWM Mode 4

In complementary PWM mode 4, the value written to the GTCCRD and GTCCRF registers is immediately applied to compare match operation by transferring data also to the GTCCRA register during buffer transfer to a temporary register before crest or trough transfer timing.

Figure 24.88 shows the block diagram in complementary PWM mode 4.

In the configuration of complementary PWM mode 4, a buffer transfer path from the GTCCRD register to the GTCCRC and GTCCRA registers and a buffer transfer path from the GTCCRF register to the GTCCRE and GTCCRA registers are added to other complementary PWM modes shown in Figure 24.64.

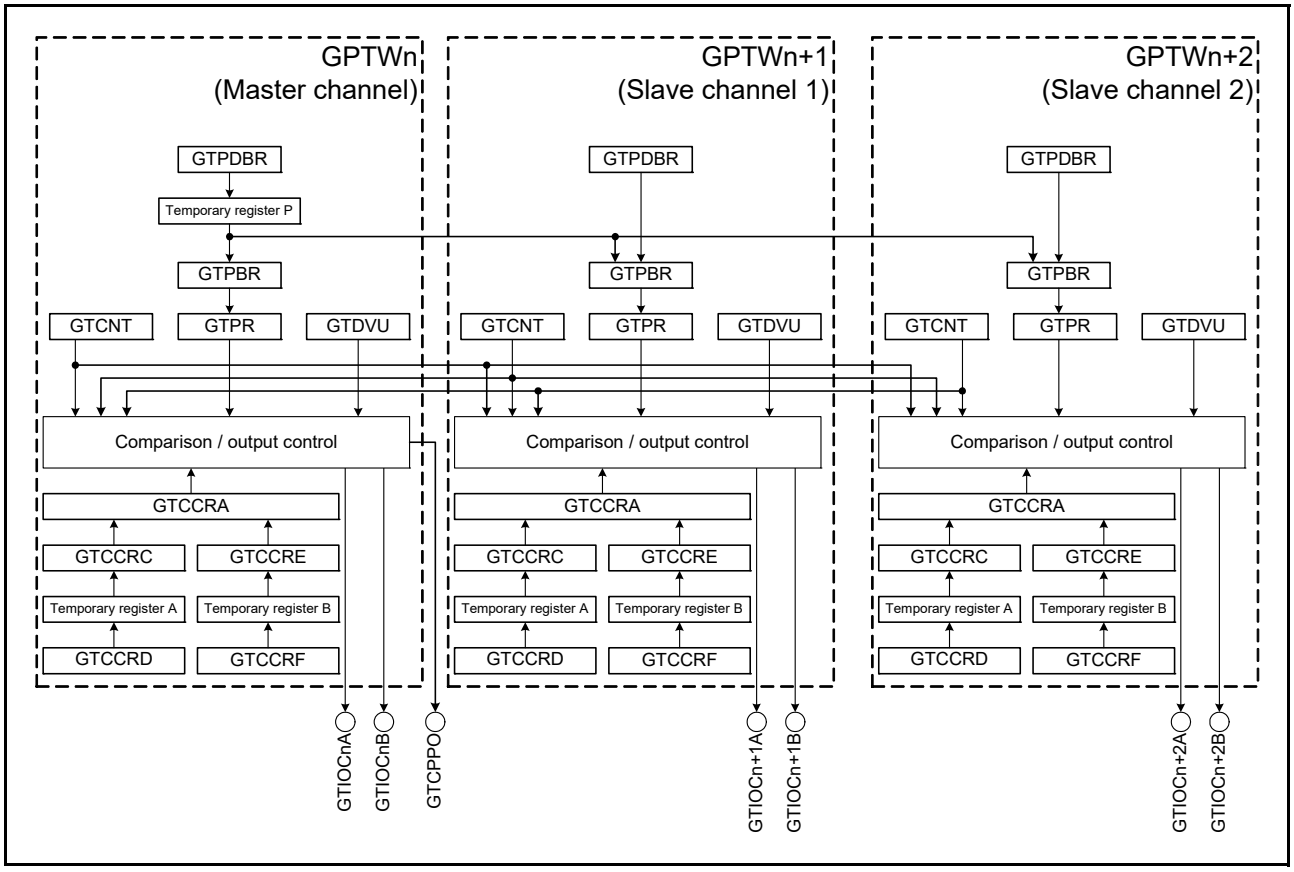

Figure 24.88 Block Diagram in Complementary PWM Mode 4 (n = 0, 4)

Count operation is performed in the same way as complementary PWM modes 1 to 3. See Table 24.12 and Table 24.13.

With respect to buffer operation and PWM waveform changes in complementary PWM mode 4, buffer transfer (shown in Figure 24.88) from the GTCCRD and GTCCRF registers is added based on the complementary PWM mode 3 operation.

Buffer transfer and PWM waveform are controlled according to operation section, state of comparison with the GTCCRA register, and write value.

The double buffer function by writing to the GTCCRF register can be enabled or disabled with the GTBER2.CP3DB bit. In double buffer operation, the value written to the GTCCRD register is used as a compare match value for positive-phase OFF (negative-phase ON) during down-counting, and the value written to the GTCCRF register is used as a compare match value for negative-phase OFF (positive-phase ON) during up-counting. Transfer register, transfer value, and PWM output changes are controlled by operation section (where the value is written), state of comparison with the GTCCRA register, and write value.

Double buffer operation is guaranteed only in the up-counting middle section and down-counting middle section. Setting a value not larger than the dead time value and not less than the count cycle is prohibited.

In single buffer operation, a compare match value is written only to the GTCCRD register, and transfer register, transfer value, and PWM output changes are controlled by operation section (where the value is written), state of comparison with the GTCCRA register, and write value.
Transfer from the GTCCRD register to the temporary register A and transfer from the GTCCRF register to the temporary register B are performed in the same way as other complementary PWM modes. Transfers are concurrently performed in three channels by writing a value to the GPTWn+2.GTCCRD register. Transfer from the GTCCRD register to the GTCCRC register, GTCCRA register, temporary register B, and GTCCRE register and transfer from the GTCCRF register to the GTCCRE register and the GTCCRA register are performed at the same time as the above-mentioned transfer to the temporary register.
Table 24.17 and Table 24.18 show immediate buffer transfer (for transfer to the temporary register by writing a value to the GPTWn+2.GTCCRD register) to the GTCCRC and GTCCRA registers by writing a value to the GTCCRD register during single buffer operation in complementary PWM mode 4 for each compare match state in each operation section. Transfers (from the GTCCRD register to the temporary register A, from the temporary register A to the GTCCRC register, and from the GTCCRC register to the GTCCRA register) other than those shown in Table 24.17 and Table 24.18 are the same as single buffer transfer in complementary PWM mode 3 shown in Table 24.14.
Table 24.19 and Table 24.20 show immediate buffer transfer (for transfer to the temporary register by writing a value to the GPTWn+2.GTCCRD register) to each register by writing a value to the GTCCRD and GTCCRF registers during double buffer operation in complementary PWM mode 4 for each compare match state in each operation section. Transfers (from the GTCCRD register to the temporary register A, from the GTCCRF register to the temporary register B, from the temporary register A to the GTCCRC register, from the temporary register B to the GTCCRE register, and from the GTCCRC and GTCCRE registers to the GTCCRA register) other than those shown in Table 24.19 and Table 24.20 are the same as double buffer transfer in complementary PWM mode 3 shown in Table 24.15.

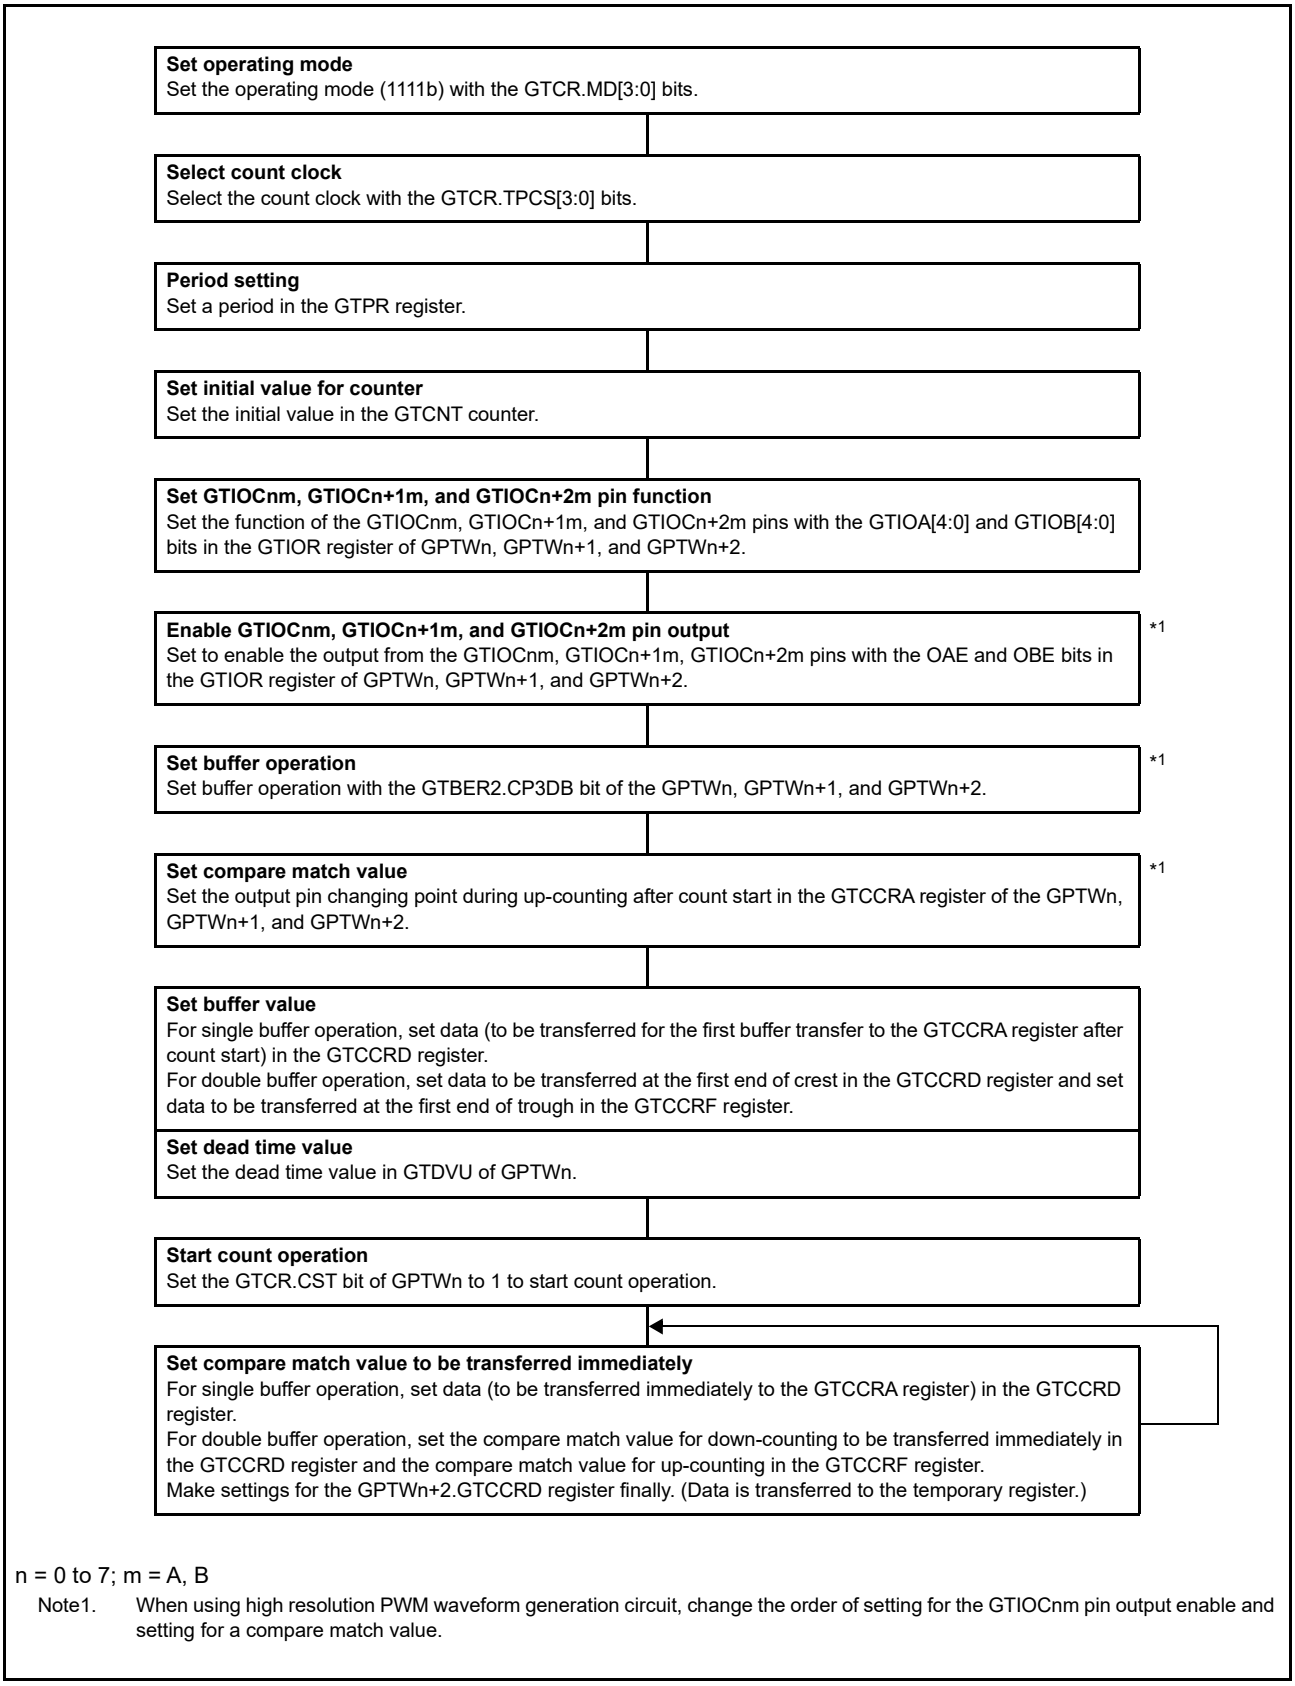
When writing to the GTCCRD register during the down-counting dead time period) (n = 0, 4)



n = 0 to 7; m = A, B

Note1. When using high resolution PWM waveform generation circuit, change the order of setting for the GTIOCnm pin output enable and setting for a compare match value.

Figure 24.98 Example for Setting Complementary PWM Mode 4

24.3.4 Automatic Dead Time Setting Function

By setting the GTDTCR register, a compare match value for a negative waveform with dead time obtained by a compare match value for a positive waveform (the GTCCRA register value) and specified dead time values (the GTDVU and GTDVD registers values) can automatically be set to the GTCCRB register.
The automatic dead time setting function can be used in sawtooth-wave one-shot pulse mode and all the triangle PWM modes.
Dead time can be separately set for the first half and second half of a waveform. Dead time for the changing point in the first half of a negative waveform is set in the GTDVU register and that in the second half is set in the GTDVD register. The same dead time can also be set for the first and second halves by setting the GTDTCR.TDFER bit to 1.
The GTDBU register can be used as a buffer register of the GTDVU register, and the GTDBD register can be used as a buffer register of the GTDVD register. Buffer transfer is performed at the end of the cycle (in sawtooth-wave mode: either of an overflow of the GTCNT counter (up-counting), an underflow (down-counting), or the GTCNT counter clearing; in triangle-wave mode: a trough).
The change point of the negative-phase waveform, which is automatically calculated, is obtained by reading the GTCCRB register. Writing to the GTCCRB register is prohibited when the automatic dead time setting function is used.

Do not set the dead-time that makes the change point of the waveform exceeding the count period. When any dead-time setting which would generate a dead-time error is made, adjust the change points of the positive- and negative-phase waveforms to generate waveforms with secured dead-time as shown in Table 24.21. The adjusted change point of the negative-phase waveform is automatically set in the GTCCRB register. An internal signal is used to judge the change point of the positive-phase waveform, thus the value of the GTCCRA register is not updated by the adjusted value.
If the order of the change point becomes inconsistent by adjustment of the waveform change point due to occurrence of dead time errors, or if the change point exceeds the count period even after the adjustment, the complementary relation between the positive- and negative-phases cannot be guaranteed.
If dead-time exceeds the count period by setting 0000 0000h or a value greater than or equal to the setting value of the GTPR register is set in the GTCCRA register in triangle-wave PWM mode, output change is controlled by the output protection function (refer to section 24.8.4, Output Protection Function for GTIOCnm Pin Output (n = 0 to 7; m = A, B)). When GTCCRA register is greater than or equal to [GTPR register + GTDVm register], [GTPR register – 1] is set in the GTCCRB register as the upper limit. (m = U, D)
Automatic setting for a dead time value to the GTCCRB register is performed at the next count clock after the register value for calculating the automatic setting value is updated. In triangle-wave mode, it also can be done at the next count clock from the current crest.

Table 24.21 Adjustment of the Waveform Change Point When a Dead-Time Error Occurs

PWM Output Operating Mode	Count Direction	Period	Condition for Dead-Time Error	Change Point of the Positive-Phase Waveform after Adjustment	Change Point of the Negative-Phase Waveform after Adjustment
Sawtooth-wave one-shot pulse mode	Up-counting	First half	GTCCRA – GTDVU < 0	GTDVU	0
		Second half	GTCCRA + GTDVD > GTPR (GTCCRA + GTDVU > GTPR)*1	GTPR – GTDVD (GTPR – GTDVU)*1	GTPR
	Down-counting	First half	GTCCRA + GTDVU > GTPR	GTPR – GTDVU	GTPR
		Second half	GTCCRA – GTDVD < 0 (GTCCRA + GTDVU < 0)*1	GTDVD (GTDVU)*1	0
Triangle-wave PWM mode 1/2/3	Up-counting	(First half)	GTCCRA – GTDVU≤0	GTDVU + 1	1
	Down-counting	(Second half)	GTCCRA – GTDVD < 0 (GTCCRA + GTDVU < 0)*1	GTDVD (GTDVU)*1	0

Note 1. In the case of GTDTCR.TDFER = 1.

Figure 24.99 to Figure 24.102 show examples of automatic dead time setting function operation. Figure 24.103 and Figure 24.104 show the setting examples.

Figure 24.104 Example for Setting Automatic Dead Time Setting Function (Triangle-Wave PWM Mode 1 or 2)

24.3.5 Count Direction Changing Function

The count direction of the GTCNT counter can be changed by modifying the GTUDDTYC.UD bit.
In sawtooth-wave mode, if the UD bit is modified during count operation, the count direction is changed at an overflow (when modified during up-counting) or an underflow (when modified during down-counting). If the UD bit is modified while count operation is stopped and the GTUDDTYC.UDF bit is 0, the UD bit modification is not reflected at the start of counting and the count direction is changed at an overflow or an underflow. If the UDF bit is set to 1 while count operation is stopped, the UD bit value at that time is reflected at the start of counting.
In triangle-wave mode, changing the value of the GTUDDTYC.UD bit during counting does not switch the direction of counting. Likewise, changing the value of the GTUDDTYC.UD bit while the GTUDDTYC.UDF bit is 0 and counting is stopped does not actually update the value of the bit. If 1 is written to the GTUDDTYC.UDF bit while counting is stopped, the value of the GTUDDTYC.UD bit at that time is reflected from the time counting is started.
When counting direction is switched during count operation in sawtooth-wave mode, the value of the GTPR register after start of up-counting is reflected to the count period in up-counting operation, and the value of the GTPR register after the start of down-counting is reflected to the count period in down-counting operation.
Figure 24.105 shows an example of count direction changing function operation.

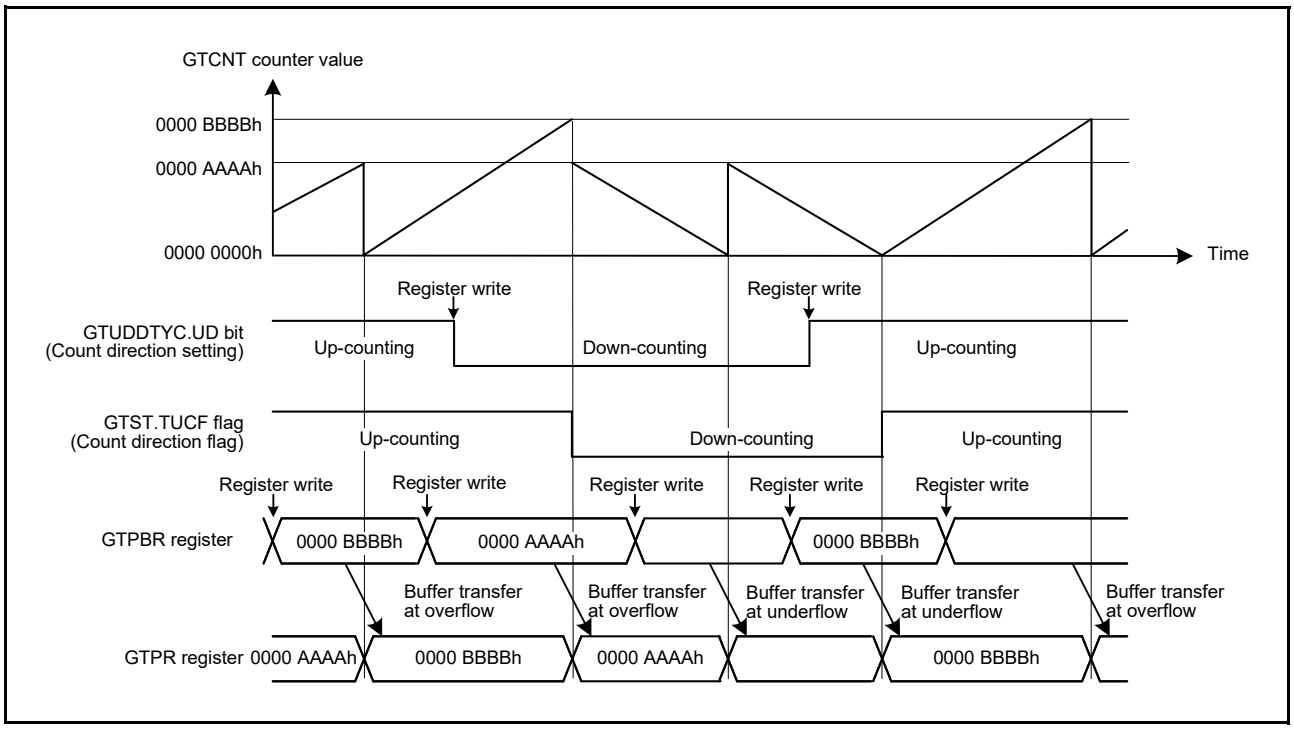

Figure 24.105 Example of Count Direction Changing Function Operation (during Buffer Operation)

24.3.6 Duty Cycle 0%/100% Output Function

Changing the value of the GTUDDTYC.OADTY[1:0] bits and GTUDDTYC.OBDTY[1:0] bits specifies the output duty setting on the GTIOCnA and GTIOCnB pins to 0% or 100%. (n = 0 to 7)

This function is invalid in sawtooth-wave PWM mode 2 or complementary PWM mode.

In sawtooth-wave mode, if the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed during the count operation, the output duty-cycle setting is reflected at an overflow (when changed during up-counting) or an underflow (when changed during down-counting). When the GTUDDTYC.OADTYF bit or GTUDDTYC.OBDTYF bit is 0 while count operation is stopped and the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed, the output duty-cycle setting changed at the start of counting is not reflected, but the output duty-cycle setting changed at an overflow or underflow is reflected. When the OADTYF bit or OBDTYF bit is 1 while count operation is stopped and the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed, the value of the OADTY[1:0] bits or OBDTY[1:0] bits at that time is reflected at the start of counting.

In triangle-wave mode, if the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed during the count operation, the output duty-cycle setting changed at an underflow is reflected.

When the OADTYF bit or OBDTYF bit is 0 while count operation is stopped and the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed, the output duty-cycle setting changed at the start of counting is not reflected, but the output duty-cycle setting changed at an underflow is reflected. When the OADTYF bit or OBDTYF bit is 1 while count operation is stopped and the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed, the value of the OADTY[1:0] bits or OBDTY[1:0] bits at that time is reflected at the start of counting.

During the operation under the settings of duty cycle for 0%/100%, compare match operation inside the GPTW continues to perform interrupt outputs and buffer operations.

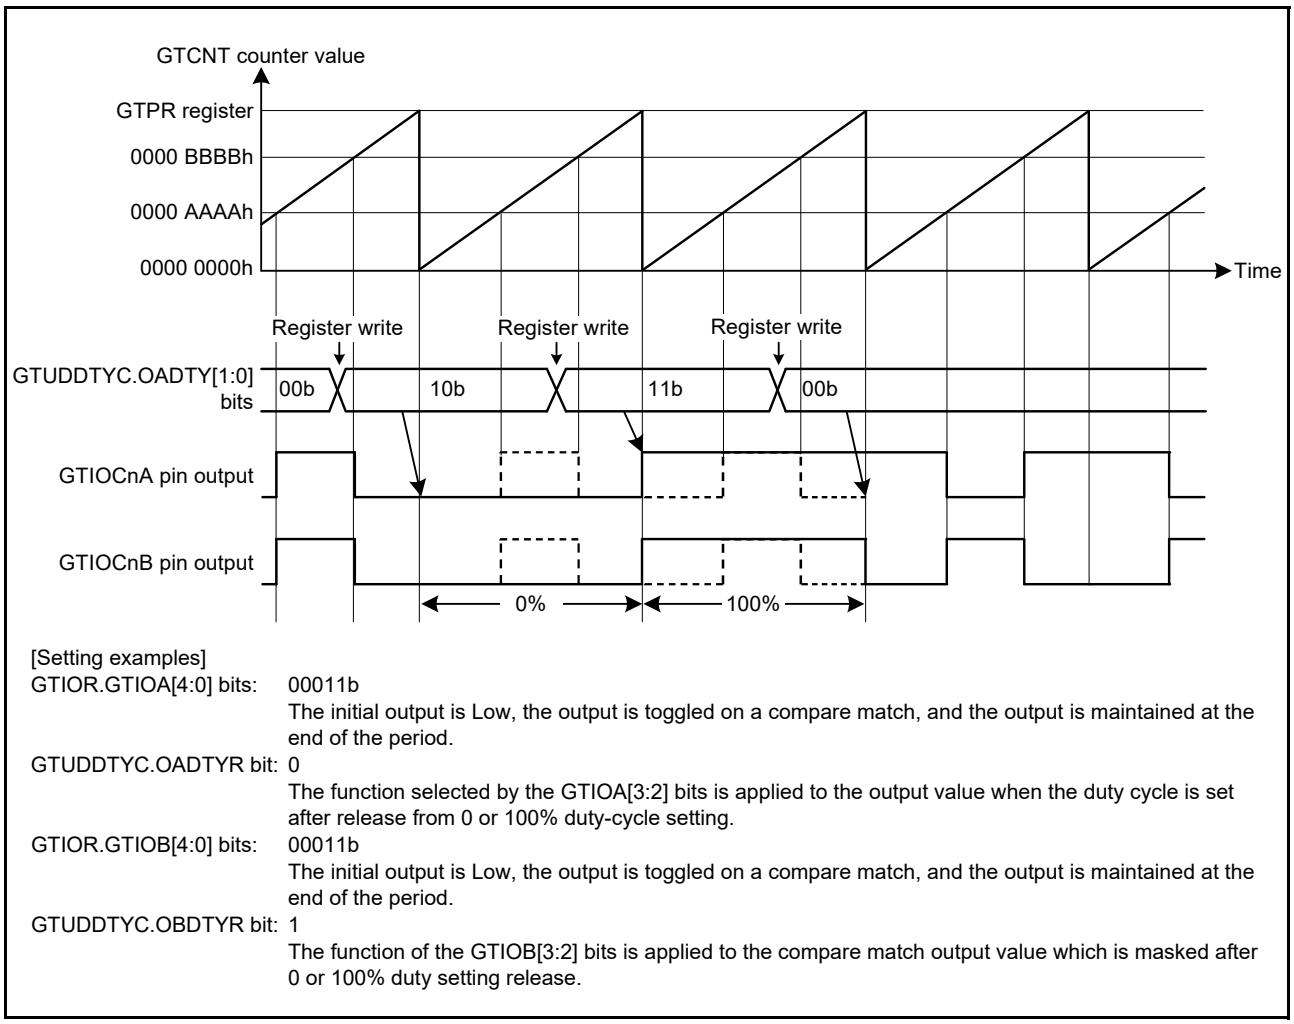
When the output duty setting is changed from 0% or 100% due to a compare match, the GTIOR.GTIOA[3:2] bits and the OADTYR bits determine the level output on the GTIOCnA pin and GTIOR.GTIOB[3:2] bits and OBDTYR bits determine the level output on the GTIOCnB pin at the end of the cycle. When the GTIOA[3:2], GTIOB[3:2] bits are set as 01b, output is driven Low at the end of the cycle, and when set as 10b, output is driven High at the end of the cycle. The output is retained at the end of the cycles when the GTIOA[3:2] or GTIOB[3:2] bits are 00b, and toggled at the end of the cycles when the GTIOA[3:2] or GTIOB[3:2] bits are 11b. A value to be output is selectable in the OADTYR or OBDTYR bit when the corresponding GTIOA[3:2] or GTIOB[3:2] bits are either 00b or 11b. Table 24.22 lists the output values at the end of the cycle when the output setting is changed from duty 0% or 100% to compare match.

Table 24.22 Output Value after Release of Duty 0%/100%

GTIOR.GTIOm[3:2]	Value at Compare Match Output at the End of the Cycle in the Case of Masking by a Duty Cycle 0% or 100%	The GTUDDTYC.OmDTYR Bit at Duty 0% Setting		The GTUDDTYC.OmDTYR Bit at Duty 100% Setting	
		0	1	0	1
00b (Output retained at the end of the cycle)	0	0	0	1	0
	1	0	1	1	1
01b (Low output at the end of the cycle)	—	0	0	0	0
10b (High output at the end of the cycle)	—	1	1	1	1
11b (Toggle output at the end of the cycle)	0	1	1	0	1
	1	1	0	0	0

m = A, B

Figure 24.106 shows an example of operation of the output of the duty cycle 0% or 100% (n = 0 to 7).



[Setting examples]

GTIOR.GTIOA[4:0] bits: 00011b
The initial output is Low, the output is toggled on a compare match, and the output is maintained at the end of the period.

GTUDDTYC.OADTYR bit: 0
The function selected by the GTIOA[3:2] bits is applied to the output value when the duty cycle is set after release from 0 or 100% duty-cycle setting.

GTIOR.GTIOB[4:0] bits: 00011b
The initial output is Low, the output is toggled on a compare match, and the output is maintained at the end of the period.

GTUDDTYC.OBDTYR bit: 1
The function of the GTIOB[3:2] bits is applied to the compare match output value which is masked after 0 or 100% duty setting release.

Figure 24.106 Example of Operation of Output of Duty Cycle 0% or 100% (n = 0 to 7)

24.3.7 Hardware Count Start/Count Stop and Clear Operation

The GTCNT counter can be started, stopped, or cleared by hardware sources in this MCU. There are 3 types of hardware sources, including external trigger input, ELC event input, and GTIOCnm pin input (n = 0 to 7; m = A, B)

24.3.7.1 Hardware Start Operation

The GTCNT counter can be started by a hardware source. Select a hardware source to start counting using the GTSSR register, and enable to start counting.
Figure 24.107 shows an example of count start operation by a hardware source. Figure 24.108 shows the setting example.

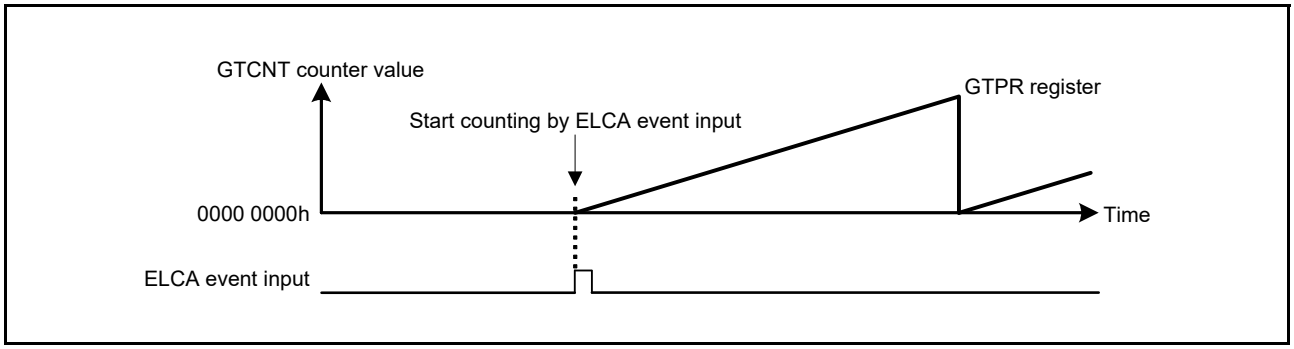


Figure 24.107 Example of Count Start Operation by Hardware Source (At starting by ELCA event)

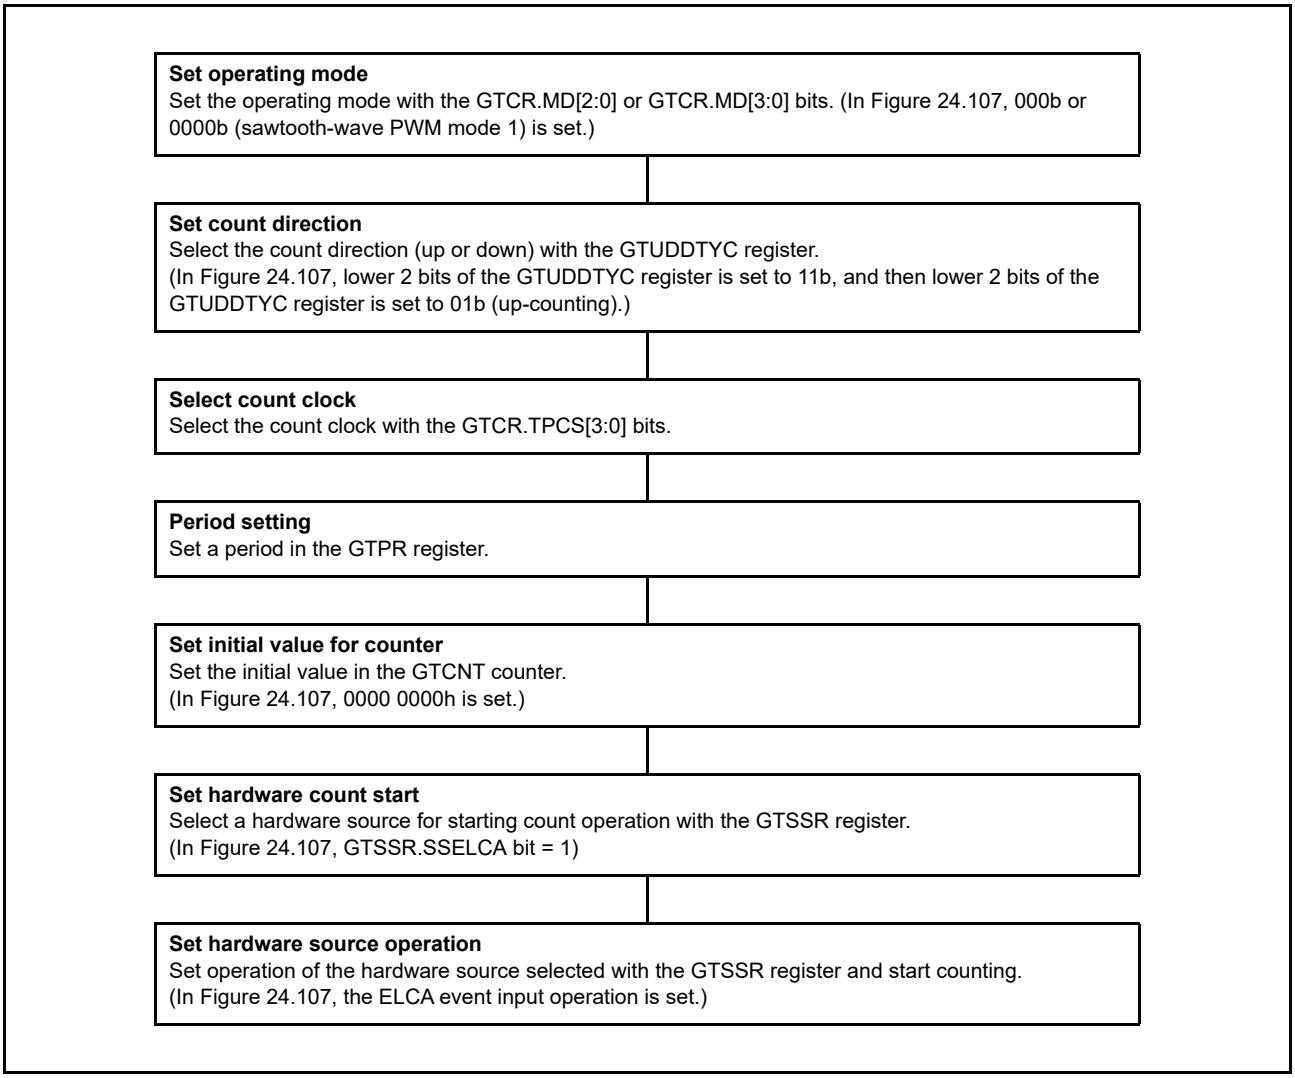

Figure 24.108 Example for Setting Count Start Operation by Hardware Source

Figure 24.109 shows an example of timing of operations to start counting in response to a rising edge of the input on the GTETRGA pin.

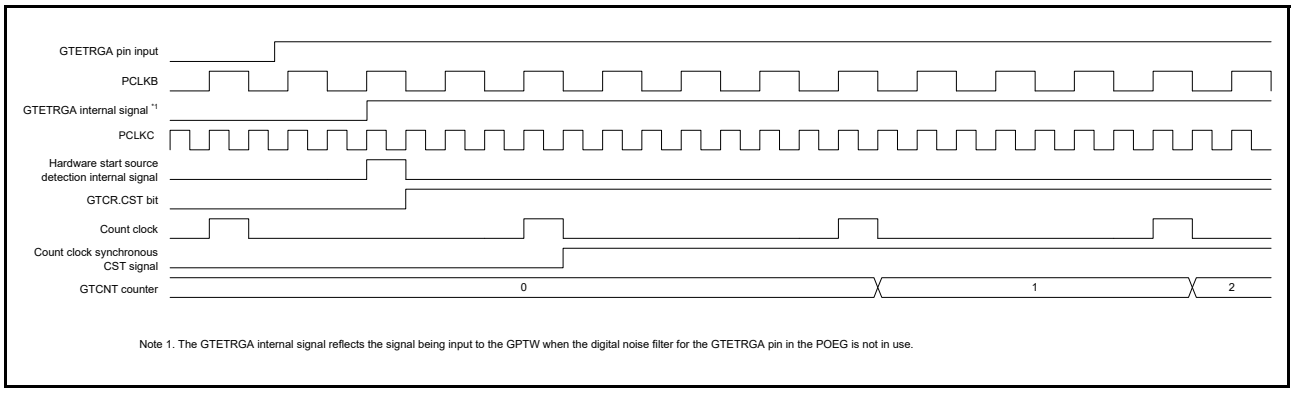

Figure 24.109 Example of Timing of Operations to Start Counting in Response to a Rising Edge of the Input on the GTETRGA Pin

Figure 24.110 shows an example of timing of operations to start counting in response to a rising edge of the input on the GTIOCnA pin.

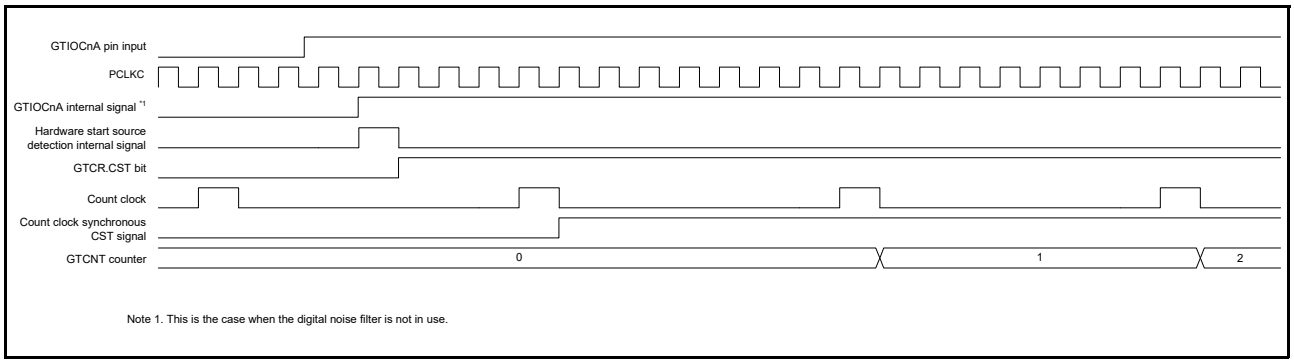

Figure 24.110 Example of Timing of Operations to Start Counting in Response to a Rising Edge of the Input on the GTIOCnA Pin

Figure 24.111 shows an example of timing of operations to start counting in response to event input from the ELCA. This is an example of operations to start counting by the GPTW1.GTCNT counter in response to a signal. An event signal is output to the ELC after matches in comparison with the GPTW0.GTCCRA register. This is selected as a trigger for output to the GPTW by the ELC as event source A. The GPTW0 compare match A signal is synchronized with PCLKC. The ELC receives the signal in synchronization with PCLKB, and outputs the GPTW event source A signal after 1 cycle of PCLKB has elapsed.

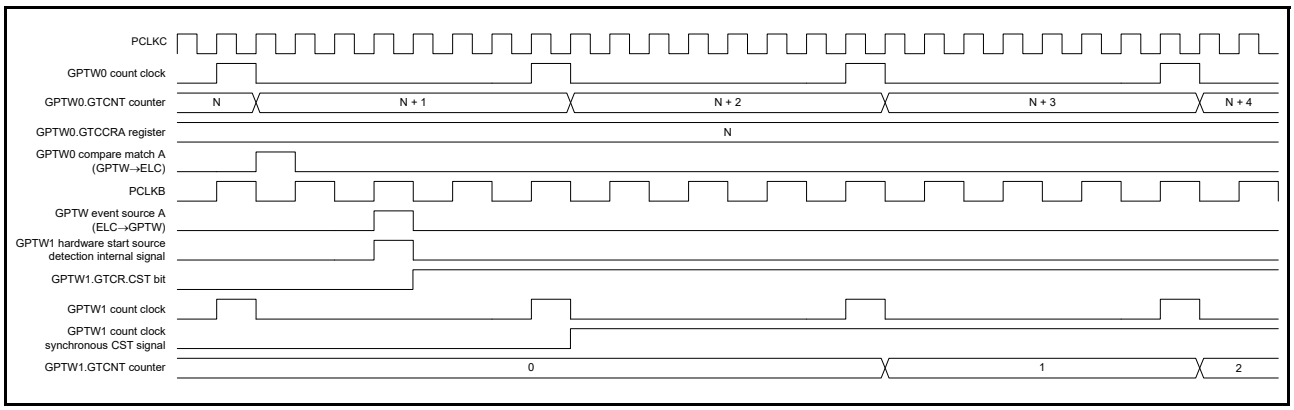

Figure 24.111 Example of Timing of Operations to Start Counting in Response to Event Input from the ELCA

24.3.7.2 Hardware Stop Operation

The GTCNT counter can be stopped by a hardware source. Select a hardware source to stop counting with the GTPSR register, and enable to stop counting.

Figure 24.112 shows an example of count stop operation by a hardware source. Figure 24.113 shows the setting example. In this example, the count operation is stopped by the ELCA event input, and is restarted by the ELCB event input.

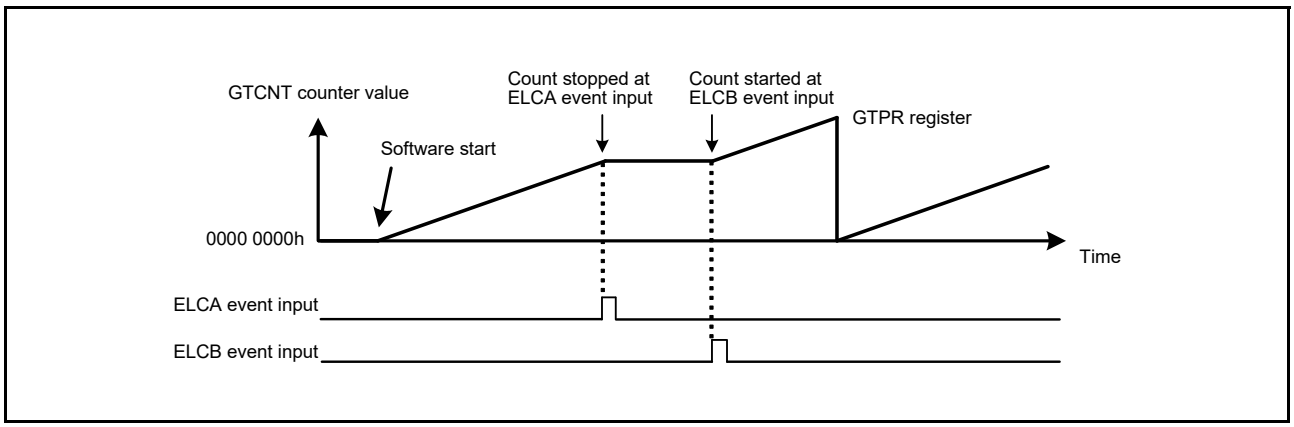

Figure 24.112 Example of Count Stop Operation by Hardware Source (Started by Software, Stopped at ELCA event input, and Restarted at ELCB event input)

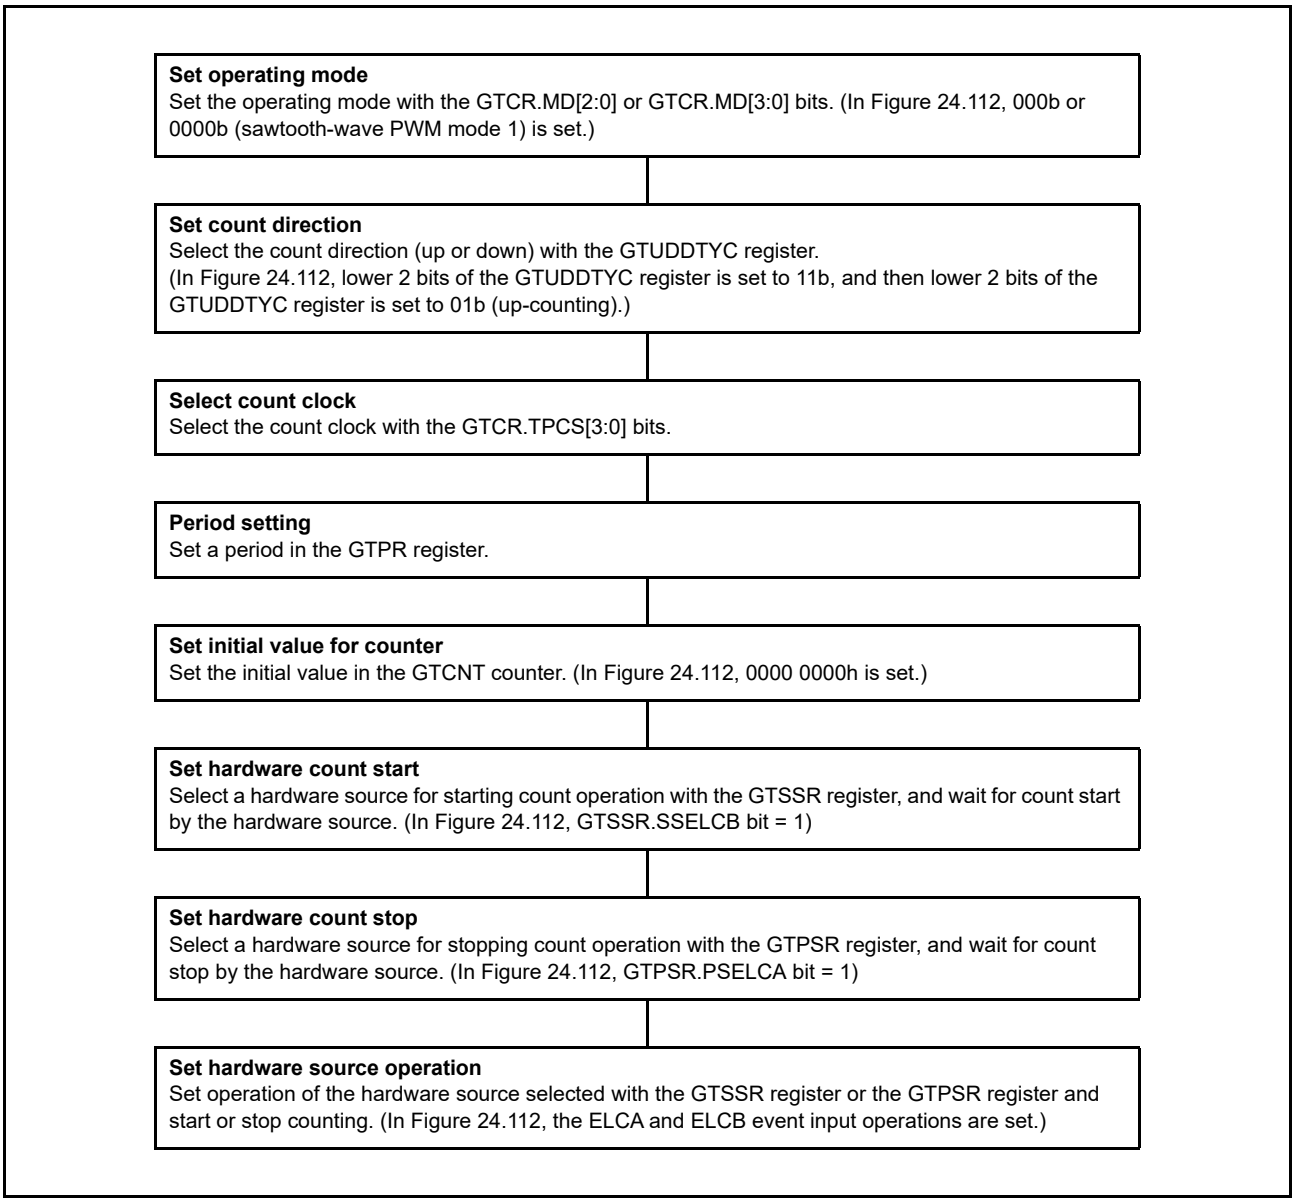

Figure 24.113 Example for Setting Count Stop Operation by Hardware Source

Figure 24.114 shows an example of count start/stop operation by a hardware source. Figure 24.115 shows the setting example. In this example, the counter operates during the high-level periods of the external trigger input GTETRGA pin.

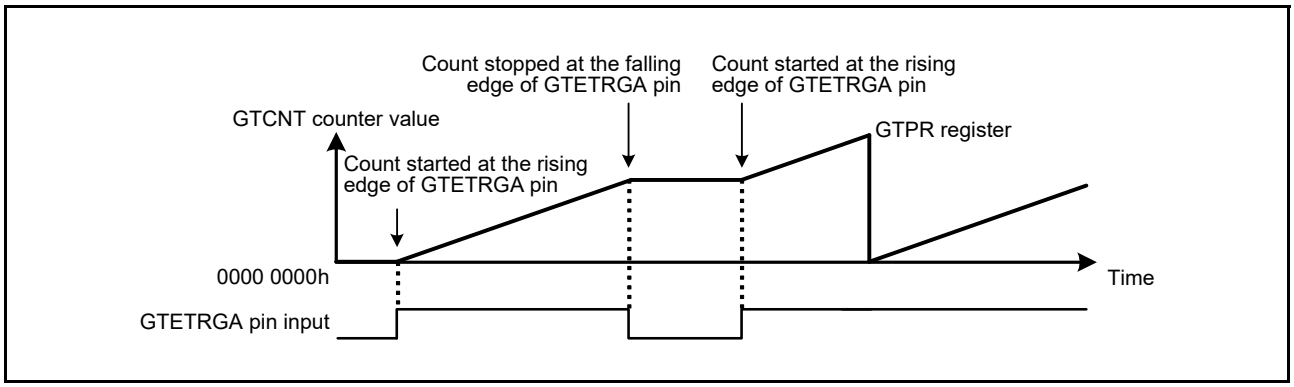

Figure 24.114 Example of Count Start/Stop Operation by Hardware Source (Started at Rising Edge of GTETRGA Pin Input, Stopped at Falling Edge of GTETRGA Pin Input)

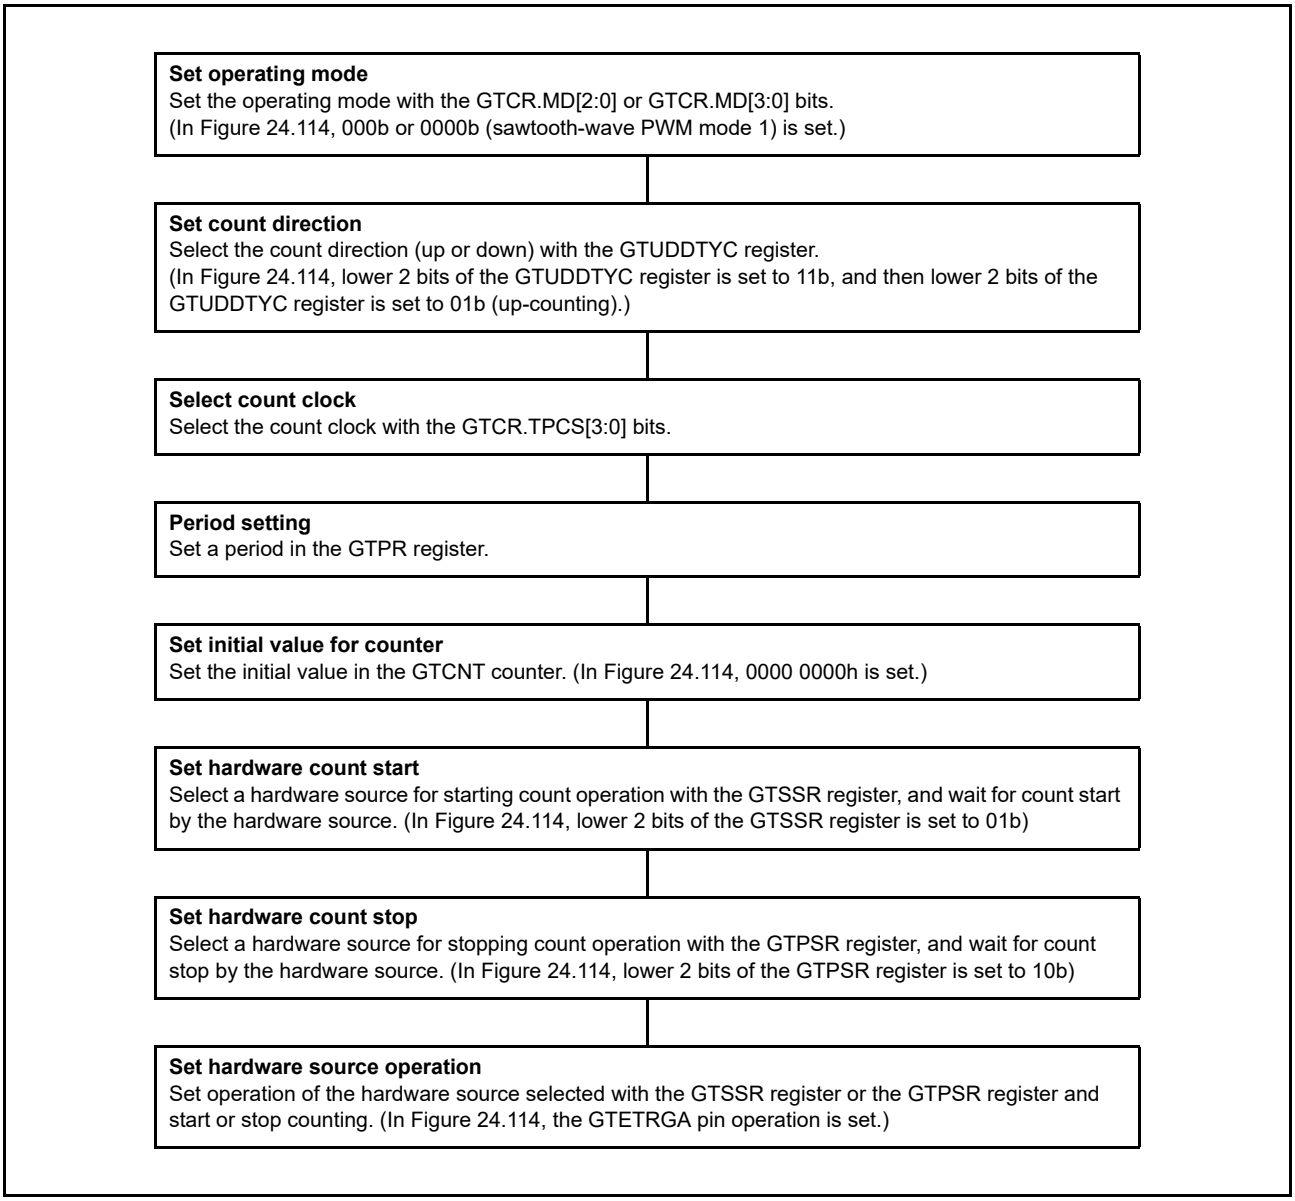

Figure 24.115 Example for Setting Count Start/Stop Operation by Hardware Source

Figure 24.116 shows an example of timing of operations to stop counting in response to a rising edge of the input on the GTETRGA pin.

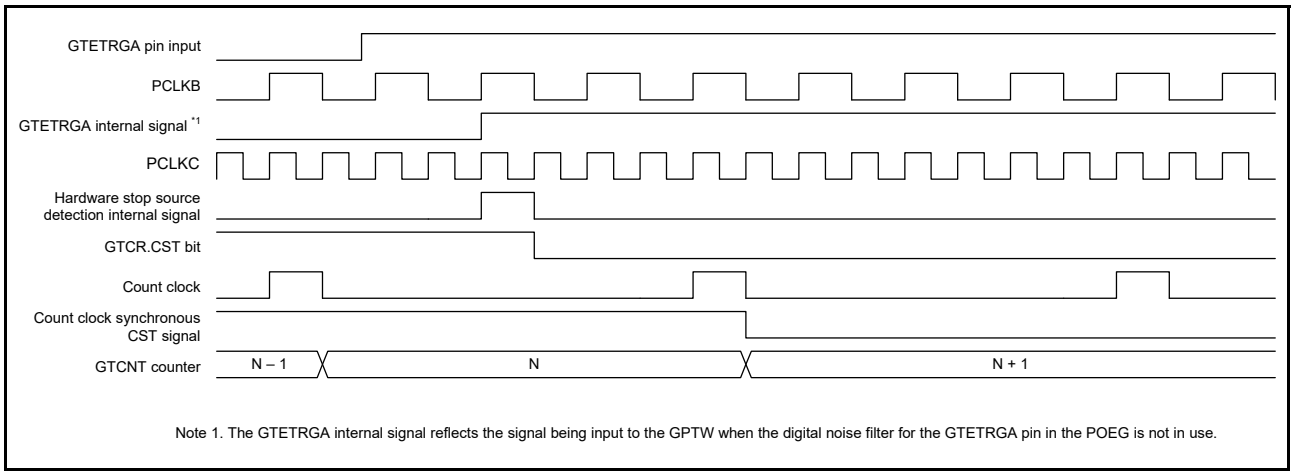

Figure 24.116 Example of Timing of Operations to Stop Counting in Response to a Rising Edge of the Input on the GTETRGA Pin

Figure 24.117 shows an example of timing of operations to stop counting in response to a rising edge of the input on the GTIOCnA pin.

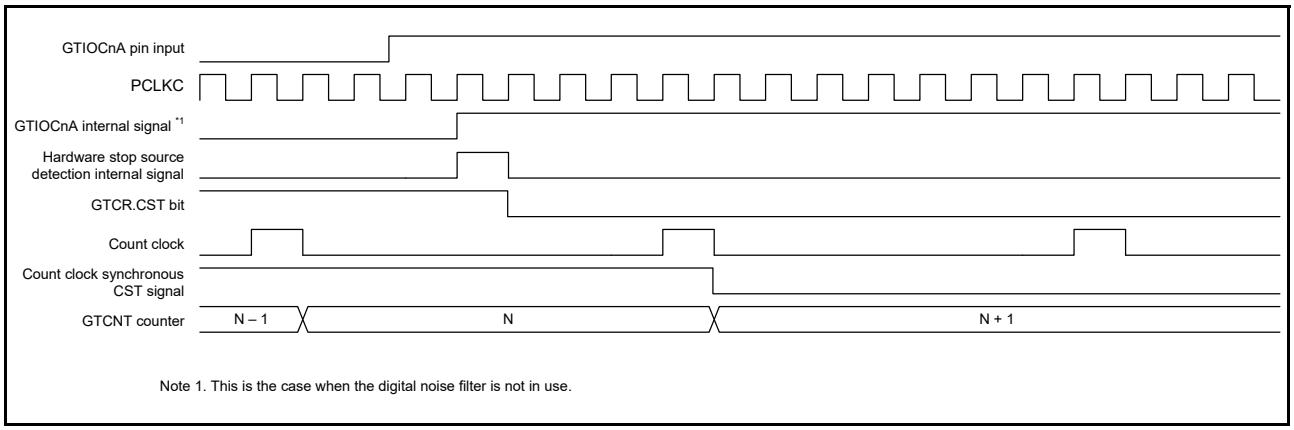

Figure 24.117 Example of Timing of Operations to Stop Counting in Response to a Rising Edge of the Input on the GTIOCnA Pin

Figure 24.118 shows an example of timing of operations to stop counting in response to event input from the ELCA. This is an example of operations to stop counting by the GPTW1.GTCNT counter in response to a signal. An event signal is output to the ELC after matches in comparison with the GPTW0.GTCCRA register. This is selected as a trigger for output to the GPTW by the ELC as event source A. The GPTW0 compare match A signal is synchronized with PCLKC. The ELC receives the signal in synchronization with PCLKB, and outputs the GPTW event source A signal after 1 cycle of PCLKB has elapsed.

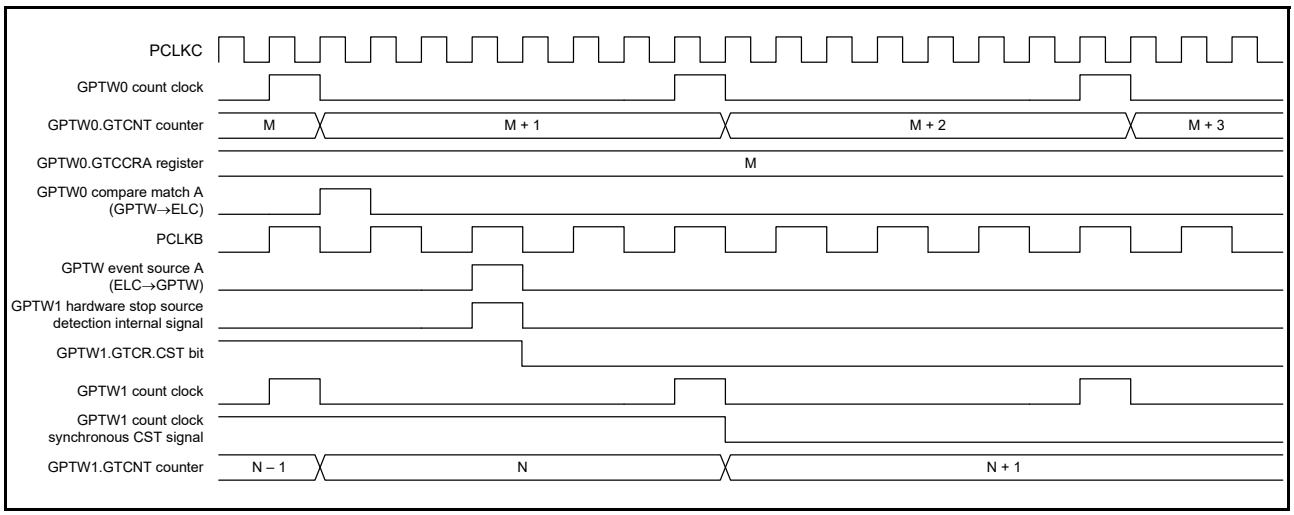

Figure 24.118 Example of Timing of Operations to Stop Counting in Response to Event Input from the ELCA

24.3.7.3 Hardware Clear Operation

The GTCNT counter can be cleared by a hardware source. Select a hardware source to clear the counter with the GTCSR register, and enable clearing the counter.

Note that the GTCIV/GTCIU interrupt (overflow/underflow interrupt) is not generated when the GTCNT counter is cleared by a hardware source or by software.

Figure 24.119 and Figure 24.120 show examples of the GTCNT counter clearing operation by a hardware source. Figure 24.121 shows the setting example. In this example, the GTCNT counter is started at the ELCA event input, and is stopped/cleared at the ELCB event input.

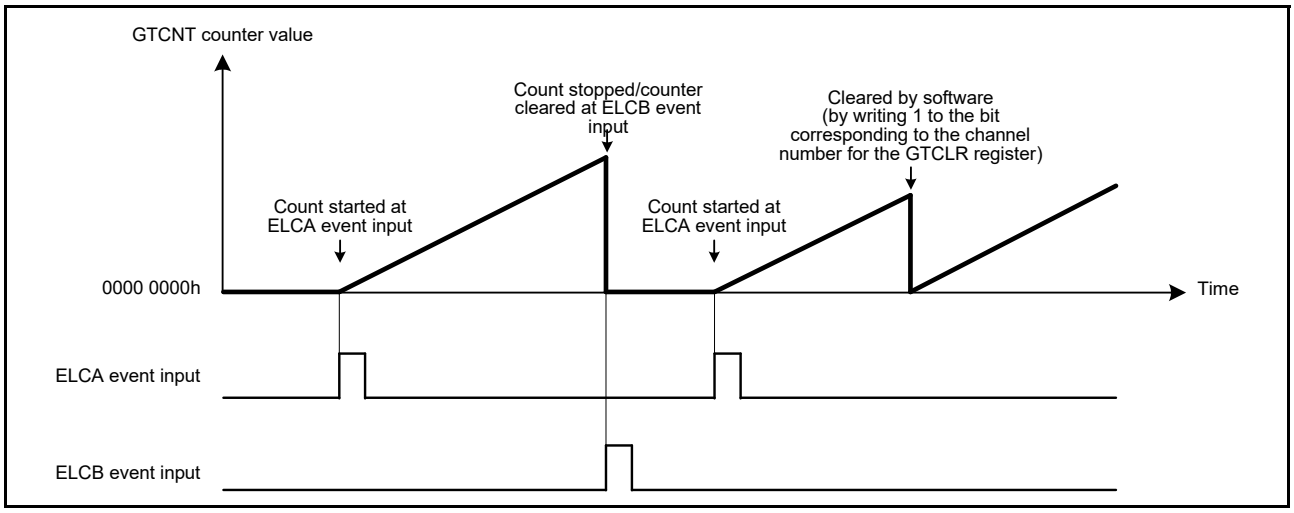

Figure 24.119 Examples of Counter Clearing Operation by Hardware Source (Sawtooth-Wave Up-Counting, Started at ELCA event input, and Count Stopped/Counter Cleared at ELCB event input)

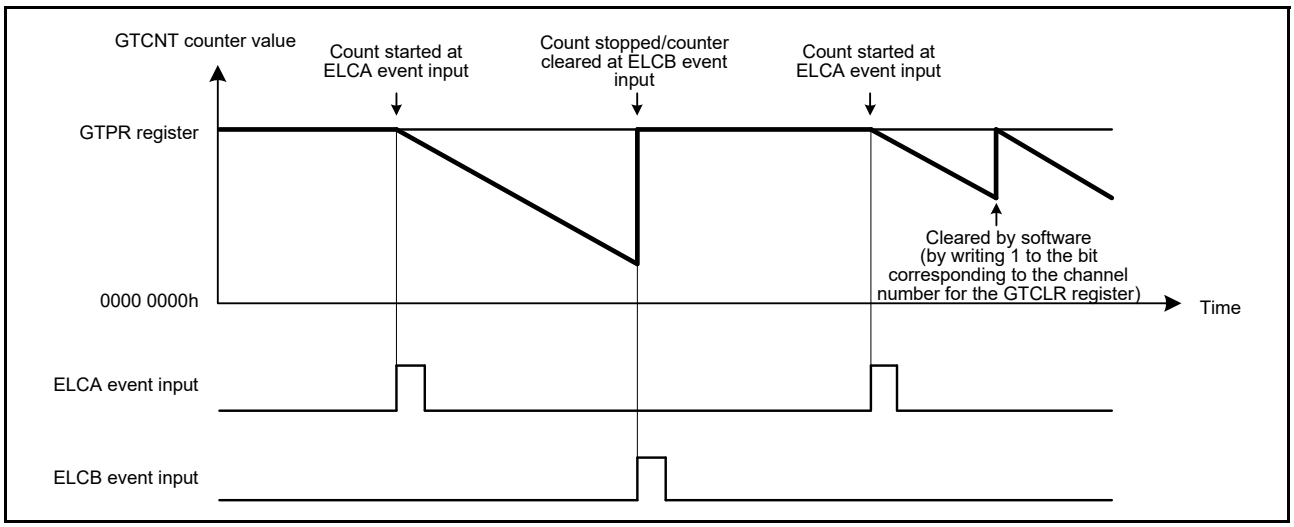

Figure 24.120 Examples of Counter Clearing Operation by Hardware Source (Sawtooth-Wave Down-Counting, Started at ELCA event input, and Count Stopped/Counter Cleared at ELCB event input)

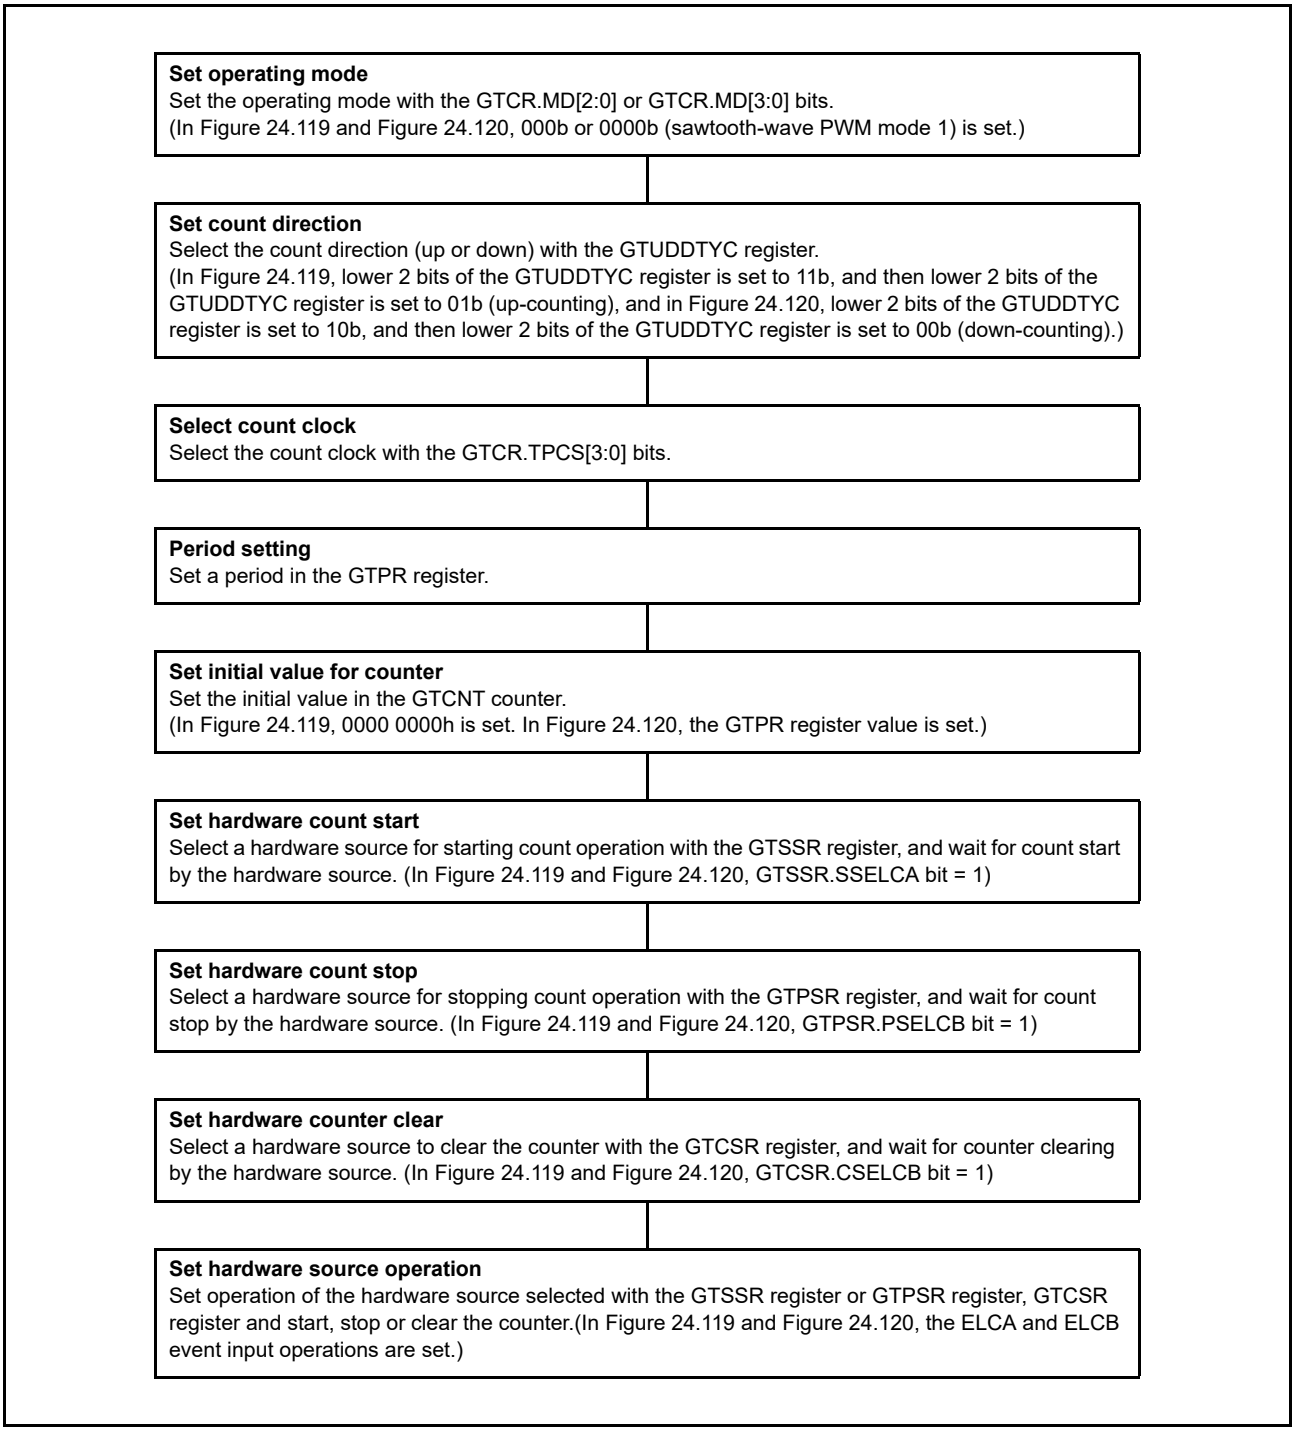

Figure 24.121 Example for Setting Counter Clearing Operation by Hardware Source

The GTCIV/GTCIU interrupt (overflow/underflow interrupt) does not occur when the counter is cleared by a hardware source. In the same way, the GTCIV/GTCIU interrupt does not occur when the counter is cleared by software.
Figure 24.122 shows the relationship between counter clearing by a hardware source and the GTCIV interrupt.

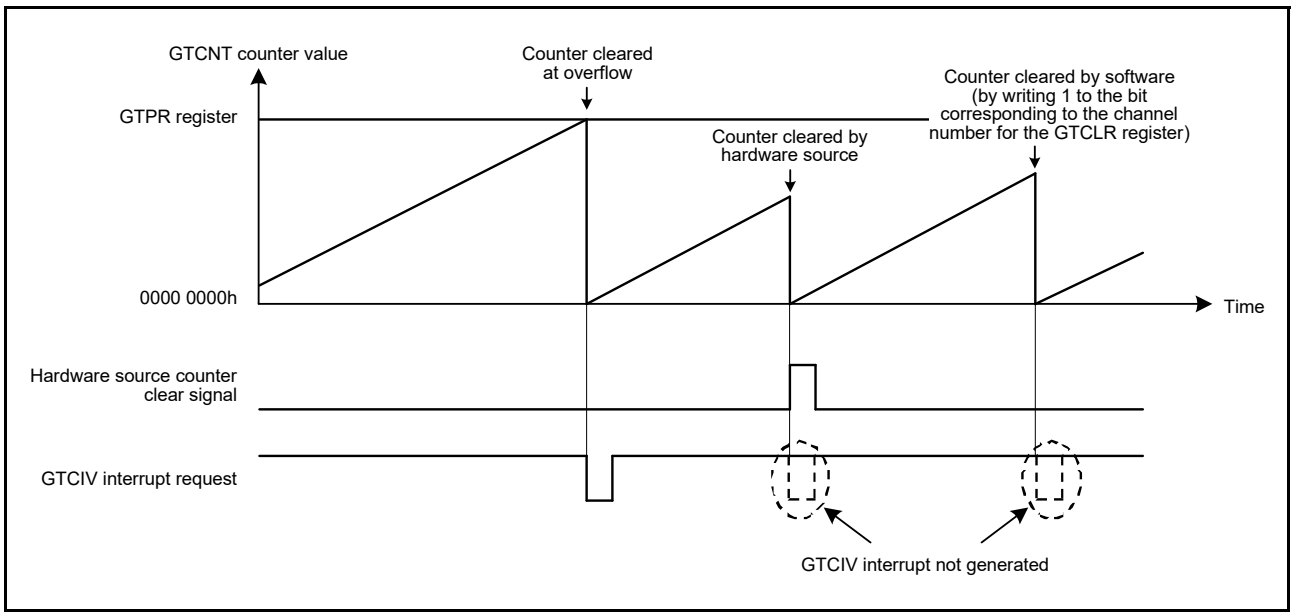

Figure 24.122 Relationship between Counter Clearing by Hardware Source and GTCIV Interrupt

Figure 24.123 shows an example of the timing of operations to clear the counter in response to a rising edge of the input on the GTETRGA pin when a clock signal produced by frequency-dividing the PCLKC signal is used as the counter clock for the GTCNT counter.
The GTCNT counter is cleared when counting is in progress after the GPTW has detected the internal clearing signal.

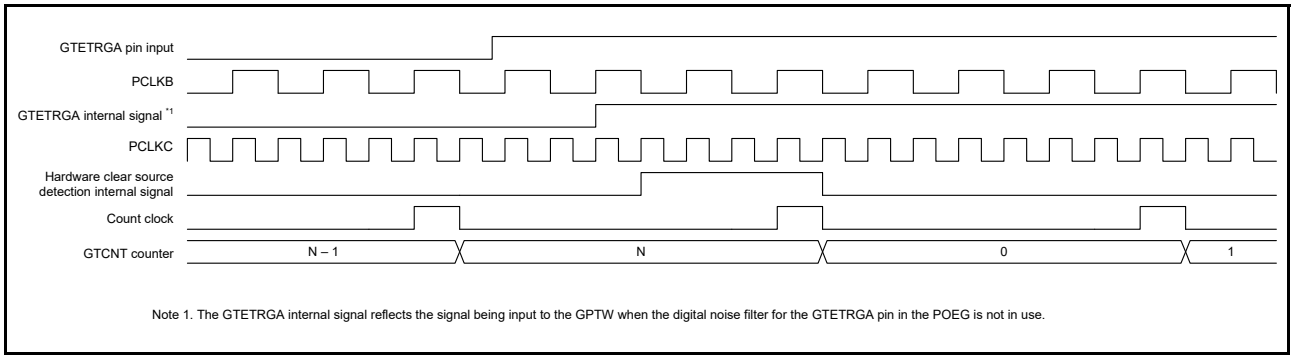

Figure 24.123 Example of the Timing of Operations for Counter Clearing in Response to a Rising Edge of the Input on the GTETRGA Pin (During the Counting of Cycles of Clock Signal Produced by Dividing the PCLKC Frequency)

Figure 24.124 shows an example of the timing of operations to clear the counter in response to a rising edge of the input on the GTIOCnA pin when a clock signal produced by frequency-dividing the PCLKC signal is used as the counter clock for the GTCNT counter.
The GTCNT counter is cleared when counting is in progress after the GPTW has detected the internal clearing signal.

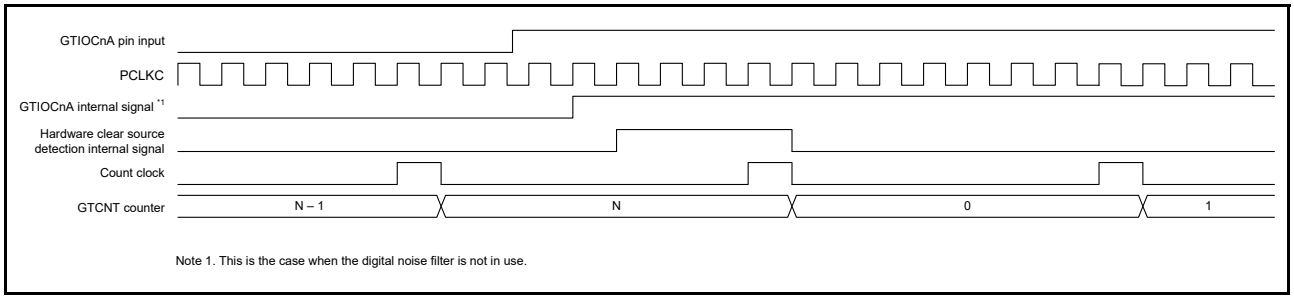

Figure 24.124 Example of the Timing of Operations for Counter Clearing in Response to a Rising Edge of the Input on the GTIOCnA Pin (During the Counting of Cycles of Clock Signal Produced by Dividing the PCLKC Frequency)

Figure 24.125 shows an example of the timing of operations to clear the counter in response to event input from the ELCA when a clock signal produced by frequency-dividing the PCLKC signal is used as the counter clock for the GTCNT counter.
This is an example of operations to clear the GPTW1.GTCNT counter in response to a signal. An event signal is output to the ELC after matches in comparison with the GPTW0.GTCCRA register. This is selected as a trigger for output to the GPTW by the ELC as event source A.
The GPTW0 compare match A signal is synchronized with PCLKC. The ELC receives the signal in synchronization with PCLKB, and outputs the GPTW event source A signal after 1 cycle of PCLKB has elapsed. The GTCNT counter is cleared when counting is in progress after the GPTW has detected the internal clearing signal.

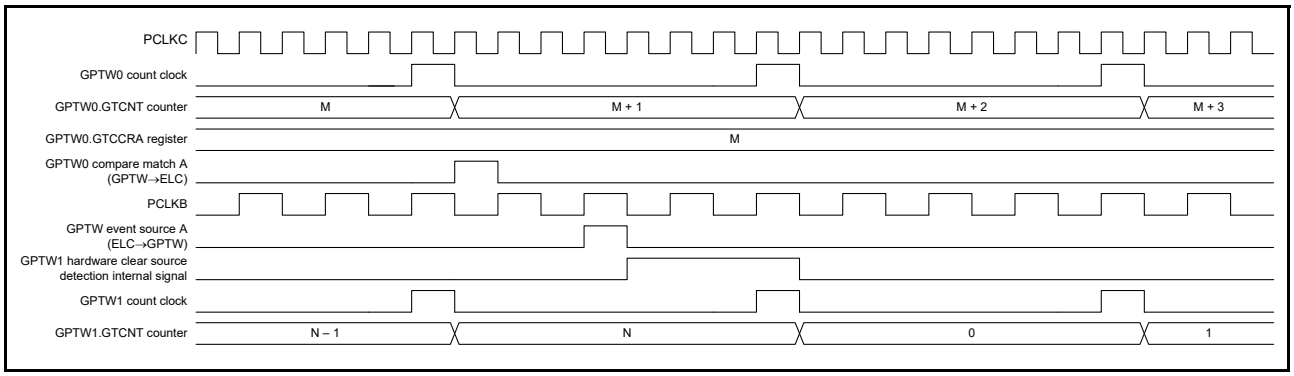

Figure 24.125 Example of the Timing of Operations for Counter Clearing in Response to Event Input from the ELCA (During the Counting of Cycles of Clock Signal Produced by Dividing the PCLKC Frequency)

Figure 24.126 shows an example of the timing of operations to clear the counter in response to a rising edge of the input on the GTETRGA pin input when counting is triggered by a hardware source.
The GTCNT counter is cleared in synchronization with PCLKC after the GPTW has detected the internal clearing signal.

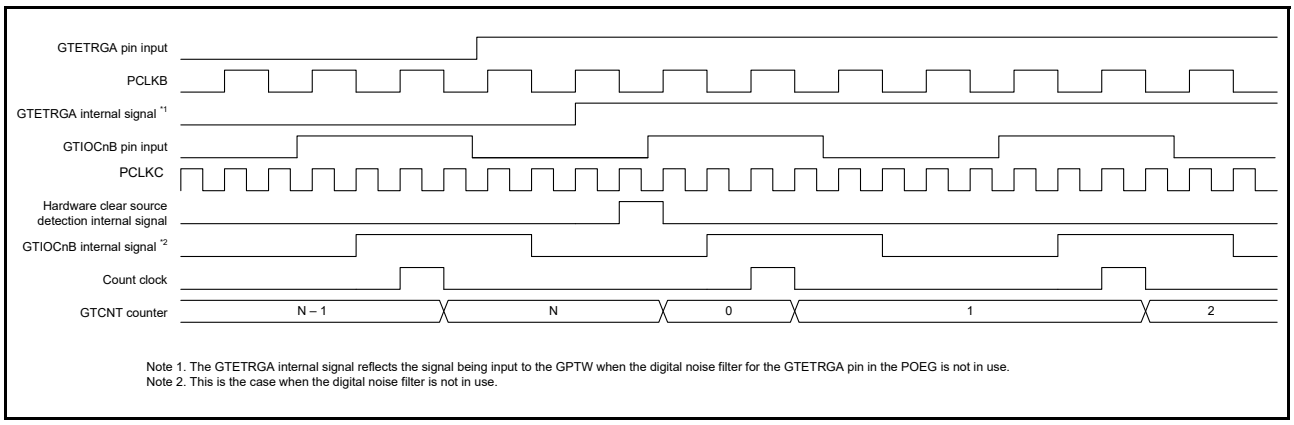

Figure 24.126 Example of the Timing of Operations for Counter Clearing in Response to a Rising Edge of the Input on the GTETRGA Pin (During Counting Triggered by Hardware Source)

Figure 24.127 shows an example of the timing of operations to clear the counter in response to a rising edge of the input on the GTIOCnA pin input when counting is triggered by a hardware source.
The GTCNT counter is cleared in synchronization with PCLKC after the GPTW has detected the internal clearing signal.

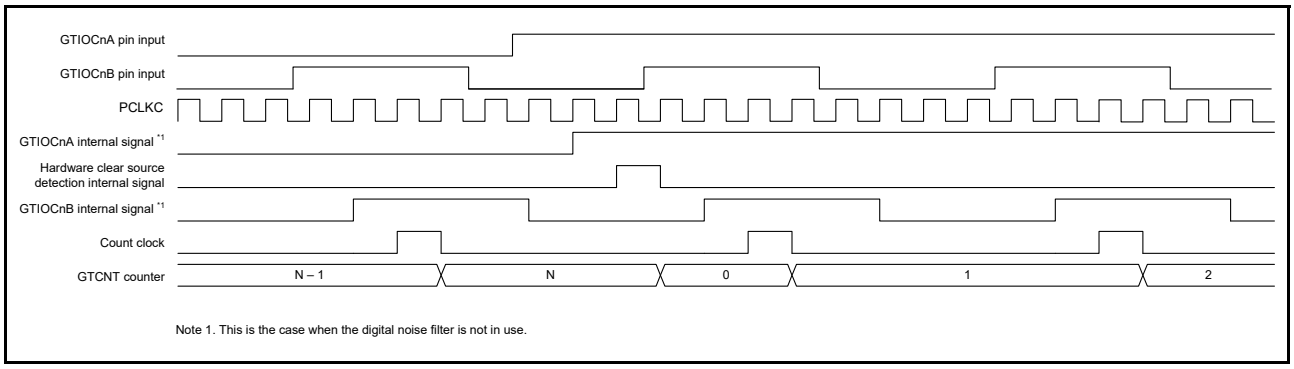

Figure 24.127 Example of the Timing of Operations for Counter Clearing in Response to a Rising Edge of the Input on the GTIOCnA Pin (During Counting Triggered by Hardware Source)

Figure 24.128 shows an example of the timing of operations for clearing the counter in response to the input of an event signal from the ELCA when counting is triggered by a hardware source.
This is an example of operations to clear the GPTW1.GTCNT counter in response to a signal. An event signal is output to the ELC after matches in comparison with the GPTW0.GTCCRA register. This is selected as a trigger for output to the GPTW by the ELC as event source A.
The GPTW0 compare match A signal is synchronized with PCLKC. The ELC receives the signal in synchronization with PCLKB, and outputs the GPTW event source A signal after 1 cycle of PCLKB has elapsed. The GTCNT counter is cleared in synchronization with PCLKC after the GPTW has detected the internal clearing signal.

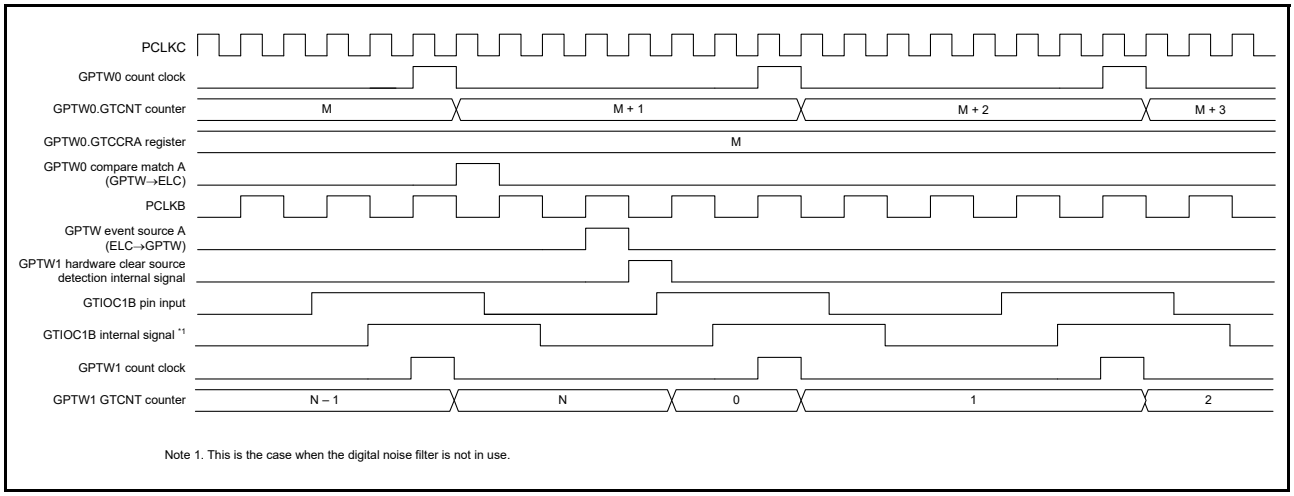

Figure 24.128 Example of the Timing of Operations for Counter Clearing in Response to Event Input from the ELCA (During Counting Triggered by Hardware Source)

24.3.8 Synchronous Operation

Synchronous operation on channels (synchronous start/stop/clear operation) can be performed.

24.3.8.1 Synchronous Operation by Software

The count operations for respective channels can be started, stopped and cleared simultaneously by setting multiple bits of the GTSTR, GTSTP, and GTCLR registers to 1 at the same time.
Count start with phase differences among channels is possible firstly by setting the GTCNT counter value before counting starts, and then, by setting simultaneously multiple bits in the GTSTR register to 1.
The GTCNT counter value settings are synchronized by setting the GTCR.SSCEN bit to 1, and can be written simultaneously to multiple channels set in the same group by the GTCR.SSCGRP[1:0] bits. Synchronous sets are not valid for channels that are set to complementary PWM mode.
When either the SSCE bit or the SSCD bit of the GTSECR register is set to 1, the GTCR.SSCEN bits of the channels that selected on the GTSECSR register are set to value and the GTCNT synchronous set/clear function of multiple channels are enabled or disabled at the same time.
Because the clock of count operation is selected by GTCR.TPCS[3:0] bits in respective channels, if the clock period of each channel that performs synchronous operation (count start/stop/clear) is different from others, the synchronous operation timings of every channels are not exact same.
The Figure 24.129 shows an example of simultaneous start/stop/clearing of four channels by software, and Figure 24.130 shows an example of phase shift start among four channels by software. Figure 24.131 to Figure 24.133 show examples of simultaneous start/stop/clearing with different count period.

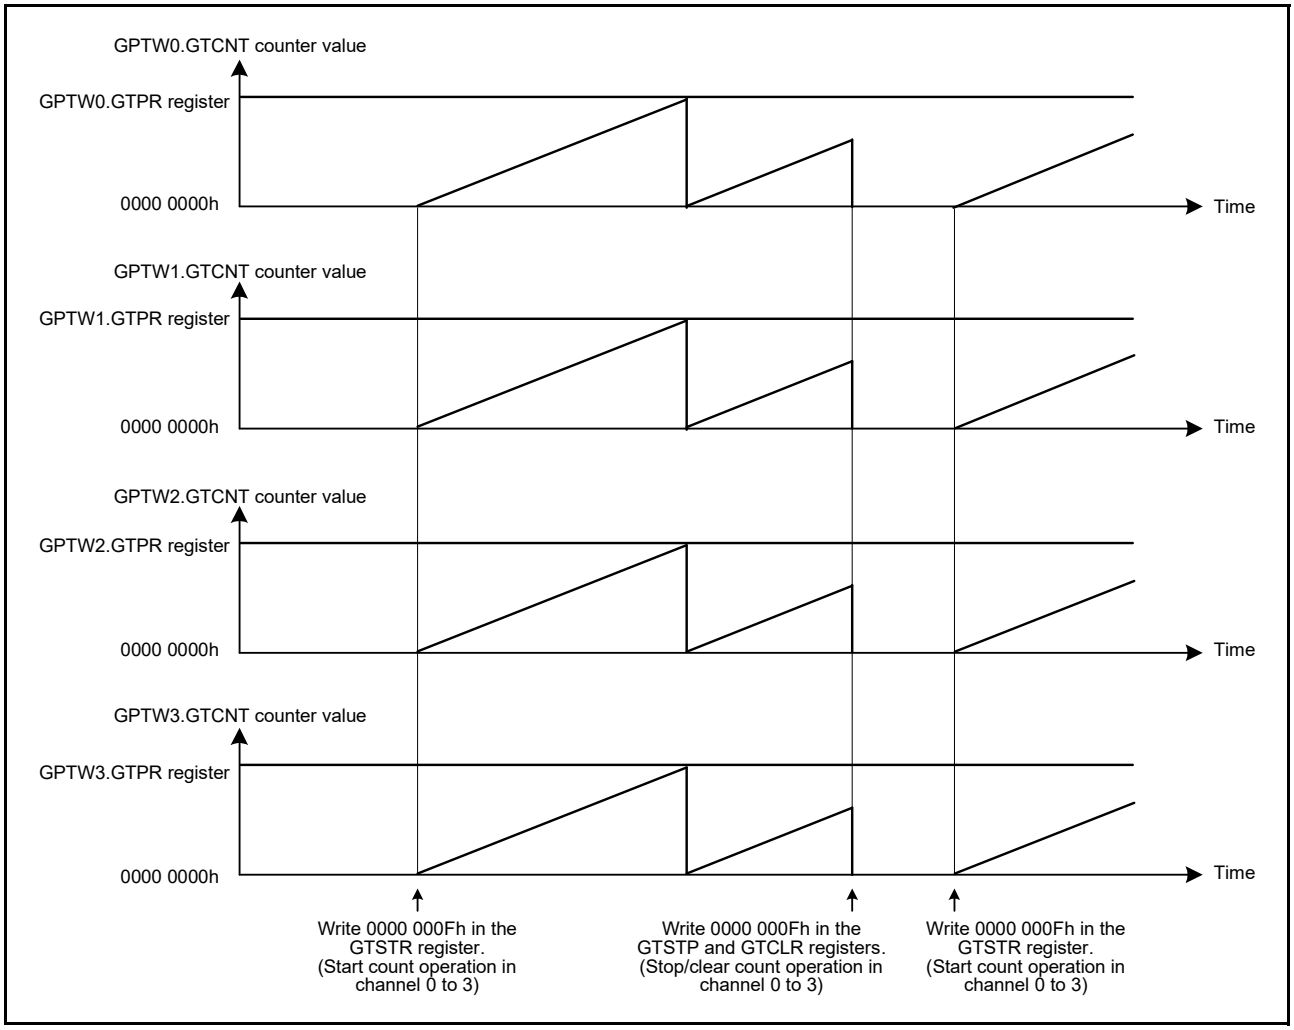

Figure 24.129 Example of Simultaneous Start/Stop/Clearing Operation by Software (with the Same Count Period (GTPR Register Value))

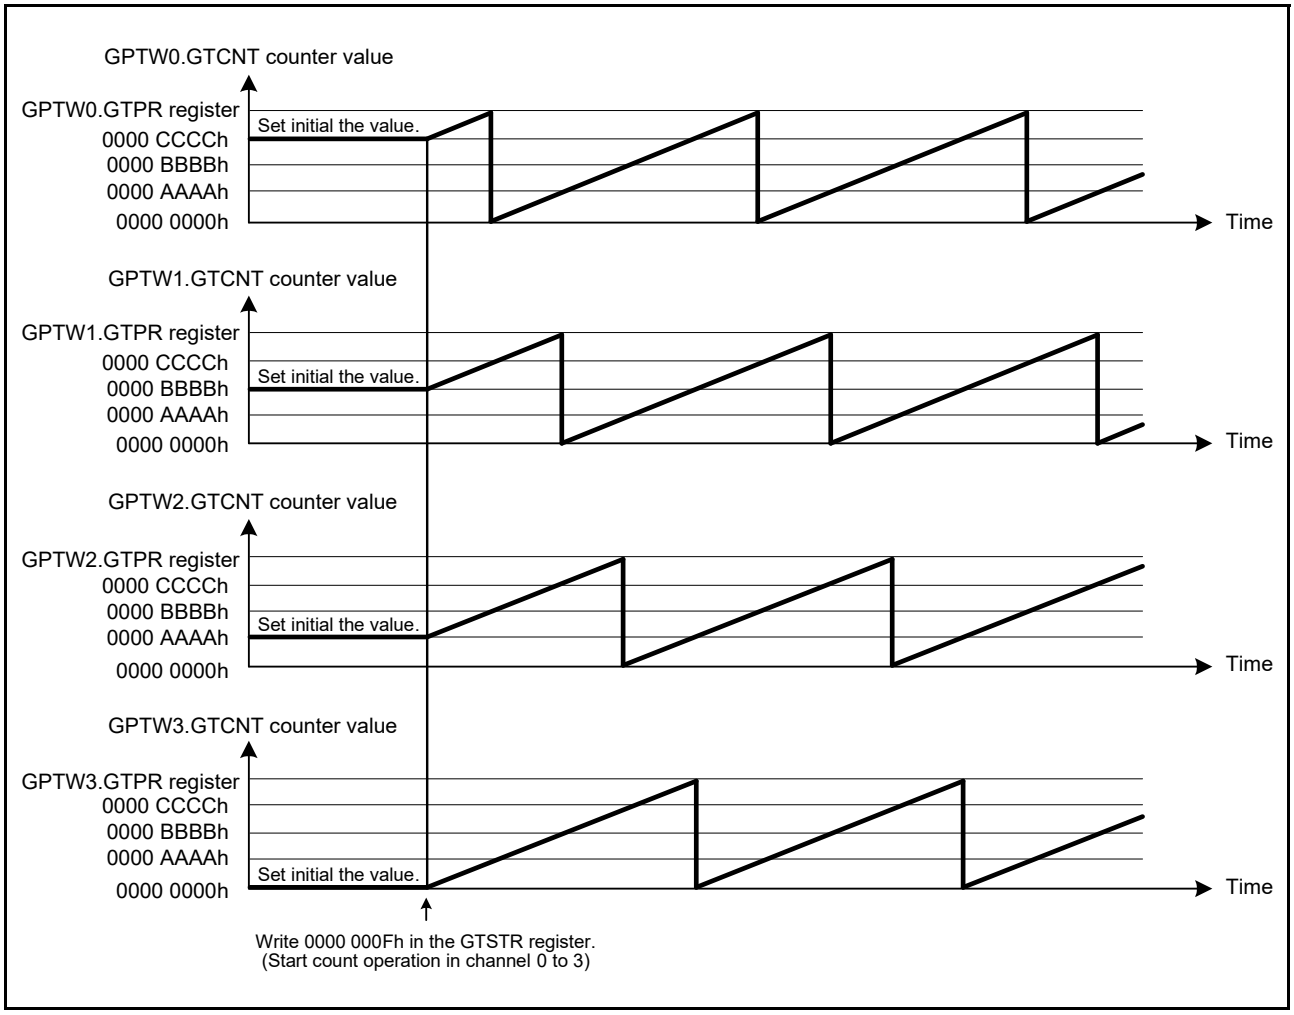

Figure 24.130 Example of Software Phase Shift Start (with Same Count Period (GTPR Register Value))

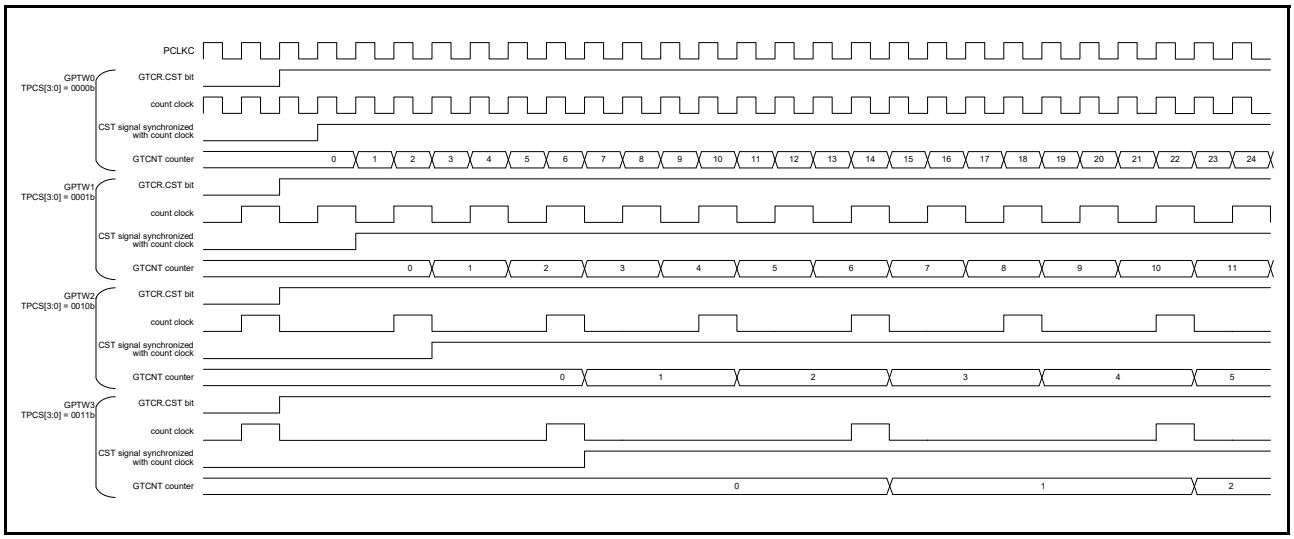

Figure 24.131 Example of Simultaneous Start Operation by Software (with Different Count Period)

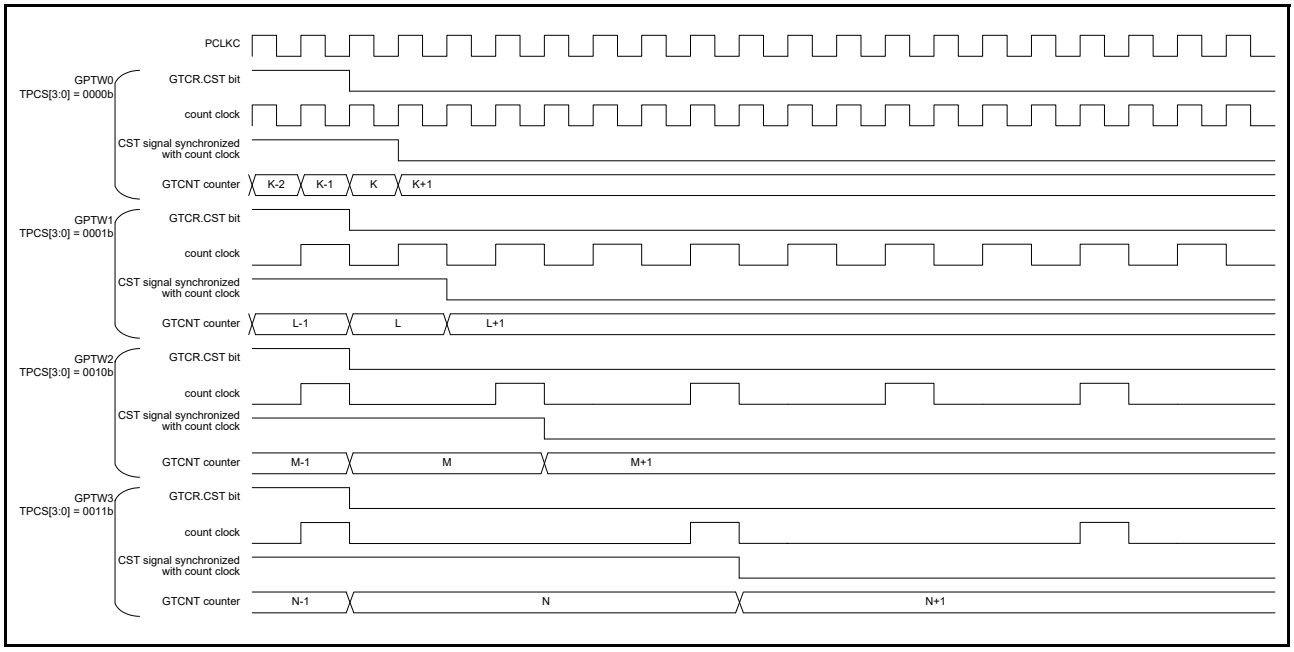

Figure 24.132 Example of Simultaneous Stop Operation by Software (with Different Count Period)

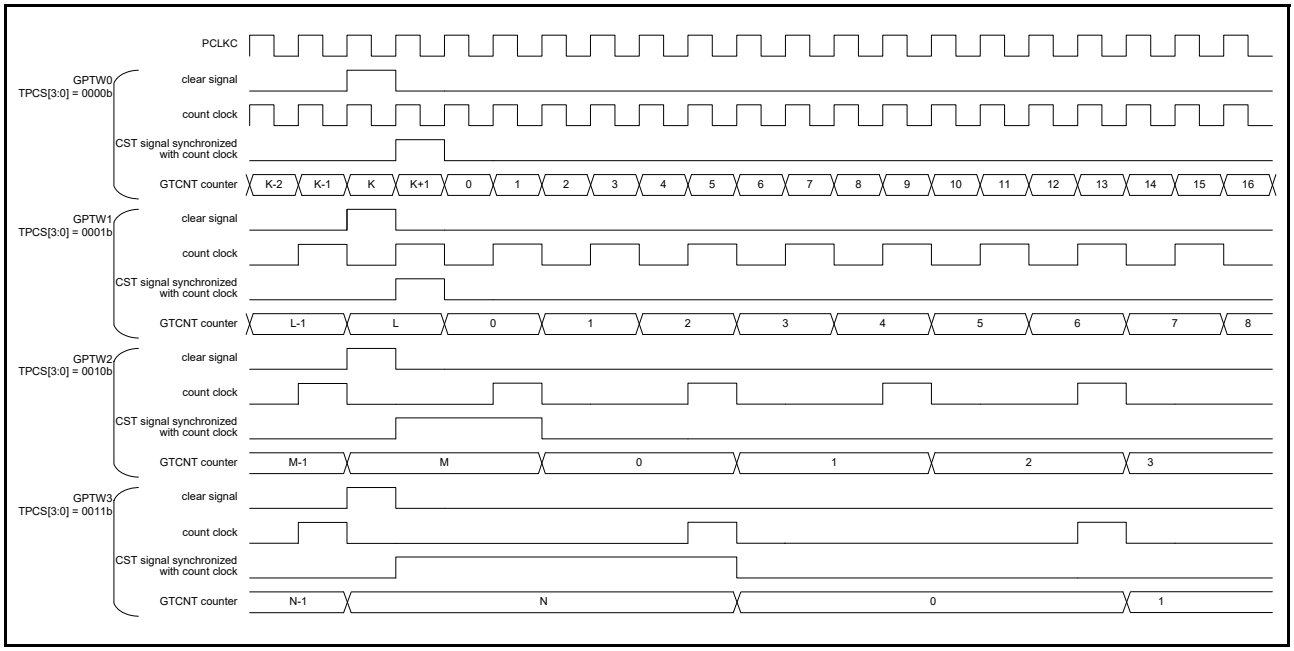

Figure 24.133 Example of Simultaneous Clearing Operation by Software (with Different Count Period)

24.3.8.2 Synchronous Operation by Hardware Source

The count operations for respective channels can be started/stopped/cleared simultaneously by following hardware sources: external trigger input, and ELC event input.

Synchronous operation by the GTIOCnA and GTIOCnB pin inputs (n = 0 to 7) can be performed by setting the ELC event by input capture as a hardware source.

Figure 24.134 shows an example of simultaneous start/stop/clearing operation of four channels by hardware source.

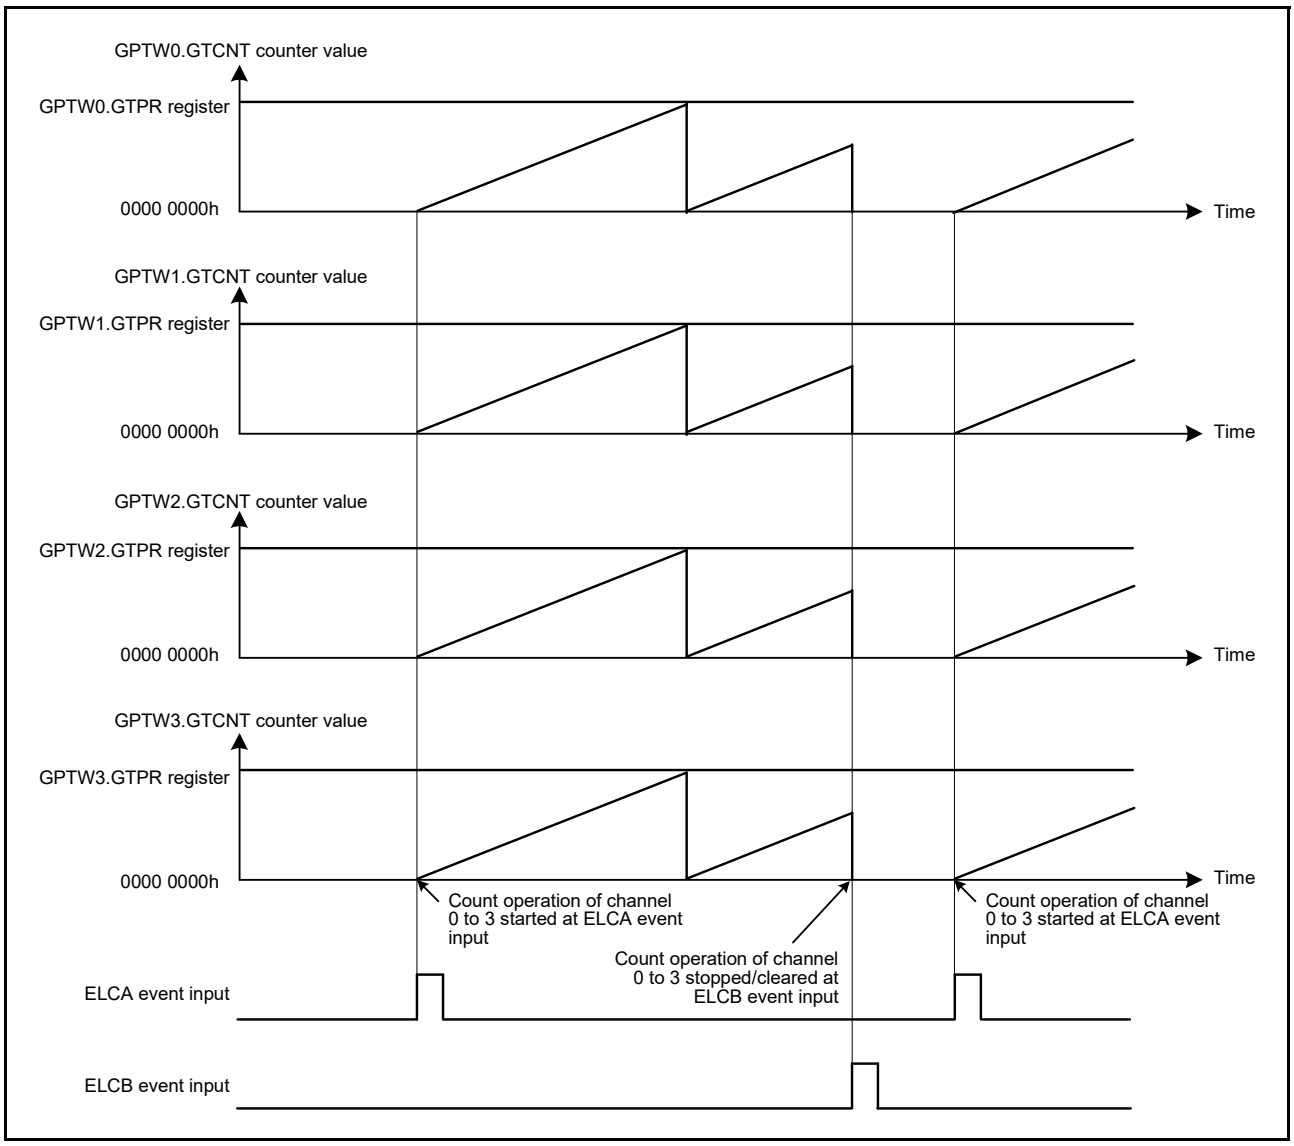

Figure 24.134 Example of Simultaneous Start/Stop/Clearing Operation by Hardware Source (with Same Count Period (GTPR Register Value))

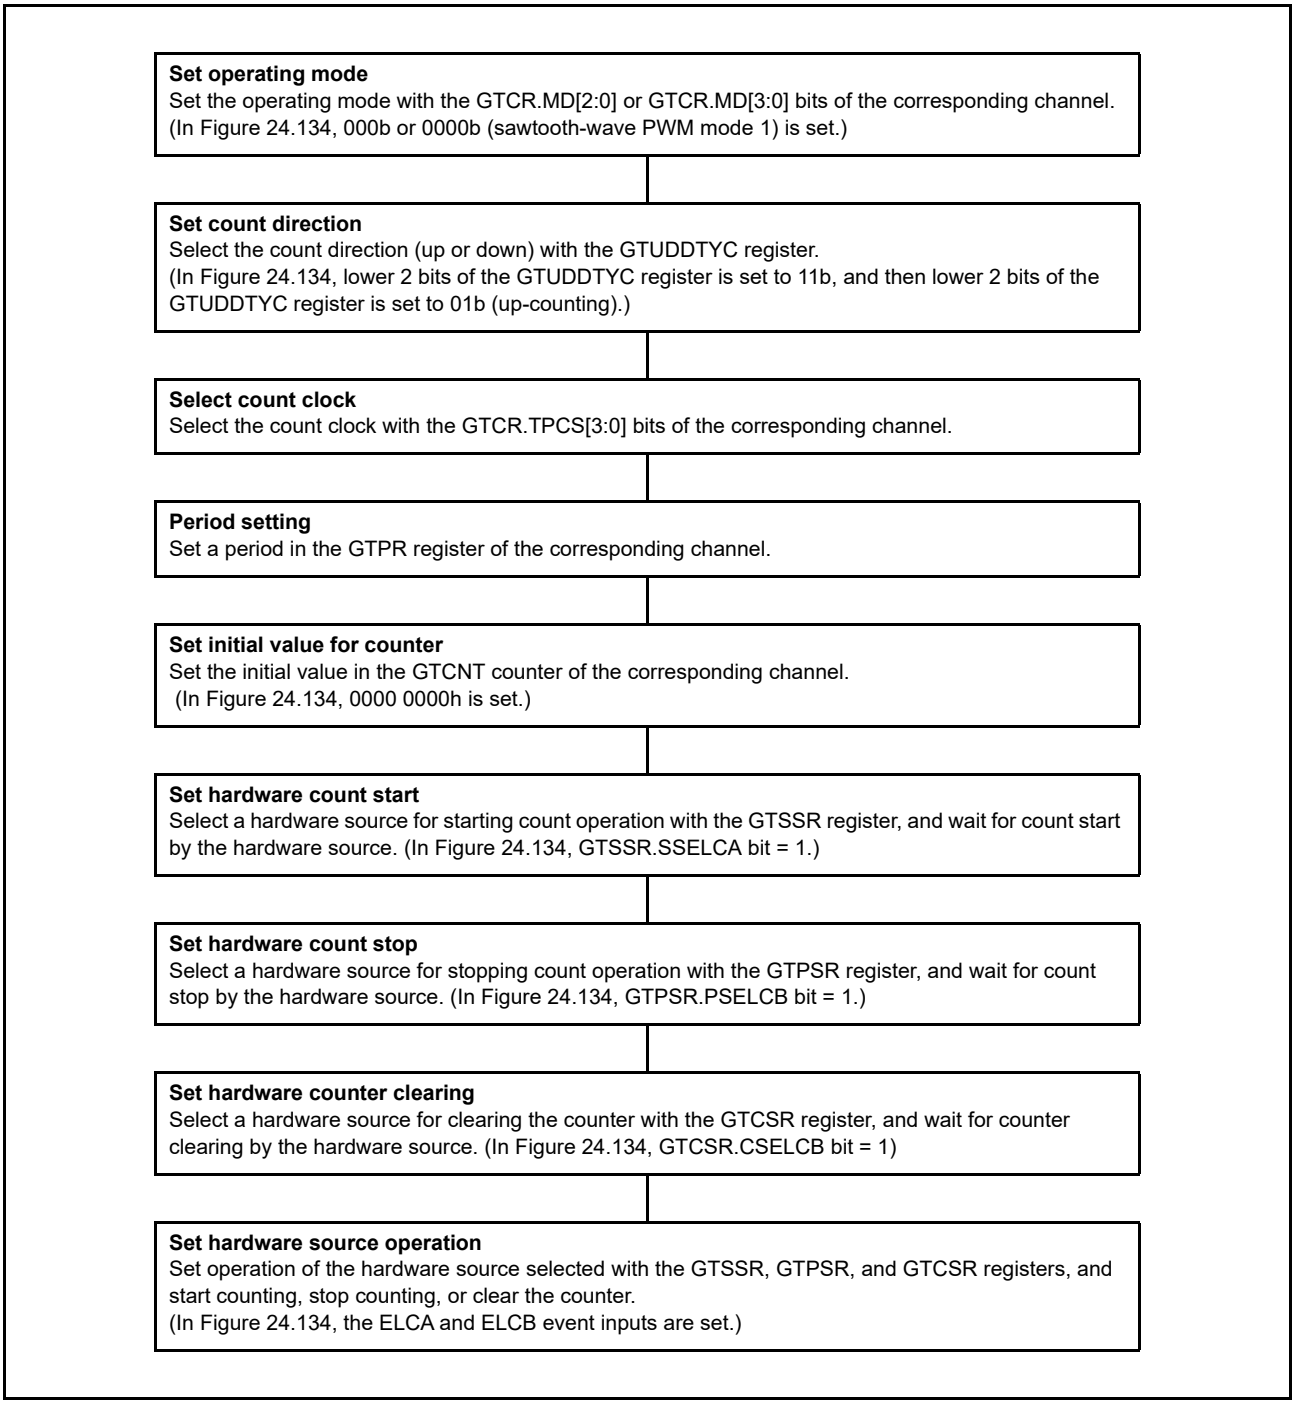

Figure 24.135 Example for Setting Simultaneous Start by Hardware Source

24.3.8.3 Synchronous Clear Operation by Inter Channel Cooperation

The counters of other channels can be cleared at the same time with the counter clear of some channel caused by the compare match, input capture, sawtooth wave up-count overflow, sawtooth wave down-count underflow, and the GTIOCnA/GTIOCnB pin input selected in the GTCSR register.

The counter clear caused by GTCLR register, external trigger input and the ELC input can perform as synchronous clear when the same counter clear factor is set to target channels of synchronous clear. Therefore, these factors are not prepared for the synchronous clear operation by inter channel cooperation.

Set the channel that generates the synchronization clear source and the channel that is synchronized clear in the same synchronous set/clear group with the GTCR.SSCGRP[1:0] bits.

Similar to the synchronous operation in section 24.3.8.1, Synchronous Operation by Software, if the count clock selected by the GTCR.TPCS[3:0] bits is different for each channel, the synchronous clear operation cannot be performed at exact same timing. Similar to the example of simultaneous clearing operation by software in Figure 24.133, if the count clock is different for each channel, the synchronous clear factor is synchronized with the count clock of each channel before counter clearing.

When either the SSCE bit or the SSCD bit of the GTSECR register is set to 1, the GTCR.SSCEN bits of the channels that selected on the GTSECSR register are set to 0 or 1 and the GTCNT synchronous set/clear function of multiple channels are enabled or disabled at the same time.

Table 24.23 lists the settings of the registers used to set sources for synchronous clearing. Figure 24.136 shows an example of synchronous clear operation by inter channel cooperation and Figure 24.137 shows an example for setting synchronous clear operation by inter channel cooperation.

Table 24.23 Settings of the Registers Used to Set Sources for Synchronous Clearing

Sources for Synchronous Clearing by Inter Channel Cooperation	Register.Bit(s)	Value
GTCCRA register compare match/input capture	GTINTAD.SCFA	1b
	GTCSR.CSCMSC[2:0]	001b
GTCCRB register compare match/input capture	GTINTAD.SCFB	1b
	GTCSR.CSCMSC[2:0]	010b
GTCCRC register compare match	GTINTAD.SCFC	1b
	GTCSR.CSCMSC[2:0]	011b
GTCCRD register compare match	GTINTAD.SCFD	1b
	GTCSR.CSCMSC[2:0]	100b
GTCCRE register compare match	GTINTAD.SCFE	1b
	GTCSR.CSCMSC[2:0]	101b
GTCCRF register compare match	GTINTAD.SCFF	1b
	GTCSR.CSCMSC[2:0]	110b
Sawtooth wave up-count overflow	GTINTAD.SCFPO	1b
Sawtooth wave down-count underflow	GTINTAD.SCFPU	1b
Clearing due to input on the GTIOCnA or GTIOCnB pin	GTCR.SCGTIOC	1b

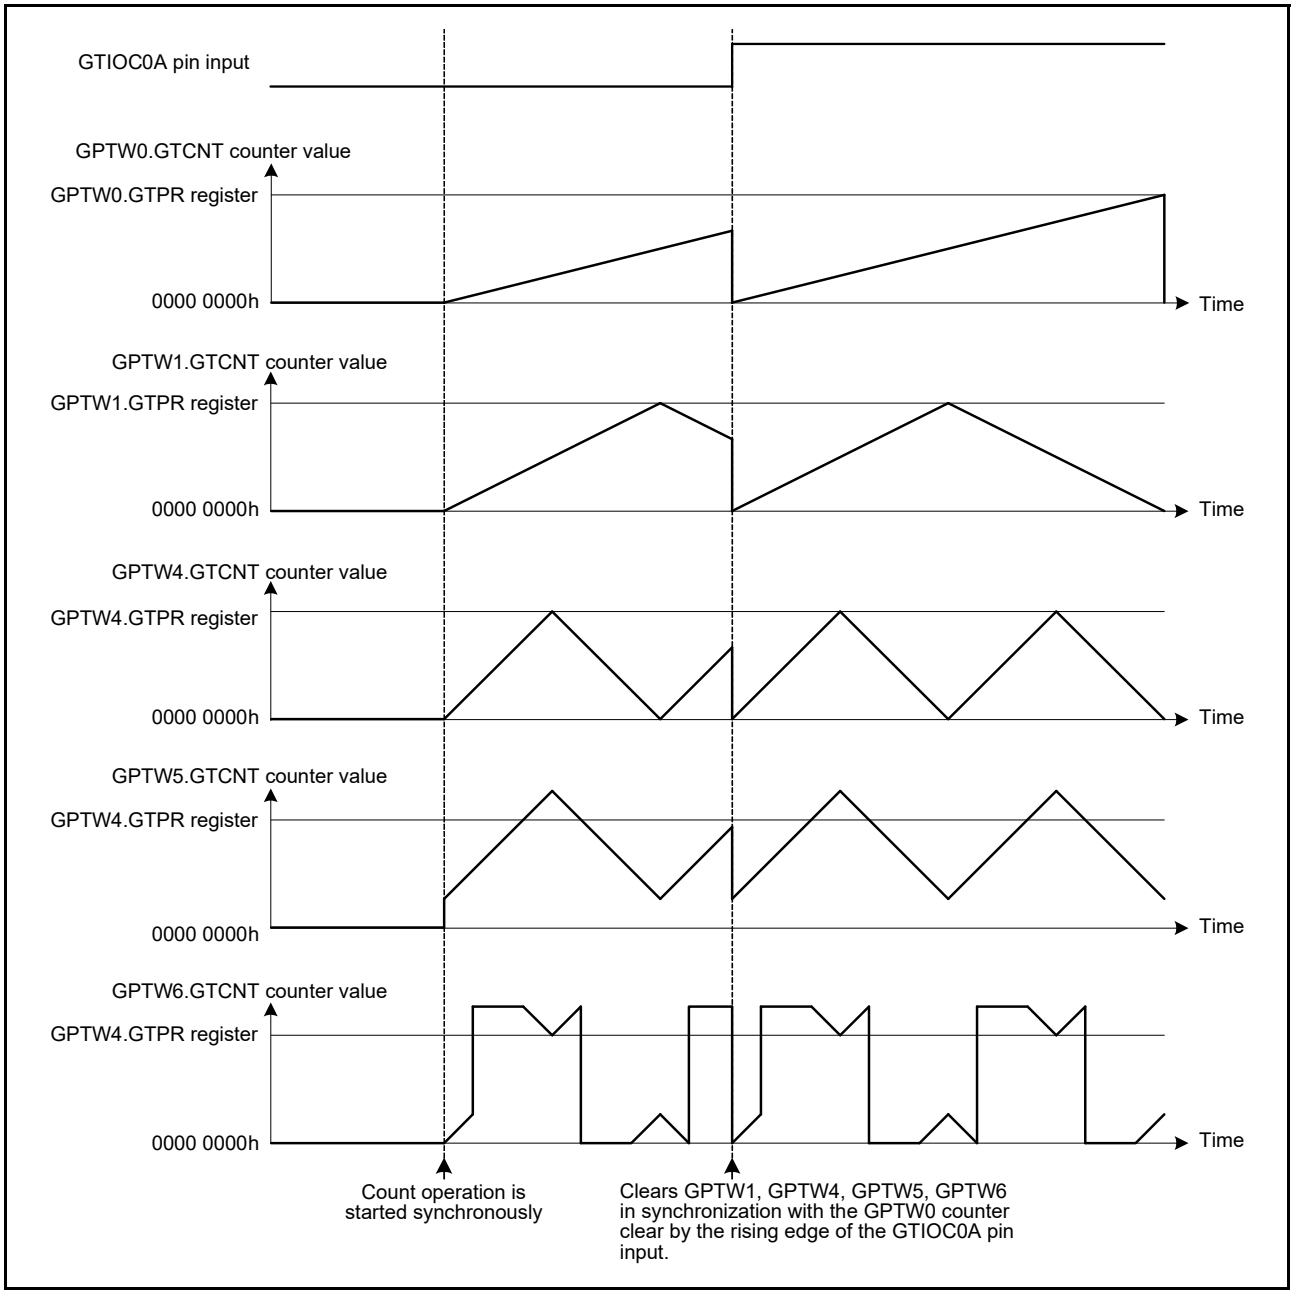

Figure 24.136 Example of Synchronous Clear Operation by Inter Channel Cooperation (GPTW0 is sawtooth wave and counter is cleared by the rising edge of the GTIOC0A, GPTW1 is triangle wave, GPTW4, GPTW5, GPTW6 are complementary PWM mode. GPTW0, GPTW1, GPTW4, GPTW5, GPTW6 are the same synchronous set/clear group)

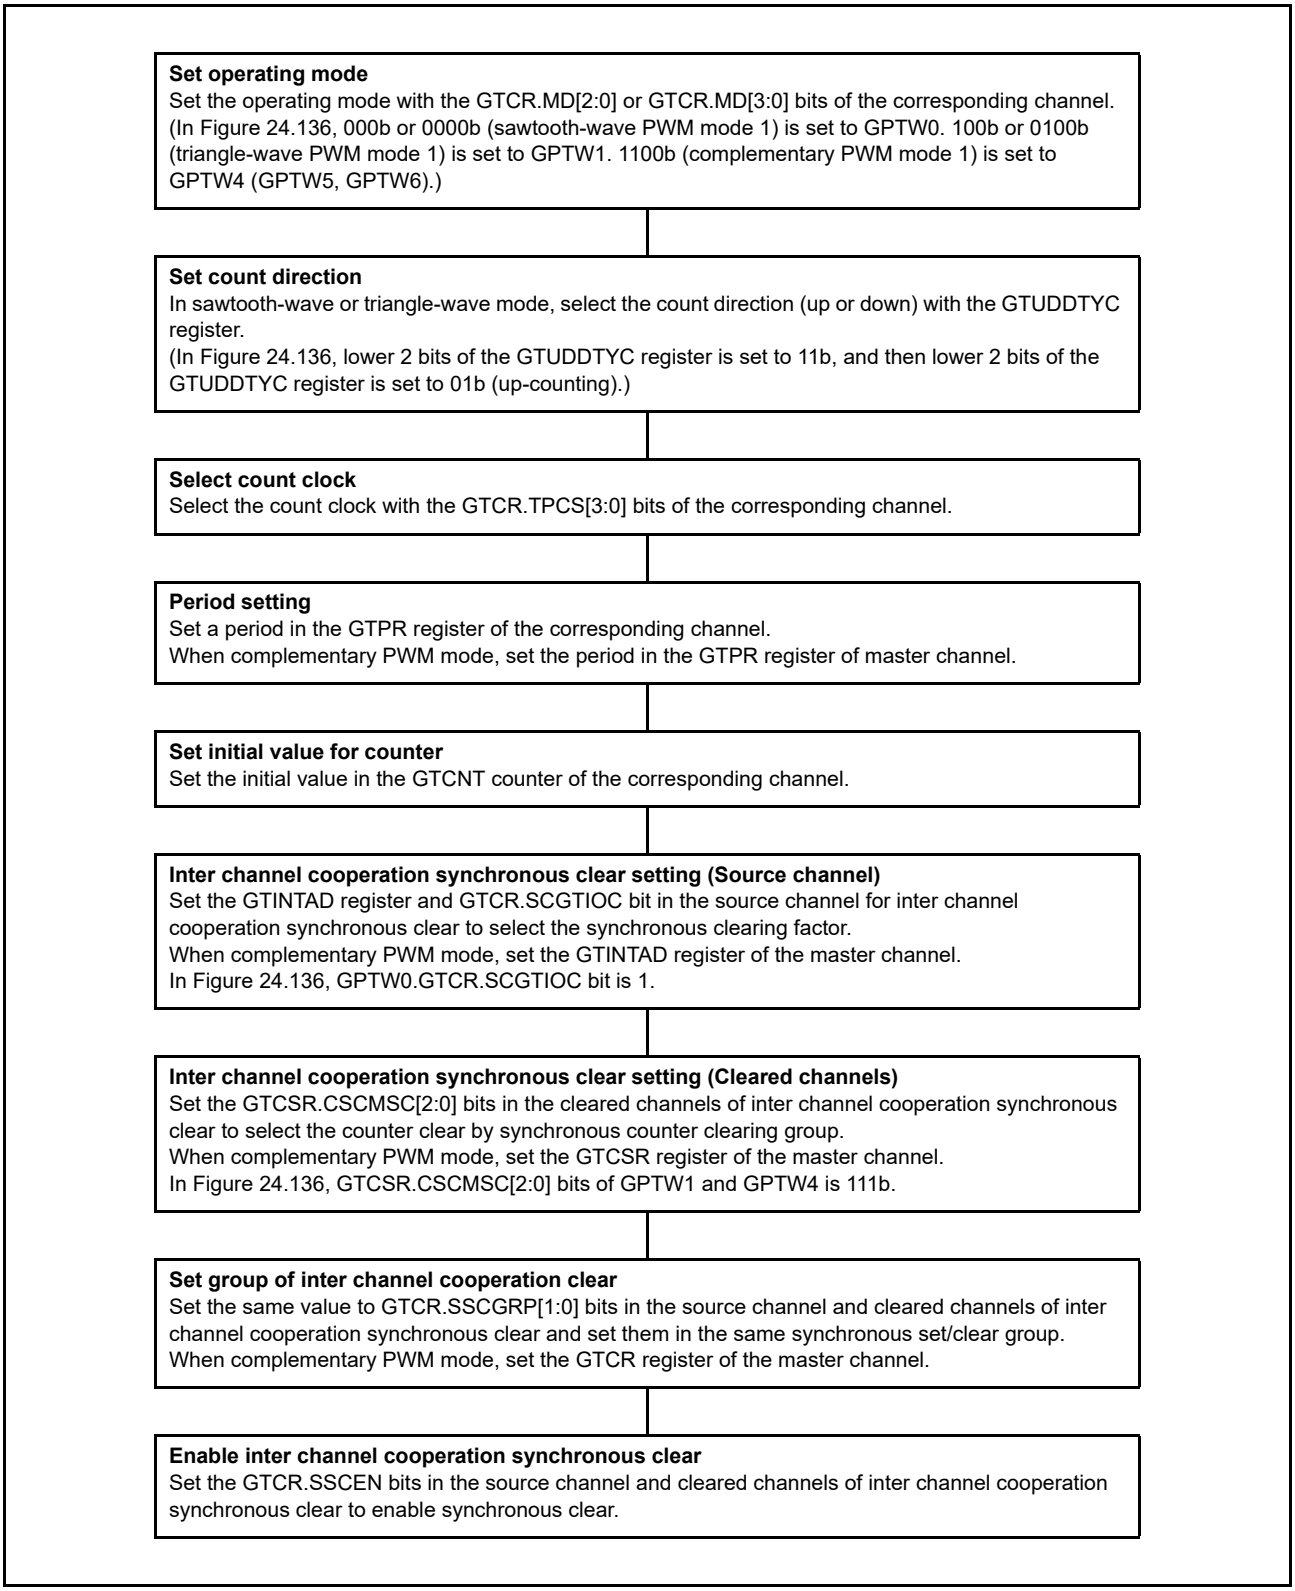

Figure 24.137 Example for Setting Synchronous Clear Operation by Inter Channel Cooperation

24.3.9 PWM Output Operation Examples

(1) Synchronous PWM Output

The GPTW can output two phases of linked PWM waveforms for one channel, or 16 phases of linked PWM waveforms for a maximum of 8 channels by synchronizing operation of the channels.

Figure 24.138 shows an example in which four channels perform synchronous operation in sawtooth-wave PWM mode and eight phases of PWM waveforms are output. The GTIOCnA pin (n = 0 to 3) is set so that it will output low as the initial output, high at a GTCCRA register compare match, and low at the end of the cycle. The GTIOCnB pin is set so that it will output low as the initial output, high at a GTCCRB register compare match, and low at the end of the cycle.

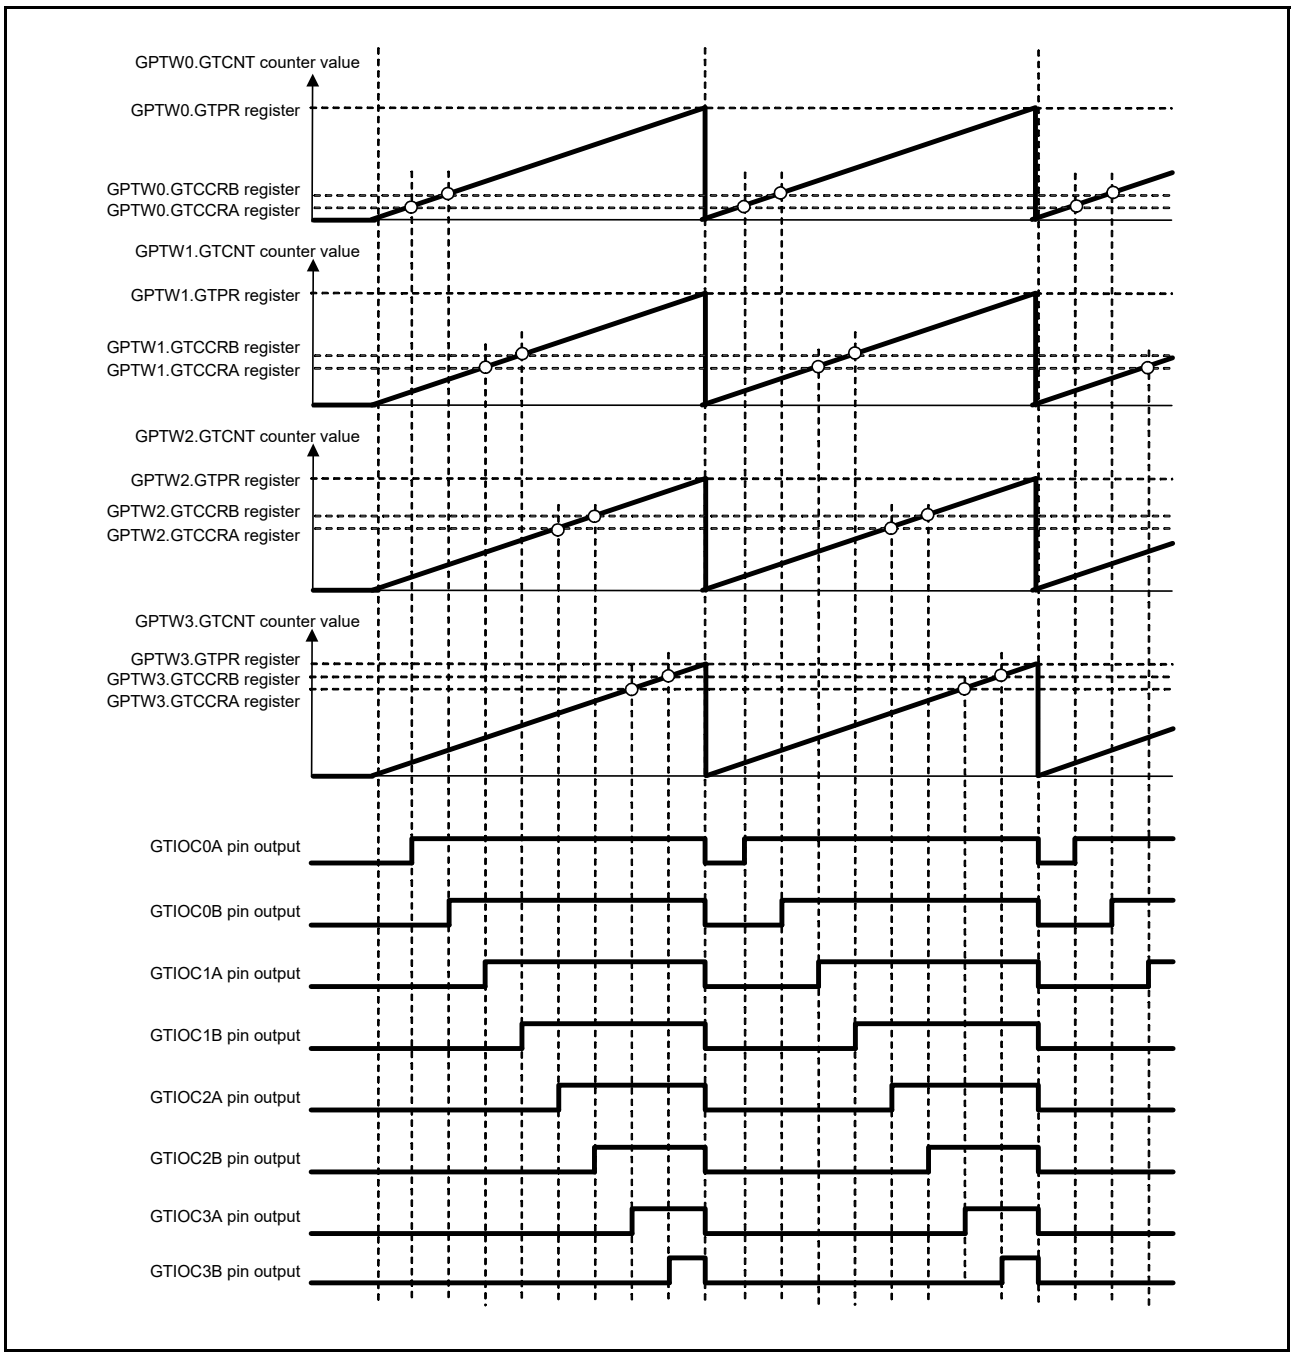

Figure 24.138 Example of Synchronous PWM Output

(2) Three-Phase Sawtooth-Wave Complementary PWM Output

Figure 24.139 shows an example in which three channels perform synchronous operation in sawtooth-wave PWM mode 1 and three-phase complementary PWM waveforms are output. The GTIOCnA pin (n = 0 to 2) is set so that it will output low as the initial output, high at a GTCCRA register compare match, and low at the end of the cycle. The GTIOCnB pin is set so that it will output high as the initial output, low at a GTCCRB register compare match, and high at the end of the cycle.

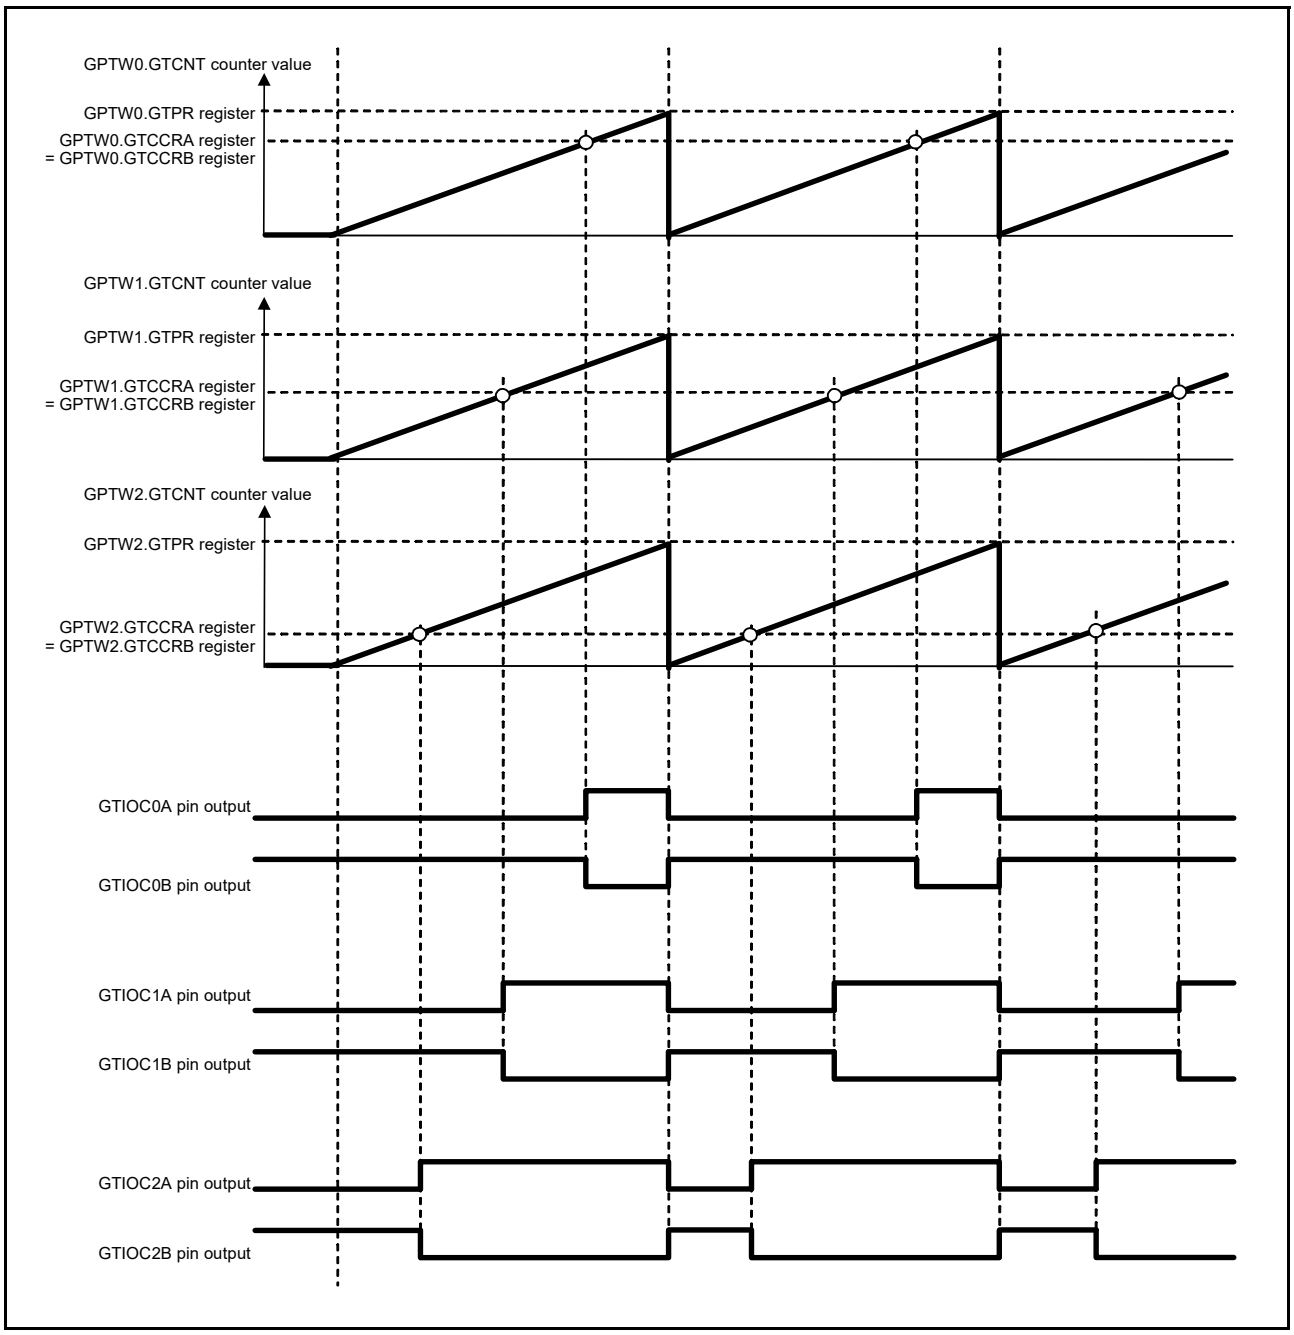

Figure 24.139 Example of Three-Phase Sawtooth-Wave Complementary PWM Output

(3) Three-Phase Sawtooth-Wave Complementary PWM Output with Automatic Dead Time Setting

Figure 24.140 shows an example in which three channels perform synchronous operation in sawtooth-wave one-shot pulse mode with automatic dead time setting and three-phase complementary PWM waveforms are output. The GTIOCnA pin (n = 0 to 2) is set so that it will output low as the initial output, toggle the output at a GTCCRA register compare match, and retain the output at the end of the cycle. The GTIOCnB pin is set so that it will output high as the initial output, toggle the output at a GTCCRB register compare match, and retain the output at the end of the cycle.

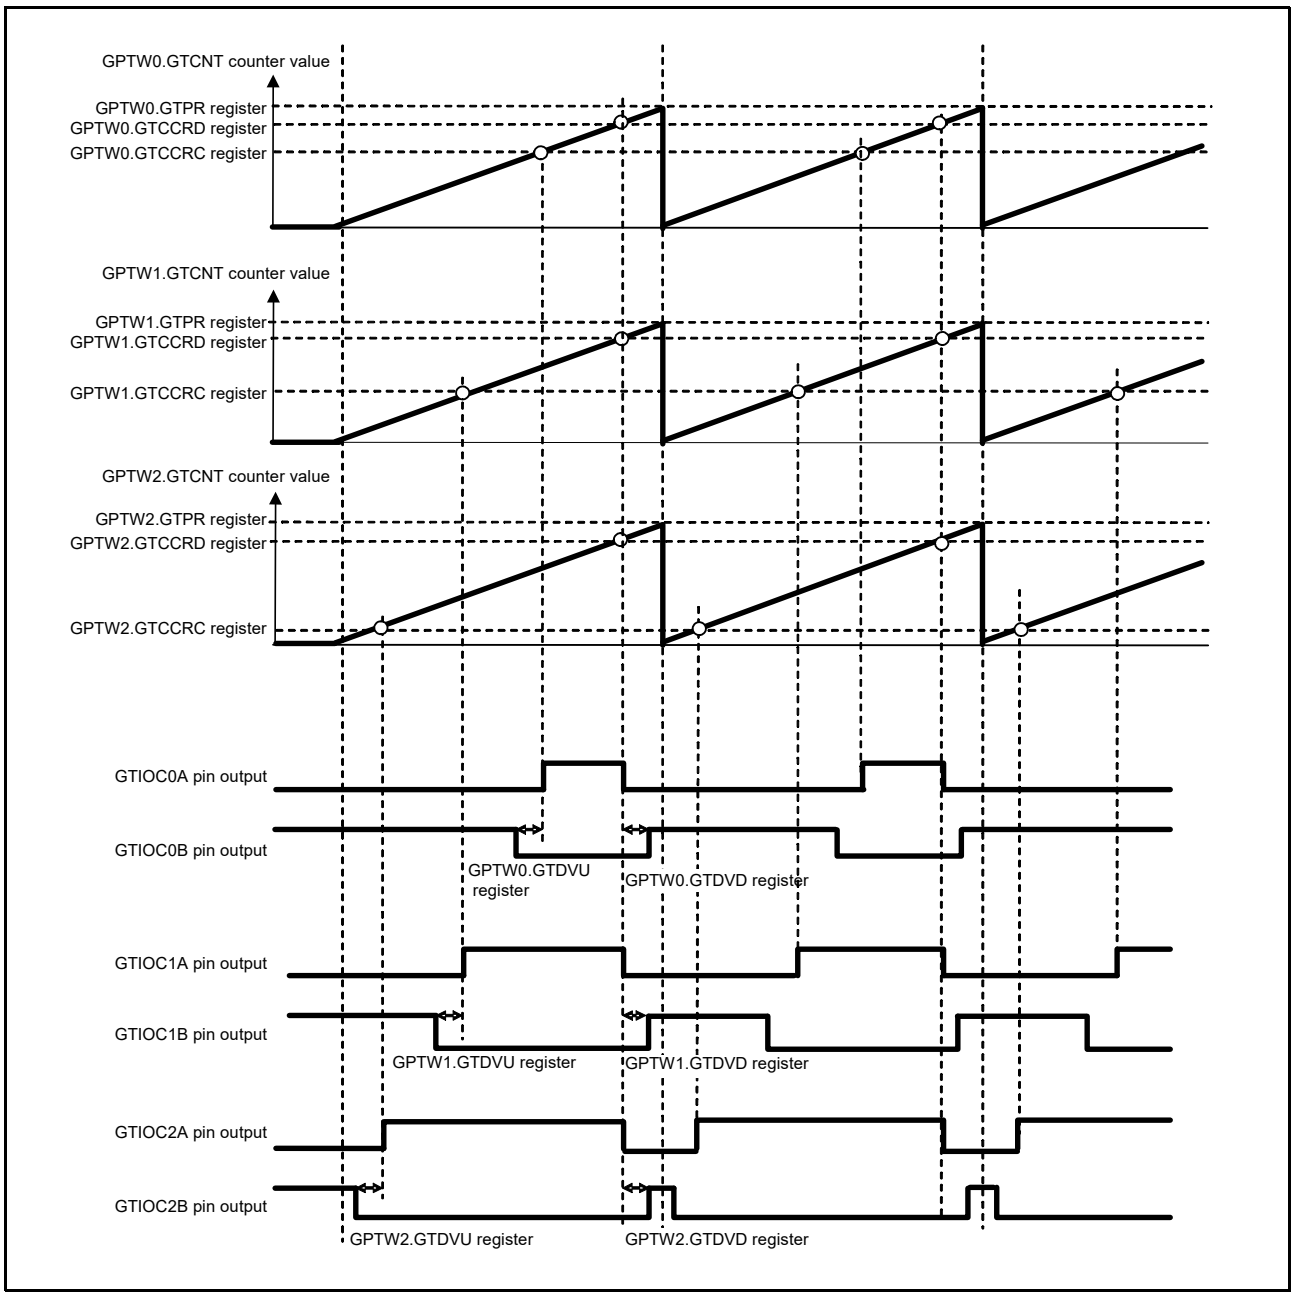

Figure 24.140 Example of Three-Phase Sawtooth-Wave Complementary PWM Output with Automatic Dead Time Setting

(4) Three-Phase Triangle-Wave Complementary PWM Output

Figure 24.141 shows an example in which three channels perform synchronous operation in triangle-wave PWM mode 1 and three-phase complementary PWM waveforms are output. The GTIOCnA pin (n = 0 to 2) is set so that it will output low as the initial output, toggle the output at a GTCCRA register compare match, and retain the output at the end of the cycle. The GTIOCnB pin is set so that it will output high as the initial output, toggle the output at a GTCCRB register compare match, and retain the output at the end of the cycle.

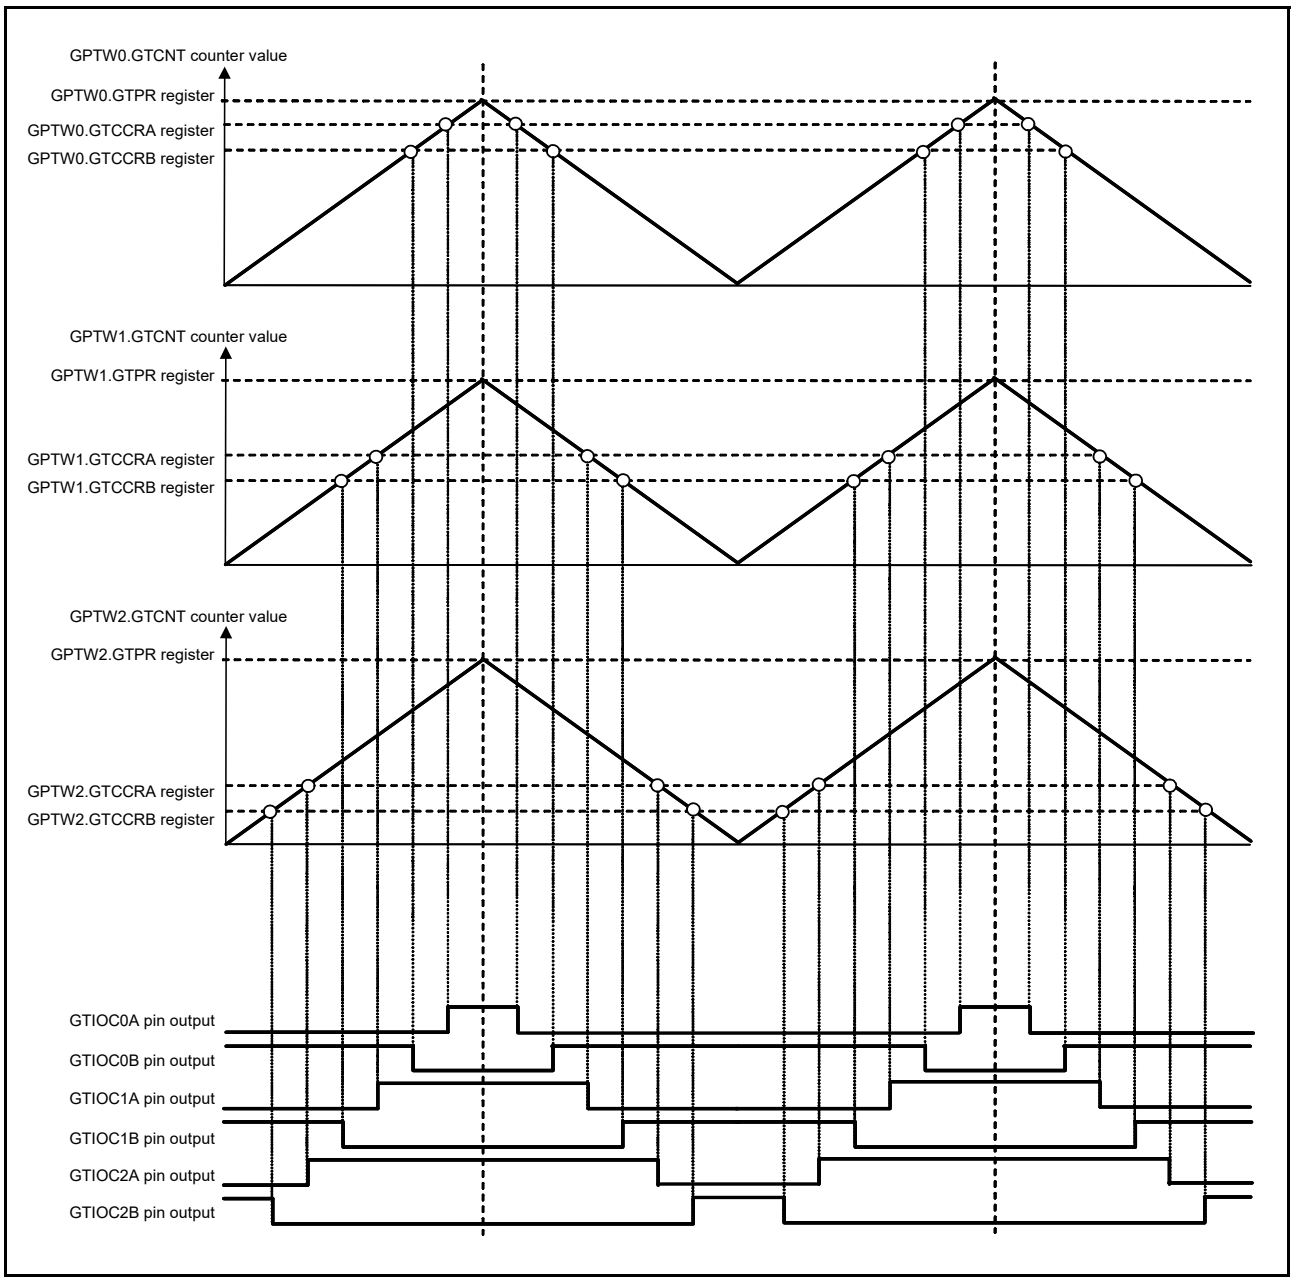

Figure 24.141 Example of Three-Phase Triangle-Wave Complementary PWM Output

(5) Three-Phase Triangle-Wave Complementary PWM Output with Automatic Dead Time Setting

Figure 24.142 shows an example in which three channels perform synchronous operation in triangle-wave PWM mode 1 with automatic dead time setting and three-phase complementary PWM waveforms are output. The GTIOCnA pin (n = 0 to 2) is set so that it will output low as the initial output, toggle the output at a GTCCRA register compare match, and retain the output at the end of the cycle. The GTIOCnB pin is set so that it will output high as the initial output, toggle the output at a GTCCRB register compare match, and retain the output at the end of the cycle.

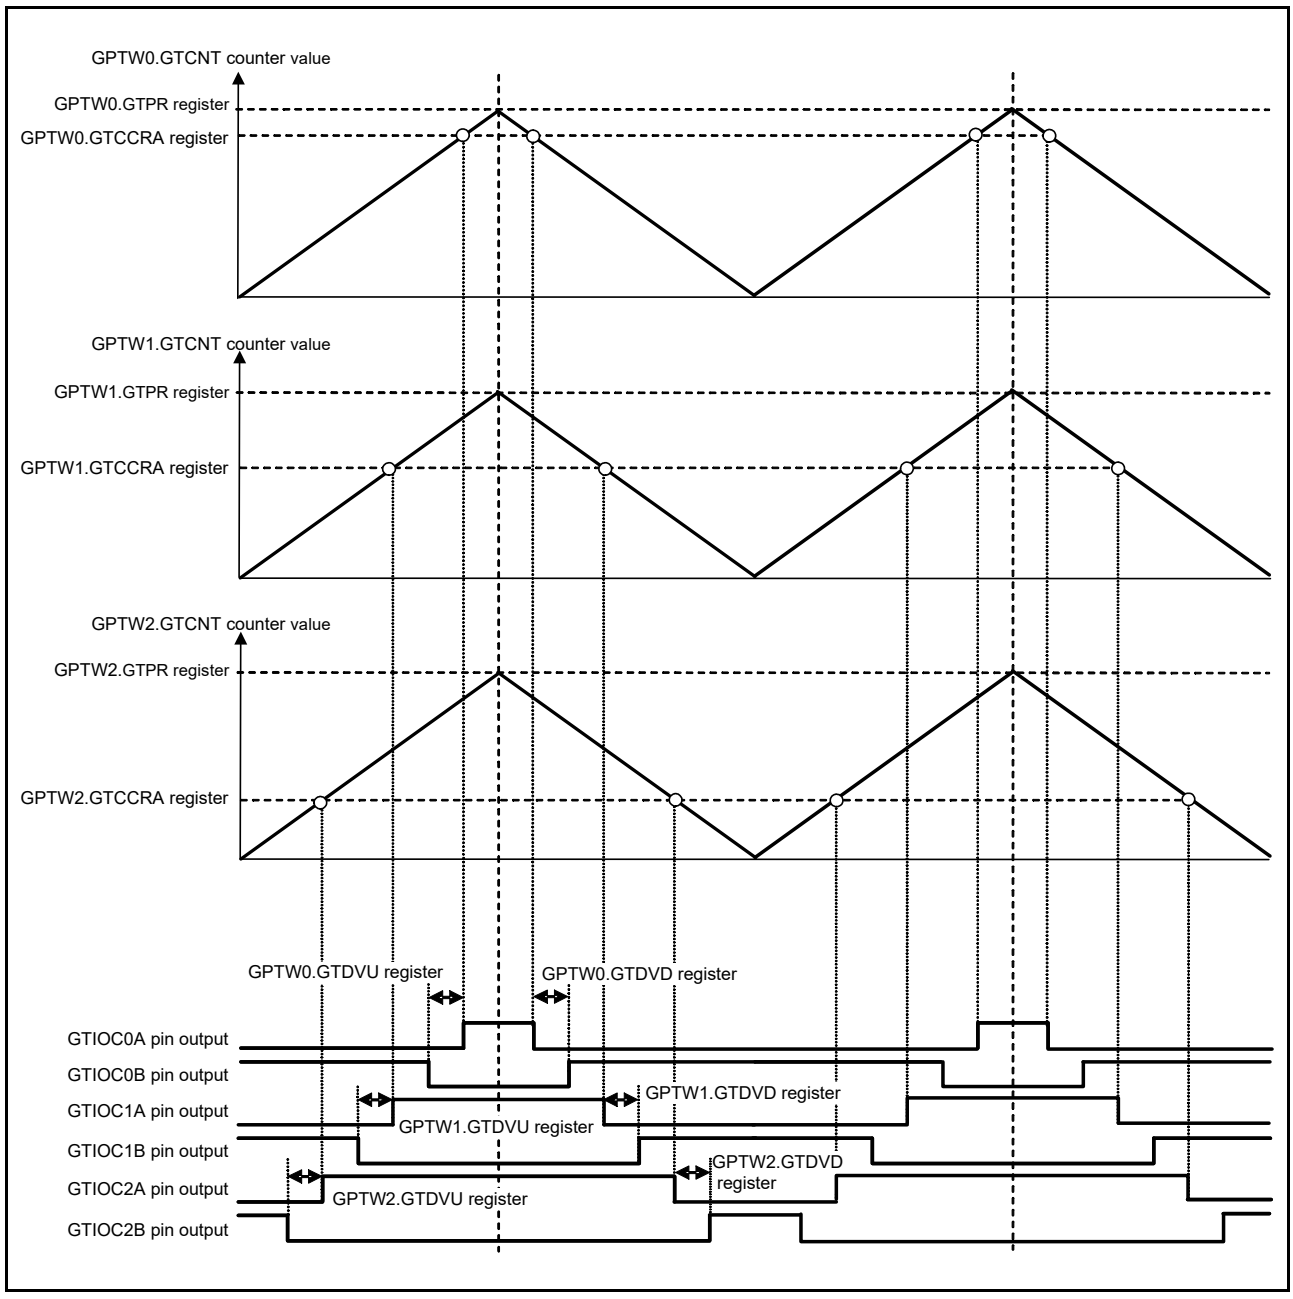

Figure 24.142 Example of Three-Phase Triangle-Wave Complementary PWM Output with Automatic Dead Time Setting

(6) Three-Phase Asymmetric Triangle-Wave Complementary PWM Output with Automatic Dead Time Setting

Figure 24.143 shows an example in which three channels perform synchronous operation in triangle-wave PWM mode 3 with automatic dead time setting and three-phase complementary PWM waveforms are output. The GTIOCnA pin (n = 0 to 2) is set so that it will output low as the initial output, toggle the output at a GTCCRA register compare match, and retain the output at the end of the cycle. The GTIOCnB pin is set so that it will output high as the initial output, toggle the output at a GTCCRB register compare match, and retain the output at the end of the cycle.

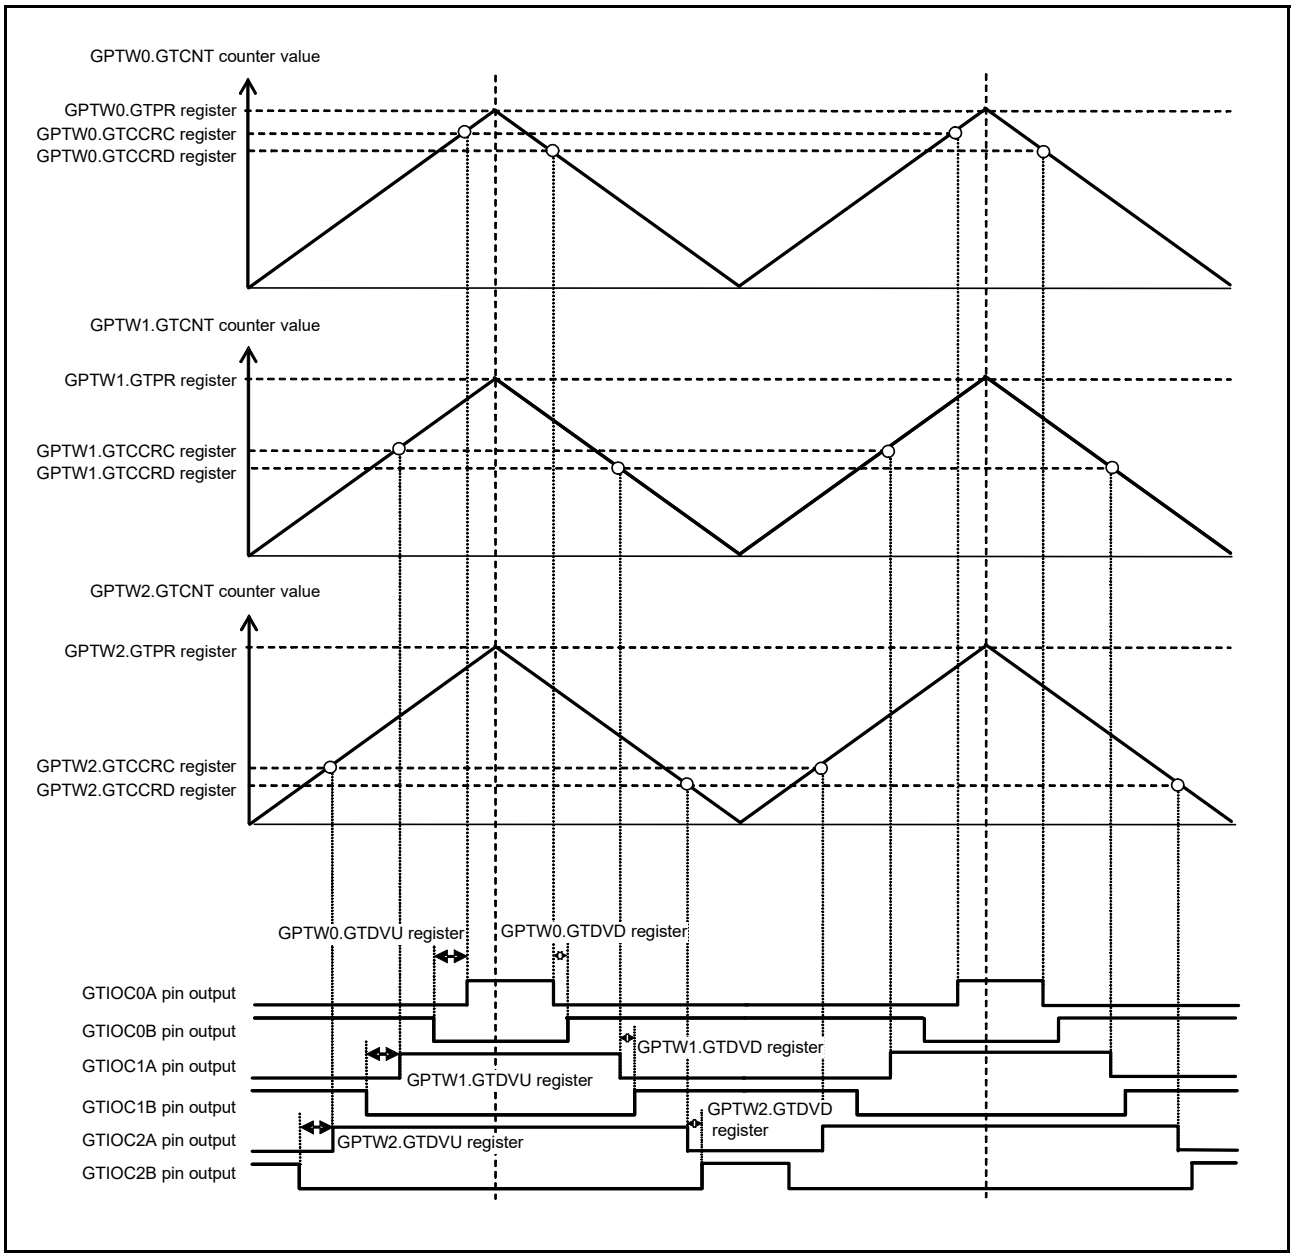

Figure 24.143 Example of Three-Phase Asymmetric Triangle-Wave Complementary PWM Output with Automatic Dead Time Setting

24.3.10 Cycle Count Function

By setting the GTPC register, the end of cycle can be counted.

The number of cycle to be counted should be set into the GTPC.PCNT counter when the GTPC.PCEN bit is 0. When the PCEN bit is 1, the PCNT counter can be read, but writing is disabled. When the PCEN bit is 1, down-counting is performed at the end of cycle. When the PCNT counter is 1 at the end of cycle, it becomes 0 and counting is stopped to finish the cycle count operation. At that time, the GTST.PCF flag is set, and a cycle count end interrupt request (GTCEIn) is generated if the setting of the GTINTAD.GTINTPC bit is 1. When the GTPC.ASTP bit is 1, the GTCNT counter is also stopped at the same time that the cycle count operation is finished.

When the GTCNT counter is stopped while cycle count function is enabled, the PCNT counter keeps its value. When the GTCNT counter restarts counting and the PCEN bit is 1, the PCNT counter restarts down-counting from the hold value. When the PCEN bit is changed from 0 to 1 while the PCNT counter is 0 and the ASTP bit is 1, the GTCNT counter is stopped at the count clock immediately after that.

When either GTSECR.SPCE bit or GTSECR.SPCD bit is set to 1, the PCEN bit in the channels set to 1 by the GTSECSR register is simultaneously set the value to enable or disable the cycle count function for multiple channels.

Figure 24.144 and Figure 24.145 show examples of PWM cycle count function.

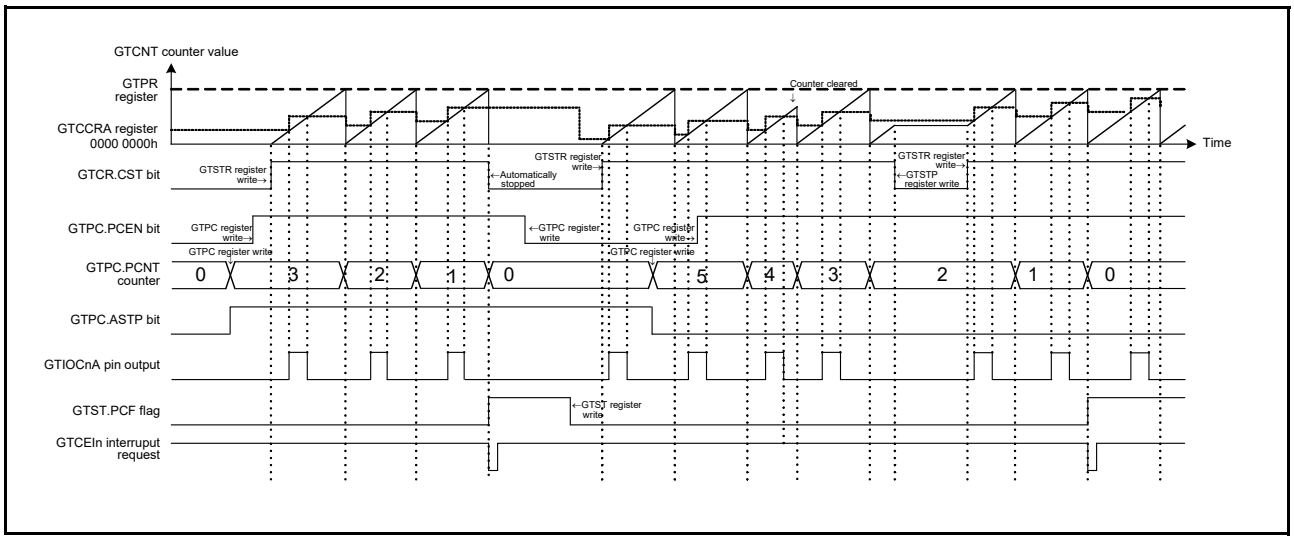

Figure 24.144 Example of PWM Cycle Count Function (Sawtooth-Wave One-Shot Pulse Mode) (n = 0 to 973)

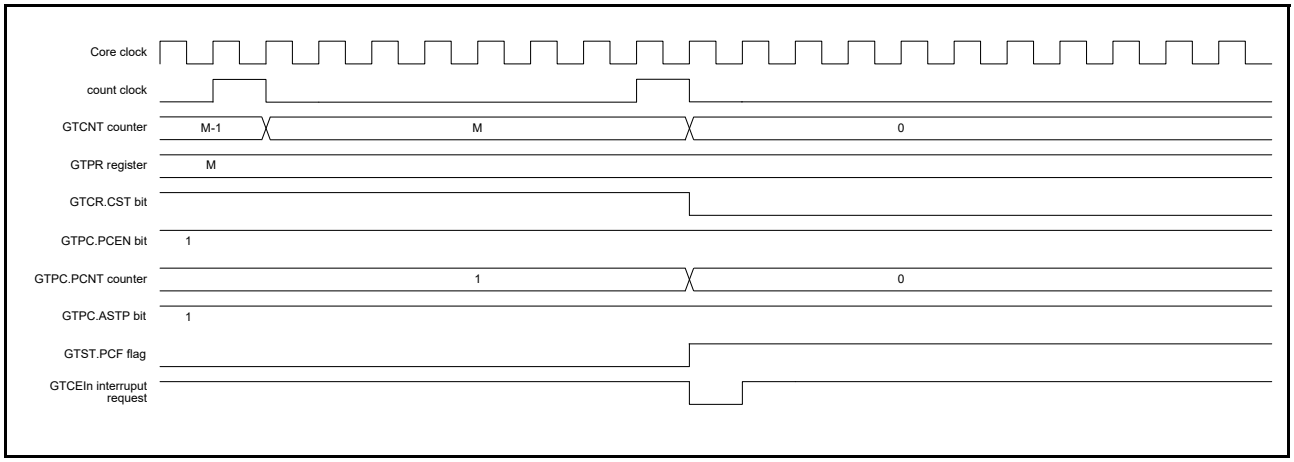

Figure 24.145 Example of the Timing of Operations for PWM Cycle Count Function (Sawtooth-Wave, Up-Counting) (n = 0 to 973)

24.3.11 Phase Counting Mode

The GTCNT counter can be up-counting or down-counting by detecting the phase difference between the GTIOCnA pin input (n = 0 to 7) and the GTIOCnB pin input.
Detection of the phase difference can be performed by setting the relationship between the edge and the level of the GTIOCnA pin input and the GTIOCnB pin input using the GTUPSR and GTDNSR registers for input combination.
Refer to section 24.3.1.1, Counter Operation for count operation.
Figure 24.146 to Figure 24.155 show the examples of setting procedure for the phase counting mode 1 to 5, and the Table 24.24 to Table 24.33 show the setting of the GTUPSR and GTDNSR registers and up-counting and down-counting conditions.

24.3.12 External Pulse Width Measuring Function

The pulse width of GTIOCnA pin input (n = 0 to 7), GTIOCnB pin input, and GTETRGA/GTETRGB/GTETRGC/GTETRGD pin inputs can be measured.

The setting to enable or disable count-up of the GTCNT counter and the input pin and level which measured pulse width are selected by the USILVL[3:0] bits of the GTUPSR register.

The setting to enable or disable count-down of the GTCNT counter and the input pin and level which measured pulse width are selected by the DSILVL[3:0] bits of the GTDNSR register.

The setting to enable both count-up and count-down of the GTCNT counter at the same time is prohibited.

The counting operation performs cycle counting with the period of the GTPR register.

If the phase counting function and the pulse width measuring function are enabled at the same time, the pulse width measuring function does not work and the phase counting function works.

Figure 24.156 and Figure 24.157 show examples of external pulse width measuring function and Figure 24.158 shows an example for setting external pulse width measuring function.

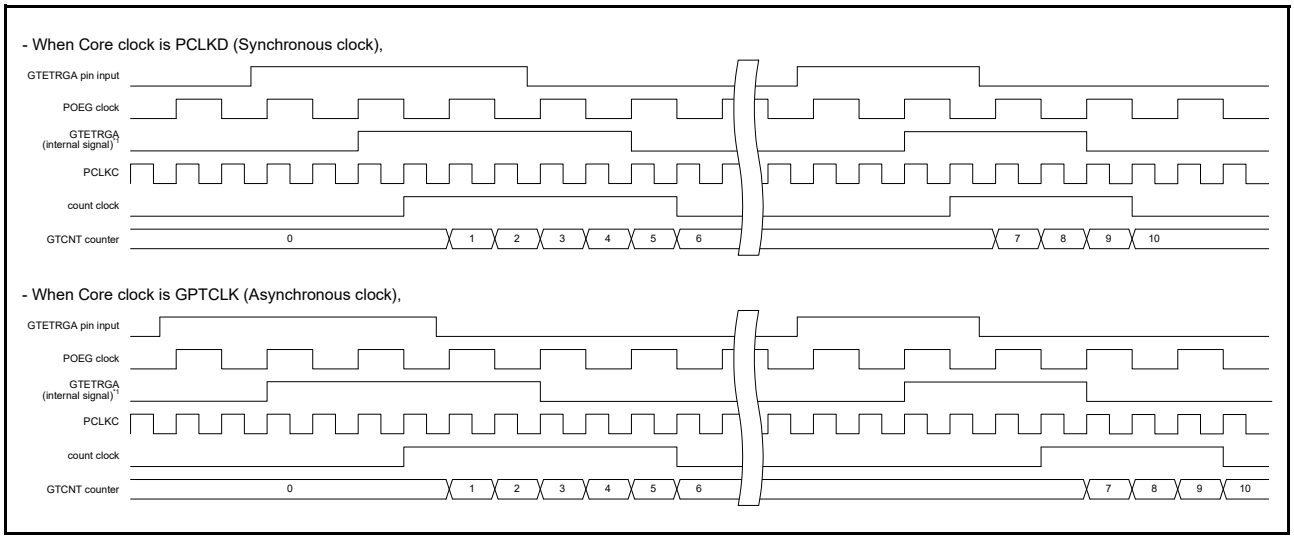

Figure 24.156 Example of External Pulse Width Measuring Function (Up-Counting)

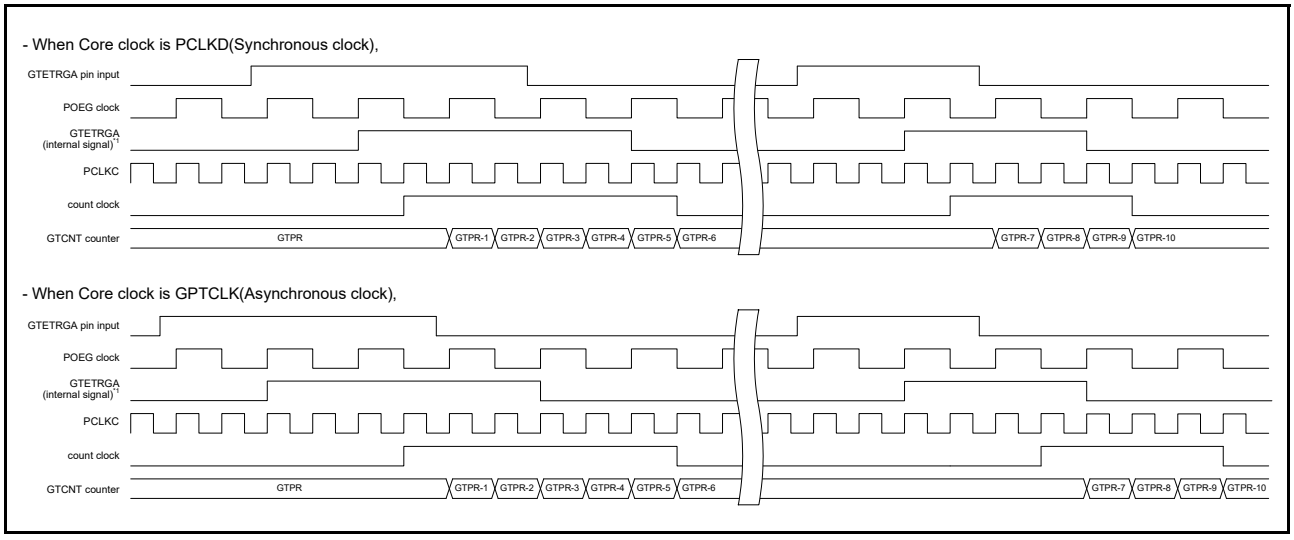

Figure 24.157 Example of External Pulse Width Measuring Function (Down-Counting)

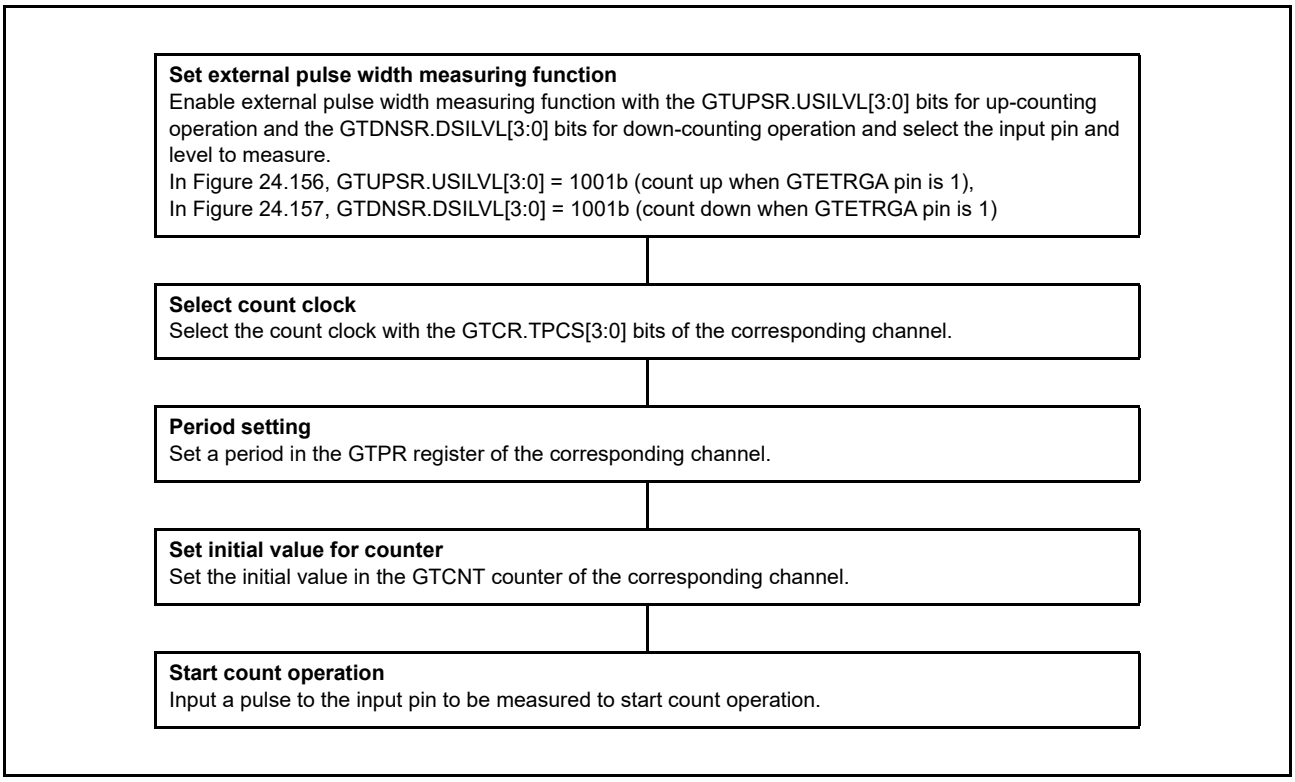

Figure 24.158 Example for Setting External Pulse Width Measuring Function

24.3.13 Output Phase Switching Control Function (OPS)

OPS can easily control Brushless DC motor using Output Phase Switching Control Register (OPSCR).
OPS uses S/W setting value (OPSCR.UF, VF, WF bits) or external signals detected by the Hall element as input signals.
OPS outputs either level signals or chopped signals by GPTW0's PWM as the 6-phase (U-positive phase/negative phase, V-positive phase/negative phase, W-positive phase/negative phase) signals to control motor.
Figure 24.159 shows the block diagram of OPS.
The GPT_UVWEDGE signal is output signal to ELC generated by detecting the edge of input signal.

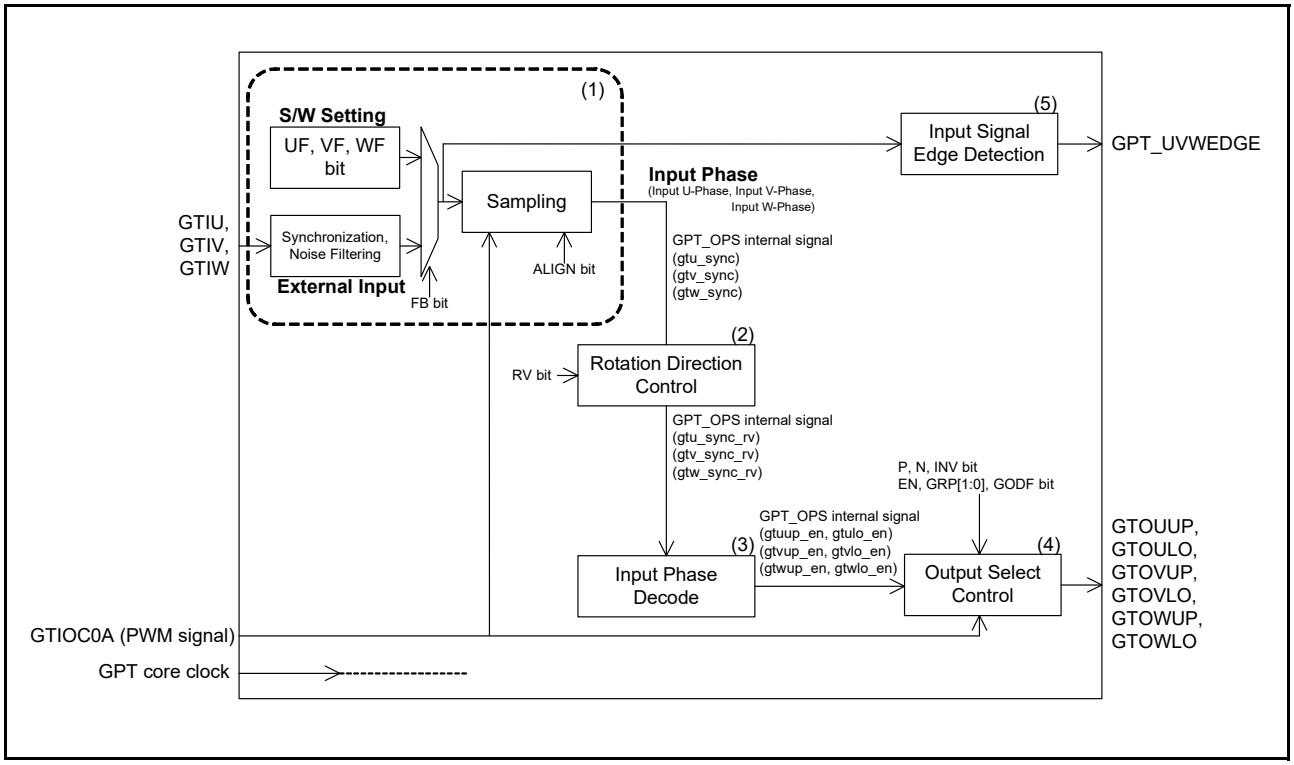

Figure 24.159 OPS Block Diagram

Figure 24.160 and Figure 24.161 show examples of OPS level output operation.

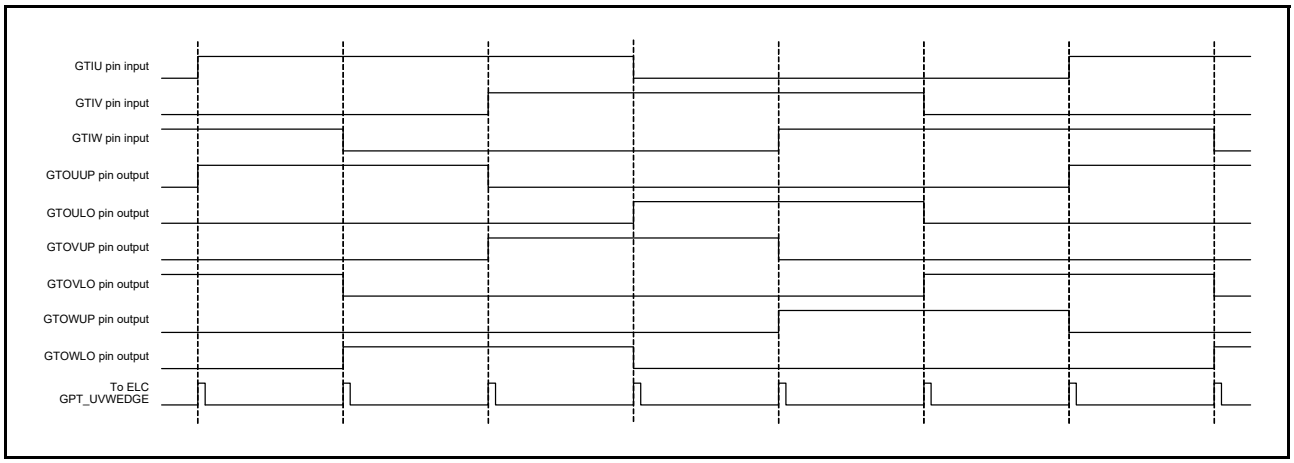

Figure 24.160 Example of OPS Level Output Operation (Forward Rotation) (FB = 0, RV = 0, P = 0, N = 0, INV = 0)

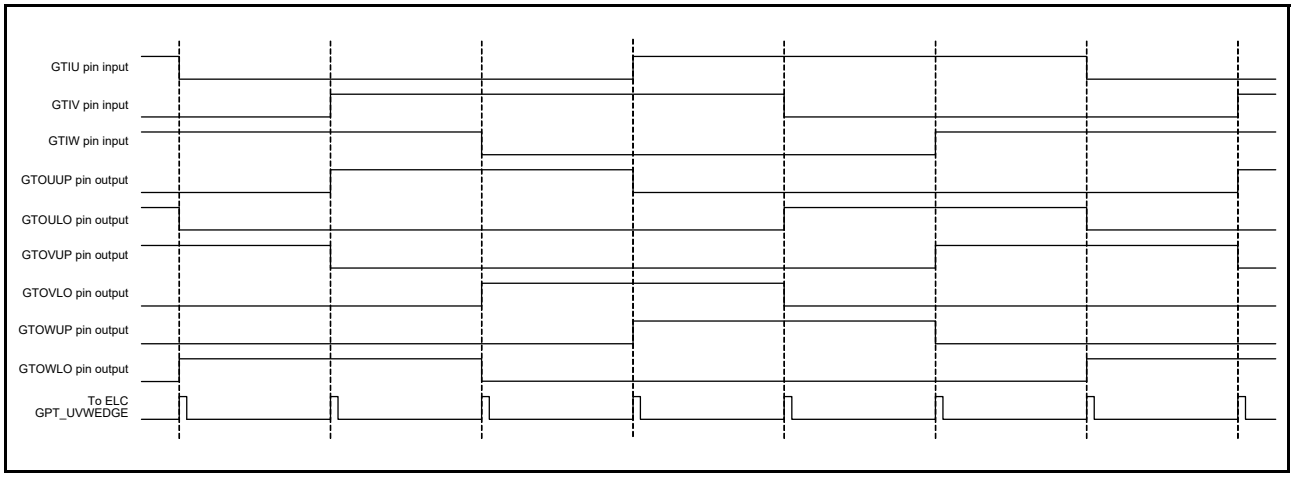

Figure 24.161 Example of OPS Level Output Operation (Reverse Rotation) (FB = 0, RV = 1, P = 0, N = 0, INV = 0)

Figure 24.164 shows an example of OPS output disable control operation.

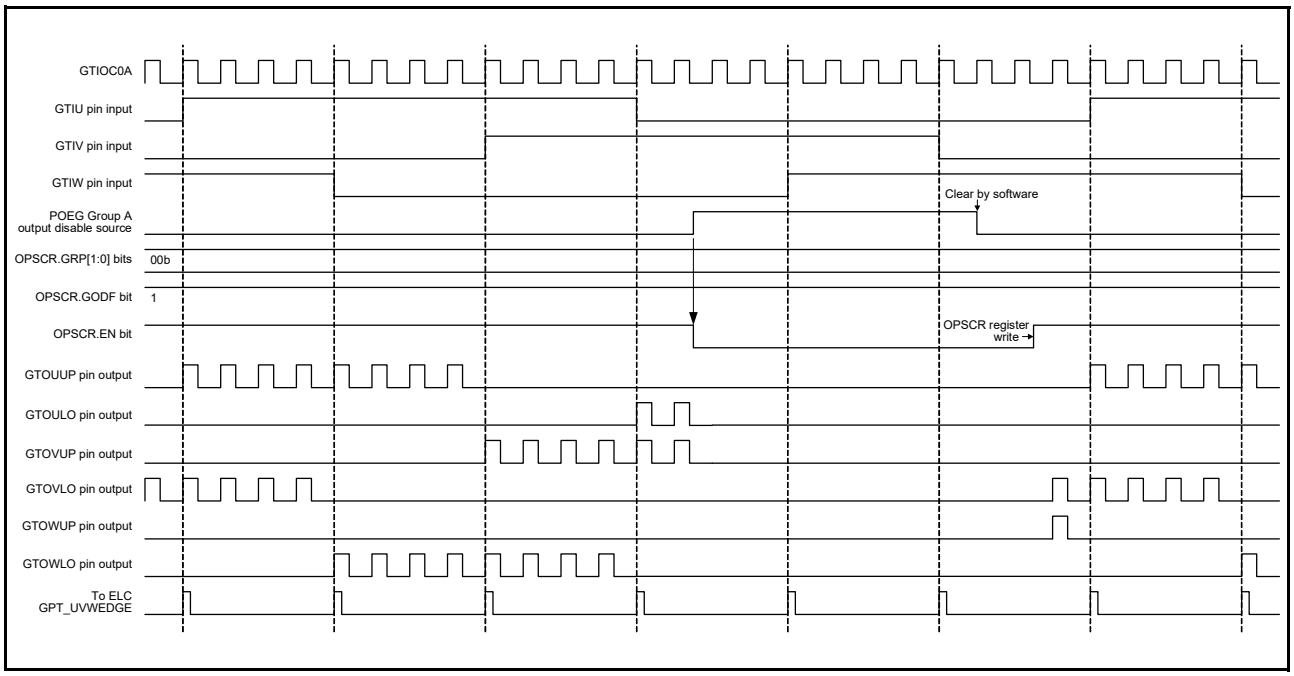

Figure 24.164 Example of OPS Output Disable Control Operation (FB = 0, RV = 0, P = 1, N = 1, INV = 0)

24.3.13.1 Input Selection and Sampling

The FB bit selects either the software setting value or external input for the input signal.
When the FB bit is 0, the GTIU, GTIV, GTIW external input are selected for the input signal to OPS after synchronization with the GPT core clock (PCLKC) and noise filtering.
When the FB bit is 1, the software setting value (UF, VF, WF bits) are selected for the input signal to OPS.
The selected input signals are sampled by the method selected by the ALIGN bit, and they are treated as input phase of OPS.
When the ALIGN bit is 0, the input signals are sampled by PCLKC.
When the ALIGN bit is 1, the input signals are sampled by the falling edge of GTIOC0A pin output.
The signals after sampling can be read by the U, V, W bits.
Table 24.34 shows the input selection by the FB bit and sampling method by the ALIGN bit.

Table 24.34 Input Selection and Sampling Method

OPSCR Register		Input Selection Sampling Method	Interrupt Phase (OPS internal signal)
FB bit	ALIGN bit		
0	0	GTIU, GTIV, GTIW external input PCLKC sampling	Input U-phase (gtu_sync) Input V-phase (gtv_sync) Input W-phase (gtw_sync)
	1	GTIU, GTIV, GTIW external input GTIOC0A falling edge sampling	
1	0	Software setting value UF, VF, WF bit PCLKC sampling	
	1	Software setting value UF, VF, WF bit GTIOC0A falling edge sampling	

24.3.13.2 Rotation Direction Control

When the rotation direction is reverse (RV = 1), the input phase is inverted.

24.3.13.3 Input Phase Decode

The 6-phase signals by decoding input phase after rotation direction control are generated.
Table 24.35 and Table 24.36 show the decode tables of input phase to rotate motor in forward (RV = 0) and reverse (RV = 1).

Table 24.35 The Decode Table of Input Phase (Forward Rotation)

Input Phase			**Input Phase after Rotation Direction Control**			**6-Phase Signals**					
U-phase	V-phase	W-phase	U-phase	V-phase	W-phase	Positive U-phase	Negative U-phase	Positive V-phase	Negative V-phase	Positive W-phase	Negative W-phase

0	1	1	1	0	0	1	0	0	0	0	1
0	0	1	1	1	0	0	0	1	0	0	1
0	0	0	0	0	0	0	0	0	0	0	0
1	1	1	1	1	1	0	0	0	0	0	0

24.3.13.4 Output Selection Control

The EN, P, N, INV bits select the output wave.
The EN bit enables output of the 6-phase output. When the EN bit is 1, output of the 6-phase output is enabled. When the EN bit is 0, the external pin output is Hi-Z.
The P, N bits select whether chopping positive and negative phase are performed or not. When P, N bits are 1, chopping is performed by GTIOC0A pin output.
When the chopping is performed, there are cases where the PWM width of output is shorter than the width of the PWM used to chop just before or after switching of output phase, depending on the phase difference between the phase output switch timing and the phase of PWM.
The INV bit selects the polarity (either positive logic or negative logic) of phase output.
Table 24.37 and Table 24.38 show the output selection control method for positive and negative phase output.

Table 24.37 Output Selection Control Method (Positive Phase)

EN bit	P bit	INV bit	GTOnUP
0	—	—	0 (External pin output Hi-z)
1	0	0	Positive logic level output (gtmup_en)
1	0	1	Negative logic level output (~gtmup_en)
1	1	0	Positive logic chopped output (GTIOC0A & gumup_en)
1	1	1	Negative logic chopped output (~(GTIOC0A & gumup_en))

n = U, V, W
m = u, v, w

Table 24.38 Output Selection Control Method (Negative Phase)

EN bit	P bit	INV bit	GTOnLO
0	—	—	0 (External pin output Hi-z)
1	0	0	Positive logic level output (gtmlo_en)
1	0	1	Negative logic level output (~gtmlo_en)
1	1	0	Positive logic chopped output (GTIOC0A & gumlo_en)
1	1	1	Negative logic chopped output (~(GTIOC0A & gumlo_en))

n = U, V, W
m = u, v, w

24.3.13.5 Output Selection Control (Group Output Disable Function)

When the GODF bit is 1 and signal value selected by the GRP[1:0] bits is High (Output Disable Request), OPS's output pins are changed to Hi-Z asynchronously and the OPSCR.EN bit is cleared by the output disable request signal synchronized with PCLKC.
For the return, after clearing the Output Disable Request by software, set the EN bit to 1.
The timing of EN bit cleared is 3 PCLKC cycles after generating the output disable request. In order to perform the output disable control surely, the output disable request flag in POEG should be cleared in the timing that terminating the output disable request is at least 4 PCLKC cycles after generating the output disable request.
The example of the operation of the group output disable control, see the above-mentioned Figure 24.164.

24.3.13.6 Event Link Controller (ELC) Output

The logical sum of the pulse detected by rising and falling edge of U, V, W phase input is output to the event link controller (ELC). When the high level period of input phase is short, there are cases that the detected edge is not transmitted to the ELC correctly because of the logical sum.

24.3.13.7 OPS Start Operation Setting Flow

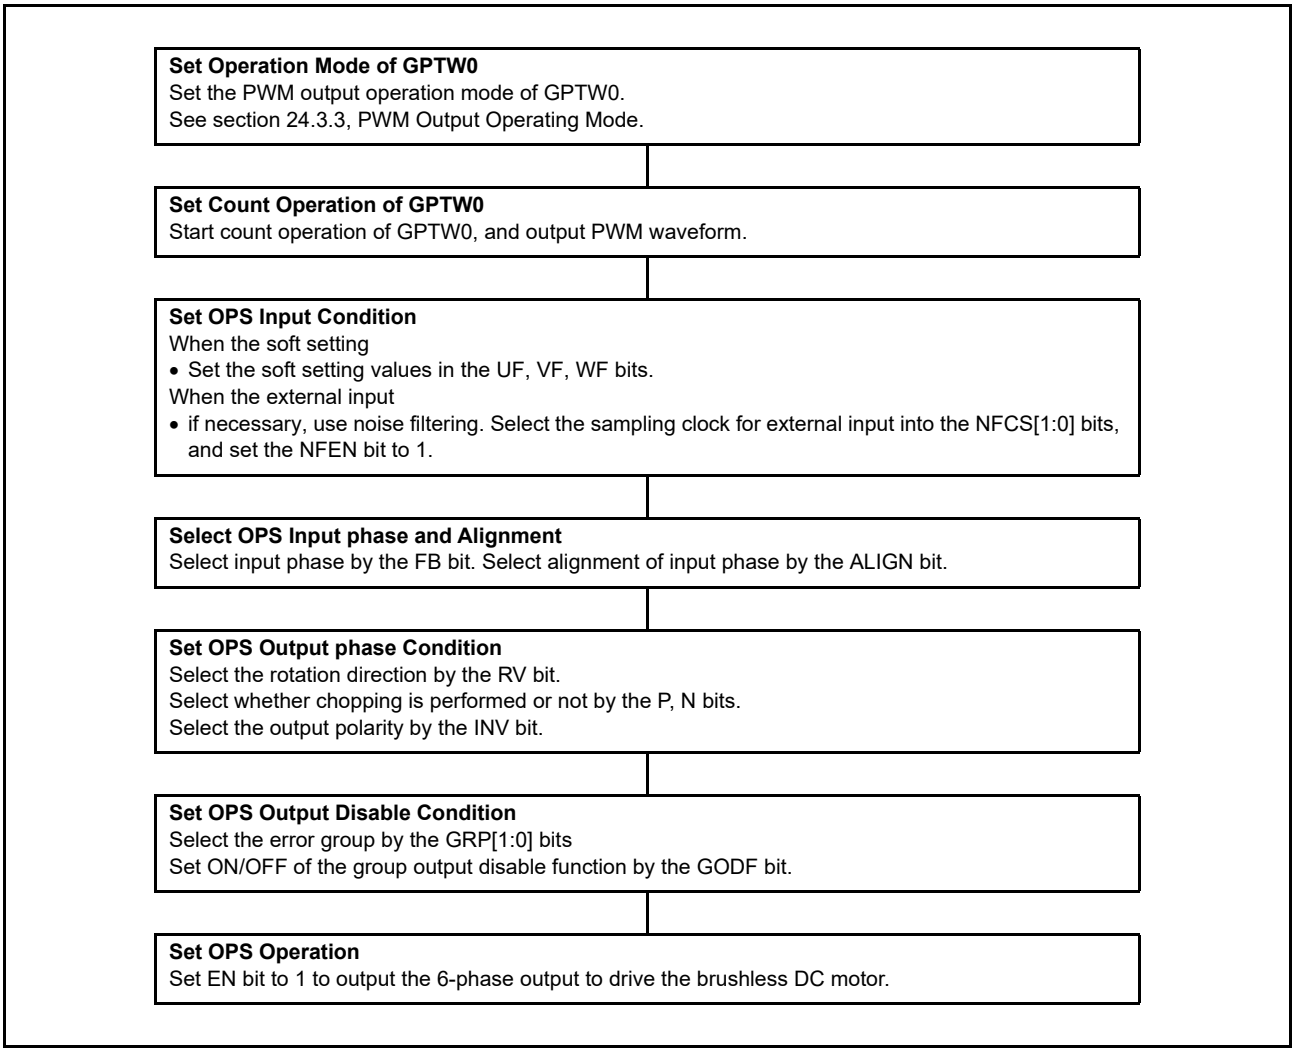

Figure 24.165 Example for Setting OPS Start Operation

24.3.14 Inter Channel Logical Operation Function

The logical operation function between compare match outputs can be performed.
Figure 24.166 shows the block diagram of inter channel logical operation.
To prevent hazard to the this function output, the signal after logical operation is latched with PCLKC. After latching, the output disable control is performed.
When the logical operation function which causes the delay of 1 PCLKC is selected, the output enable signal is also delayed with 1 PCLKC and input to the output disable control. The execution of a logical operation does not delay the interrupts, A/D conversion start requests, and event signal output to the ELC.
When the same signal (C = A or D = B) to operate logical function AND, OR, EXOR and NOR is selected, C or D is treated as 1. In the case of GTIOCnA pin output, when A of same channel is selected for C, the result of AND is A, the result of OR is 1, the result of EXOR is NOT A, and the result of NOR is 0.

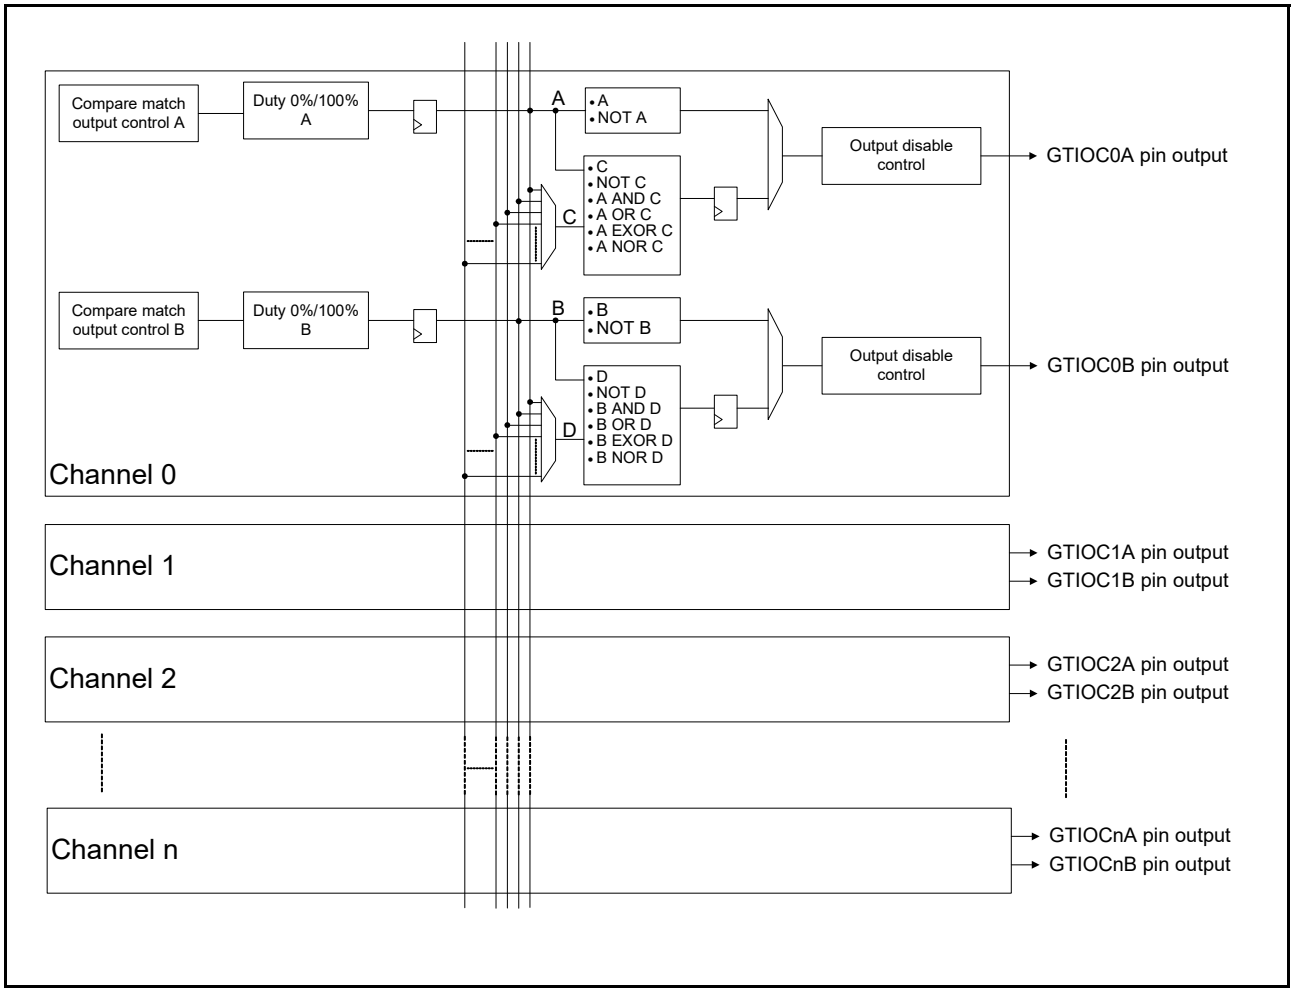

Figure 24.166 Block Diagram of Inter Channel Logical Operation

Figure 24.167 shows an example of inter channel logical operation.

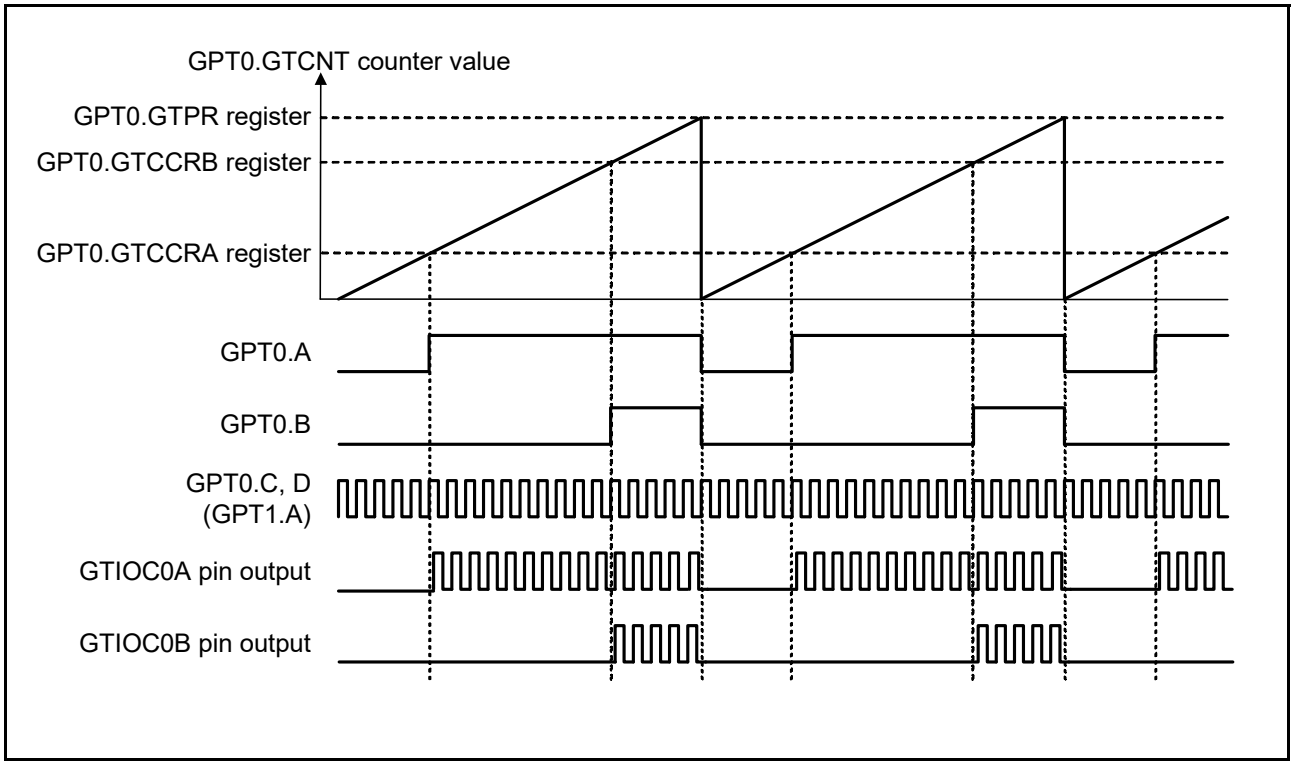

Figure 24.167 Example of Inter Channel Logical Operation (When GPTW0.GTICLF.ICLFA[2:0] = 100b, ICLFB[2:0] = 100b, GPTW0.GTICLF.ICLFSELC[5:0] = 000010b, ICLFSELD[5:0] = 000010b)

24.4 Interrupt Sources

24.4.1 Interrupt Sources and Priorities

There are three kinds of interrupt sources; GTCCRm register (m = A to F) input capture/compare match, GTCNT counter overflow (GTPR register compare match)/underflow, and dead time error.
Each interrupt source has its own status flag and control bit for generating interrupt request signals, where the generation of interrupt request signals can be enabled or disabled individually.
When an interrupt source condition is satisfied, an interrupt request is generated if the corresponding interrupt request enable or disable bit is 1.
For details, refer to section 14, Interrupt Controller (ICUG). Table 24.39 shows a list of GPTW interrupt sources.

Table 24.39 GPTW Interrupt Sources (n = 0 to 7)

Channel	Name	Interrupt Source	Interrupt Flag
GPTWn	GTCIAn	GTCCRA register input capture/compare match	GPTWn.GTST.TCFA
	GTCIBn	GTCCRB register input capture/compare match	GPTWn.GTST.TCFB
	GTCICn	GTCCRC register compare match	GPTWn.GTST.TCFC
	GTCIDn	GTCCRD register compare match	GPTWn.GTST.TCFD
	GDTEn	Dead time error	GPTWn.GTST.DTEF
	GTCEIn	Cycle count end	GPTWn.GTST.PCF
	GTCIEn	GTCCRE register compare match	GPTWn.GTST.TCFE
	GTCIFn	GTCCRF register compare match	GPTWn.GTST.TCFF
	GTCIVn	GTCNT counter overflow (GTPR register compare match)	GPTWn.GTST.TCFPO
	GTCIUn	GTCNT counter underflow	GPTWn.GTST.TCFPU

(1) GTCIAn Interrupt (n = 0 to 7)

When the GTINTAD.GTINTA bit is 1, an interrupt request is generated under the following conditions.

- When the GTCCRA register functions as a compare match register, the GTCNT counter value (in complementary PWM mode, the GTCNT counter value of master channel) matches with the GTCCRA register.
- When the GTCCRA register functions as an input capture register, the input-capture signal has caused transfer of the GTCNT counter value to the GTCCRA register. In complementary PWM mode, GTCCRA register does not function as an input capture register.

(2) GTCIBn Interrupt (n = 0 to 7)

When the GTINTAD.GTINTB bit is 1, an interrupt request is generated under the following conditions.

- When the GTCCRB register functions as a compare match register, the GTCNT counter value matches with the GTCCRB register. In complementary PWM mode, GTCCRB register does not function as a compare match register.
- When the GTCCRB register functions as an input capture register, the input-capture signal has caused transfer of the GTCNT counter value to the GTCCRB register. In complementary PWM mode, GTCCRB register does not function as an input capture register.

(3) GTCICn Interrupt (n = 0 to 7)

When the GTINTAD.GTINTC bit is 1, an interrupt request is generated under the following condition.

- When the GTCCRC register functions as a compare match register, the GTCNT counter value (in complementary PWM mode, the GTCNT counter value of master channel) matches with the GTCCRC register.

A compare match is not performed and thus interrupt is not requested under the following conditions.

- GTCR.MD[2:0] bits = 001b, GTCR.MD[3:0] bits = 0001b (sawtooth-wave one-shot pulse mode)
- GTCR.MD[2:0] bits = 110b, GTCR.MD[3:0] bits = 0110b (triangle-wave PWM mode 3)
- GTBER.CCRA[1:0] bits = 01b, 10b, 11b (buffer operation with the GTCCRC register)

(4) GTCIDn Interrupt (n = 0 to 7)

When the GTINTAD.GTINTD bit is 1, an interrupt request is generated under the following condition.

- When the GTCCRD register functions as a compare match register, the GTCNT counter value (in complementary PWM mode, the GTCNT counter value of master channel) matches with the GTCCRD register.

A compare match is not performed and thus interrupt is not requested under the following conditions.

- GTCR.MD[2:0] bits = 001b, GTCR.MD[3:0] bits = 0001b (sawtooth-wave one-shot pulse mode)
- GTCR.MD[2:0] bits = 110b, GTCR.MD[3:0] bits = 0110b (triangle-wave PWM mode 3)
- GTBER.CCRA[1:0] bits = 10b, 11b (buffer operation with the GTCCRD register)

(5) GTCIEn Interrupt (n = 0 to 7)

When the GTINTAD.GTINTE bit is 1, an interrupt request is generated under the following condition.

- When the GTCCRE register functions as a compare match register, the GTCNT counter value (in complementary PWM mode, the GTCNT counter value of master channel) matches with the GTCCRE register.

A compare match is not performed and thus interrupt is not requested under the following conditions.

- GTCR.MD[2:0] bits = 001b, GTCR.MD[3:0] bits = 0001b (sawtooth-wave one-shot pulse mode)
- GTCR.MD[2:0] bits = 110b, GTCR.MD[3:0] bits = 0110b (triangle-wave PWM mode 3)
- GTBER.CCRB[1:0] bits = 01b, 10b, 11b (buffer operation with the GTCCRE register)

(6) GTCIFn Interrupt (n = 0 to 7)

When the GTINTAD.GTINTF bit is 1, an interrupt request is generated under the following condition.

- When the GTCCRF register functions as a compare match register, the GTCNT counter value (in complementary PWM mode, the GTCNT counter value of master channel) matches with the GTCCRF register.

A compare match is not performed and thus interrupt is not requested under the following conditions.

- GTCR.MD[2:0] bits = 001b, GTCR.MD[3:0] bits = 0001b (sawtooth-wave one-shot pulse mode)
- GTCR.MD[2:0] bits = 110b, GTCR.MD[3:0] bits = 0110b (triangle-wave PWM mode 3)
- GTBER.CCRB[1:0] bits = 10b, 11b (buffer operation with the GTCCRF register)

(7) GTCIVn Interrupt (n = 0 to 7)

When the GTINTAD.GTINTPR[0] bit is 1, an interrupt request is generated under the following conditions.

- In sawtooth-wave mode, interrupt requests are enabled at overflows (the GTCNT counter value changes from the GTPR register value to 0 during up-counting).
- In sawtooth-wave PWM mode 1 and sawtooth-wave one-shot pulse mode, interrupt requests are enabled at overflows (when the GTCNT counter value changes from the GTPR register value to 0 during up-counting).
- In sawtooth-wave PWM mode 2, interrupt requests are enabled at overflows (the GTCNT counter value changes from GTCCRm (m = A to F) register value selected with GTCSR.CSCMSC[2:0] bits to 0000 0000h) or the time when GTCNT counter value matches GTPR register value.
- In triangle-wave mode, interrupt requests are enabled at crests (the GTCNT counter value changes from the GTPR register value to the GTPR register value minus 1).

- In complementary PWM mode, interrupt requests are enabled at crests (the GTCNT counter value of master channel changes from the GTPR register value to the GTPR register value minus 1).
- In counting driven by a hardware source, including counting for the external pulse width measuring function, interrupt requests are enabled on overflows (that is, when the GTCNT counter value changes from the GTPR register value to 0 during up-counting).

(8) GTCIUn Interrupt (n = 0 to 7)

When the GTINTAD.GTINTPR[1] bit is 1, an interrupt request is generated under the following conditions.

- In sawtooth-wave mode, interrupt requests are enabled at underflows (the GTCNT counter value changes from 0 to the GTPR register value during down-counting).
- In sawtooth-wave PWM mode 1 and sawtooth-wave one-shot pulse mode, interrupt requests are enabled at overflows (when the GTCNT counter value changes from the GTPR register to 0 during down-counting).
- In triangle-wave mode, interrupt requests are enabled at troughs (the GTCNT counter value changes from 0 to 1).
- In complementary PWM mode, interrupt requests are enabled at troughs (the GTCNT counter value of master channel changes from 0 to 1).
- In count operation by a hardware source, interrupt requests are enabled at underflows (the GTCNT counter value changes from 0 to the GTPR register value during down-counting).

(9) GDTEn Interrupt (n = 0 to 7)

When automatic dead time setting has been made, the GTST.DTEF flag becomes 1 when the timer output toggle point with dead time added exceeds the count period. If the GTINTAD.GRPDTE bit is 1 at this time, a dead time error interrupt request (GDTE) is generated.
In addition, when the timer output toggle point with dead time added is back within the count period, the GTST.DTEF flag changes from 1 to 0.

(10) GTCEIn Interrupt (n = 0 to 7)

When the GTPC.PCEN bit is 1 and the GTPC.PCNT counter is 1, and the end of the cycle is reached, if the GTINTAD.GTINTPC bit is 1, a cycle count end interrupt (GTCEIn) request is generated.

Table 24.40 Relationship between Interrupt Signals and Interrupt Enable Bits (n = 0 to 7)

Interrupt Signal	Interrupt Enable Bit	Status Flag
GTCIAn	GTINTAD.GTINTA bit	GTST.TCFA Flag
GTCIBn	GTINTAD.GTINTB bit	GTST.TCFB Flag
GTCICn	GTINTAD.GTINTC bit	GTST.TCFC Flag

GTCIUn		GTST.TCFPU Flag

24.4.2 DMAC/DTC Activation

The DMAC and DTC can be triggered by the interrupt request in each channel. For details, see section 14, Interrupt Controller (ICUG), section 17, DMA Controller (DMACAa), section 18, Data Transfer Controller (DTCb).

24.4.3 Interrupt and A/D Conversion Start Request Skipping Function

24.4.3.1 Interrupt Skipping Function by GTITC Register

By setting the GTITC register, the GTCNT counter overflow (GTPR register compare match) interrupt (GTCIV) and underflow interrupt (GTCIU) can be skipped. Other interrupts and A/D conversion start request signals can be skipped in coordination with the GTCIV/GTCIU skipping function. However, the dead time error interrupts cannot be linked with the GTCIV/GTCIU skipping function.

When the interrupt is skipped, the updating of relevant status flag is also skipped. The interrupt skipping is continued even if the status flag is set to 1.

The interrupt skipping function is related only to the GTITC register setting, and is not related to setting of the GTINTAD register interrupt enable bit. The interrupt enable bit is used only to control the output of the interrupt signal after thinning out.

When both troughs and crests are counted and skipped in triangle-wave mode, if the number of times of skipping is odd, GTCIV/GTCIU interrupt requests cannot be generated at troughs only or at crests only depending on the skipping counter start timing. Therefore, in order to count both troughs and crests and generate the GTCIV/GTCIU interrupts at troughs only or crests only in triangle-wave mode, the number of times of skipping should be even.

Similarly, in sawtooth-wave mode, when both overflows and underflows are counted and skipped with the count direction changed, GTCIV/GTCIU interrupt requests cannot be generated at overflows only or at underflows only. Therefore, in order to count both overflows and underflows with the count direction changed and generate the GTCIV/GTCIU interrupts at overflows only or underflows only in sawtooth-wave mode, the skipping state should be carefully checked before using.

When changing the skipping count, be sure to release the skipping count setting (GTITC.IVTC[1:0] bits = 00b).

Figure 24.168 to Figure 24.173 show examples of skipping function operation.

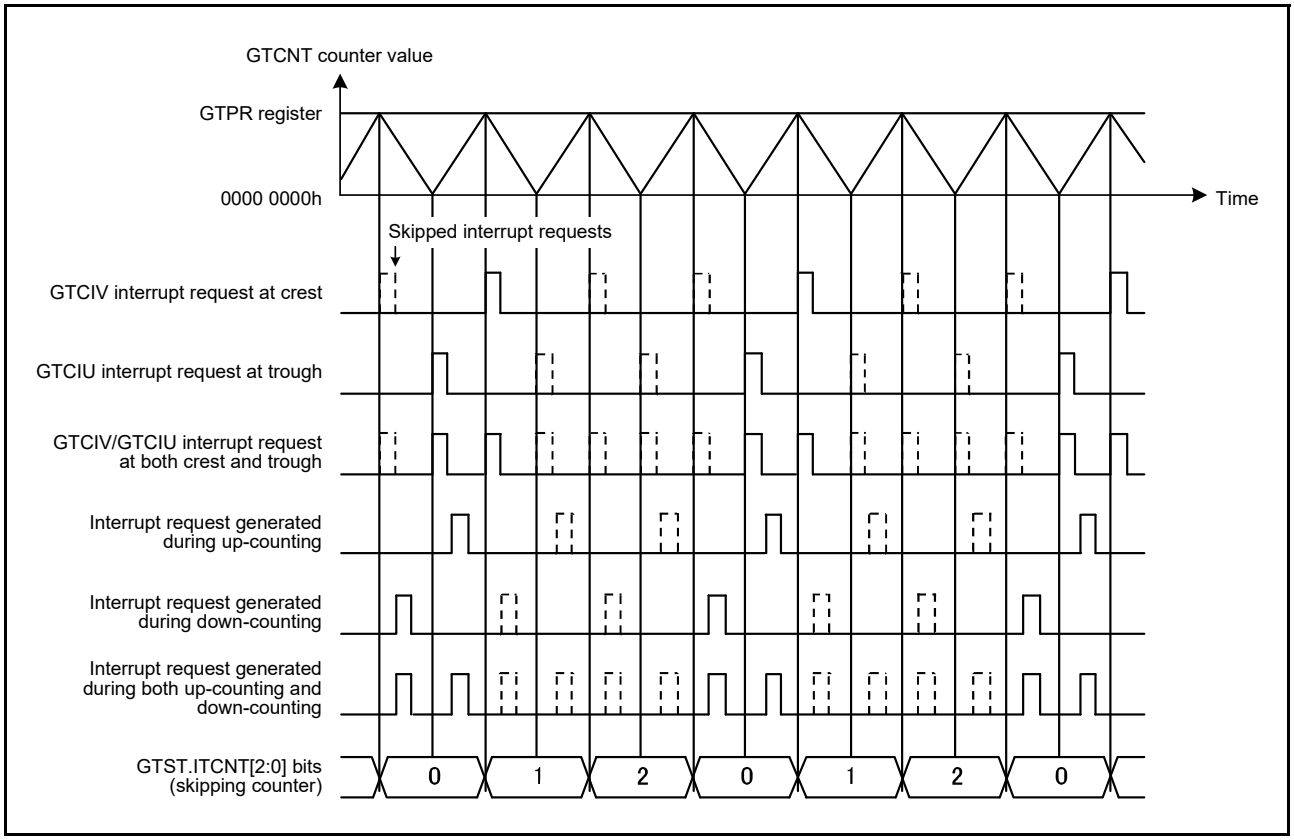

Figure 24.168 Example of Interrupt Skipping Function Operation (Triangle Waves, Counting and Skipping Crests, Skipping Count: 2)

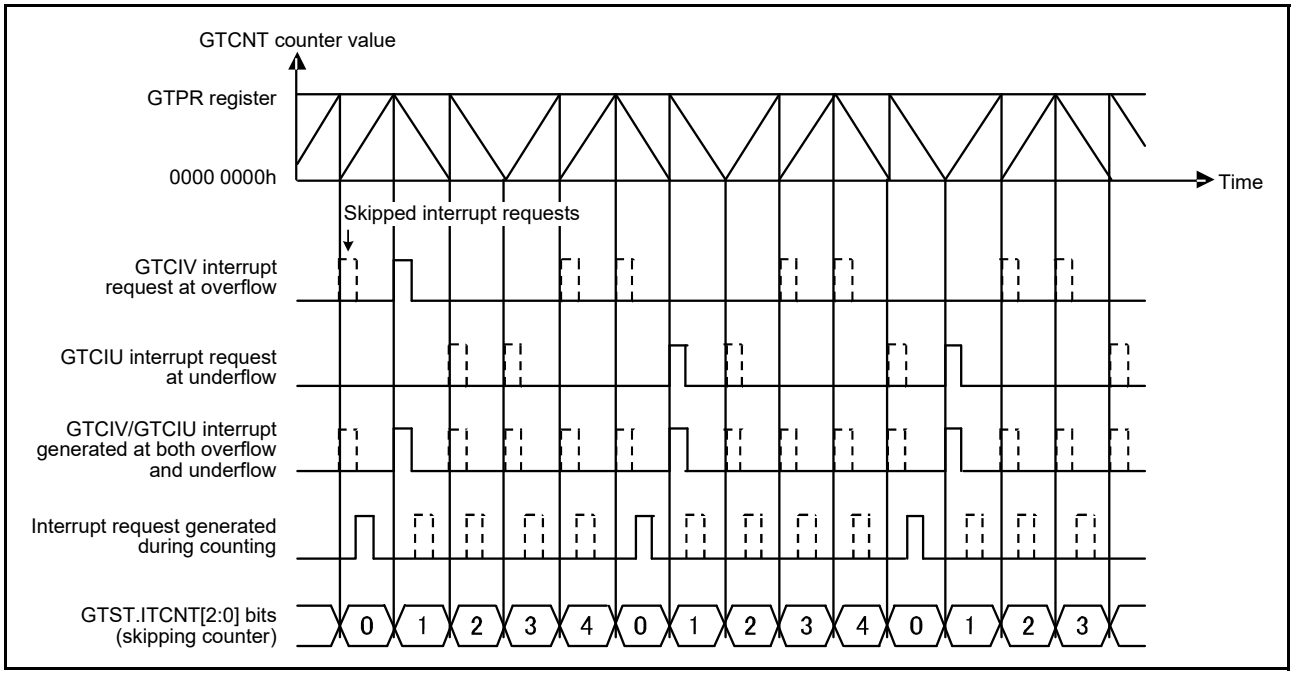

Figure 24.173 Example of Interrupt Skipping Function Operation (Sawtooth Waves, Operation with Count Direction Changed, Counting and Skipping Both Overflows and Underflows, Skipping Count: 4)

24.4.3.2 Extended Interrupt Skipping Function

Overflow/underflow interrupt, compare match/input capture interrupt, A/D conversion start request, and buffer transfer can be skipped by counting the GTCNT counter overflow or underflow based on settings of the GTEITC, GTEITLI1, GTEITLI2 and GTEITLB registers. The dead time error interrupt cannot be skipped.

Overflow/underflow interrupt, compare match/input capture interrupt, A/D conversion start request, and buffer transfer can individually be set for skipping and the skipping period using the GTEITLI1, GTEITLI2, and GTEITLB registers. The skipping period is set, related to the operation of the two independent extended interrupt skipping counters (EITCNT1[3:0] and EITCNT2[3:0] bits in the GTEITC registers), as a period that either of the counter value for such skipping counters is other than 0 or other than the skipping count. The skipping period can also be set as a period that the both skipping counters are set as other than 0 or other than the skipping count for the counter value.

Figure 24.174 shows the counter operation for interrupt skipping by the GTITC register and extended interrupt skipping.

The counter operation for extended interrupt skipping is set by the GTEITC register.

The EITCNT1[3:0] bits count the count source (in Figure 24.174, a crest is selected) selected by the extended interrupt counter 1 count source select bit (EIVTC1[1:0] bits) when the initial value is set for 0, and repeat the count operation which returns to 0 when the skipping count (in Figure 24.174, count is 2) set by the extended interrupt skipping 1 skipping count setting bit (EIVTT1[3:0] bits) is achieved.

The EITCNT2[3:0] bits can set the initial value, count the count source (in Figure 24.174, a trough is selected) selected by the extended interrupt counter 2 count source select bit (EIVTC2[1:0] bits), and repeat the count operation which return to 0 when the skipping count (in Figure 24.174, count is 2) set by the EIVTT2[3:0] bits is achieved. The initial value is set when the GTEITC register is written by the access of upper 16 bits or 32 bits and when the written value to the EIVTC2[1:0] bits is other than 00b, while the setting for the extended interrupt skipping counter 2 is not in counting (EIVTC2[1:0] bits are 00b).

When the initial value is set, the written value to the extended interrupt skipping counter 2 initial value bit (EITCNT2IV[3:0] bits) is set as the initial value for the EITCNT2[3:0] bits.

The extended interrupt skipping counter starts up-counting at the first count clock after the setting is modified from not counting to counting.

The interrupt skipping count counter (GTST.ITCNT[2:0] bits) by the GTITC register is reset to 000b when the GTCNT counter operation is stopped: however, the EITCNT1[3:0] and EITCNT2[3:0] bits which are an extended interrupt skipping function retain the value even after the GTCNT counter operation is stopped, and the counting can be resumed from the value before the counter is stopped. When values for the EITCNT1[3:0] and EITCNT2[3:0] bits are to be reset (0000b), set the EIVTC1[1:0] and EIVTC2[1:0] bits to the setting for not counting (not skipping) (00b).

When the skipping count is to be changed, change the count after stopping the skipping counter operation (set either of the EIVTC1[1:0] bit or the EIVTC2[1:0] bit to 00b).

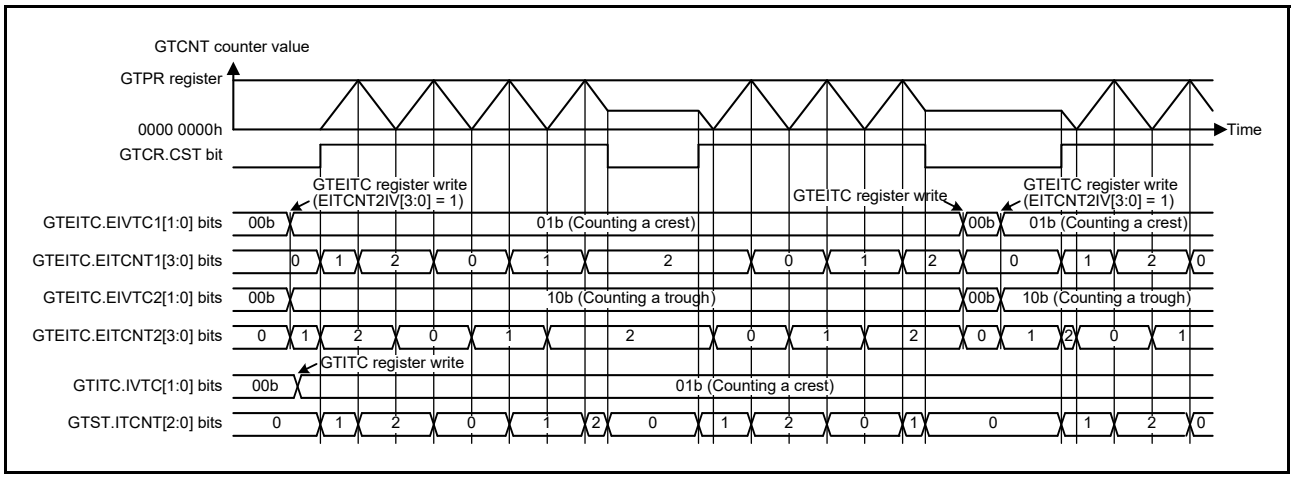

Figure 24.174 Counter Operation for Interrupt Skipping

Interrupt skipping by the GTEITLI1 register and A/D conversion start request skipping by the GTEITLI2 register can be performed simultaneously with interrupt skipping by the GTITC register or GTADCMSC register. A skipping period at this time is represented by ORed skipping periods of respective registers.
Figure 24.175 shows corresponding interrupt skipping operations by different registers are performed simultaneously.

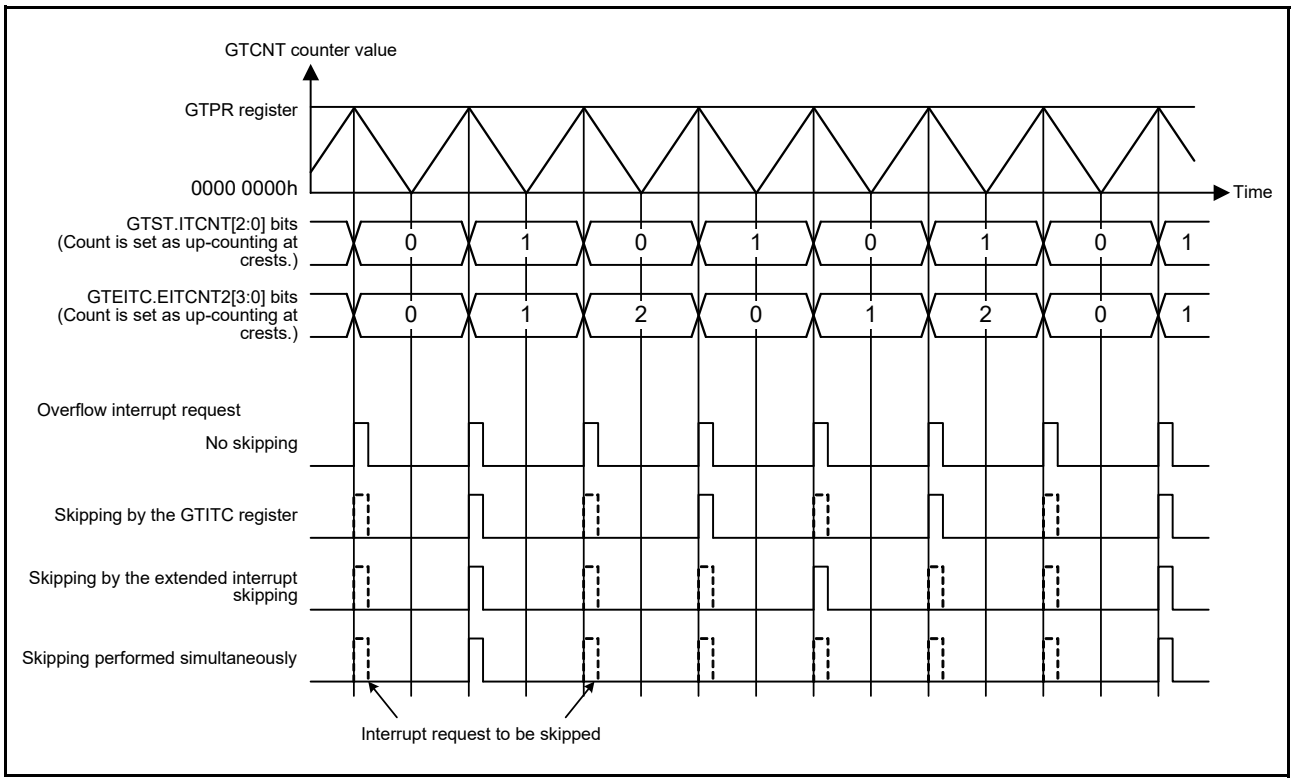

Figure 24.175 Example of Interrupt Skipping Operation (Skipping by the GTITC Register: Counting Crests, Extended Interrupt Skipping: EIVTC1[1:0] bits = 00b, EIVTC2[1:0] bits = 01b, EITLV[2:0] bits = 010b)

When the extended interrupt skipping selected by GTEITLI1 is performed, the relevant status flag is also skipped. The skipping function is continued even if the status flag is set to 1.
Skipping of updating of status flag, interrupt and ELC event source outputs corresponding to interrupts for which skipping can be set up in the GTEITLI1 register is only based on the settings of the GTITC register and the extended interrupt skipping register, and has no connection with the setting of the interrupt enable bit in the GTINTAD register. The interrupt enable bit is used only for the interrupt signal output after skipping.
When the A/D conversion start request skipping selected by GTEITLI2 is performed, the relevant status flag is also skipped. The skipping function is continued even if the status flag is set to 1.
Skipping of updating of status flag, interrupt and ELC event source outputs corresponding to A/D conversion start request for which skipping can be set up in the GTEITLI2 register is only based on the settings of the GTITC register and the extended interrupt skipping register, and has no connection with the setting of A/D conversion start request enable bit in the GTINTAD register. The A/D conversion start request enable bit is used only for A/D conversion start request output (interrupt and ELC event source output) after skipping.
A buffer transfer skipping by the GTEITLB register is performed in all of buffer operation which is enabled in the GTBER, GTDTCR, and GTBER2 registers, or all buffer operations performed by sawtooth-wave one-shot pulse mode, triangle-wave PWM mode 3, or complementary PWM mode (excludes buffer transfer from GTCCRC, GTCCRE to GTCCRA).
An interrupt skipping and a buffer transfer skipping are operated individually. An interrupt output without performing a buffer transferred performing a buffer transfer without an interrupt output can also be operated.
Figure 24.176 to Figure 24.183 show examples of skipping function operation.

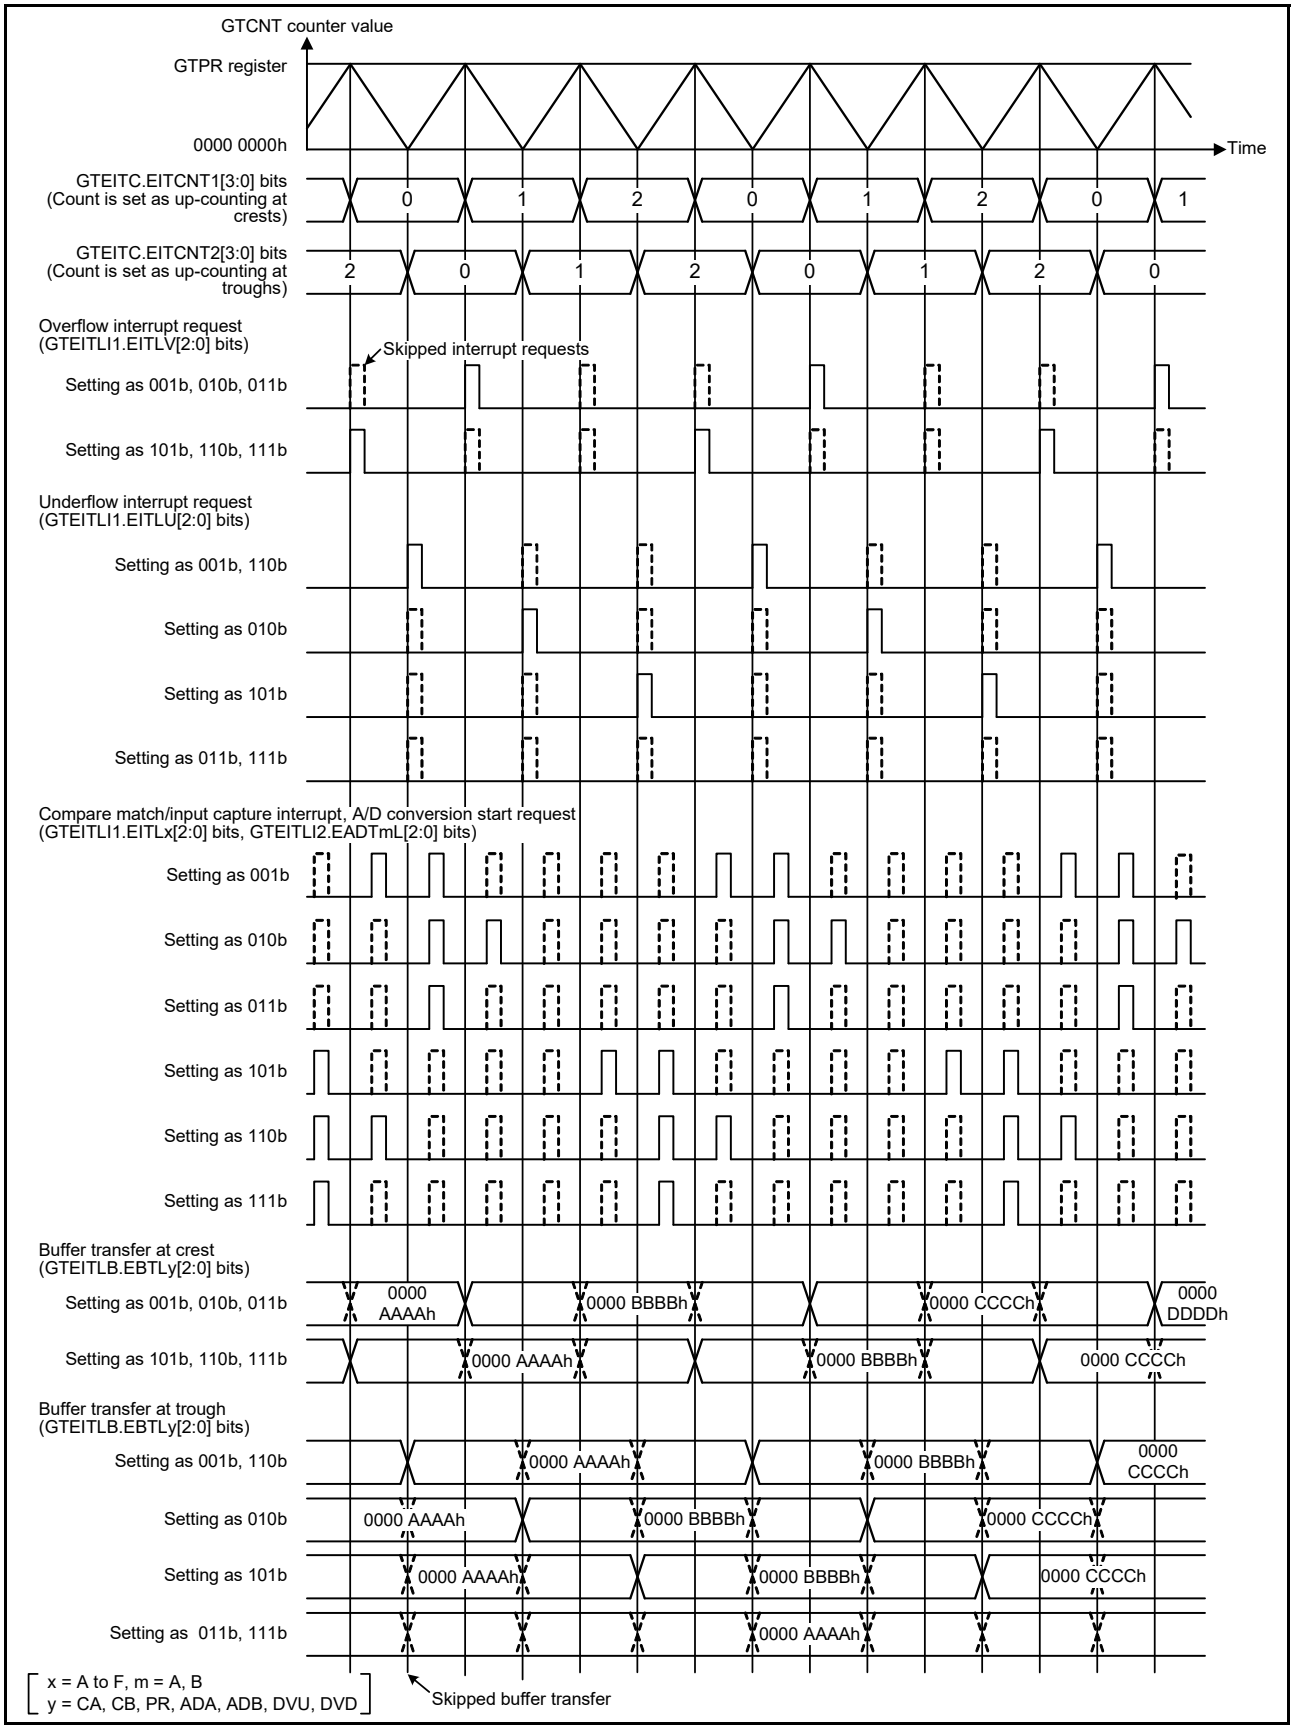

Figure 24.176 Example of Extended Interrupt Skipping Function (Triangle Waves, Counting Crests, Extended Interrupt Skipping 1 Skipping Count: 2, Counting Troughs, Extended Interrupt Skipping 2 Skipping Count: 2, Extended Interrupt Skipping Counter 2 Initial Value: 0)

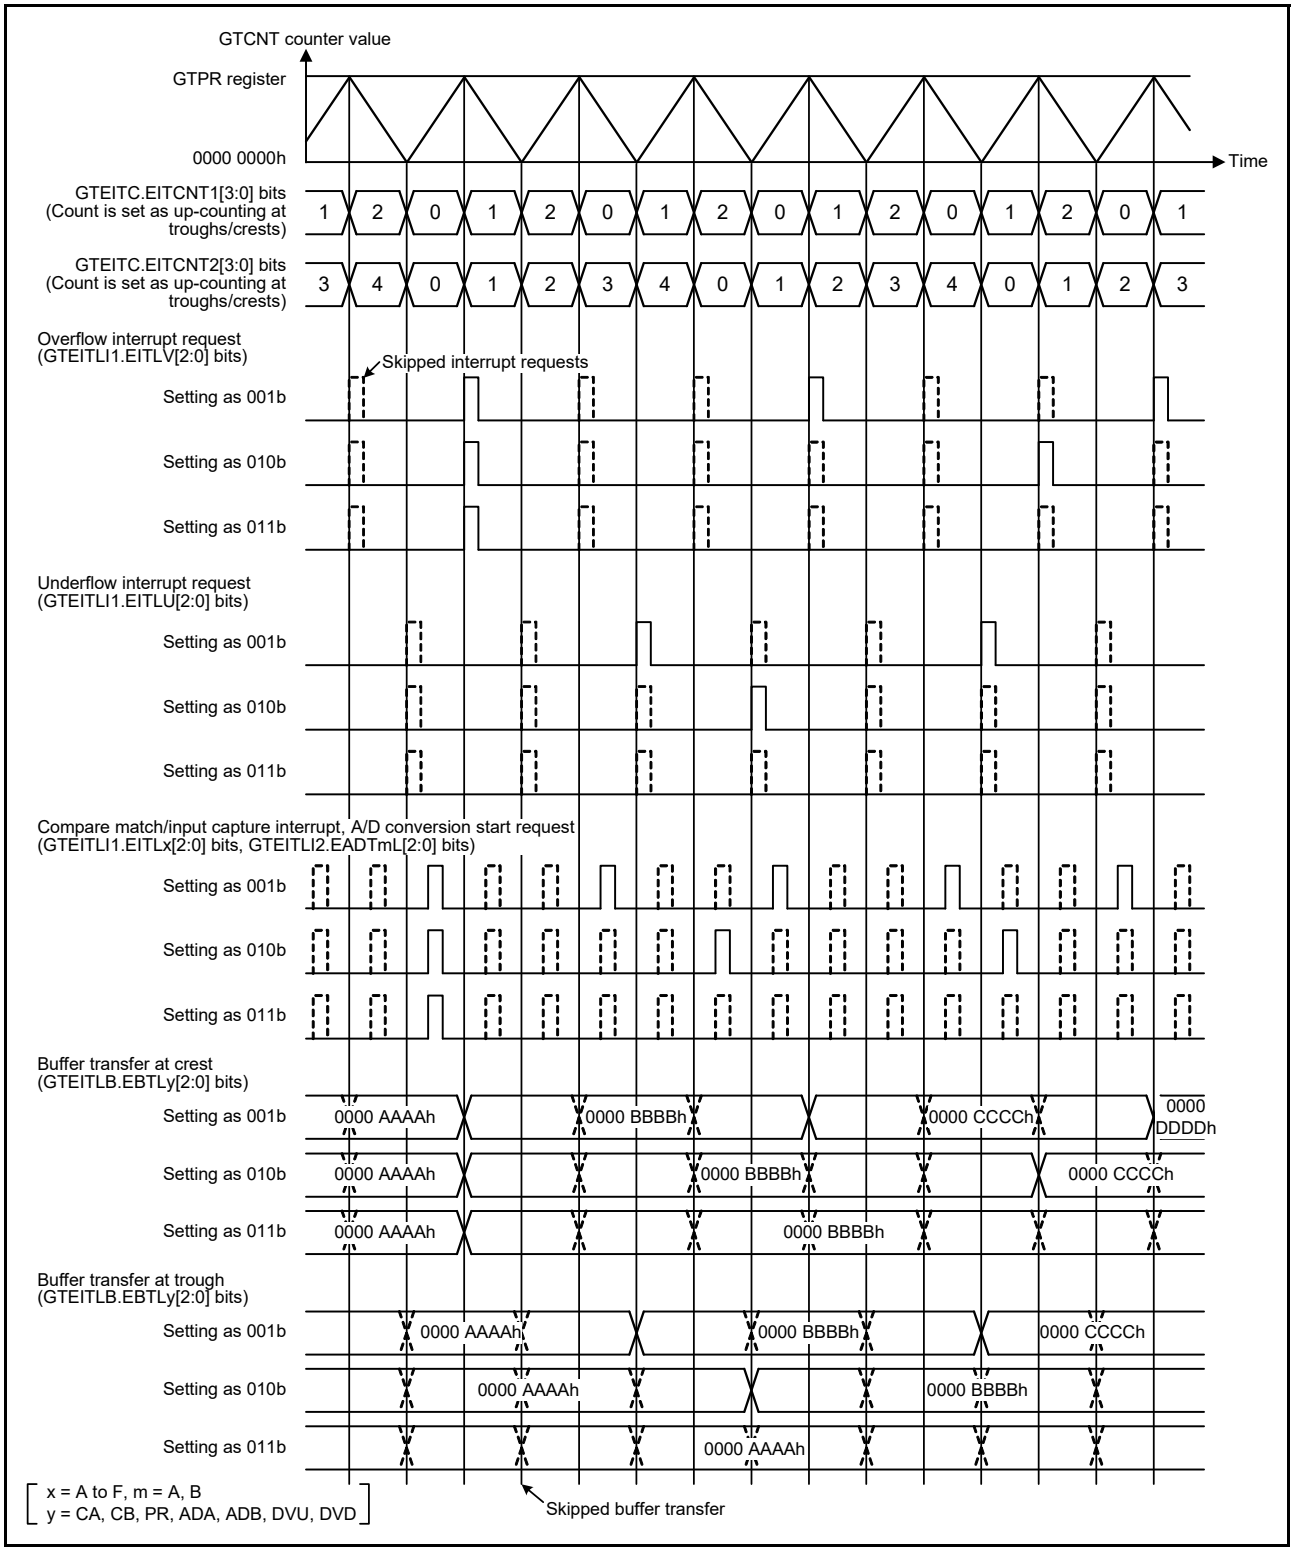

Figure 24.180 Example of Extended Interrupt Skipping Function Operation (Triangle Waves, Counting both Crests and Troughs, Extended Interrupt Skipping 1 Skipping Count: 2, Counting both Crests and Troughs, Extended Interrupt Skipping 2 Skipping Count: 4, Extended Interrupt Skipping Counter 2 Initial Value: 0, Skipped in the Period other than GTEITC.EITCNTk bits (k = 1, 2) as 0)

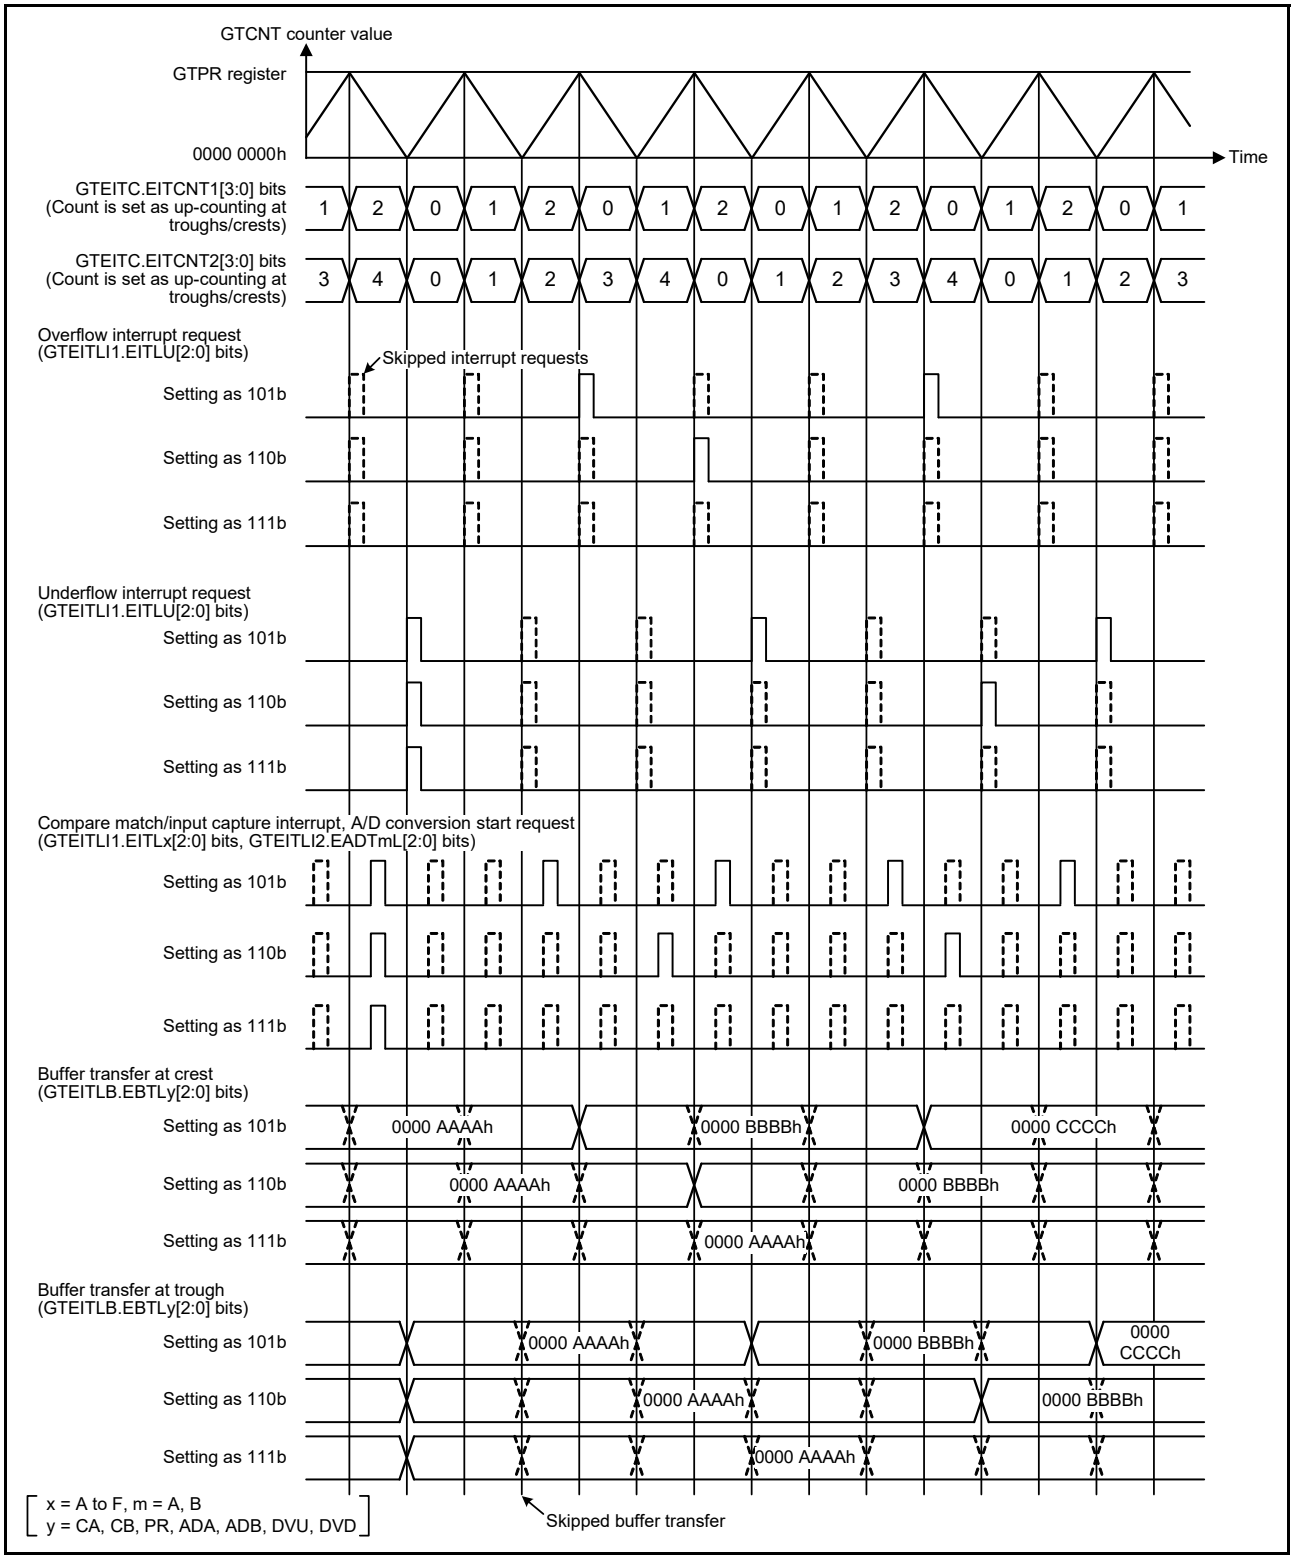

Figure 24.181 Example of Extended Interrupt Skipping Function Operation (Triangle Waves, Counting both Crests and Troughs, Extended Interrupt Skipping 1 Skipping Count: 2, Counting both Crests and Troughs, Extended Interrupt Skipping 2 Skipping Count: 4, Extended Interrupt Skipping Counter 2 Initial Value: 0, Skipped in the Period other than GTEITC.EITCNTk bits (k = 1, 2) as GTEITC.EIVTTk bit.)

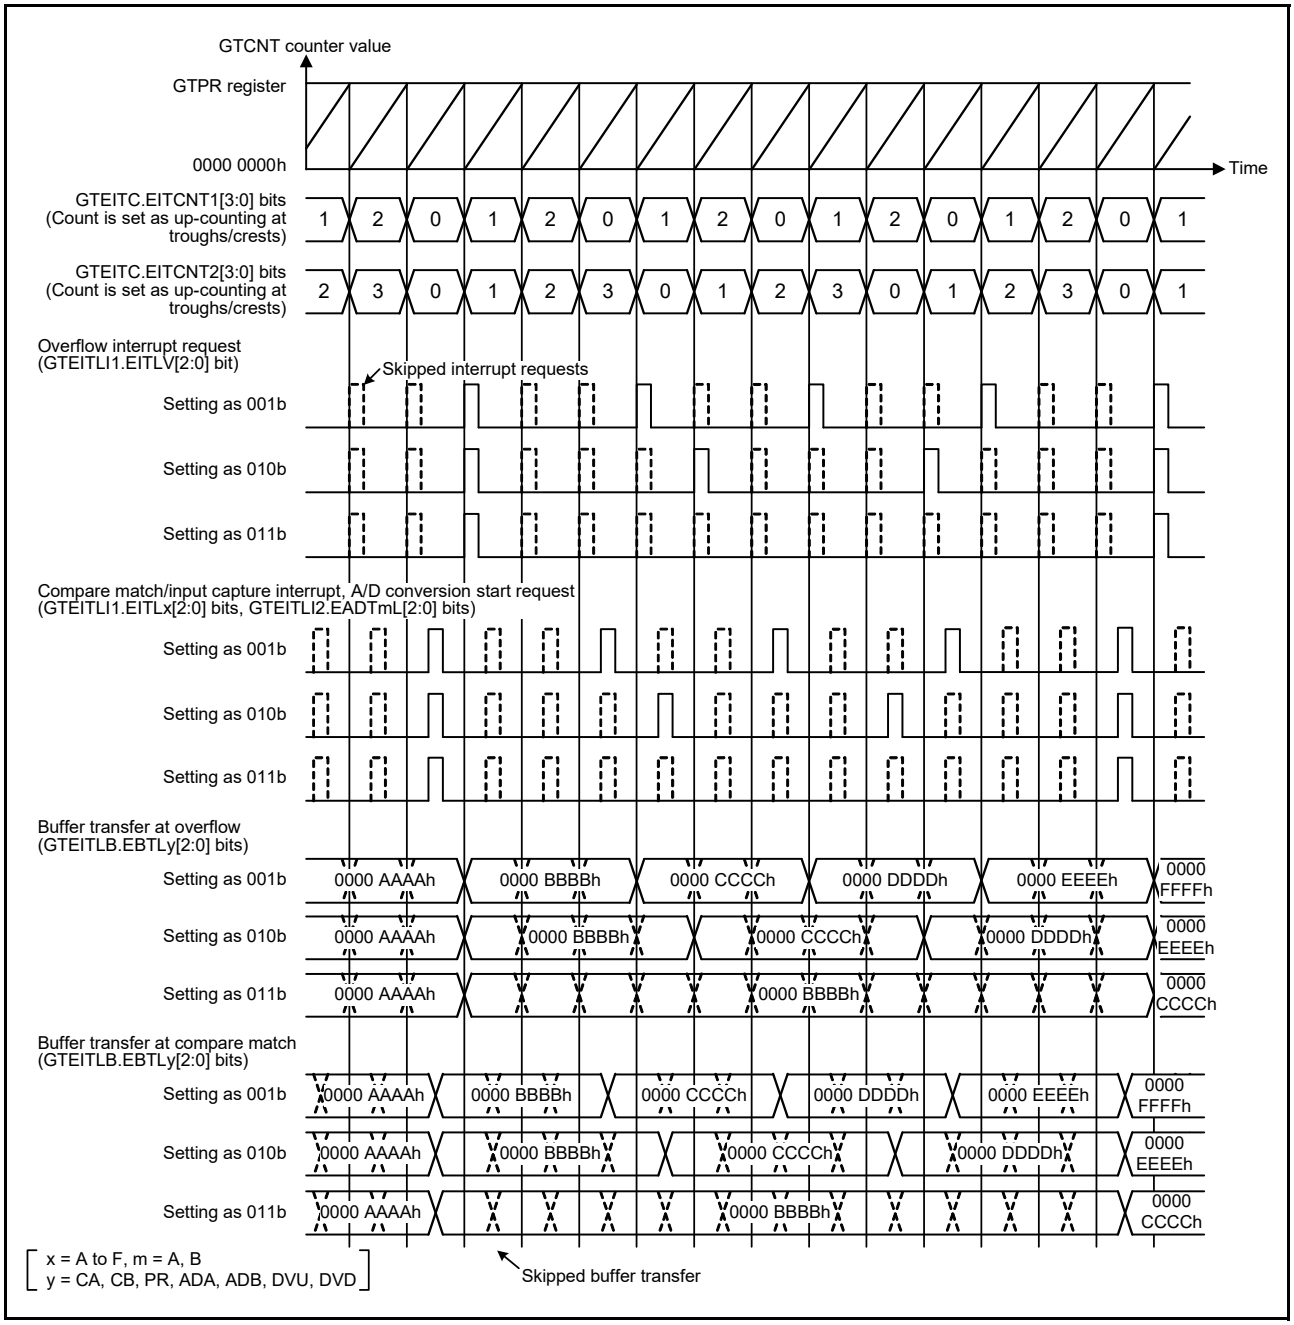

Figure 24.182 Example of Extended Interrupt Skipping Function Operation (Up-Counting in Sawtooth Waves, Counting Overflow, Extended Interrupt Skipping 1 Skipping Count: 2, Counting Overflow, Extended Interrupt Skipping 2 Skipping Count: 3, Extended Interrupt Skipping Counter 2 Initial Value: 0, Skipped in the Period other than GTEITC.EITCNTk bits (k = 1, 2) as 0)

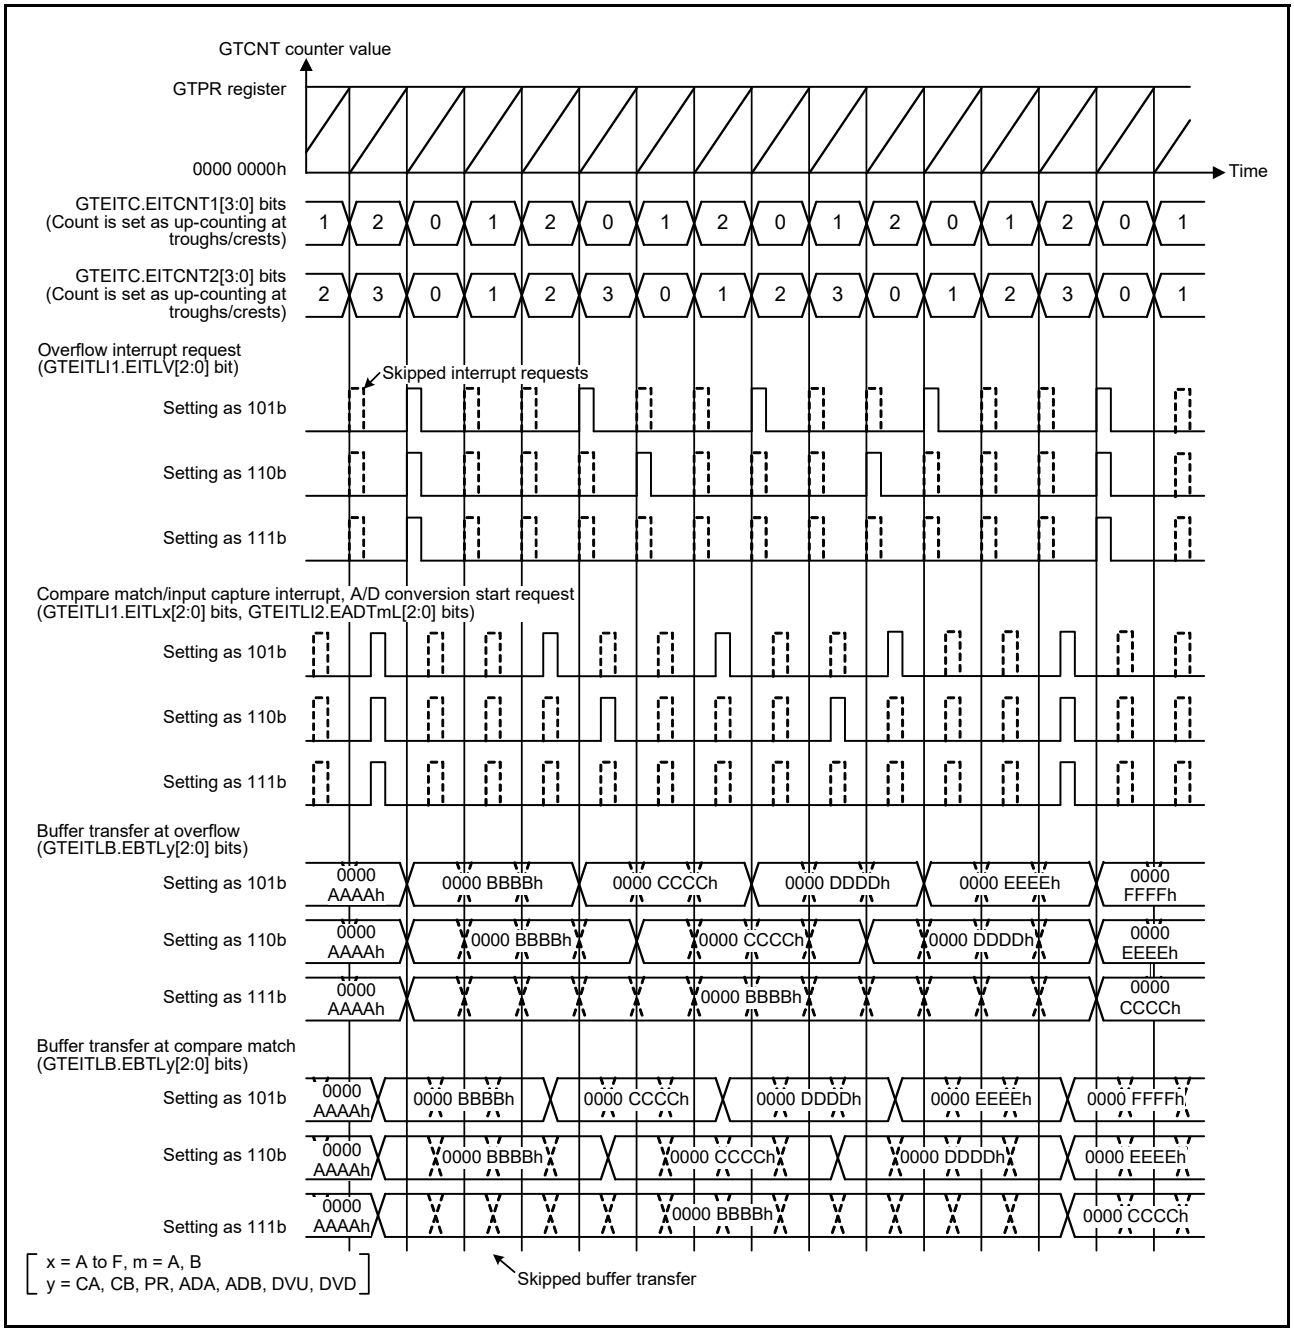

Figure 24.183 Example of Extended Interrupt Skipping Function Operation (Up-Counting Sawtooth Waves, Counting Overflow, Extended Interrupt Skipping 1 Skipping Count: 2, Counting Overflow, Extended Interrupt Skipping 2 Skipping Count: 3, Extended Interrupt Skipping Counter 2 Initial Value: 0, Skipped in the Period other than GTEITC.EITCNTk bits (k = 1, 2) as GTEITC.EIVTTk bit.)

Figure 24.184 shows an example of the extended interrupt skipping operation on the input capture. When the setting is for the input capture operation setting (GTCR.ICDS bit = 0) at count stop of the GTCNT counter, the interrupt by the input capture and the extended skipping on buffer transfer is enabled even at count stop of the GTCNT counter.
When the input capture is generated at count stop of the GTCNT counter by setting the ICDS bit as 0, an interrupt and a buffer transfer are skipped if the skipping counter value is the same with the skipping period set in a corresponding interrupt function select bit.

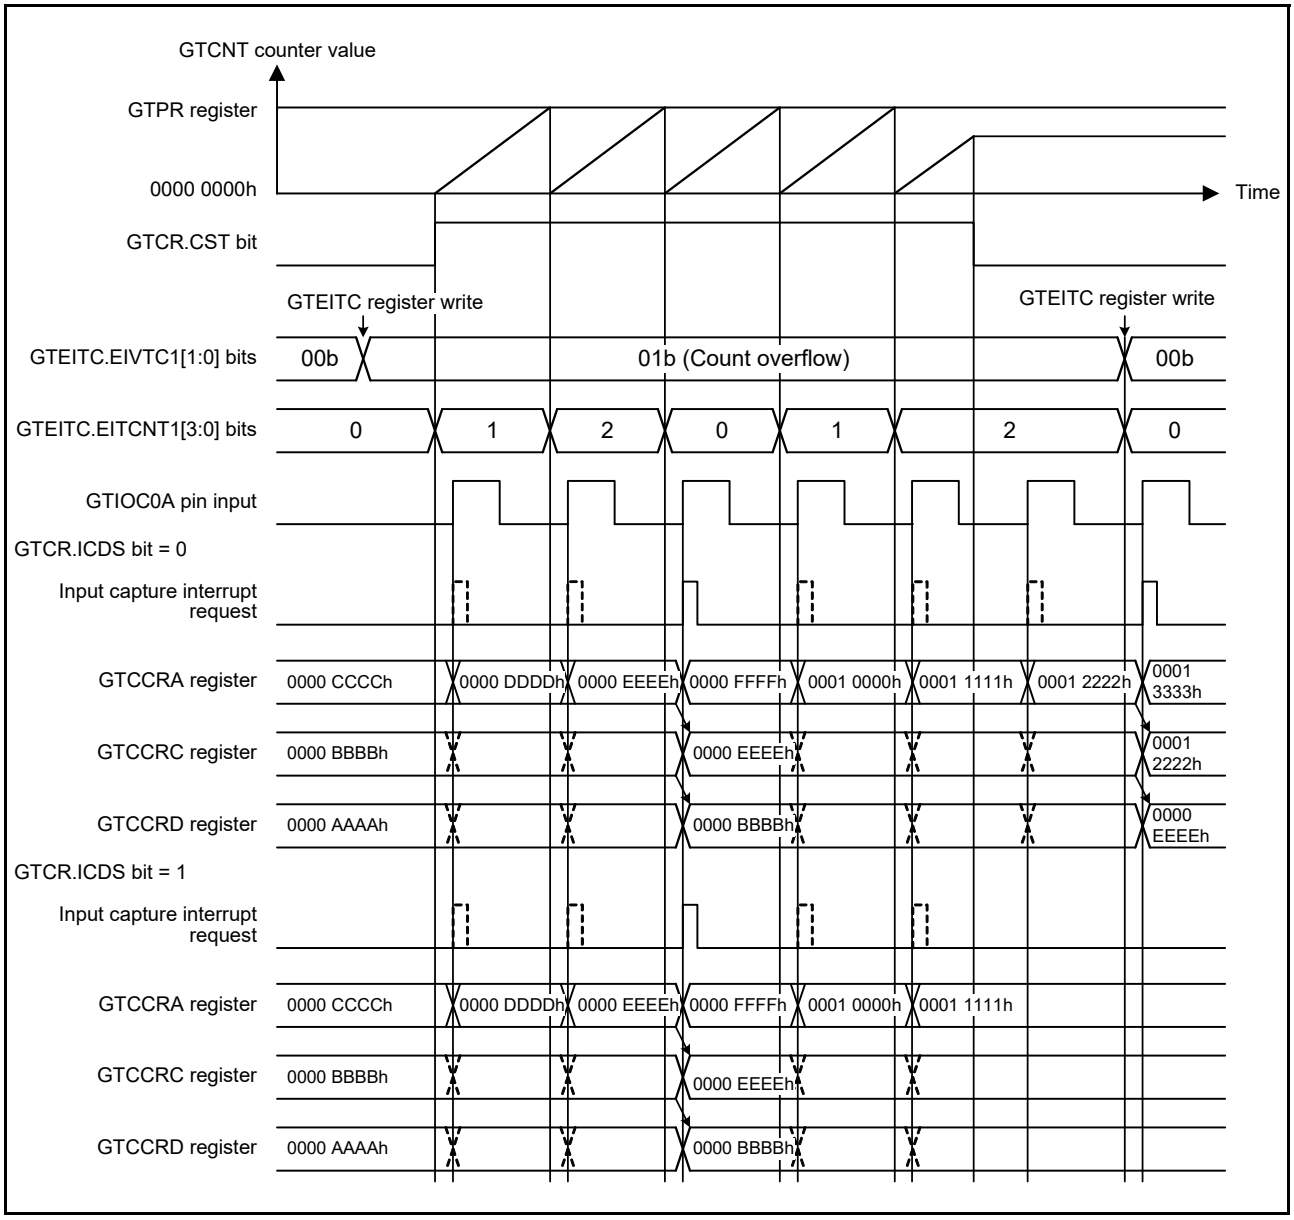

Figure 24.184 Example of Input Capture Operation in the Extended Interrupt Skipping Function Operation (Up-Counting Sawtooth Waves, Counting Overflow, Extended Interrupt Skipping 1 Skipping Count: 2, Skipped in the Period other than the EITCNT1 as 0, Input Capture at the Input Rising)

Figure 24.185 shows an example for setting the extended interrupt skipping.

The extended interrupt skipping counter 2 initial value is set by the written value to the ETICNT2IV[3:0] bits which is applied to change the setting from not counting the extended interrupt skipping counter 2 count source (GTEITC.EIVTC2[1:0] bits = 00b) to counting (EIVTC2[1:0] bits = other than 00b). Writing to the extended interrupt skipping counter 2 initial value bit (ETICNT2IV[3:0] bits) is performed only when the setting of the above mentioned extended interrupt skipping counter 2 initial value is written.

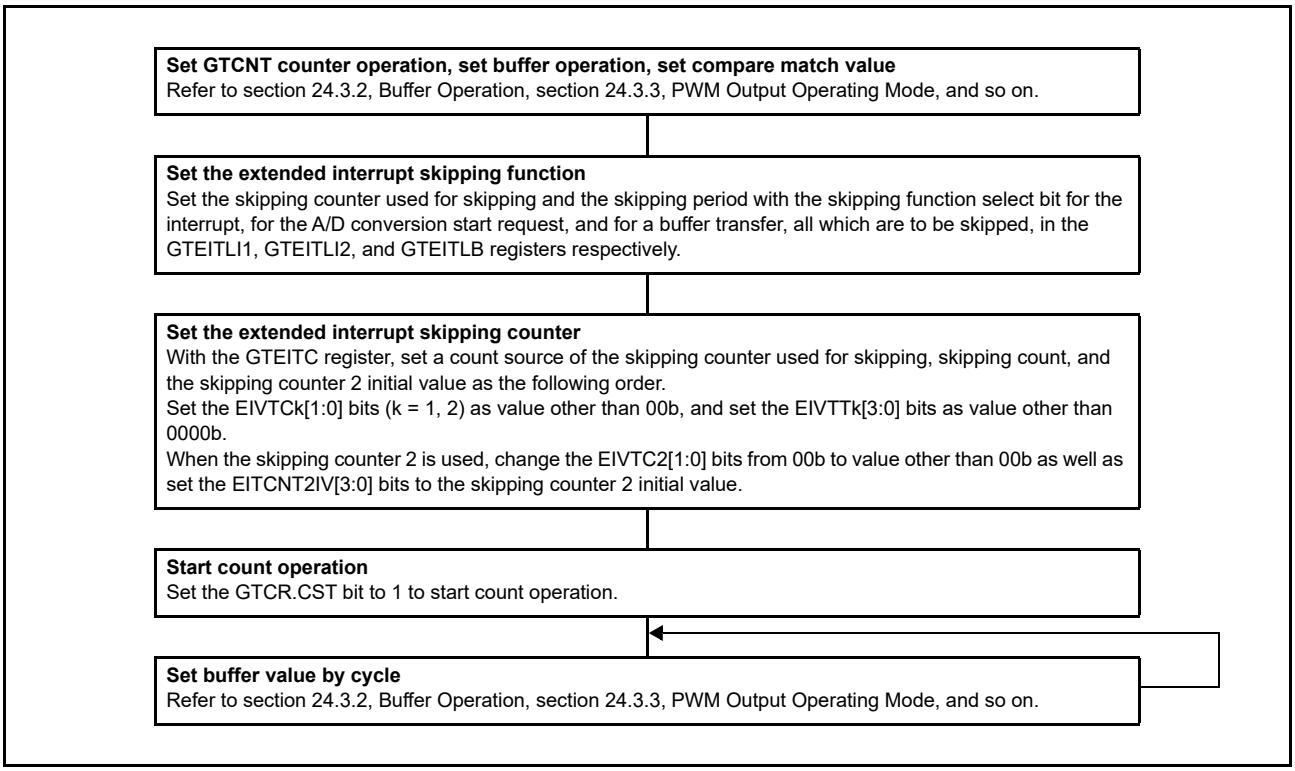

Figure 24.185 Example for Setting the Extended Interrupt Skipping

24.4.3.3 A/D conversion Start Request Compare Match Skipping Function

The A/D conversion start request and GTADTR register buffer transfer can be skipped by counting the compare matches of GTADTRA register and GTADTRB register based on settings of the GTADCMSC register and GTADCMSS register. The skipping period is set, related to the operation of the two independent A/D conversion start request compare match skipping counters (ADCMSCNT1[3:0] and ADCMSCNT2[3:0] bits in the GTADCMSC register), as a period that either of the counter value for such skipping counters is other than 0 or other than the skipping count. The skipping period can also be set as a period that the both skipping counters are set as other than 0 or other than the skipping count for the counter value.

Figure 24.186 shows the counter operation for A/D conversion start request compare match skipping.

The counter operation for A/D conversion start request compare match skipping is set by the GTADCMSC register.

The ADCMSCNT1[3:0] bits count the count source (in Figure 24.186, a crest is selected) selected by the A/D conversion start request compare match skipping counter 1 count source select bit (GTADCMSC.ADCMSC1[1:0] bits), and repeat the count operation which returns to 0 when the skipping count (in Figure 24.186, count is 2) set by the A/D conversion start request compare match skipping 1 skipping count setting bit (ADCMST1[3:0] bits) is achieved.

The ADCMSCNT2[3:0] bits count the count source (in Figure 24.186, a trough is selected) selected by the A/D conversion start request compare match skipping counter 2 count source select bit (GTADCMSC.ADCMSC2[1:0] bits), and repeat the count operation which returns to 0 when the skipping count (in Figure 24.186, count is 2) set by the A/D conversion start request compare match skipping 2 skipping count setting bit (ADCMST2[3:0] bits) is achieved.

The ADCMSCNTk[3:0] bits (k = 1, 2) can be set for the initial value. The initial value is set when the GTADCMSC register is written by the access of 16 bits or 32 bits while the setting for the A/D conversion start request compare match skipping counter k is not counted (ADCMSCk[1:0] bits are 00b) and the write value to the ADCMSCk[1:0] bits is other than 00b.

When the initial value is set, the write value to the A/D conversion start request compare match skipping counter k initial value bits (ADCMSCNTkIV[3:0] bits) are set as the initial value for the ADCMSCNT2[3:0] bits.

The A/D conversion start request compare match skipping counter starts up-counting at the first count clock after the setting is modified from not counting to counting.

The ADCMSCNT1[3:0] and ADCMSCNT2[3:0] bits for the A/D conversion start request compare match skipping function retain the value even after the GTCNT counter operation is stopped, and the counting can be resumed from the value before the counter is stopped.

When values for the ADCMSCNT1[3:0] and ADCMSCNT2[3:0] bits are to be reset (0000b), set the ADCMSC1[1:0] and ADCMSC2[1:0] bits to the setting for not counting (not skipping) (00b).

When the skipping count is to be changed, change the count after stopping the skipping counter operation (set either of the ADCMSC1[1:0] bit or the ADCMSC2[1:0] bit to 00b).

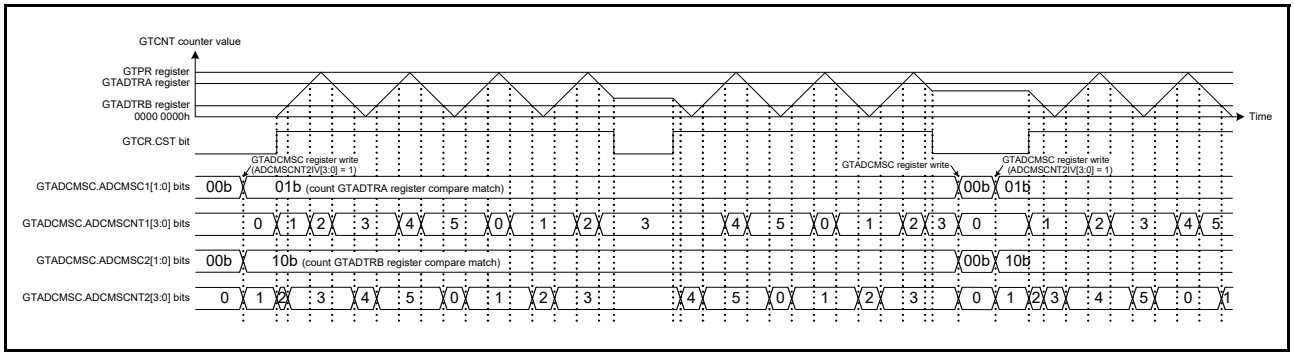

Figure 24.186 Example of A/D Conversion Start Request Compare Match Skipping Function Operation

A/D conversion start request skipping by the ADCMSC register can be performed simultaneously with skipping by the GTITC register or GTEITC register. A skipping period in this case is represented by OR-ed skipping periods of respective registers.

Figure 24.187 shows corresponding interrupt skipping operations and A/D conversion start request skipping operation are performed simultaneously.

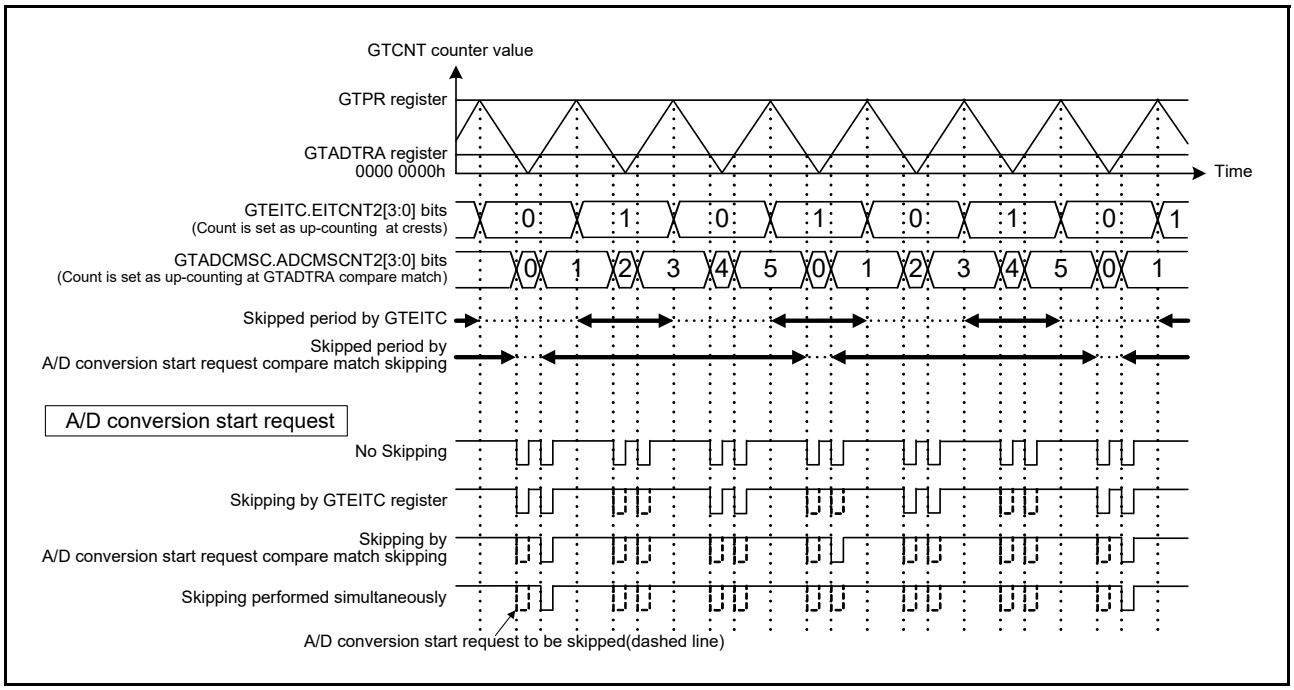

Figure 24.187 Example of A/D Conversion Start Request Compare Match Skipping Function Operation (Extended Interrupt Skipping: EIVTC2[1:0] = 01b, EADTAL[2:0] = 010b, A/D Conversion Start Request Compare Match Skipping: ADCMSC2[1:0] = 01b, ADCMSAL[2:0] = 010b)

When A/D conversion start request skipping which can be set by the GTADCMSS register is performed, updating of status flag and the ELC event output depend on the A/D conversion start request enable bit in the GTINTAD register. All the operations by A/D conversion start request which are set as disable by the GTINTAD register is not performed.
A buffer transfer skipping by the GTADCMSS register is performed in all of buffer operation which is enabled in the GTBER and GTBER2 register, or all buffer operations performed by sawtooth-wave one-shot pulse mode or triangle-wave PWM mode 3 or complementary PWM mode (excludes buffer transfer from GTCCRC, GTCCRE to GTCCRA).
An A/D conversion start request skipping and a buffer transfer skipping are operated individually.
Figure 24.188 and Figure 24.189 show examples of extended skipping function operation.

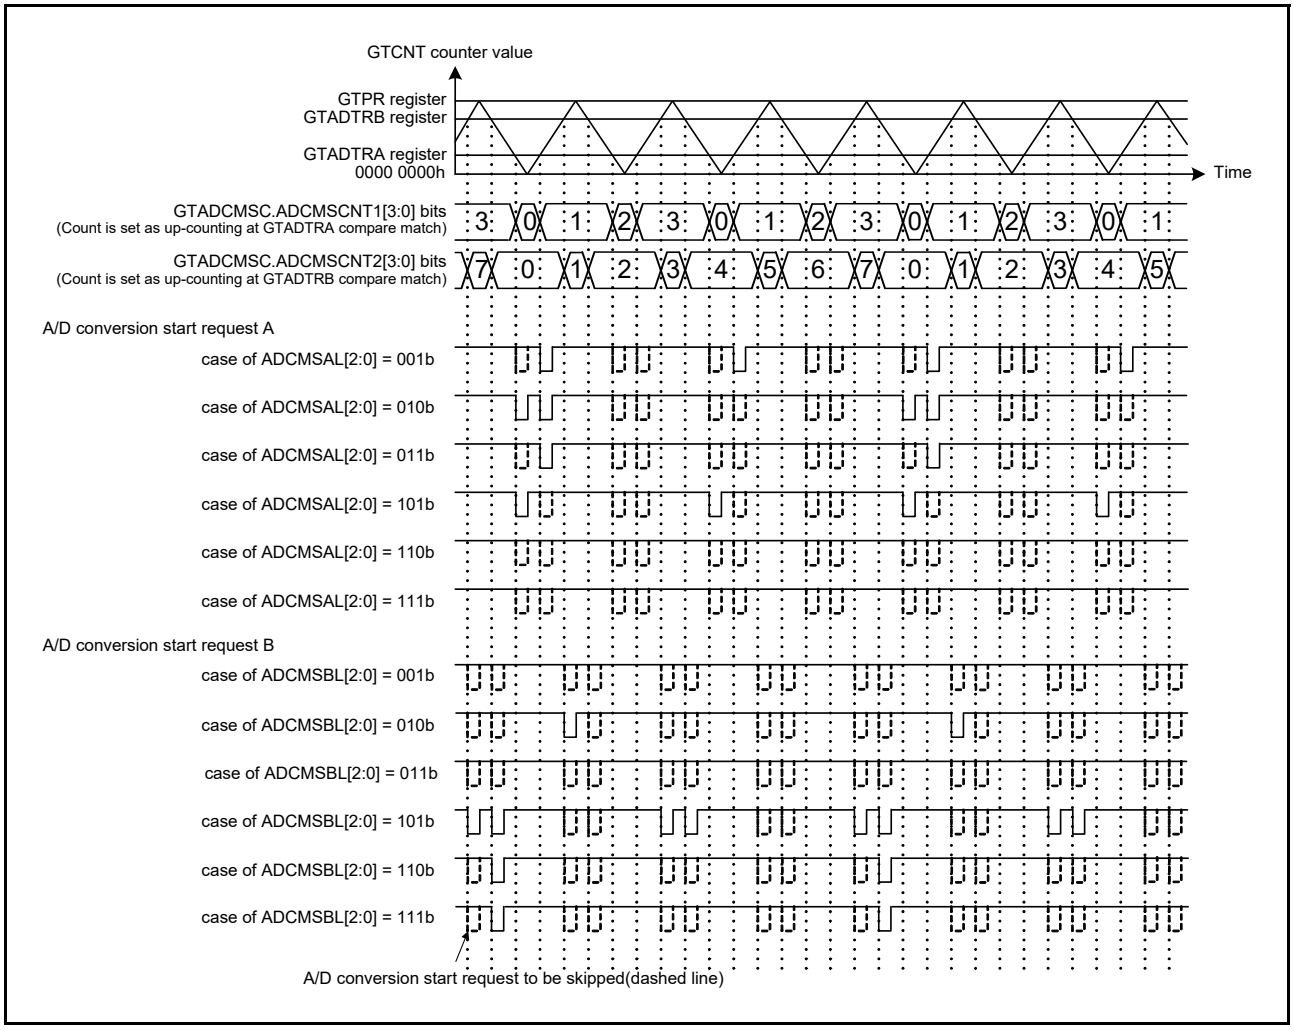

Figure 24.188 Example of A/D Conversion Start Request Compare Match Skipping Function Operation (Triangle wave, A/D Conversion Start Request Compare Match Skipping 1 Skipping Count: 3 Counting GTADTRA compare match, A/D Conversion Start Request Compare Match Skipping 2 Skipping Count: 7 Counting GTADTRB compare match)

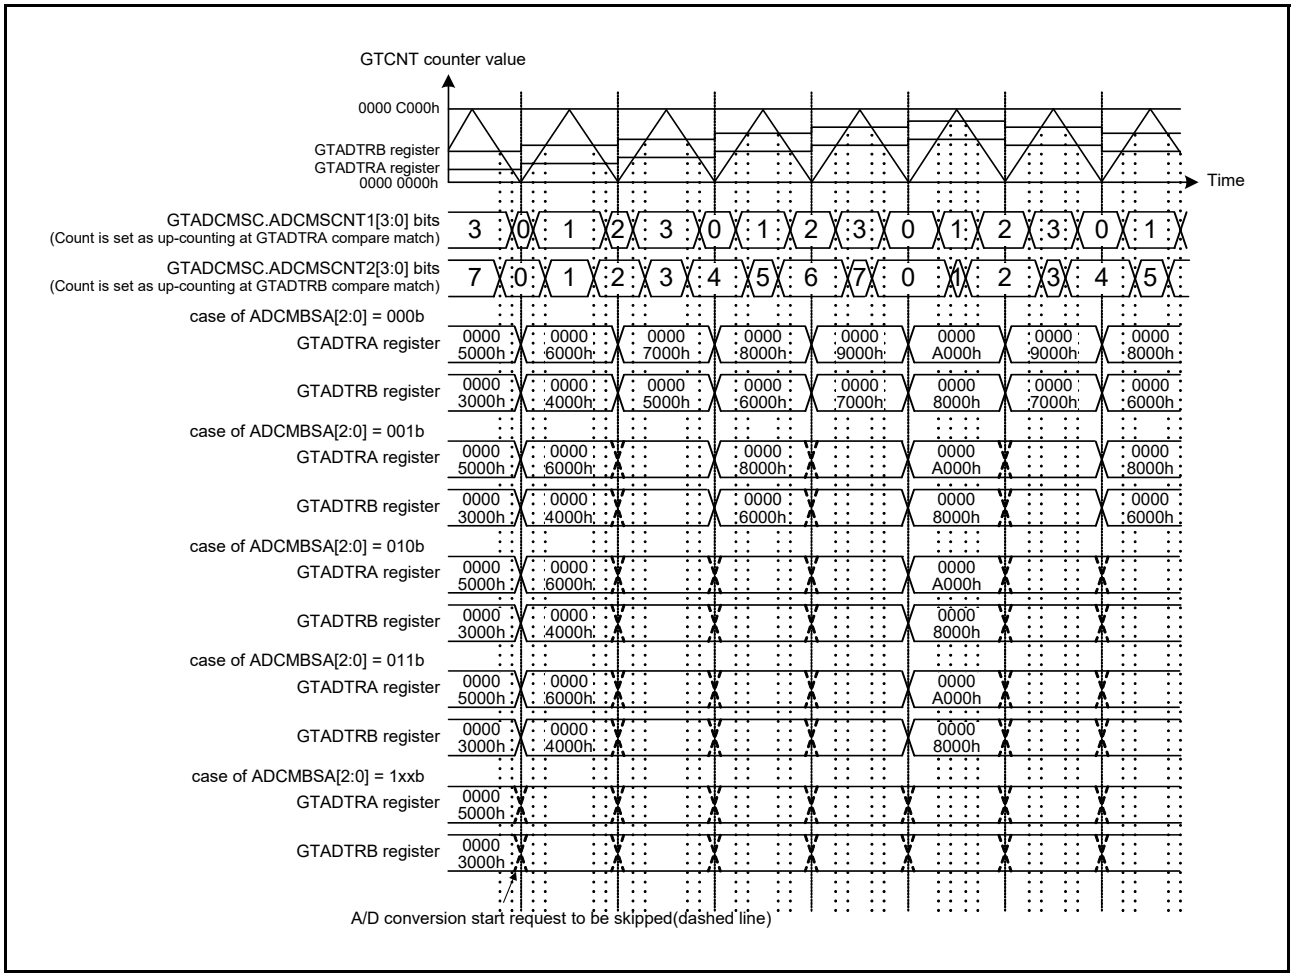

Figure 24.189 Example of A/D Conversion Start Request Compare Match Skipping Function Operation (Triangle wave, A/D Conversion Start Request Compare Match Skipping 1 Skipping Count: 3 Counting GTADTRA compare match, A/D Conversion Start Request Compare Match Skipping 2 Skipping Count: 7 Counting GTADTRB compare match, Buffer transfer of GTADTRA and GTADTRB at trough)

Figure 24.190 shows an example of setting the A/D conversion start request compare match skipping.
The A/D conversion start request compare match skipping counter 2 initial value is set by the written value to the ADCMSCNT2IV[3:0] bits which is applied to change the setting from not counting the extended interrupt skipping counter 2 count source (GTADCMSC.ADCMSC2[1:0] bits = 00b) to counting (ADCMSC2[1:0] bits = other than 00b). Writing to the A/D conversion start request compare match skipping counter 2 initial value bit (ADCMSCNT2IV[3:0] bits) is performed only when the setting of the above mentioned A/D conversion start request compare match skipping counter 2 initial value is written.

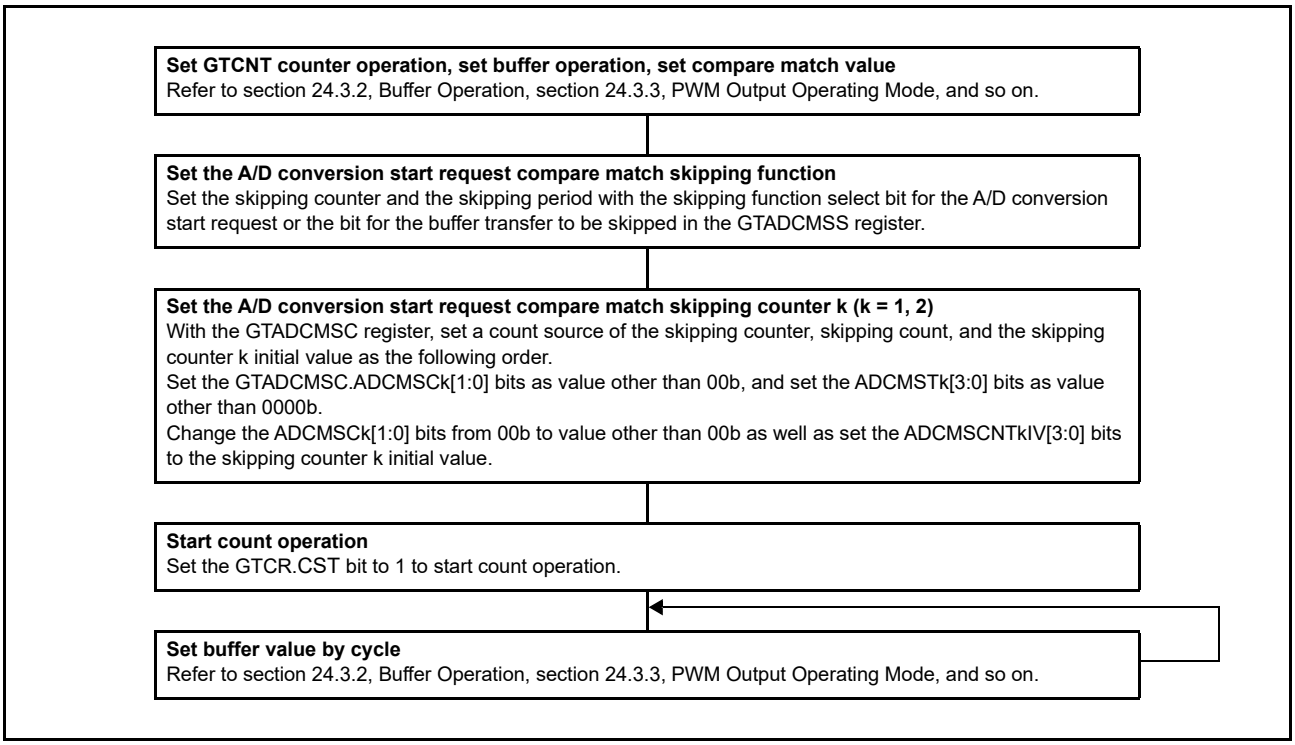

Figure 24.190 Example for Setting the A/D Conversion Start Request Compare Match Skipping

24.5 A/D Conversion Start Request

An A/D conversion start request can be issued at a compare match between the GTCNT counter and the GTADTRA or GTADTRB register, up-counting only, down-counting only, or both up-counting and down-counting can be specified by setting the GTINTAD register.

In complementary PWM mode, the A/D conversion start request can be issued at a compare match with the GTCNT counter of master channel.

During event count operation, the A/D conversion start request cannot be generated.

The A/D conversion start request is not directly output to the A/D converter, but an interrupt, and an event signal to the ELC are output.

The GTADTRA and GTADTRB registers each has two buffer registers. Buffer operation with the GTADTRA register used together with the GTADTBRA and GTADTDBRA registers, and buffer operation with the GTADTRB register used together with the GTADTBRB and GTADTDBRB registers can be performed.

The timing of the generation of requests to start A/D conversion can be monitored by an external pin. When the A/D conversion start request signal to be monitored is selected in the GTADSMR.ADSMSk bit (k = 0, 1) and when the output is enabled in the ADSMENk bit, a signal is output synchronized with a cycle frame of the timer used to generate the A/D conversion start request signal, of which the output is driven high at the generation of the A/D conversion start request signal by the GTADSMk pin, or at the end of the cycle of which the output is driven low. When a signal to request the start of A/D conversion is generated at the end of the cycle, the generation of this signal has priority in terms of monitoring output and the output remains at the high level till the end of the next cycle. The registers (GTADTRA and GTADTRB) that are sources of generating the A/D conversion start request signals and their counting directions can be checked by the A/D conversion start request flags (ADTRAUF, ADTRADF, ADTRBUF, and ADTRBDF) in the GTST register. When the output of the same A/D conversion start request signal monitoring output is enabled for multiple channels, ORed signals will be output from the GPTW.

Figure 24.191 shows an example of A/D conversion start request operation, Figure 24.192 shows an example for setting A/D conversion start request operation, and Figure 24.193 shows an example for A/D conversion start request timing operation.

Figure 24.193 shows an example of the output of A/D conversion start request A by the ELC as start source 0 for the A/D converter. The A/D conversion start request A signal is output by the ELC in response to a match in comparison with the GTADTRA register. The A/D conversion start request A signal is synchronized with PCLKC. The ELC receives the signal in synchronization with PCLKB, and then outputs the A/D conversion start source 0 signal after 1 cycle of the PCLKB has elapsed.

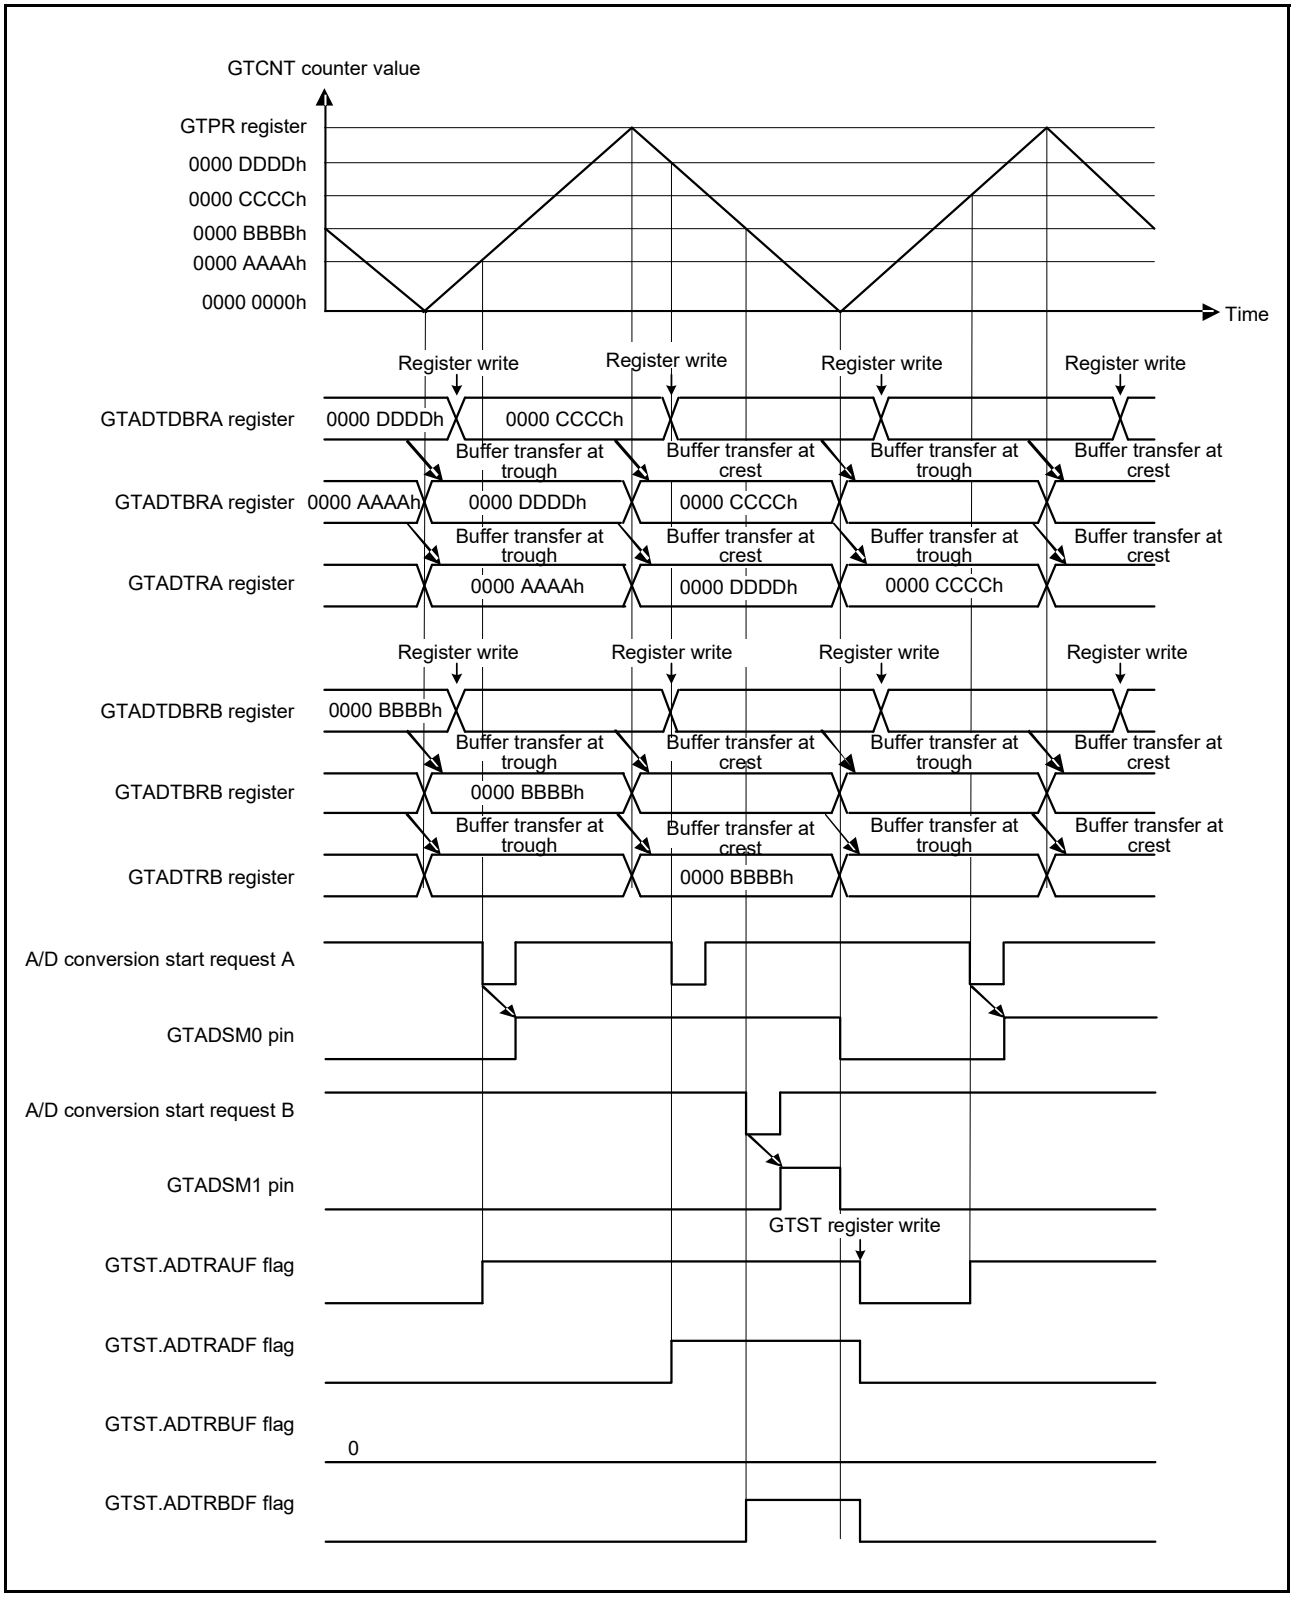

Figure 24.191 Example of A/D Conversion Start Request Timing Operation (Triangle Waves, Double Buffer Operation, Buffer Transfer at Both Troughs and Crests, A/D Conversion Start Requested by GTADTRA Register at Both Up-Counting and Down-Counting, A/D Conversion Start Requested by GTADTRB Register at Down-Counting, Monitoring of the GTADTRA Register Up-Counting by the GTADSM0 Pin, Monitoring of the GTADTRB Register Down-Counting by the GTADSM1 Pin)

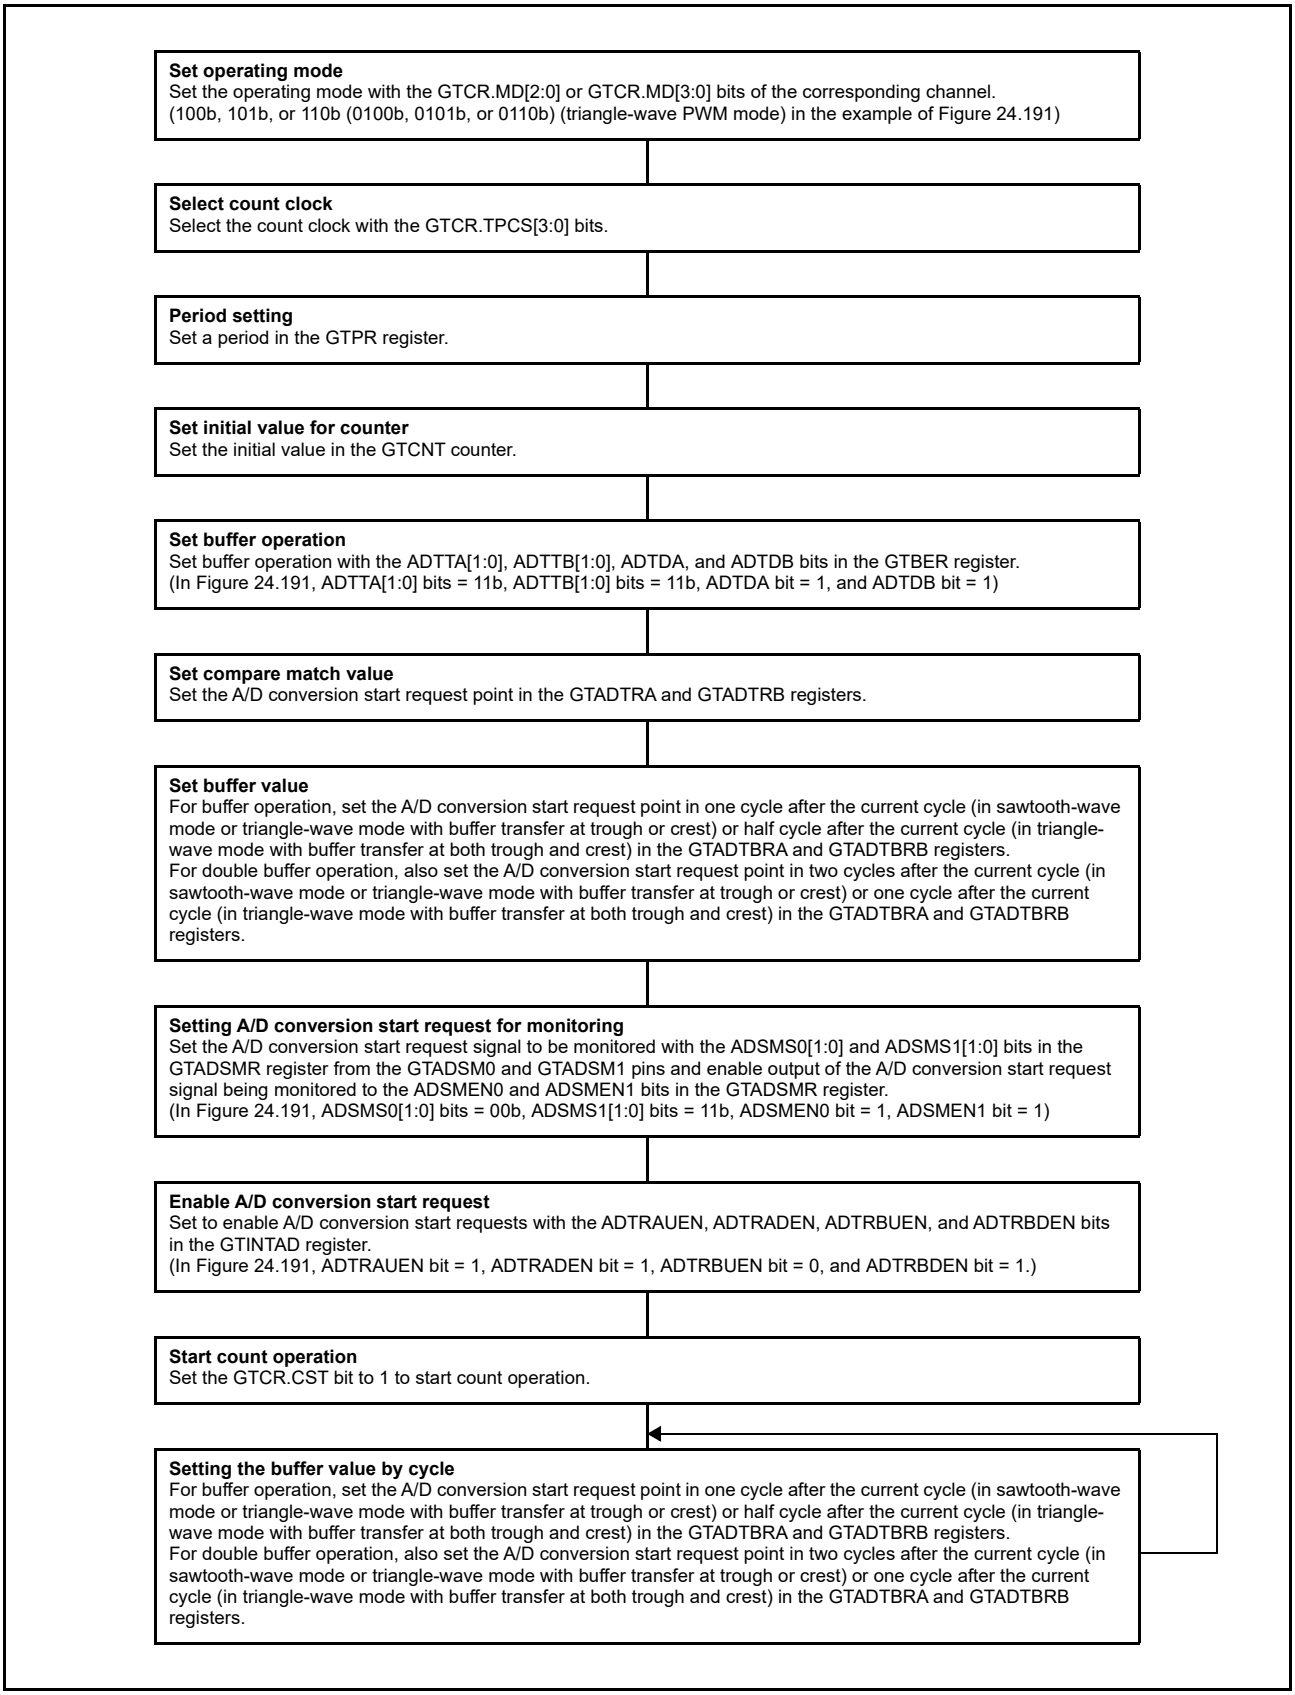

Figure 24.192 Example for Setting A/D Conversion Start Request Operation

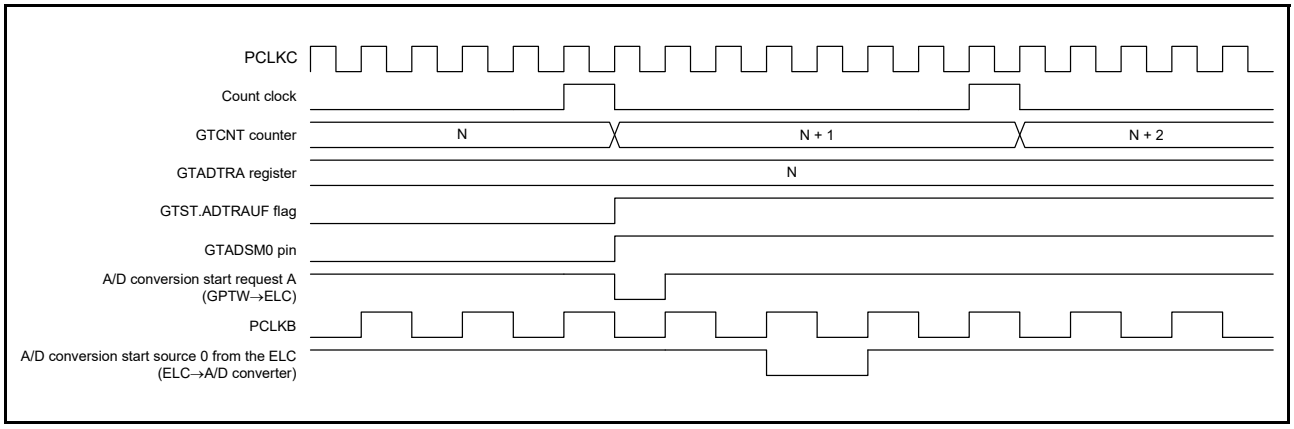

Figure 24.193 Example of A/D Conversion Start Request Timing Operation

24.6 Operations Linked by the ELC

24.6.1 Event Signal Output to the ELC

GPTW is capable of operation linked with another module set in advance when its interrupt request signal is used as an event signal by the event link controller (ELC).
The event signal can be output regardless of the setting of the corresponding interrupt request enable bits except the A/D conversion start request.
The A/D conversion start request during up-counting/down-counting can be enabled/disabled individually with the A/D conversion start request enable bit to output to the ELC.
The following is a list of the event signals output by the GPTW to the ELC. Each GPTW channel has the first 10 event signals. The last of the listed event signals is common to all channels. A dead time error interrupt does not have a corresponding event signal.

- Generation of compare match A interrupt
- Generation of compare match B interrupt
- Generation of compare match C interrupt
- Generation of compare match D interrupt
- Generation of compare match E interrupt
- Generation of compare match F interrupt
- Generation of overflow interrupt
- Generation of underflow interrupt
- Generation of A/D conversion start request A
- Generation of A/D conversion start request B
- GPTW (OPS) U-/V-/W-phase input edge detected

24.6.2 GPTW Operations in Response to Receiving Event Signals from the ELC

The GPTW can perform the following operations by the signals for sources A to H which are output from the ELC. Each signal is provided to all channels. Select an event source for a desired operation by a relevant source select register in a channel.

- Operation of count start/count stop/counter clearing
- Operation of up-counting/down-counting
- Operation of input capture A and B

Refer to operation by hardware sources in section 24.3.1.1, Counter Operation for respective operations.

24.7 Noise Filter Function

Each pin for use in input capture to the GPTW is equipped with a noise filter. The noise filter samples input signals at the sampling clock and removes the pulses of which length is less than three sampling periods.
The noise filter functionality includes enabling and disabling of the noise filter for each pin and setting of the sampling clock for each channel.
Figure 24.194 shows the timing of noise filtering.

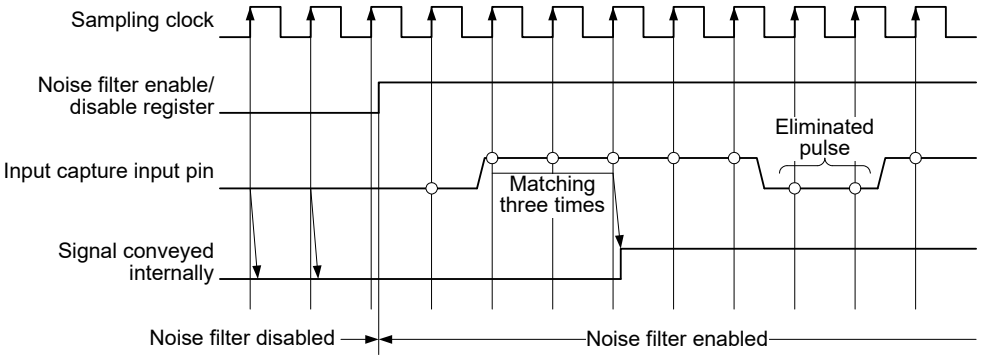

Figure 24.194 Timing of Noise Filtering

If noise filtering is enabled, input capture operation is performed on the edges of noise-filtered signal after a delay of (minimum sampling interval × 2 + PCLKC) due to noise filtering for the input capture input.

24.8 Protection Function

24.8.1 Write-Protection for Registers

In order to avoid incorrect writing to registers, write access to registers can be enabled or disabled per channel by setting the GTWP.WP bit for the given channel.
The WP bits enable or disable writing to the registered are listed below.
GTSSR, GTPSR, GTCSR, GTUPSR, GTDNSR, GTICASR, GTICBSR, GTCR, GTUDDTYC, GTIOR, GTINTAD, GTST, GTBER, GTITC, GTCNT, GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, GTCCRF, GTPR, GTPBR, GTPDBR, GTADTRA, GTADTBRA, GTADTDBRA, GTADTRB, GTADTBRB, GTADTDBRB, GTDTCR, GTDVU, GTDVD, GTDBU, GTDBD, GTSOS, GTSOTR, GTADSMR, GTEITC, GTEITLI1, GTEITLI2, GTEITLB, GTICLF, GTPC, GTADCMSC, GTADCMSS, GTBER2, GTOLBR, GTICCR
Every bit in registers GTSTR, GTSTP, and GTCLR, which can update the corresponding registers in other channels and can be updated by any of the corresponding registers in other channels conversely, can be protected by setting the GTWP.STRWP, STPWP, and CLRWP bits, respectively, per channel.
Likewise, writing to the GTSECSR and GTSECR registers, which can control all channels by writing to the GTSECSR and GTSECR registers of a given channel, can by enabled or disabled by the setting of the GTWP.CMNWP bit.
Protection by the GTWP register only targets writing operation by the CPU. Updating the register generated in related to the CPU writing is not protected.

24.8.2 Disabling of Buffer Operation

If the timing of buffer register write is too late for the buffer transfer timing, buffer operation can be suspended with setting the BD[0], BD[1], BD[2], and BD[3] bits in the GTBER resister.
Specifically, buffer transfer can be temporarily disabled, even though a buffer transfer condition is generated during buffer register write, by setting the BD[0], BD[1], BD[2], and BD[3] bits to 1 (buffer operation disabled) before buffer register write, and setting the bits to 0 (buffer operation enabled) after completion of writing to all the buffer registers.
The BD[0], BD[1], BD[2], and BD[3] bits can be set on channel basis by writing directly to the GTBER register or can be set simultaneously by setting the GTSECR register for multiple channels which were set by the GTSECSR register.
Figure 24.195 shows an example of operation for disabling buffer operation.

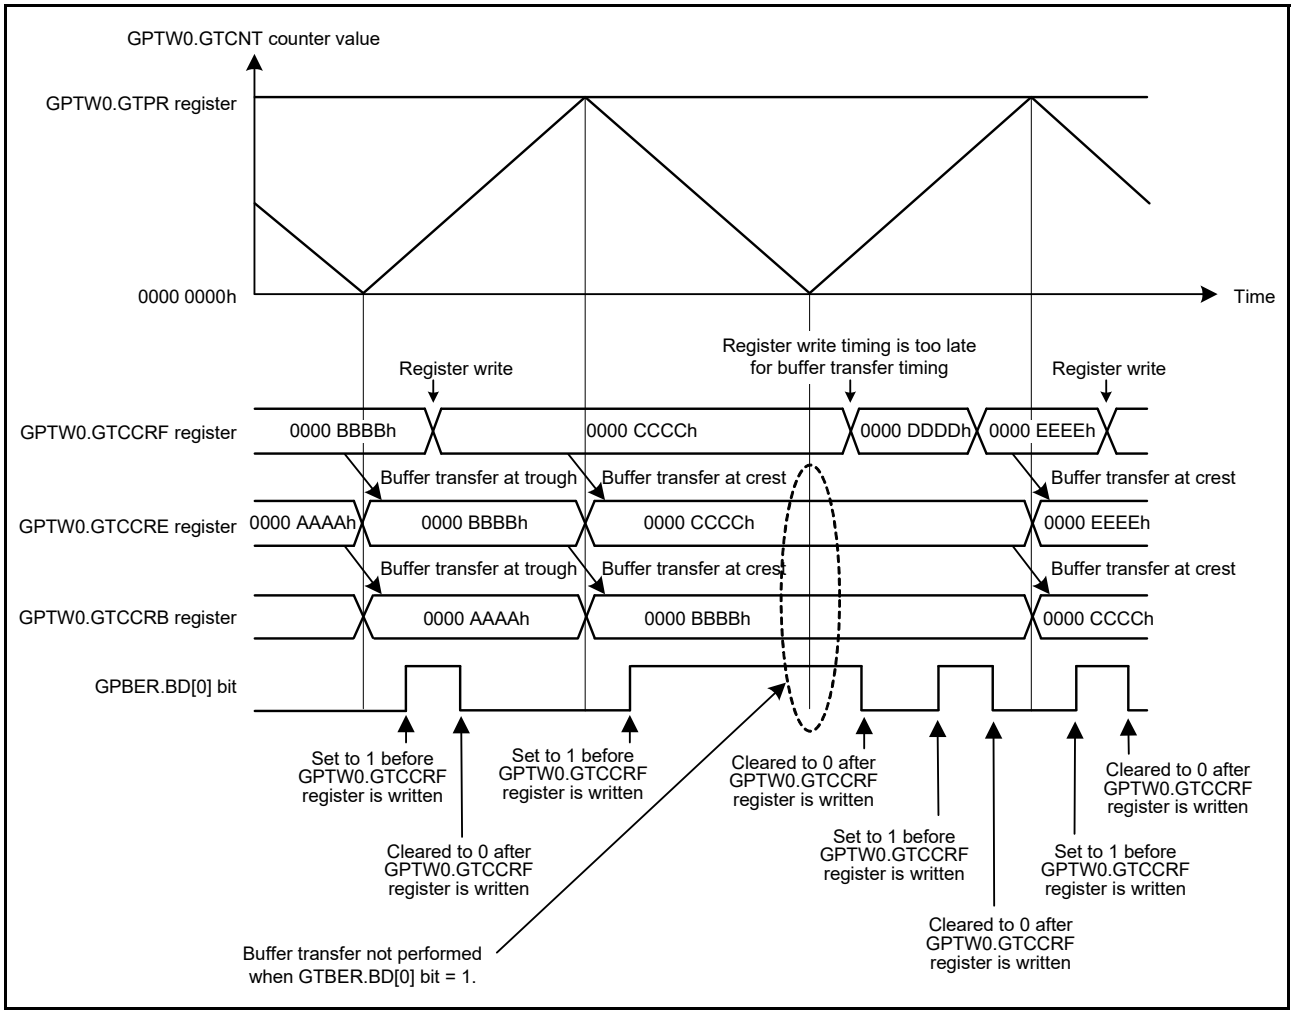

Figure 24.195 Example of Operation for Disabling Buffer Operation (Triangle Waves, Double Buffer Operation, Buffer Transfer at Both Troughs and Crests)

24.8.2.1 Simultaneous Control of Buffer Operations of Multiple Channels

The GTBER.BD bit can be set by writing directly to the GTBER register per channel or by making settings in the GTSECR register for multiple channels that have already set in the GTSECSR register.
Follow the procedure below to simultaneously set the GTBER.BD bits of multiple channels.

(1) Select the channels for simultaneously setting of the GTSECSR register

Set the GTSECSR register so that the values at the bit positions for the corresponding channels for simultaneously setting of the GTBER.BD bits become 1. All GTSECSR registers can be updated by writing to the GTSECSR register of any channel.

(2) Simultaneously set the GTBER.BD bits by updating the GTSECR register

In the GTSECR register, set the operation of the GTBER.BD bits (enabling or disabling of buffer operation) which are to be simultaneously set. Writing to a GTSECR register from any channel updates the GTBER.BD bits in all channels corresponding to the bits set as 1 in the GTSECSR register, in accordance with the value of the GTSECR register. Figure 24.196 and Figure 24.197 show examples of simultaneously controlling the enabling or disabling of buffer operation for multiple channels.

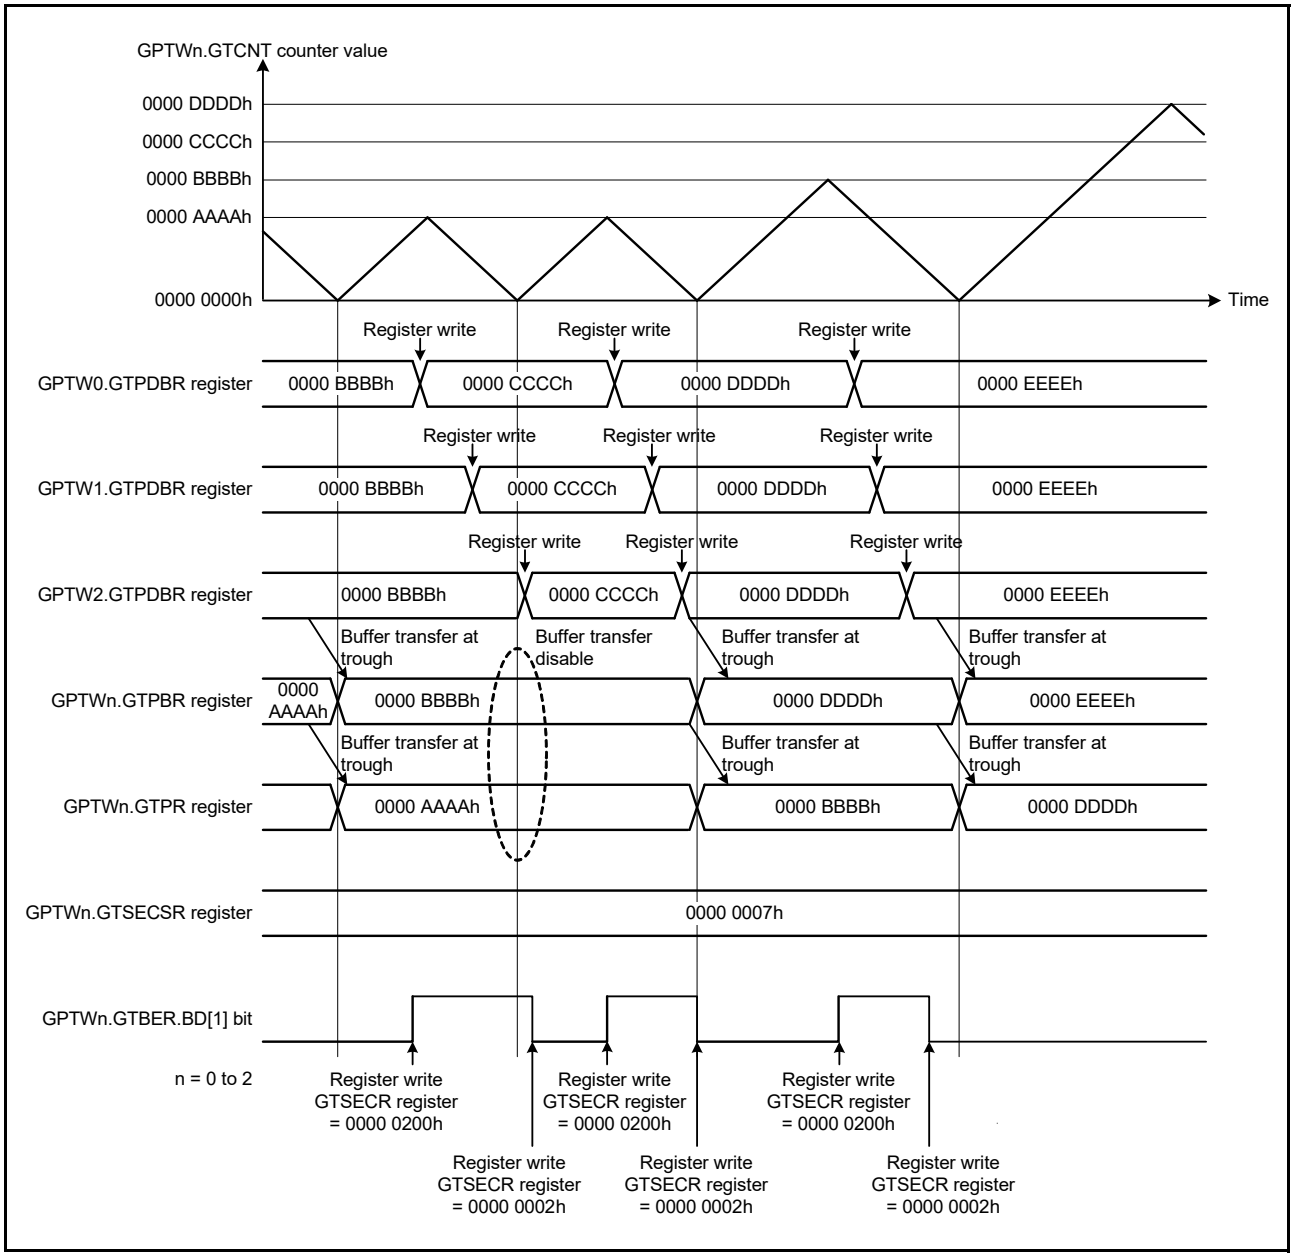

Figure 24.196 Example of Multiple Channel Operation for Disabling Buffer Operation (Triangle Waves, Double Buffer Operation)

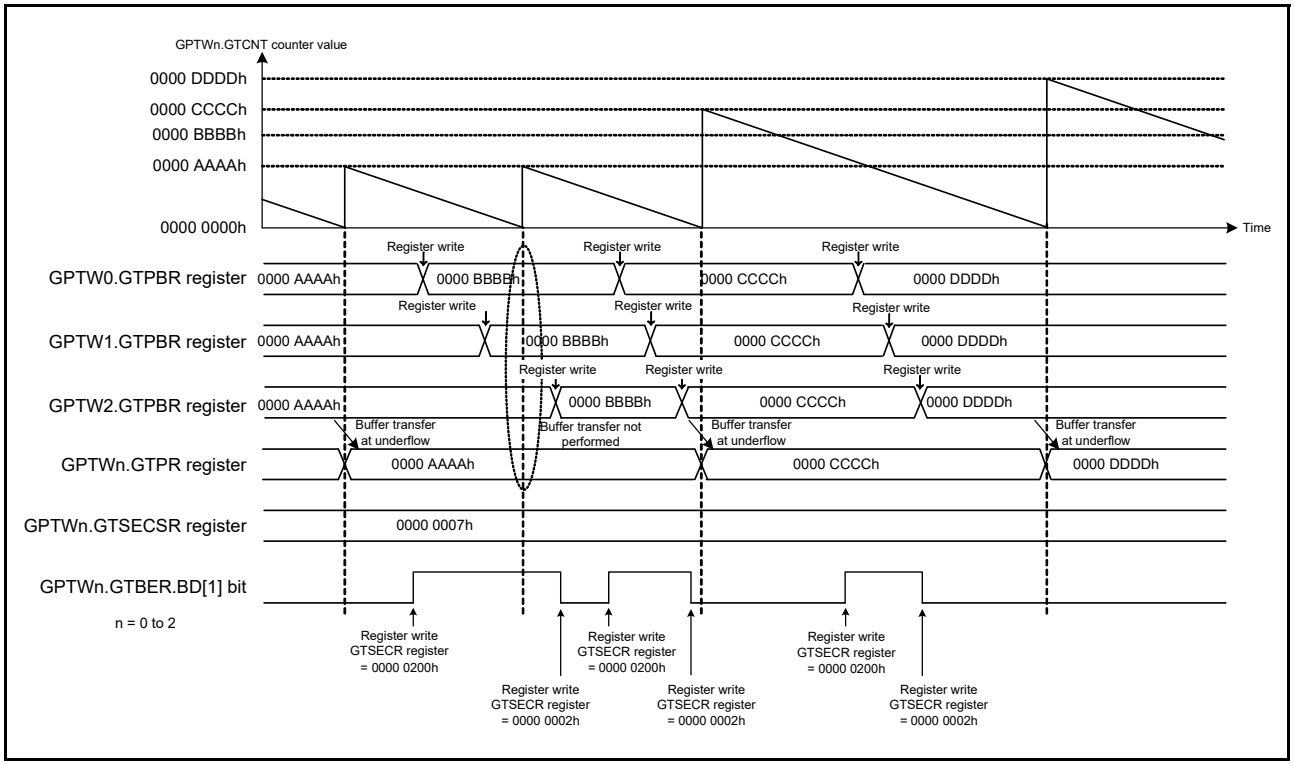

Figure 24.197 Example of Multiple Channel Operation for Disabling Buffer Operation (Sawtooth Waves, Single Buffer Operation)

24.8.2.2 Repeated Double-Buffered Operation When Disabling GTCCR Buffer Transfer

When a GTBER.DBRTECm (m = A, B) bit is set to 1 in sawtooth-wave one-shot pulse mode or triangle-wave PWM mode 3, transfer from the intermediate buffer to the GTCCRm (m = A, B) register is repeated on a cyclic basis even while buffer transfer is disabled by the setting of the GTBER.BD[0] bit or by the buffer transfer extended skipping function.

(1) In sawtooth-wave one-shot pulse mode

In sawtooth-wave one-shot pulse mode, the compare match value for the first half of a waveform is stored in temporary register x (x = C, E) as the intermediate buffer for the GTCCRx (x = C, E) register and the compare match value for the second half of a waveform is stored in temporary register m (m = A, B) as the intermediate buffer for the GTCCRy (y = D, F) register, respectively, for compare match values during repeated buffer operation, and the given values are alternately transferred to the GTCCRm (m = A, B) registers.

Table 24.41 lists the types of buffer transfer of the GTCCR register during counting in sawtooth-wave one-shot pulse mode. While counting is stopped, the setting of the value in the temporary register is transferred through forcible buffer transfer.

In forcible buffer transfer, the values of the GTCCRy (y = D, F) registers are transferred to temporary registers m (m = A, B), and the values of the GTCCRx (x = C, E) are transferred to temporary registers x (x = C, E), when the setting of the corresponding GTBER.DBRTECm (m = A, B) bit is 1, respectively.

When the setting of the GTBER.DBRTECm (m = A, B) bit is 1, values written by the CPU to the GTCCRm (m = A, B) registers are reflected as the values of temporary registers x (x = C, E).

Table 24.41 GTCCR Buffer Operation in Sawtooth-Wave One-Shot Pulse Mode

		Timing of transfer				
GTBER.DBRTECm	**Buffer transfer**	**GTCCRx ↓ GTCCRm**	**GTCCRx ↓ Temporary register x**	**Temporary register x ↓ GTCCRm**	**GTCCRy ↓ Temporary register m**	**Temporary register m ↓ GTCCRm**
0	Transfer-enabled period	Overflow or underflow	No transfer	No transfer	Overflow or underflow	GTCCRm compare match
	Transfer-disabled period	No transfer	No transfer	No transfer	No transfer	No transfer
1	Transfer-enabled period	Overflow or underflow	Overflow or underflow	No transfer	Overflow or underflow	GTCCRm compare match
	Transfer-disabled period	No transfer	No transfer	Overflow or underflow	No transfer	GTCCRm compare match

Figure 24.198 shows the operation of generating transfer-disabled period by extended buffer transfer skipping as an example of repeated double buffer operations when the GTCCR buffer transfer disabled in sawtooth-wave one-shot pulse mode.

Figure 24.199 shows the operation of generating transfer-disabled period by updating the GTBER.BD[0] bit as an example of repeated double-buffer operations when the GTCCR buffer transfer is disabled in sawtooth-wave one-shot pulse mode.

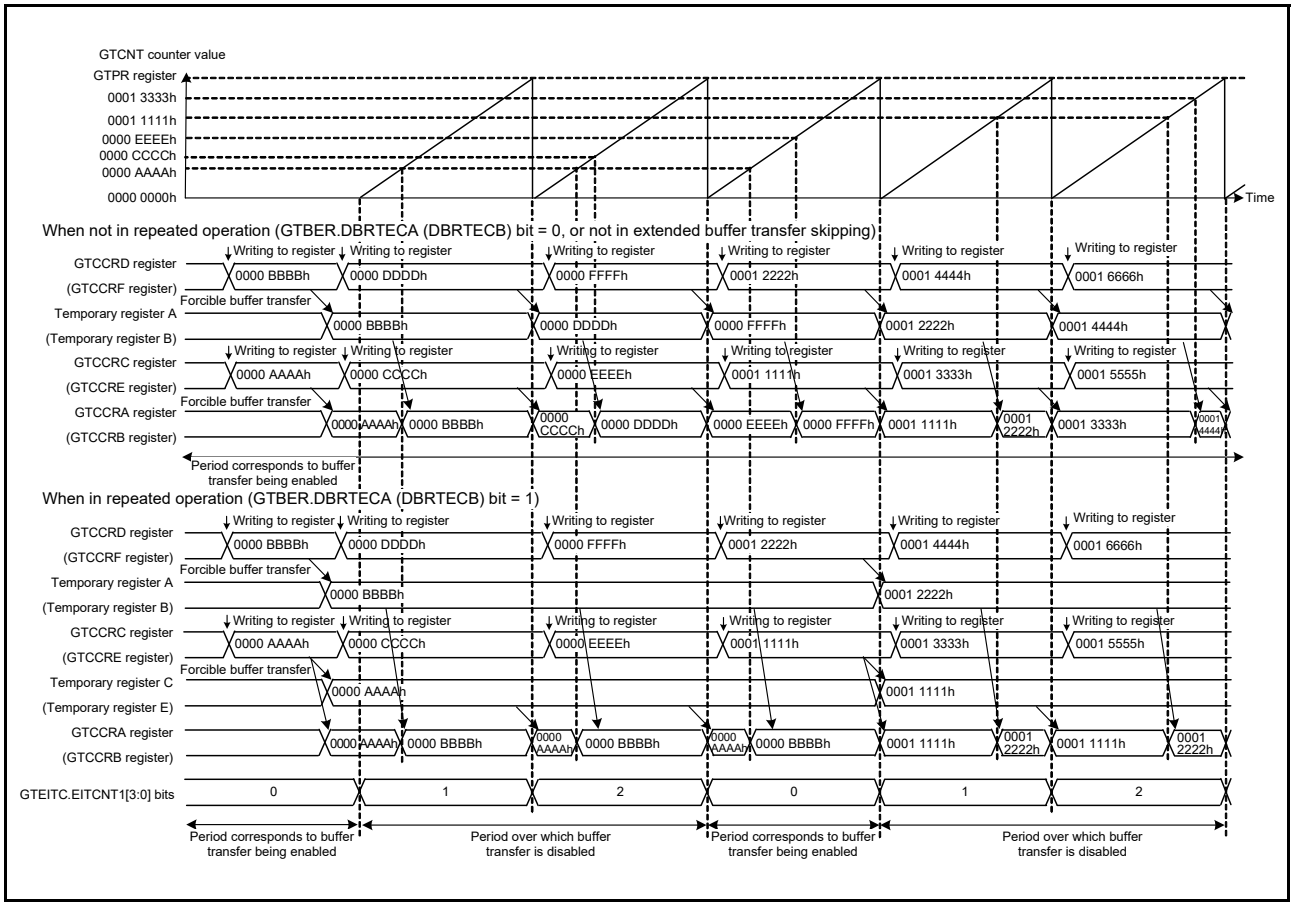

Figure 24.198 Example of Repeated Double-Buffer Operation When GTCCR Buffer Transfer is Disabled (Sawtooth-Wave One-Shot Pulse Mode, Using Extended Buffer Transfer Skipping, GTBER.BD[0] is Constantly 0)

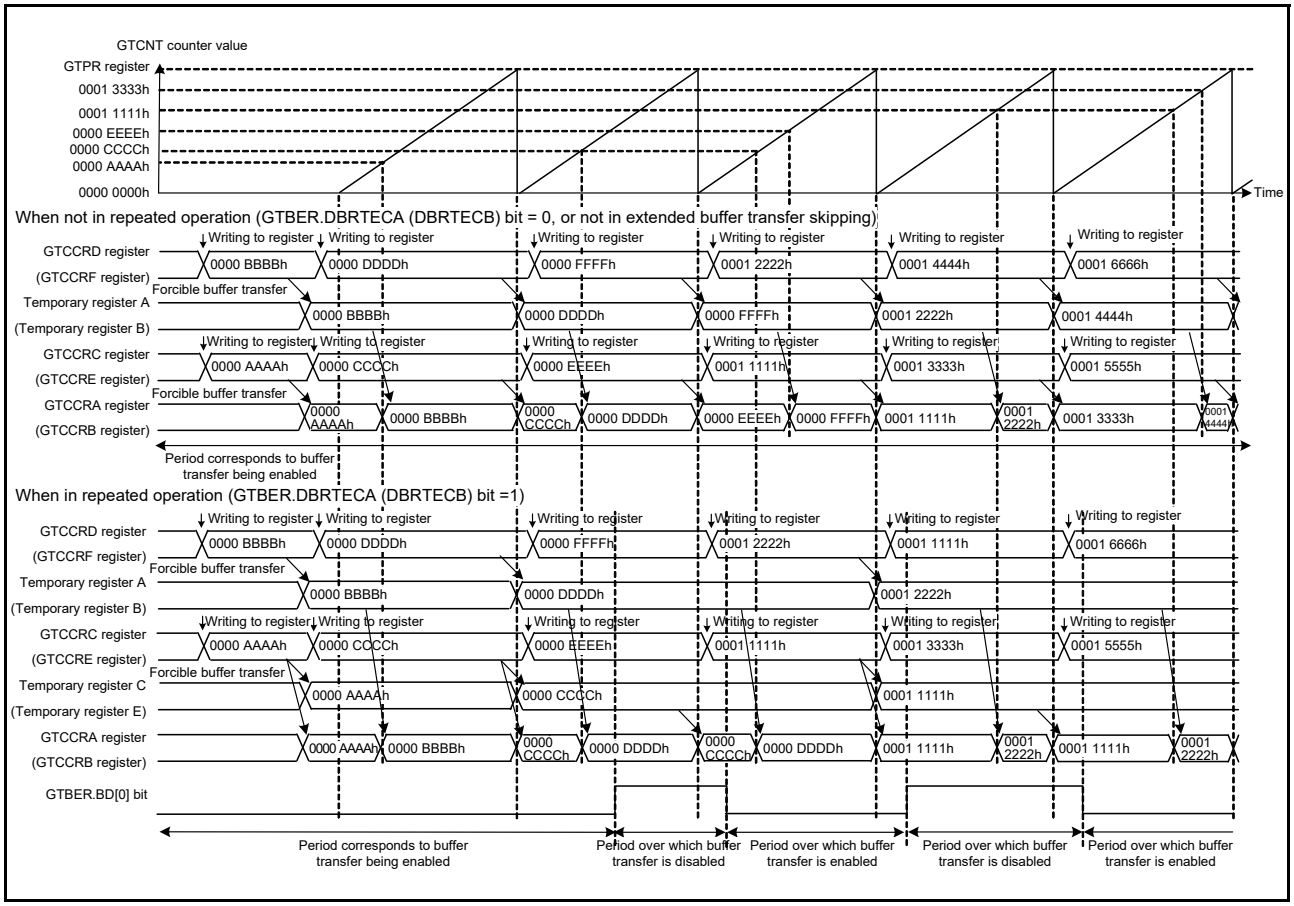

Figure 24.199 Example of Repeated Double-Buffer Operation When GTCCR Buffer Transfer is Disabled (Sawtooth-Wave One-Shot Pulse Mode, Updating the GTBER.BD[0] Bit)

(2) In triangle-wave PWM mode 3

In triangle-wave PWM mode 3, the compare match value for the first half of a waveform is stored in the temporary register x (x = C, E) as the intermediate buffer for the GTCCRx (x = C, E) register and the compare match value for the second half of a waveform is stored in temporary register m (m = A, B) as the intermediate buffer for the GTCCRy (y = D, F) register, respectively, for compare match values during repeated buffer operation, and the given values are alternately transferred to the GTCCRm (m = A, B) register.

Table 24.42 lists the types of buffer transfer of the GTCCR register during counting operation in triangle-wave PWM mode 3.

While counting is stopped, the setting of the value in the temporary register is transferred through forcible buffer transfer. In forcible buffer transfer, the values of the GTCCRy (y = D, F) registers are transferred to temporary registers m (m = A, B), and the values of the GTCCRx (x = C, E) are transferred to temporary registers x (x = C, E), when the setting of the corresponding GTBER.DBRTECm (m = A, B) bit is 1, respectively.

When the setting of the GTBER.DBRTECm (m = A, B) bit is set to 1, values written by the CPU to the GTCCRm (m = A, B) registers are reflected as the values of temporary registers x (x = C, E).

Table 24.42 GTCCR Buffer Operation in Triangle-Wave PWM Mode 3

		Timing of transfer				
GTBER.DBRTECm	**Buffer transfer**	**GTCCRx ↓ GTCCRm**	**GTCCRx ↓ Temporary register x**	**Temporary register x ↓ GTCCRm**	**GTCCRy ↓ Temporary register m**	**Temporary register m ↓ GTCCRm**
0	Transfer-enabled period	Trough	No transfer	No transfer	Trough	Crest
	Transfer-disabled period	No transfer	No transfer	No transfer	No transfer	No transfer
1	Transfer-enabled period	Trough	Trough	No transfer	Trough	Crest
	Transfer-disabled period	No transfer	No transfer	Trough	No transfer	Crest

Figure 24.200 shows the operation of generating transfer-disabled period by extended buffer transfer skipping as an example of repeated double buffer operations when the GTCCR buffer transfer disabled in triangle-wave PWM mode 3.

Figure 24.201 shows the operation of generating transfer-disabled period by updating the GTBER.BD[0] bit as an example of repeated double-buffer operations when the GTCCR buffer transfer is disabled in triangle-wave PWM mode 3.

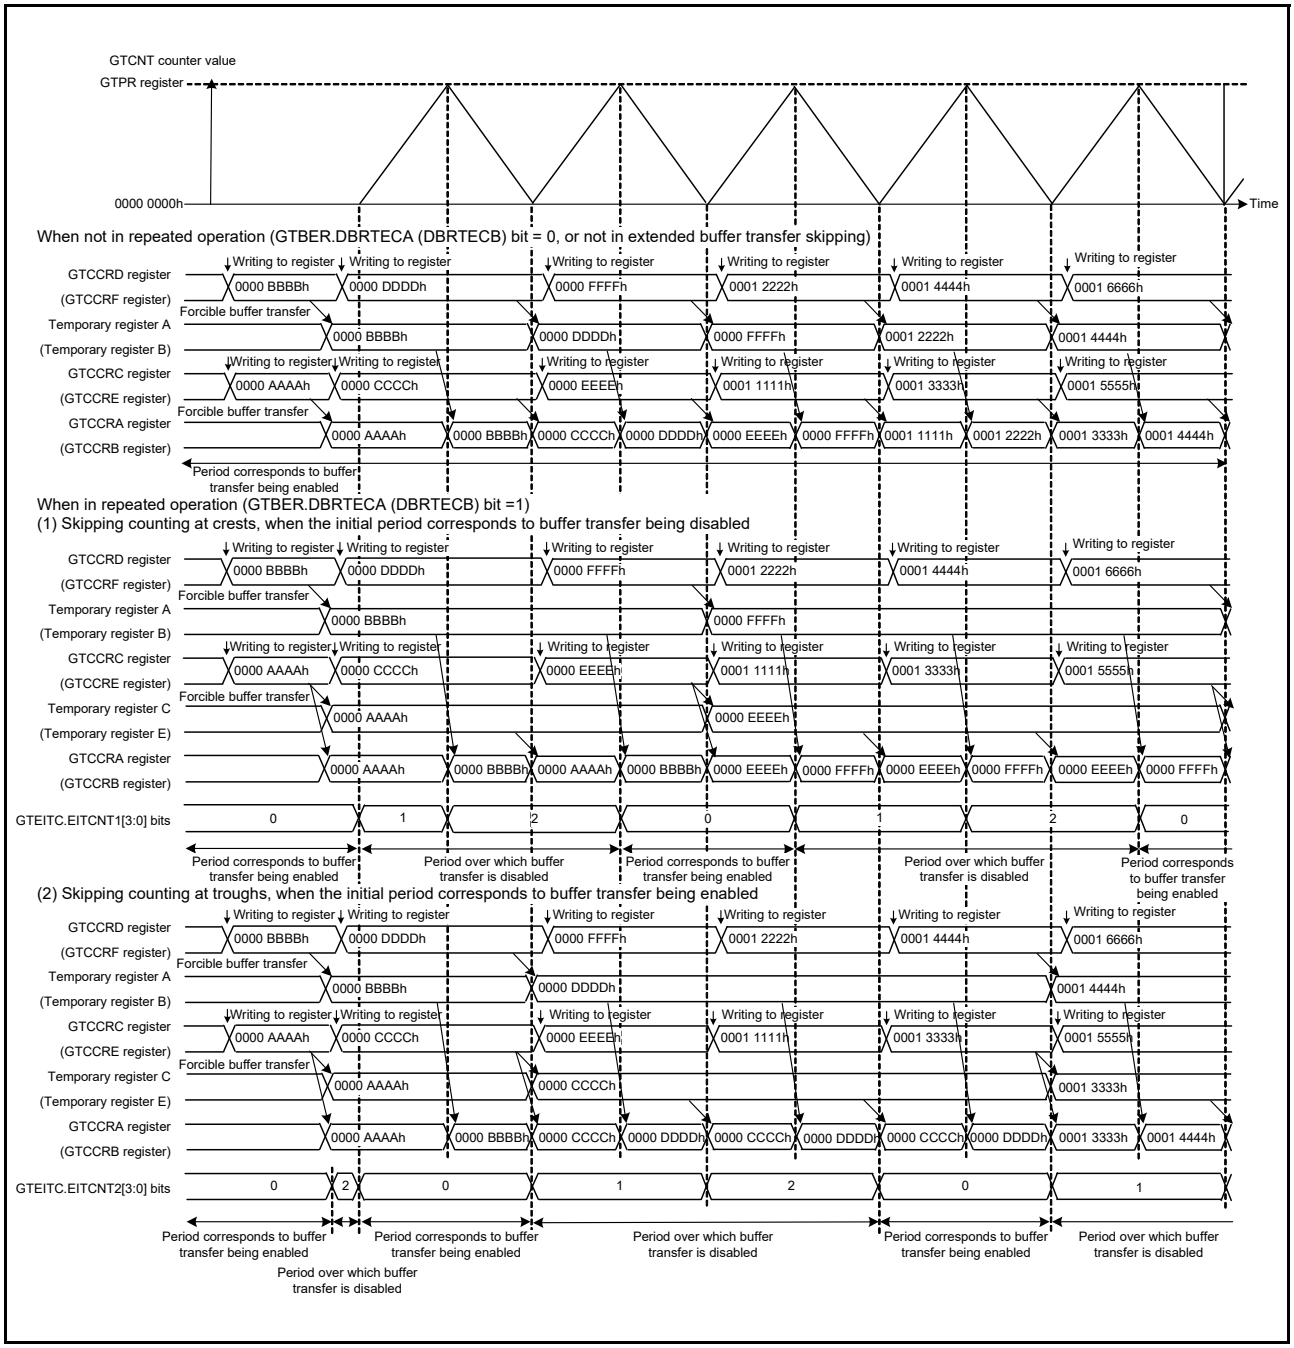

Figure 24.200 Example of Repeated Double-Buffer Operation When GTCCR Buffer Transfer is Disabled (Triangle-Wave PWM Mode 3, Using Extended Buffer Transfer Skipping, GTBER.BD[0] is Constantly 0)

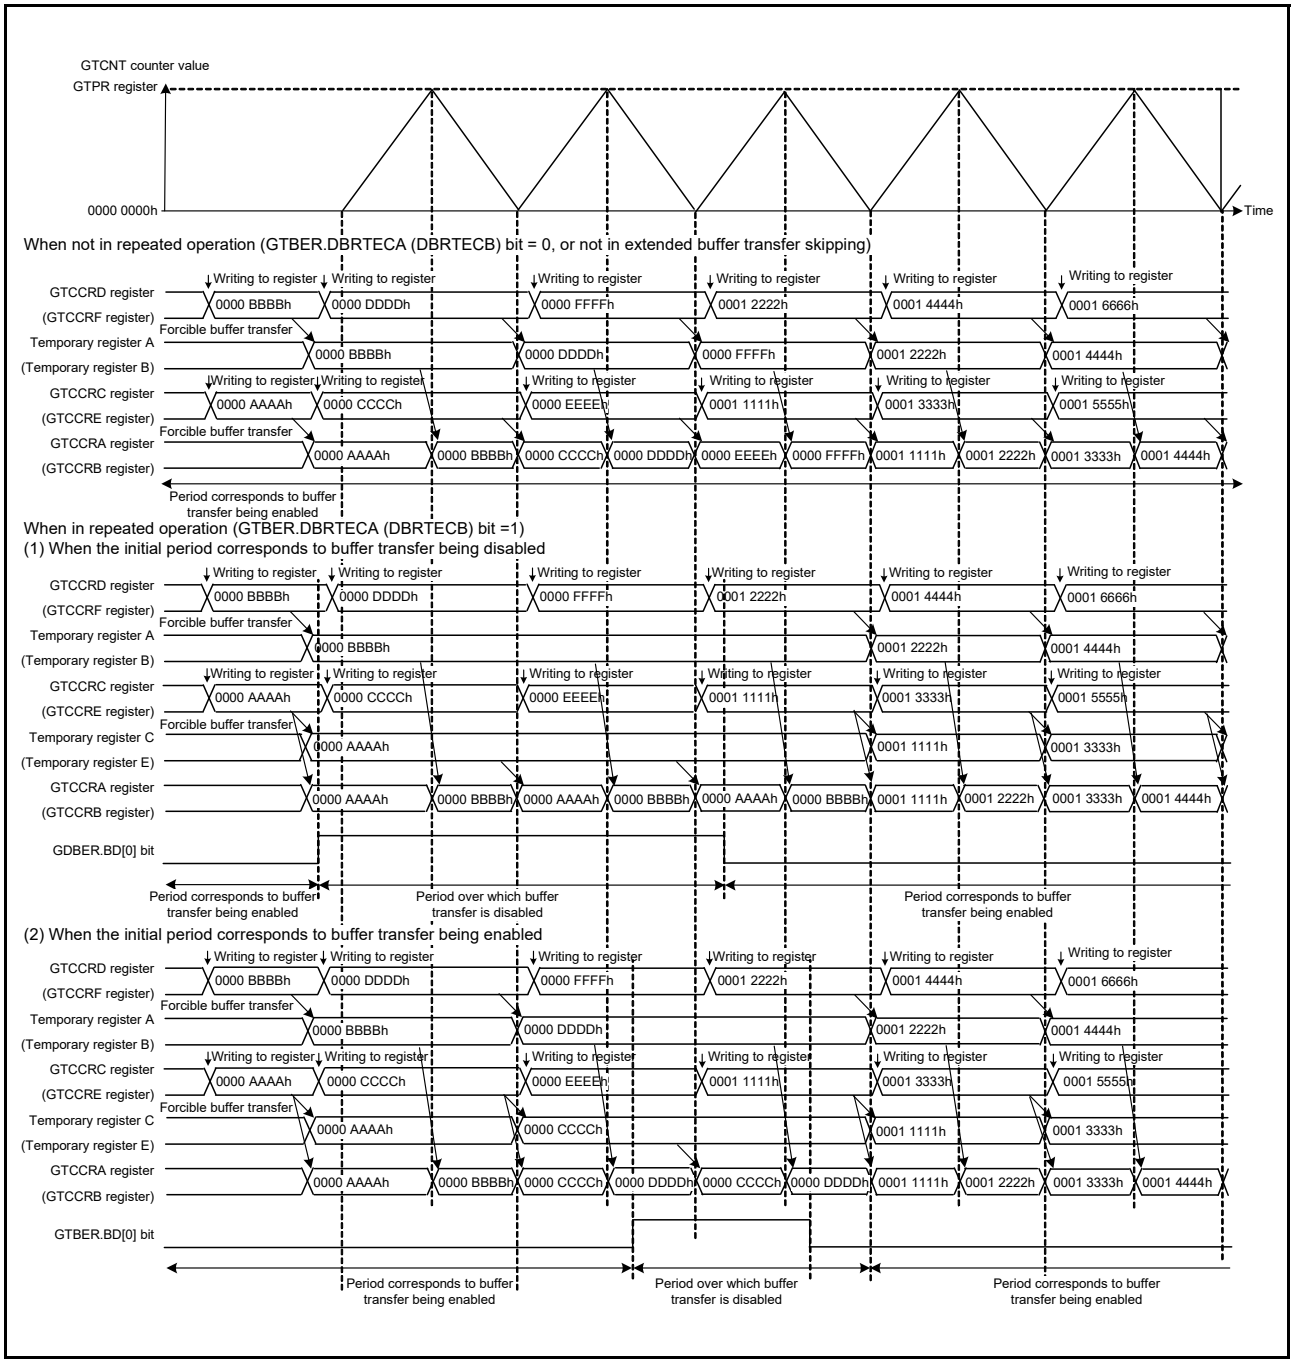

Figure 24.201 Example of Repeated Double-Buffer Operation When GTCCR Buffer Transfer is Disabled (Triangle-Wave PWM Mode 3, Updating the GTBER.BD[0] Bit)

24.8.3 GTIOCnm Pin Output Negate Control (n = 0 to 7; m = A, B)

For protection from system failure, the output negate control which changes the GTIOCnm pin output forcibly by the output stop request from the POEG is provided.

Output protection is required when a dead-time error or the same output level being on the GTIOCnA and GTIOCnB pins is detected. At that time, the detection of disabling of output is output to the group of the POEG set in the GTINTAD.GRP[1:0] bits based on the setting of the output disable detection enable bits, i.e. the GRPDTE, GRPABH, and GRPABL bits in the GTINTAD register. The POEG takes the logical OR of detection of the types described above and other forms of detection of the disabling of output, and outputs requests for the disabling of output to the GPTW.

By setting the GTINTAD.GRP[1:0] bits, one output stop request can be selected out of four output stop requests which are input from the POEG as output stop request signal common in the GTIOCnA and GTIOCnB pins. Selected output stop request can be checked by reading the GTST.ODF flag.

The states of outputs at the time of control for their negation can be set with the GTIOR.OADF[1:0] bits for the GTIOCnA pin and with the GTIOR.OBDF[1:0] bits for the GTIOCnB pin.

Transition to the output negate condition by generating the output stop request from the POEG is performed asynchronously, while a release from the output negate condition by making the output stop request no longer satisfied is performed at the end of the cycle. It is after 3 PCLKC at shortest when the output negate condition is released after the output stop request becomes no longer satisfied. To reliably control output negation, clear the flag of POEG for which the condition for the request to disable the output is no longer satisfied after 4 cycles of PCLKC.

To release the output stop condition during event count operation, in sawtooth-wave PWM mode 2, or without waiting the end of the cycle, set the OADF[1:0] bits to 00b for the GTIOCnA pin, and set the OBDF[1:0] bits to 00b for the GTIOCnB pin.

Figure 24.202 shows the output negate control operation for the GTIOCnm pin output.

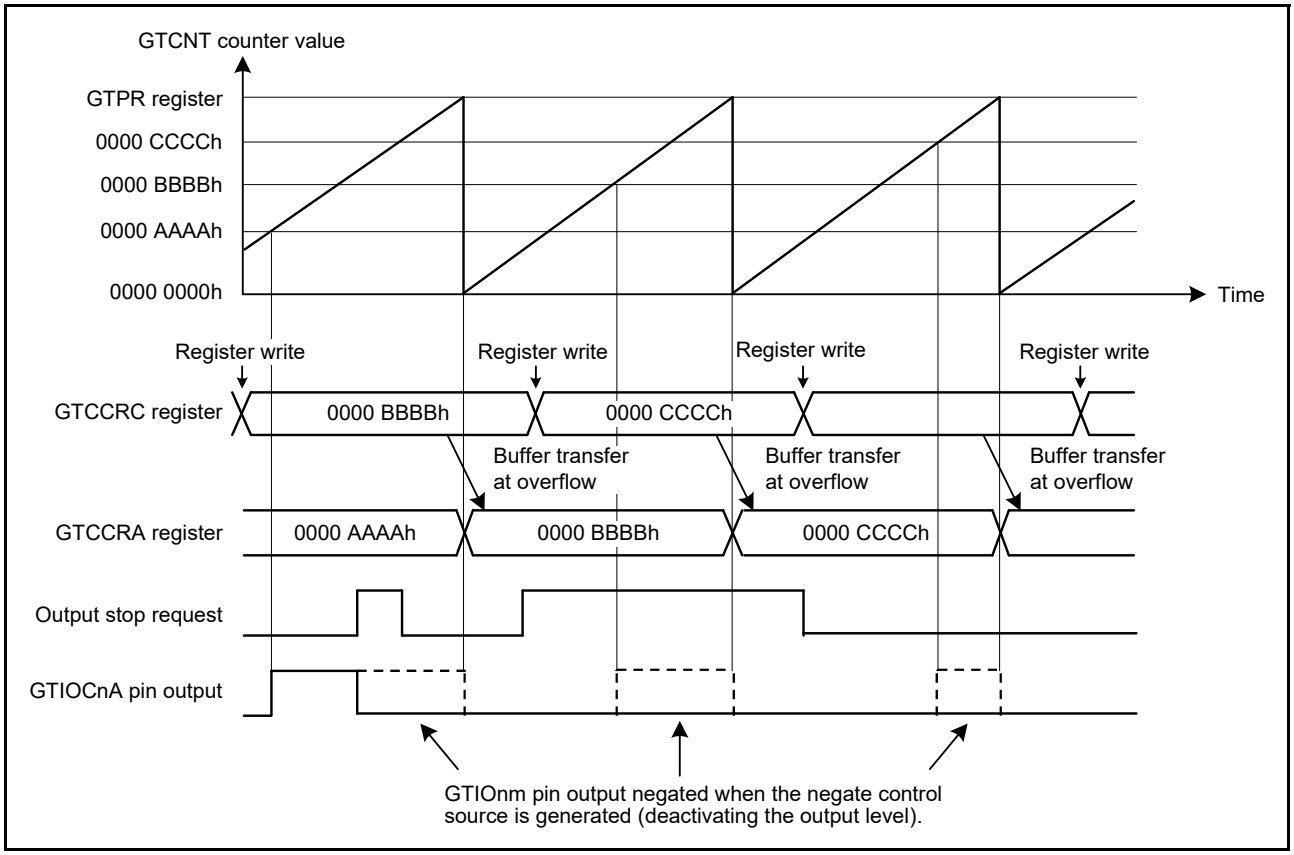

Figure 24.202 Example of Operation for GTIOCnm Pin Output Negate Control (Sawtooth-Wave Up-Counting, Buffer Operation, Active Level: High Output at GTCCRA Register Compare Match, Low Output at the End of the Cycle) and Low Output at Output Negate) (n = 0 to 7; m = A, B)

24.8.4 Output Protection Function for GTIOCnm Pin Output (n = 0 to 7; m = A, B)

To prepare for a case when an incorrect value (0000 0000h or a value greater than or equal to the GTPR register value) is set in the GTCCRA register, the output protection function for the GTIOCnm pin output (disabling function) is activated when the automatic dead time is set (GTDTCR.TDE bit = 1) in triangle-wave PWM mode.
The status of the output protection function can be read from the GTSOS.SOS[1:0] bits.
Figure 24.203 shows the output protection function state transition.

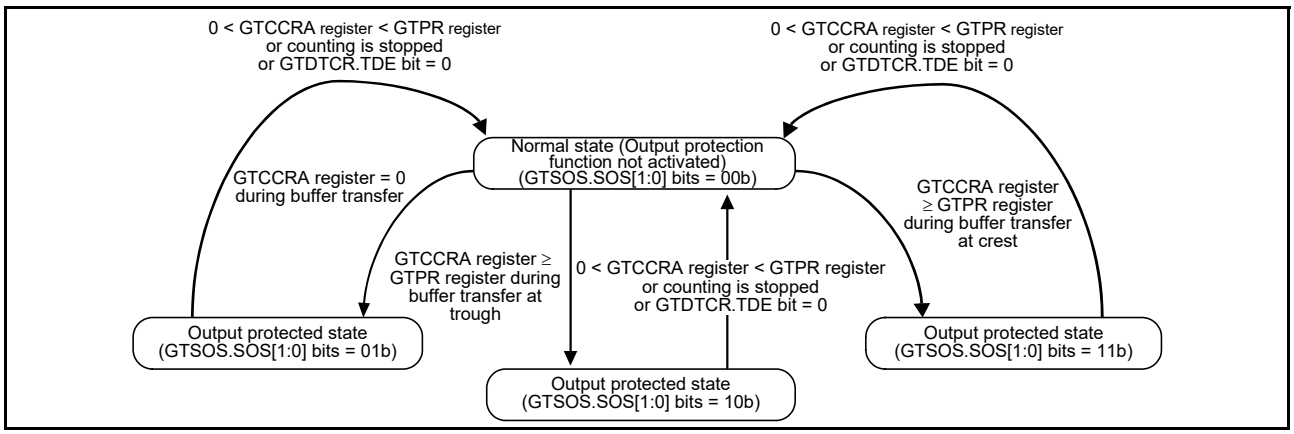

Figure 24.203 Output Protection Function

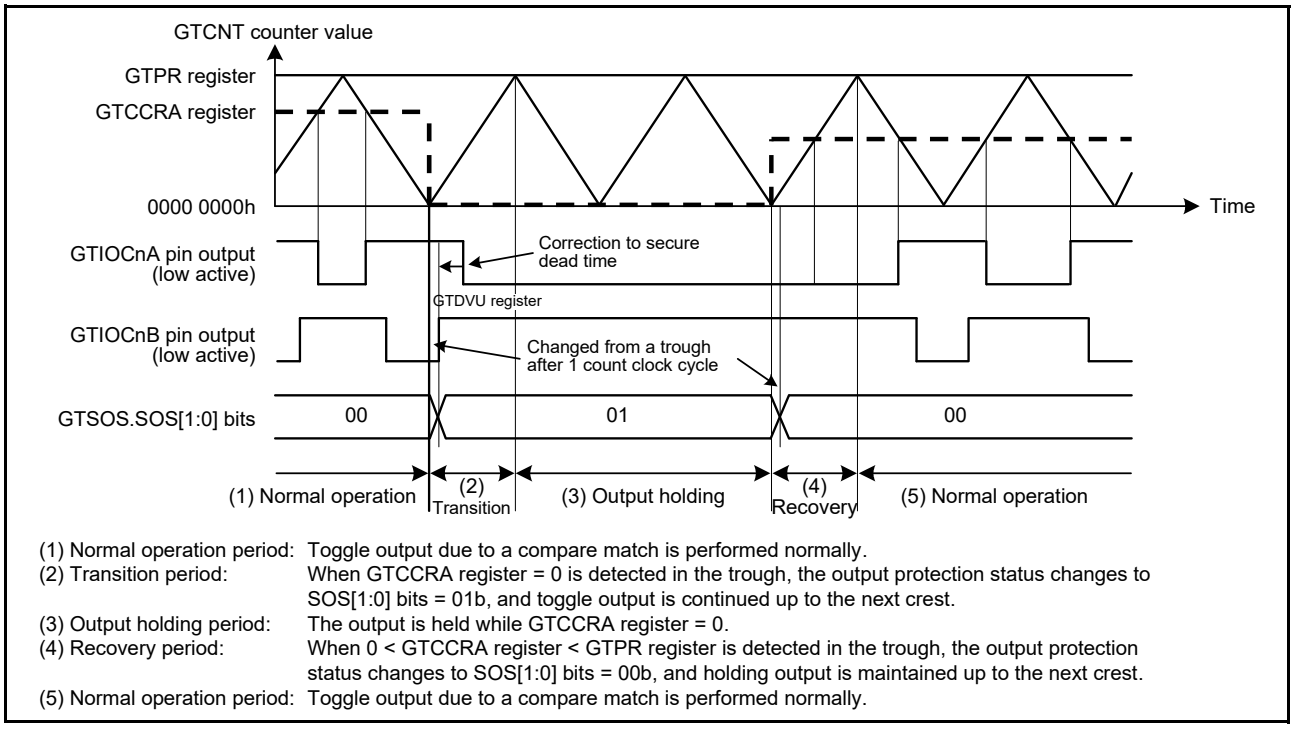
(1) Output Protection Function when the GTCCRA Register is Set to 0000 0000h during Buffer Transfer

Figure 24.204 and Figure 24.205 show examples of output protection function operation when the GTCCRA register is set to 0000 0000h during buffer transfer at troughs, and Figure 24.206 and Figure 24.207 show examples when the GTCCRA register is set to 0000 0000h during buffer transfer at crests.



(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Transition period: When GTCCRA register = 0 is detected in the trough, the output protection status changes to SOS[1:0] bits = 01b, and toggle output is continued up to the next crest.
(3) Output holding period: The output is held while GTCCRA register = 0.
(4) Recovery period: When 0 < GTCCRA register < GTPR register is detected in the trough, the output protection status changes to SOS[1:0] bits = 00b, and holding output is maintained up to the next crest.
(5) Normal operation period: Toggle output due to a compare match is performed normally.

Figure 24.204 Example of Output Protection Function Operation When the GTCCRA Register is Set to 0000 0000h during Buffer Transfer at Troughs (Restored to 0 < GTCCRA Register < GTPR Register during Buffer Transfer at Troughs, Active Level: Low) (n = 0 to 7)

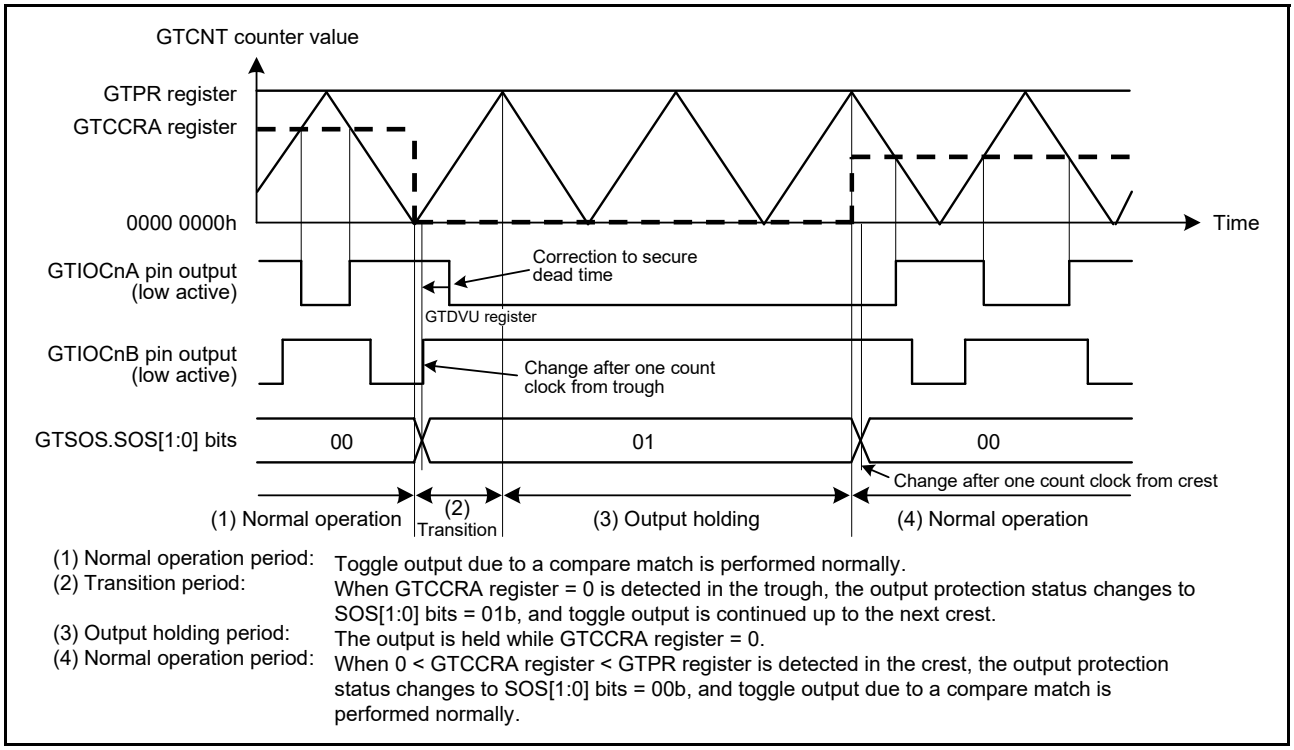


Figure 24.205 Example of Output Protection Function Operation When the GTCCRA Register is Set to 0000 0000h during Buffer Transfer at Troughs (Restored to 0 < GTCCRA Register < GTPR Register during Buffer Transfer at Crests, Active Level: Low) (n = 0 to 7)

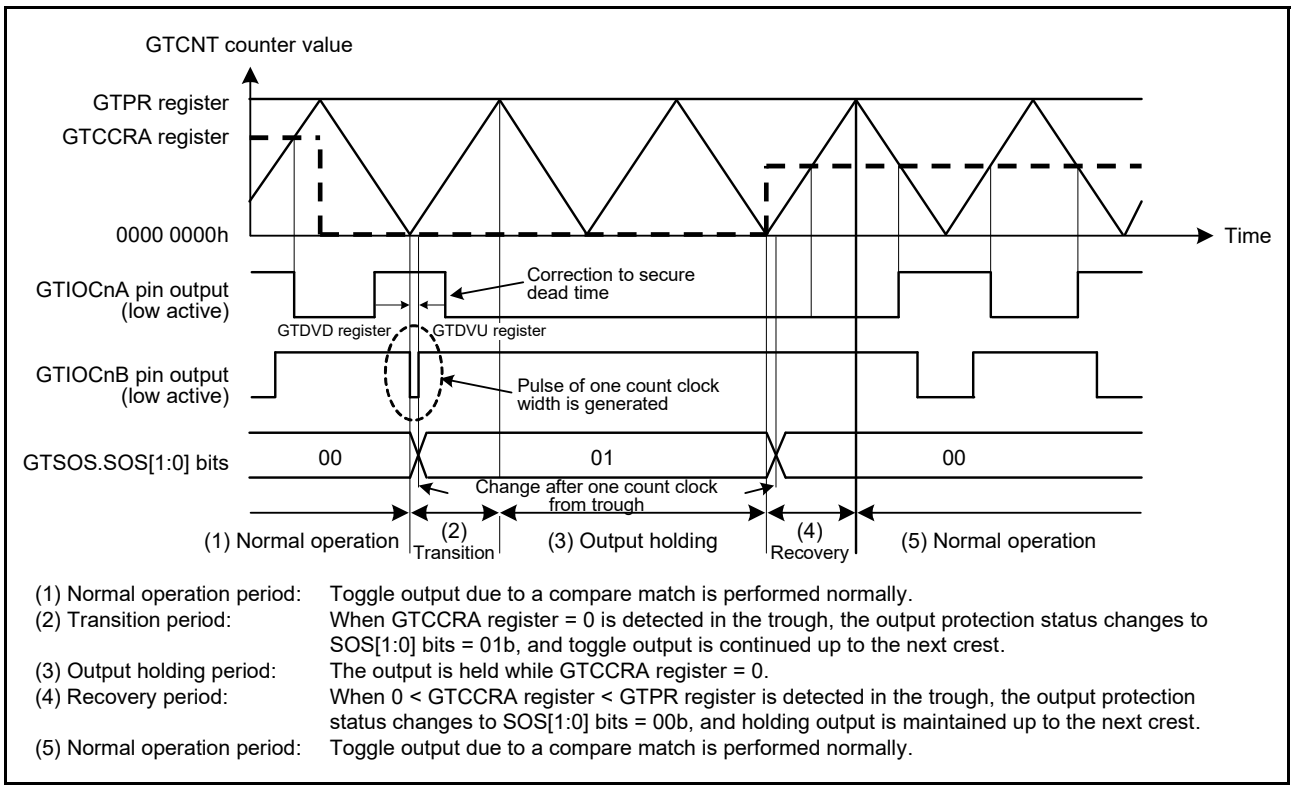

Figure 24.206 Example of Output Protection Function Operation When the GTCCRA Register is Set to 0000 0000h during Buffer Transfer at Crests (Restored to 0 < GTCCRA Register < GTPR Register during Buffer Transfer at Troughs, Active Level: Low) (n = 0 to 7)

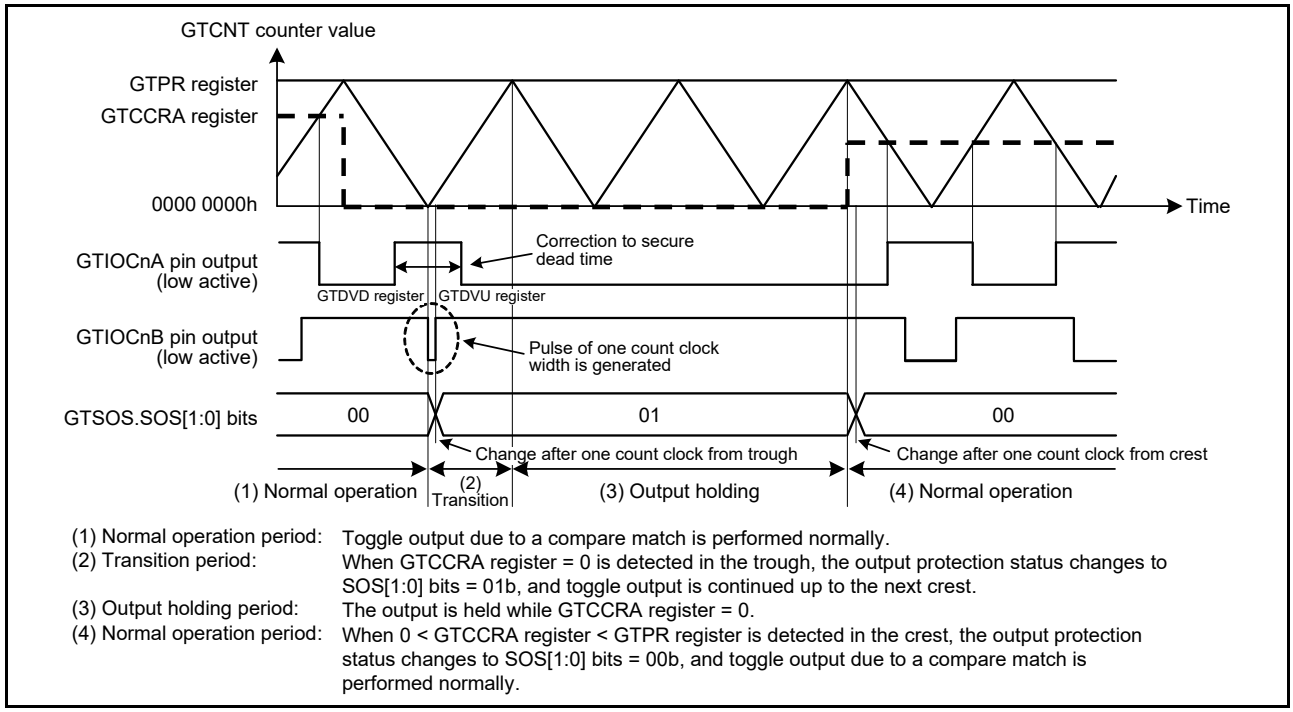

Figure 24.207 Example of Output Protection Function Operation When the GTCCRA Register is Set to 0000 0000h during Buffer Transfer at Crests (Restored to 0 < GTCCRA Register < GTPR Register during Buffer Transfer at Crests, Active Level: Low) (n = 0 to 7)

(2) Output Protection Function when GTCCRA Register ≥ GTPR Register is Set during Buffer Transfer at Troughs

Figure 24.208 and Figure 24.209 show examples of output protection function operation when GTCCRA register ≥ GTPR register is set during buffer transfer at troughs.

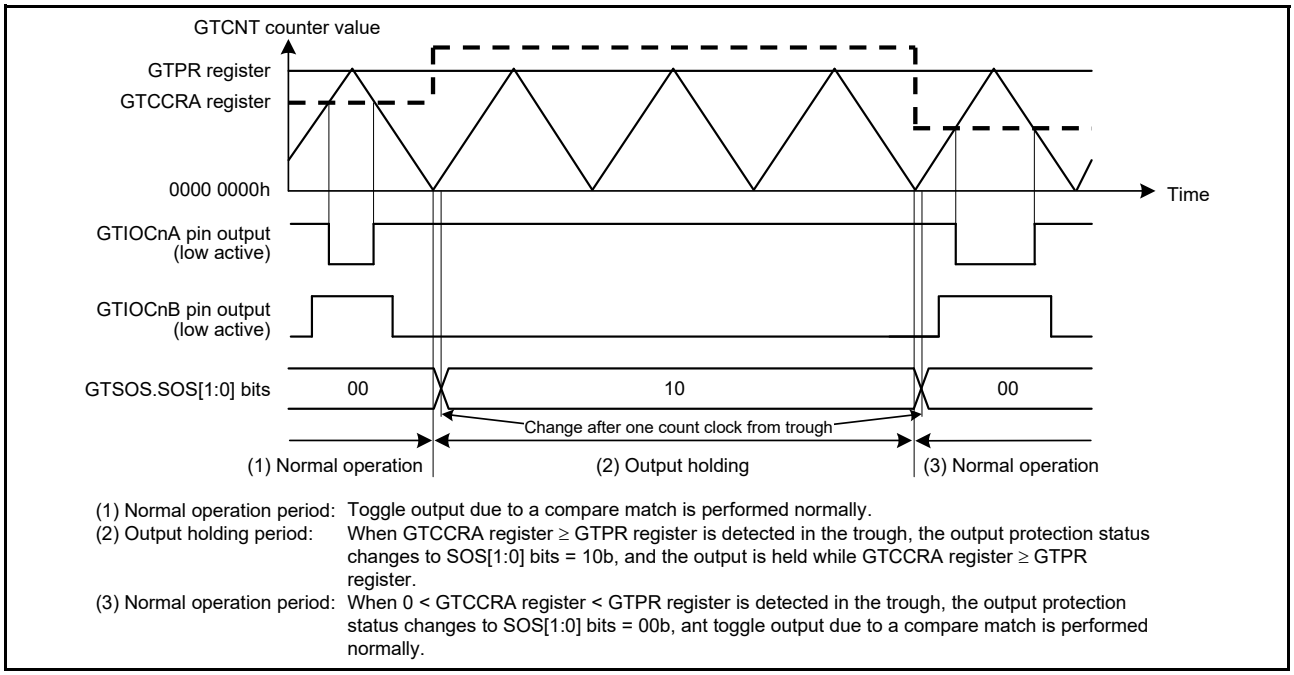

Figure 24.208 Example of Output Protection Function Operation When GTCCRA Register ≥ GTPR Register is set during Buffer Transfer at Troughs (Restored to 0 < GTCCRA Register < GTPR Register during Buffer Transfer at Troughs, Active Level: Low) (n = 0 to 7)

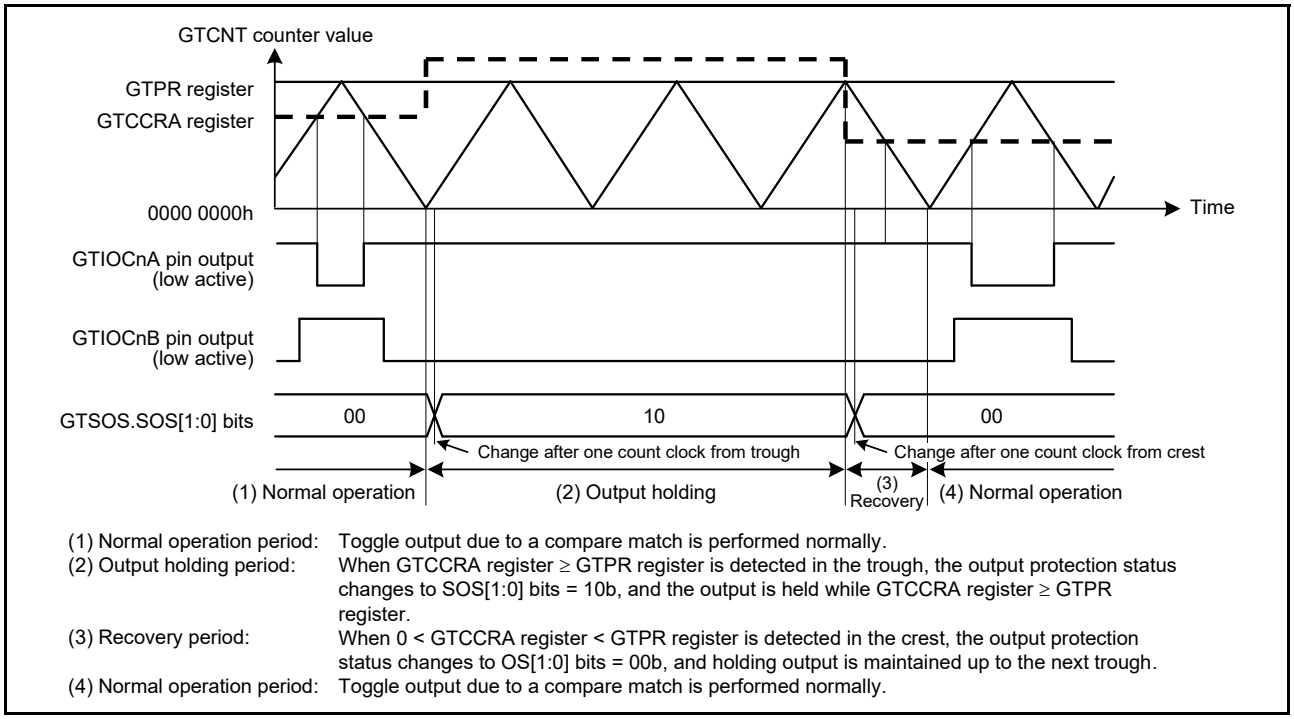
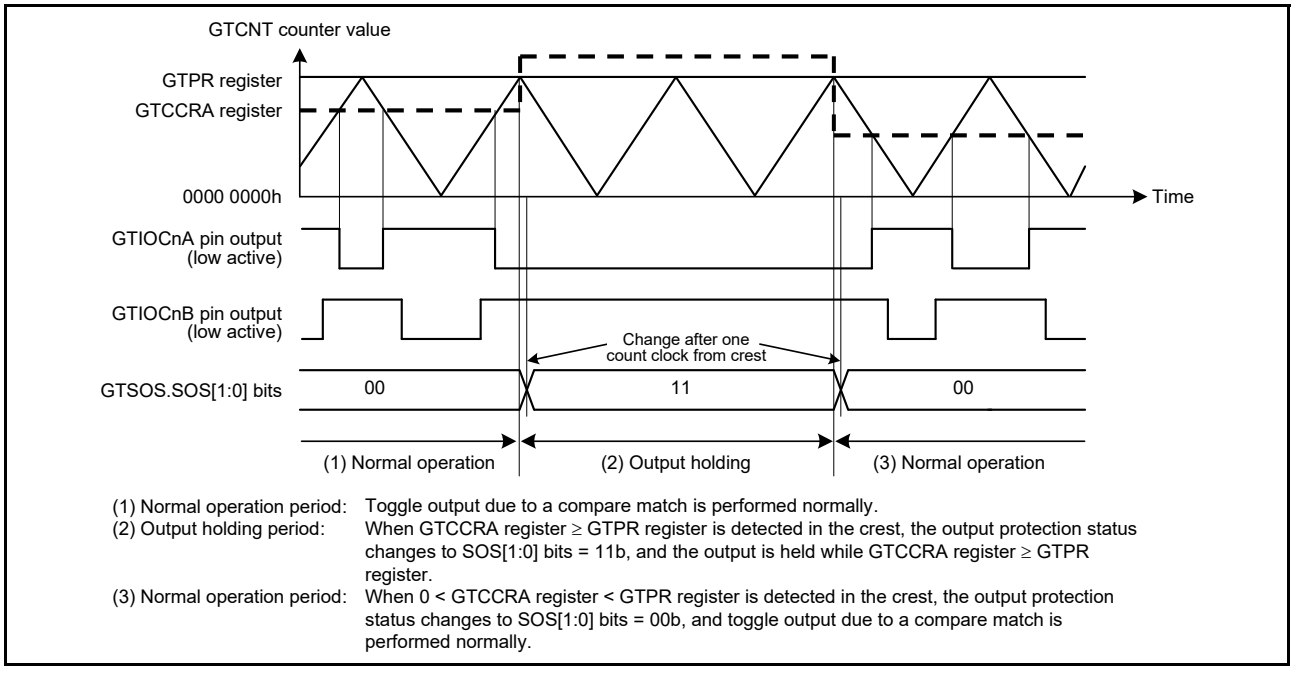


(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Output holding period: When GTCCRA register ≥ GTPR register is detected in the trough, the output protection status changes to SOS[1:0] bits = 10b, and the output is held while GTCCRA register ≥ GTPR register.
(3) Recovery period: When 0 < GTCCRA register < GTPR register is detected in the crest, the output protection status changes to OS[1:0] bits = 00b, and holding output is maintained up to the next trough.
(4) Normal operation period: Toggle output due to a compare match is performed normally.

Figure 24.209 Example of Output Protection Function Operation When GTCCRA Register ≥ GTPR Register is Set during Buffer Transfer at Troughs (Restored to 0 < GTCCRA Register < GTPR Register during Buffer Transfer at Crests, Active Level: Low) (n = 0 to 7)

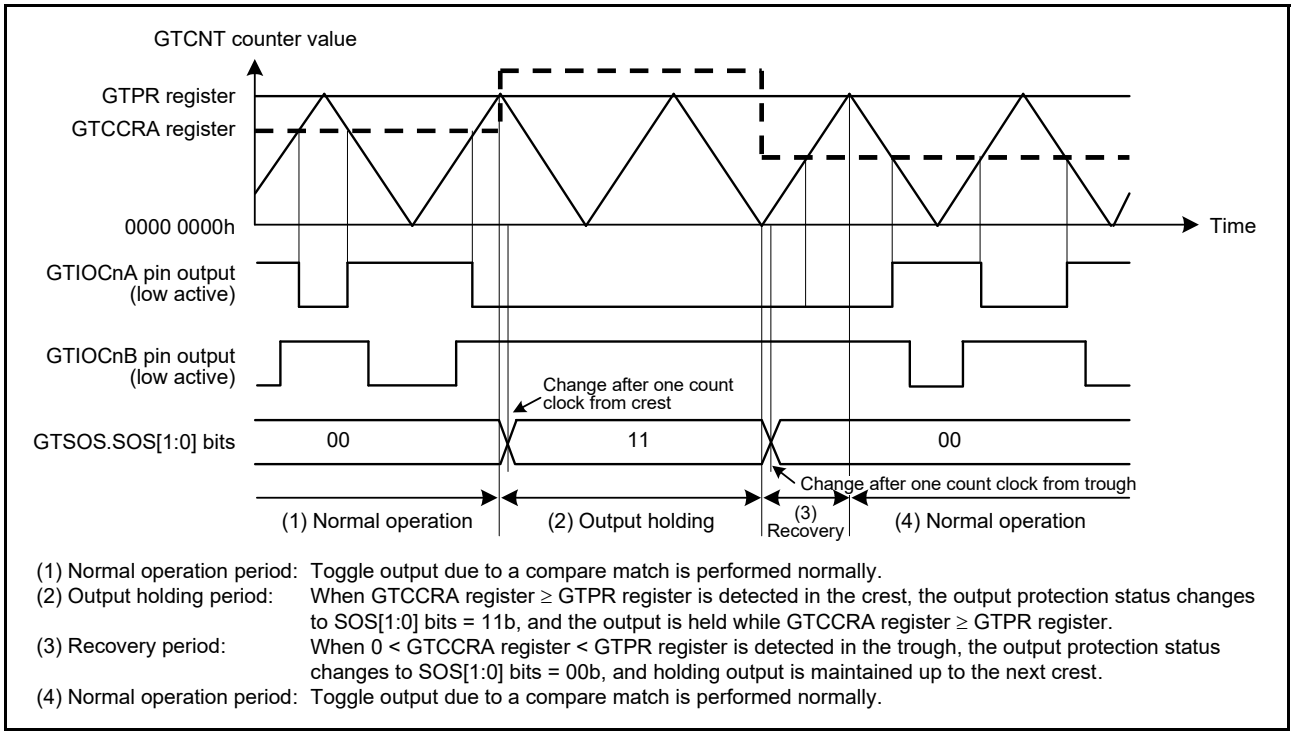
(3) Output Protection Function when GTCCRA Register ≥ GTPR Register is Set during Buffer Transfer at Crests

Figure 24.210 and Figure 24.211 show examples of output protection function operation when GTCCRA register ≥ GTPR register is set during buffer transfer at crests.



(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Output holding period: When GTCCRA register ≥ GTPR register is detected in the crest, the output protection status changes to SOS[1:0] bits = 11b, and the output is held while GTCCRA register ≥ GTPR register.
(3) Normal operation period: When 0 < GTCCRA register < GTPR register is detected in the crest, the output protection status changes to SOS[1:0] bits = 00b, and toggle output due to a compare match is performed normally.

Figure 24.210 Example of Output Protection Function Operation When GTCCRA Register ≥ GTPR Register is Set during Buffer Transfer at Crests (Restored to 0 < GTCCRA Register < GTPR Register during Buffer Transfer at Crests, Active Level: Low) (n = 0 to 7)



(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Output holding period: When GTCCRA register ≥ GTPR register is detected in the crest, the output protection status changes to SOS[1:0] bits = 11b, and the output is held while GTCCRA register ≥ GTPR register.
(3) Recovery period: When 0 < GTCCRA register < GTPR register is detected in the trough, the output protection status changes to SOS[1:0] bits = 00b, and holding output is maintained up to the next crest.
(4) Normal operation period: Toggle output due to a compare match is performed normally.

Figure 24.211 Example of Output Protection Function Operation When GTCCRA Register ≥ GTPR Register is Set during Buffer Transfer at Crests (Restored to 0 < GTCCRA Register < GTPR Register during Buffer Transfer at Troughs, Active Level: Low) (n = 0 to 7)

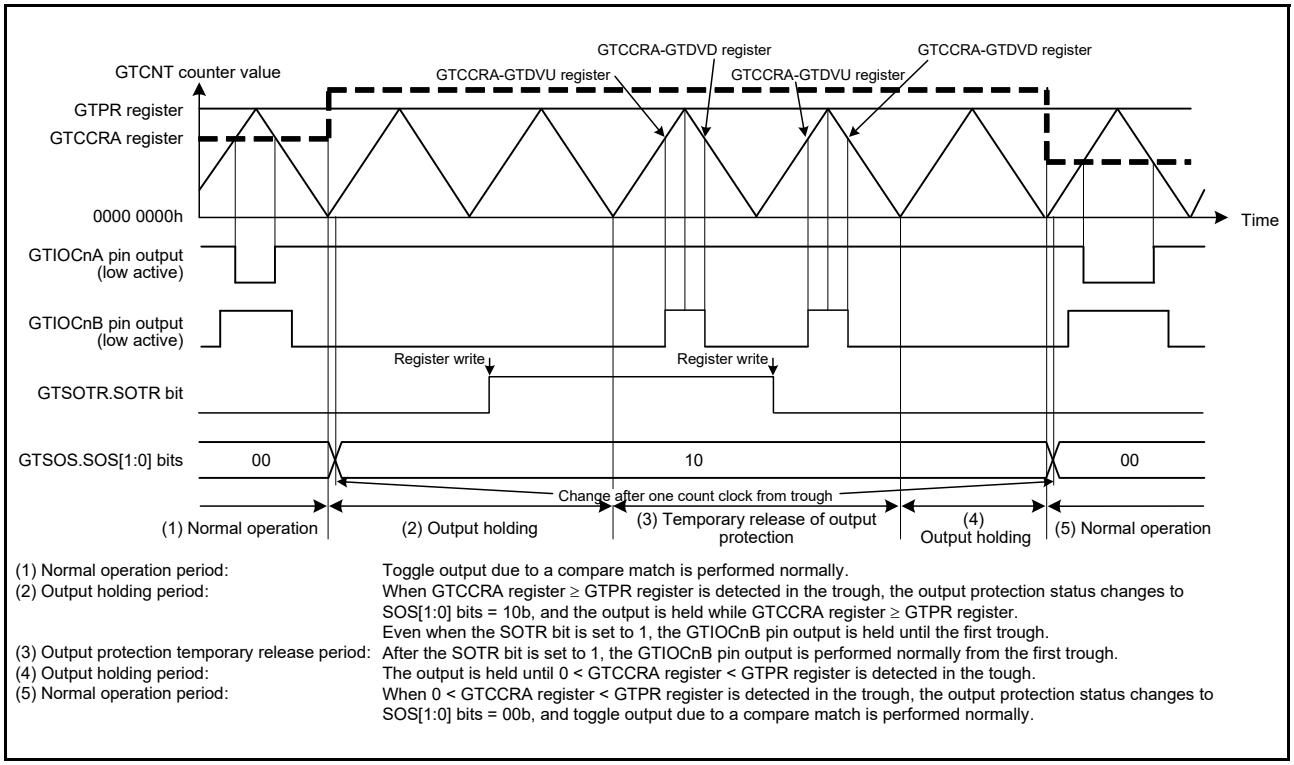
(4) Restricted Specification of Output Protection Function

Even if an incorrect value (0000 0000h or a value greater than or equal to the GTPR register value) is set in the GTCCRA register during count operation, the output protection functions in a specific way such that one of the positive- and negative-phase outputs becomes non-active. However, the output protection does not operate normally.

- When the GTCCRA register value at the start of count operation is greater than 0000 0000h, and less than the setting value of the GTPR register

(5) Temporary Release of Output Protection Function

When the GTSOS.SOS[1:0] bits = 10b (protected state in which GTCCRA register ≥ GTPR register has occurred during transfer at trough), the protected state of the GTIOCnB pin output can be temporarily released by setting the GTSOTR.SOTR bit to 1. The SOS[1:0] bits retain 10b even if the output protection function is released.
When the SOTR bit is set to 0, the GTIOCnB pin output protection can be restarted.
Figure 24.212 shows an example of the operation of temporary release of output protection when the setting of the GTCCRA register ≥ GTPR register during buffer transfer at troughs.



(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Output holding period: When GTCCRA register ≥ GTPR register is detected in the trough, the output protection status changes to SOS[1:0] bits = 10b, and the output is held while GTCCRA register ≥ GTPR register.
Even when the SOTR bit is set to 1, the GTIOCnB pin output is held until the first trough.
(3) Output protection temporary release period: After the SOTR bit is set to 1, the GTIOCnB pin output is performed normally from the first trough.
(4) Output holding period: The output is held until 0 < GTCCRA register < GTPR register is detected in the tough.
(5) Normal operation period: When 0 < GTCCRA register < GTPR register is detected in the trough, the output protection status changes to SOS[1:0] bits = 00b, and toggle output due to a compare match is performed normally.

Figure 24.212 Example of the Operation of Temporary Release of Output Protection When the Setting of the GTCCRA Register ≥ GTPR Register during Buffer Transfer at Troughs (Restored to 0 < GTCCRA Register < GTPR Register during Buffer Transfer at Troughs, Active Level: Low) (n = 0 to 7)

24.9 Initialization Method of Output Pins

24.9.1 Pin Settings after Reset

The GPTW registers are initialized at a reset. Initialize the GPTW for output to the external pins by making the port mode settings and setting the OAE and OBE bits in the GTIOR register, and then start the counter counting.

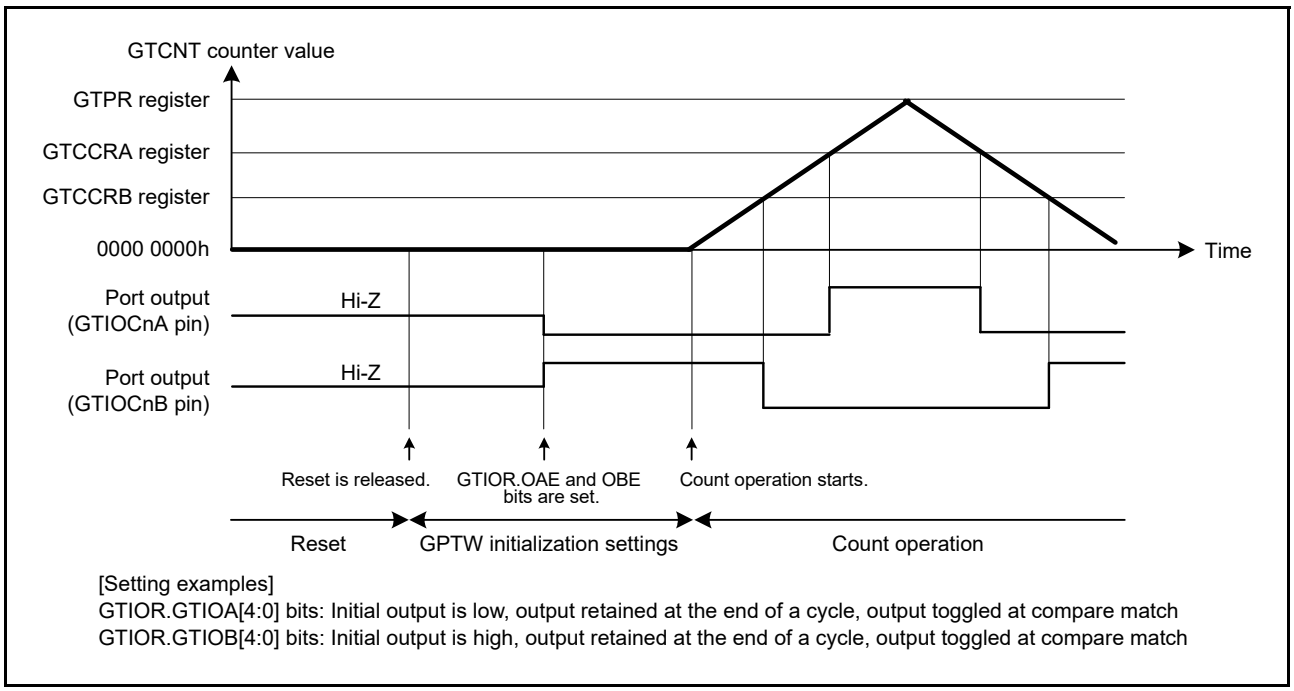


Figure 24.213 Example of Pin Settings after Reset (n = 0 to 7)

24.9.2 Pin Initialization Due to Error during Operation

If an error occurs during GPTW operation, the following four types of pin processing can be performed before pin initialization.

(1) Set OAHLD and OBHLD bits in the GTIOR register to 1 and retain the outputs at count stop.
(2) Set OAHLD and OBHLD bits to 0, specify arbitrary output values at OADFLT and OBDFLT bits in the GTIOR register, and output the arbitrary values at count stop.
(3) Set the pin to output an arbitrary value as a general output port by setting the PDR, PODR, and PMR registers of the I/O port in advance. Set the OAE and OBE bits in the GTIOR register to 0 and the control bit in PMR register that corresponds to the pin to 0 to allow the arbitrary values to be output from the pin set as a general output port when an error occurs.
(4) Drive the output to a high impedance state using the POEG function.

When automatic dead time setting has been made, set the GTDTCR.TDE bit to 0 once after counting is stopped.
When counting is stopped, only the values of registers that are changed by a GPTW external source will change. If counting is resumed, operation will carry on from where it was stopped.
If counting was stopped, registers should be initialized before counting is started.

24.10 Usage Notes

24.10.1 Module Stop Function Setting

Operation of the GPTW can be disabled or enabled by the module stop control register. The initial setting is for operation of the GPTW to be halted. Register access is enabled by clearing module stop state. For details, see section 11, Low Power Consumption.

24.10.2 Settings of the GTCCRm Register during Compare Match Operation (m = A to F)

(1) When Automatic Dead Time Setting has been Made in Triangle-Wave PWM Mode

The GTCCRA register should satisfy the following conditions:

GTCCRA register > GTDVU register,
GTCCRA register > GTDVD register, and
GTCCRA register < GTPR register.

When the GTCCRA register is set to 0000 0000h or a value greater than or equal to the GTPR register value during count operation, the output protection function is activated.
However, if the following conditions are not satisfied, the output protection does not operate normally.

- When the GTCCRA register value at the start of count operation is 0000 0001h or greater, and less than the setting value of the GTPR register

For details, refer to section 24.8.4, Output Protection Function for GTIOCnm Pin Output (n = 0 to 7; m = A, B).

(2) When Automatic Dead Time Setting has not been Made in Triangle-Wave PWM Mode

Set a value greater than 0000 0000h, and less than the setting value of the GTPR register in the GTCCRA register. When 0000 0000h or the same value as that of the GTPR register is set in the GTCCRA register, compare match is generated in one cycle only when [GTCCRA register = 0000 0000h] or [GTCCRA register = GTPR register] is met. Furthermore, a value exceeding the setting value of the GTPR register is set in the GTCCRA register, compare match does not occur. Similarly, set a value greater than 0000 0000h, and less than the setting value of the GTPR register in the GTCCRB register. When 0000 0000h or the same value as that of the GTPR register is set in the GTCCRB register, compare match is generated in one cycle only when [GTCCRB register = 0000 0000h] or [GTCCRB register = GTPR register] is met. Furthermore, a value exceeding the setting value of the GTPR register is set in the GTCCRB register, compare match does not occur.

(3) When Automatic Dead Time Setting has been Made in Sawtooth-Wave One-Shot Pulse Mode

The GTCCRC and GTCCRD registers should be set to satisfy the following restrictions. If the restrictions are not satisfied, correct output waveforms with secured dead time may not be obtained.

- In up-counting:
  GTCCRC register < GTCCRD register
  GTCCRC register > GTDVU register
  GTCCRD register < GTPR register – GTDVD register
- In down-counting:
  GTCCRC register > GTCCRD register
  GTCCRC register < GTPR register – GTDVU register
  GTCCRD register > GTDVD register

(4) When Automatic Dead Time Setting has not been Made in Sawtooth-Wave One-Shot Pulse Mode

The GTCCRC and GTCCRD registers should be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting: 0 < GTCCRC register < GTCCRD register < GTPR register
- In down-counting: GTPR register > GTCCRC register > GTCCRD register > 0

Similarly, GTCCRE and GTCCRF registers should be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting: 0 < GTCCRE register < GTCCRF register < GTPR register
- In down-counting: GTPR register > GTCCRE register > GTCCRF register > 0

(5) In Sawtooth-Wave PWM Mode

The GTCCRA register should be set with the range of 0000 0000h < GTCCRA register < GTPR register. If GTCCRA register = 0000 0000h or GTCCRA register = GTPR register is set, a compare match occurs within the cycle only when GTCCRA register = 0000 0000h or GTCCRA register = GTPR register is satisfied. If GTCCRA register > GTPR register is set, no compare match occurs.
Similarly, GTCCRB register should be set with the range of 0000 0000h < GTCCRB register < GTPR register. If GTCCRB register = 0000 0000h or GTCCRB register = GTPR register is set, a compare match occurs within the cycle only when GTCCRB register = 0000 0000h or GTCCRB register = GTPR register is satisfied. If GTCCRB register > GTPR register is set, no compare match occurs.

(6) In Complementary PWM mode 1, 2, 3

The GTCCRn register must be set with the range of 0 ≤ GTCCRn ≤ GTPR + GTDVU.

(7) In Complementary PWM mode 4

In single buffer operation, the GTCCRn register must be set with the range of 0 ≤ GTCCRn ≤ GTPR + GTDVU.
In double buffer operation, the GTCCRn register must be set with the range of GTDVU < GTCCRn < GTPR.

24.10.3 Range of Settings for the GTPBR and GTPDBR Registers in the Complementary PWM Mode

When buffer transfer with the use of the GTPR register is to proceed at the end of a crest section in complementary PWM mode 1, 3, or 4, set the GTPBR and GTPDBR registers so that the GTPR register is within the following range after the transfer.
The range consists of values no less than the GTCNT counter value of the master channel at the end of a crest section, that is, the GTPR register before the transfer – the GTDVU register (GTPBR register ≥ GTPR register – GTDVU register, GTPDBR register ≥ GTPBR register – GTDVU register)
When buffer transfer with the use of the GTPR register is to proceed at the end of a trough section or on counter clearing, no restriction applies to the ranges of settings for the GTPBR and GTPDBR registers.

24.10.4 Setting Range of the GTCNT Counter

Other than the sawtooth-wave PWM mode 2 and complementary PWM mode, set the range of the GTCNT counter within the range of 0 ≤ GTCNT counter ≤ GTPR register.

24.10.5 The GTCNT Counter Start/Stop

The GTCNT counter start/stop control by the GTCR.CST bit is synchronized with the count clock selected by the GTCR.TPCS[3:0] bits. Since the GTCNT counter starts or stops after one count clock cycle selected by the TPCS[3:0] bits following the CST bit updating, events until the GTCNT counter actually starts are ignored, where events may be accepted and the interrupt may be generated after the CST bit becomes 0.

24.10.6 Order of Priority in Events

(1) GTCNT Counter

Order of priority in events to update the GTCNT counter is shown below.

Table 24.43 Order of Priority in Updating GTCNT Counter

The GTCNT counter updating source	Order of priority
CPU writing (GTCNT counter writing/GTCLR register writing)	High
Clearing by a hardware source set by the GTCSR register	↑
Up-counting/down-counting by a hardware source set by the GTUPSR and GTDNSR registers	↑
Count operation	Low

In case of contention between up-counting by the GTUPSR register and down-counting by the GTDNSR register, the counter value is not updated.
When updating of the GTCNT counter conflicts with reading by the CPU, the value before updating is reflected.

(2) The GTCR.CST Bit

In case that start/stop by a hardware source set by the GTSSR and GTPSR registers conflicts with the CPU writing (GTCR register writing/GTSTR register writing /GTSTP register writing), the CPU writing takes priority.
In case that stop by the cycle count function conflicts with start by the CPU writing (GTCR register writing/GTSTR register writing), the cycle count operation is finished with setting the GTST.PCF flag. The CST bit is not changed and the GTCNT continues to count.
In case of contention between start by a hardware source set by the GTSSR register and stop by a hardware source set by the GTPSR register, the state of the CST bit does not change.
In case of contention between the CST bit updating and the CPU reading (GTCR register reading/GTSTR register reading /GTSTP register reading), data before updating is read.

(3) GTCCRm Register (m = A to F)

In case of contention between the GTCCRm register writing and an input capture/buffer transfer, an input capture/buffer transfer takes priority over the GTCCRm register writing.
In case that an input capture conflicts with the CPU writing or the counter updating by a hardware source, the counter value before updating is captured.
In case of contention between the GTCCRm register updating and the CPU reading, data before updating is read.

(4) GTPR Register

In case of contention between a buffer transfer and the GTPR register writing, the GTPR register writing takes priority over a buffer transfer.
In case of contention between the GTPR register updating and the CPU reading, data before updating is read.

(5) GTADTRm Register (m = A, B)

In case of contention between a buffer transfer and the GTADTRm register writing, the GTADTRm register writing takes priority over a buffer transfer.
In case of contention between the GTADTRm register updating and the CPU reading, data before updating is read.

(6) GTDVm Register (m = U, D)

In case of contention between a buffer transfer and the GTDVm register writing, the GTDVm register writing takes priority over a buffer transfer.
In case of contention between the GTDVm register updating and the CPU reading, data before updating is read.

(7) GTIOR.GTIOm bit (m = A, B)

When there is a conflict between buffer transfer operation and writing to GTIOR.GTIOm bit, writing to GTIOR.GTIOm bit has priority over buffer transfer operation.
When there is a conflict between updating the GTIOR.GTIOm bit and reading by the CPU, pre-update data is ready.

24.10.7 Note on Counter Clearing in the Complementary PWM Mode

Counter clearing at the end of a trough section or the end of the initial output section must be avoided in the complementary PWM mode. This can be achieved by using synchronous clearing in response to a match in comparison in another channel set as the source of the trigger, as described in section 24.3.8.3, Synchronous Clear Operation by Inter Channel Cooperation. When using counter clearing other than as stated above, adjust the timing of the operations to avoid counter clearing at the end of a trough section or the end of the initial output section.

24.10.8 Note on Disabling PWM Initial Output After Synchronous Clearing in the Complementary PWM Mode

When initial output on the GTIOCnA and GTIOCnB pins after synchronous clearing in a trough section in the complementary PWM mode has been disabled by setting the GTIOR.CPSCIR bit to 1, the respective values set in the compare match registers (the GTCCRA, GTCCRC, GTCCRD,GTCCRE, and GTCCRF registers) must be more than twice that of the GTDVU register.

25. High Resolution PWM Waveform Generation Circuit (HRPWM)

25.1 Overview

This MCU has a high resolution PWM waveform generation circuit (HRPWM) which finely adjusts a PWM waveform generated by GPTW0 to GPTW3 with a resolution of at least around 260 ps. Using the HRPWM, a digital power supply control with high conversion efficiency can be realized. Table 25.1 lists the specifications of the HRPWM, Figure 25.1 shows a block diagram, and Table 25.2 lists the I/O pins.

Table 25.1 Specifications of the HRPWM

Item	Description
Function	• A maximum of four channels of complementary PWM waveforms are finely adjusted at high resolution. • Using a delay locked loop (DLL) circuit, a high resolution of 1/32 times of a PCLKC period (minimum of around 260 ps). • Timing for rising and falling of the PWM waveform can be adjusted individually.*1 • A waveform generated by the GPTW can be output directly by bypassing the HRPWM.
Operating frequency (f(PCLKC))	80 to 120 MHz

Note 1. Adjustment of timing for rising and falling of PWM signals which are output from the GPTW0 to GPTW3 is realized by a delay of a resolution of 1/32 times of a PCLKC period.

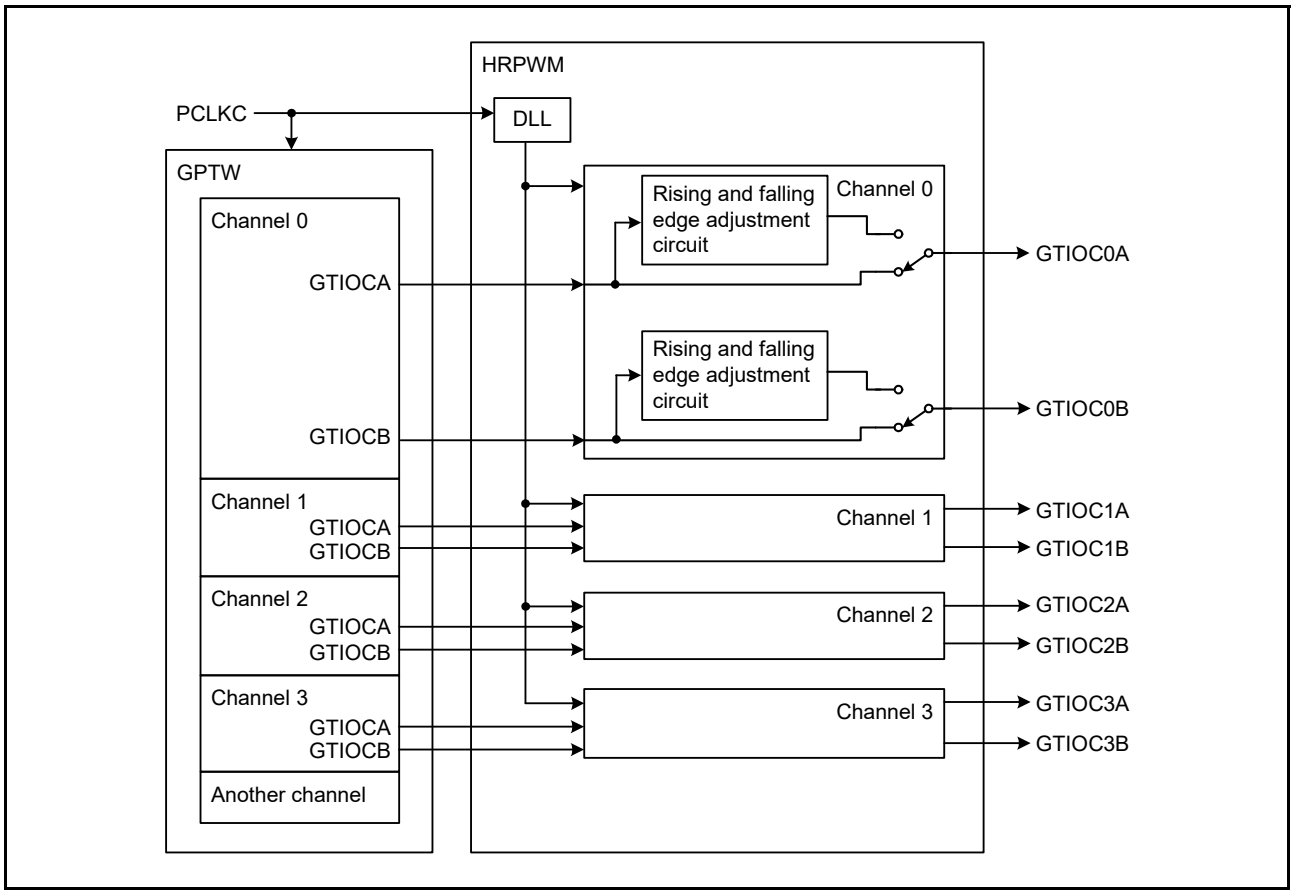

Figure 25.1 Block Diagram of the HRPWM

Table 25.2 I/O Pins of the HRPWM

Pin Name	I/O	Function
GTIOC0A	Output	High resolution output of a PWM waveform generated by the GPTW0
GTIOC0B	Output	High resolution output of a PWM waveform generated by the GPTW0
GTIOC1A	Output	High resolution output of a PWM waveform generated by the GPTW1
GTIOC1B	Output	High resolution output of a PWM waveform generated by the GPTW1
GTIOC2A	Output	High resolution output of a PWM waveform generated by the GPTW2
GTIOC2B	Output	High resolution output of a PWM waveform generated by the GPTW2
GTIOC3A	Output	High resolution output of a PWM waveform generated by the GPTW3
GTIOC3B	Output	High resolution output of a PWM waveform generated by the GPTW3

25.2 Register Descriptions

25.2.1 HRPWM Operation Control Register (HROCR)

Address(es): HRPWM.HROCR 000C 2A00h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	HRRST	DLLEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DLLEN	DLL Operation Enable	0: DLL operation is disabled 1: DLL operation is enabled	R/W
b1	HRRST	High Resolution PWM Waveform Generation Circuit Reset	0: Release from reset 1: Reset	R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register controls the operation of the entire HRPWM module. The register can be written when the register write disable bit in the GPTW write-protection register is enabled (GPTW0.GTWP.WP = 0).

DLLEN Bit (DLL Operation Enable)

This bit selects whether the internal DLL in the HRPWM is activated or not. After activation, wait for 20 µs until the output of the DLL becomes stable.

HRRST Bit (High Resolution PWM Waveform Generation Circuit Reset)

This bit resets the internal state of the HRPWM. After releasing from reset, wait for 12 cycles of PCLKC. When resetting during operation, the PWM output is fixed to low after five cycles of PCLKC.

25.2.2 HRPWM Operation Control Register 2 (HROCR2)

Address(es): HRPWM.HROCR2 000C 2A02h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	HRDIS3	HRDIS2	HRDIS1	HRDIS0	—	—	—	—	HRSEL3	HRSEL2	HRSEL1	HRSEL0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	HRSEL0	Channel 0 High Resolution PWM Waveform Output Select	0: Output an original PWM waveform generated by the GPTW0 from the GTIOC0A and GTIOC0B pins 1: Output a high resolution PWM waveform from the GTIOC0A and GTIOC0B pins	R/W
b1	HRSEL1	Channel 1 High Resolution PWM Waveform Output Select	0: Output an original PWM waveform generated by the GPTW1 from the GTIOC1A and GTIOC1B pins 1: Output a high resolution PWM waveform from the GTIOC1A and GTIOC1B pins	R/W
b2	HRSEL2	Channel 2 High Resolution PWM Waveform Output Select	0: Output an original PWM waveform generated by the GPTW2 from the GTIOC2A and GTIOC2B pins 1: Output a high resolution PWM waveform from the GTIOC2A and GTIOC2B pins	R/W
b3	HRSEL3	Channel 3 High Resolution PWM Waveform Output Select	0: Output an original PWM waveform generated by the GPTW3 from the GTIOC3A and GTIOC3B pins 1: Output a high resolution PWM waveform from the GTIOC3A and GTIOC3B pins	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	HRDIS0	Channel 0 Rising and Falling Edge Adjustment Circuit Disable	0: Enable operation of Channel 0 rising and falling edge adjustment circuit 1: Disable operation of Channel 0 rising and falling edge adjustment circuit	R/W
b9	HRDIS1	Channel 1 Rising and Falling Edge Adjustment Circuit Disable	0: Enable operation of Channel 1 rising and falling edge adjustment circuit 1: Disable operation of Channel 1 rising and falling edge adjustment circuit	R/W
b10	HRDIS2	Channel 2 Rising and Falling Edge Adjustment Circuit Disable	0: Enable operation of Channel 2 rising and falling edge adjustment circuit 1: Disable operation of Channel 2 rising and falling edge adjustment circuit	R/W
b11	HRDIS3	Channel 3 Rising and Falling Edge Adjustment Circuit Disable	0: Enable operation of Channel 3 rising and falling edge adjustment circuit 1: Disable operation of Channel 3 rising and falling edge adjustment circuit	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register controls the HRPWM module by channel. The register can be written when the register write disable bit in the GPTW write-protection register is enabled (GPTW0.GTWP.WP = 0).

HRSELn Bit (Channel n High Resolution PWM Waveform Output Select) (n = 0 to 3)

This bit allows to select whether to output a waveform generated by the HRPWM from the GTIOCnA and GTIOCnB pins (n = 0 to 3) or to output an original waveform of the GPTW by bypassing the circuit.
The PWM waveform generated by the HRPWM is output with a delay of three full cycles of PCLKC from the output when the circuit is bypassed, even if the setting for the amount of delay is 0.

HRDISn Bit (Channel n Rising and Falling Edge Adjustment Circuit Disable) (n = 0 to 3)

This bit enables/disables the operation of the rising and falling edge adjustment circuit by relevant channel in the GPTW.

Set this bit to 1 for a channel which will not be used.

25.2.3 GTIOCnA Pin Rising Edge Adjustment Register (HRREARnA) (n = 0 to 3)

Address(es): HRPWM.HRREAR0A 000C 2A18h, HRPWM.HRREAR1A 000C 2A1Ch, HRPWM.HRREAR2A 000C 2A20h, HRPWM.HRREAR3A 000C 2A24h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	DLY[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	DLY[4:0]	Amount of Delay Select	b4 b0 0 0 0 0 0: Apply delay of 0/32 times PCLKC period 0 0 0 0 1: Apply delay of 1/32 times PCLKC period 0 0 0 1 0: Apply delay of 2/32 times PCLKC period 0 0 0 1 1: Apply delay of 3/32 times PCLKC period 0 0 1 0 0: Apply delay of 4/32 times PCLKC period 0 0 1 0 1: Apply delay of 5/32 times PCLKC period 0 0 1 1 0: Apply delay of 6/32 times PCLKC period 0 0 1 1 1: Apply delay of 7/32 times PCLKC period 0 1 0 0 0: Apply delay of 8/32 times PCLKC period 0 1 0 0 1: Apply delay of 9/32 times PCLKC period 0 1 0 1 0: Apply delay of 10/32 times PCLKC period 0 1 0 1 1: Apply delay of 11/32 times PCLKC period 0 1 1 0 0: Apply delay of 12/32 times PCLKC period 0 1 1 0 1: Apply delay of 13/32 times PCLKC period 0 1 1 1 0: Apply delay of 14/32 times PCLKC period 0 1 1 1 1: Apply delay of 15/32 times PCLKC period 1 0 0 0 0: Apply delay of 16/32 times PCLKC period 1 0 0 0 1: Apply delay of 17/32 times PCLKC period 1 0 0 1 0: Apply delay of 18/32 times PCLKC period 1 0 0 1 1: Apply delay of 19/32 times PCLKC period 1 0 1 0 0: Apply delay of 20/32 times PCLKC period 1 0 1 0 1: Apply delay of 21/32 times PCLKC period 1 0 1 1 0: Apply delay of 22/32 times PCLKC period 1 0 1 1 1: Apply delay of 23/32 times PCLKC period 1 1 0 0 0: Apply delay of 24/32 times PCLKC period 1 1 0 0 1: Apply delay of 25/32 times PCLKC period 1 1 0 1 0: Apply delay of 26/32 times PCLKC period 1 1 0 1 1: Apply delay of 27/32 times PCLKC period 1 1 1 0 0: Apply delay of 28/32 times PCLKC period 1 1 1 0 1: Apply delay of 29/32 times PCLKC period 1 1 1 1 0: Apply delay of 30/32 times PCLKC period 1 1 1 1 1: Apply delay of 31/32 times PCLKC period	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register specifies the amount of delay to apply to rising edge of a PWM waveform output from the GTIOCnA pin. For the transfer timing of register settings, refer to section 25.3.2, Transfer Timing of HRREARnA, HRREARnB, HRFEARnA, and HRFEARnB Register Settings (n = 0 to 3).

This register can be written when the register write disable bit in the GPTW write-protection register is enabled (GPTWn.GTWP.WP = 0).

25.2.4 GTIOCnA Pin Falling Edge Adjustment Register (HRFEARnA) (n = 0 to 3)

Address(es): HRPWM.HRFEAR0A 000C 2A28h, HRPWM.HRFEAR1A 000C 2A2Ch, HRPWM.HRFEAR2A 000C 2A30h, HRPWM.HRFEAR3A 000C 2A34h

	—	—	—	—	—	—	—	—	—	—	—	DLY[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	DLY[4:0]	Amount of Delay Select	b4 b0 0 0 0 0 0: Apply delay of 0/32 times PCLKC period 0 0 0 0 1: Apply delay of 1/32 times PCLKC period 0 0 0 1 0: Apply delay of 2/32 times PCLKC period 0 0 0 1 1: Apply delay of 3/32 times PCLKC period 0 0 1 0 0: Apply delay of 4/32 times PCLKC period 0 0 1 0 1: Apply delay of 5/32 times PCLKC period 0 0 1 1 0: Apply delay of 6/32 times PCLKC period 0 0 1 1 1: Apply delay of 7/32 times PCLKC period 0 1 0 0 0: Apply delay of 8/32 times PCLKC period 0 1 0 0 1: Apply delay of 9/32 times PCLKC period 0 1 0 1 0: Apply delay of 10/32 times PCLKC period 0 1 0 1 1: Apply delay of 11/32 times PCLKC period 0 1 1 0 0: Apply delay of 12/32 times PCLKC period 0 1 1 0 1: Apply delay of 13/32 times PCLKC period 0 1 1 1 0: Apply delay of 14/32 times PCLKC period 0 1 1 1 1: Apply delay of 15/32 times PCLKC period 1 0 0 0 0: Apply delay of 16/32 times PCLKC period 1 0 0 0 1: Apply delay of 17/32 times PCLKC period 1 0 0 1 0: Apply delay of 18/32 times PCLKC period 1 0 0 1 1: Apply delay of 19/32 times PCLKC period 1 0 1 0 0: Apply delay of 20/32 times PCLKC period 1 0 1 0 1: Apply delay of 21/32 times PCLKC period 1 0 1 1 0: Apply delay of 22/32 times PCLKC period 1 0 1 1 1: Apply delay of 23/32 times PCLKC period 1 1 0 0 0: Apply delay of 24/32 times PCLKC period 1 1 0 0 1: Apply delay of 25/32 times PCLKC period 1 1 0 1 0: Apply delay of 26/32 times PCLKC period 1 1 0 1 1: Apply delay of 27/32 times PCLKC period 1 1 1 0 0: Apply delay of 28/32 times PCLKC period 1 1 1 0 1: Apply delay of 29/32 times PCLKC period 1 1 1 1 0: Apply delay of 30/32 times PCLKC period 1 1 1 1 1: Apply delay of 31/32 times PCLKC period	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register specifies the amount of delay to apply to falling edge of a PWM waveform output from the GTIOCnA pin. For the transfer timing of register settings, refer to section 25.3.2, Transfer Timing of HRREARnA, HRREARnB, HRFEARnA, and HRFEARnB Register Settings (n = 0 to 3).

This register can be written when the register write disable bit in the GPTW write-protection register is enabled (GPTWn.GTWP.WP = 0).

25.2.5 GTIOCnB Pin Rising Edge Adjustment Register (HRREARnB) (n = 0 to 3)

Address(es): HRPWM.HRREAR0B 000C 2A1Ah, HRPWM.HRREAR1B 000C 2A1Eh, HRPWM.HRREAR2B 000C 2A22h, HRPWM.HRREAR3B 000C 2A26h

b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register specifies the amount of delay to apply to falling edge of a PWM waveform output from the GTIOCnB pin. For the transfer timing of register settings, refer to section 25.3.2, Transfer Timing of HRREARnA, HRREARnB, HRFEARnA, and HRFEARnB Register Settings (n = 0 to 3).

This register can be written when the register write disable bit in the GPTW write-protection register is enabled (GPTWn.GTWP.WP = 0).

25.3 Operation

25.3.1 Adjustment to the Timing of Rising and Falling Edges in PWM Waveforms

The HRPWM delays timing for rising and falling of the PWM signals which are output from the GPTW with a resolution of 1/32 times (at least around 260 ps) of a PCLKC period (tC(PCLKC)) based on the delay locked loop (DLL) operating with PCLKC as a reference clock. The PWM signal which was delayed is output from the GTIOCnA and GTIOCnB pins (n = 0 to 3).

The amount of delay can be adjusted within a range of 0/32 to 31/32 of tC(PCLKC). The amount of delay out of this range cannot be specified. When setting the amount of delay with the value out of such range, change the setting in the general PWM timer compare capture register m (GTCCRm) in the GPTW.

The HRPWM is required to set the HROCR.DLLEN bit to 1 before operation and wait for stabilization time as it has the DLL. In addition, wait for 12 cycles of PCLKC after setting the HROCR.HRRST bit to 0 in order to output the reliable PWM waveform. Refer to Figure 25.2 for the detailed procedures.

Specify the amount of delay by the HRREARnA and HRFEARnA registers for the GTIOCnA pin and by the HRREARnB and HRFEARnB registers for the GTIOCnB pin. The PWM waveform has specific setting registers for delay at rising and at falling respectively, which allows fine adjustments for the width of high and low. Refer to Table 25.3 for the correspondence between pins and registers.

The amount of delay specified by a relevant register is reflected to the pin via a temporary register. Timing for reflecting the setting differs by PWM output operation mode in the general PWM timer. Refer to section 25.3.2, Transfer Timing of HRREARnA, HRREARnB, HRFEARnA, and HRFEARnB Register Settings (n = 0 to 3).

In the HRPWM, setting of DLL enabling/disabling and reset setting/releasing is common for all channels; however, the rest of settings can be specified individually by channel.

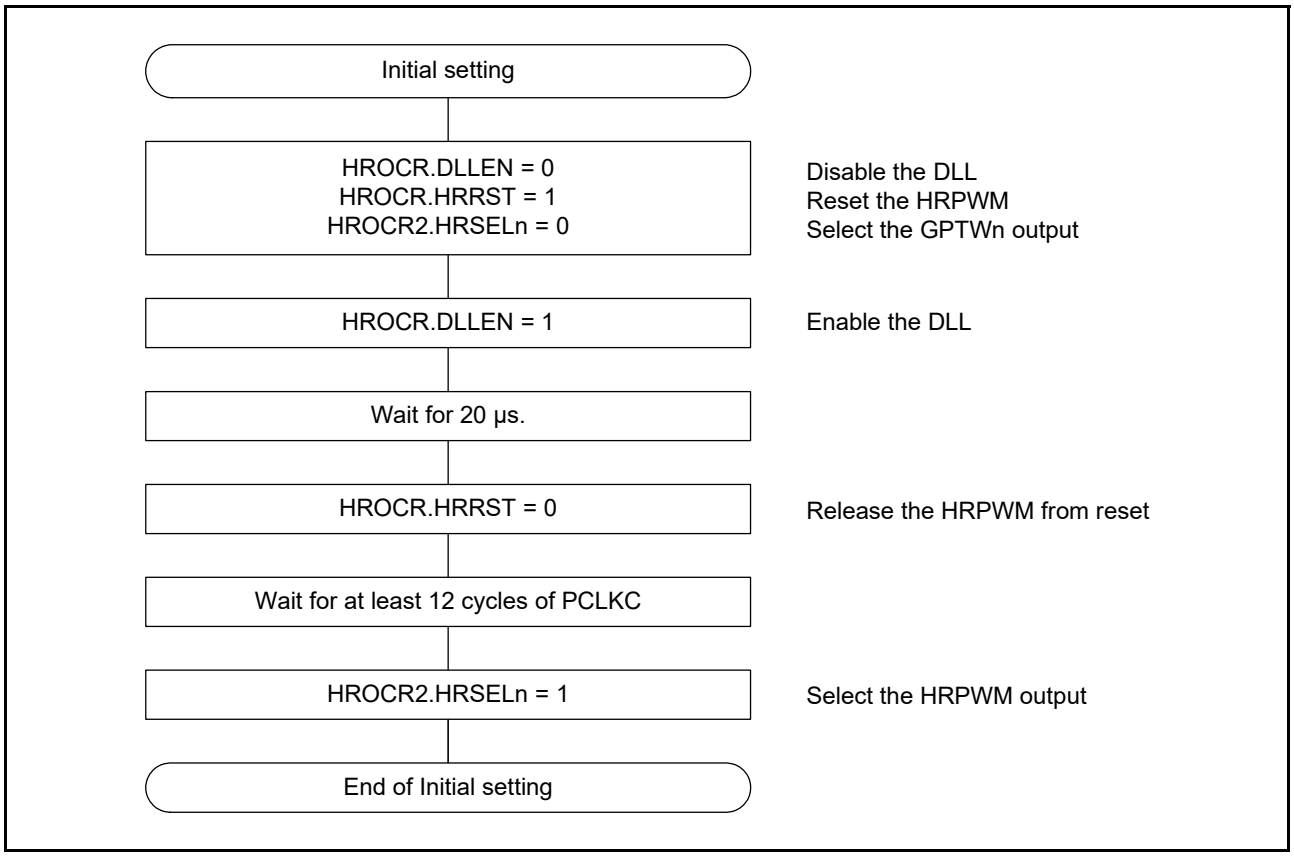

Figure 25.2 Initialization flow for the HRPWM (n = 0 to 3)

Table 25.3 Correspondence between PWM Waveform Output Pins and Delay Setting Registers

PWM Waveform Output Pin	Rising Edge Adjustment Register	Falling Edge Adjustment Register
GTIOC0A	HRREAR0A	HRFEAR0A
GTIOC0B	HRREAR0B	HRFEAR0B
GTIOC1A	HRREAR1A	HRFEAR1A
GTIOC1B	HRREAR1B	HRFEAR1B
GTIOC2A	HRREAR2A	HRFEAR2A
GTIOC2B	HRREAR2B	HRFEAR2B
GTIOC3A	HRREAR3A	HRFEAR3A
GTIOC3B	HRREAR3B	HRFEAR3B

25.3.2 Transfer Timing of HRREARnA, HRREARnB, HRFEARnA, and HRFEARnB Register Settings (n = 0 to 3)

Settings of the HRREARnA, HRREARnB, HRFEARnA, and HRFEARnB registers are transferred to a temporary register first, and reflected to the amount of delay for the PWM waveform in the GTIOCnA and GTIOCnB pins then. Such settings are transferred to a temporary register at the end of PWM period (at an overflow (during up-count operation) or an underflow (during down-count operation) in sawtooth wave mode, and at a trough in triangle wave mode).

Figure 25.3 and Figure 25.4 show examples of the operation of the HRREAR0A and HRFEAR0A registers.

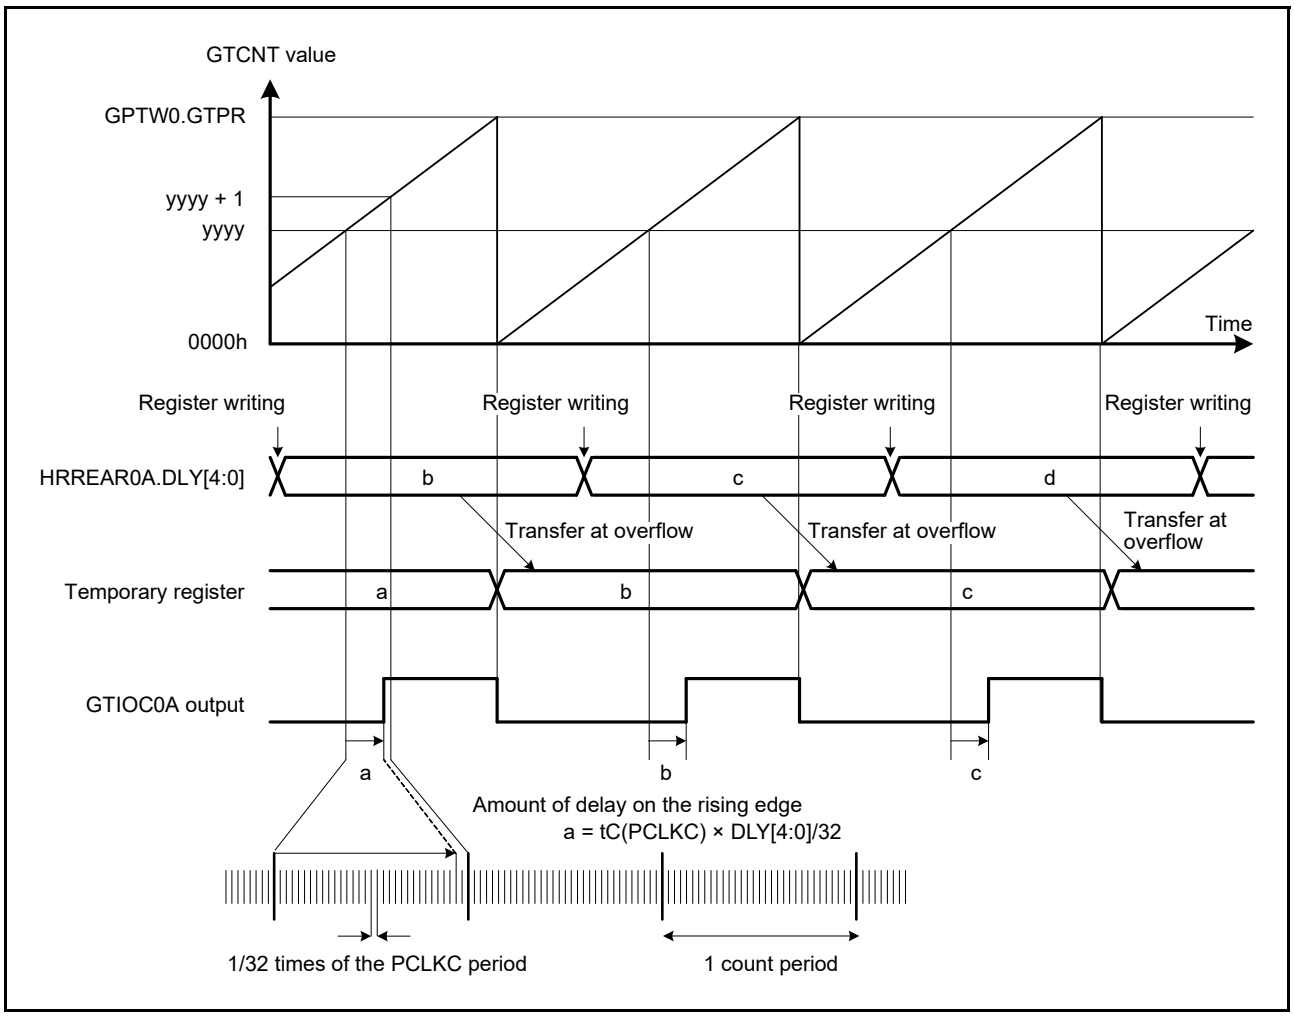

Figure 25.3 Operation Example When Changing the HRREAR0A Register Setting (in Sawtooth Wave Mode)

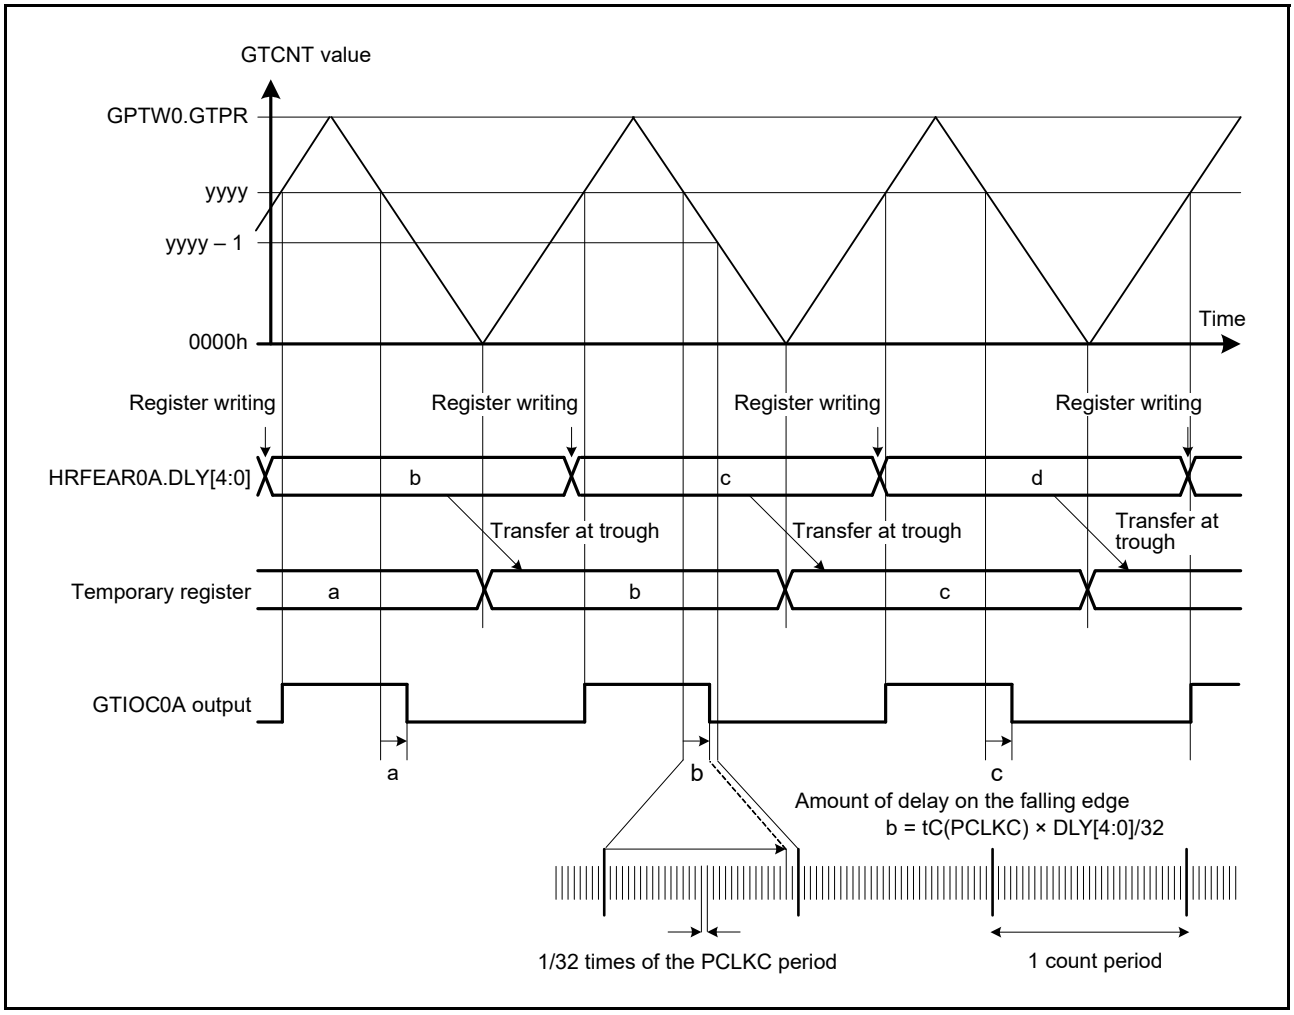

Figure 25.4 Operation Example When Changing the HRFEAR0A Register Setting (in Triangle Wave Mode)

25.4 Usage Notes

25.4.1 Settings for the Module-Stop Function

Operation of the HRPWM can be disabled or enabled using Module Stop Control Register (MSTPCRA). The HRPWM is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, refer to section 11, Low Power Consumption.

25.4.2 Note on Selecting Timer Prescaler in the GTCNT Counter While Using the HRPWM

The PWM signals output from the GPTW are generated based on the GTCNT counter operating at resolution equivalent to one clock period which is set by the GPTWn.GTCR.TPCS[3:0] bits (n = 0 to 3). Note that a delay at resolution of 0/32 × tC(PCLKC) to 31/32 × tC(PCLKC) is applied to edges of the PWM signals at low resolution generated based on a selected clock when a setting for the GPTWn.GTCCRm register (m = A to F) is changed while the TPCS[3:0] bits are specified to the setting other than 0000b (PCLKC/1).

25.4.3 Notes on Delay Settings for HRPWM

Within three cycles of PCLKC from the end of the PWM period, do not change the settings for the HRFEARnA, HRREARnA, HRFEARnB, and HRREARnB registers. Any changes made during the above period will be reflected with a delay of one cycle of the PWM waveform.

26. GPTW Port Output Enable (POEG)

26.1 Overview

The POEG issues requests to stop output from output pins of the general PWM timer (GPTW). The combination of output pins of the POEG to be stopped can be specified from any channel of the GPTW, which is a different form of operation from that of the POE3. Use the POE3 to stop output from pins of the MTU3 and GPTW at the same time. Select the method of detection for stopping the output from the list below.

- Detection of active level or edge input on the GTETRGn pin (n = A to D)
- Detection from the GPTW to stop output
- Detection by comparator (edge detection or level detection)
- Detection of stopping of oscillation by the oscillation stop detection circuit for the main clock
- Register setting

The GTETRGn pin can be used for output to the external trigger input pins of the GPTW.
Table 26.1 shows specifications, Figure 26.1 shows a schematic view of the system, Figure 26.2 shows a block diagram, and Table 26.2 shows input pins.

Table 26.1 POEG Specifications

Item	Description
Request of output stopping in response to detection of active level or edge input	• The request to stop output is issued to the GPTW when a POEGGn.PIDF flag is set in response to the detection of either input of the selected level or the selected edge on the corresponding GTETRGn pin (n = A to D). • The request to stop output is issued to the GPTW immediately upon detection of input of the selected level on the corresponding GTETRGn pin.
Requests to stop output in the form of an output stopping signal from the GPTW	• The request to stop output is issued to the GPTW when the GPTW detects the active level (high or low) on the GTIOCA and GTIOCB pins at the same time while the corresponding POEGGn.IOCF flag is set. • The request to stop output is issued to the GPTW when the GPTW detects a dead-time error while the corresponding POEGGn.IOCF flag is set.
Requests to stop output in response to detection by a comparator	• The request to stop output is issued to the GPTW when a POEGGn.IOCF flag is set in response to edge-detection by a comparator. • The request to stop output is issued directly to the GPTW upon detecting level on a comparator. • The PWM output level on the GPTW output pin selected by the POEGICRn.MSEL[4:0] bits enables or disables requests to stop output.
Requests to stop output in response to detecting the stopping of oscillation	A request to stop output is issued to the GPTW when the oscillation stop detection circuit for the main clock detects the stopping of oscillation while the corresponding POEGGn.OSTPF flag is set.
Requests by software to stop output	The request to stop output is issued to the GPTW when the software sets the POEGGn.SSF flag.
Interrupt	• An interrupt is generated in response to the request to stop output in the form of the POEGGn.PIDF flag. • An interrupt is generated in response to the request to stop output in the form of the POEGGn.IOCF flag.
External trigger output to the GPTW	The GTETRGn pin is used for output as external triggers.
Noise removal	• Each GTETRGn pin has a digital noise filter. • Eight types of sampling clock are selectable for the filter. • The number of samples is selectable as a value from 3 to 6.

R/W

Note 1. Only 0 to clear the flag can be written.
Note 2. This bit can be written only once after resetting.

The POEGGn register (n = A to D) controls requests for stopping output and an external trigger for the GPTW based in response to the detection of various signals.

SSF Flag (Software Stop Flag)

Writing 1 to the SSF flag leads to a request to stop output being issued to the GPTW, and writing 0 to the flag releases the GPTW from the request to stop output. In addition, requests to stop output issued by software can be monitored by reading the flag.

26.2.2 POEG Group n Input Control Register (POEGICRn) (n = A to D)

Address(es): POEG.POEGICRA 0009 E004h, POEG.POEGICRB 0009 E104h, POEG.POEGICRC 0009 E204h, POEG.POEGICRD 0009 E304h

Bit	Symbol	Bit Name	Description	R/W
b15 to b11	MSEL[4:0]	Negate Control Disabling Signal Select	Control for negation is disabled when the selected signal is at the high level. b15 b11 0 0 0 0 0: Control for negation is not disabled. 0 0 0 0 1: The GTIOC0A signal controls the enabling and disabling of negation. 0 0 0 1 0: The GTIOC0B signal controls the enabling and disabling of negation. 0 0 0 1 1: The GTIOC1A signal controls the enabling and disabling of negation. 0 0 1 0 0: The GTIOC1B signal controls the enabling and disabling of negation. 0 0 1 0 1: The GTIOC2A signal controls the enabling and disabling of negation. 0 0 1 1 0: The GTIOC2B signal controls the enabling and disabling of negation. 0 0 1 1 1: The GTIOC3A signal controls the enabling and disabling of negation. 0 1 0 0 0: The GTIOC3B signal controls the enabling and disabling of negation. 0 1 0 0 1: The GTIOC4A signal controls the enabling and disabling of negation. 0 1 0 1 0: The GTIOC4B signal controls the enabling and disabling of negation. 0 1 0 1 1: The GTIOC5A signal controls the enabling and disabling of negation. 0 1 1 0 0: The GTIOC5B signal controls the enabling and disabling of negation. 0 1 1 0 1: The GTIOC6A signal controls the enabling and disabling of negation. 0 1 1 1 0: The GTIOC6B signal controls the enabling and disabling of negation. 0 1 1 1 1: The GTIOC7A signal controls the enabling and disabling of negation. 1 0 0 0 0: The GTIOC7B signal controls the enabling and disabling of negation. Other settings are prohibited.	R/W

The GTONCCRn register (n = A to D) set up requests for stopping output in response to detected signals.

NE Bit (Direct Stopping Request Setting)

Writing 1 to the NE bit leads to direct output of the stopping request signal in response to the signal for detection selected by the NFS[3:0] bits.

26.3 Operation

26.3.1 Request to Stop Output in Response to Detection of Active Level or Edge Input on the Corresponding GTETRGn Pin (n = A to D)

There are two types of output stopping request: requests in response to setting of the POEGGn.PIDF flag (n = A to D), and requests directly in response to the detected signal.

(1) To request the stopping of output in response to setting of the PIDF flag, the input level or edge in accord with the settings of the following bits of the POEGGn register—inversion or non-inversion in the INV bit, detection of a level or edge in the ELSEL bit, use or non-use of the clock division ratio in the NFPSC bit, number of samples for filtering in the NFSN[1:0] bits, enabling or disabling of filtering by the NFEN bit, and the sample clock for filtering in the NFCS[1:0] bits—is detected while the POEGGn.PIDE bit is 1. After the POEGGn.PIDF flag is set to 1 in response to this, a request to stop output is issued per group to each channel of the GPTW. To de-assert the request signal for stopping output, clear the POEGGn.PIDF flag. For canceling requests to stop output, refer to section 26.3.6, Canceling Requests to Stop Output.

(2) To request the stopping of output in direct response to detection of the active level input of a selected signal, the input level in accord with the settings of the following bits of registers—inversion or non-inversion in the INV bit, use or non-use of the clock division ratio in the NFPSC bit, number of samples for filtering in the NFSN[1:0] bits, enabling or disabling of filtering by the NFEN bit, and the sample clock for filtering in the NFCS[1:0] bits of the POEGGn register, and the active sense in the NFV bit of the GTONCCRn register—on the GTETRGn pin selected in the GTONCCRn.NFS[3:0] bits is detected while the GTONCCRn.NE bit is 1, and a request to stop output is then directly issued per group to each channel of the GPTW. The signal to request stopping of output is de-asserted when the detected input level does not match the conditions for issuing a request. For details, refer to section 26.3.7, Requests to Stop Output in Response to Detected Signals and Canceling the Requests.

26.3.1.1 Digital Noise Filter

Each GTETRGn pin input has a digital noise filter. Figure 26.3 shows the operation example in detection of the high level with the use of the filter. When the digital noise filter is enabled, that is, the setting of POEGGn.NFEN bit is 1, and the high level is detected consecutively for the number of samples selected by the POEGGn.NFSN[1:0] bits with the sampling clock period selected by the combination of the POEGGn.NFPSC and POEGGn.NFCS[1:0] bits with inversion or non-inversion in accord with the setting of the POEGGn.INV bit, this is regarded as detection of the high level, and a request to stop output is issued to the GPTW.

At this time, if the low level is detected even once in the sequence, it is not regarded as detection of the high level. In addition, changes in the levels on pins GTETRGA through GTETRGD are ignored while the sampling clock is not being output.

Digital noise filters can be used with requests to stop output in response to setting of the POEGGn.PIDF flags (n = A to D), requests to stop output in direct response to a detected signal, and the output of external triggers to the GPTW.

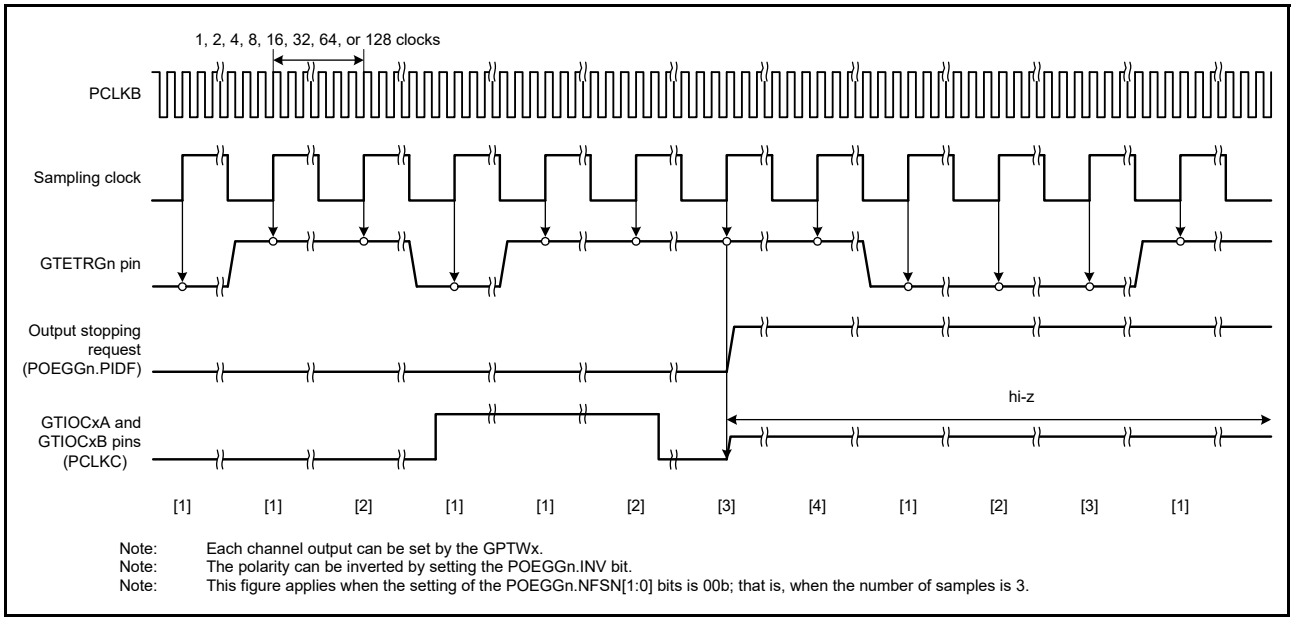

Figure 26.3 Example for Operation of Digital Noise Filter

26.3.2 Requests to Stop Output in Response to Detection of Output Stopping form GPTW

When any among a dead-time error or simultaneous high- or low-level output from the GPTW is detected, the corresponding POEGGn.IOCF flag is set to 1 and the request to stop output per group is issued to each channel in the GPTW. The POEGGn.IOCF flag is used to indicate both edge detection by the comparator and requests to stop output. To cancel a request to stop output, clear the given POEGGn.IOCF flag. For details, refer to section 26.3.6, Canceling Requests to Stop Output.

To detect any among a dead-time error or simultaneous high- or low-level output from the GPTW, detection of output stopping must be permitted in the GRPDTE, GRPABH, and GRPABL bits of the given GPTWn.GTINTAD register. Specify the group of the GPTW for which stopping is to be detected in the GPTWn.GTINTAD.GRP[1:0] bits. For details, refer to section 24.2.15, General PWM Timer Interrupt Output Setting Register (GTINTAD).

26.3.3 Request to Stop Output in Response to Comparator Detection

A request to stop output can be issued to the GPTW in response to detection by a comparator. There are two types of request to stop output: requests output in response to setting of a POEGGn.IOCF flag (n = A to D) due to edge detection by the comparator and requests that are directly output in response to level detection by the comparator. Requests to stop output due to comparator interrupt requests can be controlled in accord with the PWM output level on the GPTW output pin selected by the POEGICRn.MSEL[4:0] bits. The requests are disabled while the output on the given pin is at the high level.

(1) To stop output in response to setting of an IOCF flag, the corresponding edge is detected by the comparator while the POEGGn.CDRE[5:0] bits are 1. The POEGGn.IOCF flag is then set to 1, which leads to a request to stop output from the given group for each channel of the GPTW. The POEGGn.IOCF flag is used for both comparator edge detection and the request to stop output. To cancel the request to stop output, clear the POEGGn.IOCF flag. For details, refer to section 26.3.6, Canceling Requests to Stop Output.

(2) The output can also be stopped by using a detected signal as a direct request to stop output. When the comparator level detection signal selected in the GTONCCRn.NFS[3:0] bits matches the level set in the GTONCCRn.NFV bit, the request to stop output per group is issued to each channel of the GPTW. The request to stop output is released when the comparator level detection does not match the issuing conditions. For details, refer to section 26.3.7, Requests to Stop Output in Response to Detected Signals and Canceling the Requests.

26.3.4 Requests to Stop Output by Oscillation Stop Detection

When the circuit for detecting stopping of oscillation by the main clock oscillator detects the stopping of the oscillation while a POEGGn.OSTPE bit is 1, the POEGGn.OSTPF flag is set to 1 and a request to stop output per group is issued to each channel of the GPTW. To cancel the request to stop output, clear the POEGGn.OSTPF flag. For details, refer to section 26.3.6, Canceling Requests to Stop Output.

26.3.5 Requests to Stop Output by a Register

Writing 1 to the software stop flag (POEGGn.SSF) leads to a request to stop output per group to each channel in the GPTW. To release from the request to stop output, clear the POEGGn.SSF flag. For details, refer to section 26.3.6, Canceling Requests to Stop Output.

26.3.6 Canceling Requests to Stop Output

Requests to stop output are canceled in any of the following three ways.

(1) Cancellation by a reset (return to the initial state)

(2) Cancellation by clearing all flags in the POEGGn register

(3) Cancellation in response to direct input of a detected signal

(1) Cancellation by a reset

Any type of reset can cancel a request to stop output. For details, refer to section 6, Resets.

(2) Cancellation by clearing all flags in the POEGGn register

- POEGGn.PIDF
- POEGGn.IOCF
- POEGGn.OSTPF
- POEGGn.SSF

Cancellation of the request is taken into the GPTW at the end of the cycle of counting by the GPTW, and the output pins are released from being stopped no less than 3 PCLKC cycles from that time. Figure 26.4 shows the timing of release from the output-stopped state. To clear each of the flags, read the status flag for each source to check that the source condition is not being detected, and then write 0. Sources other than the edge detection by the comparators cannot be cleared even if the flag is cleared in the detected state. Since the comparators detect edges in edge detection, writing 0 in the detected state clears the flag, and the flag is not set until the relevant source generates the next edge. Status flags for the respective sources are listed below.

- Detection of input level — POEGGn.ST (GTETRGn input status flag)
- Comparator edge detection — CMPCn.CMPMON.CMPMON0 (comparator output monitoring flag)
- Oscillation stop detection — OSTDSR.OSTDF (oscillation stop detection flag)
- Stopping detection from the GPTW — GPTWn.GTST.DTEF (dead time error flag)
  GPTWn.GTST.OABLF (simultaneous low output flag)
  GPTWn.GTST.OABHF (simultaneous high output flag)

Note 1. CMPCn.CMPMON.CMPMON0 are the monitoring flags for the comparator outputs.

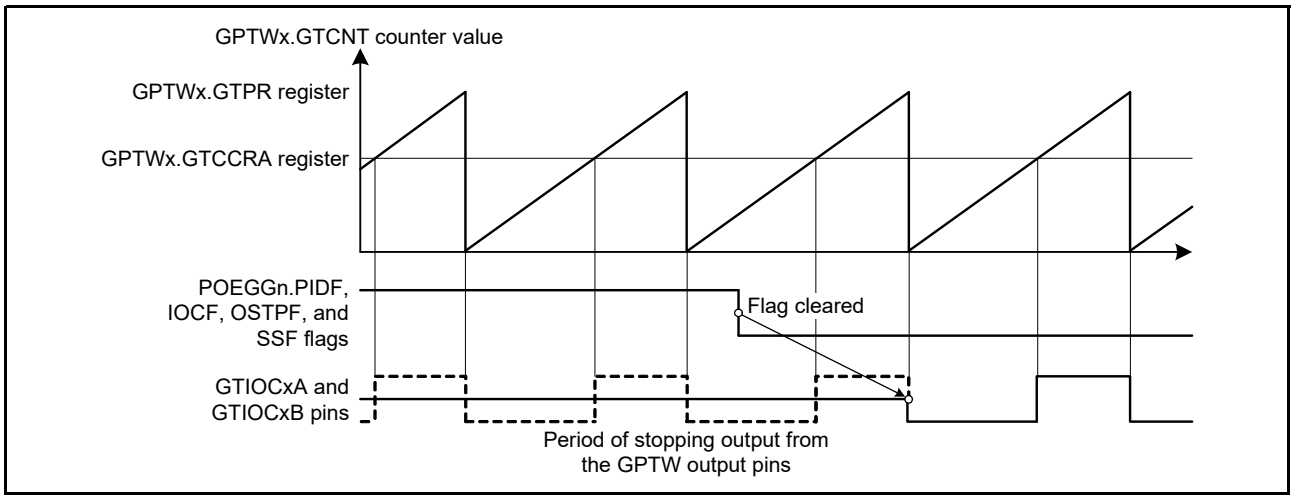

Figure 26.4 Timing of Re-enabling Output from the GPTW Output Pins Following Cancellation of a Request to Stop Output

(3) Cancellation in response to direct input of a detected signal

For details, refer to section 26.3.7, Requests to Stop Output in Response to Detected Signals and Canceling the Requests.

26.3.7 Requests to Stop Output in Response to Detected Signals and Canceling the Requests

The input level detection signals on the GTETRGn pin (n = A to D) and comparator level detection signals on the CMPCm pin (m = 0 to 5) can be used as direct requests to stop output in response to detected signals. The sources of the signals for detection are selected in the GTONCCRn.NFS[3:0] bits, and the active senses of the signals for detection are set in the GTONCCRn.NFV bit. Setting a GTONCCRn.NE bit to activate direct requests to stop output results in the issuing of a request to stop output to the GPTW when the selected source signal for output stopping detection is generated.

The request to stop output is released when the input level detection signal on the given GTETRGn pin or comparator level detection does not match the issuing conditions. To cancel a request, confirm that the values of the PIDF and IOCF flags in the POEGGn register have become 0.

Figure 26.5 shows the operation of a request to stop output issued in response to level detection by the COMP0. The example shows the case where the comparator detects the analog input voltage on CMPC0 becoming higher than the reference voltage while the GPTW is producing PWM waveforms on the GTIOC0A pin on a cyclic-counting basis, and the level-detection signal from the comparator is input to the POEG. The POEG outputs a request to stop output to the GPTW on the basis of detection as described above, and the GPTW remains stopped until the end of the cycle of counting, even if the request to stop output is canceled before then.

If the request to stop output has not been canceled at the end of the cycle of counting cycle, output from the GPTW remains stopped until the end of the next cycle of counting, and so on.

The output-stopped state can be checked by reading the ODF flag in General PWM Timer Status Register (GTST) of the GPTW. For details, refer to the description of the ODF flag in section 24.2.16, General PWM Timer Status Register (GTST). Figure 26.6 shows the procedure for setting requests to stop output in response to detected signals.

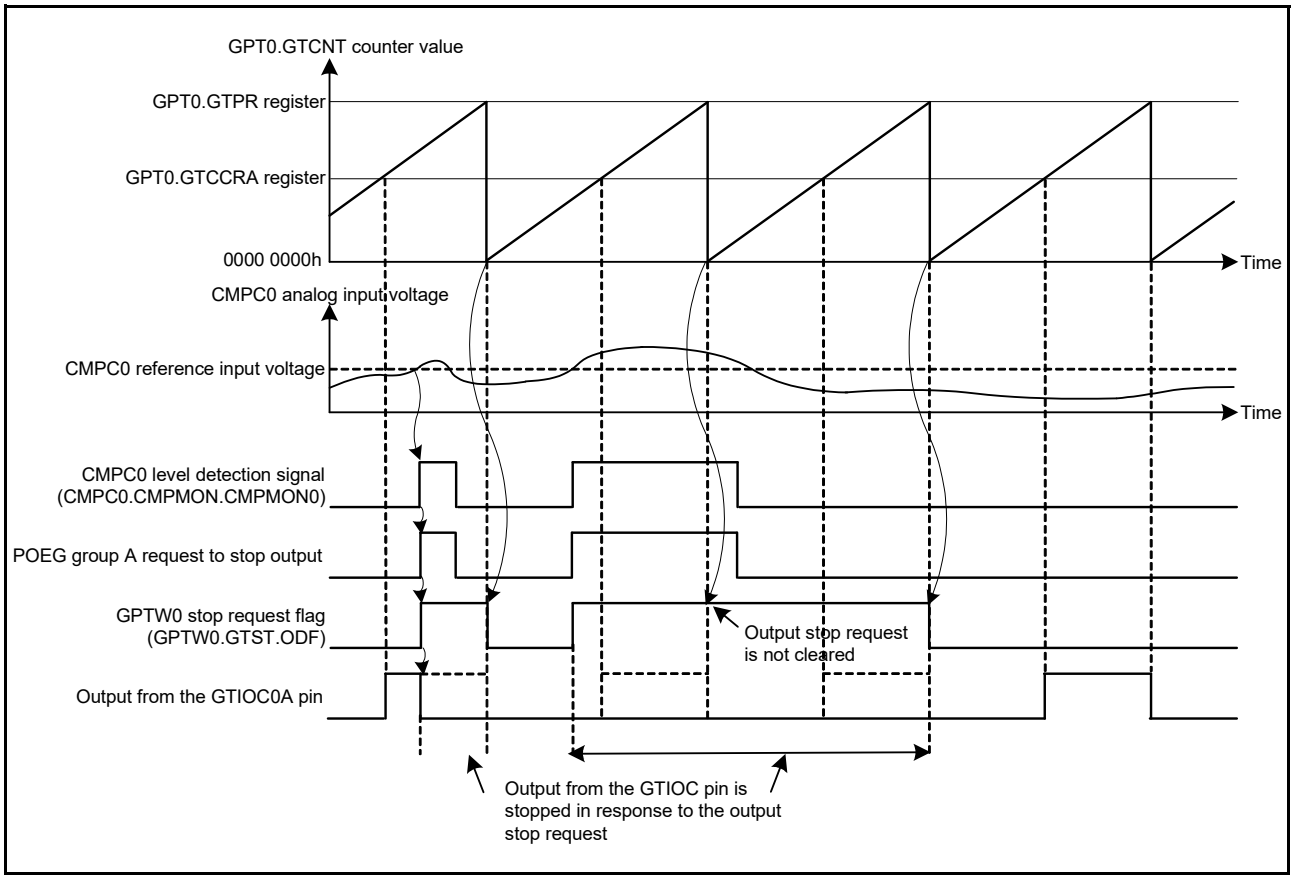

Figure 26.5 Example of Operation to Stop Output from the GTIOC Pin in Response to Level Detection by a Comparator

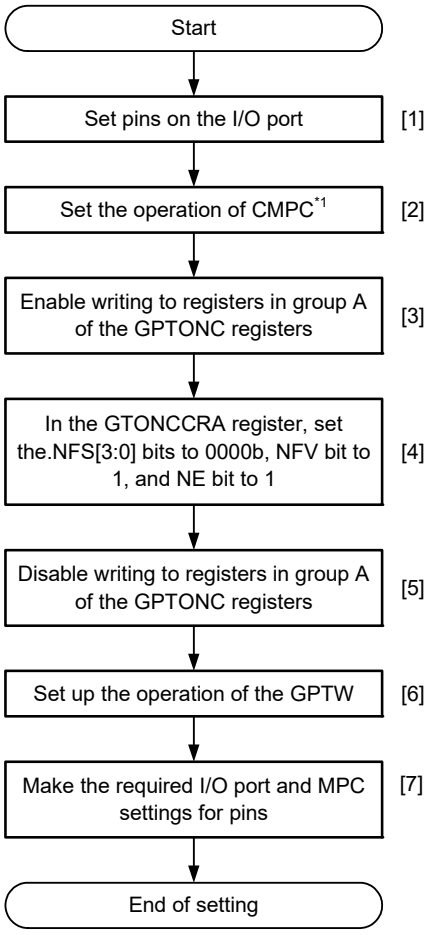

[1] Make the I/O port settings.
Set the corresponding pins of the I/O port to general purpose I/O port pins in order to use the CMPC0 analog input pin function and GPTW output pin function. For details, refer to section 20, I/O Ports.

[2] Set the operation of CMPC0 to output a level detection signal to the POEG in response to comparing the analog input voltage and reference input voltage. For details, refer to section 45, Comparator C (CMPCa).*1

[3] Write A500h to the GTONCWPA register to enable writing to the GTONCCPRA register.

[4] Select level detection for the comparator by setting the GTONCCRA.NFS[3:0] bits to 0000b. Set the GTONCCRA.NFV bit to 1 so that the request to stop output is sent when the selected source indicates 1.
Set the GTONCCRA.NE bit to 1 to enable the output of requests to stop output.

[5] Write A501h to the GTONCWPA register to disable writing to the GTONCCPRA register.

[6] Set the GPTW for the output of a PWM waveform on its GTIOCn pin. For details, refer to section 24, General PWM Timer (GPTWa).

[7] Set the I/O port and multifunction-pin controller.
Set the I/O port and multifunction-pin controller in order to use the required analog input pin of CMPC0 and output pin of the GPTW. For details, refer to section 20, I/O Ports, and section 21, Multi-Function Pin Controller (MPC).

The settings described above lead to the output of requests to stop output in response to comparison of the analog input voltage and reference input voltage while a PWM waveform is being output from the GPTW pin, stopping output from the GPTW pin.

Note 1. In this example, the comparator output is non-inverted.

Figure 26.6 Example of Settings to Stop Output on the GTIOC Pin in Response to Level Detection by a Comparator

26.4 Interrupt Sources

The POEG generates interrupts for the interrupt controller when any of the following is detected.

- Detection of level of input, indicated by the POEGGn.PIDF flag
- Detection of stopping of output from the GPTW, indicated by the POEGGn.IOCF flag
- Detection of edges by the comparator, indicated by the POEGGn.IOCF flag

Table 26.3 shows interrupt sources and conditions.

Table 26.3 Interrupt sources and conditions

Interrupt Source	Symbol	Corresponding Flag	Trigger Condition
POEG Group A Interrupt	POEGGAI	POEGGA.IOCF	Detection of stopping of output from the GPTW
			Detection of edges by the comparator
		POEGGA.PIDF	Detection of the level input from the GTETRGA pin
POEG Group B Interrupt	POEGGBI	POEGGB.IOCF	Detection of stopping of output from the GPTW
			Detection of edges by the comparator
		POEGGB.PIDF	Detection of the level input from the GTETRGB pin
POEG Group C Interrupt	POEGGCI	POEGGC.IOCF	Detection of stopping of output from the GPTW
			Detection of edges by the comparator
		POEGGC.PIDF	Detection of the level input from the GTETRGC pin
POEG Group D Interrupt	POEGGDI	POEGGD.IOCF	Detection of stopping of output from the GPTW
			Detection of edges by the comparator
		POEGGD.PIDF	Detection of the level input from the GTETRGD pin

26.5 External Trigger Output to GPTW

The POEG outputs the inputs on the GTETRGn pin (n = A to D) as external trigger signals. The external trigger signals can be monitored by the POEGGn.ST flag via active-sense selection and digital noise filtering. The GPTW can function as follows in response to external trigger signals.

- Count start
- Count stop
- Counter clearing
- Up-counting
- Down-counting
- Input capture

For details of the above functions, refer to section 24, General PWM Timer (GPTWa).

26.6 Usage Notes

26.6.1 Transitions to Low-Power Consumption Mode

When the POEG is used, it should not be transitioned to software standby mode. In this mode, the stopping of output cannot be requested since the POEG is stopped.

26.6.2 Setting the Function for Stopping the Module

The module-stop control register can be set to enable or disable operation of the POEG. The POEG is stopped immediately after a reset. Registers of the POEG become accessible following release from the module-stopped state. For details, refer to section 11, Low Power Consumption. The module-stop bit for the POEG also stops and starts the GPTW.

26.6.3 Duplication of Requests to Stop Output

While either the PIDF or IOCF flag in the POEGGn register is 1, cancellation of requests to stop by the detection signal set in the GTONCCRn register does not work due to the request to stop still being output because of the value of the flag. That is, note that requests to stop output will not be canceled when a corresponding flag is set stop output in response to detection. Request signals to stop output in response to flag setting are obtained as the logical OR of the corresponding detection signals for stopping output.

27. 8-Bit Timer (TMRb)

This MCU has four units (unit 0, unit 1, unit 2, unit 3) of an on-chip 8-bit timer (TMR) module that comprise two 8-bit counter channels, totaling eight channels. The 8-bit timer module can be used to count external events and also be used as a multi-function timer in a variety of applications, such as generation of counter reset signal, interrupt requests, and pulse output with a desired duty cycle using a compare-match signal with two registers.
Unit 0, unit 1, unit 2, and unit 3 have the same functions, and unit 0 and unit 1 can generate a base clock for the SCI.
In this section, “PCLK” is used to refer to PCLKB.

27.1 Overview

Table 27.1 lists the specifications of the TMR. Table 27.2 and Table 27.3 list the TMR functions.
Figure 27.1 shows a block diagram of the 8-bit timer module (unit 0), Figure 27.2 shows that of the 8-bit timer module (unit 1), Figure 27.3 shows that of the 8-bit timer module (unit 2), and Figure 27.3 shows that of the 8-bit timer module (unit 3).

Table 27.1 Specifications of TMR

Item	Description
Count clock	• Internal clock: PCLK/1, PCLK/2, PCLK/8, PCLK/32, PCLK/64, PCLK/1024, PCLK/8192 • External clock: external count clock
Number of channels	(8 bits × 2 channels) × 4 units
Compare match	• 8-bit mode (compare match A, compare match B) • 16-bit mode (compare match A, compare match B)
Counter clear	Selected by compare match A or B, or an external counter reset signal.
Timer output	Output pulses with a desired duty cycle or PWM output
Cascading of two channels	• 16-bit count mode 16-bit timer using TMR0 for the upper 8 bits and TMR1 for the lower 8 bits (TMR2 for the upper 8 bits and TMR3 for the lower 8 bits, TMR4 for the upper 8 bits and TMR5 for the lower 8 bits, TMR6 for the upper 8 bits and TMR7 for the lower 8 bits) • Compare match count mode TMR1 can be used to count TMR0 compare matches (TMR3 can be used to count TMR2 compare matches, TMR5 can be used to count TMR4 compare matches, TMR7 can be used to count TMR6 compare matches).
Interrupt sources	Compare match A, compare match B, and overflow
Event link function (Output)	Compare match A, compare match B, and overflow (TMR0 to TMR3)
Event link function (Input)	One of the following three operations proceeds in response to an event reception: (1) Counting start operation (TMR0 to TMR3) (2) Event counting operation (TMR0 to TMR3) (3) Counting restart operation (TMR0 to TMR3)
DTC activation	DTC can be activated by compare match A interrupts or compare match B interrupts.
A/D conversion start trigger of the A/D converter	Compare match A of TMR0, TMR2, TMR4, and TMR6
Capable of generating base clock for SCI	Generates base clock for SCI.*1
Low power consumption function	Each unit can be placed in a module stop state

Note 1. For details, refer to section 32, Serial Communications Interface (SCIk, SCIh).

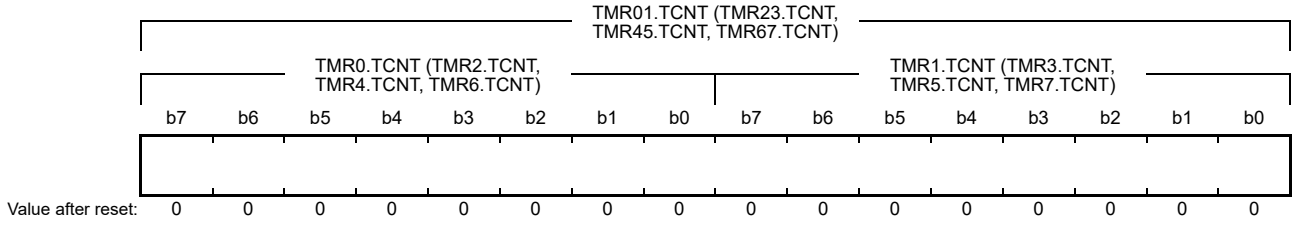
27.2.1 Timer Counter (TCNT)

Address(es): TMR0.TCNT 0008 8208h, TMR1.TCNT 0008 8209h, TMR2.TCNT 0008 8218h, TMR3.TCNT 0008 8219h, TMR4.TCNT 0008 8228h, TMR5.TCNT 0008 8229h, TMR6.TCNT 0008 8238h, TMR7.TCNT 0008 8239h, TMR01.TCNT 0008 8208h, TMR23.TCNT 0008 8218h, TMR45.TCNT 0008 8228h, TMR67.TCNT 0008 8238h



TCNT is an 8-bit readable/writable up-counter.

TMR0.TCNT and TMR1.TCNT (TMR2.TCNT and TMR3.TCNT, TMR4.TCNT and TMR5.TCNT, TMR6.TCNT and TMR7.TCNT) comprise a single 16-bit counter (TMR01.TCNT, TMR23.TCNT, TMR45.TCNT, TMR67.TCNT) so they can be accessed together in 16-bit units.

The TCCR.CSS[1:0] and CKS[2:0] bits are used to select a count clock.

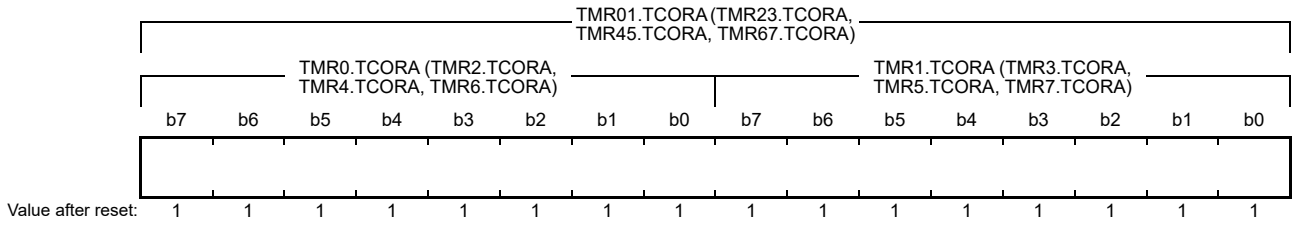
TCNT can be cleared by an external counter reset signal, compare match A, or compare match B. Which compare match to be used for clearing is selected by the TCR.CCLR[1:0] bits.

When TCNT overflows (its value changes from FFh to 00h), an overflow interrupt is output provided the interrupt request is enabled by the TCR.OVIE bit.

For details on the corresponding interrupt vector number, refer to section 14, Interrupt Controller (ICUG), and Table 27.7, TMR Interrupt Sources.

27.2.2 Time Constant Register A (TCORA)

Address(es): TMR0.TCORA 0008 8204h, TMR1.TCORA 0008 8205h, TMR2.TCORA 0008 8214h, TMR3.TCORA 0008 8215h, TMR4.TCORA 0008 8224h, TMR5.TCORA 0008 8225h, TMR6.TCORA 0008 8234h, TMR7.TCORA 0008 8235h, TMR01.TCORA 0008 8204h, TMR23.TCORA 0008 8214h, TMR45.TCORA 0008 8224h, TMR67.TCORA 0008 8234h



TCORA is an 8-bit readable/writable register.

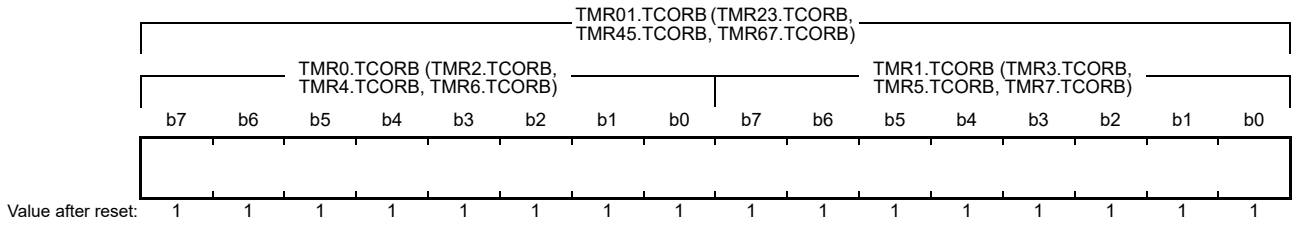
TMR0.TCORA and TMR1.TCORA (TMR2.TCORA and TMR3.TCORA, TMR4.TCORA and TMR5.TCORA, TMR6.TCORA and TMR7.TCORA) comprise a single 16-bit register (TMR01.TCORA, TMR23.TCORA, TMR45.TCORA, TMR67.TCORA) so they can be accessed together in 16-bit units.

The value in TCORA is continually compared with the value in TCNT. When a match is detected, the corresponding compare match A is generated, and a compare match A interrupt is output provided the interrupt request is enabled by the TCR.CMIEA bit.

However, comparison is not performed during writing to TCORA. The timer output from the TMOn pin can be freely controlled by this compare match A and the settings of the TCSR.OSA[1:0] bits.

27.2.3 Time Constant Register B (TCORB)

Address(es): TMR0.TCORB 0008 8206h, TMR1.TCORB 0008 8207h, TMR2.TCORB 0008 8216h, TMR3.TCORB 0008 8217h, TMR4.TCORB 0008 8226h, TMR5.TCORB 0008 8227h, TMR6.TCORB 0008 8236h, TMR7.TCORB 0008 8237h, TMR01.TCORB 0008 8206h, TMR23.TCORB 0008 8216h, TMR45.TCORB 0008 8226h, TMR67.TCORB 0008 8236h



TCORB is an 8-bit readable/writable register.

TMR0.TCORB and TMR1.TCORB (TMR2.TCORB and TMR3.TCORB, TMR4.TCORB and TMR5.TCORB, TMR6.TCORB and TMR7.TCORB) comprise a single 16-bit register (TMR01.TCORB, TMR23.TCORB, TMR45.TCORB, TMR67.TCORB) so they can be accessed together in 16-bit units.

The value in TCORB is continually compared with the value in TCNT. When a match is detected, the corresponding compare match B is generated, and a compare match B interrupt is output provided the interrupt request is enabled by the TCR.CMIEB bit.

However, comparison is not performed during writing to TCORB. The timer output from the TMOn pin can be freely controlled by this compare match B and the settings of the TCSR.OSB[1:0] bits.

27.2.4 Timer Control Register (TCR)

Address(es): TMR0.TCR 0008 8200h, TMR1.TCR 0008 8201h, TMR2.TCR 0008 8210h, TMR3.TCR 0008 8211h, TMR4.TCR 0008 8220h, TMR5.TCR 0008 8221h, TMR6.TCR 0008 8230h, TMR7.TCR 0008 8231h

	b7	b6	b5	b4	b3	b2	b1	b0
	CMIEB	CMIEA	OVIE	CCLR[1:0]		—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4, b3	CCLR[1:0]	Counter Clear	b4 b3 0 0: Clearing is disabled 0 1: Cleared by compare match A 1 0: Cleared by compare match B 1 1: Cleared by the external counter reset signal*1 (Select edge or level by the TMRIS bit in TCCR.)	R/W
b5	OVIE	Overflow Interrupt Enable	0: Overflow interrupt requests (OVIn) are disabled 1: Overflow interrupt requests (OVIn) are enabled	R/W
b6	CMIEA	Compare Match A Interrupt Enable	0: Compare match A interrupt requests (CMIAn) are disabled 1: Compare match A interrupt requests (CMIAn) are enabled	R/W
b7	CMIEB	Compare Match B Interrupt Enable	0: Compare match B interrupt requests (CMIBn) are disabled 1: Compare match B interrupt requests (CMIBn) are enabled	R/W

Note 1. To use an external counter reset signal, set the corresponding pin function. For details, refer to section 20, I/O Ports and section 21, Multi-Function Pin Controller (MPC).

CCLR[1:0] Bits (Counter Clear)

Select the condition by which TCNT is cleared.

OVIE Bit (Overflow Interrupt Enable)

Selects whether overflow interrupt requests (OVIn) issued by TCNT are enabled or disabled.

CMIEA Bit (Compare Match A Interrupt Enable)

Selects whether compare match A interrupt requests (CMIAn) that are issued when the value of TCORA corresponds to that of TCNT are enabled or disabled.

CMIEB Bit (Compare Match B Interrupt Enable)

Selects whether compare match B interrupt requests (CMIBn) that are issued when the value of TCORB corresponds to that of TCNT are enabled or disabled.

27.2.5 Timer Counter Control Register (TCCR)

Address(es): TMR0.TCCR 0008 820Ah, TMR1.TCCR 0008 820Bh, TMR2.TCCR 0008 821Ah, TMR3.TCCR 0008 821Bh, TMR4.TCCR 0008 822Ah, TMR5.TCCR 0008 822Bh, TMR6.TCCR 0008 823Ah, TMR7.TCCR 0008 823Bh, TMR01.TCCR 0008 820Ah, TMR23.TCCR 0008 821Ah, TMR45.TCCR 0008 822Ah, TMR67.TCCR 0008 823Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	TMRIS	—	—	CSS[1:0]		CKS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CKS[2:0]	Clock Select*1	See Table 27.6.	R/W
b4, b3	CSS[1:0]	Clock Source Select	See Table 27.6.	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	TMRIS	Timer Reset Detection Condition Select	0: Cleared at rising edge of the external counter reset signal 1: Cleared when the external counter reset signal is high	R/W

Note 1. To use an external count clock, set the corresponding pin function. For details, refer to section 20, I/O Ports and section 21, Multi-Function Pin Controller (MPC).

TCCR register is a 8-bit register used to configure the basic operation of the counter. Two TCCR registers can be accessed simultaneously by accessing the address of the even channel TCCR register in 16-bit units.

CKS[2:0] Bits (Clock Select)
CSS[1:0] Bits (Clock Source Select)

The CKS[2:0] and CSS[1:0] bits select a clock. For details, see Table 27.6.

TMRIS Bit (Timer Reset Detection Condition Select)

This bit is enabled when the TCR.CCLR[1:0] bits are 11b (cleared by external counter reset signal) and selects the condition for detecting counter reset (level or edge).

Table 27.6 Clock Input to TCNT and Count Condition

Channel	TCCR Register CSS[1:0] b4	b3	CKS[2:0] b2	b1	b0	Description
TMR0 (TMR2, TMR4, TMR6)	0	0	—	0	0	Clock input prohibited
					1	Uses external count clock. Counts at rising edge*1.
				1	0	Uses external count clock. Counts at falling edge*1.
					1	Uses external count clock. Counts at both rising and falling edges*1.
	0	1	0	0	0	Uses internal clock. Counts at PCLK.
					1	Uses internal clock. Counts at PCLK/2.
				1	0	Uses internal clock. Counts at PCLK/8.
					1	Uses internal clock. Counts at PCLK/32.
			1	0	0	Uses internal clock. Counts at PCLK/64.
					1	Uses internal clock. Counts at PCLK/1024.
				1	0	Uses internal clock. Counts at PCLK/8192.
					1	Clock input prohibited
	1	0	—	—	—	Setting prohibited
	1	1	—	—	—	Counts at TMR1.TCNT (TMR3.TCNT, TMR5.TCNT, TMR7.TCNT) overflow signal*2.
TMR1 (TMR3, TMR5, TMR7)	0	0	—	0	0	Clock input prohibited
					1	Uses external count clock. Counts at rising edge*1.
				1	0	Uses external count clock. Counts at falling edge*1.
					1	Uses external count clock. Counts at both rising and falling edges*1.
	0	1	0	0	0	Uses internal clock. Counts at PCLK.
					1	Uses internal clock. Counts at PCLK/2.
				1	0	Uses internal clock. Counts at PCLK/8.
					1	Uses internal clock. Counts at PCLK/32.
			1	0	0	Uses internal clock. Counts at PCLK/64.
					1	Uses internal clock. Counts at PCLK/1024.
				1	0	Uses internal clock. Counts at PCLK/8192.
					1	Clock input prohibited
	1	0	—	—	—	Setting prohibited
	1	1	—	—	—	Counts at TMR0.TCNT (TMR2.TCNT, TMR4.TCNT, TMR6.TCNT) compare match A*2.

Note 1. To use an external count clock, set the corresponding pin function. For details, refer to section 20, I/O Ports and section 21, Multi-Function Pin Controller (MPC).

Note 2. If the clock input of TMR0 (TMR2, TMR4, TMR6) is the overflow signal of the TMR1.TCNT (TMR3.TCNT, TMR5.TCNT, TMR7.TCNT) counter and that of TMR1 (TMR3, TMR5, TMR7) is the compare match signal of the TMR0.TCNT (TMR2.TCNT, TMR4.TCNT, TMR6.TCNT) counter, no TCNT count clock is generated. Do not use this setting.

27.2.6 Timer Control/Status Register (TCSR)

- TMR0.TCSR, TMR2.TCSR, TMR4.TCSR, TMR6.TCSR

Address(es): TMR0.TCSR 0008 8202h, TMR2.TCSR 0008 8212h, TMR4.TCSR 0008 8222h, TMR6.TCSR 0008 8232h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	ADTE	OSB[1:0]		OSA[1:0]	
Value after reset:	x	x	x	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b1, b0	OSA[1:0]	Output Select A*1	b1 b0 0 0: No change 0 1: Low is output 1 0: High is output 1 1: Output is inverted (toggle output)	R/W
b3, b2	OSB[1:0]	Output Select B*1	b3 b2 0 0: No change 0 1: Low is output 1 0: High is output 1 1: Output is inverted (toggle output)	R/W
b4	ADTE	A/D Trigger Enable	0: A/D conversion start request in response to compare match A is disabled. 1: A/D conversion start request in response to compare match A is enabled.	R/W
b7 to b5	—	Reserved	These bits are read as an undefined value. The write value should be 1.	R/W

Note 1. When all OSA[1:0] and OSB[1:0] bits are 0, the output enable signal corresponding to the TMOn pin is negated and a request for high-impedance output is issued to the I/O port. Timer output pin is driven low until the first compare-match occurs after a reset when at least one of the OSA[1:0] and OSB[1:0] bits is 1.

OSA[1:0] Bits (Output Select A)

These bits select a method of TMOn pin output when compare match A of TCORA and TCNT occurs.

OSB[1:0] Bits (Output Select B)

These bits select a method of TMOn pin output when compare match B of TCORB and TCNT occurs.

- TMR1.TCSR, TMR3.TCSR, TMR5.TCSR, TMR7.TCSR

Address(es): TMR1.TCSR 0008 8203h, TMR3.TCSR 0008 8213h, TMR5.TCSR 0008 8223h, TMR7.TCSR 0008 8233h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	OSB[1:0]		OSA[1:0]	
Value after reset:	x	x	x	1	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b1, b0	OSA[1:0]	Output Select A*1	b1 b0 0 0: No change 0 1: Low is output 1 0: High is output 1 1: Output is inverted (toggle output)	R/W
b3, b2	OSB[1:0]	Output Select B*1	b3 b2 0 0: No change 0 1: Low is output 1 0: High is output 1 1: Output is inverted (toggle output)	R/W
b4	—	Reserved	This bit is read as 1. The write value should be 1.	R/W
b7 to b5	—	Reserved	These bits are read as an undefined value. The write value should be 1.	R/W

Note 1. When all OSA[1:0] and OSB[1:0] bits are 0, the output enable signal corresponding to the TMOn pin is negated and a request for high-impedance output is issued to the I/O port. Timer output pin is driven low until the first compare match occurs after a reset when at least one of the OSA[1:0] and OSB[1:0] bits is 1.

OSA[1:0] Bits (Output Select A)

These bits select a method of TMOn pin output when compare match A of TCORA and TCNT occurs.

OSB[1:0] Bits (Output Select B)

These bits select a method of TMOn pin output when compare match B of TCORB and TCNT occurs.

27.2.7 Timer Counter Start Register (TCSTR)

Address(es): TMR0.TCSTR 0008 820Ch, TMR1.TCSTR 0008 820Dh, TMR2.TCSTR 0008 821Ch, TMR3.TCSTR 0008 821Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	TCS
Value after reset:	x	x	x	x	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	TCS	Timer Counter Status	0: Count stopped state in response to ELC. 1: Count start state in response to ELC.	R/W
b7 to b1	—	Reserved	These bits are read as an undefined value. The write value should be 0.	R/W

TCS Bit (Timer Counter Status)

The TCS bit is used to check the state of the timer count in response to ELC.

When this bit is read as 1, it shows the timer start state in response to ELC. When this bit is read as 0, it shows the timer stopped state in response to ELC.

This bit is cleared by writing 0. Do not write 1 to this bit.

The TCS bit is valid only when the count start operation is selected by the ELOPD register of the event controller (ELC). For details, refer to section 27.7, Link Operation by ELC, or section 19, Event Link Controller (ELC).

27.3 Operation

27.3.1 Pulse Output

Figure 27.5 shows an example of the 8-bit timer being used to generate a pulse output with a desired duty cycle.

1. Set the TCR.CCLR[1:0] bits to 01b (cleared by compare match A) so that TCNT is cleared at a compare match of TCORA.
2. Set the TCSR.OSA[1:0] bits to 10b (high is output) and TCSR.OSB[1:0] bits to 01b (low is output), causing the output to change to high at a compare match of TCORA and to low at a compare match of TCORB.

With these settings, the 8-bit timer provides pulses output at a cycle determined by TCORA with a pulse width determined by TCORB. No software intervention is required.
The timer output pin is low after the TCSR.OSA[1:0] or TCSR.OSB[1:0] bits are set until the first compare match occurs after a reset.

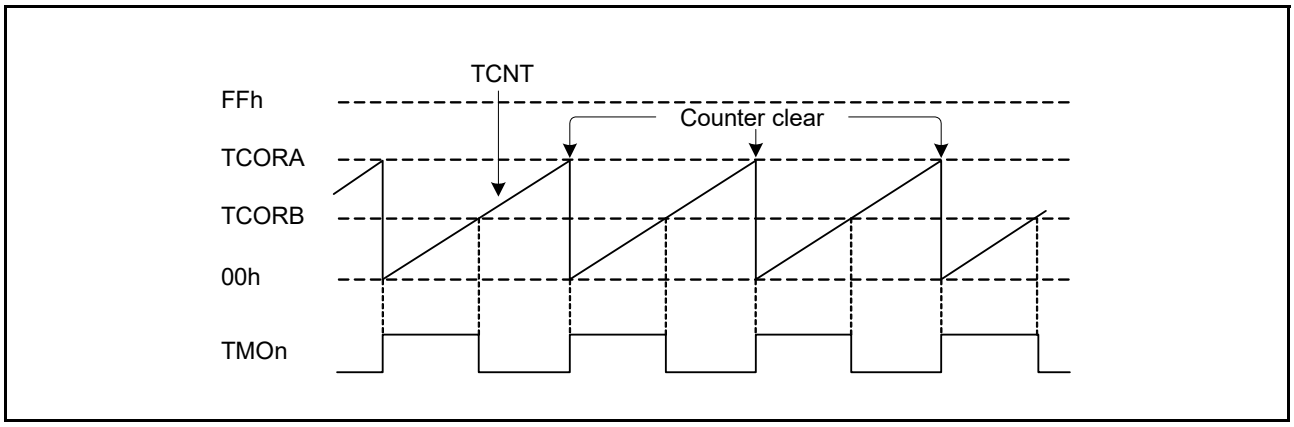


Figure 27.5 Example of Pulse Output (n = 0 to 7)

27.3.2 External Counter Reset Input

Figure 27.6 shows an example of the 8-bit timer being used to generate a pulse which is output after a desired delay time from a TMRIn input.

1. Set the TCR.CCLR[1:0] bits to 11b (cleared by external counter reset signal) and set the TMRIS bit in TCCR to 1 (cleared when the external counter reset signal is high) so that TCNT is cleared at the high level input of the TMRIn signal.
2. Set the TCSR.OSA[1:0] bits to 10b (high output) and the TCSR.OSB[1:0] bits to 01b (low output), causing the output to change to high at a compare match of TCORA and to low at a compare match of TCORB.

With these settings, the 8-bit timer provides pulses output at a desired delay time from a TMRIn input determined by TCORA and with a pulse width determined by TCORB and TCORA.

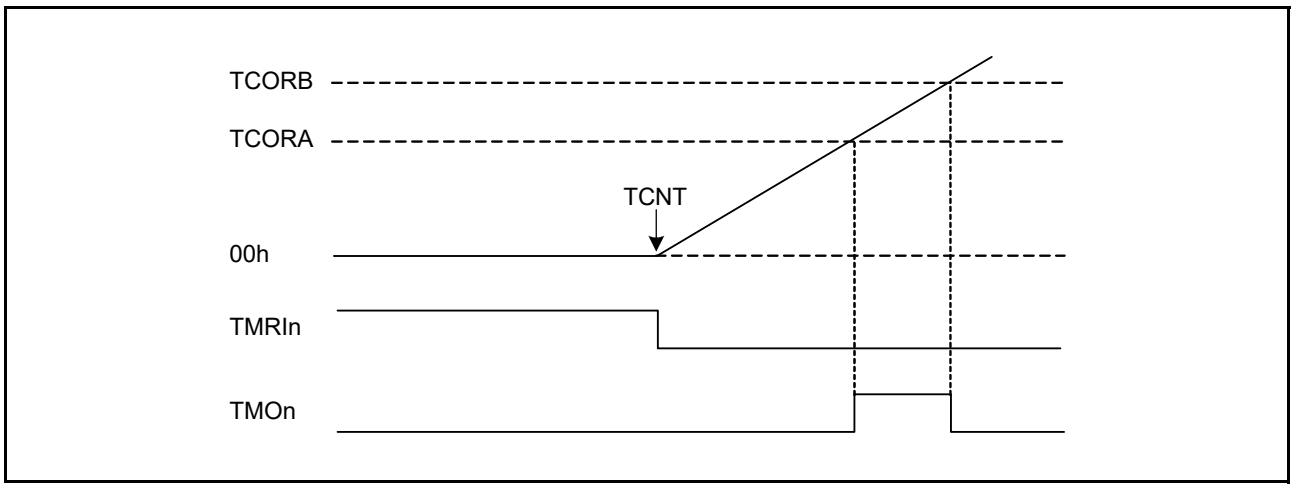

Figure 27.6 Example of External Counter Reset Signal Input (n = 0 to 7)

27.4 Operation Timing

27.4.1 TCNT Count Timing

Figure 27.7 shows the count timing of TCNT for internal clock. Figure 27.8 shows the count timing of TCNT for external clock.

Note that the external clock pulse width must be at least 1.5 PCLK cycles for increment at a single edge, and at least 2.5 PCLK cycles for increment at both edges. The counter will not increment correctly if the pulse width is less than these values.

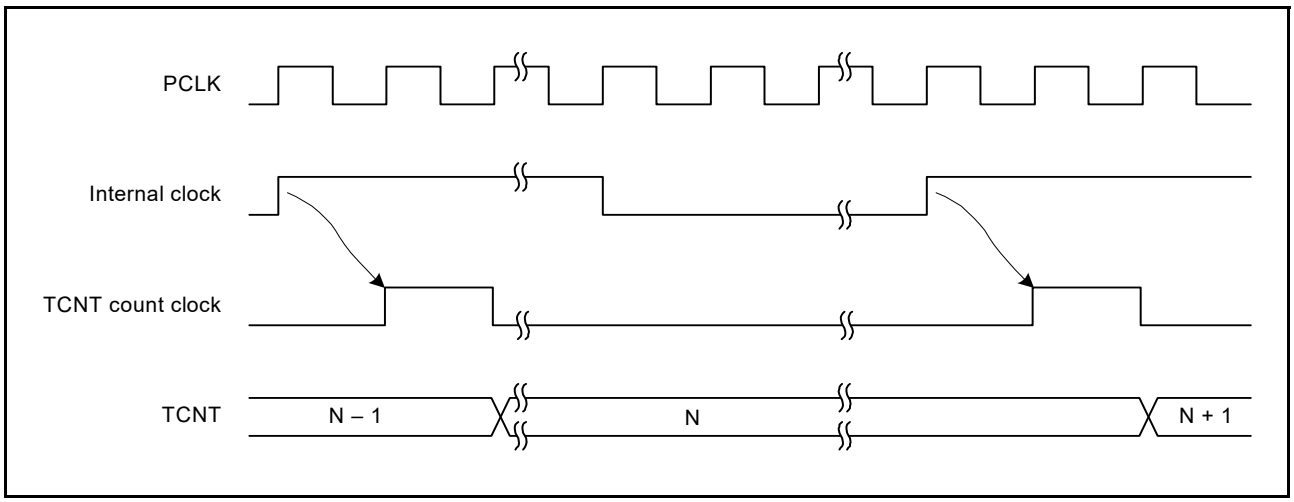

Figure 27.7 Count Timing for Internal Clock

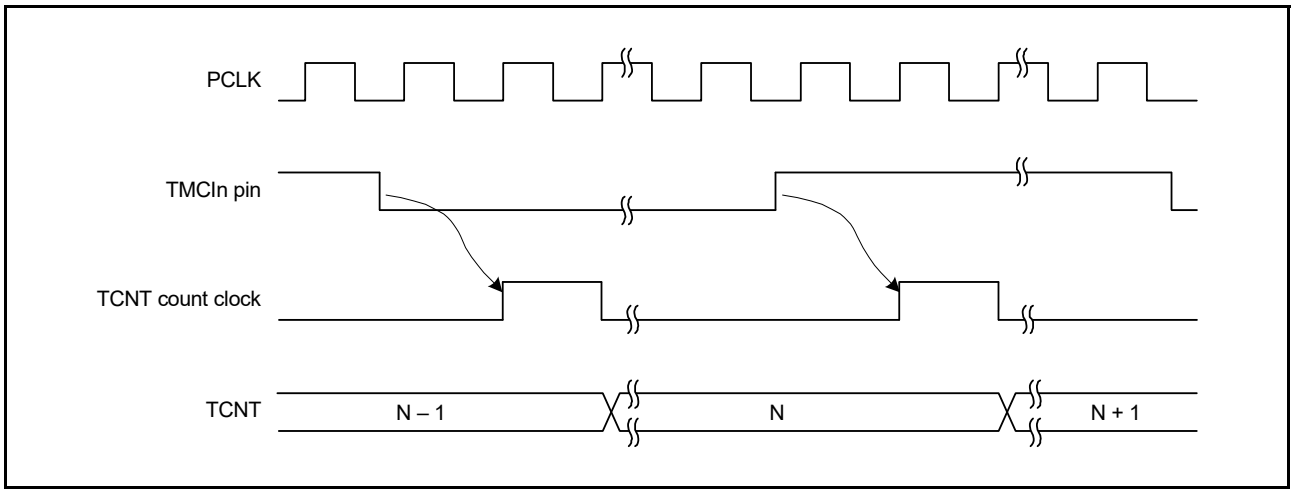

Figure 27.8 Count Timing for External Clock (at Both Edges)

27.4.2 Timing of Interrupt Signal Output on a Compare Match

A compare match refers to a match between the value of the TCORA or TCORB register and the TCNT, and a compare match interrupt signal is output at this time if the interrupt request is enabled. The compare match is generated in the last cycle in which the values match (at the time at which the value counted by TCNT to produce the match is updated). Accordingly, after a match between TCNT and the TCORA or TCORB register is detected, the compare match is not actually generated until the next cycle of the TCNT count clock. Figure 27.9 shows the timing of output of the interrupt signal.
For the corresponding interrupt vector number, refer to section 14, Interrupt Controller (ICUG) and Table 27.7.

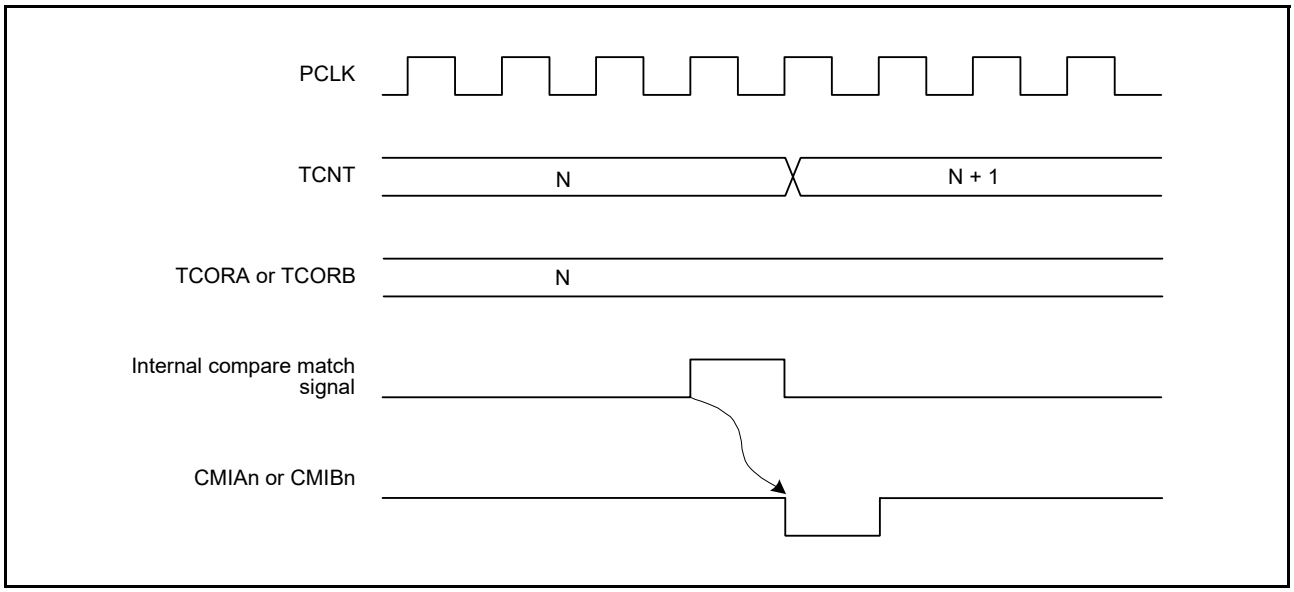

Figure 27.9 Timing of Interrupt Flag Setting to 1 at Compare Match (n = 0 to 7)

27.4.3 Timing of Timer Output Signal at Compare Match

When a compare match signal is generated, the output value specified by the TCSR.OSA[1:0] and OSB[1:0] bits is output on the timer output pin (TMOn).
Figure 27.10 shows the timing when the timer output is toggled by the compare match A signal.

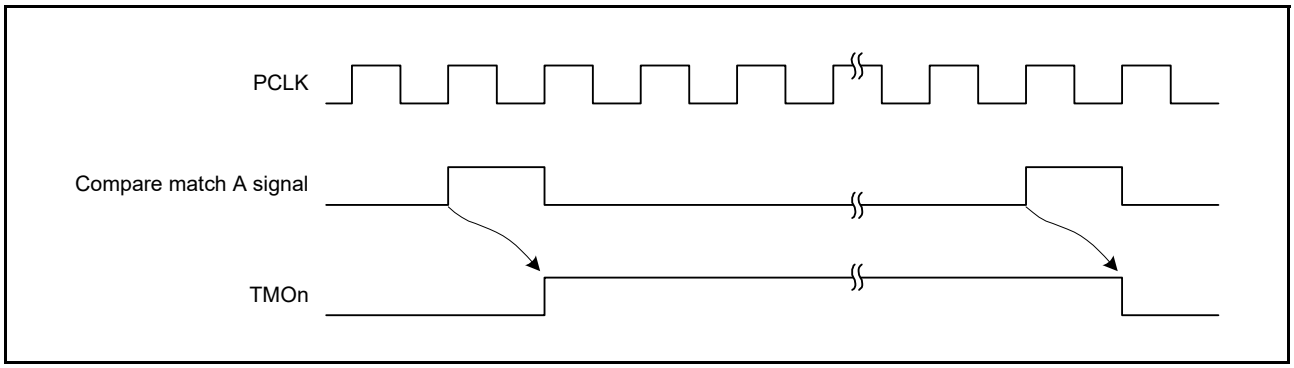

Figure 27.10 Timing of Timer Output Signal at Compare Match A Signal (n = 0 to 7)

27.4.4 Timing of Counter Clear by Compare Match

TCNT is cleared when compare match A or B occurs, depending on the settings of the TCR.CCLR[1:0] bits.
Figure 27.11 shows the timing of this operation.

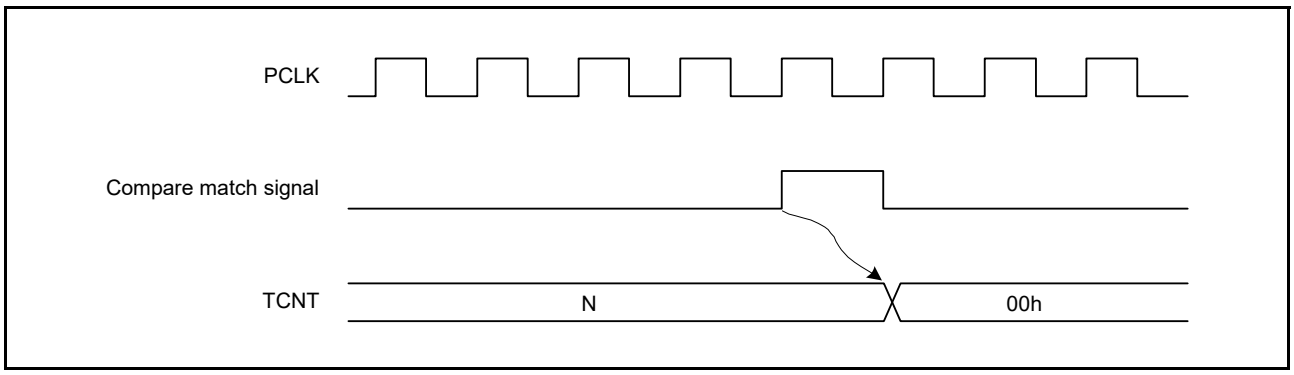

Figure 27.11 Timing of Counter Clear by Compare Match

27.4.5 Timing of the External Reset for TCNT

TCNT is cleared at the rising edge or high level of an external counter reset signal, depending on the settings of the TCR.CCLR[1:0] bits. At least 2 PCLK cycles are required from a reset input to clearing of TCNT.
Figure 27.12 and Figure 27.13 show the timing of this operation.

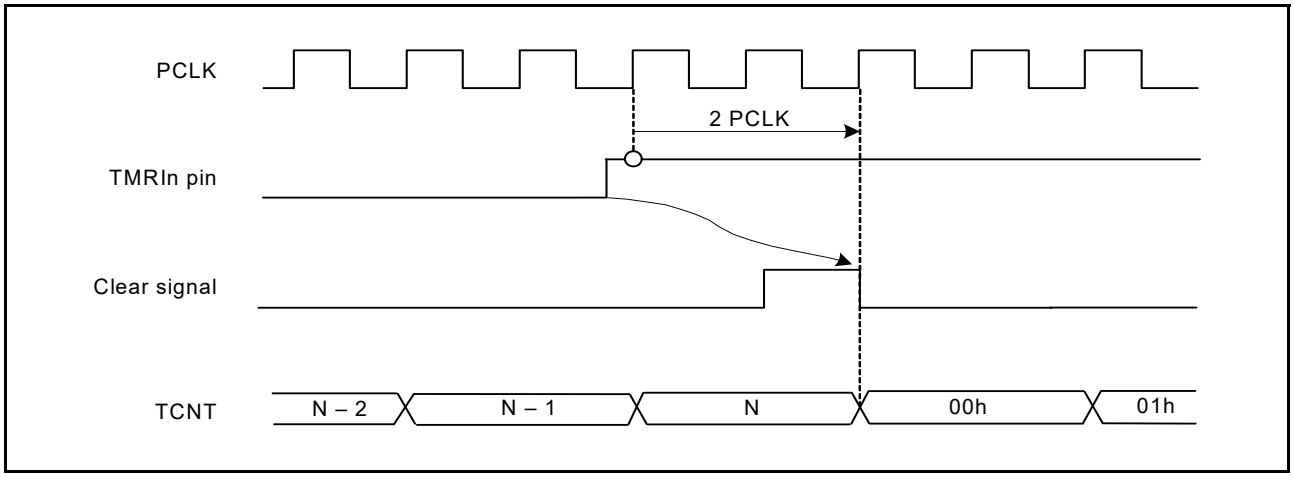

Figure 27.12 Clear Timing by External Counter Reset Signal (Rising Edge)

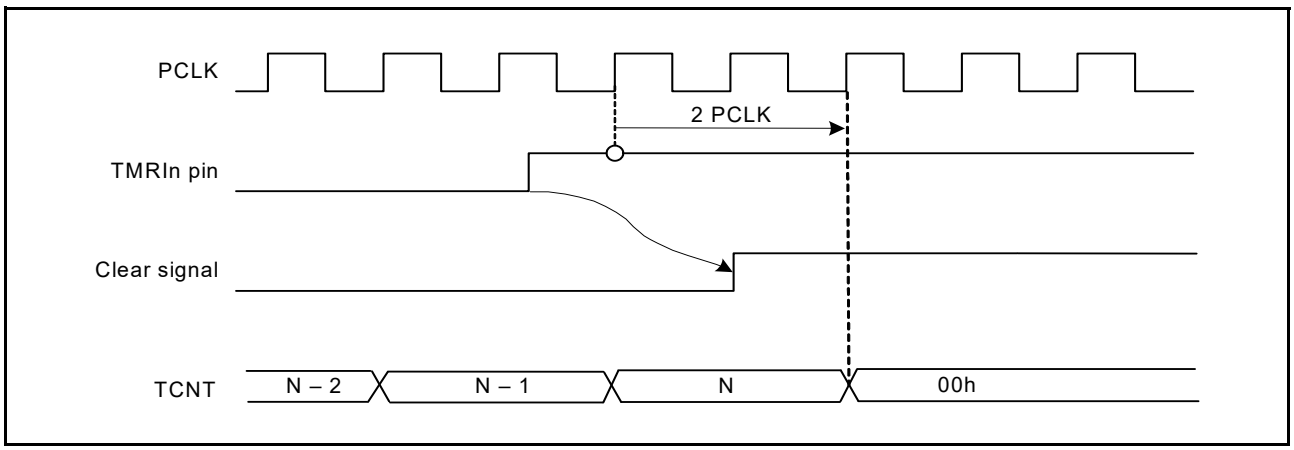

Figure 27.13 Clear Timing by External Counter Reset Signal (High Level)

27.4.6 Timing of Interrupt Signal Output on an Overflow

When TCNT overflows (changes from FFh to 00h), an overflow interrupt signal is output if this interrupt request is enabled.

Figure 27.14 shows the timing of output of the interrupt signal.

For the corresponding interrupt vector number, refer to section 14, Interrupt Controller (ICUG) and Table 27.7.

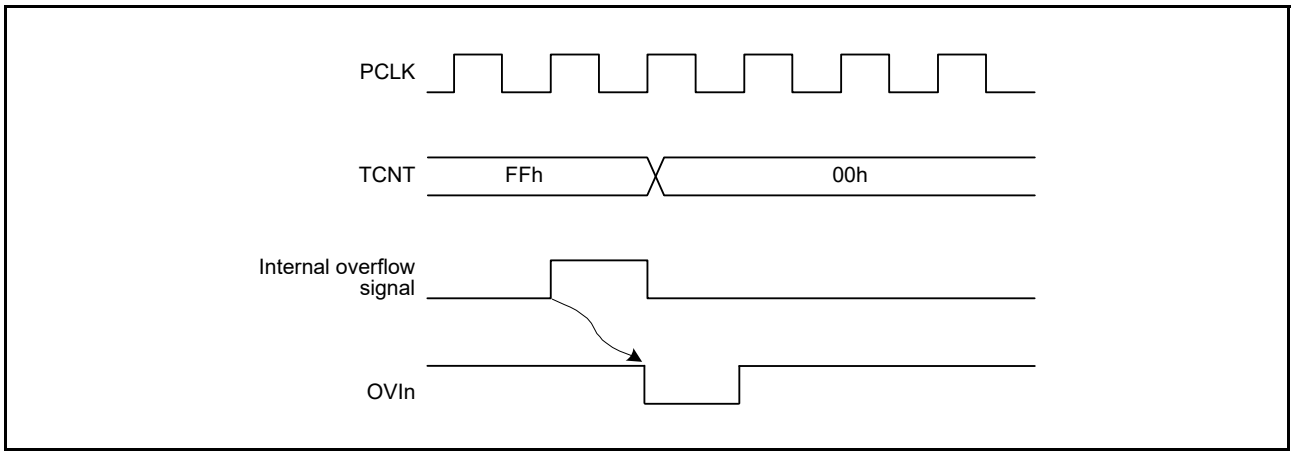

Figure 27.14 Timing of Overflow Interrupt Flag Setting to 1 (n = 0 to 7)

27.5 Operation with Cascaded Connection

If the CSS[1:0] bits in either TMR0.TCCR or TMR1.TCCR are set to 11b, the TMR of the two channels are cascaded. With this configuration, a single 16-bit timer could be used (16-bit counter mode) or compare matches of TMR0 could be counted by TMR1 (compare match count mode).
This section describes unit 0. The operation of unit 1, unit 2, and unit 3 with cascaded connection is the same as unit 0.

27.5.1 16-Bit Count Mode

When the TMR0.TCCR.CSS[1:0] bits are set to 11b, the timer functions as a single 16-bit timer with TMR0 occupying the upper 8 bits and TMR1 occupying the lower 8 bits.

(1) Counter Clear Specification

- The settings of the TMR0.TCR.CCLR[1:0] bits become effective for the 16-bit counter. If the TMR0.TCR.CCLR[1:0] bits have been set for counter clear at compare match, the 16-bit counter (TMR0.TCNT and TMR1.TCNT together) is cleared when a 16-bit compare match event occurs. The 16-bit counter (TMR0.TCNT and TMR1.TCNT together) is cleared even if counter clear by the TMRI0 pin has been set.
- The settings of the TMR1.TCR.CCLR[1:0] bits are ignored.

(2) Pin Output

- Control of output from the TMO0 pin by the TMR0.TCSR.OSA[1:0] and OSB[1:0] bits is in accordance with the 16-bit compare match conditions.
- Control of output from the TMO1 pin by the TMR1.TCSR.OSA[1:0] and OSB[1:0] bits is in accordance with the lower 8-bit compare match conditions.

27.5.2 Compare Match Count Mode

When the TMR1.TCCR.CSS[1:0] bits are set to 11b, TMR1.TCNT counts the number of occurrences of compare match A for TMR0. TMR0 and TMR1 are controlled independently. Conditions such as generation of interrupts, output from the TMOn pin (n = 0, 1), and counter clear are in accordance with the settings for each channel.

27.6 Interrupt Sources

27.6.1 Interrupt Sources and DTC Activation

There are three interrupt sources for TMRn: CMIAn, CMIBn, and OVIn. Their interrupt sources and priorities are listed in Table 27.7.
It is also possible to activate the DTC by means of CMIAn and CMIBn interrupts.

Table 27.7 TMR Interrupt Sources

Name	Interrupt Sources	DTC Activation
CMIA0	TMR0.TCORA compare match	Possible
CMIB0	TMR0.TCORB compare match	Possible
OVI0	TMR0.TCNT overflow	Not possible
CMIA1	TMR1.TCORA compare match	Possible
CMIB1	TMR1.TCORB compare match	Possible
OVI1	TMR1.TCNT overflow	Not possible
CMIA2	TMR2.TCORA compare match	Possible
CMIB2	TMR2.TCORB compare match	Possible
OVI2	TMR2.TCNT overflow	Not possible
CMIA3	TMR3.TCORA compare match	Possible
CMIB3	TMR3.TCORB compare match	Possible
OVI3	TMR3.TCNT overflow	Not possible
CMIA4	TMR4.TCORA compare match	Possible
CMIB4	TMR4.TCORB compare match	Possible
OVI4	TMR4.TCNT overflow	Not possible
CMIA5	TMR5.TCORA compare match	Possible
CMIB5	TMR5.TCORB compare match	Possible
OVI5	TMR5.TCNT overflow	Not possible
CMIA6	TMR6.TCORA compare match	Possible
CMIB6	TMR6.TCORB compare match	Possible
OVI6	TMR6.TCNT overflow	Not possible
CMIA7	TMR7.TCORA compare match	Possible
CMIB7	TMR7.TCORB compare match	Possible
OVI7	TMR7.TCNT overflow	Not possible

27.6.2 Startup of the A/D Converter

The compare match A of TMR0, TMR2, TMR4, and TMR6 allows the A/D converter to be started.
An A/D conversion start request is issued to the A/D converter in response to a generation of compare match A when the TMRn.TCSR.ADTE bit is 1 (i.e., when an A/D conversion request in response to compare match A is enabled). In this case, the conversion trigger for the 8-bit timer should be selected in the A/D converter to start A/D conversion.

Table 27.8 Startup of A/D Converter

A/D Converter	TMR Unit No.	Target	A/D Conversion Start Request
S12AD, S12AD1, S12AD2 (12-bit A/D converter)	0	Compare match between TMR0.TCORA and TMR0.TCNT	TMTRG0AN_0
	1	Compare match between TMR2.TCORA and TMR2.TCNT	TMTRG0AN_1
	2	Compare match between TMR4.TCORA and TMR4.TCNT	TMTRG0AN_2
	3	Compare match between TMR6.TCORA and TMR6.TCNT	TMTRG0AN_3

27.7 Link Operation by ELC

27.7.1 Event Signal Output to ELC

The TMR uses the event link controller (ELC) to perform link operation to the previously specified module using the interrupt request signal as the event signal. The TMR outputs compare match A, compare match B, and overflow signals as event signals. Channels that can be used in this way are TMR0 to TMR3.
The event signal can be output regardless of the setting of the corresponding interrupt request enable bits (TMRn.TCR.OVIE, TMRn.TCR.CMIEA, and TMRn.TCR.CMIEB (n = 0 to 3)). For details, refer to section 19, Event Link Controller (ELC).
The event output function can be used for the cascaded operation.

27.7.2 TMR Operation when Receiving an Event Signal from ELC

The TMR can perform either of the following operations upon the event previously specified by the ELSRn register of the ELC. However, the ELC does not support the cascaded operation.

(1) Count Start

When the TMR count start operation is selected by the ELOPD register of the ELC and the event specified by ELSRn occurs, the TCSTR.TCS bit is set to 1, starting the TMR count operation. After the TMR count start operation is selected by the ELOPD register of the ELC, use the TCCR.CKS[2:0] and CSS[1:0] bits to select the count source.
If the specified event occurs while the TCS bit is 1, the event is ignored.
Write 0 to the TCSTR.TCS bit to stop counting.
When the count start event is input in the count stopped state, the TMR starts counting again according to the CKS[2:0] and CSS[1:0] bits.
The TCS bit is valid only when the ELOPD.TMR0MD[1:0], ELOPD.TMR1MD[1:0], ELOPD.TMR2MD[1:0], and ELOPD.TMR3MD[1:0] bits of the ELC select the count start operation.

(2) Event Count

When the TMR event count operation is selected by the ELOPD register of the ELC and the event specified by ELSRn occurs, the events are counted as the count source regardless of the TCCR.CKS[2:0] and CSS[1:0] bit settings. Reading the counter value returns the number of events that have been actually input.

(3) Count Restart

When the TMR count restart operation is selected by the ELOPD register of the ELC and the event specified by ELSRn occurs, the TCNT counter value is modified to the initial value. If the CKS[2:0] and CSS[1:0] bit settings are not disabling the clock input, the count operation is continued.

27.7.3 Notes on Operating TMR According to an Event Signal from ELC

The following describes the notes on operating the TMR using the event link feature.

(1) Count Start

When the event specified by ELSRn occurs during the write cycle to the TCSTR.TCS bit, the cycle is not completed; setting 1 according to the event occurrence takes priority.

(2) Event Count

When the event specified by ELSRn occurs during the write cycle to the TCNT, the cycle is not completed; event count operation according to the event occurrence takes priority.

(3) Count Restart

When the event specified by ELSRn occurs during the write cycle to the TCNT, the cycle is not completed; count value initialization according to the event occurrence takes priority.

27.8 Usage Notes

27.8.1 Module Stop State Setting

Operation of the TMR can be disabled or enabled by using the module stop control registers. The initial setting is for halting of TMR operation. Register access becomes possible after release from the module stop state. For details, refer to section 11, Low Power Consumption.

27.8.2 Notes on Setting Cycle

If the compare match is selected for counter clear, TCNT is cleared at the last PCLK in the cycle in which the value of TCNT matches with that of TCORA or TCORB. TCNT updates the counter value at this last state. Therefore, the counter frequency is obtained by the following formula (f: Counter frequency, PCLK: Operating frequency, N: TCORA and TCORB register setting value).

$$f = PCLK / (N + 1)$$

27.8.3 Conflict between TCNT Write and Counter Clear

If a counter clear signal is generated concurrently with CPU write to TCNT, the clear takes priority and the write is not performed as shown in Figure 27.15.

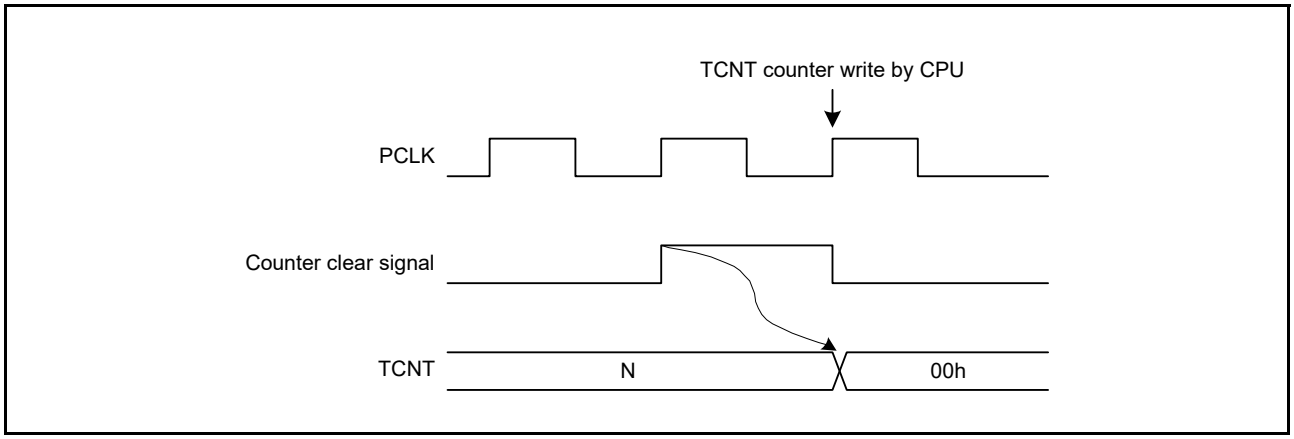

Figure 27.15 Conflict between TCNT Write and Counter Clear

27.8.4 Conflict between TCNT Write and Increment

Even if a counting-up signal is generated concurrently with CPU write to TCNT, the counting-up is not performed and the write takes priority as shown in Figure 27.16.

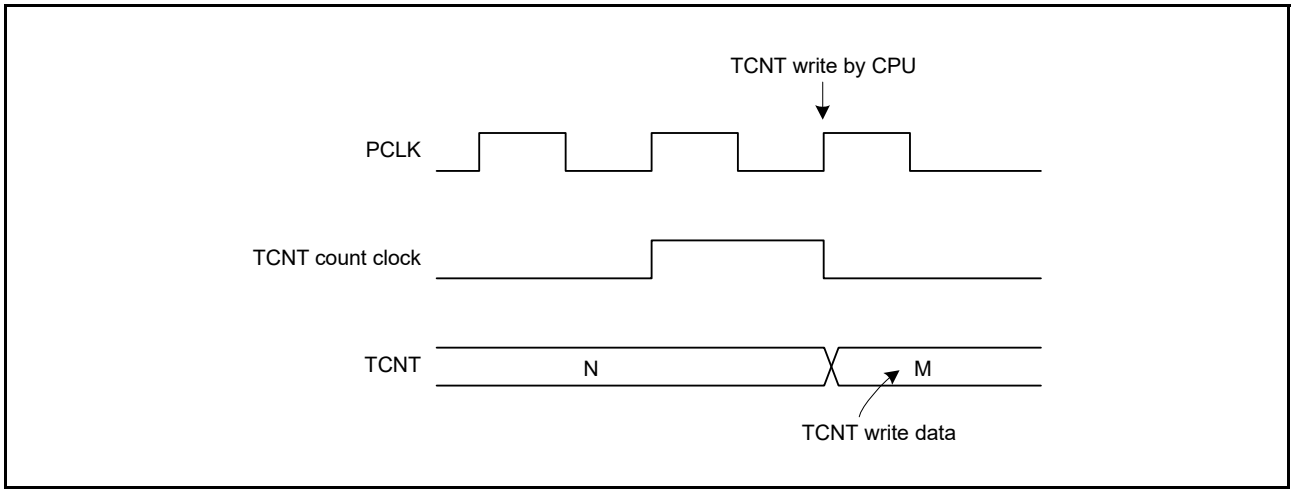

Figure 27.16 Conflict between TCNT Write and Increment

27.8.5 Conflict between TCORA or TCORB Write and Compare Match

Even if a compare match signal is generated simultaneously with CPU write to TCORA or TCORB as shown in Figure 27.17, the write takes priority and the compare match signal does not reach High level.

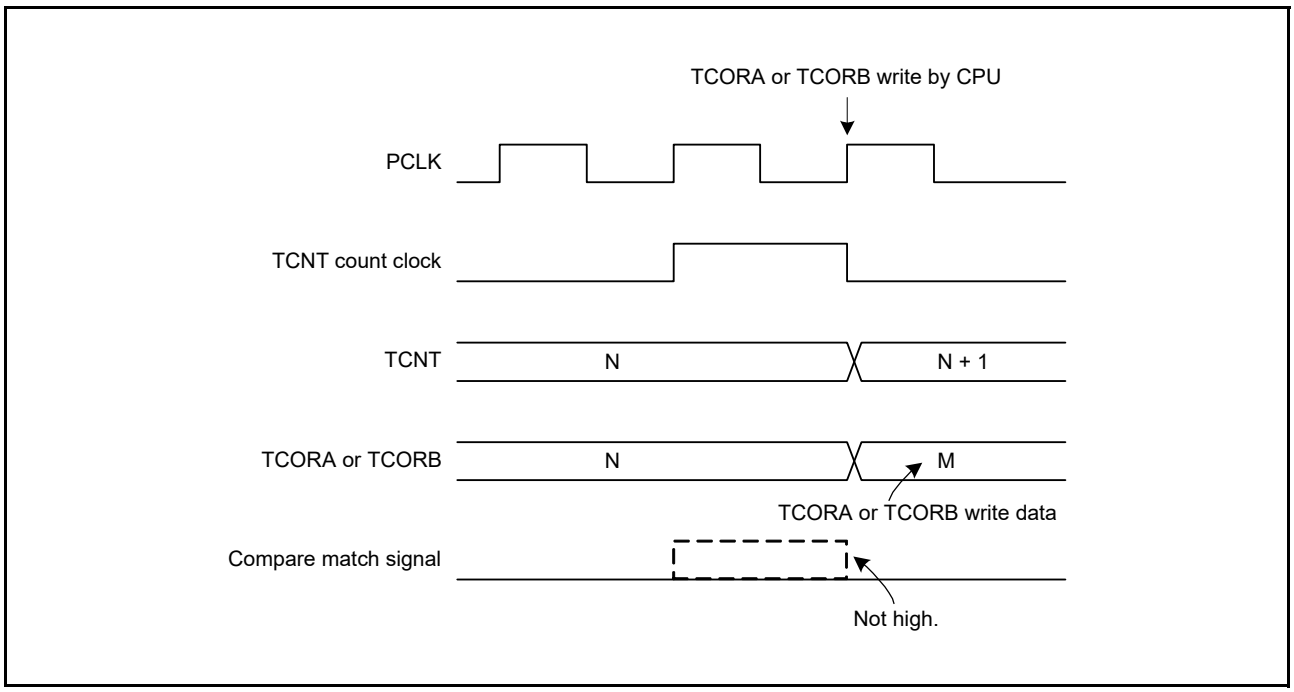

Figure 27.17 Conflict between TCORA or TCORB Write and Compare Match

27.8.6 Conflict between Compare Matches A and B

If compare match events A and B occur at the same time, the 8-bit timer operates in accordance with the priorities for the output methods high for compare match A and compare match B, as listed in Table 27.9.

Table 27.9 Timer Output Priorities

Output Setting	Priority
Toggle output	High
High output	↑
Low output	
No change	Low

27.8.7 Switching of Internal Clocks and TCNT Operation

TCNT may be incremented erroneously depending on when the internal clock is switched. Table 27.10 lists the relationship between the timing at which the internal clock is switched (by writing to the TCCR.CKS[2:0] bits) and the operation of TCNT.

When TCNT count clock is generated from an internal clock, the rising edge of the internal clock pulse are always monitored. If the signal levels of the clocks before and after switching change from low to high as shown in No. 2 in Table 27.10, the change is considered as an edge. Therefore, a TCNT count clock is generated and TCNT is incremented.

The erroneous increment of TCNT can also happen when switching between internal and internal clocks.

Table 27.10 Switching of Internal Clocks and TCNT Operation (1/2)

No.	Timing to Change the TCCR.CKS[2:0] Bits	TCNT Counter Operation
1	Switching from low to low*1	
Table 27.10 Switching of Internal Clocks and TCNT Operation (2/2)

No.	Timing to Change the TCCR.CKS[2:0] Bits	TCNT Counter Operation
2	Switching from low to high*2	3	Switching from high to low*4	4	Switching from high to high	
Note 1. Includes switching from low to stop, and from stop to low.
Note 2. Includes switching from stop to high.
Note 3. Generated because the change of the signal levels is considered as an edge; TCNT counter is incremented.
Note 4. Includes switching from high to stop.

27.8.8 Clock Source Setting with Cascaded Connection

If 16-bit counter mode and compare match count mode are specified at the same time, count clocks for TMR0.TCNT and TMR1.TCNT (TMR2.TCNT and TMR3.TCNT, TMR4.TCNT and TMR5.TCNT, TMR6.TCNT and TMR7.TCNT) are not generated, and the counter stops. Do not specify 16-bit counter mode and compare match count mode simultaneously.

27.8.9 Continuous Output of Compare Match Interrupt Signal

When TCORA or TCORB is set to 00h, PCLK/1 is set as the internal clock, and compare match is set as the counter clear source, the TCNT counter remains 00h and is not updated, and a compare match interrupt signal is output continuously to form a flat signal level.
At this time, the interrupt controller cannot detect the second and subsequent interrupts.
Figure 27.18 shows operation timing when the compare match interrupt signal is continuously output.

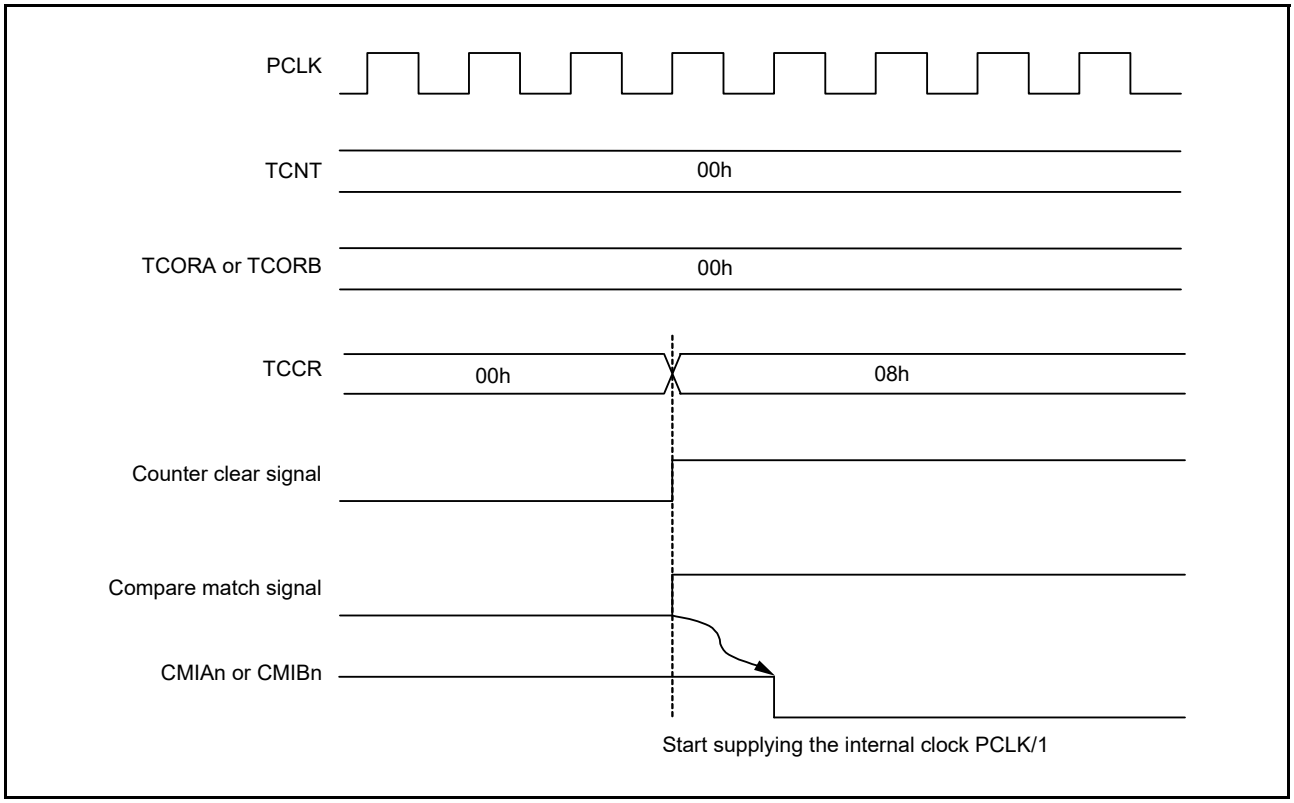

Figure 27.18 Continuous Output of Compare Match Interrupt Signal (n = 0 to 7)

28. Compare Match Timer (CMT)

This MCU has two on-chip compare match timer (CMT) units (unit 0 and unit 1), each consisting of a two-channel 16-bit timer (i.e., a total of four channels). The CMT has a 16-bit counter, and can generate interrupts at set intervals.
In this section, “PCLK” is used to refer to PCLKB.

28.1 Overview

Table 28.1 lists the specifications for the CMT.
Figure 28.1 shows a block diagram of the CMT (unit 0). A two-channel CMT constitutes a unit. Unit 0 and unit 1 are the same in terms of specifications. Compare match timer start register 0 (CMSTR0) and compare match interrupts (CMI0 and CMI1) of unit 0 correspond to compare match timer start register 1 (CMSTR1) and compare match interrupts (CMI2 and CMI3) of unit 1.

Table 28.1 CMT Specifications

Item	Description
Count clocks	• Four frequency dividing clocks One clock from PCLK/8, PCLK/32, PCLK/128, and PCLK/512 can be selected for each channel.
Interrupt	A compare match interrupt can be requested for each channel.
Event link function (output)	An event signal is output upon a CMT1 compare match.
Event link function (input)	Linking to the specified module is possible. CMT1 count start, event counter, or count restart operation is possible.
Low power consumption function	Each unit can be placed in a module stop state.

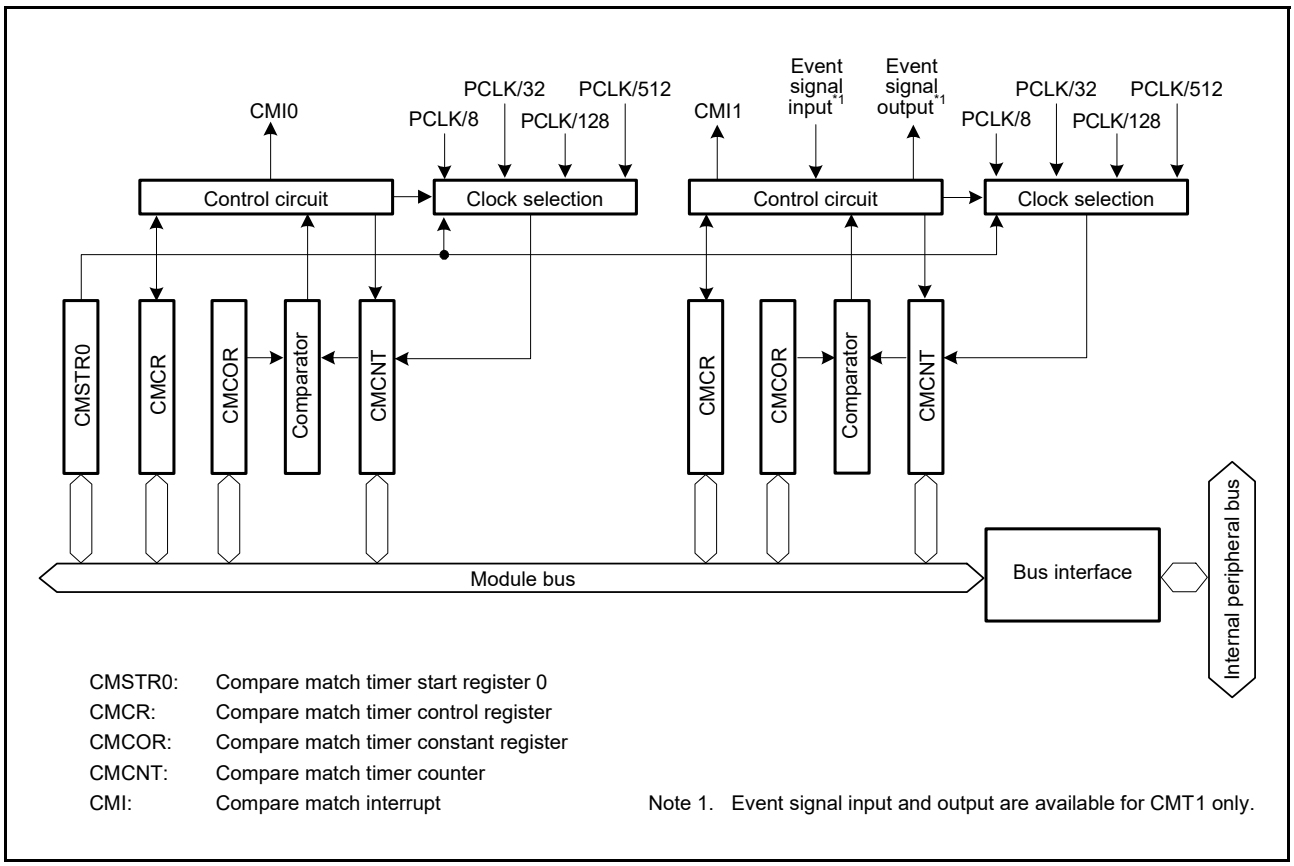

Figure 28.1 CMT (Unit 0) Block Diagram

28.2 Register Descriptions

28.2.1 Compare Match Timer Start Register 0 (CMSTR0)

Address(es): 0008 8000h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STR1	STR0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STR0	Count Start 0	0: CMT0.CMCNT count is stopped. 1: CMT0.CMCNT count is started.	R/W
b1	STR1	Count Start 1	0: CMT1.CMCNT count is stopped. 1: CMT1.CMCNT count is started.	R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

28.2.2 Compare Match Timer Start Register 1 (CMSTR1)

Address(es): 0008 8010h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STR3	STR2
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STR2	Count Start 2	0: CMT2.CMCNT count is stopped. 1: CMT2.CMCNT count is started.	R/W
b1	STR3	Count Start 3	0: CMT3.CMCNT count is stopped. 1: CMT3.CMCNT count is started.	R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

28.2.3 Compare Match Timer Control Register (CMCR)

Address(es): CMT0.CMCR 0008 8002h, CMT1.CMCR 0008 8008h, CMT2.CMCR 0008 8012h, CMT3.CMCR 0008 8018h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	CMIE	—	—	—	—	CKS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	x	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKS[1:0]	Clock Select	b1 b0 0 0: PCLK/8 0 1: PCLK/32 1 0: PCLK/128 1 1: PCLK/512	R/W
b5 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	CMIE	Compare Match Interrupt Enable	0: Compare match interrupt (CMIn) disabled 1: Compare match interrupt (CMIn) enabled	R/W
b7	—	Reserved	This bit is read as undefined. The write value should be 1.	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

CKS[1:0] Bits (Clock Select)

These bits select the count source from four frequency dividing clocks obtained by dividing the peripheral module clock (PCLK).

When the CMSTRm.STRn (m = 0, 1; n = 0 to 3) bit is set to 1, the CMCNT counter starts counting up on the clock selected with the CKS[1:0] bits.

CMIE Bit (Compare Match Interrupt Enable)

The CMIE bit enables or disables compare match interrupt (CMIn) (n = 0 to 3) generation when the CMCNT counter and the CMCOR register values match.

28.2.4 Compare Match Counter (CMCNT)

Address(es): CMT0.CMCNT 0008 8004h, CMT1.CMCNT 0008 800Ah, CMT2.CMCNT 0008 8014h, CMT3.CMCNT 0008 801Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CMCNT counter is a readable/writable up-counter.
When an frequency dividing clock is selected by the CMCR.CKS[1:0] bits and the CMSTRm.STRn (m = 0, 1; n = 0 to 3) bit is set to 1, the CMCNT counter starts counting up using the selected clock.
When the value in the CMCNT counter and the value in the CMCOR register match, the CMCNT counter is set to 0000h. At the same time, a compare match interrupt (CMIn) (n = 0 to 3) is generated.

28.2.5 Compare Match Constant Register (CMCOR)

Address(es): CMT0.CMCOR 0008 8006h, CMT1.CMCOR 0008 800Ch, CMT2.CMCOR 0008 8016h, CMT3.CMCOR 0008 801Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The CMCOR register is a readable/writable register to set a value for compare match with the CMCNT counter.

28.3 Operation

28.3.1 Periodic Count Operation

When an frequency dividing clock is selected by the CMCR.CKS[1:0] bits and the CMSTRm.STRn (m = 0, 1; n = 0 to 3) bit is set to 1, the CMCNT counter starts counting up using the selected clock.
When the value in the counter and the value in the register match, a compare match interrupt (CMIn) (n = 0 to 3) is generated. The CMCNT counter then starts counting up again from 0000h. Figure 28.2 shows the operation of the CMCNT counter.

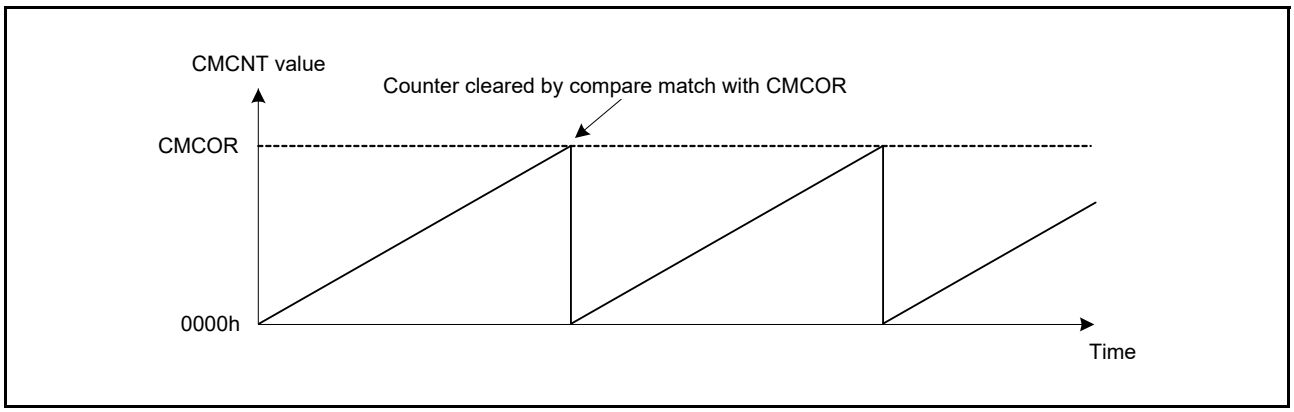

Figure 28.2 CMCNT Counter Operation

28.3.2 CMCNT Count Timing

As the count clock to be input to the CMCNT counter, one of four frequency dividing clocks (PCLK/8, PCLK/32, PCLK/128, and PCLK/512) obtained by dividing the peripheral module clock (PCLK) can be selected with the CMCR.CKS[1:0] bits. Figure 28.3 shows the timing of the CMCNT counter.

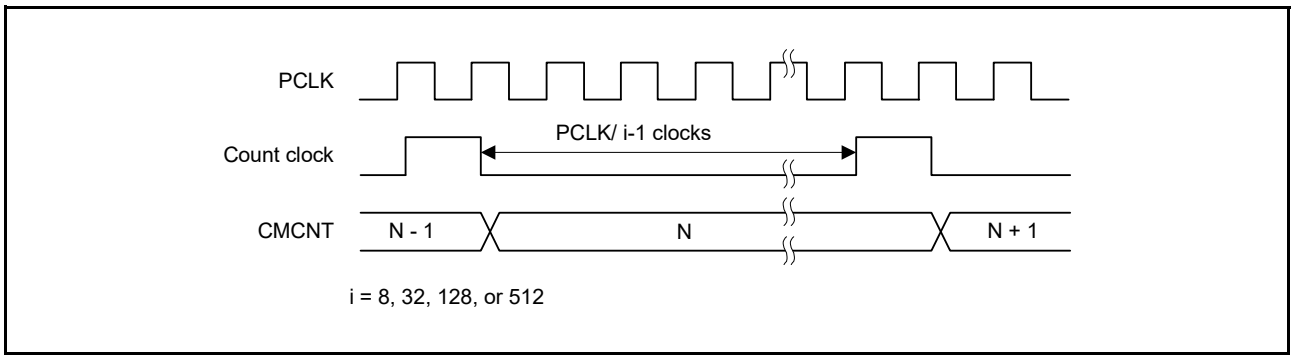

Figure 28.3 CMCNT Count Timing

28.4 Interrupts

28.4.1 Interrupt Sources

The CMT has channels and each of them to which a different vector address is allocated has a compare match interrupt (CMIn) (n = 0 to 3). When a compare match interrupt occurs, the corresponding interrupt request is output.
When the interrupt request is used to generate a CPU interrupt, the priority of channels can be changed by the interrupt controller settings. For details, see section 14, Interrupt Controller (ICUG).

Table 28.2 CMT Interrupt Sources

Name	Interrupt Sources	DTC Activation	DMAC Activation
CMI0	Compare match in CMT0	Possible	Possible
CMI1	Compare match in CMT1	Possible	Possible
CMI2	Compare match in CMT2	Possible	Possible
CMI3	Compare match in CMT3	Possible	Possible

28.4.2 Timing of Compare Match Interrupt Generation

When the CMCNT counter and the CMCOR register match, a compare match interrupt (CMIn) (n = 0 to 3) is generated. A compare match signal is generated at the last state in which the values match (the timing when the CMCNT counter updates the matched count value). That is, after a match between the CMCOR register and the CMCNT counter, the compare match signal is not generated until the next the CMCNT counter input clock.
Figure 28.4 shows the timing of a compare match interrupt.

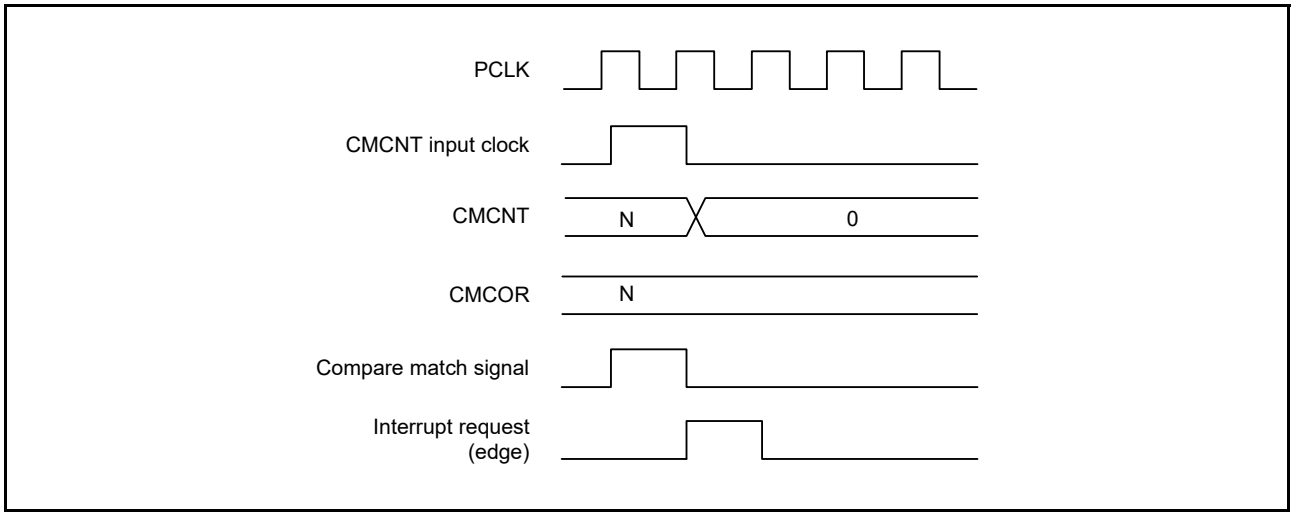

Figure 28.4 Timing of a Compare Match Interrupt

28.5 Link Operations by ELC

28.5.1 Event Signal Output to ELC

The CMT uses the event link controller (ELC) to perform link operation to a preset module using the interrupt request signal as the event signal. The CMT outputs the event signal upon a CMT1 compare match.
The event signal can be output regardless of the setting of the corresponding interrupt request enable bit (CMTn.CMCR.CMIE).

28.5.2 CMT Operation When Receiving an Event Signal from ELC

The CMT can perform either of the following operations upon the event preset by the ELSR7 register of the ELC.

(1) Count Start

When the CMT count start operation is selected by the ELOPC register of the ELC and the event specified by ELSR7 occurs, the CMSTR0.STR1 bit is set to 1, starting the CMT count operation.
However, if the specified event occurs while the CMSTR0.STR1 bit is 1, the event is ignored.

(2) Event Count

When the CMT event count operation is selected by the ELOPC register of the ELC and the event specified by ELSR7 occurs with the CMSTR0.STR1 bit being 1, the events are counted as the count source regardless of the CMT1.CMCR.CKS[1:0] bit setting. Reading the counter value returns the number of events that have been actually input.

(3) Count Restart

When the CMT count restart operation is selected by the ELOPC register of the ELC and the event specified by ELSR7 occurs, the CMT1.CMCNT counter value is modified to the initial value. If the CMSTR0.STR1 bit is 1 here, the count operation can be continued.

28.5.3 Notes on Operating CMT According to an Event Signal from ELC

The following describes the notes on operating the CMT using the event link feature.

(1) Count Start

When the event specified by ELSR7 occurs during the write cycle to the CMSTR0.STR1 bit, the cycle is not completed; setting 1 according to the event occurrence takes priority.

(2) Event Count

When the event specified by ELSR7 occurs during the write cycle to the CMT1.CMCNT, the cycle is not completed; event count operation according to the event occurrence takes priority.

(3) Count Restart

When the event specified by ELSR7 occurs during the write cycle to the CMT1.CMCNT, the cycle is not completed; count value initialization according to the event occurrence takes priority.

28.6 Usage Notes

28.6.1 Setting the Module Stop Function

The CMT can be enabled or disabled using the module stop control register. After a reset, the CMT is in the module stop state. The registers can be accessed by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

28.6.2 Conflict between CMCNT Counter Writing and Compare Match

When the compare match signal is generated while writing to the CMCNT counter, clearing the CMCNT counter has priority over writing to it. In this case, the CMCNT counter is not written to. Figure 28.5 shows the timing to clear the CMCNT counter.

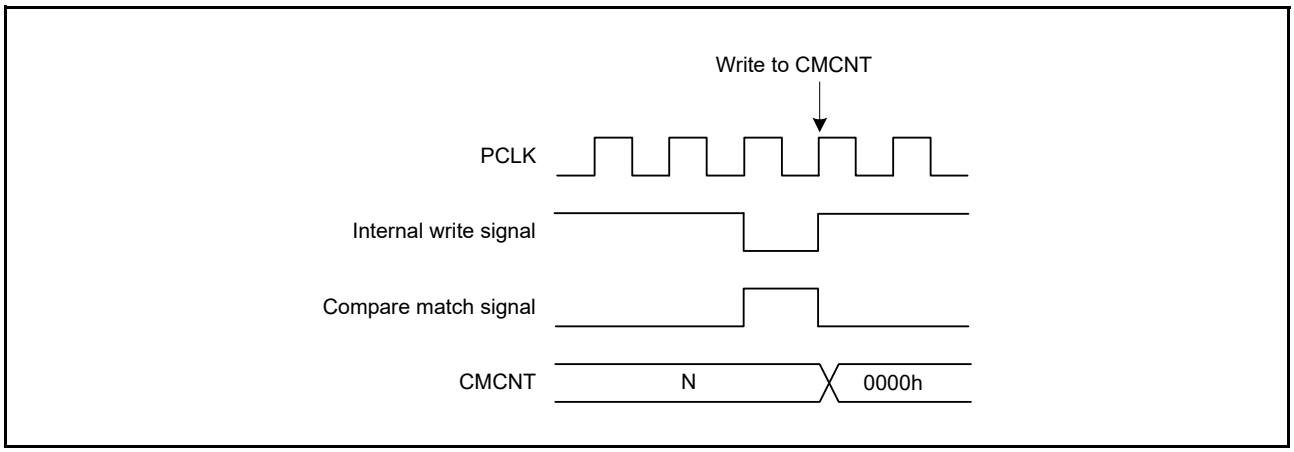

Figure 28.5 Conflict between CMCNT Counter Writing and Compare Match

28.6.3 Conflict between CMCNT Counter Writing and Incrementing

If writing to the counter and the incrementing conflict, the writing has priority over the incrementing. Figure 28.6 shows the timing to write the CMCNT counter.

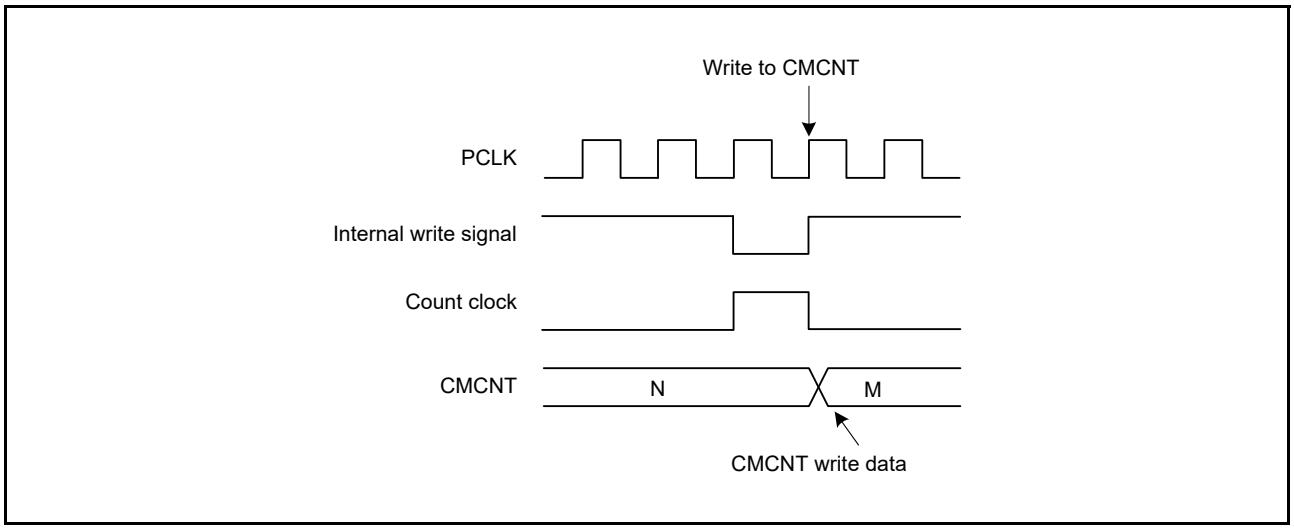

Figure 28.6 Conflict between CMCNT Counter Writing and Incrementing

29. Compare Match Timer W (CMTW)

This MCU includes two units (unit 0 and unit 1) with one channel of 32-bit compare match timer W (CMTW).
CMTW has a 32-bit counter and can generate interrupts each time a set period elapses.
In this section, “PCLK” is used to refer to PCLKB.

29.1 Overview

Table 29.1 shows the specifications of the CMTW.
Figure 29.1 shows a block diagram of the CMTW0 and Figure 29.2 shows a block diagram of the CMTW1.

Table 29.1 CMTW Specifications

Item	Function
Number of channels	Two channels (unit 0, unit 1)
Timer counter	16-bit/32-bit selectable up-counter The counter returns to 0000 0000h after a compare match.
Prescaler	Four dividing clocks are output. Selectable from any of PCLK/8, PCLK/32, PCLK/128, and PCLK/512
Input capture	Up to two input capture input signals available.
Output compare	Up to two output compare output signals available.
Compare match	One compare match available (no output compare output pin used).
Interrupts	Compare match interrupt Input capture 0 and 1 interrupts Output compare 0 and 1 interrupts
Event link function (output) (Unit 0)	Compare match
Event link function (input) (Unit 0)	One of the following operations is enabled after an event is accepted: • Count start operation • Event count operation • Count restart operation
Low power consumption function	Each unit can be placed in the module stop state.

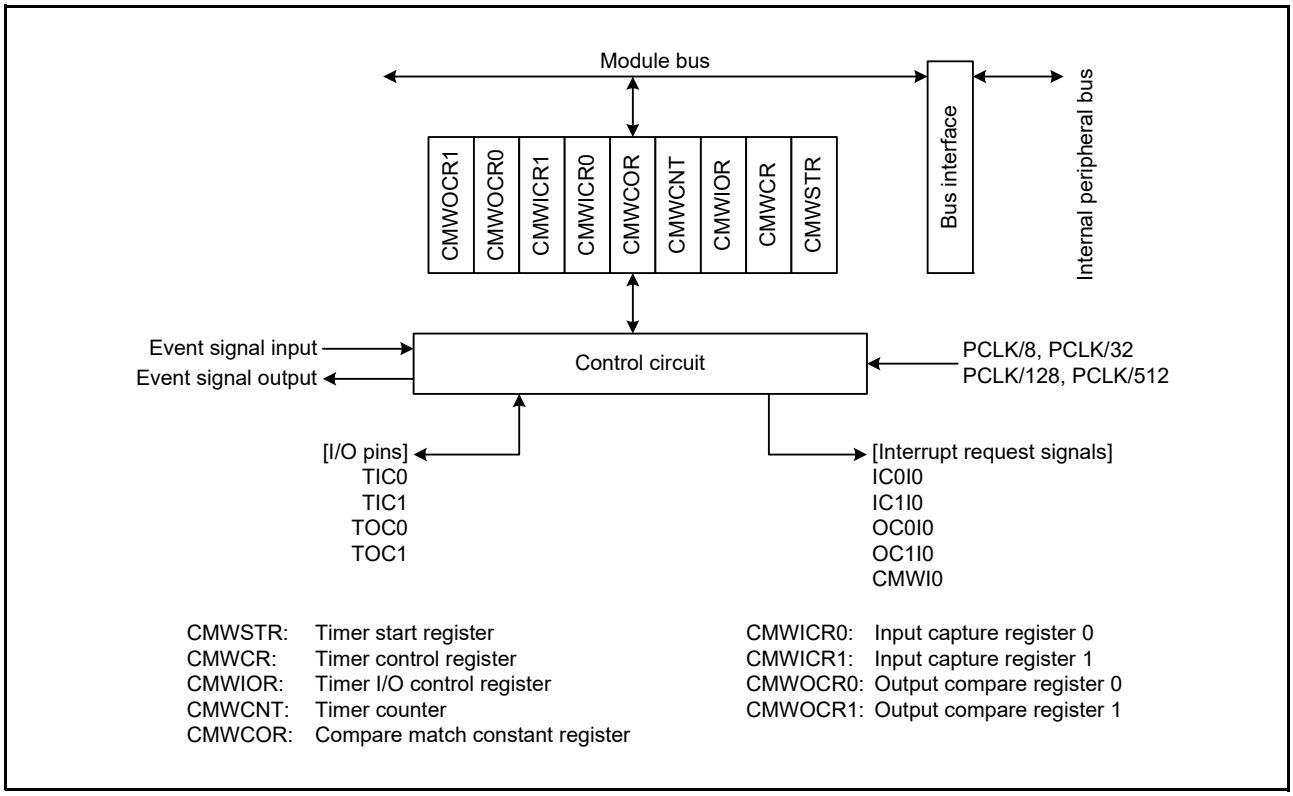

Figure 29.1 CMTW0 Block Diagram

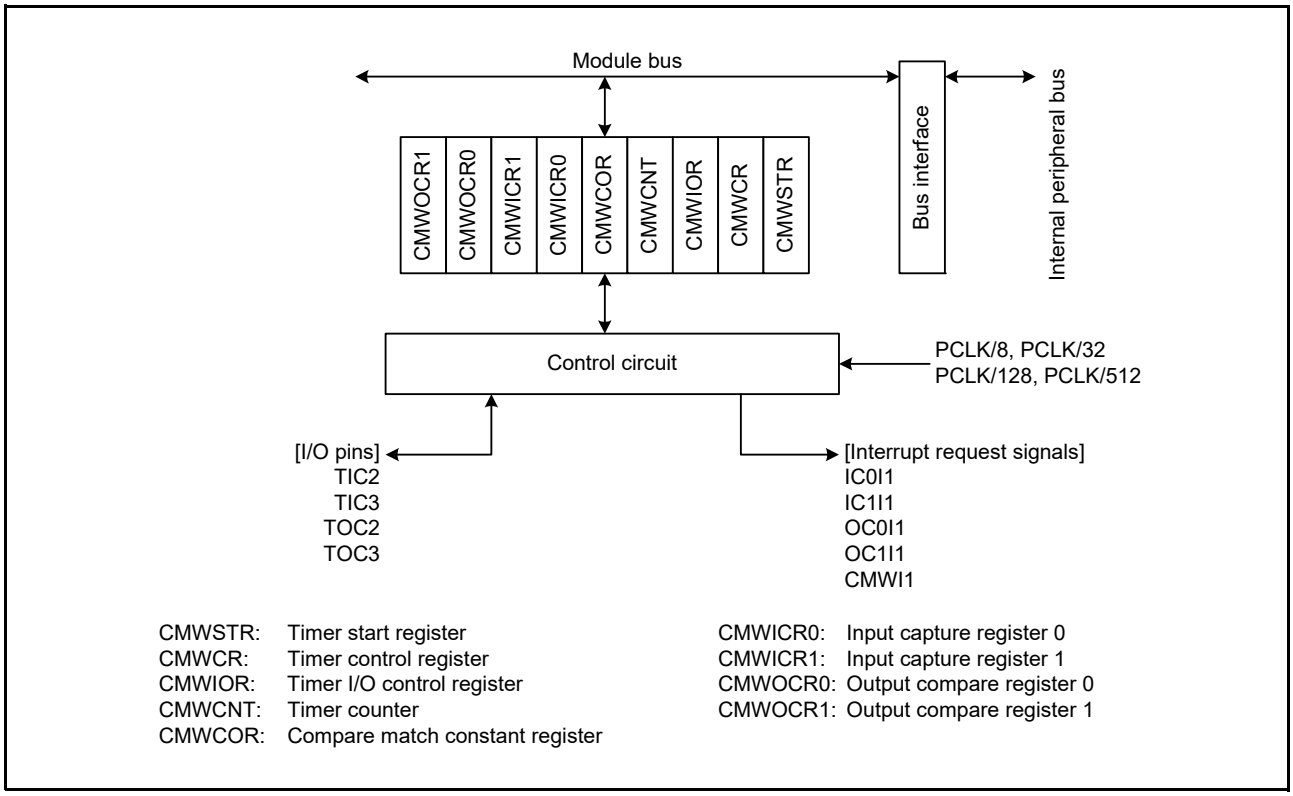

Figure 29.2 CMTW1 Block Diagram

Table 29.2 shows the CMTW pin configuration.

Table 29.2 CMTW Pin Configuration

Unit	Pin Name	I/O	Description
CMTW0	TIC0	Input	Input capture input for the CMTW0.CMWICR0 register
	TIC1	Input	Input capture input for the CMTW0.CMWICR1 register
	TOC0	Output	Output compare output for the CMTW0.CMWOCR0 register
	TOC1	Output	Output compare output for the CMTW0.CMWOCR1 register
CMTW1	TIC2	Input	Input capture input for the CMTW1.CMWICR0 register
	TIC3	Input	Input capture input for the CMTW1.CMWICR1 register
	TOC2	Output	Output compare output for the CMTW1.CMWOCR0 register
	TOC3	Output	Output compare output for the CMTW1.CMWOCR1 register

29.2 Register Descriptions

29.2.1 Timer Start Register (CMWSTR)

Address(es): CMTW0.CMWSTR 0009 4200h, CMTW1.CMWSTR 0009 4280h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STR	Counter Start	0: CMWCNT counter count is stopped. (The value immediately before count operation stops is retained and the count operation is stopped.) 1: CMWCNT counter count is started.	R/W
b15 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

STR Bit (Counter Start)

Specifies whether the timer counter operates or is stopped. The relevant prescaler operates or is stopped according to the settings of the STR bit.

29.2.2 Timer Control Register (CMWCR)

Address(es): CMTW0.CMWCR 0009 4204h, CMTW1.CMWCR 0009 4284h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CCLR[2:0]			—	—	—	CMS	—	OC1IE	OC0IE	IC1IE	IC0IE	CMWIE	—	CKS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKS[1:0]	Clock Select	b1 b0 0 0: PCLK/8 0 1: PCLK/32 1 0: PCLK/128 1 1: PCLK/512	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	CMWIE	Compare Match Interrupt Request Enable	0: Interrupt request (CMWI) disabled 1: Interrupt request (CMWI) enabled	R/W
b4	IC0IE	Input Capture 0 Interrupt Request Enable	0: Interrupt request (IC0I) disabled 1: Interrupt request (IC0I) enabled	R/W
b5	IC1IE	Input Capture 1 Interrupt Request Enable	0: Interrupt request (IC1I) disabled 1: Interrupt request (IC1I) enabled	R/W

b7	OC1IE	Output Compare 1 Interrupt Request Enable	0: Interrupt request (OC1I) disabled 1: Interrupt request (OC1I) enabled	R/W
b8	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b9	CMS	Timer Counter Size	0: 32 bits 1: 16 bits	R/W
b12 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b13	CCLR[2:0]	Counter Clear	b15 b13 0 0 0: CMWCNT counter cleared by CMWCOR register compare match 0 0 1: Clearing of CMWCNT counter disabled 0 1 0: Clearing of CMWCNT counter disabled 0 1 1: Clearing of CMWCNT counter disabled 1 0 0: CMWCNT counter cleared by CMWICR0 register input capture 1 0 1: CMWCNT counter cleared by CMWICR1 register input capture 1 1 0: CMWCNT counter cleared by CMWOCR0 register compare match 1 1 1: CMWCNT counter cleared by CMWOCR1 register compare match	R/W

The CMWCR register should be set while the timer counter (CMWCNT) operation is stopped.

CKS[1:0] Bits (Clock Select)

Select the clock to be input to the CMWCNT counter among four internal clocks obtained by dividing the peripheral module clock (PCLK). When the CMWSTR.STR bit is set to 1, the CMWCNT counter starts counting based on the clock selected with the CMWCR.CKS[1:0] bits.

CMWIE Bit (Compare Match Interrupt Request Enable)

Enables or disables compare match interrupt request (CMWI) generation when the CMWCNT counter and the CMWCOR register values match.

IC0IE Bit (Input Capture 0 Interrupt Request Enable)

Enables or disables input capture 0 interrupt request (IC0I) generation when input capture is generated in the CMWICR0 register.

IC1IE Bit (Input Capture 1 Interrupt Request Enable)

Enables or disables input capture 1 interrupt request (IC1I) generation when input capture is generated in the CMWICR1 register.

OC0IE Bit (Output Compare 0 Interrupt Request Enable)

Enables or disables output compare 0 interrupt request (OC0I) generation when the CMWCNT counter and the CMWOCR0 register values match.

OC1IE Bit (Output Compare 1 Interrupt Request Enable)

Enables or disables output compare 1 interrupt request (OC1I) generation when the CMWCNT counter and CMWOCR1 register values match.

CMS Bit (Timer Counter Size)

Selects either 16 or 32 bits as the size of the timer counter (CMWCNT). The size selected with the CMS bit is valid in the CMWCOR, CMWICR0, CMWICR1, CMWOCR0, and CMWOCR1 registers.

CCLR[2:0] Bits (Counter Clear)

Select the CMWCNT counter clearing source.

29.2.3 Timer I/O Control Register (CMWIOR)

Address(es): CMTW0.CMWIOR 0009 4208h, CMTW1.CMWIOR 0009 4288h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b11, b10	OC1[1:0]	Output Compare 1 Control	b11 b10 0 0: Retains the output value.*1 0 1: Initially outputs low and toggles the output value upon compare match. 1 0: Initially outputs high and toggles the output value upon compare match. 1 1: Setting prohibited	R/W
b12	OC0E	Output Compare 0 Enable	0: Output compare 0 operation disabled 1: Output compare 0 operation enabled	R/W
b13	OC1E	Output Compare 1 Enable	0: Output compare 1 operation disabled 1: Output compare 1 operation enabled	R/W
b14	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b15	CMWE	Compare Match Enable	0: Compare match operation disabled 1: Compare match operation enabled	R/W

Note 1. After reset, low is output until the CMWIOR register is set.

29.2.4 Timer Counter (CMWCNT)

Address(es): CMTW0.CMWCNT 0009 4210h, CMTW1.CMWCNT 0009 4290h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CMWCNT counter is a readable/writable up-counter.
Before starting count operation, the timer control register (CMWCR) should be set. When the 16-bit counter size is selected with the CMS bit in the timer control register (CMWCR), bits 15 to 0 in this register are valid. When writing to the CMWCNT counter, write data in 32-bit units with the upper bits set to 0000h. The CMWCNT counter can only be accessed in longword units.
When the CMWSTR.STR bit is set to 1, the CMWCNT counter starts counting. When the CMWSTR.STR bit is set to 0, the CMWCNT counter retains the value immediately before a stop of counting and stops counting.

29.2.5 Compare Match Constant Register (CMWCOR)

Address(es): CMTW0.CMWCOR 0009 4214h, CMTW1.CMWCOR 0009 4294h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The CMWCOR register is a readable/writable register that specifies the time up to a compare match between the timer counter (CMWCNT) value and CMWCOR value. When the 16-bit counter size is selected with the CMS bit in the timer control register (CMWCR), bits 15 to 0 in this register are valid. When writing to the CMWCOR register, write data in 32-bit units with the upper bits set to 0000h. The CMWCOR register can only be accessed in longword units. To detect an overflow, set the CMWCOR register value to FFFF FFFFh (32-bit count operation) or 0000 FFFFh (16-bit count operation). When the CMWCNT counter is set to 0, a compare match interrupt request (CMWI) can be used as an overflow detection signal.

29.2.6 Input Capture Register n (CMWICRn) (n = 0, 1)

Address(es): CMTW0.CMWICR0 0009 4218h, CMTW0.CMWICR1 0009 421Ch, CMTW1.CMWICR0 0009 4298h, CMTW1.CMWICR1 0009 429Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CMWICRn register is a read-only register in which the CMWCNT value is stored when an input capture is generated.
When the 16-bit counter size is selected with the CMWCR.CMS bit, bits 15 to 0 in these registers are valid. Writing to these registers is invalid. The CMWICRn register can only be accessed in longword units.

29.2.7 Output Compare Register n (CMWOCRn) (n = 0, 1)

Address(es): CMTW0.CMWOCR0 0009 4220h, CMTW0.CMWOCR1 0009 4224h, CMTW1.CMWOCR0 0009 42A0h, CMTW1.CMWOCR1 0009 42A4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The CMWOCRn register is a readable/writable register that set the value to be compared when an output compare is generated.
When the 16-bit counter size is selected with the CMWCR.CMS bit, bits 15 to 0 of these registers become valid. When writing to these registers, write data in 32-bit units with the upper bits set to 0000h.
The CMWOCRn register can only be accessed in longword units. The initial value of CMWOCR0 and CMWOCR1 registers is FFFF FFFFh.

29.3 Operation

When the CMWCR register is set and then the STR bit in CMWSTR is set to 1, the CMTW starts count operation. Setting the CMWSTR.STR bit to 0 enables the CMWCNT counter to retain the value immediately before a stop of counting and stop counting. Setting the CMWIOR register enables using the compare match function, input capture input function, and output compare output function.

29.3.1 Period Count Operation

When the counter clock is selected by using the CMWCR.CKS[1:0] bits and the CMWSTR.STR bit is set to 1, the CMWCNT counter starts counting cycles of the selected clock. When clearing of the counter is selected by the CMWCR.CCLR[2:0] bits and the counter clearing source is generated, the CMWCNT counter becomes 0000 0000h and continues counting. When clearing of the counter is not selected, an overflow is generated when FFFF FFFFh changes to 0000 0000h during 32-bit count operation and 0000 FFFFh changes to 0000 0000h during 16-bit count operation, and the CMWCNT counter continues counting.

29.3.2 Compare Match Function

When the values of the CMWCNT counter and CMWCOR register match, the CMWCNT counter becomes 0000 0000h. At this time, a compare match interrupt request (CMWI) is generated. The CMWCNT counter restarts counting from 0000 0000h.

To enable overflow detection, the CMWCOR register value should be set to FFFF FFFFh (when the counter size is 32 bits) or 0000 FFFFh (when the counter size is 16 bits). When the values of the CMWCNT counter and CMWCOR register match, the CMWCNT counter becomes 0000 0000h. In this case, the compare match interrupt request (CMWI) is generated. The CMWCNT counter then restarts counting from 0000 0000h.

Figure 29.3 shows an example of procedure for setting compare match operation.

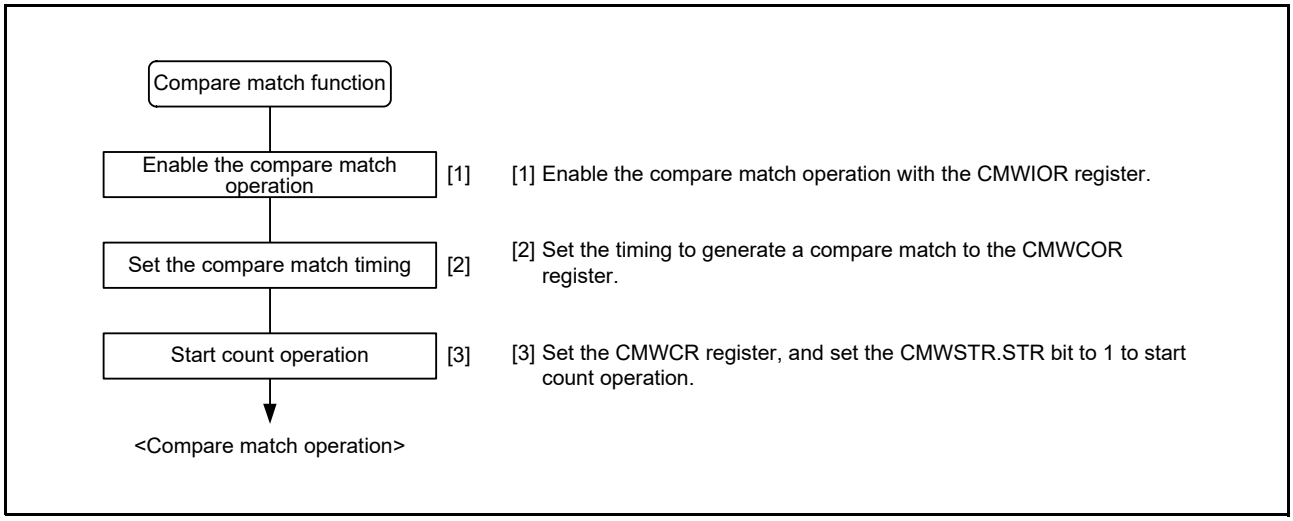

Figure 29.3 Procedure for Setting Compare Match Operation

Figure 29.4 shows an example when compare match with CMWCOR is set as a counter clearing source.

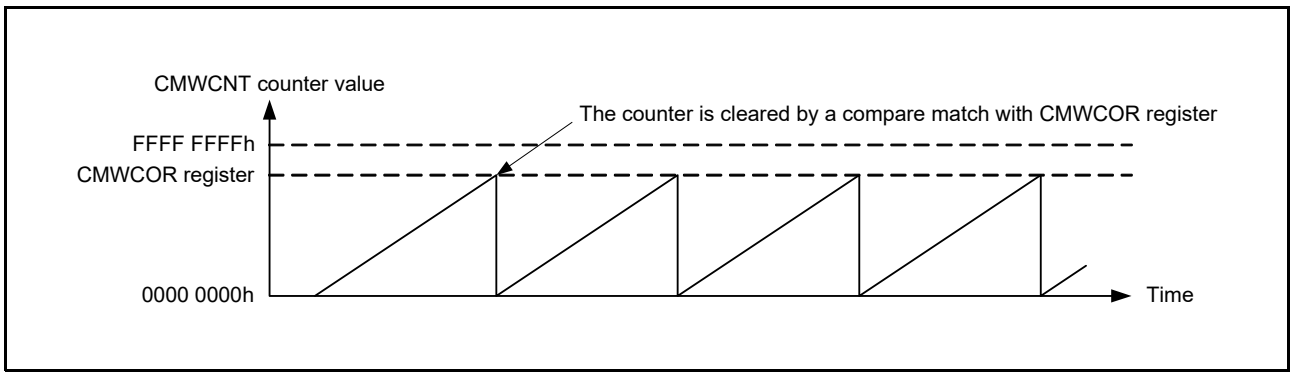

Figure 29.4 Example of Compare Match Operation

Figure 29.5 shows an example when CMWCOR is set to FFFF FFFFh and an overflow is detected.

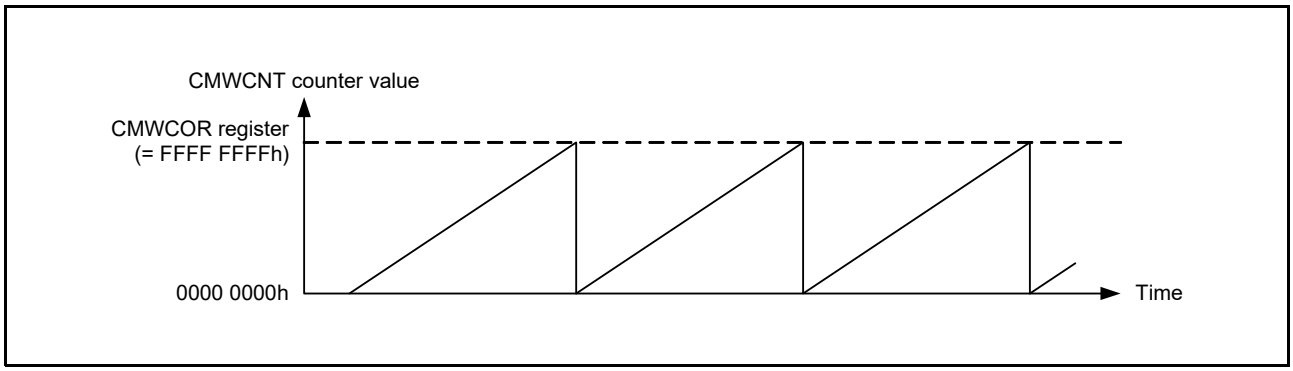

Figure 29.5 Example of Compare Match Operation (Overflow Detected)

29.3.3 Output Compare Function

The output compare function can be used for toggle waveform output. When the CMWCNT counter value matches either of the values of the CMWOCR0 or CMWOCR1 register, the output compare interrupt request (OC0I or OC1I) is generated. Figure 29.6 shows an example of procedure for setting output compare operation.

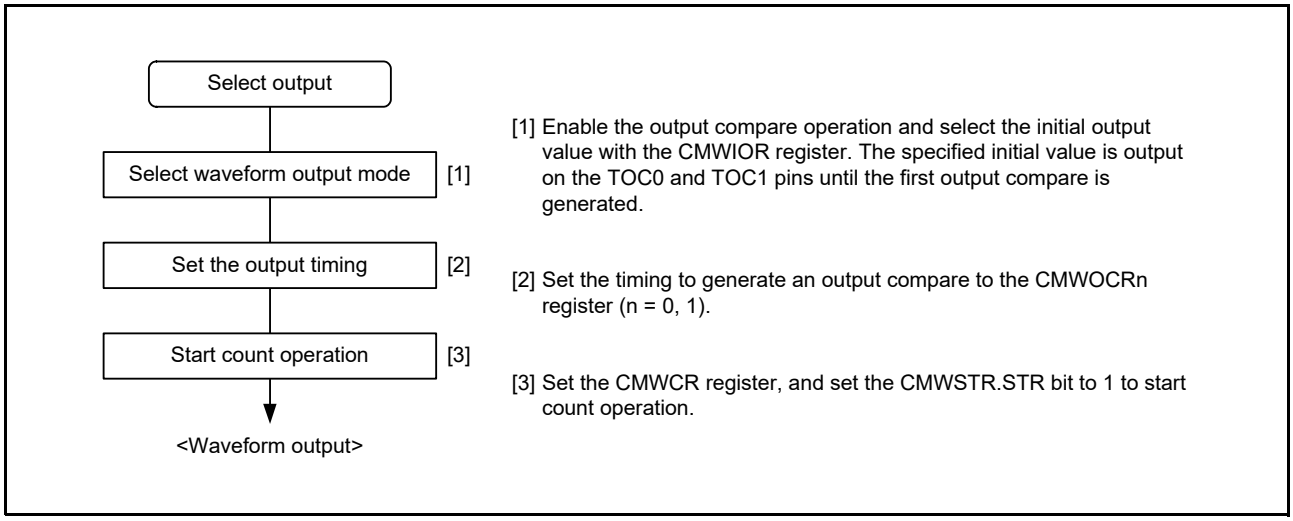

Figure 29.6 Procedure for Setting Output Compare Operation

Figure 29.7 shows an example of toggle waveform output from the TOC0 and TOC1 pins when the counter is set to be cleared by compare match with the CMWOCR1 register.

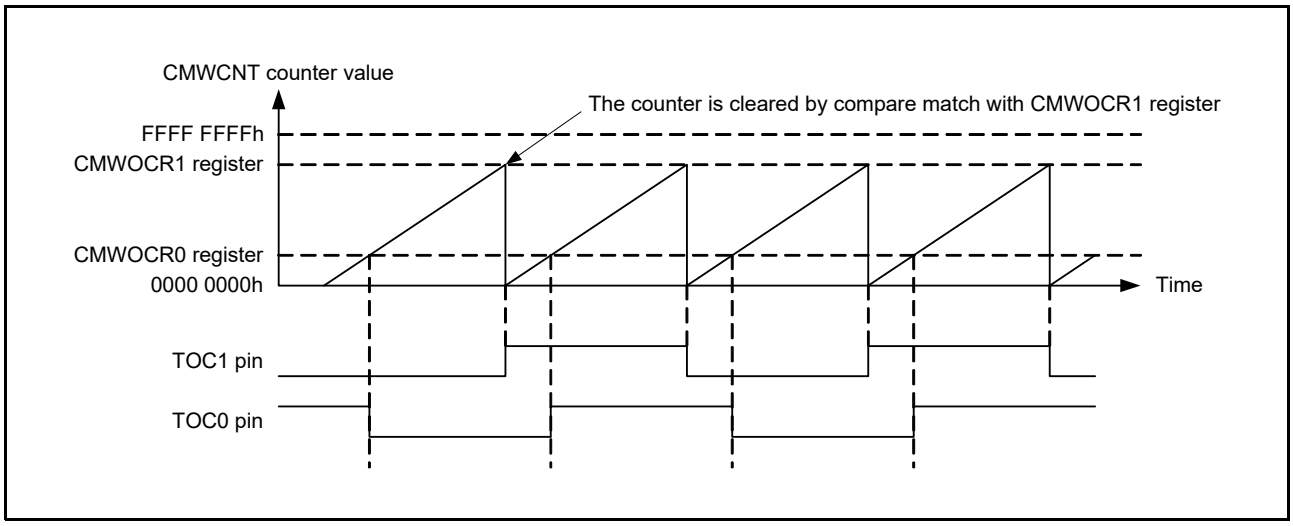

Figure 29.7 Example of Output Compare Operation (Unit 0)

29.3.4 Input Capture Function

Through detecting the edge on the TIC0 and TIC1 pin input, the CMWCNT counter value can be transferred to the CMWICR0 and CMWICR1 registers, respectively. The edges to be detected can be selected from among the rising edge alone, falling edge alone, and both the rising and falling edges. When the CMWCNT counter value is transferred to the CMWICR0 or CMWICR1 register using the input capture operation, an input capture interrupt request (IC0I or IC1I) is generated. Figure 29.8 shows an example of procedure for setting input capture operation.

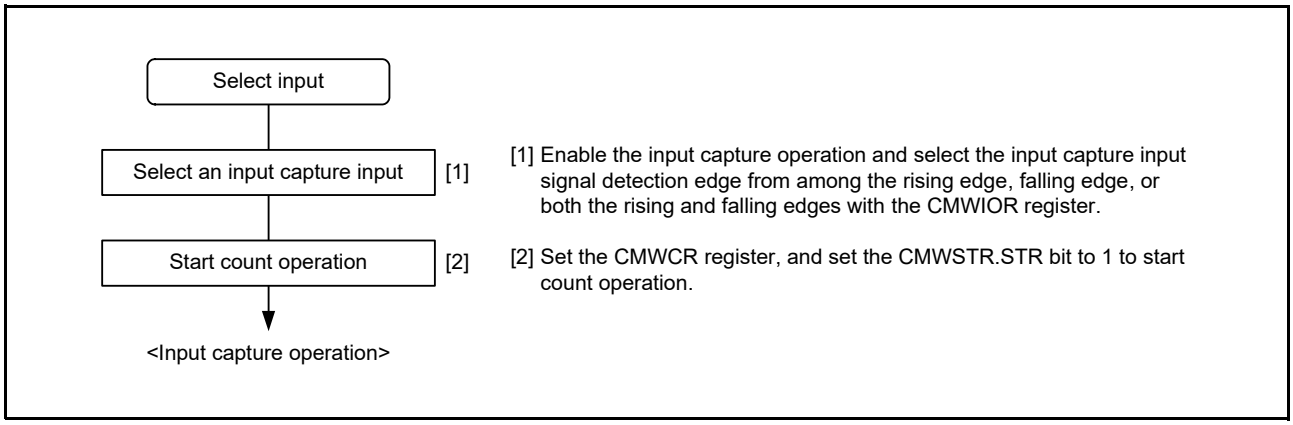

Figure 29.8 Procedure for Setting Input Capture Operation

Figure 29.9 shows an example in which both edges are selected for the TIC0 pin input capture detection edge and the falling edge for the TIC1 pin, and the CMWCNT counter is cleared by a CMWICR1 register input capture.

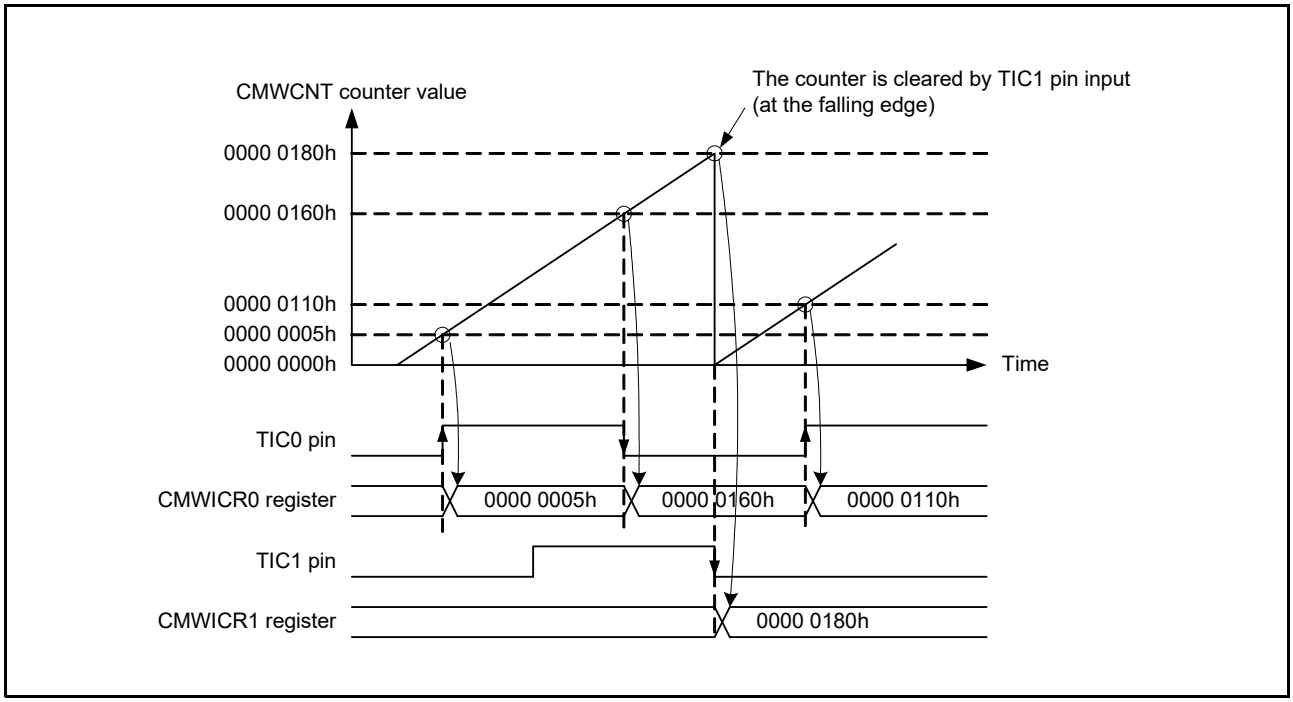

Figure 29.9 Example of Input Capture Operation (Unit 0)

29.3.5 Counter Size

With the CMTW, either 16 or 32 bits can be selected as the counter size by using the CMWCR.CMS bit.
When the counter is used as a 16-bit counter, set the value of the CMWCOR register in 32-bit units with the upper 16 bits set to 0000h. 0000 FFFFh should be set to detect an overflow. Similarly, set the values of the CMWOCR0 and CMWOCR1 registers in 32-bit units with the upper 16 bits set to 0000h. Read the CMWOCR0 and CMWOCR1 registers in 32-bit units. The upper 16 bits can be read as 0000h.

29.3.6 Count Timing of CMWCNT Counter

By setting the CMWCR.CKS[1:0] bits, one of four clocks (PCLK/8, PCLK/32, PCLK/128, and PCLK/512) obtained by dividing the peripheral module clock (PCLK) can be selected as the counter clock to be input to the CMWCNT counter.
Figure 29.10 shows the timing.

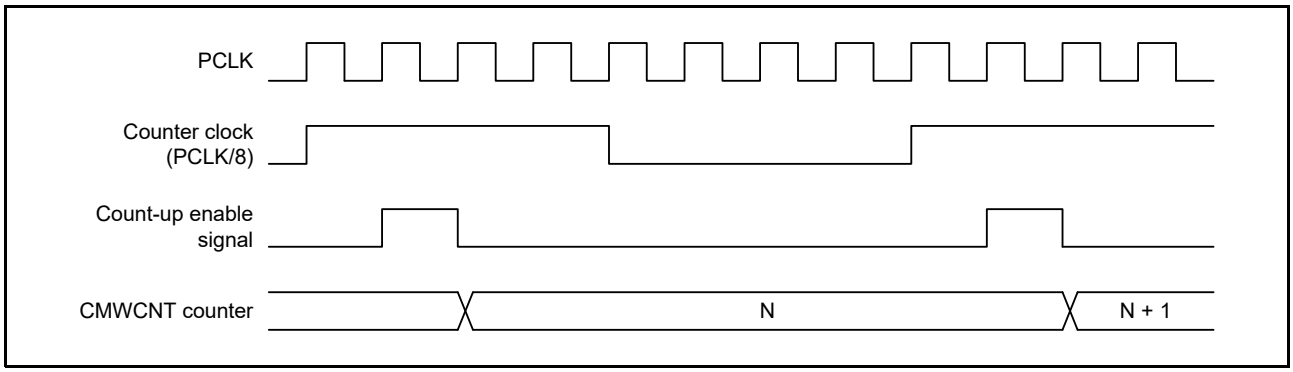

Figure 29.10 Count Timing (PCLK/8)

29.3.7 Output Compare Output Timing

A compare match signal is generated in the last state in which the CMWOCRn register (n = 0, 1) and CMWCNT counter values match (the CMWCNT counter value is updated immediately after the state). The compare match signal is generated if the CMWCNT count-up enable signal is input after a match between the CMWOCRn register and CMWCNT counter values. When a compare match signal is generated, output of the output compare pin (TOC pin) is toggled.
Figure 29.11 shows output compare output timing.

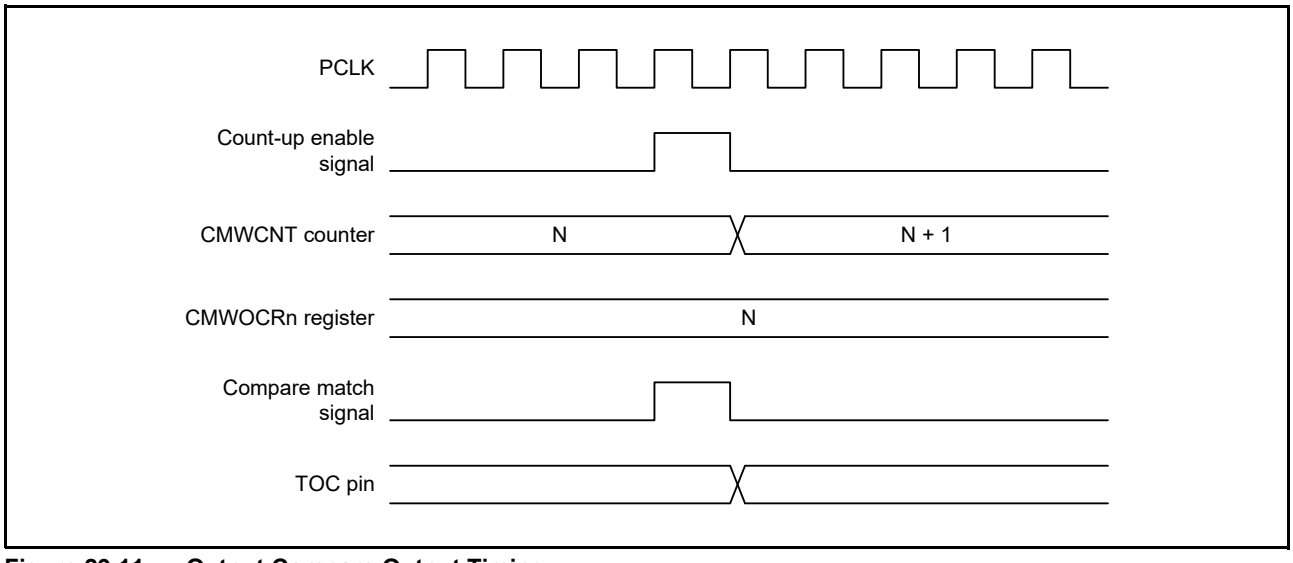

Figure 29.11 Output Compare Output Timing

29.3.8 Input Capture Timing

Figure 29.12 shows the timing of input capture operation at both edges.
When the edge of the TIC0 and TIC1 pins is detected, the CMWCNT counter value is transferred to the CMWICR0 and CMWICR1 registers, respectively.

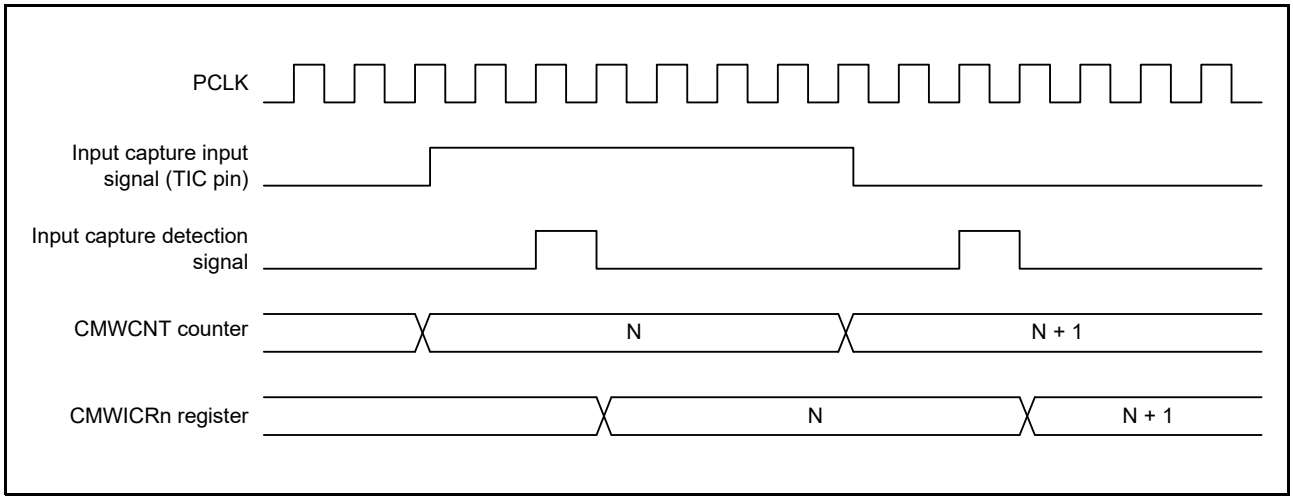

Figure 29.12 Input Capture Timing (Unit 0, Both-Edge Detection) (n = 0, 1)

29.4 Interrupts

29.4.1 CMTW Interrupt Sources and DTC/DMAC Transfer Requests

The CMTW has five interrupt sources: two input capture interrupt requests (IC0I and IC1I), two output compare interrupt requests (OC0I and OC1I), and a compare match interrupt request (CMWI).
Table 29.3 shows the interrupt sources. The interrupt sources can be enabled or disabled using the IC0IE, IC1IE, OC0IE, OC1IE, and CMWIE bits in CMWCR and are separately generated to the interrupt controller.
Each interrupt request can activate the DMAC or DTC. When the DMAC is used for data transfer, an interrupt request is not generated to the CPU. For generating an interrupt request to the CPU during data transfer using the DTC, refer to section 18, Data Transfer Controller (DTCb).

Table 29.3 CMTW Interrupt Sources

Unit	Name	Interrupt Request	Interrupt Request Enable Bit	DMAC/DTC Activation
CMTW0	CMWI0	Compare match of CMTW0.CMWCOR register	CMTW0.CMWCR.CMWIE	Possible
	IC0I0	Input capture of CMTW0.CMWICR0 register	CMTW0.CMWCR.IC0IE	Possible
	IC1I0	Input capture of CMTW0.CMWICR1 register	CMTW0.CMWCR.IC1IE	Possible
	OC0I0	Output compare of CMTW0.CMWOCR0 register	CMTW0.CMWCR.OC0IE	Possible
	OC1I0	Output compare of CMTW0.CMWOCR1 register	CMTW0.CMWCR.OC1IE	Possible
CMTW1	CMWI1	Compare match of CMTW1.CMWCOR register	CMTW1.CMWCR.CMWIE	Possible
	IC0I1	Input capture of CMTW1.CMWICR0 register	CMTW1.CMWCR.IC0IE	Possible
	IC1I1	Input capture of CMTW1.CMWICR1 register	CMTW1.CMWCR.IC1IE	Possible
	OC0I1	Output compare of CMTW1.CMWOCR0 register	CMTW1.CMWCR.OC0IE	Possible
	OC1I1	Output compare of CMTW1.CMWOCR1 register	CMTW1.CMWCR.OC1IE	Possible

29.4.2 Timing of Compare Match Interrupt Generation

When the values of the CMWCNT counter and CMWCOR register match, a compare match interrupt request (CMWI) is generated. The compare match signal is generated at the end of the cycle where the values matched (i.e. when the CMWCNT counter is updated from the matching counter value).The compare match signal, therefore, is not generated until a count-up enable signal is generated after the values of the CMWCNT counter and CMWCOR register have matched. Figure 29.13 shows the timing of compare match interrupt generation.

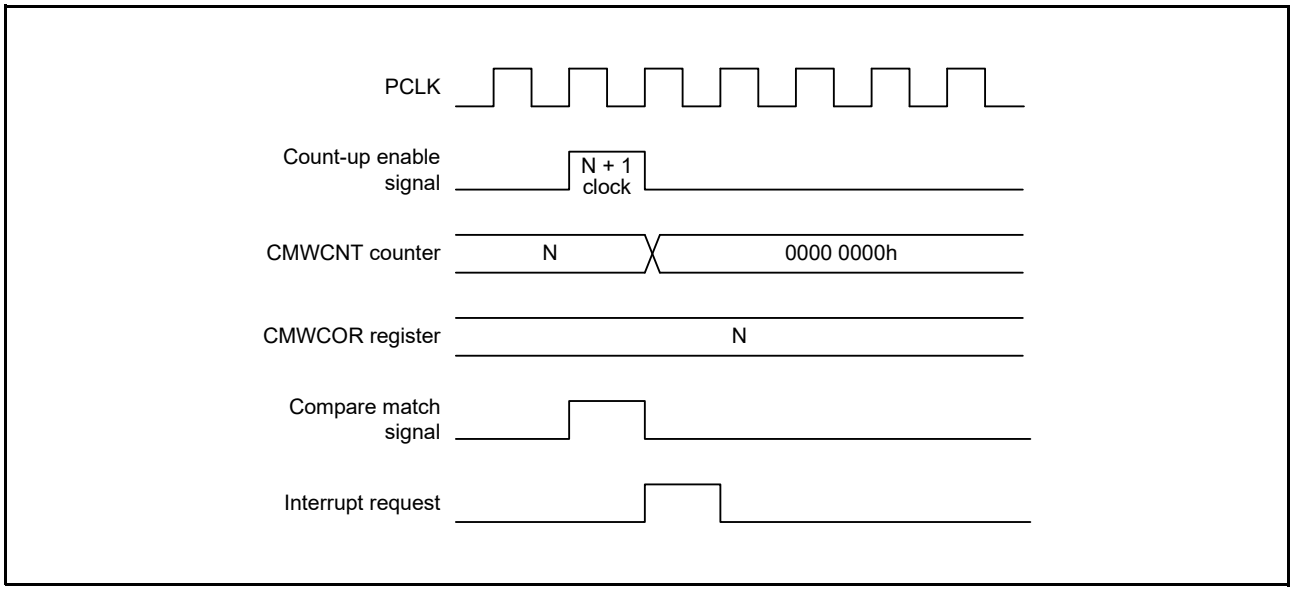

Figure 29.13 Timing of Compare Match Interrupt Generation

(a) Timing of Output Compare Interrupt Generation

Figure 29.14 shows the timing of output compare interrupt generation.

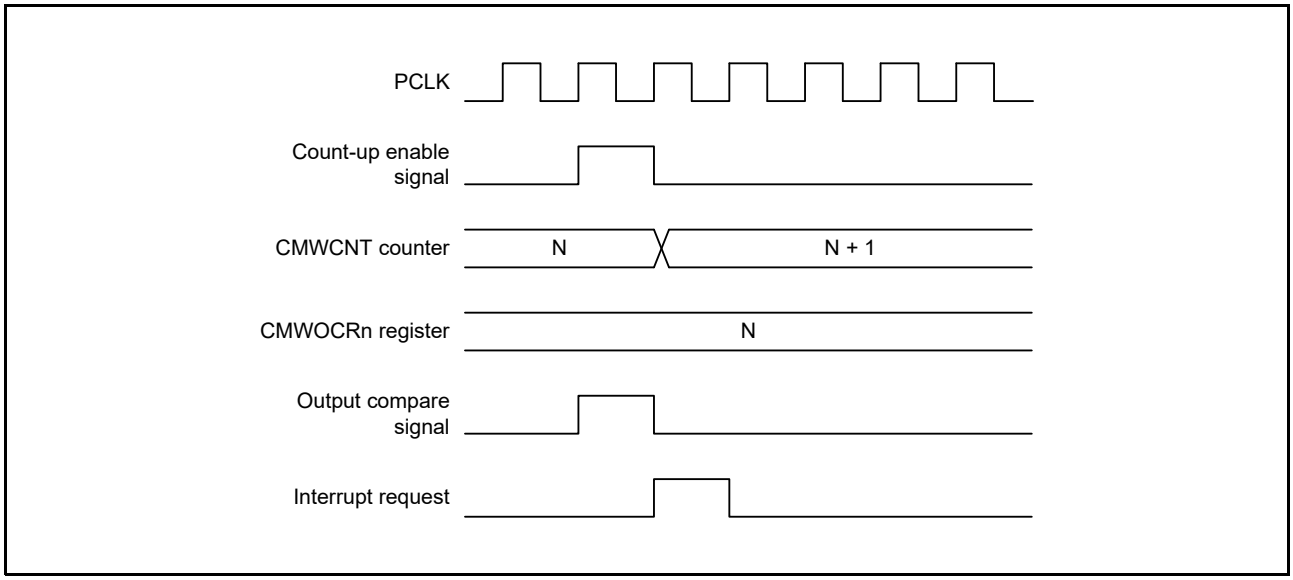

Figure 29.14 Timing of Output Compare Interrupt Generation (n = 0, 1)

(b) Timing of Input Capture Interrupt Generation

Figure 29.15 shows the timing of input capture interrupt generation.

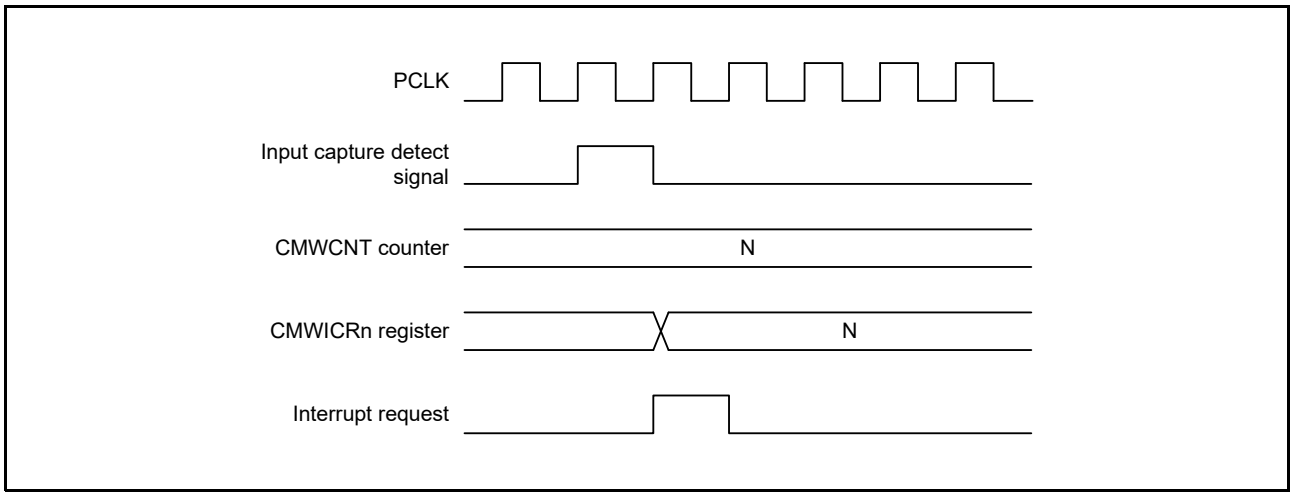

Figure 29.15 Timing of Input Capture Interrupt Generation (n = 0, 1)

29.5 Link Operations by ELC

29.5.1 Event Signal Output to ELC

The CMTW uses the event link controller (ELC) to perform link operation to a preset module using the interrupt request signal as the event signal.
The CMTW outputs the event signal upon a compare match. The corresponding channel is channel 0. The event signal can be output regardless of the corresponding interrupt request enable bit (CMWCR.CMWIE).
For details, refer to section 19, Event Link Controller (ELC).

(1) Compare Match Event

In response to a compare match, the CMTW simultaneously issues an interrupt request and a compare match event signal to the ELC. The event signal is issued regardless of the settings of the corresponding interrupt request enable bit (CMWCR.CMWIE bit).

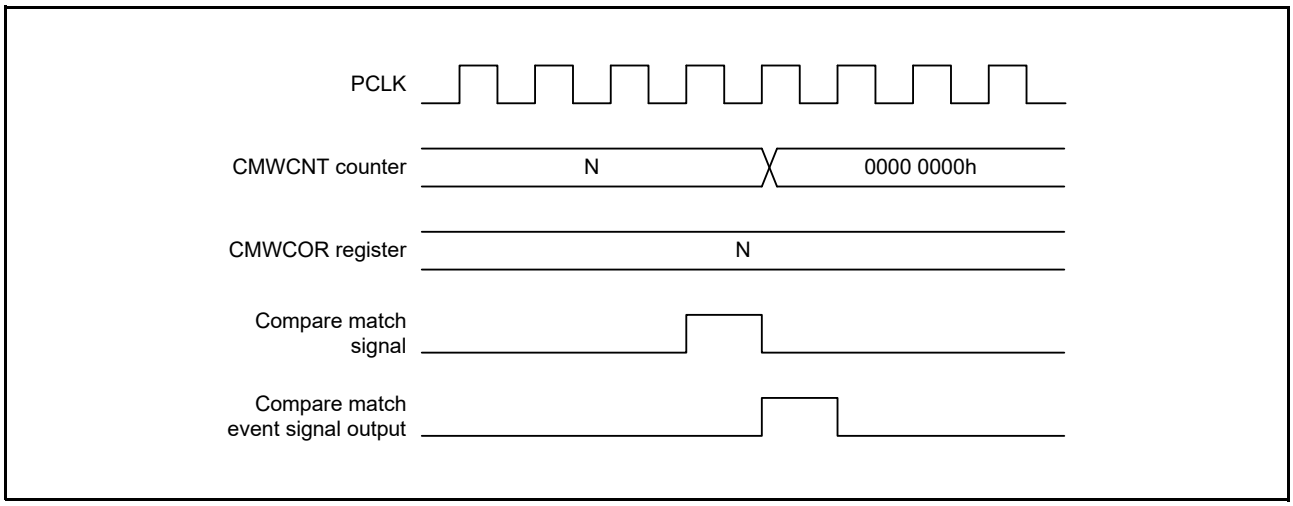

Figure 29.16 Timing of Issuing a Compare Match Event Signal

29.5.2 CMTW Operation When Receiving an Event Signal from ELC

The CMTW can perform any of the following operations according to the event preset by the ELSRn register of the ELC.

(1) Count Start

The CMTW count start operation is selected by the ELOPH register of the ELC. If the event specified by the ELSRn register occurs, the CMWSTR.STR bit is set to 1, starting the CMTW count operation.
However, if the specified event occurs while the CMWSTR.STR bit is 1, the event is ignored.

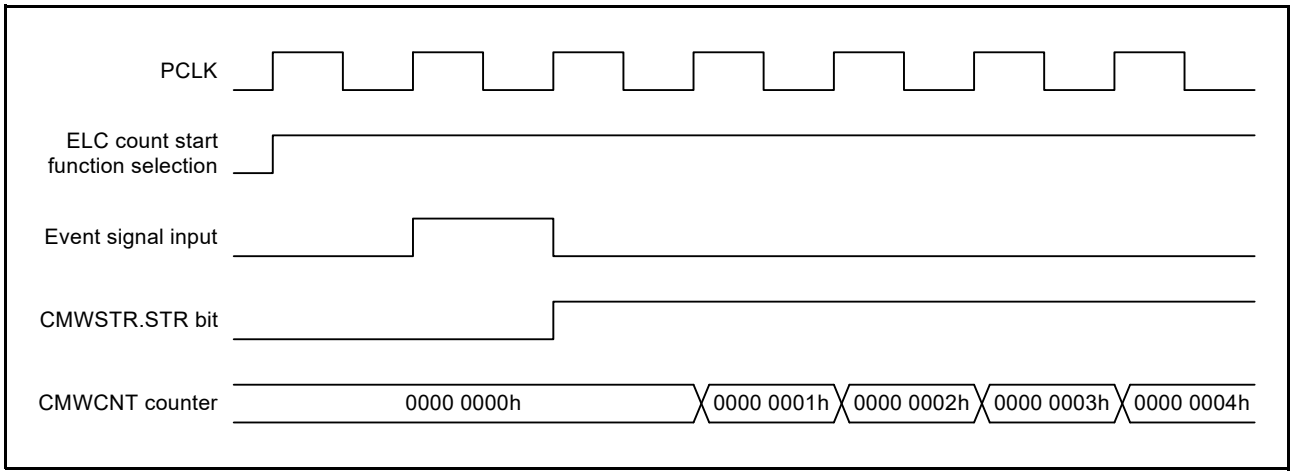

Figure 29.17 Count Start Operation on Acceptance of the Event Signal

(2) Event Count

The CMTW event count operation is selected by the ELOPH register of the ELC. If the event specified by the ELSRn register occurs when the CMWCR.STR bit is 1, the event is counted as the count source regardless of the CMWCR.CKS[1:0] bit setting.
Reading the counter value returns the number of events that have been actually input.

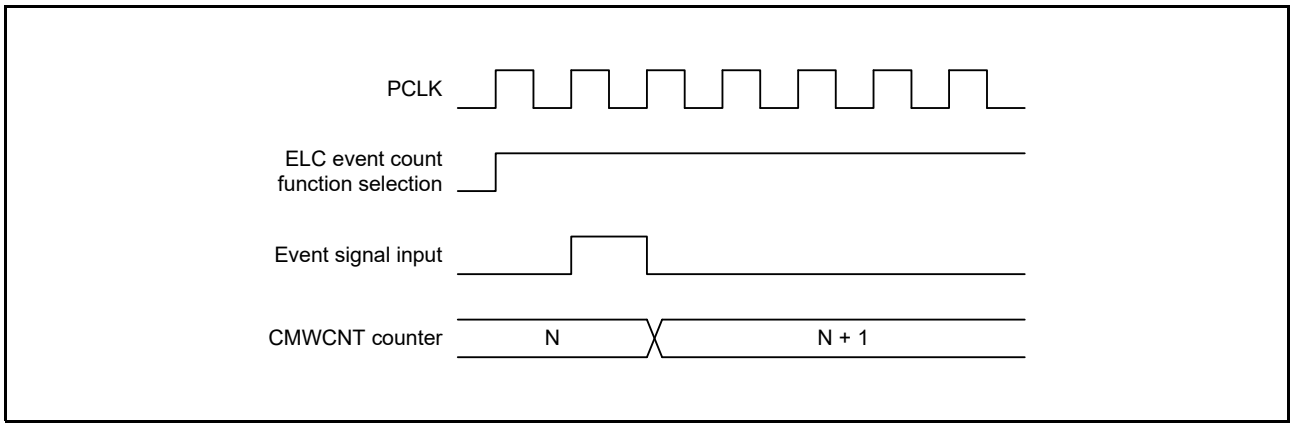

Figure 29.18 Event Count Operation on Acceptance of the Event Signal

(3) Count Restart

The CMTW count restart operation is selected by the ELOPH register of the ELC. If the event specified by the ELSRn register occurs, the CMWCNT counter value becomes 0000 0000h. If the CMWSTR.STR bit is 1, the count operation can be continued.

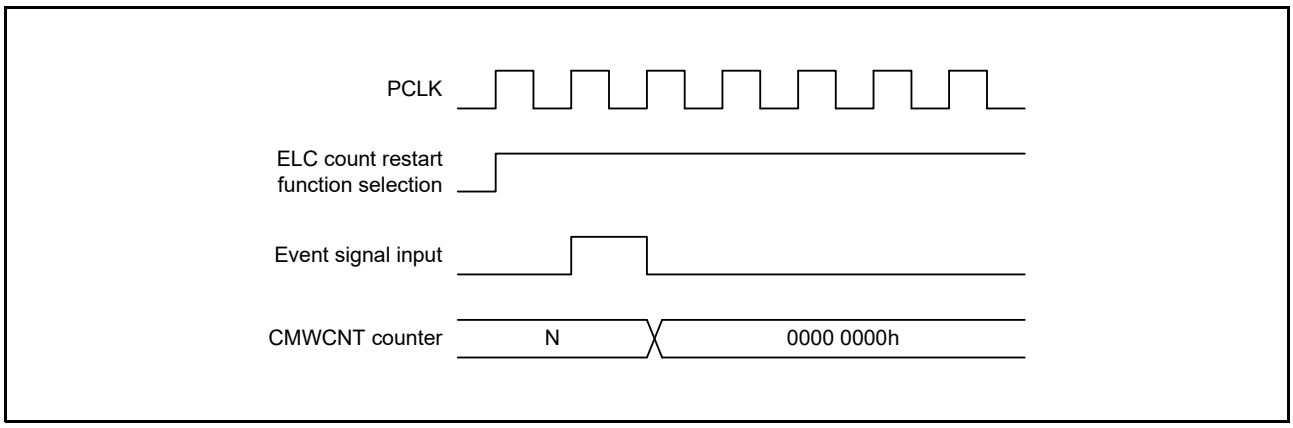

Figure 29.19 Count Restart Operation on Acceptance of the Event Signal

29.5.3 Conflict between Event Link Operation and Register Access

The followings are the notes on using CMTW for event link operations.
Table 29.4 lists count operations when event link operation and register access conflict.

Table 29.4 Count Operations When Event Link Operation and Register Access Conflict (n = 0, 1)

Event Link Operation	Register Access	CMWCNT Counter Status	Operation to be Performed
Count start	Writing to the CMWSTR.STR bit	Stopped state	Count start
		Compare match	Count start
		Counting up	Count start
Event count	Writing to CMWCNT counter	—	Event count
	Writing to CMWCOR register	Compare match	Compare match
Count restart	Writing to CMWCNT counter	Other than compare match	Count restart
	Writing to CMWCNT counter	Compare match	Compare match
	(No access to registers)	Compare match	Compare match
(No events)	Writing to CMWCNT counter	Compare match	Output of compare match interrupt request Writing to CMWCNT counter
		Counting up	Writing to CMWCNT counter
	Writing to CMWCOR register	Compare match	Compare match
	Writing to CMWOCRn register	Compare match	Compare match
	Reading from CMWCNT counter	Counting up	Counting up and reading of the previous value

(1) Count Start

When writing to the STR bit in the CMWSTR register and acceptance of the event signal are in contention, writing to the STR bit does not proceed since setting of the STR bit to 1 in response to the event takes priority.

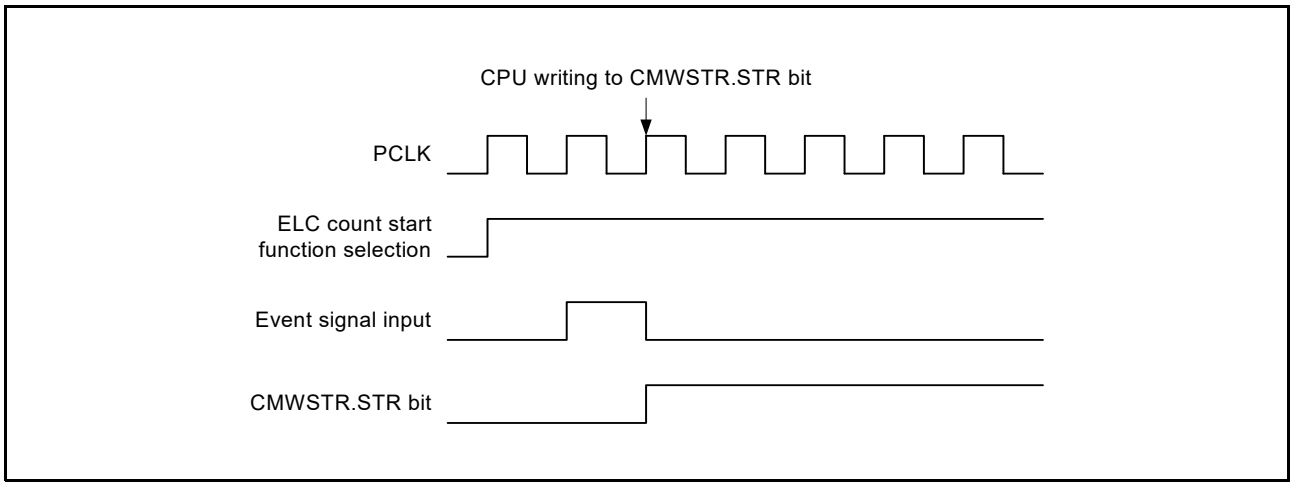

Figure 29.20 Conflict between Event Acceptance and Register Access in Count Start Operation

(2) Event Count

When writing to the CMWCNT counter and acceptance of the event signal are in contention, writing to the CMWCNT counter does not proceed since the count operation in response to the event takes priority.

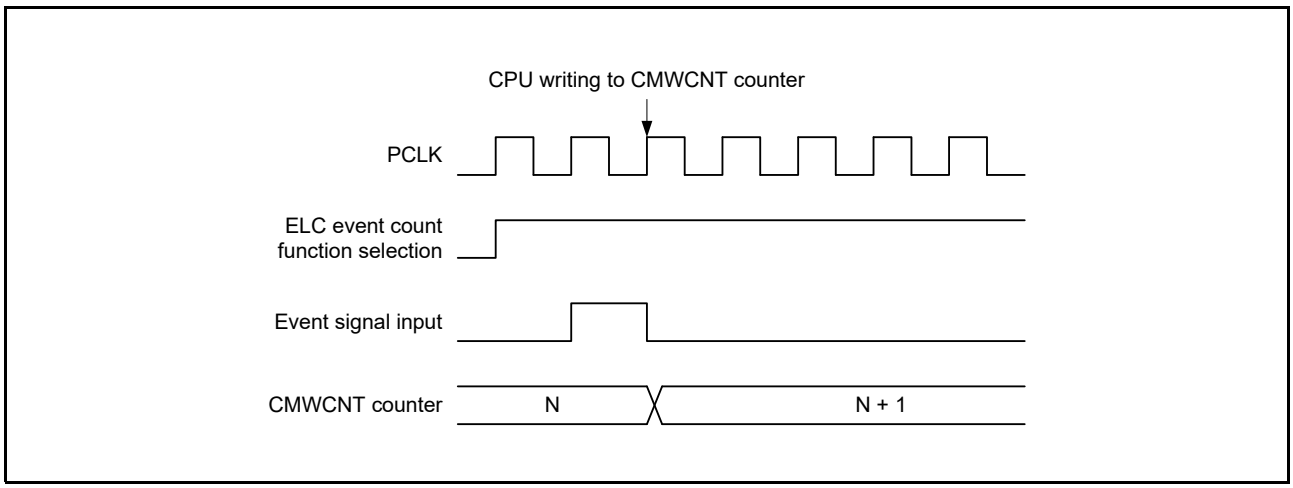

Figure 29.21 Conflict between Event Acceptance and Register Access in Event Counting Operation

(3) Count Restart

When writing to the CMWCNT counter and acceptance of the event signal are in contention, writing to the CMWCNT counter does not proceed since the counter value initialization in response to the event occurrence takes priority.

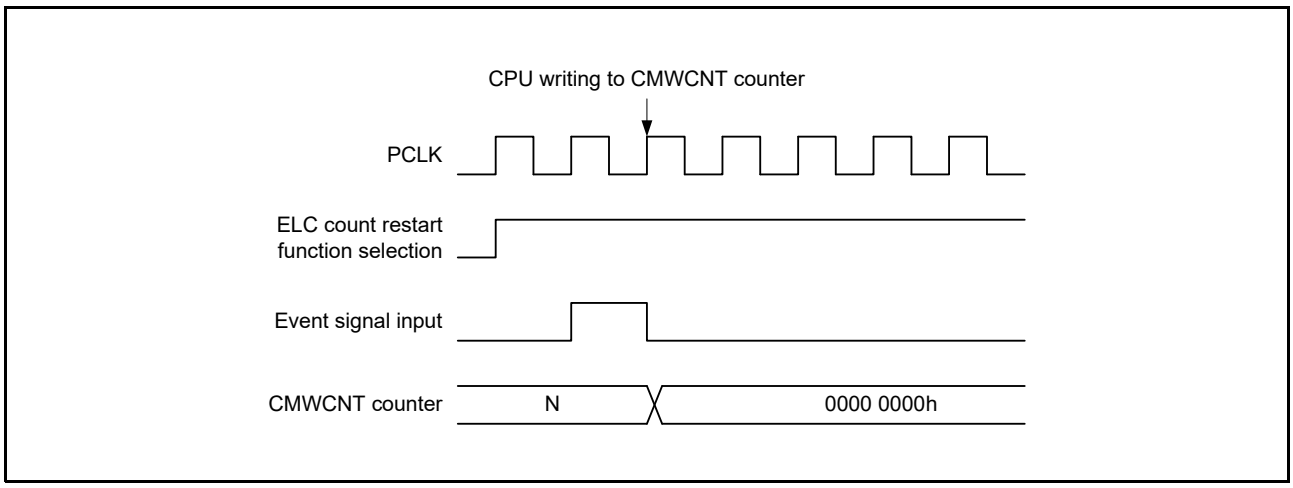

Figure 29.22 Conflict between Event Acceptance and Register Access in Count Restart Operation

29.6 Usage Notes

29.6.1 Setting the Module Stop Function

The CMTW operation can be enabled or disabled using the MSTPCRA register. The CMTW0 and CMTW1 are initially disabled after a reset. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

29.6.2 Conflict between CMWCNT Counter Writing and Compare Match

If the compare match signal is generated during writing to the CMWCNT counter, the compare match request is output but the counter is not cleared since writing to the counter takes priority.
Figure 29.23 shows the timing of conflict between CMWCNT counter writing and compare match.

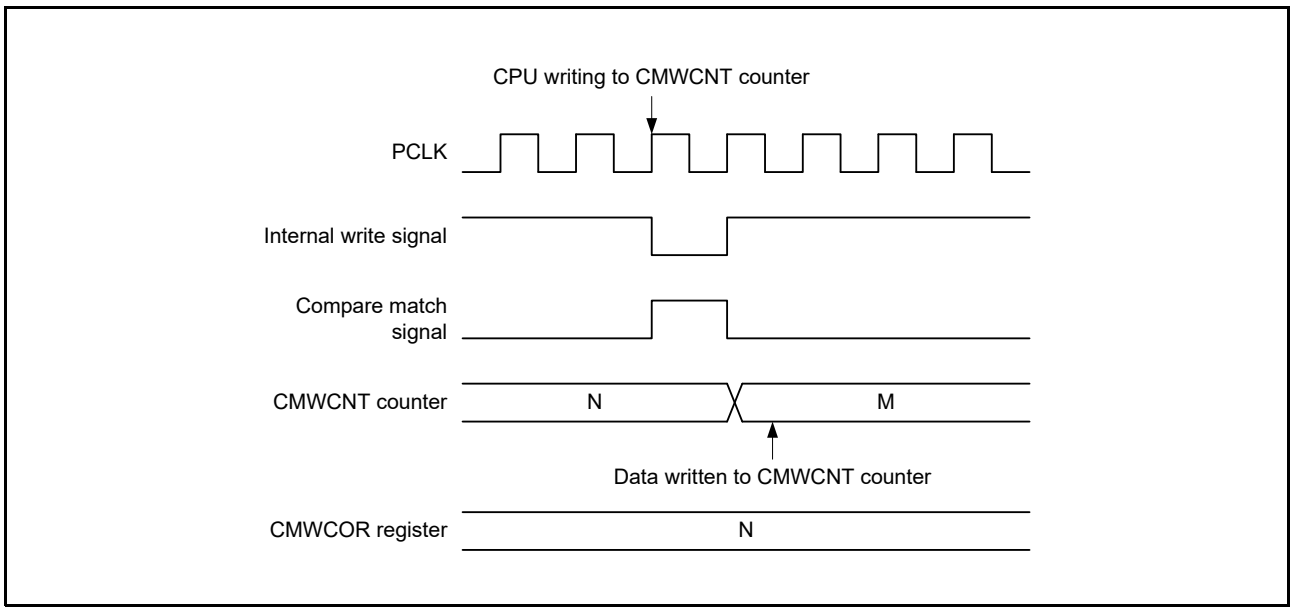

Figure 29.23 Conflict between CMWCNT Counter Writing and Compare Match

29.6.3 Conflict between CMWCNT Counter Writing and Incrementing or Clearing

In case of conflict between incrementation or clearing of the CMWCNT counter and writing to the CMWCNT counter, the counter is not actually incremented or cleared since writing to the CMWCNT counter takes priority.
Figure 29.24 shows the timing in the case of contention between writing to the CMWCNT counter and incrementation or clearing.

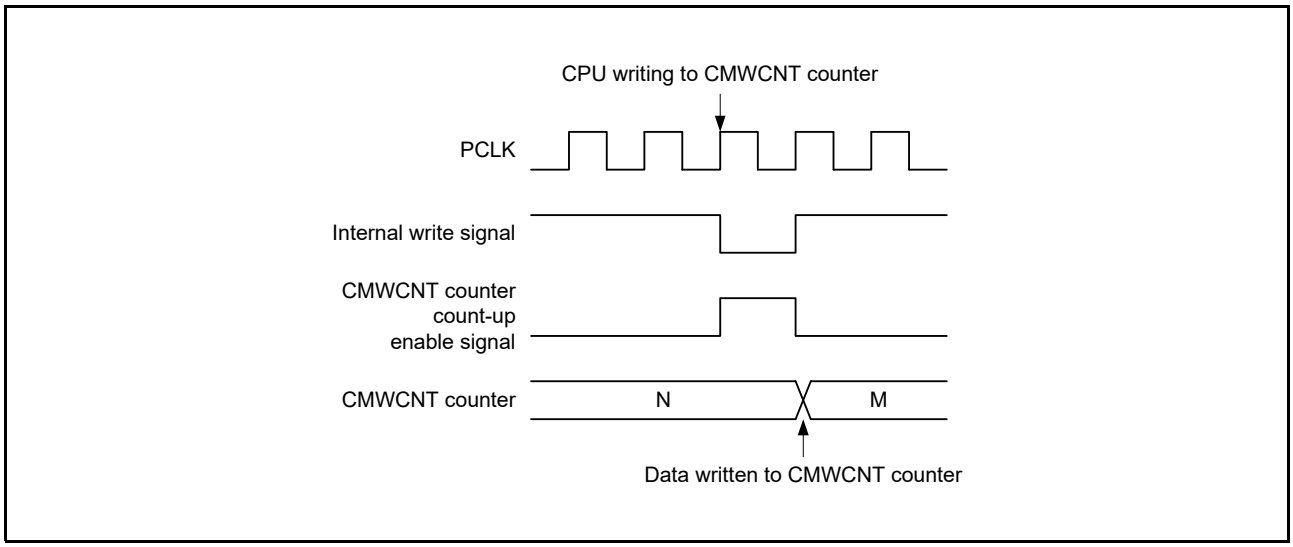

Figure 29.24 Conflict between CMWCNT Counter Writing and Incrementing

29.6.4 Conflict between CMWCOR Register Writing and Compare Match

If the compare match is generated during the CMWCOR register write cycle, the writing to the CMWCOR register takes priority and also the compare match signal is output.
Figure 29.25 shows the timing of conflict between CMWCOR register writing and compare match.

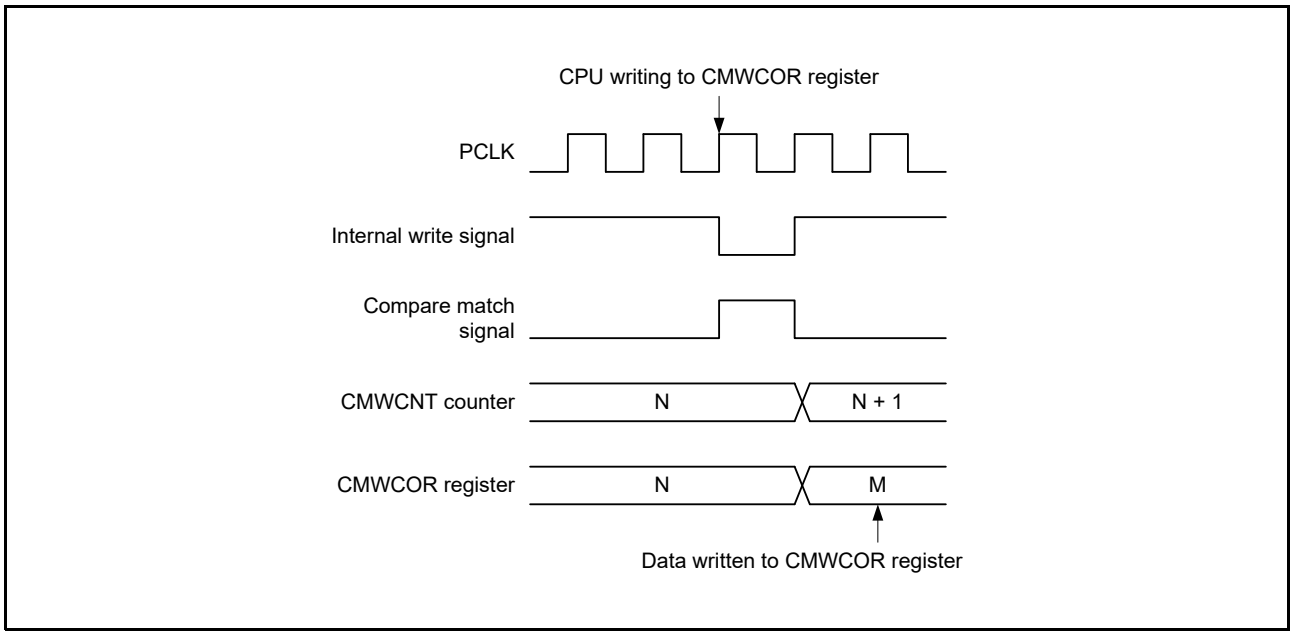

Figure 29.25 Conflict between CMWCOR Register Writing and Compare Match

29.6.5 Conflict between CMWOCRn Register Writing and Compare Match (n = 0, 1)

If the compare match is generated during the CMWOCRn register write cycle, the writing to the CMWOCRn register takes priority and also the compare match signal is output.
Figure 29.26 shows the timing of conflict between CMWOCRn register writing and compare match.

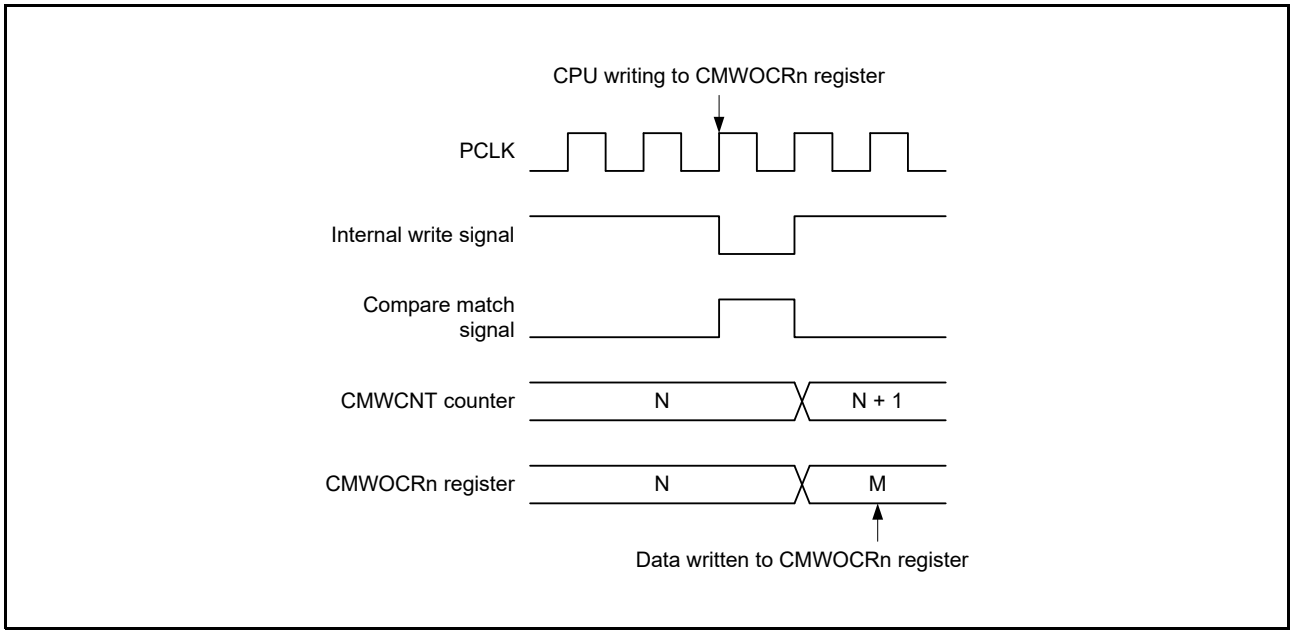

Figure 29.26 Conflict between CMWOCRn Register Writing and Compare Match

29.6.6 Conflict between CMWCNT Counter Reading and Incrementing or Clearing

If the CMWCNT counter incrementing or clearing process occurs at the same time that the data of the CMWCNT counter is read, the value having been in the CMWCNT counter before incremented or cleared is read.
Figure 29.27 shows the timing of conflict between CMWCNT counter reading and incrementing.

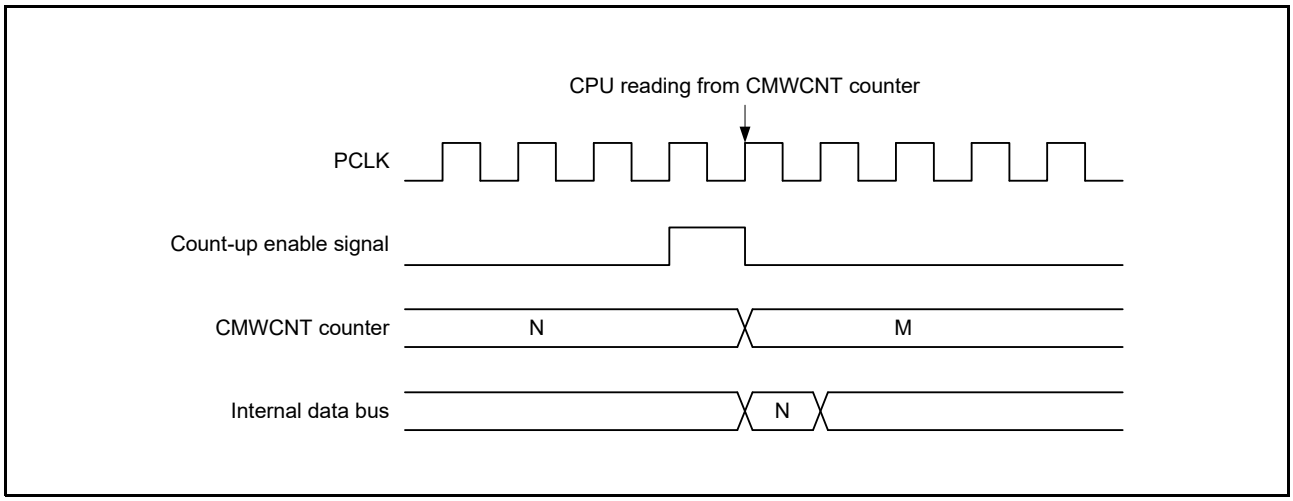

Figure 29.27 Conflict between CMWCNT Counter Reading and Incrementing

29.6.7 Conflict between CMWICRn Register Reading and Input Capture (n = 0, 1)

If the input capture detection signal is generated at the same time that the data of the CMWICRn register is read, the value having been in the CMWICRn register before updated by input capture transfer is read.
Figure 29.28 shows the timing of conflict between CMWICRn register reading and input capture.

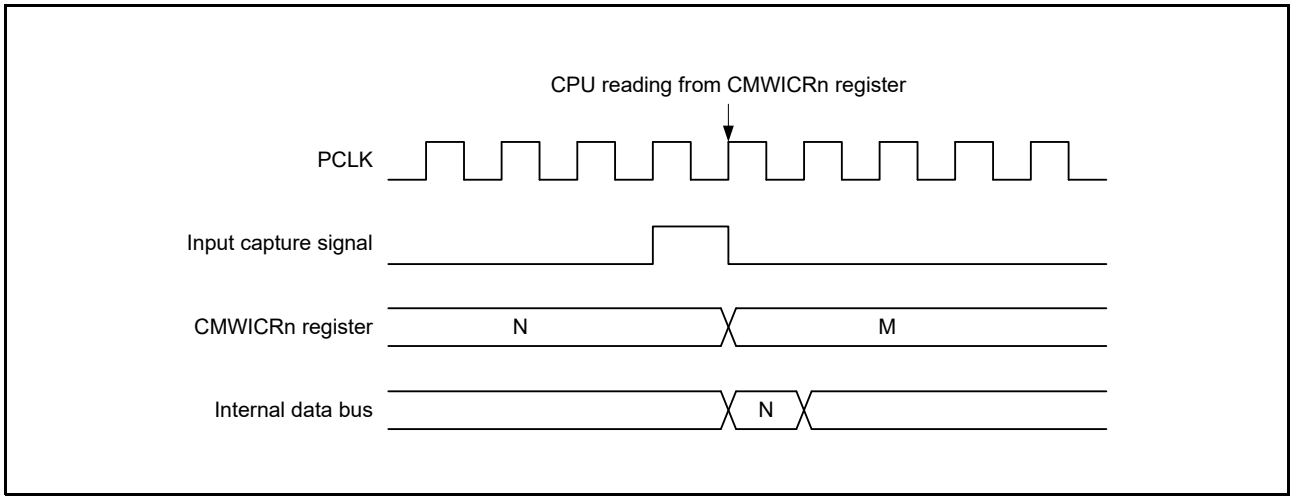

Figure 29.28 Conflict between CMWICRn Register Reading and Input Capture

30. Watchdog Timer (WDTA)

The watchdog timer (WDT) is a 14-bit down-counter. It can be used to reset this MCU when the counter underflows because its value cannot be refreshed due to the system being out of control.
In addition, a non-maskable interrupt can be generated by an underflow.
The refresh-permitted period can be set to refresh the counter and used as the condition to detect when the system runs out of control.
In this section, “PCLK” is used to refer to PCLKB.

30.1 Overview

Table 30.1 lists the specifications of the WDT and Figure 30.1 shows a block diagram of the WDT.

Table 30.1 WDT Specifications

Item	Specifications
Count source	Peripheral module clock (PCLK)
Clock division ratio	Divide by 4, 64, 128, 512, 2048, or 8192
Counter operation	Counting down using a 14-bit down-counter
Conditions for starting the counter	• Auto-start mode: Counting automatically starts after a reset is released • Register start mode: Counting is started by refresh operation (writing 00h and then FFh to the WDTRR register)
Conditions for stopping the counter	• Reset • In low power consumption states • A counter underflows or a refresh error occurs (only in register start mode)
Window function	Window start and end positions can be specified (refresh-permitted and refresh-prohibited periods)
Watchdog timer Reset sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error)
Non-maskable interrupt/interrupt sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error)
Reading the counter value	The down-counter value can be read by the WDTSR register.

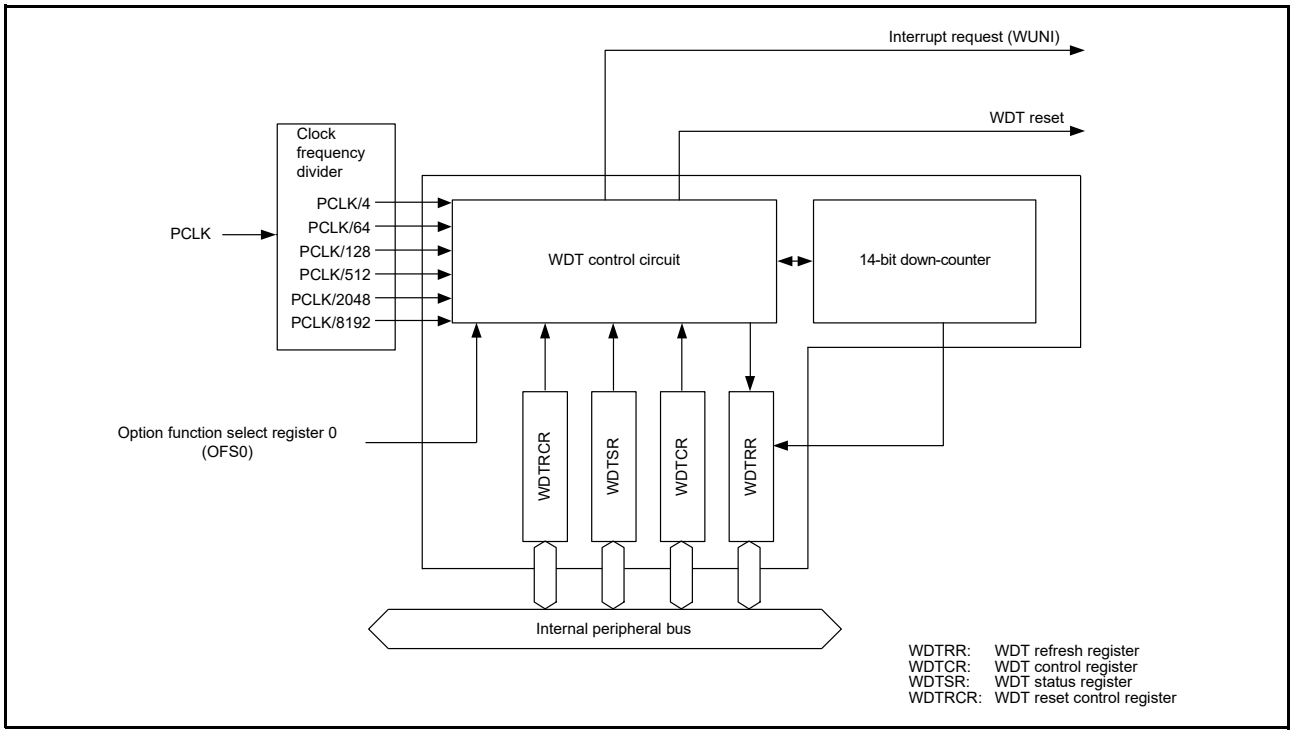

Figure 30.1 WDT Block Diagram

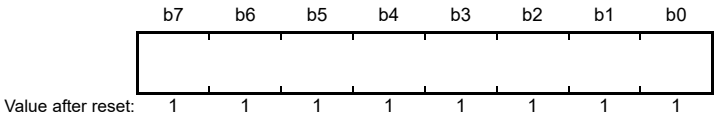
30.2 Register Descriptions

30.2.1 WDT Refresh Register (WDTRR)

Address(es): 0008 8020h



Bit	Description	R/W
b7 to b0	The down-counter is refreshed by writing 00h and then writing FFh to this register	R/W

WDTRR refreshes the down-counter of the WDT.
The down-counter of the WDT is refreshed by writing 00h and then writing FFh to WDTRR (refresh operation) within the refresh-permitted period.
After the down-counter has been refreshed, it starts counting down from the value selected by setting the WDTTOPS[1:0] bits in option function select register 0 (OFS0) in auto-start mode. In register start mode, counting down starts from the value selected by setting the WDTCR.TOPS[1:0] bits.
When 00h is written, the read value is 00h, when a value other than 00h is written, the read value is FFh.
For details of the refresh operation, refer to section 30.3.3, Refresh Operation.

30.2.2 WDT Control Register (WDTCR)

Address(es): 0008 8022h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b15, b14	—	Reserved	These bits are read as 0 and cannot be modified.	R

There are some restrictions on writing to the WDTCR register. For details, refer to section 30.3.2, Control over Writing to the WDTCR and WDTRCR Registers.
In auto-start mode, the settings in the WDTCR register are disabled, and the settings in option function select register 0 (OFS0) are enabled. The bit setting made to the WDTCR register can also be made in OFS0 register. For details, refer to section 30.3.7, Correspondence between Option Function Select Register 0 (OFS0) and WDT Registers.

TOPS[1:0] Bits (Timeout Period Selection)

These bits select the timeout period (period until the down-counter underflows) from among 1024, 4096, 8192, and 16384 cycles, taking the divided clock specified by the CKS[3:0] bits as one cycle.
After the down-counter is refreshed, the combination of the CKS[3:0] and TOPS[1:0] bits determines the time (number of PCLK cycles) until the counter underflows.
Relations between the CKS[3:0] and TOPS[1:0] bit settings, the timeout period, and the number of PCLK cycles are listed in Table 30.2.

Table 30.2 Timeout Period Settings

CKS[3:0] Bits				TOPS[1:0] Bits		Clock Division Ratio	Timeout Period (Number of Cycles)	Cycles of PCLK Clock

				1	1		16384	33554432
1	0	0	0	0	0	Divide-by-8192	1024	8388608
				0	1		4096	33554432
				1	0		8192	67108864
				1	1		16384	134217728

CKS[3:0] Bits (Clock Division Ratio Selection)

These bits specify the division ration of the clock used for the down-counter. The division ration can be selected from among the peripheral module clock (PCLK) divided by 4, 64, 128, 512, 2048, and 8192. Combined with the TOPS[1:0] bit setting, a count period between 4,096 and 134,217,728 cycles of the PCLK clock can be selected for the WDT.

RPES[1:0] Bits (Window End Position Selection)

These bits specify the window end position that indicates the refresh-permitted period. 75%, 50%, 25%, or 0% of the timeout period can be selected for the window end position. The selected window end position should be a value smaller than the window start position (window start position > window end position). If the window end position is greater than the window start position, only the window start position setting is enabled.

RPSS[1:0] Bits (Window Start Position Selection)

These bits specify the window start position that indicates the refresh-permitted period. 25%, 50%, 75%, or 100% of the timeout period can be selected for the window end position. The window start position should be set to a value greater the window end position. If the window start position is set to a value smaller than or equal to the window end position, the window end position is set to 0%.

Table 30.3 lists the counter values for the window start and end positions and Figure 30.2 shows the refresh-permitted period set by the RPSS[1:0], RPES[1:0], and TOPS[1:0] bits.

Table 30.3 Relationship between Timeout Period and Window Start and End Counter Values

TOPS[1:0] Bits		Timeout Period		Window Start and End Counter Value			
		Cycles	Counter Value	100%	75%	50%	25%
0	0	1024	03FFh	03FFh	02FFh	01FFh	00FFh
0	1	4096	0FFFh	0FFFh	0BFFh	07FFh	03FFh
1	0	8192	1FFFh	1FFFh	17FFh	0FFFh	07FFh
1	1	16384	3FFFh	3FFFh	2FFFh	1FFFh	0FFFh

RPSS[1:0] Bits		RPES[1:0] Bits		Window	
b13	b12	b9	b8	Start (%)	End (%)
1	1	1	1	100	0
		1	0		25
		0	1		50
		0	0		75
1	0	1	1	75	0
		1	0		25
		0	1		50
		0	0		75
0	1	1	1	50	0

		0	1		50
		0	0		75
0	0	1	1	25	0
		1	0		25
		0	1		50
		0	0		75

Note: If window end setting ≥ window start setting, the window end setting is set to 0%.

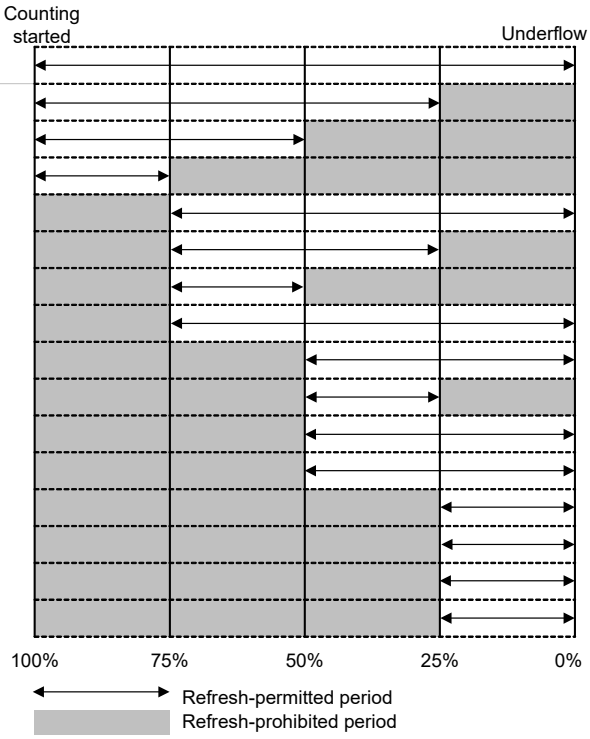

Figure 30.2 RPSS[1:0] and RPES[1:0] Bit Settings and the Refresh-Permitted Period

30.2.3 WDT Status Register (WDTSR)

Address(es): 0008 8024h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	REFEF	UNDFF	CNTVAL[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b13 to b0	CNTVAL[13:0]	Down-Counter Value	Value counted by the down-counter	R
b14	UNDFF	Underflow Flag	0: No underflow occurred 1: Underflow occurred	R(/W) *1
b15	REFEF	Refresh Error Flag	0: No refresh error occurred 1: Refresh error occurred	R(/W) *1

Note 1. Only 0 can be written to clear the flag.

CNTVAL[13:0] Bits (Down-Counter Value)

Read these bits to confirm the value of the down-counter, but note that the read value may differ from the actual count by a value of one count.

UNDFF Flag (Underflow Flag)

Read this flag to confirm whether or not an underflow has occurred in the down-counter.

The value 1 indicates that the down-counter has underflowed. The value 0 indicates that the down-counter has not underflowed.

Write 0 to the UNDFF flag to set the value to 0. Writing 1 has no effect.

REFEF Flag (Refresh Error Flag)

Read this flag to confirm whether or not a refresh error (performing a refresh operation during a refresh-prohibited period) has occurred.

The value 1 indicates that a refresh error has occurred. The value 0 indicates that no refresh error has occurred.

Write 0 to the REFEF flag to set the value to 0. Writing 1 has no effect.

30.2.4 WDT Reset Control Register (WDTRCR)

Address(es): 0008 8026h

	b7	b6	b5	b4	b3	b2	b1	b0
	RSTIRQS	—	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0 and cannot be modified.	R
b7	RSTIRQS	Reset Interrupt Request Selection	0: Non-maskable interrupt request or interrupt request output is enabled 1: Reset output is enabled	R/W

There are some restrictions on writing to the WDTRCR register. For details, refer to section 30.3.2, Control over Writing to the WDTCR and WDTRCR Registers.
In auto-start mode, the WDTRCR register settings are disabled, and the settings in option function select register 0 (OFS0) are enabled. The bit setting made to the WDTCR register can also be made in the OFS0 register. For details, refer to section 30.3.7, Correspondence between Option Function Select Register 0 (OFS0) and WDT Registers.

30.2.5 Option Function Select Register 0 (OFS0)

For details on the OFS0 register, refer to section 30.3.7, Correspondence between Option Function Select Register 0 (OFS0) and WDT Registers.

30.3 Operation

30.3.1 Count Operation in Each Start Mode

The WDT has two start modes: auto-start mode, in which counting automatically starts after a reset is released, and register start mode, in which counting is started by refresh operation (writing to the register).
In auto-start mode, counting automatically starts after a reset is released in accordance with the settings in option function select register 0 (OFS0) in the ROM.
In register start mode, counting is started by refresh operation (writing to the register) after the respective registers are set after a reset is released.
Select auto-start mode or register start mode by setting the OFS0.WDTSTRT bit.
When the auto-start mode is selected, the settings in the WDTCR and WDTRCR registers are disabled, and the settings in the OFS0 register are enabled.
On the other hand, when the register start mode is selected, the setting of the OFS0 register is disabled, and the settings of the WDTCR and WDTRCR registers are enabled.

30.3.1.1 Register Start Mode

When the OFS0.WDTSTRT bit is 1, register start mode is selected, and the WDTCR and WDTRCR registers are enabled.
After a reset is released, set the clock division ratio, window start and end positions, and timeout period in the WDTCR register, and the reset output or interrupt request output in the WDTRCR register. Then, refresh the down-counter to start counting down from the value set by the WDTCR.TOPS[1:0] bits.
Thereafter, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is re-set each time the counter is refreshed and counting down continues. The WDT does not output the reset signal as long as this continues. However, if the down-counter underflows because the down-counter cannot be refreshed due to a program runaway, or if a refresh error occurs because the counter was refreshed outside the refresh-permitted period, the WDT outputs a reset signal or a non-maskable interrupt request/interrupt request (WUNI). Reset output or interrupt request output can be selected by setting the WDTRCR.RSTIRQS bit.

Figure 30.3 shows an example of operation under the following conditions.

- Register start mode (OFS0.WDTSTRT = 1)
- Reset output is enabled (WDTRCR.RSTIRQS = 1)
- The window start position is 75% (WDTCR.RPSS[1:0] = 10b)
- The window end position is 25% (WDTCR.RPES[1:0] = 10b)

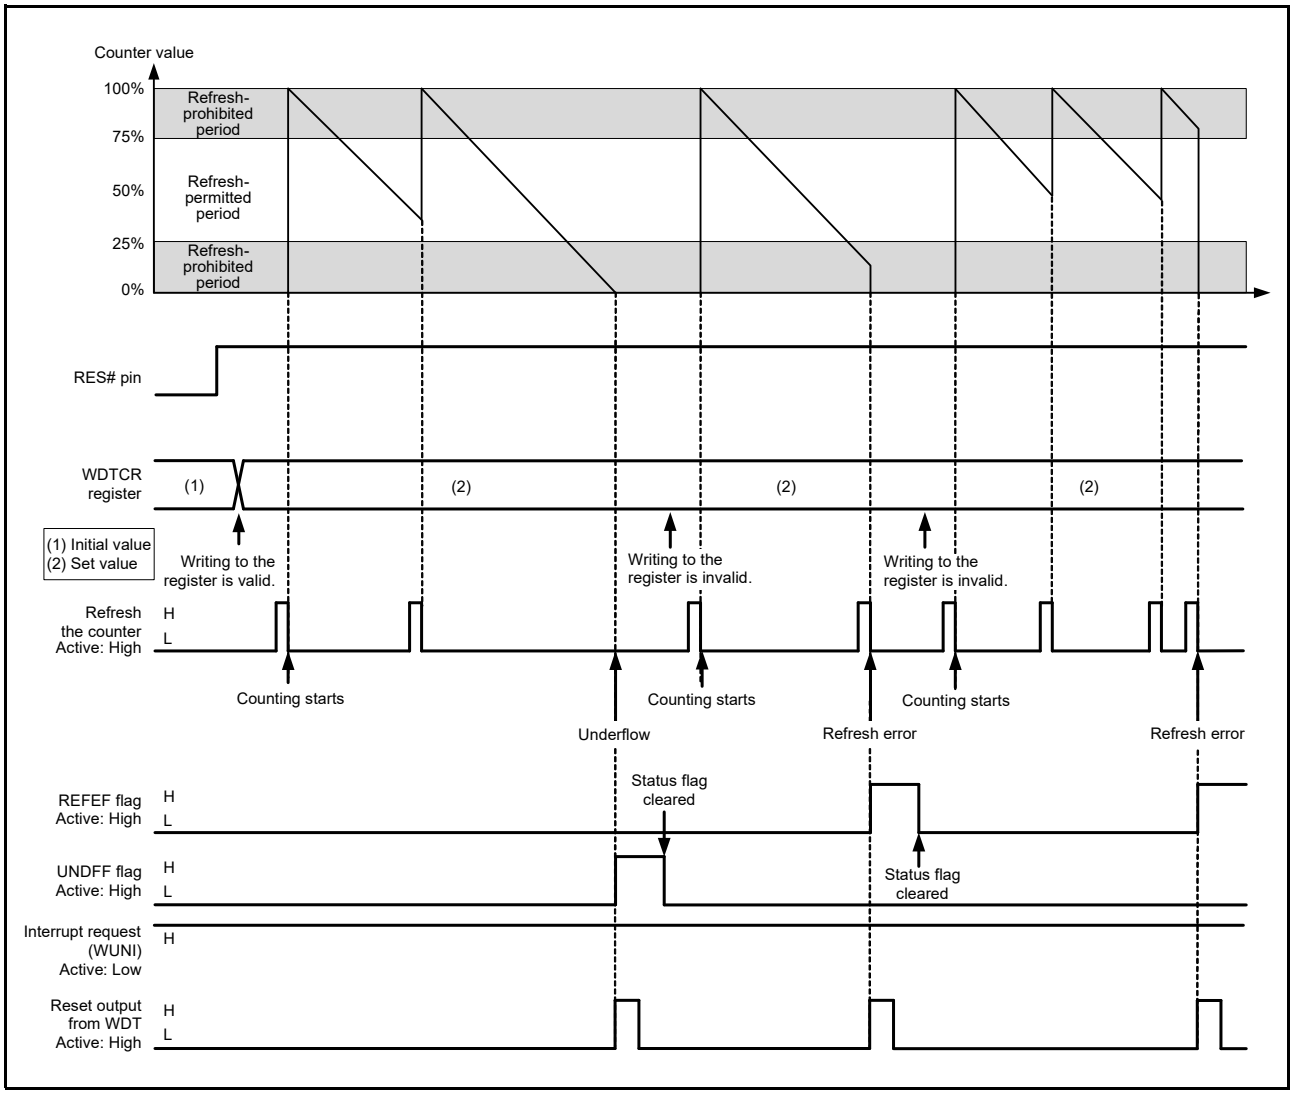

Figure 30.3 Operation Example in Register Start Mode

30.3.1.2 Auto-Start Mode

When the WDTSTRT bit in option function select register 0 (OFS0) is 0, auto-start mode is selected, the WDTCR and WDTRCR registers are disabled, and the settings in the OFS0 register are enabled.
Within the reset state, the setting values (clock division ratio, window start and end positions, timeout period, and reset output or interrupt request) of the OFS0 register are set in the WDT registers.
When the reset is released, the down-counter automatically starts counting down from the value set by the OFS0.WDTTOPS[1:0] bits.
After that, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is re-set each time the counter is refreshed and counting down continues. The WDT does not output the reset signal as long as this continues.
However, if the down-counter underflows because refreshing of the down-counter is not possible due to the program having entered crashed execution or if a refresh error occurs due to refreshing outside the refresh-permitted period, the WDT outputs the reset signal or non-maskable interrupt request/interrupt request (WUNI).
After the reset signal or non-maskable interrupt request/interrupt request is output of for one cycle of counting, the value of the timeout period is set in the down-counter counting is restarted.
Reset output or interrupt request output can be selected by setting the OFS0.WDTRSTIRQS bit.

Figure 30.4 shows an example of operation (non-maskable interrupt) under the following conditions.

- Auto start mode (OFS0.WDTSTRT = 0)
- Non-maskable interrupt request output is enabled (OFS0.WDTRSTIRQS = 0)
- The window start position is 75% (OFS0.WDTRPSS[1:0] = 10b)
- The window end position is 25% (OFS0.WDTRPES[1:0] = 10b)

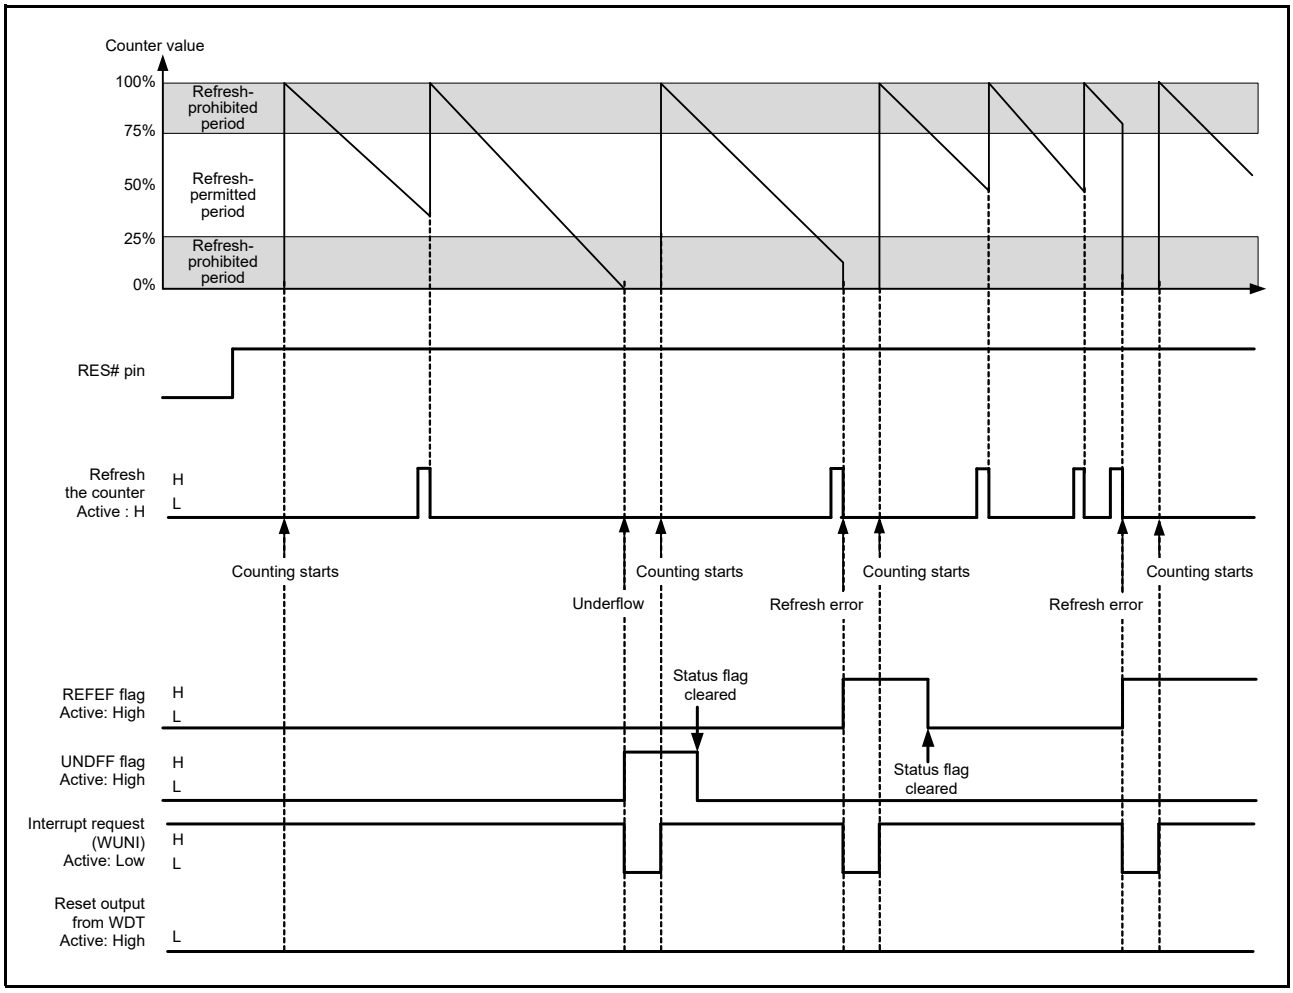

Figure 30.4 Operation Example in Auto-Start Mode

30.3.2 Control over Writing to the WDTCR and WDTRCR Registers

Writing to the WDTCR or WDTRCR register is only possible once between the release from the reset state and the first refresh operation.
After a refresh operation (counting starts) or by writing to the WDTCR or WDTRCR register, the protection signal in the WDT becomes 1 to protect the WDTCR and WDTRCR registers against subsequent attempts at writing.
This protection is released by the reset source of the WDT. With other reset sources, the protection is not released.
Figure 30.5 shows control waveforms produced in response to writing to the WDTCR register.

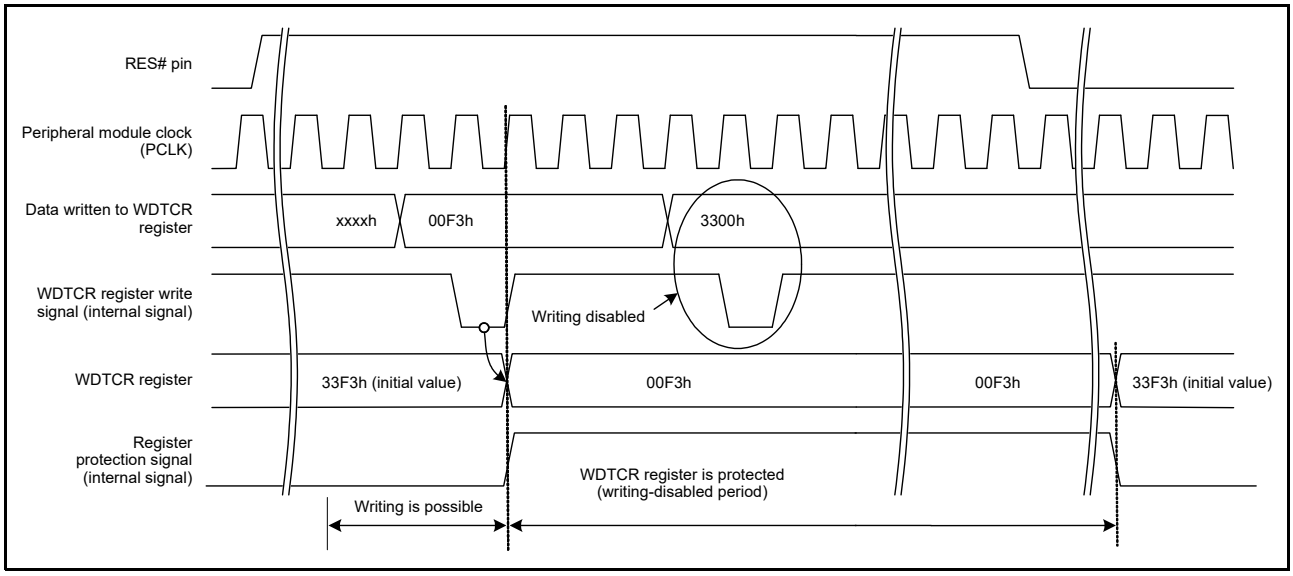

Figure 30.5 Control Waveforms Produced in Response to Writing to the WDTCR Register

30.3.3 Refresh Operation

The down-counter is refreshed by writing the values 00h and then FFh to the WDTRR register. If a value other than FFh is written after 00h, the down-counter is not refreshed. After such invalid writing, correct refreshing is performed by again writing to 00h and then FFh to the WDTRR register.
Even if a register other than the WDTRR register is accessed or the WDTRR register is read between writing 00h and writing FFh to the WDTRR register, correct refreshing will be done.
Writing to refresh the counter must be performed within the refresh-permitted period. Whether writing is done within the refresh-permitted period is determined when writing FFh. For this reason, correct refreshing will be done even if 00h is written outside the refresh-permitted period.

[Sample sequences of writing that are valid for refreshing the counter]

- 00h → FFh
- 00h (n–1-th time) → 00h (nth time) → FFh
- 00h → access to another register or read from the WDTRR register → FFh

[Sample sequences of writing that are not valid for refreshing the counter]

- 23h (a value other than 00h) → FFh
- 00h → 54h (a value other than FFh)
- 00h→ AAh (00h and a value other than FFh) → FFh

After FFh is written to the WDTRR register, refreshing the down-counter requires up to four cycles of the signal for counting. Therefore, writing FFh to the WDTRR register should be completed four-count cycles before the down-counter underflows.

Figure 30.6 shows the WDT refresh-operation waveforms when the clock division ratio = PCLK/64.

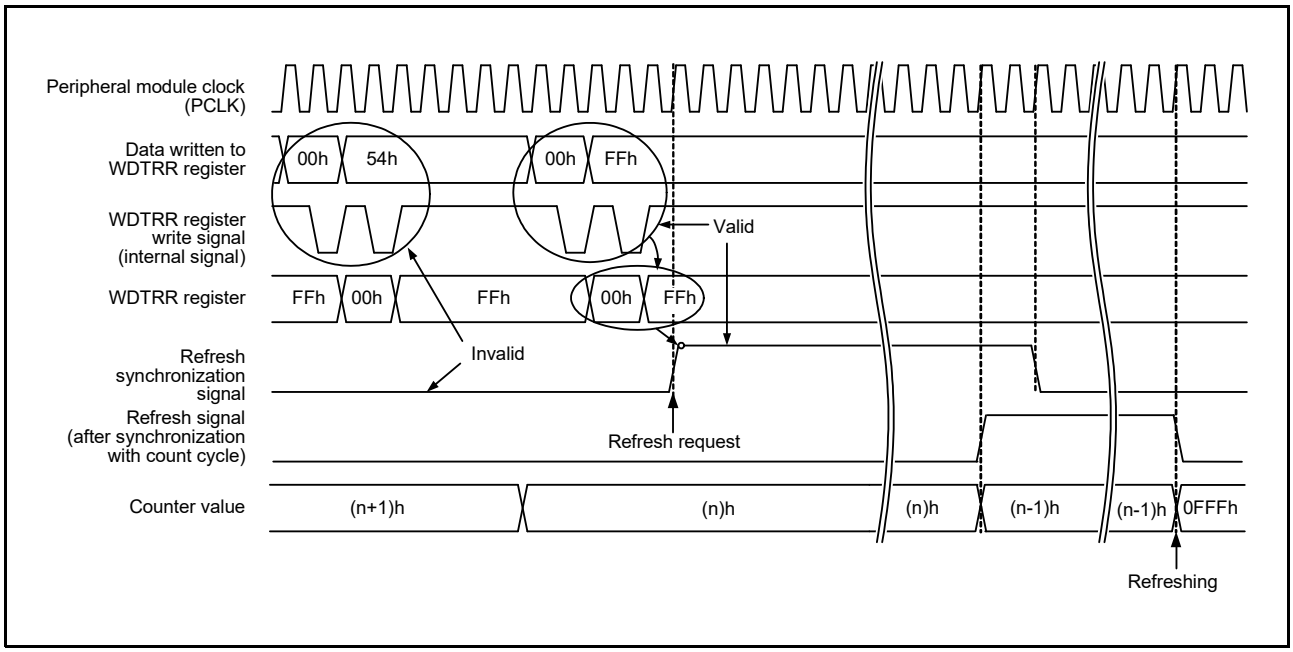

Figure 30.6 WDT Refresh Operation Waveforms (WDTCR.CKS[3:0] = 0100b, WDTCR.TOPS[1:0] = 01b)

30.3.4 Reset Output

When the WDTRCR.RSTIRQS bit is set to 1 in register start mode or when the WDTRSTIRQS bit in option function select register 0 (OFS0) is set to 1 in auto-start mode, a reset signal is output for one-count cycle when an underflow in the down-counter or a refresh error occurs.

In register start mode, the down-counter is initialized (all bits set to 0) and stopped in that state after output of the reset signal. After the reset is released and the program is restarted, the counter is set up again and counting down is started by refreshing.

In auto-start mode, counting down automatically starts after the reset is released.

30.3.5 Interrupt Source

When the WDTRCR.RSTIRQS bit is set to 0 in register start mode or when the OFS0.WDTRSTIRQS bit is set to 0 in auto-start mode, an interrupt (WUNI) signal is generated when an underflow in the counter or a refresh error occurs. This interrupt can be used as a non-maskable interrupt and an interrupt. For details, refer to section 14, Interrupt Controller (ICUG).

Table 30.4 WDT Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
WUNI	Down-counter underflow Refresh error	Not possible	Not possible

30.3.6 Reading the Down-Counter Value

The WDT stores the counter value in the WDTSR.CNTVAL[13:0] bits. Thus, the counter value can be checked through the WDTSR.CNTVAL[13:0] bits.

Figure 30.7 shows the processing for reading the WDT down-counter value when the clock division ratio = PCLK/64.

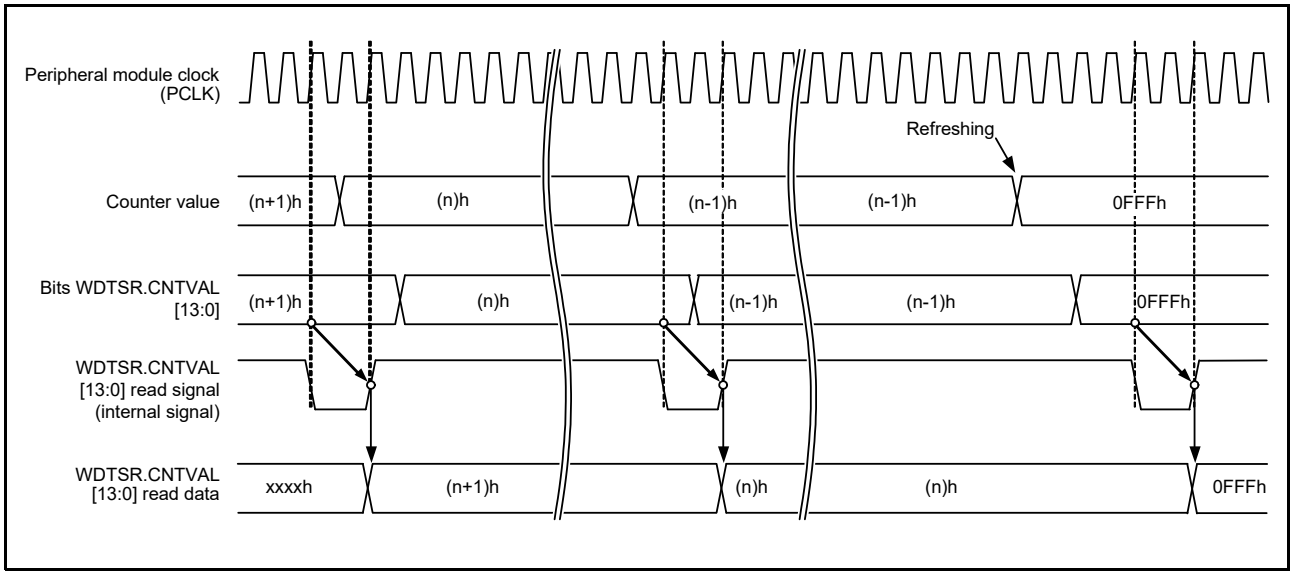

Figure 30.7 Processing for Reading WDT Down-Counter Value (WDTCR.CKS[3:0] = 0100b, WDTCR.TOPS[1:0] = 01b)

30.3.7 Correspondence between Option Function Select Register 0 (OFS0) and WDT Registers

Table 30.5 lists the correspondence between option function select register 0 (OFS0) used in auto-start mode and the registers used in register start mode.

Do not change the OFS0 register setting during WDT operation.

For details on the OFS0 register, refer to section 7.2.3, Option Function Select Register 0 (OFS0).

Table 30.5 Correspondence between Option Function Select Register 0 (OFS0) and WDT Registers

Target of Control	Function	OFS0 Register (Enabled in Auto-Start Mode) OFS0.WDTSTRT = 0	WDT Registers (Enabled in Register Start Mode) OFS0.WDTSTRT = 1
Down-counter	Timeout period selection	OFS0.WDTTOPS[1:0]	WDTCR.TOPS[1:0]
	Clock division ratio selection	OFS0.WDTCKS[3:0]	WDTCR.CKS[3:0]
	Window start position selection	OFS0.WDTRPSS[1:0]	WDTCR.RPSS[1:0]
	Window end position selection	OFS0.WDTRPES[1:0]	WDTCR.RPES[1:0]
Reset output or interrupt request output	Reset output or interrupt request output selection	OFS0.WDTRSTIRQS	WDTRCR.RSTIRQS

31. Independent Watchdog Timer (IWDTa)

In this section, “PCLK” is used to refer to PCLKB.

31.1 Overview

The independent watchdog timer (IWDT) can be used to detect programs being out of control.
The user can detect when a program runs out of control if an underflow occurs, by creating a program that refreshes the IWDT counter before it underflows.
The functions of the IWDT are different from those of the WDT in the following respects.

- The divided IWDT-dedicated clock (IWDTCLK) is used as the count source (not affected by the PCLK).
- When making a transition to sleep mode, software standby mode, or all-module clock stop mode, the IWDTCSTPR.SLCSTP bit or the OFS0.IWDTSLCSTP bit can be used to select whether to stop the counter or not.

Table 31.1 lists the specifications of the IWDT and Figure 31.1 shows a block diagram of the IWDT.

Table 31.1 IWDT Specifications

Item	Description
Count source*1	IWDT-dedicated clock (IWDTCLK)
Clock divide ratio	Divide by 1, 16, 32, 64, 128, or 256
Counter operation	Counting down using a 14-bit down-counter
Conditions for starting the counter	• Auto-start mode: Counting automatically starts after a reset is released • Register start mode: Counting is started by refresh operation (writing 00h and then FFh to the IWDTRR register).
Conditions for stopping the counter	• Reset • In low power consumption states (depends on the register setting*2) • A counter underflows or a refresh error occurs (only in register start mode)
Window function	Window start and end positions can be specified (refresh-permitted and refresh-prohibited periods)
Reset output sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error)
Non-maskable interrupt/ interrupt sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error)
Reading the counter value	The down-counter value can be read by the IWDTSR register.
Event link function (output)	• Down-counter underflow event output • Refresh error event output
Output signal (internal signal)	• Reset output • Interrupt request output • Sleep mode count stop control output
Auto-start mode (controlled by option function select register 0 (OFS0))	• Selecting the clock frequency divide ratio after a reset (OFS0.IWDTCKS[3:0] bits) • Selecting the timeout period of the independent watchdog timer (OFS0.IWDTTOPS[1:0] bits) • Selecting the window start position in the independent watchdog timer (OFS0.IWDTRPSS[1:0] bits) • Selecting the window end position in the independent watchdog timer (OFS0.IWDTRPES[1:0] bits) • Selecting the reset output or interrupt request output (OFS0.IWDTRSTIRQS bit) • Selecting the down-count stop function at transition to sleep mode, software standby mode, or all-module clock stop mode (OFS0.IWDTSLCSTP bit)
Register start mode (controlled by the IWDT registers)	• Selecting the clock frequency divide ratio after refreshing (IWDTCR.CKS[3:0] bits) • Selecting the timeout period of the independent watchdog timer (IWDTCR.TOPS[1:0] bits) • Selecting the window start position in the independent watchdog timer (IWDTCR.RPSS[1:0] bits) • Selecting the window end position in the independent watchdog timer (IWDTCR.RPES[1:0] bits) • Selecting the reset output or interrupt request output (IWDTRCR.RSTIRQS bit) • Selecting the down-count stop function at transition to sleep mode, software standby mode, or all-module clock stop mode (IWDTCSTPR.SLCSTP bit)

Note 1. Satisfy the frequency of the peripheral module clock (PCLK) ≥ 4 × (the frequency of the count source after divide).
Note 2. When the OFS0.IWDTSLCSTP bit is 1 in auto-start mode, and when the IWDTCSTPR.SLCSTP bit is 1 in register start mode.

To use the IWDT, the IWDT-dedicated clock (IWDTCLK) should be supplied so that the IWDT operates even if the peripheral module clock (PCLK) stops. The bus interface and registers operate with PCLK, and the 14-bit counter and control circuits operate with IWDTCLK.

Figure 31.1 is a block diagram of the IWDT.

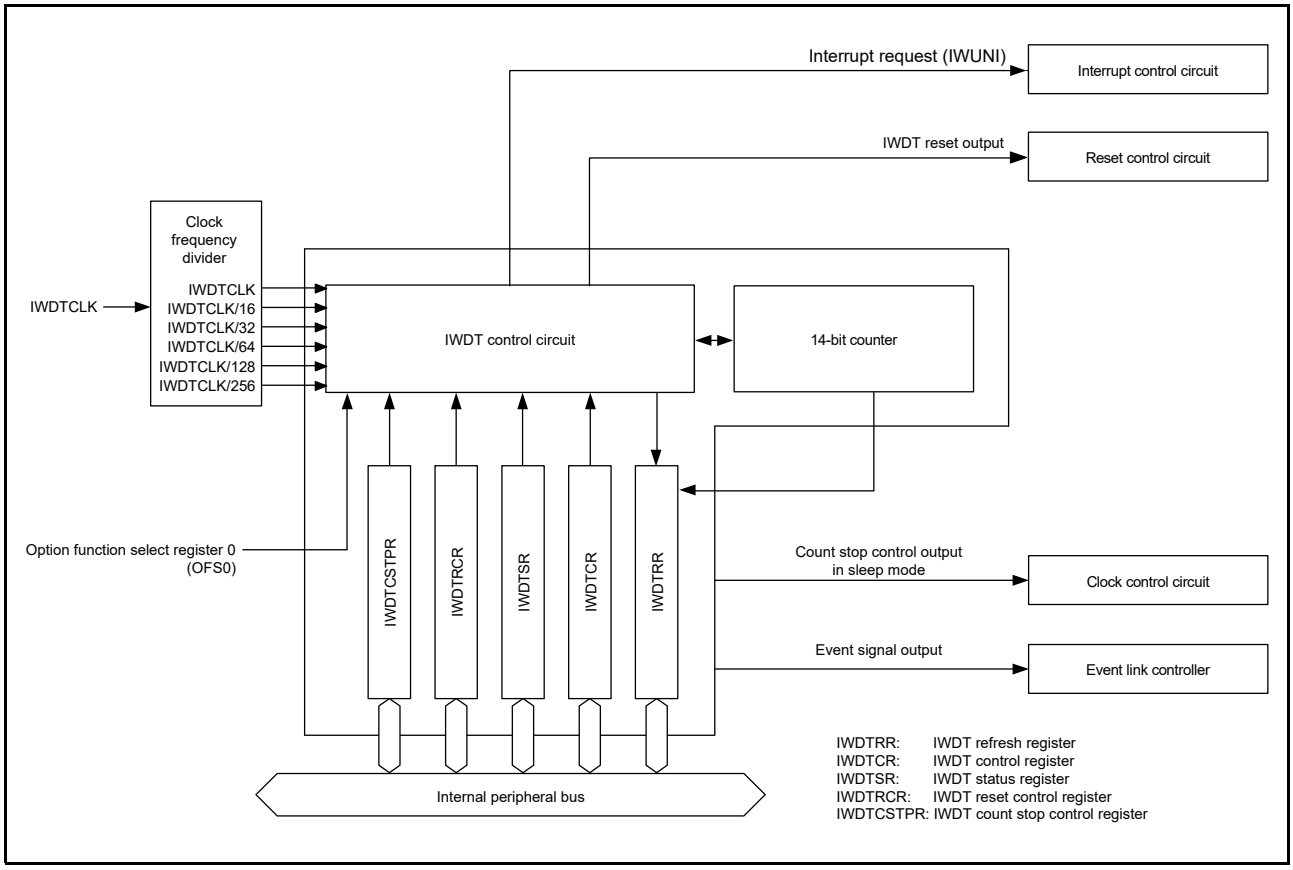

Figure 31.1 IWDT Block Diagram

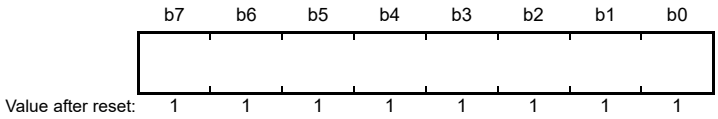
31.2 Register Descriptions

31.2.1 IWDT Refresh Register (IWDTRR)

Address(es): IWDT.IWDTRR 0008 8030h



Bit	Description	R/W
b7 to b0	The counter is refreshed by writing 00h and then writing FFh to this register.	R/W

The IWDTRR register refreshes the counter of the IWDT.
The counter of the IWDT is refreshed by writing 00h and then writing FFh to the IWDTRR register (refresh operation) within the refresh-permitted period.
After the counter has been refreshed, it starts counting down from the value selected by the IWDTTOPS[1:0] bits in option function select register 0 (OFS0) in auto-start mode. In register start mode, counting down starts from the value selected by setting the IWDTCR.TOPS[1:0] bits in the first refresh operation after a reset is released.
When 00h is written, the read value is 00h. When a value other than 00h is written, the read value is FFh.
For details of the refresh operation, refer to section 31.3.3, Refresh Operation.

31.2.2 IWDT Control Register (IWDTCR)

Address(es): IWDT.IWDTCR 0008 8032h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b15, b14	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R

There are some restrictions on writing to the IWDTCR register. For details, refer to section 31.3.2, Control over Writing to the IWDTCR, IWDTRCR, and IWDTCSTPR Registers.

In auto-start mode, the settings in the IWDTCR register are disabled, and the settings in option function select register 0 (OFS0) are enabled. The bit setting made to the IWDTCR register can also be made in the OFS0 register. For details, refer to section 31.3.8, Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers.

TOPS[1:0] Bits (Timeout Period Select)

These bits select the timeout period (period until the counter underflows) from among 1024, 4096, 8196, or 16384 cycles, taking the divided clock specified by the CKS[3:0] bits as one cycle.
After the counter is refreshed, the combination of the CKS[3:0] and TOPS[1:0] bits determines the time (number of IWDTCLK cycles) until the counter underflows.
Relations between the CKS[3:0] and TOPS[1:0] bit setting, the timeout period, and the number of IWDTCLK cycles are listed in Table 31.2.

Table 31.2 Settings and Timeout Periods

CKS[3:0] Bits				TOPS[1:0] Bits				
b7	b6	b5	b4	b1	b0	Clock Divide Ratio	Timeout Period (Number of Cycles)	Cycles of IWDTCLK
0	0	0	0	0	0	No division	1024	1024

				1	0		8192	131072
				1	1		16384	262144
0	0	1	1	0	0	Divide-by-32	1024	32768
				0	1		4096	131072
				1	0		8192	262144
				1	1		16384	524288
0	1	0	0	0	0	Divide-by-64	1024	65536
				0	1		4096	262144
				1	0		8192	524288
				1	1		16384	1048576
1	1	1	1	0	0	Divide-by-128	1024	131072
				0	1		4096	524288
				1	0		8192	1048576
				1	1		16384	2097152
0	1	0	1	0	0	Divide-by-256	1024	262144
				0	1		4096	1048576
				1	0		8192	2097152
				1	1		16384	4194304

CKS[3:0] Bits (Clock Divide Ratio Select)

These bits select the IWDTCLK clock divide ratio from among divide-by 1, 16, 32, 64, 128, and 256. Combination with the TOPS[1:0] bit setting, a count period between 1024 and 4194304 cycles of the IWDTCLK clock can be selected for the IWDT.

RPES[1:0] Bits (Window End Position Select)

These bits select 75%, 50%, 25% or 0% of the count period for the window end position of the counter. The window end position should be a value smaller than the window start position (window start position > window end position). If the window end position is greater than the window start position, only the window start position setting is enabled.
The counter values for the window start and end positions selected by setting the RPSS[1:0] and RPES[1:0] bits change depending on the TOPS[1:0] bit setting.
Table 31.3 lists the counter values for the window start and end positions corresponding to TOPS[1:0] bit values.

Table 31.3 Relationship between Timeout Period and Window Start and End Counter Values

TOPS[1:0] Bits		Timeout Period		Window Start and End Counter Value			
b1	b0	Cycles	Counter Value	100%	75%	50%	25%
0	0	1024	03FFh	03FFh	02FFh	01FFh	00FFh
0	1	4096	0FFFh	0FFFh	0BFFh	07FFh	03FFh
1	0	8192	1FFFh	1FFFh	17FFh	0FFFh	07FFh
1	1	16384	3FFFh	3FFFh	2FFFh	1FFFh	0FFFh

RPSS[1:0] Bits (Window Start Position Select)

These bits select a counter window start position from 100%, 75%, 50%, or 25% of the count period (100% when the count starts and 0% when the counter underflows). The interval between the window start position and window end position is the refresh-permitted period and the other periods are refresh-prohibited periods.
Figure 31.2 shows the relationship between of the RPSS[1:0] and RPES[1:0] bit setting and the refresh-permitted and refresh-prohibited periods.

RPSS[1:0] Bits		RPES[1:0] Bits		Window	
b13	b12	b9	b8	Start (%)	End (%)

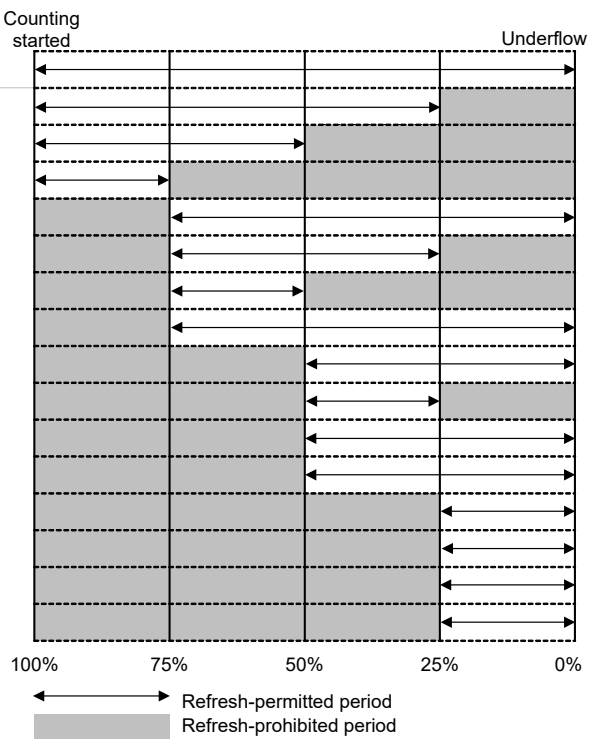

Figure 31.2 RPSS[1:0] and RPES[1:0] Bit Settings and the Refresh-Permitted Period

31.2.3 IWDT Status Register (IWDTSR)

Address(es): IWDT.IWDTSR 0008 8034h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	REFEF	UNDFF	CNTVAL[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b13 to b0	CNTVAL[13:0]	Counter Value	Value counted by the counter	R
b14	UNDFF	Underflow Flag	0: No underflow occurred 1: Underflow occurred	R/(W) *1
b15	REFEF	Refresh Error Flag	0: No refresh error occurred 1: Refresh error occurred	R/(W) *1

Note 1. Only 0 can be written to clear the flag.

CNTVAL[13:0] Bits (Counter Value)

These bits are used to confirm the counter value of the counter, but note that the read value may differ from the actual count by a value of one count.

UNDFF Flag (Underflow Flag)

This bit is used to confirm whether or not an underflow has occurred in the counter.
The value 1 indicates that the counter has underflowed. The value 0 indicates that the counter has not underflowed.
Write 0 to the UNDFF flag to set the value to 0. Writing 1 has no effect.

REFEF Flag (Refresh Error Flag)

This bit is used to confirm whether or not a refresh error (performing a refresh operation during a refresh-prohibited period).
The value 1 indicates that a refresh error has occurred. The value 0 indicates that no refresh error has occurred.
Write 0 to the REFEF flag to set the value to 0. Writing 1 has no effect.

31.2.4 IWDT Reset Control Register (IWDTRCR)

Address(es): IWDT.IWDTRCR 0008 8036h

	b7	b6	b5	b4	b3	b2	b1	b0
	RSTIRQS	—	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R
b7	RSTIRQS	Reset Interrupt Request Select	0: Non-maskable interrupt request or interrupt request output is enabled. 1: Reset output is enabled.	R/W

There are some restrictions on writing to the IWDTRCR register. For details, refer to section 31.3.2, Control over Writing to the IWDTCR, IWDTRCR, and IWDTCSTPR Registers.

In auto-start mode, the IWDTRCR register setting are disabled, and the settings in option function select register 0 (OFS0) are enabled. The bit setting mode to the IWDTRCR register can also be made in the OFS0 register. For details, refer to section 31.3.8, Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers.

31.2.5 IWDT Count Stop Control Register (IWDTCSTPR)

Address(es): IWDT.IWDTCSTPR 0008 8038h

	b7	b6	b5	b4	b3	b2	b1	b0
	SLCSTP	—	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R
b7	SLCSTP	Sleep Mode Count Stop Control	0: Count stop is disabled. 1: Count is stopped at a transition to sleep mode, software standby mode, or all-module clock stop mode.	R/W

The IWDTCSTPR register controls whether to stop the IWDT counter in a low power consumption state. There are some restrictions on writing to the IWDTCSTPR register. For details, refer to section 31.3.2, Control over Writing to the IWDTCR, IWDTRCR, and IWDTCSTPR Registers.
In auto-start mode, the IWDTCSTPR register setting are disabled, and the settings in option function select register 0 (OFS0) are enabled. The bit setting mode to the IWDTCSTPR register can also be made in the OFS0 register. For details, refer to section 31.3.8, Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers.

SLCSTP Bit (Sleep Mode Count Stop Control)

This bit selects whether to stop counting at a transition to sleep mode, software standby mode, or all-module clock stop mode.

31.2.6 Option Function Select Register 0 (OFS0)

For option function select register 0 (OFS0), refer to section 31.3.8, Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers.

31.3 Operation

31.3.1 Count Operation in Each Start Mode

Select the IWDT start mode by setting the IWDTSTRT bit in option function select register 0 (OFS0).
When the OFS0.IWDTSTRT bit is 1 (register start mode), the IWDTCR, IWDTRCR, and IWDTCSTPR registers are enabled, and counting is started by refresh operation (writing) to the IWDTRR register. When the OFS0.IWDTSTRT bit is 0 (auto-start mode), the setting of the OFS0 register is enabled, and counting automatically starts after reset.

31.3.1.1 Register Start Mode

When the OFS0.IWDTSTRT bit in option function select register 0 is 1, register start mode is selected, and the IWDTCR, IWDTRCR, and IWDTCSTPR registers are enabled.
After a reset is released, set the clock divide ratio, window start and end positions, and timeout period in the IWDTCR register, the reset output or interrupt request output in the IWDTRCR register, and the counter stop control at transitions to low power consumption states in the IWDTCSTPR register. Then refresh the counter to start counting down from the value selected by setting the IWDTCR.TOPS[1:0] bits.
Thereafter, as long as the program continues normal operation and the counter is refreshed in the refresh-permitted period, the value in the counter is re-set each time the counter is refreshed and counting down continues. The IWDT does not output the reset signal as long as this continues. However, if the counter underflows because the counter cannot be refreshed due to a program runaway, or if a refresh error occurs because the counter was refreshed outside the refresh-permitted period, the IWDT outputs a reset signal or a non-maskable interrupt request/interrupt request (IWUNI). Set the IWDTRCR.RSTIRQS bit to select either reset output or interrupt request output.

Figure 31.3 shows an example of operation under the following conditions.

- Register start mode (OFS0.IWDTSTRT = 1)
- Reset output is enabled (IWDTRCR.RSTIRQS = 1)
- The window start position is 75% (IWDTCR.RPSS[1:0] = 10b)
- The window end position is 25% (IWDTCR.RPES[1:0] = 10b)

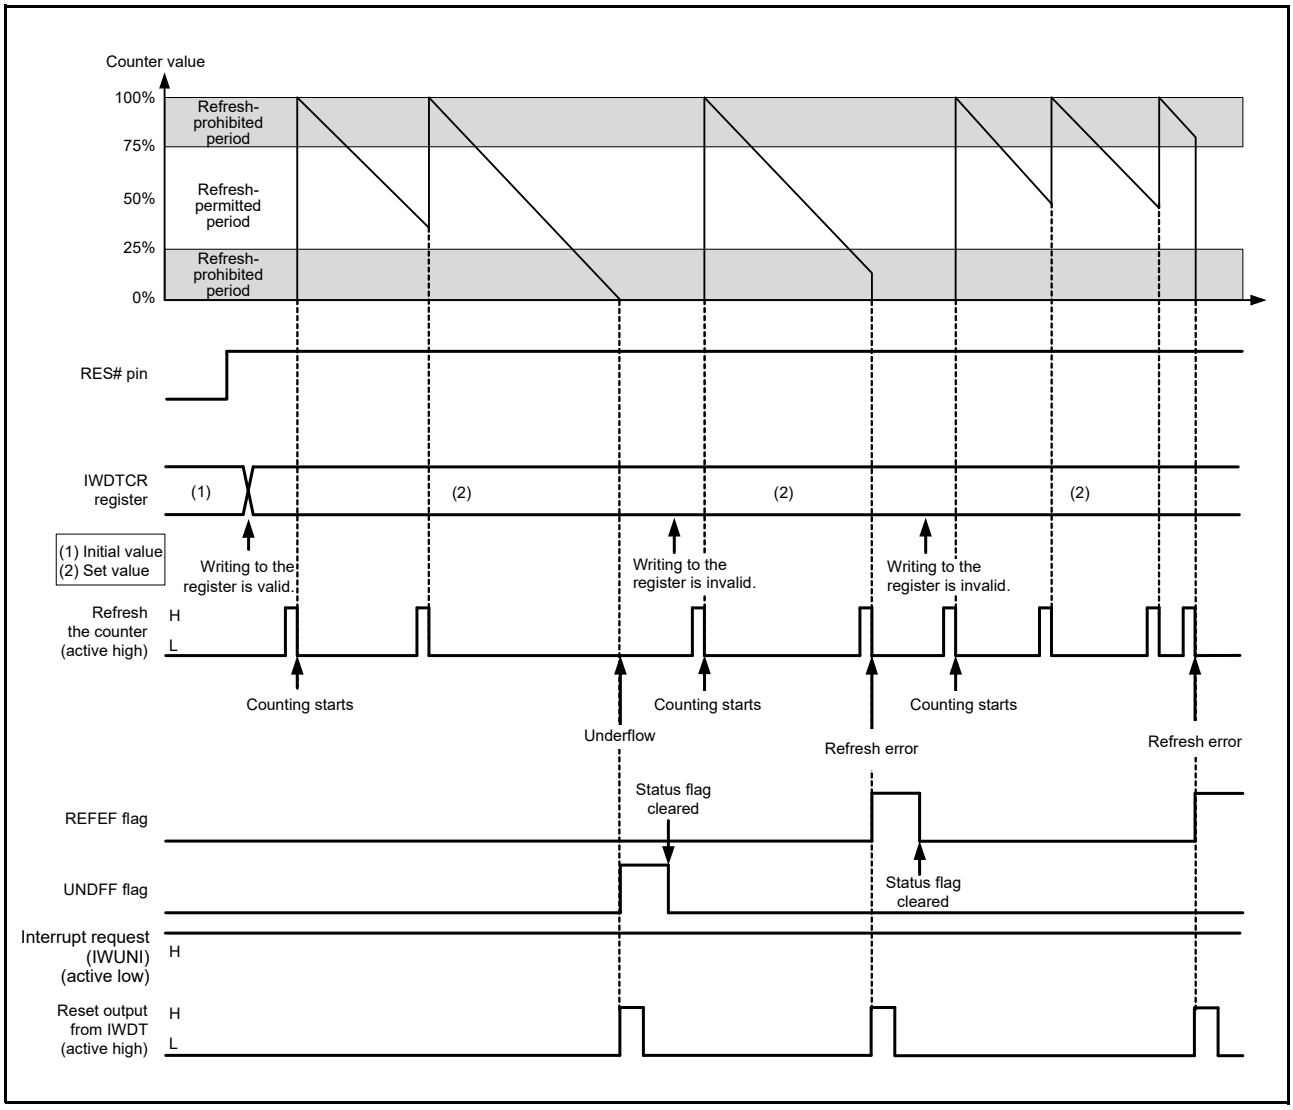

Figure 31.3 Operation Example in Register Start Mode

31.3.1.2 Auto-Start Mode

When the IWDTSTRT bit in option function select register 0 (OFS0) is 0, auto-start mode is selected, and the IWDTCR, IWDTRCR, and IWDTCSTPR registers are disabled.
Within the reset state, the clock divide ratio, window start and end positions, timeout period, reset output or interrupt request output, and counter stop control at transitions to low power consumption states are set using the values specified in the OFS0 register. When the reset is released, the counter automatically starts counting down from the value selected by the OFS0.IWDTTOPS[1:0] bits.
After that, as long as the program continues normal operation and the counter is refreshed in the refresh-permitted period, the value in the counter is re-set each time the counter is refreshed and counting down continues. The IWDT does not output the reset signal as long as this continues. However, if the counter underflows because refreshing of the counter is not possible due to the program having entered crashed execution or if a refresh error occurs due to refreshing outside the refresh-permitted period, the IWDT outputs the reset signal or non-maskable interrupt request/interrupt request (IWUNI). After the reset signal or non-maskable interrupt request/interrupt request (IWUNI) is generated, the counter reloads the timeout period after counting for one cycle, and restarts counting. Set the OFS0.IWDTRSTIRQS bit to select either reset output or interrupt request output.

Figure 31.4 shows an example of operation under the following conditions.

- Auto-start mode (OFS0.IWDTSTRT = 0)
- Non-maskable interrupt request output is enabled (OFS0.IWDTRSTIRQS = 0)
- The window start position is 75% (OFS0.IWDTRPSS[1:0] = 10b)
- The window end position is 25% (OFS0.IWDTRPES[1:0] = 10b)

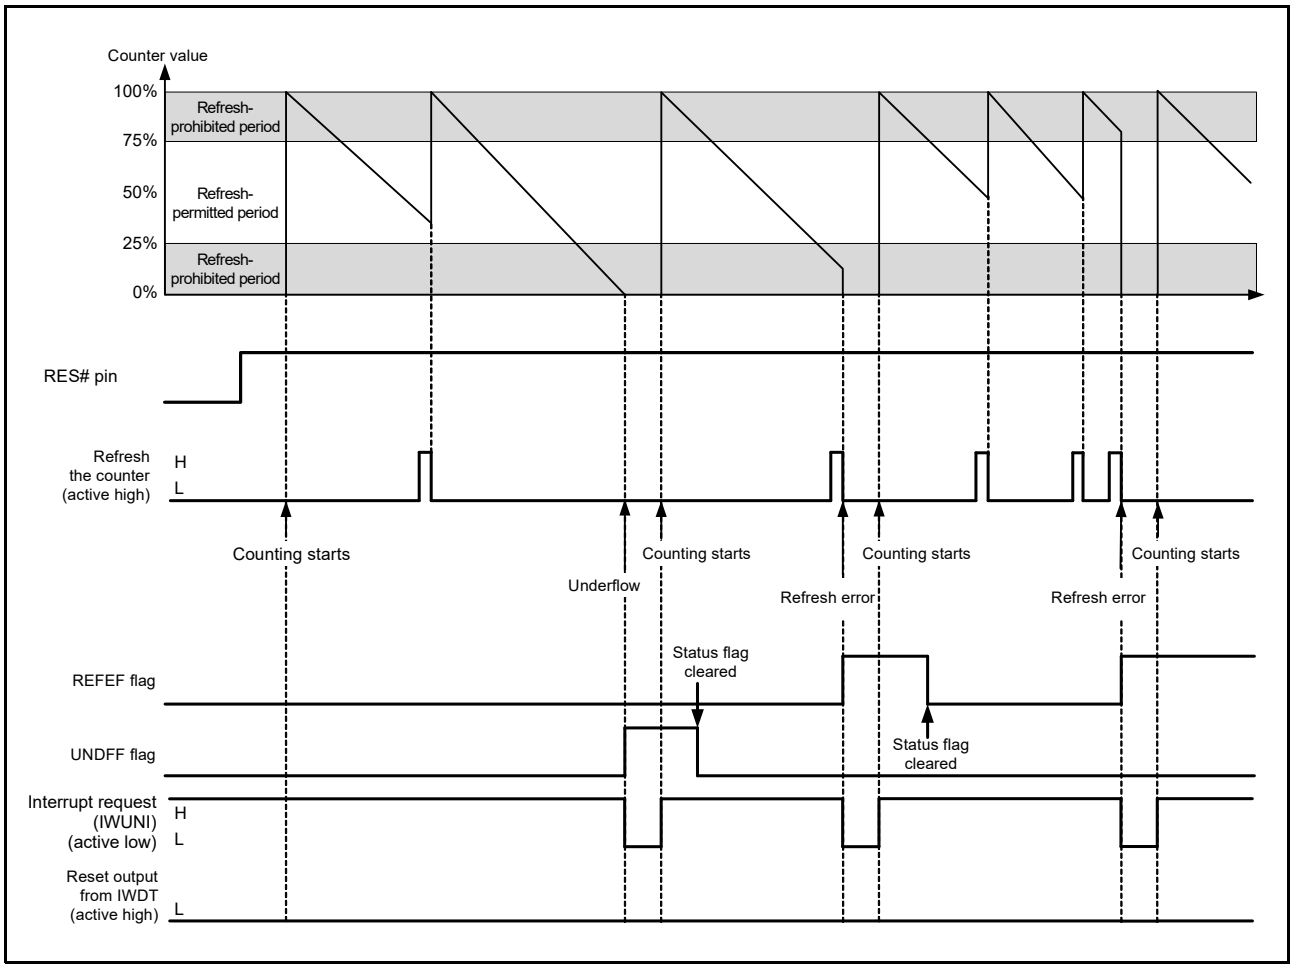

Figure 31.4 Operation Example in Auto-Start Mode

31.3.2 Control over Writing to the IWDTCR, IWDTRCR, and IWDTCSTPR Registers

Writing to the IWDTCR, IWDTRCR, or IWDTCSTPR register is only possible once between the release from the reset state and the first refresh operation.

After a refresh operation (counting starts) or the IWDTCR, IWDTRCR, or IWDTCSTPR register is written to, the protection signal in the IWDT becomes 1 to protect registers IWDTCR, IWDTRCR, and IWDTCSTPR against subsequent attempts at writing.

This protection is released by the reset source of the IWDT. With other reset sources, the protection is not released.

Figure 31.5 shows control waveforms produced in response to writing to the IWDTCR register.

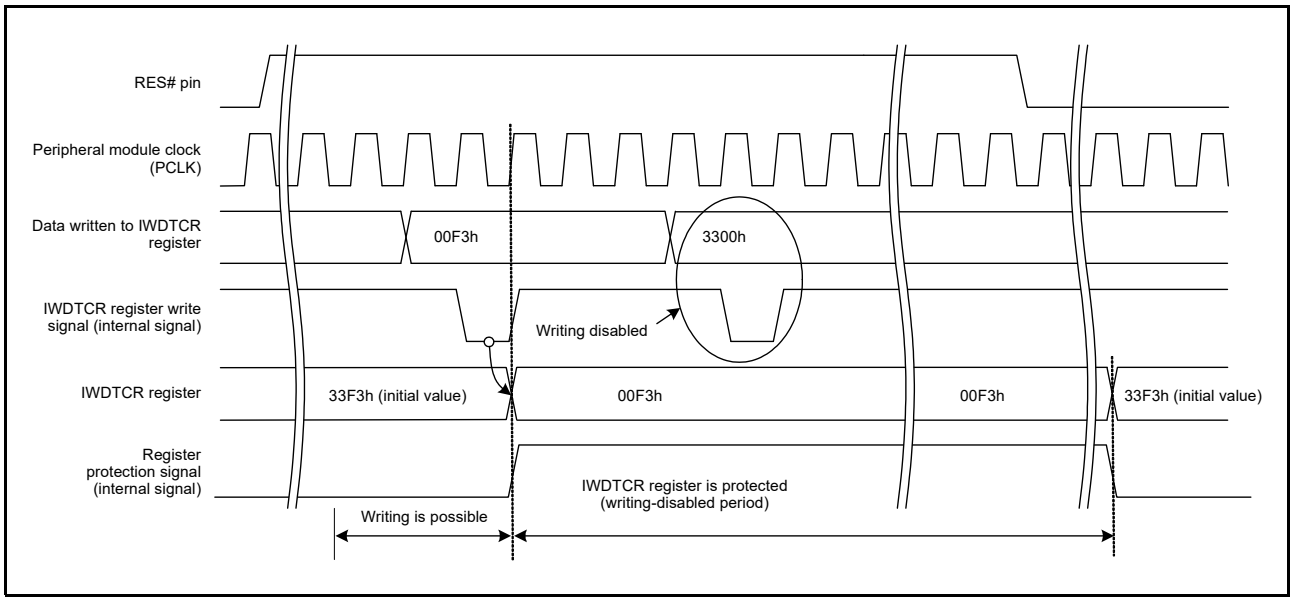

Figure 31.5 Control Waveforms Produced in Response to Writing to the IWDTCR Register

31.3.3 Refresh Operation

The counter is refreshed and starts operation (counting is started by refreshing) by writing the values 00h and then FFh to the IWDTRR register. If a value other than FFh is written after 00h, the counter is not refreshed. After such invalid writing, correct refreshing is performed by again writing 00h and then FFh to the IWDTRR register.
When writing is done in the order of 00h (first time) → 00h (second time), and if FFh is written after that, the writing order 00h → FFh is satisfied; writing 00h (n–1-th time) → 00h (nth time) → FFh is valid and correct refreshing will be done. Even when the first value written before 00h is not 00h, correct refreshing will be done if the operation contains the set of writing 00h → FFh. Moreover, even if a register other than the IWDTRR register is accessed or the IWDTRR register is read between writing 00h and writing FFh to the IWDTRR register, correct refreshing will be done.

[Sample sequences of writing that are valid for refreshing the counter]

- 00h → FFh
- 00h (n–1-th time) → 00h (nth time) → FFh
- 00h → access to another register or read from the IWDTRR register → FFh

[Sample sequences of writing that are not valid for refreshing the counter]

- 23h (a value other than 00h) → FFh
- 00h → 54h (a value other than FFh)
- 00h → AAh (00h and a value other than FFh) → FFh

Even when 00h is written to the IWDTRR register outside the refresh-permitted period, if FFh is written to the IWDTRR register in the refresh-permitted period, the writing sequence is valid and refreshing will be done.
After FFh is written to the IWDTRR register, refreshing the counter requires up to four cycles of the signal for counting (the IWDTCR.CKS[3:0] bits determine how many cycles of the IWDT-dedicated clock (IWDTCLK) make up one cycle for counting). Therefore, writing FFh to the IWDTRR register should be completed four-count cycles before the end position of the refresh-permitted period or a counter underflow. The value of the counter can be checked by the IWDTSR.CNTVAL[13:0] bits.

[Sample refreshing timings]

- When the window start position is set to 1FFFh, even if 00h is written to the IWDTRR register before 1FFFh is reached (2002h, for example), refreshing is done if FFh is written to the IWDTRR register after the value of the IWDTSR.CNTVAL[13:0] bits has reached 1FFFh.
- When the window end position is set to 1FFFh, refreshing is done if 2003h (four-count cycles before 1FFFh) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 00h → FFh to the IWDTRR register.
- When the refresh-permitted period continues until count 0000h, refreshing can be done immediately before an underflow. In this case, if 0003h (four-count cycles before an underflow) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 00h → FFh to the IWDTRR register, no underflow occurs and refreshing is done.

Figure 31.6 shows the IWDT refresh-operation waveforms when PCLK > IWDTCLK and clock divide ratio = IWDTCLK.

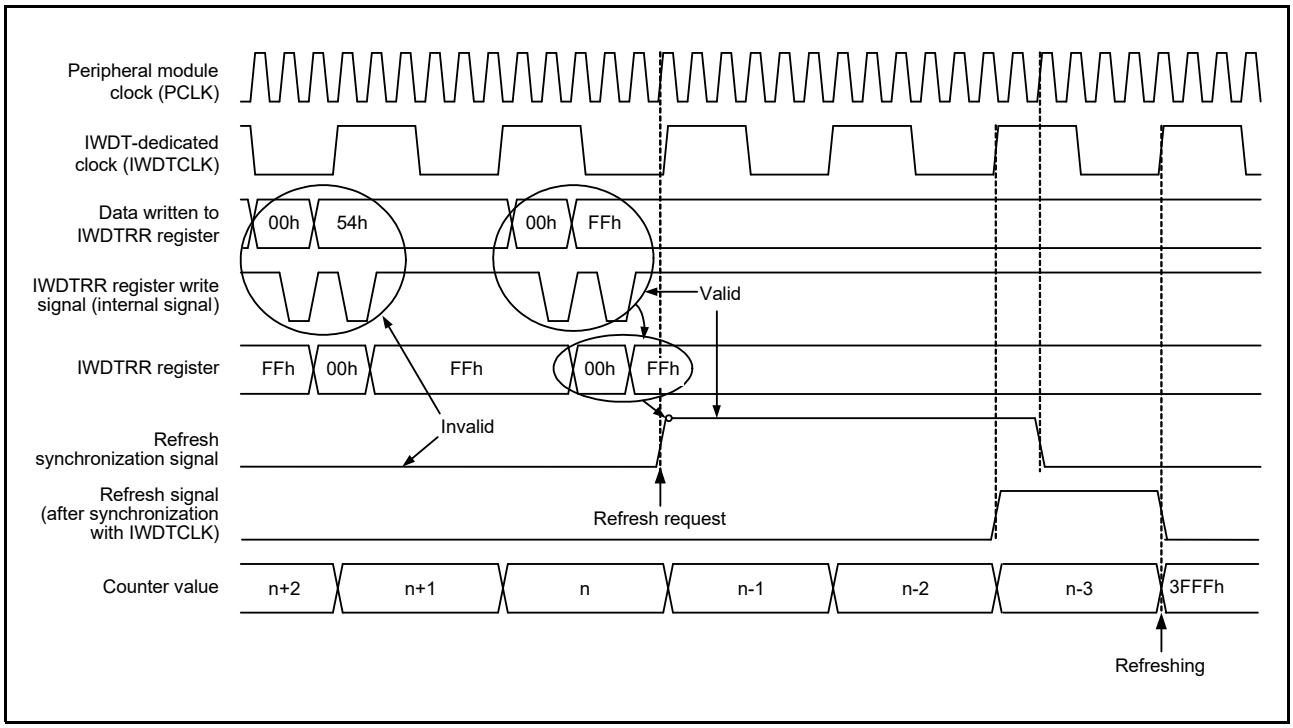

Figure 31.6 IWDT Refresh Operation Waveforms (IWDTCR.CKS[3:0] = 0000b, IWDTCR.TOPS[1:0] = 11b)

31.3.4 Status Flags

The IWDTSR.REFEF and IWDTSR.UNDFF flags retain the source of the reset signal output from the IWDT or the source of the interrupt request from the IWDT.
Thus, after release from the reset state or interrupt request generation, read the IWDTSR.REFEF and IWDTSR.UNDFF flags to check for the reset or interrupt source.
For each flag, writing 0 clears the bit and writing 1 has no effect.
Leaving the status flags unchanged does not affect operation. If the flags are not cleared, at the time of the next reset or interrupt request from the IWDT, the earlier reset or interrupt source is cleared and the new reset or interrupt source is written.
After 0 is written to each flag, up to three IWDTCLK cycles and two PCLK cycles are required before the value is reflected.

31.3.5 Reset Output

When the IWDTRCR.RSTIRQS bit is set to 1 in register start mode or when the IWDTRSTIRQS bit in option function select register 0 (OFS0) is set to 1 in auto-start mode, a reset signal is output when an underflow in the counter or a refresh error occurs.
In register start mode, the counter is initialized (0000h) and kept in that state after assertion of the reset signal. After the reset is released and the program is restarted, the counter is set up again and counting down is started by refreshing.
In auto-start mode, counting down automatically starts after the reset output.

31.3.6 Interrupt Sources

When the IWDTRCR.RSTIRQS bit is set to 0 in register start mode or when the OFS0.IWDTRSTIRQS bit is set to 0 in auto-start mode, an interrupt (IWUNI) signal is output when an underflow in the counter or a refresh error occurs. This interrupt can be used as a non-maskable interrupt or a maskable interrupt. For details, refer to section 14, Interrupt Controller (ICUG).

Table 31.4 IWDT Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
IWUNI	Counter underflow Refresh error	Not possible	Not possible

31.3.7 Reading the Counter Value

As the counter in IWDT-dedicated clock (IWDTCLK), the counter value cannot be read directly. The IWDT synchronizes the counter value with the peripheral module clock (PCLK) and stores it in the IWDTSR.CNTVAL[13:0] bits. Thus, the counter value can be checked indirectly through the IWDTSR.CNTVAL[13:0] bits.
Reading the counter value requires multiple PCLK clock cycles (up to four clock cycles), and the read counter value may differ from the actual counter value by a value of one count.
Figure 31.7 shows the processing for reading the IWDT counter value when PCLK > IWDTCLK and clock divide ratio = IWDTCLK.

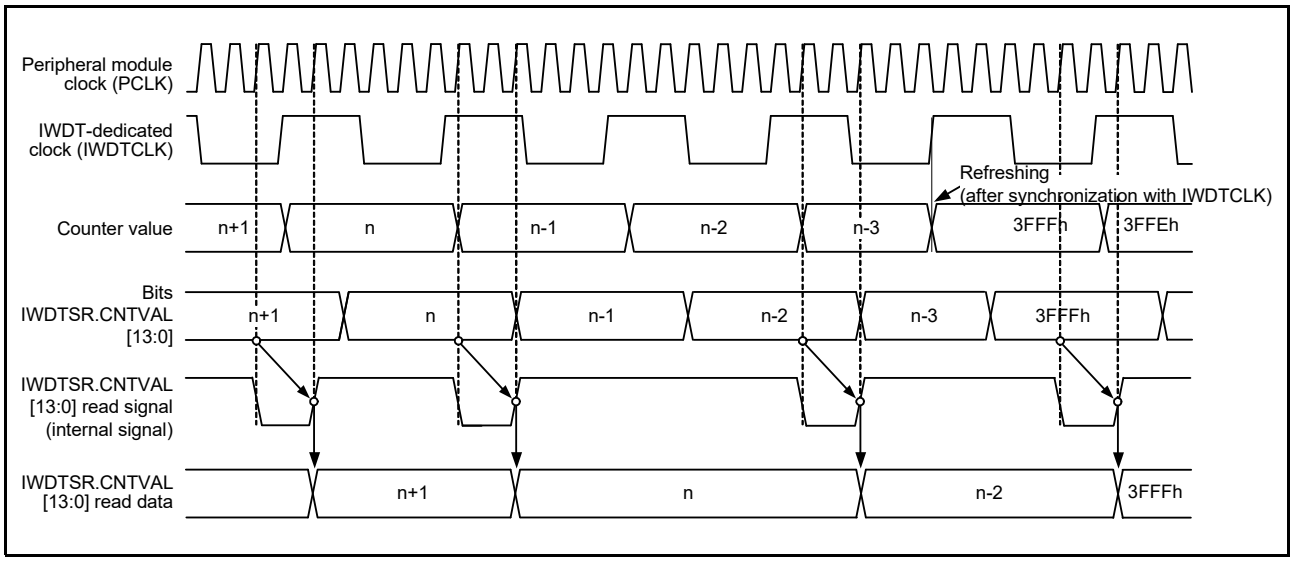

Figure 31.7 Processing for Reading IWDT Counter Value (IWDTCR.CKS[3:0] = 0000b, IWDTCR.TOPS[1:0] = 11b)

31.3.8 Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers

Table 31.5 lists the correspondence between option function select register 0 (OFS0) used in auto-start mode and the registers used in register start mode.
Do not change the OFS0 register setting during IWDT operation.
For details on the OFS0 register, refer to section 7.2.3, Option Function Select Register 0 (OFS0).

Table 31.5 Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers

Target of Control	Function	OFS0 Register (Enabled in Auto-Start Mode) OFS0.IWDTSTRT = 0	IWDT Registers (Enabled in Register Start Mode) OFS0.IWDTSTRT = 1
Counter	Timeout period selection	OFS0.IWDTTOPS[1:0]	IWDTCR.TOPS[1:0]
	Clock frequency divide ratio selection	OFS0.IWDTCKS[3:0]	IWDTCR.CKS[3:0]
	Window start position selection	OFS0.IWDTRPSS[1:0]	IWDTCR.RPSS[1:0]
	Window end position selection	OFS0.IWDTRPES[1:0]	IWDTCR.RPES[1:0]
Reset output or interrupt request output	Reset output or interrupt request output selection	OFS0.IWDTRSTIRQS	IWDTRCR.RSTIRQS
Count stop	Sleep mode count stop control	OFS0.IWDTSLCSTP	IWDTCSTPR.SLCSTP

31.4 Link Operation by ELC

The event link controller (ELC) can use the interrupt request signal generated by the IWDT as the event signal. Therefore, the ELC generates an event to the module specified previously when the IWDT outputs an interrupt request. The event signal is output by the counter underflow and refresh error.
An event signal is output regardless of the setting of the IWDTRCR.RSTIRQS bit in register start mode or the OFS0.IWDTRSTIRQS bit in auto-start mode. An event signal can also be output upon generation of the next interrupt source while the IWDTSR.REFEF or IWDTSR.UNDFF flag is 1.
For details, see section 19, Event Link Controller (ELC).

31.5 Usage Notes

31.5.1 Refresh Operations

When making the settings to control the timing of refreshing, consider variations in the range of errors due to the accuracy of the PCLK and IWDTCLK and set values which ensure that refreshing is possible.

31.5.2 Clock Divide Ratio Setting

Satisfy the frequency of the peripheral module clock (PCLK) ≥ 4 × (the frequency of the count source after divide).

32. Serial Communications Interface (SCIk, SCIh)

This MCU has four independent serial communications interface (SCI) channels. The SCI consists of the SCIk module (SCI1, SCI5, and SCI6) and the SCIh module (SCI12).
The SCIk module (SCI1, SCI5, and SCI6) can handle both asynchronous and clock synchronous serial communications. Asynchronous serial data communications can be carried out with standard asynchronous communications chips such as a Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communications Interface Adapter (ACIA). As an extended function in asynchronous communications mode, the SCI also supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards). The SCI is also supports simple SPI interfaces, and simple I^2C-bus interfaces when configured for single-master systems.
The SCIh module includes the functions of the SCIg module, and supports an extended serial communication protocol formed of Start Frames and Information Frames.
In this section, “PCLK” is used to refer to PCLKB.

32.1 Overview

Table 32.1 lists the specifications of the SCIk module, Table 32.2 lists the specifications of the SCIh module, and Table 32.3 lists the specifications of the individual SCI channels.
Figure 32.1 shows the block diagram of SCI1, Figure 32.2 shows the block diagram of SCI5 and SCI6, and Figure 32.3 shows the block diagram of SCI12 (SCIh).

Table 32.1 SCIk Specifications (1/2)

Item	Description
Serial communication modes	• Asynchronous • Clock synchronous • Smart card interface • Simple I^2C-bus • Simple SPI bus
Transfer speed	Bit rate specifiable with the on-chip baud rate generator.
Full-duplex communications	Transmitter: Continuous transmission possible using double-buffer structure. Receiver: Continuous reception possible using double-buffer structure.
I/O pins	Refer to Table 32.4 to Table 32.6.
Data transfer	Selectable as LSB first or MSB first transfer*1
I/O signal level inverting function	Input signal and output signal can be inverted independently.
RXD input signal select function (supported by SCI5 only)	If the RXD signal is attenuated by transmission line effects, it can be improved by using a comparator instead of a receiver.
Interrupt sources	Transmit end, transmit data empty, receive data full, receive error, and data match Completion of generation of a start condition, restart condition, or stop condition (for simple I^2C mode)
Low power consumption function	Module stop state can be set for each channel.

Table 32.1 SCIk Specifications (2/2)

Item		Description
Asynchronous mode	Data length	7, 8, or 9 bits
	Transmission stop bit	1 or 2 bits
	Parity	Even parity, odd parity, or no parity
	Receive error detection	Parity, overrun, and framing errors
	Hardware flow control	CTSn# and RTSn# pins can be used in controlling transmission/reception.
	Data match detection	Compares receive data and comparison data, and generates interrupt when they are matched.
	Start-bit detection	Low level or falling edge is selectable.
	Receive data sampling timing adjustment	Sampling point of receive data can be changed to front or rear of center of bit.
	Transmit signal transition timing adjustment	Falling or rising edge of the transmit data can be delayed.
	Break detection	When a framing error occurs, a break can be detected by reading the RXDn pin level directly or reading the SPTR.RXDMON flag.
	Clock source	An internal or external clock can be selected. Transfer rate clock input from the TMR can be used. (SCI5 and SCI6)
	Double-speed mode	Baud rate generator double-speed mode is selectable.
	Multi-processor communications function	Serial communication among multiple processors
	Noise cancellation	The signal paths from input on the RXDn pins incorporate digital noise filters.
Clock synchronous mode	Data length	8 bits
	Receive error detection	Overrun error
	Hardware flow control	CTSn# and RTSn# pins can be used in controlling transmission/reception.
Smart card interface mode	Error processing	An error signal can be automatically transmitted when detecting a parity error during reception
		Data can be automatically retransmitted when receiving an error signal during transmission
	Data type	Both direct convention and inverse convention are supported.
Simple I^2C mode	Transfer format	I^2C-bus format
	Operating mode	Master (single-master operation only)
	Transfer rate	Fast mode is supported (refer to section 32.2.11, Bit Rate Register (BRR) to set the transfer rate).
	Noise cancellation	The signal paths from input on the SSCLn and SSDAn pins incorporate digital noise filters, and the interval for noise cancellation is adjustable.
Simple SPI bus	Data length	8 bits
	Detection of errors	Overrun error
	SS input pin function	Applying the high level to the SSn# pin can cause the output pins to enter the high-impedance state.
	Clock settings	Four kinds of settings for clock phase and clock polarity are selectable.
Bit rate modulation function		Correction of outputs from the on-chip baud rate generator can reduce errors.
Event link function (supported by SCI5 only)		Error (receive error or error signal detection) event output
		Receive data full event output
		Transmit data empty event output
		Transmit end event output

Note 1. In simple I^2C mode, only MSB first is available.

Table 32.2 SCIh Specifications (1/2)

Item		Description
Serial communication modes		• Asynchronous • Clock synchronous • Smart card interface • Simple I²C-bus • Simple SPI bus
Transfer speed		Bit rate specifiable with the on-chip baud rate generator.
Full-duplex communications		Transmitter: Continuous transmission possible using double-buffer structure. Receiver: Continuous reception possible using double-buffer structure.
I/O pins		Refer to Table 32.4 to Table 32.7.
Data transfer		Selectable as LSB first or MSB first transfer*1
Interrupt sources		Transmit end, transmit data empty, receive data full, and receive error Completion of generation of a start condition, restart condition, or stop condition (for simple I²C mode)
Low power consumption function		Module stop state can be set.
Asynchronous mode	Data length	7, 8, or 9 bits
	Transmission stop bit	1 or 2 bits
	Parity	Even parity, odd parity, or no parity
	Receive error detection	Parity, overrun, and framing errors
	Hardware flow control	CTSn# and RTSn# pins can be used in controlling transmission/reception.
	Start-bit detection	Low level or falling edge is selectable.
	Break detection	When a framing error occurs, a break can be detected by reading the RXDn pin level directly.
	Clock source	An internal or external clock can be selected. Transfer rate clock input from the TMR can be used.
	Double-speed mode	Baud rate generator double-speed mode is selectable.
	Multi-processor communications function	Serial communication among multiple processors
	Noise cancellation	The signal paths from input on the RXDn pins incorporate digital noise filters.
Clock synchronous mode	Data length	8 bits
	Receive error detection	Overrun error
	Hardware flow control	CTSn# and RTSn# pins can be used in controlling transmission/reception.
Smart card interface mode	Error processing	An error signal can be automatically transmitted when detecting a parity error during reception
		Data can be automatically retransmitted when receiving an error signal during transmission
	Data type	Both direct convention and inverse convention are supported.
Simple I²C mode	Transfer format	I²C-bus format
	Operating mode	Master (single-master operation only)
	Transfer rate	Fast mode is supported (refer to section 32.2.11, Bit Rate Register (BRR) to set the transfer rate).
	Noise cancellation	The signal paths from input on the SSCLn and SSDAn pins incorporate digital noise filters, and the interval for noise cancellation is adjustable.
Simple SPI bus	Data length	8 bits
	Detection of errors	Overrun error
	SS input pin function	Applying the high level to the SSn# pin can cause the output pins to enter the high-impedance state.
	Clock settings	Four kinds of settings for clock phase and clock polarity are selectable.

Table 32.2 SCIh Specifications (2/2)

Item		Description
Extended serial mode	Start Frame transmission	• Output of a low level as the Break Field over a specified width and generation of interrupts on completion • Detection of bus collisions and the generation of interrupts on detection
	Start Frame reception	• Detection of the Break Field low width and generation of an interrupt on detection • Comparison of Control Fields 0 and 1 and generation of an interrupt when the two match • Two kinds of data for comparison (primary and secondary) can be set in Control Field 1. • A priority interrupt bit can be set in Control Field 1. • Handling of Start Frames that do not include a Break Field • Handling of Start Frames that do not include a Control Field 0 • Function for measuring bit rates
	I/O control function	• Selectable polarity for TXDX12 and RXDX12 signals • Selection of a digital filter for the RXDX12 signal • Half-duplex operation employing RXDX12 and TXDX12 signals multiplexed on the same pin • Selectable timing for the sampling of data received through RXDX12
	Timer function	• Usable as a reload timer
Bit rate modulation function		Correction of outputs from the on-chip baud rate generator can reduce errors.

Note 1. In simple I^2C mode, only MSB first is available.

	SIOX12	I/O	SCI12 transfer data input/output

32.2 Register Descriptions

32.2.1 Receive Shift Register (RSR)

The RSR register is a shift register which is used to receive serial data input from the RXDn pin and converts it into parallel data.
When one frame of data has been received, it is automatically transferred to the RDR register.
The RSR register cannot be directly accessed by the CPU.

32.2.2 Receive Data Register (RDR)

Address(es): SCI1.RDR 0008 A025h, SCI5.RDR 0008 A0A5h, SCI6.RDR 0008 A0C5h, SCI12.RDR 0008 B305h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

The RDR register is an 8-bit register that stores receive data.
When one frame of serial data has been received, the received serial data is transferred from the RSR register to the RDR register. Then the RSR register can receive the next data.
Since the RSR and RDR registers function as a double buffer in this way, continuous receive operations can be performed.
Read the RDR register only once after a receive data full interrupt (RXI) has occurred. Note that if next one frame of data is received before reading receive data from the RDR register, an overrun error occurs.
The RDR register cannot be written to by the CPU.

32.2.3 Receive Data Register H, L, HL (RDRH, RDRL, RDRHL)

- Receive Data Register H (RDRH)

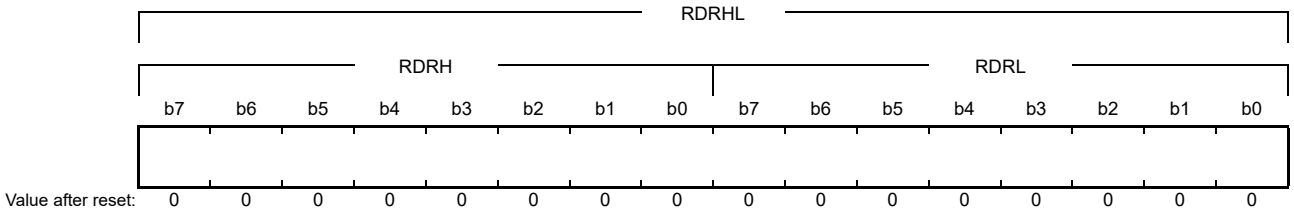
Address(es): SCI1.RDRH 0008 A030h, SCI5.RDRH 0008 A0B0h, SCI6.RDRH 0008 A0D0h, SCI12.RDRH 0008 B310h

- Receive Data Register L (RDRL)

Address(es): SCI1.RDRL 0008 A031h, SCI5.RDRL 0008 A0B1h, SCI6.RDRL 0008 A0D1h, SCI12.RDRL 0008 B311h

- Receive Data Register HL (RDRHL)

Address(es): SCI1.RDRHL 0008 A030h, SCI5.RDRHL 0008 A0B0h, SCI6.RDRHL 0008 A0D0h, SCI12.RDRHL 0008 B310h



The RDRH and RDRL registers are 8-bit registers that store receive data. Use these registers when asynchronous mode and 9-bit data length are selected.

The RDRL register is the shadow register of the RDR register; i.e. access to the RDRL register is equivalent to access to the RDR register.

After one frame of data is received, the received data is transferred from the RSR register to these registers, thus allowing the RSR register to receive the next data.

The RSR, RDRH and RDRL registers have a double-buffered construction to enable continuous reception.

Read the RDRH and RDRL registers should be performed only once in the order from the RDRH register to the RDRL register when a receive data full interrupt (RXI) request is issued. Note that an overrun error occurs when the next frame of data is received before the received data has been read from the RDRL register.

The CPU cannot write to the RDRH and RDRL registers. Bits 0 to 7 in the RDRH register are fixed to 0. These bits are read as 0.

The RDRHL register can be accessed in 16-bit units.

32.2.4 Transmit Data Register (TDR)

Address(es): SCI1.TDR 0008 A023h, SCI5.TDR 0008 A0A3h, SCI6.TDR 0008 A0C3h, SCI12.TDR 0008 B303h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

The TDR register is an 8-bit register that stores transmit data.
When the SCI detects that the TSR register is empty, it transfers the transmit data written in the TDR register to the TSR register and starts transmission.
The double-buffered structures of the TDR register and the TSR register enable continuous serial transmission. If the next transmit data has already been written to the TDR register when one frame of data is transmitted, the SCI transfers the written data to the TSR register to continue transmission.
The CPU is able to read from or write to the TDR register at any time. Only write transmit data to the TDR register once after each instance of the transmit data empty interrupt (TXI).

32.2.5 Transmit Data Register H, L, HL (TDRH, TDRL, TDRHL)

- Transmit Data Register H (TDRH)

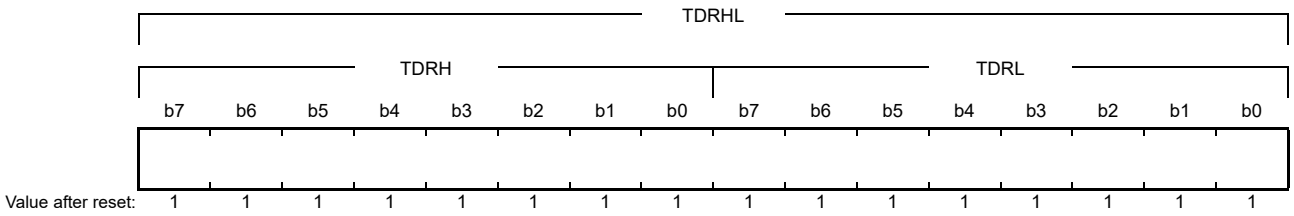
Address(es): SCI1.TDRH 0008 A02Eh, SCI5.TDRH 0008 A0AEh, SCI6.TDRH 0008 A0CEh, SCI12.TDRH 0008 B30Eh

- Transmit Data Register L (TDRL)

Address(es): SCI1.TDRL 0008 A02Fh, SCI5.TDRL 0008 A0AFh, SCI6.TDRL 0008 A0CFh, SCI12.TDRL 0008 B30Fh

- Transmit Data Register HL (TDRHL)

Address(es): SCI1.TDRHL 0008 A02Eh, SCI5.TDRHL 0008 A0AEh, SCI6.TDRHL 0008 A0CEh, SCI12.TDRHL 0008 B30Eh



The TDRH and TDRL registers are 8-bit registers that store transmit data. Use these registers when asynchronous mode and 9-bit data length are selected.
The TDRL register is the shadow register of the TDR register; i.e. access to the TDRL register is equivalent to access to the TDR register.
When empty space is detected in the TSR register, the transmit data stored in the TDRH and TDRL registers is transferred to the TSR register; i.e., transmitting is started.
The TSR, TDRH and TDRL registers have a double-buffered construction to realize continuous reception. When the next data to be transmitted is stored in the TDRL register after one frame of data has been transmitted, the transmitting operation is continued by transfer to the TSR register.
The CPU can read and write to the TDRH and TDRL registers. Bits 0 to 7 in the RDRH register are fixed to 1. These bits are read as 1. The write value should be 1.
Writing transmit data to the TDRH and TDRL registers should be performed only once in the order from the TDRH register to the TDRL register when a transmit data empty interrupt (TXI) request is issued.
The TDRHL register can be accessed in 16-bit units.

32.2.6 Transmit Shift Register (TSR)

The TSR register is a shift register that transmits serial data.
To perform serial data transmission, the SCI first automatically transfers transmit data from the TDR register to the TSR register, and then sends the data to the TXDn pin.
The TSR register cannot be directly accessed by the CPU.

32.2.7 Serial Mode Register (SMR)

Some bits in the SMR register have different functions in smart card interface mode and non-smart card interface mode.

(1) Non-Smart Card Interface Mode (SCMR.SMIF = 0)

Address(es): SCI1.SMR 0008 A020h, SCI5.SMR 0008 A0A0h, SCI6.SMR 0008 A0C0h, SCI12.SMR 0008 B300h

	b7	b6	b5	b4	b3	b2	b1	b0
	CM	CHR	PE	PM	STOP	MP	CKS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKS[1:0]	Clock Select	b1 b0 0 0: PCLK (n = 0)*1 0 1: PCLK/4 (n = 1)*1 1 0: PCLK/16 (n = 2)*1 1 1: PCLK/64 (n = 3)*1	R/W*4
b2	MP	Multi-Processor Mode	(Valid only in asynchronous mode) 0: Multi-processor communications function is disabled 1: Multi-processor communications function is enabled	R/W*4
b3	STOP	Stop Bit Length	(Valid only in asynchronous mode) 0: 1 stop bit 1: 2 stop bits	R/W*4
b4	PM	Parity Mode	(Valid only when the PE bit is 1) 0: Selects even parity 1: Selects odd parity	R/W*4
b5	PE	Parity Enable	(Valid only in asynchronous mode) • When transmitting 0: Parity bit addition is not performed 1: The parity bit is added • When receiving 0: Parity bit checking is not performed 1: The parity bit is checked	R/W*4
b6	CHR	Character Length	(Valid only in asynchronous mode*2) Selects in combination with the SCMR.CHR1 bit. CHR1 CHR 0 0: Transmit/receive in 9-bit data length 0 1: Transmit/receive in 9-bit data length 1 0: Transmit/receive in 8-bit data length (initial value) 1 1: Transmit/receive in 7-bit data length*3	R/W*4
b7	CM	Communications Mode	0: Asynchronous mode or simple I2C mode 1: Clock synchronous mode or simple SPI mode	R/W*4

Note 1. n is the decimal notation of the value of n in the BRR register (refer to section 32.2.11, Bit Rate Register (BRR)).
Note 2. In other than asynchronous mode, this bit setting is invalid and a fixed data length of 8 bits is used.
Note 3. LSB first is fixed and the MSB (bit 7) in the TDR register is not transmitted in transmission.
Note 4. Writable only when the SCR.TE bit is 0 and the SCR.RE bit is 0 (both serial transmission and reception are disabled).

CKS[1:0] Bits (Clock Select)

These bits select the clock source for the on-chip baud rate generator.

For the relation between the settings of these bits and the baud rate, refer to section 32.2.11, Bit Rate Register (BRR).

MP Bit (Multi-Processor Mode)

Disables/enables the multi-processor communications function. The settings of the PE bit and PM bit are invalid in multi-processor mode.

STOP Bit (Stop Bit Length)

Selects the stop bit length in transmission.
In reception, only the first stop bit is checked regardless of this bit setting. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.

PM Bit (Parity Mode)

Selects the parity mode (even or odd) for transmission and reception.
The setting of the PM bit is invalid in multi-processor mode.

PE Bit (Parity Enable)

When this bit is set to 1, the parity bit is added to transmit data, and the parity bit is checked in reception.
Irrespective of the setting of the PE bit, the parity bit is not added or checked in multi-processor format.

CHR Bit (Character Length)

Selects the data length for transmission and reception.
Selects in combination with the SCMR.CHR1 bit.
In other than asynchronous mode, a fixed data length of 8 bits is used.

(2) Smart Card Interface Mode (SCMR.SMIF = 1)

Address(es): SMCI1.SMR 0008 A020h, SMCI5.SMR 0008 A0A0h, SMCI6.SMR 0008 A0C0h, SMCI12.SMR 0008 B300h

	b7	b6	b5	b4	b3	b2	b1	b0
	GM	BLK	PE	PM	BCP[1:0]		CKS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKS[1:0]	Clock Select	b1 b0 0 0: PCLK (n = 0)*1 0 1: PCLK/4 (n = 1)*1 1 0: PCLK/16 (n = 2)*1 1 1: PCLK/64 (n = 3)*1	R/W*2
b3, b2	BCP[1:0]	Base Clock Pulse	Selects the number of base clock cycles in combination with the SCMR.BCP2 bit. Table 32.8 lists the combinations of the SCMR.BCP2 bit and SMR.BCP[1:0] bits.	R/W*2
b4	PM	Parity Mode	(Valid only when the PE bit is 1) 0: Selects even parity 1: Selects odd parity	R/W*2
b5	PE	Parity Enable	When this bit is set to 1, a parity bit is added to transmit data, and the parity of received data is checked. Set this bit to 1 in smart card interface mode.	R/W*2
b6	BLK	Block Transfer Mode	0: Non-block transfer mode operation 1: Block transfer mode operation	R/W*2
b7	GM	GSM Mode	0: Non-GSM mode operation 1: GSM mode operation	R/W*2

Note 1. n is the decimal notation of the value of n in the BRR register (refer to section 32.2.11, Bit Rate Register (BRR)).
Note 2. Writable only when the SCR.TE bit is 0 and the SCR.RE bit is 0 (both serial transmission and reception are disabled).

CKS[1:0] Bits (Clock Select)

These bits select the clock source for the on-chip baud rate generator.

For the relationship between the settings of these bits and the baud rate, refer to section 32.2.11, Bit Rate Register (BRR).

BCP[1:0] Bits (Base Clock Pulse)

These bits select the number of base clock cycles in a 1-bit data transfer time in smart card interface mode.

Set these bits in combination with the SCMR.BCP2 bit.

For details, refer to section 32.6.4, Receive Data Sampling Timing and Reception Margin.

Table 32.8 Combinations of the SCMR.BCP2 Bit and SMR.BCP[1:0] Bits

SCMR.BCP2 Bit	SMR.BCP[1:0] Bits		Number of Base Clock Cycles for 1-Bit Transfer Period
0	0	0	93 clock cycles (S = 93)*1
0	0	1	128 clock cycles (S = 128)*1
0	1	0	186 clock cycles (S = 186)*1
0	1	1	512 clock cycles (S = 512)*1
1	0	0	32 clock cycles (S = 32)*1 (Initial Value)
1	0	1	64 clock cycles (S = 64)*1
1	1	0	372 clock cycles (S = 372)*1
1	1	1	256 clock cycles (S = 256)*1

Note 1. S is the value of S in the BRR register (refer to section 32.2.11, Bit Rate Register (BRR)).

PM Bit (Parity Mode)

Selects the parity mode for transmission and reception (even or odd).
For details on the usage of this bit in smart card interface mode, refer to section 32.6.2, Data Format (Except in Block Transfer Mode).

PE Bit (Parity Enable)

Set the PE bit to 1.
The parity bit is added to transmit data before transmission, and the parity bit is checked in reception.

BLK Bit (Block Transfer Mode)

Setting this bit to 1 allows block transfer mode operation.
For details, refer to section 32.6.3, Block Transfer Mode.

GM Bit (GSM Mode)

Setting this bit to 1 allows GSM mode operation.
In GSM mode, the SSR.TEND flag set timing is put forward to 11.0 etu (elementary time unit = 1-bit transfer time) from the start and the clock output control function is appended. For details, refer to section 32.6.6, Serial Data Transmission (Except in Block Transfer Mode) and section 32.6.8, Clock Output Control.

32.2.8 Serial Control Register (SCR)

Some bits in the SCR register have different functions in smart card interface mode and non-smart card interface mode.

(1) Non-Smart Card Interface Mode (SCMR.SMIF = 0)

Address(es): SCI1.SCR 0008 A022h, SCI5.SCR 0008 A0A2h, SCI6.SCR 0008 A0C2h, SCI12.SCR 0008 B302h

	b7	b6	b5	b4	b3	b2	b1	b0
	TIE	RIE	TE	RE	MPIE	TEIE	CKE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKE[1:0]	Clock Enable	(Asynchronous mode) b1 b0 0 0: On-chip baud rate generator The SCKn pin becomes high-impedance. 0 1: On-chip baud rate generator The clock with the same frequency as the bit rate is output from the SCKn pin. 1 x: External clock or TMR clock*2 • The clock with a frequency 16 times the bit rate should be input from the SCKn pin. Input a clock signal with a frequency eight times the bit rate when the SEMR.ABCS bit is 1. • The SCKn pin becomes high-impedance when the TMR clock*2 is used. (Clock synchronous mode) b1 b0 0 x: Internal clock The SCKn pin functions as the clock output pin. 1 x: External clock The SCKn pin functions as the clock input pin.	R/W*1
b2	TEIE	Transmit End Interrupt Enable	0: A TEI interrupt request is disabled 1: A TEI interrupt request is enabled	R/W
b3	MPIE	Multi-Processor Interrupt Enable	(Valid in asynchronous mode when the SMR.MP bit is 1) 0: Normal reception 1: When the data with the multi-processor bit set to 0 is received, the data is not read, and setting the status flags RDRF, ORER, and FER in the SSR register to 1 is disabled. When the data with the multi-processor bit set to 1 is received, the MPIE bit is automatically cleared to 0, and normal reception is resumed.	R/W
b4	RE	Receive Enable	0: Serial reception is disabled 1: Serial reception is enabled	R/W*3
b5	TE	Transmit Enable	0: Serial transmission is disabled 1: Serial transmission is enabled	R/W*3
b6	RIE	Receive Interrupt Enable	0: RXI and ERI interrupt requests are disabled 1: RXI and ERI interrupt requests are enabled	R/W
b7	TIE	Transmit Interrupt Enable	0: A TXI interrupt request is disabled 1: A TXI interrupt request is enabled	R/W

x: Don't care

Note 1. Writable only when TE = 0 and RE = 0.

Note 2. TMR clock is selectable for SCI5, SCI6, and SCI12.

Note 3. 1 can be written only when TE = 0 and RE = 0, while the SMR.CM bit is 1. After setting TE or RE to 1, only 0 can be written to TE and RE. While the SMR.CM bit is 0 and the SIMR1.IICM bit is 0, writing is enabled under any condition.

CKE[1:0] Bits (Clock Enable)

These bits select the clock source and SCKn pin function.
The combination of the settings of these bits and of the SEMR.ACS0 bit sets the internal TMR clock.

TEIE Bit (Transmit End Interrupt Enable)

Enables or disables a TEI interrupt request.
A TEI interrupt request is disabled by setting the TEIE bit to 0.
In simple I^2C mode, the TEI is allocated to the interrupt on completion of issuing a start, restart, or stop condition (STI). In this case, the TEIE bit can be used to enable or disable the STI.

MPIE Bit (Multi-Processor Interrupt Enable)

When this bit is set to 1 and the data with the multi-processor bit set to 0 is received, the data is not read and setting the status flags RDRF, ORER, and FER in the SSR register to 1 is disabled. When the data with the multi-processor bit set to 1 is received, the MPIE bit is automatically cleared to 0, and normal reception is resumed. For details, refer to section 32.4, Multi-Processor Communications Function.
When the data with the multi-processor bit set to 0 is received, the receive data is not transferred from the RSR register to the RDR register, a receive error is not detected, and setting the flags RDRF, ORER, and FER to 1 is disabled.
When the data with the multi-processor bit set to 1 is received, the MPB bit is set to 1, the MPIE bit is automatically cleared to 0, the RXI and ERI interrupt requests are enabled (if the SCR.RIE bit is set to 1), and setting the flags RDRF, ORER, and FER to 1 is enabled.
Set the MPIE bit to 0 if multi-processor communications function is not to be used.

RE Bit (Receive Enable)

Enables or disables serial reception.
When this bit is set to 1, serial reception is started by detecting the start bit in asynchronous mode or the synchronous clock input in clock synchronous mode. Note that the SMR register should be set prior to setting the RE bit to 1 in order to designate the reception format.
Even if reception is halted by setting the RE bit to 0, the ORER, FER, PER, and RDRF flags in the SSR register are not affected and the previous value is retained.

TE Bit (Transmit Enable)

Enables or disables serial transmission.
When this bit is set to 1, serial transmission is started by writing transmit data to the TDR register. Note that the SMR register should be set prior to setting the TE bit to 1 in order to designate the transmission format.

RIE Bit (Receive Interrupt Enable)

Enables or disables RXI and ERI interrupt requests.
An RXI interrupt request is disabled by setting the RIE bit to 0.
An ERI interrupt request can be canceled by reading 1 from the ORER, FER, or PER flag in the SSR register and then setting the flag to 0, or setting the RIE bit to 0.

TIE Bit (Transmit Interrupt Enable)

Enables or disables TXI interrupt request.
A TXI interrupt request is disabled by setting the TIE bit to 0.

(2) Smart Card Interface Mode (SCMR.SMIF = 1)

Address(es): SMCI1.SCR 0008 A022h, SMCI5.SCR 0008 A0A2h, SMCI6.SCR 0008 A0C2h, SMCI12.SCR 0008 B302h

	b7	b6	b5	b4	b3	b2	b1	b0
	TIE	RIE	TE	RE	MPIE	TEIE	CKE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKE[1:0]	Clock Enable	• When SMR.GM = 0 b1 b0 0 0: Output disabled The SCKn pin becomes high-impedance. 0 1: Clock output 1 x: Setting prohibited • When SMR.GM = 1 b1 b0 0 0: Output fixed low x 1: Clock output 1 0: Output fixed high	R/W*1
b2	TEIE	Transmit End Interrupt Enable	This bit should be 0 in smart card interface mode.	R/W
b3	MPIE	Multi-Processor Interrupt Enable	This bit should be 0 in smart card interface mode.	R/W
b4	RE	Receive Enable	0: Serial reception is disabled 1: Serial reception is enabled	R/W*2
b5	TE	Transmit Enable	0: Serial transmission is disabled 1: Serial transmission is enabled	R/W*2
b6	RIE	Receive Interrupt Enable	0: RXI and ERI interrupt requests are disabled 1: RXI and ERI interrupt requests are enabled	R/W
b7	TIE	Transmit Interrupt Enable	0: A TXI interrupt request is disabled 1: A TXI interrupt request is enabled	R/W

x: Don't care

Note 1. Writable only when TE = 0 and RE = 0.

Note 2. 1 can be written only when TE = 0 and RE = 0. After setting TE or RE to 1, only 0 can be written in TE and RE.

For details on interrupt requests, refer to section 32.12, Interrupt Sources.

CKE[1:0] Bits (Clock Enable)

These bits control the clock output from the SCKn pin.

In GSM mode, clock output can be dynamically switched. For details, refer to section 32.6.8, Clock Output Control.

TEIE Bit (Transmit End Interrupt Enable)

This bit should be 0 in smart card interface mode.

MPIE Bit (Multi-Processor Interrupt Enable)

This bit should be 0 in smart card interface mode.

RE Bit (Receive Enable)

Enables or disables serial reception.

When this bit is set to 1, serial reception is started by detecting the start bit. Note that the SMR register should be set prior to setting the RE bit to 1 in order to designate the reception format.

Even if reception is halted by setting the RE bit to 0, the ORER, FER, and PER flags in the SSR register are not affected and the previous value is retained.

TE Bit (Transmit Enable)

Enables or disables serial transmission.

When this bit is set to 1, serial transmission is started by writing transmit data to the TDR register. Note that the SMR register should be set prior to setting the TE bit to 1 in order to designate the transmission format.

RIE Bit (Receive Interrupt Enable)

Enables or disables RXI and ERI interrupt requests.

An RXI interrupt request is disabled by setting the RIE bit to 0.

An ERI interrupt request can be canceled by reading 1 from the ORER, FER, or PER flag in the SSR register and then setting the flag to 0, or setting the RIE bit to 0.

TIE Bit (Transmit Interrupt Enable)

Enables or disables TXI interrupt request.

A TXI interrupt request is disabled by setting the TIE bit to 0.

32.2.9 Serial Status Register (SSR)

Some bits in the SSR register have different functions in smart card interface mode and non-smart card interface mode.

(1) Non-Smart Card Interface Mode (SCMR.SMIF = 0)

Address(es): SCI1.SSR 0008 A024h, SCI5.SSR 0008 A0A4h, SCI6.SSR 0008 A0C4h, SCI12.SSR 0008 B304h

	b7	b6	b5	b4	b3	b2	b1	b0
	TDRE	RDRF	ORER	FER	PER	TEND	MPB	MPBT
Value after reset:	1	0	0	0	0	1	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MPBT	Multi-Processor Bit Transfer	Sets the multi-processor bit for adding to the transmission frame 0: Data transmission cycles 1: ID transmission cycles	R/W
b1	MPB	Multi-Processor	Value of the multi-processor bit in the reception frame 0: Data transmission cycles 1: ID transmission cycles	R
b2	TEND	Transmit End Flag	0: A character is being transmitted. 1: Character transfer has been completed.	R
b3	PER	Parity Error Flag	0: No parity error occurred 1: A parity error has occurred	R/(W) *1
b4	FER	Framing Error Flag	0: No framing error occurred 1: A framing error has occurred	R/(W) *1
b5	ORER	Overrun Error Flag	0: No overrun error occurred 1: An overrun error has occurred	R/(W) *1
b6	RDRF	Receive Data Full Flag	0: No valid data is held in the RDR register 1: Received data is held in the RDR register	R/(W) *2
b7	TDRE	Transmit Data Empty Flag	0: Data to be transmitted is held in the TDR register 1: No data is held in the TDR register	R/(W) *2

Note 1. Only 0 can be written to this bit, to clear the flag. To clear this flag, confirm that the flag is 1 and then set it to 0.
Note 2. Write 1 when writing is necessary.

MPB Bit (Multi-Processor)

Holds the value of the multi-processor bit in the reception frame. This bit does not change when the SCR.RE bit is 0.

TEND Flag (Transmit End Flag)

Indicates completion of transmission.

[Setting conditions]

- When the SCR.TE bit is set to 0 (serial transmission is disabled)
  When the SCR.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated at the time of transmission of the tail-end bit of a character being transmitted

[Clearing condition]

- When transmit data are written to the TDR register while the SCR.TE bit is 1
  When setting the TEND flag to 0 to complete the interrupt handling, refer to section 14.5.2, Level Detection.

PER Flag (Parity Error Flag)

Indicates that a parity error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When a parity error is detected during reception while data match detection is disabled (for SCI1, SCI5, and SCI6)
- When a parity error is detected during reception (for SCI12)
  Although receive data when the parity error occurs is transferred to the RDR register, no RXI interrupt request occurs. Note that when the PER flag is being set to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to the PER flag after reading PER = 1
  When setting the PER flag to 0 to complete the interrupt handling, refer to section 14.5.2, Level Detection.
  Even when the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

FER Flag (Framing Error Flag)

Indicates that a framing error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When the stop bit is 0 while data match detection is disabled (for SCI1, SCI5, and SCI6)
- When the stop bit is 0 (for SCI12)
  In 2-stop-bit mode, only the first stop bit is checked whether it is 1 but the second stop bit is not checked. Note that although receive data when the framing error occurs is transferred to the RDR register, no RXI interrupt request occurs. In addition, when the FER flag is being set to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to the FER flag after reading FER = 1
  When setting the FER flag to 0 to complete the interrupt handling, refer to section 14.5.2, Level Detection.
  Even when the SCR.RE bit is set to 0, the FER flag is not affected and retains its previous value.

ORER Flag (Overrun Error Flag)

Indicates that an overrun error has occurred during reception and the reception ends abnormally.

[Setting condition]

- When the next data is received before receive data is read from the RDR register
  In the RDR register, receive data prior to an overrun error occurrence is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, subsequent serial reception cannot be performed. Note that, in clock synchronous mode, serial transmission also cannot continue.

[Clearing condition]

- When 0 is written to the ORER flag after reading ORER = 1
  When setting the ORER flag to 0 to complete the interrupt handling, refer to section 14.5.2, Level Detection.
  Even when the SCR.RE bit is set to 0, the ORER flag is not affected and retains its previous value.

RDRF Flag (Receive Data Full Flag)

Indicates whether the RDR register has received data.

[Setting condition]

- When data has been received normally, and transferred from the RSR register to the RDR register

[Clearing condition]

- When data is read from the RDR register

TDRE Flag (Transmit Data Empty Flag)

Indicates whether the TDR register has data to be transmitted.

[Setting condition]

- When data is transferred from the TDR register to the TSR register

[Clearing condition]

- When data is written to the TDR register

(2) Smart Card Interface Mode (SCMR.SMIF = 1)

Address(es): SMCI1.SSR 0008 A024h, SMCI5.SSR 0008 A0A4h, SMCI6.SSR 0008 A0C4h, SMCI12.SSR 0008 B304h

	b7	b6	b5	b4	b3	b2	b1	b0
	TDRE	RDRF	ORER	ERS	PER	TEND	MPB	MPBT
Value after reset:	1	0	0	0	0	1	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MPBT	Multi-Processor Bit Transfer	This bit should be set to 0 in smart card interface mode.	R/W
b1	MPB	Multi-Processor	This bit is not used in smart card interface mode. It should be set to 0.	R
b2	TEND	Transmit End Flag	0: A character is being transmitted. 1: Character transfer has been completed.	R
b3	PER	Parity Error Flag	0: No parity error occurred 1: A parity error has occurred	R/(W) *1
b4	ERS	Error Signal Status Flag	0: Low error signal not responded 1: Low error signal responded	R/(W) *1
b5	ORER	Overrun Error Flag	0: No overrun error occurred 1: An overrun error has occurred	R/(W) *1
b6	RDRF	Receive Data Full Flag	0: No valid data is held in the RDR register 1: Received data is held in the RDR register	R/(W) *2
b7	TDRE	Transmit Data Empty Flag	0: Data to be transmitted is held in the TDR register 1: No data is held in the TDR register	R/(W) *2

Note 1. Only 0 can be written to this bit, to clear the flag. To clear this flag, confirm that the flag is 1 and then set it to 0.
Note 2. Write 1 when writing is necessary.

TEND Flag (Transmit End Flag)

With no error signal from the receiving side, this bit is set to 1 when further data for transfer is ready to be transferred to the TDR register.

[Setting conditions]

- When the SCR.TE bit is 0 (serial transmission is disabled)
  When the SCR.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When a specified period has elapsed after the latest transmission of 1 byte, the ERS flag is 0, and the TDR register is not updated
  The set timing is determined by register settings as listed below.
  When SMR.GM = 0 and SMR.BLK = 0, 12.5 etu after the start of transmission
  When SMR.GM = 0 and SMR.BLK = 1, 11.5 etu after the start of transmission
  When SMR.GM = 1 and SMR.BLK = 0, 11.0 etu after the start of transmission
  When SMR.GM = 1 and SMR.BLK = 1, 11.0 etu after the start of transmission

[Clearing condition]

- When transmit data are written to the TDR register while the SCR.TE bit is 1
  When setting the TEND flag to 0 to complete the interrupt handling, refer to section 14.5.2, Level Detection.

PER Flag (Parity Error Flag)

Indicates that a parity error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When a parity error is detected during reception
  Although receive data when the parity error occurs is transferred to the RDR register, no RXI interrupt request occurs. Note that when the PER flag is being set to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to the PER flag after reading PER = 1
  When setting the PER flag to 0 to complete the interrupt handling, refer to section 14.5.2, Level Detection.
  Even when the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

ERS Flag (Error Signal Status Flag)

[Setting condition]

- When a low error signal is sampled

[Clearing condition]

- When 0 is written to the ERS flag after reading ERS = 1
  When setting the ERS flag to 0 to complete the interrupt handling, refer to section 14.5.2, Level Detection.
  Even when the SCR.RE bit is set to 0, the ERS flag is not affected and retains its previous value.

ORER Flag (Overrun Error Flag)

Indicates that an overrun error has occurred during reception and the reception ends abnormally.

[Setting condition]

- When the next data is received before receive data is read from the RDR register
  In the RDR register, the receive data prior to an overrun error occurrence is retained, but data received following the overrun error occurrence is lost. When the ORER flag is set to 1, subsequent serial reception cannot be performed.

[Clearing condition]

- When 0 is written to the ORER flag after reading ORER = 1
  When setting the ORER flag to 0 to complete the interrupt handling, refer to section 14.5.2, Level Detection.
  Even when the SCR.RE bit is set to 0, the ORER flag is not affected and retains its previous value.

RDRF Flag (Receive Data Full Flag)

Indicates whether the RDR register has received data.

[Setting condition]

- When data has been received normally, and transferred from the RSR register to the RDR register

[Clearing condition]

- When data is read from the RDR register

TDRE Flag (Transmit Data Empty Flag)

Indicates whether the TDR register has data to be transmitted.

[Setting condition]

- When data is transferred from the TDR register to the TSR register

[Clearing condition]

- When data is written to the TDR register

32.2.10 Smart Card Mode Register (SCMR)

Address(es): SCI1.SCMR 0008 A026h, SCI5.SCMR 0008 A0A6h, SCI6.SCMR 0008 A0C6h, SCI12.SCMR 0008 B306h, SMCI1.SCMR 0008 A026h, SMCI5.SCMR 0008 A0A6h, SMCI6.SCMR 0008 A0C6h, SMCI12.SCMR 0008 B306h

	b7	b6	b5	b4	b3	b2	b1	b0
	BCP2	—	—	CHR1	SDIR	SINV	—	SMIF
Value after reset:	1	1	1	1	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	SMIF	Smart Card Interface Mode Select	0: Non-smart card interface mode (Asynchronous mode, clock synchronous mode, simple SPI mode, or simple I2C mode) 1: Smart card interface mode	R/W*1
b1	—	Reserved	This bit is read as 1. The write value should be 1.	R/W
b2	SINV	Transmitted/Received Data Invert*2, *3	0: Data bits in the TDR register are transferred to the TSR register as they are. Data bits in the RSR register are transferred to the RDR register as they are. 1: Data bits in the TDR register are transferred to the TSR register with inverting. Data bits in the RSR register are transferred to the RDR register with inverting.	R/W*1
b3	SDIR	Transmitted/Received Data Transfer Direction*2, *4	0: Transfer with LSB first 1: Transfer with MSB first	R/W*1
b4	CHR1	Character Length 1*5	Selects in combination with the SMR.CHR bit. CHR1 CHR 0 0: Transmit/receive in 9-bit data length 0 1: Transmit/receive in 9-bit data length 1 0: Transmit/receive in 8-bit data length (initial value) 1 1: Transmit/receive in 7-bit data length*6	R/W*1
b6, b5	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b7	BCP2	Base Clock Pulse 2	Selects the number of base clock cycles in combination with the SMR.BCP[1:0] bits. Table 32.9 lists the combinations of the SCMR.BCP2 bit and SMR.BCP[1:0] bits.	R/W*1

Note 1. Writable only when the SCR.TE bit is 0 and the SCR.RE bit is 0 (both serial transmission and reception are disabled).
Note 2. This bit can be used in the smart card interface mode, asynchronous mode (multi-processor mode), clock synchronous mode, and simple SPI mode.
Note 3. Set this bit to 0 if operation is to be in simple I2C mode.
Note 4. Set this bit to 1 if operation is to be in simple I2C mode.
Note 5. This bit is only valid in asynchronous mode. The setting is invalid and a fixed data length of 8 bits is used in modes other than asynchronous mode.
Note 6. LSB first should be selected and the value of MSB (b7) in the TDR register cannot be transmitted.

SMIF Bit (Smart Card Interface Mode Select)

When this bit is set to 1, smart card interface mode is selected.

When this bit is set to 0, non-smart card interface mode, i.e., asynchronous mode (including multi-processor mode), clock synchronous mode, simple SPI mode, or simple I2C mode is selected.

SINV Bit (Transmitted/Received Data Invert)

This bit is used to invert the logic level of the data bits when the data is transferred between data register and shift register. This bit does not affect the logic level of the parity bit. To invert the parity bit, invert the SMR.PM bit.

CHR1 Bit (Character Length 1)

Selects the data length of transmit/receive data.

Selects in combination with the SMR.CHR bit.

A fixed data length of 8 bits is used in modes other than asynchronous mode.

BCP2 Bit (Base Clock Pulse 2)

Selects the number of base clock cycles in a 1-bit data transfer time in smart card interface mode. Set this bit in combination with the SMR.BCP[1:0] bits.

Table 32.9 Combinations of the SCMR.BCP2 Bit and SMR.BCP[1:0] Bits

SCMR.BCP2 Bit	SMR.BCP[1:0] Bits		Number of Base Clock Cycles for 1-Bit Transfer Period
0	0	0	93 clock cycles (S = 93)*1
0	0	1	128 clock cycles (S = 128)*1
0	1	0	186 clock cycles (S = 186)*1
0	1	1	512 clock cycles (S = 512)*1
1	0	0	32 clock cycles (S = 32)*1 (Initial Value)
1	0	1	64 clock cycles (S = 64)*1
1	1	0	372 clock cycles (S = 372)*1
1	1	1	256 clock cycles (S = 256)*1

Note 1. S is the value of S in the BRR register (refer to section 32.2.11, Bit Rate Register (BRR)).

32.2.11 Bit Rate Register (BRR)

Address(es): SCI1.BRR 0008 A021h, SCI5.BRR 0008 A0A1h, SCI6.BRR 0008 A0C1h, SCI12.BRR 0008 B301h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

The BRR register is an 8-bit register that adjusts the bit rate.
As each SCI channel has independent baud rate generator control, different bit rates can be set for each. Table 32.10 and Table 32.11 shows the relationship between the setting (N) in the BRR register and the bit rate (B) for normal asynchronous mode, multi-processor communication, clock synchronous mode, smart card interface mode, simple SPI mode, and simple I²C mode.
The BRR register is writable only when the TE and RE bits in the SCR register are 0.

Table 32.10 Relationship between N Setting in the BRR Register and Bit Rate B (for SCI1, SCI5, and SCI6)

Mode	SEMR Settings			BRR Setting	Error (%)
	BGDM bit	ABCS bit	ABCSE bit		
Asynchronous, multi-processor communication	0	0	0	$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 64 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
	0	1	0	$N = \frac{PCLK \times 10^6}{32 \times 2^{2n-1} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 32 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
	1	0	0		
	1	1	0	$N = \frac{PCLK \times 10^6}{16 \times 2^{2n-1} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 16 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
	0 or 1	0 or 1	1	$N = \frac{PCLK \times 10^6}{12 \times 2^{2n-1} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 12 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
Clock synchronous, simple SPI				$N = \frac{PCLK \times 10^6}{8 \times 2^{2n-1} \times B} - 1$	
Smart card interface				$N = \frac{PCLK \times 10^6}{S \times 2^{2n+1} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times S \times 2^{2n+1} \times (N+1)} - 1 \right\} \times 100$
Simple I²C*1				$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	

B: Bit rate (bps)
N: BRR setting for on-chip baud rate generator ($0 \le N \le 255$)
PCLK: Operating frequency (MHz)
n and S: Determined by the settings of the SMR and SCMR registers as listed in Table 32.13 and Table 32.14.
Note 1. Adjust the bit rate so that the widths at high and low level of the SCL output in simple I²C mode satisfy the I²C-bus standard.

Table 32.11 Relationship between N Setting in the BRR Register and Bit Rate B (for SCI12)

Mode	SEMR Settings		BRR Setting	Error (%)
	BGDM bit	ABCS bit		
Asynchronous, multi-processor communication	0	0	$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 64 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
	0	1	$N = \frac{PCLK \times 10^6}{32 \times 2^{2n-1} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 32 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
	1	0		
	1	1	$N = \frac{PCLK \times 10^6}{16 \times 2^{2n-1} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 16 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
Clock synchronous, simple SPI			$N = \frac{PCLK \times 10^6}{8 \times 2^{2n-1} \times B} - 1$	
Smart card interface			$N = \frac{PCLK \times 10^6}{S \times 2^{2n+1} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times S \times 2^{2n+1} \times (N+1)} - 1 \right\} \times 100$
Simple I^2C*1			$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	

B: Bit rate (bps)
N: BRR setting for on-chip baud rate generator ($0 \le N \le 255$)
PCLK: Operating frequency (MHz)
n and S: Determined by the settings of the SMR and SCMR registers as listed in Table 32.13 and Table 32.14.
Note 1. Adjust the bit rate so that the widths at high and low level of the SCL output in simple I^2C mode satisfy the I^2C-bus standard.

Table 32.12 Calculating Widths at High and Low Level for SCL

Mode	SCL	Formula (Result in Seconds)
I^2C	High period (minimum value)	$(N+1) \times 4 \times 2^{2n-1} \times 7 \times \frac{1}{PCLK \times 10^6}$
	Low period (minimum value)	$(N+1) \times 4 \times 2^{2n-1} \times 8 \times \frac{1}{PCLK \times 10^6}$

Table 32.13 Clock Source Settings

SMR.CKS[1:0] Bit Setting	Clock Source	n
0 0	PCLK	0
0 1	PCLK/4	1
1 0	PCLK/16	2
1 1	PCLK/64	3

Table 32.14 Base Clock Settings in Smart Card Interface Mode

SCMR.BCP2 Bit Setting	SMR.BCP[1:0] Bit Setting	Base Clock Cycles for 1-bit Period	S
0	0 0	93 clock cycles	93
0	0 1	128 clock cycles	128
0	1 0	186 clock cycles	186
0	1 1	512 clock cycles	512
1	0 0	32 clock cycles	32
1	0 1	64 clock cycles	64
1	1 0	372 clock cycles	372
1	1 1	256 clock cycles	256

Table 32.15 lists examples of N settings in the BRR register in normal asynchronous mode. Table 32.17 lists the maximum bit rate settable for each operating frequency. Examples of BRR (N) settings in clock synchronous mode and simple SPI mode are listed in Table 32.20. Examples of BRR (N) settings in smart card interface mode are listed in Table 32.22. Examples of BRR (N) settings in simple I^2C mode are listed in Table 32.24. In smart card interface mode, the number of base clock cycles S in a 1-bit data transfer time can be selected. For details, refer to section 32.6.4, Receive Data Sampling Timing and Reception Margin. Table 32.18 and Table 32.21 list the maximum bit rates with external clock input.

When either the SEMR.ABCS or BGDM bit is set to 1 in asynchronous mode, the bit rate becomes twice that listed in Table 32.15. When both of those bits are set to 1, the bit rate becomes four times the listed value.

Table 32.15 Examples of BRR Settings for Various Bit Rates (Asynchronous Mode)

Bit Rate (bps)	Operating Frequency PCLK (MHz)														
	8			9.8304			10			12			12.288

Note: This is an example when the ABCS, ABCSE, and BGDM bits in the SEMR register are 0.
When either the ABCS bit or BGDM bit is set to 1, the bit rate doubles.
When both ABCS and BGDM bits in the SEMR register are set to 1, the bit rate increases four times.
When the ABCSE bit is set to 1, the bit rate increases 16/3 times.

7.5 M											0	0*1							0	1

Blank cell: Cannot be set since the bit rate error exceeds 5%.

—: Can be set, but a bit rate error of 1 to 5% will occur.

Note 1. Continuous transmission or reception is not possible. After transmitting/receiving one frame of data, there is an interval of a 1-bit period before starting transmitting/receiving the next frame of data. The output of the synchronization clock is stopped for a 1-bit period. For this reason, it takes 9 bits worth of time to transfer one frame (8 bits) of data, and the average transfer rate is 8/9 times the bit rate.

32.2.12 Modulation Duty Register (MDDR)

Address(es): SCI1.MDDR 0008 A032h, SCI5.MDDR 0008 A0B2h, SCI6.MDDR 0008 A0D2h, SCI12.MDDR 0008 B312h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

The MDDR register corrects the bit rate adjusted by the BRR register.
When the SEMR.BRME bit is set to 1, the bit rate generated by the on-chip baud rate generator is evenly corrected according to the settings of the MDDR register (M/256). The relationship between the MDDR register setting (M) and the bit rate (B) is given in Table 32.26 and Table 32.27.
The range of the value that can be set in the MDDR register is from 80h to FFh. A value other than these cannot be set.
The MDDR register is writable only when the TE and RE bits in the SCR register are 0.

Table 32.26 Relationship between MDDR Setting (M) and Bit Rate (B) When Bit Rate Modulation Function is Used (for SCI1, SCI5, and SCI6)

Mode	SEMR Settings			BRR Setting	Error (%)
	BGDM Bit	ABCS Bit	ABCSE Bit		
Asynchronous, multi-processor communication	0	0	0	$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 64 \times 2^{2n-1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$
	1	0	0	$N = \frac{PCLK \times 10^6}{32 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 32 \times 2^{2n-1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$
	0	1	0		
	1	1	0	$N = \frac{PCLK \times 10^6}{16 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 16 \times 2^{2n-1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$
	0 or 1	0 or 1	1	$N = \frac{PCLK \times 10^6}{12 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 12 \times 2^{2n-1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$
Clock synchronous, simple SPI*1				$N = \frac{PCLK \times 10^6}{8 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	
Smart card interface				$N = \frac{PCLK \times 10^6}{S \times 2^{2n+1} \times \frac{256}{M} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times S \times 2^{2n+1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$
Simple I²C*2				$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	

B: Bit rate (bps)
M: MDDR setting (128 ≤ MDDR ≤ 256)
N: BRR setting for baud rate generator (0 ≤ N ≤ 255)
PCLK: Operating frequency (MHz)
n and S: Determined by the settings of the SMR and SCMR registers as listed in Table 32.13 and Table 32.14, section 32.2.11, Bit Rate Register (BRR).

Note 1. Do not use this function in clock synchronous mode and in the highest speed settings in simple SPI mode (SMR.CKS[1:0] =

00b, SCR.CKE[1] = 0, and BRR = 0).
Note 2. Adjust the bit rate so that the widths at high and low level of the SCL output in simple I²C mode satisfy the I²C-bus standard.

Table 32.27 Relationship between MDDR Setting (M) and Bit Rate (B) When Bit Rate Modulation Function is Used (for SCI12)

Mode	SEMR Settings		BRR Setting	Error (%)
	BGDM Bit	ABCS Bit		
Asynchronous, multi-processor communication	0	0	$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 64 \times 2^{2n-1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$
	1	0	$N = \frac{PCLK \times 10^6}{32 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 32 \times 2^{2n-1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$
	0	1		
	1	1	$N = \frac{PCLK \times 10^6}{16 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 16 \times 2^{2n-1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$
Clock synchronous, simple SPI*1			$N = \frac{PCLK \times 10^6}{8 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	
Smart card interface			$N = \frac{PCLK \times 10^6}{S \times 2^{2n+1} \times \frac{256}{M} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times S \times 2^{2n+1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$
Simple I²C*2			$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	

B: Bit rate (bps)
M: MDDR setting (128 ≤ MDDR ≤ 256)
N: BRR setting for baud rate generator (0 ≤ N ≤ 255)
PCLK: Operating frequency (MHz)
n and S: Determined by the settings of the SMR and SCMR registers as listed in Table 32.13 and Table 32.14, section 32.2.11, Bit Rate Register (BRR).
Note 1. Do not use this function in clock synchronous mode and in the highest speed settings in simple SPI mode (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0).
Note 2. Adjust the bit rate so that the widths at high and low level of the SCL output in simple I²C mode satisfy the I²C-bus standard.

Smaller settings of the SMR.CKS[1:0] bits and larger settings of the BRR register reduce difference in the length of the 1-bit period.

32.2.13 Serial Extended Mode Register (SEMR)

Address(es): SCI1.SEMR 0008 A027h, SCI5.SEMR 0008 A0A7h, SCI6.SEMR 0008 A0C7h, SCI12.SEMR 0008 B307h

	b7	b6	b5	b4	b3	b2	b1	b0
	RXDESEL	BGDM	NFEN	ABCS	ABCSE	BRME	ITE	ACS0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ACS0	Asynchronous Mode Clock Source Select	(Valid only in asynchronous mode) 0: External clock input 1: Logical AND of two compare matches output from TMR (valid for SCI5, SCI6, and SCI12 only) Available compare match output varies per SCI channel.	R/W*1
b1	ITE	Instant Transmission Enable*2	(Valid only in asynchronous mode) 0: Internal wait time is inserted after the transmission is enabled 1: Data transmission is started immediately after the transmission is enabled.	R/W*1
b2	BRME	Bit Rate Modulation Enable	0: Bit rate modulation function is disabled. 1: Bit rate modulation function is enabled.	R/W*1
b3	ABCSE	Asynchronous Mode Base Clock Select Extended*2	(Valid only when using a on-chip baud rate generator in asynchronous mode) 0: The number of clock cycles for 1-bit period depends on the BGDM and ABCS bits setting. 1: Selects 6 base clock cycles for 1-bit period.	R/W*1
b4	ABCS	Asynchronous Mode Base Clock Select	(Valid only in asynchronous mode) 0: Selects 16 base clock cycles for 1-bit period. 1: Selects 8 base clock cycles for 1-bit period.	R/W*1
b5	NFEN	Digital Noise Filter Function Enable	(In asynchronous mode) 0: Noise cancellation function for the RXDn input signal is disabled. 1: Noise cancellation function for the RXDn input signal is enabled. (in simple I^2C mode) 0: Noise cancellation function for the SSCLn and SSDAn input signals is disabled. 1: Noise cancellation function for the SSCLn and SSDAn input signals is enabled. The NFEN bit should be 0 in any mode other than above.	R/W*1
b6	BGDM	Baud Rate Generator Double-Speed Mode Select	(Only valid the SCR.CKE[1] bit is 0 in asynchronous mode) 0: Baud rate generator outputs the clock with normal frequency. 1: Baud rate generator outputs the clock with doubled frequency.	R/W*1
b7	RXDESEL	Asynchronous Start Bit Edge Detection Select	(Valid only in asynchronous mode) 0: The low level on the RXDn pin is detected as the start bit. 1: A falling edge on the RXDn pin is detected as the start bit.	R/W*1

Note 1. Writable only when the SCR.TE bit is 0 and the SCR.RE bit is 0 (both serial transmission and reception are disabled).
Note 2. This bit is reserved for SCI12. It is read as 0. The write value should be 0.

The SEMR register is used to select a clock source for 1-bit period in asynchronous mode or a detection method of the start bit.

ACS0 Bit (Asynchronous Mode Clock Source Select)

Selects the clock source in the asynchronous mode.

The ACS0 bit is valid in asynchronous mode (SMR.CM bit = 0) and when an external clock input is selected (SCR.CKE[1:0] bits = 10b or 11b). This bit is used to select an external clock input or the logical AND of compare matches output from the internal TMR.

Set the ACS0 bit to 0 in other than asynchronous mode.

For SCI5, SCI6, and SCI12, the TMOn output (n = 0 to 3) of TMR units 0 and 1 can be set as the base clock source. Refer to Table 32.28 for details.

The ACS0 bit for SCI1 is reserved. The write value to this bit for SCI1 should be 0.

Table 32.28 Correspondence between SCI Channels and Compare Match Outputs

SCI	TMR	Compare Match Output
SCI5	Unit 0	TMO0, TMO1
SCI6	Unit 1	TMO2, TMO3
SCI12	Unit 0	TMO0, TMO1

Figure 32.4 shows a setting example of when TMO0 and TMO1 in the TMR unit 0 are selected for output.

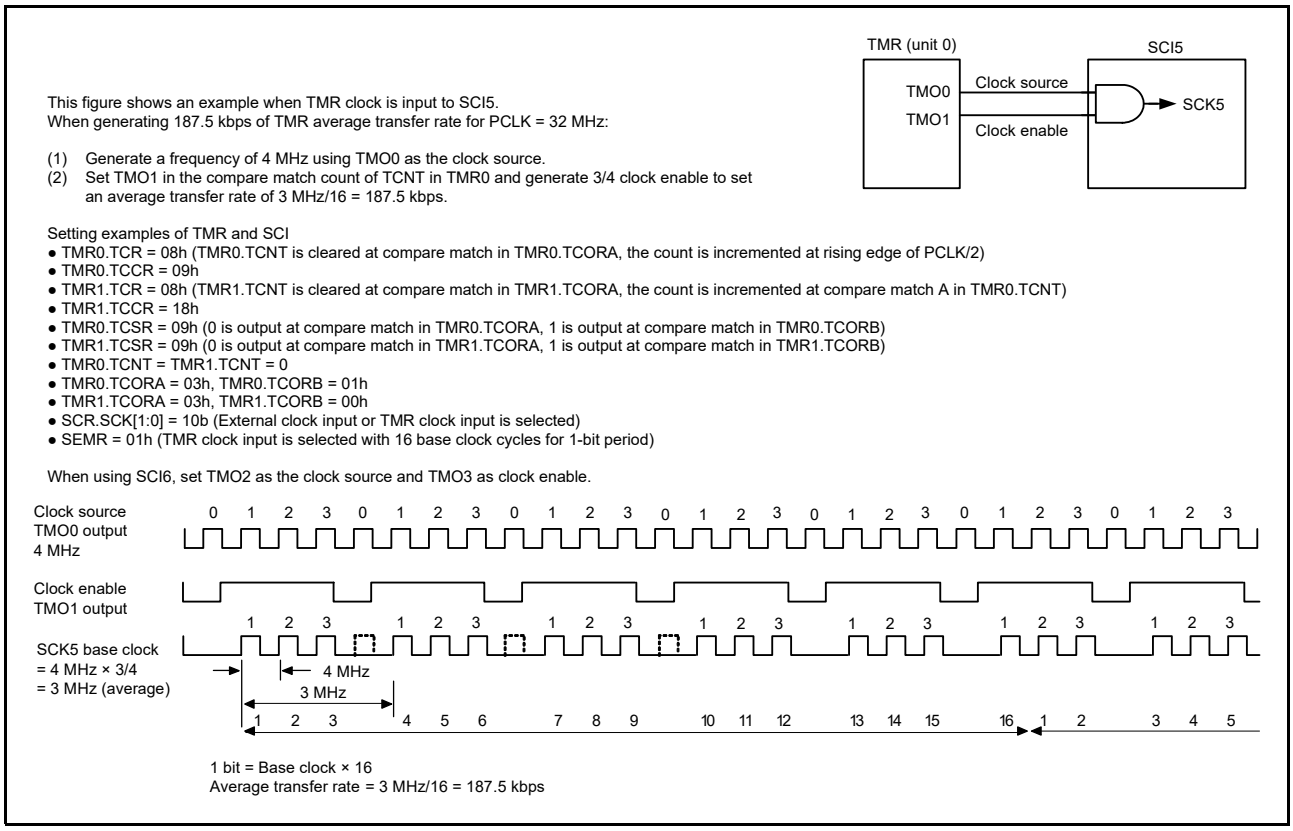

Figure 32.4 Example of Average Transfer Rate Setting When TMR Clock is Input

ITE Bit (Instant Transmission Enable)

This bit is used to start data transmission without internal wait time in asynchronous mode. When the TE bit is set to 1 while this bit is 0, one frame of internal wait time is inserted before the data transmission is started. When this bit is 1, the data transmission is started immediately after the TE bit is set to 1.

BRME Bit (Bit Rate Modulation Enable)

This bit enables and disables the bit rate modulation function. The bit rate generated by on-chip baud rate generator is evenly corrected when this function is enabled.

ABCSE Bit (Asynchronous Mode Base Clock Select Extended*2)

When setting this bit to 1, the 1-bit period becomes 6 cycles of the base clock and the clock of doubled frequency is output from the baud rate generator.
This bit is valid when the on-chip baud rate generator is selected as the clock source (SCR.CKE[1] = 0) in asynchronous mode (SMR.CM = 0).
When the bit rate is made to be 1/6 of PCLK frequency, set this bit to 1, the SMR.CKS[1:0] bits to 00b, and the BRR register to 00h.

NFEN Bit (Digital Noise Filter Function Enable)

This bit enables or disables the digital noise filter function.
When the function is enabled, noise cancellation is applied to the RXDn input signal in asynchronous mode, and noise cancellation is applied to the SSDAn and SSCLn input signals in simple I^2C mode.
In any mode other than above, set the NFEN bit to 0 to disable the digital noise filter function.
When the function is disabled, input signals are transferred as is, as internal signals.

BGDM Bit (Baud Rate Generator Double-Speed Mode Select)

Selects the cycle of output clock for the baud rate generator.
This bit is valid when the on-chip baud rate generator is selected as the clock source (SCR.CKE[1] = 0) in asynchronous mode (SMR.CM = 0). For the clock output from the baud rate generator, either normal or doubled frequency can be selected. The base clock is generated by the clock output from the baud rate generator. When the BGDM bit is set to 1, the base clock cycle is halved and the bit rate is doubled.
Set this bit to 0 in modes other than asynchronous mode.

RXDESEL Bit (Asynchronous Start Bit Edge Detection Select)

Selects the detection method of the start bit for reception in asynchronous mode. When a break occurs, data receiving operation depends on the settings of this bit. Set this bit to 1 when reception should be stopped while a break occurs or when reception should be started without retaining the RXDn pin input at high level for the period of one data frame or longer after completion of the break.
Set this bit to 0 in modes other than asynchronous mode.

32.2.14 Noise Filter Setting Register (SNFR)

Address(es): SCI1.SNFR 0008 A028h, SCI5.SNFR 0008 A0A8h, SCI6.SNFR 0008 A0C8h, SCI12.SNFR 0008 B308h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	NFCS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	NFCS[2:0]	Noise Filter Clock Select	In asynchronous mode, the standard setting for the base clock is as follows. b2 b0 0 0 0: The clock signal divided by 1 is used with the noise filter. In simple I2C mode, the standard settings for the clock source of the on-chip baud rate generator selected by the SMR.CKS[1:0] bits are given below. b2 b0 0 0 1: The clock signal divided by 1 is used with the noise filter. 0 1 0: The clock signal divided by 2 is used with the noise filter. 0 1 1: The clock signal divided by 4 is used with the noise filter. 1 0 0: The clock signal divided by 8 is used with the noise filter. Settings other than above are prohibited.	R/W*1
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (serial reception and transmission disabled).

NFCS[2:0] Bits (Noise Filter Clock Select)

These bits select the sampling clock for the digital noise filter. To use the noise filter in asynchronous mode, set these bits to 000b. In simple I2C mode, set the bits to a value in the range from 001b to 100b.

32.2.15 I²C Mode Register 1 (SIMR1)

Address(es): SCI1.SIMR1 0008 A029h, SCI5.SIMR1 0008 A0A9h, SCI6.SIMR1 0008 A0C9h, SCI12.SIMR1 0008 B309h

	b7	b6	b5	b4	b3	b2	b1	b0
	IICDL[4:0]					—	—	IICM
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IICM	Simple I²C Mode Select	SMIF IICM 0 0: Asynchronous mode, Multi-processor mode, Clock synchronous mode (in asynchronous mode, synchronous, or simple SPI mode) 0 1: Simple I²C mode 1 0: Smart card interface mode 1 1: Setting prohibited.	R/W*1
b2, b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7 to b3	IICDL[4:0]	SSDA Output Delay Select	(Cycles below are of the clock signal from the on-chip baud rate generator.) b7 b3 0 0 0 0 0: No output delay 0 0 0 0 1: 0 to 1 cycle 0 0 0 1 0: 1 to 2 cycles 0 0 0 1 1: 2 to 3 cycles 0 0 1 0 0: 3 to 4 cycles 0 0 1 0 1: 4 to 5 cycles : : 1 1 1 1 0: 29 to 30 cycles 1 1 1 1 1: 30 to 31 cycles	R/W*1

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (both serial transmission and reception are disabled).

SIMR1 is used to select simple I²C mode and the number of delay stages for the SSDA output.

IICM Bit (Simple I²C Mode Select)

In conjunction with the SCMR.SMIF bit, this bit selects the operating mode.

IICDL[4:0] Bits (SSDA Output Delay Select)

These bits are used to set a delay for output on the SSDAn pin relative to the falling edge of the output on the SSCLn pin. The available delay settings range from no delay to 31 cycles, with the clock signal from the on-chip baud rate generator as the base. The signal obtained by frequency-dividing PCLK by the divisor set in the SMR.CKS[1:0] bits is supplied as the clock signal from the on-chip baud rate generator. Set these bits to 00000b unless operation is in simple I²C mode. In simple I²C mode, set the bits to a value in the range from 00001b to 11111b.

32.2.16 I2C Mode Register 2 (SIMR2)

Address(es): SCI1.SIMR2 0008 A02Ah, SCI5.SIMR2 0008 A0AAh, SCI6.SIMR2 0008 A0CAh, SCI12.SIMR2 0008 B30Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	IICACKT	—	—	—	IICCSC	IICINTM
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IICINTM	I2C Interrupt Mode Select	0: Use ACK/NACK interrupts. 1: Use reception and transmission interrupts.	R/W*1
b1	IICCSC	Clock Synchronization	0: No synchronization with the clock signal 1: Synchronization with the clock signal	R/W*1
b4 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	IICACKT	ACK Transmission Data	0: ACK transmission 1: NACK transmission and reception of ACK/NACK	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (serial reception and transmission disabled).

SIMR2 is used to select how reception and transmission are controlled in simple I2C mode.

IICINTM Bit (I2C Interrupt Mode Select)

This bit selects the sources of interrupt requests in simple I2C mode.

IICCSC Bit (Clock Synchronization)

Set the IICCSC bit to 1 if the internally generated SSCLn clock signal is to be synchronized when the SSCLn pin has been placed at the low level in the case of a wait inserted by the other device, etc.

The SSCLn clock signal is not synchronized if the IICCSC bit is 0. The SSCLn clock signal is generated in accord with the rate selected in the BRR regardless of the level being input on the SSCLn pin.

Set the IICCSC bit to 1 except during debugging.

IICACKT Bit (ACK Transmission Data)

Transmitted data contains ACK bits. Set this bit to 1 when ACK and NACK bits are received.

32.2.17 I2C Mode Register 3 (SIMR3)

Address(es): SCI1.SIMR3 0008 A02Bh, SCI5.SIMR3 0008 A0ABh, SCI6.SIMR3 0008 A0CBh, SCI12.SIMR3 0008 B30Bh

	b7	b6	b5	b4	b3	b2	b1	b0
	IICSCLS[1:0]		IICSDAS[1:0]		IICSTIF	IICSTP REQ	IICRST AREQ	IICSTA REQ
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IICSTAREQ	Start Condition Generation	0: A start condition is not generated. 1: A start condition is generated.*1, *3, *4, *5	R/W
b1	IICRSTAREQ	Restart Condition Generation	0: A restart condition is not generated. 1: A restart condition is generated.*2, *3, *4, *5	R/W
b2	IICSTPREQ	Stop Condition Generation	0: A stop condition is not generated. 1: A stop condition is generated.*2, *3, *4, *5	R/W
b3	IICSTIF	Issuing of Start, Restart, or Stop Condition Completed Flag	0: There are no requests for generating conditions or a condition is being generated. 1: A start, restart, or stop condition is completely generated.	R/W
b5, b4	IICSDAS[1:0]	SSDA Output Select	b5 b4 0 0: Serial data output 0 1: Generate a start, restart, or stop condition. 1 0: Output the low level on the SSDAn pin. 1 1: Place the SSDAn pin in the high-impedance state.	R/W
b7, b6	IICSCLS[1:0]	SSCL Output Select	b7 b6 0 0: Serial clock output 0 1: Generate a start, restart, or stop condition. 1 0: Output the low level on the SSCLn pin. 1 1: Place the SSCLn pin in the high-impedance state.	R/W

Note 1. Generate a start condition only when the SSCLn and SSDAn pins are both high (the corresponding bits in the corresponding PIDR registers are 1).
Note 2. Generate a restart or stop condition only when the SSCLn pin is low (the corresponding bit in the PIDR register is 0).
Note 3. Do not set more than one from among the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits to 1 at a given time.
Note 4. Execute the generation of a condition after the value of the IICSTIF flag is 0.
Note 5. Do not write 0 to this bit while it is 1. Generation of a condition is suspended by writing 0 to this bit while it is 1.

SIMR3 is used to control the simple I2C mode start and stop conditions, and to hold the SSDAn and SSCLn pins at fixed levels.

IICSTAREQ Bit (Start Condition Generation)

When a start condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTAREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the start condition

IICRSTAREQ Bit (Restart Condition Generation)

When a restart condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICRSTAREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the restart condition

IICSTPREQ Bit (Stop Condition Generation)

When a stop condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTPREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the stop condition

IICSTIF Flag (Issuing of Start, Restart, or Stop Condition Completed Flag)

After generating a condition, this bit indicates that the generation is completed. When using the IICSTAREQ, IICRSTAREQ, or IICSTPREQ bit to cause generation of a condition, do so after setting the IICSTIF flag to 0.

When the IICSTIF flag is 1 while an interrupt request is enabled by setting the SCR.TEIE bit, an STI request is output.

[Setting condition]

- Completion of the generation of a start, restart, or stop condition (however, in cases where this conflicts with any of the conditions for the flag becoming 0 listed below, the other condition takes precedence)

[Clearing conditions]

- Writing 0 to the bit (confirm that the IICSTIF flag is 0 before doing so)
- Writing 0 to the SIMR1.IICM bit (when operation is not in simple I^2C mode)
- Writing 0 to the SCR.TE bit

IICSDAS[1:0] Bits (SSDA Output Select)

These bits control output from the SSDAn pin.

Set the IICSDAS[1:0] and IICSCLS[1:0] bits to the same value during normal operations.

IICSCLS[1:0] Bits (SSCL Output Select)

These bits control output from the SSCLn pin.

Set the IICSCLS[1:0] and IICSDAS[1:0] bits to the same value during normal operations.

32.2.18 I2C Status Register (SISR)

Address(es): SCI1.SISR 0008 A02Ch, SCI5.SISR 0008 A0ACh, SCI6.SISR 0008 A0CCh, SCI12.SISR 0008 B30Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	IICACKR
Value after reset:	0	0	x	x	0	x	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	IICACKR	ACK Reception Data Flag	0: ACK received 1: NACK received	R/W*1
b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b2	—	Reserved	The read value is undefined.	R
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5, b4	—	Reserved	The read value is undefined.	R
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 0 can be written to this bit, to clear the flag.

SISR is used to monitor state in relation to simple I2C mode.

IICACKR Flag (ACK Reception Data Flag)

Received ACK and NACK bits can be read from this bit.
The IICACKR flag is updated at the rising of SSCLn clock for the ACK/NACK receiving bit.

32.2.19 SPI Mode Register (SPMR)

Address(es): SCI1.SPMR 0008 A02Dh, SCI5.SPMR 0008 A0ADh, SCI6.SPMR 0008 A0CDh, SCI12.SPMR 0008 B30Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	CKPH	CKPOL	—	MFF	—	MSS	CTSE	SSE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SSE	SSn# Pin Function Enable	0: SSn# pin function is disabled. 1: SSn# pin function is enabled.	R/W*1
b1	CTSE	CTS Enable	0: CTS function is disabled (RTS output function is enabled). 1: CTS function is enabled.	R/W*1
b2	MSS	Master Slave Select	0: Transmission is through the SMOSIn pin and reception is through the SMISOn pin (master mode). 1: Reception is through the SMOSIn pin and transmission is through the SMISOn pin (slave mode).	R/W*1
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	MFF	Mode Fault Flag	0: No mode fault error 1: Mode fault error	R/W*2
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6	CKPOL	Clock Polarity Select	0: Clock polarity is not inverted. 1: Clock polarity is inverted.	R/W*1
b7	CKPH	Clock Phase Select	0: Clock is not delayed. 1: Clock is delayed.	R/W*1

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (both serial transmission and reception are disabled).
Note 2. Only 0 can be written to these bits, which clears the flag.

SPMR is used to select the extension settings in asynchronous and clock synchronous modes.

SSE Bit (SSn# Pin Function Enable)

Set this bit to 1 if the SSn# pin is to be used in control of transmission and reception (in simple SPI mode). Set this bit to 0 in any other mode. Furthermore, even for usage in simple SPI mode, the SSn# pin on the master side is not required to control reception and transmission when master mode (SCR.CKE[1:0] = 00b and MSS = 0) is selected and there is a single master, so the setting for the SSE bit is 0. Do not set both the SSE and CTSE bits to enabled (even if this setting is made, operation is the same as that when these bits are set to 0).

CTSE Bit (CTS Enable)

Set this bit to 1 if the SSn# pin is to be used for inputting of the CTS control signal to control of transmission and reception. The RTS signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode, simple SPI mode, and simple I^2C mode. Do not set both the CTSE and SSE bits to enabled (even if this setting is made, operation is the same as that when these bits are set to 0).

MSS Bit (Master Slave Select)

This bit selects between master and slave operation in simple SPI mode. When the MSS bit is set to 1, data is received through the SMOSIn pin and transmitted through the SMISOn pin.
Set this bit to 0 in modes other than simple SPI mode.

MFF Flag (Mode Fault Flag)

This bit indicates mode fault errors.
In a multi-master configuration, determine the mode fault error occurrence by reading the MFF flag.
[Setting condition]

- Input on the SSn# pin being at the low level during master operation in simple SPI mode (SSE bit = 1 and MSS bit = 0)

[Clearing condition]

- Writing 0 to the bit after it was read as 1

CKPOL Bit (Clock Polarity Select)

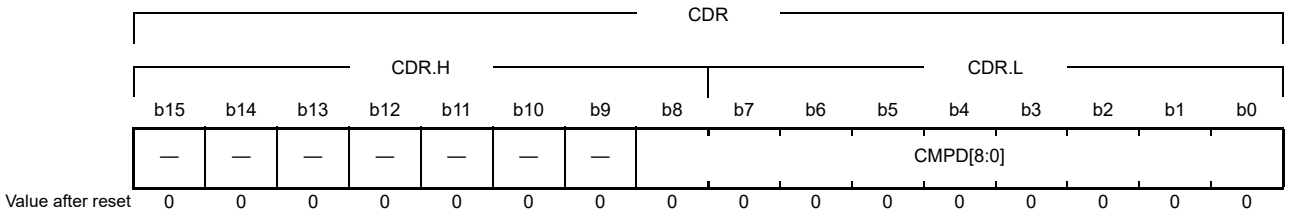
This bit selects the polarity of the clock signal output through the SCKn pin. Refer to Figure 32.62 for details.
Set the bit to 0 in other than simple SPI mode and clock synchronous mode.

CKPH Bit (Clock Phase Select)

This bit selects the phase of the clock signal output through the SCKn pin. Refer to Figure 32.62 for details.
Set the bit to 0 in other than simple SPI mode and clock synchronous mode.

32.2.20 Comparison Data Register (CDR)

Address(es): SCI1.CDR 0008 A03Ah, SCI5.CDR 0008 A0BAh, SCI6.CDR 0008 A0DAh,
SCI1.CDR.H 0008 A03Ah, SCI5.CDR.H 0008 A0BAh, SCI6.CDR.H 0008 A0DAh,
SCI1.CDR.L 0008 A03Bh, SCI5.CDR.L 0008 A0BBh, SCI6.CDR.L 0008 A0DBh



Bit	Symbol	Bit Name	Description	R/W
b8 to b0	CMPD[8:0]	Comparison Data	These bits specify the data of comparison source when using the data match detection function.	R/W
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R

CMPD[8:0] Bits (Comparison Data)

These bits are used for detecting a data match. The length of the valid bit is the same as the character length set in the SMR.CHR and SCMR.CHR1 bits.
The DCCR.DCMF flag becomes 1 when the received data matches with the value of these bits.

32.2.21 Data Comparison Control Register (DCCR)

Address(es): SCI1.DCCR 0008 A033h, SCI5.DCCR 0008 A0B3h, SCI6.DCCR 0008 A0D3h

	b7	b6	b5	b4	b3	b2	b1	b0
	DCME	IDSEL	—	DFER	DPER	—	—	DCMF
Value after reset	0	1	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DCMF	Data Match Flag	0: Data is not matched 1: Data is matched	R/(W) *1
b2, b1	—	Reserved	These bits are read as 0. The write value should be 0	R/W
b3	DPER	Match Data Parity Error Flag	0: A parity error is not found in the matched data. 1: A parity error is found in the matched data.	R/(W) *1
b4	DFER	Match Data Framing Error Flag	0: A framing error is not found in the matched data. 1: A framing error is found in the matched data.	R/(W) *1
b5	—	Reserved	This bit is read as 0. The write value should be 0	R/W
b6	IDSEL	ID Frame Select*2	0: All data is to be compared 1: The data with the multi-processor bit set to 1 is to be compared	R/W
b7	DCME	Data Match Detection Enable*2	0: Data match detection is disabled 1: Data match detection is enabled	R/W

Note 1. Only 0 can be written to this bit, which clears the flag. To clear this flag, confirm that the flag is 1, and then write 0 to the flag.
Note 2. This bit is only valid in asynchronous mode.

DCMF Flag (Data Match Flag)

This flag indicates the comparison result of the received data and the value of the CDR register.
[Setting condition]

- When the received data matches with the value in the CDR register while the DCME bit is 1

[Clearing condition]

- When 0 is written to the flag after reading this flag as 1

Even when the SCR.RE bit is set to 0, the DCMF flag has no effect and retains the previous state.

DPER Flag (Match Data Parity Error Flag)

This flag indicates if a parity error has occurred in the matched data.
[Setting condition]

- When a parity error is found in the received data in which a data match is detected.

[Clearing condition]

- When 0 is written to the flag after reading the flag as 1.

Refer to section 14.5.2, Level Detection to exit from the interrupt handling routine after setting the DPER flag to 0.
Even when the SCR.RE bit is set to 0, the DPER flag has no effect and retains the previous state.

DFER Flag (Match Data Framing Error Flag)

This flag indicates if a framing error has occurred in the matched data.
[Setting condition]

- When the stop bit of the received frame in which a data match is detected is 0

[Clearing condition]

- When 0 is written to the flag after reading the flag as 1.

Refer to section 14.5.2, Level Detection to exit from the interrupt handling routine after setting the DFER flag to 0.
Even when the SCR.RE bit is set to 0, the DFER flag has no effect and retains the previous state.

IDSEL Bit (ID Frame Select)

This bit specifies the condition of the received data to be compared. The bit is valid only when the DCME bit is 1.
When setting this bit to 1, only data in received frames (ID frames) in which the multi-processor bit has the value 1 are compared.
When this bit is set to 0, all received data is compared.

DCME Bit (Data Match Detection Enable)

This bit enables or disables the data match detection function. The function is valid only in asynchronous mode. In other modes, set this bit to 0.
This bit automatically becomes 0 when a data match is detected.

32.2.22 Serial Port Register (SPTR)

Address(es): SCI1.SPTR 0008 A03Ch, SCI5.SPTR 0008 A0BCh, SCI6.SPTR 0008 A0DCh

	b7	b6	b5	b4	b3	b2	b1	b0
	TTADJ	RTADJ	TINV	RINV	—	SPB2IO	SPB2DT	RXDMON
Value after reset	0	0	0	0	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	RXDMON	RXD Line Monitoring Flag	When the RINV bit is 0 0: The RXDn pin level is low 1: The RXDn pin level is high When the RINV bit is 1 0: The RXDn pin level is high 1: The RXDn pin level is low	R
b1	SPB2DT	Serial Port Break Data*1	Combine bits SPB2DT, SPB2IO, TINV, and SCR.TE to control the TXDn pin. Refer to Table 32.29 for details.	R/W
b2	SPB2IO	Serial Port Break I/O*1		R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R
b4	RINV	Receiver Input Invert*2	0: Does not invert the input signal from the RXD pin 1: Inverts the input signal from the RXD pin	R/W *3
b5	TINV	Transmitter Output Invert*2	0: Does not invert the output signal to the TXD pin 1: Invert the output signal to the TXD pin	R/W *3
b6	RTADJ	Receive Data Sampling Timing Adjustment*4	0: Does not adjust the sampling point of receive data 1: Adjust the sampling point of receive data	R/W *3
b7	TTADJ	Transmit Signal Transition Timing Adjustment*4	0: Does not adjust the transition timing of transmit data 1: Adjust the transition timing of transmit data	R/W *3

Note 1. This bit is only valid in asynchronous mode.
Note 2. Set this bit to 0 if operation is to be in smart card interface mode or simple I^2C mode.
Note 3. This bit is rewritable only when the TE and RE bits in the SCR register are both 0.
Note 4. This bit is only valid when the on-chip baud rate generator is selected as the clock source in asynchronous mode.

RXDMON Flag (RXD Line Monitoring Flag)

This flag is used for monitoring the level of the RXDn pin.

SPB2DT Bit (Serial Port Break Data)

This bit specifies the output level of the TXDn pin when the SCR.TE bit is 0. Refer to Table 32.29 for details.

SPB2IO Bit (Serial Port Break I/O)

This bit specifies input or output of the TXDn pin when the SCR.TE bit is 0. Set this bit to 1 (output) when controlling the TXDn pin by software.

Table 32.29 Controlling the TXDn pin

SCR.TE Bit Setting	SPB2IO Bit Setting	SPB2DT Bit Setting	TINV Bit Setting	TXDn Pin Status
0 (Transmission disabled)	0 (Input)	0 or 1	0 or 1	Hi-Z
	1 (Output)	0	0	Low is output
			1	High is output
		1	0	High is output
			1	Low is output
1 (Transmission enabled)	0 or 1	0 or 1	0 or 1	Transmit data output pin

RINV Bit (Receiver Input Invert)

This bit is used to logically invert the input signal from the RXDn pin in front of the receive shift register. Besides data bits, start bit, parity bit, and stop bit are inverted.

TINV Bit (Transmitter Output Invert)

This bit is used to logically invert the output signal from the transmit shift register in front of the TXDn pin. Besides data bits, start bit, parity bit, and stop bit are inverted.

RTADJ Bit (Receive Data Sampling Timing Adjustment)

This bit is used to change the sampling point of the receive data from the default sampling point. This bit is used to improve the receive margin when the high and low widths of the receive signal are changed due to the characteristics of the transmission line or interface devices. Normally, set this bit to 0.

TTADJ Bit (Transmit Signal Transition Timing Adjustment)

This bit is used to change the transition point of the transmit data from the default transition point. This bit is used to improve the receive margin of the receiver when the high and low widths of the transmitted signal are intended to be changed due to the characteristics of the transmission line or interface devices. Normally, set this bit to 0.

32.2.23 Transmit/Receive Timing Select Register (TMGR)

Address(es): SCI1.TMGR 0008 A03Dh, SCI5.TMGR 0008 A0BDh, SCI6.TMGR 0008 A0DDh

	b7	b6	b5	b4	b3	b2	b1	b0
	TTMG[3:0]				RTMG[3:0]			
Value after reset	0	0	0	0	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	RTMG[3:0]	Receive Data Sampling Timing Select*1	b3 b0 1 1 1 1: Data are sampled 7 clocks earlier than default point. 1 1 1 0: Data are sampled 6 clocks earlier than default point. 1 1 0 1: Data are sampled 5 clocks earlier than default point. 1 1 0 0: Data are sampled 4 clocks earlier than default point. 1 0 1 1: Data are sampled 3 clocks earlier than default point. 1 0 1 0: Data are sampled 2 clocks earlier than default point. 1 0 0 1: Data are sampled 1 clock earlier than default point. x 0 0 0: Data are sampled at default point. 0 0 0 1: Data are sampled 1 clock later than default point. 0 0 1 0: Data are sampled 2 clocks later than default point. 0 0 1 1: Data are sampled 3 clocks later than default point. 0 1 0 0: Data are sampled 4 clocks later than default point. 0 1 0 1: Data are sampled 5 clocks later than default point. 0 1 1 0: Data are sampled 6 clocks later than default point. 0 1 1 1: Data are sampled 7 clocks later than default point.	R/W *2
b7 to b4	TTMG[3:0]	Transmit Signal Transition Timing Select*3	b7 b4 1 1 1 1: Delays the 1 to 0 transitions for 7 clocks. 1 1 1 0: Delays the 1 to 0 transitions for 6 clocks. 1 1 0 1: Delays the 1 to 0 transitions for 5 clocks. 1 1 0 0: Delays the 1 to 0 transitions for 4 clocks. 1 0 1 1: Delays the 1 to 0 transitions for 3 clocks. 1 0 1 0: Delays the 1 to 0 transitions for 2 clocks. 1 0 0 1: Delays the 1 to 0 transitions for 1 clock. x 0 0 0: Does not change the waveform. 0 0 0 1: Delays the 0 to 1 transitions for 1 clock. 0 0 1 0: Delays the 0 to 1 transitions for 2 clocks. 0 0 1 1: Delays the 0 to 1 transitions for 3 clocks. 0 1 0 0: Delays the 0 to 1 transitions for 4 clocks. 0 1 0 1: Delays the 0 to 1 transitions for 5 clocks. 0 1 1 0: Delays the 0 to 1 transitions for 6 clocks. 0 1 1 1: Delays the 0 to 1 transitions for 7 clocks.	R/W *4

Note 1. These bits are only valid when the SPTR.RTADJ bit is 1.
Note 2. These bits are rewritable only when the SPTR.RTADJ bit is 0.
Note 3. These bits are only valid when the SPTR.TTADJ bit is 1.
Note 4. These bits are rewritable only when the SPTR.TTADJ bit is 0.

The TMGR register is used to adjust the sampling point of the receive data and the transition timing of the transmit data. This register is only valid when the on-chip baud rate generator is selected as the clock source in asynchronous mode. This register is not present in SCI12.

RTMG[3:0] Bits (Receive Data Sampling Timing Select)

These bit are used to select the sampling points of the receive data. These bit are only valid when the SPTR.RTADJ bit is 1. When the RTMG[3] bit is 0, each bit is sampled later than the default sampling point. When 1, each bit is sampled earlier than the default sampling point.

Set the amount of movement of the sampling points to the RTMG[2:0] bits by the number of the base clocks. Refer to Table 32.30 for the range of the value that can be set in the RTMG[2:0] bits.

Table 32.30 Range of Setting Values for the RTMG[2:0] Bits

SEMR.ABCSE Bit Setting	SEMR.ABCS Bit Setting	Number of the Base Clock Cycles for 1 Data Bit	Setting Range
0	0	16 cycles	0 to 7 (000b to 111b)
0	1	8 cycles	0 to 3 (000b to 011b)
1	0 or 1	6 cycles	0 to 2 (000b to 010b)

TTMG[3:0] Bits (Transmit Signal Transition Timing Select)

These bits are used to select the transition timing of the transmit signal in the transmit shift register. These bits are only valid when the SPTR.TTADJ bit is 1.

When the TTMG[3] bit is 0, the 0 to 1 transitions are delayed. When the TTMG[3] bit is 1, the 1 to 0 transitions are delayed. Output signal from the TXDn pin depends on the SPTR.TINV bit as follows.

(1) When the SPTR.TINV bit is 0

When the TTMG[3] bit is 0, high pulse width is narrower than low pulse width because low to high transitions (rising edges) are delayed.

When the TTMG[3] bit is 1, high pulse width is wider than low pulse width because high to low transitions (falling edges) are delayed.

(2) When the TINV bit is 1

When the TTMG[3] bit is 0, high pulse width is wider than low pulse width because high to low transitions (falling edges) are delayed.

When the TTMG[3] bit is 1, high pulse width is narrower than low pulse width because low to high transitions (rising edges) are delayed.

Set the delay amount to the TTMG[2:0] bits in number of the base clock. Refer to Table 32.31 for the range of the value that can be set in the TTMG[2:0] bits.

Table 32.31 Range of Setting Values for the TTMG[2:0] Bits

SEMR.ABCSE Bit Setting	SEMR.ABCS Bit Setting	Number of the Base Clock Cycles for 1 Data Bit	Setting Range
0	0	16 cycles	0 to 7 (000b to 111b)
0	1	8 cycles	0 to 7 (000b to 111b)
1	0 or 1	6 cycles	0 to 5 (000b to 101b)

32.2.24 Extended Serial Module Enable Register (ESMER)

Address(es): SCI12.ESMER 0008 B320h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	ESME
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ESME	Extended Serial Mode Enable	0: The extended serial mode is disabled. 1: The extended serial mode is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ESME Bit (Extended Serial Mode Enable)

When the ESME bit is 1, the facilities of the extended serial mode control section are enabled.

When the ESME bit is 0, the extended serial mode control section is initialized.

Table 32.32 Settings of the ESME Bit and Timer Operation Mode

ESME Bit	Timer Mode	Break Field Low Width Determination Mode	Break Field Low Width Output Mode
0	Available*1	Not available	Not available
1	Available	Available	Available

Note 1. Operation is only possible with PCLK selected.

32.2.25 Control Register 0 (CR0)

Address(es): SCI12.CR0 0008 B321h

	b7	b6	b5	b4	b3	b2	b1	b0

b7, b6	RTS[1:0]	RXDX12 Reception Sampling Timing Select	• When SCI12.SEMR.ABCS = 0 b7 b6 0 0: Rising edge of the 8th cycle of base clock 0 1: Rising edge of the 10th cycle of base clock 1 0: Rising edge of the 12th cycle of base clock 1 1: Rising edge of the 14th cycle of base clock • When SCI12.SEMR.ABCS = 1 b7 b6 0 0: Rising edge of the 4th cycle of base clock 0 1: Rising edge of the 5th cycle of base clock 1 0: Rising edge of the 6th cycle of base clock 1 1: Rising edge of the 7th cycle of base clock	R/W

Note: The period of the base clock is 1/16 of a single bit period when the SCI12.SEMR.ABCS is 0, and 1/8 of a single bit period when the SCI12.SEMR.ABCS is 1.
Note 1. To use the base clock, set the SCI12.SCR.TE bit to 1.
Note 2. The base clock divided by 2 is the filter clock when the SEMR.BGDM bit is 1 and the SMR.CKS[1:0] bits are 00b.

32.2.28 Control Register 3 (CR3)

Address(es): SCI12.CR3 0008 B324h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SDST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SDST	Start Frame Detection Start	0: Detection of Start Frame is not performed. 1: Detection of Start Frame is performed.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SDST Bit (Start Frame Detection Start)

Detection of a Start Frame begins when this bit is set to 1. The bit is read as 0.

32.2.29 Port Control Register (PCR)

Address(es): SCI12.PCR 0008 B325h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	SHARPS	—	—	RXDXPS	TXDXPS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TXDXPS	TXDX12 Signal Polarity Select	0: The polarity of TXDX12 signal is not inverted for output. 1: The polarity of TXDX12 signal is inverted for output.	R/W
b1	RXDXPS	RXDX12 Signal Polarity Select	0: The polarity of RXDX12 signal is not inverted for input. 1: The polarity of RXDX12 signal is inverted for input.	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	SHARPS	TXDX12/RXDX12 Pin Multiplexing Select	0: The TXDX12 and RXDX12 pins are independent. 1: The TXDX12 and RXDX12 signals are multiplexed on the same pin.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SHARPS Bit (TXDX12/RXDX12 Pin Multiplexing Select)

When this bit is set to 1, the TXDX12 and RXDX12 signals are multiplexed on the same pin so that half-duplex communications become possible.

32.2.30 Interrupt Control Register (ICR)

Address(es): SCI12.ICR 0008 B326h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	AEDIE	BCDIE	PIBDIE	CF1MIE	CF0MIE	BFDIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BFDIE	Break Field Low Width Detected Interrupt Enable	0: Interrupts on detection of the low width for a Break Field are disabled. 1: Interrupts on detection of the low width for a Break Field are enabled.	R/W
b1	CF0MIE	Control Field 0 Match Detected Interrupt Enable	0: Interrupts on detection of a match with Control Field 0 are disabled. 1: Interrupts on detection of a match with Control Field 0 are enabled.	R/W
b2	CF1MIE	Control Field 1 Match Detected Interrupt Enable	0: Interrupts on detection of a match with Control Field 1 are disabled. 1: Interrupts on detection of a match with Control Field 1 are enabled.	R/W
b3	PIBDIE	Priority Interrupt Bit Detected Interrupt Enable	0: Interrupts on detection of the priority interrupt bit are disabled. 1: Interrupts on detection of the priority interrupt bit are enabled.	R/W
b4	BCDIE	Bus Collision Detected Interrupt Enable	0: Interrupts on detection of a bus collision are disabled. 1: Interrupts on detection of a bus collision are enabled.	R/W
b5	AEDIE	Valid Edge Detected Interrupt Enable	0: Interrupts on detection of a valid edge are disabled. 1: Interrupts on detection of a valid edge are enabled.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

32.2.31 Status Register (STR)

Address(es): SCI12.STR 0008 B327h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	AEDF	BCDF	PIBDF	CF1MF	CF0MF	BFDF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BFDF	Break Field Low Width Detection Flag	[Setting conditions] • Detection of the low width for a Break Field • Completion of the output of the low width for a Break Field • Underflow of the timer [Clearing condition] • Writing 1 to the STCR.BFDCL bit	R
b1	CF0MF	Control Field 0 Match Flag	[Setting condition] • A match between the value received in Control Field 0 and the set value. [Clearing condition] • Writing 1 to the STCR.CF0MCL bit	R
b2	CF1MF	Control Field 1 Match Flag	[Setting condition] • A match between the data received in Control Field 1 and the set values. [Clearing condition] • Writing 1 to the STCR.CF1MCL bit	R
b3	PIBDF	Priority Interrupt Bit Detection Flag	[Setting condition] • Detection of the priority interrupt bit [Clearing condition] • Writing 1 to the STCR.PIBDCL bit	R
b4	BCDF	Bus Collision Detected Flag	[Setting condition] • Detection of the bus collision [Clearing condition] • Writing 1 to the STCR.BCDCL bit	R
b5	AEDF	Valid Edge Detection Flag	[Setting condition] • Detection of a valid edge [Clearing condition] • Writing 1 to the STCR.AEDCL bit	R
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R

32.2.32 Status Clear Register (STCR)

Address(es): SCI12.STCR 0008 B328h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	AEDCL	BCDCL	PIBDCL	CF1MCL	CF0MCL	BFDCL
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BFDCL	BFDF Clear	Setting this bit to 1 clears the STR.BFDF flag. This bit is read as 0.	R/W
b1	CF0MCL	CF0MF Clear	Setting this bit to 1 clears the STR.CF0MF flag. This bit is read as 0.	R/W
b2	CF1MCL	CF1MF Clear	Setting this bit to 1 clears the STR.CF1MF flag. This bit is read as 0.	R/W
b3	PIBDCL	PIBDF Clear	Setting this bit to 1 clears the STR.PIBDF flag. This bit is read as 0.	R/W
b4	BCDCL	BCDF Clear	Setting this bit to 1 clears the STR.BCDF flag. This bit is read as 0.	R/W
b5	AEDCL	AEDF Clear	Setting this bit to 1 clears the STR.AEDF flag. This bit is read as 0.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

32.2.33 Control Field 0 Data Register (CF0DR)

Address(es): SCI12.CF0DR 0008 B329h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

The CF0DR register is an 8-bit readable and writable register that holds a value for comparison with Control Field 0.

32.2.34 Control Field 0 Compare Enable Register (CF0CR)

Address(es): SCI12.CF0CR 0008 B32Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	CF0CE7	CF0CE6	CF0CE5	CF0CE4	CF0CE3	CF0CE2	CF0CE1	CF0CE0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CF0CE0	Control Field 0 Bit 0 Compare Enable	0: Comparison with bit 0 of Control Field 0 is disabled. 1: Comparison with bit 0 of Control Field 0 is enabled.	R/W
b1	CF0CE1	Control Field 0 Bit 1 Compare Enable	0: Comparison with bit 1 of Control Field 0 is disabled. 1: Comparison with bit 1 of Control Field 0 is enabled.	R/W
b2	CF0CE2	Control Field 0 Bit 2 Compare Enable	0: Comparison with bit 2 of Control Field 0 is disabled. 1: Comparison with bit 2 of Control Field 0 is enabled.	R/W
b3	CF0CE3	Control Field 0 Bit 3 Compare Enable	0: Comparison with bit 3 of Control Field 0 is disabled. 1: Comparison with bit 3 of Control Field 0 is enabled.	R/W
b4	CF0CE4	Control Field 0 Bit 4 Compare Enable	0: Comparison with bit 4 of Control Field 0 is disabled. 1: Comparison with bit 4 of Control Field 0 is enabled.	R/W
b5	CF0CE5	Control Field 0 Bit 5 Compare Enable	0: Comparison with bit 5 of Control Field 0 is disabled. 1: Comparison with bit 5 of Control Field 0 is enabled.	R/W
b6	CF0CE6	Control Field 0 Bit 6 Compare Enable	0: Comparison with bit 6 of Control Field 0 is disabled. 1: Comparison with bit 6 of Control Field 0 is enabled.	R/W
b7	CF0CE7	Control Field 0 Bit 7 Compare Enable	0: Comparison with bit 7 of Control Field 0 is disabled. 1: Comparison with bit 7 of Control Field 0 is enabled.	R/W

32.2.35 Control Field 0 Receive Data Register (CF0RR)

Address(es): SCI12.CF0RR 0008 B32Bh

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

CF0RR is a readable register that holds the value received in Control Field 0.

32.2.36 Primary Control Field 1 Data Register (PCF1DR)

Address(es): SCI12.PCF1DR 0008 B32Ch

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

PCF1DR is an 8-bit readable and writable register that holds the 8-bit primary value for comparison with Control Field 1.

32.2.37 Secondary Control Field 1 Data Register (SCF1DR)

Address(es): SCI12.SCF1DR 0008 B32Dh

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

PCF1DR is an 8-bit readable and writable register that holds the 8-bit secondary value for comparison with Control Field 1.

32.2.38 Control Field 1 Compare Enable Register (CF1CR)

Address(es): SCI12.CF1CR 0008 B32Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	CF1CE7	CF1CE6	CF1CE5	CF1CE4	CF1CE3	CF1CE2	CF1CE1	CF1CE0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CF1CE0	Control Field 1 Bit 0 Compare Enable	0: Comparison with bit 0 of Control Field 1 is disabled. 1: Comparison with bit 0 of Control Field 1 is enabled.	R/W
b1	CF1CE1	Control Field 1 Bit 1 Compare Enable	0: Comparison with bit 1 of Control Field 1 is disabled. 1: Comparison with bit 1 of Control Field 1 is enabled.	R/W
b2	CF1CE2	Control Field 1 Bit 2 Compare Enable	0: Comparison with bit 2 of Control Field 1 is disabled. 1: Comparison with bit 2 of Control Field 1 is enabled.	R/W
b3	CF1CE3	Control Field 1 Bit 3 Compare Enable	0: Comparison with bit 3 of Control Field 1 is disabled. 1: Comparison with bit 3 of Control Field 1 is enabled.	R/W
b4	CF1CE4	Control Field 1 Bit 4 Compare Enable	0: Comparison with bit 4 of Control Field 1 is disabled. 1: Comparison with bit 4 of Control Field 1 is enabled.	R/W
b5	CF1CE5	Control Field 1 Bit 5 Compare Enable	0: Comparison with bit 5 of Control Field 1 is disabled. 1: Comparison with bit 5 of Control Field 1 is enabled.	R/W
b6	CF1CE6	Control Field 1 Bit 6 Compare Enable	0: Comparison with bit 6 of Control Field 1 is disabled. 1: Comparison with bit 6 of Control Field 1 is enabled.	R/W
b7	CF1CE7	Control Field 1 Bit 7 Compare Enable	0: Comparison with bit 7 of Control Field 1 is disabled. 1: Comparison with bit 7 of Control Field 1 is enabled.	R/W

32.2.39 Control Field 1 Receive Data Register (CF1RR)

Address(es): SCI12.CF1RR 0008 B32Fh

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

CF1RR is a readable register that holds the value received in Control Field 1.

32.2.40 Timer Control Register (TCR)

Address(es): SCI12.TCR 0008 B330h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	TCST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TCST	Timer Count Start	0: Stops the timer counting 1: Starts the timer counting	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

32.2.41 Timer Mode Register (TMR)

Address(es): SCI12.TMR 0008 B331h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	TCSS[2:0]			TWRC	—	TOMS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	TOMS[1:0]	Timer Operating Mode Select*1	b1 b0 0 0: Timer mode 0 1: Break Field low width determination mode 1 0: Break Field low width output mode 1 1: Setting prohibited	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	TWRC	Counter Write Control	0: Data is written to the reload register and counter 1: Data is written to the reload register only	R/W
b6 to b4	TCSS[2:0]	Timer Count Clock Source Select*1	b6 b4 0 0 0: PCLK 0 0 1: PCLK/2 0 1 0: PCLK/4 0 1 1: PCLK/8 1 0 0: PCLK/16 1 0 1: PCLK/32 1 1 0: PCLK/64 1 1 1: PCLK/128	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. Rewrite the TOMS[1:0] and TCSS[2:0] bits only when the timer is stopped (TCST = 0).

TWRC Bit (Counter Write Control)

This bit determines whether a value written to the TPRE or TCNT register is written to the reload register only or is written to both the reload register and the counter.

32.2.42 Timer Prescaler Register (TPRE)

Address(es): SCI12.TPRE 0008 B332h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

TPRE consists of an 8-bit reload register, a read buffer, and a counter, each of which has FFh as its initial value. The counter counts down in synchronization with the counter clock selected by the TMR.TCSS[2:0] bits, and is reloaded with the value in the reload register when it underflows. Underflows of this register provide the clock source to drive counting by the TCNT register. The reload register and read buffer are allocated to the same address. Data is written to the reload register in writing, and the counter value that has been transferred to the read buffer is returned in reading.
It takes one PCLK cycle to load a value from the reload register to the counter.

32.2.43 Timer Count Register (TCNT)

Address(es): SCI12.TCNT 0008 B333h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

TCNT consists of an 8-bit reload register, a read buffer, and a counter, each of which has FFh as its initial value. This down-counter counts underflows of the TPRE register until the TCNT register underflows, and is then reloaded with the value from the reload register. The reload register and read buffer are allocated to the same address. Data is written to the reload register in writing, and the counter value that has been transferred to the read buffer is returned in reading.
It takes one PCLK cycle to load a value from the reload register to the counter.

32.2.44 Device Function Select Register 0 (PRDFR0)

Address(es): SYSTEM.PRDFR0 0008 00D0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	SCI11RXD[1:0]		—	—	SCI9RXD[1:0]		SCI8RXD[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	SCI5RXD[1:0]		—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11, b10	SCI5RXD[1:0]	SCI5 RXD Input Signal Select	These bits select the signal to be input to the RXD pin of SCI5. b11 b10 0 0: Input signal from the RXD5 pin 0 1: COMP3 level detection signal 1 0: COMP4 level detection signal Settings other than above are prohibited.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b17, b16	SCI8RXD[1:0]	RSCI8 RXD Input Signal Select	These bits select the signal to be input to the RXD pin of RSCI8. b17 b16 0 0: Input signal from the RXD008 pin 0 1: COMP3 level detection signal 1 0: COMP4 level detection signal Settings other than above are prohibited.	R/W
b19, b18	SCI9RXD[1:0]	RSCI9 RXD Input Signal Select	These bits select the signal to be input to the RXD pin of RSCI9. b19 b18 0 0: Input signal from the RXD009 pin 0 1: COMP3 level detection signal 1 0: COMP4 level detection signal Settings other than above are prohibited.	R/W
b21, b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23, b22	SCI11RXD[1:0]	RSCI11 RXD Input Signal Select	These bits select the signal to be input to the RXD pin of RSCI11. b23 b22 0 0: Input signal from the RXD011 pin 0 1: COMP3 level detection signal 1 0: COMP4 level detection signal Settings other than above are prohibited.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

If the RXD signal is attenuated by the transmission line effects and does not meet the VIH/VIL specifications, it can be improved by intervening a comparator.
When using a comparator, connect the RXD signal to one of the CMPC30 to CMPC33 or CMPC40 to CMPC43 pins. Also, disable the noise filter in the comparator. In this case, the RXD5 pin is not used.

32.3 Operation in Asynchronous Mode

Figure 32.5 shows the general format for asynchronous serial communications.
One frame consists of a start bit (low level), transmit/receive data, a parity bit, and stop bits (high level).
In asynchronous serial communications, the communications line is usually held in the mark state (high level).
The SCI monitors the communications line. When the SCI detects a low, it regards that as a start bit and starts serial communication.
Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and the receiver also have a double-buffered structure, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

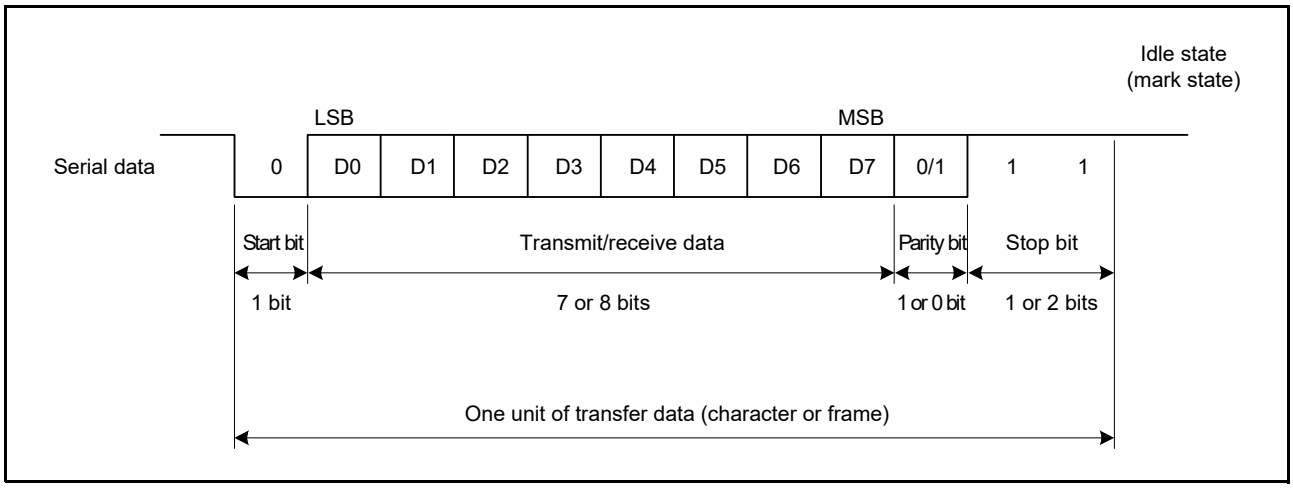

Figure 32.5 Data Format in Asynchronous Serial Communications (Example with 8-Bit Data, Parity, 2 Stop Bits)

32.3.1 Serial Data Transfer Format

Table 32.33 lists the serial data transfer formats that can be used in asynchronous mode.
Any of 18 transfer formats can be selected according to the SMR and SCMR setting. For details of multi-processor function, refer to section 32.4, Multi-Processor Communications Function.

Table 32.33 Serial Transfer Formats (Asynchronous Mode)

SCMR Setting	SMR Setting				Serial Transfer Format and Frame Length
CHR1	CHR	PE	MP	STOP	1 2 3 4 5 6 7 8 9 10 11 12 13
0	0	0	0	0	S 9-bit data STOP
0	0	0	0	1	S 9-bit data STOP STOP
0	0	1	0	0	S 9-bit data P STOP
0	0	1	0	1	S 9-bit data P STOP STOP
1	0	0	0	0	S 8-bit data STOP
1	0	0	0	1	S 8-bit data STOP STOP
1	0	1	0	0	S 8-bit data P STOP
1	0	1	0	1	S 8-bit data P STOP STOP
1	1	0	0	0	S 7-bit data STOP
1	1	0	0	1	S 7-bit data STOP STOP
1	1	1	0	0	S 7-bit data P STOP
1	1	1	0	1	S 7-bit data P STOP STOP
0	0	—	1	0	S 9-bit data MPB STOP
0	0	—	1	1	S 9-bit data MPB STOP STOP
1	0	—	1	0	S 8-bit data MPB STOP
1	0	—	1	1	S 8-bit data MPB STOP STOP
1	1	—	1	0	S 7-bit data MPB STOP
1	1	—	1	1	S 7-bit data MPB STOP STOP

S: Start bit
STOP: Stop bit
P: Parity bit
MPB: Multi-processor bit

32.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCI operates on a base clock with a frequency of 16 times*1 the bit rate.
In reception, the SCI samples the falling edge of the start bit using the base clock, and performs internal synchronization. Since receive data is sampled at the rising edge of the 8th pulse*1 of the base clock, data is latched at the middle*2 of each bit, as shown in Figure 32.6. Thus the reception margin in asynchronous mode is determined by formula (1) below.

$$M = \left| \left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\ (\%) \quad \cdots \text{Formula (1)}$$

M: Reception margin
N: Ratio of bit rate to clock
(N = 16 when SEMR.ABCSE = 0 and SEMR.ABCS = 0, N = 8 when SEMR.ABCSE = 0 and SEMR.ABCS = 1, N = 6 when SEMR.ABCSE = 1)
D: Duty cycle of clock (D = 0.5 to 1.0)
L: Frame length (L = 9 to 13)
F: Absolute value of clock frequency deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined by the formula below.

M = {0.5 – 1/(2 × 16)} × 100 (%) = 46.875 (%)

However, this is only the computed value, and a margin of 20% to 30% should be allowed in system design.

Note 1. These are values when the ABCSE and ABCS bits in the SEMR register are 0. When the ABCSE bit is 0 and the ABCS bit is 1, a frequency of 8 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 4th pulse of the base clock. When the ABCSE bit is 1, a frequency of 6 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 3rd pulse of the base clock.
Note 2. This is when the SPTR.RTADJ bit is 0.

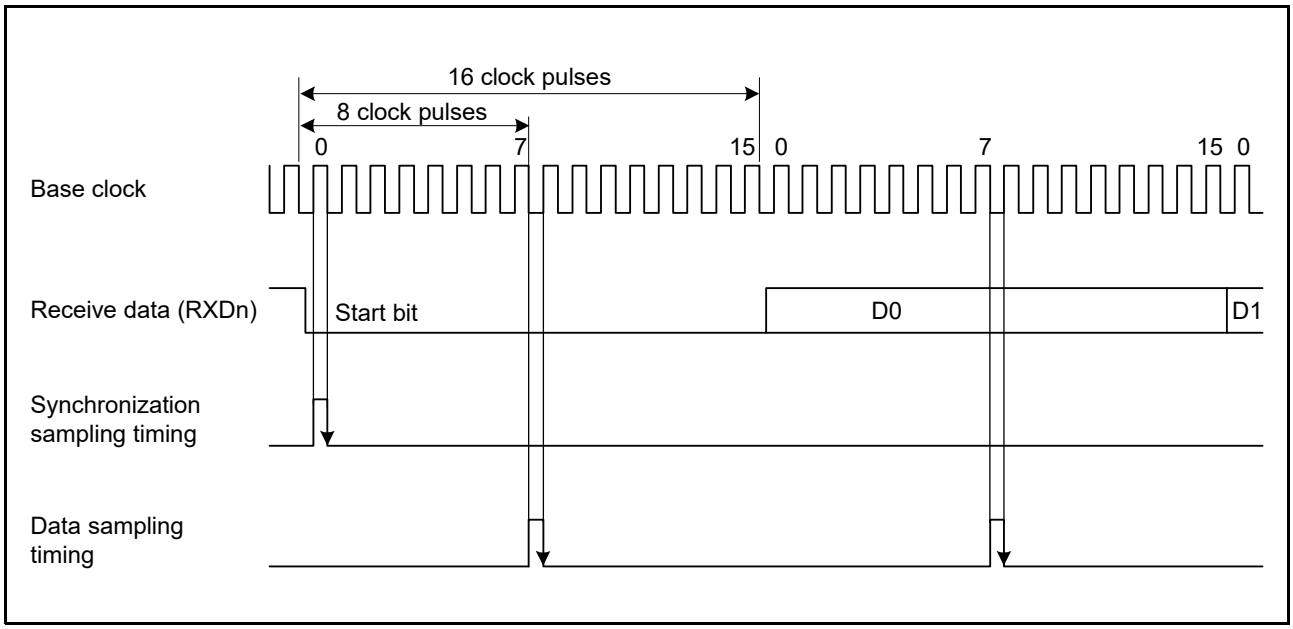

Figure 32.6 Receive Data Sampling Timing in Asynchronous Mode

In SCI1, SCI5, and SCI6, there are functions to adjust the sampling point of the receive data and the transition timing of the transmit data against that the high width and low width of the signal changes affected by the devices on the transmission line.

32.3.2.1 Receive Data Sampling Timing Adjustment

When a waveform such that high width is different from low width because the difference between rising time and falling time is large is received, adjust the timing for data to be sampled at the center of the narrower pulse. When low width is narrower than high width, move the sampling timing forward, and when high width is narrower than low width, move the sampling timing backward.

When the TMGR.RTMG[3:0] bits are set to an offset to the default sampling point and then the SPTR.RTADJ bit is set to 1, received data is sampled at the specified position.

Figure 32.7 shows an example of the sampling timing adjustment.

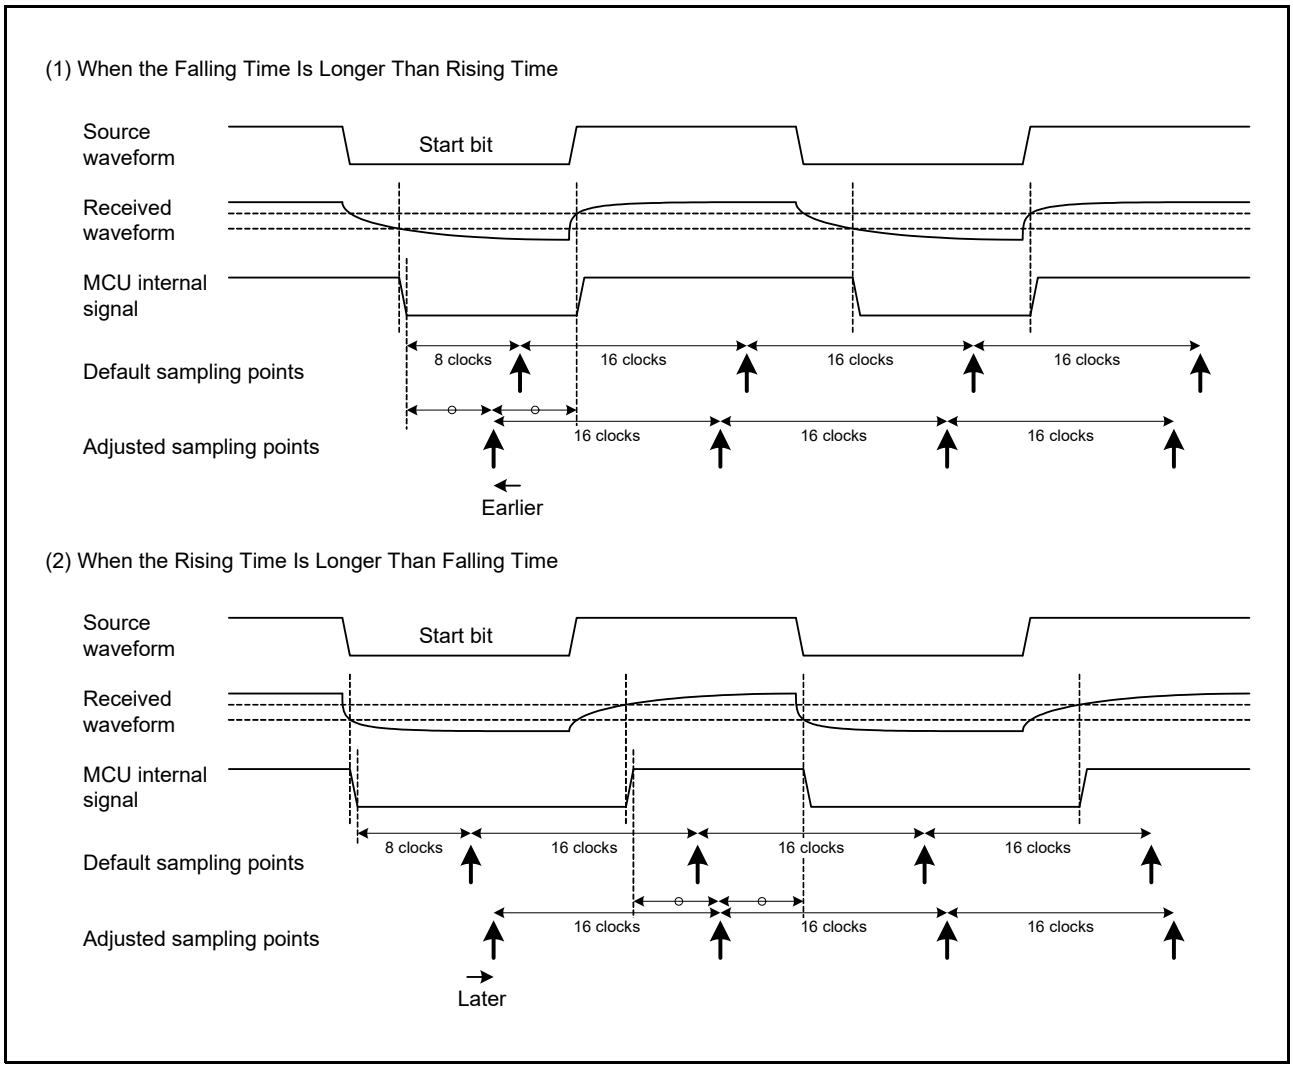

Figure 32.7 Example of Sampling Timing Adjustment (SEMR.ABCSE bit = 0 and SEMR.ABCS bit = 0)

32.3.2.2 Transmit Data Transition Timing Adjustment

When a difference between high width and low width for a waveform transmitted by this MCU arises at the receiver, it is also possible to make a difference between the high width and the low width beforehand at transmission to adjust so that the difference disappears at the receiver. When high width becomes narrower at the receiver, expand the high width of the transmit signal by delaying the falling edges, and when low width becomes narrower at the receiver, expand the low width of the transmit signal by delaying the rising edges.

When the TMGR.TTMG[3:0] bits are set to the transition direction and the delay amount and the SPTR.TTADJ bit is set to 1, transmit data changes at the specified point.

Figure 32.8 shows an example of the transition timing adjustment.

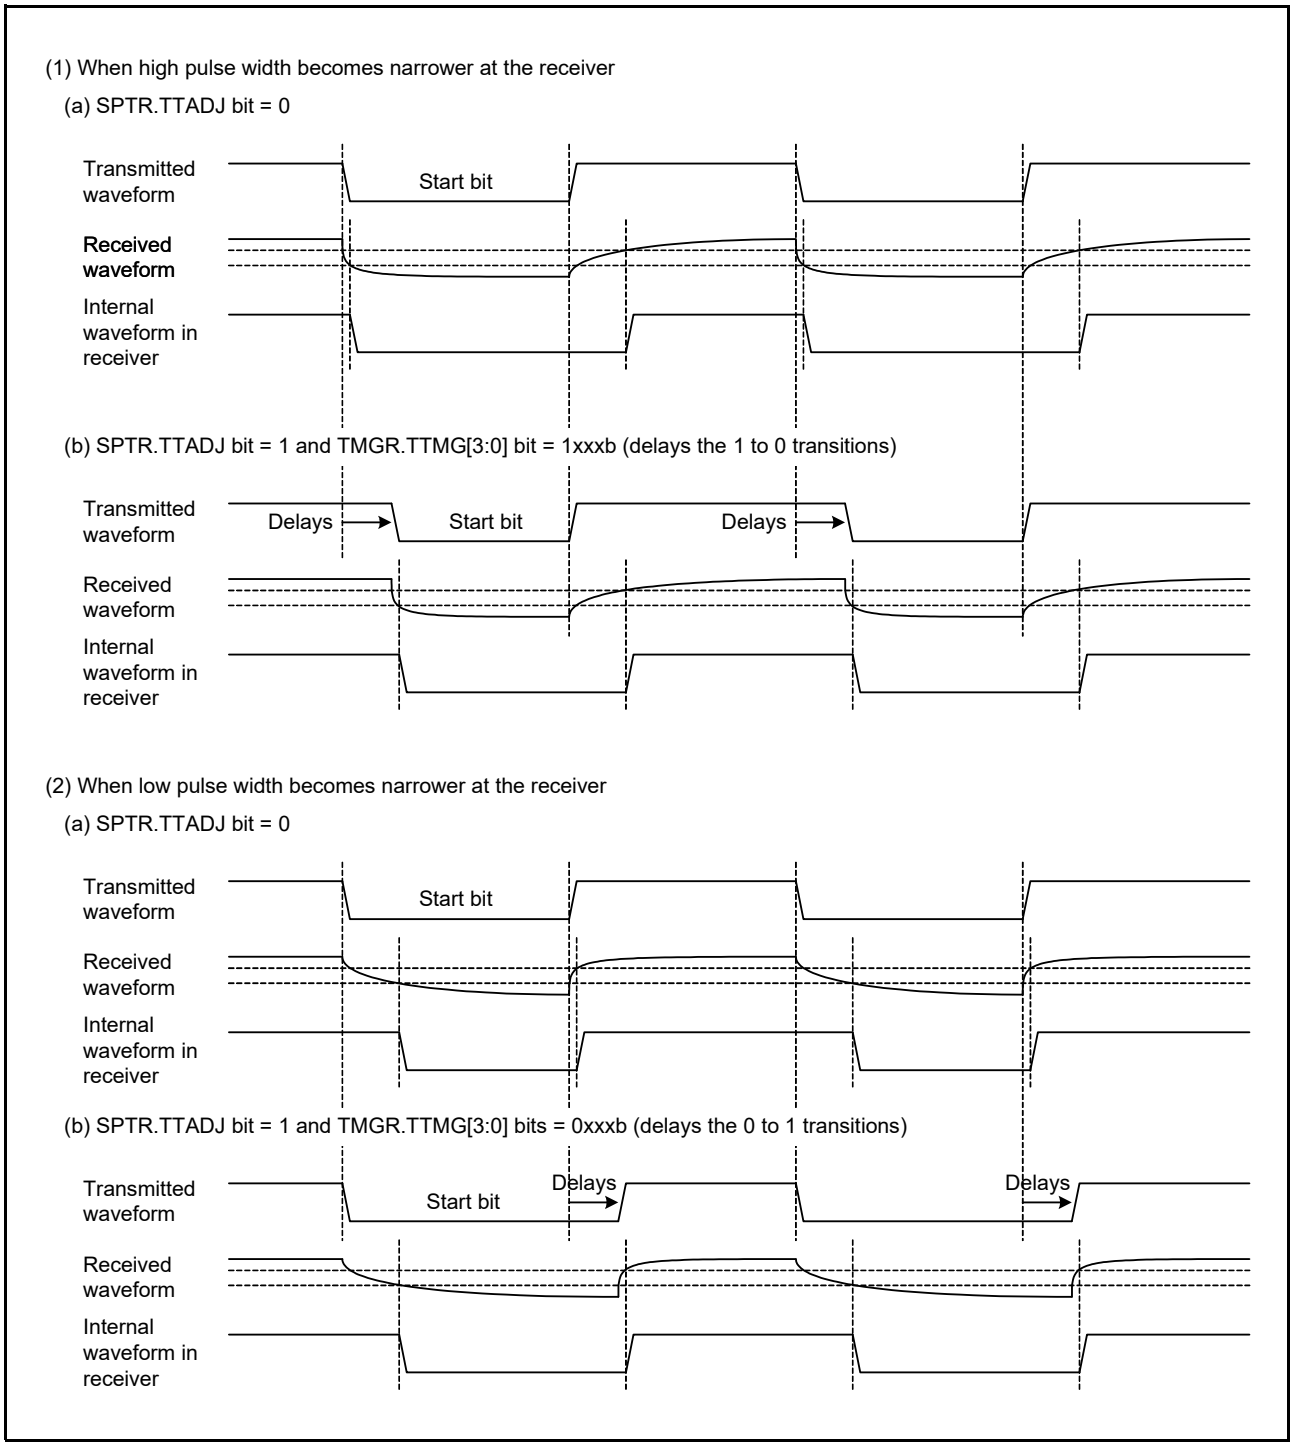

Figure 32.8 Example of Transition Timing Adjustment

32.3.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCKn pin can be selected as the SCI's transfer clock, according to the setting of the SMR.CM bit and the SCR.CKE[1:0] bits.
When an external clock is input to the SCKn pin, the clock frequency should be 16 times the bit rate (when SEMR.ABCS bit = 0) and 8 times the bit rate (when SEMR.ABCS bit = 1). In addition, when an external clock is specified, the base clock of TMR0 and TMR1 can be selected by the SCIn.SEMR.ACS0 bit (n = 5, 6, 12).
When the SCI is operated on an internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is such that the rising edge of the clock is in the middle of the transmit data, as shown in Figure 32.9.

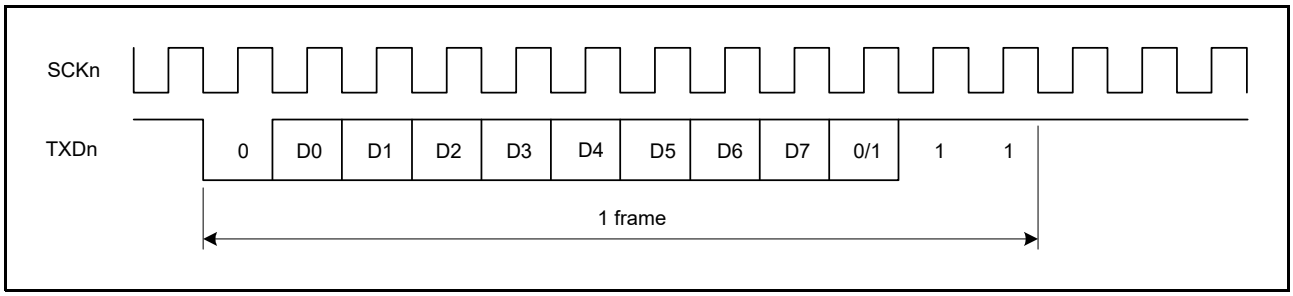

Figure 32.9 Phase Relationship between Output Clock and Transmit Data (Asynchronous Mode: SMR.CHR = 0, PE = 1, MP = 0, STOP = 1)

32.3.4 Double-Speed Mode and Divide-by-6 Mode

The output clock frequency of the on-chip baud rate generator is doubled by setting the SEMR.BGDM bit to 1, enabling high-speed communication at a doubled bit rate. If the SEMR.ABCS bit is set to 1 under the above condition, the number of base clock cycles changes from 16 to 8, so the bit rate becomes four times faster than the initial state.
When the SEMR.ABCSE bit is set to 1, the number of base clock pulses in 1-bit period becomes 6 and the period of the base clock becomes 1/2, where the bit rate becomes 16/3 times faster compared to a case that all of the ABCS, BDGM, and ABCSE bits are set to 0.
As shown by Formula (1) in section 32.3.2, Receive Data Sampling Timing and Reception Margin in Asynchronous Mode, setting the SEMR.ABCS bit to 1 changes the number of cycles to 8, and the sampling interval becomes longer. This causes the reception margin to decrease. Therefore, setting the SEMR.BGDM bit to 1 and the SEMR.ABCS bit to 0 is recommended instead of setting the SEMR.BGDM bit to 0 and the SEMR.ABCS bit to 1 for high-speed operation at a doubled bit rate.

32.3.5 CTS and RTS Functions

The CTS function is the use of input on the CTSn# pin in transmission control. Setting the SPMR.CTSE bit to 1 enables the CTS function. When the CTS function is enabled, placing the low level on the CTSn# pin causes transmission to start.
Applying the high level to the CTS# pin while transmission is in progress does not affect transmission of the current frame, which continues.
In the RTS function, by using the function of output on the RTSn# pin, a low level is output when reception becomes possible. Conditions for output of the low and high level are shown below.

[Conditions for low-level output]
When the following conditions are all satisfied.

- The SCR.RE bit is 1.
- Reception is not in progress.
- There are no received data yet to be read.
- The ORER, FER, and PER flags in the SSR register are all 0.

[Condition for high-level output]
When the conditions for low-level output are not satisfied.

Note that either one of CTS and RTS can be selected.

32.3.6 Data Match Detection

The data match detection function is available in asynchronous mode for SCI1, SCI5, and SCI6.
When the DCCR.DCME bit is set to 1, the received data is compared with the contents of the CDR.CMPD[8:0] bits*1.
Upon a match of the value, a receive data full interrupt (RXI) request is generated.
When the SMR.MP bit is 0, all received data is compared.
When the SMR.MP bit is set to 1 and if the DCCR.IDSEL bit is 1, only the data in which the multiprocessor bit is 1 is compared and data in which the bit is 0 is ignored. When the DCCR.IDSEL bit is 0, all of the received data is compared regardless of the value of the multiprocessor bit.
The received data is not stored or the flag is not updated until the received data matches with the value of the CDR.CMPD[8:0] bits. When the data is matched, the DCCR.DCME bit is automatically set to 0 and the DCMF flag becomes 1. At this time, if the DCCR.IDSEL bit is 1, the SCR.MPIE bit is automatically set to 0. In addition, an receive data full interrupt (RXI) request is generated when the SCR.RIE bit is 1.
When a framing error is found in the matched data, the DCCR.DFER flag becomes 1. When a parity error is found in the matched data, the DCCR.DPER flag becomes 1. The received data matched with the value of the CDR.CMPD[8:0] bits is not stored in the received buffer or the SSR.RDRF flag does not become 1.
After a data match is detected and the DCCR.DCME bit is set to 0, data is normally received.
When the DCCR.DFER or DCCR.DPER flag is 1, a data match is not detected. These flags should be set to 0 before enabling the data match detection function.

Note 1. Only the portion that corresponds to the character length specified by the SMR.CHR and SCMR.CHR1 bits is compared.

Figure 32.10 and Figure 32.11 show examples of data match detection.

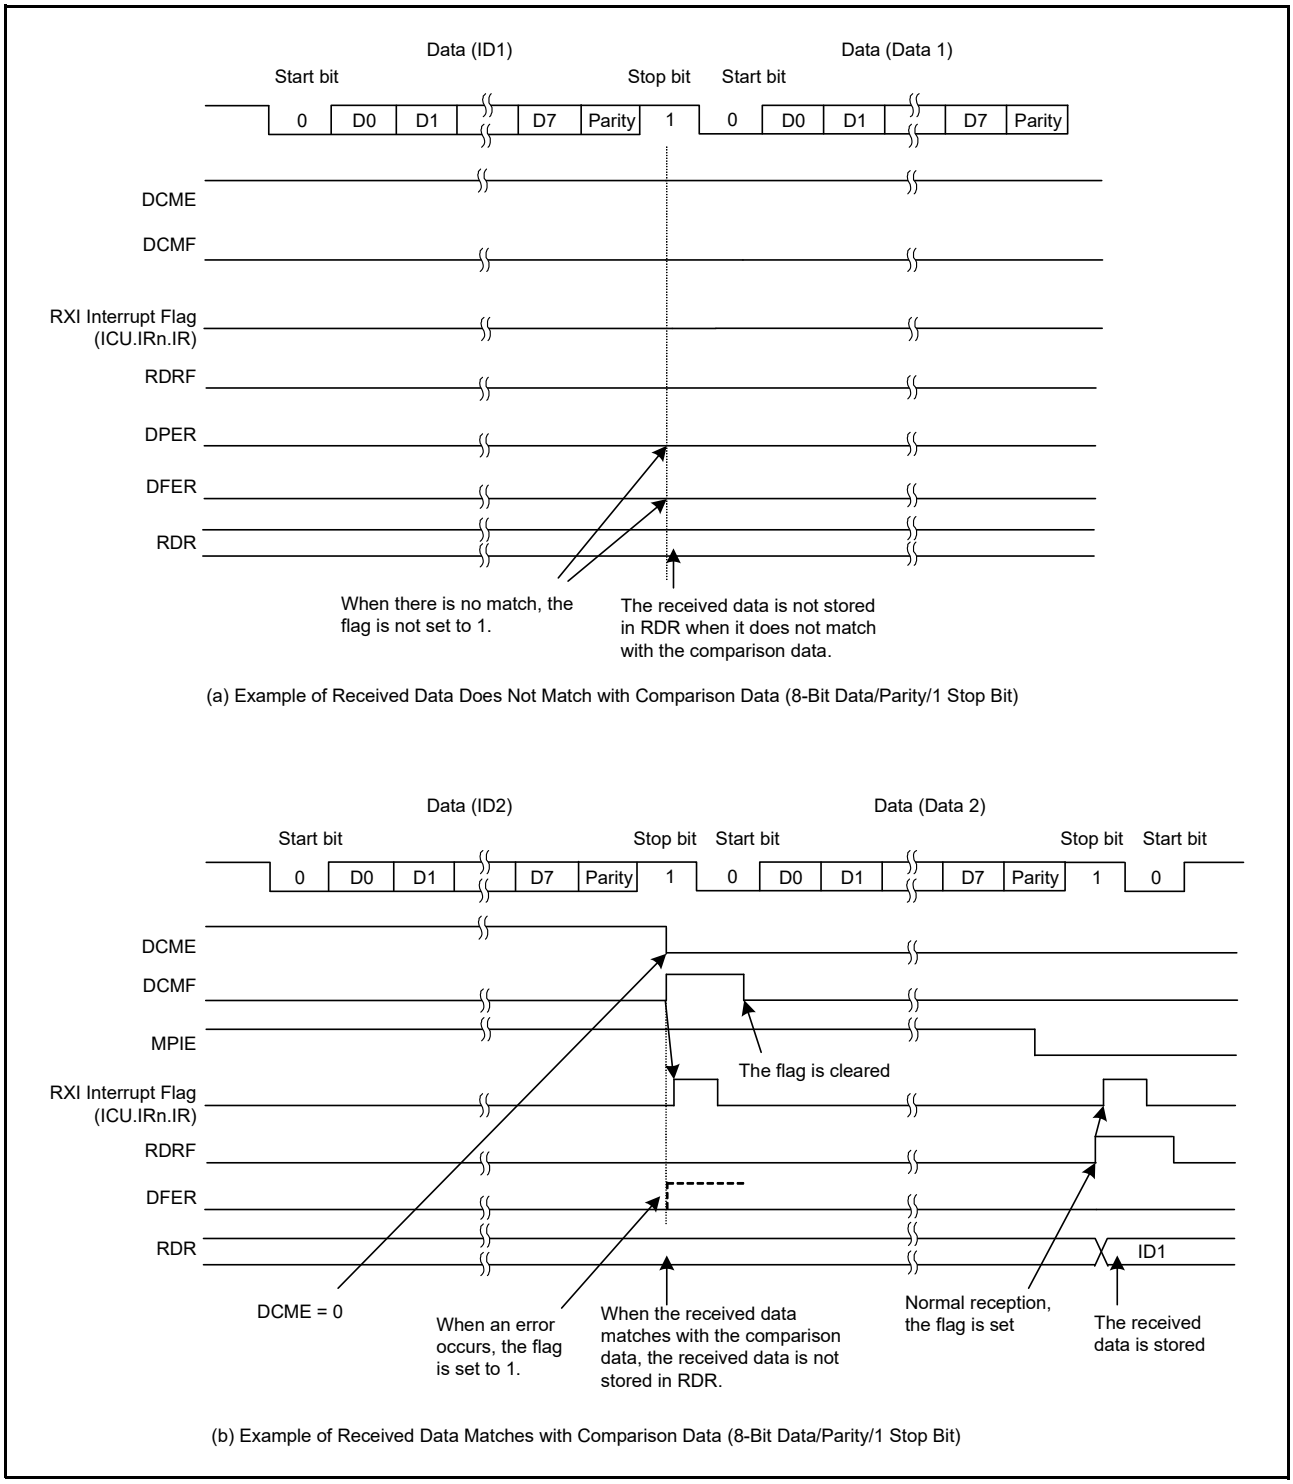

Figure 32.10 Example of Data Match Detection (1) Non Multi-Processor Mode

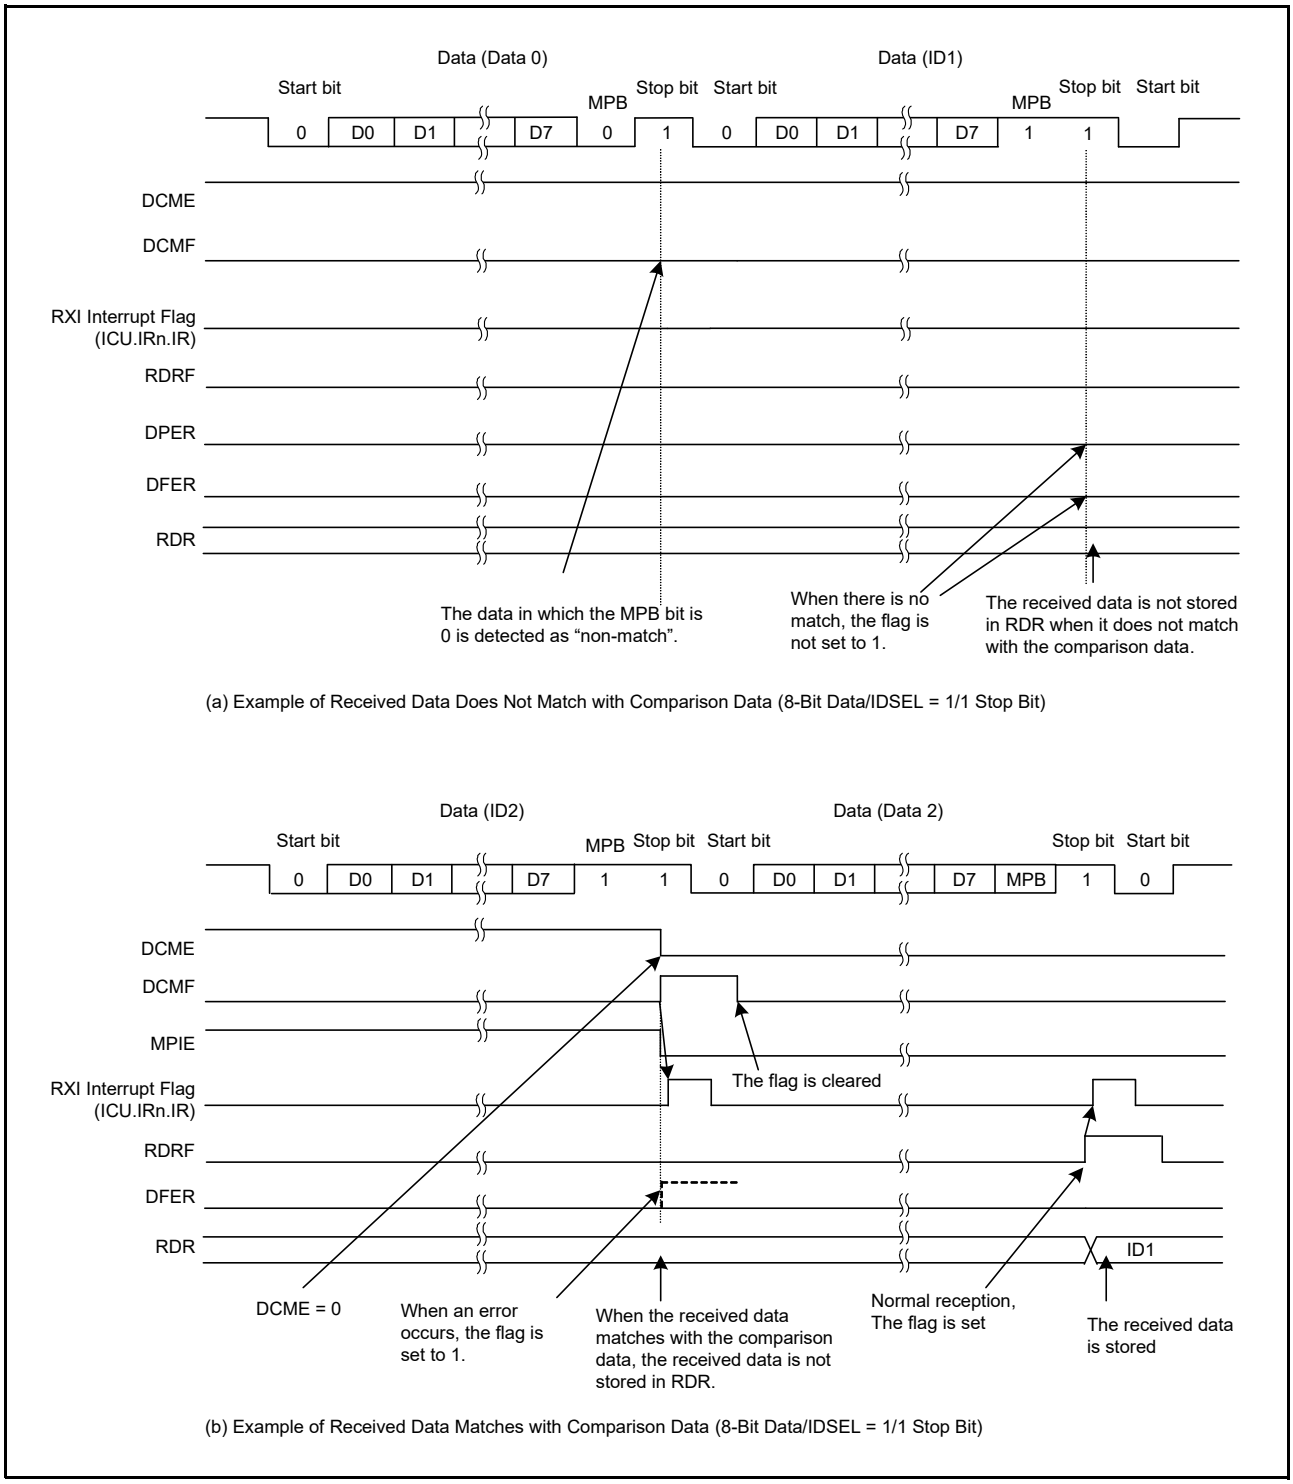

Figure 32.11 Example of Data Match Detection (2) Non Multi-Processor Mode

32.3.7 SCI Initialization (Asynchronous Mode)

Before transmitting and receiving data, start by writing the initial value 00h to the SCR register and then continue through the procedure for SCI given in Figure 32.12. Whenever the operating mode or transfer format is changed, the SCR register must be initialized before the change is made.

When the external clock is used in asynchronous mode, ensure that the clock signal is supplied even during initialization.

Note that setting the SCR.RE bit to 0 initializes neither the ORER, FER, PER, and RDRF flags in the SSR register nor registers RDR, RDRH, and RDRL.

In addition, note that setting bits TIE, TE, and TEIE in the SCR register to 1 simultaneously leads to the generation of a transmit end interrupt (TEI) request before the generation of a transmit data empty interrupt (TXI) request.

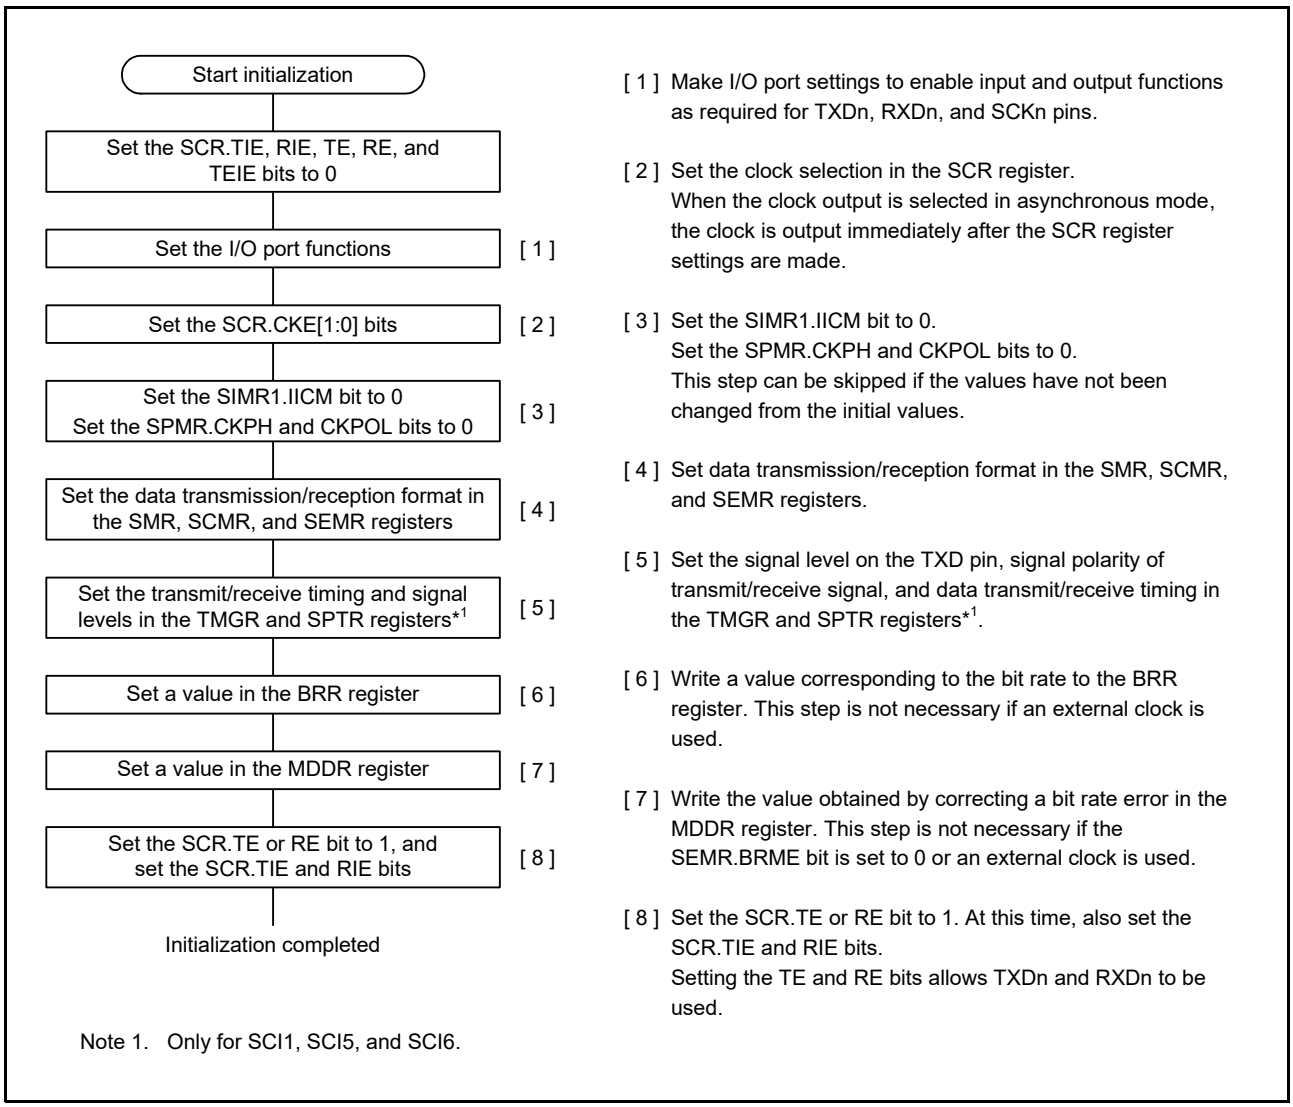

Figure 32.12 Sample SCI Initialization Flowchart (Asynchronous Mode)

Figure 32.13 shows an example of data transmission when the SCI is set to asynchronous mode according to the flow described in Figure 32.12 after a reset. When the pin function is set to the TXD pin, it is still high-impedance because the SCR.TE bit is 0. When the transmit data is written after setting the TE bit to 1, a data transmission starts. After the TE bit is set to 1, one frame of high is output from TXD pin (internal wait time)*1 and then the data transmission starts.

Note 1. This is when the SEMR.ITE bit is 0. When the ITE bit is 1, the internal wait time is not inserted.

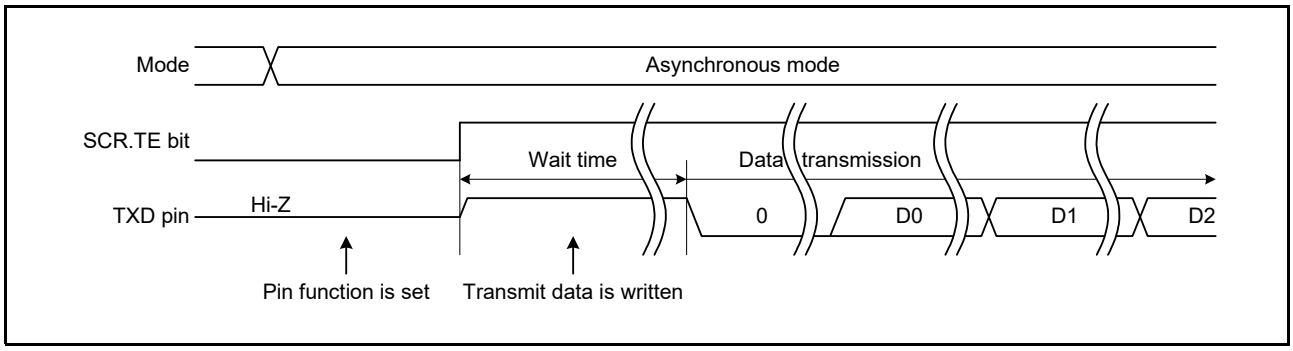

Figure 32.13 Example of Data Transmission Timing in Asynchronous Mode

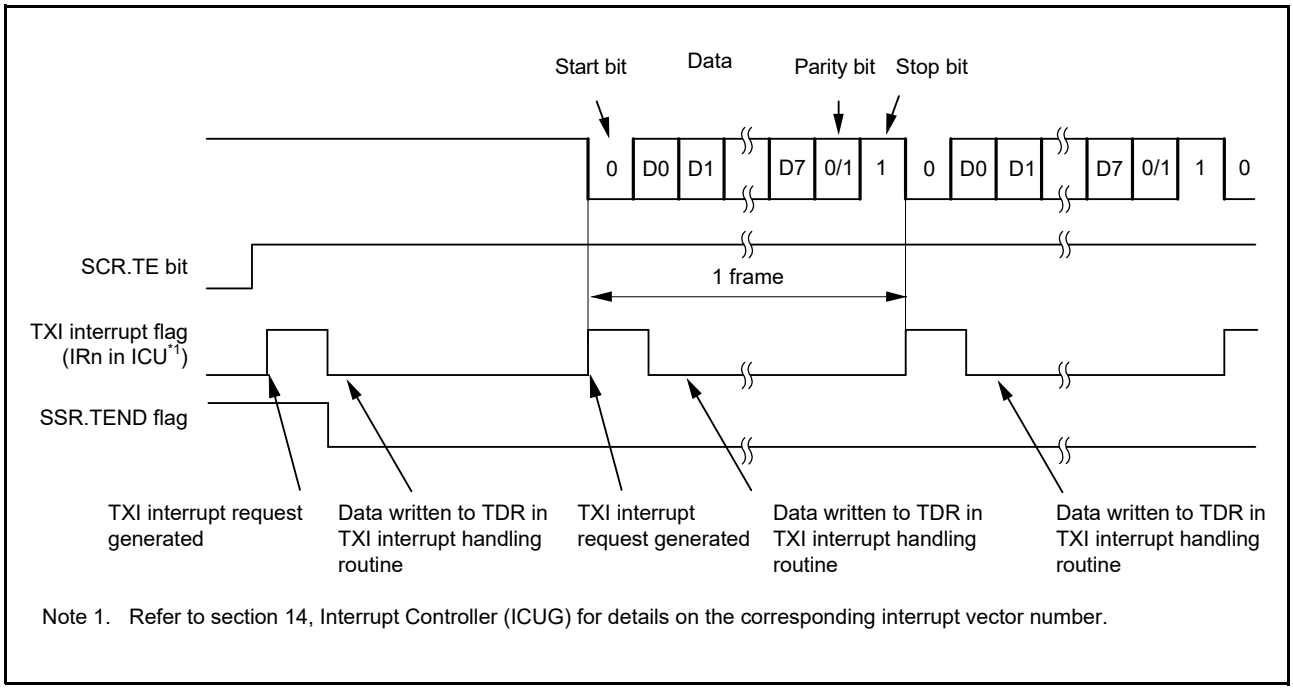
32.3.8 Serial Data Transmission (Asynchronous Mode)

Figure 32.14 to Figure 32.16 show an example of the operation for serial transmission in asynchronous mode.
In serial transmission, the SCI operates as described below.

1. The SCI transfers data from the TDR register*1 to the TSR register when data is written to the TDR register*1 in the TXI interrupt handling routine. The TXI interrupt request at the beginning of transmission is generated when the SCR.TE bit is set to 1 after the SCR.TIE bit is set to 1 or when these 2 bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the SPMR.CTSE bit is set to 0 (CTS function is disabled) and a low level on the CTSn# pin causes data transfer from the TDR register*1 to the TSR register. If the SCR.TIE bit is 1 at this time, a TXI interrupt request is generated. Continuous transmission is obtainable by writing the next transmit data to the TDR register*1 in the TXI interrupt handling routine before transmission of the current transmit data is completed. When TEI interrupt requests are in use, set the SCR.TIE bit to 0 (a TXI interrupt request is disabled) and the SCR.TEIE bit to 1 (a TEI interrupt request is enabled) after the last of the data to be transmitted are written to the TDR register*1, *2 from the handling routine for TXI requests.
3. Data is sent from the TXDn pin in the following order: start bit, transmit data, parity bit or multi-processor bit (may be omitted depending on the format), and stop bit.
4. The SCI checks for updating of (writing to) the TDR register*3 at the time of stop bit output.
5. When the TDR register*3 is updated, setting of the SPMR.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn# pin cause the next transfer of the next transmit data from the TDR register*1 to the TSR register and sending of the stop bit, after which serial transmission of the next frame starts.
6. If the TDR register*3 is not updated, the SCI sets the SSR.TEND flag to 1, sends the stop bit, and then outputs high to put the line in the mark state. If the SCR.TEIE bit is 1 at this time, the SSR.TEND flag is set to 1 and a TEI interrupt request is generated.

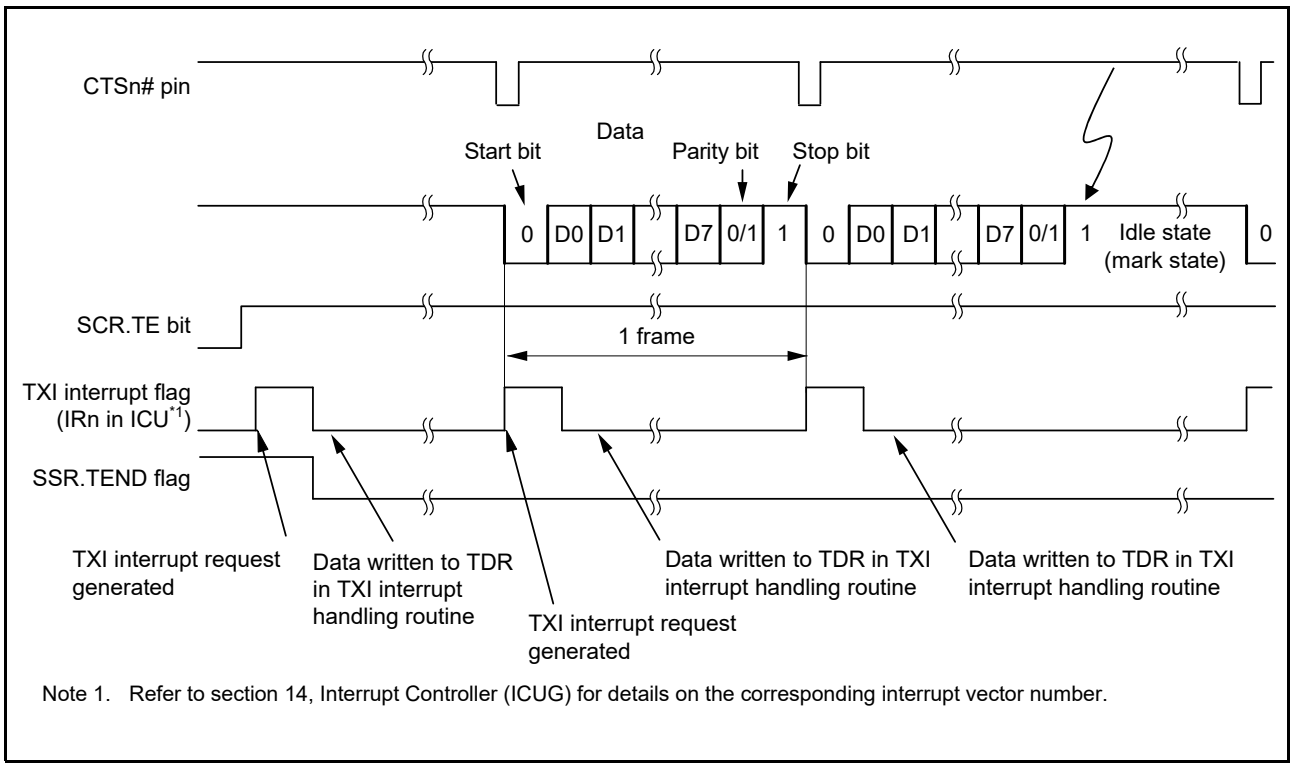
Note 1. Write data not to the TDR register but to the TDRH and TDRL registers when 9-bit data length is selected.
Note 2. Write data in the order from the TDRH register to the TDRL register when 9-bit data length is selected.
Note 3. The SCI checks for updating of the TDRL register only and does not check for updating of the TDRH register when 9-bit data length is selected.

Figure 32.17 shows a sample flowchart for serial transmission in asynchronous mode.



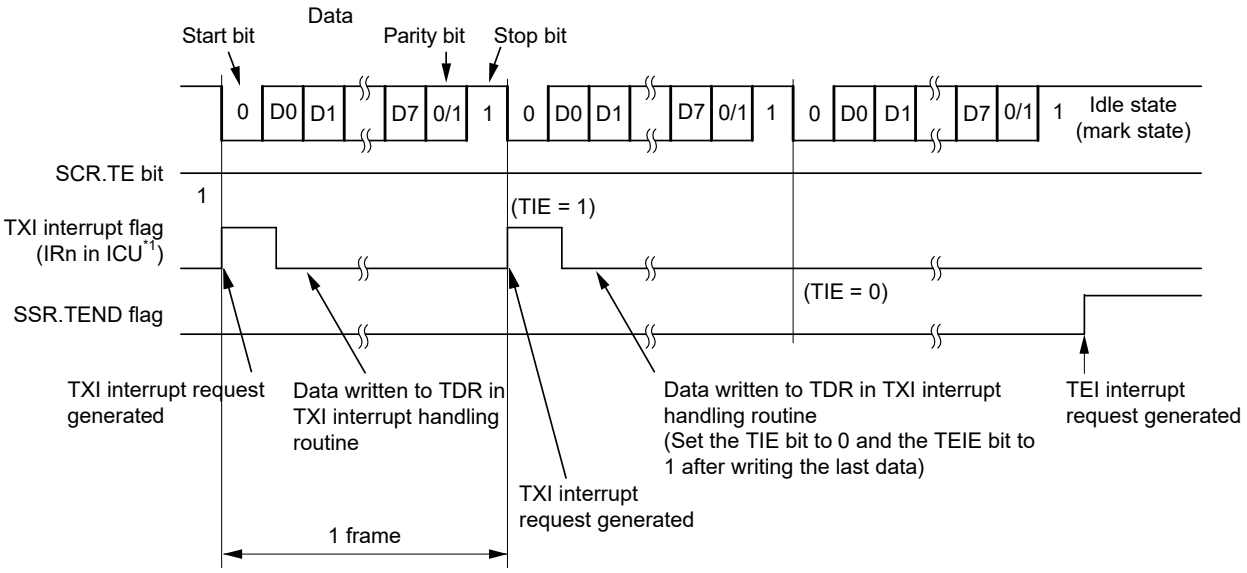
Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 32.14 Example of Operation for Serial Transmission in Asynchronous Mode (1) (with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Not Used, at the Beginning of Transmission)



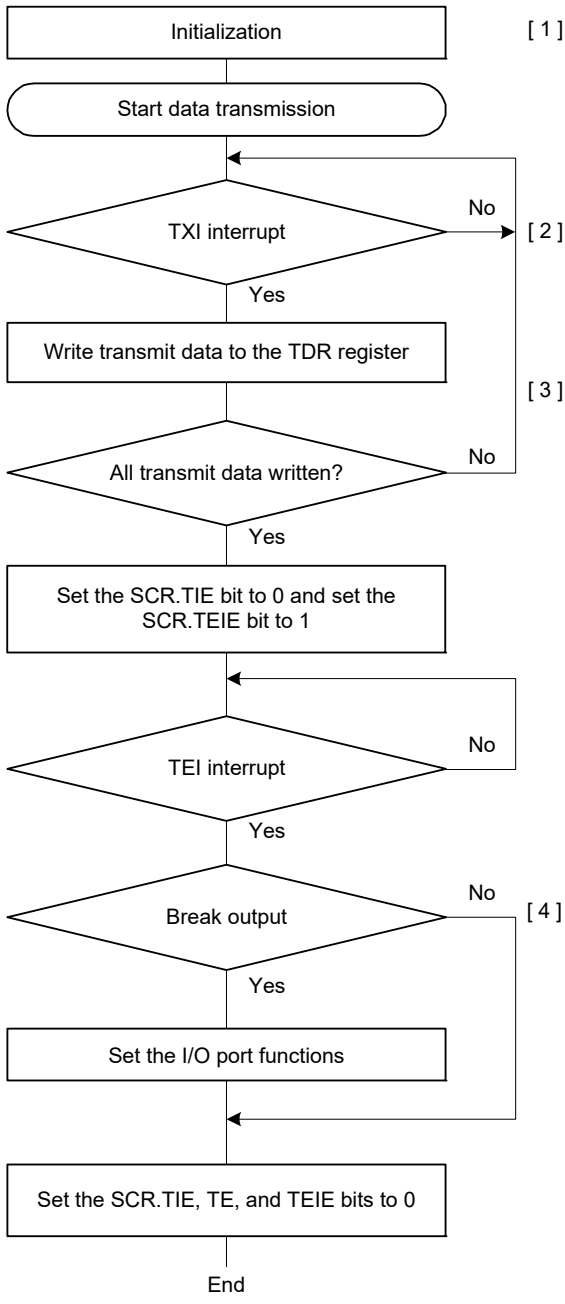
Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 32.15 Example of Operation for Serial Transmission in Asynchronous Mode (2) (with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Used, at the Beginning of Transmission)



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 32.16 Example of Operation for Serial Transmission in Asynchronous Mode (3) (with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Not Used, from the Middle of Transmission until Transmission Completion)



[1] SCI initialization:
Set data transmission.
After the SCR.TE bit is set to 1, high is output for a frame*1, and transmission is enabled.

[2] Transmit data write to the TDR register by a TXI interrupt request:
When transmit data is transferred from the TDR register to the TSR register, a transmit data empty interrupt (TXI) request is generated.
Write transmit data to the TDR register once in the TXI interrupt handling routine.

[3] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to the TDR register once using a TXI interrupt request.
Transmit data can also be written to the TDR register by activating the DMAC or DTC.
When TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted are written to the TDR register.

[4] Break output at the end of serial transmission:
To output a break in serial transmission, set the I/O port function corresponding to the TXDn pin (corresponding to output of the low level), and after switching the TXDn pin to the general I/O port function, set the SCR.TE bit to 0.

Note: The TDR register becomes the TDRH and TDRL registers when 9-bit data length is selected. Write data in the order from the TDRH register to the TDRL register.

Note 1. This is when the SEMR.ITE bit is 0. When the ITE bit is 1, transmission is enabled immediately after the TE bit is set to 1.

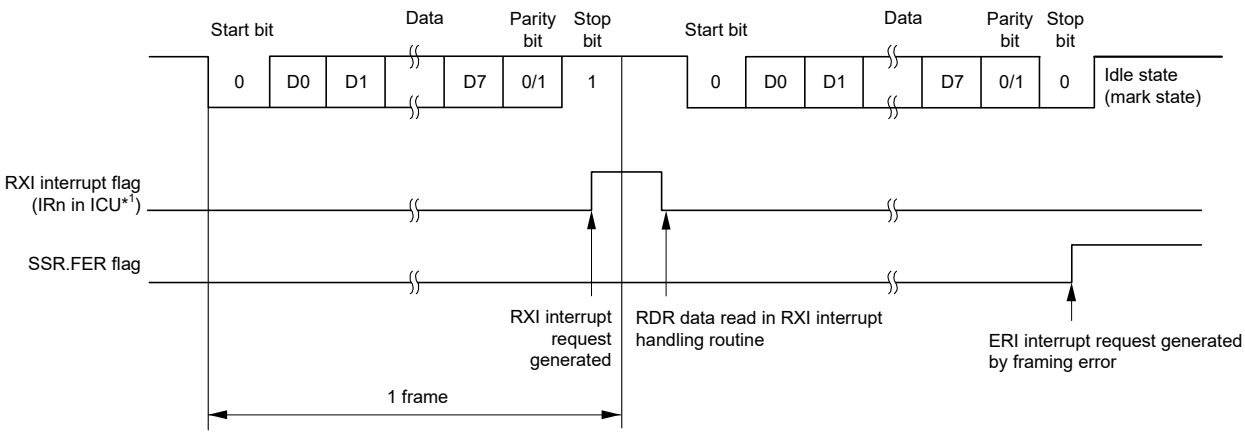
Figure 32.17 Example of Serial Transmission Flowchart in Asynchronous Mode

32.3.9 Serial Data Reception (Asynchronous Mode)

Figure 32.18 and Figure 32.19 show an example of the operation for serial data reception in asynchronous mode. In serial data reception, the SCI operates as described below.

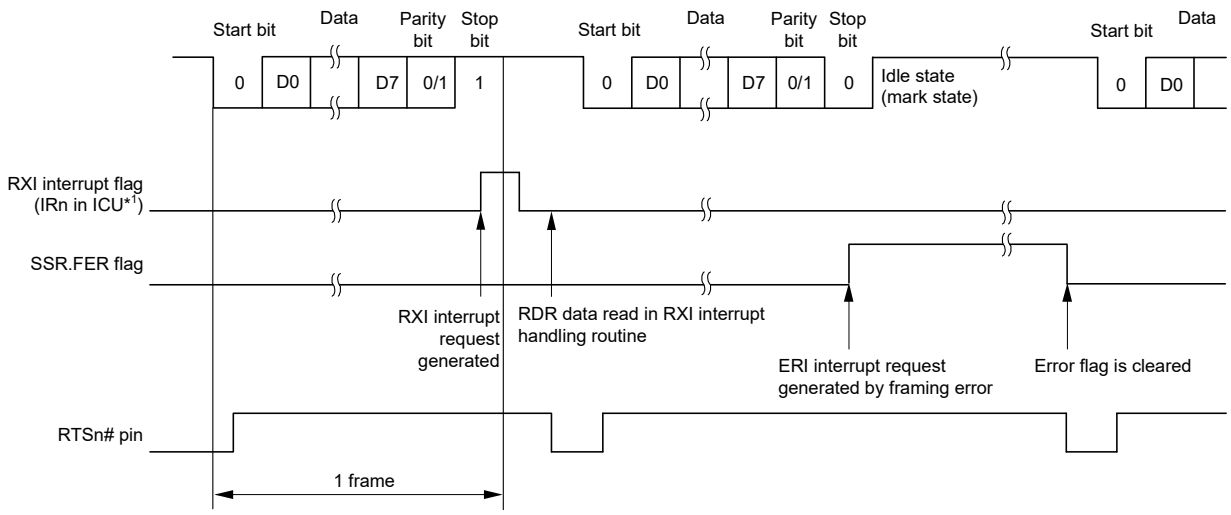
1. When the value of the SCR.RE bit becomes 1, the output signal on the RTSn# pin goes to the low level.
2. When the SCI monitors the communications line and detects a start bit, it performs internal synchronization, stores receive data in the RSR register, and checks the parity bit and stop bit.
3. If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to the RDR register*1.
4. If a parity error is detected, the SSR.PER flag is set to 1 and receive data is transferred to the RDR register*1. If the SCR.RIE bit is 1 at this time, an ERI interrupt request is generated.
5. If a framing error (when the stop bit is 0) is detected, the SSR.FER flag is set to 1 and receive data is transferred to the RDR register*1. If the SCR.RIE bit is 1 at this time, an ERI interrupt request is generated.
6. When reception finishes successfully, receive data is transferred to the RDR register*1. If the SCR.RIE bit is 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register*1 in this RXI interrupt handling routine before reception of the next receive data is completed. Reading the received data that have been transferred to the RDR register*1 causes the RTSn# pin to output the low level.

Note 1. Read data not in the RDR register but in the RDRH and RDRL registers when 9-bit data length is selected.
Note 2. The SCI checks for reading of the RDRL register only and does not check for reading of the RDRH register when 9-bit data length is selected.



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 32.18 Example of SCI Operation for Serial Reception in Asynchronous Mode (1) (When RTS Function is Not Used) (Example with 8-Bit Data, Parity, 1 Stop Bit)



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 32.19 Example of SCI Operation for Serial Reception in Asynchronous Mode (2) (When RTS Function is Used) (Example with 8-Bit Data, Parity, 1 Stop Bit)

Table 32.34 lists the states of the status flags in the SSR register and receive data handling when a receive error is detected.

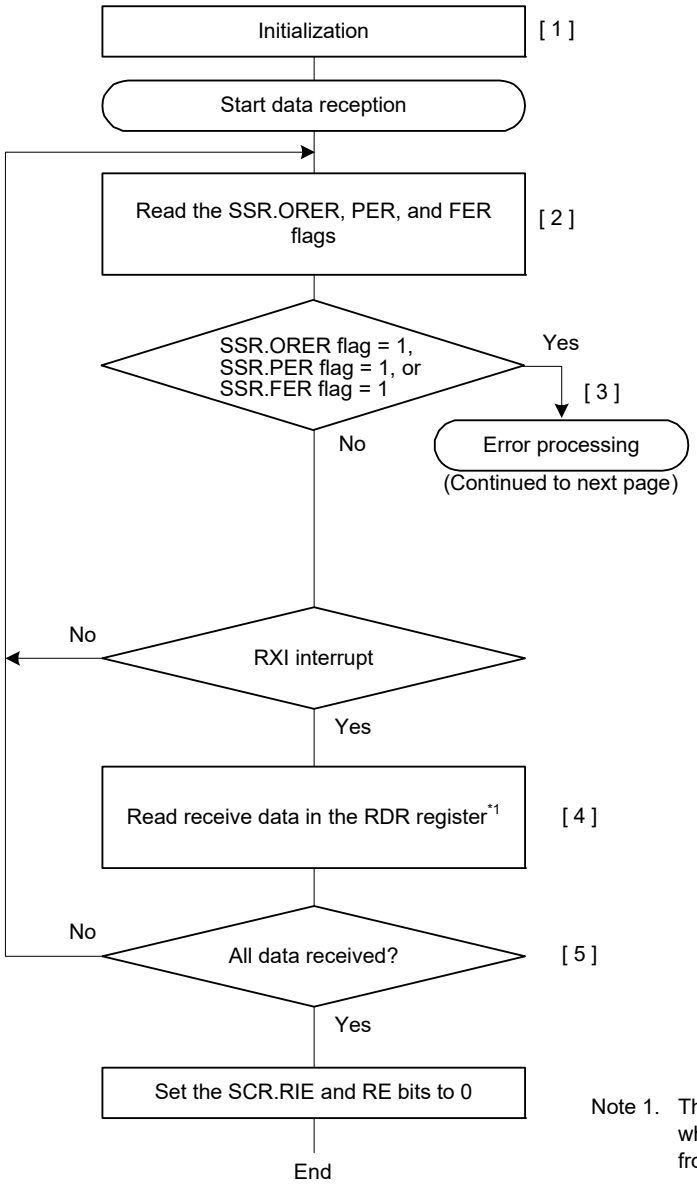
If a receive error is detected, an ERI interrupt request is generated but an RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, and PER flags to 0 before resuming reception. Moreover, be sure to read the RDR (or the RDRL) register during overrun error processing. When a reception is forcibly terminated by setting the SCR.RE bit to 0 during operation, read the RDR (or the RDRL) register because received data which has not yet been read may be left in the RDR (or the RDRL) register.

Figure 32.20 and Figure 32.21 show samples of flowcharts for serial data reception.

Table 32.34 Status Flags in the SSR Register and Receive Data Handling

Status Flags in the SSR Register				
ORER	**FER**	**PER**	**Receive Data**	**Receive Error Type**
1	0	0	Lost	Overrun error
0	1	0	Transferred to the RDR register*1	Framing error
0	0	1	Transferred to the RDR register*1	Parity error
1	1	0	Lost	Overrun error + framing error
1	0	1	Lost	Overrun error + parity error
0	1	1	Transferred to the RDR register*1	Framing error + parity error
1	1	1	Lost	Overrun error + framing error + parity error

Note 1. Read data not in the RDR register but in the RDRH and RDRL registers when 9-bit data length is selected.



[1] SCI initialization:
Set data reception.

[2] [3] Receive error processing and break detection:
If a receive error occurs, an ERI interrupt is generated. An error is identified by reading the ORER, PER, and FER flags in the SSR register. After performing the appropriate error processing, be sure to set the ORER, PER, and FER flags to 0. Reception cannot be resumed if any of these flags is set to 1. In the case of a framing error, a break can be detected by reading the value of the input port corresponding to the RXDn pin.

[4] Read the receive data in the RDR register once in the RXI interrupt handling routine.

[5] Serial reception continuation procedure:
To continue serial reception, before the stop bit of the current frame is received, read data from the RDR register in the RXI interrupt handling routine.
The RDR data can also be read by activating the DMAC or DTC.

Note 1. The RDR register becomes the RDRH and RDRL registers when 9-bit data length is selected. Read data in the order from the RDRH register to the RDRL register.

Figure 32.20 Example Flowchart of Serial Reception in Asynchronous Mode (1)

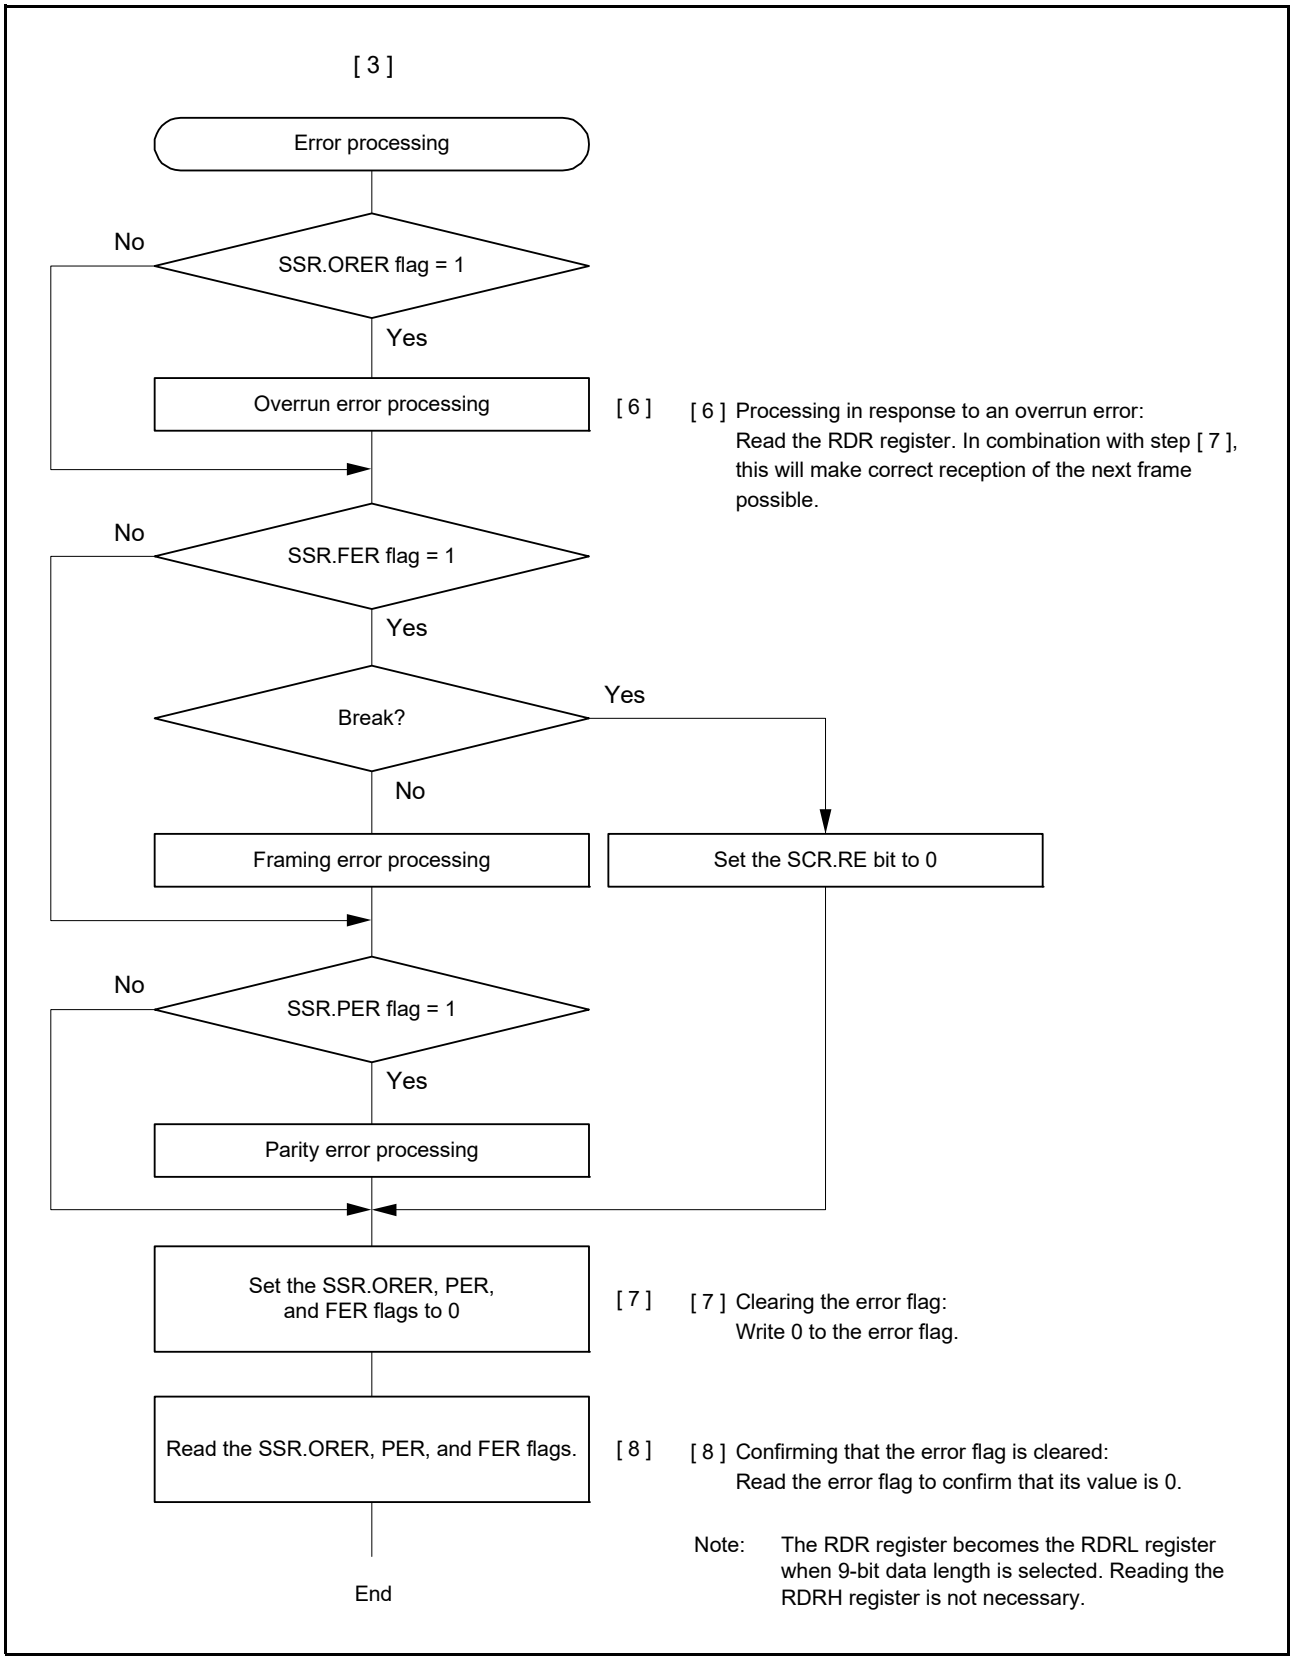


Figure 32.21 Example Flowchart of Serial Reception in Asynchronous Mode (2)

32.4 Multi-Processor Communications Function

Using the multi-processor communication functions enables to transmit and receive data by sharing a communication line between multiple processors by using asynchronous serial communication in which the multi-processor bit is added. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station. The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle. When the multi-processor bit is set to 1, it indicates the ID transmission cycle and when the multi-processor bit is set to 0, it indicates the data transmission cycle. Figure 32.22 shows an example of communication between processors by using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits the communication data in which the multi-processor bit set to 0 is added to the transmit data. Upon receiving the communication data in which the multi-processor bit is set to 1, the receiving station compares the received ID with the ID of the receiving station itself and if the two match, receives the communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until again receiving the communication data in which the multi-processor bit is set to 1.

For supporting this function, the SCI provides the SCR.MPIE bit. When the MPIE bit is set to 1, transfer of receive data from the RSR register to the RDR register (the RDRH and RDRL registers when 9-bit data length is selected), detection of a receive error, and setting the respective status flags RDRF, ORER, and FER in the SSR register are disabled until reception of data in which the multi-processor bit is set to 1. Upon receiving a reception character in which the multi-processor bit is set to 1, the SSR.MPB bit is set to 1 and the SCR.MPIE bit is automatically cleared, thus returning to a normal reception operation. During this time, an RXI interrupt is generated if the SCR.RIE bit is 1.

When the multi-processor format is specified, specification of the parity bit is disabled. Apart from this, there is no difference from the operation in the normal asynchronous mode. A clock which is used for the multi-processor communication is also the same as the clock used in the normal asynchronous mode.

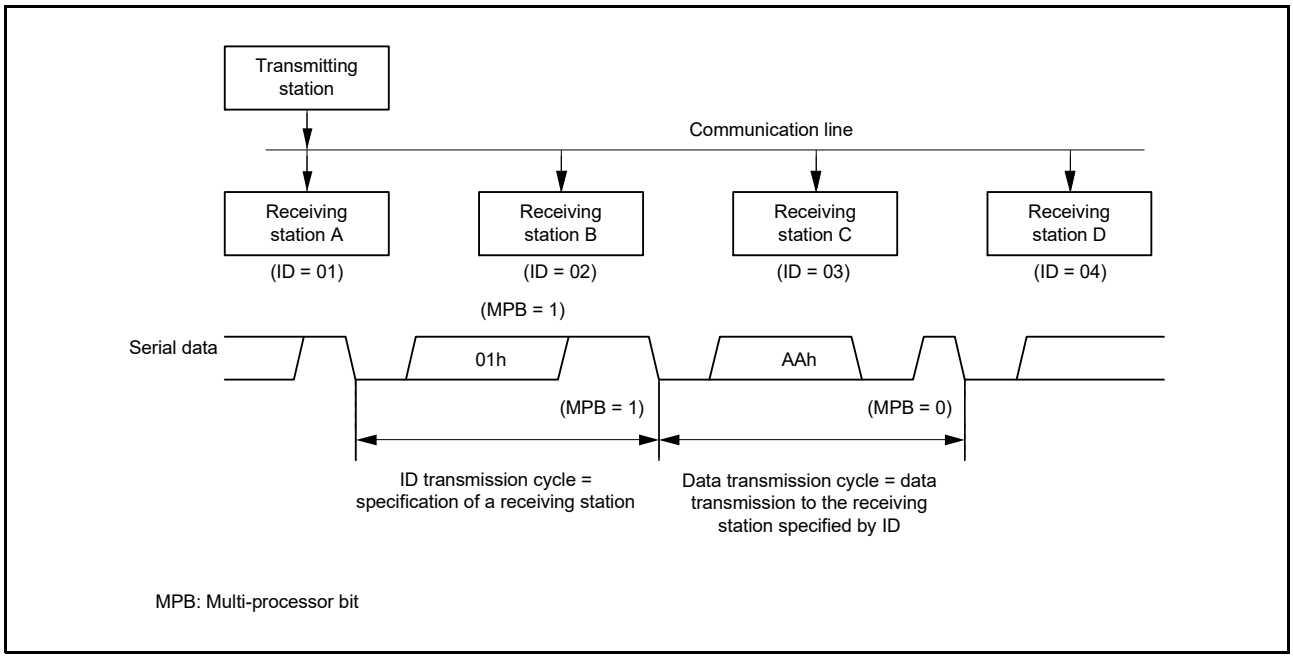

Figure 32.22 An Example of Communication using the Multi-Processor Format (Example of Transmission of Data AAh to Receiving Station A)

32.4.1 Multi-Processor Serial Data Transmission

Figure 32.23 is a sample flowchart of multi-processor data transmission. In the ID transmission cycle, the ID should be transmitted with the SSR.MPBT bit set to 1. In the data transmission cycle, the data should be transmitted with the MPBT bit set to 0. The other operations are the same as the operations in asynchronous mode.

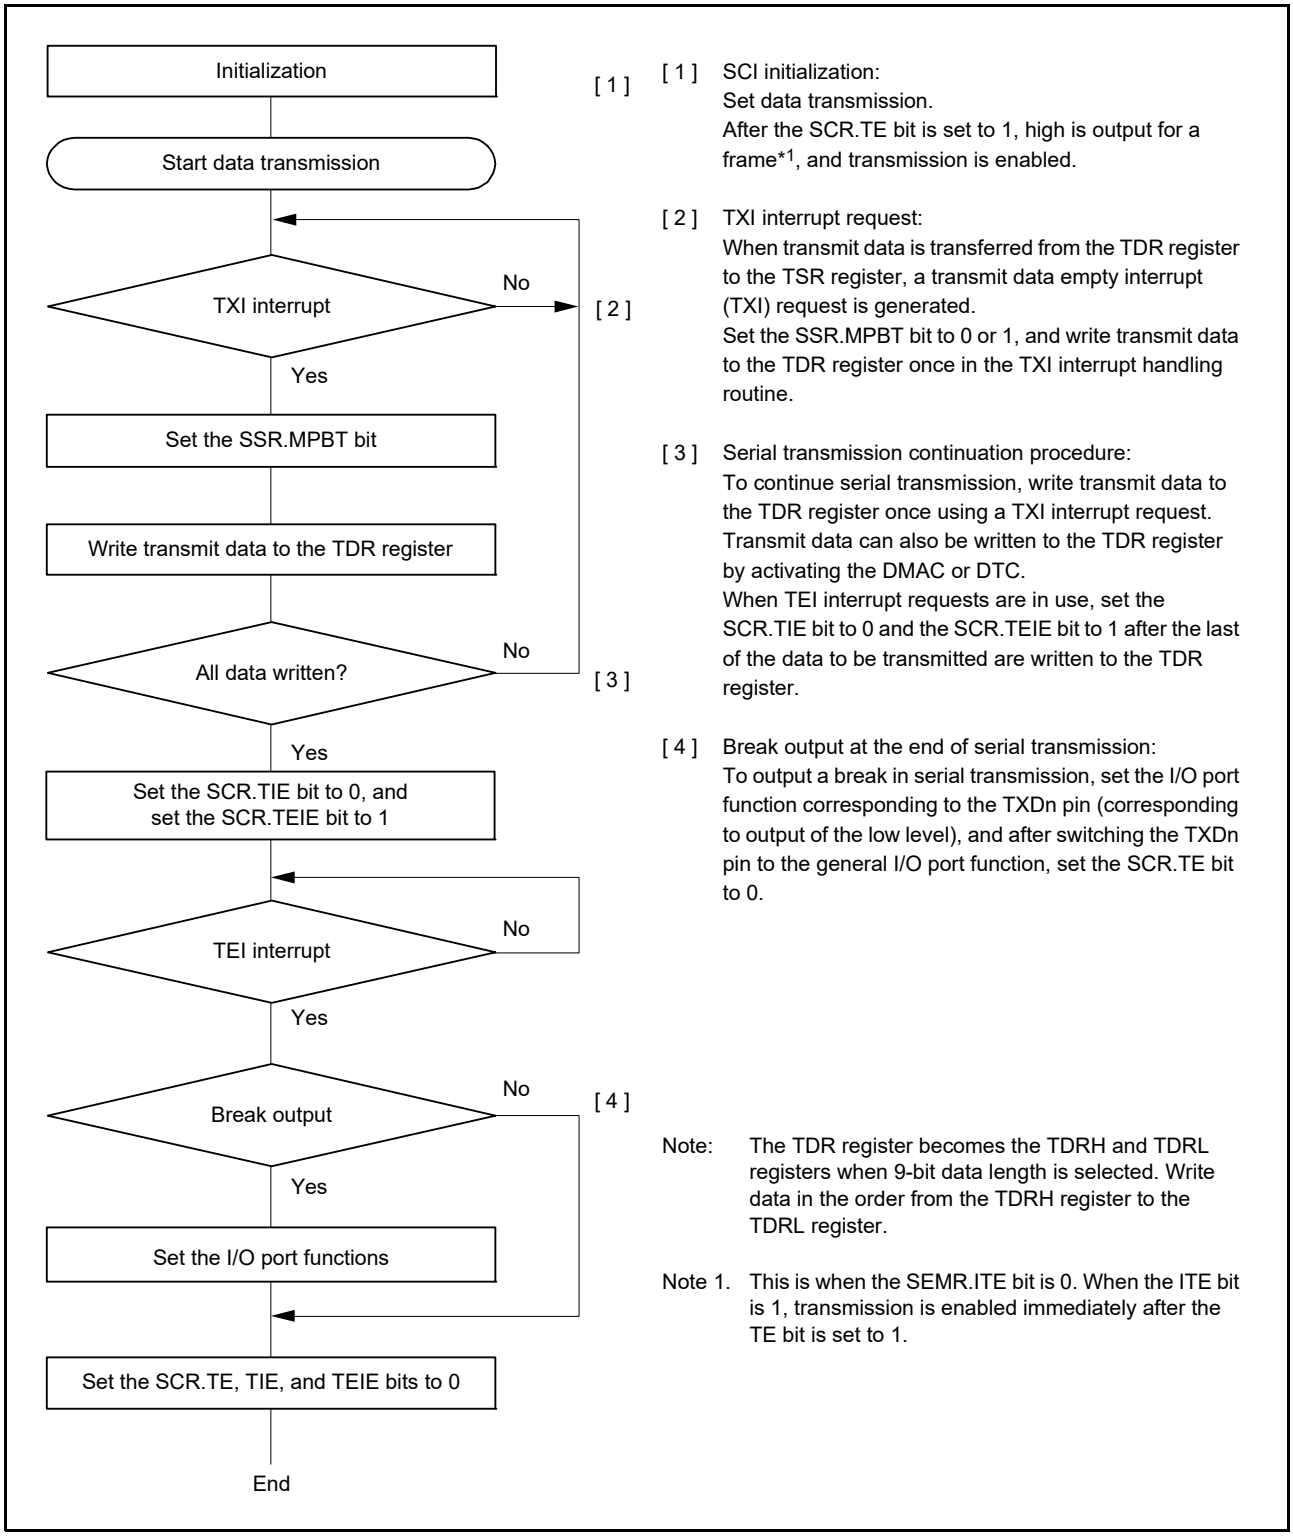

Figure 32.23 Example of Multi-Processor Serial Transmission Flowchart

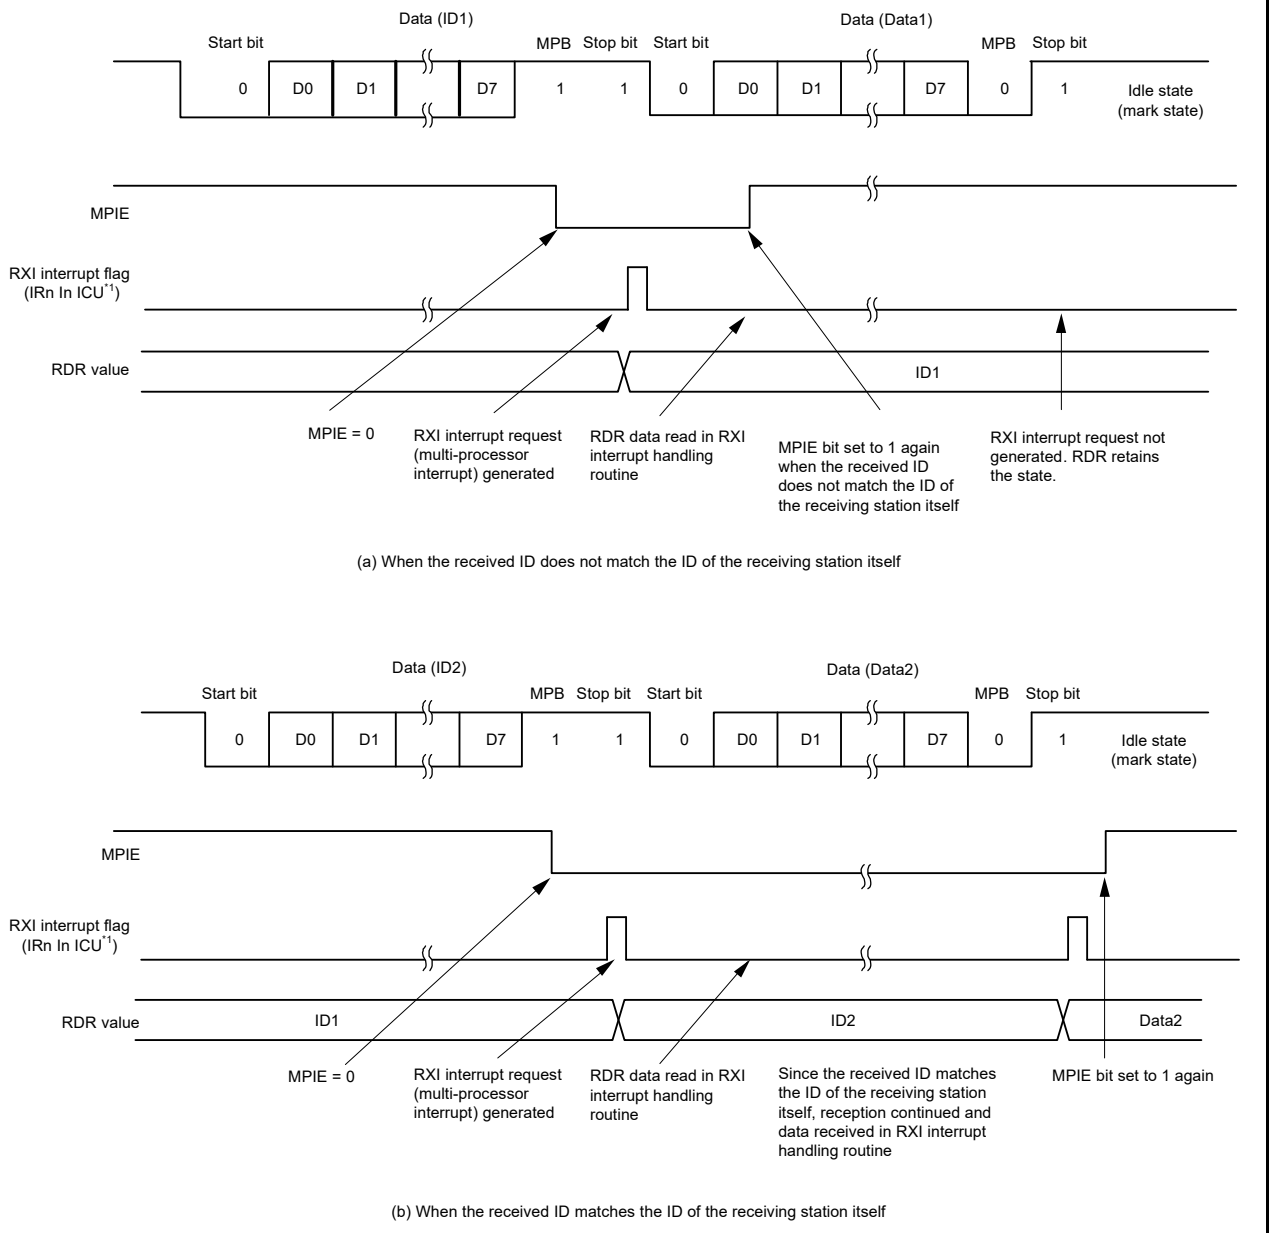
32.4.2 Multi-Processor Serial Data Reception

Figure 32.25 and Figure 32.26 are sample flowcharts of multi-processor data reception. When the SCR.MPIE bit is set to 1, reading the communication data is skipped until reception of the communication data in which the multi-processor bit is set to 1. When the communication data in which the multi-processor bit is set to 1 is received, the received data is transferred to the RDR register (the RDRH and RDRL registers when 9-bit data length is selected). During this time, the RXI interrupt request is generated. The other operations are the same as the operations in asynchronous mode.
Figure 32.24 is the example of operation for reception.



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 32.24 Example of SCI Reception (8-Bit Data/Multi-Processor Bit/1 Stop Bit)

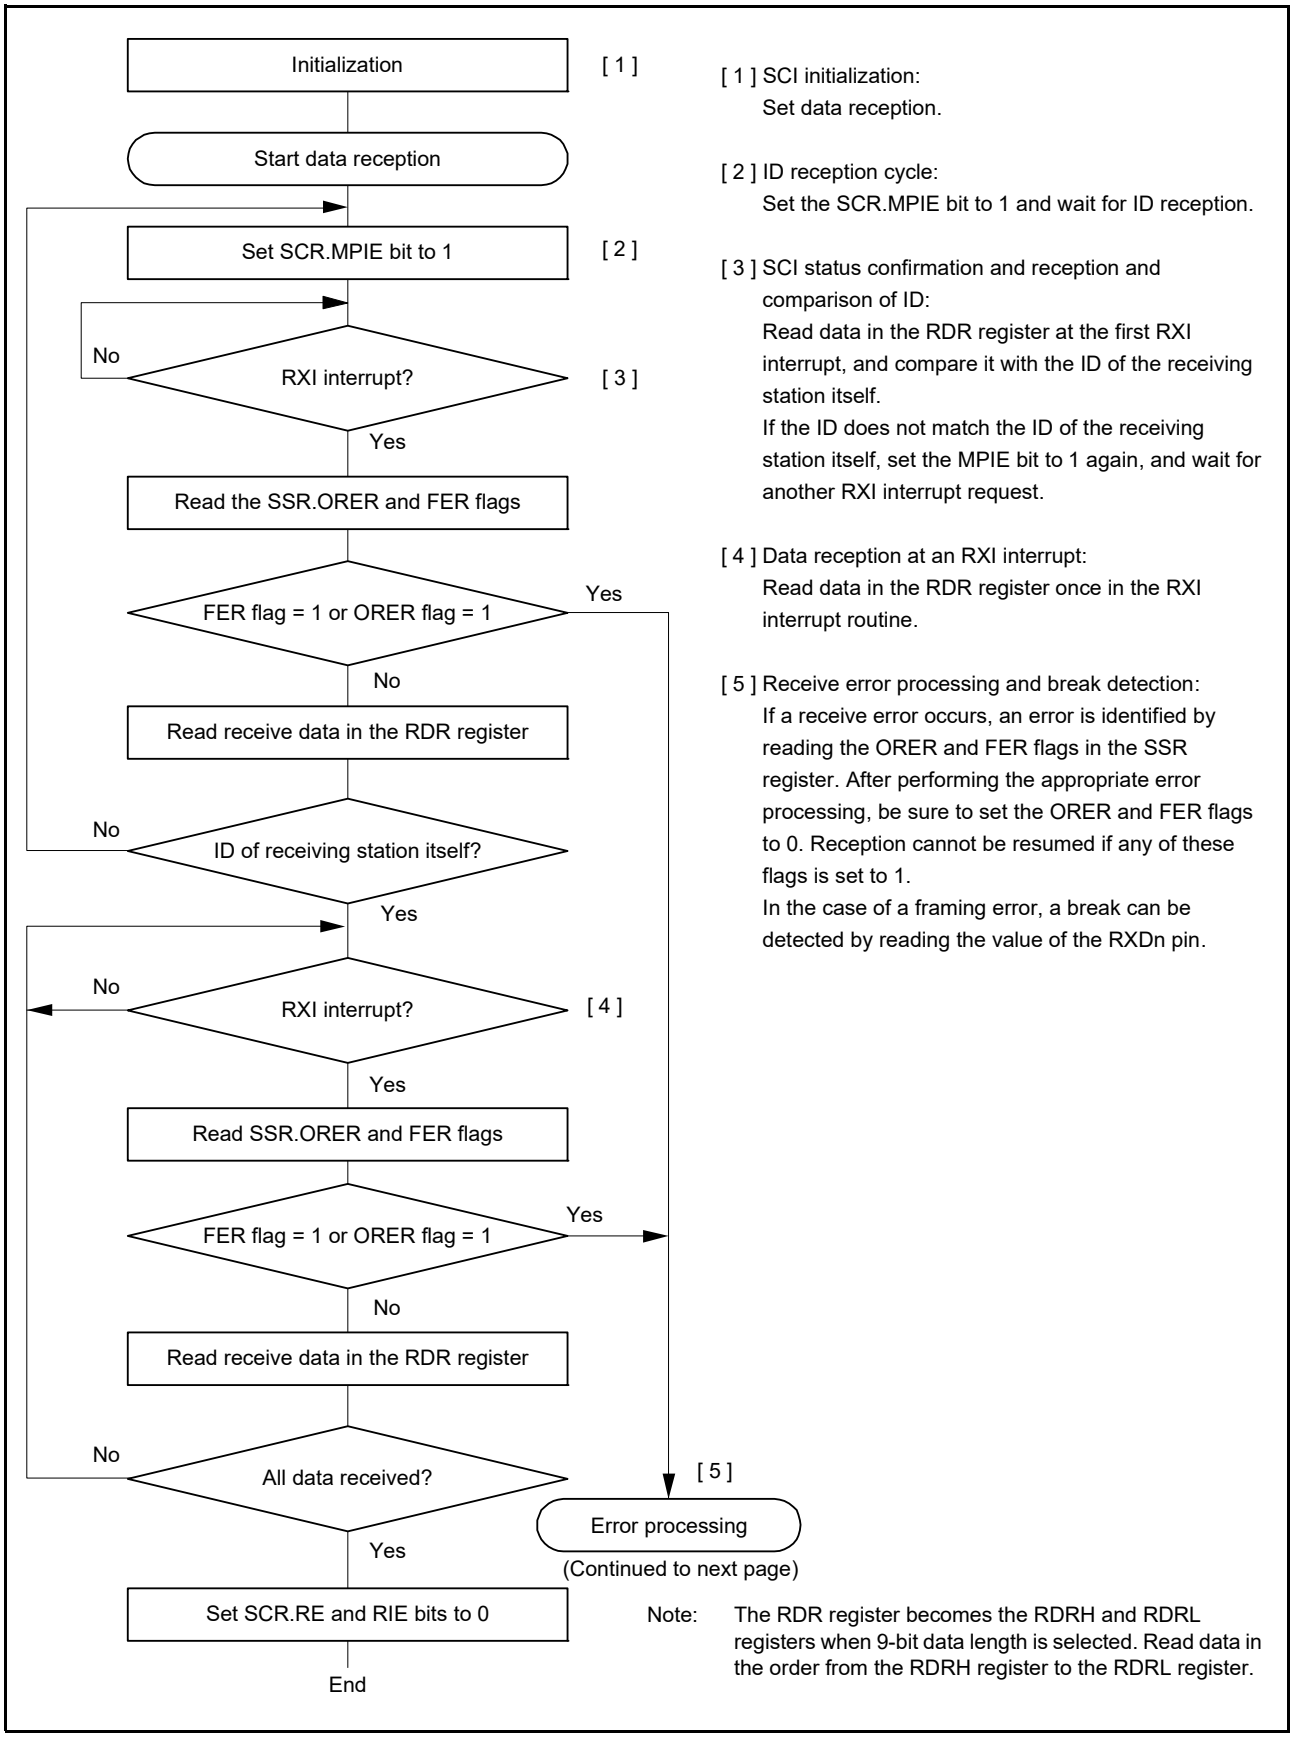


Figure 32.25 Example of Multi-Processor Serial Reception Flowchart (1)

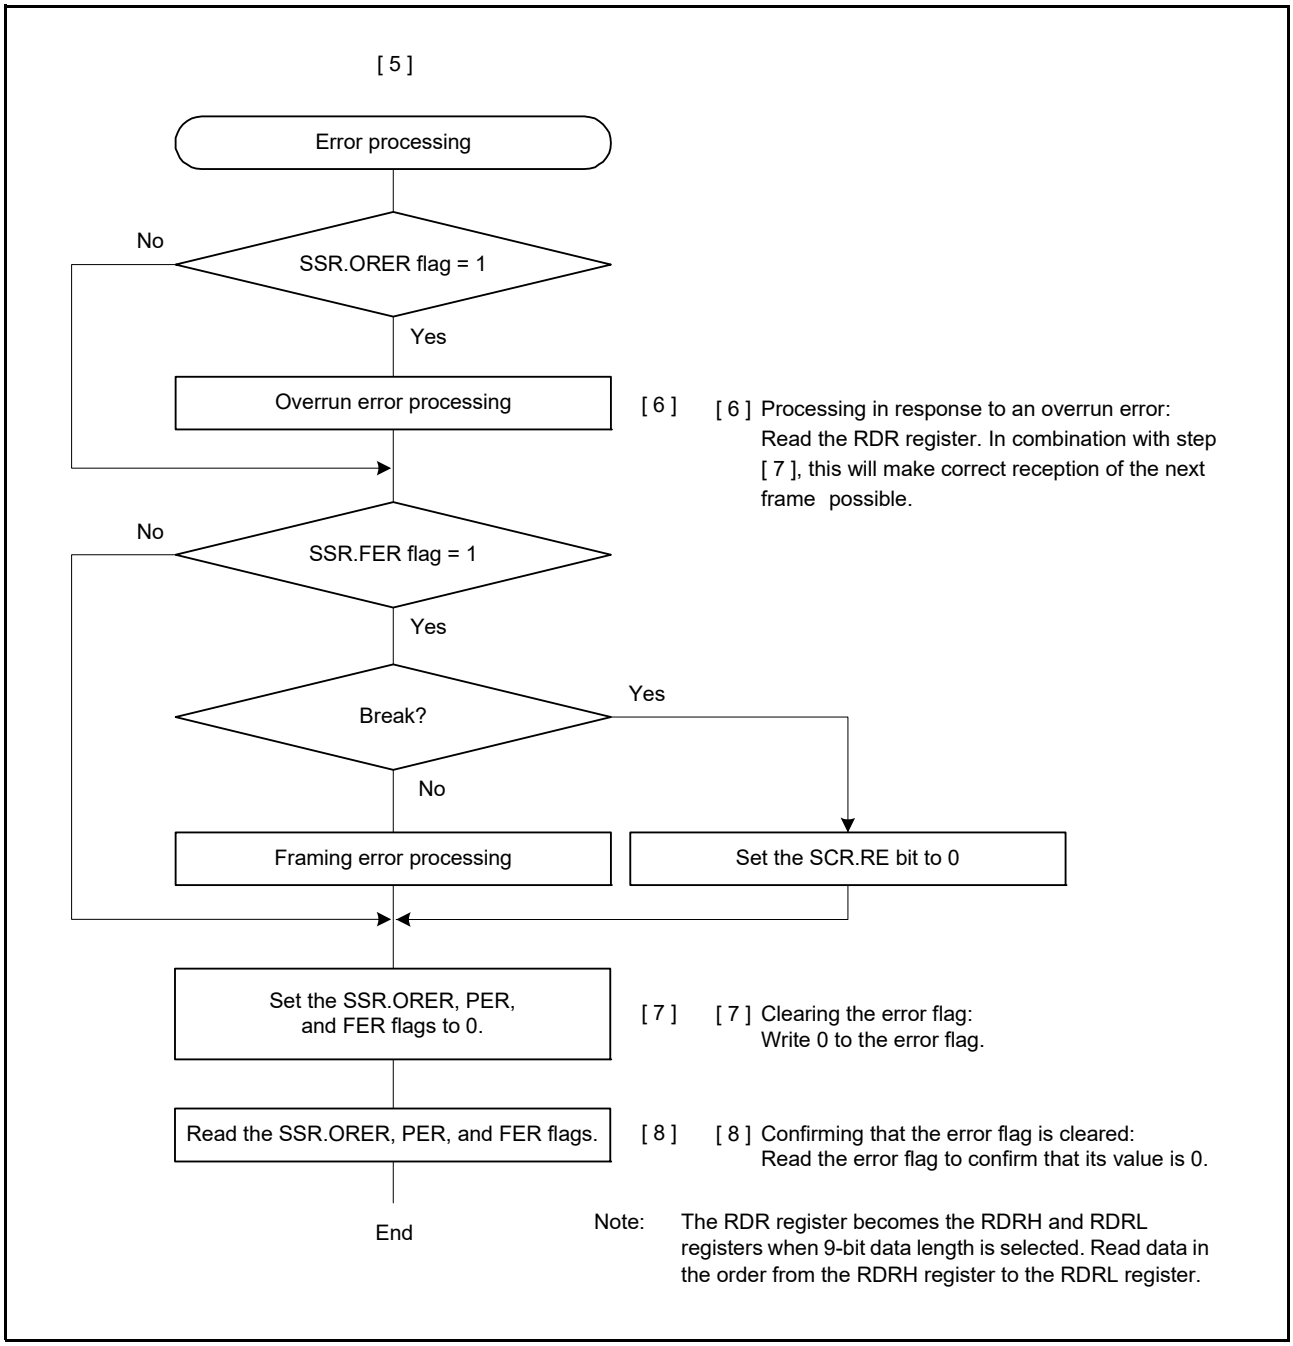

Figure 32.26 Example of Multi-Processor Serial Reception Flowchart (2)

32.5 Operation in Clock Synchronous Mode

Figure 32.27 shows the data format for clock synchronous serial data communications.
In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. One character in transfer data consists of 8-bit data. In clock synchronous mode, no parity bit can be added.
In data transmission, the SCI outputs data from one falling edge of the synchronization clock to the next. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the communication line holds the last bit output state.
Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications by use of a common clock. Both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

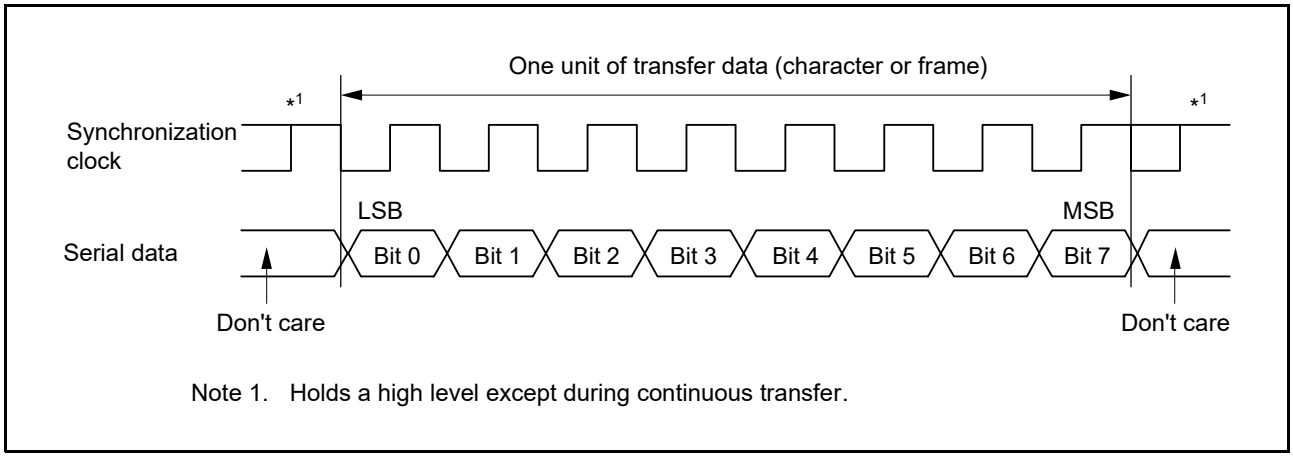

Figure 32.27 Data Format in Clock Synchronous Serial Communications (LSB First)

32.5.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCKn pin can be selected, according to the setting of the SCR.CKE[1:0] bits.
When the SCI is operated on an internal clock, the synchronization clock is output from the SCKn pin. Eight synchronization clock pulses are output in the transfer of one character, and when no transfer is performed the clock is held high. However, when only data reception is performed while the CTS function is disabled, the synchronization clock output is started at the same time when the SCR.RE bit set to 1. The synchronization clock is stopped at the high level when an overrun error occurs or the SCR.RE bit is set to 0.
When only data reception is performed and the CTS function is enabled, the clock output is not started even when the SCR.RE bit set to 1 if the CTSn# pin input is high when the SCR.RE bit is 0. The synchronization clock output is started when the SCR.RE bit is set to 1 and the CTSn# pin input is low. After that, if the CTSn# pin input is high on completion of the frame reception, the synchronization clock output is stopped at the high level. If the CTSn# pin input continues to be low, the synchronization clock is stopped at the high level when an overrun error occurs or the SCR.RE bit is set to 0.

32.5.2 CTS and RTS Functions

In the CTS function, CTSn# pin input is used to control reception/transmission start when the clock source is the internal clock. Setting the SPMR.CTSE bit to 1 enables the CTS function.
When the CTS function is enabled, placing the low level on the CTSn# pin causes reception/transmission to start. Applying the high level to the CTS# pin while reception/transmission are in progress does not affect reception/transmission of the current frame, which continues.
In the RTS function, RTSn# pin output is used to request reception/transmission start when the clock source is an external synchronizing clock. A low level is output when serial communications become possible. Conditions for output of the low and high level are shown below.

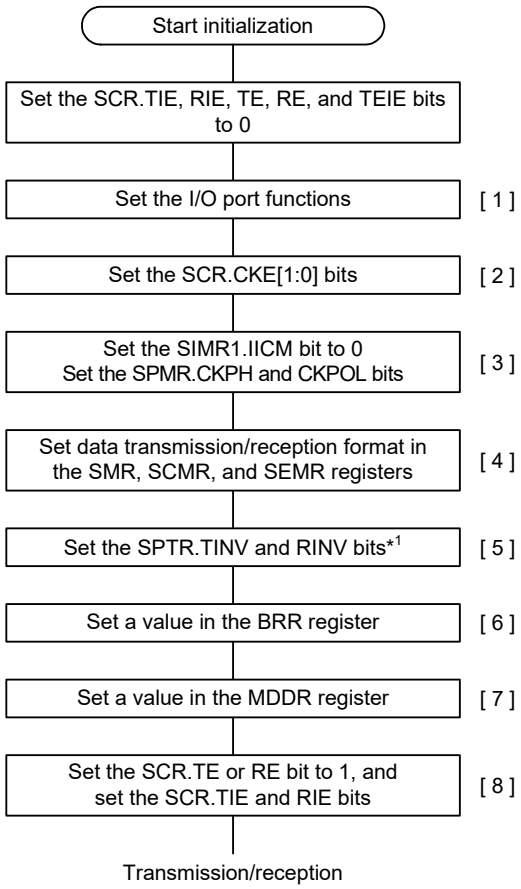
[Conditions for low-level output]
When the following conditions are all satisfied.

- The SCR.RE or SCR.TE bit is 1.
- Transmission or reception is not in progress.
- There are no received data yet to be read (when the SCR.RE bit is 1).
- Untransmitted data is present (when the SCR.TE bit is 1).
- The SSR.ORER flag is 0.

[Condition for high-level output]
The conditions for low-level output have not been satisfied.

32.5.3 SCI Initialization (Clock Synchronous Mode)

Before transmitting and receiving data, start by writing the initial value 00h to the SCR register and then continue through the procedure for SCI given in Figure 32.28. Whenever the operating mode or transfer format is changed, the SCR register must be initialized before the change is made.
Note that setting the SCR.RE bit to 0 initializes neither the ORER, FER, and PER flags in the SSR register nor the RDR register.



[1] Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.

[2] Set the clock selection in the SCR register.
When an internal clock is selected, the SCK pin functions as the clock output pin.

[3] Set the SIMR1.IICM bit to 0.
Set the SPMR.CKPH and CKPOL bits.
Step [3] can be skipped if the values have not been changed from the initial values.

[4] Set the data transmission/reception format in the SMR, SCMR, and SEMR registers.

[5] Set the polarities of transmit/receive signals by the SPTR.TINV and RINV bits*1.

[6] Write a value corresponding to the bit rate to the BRR register. This step is not necessary if an external clock is used.

[7] Write the value obtained by correcting a bit rate error in the MDDR register. This step is not necessary if the SEMR.BRME bit is set to 0 or an external clock is used.

[8] Set the SCR.TE or RE bit to 1. At this time, also set the SCR.TIE and RIE bits.
Setting the TE and RE bits allows TXDn and RXDn to be used.

Note: In simultaneous transmit and receive operations, the SCR.TE and RE bits should both be set to 0 or 1 simultaneously.
Note 1. Only for SCI1, SCI5, and SCI6.

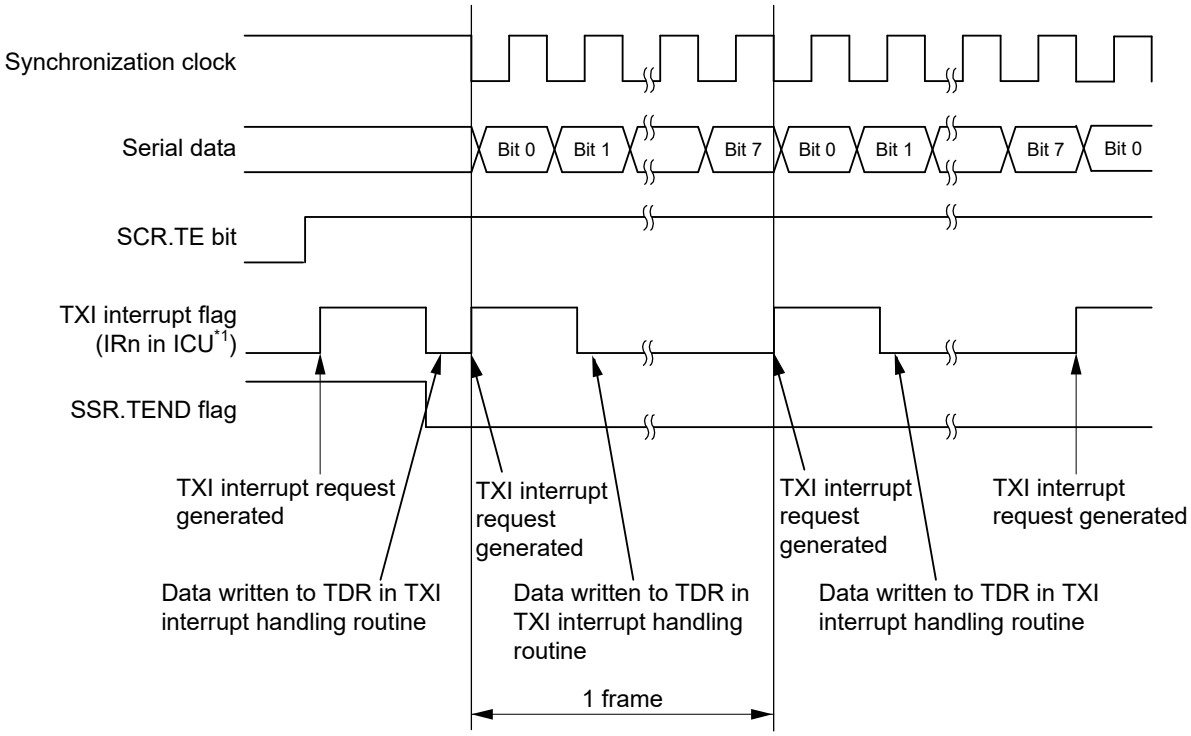
Figure 32.28 Example of SCI Initialization Flowchart (Clock Synchronous Mode)

32.5.4 Serial Data Transmission (Clock Synchronous Mode)

Figure 32.29, Figure 32.30, and Figure 32.31 show an example of the operation for serial transmission in clock synchronous mode.
In serial data transmission, the SCI operates as described below.

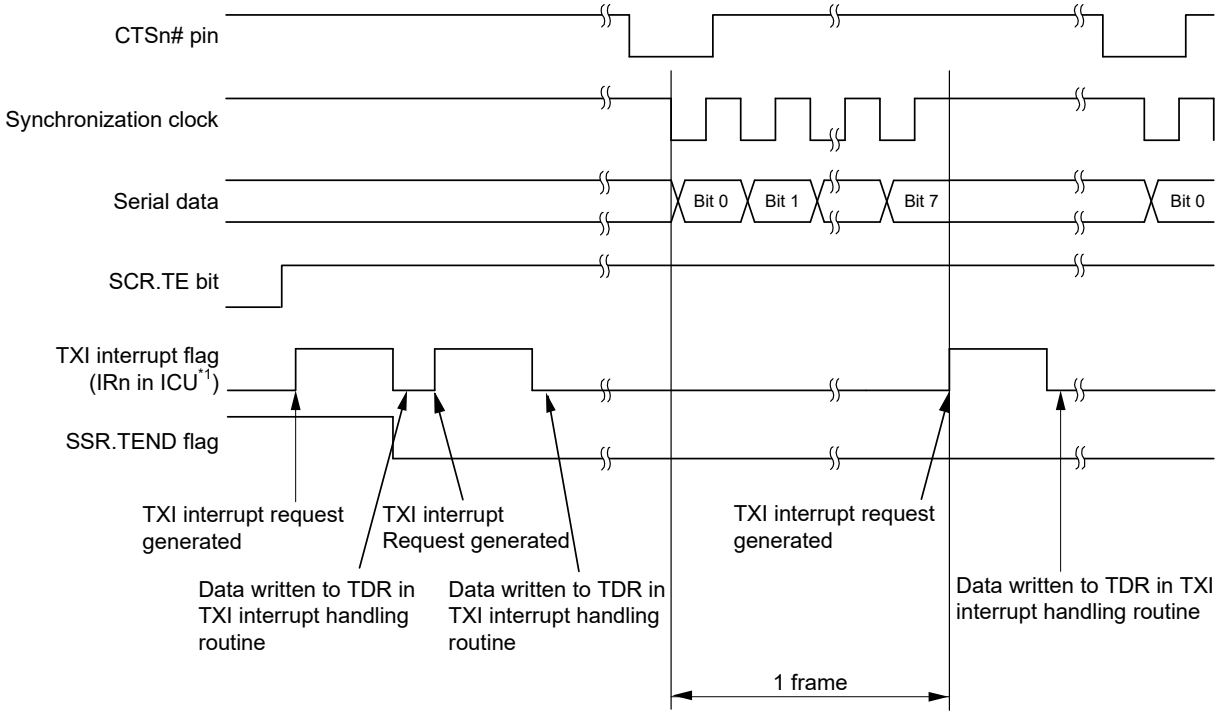
1. The SCI transfers data from the TDR register to the TSR register when data is written to the TDR register in the TXI interrupt handling routine. The TXI interrupt request at the beginning of transmission is generated when the SCR.TE bit is set to 1 after the SCR.TIE bit is set to 1 or when these 2 bits are set to 1 simultaneously by a single instruction.
2. After transferring data from the TDR register to the TSR register, the SCI starts transmission. When the SCR.TIE bit is set to 1 at this time, a TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to the TDR register in this TXI interrupt handling routine before transmission of the current transmit data has finished. When TEI interrupt requests are in use, set the SCR.TIE bit to 0 (a TXI interrupt request is disabled) and the SCR.TEIE bit to 1 (a TEI interrupt request is enabled) after the last of the data to be transmitted are written to the TDR register from the handling routine for TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when clock output mode has been specified and in synchronization with the input clock when use of an external clock has been specified. Output of the clock signal is suspended until the input CTS signal is at the low level while the SPMR.CTSE bit is 1 (CTS function is enabled).
4. The SCI checks for updating of (writing to) the TDR register at the time of the last bit output.
5. When TDR is updated, the next transmit data is transferred from the TDR register to the TSR register, and serial transmission of the next frame is started.
6. If the TDR register is not updated, set the SSR.TEND flag to 1 and the TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1 at this time, a TEI interrupt request is generated. The SCKn pin is held high.

Figure 32.32 shows a sample flowchart of serial data transmission.
Transmission will not start while a receive error flag (ORER, FER, or PER in the SSR register) is set to 1. Be sure to set the receive error flags to 0 before starting transmission. Note that setting the SCR.RE bit to 0 does not clear the receive error flags.



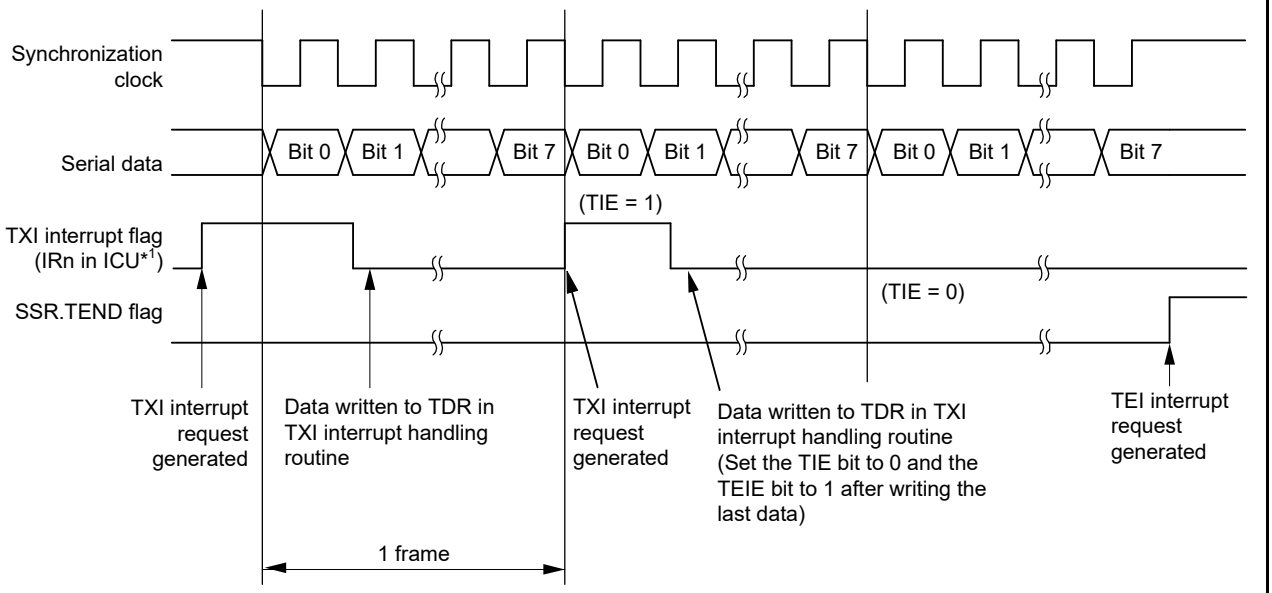
Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 32.29 Example of Serial Data Transmission in Clock Synchronous Mode When the CTS Function is Not Used at the Beginning of Transmission



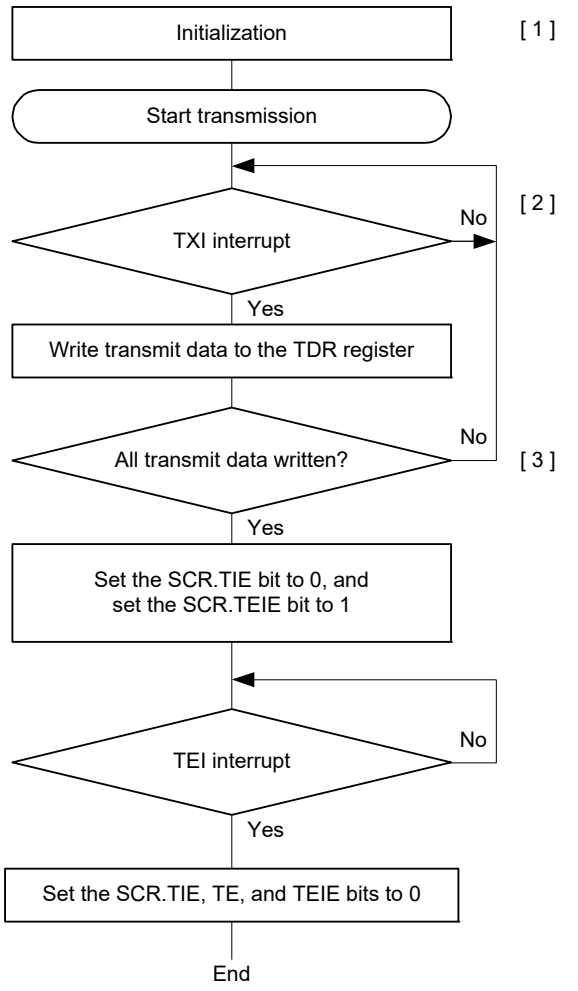
Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 32.30 Example of Serial Data Transmission in Clock Synchronous Mode When the CTS Function is Used at the Beginning of Transmission



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 32.31 Example of Serial Data Transmission in Clock Synchronous Mode from the Middle of Transmission until Transmission Completion



[1] SCI initialization:
Set data transmission.

[2] Writing transmit data write to the TDR register by a TXI interrupt request:
When transmit data is transferred from the TDR register to the TSR register, a transmit data empty interrupt (TXI) request is generated.
Transmit data is written to the TDR register once from the handling routine for TXI requests.

[3] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to the TDR register upon accepting a transmit data empty interrupt (TXI) request. Transmit data can also be written to the TDR register by activating the DMAC or DTC by the TXI interrupt request.
When TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted are written to the TDR register.

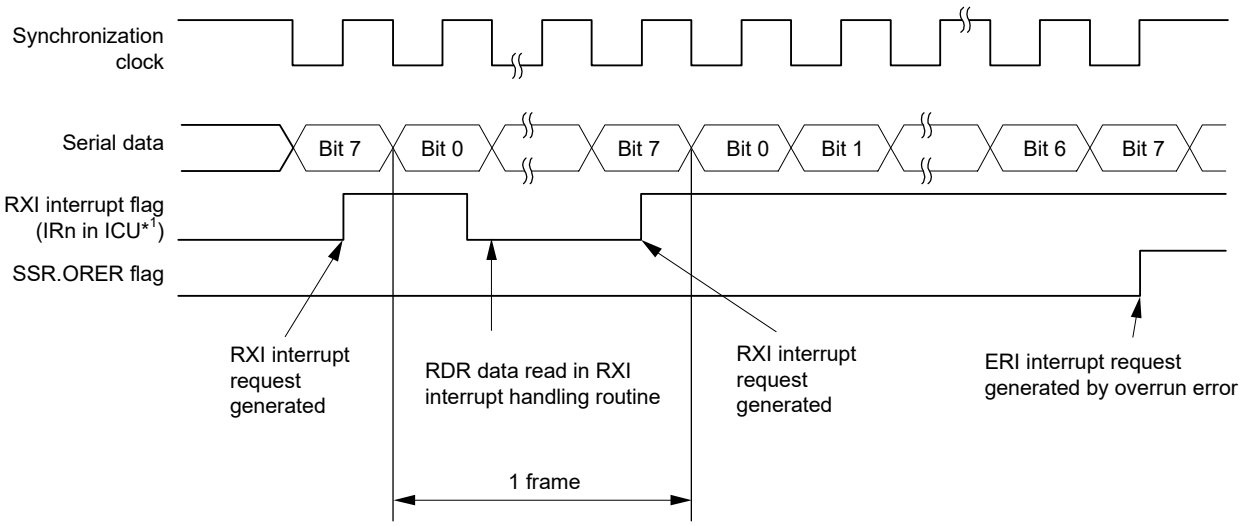
Note: When the external clock is in use (the value of the SCR.CKE[1:0] bits is 10b or 11b), the rising edge on the SCK pin for the last bit sets the SSR.TEND flag to 1. Setting the SCR.TE bit to 0 immediately after this may lead to insufficient received-data hold time on the receiver side.

Figure 32.32 Example Flowchart of Serial Transmission in Clock Synchronous Mode

32.5.5 Serial Data Reception (Clock Synchronous Mode)

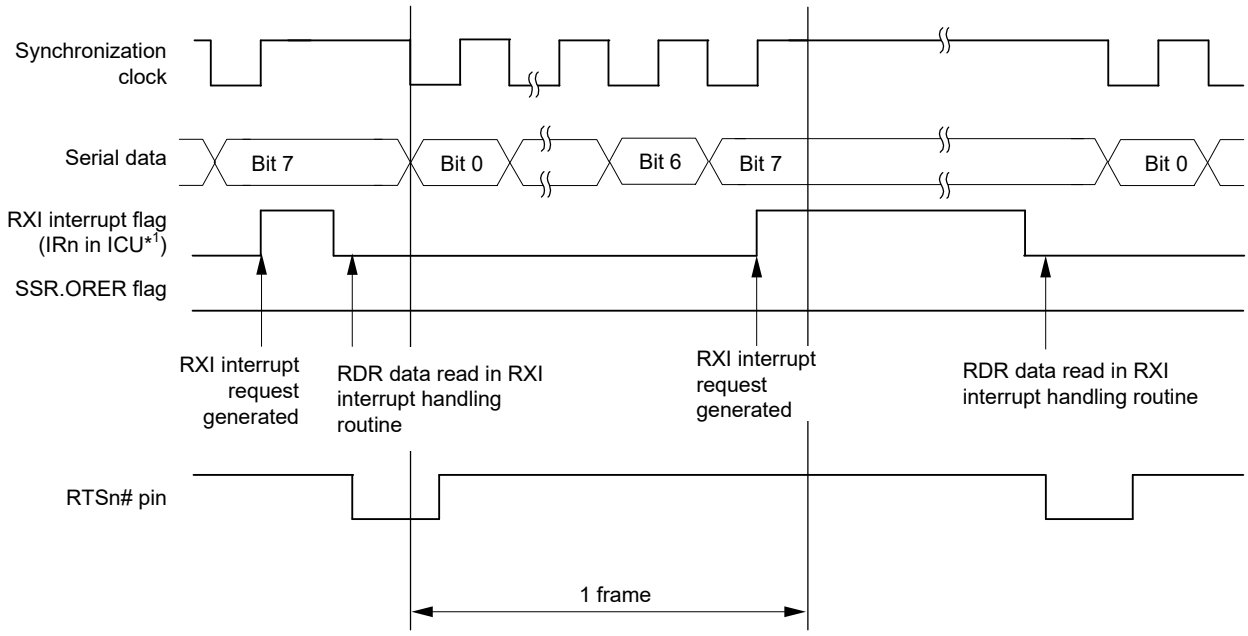
Figure 32.33 and Figure 32.34 show an example of SCI operation for serial reception in clock synchronous mode. In serial data reception, the SCI operates as described below.

1. The value of the SCR.RE bit becoming 1 places the signal output on the RTSn# pin at the low level (when the RTS function is in use).
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.
3. If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to the RDR register.
4. When reception finishes successfully, receive data is transferred to the RDR register. If the SCR.RIE bit is 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register in this RXI interrupt handling routine before reception of the next receive data is completed. Reading out the received data that have been transferred to the RDR register causes the RTSn# pin to output the low level (when the RTS function is in use).



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 32.33 Example of Operation for Serial Reception in Clock Synchronous Mode (1) (When RTS Function is Not Used)

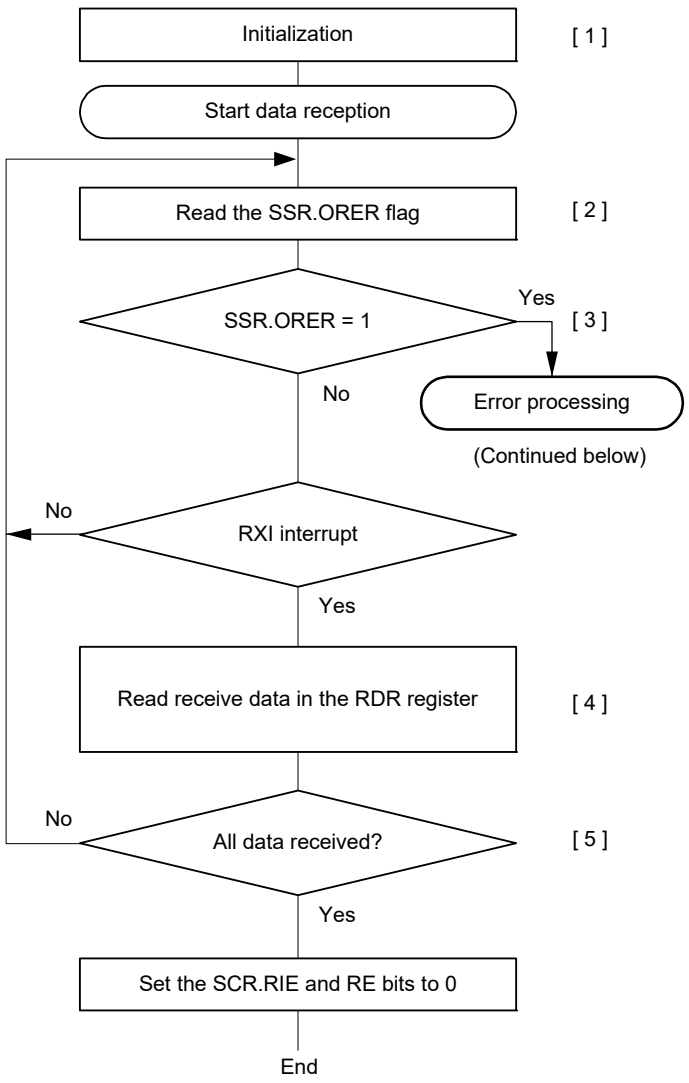


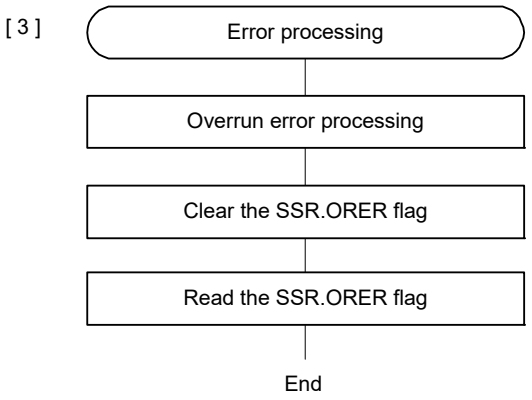
Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 32.34 Example of Operation for Serial Reception in Clock Synchronous Mode (2) (When RTS Function is Used)

Data transfer cannot be resumed while a receive error flag is 1. Accordingly, clear the ORER, FER, and PER flags in the SSR register before resuming reception. Moreover, be sure to read the RDR register during overrun error processing. When a reception is forcibly terminated by setting the SCR.RE bit to 0 during operation, read the RDR register because received data which has not yet been read may be left in the RDR register.

Figure 32.35 shows a sample flowchart for serial data reception.





[1] SCI initialization:
Make input port-pin settings for pins to be used as RXDn pins.

[2] [3] Receive error processing:
If a receive error occurs, read the SSR.ORER flag, perform the relevant error processing, and then set the ORER flag to 0. Data reception cannot be resumed while the ORER flag is 1.

[4] Read the receive data in the RDR register once in the receive data full interrupt (RXI) request handling routine.

[5] Serial reception continuation procedure:
To continue serial reception, before the MSB (bit 7) of the current frame is received, finish reading the receive data in the RDR register. The RDR data can also be read by activating the DMAC or DTC by an RXI interrupt request.

[6] Processing in response to an overrun error:
Read the RDR register. In combination with step [7], this will make correct reception of the next frame possible.

[7] Clearing the error flag:
Write 0 to the error flag.

[8] Confirming that the error flag is cleared:
Read the error flag to confirm that its value is 0.

Figure 32.35 Example Flowchart of Serial Reception in Clock Synchronous Mode

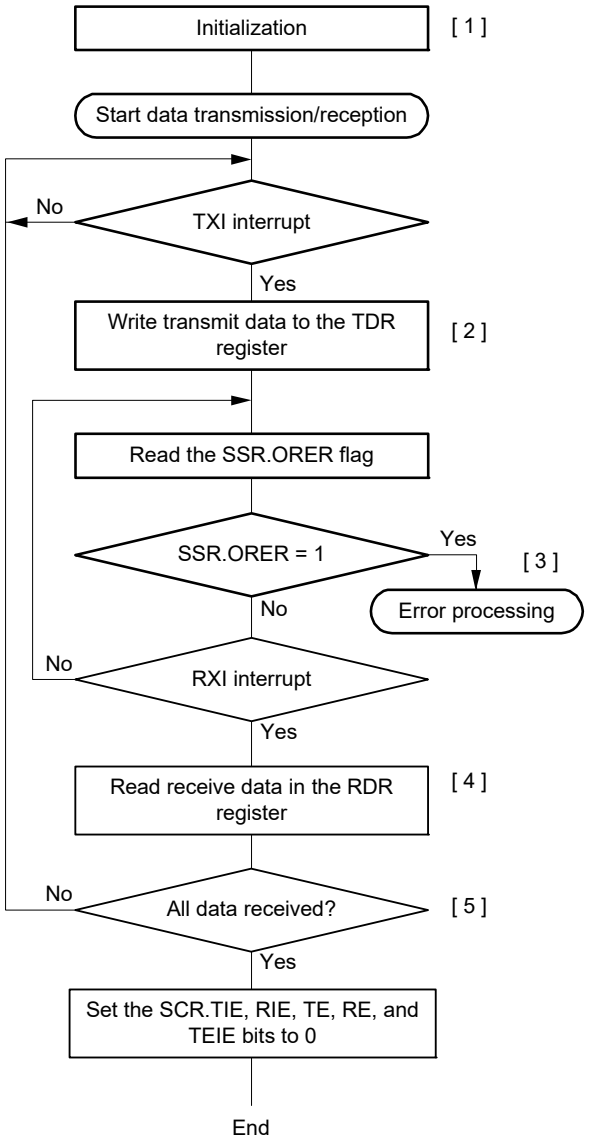
32.5.6 Simultaneous Serial Data Transmission and Reception (Clock Synchronous Mode)

Figure 32.36 shows a sample flowchart for simultaneous serial transmit and receive operations in clock synchronous mode.

After initializing the SCI, the following procedure should be used for simultaneous serial data transmit and receive operations.

To switch from transmit mode to simultaneous transmit and receive mode, check that the SCI has finished transmission by reading that the SSR.TEND flag is 1, and then initialize the SCR register. Then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode, check that the SCI has finished reception, and then set the RIE and RE bits to 0. Then check that the receive error flags (ORER, FER, and PER in the SSR register) are 0, and then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.



[1] SCI initialization:
The TXDn pin can act as the output pin for transmitted data and the RXDn pin can act as the input pin for received data at the same time.

[2] Transmit data write:
Write transmit data to the TDR register once in the TXI interrupt handling routine.

[3] Receive error processing:
If a receive error occurs, read the SSR.ORER flag, perform the relevant error processing, and then set the ORER flag to 0. Data reception cannot be resumed while the ORER flag is 1.

[4] Reading receive data:
Read the receive data in the RDR register once in the RXI interrupt request handling routine.

[5] Serial transmission/reception continuation procedure:
To continue serial transmission and reception, before the MSB (bit 7) of the current frame is received, finish reading the receive data in the RDR register by the RXI interrupt. Also, before the MSB (bit 7) of the current frame is transmitted, write data to the TDR register by the TXI interrupt. Transmit data can also be written to the TDR register by activating the DMAC or DTC by a transmit data empty interrupt (TXI) request. Similarly, the RDR data can also be read by activating the DMAC or DTC by a receive data full interrupt (RXI) request.

Note: When switching from transmit or receive operation to simultaneous transmit and receive operations first set the TIE, RIE, TE, RE, and TEIE bits in the SCR register to 0, and then set TIE, RIE, TE, and RE bits to 1 simultaneously.

Figure 32.36 Example Flowchart of Simultaneous Serial Transmission and Reception in Clock Synchronous Mode

32.6 Operation in Smart Card Interface Mode

The SCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function of the SCI.
Smart card interface mode can be selected using the appropriate register.

32.6.1 Sample Connection

Figure 32.37 shows a sample connection between a smart card (IC card) and this MCU.
As in the figure, since this MCU communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor.
Setting the TE and RE bits in the SCR register to 1 with an IC card disconnected enables closed transmission/reception allowing self-diagnosis.
To supply an IC card with the clock pulses generated by the SCI, input the SCKn pin output to the CLK pin of an IC card.
The output port of the this MCU can be used to output a reset signal.

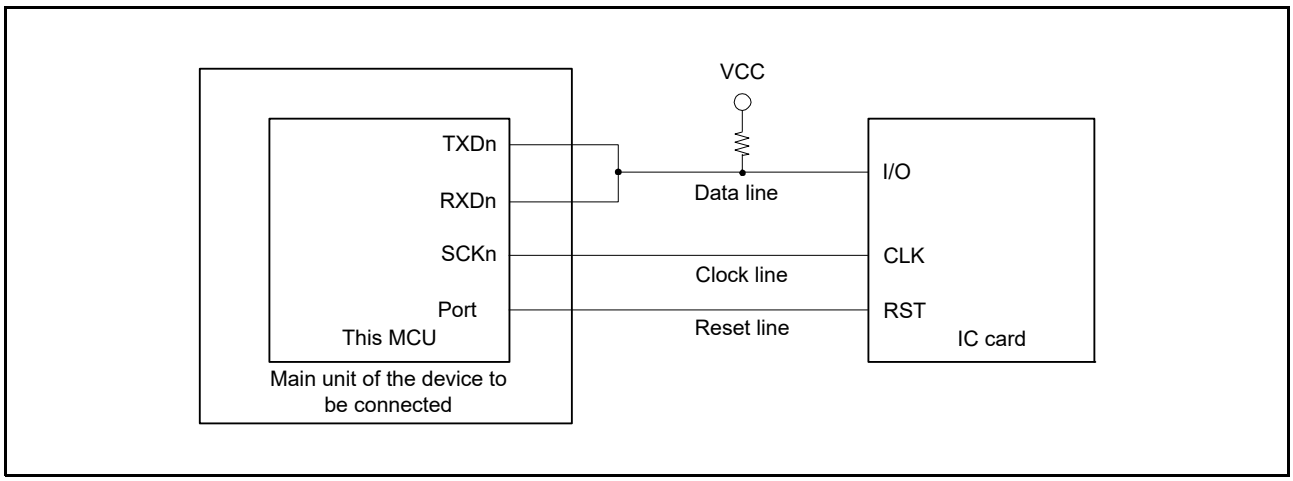


Figure 32.37 Sample Connection with a Smart Card (IC Card)

32.6.2 Data Format (Except in Block Transfer Mode)

Figure 32.38 shows the data transfer formats in smart card interface mode.

- One frame consists of 8-bit data and a parity bit in asynchronous mode.
- During transmission, at least 2 etu (elementary time unit: time required for transferring 1 bit) is secured as a guard time from the end of the parity bit until the start of the next frame.
- If a parity error is detected during reception, a low-level error signal is output for 1 etu after 10.5 etu has passed from the start bit.
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 etu.

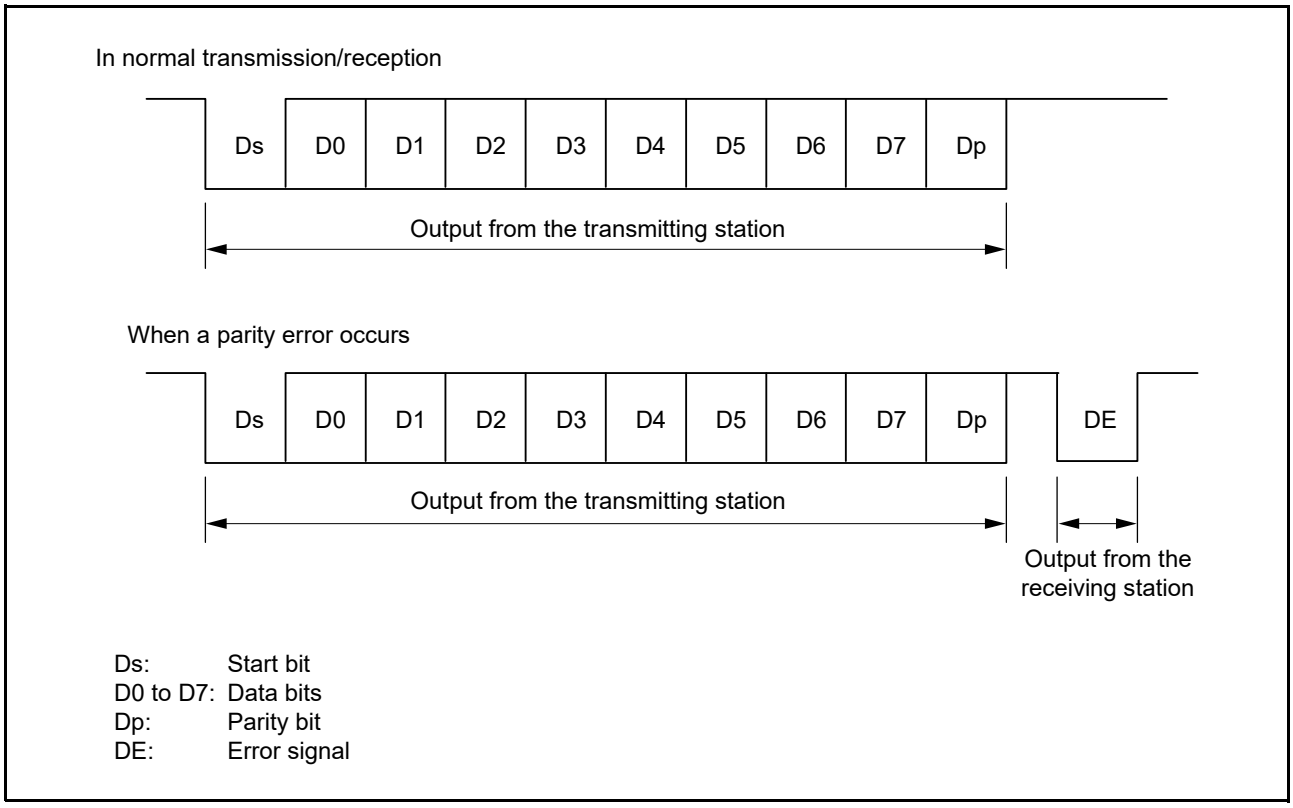

Figure 32.38 Data Formats in Smart Card Interface Mode

For communications with IC cards of the direct convention type and inverse convention type, follow the procedure below.

(1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 correspond to states Z and A, respectively, and data is transferred with LSB first as the start character, as shown in Figure 32.39. Therefore, data in the start character in the figure is 3Bh. When using the direct convention type, write 0 to both the SDIR and SINV bits in the SCMR register. Write 0 to the SMR.PM bit in order to use even parity, which is prescribed by the smart card standard.

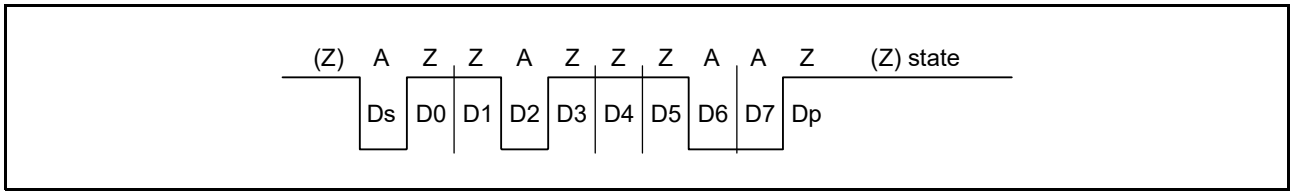

Figure 32.39 Direct Convention (SCMR.SDIR bit = 0, SCMR.SINV bit = 0, SMR.PM bit = 0)

(2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 correspond to states A and Z, respectively and data is transferred with MSB first as the start character, as shown in Figure 32.40. Therefore, data in the start character in the figure is 3Fh. When using the inverse convention type, write 1 to both the SDIR and SINV bits in the SCMR register. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to state Z. Since the SINV bit of the this MCU only inverts data bits D7 to D0, write 1 to the SMR.PM bit to invert the parity bit for both transmission and reception.

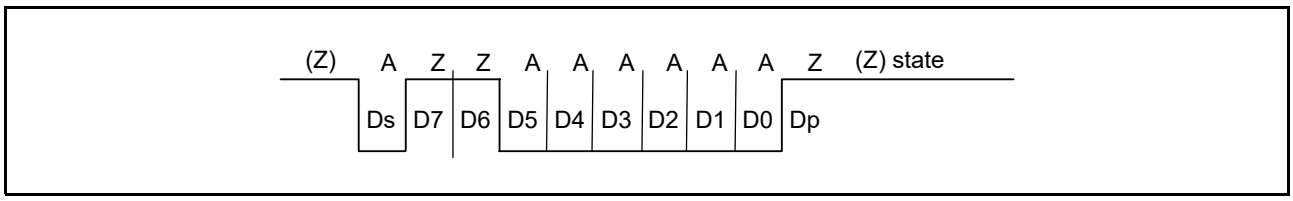

Figure 32.40 Inverse Convention (SCMR.SDIR bit = 1, SCMR.SINV bit = 1, SMR.PM bit = 1)

32.6.3 Block Transfer Mode

Block transfer mode is different from non-block transfer mode in the following respects.

- Even if a parity error is detected during reception, no error signal is output. Since the SSR.PER flag is set by error detection, clear the PER flag before receiving the parity bit of the next frame.
- During transmission, at least 1 etu is secured as a guard time from the end of the parity bit until the start of the next frame.
- Since the same data is not retransmitted during transmission, the SSR.TEND flag is set 11.5 etu after transmission start.
- In block transfer mode, the SSR.ERS flag indicates the error signal status as in non-block transfer mode, but the flag is read as 0 because no error signal is transferred.

32.6.4 Receive Data Sampling Timing and Reception Margin

Only the base clock generated by the on-chip baud rate generator can be used as a transmit/receive clock in smart card interface mode.

In this mode, the SCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate according to the settings of the SCMR.BCP2 bit and the SMR.BCP[1:0] bits.

For data reception, the falling edge of the start bit is sampled with the base clock to perform synchronization. Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 32.41. The reception margin here is determined by the following formula.

$$M = \left| \left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\ (\%)$$

M: Reception margin (%)
N: Ratio of bit rate to clock (N = 32, 64, 372, 256)
D: Duty cycle of clock (D = 0 to 1.0)
L: Frame length (L = 10)
F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the above formula, the reception margin is determined by the formula below.

M = {0.5 – 1/(2 × 372)} × 100 (%) = 49.866 (%)

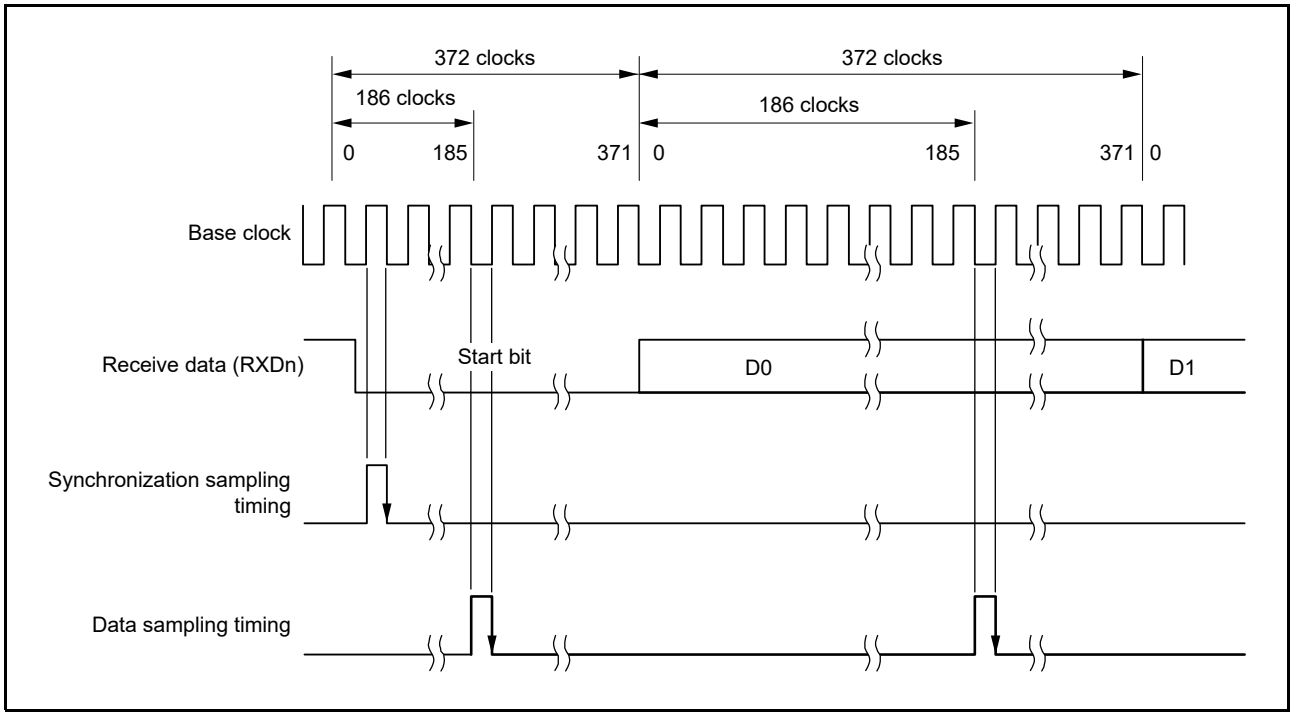

Figure 32.41 Receive Data Sampling Timing in Smart Card Interface Mode (When Clock Frequency is 372 Times the Bit Rate)

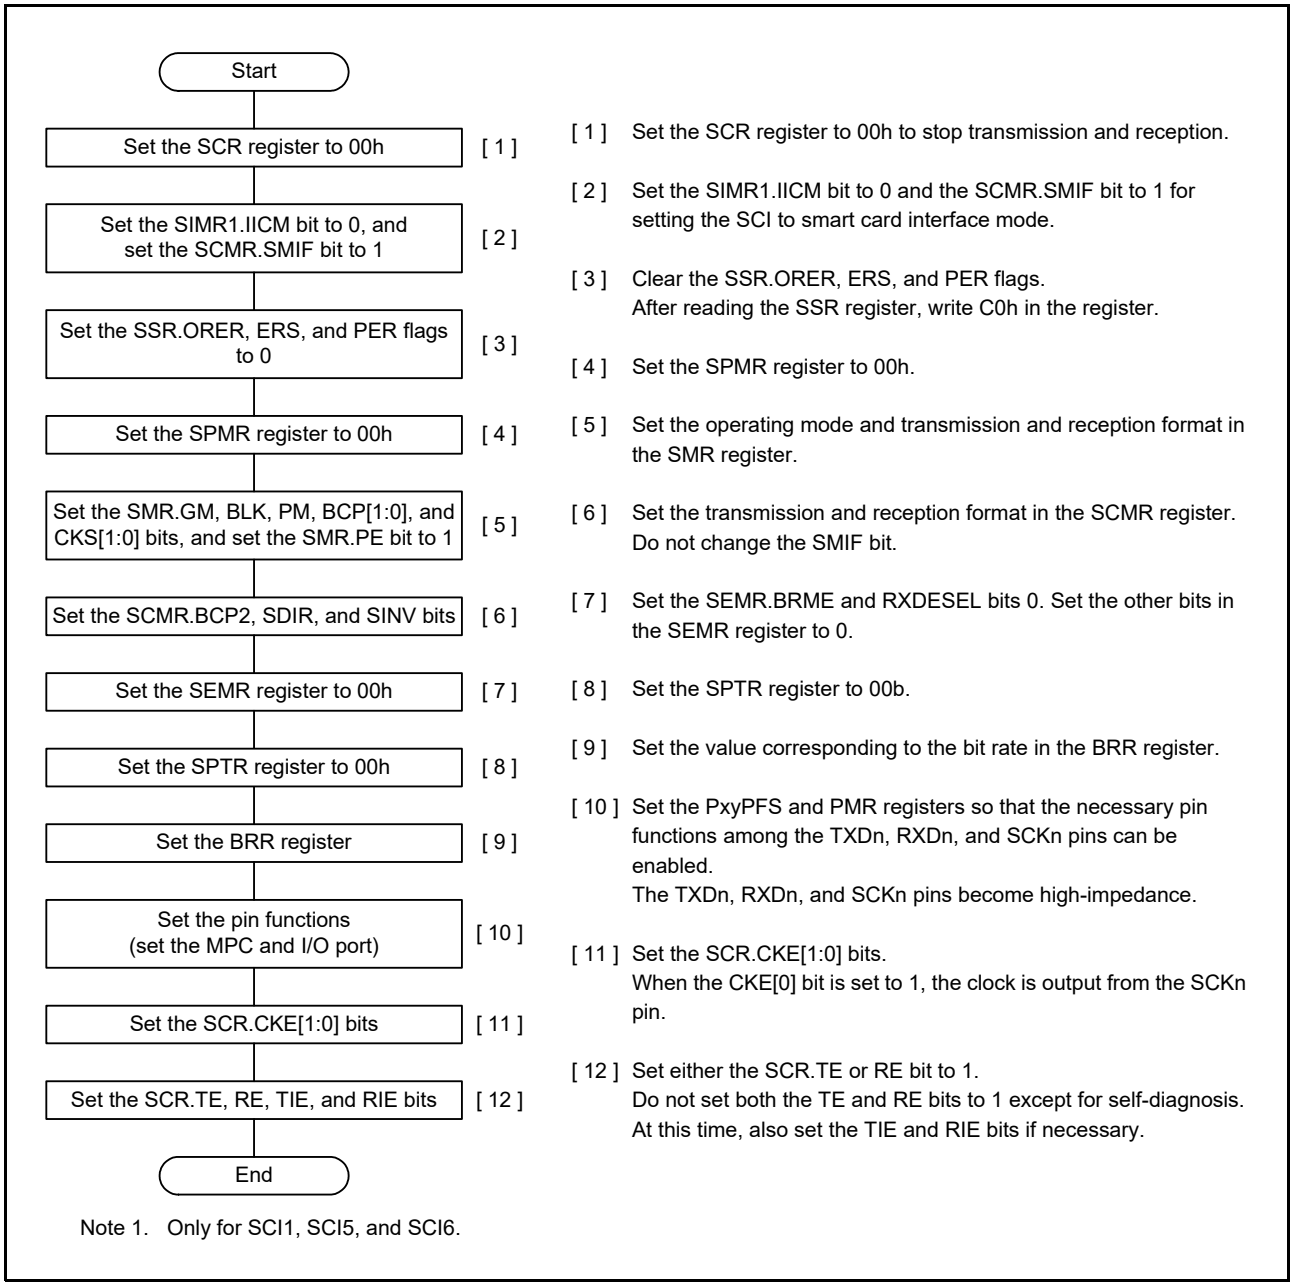
32.6.5 SCI Initialization (Smart Card Interface Mode)

Initialize the SCI following the example of flowchart shown in Figure 32.42.
Initialize the SCR and SSR registers before switching from transmit mode to receive mode and vice versa. When not changing the bit rate, it is not necessary to set the CKE[1:0] bits to 00b. Even if the RE bit is set to 0, the RDR register is not initialized.

To change receive mode to transmit mode, first check that reception has completed, and then execute steps [1] and [3] in Figure 32.42. Set TE = 1 and RE = 0 at step [11]. Reception completion can be verified by reading the RXI request, SSR.ORER, or SSR.PER flag.
To change transmit mode to receive mode, first check that transmission has completed, and then execute steps [1] and [3] in Figure 32.42. Set TE = 0 and RE = 1 at step [11]. Transmission completion can be verified by reading the SSR.TEND flag.



Note 1. Only for SCI1, SCI5, and SCI6.

Figure 32.42 Example of SCI Initialization Flowchart (Smart Card Interface Mode)

Figure 32.43 shows an example of data transmission when the SCI is set to smart card interface mode according to the flow described in Figure 32.42 after a reset. When the pin functions are set to the SCK and TXD pins, they are still high-impedance because the SCR.CKE[0] and SCR.TE bits are 0. When the CKE[0] bit is set to 1, clock is output from the SCK pin. When the transmit data is written after setting the TE bit to 1, a data transmission starts. After the TE bit is set to 1, one frame of high-impedance is output from TXD pin (internal wait time) and then the data transmission starts. In smart card interface mode, the clock is continuously output while the CKE[0] bit is set to 1 (clock output) even if both the TE and RE bits are set to 0.

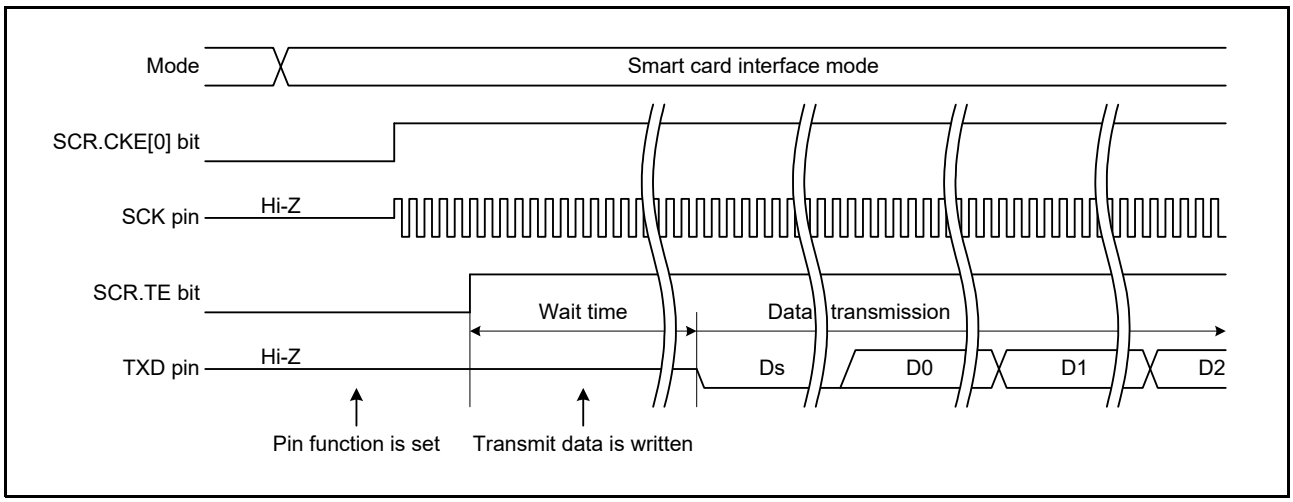


Figure 32.43 Example of Data Transmission Timing in Smart Card Interface Mode

32.6.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode), in that an error signal is sampled and data can be retransmitted, is different from that in non-smart card interface mode. Figure 32.44 shows the data retransmit operation during transmission.

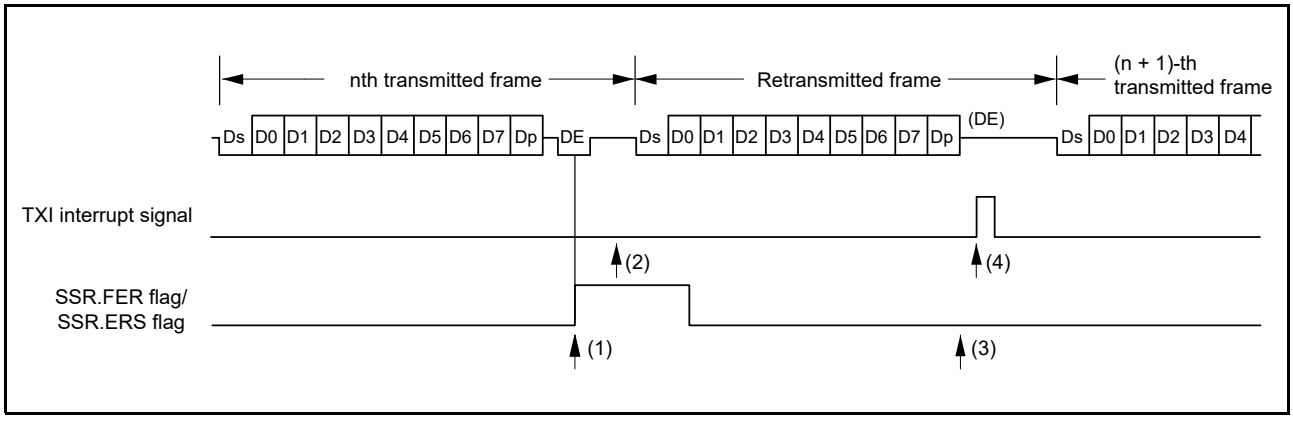

Figure 32.44 Data Retransmit Operation in SCI Transmit Mode

(1) When an error signal from the receiver end is sampled after one-frame data has been transmitted, the SSR.ERS flag is set to 1. If the SCR.RIE bit is 1 at this time, an ERI interrupt request is generated. Clear the ERS flag before the next parity bit is sampled.

(2) For a frame in which an error signal is received, the SSR.TEND flag is not set. Data is retransferred from the TDR register to the TSR register allowing automatic data retransmission.

(3) If no error signal is returned from the receiver, the ERS flag is not set to 1.

(4) In this case, the SCI judges that transmission of one-frame data (including retransmission) has been completed, and the TEND flag is set. If the SCR.TIE bit is 1 at this time, a TXI interrupt request is generated. Writing transmit data to the TDR register starts transmission of the next data.

Figure 32.45 shows a sample flowchart of serial transmission.

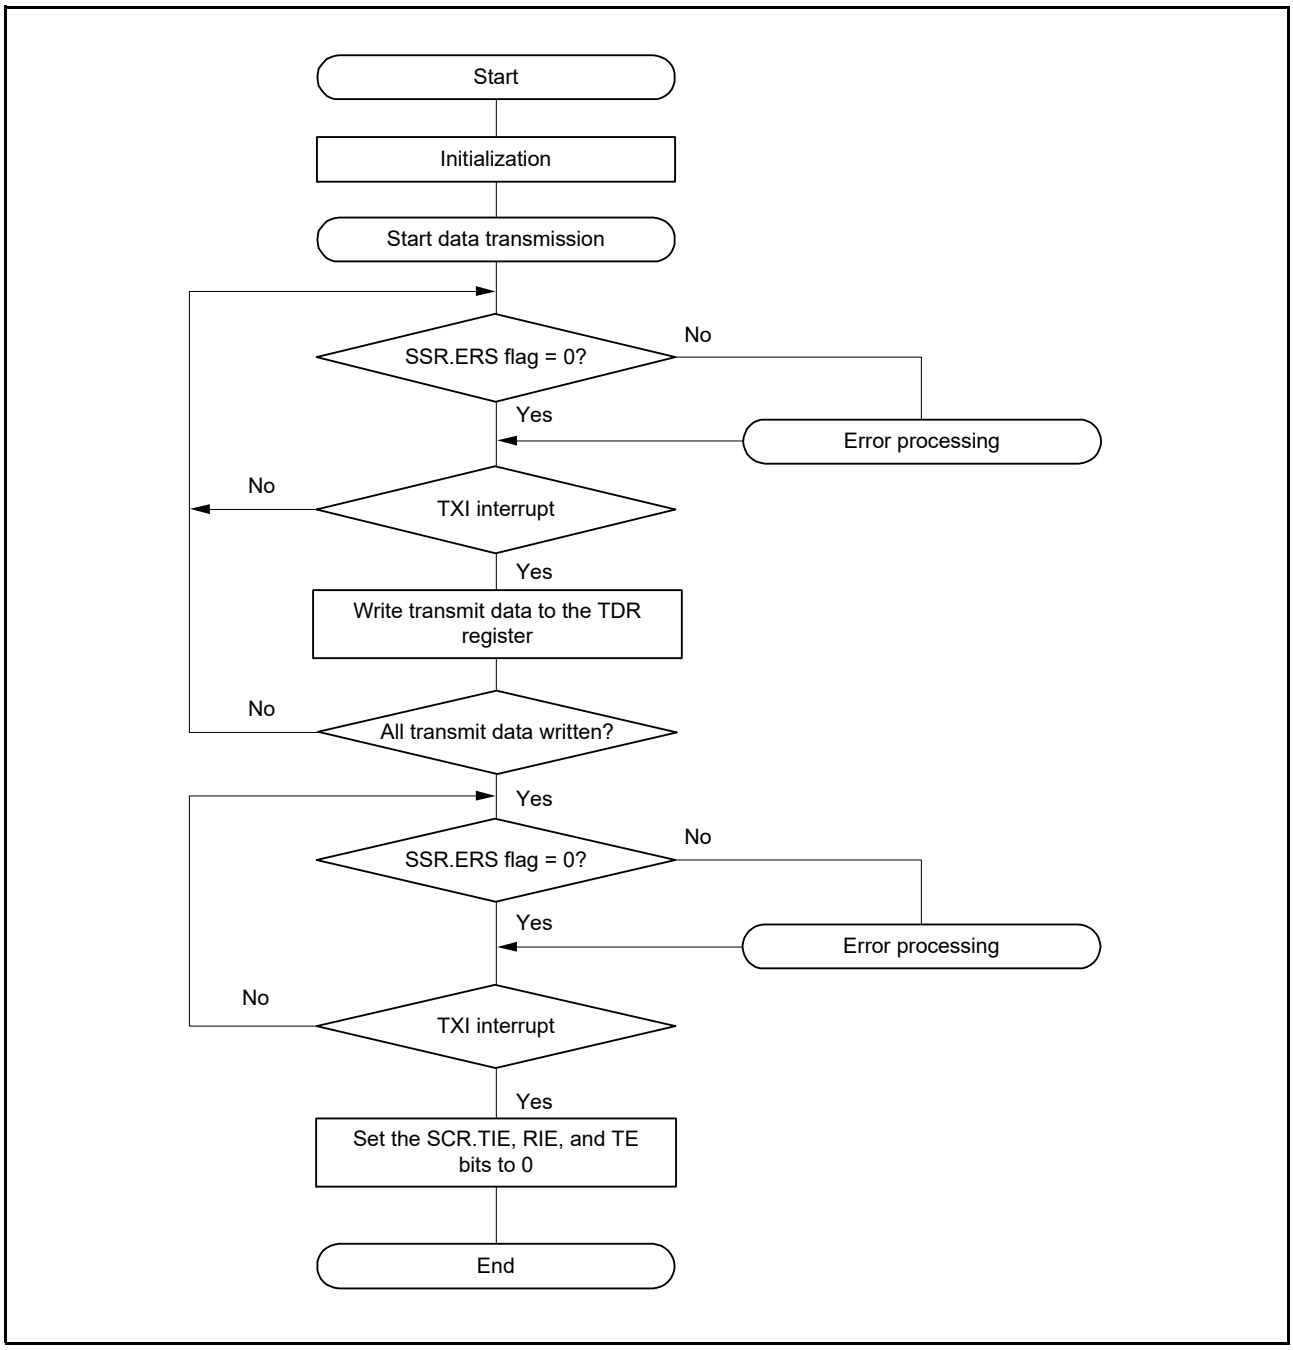

Figure 32.45 Sample Smart Card Interface Transmission Flowchart

All the processing steps are automatically performed using a TXI interrupt request to activate the DTC or DMAC. When the SSR.TEND flag is set to 1 in transmission, if the SCR.TIE bit is 1, a TXI interrupt request is generated. The DTC or DMAC is activated by a TXI interrupt request if the TXI interrupt request is specified as a source of DTC or DMAC activation beforehand, allowing transfer of transmit data. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During this retransmission, the TEND flag is kept to 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission in the case of error occurrence. However, since the ERS flag is not automatically cleared, set the RIE bit to 1 beforehand to enable an ERI interrupt request to be generated at error occurrence, and clear the ERS flag.

When transmitting/receiving data using the DTC or DMAC, be sure to make settings to enable the DTC or DMAC before making SCI settings.
For DTC or DMAC settings, refer to section 18, Data Transfer Controller (DTCb), section 17, DMA Controller (DMACAa).

Note that the SSR.TEND flag is set in different timings depending on the SMR.GM bit setting. Figure 32.46 shows the TEND flag generation timing.

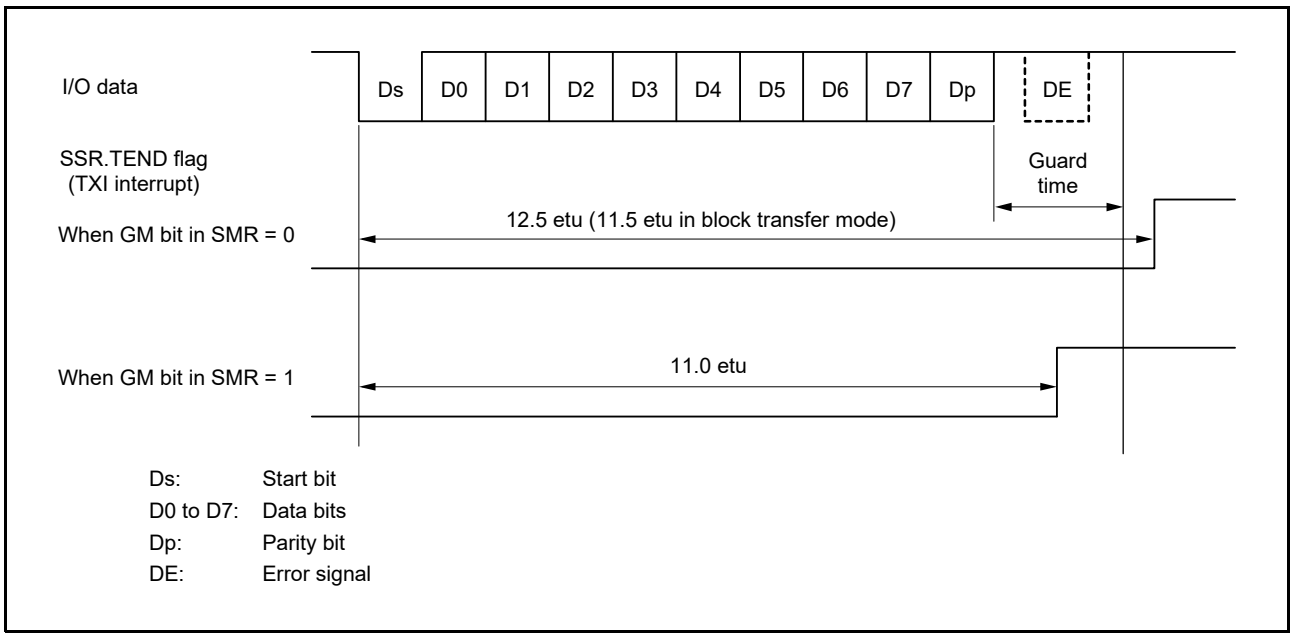

Figure 32.46 SSR.TEND Flag Generation Timing during Transmission

32.6.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in non-smart card interface mode. Figure 32.47 shows the data retransmit operation in receive mode.

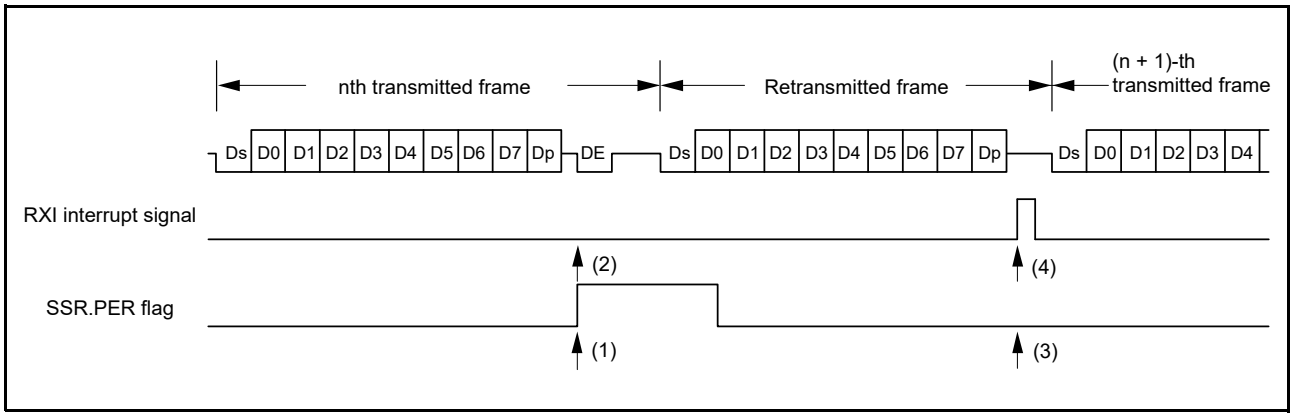

Figure 32.47 Data Retransmit Operation in SCI Receive Mode (Data Retransmit Operation during Reception)

(1) If a parity error is detected in receive data, the SSR.PER flag is set to 1. When the SCR.RIE bit is 1 at this time, an ERI interrupt request is generated. Clear the PER flag before the next parity bit is sampled.
(2) For a frame in which a parity error is detected, no RXI interrupt is generated.
(3) When no parity error is detected, the SSR.PER flag is not set to 1.
(4) In this case, data is determined to have been received successfully. When the SCR.RIE bit is 1, an RXI interrupt request is generated.

Figure 32.48 shows a sample flowchart for serial data reception.

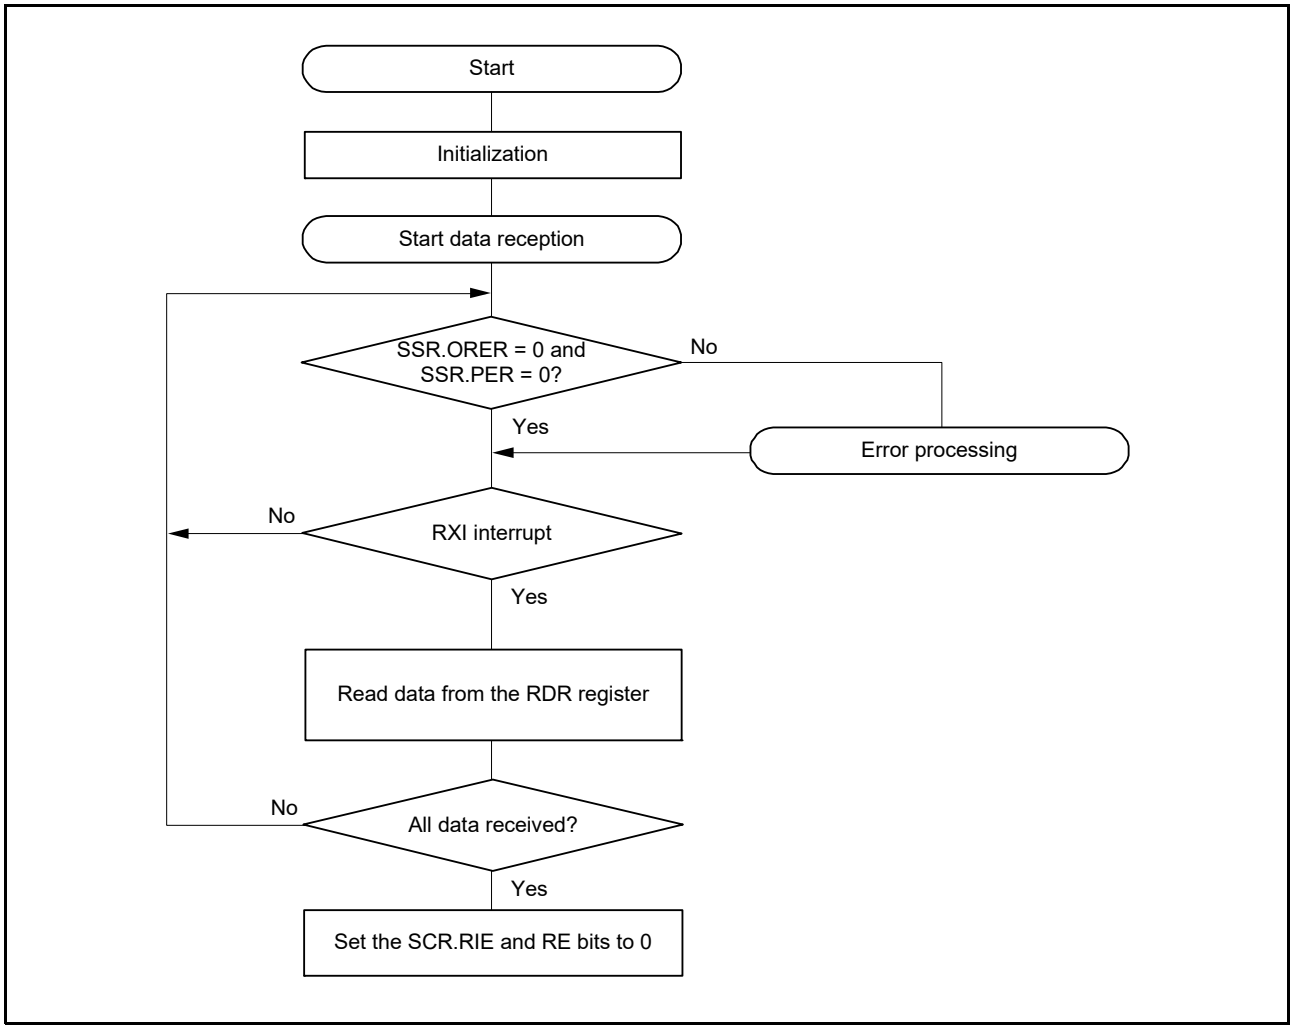

Figure 32.48 Sample Smart Card Interface Reception Flowchart

All the processing steps are automatically performed using an RXI interrupt request to activate the DTC or DMAC.
In reception, setting the RIE bit to 1 allows an RXI interrupt request to be generated. The DTC or DMAC is activated by an RXI interrupt request if the RXI interrupt request is specified as a source of DTC or DMAC activation beforehand, allowing transfer of receive data.
If an error occurs during reception and either the ORER or PER flag in the SSR register is set to 1, a receive error interrupt (ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DTC or DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DTC or DMAC is transferred.
Even if a parity error occurs and the PER flag is set to 1 during reception, receive data is transferred to the RDR register, thus allowing the data to be read.
When a reception is forcibly terminated by setting the SCR.RE bit to 0 during operation, read the RDR register because the received data which has not yet been read may be left in the RDR register.

Note 1. For operations in block transfer mode, refer to section 32.3, Operation in Asynchronous Mode.

32.6.8 Clock Output Control

Clock output can be fixed to high or low using the SCR.CKE[1:0] bits when the SMR.GM bit is 1. When the CKE[1:0] bits are set to 01b (clock output), the base clock is output from the SCK pin. For the settings of the base clock frequency (bit rate), refer to section 32.2.11, Bit Rate Register (BRR). When the CKE[1:0] bits are set to 00b (output fixed low) or 10b (output fixed to high), the SCK pin can be fixed to low or high.

Figure 32.49 shows a timing chart when the clock output is controlled.

If changing the CKE[1:0] bits while the SMR.GM bit is 0 (non-GSM mode), a pulse of unexpected width may output from SCK pin because the result is immediately reflected to the SCK pin.

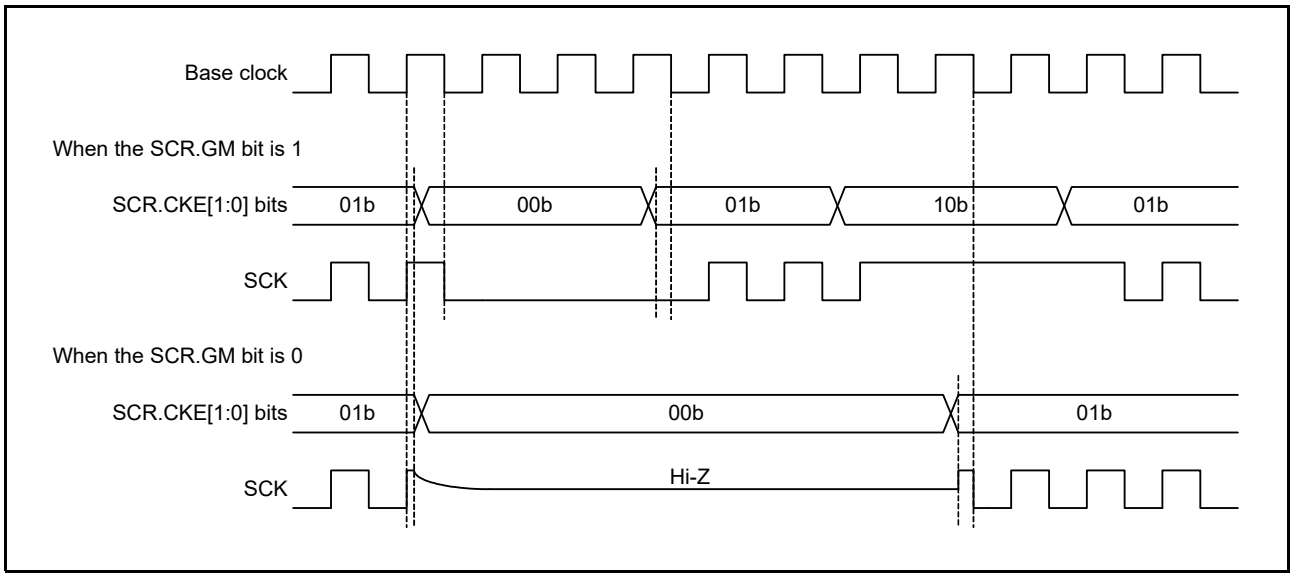

Figure 32.49 Clock Output Control

32.7 Operation in Simple I2C Mode

Simple I2C-bus format is composed of 8 data bits and an acknowledge bit. By continuing into a slave-address frame after a start condition or restart condition, a master device is able to specify a slave device as the partner for communications. The currently specified slave device remains valid until a new slave device is specified or a stop condition is satisfied.
The 8 data bits in all frames are transmitted in order from the MSB.
The I2C-bus format and timing of the I2C-bus are shown in Figure 32.50 and Figure 32.51.

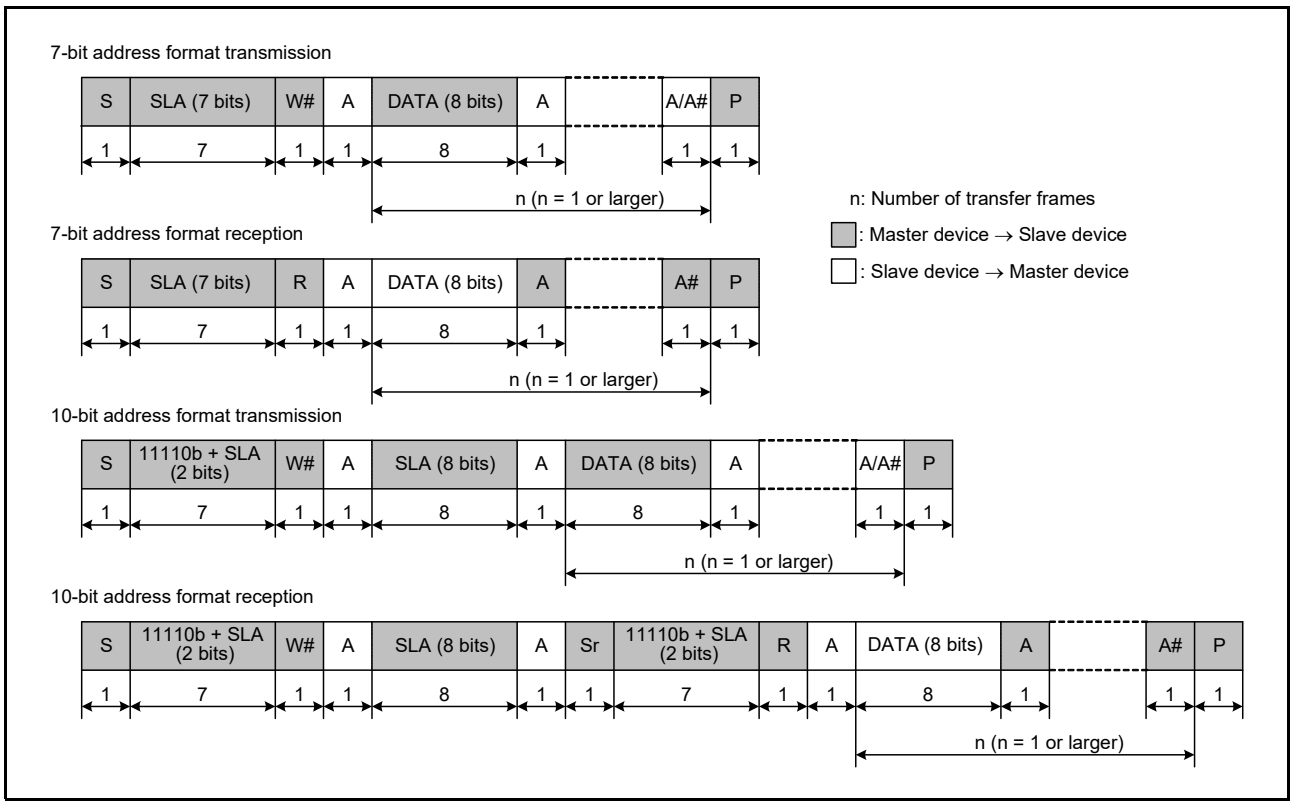

Figure 32.50 I2C-bus Format

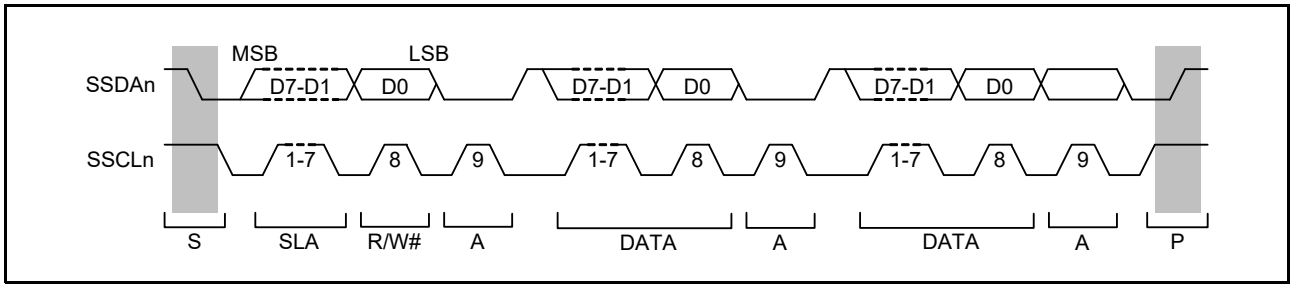

Figure 32.51 I2C-bus Timing (When SLA is 7 Bits)

S: Indicates a start condition, i.e. the master device changing the level on the SSDAn line from the high to the low level while the SSCLn line is at the high level.
SLA: Indicates a slave address, by which the master device selects a slave device.
R/W#: Indicates the direction of transfer (reception or transmission). The value 1 corresponds to transfer from the slave device to the master device and 0 corresponds to transfer from the master device to the slave device.
A/A#: Indicates an acknowledge bit. This is returned by the slave device for master transmission and by the master device for master reception. Return of the low level indicates ACK and return of the high level indicates NACK.
Sr: Indicates a restart condition, i.e. the master device changing the level on the SSDAn line from the high to the low level while the SSCLn line is at the high level and after the setup time has elapsed.
DATA: Indicates the data being received or transmitted.
P: Indicates a stop condition, i.e. the master device changing the level on the SSDAn line from the low to the high level while the SSCLn line is at the high level.

32.7.1 Generation of Start, Restart, and Stop Conditions

Writing 1 to the SIMR3.IICSTAREQ bit causes the generation of a start condition. The generation of a start condition proceeds through the following operations.

- The level on the SSDAn line falls (from the high level to the low level) and the SSCLn line is kept in the released state.
- The hold time for the start condition is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The level on the SSCLn line falls (from the high level to the low level), the SIMR3.IICSTAREQ bit is set (to 0), and a start-condition generated interrupt is output.

Writing 1 to the SIMR3.IICRSTAREQ bit causes the generation of a start condition. The generation of a start condition proceeds through the following operations.

- The SSDAn line is released and the SSCLn line is kept at the low level.
- The period at low level for the SSCLn line is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The SSCLn line is released (transition from the low to the high level).
- Once the high level on the SSCLn line is detected, the setup time for the restart condition is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The level on the SSDAn line falls (from the high level to the low level).
- The hold time for the restart condition is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The level on the SSCLn line falls (from the high level to the low level), the SIMR3.IICRSTAREQ bit is set (to 0), and a restart-condition generated interrupt is output.

Writing 1 to the SIMR3.IICSTPREQ bit causes the generation of a stop condition. The generation of a stop condition proceeds through the following operations.

- The level on the SSDAn line falls (from the high level to the low level) and the SSCLn line is kept at the low level.
- The period at low level for the SSCLn line is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The SSCLn line is released (transition from the low to the high level).
- Once the high level on the SSCLn line is detected, the setup time for the stop condition is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The SSDAn is released (transition from the low to the high level), the SIMR3.IICSTPREQ bit is set (to 0), and a stop-condition generated interrupt is output.

Figure 32.52 shows the timing of operations in the generation of start, restart, and stop conditions.

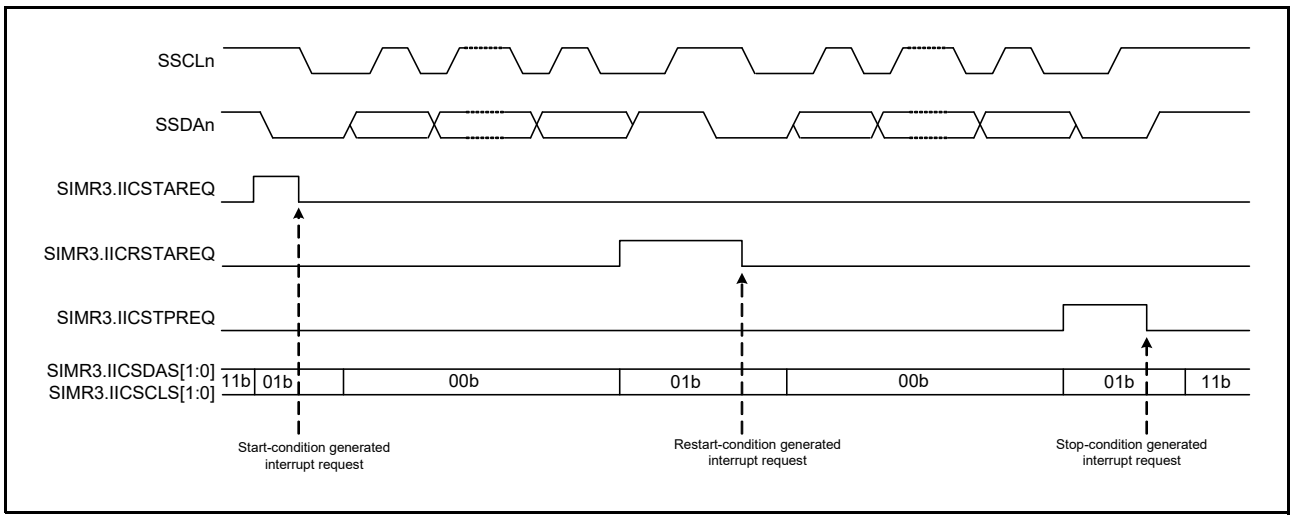

Figure 32.52 Timing of Operations in the Generation of Start, Restart, and Stop Conditions

32.7.2 Clock Synchronization

The SSCLn line may be placed at the low level in the case of a wait inserted by a slave device as the other side of transfer. Setting the SIMR2.IICCSC bit to 1 applies control to obtain synchronization when the levels of the internal SSCLn clock signal and the level being input on the SSCLn pin differ.

When the SIMR2.IICCSC bit is set to 1, the level of the internal SSCLn clock signal changes from low to high, counting to determine the period at high level is stopped while the low level is being input on the SSCLn pin, and counting to determine the period at high level starts after the transition of the input on the SSCLn pin to the high level. The interval from this time until counting to determine the period at high level starts on the transition of the SSCLn pin to the high level is the total of the delay of SSCLn output, delay for noise filtering of the input on the SSCLn pin (2 or 3 cycles of sampling clock for the noise filter), and delay for internal processing (1 or 2 cycles of PCLK). The period at high level of the internal SSCLn clock is extended even if other devices are not placing the low level on the SSCLn line. If the SIMR2.IICCSC bit is 1, synchronization is obtained for the transmission and reception of data by taking the logical AND of the input on the SSCLn pin and the internal SSCLn clock. If the SIMR2.IICCSC bit is 0, synchronization with the internal SSCLn clock is obtained for the transmission and reception of data.

If a slave device inserts a period of waiting into the interval until the transition of the internal SSCLn clock signal from the low to the high level after a request for the generation of a start, restart, or stop condition is issued, the time until generation is prolonged by that period.

If a slave device inserts a period of waiting after the transition of the internal SSCLn clock signal from the low to the high level, although the generation-completed interrupt is issued without stopping the period of waiting, generation of the condition itself is not guaranteed. Figure 32.53 shows an example of operations to synchronize the clocks.

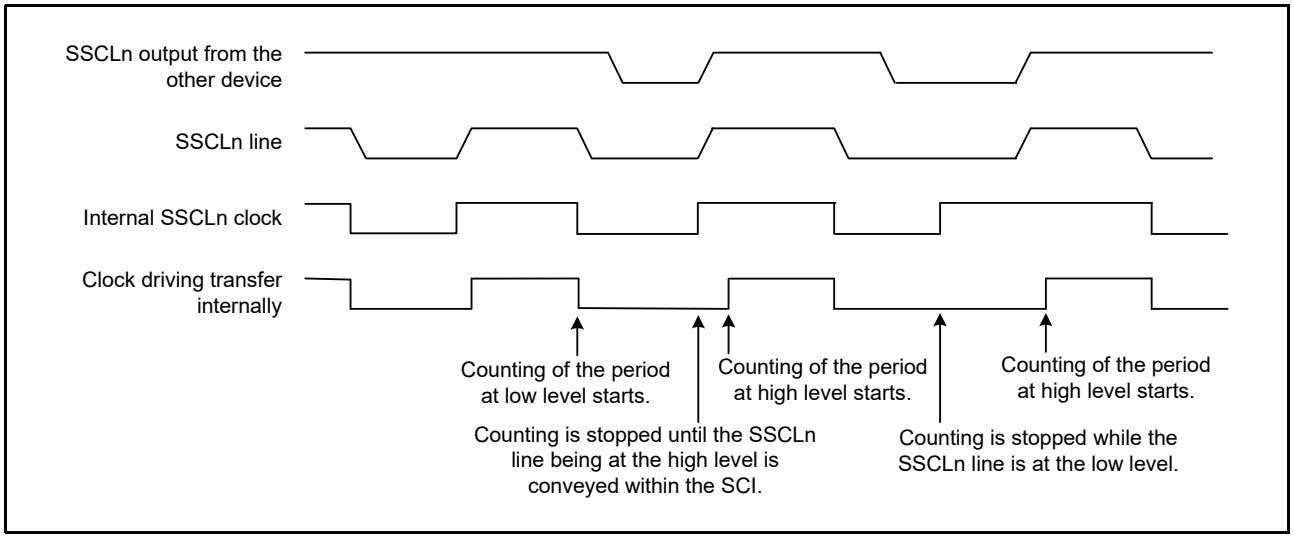

Figure 32.53 Example of Operations for Clock Synchronization

32.7.3 SSDA Output Delay

The SIMR1.IICDL[4:0] bits can be used to set a delay for output on the SSDAn pin relative to falling edges of output on the SSCLn pin. Delay-time settings from 0 to 31 are selectable, representing periods of the corresponding numbers of cycles of the clock signal from the on-chip baud rate generator (derived by frequency-dividing the base clock, PCLK, by the divisor selected by the SMR.CKS[1:0] bits). A delay for output on the SSDAn pin is for the start condition/restart condition/stop condition signal, 8-bit transmit data, and an acknowledge bit.

If the SSDA output delay is shorter than the time for the level on the SSCLn pin to fall, the change of the output on the SSDAn pin will start while the output level on the SSCLn pin is falling, creating a possibility of erroneous operation for slave devices. Ensure that settings for the delay of output on the SSDAn pin are for times greater than the time output on the SSCLn pin takes to fall (300 ns for I^2C-bus in normal mode and fast mode).

Figure 32.54 shows the timing of delays in SSDA output.

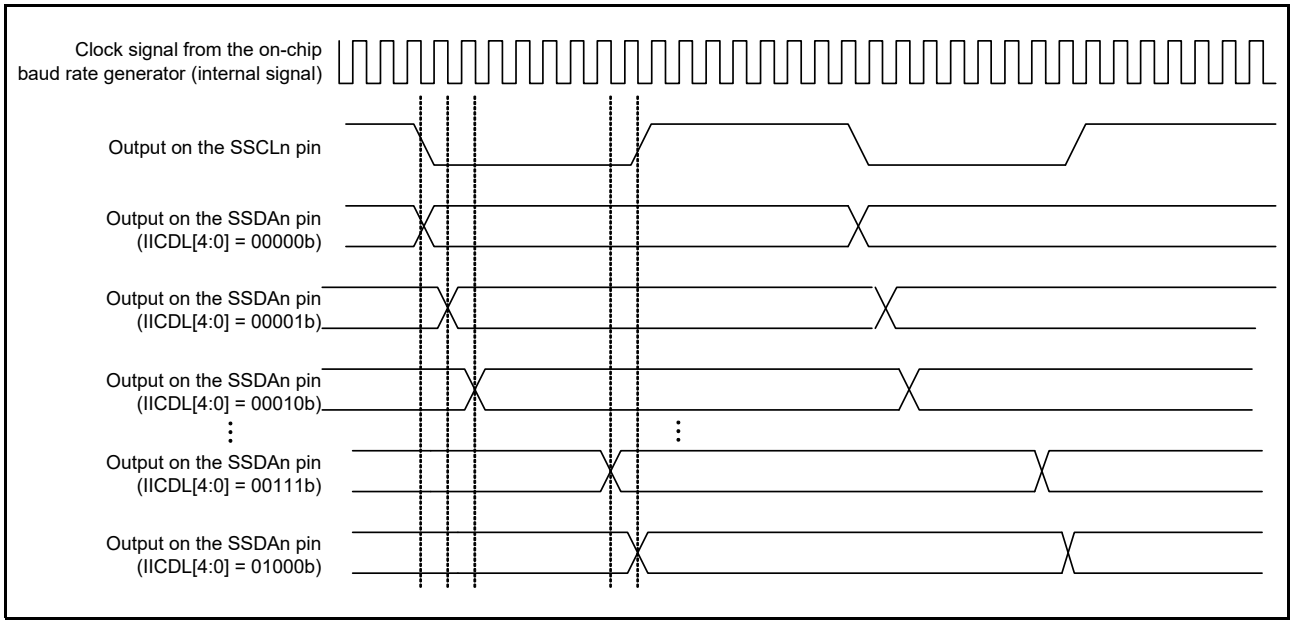

Figure 32.54 Timing of Delays in SSDA Output

32.7.4 SCI Initialization (Simple I2C Mode)

Before transferring data, write the initial value (00h) to the SCR register and initialize the interface following the example shown in Figure 32.55.
When changing the operating mode, transfer format, and so on, be sure to set the SCR register to its initial value before proceeding with the changes.
In simple I2C mode, the open-drain setting for the communication ports should be made on the port side.

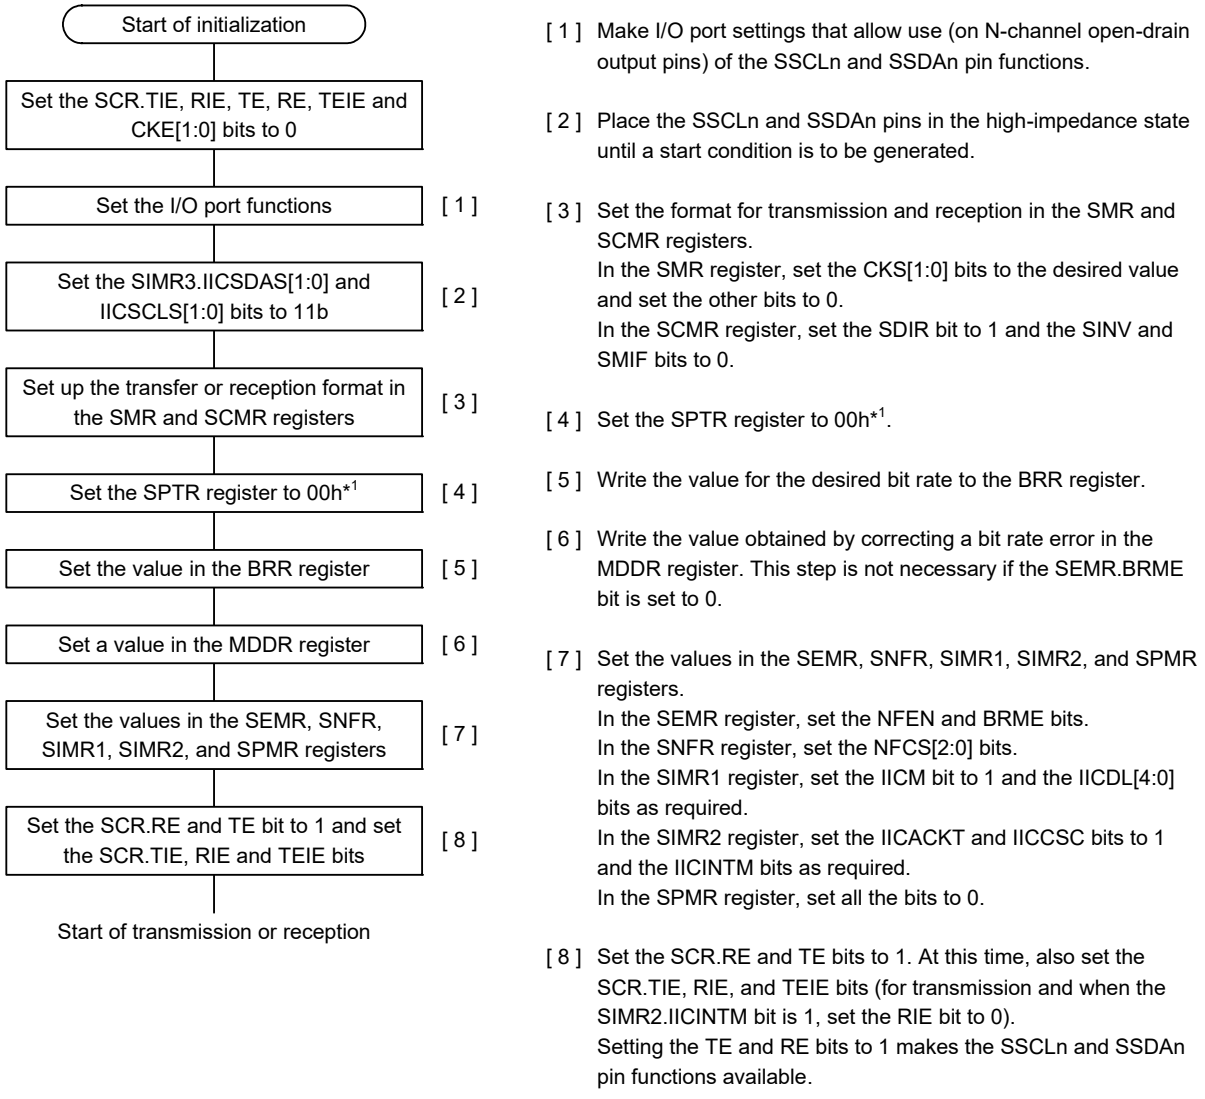

Figure 32.55 Example of the Flowchart of SCI Initialization (for Simple I2C Mode)

32.7.5 Operation in Master Transmission (Simple I2C Mode)

Figure 32.56 and Figure 32.57 show examples of operations in master transmission and Figure 32.58 is a flowchart showing the procedure for data transmission. Refer to Table 32.39 for more information on the STI interrupt.
When 10-bit slave addresses are in use, steps [3] and [4] in Figure 32.58 are repeated twice.
In simple I2C mode, the transmit data empty interrupt (TXI) is generated when communication of one frame is completed, unlike the TXI interrupt request generation timing during clock synchronous transmission.

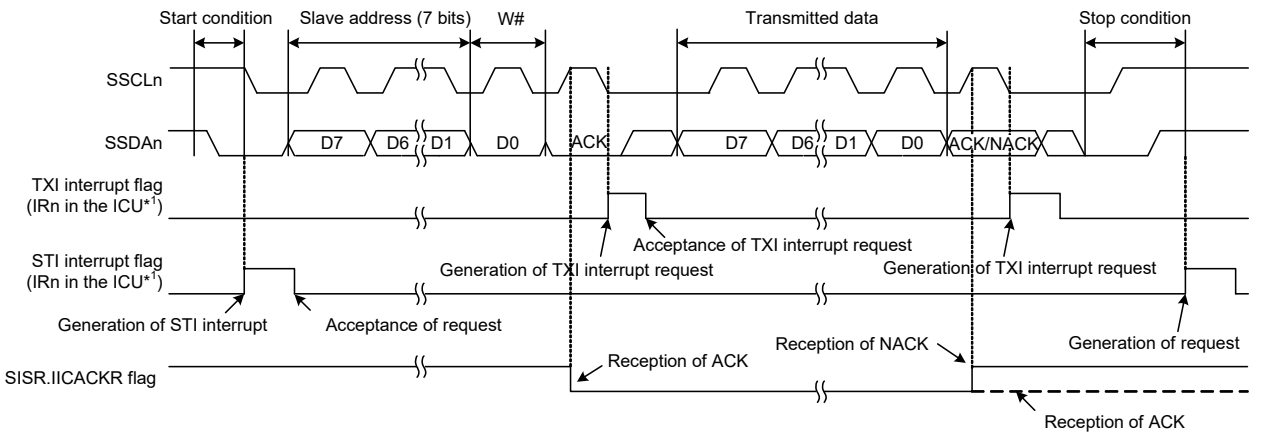

Figure 32.56 Example 1 of Operations for Master Transmission in Simple I2C-bus Mode (with 7-Bit Slave Addresses, Transmission Interrupts, and Reception Interrupts in Use)

When the SIMR2.IICINTM bit is set to 0 (use ACK/NACK interrupts) during master transmission, the DTC or DMAC is activated by the ACK interrupt as the trigger and necessary number of data bytes are transmitted. When the NACK is received, error processing, such as transmission stop and retransmission, is performed by the NACK interrupt as the trigger.

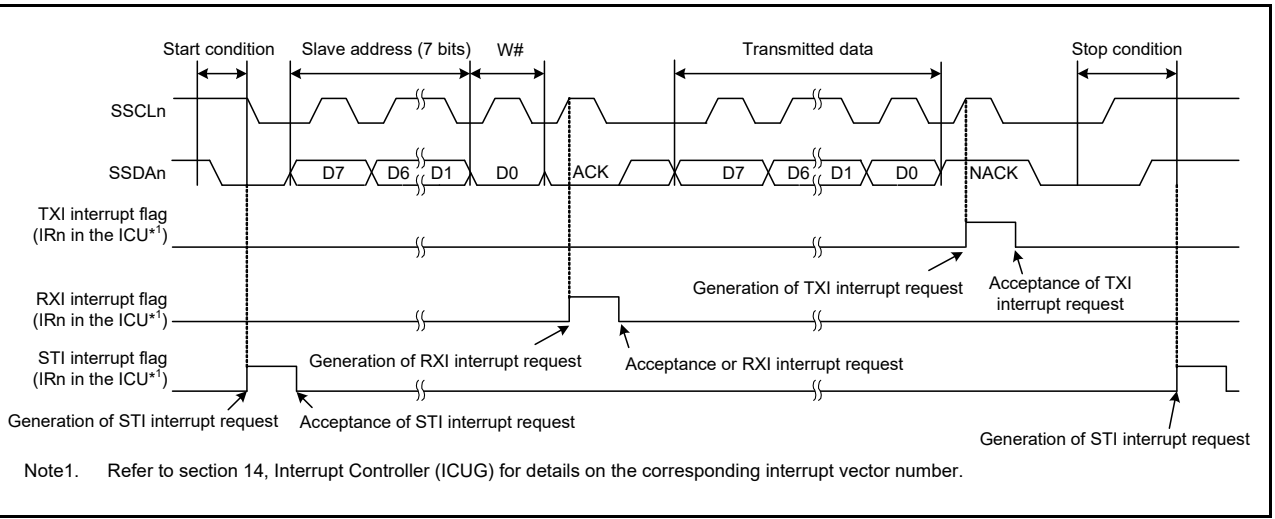

Figure 32.57 Example 2 of Operations for Master Transmission in Simple I2C-bus Mode (with 7-Bit Slave Addresses, ACK Interrupts, and NACK Interrupts in Use)

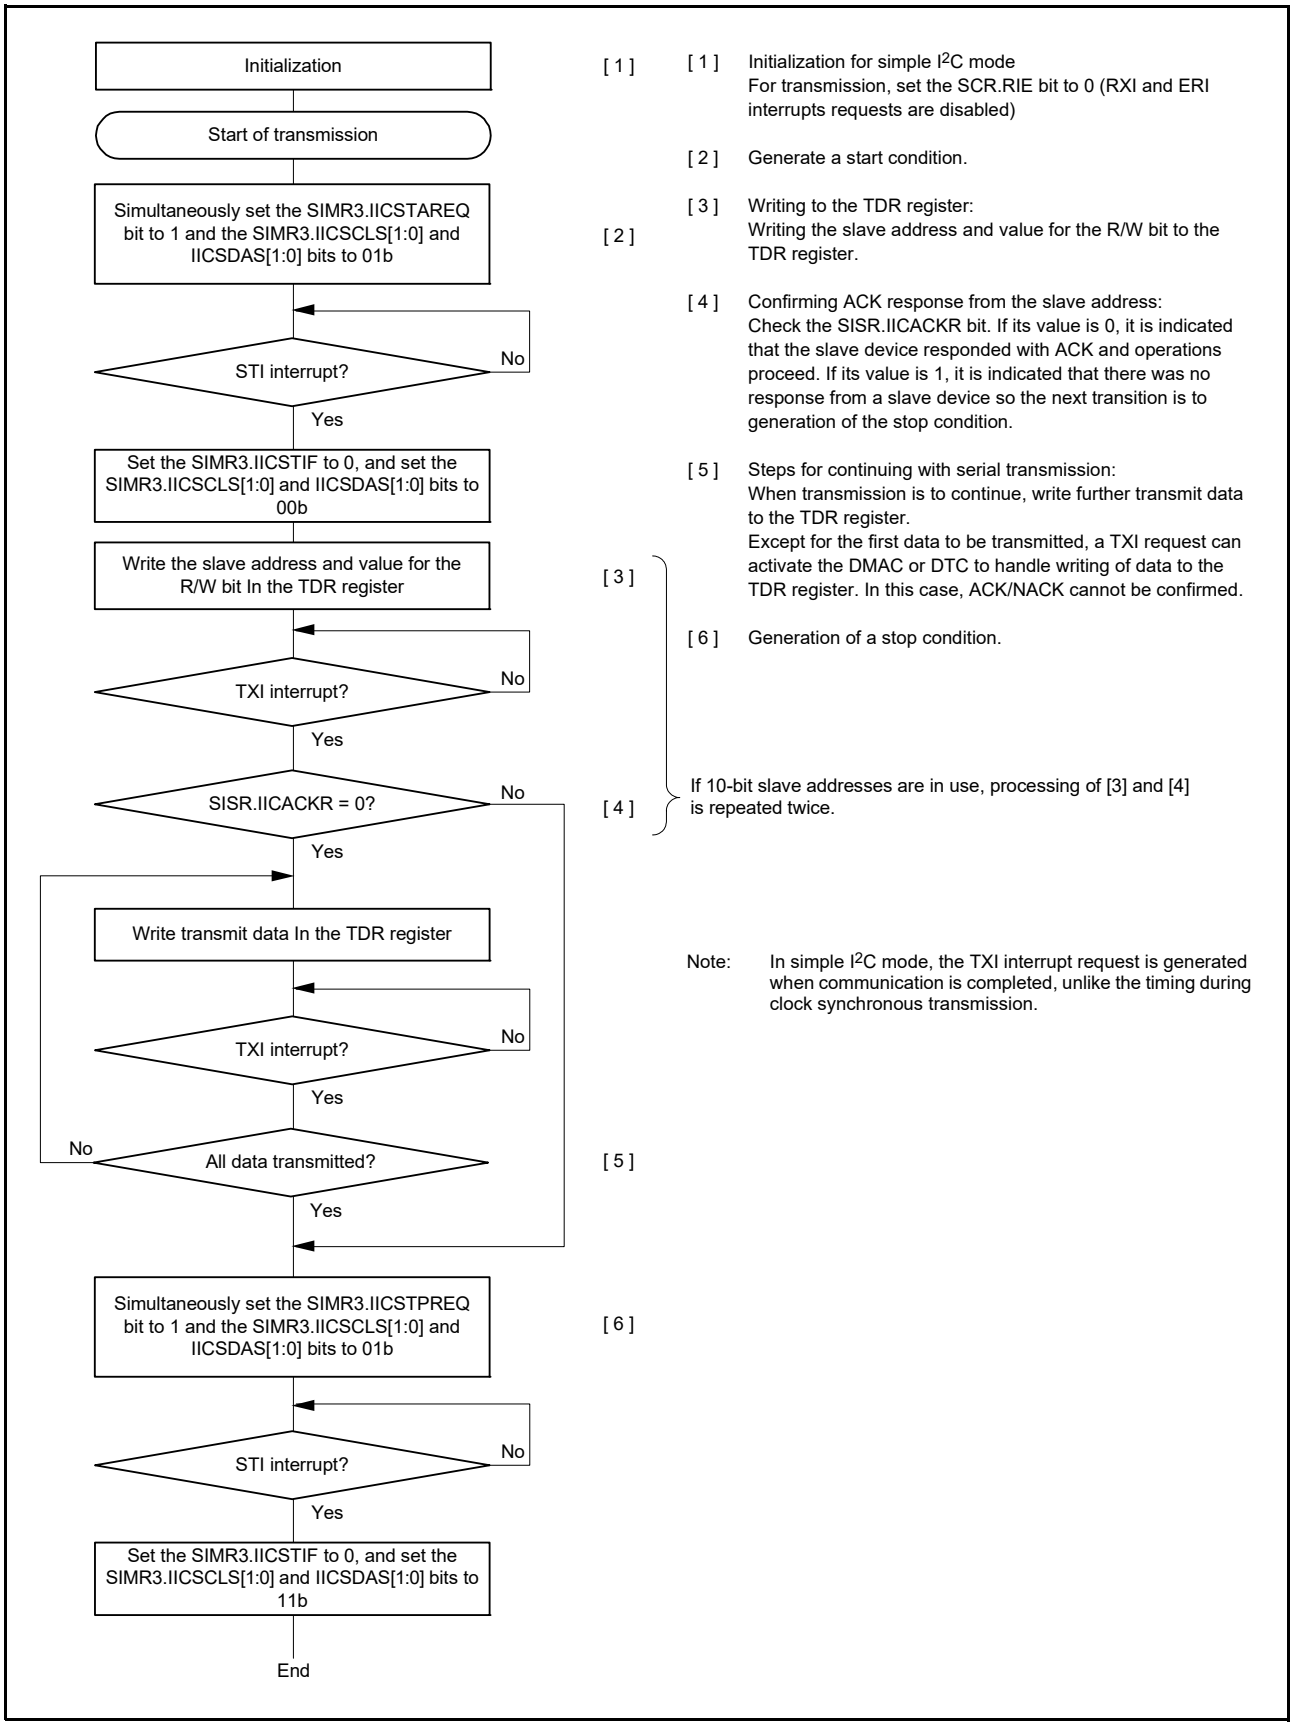

[1] Initialization for simple I²C mode
For transmission, set the SCR.RIE bit to 0 (RXI and ERI interrupts requests are disabled)

[2] Generate a start condition.

[3] Writing to the TDR register:
Writing the slave address and value for the R/W bit to the TDR register.

[4] Confirming ACK response from the slave address:
Check the SISR.IICACKR bit. If its value is 0, it is indicated that the slave device responded with ACK and operations proceed. If its value is 1, it is indicated that there was no response from a slave device so the next transition is to generation of the stop condition.

[5] Steps for continuing with serial transmission:
When transmission is to continue, write further transmit data to the TDR register.
Except for the first data to be transmitted, a TXI request can activate the DMAC or DTC to handle writing of data to the TDR register. In this case, ACK/NACK cannot be confirmed.

[6] Generation of a stop condition.

[3] to [4] If 10-bit slave addresses are in use, processing of [3] and [4] is repeated twice.

Note: In simple I²C mode, the TXI interrupt request is generated when communication is completed, unlike the timing during clock synchronous transmission.

Figure 32.58 Example of the Procedure for Master Transmission Operations in Simple I²C Mode (with Transmission Interrupts and Reception Interrupts in Use)

32.7.6 Master Reception (Simple I2C Mode)

Figure 32.59 shows an example of operations in simple I2C mode master reception and Figure 32.60 is a flowchart showing the procedure for master reception.

The value of the SIMR2.IICINTM bit is assumed to be 1 (use reception and transmission interrupts).

In simple I2C mode, the transmit data empty interrupt (TXI) is generated when communication of one frame is completed, unlike the TXI interrupt request generation timing during clock synchronous transmission.

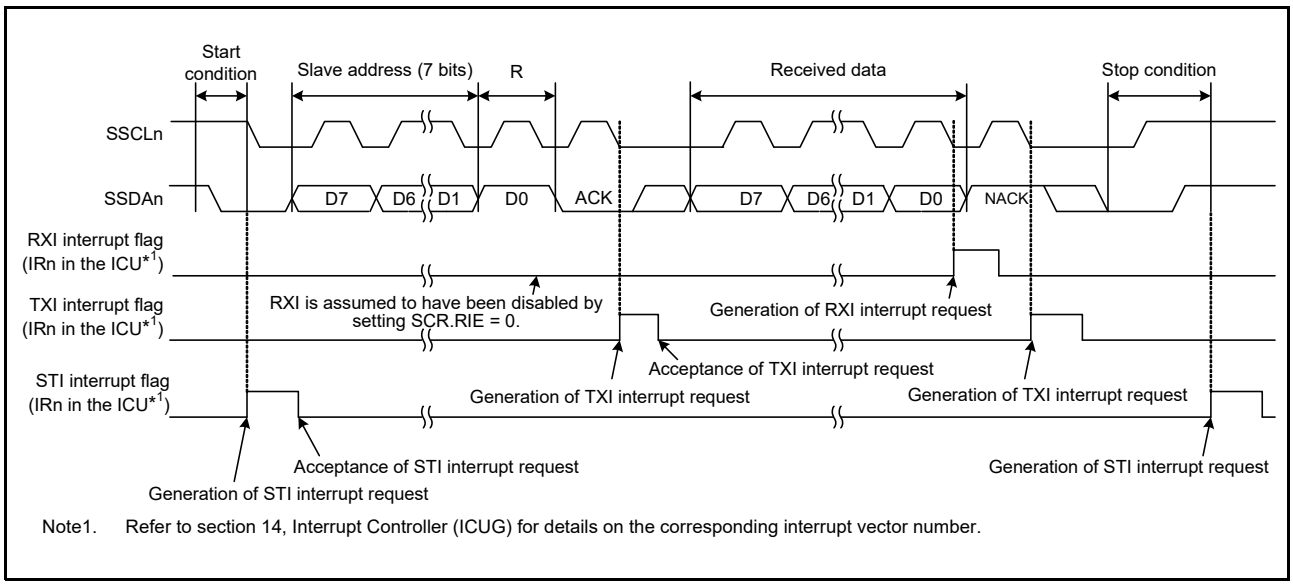

Figure 32.59 Example of Operations for Master Reception in Simple I2C-bus Mode (with 7-Bit Slave Addresses, Transmission Interrupts, and Reception Interrupts in Use)

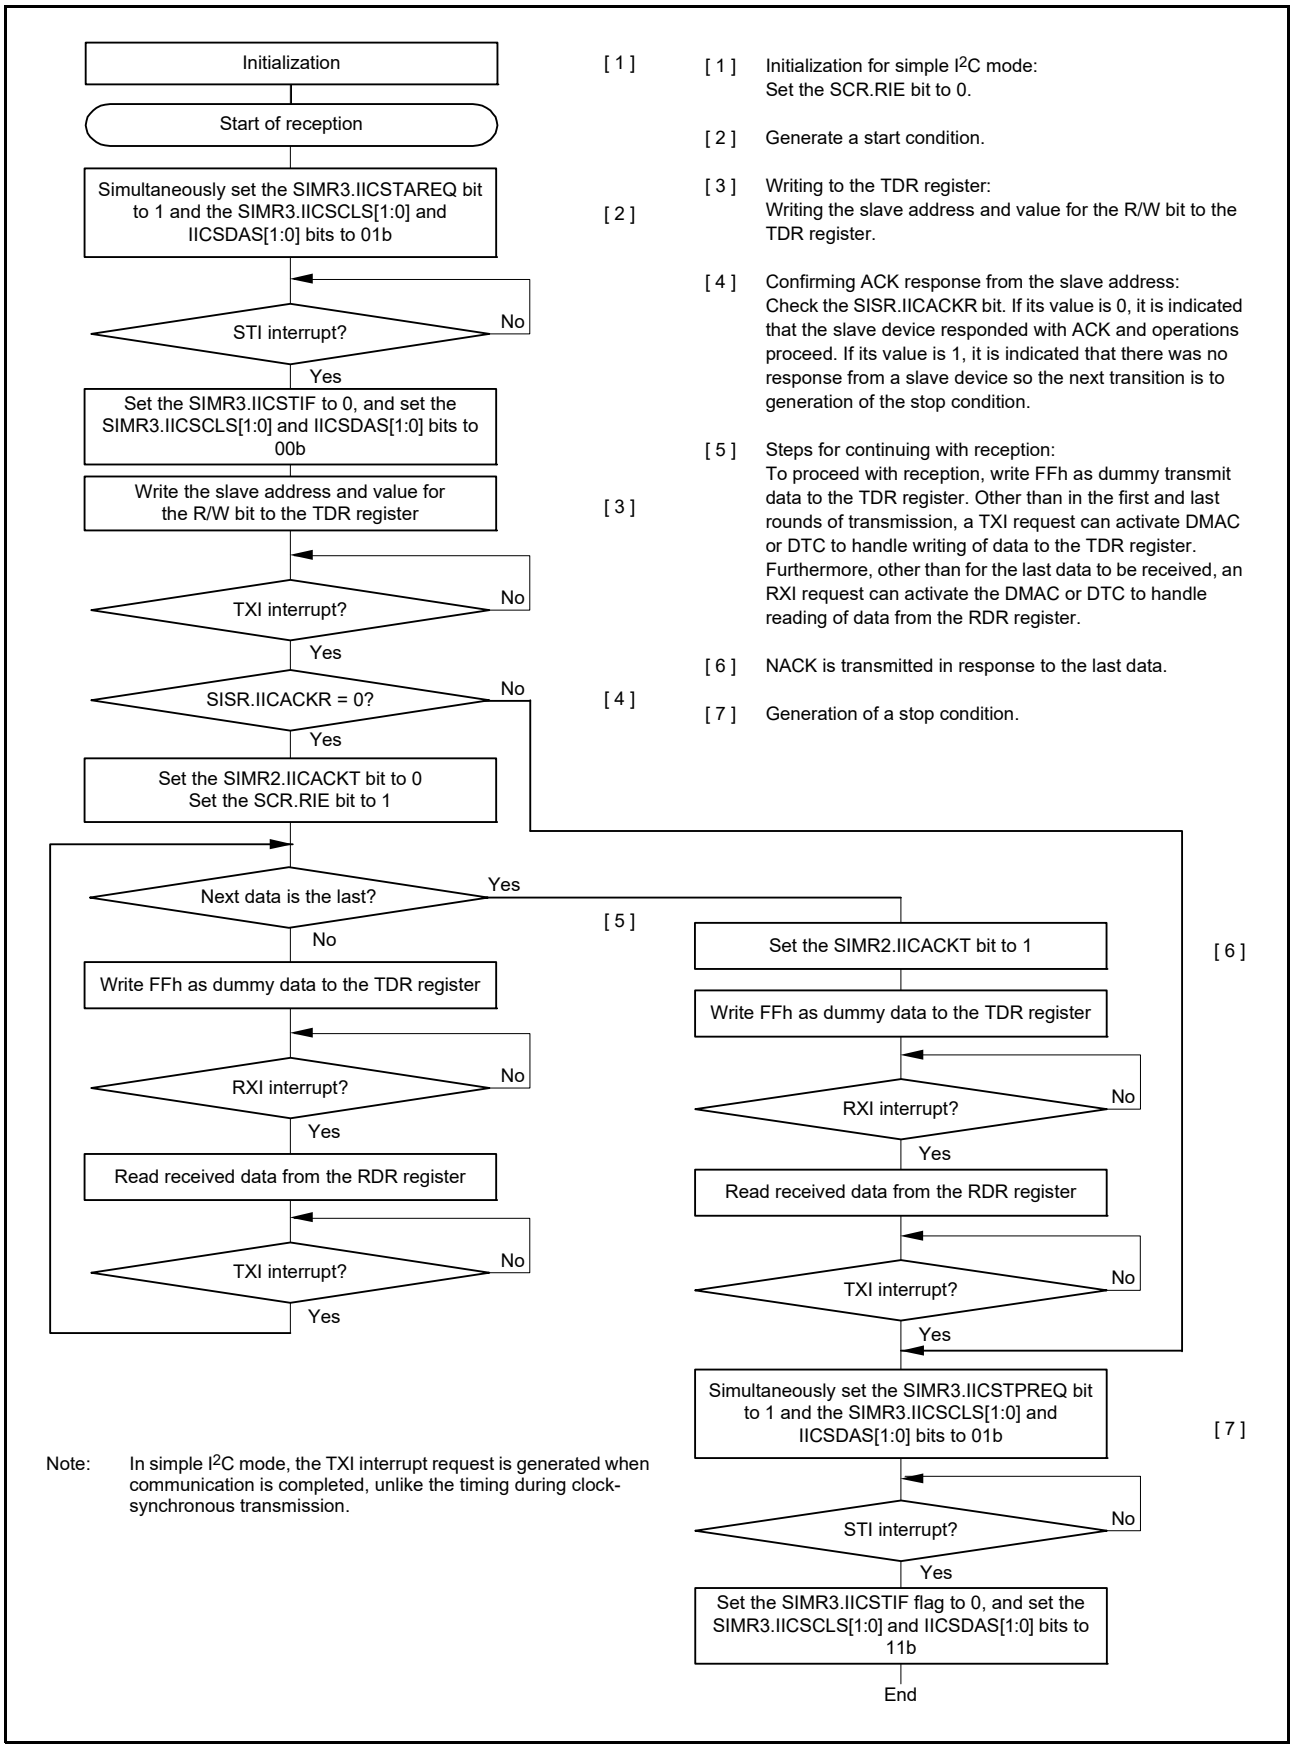


[1] Initialization for simple I²C mode:
Set the SCR.RIE bit to 0.

[2] Generate a start condition.

[3] Writing to the TDR register:
Writing the slave address and value for the R/W bit to the TDR register.

[4] Confirming ACK response from the slave address:
Check the SISR.IICACKR bit. If its value is 0, it is indicated that the slave device responded with ACK and operations proceed. If its value is 1, it is indicated that there was no response from a slave device so the next transition is to generation of the stop condition.

[5] Steps for continuing with reception:
To proceed with reception, write FFh as dummy transmit data to the TDR register. Other than in the first and last rounds of transmission, a TXI request can activate DMAC or DTC to handle writing of data to the TDR register. Furthermore, other than for the last data to be received, an RXI request can activate the DMAC or DTC to handle reading of data from the RDR register.

[6] NACK is transmitted in response to the last data.

[7] Generation of a stop condition.

Note: In simple I²C mode, the TXI interrupt request is generated when communication is completed, unlike the timing during clock-synchronous transmission.

Figure 32.60 Example of the Procedure for Master Reception Operations in Simple I²C Mode (with Transmission Interrupts and Reception Interrupts in Use)

32.7.7 Recovery from Bus Hang-up

If the bus is stuck by an abnormal state in SCI because of the communication error, reset the SCI according to the following steps and release the bus.

(1) Set the SCR.TE and RE bit to 0 at the same time to reset SCI.
(2) Set the SIMR3 register to F0h to release the bus.
(3) If the SSR.RDRF flag is 1, dummy-read the RDR register to clear the flag.
(4) Set the SCR.TE and RE bit to 1 at the same time.

32.8 Operation in Simple SPI Mode

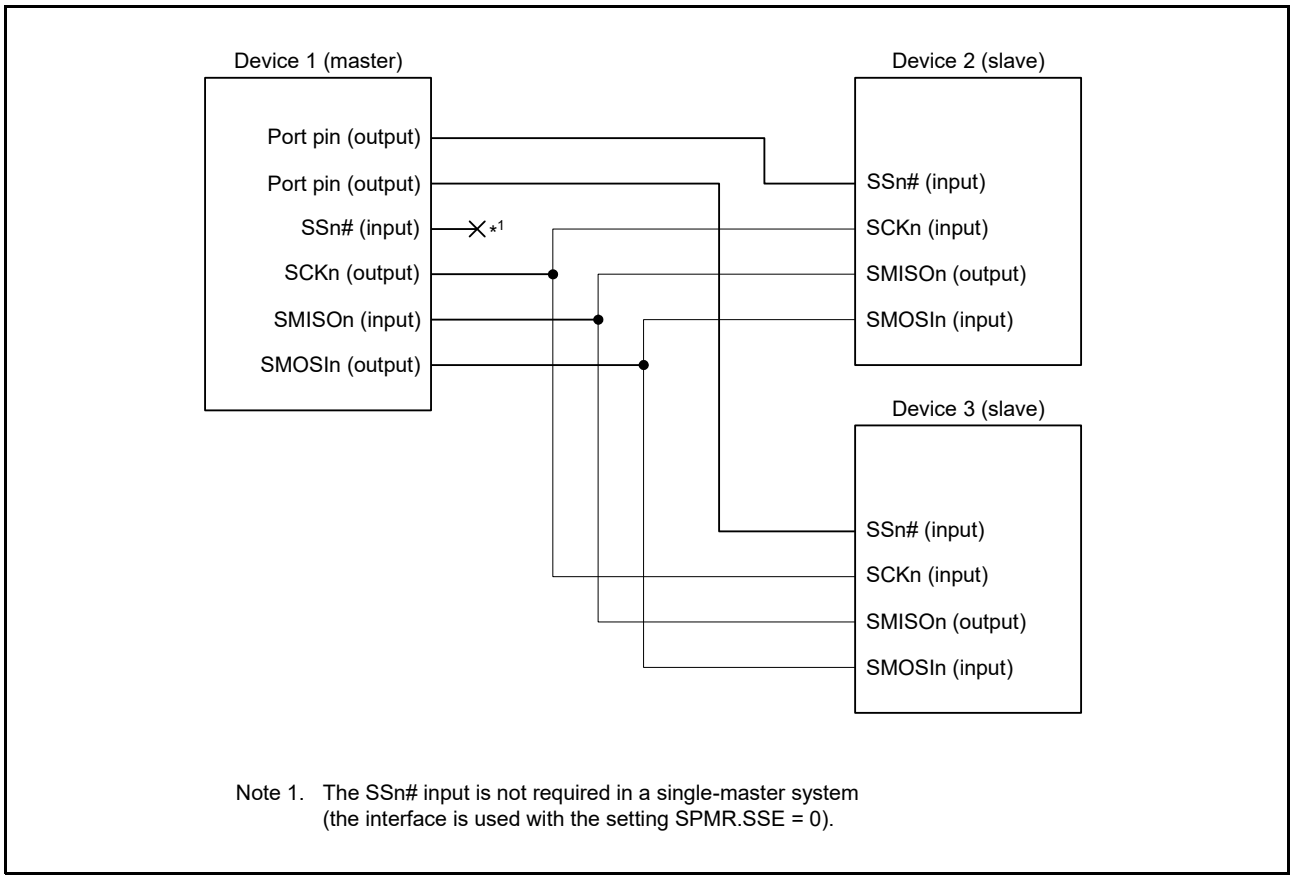
As an extended function, the SCI supports a simple SPI mode that handles transfer among one or multiple master devices and multiple slave devices.

Making the settings for clock synchronous mode (SCMR.SMIF = 0, SIMR1.IICM = 0, SMR.CM = 1) plus setting the SPMR.SSE bit to 1 places the SCI in simple SPI mode. However, the SS pin function on the master side is unnecessary for connection of the device used as the master in simple SPI mode when the configuration only has a single master, so set the SPMR.SSE bit to 0 in such cases.

Figure 32.61 shows an example of connections for simple SPI mode. Control a general port pin to produce the SS output signal from the master.

In simple SPI mode, data are transferred in synchronization with clock pulses in the same way as in clock synchronous mode. One character of data for transfer consists of 8 bits of data, and parity bits cannot be appended to this. The data can be inverted by setting the SCMR.SINV bit to 1.

Since the receiver and transmitter are independent of each other within the SCI module, full-duplex communications are possible, with a common clock signal. Furthermore, since both the transmitter and receiver have a double-buffered structure, writing of further transmit data while transmission is in progress and reading of previously received data while reception is in progress are both possible. Continuous transfer is thus possible.



Note 1. The SSn# input is not required in a single-master system (the interface is used with the setting SPMR.SSE = 0).

Figure 32.61 Example of Connections via a Simple SPI Mode (In Single Master Mode, SPMR.SSE Bit = 0)

32.8.1 States of Pins in Master and Slave Modes

The direction (input or output) of pins for the simple SPI mode interface differs according to whether the device is a master (SCR.CKE[1:0] = 00b or 01b and SPMR.MSS = 0) or slave (SCR.CKE[1:0] = 10b or 11b and SPMR.MSS = 1). Table 32.35 lists the states of pins according to the mode and the level on the SSn# pin.

Table 32.35 States of Pins by Mode and Input Level on the SSn# Pin

Mode	Input on SSn# Pin	State of SMOSIn Pin	State of SMISOn Pin	State of SCKn Pin
Master mode*1	High level (transfer can proceed)	Output for data transmission*2	Input for received data	Clock output*3
	Low level (transfer cannot proceed)	High-impedance	Input for received data (but disabled)	High-impedance
Slave mode	High level (transfer cannot proceed)	Input for received data (but disabled)	High-impedance	Clock input (but disabled)
	Low level (transfer can proceed)	Input for received data	Output for data transmission	Clock input

Note 1. When there is only a single master (SPMR.SSE = 0), transfer is possible regardless of the input level on the SSn# pin (this is equivalent to input of a high level on the SSn# pin). Since the SSn# pin function is not required, the pin is available for other purposes.
Note 2. The SMOSIn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE bit = 0).
Note 3. The SCKn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE and RE bits = 00b) in a multi-master configuration (SPMR.SSE = 1).

32.8.2 SS Function in Master Mode

Setting the SCR.CKE[1:0] bits to 00b and the SPMR.MSS bit to 0 selects master operation. The SSn# pin is not used in single-master configurations (SPMR.SSE = 0), so transmission or reception can proceed regardless of the value of the SSn# pin.

When the level on the SSn# pin is high in a multi-master configuration (SPMR.SSE = 1), a master device outputs clock signals from the SCKn pin before starting transmission or reception to indicate that there are no other masters or another master is performing reception or transmission. When the level on the SSn# pin is low in a multi-master configuration (SPMR.SSE = 1), there are other masters, and this indicates that transmission or reception is in progress. At this time the SMOSIn output and SCKn pins will be placed in the high-impedance state and starting transmission or reception will not be possible. Furthermore, the value of the SPMR.MFF bit will be 1, indicating a mode fault error. In a multi-master configuration, start error processing by reading SPMR.MFF flag. Also, even if a mode fault error occurs while transmission or reception is in progress, transmission or reception will not be stopped, but the SMOSIn and SCKn pin output will be placed in the high-impedance state after the completion of the transfer.

Control a general port pin to produce the SS output signal from the master.

32.8.3 SS Function in Slave Mode

Setting the SCR.CKE[1:0] bits to 10b and the SPMR.MSS bit to 1 selects slave operation. When the level on the SSn# pin is high, the SMISOn output pin will be in the high-impedance state and clock input through the SCKn pin will be ignored. When the level on the SSn# pin is low, clock input through the SCKn pin will be effective and transmission or reception can proceed.

If the input on the SSn# pin changes from low to high level during transmission or reception, the SMISOn output pin will be placed in the high-impedance state. Meanwhile, the internal processing for transmission or reception will continue at the rate of the clock input through the SCKn pin until processing for the character currently being transmitted or received is completed, after which it stops. At that time, an interrupt (the appropriate one from among TXI, RXI, and TEI) will be generated.

32.8.4 Relationship between Clock and Transmit/Receive Data

The CKPOL and CKPH bits in the SPMR register can be used to set up the clock for use in transmission and reception in four different ways. The relation between the clock signal and the transmission and reception of data is shown in Figure 32.62. The relation is the same for both master and slave operation.

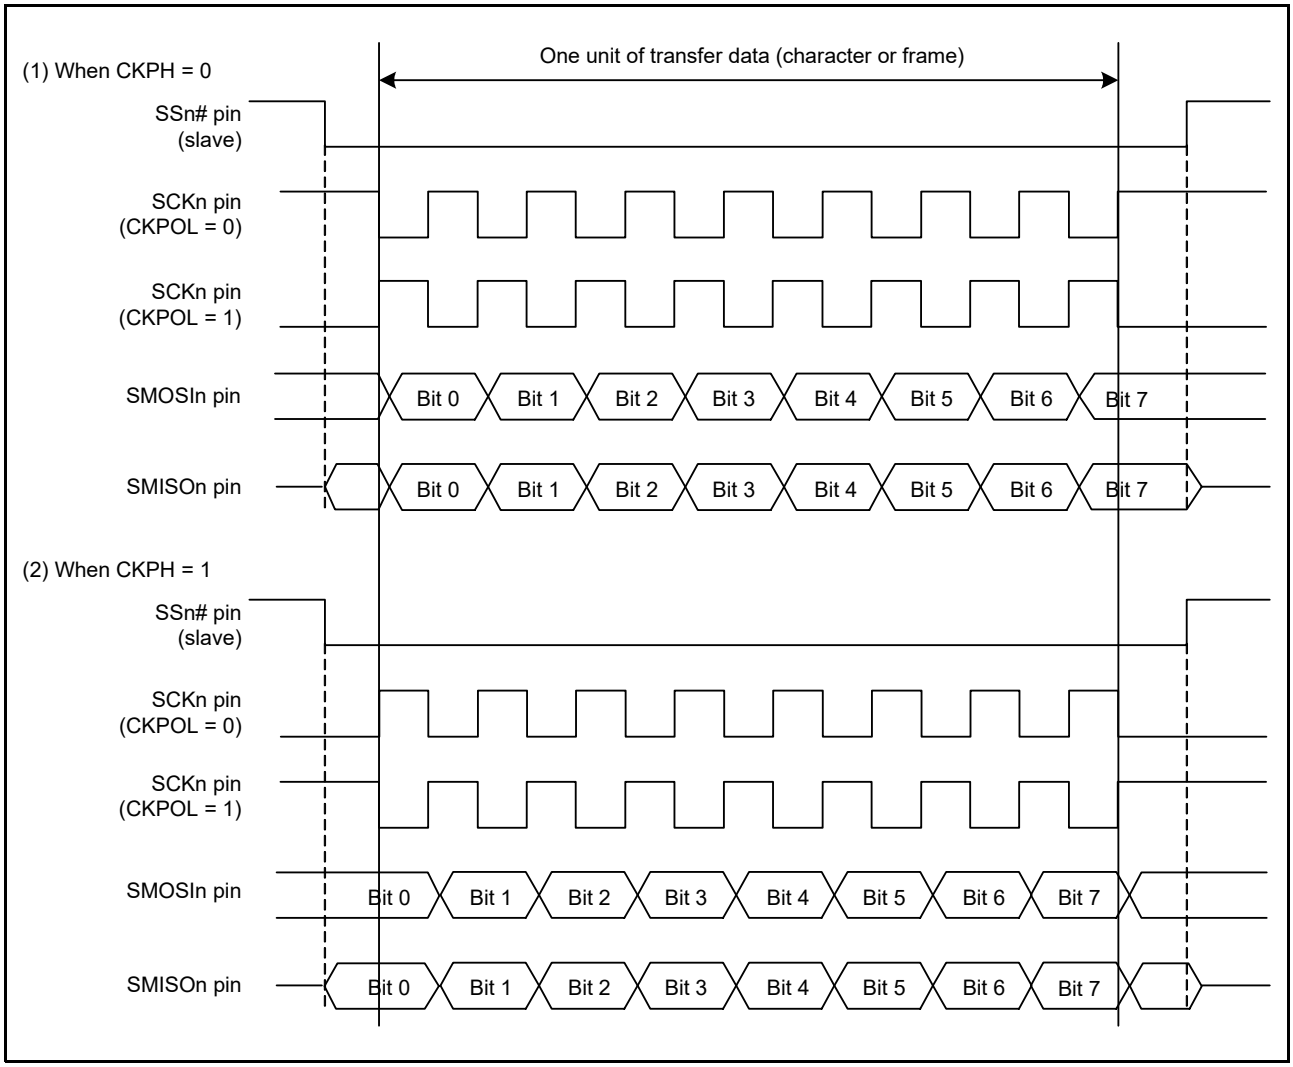


Figure 32.62 Relation between Clock Signal and Transmit/Receive Data in Simple SPI Mode

32.8.5 SCI Initialization (Simple SPI Mode)

The procedure is the same as for initialization in clock synchronous mode Figure 32.28, Sample SCI Initialization Flowchart. The CKPOL and CKPH bits in the SPMR register must be set to ensure that the kind of clock signal they select is suitable for both master and slave devices.
For initialization, changes to the operating mode, changes to the transfer format, and so on, initialize the SCR register before proceeding with changes.
As well as setting the RE bit to 0, note that the SSR.ORER, FER, and PER flags, as well as the RDR register, are not initialized.

32.8.6 Transmission and Reception of Serial Data (Simple SPI Mode)

In master operation, ensure that the SSn# pin of the slave device on the other side of the transfer is at the low level before starting the transfer and at the high level on completion of the transfer. Otherwise, the procedures are the same as in clock synchronous mode.

32.9 Bit Rate Modulation Function

The bit rate modulation function corrects the bit rate by thinning out the specified amount of clocks from those input to the baud rate generator.
When the SEMR.BRME bit is 1, the baud rate generator validates and counts the average interval of the number of clocks set in the MDDR register out of the total 256 clocks input.
Figure 32.63 assumes the SCI is in asynchronous mode, bits SMR.CKS[1:0] are 00b, the BRR register is 00h, and the MDDR register is 160. In this example, the cycle of the base clock is evenly corrected to 256/160, and the bit rate is corrected to 160/256. Note that there is an imbalance in thinning out the internal clock, and expansion and contraction occur in the pulse width of the base clock.

Note: Do not use this function in the highest speed settings (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0) in clock synchronous mode and simple SPI mode.

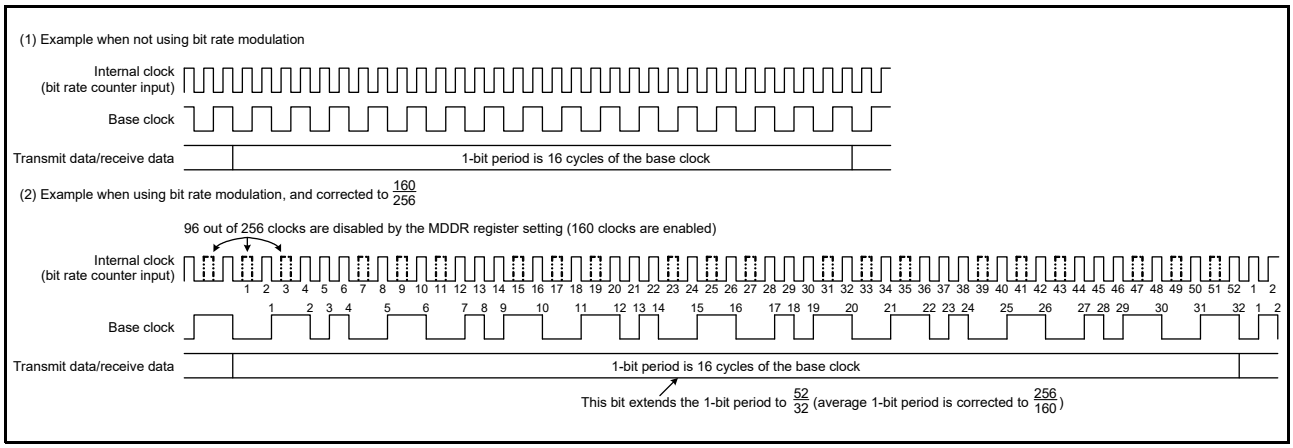

Figure 32.63 Example of the Base Clock When the Bit Rate Modulation Function is Used

The input of a clock signal with a shorter period to the baud rate generator reduces difference in the generated base clock period and, since the division ratio of the baud rate generator also becomes larger, reduces difference in the length of the 1-bit period.

32.10 Extended Serial Mode Control Section: Description of Operation

32.10.1 Serial Transfer Protocol

The extended serial mode control section of the SCI12 can realize the serial transfer protocol composed of Start Frames and Information Frames that is shown in Figure 32.64.
A Start Frame is composed of a Break Field, Control Field 0, and Control Field 1. An Information Frame is composed of a number of Data Fields, a CRC16 Upper Field, and a CRC16 Lower Field.

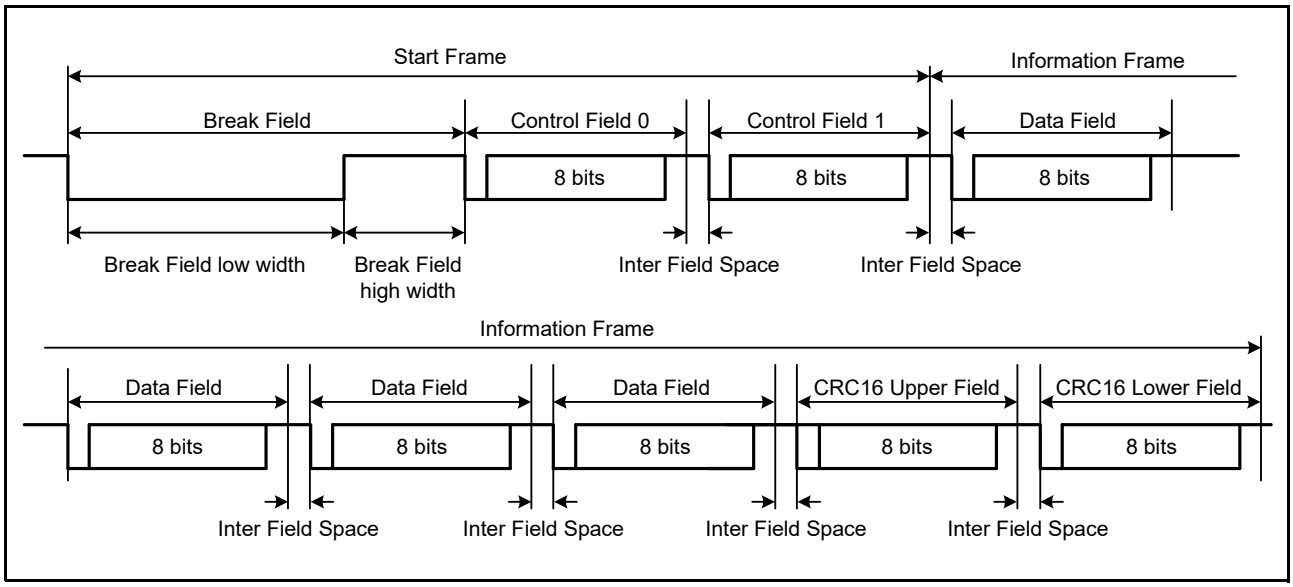

Figure 32.64 Protocol for Serial Transfer by the Extended Serial Mode Control Section

32.10.2 Transmitting a Start Frame

Figure 32.65 shows an example of operations to transmit a Start Frame, which is composed of the Break Field low width, Control Field 0, and Control Field 1. Figure 32.66 and Figure 32.67 are flowcharts for the transmission of a Start Frame.
Operations when the extended serial mode control section is to be used to transmit a Start Frame are as listed below. Be sure to use the SCI12 in asynchronous mode.

(1) With Break Field low width output mode as the operating mode for the timer, writing 1 to the TCR.TCST bit starts counting by the timer, and the low level will be output from the TXDX12 pin over the period corresponding to registers TCNT and TPRE settings.
(2) The output on the TXDX12 pin is inverted when the timer counter underflows, and the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.
(3) Write 0 to the TCR.TCST bit to stop counting by the timer, and send the data for Control Field 0. After the Break Field low width output, stop counting before the next underflow occurs.
(4) When the data for Control Field 0 have been transmitted, the data for Control Field 1 is transmitted.
(5) When the data for Control Field 1 have been transmitted, an Information Frame is transmitted.

Omit the Break Field and Control Field 0 to suit the structure of the Start Frame.

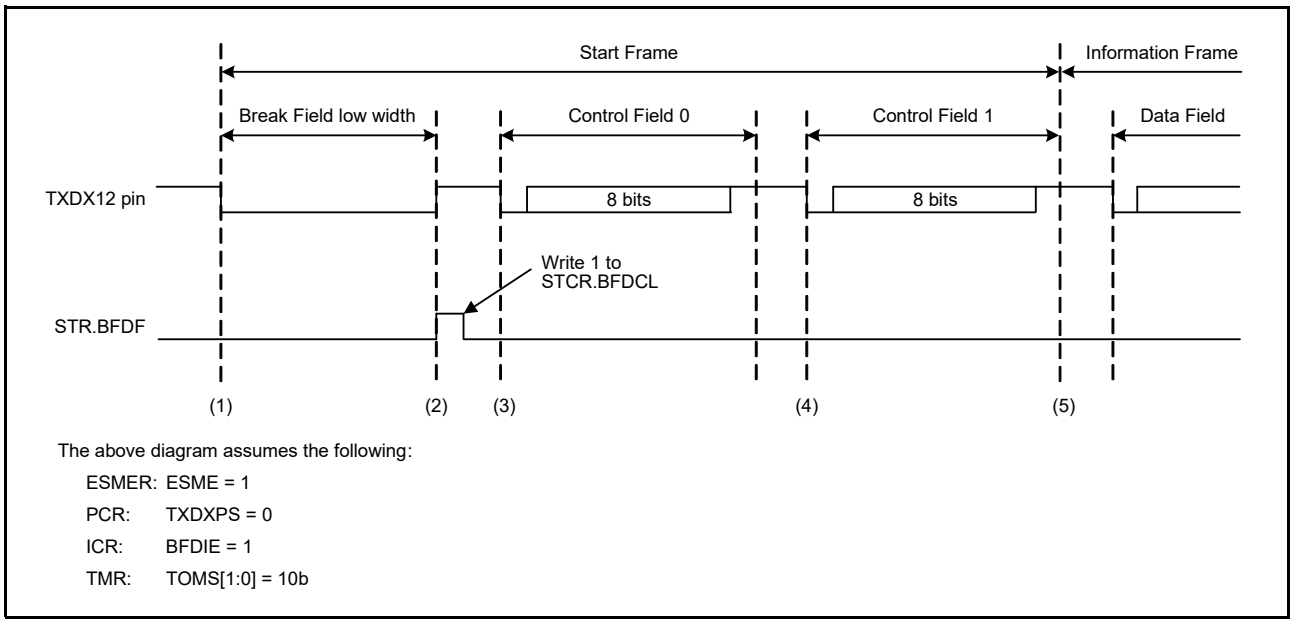

Figure 32.65 Example of Operations When Transmitting a Start Frame

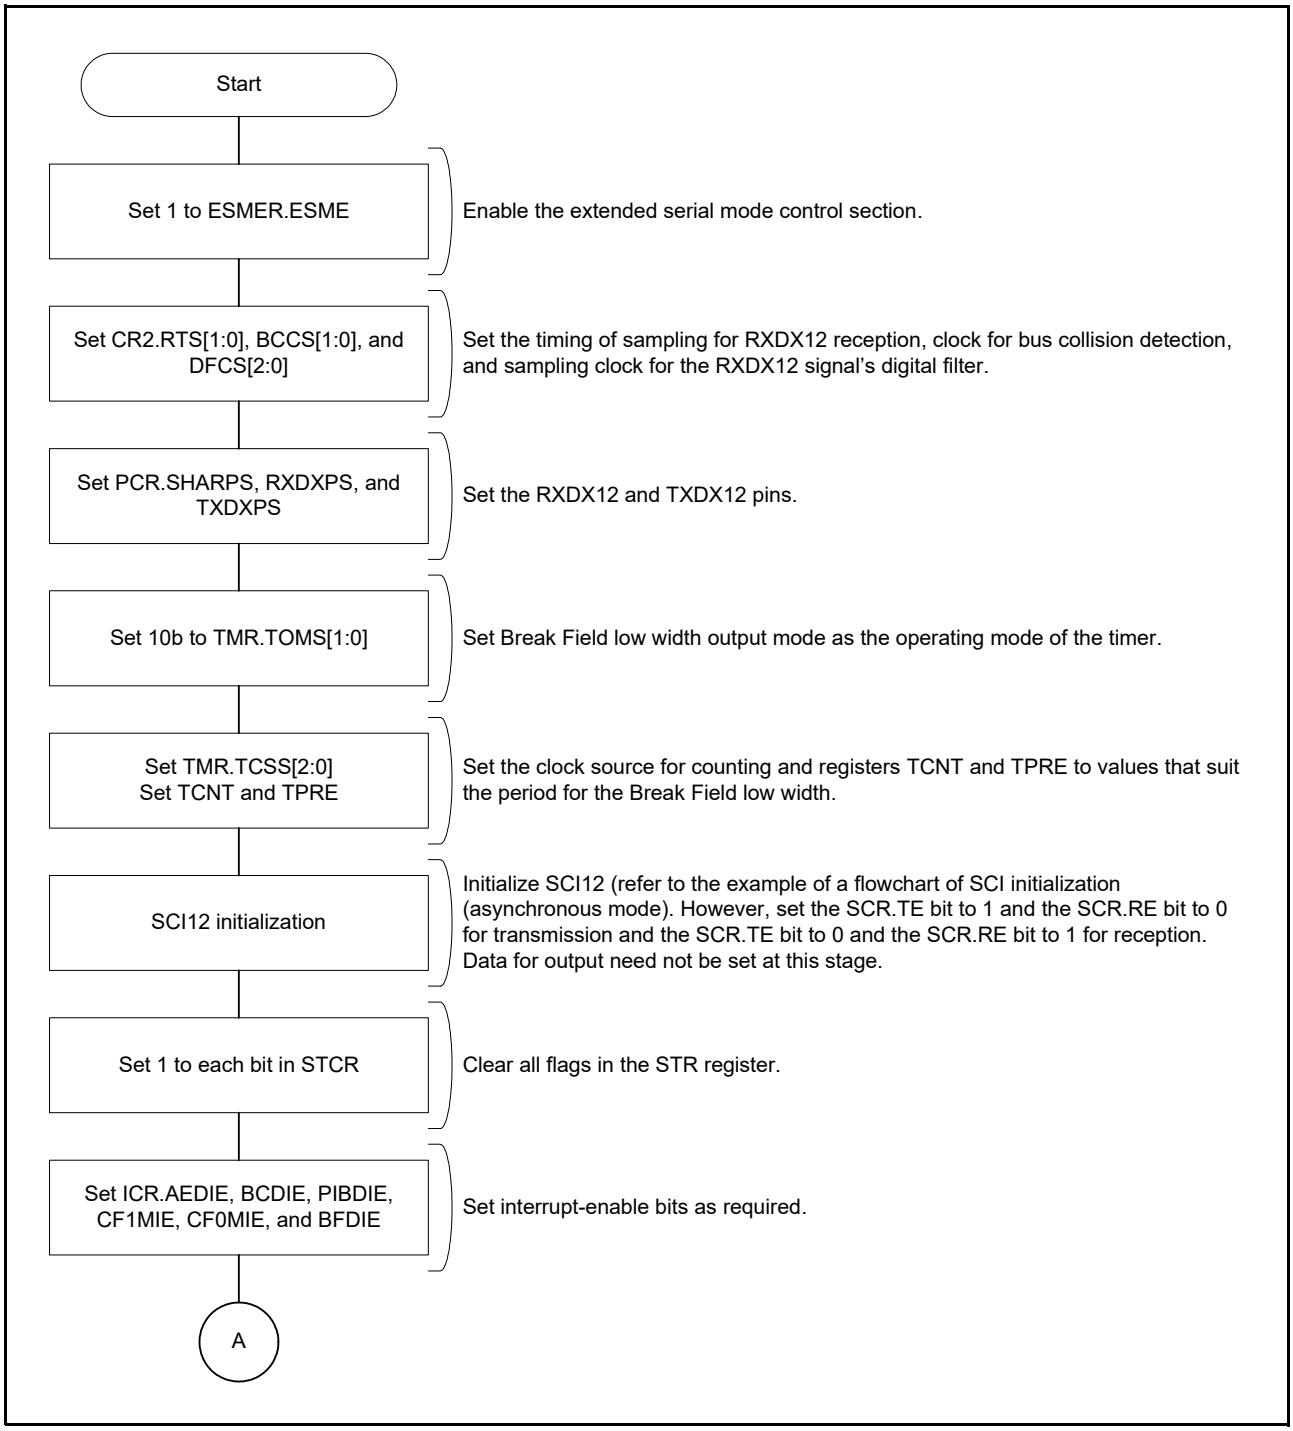

Figure 32.66 Example of Start Frame Transmission (1/2)

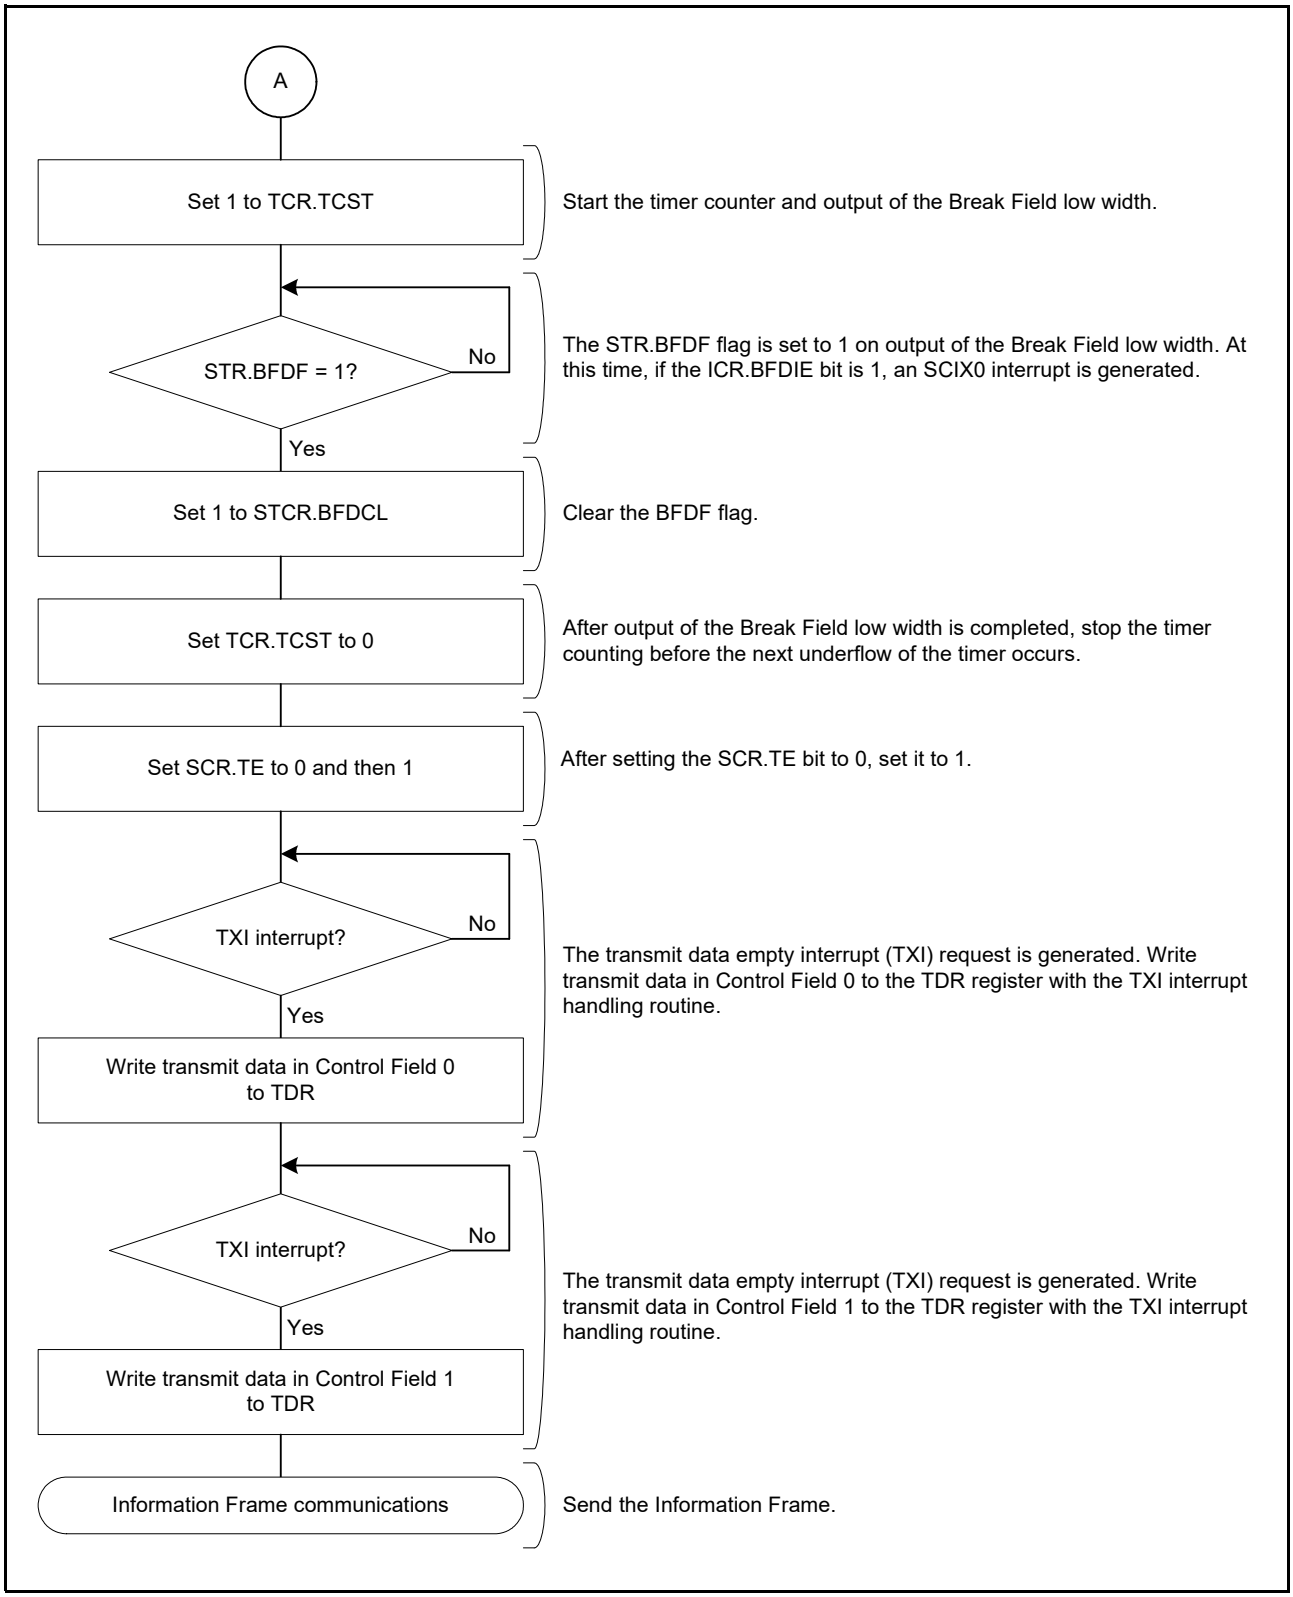

Figure 32.67 Example of Start Frame Transmission (2/2)

32.10.3 Receiving a Start Frame

The extended serial mode control section is capable of receiving Start Frames with the structures listed in Table 32.36.

Table 32.36 Structures of Start Frames

Bit Setting		Structures of Start Frames
BFE	CF0RE	
0	0	Control Field 1 (8 bits) → Information Frame
0	1	Control Field 0 (8 bits) → Control Field 1 (8 bits) → Information Frame
1	0	Break Field (low width) → Control Field 1 (8 bits) → Information Frame
1	1	Break Field (low width) → Control Field 0 (8 bits) → Control Field 1 (8 bits) → Information Frame

Figure 32.68 shows an example of operations to receive a Start Frame, which is composed of the Break Field low width, Control Field 0, and Control Field 1. Figure 32.69 and Figure 32.70 are flowcharts for the reception of a Start Frame, and Figure 32.71 is a state transition diagram when receiving a Start Frame.
Operations when the extended serial mode control section is to be used to receive a Start Frame are as listed below. Be sure to use the SCI12 in asynchronous mode.

(1) With Break Field low width detection mode as the operating mode for the timer, writing 1 to the CR3.SDST bit enables detection of the Break Field low width.
(2) Low-level input on the RXDX12 pin continuing over a period longer than that corresponding to the settings of registers TCNT and TPRE is detected as the Break Field low width. At this time, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.
(3) When the input from the RXDX12 pin goes high after the Break Field low width, the CR0.RXDSF flag becomes 0 and reception of Control Field 0 starts.
(4) If the data received in Control Field 0 match the data set in the CF0DR register, the STR.CF0MF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.CF0MIE bit is 1. Reception of Control Field 1 starts after that. If the data received in Control Field 0 do not match the data set in the CF0DR register, a transition to the state prior to Break Field low width detection proceeds.
(5) If the data received in Control Field 1 match the data set in registers PCF1DR and SCF1DR, the STR.CF1MF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.CF1MIE bit is 1. Transfer of the Information Frame starts after that. If the data received in Control Field 1 do not match the data set in either or both of registers PCF1DR and SCF1DR, a transition to the state prior to Break Field low width detection proceeds.

Omit the Break Field and Control Field 0 to suit the structure of the Start Frame.

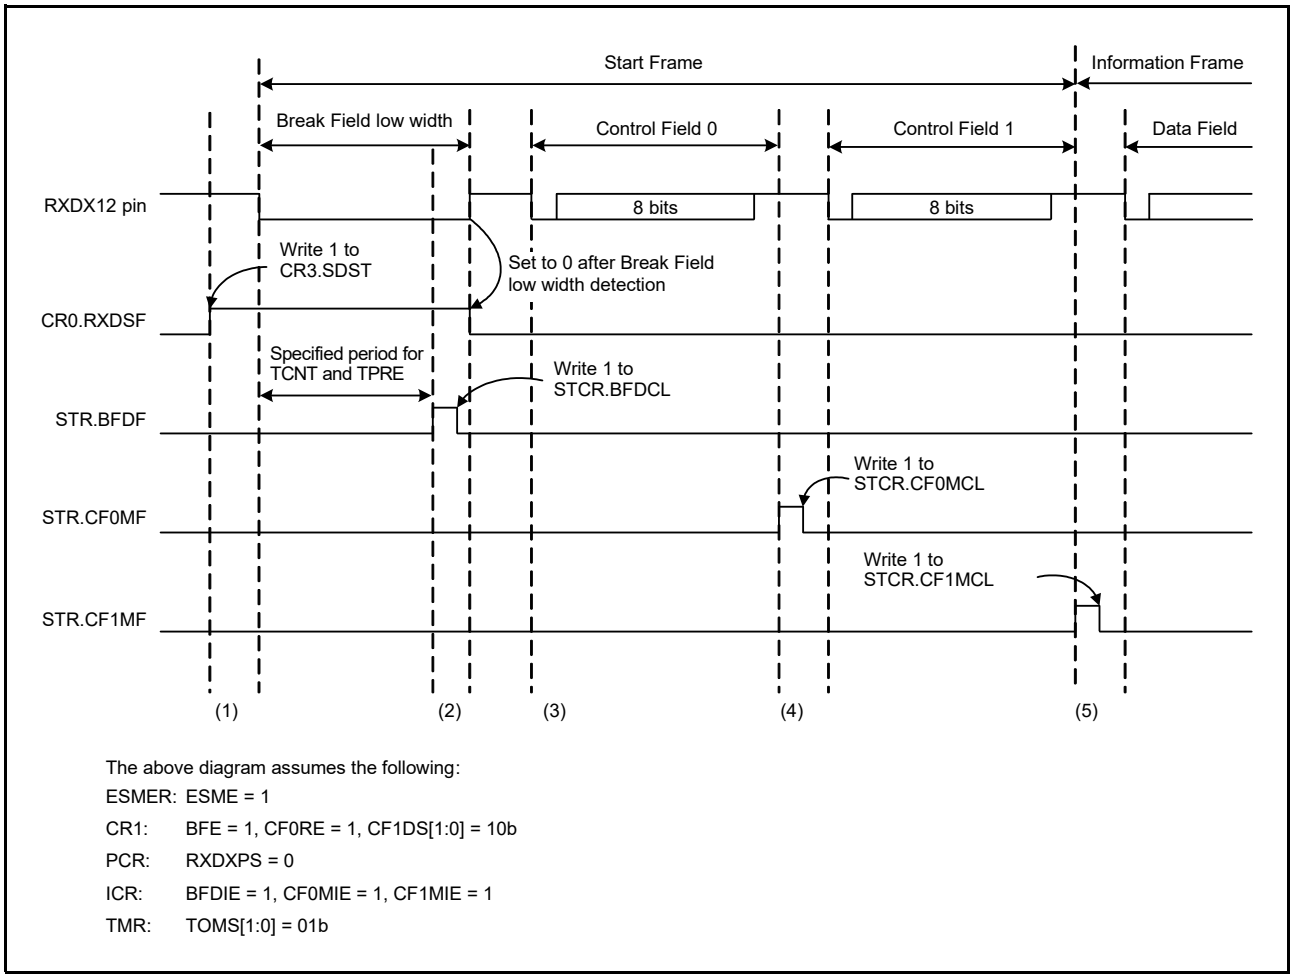

Figure 32.68 Example of Operations at the Time of Start Frame Reception

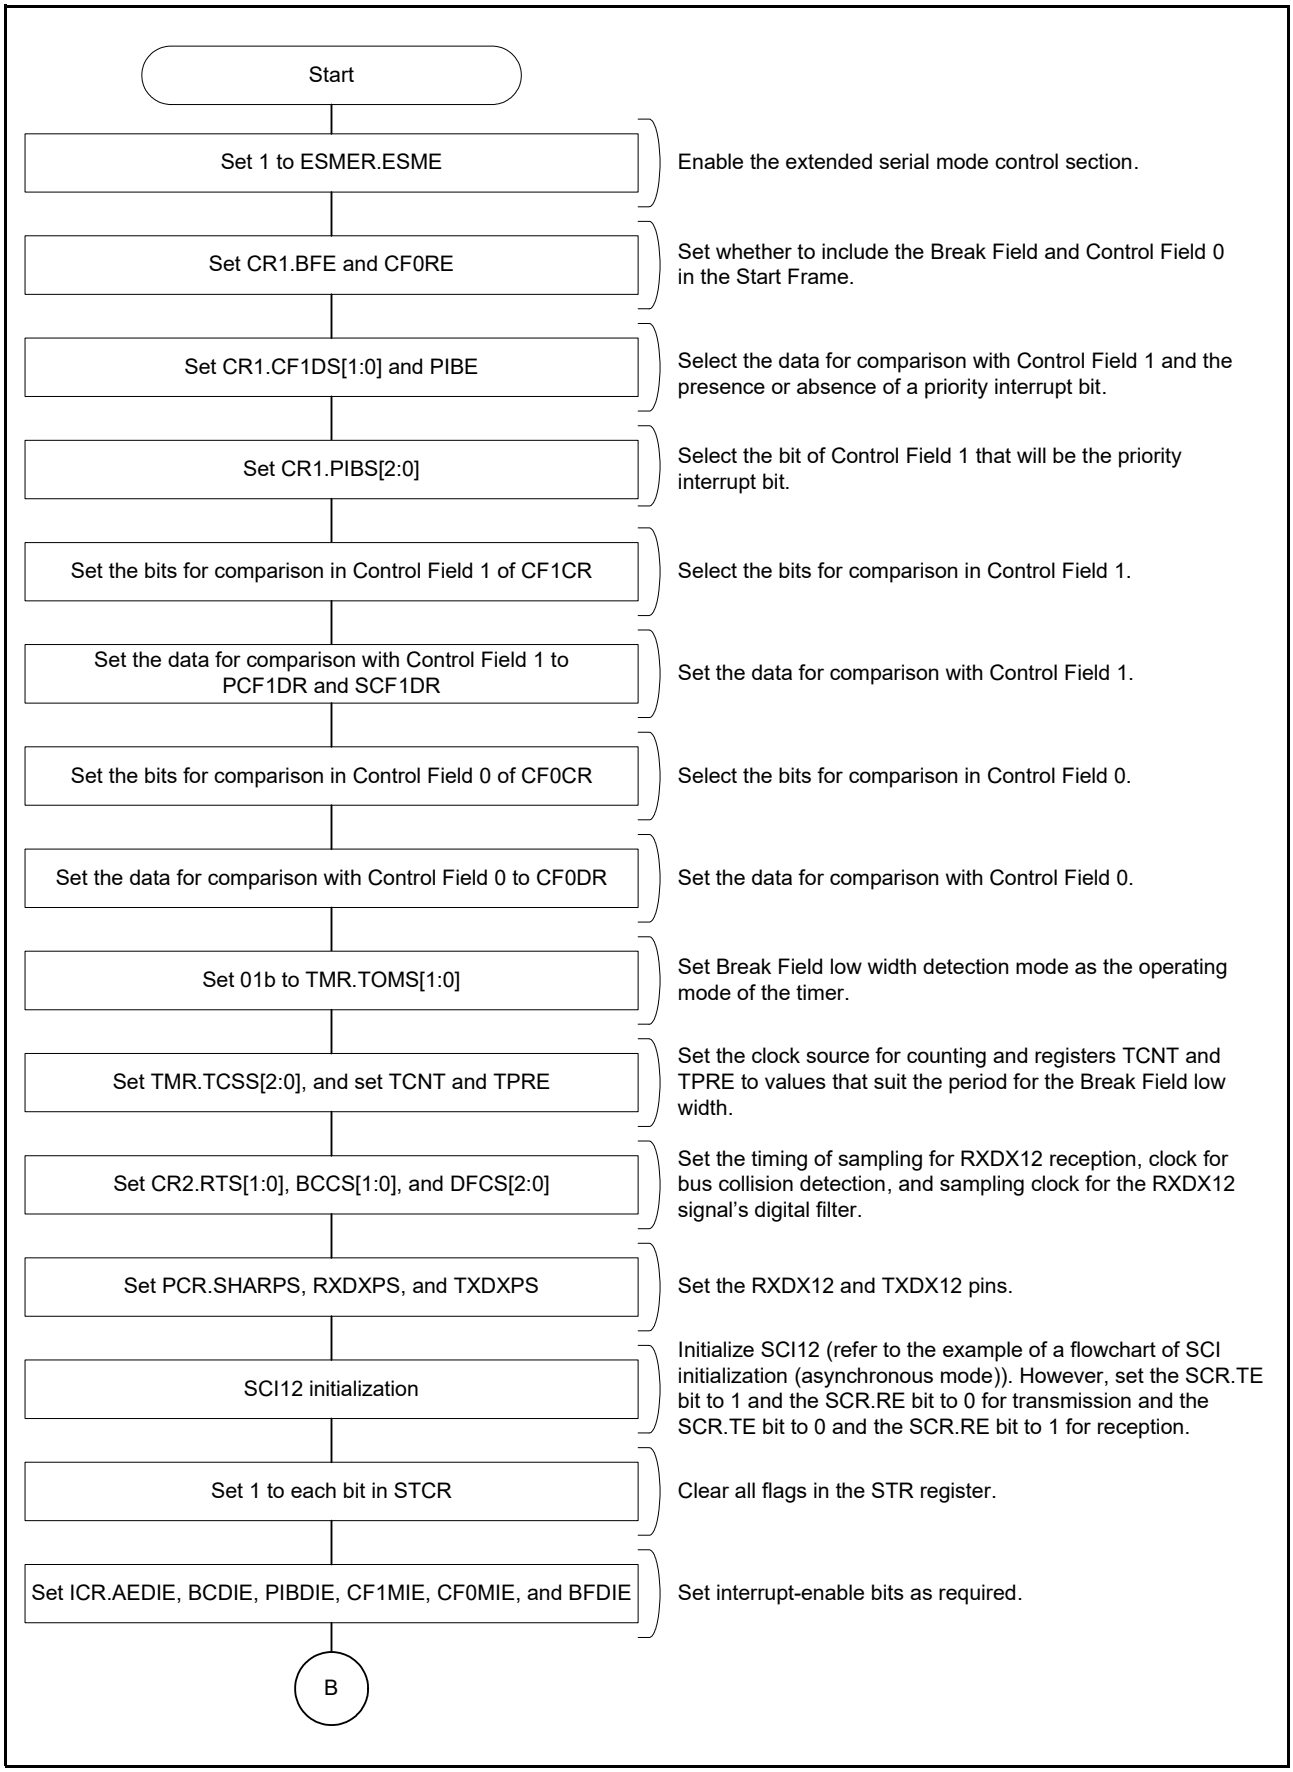

Figure 32.69 Sample Flowchart for Reception of a Start Frame (1)

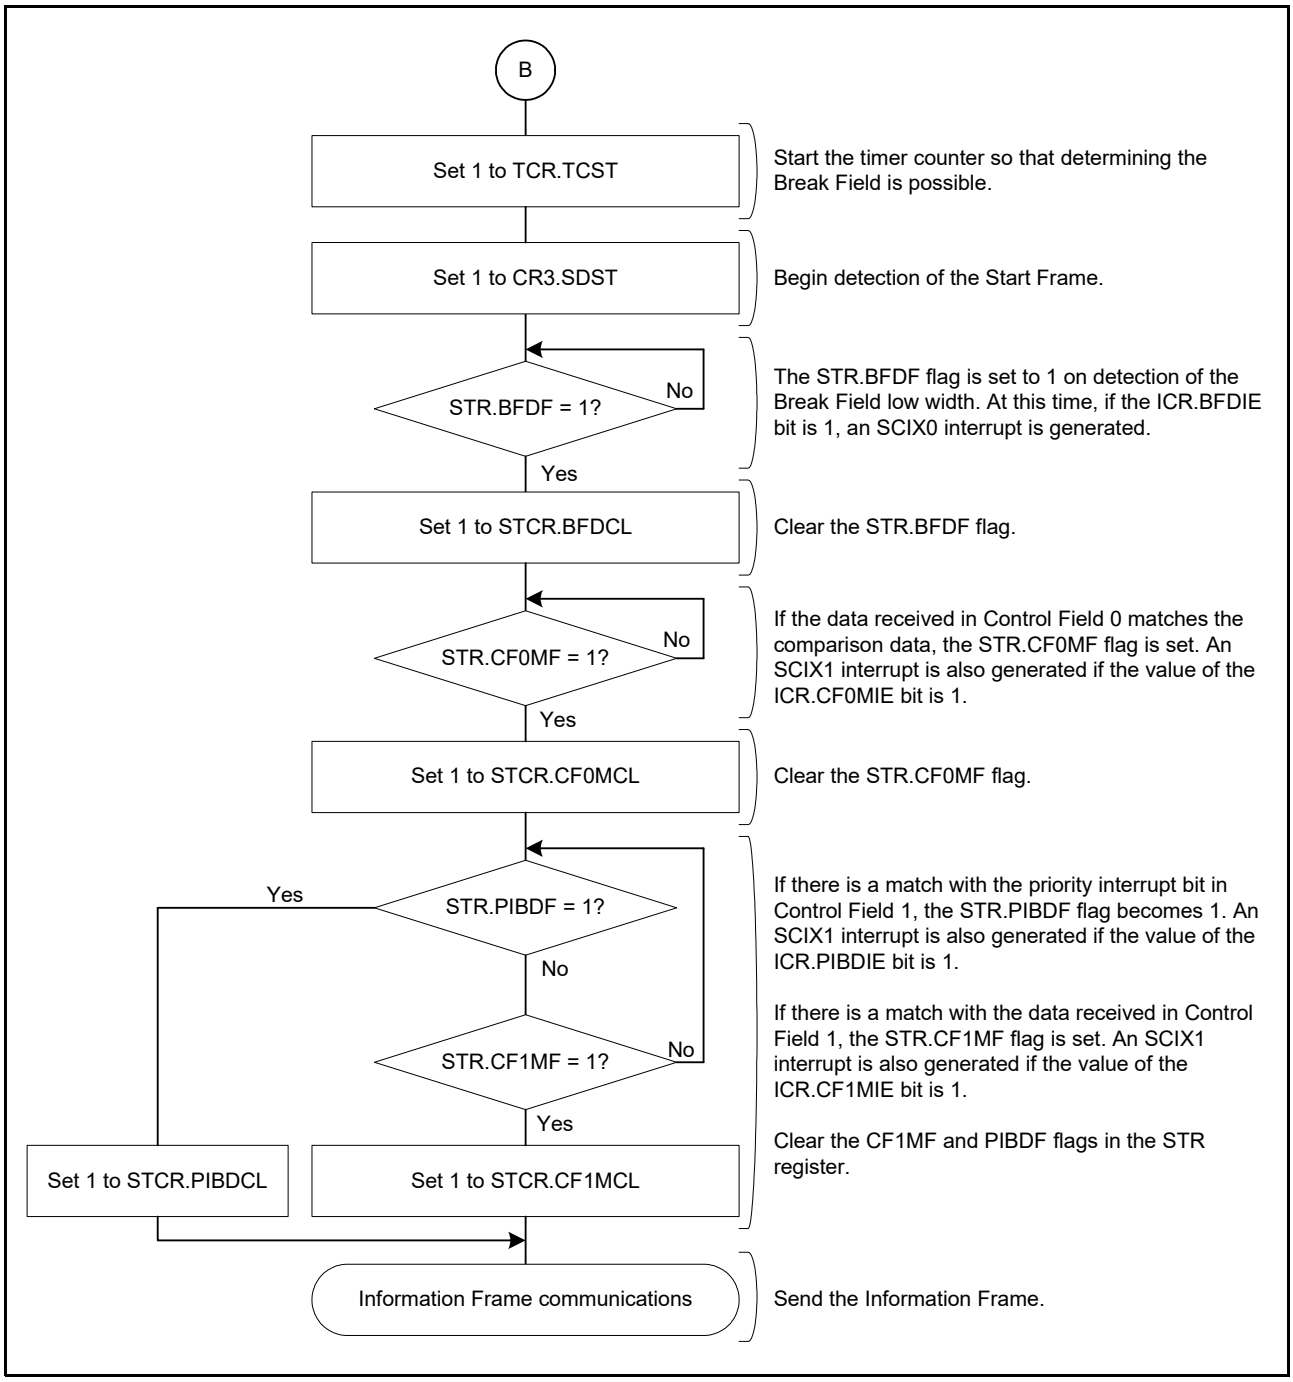

Figure 32.70 Sample Flowchart for Reception of a Start Frame (2)

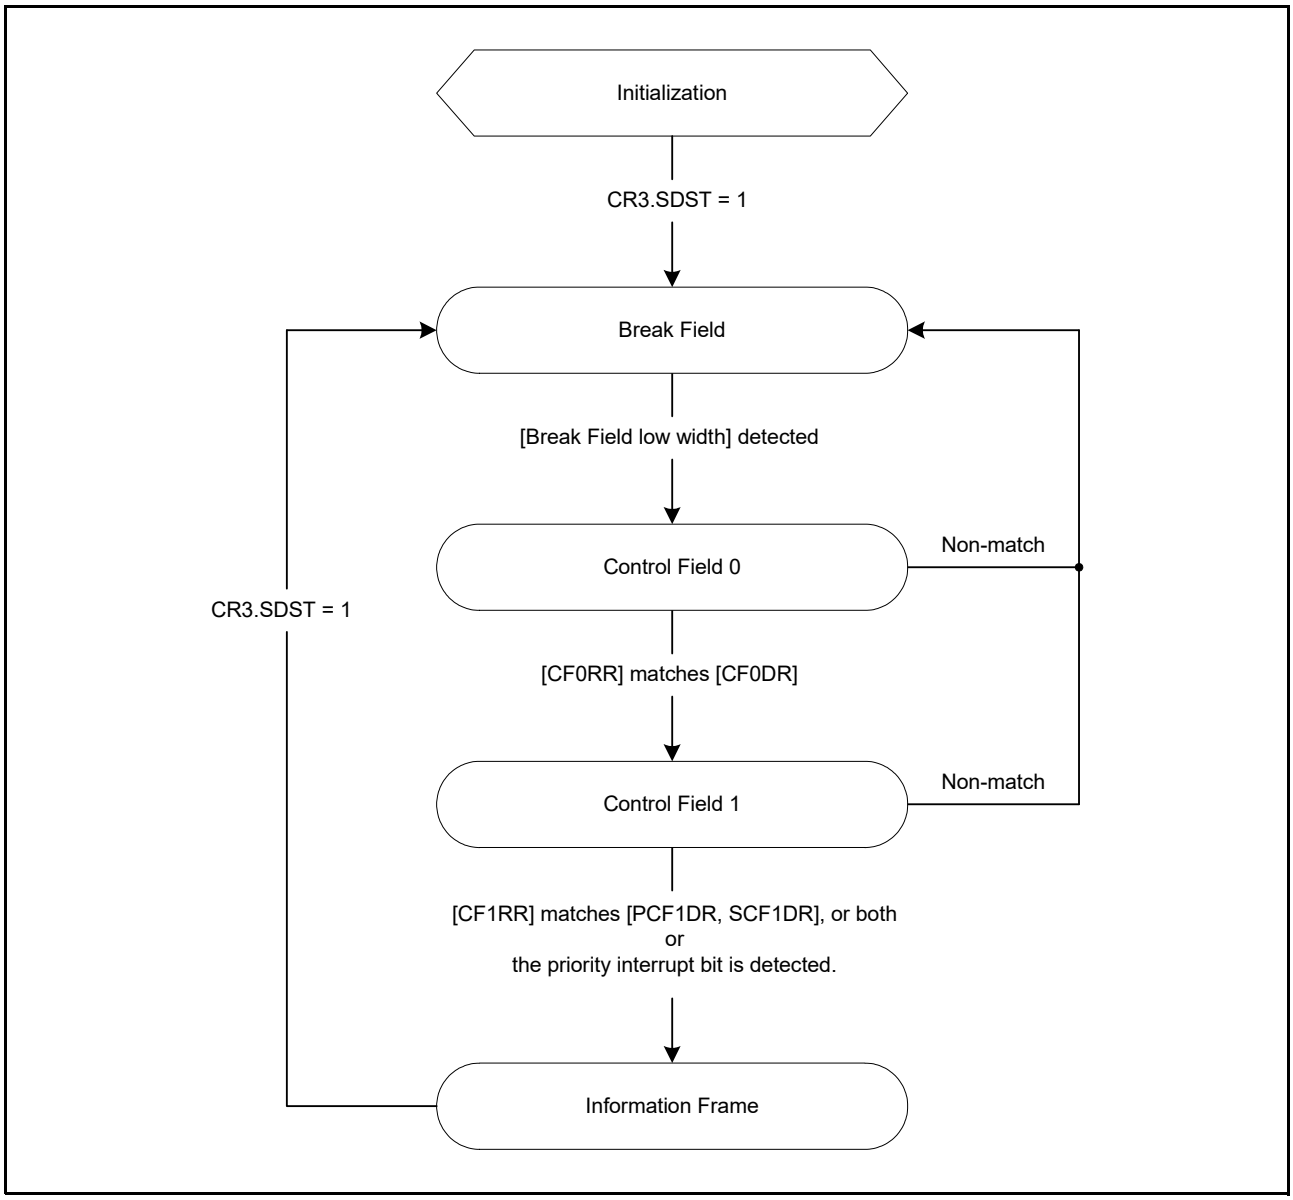

Figure 32.71 State Transitions When Receiving a Start Frame

32.10.3.1 Priority Interrupt Bit

Figure 32.72 shows an example of operation in Start Frame reception where a priority interrupt bit is in use. Setting the CR1.PIBE bit to 1 enables the use of a priority interrupt bit.
Operations of the extended serial mode control section in start Frame reception where a priority interrupt bit is in use are as described below.

Steps (1) to (4) are the same as in Figure 32.68, for Start Frame reception.

(5) If the value of the bit selected by the CR1.PIBS[2:0] bits matches the corresponding bit in the PCF1DR register, the STR.PIBDF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.PIBDIE bit is 1. Transfer of the Information Frame starts after that. If the data received in Control Field 1 do not match the data set in either or both of registers PCF1DR and SCF1DR and the priority interrupt bit is not detected, a transition to the state prior to Break Field low width detection proceeds.

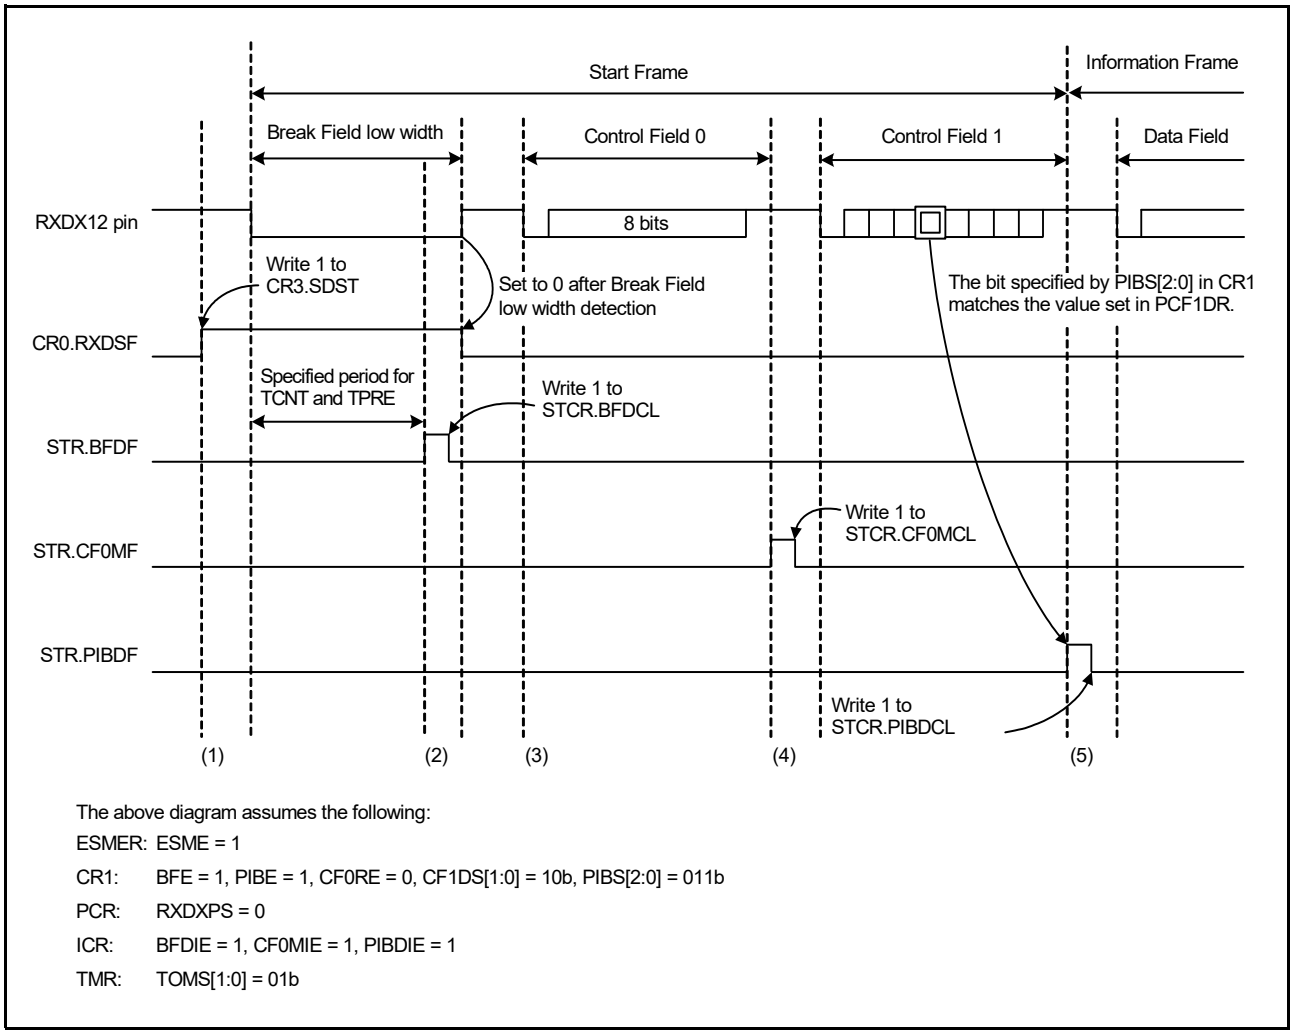

Figure 32.72 Example of Operations When Receiving a Start Frame While the CR1.PIBE Bit is 1

32.10.4 Detection of Bus Collisions

Detection of bus collisions operate for cases where output of the Break Field low width and transmission of data are in progress when the ESMER.ESME bit and the SCR.TE bit are set to 1.

Figure 32.73 shows an example of operations with bus collision detection. Signals output through TXDX12 and input through RXDX12 are sampled with the bus collision detection clock set with the CR2.BCCS[1:0] bits as the sampling clock, and the STR.BCDF flag is set to 1 if the signals fail to match three times in a row. An SCIX2 interrupt is also generated if the value of the ICR.BCDIE bit is 1.

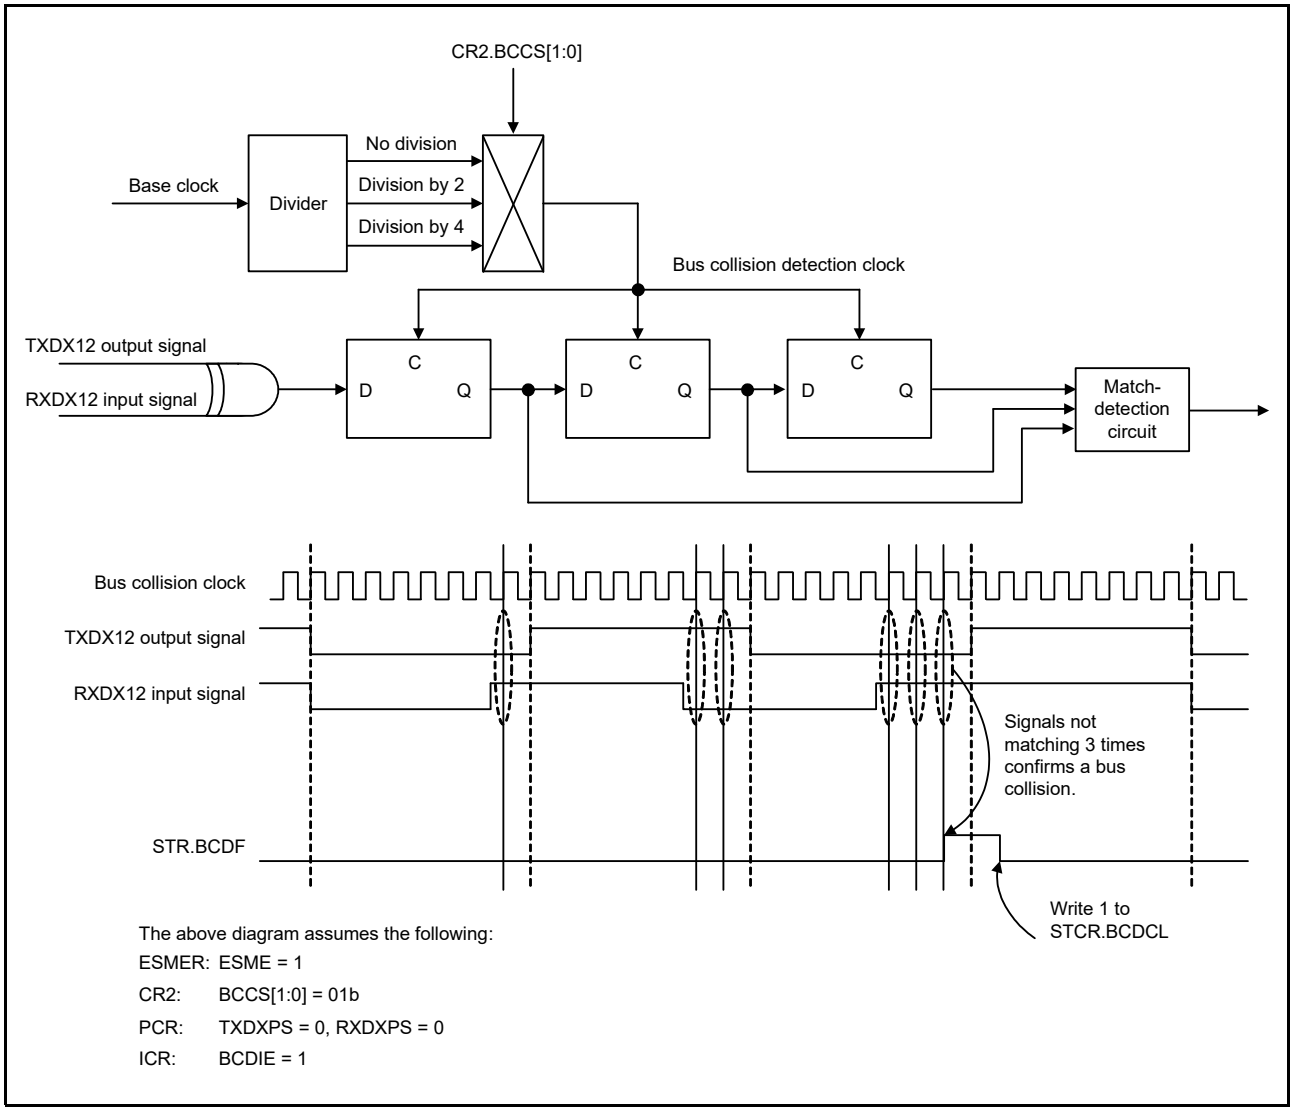

Figure 32.73 Example of Operations with Bus Collision Detection

32.10.5 Digital Filter for Input on the RXDX12 Pin

Signals input through the RXDX12 pin can be passed through a digital filter before they are conveyed to the internal circuits. The digital filter consists of three flip-flop circuit stages connected in series and a match-detecting circuit. The CR2.DFCS[2:0] bits select the sampling clock for the RXDX12 pin input signals. If the outputs of all three latches match, the given level is conveyed to subsequent circuits. If the levels do not match, the previous value is retained. In other words, levels are confirmed as being the signal if they are retained for at least three cycles of the sampling clock but judged to be noise rather than changes in the signal level if they change within three cycles of the sampling clock. Figure 32.74 shows an example of operations with the digital filter.

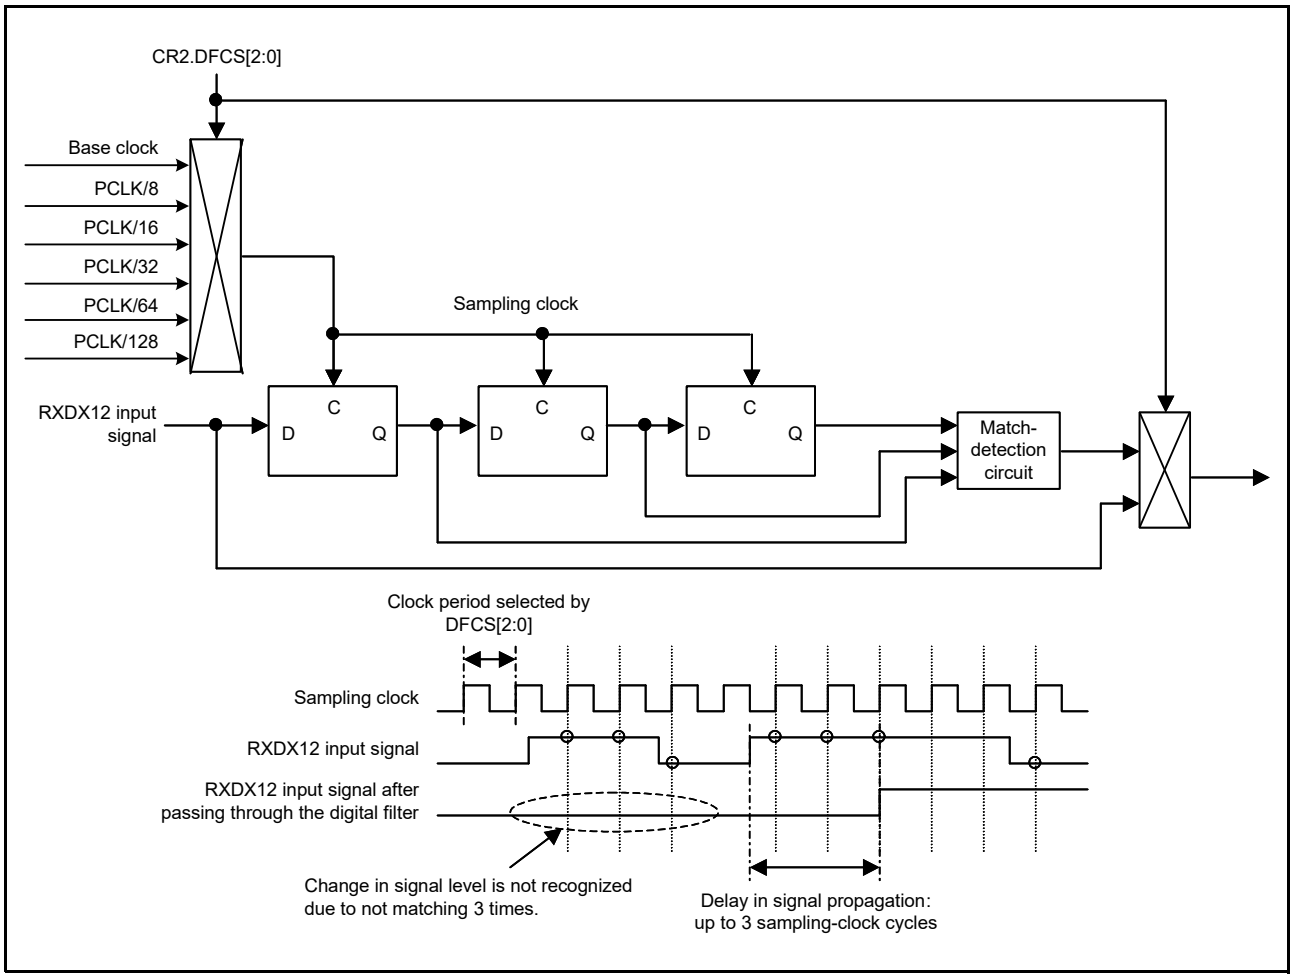

Figure 32.74 Example of Operations with the Digital Filter

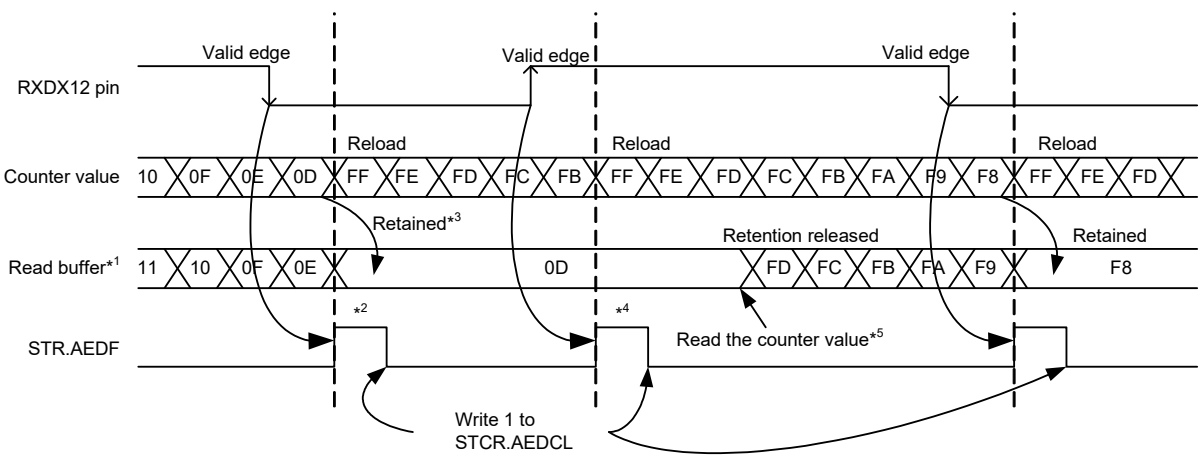
32.10.6 Bit Rate Measurement

The bit rate measurement function measures the intervals between rising and falling edges and between falling and rising edges of the signal input from the RXDX12 pin. Figure 32.75 shows an example of operations for bit rate measurement.

(1) Writing 1 to the CR0.BRME bit enables bit rate measurement. Only set the BRME bit to 1 when you wish to proceed with bit rate measurement. Furthermore, bit rate measurement will not proceed during a Break Field, even if the BRME bit is set to 1.
(2) After detection of the Break Field low width, bit rate measurement starts when the level input on the RXDX12 pin becomes high.
(3) Once bit rate measurement has started, counter values from the timer are retained in the read buffers on the input of valid edges from the RXDX12 pin (rising and falling edges) and the counter is reloaded. An SCIX3 interrupt is also generated if the value of the ICR.AEDIE bit is 1. Retention by registers TCNT and TPRE is released by reading these registers.
(4) The bit rate as calculated from the values counted during intervals between valid edges can be used for adjusting the rate by changing the settings of the BRR register. To disable the bit rate measurement after a match with Control Field 1, write 0 to the CR0.BRME bit.



Note 1. The TCNT or TPRE register indicates the contents of the read buffers.
Note 2. The STR.AEDF flag becomes 1 on detection of a valid edge.
Note 3. When an effective edge is detected, the current value of the counter is stored in the read buffer.
Note 4. The value retained in the read buffers due to one valid edge is not updated to the new value even if a further valid edge is detected.
Note 5. Retention of a value in a read buffer due to a valid edge is released by reading the TCNT or TPRE register.

Figure 32.75 Example of Operations for Bit Rate Measurement

32.10.7 Selectable Timing for Sampling Data Received through RXDX12

The extended serial mode control section provides a way of adjusting the timing for the sampling of data received through the RXDX12 pin by setting the CR2.RTS[1:0] bits to select the rising edges of 8th, 10th, 12th, or 14th cycle of the base clock. If the value of the SEMR.ABCS bit is 1, the bits select the rising edges of 4th, 5th, 6th, or 7th cycle of the base clock. Figure 32.76 shows timing for the sampling of data received through RXDX12.

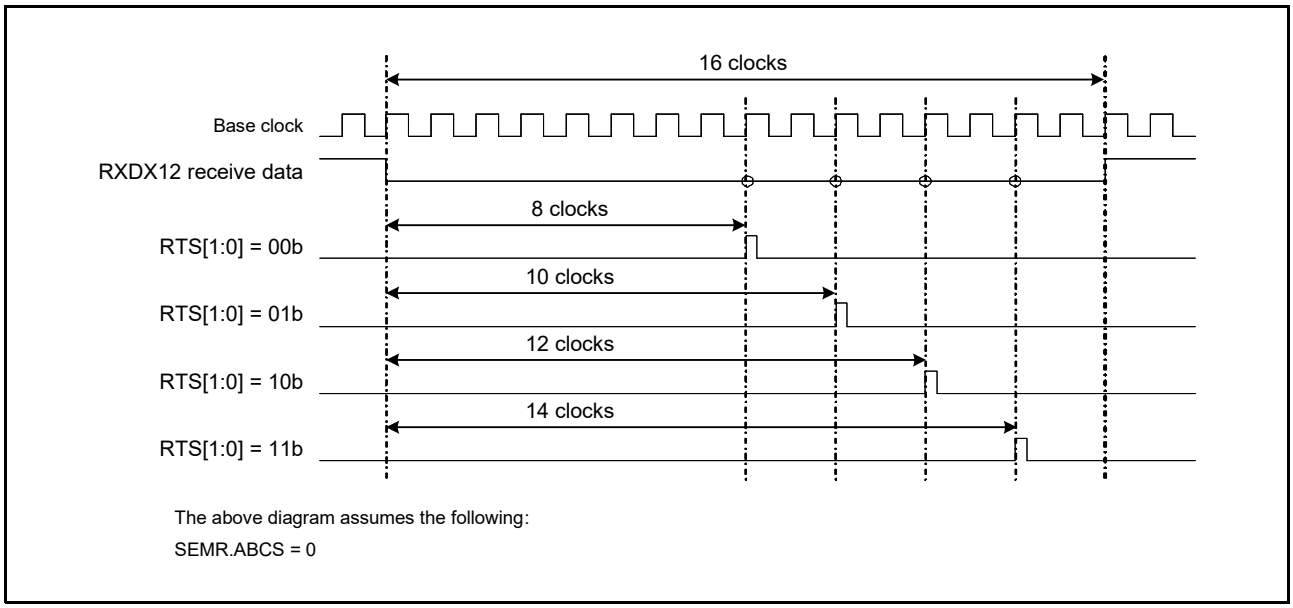


Figure 32.76 Timing for Sampling of Data Received through RXDX12

32.10.8 Timer

The timer has the following operating modes.

(1) Break Field Low Width Output Mode

This mode is for output through the TXDX12 pin of the low level over the Break Field low width at the transmission of a Start Frame. Setting the TMR.TOMS[1:0] bits to 10b switches operation to Break Field low width output mode. The TMR.TCSS[2:0] bits select the clock source for the counter. When the TCR.TCST bit is set to 1, the output on the TXDX12 pin goes to the low level and counting starts. When the timer underflows, the output on the TXDX12 pin goes to the high level and the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1. When 0 is written to the TCR.TCST bit, counting stops after reloading of registers TPRE and TCNT. After output of the Break Field low width is completed, stop the timer before it underflows again. Figure 32.77 shows an example of operations in Break Field low width output mode.

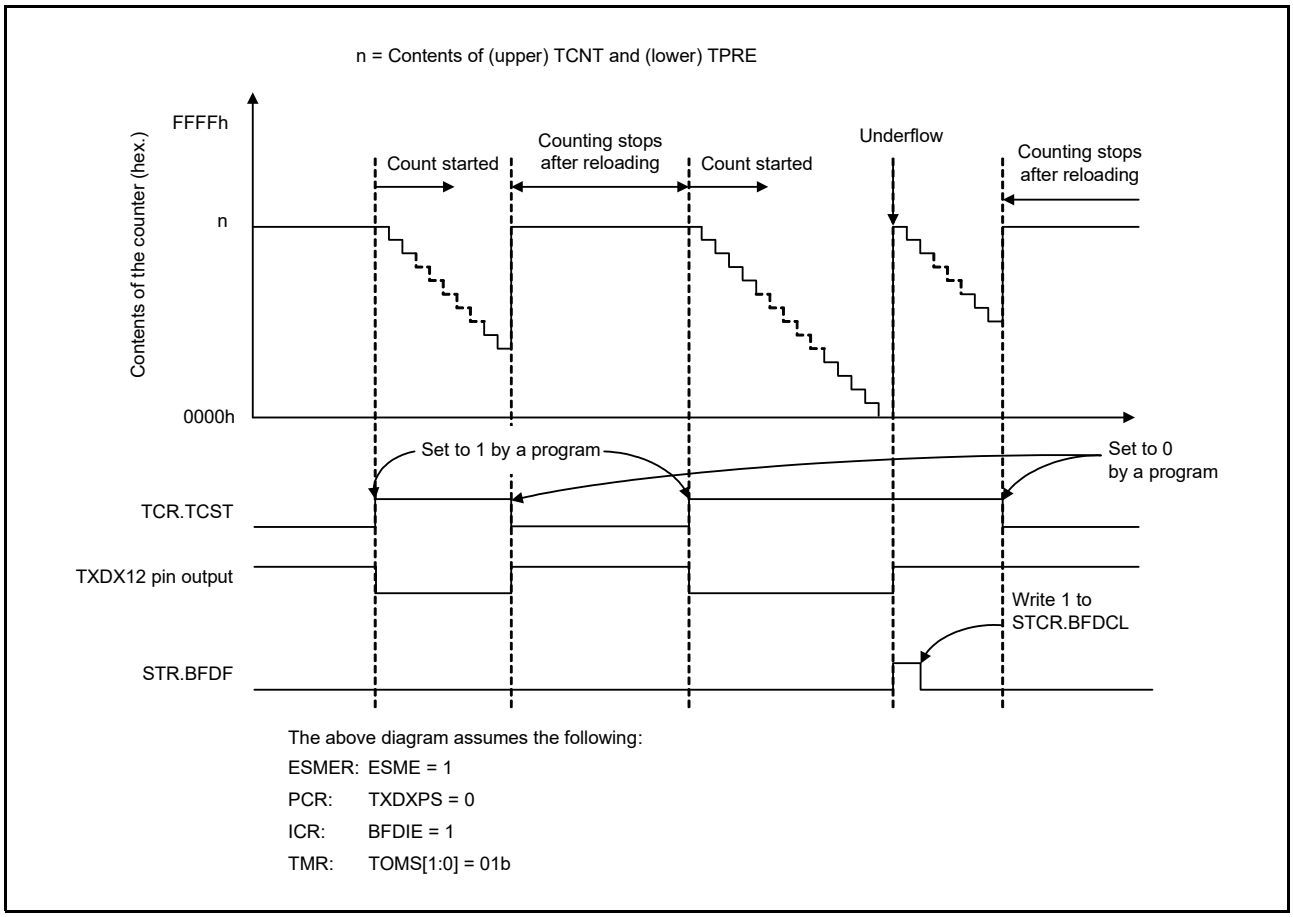

Figure 32.77 Example of Operations in Break Field Low Width Output Mode

(2) Break Field Low Width Determination Mode

This mode is for determining the Break Field low width in the input signal on the RXDX12 pin at the reception of a Start Frame. Setting the TMR.TOMS[1:0] bits to 01b switches operation to Break Field low width determination mode. The TMR.TCSS[2:0] bits select the clock source for the counter. When the TCR.TCST bit is set to 1, the interface enters the Break Field low width determinable state. Determination starts when a low level is input from the RXDX12 pin. When a high level is then input on the RXDX12 pin, registers TPRE and TCNT are reloaded and the interface enters the Break Field low width determinable state. When the timer underflows during Break Field low width determination, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1. If an underflow of the timer during data transfer cause a problem in the form of interrupt generation, stop the timer after Break Field low width determination. Figure 32.78 shows an example of operations in Break Field low width output mode.

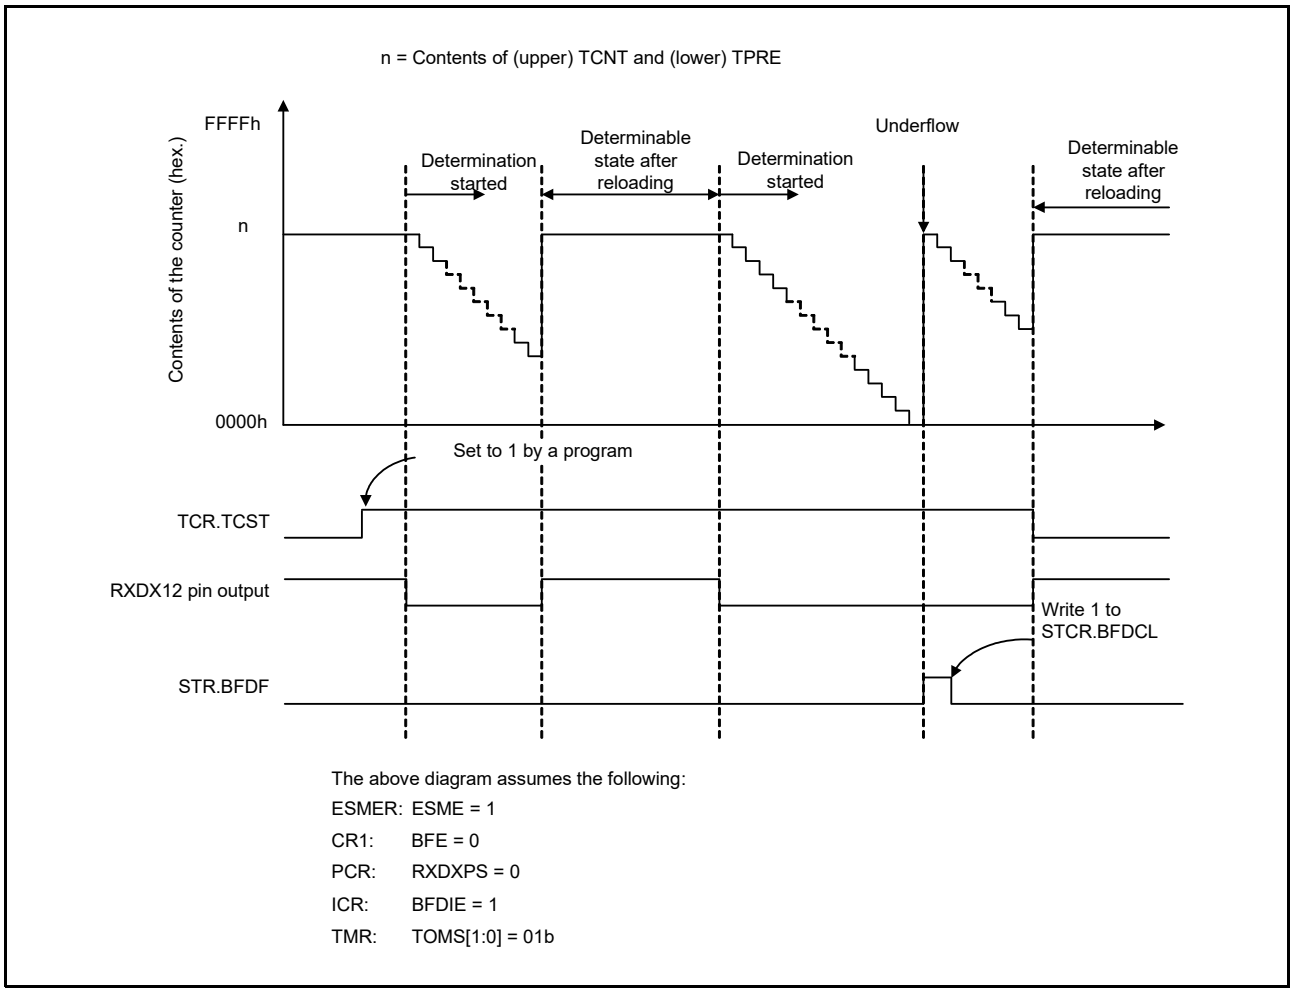

Figure 32.78 Example of Operations in Break Field Low Width Determination Mode

(3) Timer Mode

This mode is for counting cycles of the internal clock as the clock source. Setting the TMR.TOMS[1:0] bits to 00b switches operation to timer mode. The TMR.TCSS[2:0] bits select the clock source for the counter. Counting starts when 1 is written to the TCR.TCST bit and stops when 0 is written to the TCST bit. Registers TPRE and TCNT both count down. The TPRE register counts cycles of the clock source for counting, and underflows of the TPRE register provide the clock source for counting by the TCNT register. When the timer underflows, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.

32.11 Noise Cancellation Function

Figure 32.79 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of two stages of flip-flop circuits and a match-detection circuit. When the level on the pin matches in three consecutive samples taken at the set sampling interval, the matching level continues to be conveyed internally until the level on the pin again matches in three consecutive samples.

In asynchronous mode, the noise cancellation function can be applied on the RXDn input signal. The period of the base clock (1/16th of a bit-period when SEMR.ABCSE = 0 and SEMR.ABCS = 0, 1/8th of a bit-period when SEMR.ABCSE = 0 and SEMR.ABCS = 1, and 1/6th of a bit-period when SEMR.ABCSE = 1) is the sampling interval.

In simple I^2C mode, the noise cancellation function can be applied on the SSDAn and SSCLn input signals. The sampling clock is the clock signal produced by frequency-dividing the signal from the clock source for the internal baud-rate generator by one, two, four, or eight as selected by the setting of the SNFR.NFCS[2:0] bits.

If the base clock is stopped with the noise filter enabled and then the clock input is started again, the noise filter operation resumes from where the clock was stopped. If SCR.TE and SCR.RE are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, it is determined that a level match is detected and is conveyed to the internal signal. When the level being input corresponds to 0, the initial output of the noise filter is retained until the level matches in three consecutive samples.

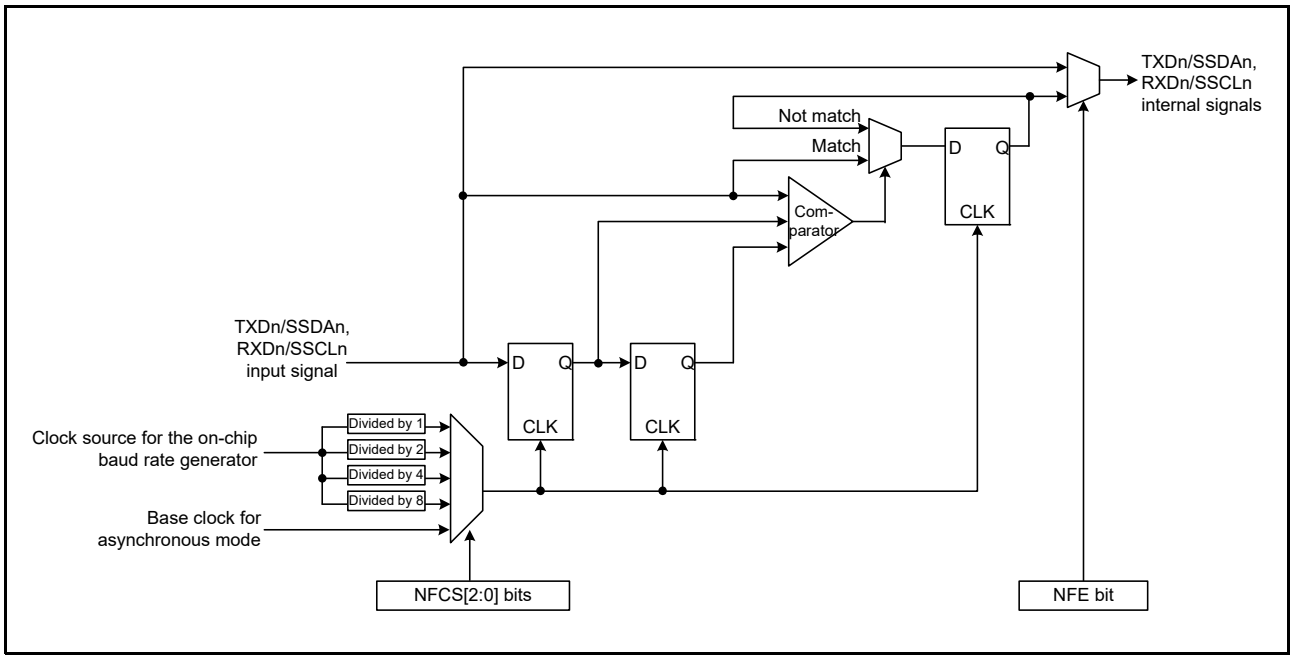

Figure 32.79 Block Diagram of Digital Noise Filter

32.12 Interrupt Sources

32.12.1 Buffer Operations for TXI and RXI Interrupts

If the conditions for a TXI and RXI interrupt are satisfied while the interrupt status flag in the interrupt controller is 1, the SCI does not output the interrupt request but retains it internally (with a capacity for retention of one request per source). When the value of the interrupt status flag in the interrupt controller becomes 0, the interrupt request retained within the SCI is output. The internally retained interrupt request is automatically discarded once the actual interrupt is output. Clearing of the corresponding interrupt enable bit (the TIE or RIE bit in the SCR register) can also be used to discard an internally retained interrupt request.

32.12.2 Interrupts in Asynchronous Mode, Clock Synchronous Mode, and Simple SPI Mode

Table 32.37 lists interrupt sources in asynchronous mode, clock synchronous mode, and simple SPI mode. Individual interrupt sources can be enabled or disabled with the enable bits in the SCR register.

If the SCR.TIE bit is 1, a TXI interrupt request is generated when transmit data is transferred from the TDR or TDRL register*1 to the TSR register. A TXI interrupt request can also be generated by setting the SCR.TE bit to 1 after setting the SCR.TIE bit to 1 or by using a single instruction to set the SCR.TE and SCR.TIE bit to 1 at the same time. A TXI interrupt request can activate the DTC or DMAC to handle data transfer.

A TXI interrupt request is not generated by setting the SCR.TE bit to 1 while the setting of the SCR.TIE bit is 0 or by setting the SCR.TIE bit to 1 while the setting of the SCR.TE bit is 1.*2

Note that setting the SCR.TE bit to 0 while the SCR.TIE bit is 1 leads to the generation of a TXI interrupt.

When new data is not written by the time of transmission of the last bit of the current transmit data and the setting of the SCR.TEIE bit is 1, the SSR.TEND flag becomes 1 and a TEI interrupt request is generated. Furthermore, when the setting of the SCR.TE bit is 1, the SSR.TEND flag retains the value 1 until further transmit data are written to the TDR or TDRL register*1, and setting the SCR.TEIE bit to 1 leads to the generation of a TEI interrupt request.

Writing data to the TDR or TDRL register*1 leads to clearing of the SSR.TEND flag and, after a certain time, discarding of the TEI interrupt request.

If the SCR.RIE bit is 1, an RXI interrupt request is generated when received data is stored in the RDR register. An RXI interrupt request can activate the DTC or DMAC to handle data transfer.

Setting of any from among the ORER, FER, and PER flags in the SSR register to 1 while the SCR.RIE bit is 1 leads to the generation of an ERI interrupt request. An RXI interrupt request is not generated at this time. Clearing all three flags (ORER, FER, and PER) leads to discarding of the ERI interrupt request.

Note 1. In the case where asynchronous mode and 9-bit data length are selected

Note 2. To temporarily disable TXI interrupts at the time of transmission of the last of the data and so on when you wish a new round of transmission to start after handling of the transmission-completed interrupt, control disabling and enabling of the interrupt by using the interrupt request enable bit in the interrupt controller rather than using the SCR.TIE bit. This can prevent the suppression of TXI interrupt requests in the transfer of new data.

Table 32.37 Interrupt Sources

Name	Interrupt Source	Interrupt Flag	DTC Activation	DMAC Activation
ERI	Receive error	ORER, FER, PER, DFER*1, or DPER*1	Not possible	Not possible
RXI	Receive data full	RDRF	Possible	Possible
	Data match*1	DCMF*1		
TXI	Transmit data empty	TDRE	Possible	Possible
TEI	Transmit end	TEND	Not possible	Not possible

Note 1. Available in SCI1, SCI5, and SCI6 only.

32.12.3 Interrupts in Smart Card Interface Mode

Table 32.38 lists interrupt sources in smart card interface mode. A transmit end interrupt (TEI) request cannot be used in this mode.

Table 32.38 SCI Interrupt Sources

Name	Interrupt Source	Interrupt Flag	DTC Activation	DMAC Activation
ERI	Receive error or error signal detection	ORER, PER, or ERS	Not possible	Not possible
RXI	Receive data full	—	Possible	Possible
TXI	Transmit data empty	TEND	Possible	Possible

Data transmission/reception using the DTC or DMAC is also possible in smart card interface mode, similar to in the normal SCI mode. In transmission, when the SSR.TEND flag is set to 1, a TXI interrupt request is generated. This TXI interrupt request activates the DTC or DMAC allowing transfer of transmit data if the TXI request is specified beforehand as a source of DTC or DMAC activation. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During the retransmission, the TEND flag is kept to 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission in the case of error occurrence. However, the SSR.ERS flag is not automatically cleared to 0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the SCR.RIE bit to 1 to enable an ERI interrupt request to be generated at error occurrence.

When transmitting/receiving data using the DTC or DMAC, be sure to make settings to enable the DTC or DMAC before making SCI settings. For DTC or DMAC settings, refer to section 18, Data Transfer Controller (DTCb) and section 17, DMA Controller (DMACAa).

In reception, an RXI interrupt request is generated when receive data is set to the RDR register. This RXI interrupt request activates the DTC or DMAC allowing transfer of receive data if the RXI request is specified beforehand as a source of DTC or DMAC activation. If an error occurs, the error flag is set. Therefore, the DTC or DMAC is not activated and an ERI interrupt request is issued to the CPU instead; the error flag must be cleared.

32.12.4 Interrupts in Simple I2C Mode

The interrupt sources in simple I2C mode are listed in Table 32.39. The STI interrupt is allocated to the transmit end interrupt (TEI) request. The receive error interrupt (ERI) request cannot be used.

The DTC or DMAC can also be used to handle transfer in simple I2C mode.

When the value of the SIMR2.IICINTM bit is 1, an RXI request will be generated on the falling edge of the SSCLn signal for the eighth bit. If the RXI has been set up as an activating request for the DTC or DMAC beforehand, the RXI request will activate the DTC or DMAC to handle transfer of the received data. Furthermore, a TXI request is generated on the falling edge of the SSCLn signal for the ninth bit (acknowledge bit). If the TXI has been set up as an activating request for the DTC or DMAC beforehand, the TXI request will activate the DTC or DMAC to handle transfer of the transmit data.

When the value of the SIMR2.IICINTM bit is 0, an RXI request (ACK detection) if the input on the SSDAn pin is at the low level or a TXI request (NACK detection) if the input on the SSDAn pin is at the high level will be generated on the rising edge of the SSCLn signal for the ninth bit (acknowledge bit). If the RXI has been set up as an activating request for the DTC or DMAC beforehand, the RXI request will activate the DTC or DMAC to handle transfer of the received data. Also, if the DTC or DMAC is used for data transfer in reception or transmission, be sure to set up and enable the DTC or DMAC before setting up the SCI.

When the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits in the SIMR3 register are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

Table 32.39 SCI Interrupt Sources

Name	Interrupt Source		Interrupt Flag	DTC Activation	DMAC Activation
	IICINTM bit = 0	IICINTM bit = 1			
RXI	ACK detection	Reception	—	Possible	Possible
TXI	NACK detection	Transmission	—	Possible*1	Possible*1
STI	Completion of generation of a start, restart, or stop condition		IICSTIF	Not possible	Not possible

Note 1. Activation of the DTC or DMAC is only possible when the SIMR2.IICINTM bit is 1 (use reception and transmission interrupts).

32.12.5 Interrupt Requests from the Extended Serial Mode Control Section

The extended serial mode control section has a total of six types of interrupt request for generating the SCIX0 interrupt (Break Field low width detected), SCIX1 interrupt (Control Field 0 match, Control Field 1 match, priority interrupt bit detected), SCIX2 interrupt (bus collision detected), and SCIX3 interrupt (valid edge detected). When any of the interrupt factors is generated, the corresponding status flag is set to 1. Details of all of the interrupt requests are listed in Table 32.40.

Table 32.40 Interrupt Sources of the Extended Serial Mode Control Section

Interrupt Request	Status Flag	Interrupt Factors
SCIX0 interrupt (Break Field low width detected)	BFDF	• Detection of a Break Field low width longer than the interval corresponding to the timer setting • Completion of the output of a Break Field low width over the interval corresponding to the timer setting • Underflow of the timer
SCIX1 interrupt (Control Field 0 match)	CF0MF	The data received in Control Field 0 matching the value set in the CF0DR register
SCIX1 interrupt (Control Field 1 match)	CF1MF	The data received in Control Field 1 matching the value set in the PCF1DR or SCF1DR register
SCIX1 interrupt (priority interrupt bit detected)	PIBDF	The value of the bit specified as the priority interrupt bit matching the value set in the PCF1DR register
SCIX2 interrupt (bus collision detected)	BCDF	The output level on the TXDX12 pin and the input level on the RXDX12 pin not matching on three consecutive cycles of the bus collision detection clock
SCIX3 interrupt (valid edge detected)	AEDF	Detection of a valid edge during bit rate measurement

32.13 Event Linking

By employing interrupt request signals as event signals, SCI5 is able to provide linked operation through the event link controller (ELC) for modules selected in advance.
Event signals can be output regardless of the values of the corresponding interrupt request enable bits.

(1) Error (receive error, error signal detected) event output

- Indicates abnormal termination due to a parity error during reception in asynchronous mode.
- Indicates abnormal termination due to a framing error during reception in asynchronous mode.
- Indicates abnormal termination due to an overrun error during reception.
- Indicates detection of the error signal during transmission in smart card interface mode.

(2) Receive data full event output

- Indicates that received data have been set in the receive data register (RDR or RDRL).
- Indicates that ACK has been detected if the SIMR2.IICINTM bit is 0 in simple I^2C mode.
- Indicates that the 8th-bit SSCL5 falling edge has been detected if the SIMR2.IICINTM bit is 1 in simple I^2C mode.
- When the SIMR2.IICINTM bit is 1 during master transmission in simple I^2C mode, set the event link controller (ELC) so that receive data full events are not used.

(3) Transmit data empty event output

- Indicates that the SCR.TE bit has been changed from 0 to 1.
- Indicates that transmit data have been transferred from the transmit data register (TDR or TDRL) to the transmit shift register (TSR).
- Indicates that transmission has been completed in smart card interface mode.
- Indicates that NACK has been detected if the SIMR2.IICINTM bit is 0 in simple I^2C mode.
- Indicates that the ninth-bit SSCL5 falling edge has been detected if the SIMR2.IICINTM bit is 1 in simple I^2C mode.

(4) Transmit end event output

- Indicates the completion of transmission.
- Indicates that the starting condition, resumption condition, or termination condition has been generated in simple I^2C mode.

32.14 Usage Notes

32.14.1 Setting the Module Stop Function

Module stop control register B (MSTPCRB) is used to stop and start SCI operations. With the value after a reset, SCI operations are stopped. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

32.14.2 Break Detection and Processing

When a framing error is detected, a break can be detected by reading the RXDn pin value directly or reading the value of the SPTR.RXDMON flag (only for SCI1, SCI5, and SCI6). In a break, the input from the RXDn pin becomes all 0s, and so the SSR.FER flag is set to 1 (framing error has occurred), and the SSR.PER flag may also be set to 1 (parity error has occurred). When the SEMR.RXDESEL bit is 0, the SCI continues the receive operation even after a break is received. Therefore, note that even if the FER flag is set to 0 (no framing error occurred), it will be set to 1 again. When the SEMR.RXDESEL bit is 1, the SCI sets the SSR.FER flag to 1 and stops receiving operation until a start bit of the next data frame is detected. If the SSR.FER flag is set to 0 at this time, the SSR.FER flag retains 0 during the break. When the RXDn pin becomes high and the break ends, detecting the beginning of the start bit at the first falling edge of the RXDn pin allows the SCI to start the receiving operation.

32.14.3 Mark State and Sending Breaks

When the SCR.TE bit is 0 (serial transmission is disabled), the TXDn pin becomes high-impedance. To forcibly set the TXDn pin to mark or space state while the TE bit is 0, set the I/O port associated registers and switch the TXDn pin to general output port.

For holding the communication line in the mark (“1”) state until the TE bit is set to 1 (serial transmission is enabled), set the corresponding bit in the PODR register to 1 for high output from general output port. To start communications, set the TE bit to 1 and then the corresponding bit in the PMR register to 1.

To send a break (the space state for longer than a certain period of time) while data transmission, set the corresponding bit in the PODR register to 0 (low output), and set the corresponding bit in the PMR register to 0 (general I/O port). Then set the TE bit to 0 if necessary. When the TE bit is set to 0, the transmitter is initialized regardless of the current transmit status.

The SPTR register, if it is included, can set the TXDn pin in mark/space state without switching the pin function to general output port. Set the SPTR.SPB2IO bit to 1 (output) and the SPB2DT bit to 1 (mark) or 0 (space), and then set the TE bit to 0.

32.14.4 Receive Error Flags and Transmit Operations (Clock Synchronous Mode and Simple SPI Mode)

Transmission cannot be started when a receive error flag (SSR.ORER) is set to 1, even if data is written to the TDR register. Be sure to set the receive error flags to 0 before starting transmission. Note also that the receive error flags cannot be set to 0 even if the SCR.RE bit is set to 0 (serial reception is disabled).

32.14.5 Writing Data to the TDR Register

Data can be written to registers TDR, TDRH, and TDRL. However, if new data is written to registers TDR, TDRH, and TDRL when transmit data is remaining in registers TDR, TDRH, and TDRL, the previous data in registers TDR, TDRH, and TDRL is lost because it has not been transferred to the TSR register yet. Be sure to write transmit data to registers TDR, TDRH, and TDRL in the TXI interrupt request handling routine.

32.14.6 Restrictions on Clock Synchronous Transmission (Clock Synchronous Mode and Simple SPI Mode)

When the external clock source is used as a synchronization clock, the following restrictions apply.

(1) Start of transmission

Update the TDR register by the CPU, DMAC, or DTC and wait for at least five PCLK cycles before allowing the transmit clock to be input (refer to Figure 32.80).

(2) Continuous transmission

(a) Write the next transmit data to the TDR or TDRL register before the falling edge of the transmit clock (bit 7) (refer to Figure 32.80).

(b) When updating the TDR register after bit 7 has started to transmit, update the TDR register while the synchronization clock is in the low-level period, and set the high-level width of the transmit clock (bit 7) to four PCLK cycles or longer (refer to Figure 32.80).

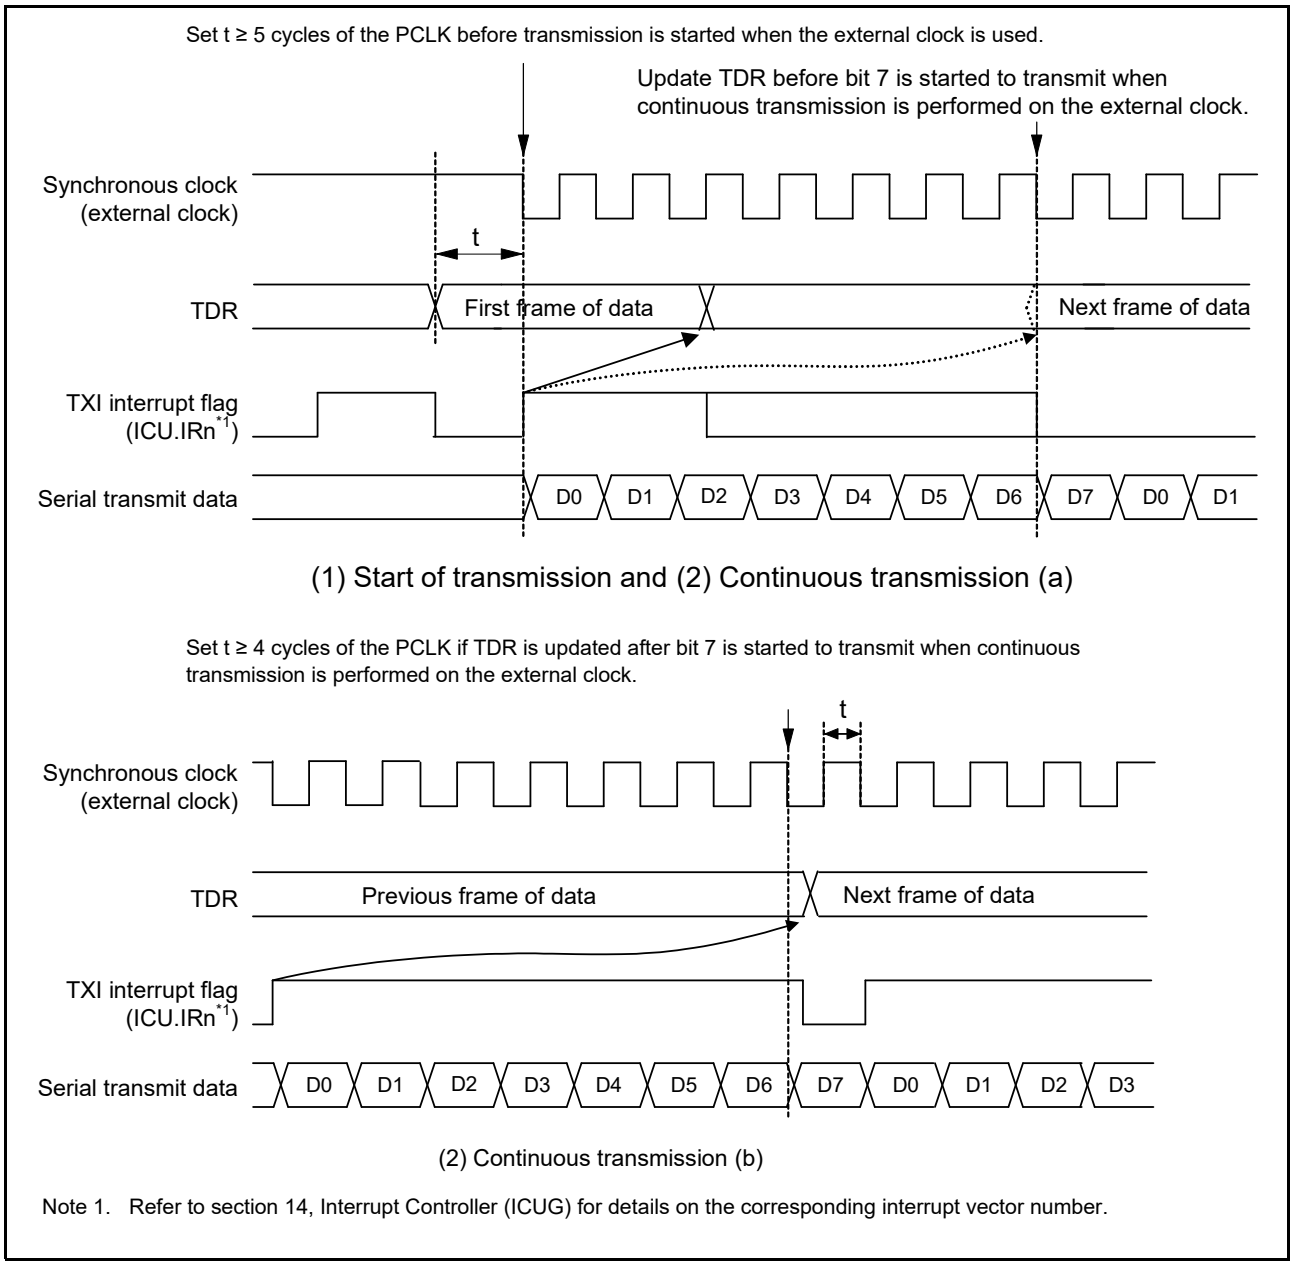

Figure 32.80 Restrictions on Use of External Clock in Clock Synchronous Transmission

32.14.7 Restrictions on Using DMAC or DTC

When using the DMAC or DTC to read the RDR, RDRH, and RDRL registers, be sure to set the receive data full interrupt (RXI) as the activation source of the relevant SCI.

32.14.8 Notes on Starting Transfer

At the point where transfer starts when the interrupt status flag (IRn.IR flag) in the interrupt controller is 1, follow the procedure below to clear interrupt requests before permitting operations (by setting the SCR.TE or SCR.RE bit to 1). For details on the interrupt status flag, refer to section 14, Interrupt Controller (ICUG).

- Confirm that transfer has stopped (the setting of the SCR.TE or SCR.RE bits is 0).
- Set the corresponding interrupt enable bit (SCR.TIE or SCR.RIE) to 0.
- Read the corresponding interrupt enable bit (SCR.TIE or SCR.RIE bit) to check that it has become 0.
- Set the interrupt status flag (IRn.IR flag) in the interrupt controller to 0.

32.14.9 SCI Operations during Low Power Consumption State

(1) Transmission

When making settings for the module stopped state or in transitions to software standby, stop operations (by setting the TIE, TE, and TEIE bits in the SCR register to 0) after switching the TXDn pin to the general I/O port pin function or fix the output level of the TXDn pin by the SPTR register (only for SCI1, SCI5, and SCI6). Setting the TE bit to 0 resets the TSR register and the SSR.TEND flag. Depending on the port settings or SPTR register setting (only for SCI1, SCI5, and SCI6), output pins may output the level before a transition to the low power consumption state is made after release from the module stopped state or software standby mode. When transitions to these states are made during transmission, the data being transmitted become indeterminate.

To transmit data in the same transmit mode after cancellation of the low power consumption state, set the TE bit to 1, read the SSR register, and write data to the TDR register sequentially to start data transmission. To transmit data with a different transmit mode, initialize the SCI first.

Figure 32.81 shows a sample flowchart for transition to software standby mode during transmission. Figure 32.82 and Figure 32.83 show the port pin states during transition to software standby mode.

Before specifying the module stop state or making a transition to software standby mode from the transmit mode using DTC/DMA transfer, stop the transmit operations (TE = 0). To start transmission after cancellation using the DTC/DMAC, set the TE and TIE bits to 1. The TXI interrupt flag is set to 1 and transmission starts using the DTC/DMAC.

(2) Reception

Before specifying the module stop state or making a transition to software standby mode, stop the receive operations (SCR.RE = 0). If transition is made during data reception, the data being received will be invalid.

To receive data in the same receive mode after cancellation of the low power consumption state, set the RE bit to 1, and then start reception. To receive data in a different receive mode, initialize the SCI first.

Figure 32.84 shows a sample flowchart for transition to software standby mode during reception.

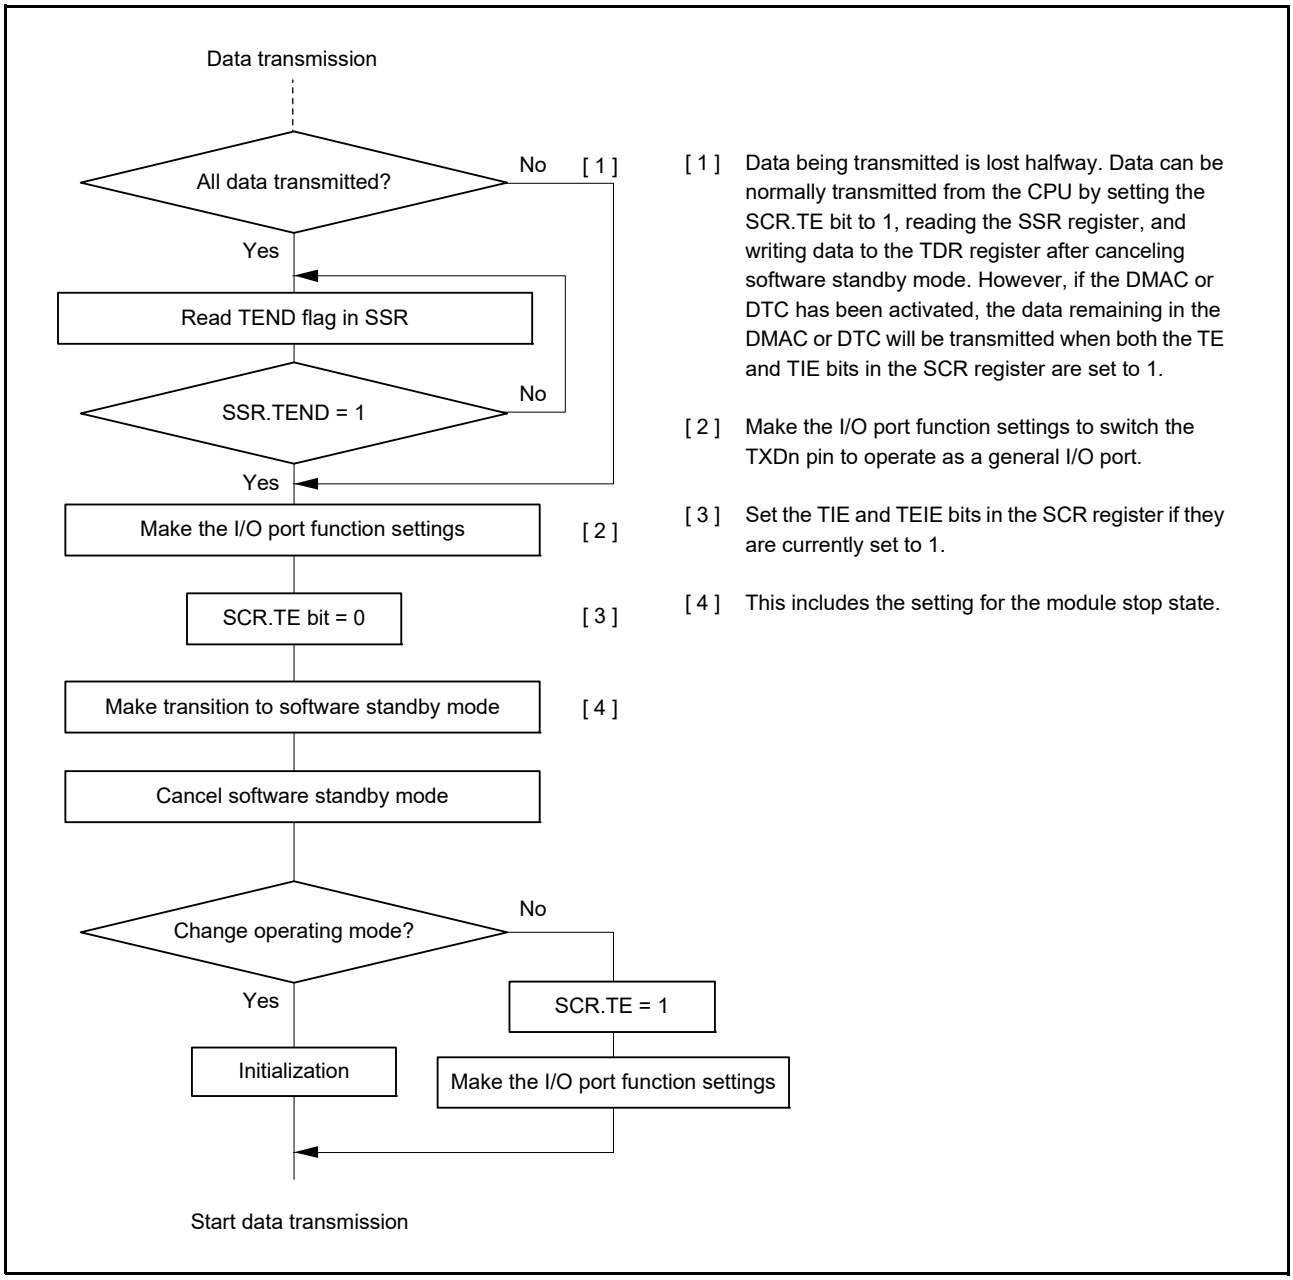

Figure 32.81 Example of Flowchart for Transition to Software Standby Mode during Transmission

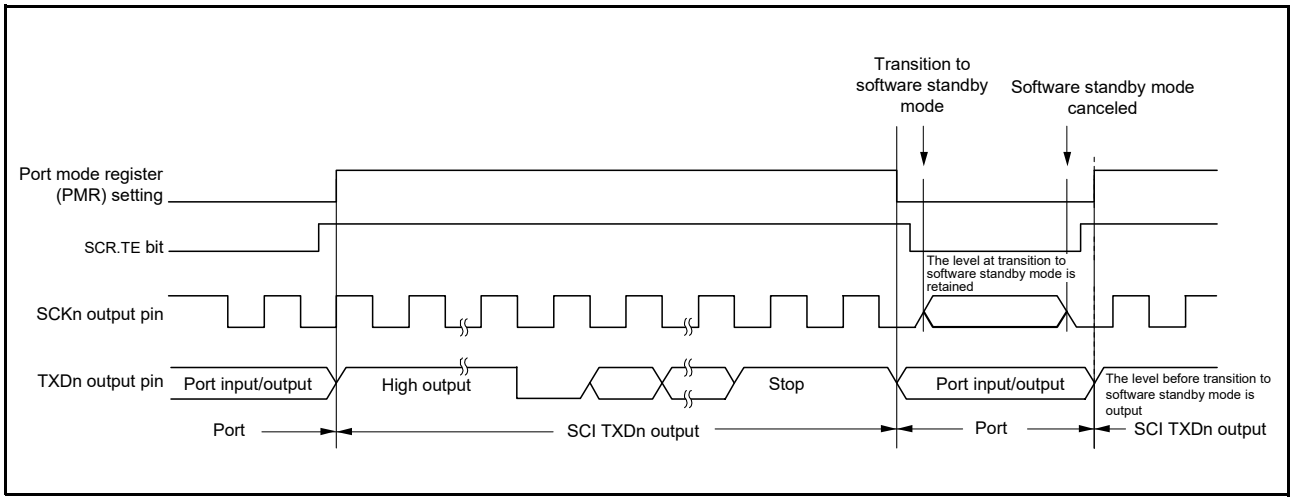

Figure 32.82 Port Pin States during Transition to Software Standby Mode (Internal Clock, Asynchronous Transmission)

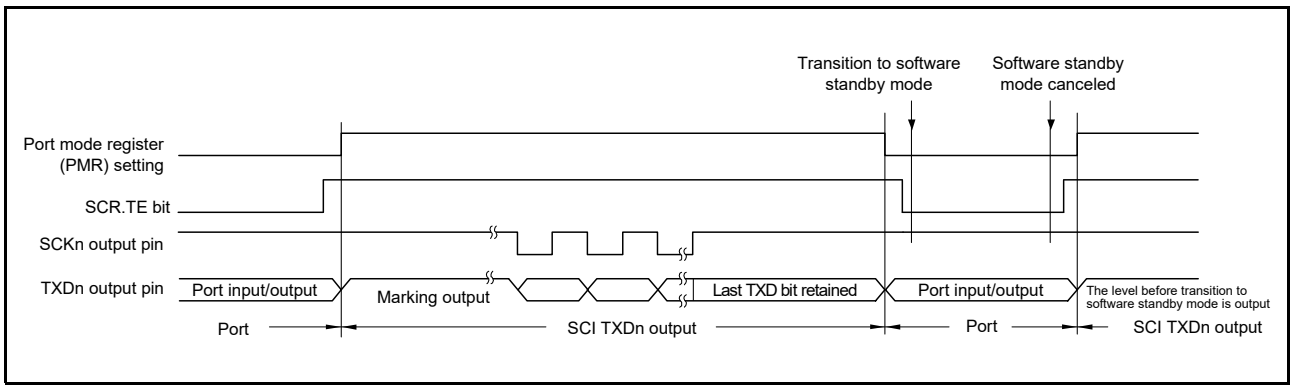

Figure 32.83 Port Pin States during Transition to Software Standby Mode (Internal Clock, Clock Synchronous Transmission)

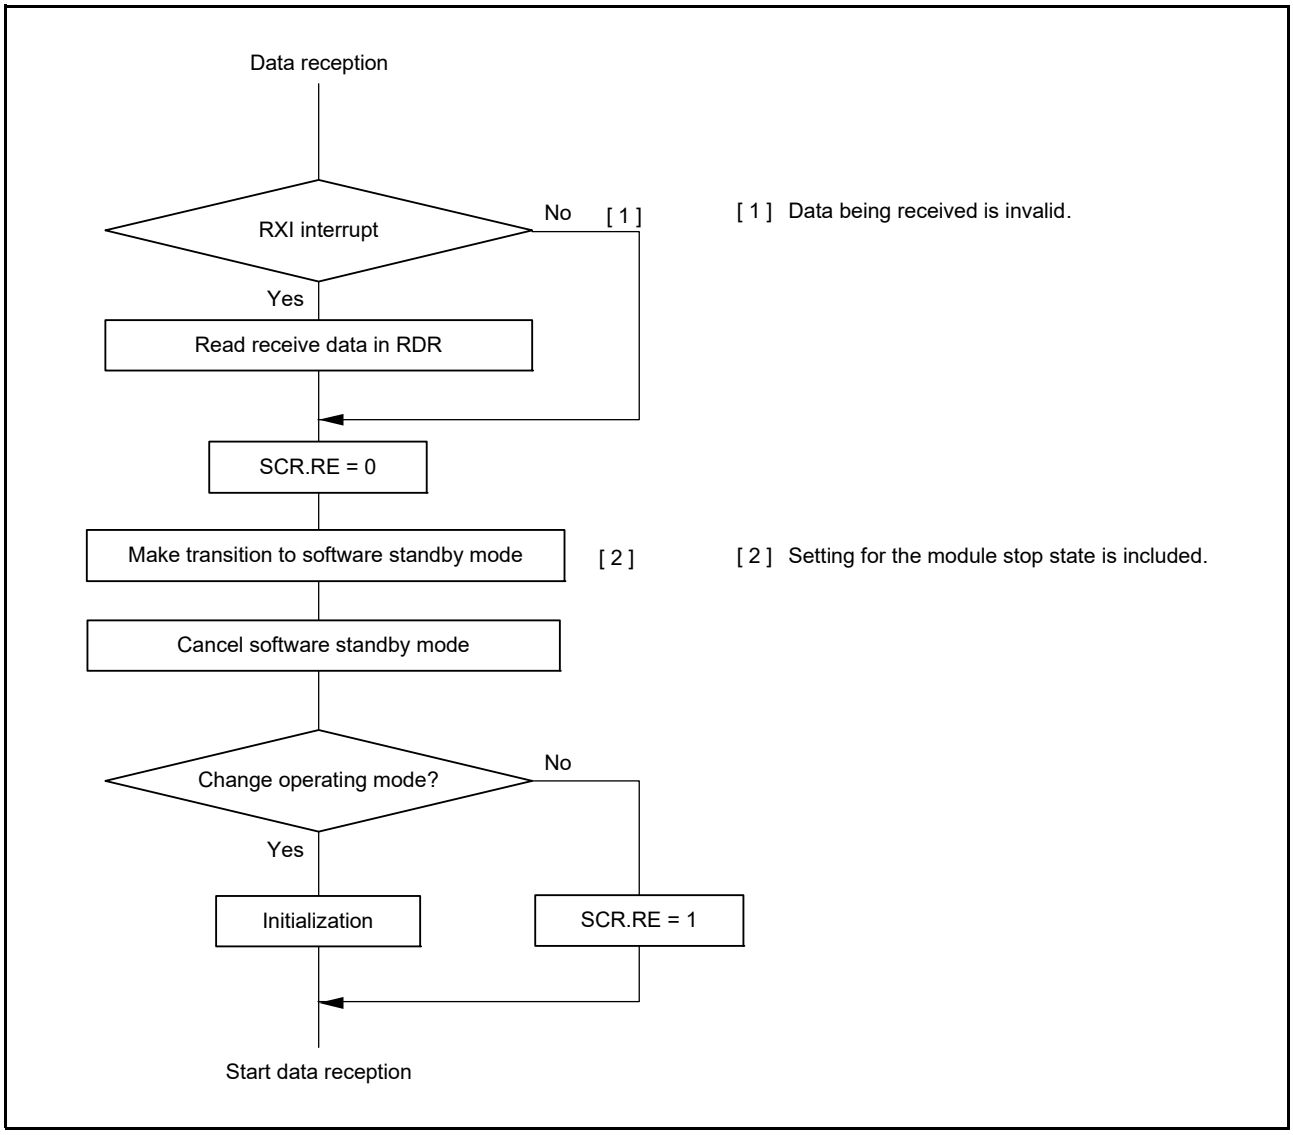

Figure 32.84 Example of Flowchart for Transition to Software Standby Mode during Reception

32.14.10 External Clock Input in Clock Synchronous Mode and Simple SPI Mode

In clock synchronous mode and simple SPI mode, the external clock SCKn must be input as follows:
High-pulse period, low-pulse period = 2 PCLK cycles or more, period = 6 PCLK cycles or more

32.14.11 Limitations on Simple SPI Mode

(1) Master Mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set by the SPMR.CKPH and CKPOL bits when the SPMR.SSE bit is 1.
  This prevents the clock line from being placed in the high-impedance state when the SCR.TE bit is set to 0 or unexpected edges from being generated on the clock line when the SCR.TE bit is changed from 0 to 1. When the SPMR.SSE bit is 0 in single master mode, pulling up or pulling down the clock line is not necessary because the clock line is not placed in the high-impedance state even when the SCR.TE bit is set to 0.
- In the case of the setting for clock delay (SPMR.CKPH bit is 1), the receive data full interrupt (RXI) is generated before the final clock edge on the SCKn pin as indicated in Figure 32.85. If the TE and RE bits in the SCR register become 0 at this time before the final edge of the clock signal on the SCKn pin, the SCKn pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Furthermore, an RXI interrupt may lead to the input signal on the SSn# pin of a connected slave going to the high level before the final edge of the clock signal on the SCKn pin, leading to incorrect operation of the slave.
- In a multi-master configuration, take care because the SCKn pin output becomes high-impedance while the input on the SSn# pin is at the low level if a mode fault error occurs as the current character is being transferred, stopping supply of the clock signal to the connected slave. Remake the settings for the connected slave to avoid misaligned bits when transfer is restarted.

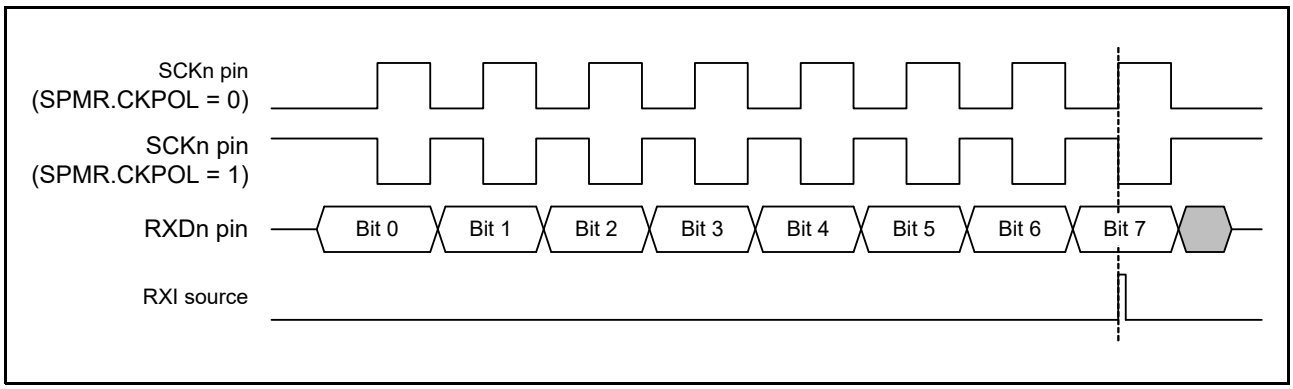

Figure 32.85 Timing of the RXI Interrupt in Simple SPI Mode (with Clock Delay)

(2) Slave Mode

- Secure at least five cycles of the PCLK from writing transmit data in the TDR register to start of the external clock input. Also secure at least five cycles of the PCLK from input of low level on the SSn# pin to start of the external clock input.
- Provide an external clock signal from the master the same as the transmit/receive data length.
- Control the input on the SSn# pin before the start and after the end of data transfer.
- When the level being input on the SSn# pin is to be changed from low to high while the current character is being transferred, set the TE and RE bits in the SCR register to 0 and, after remaking the settings, restart transfer of the first byte.

32.14.12 Limitation 1 on Usage of the Extended Serial Mode Control Section

When the PCR.SHARPS bit is set to 1, output on the TXDX12/RXDX12 pin is only possible when the following conditions apply.

- The timer is in Break Field low width output mode and the value of the TCR.TCST bit is 1 (when the TCST bit is set to 1, the high level continues to be output for up to one cycle of the clock source for counting by the timer counter before output of the low level)
- The value of the SCR.TE bit is 1.

32.14.13 Limitation 2 on Usage of the Extended Serial Mode Control Section

The TXI, RXI, ERI, and TEI interrupt requests are generated even if the extended serial mode is enabled. However, the RXI interrupt should not be enabled during reception of a Start Frame because the extended serial mode control section uses the receive data full signal.
To use the RXI interrupts during a reception of the Information Frame, use it in accordance with one of the following procedures. When a receive error is detected, clear the receive error flag and initialize the extended serial mode control section.

(1) Set the SCR.RIE bit to 0 to disable the output of interrupt requests. Check the error flags in the SSR register on completion of the reception of a Start Frame, because an ERI interrupt is not generated if a receive error occurs. After reception of the Start Frame is completed, set the SCR.RIE bit to 1 by the time the first byte of the Information Frame is received.
(2) Set the SCR.RIE bit to 1 to disable RXI interrupts and enable ERI interrupts for ICU.
Clear the IRn.IR flag to enable the acceptance of RXI interrupts by ICU by the time the first byte of the Information Frame is received after the completion of Start Frame reception.

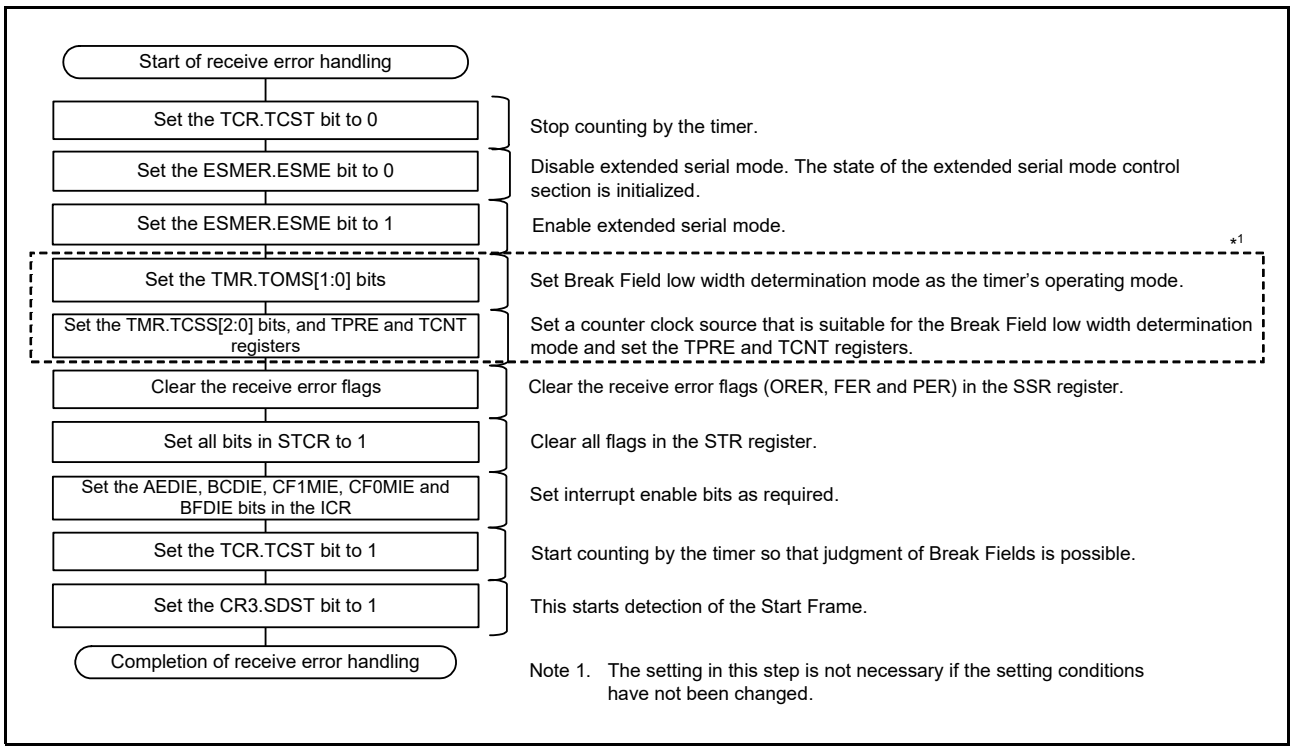

Figure 32.86 Example of Flowchart for Receive Error Handling (during Reception of the Start Frame)

32.14.14 Note on Transmit Enable Bit (TE Bit)

When setting the pin function to “TXDn” while the SCR.TE bit is 0 (serial transmission is disabled) or setting the TE bit to 0 while the pin function is “TXDn”, output of the TXDn pin becomes high-impedance.
Prevent the TXDn line from becoming high-impedance by any of the following ways:

(1) Connect a pull-up or pull-down resistor to the TXDn line.
(2) Set the TE bit to 1*1 before changing the pin function to “TXDn”. Before setting the TE bit to 0, change the pin function to “general-purpose I/O port” and drive the pin high or low.
(3) Set the SPTR.SPB2IO bit to 1 first, and change the pin function to “TXDn”. Leave the value of the SPB2IO bit as 1 after that (for SCI1, SCI5, and SCI6).

Note 1. An interrupt is generated when the TE bit is set to 1 while the TXI interrupt is enabled. If this creates a problem, change the pin function to “TXDn” first, and then set the corresponding ICU.IERm.IENj bit to 1.

32.14.15 Note on Stopping Reception When Using the RTS Function in Asynchronous Mode

One clock cycle of PCLK is required for the time from setting the SCR.RE bit to 0 to stopping the RTS signal generator in asynchronous mode.
When reading the RDR (or RDRL) register after setting the SCR.RE bit to 0, confirm that the RE bit has been set to 0 before reading the RDR (or RDRL) register to prevent these two processes from being performed consecutively.

33. Serial Communications Interface (RSCI)

In this section, “PCLK” for RSCI8 and RSCI9 is used to refer to PCLKB and “PCLK” for RSCI11 is used to refer to PCLKA.

33.1 Overview

RSCI can handle both asynchronous and clock synchronous serial communications. RSCI has 32-stage FIFO buffers in transmission/reception blocks, and it can select the FIFO composition, and it can transmit/receive efficiently, and it can also communicate continuously.

Asynchronous serial data communications can be carried out with standard asynchronous communications chips such as a Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communications Interface Adapter (ACIA). As an extended function in asynchronous communications mode, the RSCI also supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for identification cards).

The RSCI is also supports serial communication using manchester code (manchester mode), simple SPI interfaces, simple I^2C-bus interfaces (single master), and extended serial communication.

In addition, asynchronous mode has a support function for generating AMI waveform of negative logic coding with 50% duty cycle used in home bus system (HBS) communications.

Table 33.1 lists the RSCI specifications and Table 33.2 lists the functions of each channel.

Table 33.1 RSCI Specifications (1/3)

Item	Description
Serial communication modes	• Asynchronous • Manchester • Clock synchronous • Smart card interface • Simple I^2C-bus • Simple SPI bus • Extended serial
Transfer speed	Bit rate specifiable with the on-chip baud rate generator.
Full-duplex communications	Transmitter: Continuous transmission possible using double-buffer structure. Receiver: Continuous reception possible using double-buffer structure.
Half-duplex communications	Half-duplex communication is possible by using only TXDn pins
Data transfer	Selectable as LSB first or MSB first transfer
I/O signal level inverting function	Input signal and output signal can be inverted independently.
RXD input signal select function	If the RXD signal is attenuated by transmission line effects, it can be improved by using a comparator instead of a receiver.
Interrupt sources	Transmit end, transmit data empty, receive data full, receive error, receive data ready, and receive data match Break Field detection/transmission, Bus collision detection, Active edge detection Completion of generation of a start condition, restart condition, or stop condition
RS-485 driver control function	Output DE signal to enable external transceiver transmit mode
Loopback function	Self-diagnosis of communication function is possible by connecting TXD and RXD inside the RSCI
Low power consumption function	Module stop state can be set for each channel.

Table 33.1 RSCI Specifications (2/3)

Item		Description
Asynchronous mode	Data length	7, 8, or 9 bits
	Transmission stop bit	1 or 2 bits
	Parity	Even parity, odd parity, or no parity
	Receive error detection	Parity, overrun, and framing errors
	Hardware flow control	CTSn# and RTSn# pins can be used in controlling transmission/reception.
	Transmission/Reception	Selectable either 1 stage register or 32 stage FIFO
	Data match detection	The interrupt request can issue by detecting the match between receive data and comparison data.
	Start-bit detection	Low level or falling edge is selectable.
	Receive data sampling timing adjustment	Sampling point of receive data can be changed to front or rear of center of bit.
	Transmit signal transition timing adjustment	Falling or rising edge of the transmit data can be delayed.
	Break detection	When a framing error occurs, a break can be detected by reading the SSR register.
	Clock source	An internal or external clock can be selected.
	Double-speed mode	Baud rate generator double-speed mode is selectable.
	Multi-processor communications function	Serial communication among multiple processors
	Noise cancellation	The signal paths from input on the RXDn pins incorporate digital noise filters.
	HBS support mode	Transmission/reception using inverted RZI (Return to Zero, Inverted) code is possible.
Manchester mode	Data length	7, 8, or 9 bits
	Transmission stop bit	1 or 2 bits
	Receive error detection	Parity, overrun, framing, manchester code errors, preface, start bit, and receive Sync
	Hardware flow control	CTSn# and RTSn# pins can be used in controlling transmission.
	Clock source	Only internal clock can be used. (The setting of external clock is prohibited because it is not the object of operation guarantee.)
	Double-speed mode	Baud rate generator double-speed mode is selectable.
	Multi-processor communications function	Serial communication among multiple processors
	Noise cancellation	The signal paths from input on the RXDn pins incorporate digital noise filters.
	Manchester encoding/ decoding function	Function to perform manchester encoding/decoding of transmission/reception data and communicate using manchester code
	Preface setting/detection function	Function to detect the beginning of a frame from the preface pattern. Preface pattern can be selected from 4 types. The length can also be changed from 0 to 15 bits.
	Start Bit setting/detection function	The Start Bit length can be set to 1 bit or 3 bits. In the case of 3-bit length, it is possible to judge the type of subsequent data with two types of patterns.
	Reception retiming function	Function to perform timing correction for each bit center edge by using manchester code having edge at bit center
Smart card interface mode	Error processing	An error signal can be automatically transmitted when detecting a parity error during reception
		Data can be automatically retransmitted when receiving an error signal during transmission
	Data type	Both direct convention and inverse convention are supported.

Table 33.1 RSCI Specifications (3/3)

Item		Description
Extended serial mode	Start Frame Transmission	Break Field transmission possible, Break Field transmission complete interrupt output possible Bus collision detection possible, bus collision detection interrupt output possible
	Start Frame Reception	Break Field detectable, Break Field detected interrupt output possible Control Field 0/1 data comparison function Control Field 1 can set two types of comparison data of primary and secondary Priority interrupt bit can be set in Control Field 1 Bit rate measurement function
Simple I2C mode	Transfer format	I2C-bus format
	Operating mode	Master (single-master operation only)
	Transfer rate	Up to 400 kbps
	Noise cancellation	The signal paths from input on the SSCLn and SSDAn pins incorporate digital noise filters, and the interval for noise cancellation is adjustable.
Clock synchronous mode	Data length	8 bits
	Adjustment of receive sampling timing	Adjustable receive sampling timing after the default timing in master mode only when using internal clock
	Receive error detection	Overrun error
	Clock source	An internal clock (master mode) or external clock (slave mode) can be selected.
	Double-speed mode	Baud rate generator double-speed mode is selectable
	Hardware flow control	CTSn# and RTSn# pins can be used in controlling transmission/reception.
	Transmission/Reception	Selectable either 1 stage register or 32 stage FIFO
Simple SPI bus	Data length	8 bits
	Detection of errors	Overrun error
	Clock source	An internal clock (master mode) or external clock (slave mode) can be selected.
	Double-speed mode	Baud rate generator double-speed mode is selectable
	Adjustment of receive sampling timing	Adjustable receive sampling timing after the default timing in master mode only when using internal clock
	SS input pin function	When the SSn # pin is high level, the output pin can be set to high impedance
	Adjustment of receive sampling timing	Four kinds of settings for clock phase and clock polarity are selectable.
	Transmission/Reception	Selectable either 1 stage register or 32 stage FIFO
Bit rate modulation function		Correction of outputs from the on-chip baud rate generator can reduce errors.
Event link function		Error (receive error or error signal detection) event output
		Receive data full event output
		Transmit data empty event output
		Transmit end event output

33.2 Register Descriptions

This chapter describes the RSCI registers, their functional specifications, and their operating specifications.

33.2.1 Receive Shift Register (RSR)

RSR is a shift register which is used to receive serial data input from the RXDn pin and converts it into parallel data. When one frame of data has been received, it is automatically transferred to the RDR register.
The RSR register cannot be directly accessed by the CPU.

33.2.2 Receive Data Register (RDR)

Address(es): RSCI8.RDR 000A 1400h, RSCI9.RDR 000A 1480h, RSCI11.RDR 000E 2080h

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b8 to b0	RDAT[8:0]	Receive Data	RDAT[8:0] bits are a 9-bit field for storing received data. Received data is stored in [6:0] when 7-bit data is selected, in [7:0] when 8-bit data is selected, and in [8:0] when 9-bit data is selected. And 0 is stored in the unused bit.	R
b9	MPB	Multi-Processor Bit Monitor Flag	0: Data transmission cycles 1: ID transmission cycles	R
b10	DR	Receive Data Ready Flag	RFSR.DR flag can be read.	R
b11	PER	Parity Error Flag	(Valid only in asynchronous mode) 0: There is no parity error in the data read from the receive FIFO 1: There is parity error in the data read from the receive FIFO	R
b12	FER	Framing Error Flag	(Valid only in asynchronous mode) 0: There is no framing error in the data read from the receive FIFO 1: There is framing error in the data read from the receive FIFO	R
b23 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R
b24	ORER	Overrun Error Flag	SSR.ORER flag can be read.	R
b26, b25	—	Reserved	These bits are read as 0. The write value should be 0.	R
b27	APER	Aggregate Parity Error Flag	SSR.APER flag can be read.	R
b28	AFER	Aggregate Framing Error Flag	SSR.AFER flag can be read.	R
b31 to b29	—	Reserved	These bits are read as 0. The write value should be 0.	R

In FIFO mode (SCR3.FM bit = 1), this register is 32-stage FIFO buffer configuration.

RDAT[8:0] Bits (Receive Data)

After one frame of data is received, the received data is transferred from the RSR register to this registers, thus allowing the RSR register to receive the next data.
The RSR and RDR registers have a double-buffered construction to enable continuous reception.
In non-FIFO mode, read the RDR register only once when a receive data full interrupt (RXI) request is issued. Without reading received data from RDR register, if the next one frame is received, an overrun error occurs.
In FIFO mode, continuous reception is executed until 32 stages are stored. If data is read when there is no received data in the receive FIFO (RDR register), the value is undefined. When the receive FIFO (RDR register) are full of received data, subsequent serial receive data is lost.
The CPU cannot write to RDR register.
0 is stored in the bit position which isn't received (RDAT[8] or RDAT[7]) at the time of 7bit or 8bit communication of asynchronous and manchester mode.

MPB Flag (Multi-Processor Bit Monitor Flag)

In asynchronous mode and manchester mode, during multi-processor communication (SCR3.MP bit = 1), the value of the multi-processor bit corresponding to the received data (RDAT[8:0] bits) can be read.

PER Flag (Parity Error Flag)

Indicates whether the data read from the receive FIFO has a parity error.
The FER and PER flags store error information of received data only in FIFO mode. In non-FIFO mode, 0 is stored.

FER Flag (Framing Error Flag)

Indicates whether the data read from receive FIFO has a framing error.
The FER and PER flags store error information of received data only in FIFO mode. In non-FIFO mode, 0 is stored.

33.2.3 Transmit Data Register (TDR)

Address(es): RSCI8.TDR 000A 1404h, RSCI9.TDR 000A 1484h, RSCI11.TDR 000E 2084h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	SYNC	—	—	MPBT	TDAT[8:0]								
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b8 to b0	TDAT[8:0]	Transmit Data	TDAT[8:0] bits are a 9-bit field for setting transmit data. Transmit data is set in [6:0] when 7-bit data is selected, in [7:0] when 8-bit data is selected, and in [8:0] when 9-bit data is selected. When writing the TDR register in 8-bit units, write first to the TDR.LH and then TDR.LL.	R/W
b9	MPBT	Transmit Multi-Processor	Value of the multi-processor bit in the transmission frame. This bit is use in asynchronous and manchester mode. When writing to this bit when not used, write the initial value. 0: Data transmission cycles 1: ID transmission cycles	R/W
b11, b10	—	Reserved	These bits are read as 1. The write value should be 1.	R
b12	SYNC	Sync Pulse Select	It is valid when MMCR.SBLEN bit = 1 and MMCR.SYNCE bit = 1 in manchester mode. When writing to this bit when not used, write the initial value. 0: The Start Bit is transmitted as DATA Sync. 1: The Start Bit is transmitted as COMMAND Sync.	R/W
b31 to b13	—	Reserved	These bits are read as 1. The write value should be 1.	R

In FIFO mode (SCR3.FM bit = 1), this register is 32-stage FIFO buffer configuration.

TDAT[8:0] Bits (Transmit Data)

The TDAT[8:0] bits are a 9-bit field for storing transmit data.

When empty space is detected in the TSR register, the transmit data stored in the TDR register is transferred to TSR register, and transmitting is started.

The TSR and TDR registers have a double-buffered construction to realize continuous reception. When the next data to be transmitted is stored in TDR register after one frame of data has been transmitted, the transmitting operation is continued by transfer to the TSR register.

In FIFO mode, continuous serial transmission is executed until there is no transmit data left in the transmit FIFO (TDR register). When transmit FIFO is full of transmit data (32 frames), no more data can be written. If writing of new data is attempted, the data is ignored.

In non-FIFO mode, the TDR register is always readable and writable by the CPU. When a transmit data empty interrupt (TXI) request is issued and SCR0.TE bit is 1, write transmit data to the TDR register only once.

When writing the TDR register in 8-bit units, write first to the TDR.LH and then the TDR.LL.

MPBT Bit (Transmit Multi-Processor)

Selects the multi-processor bit of transmit frame.

SYNC Bit (Sync Pulse Select)

This bit is valid when the MMCR.SYNCE and MMCR.SBLEN bits are set to 1 in Manchester mode (SCR3.MOD [2: 0] bit = 101b).

The Sync type of start bit area in the transmission frame can be set to Data Sync or Command Sync.

33.2.4 Transmit Shift Register (TSR)

TSR register is a shift register that transmits serial data. TSR register cannot be directly accessed by the CPU.

To perform serial data transmission, the SCI first automatically transfers transmit data from TDR register to TSR register, and then sends the data to the TXDn pin.

33.2.5 Control Register 0 (SCR0)

Address(es): RSCI8.SCR0 000A 1408h, RSCI9.SCR0 000A 1488h, RSCI11.SCR0 000E 2088h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	SSE	—	—	TEIE	TIE	—	—	—	RIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	IDSEL	DCME	MPIE	—	—	—	TE	—	—	—	RE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RE	Receive Enable	0: Serial reception is disabled 1: Serial reception is enabled	R/W *1, *3
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b4	TE	Transmit Enable	0: Serial transmission is disabled 1: Serial transmission is enabled	R/W *1
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	MPIE	Multi-Processor Interrupt Enable	(Valid in asynchronous mode and manchester mode when SCR3.MP is 1.) This bit should set 0 in smart card interface mode. 0: Non-multi-processor reception 1: Multi-processor reception When the data with the multi-processor bit set to 0 is received, the data is not read, and setting the status flags to 1 is disabled. When the data with the multiprocessor bit set to 1 is received, the MPIE bit is automatically cleared to 0, and non-multi-processor reception is resumed. If you want to continue receiving operation using the multiprocessor function, set this bit to 1 sufficiently earlier than receiving the STOP bit of the next received frame.	R/W *2
b9	DCME	Data Compare Match Enable	(Valid only in asynchronous mode) 0: Data match detection function is disabled 1: Data match detection function is enabled	R/W *2
b10	IDSEL	ID Frame Select	(Valid only in asynchronous mode with multi-processor) 0: It's always compared data in spite of the value of the multi-processor bit. 1: It's compared data when the multi-processor bit is 1 (ID frame) only.	R/W *4
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	RIE	Receive Interrupt Enable	0: RXI and ERI interrupt requests are disabled 1: RXI and ERI interrupt requests are enabled	R/W
b19 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	TIE	Transmit Interrupt Enable	0: TXI interrupt request is disabled 1: TXI interrupt request is enabled	R/W
b21	TEIE	Transmit End Interrupt Enable	This bit should set 0 in smart card interface mode. 0: TEI interrupt request is disabled 1: TEI interrupt request is enabled	R/W
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R
b24	SSE	SSn# Pin Function Enable	(Valid in simple SPI mode.) In slave mode (SCR3.CKE[1:0] bits = 1xb), set this bit to 1. 0: SSn# pin function is disabled. 1: SSn# pin function is enabled.	R/W *4
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. In clock synchronous mode (SCR3.MOD[2:0] bits = 010b), simple SPI mode (SCR3.MOD[2:0] bits = 011b), and simple I^2C

mode (SCR3.MOD[2:0] bits = 100b), 1 can be written only when TE bit = 0 and RE bit = 0. After setting TE bit or RE bit to 1, only 0 can be written in TE bit and RE bit. In other mode, writing is enabled under any condition.

Note 2. This bit is a bit that is cleared by hardware. Note that writing to a bit other than this bit with a bit manipulation instruction may cause this bit to be unintentionally set to 1 by a read-modify-write operation.

Note 3. In clock synchronous mode and simple SPI mode, receive only setting with internal clock (master mode) is prohibited (TE bit = 0 and RE bit = 1 setting prohibited).

Note 4. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.

RE Bit (Receive Enable)

Enables or disables serial receive operation.

When this bit is set to 1, serial reception starts when RSCI detects the start bit in synchronous mode, the falling edge of the RXD input in Manchester mode, the synchronous clock input in clock synchronous mode, or the start bit in smart card interface mode.

Note that the SCR0 and SCR3 registers should be set prior to setting the RE bit to 1 in order to designate the reception format.

Except smart card interface mode, even if reception is halted by setting the RE bit to 0, the SSR.RDRF, AFER, APER, ORER, MMSR.MCER, SBER, SYER, and PFER flags in non-FIFO mode, and RFSR.DR flag in FIFO mode are not affected and the previous values is retained. In smart card interface mode, even if reception is halted by setting the RE bit to 0, the SSR.AFER, APER, and ORER flags are not affected and the previous value is retained.

TE Bit (Transmit Enable)

Enables or disables serial transmission.

When this bit is set to 1, serial transmission becomes possible. Transmission is started by writing transmit data to TDR register. Note that SCR3 should be set prior to setting the TE bit to 1 in order to designate the transmission format.

MPIE Bit (Multi-Processor Interrupt Enable)

When this bit is set to 1 and the data with the multi-processor bit set to 0 is received, the data is not read and setting the status flags (SSR.RDRF, ORER, AFER, RFSR.DR, MMSR.MCER, SYER, PFER, SBER) are not set.

When the data with the multi-processor bit set to 1 is received, the MPIE is automatically cleared to 0, and normal reception is resumed. For details, refer to section 33.4, Multi-Processor Communication Function. If you want to continue receiving operation using the multiprocessor function, set this bit to 1 sufficiently earlier than receiving the STOP bit of the next received frame.

When the receive data includes the multi-processor bit set to 0, the receive data is not transferred from the RSR register to the RDR register, a receive error is not detected, and setting the flags ORER and AFER, MCER, SYER, PFER, and SBER to 1 is disabled.

When the receive data includes the multi-processor bit set to 1, the MPB flag is set to 1, the MPIE bit is automatically set to 0, the RXI and ERI interrupt requests are enabled (if SCR0.RIE bit is set to 1), and setting the flags ORER, AFER, MCER, SYER, PFER, and SBER to 1 is enabled.

MPIE should be set to 0 if multi-processor communications function is not to be used.

DCME Bit (Data Compare Match Enable)

It can select whether the data match detection function uses or not.

When DCME bit is 1, if RSCI detects the match to the comparison data (SCR4.CMPD[8:0] bits) with receive data, DCME bit is cleared automatically, and after that, RSCI operation mode will be receive mode without data match detection function.

Refer to section 33.3.6, Data Match Detection.

The write value should be 0 other than asynchronous mode.

IDSEL Bit (ID Frame Select)

This bit specifies the condition of the received data to be compared. The bit is valid only when the DCME bit is 1.
When setting this bit to 1, only data in received frames (ID frames) in which the multi-processor bit has the value 1 are compared.
When this bit is set to 0, all received data is compared.

RIE Bit (Receive Interrupt Enable)

Enables or disables RXI and ERI interrupt requests.
RXI and ERI interrupt request is disabled by setting the RIE bit to 0.
An ERI interrupt request can be canceled by reading 1 from the SSR.ORER, AFER, or APER flag and then setting the flag to 0, or setting the RIE bit to 0.
In the case of manchester mode, the MMSR.MCER, SYER, PFER, and SBER flags are also the cause of ERI interrupt request, so the same processing is necessary. For details of these flags, see section 33.2.12, Manchester Mode Control Register (MMCR) and section 33.2.21, Manchester Mode Status Register (MMSR).

TIE Bit (Transmit Interrupt Enable)

Enables or disables TXI interrupt request.
An TXI interrupt request is disabled by setting the TIE bit to 0. At the beginning of transmission, set 1 to SCR0.TE bit and SCR0.TIE bit simultaneously. Then the TXI interrupt request is generated.

TEIE Bit (Transmit End Interrupt Enable)

T Enables or disables a TEI interrupt request.
A TEI interrupt request is disabled by setting the TEIE bit to 0.
In simple I^2C mode, the TEI is allocated to the interrupt on completion of issuing a start, restart, or stop condition (STI). In this case, the TEIE bit can be used to enable or disable the STI.

SSE Bit (SSn# Pin Function Enable)

Set this bit to 1 if the SSn# pin is to be used in control of transmission and reception (in simple SPI mode). Set this bit to 0 in any other mode. Do not set both the SSE and CTSE bits to enabled (even if this setting is made, operation is the same as that when these bits are set to 0).
In the slave mode (SCR3.CKE[1:0] bits = 10b or 11b), SSE should be set 1.
In the master mode (SCR3.CKE[1:0] bits = 00b or 01b) and single-master, the SSn# pin on the master side is not required to control reception and transmission, so SSE should be set 0.

33.2.6 Control Register 1 (SCR1)

Address(es): RSCI8.SCR1 000A 140Ch, RSCI9.SCR1 000A 148Ch, RSCI11.SCR1 000E 208Ch

b16	LOOP	Loopback Mode Setting	It can be used when internal clock operation in asynchronous mode, internal mode operation in manchester mode, internal clock operation in clock synchronous mode. 0: Normal mode 1: Loopback mode	R/W *1

Bit	Symbol	Bit Name	Description	R/W
b19 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	HDSEL	Half-Duplex Communication Select	In the smart card interface mode, the simple I2C mode, or in the simple SPI mode, this bit should be set 0. 0: TXDn pin, RXDn pin independent 1: TXDn/RXDn pin combination use (Half-duplex communication using TXDn pin)	R/W *1
b23 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R
b26 to b24	NFCS[2:0]	Noise Filter Clock Select	(Valid in asynchronous mode and manchester mode, extended serial mode, and simple I2C mode.) Select for the noise filter's clock source. b26 b24 0 0 0: The base clock signal divided by 1. 0 0 1: The on-chip baud rate generator source clock*6 divided by 1. 0 1 0: The on-chip baud rate generator source clock*6 divided by 2. 0 1 1: The on-chip baud rate generator source clock*6 divided by 4. 1 0 0: The on-chip baud rate generator source clock*6 divided by 8. Settings other than above are prohibited. In simple I2C mode, 000b setting is prohibited. “The on-chip baud rate generator source clock” means the clock selected by SCR2.CKS[1:0] bits.	R/W *1
b27	—	Reserved	This bit is read as 0. The write value should be 0.	R
b28	NFEN	Digital Noise Filter Enable	(Valid in asynchronous mode, manchester mode, extended serial mode and simple I2C) In asynchronous mode, manchester mode and extended serial mode 0: Noise cancellation function for the RXDn input signal is disabled. 1: Noise cancellation function for the RXDn input signal is enabled. In simple I2C mode 0: Noise cancellation function for the SSCLn and SSDAn input signals is disabled. 1: Noise cancellation function for the SSCLn and SSDAn input signals is enabled.	R/W *1
b31 to b29	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.
Note 2. This bit is available in asynchronous mode and manchester mode. Set this bit to 0 in other mode.
Note 3. Please use this bit in asynchronous mode and manchester mode only. Movement by other mode isn’t guaranteed.
Note 4. RINV/TINV should be set to 0 in smart card interface mode and simple I2C mode.
Note 5. When the alternate output is enabled in HBS support mode.
Note 6. The clock is selected by SCR2.CKS[1:0] bits.

CTSE Bit (CTS Enable)

Set this bit to 1 if the SSn# pin is to be used for inputting of the CTS control signal to control of transmission and reception. The RTS signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode, simple SPI mode, simple I2C mode, and extended serial mode. Do not set both the CTSE and SSE bits to enabled (even if this setting is made, operation is the same as that when these bits are set to 0).

CRSEP Bit (CTS/RTS Separation)

This bit selects usage of the CTSn#, RTSn#, and CTSn#/RTSn# pins when the CTSE bit is 1.
When either CTS or RTS function is to be used, set this bit to 0.
When both CTS and RTS functions are to be used, set this bit to 1.
When the CTSE bit is set to 0, set this bit to 0.
Refer to Table 33.7 for the relationship between the CRSEP and CTSE bit settings and the pin functions.

Table 33.7 Relationship between the CRSEP and CTSE Bit Settings and Pin Functions

CTSE Bit	CRSEP Bit	CTSn#/RTSn# Multiplexed Pin	CTSn# Dedicated Pin	RTSn# Dedicated Pin
0	0	RTSn# signal output	Disabled	RTSn# signal output
1	0	CTSn# signal input	CTSn# signal input	Disabled
1	1	RTSn# signal output	CTSn# signal input	RTSn# signal output

SPB2DT Bit (Serial Port Break Data), SPB2IO Bit (Serial Port Break I/O)

The TXDn (TXDAn/TXDBn) pins status decided by combination of SCR0.TE bit, SCR1.SPB2IO bit and SCR1.SPB2DT bit is indicated in Table 33.8.

Table 33.8 Controlling the TXDn (TXDAn/TXDBn) Pins

SCR0.TE Bit Setting	SCR1.SPB2IO Bit Setting	SCR1.SPB2DT Bit Setting	TINV Bit Setting	TXDn Pin Status
0 (Transmission disabled)	0 (Input)	0 or 1	0 or 1	Hi-Z
	1 (Output)	0	0	Low is output
			1	High is output
		1	0	High is output
			1	Low is output
1 (Transmission enabled)	0 or 1	0 or 1	0 or 1	Transmit data output pin

PE Bit (Parity Enable)

When PE bit to 1, the parity bit is added to transmit data before transmission, and the parity bit is checked in reception. In the multiprocessor format, the parity bit is not added or checked regardless of this bit setting.

PM Bit (Parity Mode)

Selects the parity mode for transmission and reception (even or odd). In multi-processor mode, this bit is invalid.
For details on the usage of this bit in smart card interface mode, refer to section 33.7.2, Data Format (Except in Block Transfer Mode).

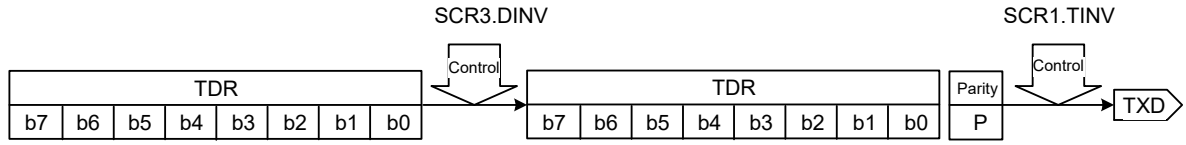
TINV Bit (Transmitter Output Invert), RINV Bit (Receiver Input Invert)

The data of RDR register is controlled by RINV bit and SCR3.DINV bit. And the data from TXDn pin is controlled by TINV bit and SCR3.DINV bit. The control by RINV/TINV bits are done to communication pins (RXDn/TXDn), so they can control not only data bits but also other bits (start bit, stop bit, parity bit). Please refer to Figure 33.2 in detail. When the TXDAn/TXDBn pins are used, the data is also inverted according to the TINV value.
During half-duplex communication and slave operation in simple SPI mode, use the TXDn pin for reception, so set the inversion control of the received data with the TINV bit.

Note: Sentences and a timing chart of the RSCI operation explanation are mentioned by TINV bit = 0 and RINV bit = 0 when TINV's value and RINV's value are not specified.

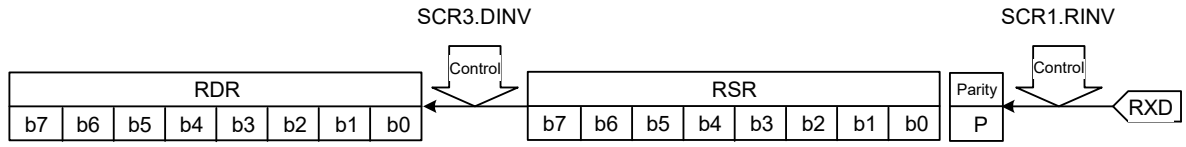
The receive/transmit data control (Data size = 8bits, Even parity, MSB first)

The transmit data is controlled by SCR1.TINV and SCR3.DINV.



SCR3. DINV	SCR1. TINV	TDR	TSR	Prity (even)	TXDn waveform
0	0	BEh	BEh	0	
0	1	BEh	BEh	0	
1	0	BEh	41h	0	
1	1	BEh	41h	0	

The received data is controlled by SCR1.RINV and SCR3.DINV.



SCR3. DINV	SCR1. RINV	RDR	RSR	Prity (even)	RXDn waveform
0	0	BEh	BEh	0	
1	0	41h	BEh	0	
0	1	BEh	BEh	0	
1	1	41h	BEh	0	

Figure 33.2 Example of the Receive/Transmit Data Control

LOOP Bit (Loopback Mode Setting)

When this bit is 1, RSCI blocks the input path from RXD and connects the output path to TXD to the reception data register.
Transmit data can be inverted and received by combining it with TINV bit.
Clock synchronous mode Set to 0 at slave operation and asynchronous mode use of external clock, and extended serial mode.

HDSEL Bit (Half-Duplex Communication Select)

Setting this bit to 1 enables half-duplex communication using the TXDn pin. However, it cannot be used in simple SPI mode, simple I^2C mode and smart card interface mode.
If this bit is set to 1 and SCR0.TE bit = 1, SCR0.RE bit = 0, the TXDn pin becomes communication output. If this bit is set to 1 and SCR0.TE bit = 0, SCR0.RE bit = 1, the TXDn pin becomes the communication input. For details, see section 33.16, Half-Duplex Communication Function.

NFCS[2:0] Bits (Noise Filter Clock Select)

These bits select the sampling clock for the digital noise filter.
To use the noise filter in asynchronous mode, manchester mode and extended serial mode set these bits from 000b to 100b. In simple I^2C mode, set the bits to a value in the range from 001b to 100b.

NFEN Bit (Digital Noise Filter Enable)

This bit enables or disables the digital noise filter function. When the function is enabled, noise cancellation is applied to the RXDn input signal in asynchronous mode, manchester mode, extended serial mode, and noise cancellation is applied to the SSDAn and SSCLn input signals in simple I^2C mode. In any mode other than above, set the NFEN bit to 0 to disable the digital noise filter function. When the function is disabled, input signals are transferred as is, as internal signals.

33.2.7 Control Register 2 (SCR2)

Address(es): RSCI8.SCR2 000A 1410h, RSCI9.SCR2 000A 1490h, RSCI11.SCR2 000E 2090h

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	BCP[2:0]	Base Clock Pulse	Selects the number of base clock cycles in smart card interface mode. b2 b0 0 0: 93 clock cycles (S = 93)*2 0 0 1: 128 clock cycles (S = 128)*2 0 1 0: 186 clock cycles (S = 186)*2 0 1 1: 512 clock cycles (S = 512)*2 1 0 0: 32 clock cycles (S = 32)*2 (Initial value) 1 0 1: 64 clock cycles (S = 64)*2 1 1 0: 372 clock cycles (S = 372)*2 1 1 1: 256 clock cycles (S = 256)*2	R/W *1
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R
b4	BGDM	Baud Rate Generator Double-Speed Mode Select	Valid in asynchronous/manchester/clock synchronous/simple SPI mode and SCR3.CKE[1] bit = 0. 0: Baud rate generator outputs the clock with single frequency. 1: Baud rate generator outputs the clock with doubled frequency.	R/W *1
b5	ABCS	Asynchronous Mode Base Clock Select	(Valid only in asynchronous mode, manchester mode and extended serial mode) 0: Selects 16 base clock cycles for 1-bit period. 1: Selects 8 base clock cycles for 1-bit period.	R/W *1
b6	ABCSE	Asynchronous Mode Base Clock Select Extended	(Valid only in asynchronous mode and SCR3.CKE[1] bit = 0) 0: Clock cycles for 1-bit period is decided with combination between SCR2.BGDM bit and SCR2.ABCS bit. 1: Baud rate is 6 base clock cycles for 1-bit period and the clock of a double frequency is output from the baud rate generator.	R/W *1
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R
b15 to b8	BRR[7:0]	Bit Rate Setting	An 8-bit field that adjusts the bit rate.	R/W *1
b16	BRME	Bit Rate Modulation Enable	0: Bit rate modulation function is disabled. 1: Bit rate modulation function is enabled.	R/W *1
b19 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R
b21, b20	CKS[1:0]	Clock Select	b21 b20 0 0: PCLK (n = 0)*3 0 1: PCLK/4 (n = 1)*3 1 0: PCLK/16 (n = 2)*3 1 1: PCLK/64 (n = 3)*3	R/W *1
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R
b31 to b24	MDDR[7:0]	Modulation Duty Setting	MDDR[7:0] bits corrects the bit rate adjusted by the BRR[7:0] bits.	R/W *1

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.
Note 2. S is the value of S in BRR[7:0] bits explanation.
Note 3. n is the decimal notation of the value of n in BRR[7:0] bits explanation.

BCP[2:0] Bits (Base Clock Pulse)

These bits select the number of base clock cycles in a 1-bit data transfer time in smart card interface mode.
For details, refer to section 33.7.4, Receive Data Sampling Timing and Reception Margin.

BGDM Bit (Baud Rate Generator Double-Speed Mode Select)

This bit is valid when the on-chip baud rate generator is selected as the clock source (SCR3.CKE[1] bit = 0) in asynchronous mode, manchester mode, clock synchronous mode, simple SPI mode. When external clock is selected (SCR3.CKE[1] bit = 1), set it to 0. For the clock output from the baud rate generator, either single or doubled frequency can be selected. The base clock is generated by the clock output from the baud rate generator. When the BGDM bit is set to 1, the base clock cycle is halved and the bit rate is doubled.
Set this bit to 0 in modes other than asynchronous mode or manchester mode or clock synchronous mode or simple SPI.

ABCS Bit (Asynchronous Mode Base Clock Select)

Selects the clock cycles for 1-bit period.
Set it to 0 in modes other than asynchronous mode, manchester mode and extended serial mode.

ABCSE Bit (Asynchronous Mode Base Clock Select Extended)

The pulse number for a base clock at 1-bit period is 6 and the clock of a double frequency is output from baud rate generator. Only when the bit rate is set to 6 dividing frequency of the bus clock, please use this bit and set SCR2.CKS[1:0] bits = 00b and BRR[7:0] bits = 0.
Set it to 0 in modes other than asynchronous mode. Even in asynchronous mode, set it to 0 when using external clock.

Table 33.9 Base Clock Cycle Number per 1-Bit

ABCSE Bit	ABCS Bit	BGDM Bit	The Base Clock Cycles/ 1-Bit	The Output Frequency of the Baud Rate Generator
0	0	0	16	×1
0	0	1	16	×2
0	1	0	8	×1
1	1	1	8	×2
1	—	—	6	×2

—: Don’t care

BRR[7:0] Bits (Bit Rate Setting)

BRR[7:0] bits are an 8-bit field that adjusts the bit rate.
RSCI has independent baud rate generator control, different bit rates can be set for each. Table 33.10 shows the relationship between the setting (N) in the BRR[7:0] bits and the bit rate (B) for asynchronous mode, multiprocessor transfer, manchester mode, clock synchronous mode, smart card interface mode, simple SPI mode, and simple I^2C mode.

Table 33.10 Relationship between N Setting in BRR[7:0] Bits and Bit Rate B

Mode	SCR2 Settings			BRR[7:0] Bits Setting	Error (%)
	BGDM bit	ABCS bit	ABCSE bit		
Asynchronous, multi-processor communication, manchester, extended serial*3	0	0	0	$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 64 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
	1	0	0	$N = \frac{PCLK \times 10^6}{32 \times 2^{2n-1} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 32 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
	0	1	0		
	1	1	0	$N = \frac{PCLK \times 10^6}{16 \times 2^{2n-1} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 16 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
	0 or 1	0 or 1	1*2	$N = \frac{PCLK \times 10^6}{12 \times 2^{2n-1} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 12 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
Clock synchronous, simple SPI	0	0 (Initial value)	0 (Initial value)	$N = \frac{PCLK \times 10^6}{8 \times 2^{2n-1} \times B} - 1$	
	1	0 (Initial value)	0 (Initial value)	$N = \frac{PCLK \times 10^6}{4 \times 2^{2n-1} \times B} - 1$	
Smart card interface				$N = \frac{PCLK \times 10^6}{S \times 2^{2n+1} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times S \times 2^{2n+1} \times (N+1)} - 1 \right\} \times 100$
Simple I^2C*1				$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	

B: Bit rate (bps)
N: BRR[7:0] bits setting ($0 \le N \le 255$)
PCLK: Operating frequency (MHz)
n and S: Determined by the settings of the SCR2 registers as listed in the table below.Please be careful about "$2^{(2n+1)}$" is used in the expression for smart card interface, "$2^{(2n-1)}$" is used in other mode.

Note 1. Adjust the bit rate so that the widths at high and low level of the SCL output in simple I^2C mode satisfy the I^2C standard.
Note 2. In manchester mode, only ABCSE bit = 0 can be selected.
Note 3. In extended serial mode, BGDM bit = 0 and ABCSE bit = 0 can be selected.

Table 33.11 Calculating Widths at High and Low Level for SCL

Mode	SCL	Formula (Result in Seconds)
I^2C	High period (minimum value)	$(N+1) \times 4 \times 2^{2n-1} \times 7 \times \frac{1}{PCLK \times 10^6}$
	Low period (minimum value)	$(N+1) \times 4 \times 2^{2n-1} \times 8 \times \frac{1}{PCLK \times 10^6}$

Table 33.12 Clock Source Settings

SCR2 Setting		
CKS[1:0] Bits	Clock Source	n
0 0	PCLK	0
0 1	PCLK/4	1
1 0	PCLK/16	2
1 1	PCLK/64	3

Table 33.13 Base Clock Settings in Smart Card Interface Mode

SCR2 Setting		
BCP[2:0] Bits	**Base Clock Cycles for 1-bit Period**	**S**
0 0 0	93 clock cycles	93
0 0 1	128 clock cycles	128
0 1 0	186 clock cycles	186
0 1 1	512 clock cycles	512
1 0 0	32 clock cycles	32
1 0 1	64 clock cycles	64
1 1 0	372 clock cycles	372
1 1 1	256 clock cycles	256

Table 33.14 and Table 33.15 list examples of N settings in BRR[7:0] in asynchronous mode and manchester mode. Table 33.16 lists the maximum bit rate settable for each operating frequency. Examples of BRR[7:0] bits (N) settings in clock synchronous mode and simple SPI mode are listed in Table 33.18. Examples of BRR[7:0] bits (N) settings in smart card interface mode are listed in Table 33.20. Examples of BRR[7:0] bits (N) settings in simple I^2C mode are listed in Table 33.22. In smart card interface mode, the number of base clock cycles S in a 1-bit data transfer time can be selected. For details, refer to section 33.7.4, Receive Data Sampling Timing and Reception Margin. Table 33.17 and Table 33.19 list the maximum bit rates with external clock input.

When either the asynchronous mode base clock select bit (ABCS) or the baud rate generator double-speed mode select bit (BGDM) is set to 1 in asynchronous mode and manchester mode, the bit rate becomes twice that listed in Table 33.14 and Table 33.15. When both of those registers are set to 1, the bit rate becomes four times the listed value.

Table 33.14 Examples of BRR[7:0] Bits Settings for Various Bit Rates (Asynchronous Mode and Manchester Mode) (1)

BRME Bit (Bit Rate Modulation Enable)

Enables and disables the bit rate modulation function. The bit rate generated by on-chip baud rate generator is evenly corrected when this function is enabled.

This bit can only be set to 1 in asynchronous mode and simple I²C mode. Set this bit to 0 in clock synchronous mode, simple SPI mode, smart card interface mode, manchester mode, and extended serial mode.

CKS[1:0] Bits (Clock Select)

These bits select the clock source for the on-chip baud rate generator.

For the relationship between the settings of these bits and the baud rate, refer to BRR[7:0] bits explanation.

MDDR[7:0] Bits (Modulation Duty Setting)

When the BRME bit is set to 1, the bit rate generated by the on-chip baud rate generator is evenly corrected according to the settings of MDDR (M/256). The relationship between the MDDR[7:0] bits setting (M) and the bit rate (B) is given in Table 33.24.

The initial value of MDDR[7:0] bits is FFh. Bit 7 in this register is fixed to 1.

Table 33.24 Relationship between MDDR[7:0] Bits Setting (M) and Bit Rate (B) When Bit Rate Modulation Function is Used

Mode*1	SCR2 Settings			BRR[7:0] Bits Setting	Error (%)
	BGDM Bit	ABCS Bit	ABCSE Bit		
Asynchronous, multi-processor communication	0	0	0	$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 64 \times 2^{2n-1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$
	1	0	0	$N = \frac{PCLK \times 10^6}{32 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 32 \times 2^{2n-1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$
	0	1	0		
	1	1	0	$N = \frac{PCLK \times 10^6}{16 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 16 \times 2^{2n-1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$
	0 or 1	0 or 1	1	$N = \frac{PCLK \times 10^6}{12 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	$Error = \left\{ \frac{PCLK \times 10^6}{B \times 12 \times 2^{2n-1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$
Simple I^2C*2				$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	

B: Bit rate (bps)
M: MDDR[7:0] bits setting (128 ≤ M ≤ 255)
N: BRR[7:0] bits setting (0 ≤ N ≤ 255)
PCLK: Operating frequency (MHz)
n: Determined by the settings of the SCR2.CKS[1:0] bits as listed in Table 33.12, Clock Source Settings.

Note 1. Do not use this function in clock synchronous mode, simple SPI mode, smart card Interface mode, manchester mode and extended serial mode.

Note 2. Adjust the bit rate so that the widths at high and low level of the SCL output in simple I^2C mode satisfy the I^2C standard.

Table 33.25 and Table 33.26 list examples of N settings in BRR[7:0] bits and M settings in MDDR[7:0] bits in asynchronous mode.

Table 33.25 Examples of BRR[7:0] Bits and MDDR[7:0] Bits Settings for Various Bit Rates (Asynchronous Mode) (1)

Bit	Symbol	Bit Name	Description	R/W
b0	CPHA	Clock Phase Select	(Valid in clock synchronous mode and simple SPI mode. Set this bit only when SCR0.TE bit = 0 and RE bit = 0.) 0: Data is sampled at an odd edge and changes at an even edge. (Clock is delayed.) 1: Data changes at an odd edge and is sampled at an even edge. (Clock is not delayed.)	R/W *1
b1	CPOL	Clock Polarity Select	(Valid in clock synchronous mode and simple SPI mode. Set this bit only when SCR0.TE bit = 0 and RE bit = 0.) 0: SCKn in idle state is 0. 1: SCKn in idle state is 1.	R/W *1
b6 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b7	SYNDIS	Synchronizer Disable	Set this bit to 1.	R/W
b9, b8	CHR[1:0]	Character Length Select	(Valid in asynchronous mode and manchester mode) *2 Select the data length for transmission and reception. b9 b8 0 0: Transmit/receive in 9-bit data length 0 1: Transmit/receive in 9-bit data length 1 0: Transmit/receive in 8-bit data length (initial value) 1 1: Transmit/receive in 7-bit data length*3	R/W *1
b11, b10	—	Reserved	These bits are read as 0. The write value should be 0.	R
b12	DDIR	Transfer Data Direction Select	0: MSB first 1: LSB first Set this bit to 0 in simple I2C mode and set this bit to 1 in extended serial mode.	R/W *1
b13	DINV	Transfer Data Invert	0: TDR register contents are transmitted to TSR register as they are. RSR register contents are stored to RDR register as they are. 1: TDR register contents are inverted before being transmitted to TSR register. RSR register contents are inverted and stored to RDR register. Set this bit to 0 in simple I2C mode. The level of communication pins (RXDn/TXDn) are controlled by combination of this bit and SCR1.TINV/RINV. Please refer to Figure 33.2 for details.	R/W *1
b14	STOP	Stop Bit Length Select	(Valid in asynchronous mode, manchester mode, extended serial mode) 0: 1 stop bit/break delimiter length is 1bit 1: 2 stop bits/break delimiter length is 2bits	R/W *1
b15	RXDESEL	Asynchronous Start Bit Edge Detection Select	(Valid only in asynchronous mode) Set this bit to 1 in extended serial mode. 0: The low level on the RXDn pin is detected as the start bit. 1: A falling edge on the RXDn pin is detected as the start bit.	R/W *1

Bit	Symbol	Bit Name	Description	R/W
b18 to b16	MOD[2:0]	Communication Mode Select	Select the RSCI communication mode. b18 b16 0 0 0: Asynchronous mode 0 0 1: Smart card interface mode 0 1 0: Clock synchronous mode 0 1 1: Simple SPI mode 1 0 0: Simple I^2C mode 1 0 1: Manchester mode 1 1 0: Extended serial mode 1 1 1: Setting prohibited	R/W *1
b19	MP	Multi-Processor Mode	(Valid in asynchronous mode, manchester mode) 0: Multi-processor communications function is disabled 1: Multi-processor communications function is enabled	R/W *1
b20	FM	FIFO Mode Select	(Valid in asynchronous mode (including multi-processor mode), clock synchronous mode, simple SPI mode) 0: TDR register, RDR register is non-FIFO buffer configuration 1: TDR register, RDR register is FIFO buffer configuration	R/W *1
b21	DEEN	Driver Control Function Enable	(Valid only in asynchronous mode) 0: RS-485 driver control function disable. 1: RS-485 driver control function enable.	R/W *1
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R
b25, b24	CKE[1:0]	Clock Enable	In the case of asynchronous mode b25 b24 0 0: On-chip baud rate generator The SCKn pin is available for use as an I/O port in accord with the I/O port settings. 0 1: On-chip baud rate generator The clock with the same frequency as the bit rate is output from the SCKn pin. 1 x: External clock • When using the external clock 16 times the bit rate should be input from the SCKn pin when SCR2.ABCS bit is 0. Input a clock signal with a frequency 8 times the bit rate when the SCR2.ABCS bit is 1. In the case of manchester mode and extended serial mode b25 b24 0 0: On-chip baud rate generator The SCKn pin functions as I/O port. Settings other than above are prohibited. In the case of clock synchronous mode and simple SPI mode b25 b24 0 x: Internal clock (master operation) The SCKn pin functions as the clock output pin. 1 x: External clock (slave operation) The SCKn pin functions as the clock input pin. In the case of smart card interface mode When SCR3.GM bit = 0 b25 b24 0 0: Output disabled (The SCKn pin is available for use as an I/O port in accord with the I/O port settings.) 0 1: Clock output 1 x: Prohibited When SCR3.GM bit = 1 b25 b24 0 0: Output fixed low 0 1: Clock output 1 0: Output fixed high 1 1: Clock output	R/W *1
b26	—	Reserved	Set this bit to 0.	R/W
b27	—	Reserved	This bit is read as 0. The write value should be 0.	R
b28	GM	GSM Mode	(Valid only in smart card interface mode) 0: Non-GSM mode operation 1: GSM mode operation	R/W *1

Bit	Symbol	Bit Name	Description	R/W
b29	BLK	Block Transfer Mode	(Valid only in smart card interface mode) 0: Non-block transfer mode operation 1: Block transfer mode operation	R/W *1
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.
Note 2. In other than asynchronous mode and manchester mode, this bit setting is invalid and a fixed data length of 8 bits is used. Set these bits to 10b in extended serial mode.
Note 3. LSB first is fixed and the MSB (bit 7) in TDR register is not transmitted in transmission.

CPHA Bit (Clock Phase Select)

This bit selects the phase of the clock signal output through the SCKn pin. Refer to Figure 33.108 for details.
Set the bit to 1 in other than simple SPI mode and clock synchronous mode.

CPOL Bit (Clock Polarity Select)

This bit selects the polarity of the clock signal output through the SCKn pin. Refer to Figure 33.108 for details.
Set the bit to 1 in other than simple SPI mode and clock synchronous mode.

CHR[1:0] Bits (Character Length Select)

Selects the data length for transmission and reception.
Except of asynchronous mode and manchester mode, a fixed data length of 8 bits is used.

DDIR Bit (Transfer Data Direction Select)

Select whether to transmit/receive data in MSB first or LSB first.

DINV Bit (Transfer Data Invert)

DINV bit can invert the transmit data bit from TDR register to TSR register, and also can invert the received data from RSR register to RDR register. This bit does not affect the logic level of the parity bit. To invert the parity bit, invert the SCR1.PM bit.

STOP Bit (Stop Bit Length Select)

Selects the stop bit length in transmission.
In reception, only the first stop bit is checked regardless of this bit setting. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.
In addition, it is used as break delimiter length setting when sending Start Frame in extended serial mode.

RXDESEL Bit (Asynchronous Start Bit Edge Detection Select)

Selects the detection method of the start bit for reception in asynchronous mode. When a break occurs, data receiving operation depends on the settings of this bit. Set this bit to 1 when reception should be stopped while a break occurs or when reception should be started without retaining the RXDn pin input at high level for the period of one data frame or longer after completion of the break.
Set this bit to 1 in extended serial mode. Set this bit to 0 in modes except of asynchronous mode and extended serial mode.

MOD[2:0] Bits (Communication Mode Select)

Selects the RSCI communication mode.

Table 33.27 Relationship between Communication Mode Selection Bits (MOD[2:0]), Other Operation Mode Setting Bits

Communication mode	Asynchronous				Smart Card I/F	Clock Synchronous		Simple SPI				Simple I²C		Manchester		Extended Serial
SCR3.MOD[2:0]	000b				001b	010b		011b				100b		101b		110b
SCR3.MP	0		1		—	—		—				—		0	1	—
SCR3.FM	0	1	0	1	—	0	1	0	1			—		—		—
SCR3.DEEN	0	1	0	1	0	1	0	1	—			—		—		—
SCR3.SSE	—				—	—		0	1	0	1	—		—		—

—: Prohibited setting

MP Bit (Multi-Processor Mode)

Disables/enables the multi-processor communications function. The settings of the PE bit and PM bit are invalid in multi-processor mode.

FM Bit (FIFO Mode Select)

When the FM bit is set to 1, the TDR register/RDR register switches to FIFO configuration, and transmit FIFO (TDR register)/receive FIFO (RDR register) can be used for serial transmission/reception.

DEEN Bit (Driver Control Function Enable)

Select RS-485 Driver control function disable or enable.

CKE[1:0] Bits (Clock Enable)

These bits select the clock source and SCKn pin function.

In smart card interface mode, these bits control the clock output from the SCKn pin.

In GSM mode, clock output can be dynamically switched. For details, refer to section 33.7.8, Clock Output Control.

GM Bit (GSM Mode)

Setting this bit to 1 allows GSM mode operation.

In GSM mode, the SSR.TEND flag set timing is put forward to 11.0 etu (elementary time unit = 1-bit transfer time) from the start and the clock output control function is appended. For details, refer to section 33.7.6, Serial Data Transmission (Except in Block Transfer Mode) and section 33.7.8, Clock Output Control.

BLK Bit (Block Transfer Mode)

Setting this bit to 1 allows block transfer mode operation.

For details, refer to section 33.7.3, Block Transfer Mode.

33.2.9 Control Register 4 (SCR4)

R/W *1

Bit	Symbol	Bit Name	Description	R/W
b31 to b28	TTMG[3:0]	Transmit Signal Transition Timing Select	b31 b28 1 1 1 1: Delays the 1 to 0 transitions for 7 clocks. 1 1 1 0: Delays the 1 to 0 transitions for 6 clocks. 1 1 0 1: Delays the 1 to 0 transitions for 5 clocks. 1 1 0 0: Delays the 1 to 0 transitions for 4 clocks. 1 0 1 1: Delays the 1 to 0 transitions for 3 clocks. 1 0 1 0: Delays the 1 to 0 transitions for 2 clocks. 1 0 0 1: Delays the 1 to 0 transitions for 1 clocks. x 0 0 0: Does not change the waveform. 0 0 0 1: Delays the 0 to 1 transitions for 1 clock. 0 0 1 0: Delays the 0 to 1 transitions for 2 clock. 0 0 1 1: Delays the 0 to 1 transitions for 3 clock. 0 1 0 0: Delays the 0 to 1 transitions for 4 clock. 0 1 0 1: Delays the 0 to 1 transitions for 5 clock. 0 1 1 0: Delays the 0 to 1 transitions for 6 clock. 0 1 1 1: Delays the 0 to 1 transitions for 7 clock.	R/W *1

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.

CMPD[8:0] Bits (Compare Match Data)

Set the comparison data for receive data, when data match detection function is enabled (SCR0.DCME bit = 1). SCR4.CMPD[8:0] bits should be written while SCR0.DCME bit is 0.

For the comparison data, it can select length from 3 types, they are CMPD[6:0] with 7bit length enable, CMPD[7:0] with 8bit, and CMPD[8:0] with 9bit length.

RTADJ Bit (Receive Data Sampling Timing Adjustment)

When this bit is 1, the receive sampling timing adjustment function is enabled. Control is different in asynchronous mode, extended serial mode, clock synchronous mode, and simple SPI mode.

In asynchronous mode using internal clock, refer to section 33.3.10, Receive Data Sampling Timing Adjustment for details. The operation when the extended serial mode internal clock is selected is the same as when the asynchronous clock internal clock is selected.

In clock synchronous mode as master, simple SPI mode operating as master, refer to section 33.10.7, Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with Internal Clock Used for details. Only the digital delay of the master mode receive sampling clock (MRCLK) can be controlled by this bit. MRCLK analog delay cannot be controlled.

TTADJ Bit (Transmit Signal Transition Timing Adjustment)

When this bit is 1, the transmit signal transition timing adjustment function is enabled. The transmit signal transition timing adjustment function can adjust the edge timing of the waveform output from the TXDn pin. Refer to section 33.3.11, Transmit Data Transition Timing Adjustment for details.

RTMG[3:0] Bits (Receive Data Sampling Timing Select)

When the RTADJ bit is 1, the receive sampling timing can be adjusted according to this bit setting value. The adjustment value in the synchronous mode and the extended serial mode is the base clock × RTMG[2:0] setting value.

TTMG[3:0] Bits (Transmit Signal Transition Timing Select)

The edge timing of the TXDn pin specified by the TTMG[3:0] bits is adjusted by the base clock × TTMG[2:0] setting value. Make sure that the TTMG[2:0] bit setting is less than the number of base clock cycles for 1-bit period.

33.2.10 I²C Mode Register (SIMR)

Address(es): RSCI8.SIMR 000A 1420h, RSCI9.SIMR 000A 14A0h, RSCI11.SIMR 000E 20A0h

b19	—	Reserved	This bit is read as 0. The write value should be 0.	R
b21, b20	IICSDAS[1:0]	SDA Output Select	b21 b20 0 0: Serial data output 0 1: Generate a start, restart, or stop condition. 1 0: Output the low level on the SSDAn pin. 1 1: Place the SSDAn pin in the high-impedance state.	R/W
b23, b22	IICSCLS[1:0]	SCL Output Select	b23 b22 0 0: Serial clock output 0 1: Generate a start, restart, or stop condition. 1 0: Output the low level on the SSCLn pin. 1 1: Place the SSCLn pin in the high-impedance state.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.
Note 2. In the bus free state, perform the start condition generation.
Note 3. In the bus busy state, perform restart or stop condition generation when the SSCLn pin after acknowledgment described in Figure 33.78 and Figure 33.79 is low level.
Note 4. Do not set more than one from among the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits to 1 at a given time.

Note 5. Execute the generation of a condition after the value of the IICSTIF flag is 0.
Note 6. Do not write 0 to this bit while it is 1. Generation of a condition is suspended by writing 0 to this bit while it is 1.

IICDL[4:0] Bits (SDA Output Delay Select)

These bits are used to set a delay for output on the SSDAn pin relative to the falling edge of the output on the SSCLn pin. The available delay settings range from no delay to 31 cycles, with the clock signal from the on-chip baud rate generators the base. The signal obtained by frequency-dividing PCLK by the divisor set in SCR2.CKS[1:0] bits is supplied as the clock signal from the on-chip baud rate generator.
Set these bits to 00000b unless operation is in simple I^2C mode. In simple I^2C mode, set the bits to a value in the range from 00001b to 11111b.

IICINTM Bit (I^2C Interrupt Mode Select)

This bit selects the sources of interrupt requests in simple I^2C mode.

IICCSC Bit (Clock Synchronization)

Set the IICCSC bit to 1 if the internally generated SCL signal is to be synchronized when the SSCLn pin has been placed at the low level in the case of a wait inserted by the other device, etc.
The internal SCL signal is not synchronized if the IICCSC bit is 0. The internal SCL signal is generated in accordance with the rate selected in the BRR[7:0] bits regardless of the level being input on the SSCLn pin.
Set the IICCSC bit to 1 except during debugging.

IICACKT Bit (ACK Transmission Data)

Transmitted data contains ACK bits. Set this bit to 1 when ACK and NACK bits are received.

IICSTAREQ Bit (Start Condition Generation)

When a start condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTAREQ bit to 1.
If you want to generate the start condition after generating the stop condition, start the generation of the start condition with a half cycle period of the bit rate from the stop condition generation interrupt request output.
[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the start condition

IICRSTAREQ Bit (Restart Condition Generation)

When a restart condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICRSTAREQ bit to 1.
[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the restart condition

IICSTPREQ Bit (Stop Condition Generation)

When a stop condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTPREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the stop condition

IICSDAS[1:0] Bits (SDA Output Select)

These bits control output from the SSDAn pin.

IICSCLS[1:0] Bits (SCL Output Select)

These bits control output from the SSCLn pin.

33.2.11 FIFO Control Register (FCR)

Address(es): RSCI11.FCR 000E 20A4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	RSTRG[4:0]					RFRST	—	—	RTRG[4:0]				
Value after reset:	0	0	0	1	1	1	1	1	0	0	0	1	1	1	1	1

	TFRST	—	—	TTRG[4:0]					—	—	—	—	—	—	—	DRES
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DRES	Receive Data Ready Interrupt Select	(Valid in asynchronous mode) This bit select the interrupt request for a reception data ready detection. 0: Reception data full interrupt (RXI) 1: Receive error interrupt (ERI)	R/W *1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b12 to b8	TTRG[4:0]	Transmit FIFO Threshold Setting	(Valid in asynchronous mode (including multi-processor mode), clock synchronous mode, simple SPI mode) b12 b8 0 0 0 0 0: Trigger number 0 : : 1 1 1 1 1: Trigger number 31	R/W *1
b14, b13	—	Reserved	These bits are read as 0. The write value should be 0.	R
b15	TFRST	Transmit FIFO Reset	This bit enables only when SCR3.FM bit is 1. The read value is always 0. 0: It is invalid. It does not affect the operation. 1: The number of data stored in transmit FIFO (TDR register) are made 0 The read value is always 0.	W*1
b20 to b16	RTRG[4:0]	Receive FIFO Threshold Setting	(Valid in asynchronous mode (including multi-processor mode), clock synchronous mode, simple SPI mode) b20 b16 0 0 0 0 0: Trigger number 0 : : 1 1 1 1 1: Trigger number 31	R/W *1
b22, b21	—	Reserved	These bits are read as 0. The write value should be 0.	R
b23	RFRST	Receive FIFO Reset	This bit enables only when SCR3.FM bit is 1. The read value is always 0. 0: It is invalid. It does not affect the operation. 1: The number of data stored in receive FIFO (RDR register) are made 0 The read value is always 0.	W*1
b28 to b24	RSTRG[4:0]	RTS# Output Threshold Setting	(Valid in asynchronous mode (including multi-processor mode), clock synchronous mode) This bit enables only when SCR3.FM bit = 1, SCR1.CTSE bit = 0, and SCR0.SSE bit = 0. b28 b24 0 0 0 0 0: Trigger number 0 : : 1 1 1 1 1: Trigger number 31	R/W *1
b31 to b29	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.

DRES Bit (Receive Data Ready Interrupt Select)

Select whether the detection of receive data ready (RFSR.DR flag = 1) is the cause of RXI interrupt request or the cause of ERI interrupt request.

TTRG[4:0] Bits (Transmit FIFO Threshold Setting)

The TDFE flag is set to 1 when the quantity of transmit data in the transmit FIFO (TDR register) is equal to or less than the specified transmit triggering number. If SCR0.TIE bit = 1, TXI interrupt request is occurred.

TFRST Bit (Transmit FIFO Reset)

When the TFRST bit is set to 1, the number of the transmission data stored in transmit FIFO (TDR register) is made 0.

RTRG[4:0] Bits (Receive FIFO Threshold Setting)

The SSR.RDRF flag is set to 1 when the quantity of receive data in the receive FIFO (RDR register) is equal to or greater than the specified receive triggering number. If SCR0.RIE bit = 1, RXI interrupt request is occurred. When FCR.RTRG[4:0] bits are set to 0, RDRF flag is set if the quantity of data in receive FIFO is greater than or equal to 1.

RFRST Bit (Receive FIFO Reset)

When the RFRST bit is set to 1, the number of the reception data stored in receive FIFO (RDR register) is made 0.

RSTRG[4:0] Bits (RTS# Output Threshold Setting)

When the quantity of receive data stored in the receive FIFO (RDR register) is equal to or greater than this number, the RTSn# signal is in the High state. When FCR.RSTRG[4:0] bits are set to 0, RTSn# is in the high state if the quantity of data in receive FIFO is greater than or equal to 1.

33.2.12 Manchester Mode Control Register (MMCR)

Address(es): RSCI9.MMCR 000A 14ACh, RSCI11.MMCR 000E 20ACh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DECS	Decoding Convention Select	Sets the polarity of the received manchester code 0: Low to high transition is decoded to a logic 0 and high to low transition is decoded to a logic 1. 1: high to low transition is decoded to a logic 0 and low to high transition is decoded to a logic 1.	R/W *1
b1	ENCS	Encoding Convention Select	Sets the polarity of the transmit manchester code 0: Logic 0 is encoded to a low to high transition and logic 1 is encoded to a high to low transition. 1: Logic 0 is encoded to a high to low transition and logic 1 is encoded to a low to high transition.	R/W *1
b2	SADJE	Receive Timing Self Adjustment Enable	Sets the receive retiming function 0: Disables the receive retiming function 1: Enables the receive retiming function	R/W *1
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R
b4	SBPTN	Start Bit Pattern Select	Sets the Sync type of the start bit(s) in the manchester code When the start bit area consists of one bit. (SBLEN bit = 0) • When transmitting 0: The start bit is added as a low to high transition. 1: The start bit is added as a high to low transition. • When receiving 0: Only when the start bit is a low to high transition, the data is received. The other cases are judged as an error. 1: Only when the start bit is a high to low transition, the data is received. The other cases are judged as an error. When the start bit area consists of three bits. (SBLEN bit = 1) • When transmitting 0: The start bits are added as a low to high transition. (DATA Sync) 1: The start bits are coded as a high to low transition. (COMMAND Sync) • When receiving When the start bit area consists of three bits, data is received regardless of the value of this bit.	R/W *1
b5	SYNCE	Sync Enable	0: The start bit pattern is set with the SBPTN bit. 1: The start bit pattern is set with the SYNC bit.	R/W *1
b6	SBLEN	Start Bit Length Select	0: The start bit area consists of one bit. 1: The start bit area consists of three bits. (COMMAND Sync or DATA Sync)	R/W *1
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R
b11 to b8	TPLEN[3:0]	Transmit Preface Length Setting	Set the preface length of the transmit data in manchester mode 0: Disables the transmit preface generation 1 to 15: Transmit preface length (bit length)	R/W *1

Bit	Symbol	Bit Name	Description	R/W
b13, b12	TPPAT[1:0]	Transmit Preface Pattern Select	Set the preface pattern of the transmit data b13 b12 0 0: ALL ZERO 0 1: ZERO ONE 1 0: ONE ZERO 1 1: ALL ONE	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R
b19 to b16	RPLEN[3:0]	Receive Preface Length Setting	Set the preface length in received frames when manchester mode is enabled 0: Disables the receive preface generation 1 to 15: Receive preface length (bit length)	R/W *1
b21, b20	RPPAT[1:0]	Receive Preface Pattern Select	Set the preface pattern of received frames b21 b20 0 0: ALL ZERO 0 1: ZERO ONE 1 0: ONE ZERO 1 1: ALL ONE	R/W *1
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R
b24	PFERIE	Preface Error Interrupt Enable	Specifies whether to handle a preface error as an interrupt source 0: Does not handle a preface error as an interrupt source 1: Handles a preface error as an interrupt source	R/W *1
b25	SYERIE	Sync Error Interrupt Enable	Specifies whether to handle a receive Sync error as an interrupt source 0: Does not handle a receive Sync error as an interrupt source 1: Handles a receive Sync error as an interrupt source	R/W *1
b26	SBERIE	Start Bit Error Interrupt Enable	Specifies whether to handle a start bit error as an interrupt source 0: Does not handle a start bit error as an interrupt source 1: Handles a start bit error as an interrupt source	R/W *1
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.

DECS Bit (Decoding Convention Select)

This bit sets the polarity of the received manchester code. For details on the data reception, see section 33.5.7, Serial Data Reception in Manchester Mode.

ENCS Bit (Encoding Convention Select)

This bit sets the polarity of the transmit manchester code. For details on the data transmission, see section 33.5.6, Serial Data Transmission in Manchester Mode.

SADJE Bit (Receive Timing Self Adjustment Enable)

This bit sets the receive retiming function in manchester mode.

For information on the receive retiming function, see section 33.5.9, Receive Retiming.

SBPTN Bit (Start Bit Pattern Select)

This bit is valid when the SYNCE bit of this register is set to 0.

The Sync type can be set by combining this bit and the SBLEN bit.

For the start bit area determined by the combination of this bit and the SBLEN bit, see Figure 33.36 and Figure 33.37.

SYNCE Bit (Sync Enable)

This bit is valid when the SBLEN bit of this register is set to 1. This bit determines the destination to be referred to for setting the Sync type of the start bit area added to manchester frames.
When this bit is set to 0, the SBPTN bit of this register is referred to.
When this bit is set to 1, the SYNC bit in the TDR register is referred to.

SBLEN Bit (Start Bit Length Select)

This bit sets the start bit area in manchester frames.
When this bit is set to 1, the start bit area added to each frame consists of three bits, and the SYNCE and SBPTN bits in this register are valid.
When this bit is set to 0, the start bit area added to each frame consists of one bit.

TPLEN[3:0] Bits (Transmit Preface Length Setting)

These bits set the preface bit length of the transmit data in manchester mode.
The settable range is 0h to Fh (0 to 15). 0h disables the transmit preface, which is not added.

TPPAT[1:0] Bits (Transmit Preface Pattern Select)

These bits set one of the four preface patterns in manchester mode. For the transmit data when the TPPAT[1:0] bits are set, see Figure 33.35.
When these bits are set to 00b, the preface area is set to all zeros.
When these bits are set to 01b, the preface area is set to the zero-one-zero-one pattern.
When these bits are set to 10b, the preface area is set to the one-zero-one-zero pattern.
When these bits are set to 11b, the preface area is set to all ones.

RPLEN[3:0] Bits (Receive Preface Length Setting)

These bits set the preface bit length of the received frames in manchester mode.
The settable range is 0h to Fh (0 to 15). 0h disables the receive preface, which is not added. When 1h to Fh is set, the set value is handled as the receive preface bit length.

RPPAT[1:0] Bits (Receive Preface Pattern Select)

These bits set one of the four preface patterns in manchester mode. For the transmit and receive data when the TPPAT[1:0] bits are set, see Figure 33.35.
When these bits are set to 00b, the preface area is handled as all zeros.
When these bits are set to 01b, the preface area is handled as the zero-one-zero-one pattern.
When these bits are set to 10b, the preface area is handled as the one-zero-one-zero pattern.
When these bits are set to 11b, the preface area is handled as all ones.

PFERIE Bit (Preface Error Interrupt Enable)

This bit specifies whether to handle a preface error as an interrupt source.
When it is set to 0, a preface error is not handled as an interrupt source. When it is set to 1, a preface error is handled as an interrupt source.

SYERIE Bit (Sync Error Interrupt Enable)

This bit specifies whether to handle a receive Sync error as an interrupt source.
When it is set to 0, a receive Sync error is not handled as an interrupt source. When it is set to 1, a receive Sync error is handled as an interrupt source.

SBERIE Bit (Start Bit Error Interrupt Enable)

This bit specifies whether to handle a start bit error as an interrupt source.

When it is set to 0, a start bit error is not handled as an interrupt source. When it is set to 1, a start bit error is handled as an interrupt source.

33.2.13 DE Signal Control Register (DECR)

Address(es): RSCI8.DECR 000A 1430h, RSCI9.DECR 000A 14B0h, RSCI11.DECR 000E 20B0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	DEHLD[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	DESU[4:0]					—	—	—	—	—	—	—	DELVL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DELVL	DE Signal Active Level Select	(Valid only in asynchronous mode) 0: The DE signal is active high. 1: The DE signal is active low.	R/W *1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b12 to b8	DESU[4:0]	DE Signal Setup Time Setting	(Valid only in asynchronous mode) Set the DE signal setup time in the number of the base clock cycles. The bit setting is enabled when the SCR3.DEEN bit is 1. Do not set 00000b.	R/W *1
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20 to b16	DEHLD[4:0]	DE Signal Hold Time Setting	(Valid only in asynchronous mode) Set the DE signal hold time in the number of the base clock cycles. The bit setting is enabled when the SCR3.DEEN bit is 1. Do not set 00000b.	R/W *1
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.

DELVL Bit (DE Signal Active Level Select)

Select the active level of the DE (driver enable) signal.

DESU[4:0] Bits (DE Signal Setup Time Setting)

Set the DE signal setup time (time from the assertion of the DE signal to the start of transmission of the start bit). It is expressed in the number of the base clock cycles (1/6, 1/8, or 1/16 bit period). The actual transmission of the start bit starts after the setup time and transmission wait time have elapsed.

DEHLD[4:0] Bits (DE Signal Hold Time Setting)

Set the DE signal hold time (time from the completion of transmission of the stop bit of the last transmission message to negation of the DE signal). It is expressed in the number of the base clock cycles (1/6, 1/8, or 1/16 bit period).
If the transmission data is written during the hold time, transmit starting operation is different depends on the writing timing (following two cases: the transmission of the start bit starts after the transmission wait time has elapsed without negating the DE signal, or it starts after the DE signal is negated and asserted again and then the setup time and transmission wait time have elapsed.).

33.2.14 Extended Serial Mode Control Register 0 (XCR0)

Address(es): RSCI9.XCR0 000A 14B4h, RSCI11.XCR0 000E 20B4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	TCSS[1:0]	Timer Count Clock Source Select	(Valid in extended serial mode) Select the clock source of the timer in the extended serial module. b1 b0 0 0: PCLK 0 1: PCLK/4 1 0: PCLK/16 1 1: PCLK/64	R/W *1, *2
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	BFE	Break Field Detection Enable	Set the presence or absence of Break Field of Start Frame. 0: No Break Field 1: With Break Field	R/W *1, *4
b9	CF0RE	Control Field 0 Reception Enable	Set the presence or absence of Control Field 0 of Start Frame 0: No Control Field 0 1: With Control Field 0	R/W *1, *4
b11, b10	CF1DS[1:0]	Control Field 1 Compare Data Select	Select the compare data for Control Field 1 b11 b10 0 0: Select XCR1.PCF1D[7:0] bits as the compare data 0 1: Select XCR1.SCF1D[7:0] bits as the compare data 1 0: Select both XCR1.PCF1D[7:0] bits and XCR1.SCF1D[7:0] bits as the compare data 1 1: Prohibition	R/W *1, *4
b12	PIBE	Priority Interrupt Bit Enable	0: Priority interrupt bit disable 1: Priority interrupt bit enable	R/W *1, *4
b15 to b13	PIBS[2:0]	Priority Interrupt Bit Select	Specify one of bits 0 to 7 of Control Field 1 as the priority interrupt bit. b15 b13 0 0 0: Bit 0 of Control Field 1 0 0 1: Bit 1 of Control Field 1 0 1 0: Bit 2 of Control Field 1 0 1 1: Bit 3 of Control Field 1 1 0 0: Bit 4 of Control Field 1 1 0 1: Bit 5 of Control Field 1 1 1 0: Bit 6 of Control Field 1 1 1 1: Bit 7 of Control Field 1	R/W *1, *4
b16	BFOIE	Break Field Low Width Output Complete Interrupt Enable	Select whether to include Break Field transmission completion as a TXI interrupt factor. 0: Break Field transmission completion is not included in TXI interrupt factor 1: Break Field transmission completion is included in TXI interrupt factor	R/W *1
b17	BCDIE	Bus Collision Detected Interrupt Enable	Select whether to output an ERI interrupt when a bus collision is detected. 0: Bus conflict detection is not included in ERI interrupt factor 1: Bus conflict detection is included in ERI interrupt factor	R/W *1
b19, b18	—	Reserved	These bits are read as 0. The write value should be 0.	R

Bit	Symbol	Bit Name	Description	R/W
b20	BFDIE	Break Field Low Width Detected Interrupt Enable	Select whether to output a BFD interrupt when a Break Field is detected. 0: Break Field detection interrupt disable 1: Break Field detection interrupt enable	R/W *1
b21	COFIE	Count Overflow Interrupt Enable	Select whether to include counter overflow as an ERI interrupt factor. 0: Counter overflow is not included in ERI interrupt factor 1: Counter overflow is included in ERI interrupt factor	R/W *1
b22	AEDIE	Effective Edge Detected Interrupt Enable	Select whether to output an AED interrupt when a valid edge is detected. 0: Active edge detection interrupt disable 1: Active edge detection interrupt enable	R/W *1
b23	—	Reserved	This bit is read as 0. The write value should be 0.	R
b25, b24	BCCS[1:0]	Bus Collision Detection Clock Select	Select the sampling clock for the bus conflict detection circuit. When SCR2.ABCS bit = 1, setting BCCS[1:0] bits = 1x is prohibited. b25 b24 0 0: Base clock*3 0 1: Base clock/2 1 0: Base clock/4 1 1: Prohibition	R/W *1
b31 to b26	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.
Note 2. Rewrite the TCSS[1:0] bits only when the timer is stopped (XCR1.TCST bit = 0, XCR1.SDST bit = 0, and XCR1.BRME bit = 0).
Note 3. Base clock: 1/16 period of 1 bit period when SCR2.ABCS bit = 0, 1/8 period of 1 bit period when SCR2.ABCS bit = 1.
Note 4. This bit is a setting bit required for Start Frame reception operation. Rewrite this bit when Start Frame reception or transmission is not in progress (XCR1.SDST bit = 0 and XCR1.TCST bit = 0).

TCSS[1:0] Bits (Timer Count Clock Source Select)

Select clock source of timer in extended serial module.

BFE Bit (Break Field Detection Enable)

Set the presence or absence of Break Field of Start Frame.

CF0RE Bit (Control Field 0 Reception Enable)

Set the presence or absence of Control Field 0 of Start Frame.

CF1DS[1:0] Bits (Control Field 1 Compare Data Select)

Select the compare data for Control Field 1.

PIBE Bit (Priority Interrupt Bit Enable)

Select whether to enable priority interrupt bit comparison of Control Field 1. When this bit is 1, regardless of the XCR1.CF1CE[7:0] bits setting value, the bit specified in PIBS[2:0] is compared with the primary comparison data for Control Field 1 (XCR1.PCF1D[7:0] bits).

PIBS[2:0] Bits (Priority Interrupt Bit Select)

Specify bit N (N = 0 to 7) of Control Field 1 as the priority interrupt bit.

BFOIE Bit (Break Field Low Width Output Complete Interrupt Enable)

Select whether to include Break Field transmission completion as a TXI interrupt factor. Set SCR0.TIE bit = 1 and SCR3.MOD[2:0] bits = 110b, to output TXI upon completion of Break Field transmission.

BCDIE Bit (Bus Collision Detected Interrupt Enable)

Select whether to output an ERI interrupt when a bus collision is detected. In extended serial mode (SCR3.MOD[2:0] bits = 110b), ERI output control is performed with this bit. When SCR3.MOD[2:0] bits = 110b and BCDIE bit = 1, an ERI interrupt is issued when a bus collision is detected even if SCR0.RIE bit = 0.

COFIE Bit (Count Overflow Interrupt Enable)

Select whether to include counter overflow as an ERI interrupt factor. Set SCR0.RIE bit = 1 and SCR3.MOD[2:0] bits = 110b are required to output ERI upon counter overflow.

AEDIE Bit (Effective Edge Detected Interrupt Enable)

Select whether to output an AED interrupt when a valid edge is detected. To output AED with valid edge detection, XCR1.BRME bit = 1 and SCR3.MOD[2:0] bits = 110b must be set.

BCCS[1:0] Bits (Bus Collision Detection Clock Select)

Select the sampling clock for the bus conflict detection circuit.

33.2.15 Extended Serial Mode Control Register 1 (XCR1)

Address(es): RSCI9.XCR1 000A 14B8h, RSCI11.XCR1 000E 20B8h

b23 to b16	SCF1D[7:0]	Secondary Control Field 1 Compare Data	The secondary compare data for Control Field 1	R/W *1
b31 to b24	CF1CE[7:0]	Control Field 1 Compare Enable	Select whether to compare bit N of Control Field 1. (N = 0 to 7) 0: Control Field 1 bit N compare disabled 1: Control Field 1 bit N compare enabled	R/W *1

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.

TCST Bit (Break Field Low Width Output Timer Count Start)

[Clearing condition]

- When 0 is written to TCST bit. Break Field transmission timer count is stopped and TXDn pin output becomes idle level.
- When Break Field transmission for the period set in XCR2.BFLW[15:0] bits is completed.

[Setting condition]

- When 1 is written to TCST bit. Start Break Field transmission from TXDn pin. Holds 1 during Break Field transmission.

SDST Bit (Start Frame Detection Start)

When 1 is written to this bit, Start Frame detection starts. When XCR0.BFE bit = 1 is set, Break Field can be detected during Start Frame is detected and after Start frame is detected. When XCR0.BFE bit = 0 is set, Break Field is not detected.

When 0 is written to this bit, Start Frame detection and Break Field detection are stopped. However, if XSR0.RXDSF flag = 0 at the time of stop, it is not possible to stop data reception with this bit. Write 0 to SCR0.RE bit to stop the

reception operation or perform reception completion processing (clearing the SSR.RDRF flag or reading the RDR register) after reception is completed.

BRME Bit (Bit Rate Measurement Enable)

Set this bit to 1 simultaneously with the SDST bit. When this bit is set to 1, the valid edge interval of Control Field 0 and Control Field 1 data is measured.

PCF1D[7:0] Bits (Primary Control Field 1 Compare Data)

Set the priority compare data for Control Field 1.

SCF1D[7:0] Bits (Secondary Control Field 1 Compare Data)

Set the secondary compare data for Control Field 1.

CF1CE[7:0] Bits (Control Field 1 Compare Enable)

Select whether to compare bit N of Control Field 1. (N = 0 to 7)
When all of these bits are set to 0 (CF1CE[7:0] bits = 00h), it is always judged that Control Field 1 matches when reception is completed, and XSR0.CF1MF flag is set. This bit is a comparison enable with PCF1D[7:0] bits or SCF1D[7:0] bits, and it is not a priority interrupt bit comparison enable.

33.2.16 Extended Serial Mode Control Register 2 (XCR2)

Address(es): RSCI9.XCR2 000A 14BCh, RSCI11.XCR2 000E 20BCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CF0CE[7:0]								CF0D[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CF0D[7:0]	Control Field Compare Data	The compare data for Control Field 0	R/W *1
b15 to b8	CF0CE[7:0]	Control Field Compare Enable	Select whether to compare bit N of Control Field 0. (N = 0 to 7) 0: Control Field 0 bit N compare disabled 1: Control Field 0 bit N compare enabled	R/W *1
b31 to b16	BFLW[15:0]	Break Field Low Width Setting	This bit sets the Break Field length. The break field length is (BFLW[15:0] setting value + 1) × clock of the timer. The upper limit for setting this register is FFFEh. (Setting prohibited for FFFFh)	R/W *1

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.

CF0D[7:0] Bits (Control Field Compare Data)

The compare data for Control Field 0.

CF0CE[7:0] Bits (Control Field Compare Enable)

Select whether to compare bit N of Control Field 0. (N = 0 to 7)

When all of these bits are set to 0 (CF0CE[7:0] bits = 00h), it is always judged that Control Field 0 matches when reception is completed, and the XSR0.CF0MF flag is set.

BFLW[15:0] Bits (Break Field Low Width Setting)

The BFLW[15:0] bits are 16-bit Break Field length setting bits and the initial value is FFFEh.

Set the break field length to 1 frame or more. The LIN standard stipulates that the Break Field length is 13 bits or more.

When sending the Break Field, writing 1 to the TCST bit leads RSCI to output the Break Field on the TXDn pin. At the same time, the timer starts counting with the timer count clock source selected by the XCR0.TCSS[1:0] bits. When the count value matches the value set in this register, up-counting is stopped and Break Field transmission from the TXDn pin is also stopped.

When detecting the Break Field, writing 1 to the SDST bit leads Start Frame detection to be enabled. RSCI starts counting from the negative edge of the RXDn signal. The timer count clock source is selected by the XCR0.TCSS[1:0] bits. When the count value matches the value set in this register, it is determined that a break field has been detected. Up-counting continues until the next valid edge or counter overflow.

33.2.17 Status Register (SSR)

Address(es): RSCI8.SSR 000A 1448h, RSCI9.SSR 000A 14C8h, RSCI11.SSR 000E 20C8h

R

ERS Flag (Error Signal Status Flag)

[Setting condition]

- When an error signal Low is sampled.

[Clearing condition]

- When write 1 to SSCR.ERSC bit.

DCMF Flag (Data Match Flag)

Indicates that RSCI detects the match to the comparison data (SCR4.CMPD[8:0] bits) with receive data.

Clearing the SCR0.RE bit to 0 does not affect the DCMF flag, which retains its previous state.

[Setting condition]

- Matched to the comparison data (SCR4.CMPD[8:0] bits) with receive data, while SCR0.DCME bit = 1.

[Clearing condition]

- When write 1 to SSCR.DCMFC bit.

DPER Flag (Matched Data Parity Error Flag)

It indicates that a parity error occurred at data match detection.

Clearing the SCR0.RE bit to 0 does not affect the DPER flag, which retains its previous state.

[Setting condition]

- When a parity error was detected by the frame in which an data match was detected.

[Clearing condition]

- When write 1 to SSCR.DPERC bit.

Refer to section 14.5.2, Level Detection to exit from the interrupt handling routine after setting the DPER flag to 0.

DFER Flag (Matched Data Framing Error Flag)

It indicates that a framing error occurred at data match detection.
Clearing the SCR0.RE bit to 0 does not affect the DFER flag, which retains its previous state.
[Setting condition]

- When a stop bit of the frame in which an data match was detected is 0.
  When it is a 2-stop mode, the 1st bit of stop bit judges only whether it's 1 and doesn't check the 2nd bit of stop bit.

[Clearing condition]

- When write 1 to SSCR.DFERC bit.

Refer to section 14.5.2, Level Detection to exit from the interrupt handling routine after setting the DFER flag to 0.

ORER Flag (Overrun Error Flag)

Indicates that an overrun error has occurred during reception and the reception ends abnormally.
Clearing the SCR0.RE bit to 0 does not affect the ORER flag, which retains its previous state. In simple I^2C mode, this bit is not use.
[Setting condition with non-FIFO mode (SCR3.FM bit = 0)]

- When the next data is received before reading out RDR register with no error reception data stored in RDR register.

In RDR register, receive data prior to an overrun error occurrence is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, reception data isn't forwarded to RDR register. Note that, in clock synchronous mode and simple SPI mode, serial reception will be stop.
[Setting condition with FIFO mode (SCR3.FM bit = 1)]

- When the next serial reception is completed while the receive FIFO is full of 32 receive data.

[Clearing condition]

- When write 1 to SSCR.ORERC bit.

Refer to section 14.5.2, Level Detection to exit from the interrupt handling routine after setting the ORER flag to 0.

MFF Flag (Mode Fault Flag)

This bit indicates mode faults. In a multi-master configuration, determine the mode fault occurrence by reading the MFF flag.
[Setting condition]

- Input on the SSn# pin being at the low level during master operation (SCR3.CKE[1:0] bits = 00b or 01b) in simple SPI mode.

[Clearing condition]

- When write 1 to SSCR.MFFC bit.

APER Flag (Aggregate Parity Error Flag)

Indicates that a parity error has occurred during reception and the reception ends abnormally.
Clearing the SCR0.RE bit to 0 does not affect the APER flag, which retains its previous state.
In clock synchronous mode, simple SPI mode and simple I^2C mode, this bit not used.
[Setting condition]

- In non-FIFO mode, when a parity error is detected during reception.
- In FIFO mode, when one or more parity error is detected for data in receive FIFO.

In non-FIFO mode, the received data when the parity error occurs is transferred to RDR register, but no RXI interrupt request occurs. Note that when the APER flag is being set to 1, the subsequent receive data is not transferred to RDR register.
[Clearing condition]

- When write 1 to SSCR.APERC bit.

Refer to section 14.5.2, Level Detection to exit from the interrupt handling routine after setting the APER flag to 0.

AFER Flag (Aggregate Framing Error Flag)

Indicates that a framing error has occurred during reception and the reception ends abnormally. Clearing the SCR0.RE bit to 0 does not affect the AFER flag, which retains its previous state.
In clock synchronous mode, simple SPI mode and simple I^2C mode, this bit not used.
[Setting condition]

- In non-FIFO mode, when 0 is sampled as the stop bit during reception.
- In FIFO mode, when one or more framing error is detected for data in receive FIFO.
- In manchester mode, when both sampling results (1/4 and 3/4 sampling points) are not 1 for 1 stop bit.

In 2 stop bit mode, only the first stop bit is checked whether it is 1 but the second stop bit is not checked.
In non-FIFO mode, the received data when the framing error occurs is transferred to RDR register, but no RXI interrupt request occurs. In addition, when the AFER flag is being set to 1, the subsequent receive data is not transferred to RDR register.
In extended serial mode, even if a condition that changes to 1 occurs when XCR1.SDST bit = 1, the AFER flag set timing is delayed up to the Break Field judgment timing at the longest, since it may be a Break Field. If an edge is detected on the RXD signal before the Break Field judgment timing, AFER is detected. If no edge is detected in the RXD signal before the Break Field judgment timing, Break Field is detected.
[Clearing condition]

- When write 1 to SSCR.AFERC bit.

Refer to section 14.5.2, Level Detection to exit from the interrupt handling routine after setting the AFER flag to 0.

TDRE Flag (Transmit Data Empty Flag)

(1) Non-FIFO selected (SCR3.FM bit = 0)
Indicates the presence of transmit data in the TDR register.
The condition of SCR0.TE bit = 0 has priority over the condition of 0.
If other conditions that become 1 and conditions that become 0 are satisfied at the same time, the TDRE flag is set to 0.
[Setting condition]

- When SCR0.TE bit is 0.
- When data is transmitted from the TDR register to the TSR register.

[Clearing condition]

- When write 1 to SSCR.TDREC bit.
- When the transmission data is written to the TDR register during SCR0.TE bit = 1.

(2) FIFO selected (SCR3.FM bit = 1)
Indicates that data has been transferred from the transmit FIFO (TDR register) into the transmit shift register (TSR), the quantity of data in transmit FIFO has fallen below the specified transmit triggering number.
When the condition which becomes 1 and the condition which becomes 0 were formed at the same time, TDRE flag will be 0. After that, when the number of data stored in transmit FIFO is judged, and if that is equal to or less than TTRG value, TDRE flag is set to 1 after 1 PCLK cycle.
[Setting condition]

- When the quantity of transmit data written in transmit FIFO is equal to or less than the specified transmit triggering number*1.

[Clearing condition]

- When write 1 to SSCR.TDREC bit.
- When the transmission data is written to transmit FIFO by the DTC or DMAC (the last block transfer when block transfer).

Note 1. Because the transmit FIFO is a 32-stage FIFO register, the maximum number of data that can be written to the TDR register when the TDRE flag is 1 is “32 – TFSR.T[5:0]”. All other data written to the TDR register above that value is ignored.

TEND Flag (Transmit End Flag)

(1) Non-FIFO selected (SCR3.FM bit = 0), and not smart card interface mode (SCR3.MOD[2:0] bits ≠ 001b)

Indicates completion of transmission.

[Setting condition]

- When SCR0.TE bit is 0.
- When the SCR0.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated at the time of transmission of the tail-end bit of a character being transmitted.
- When the TDR register is not updated at the end of DE signal hold time with DE control function enable (SCR3.DEEN bit = 1).
- When Break Field is sending.

[Clearing condition]

- When the transmission data was written to the TDR register during SCR0.TE bit = 1.
- When write 1 to SSCR.TDREC bit during SCR0.TE bit = 1.

Refer to section 14.5.2, Level Detection to exit from the interrupt handling routine after setting the TEND flag to 0.

(2) Non-FIFO selected (SCR3.FM bit = 0), and smart card interface mode (SCR3.MOD[2:0] bits = 001b)

With no error signal from the receiving side, this bit is set to 1 when further data for transfer is ready to be transferred to the TDR register.

[Setting condition]

- When SCR0.TE bit is 0.
- When the SCR0.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When a specified period has elapsed after the latest transmission of 1 byte, the ERS flag is 0, and the TDR register is not updated.
  The set timing is determined by register settings as listed below.
  When GM bit = 0 and BLK bit = 0, 12.5 etu after the start of transmission
  When GM bit = 0 and BLK bit = 1, 11.5 etu after the start of transmission
  When GM bit = 1 and BLK bit = 0, 11.0 etu after the start of transmission
  When GM bit = 1 and BLK bit = 1, 11.0 etu after the start of transmission

[Clearing condition]

- When the transmission data was written to the TDR register during SCR0.TE bit = 1.
- When write 1 to SSCR.TDREC bit during SCR0.TE bit = 1.

(3) FIFO selected (SCR3.FM bit = 1)

Indicates that the transmit FIFO does not contain valid data when transmitting the last bit of a serial character, so the transmission is halted.

[Setting condition]

- TEND is set to 1 when transmit FIFO does not contain transmit data when the last bit of a one-byte serial character is transmitted.
- When the TDR register is not updated at the end of DE signal hold time with DE control function enable (SCR3.DEEN bit = 1).

[Clearing condition]

- When the transmission data was written to the TDR.TDAT[7:0] bits during SCR0.TE bit = 1.

RDRF Flag (Receive Data Full Flag)

(1) Non-FIFO selected (SCR3.FM bit = 0)

Indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing condition]

- When write 1 to SSCR.RDRFC bit.
- When the read data is read from the RDR register.

(2) FIFO selected (SCR3.FM bit = 1)

Indicates that receive data has been transferred to the receive FIFO (RDR register), and the quantity of data in receive FIFO is equal to or greater than the specified receive triggering number. When FCR.RTRG[4:0] bits are set to 0, RDRF flag is set if the quantity of data in receive FIFO is greater than or equal to 1.

[Setting condition]

RDRF is set to 1 when the quantity of receive data in receive FIFO is equal to or greater than the specified receive triggering number*2.

[Clearing condition]

- When write 1 to SSCR.RDRFC bit.
- When the reception data is read form receive FIFO by the DTC or DMAC (the last block transfer when block transfer).

When the condition which becomes 1 and the condition which becomes 0 were formed at the same time, RDRF flag will be 0. After that, when the number of stored data in receive FIFO is judged, and if that is equal to or greater than RTRG value, RDRF flag is set to 1 after 1 PCLK cycle.

Note 2. Since the receive FIFO is a 32-stage FIFO register, the maximum number of data that can be read when RDF is 1 is indicated by the RFSR.R[5:0] bits. After reading all the data in the RDR register, continuing a read access results in an undefined value.

Note: In non-FIFO mode, do not clear the RDRF and TDRE flags by the SSCR register except when the communication is to be aborted.

33.2.18 I2C Status Register (SISR)

Address(es): RSCI8.SISR 000A 144Ch, RSCI9.SISR 000A 14CCh, RSCI11.SISR 000E 20CCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	x	x	0	x	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IICACKR	ACK Reception Data Flag	0: ACK received 1: NACK received	R
b1	—	Reserved	This bit is read as 0.	R
b2	—	Reserved	The read value is undefined.	R
b3	IICSTIF	Condition Generation Completed Flag	0: There are no requests for generating conditions or a condition is being generated. 1: A start, restart, or stop condition is completely generated.	R
b5, b4	—	Reserved	The read value is undefined.	R
b31 to b6	—	Reserved	These bits are read as 0.	R

IICACKR Flag (ACK Reception Data Flag)

Received ACK and NACK bits can be read from this flag.
The IICACKR flag is updated at the rising of SSCLn signal for the ACK/NACK receiving bit.

IICSTIF Flag (Condition Generation Completed Flag)

After generating a condition, this flag indicates that the generation is completed. When using the IICSTAREQ, IICRSTAREQ, or IICSTPREQ bit to cause generation of a condition, do so after setting the IICSTIF flag to 0.
When the IICSTIF flag is 1 while an interrupt request is enabled by setting the SCR0.TEIE bit, an STI request is output.
[Setting condition]

- Completion of the generation of a start, restart, or stop condition (however, in cases where this conflicts with any of the conditions for the flag becoming 0 listed below, the clearing condition takes precedence)

[Clearing condition]

- Writing 1 to SISCR.IICSTIFC bit
- When operation is not in simple I2C
- Writing 0 to SCR0.TE bit

33.2.19 Receive FIFO Status Register (RFSR)

Address(es): RSCI11.RFSR 000E 20D0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DR	Receive Data Ready Flag	0: Receiving is in progress, or no received data has remained in receive FIFO after normally completed receiving. (receive FIFO is empty) 1: The following receive data does not come for a fixed period after storing data below the threshold in the receive FIFO	R
b1	—	Reserved	This bit is undefined when read.	R
b7 to b2	—	Reserved	These bits are read as 0.	R
b13 to b8	R[5:0]	Receive FIFO Data Count	(Valid in asynchronous mode (including multi-processor), clock synchronous mode, simple SPI mode, when SCR3.FM bit is 1.) Indicate the quantity of receive data stored in receive FIFO	R
b15, b14	—	Reserved	These bits are read as 0.	R
b21 to b16	PEC[5:0]	Parity Error Count	(Valid only in asynchronous mode) Indicates the quantity of data with a parity error among the receive data stored in the receive FIFO data register.	R
b23, b22	—	Reserved	These bits are read as 0.	R
b29 to b24	FEC[5:0]	Framing Error Count	(Valid only in asynchronous mode) Indicates the quantity of data with a framing error among the receive data stored in the receive FIFO data register.	R
b31, b30	—	Reserved	This bit is read as 0.	R

DR Flag (Receive Data Ready Flag)

Indicates that the quantity of data stored in the receive FIFO (RDR register) falls below the specified receive triggering number, and that no next data has been received yet after the elapse of 15 etu from the last stop bit in asynchronous mode. This flag becomes 1 only when the FIFO buffer is enabled in synchronous mode (including multiprocessor mode), and does not become 1 in other modes.

[Setting conditions]

DR is set to 1 when the following conditions are met.

- After receive FIFO (RDR register) receives less data than the specified receive triggering number, no next data has been received yet after the elapse of 15 etu*1 from the last stop bit
- SSR.AFER and APER flags are 0.

[Clearing conditions]

- When all receive data in the receive FIFO (RDR register) is read and 1 is written to RFSCR.DRC bit.
- When SCR3.FM bit is 0.

Refer to section 14.5.2, Level Detection to exit from the interrupt handling routine after setting the DR flag to 0 when the DR flag is set to the source of the receive error interrupt by setting the FCR.DRES bit to 1.

Note 1. This is equivalent to one and a half (1.5) frames in the 8-bit format with one stop bit (etu: elementary time unit).

R[5:0] Bits (Receive FIFO Data Count)

Indicate the quantity of receive data stored in receive FIFO.
00h means no receive data. 20h means receive FIFO is full.

PEC[5:0] Bits (Parity Error Count)

The value indicates the quantity of data stored in the receive FIFO registers with a parity error.

FEC[5:0] Bits (Framing Error Count)

The value indicates the quantity of data stored in the receive FIFO registers with a framing error.

33.2.20 Transmit FIFO Status Register (TFSR)

Address(es): RSCI11.TFSR 000E 20D4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	T[5:0]	Transmit FIFO Data Count	(Valid in asynchronous mode (including multi-processor), clock synchronous mode, simple SPI mode, when SCR3.FM bit is 1.) Indicate the quantity of non-transmit data stored in transmit FIFO	R
b31 to b6	—	Reserved	These bits are read as 0.	R

T[5:0] Bits (Transmit FIFO Data Count)

Indicate the quantity of non-transmitted data stored in transmit FIFO.

00h means no untransmitted data. 20h means transmit FIFO is full.

33.2.21 Manchester Mode Status Register (MMSR)

Address(es): RSCI9.MMSR 000A 14D8h, RSCI11.MMSR 000E 20D8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PFER	Preface Error Flag	This bit is set when a preface error (pattern mismatch) is detected 0: No preface error detected 1: Preface error detected	R
b1	SYER	Sync Error Flag	This bit is set when no edge is detected in the adjustable range during receive retiming 0: No receive Sync error detected 1: Receive Sync error detected	R
b2	SBER	Start Bit Error Flag	This bit is set when a pattern mismatch in the start bit area is detected 0: No start bit error detected 1: Start bit error detected	R
b3	—	Reserved	This bit is read as 0.	R
b4	MCER	Manchester Code Error Flag	Valid for manchester mode only 0: No Manchester code error occurred 1: Manchester code error has occurred	R
b5	—	Reserved	This bit is read as 0.	R
b6	RSYNC	Received Sync Data	It is valid when MMCR.SBLEN bit = 1 in manchester mode, 0 is read otherwise. 0: The received the Start Bit is DATA Sync 1: The received the Start Bit is COMMAND Sync	R
b31 to b7	—	Reserved	These bits are read as 0.	R

PFER Flag (Preface Error Flag)

This bit indicates that a preface error was detected when receiving frames in manchester mode.

Even when the SCR0.RE bit is set to 0 (serial reception is disabled), the PFER flag is not affected and retains its previous value.

[Setting condition]

When detecting a preface error when receiving frames in manchester mode

The following operations are performed when a preface error occurs.

<When MMCR.PFERIE = 1>

The received data is not transferred to the RDR register and no RXI interrupt request occurs. Instead, an ERI interrupt request occurs. Note that when the PFER flag is being set to 1, the subsequently received data is not transferred to the RDR register.

<When MMCR.PFERIE = 0>

The received data is transferred to the RDR register and an RXI interrupt request occurs. An ERI interrupt request is not generated. The subsequent receive operations are not affected even with the PFER flag being set to 1.

[Clearing condition]
Write 1 to MMSCR.PFERC bit.
Refer to section 14.5.2, Level Detection to exit from the interrupt handling routine after setting the PFER flag to 0.

SYER Flag (Sync Error Flag)

This bit indicates that a receive Sync error was detected when receiving frames in manchester mode with MMCR.SADJE bit = 1 (manchester edge retiming enabled).
Even when the SCR0.RE bit is set to 0 (serial reception is disabled), the SYER flag is not affected and retains its previous value.
[Setting condition]
When detecting a receive Sync error when receiving frames in manchester mode
The following operations are performed when a receive Sync error occurs.
<When MMCR.SYERIE = 1>
Although the received data is transferred to the RDR register, no RXI interrupt request occurs. Instead, an ERI interrupt request occurs. Note that when the SYER flag is being set to 1, the subsequently received data is not transferred to the RDR register.
<When MMCR.SYERIE = 0>
The received data is transferred to the RDR register and an RXI interrupt request occurs. An ERI interrupt request is not generated. The subsequent receive operations are not affected even with the SYER flag being set to 1.
[Clearing condition]
Write 1 to MMSCR.SYERC bit.
Refer to section 14.5.2, Level Detection to exit from the interrupt handling routine after setting the SYER flag to 0.

SBER Flag (Start Bit Error Flag)

This bit indicates that a start bit error was detected when receiving frames in manchester mode.
Even when the SCR0.RE bit is set to 0 (serial reception is disabled), the SBER flag is not affected and retains its previous value.
[Setting condition]
When detecting a start bit error when receiving frames in manchester mode
The following operations are performed when a start bit error occurs.
<When MMCR.SBERIE bit = 1>
The received data is not transferred to the RDR register and no RXI interrupt request occurs. Instead, an ERI interrupt request occurs. Note that when the SBER flag is being set to 1, the subsequently received data is not transferred to the RDR register.
<When MMCR.SBERIE bit = 0>
The received data is transferred to the RDR register and an RXI interrupt request occurs. An ERI interrupt request is not generated. The subsequent receive operations are not affected even with the SBER flag being set to 1.
[Clearing condition]
Write 1 to MMSCR.SBERC bit.
Refer to section 14.5.2, Level Detection to exit from the interrupt handling routine after setting the SBER flag to 0.

MCER Flag (Manchester Code Error Flag)

When data is received in manchester mode, Manchester code error is detected, and it is displayed. Even when the SCR0.RE bit is set to 0 (serial reception is disabled), the MCER flag is not affected and retains its previous value.
[Setting conditions]
When receiving in manchester mode and detecting manchester code error in data area of received frame.
Received data when an error occurs is transferred to the RDR register, but the RXI interrupt request is not generated.
When the manchester code error flag is set to 1, subsequent receive data is not transferred to the RDR register.
For details on manchester code error, see section 33.5.11, Errors in Manchester Mode.
[Clearing condition]
Write 1 to MMSCR.MCERC bit.
Refer to section 14.5.2, Level Detection to exit from the interrupt handling routine after setting the MCER flag to 0.

RSYNC Flag (Received Sync Data)

When manchester mode (SCR3.MOD[2:0] = 101b) and MMCR.SBLEN = 1, this bit indicates the type of Sync of the received the start bit. For other settings, it is fixed to 0.

33.2.22 Extended Serial Mode Status Register 0 (XSR0)

Address(es): RSCI9.XSR0 000A 14DCh, RSCI11.XSR0 000E 20DCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SFSF	Start Frame Status Flag	0: Start Frame detection disabled or Start Frame detection complete 1: Before Start Frame detection or during detection	R*1
b1	RXDSF	RXD Input Status Flag	0: RXD input to RSCI core is enabled 1: RXD input to RSCI core is disabled (RXD is not input to the RSCI core)	R*1
b7 to b2	—	Reserved	These bits are read as 0.	R
b8	BFOF	Break Field Low Width Output Complete Flag	0: When Break Field transmission is not completed 1: When Break Field transmission is completed	R
b9	BCDF	Bus Collision Detected Flag	0: When bus conflict is not detected 1: When bus conflict is detected	R
b10	BFDF	Break Field Low Width Detection Flag	0: When Break Field is not detected 1: When Break Field is detected	R
b11	CF0MF	Control Field 0 Match Flag	0: When Control Field 0 data and the compare data do not match 1: When Control Field 0 data and the compare data match	R
b12	CF1MF	Control Field 1 Match Flag	0: When Control Field 1 data and the compare data do not match 1: When Control Field 1 data and the compare data match	R
b13	PIBDF	Priority Interrupt Bit Detection Flag	0: When priority interrupt bit is not detected 1: When Priority interrupt bit is detected	R
b14	COF	Count Overflow Flag	0: When the counter for Break Field detection does not overflow 1: When the counter for Break Field detection overflows	R
b15	AEDF	Effective Edge Detection Flag	0: When Active edge is not detected 1: When Active edge is detected	R
b23 to b16	CF0RD[7:0]	Control Field 0 Received Data	Control Field 0 received data.	R
b31 to b24	CF1RD[7:0]	Control Field 1 Received Data	Control Field 1 received data.	R

Note 1. Wait at least 1 PCLK cycle after the receive data full interrupt (RXI) before reading this register.

SFSF Flag (Start Frame Status Flag)

Indicates whether detect Start Frame is being detected.
[Setting condition]

- When 1 is written to XCR1.SDST bit.
- When a Break Field is detected in the Control Field 0/Control Field 1/Information Field phase and the transition to the Control Field 0 or Control Field 1 reception state occurs.

[Clearing condition]

- When XCR1.SDST bit is 0.
- When Start Frame detection is completed.

RXDSF Flag (RXD Input Status Flag)

Indicates the RXD input status to the RSCI core. When this bit is 1, RXD input is received only by the extended serial module and the Break Field is detected and is not input to the RSCI core.

33.2.23 Extended Serial Mode Status Register 1 (XSR1)

Address(es): RSCI9.XSR1 000A 14E0h, RSCI11.XSR1 000E 20E0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	CCV[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	CCV[15:0]	Captured Count Value	Stores the 16-bit counter capture value.	R
b31 to b16	—	Reserved	These bits are read as 0.	R

CCV[15:0] Bits (Captured Count Value)

Stores the capture value of the 16-bit counter of the extended serial module.

When sending Start Frame

This register holds the previous value.

When receiving Start Frame with bit rate measurement disabled

If a Break Field is detected in the Break Field detection state (refer to Figure 33.73), the Break Field length is captured and held (counter value is captured at the rising edge of RXD).

If a Break Field is detected in a state other than the Break Field detection state, the previous value is retained.

If the counter overflows, it will not be captured.

When receiving Start Frame with bit rate measurement enabled

The count value is captured and held at the valid edge (both RXD edges). However, in the Break Field detection state, the count value is not captured even if a valid edge occurs. Counter capture value retention is canceled by this register read. Even if a valid edge occurs before reading, the counter value is not captured.

33.2.24 Status Clear Register (SSCR)

Address(es): RSCI8.SSCR 000A 1468h, RSCI9.SSCR 000A 14E8h, RSCI11.SSCR 000E 20E8h

b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

33.2.29 HBS Support Mode Control Register (HBSCR)

Address(es): RSCI8.HBSCR 000A 141Eh, RSCI9.HBSCR 000A 149Eh, RSCI11.HBSCR 000E 209Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	LPS	AOE	—	HBSE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	HBSE	HBS Support Mode Enable	0: Pulse width for data 0 is specified as 100% of a bit period (NRZ coding). 1: Pulse width for data 0 is specified as 50% of a bit period (RZI coding and inversion).	R/W *1
b1	—	Reserved	This bit is read as 0. The write value should be 0.	R
b2	AOE	Alternate Output Enable	0: Data is output from the TXDn pin. 1: Data 0 is alternately output from the TXDAn and TXDBn pins.	R/W *1
b3	LPS	Leading Output Pin Select	0: When HBSE bit = 1 and AOE bit = 1, transmission starts from TXDAn pin 1: When HBSE bit = 1 and AOE bit = 1, transmission starts from TXDBn pin	R/W *1
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.

HBSE Bit (HBS Support Mode Enable)

When this bit is 1, the transmitter encodes the transmit data to the negative logic RZI code and the receiver decodes the receive data to the NRZ code. Also, transmit data can be output from the TXDAn/TXDBn pin. This function should be used only in asynchronous mode.

AOE Bit (Alternate Output Enable)

This bit is used to select whether the data is output from the TXDn pin or data 0 is alternately output from the TXDAn and TXDBn pins in HBS support mode.

LPS Bit (Leading Output Pin Select)

This bit is used when the AOE bit is 1 in HBS support mode.

When it is set to 0, the start bit is transmitted from TXDAn pin and the data 0 is output alternately from the TXDBn and TXDAn pins.

When it is set to 1, the start bit is transmitted from TXDBn pin and the data 0 is output alternately from the TXDAn and TXDBn pins.

For details, refer to the operation description in section 33.6, HBS Support Mode.

b11, b10	SCI5RXD[1:0]	SCI5 RXD Input Signal Select	These bits select the signal to be input to the RXD pin of SCI5. b11 b10 0 0: Input signal from the RXD5 pin 0 1: COMP3 level detection signal 1 0: COMP4 level detection signal Settings other than above are prohibited.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b17, b16	SCI8RXD[1:0]	RSCI8 RXD Input Signal Select	These bits select the signal to be input to the RXD pin of RSCI8. b17 b16 0 0: Input signal from the RXD008 pin 0 1: COMP3 level detection signal 1 0: COMP4 level detection signal Settings other than above are prohibited.	R/W
b19, b18	SCI9RXD[1:0]	RSCI9 RXD Input Signal Select	These bits select the signal to be input to the RXD pin of RSCI9. b19 b18 0 0: Input signal from the RXD009 pin 0 1: COMP3 level detection signal 1 0: COMP4 level detection signal Settings other than above are prohibited.	R/W
b21, b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23, b22	SCI11RXD[1:0]	RSCI11 RXD Input Signal Select	These bits select the signal to be input to the RXD pin of RSCI11. b23 b22 0 0: Input signal from the RXD011 pin 0 1: COMP3 level detection signal 1 0: COMP4 level detection signal Settings other than above are prohibited.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

If the RXD signal is attenuated by the transmission line effects and does not meet the VIH/VIL specifications, it can be improved by intervening a comparator.
When using a comparator, connect the RXD signal to one of the CMPC30 to CMPC33 or CMPC40 to CMPC43 pins. Also, disable the noise filter in the comparator. In this case, the RXD pin of the channel is not used.

33.3 Operation in Asynchronous Mode

Figure 33.3 shows the general format for asynchronous serial communications.
One frame consists of a start bit (low level), transmit/receive data, a parity bit, and stop bits (high level).
In asynchronous serial communications, the communications line is held in the mark state (high level) when not communicating.
The RSCI monitors the communications line. When the RSCI detects a start bit, it starts serial communication. The detection condition of the start bit changes according to the SCR3.RXDESEL bit setting. RSCI regards space (low level) as a start bit when SCR3.RXDESEL bit is 0. RSCI regards a fall edge as a start bit when RXDESEL bit is 1.
Inside the RSCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and the receiver also have a double-buffered structure (it has also FIFO mode), so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

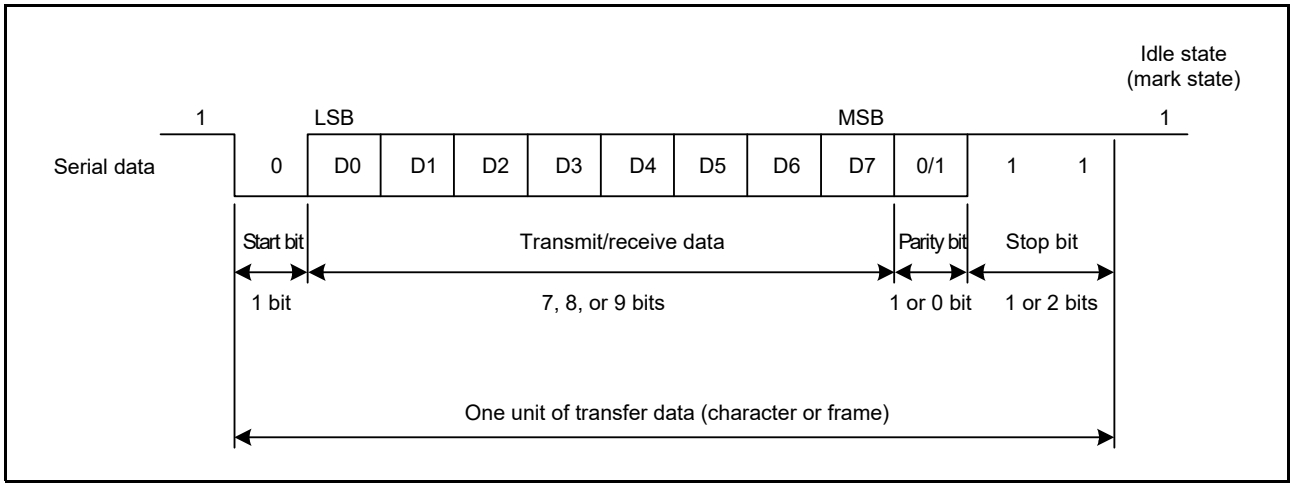

Figure 33.3 Data Format in Asynchronous Serial Communications (Example with 8-Bit Data, Parity, 2 Stop Bits)

33.3.1 Serial Data Transfer Format

Table 33.28 lists the serial data transfer formats that can be used in asynchronous mode.
Any of 18 transfer formats can be selected according to the SCR1 and SCR3 setting. For details of multi-processor function, refer to section 33.4, Multi-Processor Communication Function.

Table 33.28 Serial Transfer Formats (Asynchronous Mode)

SCR3		SCR1	SCR3		Serial Transfer Format and Frame Length
CHR[1]	CHR[0]	PE	MP	STOP	1 2 3 4 5 6 7 8 9 10 11 12 13
0	0	0	0	0	S 9-bit data STOP
0	0	0	0	1	S 9-bit data STOP STOP
0	0	1	0	0	S 9-bit data P STOP
0	0	1	0	1	S 9-bit data P STOP STOP
1	0	0	0	0	S 8-bit data STOP
1	0	0	0	1	S 8-bit data STOP STOP
1	0	1	0	0	S 8-bit data P STOP
1	0	1	0	1	S 8-bit data P STOP STOP
1	1	0	0	0	S 7-bit data STOP
1	1	0	0	1	S 7-bit data STOP STOP
1	1	1	0	0	S 7-bit data P STOP
1	1	1	0	1	S 7-bit data P STOP STOP
0	0	—	1	0	S 9-bit data MPB STOP
0	0	—	1	1	S 9-bit data MPB STOP STOP
1	0	—	1	0	S 8-bit data MPB STOP
1	0	—	1	1	S 8-bit data MPB STOP STOP
1	1	—	1	0	S 7-bit data MPB STOP
1	1	—	1	1	S 7-bit data MPB STOP STOP

S: Start bit
STOP: Stop bit
P: Parity bit
MPB: Multi-processor bit

33.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the RSCI operates on a base clock with a frequency of 16 times*1 the bit rate.
In reception, the RSCI samples the falling edge of the start bit using the base clock, and performs internal synchronization*2. When sampling timing does not adjust (SCR4.RTADJ bit = 0 or SCR4.RTADJ bit = 1 and SCR4.RTMG[2:0] bits = 000b), receive data is sampled at the rising edge of the 8th pulse*1 of the base clock, data is latched at the middle of each bit, as shown in Figure 33.4. Thus the reception margin in asynchronous mode is determined by formula (1) below.

$$M = \left| \left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\ (\%) \quad \cdots \text{Formula (1)}$$

M: Reception margin
N: Ratio of bit rate to clock
(N = 16 when SCR2.ABCSE = 0 and SCR2.ABCS = 0, N = 8 when SCR2.ABCSE = 0 and SCR2.ABCS = 1, N = 6 when SCR2.ABCSE = 1)
D: Duty cycle of clock (D = 0.5 to 1.0)
L: Frame length (L = 9 to 13)
F: Absolute value of clock frequency deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined by the formula below.

$M = \{0.5 - 1/(2 \times 16)\} \times 100\ (\%) = 46.875\ (\%)$

However, this is only the computed value, and a margin of 20% to 30% should be allowed in system design.

Note 1. This is an example when the ABCSE and ABCS bits in the SCR2 register is 0. When the ABCSE bit is 0 and the ABCS bit is 1, a frequency of 8 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 4th pulse of the base clock. When the ABCSE bit is 1, a frequency of 6 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 3rd pulse of the base clock.
Note 2. The determination condition of the start bit is as follows.
In the case of the function of adjust sampling timing is OFF (RTADJ bit = 0):
The determination condition of a start bit is that Low beyond half bit length continues. It is same as the sampling timing.
In Figure 33.4, the low period should be kept over 8-cycles to detect a start bit. If Low period does not keep over 8-cycles, the RSCI judges this as a noise. So, the RSCI does not start reception and wait start bit.
In the case of the function of adjust sampling timing is ON (RTADJ bit = 1):
The determination condition of a start bit is that Low keeps up until the sampling timing.
Adjusting the sampling timing forward (RTMG[3] bit = 1) increases the possibility of erroneously determining a noise as the start bit.

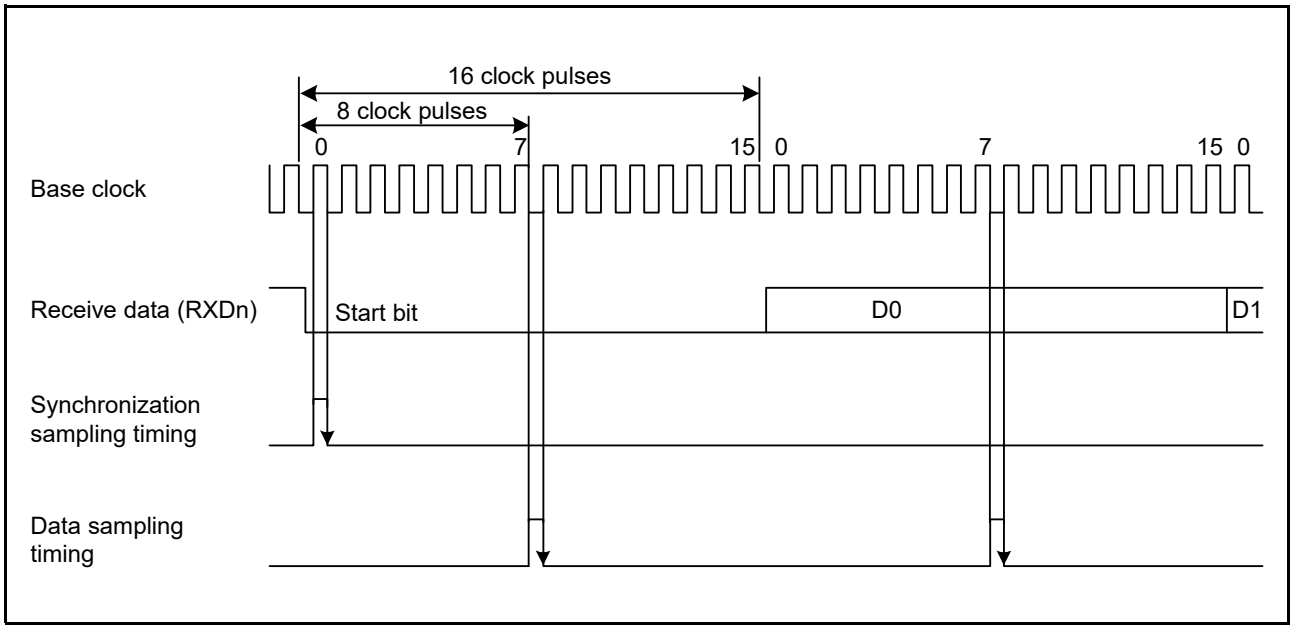

Figure 33.4 Receive Data Sampling Timing in Asynchronous Mode

33.3.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCKn pin can be selected as the RSCI's transfer clock, according to the setting of the SCR3.CKE[1:0] bits.
When an external clock is input to the SCKn pin, the clock frequency should be 16 times the bit rate (when SCR2.ABCS bit = 0) and 8 times the bit rate (when SCR2.ABCS bit = 1).
When the RSCI is operated on an internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is such that the rising edge of the clock is in the middle of the transmit data, as shown in Figure 33.5.
If you selected an internal clock, the SCKn pin is outputted after SCR0.TE bit is set to 1 or SCR0.RE bit is set to 1.

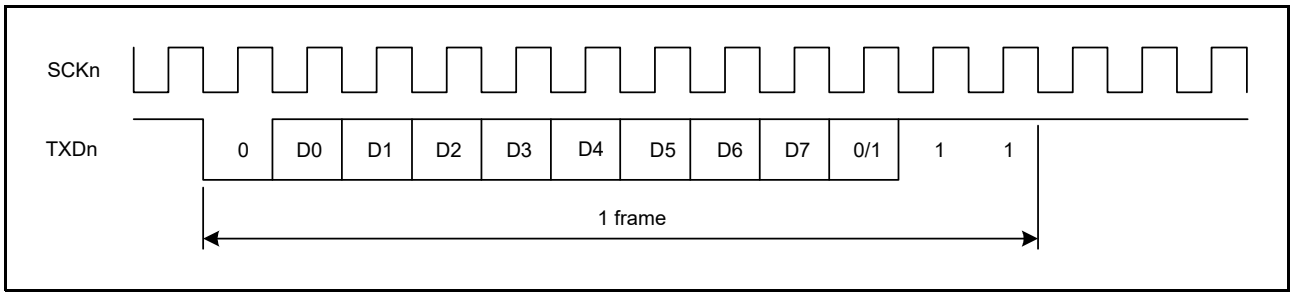

Figure 33.5 Phase Relationship between Output Clock and Transmit Data (Asynchronous Mode: SCR1.PE Bit = 1, SCR3.CHR[1:0] Bits = 10b, MP Bit = 0, STOP Bit = 1)

33.3.4 Double-Speed Mode and Divide-by-6 Mode

When SCR2.ABCS bit is set to 1, the RSCI operates on the bit rate twice that in the case where ABCS bit is set to 0. And when SCR2.BGDM bit is set to 1, the cycle of the base clock is halved and the bit rate is doubled from that in the case where BGDM bit is set to 0. When SCR3.CKE[1] bit is set to 0 and the on-chip baud rate generator is selected, setting the ABCS and BGDM bits to 1 allows the RSCI to operate on a bit rate four times that in the case ABCS bit = 0 and BGDM bit = 0.
When SCR2.ABCSE bit is set to 1, the number of base clock pulses are 6 during a period of 1 bit, and the base clock frequency is half. And RSCI works 16/3 times of bit rate compared with a case of SCR2.ABCS bit = 0, SCR2.BGDM bit = 0 and SCR2.ABCSE bit = 0.
As shown by Formula (1) in section 33.3.2, Receive Data Sampling Timing and Reception Margin in Asynchronous Mode, the reception margin decreases when SCR2.ABCS bit is set to 1 or SCR2.ABCSE bit is set to 1. Therefore, if the desired bit rate can be obtained with SCR2.ABCS bit set to 0 and SCR2.ABCSE bit set to 0, it is recommended to use the RSCI with SCR2.ABCS bit set to 0 and SCR2.ABCSE bit set to 0.

33.3.5 CTS and RTS Functions

The CTS function is the transmission control function by the CTSn# pin. Setting the SCR1.CTSE bit to 1 enables the CTS function. For the functions of CTS and RTS, you can select the alternate setting that uses either function with one pin or the dedicated setting that uses each function independently with two pins. This setting is done with the SCR1.CRSEP bit.
When the CTS function is enabled, placing the low level on the CTSn# pin causes transmission to start.
Even if the CTSn# pin goes high after transmission starts, the frame being transmitted is not affected and transmission will continue.
The RTS function is the transmission request function by the RTSn# pin. In the RTS function, the RTSn# pin output low level when reception becomes possible. Conditions for output of the low and high level are shown below.

(a) When the SCR3.FM Bit is 0 (Non-FIFO Mode)

[Conditions for low-level output]
When the following conditions are all satisfied

- The SCR0.RE bit is 1
- There are no received data yet to be read and reception is not in progress
- The ORER, AFER, and APER flags in the SSR are all 0

[Condition for high-level output]
When the conditions for low-level output are not satisfied

(b) When the SCR3.FM Bit is 1 (FIFO Mode)

[Conditions for low-level output]
When the following conditions are all satisfied

- The SCR0.RE bit is 1
- The number of data stored in the receive FIFO is less than the threshold (FCR.RSTRG[4:0] bits)
- The SSR.ORER (RDR.ORER) flag is 0

[Condition for high-level output]
When the conditions for low-level output are not satisfied

33.3.6 Data Match Detection

The data match detection function can use only the asynchronous mode.
If SCR0.DCME bit is set to 1*2, when one frame of data has been received, RSCI compares that receive data with the data which is set to SCR4.CMPD[8:0] bits. If RSCI detects the match to the comparison data (SCR4.CMPD[8:0] bits*1) with receive data, RSCI can issue RXI interrupt request.
If SCR3.MP bit is set to 0, this comparative target in communication data is valid only data field in receive format. In multi-processor mode (SCR3.MP bit = 1), if SCR0.IDSEL bit is set to 1, the reception data at which MPB is 1 detects data match or unmatch, and the reception data at which MPB is 0 detects always unmatch. If SCR0.IDSEL bit is set to 0, RSCI detects data match or unmatch despite the value of the MPB of the reception data at every reception complete.
Until RSCI detects the match to the comparison data (SCR4.CMPD[8:0] bits) with receive data, the communication data is skipped (discarded), and RSCI can not detect parity error, framing error. When RSCI detects the match, the SCR0.DCME bit is automatically cleared, and SSR.DCMF flag is set to 1. If SCR0.IDSEL bit is set to 1 at this time, SCR0.MPIE bit is automatically cleared. And if SCR0.IDSEL bit is set to 0 at this time, SCR0.MPIE bit is kept. At the same time, if SCR0.RIE bit is set to 1, RSCI issues RXI interrupt request. If RSCI detects framing error in comparative receive data which is detected the match, SSR.DFER flag is set to 1, and if RSCI detects parity error in that frame, SSR.DPER flag is set to 1. That comparative receive data and MPB are not stored to RDR register, and SSR.RDRF flag is retained to 0.
After RSCI detects the match, and the SCR0.DCME bit is automatically cleared, it receives next data continuously in current register setting.
When SSR.DFER flag or SSR.DPER flag is set, the data match isn't detected. Before making the data match detection function effective, please be sure to set SSR.DFER and SSR.DPER flags as 0.
Figure 33.6 and Figure 33.7 show the data match detection example.

Note 1. This comparative target can select one length of 3 types, they are CMPD[6:0] bits with 7bit length enable, CMPD[7:0] bits with 8bit, and CMPD[8:0] bits with 9bit length.
Note 2. Set the SCR0.DCME bit to 1 before receiving the start bit of the received frame that performs data matching.

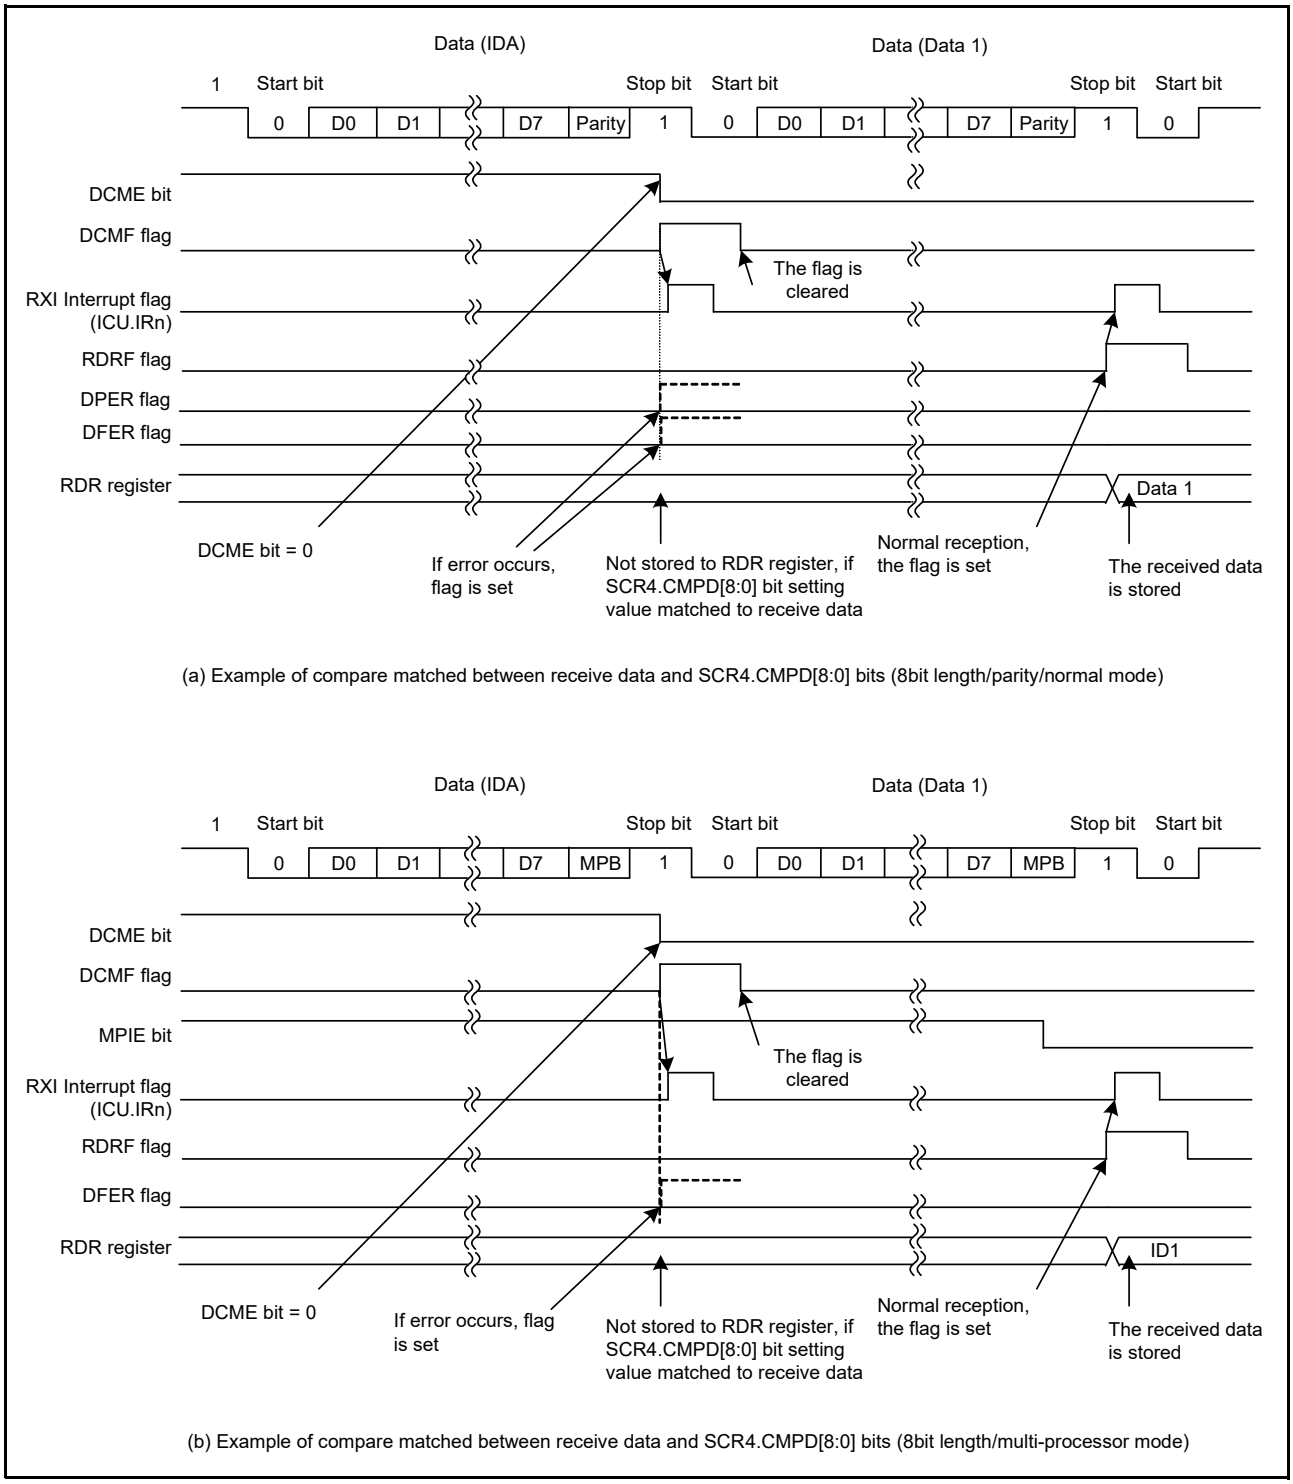

Figure 33.6 Example of Data Match Detection (1) 8bit-Data

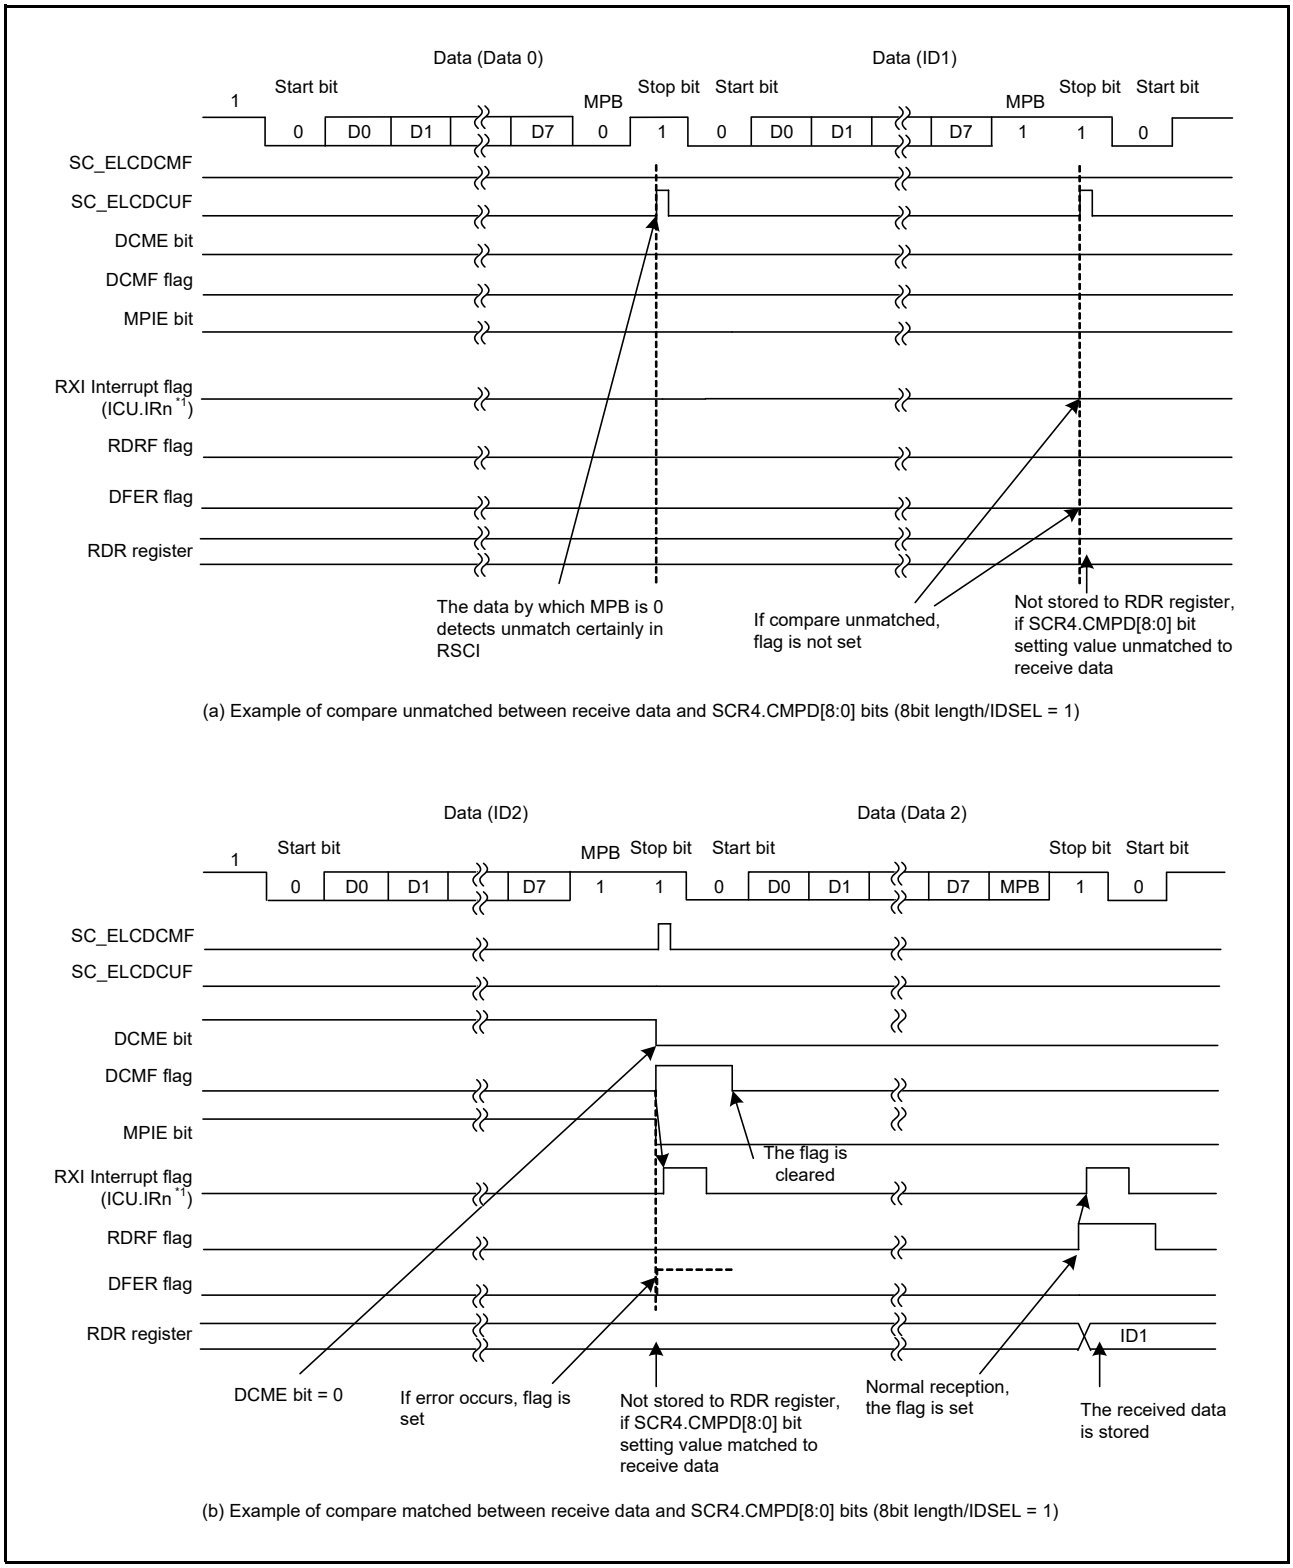

Figure 33.7 Example of Data Match Detection (2) Multi-Processor Mode/8bit-Data

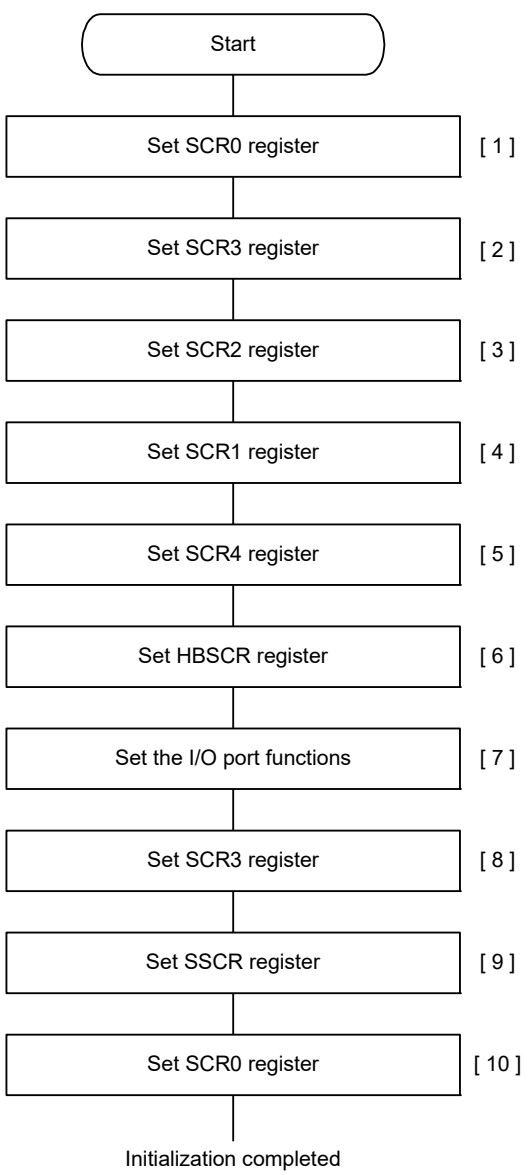
33.3.7 RSCI Initialization (Asynchronous Mode)

Before transmitting and receiving data, start by writing 0 to SCR0.TE and SCR0.RE bits (or writing the initial value to SCR0 register) and then continue through the procedure (select to non-FIFO or FIFO) for RSCI given in Figure 33.8 or Figure 33.9. Whenever the operating mode or transfer format is changed, SCR0.TE and SCR0.RE bits must be initialized before the change is made.

When the external clock is used in asynchronous mode, ensure that the clock signal is supplied even during initialization.

Note that setting the SCR0.RE bit to 0 initializes neither the ORER flags, AFER flags, APER flags, RDRF flags, DR flags, and RDR register. In FIFO mode, even if the TE bit is set as 0, the TEND flag isn't initialized, so please be careful. Please be also careful at the time of change in the operation mode.

Moreover, note that switching the value of the SCR0.TE bit from 0 to 1 while the SCR0.TIE bit is 1 leads to the generation of a TXI interrupt request.



[1] Set the following bits of SCR0 register to 0.
TEIE, TIE, RIE, TE, RE
If you have not changed from the initial settings, you can skip this step.

[2] Set up following function and communication mode.
Driver control function for RS-485
FIFO no-use
Multi-Processor mode
Communication mode (MOD[2:0] bits = 000b)
Transmission/reception format
Clock enable (Leave the CKE[1:0] bits at their initial values when outputting the clock)
Leave unused bits at their initial values.

[3] Set up the bit-rate-modulation function*1, 2, select clock, set bit rate*2.

[4] Set up the Noise-filter function, the loop-back function, communication terminal status, the parity check function, and the CTS/RTS function.

[5] Set up the adjust sampling timing function and the adjust transmit timing function.

[6] When using the HBS support mode, enable or set the function.
If this function is not used, leave the default value.

[7] Make I/O port settings to enable input and output functions as required for TXDn (TXDAn/TXDBn), RXDn, and SCKn pins.

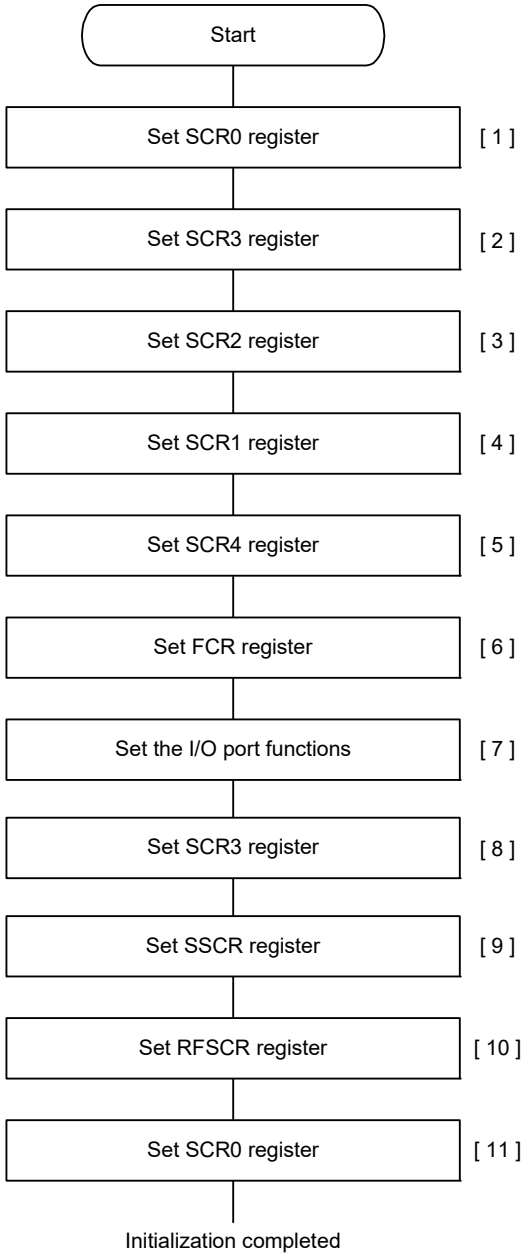
[8] Set clock enable bit (CKE[1:0] bits) at this step when outputting the clock. After setting the bits, the SCKn pin becomes output mode (the clock is output after setting the TE or RE bit to 1).

[9] Write 1 to the following bits and clear the corresponding flag.
SSCR.RDRFC, AFERC, APERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC
If it's initialization flow after a reset, you can skip this step.

[10] Set the TE or RE bit to 1.
To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time. Also, set the data match detection function and multiprocessor function.
Setting the TE and RE bits allows TXDn (TXDAn/TXDBn) and RXDn to be used.

Note 1. If you do not use the bit rate modulation function, you do not need to set it.
Note 2. If you use an external clock, you do not need to set it.

Figure 33.8 Sample RSCI Initialization Flowchart (Asynchronous Mode/Non-FIFO Mode)



[1] Set the following bits of SCR0 register to 0.
TEIE, TIE, RIE, TE, RE
If you have not changed from the initial settings, you can skip this step.

[2] Set up following function and communication mode.
Driver control function for RS-485
FIFO use
Multi-Processor mode
Communication mode (MOD[2:0] bits = 000b)
Transmission/reception format
Clock enable (Leave the CKE[1:0] bits at their initial values when outputting the clock)
Leave unused bits at their initial values.

[3] Set up the bit-rate-modulation function*1, 2,select clock, set bit rate*2.

[4] Set up the Noise-filter function, the loop-back function, communication terminal status, the parity check function, and the CTS/RTS function.

[5] Set up the adjust sampling timing function and the adjust transmit timing function.

[6] Set the TFRST and RFRST to 1 to empty FIFO.
Set the DRES, TTRG[4:0], RTRG[4:0], and RSTRG[4:0] bits

[7] Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.

[8] Set clock enable bit (CKE[1:0] bits) at this step when outputting the clock. After setting the bits, the SCKn pin becomes output mode (the clock is output after setting the TE or RE bit to 1).

[9] Write 1 to the following bits and clear the corresponding flag.
SSCR.RDRFC, AFERC, APERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC
If it is initialization flow after a reset, you can skip this step.

[10] Write 1 to The RFSCR.DRC bit and clear the corresponding flag.
If it is initialization flow after a reset, you can skip this step.

[11] Set the TE or RE bit to 1.
To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time. Also, set the data match detection function and multiprocessor function.
Setting the TE and RE bits allows TXDn and RXDn to be used.

Note 1. If you do not use the bit rate modulation function, you do not need to set it.
Note 2. If you use an external clock, you do not need to set it.

Figure 33.9 Sample RSCI Initialization Flowchart (Asynchronous Mode, FIFO Mode)

Figure 33.10 shows an example of the timing when data is transmitted after reset is released, and RSCI is set to asynchronous mode according to Figure 33.8 or Figure 33.9. As shown in the figure, when the pin function is set to the TXDn pin, the SCR0.TE bit is 0, so the pin is high impedance. When transmit data is written after setting the SCR0.TE bit to 1, data transmission starts. There is a transmission wait time from writing TDR register to data transmission starts. In asynchronous mode, TXDn is high during this period.

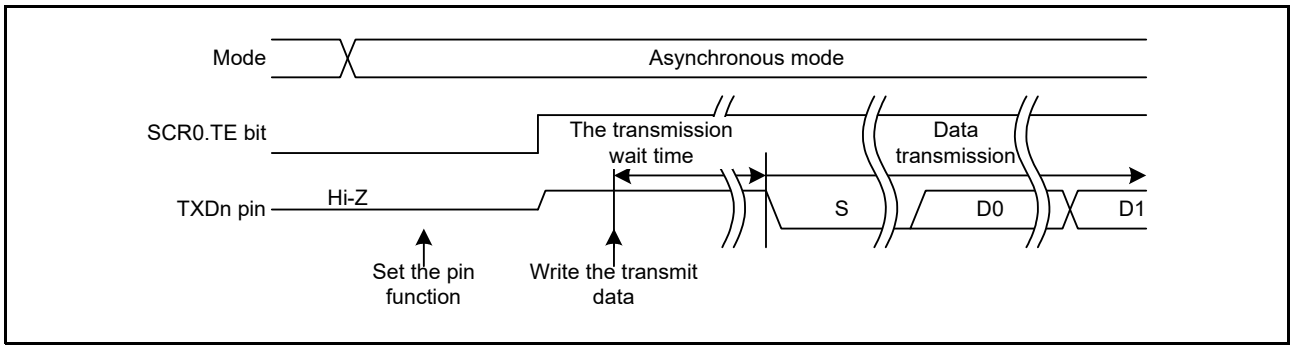


Figure 33.10 Example of Data Transmission Timing in Asynchronous Mode

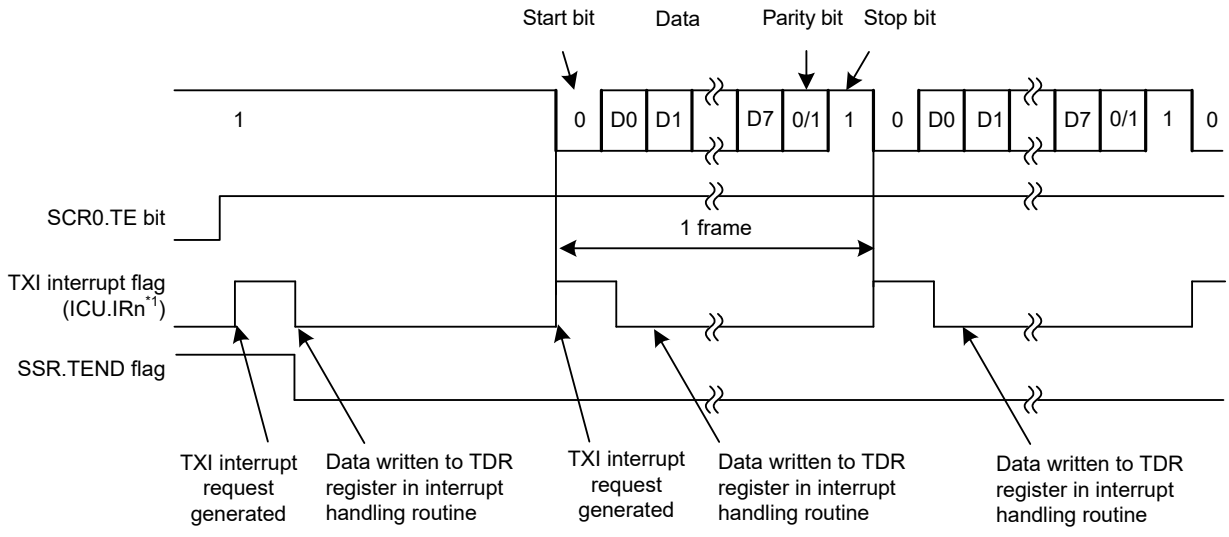
33.3.8 Serial Data Transmission (Asynchronous Mode)

(1) Non-FIFO Mode

Figure 33.11 to Figure 33.13 show an example of the operation for serial transmission in asynchronous mode.
In serial transmission, the RSCI operates as described below.

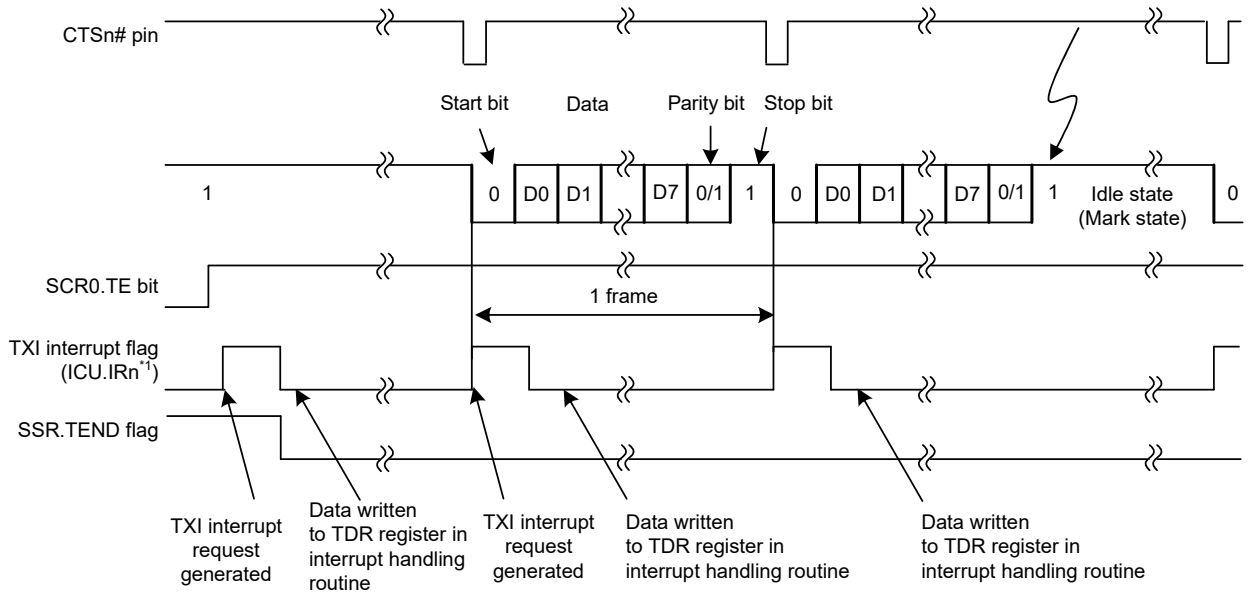
1. The RSCI transfers data from the TDR register to the TSR register when data is written to the TDR register in the TXI interrupt handling routine. At the beginning of transmission, set 1 to the SCR0.TE bit and the SCR0.TIE bit simultaneously. Then the TXI interrupt request is generated.
2. Transmission starts at data transfer from the TDR register to the TSR register when the SCR1.CTSE bit = 0 (CTS function is disabled) or when the CTS# pin level is low. If the SCR0.TIE bit is 1 at this time, a TXI interrupt request is generated. Continuous transmission is obtainable by writing the next transmit data to the TDR register in the TXI interrupt handling routine before transmission of the current transmit data is completed. Write the last transmission data, then the last data transmit start, and TXI is generated. When TEI interrupt requests are in use, before the last data transmit end, set the SCR0.TIE bit to 0 (a TXI interrupt request is disabled) and the SCR0.TEIE bit to 1 (a TEI interrupt request is enabled) using the TXI interrupt handling routine.
3. Data is sent from the TXDn pin in the following order: start bit, transmit data, parity bit or multi-processor bit (may be omitted depending on the format), and stop bit.
4. The RSCI checks for updating of (writing to) the TDR register at the time of stop bit output.
5. When the TDR register is updated, setting of the SCR1.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn# pin cause the next transfer of the next transmit data from the TDR register to the TSR register and sending of the stop bit, after which serial transmission of the next frame starts.
6. If the TDR register is not updated, the SSR.TEND flag is set to 1, the stop bit is sent, and then the mark state is entered in which 1 is output. If the SCR0.TEIE bit is 1 at this time, a TEI interrupt request is generated.

Figure 33.15 shows the example of Serial Transmission Flowchart.



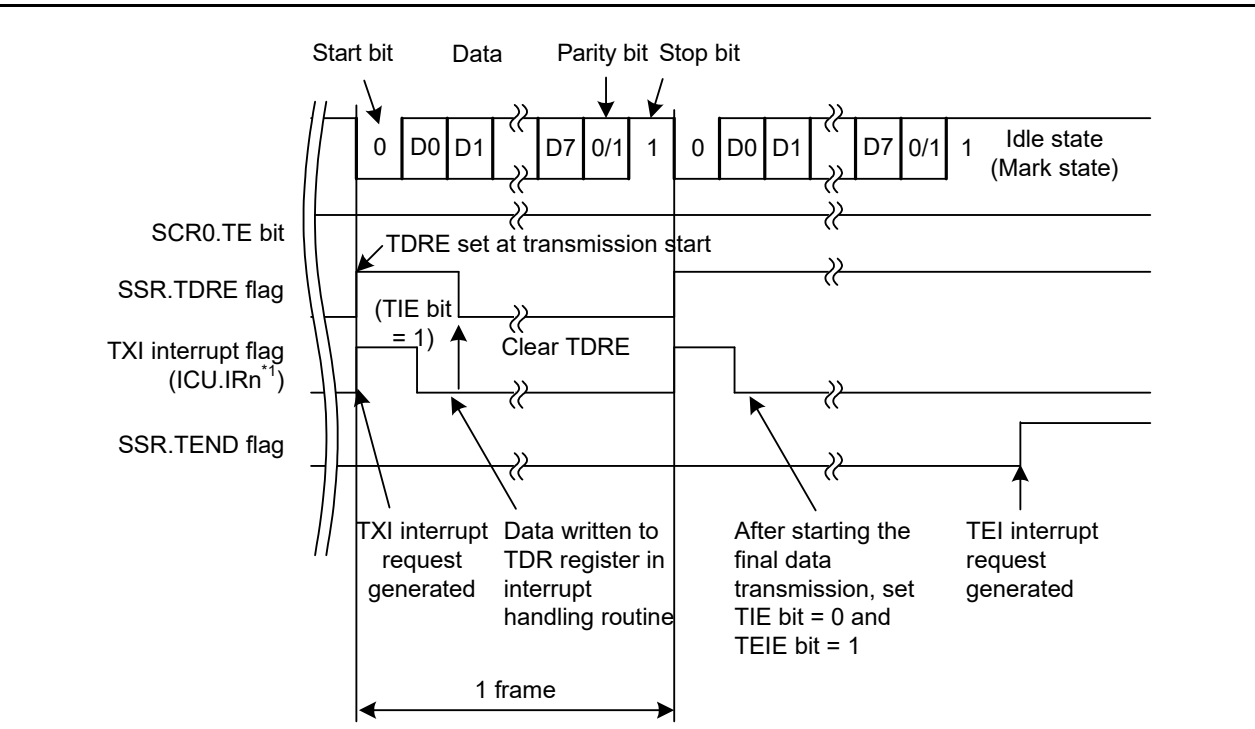
Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

**Figure 33.11 Example of Operation for Serial Transmission in Asynchronous Mode (1)
(with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Not Used, at the Beginning of Transmission)**



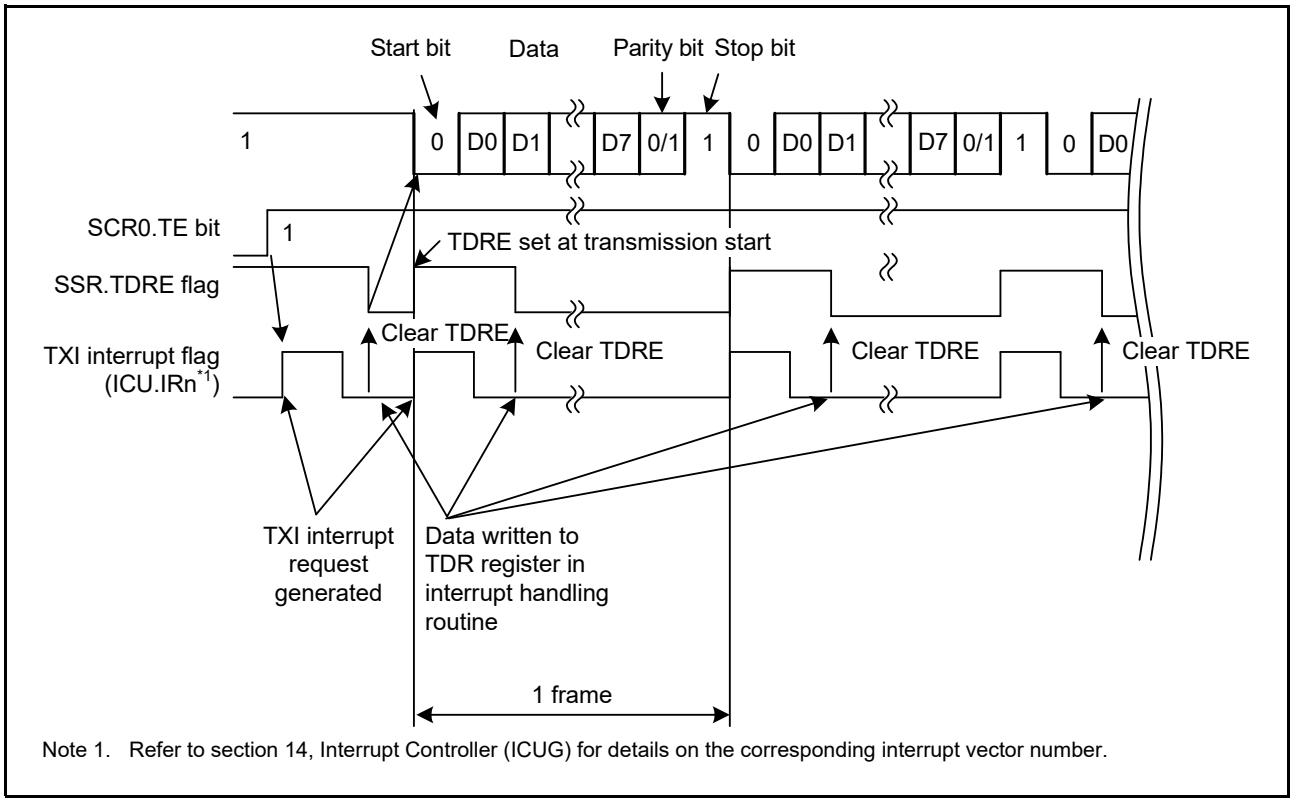
Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 33.12 Example of Operation for Serial Transmission in Asynchronous Mode (2) (with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Used, at the Beginning of Transmission)



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 33.13 Example of Operation for Serial Transmission in Asynchronous Mode (3) (with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Not Used, from the Middle of Transmission until Transmission Completion)



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 33.14 Example of Operation for Serial Transmission in Asynchronous Mode (4) (with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Not Used, during Transmission)

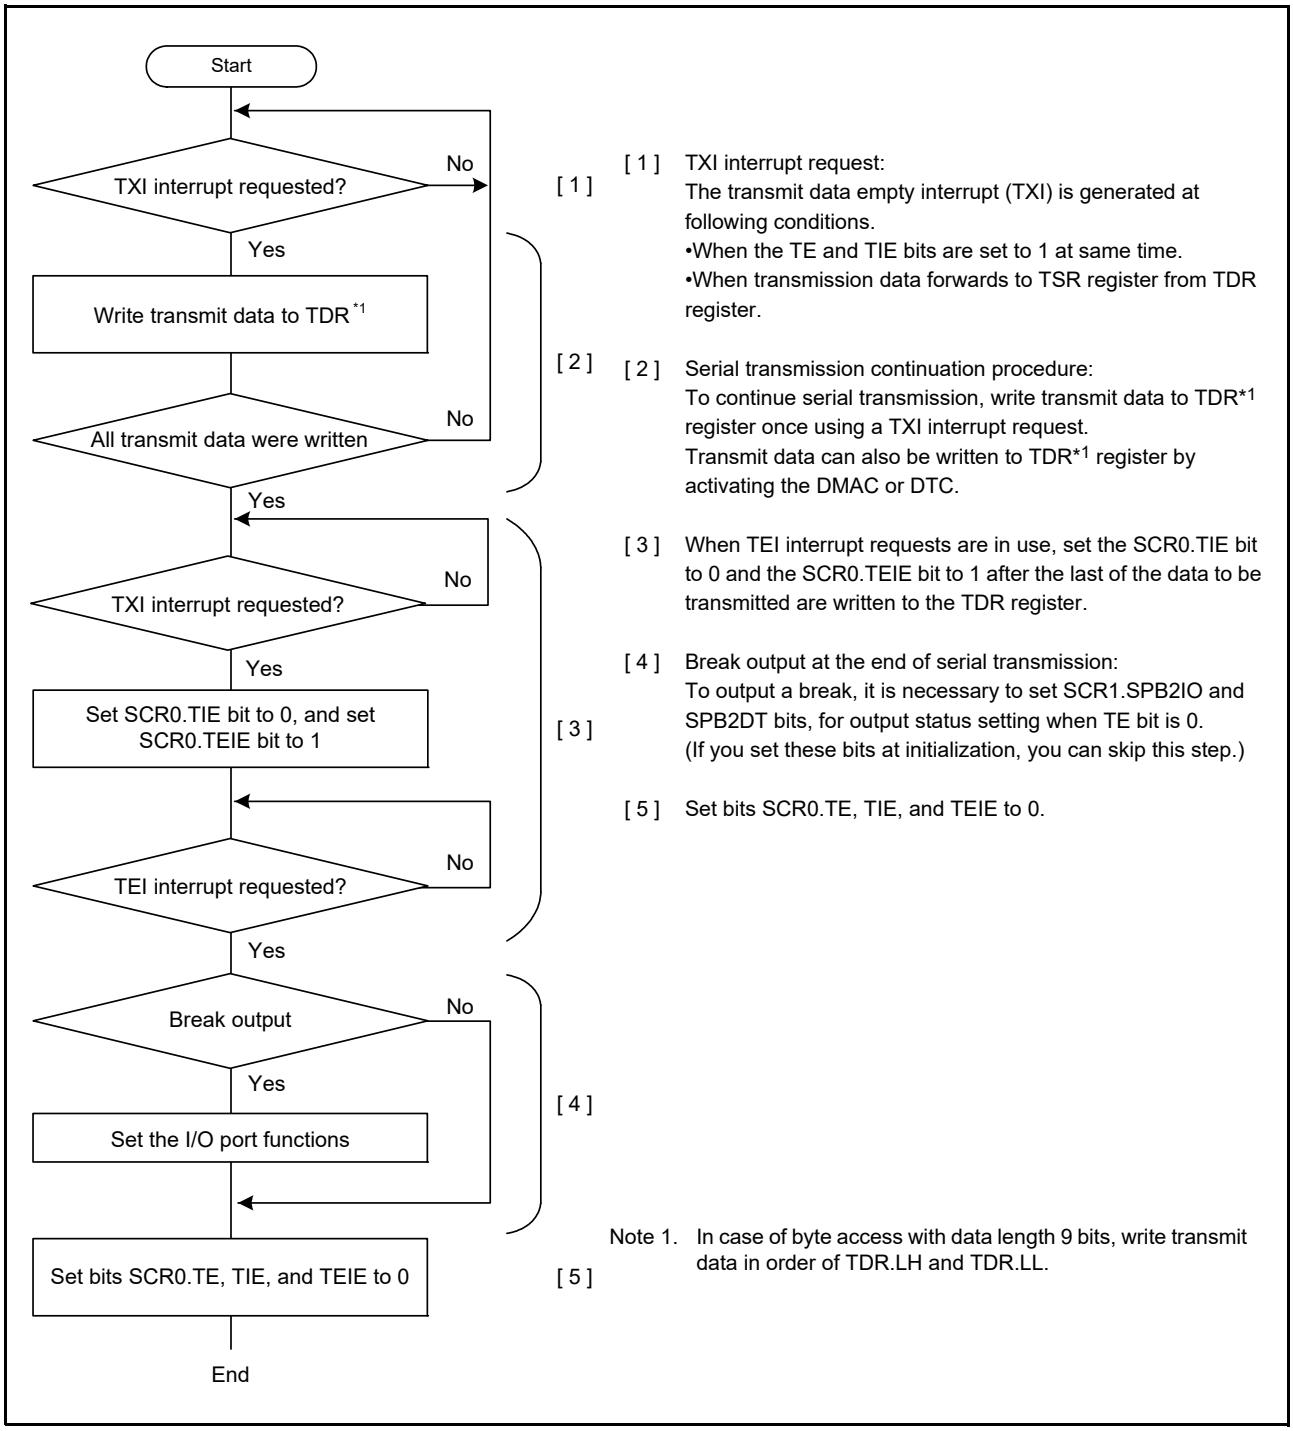


Figure 33.15 Example of Serial Transmission Flowchart in Asynchronous Mode (Non-FIFO Mode)

(2) FIFO Mode

Table 33.29 shows an example of data format that is written to transmit FIFO (TDR register) in asynchronous mode with FIFO selected.

Write the MPBT bit to bit 9 of the transmit FIFO (TDR register). When 7-bit data length is selected, write data to the TDR.TDAT[6:0] bits; when 8-bit data length is selected, write data to the TDR.TDAT[7:0] bits; when 9-bit data length is selected, write data to the TDR.TDAT[8:0] bits. Write 0 to unused bits. When accessing in byte units, write data in the order of the TDR.LH to the TDR.LL.

Table 33.29 Data Format That is Written to Transmit FIFO (TDR) (FIFO Mode)

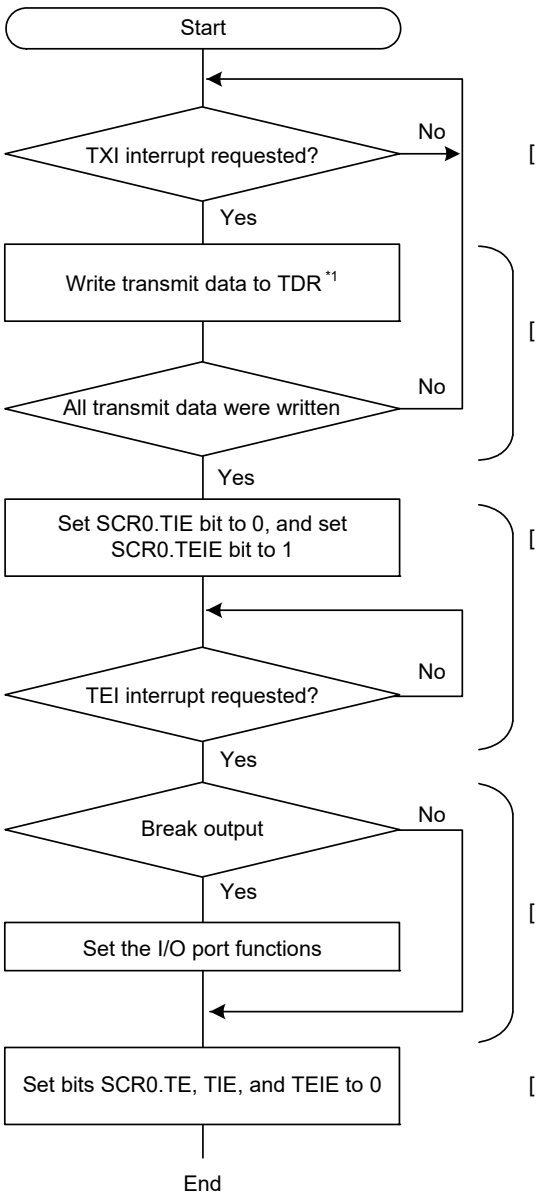
Data Length	Register setting		Transmit Data in TDR.L															
	SCR3	CHR[1:0]	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	1	—	—	—	—	—	—	MPBT	—	—	TDAT[6:0]						
8 bits	1	0	—	—	—	—	—	—	MPBT	—	TDAT[7:0]							
9 bits	0	0 or 1	—	—	—	—	—	—	MPBT	TDAT[8:0]								

—: Do not used. It should write to 0.

In serial transmission, the RSCI operates as described below.

1. The RSCI transfers data from transmit FIFO (TDR register) to TSR register when data is written to transmit FIFO (TDR register) in the TXI interrupt handling routine. The writable transmit data number is until (32 – transmit FIFO (TDR register)) bytes. At the beginning of transmission, set 1 to SCR0.TE and SCR0.TIE bits simultaneously. Then the TXI interrupt request is generated.
2. Transmission starts at data transfer from transmit FIFO (TDR register) to TSR register when SCR1.CTSE bit = 0 (CTS function is disabled) or when the CTS# pin level is low. When the quantity of transmit data written in transmit FIFO (TDR register) is equal to or less than the specified transmit triggering number, SSR.TDRE flag is set to 1. If SCR0.TIE bit is 1 at this time, a TXI interrupt request is generated. Continuous transmission is obtainable by writing the next transmit data to transmit FIFO (TDR register) in the TXI interrupt handling routine before transmission of the current transmit data is completed. Write the last transmission data, then the last data transmit start, and TXI is generated. When TEI interrupt requests are in use, before the last data transmit end, set the SCR0.TIE bit to 0 (a TXI interrupt request is disabled) and the SCR0.TEIE bit to 1 (a TEI interrupt request is enabled) using the TXI interrupt handling routine.
3. Data is sent from the TXDn pin in the following order: start bit, transmit data, parity bit or multi-processor bit (may be omitted depending on the format), and stop bit.
4. The RSCI checks whether non-transmitted data in transmit FIFO (TDR register) or not at the time of stop bit output.
5. When data is set to transmit FIFO (TDR register), setting of SCR1.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn# pin cause the next transfer of the next transmit data from transmit FIFO (TDR register) to TSR register and sending of the stop bit, after which serial transmission of the next frame starts.
6. If data is not set to transmit FIFO (TDR register), SSR.TEND flag is set to 1, the stop bit is sent, and then the mark state is entered in which 1 is output. If SCR0.TEIE bit is 1 at this time, a TEI interrupt request is generated.

Figure 33.16 shows a sample flowchart for serial transmission in asynchronous mode at FIFO selected.



[1] TXI interrupt request:
The transmit data empty interrupt (TXI) is generated at following conditions.
•When the TE and TIE bits are set to 1 at same time.
•When transmission data forwards to TSR from the transmit FIFO (TDR register) and the number of transmit data written in the transmit FIFO is equal to or less than the transmit FIFO threshold.

[2] Serial transmission continuation procedure:
To continue serial transmission, write all transmit data to the transmit FIFO (TDR register)*1 by using a TXI interrupt and clear the SSR.TDRE flag to 0. (Transmit data can also be written to the transmit FIFO (TDR register)*1 by activating the DMAC or DTC. In this case, the TDRE flag is cleared automatically, so please don't operate the TDRE flag.)
The number of transmission data it's possible to write in is 32 (the number of stored transmit FIFO data).

[3] If you use TEI, set TIE bit = 0 and TEIE bit = 1 after writing the last transmit data to TDR*1 register.

[4] Break output at the end of serial transmission:
To output a break, it is necessary to set SCR1.SPB2IO and SPB2DT bits, for output status setting when TE bit is 0.
(If you set these bits at initialization, you can skip this step.)

[5] Set bits SCR0.TE, TIE, and TEIE to 0.

Note 1. In case of byte access with data length 9 bits, write transmit data in order of TDR.LH and TDR.LL.

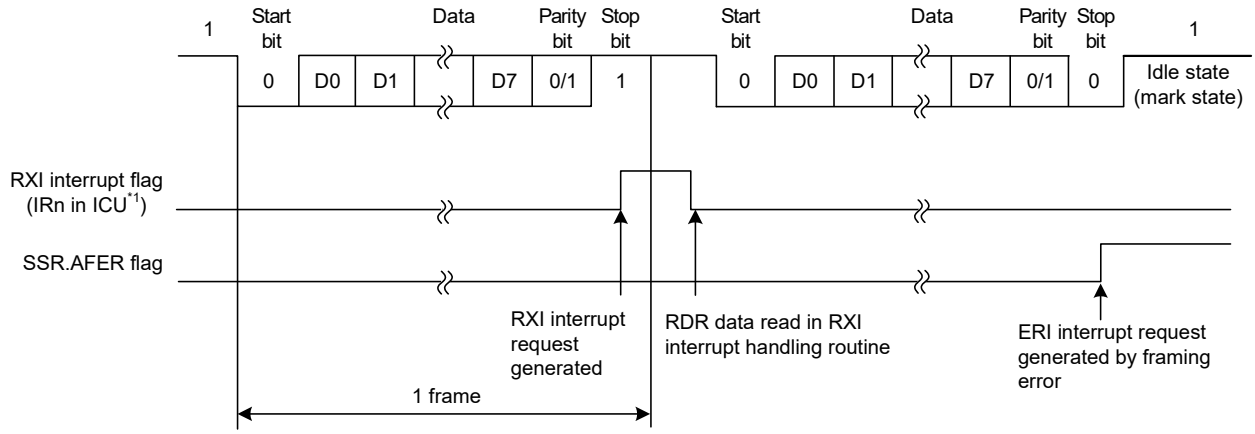
Figure 33.16 Example of Serial Transmission Flowchart in Asynchronous Mode (FIFO Mode)

33.3.9 Serial Data Reception (Asynchronous Mode)

(1) Non-FIFO Mode

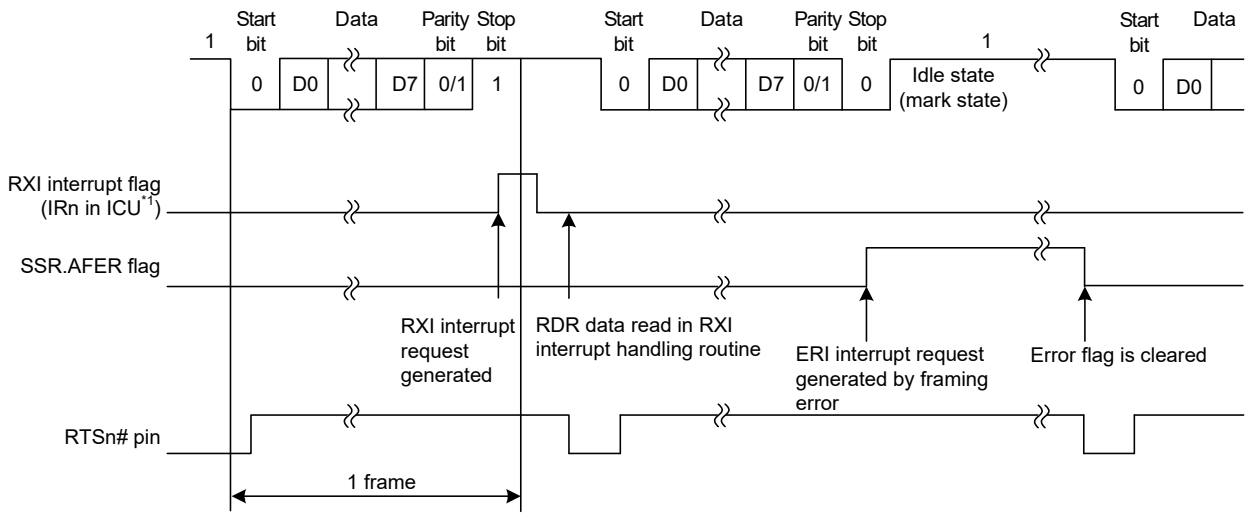
Figure 33.17 and Figure 33.18 show an example of the operation for serial data reception in asynchronous mode. In serial data reception, the RSCI operates as described below.

1. When the value of SCR0.RE bit becomes 1, the output signal on the RTSn# pin goes to the low level in the case of RTS function use.
2. When the RSCI monitors the communications line and detects a start bit, it performs internal synchronization, stores receive data in RSR register, and checks the parity bit and stop bit.
3. If an overrun error occurs, SSR.ORER flag is set to 1. If SCR0.RIE bit is 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to RDR register.
4. If a parity error is detected, SSR.APER flag is set to 1 and receive data is transferred to RDR register. If the SCR0.RIE bit is 1 at this time, an ERI interrupt request is generated.
5. If a framing error (when the stop bit is 0) is detected, SSR.AFER flag is set to 1 and receive data is transferred to RDR register. If SCR0.RIE bit is 1 at this time, an ERI interrupt request is generated.
6. When reception finishes successfully, receive data is transferred to RDR register. If SCR0.RIE bit is 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to RDR register in this RXI interrupt handling routine before reception of the next receive data is completed. Reading the received data that have been transferred to RDR register causes the RTSn# pin to output the low level in the case of RTS function use. If you do not want to turn the RTSn # pin output low after receiving the last data, set SCR0.RE bit to 0, before reading the RDR register.



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 33.17 Example of RSCI Operation for Serial Reception in Asynchronous Mode (1) (8-Bit Data, Parity, 1 Stop Bit, RTS Function is Not Used)



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 33.18 Example of RSCI Operation for Serial Reception in Asynchronous Mode (2) (8-Bit Data, Parity, 1 Stop Bit, RTS Function is Used)

Table 33.30 lists the states of the flags in SSR status register and receive data handling when a receive error is detected. If a receive error is detected, an ERI interrupt request is generated but an RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, AFER, and APER flags to 0 before resuming reception. Moreover, be sure to read the RDR register during overrun error processing. When a reception is forcibly terminated by setting SCR0.RE bit to 0 during operation, read the RDR register because received data which has not yet been read may be left in RDR register.
Figure 33.19 and Figure 33.20 show samples of flowcharts for serial data reception.

Table 33.30 Flags in the SSR Status Register and Receive Data Handling

Flags in the SSR Status Register				
ORER	**AFER**	**APER**	**Receive Data**	**Receive Error Type**
1	0	0	Lost	Overrun error
0	1	0	Transferred to RDR	Framing error
0	0	1	Transferred to RDR	Parity error
1	1	0	Lost	Overrun error + framing error
1	0	1	Lost	Overrun error + parity error
0	1	1	Transferred to RDR	Framing error + parity error
1	1	1	Lost	Overrun error + framing error + parity error

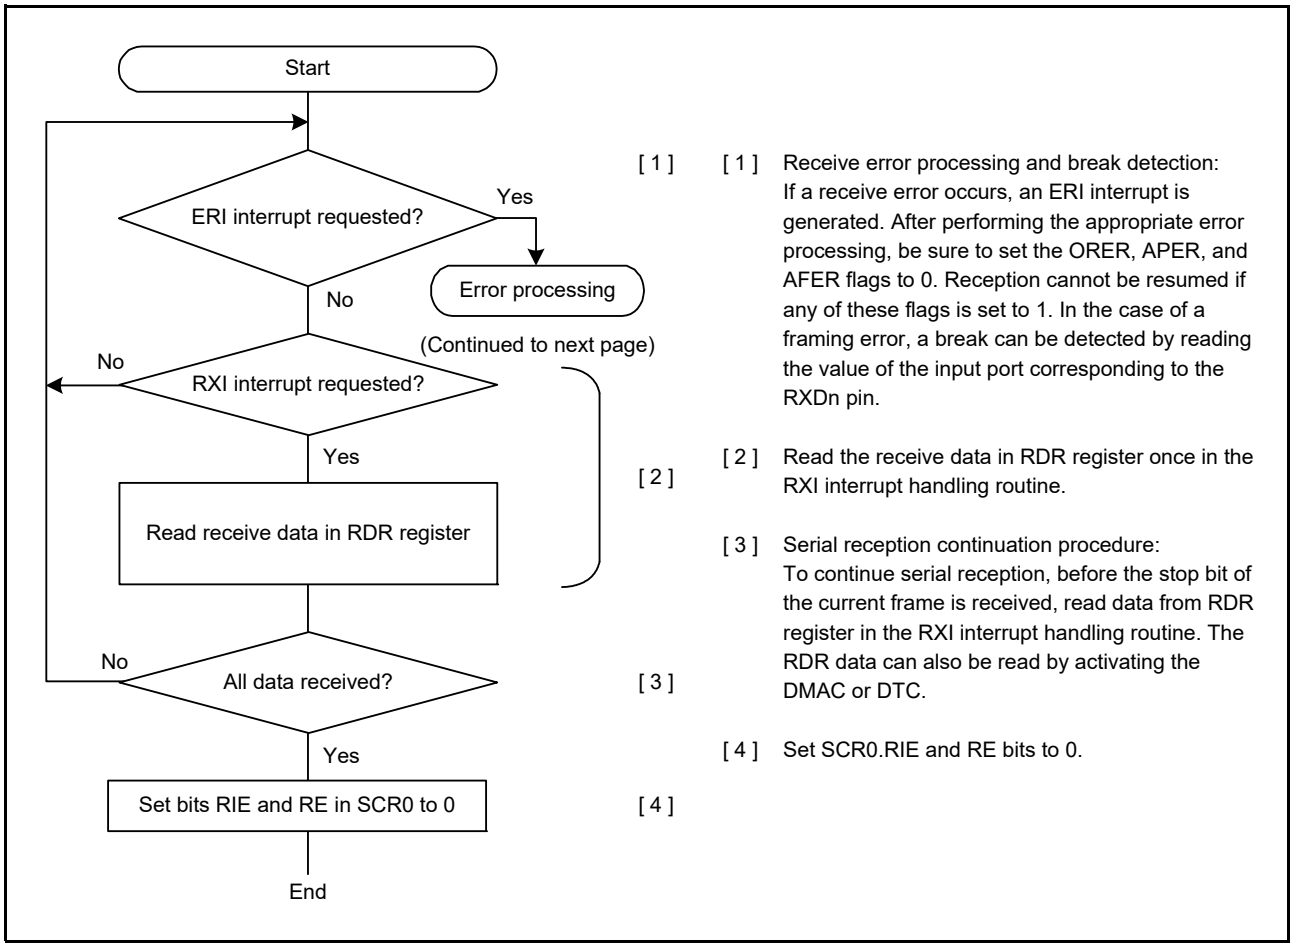


Figure 33.19 Example Flowchart of Serial Reception in Asynchronous Mode (Non-FIFO Mode) (1)

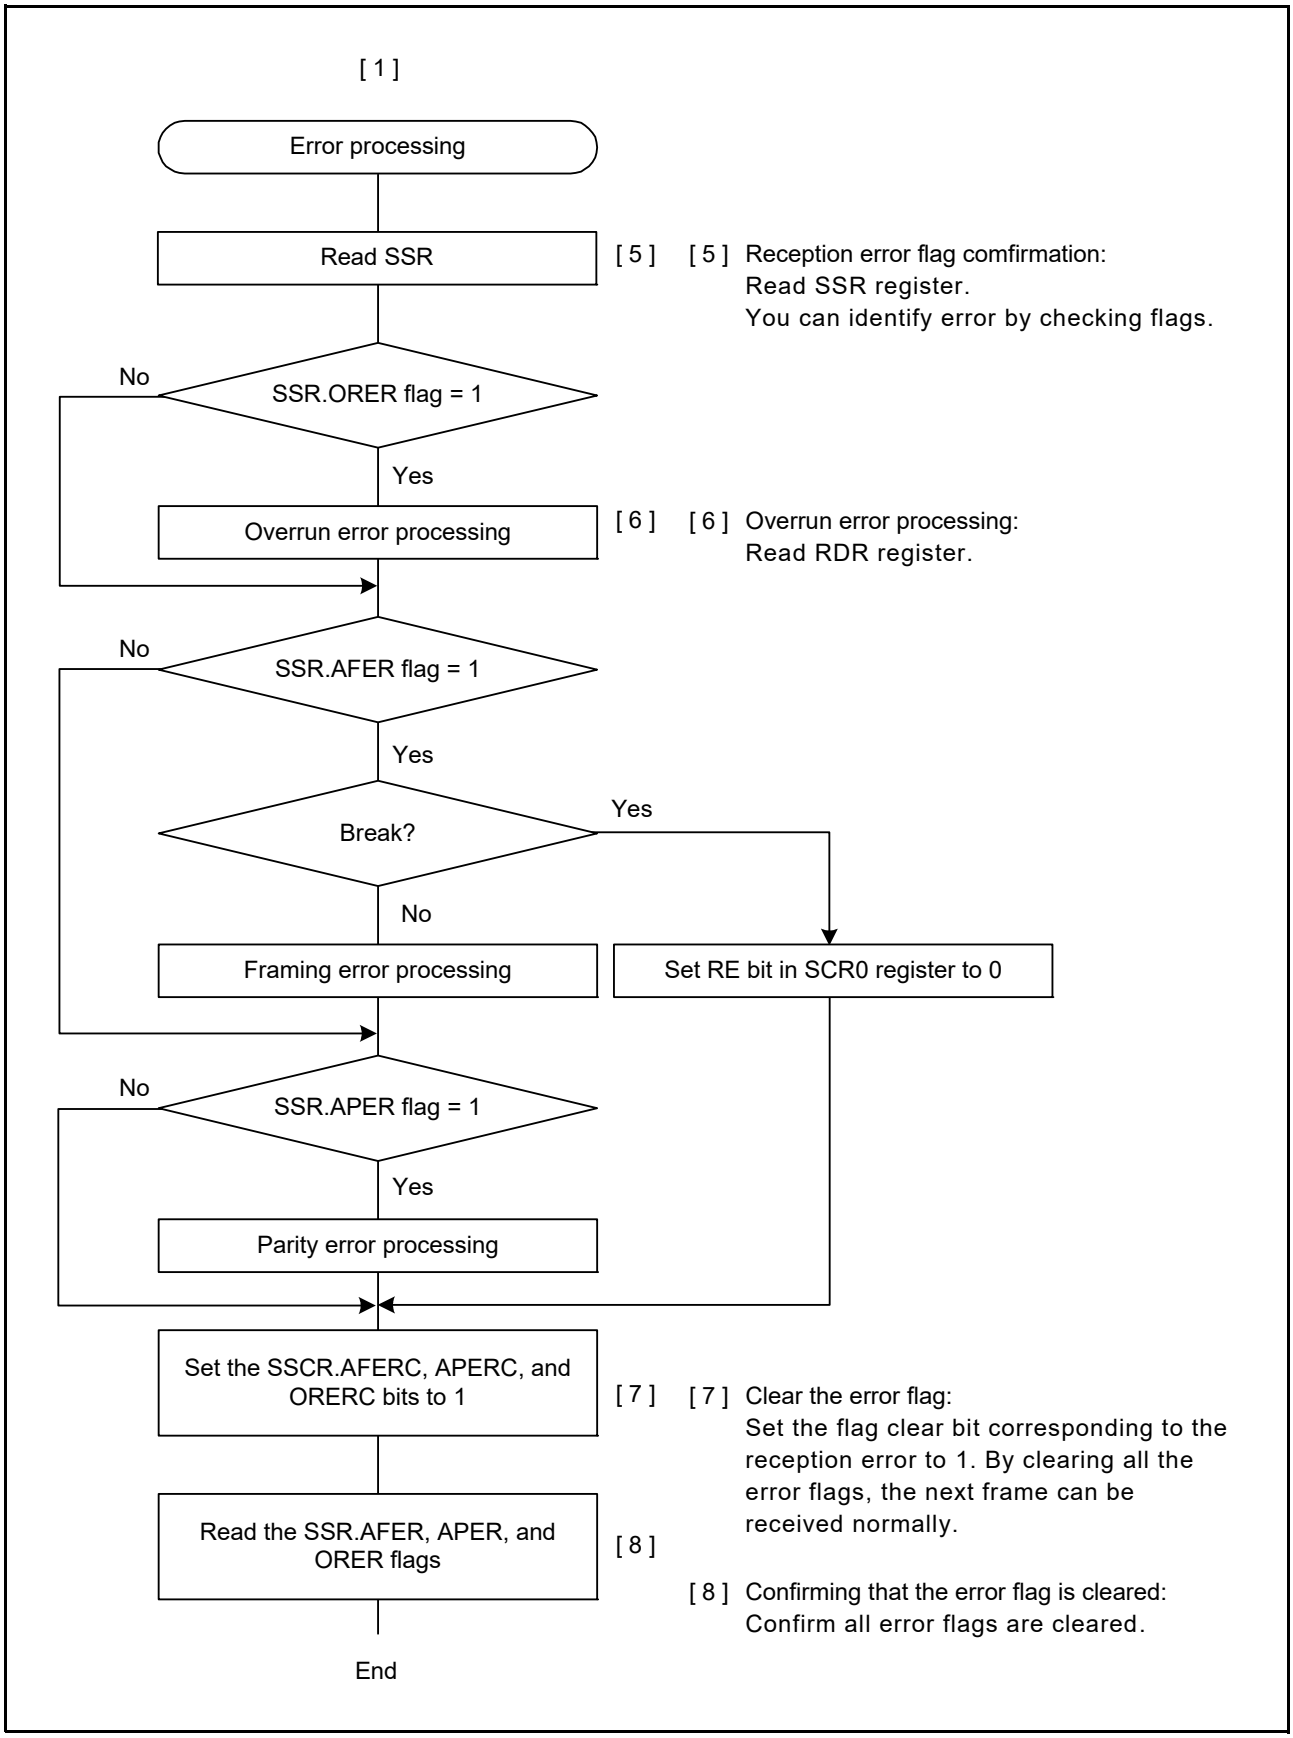

Figure 33.20 Example Flowchart of Serial Reception in Asynchronous Mode (Non-FIFO Mode) (2)

(2) FIFO Mode

Table 33.31 shows an example of data format stored to receive FIFO (RDR register) in asynchronous mode.
MPB flag (Receive FIFO (RDR register) bit9) is stored 0. Data is stored to receive FIFO (RDR register) corresponded to data length. It is stored to 0 for unused bits. If receive FIFO (RDR register) is read, RSCI updates to next data which are FER flag, PER flag, and receive data (RDAT[8:0] bits) in receive FIFO. The flags which are AFER, APER, ORER, and DR flag in receive FIFO, are always indicated to the flags corresponded to SSR register and RFSR register.

Table 33.31 Data Format Stored in the Receive FIFO (RDR) (FIFO Mode)

Data Length	Register setting		Arrangement of Receive Flag, MPB Flag and Received Data in RDR Register															
	SCR3	CHR[1:0]	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	1	—	—	—	FER	PER	DR	MPB	0	0	RDAT[6:0]						
8 bits	1	0	—	—	—	FER	PER	DR	MPB	0	RDAT[7:0]							
9 bits	0	0 or 1	—	—	—	FER	PER	DR	MPB	RDAT[8:0]								
Data Length	**SCR3**	**CHR[1:0]**	**b31**	**b30**	**b29**	**b28**	**b27**	**b26**	**b25**	**b24**	**b23**	**b22**	**b21**	**b20**	**b19**	**b18**	**b17**	**b16**
7 bits	1	1	—	—	—	AFER	APER	—	—	ORER	—	—	—	—	—	—	—	—
8 bits	1	0	—	—	—	AFER	APER	—	—	ORER	—	—	—	—	—	—	—	—
9 bits	0	0 or 1	—	—	—	AFER	APER	—	—	ORER	—	—	—	—	—	—	—	—

Note: 0 is always read from the MPB flag (RDR register bit9).
When a 7-bit data length is selected, 0 is read from the RDAT[8:7] bits.
When a 8-bit data length is selected, 0 is read from the RDAT[8] bit.

Table 33.32 lists the states of the flags in SSR register status register and receive data handling when a receive error is detected in FIFO mode. Figure 33.21 and Figure 33.22 show samples of flowcharts for serial data reception in FIFO mode.
In serial data reception, the RSCI operates as described below.

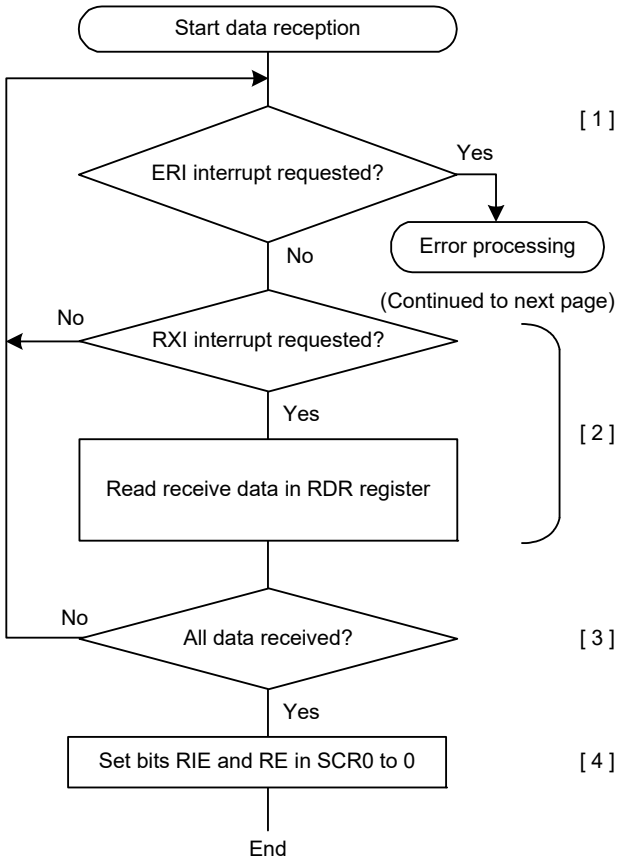
1. When the value of SCR0.RE bit becomes 1, the output signal on the RTSn# pin goes to the low level in the case of RTS function use.
2. When the RSCI monitors the communications line and detects a start bit, it performs internal synchronization, stores receive data in RSR, and checks the parity bit and stop bit.
3. If there is no space in receive FIFO (RDR register), an overrun error occurs and the SSR.ORER flag is set to 1. If SCR0.RIE bit is 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to receive FIFO (RDR register).
4. If a parity error is detected, SSR.APER flag is set to 1 and receive data is transferred to receive FIFO (RDR register). If the SCR0.RIE bit is 1 at this time, an ERI interrupt request is generated.
5. If a framing error (when the stop bit is 0) is detected, SSR.AFER flag is set to 1 and receive data is transferred to RDR register. If SCR0.RIE bit is 1 at this time, an ERI interrupt request is generated.
6. After framing error is detected, when RSCI detects that continuous receive data is 0 for 1 frame, the reception stops.
7. When quantity of data stored in the receive FIFO data register (RDR register) falls the specified receive triggering number, and that no next data has been received yet after the elapse of 15 etu from the last stop bit in asynchronous mode, RFSR.DR flag is set to 1. If RIE bit is set to 1, RSCI occurs RXI interrupt request when FCR.DRES bit is 0 and RSCI occurs ERI interrupt request when FCR.DRES bit is 1.
8. When reception finishes successfully, receive data is transferred to receive FIFO (RDR register). The SSR.RDRF flag is set to 1 when the quantity of receive data which is equal to or greater than the specified receive triggering number are stored in receive FIFO (RDR register). If SCR0.RIE bit is 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to receive FIFO (RDR register)

in this RXI interrupt handling routine, before overrun error is occurred. Reading the received data that have been transferred to receive FIFO (RDR register), and if it is less than RTS trigger number, causes the RTSn# pin to output the low level. in the case of RTS function use.

Table 33.32 Flags in the SSR Status Register and Receive Data Handling (FIFO Mode)

SSR Register				
ORER	**AFER*1**	**APER*1**	**Receive Data**	**Receive Error Type**
1	0	0	Lost	Overrun error
0	1	0	Transferred to RDR	Framing error
0	0	1	Transferred to RDR	Parity error
1	1	0	Lost	Overrun error + framing error
1	0	1	Lost	Overrun error + parity error
0	1	1	Transferred to RDR	Framing error + parity error
1	0	0	Lost	Overrun error + framing error + parity error

Note 1. This flag indicates whether there is an error in received data when reception is completed.



[1] Receive error processing and break detection:
If a receive error occurs, an ERI interrupt is generated. After performing the appropriate error processing, be sure to set the ORER flag to 0. Reception cannot be resumed if ORER flag is set to 1. Reception can continue even if APER, AFER, and DR flags are 1.

[2] Read the receive data in the receive FIFO (RDR register) in the RXI interrupt handling routine. The reception data stored in the receive FIFO (RDR register) is read until the number of stored data will be below the FCR.RTRG value at least. You can confirm the number of the reception data in the FIFO by RFSR.R[5:0] bits.

[3] Serial reception continuation procedure:
To continue serial reception, before an overrun error occurs, please read data from the receive FIFO (RDR register) in the RXI interrupt handling routine and clear SSR.RDRF flag and RFSR.DR flag to 0. The receive FIFO data can also be read by activating the DMA or DTC. The RDRF flag is cleared automatically in this case, so please don't operate the RDRF flag.

[4] Set SCR0.RIE and RE bits to 0.

Figure 33.21 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO Mode) (1)

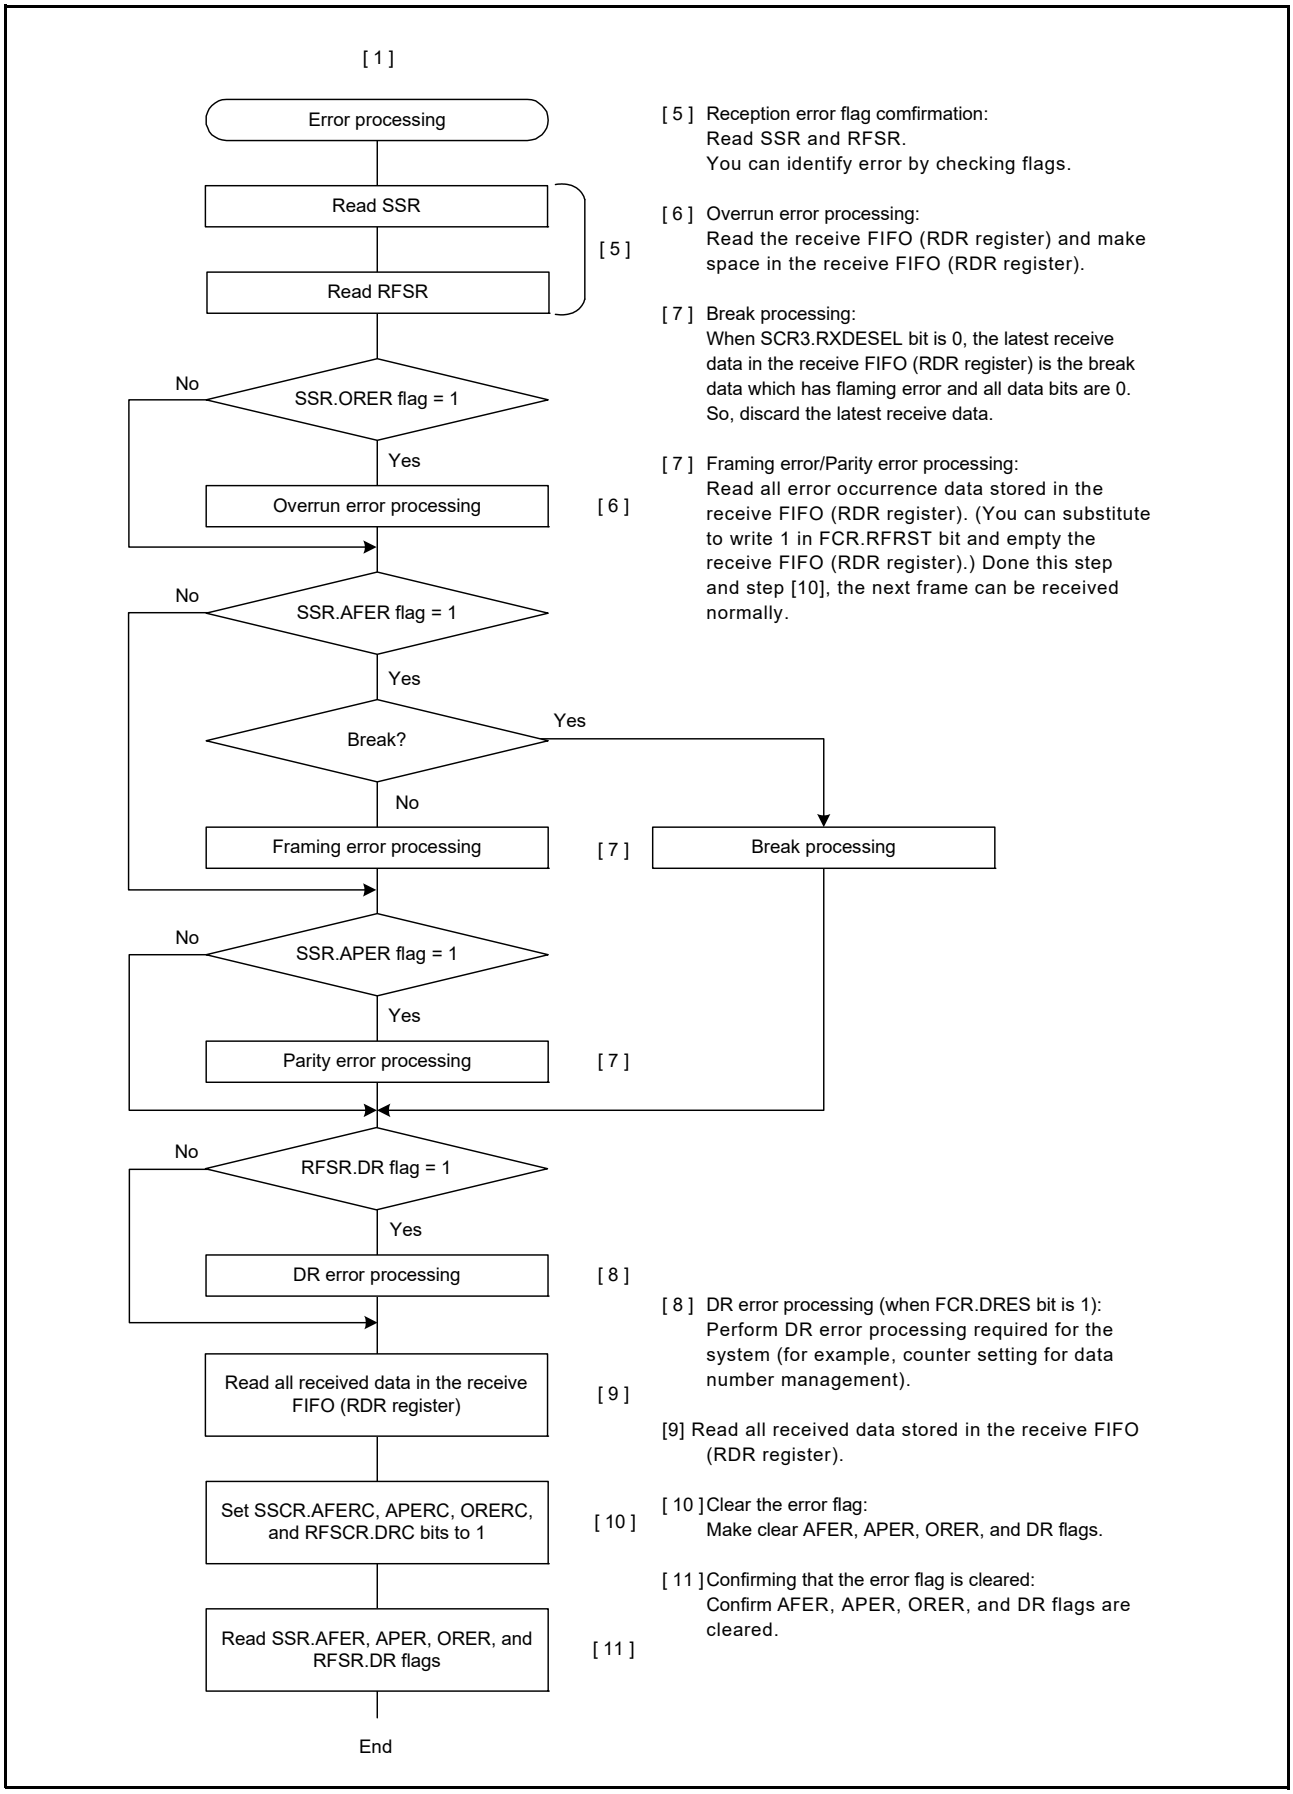


Figure 33.22 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO Mode) (2)

33.3.10 Receive Data Sampling Timing Adjustment

When a waveform such that high width is different from low width because the difference between rising time and falling time is large is received, adjust the timing for data to be sampled at the center of the narrower pulse. When low width is narrower than high width, move the sampling timing forward, and when high width is narrower than low width, move the sampling timing backward.

When the SCR4.RTMG[3:0] bits are set to an offset to the default sampling point and then the SCR4.RTADJ bit is set to 1, received data is sampled at the specified position.

Figure 33.23 shows an example of the sampling timing adjustment.

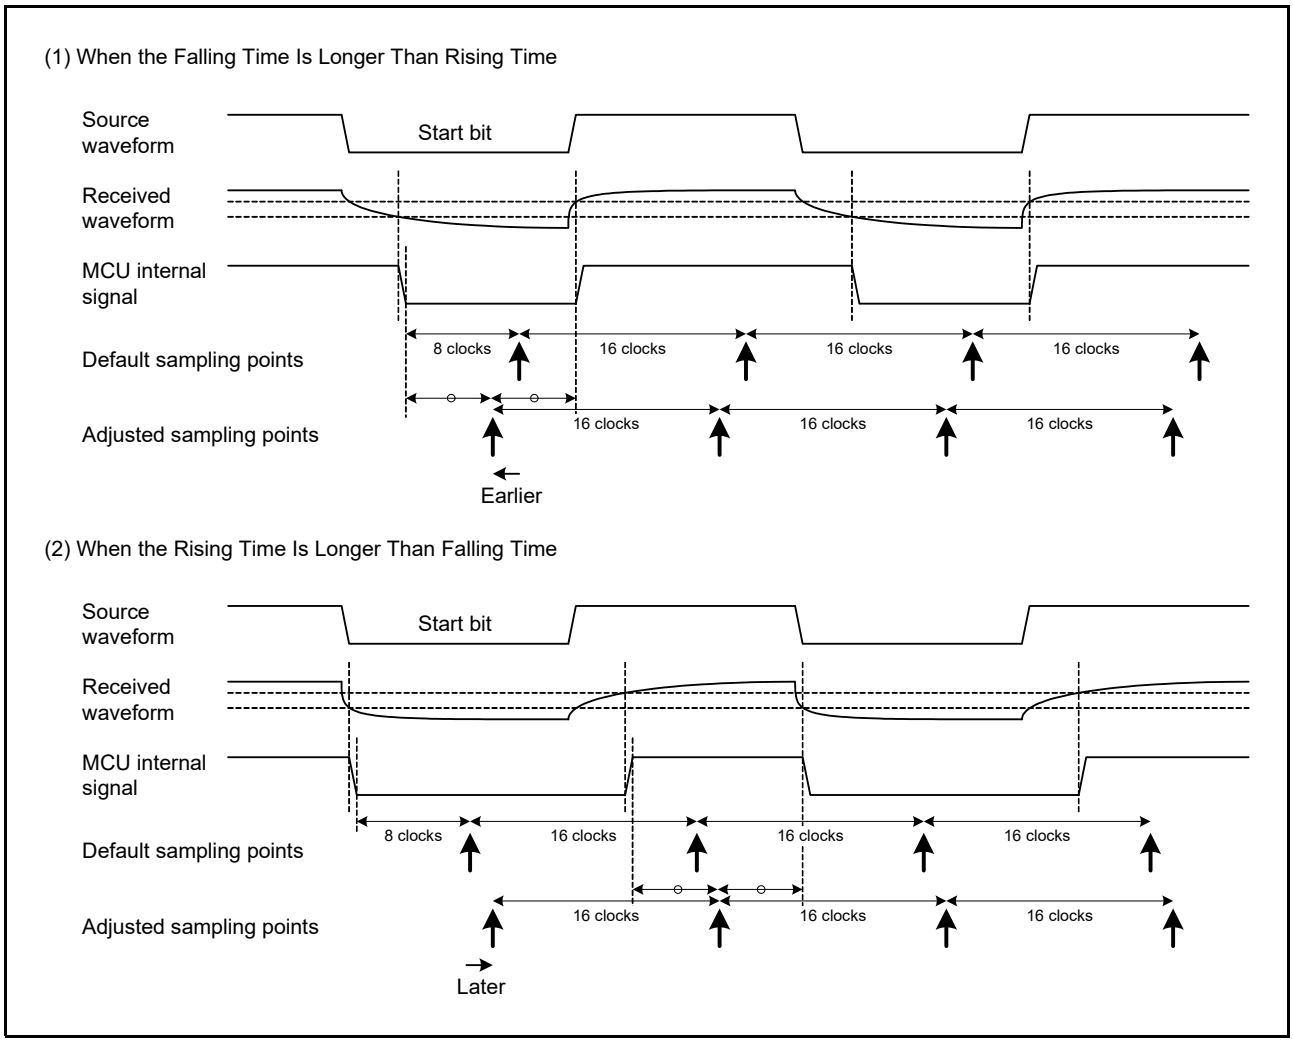

Figure 33.23 Example of Sampling Timing Adjustment (SCR2.ABCSE Bit = 0 and SCR2.ABCS Bit = 0)

33.3.11 Transmit Data Transition Timing Adjustment

When a difference between high width and low width for a waveform transmitted by this MCU arises at the receiver, it is also possible to make a difference between the high width and the low width beforehand at transmission to adjust so that the difference disappears at the receiver. When high width becomes narrower at the receiver, expand the high width of the transmit signal by delaying the falling edges, and when low width becomes narrower at the receiver, expand the low width of the transmit signal by delaying the rising edges.

When the SCR4.TTMG[3:0] bits are set to the transition direction and the delay amount and the SCR4.TTADJ bit is set to 1, transmit data changes at the specified point.

Figure 33.24 shows an example of the transition timing adjustment.

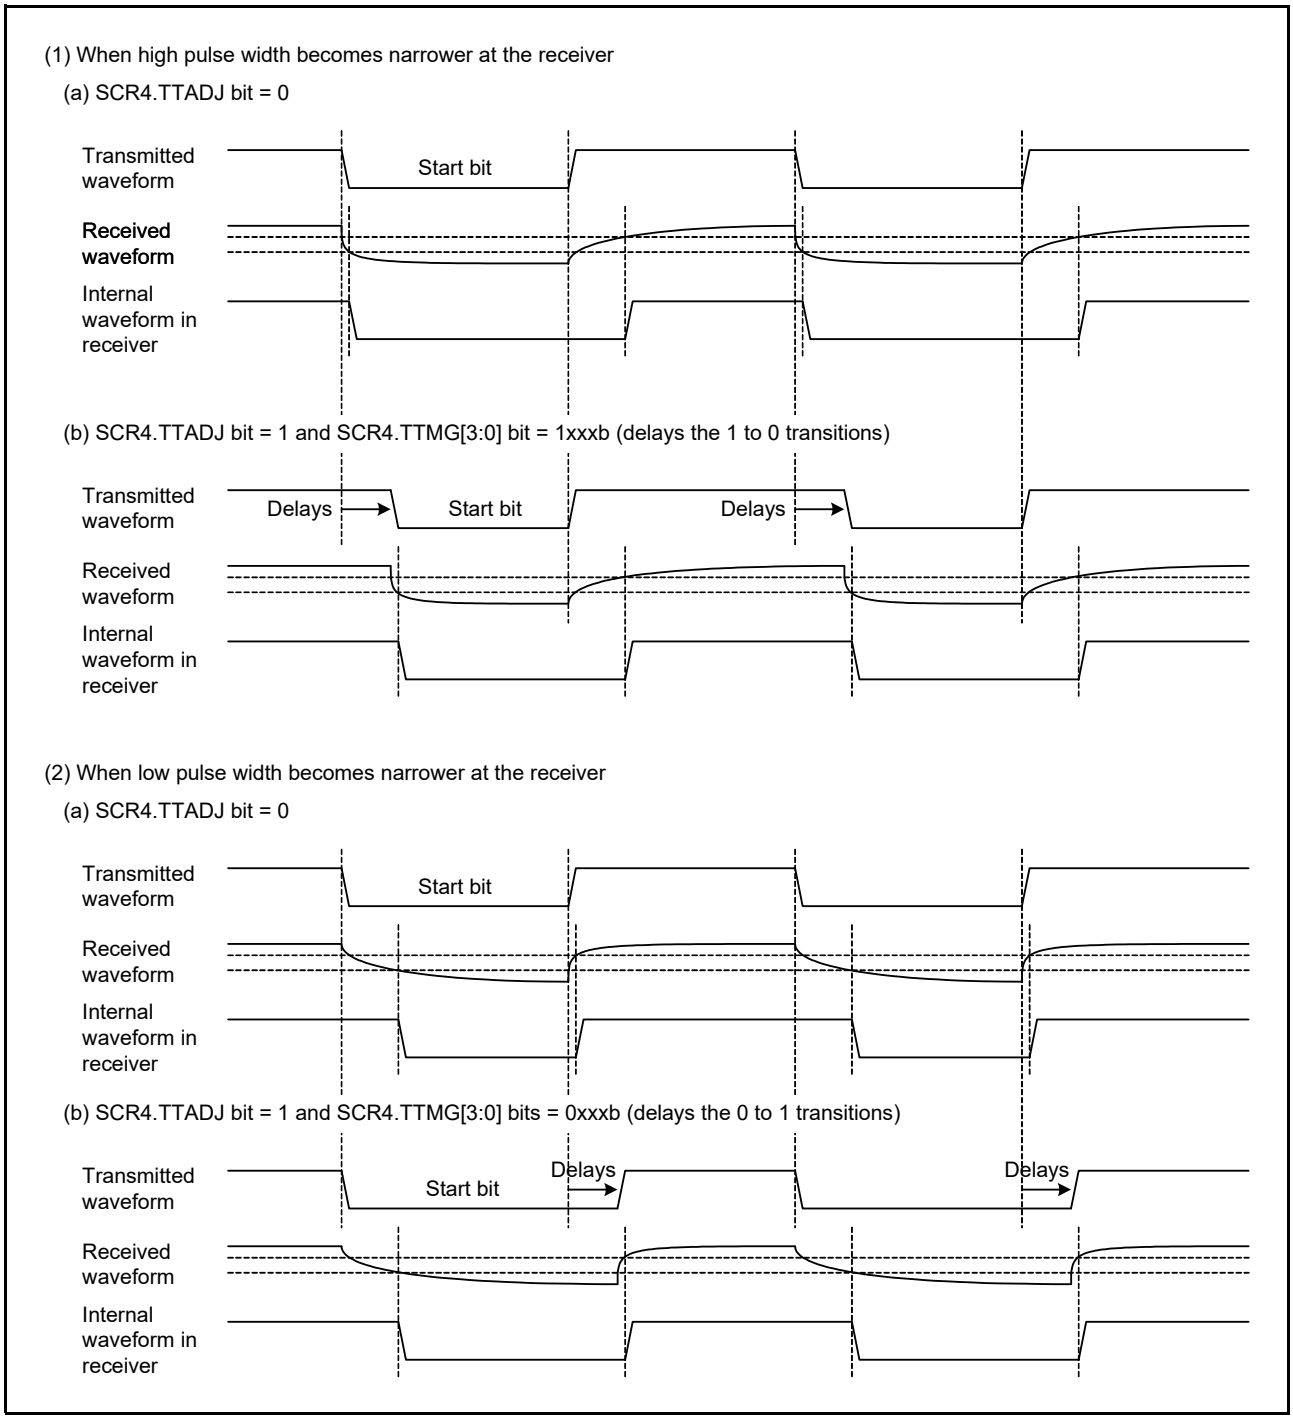

Figure 33.24 Example of Transition Timing Adjustment

33.4 Multi-Processor Communication Function

Using the multi-processor communication functions enables to transmit and receive data by sharing a communication line between multiple processors by using asynchronous serial communication in which the multi-processor bit is added. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station. The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle. When the multi-processor bit is set to 1, it indicates the ID transmission cycle and when the multiprocessor bit is set to 0, it indicates the data transmission cycle. Figure 33.25 shows an example of communication between processors by using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits the communication data in which the multi-processor bit set to 0 is added to the transmit data. Upon receiving the communication data in which the multi-processor bit is set to 1, the receiving station compares the received ID with the ID of the receiving station itself and if the two matches, receives the communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until again receiving the communication data in which the multi-processor bit is set to 1.
RTS control cannot be used at the time of multi-processor communication function use, because this is a function corresponding to one-to-many communications.

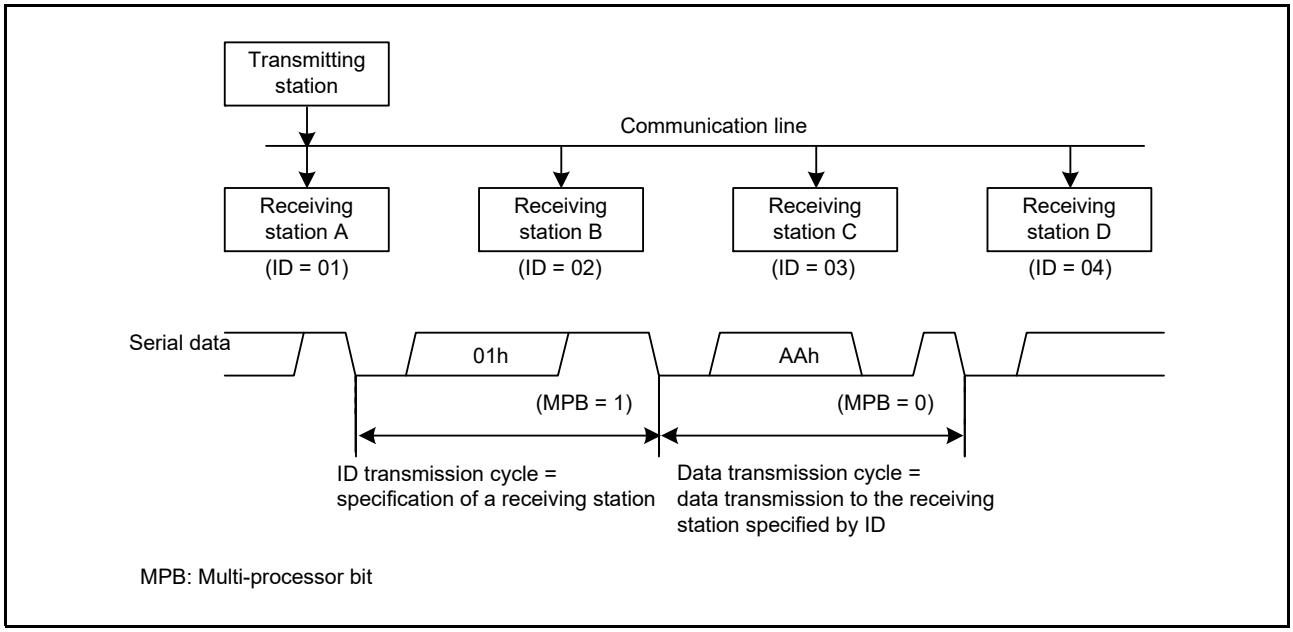

Figure 33.25 An Example of Communication using the Multi-Processor Format (Example of Transmission of Data AAh to Receiving Station A)

(1) Non-FIFO Mode

For supporting this function, the RSCI provides the MPIE bit in SCR0 register. When the MPIE bit is set to 1, transfer of receive data from the RSR register to the RDR register, detection of a receive error, and setting the respective status flags RDRF, ORER and AFER in SSR are disabled until reception of data in which the multi-processor bit is set to 1.
Upon receiving a reception character in which the multi-processor bit is set to 1, the MPB flag in RDR register is set to 1 and the MPIE bit in SCR0 register is automatically cleared, thus returning to a non-multi-processor reception operation. At this time, an RXI interrupt is generated if the RIE bit in SCR0 register is set.
When the multi-processor format is specified, specification of the parity bit is disabled.
Apart from this, there is no difference from the operation in the non-multi-processor asynchronous mode. A clock which is used for the multi-processor communication is also the same as the clock used in the non-multi-processor asynchronous mode.

(2) FIFO Mode

For transmission, SW should write to TDR.MPBT (Multi-Processor Bit Transfer) which corresponds to transmit data in TDR.TDAT[8:0] bits. For reception, multi-processor bit that is a part of receive data, is stored to RDR.MPB flag, and receive data is stored to RDR.RDAT[8:0] bits. When the MPIE bit is set to 1, transfer of receive data from the RSR to the RDR.RDAT[8:0] bits, detection of a receive error, and detection of DR flag, and setting the respective status flags RDRF, ORER, and AFER in SSR are disabled until reception of data in which the multi-processor bit is set to 1.

Upon receiving a reception character in which the multi-processor bit is set to 1, the MPB flag in RDR register is set to 1,and receive data is stored to receive FIFO (RDR.RDAT[8:0] bits), and the MPIE bit in SCR0 register is automatically cleared, thus returning to a non-multi-processor reception operation. At this time, an RXI interrupt is generated if the RIE bit in SCR0 register is set.

When the multi-processor format is specified, specification of the parity bit is disabled. Apart from this, there is no difference from the operation in the non-multi-processor asynchronous mode and FIFO mode.

33.4.1 Multi-Processor Serial Data Transmission

(1) Non-FIFO Mode

Figure 33.26 shows a sample flowchart of multi-processor data transmission. In the ID transmission cycle, the ID should be transmitted with the MPBT bit in TDR register set to 1. In the data transmission cycle, the data should be transmitted with the MPBT bit set to 0. The other operations are the same as the operations in asynchronous mode.

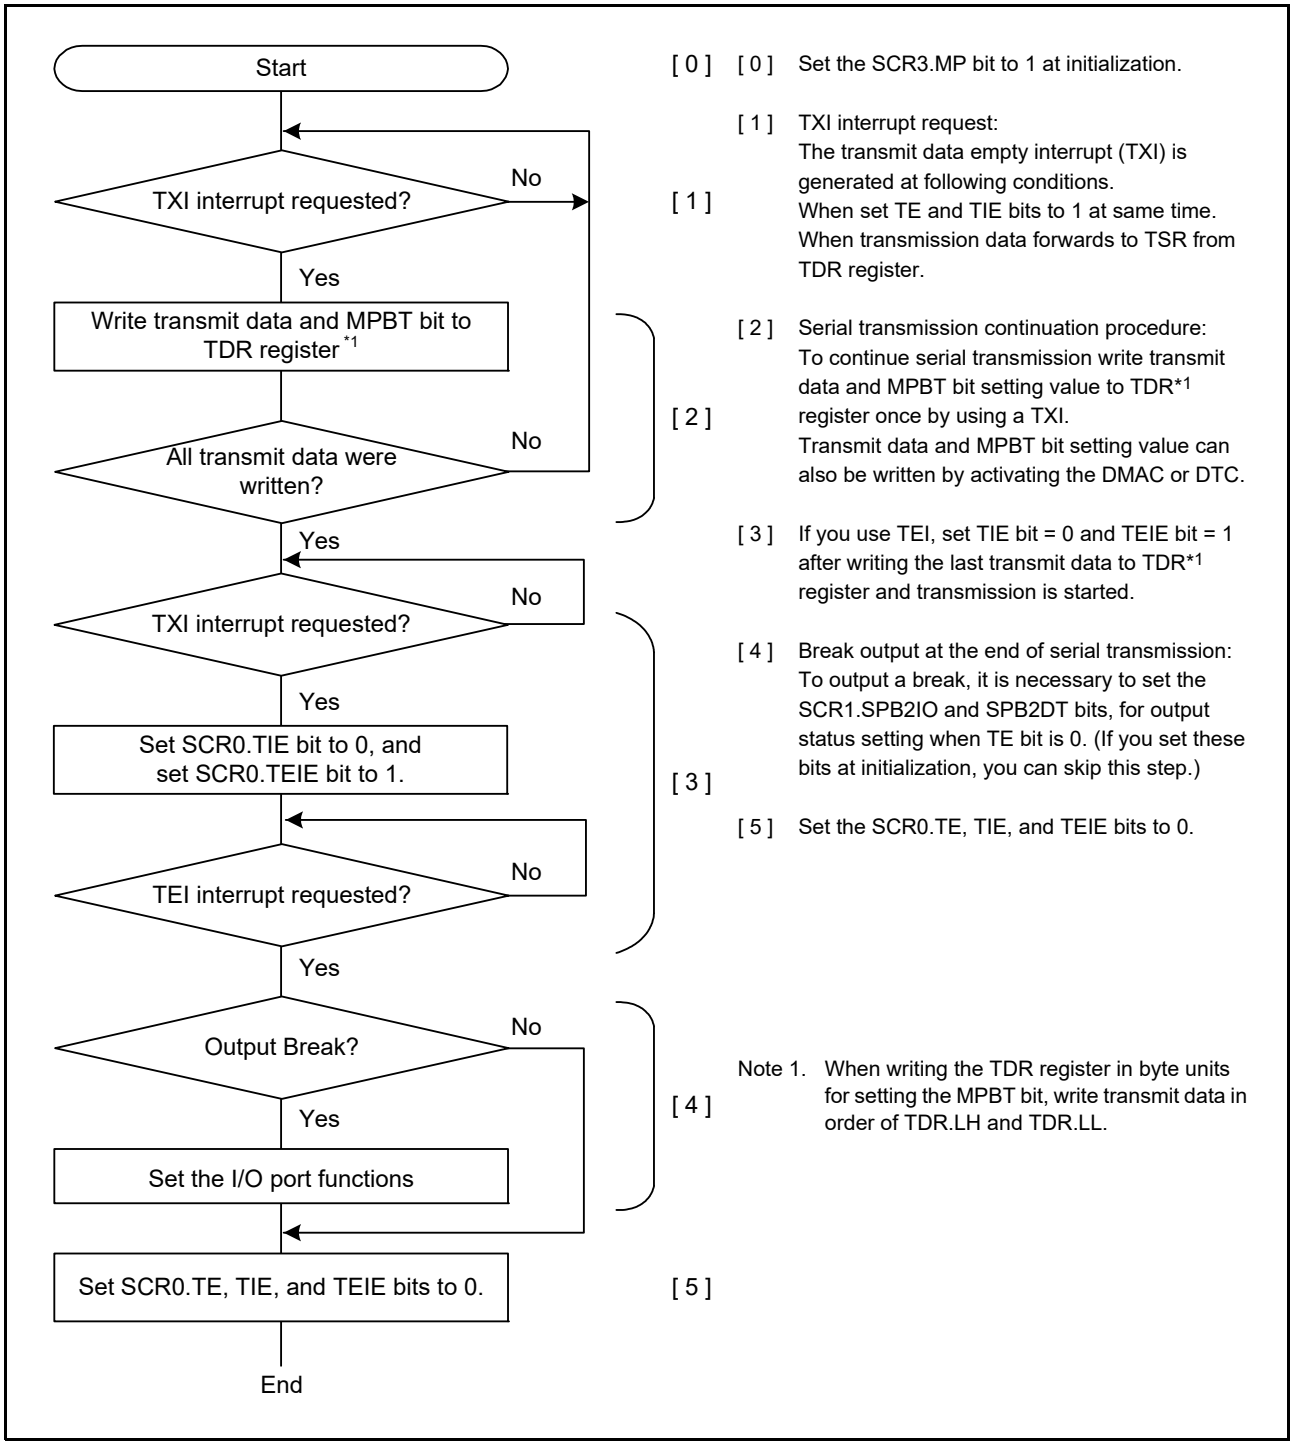

Figure 33.26 Example of Multi-Processor Serial Transmission Flowchart (Non-FIFO Mode)

(2) FIFO Mode

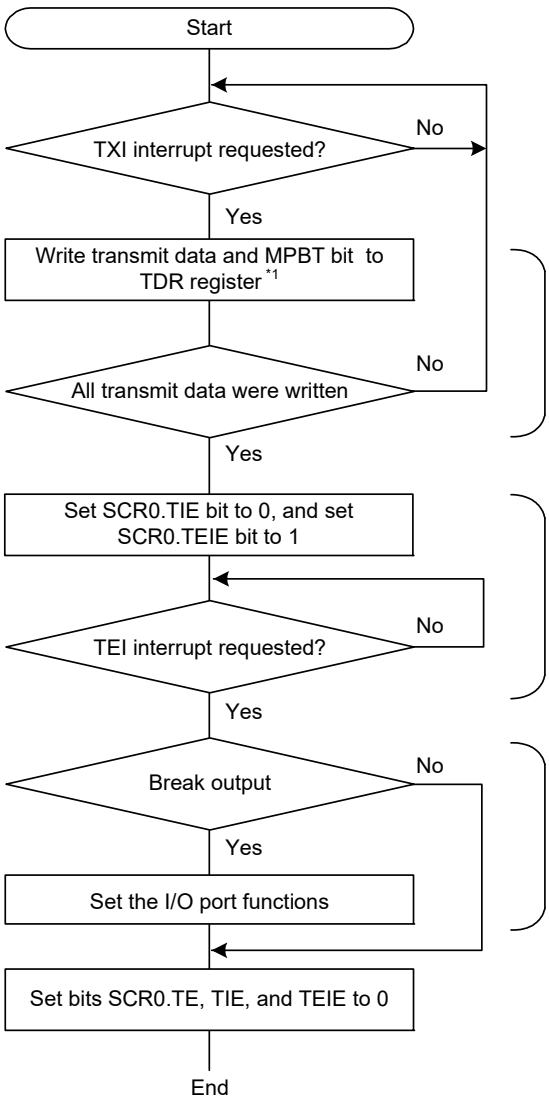
Table 33.33 shows an example of data format that is written to transmit FIFO (TDR register) in multi-processor mode. Write MPBT in bit9 of TDR. And write data to transmit FIFO (TDR register) corresponded to data length. It should write to 0 for unused bits.

Table 33.33 Data Format in Multi-processor Mode that is Written to Transmit FIFO (TDR Register)

Data Length	Register setting		Transmit Data in TDR.L															
	SCR3	CHR[1:0]	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	1	—	—	—	—	—	—	MPBT	—	—	TDAT[6:0]						
8 bits	1	0	—	—	—	—	—	—	MPBT	—	TDAT[7:0]							
9 bits	0	0 or 1	—	—	—	—	—	—	MPBT	TDAT[8:0]								

—: Do not used. It should write to 0.

Figure 33.27 shows a sample flowchart for multi-processor data transmission in FIFO mode. In the ID transmission cycle, the ID should be transmitted with the MPBT bit in TDR register set to 1. In the data transmission cycle, the data should be transmitted with the MPBT bit set to 0. The other operations are the same as the operations in asynchronous mode with FIFO enabled.



[0] Set the SCR3.FM and MP bits to 1 at initialization.

[1] TXI interrupt request:
The transmit data empty interrupt (TXI) is generated when transmission data forwards to TSR from the transmit FIFO (TDR register) and the number of transmit data written in the transmit FIFO is equal to or less than the transmit FIFO threshold.

[2] Serial transmission continuation procedure:
To continue serial transmission, write all transmit data and MPBT bit setting value to the transmit FIFO (TDR register) by using a TXI interrupt. Transmit data and MPBT bit setting value can also be written to the transmit FIFO (TDR register) by activating the DMAC or DTC.

[4] If you use TEI, set TIE bit = 0 and TEIE bit = 1 after writing the last transmit data to TDR*1 register.

[5] Break output at the end of serial transmission:
To output a break, it is necessary to set the SCR1.SPB2IO and SPB2DT bits, for output status setting when TE bit is 0.
(If you set these bits at initialization, you can skip this step.)

[6] Set bits SCR0.TE, TIE, and TEIE to 0.

Note 1. When writing the TDR register in byte units for setting the MPBT bit, write transmit data in order of TDR.LH and TDR.LL.

Figure 33.27 Example of Multi-Processor Serial Transmission Flowchart (FIFO Mode)

33.4.2 Multi-Processor Serial Data Reception

(1) Non-FIFO Mode

Figure 33.29 and Figure 33.30 are sample flowcharts of multi-processor data reception. When the MPIE bit in SCR0 register is set to 1, reading the communication data is skipped until reception of the communication data in which the multi-processor bit is set to 1. When the communication data in which the multi-processor bit is set to 1 is received, the received data is transferred to RDR register. At this time, the RXI interrupt request is generated. The other operations are the same as the operations in asynchronous mode.
Figure 33.28 is the example of operation for reception.

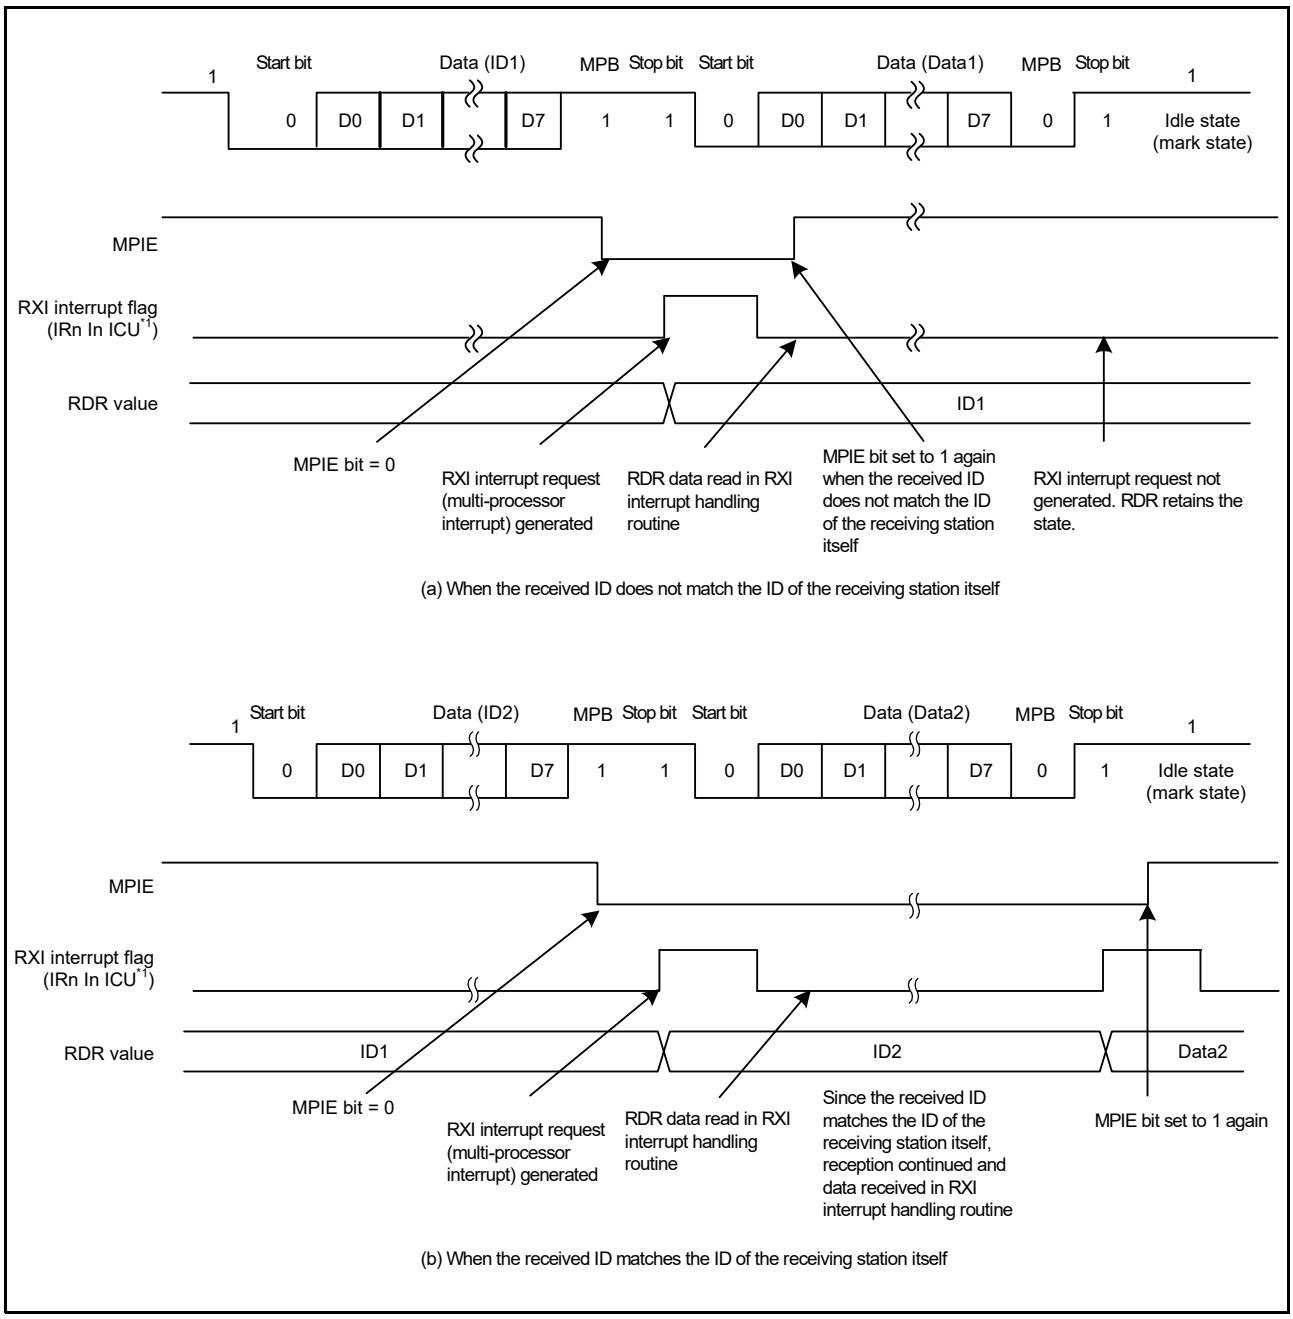


Figure 33.28 Example of RSCI Reception (8-Bit Data/Multi-Processor Bit/1 Stop Bit)

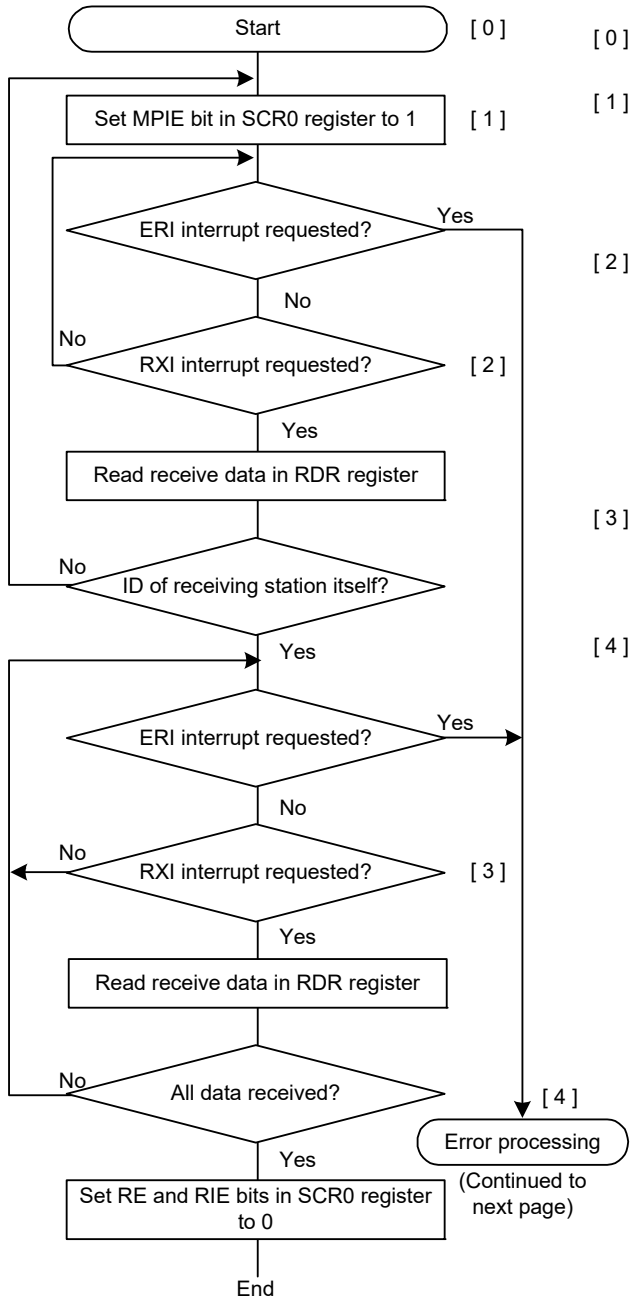

[0] Set the SCR3.MP bit to 1 at initialization.

[1] ID reception cycle:
Set SCR0.MPIE bit to 1 and wait for ID reception.
If you set this bits at initialization, you can skip this Step.

[2] RSCI status confirmation and reception and comparison of ID:
Read data in RDR register at the first RXI interrupt and compare it with the ID of the receiving station itself. If the ID does not match the ID of the receiving station itself, set the MPIE bit to 1 again, and wait for another RXI interrupt request.

[3] Data reception at an RXI interrupt:
Read data in RDR register once in the RXI interrupt routine.

[4] Receive error processing and break detection:
If a receive error occurs, an error is identified by reading ORER and AFER flags in SSR. After performing the appropriate error processing be sure to clear the ORER and AFER flags. Reception cannot be resumed if any of these flags is set to 1.
In the case of a framing error, a break can be detected by reading SSR.RXDMON flag.

Figure 33.29 Example of Multi-Processor Serial Reception Flowchart (1) (Non-FIFO Mode)

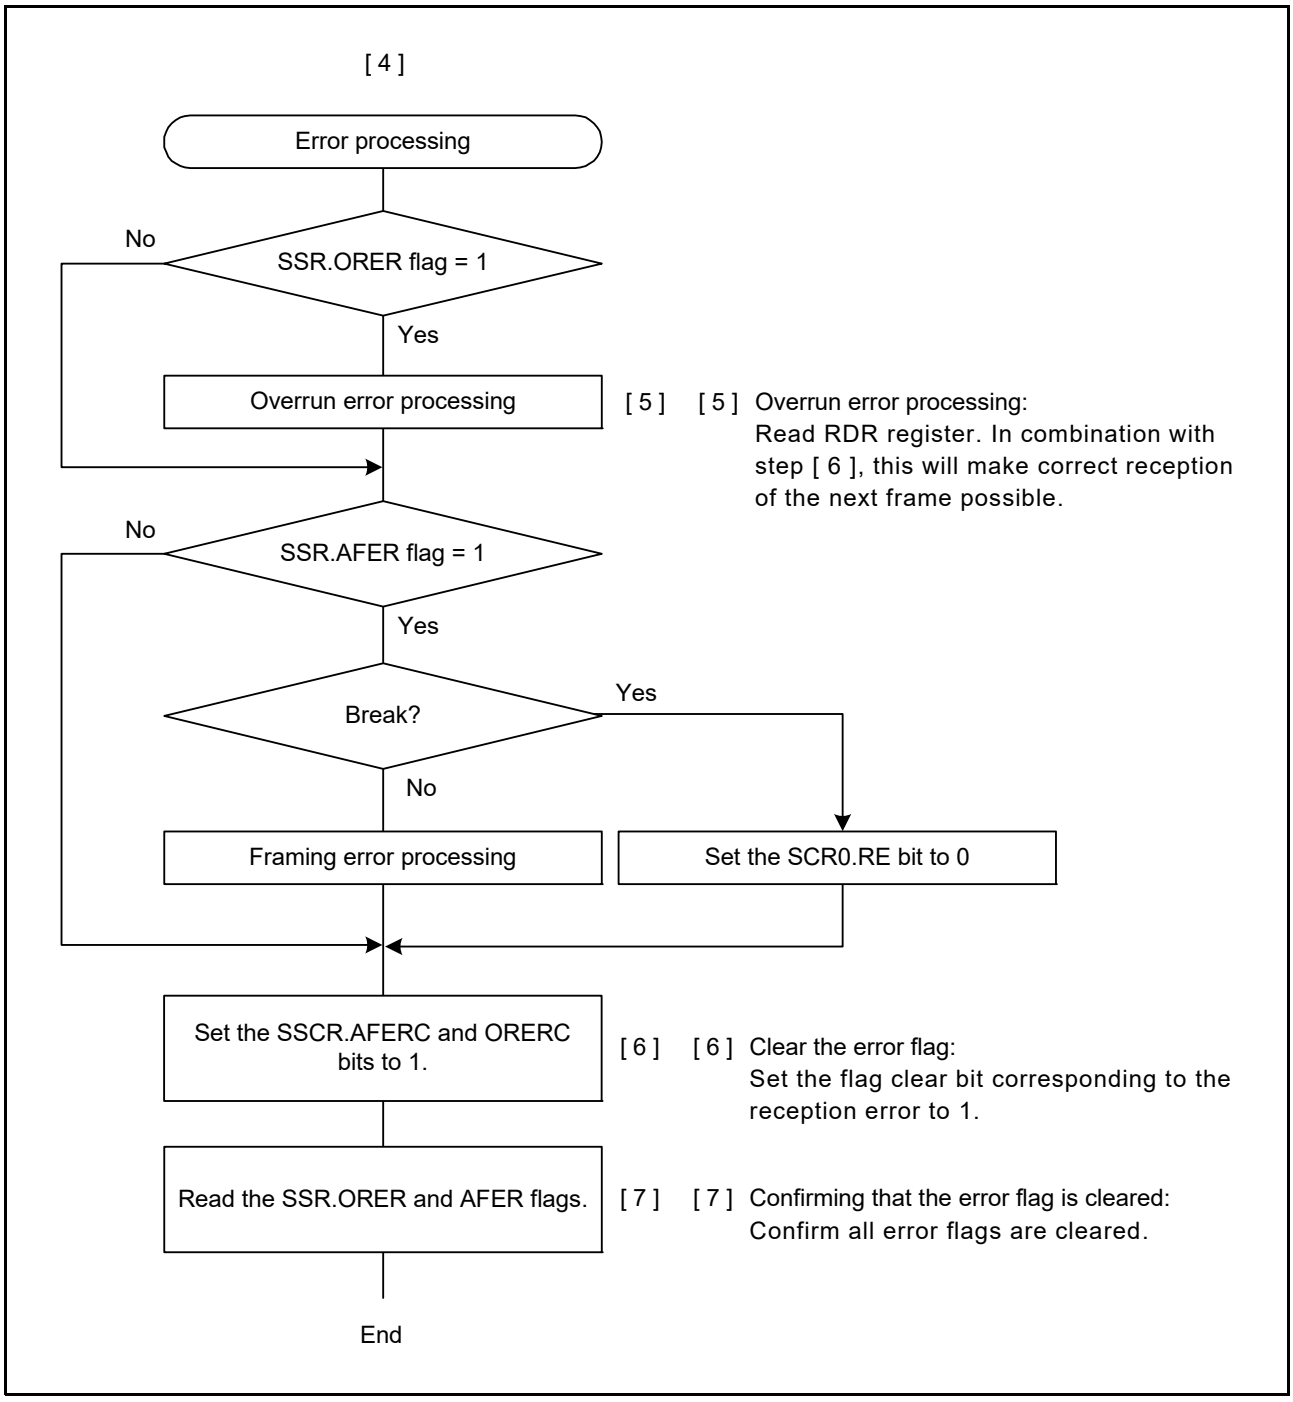

Figure 33.30 Example of Multi-Processor Serial Reception Flowchart (2) (Non-FIFO Mode)

(2) FIFO Mode

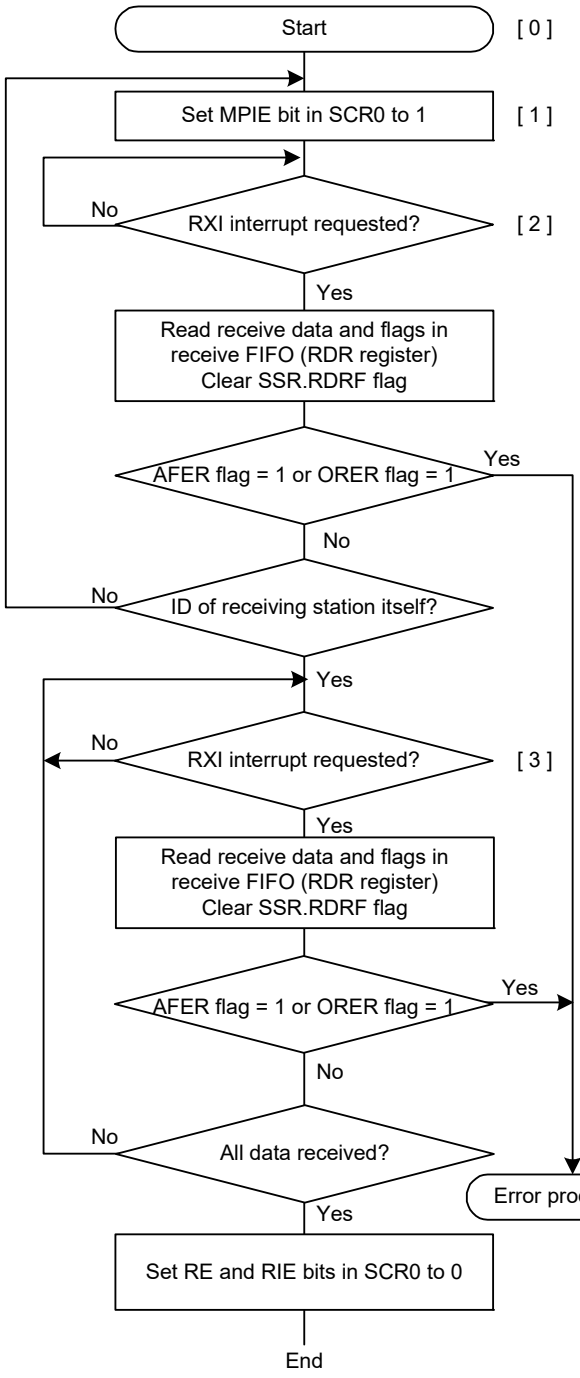
Table 33.34 shows an example of data format that is stored to receive FIFO (RDR register) in multi-processor mode. MPB flag is stored in bit9 of RDR register. 0 is stored to APER and PER flags. Data is stored to receive FIFO RDAT[8:0] bits corresponded to data length. It is stored to 0 for unused bits. Reading the receive FIFO (RDR register) updates the FER, PER, MPB flags and receive data (RDAT[8:0] bits) in the receive FIFO (RDR register) with the next received data. The AFER, APER, and ORER flags in the receive FIFO (RDR register) always reflect the status of the corresponding flags in the SSR and RFSR registers.

Table 33.34 Data Format in Multi-Processor Mode that is Stored to Receive FIFO (FIFO Mode)

Data Length	Register setting		Received Data in RDR Register															
	SCR3	CHR[1:0]	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	1	0	0	0	FER	PER	DR	MPB	0	0	RDAT[6:0]						
8 bits	1	0	0	0	0	FER	PER	DR	MPB	0	RDAT[7:0]							
9 bits	0	0 or 1	0	0	0	FER	PER	DR	MPB	RDAT[8:0]								
Data Length	**SCR3**	**CHR[1:0]**	**b31**	**b30**	**b29**	**b28**	**b27**	**b26**	**b25**	**b24**	**b23**	**b22**	**b21**	**b20**	**b19**	**b18**	**b17**	**b16**
7 bits	1	1	0	0	0	AFER	APER	0	0	ORER	0	0	0	0	0	0	0	0
8 bits	1	0	0	0	0	AFER	APER	0	0	ORER	0	0	0	0	0	0	0	0
9 bits	0	0 or 1	0	0	0	AFER	APER	0	0	ORER	0	0	0	0	0	0	0	0

Note: When data length is 7bit, it can read always 0 in RDAT[8:7] bits.
When data length is 8bit, it can read always 0 in RDAT[8] bit.

Figure 33.31 shows a sample flowchart for multi-processor data reception in FIFO mode. When the MPIE bit in SCR0 register is set to 1, reading the communication data is skipped until reception of the communication data in which the multiprocessor bit is set to 1. When the communication data in which the multi-processor bit is set to 1 is received, the received data, MPB flag and each errors are transferred to receive FIFO (RDR register), and the MPIE bit in SCR0 register is automatically cleared, thus returning to a normal reception operation. After a framing error occurred and SSR.AFER flag is set to 1, but RSCI continues data reception.
The other operations are the same as the operations in asynchronous mode with FIFO enabled.



[0] Set the SCR3.FM and MP bits to 1.
Also, set the FCR.RTRG[4:0] bits to 00001b and DRES bit to 0 to generate an RXI interrupt request when data with the MPB flag set to 1 is received.

[1] ID reception cycle:
Set SCR0.MPIE bit to 1. And wait for ID reception. If you set this bits at initialization, you can skip this Step.

[2] RSCI status confirmation and reception and comparison of ID:
RSCI skips the received data until it receives the data with the MPB flag set to 1. When receiving data with the MPB flag set to 1, RSCI generates an RXI interrupt request.
In the RXI interrupt routine, read the data from the receive FIFO (RDR register) and compare it with the ID of the receiving station itself. If the ID does not match the ID of the receiving station itself, set the MPIE bit to 1 again and wait for another RXI interrupt request. If it matches the ID of the receiving station itself, set the receive FIFO threshold to the desired value.

[3] Data reception at an RXI interrupt:
Read data in the receive FIFO (RDR register) once in the RXI interrupt routine.

[4] Receive error processing and break detection:
If a receive error occurs, an error is identified by reading ORER and AFER flags in SSR register (There is no problem reading the SSR.ORER and AFER flags again.). After performing the appropriate error processing be sure to clear the ORER and AFER flags. In the case of a framing error, a break can be detected by reading the SSR.RXDMON flag.

Figure 33.31 Example Flowchart of Serial Reception in Multi-Processor Mode (1) (FIFO Mode)

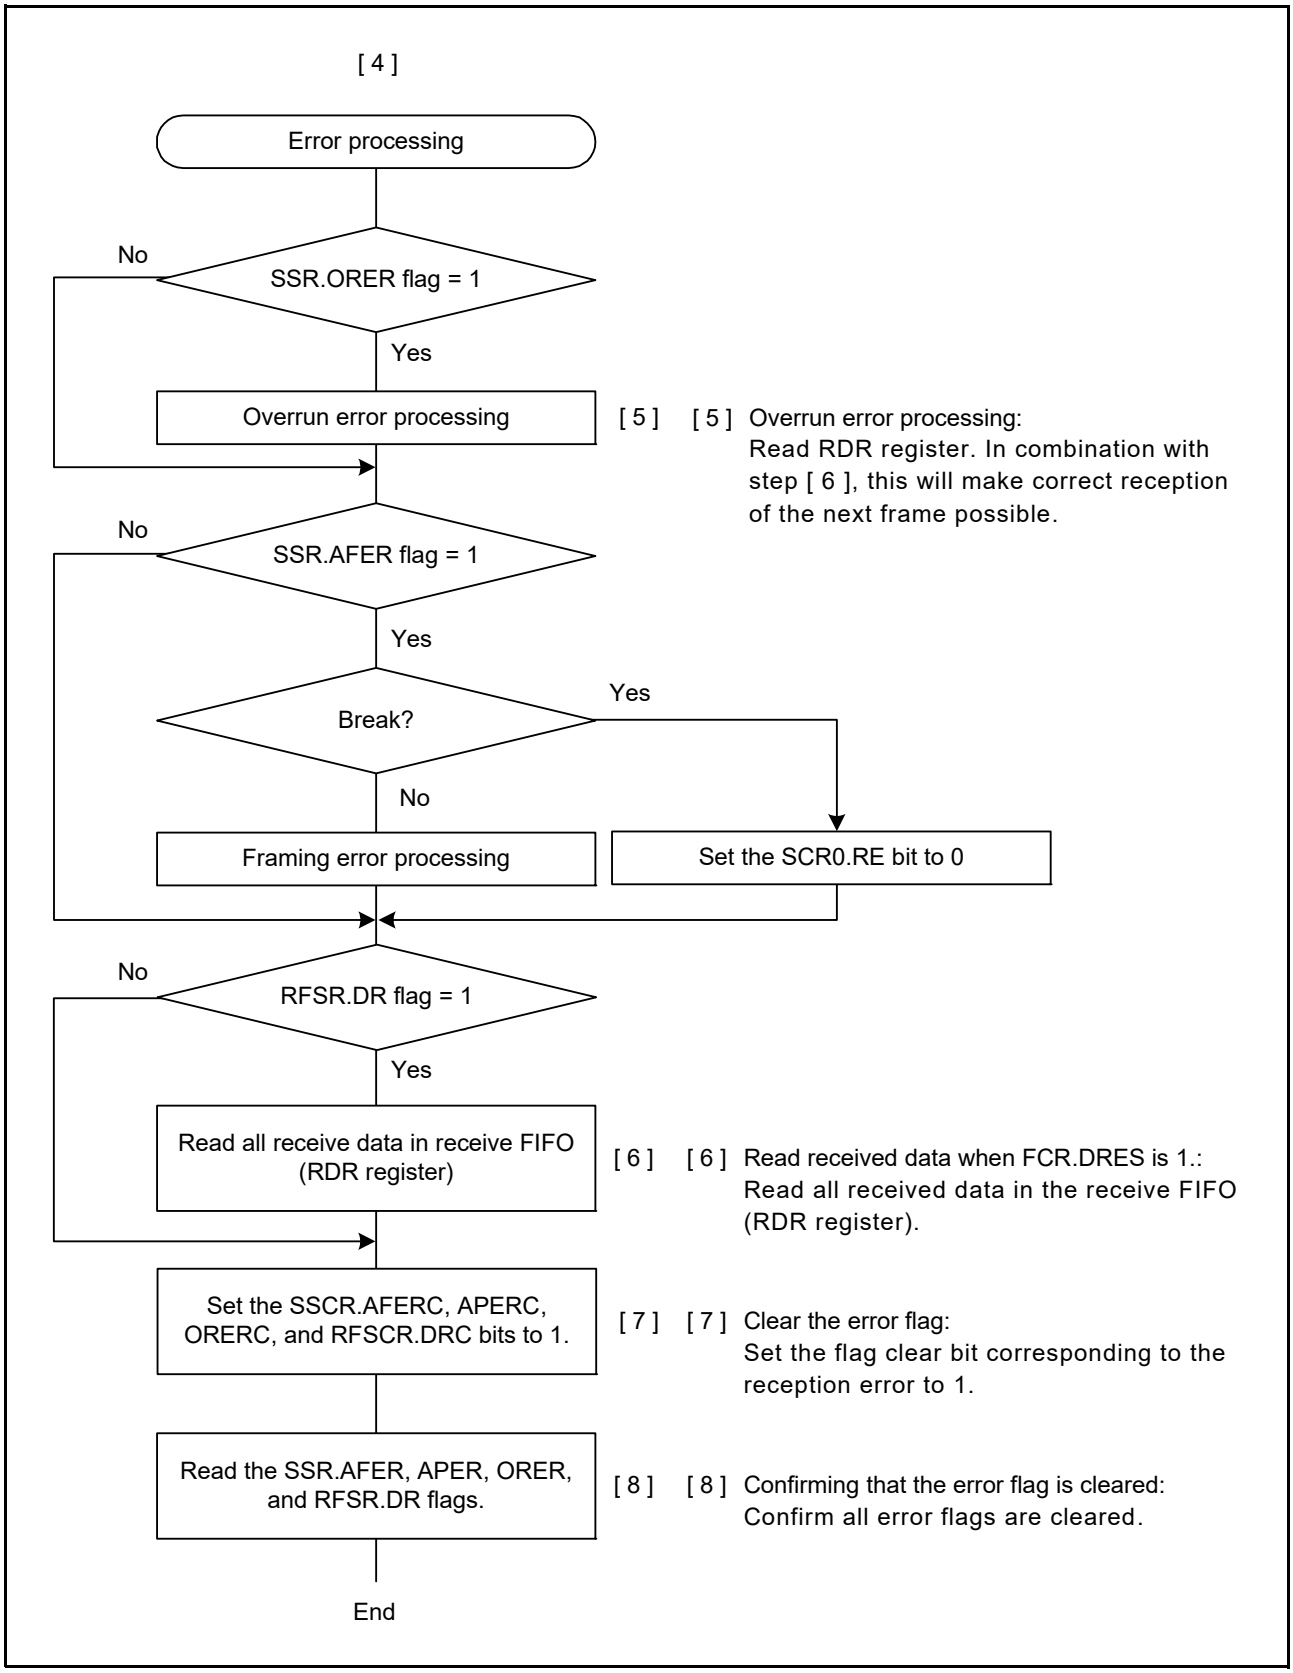


Figure 33.32 Example Flowchart of Serial Reception in Multi-Processor Mode (2) (FIFO Mode)

33.5 Manchester Mode

In manchester mode, the transmit or receive serial data is coded in Manchester encoding.
Figure 33.33 shows the conceptual image of Manchester encoding.

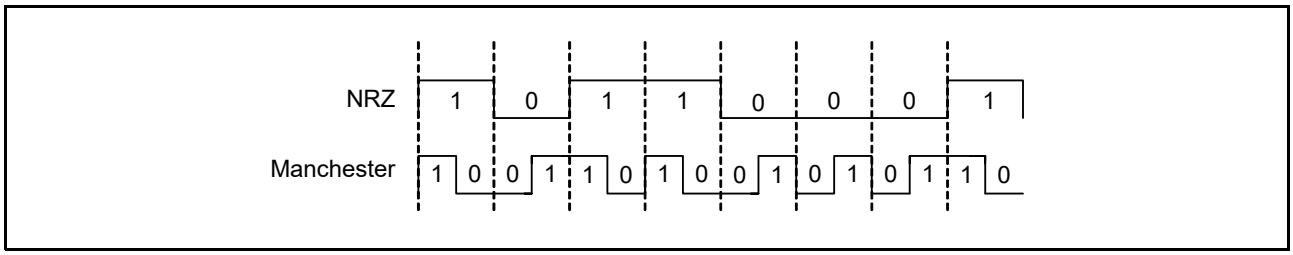

Figure 33.33 Example of Manchester Encoding

In manchester mode, a preface and a start bit area are added to the transmit data in the register to configure a transmit frame. For transmission, data is encoded in Manchester encoding. When data is received, frames having the same format as transmitted frames are detected and Manchester decoding is performed.
For details on the frame format, see section 33.5.1, Frame Format.

33.5.1 Frame Format

Figure 33.34 shows the frame format in manchester mode.
In the upper half of the figure, relevant setting registers are shown.
The preface area and the data area are encoded in Manchester encoding.

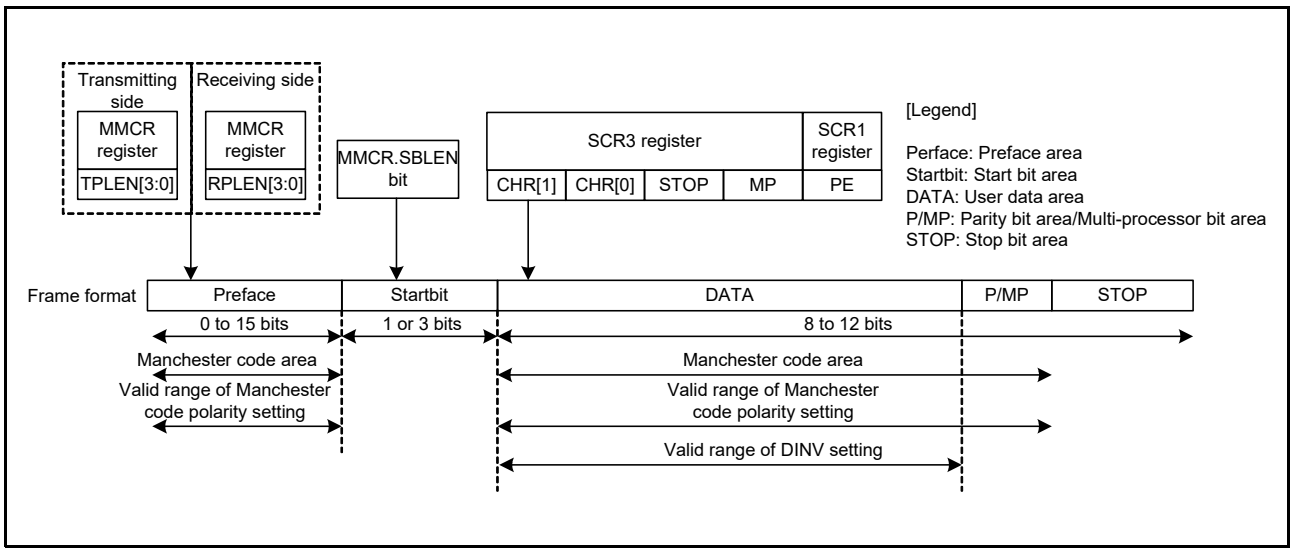

Figure 33.34 Frame Format in Manchester Mode

(1) Preface Area

This is a fixed pattern area located at the beginning of each frame.
Different registers are used to set the preface area for transmission and reception. The preface length is determined by setting MMCR.TPLEN[3:0] bits for transmission. It is determined by setting MMCR.RPLEN[3:0] bits for reception.
If it is set to 0, the transmit preface is disabled and is not added.
If it is set to 1d to 15d, a preface whose length is determined by this setting is added.
(For example, if it is set to 1d, a 1-bit preface is added. If it is set to 15d, a 15-bit preface is added.)
In addition, the preface pattern can be changed by setting, and it can be selected from four types of patterns by setting

MMCR.TPPAT[1:0] bits for transmission and MMCR.RPPAT[1:0] bits for reception.
Figure 33.35 shows how the preface pattern is set. The preface area and the start bit area are added for each communication frame.

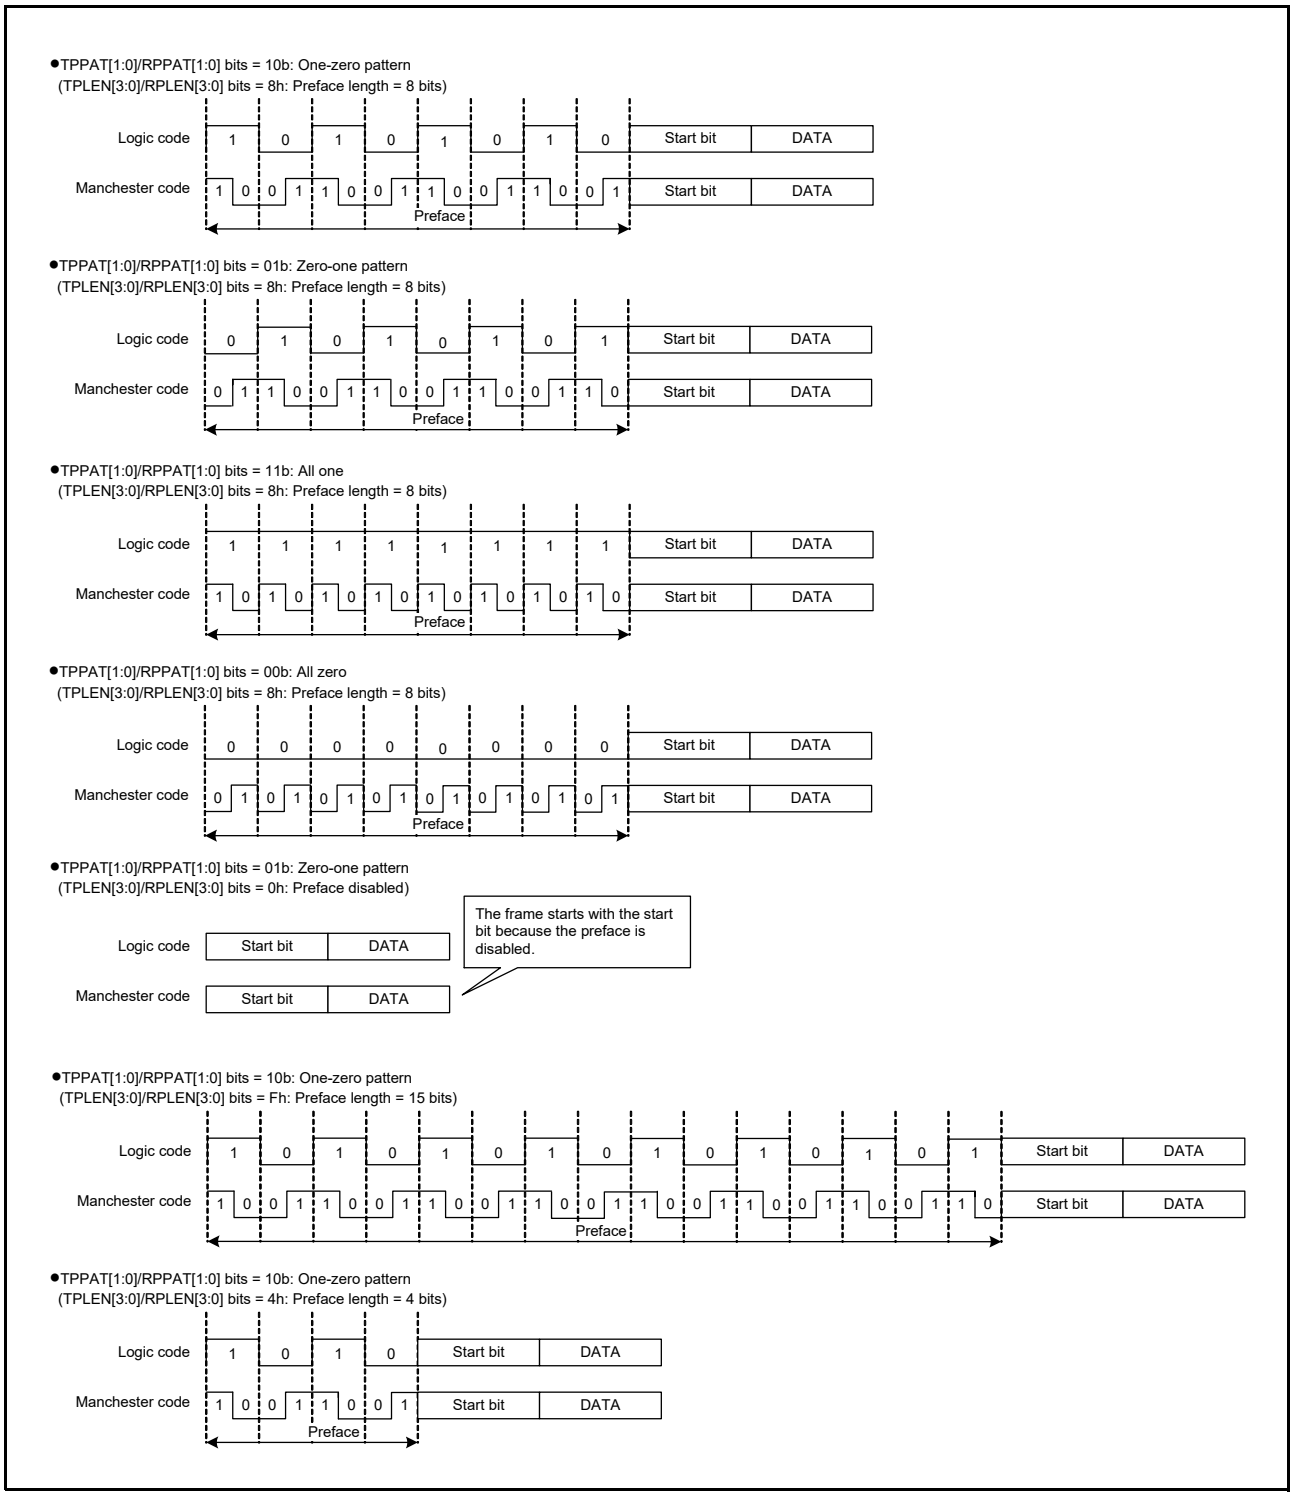

Figure 33.35 Preface Pattern Setting Example

(2) Start Bit Area

This is an area indicating the start of valid data in a frame. It is added after the preface area.
The start bit length is determined by MMCR.SBLEN bit setting. When MMCR.SBLEN bit = 0, the start bit length is 1 bit. When MMCR.SBLEN bit = 1, the start bit length is 3 bits.
When MMCR.SBLEN bit = 1, the Sync type can be selected from command Sync and data Sync.
Command Sync means the three start bits are added as a one-to-zero transition.
Data Sync means the three start bits are added as a zero-to-one transition.
The Sync type is determined by the MMCR.SYNCE, MMCR.SBPTN and TDR.SYNC bits settings. (When receiving, the received result is applied to MMSR.RSYNC bit.)
When MMCR.SBLEN bit = 0, the start bit is added as a zero-to-one or one-to-zero transition. The selection is determined by the MMCR.SBPTN setting.
The MMCR.SYNCE bit specifies the destination to be referred to when setting for transmission. When the MMCR.SYNCE bit is set to 1, the MMCR.SBPTN setting is referred to. When the MMCR.SYNCE bit is set to 0, the TDR.SYNC bit setting is referred to.
Figure 33.36 shows the state of the start bit area according to the settings in the MMCR.SYNCE, MMCR.SBPTN and TDR.SYNC bits in the case of transmission. Figure 33.37 shows that in the case of reception.
The start bit(s) is not affected by the MMCR.ENCS bit or MMCR.DECS bit setting.

Register Setting				Output Signal	Output Start Bit
MMCR			TDR	Output TXD Waveform	
SBLEN	SYNCE	SBPTN	SYNC		
0	d.c.	0	d.c.		1bit 0 to 1 transition
0	d.c.	1	d.c.		1bit 1 to 0 transition
1	0	0	d.c.		3bit 0 to 1 transition
1	0	1	d.c.		3bit 1 to 0 transition
1	1	d.c.	0		3bit 0 to 1 transition
1	1	d.c.	1		3bit 0 to 1 transition

d.c.: don't care
Preface: Preface area
START: Start bit area
DATA: User data area
P: Parity bit area
MP: Multi-processor bit area
STOP: Stop bit area

Figure 33.36 Settings Related to and Format of the Start Bit Area at Transmission

Register Setting				Input Signal	Start Bit Detection Result *1	Register Indication
MMCR			TDR	RXD Input Waveform		MMSR.RSYNC
SBLEN	SYNCE	SBPTN	SYNC			
0	d.c.	0	d.c.		Normal start bit (1 bit: 0 to 1 transition)	0

d.c.: don't care
Preface: Preface area
START: Start bit area
DATA: User data area
P: Parity bit area
MP: Multi-processor bit area
STOP: Stop bit area

Note 1. Data other than the start bit is assumed to be normal.

Figure 33.37 Settings Related to and Judgment of the Start Bit Area at Reception

(3) Data

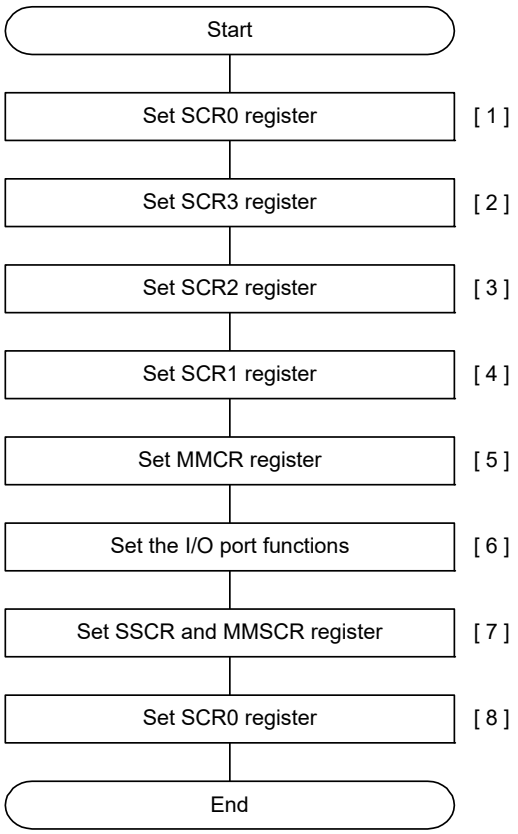
Since the format of the data area is the same as that of the asynchronous mode, see section 33.3.1, Serial Data Transfer Format.
As shown in Figure 33.34, Frame Format in Manchester Mode, the stop bit is not included in the manchester encoding range.

33.5.2 Clock

As the transfer clock in manchester mode, the clock generated by the on-chip baud rate generator is used by setting the SCR2.CKS[1:0] bits.
Also it is possible to set the oversampling (transfer rate of one bit period) by SCR2.ABCS bit. When the SCR2.ABCS bit is set to 0, oversampling ×16 is selected with the one-bit period being 16 cycles of the base clock. When the SCR2.ABCS bit is set to 1, oversampling ×8 is selected with the one-bit period being 8 cycles of the base clock.

33.5.3 RSCI Initialization of Manchester Mode

Before transferring data, write 0 to SCR0.TE and SCR0.RE bits (or write the initial value to SCR0 register), and initialize the RSCI following the example of flowchart shown in Figure 33.38.
Be sure to write 0 to SCR0.TE and SCR0.RE bits before changing the operation mode or communication format.
Note that setting the SCR0.RE bit to 0 initializes none of the SSR.ORER, AFER, APER, RDRF, MMSR.MCER, SYER, PFER and SBER flags, and the RDR registers.
Note also that switching the value of SCR0.TE bit from 0 to 1 when SCR0.TIE bit is 1 generates a TXI interrupt request.



[1] Set the following bits of SCR0 register to 0.
TEIE, TIE, RIE, TE, RE
If you have not changed from the initial settings, you can skip this step.

[2] Set the driver control, multi-processor communication, the communication mode, transmission/reception format, and clock enable.
Leave unused bits such as CPOL and CPHA bits at their initial values.

[3] Set the clock selection, bit rate setting.
Leave unused function bits at their initial values.

[4] Set the noise filter, loopback control, communication terminal status, parity check, and CTS/RTS function.

[5] Set manchester transmission/reception setting.
Start bit setting, retiming setting, manchester polarity setting, transmission preface setting, reception preface setting.

[6] Set the I/O port so that the required pin function is valid among the TXDn, RXDn, and SCKn pins.

[7] Set 1 to the following clear bits in the SSCR and MMSCR registers to clear the target flag.
SSCR.RDRFC, AFERC, APERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC
MMSCR.MCERC, SBERC, SYERC, PFERC
This procedure can be omitted for the initial setting after reset.

[8] Set the SCR0.TE or RE bit to 1. To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time. Set the multiprocessor function. The TXDn and RXDn pins can be used by setting the TE and RE bits.

Figure 33.38 RSCI Initialization Flow in Manchester Mode

33.5.4 Double Speed Operation

When the ABCS bit in SCR2 register is set to 1 and eight pulses of the base clock for a 1 bit period is selected, the RSCI operates on the bit rate twice that of when ABCS is set to 0.
When the BGDM bit in SCR2 register is set to 1, the cycle of the base clock is reduced to half and the RSCI operates on the bit rate twice that of when BGDM is set to 0.
When the ABCS bit in SCR2 register and the BGDM bit in SCR2 register are set to 1, the RSCI operates on the bit rate four times that of when the ABCS bit in SCR2 register and the BGDM bit in SCR2 register are set to 0.

33.5.5 CTS, RTS Functions

The CTS function controls transmission using the CTSn # pin input. Setting the CTSE bit in SCR1 register to 1 enables the CTS function. The CTSn#/RTSn# pin can be set as a multiplexed pin which allows one pin to be used for either function, or as dedicated pins with each pin for a single function. Use the CRSEP bit in SCR1 register for this setting.
When the CTS function is enabled, transmission starts only when the CTSn# pin is at the low level.
Even if the level of CTSn# pin goes High after transmission starts, does not affect transmission of the current frame, which continues.
The RTS function uses output on the RTSn# pin to request transmission. When the RSCI is ready to receive, it outputs a low level to the RTSn# pin, Conditions for output of the low level and high level are as follows:
[Conditions for low-level output]
When all conditions listed below are satisfied:

- The value of the SCR0.RE bit is 1.
- There are no received data yet to be read and reception is not in progress.
- All of the following flags are set to 0:
  SSR.ORER, AFER, APER and MMSR.MCER, SBER (when SBERIE bit = 1), SYER (when SYERIE bit = 1), PFER (when PFERIE bit = 1)

[Conditions for high-level output]
When the conditions for low output are not satisfied.

33.5.6 Serial Data Transmission in Manchester Mode

The RSCI encodes data in Manchester encoding and sends the resultant data in manchester mode.
When the polarity setting (MMCR.ENCS bit) set to 0, logic 0 is coded as a zero-to-one transition in Manchester code and logic 1 is coded as a one-to-zero transition in Manchester code.
When the polarity setting (MMCR.ENCS bit) set to 1, logic 0 is coded as a one-to-zero transition in Manchester code and logic 1 is coded as a zero-to-one transition in Manchester code.
For this reason, a level transition occurs with the Manchester encoded data in the middle of individual logic data. (See Figure 33.33)
The transmitter constructs transmit frames in a specific format by adding a preface area to data and setting the start bit(s) according to the polarity setting and sends resultant serial data.
For details on the frame format, see section 33.5.1, Frame Format.
Figure 33.39 shows the flowchart in transmission. At transmission starts, set the SCR0.TIE and SCR0.TE bits to 1 simultaneously with one instruction. Then, a TXI interrupt request is generated.
Figure 33.40 to Figure 33.42 show examples of the operation for serial transmission in manchester mode.

Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 33.42 Example of End-of-Transmission Operation for Serial Transmission in Manchester Mode (with Preface but without the CTS Function)

33.5.7 Serial Data Reception in Manchester Mode

In manchester mode, the RSCI operates on a base clock with a frequency of 16 times*1 the bit rate. Reception starts by sampling the falling edges of received data at the base clock. As shown in Figure 33.43, reception starts at a falling edge of the received data and it continues if the received data keeps low for the duration of 1/4 bit. If the received data goes high within the duration of 1/4 bit, the RSCI judges it as an error and waits for a falling edge again.
If a high level is expected in the first half of a bit in the received data, the RSCI judges a low level that continues for one base clock cycle as an error and ignores the change to the low level.

Note 1. This is the case when SCR2.ABCS bit = 0. When SCR2.ABCS bit = 1, the RSCI operates on a base clock with a frequency of 8 times the bit rate.

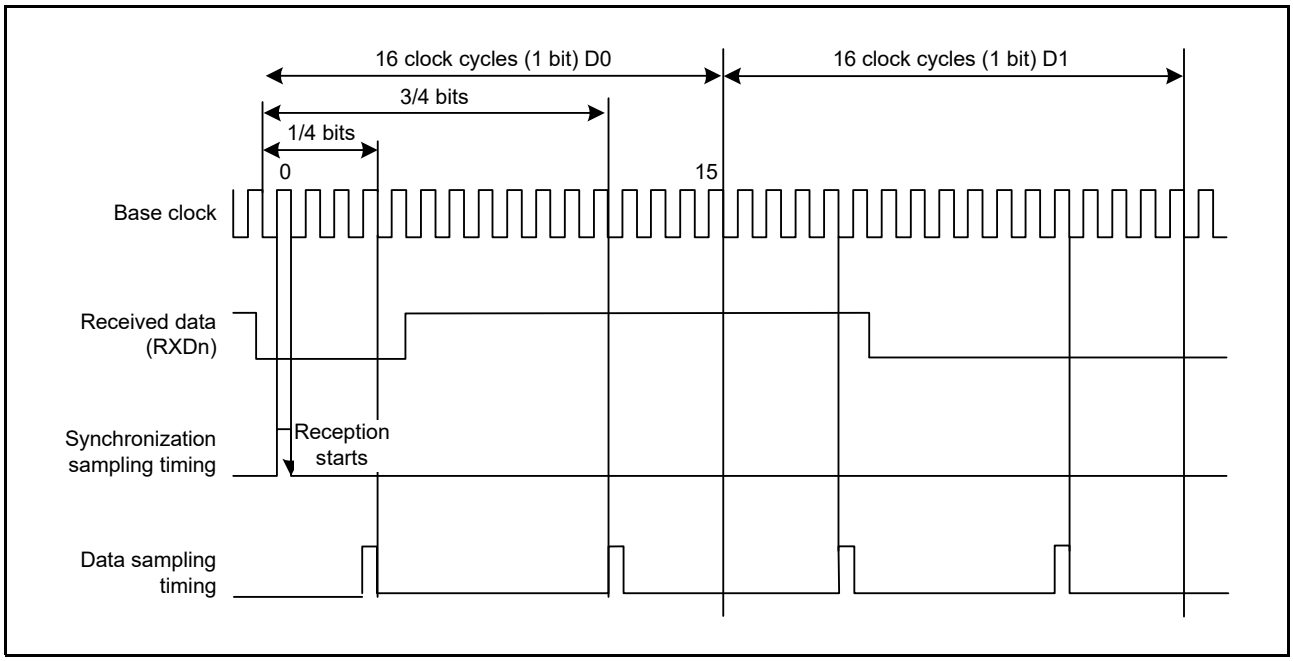

Figure 33.43 Data Reception Sampling Timing in Manchester Mode

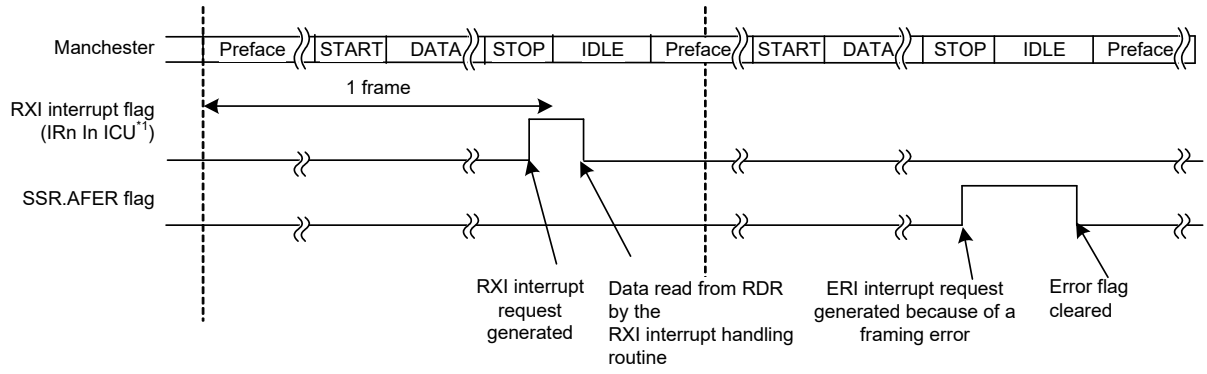
In manchester mode, data reception starts with detection of a preface and start bit area.
The RSCI checks the input from the RXDn pin to see whether a preface is added based on the value of MMCR.RPLEN[3:0] bits.
If the preface is disabled (MMCR.RPLEN[3:0] bits = 0), it moves on to the detection of a start bit area without detecting a preface.
When a preface is enabled, it identifies a preface pattern setting according to the set value in MMCR.RPPAT[1:0] bits, and compares it with the RXD input for a pattern match to detect a preface pattern.
Upon detection of a preface pattern match, it judges it as a normal preface and moves on to the detection of a start bit area.
If detecting a preface pattern mismatch or a Manchester code error in the preface area, it judges it as a preface error and asserts a preface error (PFER).
For start bit detection, the RSCI selects an expected value based on the register settings (MMCR.SBLEN and SBPTN bits), compares it with the RXD input for a pattern match to detect a start bit area. Upon detection of a start bit pattern match, it judges it as a normal start bit area and moves on to the data processing.
Only when a preface and a start bit area are detected normally, it moves on to the next phase of data reception.
Upon detection of a start bit pattern mismatch, it asserts a start bit error flag (SBER).
In data processing, the RSCI shifts the data by the expected received data length based on the register settings (SCR3.CHR[1:0] bits) through the RSR register. If two sampling points in a bit of the received data are identical, the RSCI judges this as a Manchester code error. For details, see section 33.5.11, Errors in Manchester Mode (4).
When the parity function is disabled (SCR1.PE bit = 0), the RSCI moves on to the next phase of stop bit detection. When

the parity function is enabled (SCR1.PE bit = 1), the RSCI performs parity checking. If detecting a parity error, it asserts a parity error flag (APER), and then moves on to stop-bit detection.
In stop bit detection, the RSCI checks the following in the stop bit area of the received frame:
It has two sampling points in a bit. If both points are at the high level, the bit is recognized as a normal stop bit and the data is stored in the RDR register. At least one low-level point is judged as an abnormal stop bit, causing a framing error flag (AFER) to be set. Even when an error is detected, the received data is stored in the RDR register as abnormal data.
Figure 33.44 shows an example of the operation for serial data reception in manchester mode.

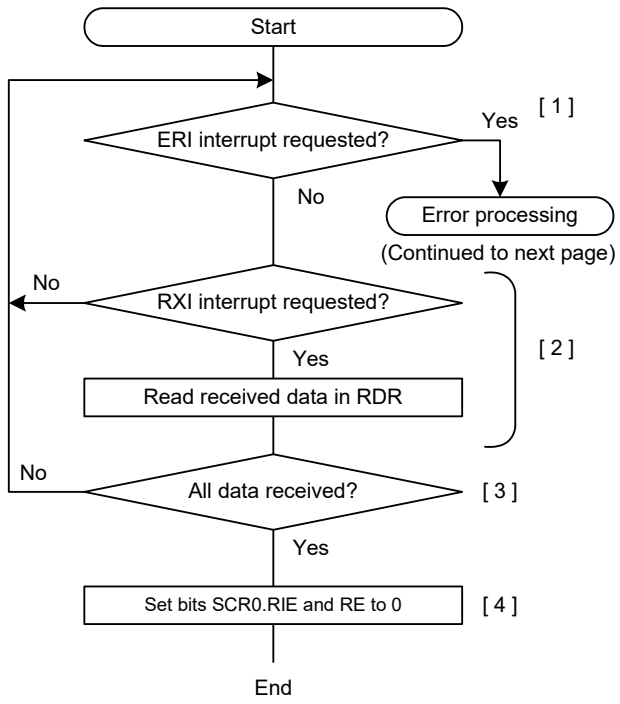


Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 33.44 Example of Operation for Serial Data Reception in Manchester Mode (with a Preface)

For the state of each status flag in the SSR and MMSR registers and RXD input processing when a receive error is detected, see section 33.5.11, Errors in Manchester Mode.
If a receive error is detected, an ERI interrupt request is generated but an RXI interrupt request is not generated.
Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, AFER, APER, MCER, SYER*2, PFER*2, SBER*2 flags to 0 before resuming reception. Also, be sure to read the RDR register during overrun error processing. When a reception is forcibly terminated by setting the SCR0.RE bit to 0 during operation, read the RDR register because received data which has not yet been read may be left in the RDR register.
Figure 33.45 and Figure 33.46 show examples of serial data reception flowchart in manchester mode.

Note 2. Effective when the corresponding bit is enabled.



[1] Receive error processing:
When a receive error occurs, RSCI generates an ERI interrupt. An error is identified by reading the ORER, APER, AFER in SSR register and MCER, SBER, SYER, PFER in MMSR register. After performing the appropriate error processing, always set the ORER, APER, AFER, MCER, SBER, SYER, PFER flags to 0. Reception cannot be resumed if any of these flags is set to 1.

Note: Each of the PFER, SYER, SBER bits in MMSR register has an enable bit (PFERIE, SYERIE, and SBERIE bits in MMCR). If the corresponding enable bit is set to 0 (disable), the flag value does not affect the communication. Perform error processing as required.

[2] Read the received data in RDR register once in the RXI interrupt handling routine.

[3] Serial reception continuation procedure:
To continue serial reception, before the stop bit of a frame is received, read data from RDR register in the RXI interrupt handling routine. The RDR data can also be read by activating the DMAC or DTC.

[4] Write 0 to SCR0.RIE and RE bits.

Figure 33.45 Example of Serial Data Reception in Manchester Mode (Normal)

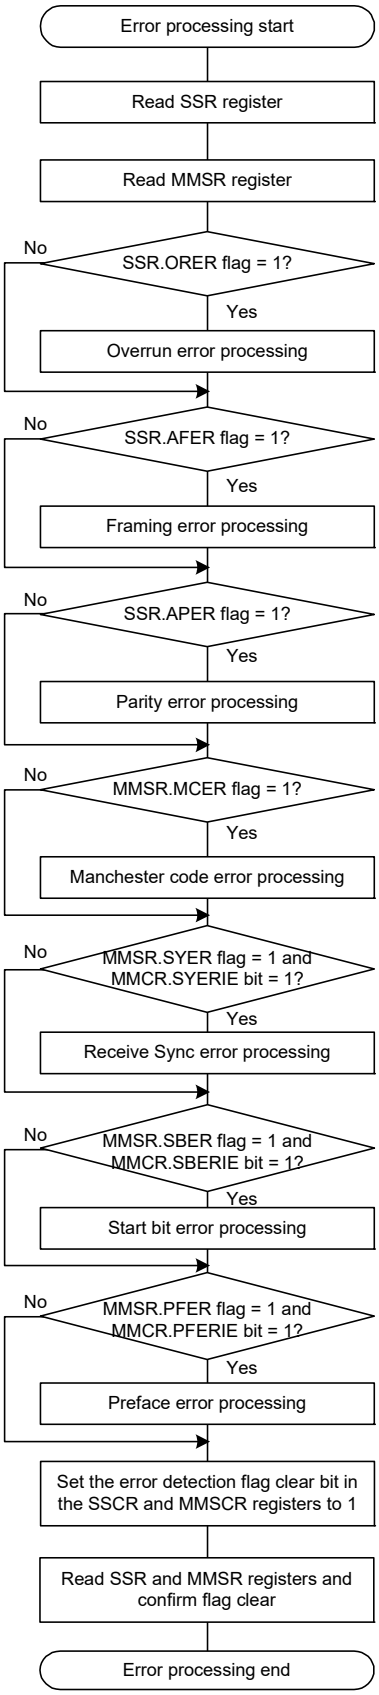


Figure 33.46 Example of Serial Reception Flowchart in Manchester Mode (Error Processing)

33.5.8 Operation When Multi-Processor Bit is Used

See section 33.4, Multi-Processor Communication Function (1) for the operation in manchester mode when using multi-processor mode because the operation is the same.
A preface and a start bit area are added to the frame format in manchester mode.
See Figure 33.46 for error processing in manchester mode for the reception flowchart (Figure 33.29). Refer to Table 33.37 for the operation status when detecting various errors.

33.5.9 Receive Retiming

This function corrects the timing for each central edge of the bit, taking advantage of the fact that each bit has an edge in the center in Manchester code.
The receive retiming function can be turned on or off by setting the SADJE bit in the MMCR register.
When the receive retiming function is turned off (MMCR.SADJE bit = 0), retiming is not performed, causing misalignment between the internal clock and the RXD input to be accumulated and the receive margin to be reduced.
When the receive retiming function is turned on (MMCR.SADJE bit = 1), retiming is performed for the preface area, the start bit area*1, and the data area (excluding the stop bit).

Note 1. Retiming is not performed for the start bit area if the preface length is 0 and the start bit length is 3.

As an example, the receive retiming when oversampling ×16 is selected is shown below.
When detecting an RXD input edge two to four cycles before the expected receive cycle, the receive processing is shortened by one sampling CLK cycle.
When detecting a RXD input edge two to three cycles after the expected receive cycle, the receive processing is extended by one sampling CLK cycle.
(Even if the clock is misaligned with the data by more than two cycles, one cycle is corrected for each bit.)
Figure 33.47 shows the conceptual image of receive retiming range.
When detecting an edge in the tolerance area in the figure, data is received as is without making correction.
When detecting an edge in the SyncJump area in the figure, data is corrected for reception.
When detecting an edge in the SyncError area in the figure, data is received as abnormal data with no correction made.
For a Manchester code error (data matches at the 1/4-phase and 3/4-phase sampling points), the RSCI reports a code error.

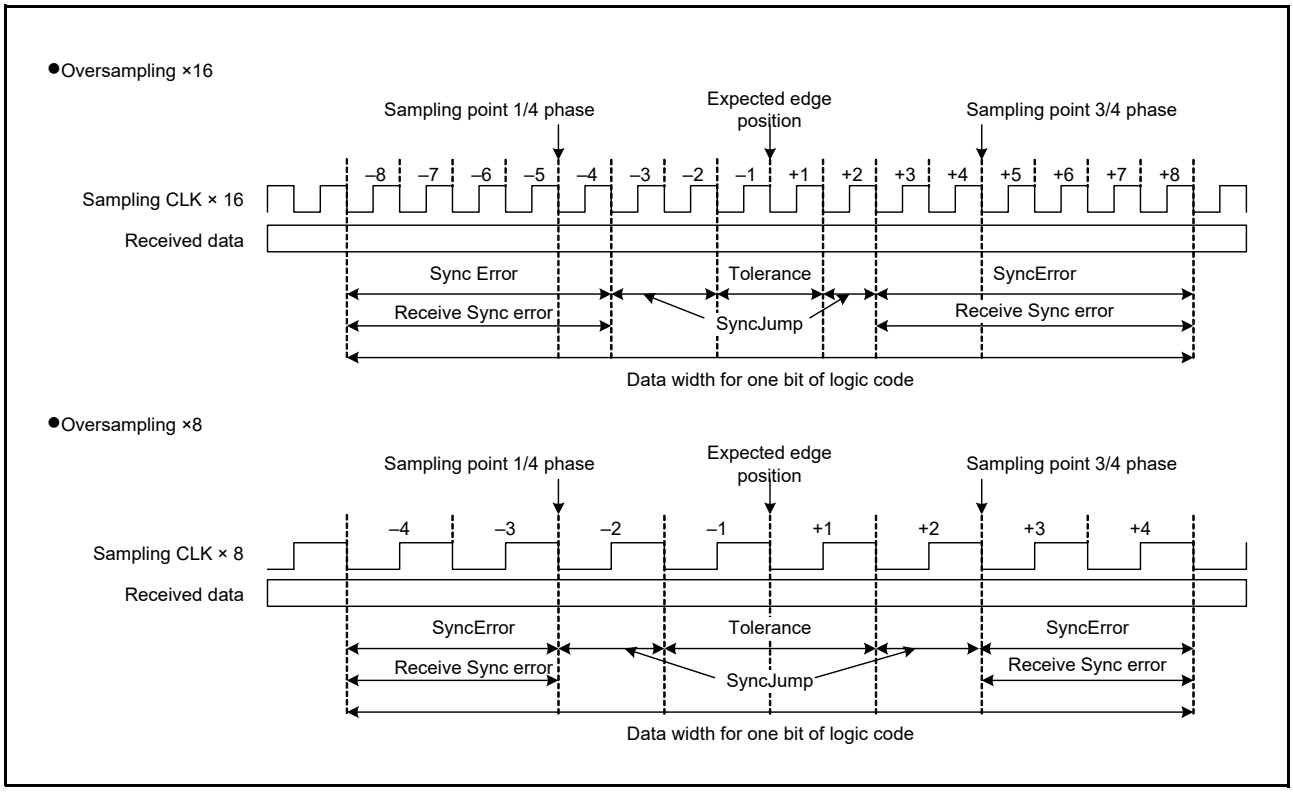

Figure 33.47 Conceptual Image of Reception Retiming Range

33.5.10 Polarity Setting for Manchester Code

The polarity of the Manchester code can be set with the Manchester Control Register (MMCR).

It can be set separately for transmission and reception. Use the MMCR.ENCS bit to set the polarity for transmission and the MMCR.DECS bit to set the polarity for reception.

The Manchester code polarity setting is valid for the preface area, the data area, and the parity or multi-processor area.

When the initial settings (ENCS/DECS bit = 0) are used for the polarity of Manchester code, logic 0 is encoded as a zero-to-one transition in Manchester code and logic 1 is encoded as a one-to-zero transition in Manchester code.

If the settings are changed to ENCS/DECS bit = 1, logic 0 is encoded as a one-to-zero transition in Manchester code and logic 1 is encoded as a zero-to-one transition in Manchester code. Figure 33.48 shows the conceptual image of the settings and operation.

Separately from the function above, the transmitted and received data in the data area can be inverted by the transmitted/received data inversion function (SCR3.DINV bit). Since the polarity of Manchester code (MMCR.ENCS/DECS bit) can be set separately from the transmitted/received data invert function (SCR3.DINV bit), if both are set to inversion (MMCR.ENCS/DECS bit = 1 and SCR3.DINV bit = 1), the transmitted and received data are set to initial state (inversion + inversion = normal).

The polarity of the start bit area can be set by a register different from the ones mentioned above.

Since a different register is used, the polarity of the start bit area is not affected by the polarity setting for Manchester code mentioned above.

For details on the setting for the start bit area, see section 33.5.1, Frame Format (2).

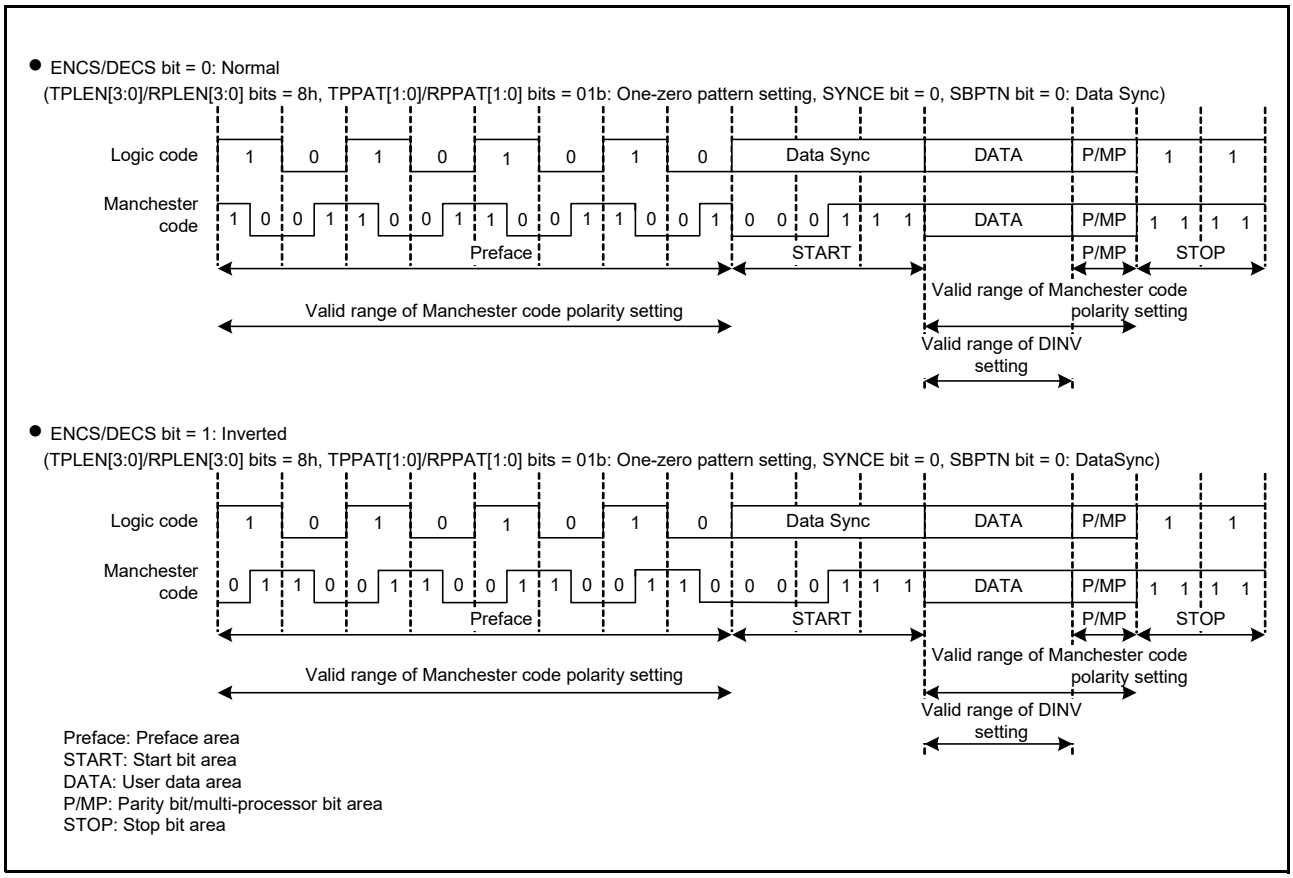

Figure 33.48 Valid Range of the Manchester Code Polarity Setting

33.5.11 Errors in Manchester Mode

There are the following errors in manchester mode:

(1) Parity error
(2) Over run error
(3) Framing error
(4) Manchester code error
(5) Preface error
(6) Start bit error
(7) Receive Sync error

For errors (1) to (3), see section 33.3.9, Serial Data Reception (Asynchronous Mode) (1) because they are the same as in asynchronous mode.
Each error is judged in each area, but they are reflected on flags and operations at the timing of 3/4-bit sampling of the STOP bit area. If a preface error or start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the previous information.
Table 33.35 lists the states of the serial status register when detecting errors and judgment about whether to store data in the RDR register.
Table 33.36 lists the errors that can be detected in each area of a Manchester frame. If a Preface error or Start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the result of the previous frame reception. Also, if an error is detected in the previous frame, data will not be received, but errors in the preface area and start bit area will update that flag. Table 33.37 shows the flags and actions in this case.

(4) Manchester Code Error

A Manchester code error is generated when a Manchester code error is detected.
In Manchester code, there must be an edge (transition) in the center of the bit.
In the data area of a received frame (including the parity/multi-processor bit), the values of the 1/4-bit and 3/4-bit sampling points are checked in each received 1-bit data, and a Manchester code error is determined if these two values matches.
If a Manchester code error is detected, the Manchester code error flag (MMSR.MCER flag) is asserted.
If a Manchester code error occurs, it is handled as an interrupt source and event source. If a Manchester error is detected, the next reception is not performed until the corresponding error flag is cleared.

(5) Preface Error

A preface error is generated when the preface pattern does not match or a Manchester code error is detected in the preface area. If a preface error is detected, the preface error flag (MMSR.PFER flag) is asserted.
It is possible to set whether to use this error flag as an interrupt source with the setting of the MMCR register.
When MMCR.PFERIE bit = 1, a preface error is handled as an interrupt source or event source. If a preface error is detected, the next reception is not performed until the corresponding error flag is cleared.
When MMCR.PFERIE bit = 0, a preface error is not handled as an interrupt source or event source, and the next reception is not halted. However, a preface error is notified to MMSR.PFER flag.

(6) Star Bit Error

A start bit error is generated when a mismatch is detected between the start bit area in the received frame and the preset start bit pattern. Upon detection of a start bit error, a start bit error flag (MMSR.SBER) is asserted.
It is possible to set whether to use the start bit error as an interrupt source with the setting of the MMCR register.
When MMCR.SBERIE bit = 1, a start bit error is handled as an interrupt source or event source. If a start bit error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MMCR.SBERIE bit = 0, a start bit error is not handled as an interrupt source or event source, and the next reception is not halted. However, a start bit error is notified to MMSR.SBER flag.

(7) Receive Sync Error (SyncError)

When the receive retiming function described in section 33.5.9, Receive Retiming is enabled, the receive retiming operation is performed.
If no edges are detected within the receive retiming range (SyncError area in Figure 33.47) when receive timing operation is being performed, a receive Sync error is generated. Upon detection of a receive Sync error, a receive Sync error flag (MMSR.SYER) is asserted. In areas not subject to receive retiming, receive Sync errors are not detected.
The preface area *1, the start bit area*1, *2, and the data area (excluding the stop bit) for which receive retiming operation is performed are checked.
It is possible to set whether to use the receive Sync error as an interrupt source with the setting of the MMCR register.
When MMCR.SYERIE bit = 1, a receive Sync error is handled as an interrupt source or event source. If a receive Sync error is detected, the next reception is not performed until the corresponding error flag is cleared.
When MMCR.SYERIE bit = 0, a receive Sync error is not handled as an interrupt source or event source, and the next reception is not halted. However, a receive Sync error is notified to MMSR.SYER flag.

Note 1. In the case of a frame that starts with a pattern that expects the first half of the bit to be High, it is excluded from retiming.
Note 2. In the start bit area, when there is no preface length and 3 bit start bit is set, it is not subject to retiming. Also, the 1st bit and the 2nd bit in the start bit area when 3 bit start bit is set are not subject to retiming.

Table 33.35 Flags in the Status Register and Receive Data Handling in Manchester

Flags in the SSR Register			Flags in the MMSR Register					
ORER	AFER	APER	MCER	SBER *1	PFER *1	SYER	Received Data	Received Error Status (ERI Interrupt/Event Generation)
0	0	0	0	0	0	0	Transfer to RDR	No error
0	1	0	0	0	0	0	Transfer to RDR	Framing error
0	0	1	0	0	0	0	Transfer to RDR	Parity error
0	1	1	0	0	0	0	Transfer to RDR	Framing error + Parity error
0	0	0	1	0	0	0	Transfer to RDR	Manchester code error
0	1	0	1	0	0	0	Transfer to RDR	Framing error + Manchester code error
0	0	1	1	0	0	0	Transfer to RDR	Parity error + Manchester code error
0	1	1	1	0	0	0	Transfer to RDR	Framing error + Parity error + Manchester code error
1	0	0	0	0	0	0	Lost	Overrun error
1	1	0	0	0	0	0	Lost	Overrun + Framing error
1	0	1	0	0	0	0	Lost	Overrun + Parity error
1	1	1	0	0	0	0	Lost	Overrun + Framing error + Parity error
1	0	0	1	0	0	0	Lost	Overrun + Manchester code error
1	1	0	1	0	0	0	Lost	Overrun + Framing error + Manchester code error
1	0	1	1	0	0	0	Lost	Overrun + Parity error + Manchester code error
1	1	1	1	0	0	0	Lost	Overrun + Framing error + Parity error + Manchester code error
0	Combination of the above errors			0	0	1	Transfer to RDR	Error above + Receive Sync error*2
1				0	0	1	Lost	Error above + Receive Sync error*2
hold	hold	hold	hold	0	1	0	Lost	Preface error*3
hold	hold	hold	hold	1	0	0	Lost	Start bit error*3
hold	hold	hold	hold	0	1	1	Lost	Preface error*3 + Receive Sync error*2
hold	hold	hold	hold	1	0	1	Lost	Start bit error*3 + Receive Sync error*2

Note 1. Start bit error and preface error never become 1 at the same time.
Note 2. When MMCR.SYERIE bit = 1, ERI interrupt/event is generated by SYER factor.
Note 3. If MMCR.PFERIE bit = 1 or MMCR.SBERIE bit = 1, an ERI interrupt/event is generated when the corresponding flag is set.

Table 33.36 Errors Detectable in Each Area

	Preface Error (PFER)	Start Bit Error (SBER)	Manchester Code Error (MCER)	Receive Sync Error (SYER)	Parity Error (APER)	Framing Error (AFER)
Preface area	✓	—	—*1	✓*2	—	—
Start bit area	—	✓	—	✓*2	—	—
Data area	—	—	✓	✓	—	—
Parity area	—	—	✓	✓	✓	—
Multi-processor area	—	—	✓	✓	—	—
Stop bit area	—	—	—	—	—	✓

✓: Detected, —: Not detected
Note 1. When an Manchester code error occurs in the preface area, it is defined as a preface error.
Note 2. It may not be subject to receive Sync error detection. For details see section 33.5.11, Errors in Manchester Mode (7)

Table 33.37 Operation Status due to Presence/Absence of Error in Previous Frame and Operation Status List in Multiprocessor Mode (SCR0.MPIE Bit = 0)

Previous Frame	Each Area of the Frame					PFE RIE	SBE RIE	SYE RIE	Received Data	Error Flag	Interrupt Request	Event Signal
	Preface	Start Bit	Data	Parity Bit	Stop Bit							
No error	PFER, No SYER*1	No error	—	—	—	0	—	—	Lost	Set PFER*1	Not output	Not output
						1					Output	Output
	No error	SBER, No SYER*1	—	—	—	—	0	—	Lost	Set SBER*1	Not output	Not output
							1				Output	Output
	SYER, No PFER	No error	—	—	—	—	—	0	Transfer to RDR	Set SYER	Not output	Not output
								1	Lost		Output	Output
	No error	SYER, No SBER	—	—	—	—	—	0	Transfer to RDR	Set SYER	Not output	Not output
								1	Lost		Output	Output
	No error	No error	SYER		No error	—	—	0	Transfer to RDR	Set SYER	Not output	Not output
								1			Output	Output
	No error	No error	MCER		No error	—	—	—	Transfer to RDR	Set MCER	Output	Output
	No error	No error	—	APER	No error	—	—	—	Transfer to RDR	Set APER	Output	Output
	No error	No error	—	—	AFER	—	—	—	Transfer to RDR	Set AFER	Output	Output
	There is some error ORER					—	—	—	Lost	Set some flags*2	Output	Output
	No error	No error	No error	No error	No error, ORER	—	—	—	Lost	Set ORER	Output	Output
Some error*3, *6	PFER, No SYER*1	No error	—	—	—	0	—	—	Lost	Set PFER*1	Output*4	Not output*5
						1						
	No error	SBER, No SYER*1	—	—	—	—	0	—		Set SBER*1		
							1					
	SYER, No PFER	No error	—	—	—	—	—	0		Set SYER		
								1				
	No error	SYER, No SBER	—	—	—	—	—	0		Set SYER		
								1				
	No error	No error	SYER		No error	—	—	0		don't set any flags		
								1				
	No error	No error	MCER		No error	—	—	—				
	No error	No error	—	APER	No error	—	—	—				
	No error	No error	—	—	AFER	—	—	—				
	There is some error ORER					—	—	—				
	No error	No error	No error	No error	No error, ORER	—	—	—				

Note 1. If SYER is detected, the SYER flag is also set. Other operations are as shown in this table.
Note 2. Other detected error flags including ORER are also set.

Note 3. If all the error flags are cleared before the STOP bit is judged, the operation will be the same as the case where there is no error in the previous frame of this table.
Note 4. Since the ERI interrupt request is level output, it remains active due to errors in the previous frame regardless of the presence or absence of errors in the relevant frame.
Note 5. Since the error cause is continuously detected, the ERI event is not newly output regardless of the presence of errors in the relevant frame.
Note 6. For MMSR.PFER, SBER, and SYER, when each enable bit is set to disable, it is treated as no error.

Table 33.38 Operation Status List in Multiprocessor Mode (SCR0.MPIE Bit = 1)

MPB*1	Each Area of the Frame					PFERIE	SBERIE	SYERIE	Received Data	Error Flag	Interrupt Request	Event Signal
	Preface	Start Bit	Data	Parity Bit	Stop Bit							
1	No error	No error	—	—	—	—	—	—	Transfer to RDR	Set some flags	Output	Output
	No PFER, SYER	No SBER, SYER	—	—	—	—	—	0				
								1	Lost	don't set any flags	Not output	Not output
	PFER	No error	—	—	—	—	—	—				
	No error	SBER	—	—	—	—	—					

Note 1. If the received MPB flag is 0, it is not received the frame, and the operation is the same as lost of the reception data of this table.
Note 2. If no error is detected, RXI interrupt request or event is output, and if it is detected, ERI interrupt request or event is output.
Note 3. When SYER is detected in the preface area or the start bit area, the behavior of handling as an error depending on the MMCR.SYERIE bit changes.

33.6 HBS Support Mode

Setting the HBSCR.HBSE bit to 1 supports the negative logic RZI coding to generate waveforms (AMI, 50% duty cycle, negative logic) required by the home bus system. Since this function operates only in the asynchronous mode, refer to the asynchronous mode for the setting, transmission flow, and reception flow.

33.6.1 Reception in HBS Support Mode

When receiving in HBS support mode, the falling edge of the input from the RXDn pin is detected and the signal after the start bit is recognized is received. One frame is sampled according to the set bit rate, and if the stop bit is correctly received without error, the data value is stored in the receive data register RDR.

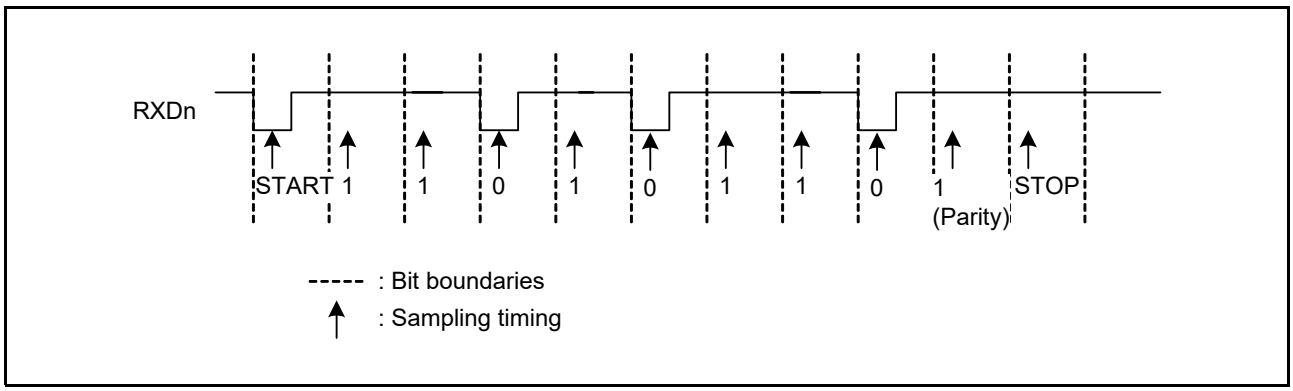

Figure 33.49 HBS Support Mode Reception Timing Chart

To receive in the HBS support mode, it is necessary to sample at the timing of 1/4 of 1 bit in order to capture the pulse in the first half of the 1 bit period. Sampling operates with a frequency 16 times the bit rate*1 as the base clock, similar to the asynchronous mode. The start bit is detected by detecting the Low level from the falling edge of RXD four times continuously with the base clock. When High is detected on the way, it is regarded as noise and waits for the next fall edge.

To set the sampling timing to 1/4 of the 1-bit period, enable the reception sampling timing adjustment function with the SCR4.RTADJ bit, set the SCR4.RTMG[3:0] bits to 1100b, and adjust Adjust from the center of the bit, which is the previous sampling timing, four clocks ahead of the base clock.

Since the sampling timing can be adjusted backward and forward using the reception sampling timing adjustment function, this timing can be adjusted according to the reception status. Increasing the SCR4.RTMG[3:0] bits value from 1100b will move the sampling timing forward, and decreasing it will move it backward. Refer to section 33.3.2, Receive Data Sampling Timing and Reception Margin in Asynchronous Mode for the details of adjustment.

After recognizing the start bit, sampling is performed at the timing according to the set bit rate, but the low width and high width of the waveform are not checked. Therefore, it is possible to receive even a normal asynchronous waveform.

Note 1. HBS support mode supports only following setting: SCR2.ABCS bit = 0 and SCR2.ABCSE bit = 0.

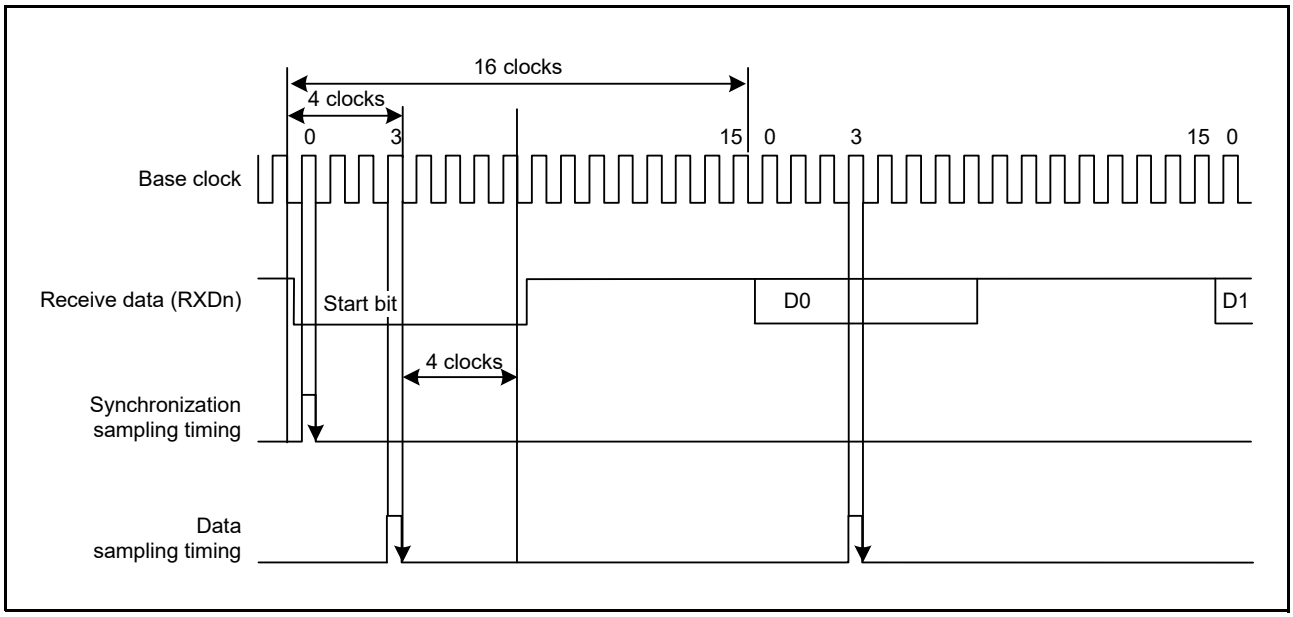

Figure 33.50 Details of Reception Sampling Timing in HBS Support Mode

33.6.2 Transmission in HBS Support Mode

Transmission in HBS support mode, data 0 is output as a low pulse for the first half of the 1-bit period.

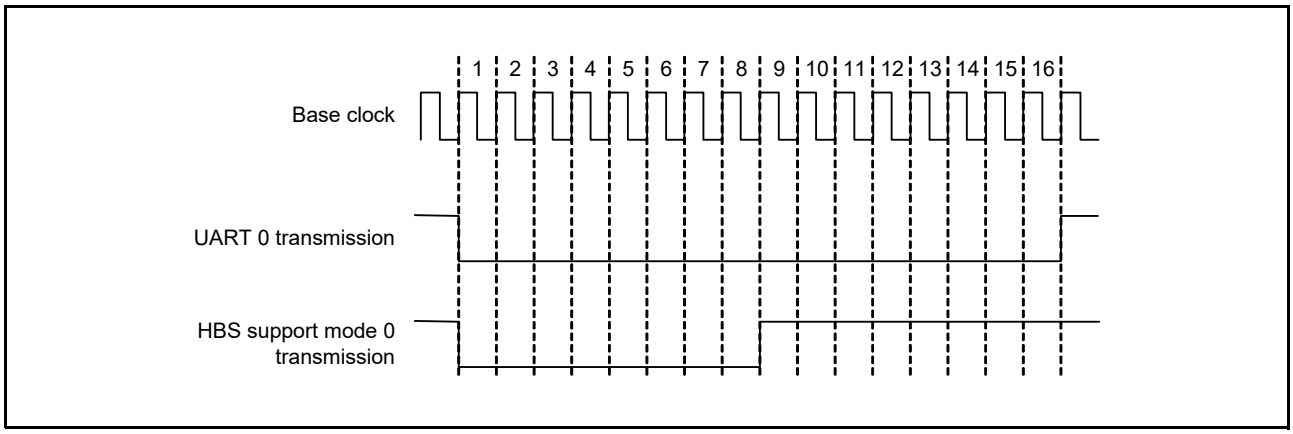

Figure 33.51 Transmission Waveform of HBS Support Mode

When HBSCR.AOE bit = 0, the all bits are output from TXDn pins, and when HBSCR.AOE bit = 1, data 0 is output alternately from TXDAn and TXDBn pins. Use the HBSCR.LPS bit to select which transmission pin starts output of the start bit.

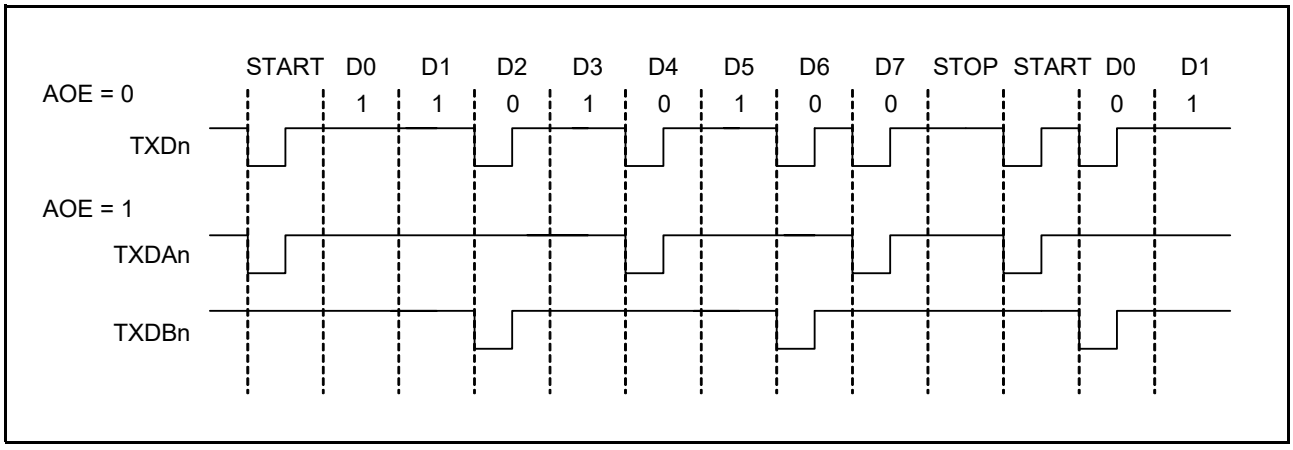

Figure 33.52 Difference in Transmission Waveform Depending on AOE Bit (When LPS Bit = 0)

Figure 33.52 shows an example of the transmission waveform for each HBSCR.AOE bit value. When the AOE bit is set to 0, the waveform is output from the TXDn pin, but when the AOE bit is set to 1, data 0 including start bit is output alternately from the TXDAn pin and the TXDBn pin.

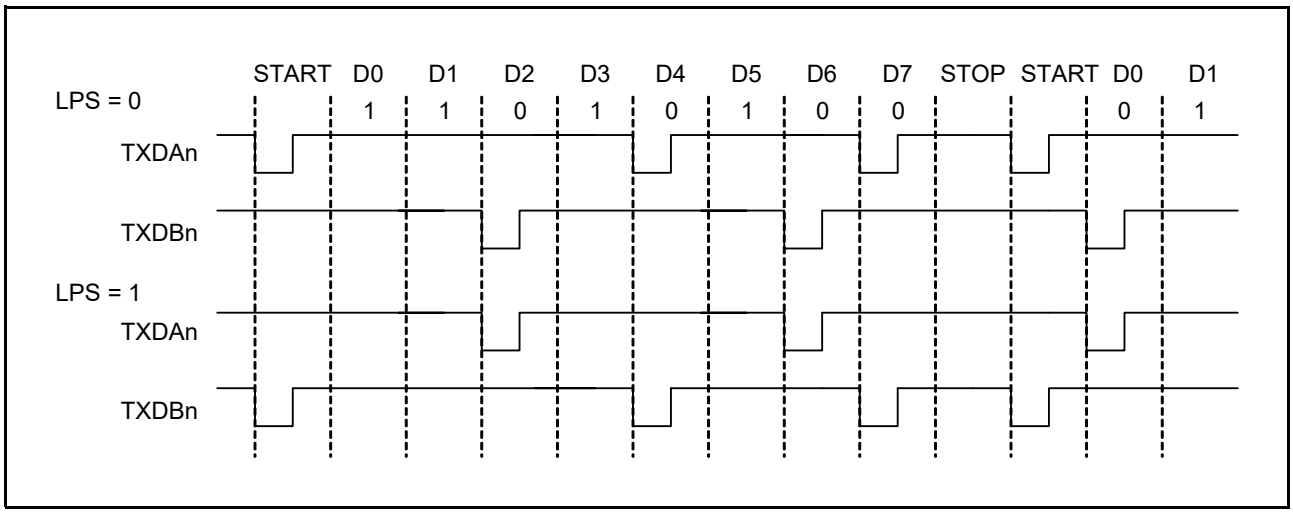

Figure 33.53 Difference in Transmission Waveform Depending on LPS Bit (When AOE Bit = 1)

Figure 33.53 shows an example of the transmission waveform for each HBSCR.LPS bit.
When the HBSCR.LPS bit = 0, the start bit is output from the TXDAn pin, and when the HBSCR.LPS bit is 1, the start bit is output from the TXDBn pin, and data 0 is output to each pin alternately. The start bit of the next frame starts output again from the pin specified by the HBSCR.LPS bit.
If the HBSCR.HBSE bit = 0, the TXDBn pin becomes High regardless of the settings of other bits.
When SCR0.TE bit = 0, both TXDn/TXDAn/TXDBn pins become high impedance, but can be controlled by SCR1.SPB2IO bit and SCR1.SPB2DT bit. At this time, the same output is applied to the TXDn/TXDAn/TXDBn pins.

33.6.3 Register Setting for HBS Support Mode

The HBS support mode is a part of asynchronous mode function, but there are some settings that are not supported when using this function. Set each bit of the control register as shown in Table 33.39 before use. Register bits not described can be set in the same way as the asynchronous mode.

Table 33.39 Control Register Setting Value for HBS Support Mode

Register Bit Name	Value	Remarks
SCR0.DCME	0	Use it when the data match detection function is disabled.
SCR1.NFCS[2:0]	000b	Use this setting when using the noise filter.
SCR1.HDSEL	0	Half-duplex communication with the TXDn pin cannot be used.
SCR1.CTSE	0	Please use it without the CTS function.
SCR2.BRME	0	Bit rate modulation function cannot be used.
SCR2.ABCSE	0	The setting that 6 cycles of the base clock becomes 1 bit cannot be used.
SCR2.ABCS	0	Only the setting that 16 cycles of the base clock becomes 1 bit can be used.
SCR3.CKE[1:0]	00b	Use with internal clock and without clock output.
SCR3.DEEN	0	Use without the RS-485 driver function.
SCR3.FM	0	Use without FIFO function.
SCR3.MOD[2:0]	000b	Set to asynchronous mode.
SCR3.RXDESEL	1	Detect the start bit at the falling edge of the RXDn pin input.
SCR3.STOP	0	Use with stop bit 1.
SCR3.DINV	0	Use without data inversion.
SCR3.DDIR	1	Use with LSB first.
SCR3.CHR[1:0]	10b	Use with 8 bit length.
SCR4.RTMG[3:0]	1100b	Use this setting when receiving in HBS support mode.*1
SCR4.TTADJ	0	Use without adjust transmit timing function.
SCR4.RTADJ	1	Use this setting when receiving in HBS support mode.

Note 1. This is the timing to sample at the center of the effective pulse. It can be adjusted if needed.

33.7 Smart Card Interface Mode

The RSCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function.
Smart card interface mode can be selected using the appropriate register.

33.7.1 Sample Connection

Figure 33.54 shows a sample connection between a smart card (IC card) and this MCU.
As in the figure, since this MCU communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor.
Setting the TE and RE bits in the SCR0 register to 1 with an IC card disconnected enables closed transmission/reception allowing self-diagnosis.
To supply an IC card with the clock pulses generated by the RSCI, input the SCKn pin output to the CLK pin of an IC card.
The output port can be used to output the reset signal.

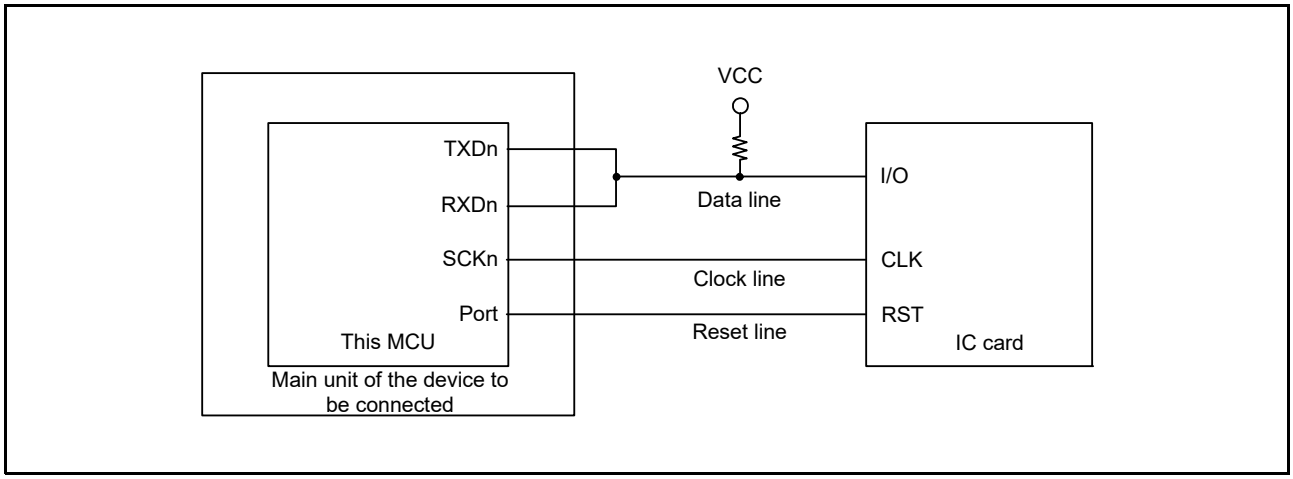

Figure 33.54 Sample Connection with a Smart Card (IC Card)

33.7.2 Data Format (Except in Block Transfer Mode)

Figure 33.55 shows the data transfer formats in smart card interface mode.

- One frame consists of 8-bit data and a parity bit in asynchronous mode.
- During transmission, at least 2 etu (elementary time unit: time required for transferring 1 bit) is secured as a guard time from the end of the parity bit until the start of the next frame.
- If a parity error is detected during reception, a low-level error signal is output for 1 etu after 10.5 etu has passed from the start bit.
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 etu.

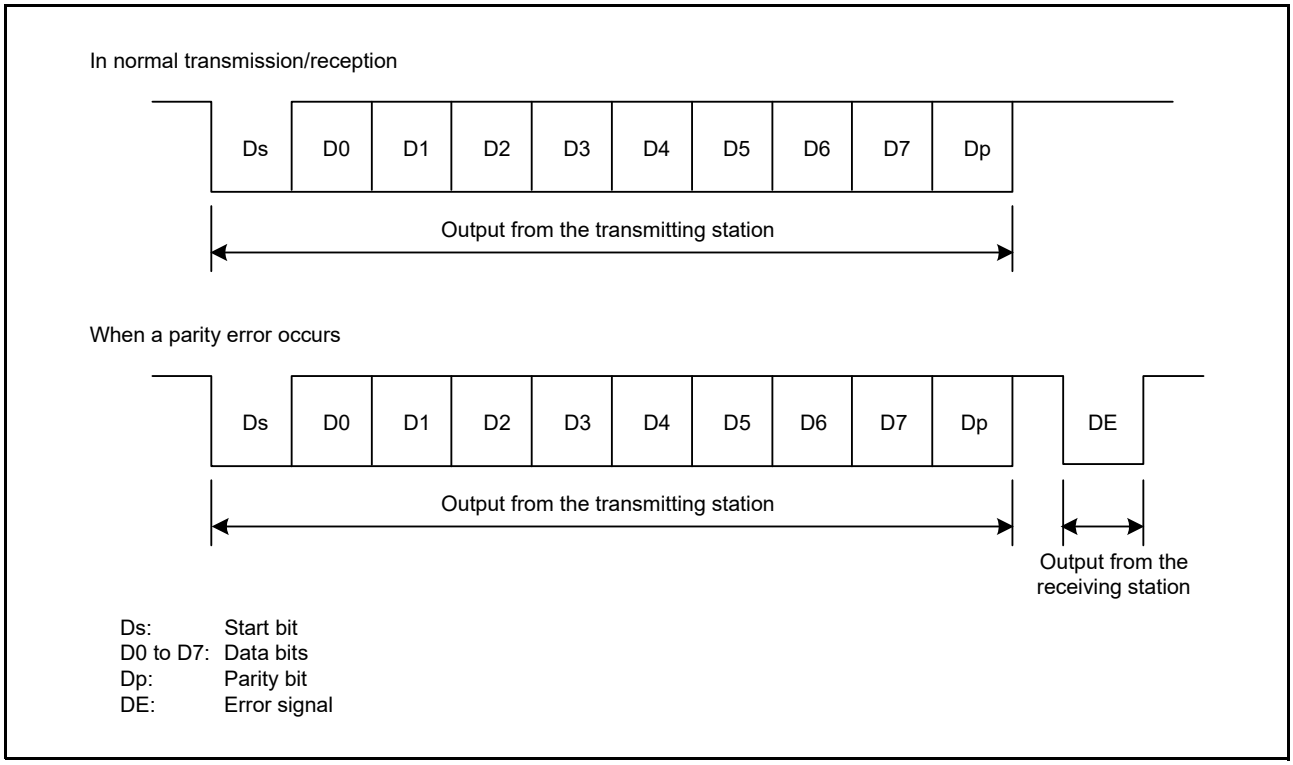

Figure 33.55 Data Formats in Smart Card Interface Mode

For communications with IC cards of the direct convention type and inverse convention type, follow the procedure below.

(1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 correspond to states Z and A, respectively, and data is transferred with LSB first as the start character, as shown in Figure 33.56. Therefore, data in the start character in the figure is 3Bh. When using the direct convention type, write 1 to the SCR3.DDIR bit and 0 to the SCR3.DINV bit. Write 0 to the PM bit in the SCR1 register in order to use even parity, which is prescribed by the smart card standard.

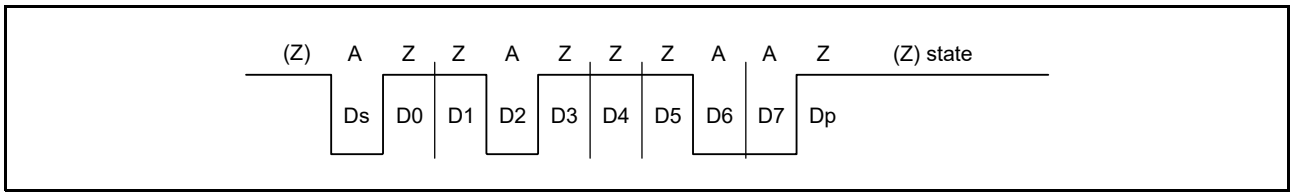

Figure 33.56 Direct Convention (SCR3.DDIR Bit = 1, SCR3.DINV Bit = 0, SCR1.PM Bit = 0)

(2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 correspond to states A and Z, respectively and data is transferred with MSB first as the start character, as shown in Figure 33.57. Therefore, data in the start character in the figure is 3Fh. When using the inverse convention type, write 0 to the SCR3.DDIR bit and 1 to the SCR3.DINV bit. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to state Z. Since the DINV bit of the this MCU only inverts data bits D7 to D0, write 1 to the PM bit in the SCR1 register to invert the parity bit for both transmission and reception.

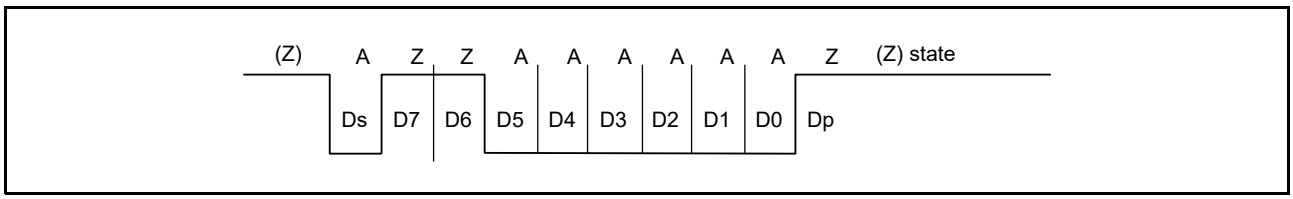

Figure 33.57 Inverse Convention (SCR3.DDIR Bit = 0, SCR3.DINV Bit = 1, SCR1.PM Bit = 1)

33.7.3 Block Transfer Mode

Block transfer mode is different from non-block transfer mode in the following respects.

- Even if a parity error is detected during reception, no error signal is output. Since the APER flag in the SSR register is set by error detection, clear the APER flag before receiving the parity bit of the next frame.
- During transmission, at least 1 etu is secured as a guard time from the end of the parity bit until the start of the next frame.
- Since the same data is not retransmitted during transmission, the TEND flag in the SSR register is set 11.5 etu after transmission start.
- In block transfer mode, the ERS flag in the SSR register indicates the error signal status as in non-block transfer mode, but the flag is read as 0 because no error signal is transferred.

33.7.4 Receive Data Sampling Timing and Reception Margin

Only the base clock generated by the on-chip baud rate generator can be used as a transmit/receive clock in smart card interface mode.

In this mode, the RSCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate according to the settings of the SCR2.BCP[2:0] bits.

For data reception, the falling edge of the start bit is sampled with the base clock to perform synchronization. Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 33.58. The reception margin here is determined by the following formula.

$$M = \left| \left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\ (\%)$$

M: Reception margin (%)
N: Ratio of bit rate to clock (N = 32, 64, 372, 256)
D: Duty cycle of clock (D = 0 to 1.0)
L: Frame length (L = 10)
F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the above formula, the reception margin is determined by the formula below.

M = {0.5 – 1/(2 × 372)} × 100 (%) = 49.866 (%)

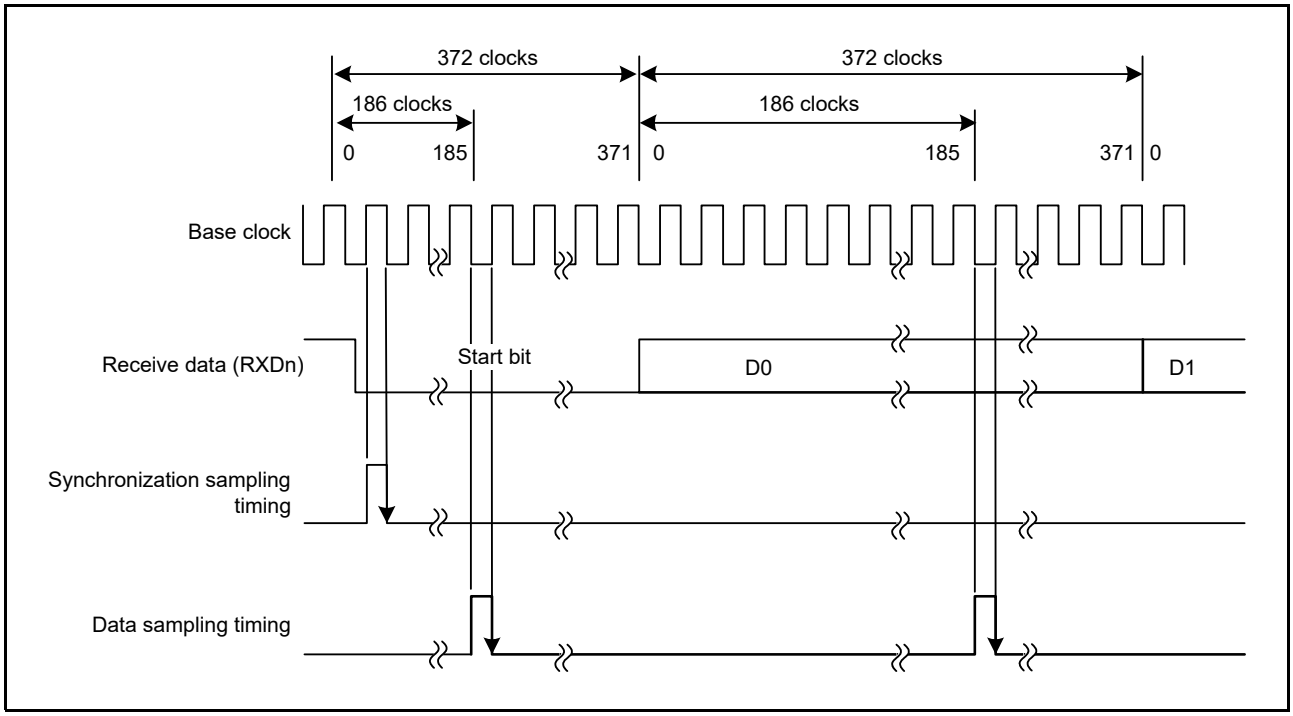

Figure 33.58 Receive Data Sampling Timing in Smart Card Interface Mode (When Clock Frequency is 372 Times the Bit Rate)

33.7.5 RSCI Initialization (Smart Card Interface Mode)

Before transmitting and receiving data, write 0 to SCR0.TE bit and SCR0.RE bit (or write the initial value to SCR0 register). And initialize RSCI following example flowchart in Figure 33.59.
Be sure to set the initial value in the TIE, RIE, TE, RE, and TEIE bits in SCR0 register before switching from transmission mode to reception mode and vice versa. Even if the RE bit is set to 0, the RDR register is not initialized. In transmission mode, set 1 to the TE bit and TIE bit simultaneously, then the TXI interrupt request is generated. To change reception mode to transmission mode, first check that reception has completed, and then initialize RSCI. At the end of initialization, set TE bit = 1 and RE bit = 0. Reception completion can be verified by RXI interrupt request, SSR.ORER, or SSR.APER flag. To change transmission mode to reception mode, first check that transmission has completed, and then initialize RSCI. At the end of initialization, set TE bit = 0 and RE bit = 1. Transmission completion can be verified by reading SSR.TEND flag.

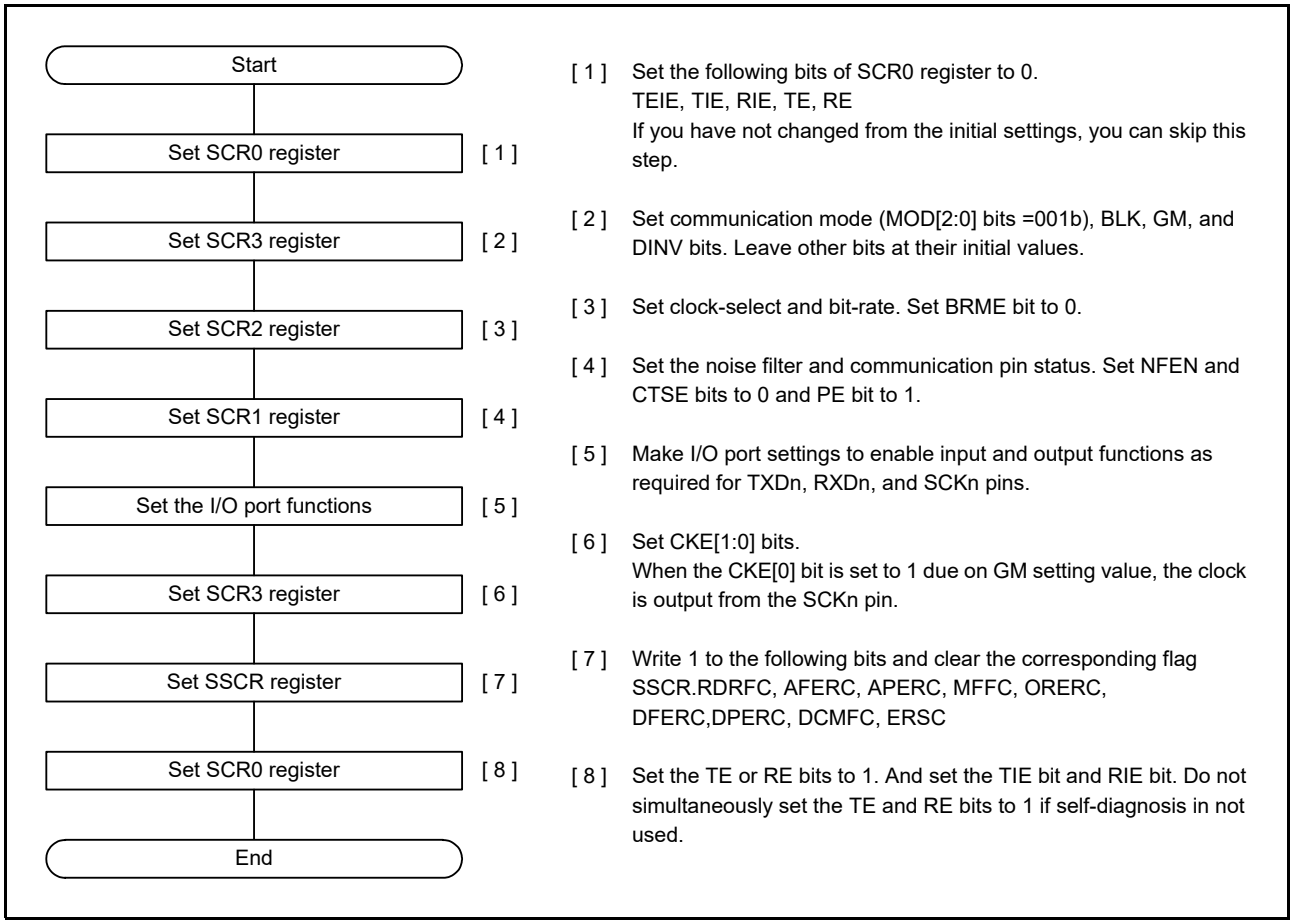

Figure 33.59 Example of RSCI Initialization Flowchart (Smart Card Interface Mode)

Figure 33.60 is a timing chart when data transmission is performed by making transition to the Smart Card Interface mode according to the above flow chart. The figure shows the case when SCR3.GM bit is 0. As shown in the figure, when the pin function is set to the SCKn pin, the SCKn pin is high impedance because the SCR3.CKE[0] bit is 0. When the TXDn pin is set, the TXDn pin is high impedance because the SCR0.TE bit is 0. Start clock output to the SCKn pin with the clock output setting SCR3.CKE[0] bit to 1, start data transmission by writing transmit data after setting SCR0.TE bit to 1.
In the smart card interface mode, even if not communicating at SCR0.TE bit = 0 and SCR0.RE bit = 0, the clock is continuously output if the clock output setting is used.

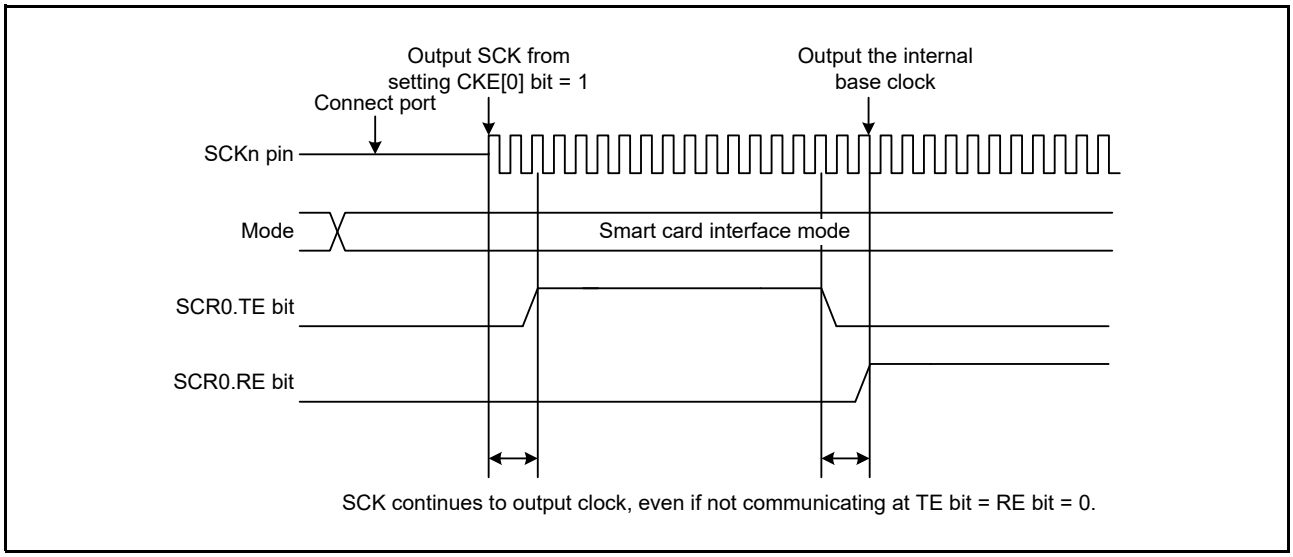

Figure 33.60 Example of Data Transmission Timing in Smart Card Interface Mode

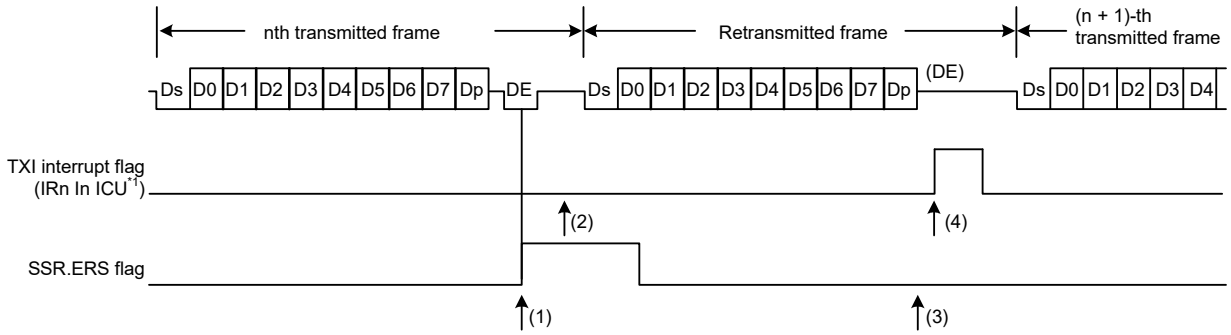
33.7.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode), in that an error signal is sampled and data can be retransmitted, is different from that in non-smart card interface mode. Figure 33.61 shows the data retransmit operation during transmission.

(1) When an error signal from the receiver end is sampled after one-frame data has been transmitted, the ERS flag in the SSR register is set to 1. If the RIE bit in the SCR0 register is 1 at this time, an ERI interrupt request is generated. Clear the ERS flag to 0 before the next parity bit is sampled.
(2) For a frame in which an error signal is received, the TEND flag in the SSR register is not set. Data is retransferred from the TDR register to the TSR register allowing automatic data retransmission.
(3) If no error signal is returned from the receiver, the ERS flag is not set to 1.
(4) In this case, the RSCI judges that transmission of one-frame data (including retransmission) has been completed, and the TEND flag is set. If the TIE bit in the SCR0 register is 1 at this time, a TXI interrupt request is generated. Writing transmit data to the TDR register starts transmission of the next data.



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 33.61 Data Retransmit Operation in RSCI Transmit Mode

Figure 33.63 shows a sample flowchart of serial transmission. All the processing steps are automatically performed by using a TXI interrupt request to activate the DTC or DMAC. When SSR.TEND flag is set to 1 in transmission, if the SCR0.TIE bit is 1, a TXI interrupt request is generated. The DTC or DMAC is activated by a TXI interrupt request if the TXI interrupt request is specified as a source of DTC or DMAC activation beforehand, allowing transfer of transmit data. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data. If an error occurs, the RSCI automatically retransmits the same data. During this retransmission, the TEND flag is kept to 0 and the DTC or DMAC is not activated. Therefore, the RSCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission in the case of error occurrence. However, since the ERS flag is not automatically cleared, set the RIE bit to 1 beforehand to enable an ERI interrupt request to be generated at error occurrence, and clear the ERS flag to 0.
When transmitting/receiving data using the DTC or DMAC, be sure to make settings to enable the DTC or DMAC before making RSCI settings. For DTC or DMAC settings, refer to section 17, DMA Controller (DMACAa) and section 18, Data Transfer Controller (DTCb).
Note that SSR.TEND flag is set in different timings depending on the SCR3.GM bit setting. Figure 33.62 shows the TEND flag generation timing.

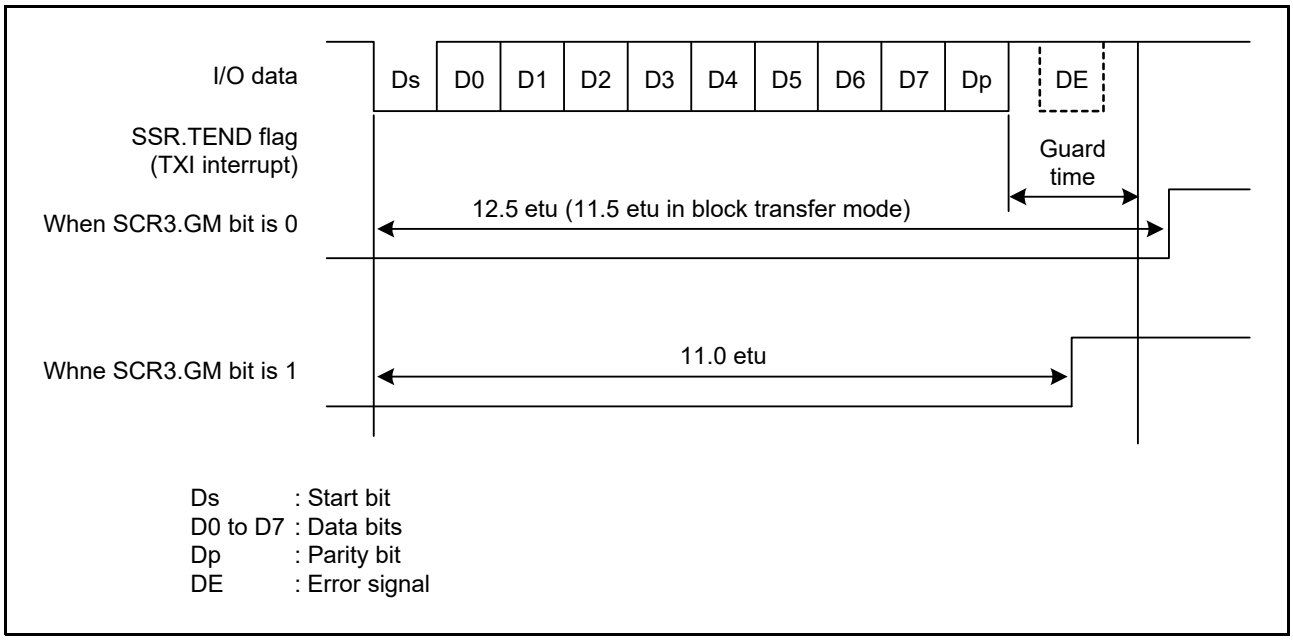


Figure 33.62 SSR.TEND Flag Generation Timing during Transmission

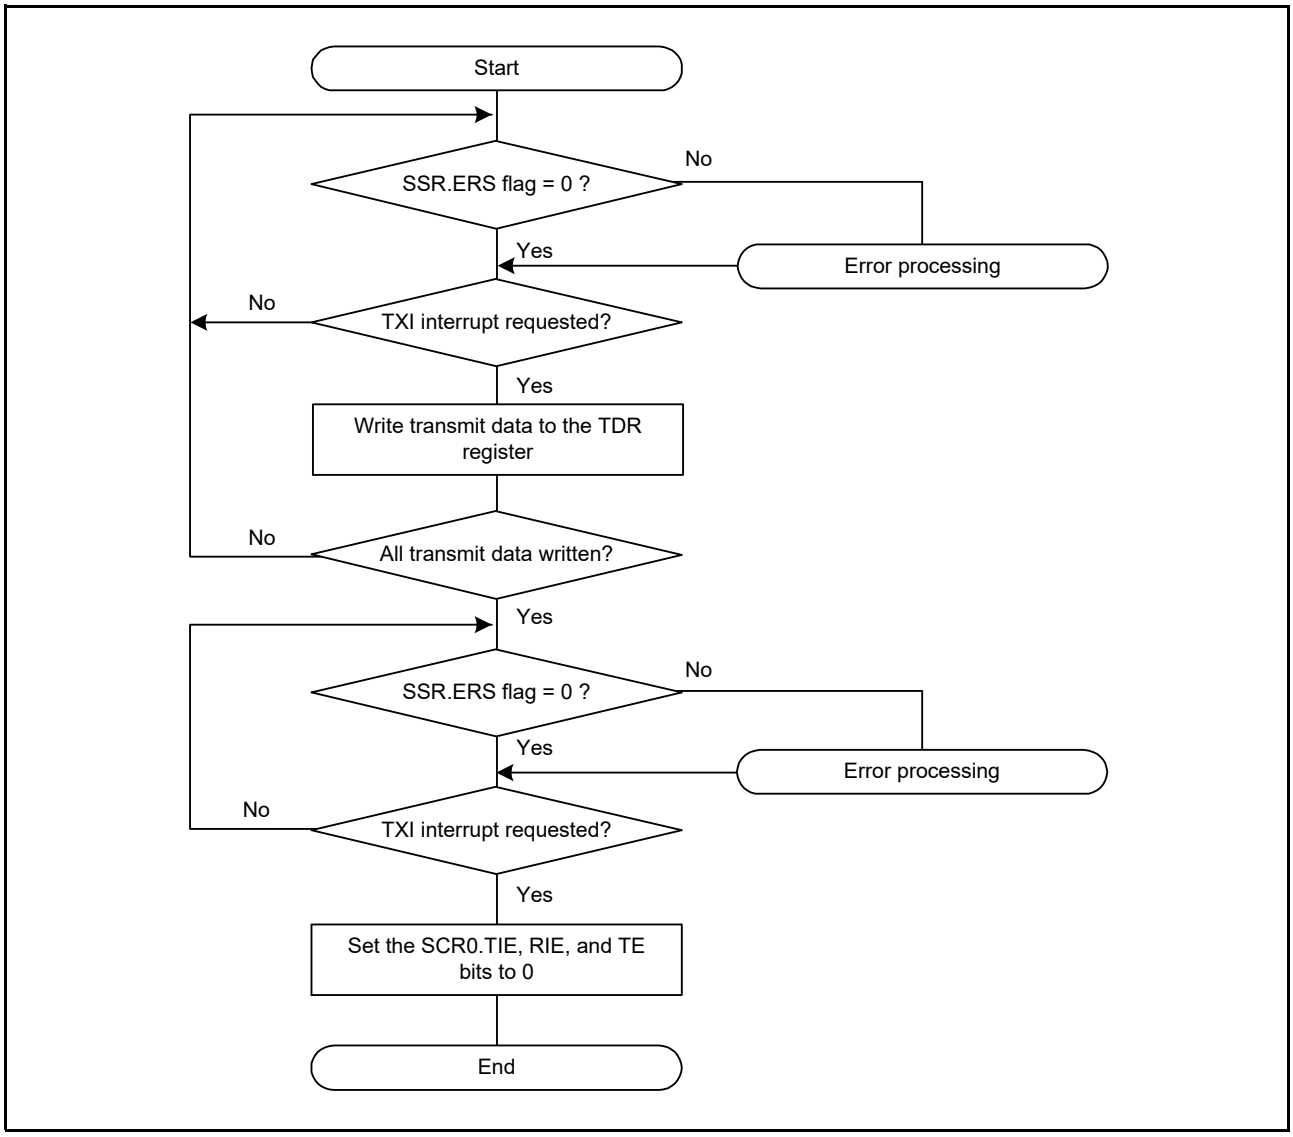

Figure 33.63 Sample Smart Card Interface Transmission Flowchart

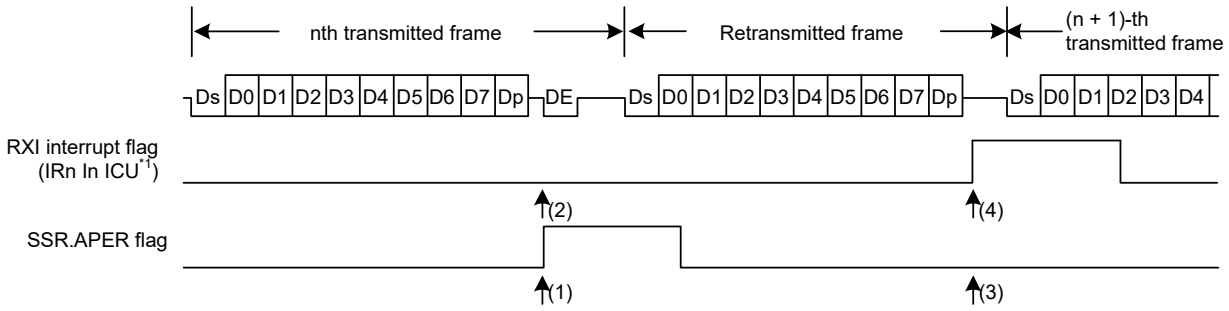
33.7.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in non-smart card interface mode. Figure 33.64 shows the data retransmit operation in receive mode.

(1) If a parity error is detected in receive data, the APER flag in the SSR register is set to 1. When the RIE bit in the SCR0 register is 1 at this time, an ERI interrupt request is generated. Clear the APER flag to 0 before the next parity bit is sampled.
(2) For a frame in which a parity error is detected, no RXI interrupt is generated.
(3) When no parity error is detected, the APER flag in the SSR register is not set to 1.
(4) In this case, data is determined to have been received successfully. When the RIE bit in the SCR0 register is 1, an RXI interrupt request is generated.



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 33.64 Data Retransmit Operation in RSCI Receive Mode (Data Retransmit Operation during Reception)

Figure 33.65 shows a sample flowchart for serial data reception. All the processing steps are automatically performed using an RXI interrupt request to activate the DTC or DMAC. In reception, setting the RIE bit to 1 allows an RXI interrupt request to be generated. The DTC or DMAC is activated by an RXI interrupt request if the RXI interrupt request is specified as a source of DTC or DMAC activation beforehand, allowing transfer of receive data. If an error occurs during reception and either the SSR.ORER or APER flag is set to 1, a receive error interrupt (ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DTC or DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DTC or DMAC is transferred. Even if a parity error occurs and the APER flag is set to 1 during reception, receive data is transferred to RDR register, thus allowing the data to be read. When a reception is forcibly terminated by setting the SCR0.RE bit to 0 during operation, read the RDR register because the received data which has not yet been read may be left in RDR register.

Note: For operations in block transfer mode, refer to section 33.3, Operation in Asynchronous Mode.

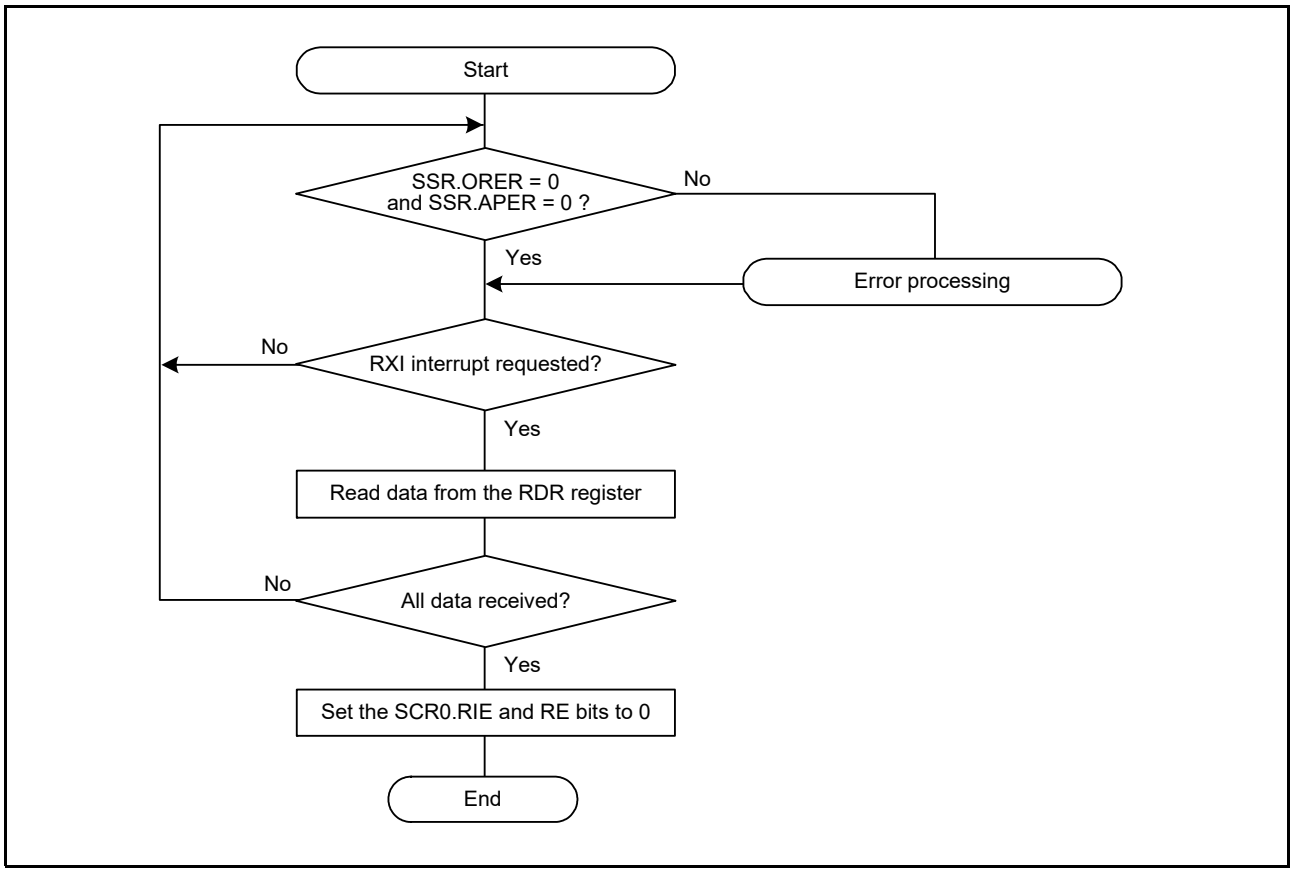


Figure 33.65 Sample Smart Card Interface Reception Flowchart

33.7.8 Clock Output Control

When the SCR3.GM bit is set to 1, the clock output can be controlled by the SCR3.CKE[1:0] bits. Refer to the description of the SCR3.CKE[1:0] bits in section 33.2.8, Control Register 3 (SCR3). When setting the clock output, the base clock described in section 33.7.4, Receive Data Sampling Timing and Reception Margin is output, so the width of the clock pulse can be kept to the width specified by setting the bit rate. It is described in section 33.2.7, Control Register 2 (SCR2), the bit rate is set by SCR2.CKS[1:0] bits, SCR2.BCP[2:0] bits and BRR[7:0] bits.
Figure 33.66 shows the timing chart for explaining clock output control. This is an example when the SCR3.CKE[1] bit is set to 0 and the SCR3.CKE[0] bit is controlled.
When the SCR3.GM bit is 0, output control by the SCR3.CKE[0] bit is immediately reflected on the SCKn pin, so there is a possibility that pulses with an unintended width may be output from the SCKn pin.
When the SCR3.GM bit is 1, the output pulse control by the SCR3.CKE[0] bit controls the pulse width set to be based on the state of the base clock.

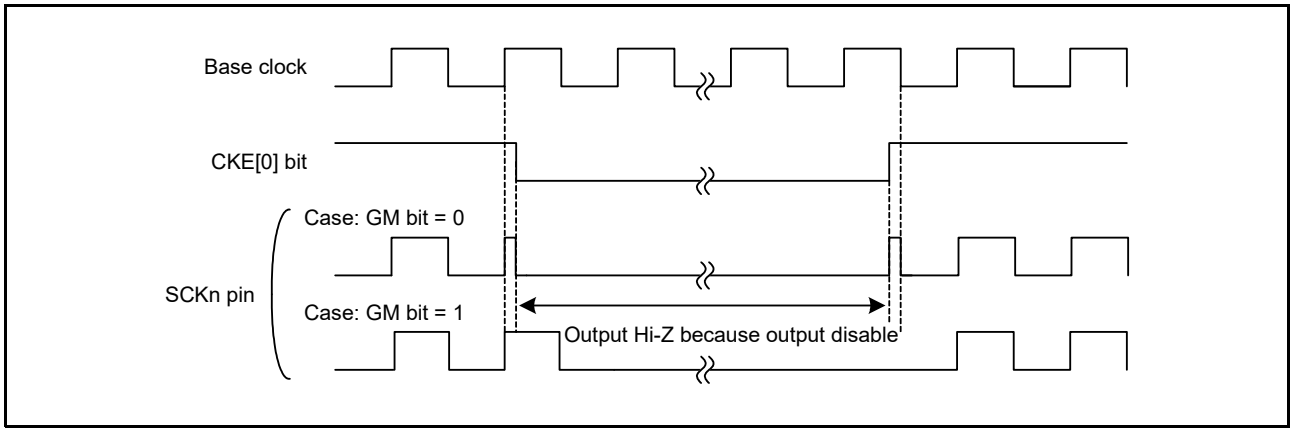

Figure 33.66 Clock Control Timing Chart by SCR3.GM Bit

33.8 Extended Serial Mode

33.8.1 Serial Transfer Protocol

As an extended function of the RSCI, the RSCI supports the serial communication protocol (Figure 33.67) consisting of a Start Frame and an Information Frame. Extended serial mode is enabled by the SCR3.MOD[2:0] bits = 110b. Since the extended serial mode uses the same circuit as the asynchronous mode for transmission/reception control other than Break Field, the basic communication settings required for the asynchronous mode are also required for the extended serial mode (however, set the SCR3.RXDESEL bit to 1).
The Start Frame consists of a Break Field, Control Field 0, and Control Field 1. The Information Frame can be configured with some Data Fields, a CRC16 Upper Field, and a CRC16 Lower Field.

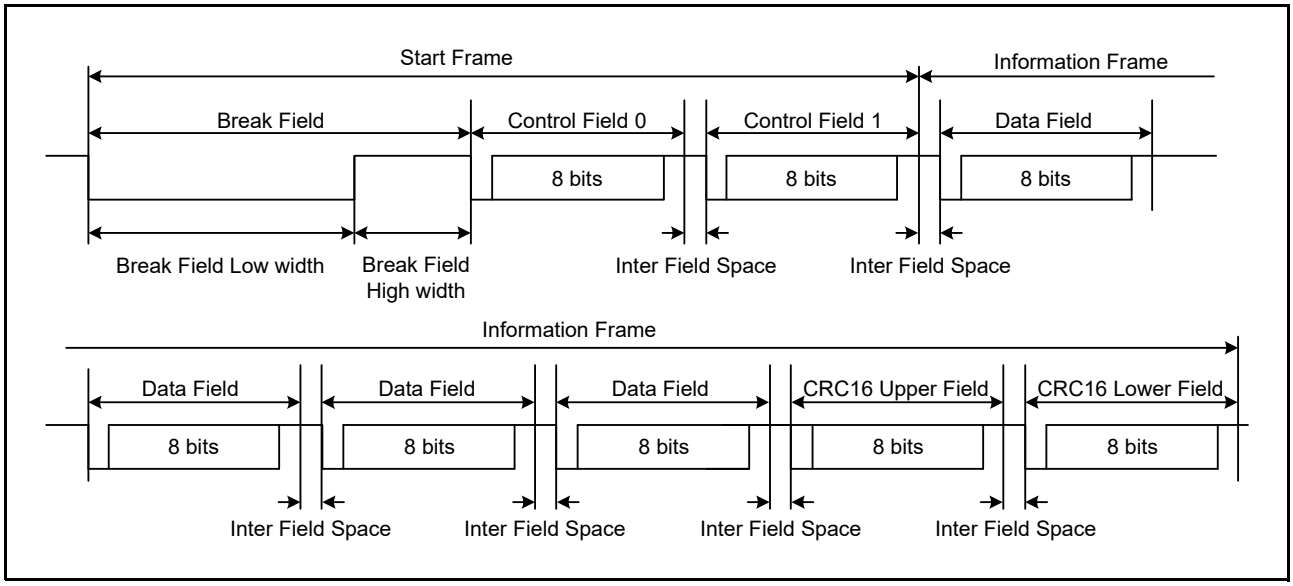

Figure 33.67 Protocol for Serial Transfer by the Extended Serial Mode

The following describes operations in extended serial mode. In this section, operations are described with the following conditions:
Communication pin (RXDn/TXDn) level inversion function: OFF (RINV bit = TINV bit = 0)
When using the communication pin (RXDn/TXDn) level inversion function enabled, replace the RXD and TXD signal levels with their inverted levels.

33.8.2 Transmitting a Start Frame

Figure 33.68 shows an example of transmission of the Start Frame consisting of a Break Field, Control Field 0, and Control Filed 1. (Omit Break Field and Control Field 0 according to the Start Frame configuration.)
Figure 33.69 shows a flowchart for Start Frame transmission.
The RSCI operates as follows during Start Frame transmission.

(1) Make the initial settings for the RSCI according to the RSCI initialization flow (Figure 33.8) in asynchronous mode. In extended serial mode, do not set SCR0.TE and TIE bits to 1 at the same time to avoid TXI output before the Break Field. Therefore, perform the following two steps sequentially to set the RSCI initialization flow (asynchronous mode) procedure [10].

- Set the bits except SCR0.TIE bit. (SCR0.TIE bit = 0, SCR0.TE bit = 1, and SCR0.RE bit = 0)
- Set SCR0.TIE bit to 1.

(2) When 1 is written to TCST, the timer in the extended serial module starts counting and outputs a low level (Break Field) from the TXDn pin for the period set in XCR2.BFLW[15:0] bits. A timer count clock source can be selected by XCR0.TCSS[1:0] bits.
Writing 0 to XCR1.TCST bit suspends output of the Break Field. After the suspension, set SCR0.TE bit = 0 and turn off the transmission.

(3) When the extended serial module timer count value matches the set XCR2.BFLW[15:0] bits value, the timer stops counting and inverts the TXDn pin output level, and the XSR0.BFOF flag is set to 1*1. Furthermore, if XCR0.BFOIE bit has been set to 1 at this time, a TXI interrupt is generated.

(4) After confirming the BFOF flag is set to 1, send the Control Field 0 data.*2

(5) After the Control Field 0 data has been transmitted, write the Control Field 1 data to TDR. And it is transmitted.

(6) After the Control Field 1 data has been transmitted, the Information Frame data is transmitted.

Note 1. After XSR0.BFOF flag is set to 1, if 1 is written to XCR1.TCST bit without clearing it, no TXI interrupt is output at the end of Break Field transmission. Clear XSR0.BFOF flag before writing 1 to XCR1.TCST bit.

Note 2. LIN communication requires a Break delimiter (IDLE period) of 1 bit or more from the end of Break Field transmission until the next data transmission starts. For this reason, the Break delimiter length is counted upon completion of Break Field transmission. If transmit data is written while the Break delimiter length is being counted, transmission does not start until the Break delimiter length counting is completed. When transmit data is written after the Break delimiter length has been counted, transmission starts at the same timing as normal data transmission.
Break delimiter length count time after Break Field transmission: 1-bit to 2-bit length (SCR3.STOP bit = 0) 2-bit to 3-bit length (SCR3.STOP bit = 1)

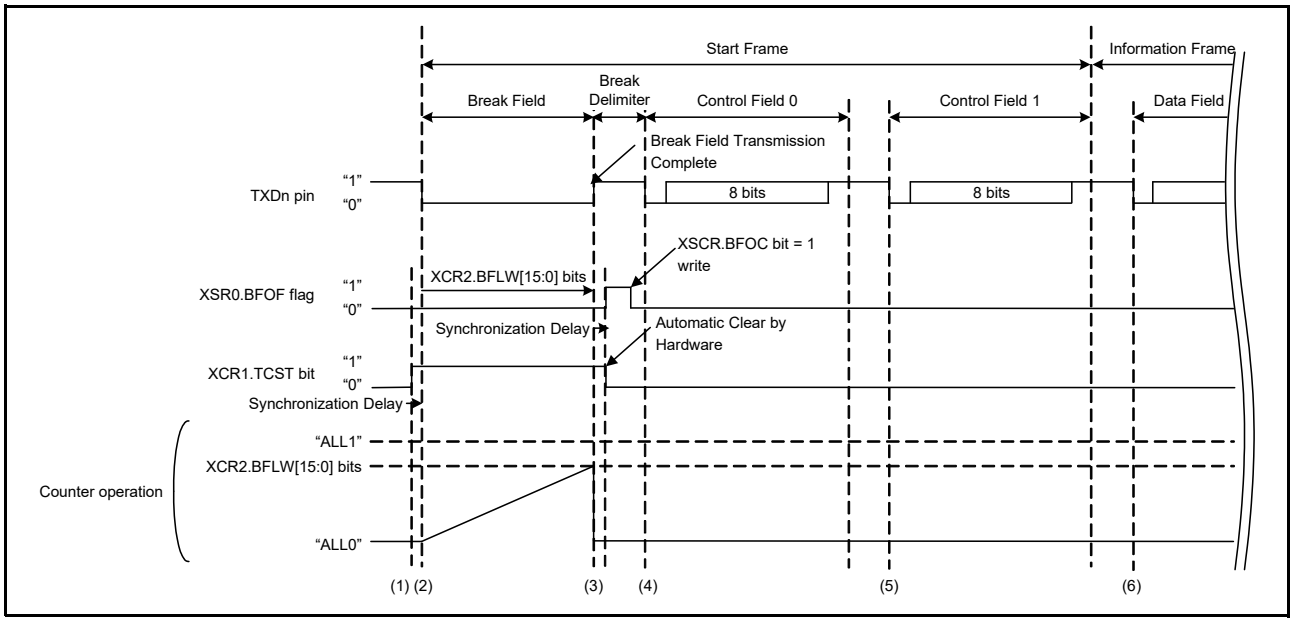

Figure 33.68 Example of Operations When Transmitting a Start Frame

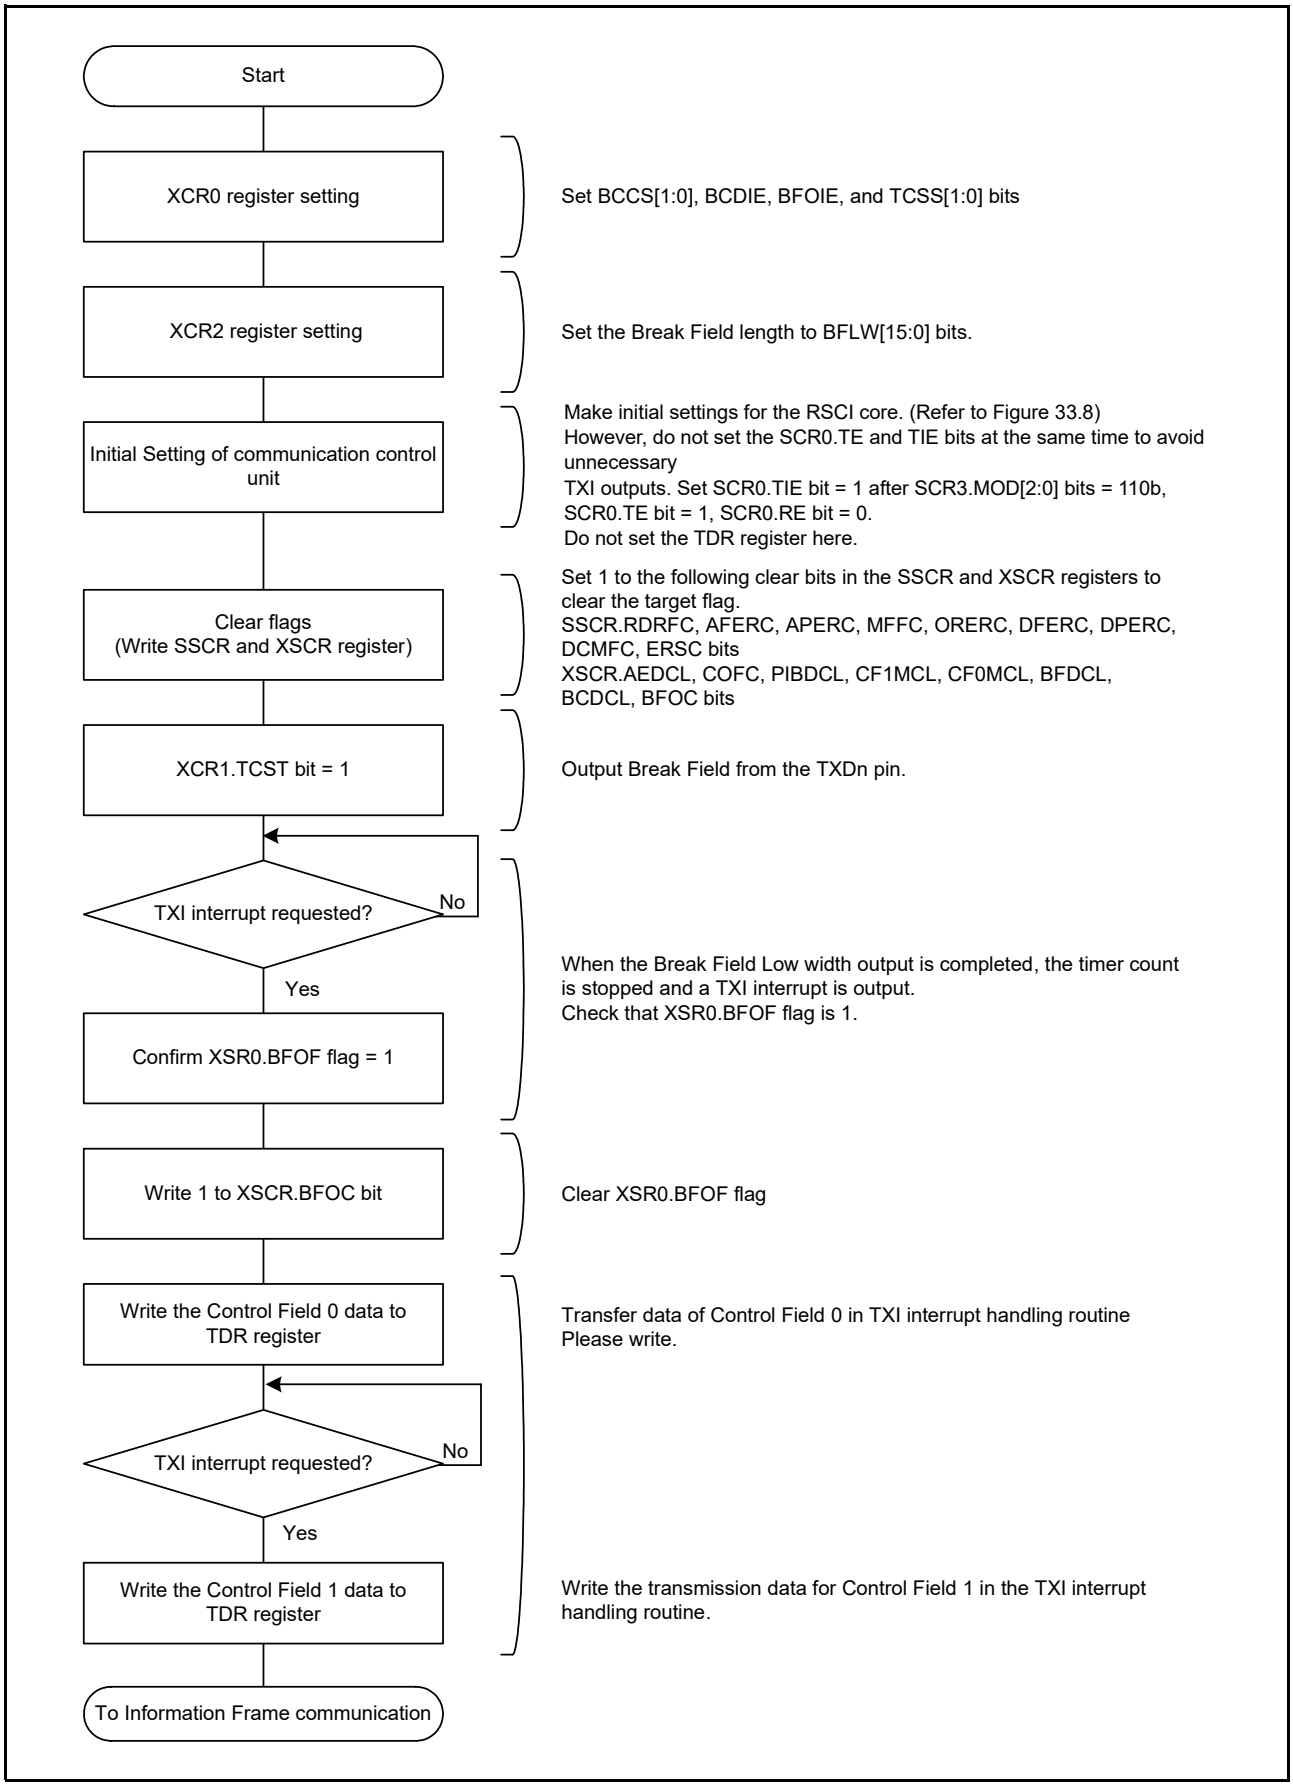

Figure 33.69 Example of Start Frame Transmission

33.8.3 Receiving a Start Frame

The extended serial mode control section is capable of receiving Start Frames with the structures listed in Table 33.40.

Table 33.40 Structures of Start Frames

XCR0		Start Frame Configuration
BFE	CF0RE	
0	0	Control Field1 (8 bits) → Information Frame
0	1	Control Field0 (8 bits) → Control Field1 (8 bits) → Information Frame
1	0	Break Field (Low width) → Control Field1 (8 bits) → Information Frame
1	1	Break Field (Low width) → Control Field0 (8 bits) → Control Field1 (8 bits) → Information Frame

33.8.3.1 Extended Serial Normal Reception of Start Frame (PIB not Used)

Figure 33.70 shows an example of normal reception of the Start Frame consisting of a Break Field, Control Field0, and Control Field1. Figure 33.71 shows an example of reception to detect the Break Field during Control Field 1. Figure 33.72 shows a flowchart to receive the Start Frame, and Figure 33.73 shows a state transition diagram.
When receiving the Start Frame, the RSCI operates as follows. Omit the processing of Break Field and Control Field0 according to the Start Frame configuration.

(1) Writing 1 to XCR1.SDST bit makes it possible to detect the Start Frame. When XCR0.BFE bit = 1, RXD input to the RSCI core is disabled until the Break Field is detected (because XSR0.RXDSF flag is set to 1). Once the Break Field is detected, RXD input can be received to the RSCI core (XSR0.RXDSF flag = 0).
(2) When a low level is input from the RXDn pin, the Break Field detection count starts. A timer count clock source can be selected by XCR0.TCSS[1:0] bits.
(3) When a low level that is equal to or longer than the period set in XCR2.BFLW[15:0] bits is input from the RXDn pin, it is determined as Break Field. At this time, XSR0.BFDF flag is set to 1. If XCR0.BFDIE bit has been set to 1 at this time, a BFD interrupt is generated.
The timer continues counting until the RXD rising edge or counter overflow.
(4) After the Break Field is detected, when the input level from the RXDn pin becomes high, the count value is captured to XSR1.CCV[15:0] bits when XCR1.BRME bit = 0. At this time, XSR0.RXDSF flag is cleared to 0 and the RSCI core starts receiving the RXD input.
(5) The RSCI core starts receiving Control Field 0. Because the extended serial continuously counts the edge interval, it determines a low level that is equal to or longer than the period set in XCR2.BFLW[15:0] bits as detection of the Break Field. When the Break Field is detected in the Control Field 0 phase, the RSCI core waits for reception of Control Field 0 again (Figure 33.71).
(6) When Control Field 0 has been received, an RXI interrupt is generated and the Control Field 0 data is stored in XSR0.CF0RD[7:0] bits. When the received data matches the set XCR2.CF0D[7:0] bits value, XSR0.CF0MF flag is set to 1. If the received data differs from the set XCR2.CF0D[7:0] bits value, the RSCI transitions to the state before the Break Field is detected.
(7) The RSCI core starts receiving Control Field 1. When BFE bit = 1, the Break Field detection function is continuously enabled while SDST bit = 1 as in the case of Control Field 0. When the Break Field is detected in the Control Field 1 phase, the RSCI core waits for reception of Control Field 0 again.
(8) When Control Field 1 has been received, an RXI interrupt is generated and the Control Field 1 data is stored in XSR0.CF1RD[7:0] bits. When the received data matches the set XCR1.PCF1D[7:0] bits value or the set

XCR1.SCF1D[7:0] bits value, XSR0.CF1MF flag is set to 1. If the received Control Field 1 data matches neither the set XCR1.PCF1D[7:0] bits value nor the set XCR1.SCF1D[7:0] bits value, the RSCI transitions to the state before the Break Field is detected.

(9) The RSCI core performs Information Frame communication.

(10) When communication is completed, write 0 to XCR1.SDST bit and 0 to SCR0.RE bit to stop reception.

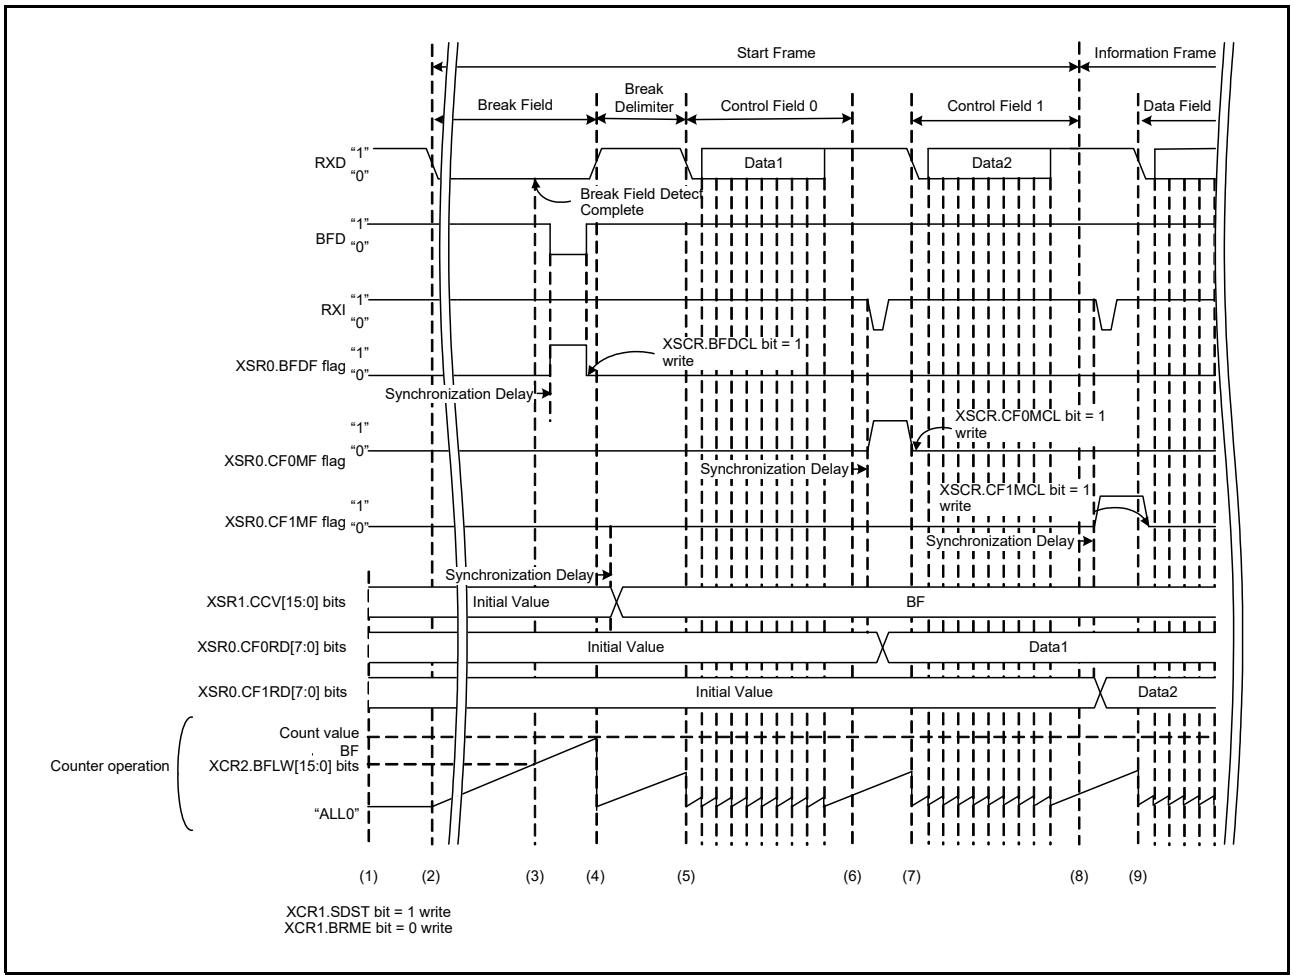

Figure 33.70 Normal Reception Example of Start Frame (PIB Not Used)

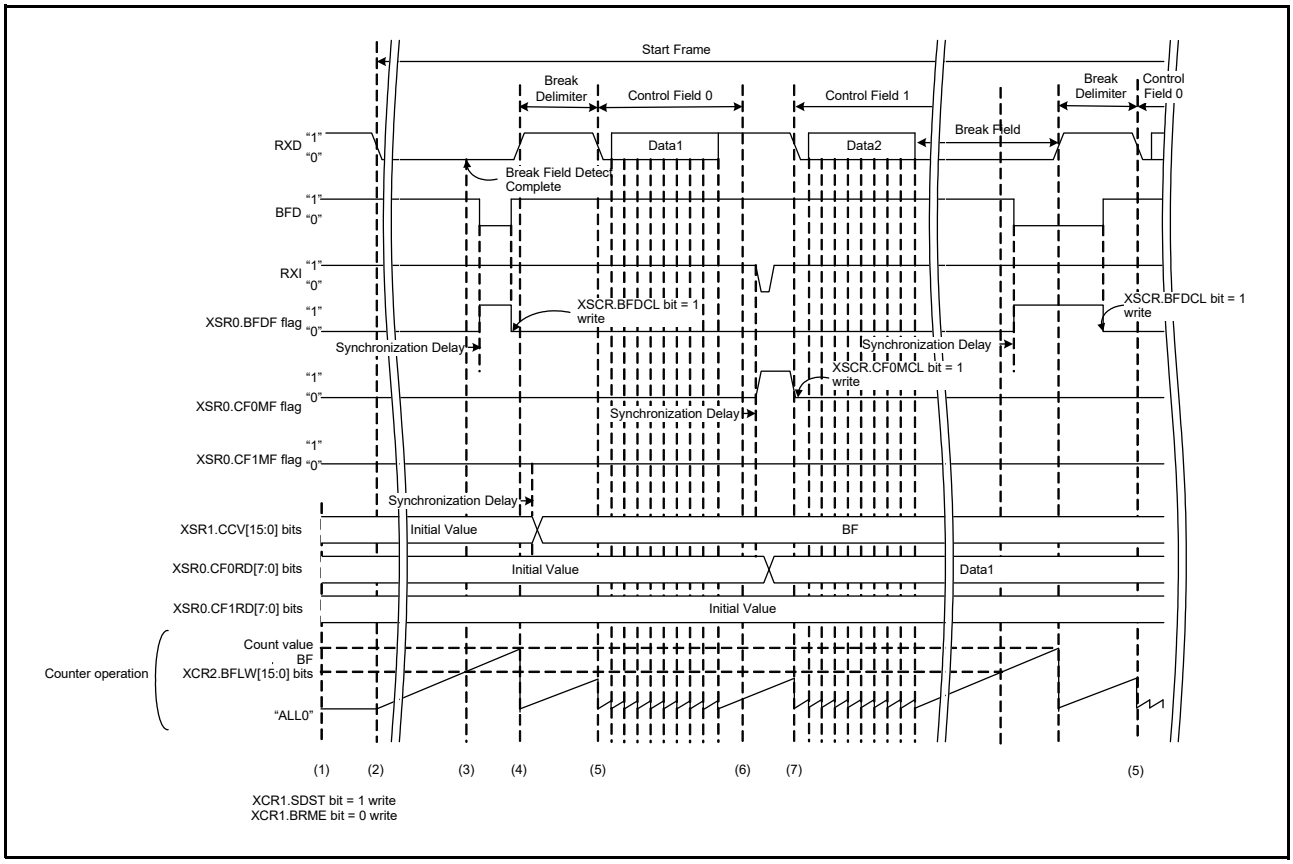

Figure 33.71 Start Frame Reception Example (PIB Not Used) Break Field Detected during Control Field 1

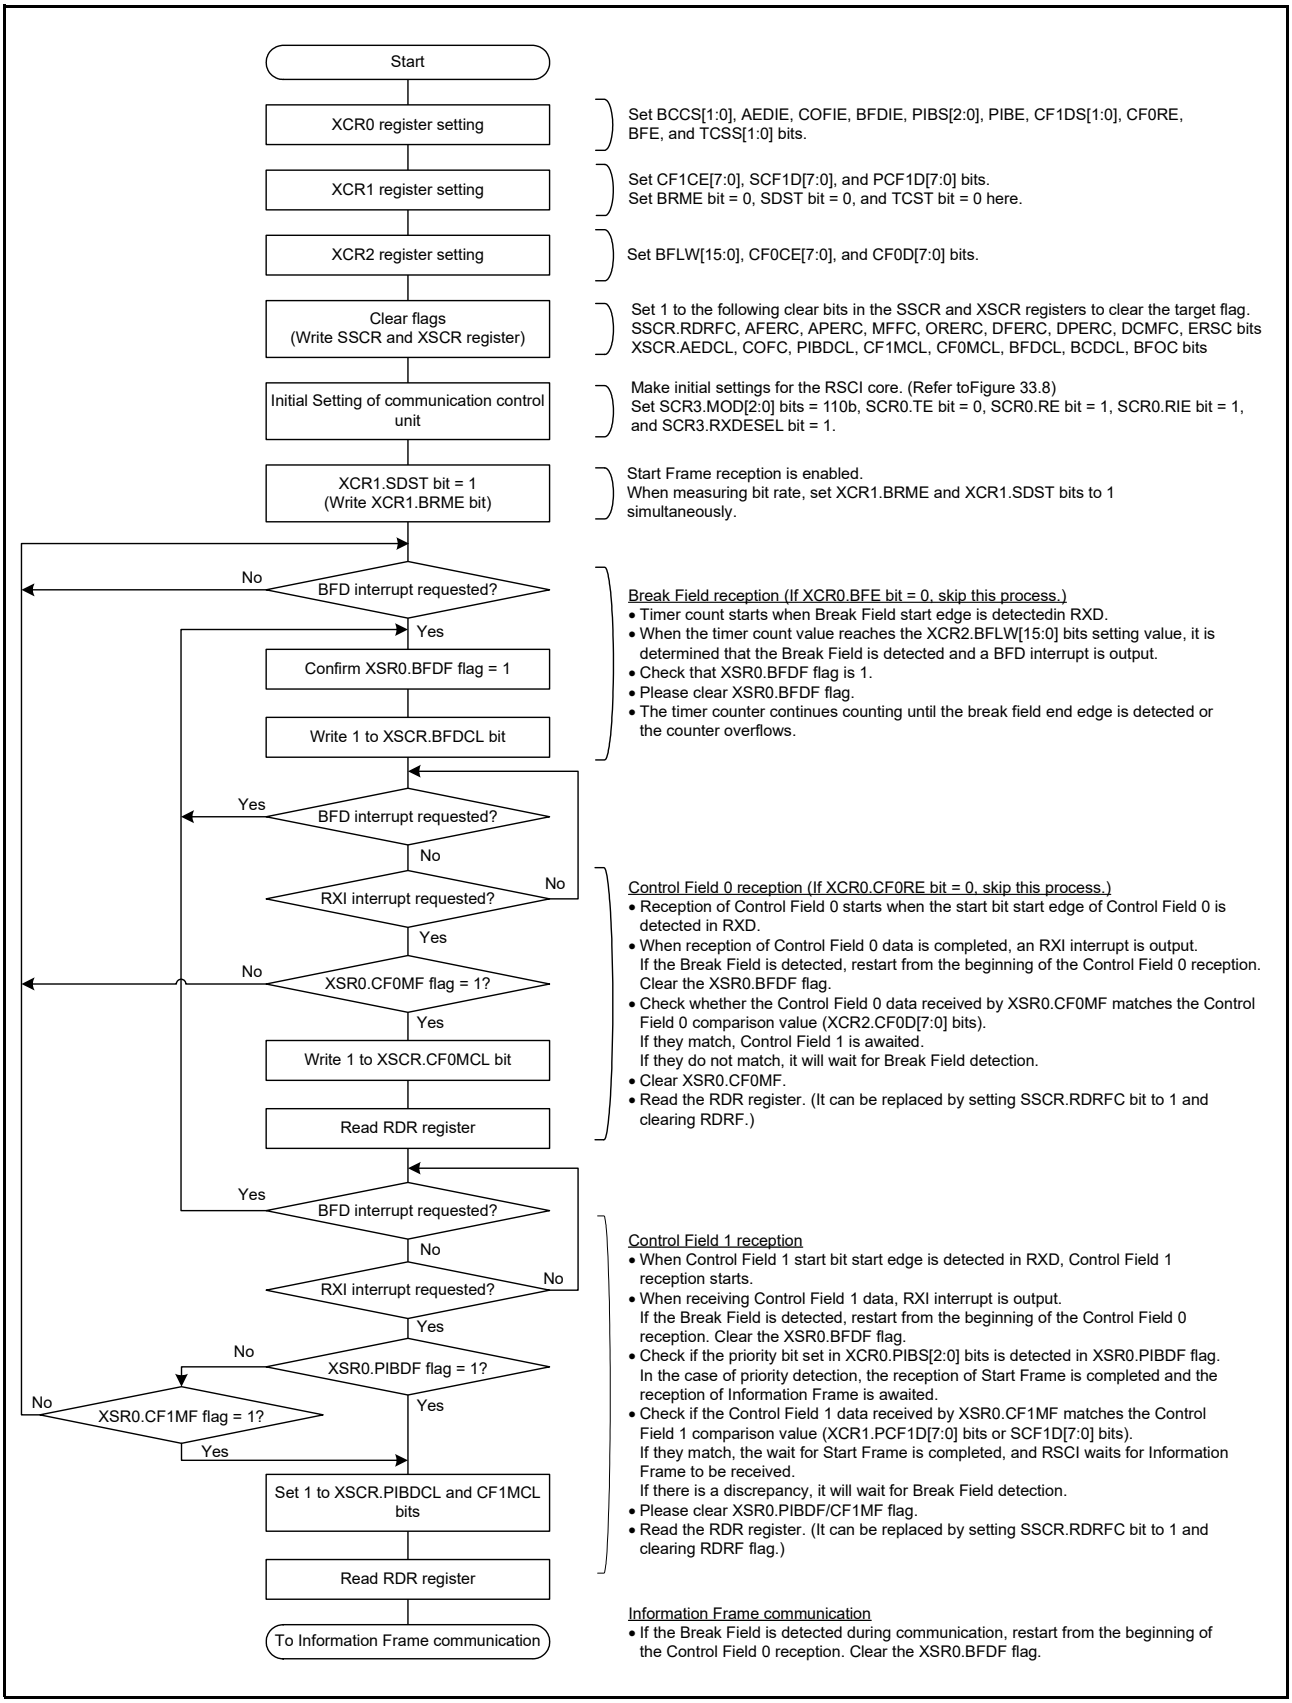

Figure 33.72 Sample Flowchart for Reception of a Start Frame

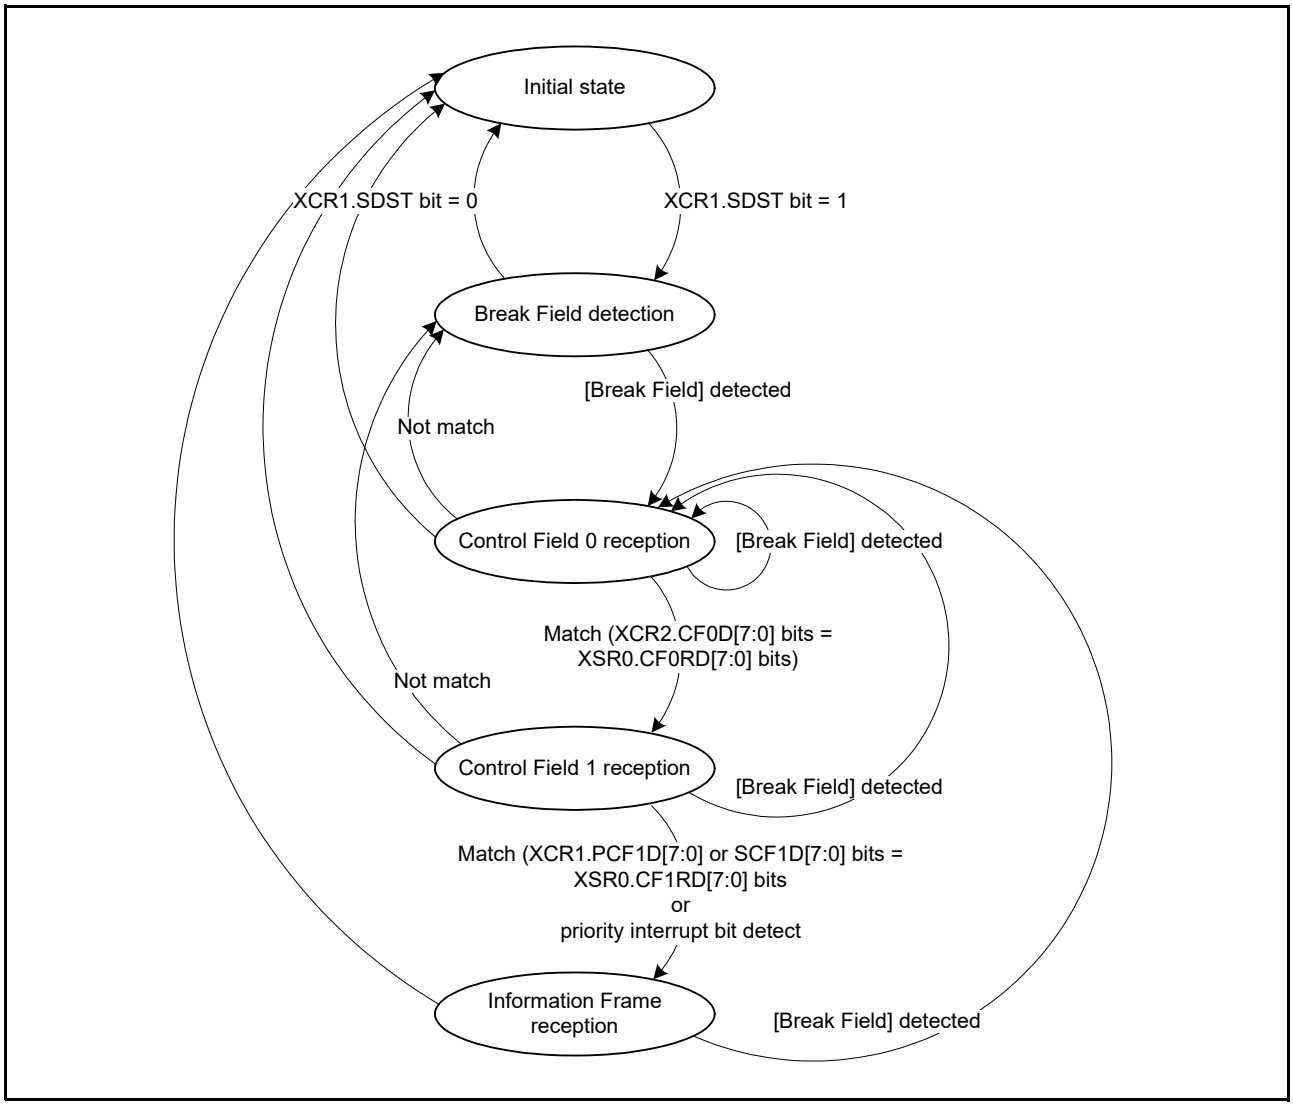

Figure 33.73 State Transition Diagram of Start Frame Reception

33.8.3.2 Priority Interrupt Bit

Figure 33.74 shows an example of Start Frame reception using the priority interrupt bit. The priority interrupt bit is enabled by setting XCR0.PIBE bit to 1.

The RSCI operates as follows during Start Frame reception using the priority interrupt bit.

Steps (1) to (7) are the same as in Figure 33.70, for Start Frame reception.

(8) When the value specified in the XCR0.PIBS[2:0] bits matches the set XCR1.PCF1D[7:0] bits value, XSR0.PIBDF flag is set to 1and the RSCI core performs communication of the Information Frame. If the data received in Control Field 1 matches neither the set XCR1.PCF1D[7:0] bits value nor the set XCR1.SCF1D[7:0] bits value and the priority interrupt bit is not detected, the RSCI transitions to the state before the Break Field is detected.

(9) The RSCI core performs Information Frame communication.

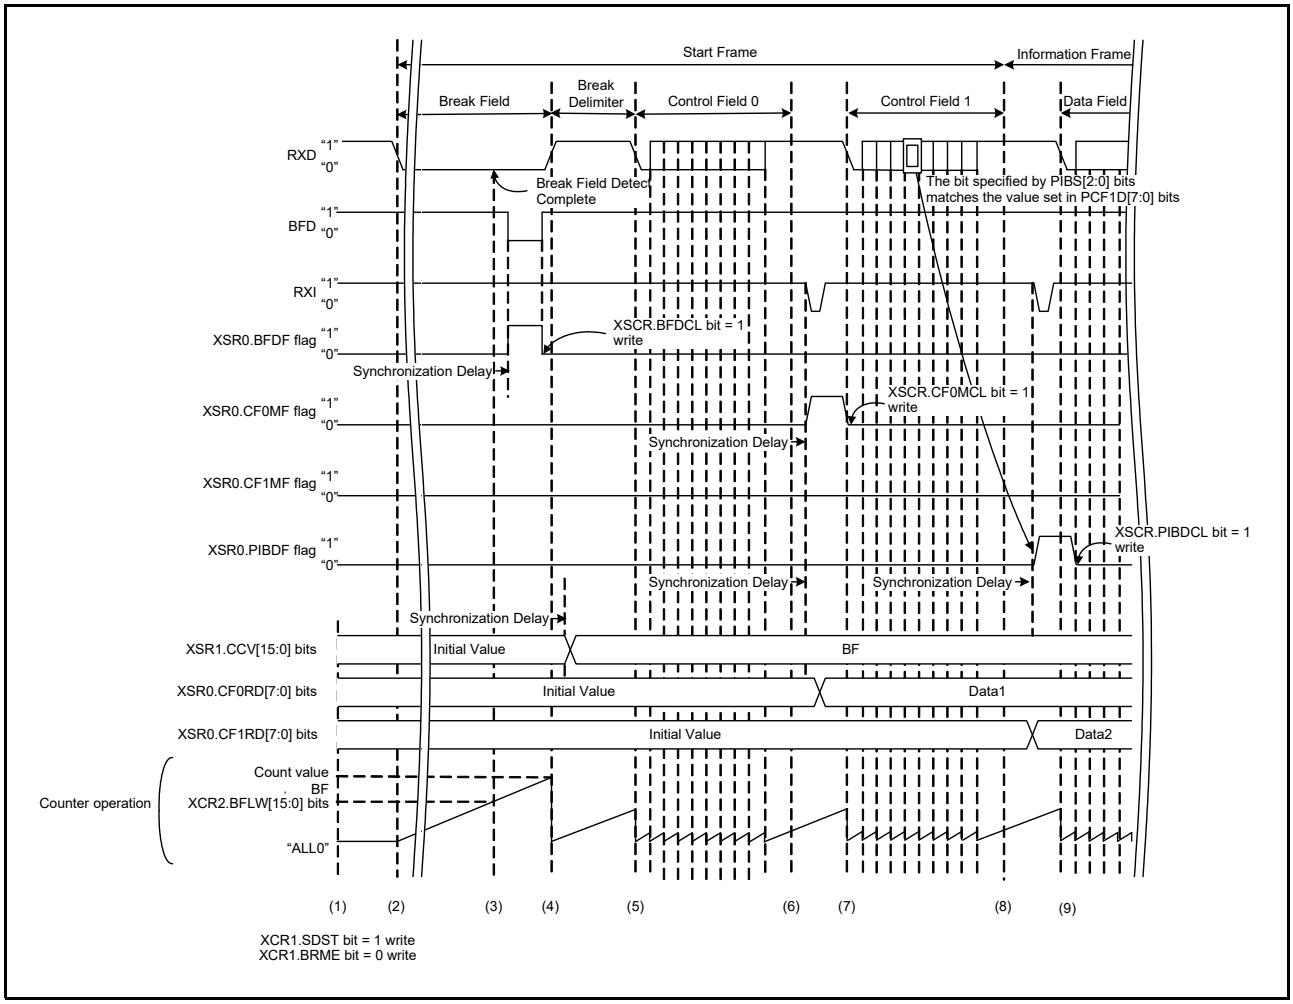

Figure 33.74 Start Frame Reception Example (Priority Interrupt Bit Used)

33.8.4 Detection of Bus Collisions

In extended serial mode (SCR3MOD[2:0] bits = 110b) when TE bit = 1, the bus conflict detection function works during Break Field transmission and during data transmission.

Figure 33.75 shows an operation example of the bus conflict detection function. The TXDn pin output and the RXDn pin input are sampled by the bus conflict detection clock set in XCR0.BCCS[1:0] bits. When a mismatch occurs three times in a row, XSR0.BCDF flag is set to 1, and if XCR0.BCDIE bit has been set to 1 at this time, an ERI interrupt is generated.

When an ERI interrupt is generated, stop transmission according to Figure 33.76. Check the bus state to decide whether to resume transmission.

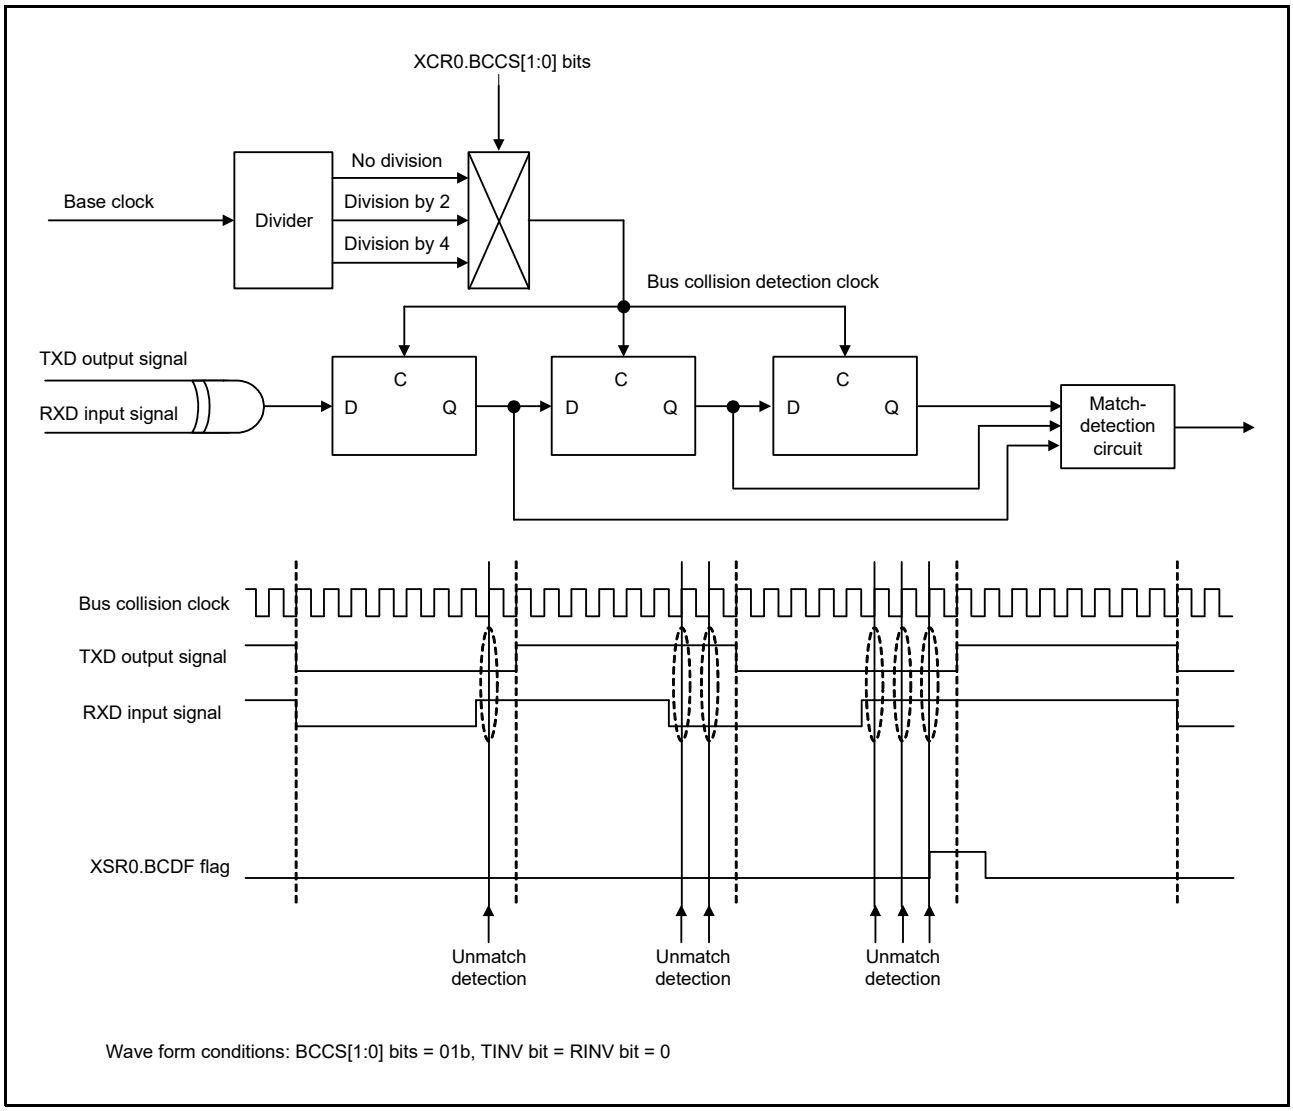

Figure 33.75 Example of Operations with Bus Collision Detection

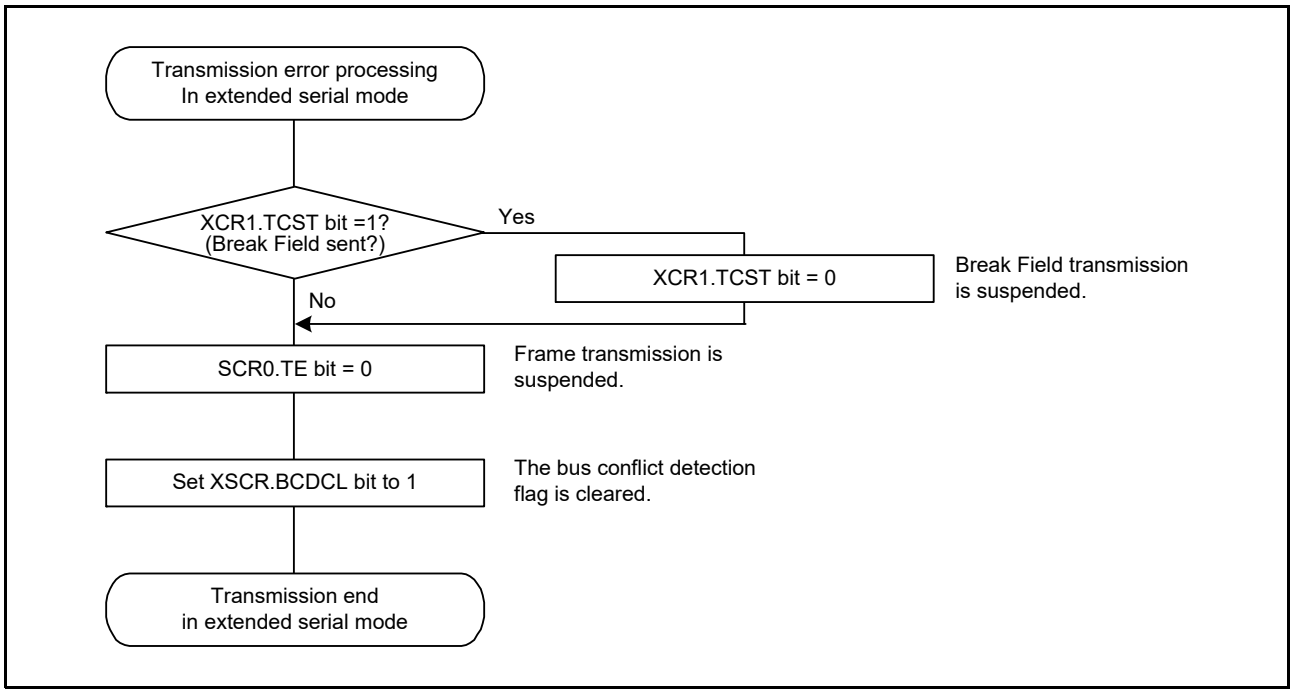

Figure 33.76 ERI Interrupt Handling Flow at Transmission in Extended Serial Mode

33.8.5 Bit Rate Measurement

This function measures a bit rate between the effective edges of the input signal from the RXDn pin. Figure 33.77 shows an operation example of the bit rate measurement function.

(1) Writing 1 to XCR1.SDST and XCR1.BRME bits enables bit rate measurement. When this bit is set to 1, the valid edge interval of Control Field 0 and Control Field 1 data is measured. However, bit rate is not measured between the Break Field and the Break Delimiter. Set XCR1.BRME and XCR1.SDST bits to 1 simultaneously, only when measuring bit rate.
(2) Because bit rate is not measured in the Break Field, the effective edge detection flag is not set to 1 at the rising edge at the end of the Break Field, and the counter capture value is not stored in XSR1.CCV[15:0] bits.
(3) The counter starts counting from the falling edge of the start bit in Control Field 0. The Break Delimiter count value is not captured in XSR1.CCV[15:0] bits.
(4) The rising edge of the start bit is detected as an effective edge, and then the XSR0.AEDF flag is set to 1. If XCR0.AEDIE bit has been set to 1 at this time, an AED interrupt is output. The start bit count value is stored in XSR1.CCV[15:0] bits. The XSR1.CCV[15:0] value is retained until the effective capture value is read.
(5) Even if an effective edge is input from the RXD input pin, the count value of this effective edge timing is not captured because the XSR1.CCV[15:0] bits value has not been read and retention has not been released. In this case, an AED interrupt is not output.
(6) The XSR1.CCV[15:0] value is read. Then the retention of XSR1.CCV[15:0] bits is released and the XSR0.AEDF flag is cleared by hardware.
(7) Because the retention of XSR1.CCV[15:0] bits has been released, the count value is captured at the effective edge and is retained. At the same time, the XSR0.AEDF flag is set to 1, and if XCR0.AEDIE bit has been set to 1, an AED interrupt is output. The bit rate can be adjusted by calculating it from the count value between effective edges by software and by changing the RSCI settings.
(8) To disable bit rate measurement, write 0 to XCR1.BRME bit.
(9) The XSR0.AEDF value and the XSR1.CCV[15:0] value remain unchanged at the effective edge timing because the bit rate measurement function is disabled.

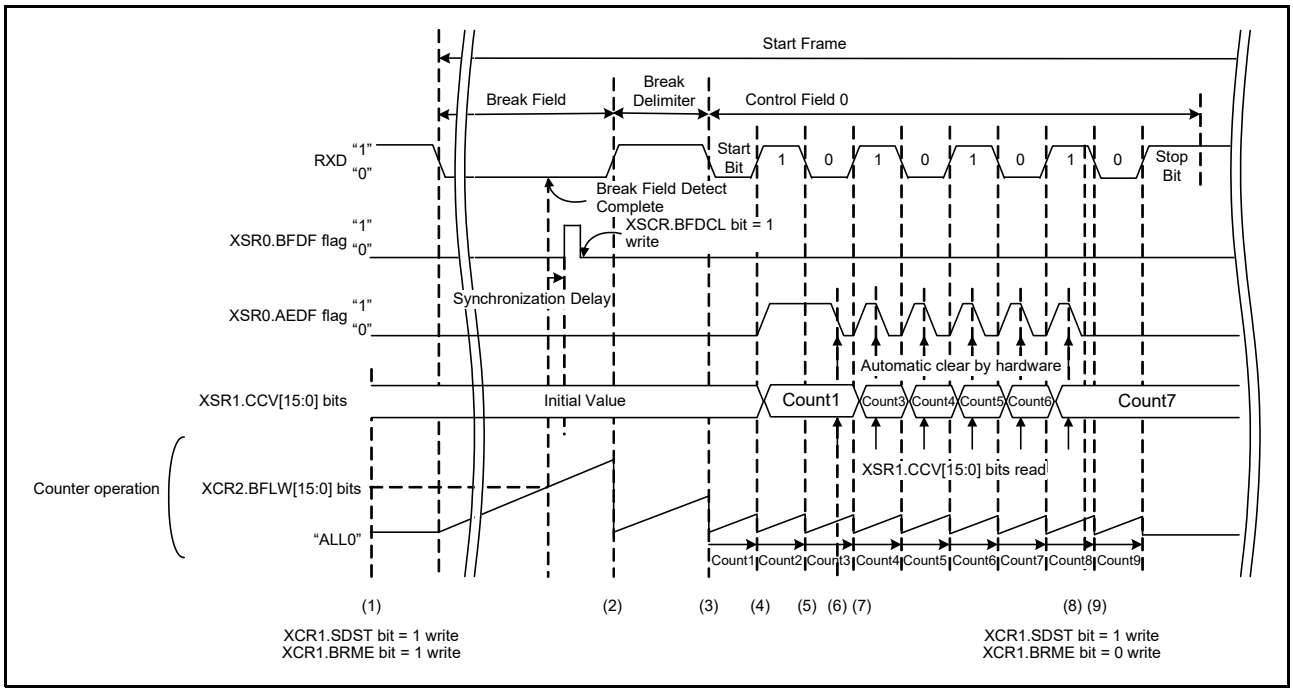

Figure 33.77 Operation Example of the Bit Rate Measurement Function

33.9 Operation in Simple I2C Mode

Simple I2C-bus format is composed of 8 data bits and an acknowledge bit. The frame following the start condition or restart condition is the slave-address frame, which is used by the master device to specify a slave device with which it is communicating. The currently specified slave device remains valid until a new slave device is specified or a stop condition is satisfied. The 8-bit data of each frame is transmitted from MSB.
Figure 33.78 shows I2C bus format, and Figure 33.79 shows the timing of I2C.

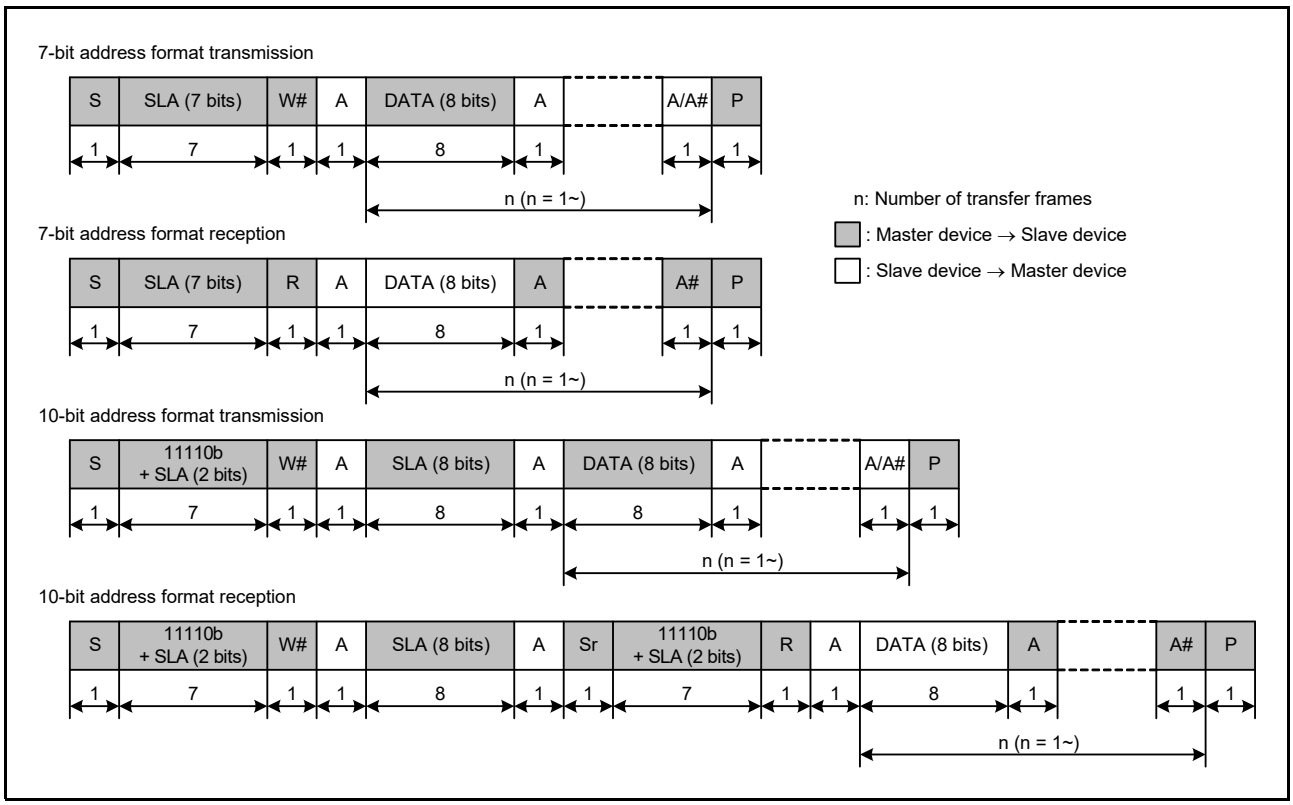

Figure 33.78 I2C-Bus Format

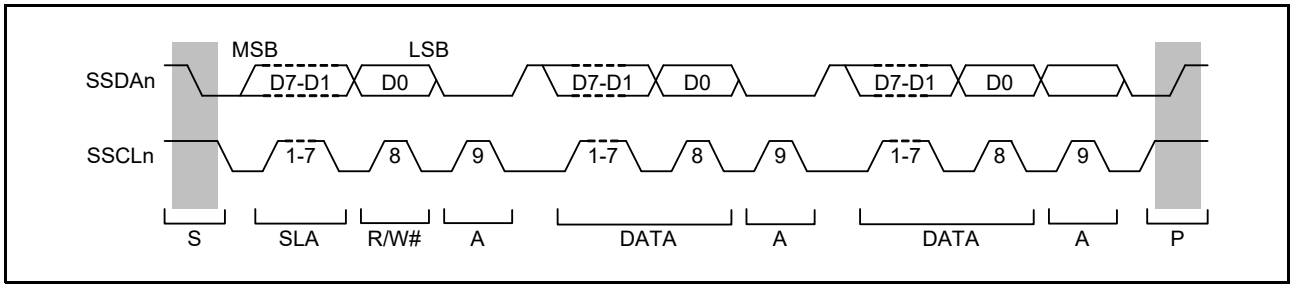

Figure 33.79 I2C-Bus Timing (When SLA is 7 Bits)

S: Indicates a start condition. The master device changing the level on the SSDAn line from the high to the low level when the SSCLn line is at the high level.
SLA: Indicates a slave address. The master device selects a slave device.
R/W#: Indicates the direction of transfer (reception or transmission). When R/W# is high, the transfer direction is from the slave device to the master device. When R/W# is low, the transfer direction is from the master device to the slave device.
A/A#: Indicates an acknowledge. This is returned by the slave device for master transmission and by the master device for master reception. The low level indicates ACK and the high level indicates NACK.
Sr: Indicates a restart condition. The master device changing the level on the SSDAn line from the high to the low level when the SSCLn line is at the high level.
DATA: Indicates the received or transmitted data.
P: Indicates a stop condition. The master device changing the level on the SSDAn line from the low to the high level when the SSCLn line is at the high level.

33.9.1 Generation of Start, Restart, and Stop Conditions

Writing 1 to SIMR.IICSTAREQ bit causes the generation of a start condition. The following operations are done at the generation of a start condition.

- The level on the SSDAn line falls (from the high level to the low level) and the SSCLn line is kept in the released state.
- The hold time for the start condition is secured as half of a bit period at the bit rate determined by the setting of the SCR2.BRR[7:0] bits.
- The level on the SSCLn line falls (from the high level to the low level), the SIMR.IICSTAREQ bit is set (to 0), and a start-condition generated interrupt is output.

Writing 1 to SIMR.IICRSTAREQ bit causes the generation of a restart condition. The following operations are done at the generation of a restart condition.

- The SSDAn line is released and the SSCLn line is kept at the low level.
- The period at low level for the SSCLn line is secured as half of a bit period at the bit rate determined by the setting of the SCR2.BRR[7:0] bits.
- The SSCLn line is released (transition from the low to the high level).
- Once the high level on the SSCLn line is detected, the setup time for the restart condition is secured as half of a bit period at the bit rate determined by the setting of the SCR2.BRR[7:0] bits.
- The level on the SSDAn line falls (from the high level to the low level).
- The hold time for the restart condition is secured as half of a bit period at the bit rate determined by the setting of the SCR2.BRR[7:0] bits.
- The level on the SSCLn line falls (from the high level to the low level), the SIMR.IICRSTAREQ bit is set (to 0), and a restart-condition generated interrupt is output.

Writing 1 to SIMR.IICSTPREQ bit causes the generation of a stop condition. The following operations are done at the generation of a stop condition.

- The level on the SSDAn line falls (from the high level to the low level) and the SSCLn line is kept at the low level.
- The period at low level for the SSCLn line is secured as half of a bit period at the bit rate determined by the setting of the SCR2.BRR[7:0] bits.
- The SSCLn line is released (transition from the low to the high level).
- Once the high level on the SSCLn line is detected, the setup time for the stop condition is secured as half of a bit period at the bit rate determined by the setting of the SCR2.BRR[7:0] bits.
- The SSDAn is released (transition from the low to the high level), the SIMR.IICSTPREQ bit is set (to 0), and a stop condition generated interrupt is output.

Figure 33.80 shows the timing of operations in the generation of start, restart and stop conditions.

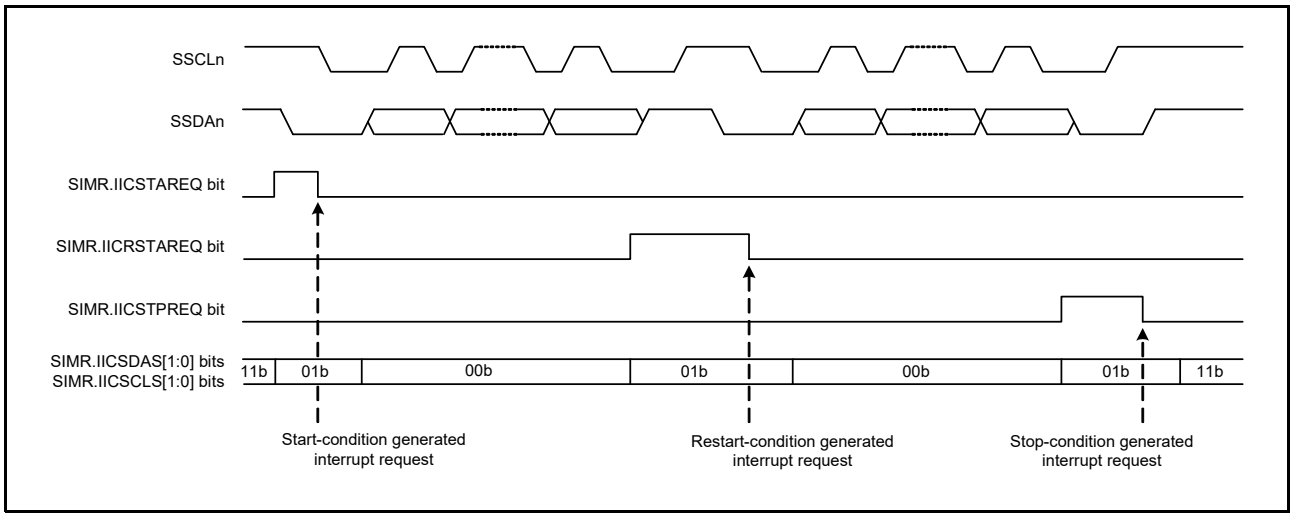

Figure 33.80 Timing of Operations in the Generation of Start, Restart, and Stop Conditions

33.9.2 Clock Synchronization

The slave device of the communication partner may make SSCLn line Low-level with a view to insert a wait. Setting the SIMR.IICCSC bit to 1, applies control to obtain synchronization when the levels of the internal SCL signal and the level being input on the SSCLn pin differ.

When the SIMR.IICCSC bit is set to 1, the level of the internal SCL signal changes from low to high, counting to determine the period at high level is stopped while the low level is being input on the SSCLn pin, and counting to determine the period at high level starts after the transition of the input on the SSCLn pin to the high level. The interval until counting to determine the period at high level starts on the transition of the SSCLn pin to the high level is the total time which contains the SSCLn input delay, the noise filtering delay of the SSCLn pin (2 or 3 cycles of the filtering clock), and the internal processing delay (1 or 2 cycles of PCLK). The period at high level of the internal SCL signal is extended even if other devices are not placing the low level on the SSCLn line.

If the SIMR.IICCSC bit is 1, synchronization is obtained for the transmission and reception of data by taking the logical AND of the input on the SSCLn pin and the internal SCL signal. If the SIMR.IICCSC bit is 0, synchronization with the internal SCL signal is obtained for the transmission and reception of data.

If a slave device inserts a period of waiting into the interval until the transition of the internal SCL signal from the low to the high level after a request for the generation of a start, restart, or stop condition is issued, the time until generation is prolonged by that period.

If a slave device inserts a period of waiting after the transition of the internal SCL signal from the low to the high level, although the generation-completed interrupt is issued without stopping the period of waiting, generation of the condition itself is not guaranteed.

Figure 33.81 shows an example of operations to synchronize the clocks.

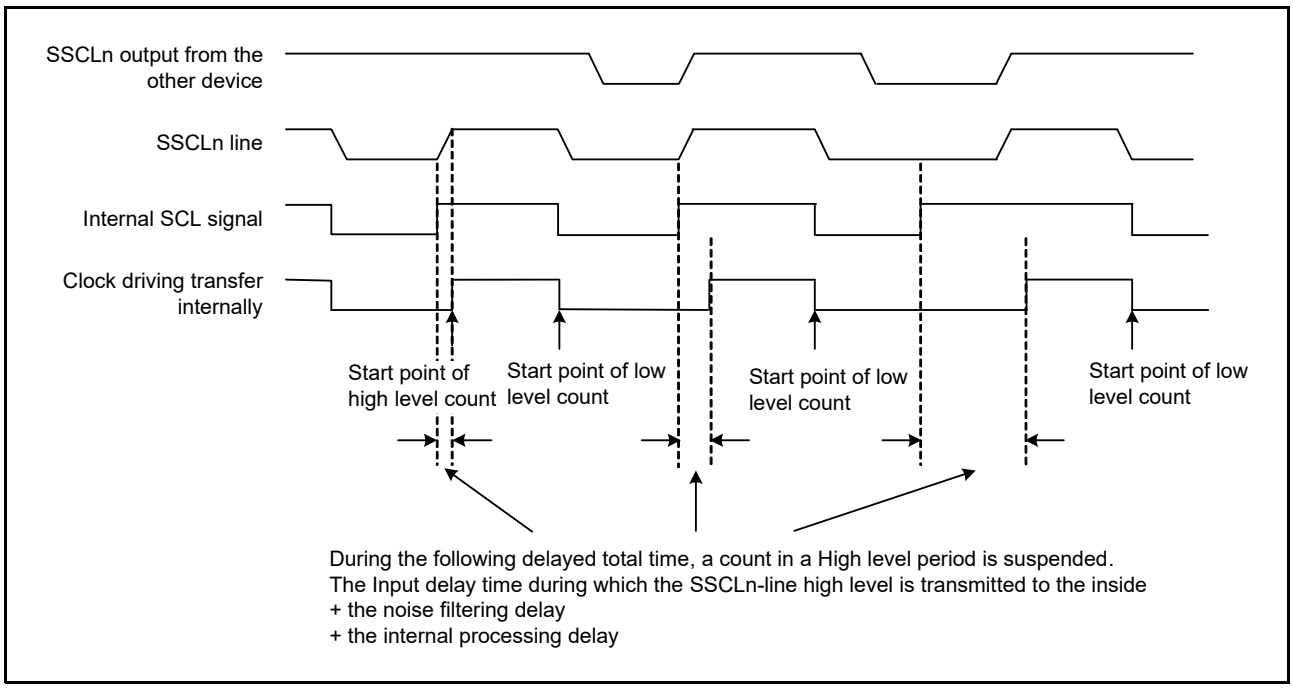

Figure 33.81 Example of Operations for Clock Synchronization

33.9.3 SDA Output Delay

The SIMR.IICDL[4:0] bits can be used to set a delay for output on the SSDAn pin relative to falling edges of output on the SSCLn pin. The delay-time settings are selectable from 0 to 31 cycles of the clock signal from the on-chip baud rate generator (The base is PCLK and selected the divided clock by the SCR2.CKS[1:0] bits). About Start/Restart/Stop conditions, 8bit-transmission data and acknowledge, the SSDAn pin output can be delayed.
If the SDA output delay is shorter than the falling time of the SSCLn output pin, the change of the SSDAn output pin will start while the SSCLn output pin level is falling, then there is a possibility of erroneous operation for slave devices. Ensure setting the SDA output delay greater than the SSCLn maximum falling time. (300 ns for I^2C normal/fast mode.)
Figure 33.82 shows the timing of delays in SDA output.

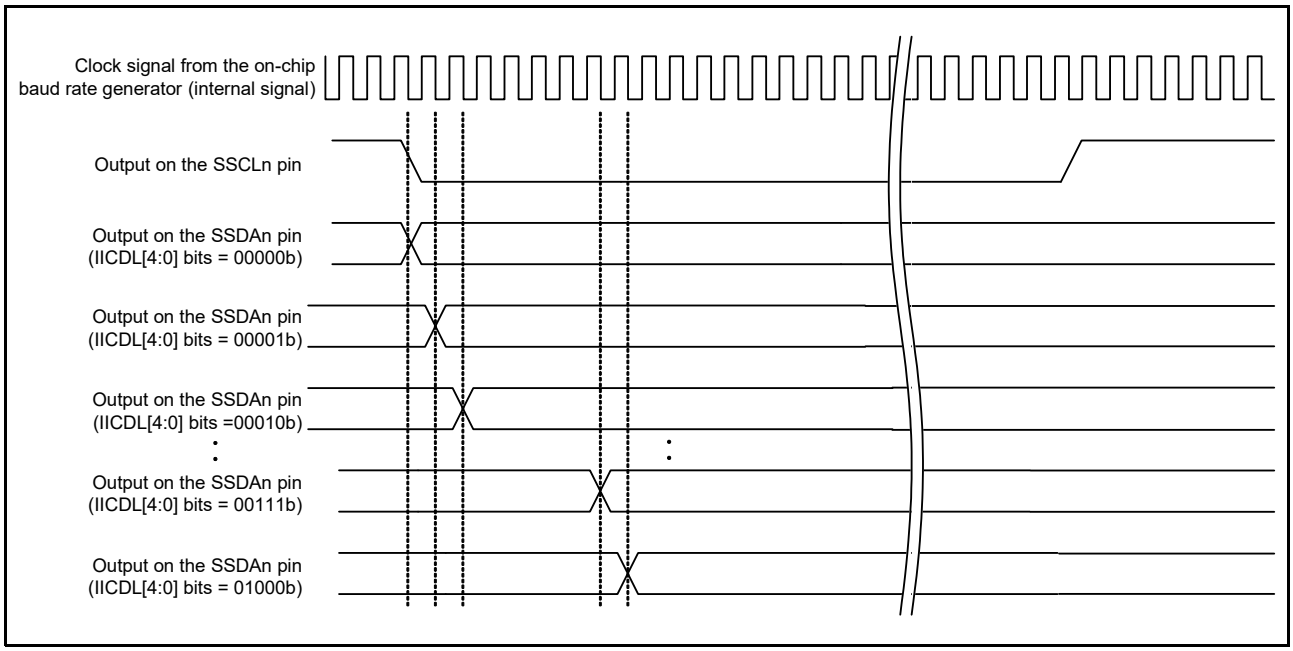

Figure 33.82 Timing of Delays in SDA Output

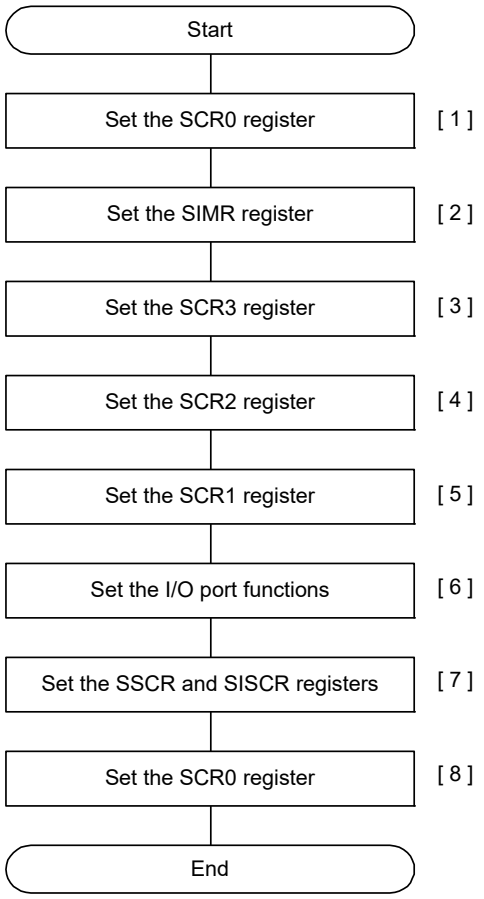
33.9.4 RSCI Initialization (Simple I2C Mode)

Write initial value (0000_0000h) to SCR0, then initialize RSCI according to Figure 33.83.
When changing the operating mode, transfer format, and so on, be sure to set 0 to SCR0.TE bit and SCR0.RE bit before proceeding with the changes. (Or write initial value to SCR0 again.) In simple I2C mode, the open-drain setting for the communication ports should be made on the port side.



[1] Set the following bits of SCR0 register to 0.
TEIE, TIE, RIE, TE, RE
If you have not changed from the initial settings, you can skip this step.

[2] Set the IICSDAS[1:0] and IICSCLS[1:0] bits to 11b.
Set the IICDL[4:0] and IICINTM bits as required.
Set the IICACKT and IICCSC bits to 1.

[3] Set the transmission/reception format as the communication mode (MOD[2:0] bits = 100b) and CKE[1:0] bits = 00b.

[4] Set the bit rate modulation function*1, the clock selection, and the bit rate.

[5] Set noise filter, communication pin status, parity check, CTS/RTS function.

[6] Set I/O port settings that allow use (on NMOS opendrain output pins and Hi-Z) of the SSCLn and SSDAn pin functions.

[7] Write 1 to the following bits and clear the corresponding flag.
SSCR.RDRFC, AFERC, APERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC
SISCR.IICSTIFC

[8] Set the TE and RE bits to 1.
To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time.
(for transmission and when the SIMR.IICINTM bit is 1, clear the RIE bit.) Setting the TE and RE bits to 1 makes the SSCLn and SSDAn pin functions available.

Note 1. If you do not use the bit rate modulation unction, you do not need to set it.

Note: Set the SCR0.TE and RE bits to 0 or 1 at the same time.

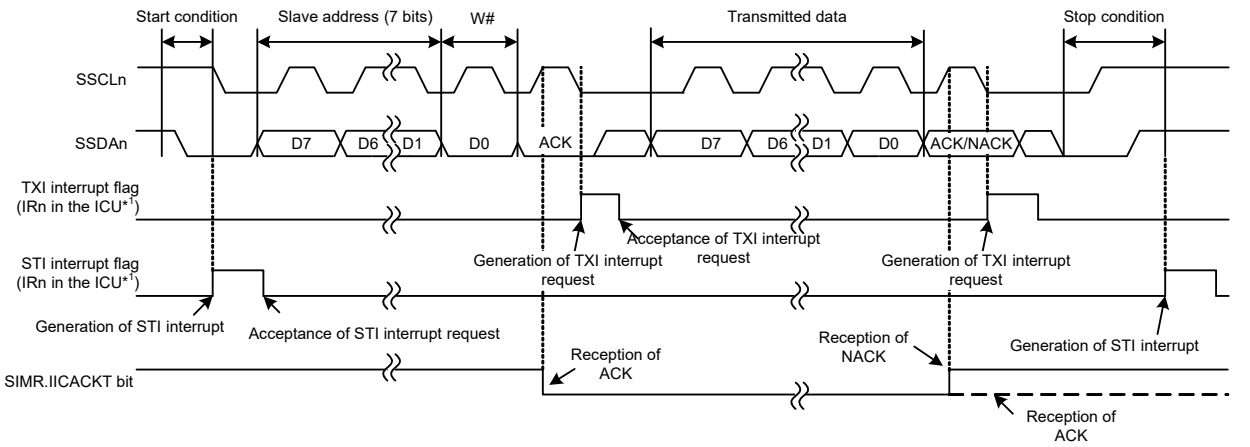
Figure 33.83 Example of the Flowchart of RSCI Initialization (for Simple I2C Mode)

33.9.5 Operation in Master Transmission (Simple I2C Mode)

Figure 33.84 and Figure 33.85 show examples of operations in master transmission, Figure 33.86 to Figure 33.88 show the example flowcharts. See Table 33.47 about the STI interrupt.

Figure 33.84 shows the operation example when SIMR.IICINTM bit is 1 (Reception/Transmission interrupt are in use). In this case, you can start DMAC or DTC by TXI interrupt. However, if use DMAC or DTC, ACK/NACK can not be confirmed. So, if you want to confirm ACK/NACK, prepare transmit data by CPU. In simple I2C mode, TXI interrupt is generated when communication of one frame is completed. And it isn't used reception interrupt in master transmission, so the SCR0.RIE bit set to 0.

Figure 33.86 shows a flow chart in the case of SIMR.IICINTM bit is 1 and address transmission by CPU and data transmission by DTC or DMAC. Figure 33.87 shows a flow chart of address and data transmission by CPU. When 10-bit slave addresses are in use, steps [3] and [4] are repeated twice.



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

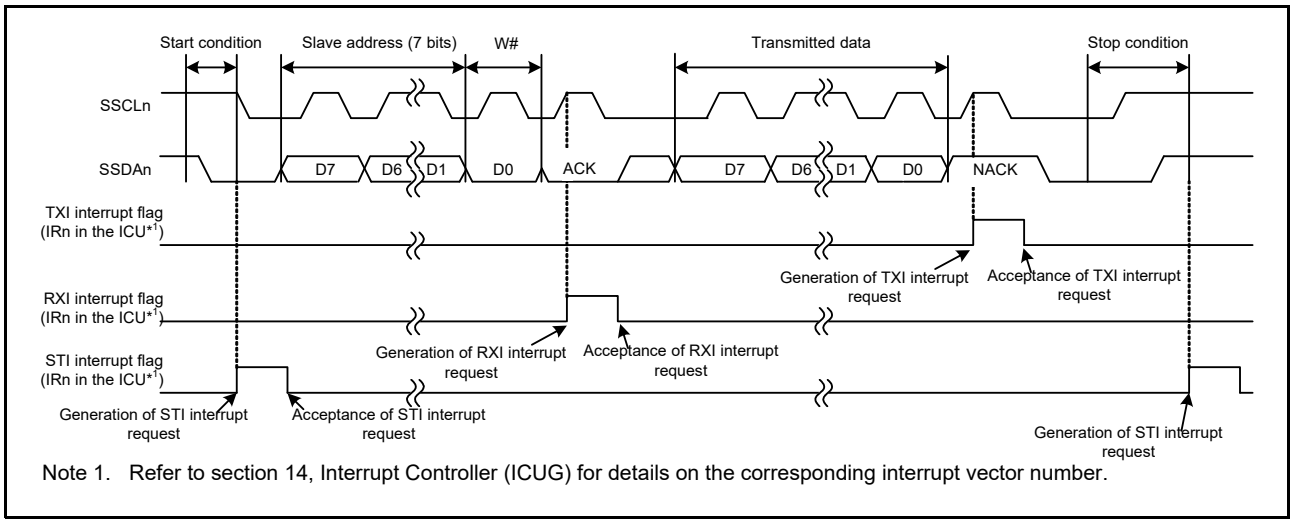
Figure 33.84 Example 1 of Operations for Master Transmission in Simple I2C Mode (with 7-Bit Slave Addresses, Transmission Interrupts, and Reception Interrupts in Use (SIMR.IICINTM Bit = 1))

Figure 33.85 shows an example of operations when SIMR.IICINTM bit is 0 (ACK and NACK interrupt in use). In this case, DTC or DMAC is activated by the ACK interrupt, and necessary number of data bytes are transmitted. When the NACK is received, error processing, such as transmission stop and retransmission, is performed by the NACK interrupt as the trigger.

Figure 33.88 shows a flow chart of SIMR.IICINTM bit is 0

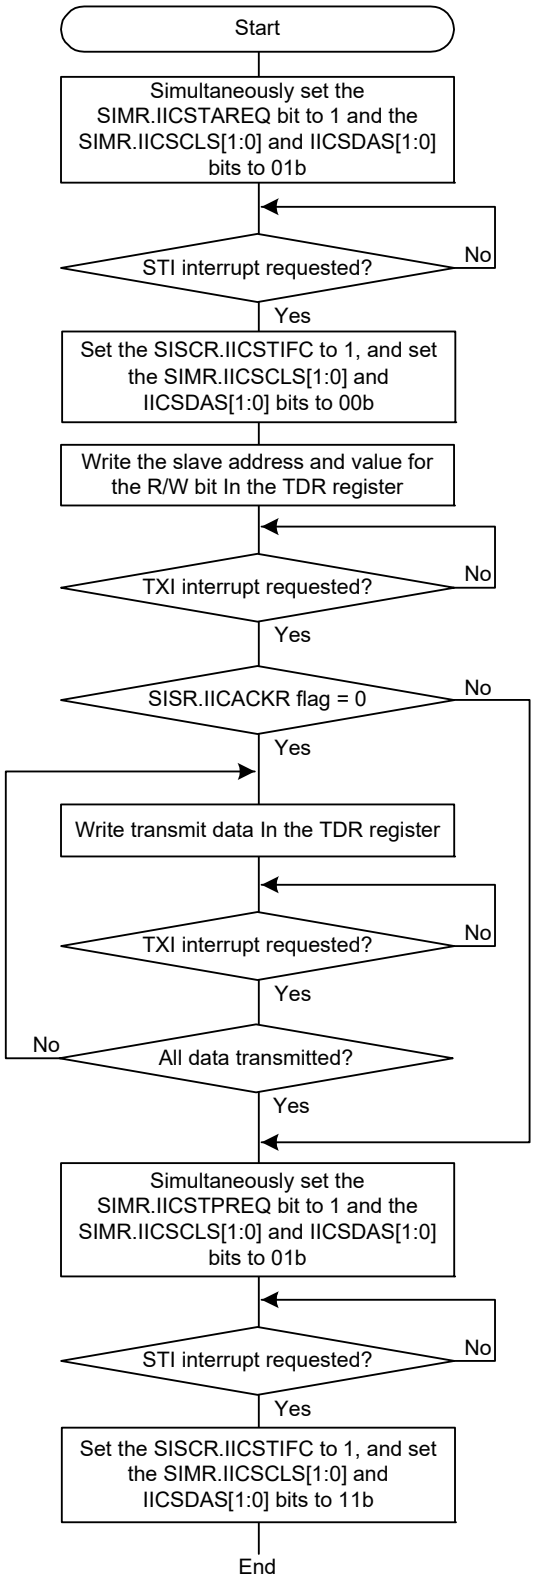
To resume communication after interrupting communication for some reason after writing transmit data to TDR, follow the procedure below.

1. Set the SCR0.TE and SCR0.RE bits to 0 to stop communication.
2. Set SIMR.IICSCLS[1:0] and SIMR.IICSDAS[1:0] bits to 11b, release the I2C bus, and clear various condition generation requests.
3. When the SSR.RDRF flag is 1, the RDR register is read by dummy and the RDRF bit is set to 0.
4. Set the SCR0.TE and SCR0.RE bits to 1 and restart communication.



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 33.85 Example 2 of Operations for Master Transmission in Simple I²C Mode (with 7-Bit Slave Addresses, ACK Interrupts, and NACK Interrupts in Use (SIMR.IICINTM Bit = 0))



[0] [0] For transmission, set the SCR0.RIE bit to 0 at initialization. (RXI and ERI interrupts requests are disabled)

[1] [1] Generate a start condition.

[2] [2] Writing to TDR register:
Writing the slave address and value for the R/W bit to TDR register.

[3] [3] Confirming ACK response from the slave address:
Check the SISR.IICACKR bit. If its value is 0, it is indicated that the slave device responded with ACK and operations proceed. If its value is 1, it is indicated that there was no response from a slave device so the next transition is to generation of the stop condition.

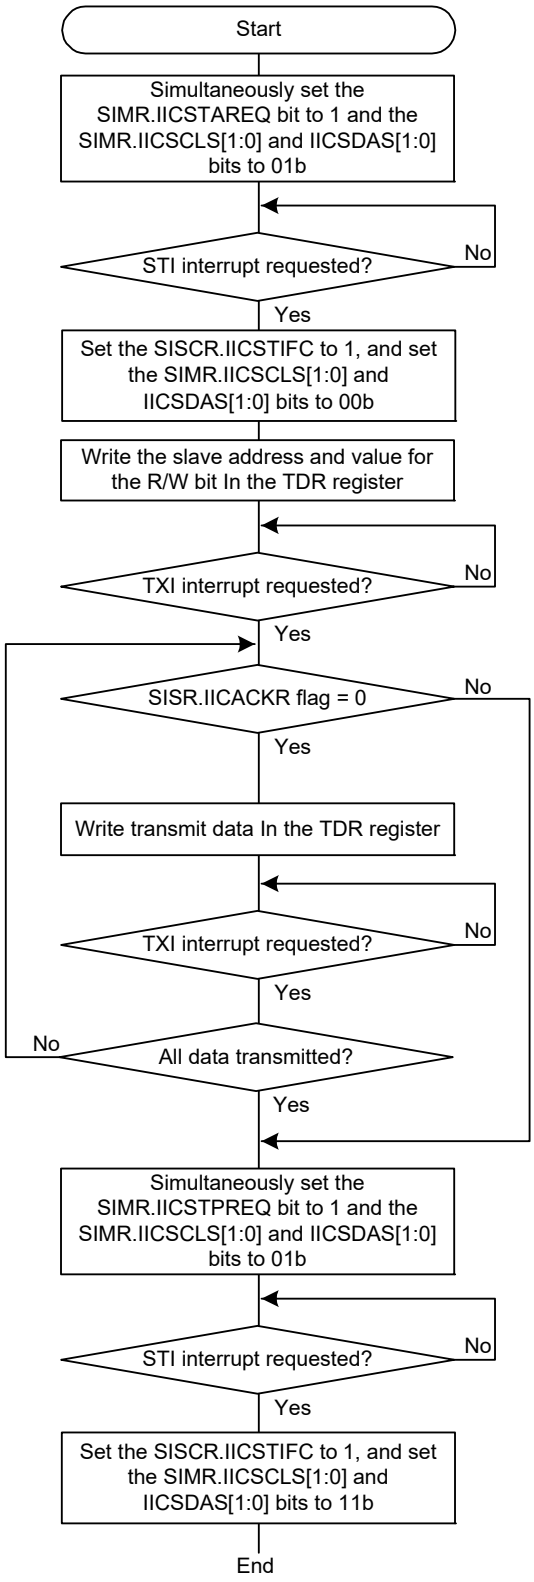
If 10-bit slave addresses are in use, processing of [2] and [3] is repeated twice.

[4] [4] Steps for continuing with serial transmission:
When transmission is to continue, write further transmit data to TDR register. Except for the first data to be transmitted, a TXI request can activate the DMAC or DTC to handle writing of data to TDR register.
But it cannot be confirmed status of ACK or NACK in this case.

[5] [5] Generation of a stop condition.

Note: In simple I^2C mode, the TXI interrupt request is generated when communication is completed, unlike the timing during clock synchronous transmission.

Figure 33.86 Example of the Procedure for Master Transmission Operations in Simple I^2C Mode (when SIMR.IICINTM Bit is 1, and when Confirming ACK/NACK by Address Transmission Only)



[0] [0] For transmission, set the SCR0.RIE bit to 0 at initialization. (RXI and ERI interrupts requests are disabled)

[1] [1] Generate a start condition.

[2] [2] Writing to TDR register:
Writing the slave address and value for the R/W bit to TDR register.

[3] Confirming ACK response from the slave address:
Check the SISR.IICACKR bit. If its value is 0, it is indicated that the slave device responded with ACK and operations proceed. If its value is 1, it is indicated that there was no response from a slave device so the next transition is to generation of the stop condition.

If 10-bit slave addresses are in use, processing of [2] and [3] is repeated twice.

[4] Steps for continuing with serial transmission:
When transmission is to continue, write further transmit data to TDR. To checking whether ACK or NACK in every transmission, you cannot use DMA or DTC.

[5] Generation of a stop condition.

Note: In simple I^2C mode, the TXI interrupt request is generated when communication is completed, unlike the timing during clock synchronous transmission.

Figure 33.87 Example of the Procedure for Master Transmission Operations in Simple I^2C Mode (when SIMR.IICINTM Bit is 1, and when Confirming ACK/NACK in All Transmissions)

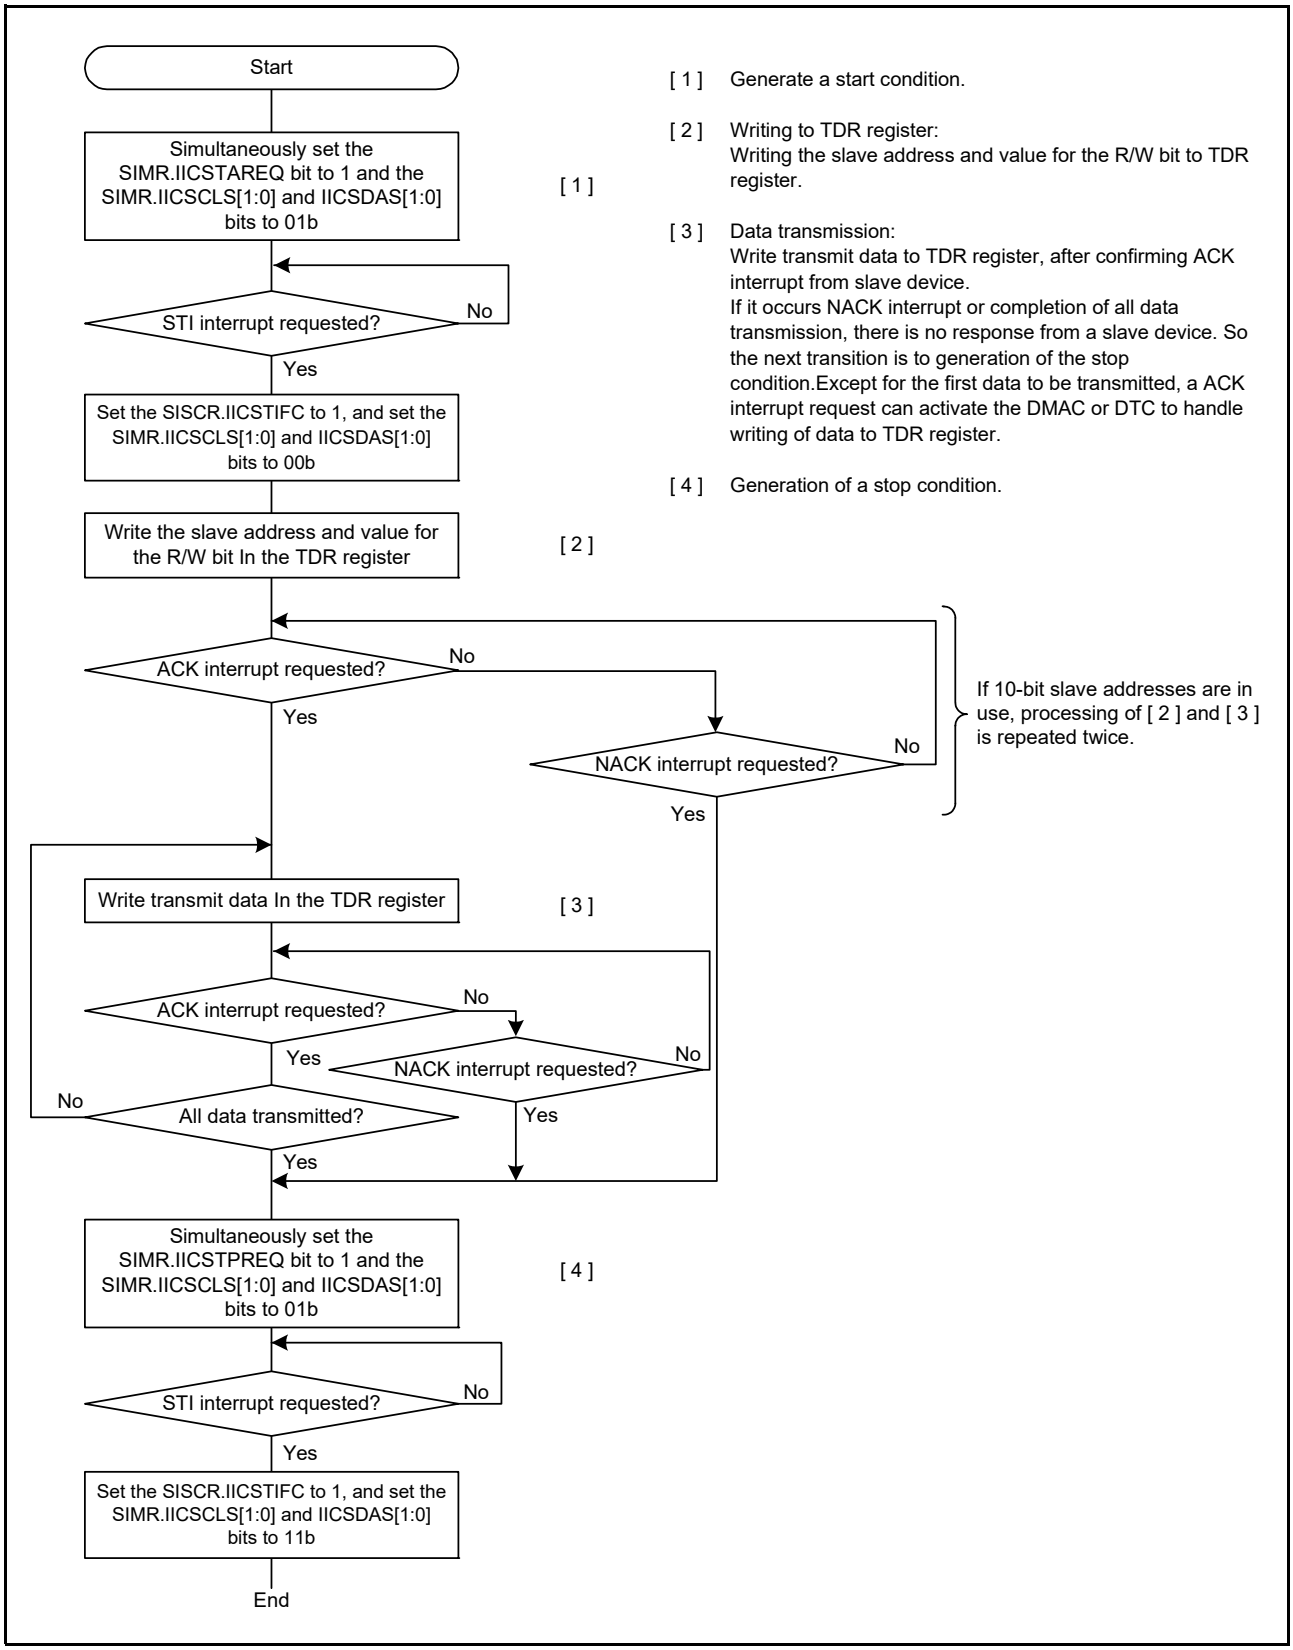


Figure 33.88 Example of the Procedure for Master Transmission Operations in Simple I²C Mode (when SIMR.IICINTM Bit is 0)

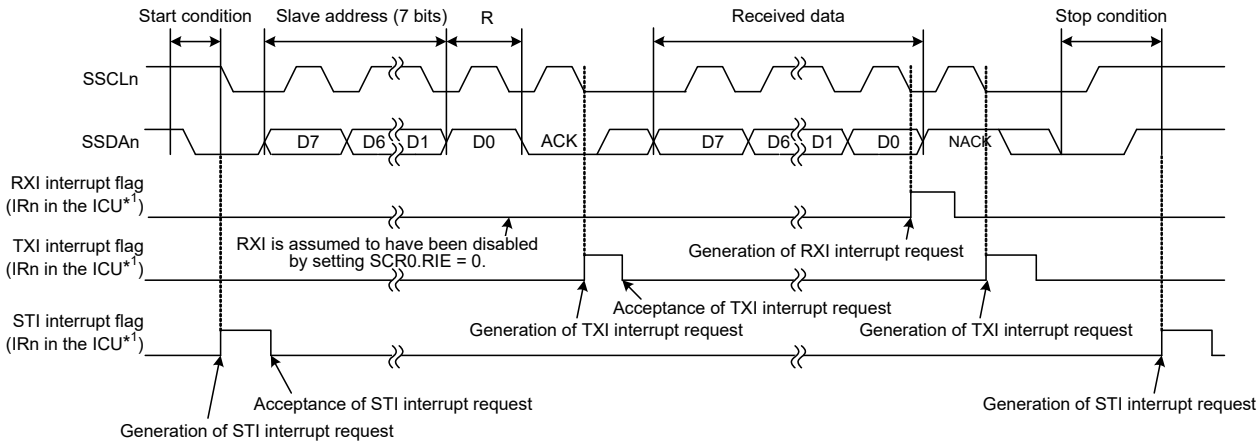
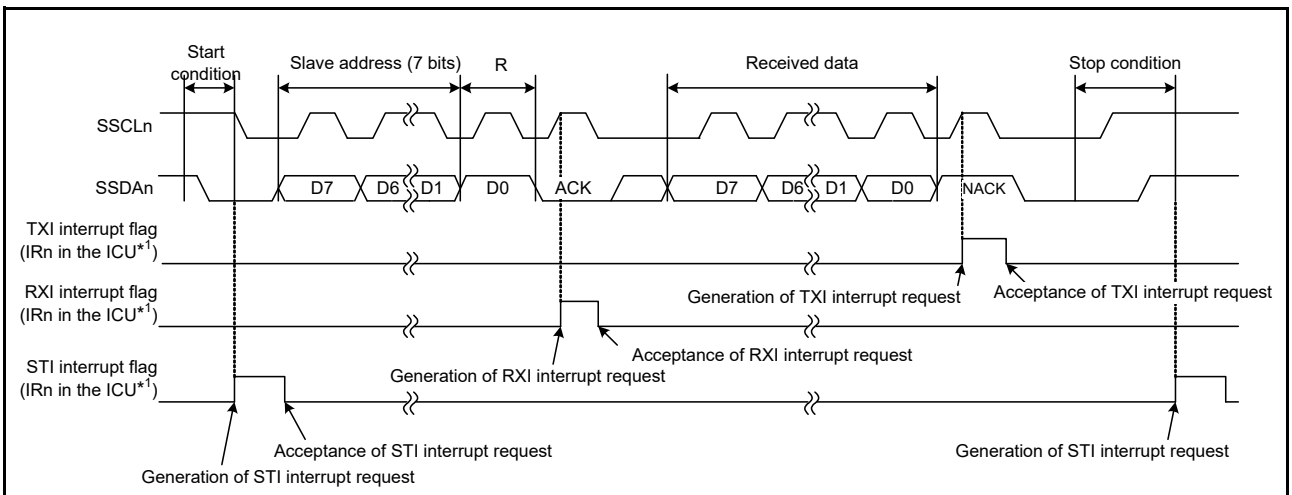
33.9.6 Master Reception (Simple I2C Mode)

Figure 33.89 and Figure 33.90 show example of operations in simple I2C mode master reception. Figure 33.91 and Figure 33.92 show flowchart of the master reception. The value of the SIMR.IICINTM bit is assumed to be 1 (use reception and transmission interrupts) and 0 (use ACK and NACK interrupts).
In simple I2C mode, the transmit end interrupt (TXI) is generated when communication of one frame is completed.



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 33.89 Example of Operations for Master Reception in Simple I2C Mode (with 7-Bit Slave Addresses, Transmission Interrupts, and Reception Interrupts in Use (SIMR.IICINTM Bit = 1))



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 33.90 Example of Operations for Master Reception in Simple I2C Mode (with 7-Bit Slave Addresses, ACK and NACK Interrupt in Use (SIMR.IICINTM Bit = 0))

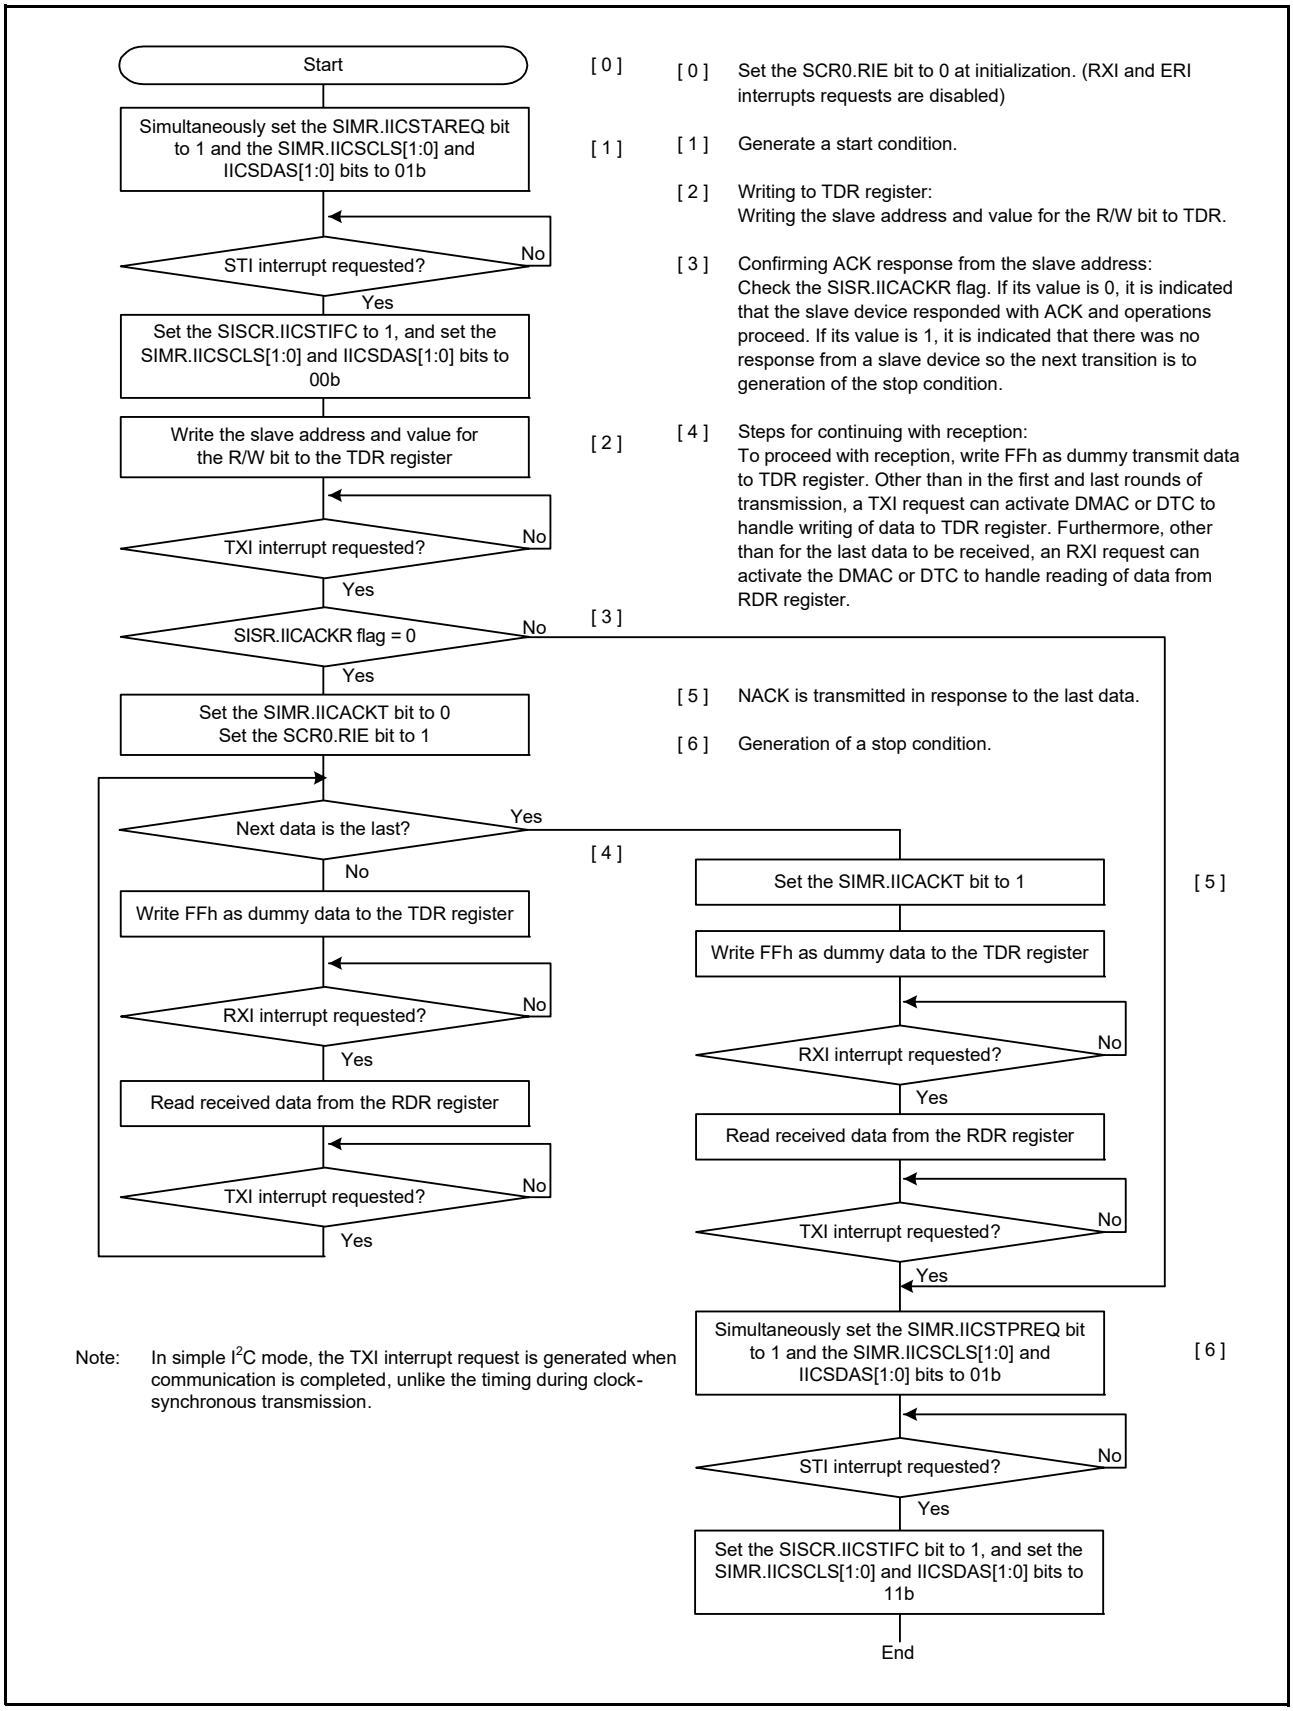


Figure 33.91 Example of the Procedure for Master Reception Operations in Simple I²C Mode (When SIMR.IICINTM Bit is 1, and Transmission Interrupts and Reception Interrupts in Use)

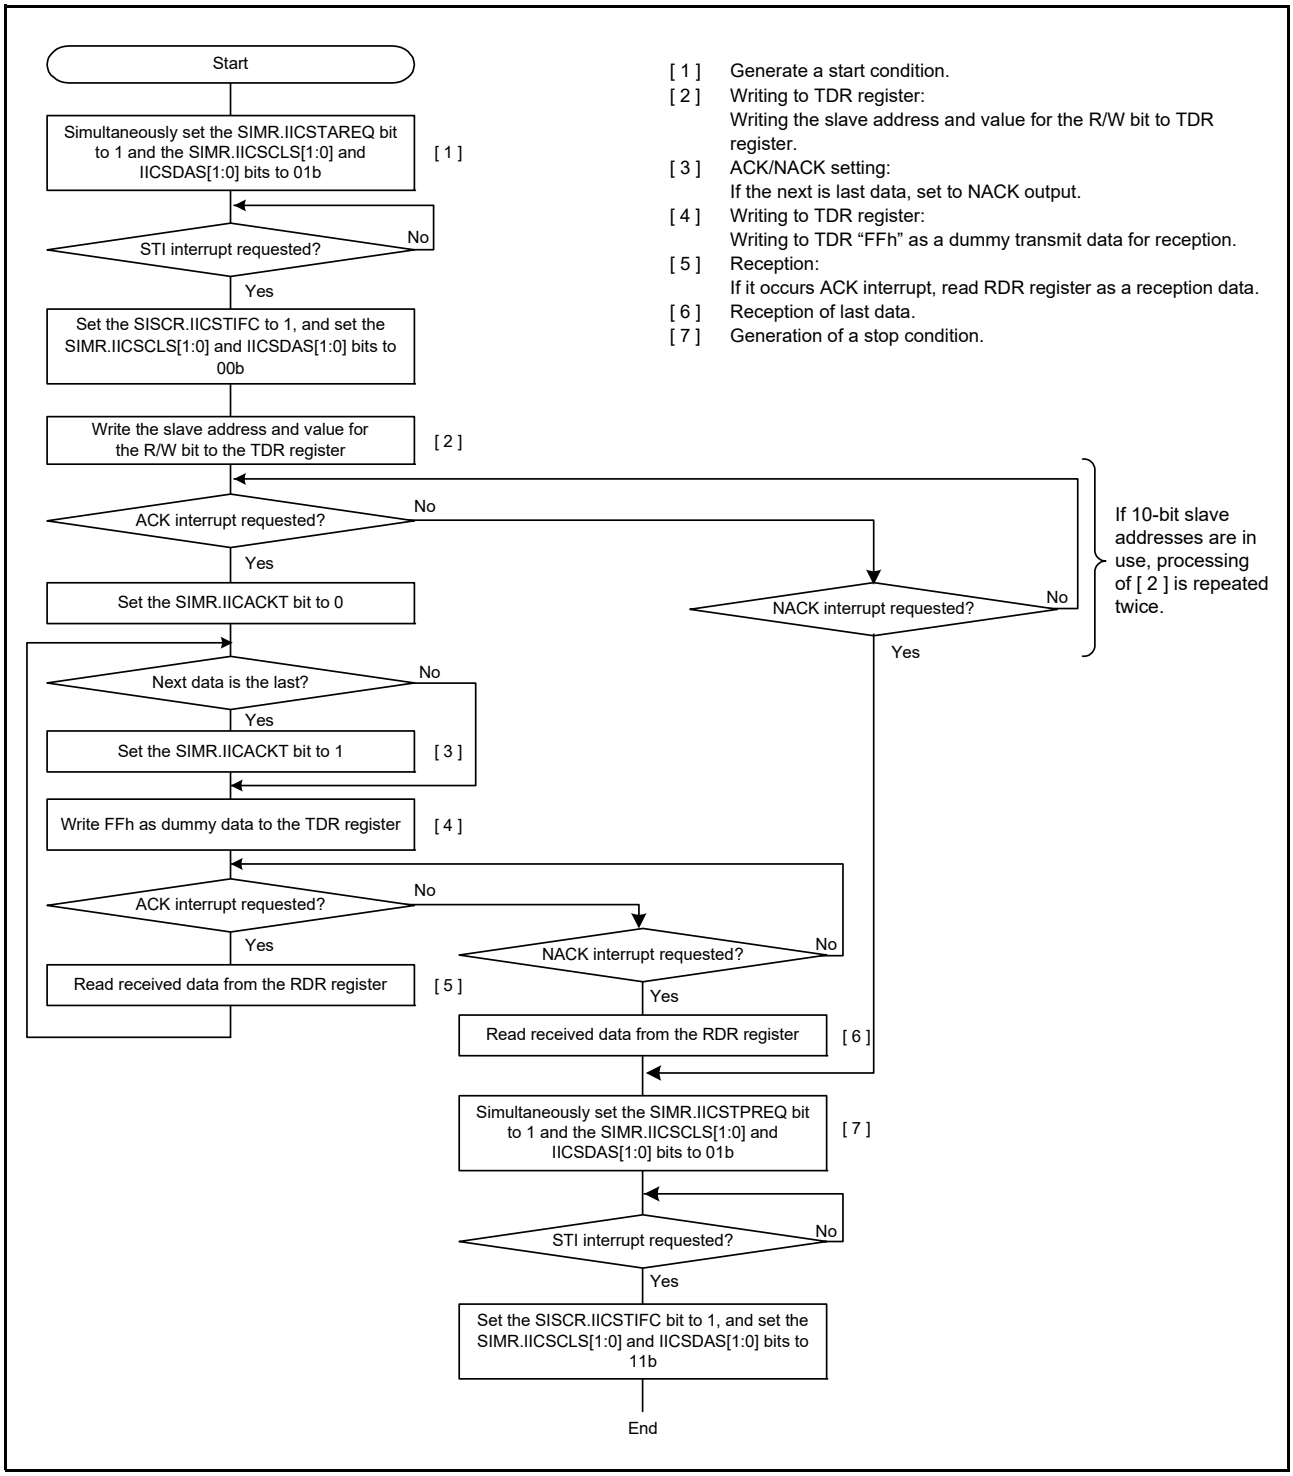

Figure 33.92 Example of the Procedure for Master Reception Operations in Simple I²C Mode (When SIMR.IICINTM Bit is 0, and ACK Interrupts and NACK Interrupts are in Use)

33.10 Operation in Clock Synchronous Mode

Figure 33.93 shows the communication data format of clock synchronous serial communication.
In clock synchronous mode, data is transmitted and received in synchronization with clock pulses. A communication data character consists of 8-bit data. In clock synchronous mode, no parity bit can be added.
In data transmission when CPHA bit = 1 and CPOL bit = 1, the RSCI outputs data from the falling edge of the sync clock until the next falling edge. In data reception, data is read at the rising edges of the sync clock. After 8-bit data is output, the communication line holds the final-bit output state. In slave communication when CPHA bit = 0, however, the communication line holds the first-bit output state.
Because the RSCI has an internal transmitter and a receiver independently, RSCI enable full-duplex communication by sharing a communication clock of the transmitter and the receiver. Furthermore, because both the transmitter and the receiver have a double- buffer structure, continuous transmission and reception are possible by writing the next transmit data during transmission and reading the previous receive data during reception.

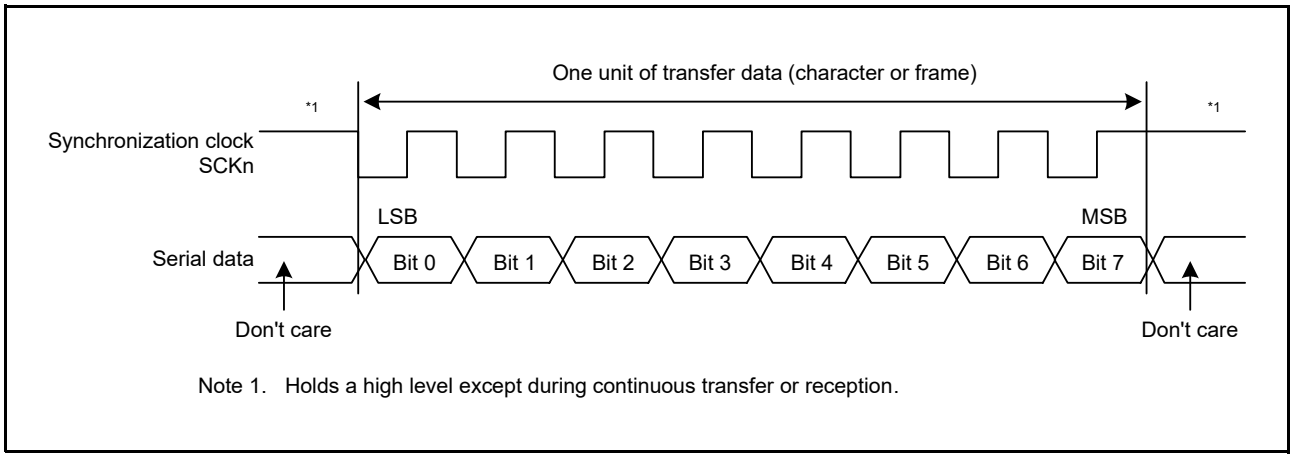

Figure 33.93 Data Format in Clock Synchronous Serial Communications (LSB First, CPHA Bit = 1, CPOL Bit = 1)

33.10.1 Clock

(1) When the Internal Clock is Selected

When the SCR3.CKE[1:0] bits are set to 00b or 01b (master mode), the internal clock generated by the on-chip baud rate generator can be selected and the sync clock is output from the SCKn pin. Eight pulses of the sync clock are output during single-character transmission/reception. The sync clock remains at a high level*1 while no transmission or reception is performed. In transmission-only or transmission/reception, the sync clock is not output unless transmit data is prepared.
When the internal clock is selected, the clock with a delay from the SCKn signal is used for the master reception sampling clock. This ensures the data setup time and hold time for high-speed communication.

Note 1. When SCR3.CPHA bit = 0 and SCR3.CPOL bit = 1 or when SCR3.CPHA bit = 1 and SCR3.CPOL bit = 1, the sync clock stops at a high level. When SCR3.CPHA bit = 0 and SCR3.CPOL bit = 0 or when SCR3.CPHA bit = 1 and SCR3.CPOL bit = 0, the sync clock stops at a low level.

(2) When the External Clock is Selected

When the SCR3.CKE[1:0] bits are set to 10b or 11b (slave mode), data is transmitted and received using the external clock that is input from the SCKn pin.

33.10.2 CTS and RTS Functions

The CTS function performs transmission/reception and controls transmission start using the CTSn# pin input when the internal clock is selected. Setting the SCR1.CTSE bit to 1 enables the CTS function. In clock synchronous communication, the CTS function can be used for the internal clock and the RTS function can be used for the external clock, so the CTS function and RTS function cannot be used at the same time.
When the CTS function is enabled, transmission/reception and transmission start only when the CTSn# pin input level is low.
When using the FIFO, if the CTSn# signal remains high before transmission, transmission will not start, but the number of data stored will be “number written to the TDR register – 1” (unlike using asynchronous FIFO). This is because data is transferred to the TSR register after writing to the TDR register, but if the CTSn# signal is set to low level, transmission starts from the TSR register, so there is no problem.
Even if the CTSn# pin input becomes high level during transmission/reception or transmission operation, frames that are being transmitted/received or being transmitted are not affected and transmission/reception or transmission operation continues.
The RTS function makes a serial communication start request using the RTSn# pin output when the external sync clock is selected. When serial communication is enabled, the RTSn# pin outputs a low level. A low level and a high level are output under the following conditions.

(a) When the SCR3.FM Bit is 0 (Non-FIFO Mode)

[Conditions for low-level output]
When the following conditions are all satisfied

- The SCR0.RE or SCR0.TE bit is 1
- No receive data are present before reading and reception is not in progress. (when SCR0.RE bit = 1)
- Data written in the TDR register is ready for transmission (when SCR0.TE bit = 1)
- The SSR.ORER flag is 0

[Condition for high-level output]
The conditions for low-level output have not been satisfied.
When SCR0.RE bit is set to 0 without reading the RDR register to terminate reception after reception is complete, the RTSn# pin output level remains high. At this time, write 0 to SCR0.RE bit.

(b) When the SCR3.FM Bit is 1 (FIFO Mode)

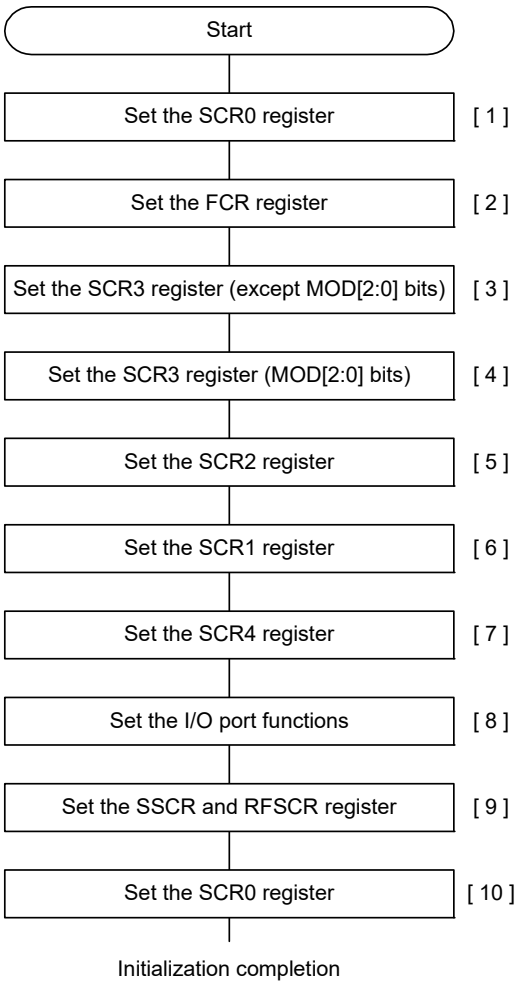
[Conditions for low-level output]
When the following conditions are all satisfied

- The SCR0.RE or SCR0.TE bit is 1
- The number of receive data stored in the receive FIFO (RDR register) is less than the value set in FCR.RSTRG[4:0] (when SCR0.RE bit = 1)
- Data written in the transmit FIFO (TDR register) is ready for transmission (when SCR0.TE bit = 1)
- The SSR.ORER flag is 0

[Condition for high-level output]
When the conditions for low-level output are not satisfied

33.10.3 RSCI Initialization (Clock Synchronous Mode)

Before starting data transmission/reception, write 0 to SCR0.TE bit and SCR0.RE bit (or write initial values to the SCR0 register) and initialize the RSCI according to the flowchart example in Figure 33.94.
Before changing operating mode or communication format, also be sure to write 0 to TE bit and RE bit.
Note that writing 0 to the RE bit does not initialize the ORER, AFER, APER, and RDRF flags in SSR register and the RDR register. Also note that writing 0 to the TE bit does not initialize the SSR.TEND flag in FIFO mode. Attention is also needed for changing operating mode.
When the SCR0.TIE bit = 1, note that setting the TE bit to 1 from 0 generates a TXI interrupt.



[1] Set the following bits of SCR0 register to 0[*1].
TEIE, TIE, RIE, TE, RE
If you have not changed from the initial settings, you can skip this step.

[2] Set the TFRST and RFRST bits to 1 to empty FIFO.
Set the TTRG[4:0], RTRG[4:0], and RSTRG[4:0] bits.

[3] Set SCR3 except of communication mode.
FIFO use/no-use
Transmission/reception format
Clock setting
Leave unused bits (CHR[1:0], STOP, RXDESEL, MP, DEEN, GM, BLK) at their initial values.[*2]

[4] Set communication mode (MOD[2:0] bits = 010b)[*2].

[5] Select clock, set bit rate[*3]. Leave unused bits (SCR2.BCP[2:0], ABCS, ABCSE, BRME, and MDDR[7:0]) at their initial values.

[6] Set up the half-duplex communication, the loop-back function, communication pin status, and the CTS/RTS function.

[7] Set up the adjust sampling timing function. Leave unused bits (SCR4.CMPD[8:0] bits) at their initial values.

[8] Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.

[9] Write 1 to the following bits and clear the corresponding flag.
SSCR.RDRFC, AFERC, APERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC
RFSCR.DRC

[10] Set the TE or RE bit to 1.[*1, *4] To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time.
Setting the TE and RE bits allows TXDn and RXDn to be used.

Note 1. In simultaneous transmit and receive operations, the TE and RE bits in SCR0 should both be to 0 or set to 1 simultaneously.
Note 2. Set the clock (CPOL and CPHA bits) before setting the communication mode.
Note 3. If you use an external clock, you do not need to set it.
Note 4. When using the internal clock (master), the setting of reception only is prohibited.

Figure 33.94 Example of RSCI Initialization Flowchart (Clock Synchronous Mode)

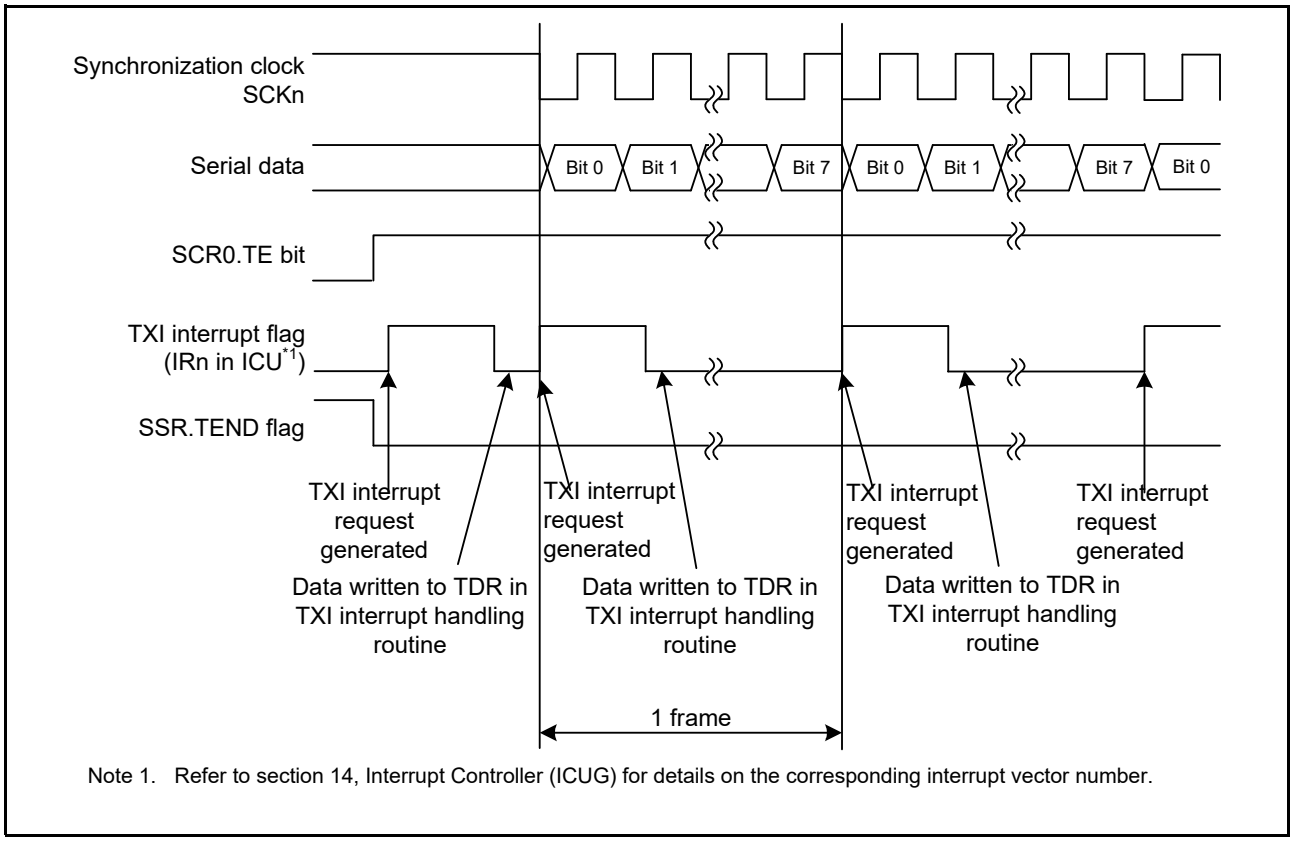
33.10.4 Serial Data Transmission (Clock Synchronous Mode)

(1) Non-FIFO Mode

Figure 33.95 to Figure 33.97 show an example of the operation for serial transmission in clock synchronous mode. In serial data transmission, the RSCI operates as described below.

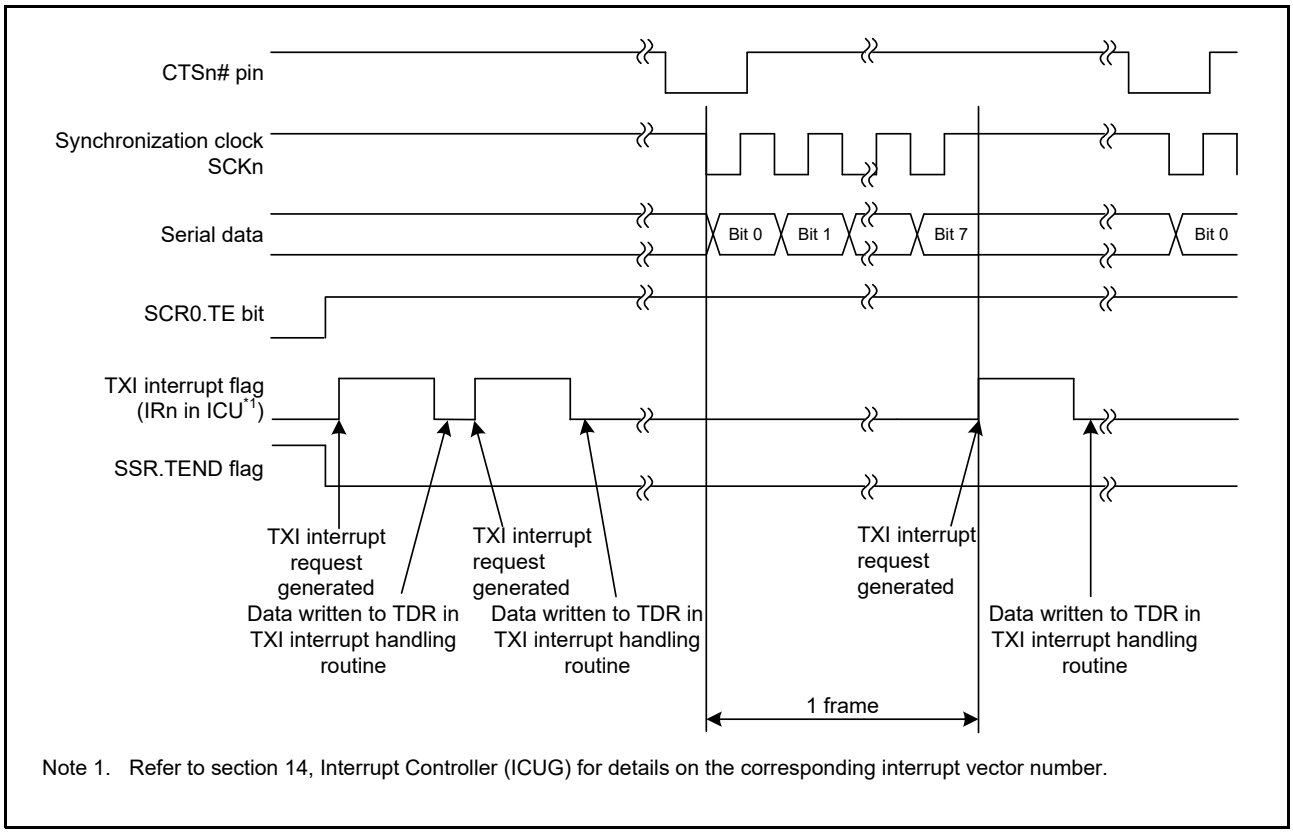
1. When data is written to the TDR register in the TXI interrupt routine, the RSCI transfers the data from the TDR register to the TSR register. When starting data transmission, set the SCR0.TIE bit and the SCR0.TE bit to 1 simultaneously by a single instruction. Then a TXI interrupt request is generated.
2. The written data is transferred from the TDR register to the TSR register, which starts transmission. When the SCR0.TIE bit is set to 1 at this time, a TXI interrupt request is generated. Writing the next transmit data to the TDR register before transmission of data transferred previously in the TXI interrupt routine is complete enables continuous transmission. When a TEI interrupt request is used, after the final transmit data is written to the TDR register in the TXI interrupt request processing routine and the final data's transmission is started, set 0 to the SCR0.TIE bit and set 1 to the TEIE bit.
3. The TXDn pin outputs 8-bit data in synchronization with the output clock (in clock output mode) or with the input clock (when external clock is selected). When the SCR1.CTSE bit = 1 (CTS function enabled), the output clock starts after the CTS signal input becomes low level.
4. Update (data write) of the TDR register is checked at the final-bit transmission timing.
5. When the TDR register has been updated, data is transferred from the TDR register to the TSR register to start sending the next frame.
6. If the TDR register has not been updated, the SSR.TEND flag is set to 1 and the final-bit output state is retained. When the SCR0.TEIE bit is set to 1 at this time, a TEI interrupt request is generated. The SCKn pin is held high.

Figure 33.98 shows a sample flowchart of serial data transmission.



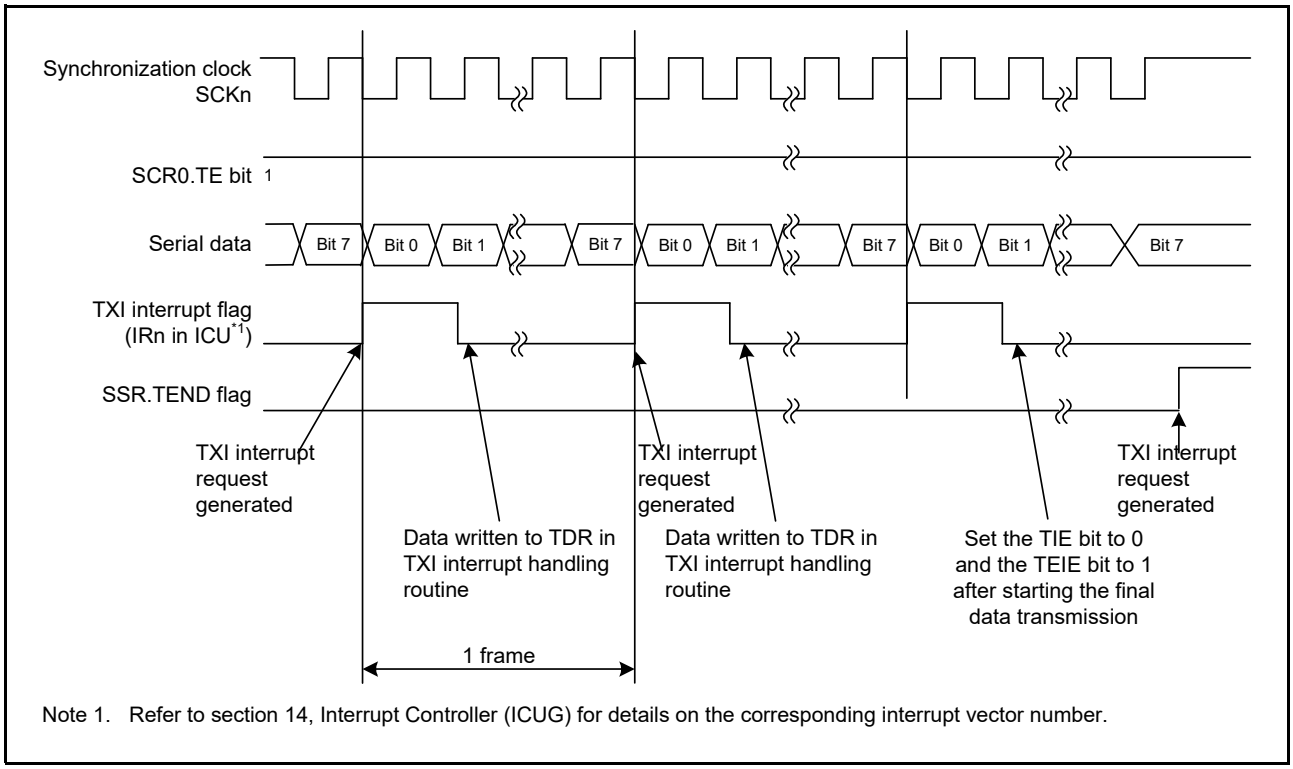
Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 33.95 Serial Transmission Example in Clock Synchronous Mode (1) (CTS Function Not Used/ Transmission Start/CPHA Bit = 1, CPOL Bit = 1)



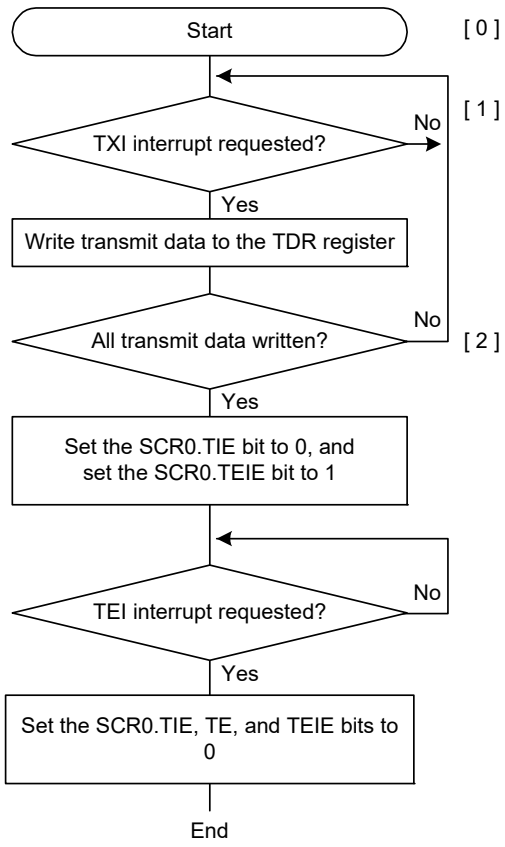
Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 33.96 Serial Transmission Example in Clock Synchronous Mode (2) (CTS Function Used/Transmission Start/CPHA Bit = 1, CPOL Bit = 1)



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 33.97 Serial Transmission Example in Clock Synchronous Mode (3) (During Transmission to Transmission End/CPHA Bit = 1, CPOL Bit = 1)



[0] Set the SCR0.TE and TIE bits to 1 at initialization.

[1] Writing transmit data to TDR register by a TXI interrupt request:
The transmit data empty interrupt (TXI) is generated when transmission data forwards to TSR from TDR register. Write transmit data to TDR register once in the TXI interrupt handling routine.

[2] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR register in the TXI interrupt handling routine. Transmit data can also be written by activating the DMAC or DTC.
If you use TEI interrupt request, set SCR0.TIE bit to 0 and TEIE bit to 1 after writing the last transmit data to TDR register.

Note: When the external clock is in use (the value of the SCR3.CKE[1:0] bits is 10b or 11b), the rising edge on the SCKn pin for the last bit sets the SSR.TEND flag to 1. Setting SCR0.TE bit to 0 immediately after this, then it may lead to insufficient received data hold time on the receiver side.

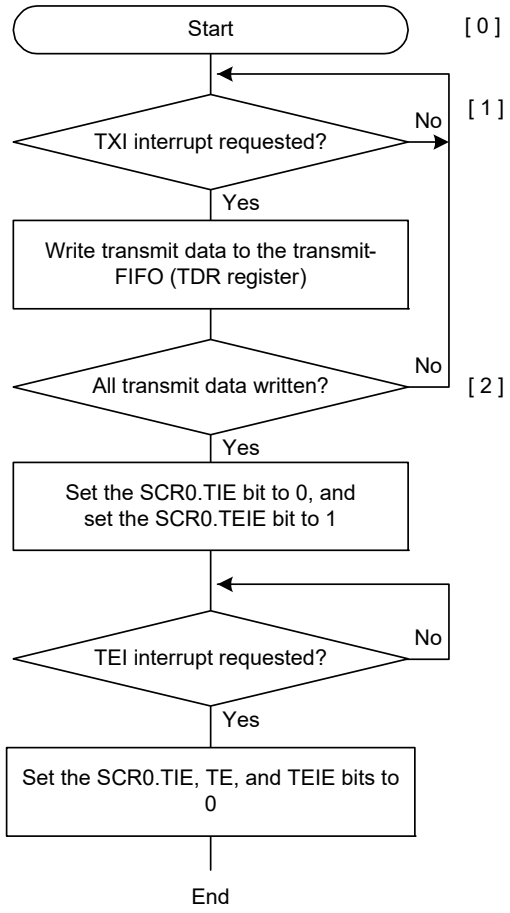
Figure 33.98 Example Flowchart of Serial Transmission in Clock Synchronous Mode (Non-FIFO Mode)

(2) FIFO Mode

Figure 33.99 shows an example of flowchart of serial transmission (a FIFO buffer selected) in clock synchronous mode with FIFO enabled.
The RSCI operates as follows when serial data transmission.

1. When data is written to the transmit FIFO (TDR register) in the TXI interrupt routine, the RSCI transfers the data from the transmit FIFO (TDR register) to the TSR register. The number of writable transmit data is [32 – number of unsent transmit data stored in the transmit FIFO (TDR register)]. If the SCR0.TIE and SCR0.TE bits are simultaneously set to 1 at the start of data transmission, a TXI interrupt request is generated.
2. Data is transferred from the transmit FIFO (TDR register) to the TSR register and transmission starts. When the number of data stored in the transmit FIFO (TDR register) is equal to or less than the threshold value of the transmit FIFO, the SSR.TDRE flag is set to 1. When the SCR0.TIE bit is set to 1 at this time, a TXI interrupt request is generated. Writing the next transmit data to the transmit FIFO (TDR register) in the TXI interrupt routine before transmission of data written to the transmit FIFO (TDR register) is complete enables continuous transmission. When a TEI interrupt request is used, after the final transmit data is written to the transmit FIFO (TDR register) in the TXI interrupt request processing routine, set 0 to the SCR0.TIE bit and set 1 to the TEIE bit.
3. The TXDn pin outputs 8-bit data in synchronization with the output clock (in clock output mode) or with the input clock (when external clock is selected). When the SCR1.CTSE bit = 1 (CTS function enabled), the output clock starts after the CTSn# pin input becomes low level.
4. The RSCI checks whether unsent transmit data is remaining in the transmit FIFO (TDR register)*1 at the final-bit transmission timing.
5. When data is remaining in the transmit FIFO (TDR register), the data is transferred from the transmit FIFO (TDR register) to the TSR register to start sending the next frame.
6. If no data is remaining in the transmit FIFO (TDR register), the SSR.TEND flag is set to 1 and the final-bit output state is retained. When the SCR0.TEIE bit is set to 1 at this time, a TEI interrupt request is generated. The SCKn pin is held high.

Note 1. The number of unsent transmit data stored in the TDR register (transmit FIFO) can be monitored by reading the TFSR.T[5:0] bits.



[0] Set the SCR0.TE and TIE bits to 1 at initialization.

[1] Writing transmit data to transmit FIFO (TDR) by a TXI interrupt request:
The transmit data empty interrupt (TXI) is generated when transmission data forwards to TSR from the transmit FIFO (TDR register) and the number of transmit-data written in the transmit FIFO is equal to or less than the transmit FIFO threshold.

[2] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to the transmit FIFO (TDR register) by using a TXI interrupt and clear the SSR.TDRE flag to 0.
The number of transmission data it's possible to write in is 32 minus (the number of stored data in transmit FIFO).
Transmit data can also be written to the transmit FIFO (TDR register) by activating the DMAC or DTC by TXI interrupt request. In this case, the TDRE flag is cleared automatically, so please don't operate the TDRE flag.
If you use TEI, set TIE bit to 0 and TEIE bit to 1 after writing the last transmit data to TDR register.

Note: When the external clock is in use (the value of the CKE[1:0] bits is 10b or 11b), the rising edge on the SCKn pin for the last bit sets the SSR.TEND flag to 1. Setting SCR0.TE bit to 0 immediately after this, then it may lead to insufficient received data hold time on the receiver side.

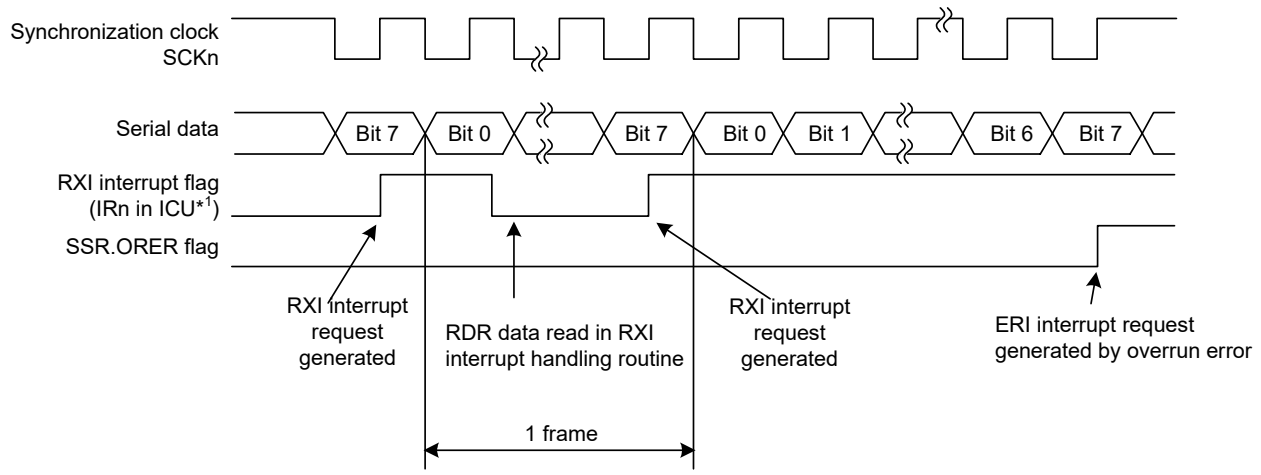
Figure 33.99 Example Flowchart of Serial Transmission in Clock Synchronous Mode (FIFO Mode)

33.10.5 Serial Data Reception (Clock Synchronous Mode)

(1) Non-FIFO Mode

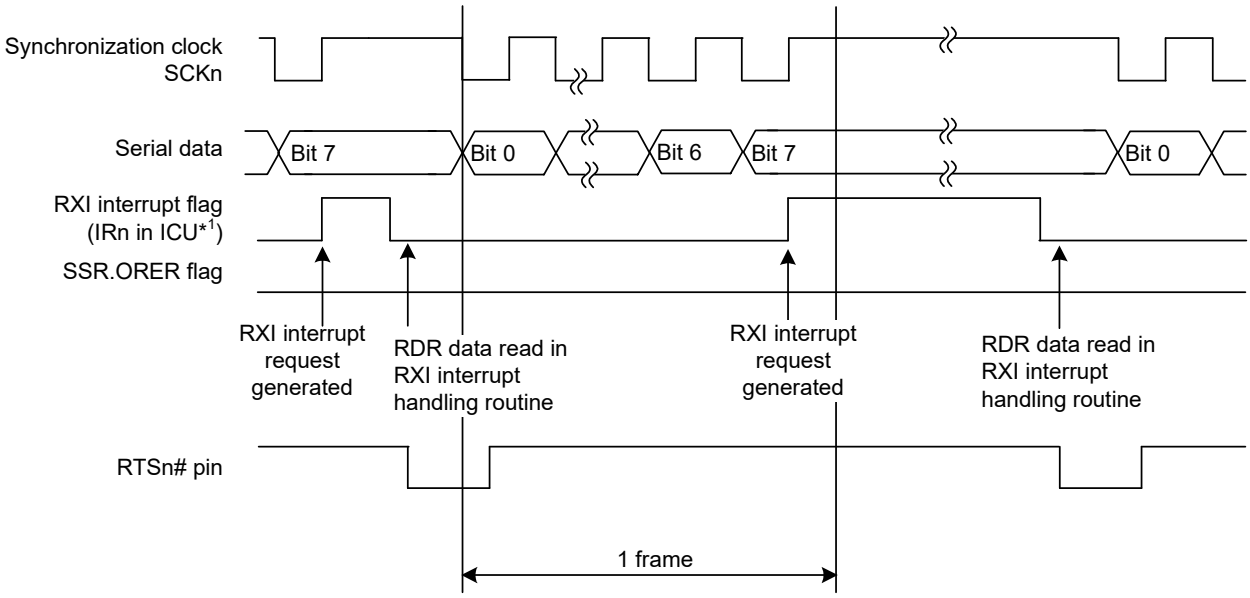
Figure 33.100 and Figure 33.101 show operation examples of serial data reception in clock synchronous mode.
The RSCI operates as follows during serial data reception. Reception-only operation is possible only in slave mode. (In master mode, reception-only operation is prohibited.)

1. When the SCR0.RE bit is set to 1, the RTSn# pin output becomes low (when the RTS function is used).
2. The RSCI starts data reception in synchronization with input or output of the sync clock, and transfers receive data to the RSR register.
3. When an overrun error occurs, the SSR.ORER flag is set to 1. When the SCR0.RIE bit = 1 at this time, an ERI interrupt request is generated and the received data is not transferred to the RDR register.
4. When data is normally received, the received data is transferred to the RDR register. When the RIE bit = 1 at this time, an RXI interrupt request is generated. Reading the received data transferred to the RDR register in the RXI interrupt handling routine before the next data is completely received enables continuous reception. When the received data transferred to the RDR register is read, the RTSn# pin output becomes low (when the RTS function is used).
   If you want to prevent the RTSn# pin output from turning low after the final data is received, clear the SCR0.RE bit to 0 and then read the RDR register.



Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 33.100 Example of Operation for Serial Reception in Clock Synchronous Mode (1) (When RTS Function is Not Used/CPHA Bit = 1, CPOL Bit = 1)

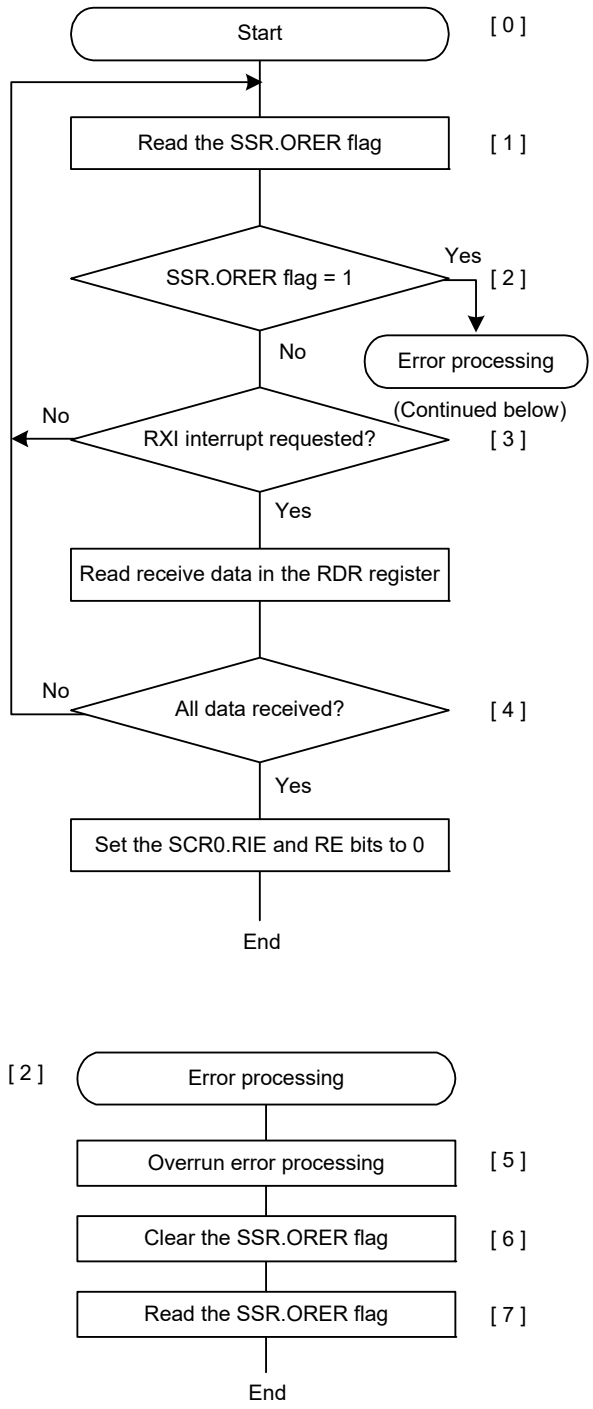


Note 1. Refer to section 14, Interrupt Controller (ICUG) for details on the corresponding interrupt vector number.

Figure 33.101 Example of Operation for Serial Reception in Clock Synchronous Mode (2) (When RTS Function is Used/CPHA Bit = 1, CPOL Bit = 1)

While the reception error flag is set to 1, subsequent reception are disabled. Therefore, before continuing reception, be sure to clear the ORER, AFER, and APER flag in SSR to 0. Also be sure to read the RDR register in the overrun error processing. If the SCR0.RE bit is set to 0 during reception to forcibly terminate the reception operation, unread receive data may be remaining in the RDR register. In this case, read the RDR register.

Figure 33.102 shows a sample flowchart for serial data reception.



[0] Set the SCR0.RE and RIE bits to 1 at initialization.

[1][2]Receive error processing:
If a receive error occurs, after performing the appropriate error processing, be sure to ORER flag is 0. Reception cannot be resumed if ORER flag is 1.

[3] Read the receive data in the RDR register once in the receive data full interrupt (RXI) request handling routine.

[4] Serial reception continuation procedure:
To continue serial reception, before the MSB (bit 7) of the current frame is received, read data from RDR register in the RXI interrupt handling routine. The RDR data can also be read by activating the DMAC or DTC by the receive data full interrupt (RXI) request.

[5] Overrun error processing:
Read the RDR register.

[6] Clearing the error flag:
Set the flag clear bit corresponding to the reception error to 1. Done this step and step [5], the next frame can be received normally.

[7] Confirming that the error flag is cleared:
Confirm all error flags are cleared.

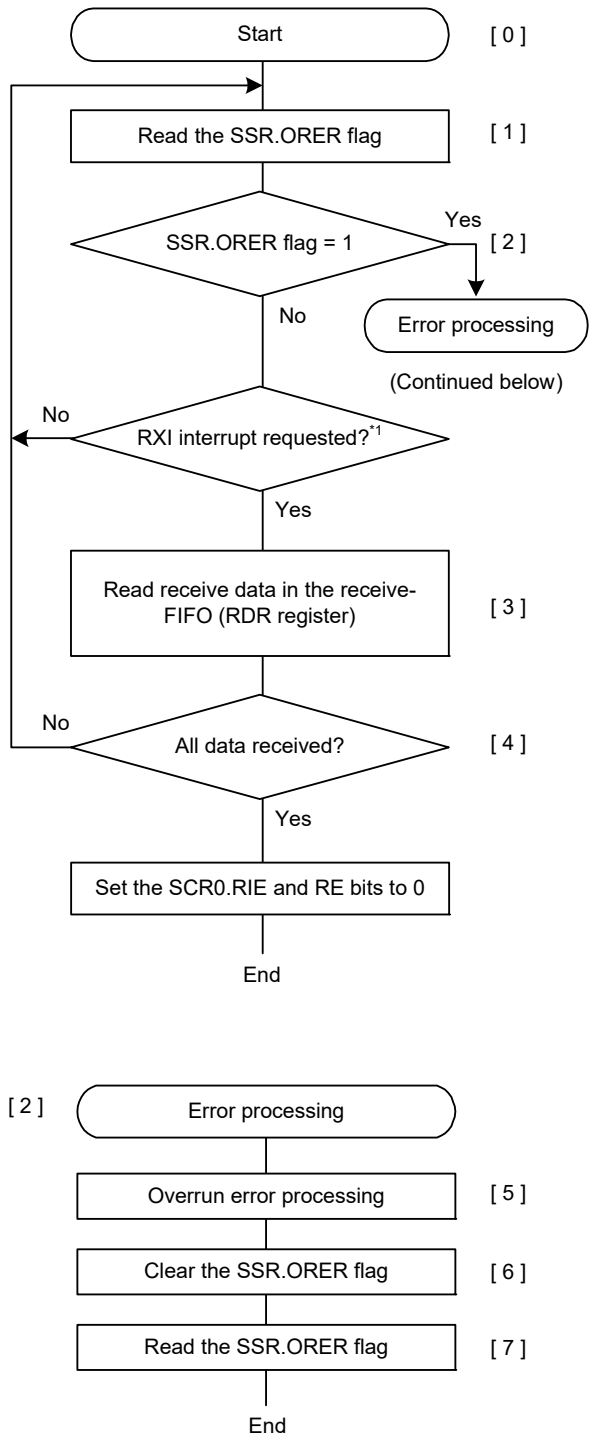
Figure 33.102 Example Flowchart of Serial Reception in Clock Synchronous Mode (Non-FIFO Mode)

(2) FIFO Mode

Figure 33.103 shows an example of serial data reception flowchart in clock synchronous mode with FIFO enabled. The RSCI operates as follows during serial data reception. Reception-only operation is possible only in slave mode. (In master mode, reception-only operation is prohibited.)

1. When the SCR0.RE bit is set to 1, the RTSn# pin output turns low (when the RTS function is used).
2. The RSCI starts receiving data in synchronization with input or output of the sync clock, and transfers the received data to the receive FIFO (RDR register).
3. When an overrun error occurs, the SSR.ORER flag is set to 1. When the SCR0.RIE bit = 1 at this time, an ERI interrupt request is generated and the received data is not transferred to the receive FIFO (RDR register)*1.
4. When data is normally received, the received data is transferred to the receive FIFO (RDR register)*1. When the number of receive data stored in the receive FIFO (RDR register) is equal to or more than the threshold value of the receive FIFO, the SSR.RDRF flag is set to 1. When the RIE bit = 1 at this time, an RXI interrupt request is generated. Reading the received data transferred to the receive FIFO (RDR register) in the RXI interrupt handling routine before an overrun error occurs enables continuous reception. When the received data transferred to the receive FIFO (RDR register) is read and the number of data becomes lower than the RTS# output threshold value, the RTSn# pin output becomes low (when the RTS function is used).

Note 1. The RDR.RDAT[8] bit is not used.



[0] Set the SCR0.RE and RIE bits to 1 at initialization.

[1][2]Receive error processing:
If a receive error occurs, after performing the appropriate error processing, be sure to ORER flag is 0. Reception cannot be resumed if ORER flag is 1.

[3] Read the receive data in the receive FIFO (RDR register) in the RXI interrupt handling routine. The reception data stored in the receive FIFO (RDR register) is read until the number of stored data will be below the FCR.RTRG value at least. When the RDR register is read, the SSR.RDRF flag is cleared. You can confirm the number of the reception data in the FIFO by RFSR.R[5:0] bits.

[4] Serial reception continuation procedure:
To continue serial reception, before the overrun error occurs, read data from RDR register. The RDR data can also be read by activating the DMAC or DTC by the receive data full interrupt (RXI) request.

Note 1. Set all received data to an integer multiple of the receive FIFO threshold. If it is not an integral multiple, an RXI interrupt is not generated and it will become an infinite loop, so set a timeout time separately using a timer etc.

[5] Overrun error processing:
Read the RDR register.

[6] Clearing the error flag:
Set the flag clear bit corresponding to the reception error to 1. Done this step and step [5], the next frame can be received normally.

[7] Confirming that the error flag is cleared:
Confirm all error flags are cleared.

Figure 33.103 Example Flowchart of Serial Reception in Clock Synchronous Mode (FIFO Mode)

33.10.6 Simultaneous Serial Data Transmission and Reception (Clock Synchronous Mode)

In clock synchronous mode, transmission and reception are simultaneously performed, so the number of transmitted data and the number of received data are the same.

(1) Non-FIFO Mode

Figure 33.104 shows an example of serial data concurrent transmission/reception flowchart in clock synchronous mode.
After the RSCI is initialized, perform the following procedure for serial data concurrent transmission/reception.
When switching mode from transmission to concurrent transmission/reception, check that the SSR.TEND flag is set to 1 to ensure that the RSCI is in the transmission complete state. Then set SCR0.TE bit = 0 and RE bit = 0 and then set the TE, RE, TIE, and RIE bits in SCR0 register to 1 simultaneously by a single instruction.
When switching mode from reception to concurrent transmission/reception, check that the RSCI is in the reception complete state, and then set SCR0.TE bit = 0 and RE bit = 0. After that, check that the error flags (ORER, AFER, and APER flags) in SSR are cleared to 0, and then set the TE, RE, TIE, and RIE bits in SCR0 register to 1 simultaneously by a single instruction.
When the RTS function is used in the concurrent transmission/reception operation, if you want to prevent the RTSn# pin output from turning to low after the final data is received as in the reception operation, clear the RE and TE bits in SCR0 register to 0 simultaneously, and then read the RDR register.

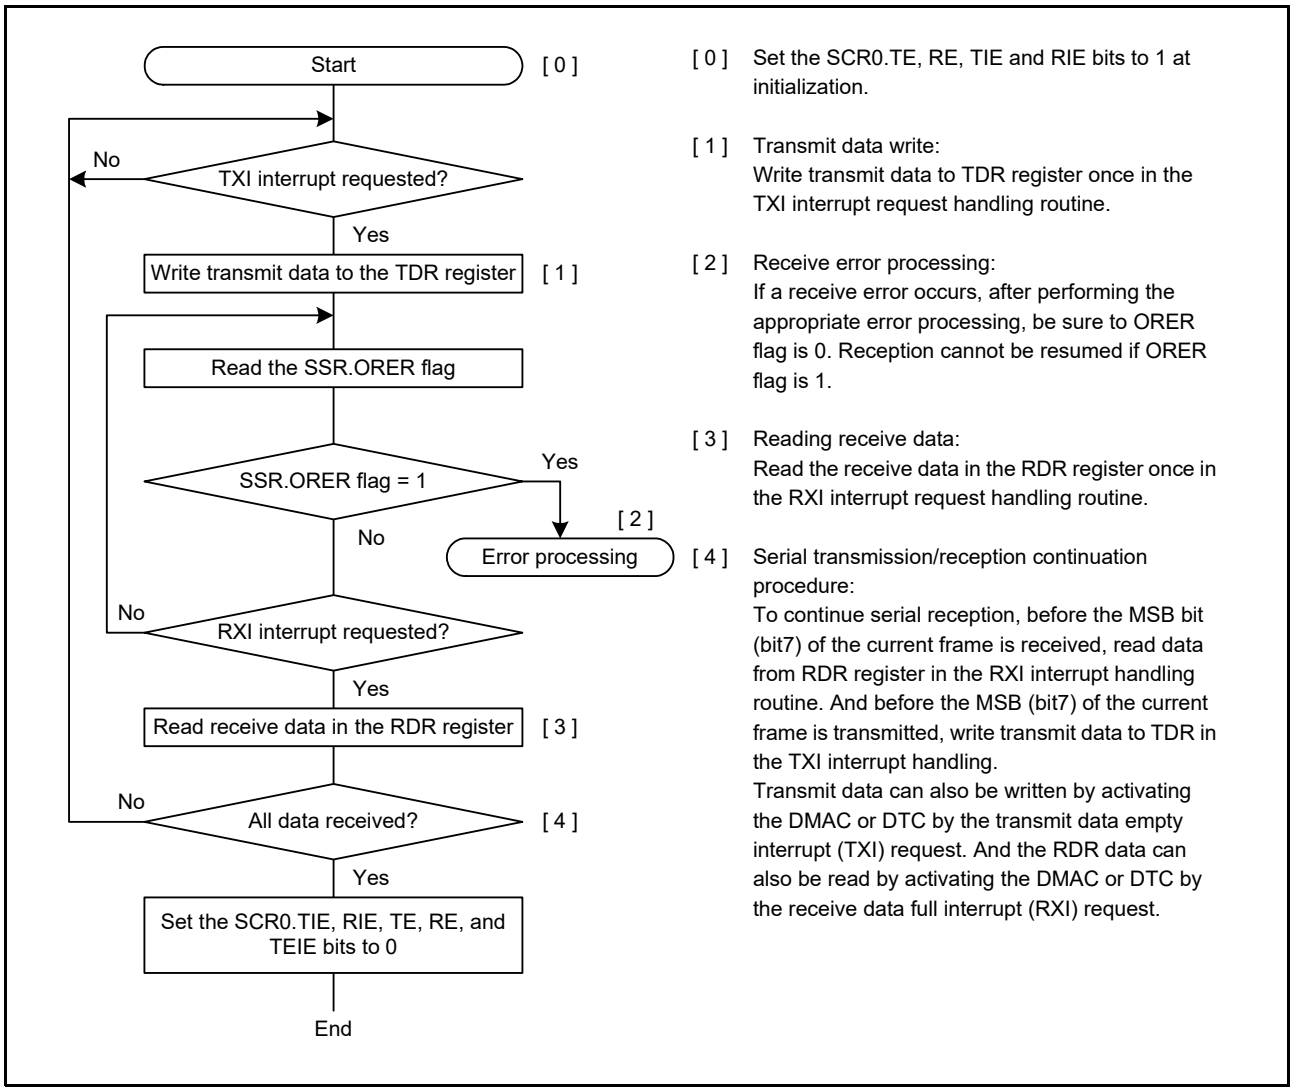


Figure 33.104 Example Flowchart of Simultaneous Serial Transmission and Reception in Clock Synchronous Mode (Non-FIFO Mode)

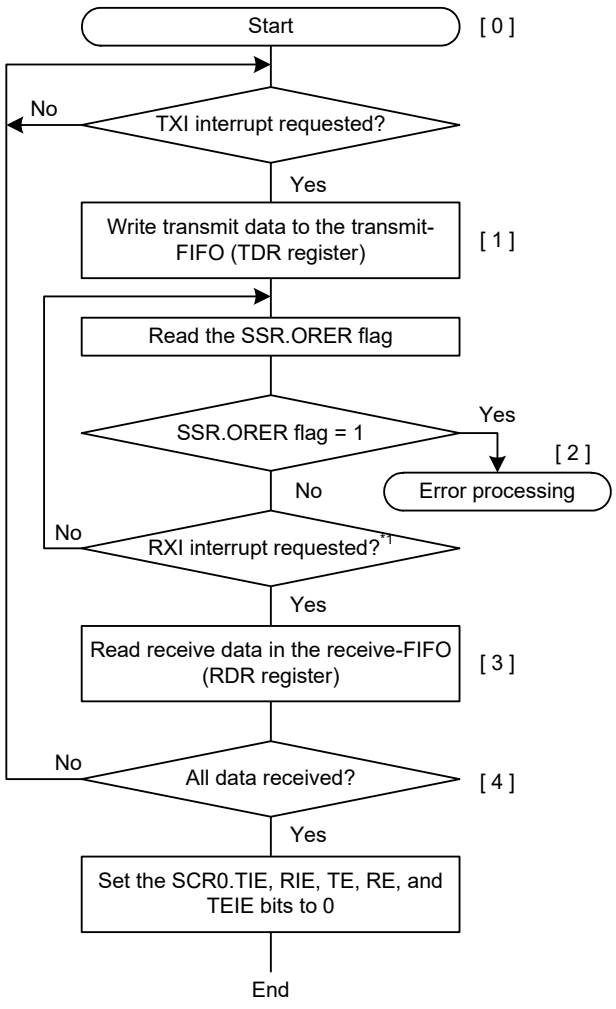
(2) FIFO Mode

Figure 33.105 shows an example of serial data concurrent transmission/reception flowchart in clock synchronous mode with FIFO enabled.

After the RSCI is initialized, perform the following procedure for serial data concurrent transmission/reception.When switching mode from transmission to concurrent transmission/reception, check that the SSR.TEND flag is set to 1 to ensure that the RSCI is in the transmission complete state. Then set SCR0.TE bit = 0 and RE bit = 0 and then set the TE, RE, TIE, and RIE bits in SCR0 register to 1 simultaneously by a single instruction.

When switching mode from reception to concurrent transmission/reception, check that the RSCI is in the reception complete state, and then set SCR0.TE bit = 0 and RE bit = 0. After that, check that the error flags (ORER, AFER, and APER flags) in SSR are cleared to 0, and then set the TE, RE, TIE, and RIE bits in SCR0 to 1 simultaneously by a single instruction.



Note 1. Set the number of all received data to an integer multiple of the receive FIFO threshold. If it is not an integral multiple, an RXI interrupt is not generated and it will become an infinite loop, so set a timeout time separately using a timer etc.

[0] Set the SCR0.TE, RE, TIE and RIE bits to 1 at initialization.

[1] Transmit data write:
Write transmit data to transmit FIFO (TDR register) in the TXI Interrupt request handling routine. The number of data to be written should match the number specified in the receive FIFO threshold.

[2] Receive error processing:
If a receive error occurs, read the SSR.ORER flag, perform the appropriate error processing such as stopping communication and reading all received data to clear the SSR.RDRF flag, and then set the ORER flag to 0. Reception cannot be resumed if ORER flag is 1.

[3] Reading receive data:
Read the same number of received data stored in the receive FIFO (RDR register) as the number specified in the receive FIFO threshold.

[4] Serial transmission/reception continuation procedure:
To continue serial reception, before the overrun error occurs, read data from the receive FIFO (RDR register) and clear SSR.RDRF flag. To continue serial transmission, write transmit data to the transmit FIFO (TDR) by using a TXI interrupt and clear TDRE flag to 0. Transmit data can also be written to the transmit FIFO (TDR register) by activating the DMAC or DTC by the transmit data empty interrupt (TXI) request. And The RDR data can also be read by activating the DMAC or DTC by the receive data full interrupt (RXI) request. In this case, the TDRE and RDRF flags are cleared automatically, so please don't operate the TDRE and RDRF flags.

Figure 33.105 Example Flowchart of Simultaneous Serial Transmission and Reception in Clock Synchronous Mode (FIFO Mode)

33.10.7 Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with Internal Clock Used

When the clock synchronous mode with internal clock is used (master mode), MRCLK is used as a reception sampling clock.

This function adjusts the reception sampling timing by delaying MRCLK by 1 to 4 PCLK cycles and adding a digital delay. MRCLK's analog delay cannot be adjusted by this function.

Setting the SCR4.RTADJ bit to 1 enables this function. The delay value is set in SCR4.RTMG[3:0] bits.

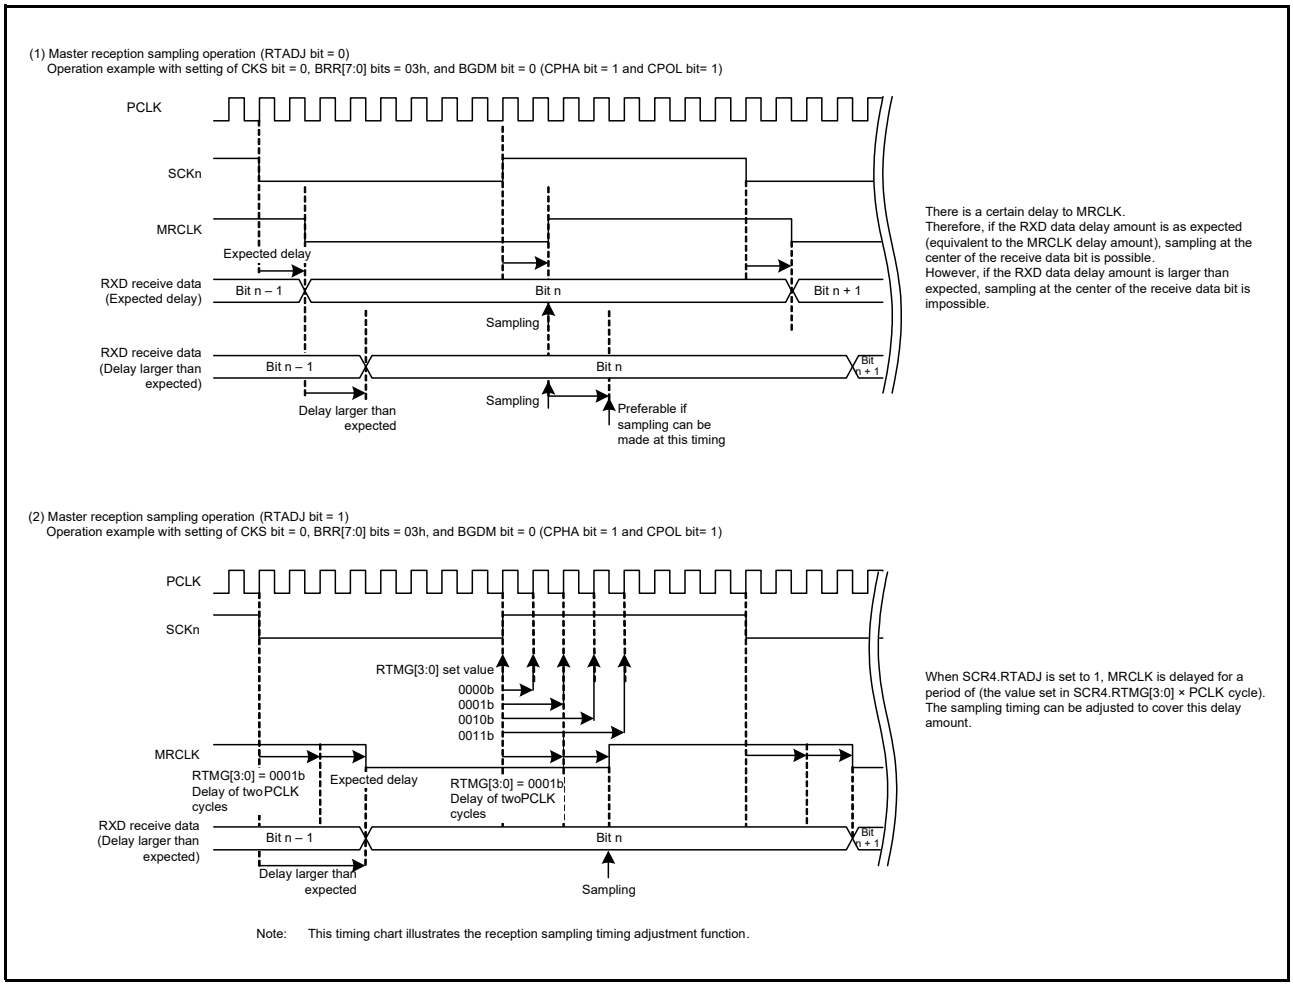


Figure 33.106 Reception Sampling Timing Adjustment Operation in Clock Synchronous Mode (Master) and Simple SPI Mode (Master)

33.11 Operation in Simple SPI Mode

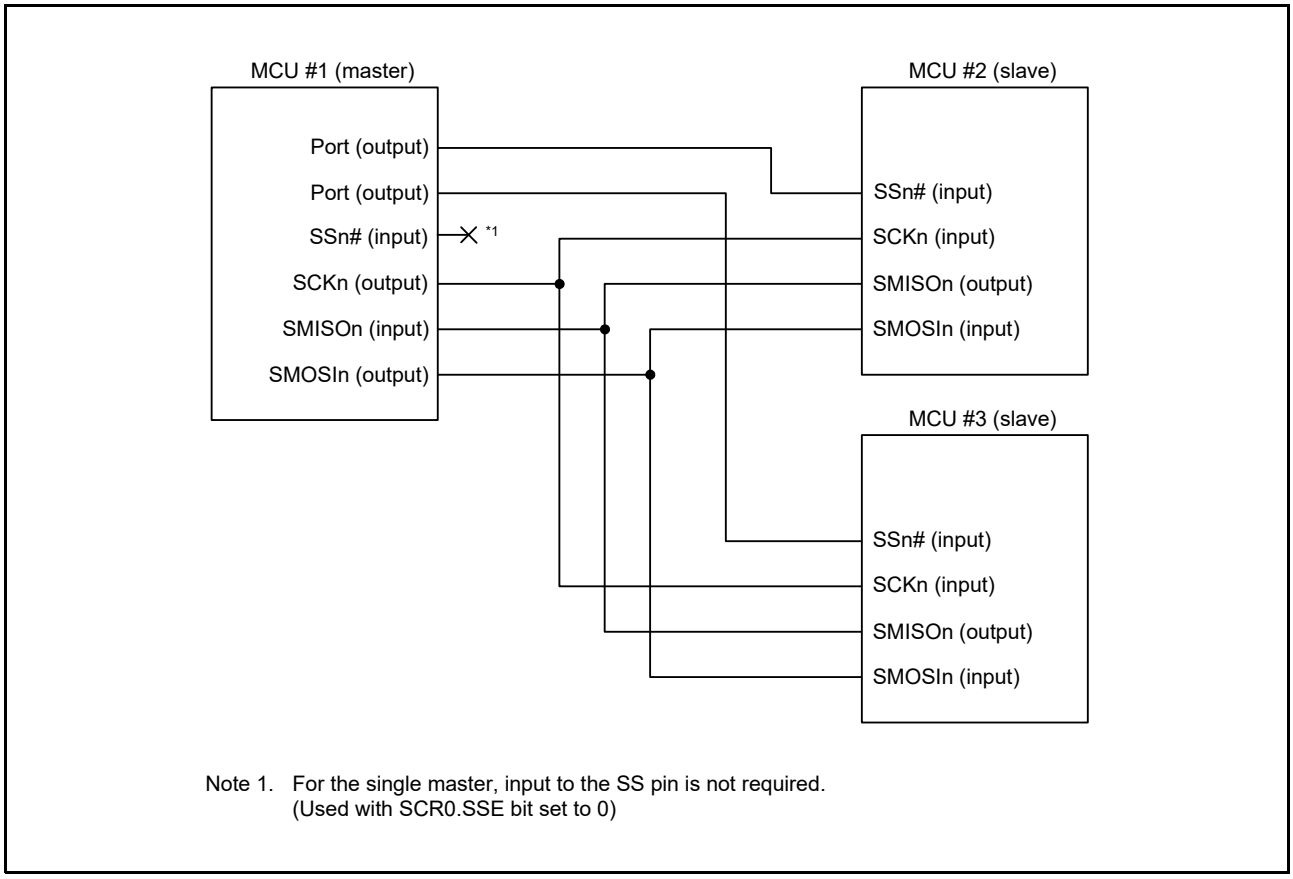
As an extended function, the RSCI supports a simple SPI mode that handles transfer among one or multiple master devices and multiple slave devices.

Making the settings for simple SPI mode (SCR3.MOD[2:0] bits = 011b) plus setting the SSE bit in the SCR0 register to 1 places the RSCI in simple SPI mode. However, the SS pin function on the master side is unnecessary for connection of the device used as the master in simple SPI mode when the configuration only has a single master, so set the SSE bit in the SCR0 to 0 in such cases.

Figure 33.107 shows an example of connections for simple SPI mode.

In simple SPI mode, data are transferred in synchronization with clock pulses in the same way as in clock synchronous mode. One character of data for transfer consists of 8 bits of data, and parity bits cannot be appended to this.

Since the receiver and transmitter are independent of each other within the RSCI module, full-duplex communications are possible, with a common clock signal. Furthermore, since both the transmitter and receiver have a double-buffered structure, writing of further transmit data while transmission is in progress and reading of previously received data while reception is in progress are both possible. Continuous transfer is thus possible.



Note 1. For the single master, input to the SS pin is not required.
(Used with SCR0.SSE bit set to 0)

Figure 33.107 Example of Connections via a Simple SPI Mode

33.11.1 States of Pins in Master and Slave Modes

In simple SPI mode, input and output directions of each pin vary depending on master mode (SCR3.CKE[1:0] bits = 00b or 01b) and slave mode (SCR3.CKE[1:0] bits = 10b or 11b).
Table 33.41 lists the states of pins according to the mode and the level on the SSn# pin.

Table 33.41 States of Pins by Mode and Input Level on the SSn# Pin

Mode	Input on SSn# Pin	State of SMOSIn Pin	State of SMISOn Pin	State of SCKn Pin
Master mode*1	High level (transfer can proceed)	Output for data transmission*2	Input for received data	Clock output*3
	Low level (transfer cannot proceed)	High-impedance	Input for received data (but disabled)	High-impedance
Slave mode	High level (transfer cannot proceed)	Input for received data (but disabled)	High-impedance	Clock input (but disabled)
	Low level (transfer can proceed)	Input for received data	Output for data transmission*2	Clock input

Note 1. When there is only a single master (SCR0.SSE bit = 0), transfer is possible regardless of the input level on the SSn# pin (this is equivalent to input of a high level on the SSn# pin). Since the SSn# pin function is not required, the pin is available for other purposes.
Note 2. The SMISOn pin is in the high-impedance state when serial transmission is disabled (SCR0.TE bit = 0).
Note 3. The SCKn pin is in the high-impedance state when serial transmission is disabled (SCR0.TE bit = 0 and RE bit = 0) in a multi-master configuration (SCR0.SSE bit = 1).

33.11.2 SS Function in Master Mode

Setting the SCR3.CKE[1:0] bits to 00b or 01b enables master mode.
In single master mode (SSE bit = 0), the SSn# pin is not used and data transmission and reception are enabled regardless of the SSn# pin input level. The SSn# pin is available for other purposes.
When in multi-master mode (SSE bit = 1) and the SSn # pin input is high, the master outputs a clock from the SCKn pin and performs transmission and reception operations. And outputting clock indicates “There are no other masters” or “Another master is not performing reception or transmission”. When the SSn# pin input level is low in multi-master mode (SSE bit = 1), this means that another master exists and it is performing data transmission/reception. At this time, the RSCI makes the TXDn pin output and the SCKn pin output high impedance and does not start data transmission/reception. In addition, the SSR.MFF flag is set to 1 as a mode fault. In multi-master mode, read this flag bit to perform the error processing. If a mode fault occurs during the transmission/reception operation, the SCKn pin and the TXDn pin output are made high impedance while the SSn# pin input level is low. In this case, any of TXI, RXI, and TEI interrupts occurs.
Control the SS signal output in master mode with a general-purpose port.

33.11.3 SS Function in Slave Mode

Setting the SCR3.CKE[1:0] bits to 10b or 11b enables slave mode.
When the SSn# pin input level is high, the RXDn pin output becomes high impedance and the clock input from the SCKn pin is ignored. When the SSn# pin input level is low, the clock input from the SCKn pin becomes effective, enabling data transmission and reception.
When the SSn# pin input changes from low to high level during the transmission/reception operation, the RXDn pin output is made high impedance and the transmission/reception operation is immediately suspended. If the transmission is in progress, the SSR.TEND flag will not be set, a transmit end interrupt will not be output, and an abnormal stop status will occur. So, do not negate the SSn # pin during slave transmission/reception. If an abnormal stop occurs, set SCR0.RE bit and SCR0.TE bit to 0 to stop transmission/reception. To resume transmission/reception, set SCR0.RE bit and SCR0.TE bit to 1 after at least 3 PCLK cycles.

33.11.4 Relationship between Clock and Transmit/Receive Data

The clock to be used for data transmission/reception is selectable from four types using the SCR3.CPOL and CPHA bits. Figure 33.108 shows the relationship between clock and transmit data/receive data. The same relationship applies to master mode and slave mode.

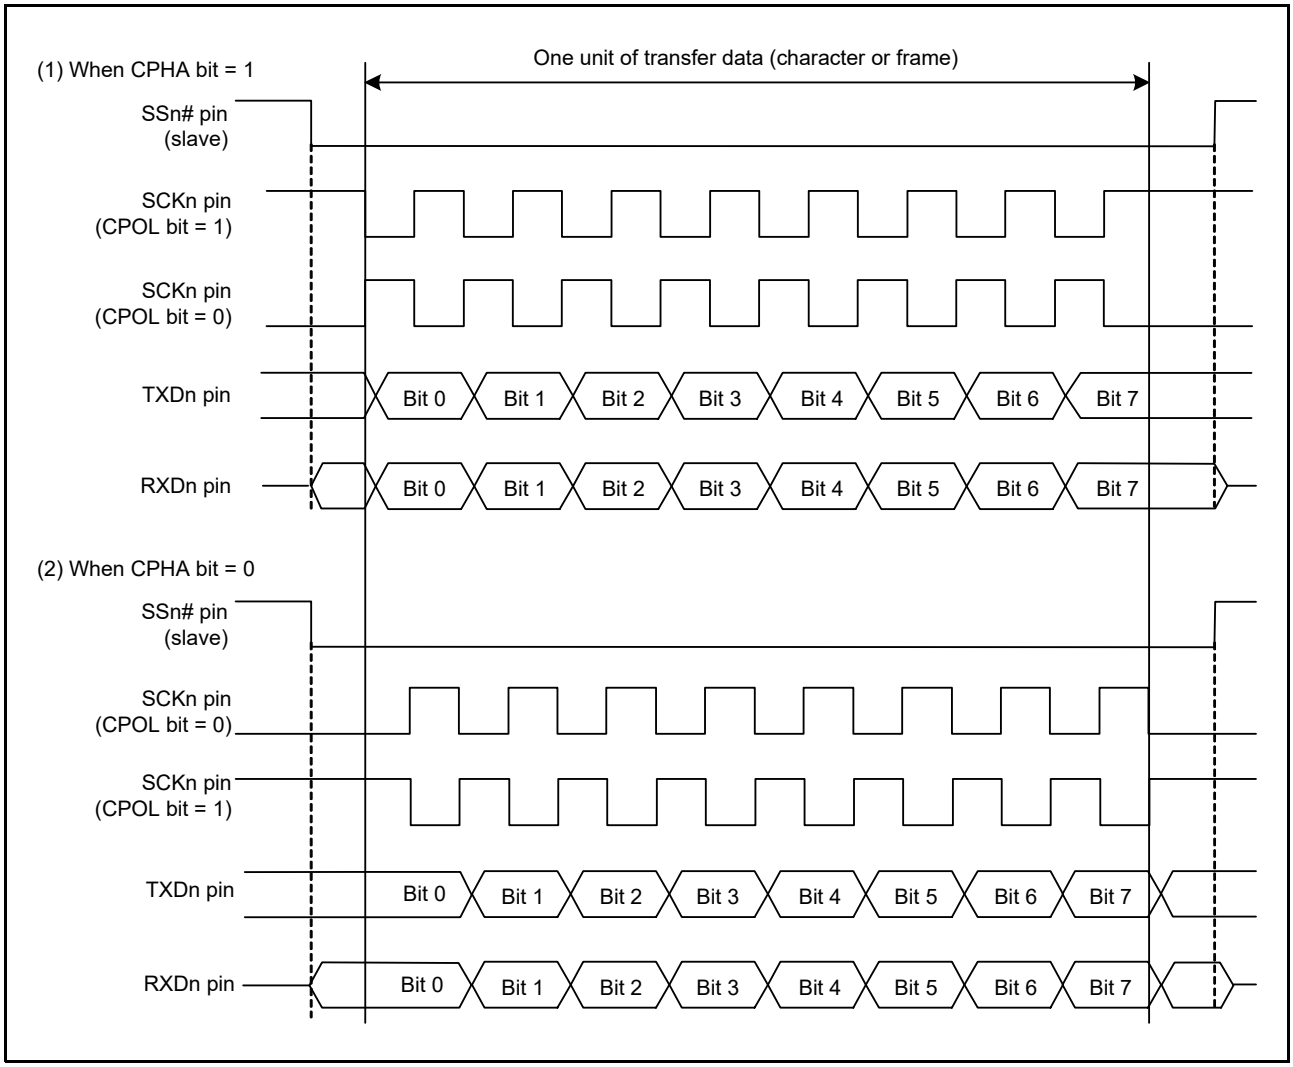


Figure 33.108 Relation between Clock Signal and Transmit/Receive Data in Simple SPI Mode

33.11.5 RSCI Initialization (Simple SPI Mode)

The RSCI can be initialized using the same initialization procedure as for clock synchronous mode (Figure 33.94, Example of RSCI Initialization Flowchart (Clock Synchronous Mode)). The master devices and slave devices use the same clock type selected by the SCR3.CPOL and CPHA bits.
Before performing initialization or changing operating mode or communication format, be sure to stop communication (SCR0.RE bit = 0 and SCR0.TE bit = 0).
Note that setting the RE bit to 0 does not initialize the ORER, AFER, and APER flags in SSR register and the RDR register.
Note that, when SCR0.TIE bit = 1, setting the TE bit to 1 from 0 generates a TXI interrupt.

33.11.6 Transmission and Reception of Serial Data (Simple SPI Mode)

In master mode, set the SSn# pin of the destination slave device to low level before starting data transmission/reception and set to high level after the end of data transmission/reception. In multiple master operation with SCR0.SSE bit = 1 even in master mode, a mode fault will occur if the SSn# pin goes low. Therefore, make sure that no mode fault has occurred before starting communication, and start communication, and make sure that no mode fault has occurred even after communication ends. If a mode fault has occurred, communication may be incomplete, so measures such as retransmission are required. The other procedures are the same as in clock synchronous mode.
In slave mode, it operates according to the SSn# pin input level. Other steps are the same as those of clock synchronous mode.

33.11.7 Reception Sampling Timing Adjustment Function in Simple-SPI Mode with Internal Clock Used

The reception sampling timing adjustment function in simple SPI mode is the same as the reception sampling timing adjustment function in clock synchronous mode. For the description of operation, see section 33.10.7, Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with Internal Clock Used.

33.12 Bit Rate Modulation Function

Using the bit rate modulation function, the bit rate can be corrected by evenly enabling the clocks of the number specified in the SCR2.MDDR[7:0] bits among 256 clock cycles of internal clocks which is selected by the CKS[1:0] bits in SCR2 register.
Figure 33.109 shows an example where the PCLK is selected by the CKS[1:0] bits in SCR2 register and the BRR[7:0] bits and MDDR[7:0] bits are set to 0 and 160 respectively in asynchronous mode. In this example, the cycle of the base clock is evenly corrected (256/160) and the bit rate is also corrected (160/256). Note that there is an imbalance in enabling the internal clock, and expansion and contraction occur in the pulse width of the base clock.

Note: Do not use this function in clock synchronous mode, simple-SPI mode, smart card Interface mode, manchester mode and extended serial mode.

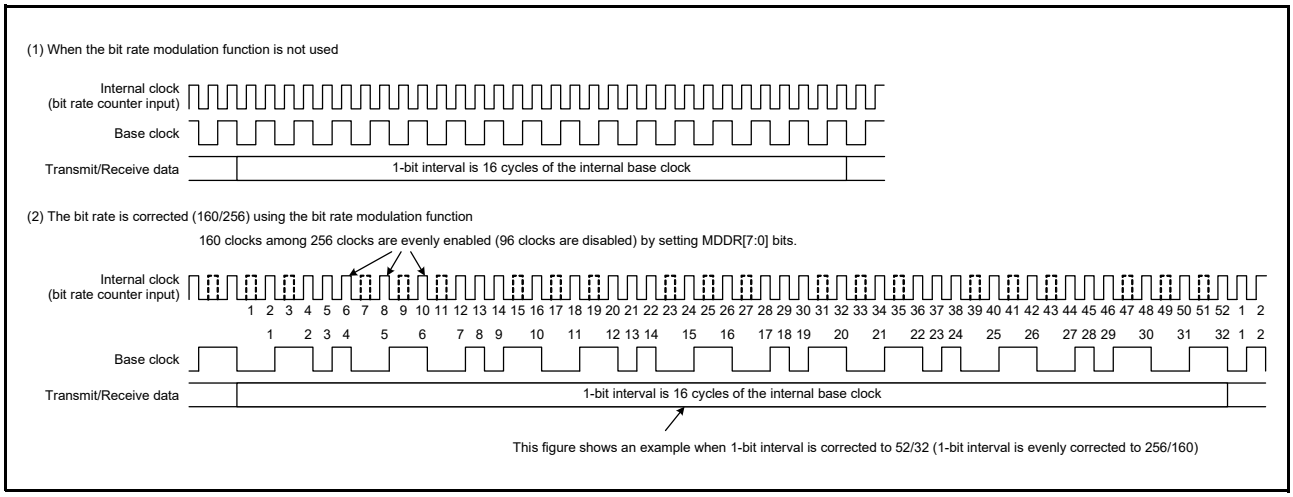

Figure 33.109 Example of Base Clock when Using the Bit Rate Modulation Function

33.13 Noise Cancellation Function

Figure 33.110 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a two-stage flip-flop circuits and a match detection circuit. When the input signals of the noise filter and the output signals of the two-stage flip-flop circuits completely match, the matched level is conveyed as an internal signal. Unless otherwise matched, the previous value is retained. (When the same level is retained for three cycles or longer on the sampling clock of the noise filter, it is considered as a valid receive signal. A change in pulse for three cycles or shorter is considered as a noise, not as a receive signal).

In asynchronous mode, manchester mode and extended serial mode, the noise cancellation function can be applied to the receive signal input to the RXDn pin. The sampling period of the noise filter can be selected from the base clock period and the divided clock of the baud rate generator clock source by SCR1.NFCS[2:0] bits.

(When SCR1.NFCS[2:0] bits = 000b, SCR2.ABCS bit = 0 and SCR2.ABCSE bit = 0, the cycle is 1/16 of a period 1 transfer bit.

When SCR1.NFCS[2:0] bits = 000b, SCR2.ABCS bit = 1 and SCR2.ABCSE bit = 0, the cycle is 1/8 of a period 1 transfer bit.

When SCR1.NFCS[2:0] bits = 000b, SCR2.ABCSE bit = 1, the cycle is 1/6 of a period 1 transfer bit.)

In simple I^2C mode, the noise elimination function can be used for the input pins of TXDn/SSDAn and RXDn/SSCLn. The sampling period of the noise filter can be selected from the divided clock of the baud rate generator clock source by SCR1.NFCS[2:0] bits.

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When SCR0.TE and SCR0.RE bits are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, it is determined that a level match is detected and is conveyed as an internal signal. When the level being input corresponds to 0, the initial output of the noise filter is retained until the level matches in three consecutive sampling cycles.

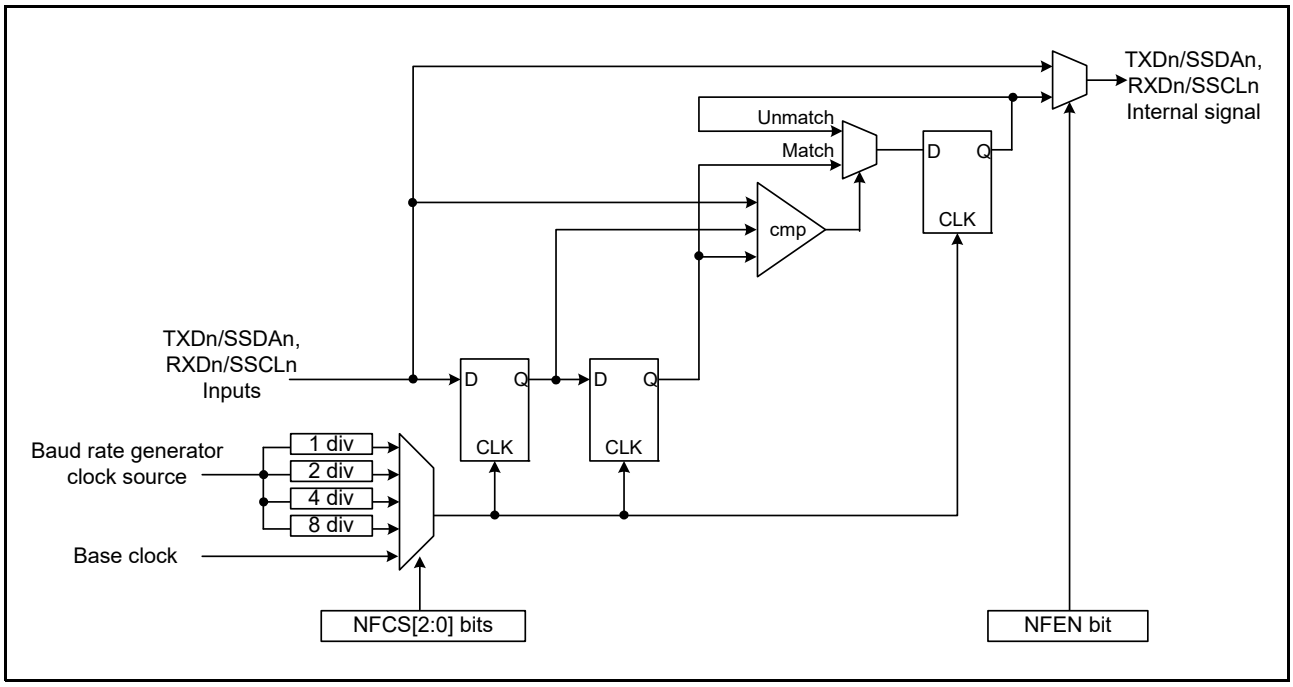

Figure 33.110 Block Diagram of Digital Noise Filter

33.14 RS-485 Driver Control Function

Setting the DEEN bit in the RSCI control register 3 (SCR3) to 1 enables the RS-485 driver control function and generates a DE (Driver Enable) signal that enables the external transceiver transmission mode. The DE signal outputs a valid level for the period with setup time and hold time added before and after data transmission. The DE signal valid level is set by the DELVL bit in the DE signal control register (DECR).

The setup time is the time from when the DE signal is valid until the start bit starts. Set by DESU[4:0] bits of DE signal control register (DECR).

The hold time is the time from the end of the last stop bit of the transmitted message to the invalidation of the DE signal. Set with DEHLD[4:0] bits of the DE signal control register (DECR).

DESU[4:0] and DEHLD[4:0] bits are expressed in base clock units (1/6, 1/8, or 1/16 bit time). For details, refer to section 33.2.13, DE Signal Control Register (DECR).

When this function is used (DEEN bit = 1), the TEND set timing and TEI interrupt output timing are at the end of the DE signal hold time.

When transmission is completed and the next transmission data is not written before the DE signal is negated, the DE signal is negated once. If the timing for writing the next transmit data is not in time, the DE signal is negated and asserted again, the setup time is inserted, and the next data is transmitted. If you want to perform the next transmission with the DE signal asserted, write the next transmission data to the TDR quickly enough.

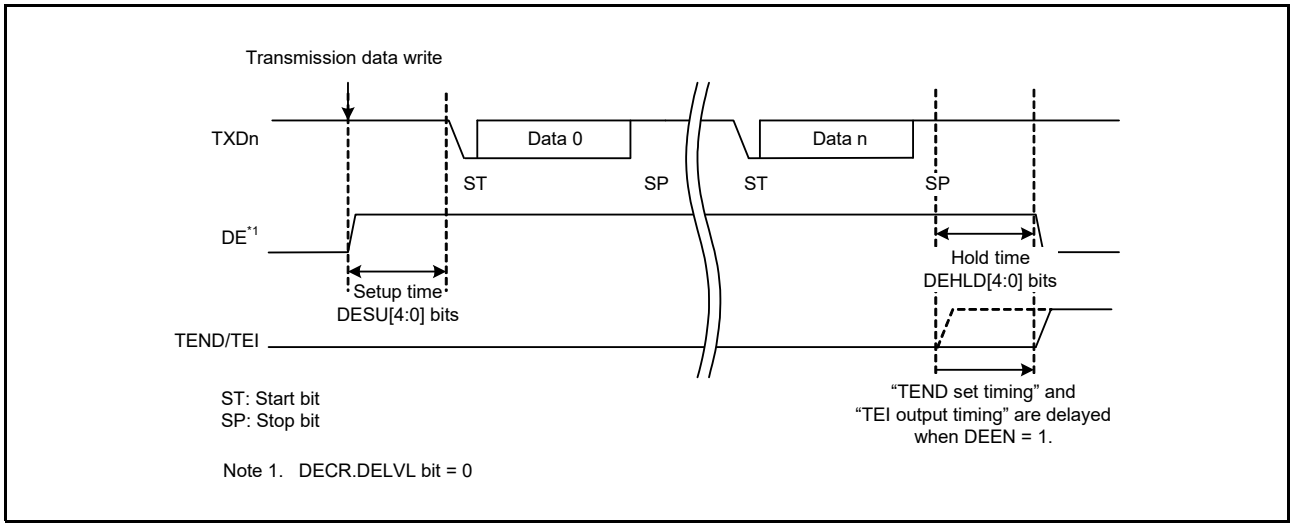

Figure 33.111 Image Waveform for RS-485 Driver Control DE Signal Output

33.15 Loopback Function

The loopback function can be used in Asynchronous mode with the internal clock, and manchester mode with the internal clock, and Clock synchronous mode with the internal clock.
When 1 is written to the LOOP bit in the SCR1 register, RSCI blocks the external input (RXD) path and connects the output path of the transmit data register and the input path of the receive data register.
When this function is used with TINV bit = 1, inversion of transmission data becomes reception data. However, this function can be used with TINV bit = 1 only when operating in clock synchronous mode internal clock.
Table 33.42 shows the relationship between the TINV and LOOP bit settings and the received data.

Table 33.42 TINV and LOOP Bit Settings and Received Data

			Communication Mode		
TINV	**LOOP**	**Receive Data**	**Async Internal Clock**	**Manchester Internal Clock**	**Clock Sync Internal Clock**
0 or 1	0	Receive data from RXDn pin	Possible	Possible	Possible
0	1	Transmit data	Possible	Possible	Possible
1	1	Inverted transmit data	Impossible	Impossible	Possible

Figure 33.112 shows the configuration of the shift register input/output path in loopback mode.

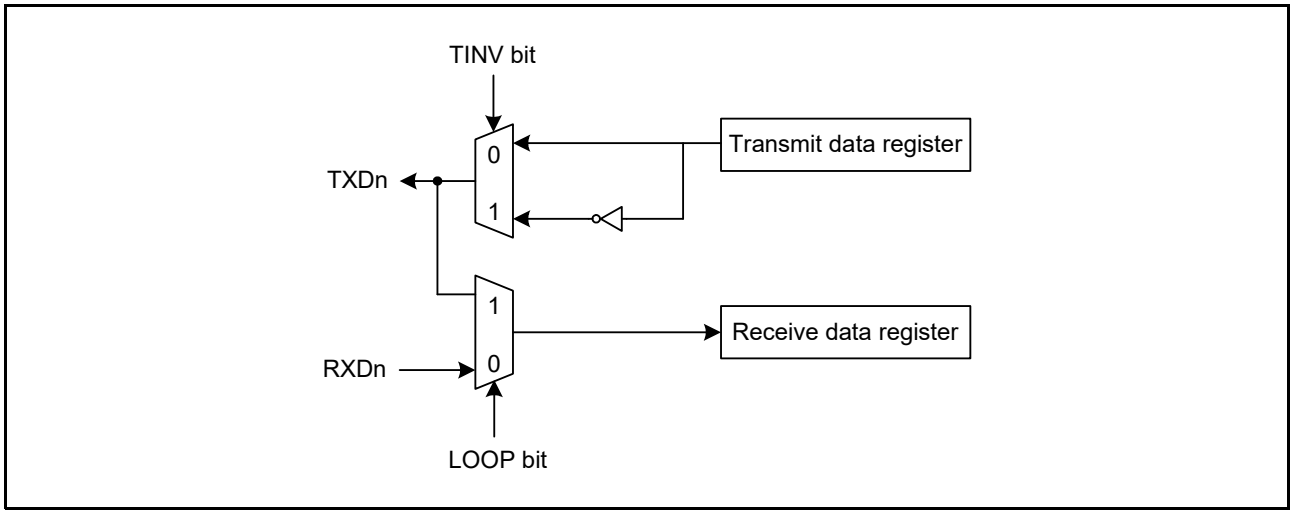

Figure 33.112 Shift Register Input/Output Configuration Image in Loopback Mode

33.16 Half-Duplex Communication Function

Do not use the half-duplex communication function in simple I^2C mode, simple-SPI mode and smart card interface mode.

In other communication modes, if the SCR1.HDSEL bit is set to 1, half-duplex communication using the TXDn pin is possible. When half-duplex communication is used, transmission and reception must be performed exclusively. Transmission and reception settings (SCR0.TE bit = 1 and SCR0.RE bit = 1) is prohibited.

However, if half-duplex communication is performed as the master reception in clock synchronous mode, perform transmission/reception settings (SCR0.TE bit = 1 and SCR0.RE bit = 1) and perform dummy transmission. By dummy transmission (arbitrary transmission data is written to TDR), SCKn is output and reception is enabled. The dummy transmission data is discarded inside the RSCI and is not actually transmitted.

During half-duplex communication, the only communication port terminal used is the TXDn pin. Output when SCR0.TE bit = 1, input when SCR0.TE bit = 0.

33.17 Interrupt Signal

Table 33.43 lists RSCI interrupt signals.

The interrupt explanation corresponding to each operation mode is described in sections 33.17.2 to 33.17.5. Also, TXI and RXI have an interrupt buffer function. Refer to section 33.17.1, Buffer Operations for TXI and RXI Interrupts. When performing transmission and reception using DTC or DMAC, be sure to set DTC or DMAC first, and then enable RSCI before setting. Refer to section 18, Data Transfer Controller (DTCb) and section 17, DMA Controller (DMACAa) for how to set DTC or DMAC.

Table 33.43 RSCI Interrupt List

Interrupt Symbol	Interrupt Function	Pulse/ Level	Pulse Width	Active Level	SYNC Clock	Note
ERI	Error interrupt Bus collision detection interrupt	Level	—	Low	PCLK	
RXI	Simple I²C: Reception end interrupt Other mode: Receive data full interrupt	Pulse	1 cycle	Low	PCLK	
TXI	Simple I²C and smart card interface: Transmit end interrupt Other mode: Transmit data empty interrupt, Break Field transmission completion	Pulse	1 cycle	Low	PCLK	
TEI	Simple I²C: Completion of generation of a start, restart, or stop condition (STI) Other mode: Transmit end interrupt	Level	—	Low	PCLK	
AED	Active edge detection interrupt	Pulse	1 cycle	Low	PCLK	
BFD	Break Field detection interrupt	Level	—	Low	PCLK	Only when extended serial mode

33.17.1 Buffer Operations for TXI and RXI Interrupts

The TXI and RXI interrupts have an interrupt buffer function. When the first interrupt request is generated during interrupt handling and the next interrupt request is generated (when the status flag of the interrupt controller (ICU) is 1), the RSCI does not output the interrupt request, and holds it internally. The interrupt that can be held is up to one.

33.17.2 Interrupt in Asynchronous Mode, Manchester Mode, Clock Synchronous Mode, and Simple SPI Mode

A different interrupt vector is assigned to each interrupt source, and individual interrupt sources can be enabled or disabled with the enable bits in SCR0 register.

(1) Non-FIFO Mode

Table 33.44 lists interrupt sources in asynchronous mode, manchester mode, clock synchronous mode, and simple SPI mode with FIFO disabled.

If the SCR0.TIE bit is 1, a TXI interrupt request is generated when transmit data is transferred from the TDR register to the TSR register. At the start of transmission, a TXI interrupt request can also be generated by using a single instruction to set the SCR0.TE and SCR0.TIE bit to 1 at the same time. A TXI interrupt request can activate the DTC or DMAC to handle data transfer.

A TXI interrupt request is not generated by setting the SCR0.TIE bit to 1 while the setting of the SCR0.TE bit is 1.*1

When the SCR0.TEIE bit is 1, the SSR.TEND flag becomes 1 and the TEI interrupt request is generated if the next data is not written to the TDR register by the timing to transmit the last bit of transmission data. In addition, the TEND flag holds 1 during the period from setting the SCR0.TE bit to 1 until writing transmit data to the TDR register, and if the TEIE bit is set to 1, a TEI interrupt request is generated.

Writing data to the TDR register clears the TEND flag and cancels the TEI interrupt request, but it takes time to cancel it.

If the SCR0.RIE bit is 1, an RXI interrupt request is generated when received data is stored in the RDR register. An RXI interrupt request can activate the DTC or DMAC to handle data transfer.

Setting of any from among the ORER, AFER, and APER flags in the SSR register or the MCER, SYER (if SYERIE = 1)*2, PFER (if PFERIE = 1)*2, and SBER (if SBERIE = 1)*2 flags in MMSR register to 1 while the SCR0.RIE bit is 1 leads to the generation of an ERI interrupt request.

An RXI interrupt request is not generated at this time. Clearing all flags (ORER, AFER, APER, MCER, SYER (if SYERIE = 1)*2, PFER (if PFERIE = 1)*2, and SBER (if SBERIE = 1)*2) leads to discarding of the ERI interrupt request.

Note 1. To temporarily prohibit TXI interrupts at the time of transmission of the last of the data and so on when you wish a new round of transmission to start after handling of the transmit end interrupt, control prohibiting and permitting of the interrupt by using the interrupt request enable bit in the interrupt controller rather than using the TIE bit. This can prevent the suppression of TXI interrupt requests in the transfer of new data.

Note 2. In manchester mode only, MMSR.SYER (if SYERIE bit = 1), PFER (if PFERIE bit = 1), SBER (if SBERIE bit = 1) flags are added to the ERI interrupt sources.

(2) FIFO Mode

Table 33.45 lists interrupt sources in asynchronous mode, manchester mode, clock synchronous mode, and simple SPI mode with FIFO enabled.

If the SCR0.TIE bit is 1, a TXI interrupt request is generated when the stored number of data in transmit FIFO becomes equal to or less than the transmit FIFO threshold. A TXI interrupt request can also be generated by using a single instruction to set the SCR0.TE and SCR0.TIE bit to 1 at the same time. A TXI interrupt request is not generated by setting the SCR0.TE bit to 1 while the setting of the SCR0.TIE bit is 0 or by setting the SCR0.TIE bit to 1 while the setting of the SCR0.TE bit is 1.

If SCR0.TEIE bit is 1, when the next data isn't being written in transmit FIFO by the timing to which the last bit of the transmission data is sent, SSR.TEND flag will be 1 and TEI interrupt request is generated.

If the SCR0.RIE bit is 1, RXI interrupt request is generated when the stored number of data in receive FIFO exceeds the threshold. When the threshold value is set to 0, RXI interrupt request is occurred if the quantity of data in receive FIFO is greater than or equal to 1.

If the SCR0.RIE bit is 1, when SSR.ORER flag is set to 1 or the data a framing error or a parity error generated is stored in receive FIFO, ERI interrupt request is generated.

When the number of data stored in a receive FIFO at this time is a threshold value or above, RXI interrupt request is also

generated. The ERI interrupt request can be canceled by clearing all flags (SSR.ORER, AFER, APER).

Table 33.44 RSCI Interrupt Sources with FIFO Disabled

Name	Interrupt Source	Interrupt Flag	Interrupt Enable	DTC/DMAC Activation
ERI	Receive error	ORER, AFER, APER, DFER, DPER, MCER, SYER (SYERIE = 1), PFER (PFERIE = 1), SBER (SBERIE = 1)	RIE	Not possible
RXI	Receive data full	RDRF	RIE	Possible
	Receive data match	DCMF		
TXI	Transmit data empty	TDRE	TIE	Possible
	TE = 0 → 1 detection			
TEI	Transmit end	TEND	TEIE	Not possible

Table 33.45 RSCI Interrupt Sources with FIFO Enabled

Name	Interrupt Source	Interrupt Flag	Interrupt Enable	DTC/DMAC Activation
ERI	Receive error	ORER, AFER, APER, DFER, DPER, DR (FCR.DRES bit = 1)	RIE	Not possible
RXI	Receive FIFO data full	RDRF	RIE	Possible
	Receive data ready	DR (FCR.DRES bit = 0)		
	Receive data match	DCMF		
TXI	Transmit FIFO data empty	TDRE	TIE	Possible
	TE = 0 → 1 detection			
TEI	Transmit end	TEND	TEIE	Not possible

33.17.3 Interrupt in Smart Card Interface Mode

Table 33.46 lists interrupt sources in smart card interface mode. A transmit end interrupt (TEI) request cannot be used in this mode.

Table 33.46 RSCI Interrupt Sources in Smart Card Interface Mode

Name	Interrupt Source	Interrupt Flag	Interrupt Enable	DTC/DMAC Activation
ERI	Receive error or error signal detection	ORER, APER, ERS	RIE	Not possible
RXI	Receive data full	RDRF	RIE	Possible
TXI	Transmit end	TNED	TIE	Possible
	TE = 0 → 1 detection			

Data transmission/reception using the DTC or DMAC is also possible in smart card interface mode. In transmission operation, when the SSR.TEND flag is set to 1, a TXI interrupt request is generated. This TXI interrupt request activates the DTC or DMAC allowing transfer of transmit data if the TXI request is specified beforehand as a source of DTC or DMAC activation. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.
If an error occurs, the RSCI automatically retransmits the same data. During the retransmission, the TEND flag is kept to 0 and the DTC or DMAC is not activated. Therefore, the RSCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission in the case of error occurrence. However, the SSR.ERS flag is not automatically cleared to 0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the SCR0.RIE bit to 1 to enable an ERI interrupt request to be generated at error occurrence.
In reception operation, an RXI interrupt request is generated when receive data is set to RDR register. This RXI interrupt request activates the DTC or DMAC allowing transfer of receive data if the RXI request is specified beforehand as a source of DTC or DMAC activation. If an error occurs, the error flag is set. Therefore, the DTC or DMAC is not activated and an ERI interrupt request is issued to the CPU instead; the error flag must be cleared.
When transmitting/receiving data using the DTC or DMAC, be sure to make settings to enable the DTC or DMAC before making RSCI settings. For DTC or DMAC settings, refer to section 18, Data Transfer Controller (DTCb) and section 17, DMA Controller (DMACAa).

33.17.4 Interrupts in Simple I2C Mode

Table 33.47 lists RSCI interrupts in Simple I2C mode.

The STI interrupt is allocated to the transmit end interrupt (TEI) request. The receive error interrupt (ERI) request cannot be used.

The DTC or DMAC can also be used to handle transfer in simple I2C mode.

When the value of the SIMR.IICINTM bit is 1, a RXI request will be generated on the falling edge of the SSCLn signal for the eighth bit. If the RXI has been set up as an activating request for the DTC or DMAC beforehand, the RXI request will activate the DTC or DMAC to handle transfer of the received data. Furthermore, a TXI request is generated on the falling edge of the SSCLn signal for the ninth bit (acknowledge bit). If the TXI has been set up as an activating request for the DTC or DMAC beforehand, the TXI request will activate the DTC or DMAC to handle transfer of the transmit data. (In this case, ACK/NACK judging are impossible.)

When the value of the SIMR.IICINTM bit is 0, RSCI moves as follows. RXI request (ACK detection) is generated if the input on the SSDAn pin is at the low level on the rising edge of the SSCLn signal for the ninth bit (acknowledge bit). TXI request (NACK detection) is generated if the input on the SSDAn pin is at the high level on the rising edge of the SSCLn signal for the ninth bit (acknowledge bit). If the RXI has been set up as an activating request for the DTC or DMAC beforehand, the RXI request will activate the DTC or DMAC to handle transfer of the received data. Also, if the DTC or DMAC is used for data transfer in reception or transmission, be sure to set up and enable the DTC or DMAC before setting up the RSCI.

When the SIMR.IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

Table 33.47 RSCI Interrupt Sources in Simple I2C Mode

Name	Interrupt Source		Interrupt Flag	Interrupt Enable	DTC/DMAC Activation
	IICINTM bit = 1	IICINTM bit = 0			
RXI	Reception end	—	—	RIE	Possible*1
	—	ACK detection	—		Possible
TXI	Transmit end	—	—	TIE	Possible*1
	—	NACK detection	—		Possible
STI	Completion of generation of a start, restart, or stop condition		IICSTIF	TEIE	Not possible

Note 1. If the DMAC or DTC are being used, you can not confirm whether ACK or NACK.

33.17.5 Interrupts in Extended Serial Mode

Table 33.48 lists interrupt sources in extended serial mode.

Table 33.48 RSCI Interrupt Sources in Extended Serial Mode

Name	Interrupt Source	Interrupt Flag	Flag the needs to be confirmed	Interrupt Enable	DTC/DMAC Activation
ERI	Error	ORER, AFER, APER	—	RIE	Not possible
		BCDF		BCDIE	
		COF		RIE, COFIE	
RXI	Reception data full	RDRF	CF0MF, CF1MF, PIBDF	RIE	XSR0.SFSF flag = 0: Possible XSR0.SFSF flag = 1: Not possible
AED	Active edge detection	AEDF	—	AEDIE	Possible
TXI	Transmit data empty	TDRE	—	TIE	Possible
	TE = 0 → 1 detection				
	Break Field transmission completion	BFOF	—	TIE, BFOIE	
TEI	Transmit end	TEND	—	TEIE	Not possible
BFD	Break Field detection	BFDF	—	BFDIE	Not Possible (Unnecessary)

In extended serial mode, in addition to reception errors (overrun, framing, and parity errors), an ERI interrupt request is output when a bus conflict is detected during transmission, or when a counter overflow of the extended serial module occurs. At this time, a RXI interrupt request is not output. The ERI interrupt request can be canceled by clearing all the flags.

When transmitting Start Frame, if SCR0.TIE bit = 1 and XCR0.BFOIE bit = 1, a TXI interrupt request is output when Break Field transmission is completed. When Control Field 0 data is written to the TDR register, data transmission starts. Therefore, transmission using DTC or DMAC is possible.

Set SCR0.TEIE bit = 1 after writing the last transmit data to the TDR register and transmission starts.

During Start Frame reception (XSR0.SFSF flag = 1), reception using DTC or DMAC by RXI interrupt is not possible. Check the SSR register and XSR0 register, check the reception status (See Figure 33.72), and then clear the flag.When data is received, read the RDR register so that an overrun error does not occur (if you do not need to check the received data value, clear the RDRF flag without reading the RDR register). When reception of Control Field 1 is completed (XSR0.CF1MF flag = 1), Start Frame detection is disabled (XSR0.SFSF flag = 0) and reception using DTC or DMAC is possible. Be sure to read the RDR register.

When Start Frame/Break Field detection is enabled (XCR1.SDST bit = 1), if a Break Field longer than the period set in XCR2.BFLW[15: 0] bits is received, the BFDF flag is set and a BFD interrupt request is output. Then RSCI becomes the Start Frame reception state. Clear the BFDF flag.

When Start Frame/Break Field detection is enabled (XCR1.SDST bit = 1) and the bit rate measurement function is enabled (XCR1.BRME bit = 1), an AED interrupt factor is output when an active edge is detected. Read the timer count capture value (XSR1.CCV[15:0] bits).

33.18 Event Linking

By employing interrupt request signals as event signals, RSCI can provide linked operation through the event link controller (ELC) for modules selected in advance.
Event signals can be output regardless of the values of the corresponding interrupt request enable bits. And even when the next interrupt source occurs while the corresponding interrupt status flag is 1, the event signal can be output.
All event output is a pulsed output and becomes negated behind 1 PCLK of asserting.
Table 33.49 lists RSCI event link signals.

Table 33.49 RSCI Event Link Signal List

Function	Pulse/Level	Pulse Width	Active Level	Synchronize Clock
Error event	Pulse	1 cycle	High	PCLK
Receive data full event	Pulse	1 cycle	High	PCLK
Transmit data empty event	Pulse	1 cycle	High	PCLK
Transmit end event	Pulse	1 cycle	High	PCLK

(1) Error Event Output (Receive Error, Error Signal Detection)

- Indicates abnormal termination due to a parity error during reception.
- Indicates abnormal termination due to a framing error during reception.
- Indicates abnormal termination due to an overrun error during reception.
- Indicates abnormal termination due to a manchester code error during reception (only in manchester mode).
- Indicates that a preface error occurred upon reception and abnormal termination occurred (only in manchester mode and MMCR.PFERIE bit = 1).
- Indicates that a start bit error occurred during reception and abnormal termination occurred (only in manchester mode and MMCR.SBERIE bit = 1).
- Indicates that a reception sync error occurred during reception and abnormal termination occurred (only in manchester mode and only when MMCR.SYERIE bit = 1).
- Indicates detection of the error signal during transmission in smart card interface mode.
- SSR.AFER and APER flags are 0, and reception data less than receive FIFO data trigger number is set in a receive FIFO buffer, and it indicates that time of 15etu has passed when FIFO enabled and FCR.DRES bit is 1.
- In extended serial mode, indicates that the 16-bit counter in the extended serial module has overflowed.
- In extended serial mode, a bus collision is detected during transmission (SCR0.TE bit = 1).

(2) Receive Data Full Event Output

- In non-FIFO mode, indicates that received data have been set in the receive data register (RDR).
- In FIFO mode, indicates that receive data has been transferred to the receive FIFO (RDR register), and the quantity of data in the register has exceeded the specified receive triggering number. If the receive FIFO threshold is set to 0, no event output occurs unless at least one data is received. However, in FIFO mode, it is prohibited because it causes inconvenience when processing events.
- When FIFO is enabled and FCR.DRES bit is 0, indicates followings.
  - SSR.AFER flag = 0 and SSR.APER flag = 0
  - Time of 15 etu has passed after the reception data less than receive FIFO data trigger number is set in receive FIFO
- Indicates that ACK has been detected if the SIMR.IICINTM bit is 0 in simple I^2C mode.
- Indicates that the 8th-bit SSCLn falling edge has been detected if the SIMR.IICINTM bit is 1 in simple I^2C mode.
- When the SIMR.IICINTM bit is 1 during master transmission in simple I^2C mode, set the event link controller (ELC) so that receive data full events are not used.

(3) Transmit Data Empty Event Output

- Indicates that the SCR0.TE bit has been changed from 0 to 1.
- In non-FIFO mode, indicates that transmit data have been transferred from the transmit data register (TDR) to the transmit shift register (TSR).
- In FIFO mode, indicates that the quantity of data in transmit FIFO (TDR register) has fallen below the specified transmit triggering number. However, in FIFO mode, it is prohibited because it causes inconvenience when processing events.
- Indicates that transmission has been completed in smart card interface mode.
- Indicates that NACK has been detected if the SIMR.IICINTM bit is 0 in simple I^2C mode.
- Indicates that the ninth-bit SSCLn falling edge has been detected if the SIMR.IICINTM bit is 1 in simple I^2C mode.
- In extended serial mode, indicates that Break Field transmission is complete.

(4) Transmit End Event Output

- Indicates the completion of transmission. In FIFO mode, it is prohibited because it causes inconvenience when processing events.
- Indicates that the starting condition, resumption condition, or termination condition has been generated in simple I^2C mode.
- In smart card interface mode, the transmit end event is not output.

33.19 Usage Notes

33.19.1 Setting the Module Stop Function

Module stop control register D (MSTPCRD) is used to stop and start RSCI operations. With the value after a reset, RSCI operations are stopped. The registers of the modules only become accessible after release from the module stop state. For details, refer to section 11, Low Power Consumption.

33.19.2 RSCI Operations during Low Power Consumption State

(1) Transmission

Before using the power consumption reduction function to reduce RSCI's power consumption, please do the following to confirming transmission end (SSR.TEND flag = 1):

- Set the output terminal state after transmission operation is stopped by SCR1.SPB2DT and SPB2IO bits.
- Stop the transmission (SCR0.TIE bit = 0, TE bit = 0, TEIE bit = 0)

When transitions to these states are made during transmission, the data being transmitted become indeterminate.
To transmit data in the same operating mode after cancellation of the low power consumption state, set the TE bit to 1, read SSR register, and write data to TDR sequentially to start data transmission. To transmit data with a different operating mode, initialize the RSCI first.
To start transmission using the DMAC/DTC after cancellation from software standby mode, set the TE and TIE bit to 1 simultaneously. The TXI interrupt is generated and transmission starts using the DMAC/DTC.
Figure 33.113 shows a sample flowchart for transition to software standby mode during transmission. Figure 33.114 and Figure 33.115 show the port pin states during transition to software standby mode.

(2) Reception

Before specifying the module stop state or making a transition to software standby mode, stop the receive operations (SCR0.RE bit = 0). If transition is made during data reception, the data being received will be invalid.
Figure 33.116 shows a sample flowchart for reception to software standby mode during reception.

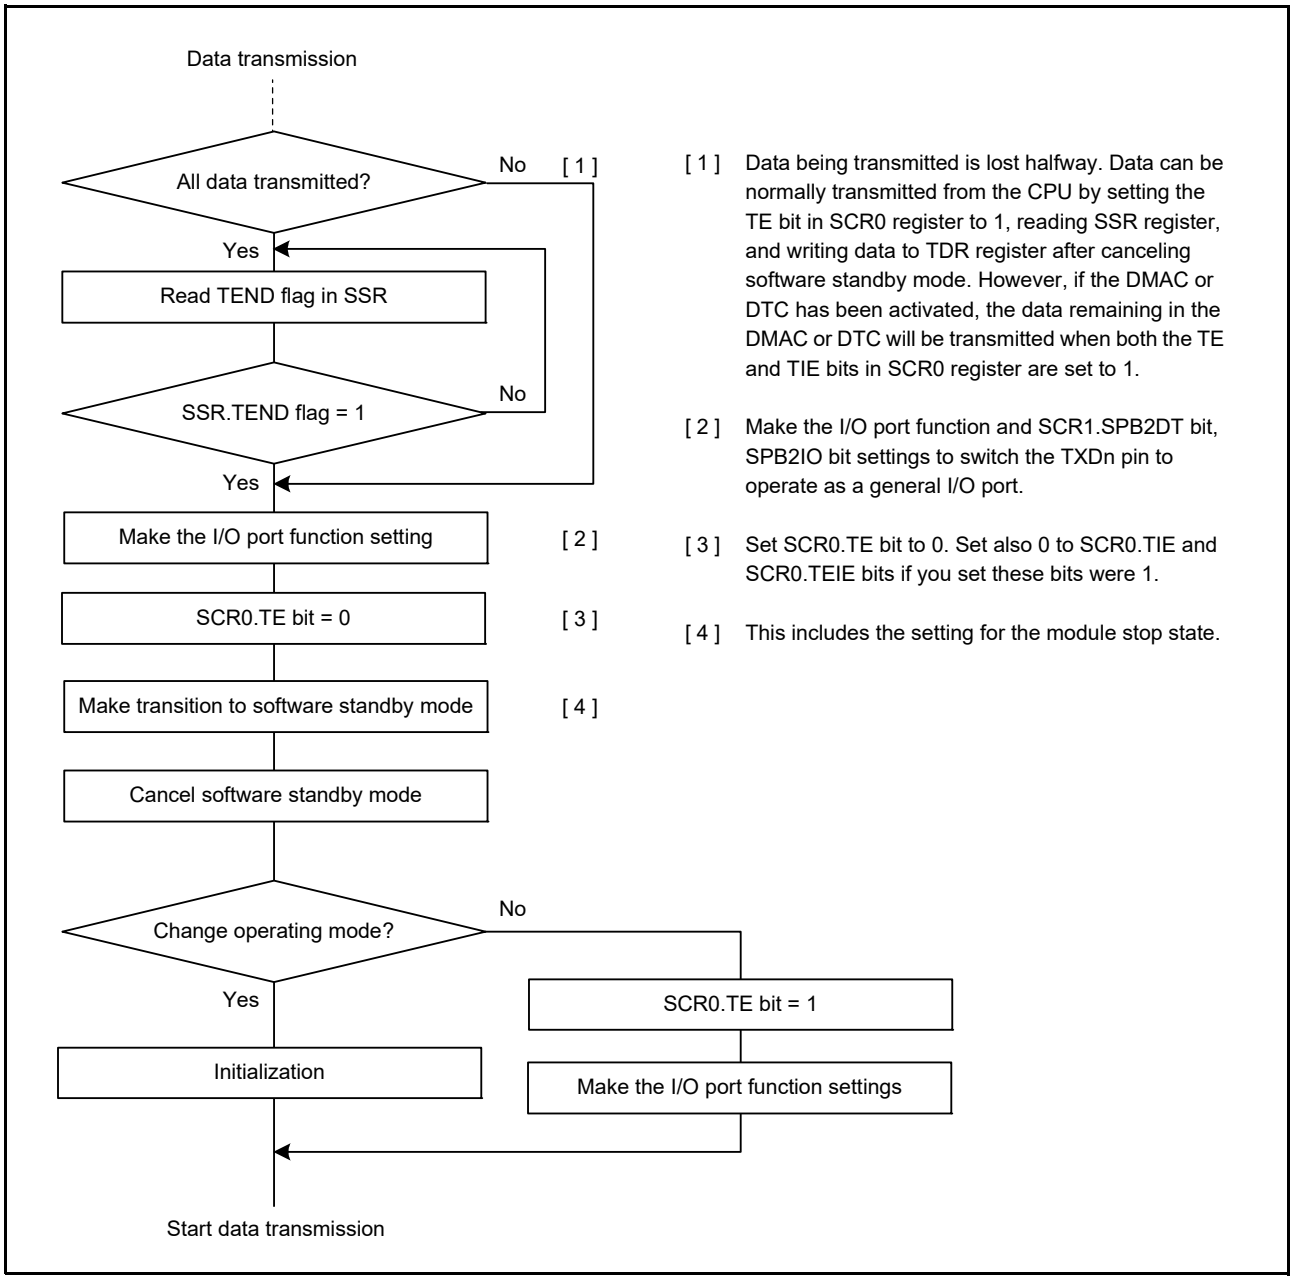

Figure 33.113 Example of Flowchart for Transition to Software Standby Mode during Transmission

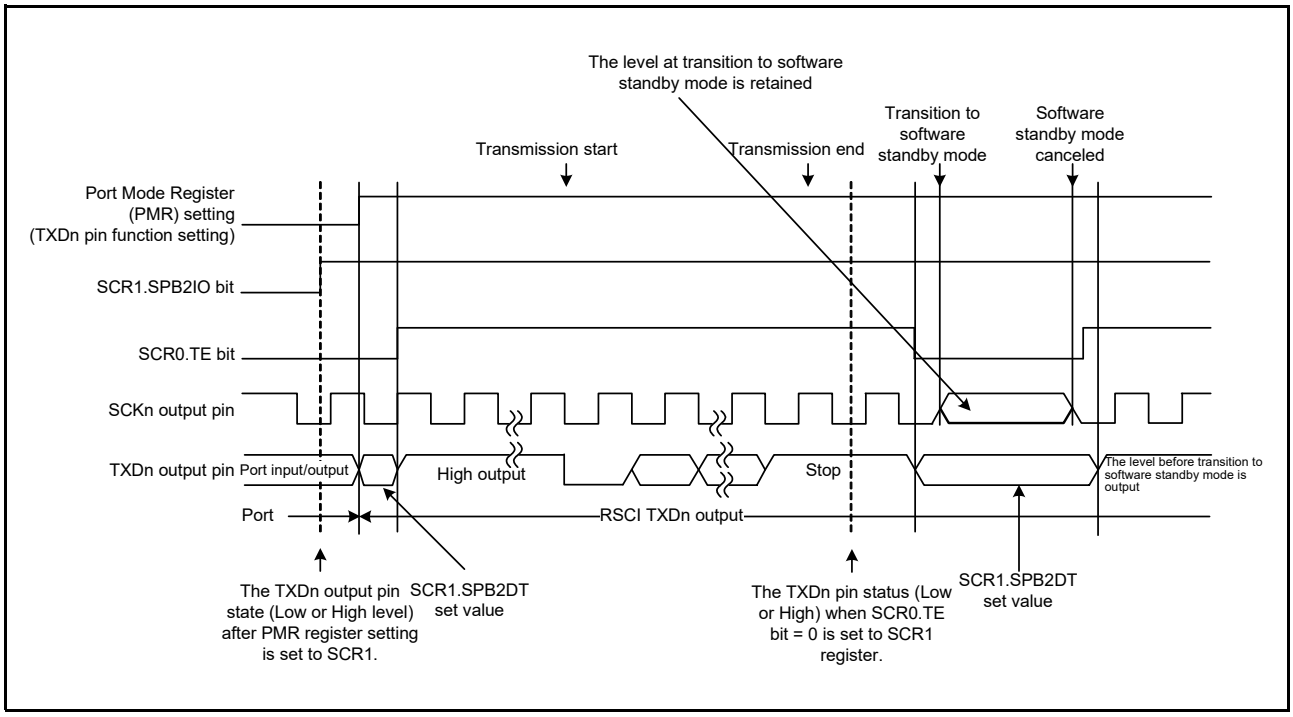

Figure 33.114 Port Pin States during Transition to Software Standby Mode (Internal Clock, Asynchronous Transmission)

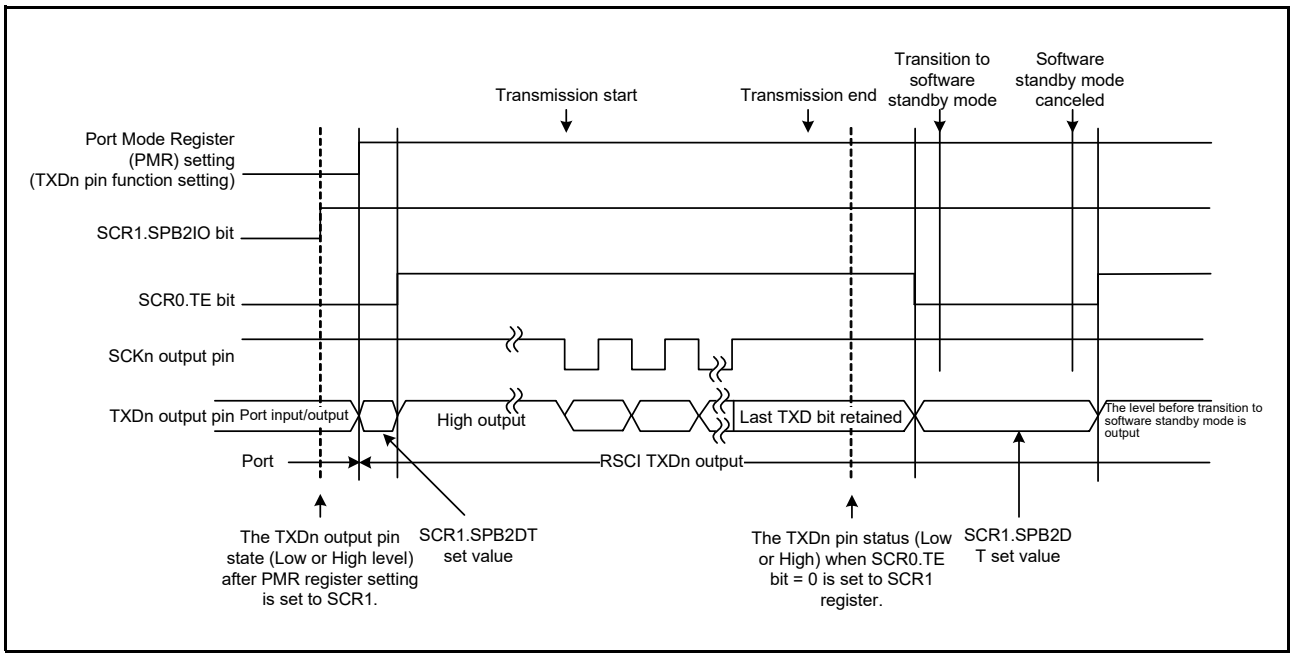

Figure 33.115 Port Pin States during Transition to Software Standby Mode (Internal Clock, Clock Synchronous Transmission)

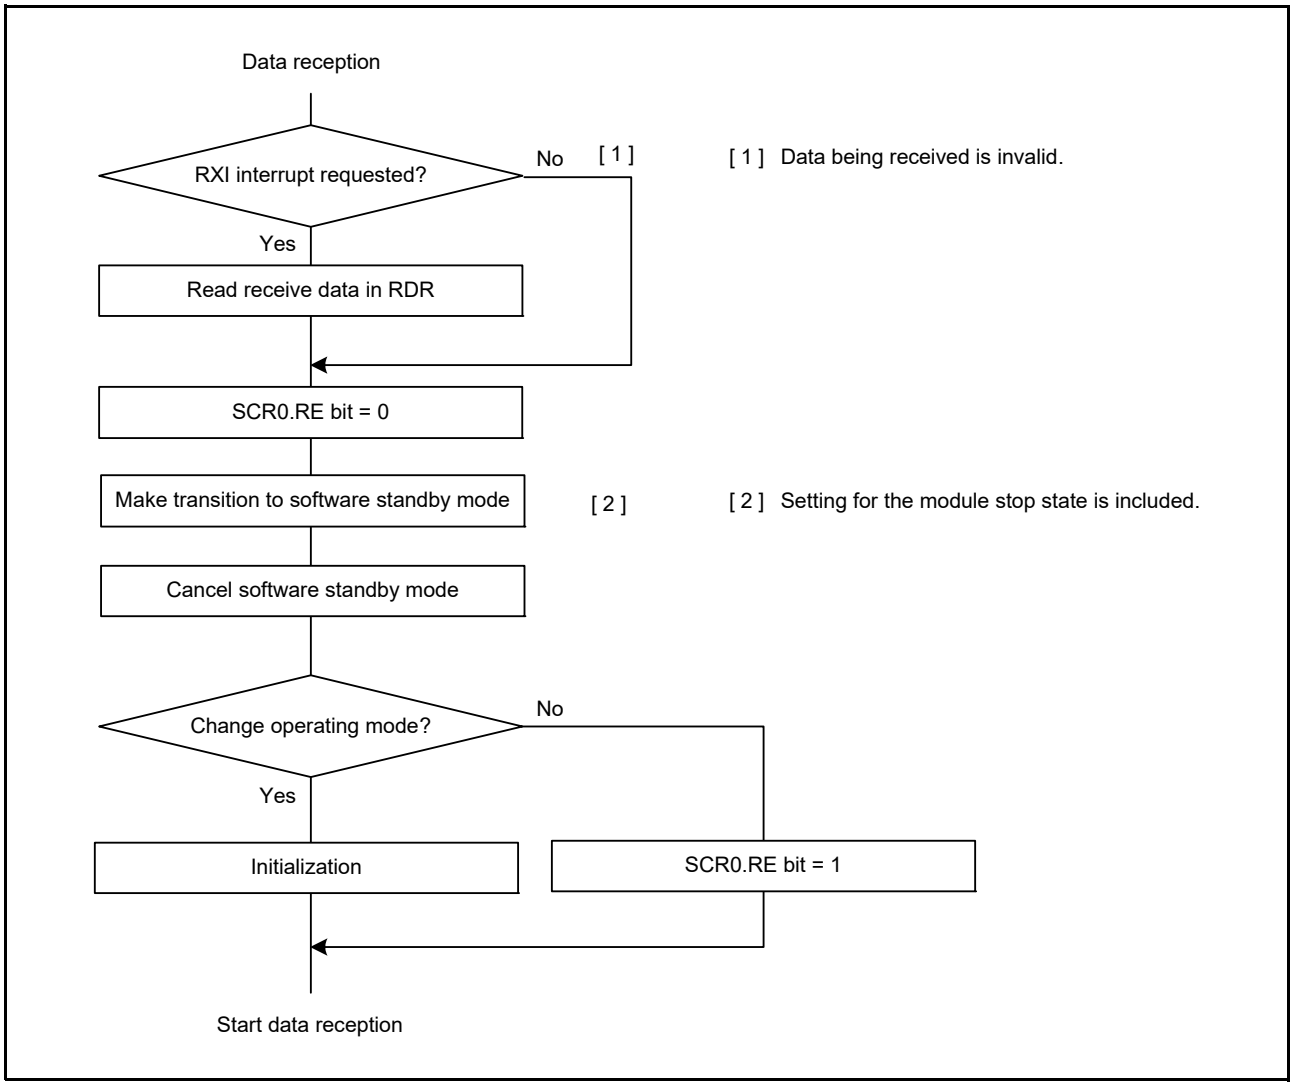

Figure 33.116 Example of Flowchart for Transition to Software Standby Mode during Reception

33.19.3 Break Detection and Processing

(1) Non-FIFO Mode

When a framing error is detected, a break can be detected by reading SSR.RXDMON flag value. In a break, the input from the RXDn pin becomes all low, and so the SSR.AFER flag is set to 1 (framing error has occurred), and the SSR.APER flag may also be set to 1 (parity error has occurred). When the SCR3.RXDESEL bit is 0, the RSCI continues the receive operation even after a break is received. Therefore, note that even if the AFER flag is set to 0 (no framing error occurred), it will be set to 1 again. When the SCR3.RXDESEL bit is 1, the RSCI sets the SSR.AFER flag to 1 and stops receiving operation until a start bit of the next data frame is detected. If the SSR.AFER flag is set to 0 at this time, the SSR.AFER flag retains 0 during the break. When the RXDn pin becomes high and the break ends, detecting the start bit at the first falling edge of the RXDn pin allows the RSCI to start the receiving operation.

(2) FIFO Mode

After a framing error is detected, when RSCI detects that continuous receive data is low for 1 frame, the data stored into the receive FIFO (RDR register) and reception stops. When a framing error is detected, a break can be detected by reading SSR.RXDMON flag value. After the RXD signal is in the mark state and it has finished the break, a stock of reception data to the receive FIFO (RDR register) resumes.

33.19.4 Mark State and Sending Breaks

When the SCR0.TE bit is 0 (serial transmission is disabled), the state of the TXDn pin can be set by SCR1.SPB2IO bit and SCR1.SPB2DT bit. Using this, it's possible to do a TXDn pin in the mark state and send a break out. When you want to make a communication-line is in the mark state (the state of 1) until the SCR0.TE bit is set to 1 (serial transmission is enabled). First, set it as High-level output by setting SPB2IO bit and SPB2DT. Next, it's changed to a TXDn pin by I/O port function. On the other hand, if you want to send a break when sending data, set the SCR0.TE bit to 0 after setting the SPB2IO and SPB2DT bits in the SCR1 register to low level output. Setting the TE bit to 0 initializes the transmitter regardless of the current transmission status.

33.19.5 Receive Error Flags and Transmit Operations (Clock Synchronous Mode and Simple SPI Mode)

Transmission can be start by writing transmit-data to TDR register even if SSR.ORER flag is 1. However, reception can not be started. Note also that the receive error flags cannot be set to 0 even if the SCR0.RE bit is set to 0 (serial reception is disabled).

33.19.6 Writing Data to the TDR Register

(1) Non-FIFO Mode

Data can be written to TDR register anytime when TE bit is 1. However, if new data is written to TDR register when transmit data is remaining in TDR register, the previous data in TDR register is lost because it has not been transferred to TSR register yet. If you use DTC or DMAC, be sure to write transmit data to TDR register in the TXI interrupt request handling routine.

(2) FIFO Mode

Data can be written to transmit FIFO (TDR register) when TE bit is 1. Check the number of writable data with the TFSR.T[5:0] bits.

33.19.7 Restrictions on Clock Synchronous Transmission (Clock Synchronous Mode and Simple SPI Mode)

When the external clock source is used as a synchronization clock, the following restrictions apply.

(1) Start of Transmission

Update TDR register by the CPU, DMAC, or DTC and wait at least the following time until the start of the external clock input: (See Figure 33.117)
Time considering the output AC characteristics of the SMISO pin of this product and the input AC characteristics of the master reception + 1 PCLK cycle.

(2) Continuous Transmission

The next transmit data must be transferred to the TSR register before the falling edge*1 of the transmit clock for bit 7. Please write the transmit data to TDR register with this in mind. If the transmit data can not be written in time, the previous frame data is resent. (See Figure 33.117)

Note 1. When SCR3.CPOL bit = 1 and SCR3.CPHA bit = 0, or SCR3.CPOL bit = 0 and SCR3.CPHA bit = 1. In the case of SCR3.CPOL bit = 0 and SCR3.CPHA bit = 0, or SCR3.CPOL bit = 1 and SCR3.CPHA bit = 1, it's the rising edge.

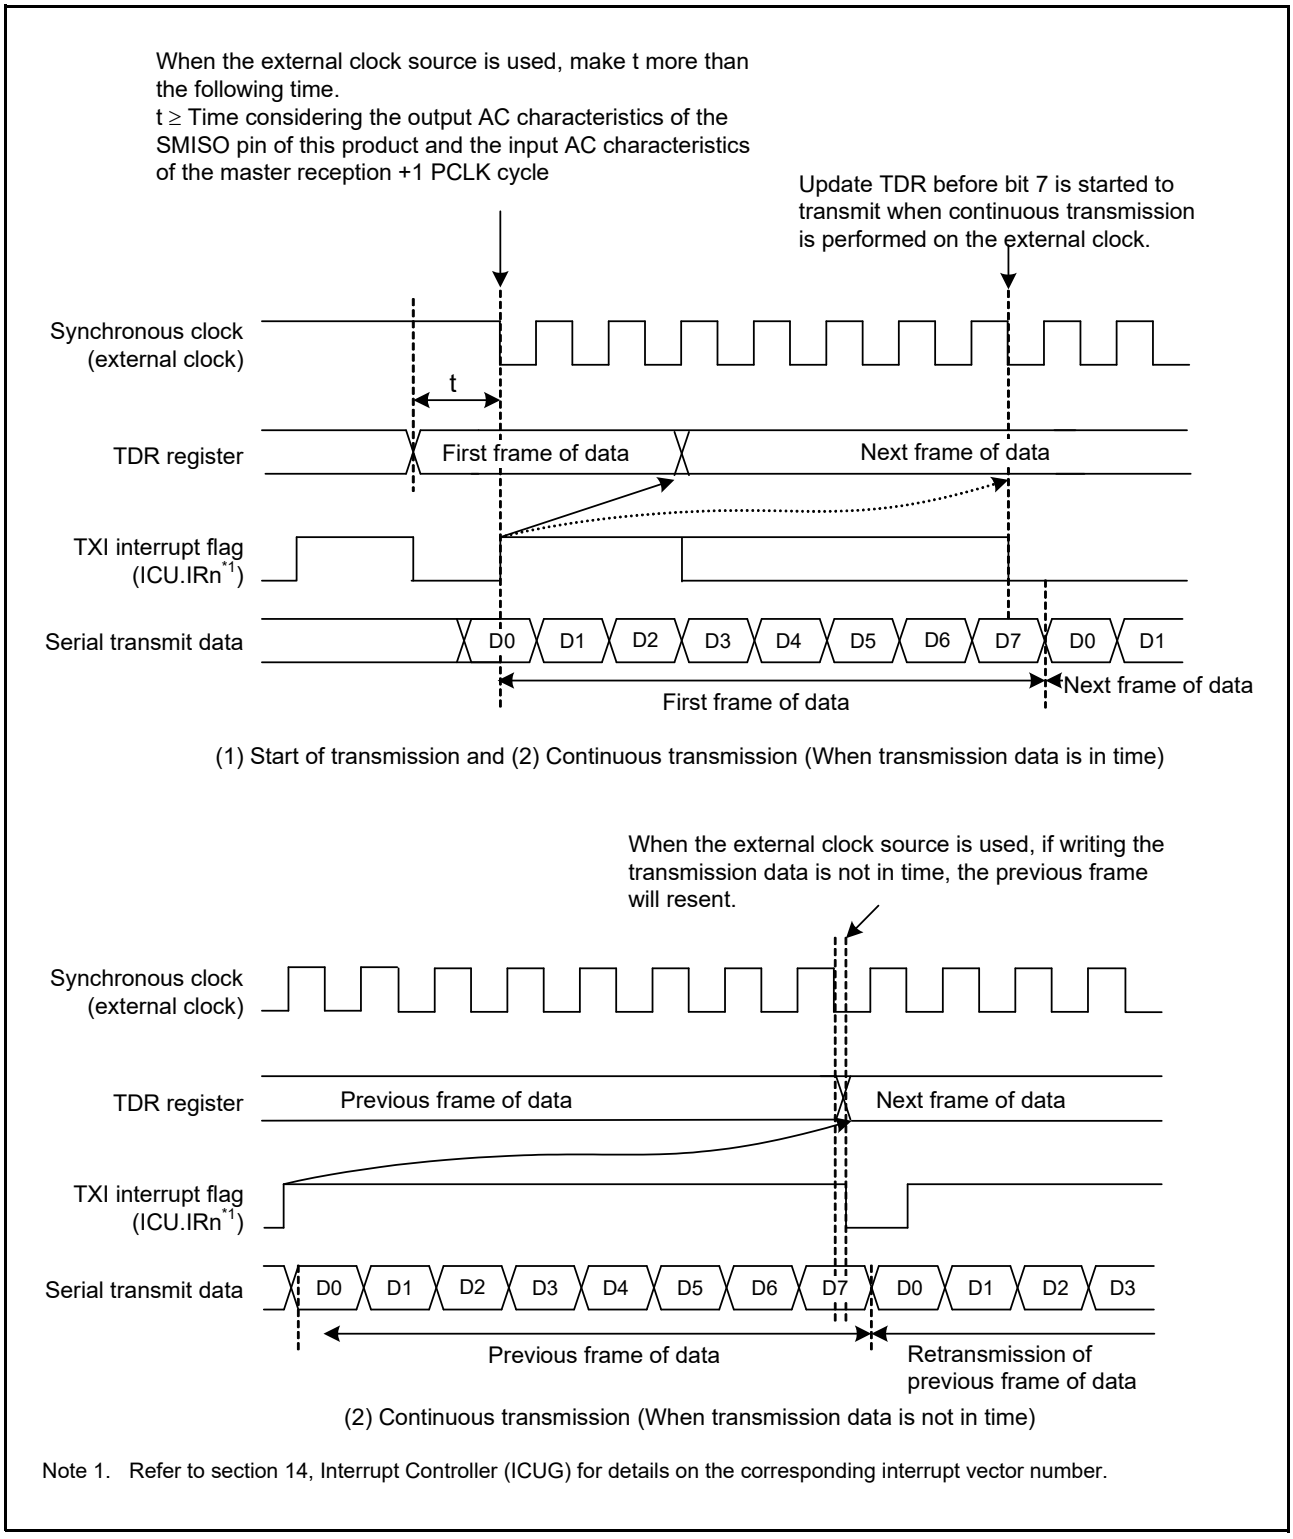

Figure 33.117 Restrictions on Use of External Clock in Clock Synchronous Transmission

33.19.8 Restrictions on Using DMAC or DTC

When using the DMAC or DTC to read RDR register, be sure to set the receive data full interrupt (RXI) as the activation source of the relevant RSCI.
During the operation in transmission/reception using the DMAC or DTC, it should not set transfer information of DMAC/DTC.

33.19.9 Notes on Starting Transfer

At the point where transfer starts when the interrupt status flag (IRn.IR flag) in the interrupt controller is 1, follow the procedure below to clear interrupt requests before permitting operations (by setting the SCR0.TE or SCR0.RE bit to 1). For details on the interrupt status flag, refer to section 14, Interrupt Controller (ICUG).

- Confirm that transfer has stopped (the setting of the SCR0.TE or SCR0.RE bits is 0).
- Set the corresponding interrupt enable bit (SCR0.TIE or SCR0.RIE) to 0.
- Read the corresponding interrupt enable bit (SCR0.TIE or SCR0.RIE bit) to check that it has become 0.
- Set the interrupt status flag (IRn.IR flag) in the interrupt controller to 0.

33.19.10 Limitations on Simple SPI Mode

(1) Master Mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set by the SCR3.CPHA and CPOL bits when the SCR0.SSE bit is 1. This prevents the clock line from being placed in the high-impedance state when the SCR0.TE bit is set to 0 or unexpected edges from being generated on the clock line when the SCR0.TE bit is changed from 0 to 1.
  In a single-master configuration, pull up or pull down the clock line is not necessary because the clock line does not become high-impedance state when SCR0.SSE bit = 0 and SCR0.TE bit = 0.
- In the case of the setting for clock delay (SCR3.CPHA bit is 0), the receive data full interrupt (RXI) is generated before the final clock edge on the SCKn pin as indicated in Figure 33.118. If the TE and RE bits become 0 at this time before the final edge of the clock signal on the SCKn pin, the SCKn pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Furthermore, an RXI interrupt may lead to the input signal on the SSn# pin of a connected slave going to the high level before the final edge of the clock signal on the SCKn pin, leading to incorrect operation of the slave.
- In a multi-master configuration, take care because the SCKn pin output becomes high-impedance while the input on the SSn# pin is at the low level if a mode fault occurs as the current character is being transferred. And stopping supply of the clock signal to the connected slave. Remake the settings for the connected slave to avoid misaligned bits when transfer is restarted.

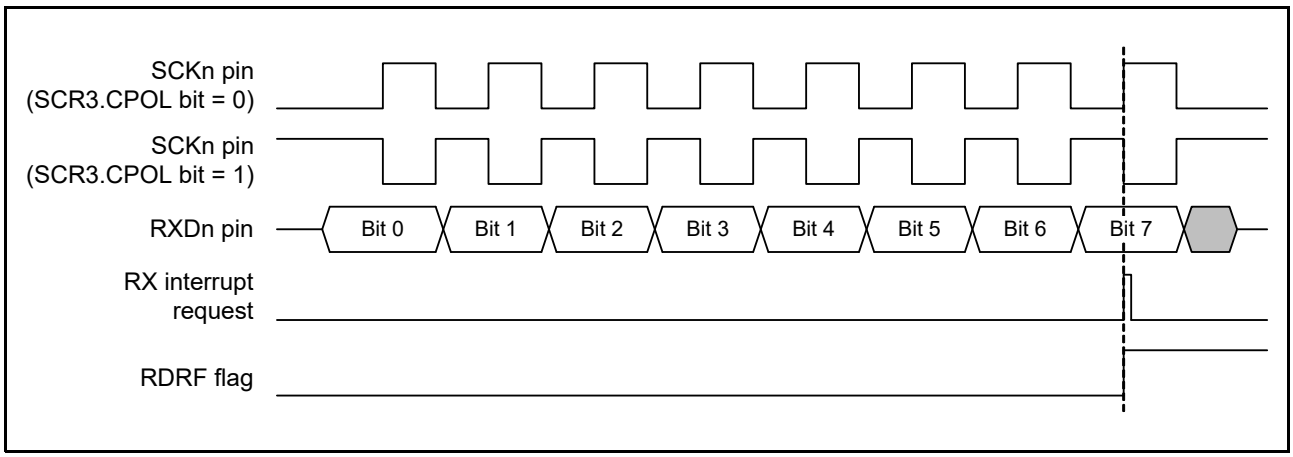

Figure 33.118 Timing of the RXI Interrupt in Simple SPI Mode (with Clock Delay)

(2) Slave Mode

- It takes “1 PCLK + data output delay time (AC characteristics)” from writing the transmit data to the TDR register until the data is output to the RXDn pin. Take these into account when starting external clock input.
- Provide an external clock signal to the master the same as the data length for transfer.
- Secure the SS input setup time (AC characteristics) from the SSn# low-level input to the start of external clock input.
- Control the input on the SSn# pin before the start and after the end of data transfer.
- When the level being input on the SSn# pin is to be changed from low to high while the current character is being transferred, the transmission and reception is stopped immediately. Set the TE and RE bits in the SCR0 register to 0 and, after remaking the settings, restart transfer of the first byte.

33.19.11 Note on Transmit Enable Bit (TE Bit)

In the initial register value, when setting the SCR.TE bit to 0 (serial transmission is disabled) while the pin function is "TXDn", output of the TXDn pin becomes high-impedance.
Prevent the TXDn line from becoming high-impedance by any of the following ways:

(a) Connect a pull-up or pull-down resistor to the TXDn line.
(b) Set the SCR1 register to determine the level of the TXDn pin when the TE bit is 0.

33.19.12 Notes on Extended Serial Mode

In extended serial mode (SCR3.MOD[2:0] bits = 110b), the following functions cannot be used.

- CTS and RTS functions
- Multi-processor communication function
- Bit Rate Modulation function
- Loopback function
- FIFO buffer

33.19.13 Notes on RS-485 Driver Control Function

- RS-485 Driver control function is valid only in Asynchronous mode.
- When RS-485 Driver control function is active (SCR3.DEEN bit = 1), the TEND set timing/TEI output timing changes as follows. Wait for the TEI interrupt and set the TE bit to 0.
  When RS-485 Driver control function is inactive: When STOP bit output is completed.
  When RS-485 Driver control function is active: At the end of DE signal hold time.

33.19.14 Notes on Loopback Function

The Loopback function is valid in Asynchronous mode with internal clock, in manchester mode with internal clock and Clock synchronous mode with internal clock.
It can also operate in the asynchronous HBS support mode, and when the HBSCR.AOE bit = 1, it loops back the signal with the logical AND of the TXDAn and TXDBn pin outputs (Use with TINV bit = RINV bit = 0).

33.19.15 Notes on Aborting Operation

If 0 is written to SCR0.RE bit during data reception and the receive operation is aborted, the status may become invalid depending on the timing. Therefore, do not use the received data (value stored in the RDR register) or the flag value of each status register. To abort the receive operation, disable the interrupt and event link related to reception, and then write 0 to the SCR0.RE bit.

34. I2C-bus Interface (RIICa)

This MCU has a single-channel I2C-bus interface (RIIC0).
The RIIC module conforms with the NXP I2C-bus (Inter-IC bus) interface and provides a subset of its functions.
In this section, “PCLK” is used to refer to PCLKB.

34.1 Overview

Table 34.1 lists the specifications of the RIIC, Figure 34.1 shows a block diagram of the RIIC. Table 34.2 lists the I/O pins of the RIIC.

Table 34.1 RIIC Specifications (1/2)

Item	Description
Communications format	• I2C-bus format or SMBus format • Master mode or slave mode selectable • Automatic securing of the various setup times, hold times, and bus-free times for the transfer rate
Transfer rate	Fast-mode is supported (up to 400 kbps)
Serial clock (SCL)	For master operation, the duty cycle of the SCL is selectable in the range from 4 to 96%.
Generating and detecting conditions	Start, restart, and stop conditions are automatically generated. Start conditions (including restart conditions) and stop conditions are detectable.
Slave address	• Up to three different slave addresses can be set. • 7-bit and 10-bit address formats are supported (along with the use of both at once). • General call addresses, device ID addresses, and SMBus host addresses are detectable.
Acknowledgment	• For transmission, the acknowledgment bit is automatically loaded. Transfer of the next data for transmission can be automatically suspended on detection of a not-acknowledge signal. • For reception, the acknowledgment bit is automatically transmitted. If a wait between the eighth and ninth clock pulses has been selected, software control of the acknowledgment in response to the received data is possible.
Wait function	• During reception, cycles of waiting by holding the SCL line low can be inserted at the following two types of timing: Waiting between the eighth and ninth clock pulses Waiting between the ninth clock pulse and the first clock pulse of the next byte
SDA output delay function	Changes in the timing of the output of data bits for transmission, and of the acknowledgment bit, can be delayed relative to the falling edge of SCL.
Arbitration	• For multi-master operation Clock synchronization for the SCL line in cases of conflict with the SCL signal from another master is possible. When generating the start condition would create conflict on the bus, loss in arbitration is detected by testing for non-matching between the internal data level and the actual level on the SDA line. During master operation, loss in arbitration is detected by testing for non-matching between the actual level on the SDA line and the internal data level. • Loss in arbitration due to detection of the start condition while the bus is busy is detectable (to prevent the generating of double start conditions). • Loss in arbitration in transfer of a not-acknowledge signal due to the internal signal (NACK) and the actual level on the SDA line not matching is detectable. • Loss in arbitration due to non-matching of internal data level and the actual level on the SDA line is detectable in slave transmission.
Timeout function	The internal timeout function is capable of detecting long-interval stop of the SCL.
Noise cancellation	The interface incorporates digital noise filters for both the SCL and SDA signals, and the width for noise cancellation by the filters is adjustable by software.
Interrupt sources	Four sources: • Communication error/communication event Detection of arbitration-lost, NACK, timeout, a start condition including a restart condition, or a stop condition • Receive data full (including matching with a slave address) • Transmit data empty (including matching with a slave address) • Transmission end

Table 34.1 RIIC Specifications (2/2)

Item	Description
Low power consumption function	Module stop state can be set.
RIIC operating modes	• Four Master transmit mode, master receive mode, slave transmit mode, and slave receive mode
Event link function (output)	Four sources (RIIC0): • Communication error/communication event Detection of arbitration-lost, NACK, timeout, a start condition including a restart condition, or a stop condition • Receive data full (including matching with a slave address) • Transmit data empty (including matching with a slave address) • Transmission end

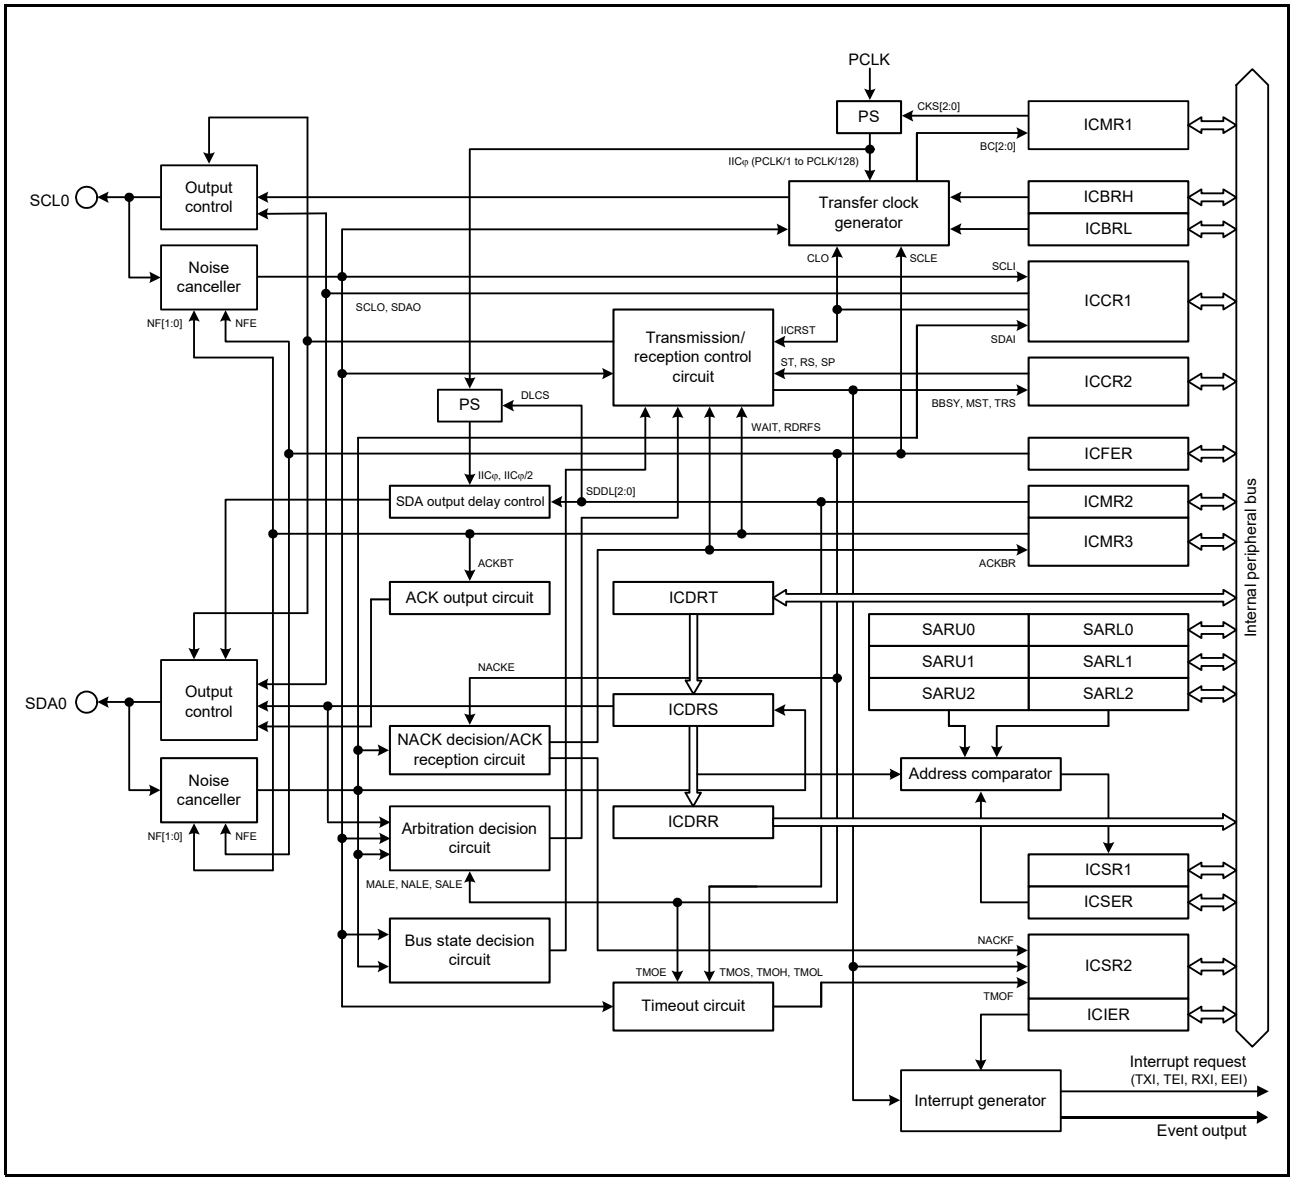

Figure 34.1 RIIC Block Diagram

The logic levels of the input signals for RIIC are CMOS when the I2C-bus is selected (ICMR3.SMBS bit is 0), or TTL when the SMBus is selected (ICMR3.SMBS bit is 1).

Table 34.2 RIIC Pin Configuration

Channel	Pin Name	I/O	Function
RIIC0	SCL0	I/O	RIIC0 serial clock I/O pin
	SDA0	I/O	RIIC0 serial data I/O pin

34.2 Register Descriptions

34.2.1 I2C-bus Control Register 1 (ICCR1)

Address(es): RIIC0.ICCR1 0008 8300h

	b7	b6	b5	b4	b3	b2	b1	b0
	ICE	IICRST	CLO	SOWP	SCLO	SDAO	SCLI	SDAI
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	SDAI	SDA Line Monitor	0: SDA0 line is low. 1: SDA0 line is high.	R
b1	SCLI	SCL Line Monitor	0: SCL0 line is low. 1: SCL0 line is high.	R
b2	SDAO	SDA Output Control/Monitor	• Read: 0: The RIIC has driven the SDA0 pin low. 1: The RIIC has released the SDA0 pin. • Write: 0: The RIIC drives the SDA0 pin low. 1: The RIIC releases the SDA0 pin. (High level output is achieved through an external pull-up resistor.)	R/W
b3	SCLO	SCL Output Control/Monitor	• Read: 0: The RIIC has driven the SCL0 pin low. 1: The RIIC has released the SCL0 pin. • Write: 0: The RIIC drives the SCL0 pin low. 1: The RIIC releases the SCL0 pin. (High level output is achieved through an external pull-up resistor.)	R/W
b4	SOWP	SCLO/SDAO Write Protect	0: SCLO and SDAO bits can be written. 1: SCLO and SDAO bits are protected. (This bit is read as 1.)	R/W
b5	CLO	Additional SCL Output	0: Does not output an additional SCL (default). 1: Outputs an additional SCL. (The CLO bit is cleared automatically after one clock pulse is output.)	R/W
b6	IICRST	I2C-bus Interface Internal Reset	0: Releases the RIIC reset or internal reset. 1: Initiates the RIIC reset or internal reset. (Clears the bit counter and the SCL0/SDA0 output latch)	R/W
b7	ICE	I2C-bus Interface Enable	0: Disable (SCL0 and SDA0 pins in inactive state) 1: Enable (SCL0 and SDA0 pins in active state) (Combined with the IICRST bit to select either RIIC or internal reset.)	R/W

SDAO Bit (SDA Output Control/Monitor) and SCLO Bit (SCL Output Control/Monitor)

These bits are used to directly control the SDA0 and SCL0 signals output from the RIIC.

When writing to these bits, also write 0 to the SOWP bit.

The result of setting these bits is input to the RIIC via the input buffer. When slave mode is selected, a start condition may be detected and the bus may be released depending on the bit settings.

Do not rewrite these bits during a start condition, stop condition, restart condition, or during transmission or reception. Operation after rewriting under the above conditions is not guaranteed.

When reading these bits, the state of signals output from the RIIC can be read.

CLO Bit (Additional SCL Output)

This bit is used to output an additional SCL for debugging or error processing.
Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error.
For details on this function, refer to section 34.11.2, Additional SCL Output Function.

IICRST Bit (I2C-bus Interface Internal Reset)

This bit is used to reset the internal states of the RIIC.
Setting this bit to 1 initiates an RIIC reset or internal reset.
Whether an RIIC reset or internal reset is initiated is determined according to the combination with the ICE bit. Table 34.3 lists the resets of the RIIC.
The RIIC reset initializes all registers and internal states of the RIIC, and the internal reset initializes the bit counter (ICMR1.BC[2:0] bits), the I2C-bus shift register (ICDRS), and the I2C-bus status registers (ICSR1 and ICSR2) as well as the internal states of the RIIC. For the reset conditions for each register, refer to section 34.14, Initialization of Registers and Functions When a Reset is Applied or a Condition is Detected.
An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the RIIC without initializing the port settings and the control and setting registers of the RIIC when the bus or RIIC hangs up due to a communication error.
If the RIIC hangs up in a low level output state, resetting the internal states cancels the low level output state and releases the bus with the SCL0 pin and SDA0 pin at a high impedance.

Note: If an internal reset is initiated using the IICRST bit for a bus hang-up occurred during communication with the master device in slave mode, the states may become different between the slave device and the master device (due to the difference in the bit counter information). For this reason, do not initiate an internal reset in slave mode, but initiate restoration processing from the master device. If it is necessary to perform an internal reset in slave mode, perform it during bus free state. If an internal reset is necessary because the RIIC has hung with the SCL0 line in a low level output state in slave mode, initiate an internal reset and then generate a restart condition from the master device or resume communications from the start condition after having generated a stop condition. If communication is restarted by initiating a reset solely in the slave device without generating a start condition or restart condition from the master device, synchronization will be lost because the master and slave devices operate asynchronously.

Table 34.3 RIIC Resets

IICRST	ICE	State	Specifications
1	0	RIIC reset	Resets all registers and internal states of the RIIC.
	1	Internal reset	Resets the ICMR1.BC[2:0] bits, registers ICSR1, ICSR2, and ICDRS, and the internal states of the RIIC.

ICE Bit (I2C-bus Interface Enable)

This bit selects the active or inactive state of the SCL0 and SDA0 pins. It can also be combined with the IICRST bit to initiate two types of resets. See Table 34.3, RIIC Resets, for the types of resets.
Set the ICE bit to 1 when using the RIIC. The SCL0 and SDA0 pins are placed in the active state when the ICE bit is set to 1.
Set the ICE bit to 0 when the RIIC is not to be used. The SCL0 and SDA0 pins are placed in the inactive state when the ICE bit is set to 0. Do not assign the SCL0 or SDA0 pin to the RIIC when setting up the multi-function pin controller (MPC). Note that the slave address comparison operation is carried out if the pins are assigned to the RIIC.

34.2.2 I2C-bus Control Register 2 (ICCR2)

Address(es): RIIC0.ICCR2 0008 8301h

	b7	b6	b5	b4	b3	b2	b1	b0
	BBSY	MST	TRS	—	SP	RS	ST	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	ST	Start Condition Generation Request	0: Does not request to generate a start condition. 1: Requests to generate a start condition.	R/W
b2	RS	Restart Condition Generation Request	0: Does not request to generate a restart condition. 1: Requests to generate a restart condition.	R/W
b3	SP	Stop Condition Generation Request	0: Does not request to generate a stop condition. 1: Requests to generate a stop condition.	R/W
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	TRS	Transmit/Receive Mode	0: Receive mode 1: Transmit mode	R/W*1
b6	MST	Master/Slave Mode	0: Slave mode 1: Master mode	R/W*1
b7	BBSY	Bus Busy Detection Flag	0: The I2C-bus is released (bus free state). 1: The I2C-bus is occupied (bus busy state).	R

Note 1. When the ICMR1.MTWP bit is set to 1, bits MST and TRS can be written to.

ST Bit (Start Condition Generation Request)

This bit is used to request transition to master mode and generation of a start condition.

When this bit is set to 1 to request to generate a start condition, a start condition is generated when the BBSY flag is set to 0 (bus free state).

For details on the start condition generation, refer to section 34.10, Start Condition/Restart Condition/Stop Condition Generating Function.

[Setting condition]

- When 1 is written to the ST bit

[Clearing conditions]

- When 0 is written to the ST bit
- When a start condition has been generated (a start condition is detected)
- When the ICSR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

Note: Set the ST bit to 1 (requests to generate a start condition) when the BBSY flag is set to 0 (bus free state). Note that arbitration may be lost due to a start condition generation error if the ST bit is set to 1 (requests to generate a start condition) when the BBSY flag is set to 1 (bus busy state).

RS Bit (Restart Condition Generation Request)

This bit is used to request that a restart condition be generated in master mode.
When this bit is set to 1 to request to generate a restart condition, a restart condition is generated when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode).
For details on the restart condition generation, refer to section 34.10, Start Condition/Restart Condition/Stop Condition Generating Function.
[Setting condition]

- When 1 is written to the RS bit with the ICCR2.BBSY flag set to 1

[Clearing conditions]

- When 0 is written to the RS bit
- When a restart condition has been generated (a start condition is detected)
- When the ICSR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

Note: Do not set the RS bit to 1 while generating a stop condition.
Note: If 1 (requests to generate a restart condition) is written to the RS bit in slave mode, the restart condition is not generated but the RS bit remains set to 1. If the operating mode changes to master mode with the bit not being cleared, note that the restart condition may be generated.

SP Bit (Stop Condition Generation Request)

This bit is used to request that a stop condition be generated in master mode.
When this bit is set to 1 to request to generate a stop condition, a stop condition is generated when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode).
For details on the stop condition generation, refer to section 34.10, Start Condition/Restart Condition/Stop Condition Generating Function.
[Setting condition]

- When 1 is written to the SP bit with both the BBSY flag and the ICCR2.MST bit set to 1

[Clearing conditions]

- When 0 is written to the SP bit
- When a stop condition has been generated (a stop condition is detected)
- When the ICSR2.AL (arbitration-lost) flag is set to 1
- When a start condition and a restart condition are detected
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

Note: Writing to the SP bit is not possible while the setting of the BBSY flag is 0 (bus free state).
Note: Do not set the SP bit to 1 while a restart condition is being generated.

TRS Bit (Transmit/Receive Mode)

This bit indicates transmit or receive mode.
The RIIC is in receive mode when the TRS bit is set to 0 and is in transmit mode when the bit is set to 1. Combination of this bit and the MST bit indicates the operating mode of the RIIC.
The value of the TRS bit is automatically changed to 1 for transmission or 0 for reception in response to the generation or detection of a start condition and setting of the R/W# bit. Although writing to the TRS bit is possible when the ICMR1.MTWP bit is set to 1, writing to this bit is not necessary during normal usage.
[Setting conditions]

- When a start condition is generated normally according to the start condition generation request (when a start condition is detected with the ST bit set to 1)
- When a restart condition is generated normally according to the restart condition generation request (when a restart condition is detected with the RS bit set to 1)
- When the R/W# bit added to the slave address is set to 0 in master mode
- When the address received in slave mode matches the address enabled in the ICSER register, with the R/W# bit set to 1
- When 1 is written to the TRS bit with the ICMR1.MTWP bit set to 1

[Clearing conditions]

- When a stop condition is detected
- The ICSR2.AL (arbitration-lost) flag being set to 1
- In master mode, reception of a slave address to which an R/W# bit with the value 1 is appended
- In slave mode, a match between the received address and the address enabled in the ICSER register when the value of the received R/W# bit is 0 (including cases where the received address is the general call address)
- In slave mode, a restart condition is detected (that is, a start condition is detected while the ICCR2.BBSY flag is 1 and the ICCR2.MST bit is 0)
- When 0 is written to the TRS bit with the ICMR1.MTWP bit set to 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

MST Bit (Master/Slave Mode)

This bit indicates master or slave mode.
The RIIC is in slave mode when the MST bit is set to 0 and is in master mode when the bit is set to 1. Combination of this bit and the TRS bit indicates the operating mode of the RIIC.
The value of the MST bit is automatically changed to 1 for master mode or 0 for slave mode by generating of a start condition and generating or detection of a stop condition, etc. Although writing to the MST bit is possible when the ICMR1.MTWP bit is set to 1, writing to this bit is not necessary during normal usage.
[Setting conditions]

- When a start condition is generated normally according to the start condition generation request (when a start condition is detected with the ST bit set to 1)
- When 1 is written to the MST bit with the ICMR1.MTWP bit set to 1

[Clearing conditions]

- When a stop condition is detected
- When the ICSR2.AL (arbitration-lost) flag is set to 1
- When 0 is written to the MST bit with the ICMR1.MTWP bit set to 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

BBSY Flag (Bus Busy Detection Flag)

The BBSY flag indicates whether the I2C-bus is occupied (bus busy state) or released (bus free state).
This bit is set to 1 when the SDA0 line changes from high to low under the condition of SCL0 line = high, assuming that a start condition has been generated.
The RIIC recognizes the SDA0 line changing from low to high while the SCL0 line is high as generation of the stop condition. After that, this flag becomes 0 if the RIIC does not detect a start condition during the bus free time (the period set in the ICBRL register).
[Setting condition]

- When a start condition is detected

[Clearing conditions]

- When the bus free time (specified in the ICBRL register) start condition is not detected after detecting a stop condition
- When 1 is written to the ICCR1.IICRST bit with the ICCR1.ICE bit set to 0 (RIIC reset)

34.2.3 I2C-bus Mode Register 1 (ICMR1)

Address(es): RIIC0.ICMR1 0008 8302h

	b7	b6	b5	b4	b3	b2	b1	b0
	MTWP	CKS[2:0]			BCWP	BC[2:0]		
Value after reset:	0	0	0	0	1	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	BC[2:0]	Bit Counter	b2 b0 0 0 0: 9 bits 0 0 1: 2 bits 0 1 0: 3 bits 0 1 1: 4 bits 1 0 0: 5 bits 1 0 1: 6 bits 1 1 0: 7 bits 1 1 1: 8 bits	R/W*1
b3	BCWP	BC Write Protect	0: Enables a value to be written in the BC[2:0] bits. (This bit is read as 1.)	R/W*1
b6 to b4	CKS[2:0]	Internal Reference Clock Select	Select the internal reference clock (IICφ) source for the RIIC. b6 b4 0 0 0: PCLK/1 0 0 1: PCLK/2 0 1 0: PCLK/4 0 1 1: PCLK/8 1 0 0: PCLK/16 1 0 1: PCLK/32 1 1 0: PCLK/64 1 1 1: PCLK/128	R/W
b7	MTWP	MST/TRS Write Protect	0: Disables writing to the ICCR2.MST and TRS bits. 1: Enables writing to the ICCR2.MST and TRS bits.	R/W

Note 1. Rewrite the BC[2:0] bits and set the BCWP bit to 0 at the same time.

BC[2:0] Bits (Bit Counter)

These bits function as a counter that indicates the number of bits remaining to be transferred at the detection of a rising edge on the SCL0 line. Although these bits are writable and readable, it is not necessary to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one (data is transferred with an additional acknowledgment bit) between transferred bytes when the SCL0 line is low.

The values of the BC[2:0] bits return to 000b at the end of a data transfer including the acknowledgment bit or when a start condition including a restart condition is detected.

34.2.4 I2C-bus Mode Register 2 (ICMR2)

Address(es): RIIC0.ICMR2 0008 8303h

	b7	b6	b5	b4	b3	b2	b1	b0
	DLCS	SDDL[2:0]			—	TMOH	TMOL	TMOS
Value after reset:	0	0	0	0	0	1	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	TMOS	Timeout Detection Time Select	0: Long mode is selected. 1: Short mode is selected.	R/W
b1	TMOL	Timeout L Count Control	0: Count-up is disabled while the SCL0 line is low. 1: Count-up is enabled while the SCL0 line is low.	R/W
b2	TMOH	Timeout H Count Control	0: Count-up is disabled while the SCL0 line is high. 1: Count-up is enabled while the SCL0 line is high.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6 to b4	SDDL[2:0]	SDA Output Delay Counter	• When ICMR2.DLCS bit is 0 (IICφ) b6 b4 0 0: No output delay 0 1: 1 IICφ cycle 1 0: 2 IICφ cycles 1 1: 3 IICφ cycles 0 0: 4 IICφ cycles 0 1: 5 IICφ cycles 1 0: 6 IICφ cycles 1 1: 7 IICφ cycles • When ICMR2.DLCS bit is 1 (IICφ/2) b6 b4 0 0: No output delay 0 1: 1 or 2 IICφ cycles 1 0: 3 or 4 IICφ cycles 1 1: 5 or 6 IICφ cycles 0 0: 7 or 8 IICφ cycles 0 1: 9 or 10 IICφ cycles 1 0: 11 or 12 IICφ cycles 1 1: 13 or 14 IICφ cycles	R/W
b7	DLCS	SDA Output Delay Clock Source Select	0: The internal reference clock (IICφ) is selected as the clock source of the SDA output delay counter. 1: The internal reference clock divided by 2 (IICφ/2) is selected as the clock source of the SDA output delay counter.*1	R/W

Note 1. The DLCS bit setting of 1 (IICφ/2) only becomes valid when SCL pin is low. When SCL pin is high, the DLCS bit setting of 1 becomes invalid and the clock source becomes the internal reference clock (IICφ).

TMOS Bit (Timeout Detection Time Select)

This bit is used to select long mode or short mode for the timeout detection time when the timeout function is enabled (ICFER.TMOE bit is 1). When this bit is set to 0, long mode is selected. When this bit is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16-bit counter. In short mode, the counter functions as a 14-bit counter. While the SCL0 line is in the state that enables this counter as specified by bits TMOH and TMOL, the counter counts up in synchronization with the internal reference clock (IICφ) as a count source.

For details on the timeout function, refer to section 34.11.1, Timeout Function.

TMOL Bit (Timeout L Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL0 line is held low when the timeout function is enabled (ICFER.TMOE bit is 1).

TMOH Bit (Timeout H Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL0 line is held high when the timeout function is enabled (ICFER.TMOE bit is 1).

SDDL[2:0] Bits (SDA Output Delay Counter)

The SDA output can be delayed by the SDDL[2:0] setting. This counter works with the clock source selected by the DLCS bit. The setting of this function can be used for all types of SDA output, including the transmission of the acknowledgment bit.

Set the SDA output delay time to meet the I2C-bus specification (within the data valid time/data valid acknowledge time*1) or the SMBus specification (more than the data hold time (300 ns) and less than "clock low period – data setup time (250 ns)"). Note that, if a value outside the specification is set, communication with communication devices may malfunction or it may seemingly become a start condition or stop condition depending on the bus state.

For details on this function, refer to section 34.5, SDA Output Delay Function.

Note 1. Data valid time/data valid acknowledge time
3,450 ns (up to 100 kbps: Standard-mode (Sm))
900 ns (up to 400 kbps: Fast-mode (Fm))

34.2.5 I2C-bus Mode Register 3 (ICMR3)

Address(es): RIIC0.ICMR3 0008 8304h

	b7	b6	b5	b4	b3	b2	b1	b0
	SMBS	WAIT	RDRFS	ACKWP	ACKBT	ACKBR	NF[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	NF[1:0]	Noise Filter Stage Select	b1 b0 0 0: Noise of up to one IICφ cycle is filtered out (single-stage filter). 0 1: Noise of up to two IICφ cycles is filtered out (2-stage filter). 1 0: Noise of up to three IICφ cycles is filtered out (3-stage filter). 1 1: Noise of up to four IICφ cycles is filtered out (4-stage filter).	R/W
b2	ACKBR	Received Acknowledge	0: 0 is received as the acknowledgment bit (ACK reception). 1: 1 is received as the acknowledgment bit (NACK reception).	R
b3	ACKBT	Transmit Acknowledge	0: 0 is to be sent as the acknowledgment bit (ACK transmission). 1: 1 is to be sent as the acknowledgment bit (NACK transmission).	R/W*1
b4	ACKWP	ACKBT Write Protect	0: Modification of the ACKBT bit is disabled. 1: Modification of the ACKBT bit is enabled.	R/W*1
b5	RDRFS	RDRF Flag Set Timing Select	0: The RDRF flag is set at the rising edge of the ninth SCL. (The SCL0 line is not held low at the falling edge of the eighth clock pulse.) 1: The RDRF flag is set at the rising edge of the eighth SCL. (The SCL0 line is held low at the falling edge of the eighth clock pulse.) Low-hold is released by writing a value to the ACKBT bit.	R/W*2
b6	WAIT	WAIT	0: No WAIT (The period between ninth clock pulse and first clock pulse is not held low.) 1: WAIT (The period between ninth clock pulse and first clock pulse is held low.) Low-hold is released by reading the ICDRR register.	R/W*2
b7	SMBS	SMBus/I2C-bus Select	0: The I2C-bus is selected. 1: The SMBus is selected.	R/W

Note 1. Write to the ACKBT bit only while the ACKWP bit is already 1. If it is attempted to write 1 to both the ACKWP and ACKBT bits at the same time, the ACKBT bit will not be set to 1.

Note 2. The WAIT and RDRFS bits are valid only in receive mode (invalid in transmit mode).

NF[1:0] Bits (Noise Filter Stage Select)

These bits are used to select the number of stages in the digital noise filter.

For details on the digital noise filter function, refer to section 34.6, Digital Noise Filters.

Note: Set the noise range to be filtered out by the noise filter within a range less than the SCL0 line high period or low period. If the noise filter width is set to a value of [the shorter one of either SCL high width or SCL low width] – 1.5 × t_{IICcyc} (cycle time of internal reference clock (IICφ)) or a greater value, the serial clock is regarded as noise by the noise filter function of the RIIC, which may prevent the RIIC from operating normally.

ACKBR Bit (Received Acknowledge)

This bit is used to store the value of the acknowledgment bit received from the receiver in transmit mode.
[Setting condition]

- When 1 is received as the acknowledgment bit with the ICCR2.TRS bit set to 1

[Clearing conditions]

- When 0 is received as the acknowledgment bit with the ICCR2.TRS bit set to 1
- When 1 is written to the ICCR1.IICRST bit while the ICCR1.ICE bit is 0 (RIIC reset)

ACKBT Bit (Transmit Acknowledge)

This bit is used to set the bit to be sent at the acknowledgment timing in receive mode.
[Setting condition]

- When 1 is written to this bit with the ACKWP bit set to 1

[Clearing conditions]

- When 0 is written to this bit with the ACKWP bit set to 1
- When stop condition generation is detected (when a stop condition is detected with the ICCR2.SP bit set to 1)
- When 1 is written to the ICCR1.IICRST bit while the ICCR1.ICE bit is 0 (RIIC reset)

ACKWP Bit (ACKBT Write Protect)

This bit is used to control the modification of the ACKBT bit.

RDRFS Bit (RDRF Flag Set Timing Select)

This bit is used to select the RDRF flag set timing in receive mode and also to select whether to hold the SCL0 line low at the falling edge of the eighth SCL.
When the RDRFS bit is 0, the SCL0 line is not held low at the falling edge of the eighth SCL, and the RDRF flag is set to 1 at the rising edge of the ninth SCL.
When the RDRFS bit is 1, the RDRF flag is set to 1 at the rising edge of the eighth SCL and the SCL0 line is held low at the falling edge of the eighth SCL. The low-hold of the SCL0 line is released by writing a value to the ACKBT bit.
After data is received with this setting, the SCL0 line is automatically held low before the acknowledgment bit is sent. This enables processing to send ACK (ACKBT bit is 0) or NACK (ACKBT bit is 1) according to receive data.

WAIT Bit (WAIT)

This bit is used to control whether to hold the period between the ninth SCL and the first SCL low until the I2C-bus receive data register (ICDRR) is completely read each time single-byte data is received in receive mode.
When the WAIT bit is 0, the receive operation is continued without holding the period between the ninth and the first SCL low. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.
When the WAIT bit is 1, the SCL0 line is held low from the falling edge of the ninth SCL until the ICDRR register value is read each time single-byte data is received. This enables receive operation in byte units.

Note: When the value of the WAIT bit is to be read, be sure to read the ICDRR register beforehand.

SMBS Bit (SMBus/I2C-bus Select)

Setting this bit to 1 selects the SMBus and enables the ICSER.HOAE bit.

34.2.6 I2C-bus Function Enable Register (ICFER)

Address(es): RIIC0.ICFER 0008 8305h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	SCLE	NFE	NACKE	SALE	NALE	MALE	TMOE
Value after reset:	0	1	1	1	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	TMOE	Timeout Function Enable	0: The timeout function is disabled. 1: The timeout function is enabled.	R/W
b1	MALE	Master Arbitration-Lost Detection Enable	0: Master arbitration-lost detection is disabled. (Disables the arbitration-lost detection function and does not clear the ICCR2.MST and TRS bits automatically when arbitration is lost.) 1: Master arbitration-lost detection is enabled. (Enables the arbitration-lost detection function and clears the ICCR2.MST and TRS bits automatically when arbitration is lost.)	R/W
b2	NALE	NACK Transmission Arbitration-Lost Detection Enable	0: NACK transmission arbitration-lost detection is disabled. 1: NACK transmission arbitration-lost detection is enabled.	R/W
b3	SALE	Slave Arbitration-Lost Detection Enable	0: Slave arbitration-lost detection is disabled. 1: Slave arbitration-lost detection is enabled.	R/W
b4	NACKE	NACK Reception Transfer Suspension Enable	0: Transfer operation is not suspended during NACK reception (transfer suspension disabled). 1: Transfer operation is suspended during NACK reception (transfer suspension enabled).	R/W
b5	NFE	Digital Noise Filter Enable	0: Digital noise filters are not used. 1: Digital noise filters are used.	R/W
b6	SCLE	SCL Synchronization Enable	0: SCL synchronization is disabled. 1: SCL synchronization is enabled.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

TMOE Bit (Timeout Function Enable)

This bit is used to enable or disable the timeout function.

For details on the timeout function, refer to section 34.11.1, Timeout Function.

MALE Bit (Master Arbitration-Lost Detection Enable)

This bit is used to specify whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

NALE Bit (NACK Transmission Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode (such as when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with different number of receive bytes).

SALE Bit (Slave Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode (such as when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs due to noise).

NACKE Bit (NACK Reception Transfer Suspension Enable)

This bit is used to specify whether to continue or discontinue the data transfer when NACK is received in transmit mode. Normally, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended.

When the NACKE bit is 0, the next transfer operation is continued regardless of the value of the received acknowledgment bit.

For details on the NACK reception transfer suspension function, refer to section 34.8.2, NACK Reception Transfer Suspension Function.

SCLE Bit (SCL Synchronization Enable)

This bit is used to specify whether to the SCL output is to be synchronized with the SCL input. Normally, set this bit to 1.

When the SCLE bit is set to 0 (SCL synchronization is disabled), the RIIC does not synchronize the SCL output with the SCL input. In this setting, the RIIC outputs the clock with the transfer rate set in registers ICBRH and ICBRL regardless of the SCL0 line state. For this reason, if the load of the I2C-bus line is much larger than the specification value or if the SCL output overlaps in multiple masters, the short-cycle SCL that does not meet the specification may be output. When the SCL synchronization is not used, it also affects the generation of a start condition, restart condition, and stop condition, and the continuous output of additional SCL.

This bit must not be set to 0 except for checking the output of the set transfer rate.

34.2.7 I2C-bus Status Enable Register (ICSER)

Address(es): RIIC0.ICSER 0008 8306h

	b7	b6	b5	b4	b3	b2	b1	b0
	HOAE	—	DIDE	—	GCAE	SAR2E	SAR1E	SAR0E
Value after reset:	0	0	0	0	1	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	SAR0E	Slave Address Register 0 Enable	0: Slave address in registers SARL0 and SARU0 is disabled. 1: Slave address in registers SARL0 and SARU0 is enabled.	R/W
b1	SAR1E	Slave Address Register 1 Enable	0: Slave address in registers SARL1 and SARU1 is disabled. 1: Slave address in registers SARL1 and SARU1 is enabled.	R/W
b2	SAR2E	Slave Address Register 2 Enable	0: Slave address in registers SARL2 and SARU2 is disabled. 1: Slave address in registers SARL2 and SARU2 is enabled.	R/W
b3	GCAE	General Call Address Enable	0: General call address detection is disabled. 1: General call address detection is enabled.	R/W
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	DIDE	Device-ID Address Detection Enable	0: Device-ID address detection is disabled. 1: Device-ID address detection is enabled.	R/W
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	HOAE	Host Address Enable	0: Host address detection is disabled. 1: Host address detection is enabled.	R/W

SARyE Bit (Slave Address Register y Enable) (y = 0 to 2)

This bit is used to enable or disable the slave address set in registers SARLy and SARUy.

When this bit is set to 1, the slave address set in registers SARLy and SARUy is enabled and is compared with the received slave address.

When this bit is set to 0, the slave address set in registers SARLy and SARUy is disabled and is ignored even if it matches the received slave address.

GCAE Bit (General Call Address Enable)

This bit is used to specify whether to ignore the general call address (0000 000b + 0 (write): All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the RIIC recognizes the received slave address as the general call address independently of the slave addresses set in registers SARLy and SARUy (y = 0 to 2) and performs data receive operation.

When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

DIDE Bit (Device-ID Address Detection Enable)

This bit is used to specify whether to recognize and execute the device-ID address when a device ID (1111 100b) is received in the first byte after a start condition or restart condition is detected.

When this bit is set to 1, if the received first byte matches the device ID, the RIIC recognizes that the device-ID address has been received. When the following R/W# bit is 0 (write), the RIIC recognizes the second and the following bytes as slave addresses and continues the receive operation.

When this bit is set to 0, the RIIC ignores the received first byte even if it matches the device ID address and recognizes the first byte as a normal slave address.

For details on the device-ID address detection, refer to section 34.7.3, Device-ID Address Detection.

HOAE Bit (Host Address Enable)

This bit is used to specify whether to ignore received host address (0001 000b) when the ICMR3.SMBS bit is 1.
When this bit is set to 1 while the ICMR3.SMBS bit is 1, if the received slave address matches the host address, the RIIC recognizes the received slave address as the host address independently of the slave addresses set in registers SARLy and SARUy (y = 0 to 2) and performs the receive operation.
When the ICMR3.SMBS bit or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

34.2.8 I2C-bus Interrupt Enable Register (ICIER)

Address(es): RIIC0.ICIER 0008 8307h

	b7	b6	b5	b4	b3	b2	b1	b0
	TIE	TEIE	RIE	NAKIE	SPIE	STIE	ALIE	TMOIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TMOIE	Timeout Interrupt Request Enable	0: Timeout interrupt (TMOI) request is disabled. 1: Timeout interrupt (TMOI) request is enabled.	R/W
b1	ALIE	Arbitration-Lost Interrupt Request Enable	0: Arbitration-lost interrupt (ALI) request is disabled. 1: Arbitration-lost interrupt (ALI) request is enabled.	R/W
b2	STIE	Start Condition Detection Interrupt Request Enable	0: Start condition detection interrupt (STI) request is disabled. 1: Start condition detection interrupt (STI) request is enabled.	R/W
b3	SPIE	Stop Condition Detection Interrupt Request Enable	0: Stop condition detection interrupt (SPI) request is disabled. 1: Stop condition detection interrupt (SPI) request is enabled.	R/W
b4	NAKIE	NACK Reception Interrupt Request Enable	0: NACK reception interrupt (NAKI) request is disabled. 1: NACK reception interrupt (NAKI) request is enabled.	R/W
b5	RIE	Receive Data Full Interrupt Request Enable	0: Receive data full interrupt (RXI) request is disabled. 1: Receive data full interrupt (RXI) request is enabled.	R/W
b6	TEIE	Transmission End Interrupt Request Enable	0: Transmission end interrupt (TEI) request is disabled. 1: Transmission end interrupt (TEI) request is enabled.	R/W
b7	TIE	Transmit Data Empty Interrupt Request Enable	0: Transmit data empty interrupt (TXI) request is disabled. 1: Transmit data empty interrupt (TXI) request is enabled.	R/W

TMOIE Bit (Timeout Interrupt Request Enable)

This bit is used to enable or disable timeout interrupt (TMOI) requests when the ICSR2.TMOF flag is set to 1. A TMOI interrupt request is canceled by setting the TMOF flag or the TMOIE bit to 0.

ALIE Bit (Arbitration-Lost Interrupt Request Enable)

This bit is used to enable or disable arbitration-lost interrupt (ALI) requests when the ICSR2.AL flag is set to 1. An ALI interrupt request is canceled by setting the AL flag or the ALIE bit to 0.

STIE Bit (Start Condition Detection Interrupt Request Enable)

This bit is used to enable or disable start condition detection interrupt (STI) requests when the ICSR2.START flag is set to 1. An STI interrupt request is canceled by setting the START flag or the STIE bit to 0.

SPIE Bit (Stop Condition Detection Interrupt Request Enable)

This bit is used to enable or disable stop condition detection interrupt (SPI) requests when the ICSR2.STOP flag is set to 1. An SPI interrupt request is canceled by setting the STOP flag or the SPIE bit to 0.

NAKIE Bit (NACK Reception Interrupt Request Enable)

This bit is used to enable or disable NACK reception interrupt (NAKI) requests when the ICSR2.NACKF flag is set to 1. An NAKI interrupt request is canceled by setting the NACKF flag or the NAKIE bit to 0.

RIE Bit (Receive Data Full Interrupt Request Enable)

This bit is used to enable or disable receive data full interrupt (RXI) requests when the ICSR2.RDRF flag is set to 1.

TEIE Bit (Transmission End Interrupt Request Enable)

This bit is used to enable or disable transmission end interrupt (TEI) requests when the ICSR2.TEND flag is set to 1. An TEI interrupt request is canceled by setting the TEND flag or the TEIE bit to 0.

TIE Bit (Transmit Data Empty Interrupt Request Enable)

This bit is used to enable or disable transmit data empty interrupt (TXI) requests when the ICSR2.TDRE flag is set to 1.

34.2.9 I2C-bus Status Register 1 (ICSR1)

Address(es): RIIC0.ICSR1 0008 8308h

	b7	b6	b5	b4	b3	b2	b1	b0
	HOA	—	DID	—	GCA	AAS2	AAS1	AAS0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	AAS0	Slave Address 0 Detection Flag	0: Slave address 0 is not detected. 1: Slave address 0 is detected.	R/(W) *1
b1	AAS1	Slave Address 1 Detection Flag	0: Slave address 1 is not detected. 1: Slave address 1 is detected.	R/(W) *1
b2	AAS2	Slave Address 2 Detection Flag	0: Slave address 2 is not detected. 1: Slave address 2 is detected.	R/(W) *1
b3	GCA	General Call Address Detection Flag	0: General call address is not detected. 1: General call address is detected.	R/(W) *1
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	DID	Device-ID Address Detection Flag	0: Device-ID command is not detected. 1: Device-ID command is detected. • This bit is set to 1 when the first byte received immediately after a start condition is detected matches a value of (device ID (1111 100b) + 0 (write)).	R/(W) *1
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	HOA	Host Address Detection Flag	0: Host address is not detected. 1: Host address is detected. • This bit is set to 1 when the received slave address matches the host address (0001 000b).	R/(W) *1

Note 1. Only 0 can be written to clear the flag.

AASy Flag (Slave Address y Detection Flag) (y = 0 to 2)

[Setting conditions]

For 7-bit address format: SARUy.FS bit = 0

- When the received slave address matches the SARLy.SVA[6:0] bits value with the ICSER.SARyE bit set to 1 (slave address y detection enabled)
  This flag is set to 1 at the rising edge of the ninth SCL in the first byte.

For 10-bit address format: SARUy.FS bit = 1

- When the received slave address matches a value of (11110b + SARUy.SVA[1:0] bits) and the following address matches the SARLy value with the ICSER.SARyE bit set to 1 (slave address y detection enabled)
  This flag is set to 1 at the rising edge of the ninth SCL in the second byte.

[Clearing conditions]

- When 0 is written to the AASy flag after reading the AASy flag to be 1
- When a stop condition is detected
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

For 7-bit address format: SARUy.FS bit = 0

- When the received slave address does not match the SARLy.SVA[6:0] bits value with the ICSER.SARyE bit set to 1 (slave address y detection enabled)
  This flag is set to 0 at the rising edge of the ninth SCL in the first byte.

For 10-bit address format: SARUy.FS bit = 1

- When the received slave address does not match a value of (11110b + SARUy.SVA[1:0] bits) with the ICSER.SARyE bit set to 1 (slave address y detection enabled)
  This flag is set to 0 at the rising edge of the ninth SCL in the first byte.
- When the received slave address matches a value of (11110b + SARUy.SVA[1:0] bits) and the following address does not match the SARLy value with the ICSER.SARyE bit set to 1 (slave address y detection enabled)
  This flag is set to 0 at the rising edge of the ninth SCL in the second byte.

GCA Flag (General Call Address Detection Flag)

[Setting condition]

- When the received slave address matches the general call address (0000 000b + 0 (write)) with the ICSER.GCAE bit set to 1 (general call address detection is enabled)
  This flag is set to 1 at the rising edge of the ninth SCL in the first byte.

[Clearing conditions]

- When 0 is written to the GCA flag after reading GCA flag to be 1
- When a stop condition is detected
- When the received slave address does not match the general call address (0000 000b + 0 (write)) with the ICSER.GCAE bit set to 1 (general call address detection is enabled)
  This flag is set to 0 at the rising edge of the ninth SCL in the first byte.
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

DID Flag (Device-ID Address Detection Flag)

[Setting condition]

- When the first byte received immediately after a start condition or restart condition is detected matches a value of (device ID (1111 100b) + 0 (write)) with the ICSER.DIDE bit set to 1 (device-ID address detection is enabled)
  This flag is set to 1 at the rising edge of the ninth SCL in the first byte.

[Clearing conditions]

- When 0 is written to the DID flag after reading DID flag to be 1
- When a stop condition is detected
- When the first byte received immediately after a start condition or restart condition is detected does not match a value of (device ID (1111 100b)) with the ICSER.DIDE bit set to 1 (device-ID address detection is enabled)
  This flag is set to 0 at the rising edge of the ninth SCL in the first byte.
- When the first byte received immediately after a start condition or restart condition is detected matches a value of (device ID (1111 100b) + 0 (write)) and the second byte does not match any of slave addresses 0 to 2 with the ICSER.DIDE bit set to 1 (device-ID address detection is enabled)
  This flag is set to 0 at the rising edge of the ninth SCL in the second byte.
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

HOA Flag (Host Address Detection Flag)

[Setting condition]

- When the received slave address matches the host address (0001 000b) with the ICSER.HOAE bit set to 1 (host address detection is enabled)
  This flag is set to 1 at the rising edge of the ninth SCL in the first byte.

[Clearing conditions]

- When 0 is written to the HOA flag after reading HOA flag to be 1
- When a stop condition is detected
- When the received slave address does not match the host address (0001 000b) with the ICSER.HOAE bit set to 1

(host address detection is enabled)
This flag is set to 0 at the rising edge of the ninth SCL in the first byte.

- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

34.2.10 I2C-bus Status Register 2 (ICSR2)

Address(es): RIIC0.ICSR2 0008 8309h

	b7	b6	b5	b4	b3	b2	b1	b0
	TDRE	TEND	RDRF	NACKF	STOP	START	AL	TMOF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TMOF	Timeout Detection Flag	0: Timeout is not detected. 1: Timeout is detected.	R/(W) *1
b1	AL	Arbitration-Lost Flag	0: Arbitration is not lost. 1: Arbitration is lost.	R/(W) *1
b2	START	Start Condition Detection Flag	0: Start condition is not detected. 1: Start condition is detected.	R/(W) *1
b3	STOP	Stop Condition Detection Flag	0: Stop condition is not detected. 1: Stop condition is detected.	R/(W) *1
b4	NACKF	NACK Detection Flag	0: NACK is not detected. 1: NACK is detected.	R/(W) *1
b5	RDRF	Receive Data Full Flag	0: The ICDRR register contains no receive data. 1: The ICDRR register contains receive data.	R/(W) *1
b6	TEND	Transmission End Flag	0: Data is being transmitted. 1: Data has been transmitted.	R/(W) *1
b7	TDRE	Transmit Data Empty Flag	0: The ICDRT register contains transmit data. 1: The ICDRT register contains no transmit data.	R

Note 1. Only 0 can be written to clear the flag.

TMOF Flag (Timeout Detection Flag)

This flag is set to 1 when the RIIC recognizes timeout after the SCL0 line state remains unchanged for a certain period.
[Setting condition]

- When the SCL0 line state remains unchanged for the period specified by bits ICMR2.TMOH, TMOL, and TMOS while the ICFER.TMOE bit is 1 (the timeout function is enabled) in master mode or in slave mode and the received slave address matches.

[Clearing conditions]

- When 0 is written to the TMOF bit after reading TMOF = 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

AL Flag (Arbitration-Lost Flag)

This flag shows that bus mastership has been lost (loss in arbitration) due to a bus conflict or some other reason when a start condition is generated or an address and data are transmitted. The RIIC monitors the level on the SDA0 line during transmission and, if the level on the line does not match the value of the bit being output, sets the value of the AL flag to 1 to indicate that the bus is occupied by another device.
The RIIC can also detect loss of arbitration during NACK transmission in receive mode or during data transmission in slave mode.

[Setting conditions]

When master arbitration-lost detection is enabled: ICFER.MALE = 1

- When the internal SDA output state does not match the SDA0 line level at the rising edge of SCL except for the ACK period during data (including slave address) transmission in master transmit mode (when the SDA0 line is driven low while the internal SDA output is high (the SDA0 pin is in the high-impedance state))
- When a start condition is detected while the ICCR2.ST bit is 1 (requests to generate a start condition) or the internal SDA output state does not match the SDA0 line level
- When the ICCR2.ST bit is set to 1 (requests to generate a start condition) with the ICCR2.BBSY flag set to 1.

When NACK arbitration-lost detection is enabled: ICFER.NALE = 1

- When the internal SDA output state does not match the SDA0 line level at the rising edge of SCL in the ACK period during NACK transmission in receive mode

When slave arbitration-lost detection is enabled: ICFER.SALE = 1

- When the internal SDA output state does not match the SDA0 line level at the rising edge of SCL except for the ACK period during data transmission in slave transmit mode

[Clearing conditions]

- When 0 is written to the AL flag after reading AL = 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

Table 34.4 Relationship between Arbitration-Lost Generation Sources and Arbitration-Lost Enable Functions

ICFER			ICSR2		
MALE	NALE	SALE	AL	Error	Arbitration-Lost Generation Source
1	×	×	1	Start condition generation error	When internal SDA output state does not match SDA0 line level when a start condition is detected while the ICCR2.ST bit is 1
					When ICCR2.ST bit is set to 1 with ICCR2.BBSY flag set to 1
			1	Transmit data mismatch	When transmit data (including slave address) does not match the bus state in master transmit mode
×	1	×	1	NACK transmission mismatch	When ACK is detected during transmission of NACK in master receive mode or slave receive mode
×	×	1	1	Transmit data mismatch	When transmit data does not match the bus state in slave transmit mode

×: Don't care

START Flag (Start Condition Detection Flag)

[Setting condition]

- When a start condition (or a restart condition) is detected

[Clearing conditions]

- When 0 is written to the START bit after reading START = 1
- When a stop condition is detected
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

STOP Flag (Stop Condition Detection Flag)

[Setting condition]

- When a stop condition is detected

[Clearing conditions]

- When 0 is written to the STOP bit after reading STOP = 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

NACKF Flag (NACK Detection Flag)

[Setting condition]

- When ACK is not received (NACK is received) from the receiver in transmit mode with the ICFER.NACKE bit set to 1 (transfer suspension enabled)

[Clearing conditions]

- When 0 is written to the NACKF bit after reading NACKF = 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

Note: When the NACKF flag is set to 1, the RIIC suspends data transmission/reception. Writing to the ICDRT register in transmit mode or reading from the ICDRR register in receive mode with the NACKF flag set to 1 does not enable data transmit/receive operation. To restart data transmission/reception, set the NACKF flag to 0.

RDRF Flag (Receive Data Full Flag)

[Setting conditions]

- When receive data has been transferred from the ICDRS register to the ICDRR register
  This flag is set to 1 at the rising edge of the eighth or ninth SCL (selected by the ICMR3.RDRFS bit)
- When the received slave address matches after a start condition (or a restart condition) is detected with the ICCR2.TRS bit set to 0

[Clearing conditions]

- When 0 is written to the RDRF bit after reading RDRF = 1
- When data is read from the ICDRR register
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

TEND Flag (Transmission End Flag)

[Setting condition]

- At the rising edge of the ninth SCL while the TDRE flag is 1

[Clearing conditions]

- When 0 is written to the TEND bit after reading TEND = 1
- When data is written to the ICDRT register
- When a stop condition is detected
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

TDRE Flag (Transmit Data Empty Flag)

[Setting conditions]

- When data has been transferred from the ICDRT register to the ICDRS register and the ICDRT register becomes empty
- When the ICCR2.TRS bit is set to 1
- When the received slave address matches while the TRS bit is 1

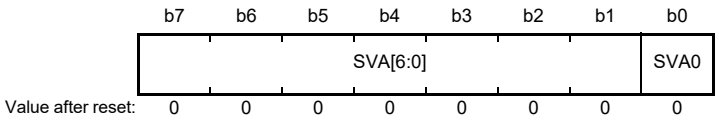
[Clearing conditions]

- When data is written to the ICDRT register
- When the ICCR2.TRS bit is set to 0
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

Note: The NACKF flag becoming 1 while the ICFER.NACKE bit is 1 suspends data transmission and reception by the RIIC. Even if the next data for transmission has already been written to the ICDRT register (the TDRE flag is 0), the data in the ICDRT register is retained but not transferred to the ICDRS register. At this point, the TDRE flag does not become 1.

34.2.11 Slave Address Register Ly (SARLy) (y = 0 to 2)

Address(es): RIIC0.SARL0 0008 830Ah, RIIC0.SARL1 0008 830Ch, RIIC0.SARL2 0008 830Eh



Bit	Symbol	Bit Name	Description	R/W
b0	SVA0	10-Bit Address LSB	Set a slave address	R/W
b7 to b1	SVA[6:0]	7-Bit Address/10-Bit Address Lower Bits	Set a slave address	R/W

SVA0 Bit (10-Bit Address LSB)

When the 10-bit address format is selected (SARUy.FS bit is 1), this bit functions as the LSB of a 10-bit address and forms the lower 8 bits of a 10-bit address in combination with the SVA[6:0] bits.
When the ICSER.SARyE bit is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1, this bit is valid. While the SARUy.FS bit or SARyE bit is 0, the setting of this bit is ignored.

SVA[6:0] Bits (7-Bit Address/10-Bit Address Lower Bits)

When the 7-bit address format is selected (SARUy.FS bit is 0), these bits function as a 7-bit address. When the 10-bit address format is selected (SARUy.FS bit is 1), these bits function as the lower 8 bits of a 10-bit address in combination with the SVA0 bit.
While the ICSER.SARyE bit is 0, the setting of these bits is ignored.

34.2.12 Slave Address Register Uy (SARUy) (y = 0 to 2)

Address(es): RIIC0.SARU0 0008 830Bh, RIIC0.SARU1 0008 830Dh, RIIC0.SARU2 0008 830Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SVA[1:0]		FS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	FS	7-Bit/10-Bit Address Format Select	0: The 7-bit address format is selected. 1: The 10-bit address format is selected.	R/W
b2, b1	SVA[1:0]	10-Bit Address Upper Bits	Set a slave address	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

FS Bit (7-Bit/10-Bit Address Format Select)

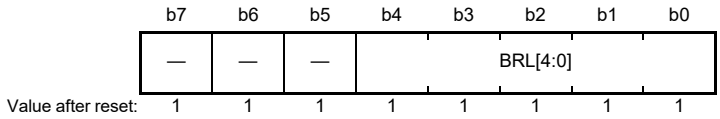
This bit is used to select 7-bit address or 10-bit address for slave address y (in registers SARLy and SARUy).
When the ICSER.SARyE bit is set to 1 (registers SARLy and SARUy enabled) and the SARUy.FS bit is 0, the 7-bit address format is selected for slave address y, the SARLy.SVA[6:0] bits setting is valid, and the settings of the SVA[1:0] bits and the SARLy.SVA0 bit are ignored.
When the ICSER.SARyE bit is set to 1 (registers SARLy and SARUy enabled) and the SARUy.FS bit is 1, the 10-bit address format is selected for slave address y and the settings of the SVA[1:0] bits and SARLy are valid.
While the ICSER.SARyE bit is 0 (registers SARLy and SARUy disabled), the setting of the SARUy.FS bit is invalid.

SVA[1:0] Bits (10-Bit Address Upper Bits)

When the 10-bit address format is selected (FS = 1), these bits function as the upper 2 bits of a 10-bit address.
When the ICSER.SARyE bit is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1, these bits are valid.
While the SARUy.FS bit or SARyE bit is 0, the setting of these bits is ignored.

34.2.13 I2C-bus Bit Rate Low-Level Register (ICBRL)

Address(es): RIIC0.ICBRL 0008 8310h



Bit	Symbol	Bit Name	Description	R/W
b4 to b0	BRL[4:0]	Bit Rate Low Period	Low period of SCL	R/W
b7 to b5	—	Reserved	These bits are read as 1. The write value should be 1.	R/W

ICBRL is a 5-bit register to set the low period of SCL.
It also works to generate the data setup time for automatic SCL low-hold operation (refer to section 34.8, Automatic Low-Hold Function for SCL); when the RIIC is used only in slave mode, this register needs to be set to a value longer than the data setup time*1.
ICBRL counts the low period with the internal reference clock (IICφ) specified by the ICMR1.CKS[2:0] bits.
If the digital noise filter is enabled (the ICFER.NFE bit is 1), set the ICBRL register to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the ICMR3.NF[1:0] bits.

Note 1. Data setup time (tSU: DAT)
250 ns (up to 100 kbps: Standard-mode (Sm))
100 ns (up to 400 kbps: Fast-mode (Fm))

34.2.14 I2C-bus Bit Rate High-Level Register (ICBRH)

Address(es): RIIC0.ICBRH 0008 8311h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	BRH[4:0]				
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	BRH[4:0]	Bit Rate High Period	High period of SCL	R/W
b7 to b5	—	Reserved	These bits are read as 1. The write value should be 1.	R/W

ICBRH is a 5-bit register to set the high period of SCL. ICBRH is valid in master mode. If the RIIC is used only in slave mode, this register need not to set the high period.
ICBRH counts the high period with the internal reference clock (IICφ) specified by the ICMR1.CKS[2:0] bits.
If the digital noise filter is enabled (the ICFER.NFE bit is 1), set the ICBRH register to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the ICMR3.NF[1:0] bits.

The I2C transfer rate and the SCL duty are calculated using the following expression.
Transfer rate = 1 / {[(ICBRH + 1) + (ICBRL + 1)] / IICφ*1 + SCL0 line rise time [tr] + SCL0 line fall time [tf]}
Duty cycle = {SCL0 line rise time [tr]*2 + (ICBRH + 1) / IICφ} / {SCL0 line fall time [tf]*2 + (ICBRL + 1) / IICφ}

Note 1. IICφ = PCLK × Division ratio
Note 2. The SCL0 line rise time [tr] and SCL0 line fall time [tf] depend on the total bus line capacitance [Cb] and the pull-up resistor [Rp]. For details, refer to the I2C-bus specification from NXP Semiconductors.

Table 34.5 lists examples of ICBRH/ICBRL settings.

Table 34.5 Examples of ICBRH/ICBRL Settings for Transfer Rate

Transfer Rate (kbps)	Operating Frequency PCLK (MHz)								
	8			10			12.5

Note: ICBRH/ICBRL settings in these tables are calculated using the following values:
SCL0 line rise time (tr): 100 kbps or less (Sm): 1000 ns, 400 kbps or less (Fm): 300 ns
SCL0 line fall time (tf): 400 kbps or less (Sm/Fm): 300 ns
For the specified values of rise time (tr) and fall time (tf) of the SCL0 signal, refer to the I2C-bus specification from NXP Semiconductors.

34.2.15 I2C-bus Transmit Data Register (ICDRT)

Address(es): RIIC0.ICDRT 0008 8312h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

When the ICDRT register detects a space in the I2C-bus shift register (ICDRS), it transfers the transmit data that has been written to the ICDRT register to the ICDRS register and starts transmitting data in transmit mode.
The double-buffer structure of the ICDRT register and the ICDRS register allows continuous transmit operation if the next transmit data has been written to the ICDRT register while the ICDRS register data is being transmitted.
The ICDRT register can always be read and written. Write transmit data to the ICDRT register once when a transmit data empty interrupt (TXI) request is generated.

34.2.16 I2C-bus Receive Data Register (ICDRR)

Address(es): RIIC0.ICDRR 0008 8313h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

When 1 byte of data has been received, the received data is transferred from the I2C-bus shift register (ICDRS) to the ICDRR register to enable the next data to be received.
The double-buffer structure of the ICDRS register and the ICDRR register allows continuous receive operation if the received data has been read from the ICDRR register while the ICDRS register is receiving data.
The ICDRR register cannot be written. Read data from the ICDRR register once when a receive data full interrupt (RXI) request is generated.
If the ICDRR register receives the next receive data before the current data is read from the ICDRR register (while the ICSR2.RDRF flag is 1), the RIIC automatically holds the SCL line low one cycle before the RDRF flag is set to 1 next.

34.2.17 I2C-bus Shift Register (ICDRS)

The ICDRS register is an 8-bit shift register to transmit and receive data.
During transmission, transmit data is transferred from the ICDRT register to the ICDRS register and is sent from the SDA0 pin. During reception, data is transferred from the ICDRS register to the ICDRR register after 1 byte of data has been received.
The ICDRS register cannot be accessed directly.

34.3 Operation

34.3.1 Communication Data Format

The I2C-bus format consists of 8-bit data and 1-bit acknowledgment. The first byte following a start condition or restart condition is an address byte used to specify a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a stop condition is generated.
Figure 34.2 shows the I2C-bus format, and Figure 34.3 shows the I2C-bus timing.

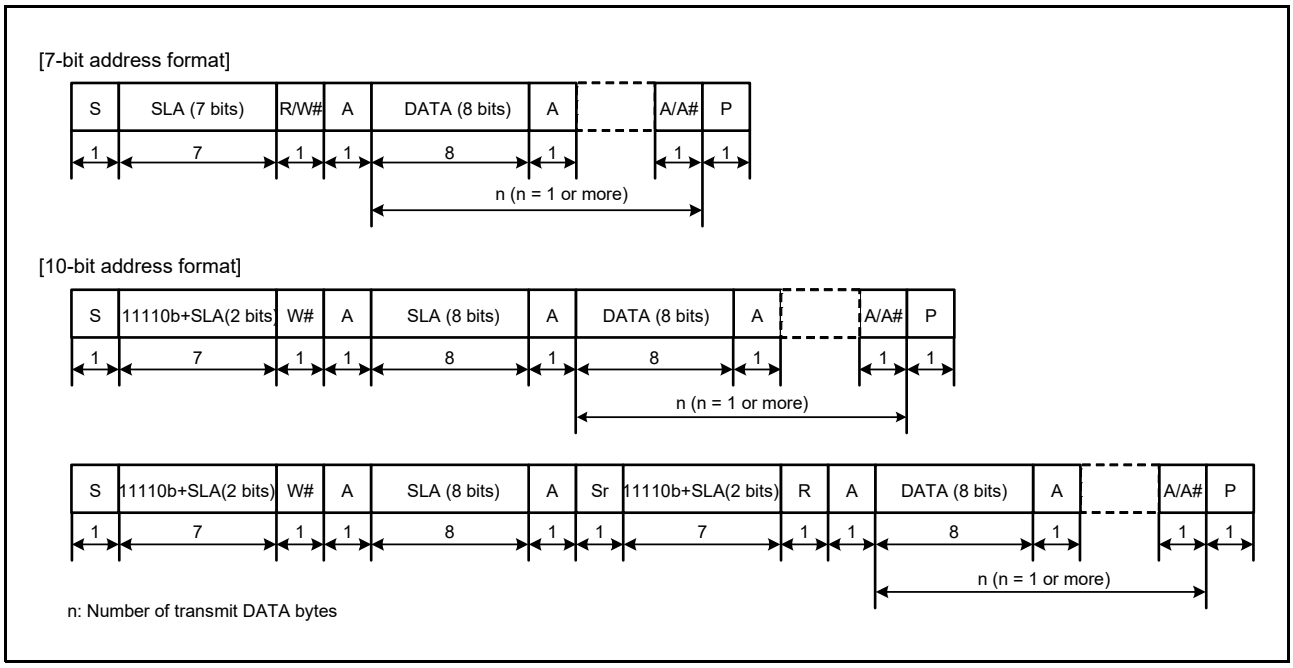

Figure 34.2 I2C-bus Format

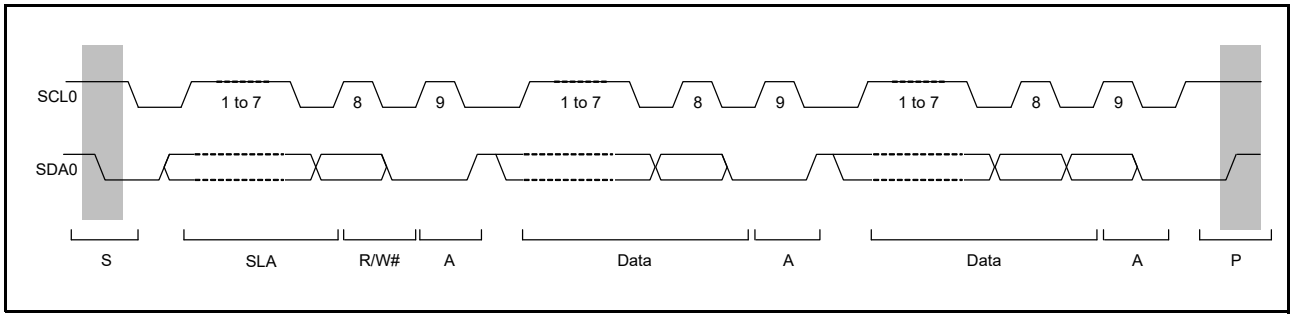

Figure 34.3 I2C-bus Timing (SLA = 7 Bits)

S: Start condition. The master device drives the SDA0 line low from high while the SCL0 line is high.

SLA: Slave address, by which the master device selects a slave device.

R/W#: Indicates the direction of data transfer: from the slave device to the master device when R/W is 1, or from the master device to the slave device when R/W is 0.

A: Acknowledge. The receiver drives the SDA0 line low. (In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.)

A#: Not Acknowledge. The receiver drives the SDA0 line high.

Sr: Restart condition. The master device drives the SDA0 line low from high after the setup time has elapsed with the SCL0 line high.

DATA: Transmitted or received data

P: Stop condition. The master device drives the SDA0 line high from low while the SCL0 line is high.

34.3.2 Initial Settings

Before starting data transmission and reception, initialize the RIIC according to the procedure in Figure 34.4.
Set the ICCR1.ICE bit to 1 (internal reset) after setting the ICCR1.IICRST bit to 1 (RIIC reset) with the ICCR1.ICE bit set to 0 (SCL0 and SDA0 pins in inactive state). This initializes the various flags and internal state of the ICSR1 register. After that, set registers SARLy, SARUy, ICSER, ICMR1, ICBRH, and ICBRL (y = 0 to 2), and set the other registers as necessary (for initial settings of the RIIC, see Figure 34.4). When the necessary register settings have been completed, set the ICCR1.IICRST bit to 0 (releases the RIIC reset). This step is not necessary if initialization of the RIIC has already been completed.

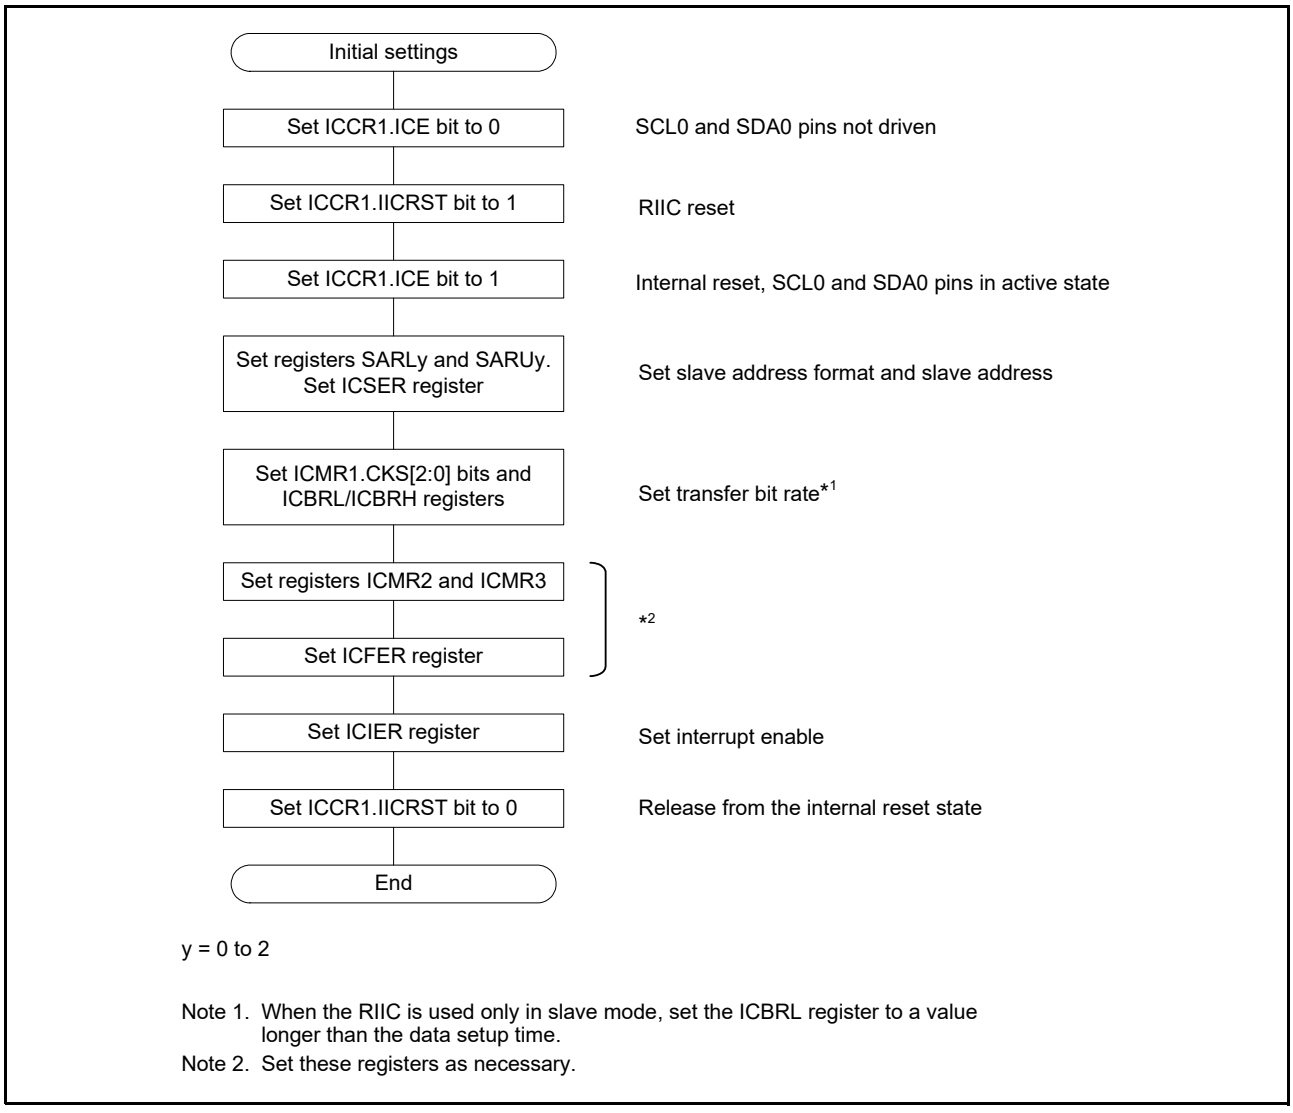

Figure 34.4 Example of RIIC Initialization Flowchart

34.3.3 Master Transmit Operation

In master transmit operation, the RIIC generates clock signals and sends data as the master device, and the slave device returns acknowledgments. Figure 34.5 shows an example of usage of master transmission and Figure 34.6 to Figure 34.8 show the timing of operations in master transmission.
The following describes the procedure and operations for master transmission.

(1) Initial settings. For details, refer to section 34.3.2, Initial Settings.
(2) Read the ICCR2.BBSY flag to check that the bus is open, and then set the ICCR2.ST bit to 1 (requests to generate a start condition). Upon receiving the request, the RIIC generates a start condition. At the same time, the BBSY flag and the ICSR2.START flag are automatically set to 1 and the ST bit is automatically set to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDA0 line have matched while the ST bit is 1, the RIIC recognizes that generating of the start condition as requested by the ST bit has been successfully completed, and bits MST and TRS in the ICCR2 register are automatically set to 1, placing the RIIC in master transmit mode. The ICSR2.TDRE flag is also automatically set to 1 in response to setting of the TRS bit to 1.
(3) Check that the ICSR2.TDRE flag is 1, and then write the value for transmission (the slave address and the R/W# bit) to the ICDRT register. Once the data for transmission are written to the ICDRT register, the TDRE flag is automatically set to 0, the data are transferred from the ICDRT register to the ICDRS register, and the TDRE flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the RIIC continues in master transmit mode.
Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to generate a stop condition.
For data transmission with an address in the 10-bit format, start by writing 1111 0b, the 2 higher-order bits of the slave address, and W to the ICDRT register as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to the ICDRT register.
(4) After confirming that the ICSR2.TDRE flag is 1, write the data for transmission to the ICDRT register. The RIIC automatically holds the SCL0 line low until the data for transmission are ready or a stop condition is generated.
(5) After all bytes of data for transmission have been written to the ICDRT register, wait until the ICSR2.NACKF or ICSR2.TEND flag becomes 1, and then set the ICCR2.SP bit to 1 (requests to generate a stop condition). Upon receiving a stop condition generation request, the RIIC generates the stop condition.
(6) Upon detecting the stop condition, the RIIC automatically sets bits MST and TRS in the ICCR2 register to 00b and enters slave receive mode. Furthermore, it automatically sets the TDRE and TEND flags to 0, and sets the ICSR2.STOP flag to 1.
(7) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

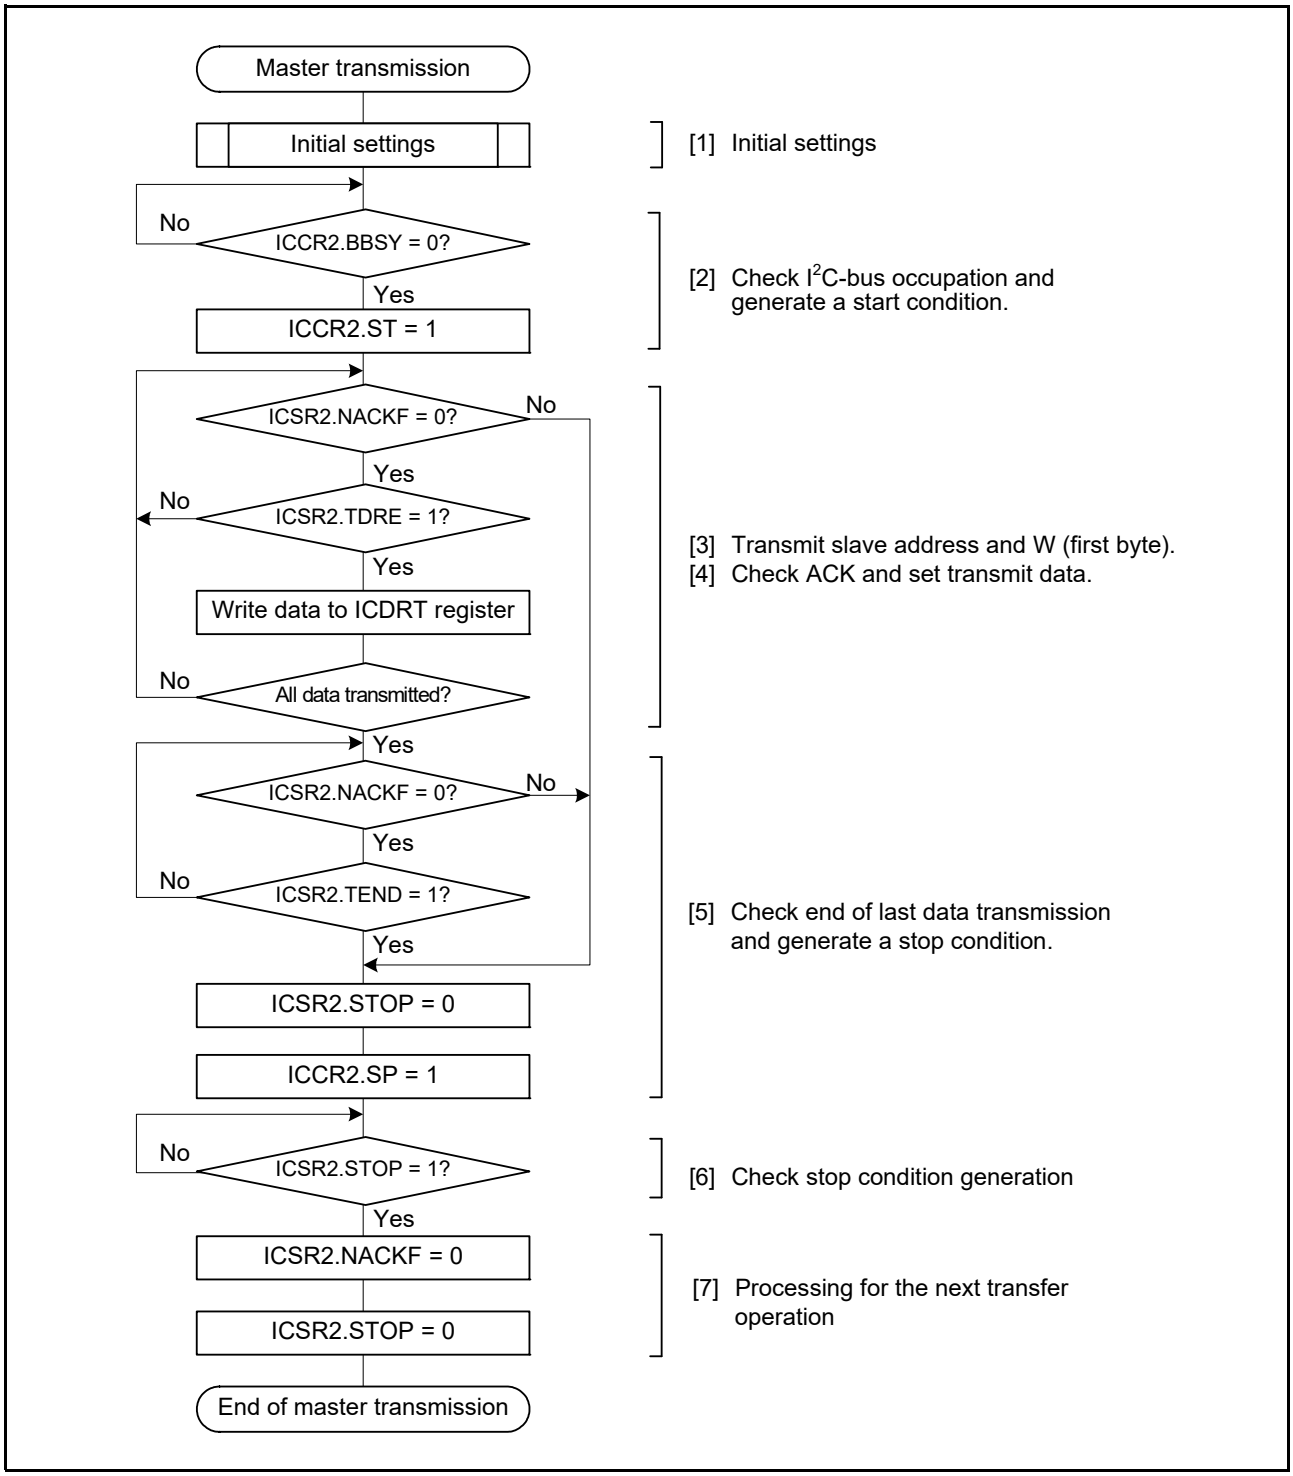

Figure 34.5 Example of Master Transmission Flowchart

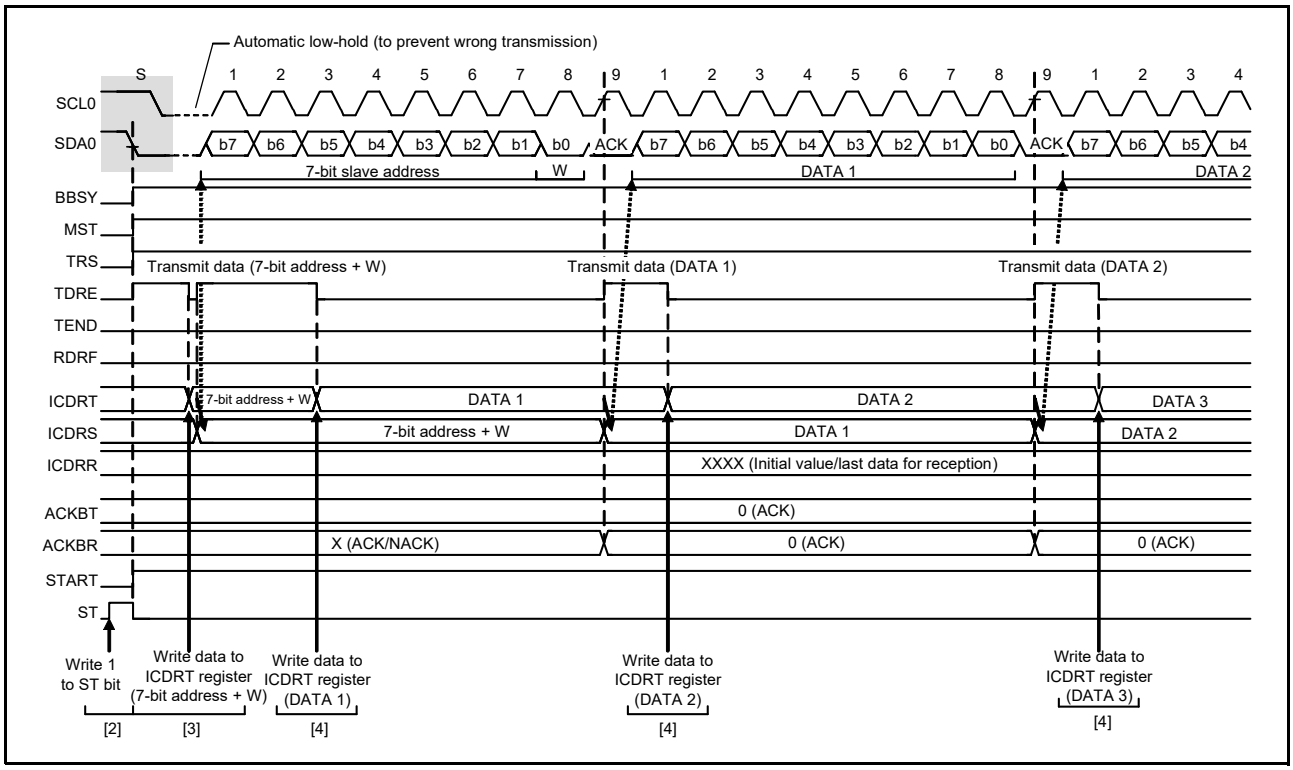

Figure 34.6 Master Transmit Operation Timing (1) (7-Bit Address Format)

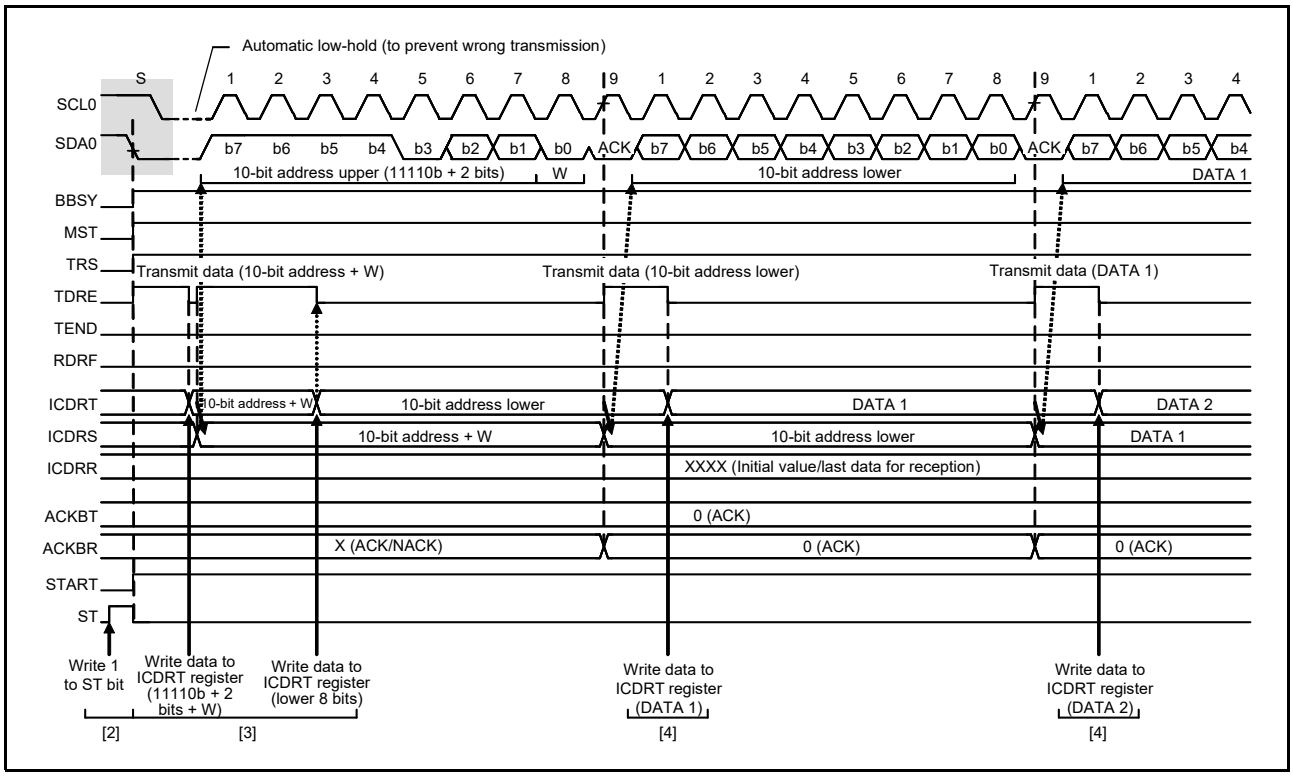

Figure 34.7 Master Transmit Operation Timing (2) (10-Bit Address Format)

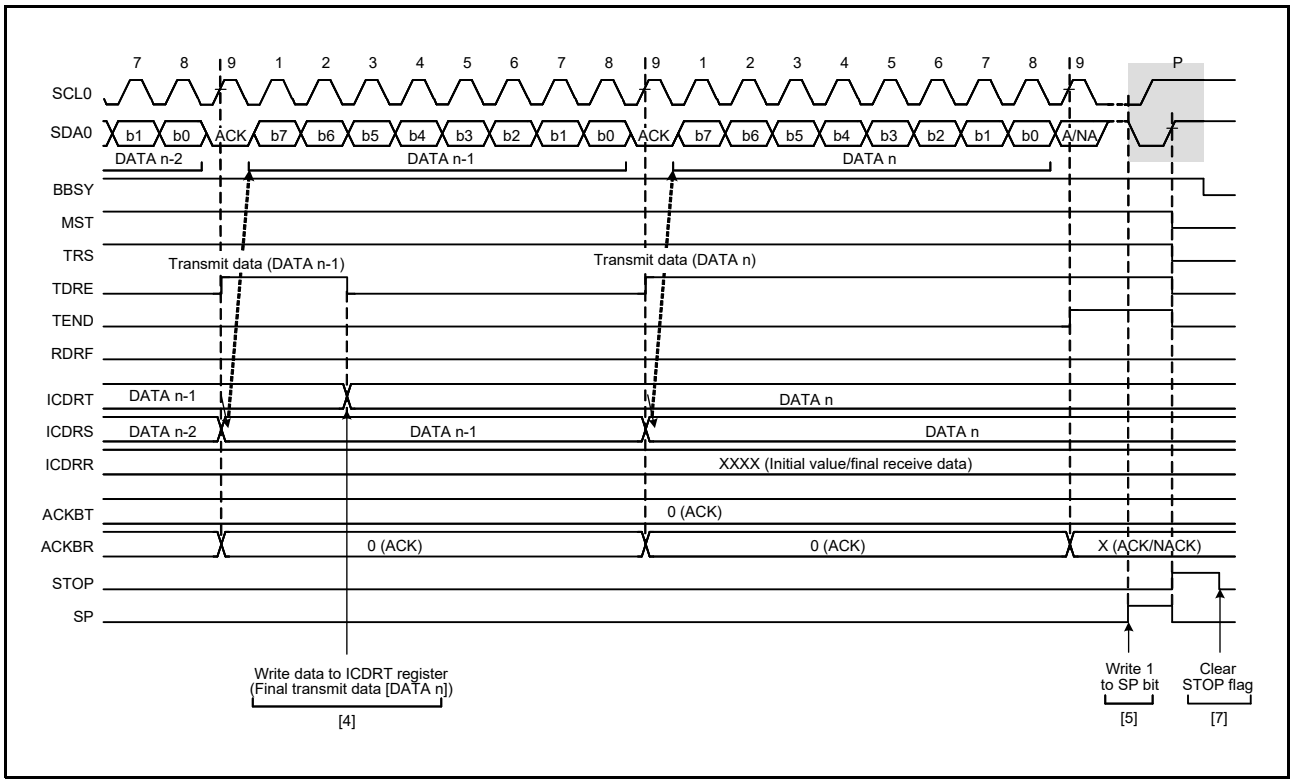

Figure 34.8 Master Transmit Operation Timing (3)

34.3.4 Master Receive Operation

In master receive operation, the RIIC as a master device generates clock signals, receives data from the slave device, and returns acknowledgments. Because the RIIC must start by sending a slave address to the corresponding slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.
Figure 34.9 and Figure 34.10 show examples of usage of master reception (7-bit address format) and Figure 34.11 to Figure 34.13 show the timing of operations in master reception.
The following describes the procedure and operations for master reception.

(1) Initial settings. For details, refer to section 34.3.2, Initial Settings.

(2) Read the ICCR2.BBSY flag to check that the bus is open, and then set the ICCR2.ST bit to 1 (requests to generate a start condition). Upon receiving the request, the RIIC generates a start condition. When the RIIC detects the start condition, the BBSY flag and the ICSR2.START flag are automatically set to 1 and the ST bit is automatically set to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDA0 line have matched while the ST bit is 1, the RIIC recognizes that generating of the start condition as requested by the ST bit has been successfully completed, and bits MST and TRS in the ICCR2 register are automatically set to 1, placing the RIIC in master transmit mode. The ICSR2.TDRE flag is also automatically set to 1 in response to setting of the TRS bit to 1.

(3) Check that the ICSR2.TDRE flag is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to the ICDRT register. Once the data for transmission are written to the ICDRT register, the TDRE flag is automatically set to 0, the data are transferred from the ICDRT register to the ICDRS register, and the TDRE flag is again set to 1. Once the byte containing the slave address and R/W# bit has been transmitted, the value of the ICCR2.TRS bit is automatically updated to select transmit or receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 1, the TRS bit is set to 0 on the rising edge of the ninth SCL, placing the RIIC in master receive mode. At this time, the TDRE flag is set to 0 and the ICSR2.RDRF flag is automatically set to 1.

Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to generate a stop condition.
For master reception from a device with a 10-bit address, start by using master transmission to send the 10-bit address, and then generate a restart condition. After that, transmitting 1111 0b, the two higher-order bits of the slave address, and the R bit places the RIIC in master receive mode.

(4) Dummy read the ICDRR register after confirming that the ICSR2.RDRF flag is 1; this makes the RIIC start output of the SCL and start data reception.

(5) After 1 byte of data has been received, the ICSR2.RDRF flag is set to 1 on the rising edge of the eighth or ninth SCL (the clock signal) as selected by the ICMR3.RDRFS bit. Reading the ICDRR register at this time will produce the received data, and the RDRF flag is automatically set to 0 at the same time. Furthermore, the value of the acknowledgment bit received during the ninth SCL is returned as the value set in the ICMR3.ACKBT bit. Furthermore, if the next byte to be received is the next to last byte, set the ICMR3.WAIT bit to 1 (for wait insertion) before reading the ICDRR register (containing the second byte from last). As well as enabling NACK output even in the case of delays in processing to set the ICMR3.ACKBT bit to 1 (NACK) in step (6), due to other interrupts, etc., this fixes the SCL0 line to low on the falling edge of the ninth clock pulse in reception of the last byte, so the state is such that generating a stop condition is possible.

(6) When the ICMR3.RDRFS bit is 0 and the slave device must be notified that it is to end transfer for data reception after transfer of the next (final) byte, set the ICMR3.ACKBT bit to 1 (NACK).

(7) After reading the byte before last from the ICDRR register, if the value of the ICSR2.RDRF flag is confirmed to be 1, write 1 to the ICCR2.SP bit (requests to generate a stop condition) and then read the last byte from the ICDRR register. When the ICDRR register is read, the RIIC is released from the wait state and generates the stop condition after low-level output in the ninth clock pulse is completed or the SCL0 line is released from the low-hold state.

(8) Upon detecting the stop condition, the RIIC automatically sets bits MST and TRS in the ICCR2 register to 00b and enters slave receive mode. Furthermore, detection of the stop condition leads to setting of the ICSR2.STOP flag to 1.

(9) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

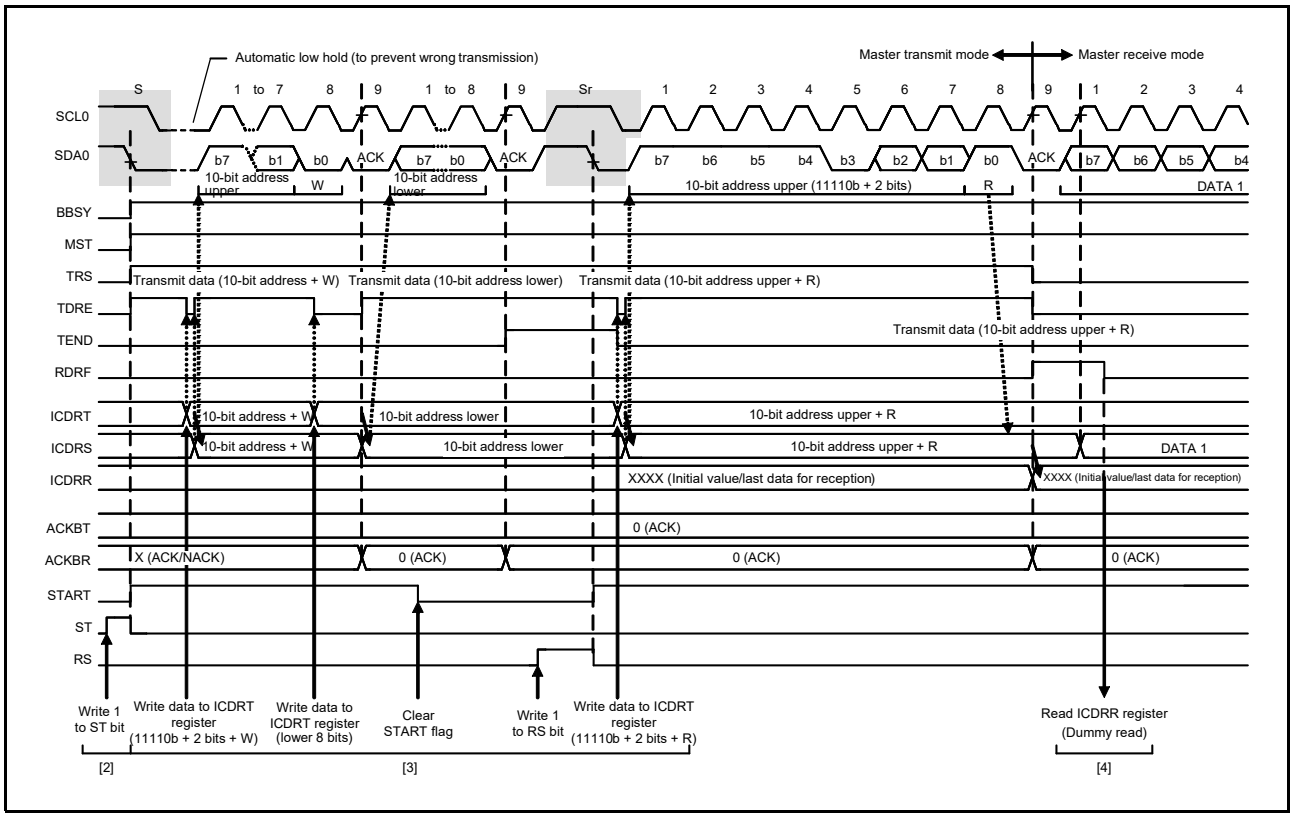

Figure 34.12 Master Receive Operation Timing (2) (10-Bit Address Format, When RDRFS bit is 0)

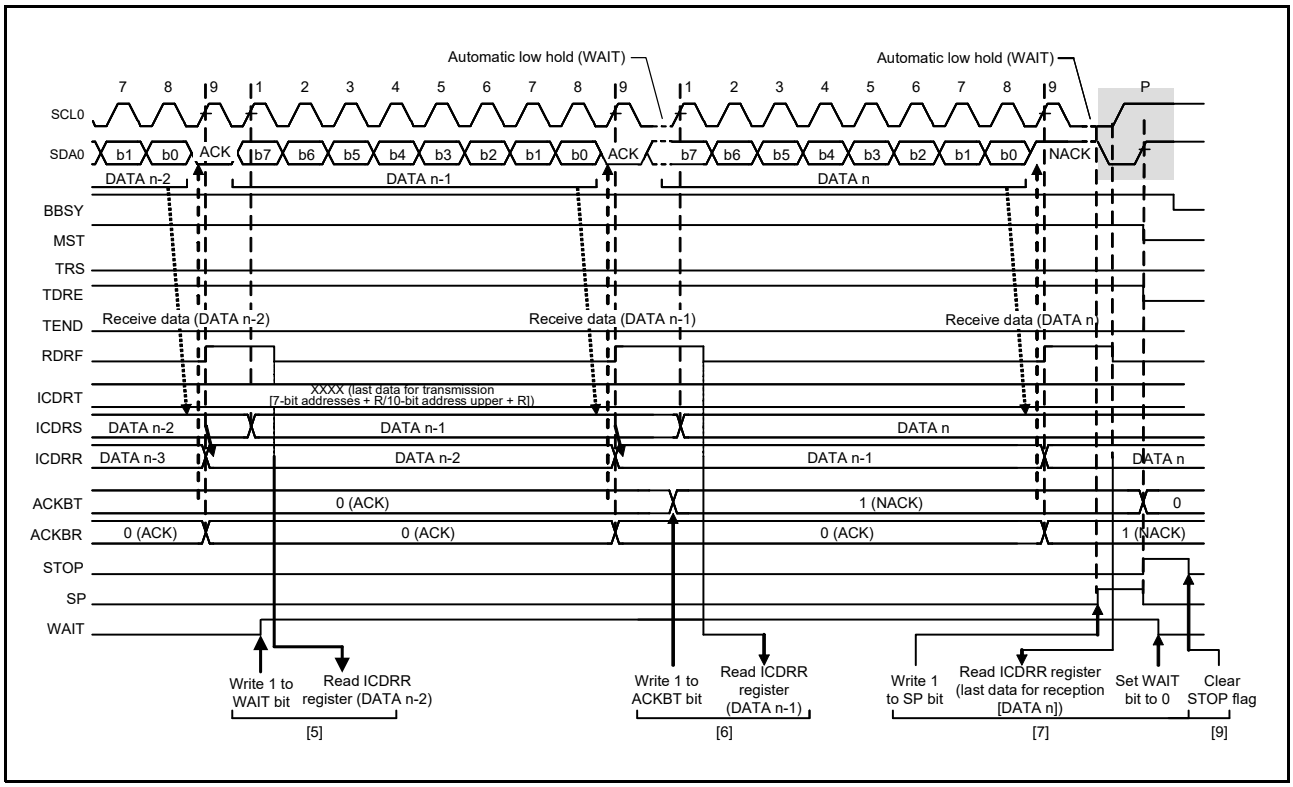

Figure 34.13 Master Receive Operation Timing (3) (When RDRFS bit is 0)

34.3.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL, the RIIC transmits data as a slave device, and the master device returns acknowledgments.

Figure 34.14 shows an example of usage of slave transmission and Figure 34.15 and Figure 34.16 show the timing of operations in slave transmission.

The following describes the procedure and operations for slave transmission.

(1) Initial settings. For details, refer to section 34.3.2, Initial Settings.
After initial settings, the RIIC will stay in the standby state until it receives a slave address that it matches.

(2) After receiving a matching slave address, the RIIC sets one of the corresponding bits ICSR1.HOA, GCA, and AASy (y = 0 to 2) to 1 on the rising edge of the ninth SCL (the clock signal) and outputs the value set in the ICMR3.ACKBT bit to the acknowledgment bit on the ninth SCL. If the value of the R/W# bit that was also received at this time is 1, the RIIC automatically places itself in slave transmit mode by setting both the ICCR2.TRS bit and the ICSR2.TDRE flag to 1.

(3) After the ICSR2.TDRE flag is confirmed to be 1, write the data for transmission to the ICDRT register. At this time, if the RIIC does not receive ACK from the master device (receives an NACK signal) while the ICFER.NACKE bit is 1, the RIIC suspends transfer of the next data.

(4) Wait until the ICSR2.TEND flag is set to 1 while the ICSR2.TDRE flag is 1, after the ICSR2.NACKF flag is set to 1 or the last byte for transmission is written to the ICDRT register. When the ICSR2.NACKF flag or the TEND flag is 1, the RIIC drives the SCL0 line low on the falling edge of ninth SCL.

(5) When the ICSR2.NACKF flag or the ICSR2.TEND flag is 1, dummy read the ICDRR register to complete the processing. This releases the SCL0 line.

(6) Upon detecting the stop condition, the RIIC automatically sets bits ICSR1.HOA, GCA, and AASy (y = 0 to 2), flags ICSR2.TDRE and TEND, and the ICCR2.TRS bit to 0, and enters slave receive mode.

(7) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

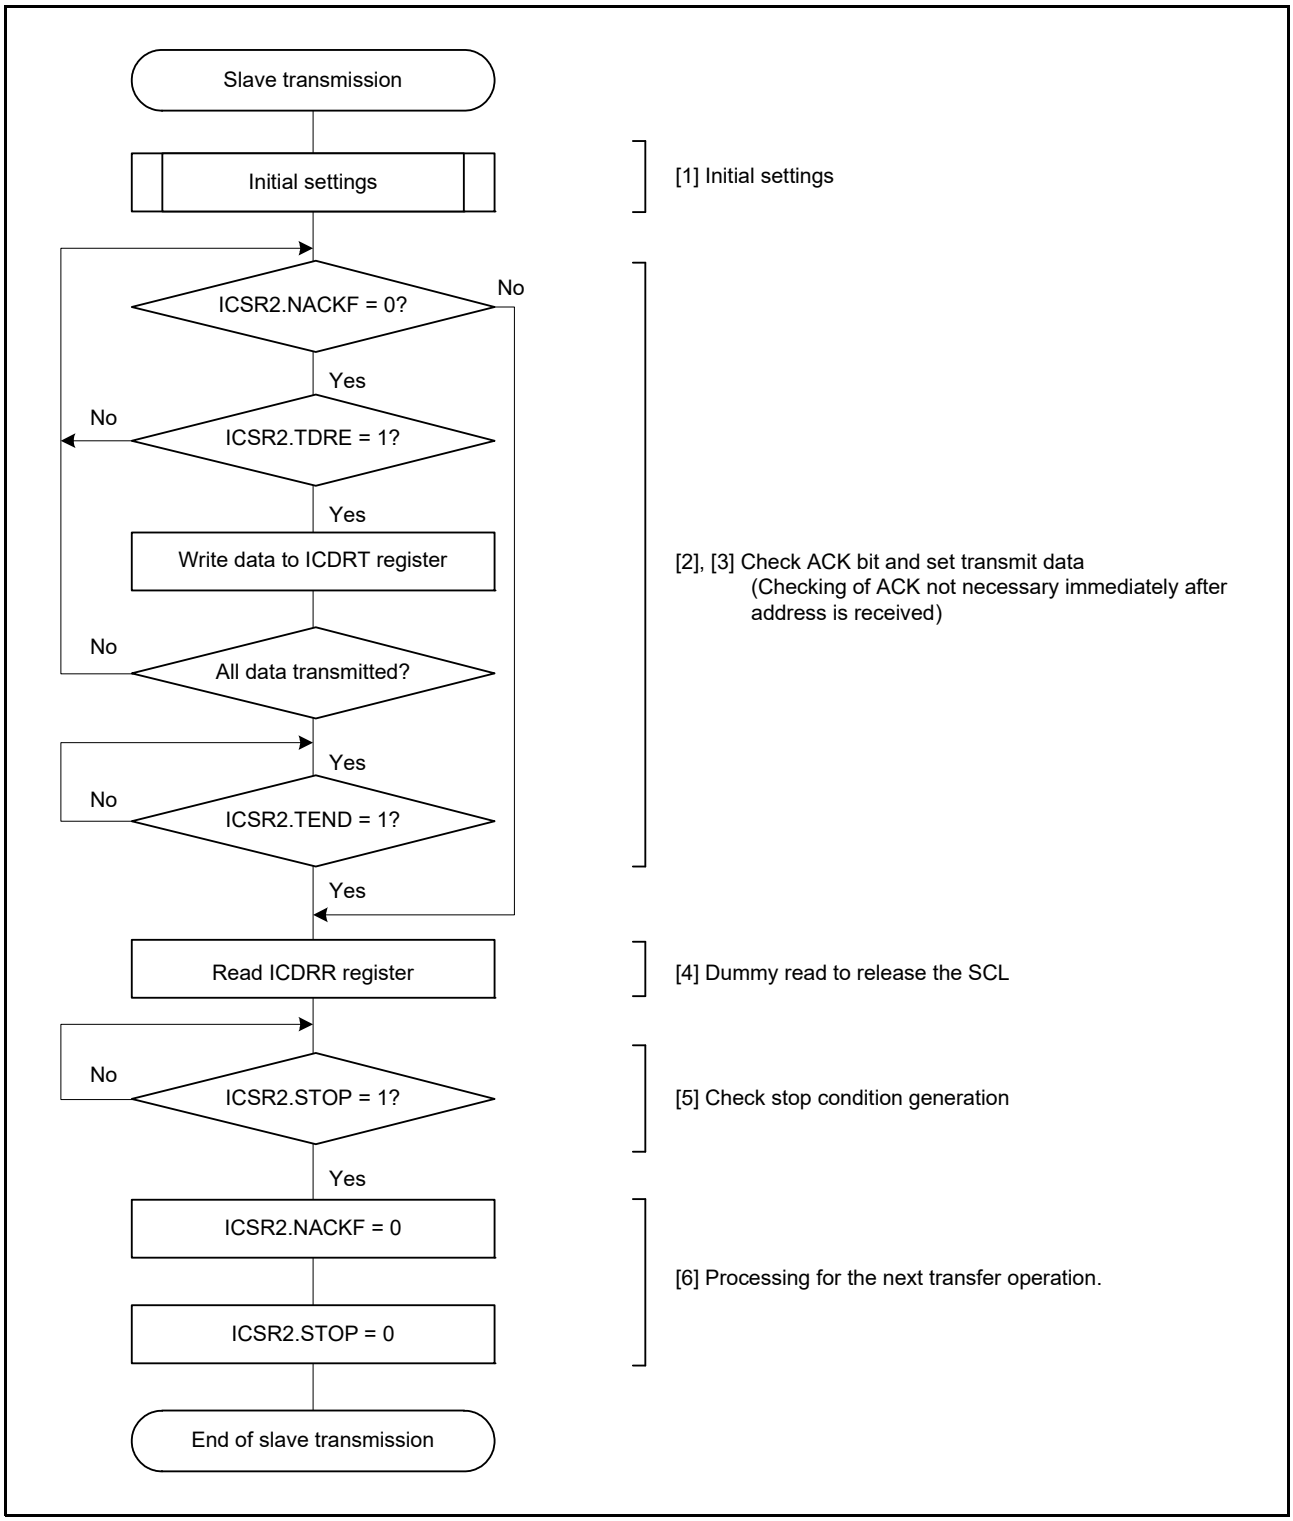

Figure 34.14 Example of Slave Transmission Flowchart

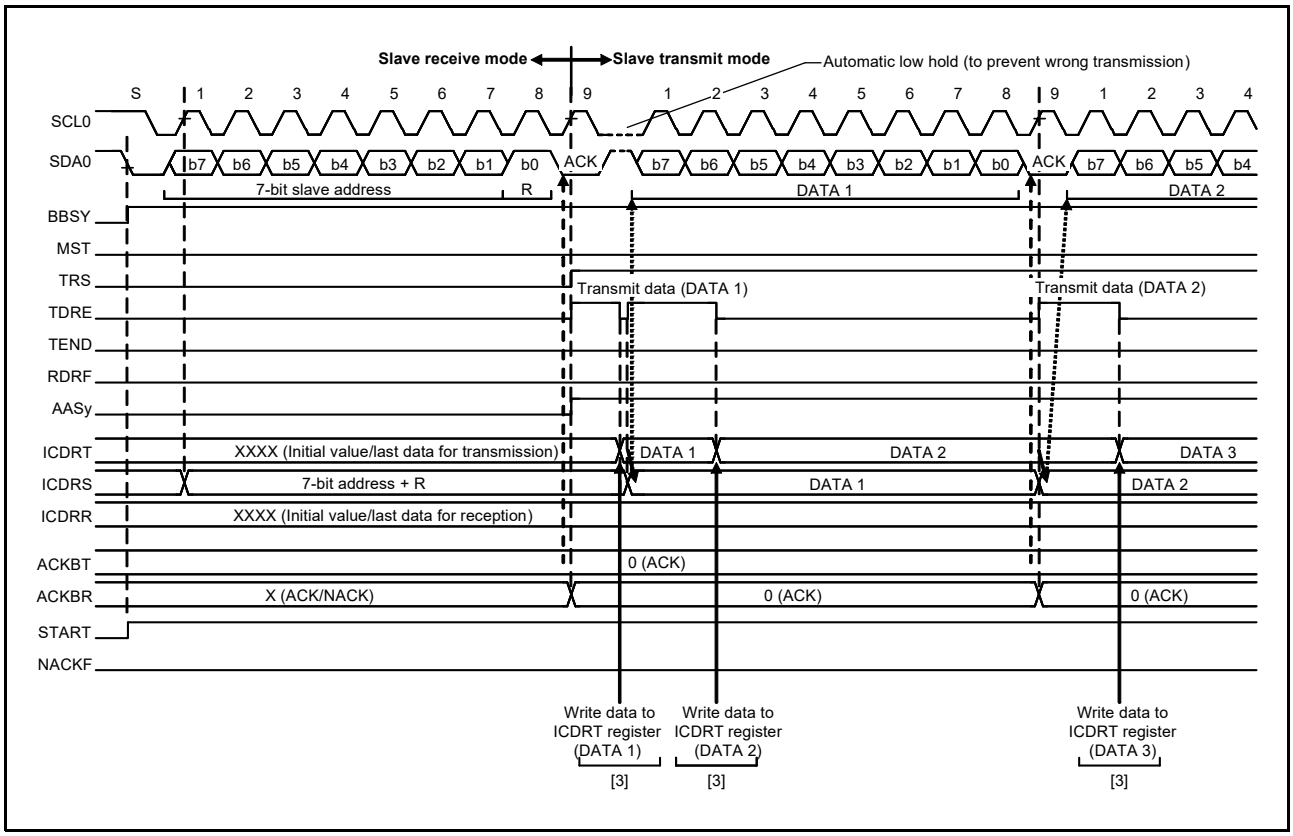

Figure 34.15 Slave Transmit Operation Timing (1) (7-Bit Address Format)

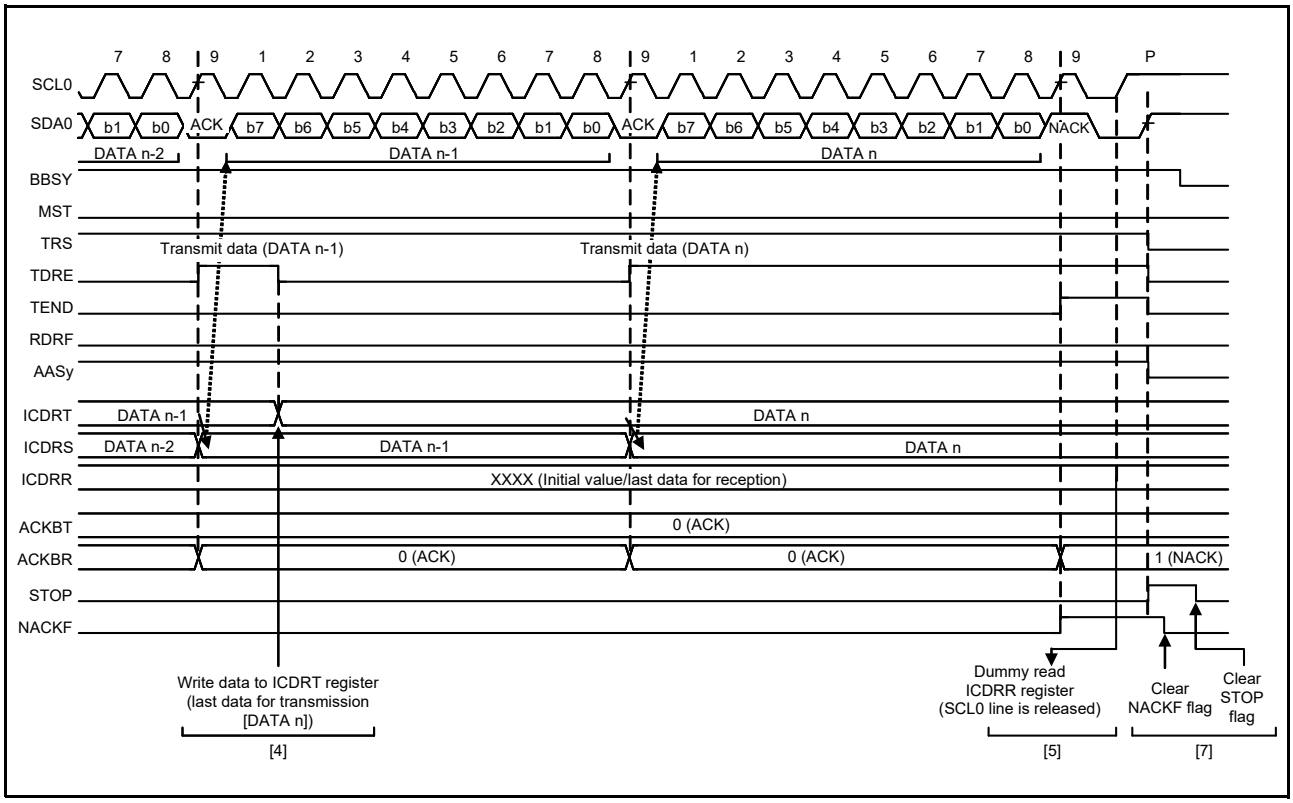

Figure 34.16 Slave Transmit Operation Timing (2)

34.3.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL and transmit data, and the RIIC returns acknowledgments as a slave device.

Figure 34.17 shows an example of usage of slave reception and Figure 34.18 and Figure 34.19 show the timing of operations in slave reception.

The following describes the procedure and operations for slave reception.

(1) Initial settings. For details, refer to section 34.3.2, Initial Settings.
After initial settings, the RIIC will stay in the standby state until it receives a slave address that it matches.

(2) After receiving a matching slave address, the RIIC sets one of the corresponding bits ICSR1.HOA, GCA, and AASy (y = 0 to 2) to 1 on the rising edge of the ninth SCL (the clock signal) and outputs the value set in the ICMR3.ACKBT bit to the acknowledgment bit on the ninth SCL. If the value of the R/W# bit that was also received at this time is 0, the RIIC continues to place itself in slave receive mode and sets the ICSR2.RDRF flag to 1.

(3) After the ICSR2.STOP flag is confirmed to be 0 and the ICSR2.RDRF flag to be 1, dummy read the ICDRR register (the dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected).

(4) When the ICDRR register is read, the RIIC automatically sets the ICSR2.RDRF flag to 0. If reading of the ICDRR register is delayed and a next byte is received while the RDRF flag is still set to 1, the RIIC holds the SCL0 line low from one SCL cycle before the timing with which RDRF should be set. In this case, reading the ICDRR register releases the SCL0 line from being held low.
When the ICSR2.STOP flag is 1 and the ICSR2.RDRF flag is also 1 or when all the data is completely received, read the ICDRR register.

(5) Upon detecting the stop condition, the RIIC automatically clears bits ICSR1.HOA, GCA, and AASy (y = 0 to 2) to 0.

(6) After checking that the ICSR2.STOP flag is 1, set the ICSR2.STOP flag to 0 for the next transfer operation.

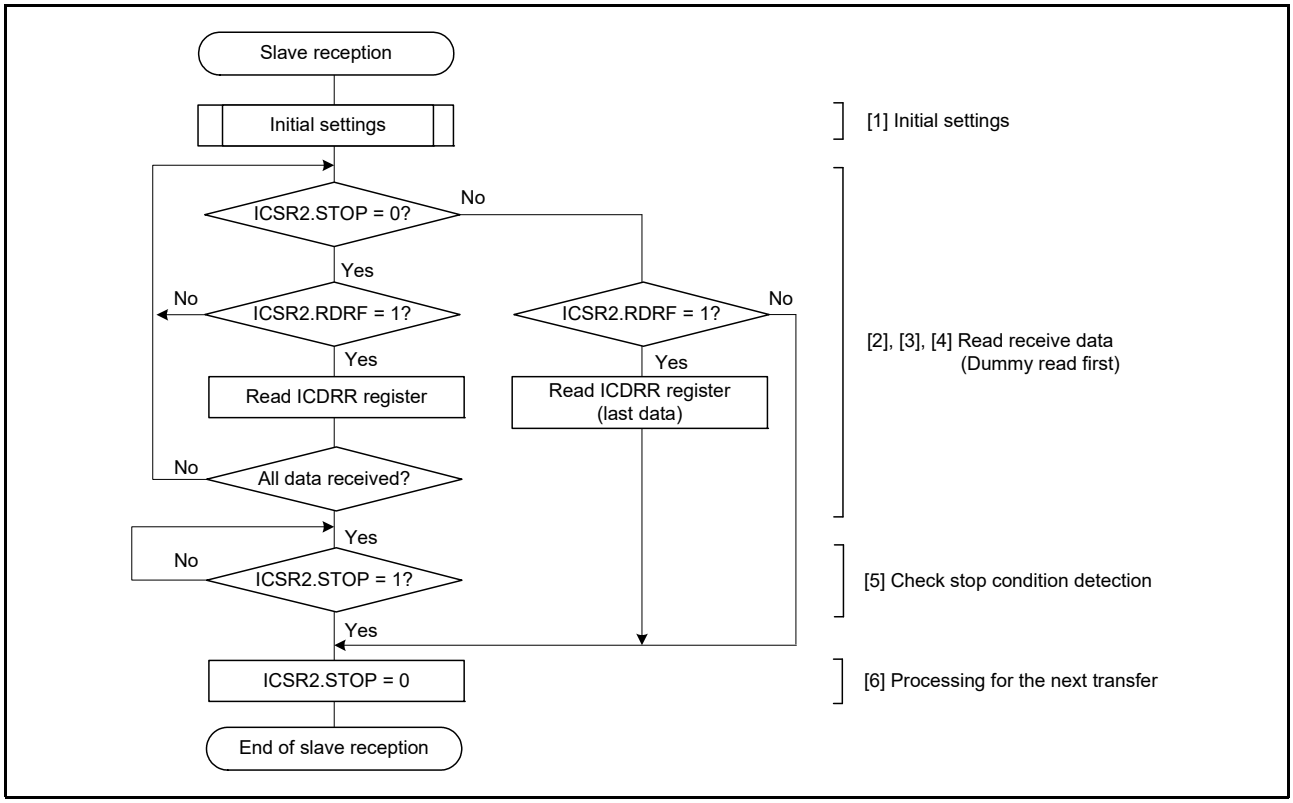

Figure 34.17 Example of Slave Reception Flowchart

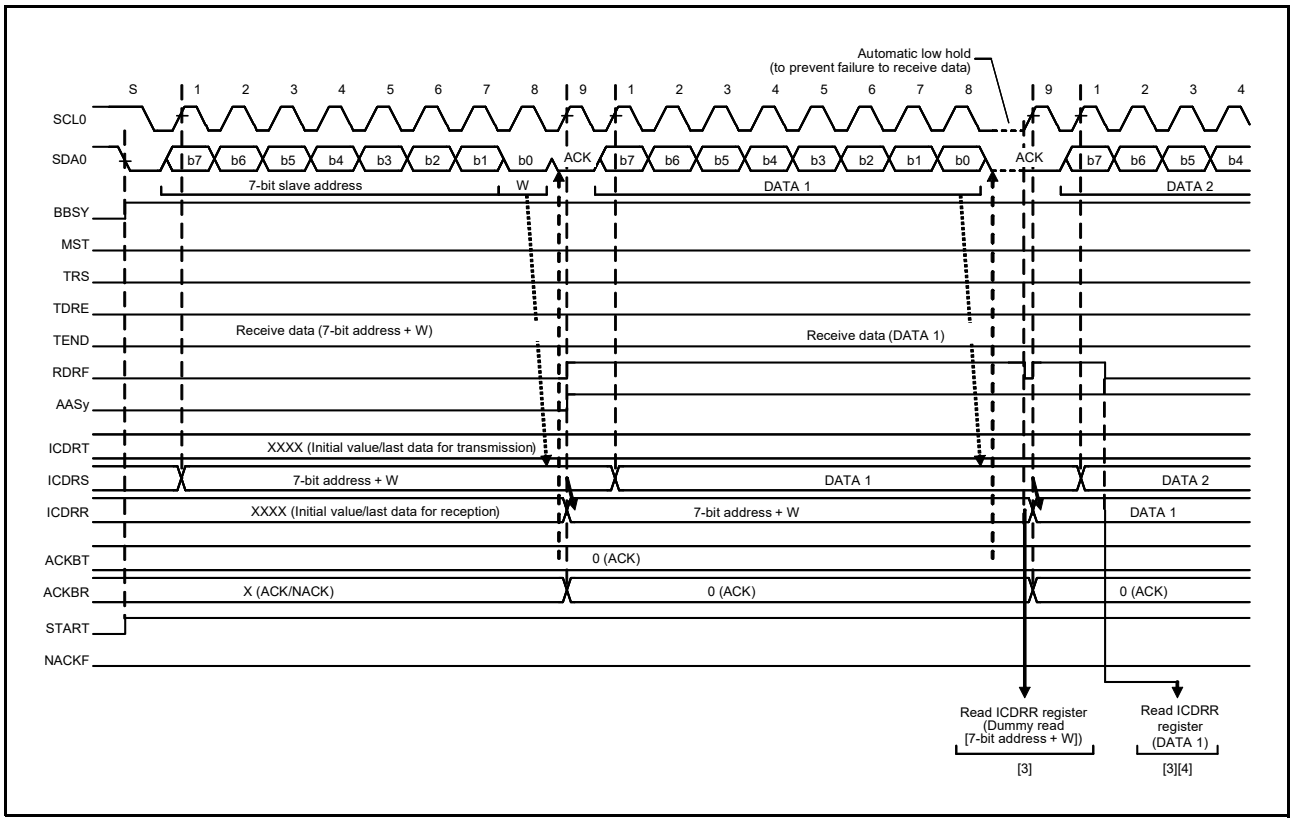

Figure 34.18 Slave Receive Operation Timing (1) (7-Bit Address Format, when RDRFS bit is 0)

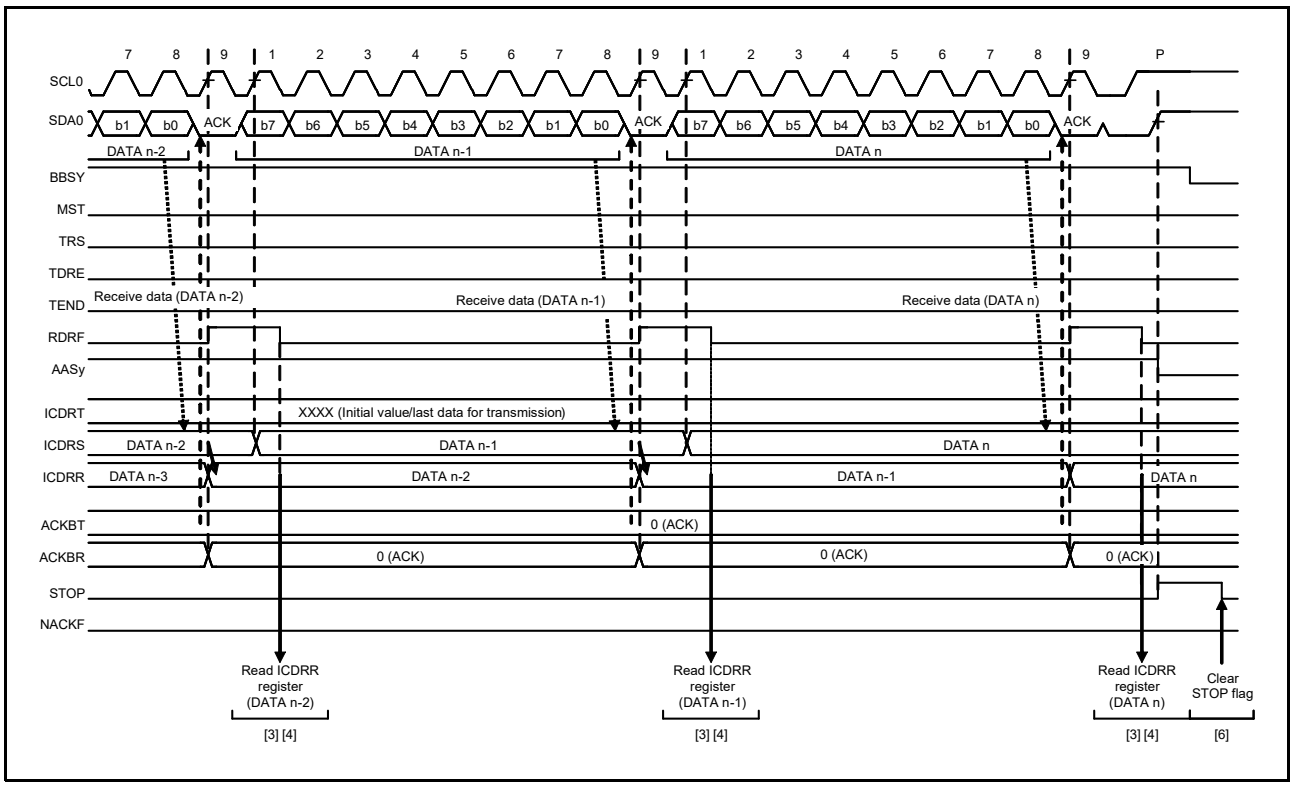

Figure 34.19 Slave Receive Operation Timing (2) (when RDRFS bit is 0)

34.4 SCL Synchronization Circuit

In generation of the SCL, the RIIC starts counting out the value for width at high level specified in the ICBRH register when it detects a rising edge on the SCL0 line and drives the SCL0 line low once counting of the width at high level is complete. When the RIIC detects the falling edge of the SCL0 line, it starts counting out the width at low period specified in the ICBRL register, and then stops driving the SCL0 line (releases the line) once counting of the width at low level is complete. The SCL is thus generated.

If multiple master devices are connected to the I2C-bus, a collision of SCL signals may arise due to contention with another master device. In such cases, the master devices have to synchronize their SCL signals. Since synchronization of the SCL signals must be handled bit by bit, the RIIC is equipped with a facility (the SCL synchronization circuit) for obtaining bit-by-bit synchronization of the SCL signals by monitoring the SCL0 line while in master mode.

When the RIIC has detected a rising edge on the SCL0 line and thus started counting out the width at high level specified in the ICBRH register, and the level on the SCL0 line falls because an SCL signal is being generated by another master device, the RIIC stops counting when it detects the falling edge, drives the level on the SCL0 line low, and starts counting out the width at low level specified in the ICBRL register. When the RIIC finishes counting out the width at low level, it stops driving the SCL0 line low (i.e. releases the line). At this time, if the width at low level of the SCL signal from the other master device is longer than the width at low level set in the RIIC, the width at low level of the SCL signal will be extended. Once the width at low level for the other master device has ended, the SCL signal rises because the SCL0 line has been released. When the RIIC finishes outputting the low period of the SCL, the SCL0 line is released and the SCL rises. That is, in cases of contention of SCL signals from more than one master, the width at high level of the SCL signal is synchronized with that of the clock having the narrower width, and the width at low level of the SCL signal is synchronized with that of the clock having the broader width. However, such synchronization of the SCL signal is only enabled when the ICFER.SCLE bit is set to 1.

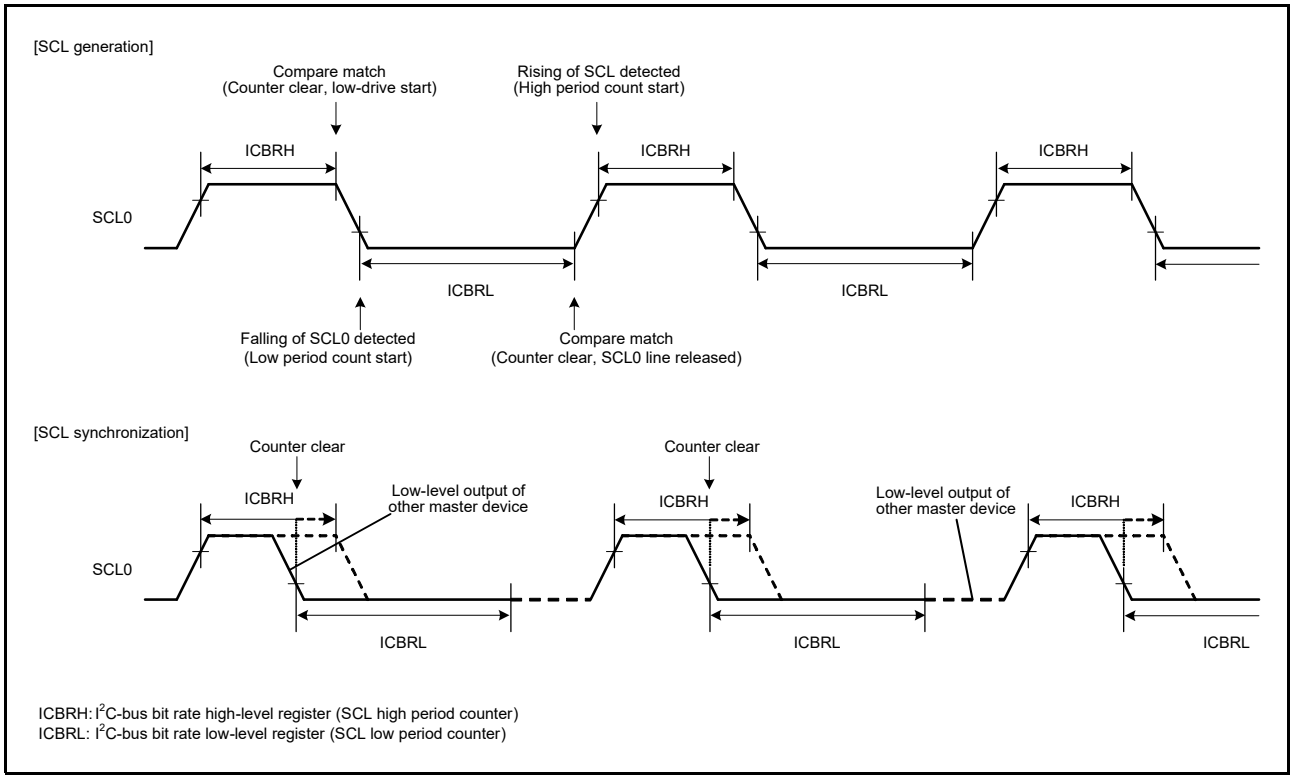

Figure 34.20 Generation and Synchronization of the SCL Signal from the RIIC

34.5 SDA Output Delay Function

The RIIC module incorporates a function for delaying output on the SDA line. The delay can be applied to all output (generation of the start, restart, and stop conditions, data, and the ACK and NACK signals) on the SDA line.

The SDA output delay function is used to delay the SDA output timing relative to falling edges of SCL to ensure that the SDA signal changes while the SCL is low and can be used to prevent erroneous operation of communications devices. This function is also used to satisfy the 300 ns (min.) data hold time prescribed by the SMBus specification.

The output delay function is enabled by setting the ICMR2.SDDL[2:0] bits to any value other than 000b, and disabled by setting the same bits to 000b.

When the SDA output delay function is enabled (the SDDL[2:0] bits are not “000b”), the SDA output delay counter counts the number of cycles set in the SDDL[2:0] bits of the count source selected by the ICMR2.DLCS bit (the internal reference clock (IICφ) or internal reference clock divided by 2 (IICφ/2)). On completion of counting of cycles of delay, the RIIC changes the bit being output as the SDA signal (generation of the start, restart, or stop condition, a new bit, or an ACK or NACK signal).

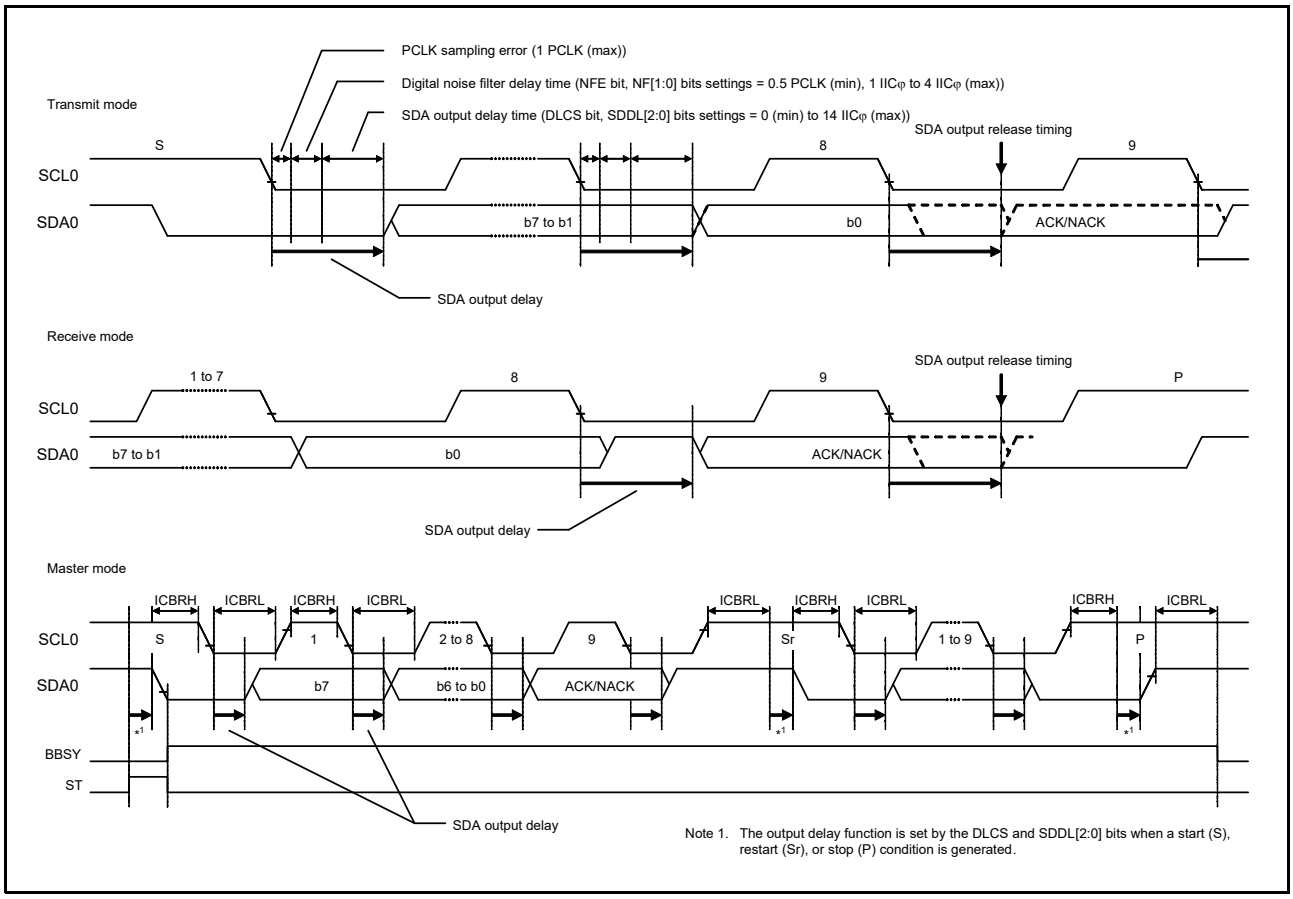

Figure 34.21 SDA Output Delay Function

34.6 Digital Noise Filters

The states of the SCL0 and SDA0 pins are conveyed to the internal circuitry through digital noise filters. Figure 34.22 is a block diagram of the digital noise filter.

The on-chip digital noise filter of each RIIC consists of four flip-flop circuit stages connected in series and a match detection circuit.

The number of effective stages in the digital noise filter is selected by the ICMR3.NF[1:0] bits. The selected number of effective stages determines the noise-filtering capability as a period from one to four cycles of IICφ.

The input signal to the SCL0 pin (or SDA0 pin) is sampled on falling edges of the IICφ signal. When the input signal level matches the output level for the number of effective flip-flop circuit stages selected by the ICMR3.NF[1:0] bits, the signal level is conveyed to the subsequent stages. If the signal levels do not match, the previous value is retained.

If the ratio between the frequency of the internal operating clock (PCLK) and the transfer rate is relatively small (e.g. data transfer at 400 kbps with PCLK = 4 MHz), the characteristics of the digital noise filter may lead to the elimination of needed signals as noise.

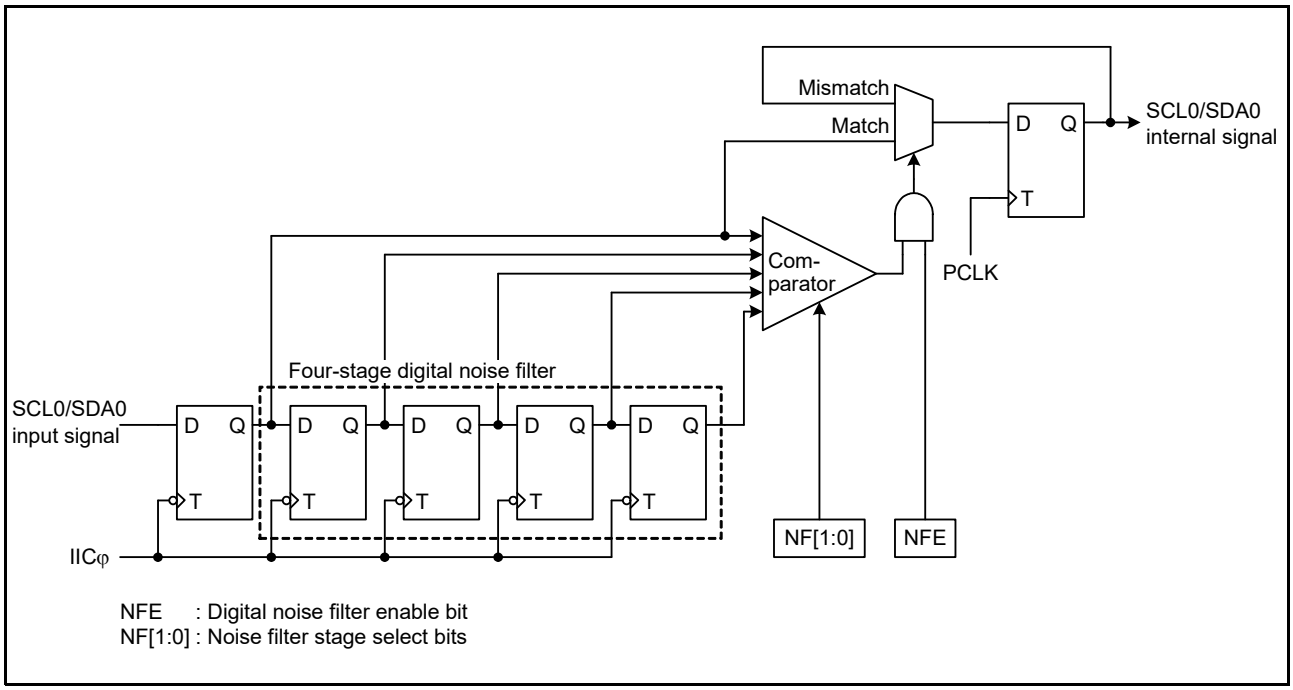

Figure 34.22 Block Diagram of the Digital Noise Filter

34.7 Address Match Detection

The RIIC can set three unique slave addresses in addition to the general call address and host address, and also can set 7-bit or 10-bit slave addresses.

34.7.1 Slave-Address Match Detection

The RIIC can set three unique slave addresses, and has a slave address detection function for each unique slave address. When the ICSER.SARyE bit (y = 0 to 2) is set to 1, the slave addresses set in registers SARUy and SARLy (y = 0 to 2) can be detected.

When the RIIC detects a match with its set slave address, the corresponding ICSR1.AASy flag (y = 0 to 2) is set to 1 on the rising edge of the ninth SCL, and the ICSR2.RDRF flag or the ICSR2.TDRE flag is set to 1 according to the level of the R/W# bit. This causes a receive data full interrupt (RXI) or transmit data empty interrupt (TXI) to be generated. The AASy flag is used to identify which slave address has been specified.

Figure 34.23 to Figure 34.25 show the AASy flag set timing in three cases.

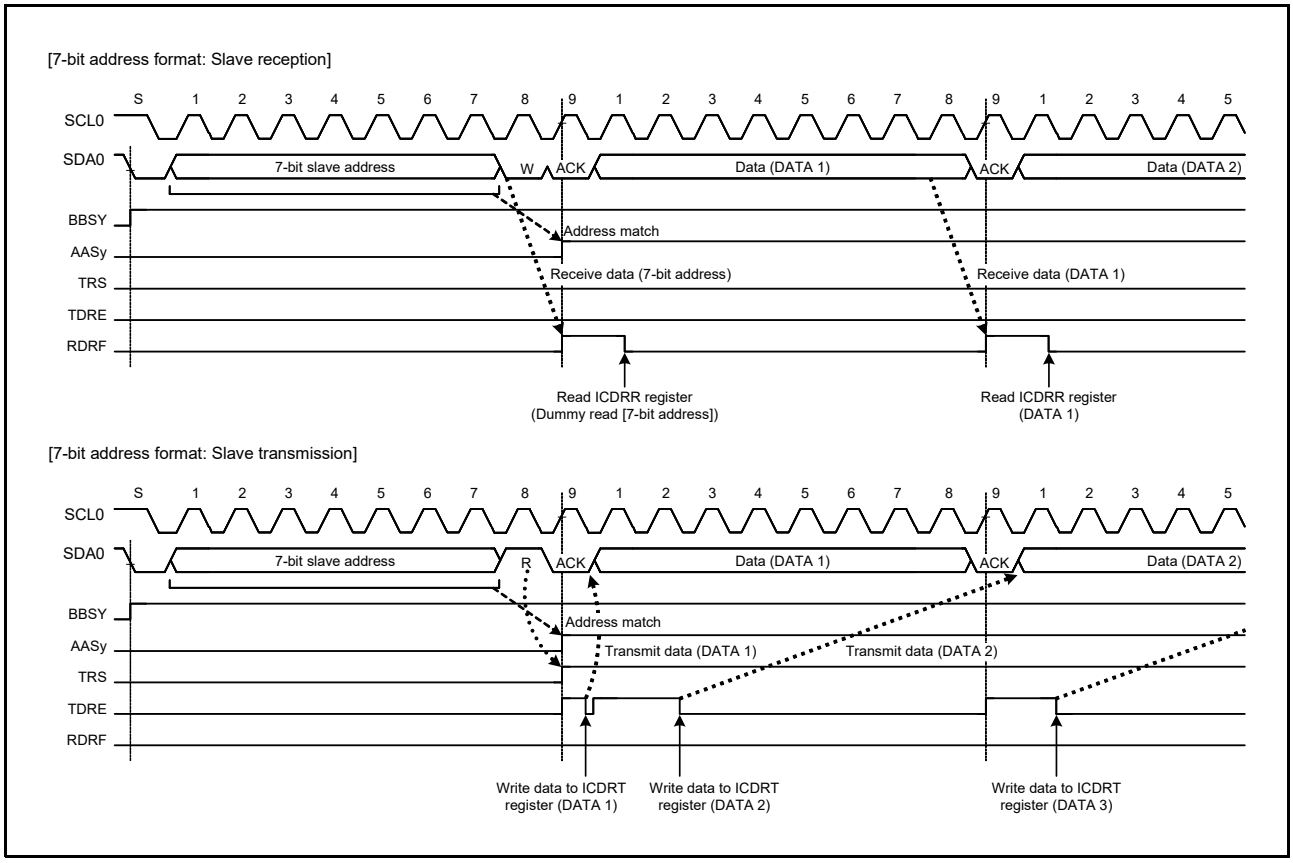

Figure 34.23 AASy Flag Set Timing with 7-Bit Address Format Selected

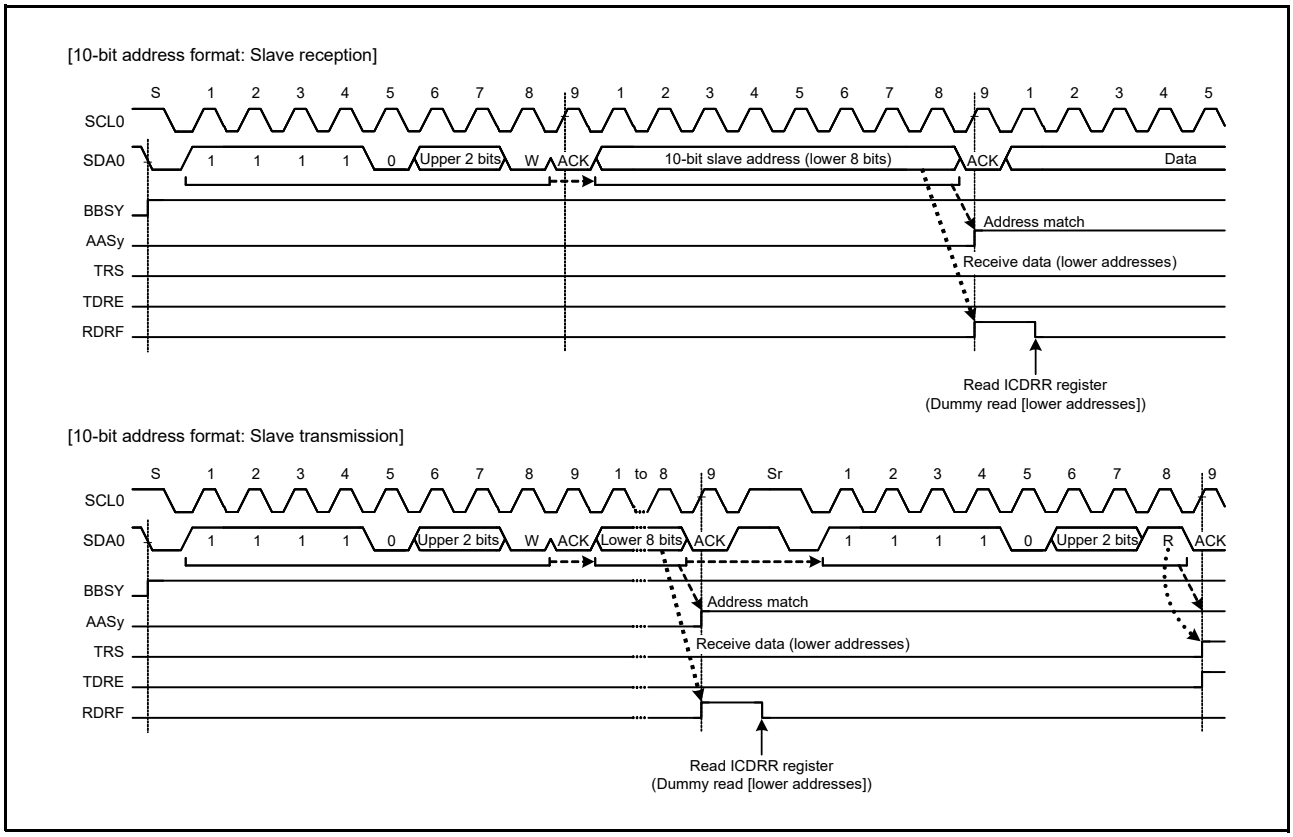

Figure 34.24 AASy Flag Set Timing with 10-Bit Address Format Selected

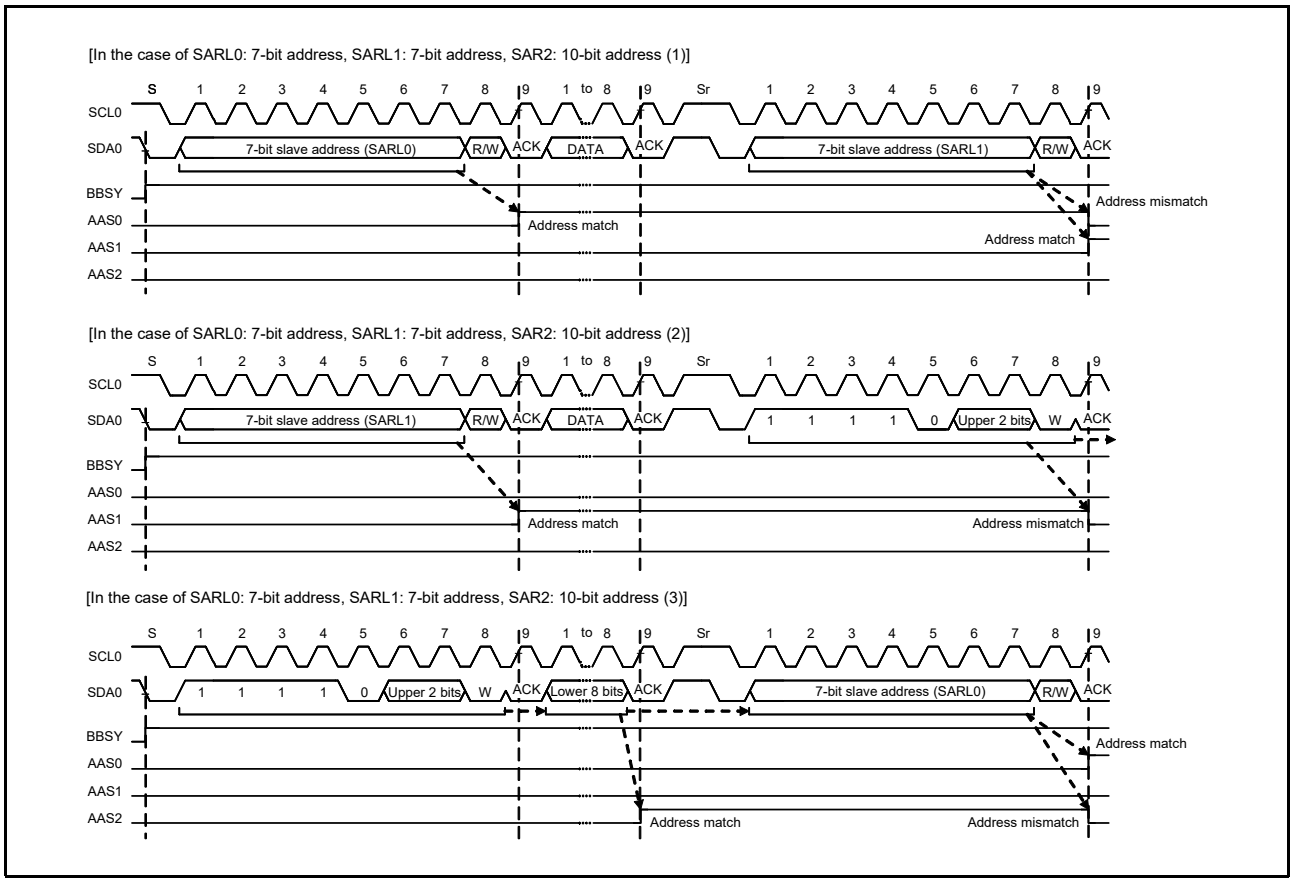

Figure 34.25 AASy Flag Set/Clear Timing with 7-Bit/10-Bit Address Formats Mixed

34.7.2 Detection of the General Call Address

The RIIC also has a facility for detecting the general call address (0000 000b + 0 (write)). This is enabled by setting the ICSER.GCAE bit to 1.

If the address following a start or restart condition is 0000 000b + 1 (read) (start byte), the RIIC recognizes this as the address of a slave device with an “all-zero” address but not as the general call address.

When the RIIC detects the general call address, both the ICSR1.GCA flag and the ICSR2.RDRF flag are set to 1 on the rising edge of the ninth SCL. This leads to the generation of a receive data full interrupt (RXI). The value of the GCA flag can be confirmed to recognize that the general call address has been transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

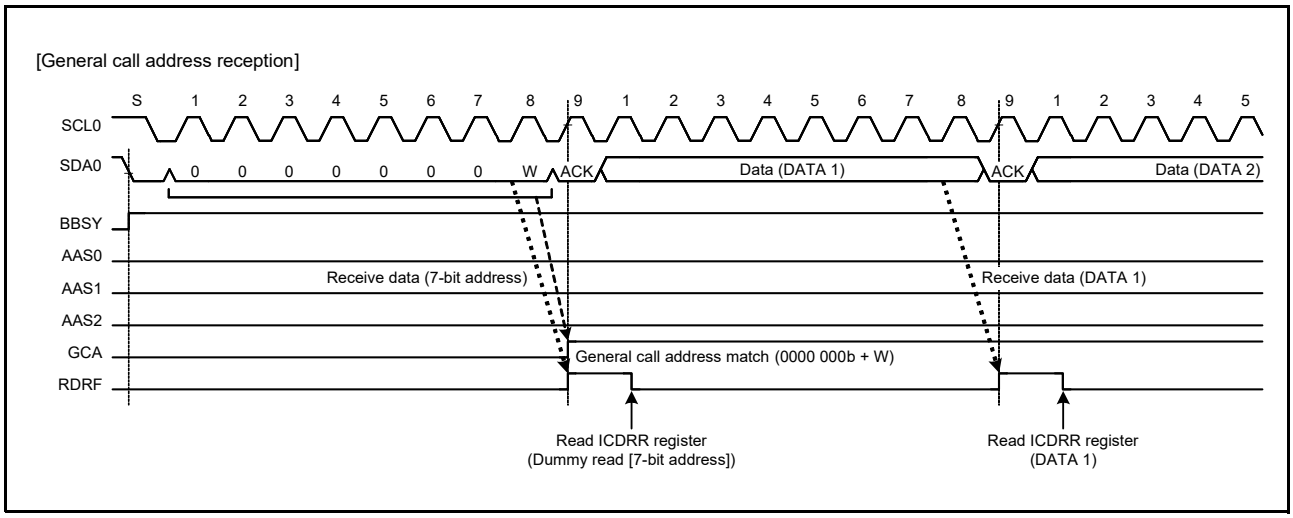

Figure 34.26 Timing of GCA Flag Setting during Reception of General Call Address

34.7.3 Device-ID Address Detection

The RIIC module has a function to detect device-ID addresses complying with the I2C-bus specification. When the RIIC receives 1111 100b as the first seven bits of the first byte following a start condition or a restart condition while the ICSER.DIDE bit is 1, the RIIC recognizes the address as a device-ID address, sets the ICSR1.DID flag to 1 on the rising edge of the ninth SCL when the following R/W# bit is 0, and then compares the second and following bytes with its own slave address. If the received address matches the value in the slave address register, the RIIC sets the corresponding ICSR1.AASy flag (y = 0 to 2) to 1.

After that, when the first byte received after a start or restart condition is generated matches the device ID address (1111 100b) again and the following R/W# bit is 1, the RIIC does not compare the second and subsequent bytes and sets the ICSR2.TDRE flag to 1.

In the device-ID address detection function, the RIIC sets the DID flag to 0 if a match with the RIIC's own slave address is not obtained or a match with the device ID address is not obtained after a match with the RIIC's own slave address and the detection of a restart condition. If the first byte after detection of a start or restart condition matches the device ID address (1111 100b) and the R/W# bit is 0, the RIIC sets the DID flag to 1 and compares the second and subsequent bytes with the RIIC's slave address. If the R/W# bit is 1, the DID flag holds the previous value and the RIIC does not compare the second and subsequent bytes. Therefore, the reception of a device-ID address can be checked by reading the DID flag after confirming that TDRE flag is 1.

Furthermore, prepare the device-ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal data for transmission. For details of the information that must be included in device-ID fields, contact NXP Semiconductors.

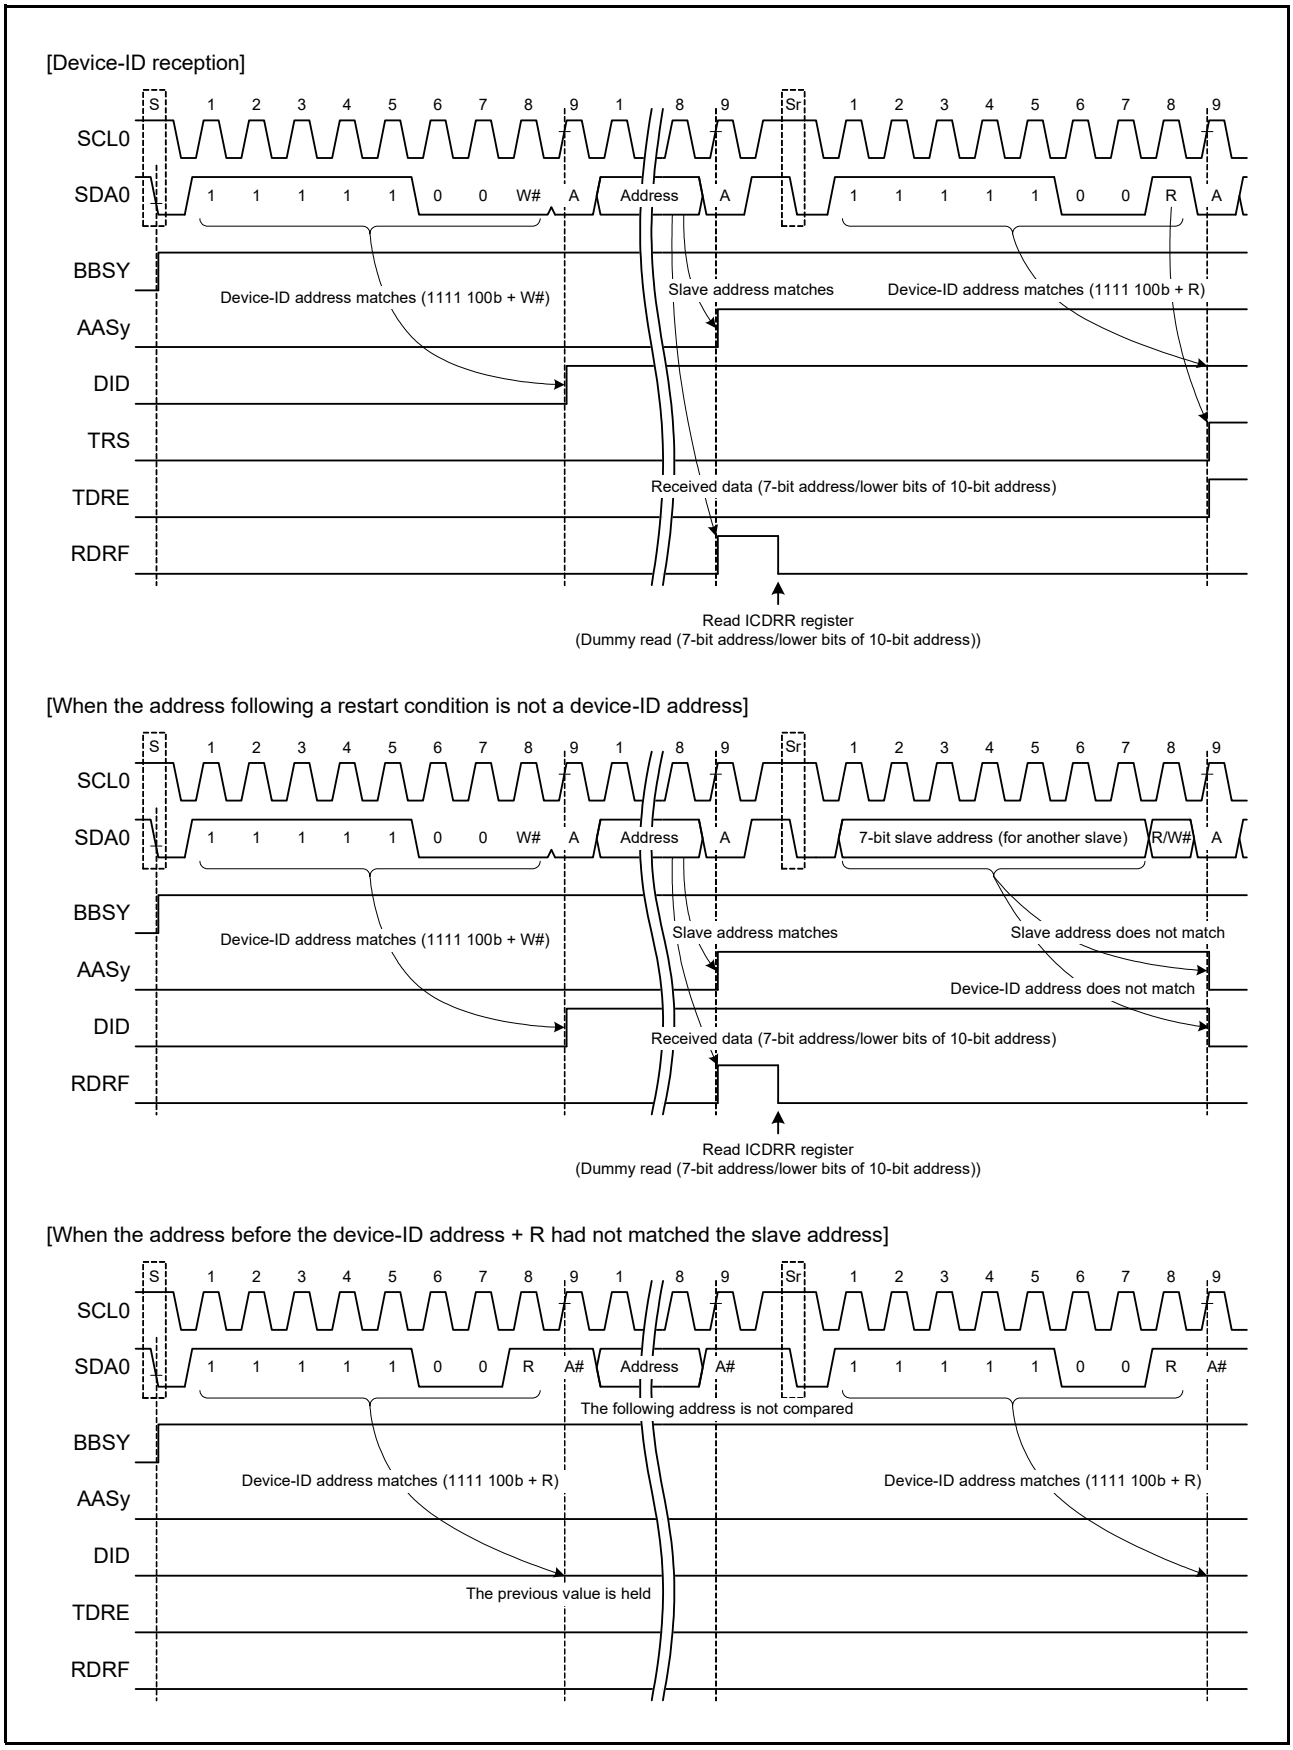

Figure 34.27 Set/Clear Timing of the AASy and DID Flags during Reception of Device-ID Address

34.7.4 Host Address Detection

The RIIC has a function to detect the host address while the SMBus is operating. When the ICSER.HOAE bit is set to 1 while the ICMR3.SMBS bit is 1, the RIIC can detect the host address (0001 000b) in slave receive mode (bits MST and TRS in the ICCR2 register are 00b).

When the RIIC detects the host address, the ICSR1.HOA flag is set to 1 at the rising edge of the ninth SCL, and at the same time, the ICSR2.RDRF flag is set to 1 when the R/W# bit is 0 (Wr bit). This causes a receive data full interrupt (RXI) to be generated. The HOA flag is used to recognize that the host address was sent from the smart battery or other devices.

If the bit following the host address (0001 000b) is an Rd bit (R/W# bit is 1), the RIIC can also detect the host address. After the host address is detected, the RIIC operates in the same manner as normal slave operation.

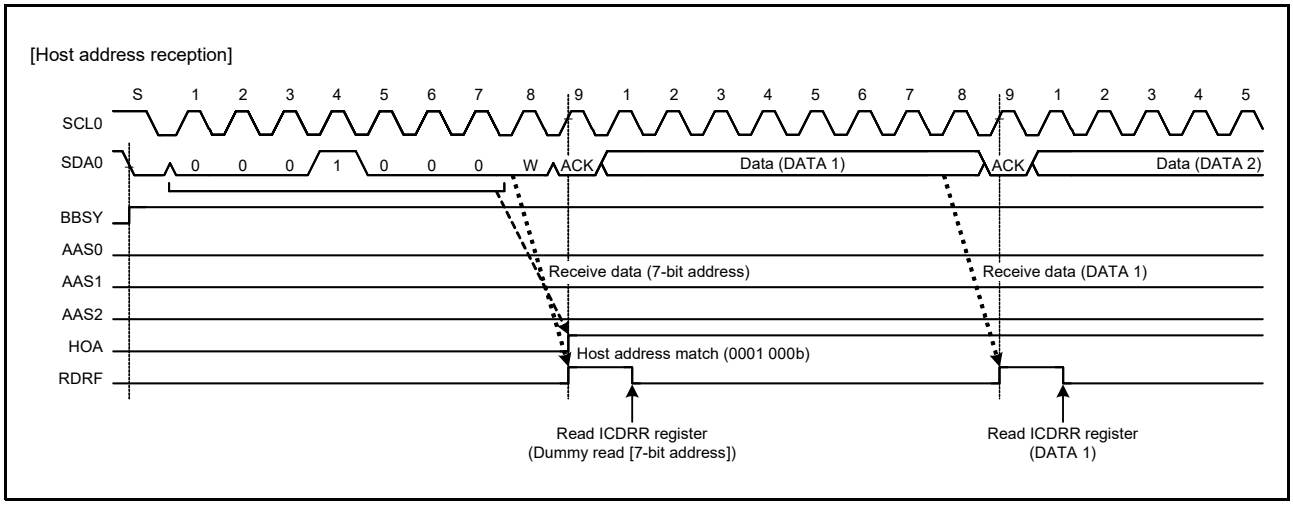

Figure 34.28 HOA Flag Set Timing during Reception of Host Address

34.8 Automatic Low-Hold Function for SCL

34.8.1 Function to Prevent Wrong Transmission of Transmit Data

If the shift register (ICDRS) is empty when data have not been written to the I2C-bus transmit data register (ICDRT) with the RIIC in transmission mode (ICCR2.TRS bit is 1), the SCL0 line is automatically held low over the intervals shown below. This low period is extended until data for transmission have been written, which prevents the unintended transmission of erroneous data.

Master transmit mode

- Low period after a start condition or restart condition is generated
- Low period between the ninth clock pulse of one transfer and the first clock pulse of the next

Slave transmit mode

- Low period between the ninth clock pulse of one transfer and the first clock pulse of the next

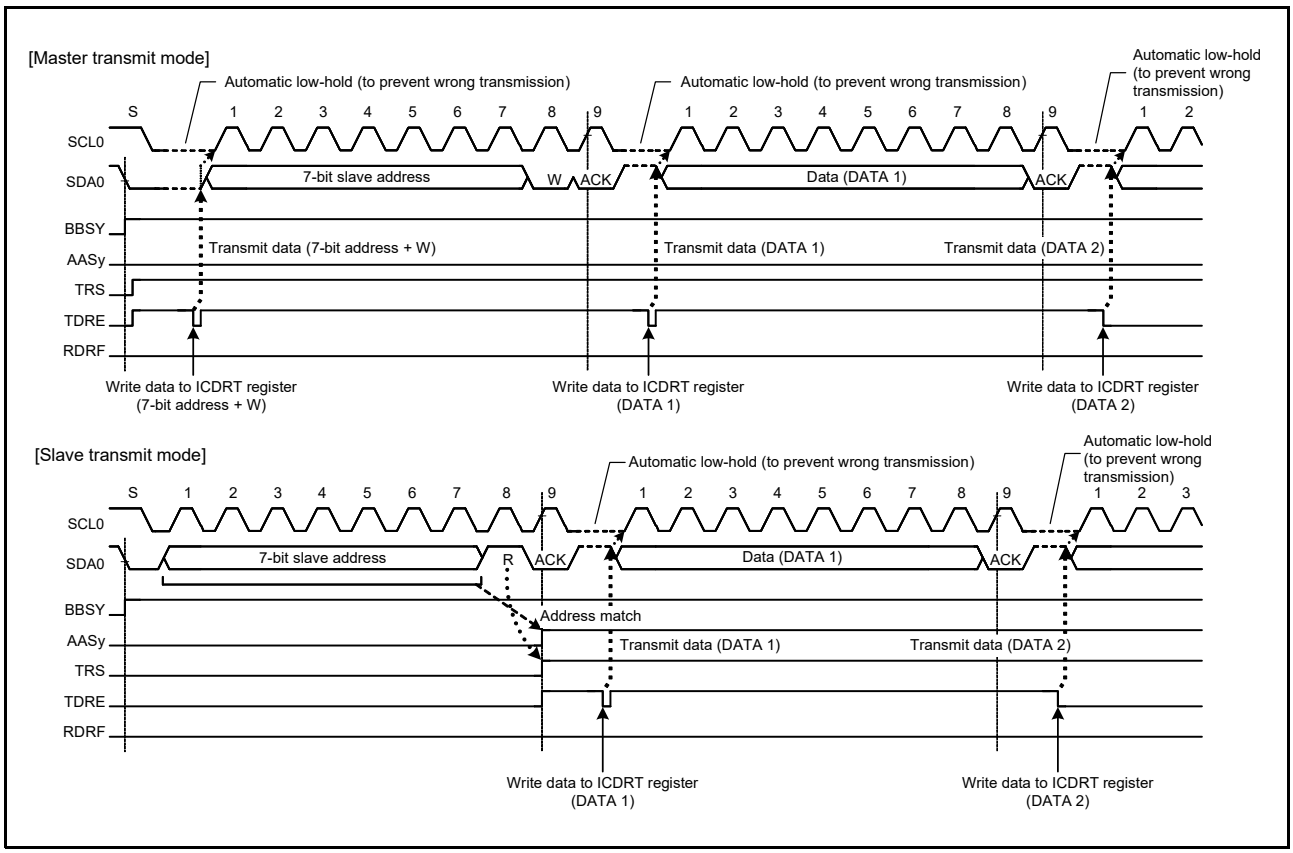

Figure 34.29 Automatic Low-Hold Operation in Transmit Mode

34.8.2 NACK Reception Transfer Suspension Function

The RIIC has a function to suspend transfer operation when NACK is received in transmit mode (ICCR2.TRS bit is 1). This function is enabled when the ICFER.NACKE bit is set to 1 (transfer suspension enabled). If the next transmit data has already been written (ICSR2.TDRE flag is 0) when NACK is received, next data transmission at the falling edge of the ninth SCL is automatically suspended. This prevents the SDA0 line output level from being held low when the MSB of the next transmit data is 0.

If the data transmission is suspended (ICSR2.NACKF flag is 1) by this function, the following data transmission and data reception are not started. To resume data transfer, set the NACKF flag to 0. In master transmit mode, restart data transfer by setting the NACKF flag to 0 after generating a restart condition, or restart data transfer from a start condition after generating a stop condition then setting the NACKF flag to 0.

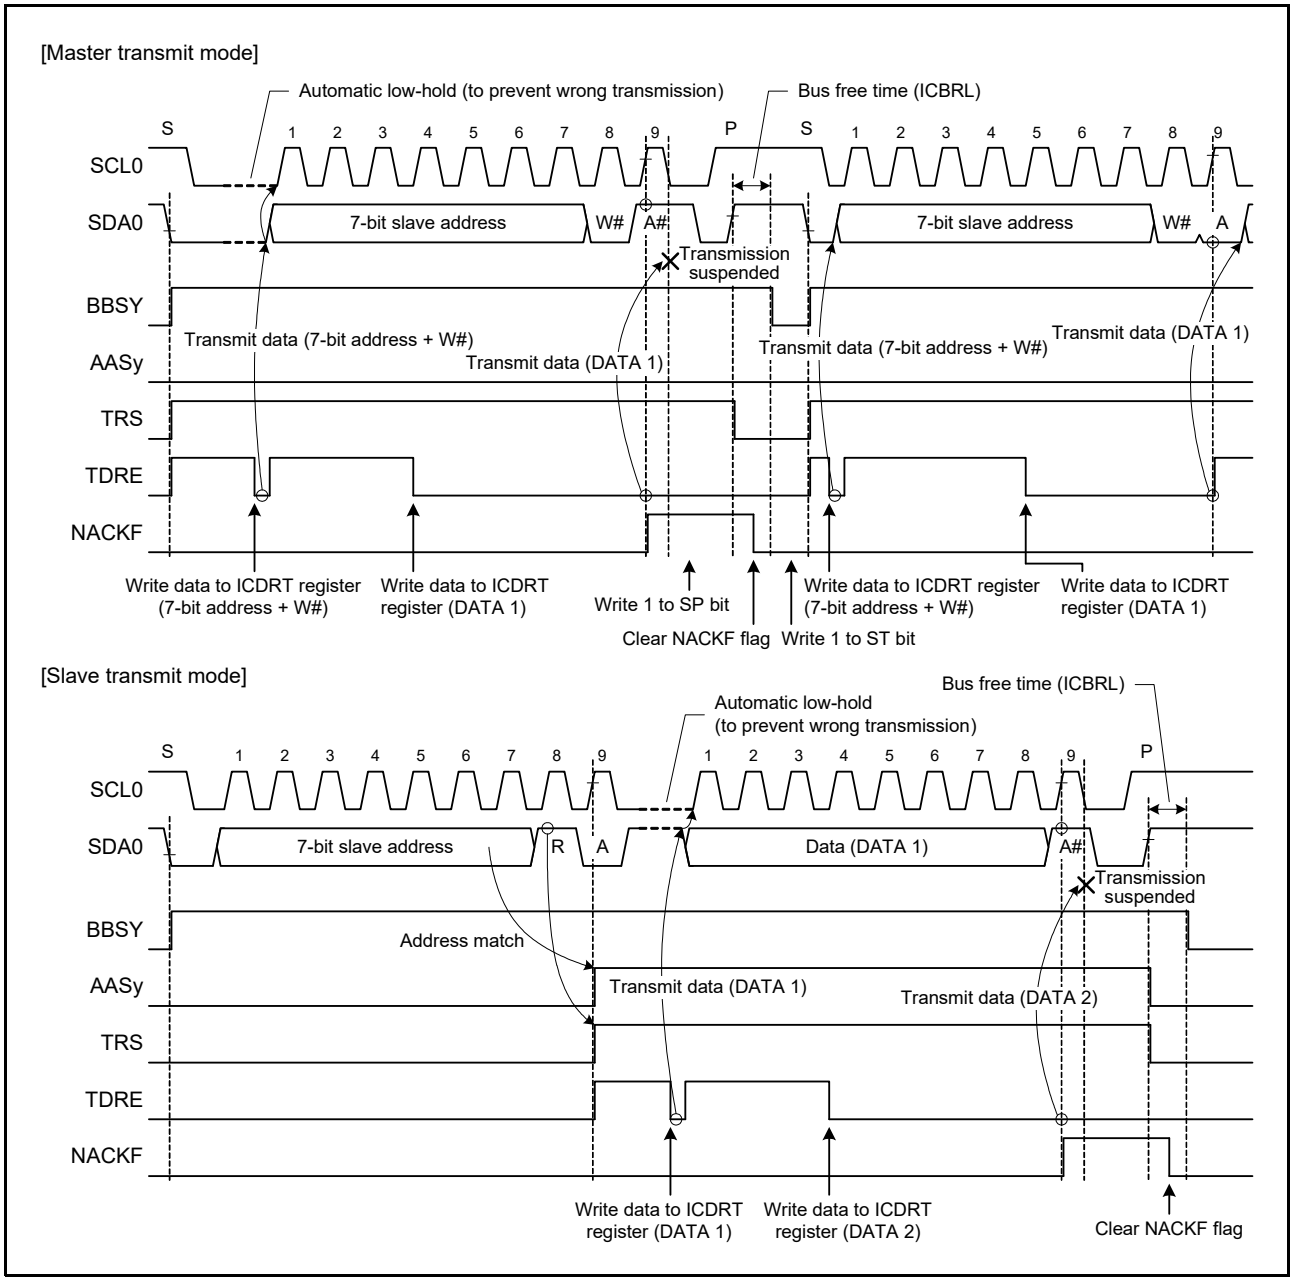

Figure 34.30 Suspension of Data Transmission When NACK is Received (NACKE = 1)

34.8.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (ICDRR) read is delayed for a period of one transfer byte or more with receive data full (ICSR2.RDRF flag is 1) in receive mode (ICCR2.TRS bit is 0), the RIIC holds the SCL0 line low automatically immediately before the next data is received to prevent failure to receive data.
This function to prevent failure to receive data using the automatic low-hold function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, the RIIC's own slave address is designated after a stop condition is generated. This function does not disturb other communication because the RIIC does not hold the SCL0 line low when a mismatch with its own slave address occurs after a stop condition is generated.
Sections in which the SCL0 line is held low can be selected with a combination of the WAIT and RDRFS bits in the ICMR3 register.

(1) 1-Byte Receive Operation and Automatic Low-Hold Function Using the WAIT Bit

When the ICMR3.WAIT bit is set to 1, the RIIC performs 1-byte receive operation using the WAIT bit function. Furthermore, when the ICMR3.RDRFS bit is 0, the RIIC automatically sends the ICMR3.ACKBT bit value for the acknowledgment bit in the period from the falling edge of the eighth SCL to the falling edge of the ninth SCL, and automatically holds the SCL0 line low at the falling edge of the ninth SCL using the WAIT bit function. This low-hold is released by reading data from the ICDRR register, which enables bytewise receive operation.
The WAIT bit function is enabled for receive bytes after a match with the RIIC's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

(2) 1-Byte Receive Operation (ACK/NACK Transmission Control) and Automatic Low-Hold Function Using the RDRFS Bit

When the ICMR3.RDRFS bit is set to 1, the RIIC performs 1-byte receive operation using the RDRFS bit function. When the RDRFS bit is set to 1, the ICSR2.RDRF flag (receive data full) is set to 1 at the rising edge of the eighth SCL, and the SCL0 line is automatically held low at the falling edge of the eighth SCL. This low-hold is released by writing a value to the ICMR3.ACKBT bit, but cannot be released by reading data from the ICDRR register, which enables receive operation by the ACK/NACK transmission control according to the data received in byte units.
The RDRFS bit function is enabled for receive bytes after a match with the RIIC's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

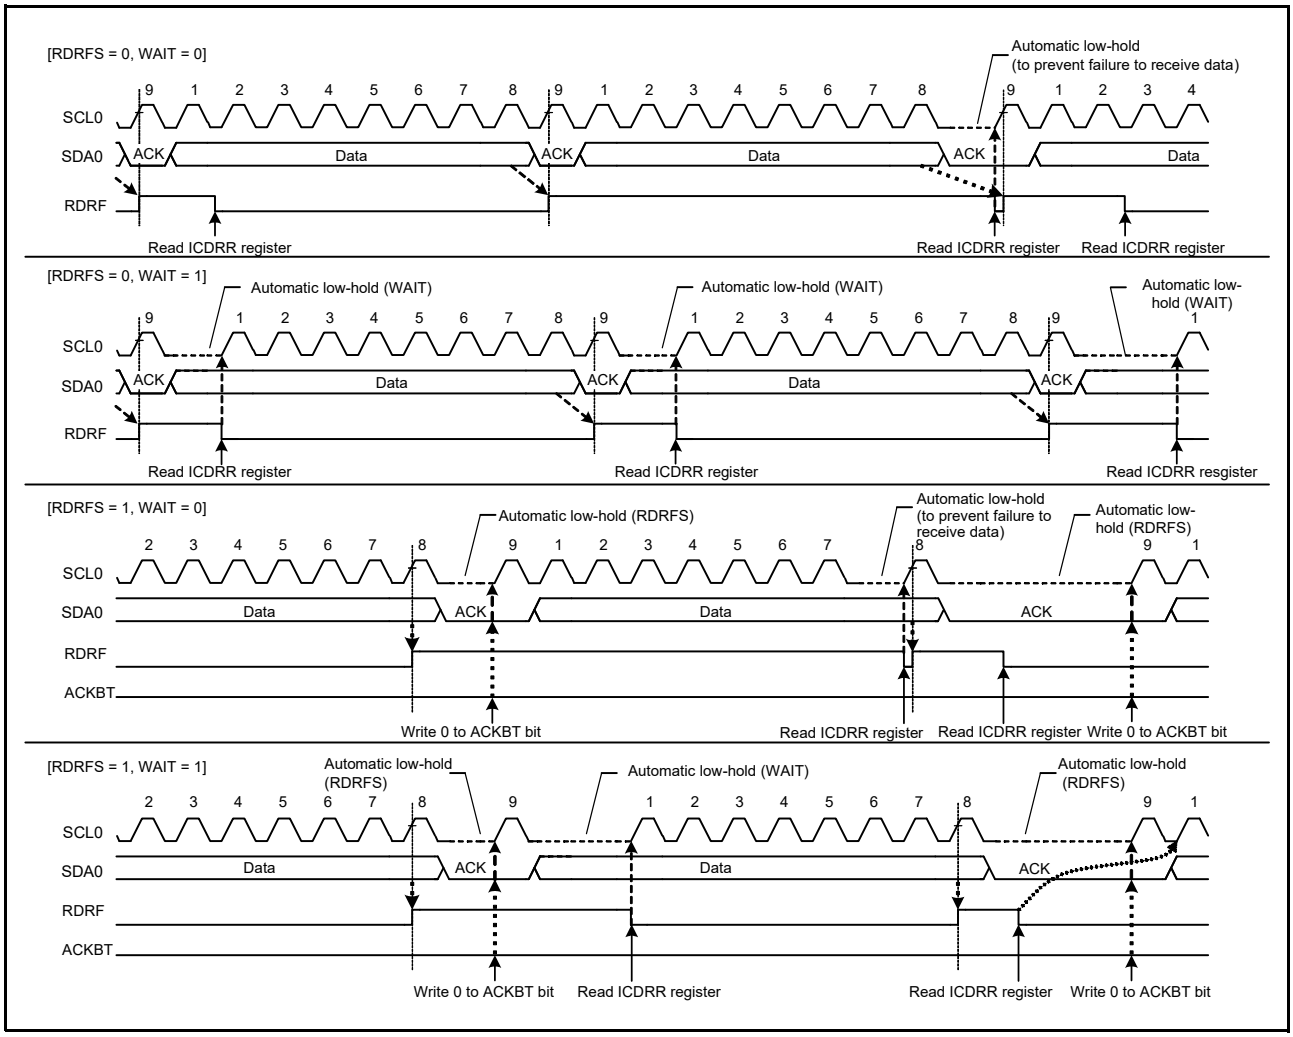

Figure 34.31 Automatic Low-Hold Operation in Receive Mode (Using RDRFS and WAIT Bits)

34.9 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I2C-bus specification, the RIIC has functions to prevent double-generation of a start condition, to detect arbitration-lost during transmission of NACK, and to detect arbitration-lost in slave transmit mode.

34.9.1 Master Arbitration-Lost Detection (MALE Bit)

The RIIC drives the SDA0 line low to generate a start condition. However, if the SDA0 line has already been driven low by another master device generating a start condition, the RIIC causes arbitration to be lost, so priority is given to transfer by the other master device. Similarly, if the ICCR2.ST bit is set to 1 while the ICCR2.BBSY flag is 1 (bus busy state), arbitration is lost, so priority is given to transfer by the other master device. No start condition is generated in this case.
When a start condition is generated successfully, if the data for transmission including the address bits (i.e. the internal SDA output level) and the level on the SDA0 line do not match (the high output as the internal SDA output; i.e. the SDA0 pin is in the high-impedance state) and the low is detected on the SDA0 line, the RIIC loses the arbitration.
After a master arbitration-lost is generated, the RIIC immediately enters slave receive mode. If a slave address (including the general call address) matches its own address at this time, the RIIC continues in slave operation.
A master arbitration-lost is detected when the following conditions are met while the ICFER.MALE bit is 1 (master arbitration-lost detection enabled).

Conditions for detecting master arbitration-lost

- Non-matching of the internal level for output on SDA and the level on the SDA0 line after a start condition was generated by setting the ICCR2.ST bit to 1 while the ICCR2.BBSY flag was set to 0 (erroneous generation of a start condition)
- Setting of the ICCR2.ST bit to 1 while the BBSY flag is set to 1 (start condition double-generation error)
- When the transmit data excluding acknowledgment bit (internal SDA output level) does not match the level on the SDA0 line in master transmit mode (bits MST and TRS in the ICCR2 register = 11b)

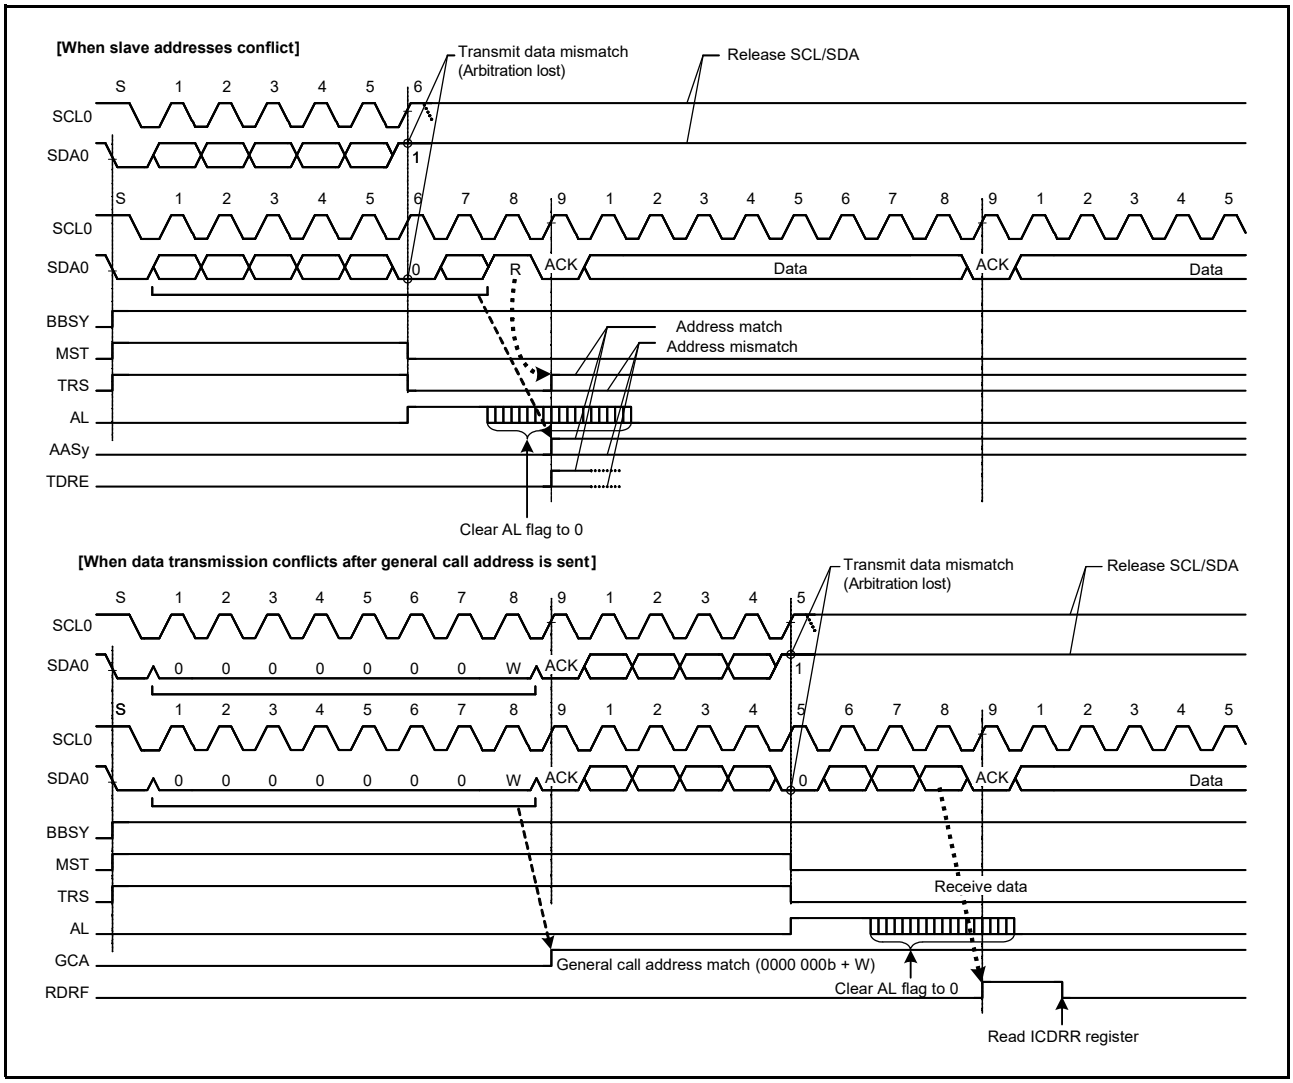

Figure 34.32 Examples of Master Arbitration-Lost Detection (MALE = 1)

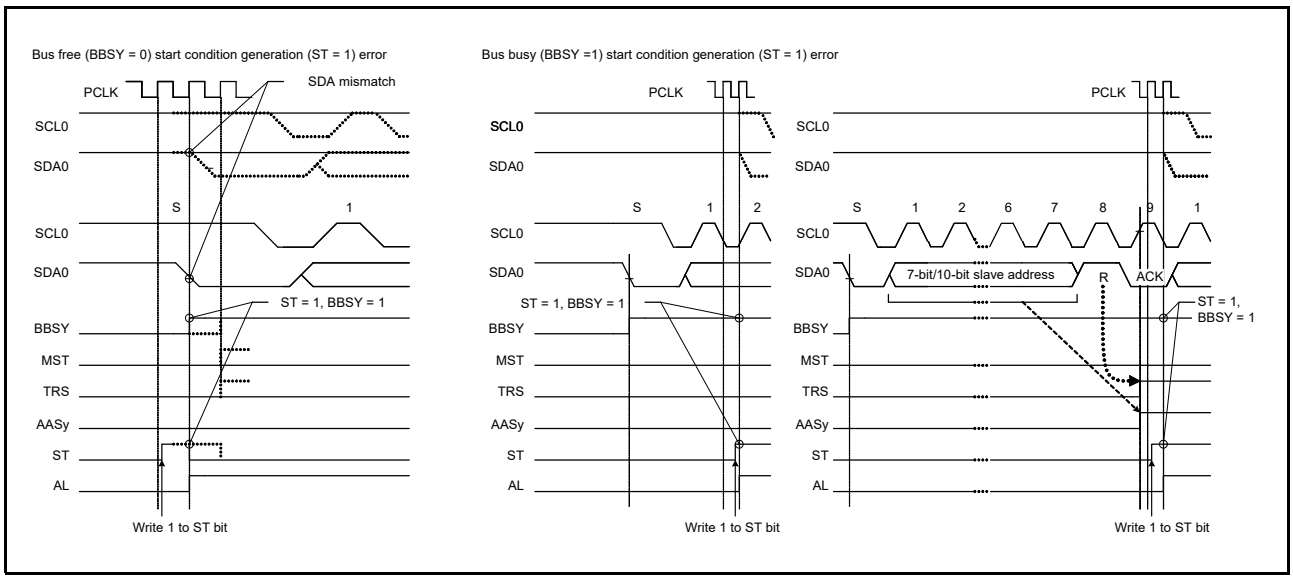

Figure 34.33 Arbitration-Lost When a Start Condition is Generated (MALE = 1)

34.9.2 NACK Transmission Arbitration-Lost Detection Function (NALE Bit)

The RIIC has a function to cause arbitration to be lost if the internal SDA output level does not match the level on the SDA0 line (the high output as the internal SDA output; i.e. the SDA0 pin is in the high-impedance state) and the low is detected on the SDA0 line during transmission of NACK in receive mode. Arbitration is lost due to a conflict of NACK transmission and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send/receive the same information through a single slave device. Figure 34.34 shows an example of NACK transmission arbitration-lost detection.

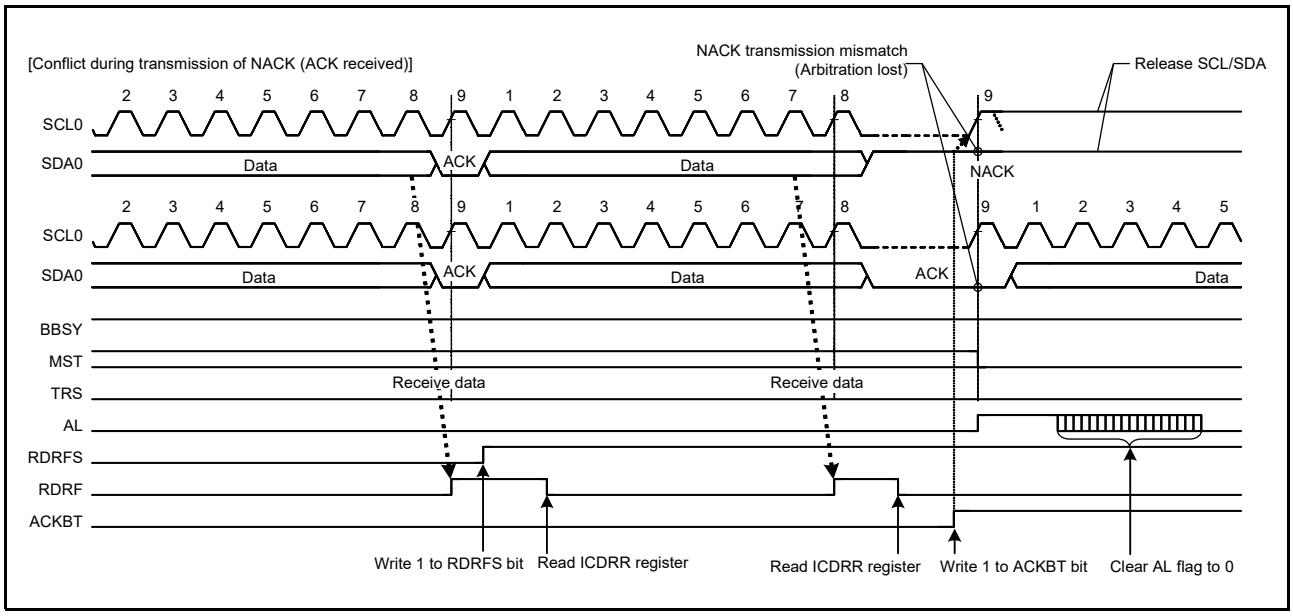

Figure 34.34 Example of NACK transmission arbitration-lost Detection (NALE = 1)

The following explains arbitration-lost detection using an example where two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives two bytes of data from the slave device, and master B receives four bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in both master A and master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Here, master A sends NACK when it has received second byte of data from the slave device. Meanwhile, master B sends ACK because it has not received necessary four bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like this occurs, master A cannot detect ACK transmitted by master B and generates a stop condition. Therefore, the generation of the stop condition conflicts with the SCL output of master B, which disturbs communication.

When the RIIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost.

If a NACK transmission arbitration-lost occurs, the RIIC immediately cancels the slave address matched state and enters slave receive mode. This prevents a stop condition from being generated, preventing a communication failure on the bus. Also, in the ARP command processing of SMBus, it is possible to omit surplus processing (FFh transmission processing) after NACK transmission when the UDID (Unique Device Identifier) of “Assign Address” does not match and after the NACK transmission of the “Get UDID (General)” after the “Assign Address” is confirmed.

The RIIC detects NACK transmission arbitration-lost when the following condition is met with the ICFER.NALE bit set to 1 (NACK transmission arbitration-lost is enabled).

Condition for detecting NACK transmission arbitration-lost

- When the internal SDA output level does not match the SDA0 line (ACK is received) during transmission of NACK (ICMR3.ACKBT bit = 1)

34.9.3 Slave Arbitration-Lost Detection (SALE Bit)

The RIIC has a function to cause arbitration to be lost if the data for transmission (i.e. the internal SDA output level) and the level on the SDA0 line do not match (the high output as the internal SDA output; i.e. the SDA0 pin is in the high-impedance state and the low is detected on the SDA0 line in slave transmit mode). The slave arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) of SMBus.
When the slave arbitration-lost occurs, the RIIC is immediately released from the slave address matched state and enters slave receive mode. This function can detect a data conflict during UDID transmission of SMBus and omit surplus processing (FFh transmission processing) after the data conflict.
The RIIC detects slave arbitration-lost when the following condition is met with the ICFER.SALE bit set to 1 (slave arbitration-lost detection enabled).

Condition for detecting slave arbitration-lost

- When transmit data excluding acknowledgment bit (internal SDA output level) does not match the SDA0 line in slave transmit mode (bits MST and TRS in the ICCR2 register are 01b)

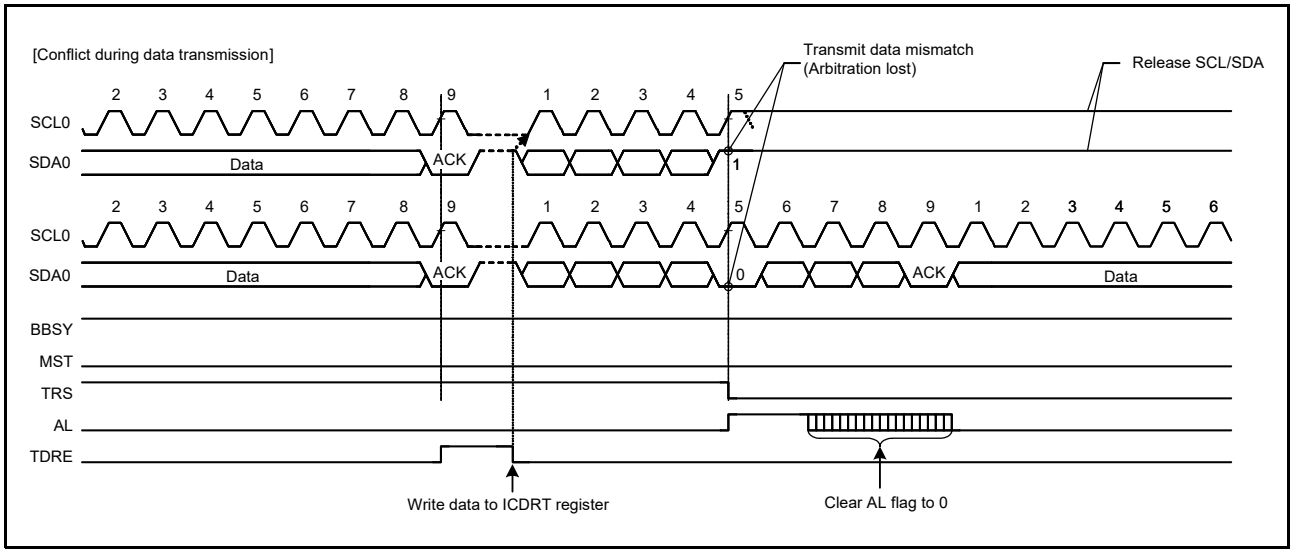

Figure 34.35 Example of Slave Arbitration-Lost Detection (SALE = 1)

34.10 Start Condition/Restart Condition/Stop Condition Generating Function

34.10.1 Generating a Start Condition

The RIIC generates a start condition when the ICCR2.ST bit is set to 1.
When the ST bit is set to 1, a start condition generation request is made and the RIIC generates a start condition when the ICCR2.BBSY flag is 0 (bus free state). When a start condition is generated normally, the RIIC automatically shifts to the master transmit mode.
A start condition is generated in the following sequence.

Start condition generation

(1) Drive the SDA0 line low (high to low).
(2) Secure the time set in the ICBRH register and the start condition hold time.
(3) Drive the SCL0 line low (high to low).
(4) Detect the low level on the SCL0 line and secure the low period of the signal on the SCL0 line set in the ICBRL register.

34.10.2 Generating a Restart Condition

The RIIC generates a restart condition when the ICCR2.RS bit is set to 1.
When the RS bit is set to 1, a restart condition generation request is made and the RIIC generates a restart condition when the ICCR2.BBSY flag is 1 (bus busy state) and the ICCR2.MST bit is 1 (master mode).
A restart condition is generated in the following sequence.

Restart condition generation

(1) Release the SDA0 line.
(2) Secure the low period of the signal on the SCL0 line set in the ICBRL register.
(3) Release the SCL0 line (low to high).
(4) Detect the high level on the SCL0 line and secure the time set in the ICBRL register and the restart condition setup time.
(5) Drive the SDA0 line low (high to low).
(6) Secure the time set in the ICBRH register and the restart condition hold time.
(7) Drive the SCL0 line low (high to low).
(8) Detect the low level on the SCL0 line and secure the low period of the signal on the SCL0 line set in the ICBRL register.

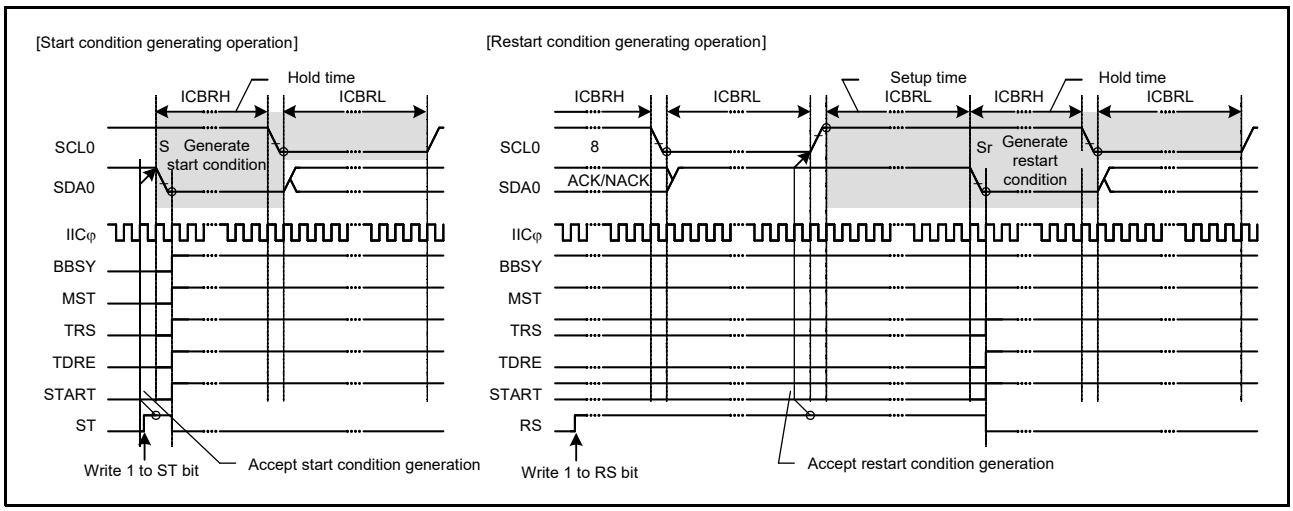

Figure 34.36 Start Condition/Restart Condition Generation Timing (ST and RS Bits)

34.10.3 Generating a Stop Condition

The RIIC generates a stop condition when the ICCR2.SP bit is set to 1.
When the SP bit is set to 1, a stop condition generation request is made and the RIIC generates a stop condition when the ICCR2.BBSY flag is 1 (bus busy state) and the ICCR2.MST bit is 1 (master mode).
A stop condition is generated in the following sequence.

Stop condition generation

(1) Drive the SDA0 line low (high to low).
(2) Secure the low period of the signal on the SCL0 line set in the ICBRL register.
(3) Release the SCL0 line (low to high).
(4) Detect the high level on the SCL0 line and secure the time set in the ICBRH register and the stop condition setup time.
(5) Release the SDA0 line (low to high).
(6) Secure the time set in the ICBRL register and the bus free time.
(7) Set the BBSY flag to 0 (to release the bus mastership).

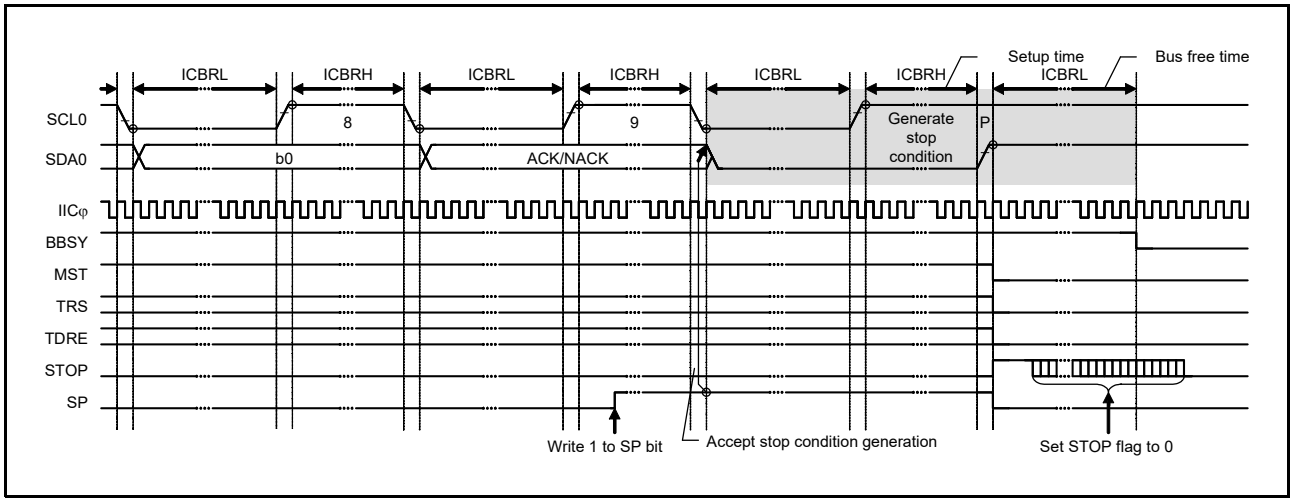

Figure 34.37 Stop Condition Generation Timing (SP Bit)

34.11 Bus Hanging

If the clock signals from the master and slave devices go out of synchronization due to noise or other factors, the I2C-bus might hang with a fixed level on the SCL0 line and/or SDA0 line.
As measures against the bus hanging, the RIIC has a timeout function to detect hanging by monitoring the SCL0 line, a function for the output of an additional SCL to release the bus from a hung state due to clock signals being out of synchronization, the RIIC reset function, and internal reset function.
By checking bits SCLO, SDAO, SCLI, and SDAI in the ICCR1 register, it is possible to see whether the RIIC or its partner in communications is placing the low level on the SCL0 or SDA0 lines.

34.11.1 Timeout Function

The RIIC includes a timeout function for detecting when the SCL0 line has been stuck longer than the predetermined time. The RIIC can detect an abnormal bus state by monitoring that the SCL0 line is stuck low or high for a predetermined time.
The timeout function monitors the SCL0 line state and counts the low period or high period using the internal counter. The timeout function resets the internal counter each time the SCL0 line changes (rising or falling), but continues to count unless the SCL0 line changes. If the internal counter overflows due to no SCL0 line change, the RIIC can detect the timeout and report the bus hung state.
This timeout function is enabled when the ICFER.TMOE bit is 1. It detects a hung state that the SCL0 line is stuck low or high during the following conditions:

- The bus is busy (ICCR2.BBSY flag is 1) in master mode (ICCR2.MST bit is 1).
- The RIIC's own slave address is detected (ICSR1 register is not 00h) and the bus is busy (ICCR2.BBSY flag is 1) in slave mode (ICCR2.MST bit is 0).
- The bus is free (ICCR2.BBSY flag is 0) while generation of a start condition is requested (ICCR2.ST bit is 1).

The internal counter of the timeout function works using the internal reference clock (IICφ) set by the ICMR1.CKS[2:0] bits as a count source. It functions as a 16-bit counter when long mode is selected (ICMR2.TMOS bit is 0) or a 14-bit counter when short mode is selected (TMOS bit is 1).
The SCL0 line level (low/high or both levels) during which this counter is activated can be selected by the setting of bits TMOH and TMOL in the ICMR2 register. If both bits TMOL and TMOH are set to 0, the internal counter does not work.

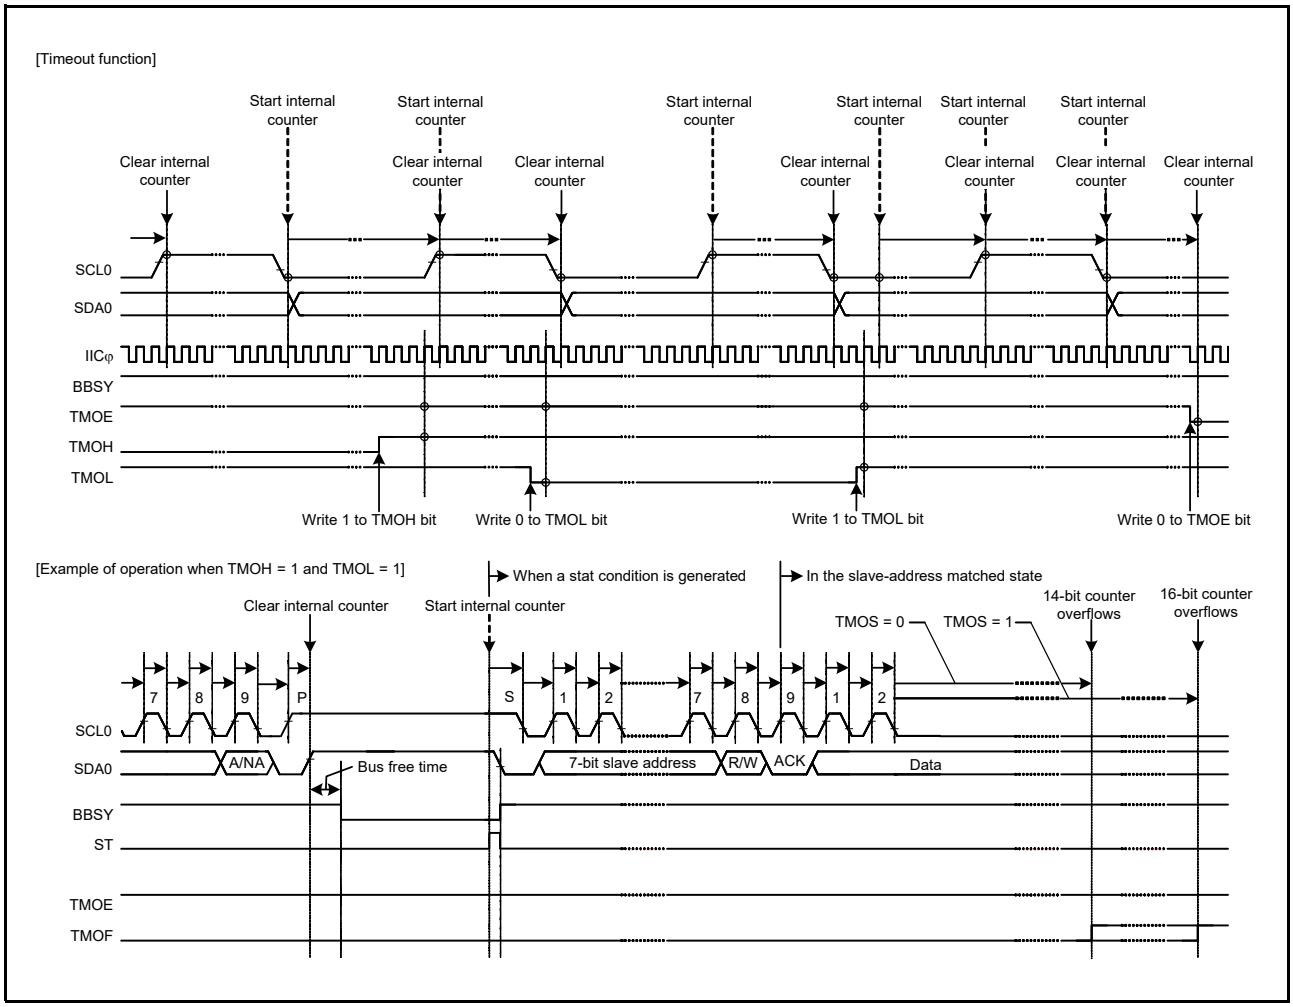

Figure 34.38 Timeout Function

34.11.2 Additional SCL Output Function

In master mode, the RIIC module has a facility for the output of additional SCL to release the SDA0 line from being held low by the slave device due to the master being out of synchronization with the slave device.
This function is mainly used in master mode to release the SDA0 line from the state of being stuck low by including additional SCL output from the RIIC with single cycles of the SCL as the unit if the RIIC cannot generate a stop condition because the slave device is holding the SDA0 line low. Do not use this function in normal situations. Using it when communications are proceeding correctly will lead to malfunctions.
When the ICCR1.CLO bit is set to 1, an additional clock pulse at the frequency set by the ICMR1.CKS[2:0] bits and the ICBRH and ICBRL registers is output from the SCL0 pin. After output of this clock pulse, the CLO bit automatically becomes 0. The SCL0 pin is held low when the ICCR2.BBSY flag is 1 and held high when the BBSY flag is 0.
Consecutive additional clock pulses can be output by writing 1 to the CLO bit after confirming the CLO bit to be 0.
When the RIIC module is in master mode and the slave device is holding the SDA0 line low because synchronization with the slave device has been lost due to the effects of noise, etc., the output of a stop condition is not possible. The additional SCL output function can be used to output additional clock pulses one by one to make the slave device release the SDA0 line from being held low, thus recovering the bus from an unusable state. Release of the SDA0 line by the slave device can be monitored by reading the ICCR1.SDAI bit. After confirming release of the SDA0 line by the slave device, complete communications by regenerating a stop condition.
Use this function with the ICFER.MALE bit set to 0 (master arbitration-lost detection disabled).

Conditions for using the ICCR1.CLO bit

- When the bus is free (ICCR2.BBSY flag is 0) or in master mode (ICCR2.MST bit is 1 and ICCR2.BBSY flag is 1)
- When the communication device does not hold the SCL0 line low

Figure 34.39 shows the operation timing of the additional SCL output function (CLO bit).

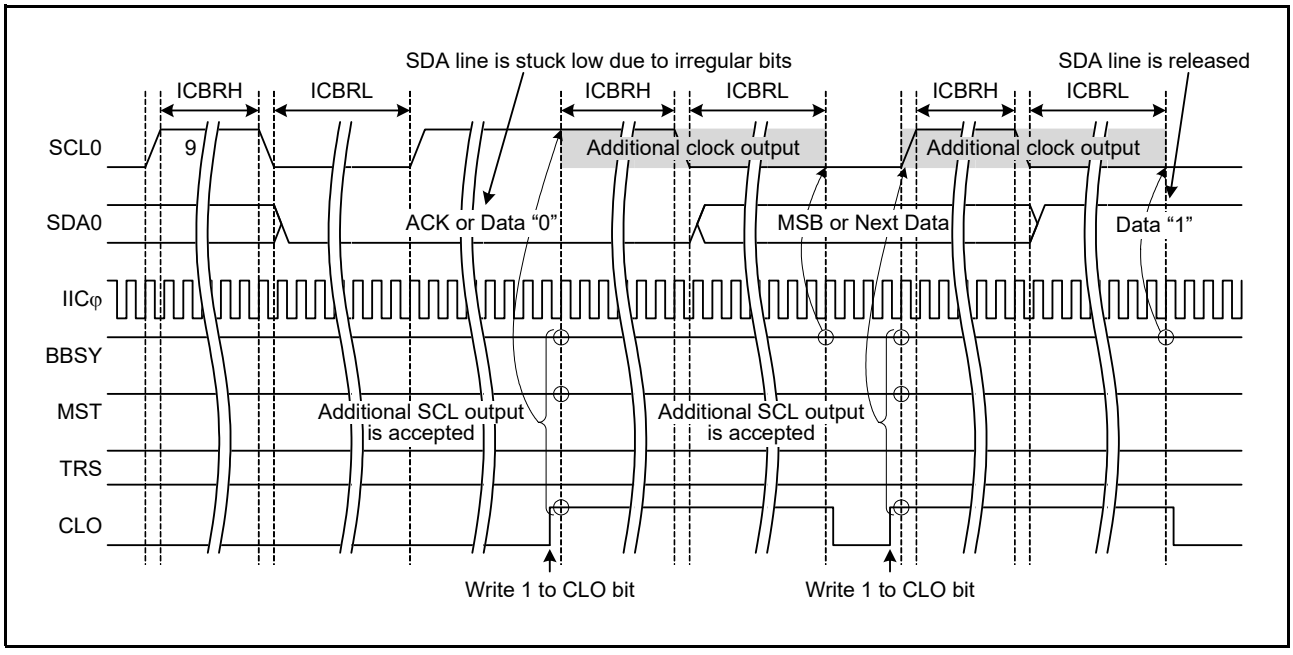

Figure 34.39 Additional SCL Output Function (CLO Bit)

34.11.3 RIIC Reset and Internal Reset

The RIIC module incorporates a function for resetting itself. There are two types of reset. One is referred to as an RIIC reset; this initializes all registers including the ICCR2.BBSY flag. The other is referred to as an internal reset; this releases the RIIC from the slave-address matched state and initializes the internal counter while retaining other settings. After applying a reset, be sure to set the ICCR1.IICRST bit to 0.

Both types of reset are effective for release from bus-hung states because both restore the output state of the SCL0 and SDA0 pins to the high-impedance state.

Applying a reset during slave operation may lead to a loss of synchronization between the master device clock and the slave device clock, so avoided this where possible. Note that monitoring of the bus state, such as for the presence of a start condition, is not possible during an RIIC reset (bits ICE and IICRST in the ICCR1 register are 01b).

For a detailed description of the RIIC and internal resets, refer to section 34.14, Initialization of Registers and Functions When a Reset is Applied or a Condition is Detected.

34.12 SMBus Operation

The RIIC is available for data communication conforming to the SMBus (Version 2.0). To perform SMBus communication, set the ICMR3.SMBS bit to 1. To use the transfer rate within a range of 10 kbps to 100 kbps of the SMBus specification, set the ICMR1.CKS[2:0] bits, the ICBRH register, and the ICBRL register. In addition, determine the values of the ICMR2.DLCS bit and the ICMR2.SDDL[2:0] bits to meet the data hold time (300 ns (min.)). If the RIIC is used only as a slave device, the transfer rate setting is not necessary, whereas the ICBRL register needs to be set to a value longer than the data setup time (250 ns).
For the SMBus device default address (1100 001b), use one of the slave address registers L0 to L2 (registers SARL0, SARL1, and SARL2), and set the corresponding SARUy.FS bit (7-bit/10-bit address format select) (y = 0 to 2) to 0 (7-bit address format).
When transmitting the UDID (Unique Device Identifier), set the ICFER.SALE bit to 1 to enable the slave arbitration-lost detection function.

34.12.1 SMBus Timeout Measurement

(1) Measuring timeout of slave device

The following period (timeout interval: $T_{LOW:SEXT}$) must be measured for slave devices in SMBus communication.

- From start condition to stop condition

To measure timeout for slave devices, measure the period from start condition detection to stop condition detection with the MTU or TMR timer using a start condition detection interrupt (STI) and stop condition detection interrupt (SPI) of the RIIC. The measured timeout period must be within the cumulative clock low extend time (slave device) ($T_{LOW:SEXT}$: 25 ms (max.)) of the SMBus specification.
If the time measured with the MTU or TMR exceeds the detect clock low timeout ($T_{TIMEOUT}$: 25 ms (min.)) of the SMBus specification, the slave device must release the bus by writing 1 to the ICCR1.IICRST bit to apply an internal reset of the RIIC. When an internal reset is applied to the RIIC, it stops driving the SCL0 and SDA0 pins of the bus and makes the SCL0/SDA0 pin outputs high-impedance, thus releasing the bus.

(2) Measuring timeout of master device

The following periods (timeout interval: $T_{LOW:MEXT}$) must be measured for master devices in SMBus communication.

- From start condition to acknowledgment bit
- Between acknowledgment bits
- From acknowledgment bit to stop condition

To measure timeout for master devices, measure these periods with the MTU or TMR timer using a start condition detection interrupt (STI), stop condition detection interrupt (SPI), and transmission end interrupt (TEI) or receive data full interrupt (RXI) of the RIIC. The measured timeout period must be within the cumulative clock low extend time (master device) ($T_{LOW:MEXT}$: 10 ms (max.)) of the SMBus specification, and the total of all $T_{LOW:MEXT}$ from start condition to stop condition must be within $T_{LOW:SEXT}$: 25 ms (max.).
For the ACK receive timing (rising edge of the ninth SCL), monitor the ICSR2.TEND flag in master transmit mode (master transmitter) and the ICSR2.RDRF flag in master receive mode (master receiver). For this reason, perform bytewise transmit operation in master transmit mode, and hold the ICMR3.RDRFS bit 0 until the byte just before reception of the final byte in master receive mode. While the RDRFS bit is 0, the RDRF flag is set to 1 at the rising edge of the ninth SCL.
If the period measured with the MTU or TMR exceeds the cumulative clock low extend time (master device) ($T_{LOW:MEXT}$: 10 ms (max.)) of the SMBus specification or the total of measured periods exceeds the detect clock low timeout ($T_{TIMEOUT}$: 25 ms (min.)) of the SMBus specification, the master device must stop the transaction by generating a stop condition. In master transmit mode, immediately stop the transmit operation (writing data to the ICDRT register).

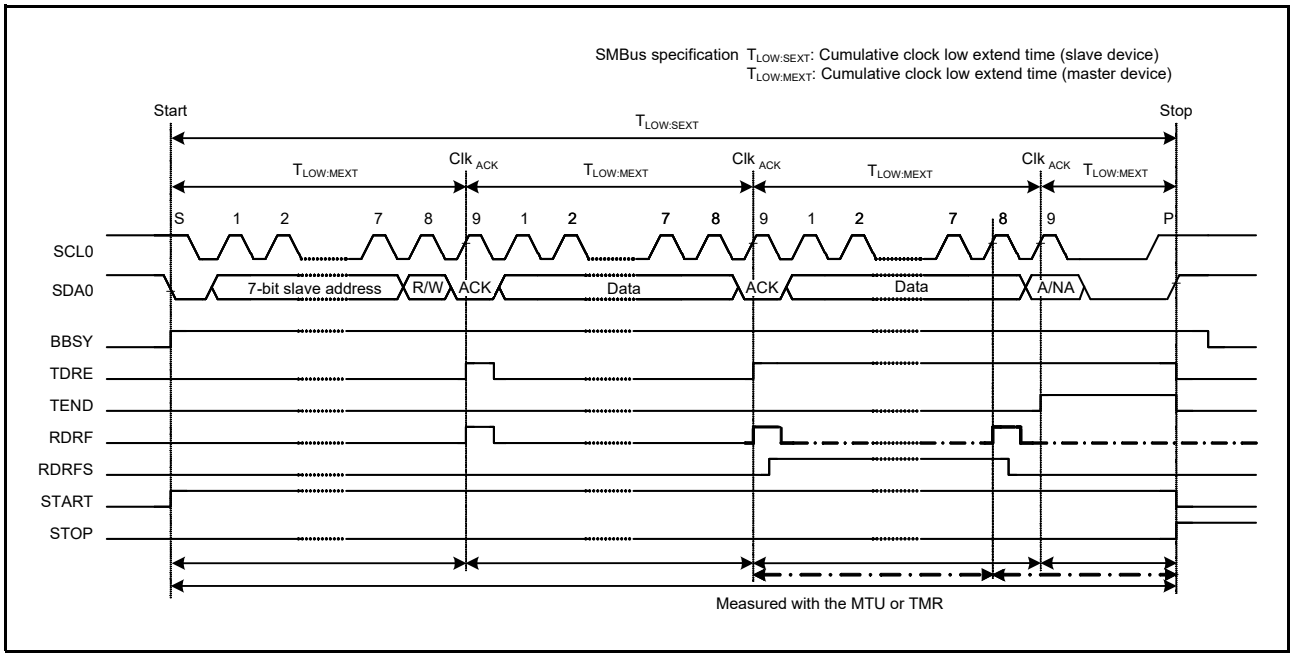

Figure 34.40 SMBus Timeout Measurement

34.12.2 Packet Error Code (PEC)

This MCU incorporates a CRC calculator. The CRC calculator enables transmission of a packet error code (PEC) or checking the received data of the SMBus in data communication of the RIIC. For the CRC generating polynomials of the CRC calculator, refer to section 39, CRC Calculator (CRCA).

The PEC data in master transmit mode can be generated by writing all transmit data to the CRC data input register (CRCDIR) in the CRC calculator.

The PEC data in master receive mode can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC data output register (CRCDOR) with the received PEC data.

To send ACK or NACK according to the match or mismatch result when the final byte is received as a result of the PEC code check, set the ICMR3.RDRFS bit to 1 before the rising edge of the eighth SCL during reception of the final byte, and hold the SCL0 line low at the falling edge of the eighth clock pulse.

34.12.3 SMBus Host Notification Protocol (Notify ARP Master Command)

In communications over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of its own slave address or to request its own slave address from the SMBus host.

For a product of this MCU to operate as an SMBus host (or ARP master), the host address (0001 000b) sent from the slave device must be detected as a slave address, so the RIIC has a function for detecting the host address. To detect the host address as a slave address, set the ICMR3.SMBS bit and the ICSER.HOAE bit to 1. Operation after the host address has been detected is the same as normal slave operation.

34.13 Interrupt Sources

The RIIC generates four types of interrupt requests: communication error or communication event (arbitration-lost detection, NACK detection, timeout detection, start condition detection, and stop condition detection), receive data full, transmit data empty, and transmission end.

Table 34.6 lists details of the several interrupt requests. The receive data full and transmit data empty interrupt requests allow the DTC or DMAC to start data transfer.

Table 34.6 Interrupt Sources

Symbol	Interrupt Source	Interrupt Flag	Start DTC/DMA Transfer	Interrupt Generation Condition
EEI	Communication error/ communication event	AL	Not possible	AL = 1 and ALIE = 1
		NACKF		NACKF = 1 and NAKIE = 1
		TMOF		TMOF = 1 and TMOIE = 1
		START		START = 1 and STIE = 1
		STOP		STOP = 1 and SPIE = 1
RXI*2	Receive data full	RDRF	Possible	RDRF = 1 and RIE = 1
TXI*1	Transmit data empty	TDRE	Possible	TDRE = 1 and TIE = 1
TEI*3	Transmission end	TEND	Not possible	TEND = 1 and TEIE = 1

Note: There is a delay time between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. Thus, when an interrupt flag has been cleared or an interrupt request has been masked, read the relevant flag again to check whether clearing or masking has been completed, and then return from interrupt handling. Returning from interrupt handling without checking that writing to the module has been completed creates a possibility of repeated processing of the same interrupt.

Note 1. Because TXI is an edge-detected interrupted, it does not require clearing. Furthermore, the ICSR2.TDRE flag (a condition for TXI) is automatically set to 0 when data for transmission are written to the ICDRT register or a stop condition is detected (ICSR2.STOP flag is 1).

Note 2. Because RXI is an edge-detected interrupted, it does not require clearing. Furthermore, the ICSR2.RDRF flag (a condition for RXI) is automatically set to 0 when data are read from the ICDRR register.

Note 3. When using the TEI interrupt, clear the ICSR2.TEND flag in the TEI interrupt handling.
Note that the ICSR2.TEND flag is automatically set to 0 when data for transmission are written to the ICDRT register or a stop condition is detected (ICSR2.STOP flag is 1).

Clear the each flag or mask the interrupt request during interrupt handling.

34.13.1 Buffer Operation for TXI and RXI Interrupts

If the conditions for generating a TXI and RXI interrupt are satisfied while the corresponding ICU.IRn.IR flag is 1, the interrupt request is not output for the ICU but retained internally (the capacity for internal retention is one request per source).

An interrupt request that was being retained internally is output to the ICU when the value of the IR flag becomes 0.

Internally retained interrupt requests are automatically cleared under normal conditions of usage.

Internally retained interrupt requests can also be cleared by writing 0 to the corresponding interrupt enable bit in the ICIER register.

34.14 Initialization of Registers and Functions When a Reset is Applied or a Condition is Detected

The RIIC can be reset by MCU reset, RIIC reset, and internal reset functions. Table 34.7 lists the reset states of registers and functions when a reset is applied or a condition is detected.

Table 34.7 Reset States of Registers and Functions When a Reset is Applied or a Condition is Detected

		MCU Reset	RIIC Reset (ICE = 0, IICRST = 1)	Internal Reset (ICE = 1, IICRST = 1)	Start Condition/ Restart Condition Detection	Stop Condition Detection
ICCR1	SDAO, SCLO	To be reset	To be reset	To be reset	Retained	Retained
	IICRST, ICE		Retained	Retained		
	Others		To be reset			
ICCR2	ST, RS	To be reset	To be reset	To be reset	To be reset	Retained
	SP					To be reset
	TRS				See note 1	
	MST				See note 1	
	BBSY			Retained	Becomes 1	
ICMR1	BC[2:0]	To be reset	To be reset	To be reset	To be reset	Retained
	Others			Retained	Retained	
ICMR2		To be reset	To be reset	Retained	Retained	Retained
ICMR3	ACKBT	To be reset	To be reset	Retained	Retained	To be reset
	Others					Retained
ICFER		To be reset	To be reset	Retained	Retained	Retained
ICSER		To be reset	To be reset	Retained	Retained	Retained
ICIER		To be reset	To be reset	Retained	Retained	Retained
ICSR1		To be reset	To be reset	To be reset	Retained	To be reset
ICSR2	START	To be reset	To be reset	To be reset	Becomes 1	To be reset
	STOP				Retained	Becomes 1
	TEND					To be reset
	TDRE				See note 1	
	Others				Retained	Retained
SARL0, SARL1, SARL2, SARU0, SARU1, SARU2		To be reset	To be reset	Retained	Retained	Retained
ICBRH, ICBRL		To be reset	To be reset	Retained	Retained	Retained
ICDRT		To be reset	To be reset	Retained	Retained	Retained
ICDRR		To be reset	To be reset	Retained	Retained	Retained
ICDRS		To be reset	To be reset	To be reset	Retained	Retained
Timeout function		To be reset	To be reset	To be reset	Operation	Operation
Bus free time measurement		To be reset	To be reset	Operation	Operation	Operation

Note 1. This bit is not reset. This bit becomes 0 or 1 in accordance with the conditions.

34.15 Event Link Function (Output)

The RIIC0 handles event output for the event link controller (ELC) corresponding to the following sources.

- Communication error/communication event
- Receive data full
- Transmit data empty
- Transmission end

34.15.1 Interrupt Handling and Event Linking

The RIIC has four types of interrupts: communication error or communication event (arbitration-lost detection, NACK detection, timeout detection, start condition detection, or stop condition detection), receive data full, transmit data empty, and transmission end. Each of these has an enable bit to control enabling and disabling of the interrupt signal. An interrupt request signal is output for the ICU when an interrupt source condition is satisfied while the setting of the corresponding enable bit is enabled.
The corresponding event signals are sent to other modules via the ELC when the interrupt source conditions are satisfied, regardless of the settings of the interrupt enable bits.
For details on interrupt sources, see Table 34.6.

34.16 Usage Notes

34.16.1 Setting Module Stop Function

Module stop state can be entered or released using module stop control register B (MSTPCRB). The initial setting is for operation of the RIIC to be stopped. RIIC register access is enabled by releasing the module stop state.
For details on module stop control register B, refer to section 11, Low Power Consumption.

34.16.2 Notes on Starting Transfer

If the IR flag corresponding to the RIIC interrupt is 1 when transfer is started (ICCR1.ICE bit is 1), follow the procedure below to clear interrupts before enabling operations. Starting transfer with the IR flag set to 1 while the ICCR1.ICE bit is 1 leads to an interrupt request being internally retained after transfer starts, and this can lead to unanticipated behavior of the IR flag.

1. Confirm that the ICCR1.ICE bit is 0.
2. Set the relevant interrupt enable bits (ICIER.TIE, etc.) on the peripheral function side to 0.
3. Read the relevant interrupt enable bits (ICIER.TIE, etc.) on the peripheral function side and confirm that its value is 0.
4. Set the IR flag to 0.

35. I3C Bus Interface (RI3C)

This MCU has a single-channel I3C bus interface (RI3C0).
The RI3C module conforms with the MIPI Alliance I3C bus interface and provides a subset of its functions.

35.1 Overview

Table 35.1 lists the specifications of the RI3C and Figure 35.1 shows a block diagram of the RI3C. Table 35.2 lists the I/O pins of the RI3C.

Table 35.1 RI3C Specifications

Item	Specification
Operation mode	Controller (Primarily Controller/Secondary Controller) mode and Target mode selectable
Data handler	• Controller: - FIFO buffer transfer • Target: - FIFO buffer transfer
Communication protocol	• SDR (I3C single data rate) mode - Private message - Broadcast message (common command code (CCC)) - Direct message (common command code (CCC)) • Legacy I^2C message - Fast-mode (Fm): 0 to 400 kbps - Fast-mode Plus (Fm+): 0 to 1 Mbps
IBI	• Target Interrupt Request (TIR) • Controller Role Request (CRR) (Secondary Controller only) • Hot-Join event
Address format	7-bit address
Address detection	• Target address (Static Address or Dynamic Address) • Broadcast Address (7Eh)
Clock stalling	The I3C Controller can stall the I3C bus while the SCL line is low.
Interrupt source	Seven sources: • Response queue full (RESPI) • Command queue empty (CMDI) • IBI queue empty/full (IBII) • Receive status queue full (RCVI) • Receive data full (RXI) • Transmit data empty (TXI) • Communication error or communication event (EEI) - START condition detection (including repeated START condition) - STOP condition detection - HDR Exit Pattern detection - Timeout detection - Buffer access error detection - Data transfer abort - Data transfer error
Error detection	• Buffer access error • Address header error • Address NACKed or Dynamic Address Assignment NACKed • Receive overflow or transmit underflow error • Transfer abort • NACK is received during an I2C write data transfer • Timeout error
Event link output	• Receive data full event • Transmit data empty event • Communication error or communication event

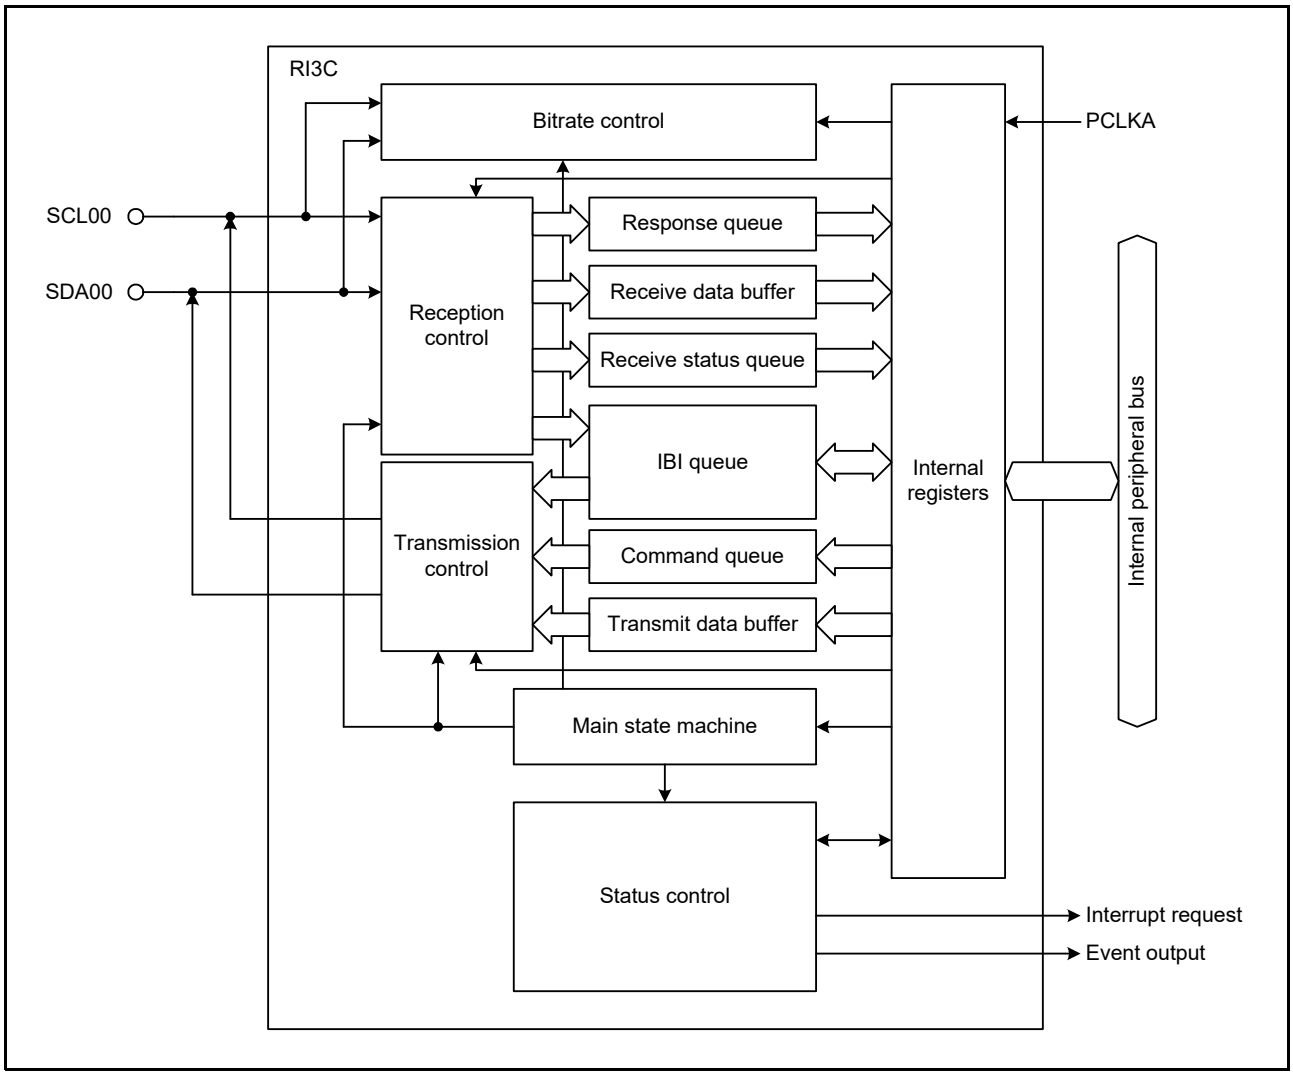

Figure 35.1 RI3C Block Diagram

Table 35.2 RI3C Pin Configuration

Channel	Pin Name	I/O	Function
RI3C0	SCL00	I/O	Serial clock I/O pin
	SDA00	I/O	Serial data I/O pin

35.2 Register Descriptions

35.2.1 Mode Register (ICMR)

Address(es): RI3C0.ICMR 000E C000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OMS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	OMS	Operating Mode Select	Set this bit to 0.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

OMS Bit (Operating Mode Select)

Set this bit to 0.

35.2.2 Control Register (ICCR)

Address(es): RI3C0.ICCR 000E C014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ICE	RESUME	ABORT	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	HJC	—	—	—	—	—	—	—	IBAINC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IBAINC	I3C Broadcast Address Include *1	0: Do not include I3C Broadcast Address for private transfers 1: Include I3C Broadcast Address for private transfers	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	HJC	Hot-Join Control*1	0: ACK the Hot-Join Request 1: NACK and send Broadcast CCC to disable Hot-Join	R/W
b28 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R
b29	ABORT	Host Controller Abort*1	Writing 1 to this bit aborts the currently issued transfer. Write 0 to this bit to clear the Aborted state. Values when read: 0: Aborted state is cleared. 1: RI3C remains in Aborted state.	R/W
b30	RESUME	Host Controller Resume	Writing 1 to this bit while RI3C is in the Halt state can resume the operation. Values when read: 0: RI3C is running. 1: RI3C is suspended.	R/W
b31	ICE	Bus Interface Enable	0: The I3C bus operation is disabled. (SCL00 and SDA00 pins in inactive state) 1: The I3C bus operation is enabled. (SCL00 and SDA00 pins in active state)	R/W

Note 1. This bit is used in I3C Primarily Controller and I3C Secondary Controller modes.

IBAINC Bit (I3C Broadcast Address Include)

This bit controls whether the I3C Broadcast Address (7Eh) is included for private transfers.

If the I3C Broadcast Address is not included for private transfers, then IBIs driven from Target devices might not win the arbitration, potentially delaying acceptance of the IBIs.

HJC Bit (Hot-Join Control)

This bit acts as global control to either ACK or NACK all Hot-Join Requests arriving from the devices on the I3C bus. If set to NACK, then the NACK will be followed by the Broadcast CCC to disable Hot-Join.

ABORT Bit (Host Controller Abort)

When 1 is written to this bit, RI3C starts the abort operation which terminates the currently issued transfer.

In response to an Abort request, RI3C issues the STOP condition to terminate the current transaction on the I3C bus after the complete data byte is transferred or received. At this time, this bit becomes 1.

To resume operation, write 0 to this bit.

If this bit is set to 1 to abort the transaction, ignore the ERR_STATUS field in the Response Descriptor.

RESUME Bit (Host Controller Resume)

This bit is used to resume I3C operation following the Halt state.
RI3C enters the Halt state as a result of any type of error occurring in a transfer. The error type is indicated by the ERR_STATUS field in Response Descriptor.
After RI3C has entered the Halt state, the application must write 1 to this bit to resume operation. This bit is automatically set to 0 when RI3C restarts the transfer (starting the next command).

ICE Bit (Bus Interface Enable)

Enables or disables the operation on the I3C bus.
When using RI3C, set this bit to 1. When this bit is 1, the SCL00 and SDA00 pins are active.
Set this bit to 0 when RI3C is not used. When the ICE bit is 0, the SCL00 and SDA00 pins are inactive.
When this bit is read as 0, it indicates that I3C bus operation is prohibited.

35.2.3 Controller Device Address Register (ICCAR)

Address(es): RI3C0.ICCAR 000E C018h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DAV	—	—	—	—	—	—	—	—	DADR[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b22 to b16	DADR[6:0]	Dynamic Address	Set the Dynamic Address of RI3C.	R/W
b30 to b23	—	Reserved	These bits are read as 0. The write value should be 0.	R
b31	DAV	Dynamic Address Valid	0: The DADR[6:0] bits are not valid. 1: The DADR[6:0] bits are valid.	R/W

Note: This register is used in I3C Primarily Controller mode.

This register is used to store the Dynamic Address of RI3C.
When the ICCR.ICE bit is set to 1 after setting this register, the device will act as Primary Controller.
If the ICCR.ICE bit is set to 1 after setting the ICDCTR.ROLE[1:0] bits to 00b (I3C Target) or the ICTDCTRm.ROLE[1:0] bits to 01b (I3C Controller capable) without setting this register, the device will act as Target.

DADR[6:0] Bits (Dynamic Address)

These bits are used to program RI3C Controller Dynamic Address. RI3C uses this address to respond to Controller transactions in I3C interface mode (Target or Secondary Controller mode).
In I3C Active Controller mode, the software shall program the Dynamic Address as it self-assigns its Dynamic Address.

DAV Bit (Dynamic Address Valid)

This bit indicates whether or not the value in the DADR[6:0] bits is valid.
In I3C Active Controller mode, set this bit to 1 as it self-assigns its Dynamic Address.

35.2.4 Reset Control Register (ICRCR)

Address(es): RI3C0.ICRCR 000E C020h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ISRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	SQRST	IQRST	RBRST	TBRST	RQRST	CQRST	MRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MRST	Module Reset*1	Writing 1 to this bit resets all registers and internal circuits. This bit automatically returns to 0 when the reset is complete.	R/W
b1	CQRST	Command Queue Reset	Writing 1 to this bit flushes the command queue. This bit automatically returns to 0 when the command queue has been flushed.	R/W
b2	RQRST	Response Queue Reset	Writing 1 to this bit flushes the response queue. This bit automatically returns to 0 when the response queue has been flushed.	R/W
b3	TBRST	Transmit Data Buffer Reset	Writing 1 to this bit flushes the transmit data buffer. This bit automatically returns to 0 when the transmit data buffer has been flushed.	R/W
b4	RBRST	Receive Data Buffer Reset	Writing 1 to this bit flushes the receive data buffer. This bit automatically returns to 0 when the receive data buffer has been flushed.	R/W
b5	IQRST	IBI Queue Reset	Writing 1 to this bit flushes the IBI queue. This bit automatically returns to 0 when the IBI queue has been flushed.	R/W
b6	SQRST	Receive Status Queue Reset*2	Writing 1 to this bit flushes the receive status queue. This bit automatically returns to 0 when the receive status queue has been flushed.	R/W
b15 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	ISRST	Internal Status Reset	0: Some registers and internal circuits are released from reset. 1: Some registers and internal circuits are reset.	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Do not write any value to this register when this bit is 1.
Note 2. This bit is used in I3C Secondary Controller and I3C Target modes.

ISRST Bit (Internal Status Reset)

When this bit is set to 1, some registers and internal circuits are reset. Refer to section 35.8, Reset Description for detail on the registers.
Set this bit to 0 to release from the reset.

35.2.5 Operating Mode Monitor Register (ICMMR)

Address(es): RI3C0.ICMMR 000E C024h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	WP	—	—	—	—	ACF	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b2	ACF	Active Controller Flag*2	0: RI3C is not the Active Controller. 1: RI3C is the Active Controller.	R/W*1
b6 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R
b7	WP	Write Protect*2	0: Writing to the ACF flag is disabled. 1: Writing to the ACF flag is enabled (when writing simultaneously with the value of the target bit).	W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. When setting a value to the ACF flag, set the WP bit to 1 at the same time.
Note 2. This bit is used in I3C Primarily Controller and I3C Secondary Controller modes.

ACF Flag (Active Controller Flag)

This flag indicates whether the RI3C is presently the Active Controller.
[Setting conditions]

- When 1 is written to the WP bit and the ACF flag at the same time.
- When 1 is written to the ICCAR.DAV bit. (in I3C Primarily Controller mode)
- When GETACCCR reception is successfully completed by issuing STOP condition, after the ACK is responded to the Controller Role Request transmitted to the Secondary Controller. (in I3C Primarily Controller mode)
- When GETACCCR reception is successfully completed by issuing STOP condition, after the ACK is responded to the Controller Role Request transmitted to the Active Controller. (in I3C Secondary Controller mode)

[Clearing conditions]

- When the RI3C is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.
- When 1 is written to the WP bit and 0 is written to the ACF flag at the same time.
- When 0 written to the ICCAR.DAV bit. (in I3C Primarily Controller mode)
- When GETACCCR transmission is successfully completed by issuing STOP condition, after responding ACK to the Controller Role Request received from the Secondary Controller. (in I3C Primarily Controller mode)
- When GETACCCR transmission is successfully completed by issuing STOP condition, after responding ACK to the Controller Role Request received from another Controller-capable device. (in I3C Secondary Controller mode)

WP Bit (Write Protect)

This bit is used to rewrite the ACF flag.
When setting a value to the ACF flag, set this bit to 1 at the same time.
This bit is automatically set to 0. The read value is 0.

35.2.6 Internal Status Register (ICISR)

Address(es): RI3C0.ICISR 000E C030h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	BERF	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b10	BERF	Buffer Access Error Flag	0: Buffer access error has not been detected. 1: Buffer access error was detected.	R/W*1
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. To clear this flag, confirm that the flag is 1 and then set it to 0.

BERF Flag (Buffer Access Error Flag)

This flag indicates that an access error to data buffers or queue buffers has been detected.

[Setting conditions]

When any of the following conditions is satisfied while the ICISER.BERDE bit is 1.

- When a transmit data is written while the transmit data buffer is completely full.
- When a received data is read while the receive data buffer is completely empty.
- When a Command Descriptor is written while the command queue is completely full.
- When a Response Descriptor is read while the response queue is completely empty.
- When a Receive Status Descriptor is read while the receive status queue is completely empty.
- When an IBI Status Descriptor is read while the ICMMR.ACF flag is 1 (Active Controller) and the IBI queue is completely empty.
- When an IBI data is written while the ICMMR.ACF flag is 0 (not Active Controller) and the IBI queue is completely full.
- When the response queue, IBI queue, or receive status queue overflows.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.

35.2.7 Internal Status Detection Enable Register (ICISER)

Address(es): RI3C0.ICISER 000E C034h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	BERDE	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b10	BERDE	Buffer Access Error Detection Enable	0: Buffer access error detection is disabled. 1: Buffer access error detection is enabled.	R/W
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R

35.2.8 Internal Status Interrupt Enable Register (ICISIER)

Address(es): RI3C0.ICISIER 000E C038h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	BERIE	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b10	BERIE	Buffer Access Error Detection Interrupt Enable	0: Buffer access error detection interrupt is disabled. 1: Buffer access error detection interrupt is enabled.	R/W
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R

BERIE Bit (Buffer Access Error Detection Interrupt Enable)

When the BERF flag becomes 1 while this bit is 1, an interrupt is generated.

35.2.9 Device Characteristics Table Index Register (ICDCTIR)

Address(es): RI3C0.ICDCTIR 000E C044h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	INDEX[4:0]					—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b18 to b0	—	Reserved	These bits are read as 0.	R
b23 to b19	INDEX[4:0]	DCT Table Index	Current index of the DCT, which is used as the starting index for the I3C ENTDAA CCC.	R
b31 to b24	—	Reserved	These bits are read as 0.	R

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

INDEX[4:0] Bits (DCT Table Index)

Once the complete characteristics of device that won the arbitration are written to the Device Characteristics Table (DCT) during ENTDAA using address assignment command, this index is incremented by 1.

35.2.10 IBI Notify Control Register (ICINCR)

Address(es): RI3C0.ICINCR 000E C058h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	RTIRN	—	RCRRN	RHJRN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RHJRN	Rejected Hot-Join Request Notify	0: Do not pass the rejected IBI status to the IBI queue, if a Hot-Join Request is rejected. 1: Pass the rejected IBI status to the IBI queue, if a Hot-Join Request is rejected.	R/W
b1	RCRRN	Rejected Controller Role Request Notify	0: Do not pass the rejected IBI status to the IBI queue, if a Controller Role Request is rejected. 1: Pass the rejected IBI status to the IBI queue, if a Controller Role Request is rejected.	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R
b3	RTIRN	Rejected Target Interrupt Request Notify	0: Do not pass the rejected IBI status to the IBI queue, if a Target Interrupt Request is rejected. 1: Pass the rejected IBI status to the IBI queue, if a Target Interrupt Request is rejected.	R/W
b31 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

RHJRN Bit (Rejected Hot-Join Request Notify)

This bit enables or disables reporting rejection of individual Hot-Join Requests, if the incoming Hot-Join Request is NACKed and is auto-disabled based on the setting of the ICCR.HJC bit.

RCRRN Bit (Rejected Controller Role Request Notify)

This bit enables or disables reporting rejection of individual Controller Role Requests (CRR), if the incoming CRR is NACKed and is auto-disabled based on the setting of the relevant ICTDATRm.CRRRJ bit (m = 0 to 3).

RTIRN Bit (Rejected Target Interrupt Request Notify)

This bit enables or disables reporting rejection of individual Target Interrupt Requests (TIR), if the incoming TIR is NACKed and is auto-disabled based on the setting of the relevant ICTDATRm.TIRRJ bit (m = 0 to 3).

35.2.11 Target Mode Control Register (ICTCR)

Address(es): RI3C0.ICTCR 000E C064h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TA0DE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	TA0DE	Target Address 0 Detection Enable*1	0: The value of the ICDAMR0.TADR[9:0] bits is disabled. 1: The value of the ICDAMR0.TADR[9:0] bits is enabled.	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. These bits are used in I3C Secondary Controller and I3C Target modes.

TA0DE Bit (Target Address 0 Detection Enable)

This bit is used to enable or disable the Target address set in ICDAMR0.TADR[9:0] bits.

When this bit is set to 1, the Target address set in ICDAMR0.TADR[9:0] bits is enabled and is compared with the received Target address.

When this bit is set to 0, the Target address set in ICDAMR0.TADR[9:0] bits is disabled and is ignored even if it matches the received Target address.

35.2.12 Standard Bitrate Register (ICSBR)

Address(es): RI3C0.ICSBR 000E C074h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ODDBL	—	PPHW[5:0]						—	—	PPLW[5:0]					
Value after reset:	0	0	1	1	1	1	1	1	0	0	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ODHW[7:0]								ODLW[7:0]							
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	ODLW[7:0]	Open-Drain Low Width Setting*1	Count value for the low period of SCL in Open-Drain mode.	R/W
b15 to b8	ODHW[7:0]	Open-Drain High Width Setting*1	Count value for the high period of SCL in Open-Drain mode.	R/W
b21 to b16	PPLW[5:0]	Push-Pull Low Width Setting*1	Count value for the low period of SCL in Push-Pull mode.	R/W
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R
b29 to b24	PPHW[5:0]	Push-Pull High Width Setting*1	Count value for the high period of SCL in Push-Pull mode.	R/W
b30	—	Reserved	These bits are read as 0. The write value should be 0.	R
b31	ODDBL	Open-Drain High/Low Width Doubling*1	0: Set the high and low widths to the set value in Open-Drain mode. 1: Double the high and low widths of the set values in Open-Drain mode.	R/W

Note 1. These bits are used in I3C Primarily Controller and I3C Secondary Controller modes.

This register is used to set the bit rate when the I3C SDR0 mode is specified in the MODE field of the Command Descriptor. When the I3C SDR2 mode is specified, a bit rate of 1/2 the bit rate set in this register is used.

ODLW[7:0] Bits (Open-Drain Low Width Setting)

The ODLW[7:0] bits are used to set the low period of SCL in Open-Drain mode.
The RI3C counts the low period with PCLKA.

ODHW[7:0] Bits (Open-Drain High Width Setting)

The ODHW[7:0] bits are used to set the high period of SCL in Open-Drain mode.
These bits are valid in Controller mode.
The RI3C counts the high period with PCLKA.

PPLW[5:0] Bits (Push-Pull Low Width Setting)

The PPLW[5:0] bits are used to set the low period of SCL in Push-Pull mode.
RI3C counts the low period with PCLKA.

PPHW[5:0] Bits (Push-Pull High Width Setting)

The PPHW[5:0] bits are used to set the high period of SCL in Push-Pull mode.
These bits are valid in Controller mode.
RI3C counts the high period with PCLKA.

The transfer rate and the duty cycle are calculated using the following expression.

t_{LOW} = ODLW[7:0] / PCLKA
t_{HIGH} = ODHW[7:0] / PCLKA
Transfer rate = 1 / (t_{LOW} + t_{HIGH} + t_r + t_f)
Duty cycle = (t_r + t_{HIGH}) / (t_{LOW} + t_{HIGH} + t_r + t_f)

t_{LOW}: Low period of the SCL
t_{HIGH}: high period of the SCL
t_r: Rise time of the SCL signal*1
t_f: Fall time of the SCL signal*1

Note 1. The SCL line rise time [t_r] and SCL line fall time [t_f] depend on the total bus line capacitance [C_b] and the pull-up resistor [R_p]. For details, refer to the I3C bus standard from MIPI Alliance.

35.2.13 Extended Bitrate Register (ICEBR)

Address(es): RI3C0.ICEBR 000E C078h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	PPHW[5:0]						—	—	PPLW[5:0]					
Value after reset:	0	0	1	1	1	1	1	1	0	0	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ODHW[7:0]								ODLW[7:0]							
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	ODLW[7:0]	Open-Drain Low Width Setting*1	Count value for the low period of SCL in Open-Drain mode.	R/W
b15 to b8	ODHW[7:0]	Open-Drain High Width Setting*1	Count value for the high period of SCL in Open-Drain mode.	R/W
b21 to b16	PPLW[5:0]	Push-Pull Low Width Setting*1	Count value for the low period of SCL in Push-Pull mode.	R/W
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R
b29 to b24	PPHW[5:0]	Push-Pull Low Width Setting*1	Count value for the high period of SCL in Push-Pull mode.	R/W
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. These bits are used in I3C Primarily Controller and I3C Secondary Controller modes.

This register is used to set the bit rate when the I3C SDR1 mode is specified in the MODE field of the Command Descriptor. When the I3C SDR3 mode is specified, a bit rate of 1/2 the bit rate set in this register is used. When the I3C SDR4 mode is specified, a bit rate of 1/4 the bit rate set in this register is used.

ODLW[7:0] Bits (Open-Drain Low Width Setting)

The ODLW[7:0] bits are used to set the low period of SCL in Open-Drain mode.
The RI3C counts the low period with PCLKA.

ODHW[7:0] Bits (Open-Drain High Width Setting)

The ODHW[7:0] bits are used to set the high period of SCL in Open-Drain mode.
These bits are valid in Controller mode.
The RI3C counts the high period with PCLKA.

PPLW[5:0] Bits (Push-Pull Low Width Setting)

The PPLW[5:0] bits are used to set the low period of SCL in Push-Pull mode.
The RI3C counts the low period with the PCLKA.

PPHW[5:0] Bits (Push-Pull Low Width Setting)

The PPHW[5:0] bits are used to set the high period of SCL in Push-Pull mode.
These bits are valid in Controller mode.
The RI3C counts the high period with the PCLKA.

The transfer rate and the duty cycle are calculated using the following expression.

t_{LOW} = ODLW[7:0] / PCLKA
t_{HIGH} = ODHW[7:0] / PCLKA
Transfer rate = 1 / (t_{LOW} + t_{HIGH} + t_r + t_f)
Duty cycle = (t_r + t_{HIGH}) / (t_{LOW} + t_{HIGH} + t_r + t_f)

t_{LOW}: Low period of the SCL
t_{HIGH}: high period of the SCL
t_r: Rise time of the SCL signal*1
t_f: Fall time of the SCL signal*1

Note 1. The SCL line rise time [t_r] and SCL line fall time [t_f] depend on the total bus line capacitance [C_b] and the pull-up resistor [R_p]. For details, refer to the I3C bus standard from MIPI Alliance.

35.2.14 Bus Free Time Setting Register (ICBFTR)

Address(es): RI3C0.ICBFTR 000E C07Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to specify the time from when the STOP condition is detected until the ICBSR.BFREE flag is set to 1. The upper 23 bits are reserved. These bits are read as 0 and the write value should be 0.
The number set in this register is counted using PCLKA as the count source.

35.2.15 Bus Available Time Setting Register (ICBATR)

Address(es): RI3C0.ICBATR 000E C080h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to specify the time from when the STOP condition is detected until the ICBSR.BAVL flag is set to 1. The upper 23 bits are reserved. These bits are read as 0 and the write value should be 0.
The number set in this register is counted using PCLKA as the count source.

35.2.16 Bus Idle Time Setting Register (ICBITR)

Address(es): RI3C0.ICBITR 000E C084h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to specify the time from when the STOP condition is detected until the ICBSR.BIDL flag is set to 1.
The upper 14 bits are reserved. These bits are read as 0 and the write value should be 0.
The number set in this register is counted using PCLKA as the count source.

35.2.17 Output Signal Control Register (ICOCR)

Address(es): RI3C0.ICOCR 000E C088h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	SOWP	SCLO	SDAO
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	SDAO	SDA Output Control*1	0: The RI3C drives the SDA00 pin low. 1: The RI3C releases the SDA00 pin.	R/W
b1	SCLO	SCL Output Control*1	0: The RI3C drives the SCL00 pin low. 1: The RI3C releases the SCL00 pin.	R/W
b2	SOWP	SCLO/SDAO Write Protect*1	0: Writing to the SCLO and SDAO bits is disabled. 1: Writing to the SCLO and SDAO bits is enabled (when writing simultaneously with the value of the target bit). This bit is read as 0.	W
b31 to b3	—	Reserved	This bit is read as 0. The write value should be 0.	R

Note 1. This bit is used in I3C Primarily Controller and I3C Secondary Controller modes.

SDAO Bit (SDA Output Control) and SCLO Bit (SCL Output Control)

These bits are used to directly control the SDA00 and SCL00 signals output from the RI3C.

When writing to these bits, also write 1 to the SOWP bit at the same time.

The result of setting these bits is input to the RI3C via the input buffer. When Target mode is selected, a START condition may be detected and the bus may be released depending on the bit settings.

Do not rewrite these bits during a START condition, STOP condition, repeated START condition, transmission, or reception. Operation after rewriting under the above conditions is not guaranteed.

35.2.18 Timeout Control Register (ICTOR)

Address(es): RI3C0.ICTOR 000E C090h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TMOM[1:0]		TMOH	TMOL	—	—	TMOS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	TMOS[1:0]	Timeout Detection Time Select	b1 b0 0 0: Timeout counter is 16 bits (up to 65536 counts) 0 1: Timeout counter is 14 bits (up to 16384 counts) 1 0: Timeout counter is 8 bits (up to 256 counts) 1 1: Timeout counter is 6 bits (up to 64 counts)	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b4	TMOL	Timeout L Count Control	0: Count is disabled while the SCL00 line is low. 1: Count is enabled while the SCL00 line is low.	R/W
b5	TMOH	Timeout H Count Control	0: Count is disabled while the SCL00 line is high. 1: Count is enabled while the SCL00 line is high.	R/W
b7, b6	TMOM[1:0]	Timeout Detection Mode Select	b7 b6 0 0: Timeout function is enabled in any of the following conditions. • When the ICBSR.BFREE flag is 0 (bus busy) in Controller mode • When the ICBSR.BFREE flag is 0 (bus busy) when the received Target address matches its own Target address in Target mode 0 1: Timeout function is enabled during ICBSR.BFREE flag is 0 (bus busy). 1 0: Timeout function is enabled during ICBSR.BFREE flag is 1 (bus free). 1 1: Setting prohibited	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

TMOS[1:0] Bits (Timeout Detection Time Select)

These bits are used to select for the timeout detection time when the timeout function is enabled (ICSER.TMOE bit = 1). While the SCL00 line is in the state that enables this counter as specified by bits TMOH and TMOL, the counter counts up in synchronization with PCLKA as a count source.

For details on the timeout function, refer to 35.5.5.3 Timeout Error Detection in section 35.5.5, Error Detection.

TMOL Bit (Timeout L Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL00 line is held low when the timeout function is enabled (ICSER.TMOE bit = 1).

TMOH Bit (Timeout H Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL00 line is held high when the timeout function is enabled (ICSER.TMOE bit = 1).

TMOM[1:0] Bits (Timeout Detection Mode Select)

These bits are used to set the timeout detection condition when the timeout function is enabled (ICSER.TMOE bit = 1).

When these bits are set to 00b, timeout detection is enabled during one of the following periods.

- When the bus is busy in Controller mode
- When RI3C is the target of the communication in Target mode and the bus is busy

When these bits are set to 01b, timeout detection is enabled when the bus is busy.

When these bits are set to 10b, timeout detection is enabled when the bus is free.

35.2.19 Clock Stall Control Register (ICSTCR)

Address(es): RI3C0.ICSTCR 000E C0B0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	APSE	PBSE	—	AASE	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	STT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	STT[15:0]	Stall Time Setting	Set the clock stall time for each phase.	R/W
b27 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R
b28	AASE	Assigned Address Phase Stall Enable	0: Do not stall SCL before the Assigned Address phase. 1: Stall SCL before the Assigned Address phase.	R/W
b29	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b30	PBSE	Parity Bit Stall Enable	0: Does not stall the SCL during the parity bit period. 1: Stall the SCL during the parity bit period.	R/W
b31	APSE	ACK/NACK Phase Stall Enable	0: Does not stall the SCL during the ACK/NACK phase. 1: Stall the SCL during the ACK/NACK phase.	R/W

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

When setting this register, follow section 5.1.2.5, Controller Clock Stalling of MIPI I3C Specification, and use it only when necessary because of its negative impacts on bus performance.

STT[15:0] Bits (Stall Time Setting)

These bits is used to set the SCL stall time. The SCL stall time is counted by PCLKA. This is a counter common to the enable bits of each phase.

AASE Bit (Assigned Address Phase Stall Enable)

This bit is used to select whether the Controller stalls SCL during the low period of the first bit of the Assigned Address phase of the ENTDAA CCC command. It can gain time in assigning Dynamic Address to the Device based on the BCR and DCR of the Target. However, because the Dynamic Address Assignment procedure sends the Dynamic Address set in the ICTDATRm register in sequence, it is not necessary to set this bit and it is prohibited.

PBSE Bit (Parity Bit Stall Enable)

This bit is used to select whether the Controller stalls SCL at the parity bit of the transmit data of I3C write transfer to avoid underrun of the transmit FIFO. However, when the transmit FIFO of the I3C Controller becomes empty, SCL stalling is performed regardless of the setting of this bit, it is not necessary to set this bit and it is prohibited.

APSE Bit (ACK/NACK Phase Stall Enable)

Determine the need to perform SCL stalling during the ACK/NACK phase based on the following criteria:

- It is necessary to set this bit when the I3C and I^2C Targets connected to the bus require preparation time to receive or transmit data.
- In legacy I^2C communication, if there is a possibility that the FIFO of the I3C Controller might underrun or overrun. It is not necessary to set this bit because SCL stalling is performed by FIFO Empty or Full regardless of the setting

of this bit.

- Other than legacy I2C communication, the FIFO of I3C Controller might underrun or overrun, and if SCL stalling is required in ACK phase, this bit can be set. However, it is necessary to build the software so that the FIFO does not underrun or overrun due to the interrupt generated according to the FIFO threshold setting (ICQBTCR, ICDBTCR, ICSQTCR).
- When I3C Controller responds ACK/NACK to IBI, it is not necessary to set this bit because ACK/NACK response can be set in advance by ICCR.HJC, ICTDATRm.CRRRJ, and ICTDATRm.TIRRJ.
- It is necessary to set this bit when the I3C Target connected to the bus requires preparation time to transmit data for Direct GET CCC.

35.2.20 Target Transmit/Receive Data Length Register (ICTDLR)

Address(es): RI3C0.ICTDLR 000E C0C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DLGTH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b31 to b16	DLGTH[15:0]	Data Length	Indicates the number of bytes to be transferred.	R/W

Note: This register is used in I3C Secondary Controller and I3C Target modes.

This register is used to set the number of bytes of data to be transmitted with the regular data transfer command.

35.2.21 Command Queue Register (ICCQR)

Address(es): RI3C0.ICCQR 000E C150h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ICCQR register is a 32-bit write-only register used to enqueue Command Descriptors into the command queue. Command Descriptors should be written in order from lower (b31-b0) to higher (b63-b32).
Refer to section 35.3.1, Command Descriptor for details on Command Descriptors.

35.2.22 Response Queue Register (ICRQR)

Address(es): RI3C0.ICRQR 000E C154h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ICRQR register is a 32-bit read-only register used to read the Response Descriptors generated in the response queue after a command has been processed.
Refer to section 35.3.2, Response Descriptor for details on Response Descriptors.

35.2.23 Transmit/Receive Data Register (ICDR)

Address(es): RI3C0.ICDR 000E C158h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ICDR register is a 32-bit read/write register used to read data from the receive data buffer and write data to the transmit data buffer.

For Read Operation:

Receive data is stored in the receive data buffer every 4 bytes. If the number of data received is not an integer multiple of 4 bytes, the last 32 bits of the stored data will contain invalid bytes. Check the number of valid data bytes in the DATA_LENGTH field of the Response Descriptor.

For Write Operation:

Transmit data must be written to the ICDR register in 4-byte units. If the number of data to be transmitted is not an integer multiple of 4 bytes, add dummy data after the final data to make it 4 bytes before writing to the ICDR register. RI3C sends the number of bytes of data specified in the DATA_LENGTH field of the Command Descriptor.

35.2.24 IBI Queue Register (ICIQR)

Address(es): RI3C0.ICIQR 000E C17Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ICIQR register is a 32-bit read-only register used to read an IBI Status Descriptor and IBI data from the IBI queue after an IBI has been received.
Refer to section 35.3.3, IBI Status Descriptor for details on IBI Status Descriptors.

35.2.25 Receive Status Queue Register (ICSQR)

Address(es): RI3C0.ICSQR 000E C180h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register is used in I3C Secondary Controller and I3C Target modes.

The ICSQR register is a 32-bit read-only register used to read an Receive Status Descriptor from the receive status queue.
Refer to section 35.3.4, Receive Status Descriptor for details on Receive Status Descriptors.

35.2.26 Queue Buffer Threshold Control Register (ICQBTCR)

Address(es): RI3C0.ICQBTCR 000E C190h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	IQTH[7:0]								IDSS[7:0]							
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	RQTH[7:0]								CQTH[7:0]							
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CQTH[7:0]	Command Queue Empty Interrupt Threshold Setting	00h: Interrupt is generated when command queue is completely empty. 01h: Interrupt is generated when command queue has one free entry. Settings other than above are prohibited.	R/W
b15 to b8	RQTH[7:0]	Response Queue Full Interrupt Threshold Setting	00h: Interrupt is generated when response queue contains one entry (4 bytes). 01h: Interrupt is generated when response queue contains two entries (8 bytes). Settings other than above are prohibited.	R/W
b23 to b16	IDSS[7:0]	IBI Data Segment Size Setting*1	Set the maximum size of IBI data segments in 4-byte units. Setting range: 1 (4 bytes) to 5 (20 bytes)	R/W
b31 to b24	IQTH[7:0]	IBI Queue Empty/Full Interrupt Threshold Setting	• I3C Controller mode: 00h: Interrupt is generated when there is at least one outstanding IBI status. 01h: Interrupt is generated when there are two outstanding IBI status. Settings other than above are prohibited. • I3C Target mode: 00h: Interrupt is generated when IBI queue is completely empty. 01h: Interrupt is generated when IBI queue has one free entry. : 05h: Interrupt is generated when IBI queue has five free entries. Settings other than above are prohibited.	R/W

Note 1. These bits are used in I3C Primarily Controller and I3C Secondary Controller modes.

This register controls the interrupt generation thresholds for the command queue, response queue, and IBI queue.

CQTH[7:0] Bits (Command Queue Empty Interrupt Threshold Setting)

These bits control the minimum number of free command queue entries needed to generate the command queue empty interrupt (CMDI).

RQTH[7:0] Bits (Response Queue Full Interrupt Threshold Setting)

These bits control the minimum number of response queue entries needed to generate the response queue full interrupt (RESPI).

IDSS[7:0] Bits (IBI Data Segment Size Setting)

These bits specify the maximum size of IBI data segments in 4-byte units.

These bits allow the incoming IBI data to be sliced into multiple segments generating status individually, to support cut-

through readout of a long IBI payload data.

IQTH[7:0] Bits (IBI Queue Empty/Full Interrupt Threshold Setting)

(1) For I3C Controller mode (ICMMR.ACF flag = 1):

These bits control generation of the IBI queue empty/full interrupt (IBII), based on the value of the number of outstanding IBI status in the IBI queue.

Each IBI status entry can represent either the complete IBI payload (if the IBI payload size is 4 × IDSS[7:0] bytes or less), or a segment of the IBI payload (if the IBI payload size is more than 4 × IDSS[7:0] bytes).

(2) For I3C Target mode (ICMMR.ACF flag = 0):

These bits control the minimum number of free IBI data buffer entries needed to generate the IBI queue empty/full interrupt (IBII).

35.2.27 Data Buffer Threshold Control Register (ICDBTCR)

Address(es): RI3C0.ICDBTCR 000E C194h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	RSTH[2:0]			—	—	—	—	—	TSTH[2:0]		
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	RFTH[2:0]			—	—	—	—	—	TETH[2:0]		
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	TETH[2:0]	Transmit Data Empty Interrupt Threshold Setting	b2 b0 0 0 0: Interrupt is generated when the free level of the transmit data buffer reaches 2 stages (8 bytes). 0 0 1: Reserved Settings other than above are prohibited.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R
b10 to b8	RFTH[2:0]	Receive Data Full Interrupt Threshold Setting	b10 b8 0 0 0: Interrupt is generated when the fill level of the receive data buffer reaches 2 stages (5 to 8 bytes). 0 0 1: Reserved Settings other than above are prohibited.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R
b18 to b16	TSTH[2:0]	Transmit Start Threshold Setting *1	b18 b16 0 0 0: Transmission starts when the fill level of the transmit data buffer reaches 2 stages (5 to 8 bytes). 0 0 1: Reserved Settings other than above are prohibited.	R/W
b23 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R
b26 to b24	RSTH[2:0]	Receive Start Threshold Setting *1	b26 b24 0 0 0: Reception starts when the free level of the receive data buffer reaches 2 stages (8 bytes). 0 0 1: Reserved Settings other than above are prohibited.	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. These bits are used in I3C Primarily Controller and I3C Secondary Controller modes.

The ICDBTCR register controls the interrupt trigger thresholds for the receive data buffer and the transmit data buffer.

TETH[2:0] Bits (Transmit Data Empty Interrupt Threshold Setting)

These bits specify the minimum number of free transmit data buffer stages needed to generate the transmit data empty interrupt (TXI).

RFTH[2:0] Bits (Receive Data Full Interrupt Threshold Setting)

These bits specify the minimum number of filled receive data buffer stages needed to generate the receive data full interrupt (RXI).

TSTH[2:0] Bits (Transmit Start Threshold Setting)

When preparing to initiate a Write Transfer on the I3C bus, RI3C waits until the indicated number of stages of data have been written to the transmit buffer.

RSTH[2:0] Bits (Receive Start Threshold Setting)

When preparing to initiate a Read Transfer on the I3C bus, RI3C waits until the receive buffer has the indicated number of free stages to receive the data bytes.

35.2.28 Receive Status Queue Threshold Control Register (ICSQTCR)

Address(es): RI3C0.ICSQTCR 000E C1C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	SQTH[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	SQTH[7:0]	Receive Status Queue Full Interrupt Threshold Setting	00h: Interrupt is generated when receive status queue contains one entry (4 bytes). 01h: Interrupt is generated when receive status queue contains two entries (8 bytes). Settings other than above are prohibited.	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

SQTH[7:0] Bits (Receive Status Queue Full Interrupt Threshold Setting)

These bits control the minimum number of receive status queue entries needed to generate the receive status queue full interrupt (RCVI).

35.2.29 Status Register 2 (ICSR2)

Address(es): RI3C0.ICSR2 000E C1D0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	TMOF	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	HDRXDF	STOP	START
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	START	START Condition Detection Flag	0: START condition is not detected. 1: START condition is detected.	R/(W) *1
b1	STOP	STOP Condition Detection Flag	0: STOP condition is not detected. 1: STOP condition is detected.	R/(W) *1
b2	HDRXDF	HDR Exit Pattern Detection Flag	0: HDR Exit Pattern is not detected. 1: HDR Exit Pattern is detected.	R/(W) *1
b19 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	TMOF	Timeout Detection Flag	0: Timeout is not detected. 1: Timeout is detected.	R/(W) *1
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Only 0 can be written to this bit.

START Flag (START Condition Detection Flag)

[Setting condition]

- When a START condition (or a repeated START condition) is detected while the ICSER.STDE bit is 1.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When a STOP condition is detected.
- When the RI3C is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

STOP Flag (STOP Condition Detection Flag)

[Setting condition]

- When a STOP condition is detected while the ICSER.SPDE bit is 1.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When the RI3C is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

HDRXDF Flag (HDR Exit Pattern Detection Flag)

[Setting condition]

- When a HDR Exit Pattern is detected while the ICSER.HDRXDE bit is 1.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.

TMOF Flag (Timeout Detection Flag)

[Setting condition]

- All of the following 1 to 3 are satisfied.
  1. The ICSER.TMOE bit is 1 (timeout detection is enabled).
  2. When the Controller mode or the received Target address matches the Target address n in Target mode.
  3. When the SCL00 line state remains unchanged for the period specified by ICTOR register.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.

35.2.30 Status Detection Enable Register (ICSER)

Address(es): RI3C0.ICSER 000E C1D4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	TMOE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	HDRXDE	SPDE	STDE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STDE	START Condition Detection Enable	0: START condition detection is disabled. 1: START condition detection is enabled.	R/W
b1	SPDE	STOP Condition Detection Enable	0: STOP condition detection is disabled. 1: STOP condition detection is enabled.	R/W
b2	HDRXDE	HDR Exit Pattern Detection Enable	0: HDR Exit Pattern detection is disabled. 1: HDR Exit Pattern detection is enabled.	R/W
b19 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	TMOE	Timeout Detection Enable	0: Timeout detection is disabled. 1: Timeout detection is enabled.	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R

This register is used to enable or disable detection of each status. When the status enabled by this register is detected, the corresponding flag in the ICSR2 register is set to 1.

35.2.31 Status Interrupt Enable Register (ICSIER)

Address(es): RI3C0.ICSIER 000E C1D8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	TMOIE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	HDRXIE	SPIE	STIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STIE	START Condition Detection Interrupt Enable	0: START condition detection interrupt is disabled. 1: START condition detection interrupt is enabled.	R/W
b1	SPIE	STOP Condition Detection Interrupt Enable	0: STOP condition detection interrupt is disabled. 1: STOP condition detection interrupt is enabled.	R/W
b2	HDRXIE	HDR Exit Pattern Detection Interrupt Enable	0: HDR Exit Pattern detection interrupt is disabled. 1: HDR Exit Pattern detection interrupt is enabled.	R/W
b19 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20	TMOIE	Timeout Detection Interrupt Enable	0: Timeout detection interrupt is disabled. 1: Timeout detection interrupt is enabled.	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R

This register is used to enable or disable interrupts for each status. When a flag in the ICSR2 register becomes 1 and the corresponding interrupt enable bit is 1, an interrupt request is output.

35.2.32 Communication Status Register (ICCSR)

Address(es): RI3C0.ICCSR 000E C1E0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	SQFF	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	DTEF	—	—	—	DTAF	RQFF	CQEF	IQEFF	RDRF	TDRE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TDRE	Transmit Data Empty Flag	0: The free level of the transmit data buffer is less than the threshold specified by the ICDBTCR.TETH[2:0] bits. 1: The free level of the transmit data buffer is equal to or more than the threshold specified by the TETH[2:0] bits.	R/(W) *1
b1	RDRF	Receive Data Full Flag	0: The fill level of the receive data buffer is less than the threshold specified by the ICDBTCR.RFTH[2:0] bits 1: The fill level of the receive data buffer is equal to or more than the threshold specified by the RFTH[2:0] bits.	R/(W) *1
b2	IQEFF	IBI Queue Empty/Full Flag	• In I3C Controller mode 0: The number of IBI statuses in IBI queue is less than the threshold specified by the ICQBTCR.IQTH[7:0] bits. 1: The number of IBI statuses in IBI queue is equal to or more than the threshold specified by the IQTH[7:0] bits. • In I3C Target mode and if the IQTH[7:0] bits are 00h: 0: IBI queue contains entry. 1: IBI queue contains no entries. • In I3C Target mode and if the IQTH[7:0] bits are not 00h: 0: The number of free IBI queue entries is less than the threshold specified by the IQTH[7:0] bits. 1: The number of free IBI queue entries is equal to or more than the threshold specified by the IQTH[7:0] bits.	R/(W) *1
b3	CQEF	Command Queue Empty Flag	• If the ICQBTCR.CQTH[7:0] bits are 00h: 0: Command queue contains data. 1: Command queue contains no data. • If the CQTH[7:0] bits are not 00h: 0: The number of free command queue entries is less than the threshold specified by the CQTH[7:0] bits. 1: The number of free command queue entries is equal to or more than the threshold specified by the CQTH[7:0] bits.	R/(W) *1
b4	RQFF	Response Queue Full Flag	0: The number of response queue entries is less than the threshold specified by the ICQBTCR.RQTH[7:0] bits. 1: The number of response queue entries is equal to or more than the threshold specified by the RQTH[7:0] bits.	R/(W) *1
b5	DTAF	Data Transfer Abort Flag	0: Data transfer abort does not occur. 1: Data transfer abort occurs.	R/(W) *1
b8 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R
b9	DTEF	Data Transfer Error Flag	0: Data transfer error does not occur. 1: Data transfer error occurs.*2	R/(W) *1
b19 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	SQFF	Receive Status Queue Full Flag *3	0: The number of receive status queue entries is less than the threshold specified by the ICSQTCR.SQTH[7:0] bits. 1: The number of receive status queue entries is equal to or more than the threshold specified by the SQTH[7:0] bits.	R/(W) *1
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. To clear this flag, confirm that the flag is 1 and then set it to 0.

Note 2. The Error type for this error is available in the Response or Receive Status Descriptor structure corresponding to the transfer or command.
Note 3. This bit is used in I3C Secondary Controller and I3C Target modes.

TDRE Flag (Transmit Data Empty Flag)

[Setting condition]

- When the free level of the transmit data buffer is equal to or more than the threshold specified by the ICDBTCR.TETH[2:0] bits while the ICCSER.TDE bit is 1 (detection of transmit data empty is enabled).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last write access to the transmit data buffer by DMAC/DTC.
- When the free level of the transmit data buffer is less than the threshold specified by the TETH[2:0] bits.

RDRF Flag (Receive Data Full Flag)

[Setting condition]

- When the fill level of the receive data buffer is equal to or more than the threshold specified by the ICDBTCR.RFTH[2:0] bits while the ICCSER.RDE bit is 1 (detection of receive data full is enabled).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last read access to the receive data buffer by DMAC/DTC.
- When the fill level of the receive data buffer is less than the threshold specified by the RFTH[2:0] bits.

IQEFF Flag (IBI Queue Empty/Full Flag)

[Setting condition]

When any of the following conditions is satisfied while the ICCSER.IQEFDE bit is 1 (detection of IBI queue empty/full is enabled).

In I3C Controller mode:

- When the number of the IBI queue entries is equal to or more than the threshold specified by the ICQBTCR.IQTH[7:0] bits.

In I3C Target mode:

- When the IBI queue is completely empty (when the IQTH[7:0] bits are 00h).
- When the number of the free IBI queue entries is equal to or more than the threshold specified by the IQTH[7:0] bits (when the IQTH[7:0] bits are other than 00h).

[Clearing condition]

In I3C Controller mode:

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last read access to the IBI queue by DMAC/DTC.
- When the number of the IBI queue entries is less than the threshold specified by the IQTH[7:0] bits.

In I3C Target mode:

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last write access to the IBI queue by DMAC/DTC.
- When the IBI queue is not completely empty (when the IQTH[7:0] bits are 00h).
- When the number of the free IBI queue entries is less than the threshold specified by the IQTH[7:0] bits (when the IQTH[7:0] bits are other than 00h).

CQEF Flag (Command Queue Empty Flag)

[Setting condition]

When any of the following conditions is satisfied while the ICCSER.CQEDE bit is 1 (detection of command queue empty is enabled).

- When the command queue is completely empty (when the ICQBTCR.CQTH[7:0] bits are 00h).
- When the number of the free command queue entries is equal to or more than the threshold specified by the CQTH[7:0] bits (when the CQTH[7:0] bits are other than 00h).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last write access to the command queue by DMAC/DTC.
- When the command queue is not completely empty (when the CQTH[7:0] bits are 00h).
- When the number of the free command queue entries is less than the threshold specified by the CQTH[7:0] bits (when the CQTH[7:0] bits are other than 00h).

RQFF Flag (Response Queue Full Flag)

[Setting condition]

- When the number of the response queue entries is more than the threshold specified by the ICQBTCR.RQTH[7:0] bits while the ICCSER.RQFDE bit is 1 (detection of response queue full is enabled).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last read access to the response queue by DMAC/DTC.
- When the number of the response queue entries is equal to or less than the threshold specified by the RQTH[7:0] bits.

DTAF Flag (Data Transfer Abort Flag)

[Setting condition]

- When any data transfer is aborted while the ICCSER.DTADE bit is 1 (detection of data transfer abort is enabled).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.

DTEF Flag (Data Transfer Error Flag)

[Setting condition]

- When any data transfer error occurs on the I3C bus while the ICCSER.DTEDE bit is 1 (detection of data transfer error is enabled).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.

SQFF Flag (Receive Status Queue Full Flag)

[Setting condition]

- When the number of the receive status queue entries is equal to or more than the threshold specified by the ICSQTCR.SQTH[7:0] bits while the ICCSER.SQFDE bit is 1 (detection of receive status queue full is enabled).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last read access to the receive status queue by DMAC/DTC.
- When the number of the receive status queue entries is less than the threshold specified by the SQTH[7:0] bits.

35.2.33 Communication Status Detection Enable Register (ICCSER)

Address(es): RI3C0.ICCSER 000E C1E4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	SQFDE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	DTEDE	—	—	—	DTADE	RQFDE	CQEDE	IQEFDE	RDE	TDE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TDE	Transmit Data Empty Detection Enable	0: Detection of transmit data empty is disabled. 1: Detection of transmit data empty is enabled.	R/W
b1	RDE	Receive Data Full Detection Enable	0: Detection of receive data full is disabled. 1: Detection of receive data full is enabled.	R/W
b2	IQEFDE	IBI Queue Empty/Full Detection Enable	0: Detection of IBI queue empty/full is disabled. 1: Detection of IBI queue empty/full is enabled.	R/W
b3	CQEDE	Command Queue Empty Detection Enable	0: Detection of command queue empty is disabled. 1: Detection of command queue empty is enabled.	R/W
b4	RQFDE	Response Queue Full Detection Enable	0: Detection of response queue full is disabled. 1: Detection of response queue full is enabled.	R/W
b5	DTADE	Data Transfer Abort Detection Enable	0: Detection of data transfer abort is disabled. 1: Detection of data transfer abort is enabled.	R/W
b8 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R
b9	DTEDE	Data Transfer Error Detection Enable	0: Detection of data transfer error is disabled. 1: Detection of data transfer error is enabled.	R/W
b19 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	SQFDE	Receive Status Queue Full Detection Enable*1	0: Detection of receive status queue full is disabled. 1: Detection of receive status queue full is enabled.	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. This bit is used in I3C Secondary Controller and I3C Target modes.

This register is used to enable or disable detection of each status. When the status enabled by this register is detected, the corresponding flag in the ICCSR register is set to 1.

35.2.34 Communication Status Interrupt Enable Register (ICCSIER)

Address(es): RI3C0.ICCSIER 000E C1E8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	SQFIE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	DTEIE	—	—	—	DTAIE	RQFIE	CQEIE	IQEFIE	RIE	TIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TIE	Transmit Data Empty Interrupt Enable	0: Transmit data empty interrupt is disabled. 1: Transmit data empty interrupt is enabled.	R/W
b1	RIE	Receive Data Full Interrupt Enable	0: Receive data full interrupt is disabled. 1: Receive data full interrupt is enabled.	R/W
b2	IQEFIE	IBI Queue Empty/Full Interrupt Enable	0: IBI queue empty/full interrupt is disabled. 1: IBI queue empty/full interrupt is enabled.	R/W
b3	CQEIE	Command Queue Empty Interrupt Enable	0: Command queue empty interrupt is disabled. 1: Command queue empty interrupt is enabled.	R/W
b4	RQFIE	Response Queue Full Interrupt Enable	0: Response queue full interrupt is disabled. 1: Response queue full interrupt is enabled.	R/W
b5	DTAIE	Data Transfer Abort Interrupt Enable	0: Data transfer abort interrupt is disabled. 1: Data transfer abort interrupt is enabled.	R/W
b8 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R
b9	DTEIE	Data Transfer Error Interrupt Enable	0: Data transfer error interrupt is disabled. 1: Data transfer error interrupt is enabled.	R/W
b19 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	SQFIE	Receive Status Queue Full Interrupt Enable*1	0: Receive status queue full interrupt is disabled. 1: Receive status queue full interrupt is enabled.	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. This bit is used in I3C Secondary Controller and I3C Target modes.

This register is used to enable or disable interrupts for each status. When a flag in the ICCSR register becomes 1 and the corresponding interrupt enable bit is 1, an interrupt request is generated.

35.2.35 Bus Status Register (ICBSR)

Address(es): RI3C0.ICBSR 000E C210h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	BIDL	BAVL	BFREE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BFREE	Bus Free Flag	0: Have not detected bus free. 1: Have detected bus free.	R
b1	BAVL	Bus Available Detection Flag	0: Have not detected bus available. 1: Have detected bus available.	R
b2	BIDL	Bus Idle Detection Flag	0: Have not detected bus idle. 1: Have detected bus idle.	R
b31 to b3	—	Reserved	These bits are read as 0.	R

BFREE Flag (Bus Free Flag)

This flag indicates whether the I3C bus is occupied (bus busy) or released (bus free).

[Setting condition]

- When the number of cycles set in the ICBFTR register has elapsed when the SCL00 and SDA00 lines are high after a STOP condition is detected.
- When the number of cycles set in the ICBFTR register has elapsed when the SCL00 and SDA00 lines are high after setting the ICCR.ICE bit to 1.

[Clearing condition]

- When SCL00 line and SDA00 line are other than high.
- When the ICCR.ICE bit is set to 0.

BAVL Flag (Bus Available Detection Flag)

The Bus Available condition is a period during which the Bus Free condition is sustained continuously for a duration of at least tAVAL (refer to section 49.4.5.14, RI3C). A Target can only issue a START Request (for an IBI or for a CRR) after a Bus Available condition.

[Setting condition]

- When the number of cycles set in the ICBATR register has elapsed when the SCL00 and SDA00 lines are high after a STOP condition is detected.
- When the number of cycles set in the ICBATR register has elapsed when the SCL00 and SDA00 lines are high after setting the ICCR.ICE bit to 1.

[Clearing condition]

- When SCL00 line and SDA00 line are other than high.
- When the ICCR.ICE bit is set to 0.

BIDL Flag (Bus Idle Detection Flag)

The I3C Bus Idle condition is in order to help ensure bus stability during Hot-Join events. The Bus Idle condition is a period during which the Bus Available condition is sustained continuously for a duration of at least tIDLE (refer to section 49.4.5.14, RI3C).

If a Hot-Join Device is powered up onto the I3C bus at the same time as the Primarily Controller, then the Hot-Join Device may pull SDA00 line Low after 1 ms if (1) the Primarily Controller has SCL00 line and SDA00 line pulled up, and (2) the Controller does not act on the I3C bus within the same Idle period.

[Setting condition]

- When the number of cycles set in the ICBITR register has elapsed when the SCL00 and SDA00 lines are high after a STOP condition is detected.
- When the number of cycles set in the ICBITR register has elapsed when the SCL00 and SDA00 lines are high after setting the ICCR.ICE bit to 1.

[Clearing condition]

- When SCL00 line and SDA00 line are other than High.
- When the ICCR.ICE bit is set to 0.

35.2.36 Target Device Address Table Register m (ICTDATRm) (m = 0 to 3)

Address(es): RI3C0.ICTDATR0 000E C224h, RI3C0.ICTDATR1 000E C22Ch, RI3C0.ICTDATR2 000E C234h, RI3C0.ICTDATR3 000E C23Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TYPE	NACKRC[1:0]		—	—	—	—	—	DADR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	SADR[6:0]	Static Address	I3C/I^{2}C static address	R/W
b11 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R
b12	IBIPL	IBI Payload	0: IBIs from this device do not carry data payload. 1: IBIs from this device carry data payload.	R/W
b13	TIRRJ	Target Interrupt Request Reject	0: RI3C ACKs Target Interrupt Requests from this device. 1: RI3C NACKs Target Interrupt Requests from this device and automatically sends DISEC CCC.	R/W
b14	CRRRJ	Controller Role Request Reject	0: RI3C ACKs Controller Role Requests from this device. 1: RI3C NACKs Controller Role Requests from this device and automatically sends DISEC CCC.	R/W
b15	IBITSE	IBI Timestamp Enable	0: RI3C does not timestamp IBIs from this device with Controller timestamps. 1: RI3C timestamps IBIs from this device with Controller timestamps.	R/W
b23 to b16	DADR[7:0]	Dynamic Address	DADR[6:0] bits: Dynamic Address for this device DADR[7] bit: Parity bit	R/W
b28 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R
b30, b29	NACKRC[1:0]	NACK Retry Count Setting	0h: No retries on NACK 1h to 3h: Up to 1 to 3 retries on NACK	R/W
b31	TYPE	Device Type	0: I3C device 1: I^{2}C device	R/W

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

The Device Address Table (DAT) stores the device addresses and control informations of Target devices attached to the I3C bus and is implemented in RI3C as the ICTDATRm registers. The Command Descriptor of a command that requires this register informations has a DEV_INDEX field, and the register is selected by the field.

IBIPL Bit (IBI Payload)

This bit indicates whether IBIs from the corresponding device have a data payload. This bit reflects the ICTDCTRm.IBIPL bit (BCR[2]: IBI Payload bit in the Bus Characteristics Register).
During IBI handling for this device, the Controller shall use this bit to determine whether or not to drive reception of the IBI data payload. Data continuation is indicated by the T-Bit.

TIRRJ Bit (Target Interrupt Request Reject)

This bit controls whether RI3C, when operating in the Active Controller role, will accept or reject Target Interrupt Requests (TIR) from the Target device indicated by this register.

CRRRJ Bit (Controller Role Request Reject)

This bit controls whether RI3C, when operating in the Active Controller role, will accept or reject Controller Role Requests (CRR) from the Secondary Controller indicated by this register.

IBITSE Bit (IBI Timestamp Enable)

This bit enables or disables IBI timestamping for a specific device.

Note: The IBI Status Descriptor for each IBI event indicates whether or not the individual IBI event was actually timestamped. Set to 0 except for Async Mode 0 and Async Mode 1 of Timing Control Mode.

NACKRC[1:0] Bits (NACK Retry Count Setting)

These bits set the number of retries when a NACK response is received from the Target for the transaction set in the Command Descriptor.

Note: When ENTDAA CCC is executed by address assignment command (refer to section 35.3.1.1, Address Assignment Command), the setting of this bit is ignored and the transaction ends when NACK is received once.

35.2.37 Extended Target Device Address Table Register (ICEDATR)

Address(es): RI3C0.ICEDATR 000E C2A0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TYPE	NACKRC[1:0]		—	—	—	—	—	DADR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	SADR[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	SADR[6:0]	Static Address	I3C/I^{2}C static address	R/W
b15 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R
b23 to b16	DADR[7:0]	Dynamic Address	DADR[6:0] bits: Dynamic Address for this device DADR[7] bit: Parity bit	R/W
b28 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R
b30, b29	NACKRC[1:0]	NACK Retry Count Setting	0h: No retries on NACK 1h to 3h: Up to 1 to 3 retries on NACK	R/W
b31	TYPE	Device Type	0: I3C device 1: I^{2}C device	R/W

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

35.2.38 Device Address Register 0 (ICDAR0)

Address(es): RI3C0.ICDAR0 000E C2B0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	DADR[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	IBIPL	—	—	SADR[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	SADR[9:0]	Static Address*2	Set a static address.	R/W
b11, b10	—	Reserved	These bits are read as 0. The write value should be 0.	R
b12	IBIPL	IBI Payload*1	This bit is the mirror bit of the ICDCTR.IBIPL. 0: IBIs from this device do not carry a data payload. 1: IBIs from this device carry a data payload.	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R
b22 to b16	DADR[6:0]	Dynamic Address*2	Dynamic Address is set.	R/W
b31 to b23	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: Do not write to this register when RI3C is Primary Controller.
Note 1. This bit is used in I3C Secondary Controller and I3C Target modes.
Note 2. These bits are used in I3C Secondary Controller and I3C Target modes.

The Device Characteristics Table (DCT) is a register set that stores the Device characteristics (PID, BCR, DCR) and assigned Dynamic Address of each device on the I3C bus that participates in the Dynamic Address Allocation (ENTDAA) procedure.
The ICDAR0 register is used to store the values of the assigned Dynamic Address.

SADR[9:0] Bits (Static Address)

Set the static address in Target mode to the lower 7 bits.
The upper 3 bits are reserved. Set them to 0.

IBIPL Bit (IBI Payload)

Indicates whether IBIs from this Device have a Data Payload. This bit reflects the IBI Payload bit in the Device's Bus Characteristics Register (BCR).
During IBI handling for this Device, the Controller shall use this bit to determine whether or not to drive reception of the IBI Data Payload. Data continuation is indicated by the T-Bit.

DADR[6:0] Bits (Dynamic Address)

These bits store the Dynamic Address assigned in Target mode.
These bits are updated when one any of the following events occurs.

- When writing Dynamic Address value.
- When Target Address is equal to its own Static Address in receiving SETDASA CCC (Direct), these bits are updated to the value of the subsequent Dynamic Address.
- When Dynamic Address Assignment procedure that starts by receiving ENTDAA CCC (Broadcast) is established.
- When receiving RSTDAA CCC (Broadcast), all bits are set to 0.
- When Target Address is equal to its own Dynamic Address in receiving RSTDAA CCC (Direct), all bits are set to 0.

- When Target Address is equal to its own Dynamic Address in receiving SETNEWDA CCC (Direct), these bits are updated to the value of the subsequent new Dynamic Address.
- When receiving SETAASA CCC (Broadcast), these bits are updated to the value of the SADR[6:0] bits.

35.2.39 Target Device Characteristics Table Register m (ICTDCTRm) (m = 0 to 3)

Address(es): RI3C0.ICTDCTR0 000E C2D0h, RI3C0.ICTDCTR1 000E C2D4h, RI3C0.ICTDCTR2 000E C2D8h, RI3C0.ICTDCTR3 000E C2DCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ROLE[1:0]		—	—	OFLC	IBIPL	IBIRQC	LIMIT	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	LIMIT	Max Data Speed Limitation	0: No limitation 1: Limitation	R/W
b9	IBIRQC	IBI Request Capable	0: Not capable 1: Capable	R/W
b10	IBIPL	IBI Payload	0: No data byte follows the accepted IBI. 1: One or more data bytes follow the accepted IBI. Data byte continuation is indicated by T-Bit.	R/W
b11	OFLC	Offline Capable	0: Device will always respond to I3C bus commands. 1: Device will not always respond to I3C bus commands.	R/W
b13, b12	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b15, b14	ROLE[1:0]	Device Role Setting	b15 b14 0 0: I3C Target 0 1: I3C Controller capable*1 Settings other than above are prohibited.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.
Note 1. For an I3C Device acting as I3C Primary Controller, the ROLE[1:0] bits will contain the value 01b.

The Device Characteristics Table (DCT) is a register set that stores the Device characteristics (PID, BCR, DCR) and assigned Dynamic Address of each device on the I3C bus that participates in the Dynamic Address Allocation (ENTDAA) procedure.
The ICTDCTRm register contains the value of the Bus Characteristic Register (BCR) of the Target device captured by the RI3C during Controller operation.
This register is updated when the Bus Characteristics Register (BCR) is received from the device in the Dynamic Address Allocation procedure starting by receiving the ENTDAA CCC (Broadcast).

LIMIT Bit (Max Data Speed Limitation)

This bit corresponds to bit 0 in the BCR (BCR[0]).
Controller shall use the GETMXDS CCC to interrogate the Target for specific limitation.

IBIRQC Bit (IBI Request Capable)

This bit corresponds to bit 1 in the BCR (BCR[1]).

IBIPL Bit (IBI Payload)

This bit corresponds to bit 2 in the BCR (BCR[2]).

OFLC Bit (Offline Capable)

This bit corresponds to bit 3 in the BCR (BCR[3]).
Offline capable devices retain the Dynamic Address.

ROLE[1:0] Bits (Device Role Setting)

This bit corresponds to bits 7 and 6 in the BCR (BCR[7:6]).

35.2.40 Device Characteristics Table Register (ICDCTR)

Address(es): RI3C0.ICDCTR 000E C320h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ROLE[1:0]		—	—	OFLC	IBIPL	IBIRQC	LIMIT	DCR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	DCR[7:0]	Device Characteristics	255 available codes for describing the type of sensor, or device. Examples: Accelerometer, gyroscope, composite devices Default value is 00h: Generic device	R/W
b8	LIMIT	Max Data Speed Limitation*1	0: No limitation 1: Limitation	R/W
b9	IBIRQC	IBI Request Capable	0: Not capable 1: Capable	R/W
b10	IBIPL	IBI Payload	0: No data byte follows the accepted IBI. 1: One or more data bytes follow the accepted IBI. Data byte continuation is indicated by T-Bit.	R/W
b11	OFLC	Offline Capable*2	0: Device will always respond to I3C bus commands. 1: Device will not always respond to I3C bus commands.	R/W
b13, b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15, b14	ROLE[1:0]	Device Role Setting	b15 b14 0 0: I3C Target 0 1: I3C Controller capable*3 Settings other than above are prohibited.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.
Note 1. Controller shall use the GETMXDS CCC to interrogate the Target for specific limitation.
Note 2. Offline Capable Devices retain the Dynamic Address.
Note 3. For an I3C Device acting as I3C Primarily Controller, the ROLE[1:0] bits will contain the value 01b.

The Device Characteristics Table (DCT) is a register set that stores the Device characteristics (PID, BCR, DCR) and assigned Dynamic Address of each device on the I3C bus that participates in the Dynamic Address Allocation (ENTDAA) procedure.
The ICDCTR register is used to store the values of the RI3C Bus Characteristics Register (BCR) and Device Characteristics Register (DCR). The BCR consists of the ROLE[1:0], OFLC, IBIPL, IBIRQC, and LIMIT bits.

DCR[7:0] Bits (Device Characteristics)

Each I3C device that is connected to the I3C bus has an associated Device Characteristics Register (DCR). This register describes the I3C compliant device type such as accelerometer and gyroscope, for use in Dynamic Address assignment and Common Command Codes.

LIMIT Bit (Max Data Speed Limitation)

This bit corresponds to bit 0 in the BCR (BCR[0]).

IBIRQC Bit (IBI Request Capable)

This bit corresponds to bit 1 in the BCR (BCR[1]).

IBIPL Bit (IBI Payload)

This bit corresponds to bit 2 in the BCR (BCR[2]).

OFLC Bit (Offline Capable)

This bit corresponds to bit 3 in the BCR (BCR[3]).

ROLE[1:0] Bits (Device Role Setting)

This bit corresponds to bits 7 and 6 in the BCR (BCR[7:6]).

When RI3C is in Target mode and issues IBI by Command Descriptor, set the BCR as follows:

(1) Target Interrupt Request: No IBI Payload follow the accepted IBI:

- IBIRQC = 1
- IBIPL = 0

Note: Set DATA_LENGTH field of Command Descriptor to 0000h.

(2) Target Interrupt Request: IBI Payload follow the accepted IBI:

- IBIRQC = 1
- IBIPL = 1

Note: Set DATA_LENGTH field of Command Descriptor to any value.

(3) Controller Role Request:

- IBIRQC = 1
- ROLE[1:0] = 01b

(4) Hot-Join Event:

- IBIRQC = 1

When RI3C is in Target mode and receives CCC from I3C Controller, it performs the following operations according to the setting of the BCR:

- When the IBIPL bit is 1, RI3C sends the value set in the ICMRLR.IBIPL[7:0] bits as the 3rd byte data to GETMRL CCC from I3C Controller.
- When the LIMIT bit is 0, RI3C NACKs GETMXDS CCC from I3C Controller.
- When the LIMIT bit is 1, RI3C ACKs GETMXDS CCC from I3C Controller and sends data set in the ICMWSR, ICMRSR, and ICMTTR registers.

35.2.41 Provisioned ID Low Register (ICPIDLR)

Address(es): RI3C0.ICPIDLR 000E C324h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register is used in I3C Secondary Controller and I3C Target modes.

The Device Characteristics Table (DCT) is a register set that stores the Device characteristics (PID, BCR, DCR) and assigned Dynamic Address of each device on the I3C bus that participates in the Dynamic Address Allocation (ENTDAA) procedure.
This register stores the lower 16 bits of the provisioned ID (b15 to b0 of the PID).
The upper 16 bits are reserved. These bits are read as 0 and the write value should be 0.

35.2.42 Provisioned ID High Register (ICPIDHR)

Address(es): RI3C0.ICPIDHR 000E C328h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register is used in I3C Secondary Controller and I3C Target modes.

The Device Characteristics Table (DCT) is a register set that stores the Device characteristics (PID, BCR, DCR) and assigned Dynamic Address of each device on the I3C bus that participates in the Dynamic Address Allocation (ENTDAA) procedure.
This register stores the upper 32 bits of the provisioned ID (b47 to b16 of the PID).

35.2.43 Device Address Monitor Register 0 (ICDAMR0)

Address(es): RI3C0.ICDAMR0 000E C330h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DAV	SAV	—	—	—	—	TADR[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0.	R
b25 to b16	TADR[9:0]	Target Address*1	Target address is set.	R
b29 to b26	—	Reserved	These bits are read as 0.	R
b30	SAV	Static Address Valid Flag*2	0: Static address is disabled. 1: Static address is enabled.	R
b31	DAV	Dynamic Address Valid Flag*2	0: Dynamic Address is disabled. 1: Dynamic Address is enabled.	R

Note 1. These bits are used in I3C Secondary Controller and I3C Target modes.
Note 2. This bit is used in I3C Secondary Controller and I3C Target modes.

TADR[9:0] Bits (Target Address)

The TADR[9:0] bits indicate a valid Target address.

- When the DAV flag is 1:
  The TADR[9:7] bits are 000b.
  The TADR[6:0] bits are the ICDAR0.DADR[6:0] bits.
- When the SAV flag is 1:
  The TADR[9:7] bits are 000b.
  The TADR[6:0] bits are the ICDAR0.SADR[6:0] bits.

SAV Flag (Static Address Valid Flag)

[Setting condition]

- All of the following are satisfied.
  1. The ICTCR.TA0DE bit is 1 (detection of Target address 0 is enabled).
  2. The DAV flag is 0 (Dynamic Address is disabled).
  3. The ICDAR0.SADR[6:0] bits are not 0000000b

[Clearing condition]

- [Setting condition] is not satisfied.

DAV Flag (Dynamic Address Valid Flag)

[Setting condition]

- All of the following are satisfied.
  1. The ICTCR.TA0DE bit is 1 (detection of Target address 0 is enabled).
  2. The ICDAR0.DADR[6:0] bits are not 0000000b.

[Clearing condition]

- [Setting condition] is not satisfied.

35.2.44 Target Event Register (ICTEVR)

Address(es): RI3C0.ICTEVR 000E C350h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	ENHJ	—	ENCR	ENINT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ENINT	Target Interrupt Request Enable Flag	0: Target-initiated interrupts is disabled by the Controller. 1: Target-initiated interrupts is enabled by the Controller.	R/W
b1	ENCR	Controller Role Request Enable Flag	0: Controller Role Requests from Secondary Controllers is disabled by the Active Controller. 1: Controller Role Requests from Secondary Controllers is enabled by the Active Controller.	R/W
b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b3	ENHJ	Hot-Join Event Enable Flag	0: Target-initiated Hot-Join is disabled by the Controller. 1: Target-initiated Hot-Join is enabled by the Controller.	R/W
b31 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

ENINT Flag (Target Interrupt Request Enable Flag)

This flag allows the Controller to control when Target-initiated interrupts are allowed on the I3C bus.

[Setting conditions]

- When writing 1.
- When receiving ENEC CCC (Broadcast) with the ENINT field set to 1.
- When receiving ENEC CCC (Direct) with the ENINT field set to 1 and with its own Target address.

[Clearing conditions]

- When writing 0.
- When receiving DISEC CCC (Broadcast) with the DISINT field set to 1.
- When receiving DISEC CCC (Direct) with the DISINT field set to 1 and with its own Target address.

ENCR Flag (Controller Role Request Enable Flag)

This flag allows the Active Controller to control when Controller Role Requests from Secondary Controller are allowed on the I3C bus.

[Setting conditions]

- When writing 1.
- When receiving ENEC CCC (Broadcast) with the ENCR field set to 1.
- When receiving ENEC CCC (Direct) with the ENCR field set to 1 and with its own Target address.

[Clearing conditions]

- When writing 0.
- When receiving DISEC CCC (Broadcast) with the DISCR field set to 1.
- When receiving DISEC CCC (Direct) with the DISCR field set to 1 and with its own Target address.

ENHJ Flag (Hot-Join Event Enable Flag)

This flag allows the Controller to control when Target-initiated Hot-Join is allowed on the I3C bus.

[Setting conditions]

- When writing 1.
- When receiving ENEC CCC (Broadcast) with the ENHJ field set to 1.
- When receiving ENEC CCC (Direct) with the ENHJ field set to 1 and with its own Target address.

[Clearing conditions]

- When writing 0.
- When receiving DISEC CCC (Broadcast) with the DISHJ field set to 1.
- When receiving DISEC CCC (Direct) with the DISHJ field set to 1 and with its own Target address.

35.2.45 Activity State Register (ICASR)

Address(es): RI3C0.ICASR 000E C354h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	ENTAS3	ENTAS2	ENTAS1	ENTAS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ENTAS0	Activity State 0 Flag*1	0: Other than activity state 0 1: Activity state 0	R/W
b1	ENTAS1	Activity State 1 Flag*1	0: Other than activity state 1 1: Activity state 1	R/W
b2	ENTAS2	Activity State 2 Flag*1	0: Other than activity state 2 1: Activity state 2	R/W
b3	ENTAS3	Activity State 3 Flag*1	0: Other than activity state 3 1: Activity state 3	R/W
b31 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.
Note 1. Do not set multiple bits to 1 at the same time.

ENTAS0 Flag (Activity State 0 Flag)

[Setting conditions]

- When writing 1.
- When receiving ENTAS0 CCC (Broadcast).
- When receiving ENTAS0 CCC (Direct) with its own Target address.

[Clearing conditions]

- When writing 0.
- When receiving ENTAS1 CCC (Broadcast), ENTAS2 CCC (Broadcast), or ENTAS3 CCC (Broadcast).
- When receiving ENTAS1 CCC (Direct), ENTAS2 CCC (Direct), or ENTAS3 CCC (Direct) with its own Target address.

ENTAS1 Flag (Activity State 1 Flag)

[Setting conditions]

- When writing 1.
- When receiving ENTAS1 CCC (Broadcast).
- When receiving ENTAS1 CCC (Direct) with its own Target address.

[Clearing conditions]

- When writing 0.
- When receiving ENTAS0 CCC (Broadcast), ENTAS2 CCC (Broadcast), or ENTAS3 CCC (Broadcast).
- When receiving ENTAS0 CCC (Direct), ENTAS2 CCC (Direct), or ENTAS3 CCC (Direct) with its own Target address.

ENTAS2 Flag (Activity State 2 Flag)

[Setting conditions]

- When writing 1.
- When receiving ENTAS2 CCC (Broadcast).
- When receiving ENTAS2 CCC (Direct) with its own Target address.

[Clearing conditions]

- When writing 0.
- When receiving ENTAS0 CCC (Broadcast), ENTAS1 CCC (Broadcast), or ENTAS3 CCC (Broadcast).
- When receiving ENTAS0 CCC (Direct), ENTAS1 CCC (Direct), or ENTAS3 CCC (Direct) with its own Target address.

ENTAS3 Flag (Activity State 3 Flag)

[Setting conditions]

- When writing 1.
- When receiving ENTAS3 CCC (Broadcast).
- When receiving ENTAS3 CCC (Direct) with its own Target address.

[Clearing conditions]

- When writing 0.
- When receiving ENTAS0 CCC (Broadcast), ENTAS1 CCC (Broadcast), or ENTAS2 CCC (Broadcast).
- When receiving ENTAS0 CCC (Direct), ENTAS1 CCC (Direct), or ENTAS2 CCC (Direct) with its own Target address.

35.2.46 Max Write Length Register (ICMWLR)

Address(es): RI3C0.ICMWLR 000E C358h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MWL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	MWL[15:0]	Max Write Length	Set the maximum data write length in bytes to respond to GETMWL CCC. Set a value of 8 or more. These bits are automatically updated when SETMWL CCC is received.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

MWL[15:0] Bits (Max Write Length)

These bits are used when the I3C Controller sets the maximum data write length in RI3C or gets the maximum data write length from RI3C.

The value of these bits is automatically transmitted in response to GETMRL CCC.

When receiving SETMWL CCC (Broadcast) or SETMWL CCC (Direct) with its own Target address, these bits are automatically updated to the received MWL value.

35.2.47 Max Read Length Register (ICMRLR)

Address(es): RI3C0.ICMRLR 000E C35Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	IBIPL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MRL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	MRL[15:0]	Max Read Length	Set the maximum data read length in bytes to respond to GETMRL CCC. Set a value of 16 or more. These bits are automatically updated when SETMRL CCC is received.	R/W
b23 to b16	IBIPL[7:0]	IBI Payload Size	Set the maximum IBI payload size in bytes to respond to GETMRL CCC. These bits are automatically updated when SETMRL CCC is received.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

MRL[15:0] Bits (Max Read Length)

These bits are used when the I3C Controller sets the maximum data read length in RI3C or gets the maximum data read length from RI3C.

The value of these bits is automatically transmitted as the first two bytes of the response to GETMRL CCC.

When receiving SETMRL CCC (Broadcast) or SETMRL CCC (Direct) with its own Target address, these bits are automatically updated to the received MRL value.

IBIPL[7:0] Bits (IBI Payload Size)

These bits are used when the I3C Controller sets the maximum IBI payload size in RI3C or gets the maximum IBI payload size from RI3C.

When the ICDCTR.IBIPL bit is 1, the value of these bits is transmitted as the third byte of the response to GETMRL CCC. When the IBIPL bit is 0, these bits are not transmitted.

When receiving SETMRL CCC (Broadcast) or SETMRL CCC (Direct) with its own Target address, these bits are automatically updated to the received IBI Payload Size value.

35.2.48 Test Mode Register (ICTMR)

Address(es): RI3C0.ICTMR 000E C360h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TM[7:0]	Test Mode	00h: Exit test mode This value removes all I3C devices from test mode. 01h: Vendor test mode This value indicates that I3C devices shall return a random 32-bit value in the provisioned ID during the Dynamic Address Assignment procedure. Settings other than above are prohibited.	R
b31 to b8	—	Reserved	These bits are read as 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

TM[7:0] Bits (Test Mode)

These bits are used when the I3C Controller puts RI3C into test mode.

When receiving ENTTM CCC (Broadcast), these bits are automatically updated to the received Test Mode Byte value.

35.2.49 Device Status Register (ICDSR)

Address(es): RI3C0.ICDSR 000E C364h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	VRSV[7:0]								CAS[1:0]		PERR	—	PNDINT[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	PNDINT[3:0]	Pending Interrupt Number	Contains the interrupt number of any pending interrupt, or 0000b if no interrupts are pending.	R/W
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R
b5	PERR	Protocol Error Flag	0: The Target has not detected a protocol error since the last status read. 1: The Target has detected a protocol error since the last status read.	R
b7, b6	CAS[1:0]	Current Activity State	b7 b6 0 0: Activity state 0 0 1: Activity state 1 1 0: Activity state 2 1 1: Activity state 3	R/W
b15 to b8	VRSV[7:0]	Vendor Reserved Area	Reserved for vendor-specific meaning	R/W
b31 to b16	—	Reserved	This bit is read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

This register is used to store the status to be returned when current status is requested from I3C Controller.
The value of bits b15 to b0 in this register is automatically transmitted when a GETSTATUS CCC (Direct) is received.

PNDINT[3:0] Bits (Pending Interrupt Number)

These bits are used to indicate whether any interrupts are pending. If no interrupts are pending, set these bits to 0000b.
If multiple interrupts are pending, set the interrupt number of the highest priority interrupt.

PERR Flag (Protocol Error Flag)

This bit indicates whether the Target has detected a protocol error since the last status read.
This flag is automatically cleared each time the Controller successfully reads the Target status.
[Setting condition]

- When the Target detected a protocol error.

[Clearing condition]

- When a transmission of status (value set in this register) is successfully completed in response to GETSTATUS CCC (Direct) with its own Target address.

CAS[1:0] Bits (Current Activity State)

These bits are used to indicate the current Activity state of RI3C.

35.2.50 Max Write Speed Register (ICMWSR)

Address(es): RI3C0.ICMWSR 000E C368h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	MSWDR[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	MSWDR[2:0]	Maximum Sustained Write Data Rate	b2 b0 0 0 0: Maximum value of f_{SCL} 0 0 1: 8 MHz 0 1 0: 6 MHz 0 1 1: 4 MHz 1 0 0: 2 MHz Settings other than above are prohibited.	R/W
b31 to b3	—	Reserved	This bit is read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

This register is used to store the maximum write speed to be returned when the maximum data speed is requested from I3C Controller.

The value of bits b7 to b0 in this register is automatically transmitted as MaxWr when a GETMXDS CCC (Direct) is received.

35.2.51 Max Read Speed Register (ICMRSR)

Address(es): RI3C0.ICMRSR 000E C36Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	TSCO[2:0]			MSRDR[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	MSRDR[2:0]	Maximum Sustained Read Data Rate	b2 b0 0 0 0: Maximum value of f_{SCL} 0 0 1: 8 MHz 0 1 0: 6 MHz 0 1 1: 4 MHz 1 0 0: 2 MHz Settings other than above are prohibited.	R/W
b5 to b3	TSCO[2:0]	Clock-to-Data Turnaround Time	b5 b3 0 0 0: 8 ns or less 0 0 1: 9 ns or less 0 1 0: 10 ns or less 0 1 1: 11 ns or less 1 0 0: 12 ns or less 1 1 1: t_{SCO} is more than 12 ns, and is reported by private agreement. Settings other than above are prohibited.	R/W
b31 to b6	—	Reserved	This bit is read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

This register is used to store the maximum read speed to be returned when the maximum data speed is requested from I3C Controller.

The value of bits b7 to b0 in this register is automatically transmitted as MaxRd when a GETMXDS CCC (Direct) is received.

35.2.52 Maximum Read Turnaround Time Register (ICMTTR)

Address(es): RI3C0.ICMTTR 000E C370h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MRTTE	—	—	—	—	—	—	—	MRTT[23:16]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MRTT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b23 to b0	MRTT[23:0]	Maximum Read Turnaround Time	Set the read turnaround time in 1 µs units in the range of 0 to 16 seconds. 000000h: 0 µs (minimum value) 000001h: 1 µs : : F42400h: 16 seconds (maximum value) Settings other than above are prohibited.	R/W
b30 to b24	—	Reserved	This bit is read as 0. The write value should be 0.	R
b31	MRTTE	Maximum Read Turnaround Time Transmit Enable	0: Disables transmission of the maximum read turnaround time. (GETMXDS format 1: without turnaround) 1: Enables transmission of the maximum read turnaround time. (GETMXDS format 2: with turnaround)	R/W

Note: This register is used in I3C Secondary Controller and I3C Target modes.

This register is used to store the three-byte maximum read turnaround time to be returned when the maximum data speed is requested from I3C Controller.

The value of bits b23 to b0 in this register is automatically transmitted as MaxRdTurn when a GETMXDS CCC (Direct) is received.

35.2.53 Timing Support Information Register (ICTSIR)

Address(es): RI3C0.ICTSIR 000E C374h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	INAC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	FREQ[7:0]								—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	This bit is read as 0. The write value should be 0.	R
b15 to b8	FREQ[7:0]	Frequency Setting	These bits specify the Target's internal oscillation frequency in increments of 0.5 MHz. b15 b8 00000000: 32.0 kHz 00000001: 0.5 MHz 00000010: 1.0 MHz : : 01111111: 63.5 MHz Settings other than above are prohibited.	R/W
b23 to b16	INAC[7:0]	Frequency Inaccuracy Setting	These bits specify the inaccuracy of the oscillation frequency from 0.0% to 25.5% in increments of 0.1%. b23 b16 00000000: 0.0% 00000001: 0.1% : : 11111110: 25.4% 11111111: 25.5%	R/W
b31 to b24	—	Reserved	This bit is read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

This register is used to store the value to be returned when the timing information is requested from I3C Controller. When a GETMXDS CCC (Direct) is received, the value of bits b15 to b8 and b23 to b16 in this register is automatically transmitted as Frequency Byte and Inaccuracy Byte, respectively.

35.2.54 Bit Count Register (ICBCR)

Address(es): RI3C0.ICBCR 000E C380h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	BC[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	BC[4:0]	Bit Counter	These bits indicate the number of bits remaining to be transferred. Refer to Table 35.3 and Table 35.4 for details.	R
b31 to b5	—	Reserved	These bits are read as 0.	R

BC[4:0] Bits (Bit Counter)

These bits function as a counter that indicates the number of bits remaining to be transferred at the detection of a rising edge on the SCL00 line.

Table 35.3 Counter Value and Number of Remaining Bits (Legacy I²C Transfer)

	Controller		Target	
BC[4:0]	Address Phase	Data Phase	Address Phase	Data Phase
00h	2 or 1 bits	2 or 1 bits	3 to 1 bits	2 or 1 bits
01h	3 bits	3 bits	4 bits	3 bits
02h	4 bits	4 bits	5 bits	4 bits
03h	5 bits	5 bits	6 bits	5 bits
04h	6 bits	6 bits	7 bits	6 bits
05h	7 bits	7 bits	8 bits	7 bits
06h	8 bits	8 bits	9 bits	8 bits
07h	9 bits	9 bits	—	9 bits

Table 35.4 Counter Value and Number of Remaining Bits (I3C Transfer)

	SDR*1	
BC[4:0]	Transmission	Reception
00h	1 bit	2 or 1 bits
01h	2 bits	3 bits
02h	3 bits	4 bits
03h	4 bits	5 bits
04h	5 bits	6 bits
05h	6 bits	7 bits
06h	7 bits	8 bits
07h	8 bits	9 bits
08h	9 bits	—

Note 1. The address phase is the same as in Table 35.3.

35.2.55 Queue Buffer Status Register (ICQBSR)

Address(es): RI3C0.ICQBSR 000E C394h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	ISC[4:0]					IQFL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	RQFL[7:0]								CQFL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CQFL[7:0]	Command Queue Free Level	Number of free entries currently in the command queue.	R
b15 to b8	RQFL[7:0]	Response Queue Fill Level	Number of entries currently in the response queue.	R
b23 to b16	IQFL[7:0]	IBI Queue Fill Level	Number of entries currently in the IBI queue.	R
b28 to b24	ISC[4:0]	IBI Status Count*1	Number of IBI status entries currently in the IBI queue.	R
b31 to b29	—	Reserved	These bits are read as 0.	R

Note 1. These bits are used in I3C Primarily Controller and I3C Secondary Controller modes.

35.2.56 Data Buffer Status Register (ICDBSR)

Address(es): RI3C0.ICDBSR 000E C398h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	RBFL[7:0]								TBFL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TBFL[7:0]	Transmit Data Buffer Free Level	Indicates the free level of the transmit data buffer.	R
b15 to b8	RBFL[7:0]	Receive Data Buffer Fill Level	Indicates the fill level of the receive data buffer.	R
b31 to b16	—	Reserved	These bits are read as 0.	R

35.2.57 Receive Status Queue Status Register (ICSQSR)

Address(es): RI3C0.ICSQSR 000E C3C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	SQFL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	SQFL[7:0]	Receive Status Queue Fill Level	Number of entries currently in the receive status queue.	R
b31 to b8	—	Reserved	These bits are read as 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

35.2.58 Internal Status Monitor Register (ICIMR)

Address(es): RI3C0.ICIMR 000E C3CCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	SDAO	SCLO	SDAI	SCLI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	SCLI	SCL Line Monitor Flag	0: SCL00 line is low. 1: SCL00 line is high.	R
b1	SDAI	SDA Line Monitor Flag	0: SDA00 line is low. 1: SDA00 line is high.	R
b2	SCLO	SCL Output Monitor Flag	0: The RI3C drives the SCL00 pin low. 1: The RI3C releases the SCL00 pin.	R
b3	SDAO	SDA Output Monitor Flag	0: The RI3C drives the SDA00 pin low. 1: The RI3C releases the SDA00 pin.	R
b31 to b4	—	Reserved	These bits are read as 0.	R

SCLO Flag (SCL Output Monitor Flag) and SDAO Flag (SDA Output Monitor Flag)

When reading these bits, the state of signals output from the RI3C can be read.

35.2.59 Controller Error Count Register (ICCECR)

Address(es): RI3C0.ICCECR 000E C3D0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	CE2C[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CE2C[7:0]	CE2 Error Counter	These bits counts I3C Type CE2 errors on the I3C bus. These bits are cleared when read.	R
b31 to b8	—	Reserved	These bits are read as 0.	R

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

35.3 Data Structures

35.3.1 Command Descriptor

The Command Descriptor is 64 bits in length. The Command Descriptor is added to the command queue via writes to the command queue register (ICCQR).
Write to the ICCQR register in the following order:

1. First write: The lower 32 bits of Command Descriptor
2. Second write: The upper 32 bits of Command Descriptor.

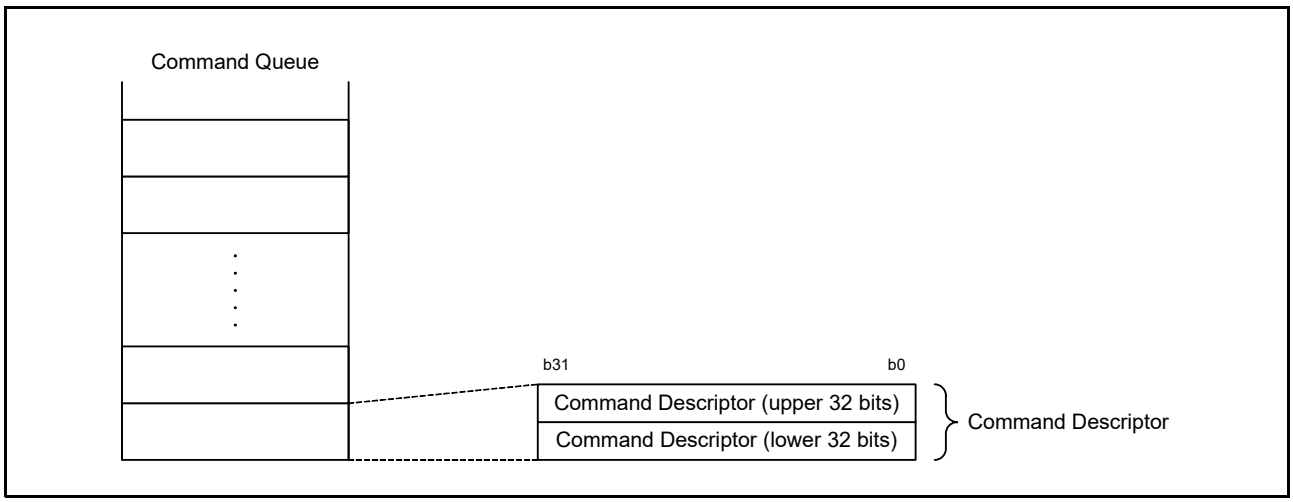

Figure 35.2 Command Descriptor Data Structure

RI3C provides a Command Descriptor structure for each command type as follows:

- Address Assignment Command
- Immediate Data Transfer Command
- Regular Data Transfer Command
- Combo Transfer Command
- Internal Control Command

35.3.1.1 Address Assignment Command

This command is used for Address Assignment (ENTDAA, SETDASA)*1.
Details of the address assignment command structure are as follows.

Note 1. When issuing SETAASA CCC, use the immediate data transfer command.

	b63	b62	b61	b60	b59	b58	b57	b56	b55	b54	b53	b52	b51	b50	b49	b48
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b47	b46	b45	b44	b43	b42	b41	b40	b39	b38	b37	b36	b35	b34	b33	b32
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TOC	ROC	DEV_COUNT				—	—	—	—	EXT_DEVICE	DEV_INDEX				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	CMD								TID				CMD_ATTR		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CMD_ATTR	Command Attributes	Set this field to 010b (address assignment command).	W
b6 to b3	TID	Transaction ID	Used as a tag for this command. Specify in the range of 0h to 7h.	W
b14 to b7	CMD	Transfer Command CCC Value	Specify the command code of the command to be used. ENTDAA (Broadcast): 07h SETDASA (Direct): 87h	W
b15	—	Reserved	Set this field to 0.	W
b20 to b16	DEV_INDEX	Device Index	Specify the DAT table index (m of the ICTDATRm register) for the Target device being assigned an address via Dynamic Address Assignment.	W
b21	EXT_DEVICE	Extended Device Index	0: Use the ICTDATRm register indicated by the DEV_INDEX field. 1: Use the ICEDATR register.	W
b25 to b22	—	Reserved	The write value should be 0.	W
b29 to b26	DEV_COUNT	Device Count	Specify the number of devices that a Dynamic Address shall be assigned to.	W
b30	ROC	Response on Completion	0: NOT_REQUIRED: Response status is not required. 1: REQUIRED: Response status is required.	W
b31	TOC	Terminate on Completion	0: RESTART: Issue repeated START condition (Sr) at end of transfer 1: STOP: Issue STOP condition (P) at end of transfer	W
b63 to b32	—	Reserved	The write value should be 0.	W

TID Field (Transaction ID)

The value specified in this field is reflected in the TID field of the Response Descriptor.

DEV_INDEX Field (Device Index)

Indicates the DAT table index for the Target device being assigned an address via Dynamic Address Assignment.
Write a Dynamic Address into each DAT entry (the ICTDATRm registers) that will be used with this command type, as well as a Static Address (when used with the SETDASA CCC).

DEV_COUNT Field (Device Count)

Indicates the number of devices that a Dynamic Address is assigned to. The DAT entries are processed starting at index DEV_INDEX for up to DEV_COUNT times.

ROC Field (Response on Completion)

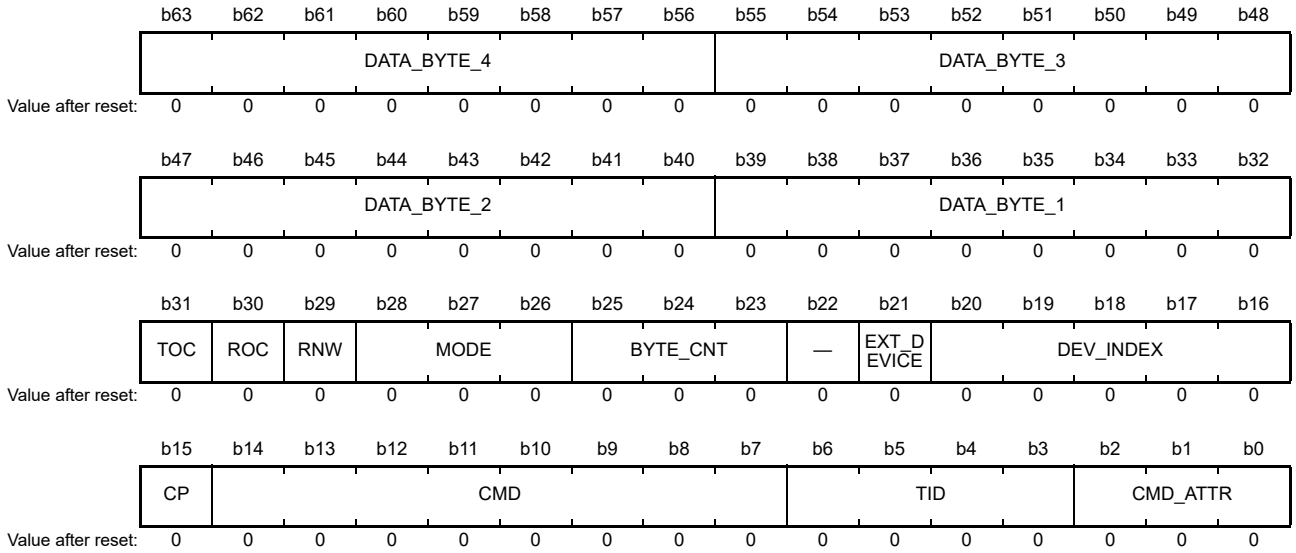
Controls whether Response status is sent after successful completion of the transfer command. The successful completion shall be read from the ICRQR register. Upon unsuccessful transfer the Response status shall always be sent.

TOC Field (Terminate on Completion)

Controls what bus condition to issue after the transfer command completes.
For ENTDAA, a STOP condition is issued regardless of the value set in this field.
When sending SETDASA CCC with the TOC field set to 0 (RESTART), the next command must also be set to an address assignment command specifying SETDASA CCC. When the next command is not SETDASA CCC, the TOC field must be set to 1 (STOP).

35.3.1.2 Immediate Data Transfer Command

This Command Descriptor directly contains data bytes (up to 4 bytes) to be transferred, and as a result is only useful for shorter write-type transfers or CCCs that write data. This command shall not be used for read-type transfers.
Details of the immediate data transfer command structure are as follows.



Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CMD_ATTR	Command Attribute	Set this field to 001b (immediate data transfer command).	W
b6 to b3	TID	Transaction ID	Used as a tag for this command. Specify in the range of 0h to 7h.	W
b14 to b7	CMD	Transfer Command CCC Value	Specify the command code of the command to be used.	W
b15	CP	Command Present	0: TRANSFER: This structure describes an SDR transfer, so the CMD field is not valid. 1: CCC: This structure describes a CCC transfer, so the CMD field is valid.	W
b20 to b16	DEV_INDEX	Device Index	Specify the DAT table index (m of the ICTDATRm register) for the Target device being addressed with the transfer.	W
b21	EXT_DEVICE	Extended Device Index	0: Use the ICTDATRm table indicated by DEV_INDEX. 1: Use the ICEDATR table.	W
b22	—	Reserved	The write value should be 0.	W
b25 to b23	BYTE_CNT	Byte Count	Number of valid data bytes to use in this descriptor. Specify in the range of 0h (no payload) to 4h (4 bytes).	W
b28 to b26	MODE	Mode and Speed	• I3C transfer b28 b26 0 0 0: I3C SDR0, ICSBR register setting (up to 12.5 MHz) 0 0 1: I3C SDR1, ICEBR register setting (up to 8 MHz) 0 1 1: I3C SDR2, ICSBR register setting × 2 (up to 6 MHz) 1 0 0: I3C SDR3, ICEBR register setting × 2 (up to 4 MHz) 1 0 1: I3C SDR4, ICEBR register setting × 4 (up to 2 MHz) Settings other than above are prohibited. • I^2C transfer b28 b26 0 0 0: I^2C FM, ICSBR register setting (up to 400 kHz) 0 0 1: I^2C FM+, ICEBR register setting (up to 1 MHz) Settings other than above are prohibited.	W
b29	RNW	Transfer Direction (RnW)	Set this field to 0 (write transfer)	W
b30	ROC	Response on Completion	0: NOT_REQUIRED: Response status is not required. 1: REQUIRED: Response status is required.	W

Bit	Symbol	Bit Name	Description	R/W
b31	TOC	Terminate on Completion	0: RESTART: Issue repeated START condition (Sr) at end of transfer 1: STOP: Issue STOP condition (P) at end of transfer	W
b39 to b32	DATA_BYTE_1	Data Byte 1	First byte of data to be transmitted	W
b47 to b40	DATA_BYTE_2	Data Byte 2	Second byte of data to be transmitted	W
b55 to b48	DATA_BYTE_3	Data Byte 3	Third byte of data to be transmitted	W
b63 to b56	DATA_BYTE_4	Data Byte 4	Fourth byte of data to be transmitted	W

DEV_INDEX Field (Device Index)

Indicates the DAT table (the ICTDATRm register) index for the Target device being addressed with the transfer. The ICTDATRm register indicated by this field must contain a valid Dynamic Address. This field is ignored for Broadcast CCCs.

BYTE_CNT Field (Byte Count)

Number of valid data bytes to use in this descriptor. This field should be set to non-zero value, except for CCCs that do not have any payload defined.

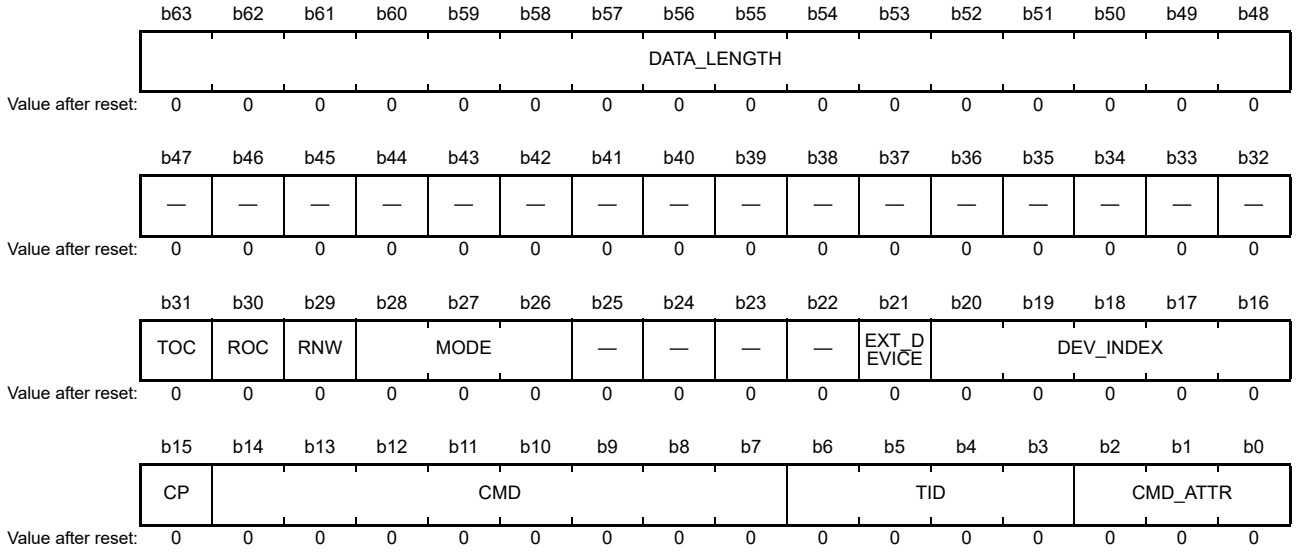
MODE Field (Mode and Speed)

Sets the mode and speed for the I3C or I^2C transfer.
Interpretation of this field depends on the TYPE bit in the ICTDATRm register indexed by the DEV_INDEX field.

35.3.1.3 Regular Data Transfer Command

This Command Descriptor does not contain data to be transferred. For I3C Controller mode, data is transferred via the transmit/receive data register (ICDR), and for I3C Target mode, data is transferred via the IBI queue register (ICIQR). Details of the regular data transfer command structure of each mode are as follows.

(1) I3C Controller Mode



Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CMD_ATTR	Command Attribute	Set this field to 000b (regular data transfer command).	W
b6 to b3	TID	Transaction ID	Used as a tag for this command. Specify in the range of 0h to 7h.	W
b14 to b7	CMD	Transfer Command CCC Value	Specify the command code of the command to be used.	W
b15	CP	Command Present	0: TRANSFER: This structure describes an SDR transfer, so the CMD field is not valid. 1: CCC: This structure describes a CCC transfer, so the CMD field is valid.	W
b20 to b16	DEV_INDEX	Device Index	Specify the DAT table index (m of the ICTDATRm register) for the Target device being addressed with the transfer.	W
b21	EXT_DEVICE	Extended Device Index	0: Use the ICTDATRm table indicated by DEV_INDEX. 1: Use the ICEDATR table.	W
b25 to b22	—	Reserved	The write value should be 0.	W
b28 to b26	MODE	Mode and Speed	• I3C transfer b28 b26 0 0 0: I3C SDR0, ICSBR register setting (up to 12.5 MHz) 0 0 1: I3C SDR1, ICEBR register setting (up to 8 MHz) 0 1 1: I3C SDR2, ICSBR register setting × 2 (up to 6 MHz) 1 0 0: I3C SDR3, ICEBR register setting × 2 (up to 4 MHz) 1 0 1: I3C SDR4, ICEBR register setting × 4 (up to 2 MHz) Settings other than above are prohibited. • I^2C transfer b28 b26 0 0 0: I^2C FM, ICSBR register setting (up to 400 kHz) 0 0 1: I^2C FM+, ICEBR register setting (up to 1 MHz) Settings other than above are prohibited.	W
b29	RNW	Transfer Direction (RnW)	0: WRITE: Write transfer 1: READ: Read transfer	W

Bit	Symbol	Bit Name	Description	R/W
b30	ROC	Response on Completion	0: NOT_REQUIRED: Response status is not required. 1: REQUIRED: Response status is required.	W
b31	TOC	Terminate on Completion	0: RESTART: Issue repeated START condition (Sr) at end of transfer 1: STOP: Issue STOP condition (P) at end of transfer	W
b47 to b32	—	Reserved	The write value should be 0.	W
b63 to b48	DATA_LENGTH	Data Length	Indicates the number of bytes to be transferred.	W

RNW Field (Transfer Direction (RnW))

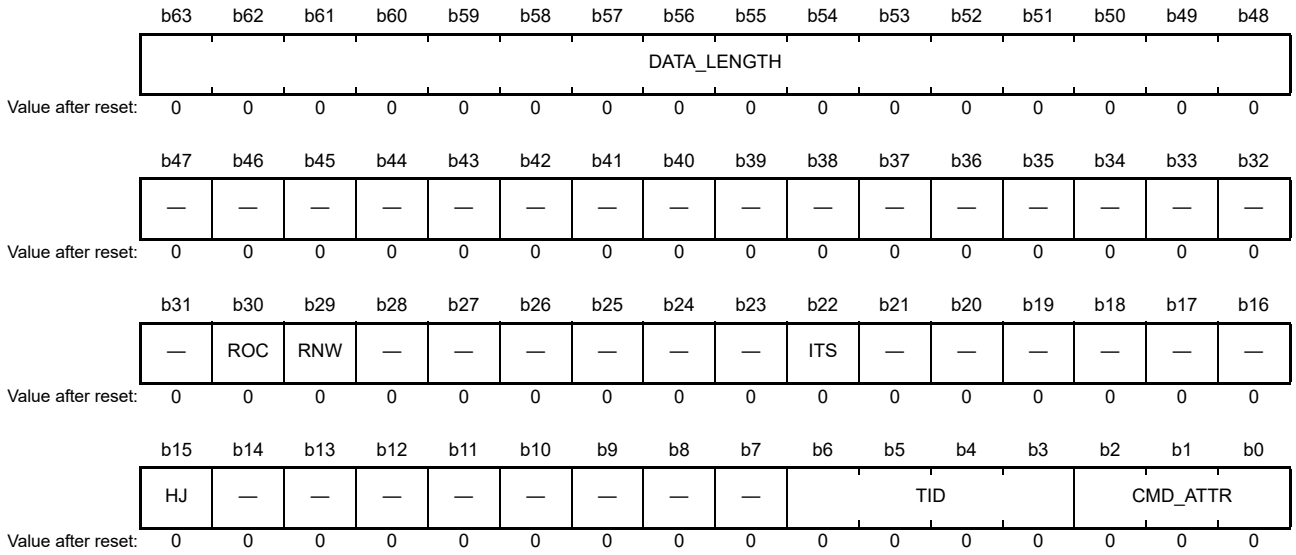
Identifies the direction of this transfer.

DATA_LENGTH Field (Data Length)

Number of bytes to be transferred.

This field should be set to a non-zero value, except for CCCs that do not have payload defined. Length setting of GETMXDS command should be fixed to “0005h”.

(2) I3C Target Mode



Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CMD_ATTR	Command Attribute	Set this field to 000b (regular data transfer command).	W
b6 to b3	TID	Transaction ID	Used as a tag for this command. Specify in the range of 0h to 7h.	W
b14 to b7	—	Reserved	The write value should be 0.	W
b15	HJ	Hot-Join Event	0: Target Interrupt Request or Controller Role Request 1: Hot-Join event	W
b21 to b16	—	Reserved	The write value should be 0.	W
b22	ITS	Include Timestamp	0: Do not include timestamp. 1: Include timestamp.	W
b28 to b23	—	Reserved	The write value should be 0.	W
b29	RNW	Transfer Direction (RnW)	0: WRITE: Write transfer (Controller Role Request) 1: READ: Read transfer (Target Interrupt Request)	W
b30	ROC	Response on Completion	0: NOT_REQUIRED: Response status is not required. 1: REQUIRED: Response status is required.	W
b47 to b31	—	Reserved	The write value should be 0.	W
b63 to b48	DATA_LENGTH	Data Length	Indicates the number of bytes to be transferred.	W

HJ Field (Hot-Join Event)

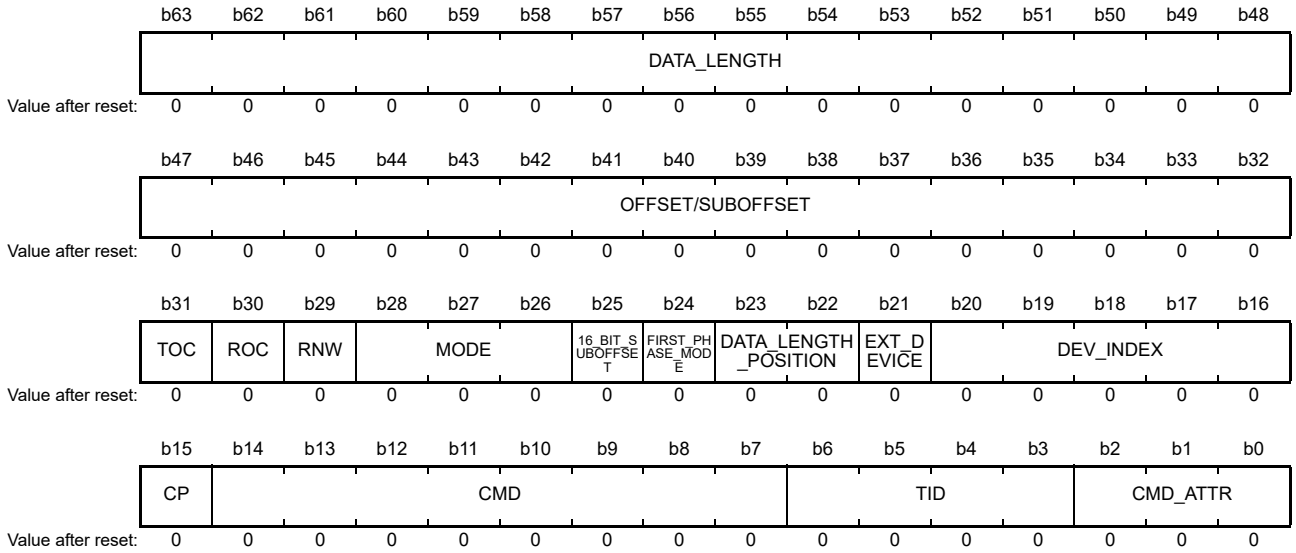
Indicates whether Hot-Join Event is valid in this IBI Data transfer.

RNW Field (Transfer Direction (RnW))

Identifies the direction of this transfer. This field is invalid for Hot-Join event.

35.3.1.4 Combo Transfer Command

This Command Descriptor describes a combined Write + Read or Write + Write operation.
Data is transferred via the transmit/receive data register (ICDR).
Details of the combo transfer command structure are as follows.



Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CMD_ATTR	Command Attribute	Set this field to 011b (combo transfer command).	W
b6 to b3	TID	Transaction ID	Used as a tag for this command. Specify in the range of 0h to 7h.	W
b14 to b7	CMD	Transfer Command CCC Value	This field is reserved for this command. Set it to 00h.	W
b15	CP	Command Present	Set this field to 0 for this command.	W
b20 to b16	DEV_INDEX	Device Index	Specify the DAT table index (m of the ICTDATRm register) for the Target device being addressed with the transfer.	W
b21	EXT_DEVICE	Extended Device Index	0: Use the ICTDATRm table indicated by DEV_INDEX. 1: Use the ICEDATR table.	W
b23, b22	DATA_LENGTH_POSITION	Data Length Field Position	Set this field to 00b.	W
b24	FIRST_PHASE_MODE	First Phase Mode	0: SDR: First phase is executed in SDR mode. 1: MODE: First phase is executed in the mode indicated by the MODE field.	W
b25	16_BIT_SUBOFFSET	Sub Offset Size	0: 8_BIT_SUBOFFSET: Sub-offset is 8 bits long. Value is encoded in lower byte of OFFSET/SUBOFFSET field. 1: 16_BIT_SUBOFFSET: Sub-offset is 16 bits long.	W
b28 to b26	MODE	Mode and Speed	• I3C transfer b28 b26 0 0 0: I3C SDR0, ICSBR register setting (up to 12.5 MHz) 0 0 1: I3C SDR1, ICEBR register setting (up to 8 MHz) 0 1 1: I3C SDR2, ICSBR register setting × 2 (up to 6 MHz) 1 0 0: I3C SDR3, ICEBR register setting × 2 (up to 4 MHz) 1 0 1: I3C SDR4, ICEBR register setting × 4 (up to 2 MHz) Settings other than above are prohibited. • I²C transfer b28 b26 0 0 0: I²C FM, ICSBR register setting (up to 400 kHz) 0 0 1: I²C FM+, ICEBR register setting (up to 1 MHz) Settings other than above are prohibited.	W

Bit	Symbol	Bit Name	Description	R/W
b29	RNW	Transfer Direction (RnW)	0: WRITE: Write transfer 1: READ: Read transfer	W
b30	ROC	Response on Completion	0: NOT_REQUIRED: Response status is not required. 1: REQUIRED: Response status is required.	W
b31	TOC	Terminate on Completion	0: RESTART: Issue repeated START condition (Sr) at end of transfer 1: STOP: Issue STOP condition (P) at end of transfer	W
b47 to b32	OFFSET/ SUBOFFSET	Offset/Sub-Offset	Set the value of the Offset field to be transferred in the first phase.	W
b63 to b48	DATA_LENGTH	Data Length	Specify the number of bytes to be transferred in the second phase. This field must be set to non-zero value.	W

DATA_LENGTH_POSITION Field (Data Length Field Position)

Indicates whether and where to put Data Length (DATA_LENGTH) in the first phase of the transfer.

FIRST_PHASE_MODE Field (First Phase Mode)

Indicates whether the first phase of the combo transfer is executed in SDR mode, vs. the mode indicated by the MODE field.

16_BIT_SUBOFFSET Field (Sub Offset Size)

Indicates whether the length of the Offset and Length fields in the first phase of the transfer is 8 bits or 16 bits. For 8-bit, data should be written in lower bytes of the OFFSET/SUBOFFSET and DATA_LENGTH fields.

RNW Field (Transfer Direction (RnW))

Identifies the direction of the second phase of the transfer.

35.3.1.5 Internal Control Command

This Command Descriptor is used for controlling RI3C itself (not for I3C transfer commands).
Details of the internal control command structure are as follows.

	b63	b62	b61	b60	b59	b58	b57	b56	b55	b54	b53	b52	b51	b50	b49	b48
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b47	b46	b45	b44	b43	b42	b41	b40	b39	b38	b37	b36	b35	b34	b33	b32
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	ON_OFF	MIPI_CMD				—	TID				CMD_ATTR		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CMD_ATTR	Command Attribute	Set this field to 111b (internal control command).	W
b6 to b3	TID	Transaction ID*1	Used as a tag for this command. Specify in the range of 0h to 7h.	W
b7	—	Reserved	The write value should be 0.	W
b11 to b8	MIPI_CMD	MIPI Alliance Command	b11 b8 0 0 0 0: NoOp (performs no transfer) 0 0 1 0: Broadcast Address automatic transmission Settings other than above are prohibited.	W
b12	ON_OFF	On/Off	0: disables automatic transmission of Broadcast Address 1: enables automatic transmission of Broadcast Address*2	W
b63 to b13	—	Reserved	The write value should be 0.	W

Note 1. The Response Descriptor is not stored when the internal control command is executed.
Note 2. Automatic transmission of Broadcast Address enabled by this command is disabled when the ICRCR.ISRST is set to 1.

35.3.2 Response Descriptor

The Response Descriptor is a 32-bit read-only structure describing the success or failure of a command, and the amount of data transferred.
The Response Descriptor is read from the response queue via the response queue register (ICRQR).

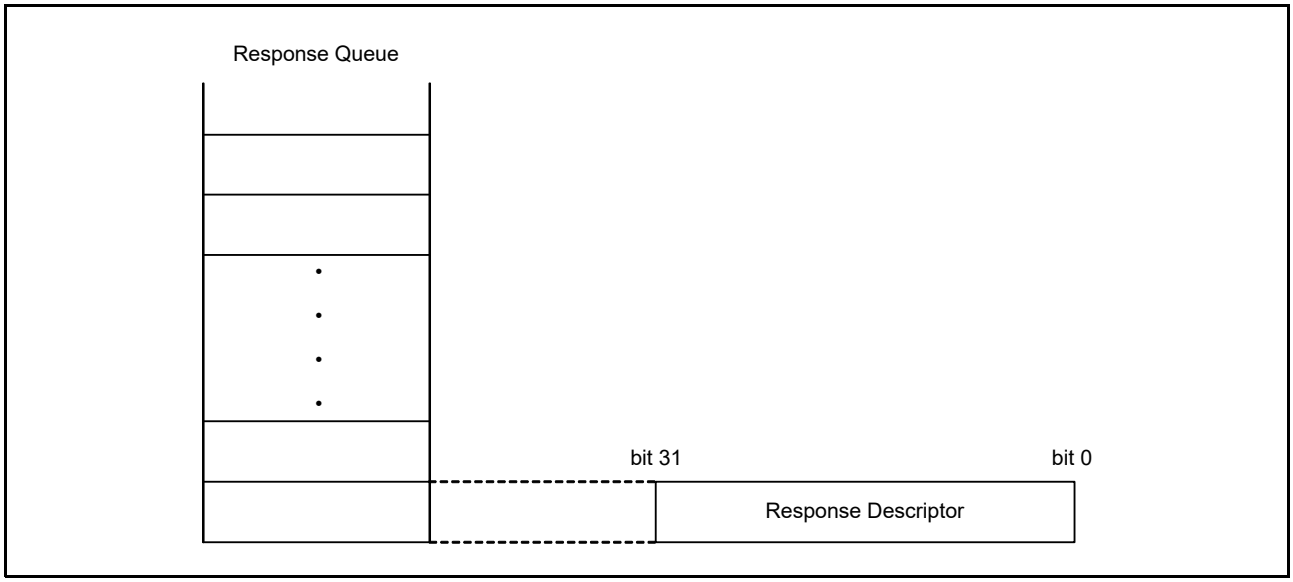


Figure 35.3 Response Descriptor Data Structure

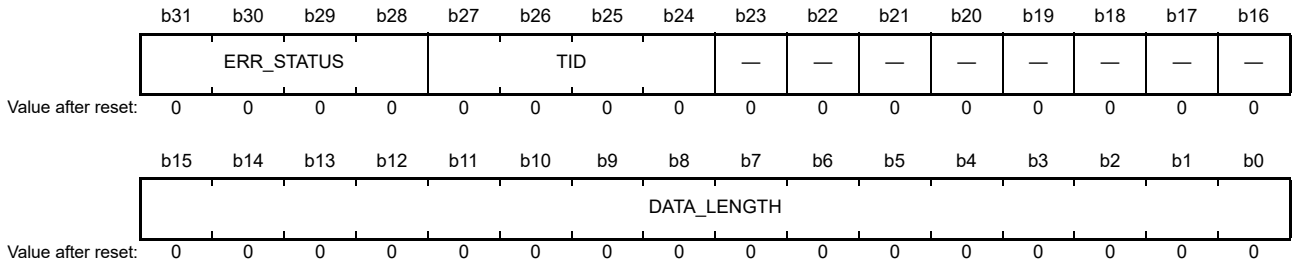
The Response Descriptor structure differs between I3C Controller mode and I3C Target mode.
Details of the Response Descriptor structure of each mode are as follows.

(1) I3C Controller Mode



Bit	Symbol	Bit Name	Description	R/W
b15 to b0	DATA_LENGTH	Data Length/Device Count	For write transfer: Remaining data length (in bytes) For read transfer: Received data length (in bytes) For address assignment: Remaining device count	R
b23 to b16	—	Reserved	These bits are read as 0.	R
b27 to b24	TID	Transaction ID	This value shall match the value of the TID field, for a previously enqueued Command Descriptor that was sent on the bus.	R
b31 to b28	ERR_STATUS	Error Status	b31 b28 0 0 0 0: SUCCESS: Transfer successful, no error 0 1 0 0: ADDR_HEADER: Address header error 0 1 0 1: NACK: Address NACKed or Dynamic Address Assignment NACKed 0 1 1 0: OVL: Receive overflow or transmit underflow error 1 0 0 0: ABORTED: Transfer aborted 1 0 0 1: I2C_WR_DATA_NACK: NACK is received during an I^2C write data transfer 1 0 1 0: NOT_SUPPORTED: Command is not supported	R

TID Field (Transaction ID)

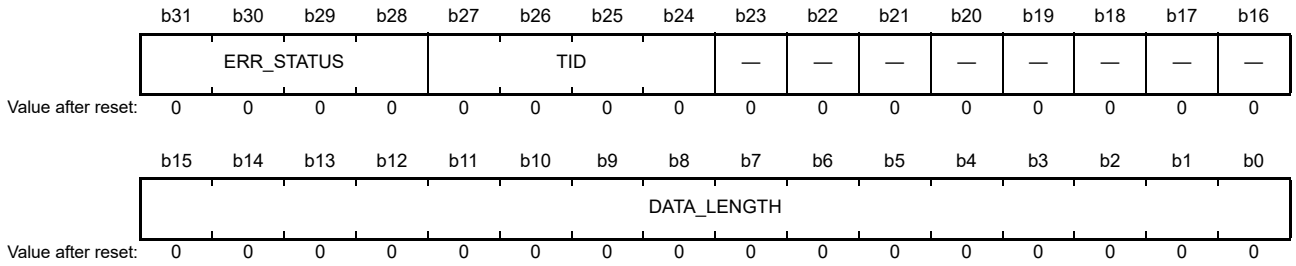
This field reflects the value specified in the TID field of the Command Descriptor. Software can determine which command the response is for by checking this field.

ERR_STATUS Field (Error Status)

This field indicates the transfer status of the command indicated by the TID field.
The details of each error are as follows.

- ADDR_HEADER: No Target devices acknowledge the Broadcast Address.
- NACK: Any Target device that responds to the ENTDAA procedure does not accept the Dynamic Address or an addressed Target device does not acknowledge its Dynamic Address.
- OVL: Transmit data buffer underflowed or receive data buffer overflowed.
- ABORTED: A transaction was aborted.
- I2C_WR_DATA_NACK: The I^2C Target device does not acknowledge the I^2C write data transfer.
- NOT_SUPPORTED: A Command Descriptor structure with an illegal or invalid combination of field values was stored.

(2) I3C Target Mode



Bit	Symbol	Bit Name	Description	R/W
b15 to b0	DATA_LENGTH	Data Length	For Target Interrupt Request: Remaining data length (in bytes)	R
b23 to b16	—	Reserved	These bits are read as 0.	R
b27 to b24	TID	Transaction ID	This value shall match the value of the TID field, for a previously enqueued Command Descriptor that was sent on the bus.	R
b31 to b28	ERR_STATUS	Error Status	b31 b28 0 0 0 0: SUCCESS: Transfer successful, no error 0 1 0 0: ADDR_HEADER: Address header error 0 1 0 1: NACK: Address NACKed or Dynamic Address Assignment NACKed 0 1 1 0: OVL: Receive overflow or transmit underflow error 1 0 0 0: ABORTED: Transfer aborted 1 0 1 0: NOT_SUPPORTED: Command is not supported	R

ERR_STATUS Field (Error Status)

This field indicates the transfer status of the command indicated by the TID field.

The details of each error are as follows.

- ADDR_HEADER: No Target devices acknowledge the Broadcast Address.
- NACK: Any Target device that responds to the ENTDAA procedure does not accept the Dynamic Address or an addressed Target device does not acknowledge its Dynamic Address.
- OVL: Transmit data buffer underflowed or receive data buffer overflowed.
- ABORTED: A transaction was aborted.
- NOT_SUPPORTED: A Command Descriptor structure with an illegal or invalid combination of field values was stored, an IBI disabled by the ICTEVR register is requested, or an IBI is disabled by DISEC CCC after a Command Descriptor structure for the IBI was enqueued in the command queue.

35.3.3 IBI Status Descriptor

The IBI Status Descriptor is a 32-bit read-only structure describing an IBI event received from a Target device on the I3C bus. This Descriptor is used in I3C Controller mode.
The IBI Status Descriptor is read from the IBI queue via the IBI queue register (ICIQR).

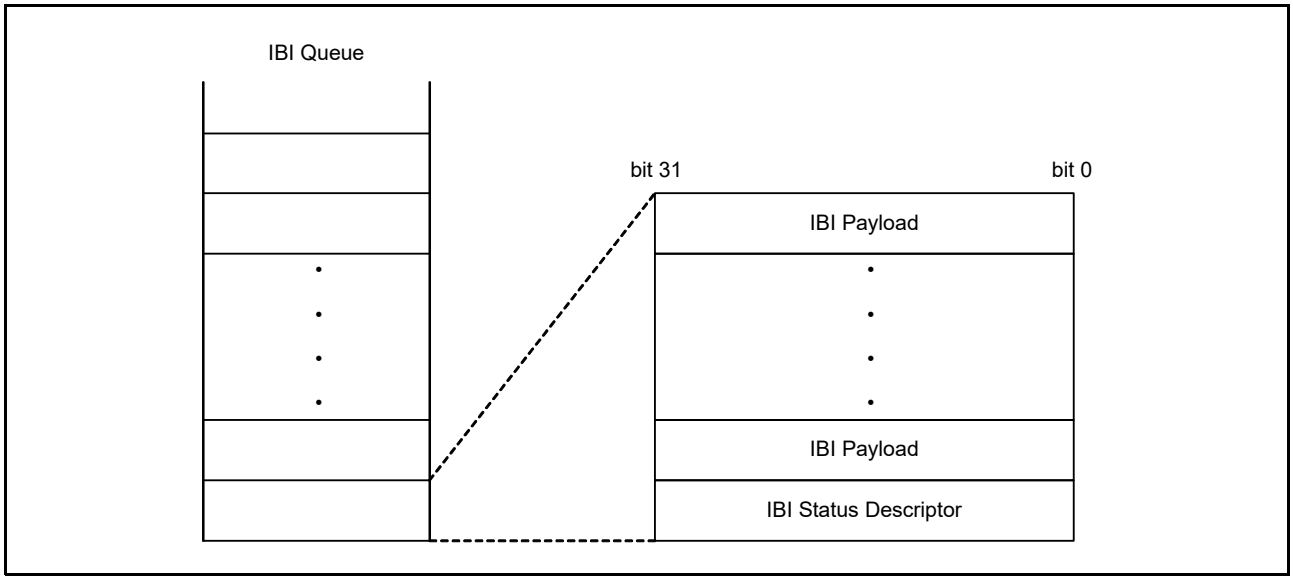


Figure 35.4 IBI Status Descriptor Data Structure

Details of the IBI Status Descriptor Structure are as follows.

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	IBI_STS	—	—	ERR_STATUS			TS	LAST_STATUS	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	IBI_ID								DATA_LENGTH							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	DATA_LENGTH	IBI Data Length	Number of data bytes in IBI data.	R
b15 to b8	IBI_ID	IBI Received ID	• Target Interrupt Request or Controller Role Request: b15 to b9: Target's Device Address b8: Value of RnW bit • Hot-Join Request: b15 to b9: Hot-Join ID (= 02h) b8: Value of RnW bit (= 0)	R
b23 to b16	—	Reserved	These bits are read as 0.	R
b24	LAST_STATUS	Last IBI Status	Last IBI status for the IBI transaction.*1	R
b25	TS	IBI Timestamp Present	Indicates whether a timestamp is available for the IBI. 0: OFF: IBI is not timestamped. 1: ON: IBI is timestamped.	R

Bit	Symbol	Bit Name	Description	R/W
b28 to b26	ERR_STATUS	IBI Error Status	b28 b26 0 0 0: SUCCESS 0 1 1: FRAME: Frame error 1 0 0: ADDR_HEADER: Address header error 1 0 1: NACK: Address NACKed 1 1 1: ABORT: Aborted to Controller	R
b30, b29	—	Reserved	These bits are read as 0.	R
b31	IBI_STS	IBI Received Status	0: The IBI was handled with ACK. 1: The IBI was handled with NACK, and then Auto-Disabled.	R

Note 1. Even if the LAST_STATUS field is set to 0, examine the DATA_LENGTH field to evaluate the data payload length.

LAST_STATUS Field (Last IBI Status)

For some IBIs, multiple IBI Status Descriptors might be needed to describe a single IBI event. A 0 in this field indicates that there is a subsequent IBI Status Descriptor.
Even if this field is set to 0, examine the DATA_LENGTH field to evaluate the data payload length.

IBI_STS Field (IBI Received Status)

Indicates how the received IBI was handled by Active Controller.

35.3.4 Receive Status Descriptor

The Receive Status Descriptor is a 32-bit read-only structure describing the success or failure of read/write transfer issued by the Controller, and the amount of data transferred. This Descriptor is used in I3C Target mode.
The Receive Status Descriptor is read from the receive status queue via the receive status queue register (ICSQR).

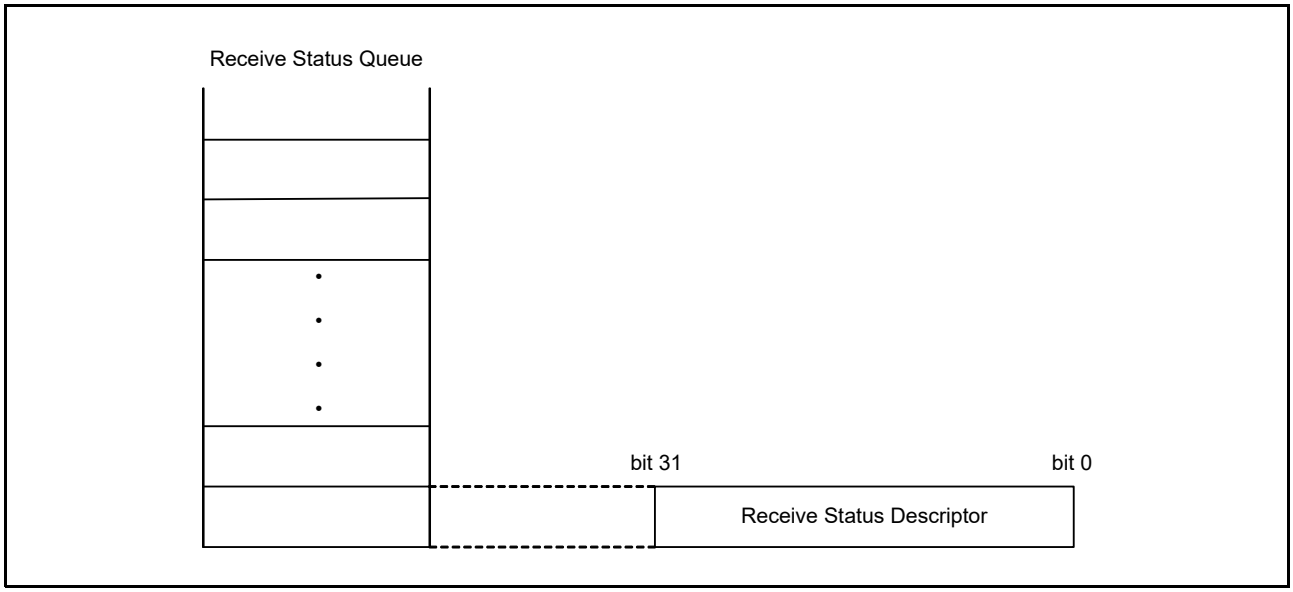

Figure 35.5 Receive Status Descriptor Data Structure

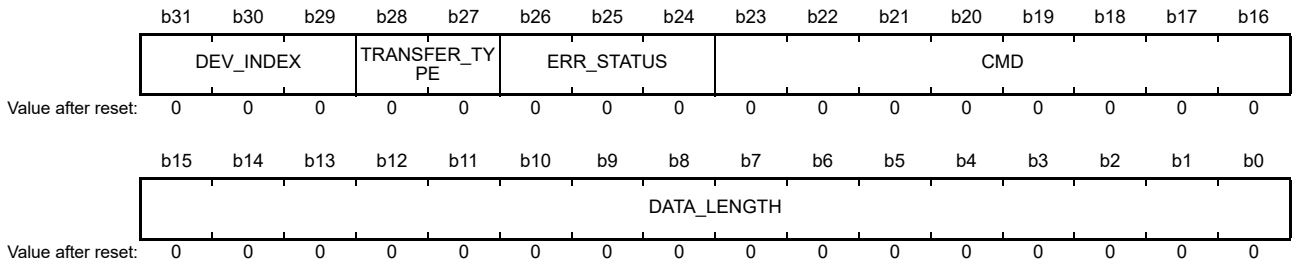
Details of the Receive Status Descriptor structure are as follows.



Bit	Symbol	Bit Name	Description	R/W
b15 to b0	DATA_LENGTH	Data Length	For Write Transfer: Received data length (in bytes) For Read Transfer: Transmitted data length (in bytes)	R
b23 to b16	CMD	Command Code	• I3C SDR private transfer or Legacy I2C transfer: b23: Transfer type (0: Write/1: Read) b22 to b20: Reserved b19: Transfer mode (0: I3C SDR/1: Legacy I2C) b18 to b16: Reserved • SDR CCC transfer: Indicates the CCC command code specified in the Command Descriptor of the transfer.	R
b26 to b24	ERR_STATUS	Error Status	b26 b24 0 0 0: SUCCESS: Transfer successful, no error 1 0 0: ADDR_HEADER: Address header error 1 0 1: NACK: Target NACKed 1 1 0: OVL: FIFO overflow/underflow 1 1 1: ABORTED: Aborted to Controller	R

Bit	Symbol	Bit Name	Description	R/W
b28, b27	TRANSFER_TYPE	Transfer Type	b28 b27 0 0: I3C SDR private transfer or Legacy I^2C transfer 0 1: I3C CCC	R
b31 to b29	DEV_INDEX	Device Index	Indicates the DAT table index (m of the ICTDATRm register) for the responded device with the transfer.	R

35.4 Operation

35.4.1 Data Handler

The relationship between the transfer method and the queue is shown in Table 35.5.
RI3C supports only FIFO buffer transfer. RI3C autonomously starts transfer when data and command are written.

Table 35.5 Transfer Method and Queue

Protocol	Transfer Method	Queue/Buffer	Size	Controller	Target	Secondary Controller
I3C Mode	FIFO buffer transfer	Command Queue	64 bits × 2 stages	✓	✓	✓
		Response Queue	32 bits × 2 stages	✓	✓	✓
		Transmit Data Buffer	32 bits × 2 stages	✓	✓	✓
		Receive Data Buffer	32 bits × 2 stages	✓	✓	✓
		Receive Status Queue	32 bits × 2 stages	—	✓	✓
		IBI Status Queue	32 bits × 2 stages	✓	—	✓
		IBI Data Buffer	32 bits × 6 stages	✓	✓	✓

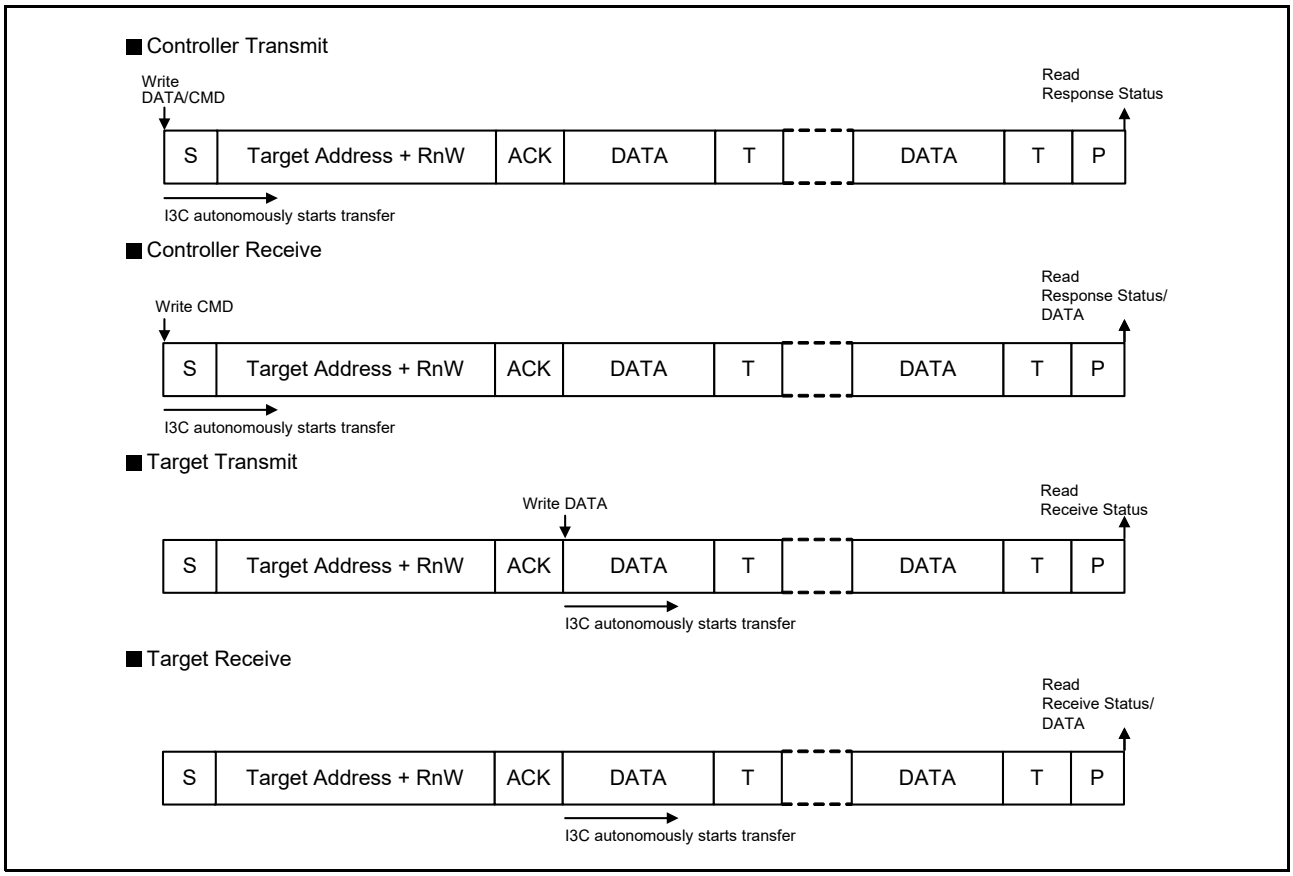


Figure 35.6 Data Handler with FIFO Buffer Transfer

35.4.2 I3C Protocol

35.4.2.1 Communication Protocol

(1) I3C Communication Data Format

Figure 35.7 through Figure 35.10 illustrate a typical communication for each of the supported I3C Protocols. While these diagrams do not exhaustively illustrate all possible RI3C communications, they do serve as useful introductions to the signaling and transmission formatting used in each supported I3C Protocol.

Figure 35.7 illustrates example communication using I3C Single Data Rate (SDR) mode with Broadcast Address (7Eh). It shows the Controller reading a byte of data from the Target at Address 2Bh in SDR Mode.
From the Bus Free condition, the Controller issues a START condition by driving the SDA line Low while keeping the SCL line High. It then issues the Broadcast Address (7Eh) followed by RnW (0 for Write). Then the Controller turns on a pull-up resistor and goes to Open Drain. All Targets ACK by pulling the SDA line Low (in the Figure, pink fill means the Target is in control of the SDA line at this time). The Controller then issues a repeated START condition, then the Address of the Target (2Bh) it wants to read followed by RnW (1 for Read). The Controller then turns on a pull-up resistor and goes to Open Drain, allowing the Target to acknowledge by pulling the SDA line Low. At this point, the Controller continues to toggle the SCL line and release the SDA line, allowing the Target to drive SDA to send one byte of data (4Ah) followed by T. T = 1 informs the Controller that there is additional data, whereas T = 0 signals the end. Here there is additional data, so the Target drives SDA High until SCL goes High, at which time it releases SDA. The Controller has the option of holding SDA High with a weak pull-up, which signals to the Target that the Controller allows another byte to be transmitted, or to pull SDA Low (while SCL is High – hence a repeated START condition), which would signal to the Target that the Controller has terminated the Read and is taking over.

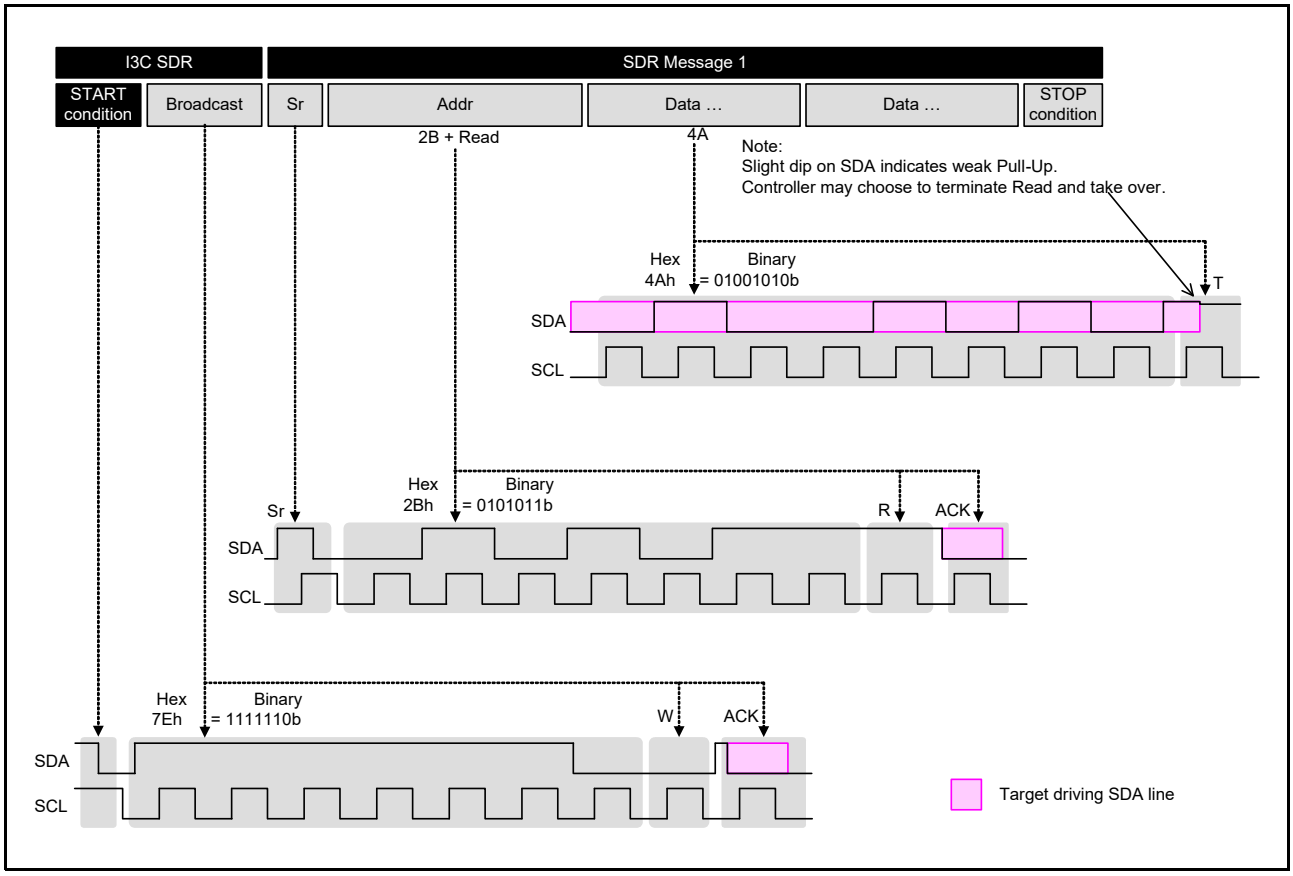

Figure 35.7 Example Communication Using I3C Mode SDR with Broadcast Address (7Eh)

Figure 35.8 illustrates example communication using I3C Single Data Rate (SDR) mode without Broadcast Address (7Eh). It shows the Controller reading a byte of data from the Target at Address 2Bh in SDR Mode.
From the Bus Free condition, the Controller issues a START condition, then the Address of the Target (2Bh) it wants to read followed by RnW (1 for Read). The Controller then turns on a pull-up resistor and goes to Open Drain, allowing the Target to acknowledge by pulling the SDA line Low. At this point, the Controller continues to toggle the SCL line and release the SDA line, allowing the Target to drive SDA to send one byte of data (4Ah) followed by T. T = 1 informs the Controller that there is additional data, whereas T = 0 signals the end. Here there is additional data, so the Target drives SDA High until SCL goes High, at which time it releases SDA. The Controller has the option of holding SDA High with a weak pull-up, which signals to the Target that the Controller allows another byte to be transmitted, or to pull SDA Low (while SCL is High – hence a repeated START condition), which would signal to the Target that the Controller has terminated the Read and is taking over.

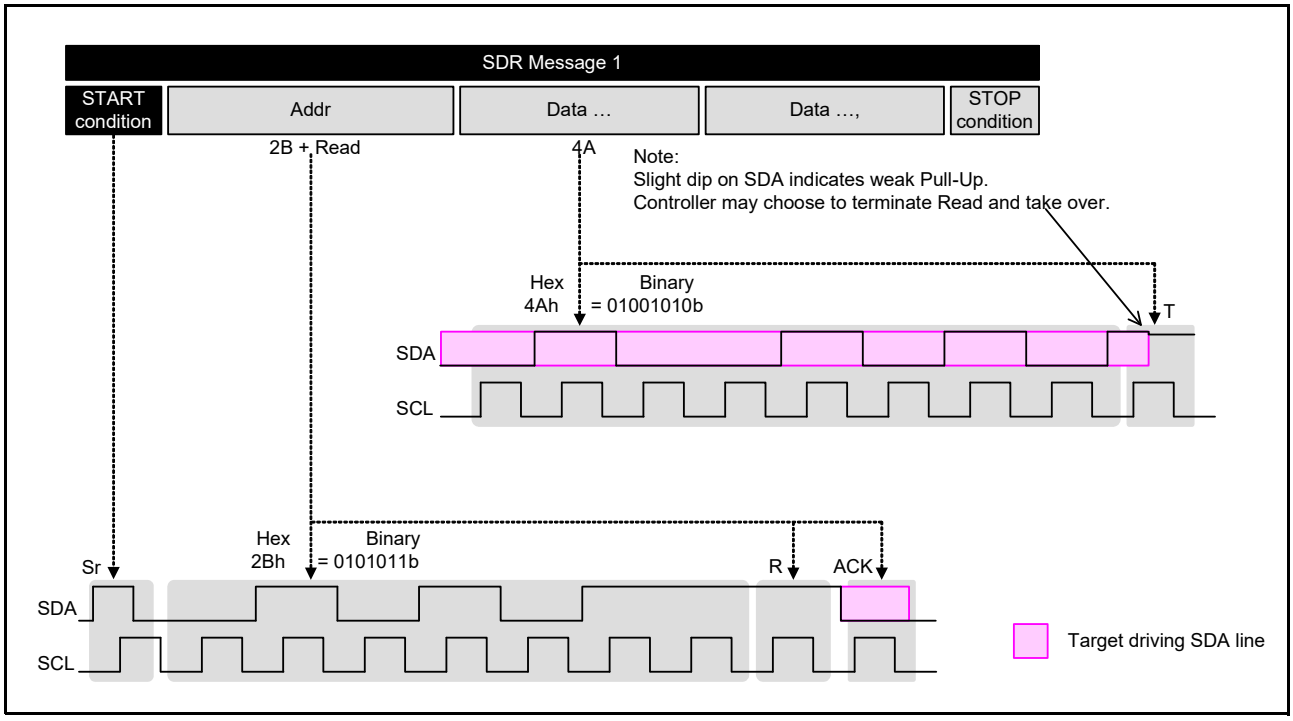

Figure 35.8 Example Communication Using I3C Mode SDR without Broadcast Address (7Eh)

Figure 35.9 shows the Controller issuing a Direct CCC to a single Target. This particular command (GETPID) reads the Provisioned ID of a Target.

From the Bus Free condition, the Controller issues a START condition by driving the SDA line Low while keeping the SCL line High. It then issues the Broadcast Address (7Eh) followed by RnW (0 for Write). Then the Controller turns on a pull-up resistor and goes to Open Drain. All Targets ACK by pulling SDA Low (in the Figure, pink fill means the Targets are in control of SDA at this time). The Controller then issues the Direct Common Command Code for GETPID (8Dh) followed by parity bit T (odd parity = 1 for 8Dh) then the 7-bit Dynamic Address of the Target (chosen arbitrarily here to be 2Bh) followed by a RnW bit (1 for Read). Then the Controller turns on a pull-up resistor and goes to Open Drain, allowing the Target at Address 2Bh to ACK by pulling SDA Low, which tells the Controller that the Target acknowledges the command and will comply. (Alternatively, the Target may NACK by not pulling SDA Low, which would inform the Controller that the Target will not comply – in this case, that an error occurred.) Following the ACK the Target outputs its 48-bit PID one byte at a time, and then the Controller issues a repeated START condition (this part of the waveform sequence is not shown in the Figure).

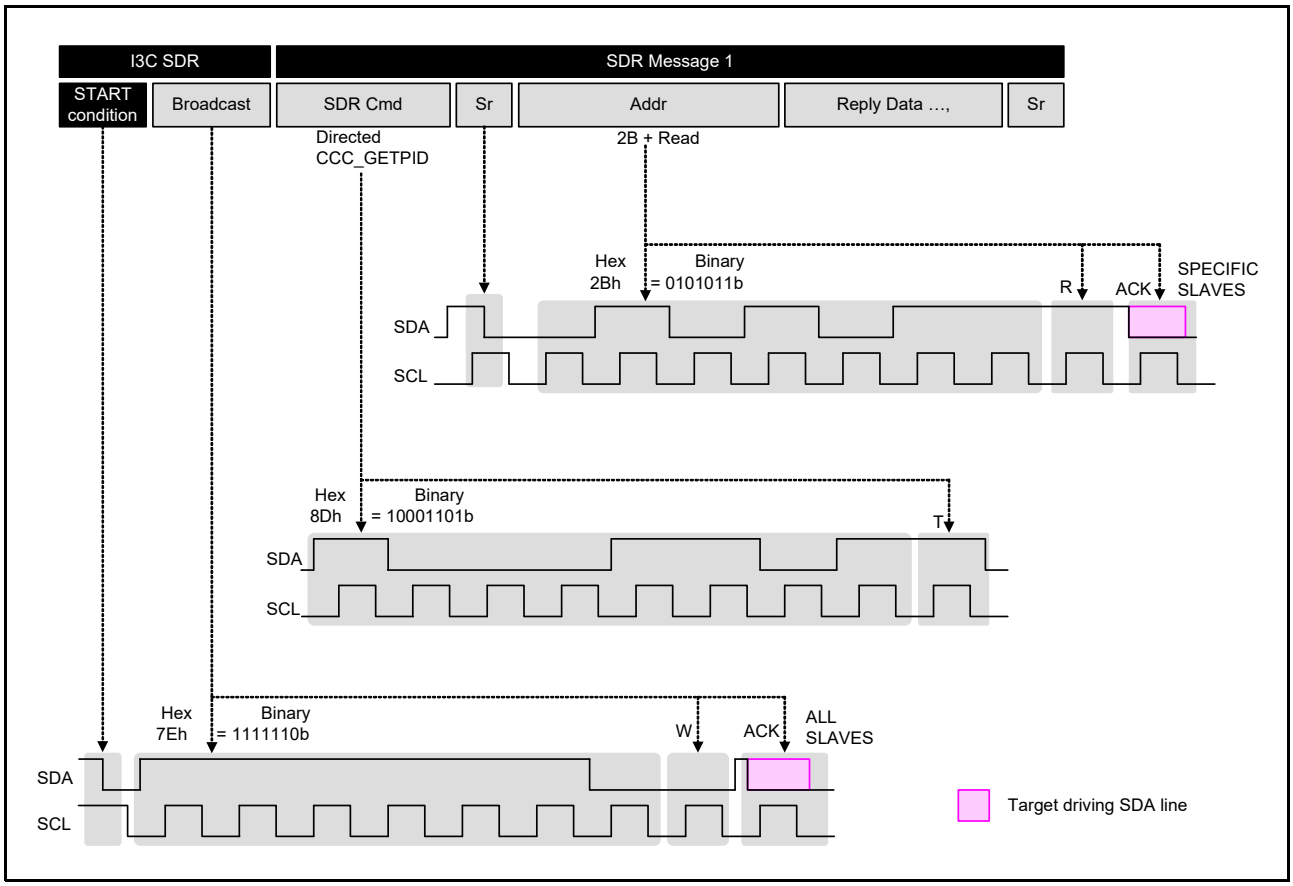

Figure 35.9 Example Communication Using I3C Mode SDR with Direct CCC

Figure 35.10 illustrates example SDR communication with a Broadcast CCC. The command used in this example sets the Maximum Read Length of all Targets to 43 bytes (002Bh).
From the Bus Free condition, the Controller issues a START condition by driving the SDA line Low while keeping the SCL line High. It then issues the Broadcast Address (7Eh) followed by RnW (0 for Write). Then the Controller turns on a pull-up resistor and goes to Open Drain. All Targets ACK by pulling SDA Low (in the Figure, pink fill means the Targets are in control of SDA at this time). The Controller then issues the Broadcast Common Command Code for SETMRL (0Ah) followed by parity bit T (odd parity = 1 for 0Ah), and then 2 data bytes (MSB first) to define the maximum number of bytes that can be read from a Target in a single read operation. Each data byte is followed by a T bit (parity bit – odd parity). After this the Controller issues a repeated START condition.

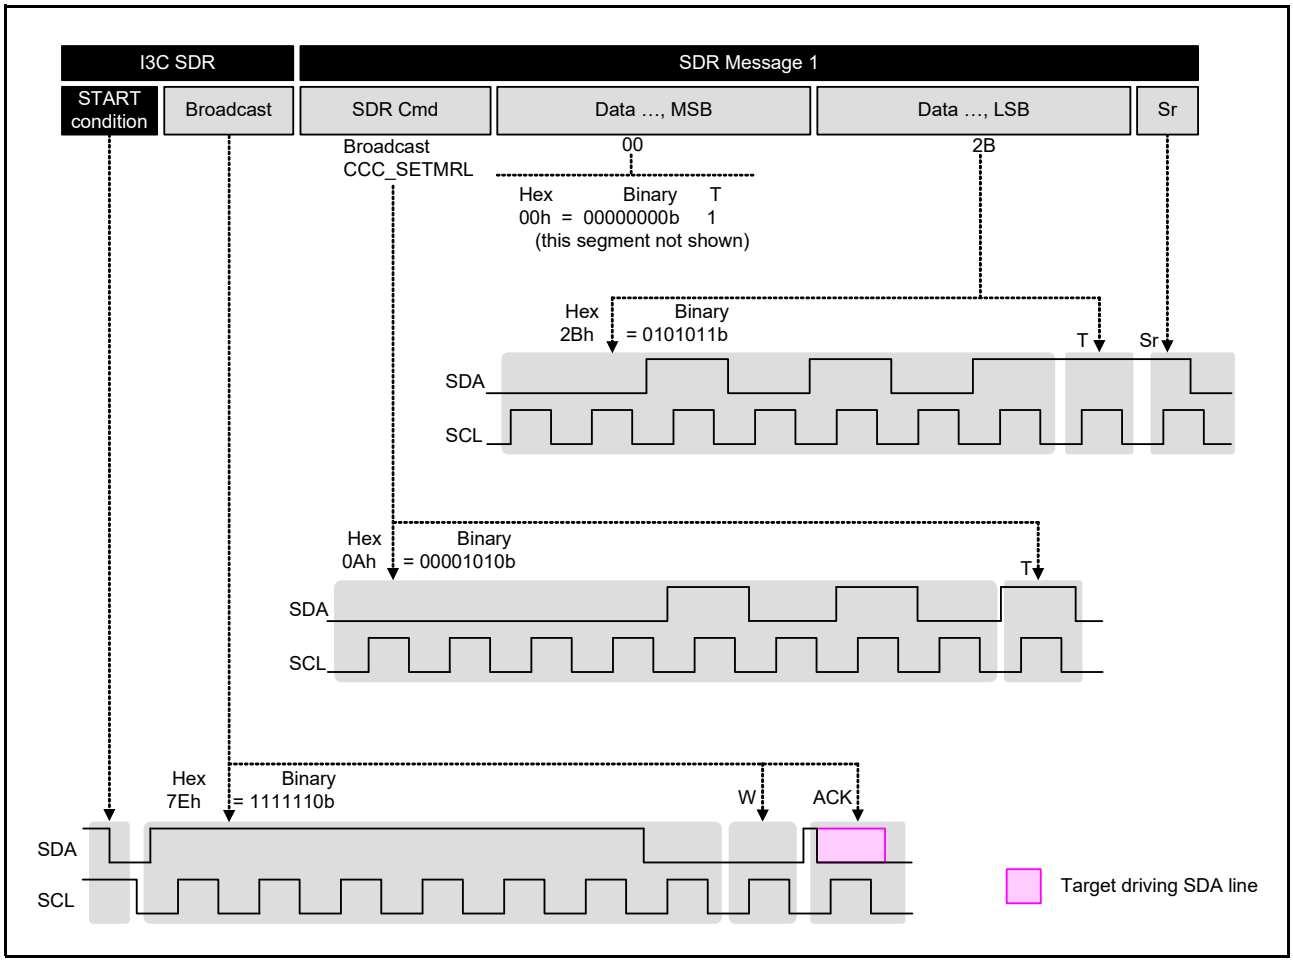

Figure 35.10 Example Communication Using I3C Mode SDR with Broadcast CCC

35.4.2.2 Bus Conditions

RI3C defines three distinct conditions in which the I3C bus shall be considered inactive: Bus Free, Bus Available, and Bus Idle (see Figure 35.11).

(1) Bus Free Condition

State on the I3C bus where both the SCL line and the SDA line are High for at least the period set by ICBFTR register.

(2) Bus Available Condition

State on the I3C bus where both the SCL line and the SDA line are High for at least the period set by ICBATR register.

A Target may only issue a START Request (For example, for an IBI, or for a CRR) after a Bus Available condition.

(3) Bus Idle Condition

State on the I3C bus where both the SCL line and the SDA line are High for at least the period set by ICBITR register.

A Target may only issue a START Request (For example, for a Hot-Join) after a Bus Idle condition.

Specifications are as follows. Bus Idle period needs to be the largest.

ICBFTR < ICBATR < ICBITR

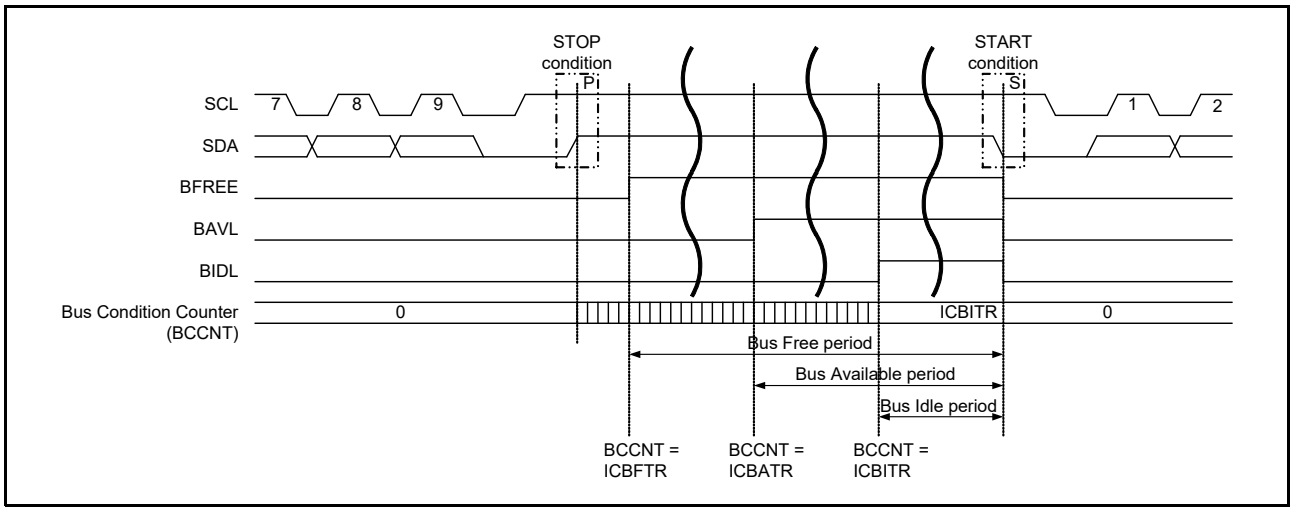

Figure 35.11 Bus Conditions

35.4.3 Initial Settings

Before starting data transmission and reception, initialize the RI3C according to the procedure in Figure 35.12.

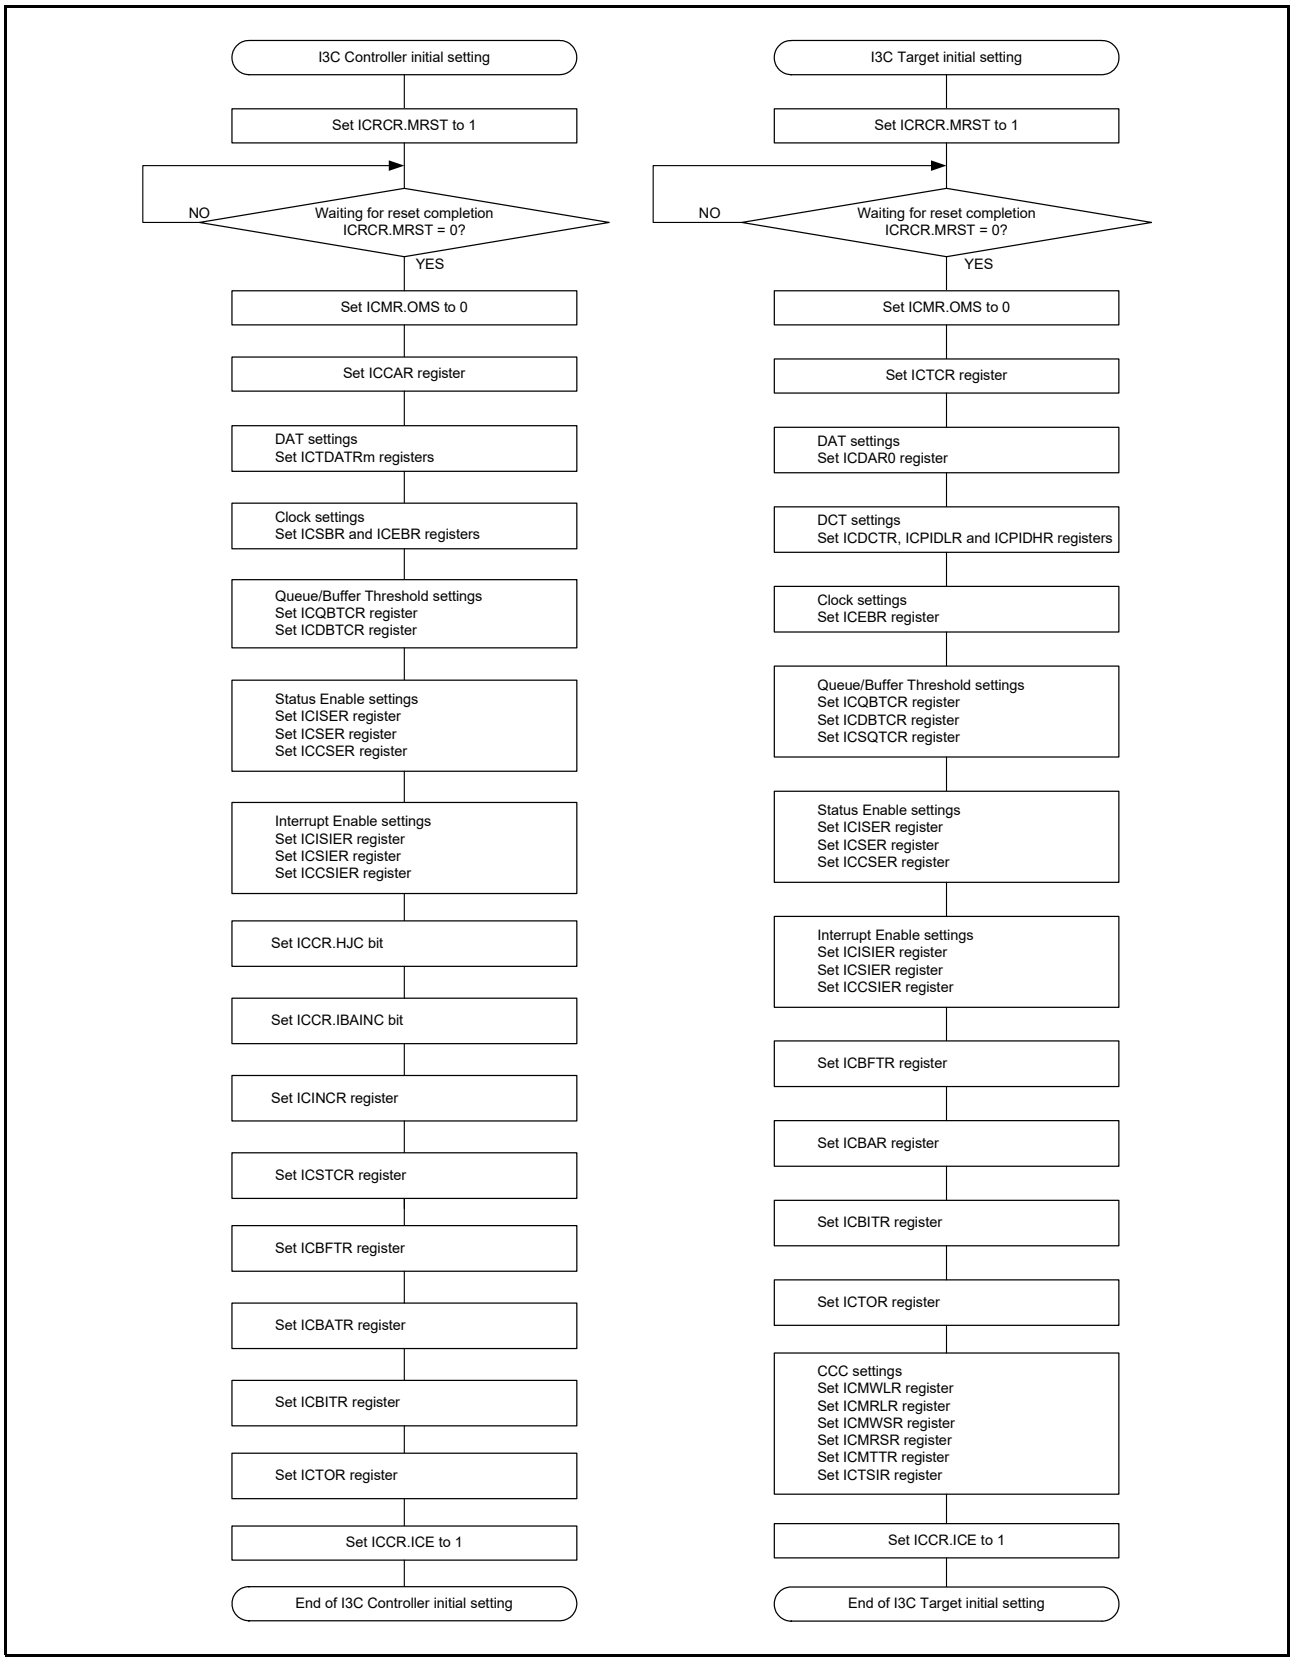

Figure 35.12 Example of RI3C Initialization Flowchart

35.4.4 I3C Communication Flow

Figure 35.13 illustrates how I3C communication is initiated:

- All I3C communication occurs within a frame. The frame begins with a START condition, followed by one or more transfers, and a STOP condition.

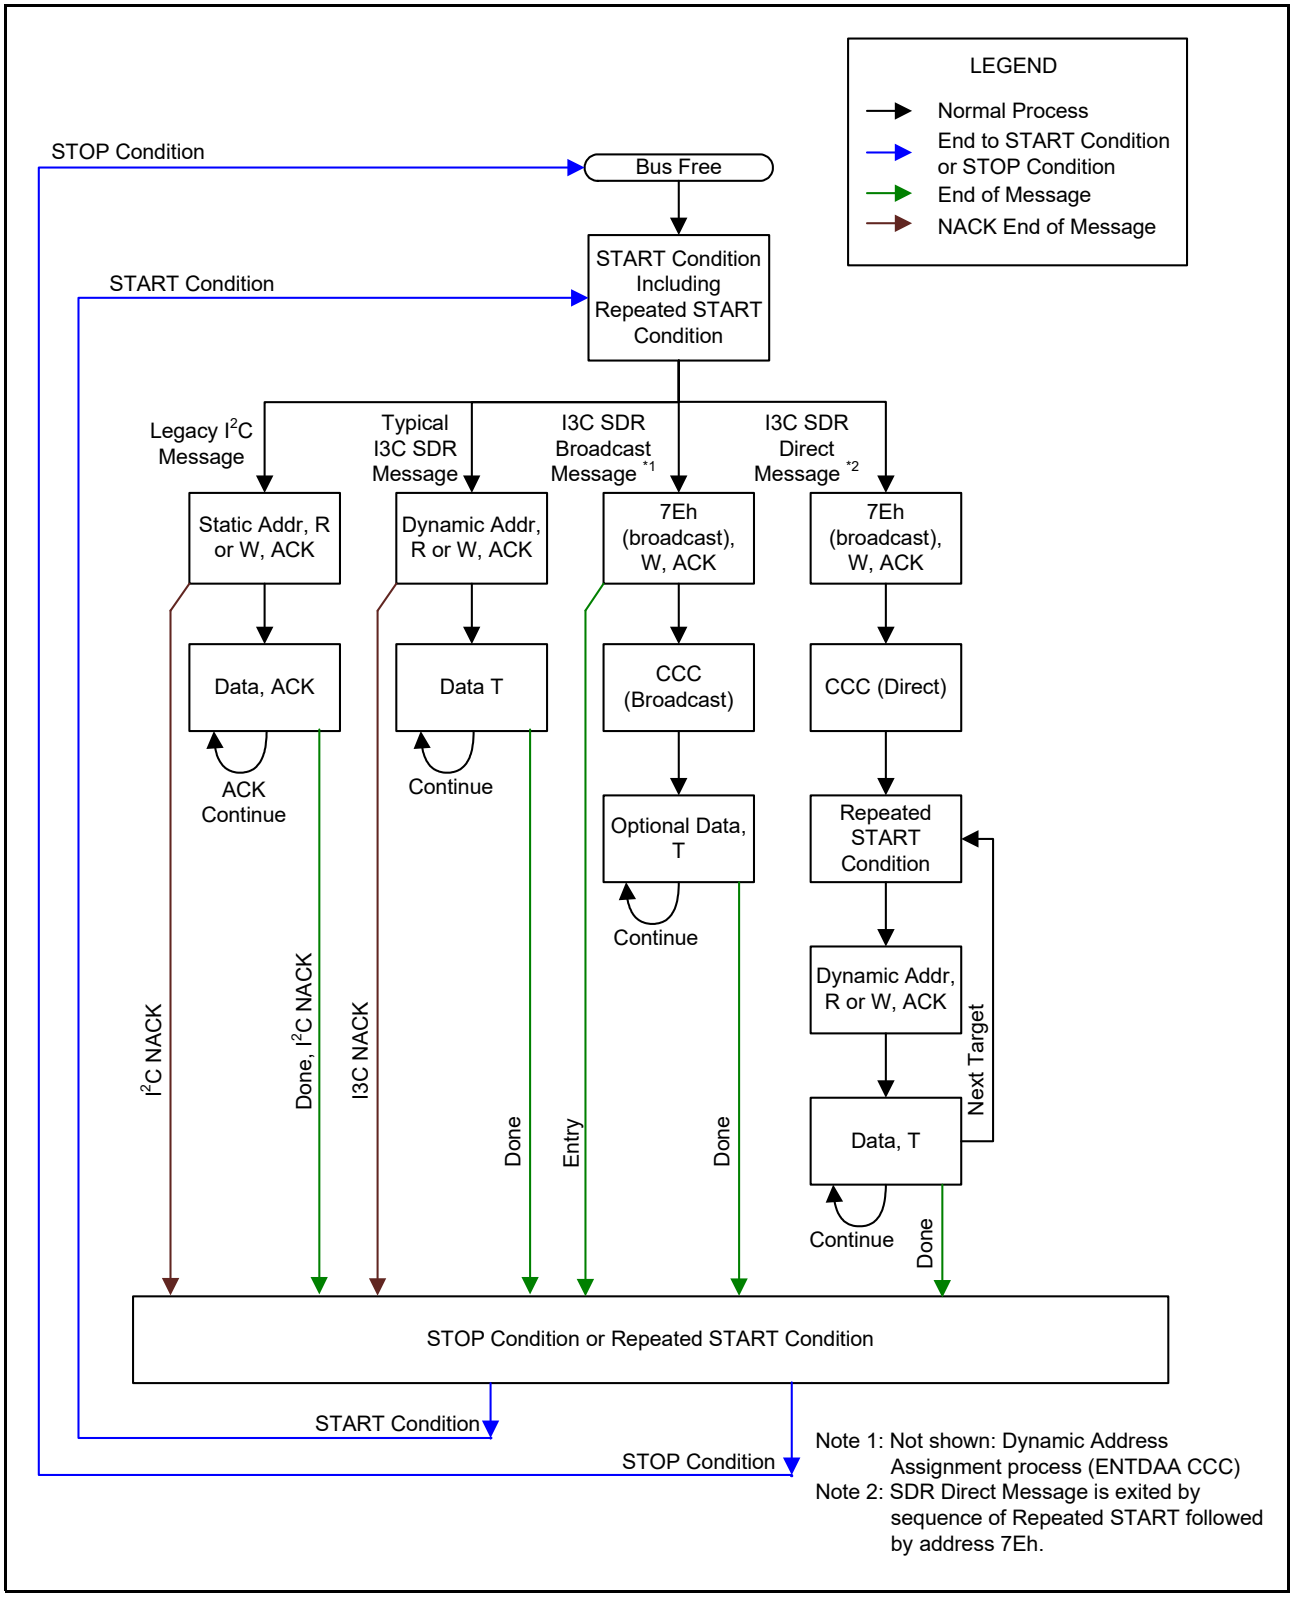

Figure 35.13 I3C Communication Flow

I3C is based on a frame encapsulation approach. A frame includes a data payload. The transfer protocol for the data payload is SDR. Frames are bordered by I^2C-like bus management.
The I3C frame always includes at least the START condition, the Header, the Data, and the STOP condition. The Header following a START condition allows for bus arbitration. The Controller uses the Header to address Target device(s). Target device(s) may use the Header Arbitration for multiple purposes: for IBI, for Hot-Join, and for Secondary Controller functionality.
I3C allows only one Controller to have control of the I3C bus at a time. Mechanisms for handoff of the Controller role from one device to another device are provided.

35.4.5 I3C Controller Operation

35.4.5.1 Dynamic Address Assignment Procedure

After initializing RI3C, first execute Dynamic Address Assignment Procedure for I3C Target connected on the I3C bus. The following describes the procedure.

(1) Initial setting (refer to section 35.4.3, Initial Settings for details)

(2) Execute Dynamic Address Assignment with ENTDAA or SETDASA Common Command Code (CCC) for I3C Target set in DAT (ICTDATRm register).
Write Command Descriptor (address assignment command) to command queue via the ICCQR register.

(3) When Command Descriptor is written to command queue, Transaction is issued on I3C bus.

(4) When ENTDAA is specified for the CMD field of address assignment command:
Executes Dynamic Address Assignment for I3C Targets corresponding to the number of the ICTDATRm registers specified by the DEV_COUNT filed starting with the ICTDATRm register indexed by the DEV_INDEX filed of address assignment command.
When SETDASA is specified for the CMD filed of address assignment command:
Execute Dynamic Address Assignment for I3C Target indicated by the ICTDATRm register indexed by the DEV_INDEX filed of address assignment command.

(5) In case of ENTDAA, the Provisioned ID, BCR, DCR transmitted from I3C Target is stored in Receive Data Buffer (BCR is also automatically stored in the ICTDCTRm register).
Read the Provisioned ID, BCR, and DCR from the receive data buffer via the ICDR register with a receive data full interrupt.

(6) When execution of Dynamic Address Assignment is completed, issue STOP condition and store the Response Descriptor into the response queue.

(7) Read the Response Descriptor via the ICRQR register and check the status.

(8) Check whether the value of the DATA_LENGTH filed of the Response Descriptor matches the value of the DEV_COUNT filed of the address assignment command.

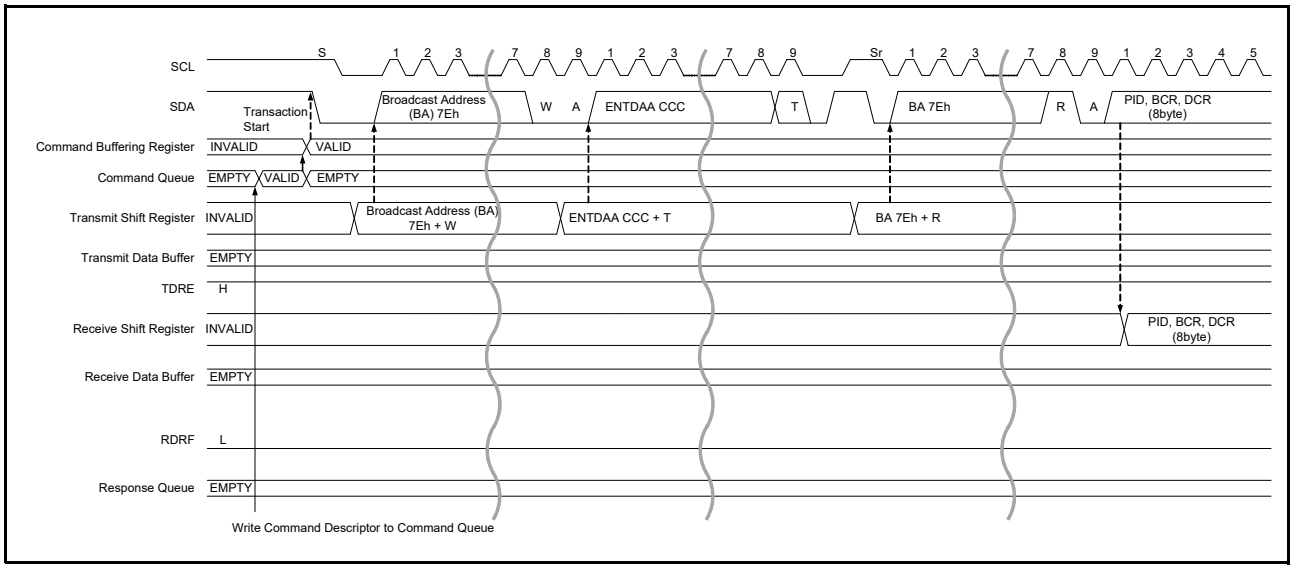

Figure 35.14 Dynamic Address Assignment Procedure (ENTDAA CCC) Timing (1/3)

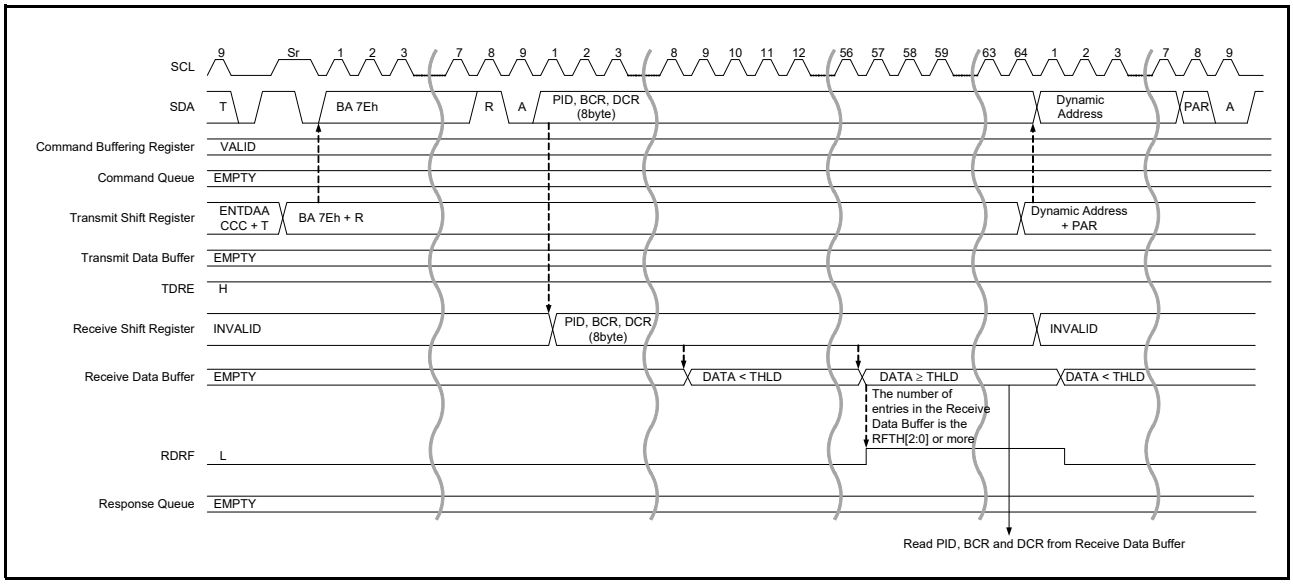

Figure 35.15 Dynamic Address Assignment Procedure (ENTDAA CCC) Timing (2/3)

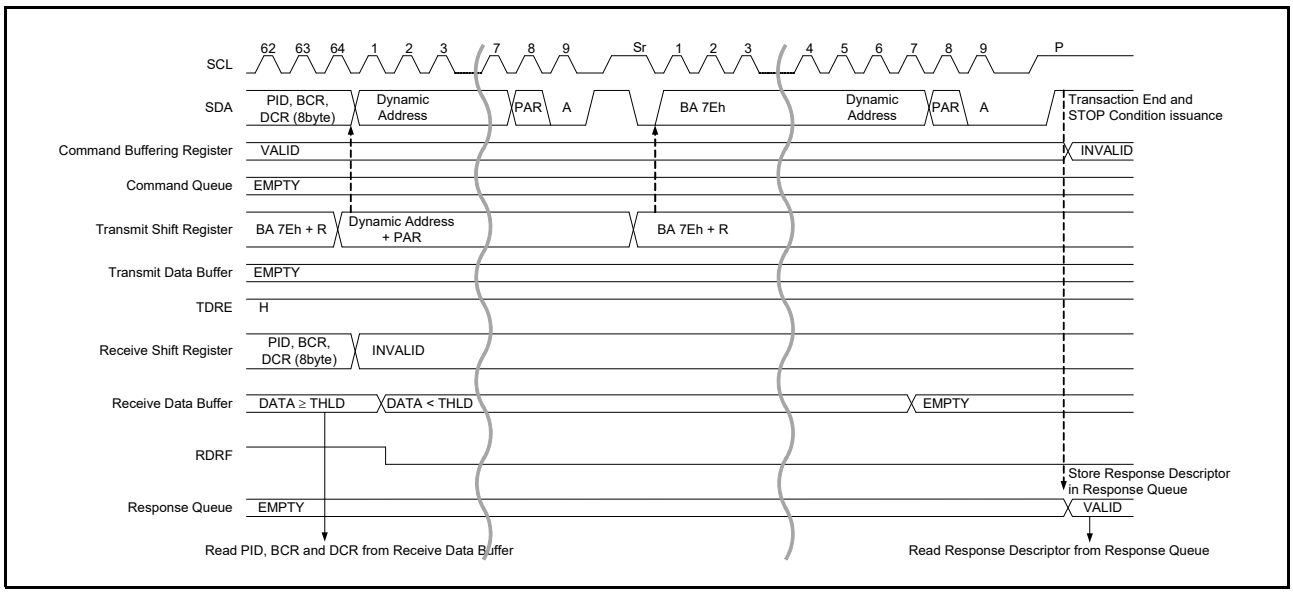

Figure 35.16 Dynamic Address Assignment Procedure (ENTDAA CCC) Timing (3/3)

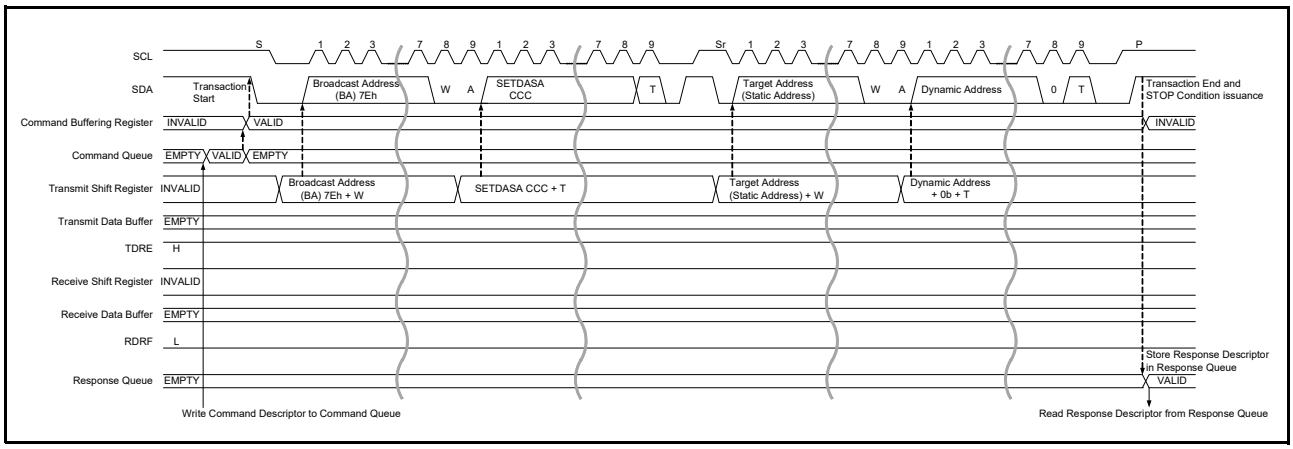

Figure 35.17 Dynamic Address Assignment Procedure (SETDASA CCC) Timing

35.4.5.2 SDR Write Transfer

(1) Write data for transmission to the Transmit Data Buffer via the ICDR register.
(2) Write a Command Descriptor (immediate data transfer command or regular data transfer command or combo transfer command) for Data Transfer to the command queue via the ICCQR register.
(3) When Command Descriptor is written to command queue, transaction is issued on I3C bus.
When NACK is received with the Address header, transaction of the same command is automatically issued according to the NACK Retry Count value (ICTDATRm.NACKRC[1:0]) of DAT.
(4) If data for transmission still remain, write data for transmission by a transmit data empty interrupt to the Transmit Data Buffer via the ICDR register.
(5) When data transmission for the number of bytes specified in the DATA_LENGTH field of the Command Descriptor is completed, the repeated START condition or STOP condition is issued and the Response Descriptor is stored in the response queue.
(6) Read the Response Descriptor via the ICRQR register and check the status.
(7) Check that the value of the DATA_LENGTH field of the Response Descriptor is 0.

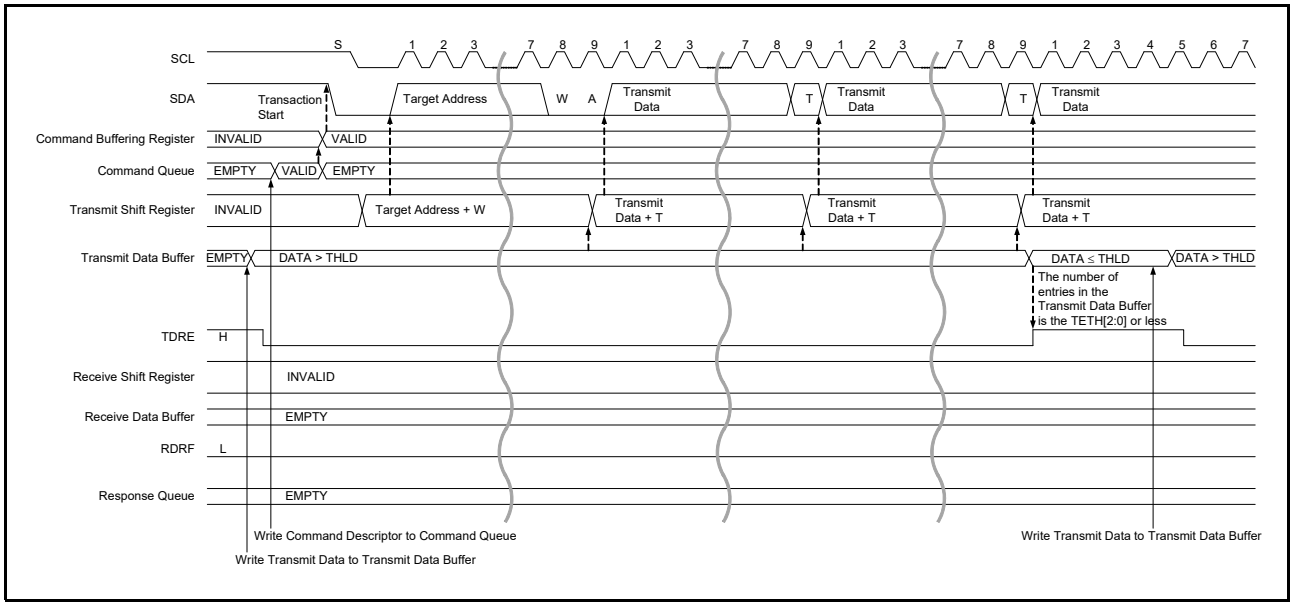

Figure 35.18 SDR Write Transfer Timing (1/2)

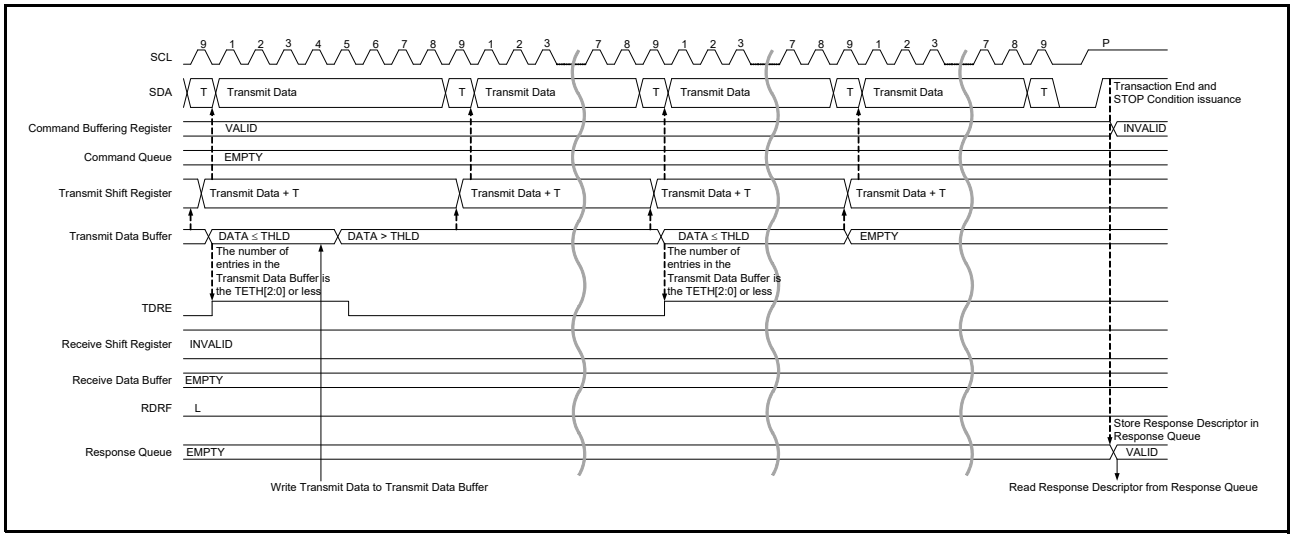

Figure 35.19 SDR Write Transfer Timing (2/2)

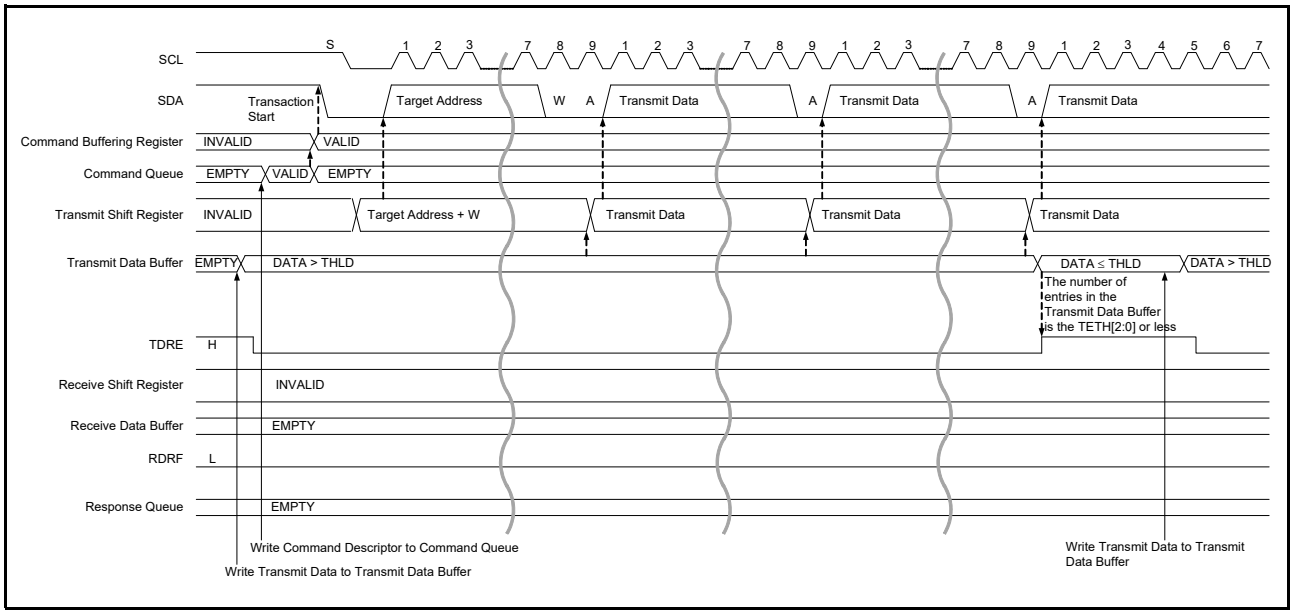

Figure 35.20 Legacy I²C Write Transfer Timing (1/2)

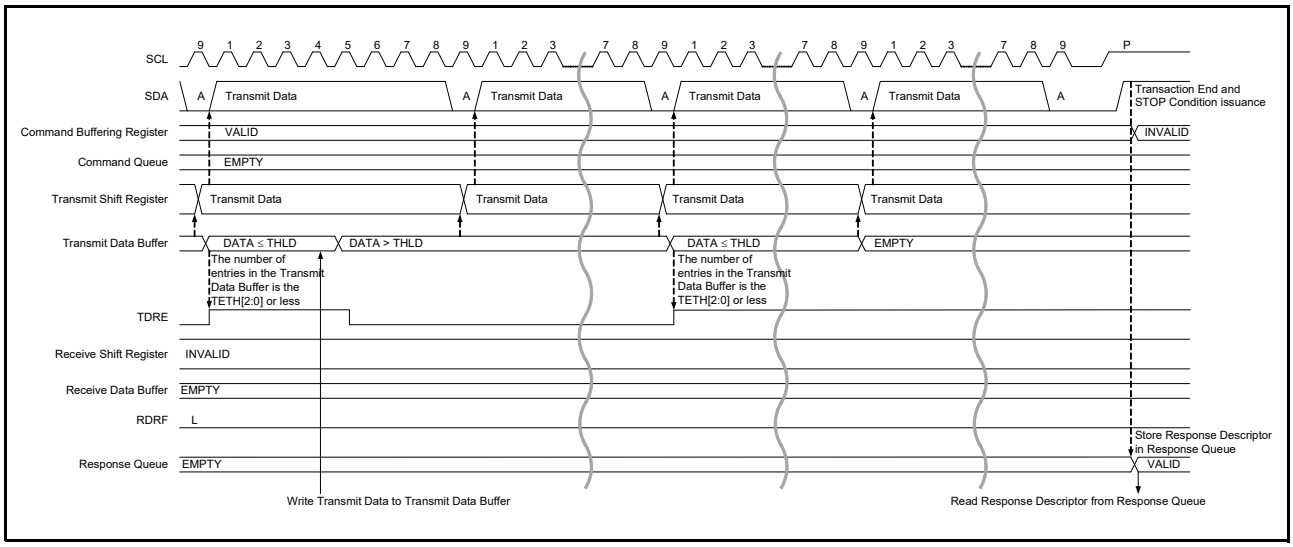

Figure 35.21 Legacy I²C Write Transfer Timing (2/2)

35.4.5.3 SDR Read Transfer

(1) Write a Command Descriptor (immediate data transfer command or regular data transfer command or combo transfer command) for Data Transfer to the command queue via the ICCQR register.

(2) When Command Descriptor is written to command queue, transaction is issued on I3C bus.
When NACK is received with the Address header, transaction of the same command is automatically issued according to the NACK Retry Count value (ICTDATRm.NACKRC[1:0]) of DAT.

(3) Data received from the I3C Target is stored in the Receive Data Buffer.

(4) In the receive data full interrupt, read the received data from the Receive Data Buffer via the ICDR register.

(5) SDR:
Detecting Low in T-bit or receiving Data for the number of bytes specified in the DATA_LENGTH filed of Command Descriptor is completed, issue repeated START condition or STOP condition and store the Response Descriptor into the response queue.
Legacy I^2C Message:
When data reception for the number of bytes specified in the DATA_LENGTH filed of Command Descriptor is completed, NACK is issued. After that, issue a repeated START condition or STOP condition and store the Response Descriptor into the response queue.

(6) Read the Response Descriptor via the ICRQR register and check the status.

(7) Check whether the value of the DATA_LENGTH filed of the Response Descriptor matches the data length setting value of the Command Descriptor.

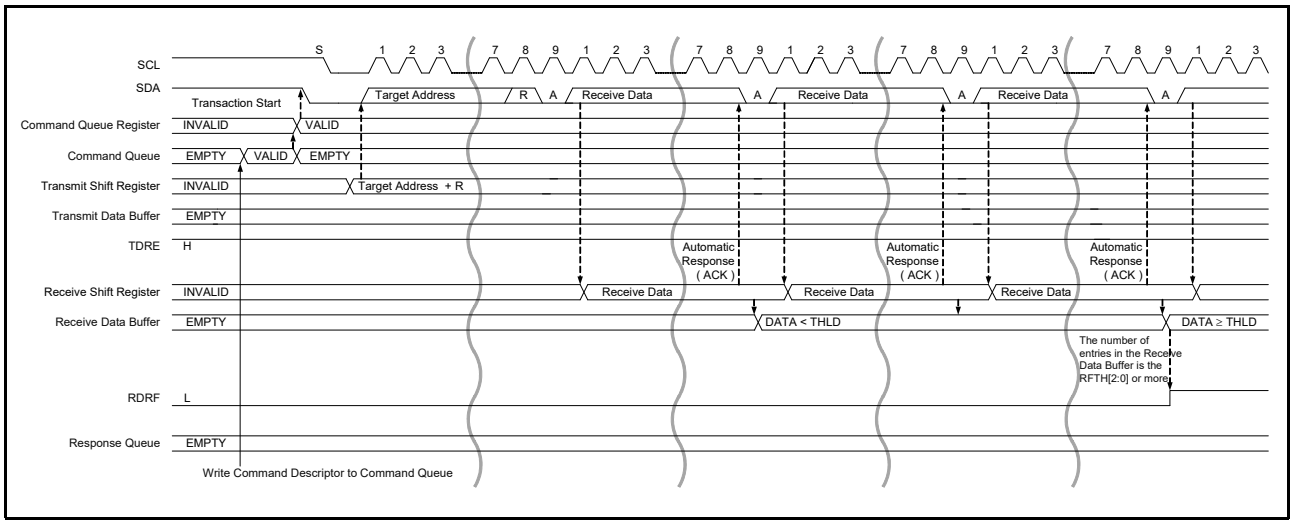

Figure 35.22 SDR Read Transfer Timing (1/2)

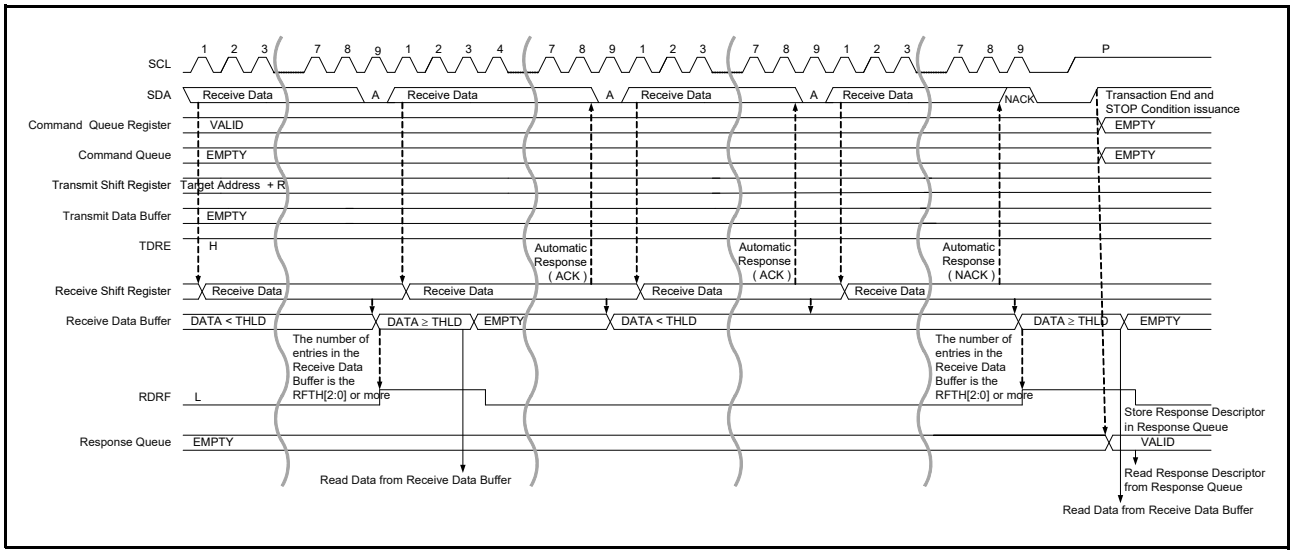

Figure 35.23 SDR Read Transfer Timing (2/2)

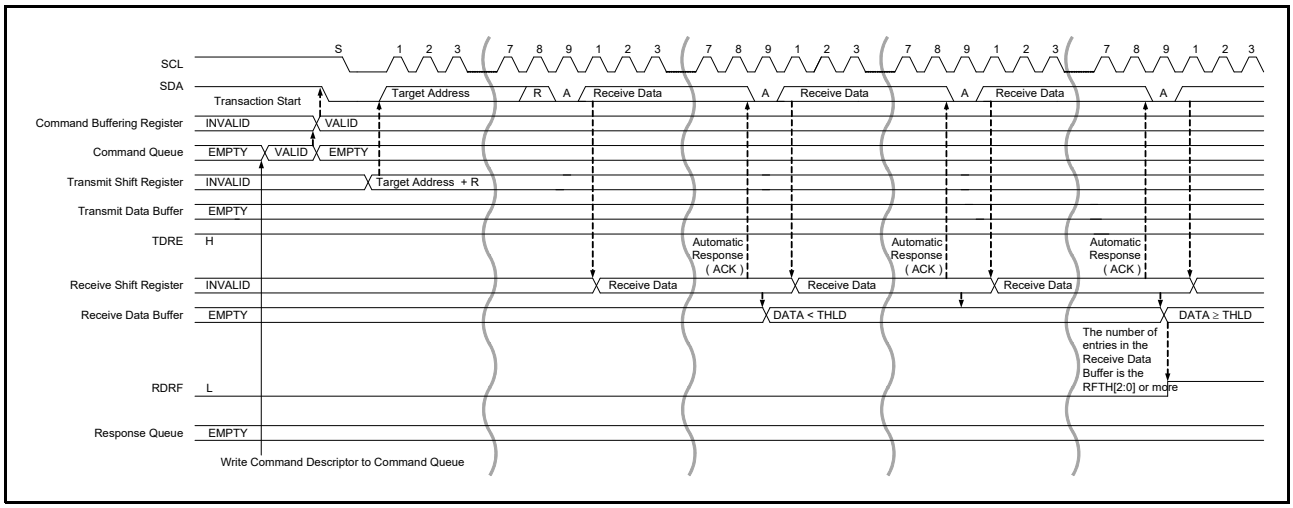

Figure 35.24 Legacy I²C Read Transfer Timing (1/2)

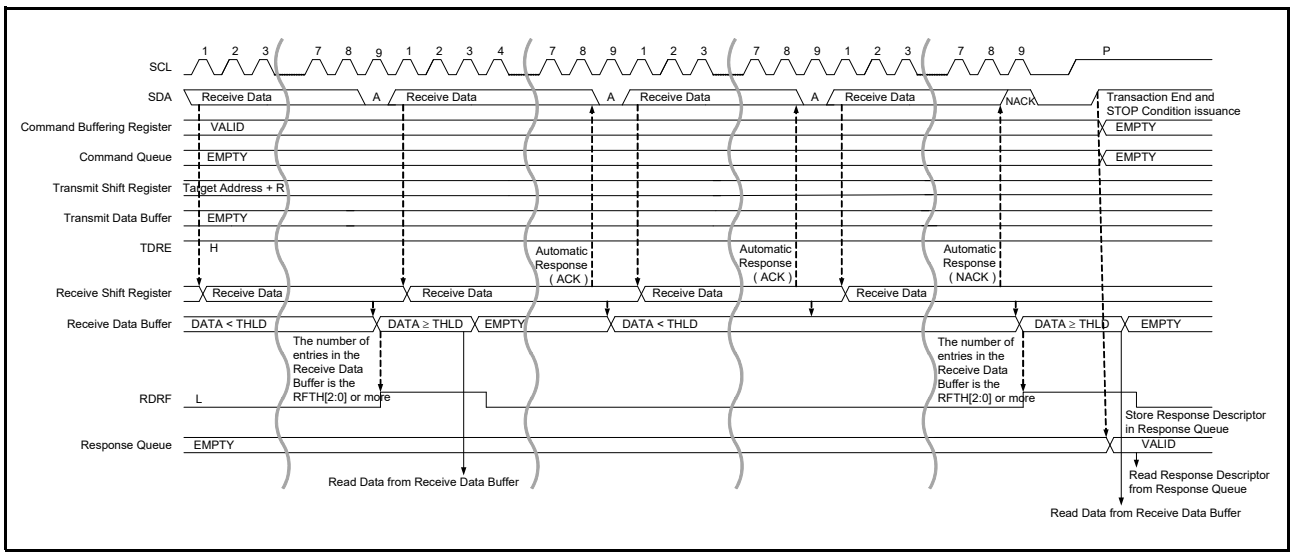

Figure 35.25 Legacy I²C Read Transfer Timing (2/2)

35.4.5.4 IBI Transfer

(1) Write Command Descriptor to the command queue and issue Transaction on I3C bus.
If START Request (SDA Low Drive) is issued from the Target device, RI3C drives SCL to Low and completes START condition.
Thereafter, the SCL is supplied and IBI Request is received.
(2) In Target Address and RnW field in the Address header, if losing Arbitration by issuing IBI from I3C Target, stop issuing Transaction.
(3) According to section 35.5.3, IBI, detect IBI and process.
(4) In the IBI queue empty/full interrupt routine, read the IBI Status Descriptor from the IBI queue via the ICIQR register and check the status.
When detected a Target Interrupt Request and responded with ACK, Read the IBI Data for the Data Length indicated by the DATA_LENGTH filed of the IBI Status Descriptor from the IBI queue via the ICIQR register.
(5) Restart issuing Transaction of Command of Step1.

An example of the processing procedure after detection of IBI is shown below.
Processing procedure for detecting Controller Role Request and transferring Controller role to Secondary Controller
(1) If the I3C Secondary Controller wins the Arbitration, issue a DEFTGTS CCC and notify Target information to Secondary Controller.
(2) Issue a GETACCCR CCC and complete CCC by a STOP condition.

Note: • After transferring Controller role to Secondary Controller, to get Controller role again, issue a Controller Role Request according to section 35.4.5.4, IBI Transfer.
• After Controller Role Request is accepted by the Active Controller, to get Controller role again at receiving the GETACCCR CCC and complete CCC by a STOP condition.

Processing procedure when Hot-Join Event is detected
(1) Issue a Broadcast Command Code Enter Dynamic Address Assignment (ENTDAA) to start the Dynamic Address Assignment process.
(2) Issue a DEFTGTS CCC and notify Target information to Secondary Controller.

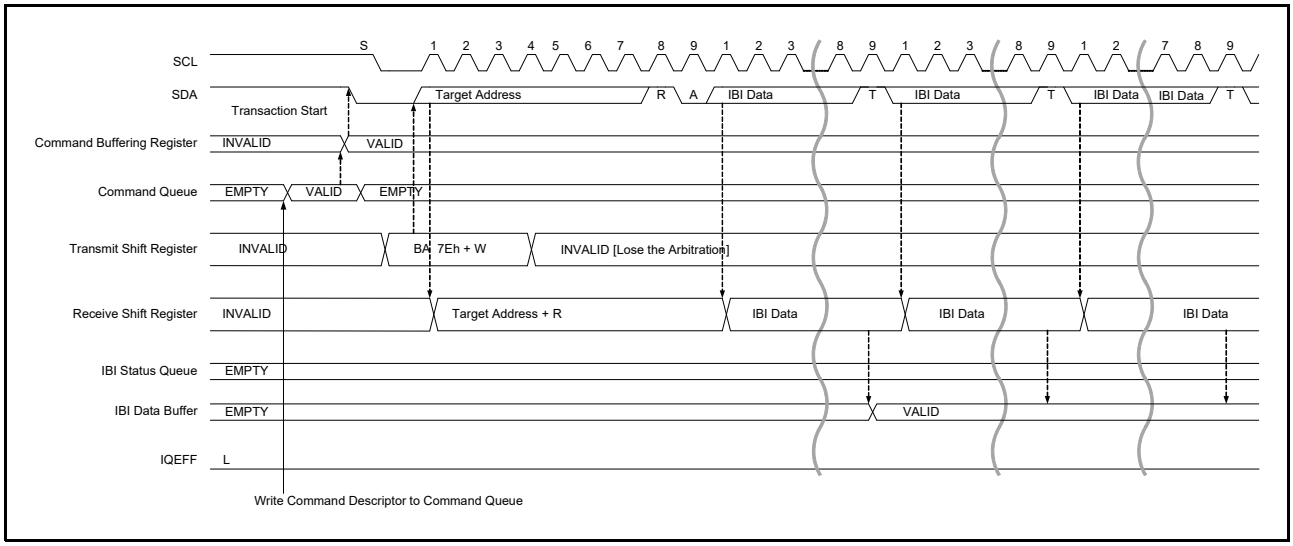

Figure 35.26 I3C Controller IBI Transfer Timing (1/2)

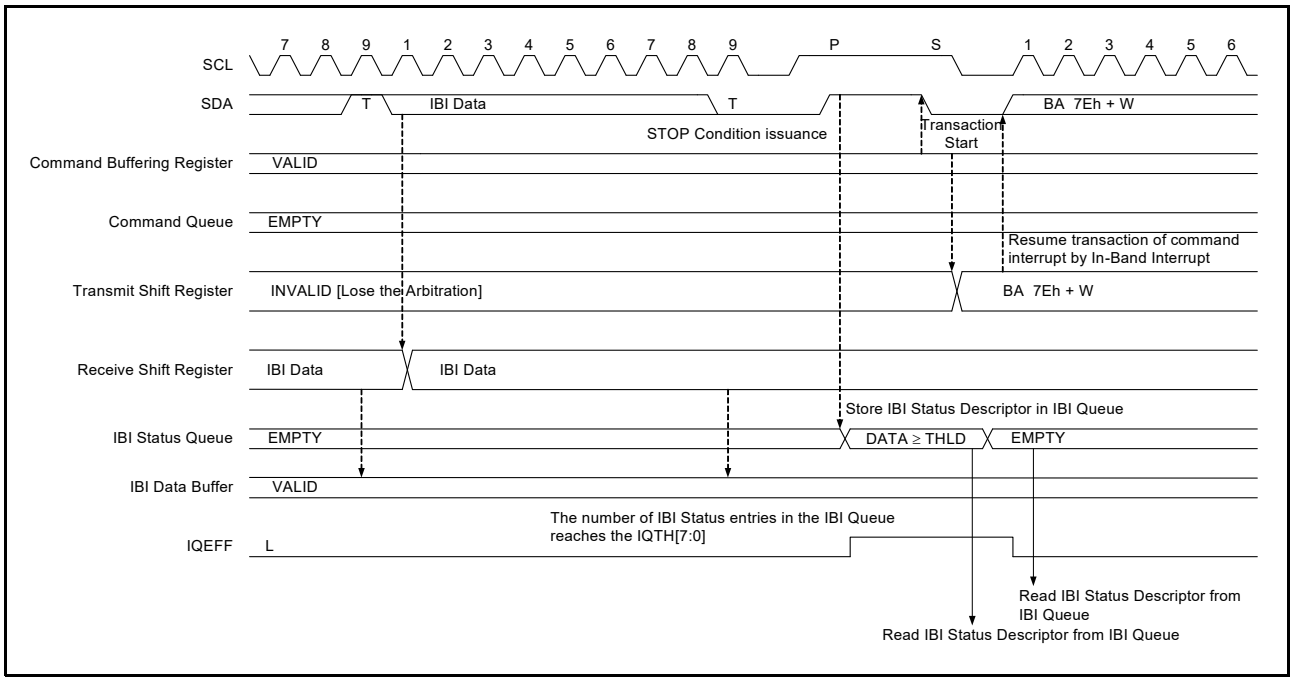

Figure 35.27 I3C Controller IBI Transfer Timing (2/2)

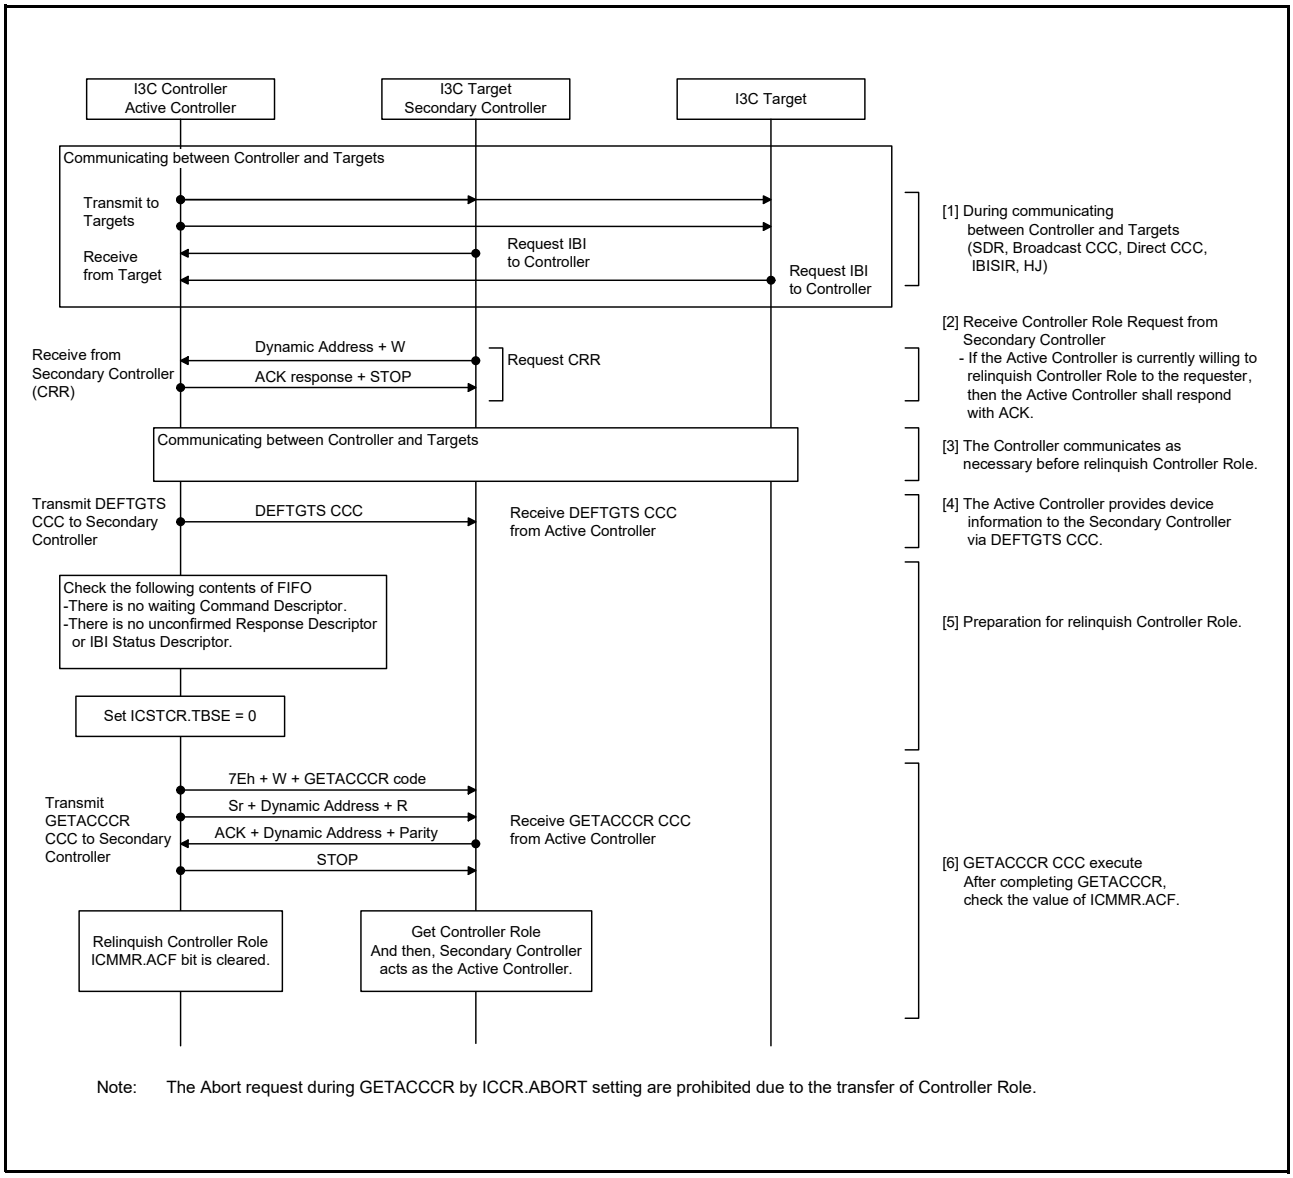
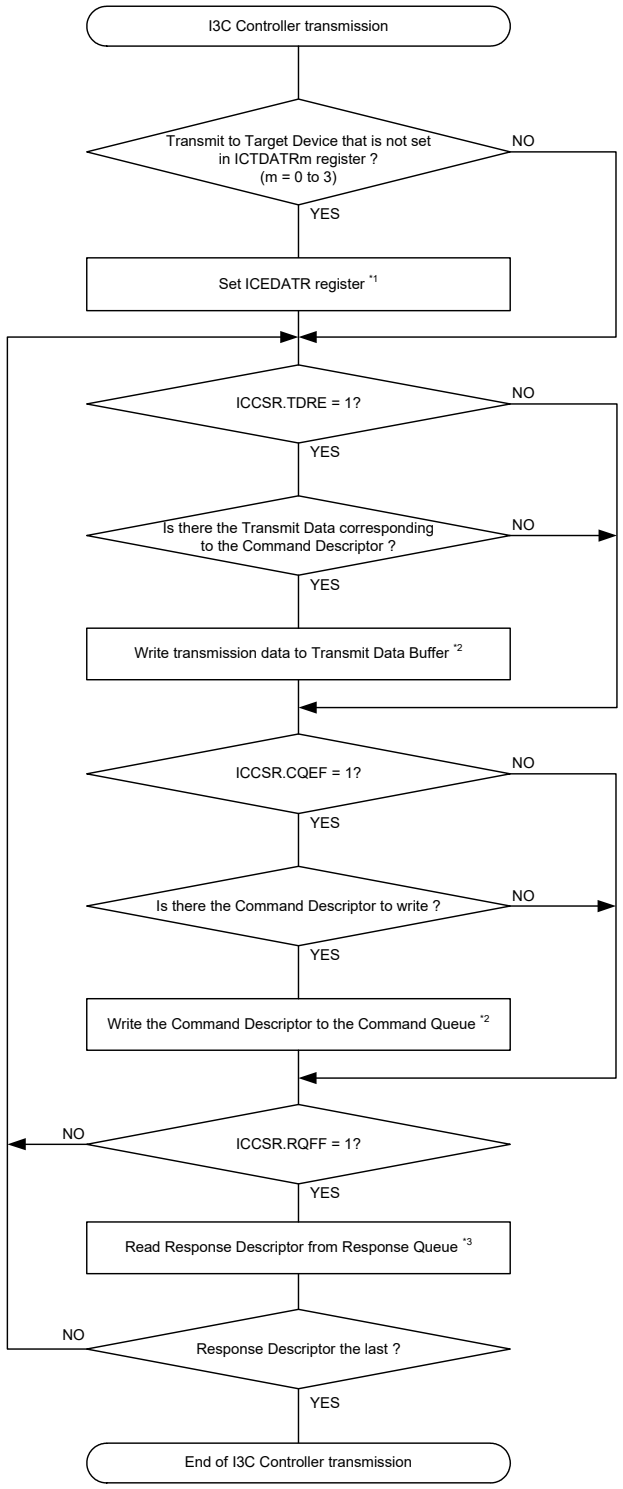


Note: The Abort request during GETACCCR by ICCR.ABORT setting are prohibited due to the transfer of Controller Role.

Figure 35.28 I3C Controller CRR Processing Flow

35.4.5.5 I3C Controller Transmission Flow (FIFO Buffer Transfer)

Controller transmission flow in FIFO buffer transfer is common to Legacy I^2C, SDR (Private Transfer, Broadcast CCC, Direct CCC).

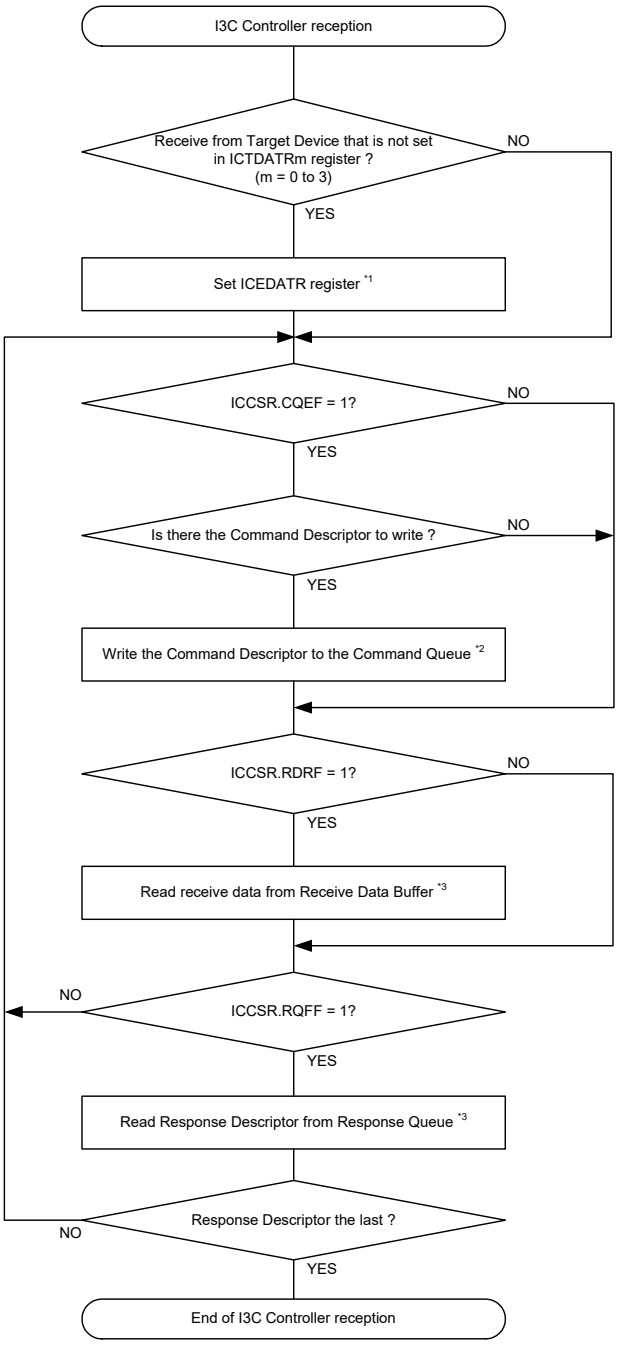


Note 1. Changing the ICEDATR register is prohibited until all Response Descriptors of command for the Target device set in the ICEDATR register are stored.
Note 2. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 3. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 35.29 Example of I3C Controller Transmission Flowchart (FIFO Buffer Transfer)

35.4.5.6 I3C Controller Reception Flow (FIFO Buffer Transfer)

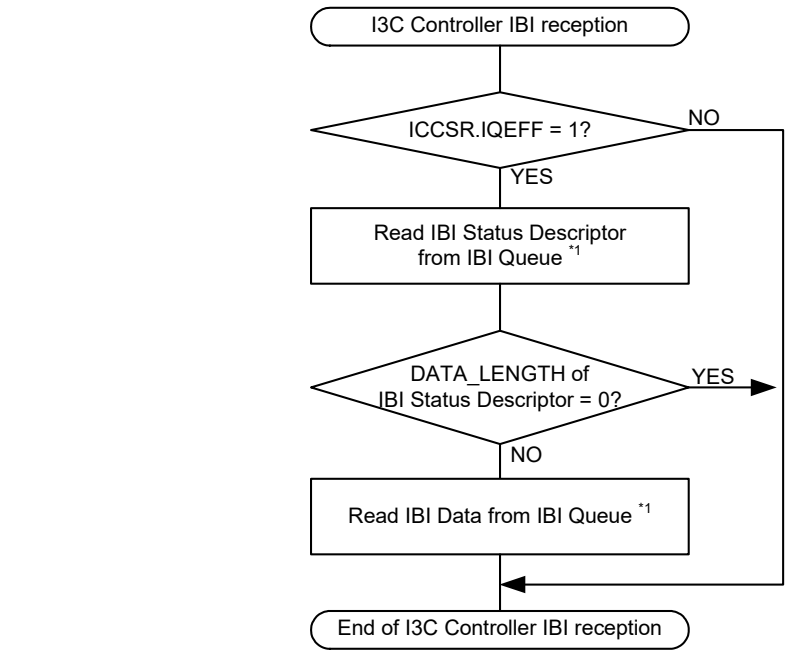
Controller reception flow in FIFO buffer transfer is common to Legacy I^2C, SDR (Private Transfer, Broadcast CCC, Direct CCC).



Note 1. Changing the ICEDATR register is prohibited until all Response Descriptors of command for the Target device set in the ICEDATR register are stored.
Note 2. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 3. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 35.30 Example of I3C Controller Reception Flowchart (FIFO Buffer Transfer)

35.4.5.7 I3C Controller IBI Reception Flow



Note 1. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 35.31 Example of I3C Controller IBI Reception Flowchart

35.4.6 I3C Target Operation

35.4.6.1 Dynamic Address Assignment Procedure

After initializing RI3C, the I3C Controller first performs Dynamic Address Assignment Procedure.
The operation of RI3C during the Dynamic Address Assignment Procedure by ENTDAA CCC is described below.

(1) Initial setting (For details, refer to section 35.4.3, Initial Settings)
(2) When ENTDAA CCC is received, RI3C transmits Provisioned ID (the ICPIDHR register and bits b15 to b0 of the ICPIDLR register), BCR (bits b15 to b8 of the ICDCTR register), DCR (bits b7 to b0 of the ICDCTR register) until a Dynamic Address is assigned. (For details, refer to In case of Broadcast CCC (ENTDAA) of 35.5.1 CCC detection function.)
(3) When ENTDAA CCC is completed and a STOP condition is detected, Receive Status Descriptor is stored in the receive status queue.
(4) Read Receive Status Descriptor via the ICSQR register and check the status.
(5) Read the data for the data length indicated by the DATA_LENGTH filed of the Receive Status Descriptor from the Receive Data Buffer via the ICDR register.

Note: When multiple RI3C (I3C Target) are connected on the I3C bus assign Dynamic Addresses in the following order.
1. Set the ICPIDHR and ICPIDLR registers (6 bytes in total) of the RI3C (I3C Target) to a value (all 1 etc.) that has a lower priority than other Target devices by Dynamic Address Arbitration.
2. After setting the Static Address in the RI3C (I3C Target), assign the Dynamic Address using the SETDASA/ SETAASA command.
3. Assign a Dynamic Address to an I3C Target Device other than the RI3C (I3C Target) using the ENTDAA command.

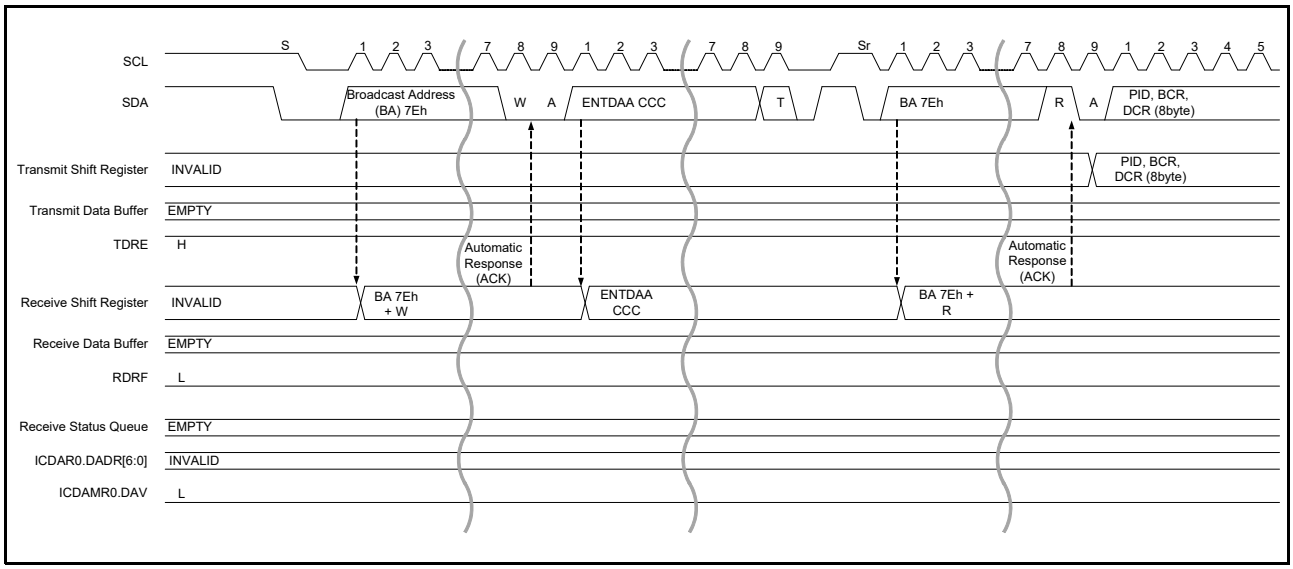


Figure 35.32 Dynamic Address Assignment Procedure (ENTDAA CCC) Timing (1/3)

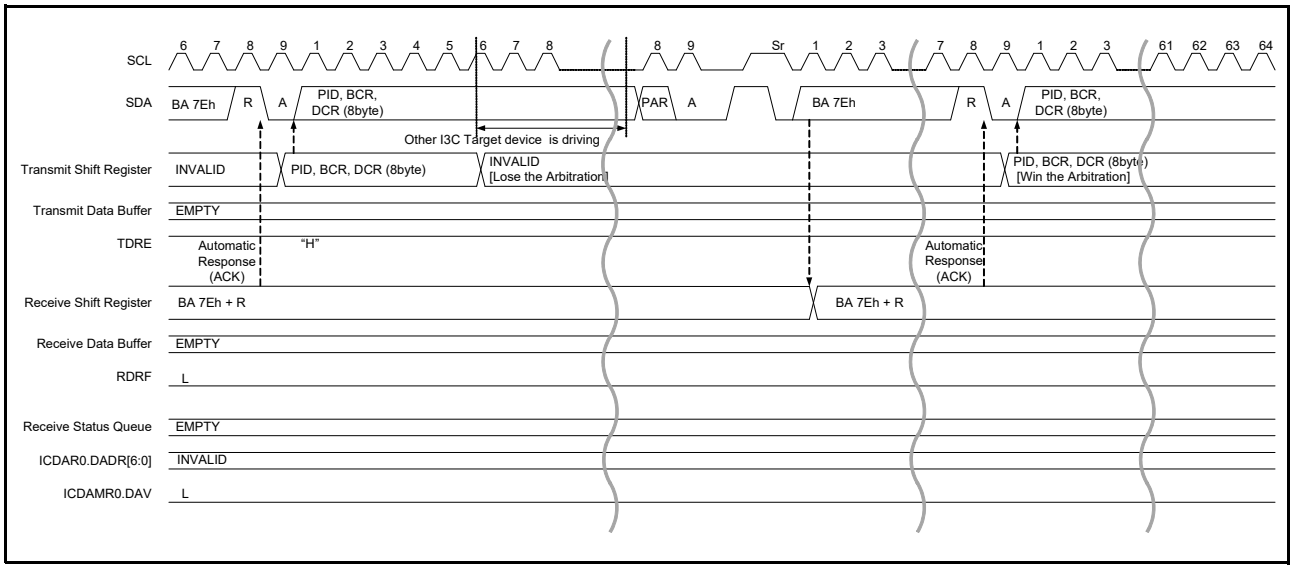

Figure 35.33 Dynamic Address Assignment Procedure (ENTDAA CCC) Timing (2/3)

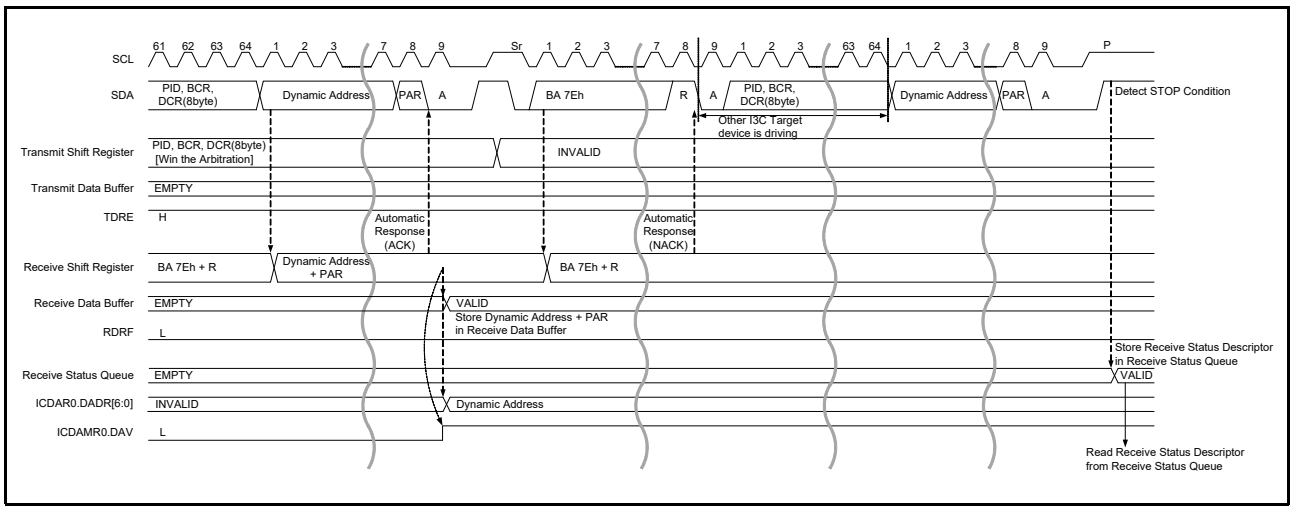

Figure 35.34 Dynamic Address Assignment Procedure (ENTDAA CCC) Timing (3/3)

When communicating with a Static Address until the Dynamic Address is assigned from the I3C Controller, by setting to the ICDAR0.SADR[6:0] bits, the ICDAMR0.SAV flag is set to 1 and the Static Address Will be effective.

If the I3C Target has a Static Address and the I3C Controller executes the Dynamic Address Assignment Procedure, it is possible to assign a Dynamic Address with SETDASA CCC.

The operation of RI3C during SETDASA CCC Dynamic Address Assignment Procedure is described below.

(1) Initial setting (For details, refer to section 35.4.3, Initial Settings)

(2) When SETDASA CCC which agrees with its own Static Address is received, the ICDAR0.DADR[6:0] bits are renewed and the ICDAMR0.DAV flag is set to 1. (For details, refer to In case of Direct Write CCC of 35.5.1 CCC detection function.)

(3) When SETDASA CCC is completed and a STOP condition is detected, Receive Status Descriptor is stored in receive status queue.

(4) Read Receive Status Descriptor via ICSQR register and check the status.

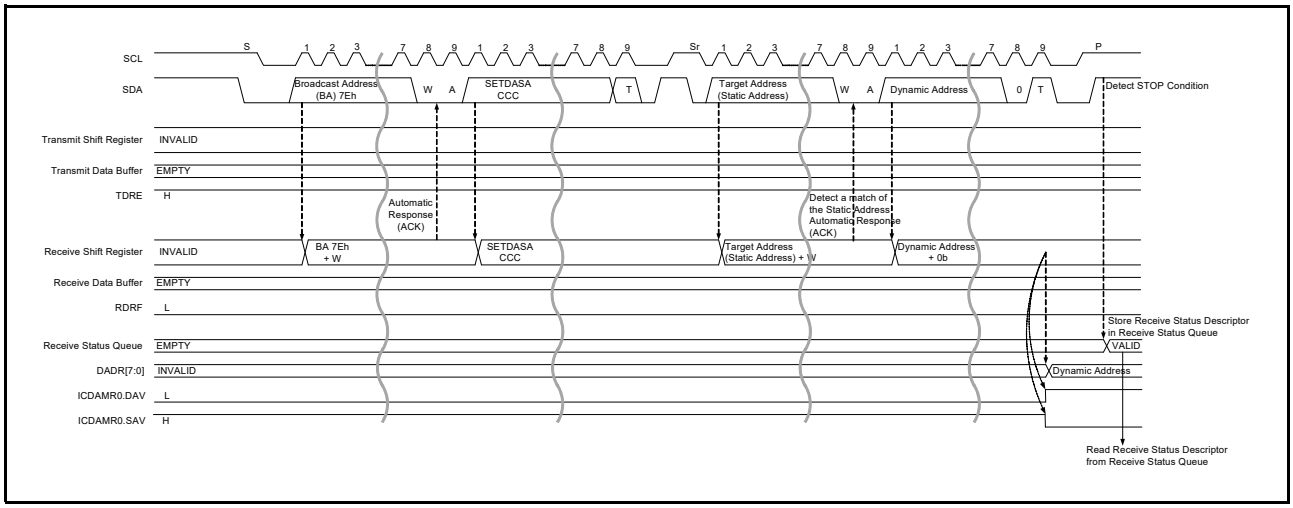

Figure 35.35 Dynamic Address Assignment Procedure (SETDASA CCC) Timing

35.4.6.2 SDR Write Transfer

(1) When Transaction is issued from the I3C Controller, it compares the Target Address in Address header with its own Target Address, and if it matches, RI3C responds with ACK.
When a Transaction is received, if the Receive Data Buffer is full, the I3C Target will respond with NACK in the Address header.
In preparation for retrying the I3C Controller, read the data from the Receive Data Buffer via the ICDR register, and empty the Receive Data Buffer.

(2) Data received from I3C Controller is stored in the Receive Data Buffer.

(3) In the receive data full interrupt, read the received data from the Receive Data Buffer via the ICDR register.

(4) When repeated START condition or STOP condition is detected, the Receive Status Descriptor is stored in the receive status queue.

(5) Read Receive Status Descriptor via ICSQR register and check the status.

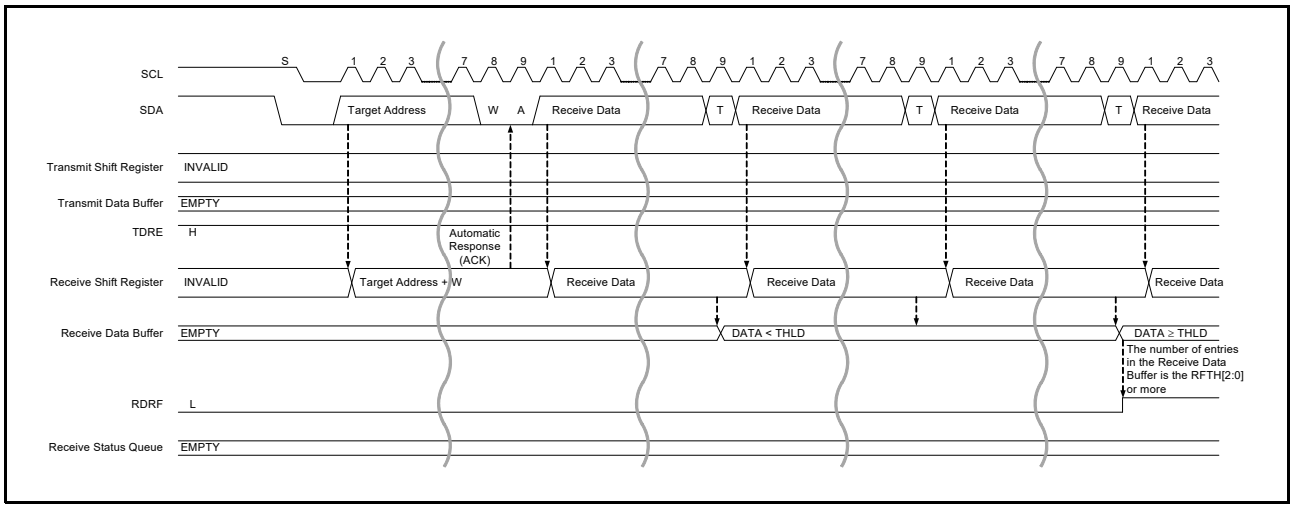

Figure 35.36 SDR Write Transfer Timing (1/2)

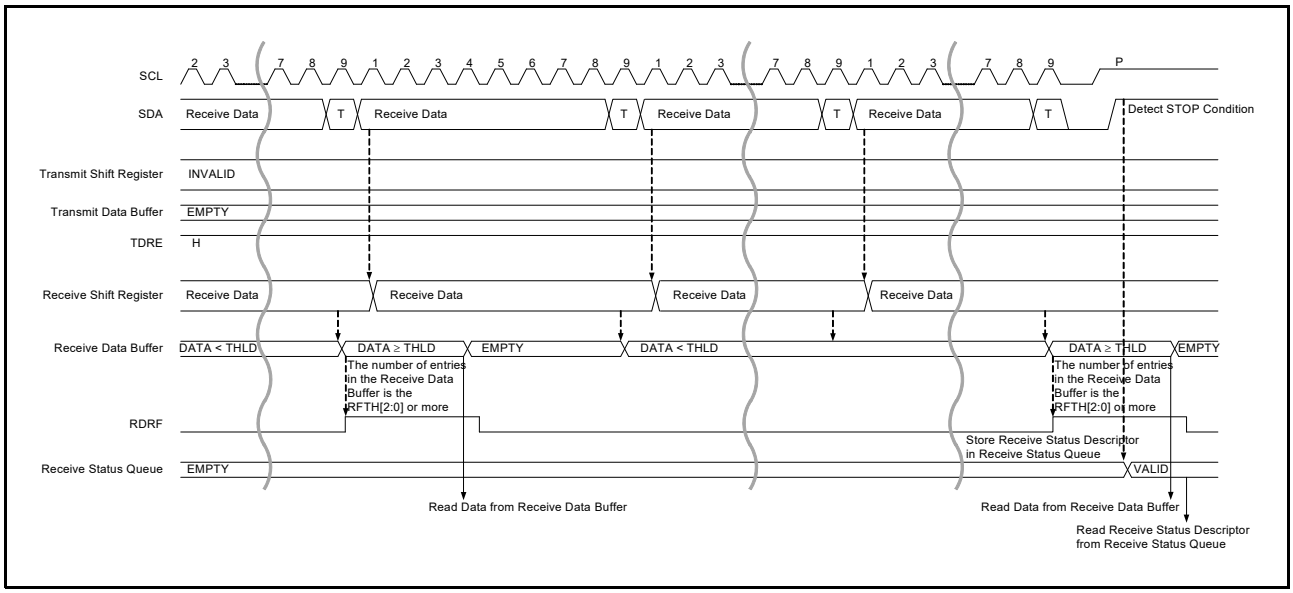

Figure 35.37 SDR Write Transfer Timing (2/2)

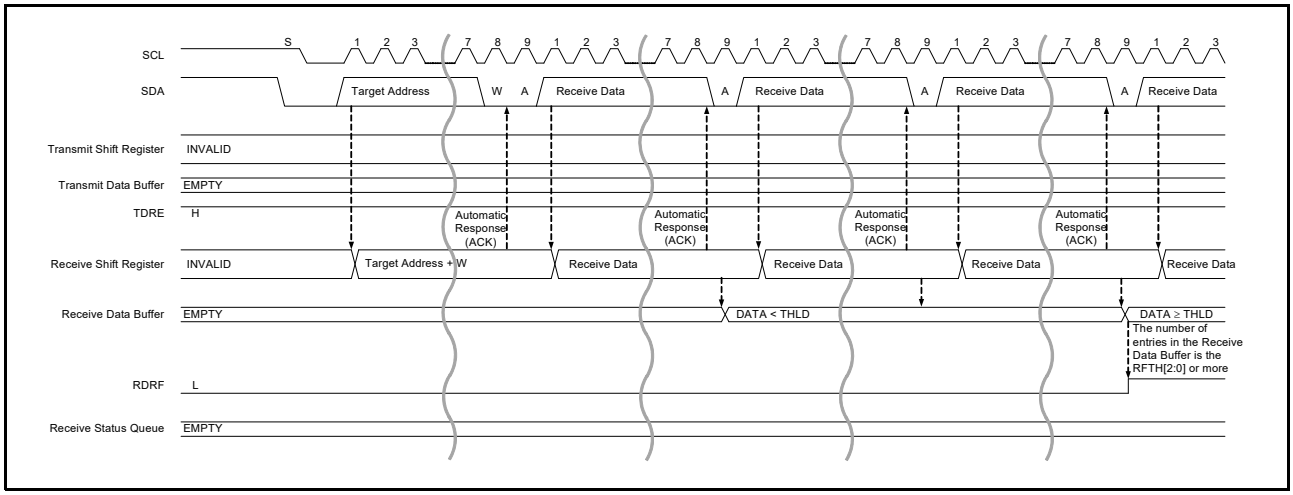

Figure 35.38 Legacy I²C Write Transfer Timing (1/2)

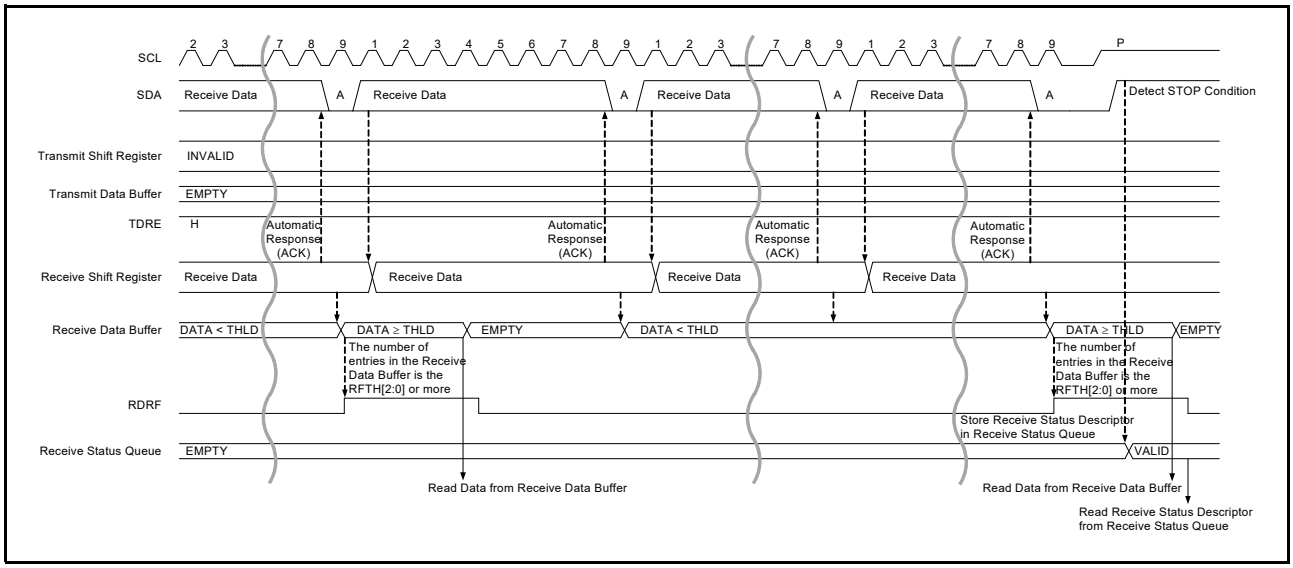

Figure 35.39 Legacy I²C Write Transfer Timing (2/2)

35.4.6.3 SDR Read Transfer

(1) Write the data requested from the I3C Controller to the Transmit Data Buffer via the ICDR register.

(2) When Transaction is issued from the I3C Controller, it compares the Target Address in Address header with its own Target Address, and if it matches, RI3C responds with ACK.
When a Transaction is received, if the Transmit Data Buffer is EMPTY, I3C Target responds with NACK with the Address header.
In preparation for retrying the I3C Controller, write data to the Transmit Data Buffer via the ICDR register.

(3) Transmit the data stored in the Transmit Data Buffer.

(4) If data to be transmitted still remains, write the data to be transmitted with a transmit data empty interrupt to the Transmit Data Buffer via the ICDR register.

(5) SDR:
When the transmission of the data stored in the Transmit Data Buffer is completed, Low is output to the T-bit following Data, and it is notified to the I3C Controller that it is the final data.
Legacy I^2C Message:
When NACK is detected, data transmission is terminated.

(6) When a repeated START condition or STOP condition is detected, the Receive Status Descriptor is stored in the receive status queue.

(7) Read the Receive Status Descriptor via ICSQR and check the status.
MCU Ver.1 has the following restriction and workaround. This restriction and workaround are not required for MCU Ver.2.
If the data length does not match, set the ICRCR.ISRST bit to 1 and then reset the internal states of this module.
For details, refer to 35.5.5.6 Error Recovery Operation.

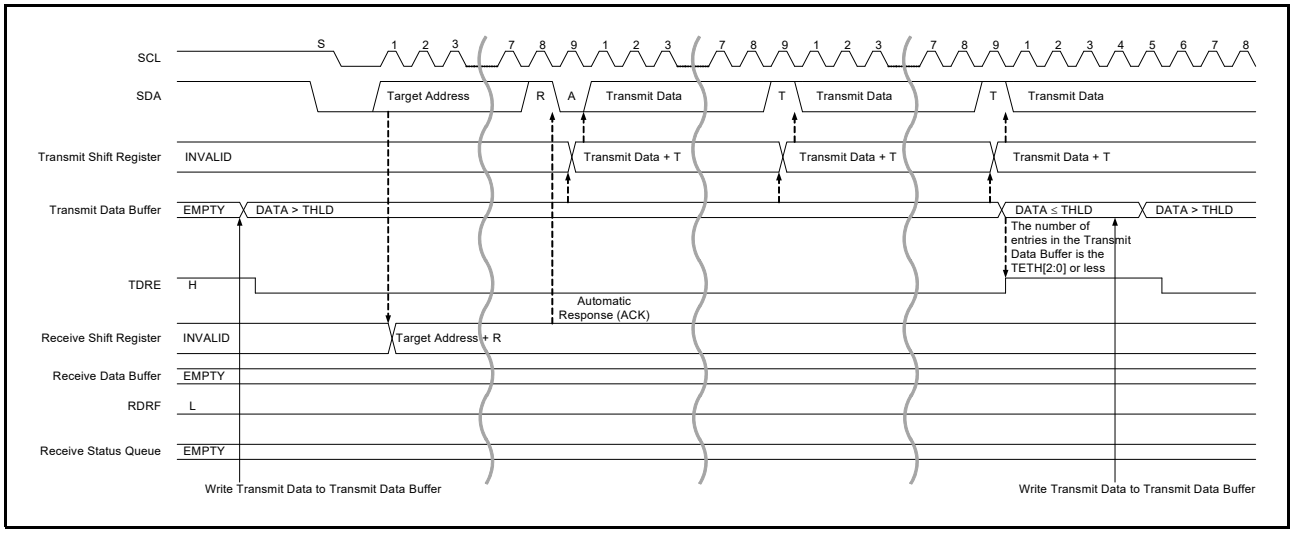

Figure 35.40 SDR Read Transfer Timing (1/2)

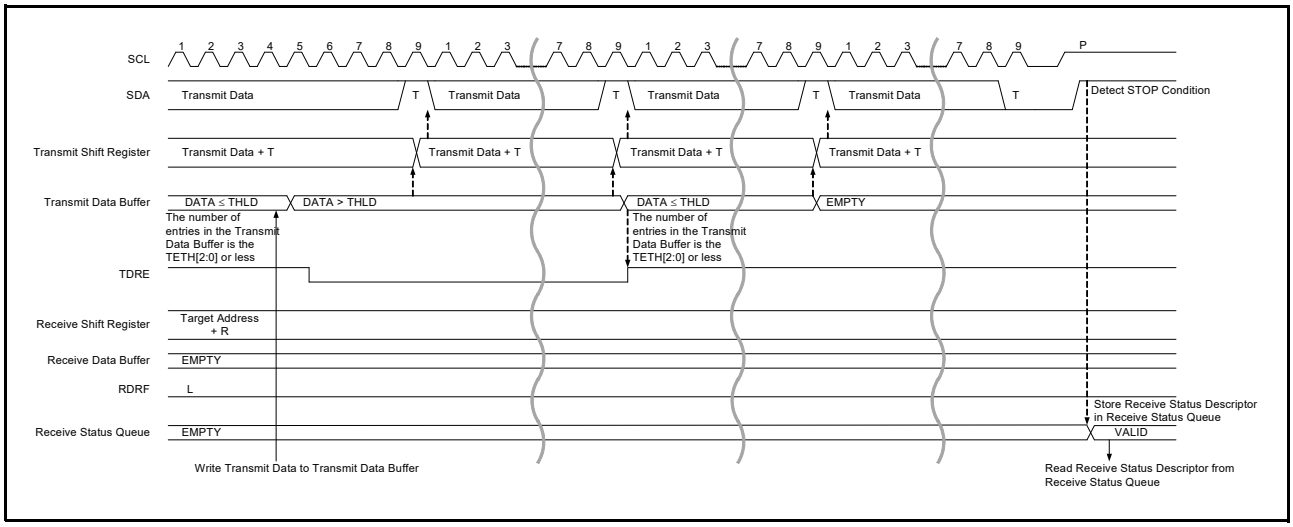

Figure 35.41 SDR Read Transfer Timing (2/2)

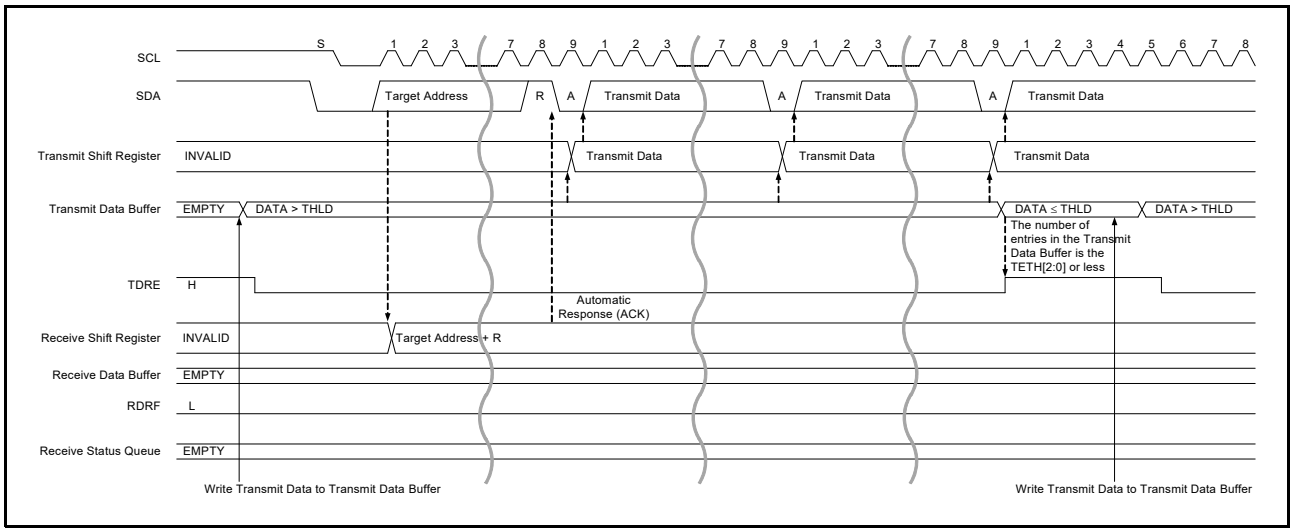

Figure 35.42 Legacy I²C Read Transfer Timing (1/2)

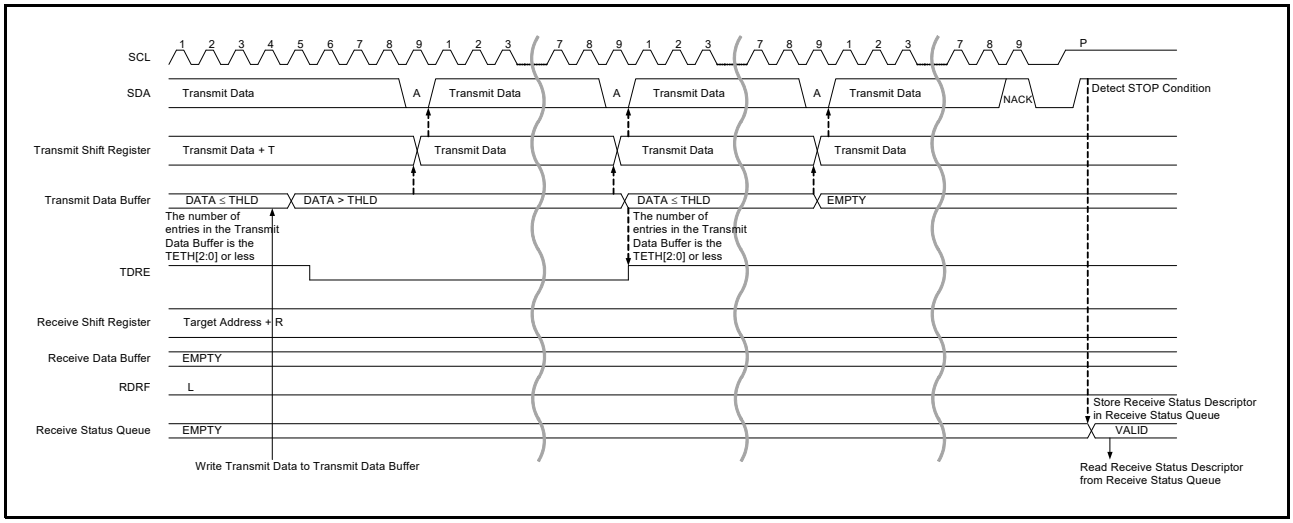

Figure 35.43 Legacy I²C Read Transfer Timing (2/2)

35.4.6.4 IBI Transfer

(1) When sending Target Interrupt Request.
When transmitting IBI Data, write IBI Data to the IBI Data Buffer via the ICIQR register.

(2) Write Command Descriptor (immediate data transfer command or regular data transfer command) to the command queue for IBI Transfer via the ICCQR register.

(3) When Command Descriptor is written to command queue, IBI Transaction is issued under the following conditions.

- Detect a START condition. (Does not apply a repeated START condition)
- If no START condition is forthcoming within the following bus condition, then this module issue a START Request by pulling the SDA line Low.
- (a) Target Interrupt Request, Controller Role Request: Bus Available
  (b) Hot-Join Event: Bus Idle

(4) In Target Address and RnW field in the Address header, if losing Arbitration by issuing a Transaction from I3C Controller, stop issuing Transaction.
When detecting repeated START condition or STOP condition, store the Response Descriptor into the response queue.

(5) When sending Target Interrupt Request:

- When IBI data for transmission still remain, write IBI data with an IBI queue empty/full interrupt to the IBI queue via the ICIQR register.
- When the transmission of IBI Data for the number of data length specified by the DATA_LENGTH filed of the Command Descriptor is completed, output Low to the T-bit following IBI Data and notify the I3C Controller that it is the final IBI Data.

(6) When detecting repeated START condition or STOP condition, store the Response Descriptor into the response queue.

(7) Read the Response Descriptor form the response queue with the ICRQR register and check the status. If NACK is responded, repeat steps (1) to (7).

(8) When sending Target Interrupt Request:
Check that the value of the DATA_LENGTH field of the Response Descriptor is 0.

The CRR processing flow is shown in Figure 35.46. When joining the I3C bus by Hot-Join after the I3C bus has already been configured, issue the Hot-Join according to the flow shown in Figure 35.51.

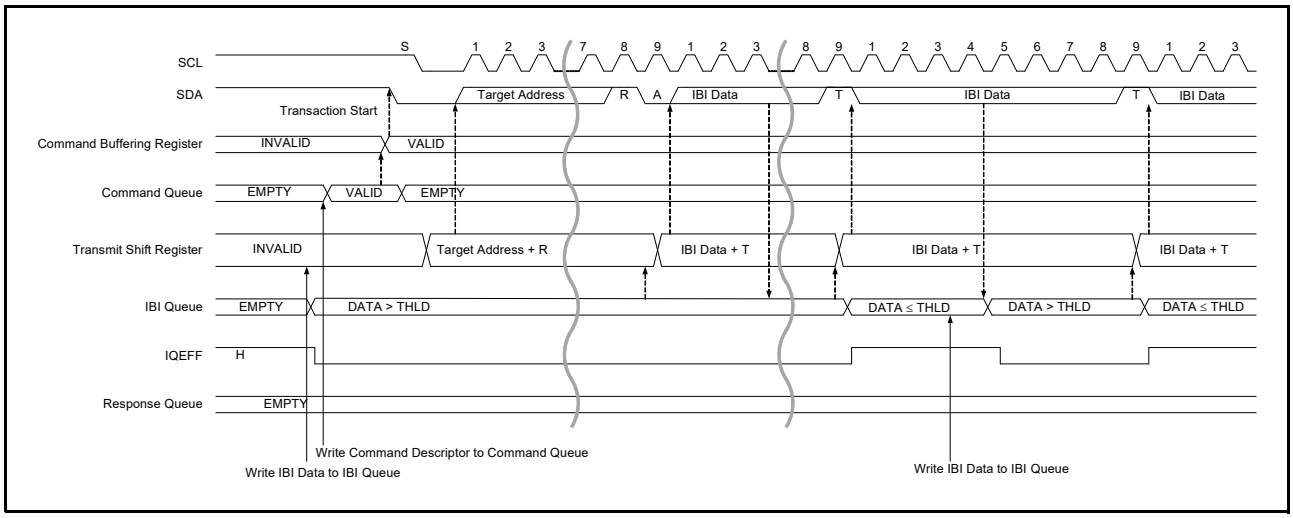

Figure 35.44 I3C Target IBI Transfer Timing (1/2)

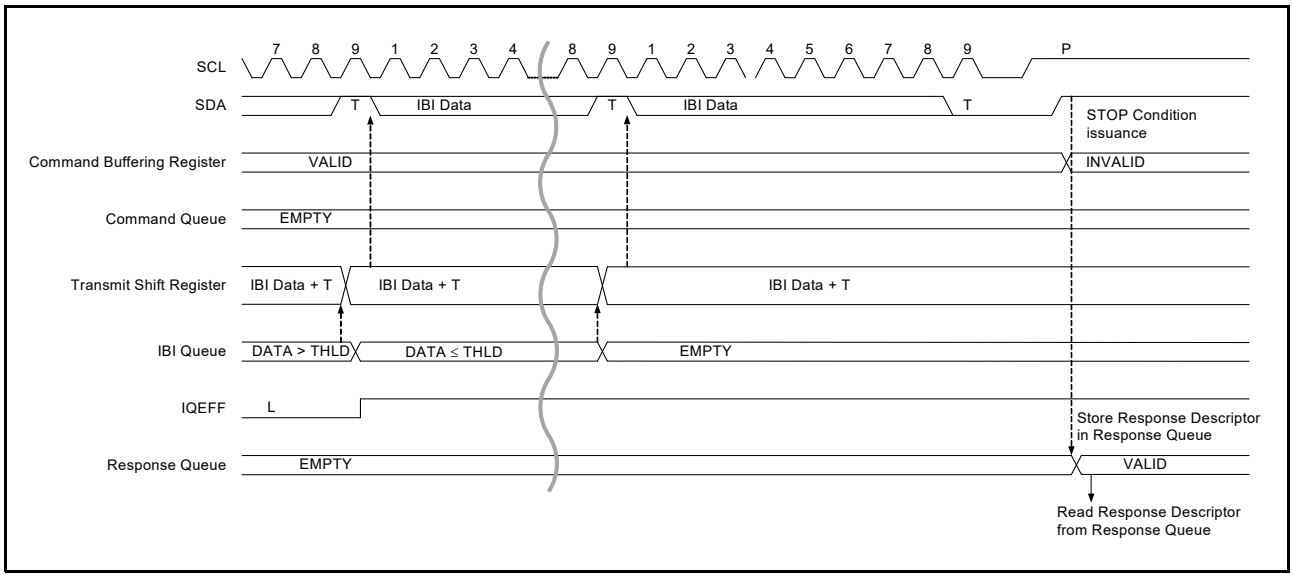

Figure 35.45 I3C Target IBI Transfer Timing (2/2)

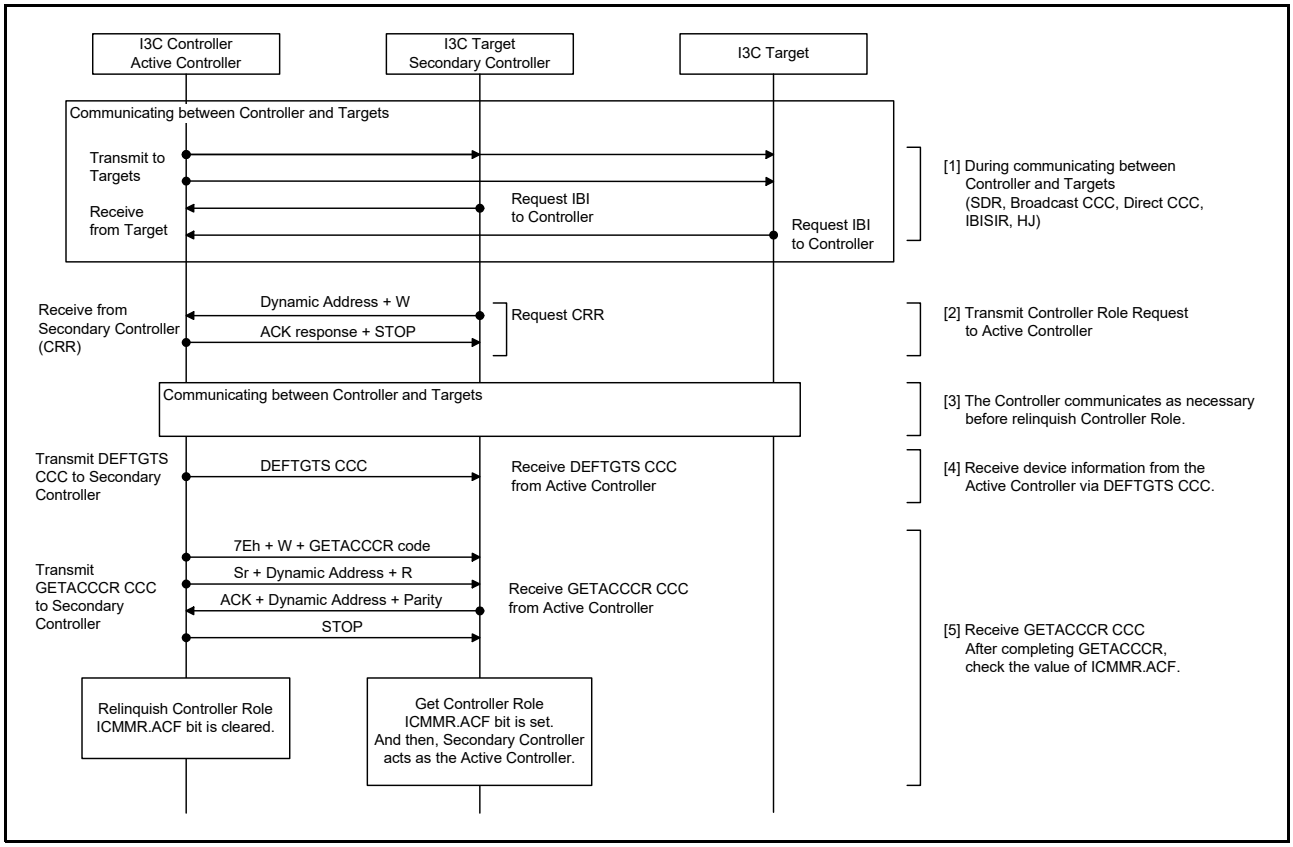

Figure 35.46 I3C Target CRR Processing Flow

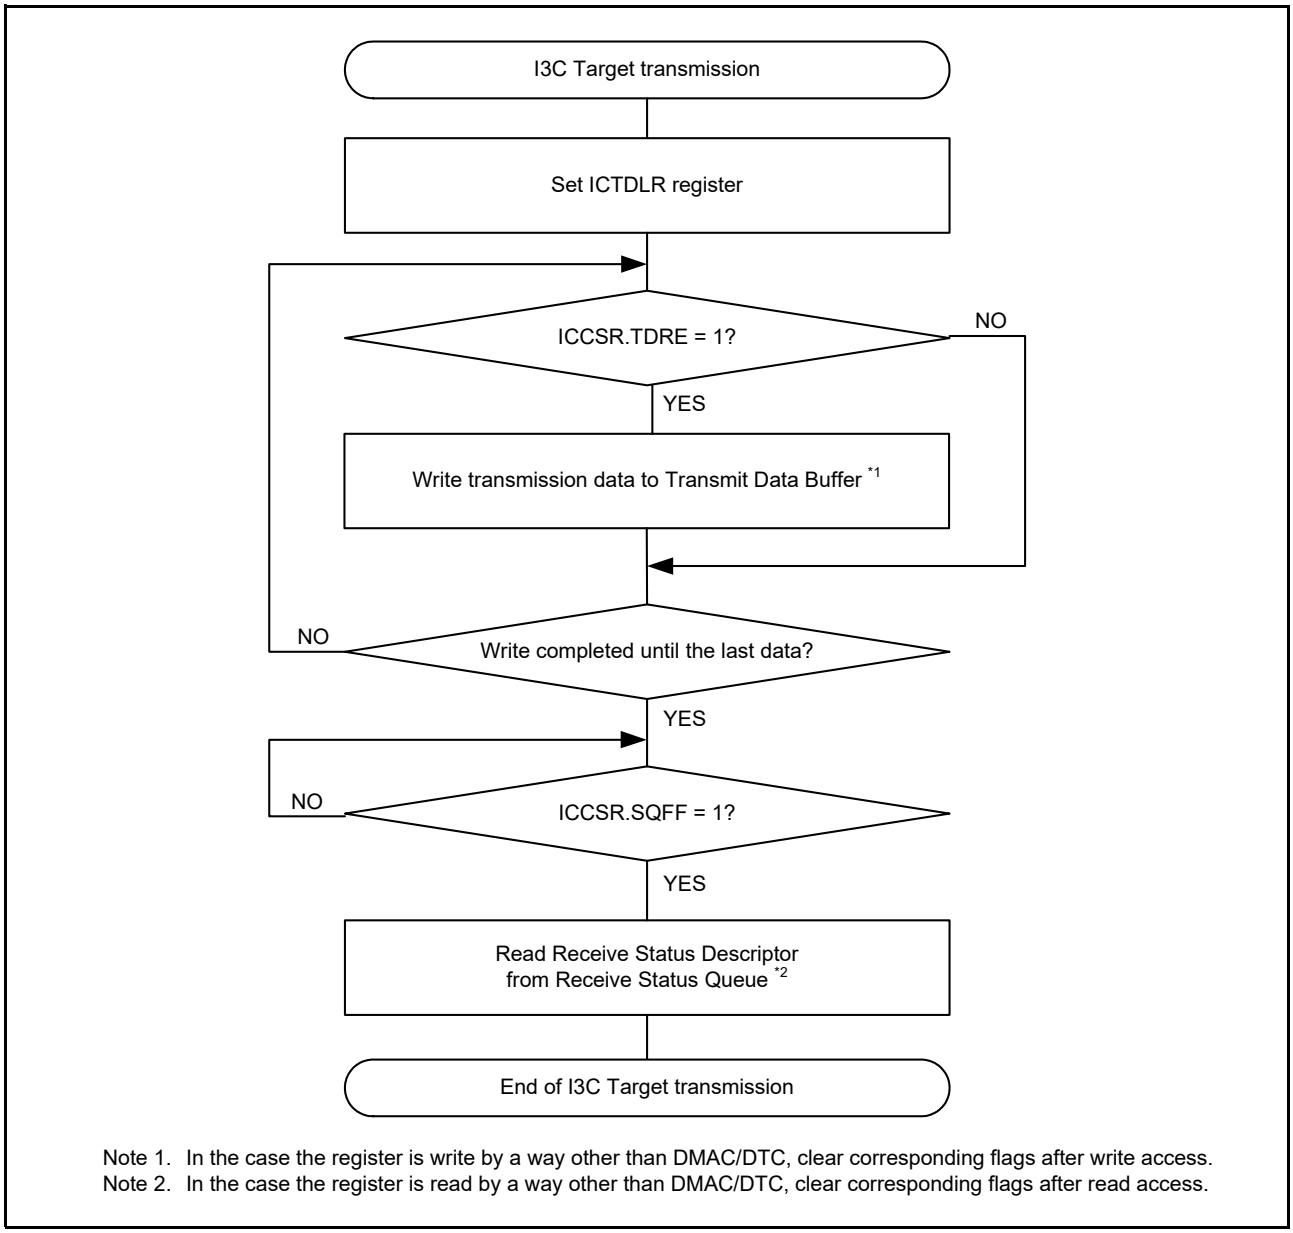
35.4.6.5 I3C Target Transmission Flow (FIFO Buffer Transfer)

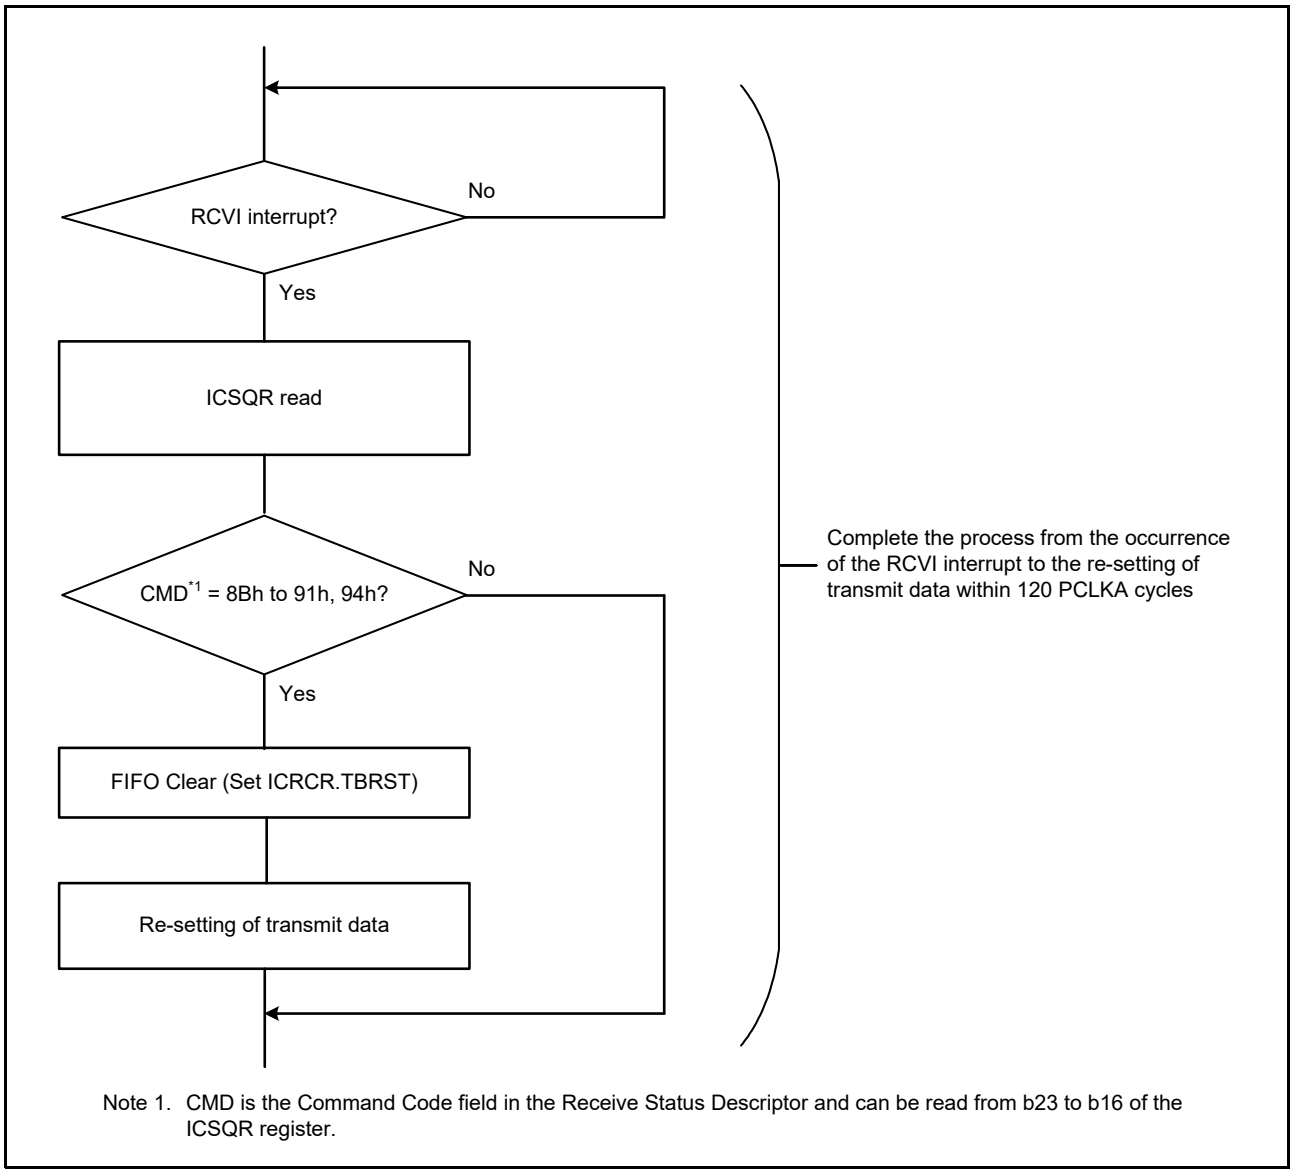
Target Transmission Flow in FIFO buffer transfer is common to Legacy I^2C, SDR (Private Transfer, Broadcast CCC, Direct CCC).



Note 1. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 2. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 35.47 Example of I3C Target Transmission Flowchart (FIFO Buffer Transfer)

When using the RI3C as an I3C Target, if I3C Target receives GET CCC while data exists by writing from the ICDR register to the transmit buffer, follow the flow below.

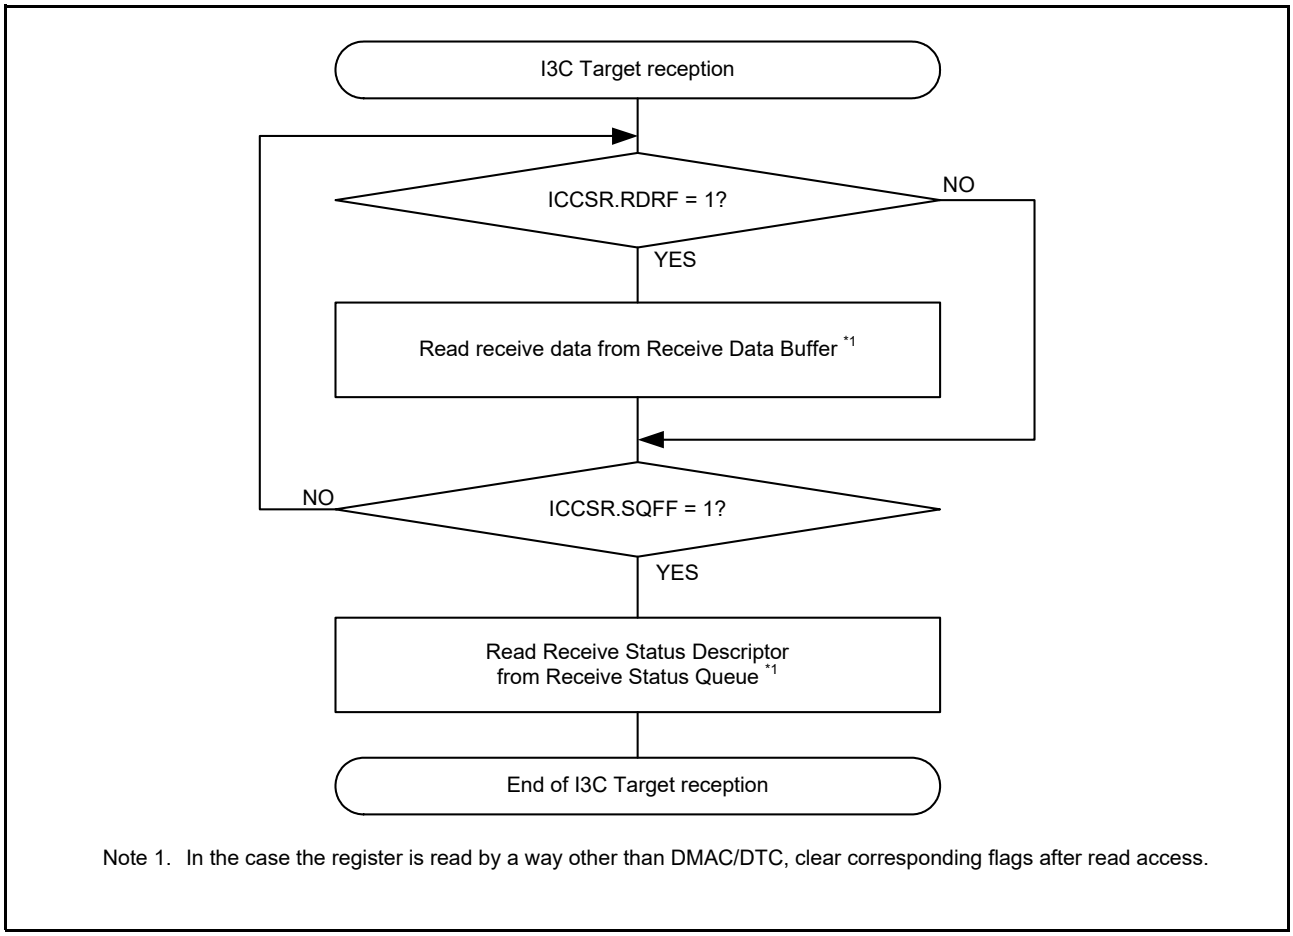


Note 1. CMD is the Command Code field in the Receive Status Descriptor and can be read from b23 to b16 of the ICSQR register.

Figure 35.48 I3C Target Receives GET CCC Command while Data Exists by Writing from the ICDR Register to the Transmit Buffer

35.4.6.6 I3C Target Reception Flow (FIFO Buffer Transfer)

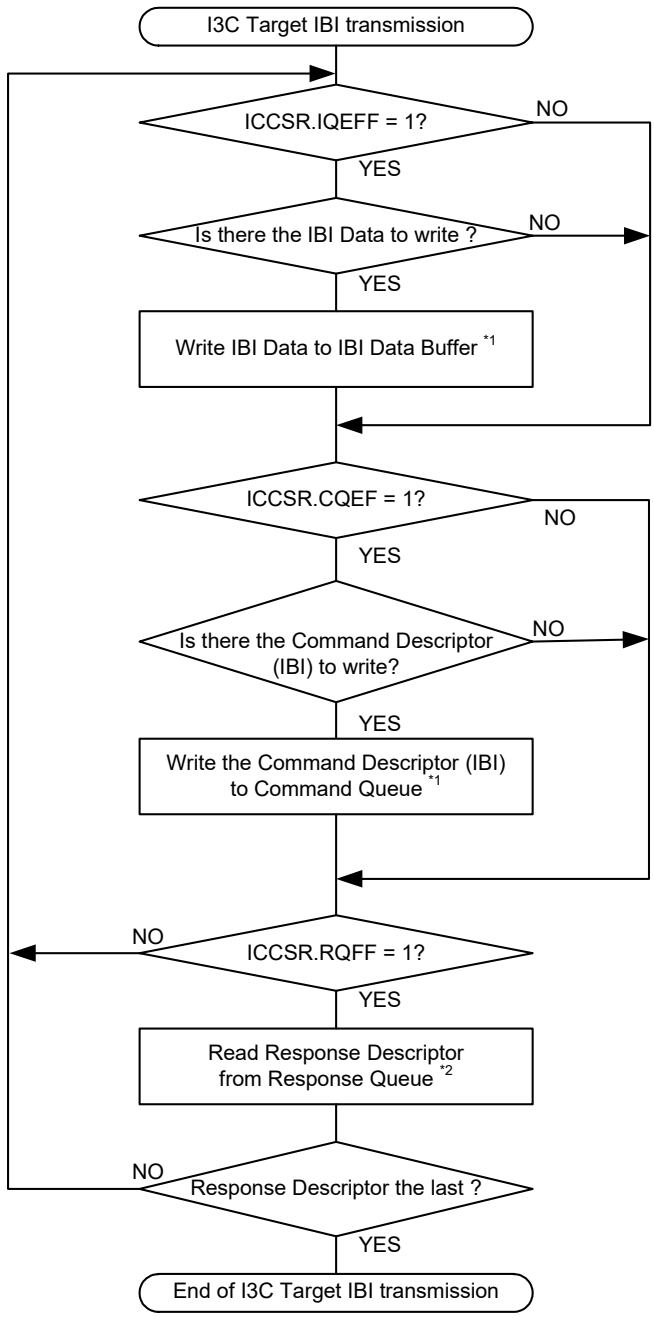
Target Reception Flow in FIFO buffer transfer is common to Legacy I^2C, SDR (Private Transfer, Broadcast CCC, Direct CCC).



Note 1. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 35.49 Example of I3C Target Reception Flowchart (FIFO Buffer Transfer)

35.4.6.7 I3C Target IBI Transmission Flow



Note 1. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 2. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 35.50 Example of I3C Target IBI Transmission Flowchart

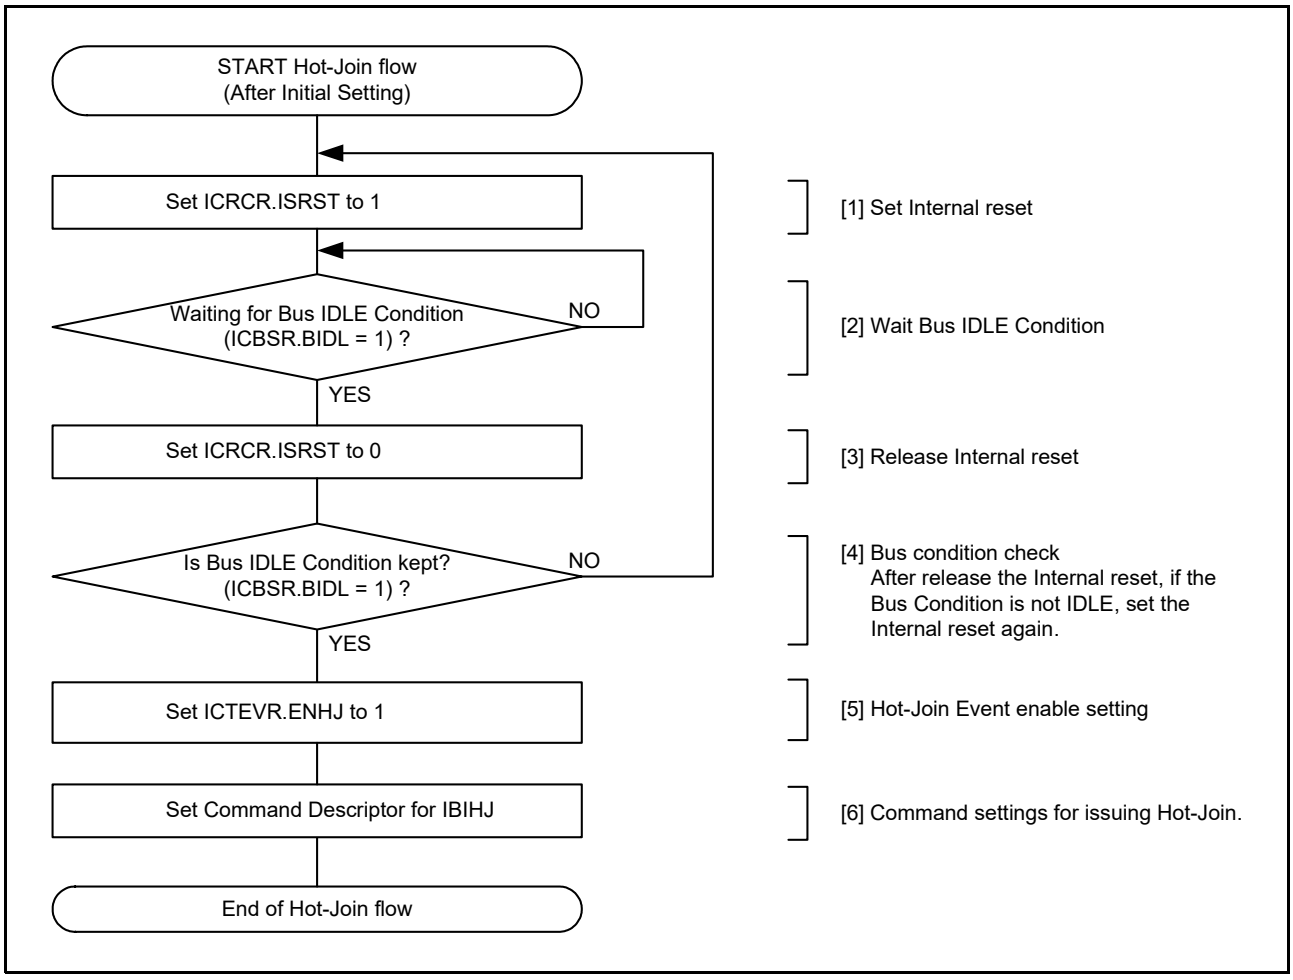


Figure 35.51 Hot-Join Flowchart after the I3C Bud has Already been Configured

35.5 Details of Function

35.5.1 CCC detection function

In case of Broadcast CCC

(1) Receive Broadcast Address (7Eh) and RnW = 0 after START condition or repeated START condition.
(2) Respond with ACK.
(3) Receive Common Command Code (CCC).
(4) In accordance with the CCC, the following data is stored. (Storage destination: refer to Table 35.6)
(5) Store the Receive Status Descriptor into the receive status queue.

In case of Broadcast CCC (ENTDAA)

(1) Receive Broadcast Address (7Eh) and RnW = 0 after START condition.
(2) Respond with ACK.
(3) Receive ENTDAA.
(4) If receives Broadcast Address (7Eh) and RnW = 1 after repeated START condition.
(5) When the Dynamic Address is not assigned, ACK response is done.
(6) This Provisioned ID (the ICPIDHR register and bits b15 to b0 of the ICPIDLR register), BCR (bits b15 to b8 of the ICDCTR register), DCR (bits b7 to b0 of the ICDCTR register) are transmitted.
(7) When winning the arbitration in a transmission of the above Step 6, the Dynamic Address following that is received.
When losing arbitration in a transmission of the above Step 6, processing of Step 6 is repeated from Step 4.
(8) When parity of the Dynamic Address is valid, ACK response is done.
(9) When parity of the Dynamic Address is invalid, NACK replies, and repeat the process from Steps 4 to 7.
(10) ICDAR0.DADR[6:0] bits are renewed and the ICDAMR0.DAV flag is set to 1.
(11) Upon detecting the STOP condition, Store the Receive Status Descriptor into the receive status queue.

In case of Direct Write CCC

(1) Receive Broadcast Address (7Eh) and RnW = 0 after START condition or repeated START condition.
(2) Respond with ACK.
(3) Receive Common Command Code (CCC).
(4) Receive Dynamic Address and RnW = 0 after repeated START condition.
(5) Compare the received Dynamic Address with the assigned Dynamic Address, and if it matches, RI3C responds with ACK.
If they do not match, it responds with NACK and waits for repeated START condition or STOP condition.
(6) In accordance with the CCC, the following data is stored. (Storage destination: refer to Table 35.6)
(7) Store the Receive Status Descriptor into the receive status queue.

In case of Direct Read CCC

(1) It receives Broadcast Address (7Eh) and RnW = 1 after START condition or repeated START condition.
(2) Respond with ACK.
(3) Receive Common Command Code (CCC).
(4) Receive Dynamic Address and RnW = 1 after repeated START condition.
(5) Compare the received Dynamic Address with the assigned Dynamic Address, and if it matches, RI3C responds with ACK.
If they do not match, it responds with NACK and waits for repeated START condition or STOP condition.
(6) Respond from register according to CCC. (Responding CCC: refer to Table 35.6)
(7) Store the Receive Status Descriptor into the receive status queue.

Table 35.6 Common Command Code Operation

35.5.2 Clock Stalling

RI3C has the function of stalling the SCL during the SCL Low period.
The SCL stall control is described in the table below.

Table 35.7 I3C Clock Stalling

Clock Stalling Condition	Clock Stalling Control	Clock Stalling Period
I3C Transfer, ACK/NACK Phase	ICSTCR.APSE bit setting	During the count period of ICSTCR.STT[15:0] value
	Transmit FIFO Empty	Until data is written to the transmit FIFO
	Receive FIFO Full	Until data is read from the receive FIFO
I3C Write Data Transfer, Parity Bit	ICSTCR.PBSE bit setting	During the count period of ICSTCR.STT[15:0] value
	Transmit FIFO Empty	Until data is written to the transmit FIFO
I3C Read Transfer, Transition Bit	Receive FIFO Full	Until data is read from the receive FIFO
Assigned Address Phase	ICSTCR.AASE bit setting	During the count period of ICSTCR.STT[15:0] value

The following figure shows the stalling timing of each condition.

(1) I3C Transfer, ACK/NACK Phase

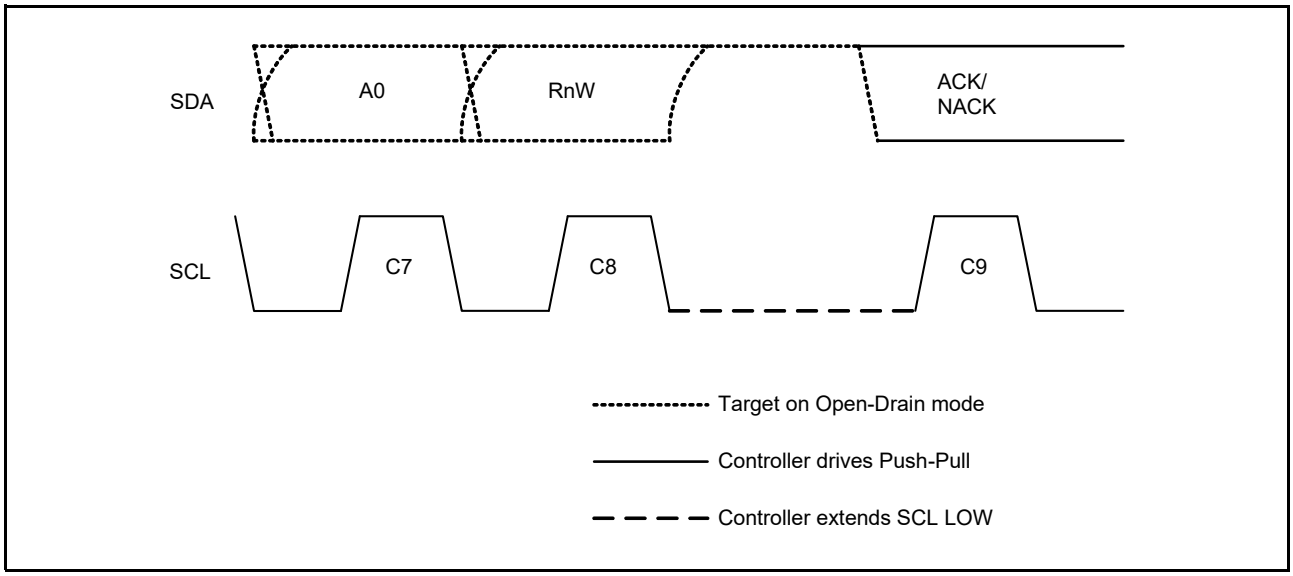

Figure 35.52 Controller Clock Stalling in ACK Phase

(2) I3C Write Data Transfer, Parity Bit

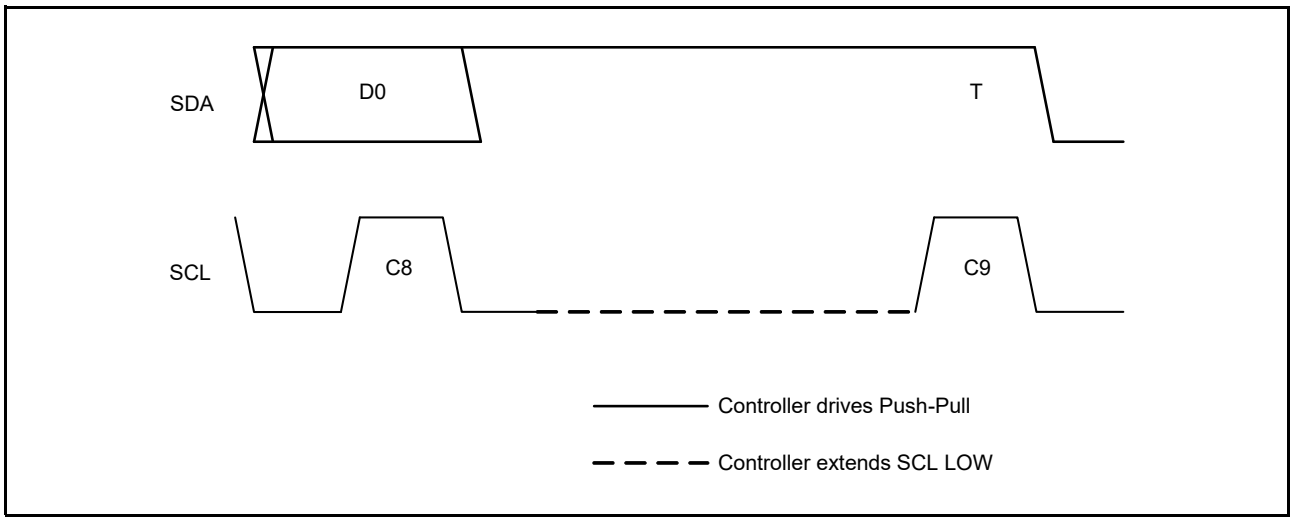

Figure 35.53 Controller Clock Stalling in Write Parity Bit

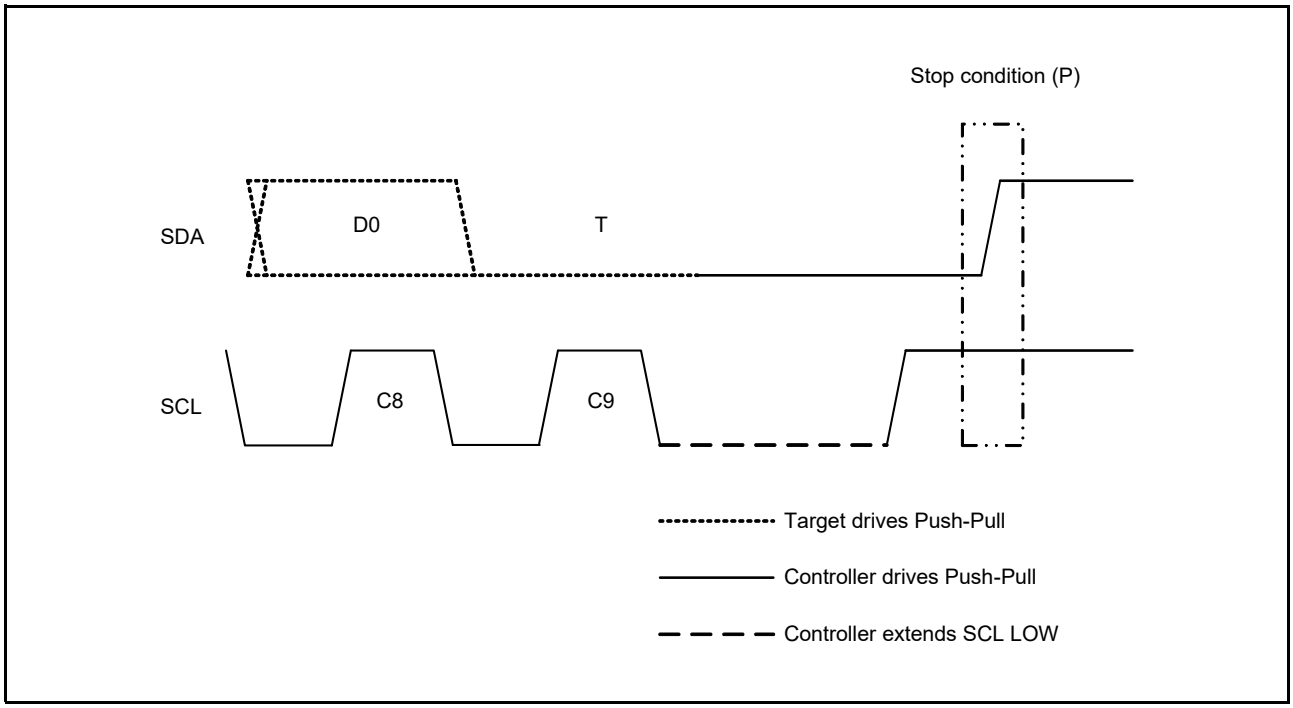

Figure 35.55 Controller Clock Stalling in T-bit Before STOP Condition

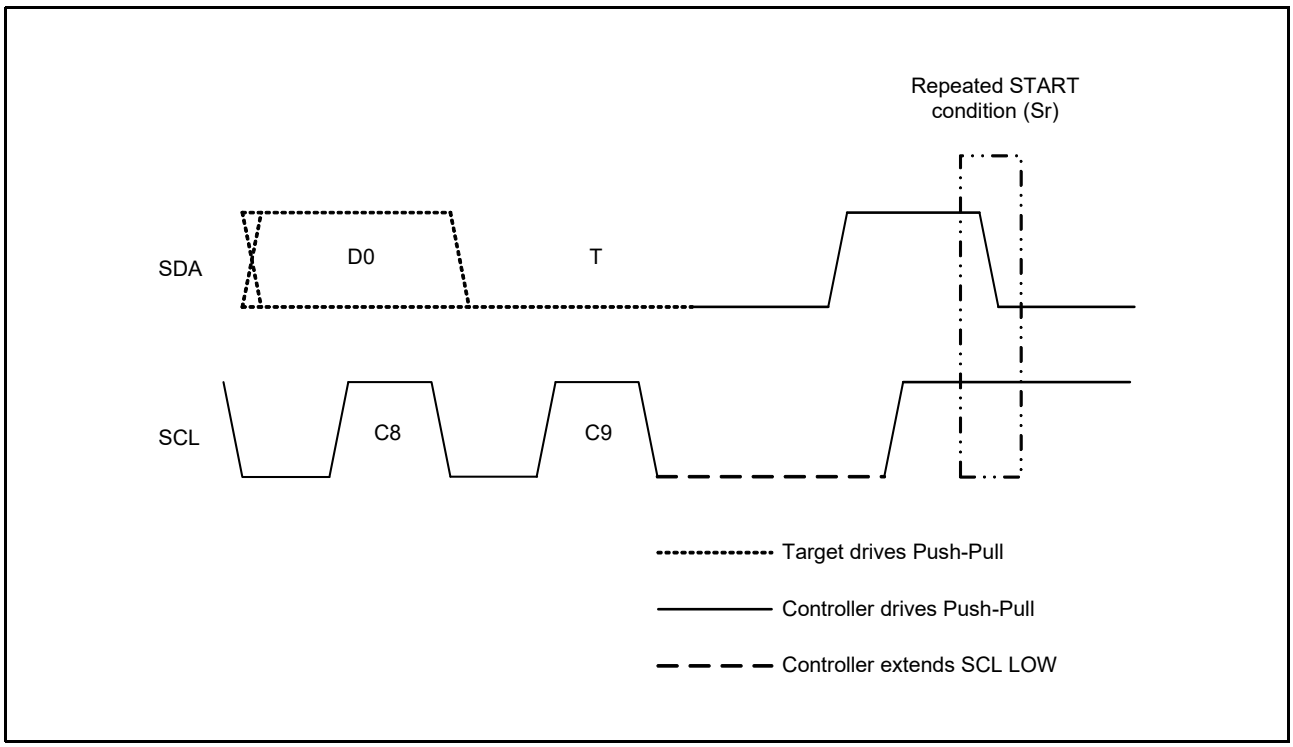

Figure 35.56 Controller Clock Stalling in Low T-bit before Repeated START Condition

(4) Dynamic Address Assignment, First Bit of Assigned Address

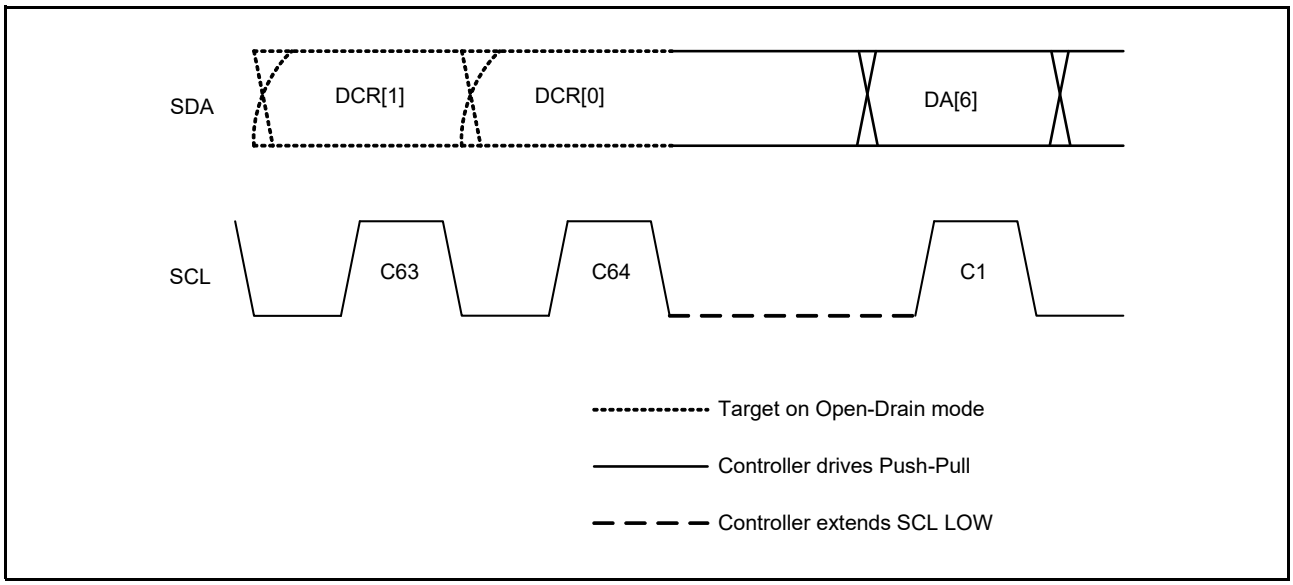

Figure 35.57 Controller Clock Stalling in Dynamic Address First Bit

35.5.3 IBI

RI3C detects IBI in the arbitrated Address header following a START condition (but not following a repeated START condition). If START Request (SDA Low Drive) is issued from Target Device, RI3C drives SCL low and completes START condition. After that, it supplies SCL and receives IBI Request.
The IBI to be detected is classified into the following three types.

- Target Interrupt Request
- Controller Role Request
- Hot-Join Event

The operation when detecting each IBI is described below.

35.5.3.1 Target Interrupt Request

(1) Detect Target Address with RnW bit High in Address header.
(2) Compare the detected Target Address with the DADR[7:0] bits in each DAT (the ICTDATRm register).
(3) When it does not match the ICTDATRm.DADR[7:0] bits:
• Responds with NACK, then issues a STOP condition.
When it matches the ICTDATRm.DADR[7:0] bits and the ICTDATRm.TIRRJ bit = 1:
• RI3C operates in the following order:
1. Responds with NACK.
2. Issues a repeated START condition, then automatically issues Direct DISEC CCC to the detected Target.
3. Issues a STOP condition.
When it matches the ICTDATRm.DADR[7:0] bits and the ICTDATRm.TIRRJ bit = 0:
• Responds with ACK.
(4) When the ICTDATRm.IBIPL bit is 0:
• Issues a STOP condition.
When the ICTDATRm.IBIPL bit is 1:
• RI3C operates in the following order:
1. Drives the SCL to receive the IBI Data from the Target following the ACK response and receives IBI Data.
2. It stores the received IBI Data into the IBI queue.
3. Each time IBI Data of the size set by the ICQBTCR.IDSS[7:0] bits is received, the IBI Status Descriptor is stored in the IBI queue.
(5) After detection of Low of T-bit following IBI Data, issues a STOP condition.
(6) After issuing the STOP condition,
NACK response:
• If the ICINCR.RTIRN bit is 0, the IBI Status Descriptor is not stored into the IBI queue.
• If the ICINCR.RTIRN bit is 1, the IBI Status Descriptor is stored into the IBI queue.
ACK response:
• Stores the IBI Status Descriptor into the IBI queue.

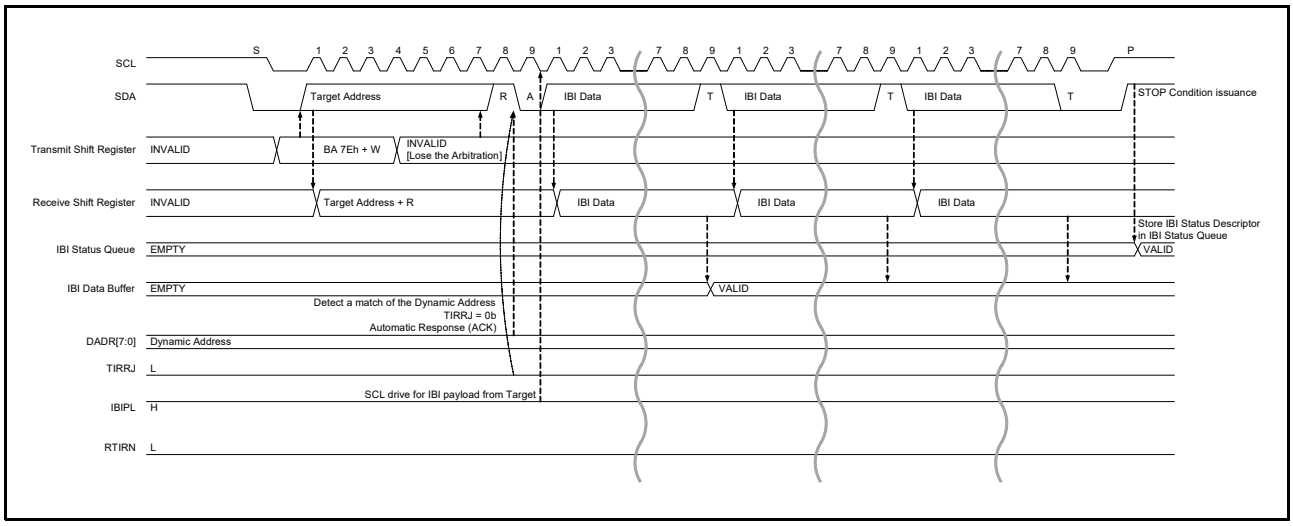

Figure 35.58 Target Interrupt Request: ACK and IBIPL = 1

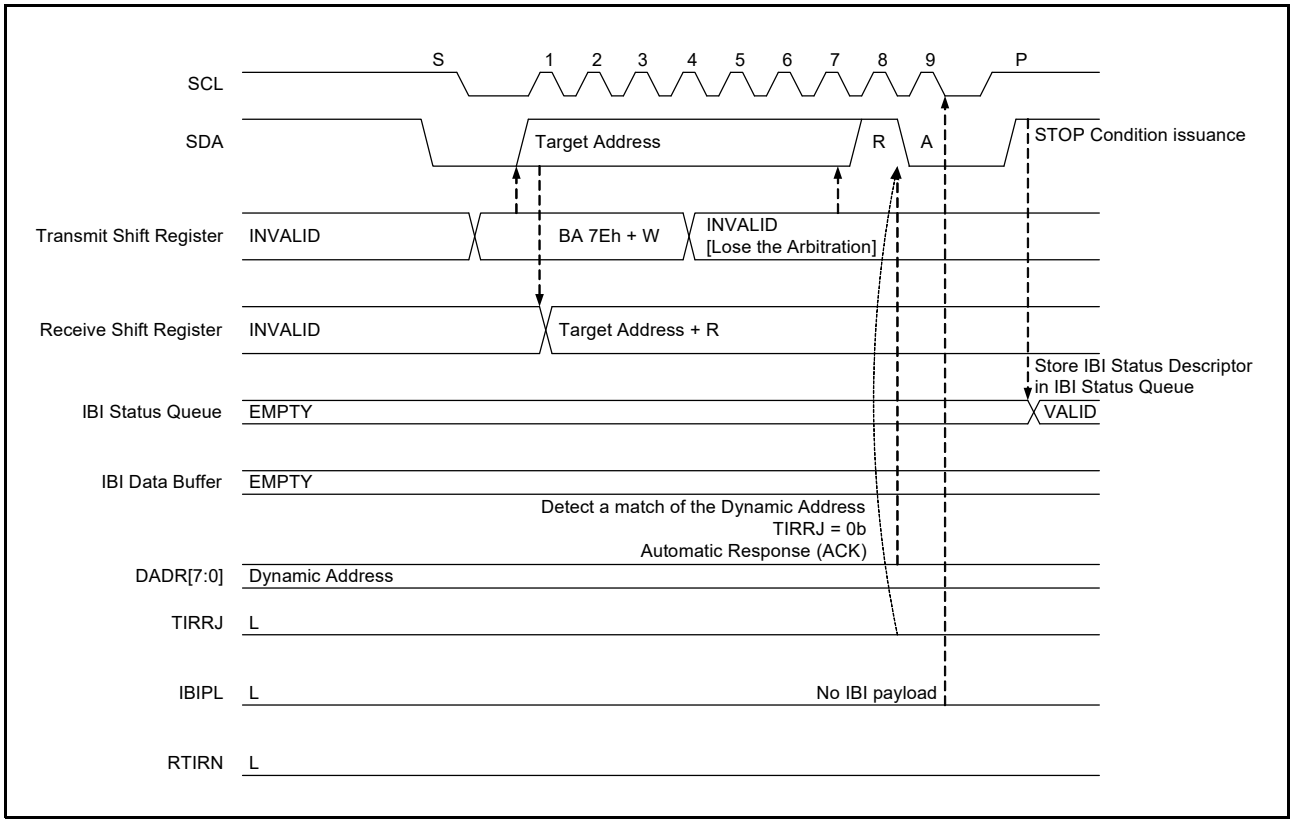

Figure 35.59 Target Interrupt Request: ACK and IBIPL = 0

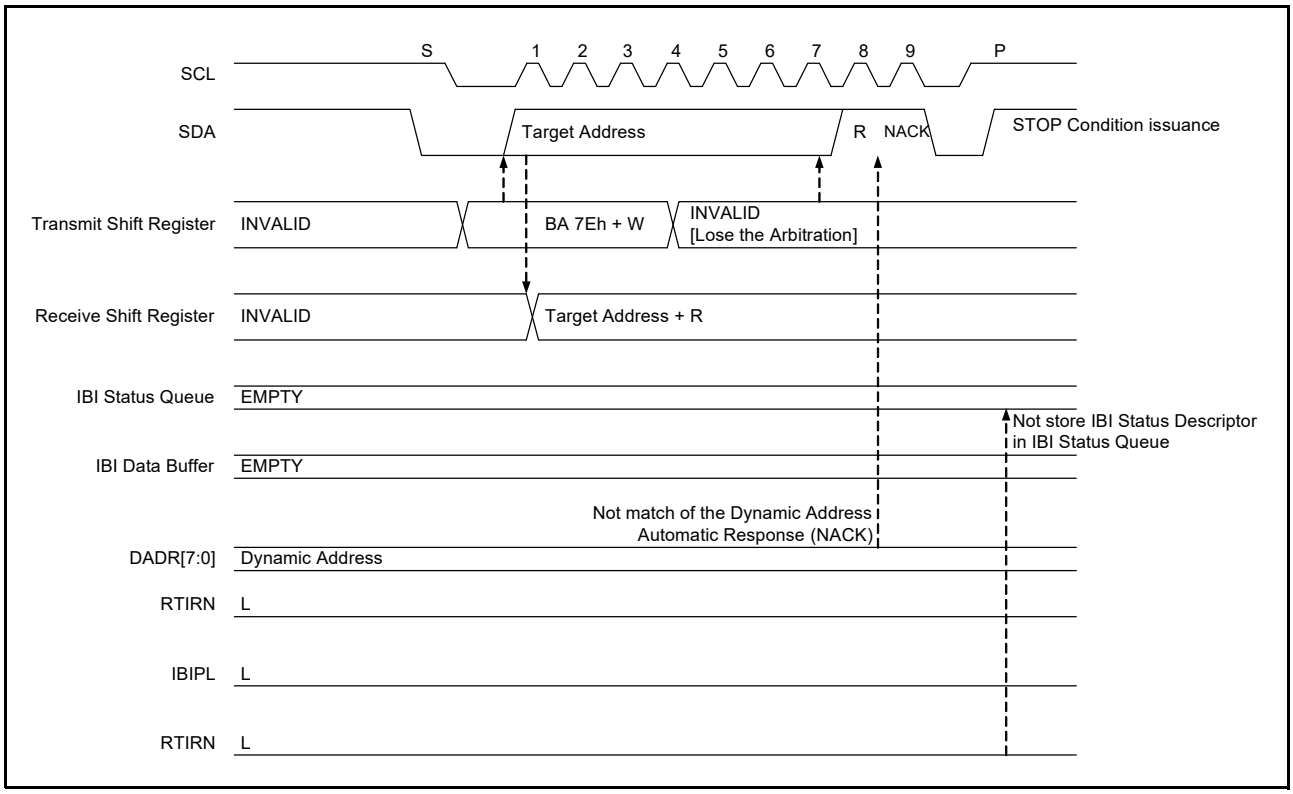

Figure 35.60 Target Interrupt Request: NACK (Not Match the DADR[7:0] Bits) and RTIRN = 0

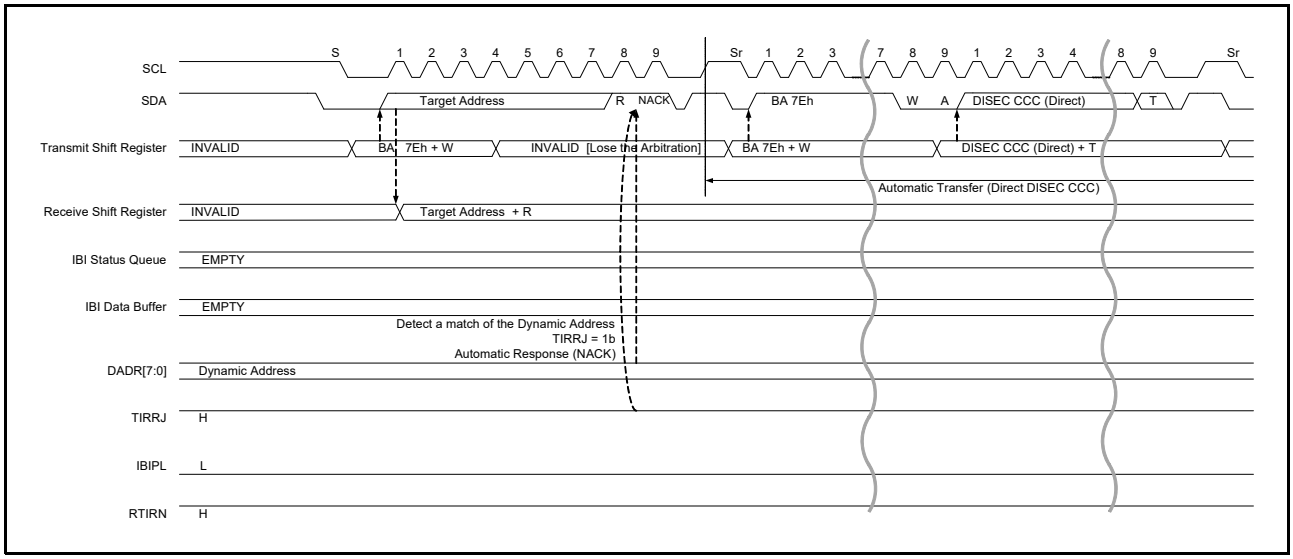

Figure 35.61 Target Interrupt Request: NACK (TIRRJ = 1) and RTIRN = 1 (1/2)

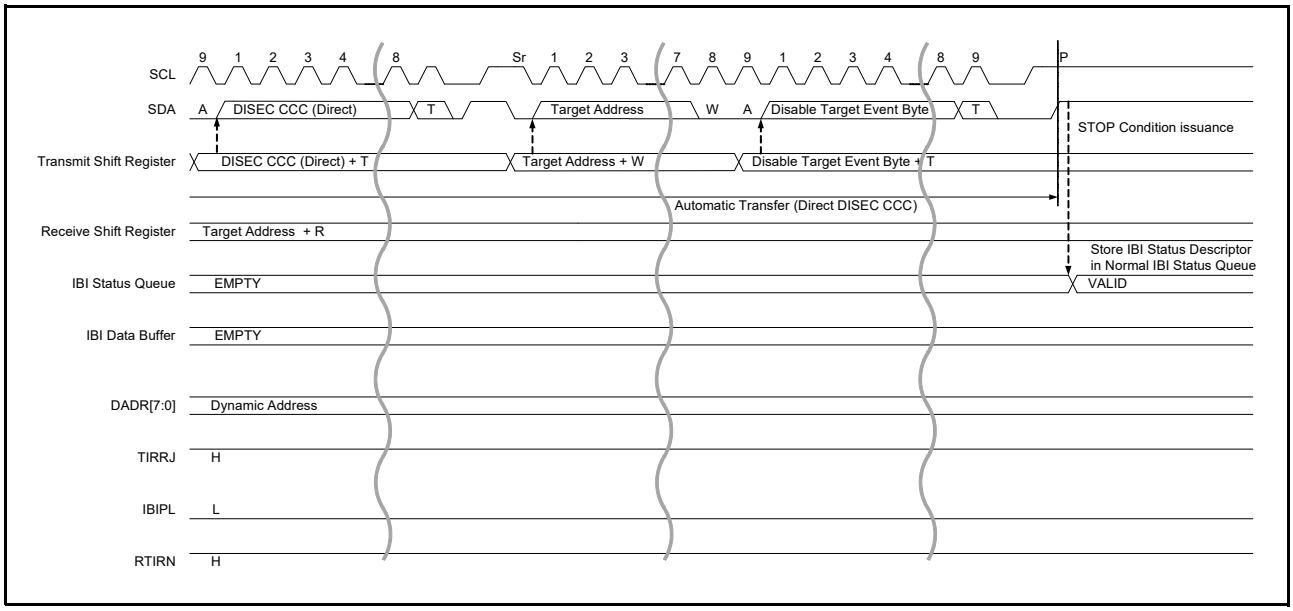

Figure 35.62 Target Interrupt Request: NACK (TIRRJ = 1) and RTIRN = 1 (2/2)

35.5.3.2 Controller Role Request

(1) Detect Target Address with RnW bit Low in Address header.

(2) Compare the detected Target Address with the DADR[7:0] bits in each DAT (the ICTDATRm register).

(3) When it does not match the ICTDATRm.DADR[7:0] bits:

• Responds with NACK, then issues a STOP condition.

When it matches the ICTDATRm.DADR[7:0] bits and the ICTDCTRm.ROLE[1:0] bits (BCR[7:6]) are “00b” (I3C Target):

• Responds with NACK, then issues a STOP condition.

When it matches the ICTDATRm.DADR[7:0] bits and the ICTDCTRm.ROLE[1:0] bits (BCR[7:6]) are “01b” (I3C Controller capable):

(a) When the ICTDATRm.CRRRJ bit is 1:

• RI3C operates in the following order.

1. Responds with NACK.
2. Issues a repeated START condition and automatically issues Direct DISEC CCC to the detected Target.
3. Issues a STOP condition.

(b) When the ICTDATRm.CRRRJ bit is 0:

• Responds with ACK, then issues a STOP condition.

(4) After issuing the STOP condition,

NACK response:

• If the ICINCR.RCRRN bit is 0, the IBI Status Descriptor is not stored into the IBI queue.

• If the ICINCR.RCRRN bit is 1, the IBI Status Descriptor is stored into the IBI queue.

ACK response:

• Stores the IBI Status Descriptor into the IBI queue.

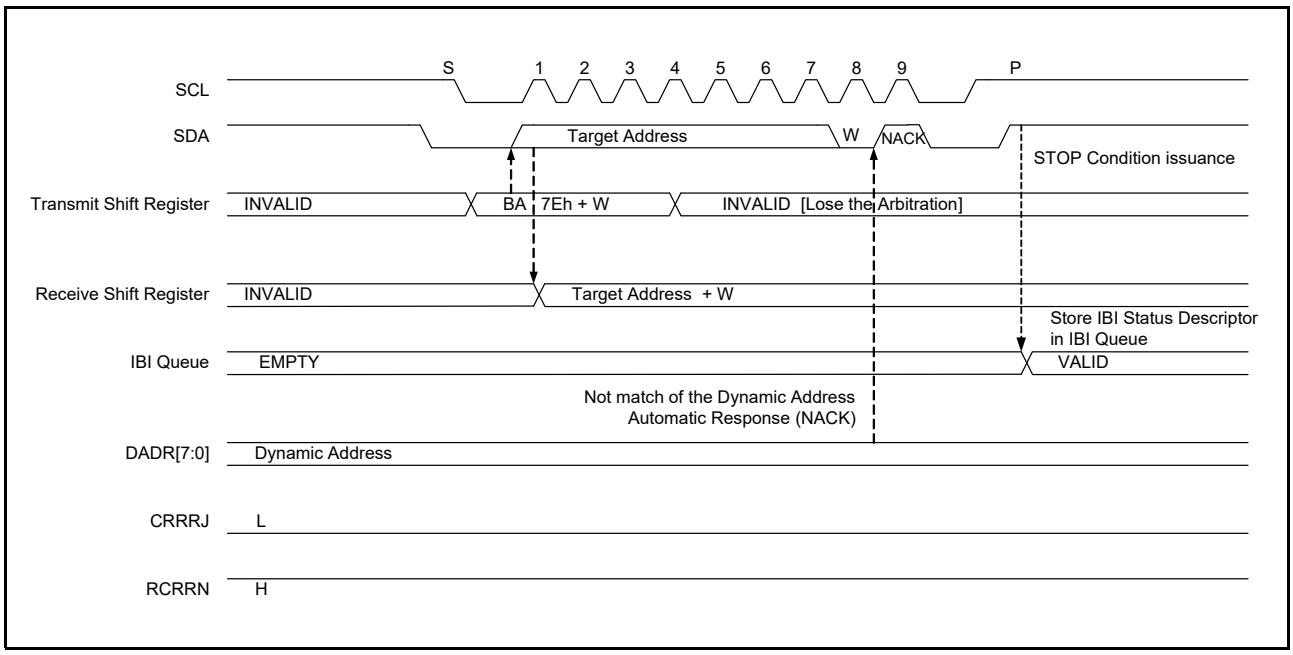

Figure 35.64 Controller Role Request: NACK (Not Match the DADR[7:0] Bits) and RCRRN = 1

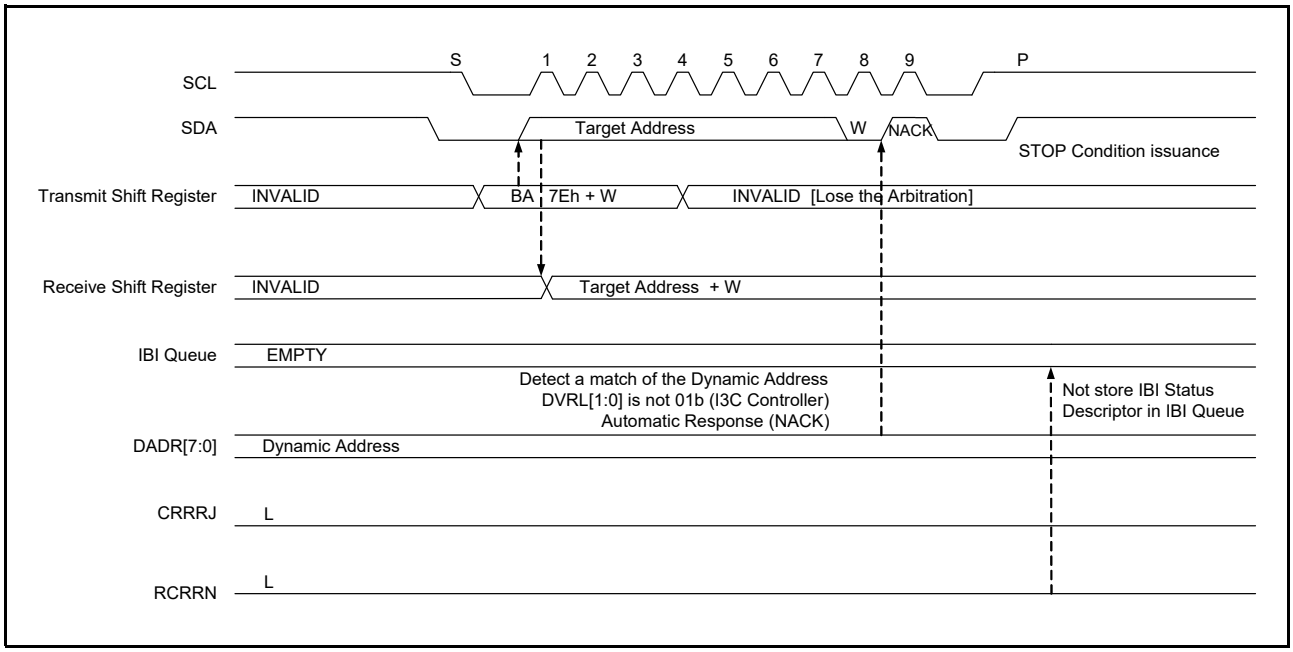

Figure 35.65 Controller Role Request: NACK (ROLE[1:0] = 00b (I3C Target)) and RCRRN = 0

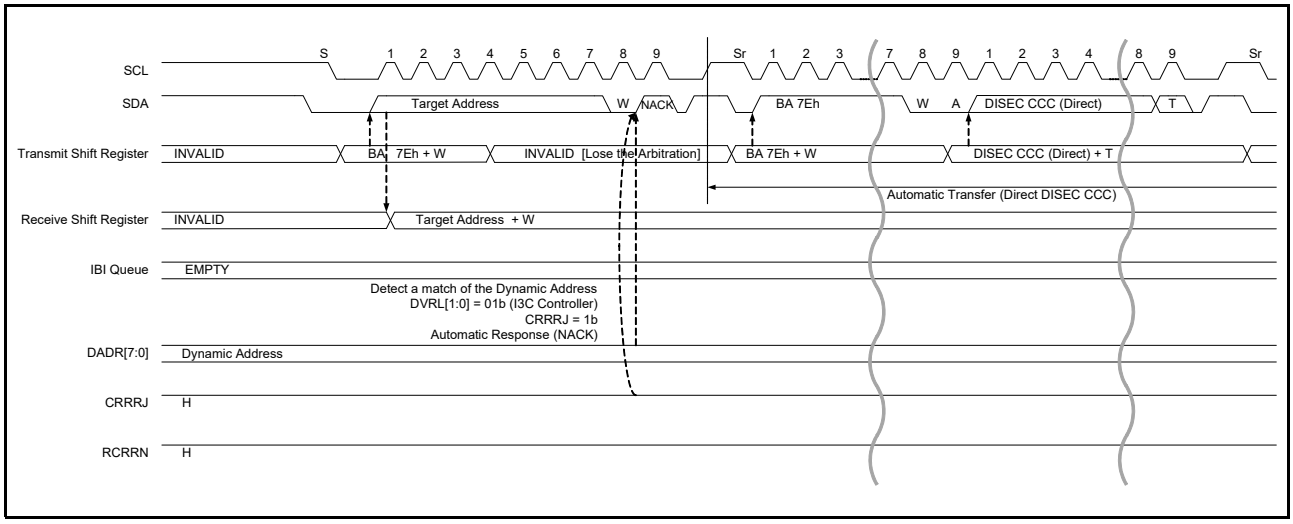

Figure 35.66 Controller Role Request: NACK (CRRRJ = 1) and RCRRN = 1 (1/2)

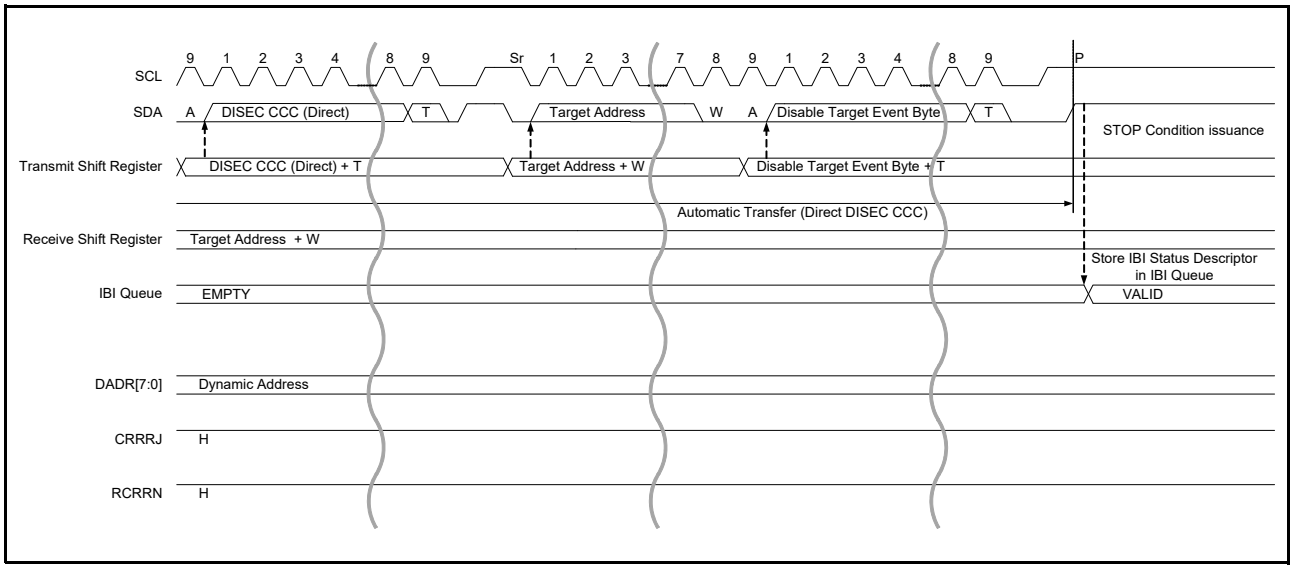

Figure 35.67 Controller Role Request: NACK (CRRRJ = 1) and RCRRN = 1 (2/2)

35.5.3.3 Hot-Join Event

(1) Detect the Hot-Join Address (02h) with RnW bit Low in the Address header.

(2) When the ICCR.HJC bit is 1:

• It operates in the following order.

1. Responds with NACK.
2. Issues a repeated START condition and automatically issues Broadcast DISEC CCC.
3. Issues a STOP condition.

When the ICCR.HJC bit is 0:

• Responds with ACK, then issues a STOP condition.

(3) After issuing the STOP condition,

NACK response:

• If the ICINCR.RHJRN bit is 0, the IBI Status Descriptor is not stored into the IBI queue.

• If the ICINCR.RHJRN bit is 1, store the IBI Status Descriptor into the IBI queue.

ACK response:

• Stores the IBI Status Descriptor into the IBI queue.

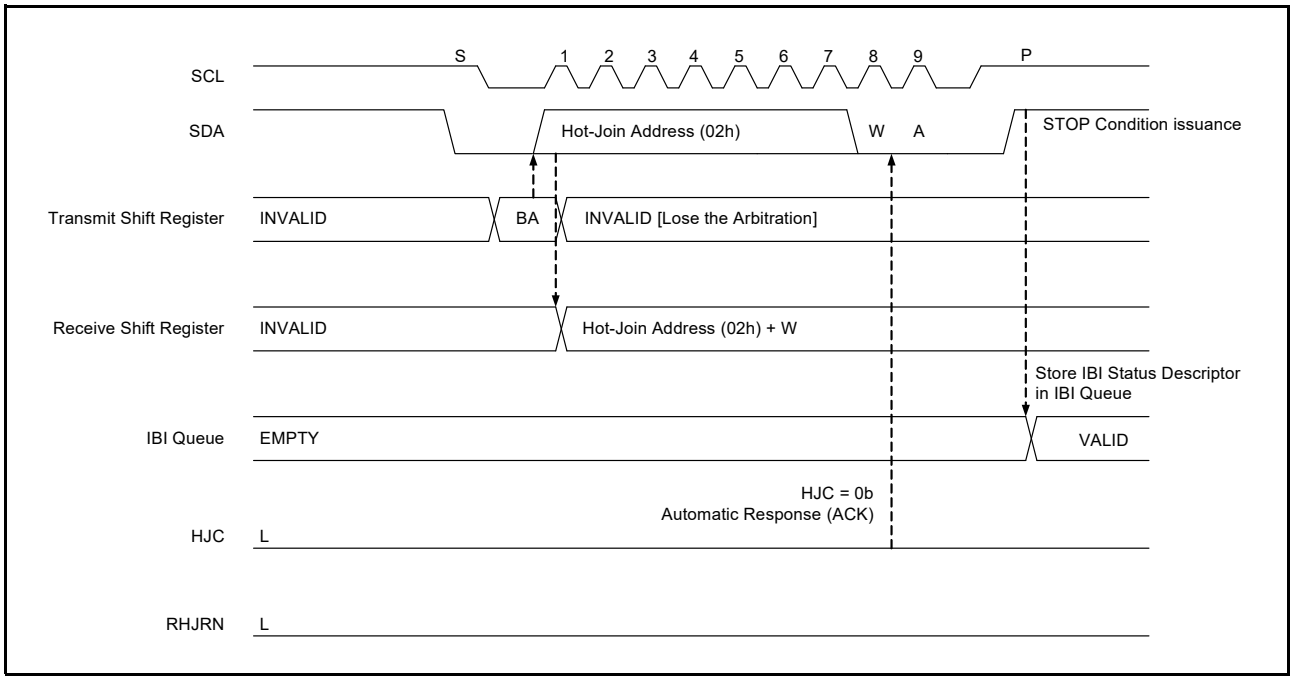

Figure 35.68 Hot-Join Event: ACK

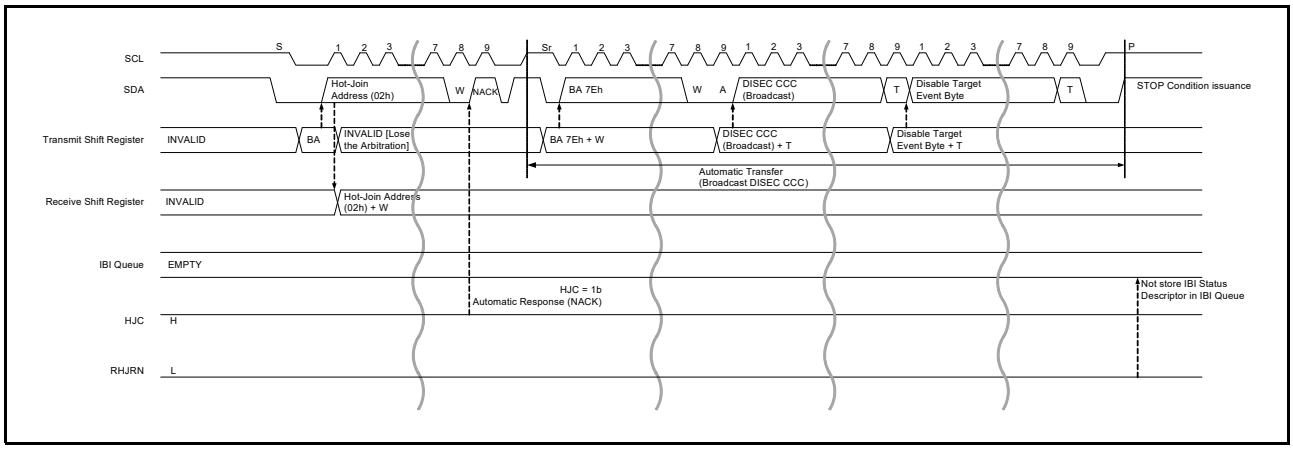

Figure 35.69 Hot-Join Event: NACK (HJC = 1) and RHJRN = 0

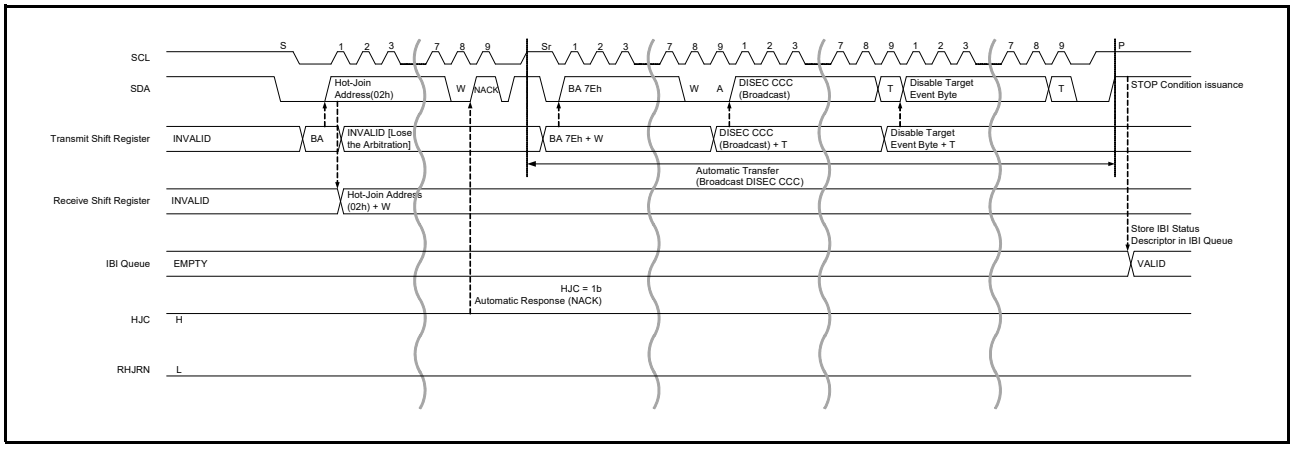

Figure 35.70 Hot-Join Event: NACK (HJC = 1) and RHJRN = 1

35.5.4 Common Command Codes (CCC)

Command Code E0h to FEh Vendor Extension-Direct CCCs defined are not supported.
The MIPI reserved area and Vendor Extension area of Command Code are not supported.
Do not use an unsupported CCC when using this module with I3C Target.
If the I3C Controller must use an unsupported CCC, use the added CCC after using ENTASx CCC to put this module to Sleep mode.

35.5.5 Error Detection

35.5.5.1 SDR Error Detection and Recovery Methods for I3C Target Devices

The seven error types summarized in Table 35.8 are supported for all I3C Target devices. Each error type is further explained below the table.

Table 35.8 SDR Target Error Types

Error Type	Description	Error Detection Method	Error Recovery Method
TE0	Broadcast Address/W (= 7Eh/W) or Dynamic Address/RW	Detect any of the following: 3Eh/W 5Eh/W 6Eh/W 76h/W 7Ah/W 7Ch/W 7Fh/W 7Eh/R	Enable HDR Exit Detector and ignore all other patterns
TE1	CCC code	Parity check, using T-Bit	Enable HDR Exit Detector and neglect other patterns
TE2	Write data	Parity check, using T-Bit	Enable STOP condition detector and neglect other patterns
TE3	Assigned address during Dynamic Address arbitration	Parity check, using PAR Bit	Generate NACK (after PAR), then wait for another repeated START condition and 7Eh/R to re-transmit the Provisioned ID
TE4	7Eh/R after Sr during Dynamic Address arbitration	Detect any value other than 7Eh/R after Sr during Dynamic Address Arbitration	Generate NACK (after 7Eh/R), then enable STOP condition detector and ignore all other patterns
TE5	Transaction after detecting CCC	Detect illegally formatted CCC	Generate NACK (after Target Address), then enable STOP condition detector and ignore all other patterns
TE6 (optional)	Monitoring error	Target detects (through monitoring) that transmitted Data differs from what it intended to transmit (Does not apply during Dynamic Address arbitration)	Stop the transmission, then enable STOP condition detector and ignore all other patterns

35.5.5.2 SDR Error Detection and Recovery Methods for I3C Controller Devices

The two error types summarized in Table 35.9 are supported for all I3C Controller devices. Each error type is further explained below the table.

Table 35.9 SDR Controller Error Types

Error Type	Description	Error Detection Method	Error Recovery Method
CE0	Transaction after sending CCC	Detect illegally formatted CCC	Stop the transmission, then send STOP condition and retry the transmission.
CE1 (optional)	Monitoring error	Controller detects (through monitoring) transmitted data different from what it intended to transmit (does not apply during Dynamic Address arbitration)	Stop the transmission, then send STOP condition and retry the transmission.
CE2	No response to Broadcast Address (7Eh)	Controller detects NACK after Broadcast Address (7Eh) transmission	Upon detection of NACK, Controller transmits HDR Exit Pattern followed by STOP condition

35.5.5.3 Timeout Error Detection

RI3C includes a timeout function for detecting when the SCL line has been stuck longer than the predetermined time. RI3C can detect an abnormal bus state by monitoring that the SCL line is stuck low or high for a predetermined time. The timeout function monitors the SCL line state and counts the low-level period or high-level period using the internal counter. The timeout function resets the internal counter each time the SCL line changes (rising or falling), but continues to count unless the SCL line changes. If the internal counter overflows due to no SCL line change, RI3C can detect the timeout and report the bus hung state.

This timeout function is enabled when ICSER.TMOE = 1. It detects a hung state that the SCL line is stuck low or high during the following conditions: (When ICTOR.TMOM[1:0] = 00b)

- The bus is busy (ICBSR.BFREE = 0) in Controller mode (ICMMR.ACF = 1).
- The bus is busy (ICBSR.BFREE = 0) in Target mode (ICMMR.ACF = 0).

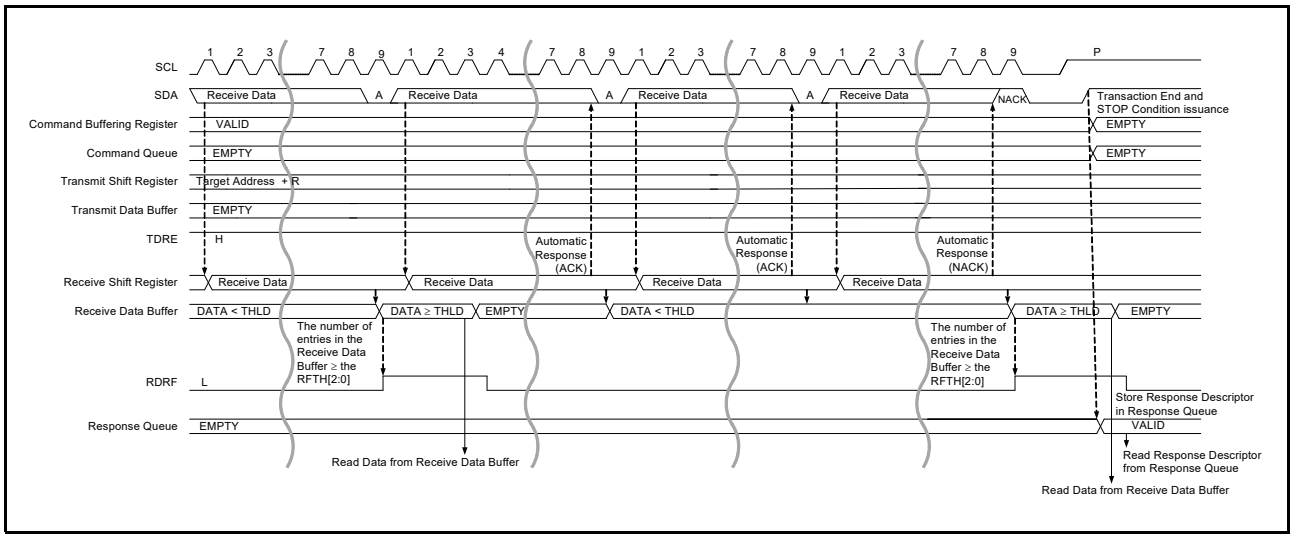

Figure 35.71 Timeout Error Detection (TMOE, TMOS[1:0], TMOH, and TMOL bits)

35.5.5.4 Resume Operation

I3C enters the Halt state as a result of any type of error occurring in a transfer.
The error type is indicated by the field ERR_STATUS in Response Descriptor or Receive Status Descriptor. After I3C has entered the Halt state, the user must write the value 1 to the RESUME bit to resume operation. I3C shall auto-clear the RESUME bit once it has initiated the next Command transfer or detected the START condition.

35.5.5.5 Abort Operation

When the ICCR.ABORT bit is set to 1, RI3C relinquish control of the bus before completing the currently issued transfer. In response to an Abort request, RI3C issues the STOP condition on the bus after the complete data byte is transmitted or received. After RI3C has aborted, the user shall clear the ICCR.ABORT bit to allow operation on the bus.

Note: For Read transaction, received data are stored in the receive data buffer even if the ICCR.ABORT bit is set to 1.

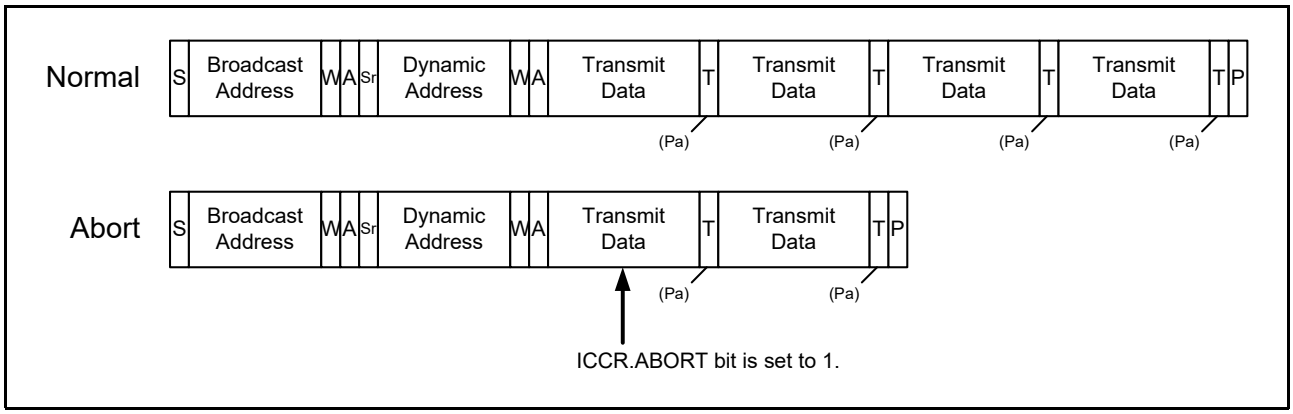

Figure 35.72 Abort Operation of SDR Write Transfer

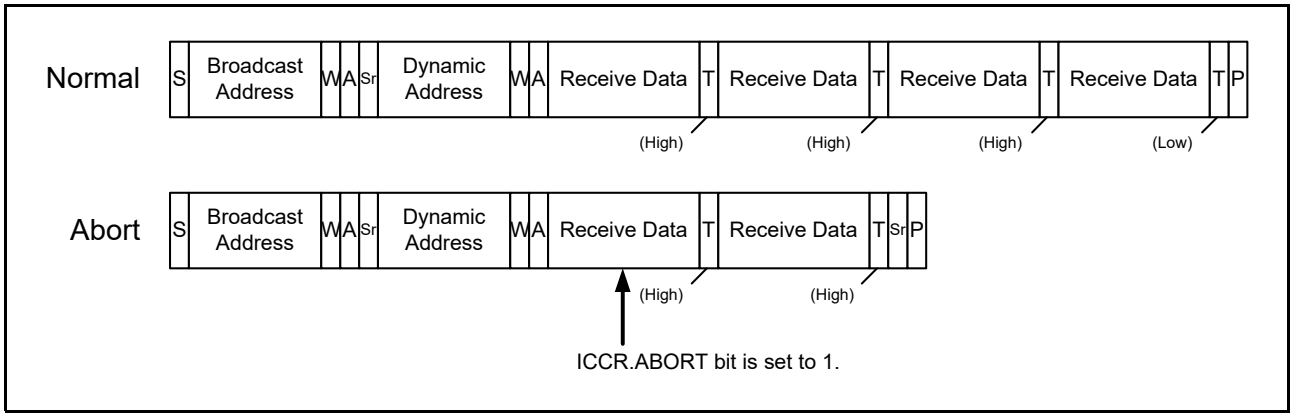

Figure 35.73 Abort Operation of SDR Read Transfer

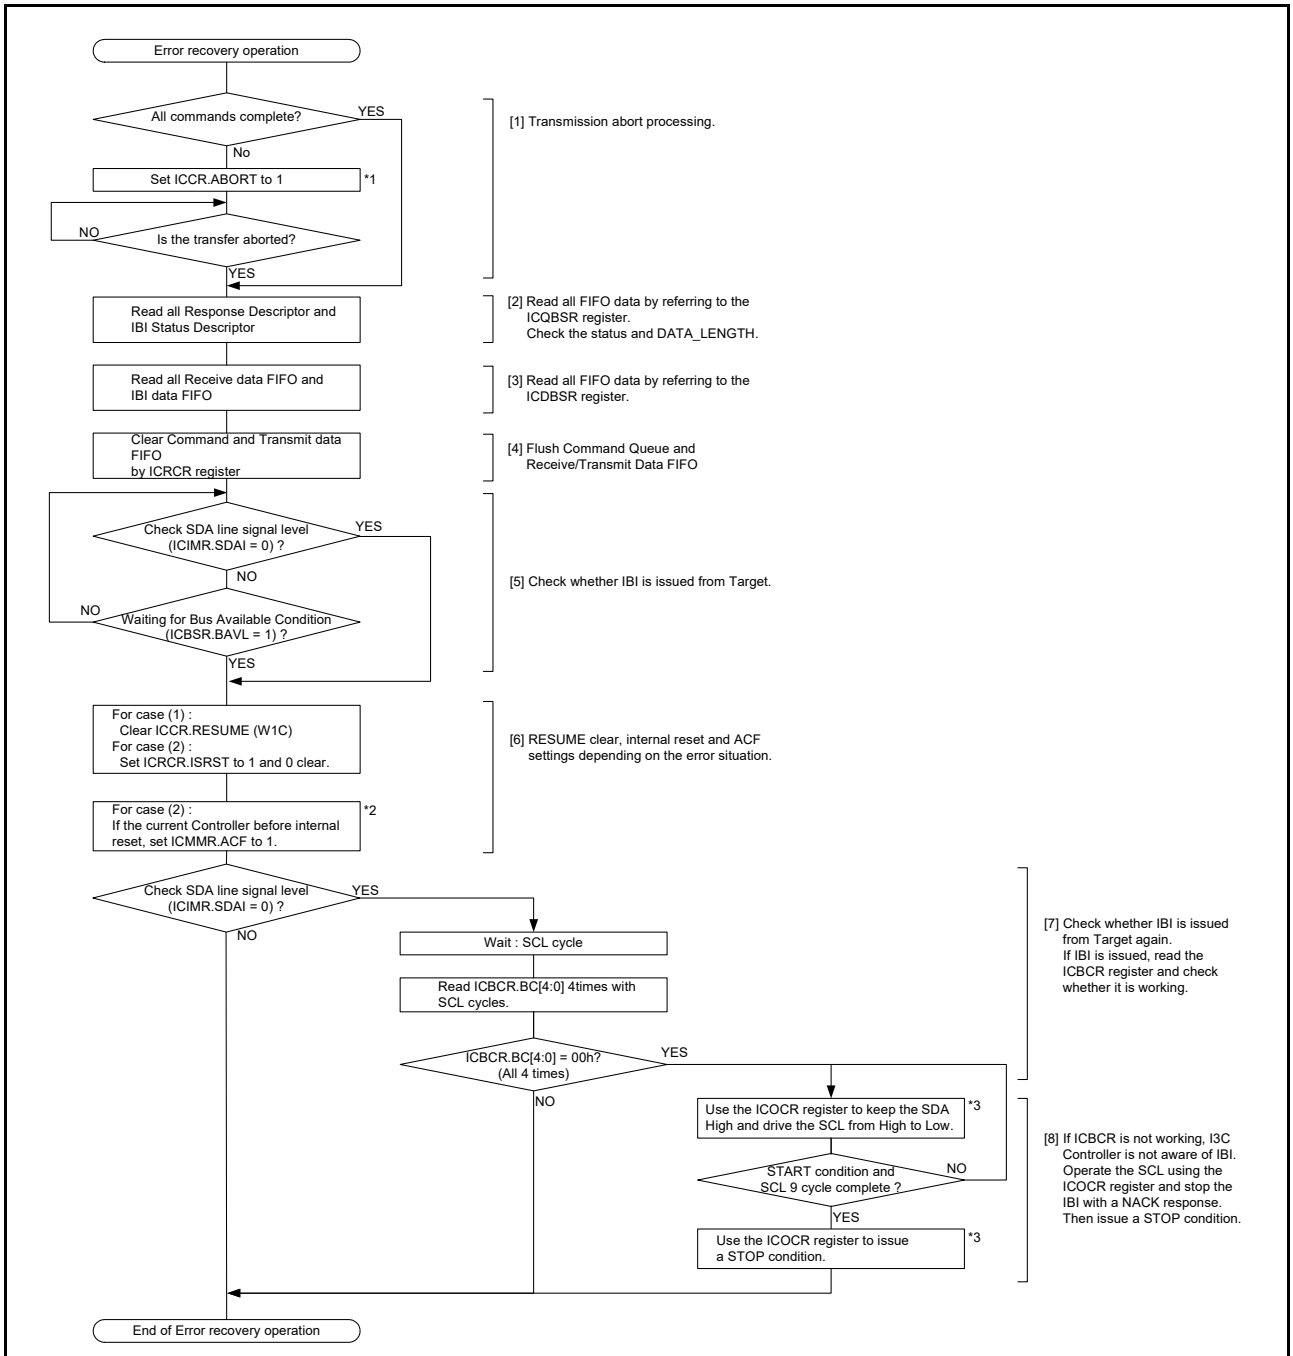
35.5.5.6 Error Recovery Operation

When an error occurs, the ICISR.BERF, ICCSR.DTEF, and ICCSR.DTAF flags are set to 1 according to the cause of the error, or the interrupts associated with each flag are asserted (when detection and interrupts are enabled).
There is a possibility of communication error or internal module error.
The I3C Controller must perform an error recovery flow according to the following case:

- When DTEF is detected.

Figure 35.74 and Figure 35.75 show the error recovery flow.



Note 1. If the transfer is not aborted due to an error, set the ICCR.ABORT bit to 1 and then abort the transfer.
Note 2. When writing to the ACF flag, set ICMMR.WP bit to 1 at the same time.
Note 3. When writing to the SDAO and SCLO bit, set ICOCR.SOWP bit to 1 at the same time.

Figure 35.74 Example of Error Recovery Operation Flowchart for I3C Controller

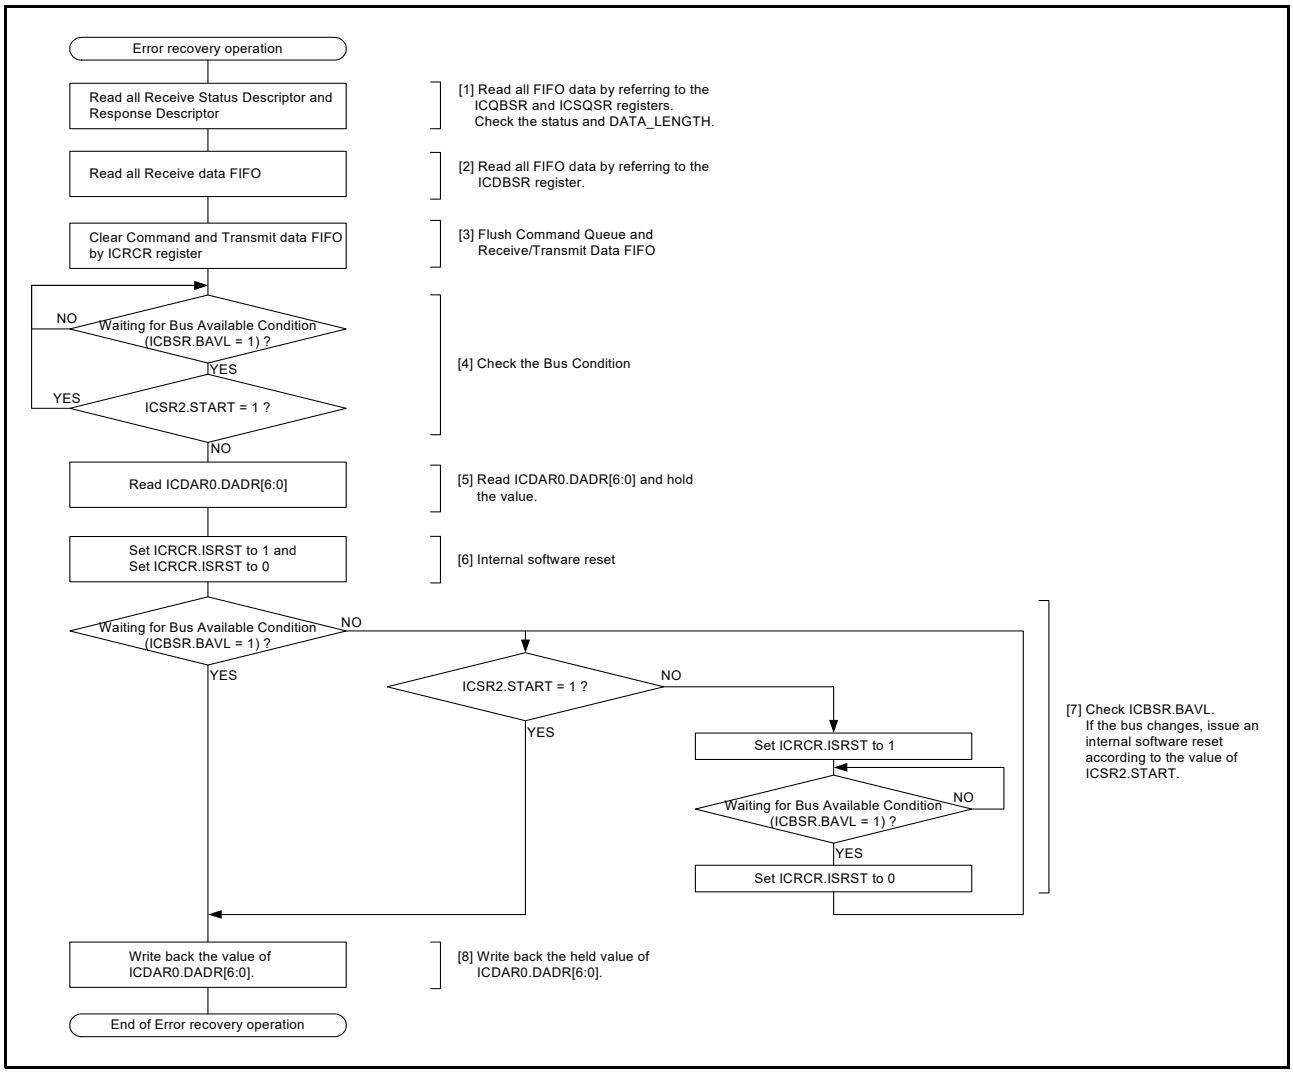


Figure 35.75 Example of Error Recovery Operation Flowchart for I3C Target

35.6 Interrupt Sources

The RI3C generates seven types of interrupt requests: transmit data empty, receive data full, IBI queue empty/full, command queue empty, response queue full, receive status queue full, and communication error or communication event (START condition detection, STOP condition detection, HDR Exit Pattern detection, timeout detection, buffer access error detection, data transfer abort, and data transfer error).

Table 35.10 lists details of the interrupt requests. The transmit data empty, receive data full, IBI queue empty/full, command queue empty, response queue full, and receive status queue full interrupt requests allow the DTC or DMAC to start data transfer.

Table 35.10 Interrupt Sources

Symbol	Interrupt Source	Interrupt Flag	Interrupt Enable Bit	Start DTC/DMA Transfer	Interrupt Generation Condition
TXI*1	Transmit data empty	ICCSR.TDRE	ICCSIER.TIE	Possible	TDRE = 1 and TIE = 1
RXI*2	Receive data full	ICCSR.RDRF	ICCSIER.RIE	Possible	RDRF = 1 and RIE = 1
IBII*3	IBI queue empty/full	ICCSR.IQEFF	ICCSIER.IQEFIE	Possible	IQEFF = 1 and IQEFIE = 1
CMDI*3	Command queue empty	ICCSR.CQEF	ICCSIER.CQEIE	Possible	CQEF = 1 and CQEIE = 1
RESPI*3	Response queue full	ICCSR.RQFF	ICCSIER.RQFIE	Possible	RQFF = 1 and RQFIE = 1
RCVI*3	Receive status queue full	ICCSR.SQFF	ICCSIER.SQFIE	Possible	SQFF = 1 and SQFIE = 1
EEI	Communication error/ communication event	ICSR2.START	ICSIER.STIE	Not possible	START = 1 and STIE = 1
		ICSR2.STOP	ICSIER.SPIE		STOP = 1 and SPIE = 1
		ICSR2.HDRXDF	ICSIER.HDRXIE		HDRXDF = 1 and HDRXIE = 1
		ICSR2.TMOF	ICSIER.TMOIE		TMOF = 1 and TMOIE = 1
		ICISR.BERF	ICISIER.BERIE		BERF = 1 and BERIE = 1
		ICCSR.DTAF	ICCSIER.DTAIE		DTAF = 1 and DTAIE = 1
		ICCSR.DTEF	ICCSIER.DTEIE		DTEF = 1 and DTEIE = 1

Note: There is a delay between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. Thus, when an interrupt flag has been cleared or an interrupt request has been masked, read the relevant flag again to check whether clearing or masking has been completed, and then return from interrupt handling. Returning from interrupt handling without checking that writing to the module has been completed creates a possibility of repeated processing of the same interrupt.

Note 1. Because TXI is an edge-detected interrupted, it does not require clearing. Furthermore, the ICCSR.TDRE flag (a condition for TXI) is automatically set to 0 when transmit data is written to the ICDR register or when a STOP condition is detected (ICSR2.STOP flag is 1).

Note 2. Because RXI is an edge-detected interrupted, it does not require clearing. Furthermore, the ICCSR.RDRF flag (a condition for RXI) is automatically set to 0 when data is read from the ICDR register.

Note 3. Because these interrupts are edge-detected interrupted, they do not require clearing. Furthermore, the each flag (a condition for interrupt) is automatically set to 0 when the corresponding queue is read or written to.

Clear each flag or mask the interrupt request during interrupt handling.

35.6.1 Buffer Operation for Empty and Full Interrupts

If the conditions for generating a Empty or Full interrupt is satisfied while the corresponding ICU.IRn.IR flag is 1, the interrupt request is not output to the ICU but retained internally (up to one request can be retained internally for each source).

When the IR flag becomes 0, the retained interrupt request is output to the ICU. The retained interrupt request is automatically cleared under normal conditions of usage.

The retained interrupt request can also be cleared by writing 0 to the corresponding interrupt enable bit in the ICCSIER register.

35.7 Event Link Function

The RI3C outputs the corresponding event signal to the event link controller (ELC) when any of the following events occur.

- Transmit data empty
- Receive data full
- Communication error/communication event

35.7.1 Interrupt Handling and Event Linking

Each of the RI3C interrupts: transmit data empty, receive data full, and communication error/communication event (START condition detection, STOP condition detection, and timeout detection) has an enable bit that controls whether the interrupt is enabled or disabled. When an interrupt request source occurs, an interrupt request signal is output to the ICU if the corresponding interrupt enable bit is 1.
On the other hand, the event signal is transmitted via the ELC to other modules when the corresponding interrupt request source occurs, regardless of the interrupt enable bit.
For details on interrupt sources, refer to Table 35.10.

35.9 Usage Notes

35.9.1 Settings of the Module Stop Function

RI3C operation can be disabled or enabled by module stop control register D (MSTPCRD).
After a reset, the RI3C is stopped. The registers become accessible when it is released from the module stop state. For details, refer to section 11, Low Power Consumption.

36. CAN FD Module (CANFD)

36.1 Overview

This MCU implements one channel of the CAN FD (Controller Area Network with Flexible Data Rate) module that complies with the ISO 11898-1:2015 Standard.

Table 36.1 lists the specifications of the CAN FD module, and Figure 36.1 shows a block diagram of the CAN FD module.

Table 36.1 CAN FD Module Specifications

Item	Description
Protocol	ISO 11898-1:2015 compliant
Data transfer rate	Arbitration phase: up to 1 Mbps Data phase: up to 8 Mbps*1
Operating frequency*2	Register block: up to 60 MHz (PCLKB) Message buffer RAM: up to 120 MHz (PCLKA)
Operating clock for data link layer (DLL clock)	Up to 60 MHz (either CANFDMCLK or CANFDCLK can be selected)
Frame types	Classic CAN (CAN 2.0) • Data frame in base format (11-bit ID) • Data frame in extended format (29-bit ID) • Remote frame in base format (11-bit ID) • Remote frame in extended format (29-bit ID) CAN FD*1 • Data frame in base format (11-bit ID) • Data frame in extended format (29-bit ID)
Data length	Classic CAN: 0 to 8 bytes CAN FD: 0 to 8, 12, 16, 20, 24, 32, 48, or 64 bytes*1
Message buffers	• 32 receive message buffers • Four transmit message buffers • One transmit queue Messages can be automatically transfered to the transmit queue.
FIFOs	Variable size FIFO buffers • Two receive FIFOs • One common FIFO that can be configured as a receive FIFO or transmit FIFO
Automatic transmission interval adjustment	Available when the common FIFO is configured as a transmit FIFO The interval between messages sent from the FIFO can be adjusted.
Acceptance filter	Filterable in the following fields: • IDE bit (base format, extended format, or both) • ID field • RTR bit (data frame or remote frame) (only for Classic CAN) • DLC field (data length) Protection function when the payload size is exceeded Acceptance filter list (AFL) entries can be updated during communication.
Software support	Label information is automatically added to received messages
Timer	Transmission and reception timestamp function
Power down function	Module start/stop function for each CAN node (CH_SLEEP and GL_SLEEP mode) Transition to module stop state is possible.
RAM	RAM with ECC protection

Note 1. This is only available for products that support the CAN FD protocol.
Note 2. The frequency ratio of PCLKA and PCLKB should be 2 : 1. Also, the frequency of PCLKB should be equal to or higher than that of the DLL clock.

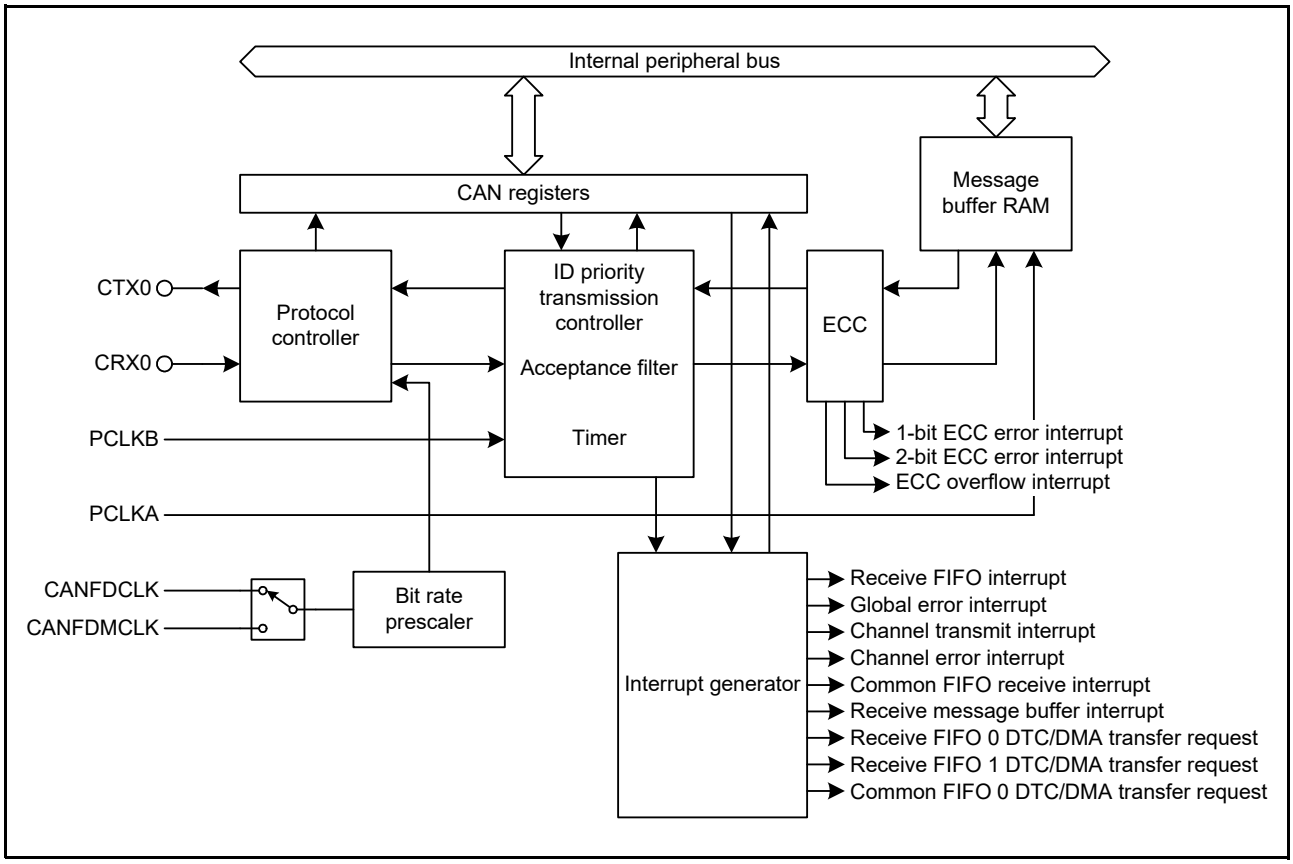

Figure 36.1 CAN FD Module Block Diagram

- CRX0, CTX0
  I/O pins of the CAN FD module
- Protocol controller
  Handles CAN FD protocol processing such as bus arbitration, bit timing at transmission and reception, stuffing, error handling, etc.
- Message buffer RAM
  Used for message buffers or FIFOs for transmitting and receiving messages. Each message has an individual identifier, data length code, a data field, a message pointer for upper layer application, and a timestamp.
- Acceptance filter
  Performs filtering of received messages. The entries set in the acceptance filter list are used for the filtering process.
- Timers
  Two timers: one used for the receive timestamp function and the other for adjusting the message transmission interval from the transmit FIFO.

Table 36.2 lists the pin configuration of the CAN FD module.

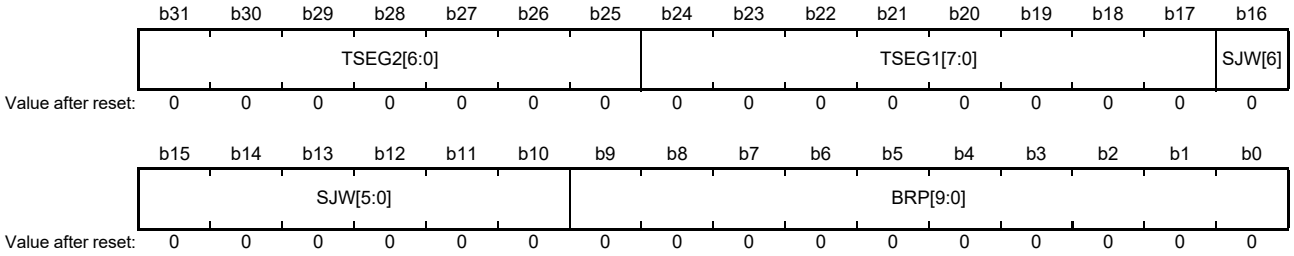
Table 36.2 CAN FD Module Pin Configuration

Pin Name	I/O	Function
CRX0	Input	Receive data input
CTX0	Output	Transmit data output

36.2 Register Descriptions

36.2.1 Nominal Bit Rate Configuration Register (NBCR)

Address(es): CANFD0.NBCR 000A 8000h



Bit	Symbol	Bit Name	Description	R/W
b9 to b0	BRP[9:0]	Bit Rate Prescaler Setting	000h: No division 001h: Divided by 2 : : 3FEh: Divided by 1023 3FFh: Divided by 1024	R/W
b16 to b10	SJW[6:0]	Resynchronization Jump Width Control	00h: 1 Tq 01h: 2 Tq : : 7Eh: 127 Tq 7Fh: 128 Tq	R/W
b24 to b17	TSEG1[7:0]	Time Segment 1 Control	00h: Setting prohibited 01h: 2 Tq 02h: 3 Tq 03h: 4 Tq : : FEh: 255 Tq FFh: 256 Tq	R/W
b31 to b25	TSEG2[6:0]	Time Segment 2 Control	00h: Setting prohibited 01h: 2 Tq 02h: 3 Tq : : 7Eh: 127 Tq 7Fh: 128 Tq	R/W

This register is used to set the nominal bit rate during transmission and reception.
The value cannot be changed in CH_OPERATION or CH_SLEEP mode. Rewrite this register in CH_RESET or CH_HALT mode.
For details on the setting values, refer to section 36.4.1.2, Bit Timing.

BRP[9:0] Bits (Bit Rate Prescaler Setting)

These bits are used to define a period of 1 Tq (Time Quantum) that is the basis for CAN communication. Set the division ratio for the operating clock of the data link layer (DLL clock) selected by the GCFG.DLLCS bit. If the set value is n, the bit rate prescaler divides the DLL clock by n + 1.

SJW[6:0] Bits (Resynchronization Jump Width Control)

These bits are used to specify the resynchronization jump width with a Tq value. A value from 1 to 128 Tq can be set. Set a value less than or equal to that of the TSEG2[6:0] bits.

TSEG1[7:0] Bits (Time Segment 1 Control)

These bits are used to specify the total value (TSEG1) of the propagation time segment (PROP_SEG) and phase buffer segment 1 (PHASE_SEG1) with a Tq value. A value from 2 to 256 Tq can be set.

TSEG2[6:0] Bits (Time Segment 2 Control)

These bits are used to specify the value (TSEG2) of the phase buffer segment 2 (PHASE_SEG2) with a Tq value. A value from 2 to 128 Tq can be set. Set a value less than that of the TSEG1[7:0] bits.

36.2.2 Channel Control Register (CHCR)

Address(es): CANFD0.CHCR 000A 8004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b30	BFT	Bit Flip Test*5	0: First bit of received data stream is not inverted. 1: First bit of received data stream is inverted.	R/W
b31	ROME	Restricted Operation Mode Enable *3, *5	0: Limited operation mode is disabled. 1: Limited operation mode is enabled.	R/W

Note 1. Set this bit in CH_OPERATION mode.
Note 2. Rewrite these bits in CH_RESET mode.
Note 3. Do not set this bit to 1 in Classic Only mode.
Note 4. Set this bit in CH_RESET or CH_HALT mode.
Note 5. Set these bits in CH_HALT mode.

This register controls the modes of the channel. It is also used to enable interrupt generation when an error is detected on the CAN bus and to set the test mode.
In CH_SLEEP mode, values other than the SLPRQ bit cannot be changed.

MDC[1:0] Bits (Channel Mode Control)

The MDC[1:0] bits are used to specify the mode of the CAN channel. For the CAN mode transition, refer to section 36.3.2, Channel Modes.
When the CANFD module is in GL_HALT mode, these bits can only be set to 10b (CH_HALT mode) or 01b (CH_RESET mode).
These bits automatically become 10b when the mode is changed to CH_HALT mode by the setting of the CHCR.BOM[1:0] bits.
When writing to these bits and transition to CH_HALT mode (at the entry to bus-off state when the CHCR.BOM[1:0] bits are 01b, and at the end of bus-off state when the CHCR.BOM[1:0] bits are 10b) occur at the same time, priority is given to writing from the CPU. The value of these bits are automatically updated only if the above event occurs when these bits are 00b (CH_OPERATION mode).

SLPRQ Bit (CH_SLEEP Mode Request)

This bit is used to control the transition to CH_SLEEP mode and the return from CH_SLEEP mode.
Setting this bit to 1 in CH_RESET mode requests the channel to transition to CH_SLEEP mode. Setting this bit to 0 in CH_SLEEP mode requests the channel to transition to CH_RESET mode. These bits cannot be changed in other modes.

RTBO Bit (Forced Recovery from Bus-Off)

This bit is used to forcibly recover from the bus-off state. Use this bit only when the CHCR.BOM[1:0] bits are 00b.
This bit is automatically set to 0. The read value is always 0.
When this bit is set to 1 during bus-off state, the channel transitions from bus-off state to integrating state within 1 bit time. Also the CHSR.REC[7:0] and TEC[7:0] bits are set to 00h and the CHSR.BOST flag is set to 0. Other registers and

bits do not change. In this case, even if the bus-off recovery interrupt is enabled, the bus-off recovery interrupt does not generated.
If this bit is set to 1 except in the bus-off state, nothing occurs.

BEIE Bit (Bus Error Interrupt Enable)

When the CHESR.BEDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

EWIE Bit (Error Warning Interrupt Enable)

When the CHESR.EWDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

EPIE Bit (Error Passive Interrupt Enable)

When the CHESR.EPDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

BOEIE Bit (Bus-Off Entry Interrupt Enable)

When the CHESR.BOEDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

BORIE Bit (Bus-Off Recovery Interrupt Enable)

When the CHESR.BORDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

OLIE Bit (Overload Interrupt Enable)

When the CHESR.OLDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

BLIE Bit (Bus Lock Interrupt Enable)

When the CHESR.BLDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

ALIE Bit (Arbitration Lost Interrupt Enable)

When the CHESR.ALDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

TAIE Bit (Transmission Abort Interrupt Enable)

When the transmission from the transmit message buffer of the channel is successfully aborted while this bit is 1, a channel transmit interrupt request is generated.

ECOVIE Bit (Error Occurrence Counter Overflow Interrupt Enable)

When the FDSTS.ECOV flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

SCOVIE Bit (Success Occurrence Counter Overflow Interrupt Enable)

When the FDSTS.SCOV flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

TDCVIE Bit (Transceiver Delay Compensation Violation Interrupt Enable)

When the FDSTS.TDCFVF flag is set to 1 while this bit is 1, a channel error interrupt request is generated. Do not set this bit to 1 in Classic only mode.

BOM[1:0] Bits (Bus-Off Recovery Mode Select)

These bits control the recovery timing from the bus-off state.

EDM Bit (Error Display Mode Select)

This bit controls the indication mode of the error flags (b14 to b8) in the CHESR register.
When this bit is 0, only the flag corresponding to the first error detected becomes 1. If multiple errors are detected at the

same time, all corresponding flags become 1. The other flags do not become 1 until all the flags in b14 to b8 have been cleared.
When this bit is 1, the error flags are updated each time an error is detected.

CTME Bit (Channel Test Mode Enable)

This bit is used to enable the channel test mode.
When the channel transitions to CH_RESET mode, this bit becomes 0.

CTMS[1:0] Bits (Channel Test Mode Select)

These bits are used to select the test mode.
When the channel transitions to CH_RESET mode, these bits become 00b.

BFT Bit (Bit Flip Test)

This bit is used to check the CRC generator in the protocol controller.
Setting this bit to 1 inverts the first bit of the message data stream (ID bit) so that the result of the internally generated CRC does not match the received CRC value.
Note that as a result of bit inversion, a stuff error may be detected instead of a CRC error. Refer to the bit stuffing rule when using this function.
The CRC value generated internally can be checked in the following bits.

- The CHESR.CRC15[14:0] bits (for Classical CAN frames)
- The FDCRC.CRC21[20:0] bits (for CAN FD frames)

When using the BFT bit, it is required for other CAN nodes to send the reference message.

Note: Since the transmit and receive modes share the same CRC generator, there is no need to test individually CRC errors in transmit mode.

Bit flip test mode is enabled when both the BFT and CTME bits are 1 and the CTMS[1:0] bits are 00b (basic test mode).
Using this function on the transmit node causes a bit error or arbitration lost.
When the channel transitions to CH_RESET mode, this bit becomes 0.

ROME Bit (Restricted Operation Mode Enable)

When both this bit and the CTME bit are 1, the limited operation mode is enabled. Use this mode only in basic test mode (CTMS[1:0] bits = 00b). Also, do not set this bit to 1 in Classic only mode.
When the channel transitions to CH_RESET mode, this bit becomes 0.

36.2.3 Channel Status Register (CHSR)

Address(es): CANFD0.CHSR 000A 8008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b7	CRDY	Communication Ready Flag	0: Channel is not ready for communication 1: Channel is ready for communication	R
b8	RESI	Receive ESI Flag*1	0: No message with ESI flag set to 1 was received. 1: At least 1 message with ESI flag set to 1 was received.	R/(W) *2
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	REC[7:0]	Reception Error Count	These bits increment or decrement the counter value according to error status of the CAN channel during reception.	R
b31 to b24	TEC[7:0]	Transmission Error Count	These bits increment or decrement the counter value according to error status of the CAN channel during transmission.	R

Note 1. This flag can be set to 0 only in CH_OPERATION or CH_HALT mode.
Note 2. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register shows the mode, error and transmission or reception status of the CAN channel together with its reception and transmission error count values.

RSTST Flag (CH_RESET Status Flag)

The RSTST flag indicates whether the CAN channel is in CH_RESET mode.
This flag is automatically set to 1 when the CAN channel enters CH_RESET mode, and is automatically set to 0 when the CAN channel exits CH_RESET mode. When the mode is changed from CH_RESET mode to CH_SLEEP mode, the RSTST flag remains 1.

HLTST Flag (CH_HALT Status Flag)

The HLTST flag indicates whether the CAN channel is in CH_HALT mode.

This flag is automatically set to 1 when the CAN channel enters CH_HALT mode, and is automatically set to 0 when the CAN channel exits CH_HALT mode.

SLPST Flag (CH_SLEEP Status Flag)

The SLPST flag indicates whether the CAN channel is in CH_SLEEP mode.
This flag is automatically set to 1 when the CAN channel enters CH_SLEEP mode, and is automatically set to 0 when the CAN channel exits CH_SLEEP mode.

EPST Flag (Error Passive Status Flag)

The EPST flag indicates whether the CAN channel has entered the error passive state.
This flag is automatically set to 1 when the value of the REC[7:0] or TEC[7:0] bits exceeds 127.
This flag is automatically set to 0 when the CAN channel exits the error passive state or enters CH_RESET mode.

BOST Flag (Bus-Off Status Flag)

The BOST flag indicates whether the CAN channel has entered the bus-off state.
This flag is automatically set to 1 when the value of the TEC[7:0] bits exceeds 255 and the CAN channel is in the bus-off state.
This flag is automatically set to 0 when the CAN channel exits bus-off state.

TRMST Flag (Transmit Status Flag)

The TRMST flag indicates whether the CAN channel is transmitting a message.
This flag is automatically set to 1 when the CAN channel is operating as a transmitter node or is in the bus-off state, and is automatically set to 0 when the CAN channel is in the idle state or starts operating as a receiver node.

RECST Flag (Receive Status Flag)

The RECST flag indicates whether the CAN channel is receiving a message.
This flag is automatically set to 1 when the CAN channel is operating as a receiver node, and is automatically set to 0 when the CAN channel is in the idle state or starts operating as a transmitter node.

CRDY Flag (Communication Ready Flag)

The CRDY flag indicates whether the CAN channel is ready for communication.
This flag is automatically set to 1 when the CAN channel is ready to perform communication following the detection of 11 consecutive recessive bits after exiting CH_RESET or CH_HALT mode.
This flag is automatically set to 0 when the CAN channel is in CH_RESET or CH_HALT mode.

Note: This flag is 1 in the bus-off state.

RESI Flag (Receive ESI Flag)

The RESI flag is set to 1 when the ESI bit is sampled recessively for a received message without any error. When in Loopback or Mirror mode, the self-transmitted messages are considered reception messages.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is cleared by writing 0 to it. This flag is automatically set to 0 when the CAN channel is in CH_RESET mode.
Do not use the bit clear instruction to clear this flag. Set only this flag to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

REC[7:0] Bits (Reception Error Count)

The REC[7:0] bits indicate the value of the reception error counter.
The value in bus-off state is indeterminate.
These bits are automatically set to 00h when the CANFD module enters GL_RESET or the CAN channel is in

CH_RESET mode.

TEC[7:0] Bits (Transmission Error Count)

The TEC[7:0] bits indicate the value of the transmission error counter.

These bits are automatically set to 00h when CANFD module is in GL_RESET or CAN channel is in CH_RESET mode.

36.2.4 Channel Error Status Register (CHESR)

Address(es): CANFD0.CHESR 000A 800Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b14	ADEDF	ACK Delimiter Error Detect Flag*1	0: Acknowledge delimiter error is not detected 1: Acknowledge delimiter error is detected	R/(W) *2
b15	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b30-b16	CRC15[14:0]	CRC_15 Test	These bits show the CRC_15 value calculated for the CAN2.0 CAN frame.	R
b31	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. This flag can be set to 0 only in CH_OPERATION or CH_HALT mode.
Note 2. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register shows the status of various error conditions detectable regardless of the interrupt enable/disable setting of the Channel Control Register (CHCR). It also shows the status of the various bus errors detectable by the CAN channel. Refer to the CAN specification (ISO 11898-1) for the conditions under which each error occurs.

Only a single bit can be cleared at a time. Do not use the bit clear instruction to clear the flag. Set only the flag to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

BEDF Flag (Bus Error Detect Flag)

The BEDF flag indicates a detection of an error state, flagged by b14 to b8 in this register.
This flag is automatically set to 1 when a bus error is detected, and is automatically set to 0 when the CAN channel is in CH_RESET mode.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.

EWDF Flag (Error Warning Detect Flag)

The EWDF flag indicates whether an error warning condition has been detected for the CAN channel.
This flag is automatically set to 1 when the value of either the CHSR.TEC[7:0] or REC[7:0] bits exceeds 95.
The setting of this flag only occurs when the value of the TEC[7:0] or REC[7:0] bits initially exceeds 95. Therefore, if the TEC[7:0] or REC[7:0] bits remains > 95 and the EWDF flag is cleared by software, it is not set to 1 again until the value of both the TEC[7:0] and REC[7:0] bits go below 96 and either TEC[7:0] or REC[7:0] bits crosses over again from a value ≤ 95 to a value > 95.
If a set condition occurs simultaneously with a clear condition, then the flag is set to 1. It is automatically set to 0 when the CAN channel is in CH_RESET mode.

EPDF Flag (Error Passive Detect Flag)

The EPDF flag indicates a detection of a CAN channel error passive state.
This flag is automatically set to 1 when the CAN error state becomes error passive state.
The setting of this flag only occurs when the value of either the CHSR.TEC[7:0] or REC[7:0] bits initially exceeds 127. Therefore, if the value of either the TEC[7:0] or REC[7:0] bits remains > 127 and the flag is cleared by software, it is not set to 1 again until the value of both the TEC[7:0] and REC[7:0] bits go below 128 and either TEC[7:0] or REC[7:0] bits crosses over again from a value ≤ 127 to a value > 127.
If a set condition occurs simultaneously with a clear condition, then the flag is set to 1. It is automatically set to 0 when the CAN channel is in CH_RESET mode.

BOEDF Flag (Bus-Off Entry Detect Flag)

The BOEDF flag indicates a detection of a CAN channel bus-off entry state.
This flag is automatically set to 1 when the CAN error state enters the bus-off state.
This flag is automatically set to 0 when the CAN channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, then the flag is set to 1.

BORDF Flag (Bus-Off Recovery Detect Flag)

The BORDF flag indicates a detection of a CAN channel bus-off recovery state.
This flag is automatically set to 1 if CAN channel recovers from bus-off state in the following conditions:

- When the CHCR.BOM[1:0] bits are 00b and normal recovery (128 occurrence of 11 consecutive recessive bits are detected) occurs
- When the CHCR.BOM[1:0] bits are 10b and normal recovery (128 occurrence of 11 consecutive recessive bits are detected) occurs
- When the CHCR.BOM[1:0] bits are 11b and normal recovery (128 occurrence of 11 consecutive recessive bits are detected) occurs.

The flag is not set to 1 if CAN channel recovers from bus-off state in the following conditions:

- When the CH_RESET mode is requested
- When setting the CHCR.RTBO bit to 1 (the CAN channel returns to error active)
- When the CHCR.BOM[1:0] bits are 01b

- When the CHCR.BOM[1:0] bits are 11b and a halt request is asserted before the CAN channel reaches the end of the bus-off state.

This flag is automatically set to 0 when the CAN channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, the flag is set to 1.

OLDF Flag (Overload Detect Flag)

The OLDF flag indicates a detection of a CAN channel overload state.
This flag is automatically set to 1 when an overload condition is detected. If a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the CAN channel is in CH_RESET mode.

BLDF Flag (Bus Lock Detect Flag)

The BLDF flag indicates a detection of a CAN channel bus lock condition.
This flag is automatically set to 1 when 32 consecutive dominant bits are detected on the CAN bus while the CAN channel is in Operation mode.
If a set condition occurs simultaneously with a clear condition, then the flag is set to 1. This flag is automatically set to 0 when the CAN channel is in CH_RESET mode.

ALDF Flag (Arbitration Lost Detect Flag)

The ALDF flag indicates a detection of a CAN channel bus arbitration lost condition.
The flag is automatically set to 1 when an arbitration lost condition is detected on the CAN bus while the CAN channel is in Operation mode.
If a set condition occurs simultaneously with a clear condition, then the flag is set to 1. This flag is automatically set to 0 when the CAN channel is in CH_RESET mode.

SEDF Flag (Stuff Error Detect Flag)

The SEDF flag indicates a detection of a CAN stuff error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a stuff error is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the CAN channel is in CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

FEDF Flag (Form Error Detect Flag)

The FEDF flag indicates a detection of a CAN form error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a form error is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the CAN channel is in CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

AEDF Flag (Acknowledge Error Detect Flag)

The AEDF flag indicates a detection of a CAN acknowledge error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.

This flag is automatically set to 1 when an acknowledge error is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the CAN channel is in CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

CEDF Flag (CRC Error Detect Flag)

The CEDF flag indicates a detection of a CAN CRC error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a CRC error is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the CAN channel is in CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

B1EDF Flag (Bit 1 Error Detect Flag)

The B1EDF flag indicates a detection of a recessive bit error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a recessive bit error (expected recessive bit, sampled as dominant bit) is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the CAN channel is in CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

B0EDF Flag (Bit 0 Error Detect Flag)

The B0EDF flag indicates a detection of a dominant bit error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a dominant bit error (expected dominant bit, sampled as recessive bit) is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the CAN channel is in CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

ADEDF Flag (ACK Delimiter Error Detect Flag)

The ADEDF flag indicates a detection of an acknowledge delimiter bit error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a form error is detected during the acknowledge delimiter state of frame transmission. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the CAN channel is in CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

CRC15[14:0] Bits (CRC_15 Test)

The CRC15[14:0] bits indicate the calculated CRC_15 value when the CHCR.CTME bit is 1 (channel test mode enabled). If the CHCR.CTME bit is 0, then these bits are always read as 0000h.
The CRC_15 value which is read from these bits show the CAN2.0 CRC value calculated by the CAN channel logic.
The value of the CRC15[14:0] bits is updated in the first bit of the CRC field of the Classical CAN frame.
These bits are automatically set to 0000h when the CAN channel is in CH_RESET mode.

36.2.5 Data Bit Rate Configuration Register (DBCR)

Address(es): CANFD0.DBCR 000A 8100h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	TSEG1[4:0]					BRP[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	BRP[7:0]	Bit Rate Prescaler Setting	00h: No division 01h: Divided by 2 : : FEh: Divided by 255 FFh: Divided by 256	R/W
b12 to b8	TSEG1[4:0]	Time Segment 1 Control	00h: Setting prohibited 01h: 2 Tq 02h: 3 Tq 03h: 4 Tq : : 1Eh: 31 Tq 1Fh: 32 Tq	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b19 to b16	TSEG2[3:0]	Time Segment 2 Control	0h: Setting prohibited 1h: 2 Tq : : Eh: 15 Tq Fh: 16 Tq	R/W
b23 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b27 to b24	SJW[3:0]	Resynchronization Jump Width Control	0h: 1 Tq 1h: 2 Tq : : Fh: 16 Tq	R/W
b31 to b28	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Set this register in CH_RESET or CH_HALT mode.

This register configures the transmission/reception data bit rate parameters of the channel.
In Classic only mode, there is no need to configure this register.

BRP[7:0] Bits (Bit Rate Prescaler Setting)

The BRP[7:0] bits define the number of the DLL clock contained in 1 Tq (Time Quantum).

TSEG1[4:0] Bits (Time Segment 1 Control)

The TSEG1[4:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. A value from 2 to 32 Tq can be set.
The TSEG1[4:0] bits are also used to set the propagation time segment.
Do not write any other value to these bits. Refer to section 36.4.1.2, Bit Timing for more details.

TSEG2[3:0] Bits (Time Segment 2 Control)

The TSEG2[3:0] bits set the segment TSEG2 to compensate for edges on the CAN bus with a negative phase error. A

value from 2 to 16 Tq can be set.
Do not write any other value to these bits.

SJW[3:0] Bits (Resynchronization Jump Width Control)

The SJW[3:0] bits set the resynchronization jump width. A value from 1 to 16 Tq can be set.

36.2.6 CAN FD Configuration Register (FDCFG)

Address(es): CANFD0.FDCFG 000A 8104h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	—	—	—	—	—	TESI	TDCE	SSPC	—	—	—	—	—	ECC[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	ECC[2:0]	Error Occurrence Counter Configuration*2	b2 b0 0 0 0: All CAN transmitter or receiver frames 0 0 1: All CAN transmitter frames 0 1 0: All CAN receiver frames 0 1 1: Setting prohibited 1 0 0: Only transmitter or receiver CAN FD data-phase 1 0 1: Only transmitter CAN FD data-phase 1 1 0: Only receiver CAN FD data-phase 1 1 1: Setting prohibited	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	SSPC	Secondary Sample Point Configuration*2	0: Measured + offset 1: Offset-only	R/W
b9	TDCE	Transceiver Delay Compensation Enable*2	0: Transceiver delay compensation is disabled 1: Transceiver delay compensation is enabled	R/W
b10	TESI	Transmit ESI Configuration*2	0: The ESI flag in the transmission frame reflects the error status of the node itself. 1: The ESI flag in the transmission frame reflects the ESI bit in the message buffer if the node is not error passive, and the error status of the node itself If the node is error passive.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	TDCO[7:0]	Transceiver Delay Compensation Offset*2	Sets the offset value for the transceiver delay compensation	R/W
b27 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b28	FDOE	FD Only Mode Enable*3	0: FD only mode is disabled 1: FD only mode is enabled	R/W
b29	REFE	Receive Edge Filter Enable*3	0: Reception edge filter is disabled 1: Reception edge filter is enabled	R/W
b30	CLOE	Classic Only Mode Enable*3, *4	0: Classic only mode is disabled 1: Classic only mode is enabled	R/W
b31	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. The value after reset is 0 for products that support the CAN FD protocol, and 1 for products that support only CAN 2.0 protocol.
Note 2. Set these bits in CH_RESET or CH_HALT mode.
Note 3. Set these bits in CH_RESET mode.
Note 4. This bit can only be written for products that support the CAN FD protocol. For products that support only CAN 2.0 protocol, this bit is reserved and fixed to 1.

This register configures which communication direction (transmitter/receiver) errors are counted.

ECC[2:0] Bits (Error Occurrence Counter Configuration)

The ECC[2:0] bits select which type of CAN frame the protocol errors should be counted for.

SSPC Bit (Secondary Sample Point Configuration)

The SSPC bit selects which offset is used when defining the position of the secondary sample point (SSP) for the CAN channel. If the bit is 0, the position of the SSP is the measured transceiver delay plus the fixed offset. If the bit is 1, the position of the SSP is defined only by the offset.
Do not set this bit to 1 in Classic only mode.

TDCE Bit (Transceiver Delay Compensation Enable)

The TDCE bit enables the transceiver delay compensation for the CAN channel.
Do not set this bit to 1 in Classic only mode.

TESI Bit (Transmit ESI Configuration)

The TESI bit selects whether to reflect the error status of the node itself or the value of the ESI bit in the message buffer (CFB0.HF2.ESI bit or TMBn.HF2.ESI bit) in the ESI flag of the transmission message.
Do not set this bit to 1 in Classic only mode.

TDCO[7:0] Bits (Transceiver Delay Compensation Offset)

The TDCO[7:0] bits set the offset of the secondary sample point. How this value is used, depends on the SSPC setting. If the SSPC bit is 0, the transceiver delay compensation result is equal to the Trv_Delay (measured delay) + the value in the TDCO[7:0] bits, rounded down to the nearest integer number of Tq. Otherwise, the result is equal to the value in the TDCO[7:0] bits. Refer to section 36.4.1.5, Transceiver Delay Compensation for details.
The actual offset value is interpreted as TDCO[7:0] + 1. For example, if 4 is set in TDCO[7:0], the offset is 5 clock cycles. Clock cycle is 1 cycle of CAN channel DLL clock.
Do not set to these bits in Classic only mode.

FDOE Bit (FD Only Mode Enable)

The FDOE bit enables the transmission and reception of CAN FD frames only. If enabled, communication in Classical CAN frame format is disabled. The value of the FDF bit in the message buffer (CFB0.HF2.FDF bit or TMBn.HF2.FDF bit) is arbitrary because transmission of Classical CAN frames is not possible.
If messages with Classical CAN frame format are received, the protocol controller treats them as invalid frames and responds with error frames. If a Classical CAN frame is configured for transmission, the FDF bit is transmitted recessive, therefore a CAN FD frame is transmitted. If the data length code (DLC) is configured to be 9 bytes or more, the remaining data bytes are padded with CCh.
Do not set the FDOE and CLOE bits to 1 simultaneously.

REFE Bit (Receive Edge Filter Enable)

The REFE bit enables the reception edge filter during the integrating state. When this bit is 1, two or more consecutive dominant Tq are required to detect an edge for hard synchronization.
Do not set this bit to 1 in Classic only mode.

CLOE Bit (Classic Only Mode Enable)

The CLOE bit enables the Classic only mode. If this bit is set to 1, the protocol controller can only transmit Classical CAN frames and responds to CAN FD frames with a form error or CRC error.
Do not set the CLOE and FDOE bits to 1 simultaneously.

Table 36.3 Operation Mode Configuration

CLOE bit	FDOE bit	Operation mode
0	0	CAN FD mode
0	1	FD only mode
1	0	Classic only mode
1	1	Setting prohibited

36.2.7 CAN FD Control Register (FDCTR)

Address(es): CANFD0.FDCTR 000A 8108h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SCCL	ECCL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ECCL	Error Occurrence Counter Clear	When 1 is written to this bit, the error occurrence counter is cleared. This bit is read as 0.	R/W
b1	SCCL	Success Occurrence Counter Clear	When 1 is written to this bit, the success occurrence counter is cleared. This bit is read as 0.	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register controls the error and success occurrence counters.

ECCL Bit (Error Occurrence Counter Clear)

The ECCL bit is used to clear the error occurrence counter.
This bit cannot be written in CH_SLEEP or CH_RESET mode.
This bit is automatically set to 0 and is also set to 0 when the CAN channel is in CH_RESET mode.

SCCL Bit (Success Occurrence Counter Clear)

The SCCL bit is used to clear the success occurrence counter.
This bit cannot be written in CH_SLEEP or CH_RESET mode.
This bit is automatically set to 0 and is also set to 0 when the CAN channel is in CH_RESET mode.

36.2.8 CAN FD Status Register (FDSTS)

Address(es): CANFD0.FDSTS 000A 810Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	SC[7:0]								EC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TDCV	—	—	—	—	—	SCOV	ECOV	TDCR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TDCR[7:0]	Transceiver Delay Compensation Result	Indicates the transceiver delay compensation result when the transceiver delay has been measured	R
b8	ECOV	Error Occurrence Counter Overflow Flag*1	0: Error occurrence counter has not overflowed 1: Error occurrence counter has overflowed	R/(W) *2
b9	SCOV	Success Occurrence Counter Overflow Flag*1	0: Success occurrence counter has not overflowed 1: Success occurrence counter has overflowed	R/(W) *2
b14 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	TDCV	Transceiver Delay Compensation Violation Flag*1	0: Transceiver delay compensation violation has not occurred 1: Transceiver delay compensation violation has occurred	R/(W) *2
b23 to b16	EC[7:0]	Error Occurrence Counter	These bits show the error occurrence counter value.	R
b31 to b24	SC[7:0]	Success Occurrence Counter	These bits show the success occurrence counter value.	R

Note 1. Set this flag to 0 only in CH_OPERATION or CH_HALT mode.
Note 2. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register indicates the transceiver compensation delay result and its related FIFO message lost status.

TDCR[7:0] Bits (Transceiver Delay Compensation Result)

The TDCR[7:0] bits are set when the transceiver delay has been measured.
The measured delay is represented by the number of the DLL clock cycles. The result depends on the configuration of the FDCFG.SSPC bit and the offset value in the FDCFG.TDCO[7:0] bits. Refer to section 36.4.1.5, Transceiver Delay Compensation for details.
The TDCR[7:0] bits are updated at the falling edge between the FDF bit and res bit when the FDCFG.SSPC bit is 0 and the FDCFG.TDCE bit is 1 (transceiver delay compensation is enabled).
These bits are automatically set to 0 when the CAN channel is in CH_RESET mode.

ECOV Flag (Error Occurrence Counter Overflow Flag)

The ECOV flag indicates whether the CAN channel error occurrence counter has overflowed.
This flag is set to 1 if a CAN bus error specified in the FDCFG.ECC[2:0] bits is detected when the EC[7:0] bits are FFh.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is automatically set to 0 when the CAN channel is in CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

SCOV Flag (Success Occurrence Counter Overflow Flag)

The SCOV flag indicates whether the CAN channel success occurrence counter has overflowed.

This flag is set to 1 if a successful message reception or successful message transmission occurs when the SC[7:0] bits are FFh.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is automatically set to 0 when the CAN channel is in CH_RESET mode.
Do not use the bit clear instruction to clear this flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

TDCV Flag (Transceiver Delay Compensation Violation Flag)

The CANFD module captures internally the transmitted data bit-by-bit. This data is then compared against the received CAN bus level which is delayed by the transceiver loop delay.
The transceiver delay has some variations depending on the physical parameters such as temperature. The TDCR[7:0] bits are updated by each message. However, temporary maximum delay violation could be missed. Therefore, the TDCV flag captures this violation.
This flag is set to 1 when the transceiver delay compensation is greater than the maximum delay compensation (6 data bit times – 2 DLL clock) and the internal bit overruns.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is automatically set to 0 when the CAN channel is in CH_RESET mode.
Do not use the bit clear instruction to clear this flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

EC[7:0] Bits (Error Occurrence Counter)

The EC[7:0] bits are used together with the SC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.
This higher error rate can be detected depending on the configuration of the FDCFG.ECC[2:0] bits.
The EC[7:0] bits are set only by CANFD module logic. These bits are cleared by writing 1 to the FDCTR.ECCL bit.
These bits are updated when an error occurs, according to the configuration of the FDCFG.ECC[2:0] bits. When the counter reaches the value of FFh, the update stops.
These bits are automatically set to 00h when the CAN channel is in CH_RESET mode.

SC[7:0] Bits (Success Occurrence Counter)

The SC[7:0] bits are used together with the EC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.
The SC[7:0] bits are set only by CANFD module logic. These bits are cleared by writing 1 to the FDCTR.SCCL bit.
These bits are updated when the occurrence of any error-free messages on the bus is detected through reception or transmission. When the counter reaches the value of FFh, the update stops.
These bits are automatically set to 00h when the CAN channel is in CH_RESET mode.

Note: In Loopback mode, the counter is incremented twice.

36.2.9 CAN FD CRC Register (FDCRC)

Address(es): CANFD0.FDCRC 000A 8110h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	SBC[3:0]				—	—	—	CRC21[20:16]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CRC21[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b20 to b0	CRC21[20:0]	CRC_21 Test	These bits show the CRC_17 value or CRC_21 value calculated for the CAN FD frame.	R
b23 to b21	—	Reserved	These bits are read as 0.	R
b27 to b24	SBC[3:0]	Stuff Bit Counter	These bits shows the stuff bit count (Mod 8) for the CAN FD frame.	R
b31 to b28	—	Reserved	These bits are read as 0.	R

This register holds the CRC value calculated for the CAN FD frame.

CRC21[20:0] Bits (CRC_21 Test)

The calculated CRC_17 value or CRC_21 value can be read from this bits when the CHCR.CTME bit is 1 (channel test mode).
When the CHCR.CTME bit is 0, the CRC21[20:0] bits are read as 000000h.
The CRC21[20:0] bits is updated in the first bit of the CRC field of the CAN FD frame.
When the CRC_17 field is used, the CRC21[20:17] bits are read as 0.
These bits are automatically set to 000000h when the CAN channel is in CH_RESET mode.

SBC[3:0] Bits (Stuff Bit Counter)

The SBC[3:0] bits contain the stuff count value of the CAN FD frame. These bits indicate the number of inserted stuff bits (modulo 8, Graycoded) for a CAN FD frame when the CHCR.CTME bit is enabled in SBC[3:1]. SBC[0] is the parity bit.
When the CHCR.CTME bit is 0, the SBC[3:0] bits are always read as 0000b.
The value of the SBC[3:0] bits is updated in the first bit of CRC field of the CAN FD frame. These bits are automatically set to 0000b when the CAN channel is in CH_RESET mode.

36.2.10 Global Configuration Register (GCFG)

Address(es): CANFD.GCFG 000A 8014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ITP[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

b12	TSCS	Timestamp Counter Source Select	0: Count source for timestamp counter is peripheral module clock (PCLKB) 1: Count source for timestamp counter is bit time clock	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b16	ITP[15:0]	Interval Timer Prescaler Setting	FIFO interval timer prescaler value. Set the divided value for the peripheral module clock (PCLKB)	R/W

This register is used to select the transmission priority to be used for all the transmit message buffers and the clock source for the CAN protocol engine. The GCFG register is also used to select the source for the timestamp clock and to configure the frequency for the timestamp clock and interval timer reference clock.

TPRI Bit (Transmission Priority Setting)

The TPRI bit selects the transmission priority for the CAN channel.

This bit cannot be written in GL_SLEEP mode. Write to this bit only when CANFD module is in GL_RESET mode. Do not select message buffer number priority when using the transmit queue.

DCE Bit (DLC Check Enable)

The DCE bit enables data length code (DLC) check for the CAN channel.
This bit cannot be written in GL_SLEEP mode. Write to this bit only when CANFD module is in GL_RESET mode.

DRE Bit (DLC Replacement Enable)

When the DRE bit is 1 and the DCE bit is 1, the CANFD module stores the configured value (AFLn.PTR0.DLC[3:0]) of the DLC in the destination receive message buffer or FIFO buffer if the DLC check passes. Otherwise, the DLC value in the destination receive message buffer or FIFO buffer is unchanged.
This bit cannot be written in GL_SLEEP mode. Write to this bit only when CANFD module is in GL_RESET mode.

MME Bit (Mirror Mode Enable)

The MME bit enables the Mirror mode for the CAN channel.
This bit cannot be written in GL_SLEEP mode. Write to this bit only when CANFD module is in GL_RESET mode.

DLLCS Bit (DLL Clock Select)

The DLLCS bit selects the clock source for CAN communication.This bit cannot be written in GL_SLEEP or GL_OPERATION mode. Write to this bit only when CANFD module is in GL_RESET mode.

OMRC Bit (Payload-Overflowed Message Reception Configuration)

The OMRC bit controls the message payload acceptance mechanism when the received payload is higher than the message buffer payload size (RMCR.PLS[2:0], RFCRn.PLS[2:0], and CFCR0.PLS[2:0]). The received message payload is always compared with the available message payload size in the message buffer.
This bit cannot be written in GL_SLEEP or GL_OPERATION mode. Write to this bit only when CANFD module is in GL_RESET mode.
When this bit is set to 1 and payload overflow occurs, the DLC value is stored in the receive message buffer or FIFO buffer unchanged.

TSP[3:0] Bits (Timestamp Counter Prescaler Setting)

The value configured in the TSP[3:0] bits defines the period of the count source used for the timestamp counter.
These bits cannot be written in GL_SLEEP mode. Write to this bit only when CANFD module is in GL_RESET mode.

TSCS Bit (Timestamp Counter Source Select)

The TSCS bit allows the selection of the count source for the timestamp counter.
This bit cannot be written in GL_SLEEP mode. Write to this bit only when CANFD module is in GL_RESET mode.
Additionally, do not set this bit to 1 when CAN FD communication is used.

Note: The bit time clock varies depending on the nominal bit rate and data bit rate configuration.

ITP[15:0] Bits (Interval Timer Prescaler Setting)

The ITP[15:0] bits allow the definition of a reference clock for the FIFO interval timer count source. When these bits are 0000h, the timer is disabled.
These bits cannot be written in GL_SLEEP mode. Write to these bits only when CANFD module is in GL_RESET mode.

36.2.11 Global Control Register (GCR)

Address(es): CANFD.GCR 000A 8018h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	—	—	—	—	POIE	THLIE	MLIE	DEIE	—	—	—	—	—	SLPRQ	MDC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b1, b0	MDC[1:0]	Global Mode Control	b1 b0 0 0: Request transition to GL_OPERATION mode 0 1: Request transition to GL_RESET mode 1 0: Request transition to GL_HALT mode 1 1: Keep current value	R/W
b2	SLPRQ	GL_SLEEP Mode Request	0: Request to release GL_SLEEP 1: Request transition to GL_SLEEP	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	DEIE	DLC Error Interrupt Enable	0: DLC error interrupt is disabled 1: DLC error interrupt is enabled	R/W
b9	MLIE	Message Lost Interrupt Enable	0: Message lost interrupt is disabled 1: Message lost interrupt is enabled	R/W
b10	THLIE	Transmission History Entry Lost Interrupt Enable	0: Transmission history entry lost interrupt is disabled 1: Transmission history entry lost interrupt is enabled	R/W
b11	POIE	Payload Overflow Interrupt Enable	0: Payload overflow interrupt is disabled 1: Payload overflow interrupt is enabled	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	TSCR	Timestamp Counter Reset	When 1 is written to this bit, the timestamp counter is reset. This bit is read as 0.	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register controls the Global mode of the CANFD module and the timestamp function. The register also enables and disables the global error interrupts.

MDC[1:0] Bits (Global Mode Control)

The MDC[1:0] bits are used to specify the modes of the CANFD module. For the mode transition of the CANFD module, refer to section 36.3.1, Global Modes.

These bits cannot be written in GL_SLEEP mode.

To request the CANFD module to transition to GL_SLEEP mode, first set these bits to 01b to enter GL_RESET mode, then set the GCR.SLPRQ bit to 1.

SLPRQ Bit (GL_SLEEP Mode Request)

The SLPRQ bit is used to control the transition to GL_SLEEP mode and the return from GL_SLEEP mode.

When this bit is set to 1, the transition to CH_SLEEP mode is also requested for CAN channel.

This bit can only be written when the CANFD module is in GL_RESET or GL_SLEEP mode.

DEIE Bit (DLC Error Interrupt Enable)

When the DEIE bit is 1, an interrupt is generated if a DLC error is detected in the received frames.

This bit cannot be written in GL_SLEEP mode.

MLIE Bit (Message Lost Interrupt Enable)

When the MLIE bit is 1, an interrupt is generated if a message lost condition occurs.
This bit cannot be written in GL_SLEEP mode.

THLIE Bit (Transmission History Entry Lost Interrupt Enable)

When the THLIE bit is 1, an interrupt is generated if a transmission history entry lost condition occurs.
This bit cannot be written in GL_SLEEP mode.

POIE Bit (Payload Overflow Interrupt Enable)

When the POIE bit is 1, an interrupt is generated when a message payload overflow condition occurs.
This bit cannot be written in GL_SLEEP mode.

TSCR Bit (Timestamp Counter Reset)

When the TSCR bit is 1, the Timestamp Counter Register (TSCR) is reset to 00000000h.
This bit cannot be written in GL_SLEEP mode. Do not write to this bit in GL_RESET mode.
This bit is automatically set to 0.

36.2.12 Global Status Register (GSR)

Address(es): CANFD.GSR 000A 801Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	RAMST	SLPST	HLTST	RSTST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	RSTST	GL_RESET Status Flag	0: Not in GL_RESET mode 1: In GL_RESET mode	R
b1	HLTST	GL_HALT Status Flag	0: Not in GL_HALT mode 1: In GL_HALT mode	R
b2	SLPST	GL_SLEEP Status Flag	0: Not in GL_SLEEP mode 1: In GL_SLEEP mode	R
b3	RAMST	RAM Initialization Status Flag	0: RAM initialization is completed 1: RAM initialization is in progress	R
b31 to b4	—	Reserved	These bits are read as 0.	R

This register indicates the global status of the CANFD module.

RSTST Flag (GL_RESET Status Flag)

The RSTST flag indicates the status of the CANFD module in GL_RESET mode.
This flag is automatically set to 1 when the CANFD module enters GL_RESET mode. When the mode changes from GL_RESET mode to GL_SLEEP mode, this bit remains 1. This flag is automatically set to 0 when the CANFD module enters GL_HALT or GL_OPERATION mode.

HLTST Flag (GL_HALT Status Flag)

The HLTST flag indicates the status of the CANFD module in GL_HALT mode.
This flag is automatically set to 1 when the CANFD module enters GL_HALT mode. This flag is automatically set to 0 when the CANFD module exits the GL_HALT mode.

SLPST Flag (GL_SLEEP Status Flag)

The SLPST flag indicates the status of the CANFD module in GL_SLEEP mode.
This flag is automatically set to 1 when the CANFD module enters GL_SLEEP mode. This flag is automatically set to 0 when the CANFD module exits the GL_SLEEP mode.

RAMST Flag (RAM Initialization Status Flag)

The RAMST flag indicates the status of the CANFD module's RAM initialization.
This flag is automatically set to 1 when the CANFD module enters GL_SLEEP mode after release from MCU reset. This flag is automatically set to 0 when the CANFD module completed RAM initialization.

36.2.13 Global Error Status Register (GESR)

Address(es): CANFD.GESR 000A 8020h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EEDF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	PODF	THLDF	MLDF	DEDF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DEDF	DLC Error Detect Flag	0: DLC error is not detected 1: DLC error is detected	R/(W) *1
b1	MLDF	Message Lost Detect Flag	0: Message lost error is not detected 1: Message lost error is detected	R
b2	THLDF	Transmission History Entry Lost Detect Flag	0: Transmission history entry lost is not detected 1: Transmission history entry lost is detected	R
b3	PODF	Payload Overflow Detect Flag	0: Payload overflow is not detected 1: Payload overflow is detected	R/(W) *1
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	EEDF0	Channel 0 ECC Error Detect Flag	0: ECC error is not detected during transmission scan 1: ECC error is detected during transmission scan	R/(W) *1
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register indicates the detection of global errors.

DEDF Flag (DLC Error Detect Flag)

The DEDF flag indicates the error status of the DLC.
This flag cannot be written in GL_SLEEP or GL_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is automatically set to 1 when a DLC error is detected in a received frame.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
The flag is cleared by writing 0 to it. This flag is automatically set to 0 in GL_RESET mode.

MLDF Flag (Message Lost Detect Flag)

The MLDF flag indicates the status of the message lost error.
This flag is automatically set to 1 when a FIFO message lost error is detected.
This flag is automatically set to 0 when:

- All FIFO message lost flags (RFSRn.LOST, CFSR0.LOST) are cleared
- The CANFD module is in GL_RESET mode.

THLDF Flag (Transmission History Entry Lost Detect Flag)

The THLDF flag indicates the status of the transmission history entry lost error.
This flag is automatically set to 1 when a transmission history entry lost error is detected.
This flag is automatically set to 0 when:

- The transmission history lost flag (THSR.LOST) is cleared
- The CANFD module is in GL_RESET mode.

PODF Flag (Payload Overflow Detect Flag)

The PODF flag is automatically set to 1 when a message payload overflow is detected on at least one channel.
This flag cannot be written in GL_SLEEP or GL_RESET mode.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is automatically set to 0 in GL_RESET mode.

EEDF0 Flag (Channel 0 ECC Error Detect Flag)

The EEDF0 flag specifies whether an ECC error has occurred.
This flag cannot be written in GL_SLEEP or GL_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This bit is automatically set to 0 in GL_RESET mode.

36.2.14 Transmit Interrupt Status Register (TISR)

Address(es): CANFD.TISR 000A 80A4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	THIF0	CFTIF0	TQIF0	TAIF0	TSIF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TSIF0	Channel 0 Transmission Successful Interrupt Flag	0: Channel 0 transmission successful interrupt is not generated. 1: Channel 0 transmission successful interrupt is generated.	R
b1	TAIF0	Channel 0 Transmission Abort Interrupt Flag	0: Channel 0 transmission abort interrupt is not generated. 1: Channel 0 transmission abort interrupt is generated.	R
b2	TQIF0	Channel 0 Transmit Queue Interrupt Flag	0: Channel 0 transmit queue interrupt is not generated. 1: Channel 0 transmit queue interrupt is generated.	R
b3	CFTIF0	Channel 0 Common FIFO Transmission Interrupt Flag	0: Channel 0 common FIFO transmission interrupt is not generated. 1: Channel 0 common FIFO transmission interrupt is generated.	R
b4	THIF0	Channel 0 Transmission History Interrupt Flag	0: Channel 0 transmission history interrupt is not generated. 1: Channel 0 transmission history interrupt is generated.	R
b31 to b5	—	Reserved	These bits are read as 0.	R

This register indicates the detection of transmit specific interrupts.

TSIF0 Flag (Channel 0 Transmission Successful Interrupt Flag)

The TSIF0 flag becomes 1 if transmission from the transmit message buffer n on channel 0 is successful when the transmit message buffer n interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (TMIER0.TMIEn bits = 0)
- When the Transmission Result flags (TMSRn.TXRF[1:0]) are cleared
- When in GL_RESET or CH_RESET mode.

TAIF0 Flag (Channel 0 Transmission Abort Interrupt Flag)

The TAIF0 flag becomes 1 if transmission from the transmit message buffer n on channel 0 is aborted when the transmission abort interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (CHCR.TAIE bit = 0)
- When the Transmission Result flags (TMSRn.TXRF[1:0]) are cleared
- When in GL_RESET or CH_RESET mode.

TQIF0 Flag (Channel 0 Transmit Queue Interrupt Flag)

The TQIF0 flag becomes 1 if the Transmit Queue Interrupt flag of channel 0 is set to 1 when the transmit queue interrupt is enabled.

This flag is automatically set to 0:

- When the interrupt is disabled (TQCR0.TQIE bit = 0)
- When the Transmission Result flags (TQSR0.TQIF) is cleared
- When in GL_RESET or CH_RESET mode.

CFTIF0 Flag (Channel 0 Common FIFO Transmission Interrupt Flag)

The CFTIF0 flag becomes 1 if the Common FIFO Transmit Interrupt flag (CFSR0.CFTIF) of channel 0 is set to 1 when the common FIFO transmit interrupt is enabled.

This flag is automatically set to 0:

- When the interrupt is disabled (CFCR0.CFTIE bit = 0)
- When the Common Transmit FIFO Interrupt flag (CFSR0.CFTIF) is cleared
- When in GL_RESET or CH_RESET mode.

THIF0 Flag (Channel 0 Transmission History Interrupt Flag)

The THIF0 flag becomes 1 if the Transmission History Interrupt flag (THSR.THIF) of channel 0 is set to 1 when the transmission history interrupt is enabled.

This flag is automatically set to 0:

- When the interrupt is disabled (THCR.THIE bit = 0)
- When the Transmission History Interrupt flag (THSR.THIF) is cleared
- When in GL_RESET or CH_RESET mode.

36.2.15 Timestamp Counter Register (TSCR)

Address(es): CANFD.TSCR 000A 8024h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register stores the timestamp based on the selected configuration.
The timestamp value is stored in the TSCR register based on the configuration of the GCFG.TSCS bit and GCFG.TSP[3:0] bits. The accuracy of the timestamp counter cannot be guaranteed when transitioning to GL_HALT state.
This register is automatically set to 00000000h in GL_RESET mode.

36.2.16 Acceptance Filter List Control Register (AFCR)

Address(es): CANFD.AFCR 000A 8028h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	AFLWE	—	—	—	—	—	—	—	PAGE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PAGE	Access Page Setting	Select the page number of the Acceptance Filter List	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	AFLWE	AFL Write Enable	0: Acceptance Filter List data access is disabled 1: Acceptance Filter List data access is enabled	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to select the Acceptance Filter List page for reading or writing entries into the Acceptance Filter List.

PAGE Bit (Access Page Setting)

The PAGE bit is used to select the page number to access the desired RAM area of the Acceptance Filter List. One Acceptance Filter List page consists of 16 Acceptance Filter List entries.
Read/write accesses to the Acceptance Filter List can only be performed through a fixed window.
This bit cannot be written in GL_SLEEP mode.

AFLWE Bit (AFL Write Enable)

The AFLWE bit prevents write access to the Acceptance Filter List by setting this bit to 0 after configuration of the Acceptance Filter List.
Data can be read from the Acceptance Filter List independent of the status of this bit.
This bit cannot be written in GL_SLEEP mode.
Setting this bit to 1 enables write access for the Acceptance Filter List.

36.2.17 Acceptance Filter List Configuration Register (AFCFG)

Address(es): CANFD.AFCFG 000A 802Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	RN0[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b21 to b16	RN0[5:0]	Channel 0 Number of Rules Setting	Number of rules in the Acceptance Filter List	R/W
b31 to b22	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to define the number of rules for entry in the Acceptance Filter List.
The maximum number of available entries in the Acceptance Filter List is 32.

RN0[5:0] Bits (Channel 0 Number of Rules Setting)

The RN0[5:0] bits define the number of rules in the Acceptance Filter List. This bit can set 32 rules or less.
These bits can only be written in GL_RESET mode.

36.2.18 Acceptance Filter List n ID Register (AFLn.IDR) (n = 0 to 15)

Address(es): CANFD.AFL0.IDR 000A 8120h, CANFD.AFL1.IDR 000A 8130h, CANFD.AFL2.IDR 000A 8140h, CANFD.AFL3.IDR 000A 8150h, CANFD.AFL4.IDR 000A 8160h, CANFD.AFL5.IDR 000A 8170h, CANFD.AFL6.IDR 000A 8180h, CANFD.AFL7.IDR 000A 8190h, CANFD.AFL8.IDR 000A 81A0h, CANFD.AFL9.IDR 000A 81B0h, CANFD.AFL10.IDR 000A 81C0h, CANFD.AFL11.IDR 000A 81D0h, CANFD.AFL12.IDR 000A 81E0h, CANFD.AFL13.IDR 000A 81F0h, CANFD.AFL14.IDR 000A 8200h, CANFD.AFL15.IDR 000A 8210h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	ID[28:0]	ID Field	ID part of the Acceptance Filter List entry	R/W
b29	LPC	Loopback Configuration	0: Message with reception attribute 1: Message with transmission attribute	R/W
b30	RTR	RTR	0: Data frame 1: Remote frame	R/W
b31	IDE	IDE	0: Standard ID 1: Extended ID	R/W

This register is used to configure the ID field in the rule entry of the Acceptance Filter List.
When rewriting this register, set the AFCR.AFLWE bit to 1. When the AFLWE bit is 0, it cannot be rewritten.

ID[28:0] Bits (ID Field)

The ID[28:0] bits indicate the CAN identifier (ID) field of each entry in the Acceptance Filter List.
The acceptance filter process compares this field against the ID of a received message. For alignment of these bits in base and extended formats, refer to section 36.2.60, Identifier Bits Alignment.
Write to these bits only when the CAN channel is in CH_RESET or CH_HALT mode.

LPC Bit (Loopback Configuration)

The LPC bit is used to select whether entry in the Acceptance Filter List gets the reception or transmission attribute. This attribute determines the validity of the entry in Mirror mode, Loopback mode, and during standard (non-loopback) reception. Refer to section 36.5.8, Loopback Modes for detailed description of the validity of the Acceptance Filter List entry depending on transmitter/receiver case, the type of loopback mode, and reception/transmission attribute.
Write to this bit only when the CAN channel is in CH_RESET or CH_HALT mode.

RTR Bit (RTR)

The RTR bit allows the configuration of the specified frame format (data frame or remote frame) for each entry of the Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the RTR bit of the received message.
Write to this bit only when the CAN channel is in CH_RESET or CH_HALT mode.

IDE Bit (IDE)

The IDE bit allows the configuration of the ID format (standard ID or extended ID) for each entry in the Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the IDE bit of the

received message.
Write to this bit only when the CAN channel is in CH_RESET or CH_HALT mode.

36.2.19 Acceptance Filter List n Mask Register (AFLn.MASK) (n = 0 to 15)

Address(es): CANFD.AFL0.MASK 000A 8124h, CANFD.AFL1.MASK 000A 8134h, CANFD.AFL2.MASK 000A 8144h, CANFD.AFL3.MASK 000A 8154h, CANFD.AFL4.MASK 000A 8164h, CANFD.AFL5.MASK 000A 8174h, CANFD.AFL6.MASK 000A 8184h, CANFD.AFL7.MASK 000A 8194h, CANFD.AFL8.MASK 000A 81A4h, CANFD.AFL9.MASK 000A 81B4h, CANFD.AFL10.MASK 000A 81C4h, CANFD.AFL11.MASK 000A 81D4h, CANFD.AFL12.MASK 000A 81E4h, CANFD.AFL13.MASK 000A 81F4h, CANFD.AFL14.MASK 000A 8204h, CANFD.AFL15.MASK 000A 8214h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	IDEM	RTRM	IFL1	IDM[28:16]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	IDM[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	IDM[28:0]	ID Mask Field	0: Corresponding ID bit is not used for ID matching 1: Corresponding ID bit is used for ID matching	R/W
b29	IFL1	Information Label 1	Configure an information label 1 to be attached to a received message	R/W
b30	RTRM	RTR Mask	0: RTR bit is not used for ID matching 1: RTR bit is used for ID matching	R/W
b31	IDEM	IDE Mask	0: IDE bit is not used for ID matching 1: IDE bit is used for ID matching	R/W

This register is used to configure the mask field of each rule for entries in the Acceptance Filter List.
When rewriting this register, set the AFCR.AFLWE bit to 1. When the AFLWE bit is 0, it cannot be rewritten.

IDM[28:0] Bits (ID Mask Field)

The IDM[28:0] bits are the filter mask bits for the related bits in the CAN Identifier field of each Acceptance Filter List entry.
Write to these bits only when the CAN channel is in CH_RESET or CH_HALT mode.

IFL1 Bit (Information Label 1)

The IFL1 bit is the upper bit of a 2-bit information label to be attached to a received message accepted by the associated entry in the Acceptance Filter List.
Write to this bit only when the CAN channel is in CH_RESET or CH_HALT mode.
This bit is stored in the upper bit of the Information Label Field (RMBn.HF2.IFL[1], RFBn.HF2.IFL[1], CFB0.HF2.IFL[1]) of the storage location of a received message.

RTRM Bit (RTR Mask)

The RTRM bit is the RTR mask bit for each entry in the Acceptance Filter List.
Write to this bit only when the CAN channel is in CH_RESET or CH_HALT mode.

IDEM Bit (IDE Mask)

The IDEM bit is the IDE mask bit for each entry in the Acceptance Filter List.
When the IDE mask bit is 0, the ID comparison depends on the IDE bit of the received message.

- If the IDE bit of the received message is 0, the standard ID comparison takes place.
- If the IDE bit of the received message is 1, the extended ID comparison takes place.

Write to this bit only when the CAN channel is in CH_RESET or CH_HALT mode.

36.2.20 Acceptance Filter List n Pointer 0 Register (AFLn.PTR0) (n = 0 to 15)

Address(es): CANFD.AFL0.PTR0 000A 8128h, CANFD.AFL1.PTR0 000A 8138h, CANFD.AFL2.PTR0 000A 8148h, CANFD.AFL3.PTR0 000A 8158h, CANFD.AFL4.PTR0 000A 8168h, CANFD.AFL5.PTR0 000A 8178h, CANFD.AFL6.PTR0 000A 8188h, CANFD.AFL7.PTR0 000A 8198h, CANFD.AFL8.PTR0 000A 81A8h, CANFD.AFL9.PTR0 000A 81B8h, CANFD.AFL10.PTR0 000A 81C8h, CANFD.AFL11.PTR0 000A 81D8h, CANFD.AFL12.PTR0 000A 81E8h, CANFD.AFL13.PTR0 000A 81F8h, CANFD.AFL14.PTR0 000A 8208h, CANFD.AFL15.PTR0 000A 8218h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DMBE	—	—	DMB[4:0]					IFL0	—	—	—	DLC[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	DLC[3:0]	DLC Field	Configure a minimum DLC value of received message	R/W
b6 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	IFL0	Information Label 0	Configure an information label 0 to be attached to a received message	R/W
b12 to b8	DMB[4:0]	Destination Message Buffer Setting	Configure the receive message buffer number for storage of received messages	R/W
b14 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	DMBE	Destination Message Buffer Setting Enable	0: The Destination Message Buffer Setting bit is disabled 1: The Destination Message Buffer Setting bit is enabled	R/W
b31 to b16	PTR[15:0]	Pointer	Configure a 16-bit pointer to be attached to a received message	R/W

This register is used to configure the data length code (DLC), software pointer, and destination message buffer for each rule entry in the Acceptance Filter List.
When rewriting this register, set the AFCR.AFLWE bit to 1. When the AFLWE bit is 0, it cannot be rewritten.

DLC[3:0] Bits (DLC Field)

The DLC[3:0] bits allow the configuration of a minimum data length code (DLC) value for a message to be accepted by the associated entry in the Acceptance Filter List (automatic DLC filter function).
DLC filter process is only passed if the DLC value of the message accepted by an entry in the Acceptance Filter List is equal to or higher than the DLC value configured for this associated Acceptance Filter List entry. Automatic DLC filter function is disabled for the corresponding rule entry when this field is set to 0000b.
Write to these bits only when the CAN channel is in CH_RESET or CH_HALT mode.

IFL0 Bit (Information Label 0)

The IFL0 bit is the lower bit of a 2-bit information label that can be attached to a received message accepted by the Acceptance Filter List entry.
Write to this bit only when the CAN channel is in CH_RESET or CH_HALT mode.
This bit is stored in the lower bit of the Information Label Field (RMBn.HF2.IFL[0], RFBn.HF2.IFL[0], CFB0.HF2.IFL[0]) of the storage location of a received message.

DMB[4:0] Bits (Destination Message Buffer Setting)

The DMB[4:0] bits allow the configuration of a message buffer as the destination for a received message that passes the acceptance check of the Acceptance Filter List entry. Configure the destination message buffer number.
Write to these bits only when the CAN channel is in CH_RESET or CH_HALT mode.
Write the RMCR.NMB[5:0] bits to configure the number of receive message buffers. The value to be entered in the DMB[4:0] bits should only be between 00000b and 'NMB[5:0] – 1'.
If RMCR.NMB[5:0] is 000000b, set the DMBE bit to 0.

DMBE Bit (Destination Message Buffer Setting Enable)

The DMBE bit allows the enabling or disabling of the receive message buffer as the destination message buffer for a received message that passes the acceptance check of the Acceptance Filter List entry.
Write to this bit only when the CAN channel is in CH_RESET or CH_HALT mode.

PTR[15:0] Bits (Pointer)

The PTR[15:0] bits allow the configuration of a 16-bit pointer to be attached to a received message accepted by the Acceptance Filter List entry. The pointer is added during message storage in the message buffer area and can be used by the application as a support function. The pointer information can be used for example, to support PDU Identifier allocation for the received message in AUTOSAR systems.
Write to these bits only when the CAN channel is in CH_RESET or CH_HALT mode.

36.2.21 Acceptance Filter List n Pointer 1 Register (AFLn.PTR1) (n = 0 to 15)

Address(es): CANFD.AFL0.PTR1 000A 812Ch, CANFD.AFL1.PTR1 000A 813Ch, CANFD.AFL2.PTR1 000A 814Ch, CANFD.AFL3.PTR1 000A 815Ch, CANFD.AFL4.PTR1 000A 816Ch, CANFD.AFL5.PTR1 000A 817Ch, CANFD.AFL6.PTR1 000A 818Ch, CANFD.AFL7.PTR1 000A 819Ch, CANFD.AFL8.PTR1 000A 81ACh, CANFD.AFL9.PTR1 000A 81BCh, CANFD.AFL10.PTR1 000A 81CCh, CANFD.AFL11.PTR1 000A 81DCh, CANFD.AFL12.PTR1 000A 81ECh, CANFD.AFL13.PTR1 000A 81FCh, CANFD.AFL14.PTR1 000A 820Ch, CANFD.AFL15.PTR1 000A 821Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CF0E	—	—	—	—	—	—	RF1E	RF0E
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RF0E	Receive FIFO 0 Destination Enable	0: Do not select receive FIFO 0 as the message storage destination 1: Selects receive FIFO 0 as the message storage destination	R/W
b1	RF1E	Receive FIFO 1 Destination Enable	0: Do not select receive FIFO 1 as the message storage destination 1: Selects receive FIFO 1 as the message storage destination	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	CF0E	Common FIFO 0 Destination Enable	0: Do not select common FIFO 0 as the message storage destination 1: Selects common FIFO 0 as the message storage destination	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to configure the destination FIFO buffer for each rule entry in the Acceptance Filter List.
Up to two storage destinations can be specified for received messages. Two FIFO buffers, or one FIFO buffer and one receive message buffer are valid.
When rewriting this register, set the AFCR.AFLWE bit to 1. When the AFLWE bit is 0, it cannot be rewritten.
Write to this register only when the CAN channel is in CH_RESET or CH_HALT mode.

RF0E Bit (Receive FIFO 0 Destination Enable)

The RF0E bit allows the configuration of the receive FIFO 0 as a storage destination of a received message that passes the acceptance check of the Acceptance Filter List entry.

RF1E Bit (Receive FIFO 1 Destination Enable)

The RF1E bit allows the configuration of the receive FIFO 1 as a storage destination of a received message that passes the acceptance check of the Acceptance Filter List entry.

CF0E Bit (Common FIFO 0 Destination Enable)

The CF0E bit allows the configuration of the common FIFO 0 as a storage destination of a received message that passes the acceptance check of the Acceptance Filter List entry.
The common FIFO 0 must be configured as the receive FIFO.

36.2.22 Receive Message Buffer Configuration Register (RMCR)

Address(es): CANFD.RMCR 000A 8030h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	PLS[2:0]			—	—	NMB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	NMB[5:0]	Number of Message Buffer Setting	Configure the number of receive message buffers	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b10 to b8	PLS[2:0]	Payload Size Setting	b10 b8 0 0 0: 8 bytes 0 0 1: 12 bytes 0 1 0: 16 bytes 0 1 1: 20 bytes 1 0 0: 24 bytes 1 0 1: 32 bytes 1 1 0: 48 bytes 1 1 1: 64 bytes	R/W
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to configure the total number of receive message buffers allocated to a channel.

NMB[5:0] Bits (Number of Message Buffer Setting)

The NMB[5:0] bits are used to configure the number of receive message buffers.
These bits can only be written in GL_RESET mode.
Set a value between 0 and 32. 0 indicates that no receive message buffer is allocated.

PLS[2:0] Bits (Payload Size Setting)

The PLS[2:0] bits are used to configure the message buffer payload size.
These bits can only be written in GL_RESET mode.

36.2.23 Receive Message Buffer New Data Register (RMNDR)

Address(es): CANFD.RMNDR 000A 8034h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	NDF[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	NDF[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	NDF[31:0]	New Data Flag	0: New data is not stored in corresponding receive message buffer 1: New data is stored in corresponding receive message buffer	R/(W) *1

Note 1. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register specifies the new data storage status of the receive message buffers.
The bit number of this register corresponds to the buffer number of the received message buffer.

NDF[31:0] Flags (New Data Flag)

The NDF[31:0] flags indicate that the new data is stored in the corresponding receive message buffer. The NDF[0] flag corresponds to receive message buffer 0.
These flags are automatically set to 1 when storage of new messages are in the corresponding receive message buffer.
When RMCR.PLS[2:0] = 000b (up to 8 bytes payload), the duration of message storage is 6 PCLKB cycles.
When RMCR.PLS[2:0] > 000b, the duration of message storage is 6 PCLKB cycles + 1 for each 4 bytes (up to 20 PCLKB cycles for 64 bytes).
Do not write to these flags when the CANFD module is in GL_RESET or GL_SLEEP mode.
These flags are automatically set to 0 when the CANFD module is in GL_RESET mode.
These flags cannot be cleared when message storage in the corresponding receive message buffer is in progress.
Do not use the bit clear instruction to clear the flags. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

36.2.24 Receive FIFO n Configuration Register (RFCRn) (n = 0, 1)

Address(es): CANFD.RFCR0 000A 803Ch, CANFD.RFCR1 000A 8040h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	RFITH[2:0]			RFIM	—	FDS[2:0]			—	PLS[2:0]			—	—	RFIE	RFE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFE	Receive FIFO Enable	0: FIFO is disabled 1: FIFO is enabled	R/W
b1	RFIE	Receive FIFO Interrupt Enable	0: FIFO interrupt generation is disabled 1: FIFO interrupt generation is enabled	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6 to b4	PLS[2:0]	Payload Size Setting	b6 b4 0 0 0: 8 bytes 0 0 1: 12 bytes 0 1 0: 16 bytes 0 1 1: 20 bytes 1 0 0: 24 bytes 1 0 1: 32 bytes 1 1 0: 48 bytes 1 1 1: 64 bytes	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b10 to b8	FDS[2:0]	FIFO Depth Setting	b10 b8 0 0 0: 0 messages 0 0 1: 4 messages 0 1 0: 8 messages 0 1 1: 16 messages 1 0 0: 32 messages 1 0 1: 48 messages Settings other than above are prohibited.	R/W
b11	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b12	RFIM	Receive FIFO Interrupt Mode Setting	0: Interrupt is generated when the number of messages stored in the receive FIFO reaches the value of the RFITH[2:0] bits from a value smaller than the RFITH[2:0] bits 1: Interrupt is generated at the end of every received message storage	R/W
b15 to b13	RFITH[2:0]	Receive FIFO Interrupt Threshold Setting	b15 b13 0 0 0: Interrupt generated when FIFO is 1/8 full 0 0 1: Interrupt generated when FIFO is 1/4 full 0 1 0: Interrupt generated when FIFO is 3/8 full 0 1 1: Interrupt generated when FIFO is 1/2 full 1 0 0: Interrupt generated when FIFO is 5/8 full 1 0 1: Interrupt generated when FIFO is 3/4 full 1 1 0: Interrupt generated when FIFO is 7/8 full 1 1 1: Interrupt generated when FIFO is full	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

These registers are used to configure and control the two receive FIFOs.

RFE Bit (Receive FIFO Enable)

The RFE bit enables the FIFO. When this bit is set to 0, the receive FIFO is cleared to empty.
This bit can only be written in GL_HALT or GL_OPERATION mode.
This bit can be set to 1 only when the FIFO depth is 4 to 48 (001b ≤ FDS[2:0] ≤ 101b).
Set the RFE bit to 1 with a separate write access to the RFCRn register, after all the other flags in the RFCRn register are set.
This bit is automatically set to 0 when the CANFD module is in GL_RESET mode.

RFIE Bit (Receive FIFO Interrupt Enable)

The RFIE bit enables generation of the FIFO interrupt.
This bit cannot be written in GL_SLEEP mode.

PLS[2:0] Bits (Payload Size Setting)

The PLS[2:0] bits define the message data payload size in the RAM.
This is the maximum number of bytes which can be received by this FIFO.
These bits can only be written in GL_RESET mode.

FDS[2:0] Bits (FIFO Depth Setting)

The FDS[2:0] bits select the depth of the FIFO in units of the number of messages. If the FIFO depth is set to 0, the FIFO cannot be used.
These bits can only be written in GL_RESET mode.

RFIM Bit (Receive FIFO Interrupt Mode Setting)

The RFIM bit selects the interrupt generation condition for the FIFO.
This bit cannot be written in GL_SLEEP mode.
Write to this bit only in GL_RESET mode.

RFITH[2:0] Bits (Receive FIFO Interrupt Threshold Setting)

The RFITH[2:0] bits select the counter value of the FIFO for generation of receive FIFO interrupts. These values represent fractions of the FIFO depth for which an interrupt is generated.
These bits cannot be written in GL_SLEEP mode.
The setting of the RFITH[2:0] bits is restricted by the value of the FDS[2:0] bits. For details, refer to section 36.6.2.1, FIFO Buffers Configuration.
Write to these bits only in GL_RESET mode.

36.2.25 Receive FIFO n Status Register (RFSRn) (n = 0, 1)

Address(es): CANFD.RFSR0 000A 8044h, CANFD.RFSR1 000A 8048h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	FLVL[5:0]						—	—	—	—	RFIF	LOST	FULL	EMPTY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	EMPTY	Receive FIFO Empty Flag	0: Message in receive FIFO 1: No message in receive FIFO (empty)	R
b1	FULL	Receive FIFO Full Flag	0: Receive FIFO not full 1: Receive FIFO full	R
b2	LOST	Message Lost Flag	0: Receive FIFO message lost has not occurred 1: Receive FIFO message lost has occurred	R/(W) *1
b3	RFIF	Receive FIFO Interrupt Flag	0: Receive FIFO interrupt condition is not satisfied 1: Receive FIFO interrupt condition is satisfied	R/(W) *1
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13 to b8	FLVL[5:0]	Receive FIFO Fill Level	Indicate the number of messages stored in receive FIFO	R
b31 to b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 has no effect. This flag is cleared by writing 0 to it.

These registers show the status of messages stored in the corresponding FIFO buffers.

EMPTY Flag (Receive FIFO Empty Flag)

The EMPTY flag is automatically set to 1 when:

- The FLVL[5:0] flags are 00000b
- The RFCRn.RFE bit is set to 0 (receive FIFO is disabled)
- The CANFD module is in GL_RESET mode.

The EMPTY flag is automatically set to 0 when the first message is stored in the receive FIFO.

FULL Flag (Receive FIFO Full Flag)

The FULL flag is automatically set to 1 when the number of messages stored in the FIFO buffer matches the configured FIFO depth.

The FULL flag is automatically set to 0 when:

- The number of messages stored in the FIFO buffer is less than the configured FIFO depth
- The RFCRn.RFE bit is set to 0 (receive FIFO is disabled)
- The CANFD module is in GL_RESET mode.

LOST Flag (Message Lost Flag)

The LOST flag is automatically set to 1 whenever a message is lost due to attempted storage when the FIFO buffer is already full. This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.

The flag is set to 0:

- By writing 0 to it

- When the CANFD module is in GL_RESET mode.

Write to the LOST flag only when CANFD module is in GL_HALT or GL_OPERATION mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

RFIF Flag (Receive FIFO Interrupt Flag)

The RFIF flag is automatically set to 1 when the configured interrupt condition is satisfied. This flag is not automatically cleared when the receive FIFO is disabled.
The flag is set to 0:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode.

Write to this flag only when the CANFD module is in GL_HALT or GL_OPERATION mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.

FLVL[5:0] Bits (Receive FIFO Fill Level)

The FLVL[5:0] bits indicate the number of messages stored in the receive FIFO that can be read by the CPU. These bits are automatically set to 000000b when the FIFO is disabled and when the CANFD module is in GL_RESET mode.

36.2.26 Receive FIFO n Pointer Control Register (RFPCRn) (n = 0, 1)

Address(es): CANFD.RFPCR0 000A 804Ch, CANFD.RFPCR1 000A 8050h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register can be used to increment the read pointer of the corresponding receive FIFOs.
When the value 000000FFh is written to this register, the pointer of the corresponding receive FIFO is moved to the next FIFO entry. Write to this register only when the corresponding receive FIFO is enabled and not empty.
The read value from this register is always 00000000h.
This register can only be written in GL_HALT or GL_OPERATION mode.
Do not write to this register when DTC/DMA transfer is enabled (DTCR.RFDTEn bit = 1).

36.2.27 Common FIFO 0 Configuration Register (CFCR0)

Address(es): CANFD.CFCR0 000A 8054h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TINT[7:0]								FDS[2:0]			—	—	—	LTM[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CFITH[2:0]			CFIM	ITR	ITCS	—	MODE	—	PLS[2:0]			—	CFTIE	CFRIE	CFE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CFE	Common FIFO Enable	0: FIFO is disabled 1: FIFO is enabled	R/W
b1	CFRIE	Common FIFO Receive Interrupt Enable	0: FIFO receive interrupt generation is disabled 1: FIFO receive interrupt generation is enabled	R/W
b2	CFTIE	Common FIFO Transmit Interrupt Enable	0: FIFO transmit interrupt generation is disabled 1: FIFO transmit interrupt generation is enabled	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6 to b4	PLS[2:0]	Payload Size Setting	b6 b4 0 0 0: 8 bytes 0 0 1: 12 bytes 0 1 0: 16 bytes 0 1 1: 20 bytes 1 0 0: 24 bytes 1 0 1: 32 bytes 1 1 0: 48 bytes 1 1 1: 64 bytes	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b8	MODE	Operation Mode Setting	0: Receive FIFO mode 1: Transmit FIFO mode	R/W
b9	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b10	ITCS	Interval Timer Count Source Select	0: Reference clock (× 1 / × 10 period) 1: Bit time clock	R/W
b11	ITR	Interval Timer Resolution Select	0: Reference clock period × 1 1: Reference clock period × 10	R/W
b12	CFIM	Common FIFO Interrupt Mode Setting	Receive FIFO mode: 0: Reception interrupt generated when the number of messages stored in the common FIFO reaches CFITH[2:0] value from a lower value 1: Reception interrupt generated at the end of every received message storage Transmit FIFO mode: 0: Transmission interrupt generated when common FIFO transmits the last message successfully 1: Transmission interrupt generated for every successfully transmitted message	R/W
b15 to b13	CFITH[2:0]	Common FIFO Receive Interrupt Threshold Setting	b15 b13 0 0 0: Interrupt is generated when FIFO is 1/8 full 0 0 1: Interrupt is generated when FIFO is 1/4 full 0 1 0: Interrupt is generated when FIFO is 3/8 full 0 1 1: Interrupt is generated when FIFO is 1/2 full 1 0 0: Interrupt is generated when FIFO is 5/8 full 1 0 1: Interrupt is generated when FIFO is 3/4 full 1 1 0: Interrupt is generated when FIFO is 7/8 full 1 1 1: Interrupt is generated when FIFO is full	R/W

Bit	Symbol	Bit Name	Description	R/W
b17 to b16	LTM[1:0]	Linked Transmit Message Buffer Select	Transmission scan link position of the corresponding channel	R/W
b20 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b21	FDS[2:0]	FIFO Depth Setting	b23 b21 0 0 0: 0 messages 0 0 1: 4 messages 0 1 0: 8 messages 0 1 1: 16 messages 1 0 0: 32 messages 1 0 1: 48 messages Settings other than the above are prohibited.	R/W
b31 to b24	TINT[7:0]	Transmission Interval Setting	Delay the start of transmission from the FIFO if configured in transmit mode, delay is a multiple of basic interval timer clock source unit	R/W

CFE Bit (Common FIFO Enable)

Setting the CFE bit to 1 enables the FIFO. The FIFO is disabled when this bit is set to 0.
This bit can also be used, by clearing it, to abort transmission from common FIFO when configured in transmit FIFO mode, or to stop reception into the common FIFO in receive FIFO mode.
This bit can only be written in GL_HALT or GL_OPERATION mode. Also, if the common FIFO is configured as transmit FIFO mode, this bit can only be written when the CAN channel is not in CH_RESET mode.
This bit can only be set to 1 when the FIFO depth is between 4 and 48 (001b ≤ FDS[2:0] ≤ 101b).
Set the CFE bit to 1 with a separate write access to the CFCR0 register, after setting all the other bits in this register.
This bit is automatically set to 0 when the CANFD module is in GL_RESET mode. Also, if the common FIFO is configured as transmit FIFO mode, this bit is automatically set to 0 when the CAN channel is in CH_RESET mode.

CFRIE Bit (Common FIFO Receive Interrupt Enable)

The CFRIE bit enables or disables generation of common FIFO receive interrupt. If this flag is 1, common FIFO receive interrupt is generated when the common FIFO receive interrupt flag is set to 1 after reception of a frame in the corresponding FIFO buffer.
Do not write to this bit when the CANFD module is in GL_SLEEP mode.

CFTIE Bit (Common FIFO Transmit Interrupt Enable)

The CFTIE bit enables or disables generation of common FIFO transmit interrupt. If this flag is 1, common FIFO transmit interrupt is generated when the common FIFO transmit interrupt flag is set to 1 after transmission of a frame from the corresponding FIFO buffer.
Do not write to this bit when the CANFD module is in GL_SLEEP mode.

PLS[2:0] Bits (Payload Size Setting)

The PLS[2:0] bits define the message data payload size in the RAM. This is the maximum number of bytes which can be received or transmitted by the FIFO buffer.
For details, refer to section 36.6, FIFO Buffers and Message Buffer Configuration.
These bits can only be written in GL_RESET mode.

MODE Bit (Operation Mode Setting)

The MODE bit is used to select the operation mode of the common FIFO. When the MCU reset is applied, all the common FIFO are configured in receive FIFO mode.
This bit cannot be written in GL_OPERATION or GL_SLEEP mode.
Write to this bit only when the CANFD module is in GL_RESET mode.

ITCS Bit (Interval Timer Count Source Select)

The ITCS bit is used to select the count source for the transmission interval timer.
Do not write to this bit when the CANFD module is in GL_SLEEP mode. Also, do not write to this bit when the CFE bit is set to 1.
Do not write 1 to this bit when CAN FD communication is used.

Note: The bit time clock can vary depending on the nominal bit rate and data bit rate configuration.

ITR Bit (Interval Timer Resolution Select)

The ITR bit is used to select the resolution of the reference clock for the transmission interval timer.
This bit cannot be written in GL_SLEEP mode. Do not write to this bit when the CFE bit is set to 1.

CFIM Bit (Common FIFO Interrupt Mode Setting)

The CFIM bit is used to select the condition for the generation of common FIFO interrupts.
This bit cannot be written in GL_SLEEP mode.
Write to this bit only when the CANFD module is in GL_RESET mode.

CFITH[2:0] Bits (Common FIFO Receive Interrupt Threshold Setting)

The CFITH[2:0] bits are used to select the message counter value for the generation of common FIFO interrupts. These values represent fractions of the FIFO depth at which the interrupt is to be generated.
These bits cannot be written in GL_SLEEP mode.
The setting of the CFITH[2:0] bits is restricted by the value of the FDS[2:0] bits. For details, refer to section 36.6.2.1, FIFO Buffers Configuration.
Write to these bits only when the CANFD module is in GL_RESET mode.

LTM[1:0] Bits (Linked Transmit Message Buffer Select)

The LTM[1:0] bits are used to select the number of the transmit message buffer that links common FIFO configured in transmit FIFO mode, for transmission scanning.
These bits cannot be written in GL_OPERATION or GL_SLEEP mode.
Write to these bits only when the CANFD module is in GL_RESET mode.

FDS[2:0] Bits (FIFO Depth Setting)

The FDS[2:0] bits are used to select the FIFO depth in units of the number of messages. If the FIFO depth is configured to 0, the FIFO cannot be used.
These bits can only be written in GL_RESET mode.

TINT[7:0] Bits (Transmission Interval Setting)

The TINT[7:0] bits are used to select the delay in the start of transmission for all messages transmitted from the common FIFO configured in transmit FIFO mode. The delay is an integral multiple of the count source cycle of the interval timer (reference clock period × 1, reference clock period × 10, or bit-time clock period).
These bits cannot be written in GL_SLEEP mode.
Do not write to these bits when the CFE bit is set to 1.
When the GCFG.ITP[15:0] bits are set to 0000h, set the TINT[7:0] bits to 00h.

36.2.28 Common FIFO 0 Status Register (CFSR0)

Address(es): CANFD.CFSR0 000A 8058h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	FLVL[5:0]						—	—	—	CFTIF	CFRIF	LOST	FULL	EMPTY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	EMPTY	Common FIFO Empty Flag	0: Message in common FIFO 1: No message in common FIFO (empty)	R
b1	FULL	Common FIFO Full Flag	0: Common FIFO is not full 1: Common FIFO is full	R
b2	LOST	Message Lost Flag	0: No message lost in common FIFO 1: Common FIFO message lost	R/(W) *1
b3	CFRIF	Common FIFO Receive Interrupt Flag	0: Common FIFO receive interrupt condition is not satisfied 1: Common FIFO receive interrupt condition is satisfied	R/(W) *1
b4	CFTIF	Common FIFO Transmit Interrupt Flag	0: Common FIFO transmit interrupt condition is not satisfied 1: Common FIFO transmit interrupt condition is satisfied	R/(W) *1
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13 to b8	FLVL[5:0]	Common FIFO Fill Level	Indicate the number of messages stored in common FIFO	R
b31 to b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register shows the status of messages stored in the corresponding FIFO buffers.

EMPTY Flag (Common FIFO Empty Flag)

The EMPTY flag is automatically set to 1 when:

- The CPU has read all messages from the FIFO buffer in receive FIFO mode
- All messages have been transmitted from the FIFO buffer in transmit FIFO mode
- The common FIFO is disabled by setting the CFCR0.CFE bit to 0
- The CANFD module is in GL_RESET mode
- The CAN channel transits to CH_RESET mode in transmit FIFO mode.

The EMPTY flag is automatically set to 0 when:

- The first reception message is stored in the FIFO buffer in receive FIFO mode
- The first message to be transmitted is stored in the FIFO buffer in transmit FIFO mode.

FULL Flag (Common FIFO Full Flag)

The FULL flag is automatically set to 1 when the number of messages stored in the FIFO matches the configured FIFO depth.

The FULL flag is automatically set to 0 when:

- The number of messages stored in the FIFO is less than the configured FIFO depth
- The common FIFO is disabled by setting the CFCR0.CFE bit to 0
- The CANFD module is in GL_RESET mode
- The CAN channel transits to CH_RESET mode in transmit FIFO mode.

LOST Flag (Message Lost Flag)

The LOST flag is automatically set to 1 whenever a message is lost due to attempted storage of a new message when FIFO buffer is already full in receive FIFO mode.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag can only be written in GL_HALT or GL_OPERATION mode. Also, if the common FIFO is configured as transmit FIFO mode, this bit can only be written when the CAN channel is not in CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
The LOST flag is set to 0:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode
- When the CAN channel transits to CH_RESET mode in transmit FIFO mode.

CFRIF Flag (Common FIFO Receive Interrupt Flag)

The CFRIF flag is set to 1 when the configured interrupt condition is satisfied in receive FIFO mode.
The CFRIF flag is not cleared automatically if the common FIFO is disabled.
This flag can only be written in GL_HALT or GL_OPERATION mode. Also, if the common FIFO is configured as transmit FIFO mode, this bit can only be written when the CAN channel is not in CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
The CFRIF flag is set to 0:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode.

CFTIF Flag (Common FIFO Transmit Interrupt Flag)

The CFTIF flag is set to 1 when the configured interrupt condition is satisfied in transmit FIFO mode.
The CFTIF flag is not cleared automatically if the common FIFO is disabled.
This flag can only be written in GL_HALT or GL_OPERATION mode. Also, if the common FIFO is configured as transmit FIFO mode, this bit can only be written when the CAN channel is not in CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
The CFTIF flag is set to 0:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode
- When the CAN channel is in CH_RESET mode.

FLVL[5:0] Bits (Common FIFO Fill Level)

The FLVL[5:0] bits indicate the following:

- The number of messages stored by the CPU and waiting to be transmitted in the transmit FIFO mode

- The number of CPU-readable messages stored by CANFD in the receive FIFO mode.

The FLVL[5:0] bits are automatically set to 000000b when:

- The FIFO is disabled
- The CANFD module is in GL_RESET mode
- The CAN channel transits to CH_RESET mode in the transmit FIFO mode.

36.2.29 Common FIFO 0 Pointer Control Register (CFPCR0)

Address(es): CANFD.CFPCR0 000A 805Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register can be used to increment the read or write pointer of the corresponding common FIFO.
When the value 000000FFh is written into this register, the read pointer of the corresponding common FIFO in receive FIFO mode, or the write pointer of the corresponding common FIFO in transmit FIFO mode moves to the next FIFO entry.
The read value from this register is always 00000000h.
This register can only be written in GL_HALT or GL_OPERATION mode.
Write to this register only when:

- The common FIFO is enabled and is not empty in receive FIFO mode
- The common FIFO is enabled and is not full in transmit FIFO mode.

Do not write to the CFPCR0 register when DTC/DMA transfer is enabled (DTCR.CFDTE0 bit = 1).

36.2.30 FIFO Empty Status Register (FESR)

Address(es): CANFD.FESR 000A 8060h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CFEMP0	—	—	—	—	—	—	RFEMP1	RFEMP0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	RFEMP0	Receive FIFO 0 Empty Flag	0: Message in corresponding receive FIFO 0 1: No message in corresponding receive FIFO 0 (empty)	R
b1	RFEMP1	Receive FIFO 1 Empty Flag	0: Message in corresponding receive FIFO 1 1: No message in corresponding receive FIFO 1 (empty)	R
b7 to b2	—	Reserved	These bits are read as 0	R
b8	CFEMP0	Common FIFO 0 Empty Flag	0: Message in corresponding common FIFO 0 1: No message in corresponding common FIFO 0 (empty)	R
b31 to b9	—	Reserved	These bits are read as 0	R

This register shows the status of the empty flags of the FIFO buffers.

RFEMP0 Flag (Receive FIFO 0 Empty Flag)

The RFEMP0 flag is set to 1 when the RFSR0.EMPTY flag is set to 1, and is set to 0 when the RFSR0.EMPTY flag is set to 0.

The RFEMP0 flag is set to 1 when the CANFD module is in GL_RESET mode.

RFEMP1 Flag (Receive FIFO 1 Empty Flag)

The RFEMP1 flag is set to 1 when the RFSR1.EMPTY flag is set to 1, and is set to 0 when the RFSR1.EMPTY flag is set to 0.

The RFEMP1 flag is set to 1 when the CANFD module is in GL_RESET mode.

CFEMP0 Flag (Common FIFO 0 Empty Flag)

The CFEMP0 flag is set to 1 when the CFSR0.EMPTY flag is set to 1, and is set to 0 when the CFSR0.EMPTY flag is set to 0.

The CFEMP0 flag is set to 1 when the CANFD module is in GL_RESET mode.

36.2.31 FIFO Full Status Register (FFSR)

Address(es): CANFD.FFSR 000A 8064h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CFFUL0	—	—	—	—	—	—	RFFUL1	RFFUL0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFFUL0	Receive FIFO 0 Full Flag	0: Corresponding receive FIFO 0 is not full 1: Corresponding receive FIFO 0 is full	R
b1	RFFUL1	Receive FIFO 1 Full Flag	0: Corresponding receive FIFO 1 is not full 1: Corresponding receive FIFO 1 is full	R
b7 to b2	—	Reserved	These bits are read as 0	R
b8	CFFUL0	Common FIFO 0 Full Flag	0: Common FIFO 0 is not full 1: Common FIFO 0 is full	R
b31 to b9	—	Reserved	These bits are read as 0	R

This register shows the status of the full flags of the FIFO buffers.

RFFUL0 Flag (Receive FIFO 0 Full Flag)

The RFFUL0 flag is set to 1 when the RFSR0.FULL flag is set to 1, and is set to 0 when the RFSR0.FULL flag is set to 0.

The RFFUL0 flag is set to 0 when CANFD module is in GL_RESET mode.

RFFUL1 Flag (Receive FIFO 1 Full Flag)

The RFFUL1 flag is set to 1 when the RFSR1.FULL flag is set to 1, and is set to 0 when the RFSR1.FULL flag is set to 0.

The RFFUL1 flag is set to 0 when CANFD module is in GL_RESET mode.

CFFUL0 Flag (Common FIFO 0 Full Flag)

The CFFUL0 flag is set to 1 when the CFSR0.FULL flag is set to 1 is set to 0 when the CFSR0.FULL flag is set to 0.

The CFFUL0 flag is set to 0 when the CANFD module is in GL_RESET mode.

36.2.32 FIFO Message Lost Status Register (FMLSR)

Address(es): CANFD.FMLSR 000A 8068h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CFML0	—	—	—	—	—	—	RFML1	RFML0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFML0	Receive FIFO 0 Message Lost Flag	0: Message lost has not occurred in the receive FIFO 0 1: Message lost has occurred in the receive FIFO 0	R
b1	RFML1	Receive FIFO 1 Message Lost Flag	0: Message lost has not occurred in the receive FIFO 1 1: Message lost has occurred in the receive FIFO 1	R
b7 to b2	—	Reserved	These bits are read as 0	R
b8	CFML0	Common FIFO 0 Message Lost Flag	0: Message lost has not occurred in the common FIFO 0 1: Message lost has occurred in the common FIFO 0	R
b31 to b9	—	Reserved	These bits are read as 0	R

This register shows the status of the message lost flags of the FIFO buffers.

RFML0 Flag (Receive FIFO 0 Message Lost Flag)

The RFML0 flag is set to 1 when the RFSR0.LOST flag is set to 1, and is set to 0 when the RFSR0.LOST flag is set to 0. The RFML0 flag is cleared when the CANFD module is in GL_RESET mode.

RFML1 Flag (Receive FIFO 1 Message Lost Flag)

The RFML1 flag is set to 1 when the RFSR1.LOST flag is set to 1, and is set to 0 when the RFSR1.LOST flag is set to 0. The RFML1 flag is cleared when the CANFD module is in GL_RESET mode.

CFML0 Flag (Common FIFO 0 Message Lost Flag)

The CFML0 flag is set to 1 when the CFSR0.LOST flag is set to 1, and is set to 0 when the CFSR0.LOST flag is set to 0. The CFML0 flag is cleared when the CANFD module is in GL_RESET mode.

36.2.33 Receive FIFO Interrupt Status Register (RFISR)

Address(es): CANFD.RFISR 000A 806Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RFIF1	RFIF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFIF0	Receive FIFO0 Interrupt Flag	0: Receive FIFO 0 interrupt condition is not satisfied 1: Receive FIFO 0 interrupt condition is satisfied	R
b1	RFIF1	Receive FIFO1 Interrupt Flag	0: Receive FIFO 1 interrupt condition is not satisfied 1: Receive FIFO 1 interrupt condition is satisfied	R
b31 to b2	—	Reserved	These bits are read as 0	R

This register shows the status of the interrupt flags of the receive FIFOs.

RFIF0 Flag (Receive FIFO0 Interrupt Flag)

The RFIF0 flag is set to 1 when the RFSR0.RFIF flag is set to 1, and is set to 0 when the RFSR0.RFIF flag is set to 0. The RFIF0 flag is cleared when the CANFD module is in GL_RESET mode.

RFIF1 Flag (Receive FIFO1 Interrupt Flag)

The RFIF1 flag is set to 1 when the RFSR1.RFIF flag is set to 1, and is set to 0 when the RFSR1.RFIF flag is set to 0. The RFIF1 flag is cleared when the CANFD module is in GL_RESET mode.

36.2.34 DMA Transfer Control Register (DTCR)

Address(es): CANFD.DTCR 000A 80C8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CFDTE0	—	—	—	—	—	—	RFDTE1	RFDTE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFDTE0	Receive FIFO 0 DMA Transfer Enable	0: DTC/DMA transfer request is disabled 1: DTC/DMA transfer request is enabled	R/W
b1	RFDTE1	Receive FIFO 1 DMA Transfer Enable	0: DTC/DMA transfer request is disabled 1: DTC/DMA transfer request is enabled	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	CFDTE0	Common FIFO 0 DMA Transfer Enable	0: DTC/DMA transfer request is disabled 1: DTC/DMA transfer request is enabled	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register controls the start and stop of DTC/DMA transfer operation.

RFDTE0 Bit (Receive FIFO 0 DMA Transfer Enable)

The RFDTE0 bit enables or disables DTC/DMA transfer request for receive FIFO 0.
This bit cannot be set to 1 in GL_SLEEP or GL_RESET mode.
This bit is set to 0 when the CANFD module is in GL_RESET mode.

RFDTE1 Bit (Receive FIFO 1 DMA Transfer Enable)

The RFDTE1 bit enables or disables DTC/DMA transfer request for receive FIFO 1.
This bit cannot be set to 1 in GL_SLEEP or GL_RESET mode.
This bit is set to 0 when the CANFD module is in GL_RESET mode.

CFDTE0 Bit (Common FIFO 0 DMA Transfer Enable)

The CFDTE0 bit enables or disables DTC/DMA transfer request for common FIFO.
This bit cannot be set to 1 in GL_SLEEP or GL_RESET mode.
Do not enable DTC/DMA transfer for the common FIFO that is configured as transmit FIFO.
This bit is set to 0 when the CANFD module is in GL_RESET mode.

36.2.35 DMA Transfer Status Register (DTSR)

Address(es): CANFD.DTSR 000A 80CCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CFDTS0	—	—	—	—	—	—	RFDTS1	RFDTS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFDTS0	Receive FIFO 0 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped state 1: DTC/DMA transfer is in progress	R
b1	RFDTS1	Receive FIFO 1 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped state 1: DTC/DMA transfer is in progress	R
b7 to b2	—	Reserved	These bits are read as 0.	R
b8	CFDTS0	Common FIFO 0 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped state 1: DTC/DMA transfer is in progress	R
b31 to b9	—	Reserved	These bits are read as 0.	R

This register shows the status of the DTC/DMA transfer.

RFDTS0 Flag (Receive FIFO 0 DMA Transfer Status Flag)

The RFDTS0 flag is automatically set to 1 when the DTCR.RFDTE0 bit is set to 1 and the receive FIFO 0 is not empty. This flag is automatically set to 0 when the DTC/DMA transfer stops either because the DTCR.RFDTE0 bit is set to 0 or the receive FIFO 0 is empty.

When the DTCR.RFDTE0 bit is set to 0 while DTC/DMA transfer for the receive FIFO 0 is in progress, the RFDTS0 flag becomes 0 when the DTC/DMA transfer is completed.

This flag is set to 0 when the CANFD module is in GL_RESET mode.

RFDTS1 Flag (Receive FIFO 1 DMA Transfer Status Flag)

The RFDTS1 flag is automatically set to 1 when the DTCR.RFDTE1 bit is set to 1 and the receive FIFO 1 is not empty. This flag is automatically set to 0 when the DTC/DMA transfer stops either because the DTCR.RFDTE1 bit is set to 0 or the receive FIFO 1 is empty.

When the DTCR.RFDTE1 bit is set to 0 while DTC/DMA transfer for the receive FIFO 1 is in progress, the RFDTS1 flag becomes 0 when the DTC/DMA transfer is completed.

This flag is set to 0 when the CANFD module is in GL_RESET mode.

CFDTS0 Flag (Common FIFO 0 DMA Transfer Status Flag)

The CFDTS0 flag is automatically set to 1 when the DTCR.CFDTE0 bit is set to 1 and the common FIFO 0 is not empty. This flag is automatically set to 0 when the DTC/DMA transfer stops either because the DTCR.CFDTE0 bit is set to 0 or the common FIFO 0 is empty.

When the DTCR.CFDTE0 bit is set to 0 while DTC/DMA transfer for the common FIFO 0 is in progress, the CFDTS0 flag becomes 0 when the DTC/DMA transfer is complete.

This flag is set to 0 when the CANFD module is in GL_RESET mode.

36.2.36 Transmit Message Buffer n Control Register (TMCRn) (n = 0 to 3)

Address(es): CANFD.TMCR0 000A 8070h, CANFD.TMCR1 000A 8071h, CANFD.TMCR2 000A 8072h, CANFD.TMCR3 000A 8073h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	ONESHOT	TARQ	TXRQ
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TXRQ	Transmission Request	0: Message transmission is not requested 1: Message transmission is requested	R/W
b1	TARQ	Transmission Abort Request	0: Message transmission abort is not requested 1: Message transmission abort is requested	R/W
b2	ONESHOT	One-shot Transmission Enable	0: Transmission in one-shot mode is disabled 1: Transmission in one-shot mode is enabled	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register configures the transmit message buffer functions.

TXRQ Bit (Transmission Request)

When the TXRQ bit is set to 1, the CANFD module logic requests transmitting the message stored in the corresponding message buffer.
This bit can only be written in CH_HALT or CH_OPERATION mode.
This bit cannot be set to 1 if the corresponding transmit message buffer is linked to the common FIFO configured in transmit FIFO or is a part of the transmit queue.
This bit can be set to 1 only when the TMSRn.TXRF[1:0] flags are set to 00b.
This bit cannot be directly cleared by a CPU write access. The TXRQ bit is automatically set to 0:

- At the end of a successful transmission
- At the end of a transmission abort, requested by the TARQ bit
- When a CAN bus error or arbitration lost is detected if the ONESHOT bit is set to 1
- When the CANFD module is in GL_RESET or the CAN channel is in CH_RESET mode.

TARQ Bit (Transmission Abort Request)

When the TARQ bit is set to 1, the CANFD module logic requests aborting the transmission of the frame stored in the corresponding message buffer.
In most cases, transmission cannot be aborted if the internal scan for transmission is complete and the message buffer has already been selected for transmission. In this case, frame will be transmitted successfully from the message buffer. The message buffer selection is released by entering CH_HALT mode.
However, message buffer selected for transmission can be aborted by an abort request when the CAN node detects a new message on the bus (pin for reception) before it starts transmission from the selected message buffer.
Write to the TARQ bit only when the CAN channel is in CH_HALT or CH_OPERATION mode. This bit can be set to 1 only when the TXRQ bit is set to 1.
This bit cannot be set to 0 by a CPU write access. This bit is set to 0 if writing 1 by CPU and clearing by the CAN channel occur at the same time.
The TARQ bit is automatically set to 0:

- At the end of a successful transmission
- At the end of a transmission abort
- When a CAN bus error or arbitration lost is detected

- When the CANFD module is in GL_RESET or the CAN channel enters CH_RESET mode.

ONESHOT Bit (One-shot Transmission Enable)

When the ONESHOT bit is set to 1, the CANFD module logic request transmitting the message only once.
If the transmission is successful, the TMSRn.TXRF[1:0] flags are set to 10b or 11b. Otherwise, the transmission is automatically aborted and TMSRn.TXRF[1:0] flags are set to 01b due to a bus error or an arbitration lost detection.
The ONESHOT bit remains 1 if the transmission has completed successfully or aborted due to a CAN bus error or an arbitration lost detection.
Write to this bit only when the CAN channel is in CH_HALT or CH_OPERATION mode.
Set this bit at the same time as the TXRQ bit. Clear this bit with a write access.
If a message has already been requested for transmission, do not write to this bit until the message has been successfully transmitted or transmission has been aborted.
The ONESHOT bit is automatically set to 0 when the CANFD module is in GL_RESET or the CAN channel is in CH_RESET mode.

36.2.37 Transmit Message Buffer n Status Register (TMSRn) (n = 0 to 3)

Address(es): CANFD.TMSR0 000A 8074h, CANFD.TMSR1 000A 8075h, CANFD.TMSR2 000A 8076h, CANFD.TMSR3 000A 8077h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	TARQS	TXRQS	TXRF[1:0]		TXSF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TXSF	Transmission Status Flag	0: No transmission is in progress 1: Transmission is in progress	R
b2, b1	TXRF[1:0]	Transmission Result Flag	b2 b1 0 0: No result (transmission is not requested or in progress) 0 1: Transmission was aborted. 1 0: Transmission was successful and transmission abort is not requested. 1 1: Transmission was successful and transmission abort is requested.	R/W
b3	TXRQS	Transmission Request Status Flag	0: Transmission is not requested 1: Transmission is requested	R
b4	TARQS	Transmission Abort Request Status Flag	0: Transmission abort is not requested 1: Transmission abort is requested	R
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register shows the status of the transmission and transmission abort for the transmit message buffers.

TXSF Flag (Transmission Status Flag)

The TXSF flag is automatically set to 1 at the start of the transmission from the corresponding transmit message buffer. This flag is automatically set to 0 when:

- Transmission stops
- The CANFD module is in GL_RESET mode
- The CAN channel is in CH_RESET mode.

TXRF[1:0] Flags (Transmission Result Flag)

The TXRF[1:0] flags show the transmission result for the transmit message buffer.
Write to these flags only when the CAN channel is in CH_HALT or CH_OPERATION mode.
Each bit of these flags is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
The TXRF[1:0] flags are automatically set to 00b when the CANFD module is in GL_RESET or the CAN channel is in CH_RESET mode.

TXRQS Flag (Transmission Request Status Flag)

The TXRQS flag reflects the value of the TMCRn.TXRQ bit.
The TXRQS flag is set to 1 when the TMCRn.TXRQ bit is set to 1. This flag is set to 0 when the TMCRn.TXRQ bit is set to 0.

TARQS Flag (Transmission Abort Request Status Flag)

The TARQS flag reflects the value of the TMCRn.TARQ bit.
The TARQS flag is set to 1 when the TMCRn.TARQ bit is set to 1. This flag is set to 0 when the TMCRn.TARQ bit is set to 0.

36.2.38 Transmit Message Buffer Transmission Request Status Register 0 (TMTRSR0)

Address(es): CANFD.TMTRSR0 000A 8078h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	TXRQS3	TXRQS2	TXRQS1	TXRQS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TXRQS0	Transmit Message Buffer 0 Transmission Request Status Flag	0: Transmission is not requested for the transmit message buffer 0. 1: Transmission is requested for the transmit message buffer 0	R
b1	TXRQS1	Transmit Message Buffer 1 Transmission Request Status Flag	0: Transmission is not requested for the transmit message buffer 1. 1: Transmission is requested for the transmit message buffer 1.	R
b2	TXRQS2	Transmit Message Buffer 2 Transmission Request Status Flag	0: Transmission is not requested for the transmit message buffer 2. 1: Transmission is requested for the transmit message buffer 2.	R
b3	TXRQS3	Transmit Message Buffer 3 Transmission Request Status Flag	0: Transmission is not requested for the transmit message buffer 3. 1: Transmission is requested for the transmit message buffer 3.	R
b31 to b4	—	Reserved	These bits are read as 0	R

This register shows the status of the transmission request in each transmit message buffer.

TXRQSn Flag (Transmit Message Buffer n Transmission Request Status Flag) (n = 0 to 3)

The TXRQSn flag indicates status of the TMCRn.TXRQ bit.

Each flag is set to 1 only when the TMCRn.TXRQ bit is set to 1 and the message buffer does not belong to a transmit queue.

Each flag is automatically set to 0 when:

- The TMCRn.TXRQ bit is set to 0
- The CANFD module is in GL_RESET mode
- The CAN channel is in CH_RESET mode.

36.2.39 Transmit Message Buffer Transmission Abort Request Status Register 0 (TMARSR0)

Address(es): CANFD.TMARSR0 000A 807Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	TARQS3	TARQS2	TARQS1	TARQS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TARQS0	Transmit Message Buffer 0 Transmission Abort Request Status Flag	0: Transmission abort is not requested for the transmit message buffer 0 1: Transmission abort is requested for the transmit message buffer 0	R
b1	TARQS1	Transmit Message Buffer 1 Transmission Abort Request Status Flag	0: Transmission abort is not requested for the transmit message buffer 1 1: Transmission abort is requested for the transmit message buffer 1	R
b2	TARQS2	Transmit Message Buffer 2 Transmission Abort Request Status Flag	0: Transmission abort is not requested for the transmit message buffer 2 1: Transmission abort is requested for the transmit message buffer 2	R
b3	TARQS3	Transmit Message Buffer 3 Transmission Abort Request Status Flag	0: Transmission abort is not requested for the transmit message buffer 3 1: Transmission abort is requested for the transmit message buffer 3	R
b31 to b4	—	Reserved	These bits are read as 0	R

This register shows the status of the transmission abort request in each transmit message buffer.

TARQSn Flag (Transmit Message Buffer n Transmission Abort Request Status Flag) (n = 0 to 3)

The TARQSn flag indicates status of the TMCRn.TARQ bit.

Each flag is set to 1 when the TMCRn.TARQ bit is set to 1 or the message buffer belongs to a transmit queue.

Each flag is automatically set to 0 when:

- The TMCRn.TARQ bit is set to 0
- The CANFD module is in GL_RESET mode
- The CAN channel is in CH_RESET mode.

36.2.40 Transmit Message Buffer Transmission Completion Status Register 0 (TMTCSR0)

Address(es): CANFD.TMTCSR0 000A 8080h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	TXCF3	TXCF2	TXCF1	TXCF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TXCF0	Transmit Message Buffer 0 Transmission Complete Flag	0: Transmission is not completed for the transmit message buffer 0 1: Transmission is completed for the transmit message buffer 0	R
b1	TXCF1	Transmit Message Buffer 1 Transmission Complete Flag	0: Transmission is not completed for the transmit message buffer 1 1: Transmission is completed for the transmit message buffer 1	R
b2	TXCF2	Transmit Message Buffer 2 Transmission Complete Flag	0: Transmission is not completed for the transmit message buffer 2 1: Transmission is completed for the transmit message buffer 2	R
b3	TXCF3	Transmit Message Buffer 3 Transmission Complete Flag	0: Transmission is not completed for the transmit message buffer 3 1: Transmission is completed for the transmit message buffer 3	R
b31 to b4	—	Reserved	These bits are read as 0	R

This register shows the transmission completion status for each transmit message buffer.

TXCFn Flag (Transmit Message Buffer n Transmission Completion Status) (n = 0 to 3)

The TXCFn flag indicates the transmission completion status for the transmit message buffer n.

Each flag is automatically set to 1 when the TMSRn.TXRF[1] bit is set to 1.

Each flag is automatically set to 0 when:

- The TMSRn.TXRF[1] bit is set to 0
- The CANFD module is in GL_RESET mode
- The CAN channel is in CH_RESET mode.

36.2.41 Transmit Message Buffer Transmission Abort Status Register 0 (TMTASR0)

Address(es): CANFD.TMTASR0 000A 8084h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	TAF3	TAF2	TAF1	TAF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TAF0	Transmit Message Buffer 0 Transmission Abort Status Flag	0: Transmission is not aborted for the transmit message buffer 0. 1: Transmission is aborted for the transmit message buffer 0.	R
b1	TAF1	Transmit Message Buffer 1 Transmission Abort Status Flag	0: Transmission is not aborted for the transmit message buffer 1. 1: Transmission is aborted for the transmit message buffer 1.	R
b2	TAF2	Transmit Message Buffer 2 Transmission Abort Status Flag	0: Transmission is not aborted for the transmit message buffer 2. 1: Transmission is aborted for the transmit message buffer 2.	R
b3	TAF3	Transmit Message Buffer 3 Transmission Abort Status Flag	0: Transmission is not aborted for the transmit message buffer 3. 1: Transmission is aborted for the transmit message buffer 3.	R
b31 to b4	—	Reserved	These bits are read as 0	R

This register shows the transmission abort status for each transmit message buffer.

TAFn Flag (Transmit Message Buffer n Transmission Abort Status Flag) (n = 0 to 3)

The TAFn flag indicates the transmission abort status for the transmit message buffer n.

Each flag is automatically set to 1 when the TMSRn.TXRF[1:0] flags are set to 01b.

Each flag is automatically set to 0 when:

- The TMSRn.TXRF[1:0] flags are set to 00b
- The CANFD module is in GL_RESET mode
- The CAN channel is in CH_RESET mode.

36.2.42 Transmit Message Buffer Interrupt Enable Register (TMIER0)

Address(es): CANFD.TMIER0 000A 8088h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	TMIE3	TMIE2	TMIE1	TMIE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TMIE0	Transmit Message Buffer 0 Interrupt Enable	0: Interrupt for transmit message buffer 0 is disabled. 1: Interrupt for transmit message buffer 0 is enabled.	R/W
b1	TMIE1	Transmit Message Buffer 1 Interrupt Enable	0: Interrupt for transmit message buffer 1 is disabled. 1: Interrupt for transmit message buffer 1 is enabled.	R/W
b2	TMIE2	Transmit Message Buffer 2 Interrupt Enable	0: Interrupt for transmit message buffer 2 is disabled. 1: Interrupt for transmit message buffer 2 is enabled.	R/W
b3	TMIE3	Transmit Message Buffer 3 Interrupt Enable	0: Interrupt for transmit message buffer 3 is disabled. 1: Interrupt for transmit message buffer 3 is enabled.	R/W
b31 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register enables or disables the interrupt for each transmit message buffer.

TMIEn Bit (Transmit Message Buffer n Interrupt Enable) (n = 0 to 3)

If the TMIEn bit is set to 1, an interrupt is generated when transmission from the transmit message buffer n is completed successfully.

Refer to section 36.10, Interrupts and DTC/DMA Requests for the specification of the interrupt for transmit message buffer.

This bit cannot be written when the CANFD module is in GL_SLEEP mode.

Do not write to the TMIEn bit when:

- The CAN channel is in CH_SLEEP mode
- The transmit message buffer n is part of a transmit queue
- The transmit message buffer n is linked to a common FIFO by the CFCR0.LTM[1:0] bits.

36.2.43 Transmit Queue 0 Configuration Register (TQCR0)

Address(es): CANFD0.TQCR0 000A 808Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TQE	Transmit Queue Enable	0: Transmit queue is disabled. 1: Transmit queue is enabled.	R/W
b4 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	TQIE	Transmit Queue Interrupt Enable	0: Transmit queue transmission interrupt is disabled. 1: Transmit queue transmission interrupt is enabled.	R/W
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	TQIM	Transmit Queue Interrupt Mode Setting	0: When the last message is successfully transmitted 1: At every successful transmission	R/W
b9, b8	QDS[1:0]	Queue Depth Setting	b9 b8 0 0: 0 messages (disabled) 0 1: Setting prohibited 1 0: 3 messages (transmit message buffer 0 to 2) 1 1: 4 messages (transmit message buffer 0 to 3)	R/W
b31 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to configure the transmit queue 0.

TQE Bit (Transmit Queue Enable)

The TQE bit enables the transmit queue. When the TQE bit is set to 1, the transmit message buffer is used to configure the transmit queue.

The TQE bit cannot be set to 1 if the configured transmit queue depth is 0 (QDS[1:0] = 00b).

This bit cannot be written in GL_SLEEP mode.

Also, this bit cannot be written in CH_RESET or CH_SLEEP mode.

The TQE bit is automatically set to 0 when the CAN channel is in CH_RESET mode.

TQIE Bit (Transmit Queue Interrupt Enable)

When the TQIE bit is set to 1, an interrupt is generated based on the setting of the TQIM bit.

This bit cannot be written in GL_SLEEP mode.

Do not write to this bit when the CAN channel is in CH_SLEEP mode.

TQIM Bit (Transmit Queue Interrupt Mode Setting)

The TQIM bit selects the interrupt generation condition for the transmit queue.

This bit cannot be written in GL_SLEEP mode.

Do not write to this bit when the CAN channel is in CH_SLEEP, CH_HALT, or CH_OPERATION mode.

QDS[1:0] Bits (Queue Depth Setting)

The QDS[1:0] bits select the depth of the transmission queue.

When these bits are set to 10b, the message buffers 0 to 2 are used, and when these bits are set to 11b, the message buffers 0 to 3 are used.
These bits cannot be written in GL_SLEEP mode.
Also, these bits cannot be written in CH_HALT or CH_OPERATION mode.
Do not write to these bits when the CAN channel is in CH_SLEEP mode.

36.2.44 Transmit Queue 0 Status Register (TQSR0)

Address(es): CANFD0.TQSR0 000A 8090h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	FLVL[2:0]			—	—	—	—	—	TQIF	FULL	EMPTY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	EMPTY	Transmit Queue Empty Flag	0: There is at least one message in transmit queue 1: No message in transmit queue (empty)	R
b1	FULL	Transmit Queue Full Flag	0: Transmit queue is not full 1: Transmit queue is full	R
b2	TQIF	Transmit Queue Interrupt Flag	0: Transmit queue interrupt condition is not satisfied 1: Transmit queue interrupt condition is satisfied	R/(W) *1
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b10 to b8	FLVL[2:0]	Transmit Queue Fill Level	Indicates the number of messages in the transmit queue	R
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register shows the status of the transmit queue 0.

EMPTY Flag (Transmit Queue Empty Flag)

This flag is automatically set to 1 when:

- The TQCR0.TQE bit is set to 0 (transmit queue is disabled)
- No messages are stored in the transmit queue
- The last message is transmitted from the transmit queue
- The CAN channel is in CH_RESET mode.

This flag is automatically set to 0 when the first message to be transmitted is stored in the transmit queue.

FULL Flag (Transmit Queue Full Flag)

The FULL flag is automatically set to 1 when the number of messages stored in the transmit queue matches the configured transmit queue depth.

This flag is automatically set to 0 when:

- The number of messages stored in the transmit queue is less than the configured transmit queue depth
- The CAN channel is in CH_RESET mode.

TQIF Flag (Transmit Queue Interrupt Flag)

The TQIF flag is not cleared automatically if the transmit queue is disabled.

When stopping the transmit queue, this flag should be cleared, after setting the TQCR0.TQE bit to 0 and checking an empty state of transmit queue.

Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

This flag is automatically set to 1 when the configured interrupt condition is satisfied for the transmit queue.

This flag is set to 0:

- By writing 0 to it
- When the CAN channel is in CH_RESET mode.

This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag cannot be written when the CAN channel is in CH_SLEEP or CH_RESET mode.

FLVL[2:0] Bits (Transmit Queue Fill Level)

The FLVL[2:0] bits indicates the number of messages in the transmit queue.
These bits are automatically set to 000b when the CAN channel is in CH_RESET mode.

36.2.45 Transmit Queue 0 Pointer Control Register (TQPCR0)

Address(es): CANFD0.TQPCR0 000A 8094h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to increment the write pointer to the transmit queue.
When the value 000000FFh is written to this register, the write pointer to the transmit queue is updated and transmission of the existing message is requested.
The read value from this register is always 00000000h.
This register cannot be written when the CAN channel is in CH_SLEEP or CH_RESET mode.
Write to this register only when:

- The transmit queue is enabled and not full.

36.2.46 Transmission History Configuration Register (THCR)

Address(es): CANFD0.THCR 000A 8098h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	THRC	THIM	THIE	—	—	—	—	—	—	—	THE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	THE	Transmission History Enable	0: Transmission history buffer is disabled 1: Transmission history buffer is enabled	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	THIE	Transmission History Interrupt Enable	0: Transmission history interrupt is disabled 1: Transmission history interrupt is enabled	R/W
b9	THIM	Transmission History Interrupt Mode Setting	0: Interrupt is generated if transmission history level reaches 3/4 of the transmission history depth 1: Interrupt is generated for every successfully stored entry	R/W
b10	THRC	Transmission History Recording Condition Setting	0: Transmit FIFO + Transmit queue 1: Transmit message buffer + Transmit FIFO + Transmit queue	R/W
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register configures the transmission history functions.

THE Bit (Transmission History Enable)

The THE bit enables the transmission history buffer when it is set to 1.
This bit cannot be written when the CAN channel is in CH_RESET or CH_SLEEP mode.
This bit is automatically set to 0 when the CAN channel is in CH_RESET mode.

THIE Bit (Transmission History Interrupt Enable)

The THIE bit enables the generation of the transmission history interrupt when it is set to 1.
This bit cannot be written when the CANFD module is in GL_SLEEP mode.

THIM Bit (Transmission History Interrupt Mode Setting)

The THIM bit selects the transmission history interrupt generation condition.
This bit cannot be written when the CANFD module is in GL_SLEEP mode.
Do not write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode.

THRC Bit (Transmission History Recording Condition Setting)

The THRC bit selects the condition for storing an entry in the transmission history buffer after successful transmission.
This bit cannot be written when the CANFD module is in GL_SLEEP mode.
Do not write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode.

36.2.47 Transmission History Status Register (THSR)

Address(es): CANFD0.THSR 000A 809Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	FLVL[3:0]				—	—	—	—	THIF	LOST	FULL	EMPTY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	EMPTY	Transmission History Empty Flag	0: There is a transmission history in the transmission history buffer 1: There is no transmission history in the transmission history buffer (empty)	R
b1	FULL	Transmission History Full Flag	0: Transmission history buffer is not full 1: Transmission history buffer is full	R
b2	LOST	Transmission History Lost Flag	0: Transmission history has not been lost 1: Transmission history has been lost	R/(W) *1
b3	THIF	Transmission History Interrupt Flag	0: Transmission history interrupt condition is not satisfied 1: Transmission history interrupt condition is satisfied	R/(W) *1
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11 to b8	FLVL[3:0]	Transmission History Fill Level	Number of transmission histories stored in transmission history buffer	R
b31 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register shows the status of data stored in the transmission history buffer.

EMPTY Flag (Transmission History Empty Flag)

This flag is automatically set to 0 when the first transmission history is stored to the transmission history buffer.
This flag is automatically set to 1 when:

- The CPU has read all the transmission histories from the transmission history buffer
- The THCR.THE bit is set to 0 (transmission history buffer is disabled)
- The CAN channel is in CH_RESET mode.

FULL Flag (Transmission History Full Flag)

The FULL flag is automatically set to 1 when the number of transmission histories in the transmission history buffer is eight.
This flag is automatically set to 0 when:

- The number of transmission histories in the transmission history buffer is less than eight
- The THCR.THE bit is set to 0 (transmission history buffer is disabled)
- The CAN channel is in CH_RESET mode.

LOST Flag (Transmission History Lost Flag)

The LOST flag is set to 1 when a new transmission history cannot be stored because the related transmission history buffer is already full.

Write to this flag only when the CAN channel is in CH_HALT or CH_OPERATION mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is set to 0:

- By writing 0 to it
- When the CAN channel is in CH_RESET mode.

THIF Flag (Transmission History Interrupt Flag)

The THIF flag is set to 1 when the configured interrupt condition is satisfied.
Write to this flag only when the CAN channel is in CH_HALT or CH_OPERATION mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is set to 0:

- By writing 0 to it
- When the CAN channel is in CH_RESET mode.

FLVL[3:0] Bits (Transmission History Fill Level)

The FLVL[3:0] bits show the number of transmission histories stored in the transmission history buffer.
These bits are automatically set to 0000b when the CAN channel is in CH_RESET mode.

36.2.48 Transmission History Access Register 0 (THACR0)

Address(es): CANFD0.THACR0 000A 8740h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	BN[1:0]		BT[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	BT[2:0]	Transmitted Buffer Type	b2 b0 0 0 1: Transmit message buffer 0 1 0: Common FIFO 1 0 0: Transmit Queue	R
b4, b3	BN[1:0]	Transmitted Buffer Number	Number of the message buffer	R
b15 to b5	—	Reserved	These bits are read as 0	R
b31 to b16	TS[15:0]	Transmitted Timestamp	Transmit timestamp value	R

This register is used to access to the histories in the transmission history buffer based on the read pointer value.

BT[2:0] Bits (Transmitted Buffer Type)

The BT[2:0] bits indicate which type of buffer the read history came from.

BN[1:0] Bits (Transmitted Buffer Number)

The BN[1:0] bits indicate which buffer number the read history came from.
For a common FIFO, these bits indicate the number of the linked transmit message buffer.

TS[15:0] Bits (Transmitted Timestamp)

The TS[15:0] bits indicate the timestamp used by the software driver.

36.2.49 Transmission History Access Register 1 (THACR1)

Address(es): CANFD0.THACR1 000A 8744h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	IFL[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	PTR[15:0]	Transmitted Pointer	Stores the value of the PTR[15:0] field attached to the transmit message	R
b17, b16	IFL[1:0]	Transmitted Information Label	Stores the value of the IFL[1:0] field attached to the transmit message	R
b31 to b18	—	Reserved	These bits are read as 0	R

This register is used to access to the histories in the transmission history buffer based on the read pointer value.

PTR[15:0] Bits (Transmitted Pointer)

The PTR[15:0] bits store the value of the pointer field (TMBn.HF2.PTR[15:0] bits or CFB0.HF2.PTR[15:0] bits) attached to the transmit message.

IFL[1:0] Bits (Transmitted Information Label)

The IFL[1:0] bits store the value of the information label field (TMBn.HF2.IFL[1:0] bits or CFB0.HF2.IFL[1:0] bits) attached to the transmit message.

36.2.50 Transmission History Pointer Control Register (THPCR)

Address(es): CANFD0.THPCR 000A 80A0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to increment the read pointer of the transmission history buffer.
When 000000FFh is written to this register, the read pointer of the transmission history buffer is moved to the next history.
The read value from this register is 00000000h.
This register can only be written in CH_HALT or CH_OPERATION mode.
Write 000000FFh to this register only when the transmission history buffer is enabled and not empty.

36.2.51 Global Reset Control Register (GRCR)

Address(es): CANFD.GRCR 000A 80D8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	SRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SRST	Software Reset	0: Releases the software reset 1: Initiates the software reset	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	These bits control rewriting of the SRST bit. These bits are read as 00h.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SRST Bit (Software Reset)

When the SRST bit is set to 1, the CANFD module is in the same state as the MCU reset. When a reset is required, write 1 to this bit and then 0.

After releasing the software reset, the CANFD module is in GL_SLEEP mode.

After a software reset, the RAM initialization sequence is not performed. Initialize the RAM with software.

Similarly, if a software reset is performed during RAM initialization, the RAM is not initialized. Initialize the RAM with software.

KEY[7:0] Bits (Key Code)

When rewriting the value of the SRST bit, set these bits to C4h at the same time (write this register in 32 bits).

36.2.52 Global Test Mode Configuration Register (GTMCR)

Address(es): CANFD.GTMCR 000A 80A8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b19 to b16	RTPS[3:0]	RAM Test Page Select	Select the page of RAM to be tested	R/W
b31 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to specify the page number of the RAM to be tested in RAM test mode.

RTPS[3:0] Bits (RAM Test Page Select)

The RTPS[3:0] bits select the RAM page number that the CPU reads and writes when the CANFD module is in RAM test mode. Specify the page number in the range of 0 to 9.

Refer to section 36.9.2.1, RAM Test Mode for the specifications of the RAM test mode.

These bits cannot be written in GL_RESET or GL_SLEEP mode. Write to these bits only in GL_HALT mode.

These bits are automatically set to 0000b when the CAN channel is in GL_RESET mode.

36.2.53 Global Test Mode Enable Register (GTMER)

Address(es): CANFD.GTMER 000A 80ACh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	RTME	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b2	RTME	RAM Test Mode Enable	0: RAM Test mode is disabled. 1: RAM Test mode is enabled.	R/W
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to control the global test modes of the CANFD module.

RTME Bit (RAM Test Mode Enable)

When the RTME bit is set to 1, the CANFD module is in RAM test mode. Refer to section 36.9.2.1, RAM Test Mode for the specifications of the RAM test mode.

This bit can only be set to 1 when the CANFD module is in GL_HALT mode. To exit the RAM test mode, set this bit to 0 in GL_HALT mode.

This bit is automatically set to 0 when the CANFD module is in GL_RESET mode.

36.2.54 Global CAN FD Configuration Register (GFDCFG)

Address(es): CANFD.GFDCFG 000A 80B0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	TSCPS[1:0]		—	—	—	—	—	—	—	PXEDIS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PXEDIS	Protocol Exception Event Detection Disable	0: Protocol exception event detection is enabled. 1: Protocol exception event detection is disabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	TSCPS[1:0]	Timestamp Capturing Point Select	b9 b8 0 0: Sample point of SOF (start of frame) 0 1: EOF (end of frame) when frame is taken valid 1 0: Sample point of SOF (Classical CAN frame), or sample point of res bit following the FDF bit (CAN FD frame) 1 1: Setting prohibited	R/W
b31 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

PXEDIS Bit (Protocol Exception Event Detection Disable)

The PXEDIS bit configures the protocol exception event handling according to ISO 11898-1.

When this bit is set to 1, protocol exception event detection is disabled, and an error frame is transmitted if a protocol exception (a recessive reserved bit following the FDF bit) is detected.

This bit can only be written in GL_RESET mode.

TSCPS[1:0] Bits (Timestamp Capturing Point Select)

The TSCPS[1:0] bits selects the capture point of the timestamps for transmitted and received messages.

When the TSCPS[1:0] bits are 10b, the timestamp is captured at the reserved bit following the FDF bit in CAN FD frames and at the SOF in Classical CAN frames.

These bits can only be written in GL_RESET mode.

36.2.55 Global Test Mode Lock Key Register (GTMLKR)

Address(es): CANFD.GTMLKR 000A 80B8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to unlock the protection for RAM test mode. Refer to section 36.9.2, Global Test Modes for the specification of the lock key.
To put the CANFD module into RAM test mode, two unlock keys must be written to this register in consecutive bus cycles.
The read value from this register is always 00000000h.
This register cannot be written when the CANFD module is in GL_SLEEP or GL_RESET mode.
Do not write to this register when the CANFD module is in GL_OPERATION mode.

36.2.56 RAM Test Page Access Register k (RTPARk) (k = 0 to 63)

Address(es): CANFD.RTPAR0 000A 8280h to CANFD.RTPAR63 000A 837Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register can be read or written when the CANFD module is in RAM test mode.
This register can only be written in GL_HALT mode when RAM test mode is enabled.

36.2.57 Acceptance Filter List Ignore Entry Setting Register (AFIGSR)

Address(es): CANFD.AFIGSR 000A 80C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	IGES[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	IGES[4:0]	Ignore Entry Select	Set the rule number to be ignored during acceptance filtering.	R/W
b31 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

IGES[4:0] Bits (Ignore Entry Select)

The IGES[4:0] bits are used to specify the rule number to update when updating the acceptance filter.

Write to these bits only when the AFIGER.IGEE bit is 0.
These bits cannot be written in GL_SLEEP mode.

36.2.58 Acceptance Filter List Ignore Entry Enable Register (AFIGER)

Address(es): CANFD.AFIGER 000A 80C4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	IGEE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IGEE	Ignore Entry Enable	0: The value of the AFIGSR.IGES[4:0] bits is invalid. 1: The value of the AFIGSR.IGES[4:0] bits is valid.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	Controls the validity of rewriting the IGEE bit	W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

IGEE Bit (Ignore Entry Enable)

When the IGEE bit is set to 1, the entry selected by the AFIGSR.IGES[4:0] bits is ignored.
This bit is automatically set to 0 when the CANFD module is in GL_RESET mode.

KEY[7:0] Bits (Key Code)

Writing to the IGEE bit is enabled when C4h is written to the KEY[7:0] bits. The value read from these bits is always 00h.
Write the IGEE bit and the KEY [7:0] bits at the same time.

36.2.59 Receive Message Buffer Interrupt Enable Register (RMIER)

Address(es): CANFD.RMIER 000A 8038h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RMIE0	Receive Message Buffer 0 Interrupt Enable	0: Interrupt for receive message buffer 0 is disabled. 1: Interrupt for receive message buffer 0 is enabled.	R/W
b1	RMIE1	Receive Message Buffer 1 Interrupt Enable	0: Interrupt for receive message buffer 1 is disabled. 1: Interrupt for receive message buffer 1 is enabled.	R/W
b2	RMIE2	Receive Message Buffer 2 Interrupt Enable	0: Interrupt for receive message buffer 2 is disabled. 1: Interrupt for receive message buffer 2 is enabled.	R/W
b3	RMIE3	Receive Message Buffer 3 Interrupt Enable	0: Interrupt for receive message buffer 3 is disabled. 1: Interrupt for receive message buffer 3 is enabled.	R/W
b4	RMIE4	Receive Message Buffer 4 Interrupt Enable	0: Interrupt for receive message buffer 4 is disabled. 1: Interrupt for receive message buffer 4 is enabled.	R/W
b5	RMIE5	Receive Message Buffer 5 Interrupt Enable	0: Interrupt for receive message buffer 5 is disabled. 1: Interrupt for receive message buffer 5 is enabled.	R/W
b6	RMIE6	Receive Message Buffer 6 Interrupt Enable	0: Interrupt for receive message buffer 6 is disabled. 1: Interrupt for receive message buffer 6 is enabled.	R/W
b7	RMIE7	Receive Message Buffer 7 Interrupt Enable	0: Interrupt for receive message buffer 7 is disabled. 1: Interrupt for receive message buffer 7 is enabled.	R/W
b8	RMIE8	Receive Message Buffer 8 Interrupt Enable	0: Interrupt for receive message buffer 8 is disabled. 1: Interrupt for receive message buffer 8 is enabled.	R/W
b9	RMIE9	Receive Message Buffer 9 Interrupt Enable	0: Interrupt for receive message buffer 9 is disabled. 1: Interrupt for receive message buffer 9 is enabled.	R/W
b10	RMIE10	Receive Message Buffer 10 Interrupt Enable	0: Interrupt for receive message buffer 10 is disabled. 1: Interrupt for receive message buffer 10 is enabled.	R/W
b11	RMIE11	Receive Message Buffer 11 Interrupt Enable	0: Interrupt for receive message buffer 11 is disabled. 1: Interrupt for receive message buffer 11 is enabled.	R/W
b12	RMIE12	Receive Message Buffer 12 Interrupt Enable	0: Interrupt for receive message buffer 12 is disabled. 1: Interrupt for receive message buffer 12 is enabled.	R/W
b13	RMIE13	Receive Message Buffer 13 Interrupt Enable	0: Interrupt for receive message buffer 13 is disabled. 1: Interrupt for receive message buffer 13 is enabled.	R/W
b14	RMIE14	Receive Message Buffer 14 Interrupt Enable	0: Interrupt for receive message buffer 14 is disabled. 1: Interrupt for receive message buffer 14 is enabled.	R/W
b15	RMIE15	Receive Message Buffer 15 Interrupt Enable	0: Interrupt for receive message buffer 15 is disabled. 1: Interrupt for receive message buffer 15 is enabled.	R/W
b16	RMIE16	Receive Message Buffer 16 Interrupt Enable	0: Interrupt for receive message buffer 16 is disabled. 1: Interrupt for receive message buffer 16 is enabled.	R/W
b17	RMIE17	Receive Message Buffer 17 Interrupt Enable	0: Interrupt for receive message buffer 17 is disabled. 1: Interrupt for receive message buffer 17 is enabled.	R/W
b18	RMIE18	Receive Message Buffer 18 Interrupt Enable	0: Interrupt for receive message buffer 18 is disabled. 1: Interrupt for receive message buffer 18 is enabled.	R/W
b19	RMIE19	Receive Message Buffer 19 Interrupt Enable	0: Interrupt for receive message buffer 19 is disabled. 1: Interrupt for receive message buffer 19 is enabled.	R/W

Bit	Symbol	Bit Name	Description	R/W
b20	RMIE20	Receive Message Buffer 20 Interrupt Enable	0: Interrupt for receive message buffer 20 is disabled. 1: Interrupt for receive message buffer 20 is enabled.	R/W
b21	RMIE21	Receive Message Buffer 21 Interrupt Enable	0: Interrupt for receive message buffer 21 is disabled. 1: Interrupt for receive message buffer 21 is enabled.	R/W
b22	RMIE22	Receive Message Buffer 22 Interrupt Enable	0: Interrupt for receive message buffer 22 is disabled. 1: Interrupt for receive message buffer 22 is enabled.	R/W
b23	RMIE23	Receive Message Buffer 23 Interrupt Enable	0: Interrupt for receive message buffer 23 is disabled. 1: Interrupt for receive message buffer 23 is enabled.	R/W
b24	RMIE24	Receive Message Buffer 24 Interrupt Enable	0: Interrupt for receive message buffer 24 is disabled. 1: Interrupt for receive message buffer 24 is enabled.	R/W
b25	RMIE25	Receive Message Buffer 25 Interrupt Enable	0: Interrupt for receive message buffer 25 is disabled. 1: Interrupt for receive message buffer 25 is enabled.	R/W
b26	RMIE26	Receive Message Buffer 26 Interrupt Enable	0: Interrupt for receive message buffer 26 is disabled. 1: Interrupt for receive message buffer 26 is enabled.	R/W
b27	RMIE27	Receive Message Buffer 27 Interrupt Enable	0: Interrupt for receive message buffer 27 is disabled. 1: Interrupt for receive message buffer 27 is enabled.	R/W
b28	RMIE28	Receive Message Buffer 28 Interrupt Enable	0: Interrupt for receive message buffer 28 is disabled. 1: Interrupt for receive message buffer 28 is enabled.	R/W
b29	RMIE29	Receive Message Buffer 29 Interrupt Enable	0: Interrupt for receive message buffer 29 is disabled. 1: Interrupt for receive message buffer 29 is enabled.	R/W
b30	RMIE30	Receive Message Buffer 30 Interrupt Enable	0: Interrupt for receive message buffer 30 is disabled. 1: Interrupt for receive message buffer 30 is enabled.	R/W
b31	RMIE31	Receive Message Buffer 31 Interrupt Enable	0: Interrupt for receive message buffer 31 is disabled. 1: Interrupt for receive message buffer 31 is enabled.	R/W

This register enables or disables the interrupt for each receive message buffer.

RMIEn Bit (Receive Message Buffer n Interrupt Enable) (n = 0 to 31)

If the RMIEn bit is set to 1, an interrupt is generated when reception to the receive message buffer n is completed successfully.

Refer to section 36.10, Interrupts and DTC/DMA Requests for the specification of the receive message buffer interrupt.

This bit cannot be written when the CANFD module is in GL_SLEEP mode.

36.2.60 Identifier Bits Alignment

Base format (11-bit length identifier): ID-28 to ID-18 are located in b10 to b0, and b28 to b11 are 0.
Extended format (29-bit length identifier): ID-28 to ID-0 are located in b28 to b0

Table 36.4 Standard Identifier (11-bit format)

b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

36.2.61 Message Buffer Structure

The message buffer configuration consists of four types of message buffer:

- Receive message buffer (RMBn)
- Receive FIFO (RFBn)
- Common FIFO (CFB0)
- Transmit message buffer (TMBn)

n is a message buffer number whose range changes depending on the type of message buffer.
Refer to Figure 36.33 for an overview of this configuration. For more information on the number and types of message buffers, refer to section 36.6, FIFO Buffers and Message Buffer Configuration.

36.2.61.1 Start Addresses

The start address of each message buffer is calculated using the number of related message buffer components.
The start addresses for each register in the message buffer are listed in Table 36.6.

Table 36.6 Start Address for Each Register of the Message Buffer Component

Message Buffer	Symbol	n	Register	p	Start Address
Receive Message Buffer	RMBn	0 to 7	HF0	—	000A 8920h + n × 4Ch
			HF1	—	000A 8924h + n × 4Ch
			HF2	—	000A 8928h + n × 4Ch
			DFp	0 to 15	000A 892Ch + n × 4Ch + p × 4
	RMBn	8 to 15	HF0	—	000A 8D20h + (n – 8) × 4Ch
			HF1	—	000A 8D24h + (n – 8) × 4Ch
			HF2	—	000A 8D28h + (n – 8) × 4Ch
			DFp	0 to 15	000A 8D2Ch + (n – 8) × 4Ch + p × 4
	RMBn	16 to 23	HF0	—	000A 9120h + (n – 16) × 4Ch
			HF1	—	000A 9124h + (n – 16) × 4Ch
			HF2	—	000A 9128h + (n – 16) × 4Ch
			DFp	0 to 15	000A 912Ch + (n – 16) × 4Ch + p × 4
	RMBn	24 to 31	HF0	—	000A 9520h + (n – 24) × 4Ch
			HF1	—	000A 9524h + (n – 24) × 4Ch
			HF2	—	000A 9528h + (n – 24) × 4Ch
			DFp	0 to 15	000A 952Ch + (n – 24) × 4Ch + p × 4
Receive FIFO	RFBn	0, 1	HF0	—	000A 8520h + n × 4Ch
			HF1	—	000A 8524h + n × 4Ch
			HF2	—	000A 8528h + n × 4Ch
			DFp	0 to 15	000A 852Ch + n × 4Ch + p × 4
Common FIFO	CFB0	0	HF0	—	000A 85B8h
			HF1	—	000A 85BCh
			HF2	—	000A 85C0h
			DFp	0 to 15	000A 85C4h + p × 4
Transmit FIFO Buffer	TMBn	0 to 3	HF0	—	000A 8604h + n × 4Ch
			HF1	—	000A 8608h + n × 4Ch
			HF2	—	000A 860Ch + n × 4Ch
			DFp	0 to 15	000A 8610h + n × 4Ch + p × 4

36.2.61.2 Receive Message Buffer n (RMBn) (n = 0 to 31)

The total number of the receive message buffer (RMB) is 32, as shown in Figure 36.33.
The receive message buffer consists of the following registers:

- RMBn.HF0
- RMBn.HF1
- RMBn.HF2
- RMBn.DF0 to RMBn.DF15

Table 36.7 shows the structure of this buffer.

Table 36.7 Structure of Receive Message Buffer

Address Offset	Symbol	Register Name	Contents
+00h	RMBn.HF0	Receive Message Buffer n Header Field 0	IDE, RTR, ID
+04h	RMBn.HF1	Receive Message Buffer n Header Field 1	DLC, timestamp
+08h	RMBn.HF2	Receive Message Buffer n Header Field 2	Pointer, information label, FDF, BRS, ESI
+0Ch	RMBn.DF0	Receive Message Buffer n Data Field 0	DATA0 to DATA3
+10h	RMBn.DF1	Receive Message Buffer n Data Field 1	DATA4 to DATA7
+14h	RMBn.DF2	Receive Message Buffer n Data Field 2	DATA8 to DATA11
+18h	RMBn.DF3	Receive Message Buffer n Data Field 3	DATA12 to DATA15
+1Ch	RMBn.DF4	Receive Message Buffer n Data Field 4	DATA16 to DATA19
+20h	RMBn.DF5	Receive Message Buffer n Data Field 5	DATA20 to DATA23
+24h	RMBn.DF6	Receive Message Buffer n Data Field 6	DATA24 to DATA27
+28h	RMBn.DF7	Receive Message Buffer n Data Field 7	DATA28 to DATA31
+2Ch	RMBn.DF8	Receive Message Buffer n Data Field 8	DATA32 to DATA35
+30h	RMBn.DF9	Receive Message Buffer n Data Field 9	DATA36 to DATA39
+34h	RMBn.DF10	Receive Message Buffer n Data Field 10	DATA40 to DATA43
+38h	RMBn.DF11	Receive Message Buffer n Data Field 11	DATA44 to DATA47
+3Ch	RMBn.DF12	Receive Message Buffer n Data Field 12	DATA48 to DATA51
+40h	RMBn.DF13	Receive Message Buffer n Data Field 13	DATA52 to DATA55
+44h	RMBn.DF14	Receive Message Buffer n Data Field 14	DATA56 to DATA59
+48h	RMBn.DF15	Receive Message Buffer n Data Field 15	DATA60 to DATA63

36.2.61.3 Receive Message Buffer n Header Field 0 (RMBn.HF0) (n = 0 to 31)

Address(es): CANFD.RMB0.HF0 000A 8920h, CANFD.RMB1.HF0 000A 896Ch, CANFD.RMB2.HF0 000A 89B8h, CANFD.RMB3.HF0 000A 8A04h, CANFD.RMB4.HF0 000A 8A50h, CANFD.RMB5.HF0 000A 8A9Ch, CANFD.RMB6.HF0 000A 8AE8h, CANFD.RMB7.HF0 000A 8B34h, CANFD.RMB8.HF0 000A 8D20h, CANFD.RMB9.HF0 000A 8D6Ch, CANFD.RMB10.HF0 000A 8DB8h, CANFD.RMB11.HF0 000A 8E04h, CANFD.RMB12.HF0 000A 8E50h, CANFD.RMB13.HF0 000A 8E9Ch, CANFD.RMB14.HF0 000A 8EE8h, CANFD.RMB15.HF0 000A 8F34h, CANFD.RMB16.HF0 000A 9120h, CANFD.RMB17.HF0 000A 916Ch, CANFD.RMB18.HF0 000A 91B8h, CANFD.RMB19.HF0 000A 9204h, CANFD.RMB20.HF0 000A 9250h, CANFD.RMB21.HF0 000A 929Ch, CANFD.RMB22.HF0 000A 92E8h, CANFD.RMB23.HF0 000A 9334h, CANFD.RMB24.HF0 000A 9520h, CANFD.RMB25.HF0 000A 956Ch, CANFD.RMB26.HF0 000A 95B8h, CANFD.RMB27.HF0 000A 9604h, CANFD.RMB28.HF0 000A 9650h, CANFD.RMB29.HF0 000A 969Ch, CANFD.RMB30.HF0 000A 96E8h, CANFD.RMB31.HF0 000A 9734h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	IDE	RTR	—	ID[28:16]

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ID[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	ID[28:0]	Identifier	Standard ID/extended ID field	R
b29	—	Reserved	This bit is read as 0	R
b30	RTR	Remote Transmission Request	0: Data frame 1: Remote frame	R
b31	IDE	Identifier Extension	0: Standard ID 1: Extended ID	R

This register stores the ID field, IDE bit, and RTR bit of the received message.

ID[28:0] Bits (Identifier)

The ID[28:0] bits store the standard or extended identifier field of message stored in the receive message buffer.
For alignment of these bits in base and extended format, refer to section 36.2.60, Identifier Bits Alignment.

RTR Bit (Remote Transmission Request)

The RTR bit stores the value of the RTR bit of the received message.
The RTR bit indicates whether the receive message buffer stores a data frame or a remote frame.

Note: There are no remote frames in CAN FD format. When a CAN FD frame is received, this bit reflects the value of the RRS bit.

IDE Bit (Identifier Extension)

The IDE bit stores the value of the IDE bit of the received message.
The IDE bit indicates whether the message stored in the receive message buffer has a standard identifier or extended identifier.

36.2.61.4 Receive Message Buffer n Header Field 1 (RMBn.HF1) (n = 0 to 31)

Address(es): CANFD.RMB0.HF1 000A 8924h, CANFD.RMB1.HF1 000A 8970h, CANFD.RMB2.HF1 000A 89BCh, CANFD.RMB3.HF1 000A 8A08h, CANFD.RMB4.HF1 000A 8A54h, CANFD.RMB5.HF1 000A 8AA0h, CANFD.RMB6.HF1 000A 8AECh, CANFD.RMB7.HF1 000A 8B38h, CANFD.RMB8.HF1 000A 8D24h, CANFD.RMB9.HF1 000A 8D70h, CANFD.RMB10.HF1 000A 8DBCh, CANFD.RMB11.HF1 000A 8E08h, CANFD.RMB12.HF1 000A 8E54h, CANFD.RMB13.HF1 000A 8EA0h, CANFD.RMB14.HF1 000A 8EECh, CANFD.RMB15.HF1 000A 8F38h, CANFD.RMB16.HF1 000A 9124h, CANFD.RMB17.HF1 000A 9170h, CANFD.RMB18.HF1 000A 91BCh, CANFD.RMB19.HF1 000A 9208h, CANFD.RMB20.HF1 000A 9254h, CANFD.RMB21.HF1 000A 92A0h, CANFD.RMB22.HF1 000A 92ECh, CANFD.RMB23.HF1 000A 9338h, CANFD.RMB24.HF1 000A 9524h, CANFD.RMB25.HF1 000A 9570h, CANFD.RMB26.HF1 000A 95BCh, CANFD.RMB27.HF1 000A 9608h, CANFD.RMB28.HF1 000A 9654h, CANFD.RMB29.HF1 000A 96A0h, CANFD.RMB30.HF1 000A 96ECh, CANFD.RMB31.HF1 000A 9738h

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TS[15:0]	Timestamp	Timestamp value stored for the message in the receive message buffer	R
b27 to b16	—	Reserved	These bits are read as 0	R
b31 to b28	DLC[3:0]	Data Length Code	Number of data bytes received in a CAN frame.	R

This register stores the data length code (DLC) and timestamp of the received message.

TS[15:0] Bits (Timestamp)

The TS[15:0] bits store the timestamp of the received message captured at the point specified by the GFDCFG.TSCPS[1:0] bits.

DLC[3:0] Bits (Data Length Code)

The DLC[3:0] bits store the number of data bytes of the received message.
Refer to Table 5 in ISO 11898-1:2015 Standard for details on defining the number of data bytes.

Note: The maximum number of data bytes in the buffer is specified by the RMCR.PLS[2:0] bits.

36.2.61.5 Receive Message Buffer n Header Field 2 (RMBn.HF2) (n = 0 to 31)

Address(es): CANFD.RMB0.HF2 000A 8928h, CANFD.RMB1.HF2 000A 8974h, CANFD.RMB2.HF2 000A 89C0h, CANFD.RMB3.HF2 000A 8A0Ch, CANFD.RMB4.HF2 000A 8A58h, CANFD.RMB5.HF2 000A 8AA4h, CANFD.RMB6.HF2 000A 8AF0h, CANFD.RMB7.HF2 000A 8B3Ch, CANFD.RMB8.HF2 000A 8D28h, CANFD.RMB9.HF2 000A 8D74h, CANFD.RMB10.HF2 000A 8DC0h, CANFD.RMB11.HF2 000A 8E0Ch, CANFD.RMB12.HF2 000A 8E58h, CANFD.RMB13.HF2 000A 8EA4h, CANFD.RMB14.HF2 000A 8EF0h, CANFD.RMB15.HF2 000A 8F3Ch, CANFD.RMB16.HF2 000A 9128h, CANFD.RMB17.HF2 000A 9174h, CANFD.RMB18.HF2 000A 91C0h, CANFD.RMB19.HF2 000A 920Ch, CANFD.RMB20.HF2 000A 9258h, CANFD.RMB21.HF2 000A 92A4h, CANFD.RMB22.HF2 000A 92F0h, CANFD.RMB23.HF2 000A 933Ch, CANFD.RMB24.HF2 000A 9528h, CANFD.RMB25.HF2 000A 9574h, CANFD.RMB26.HF2 000A 95C0h, CANFD.RMB27.HF2 000A 960Ch, CANFD.RMB28.HF2 000A 9658h, CANFD.RMB29.HF2 000A 96A4h, CANFD.RMB30.HF2 000A 96F0h, CANFD.RMB31.HF2 000A 973Ch

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ESI	Error State Indicator Flag	0: CAN FD frame received from error active node 1: CAN FD frame received from error passive node	R
b1	BRS	Bit Rate Switch Flag	0: CAN FD frame received with no bit rate switch 1: CAN FD frame received with bit rate switch	R
b2	FDF	FD Format Indicator Flag	0: Non CAN FD frame received 1: CAN FD frame received	R
b7 to b3	—	Reserved	These bits are read as 0	R
b9, b8	IFL[1:0]	Information Label	A field that stores the information label attached by the Acceptance Filter	R
b15 to b10	—	Reserved	These bits are read as 0	R
b31 to b16	PTR[15:0]	Pointer	A field that stores the pointer attached by the Acceptance Filter	R

This register stores the FDF bit, BRS bit, and ESI flag of the received message, and pointer for the received message.

ESI Flag (Error State Indicator Flag)

The ESI flag stores the value of the ESI flag of the received CAN FD frame.
When the received FDF bit is 0, this means a Classical CAN frame is received and 0 is stored to this flag.

BRS Flag (Bit Rate Switch Flag)

The BRS flag stores the value of the BRS bit of the received CAN FD frame.
When the received FDF bit is 0, this means a Classical CAN frame is received and 0 is stored to this flag.

FDF Flag (FD Format Indicator Flag)

The FDF flag stores the value of the FDF bit of the received CAN FD frame.

IFL[1:0] Bits (Information Label)

The IFL[1:0] bits store the information label value set in the corresponding entry in the acceptance filter list.

PTR[15:0] Bits (Pointer)

The PTR[15:0] bits store the pointer value set in the corresponding entry in the acceptance filter list.

36.2.61.6 Receive Message Buffer n Data Field p (RMBn.DFp) (n = 0 to 31; p = 0 to 15)

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

These registers are read-only registers that store the data bytes of the received message.
Unused data bytes are filled with 00h.

36.2.61.8 Receive FIFO n (RFBn) (n = 0, 1)

The total number of the receive FIFO (RFB) is two, as shown in Figure 36.33.
The receive FIFO consists of the following registers:

- RFBn.HF0
- RFBn.HF1
- RFBn.HF2
- RFBn.DF0 to RFBn.DF15

Table 36.8 shows the structure of this buffer.

Table 36.8 Structure of Receive FIFO

Address Offset	Symbol	Register Name	Contents
+00h	RFBn.HF0	Receive FIFO n Header Field 0	IDE, RTR, ID
+04h	RFBn.HF1	Receive FIFO n Header Field 1	DLC, timestamp
+08h	RFBn.HF2	Receive FIFO n Header Field 2	Pointer, information label, FDF, BRS, ESI
+0Ch	RFBn.DF0	Receive FIFO n Data Field 0	DATA0 to DATA3
+10h	RFBn.DF1	Receive FIFO n Data Field 1	DATA4 to DATA7

b29	—	Reserved	This bit is read as 0	R
b30	RTR	Remote Transmission Request	0: Data frame 1: Remote frame	R
b31	IDE	Identifier Extension	0: Standard ID 1: Extended ID	R

This register stores the ID field, IDE bit, and RTR bit of the received message.

ID[28:0] Bits (Identifier)

The ID[28:0] bits store the standard or extended identifier field of message stored in the receive FIFO.
For alignment of these bits in base and extended format, refer to section 36.2.60, Identifier Bits Alignment.

RTR Bit (Remote Transmission Request)

The RTR bit stores the value of the RTR bit of the received message.

Note: There are no remote frames in CAN FD format. When a CAN FD frame is received, this bit reflects the value of the RRS bit.

IDE Bit (Identifier Extension)

The IDE bit stores the value of the IDE bit of the received message.

36.2.61.10 Receive FIFO n Header Filed 1 (RFBn.HF1) (n = 0, 1)

b27 to b16	—	Reserved	These bits are read as 0	R
b31 to b28	DLC[3:0]	Data Length Code	Number of data bytes received in a CAN frame	R

This register stores the data length code (DLC) and timestamp of the received message.

TS[15:0] Bits (Timestamp)

The TS[15:0] bits store the timestamp of the received message captured at the point specified by the GFDCFG.TSCPS[1:0] bits.

DLC[3:0] Bits (Data Length Code)

The DLC[3:0] bits store the number of data bytes of the received message.
Refer to Table 5 in ISO 11898-1:2015 Standard for details on defining the number of data bytes.

Note: The maximum number of data bytes in the buffer is specified by the RFCRn.PLS[2:0] bits.

36.2.61.11 Receive FIFO n Header Field 2 (RFBn.HF2) (n = 0, 1)

b0	ESI	Error State Indicator Flag	0: CAN FD frame received from error active node 1: CAN FD frame received from error passive node	R
b1	BRS	Bit Rate Switch Flag	0: CAN FD frame received with no bit rate switch 1: CAN FD frame received with bit rate switch	R
b2	FDF	FD Format Indicator Flag	0: Non CAN FD frame received 1: CAN FD frame received	R
b7 to b3	—	Reserved	These bits are read as 0	R
b9, b8	IFL[1:0]	Information Label	A field that stores the information label attached by the Acceptance Filter	R
b15 to b10	—	Reserved	These bits are read as 0	R
b31 to b16	PTR[15:0]	Pointer	A field that stores the pointer attached by the Acceptance Filter	R

This register stores the FDF bit, BRS bit, and ESI flag of the received message, and pointer for the received message.

ESI Flag (Error State Indicator Flag)

The ESI flag stores the value of the ESI flag of the received CAN FD frame.
When the received FDF bit is 0, this means a Classical CAN frame is received and 0 is stored to this flag.

BRS Flag (Bit Rate Switch Flag)

The BRS flag stores the value of the BRS bit of the received CAN FD frame.
When the received FDF bit is 0, this means a Classical CAN frame is received and 0 is stored to this flag.

FDF Flag (FD Format Indicator Flag)

The FDF flag stores the value of the FDF bit of the received CAN FD frame.

IFL[1:0] Bits (Information Label)

The IFL[1:0] bits store the information label value set in the corresponding entry in the acceptance filter list.

PTR[15:0] Bits (Pointer)

The PTR[15:0] bits store the pointer value set in the corresponding entry in the acceptance filter list.

36.2.61.12 Receive FIFO n Data Field p (RFBn.DFp) (n = 0, 1; p = 0 to 15)

Address(es): CANFD.RFB0.DF0 000A 852Ch to CANFD.RFB0.DF15 000A 8568h,
CANFD.RFB1.DF0 000A 8578h to CANFD.RFB1.DF15 000A 85B4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

These registers are read-only registers that store the data byte (p × 4 + 3) to data byte (p × 4) of the received message.
Unused data bytes are filled with 00h.

36.2.61.13 Receive FIFO n Data Register k (RFBn.DATAk) (n = 0, 1; k = 0 to 63)

Address(es): CANFD.RFB0.DATA0 000A 852Ch to CANFD.RFB0.DATA63 000A 856Bh,
CANFD.RFB1.DATA0 000A 8578h to CANFD.RFB1.DATA63 000A 85B7h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

These registers are read-only registers that store the data bytes of the received message.
Unused data bytes are filled with 00h.

36.2.61.14 Common FIFO 0 (CFB0)

The total number of the common FIFO (CFB) is one, as shown in Figure 36.33.
The common FIFO consists of the following registers:

- CFB0.HF0
- CFB0.HF1
- CFB0.HF2
- CFB0.DF0 to CFB0.DF15

Table 36.9 shows the structure of this buffer.

Table 36.9 Structure of Common FIFO

Address Offset	Symbol	Register Name	Contents
+00h	CFB0.HF0	Common FIFO 0 Header Field 0	IDE, RTR, ID
+04h	CFB0.HF1	Common FIFO 0 Header Field 1	DLC, timestamp
+08h	CFB0.HF2	Common FIFO 0 Header Field 2	Pointer, information label, FDF, BRS, ESI
+0Ch	CFB0.DF0	Common FIFO 0 Data Field 0	DATA0 to DATA3
+10h	CFB0.DF1	Common FIFO 0 Data Field 1	DATA4 to DATA7
+14h	CFB0.DF2	Common FIFO 0 Data Field 2	DATA8 to DATA11
+18h	CFB0.DF3	Common FIFO 0 Data Field 3	DATA12 to DATA15
+1Ch	CFB0.DF4	Common FIFO 0 Data Field 4	DATA16 to DATA19
+20h	CFB0.DF5	Common FIFO 0 Data Field 5	DATA20 to DATA23
+24h	CFB0.DF6	Common FIFO 0 Data Field 6	DATA24 to DATA27
+28h	CFB0.DF7	Common FIFO 0 Data Field 7	DATA28 to DATA31
+2Ch	CFB0.DF8	Common FIFO 0 Data Field 8	DATA32 to DATA35
+30h	CFB0.DF9	Common FIFO 0 Data Field 9	DATA36 to DATA39
+34h	CFB0.DF10	Common FIFO 0 Data Field 10	DATA40 to DATA43
+38h	CFB0.DF11	Common FIFO 0 Data Field 11	DATA44 to DATA47
+3Ch	CFB0.DF12	Common FIFO 0 Data Field 12	DATA48 to DATA51
+40h	CFB0.DF13	Common FIFO 0 Data Field 13	DATA52 to DATA55
+44h	CFB0.DF14	Common FIFO 0 Data Field 14	DATA56 to DATA59
+48h	CFB0.DF15	Common FIFO 0 Data Field 15	DATA60 to DATA63

36.2.61.15 Common FIFO 0 Header Field 0 (CFB0.HF0)

Address(es): CANFD.CFB0.HF0 000A 85B8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	IDE	RTR	THENT	ID[28:16]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ID[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	ID[28:0]	Identifier	Standard ID/extended ID field	R/W
b29	THENT	Transmission History Entry	Receive FIFO mode: Reserved. This bit is read as 0. Transmit FIFO mode: 0: Entry is not stored to the Transmission History after successful transmission. 1: Entry is stored to the Transmission History after successful transmission.	R/W
b30	RTR	Remote Transmission Request	0: Data frame 1: Remote frame	R/W
b31	IDE	Identifier Extension	0: Standard ID 1: Extended ID	R/W

In receive FIFO mode, this register is a read-only register for reading the ID field, IDE bit, and RTR bit of the received message from the beginning of the FIFO buffer.
In transmit FIFO mode, this register is a read/write register for writing the ID field, IDE bit, and RTR bit of the message to be transmitted at the end of the FIFO buffer.

ID[28:0] Bits (Identifier)

In receive FIFO mode, the ID[28:0] bits store the standard or extended identifier field of the received message.
In transmit FIFO mode, the ID[28:0] bits are used to set the value of the standard or extended identifier field of the message to be transmitted.
For alignment of these bits in base and extended format, refer to section 36.2.60, Identifier Bits Alignment.

THENT Bit (Transmission History Entry)

This bit is valid only in transmit FIFO mode.
The THENT bit controls whether the corresponding entry is stored in the transmission history after a successful transmission of the message.

RTR Bit (Remote Transmission Request)

In receive FIFO mode, the RTR bit stores the value of the RTR bit of the received message.
In transmit FIFO mode, the RTR bit is used to specify the value of the RTR bit of the message to be transmitted.

Note: There are no remote frames in CAN FD format. When a CAN FD frame was received (receive mode), this bit reflects the value of the RRS bit. When transmitting a CAN FD frame (CFB0.HF2.FDF = 1), this bit is transmitted dominant regardless of the value of this bit.

IDE Bit (Identifier Extension)

In receive FIFO mode, the IDE bit stores the value of the IDE bit of the received message.
In transmit FIFO mode, the IDE bit is used to specify the value of the IDE bit of the message to be transmitted.

36.2.61.16 Common FIFO 0 Header Field 1 (CFB0.HF1)

Address(es): CANFD.CFB0.HF1 000A 85BCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DLC[3:0]				—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TS[15:0]	Timestamp	Timestamp value of the received CAN frame (in receive FIFO mode)	R/W
b27 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b28	DLC[3:0]	Data Length Code	Number of data bytes received in a CAN frame, or to be transmitted in a CAN frame	R/W

In receive FIFO mode, this register is a read-only register for reading the data length code (DLC) and timestamp of the received message from the beginning of the FIFO buffer.
In transmit FIFO mode, this register is a read/write register for writing the data length code (DLC) of the message to be transmitted at the end of the FIFO buffer.

TS[15:0] Bits (Timestamp)

These bits are valid only in receive FIFO mode.
The TS[15:0] bits store the timestamp of the received message captured at the point specified by the GFDCFG.TSCPS[1:0] bits.

DLC[3:0] Bits (Data Length Code)

In receive FIFO mode, the DLC[3:0] bits store the number of data bytes of the received message.
In transmit FIFO mode, The DLC[3:0] bits are used to specify the number of data bytes of the message to be transmitted.
Refer to Table 5 in ISO 11898-1:2015 Standard for details on defining the number of data bytes.

Note: The maximum number of data bytes in the buffer is specified by the CFCR0.PLS[2:0] bits.

36.2.61.17 Common FIFO 0 Header Field 2 (CFB0.HF2)

Address(es): CANFD.CFB0.HF2 000A 85C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	IFL[1:0]		—	—	—	—	—	FDF	BRS	ESI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ESI	Error State Indicator	0: CAN FD frame received or to transmit by error active node 1: CAN FD frame received or to transmit by error passive node	R/W
b1	BRS	Bit Rate Switch	0: CAN FD frame received or to transmit with no bit rate switch 1: CAN FD frame received or to transmit with bit rate switch	R/W
b2	FDF	FD Format Indicator	0: Non CAN FD frame received or to transmit 1: CAN FD frame received or to transmit	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	IFL[1:0]	Information Label	A field that stores the information label attached by the Acceptance Filter or sets the information label to be stored in the Transmission History	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b16	PTR[15:0]	Pointer	A field that stores the pointer attached by the Acceptance Filter or sets the pointer to be stored in the Transmission History	R/W

In receive FIFO mode, this register is a read-only register for reading the FDF bit, BRS bit, and ESI flag of the received message, and information label and pointer for the received message from the beginning of the FIFO buffer.
In transmit FIFO mode, this register is a read/write register for writing the FDF bit, BRS bit, and ESI flag of the message to be transmitted, and the information label and pointer to be stored in the transmission history at the end of the FIFO buffer.

ESI Bit (Error State Indicator)

In receive FIFO mode, the ESI bit stores the value of the ESI flag of the received CAN FD frame. When the received FDF bit is 0 (Classical CAN frame), 0 is stored to this bit.
In transmit FIFO mode, the ESI bit is used to specify the value of the ESI flag of the CAN FD frame to be transmitted. If the channel is not in error passive, the ESI flag of the transmitted message equals the value of this bit. If the channel is in error passive, this bit is transmitted recessive regardless of the value of this bit.

BRS Bit (Bit Rate Switch)

In receive FIFO mode, the BRS bit stores the value of the BRS bit of the received CAN FD frame. When the received FDF bit is 0 (Classical CAN frame), 0 is stored to this bit.
In transmit FIFO mode, the BRS bit is used to specify the value of the BRS bit of the CAN FD frame to be transmitted.

FDF Bit (FD Format Indicator)

In receive FIFO mode, the FDF bit stores the value of the FDF bit of the received CAN FD frame.
In transmit FIFO mode, the FDF bit is used to specify the value of the FDF bit of the CAN FD frame to be transmitted.

IFL[1:0] Bits (Information Label)

In receive FIFO mode, the IFL[1:0] bits store the information label value set in the corresponding entry in the acceptance filter list.
In transmit FIFO mode, the IFL[1:0] bits are used to specify the information label value to be stored in the transmission history after a successful transmission of the message.

PTR[15:0] Bits (Pointer)

In receive FIFO mode, the PTR[15:0] bits store the pointer value set in the corresponding entry in the acceptance filter list.
In transmit FIFO mode, the PTR[15:0] bits are used to specify the pointer value to be stored in the transmission history after a successful transmission of the message.

36.2.61.18 Common FIFO 0 Data Field p (CFB0.DFp) (p = 0 to 15)

Address(es): CANFD.CFB0.DF0 000A 85C4h to CANFD.CFB0.DF15 000A 8600h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

In receive FIFO mode, these registers are read-only registers for reading the data byte (p × 4 + 3) to data byte (p × 4) of the received message from the beginning of the FIFO buffer. Unused data bytes are filled with 00h.
In transmit FIFO mode, these registers are read/write registers for storing data byte (p × 4 + 3) to data byte (p × 4) of the message to be transmitted.

36.2.61.19 Common FIFO 0 Data Register k (CFB0.DATAk) (k = 0 to 63)

Address(es): CANFD.CFB0.DATA0 000A 85C4h to CANFD.CFB0.DATA63 000A 8603h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

In receive FIFO mode, these registers are read-only registers for reading the data bytes of the received message from the beginning of the FIFO buffer. Unused data bytes are filled with 00h.
In transmit FIFO mode, these registers are read/write registers for storing the data bytes of the message to be transmitted.

36.2.61.20 Transmit Message Buffer n (TMBn) (n = 0 to 3)

The total number of transmit message buffer (TMB) is four, as shown in Figure 36.33.
The transmit message buffer consists of the following registers:

- TMBn.HF0
- TMBn.HF1
- TMBn.HF2
- TMBn.DF0 to TMBn.DF15

Table 36.10 shows the structure of this buffer.

Table 36.10 Structure of Transmit Message Buffer

Address Offset	Symbol	Register Name	Contents
+00h	TMBn.HF0	Transmit Message Buffer n Header Field 0	IDE, RTR, ID
+04h	TMBn.HF1	Transmit Message Buffer n Header Field 1	DLC
+08h	TMBn.HF2	Transmit Message Buffer n Header Field 2	Pointer, information label, FDF, BRS, ESI
+0Ch	TMBn.DF0	Transmit Message Buffer n Data Field 0	DATA0 to DATA3
+10h	TMBn.DF1	Transmit Message Buffer n Data Field 1	DATA4 to DATA7
+14h	TMBn.DF2	Transmit Message Buffer n Data Field 2	DATA8 to DATA11
+18h	TMBn.DF3	Transmit Message Buffer n Data Field 3	DATA12 to DATA15
+1Ch	TMBn.DF4	Transmit Message Buffer n Data Field 4	DATA16 to DATA19
+20h	TMBn.DF5	Transmit Message Buffer n Data Field 5	DATA20 to DATA23
+24h	TMBn.DF6	Transmit Message Buffer n Data Field 6	DATA24 to DATA27
+28h	TMBn.DF7	Transmit Message Buffer n Data Field 7	DATA28 to DATA31
+2Ch	TMBn.DF8	Transmit Message Buffer n Data Field 8	DATA32 to DATA35
+30h	TMBn.DF9	Transmit Message Buffer n Data Field 9	DATA36 to DATA39
+34h	TMBn.DF10	Transmit Message Buffer n Data Field 10	DATA40 to DATA43
+38h	TMBn.DF11	Transmit Message Buffer n Data Field 11	DATA44 to DATA47
+3Ch	TMBn.DF12	Transmit Message Buffer n Data Field 12	DATA48 to DATA51
+40h	TMBn.DF13	Transmit Message Buffer n Data Field 13	DATA52 to DATA55
+44h	TMBn.DF14	Transmit Message Buffer n Data Field 14	DATA56 to DATA59
+48h	TMBn.DF15	Transmit Message Buffer n Data Field 15	DATA60 to DATA63

36.2.61.21 Transmit Message Buffer n Header Field 0 (TMBn.HF0) (n = 0 to 3)

Address(es): CANFD.TMB0.HF0 000A 8604h, CANFD.TMB1.HF0 000A 8650h, CANFD.TMB2.HF0 000A 869Ch, CANFD.TMB3.HF0 000A 86E8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	IDE	RTR	THENT	ID[28:16]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ID[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	ID[28:0]	Identifier	Standard ID/extended ID field	R/W
b29	THENT	Transmission History Entry	0: Entry is not stored in transmission history after successful transmission. 1: Entry is stored in transmission history after successful transmission.	R/W
b30	RTR	Remote Transmission Request	0: Data frame 1: Remote frame	R/W
b31	IDE	Identifier Extension	0: Standard ID 1: Extended ID	R/W

This register is used to store the ID field, IDE bit, and RTR bit of the message to be transmitted, and to specify whether to store it in the transmission history.
Do not write to this register when the CAN channel is in CH_SLEEP mode.

ID[28:0] Bits (Identifier)

The ID[28:0] bits are used to set the value of the standard or extended identifier field of the message stored in the transmit message buffer.
For alignment of these bits in base and extended format, refer to section 36.2.60, Identifier Bits Alignment.

THENT Bit (Transmission History Entry)

The THENT bit controls whether the corresponding entry is stored in the transmission history after a successful transmission of the message stored in the transmit message buffer.

RTR Bit (Remote Transmission Request)

The RTR bit is used to specify the value of the RTR bit of the message to be transmitted.

Note: There are no remote frames in CAN FD format. When transmitting a CAN FD frame (TMBn.HF2.FDF = 1), this bit is transmitted dominant regardless of the value of this bit.

IDE Bit (Identifier Extension)

The IDE bit is used to specify the value of the IDE bit of the message to be transmitted.

36.2.61.22 Transmit Message Buffer n Header Field 1 (TMBn.HF1) (n = 0 to 3)

Address(es): CANFD.TMB0.HF1 000A 8608h, CANFD.TMB1.HF1 000A 8654h, CANFD.TMB2.HF1 000A 86A0h, CANFD.TMB3.HF1 000A 86ECh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DLC[3:0]				—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b27 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b28	DLC[3:0]	Data Length Code	Number of data bytes to be transmitted in a CAN frame.	R/W

This register is used to store the data length code (DLC) fields of the message to be transmitted.
Do not write to this register when the CAN channel is in CH_SLEEP mode.

DLC[3:0] Bits (Data Length Code)

The DLC[3:0] bits are used to specify the number of data bytes of the message to be transmitted when the corresponding TMBn.HF0.RTR bit is set to 0.
Refer to Table 5 in ISO 11898-1:2015 Standard for details on defining the number of data bytes.

36.2.61.23 Transmit Message Buffer n Header Field 2 (TMBn.HF2) (n = 0 to 3)

Address(es): CANFD.TMB0.HF2 000A 860Ch, CANFD.TMB1.HF2 000A 8658h, CANFD.TMB2.HF2 000A 86A4h, CANFD.TMB3.HF2 000A 86F0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	IFL[1:0]		—	—	—	—	—	FDF	BRS	ESI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ESI	Error State Indicator	0: CAN FD frame to transmit by error active node 1: CAN FD frame to transmit by error passive node	R/W
b1	BRS	Bit Rate Switch	0: CAN FD frame to transmit with no bit rate switch 1: CAN FD frame to transmit with bit rate switch	R/W
b2	FDF	FD Format Indicator	0: Non CAN FD frame to transmit 1: CAN FD frame to transmit	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	IFL[1:0]	Information Label	A field that sets the information label to be stored in the Transmission History	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b16	PTR[15:0]	Pointer	A field that sets the pointer to be stored in the Transmission History	R/W

This register is used to store the FDF bit, BRS bit, and ESI flag of the message to be transmitted, and the information label and pointer to be stored in the transmission history.
Do not write to this register when the CAN channel is in CH_SLEEP mode.

ESI Bit (Error State Indicator)

The ESI bit is used to specify the value of the ESI flag of the CAN FD frame to be transmitted.
If the channel is not in error passive, the ESI flag of the transmitted message equals the value of this bit. If the channel is in error passive, this bit is transmitted recessive regardless of the value of this bit.

BRS Bit (Bit Rate Switch)

The BRS bit is used to specify the value of the BRS bit of the CAN FD frame to be transmitted.

FDF Bit (FD Format Indicator)

The FDF bit is used to specify the value of the FDF bit of the CAN FD frame to be transmitted.

IFL[1:0] Bits (Information Label)

The IFL[1:0] bits are used to specify the information label value to be stored in the transmission history after a successful transmission of the message.

PTR[15:0] Bits (Pointer)

The PTR[15:0] bits are used to specify the pointer value to be stored in the transmission history after a successful transmission of the message.

36.2.61.24 Transmit Message Buffer n Data Field p (TMBn.DFp) (n = 0 to 3; p = 0 to 15)

Address(es): CANFD.TMB0.DF0 000A 8610h to CANFD.TMB0.DF15 000A 864Ch,
CANFD.TMB1.DF0 000A 865Ch to CANFD.TMB1.DF15 000A 8698h,
CANFD.TMB2.DF0 000A 86A8h to CANFD.TMB2.DF15 000A 86E4h,
CANFD.TMB3.DF0 000A 86F4h to CANFD.TMB3.DF15 000A 8730h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

These registers are read/write registers for storing data byte (p × 4 + 3) to data byte (p × 4) of the message to be transmitted.
Do not write to these registers when the CAN channel is in CH_SLEEP mode.

36.2.61.25 Transmit Message Buffer n Data Register k (TMBn.DATAk) (n = 0 to 3; k = 0 to 63)

Address(es): CANFD.TMB0.DATA0 000A 8610h to CANFD.TMB0.DATA63 000A 864Fh,
CANFD.TMB1.DATA0 000A 865Ch to CANFD.TMB1.DATA63 000A 869Bh,
CANFD.TMB2.DATA0 000A 86A8h to CANFD.TMB2.DATA63 000A 86E7h,
CANFD.TMB3.DATA0 000A 86F4h to CANFD.TMB3.DATA63 000A 8733h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

These registers are read/write registers for storing the data bytes of the message to be transmitted.
Do not write to these registers when the CAN channel is in CH_SLEEP mode.

36.2.62 ECC Control/Status Register (ECCSR)

Address(es): CANFD.ECCSR 000E D000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EC2EAS	EC1EAS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ECEF	ECC Error Flag	0: These is no ECC error in the last read RAM data. 1: There is an ECC error in the last read RAM data.	R
b1	EC1EF	1-Bit ECC Error Detection Flag	0: 1-bit ECC error is not detected. 1: 1-bit ECC error is detected.	R
b2	EC2EF	2-Bit ECC Error Detection Flag	0: 2-bit ECC error is not detected. 1: 2-bit ECC error is detected.	R
b3	EC1EIE	1-Bit ECC Error Detection Interrupt Enable	0: 1-bit ECC error detection interrupt is disabled. 1: 1-bit ECC error detection interrupt is enabled.	R/W
b4	EC2EIE	2-Bit ECC Error Detection Interrupt Enable	0: 2-bit ECC error detection interrupt is disabled. 1: 2-bit ECC error detection interrupt is enabled.	R/W
b5	EC1ECD	1-Bit ECC Error Correction Disable	0: At 1-bit ECC error detection, the error correction is executed. 1: At 1-bit ECC error detection, the error correction is not executed.	R/W
b6	ECEDE	ECC Error Detection Enable	0: ECC error detection is disabled. 1: ECC error detection is enabled.	R/W
b8, b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9	EC1EC	EC1EF Flag Clear	Writing 1 to this bit clears the EC1EF flag. Writing 0 is ignored. This bit is read as 0.	R/W
b10	EC2EC	EC2EF Flag Clear	Writing 1 to this bit clears the EC2EF flag. Writing 0 is ignored. This bit is read as 0.	R/W
b11	ECOVF	ECC Overflow Detection Flag	0: The ECEAR register overflow has not occurred. 1: The ECEAR register overflow has occurred.	R
b13, b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15, b14	ECEDWC[1:0]	ECEDE Bit Write Control	Enables or disables write access to the ECEDE bit.	R/W
b16	EC1EAS	1-Bit ECC Error Detected Address Stored Flag	0: No valid address is stored in the ECEAR register. 1: The address where 1-bit ECC error occurred is stored in the ECEAR register.	R
b17	EC2EAS	2-Bit ECC Error Detected Address Stored Flag	0: No valid address is stored in the ECEAR register. 1: The address where 2-bit ECC error occurred is stored in the ECEAR register.	R
b31 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ECEF Flag (ECC Error Flag)

The ECEF flag indicates whether there is an ECC error in the last read RAM data. This flag is updated each time the RAM is read.

If the ECEDE bit is set to 1 without initializing the RAM, the value of this flag has no meaning.

[Setting condition]

- If there is an ECC error in read RAM data when the ECEDE bit is set to 1 (ECC error detection is enabled)

[Clearing condition]

- Under the condition that there is no ECC error in read RAM data
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

EC1EF Flag (1-Bit ECC Error Detection Flag)

The EC1EF flag indicates that the 1-bit ECC error is detected in the RAM read data.
When the 1-bit ECC error interrupt is enabled and this flag is set to 1, the 1-bit ECC error interrupt (EC1EI) is generated.
When the 1-bit ECC error is detected again under the condition that this flag is set to 1, the interrupt is not generated.

[Setting condition]

- If there is a 1-bit ECC error in read RAM data when the ECEDE bit is set to 1 (ECC error detection is enabled)

[Clearing condition]

- Writing 1 to the EC1EC bit
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

If writing 1 to the EC1EC bit and detecting a 1-bit ECC error occur at the same time, the EC1EF flag becomes 0.

EC2EF Flag (2-Bit ECC Error Detection Flag)

The EC2EF flag indicates that the 2-bit ECC error is detected in the RAM read data.
When the 2-bit ECC error interrupt is enabled and this flag is set to 1, the 2-bit ECC error interrupt (EC2EI) is generated.
When the 2-bit ECC error is detected again under the condition that this flag is set to 1, the interrupt is not generated.

[Setting condition]

- If there is a 2-bit ECC error in read RAM data when the ECEDE bit is set to 1 (ECC error detection is enabled)

[Clearing condition]

- Writing 1 to the EC2EC bit
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

If writing 1 to the EC2EC bit and detecting a 2-bit ECC error occur at the same time, the EC2EF flag becomes 0.

EC1EIE Bit (1-Bit ECC Error Detection Interrupt Enable)

The EC1EIE bit enables or disables a 1-bit ECC error detection interrupt.
If the EC1EF flag becomes 1 when this bit is 1, a 1-bit ECC error detection interrupt (EC1EI) is generated.

EC2EIE Bit (2-Bit ECC Error Detection Interrupt Enable)

The EC2EIE bit enables or disables a 2-bit ECC error detection interrupt.
If the EC2EF flag becomes 1 when this bit is 1, a 2-bit ECC error detection interrupt (EC2EI) is generated.

EC1ECD Bit (1-Bit ECC Error Correction Disable)

The EC1ECD bit enables or disables to correct the 1-bit ECC error when the ECEDE bit is set to 1 (ECC error detection is enabled). When this bit is set to 1, the RAM output data is not corrected even if a 1-bit ECC error is detected.

ECEDE Bit (ECC Error Detection Enable)

Setting the ECEDE bit to 1 enables ECC error detection.
Writing to this bit is valid only when the ECEDWC[1:0] bits are set to 01b.

EC1EC Bit (EC1EF Flag Clear)

The EC1EC bit is used to clear the EC1EF flag.
The EC1EF flag is cleared by writing 1 to this bit while the EC1EF flag is set to 1. Additionally, the ECOVF flag, EC1EAS flag, and EC2EAS flag are also cleared.
If the EC1EF flag is cleared by the EC1EC bit and the setting factor of the EC1EF flag occurs at the same time, the

EC1EF flag becomes 0.

EC2EC Bit (EC2EF Flag Clear)

The EC2EC bit is used to clear the EC2EF flag.
The EC2EF flag is cleared by writing 1 to this bit while the EC2EF flag is set to 1. Additionally, the ECOVF flag, EC1EAS flag, and EC2EAS flag are also cleared.
If the EC2EF flag is cleared by the EC2EC bit and the setting factor of the EC2EF flag occurs at the same time, the EC2EF flag becomes 0.

ECOVF Flag (ECC Overflow Detection Flag)

If a new ECC error is detected and the address is overwritten when the address is already stored in the ECEAR register, the ECOVF flag becomes 1 and an ECC overflow interrupt (ECOVI) is generated.
The ECC overflow interrupt is generated again when this flag is set to 1 and new ECC error is detected.

[Setting condition]

- When new error address is captured under the condition that error address is already captured in the ECEAR register.

[Clearing condition]

- Writing 1 to the EC1EC bit
- Writing 1 to the EC2EC bit
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

If the ECOVF flag is cleared by the EC1EC or EC2EC bit and the setting condition of the ECOVF flag occurs at the same time, the ECOVF flag becomes 0.

ECEDWC[1:0] Bits (ECEDE Bit Write Control)

The ECEDWC[1:0] bits are used to enable or disable write access to the ECEDE bit. The read value is always 00b.
When the value of these bits is 01b, it is possible to have write access to the ECEDE bit. If these bits are other than 01b, write access to the ECEDE bit is ignored and the value does not change.

EC1EAS Flag (1-Bit ECC Error Detected Address Stored Flag)

The EC1EAS flag indicates that the address where the 1-bit ECC error occurred is stored in the ECEAR register when the ECEDE bit is set to 1 (ECC error detection is enabled).
When 1-bit ECC error is detected while the 2-bit ECC error address has already been captured in the ECEAR register, the ECEAR register is not updated and this flag is not updated.

[Setting condition]

- When a 1-bit ECC error is detected under the condition that the ECEDE bit is set to 1 (ECC error detection is enabled), and the address is stored in the ECEAR register

[Clearing condition]

- Writing 1 to the EC1EC bit
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

If the EC1EAS flag is cleared by the EC1EC bit and the setting factor of the EC1EAS flag occurs at the same time, the EC1EAS flag becomes 0.

EC2EAS Flag (2-Bit ECC Error Detected Address Stored Flag)

The EC2EAS flag indicates that the address where the 2-bit ECC error occurred is stored in the ECEAR register when the ECEDE bit is set to 1 (ECC error detection is enabled).
When 2-bit ECC error is detected while the 1-bit ECC error address has already been captured in the ECEAR register, the ECEAR register is updated and this flag becomes 1.

[Setting condition]

- When a 2-bit ECC error is detected under the condition that the ECEDE bit is set to 1 (ECC error detection is enabled), and the address is stored in the ECEAR register

[Clearing condition]

- Writing 1 to the EC2EC bit
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

If the EC2EAS flag is cleared by the EC2EC bit and the setting factor of the EC2EAS flag occurs at the same time, the EC2EAS flag becomes 0.

36.2.63 ECC Test Mode Register (ECTMR)

Address(es): CANFD.ECTMR 000E D004h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ECTMWC[1:0]		—	—	—	—	—	—	ECTME	—	—	—	—	—	ECDIS	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	ECDIS	ECC Decoder Input Select	0: Input RAM output data to data input of decode circuit 1: Select the ECTDR register to data input of decode circuit	R/W
b6 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	ECTME	ECC Test Mode Enable	0: Access to the ECDIS bit and the ECTDR register is disabled 1: Access to the ECDIS bit and the ECTDR register is enabled	R/W
b13 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15, b14	ECTMWC[1:0]	ECTME Bit Write Control	Enable or disable write access to the ECTME bit.	R/W

ECDIS Bit (ECC Decoder Input Select)

The ECDIS bit selects which of the data value read from RAM and the value of the ECTDR register is used as input data to the ECC decoder.

The write access to this bit is enabled when the ECTME bit is set to 1. It is also possible to set them at the same time.

This bit is cleared by setting the ECTME bit to 0.

ECTME Bit (ECC Test Mode Enable)

The ECTME bit is used to enable or disable the access to the ECDIS bit and the ECTDR register.

This bit can be written only when the ECTMWC[1:0] bits is set to 10b.

ECTMWC[1:0] Bits (ECTME Bit Write Control)

The ECTMWC[1:0] bits are used to enable or disable the write access to the ECTME bit. The read value is always 00b.

When the value of these bits is 10b, it is possible to have write access to the ECTME bit. If these bits are other than 10b, write access to the ECTME bit is ignored and the value does not change.

36.2.64 ECC Decoder Test Data Register (ECTDR)

Address(es): CANFD.ECTDR 000E D00Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to set the data for testing the ECC decode.
When the ECTMR.ECTME bit is set to 1, this register can be read and written.
When the ECTMR.ECTME bit is set to 0, the value of this register becomes 00000000h.
When the ECTMR.ECDIS bit is set to 1, the value set in this register is used as the input data of the ECC decoder instead of the data read from RAM.

36.2.65 ECC Error Address Register (ECEAR)

Address(es): CANFD.ECEAR 000E D010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register holds the address where the ECC error occurred.

If an ECC error is detected when the ECCSR.ECEDE bit is 1 (ECC error detection is enabled), b12 to b2 of the RAM address are stored in b10 to b0 of this register.
If the same error occurred again, this register is not updated.
If a 2-bit ECC error is detected while the address where the 1-bit ECC error occurred is already stored, the ECEAR register is overwritten with the new address and the ECCSR.EC2EAS flag is set to 1.
If a 1-bit ECC error is detected while the address where the 2-bit ECC error occurred is already stored, the ECEAR register is not updated and the ECCSR.EC1EAS flag is not updated.

36.3 Operating Mode

The operating modes of the CANFD module can be classified into two groups:

- Global modes
- Channel modes.

36.3.1 Global Modes

These modes are applicable for the complete CANFD module and therefore are called Global modes.
The Global modes of the CANFD module are:

- GL_SLEEP
- GL_RESET
- GL_HALT
- GL_OPERATION.

Figure 36.2 shows the possible transitions between the Global modes.

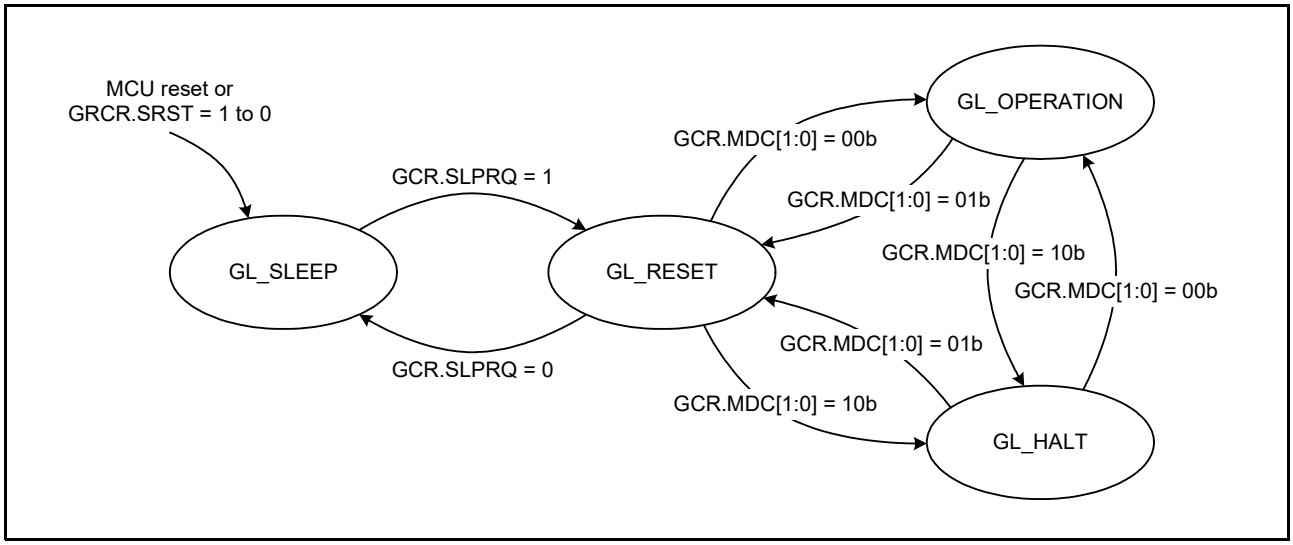

Figure 36.2 Transition between CANFD Global Modes

Change in the Global mode can affect the Channel mode. For details, refer to section 36.3.3, Global Mode and Channel Mode Transition Interactions.

36.3.1.1 GL_SLEEP Mode

The CANFD module automatically enters GL_SLEEP mode when the MCU reset is released or the software reset bit (GRCR.SRST) is changed from 1 to 0.
The CANFD module also enters the GL_SLEEP mode when the GCR.SLPRQ bit is set to 1 while it is in GL_RESET mode. The SLPRQ bit cannot be set to 1 in GL_HALT or GL_OPERATION mode.
Setting the GCR.SLPRQ bit to 1 sets the CHCR.SLPRQ bit to 1 and forces CAN channel into the CH_SLEEP mode.
GL_SLEEP mode is used for power saving purpose. When CANFD module is in GL_SLEEP mode, only the clock for writing to the SLPRQ bit is active. All other clocks are stopped and all other functions of the CANFD module are suspended.
Read access from all registers is still possible and all register values are preserved.
After setting the GCR.SLPRQ bit to 1, it is necessary to confirm the GSR.SLPST flag that the GL_SLEEP status has been updated, indicating successful transition to GL_SLEEP mode before the GCR.SLPRQ bit can be cleared again.

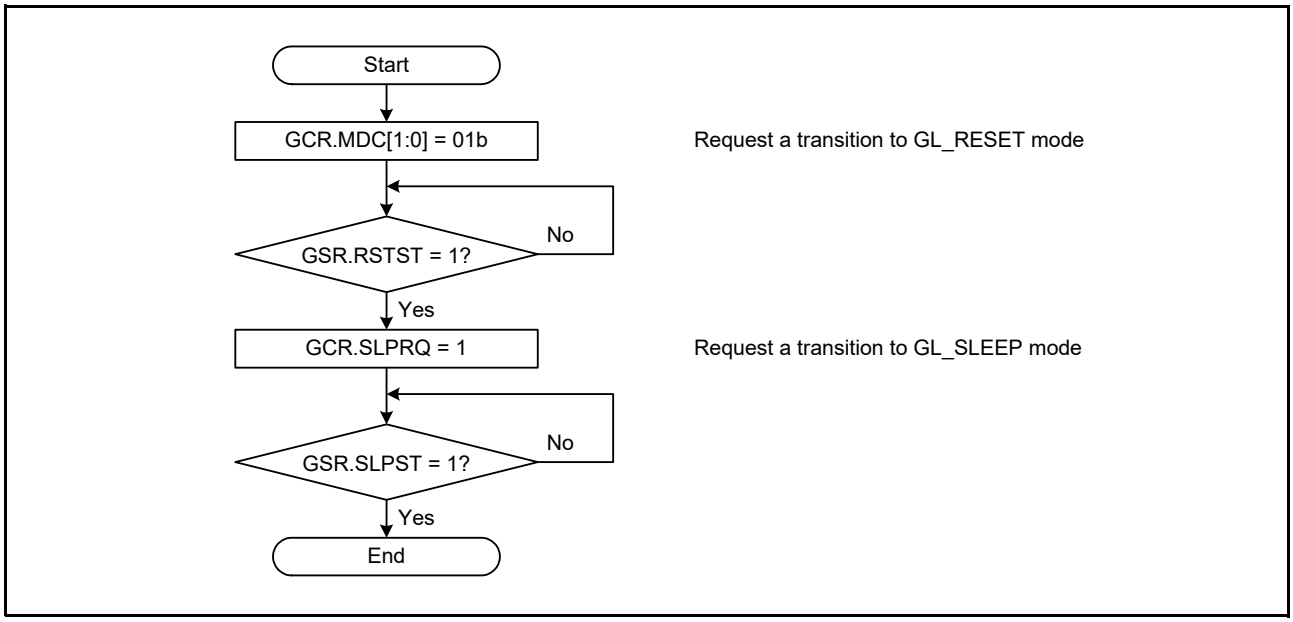

Figure 36.3 Procedure for Entering GL_SLEEP Mode

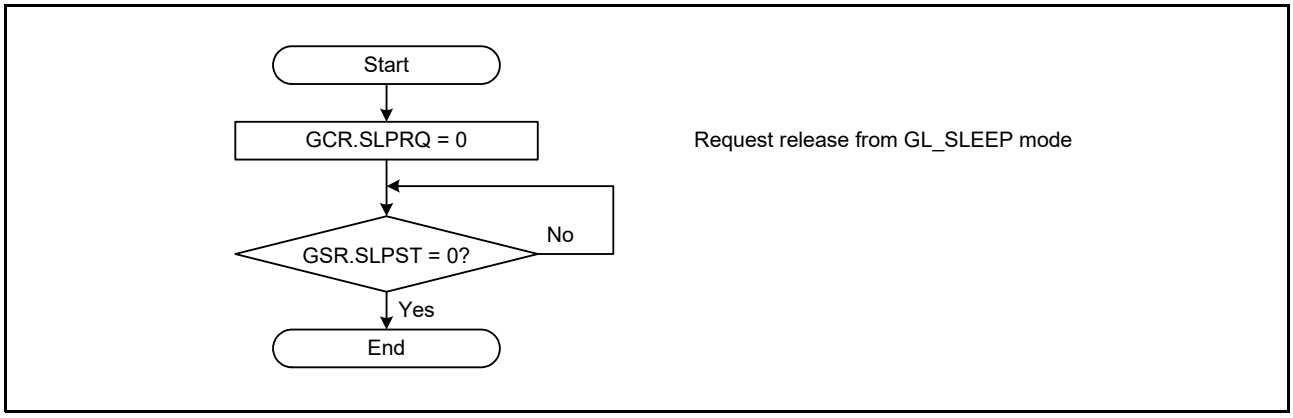

Figure 36.4 Procedure for Exiting GL_SLEEP Mode

36.3.1.2 GL_RESET Mode

The CANFD module enters GL_RESET mode in the following ways:

- The GCR.MDC[1:0] bits are set to 01b while the CANFD module is in GL_HALT or GL_OPERATION mode
- The GCR.SLPRQ bit is set to 0 while the CANFD module is in GL_SLEEP mode.

In GL_RESET mode, all CANFD module functions are suspended and all status and flag registers are initialized. Additionally all FIFOs and all transmit queues are disabled and transmission control bits are cleared.
In this mode, configuration registers other than the GTMCR register and interrupt enable registers are not initialized, so the CANFD module can be configured.
Setting the Global mode to GL_RESET by setting the GCR.MDC[1:0] bits to 01b sets the CHCR.MDC[1:0] bits to 01b and forces the channel into the CH_RESET mode.
When the channel is already in CH_RESET or CH_SLEEP mode, this automatic transition is not performed.
After setting the GCR.MDC[1:0] bits to 01b (GL_RESET mode), it is necessary to confirm that the GSR.RSTST flag has been updated, indicating successful transition to GL_RESET mode before the GCR.MDC[1:0] bits can be changed again.

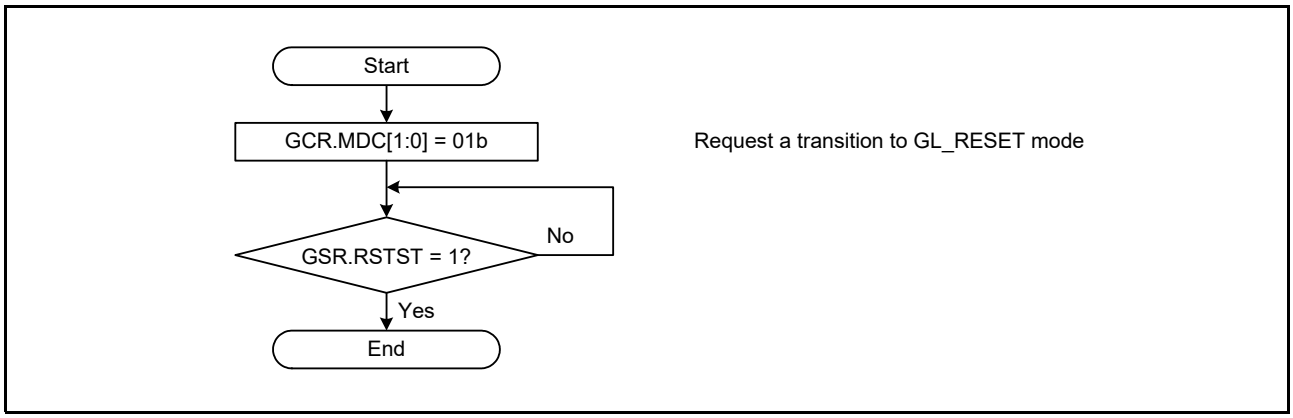

Figure 36.5 Procedure for Entering GL_RESET Mode

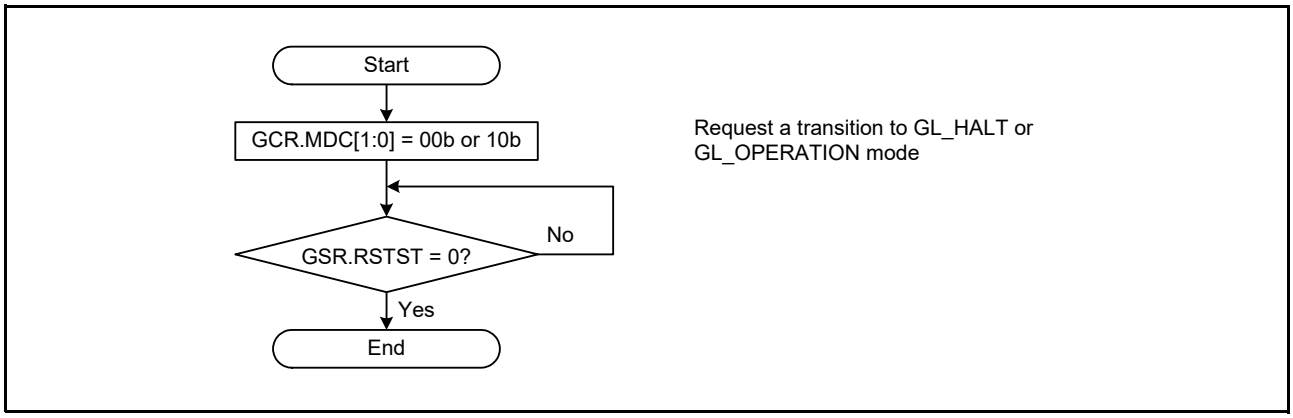

Figure 36.6 Procedure for Exiting GL_RESET Mode

36.3.1.3 GL_HALT Mode

The CANFD module enters GL_HALT mode in the following ways:

- Set the GCR.MDC[1:0] bits to 10b while the CANFD module is in GL_RESET mode:
  – the channels is in either CH_RESET or CH_SLEEP mode and remains in this mode.
- Set the GCR.MDC[1:0] bits to 10b while the CANFD module is in GL_OPERATION mode:
  – CAN channel in CH_RESET, CH_HALT, or CH_SLEEP mode remains in this mode
  – CAN channel in CH_OPERATION mode transits to CH_HALT mode
  – the GSR.HLTST flag is set to 1 when CAN channel exits CH_OPERATION mode.

If a transmission or reception is in progress for a CAN channel, the channel enters CH_HALT mode after waiting for completion of the communication.
Similarly, if a CAN channel is in bus-off, the channel may not enter CH_HALT mode until the bus-off recovery sequence is completed, depending on the channel configuration.
In GL_HALT mode, all communications are suspended and the status and flag registers do not change (only when a channel is in the bus-off, its CHSR.REC[7:0] and TEC[7:0] bits are set to 00h).
Additionally, the GTMCR register and GTMER register are not initialized in this mode. The GL_HALT mode is used to configure Global Test Modes.
Setting the Global mode to GL_HALT by setting the GCR.MDC[1:0] bits to 10b sets the CHCR.MDC[1:0] bits to 10b for the channels that are in CH_OPERATION mode and forces these channels into the CH_HALT mode.
For channels that are already in CH_RESET, CH_HALT, or CH_SLEEP mode, this automatic transition is not performed.
Therefore, the GL_HALT mode request can be used to shut down all CAN channel communications without loss of messages and disruption on the related CAN bus (no interruption of reception/transmission processes on the channels).
After setting the GCR.MDC[1:0] bits to 10b (GL_HALT mode), it is necessary to confirm that the GSR.HLTST flag has been updated to indicate a successful transition to GL_HALT mode. Do not set any other registers until confirming the GSR.HLTST flag is set.

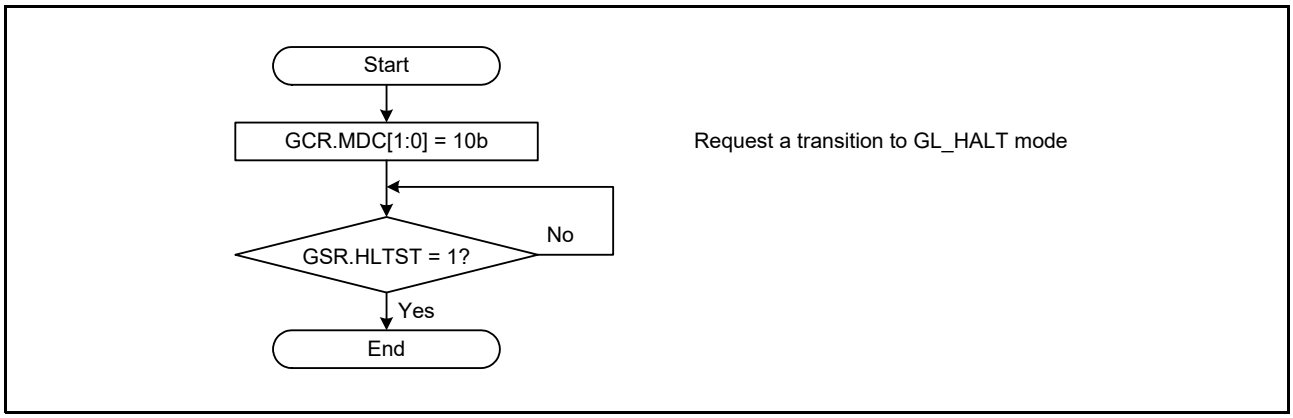

Figure 36.7 Procedure for Entering GL_HALT Mode

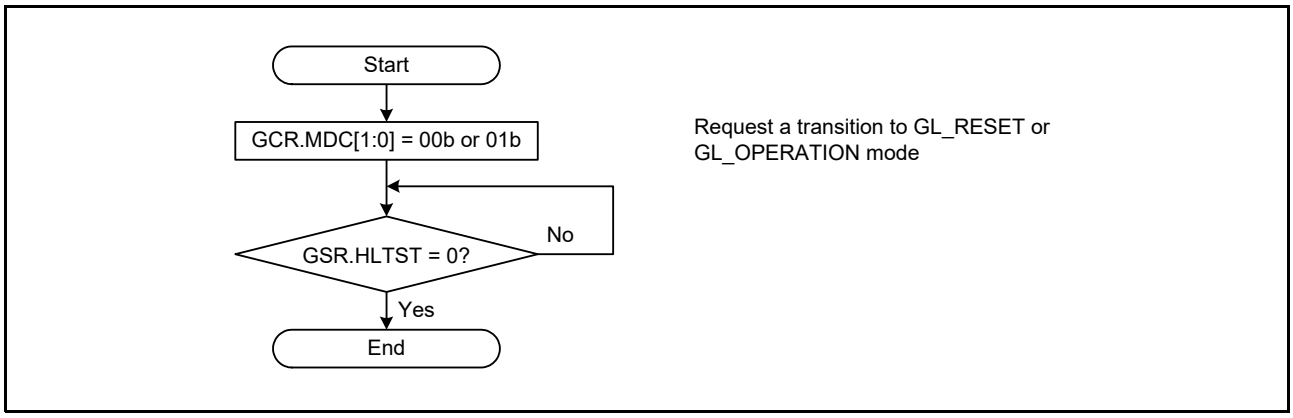

Figure 36.8 Procedure for Exiting GL_HALT Mode

36.3.1.4 GL_OPERATION Mode

The CANFD module enters this mode when the GCR.MDC[1:0] bits are set to 00b.
The CANFD channel can be set to CH_OPERATION mode and start CAN communication only when CANFD is in GL_OPERATION mode.
After setting the GCR.MDC[1:0] bits to 00b (GL_OPERATION mode), it is necessary to confirm that the GSR.RSTST flag and the GSR.HLTST flag have been set to 0 to indicate a successful transition to GL_OPERATION mode before the GCR.MDC[1:0] bits can be modified again.

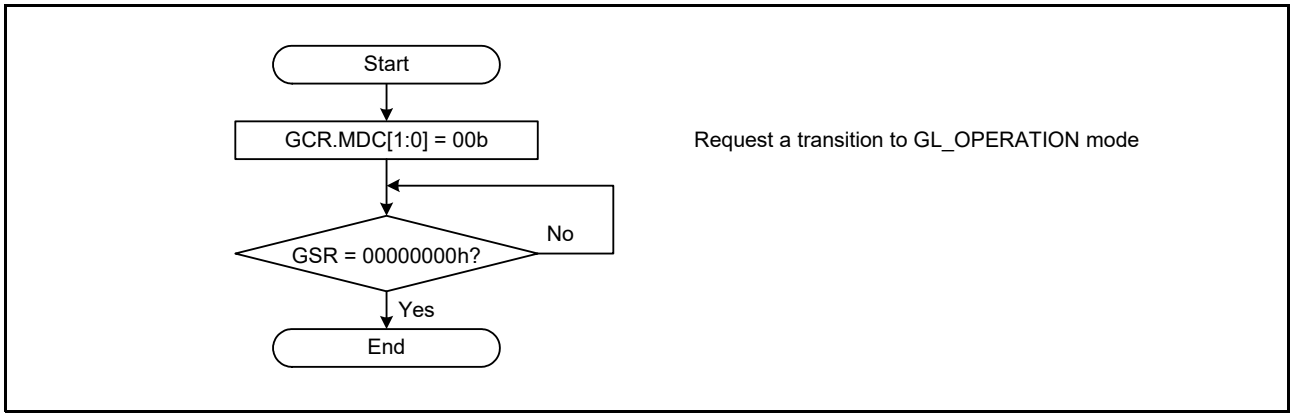

Figure 36.9 Procedure for Entering GL_OPERATION Mode

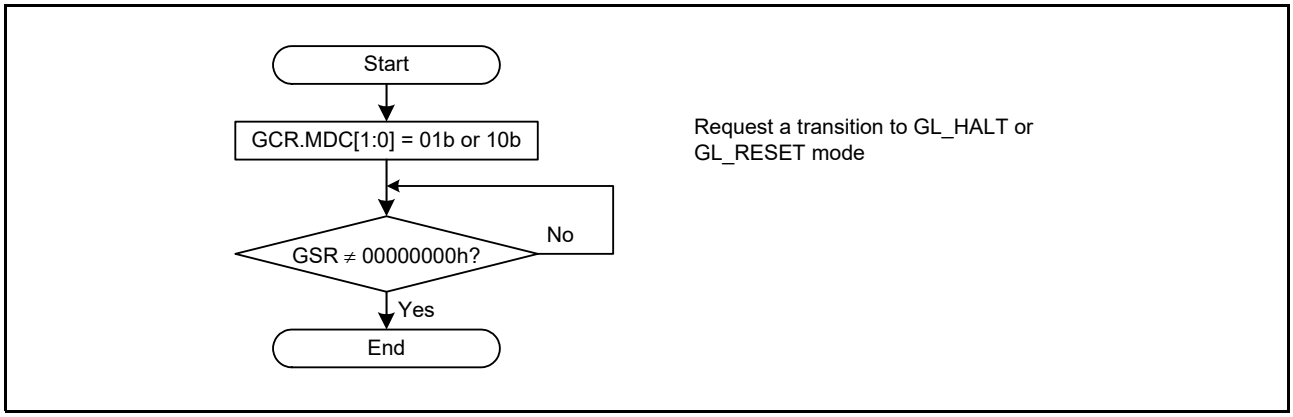

Figure 36.10 Procedure for Exiting GL_OPERATION Mode

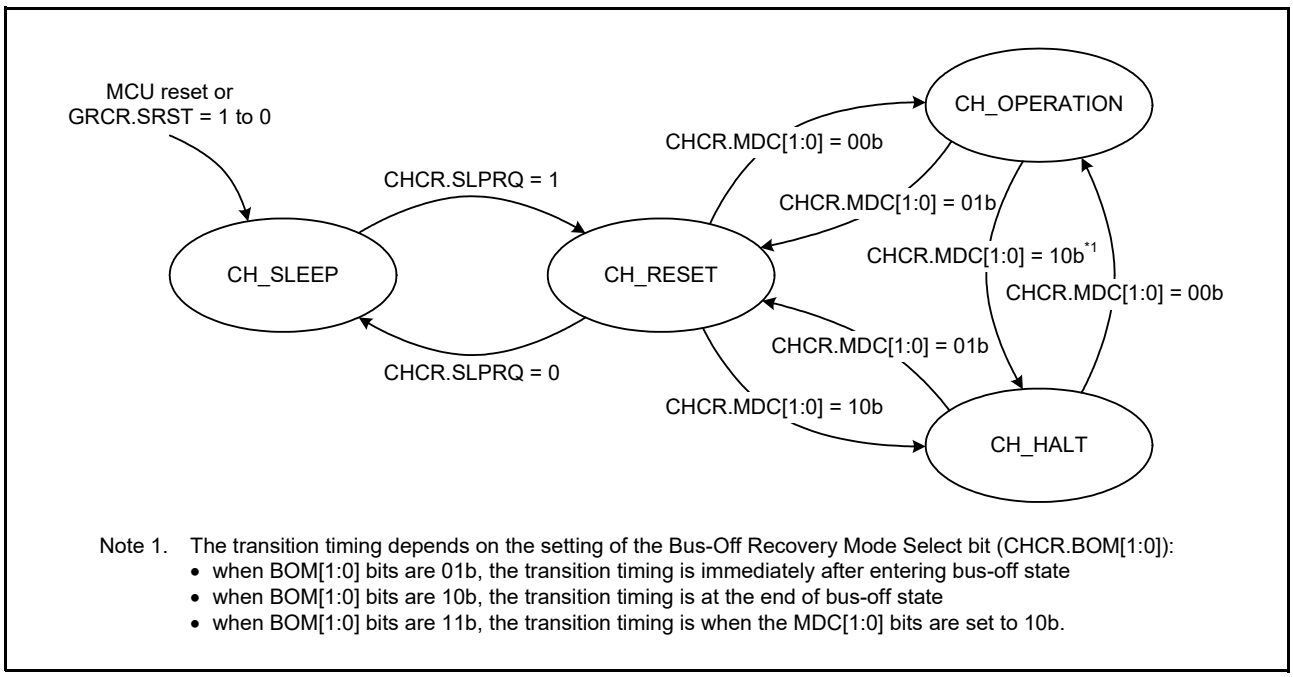
36.3.2 Channel Modes

The Channel modes of the CANFD module are:

- CH_RESET
- CH_HALT
- CH_OPERATION
- CH_SLEEP.

Figure 36.11 shows the possible transitions between the channel modes.



Note 1. The transition timing depends on the setting of the Bus-Off Recovery Mode Select bit (CHCR.BOM[1:0]):
- when BOM[1:0] bits are 01b, the transition timing is immediately after entering bus-off state
- when BOM[1:0] bits are 10b, the transition timing is at the end of bus-off state
- when BOM[1:0] bits are 11b, the transition timing is when the MDC[1:0] bits are set to 10b.

Figure 36.11 Transition between CAN Channel Modes

36.3.2.1 CH_SLEEP Mode

The CAN channel of the CANFD module automatically enters CH_SLEEP mode when the MCU reset is released or the software reset bit (GRCR.SRST) is changed from 1 to 0.
The CAN channel also enters CH_SLEEP mode when the CHCR.SLPRQ bit is set to 1 while the CAN channel is in CH_RESET mode. The CHCR.SLPRQ bit cannot be set to 1 in CH_HALT or CH_OPERATION mode.
Entering CH_SLEEP mode instantly stops the clock supplied to the CAN channel unit and therefore reduces power consumption.
After setting the CHCR.SLPRQ bit to 1 and before setting it to 0 again, it is necessary to use the CHSR.SLPST flag to confirm that transition to CH_SLEEP mode was successful.
During CH_SLEEP mode, do not write to channel related registers. Read operation is still possible.

36.3.2.2 CH_RESET Mode

The CAN channel of CANFD module enters this mode in the following ways:

- The CHCR.MDC[1:0] bits are set to 01b while the CAN channel is in CH_HALT or CH_OPERATION mode
- The CHCR.SLPRQ bit is set to 0 while the CAN channel is in CH_SLEEP mode
- The GCR.MDC[1:0] bits are set to 01b while the CAN channel is not in CH_SLEEP or CH_RESET mode.

In CH_RESET mode, all CAN channel status and flags are initialized.
In addition, all transmission-related control bits of the channel are cleared, and the transmit queue of the channel is also disabled.
In this mode, the configuration registers except for the bits related to the channel test mode are not initialized, so the CAN channel can be configured for communication.
After setting the CHCR.MDC[1:0] bits to 01b (CH_RESET mode) and before modifying these bits again, it is necessary to use the CHSR.RSTST flag to confirm that transition to CH_RESET mode was successful.
Refer to Table 36.11 for the behavior of transitioning to CH_RESET mode while CAN communication is in progress.

36.3.2.3 CH_HALT Mode

The CAN channel of CANFD module enters this mode in the following ways:

- The CHCR.MDC[1:0] bits are set to 10b while the CAN channel is in CH_RESET or CH_OPERATION mode
- The GCR.MDC[1:0] bits are set to 10b while the CAN channel is in CH_OPERATION mode.

In CH_HALT mode, all CAN communication of the channel is suspended, but all statuses and flags remain unchanged during CH_HALT mode (except for the bus-off state where the CHSR.REC[7:0] and TEC[7:0] bits for the channel are set to 00h).
In addition, in this mode, the bits related to the channel test mode are not initialized. Use CH_HALT mode to configure the channel test mode.
After setting the CHCR.MDC[1:0] bits to 10b (CH_HALT mode) and before modifying these bits again, it is necessary to use the CHSR.HLTST flag to confirm that transition to CH_HALT mode was successful.
Refer to Table 36.11 for the transition behavior to CH_HALT mode while CAN communication is in progress.

Table 36.11 Transition Behavior in CH_RESET Mode and CH_HALT Mode

Mode	State		
	Receiver	**Transmitter**	**Bus-Off**
CH_RESET mode (CHCR.MDC[1:0] = 01b)	The CAN channel transits to CH_RESET mode without waiting for the completion of the ongoing reception.*1	The CAN channel transits to CH_RESET mode without waiting for the completion of the ongoing transmission.*1	The CAN channel transits to CH_RESET mode without waiting for the completion of the bus-off recovery.
CH_HALT mode (CHCR.MDC[1:0] = 10b)	CAN channel transits to CH_HALT mode at the end of the ongoing reception or when an error occurs.*2	CAN channel transits to CH_HALT mode after completion of the ongoing transmission.	When the CHCR.BOM[1:0] bits are 00b, a CH_HALT mode request is accepted only after the completion of the full bus-off recovery sequence. When the CHCR.BOM[1:0] bits are 10b, the CAN channel transits automatically to CH_HALT mode after waiting for the completion of the bus-off recovery. When the CHCR.BOM[1:0] bits are 01b, the CAN channel transits automatically to CH_HALT mode without waiting for the completion of the bus-off recovery. When the CHCR.BOM[1:0] bits are 11b, the CAN channel transits to CH_HALT mode as soon as CH_HALT mode is requested (without waiting for the completion of the bus-off recovery).

Note 1. If the entry to CH_RESET mode is required only at the end of an ongoing communication, then CH_HALT mode can be requested first to prevent interruption of CAN communication by direct transition to CH_RESET mode. After the CAN channel enters CH_HALT mode, the CH_RESET mode can be requested.

Note 2. If CAN communication is locked at dominant level after an error flag, software can detect this situation by monitoring the channel related BusLock flag and resolve lock condition by setting the CAN channel to CH_RESET mode.

36.3.2.4 CH_OPERATION Mode (in Other than Bus-Off State)

The CH_OPERATION mode is activated by setting the CHCR.MDC[1:0] bits to 00b. If 11 consecutive recessive bits are detected after entering the CH_OPERATION mode, the CHSR.CRDY flag is set to 1 and the CAN channel:

- Enables the functions of the communication by allowing the channel to become an active node on the CAN network
- Releases the internal fault confinement logic including receive and transmit error counters.

At this point, the CAN channel can start transmission and reception of messages.
Within the CH_OPERATION mode, the channel may be in four different sub-modes, depending on which type of communication functions are performed (refer to Figure 36.12):

- Idle mode: The CAN channel is neither receiving nor transmitting
- Receive mode: The channel is receiving a message transmitted by another CAN node
- Transmit mode: The channel is transmitting a message
  (The channel may receive its own message simultaneously when Self Test mode is enabled.)
- Bus-off mode: The CAN channel is cut-off from CAN bus communication.

After setting the CHCR.MDC[1:0] bits to 00b (CH_OPERATION mode) and before modifying these bits again, it is necessary to use the CHSR.RSTST flag and the CHSR.HLTST flag to confirm that transition to CH_OPERATION mode was successful.

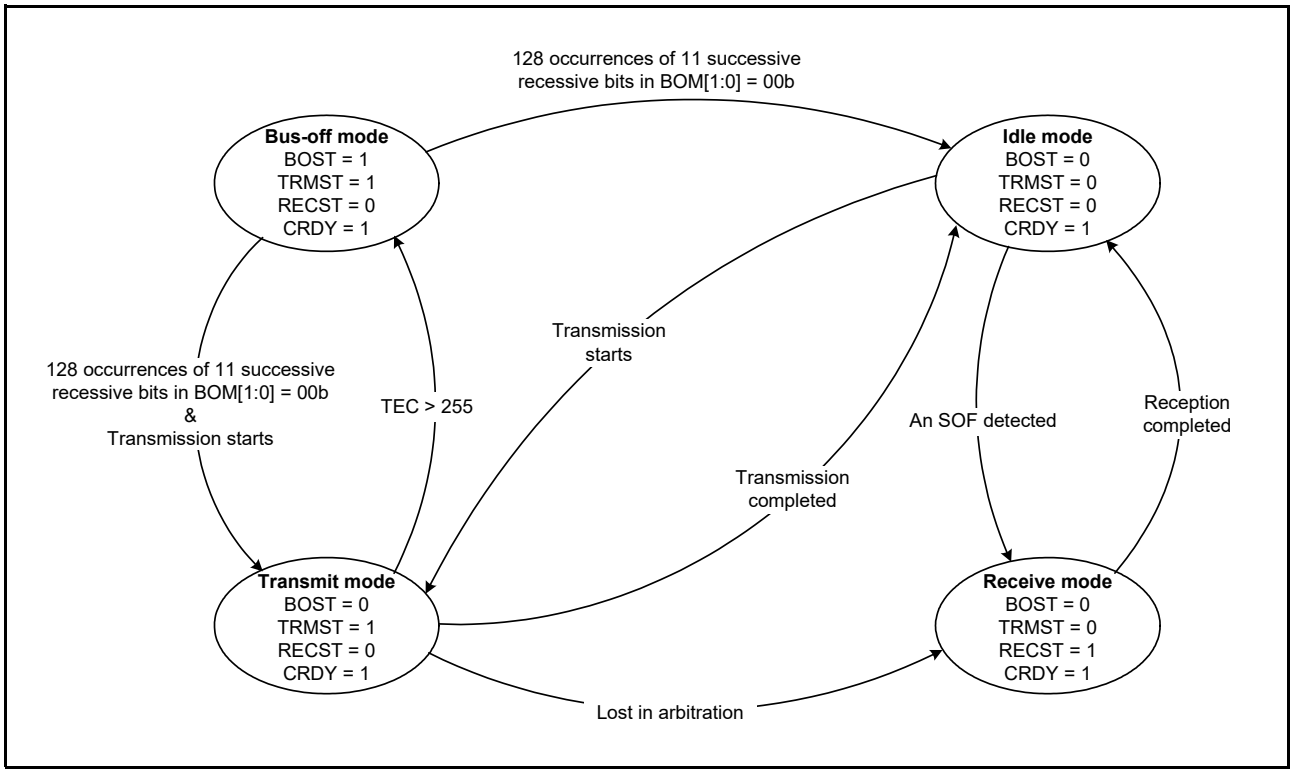


Figure 36.12 Sub-modes of CH_OPERATION Mode (only when CHCR.BOM[1:0] = 00b)

36.3.2.5 CH_OPERATION Mode (in Bus-Off State)

The CAN channel bus-off state is entered according to the fault confinement rules of the CAN specification. The following modes can be configured for returning to the CH_OPERATION mode from the bus-off state:

- CHCR.BOM[1:0] = 00b:
  Bus-off recovery is compliant to ISO 11898-1. The CAN channel re-enters CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. The CHSR.TEC[7:0] and REC[7:0] bits are initialized to 00h, and the CHESR.BORDF flag is set to 1 in this case.
- CHCR.BOM[1:0] = 01b:
  When entering bus-off state, the CAN channel changes the value of the CHCR.MDC[1:0] bits to 10b and enters CH_HALT mode automatically. The CHSR.TEC[7:0] and REC[7:0] bits are initialized to 00h and the CHESR.BORDF flag is not set to 1 in this case.
- CHCR.BOM[1:0] = 10b:
  When entering bus-off state, the CAN channel changes the value of the CHCR.MDC[1:0] bits to 10b and enters CH_HALT mode automatically after the CAN channel has completed the bus-off recovery sequence (after 11 consecutive recessive bits are detected 128 times). The CHSR.TEC[7:0] and REC[7:0] bits are initialized to 00h and the CHESR.BORDF flag is set to 1 in this case.
- CHCR.BOM[1:0] = 11b:
  Bus-off recovery is initiated but CAN channel can immediately enter CH_HALT mode when still in bus-off state if a request is made to enter CH_HALT mode. The CHSR.TEC[7:0] and REC[7:0] bits are initialized to 00h and the CHESR.BORDF flag is not set to 1.
  Without setting CHCR.MDC[1:0] = 10b and when 11 recessive bits is detected 128 times continuously, transition conditions become the same as CHCR.BOM[1:0] = 00b.

If the recovery from bus-off occurs normally in this mode (after waiting for 128 sequences of 11 consecutive recessive bits), and no CH_HALT request has been generated during this period, then the CHESR.BORDF flag is set to 1.
When software writes to the CHCR.MDC[1:0] bits at the same time as the CAN channel enters CH_HALT mode (at the start of bus-off when CHCR.BOM[1:0] = 01b, or at the end of bus-off when CHCR.BOM[1:0] = 10b), the software request has the highest priority.

Note: In the above case, the automatic setting of the CHCR.MDC[1:0] bits to CH_HALT mode request is performed when the CHCR.MDC[1:0] bits value is previously 00b (CH_OPERATION mode).

Additionally, it is possible to force the CAN channel to recover from the bus-off state by setting the CHCR.RTBO bit to 1. The error state changes from bus-off state to integrating state with a maximum delay of 1 bit time, and the CAN communication becomes possible again after 11 consecutive recessive bits are detected. The CHESR.BORDF flag is not set to 1 in this case, and the CHSR.TEC[7:0] and REC[7:0] bits are initialized to 00h.
Before setting the CHCR.RTBO bit to 1, all pending transmissions from the transmit message buffers, transmit queues and/or common FIFO in transmit mode should be disabled.
The disable of the pending transmit message buffer, transmit queue or common FIFO must be confirmed by the corresponding acknowledge flags (TMSRn.TXRF[1:0] flags, TQSR0.EMPTY flag, and CFSR0.EMPTY flag).
The CHCR.RTBO bit should be used for bus-off recovery only when the CHCR.BOM[1:0] bits are set to 00b.
Setting this bit in any state other than bus-off has no effect and the bit is cleared immediately.
Table 36.12 lists the behavior of the bus-off entry detect flag (CHESR.BOEDF) and the bus-off recovery detect flag (CHESR.BORDF) according to the CHCR.BOM[1:0] bit settings.

Table 36.12 Behavior of Bus-off Entry and Recovery Flags

CHCR.BOM[1:0]	CHESR.BOEDF Flag	CHESR.BORDF Flag
00b	Becomes 1 on entry to bus-off state.	Becomes 1 on exit from bus-off state.
00b Set the CHCR.RTBO bit to 1		Becomes 1 only if normal bus-off recovery occurs before setting the CHCR.RTBO bit to 1.
01b		Does not become 1.
10b		Becomes 1 on exit from bus-off state.
11b		Becomes 1 only if normal bus-off recovery occurs before requesting a transition to CH_HALT mode.

To make efficient software, it is not necessary to wait for the bus-off recovery sequence to end.
It is possible to perform a transmission re-initialization during bus-off recovery. To do this, follow the recommended software flow in Figure 36.13.

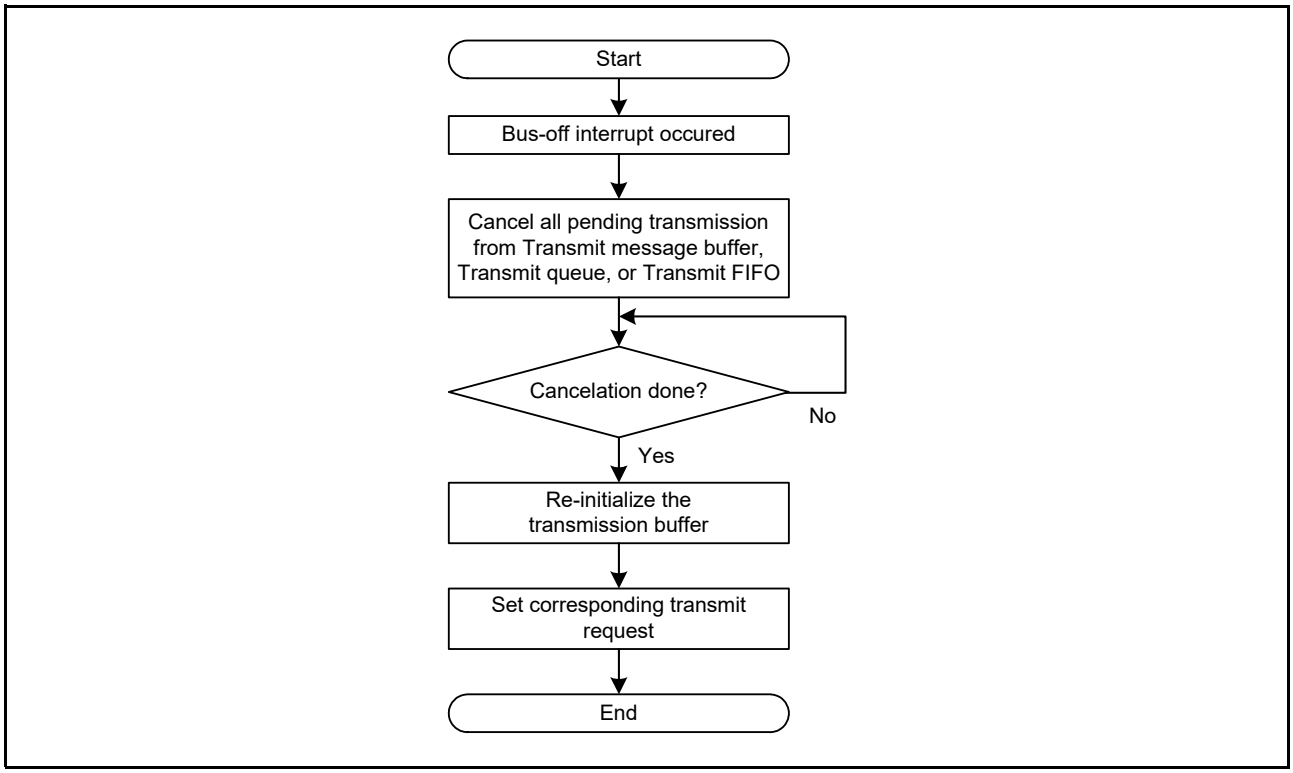

Figure 36.13 Transmission Re-Initialization During Bus-Off

36.3.3 Global Mode and Channel Mode Transition Interactions

The interaction between Global mode setting and Channel mode setting is as follows:

- Changing the CHCR.MDC[1:0] bits does not affect the GCR.MDC[1:0] bits.
- Changing the GCR.MDC[1:0] bits affects the channel mode control as described in Table 36.13.

Table 36.13 Interaction between Global Mode and Channel Mode Transition

Global Mode Change	Channel Mode before Changing Global Mode	Channel Mode after Changing Global Mode
GL_SLEEP → GL_RESET	CH_SLEEP	CH_SLEEP (no change)
GL_RESET → GL_SLEEP	CH_SLEEP	CH_SLEEP (no change)
	CH_RESET	CH_SLEEP
GL_RESET → GL_HALT	CH_SLEEP	CH_SLEEP (no change)
	CH_RESET	CH_RESET (no change)
GL_RESET → GL_OPERATION	CH_SLEEP	CH_SLEEP (no change)
	CH_RESET	CH_RESET (no change)
GL_HALT → GL_RESET	CH_SLEEP	CH_SLEEP (no change)
	CH_RESET	CH_RESET (no change)
	CH_HALT	CH_RESET
GL_HALT → GL_OPERATION	CH_SLEEP	CH_SLEEP (no change)
	CH_RESET	CH_RESET (no change)
	CH_HALT	CH_HALT (no change)
GL_OPERATION → GL_RESET	CH_SLEEP	CH_SLEEP (no change)
	CH_RESET	CH_RESET (no change)
	CH_HALT	CH_RESET
	CH_OPERATION	CH_RESET
GL_OPERATION → GL_HALT	CH_SLEEP	CH_SLEEP (no change)
	CH_RESET	CH_RESET (no change)
	CH_HALT	CH_HALT (no change)
	CH_OPERATION	After communication ends, CH_HALT

36.3.3.1 Timing of Global Mode Change

The transition time for the Global mode changes are shown in the following table.

Table 36.14 Maximum Transition Time for the Global Mode

From	To	Maximum Transition Time
GL_SLEEP	GL_RESET	3 × PCLKB*2
GL_RESET	GL_SLEEP	3 × PCLKB
GL_RESET	GL_HALT	10 × PCLKB
GL_RESET	GL_OPERATION	10 × PCLKB
GL_HALT	GL_RESET	2 bit times (1 Tq + 16 × PCLKB + 2 DLL clock cycles)
GL_HALT	GL_OPERATION	3 × PCLKB
GL_OPERATION	GL_RESET	2 bit times (1 Tq + 16 × PCLKB + 2 DLL clock cycles)
GL_OPERATION	GL_HALT	3 CAN frames (1 CAN frame + 3424 × PCLKB)*1 *3

Note 1. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked receive lines or continued error conditions.
Note 2. Exit GL_SLEEP mode only when the GSR.RAMST flag is cleared.
Note 3. Tq, CAN frame and bit times are related to the individual channels. For the maximum transition time, the channel with the lowest bit rate must be used.

36.3.3.2 Timing of Channel Mode Change

Table 36.15 shows the transition time for the Channel mode changes.

Table 36.15 Maximum Transition Time for the Channel Mode

From	To	Maximum Transition Time
CH_SLEEP	CH_RESET	3 × PCLKB
CH_RESET	CH_SLEEP	3 × PCLKB
CH_RESET	CH_HALT	3 bit times (1 CAN bit + 2 Tq + 8 × PCLKB + 2 DLL clock cycles)
CH_RESET	CH_OPERATION	4 bit times (2 CAN bits + 1 TSEG1 + 12 × PCLKB + 2 DLL clock cycles)
CH_HALT	CH_RESET	2 bit times (1 Tq + 10 × PCLKB + 2 DLL clock cycles)
CH_HALT	CH_OPERATION	4 bit times (< 4 CAN bits)*3
CH_OPERATION	CH_RESET	2 bit times (1 Tq + 10 × PCLKB + 2 DLL clock cycles)
CH_OPERATION	CH_HALT	2 CAN frames (1 CAN frame + 13 CAN bits)*1 *2

Note 1. The time specified for this transition does not include the case where channel enters bus-off state. For bus-off, the timing depends on the configuration of the CHCR.BOM[1:0] bits.

Note 2. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked receive lines or continued error conditions.

Note 3. In general, if the bit rate prescaler value (NBCR.BRP[9:0]) is changed in CH_HALT mode, the transition time can deviate. The internal prescaler is a free running down counter that creates the Tq clock, and new BRP value is captured when the counter reaches the value 0.

36.4 Initialization of CANFD Module

Before starting CAN communications, configure the following settings:

- Clock setting
- Bit timing setting (nominal and data bit rate)
- Bit Rate setting (nominal and data bit rate)
- CANFD setting
- Acceptance Filter setting (configuration of Acceptance Filter List)
- Receive FIFO and Transmit FIFO setting
- CAN operating mode setting.

36.4.1 Initialization of CAN Clock, Bit Timing and Bit Rate

36.4.1.1 Bit Timing Conditions

The following lines describe the composition of each segment and the limitations that apply to the segment setting.

1. Each segment setting

- SS = Fixed to 1 Tq
  TSEG1 = 2 Tq to 256 Tq (NBCR), 2 Tq to 32 Tq (DBCR)
  TSEG2 = 2 Tq to 128 Tq (NBCR), 2 Tq to 16 Tq (DBCR)
  SJW = 1 Tq to 128 Tq (NBCR), 1 Tq to 16 Tq (DBCR)
  SS + TSEG1 + TSEG2 = 8 Tq to 385 Tq (NBCR), 5 Tq to 49 Tq (DBCR)

2. Limitations on TSEG1, TSEG2 and SJW
   NBCR register: TSEG1 > TSEG2 ≥ SJW
   DBCR register: TSEG1 ≥ TSEG2 ≥ SJW

Table 36.16 shows an example of how to set the bit timing to achieve the required sample point settings.

Table 36.16 Bit Timing Examples

1 Bit	Set Value (Tq)				Sample Point (%)
	SS	TSEG1	TSEG2	SJW	
5 Tq	1	2	2	1	60.00
8 Tq	1	4	3	1	62.50
	1	5	2	1	75.00
10 Tq	1	6	3	1	70.00
	1	7	2	1	80.00
12 Tq	1	8	3	1	75.00
	1	9	2	1	83.33
15 Tq	1	10	4	1	73.33
	1	11	3	1	80.00
16 Tq	1	10	5	1	68.75
	1	11	4	1	75.00
20 Tq	1	12	7	1	65.00
	1	13	6	1	70.00
24 Tq	1	15	8	1	66.66
	1	16	7	1	70.83
50 Tq	1	39	10	4	80.00

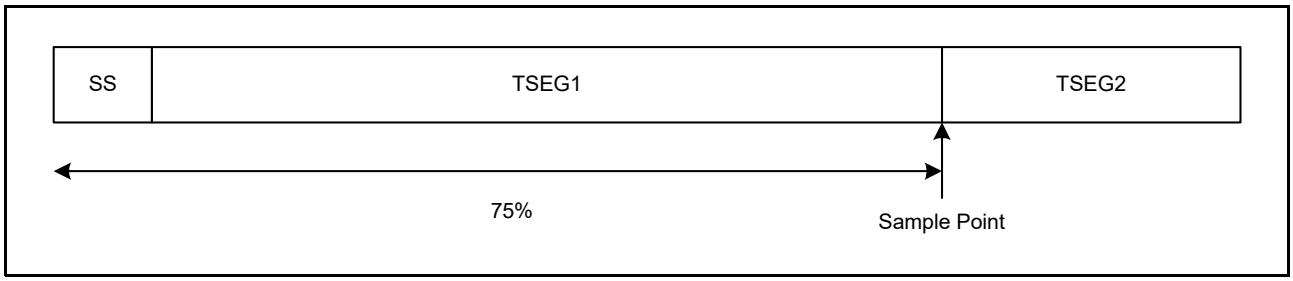

Figure 36.14 The Sample Point (in Case of 75%)

36.4.1.2 Bit Timing

In the CAN protocol, each bit in a communication frame is composed of three segments that can be configured using the NBCR and DBCR registers.

Figure 36.15 shows the segment composition of a bit and the sample point in it.

Of these segments, the Time Segment 1 (TSEG1) and Time Segment 2 (TSEG2) are used to specify the position of the sample point, so that the timing at which each bit on the CAN bus is sampled can be altered by changing the values of these segments.

The minimum resolution for this timing is referred to as Time Quantum (Tq), which is determined by the clock frequency supplied to the CAN channel and the divide-by-N value of the bit rate prescaler (nominal and data bit rate).

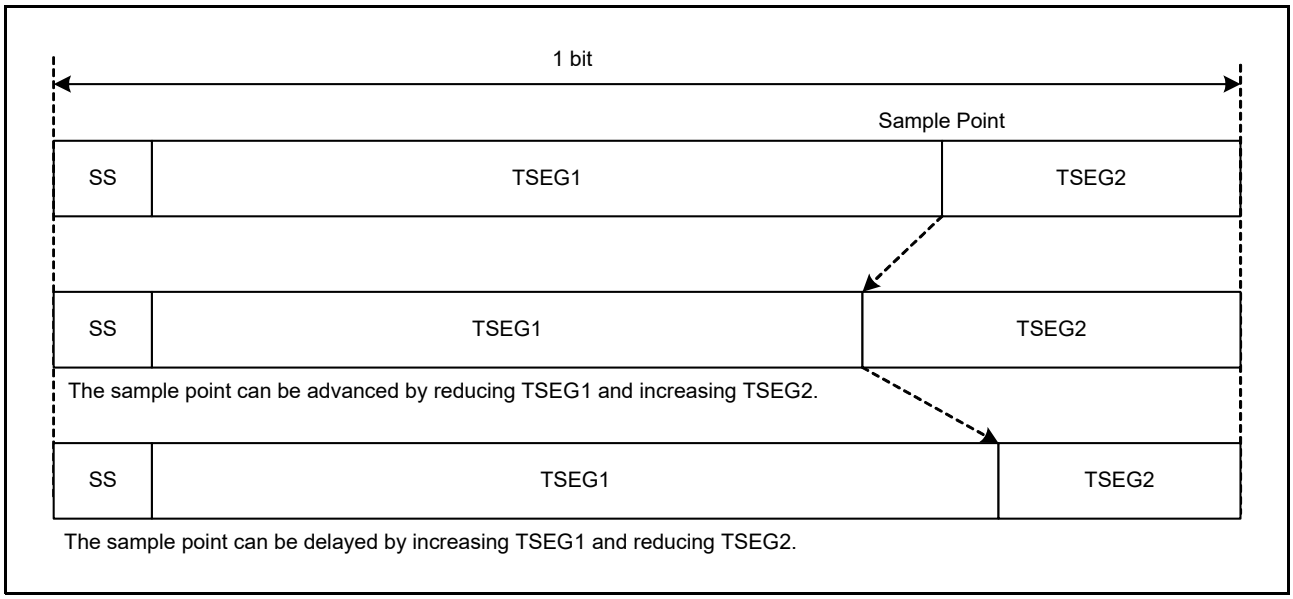

Figure 36.15 Segment Composition of A Bit and The Sample Point

1. SS: Synchronization Segment
   This segment is used to synchronize bits by monitoring a recessive-to-dominant edge during the interframe space. This comprises of intermission, suspend transmission, bus idle, during bus idle, and all nodes that can start transmission.
2. TSEG1: Time Segment 1
   This segment absorbs physical delays on the CAN network. A physical delay on the network is two times the total sum of a bus delay, input comparator delay, and output driver delay. It can be lengthened by SJW.
3. TSEG2: Time Segment 2
   This segment is used to correct a phase error by performing resynchronization. It can be shortened by SJW. While sending or receiving a message, communication frames between some nodes may get out of sync due to a drift in

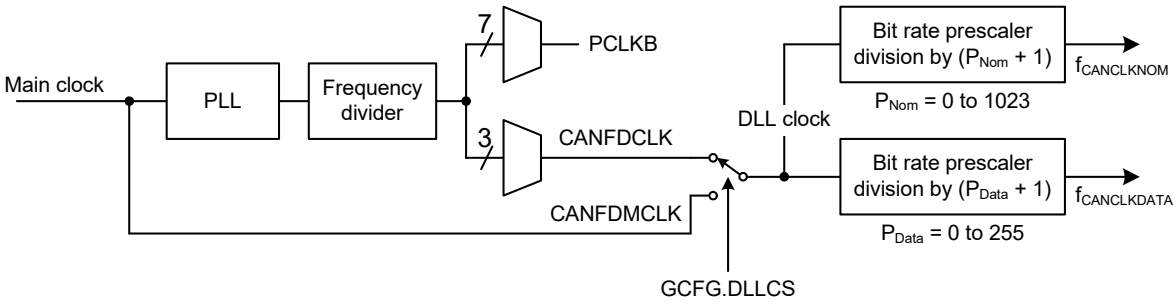
the oscillator frequency or a delay in the transmission path. This is referred to as a phase error.

4. SJW: Resynchronization Jump Width
   This is the maximum width by which bits that have become out of sync due to a phase error may be corrected.

Figure 36.15 shows an example of a typical sample point.

36.4.1.3 Bit Rate

The CAN communication clocks are generated by dividing the operating clock for data link layer (DLL clock). The DLL clock can be selected from either the internal clock (CANFDCLK) or the external clock (CANFDMCLK).
Figure 36.16 shows a block diagram of the circuit that generates the CAN communication clock.



Main clock:	External oscillator clock
CANFDCLK:	Clock equivalent to peripheral module clock
DLL clock:	Data Link Layer clock DLL clock ≤ PCLKB
PCLKB:	CANFD module system clock
P_{Nom}, P_{Data}	Value selected by the NBCR.BRP[9:0] bits and DBCR.BRP[7:0] bits
$f_{CANCLKNOM}$:	CAN nominal communication clock, f(CANCLKNOM) = (DLL clock) / (P_{Nom} + 1)
$f_{CANCLKDATA}$:	CAN data communication clock, f(CANCLKDATA) = (DLL clock) / (P_{Data} + 1)

Figure 36.16 Block Diagram of the Circuit that Generates the CAN Communication Clock

The bit rate is determined by the DLL clock frequency, the division value of the bit rate prescaler (P + 1), and the number of Tq per bit.

$$\text{Bit rate} = \frac{\text{DLL clock frequency}}{\text{Number of Tq per bit} \times (\text{P} + 1)} = \frac{\text{CAN communication clock frequency}}{\text{Number of Tq per bit}}$$

Table 36.17 lists examples of setting the nominal bit rate for Classical CAN frame.

Table 36.17 Nominal Bit Rate Setting Examples for Classical CAN Frame

Bit Rate	DLL Clock Frequency															
	60 MHz		40 MHz		32 MHz		30 MHz		24 MHz		20 MHz		16 MHz		10 MHz		8 MHz*1

Note 1. Minimum frequency to achieve a nominal bit rate of 1 Mbps.

For optimum clock tolerance in networks using the CAN FD frame, the length of the time quantum should be the same in nominal bit time and in data bit time. This means NBCR.BRP[9:0] = DBCR.BRP[7:0].
In addition, do not set the DBCR.BRP[7:0] bits greater than 1 when using transceiver delay compensation.
Table 36.18 lists examples of setting the nominal and data bit rate for CAN FD frame.

Table 36.18 Nominal and Data Bit Rate Setting Examples for CAN FD Frame

Bit Rate		DLL Clock Frequency											
		60 MHz			40 MHz			30 MHz			20 MHz		
		No. of Tq			No. of Tq			No. of Tq			No. of Tq		
Nominal	Data	Nom.	Data	P+1	Nom.	Data	P+1	Nom.	Data	P+1	Nom.	Data	P+1

36.4.1.4 Setting of CAN Clock, Bit Timing and Bit Rate

Figure 36.17 shows the procedure for setting the bit timing and the bit rate.
These settings should be configured when the CAN channel is in CH_RESET mode.
The bit rate must be configured before moving to the channel communication state. Otherwise the mode does not switch correctly.

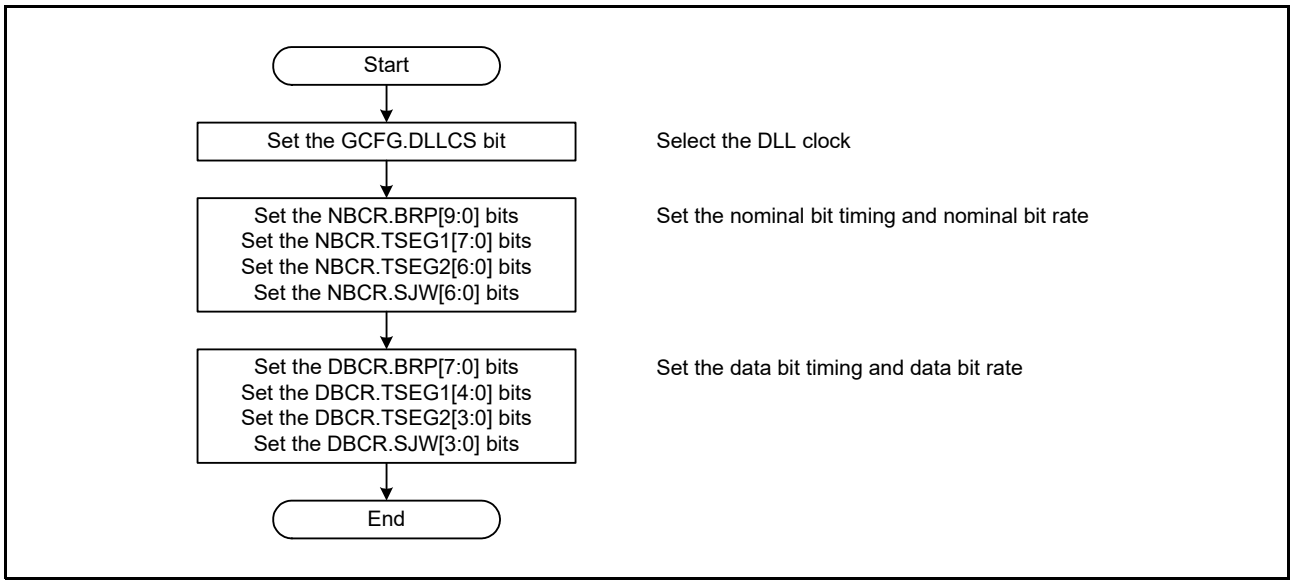

Figure 36.17 Procedure for Setting the Bit Timing and Bit Rate

36.4.1.5 Transceiver Delay Compensation

When a high bit rate is used such as 5 to 8 Mbps for the data phase, the transceiver delay can become greater than TSEG1. In this case, the transmitter always detects a bit-error in the data phase of the CAN FD frame. The TDC compensates for the inability of the transmitter to receive its own transmitted bit at the sample point of that bit.
There is another symbolic sample point known as the Secondary Sample Point (SSP) that is used only during the data phase of CAN FD frames. This is derived from the Transceiver Delay Compensation Result bit (FDSTS.TDCR[7:0]) as shown in Figure 36.18.
The resolution of the configuration, measured and offset values is based on the CAN channel DLL clock.

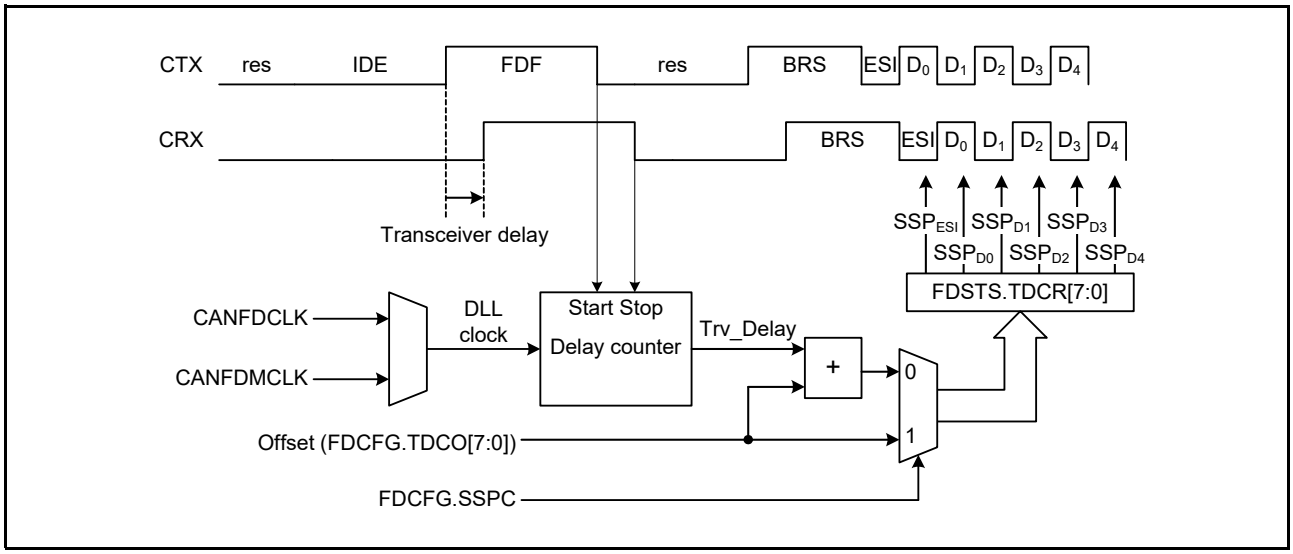

Figure 36.18 Transceiver Delay Compensation

The measured Trv_Delay is based on the number of DLL clock cycles. It counts up by one for each start clock until the dominant value can be observed at the CRX0 pin. Figure 36.19 shows the measurement example. Trv_Delay is counted up to 127 on each DLL clock.

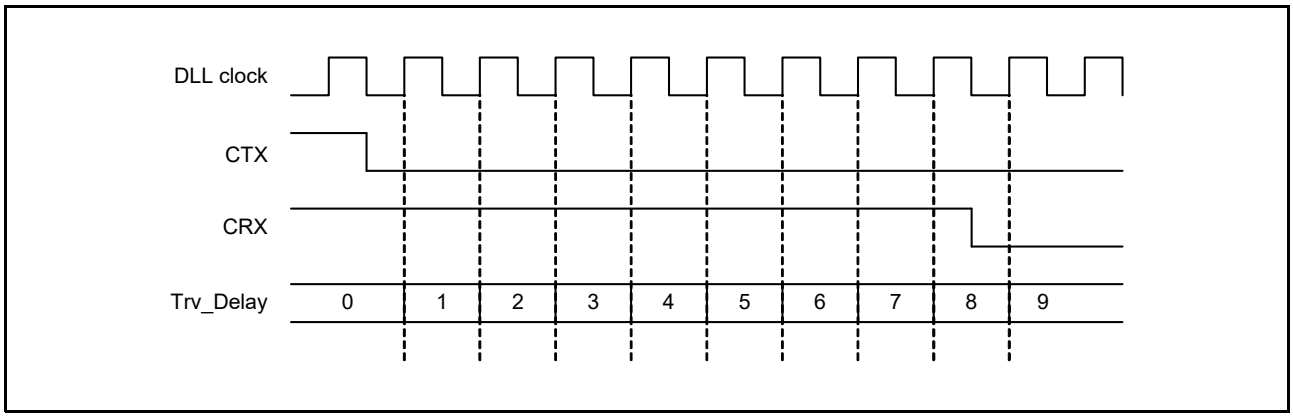

Figure 36.19 Trv_Delay Measurement Example

The SSP is calculated by taking the result from the FDSTS.TDCR[7:0] bits and rounding the value down to the nearest integer number of data Tq.
Figure 36.20 shows the positioning of the secondary sample point (SSP). When the FDCFG.SSPC bit is set to 0, the SSP is equal to the Trv_Delay (measured delay) + FDCFG.TDCO[7:0], rounded down to the nearest integer number of Tq. Normally, the TDCO[7:0] value has the magnitude of SS + TSEG1 in the data phase to position the SSP to a theoretical location of the sample point.
If the FDCFG.SSPC bit is set to 1, the SSP is defined by the FDCFG.TDCO[7:0] bits. If the DBCR.BRP[7:0] bits are greater than 00h, the value is also rounded down to the nearest integer number of Tq.

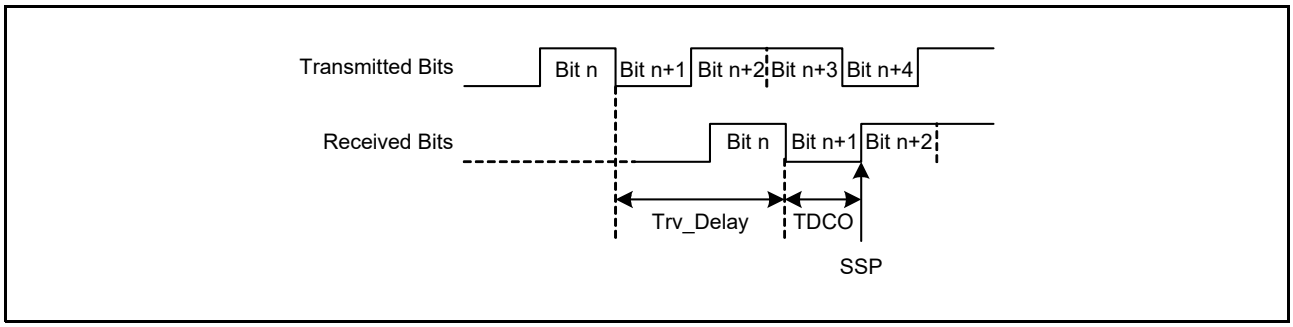

Figure 36.20 Positioning of the Secondary Sample Point (SSP)

The maximum delay time (Trv_Delay + TDCO[7:0]) which can be compensated by the CANFD module is (6 data bits – 2 DLL clock). The ISO 11898-1 allows you to set different values for BRP_data and BRP_nom.
If different values are used for the NBCR.BRP[9:0] bits and DBCR.BRP[7:0] bits, then two CAN nodes may be out of synchronization at the point when the bit rate changes from nominal bit rate to data bit rate after sample point of the BRS bit. This condition is shown in Figure 36.21.
The length of the time quantum should be the same in the nominal bit time and in the data bit time. This means NBCR.BRP[9:0] = DBCR.BRP[7:0].
The bit rate can be changed by selecting different settings for the time segments. The nominal bit rate can be set from 8 to 385 Tqs and the data bit rate from 5 to 49 Tqs.

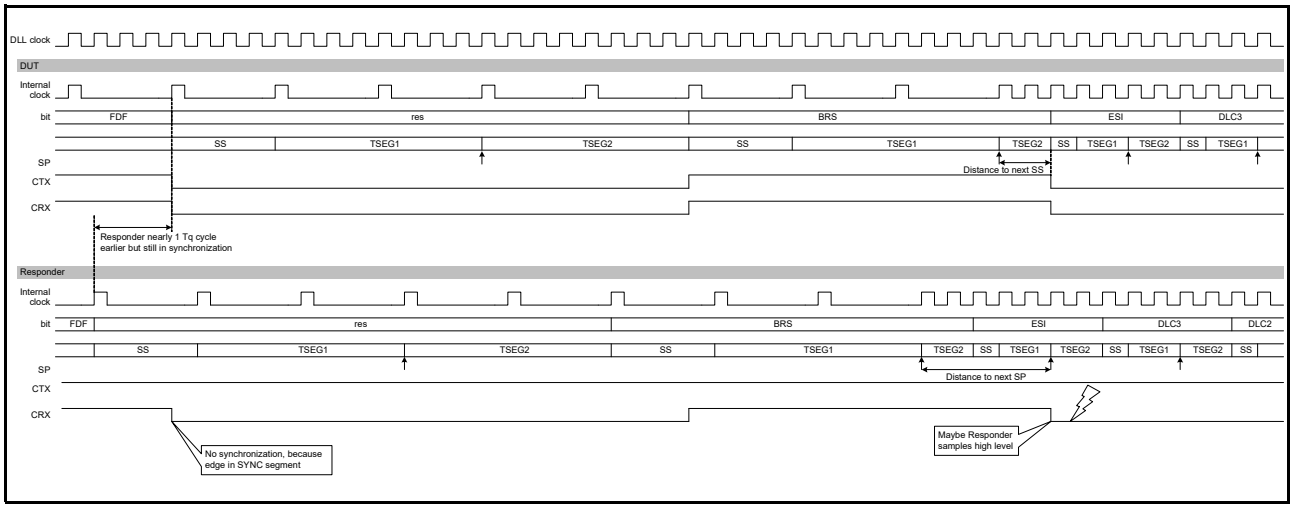

Figure 36.21 Loss of Synchronization Between Two CAN Nodes

The transceiver delay compensation measurement result is updated at the falling edge from FDF bit to res bit when configured accordingly (FDCFG.TDCE = 1, FDCFG.SSPC = 0).
Figure 36.22 shows the read flow to get the measured transceiver delay compensation result.

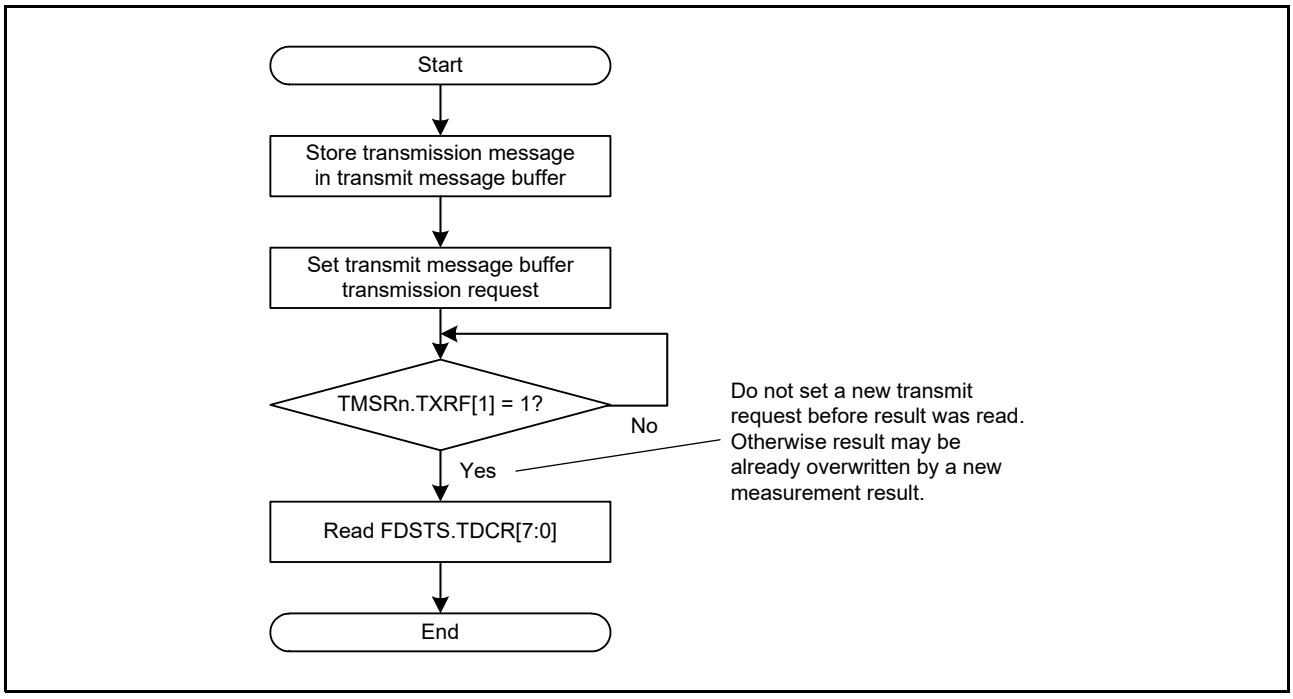

Figure 36.22 Transceiver Delay Compensation Result Read Flow

36.4.2 CANFD Module Configuration after a Reset

After release from a MCU reset or after setting and clearing the GRCR.SRST bit, the CANFD module enters GL_SLEEP mode automatically.

To configure the CANFD module settings, exit GL_SLEEP mode by setting the GCR.SLPRQ bit to 0.

After release from a MCU reset, the CANFD module starts RAM initialization. At this time, the GSR.RAMST flag is automatically set to 1 indicating that the CANFD module logic is initializing the RAM.

After RAM initialization is complete, this bit is automatically set to 0.

RAM initialization is necessary to prevent indefinite data in RAM from detecting the wrong ECC error after release from a MCU reset.

Do not access (read or write) other CANFD registers until the RAM initialization is complete and the GSR.RAMST flag is becomes 0.

Before going to communication mode, the Acceptance Filter List and message FIFO buffers must be configured. In addition, the CAN channel setting such as CAN bit timing must be configured. To make this configuration, the CAN channel must be released from CH_SLEEP mode and must be set for communication in CH_RESET mode (configuration mode).

Figure 36.23 shows the configuration procedure. For details about each step, refer to section 36.5, Filtering Using Acceptance Filter List (AFL), section 36.6, FIFO Buffers and Message Buffer Configuration, section 36.10, Interrupts and DTC/DMA Requests, and section 36.4.1.3, Bit Rate.

The CANFD module does not perform the RAM initialization sequence after executing a software reset by setting the GRCR.SRST bit to 1.

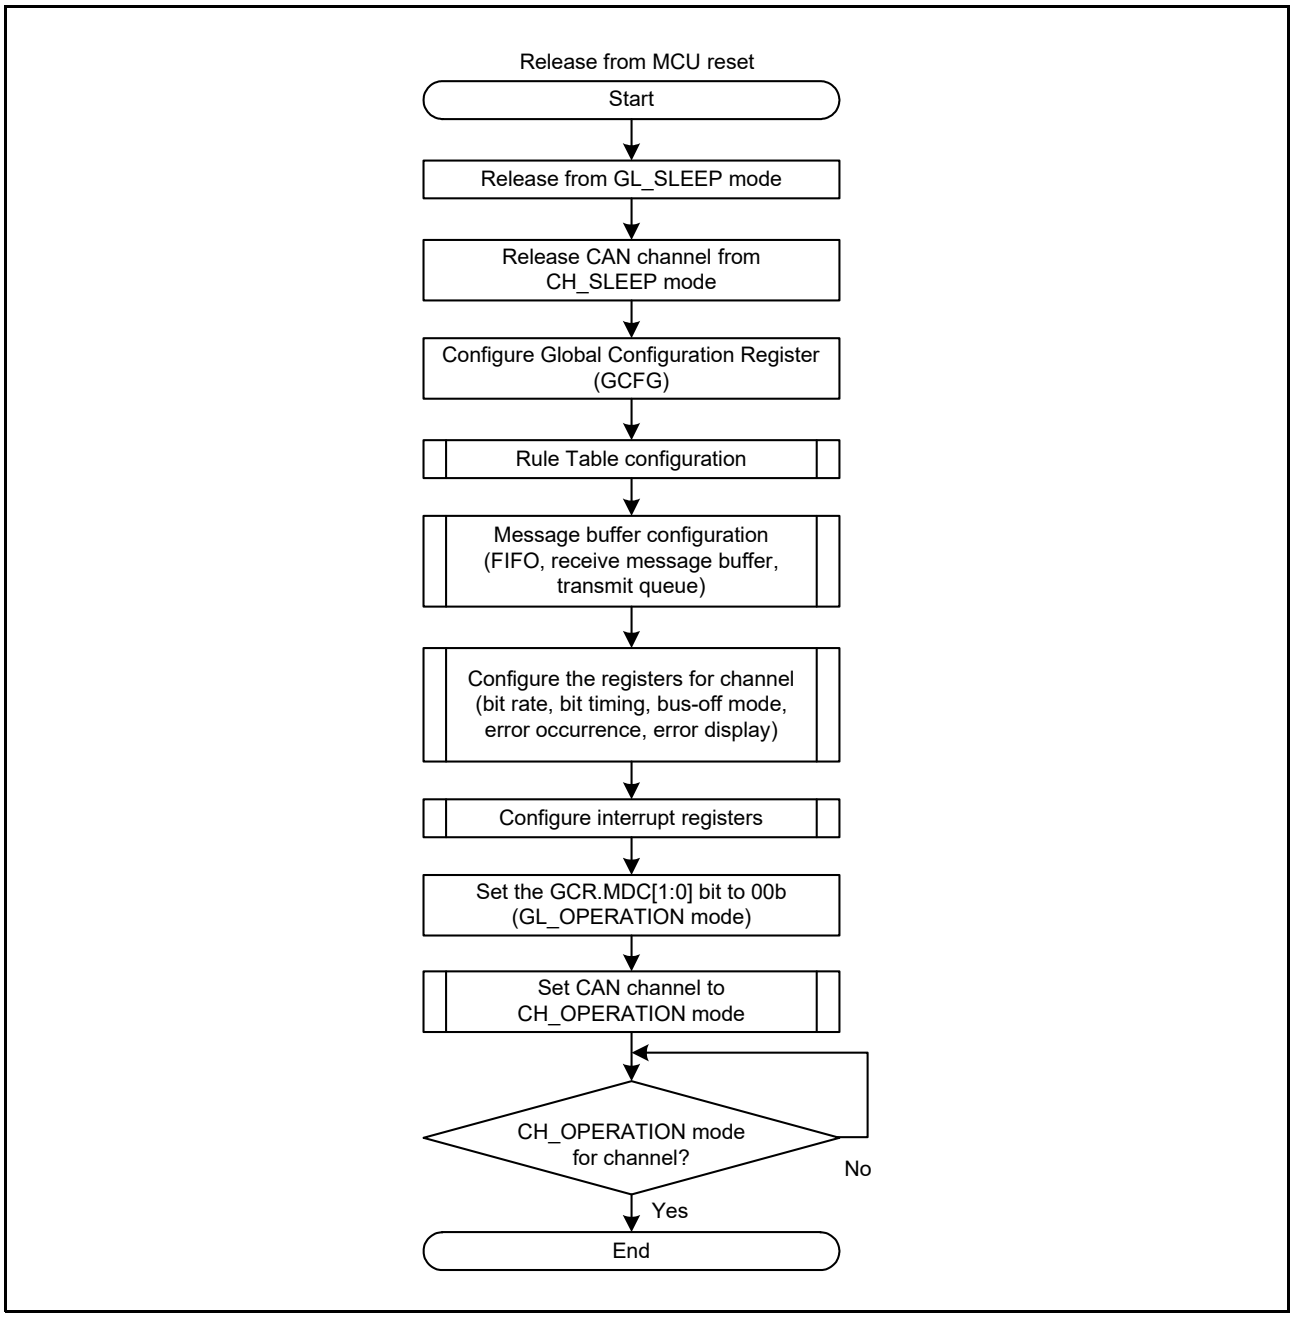

Figure 36.23 Configuration Procedure After A MCU Reset

36.5 Filtering Using Acceptance Filter List (AFL)

The CANFD module allows you to use the Acceptance Filter List (AFL) to filter message acceptance for channels. Each entry of the AFL defines a filter rule for received messages.
The followings are performed based on the AFL entries:

- Acceptance filtering based on the RTR value, IDE value, and ID value of received message
- DLC filtering based on DLC value of received message
- Payload overflow based on the GCFG.OMRC bit
- Storage of accepted messages in the specified message buffer/FIFO buffer
- Attaching a 16-bit pointer to the stored messages, for example to support AUTOSAR applications
- Attaching a 2-bit information label to the stored messages.

The CANFD module allows a maximum of 32 AFL entries.

36.5.1 Acceptance Filtering Process

Acceptance filtering matches each AFL entry with the received message. Matching starts with the lowest AFL entry number.
The AFL search stops when the received message ID matches the specified ID/mask combination, or when the received message ID has been matched against all defined AFL entries. If no match occurs, then the received message is discarded. No notification is given to the application in this case.

36.5.2 DLC Filtering Process

DLC filtering is performed for each accepted message if DLC check is enabled (GCFG.DCE bit = 1). If the DLC value of the received message is equal to or higher than the DLC value specified for the AFL entry whose ID matches in the Acceptance Filtering process (the matching AFL entry), the DLC check is passed.
If DLC replacement (GCFG.DRE bit) is enabled, DLC value configured in the matching AFL entry is greater than 0000b and DLC check passes, then the configured value of DLC in the matching AFL entry is stored in the destination receive message buffer (RMBn) or FIFO buffer. If DLC value of the received message is greater than the DLC value specified in the matching AFL entry, the excess data bytes are not stored in the RMBn/FIFO buffer. These excess data bytes are stored as 00h in the RMBn/FIFO buffer.
If DLC replacement is enabled and the DLC value specified in the matching AFL entry is 0000b (DLC filter function is disabled), the DLC value of the received message is stored in the RMBn/FIFO buffer.
If DLC replacement is disabled (GCFG.DRE bit = 0) and DLC check passes, the DLC value of the received message is stored in the RMBn/FIFO buffer. If the DLC value of the received message is greater than the DLC value specified in the matching AFL entry, the excess data bytes are also stored in the RMBn/FIFO buffer.
If DLC value of the received message is less than the DLC value specified in the matching AFL entry, DLC check fails. In this case, the received message is discarded and is not stored in anywhere.
Additionally, when the DLC check fails, the GESR.DEDF flag is set to 1. If interrupts are enabled, an error interrupt is also generated. If the DLC check fails, the DLC replacement setting has no effect.

36.5.3 Message Storage

If a received message has passed both acceptance filtering and DLC filtering, the message is stored in receive message buffers 0 to 31, receive FIFO 0, 1, or common FIFO 0 configured in receive FIFO mode.
This message storage target information is also defined in the AFL entry. Do not set a target at the AFL entry which is not configured.
Up to two message storage destinations can be specified. Do not specify more than 3 destinations.

36.5.4 Payload Overflow Process

There is a protection mechanism in case the received message contains data with a payload size that is longer than the size that can be stored in the storage (RMCR.PLS[2:0], RFCR0.PLS[2:0], RFCR1.PLS[2:0], or CFCR0.PLS[2:0]).
If GCFG.OMRC = 0 (message is discarded), the message with data byes that exceed the specified payload size are discarded and not stored. In this case, even if the FIFO is full, the corresponding FMLSR.RFML0, RFML1, or CFML0 flag is not set to 1.
If GCFG.OMRC = 1 (cut to specified size), only data bytes that exceed the specified payload size are discarded. In this case, if the FIFO is full, the corresponding FMLSR.RFML0, RFML1, or CFML0 flag is set to 1 (message lost has occurred).
Depending on the GCFG.DRE bit setting, either the DLC value of the received message or the DLC value specified in the AFL entry is stored.
Regardless of the GCFG.OMRC bit setting, the GESR.PODF flag is set to 1 if a payload overflow condition is detected.
The DLC filtering is performed before the payload overflow process. So for one reception frame, only one flag can be set to 1 at the same time with the GESR.DEDF flag or GESR.PODF flag.

36.5.5 Allocation of AFL Entries

The number of AFL entries (number of rules) can be configured using the AFCFG.RN0[5:0] bits (refer to Figure 36.24).

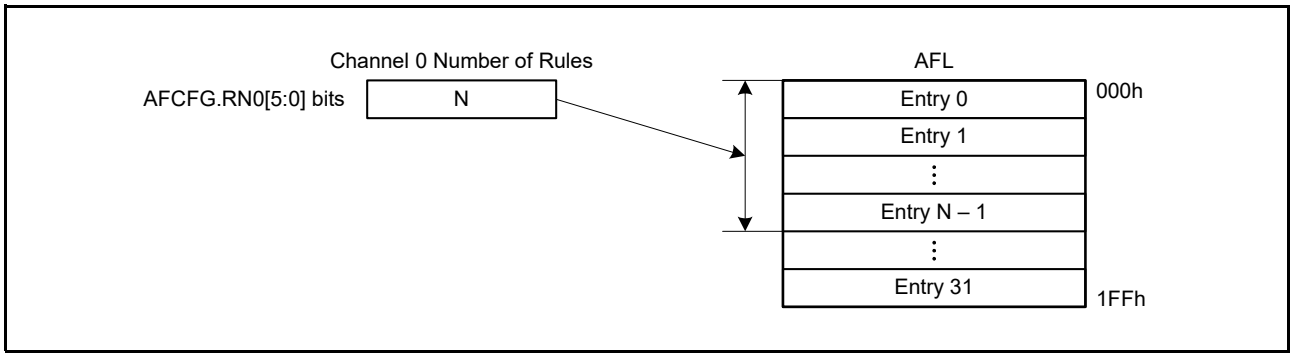

Figure 36.24 Configuration of AFL

The minimum number of entries for one channel is 0 (no entries defined for the channel) and the maximum number of entries for one channel is 32.
The CANFD module does not flag errors related to the configuration of the AFL.

36.5.6 AFL Entry Description

Each AFL entry consists of 16 bytes. The fields in all entries are identical.
Each entry contains the following information for acceptance filtering and DLC filtering:

- Identifier field (11 bits for Standard Frame format, 29 bits for Extended Frame format):
  Acceptance filter unit matches this filed with the identifier field of the received message (29 bits of identifier field can be masked individually, refer to the description of Mask for Identifier field below).
- IDE bit:
  Acceptance filter unit matches this bit with the IDE bit of the received message and selects the relevant part of the identifier field for acceptance filtering (masking of IDE bit is possible, refer to the description of Mask for IDE bit below).
- RTR bit:
  Acceptance filter unit only accepts data frames (RTR = 0) or remote frames (RTR = 1) according to the setting of this bit (masking of RTR bit is possible, refer to the description of Mask for RTR bit below).
- Loopback Configuration bit:
  This bit can enable or disable the AFL entry depending on the Loopback Configuration or Mirror mode condition.
- Mask for Identifier field (29 bits):
  Each bit in the identifier mask field can mask the corresponding identifier bit in the AFL entry (refer to Figure 36.25).
- Mask for IDE bit:
  If this Mask bit masks the IDE bit of an AFL entry, the AFL entry can accept messages in both Standard Identifier format and Extended Identifier format. For messages in Standard Identifier format, the Standard Identifier part of the AFL entry is compared, and for messages in Extended Identifier format, the Extended Identifier part of the AFL entry is compared.
- Mask for RTR bit:
  If this Mask bit masks the RTR bit of an AFL entry, the AFL entry can accept frame formats in both data frame and remote frame.
- Pointer (16 bits):
  This 16-bit pointer is attached to a received message accepted by the related AFL entry. The pointer is added when storing a message in the message buffer area and can be used as a support function in the application.
  For example, the pointer information can be used to support the assignment of PDU IDs to the received message in AUTOSAR systems.
- Information label (2 bits):
  This 2-bit label is attached to a message accepted by the related AFL entry. This label is added when storing a message in the message buffer area and can be used as support function in the application.
- DLC field:
  If the DLC value of the received message is equal to or higher than the value set in this field, the DLC check is passed.
  If the DLC value of an AFL entry is set to 0000b, the DLC filtering for this entry is effectively disabled (all accepted messages pass DLC filtering).

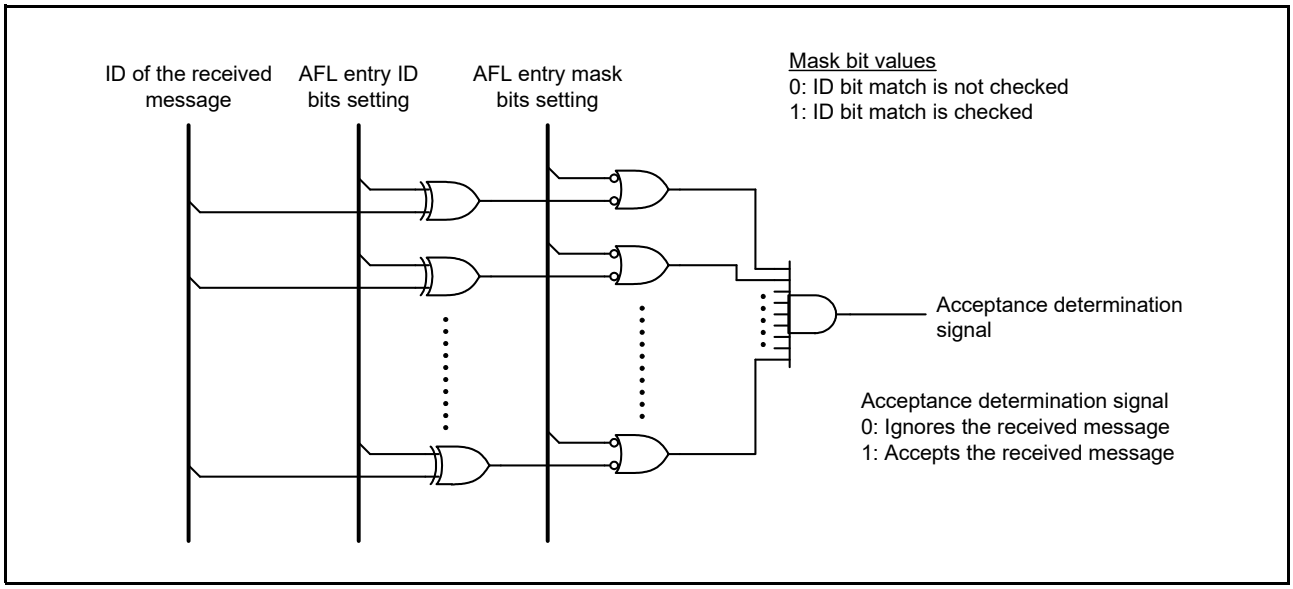

Figure 36.25 Acceptance Filter Function

Each AFL entry contains the following information for processing the received messages:

- Message buffer number of the receive message buffer used as the storage destination for received messages
- The Destination Message Buffer Setting Enable bit to specify the receive message buffer as the storage destination for received messages
- The FIFO Destination Enable bit to specify the FIFO as the storage destination for received messages.

There is no protection function for storing messages. Therefore, the FIFOFIFO Destination Enable bit must be set carefully.

36.5.7 Entering Entries in the AFL

One complete entry can be entered into AFL via the following registers:

- AFLn.IDR register: First part of the AFL entry
- AFLn.MASK register: Second part of the AFL entry
- AFLn.PTR0 register: Third part of the AFL entry
- AFLn.PTR1 register: Fourth part of the AFL entry.

These 16 sets of registers make up one page of AFL entries. There are 32 entries in the CANFD module, and all of these entries can be accessed by specifying the page with the AFCR.PAGE bit. The AFL should only be configured in CH_RESET or CH_HALT mode. Table 36.19 shows pages linked to the AFL entries.

Table 36.19 Pages Linked to the AFL Entries

Page	Linked AFL Entries
Page 0	Entry 0 to 15
Page 1	Entry 16 to 31

AFL access control is performed using the AFCR register (Figure 36.26). This register has the following bits:

- The PAGE bit for selecting the AFL page number
- The AFLWE bit that enables or disables the writing of data to prevent unnecessary write access to the AFL.

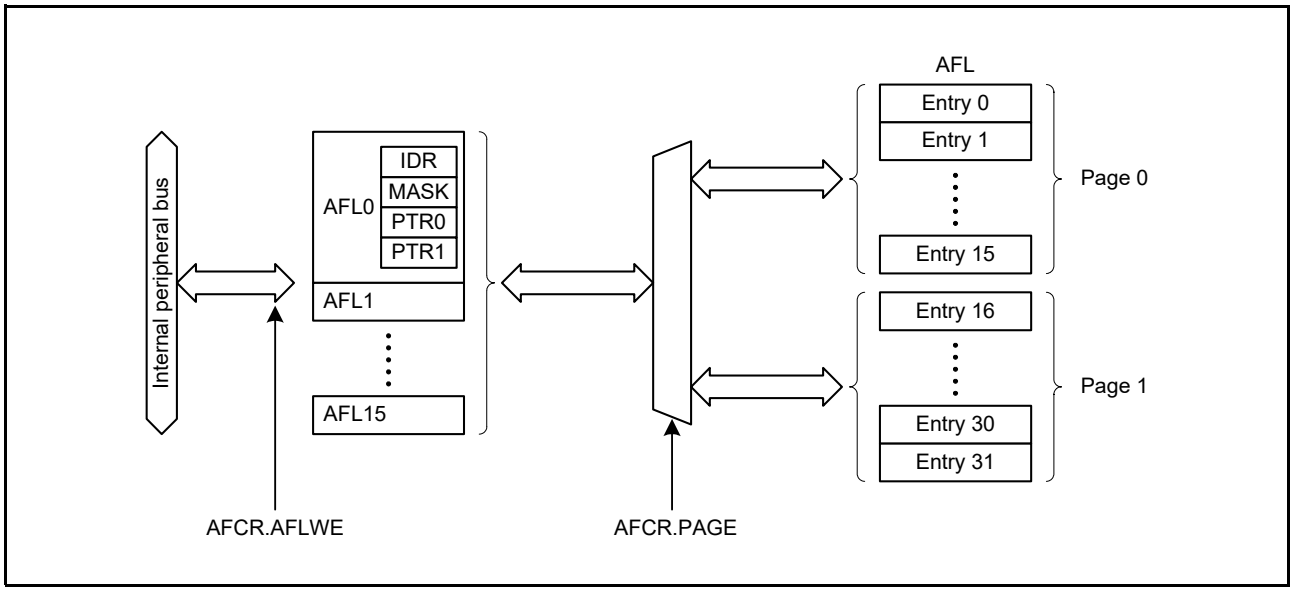

Figure 36.26 AFL Page Access

Follow the flow shown in Figure 36.27 to configure the AFL.
After entering all the entries, writing to the AFL must be disabled to prevent unnecessary write access to the AFL.
If the AFCR.AFLWE bit is set to 0, write protection is enabled during all Global modes (GL_RESET, GL_HALT, and GL_OPERATION).
Even if the AFCR.AFLWE bit is set to 0, reading from AFL is possible during all Global modes (the consistency of AFL contents can be checked during execution).

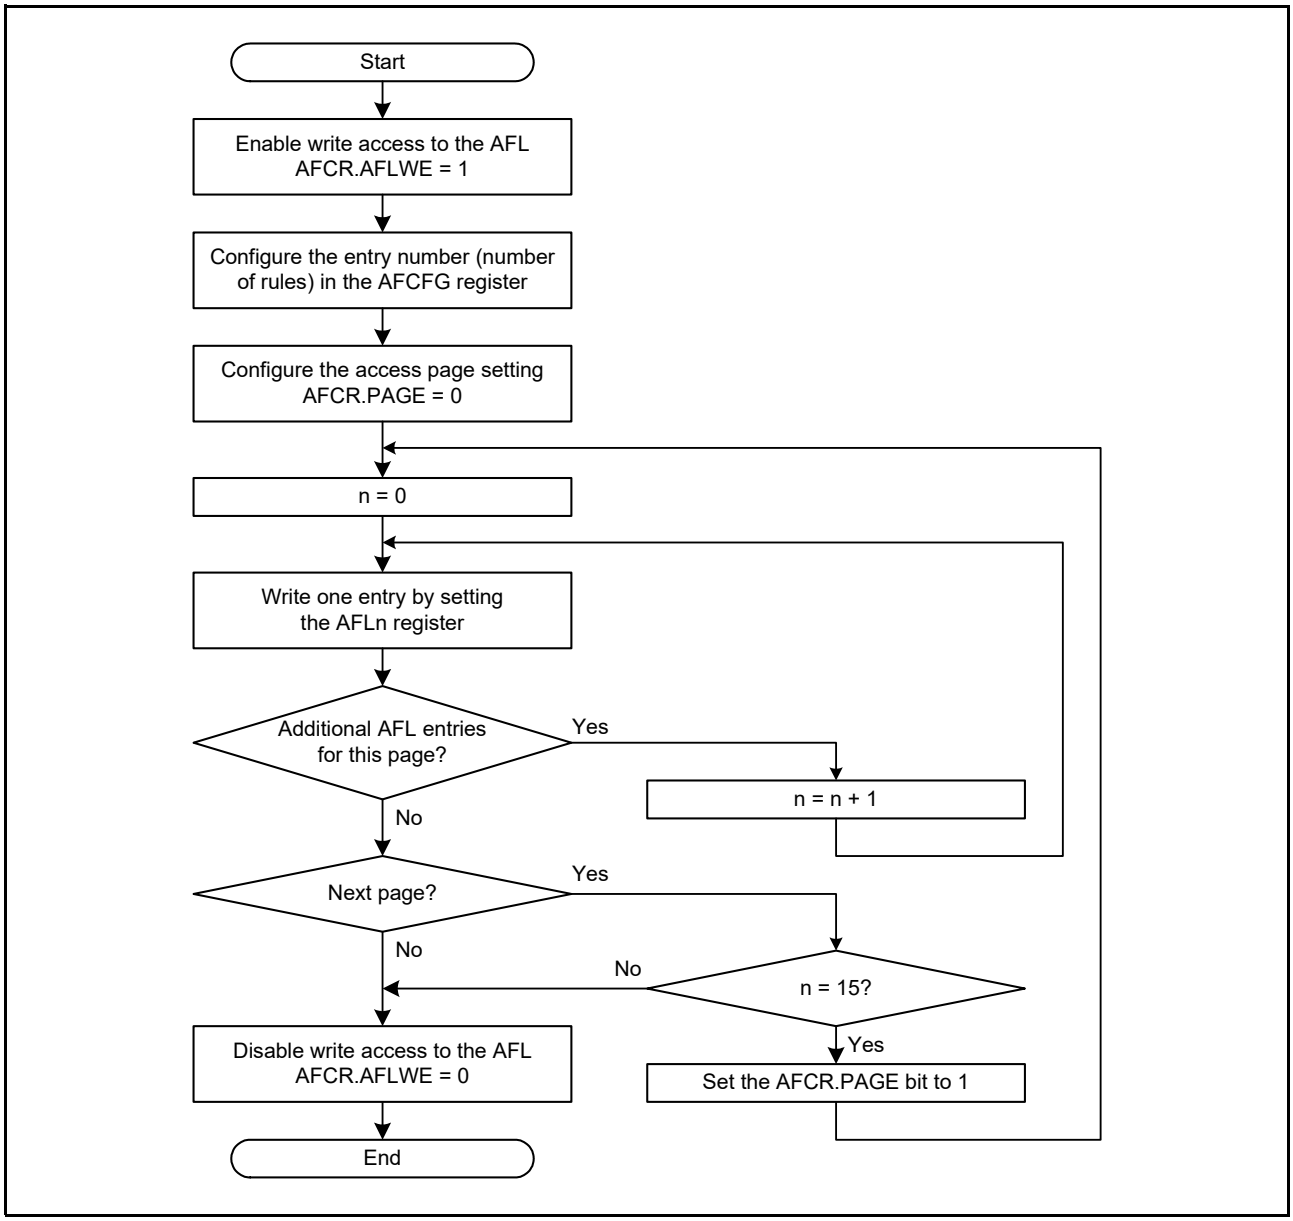

Figure 36.27 AFL Configuration Flow

36.5.8 Loopback Modes

AFL entries with the AFLn.IDR.LPC bit set to 1 are used only in loopback mode (self-test mode 0 or self-test mode 1) or mirror mode. If a message transmitted by another node on the CAN bus is received while in loopback mode, the AFL entry will not be used.
AFL entries with the AFLn.IDR.LPC bit set to 0 are used only for:

- Received messages transmitted by other nodes in normal (non-loopback mode) and mirror modes
- Received messages transmitted by other nodes or the local node in loopback mode.

The mirror mode can be enabled with the GCFG.MME bit. If the message is successfully transmitted when the GCFG.MME bit is 1, the message is stored in the received message buffer or FIFO buffer if there is a matching entry in the AFL. The AFLn.IDR.LPC bit in the matching AFL entry must be set to 1 to store this frame.
If mirror mode and loopback mode are set at the same time, the loopback mode behavior is applied. Table 36.20 shows the behavior of the acceptance filter unit depending on the setting of the related input signals.

Table 36.20 Behavior of Acceptance Filter Based on the Loopback Setting in AFL Entry

Mirror Mode (MME Bit)	Loopback Mode (Self-test Mode 0 or Self-test Mode 1)	Channel Mode	LPC Bit	AFL Entry
0	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Invalid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid
1	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Valid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid

Note: The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID, respectively.

36.5.9 IDE Masking

The IDE bit set in the AFL entry with the AFLn.MASK.IDEM bit set to 0 is not used for ID matching. In this case, the use of ID[10:0] or ID[28:0] matching is selected based on the received IDE bit.
The following lines show the examples.

- The ID and mask fields of an AFL entry x is configured as follows:
  – AFLx.IDR = C0553A20h → IDE = 1, RTR = 1, LPC = 0, ID[10:0] = 220h/ID[28:0] = 0553A20h
  – AFLx.MASK = 0000FFFFh → IDEM = 0. RTRM = 0, IDM[10:0] = 7FFh/IDM[28:0] = 0000FFFFh
- The comparison result for the four different received IDs with AFL entry x is described as follows:
  – If a frame with IDE = 0 and ID = 220h is received, this is considered as a match
  – If a frame with IDE = 0 and ID = 320h is received, this is not a match
  – If a frame with IDE = 1 and ID = 1FFF3A20h is received, this is considered as a match
  – If a frame with IDE = 1 and ID = 08803220h is received, this is not a match.

36.5.10 Updating AFL Entry during Communication

The AFL entry can be updated without disabling CAN communications.
Set the AFL entry number to update to the ignore entry select bits and set the ignore entry enable bit to 1.
The entry number specified here is ignored by AFL matching while the entry is being updated.
Figure 36.28 shows the update flow for an AFL entry.

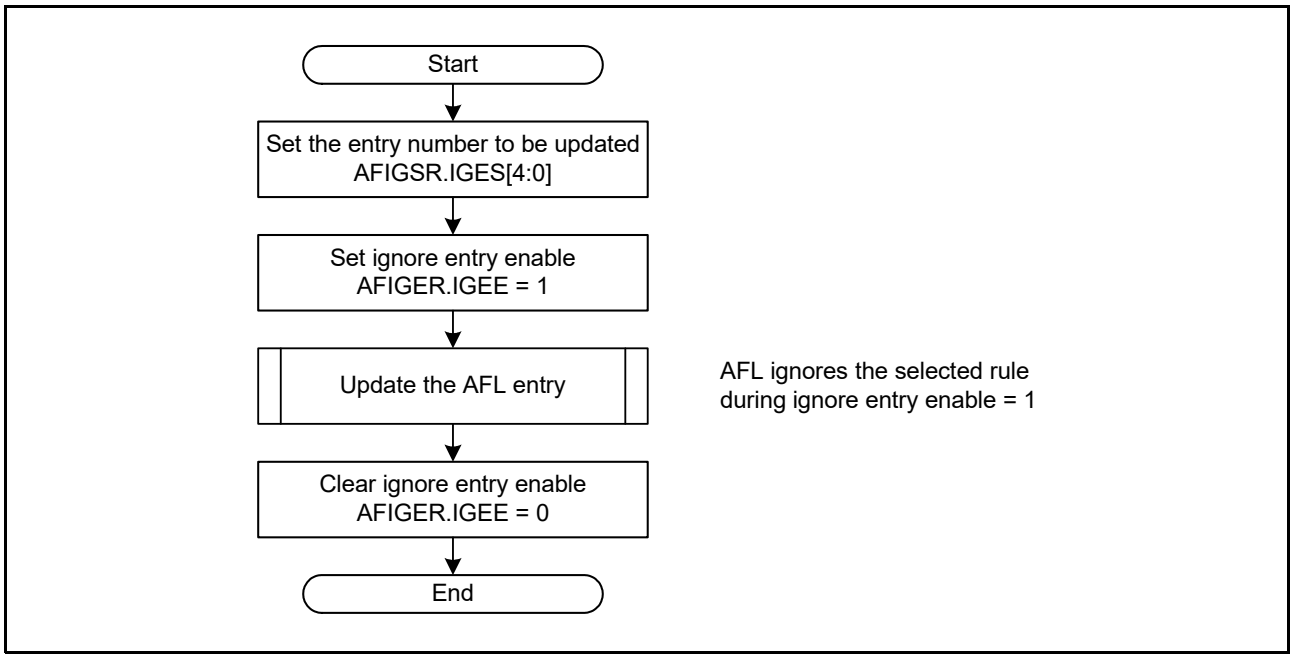

Figure 36.28 Update Flow for An AFL Entry

The method to update an AFL entry is as follows:

1. Set the entry number*1 to be updated to the AFIGSR.IGES[4:0] bit.
2. Set the value 0000C401h (key code and ignore entry enabled) to the AFIGER register.
3. Set the page number which includes the entry to be updated to the AFCR.PAGE bit. Set the AFCR.AFLWE bit to 1.
4. Set the new rule to the AFLn.IDR, AFLn.MASK, AFLn.PTR0, AFLn.PTR1 registers.
5. The AFCR.AFLWE bit is set to 0.
6. Set the value 0000C400h (key code and ignore entry disabled) to the AFIGER register.

Note 1. This entry number is not used for acceptance filtering between (2) and (5).

(1) Example 1: Deleting an Entry

The following describes how to delete entry 3 when the total number of entries is 6.

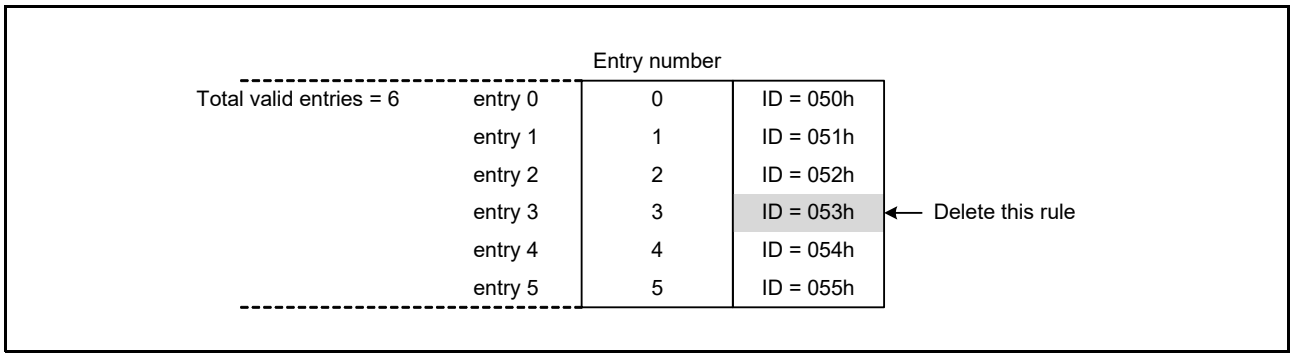

Figure 36.29 Example of Deleting an Entry (Before Deleting Entry 3)

[How to delete an entry]

(1) Set 00000003h to the AFIGSR register.
(2) Set 0000C401h to the AFIGER register.
(3) Set 00000100h to the AFCR register.
(4) Set the same rule as the previous rule by accessing the AFL3.IDR, AFL3.MASK, AFL3.PTR0, AFL3.PTR1 registers.
(5) Set 00000000h to the AFCR register.
(6) Set 0000C400h to the AFIGER register.

Entry 3 is now deleted.

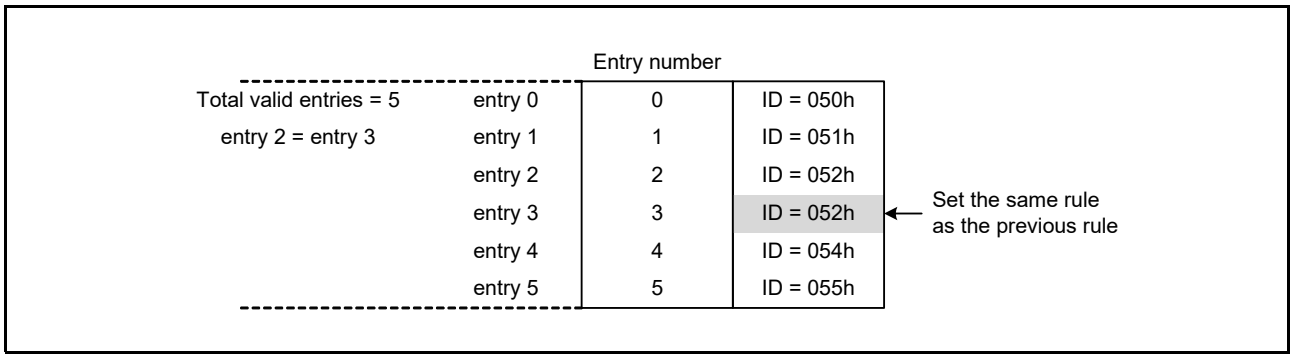

Figure 36.30 Example of Deleting an Entry (After Deleting Entry 3)

(2) Example 2: Adding an Entry (Update Unused Entry)

The following describes how to add a new entry to entry 3 when the total number of entries is 6.

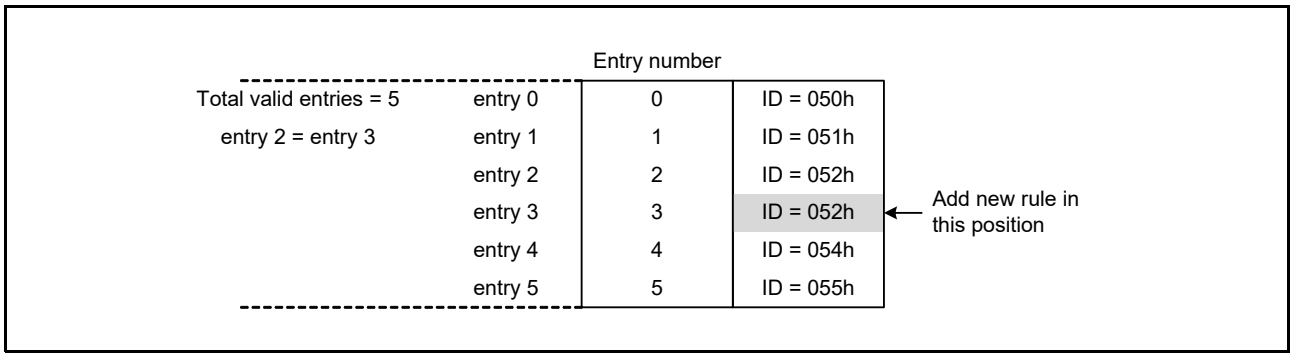

Figure 36.31 Example of Adding an Entry (Before Updating Entry 3)

[How to add an entry]

(1) Set 00000003h to the AFIGSR register.
(2) Set 0000C401h to the AFIGER register.
(3) Set 00000100h to the AFCR register.
(4) Set the new rule by accessing the AFL3.IDR, AFL3.MASK, AFL3.PTR0, AFL3.PTR1 registers.
(5) Set 00000000h to the AFCR register.
(6) Set 0000C400h to the AFIGER register.

The new entry is now added.

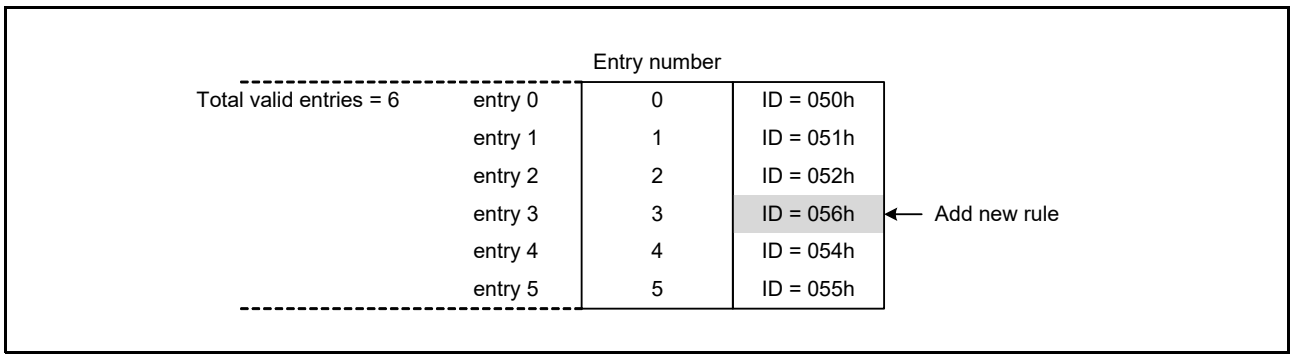

Figure 36.32 Example of Adding an Entry (After Updating Entry 3)

The acceptance filter can use entries in the range of value set in the AFCFG register and entries can be added/deleted within that range. Therefore, the AFCFG register should be set to the maximum number of entries to use.

36.6 FIFO Buffers and Message Buffer Configuration

This section describes the process for configuring the number of receive message buffers, the FIFO buffers, and the transmit message buffers in the CANFD module. The message buffers are mapped as shown in Figure 36.33.
The receive message buffers can be accessed with the RMBn register (n = 0 to 31).
The receive FIFOs can be accessed with the RFBn register (n = 0, 1).
The common FIFO can be accessed with the CFB0 register.
If the common FIFO is configured in transmit mode, only data can be written to the FIFO buffer by the CFB0 register.
If the common FIFO is configured in receive mode, only data can be read by the CFB0 register.
The transmit message buffers can be accessed with the TMBn register (n = 0 to 3).
If unused message buffer is read, it is read as undefined.

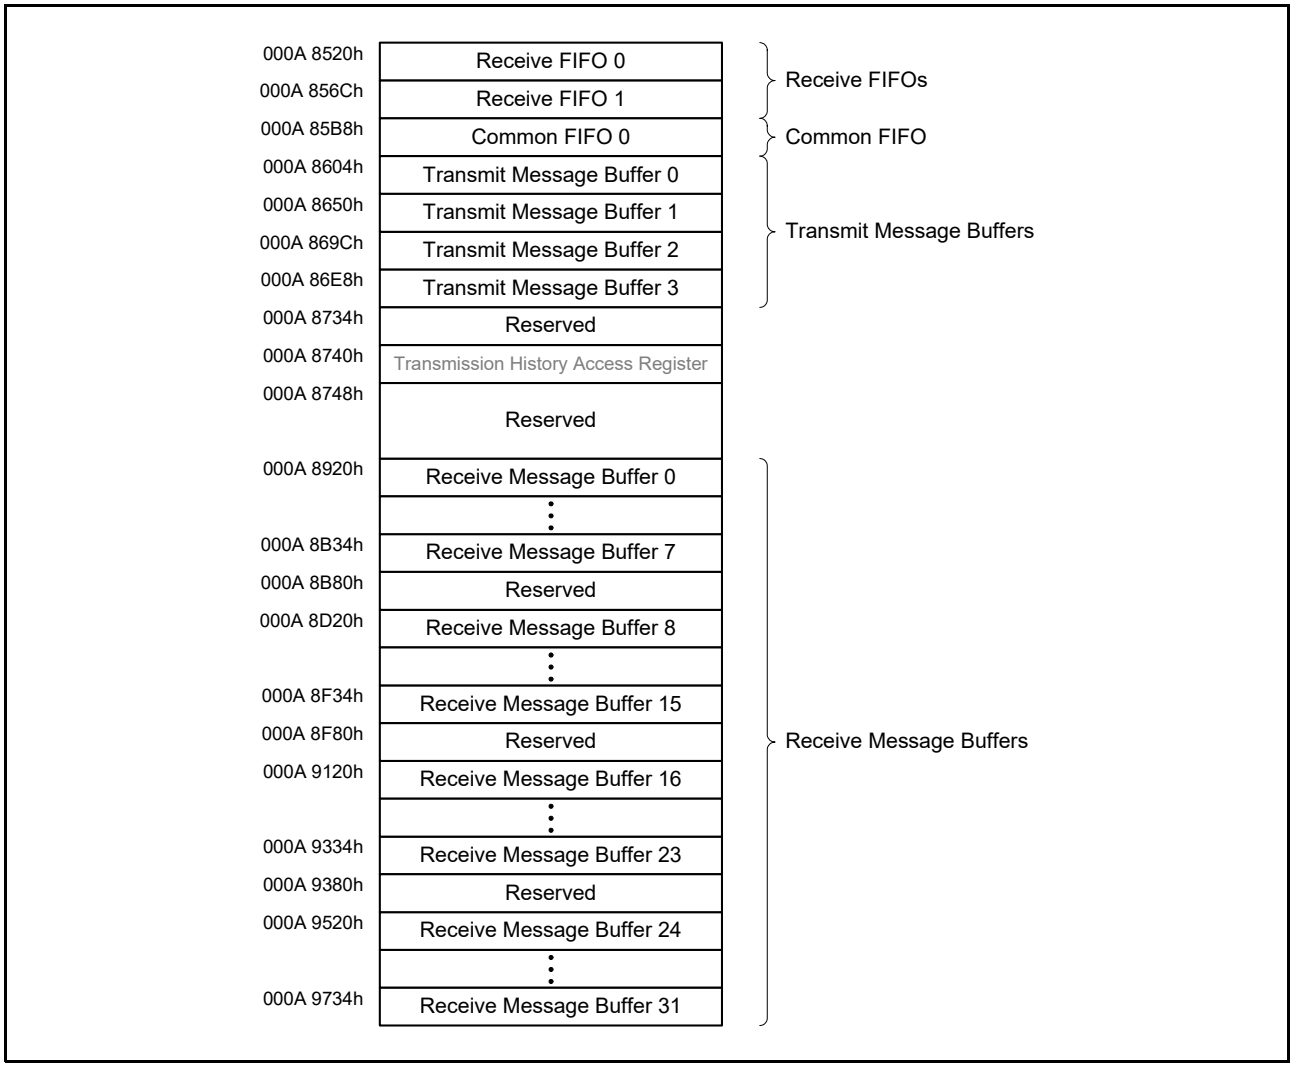

Figure 36.33 Message Buffer Configuration

36.6.1 Receive Message Buffers

In CANFD module, the received frames can be stored in receive message buffers based on the configuration of the AFL entries.
Additionally, the number of receive message buffers required by the system can be selected from 0 to 32.

36.6.1.1 Receive Message Buffer Configuration

The number of receive message buffers in CANFD module can be configured by writing to the RMCR.NMB[5:0] bits. Set the number of message buffers in the range 0 (no receive message buffers) to 32. Do not set a value larger than this.
The AFL entries for routing the received messages to receive message buffers must be configured to match the requirements of the system.
The AFL entries must also be configured properly, and an AFL entry for receive message buffers should not exceed the number of message buffers configured in the RMCR.NMB[5:0] bits.

Note: There is no internal check procedure provided in CANFD module against wrong configuration of the AFL.

The payload size of the receive message buffer can be configured with the RMCR.PLS[2:0] bits. The default size is 8 bytes and the maximum size is 64 bytes.
If the payload size of the received frame exceeds the specified payload size, the message is discarded or the payload is cut according to the setting of the GCFG.OMRC bit.

36.6.2 FIFO Buffers

The CANFD module provides a FIFO buffers to store each receive/transmit frame.
There are two receive-only FIFOs, but common FIFO can be configured to store messages for transmission or reception.
These FIFO buffers can be enabled or disabled, and the following parameters can be configured to match the system requirements:

- FIFO depth
- Interrupt structure
- Message lost mechanism
- Message overwrite mechanism of the FIFO buffers
- Location of the transmit FIFO

If the payload size of the received frame exceeds the specified payload size, the message is discarded or the payload is cut according to the setting of the GCFG.OMRC bit.

36.6.2.1 FIFO Buffers Configuration

In CANFD module, the FIFO buffers can be configured to match the system requirements.
The total number of FIFO buffers is three (two receive FIFOs + one common FIFO).

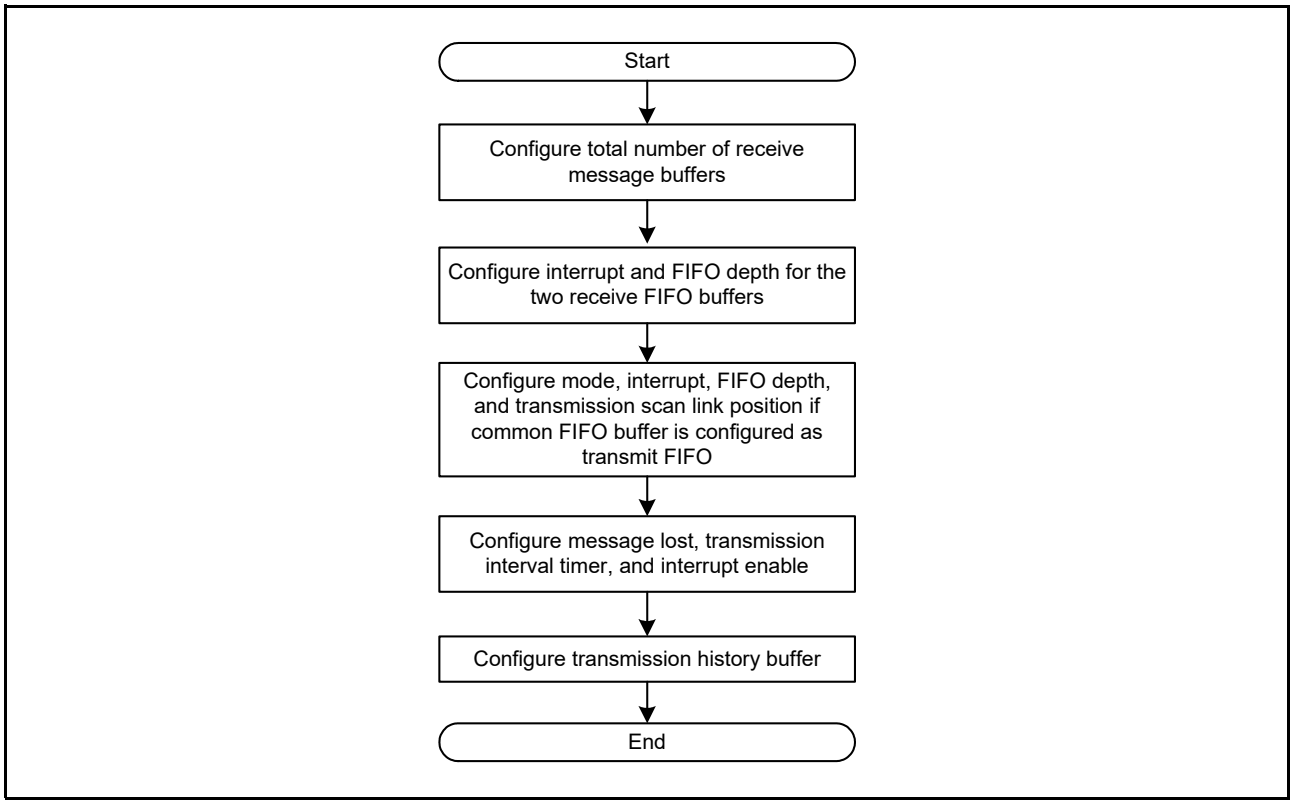

Figure 36.34 FIFO Buffer Configuration Flow in CANFD Module

As shown in Figure 36.34, the various FIFO buffers can be configured by writing to the Receive FIFO n Configuration Register and the Common FIFO 0 Configuration Register.

For the two receive FIFOs, the following parameters can be configured:

- Interrupts
- FIFO depth
- Payload size

For the common FIFO, the following parameters can be configured:

- Mode
- Interrupts
- FIFO depth
- Payload size
- Transmission scan link position

(1) FIFO mode configuration of common FIFO

The mode of the common FIFO can be configured by writing to the CFCR0.MODE bit. The modes that can be configured in the common FIFO are as follows:

- 00b: Receive FIFO mode (default mode after a MCU reset)
- 01b: Transmit FIFO mode.

Messages can only be read from the receive FIFOs and the common FIFO configured in receive FIFO mode. Messages are stored by the CANFD module in these FIFO buffers based on the AFL entries.
Messages can be read and written into the common FIFO configured in transmit FIFO mode.
The pointers can be incremented only when a new message is stored in the FIFO buffer and decremented only when a message is transmitted on the corresponding CAN channel by the CANFD module.
After a MCU reset, all the common FIFO is configured in receive FIFO mode by default. Only enable the FIFO buffers after configuring the common FIFO in the required modes.

(2) FIFO transmit message buffer link configuration

When the common FIFO is configured as transmit FIFO, the FIFO buffer must be linked to a normal transmit message buffer to participate in the transmission scan of a CAN channel.
Do not write data into a transmit message buffer that is linked to a common FIFO. Also, the transmit message buffer linked to a common FIFO should not be a part of the transmit queue.
The link to the transmit message buffer of common FIFO can be configured by writing to the CFCR0.LTM[1:0] bits. The options available for linking the transmit message buffer are:

- 00b: Transmit message buffer 0
- 01b: Transmit message buffer 1
- 10b: Transmit message buffer 2
- 11b: Transmit message buffer 3.

(3) FIFO depth configuration

The depth of each FIFO buffer can be configured by writing to the RFCRn.FDS[2:0] bits and CFCR0.FDS[2:0] bits. The six available options for depth configuration are:

- 000b: 0 messages (FIFO buffer cannot be used)
- 001b: 4 messages
- 010b: 8 messages
- 011b: 16 messages
- 100b: 32 messages
- 101b: 48 messages.

The RAM allocated to the receive message buffers and FIFO buffers is limited to 16 messages (1216 bytes) when the payload size is set to 64 bytes. Do not configure the receive message buffers and FIFO buffers that exceed this maximum limit. CANFD module does not have the function to check the validity of the configuration.

Note: If the FIFO depth of the common FIFO is 4 messages or more (CFCR0.FDS[2:0] > 000b), the link between the common FIFO and the transmit message buffer is valid regardless of whether the FIFO is disabled or enabled. If the FIFO depth is 0 messages, the link between the common FIFO and transmit message buffer is invalid regardless of whether the FIFO is disabled or enabled.

(4) FIFO payload size configuration

The payload size of each FIFO buffer can be configured by writing to the RFCRn.PLS[2:0] bits and CFCR0.PLS[2:0] bits. The eight available options for depth configuration are:

- 000b: 8 bytes
- 001b: 12 bytes
- 010b: 16 bytes
- 011b: 20 bytes
- 100b: 24 bytes
- 101b: 32 bytes
- 110b: 48 bytes
- 111b: 64 bytes.

The RAM allocated to the receive message buffers and FIFO buffers is limited to 16 messages (1216 bytes) when the payload size is set to 64 bytes. Do not configure the receive message buffers and FIFO buffers that exceed this maximum limit. CANFD module does not have the function to check the validity of the configuration.

(5) FIFO interrupt configuration

The interrupt generation conditions for the FIFO buffers can be configured by writing to the RFCRn.RFIM bit and CFCR0.CFIM bit. The two available options are:

- RFIM/CFIM = 0:
  - Receive FIFO mode: An interrupt is generated when the FIFO fill level reaches RFCRn.RFITH[2:0] or CFCR0.CFITH[2:0] value
  - Transmit FIFO mode: An interrupt is generated when the FIFO transmits the last message successfully
- RFIM/CFIM = 1:
  - Receive FIFO mode: An interrupt is generated each time the received message is stored
  - Transmit FIFO mode: An interrupt is generated each time a message is successfully transmitted.

If the RFCRn.RFIM bit for the receive FIFO is 0, an interrupt is generated based on the setting of the RFCRn.RFITH[2:0] bits.
Similarly, if the CFCR0.CFIM bit for a common FIFO set to receive FIFO mode is 0, an interrupt is generated based on the setting of the CFCR0.CFITH[2:0] bits.
The eight options available to set the FIFO fill level for generating interrupts are:

- 000b: Interrupt generated when FIFO is 1/8 Full
- 001b: Interrupt generated when FIFO is 1/4 Full
- 010b: Interrupt generated when FIFO is 3/8 Full
- 011b: Interrupt generated when FIFO is 1/2 Full
- 100b: Interrupt generated when FIFO is 5/8 Full
- 101b: Interrupt generated when FIFO is 3/4 Full
- 110b: Interrupt generated when FIFO is 7/8 Full
- 111b: Interrupt generated when FIFO is Full.

In this case, an interrupt is generated when the message fill level matches the set value.
However, as shown in Table 36.21, there are some restrictions on the RFITH[2:0] and CFITH[2:0] bit settings, depending on the FDS[2:0] bits (FIFO depth setting) of each register.

Table 36.21 FIFO Interrupt Threshold and FIFO Depth Settings

	RFITH[2:0]/CFITH[2:0]							
FDS[2:0]	**111b (full)**	**110b (7/8)**	**101b (3/4)**	**100b (5/8)**	**011b (1/2)**	**010b (3/8)**	**001b (1/4)**	**000b (1/8)**
000b (0 messages)	Invalid (FIFO cannot be enabled)							
001b (4 messages)	Allowed	Prohibited	Allowed	Prohibited	Allowed	Prohibited	Allowed	Prohibited
010b (8 messages)	Allowed							
011b (16 messages)	Allowed							
100b (32 messages)	Allowed							
101b (48 messages)	Allowed							

36.6.2.2 FIFO Buffers Control

To enable the receive FIFO interrupt, set the RFIE bit in the RFCRn register (n = 0, 1) to 1.
To enable the common FIFO interrupt, set either the CFRIE or CFTIE bit in the CFCR0 register:
After configuration is complete, each FIFO can be enabled by setting the RFCRn.RFE bit and CFCR0.CFE bit to 1 to allow transmission and reception of messages.

36.7 Reception and Transmission

36.7.1 Reception

In the CANFD module, messages received on any of the channels, will be stored in receive message buffers or in receive FIFOs or common FIFO configured in receive FIFO mode depending upon the Acceptance Filter List entries:

- up to 32 receive message buffers can be configured
- two receive FIFOs available
- up to one common FIFO can be configured in receive mode

36.7.1.1 Message Storage in Receive Message Buffers

When a message is successfully received and stored in a receive message buffer, the corresponding NDR[n] flag in the RMNDR register is set to 1.
The stored message can be read from the corresponding receive message buffer.
If a new message is stored into a receive message buffer before the previous message in this message buffer is read, the original message is overwritten. There is no mechanism for preventing a new message from overwriting the current message in the receive message buffer. If such a loss of messages is not acceptable, store related messages by using receive FIFO.

Note: Unused data bytes are filled with 00h depending on the DLC value.

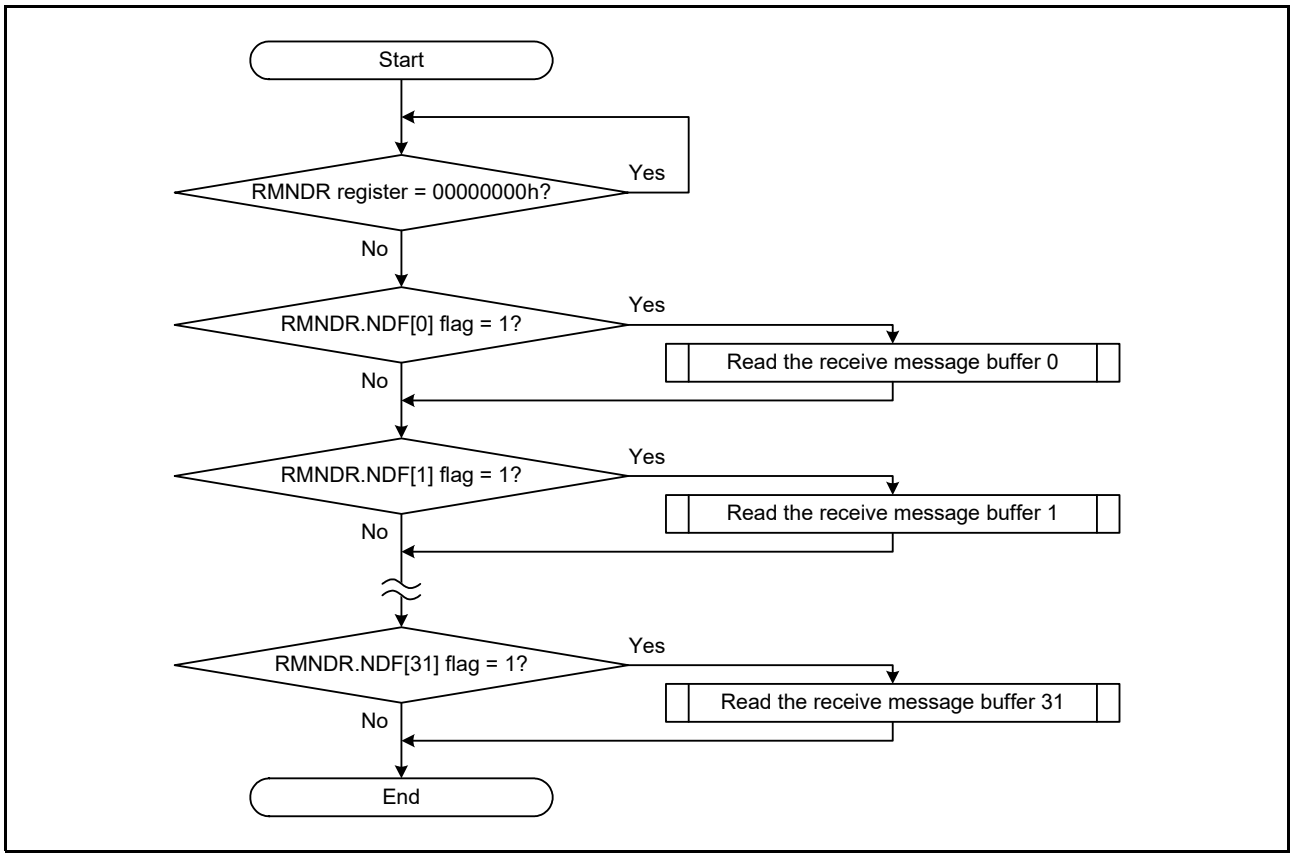

Figure 36.35 Receive Message Buffer Message Access Flow (Example for Polling Case)

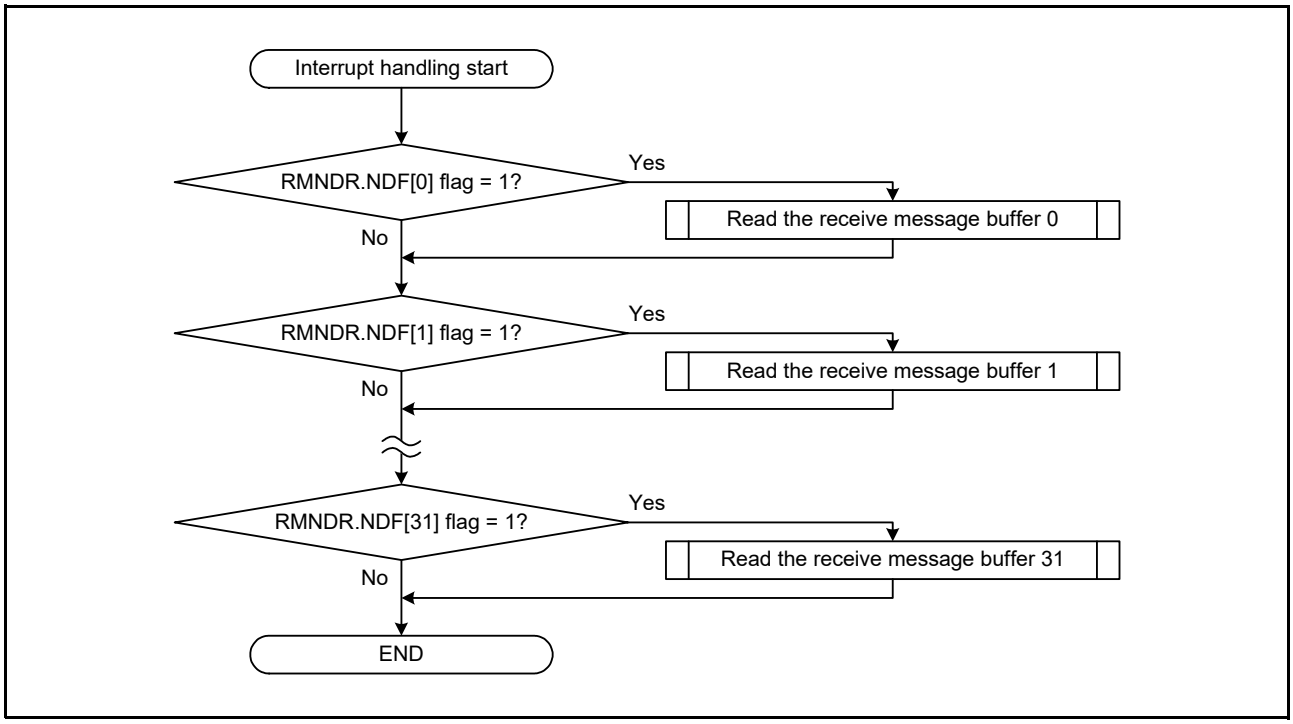

Figure 36.36 Receive Message Buffer Message Access Flow (Example for Interrupt Case)

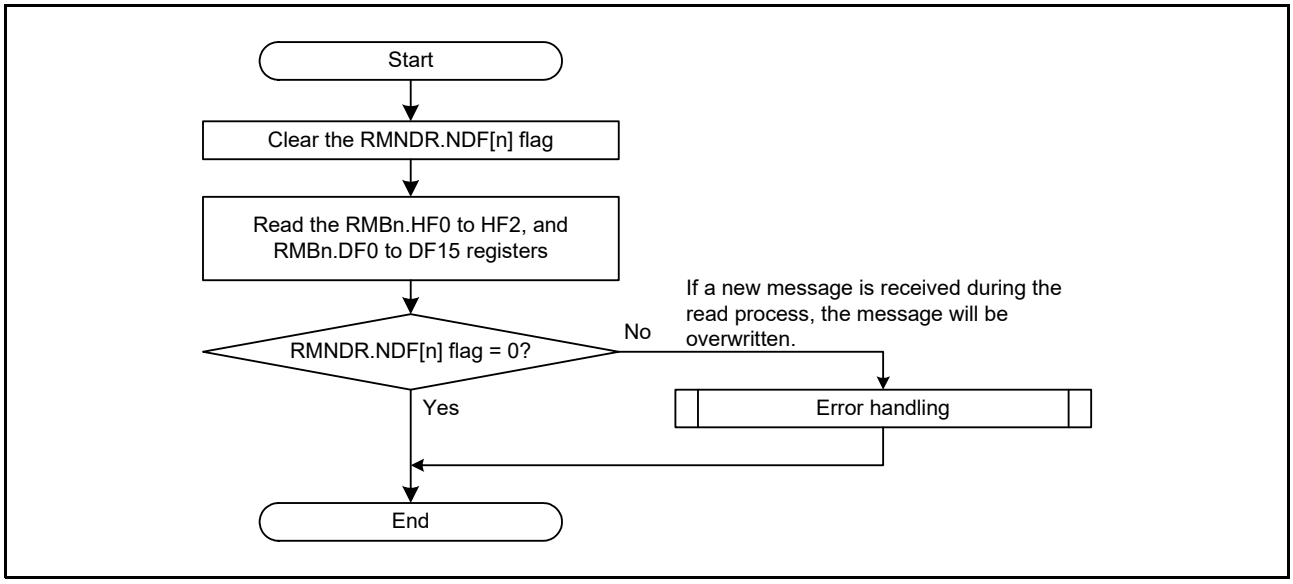

Figure 36.37 Receive Message Buffer n Read Flow

36.7.1.2 Message Storage in FIFO Buffers

The AFL entries for routing the received messages to receive FIFOs or common FIFO configured in receive mode should be configured based on the requirements of the system.
The AFLn.PTR1.RF0E, RF1E, or CF0E bit in the matching AFL entry selects the FIFO buffers to which the related reception message will be stored.
When the received message is stored in one or more receive FIFOs or common FIFO configured in receive FIFO mode, the message counter value is incremented in the corresponding Receive FIFO n Status Register or Common FIFO 0 Status Register.
Depending upon the configuration of the FIFO buffers, an interrupt may also be generated. The message can be read from the corresponding FIFO access registers.

Note: Since many messages can be stored in the FIFO buffers, reading more than one message may be required to read the latest message stored in a FIFO buffer.

If the message count value matches the FIFO depth, then the FIFO full flag is set.
When the value 000000FFh is written to the corresponding FIFO Pointer Control Register, then the message count is decremented by 1.

Only write 000000FFh to the FIFO Pointer Control Register after completely reading the message from the FIFO Access Register of the corresponding FIFO.
When all the messages stored in the FIFO are read, then the FIFO empty flag is set.
If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO full condition), the FIFO message lost flag is set and the new message will be lost (messages already stored will not be overwritten).
To prevent message loss due to overrun, set an appropriate interrupt generation threshold and generate an interrupt before the FIFO becomes full.

The receive FIFOs and the common FIFO configured in receive FIFO mode can be disabled at any time by clearing the RFCRn.RFE bit or CFCR0.CFE bit.
When the RFCRn.RFE bit or CFCR0.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Hence, all messages in the FIFO buffers will be lost and no further messages can be stored into the FIFO.
When the receive FIFOs or common FIFO configured in receive FIFO mode is set to be read by DTC/DMA transfer, do not read the FIFO buffer on the CPU or write 000000FFh to the FIFO Pointer Control Register (RFPCR0, RFPCR1, or CFPCR0). The FIFO read pointer is automatically updated when read by DTC / DMA transfer.

Note: If the interrupt flag is set for a FIFO buffer and then the FIFO is disabled, then the interrupt flag will not be cleared automatically. The interrupt flag should be cleared before disabling the FIFO.
Note: When the next frame is received before clearing the receive interrupt flag, the receive interrupt flag is not set again.

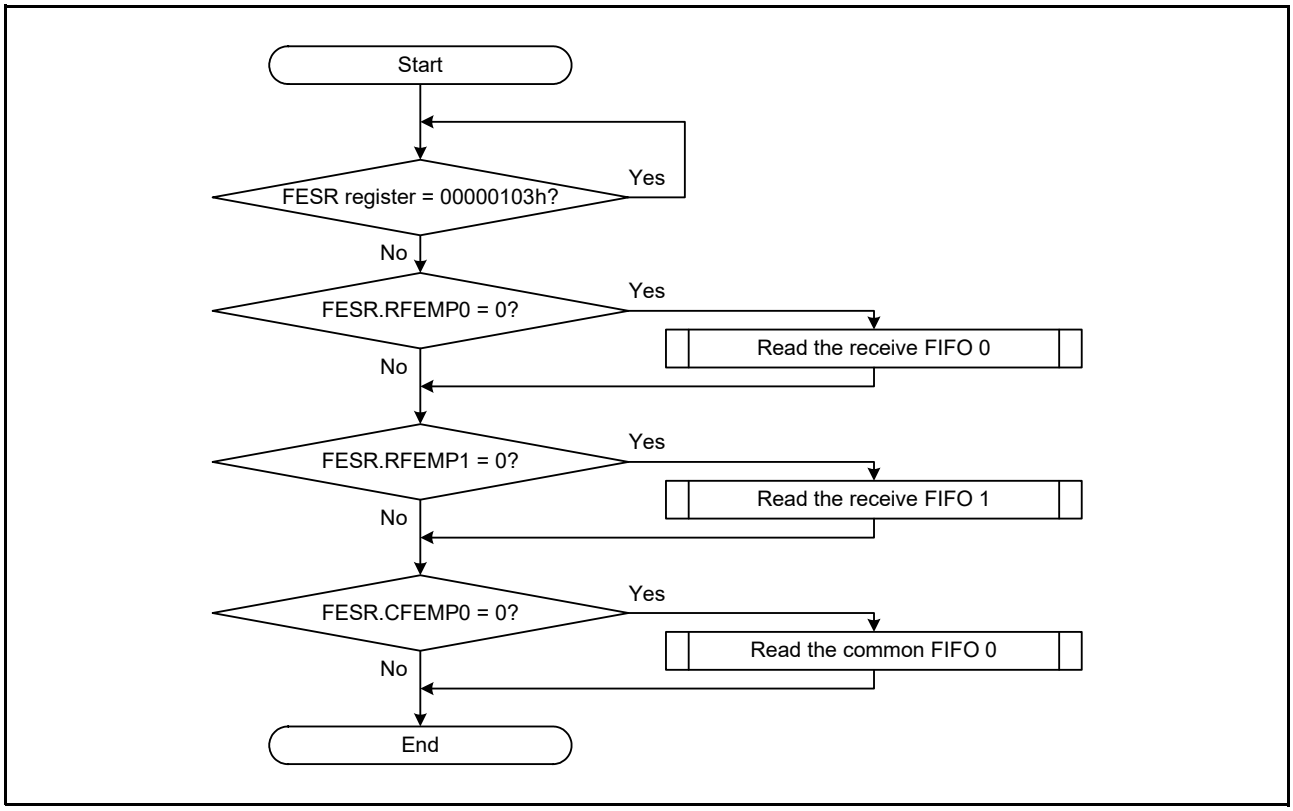

Figure 36.38 FIFO Buffer Message Access Flow (Example for Polling Case)

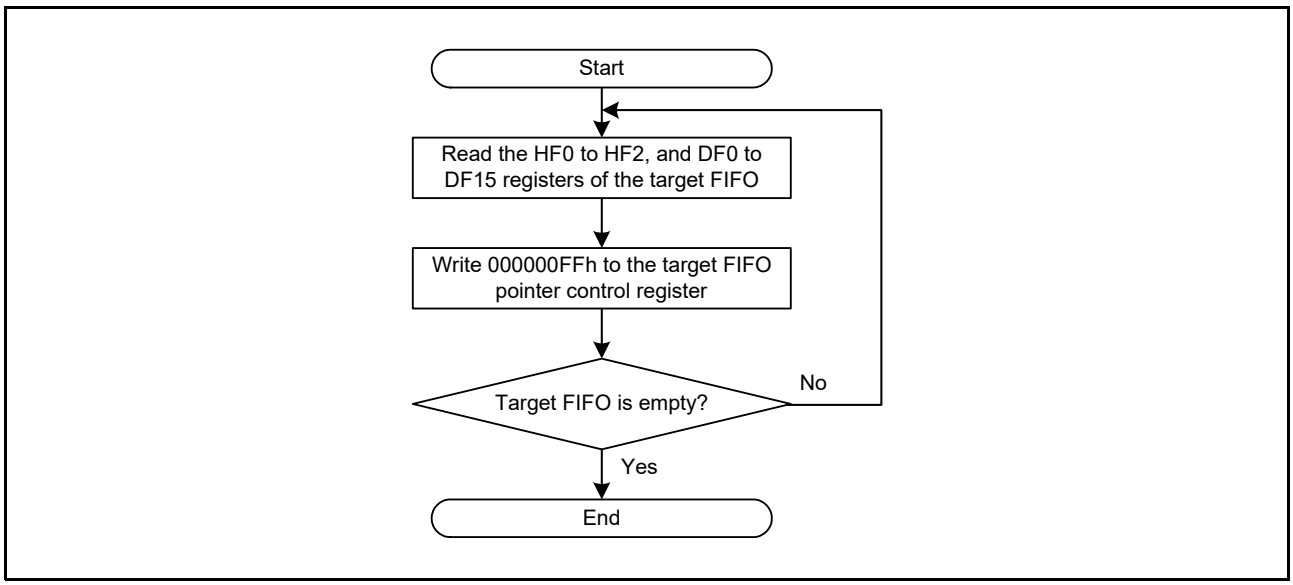

Figure 36.39 Receive FIFO Read Flow (Example for Polling Case)

If the interrupt flag is cleared after the FIFO read process is completed, the interrupt flag is not set even if the next frame has already been received. The FIFO read process must be performed and the interrupt flag must be cleared before the reception of the next frame is completed. If the process is not in time, make sure the FIFO is empty, clear the interrupt flag, and make sure the FIFO is empty again.

36.7.1.3 Timestamp

The timestamp counter is a free-running counter that can be used to check reception time of a received message or transmission time of a successful transmitted message. The timestamp counter value will be captured based on the GFDCFG.TSCPS[1:0] bit setting (sample point of SOF, EOF when the frame is taken valid, or sample point of res bit following the FDF bit in case of a CAN FD frame). For reception the timestamp counter value is stored together with the message ID and data into the target receive message buffer or receive FIFO.
For transmit message the timestamp counter value is stored as part of the transmission history entry.
The counter can be clocked from PCLKB or the bit timing clock of the CAN channel. The counter count source can be set with the GCFG.TSCS bit. If the GCFG.TSCS bit is 0, PCLKB is used. If it is 1, the bit time clock of CAN channel is used.
The count source of the timestamp counter can be divided by the coefficient defined by the GCFG.TSP bit (timestamp prescaler).
The timestamp counter can be reset to 0000h with the GCR.TSCR bit (timestamp counter reset).

36.7.2 Transmission

There are several possible transmission configurations:

- Normal transmission
- FIFO transmission
- Transmit queue transmission

The CANFD module has four transmit message buffers. These message buffers are only used for transmission and cannot be configured for reception.
Additionally transmission from transmit queue and/or common FIFO configured in transmit FIFO mode can be set in the following way (refer to Figure 36.33):

- Transmit queue
  3 or 4 transmit message buffers for one channel can be grouped to form a transmit queue with a common access window.
  Transmit message buffer 0 acts as an access window for transmit queue 0 (TXQ0).
- Common FIFO (transmit FIFO mode)
  The CANFD module has one common FIFO. Common FIFO configured in transmit FIFO mode is linked to any of the transmit message buffers 0 to 3.
  The linked transmit message buffer replaces the common FIFO. Do not access the TMCRn or TMSRn registers of the linked send message buffer.

Note: Common FIFO should not be linked to transmit message buffers that are already part of a transmit queue.

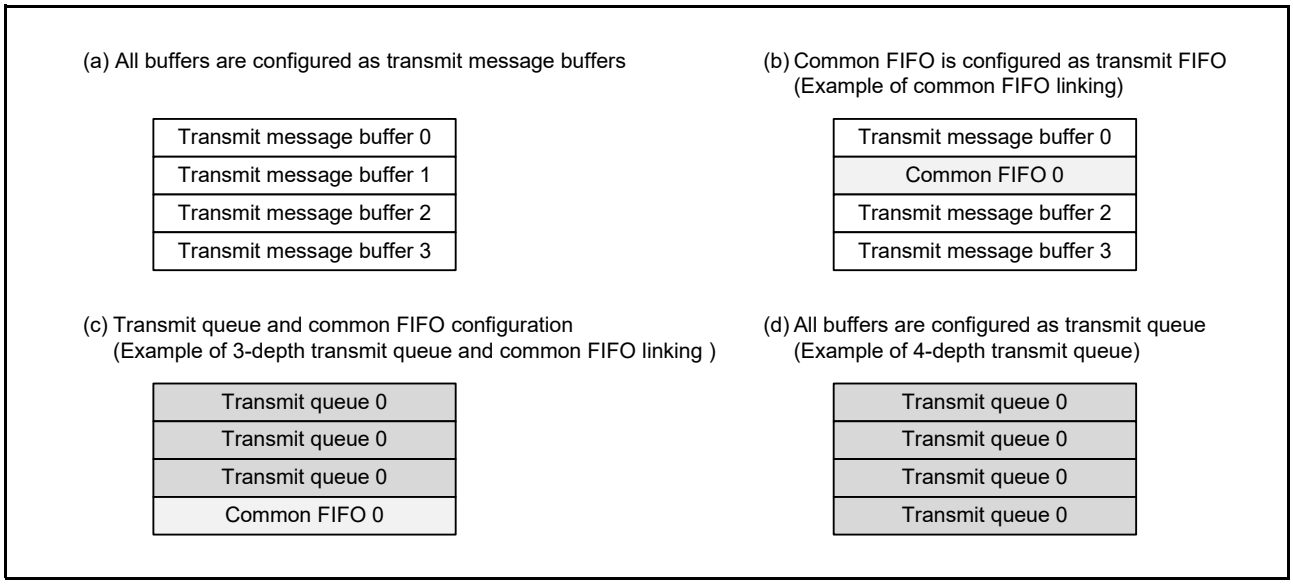

Figure 36.40 Channel Transmit Message Buffer Configuration

36.7.2.1 Transmission Priority

If two or more transmit message buffers of a channel are configured for transmission, the transmission priority in the CANFD module can be selected from the followings:

- CAN ID priority
- Message buffer number priority

The transmission priority is common for all message buffers. It can be configured via the GCFG.TPRI bit.
For message buffer number priority transmission, the smallest message buffer number with transmission request has the highest priority for transmission. This also includes the transmit message buffers linked to the common FIFO configured in transmit FIFO mode.
Do not select message buffer number priority when using the transmit queue.
For CAN ID priority transmission, ID priority complies with the CAN bus arbitration rule (as specified in ISO 11898-1 specification). All transmit message buffers can enter the ID priority comparison for message buffers configured for transmission. This also includes the transmit message buffers linked to the common FIFO configured in transmit FIFO mode and includes the transmit queue message buffers.
If the ID of two or more message buffers is the same, then the smaller message buffer number will have higher priority for transmission.

Note: For common FIFO configured in transmit FIFO mode, only the message currently being pointed to by the FIFO read pointer can be included in the transmission arbitration.
If the message is being transmitted from the FIFO, then the next pending message within the same FIFO will be considered in the transmission arbitration.
In contrast to this, all transmit message buffers of a transmit queue will participate in internal transmission arbitration.

Figure 36.41 below shows the transmission configuration flow.

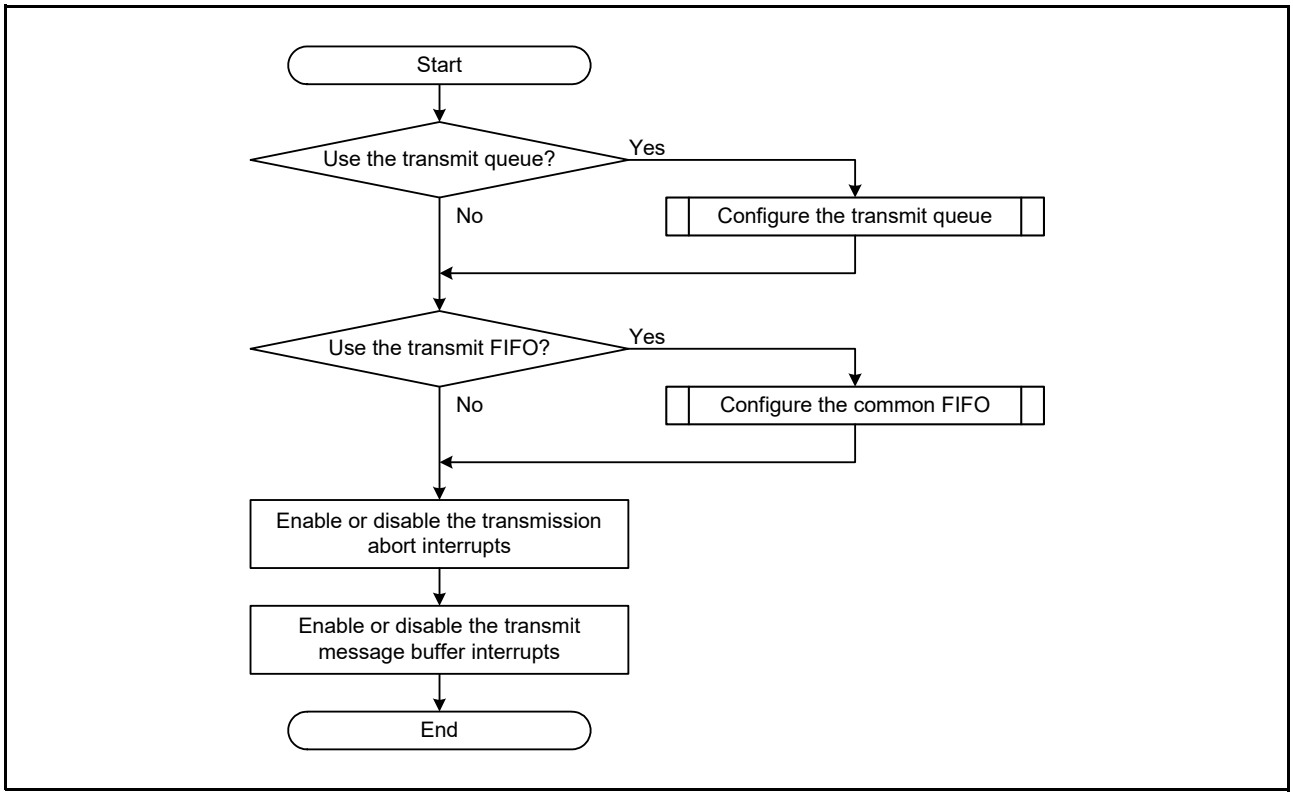

Figure 36.41 Transmission Configuration Flow

36.7.2.2 Message Transmission from Transmit Message Buffer

Each transmit message buffer has two modes of message transmission:

- Normal Transmission Mode
  When the message buffer is set to normal transmission mode, the data frames or remote frames set in that message buffer can be transmitted.
  Completion of normal transmission can be checked by the TMSRn.TXRF[1:0] flags. These flags are set to 10b or 11b when a normal transmission is successful.
  When arbitration is lost or an error occurs during transmission, the message transmission will be retried if no transmission abort request is set in the transmit message buffer.
  A new internal transmission arbitration is performed for all message buffers that have a transmission request.
- One-Shot Transmission Mode
  When the TMCRn.ONESHOT bit is set to 1, the message buffer is placed in one-shot transmission mode and attempts to transmit the message only once.
  Completion of one-shot transmission can be checked by the TMSRn.TXRF[1:0] flags. These flags are set to 10b or 11b when the one-shot transmission is successful.
  The TXRF[1:0] flags are set to 01b when arbitration is lost or an error occurs during transmission. In this case, message transmission will not be retried.

Figure 36.42 shows the transmission request procedure from transmit message buffer.

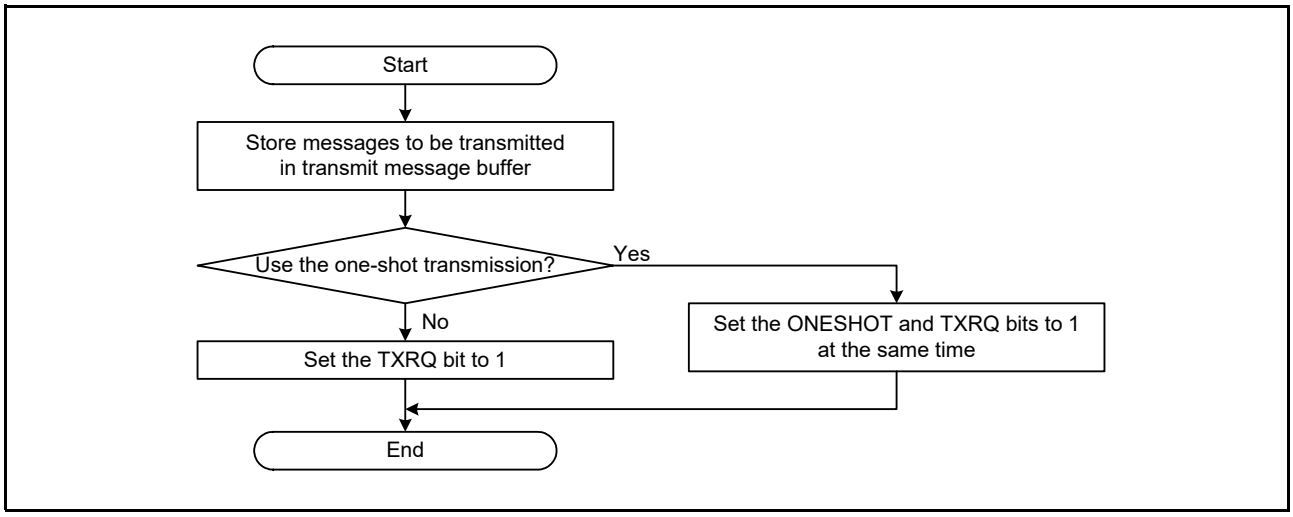

Figure 36.42 Transmission Request Procedure from Transmit Message Buffer

Table 36.22 shows configuration of the TMCRn register.

Table 36.22 Configuration of TMCRn Register

Transmission Request TXRQ Bit	Transmission Abort Request TARQ Bit	One-Shot Transmission Enable ONESHOT Bit	Message Buffer Status
0	0	0	Normal transmission is stopped.
0	0	1	One-shot transmission is stopped.
1	0	0	Data frames or remote frames are transmitted in normal transmission mode.
1	0	1	A data frame or a remote frame is transmitted in one-shot transmission mode.
1	1	0	Transmission abort is requested.
1	1	1	One-shot transmission abort is requested.

Figure 36.43 shows timings for successful transmission from two message buffers.

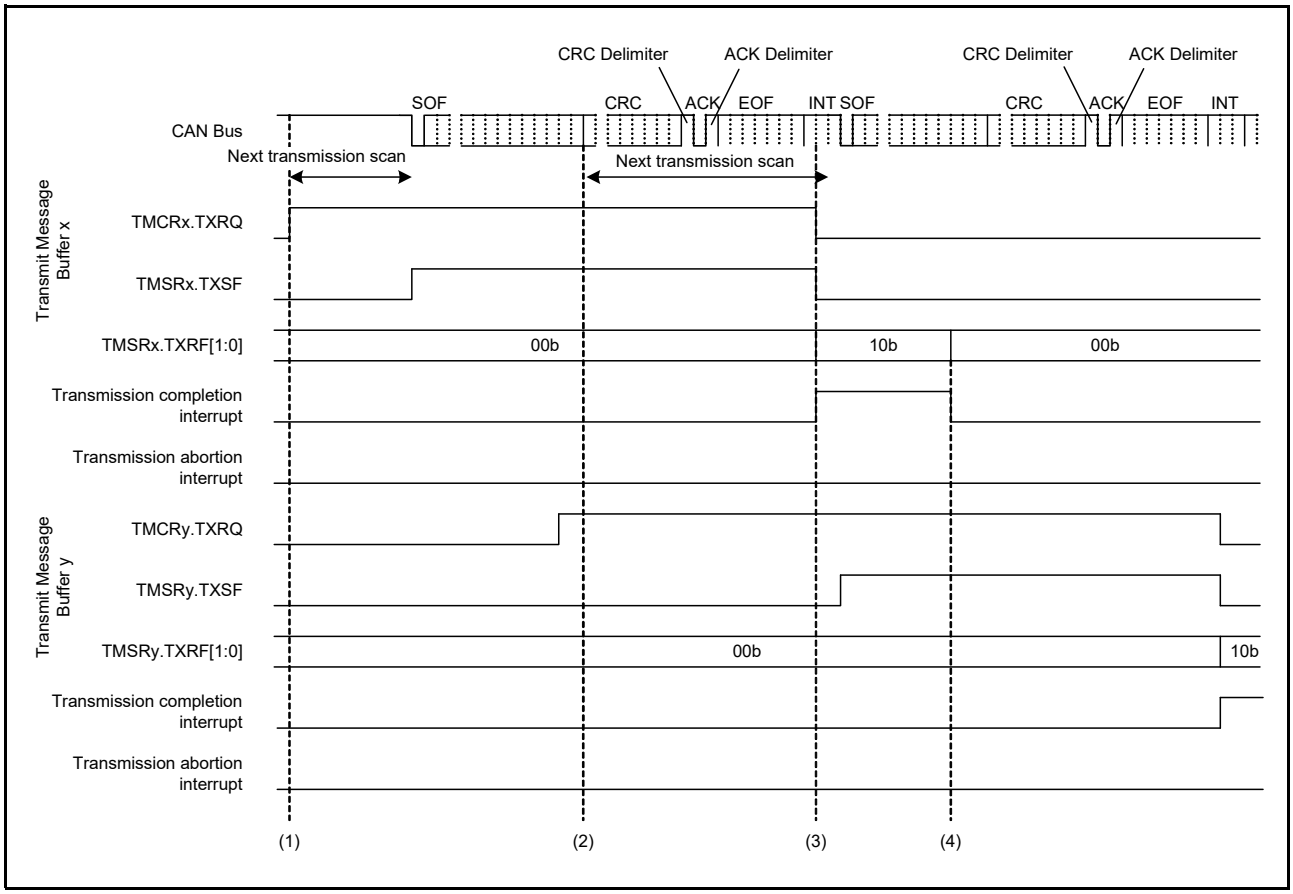

Figure 36.43 Timing of Request and Flag Bits for Successful Transmission

(1) If the TMCRx.TXRQ bit is set to 1 in the bus idle state, message buffer scanning procedure starts to decide the highest priority message buffer for transmission.
When the transmit message buffer is decided, the TMSRx.TXSF bit is set to 1 (transmitting), and CAN channel starts the transmission*1.

(2) At the first bit of CRC, the transmission scanning procedure starts for the next possible transmission when pending transmission requests exist.

(3) If the message has been successfully transmitted, the TMSRx.TXRF[1:0] flags are set to 10b and the TMSRx.TXSF flag and the TMCRx.TXRQ bit are cleared.
When the TMIER0.TMIEx bit is set to 1 (transmit message buffer interrupt enabled), the successful transmission interrupt request is generated. To clear the related interrupt line the TMSRx.TXRF[1:0] flags have to be cleared.

(4) Before starting the next transmission, clear the TMSRx.TXRF[1:0] flags. Load the next message in the transmit message buffer and set the TMCRx.TXRQ bit to 1 again.
The TMCRx.TXRQ bit cannot be set to 1 again before TMSRx.TXRF[1:0] flags are cleared.

Note: The setting point of the TMSRx.TXSF flag is not always fixed at the start of the SOF. It may be delayed up to the start of the standard ID.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the TMSRx.TXSF flag is cleared. Then the transmission scanning procedure is performed again to search for the highest priority transmit message buffer from the beginning of the first bit of CRC.
If an error occurs either during the transmission or following the loss of arbitration, the transmission scanning procedure is performed again during error frame to search for the highest priority transmit message buffer.

The Figure 36.44 shows timings for transmission abort for two message buffers.

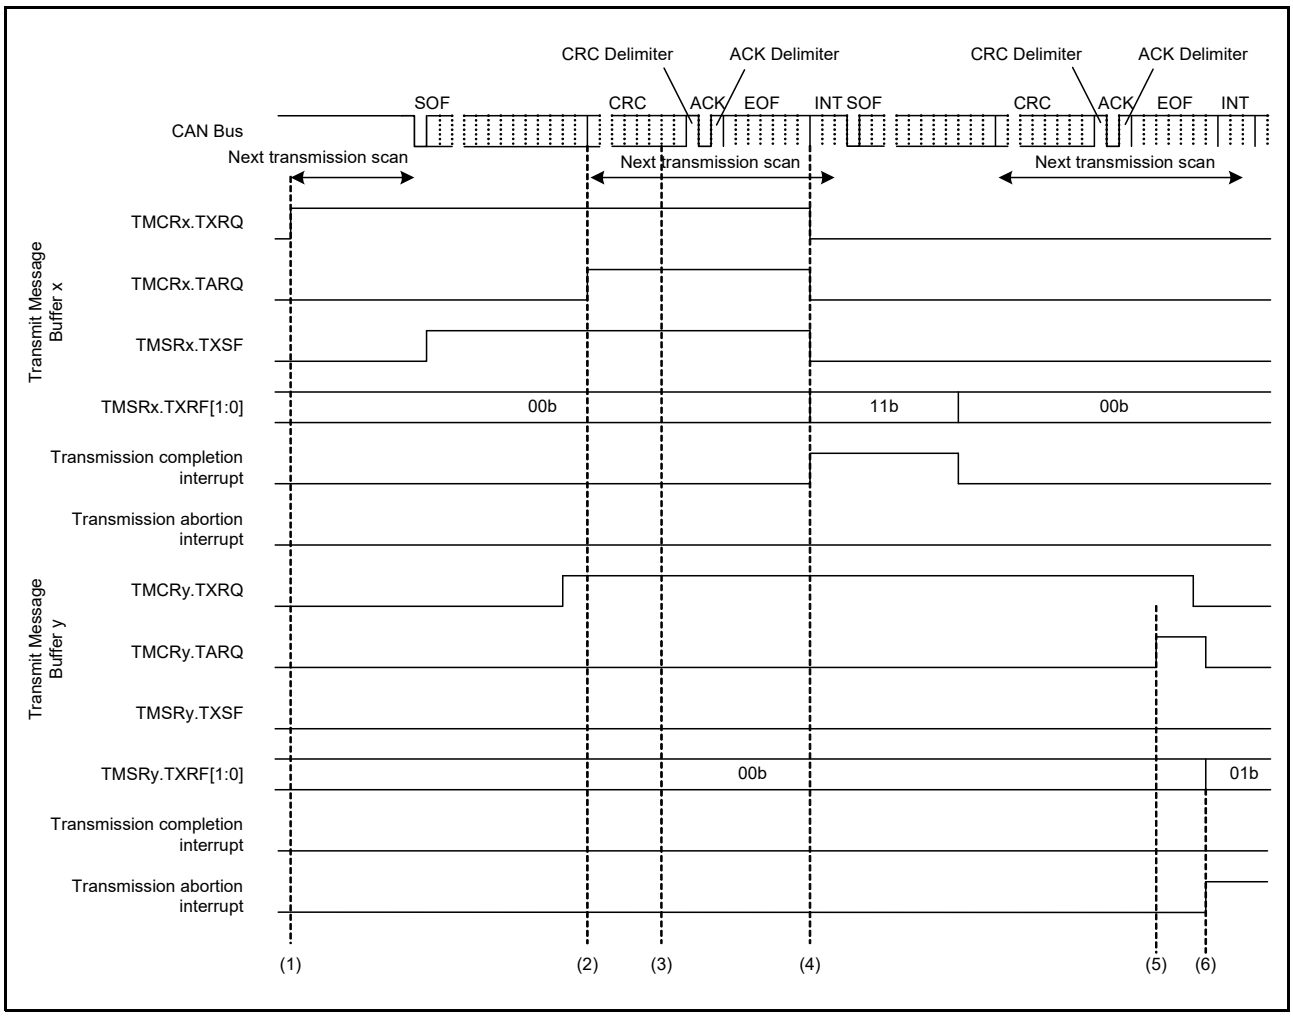

Figure 36.44 Timing of Request and Flag Bits for Transmission Abort

(1) If the TMCRx.TXRQ bit is set in the bus idle state, message buffer scanning procedure starts to decide the highest priority message buffer for transmission.
When the transmit message buffer is decided, the TMSRx.TXSF flag is set (transmitting), and CAN channel starts the transmission*1.

(2) If the TMCRx.TARQ bit is set to 1 when the related message buffer is already selected for transmission or currently transmitting, the message will not be aborted, if no error occurs or arbitration is lost.

(3) At the first bit of CRC, the transmission scanning procedure starts for the next transmission. In this example timing chart message buffer y is not selected as next transmit message buffer.

(4) If the message has been successfully transmitted, the TMSRx.TXRF[1:0] flags are set to 11b and the TMSRx.TXSF flag and TMCRx.TXRQ bit are cleared.
When the TMIER0.TMIEx bit is set to 1 (transmit message buffer interrupt enabled), the CAN successful transmission interrupt request is generated.
To clear the related interrupt line the TMSRx.TXRF[1:0] flags has to be cleared.

(5) Another CAN node is transmitting on the CAN bus (the TMSRy.TXSF flag is not set): if the TMCRy.TARQ bit is set to 1 when the related channel is under transmission scan, the transmission request cannot be cleared.

(6) After internal processing time the transmission is aborted and the TMSRy.TXRF[1:0] flags are set to 01b.
If the message buffer is not transmitting or selected as next transmit message buffer or under transmit scan, the abort is immediately accepted and the corresponding TMSRy.TXRF[1:0] flags are set to 01b.
In addition, the TMCRy.TXRQ and TMCRy.TARQ bits are cleared automatically.

When the CHCR.TAIE bit is set to 1 (transmission abort interrupt enabled), an interrupt is generated for successful transmission abort.
To clear the related interrupt the TMSRy.TXRF[1:0] flags have to be cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the TMSRx.TXSF flag is cleared. Then the transmission scanning procedure is performed again to search for the highest priority transmit message buffer from the beginning of the first bit of CRC.
If an error occurs, either during the transmission, or following the loss of arbitration, the transmission scanning procedure is performed again during error frame to search for the highest priority transmit message buffer.

36.7.2.3 Message Transmission from FIFO Buffer

The CANFD module has one common FIFO. The common FIFO can be linked to the transmit message buffer by the CFCR0.LTM[1:0] bits if configured in transmit FIFO mode.
When a transmission scan is started and the common FIFO corresponding to that transmit message buffer is enabled, the relevant message in the common FIFO will participate in the transmission scan.
Do not configure the transmit message buffer linked to the common FIFO configured in transmit FIFO mode.

(1) Transmit FIFO Operation

Messages can be written into the transmit FIFO by writing to the common FIFO buffer 0 (CFB0).
When the value 000000FFh is written into the CFPCR0 register, the message count of the FIFO is incremented by 1. Before writing to the CFPCR0 register, wait until the message has been completely written to the CFB0. If the message count matches the FIFO depth, the CFSR0.FULL flag is set to 1.
The oldest message in the transmit FIFO is included in the scan for transmission.
When a message is successfully transmitted from the transmit FIFO, the message count value is decremented by 1. When all the messages from the FIFO are transmitted, the CFSR0.EMPTY flag is set to 1.
The interrupt generation conditions for the transmit FIFO buffers can be set by the CFCR0.CFIM bit.
If the CFCR0.CFIM bit is set to 0, interrupt is generated when last message is successfully transmitted from the transmit FIFO buffer. If the CFCR0.CFIM bit is set to 1, interrupt is generated for every successfully transmitted message from the transmit FIFO buffer.
Common FIFO can set interrupt, when CAN frame transmission is completed.
The common FIFO configured in transmit FIFO mode can be disabled by setting the CFCR0.CFE bit to 0. If this bit is set to 0, the CFSR0.EMPTY flag is set to 1 as described below:

- immediately if the message from the transmit FIFO is neither scheduled for the next transmission nor in transmission
- following the transmission completion, the detection of an error on the CAN bus, arbitration lost or transition to CH_HALT or GL_HALT mode if the transmission from the transmit FIFO is already scheduled for transmission or already in transmission.

Note: The common FIFO is considered as disabled after setting the CFCR0.CFE bit to 0 only when the CFSR0.EMPTY flag is set to 1 for the corresponding common FIFO.

If there are other pending messages in the transmit FIFO buffer, they will be lost and the transmission needs to be requested again. Before the CFCR0.CFE bit is set to 1 again ensure that the CFSR0.EMPTY flag is set to 1 and that there is no pending abort request from the transmit FIFO.
When the CFCR0.CFE bit is set to 0, the message read and write pointers of the FIFO are cleared and are no longer active. Hence, all messages in the FIFO buffers will be lost and no further message can be stored into the FIFO.

The FIFO transmission request procedure after a configuration is shown in Figure 36.45.

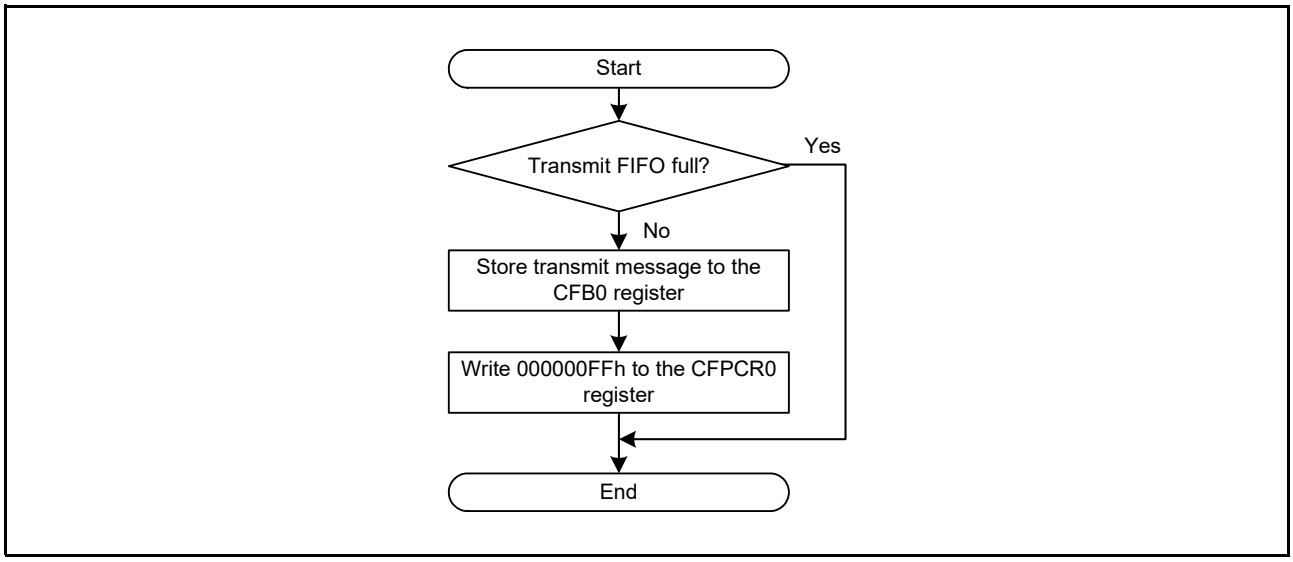

Figure 36.45 Transmit FIFO Transmission Request Procedure

(2) Interval Timer for FIFO Transmission

For the common FIFO in transmit mode it is possible to specify a delay between two consecutive messages that are configured for transmission from the same FIFO buffer. This delay is called interval time. This interval time starts after the first message has been successfully transmitted from the FIFO buffer after the CFCR0.CFE bit is set to 1.
When the common FIFO in transmit mode is enabled, then the first message will be transmitted without considering this interval time.
The interval timer will stop counting when:

- FIFO is disabled by set the CFCR0.CFE bit to 0
- CAN channel is in CH_RESET mode.

The interval time is specified by the value of the CFCR0.TINT[7:0] bits and can be specified from 0 to 255 timer units. The timer unit can be defined based on two different count sources for the interval timer. Select the value 0 to disable the interval timer for FIFO transmission.
The count source can be selected by the CFCR0.ITCS bit. For the count source the CAN bit timing clock of the related channel or a reference clock could be selected.
If CAN channel bit time clock is configured as count source and the CAN channel enters CH_HALT, CH_RESET, or CH_SLEEP mode, then the interval timer is stopped for that channel.
If peripheral clock is selected as interval timer clock source, then the interval timer is stopped only when the CAN channel is in CH_RESET or CH_SLEEP mode.
The reference clock can be used to configure the interval time in fixed time units. It is based on the PCLKB. The GCFG.ITP[15:0] bits define the relation between the PCLKB frequency/period and the reference clock period.
Refer to Table 36.23 for configuration values of the GCFG.ITP[15:0] bits to achieve different reference clock periods based on the PCLKB frequency/period.

Table 36.23 Configuration Example for Interval Timer Prescaler

	Reference clock period		
PCLKB frequency (period)	**1 µs**	**100 µs**	**500 µs**
16 MHz (62.5 ns)	16	1600	8000
20 MHz (50 ns)	20	2000	10000
32 MHz (31.25 ns)	32	3200	16000
50 MHz (20 ns)	50	5000	25000

Additionally the reference clock resolution can be specified by the CFCR0.ITR bit.
The interval time is based on the reference clock period multiplied by the configured value (×1 or ×10).
The reference clock based interval timer can be used to follow the requirements of the ISO 15765-2 Separation Time.
The whole range for the separation time from 100 µs to 127 ms can be covered.
The specified interval time starts after successful transmission event (after EOF7 state of the CAN protocol).
When the interval time has elapsed, the next transmission request is raised by the related transmit FIFO. Hence, the interval time defines the minimum time between two messages transmitted from one FIFO.
The next message will earliest be sent after this interval time. The Figure 36.46 shows an example timing of the internal processing.

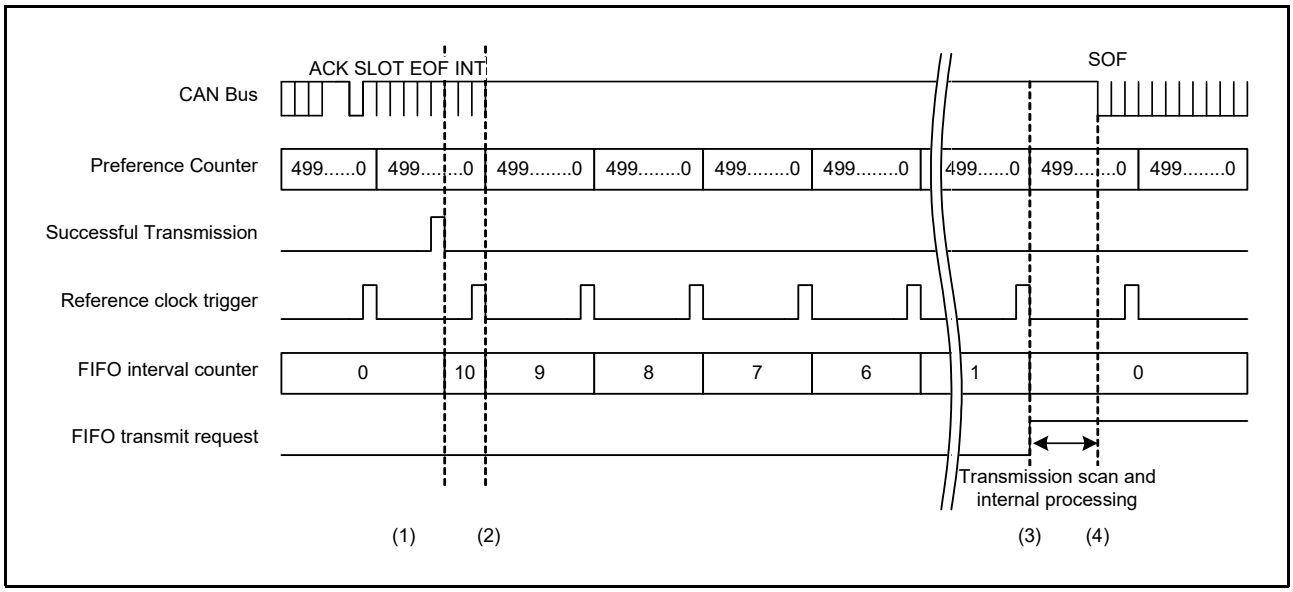

Figure 36.46 Example for Interval Processing Time

The configuration for this timing above is following:

- PCLKB frequency = 50 MHz
- Interval timer prescaler (GCFG.ITP[15:0]) = Divided by 500
- Reference clock due to the settings above = 10 µs
- Common FIFO interval timer count source selection (CFCR0.ITCS) = 0
- Common FIFO interval timer resolution (CFCR0.ITR) = 0
- Common FIFO transmission interval (CFCR0.TINT) = 10 counts
- Theoretical message separation interval = 100 µs

(1) Internal FIFO interval timer is restarted with the occurrence of successful transmission result. This restart is not synchronized to the reference clock trigger. Therefore the first interval is counting less or equal to one reference clock interval.
(2) With the next reference clock trigger the FIFO interval timer is decremented.
(3) When the FIFO interval timer reached the value 0, the FIFO transmit request is set.
(4) When the FIFO is selected for transmission then the transmission will start soon. Due to internal processing this usually takes less than 3 bit time, between internal FIFO transmit request set 3. (shown above) and actual transmission.
When multi events like reception scan, internal message routing, transmit scan happen, then it could take up to 126 PCLKB cycles.

As shown in Figure 36.46, it is not guaranteed that the minimum interval is always equal to the configured value. If a minimum time must never be breached, configure the CFCR0.TINT bit to required minimum value + 1.
If transmit message buffers or transmit FIFOs are configured for transmission for the channel the real delay between two messages transmitted from a transmit FIFO can be much longer than specified by the interval time due to higher priority message transmission from these transmit message buffers or transmit FIFOs.
Figure 36.47 shows a block diagram of the FIFO interval timer.

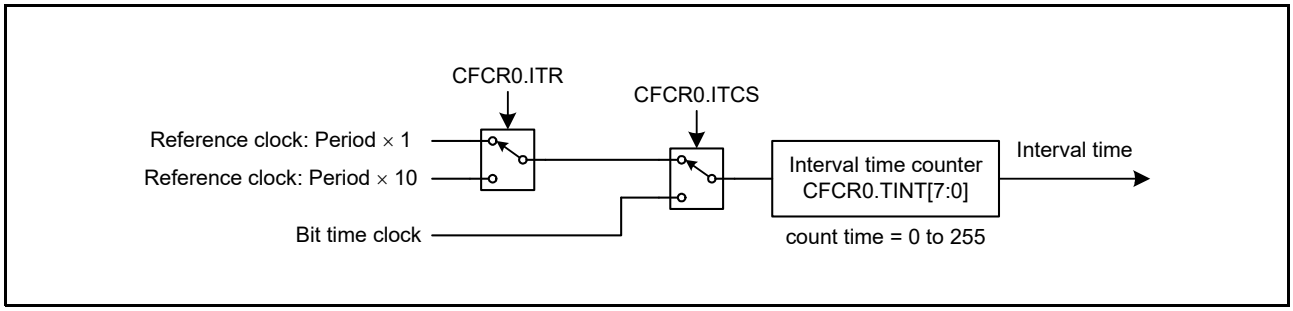

Figure 36.47 Block Diagram of FIFO Interval Timer

36.7.2.4 Transmit Queue

Each enabled transmit queue consists of three or four transmit message buffers, which are accessed via one access window.
The transmit queue 0 (hereafter TXQ0) can be configured with a depth of three to four, and it is using the transmit message buffer 0 as access window. All the message of TXQ0 enter the priority comparison for the transmission, which should be ID priority (GCFG.TPRI = 0).
The registers for TXQ0 are TQCR0, TQSR0, and TQPCR0.
As access window transmit message buffer 0 (TXQ0) is used, refer to related access registers TMBn.HF0, TMBn.HF1, TMBn.HF2, and TMBn.DF0 to TMBn.DF15.
The depth of each TXQ0 buffer can be configured by writing to the TQCR0.QDS[1:0] bits. TXQ0 can be set from TMB0 to TMB3 as a queue buffer at the maximum.
The available options for depth configuration are:

- 10b: 3 messages
- 11b: 4 messages.

Do not access all transmit message buffers except transmit message buffer 0 that configure the transmit queue. Also, do not access the TMCRn registers that correspond to the transmit message buffers that configure the transmit queue.
When writing data to TXQ0, check the status of TXQ0 before writing the data to be transmitted.
The messages stored to the transmit queue access window are internally stored to a free buffer of the transmit queue.
When the TXQ0 buffer is full, do not access the queue anymore. If the transmit data is written when the TXQ0 is full, the

transmit data will be overwritten.
The transmit queue can be disabled by setting the TQCR0.TQE bit to 0. If this bit is set to 0, the TQSR0.EMPTY flag is set as described below:

- immediately: if a message from the transmit queue is not scheduled for the next transmission and is not being transmitted
- after the transmission completion, error detection on the CAN bus, loss of arbitration, or transition to CH_HALT or GL_HALT mode: if a message from the transmit queue is scheduled for transmission or is being transmitted.

Note: The transmit queue is disabled only when the TQSR0.EMPTY flag is set to 1 after setting the TQCR0.TQE bit to 0.

If there are other pending messages in the transmit queue, they will be lost, so their transmission needs to be requested again.
Before the TQCR0.TQE bit is set to 1 again, ensure that the TQSR0.EMPTY bit is set to 1 and that there is no pending abort request from the transmit queue.
When the TQE bit is set to 0, all messages in the transmit queue buffers will be lost and no further message should be stored into the transmit queue.
When a message has been stored to the transmit queue, 000000FFh must be written in to the TQPCR0 register. This will set the transmit request automatically and change the internal message buffer pointer to the next free message buffer location of the transmit queue.

Note: If two messages with the same ID are stored in the transmit queue, then the order of transmission of these messages could be different from the order in which they were stored in the transmit queue.
To avoid this condition, it is important to confirm that the previous message with the same ID was successfully transmitted before a new message with the same ID is stored in the transmit queue.

For the transmit queue a dedicated interrupt can be enabled by setting the TQCR0.TQIE bit.
The interrupt mode can be configured with the TQCR0.TQIM bit either to generate an interrupt for every transmitted message or for the last transmitted message.
The transmit queue transmission request procedure after configuration is shown in Figure 36.48.

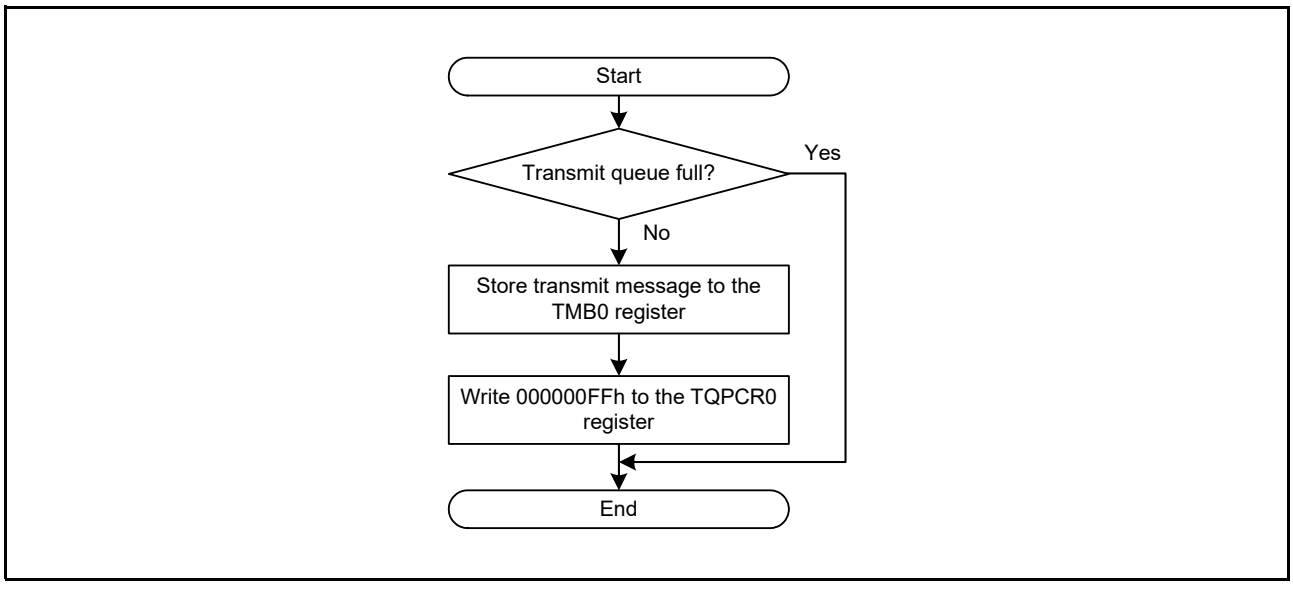

Figure 36.48 Transmit Queue Transmission Request

36.7.2.5 Transmission History

The transmission history function records the information of the successfully transmitted message in the transmission history buffer. The transmission history buffer can store up to eight transmission history entries.
The THCR.THRC bit can select whether to store information only for messages transmitted from transmit FIFO and transmit queue, or also for messages transmitted from the transmit message buffers.
Each transmit message can be individually configured for acceptance to the transmission history by the CFB0.HF0.THENT bit.
The message information is stored to the transmission history buffer of a CAN channel after the message is successfully transmitted on that CAN channel.
Storing to the list is not synchronized with the status of TMSRn.TXRF[1:0] flags.
Due to internal processing, the storage to the list could happen with a delay after the successful transmission indication.
Storing the transmission history data can be recognized by the condition that the THSR.THIF flag is set to 1 when the THCR.THIE bit is set to 1 or when the transmission history counter (THSR.FLVL[3:0]) is increased.
Multiple events could occur, such as reception scans and internal message routing.
Maximum delay time from setting the TMSRn.TXRF[1:0] flags to storing the transmission history data is 76 PCLKB cycles.

The transmission history records following information of the transmitted message:

- Transmitted Buffer type:
  – 001: Transmit message buffer
  – 010: Common FIFO in transmit FIFO mode (hereinafter referred to as transmit FIFO)
  – 100: Transmit queue
- Transmitted Buffer number:
  Transmit message buffer, transmit queue message buffer or transmit message buffer link for the common FIFO from which the transmission occurred. The number depends upon the buffer type, refer to Table 36.24.
- Transmitted pointer:
  Pointer set in header field 2 of transmit message (HF2.PTR[15:0])
- Transmitted timestamp:
  Message timestamp captured at capture point as set by the GFDCFG.TSCPS[1:0] bits
- Transmitted information label:
  Information label set in header field 2 of transmit message (HF2.IFL[1:0])

Table 36.24 Transmission History Buffer Number Entry

Transmitted Buffer Number (THACR0.BN[1:0])	Transmitted Buffer Type (THACR0.BT[2:0])		
	001b	010b	100b
	Transmit Message Buffer	Transmit FIFO	Transmit Queue
00b	TXMB0	The value of the BN[1:0] bits corresponds to the setting of the CFCR0.LTM[1:0] bits.	The value of the BN[1:0] bits indicates the number of the transmit message buffer from which the message was transmitted.
01b	TXMB1		
10b	TXMB2		
11b	TXMB3		

The transmission pointer is used to identify which message of a transmit FIFO or transmit queue has been successfully transmitted because the transmit FIFO or transmit queue number alone is not sufficient.
Therefore, a unique number (pointer) can be attached to each transmission message stored in a transmit FIFO or transmit queue. This unique pointer should be written to the CFB0.HF2.PTR[15:0] part for a transmit FIFO or to the TMB0.HF2.PTR[15:0] part of the transmit queue.
When the message is successfully transmitted then this pointer is stored together with the other message related

information to the transmission history and can be read via the transmission pointer field (PTR[15:0]) in the Transmission History Access Register.
Also for normal transmit message buffers, the TMBn.HF2.PTR[15:0] part will be stored in the transmission history. An information label is the same.
Read access to the Transmission History Access Register will be done for every single entry.
After reading one entry, 000000FFh has to be written to the THPCR register to be able to access the next entry until transmission history is empty.
Figure 36.49 shows an example flow for processing the transmission history.
The transmission history has dedicated interrupts, which can be configured with the THCR.THIM bit and enabled with the THCR.THIE bit, either to generate an interrupt when the transmission history reached a filling level of 75% or for every new transmission history entry.
Loss of transmission history is indicated by the THSR.LOST flag. Status of this flag is also shown by the GESR.THLDF flag.

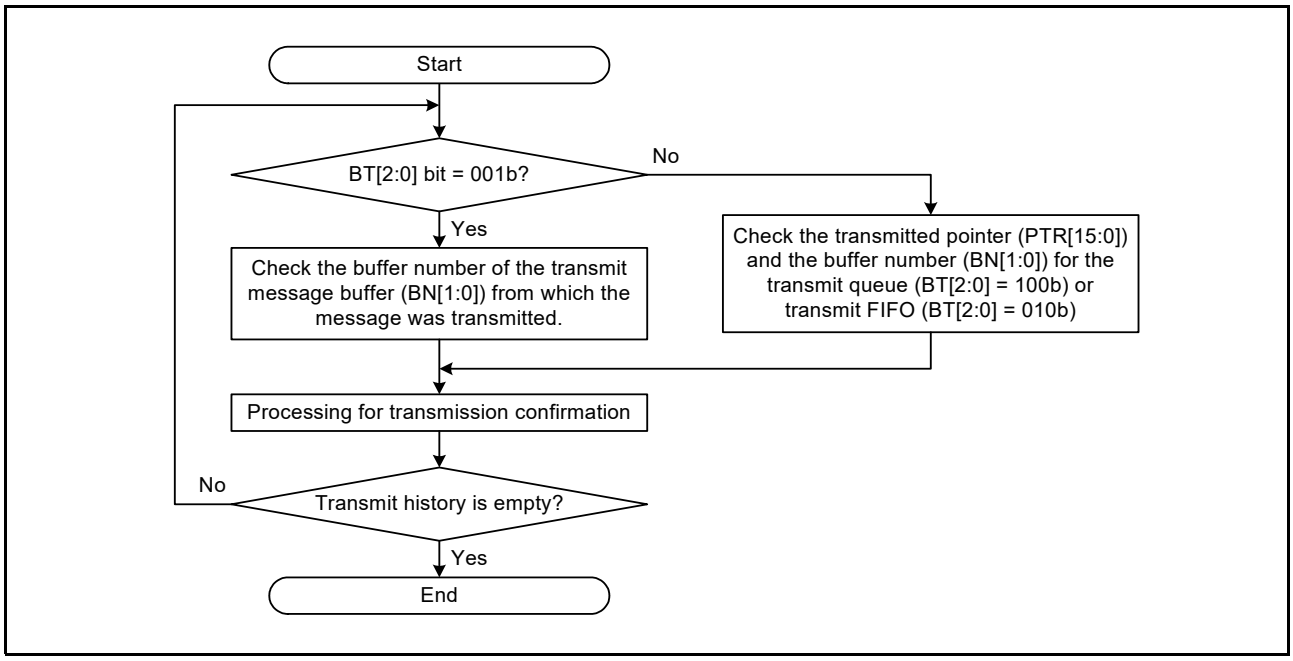

Figure 36.49 Example of Transmission History Processing Flow

36.7.2.6 Transmit Data Padding

If the data length code (DLC) of the transmit message is higher number of data bytes than the buffer size, the data bytes beyond the restricted range will be replaced by bytes with the value of CCh.
This could occur for common FIFO configured in transmit FIFO mode when the DLC of the transmit message is larger than the payload size set in the CFCR0.PLS[2:0] bits.
This can also occur in FD only mode, if the DLC value for a Classical CAN frame is greater than 8.

36.8 ECC Check

Message buffer RAM has ECC function of the 2-bit error detection and 1-bit error detection/correction.*1 The ECC module appends 7-bit ECC data to 32-bit RAM data.

Note 1. The ECC module cannot detect errors larger than 3 bits. In this case, the ECC module detects a 1-bit or 2-bit error, does not detect the error, or corrects the error bit to error data by configuration. If all RAM data is fixed at 0 or 1, it will be detected as a 2-bit ECC error.

36.8.1 ECC Function Setting

Figure 36.50 shows a procedure for ECC function setting.

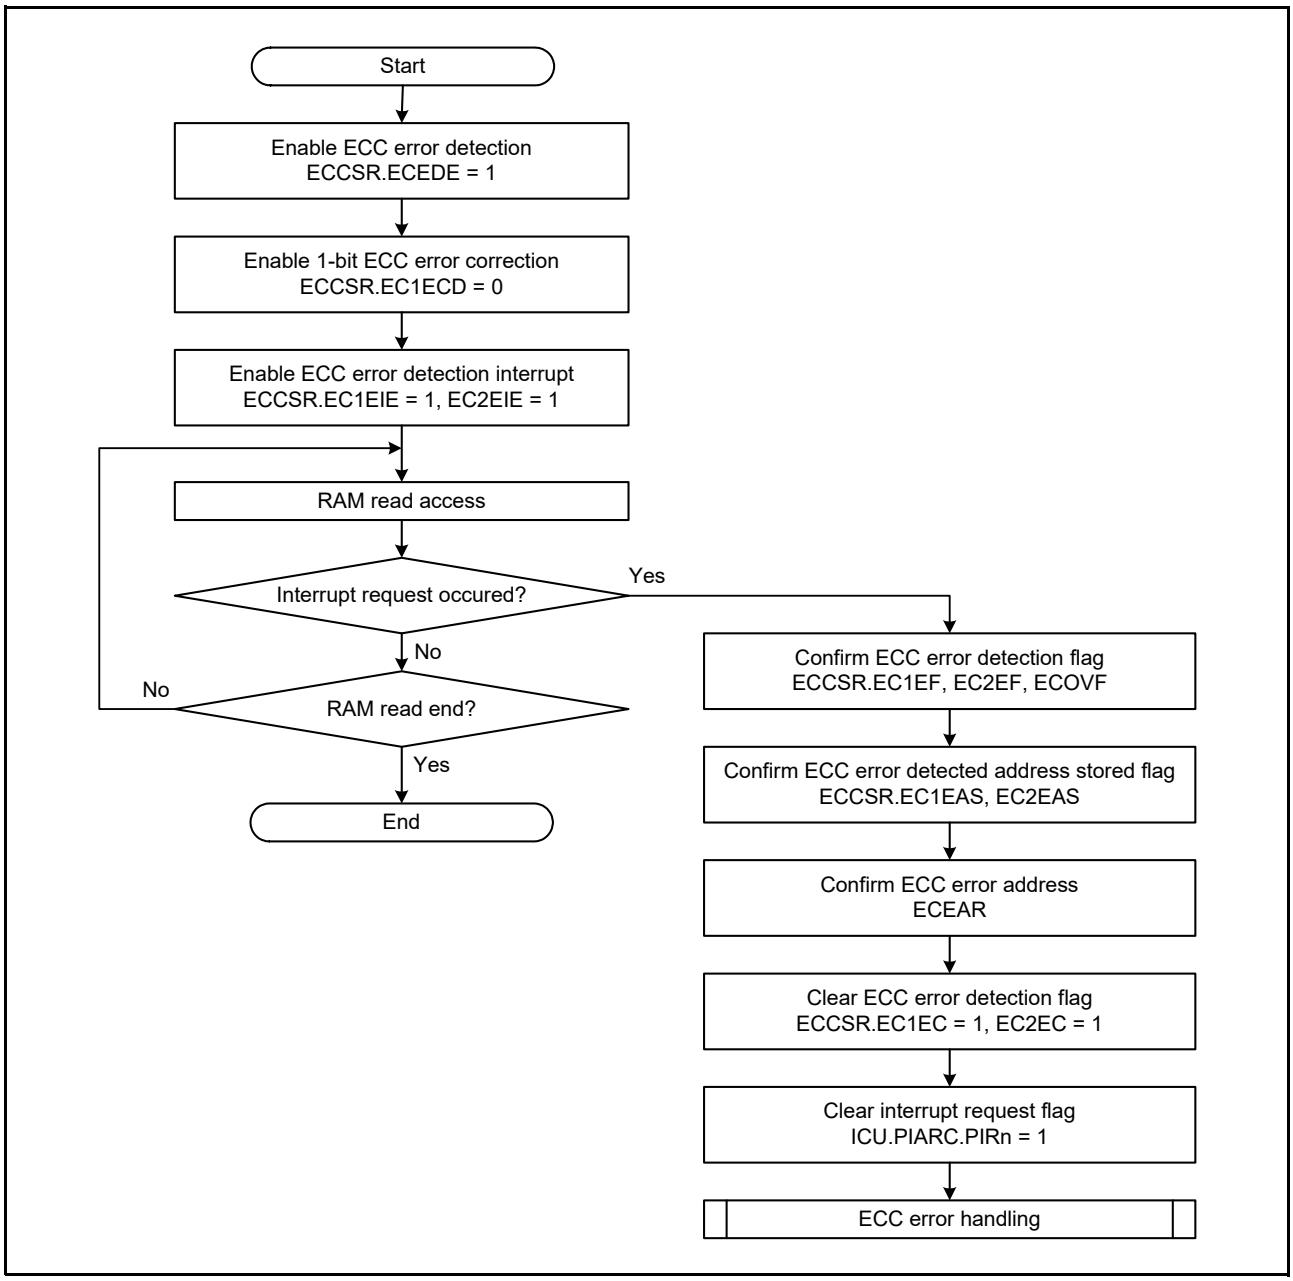

Figure 36.50 Setting Procedure for ECC Function

36.8.2 ECC Decoder Testing

ECC interrupts can be intentionally generated by ECC test mode. Figure 36.51 shows a procedure for ECC decoder testing.

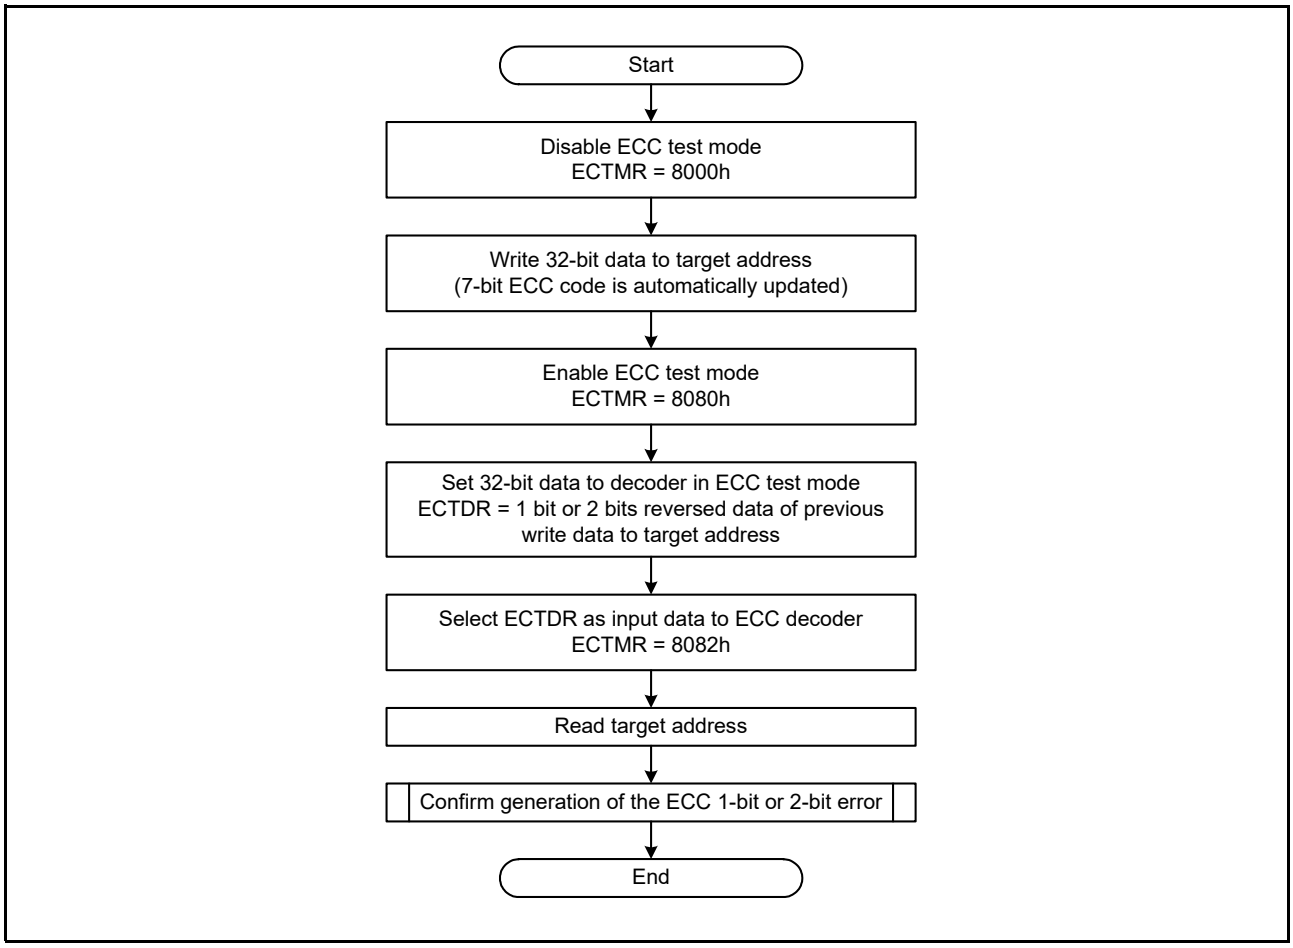

Figure 36.51 Testing Procedure for ECC Decoder

36.9 Test Mode

The CANFD module can be configured into test modes to allow testing of certain features. These features are provided only for special purposes and care must be taken when configuring the CANFD module in the test modes.

Note: All test modes are mutually exclusive unless it is explicitly stated that some functions can be enabled across other test modes.

Do not enable any combinations of the various test modes specified in this section.
The test modes can be broadly split into two groups:

- Channel specific test modes
- Global test modes

36.9.1 Channel Specific Test Modes

CAN channel can be configured into following test modes:

- Basic test mode
- Listen-only mode
- Self test mode 0 (external loop back mode)
- Self test mode 1 (internal loop back mode)
- Restricted operation mode

36.9.1.1 Basic Test Mode

The basic test mode should be used when a particular test setting needs to be enabled other than when in listen-only and self-test modes.

36.9.1.2 Listen-Only Mode

The ISO 11898-1 recommends an optional bus monitoring mode. In this mode, the CAN channel can receive valid data frames and valid remote frames. However, it sends only recessive bits on the CAN bus and is not allowed to transmit. If the CAN engine is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the CAN engine monitors this dominant bit, although the CTX0 pin remain in recessive state.
This mode can be used for bit rate detection. In this mode, an error interrupt is generated if a bus error occurs and the interrupt is enabled.
In this mode, it is not permitted to request transmission from any transmit message buffer, transmit queue, or common FIFO.

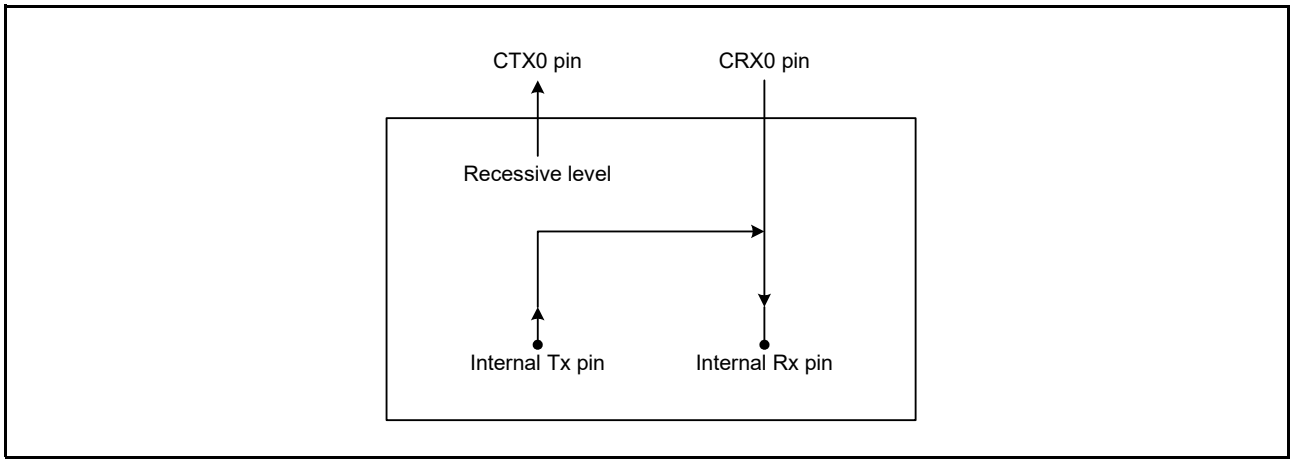

Figure 36.52 Listen-only Mode Configuration

36.9.1.3 Self Test Mode 0 (External Loop Back Mode)

In self test mode 0, the CAN engine treats its own transmitted messages as received messages via the CAN transceiver and can store them into its receive message buffers.
To be independent from external stimulation the engine generates its own acknowledge bit. This test can be used for CAN transceiver tests.
The CRX0 and CTX0 pins should be connected to the transceiver.

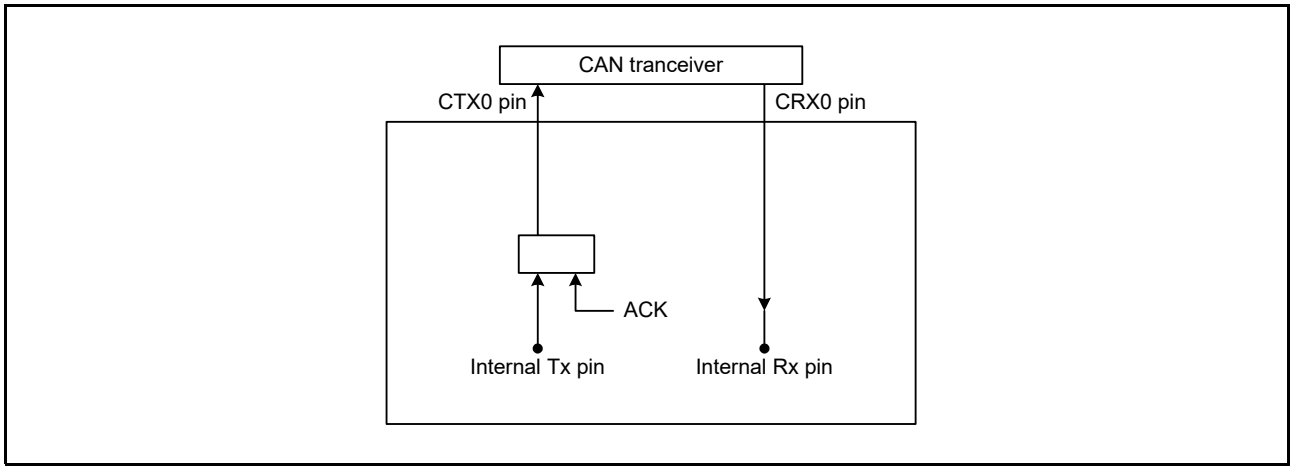

Figure 36.53 Self Test Mode 0 Configuration

36.9.1.4 Self Test Mode 1 (Internal Loop Back Mode)

In self test mode 1, the CAN engine treats its own transmitted messages as received messages and stores them into the receive buffer. This mode is provided for self-test functions. To be independent from external stimulation the CAN engine generates its own acknowledge bit. In this mode the CAN engine performs an internal feedback from internal Tx pin to internal Rx pin. The actual input level of the CRX0 pin is disregarded by the CAN engine.
The CTX0 pin outputs only recessive bits. The CRX0 and CTX0 pins do not need to be connected to the CAN bus or any external device.

Note: The channel pins are also disconnected from the Internal CAN bus communication line.

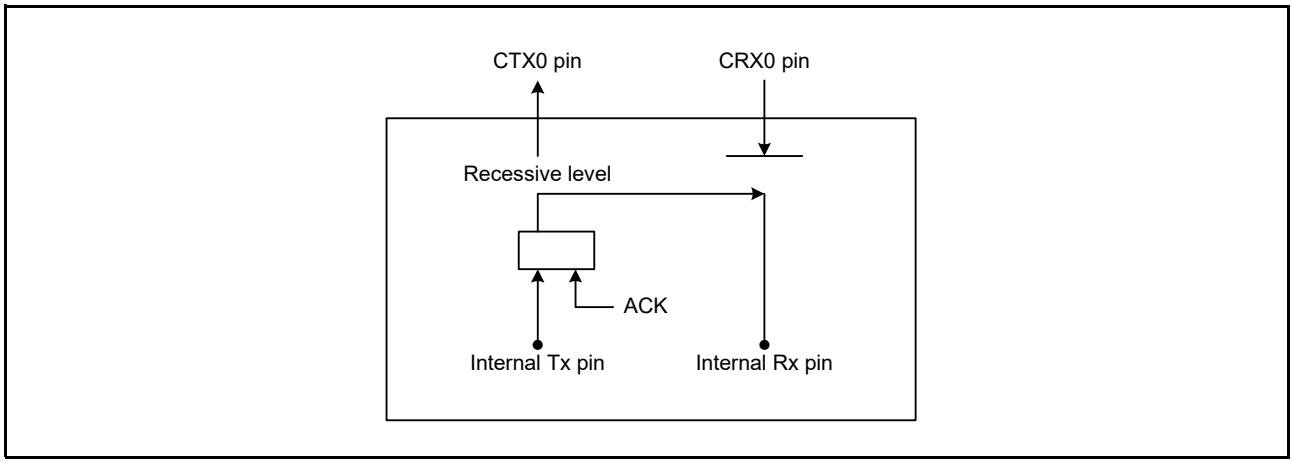

Figure 36.54 Self Test Mode 1 Configuration

36.9.1.5 Restricted Operation Mode

In restricted operation mode the CAN node is able to receive valid data and remote frames generating the acknowledge bit.
Active error and overload frames cannot be transmitted instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication after an error or overload condition occurs.
Moreover the receive error counter (CHSR.REC[7:0]) and transmit error counter (CHSR.TEC[7:0]) are frozen independently from the occurrence of errors.
The mode is specified as in ISO 11898-1; however it is permitted to set any transmit requested.

36.9.2 Global Test Modes

The CANFD module can be configured into following test modes:

- RAM test mode
- Bit flip test

For following test modes are protected by a special software procedure to enable the mode. This software procedure enables the write access to the test mode by specific unlock key, the related unlock key can be seen in the table below:

Table 36.25 Test Mode Unlock Key

Test Mode	Unlock Key 1	Unlock Key 2
RAM Test Mode	00007575h	00008A8Ah

If the software sequence of the two consecutive unlock key write accesses is interrupted by any other write access to the SFR or if incorrect data is written to the Global Test Mode Lock Key Register then the corresponding test mode cannot be set and the sequence should be re-started.
After the two unlock key write accesses, the next write access should be to set the corresponding test mode enable bit. If this is not followed, the unlock mechanism resets and the test mode enable bit cannot be set and then the unlock sequence should be restarted.

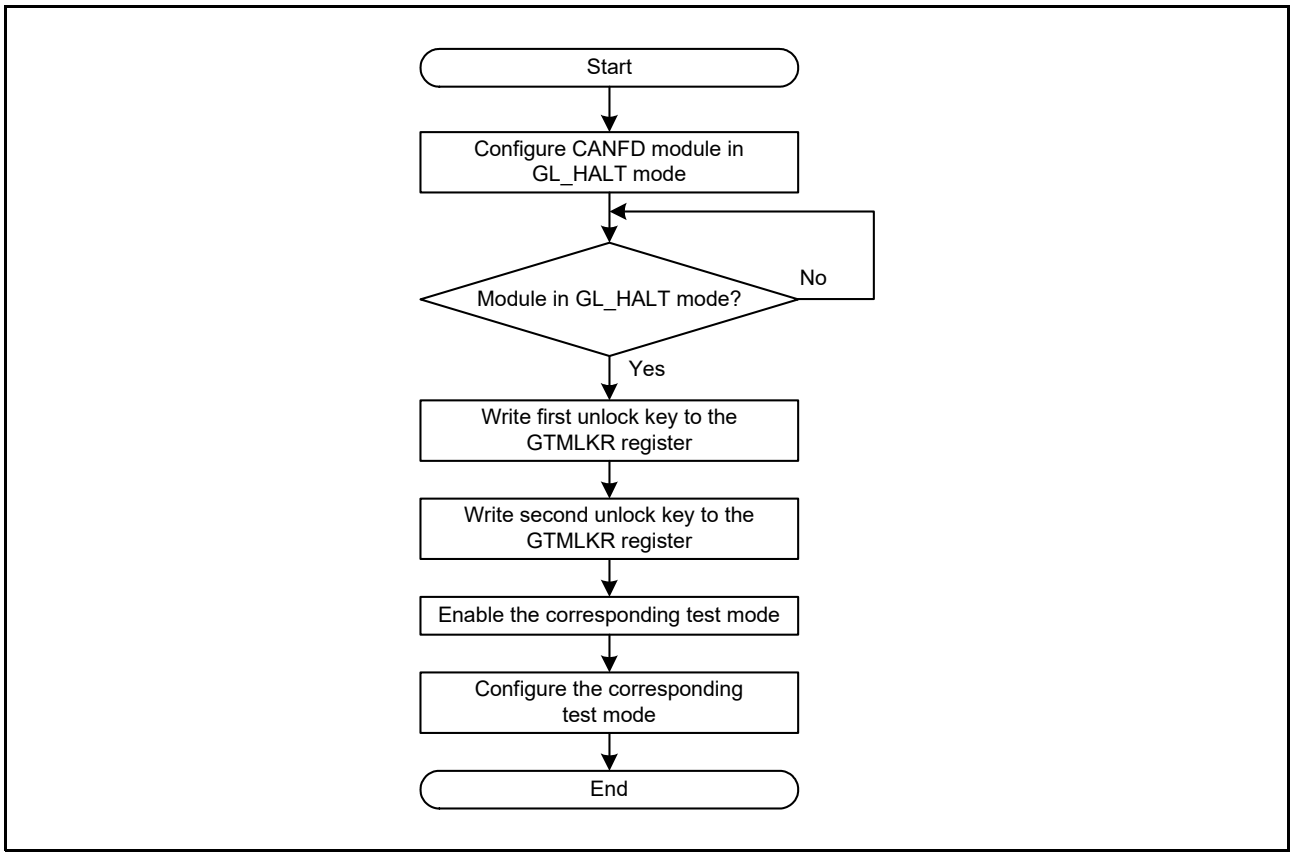

Figure 36.55 Unlock Software Protection Routine

36.9.2.1 RAM Test Mode

The CANFD module can be configured in RAM test mode by setting the GTMER.RTME bit when the corresponding lock key is written before. This is a special test mode, in which, the complete RAM area can be accessed.

Note: The actual RAM size is bigger than the RAM area initialized after MCU reset. Hence, ECC error flag (of the ECC macro) may be set if CPU reads data from this uninitialized RAM area while CANFD module is in RAM test mode.

In this mode, the RAM area is split into number of pages of 256 bytes each. Which can be accessed via RTPARk register (k = 0 to 63).
The page should be selected for read/write access by writing to the GTMCR.RTPS[3:0] bits. Then, data can be read from or written in to the RAM Test Page Access Register.
Figure 36.56 shows the structure of the pages in the RAM when performing a RAM test mode.

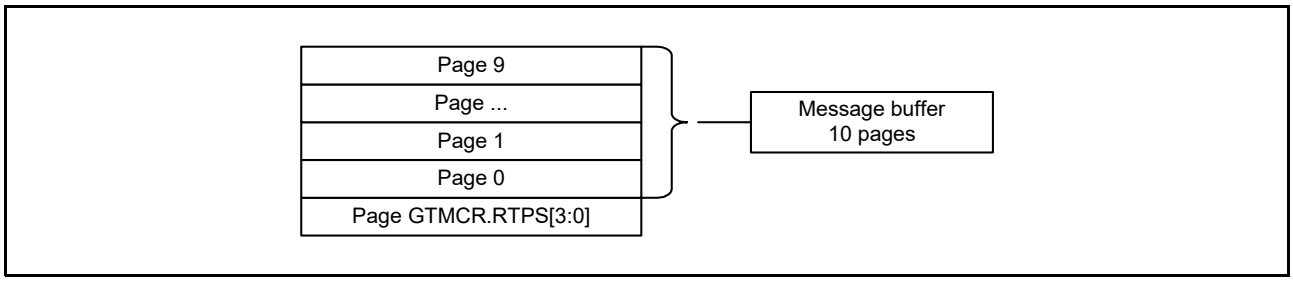

Figure 36.56 RAM Page Structure

The total available RAM size is, 2328 bytes for the message buffer RAM.
Total number of pages for the RAMs and the GTMCR.RTPS[3:0] values are calculated in the following way:

Total number of pages = ceil (total RAM size in bytes / number of bytes per page)

Message buffer RAM:

Total number of pages = ceil (2328 / 256) = 10 pages
GTMCR.RTPS[3:0] = 0 to 9

Figure 36.57 below shows the software flow for RAM test mode.

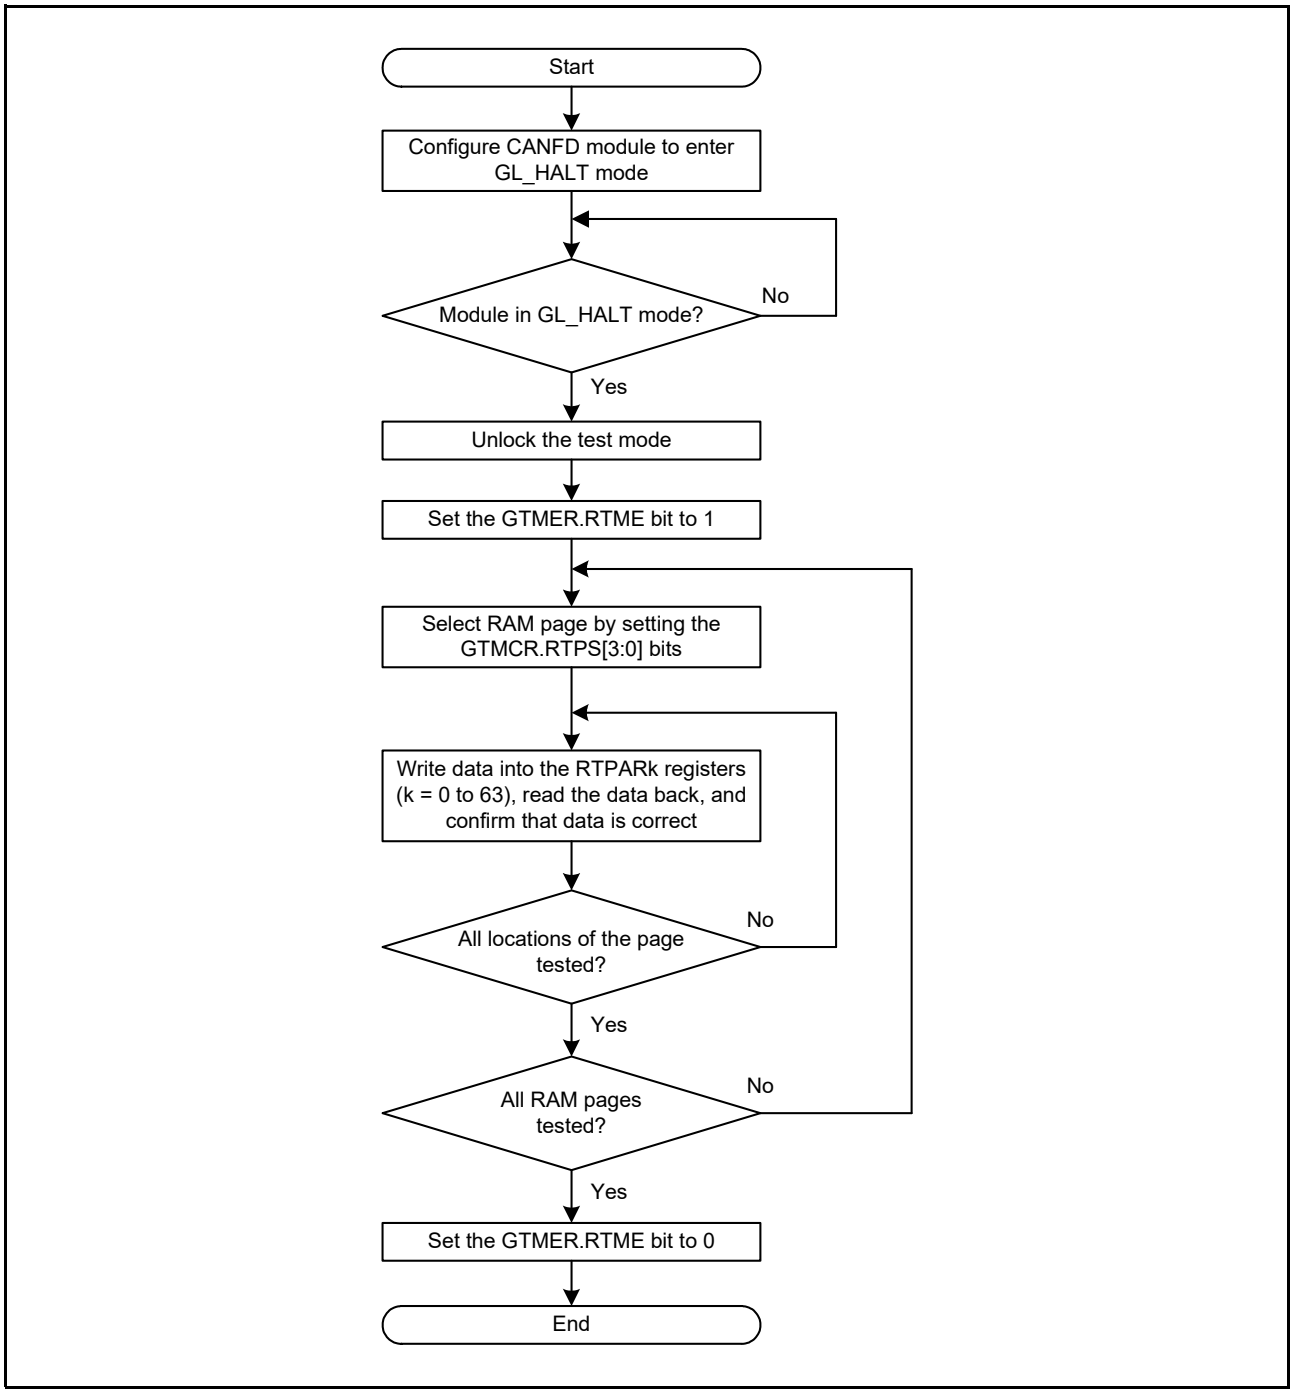

Figure 36.57 RAM Test Mode Software Flow

To exit RAM test mode, set the GTMER.RTME bit to 0.
The GTMER.RTME bit is automatically set to 0 when the CANFD module enters GL_RESET mode from the test mode.

36.9.2.2 Bit Flip Test

Bit flip test can invert the bit (the first bit of ID) of the beginning of the bit stream to receive.
If this function is used by a transmitting node, a bit error or an arbitration lost will occur.
If this function is used by a receiving node, a CRC error or a stuff error will occur.
Users should refer to the bit stuffing rule when using this feature, as there is the possibility of receiving a stuff error (due to the inversion) rather than a CRC error.
The following sequence should be used to perform CRC error testing. In the sequence below CANFD module is the receiver.

1. Set the CTR.BFT bit to 1, in order to invert the first bit of the incoming bit stream from sending node
2. Wait for the can_cherr_int output signal to set to 1
3. Read either the CHESR.CRC15[14:0] or FDCRC.CRC21[20:0] bits (depending on the received frame type: Classical CAN or CAN FD). The value should be different from the received CRC value of the reference message from sending node.
4. Check that CHESR.CEDF is 1
   As the CRC generator logic is shared for receive and transmit there is no need to create a separate transmit CRC error test.

36.10 Interrupts and DTC/DMA Requests

36.10.1 CANFD Interrupts

The CANFD module generates several Interrupts. The interrupt output, which is connected to the interrupt controller, can be controlled by the corresponding interrupt enable bit.
The status flag will be set independent from this enable bit.
The channel transmit interrupt has an additional status flag register; these status bits will only be set when the corresponding interrupt enables are set.
This register supports the identification of the interrupt source for the channel transmission, as this interrupt is driven by several trigger sources.
The interrupts in the CANFD module can be classified into two groups: global interrupts and channel interrupts.

(1) Global Interrupts

The CANFD module can generate the following three global interrupts.

1. Receive FIFO interrupt
2. Global error interrupt
3. Receive message buffer interrupt

(2) Channel Interrupts

The CAN channel can generate the following three channel interrupts.

1. Channel transmit interrupt
   (a) Successful transmission interrupt
   (b) Transmission abort interrupt
   (c) Transmit queue interrupt
   (d) Common FIFO transmission interrupt
   (e) Transmission history interrupt
2. Channel error interrupt
3. Common FIFO receive interrupt

The interrupts are cleared when the corresponding flag bits are cleared or interrupt enable bits are cleared.

Table 36.26 lists the interrupt sources for CANFD module.
To clear each interrupt request, clear all flags set to 1 from among the sources for which interrupts are enabled. The interrupt request can also be cleared by setting all corresponding interrupt enable bits to 0.

Table 36.26 Interrupt Sources

Interrupt Name			Interrupt Source Flag	Interrupt Enable Bit	Interrupt Status Flag
Global interrupts	Receive FIFO interrupt (RFRI)		RFSRn.RFIF	RFCRn.RFIE	—
	Global error interrupt (GLEI)		GESR.DEDF GESR.MLDF GESR.THLDF GESR.PODF	GCR.DEIE GCR.MLIE GCR.THLIE GCR.POIE	—
	Receive message buffer interrupt (RMRI)		RMNDR.NDF[n]	RMIER.RMIEn	—
Channel interrupts	Channel transmit interrupt (CHTI)	Transmission successful interrupt*1	TMSRn.TXRF[1]	TMIER0.TMIEn	TISR.TSIF0
		Transmission abort interrupt*1	TMSRn.TXRF[1:0] (TXRF[1:0] = 01b)	CHCR.TAIE	TISR.TAIF0
		Transmit queue interrupt	TQSR0.TQIF	TQCR0.TQIE	TISR.TQIF0
		Common FIFO transmission interrupt	CFSR0.CFTIF	CFCR0.CFTIE	TISR.CFTIF0
		Transmission history interrupt	THSR.THIF	THCR.THIE	TISR.THIF0
	Channel error interrupt (CHEI)		CHESR.BEDF CHESR.EWDF CHESR.EPDF CHESR.BOEDF CHESR.BORDF CHESR.OLDF CHESR.BLDF CHESR.ALDF FDSTS.ECOV FDSTS.SCOV FDSTS.TDCV	CHCR.BEIE CHCR.EWIE CHCR.EPIE CHCR.BOEIE CHCR.BORIE CHCR.OLIE CHCR.BLIE CHCR.ALIE CHCR.ECOVIE CHCR.SCOVIE CHCR.TDCVIE	—
	Common FIFO receive interrupt (CFRI)		CFSR0.CFRIF	CFCR0.CFRIE	—

Note 1. These interrupts are only generated for transmit message buffers that are not part of a valid transmit queue and are not linked to a common FIFO. The common FIFO and the transmit queue have other interrupts respectively.

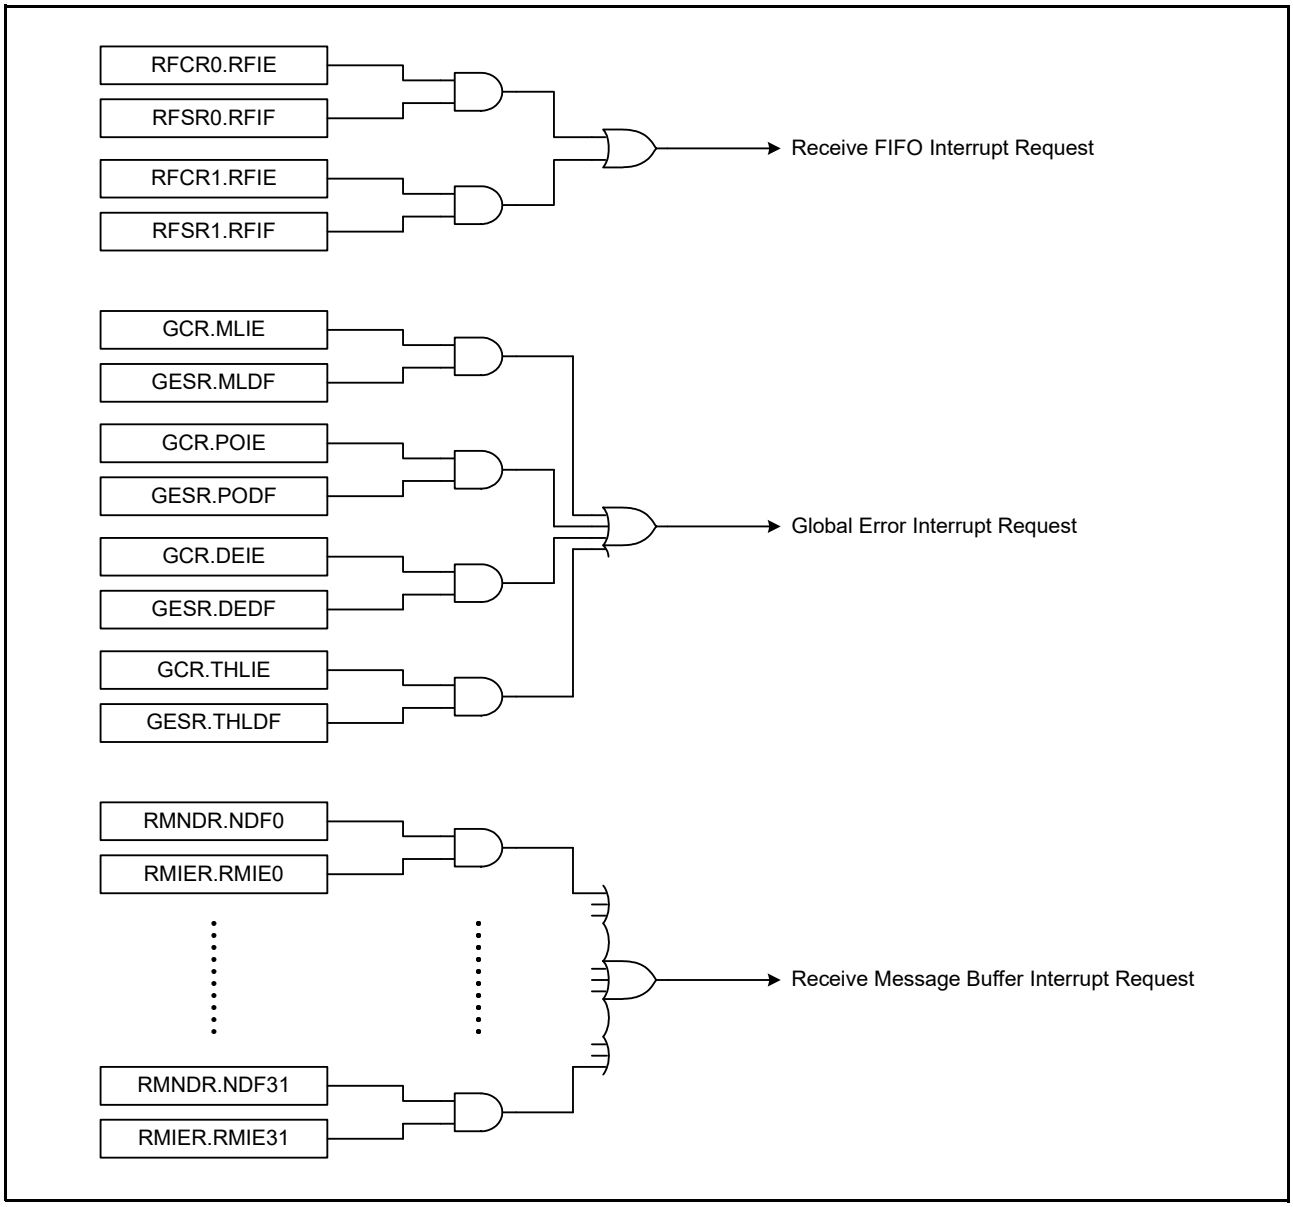

Figure 36.58 Global Interrupt Block Diagram

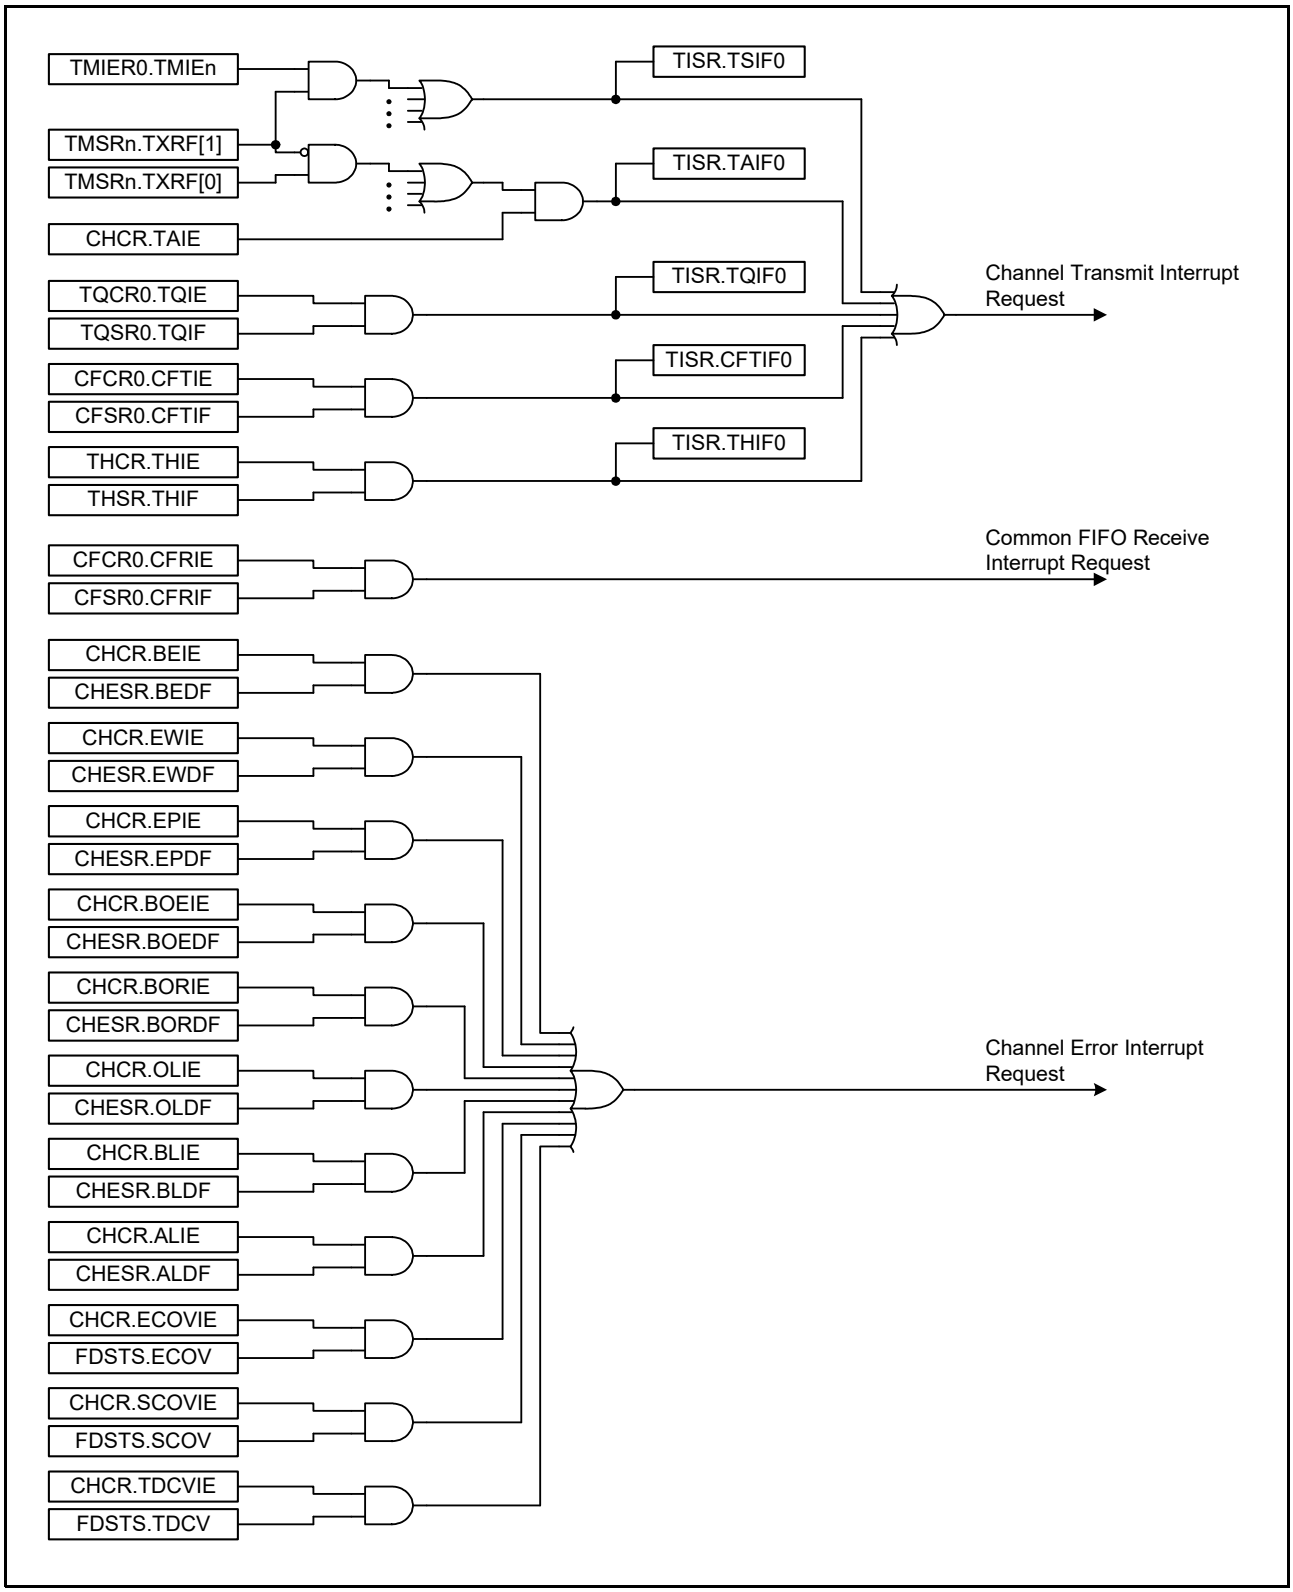

Figure 36.59 Channel Interrupt Block Diagram

36.10.2 ECC Interrupts

There are three types of interrupts generated by the ECC decoder:

- 1-bit ECC error detection interrupt
- 2-bit ECC error detection interrupt
- ECC overflow interrupt.

36.10.3 DTC/DMA Transfer Requests

The CANFD module has message buffers that can be read by DTC/DMA transfer:

- Two receive FIFO message buffers
- Common FIFO message buffer

A DTC/DMA transfer request is generated when the DTCR.RFDTE0, RFDTE1, or CFDTE0 bits are set to 1 and the corresponding FIFO is not empty.
For FIFOs with DTC / DMA transfer enabled, disable receive FIFO interrupts (the RFCR0.RFIE, RFCR1.RFIE or CFCR0.CFRIE bits).
Use the regular start address for the DMA access window address.
When the data of the specified payload size (the RFCR0.PLS[2:0], RFCR1.PLS[2:0] or CFCR0.PLS[2:0] bit) is read*1, the FIFO read pointer is automatically read.
When DTC/DMA transfer is permitted, do not write to the FIFO pointer control register (RFPCR0, RFPCR1, or CFPCR0).

Note 1. The DTC/DMA should read the exact length of the specified data payload size (the RFCR0.PLS[2:0], RFCR1.PLS[2:0] or CFCR0.PLS[2:0] bit).

The permission for DTC/DMA transfer (the DTCR.RFDTE0, RFDTE1 or CFDTE0 bit) can be set to 1 at any time. Figure 36.60 shows the DTC/DMA transfer configuration flow.

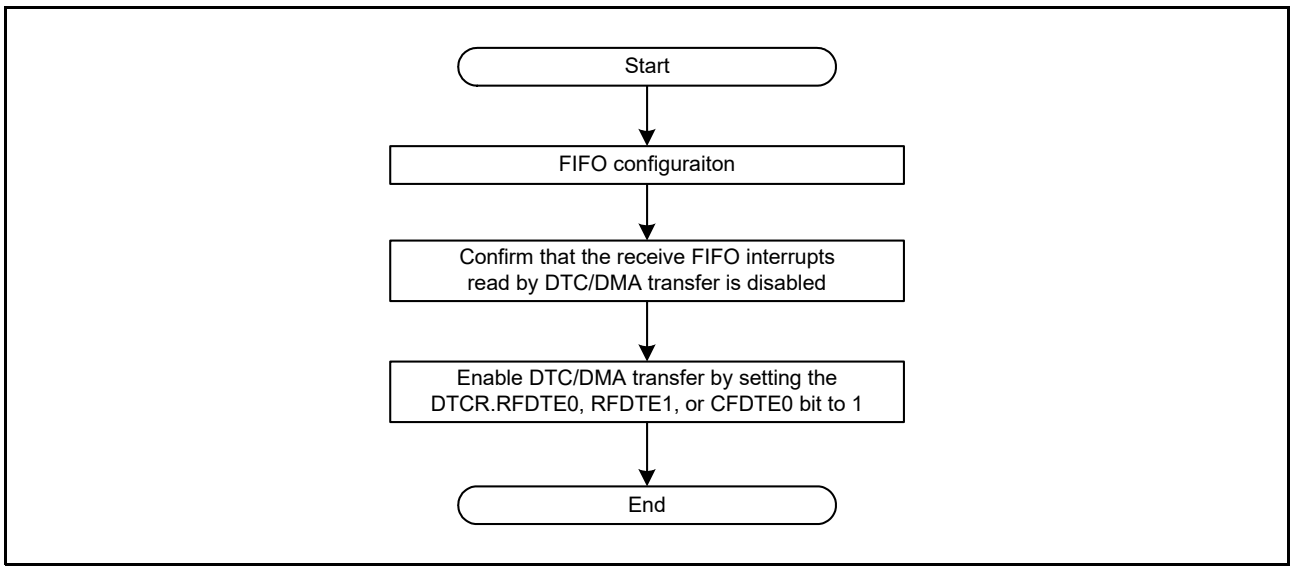

Figure 36.60 DTC/DMA Transfer Enable Flow

To disable the DTC/DMA transfer, set the corresponding DMA transfer enable bit (the DTCR.RFDTE0, RFDTE1 or CFDTE0 bit) to 0. If the disable is made during a DTC/DMA transfer, wait until the ongoing transfer is complete before performing the following operations. The transfer status can be confirmed by the DTSR.RFDTS0, RFDTS1 or CFDTS0

bit. Figure 36.61 shows the DTC/DMA transfer disable flow.
When the DTC/DMA transfer is disabled then consider what to do with the remaining or new incoming messages to this particular reception FIFOs. When the FIFO is not disabled then reception to the FIFO will continue.

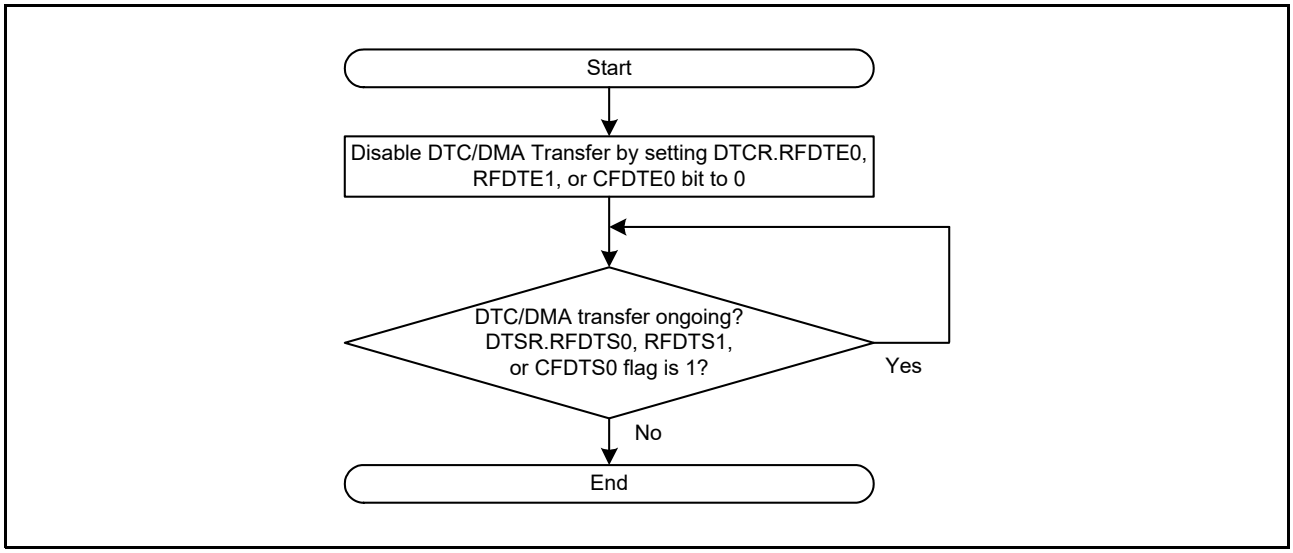

Figure 36.61 DTC/DMA Transfer Disable Flow

36.11 Usage Notes

36.11.1 Setting the Module Stop Function

The module-stop control register D (MSTPCRD) can be used to stop and start the CANFD module operations. After release from a reset, the CANFD module is placed in the module-stop state. The registers of the module become accessible after release from the module-stop state. For details, refer to section 11, Low Power Consumption.

36.11.2 Note on Configuration of Receive Message Buffers and FIFO Buffers

The maximum memory size available for receive message buffers and FIFO buffers is 1216 bytes.
For example, if all payload sizes are set to 8 bytes, each message size becomes 20 bytes, so the total number of messages must be 60 or less. If 32 receive message buffers are reserved, the total FIFO depth must be 28 or less.
Similarly, if all payload sizes are set to 64 bytes, each message size becomes 76 bytes, so the total number of messages must be 16 or less. If all FIFO depths are set to 4 messages, up to four receive message buffers can be used.
Operation is not guaranteed if the setting exceeds 1216 bytes.

37. Serial Peripheral Interface (RSPId)

In this section, “PCLK” is used to refer to PCLKA.

37.1 Overview

This MCU includes one channel of Serial Peripheral Interface (RSPI).
The RSPI channels are capable of high-speed, full-duplex or simplex synchronous serial communications with multiple processors and peripheral devices.
Table 37.1 lists the specifications of the RSPI, and Figure 37.1 shows a block diagram of the RSPI.
In this section, m as used with the RSPI command registers (SPCMDm) indicates 0 to 7.

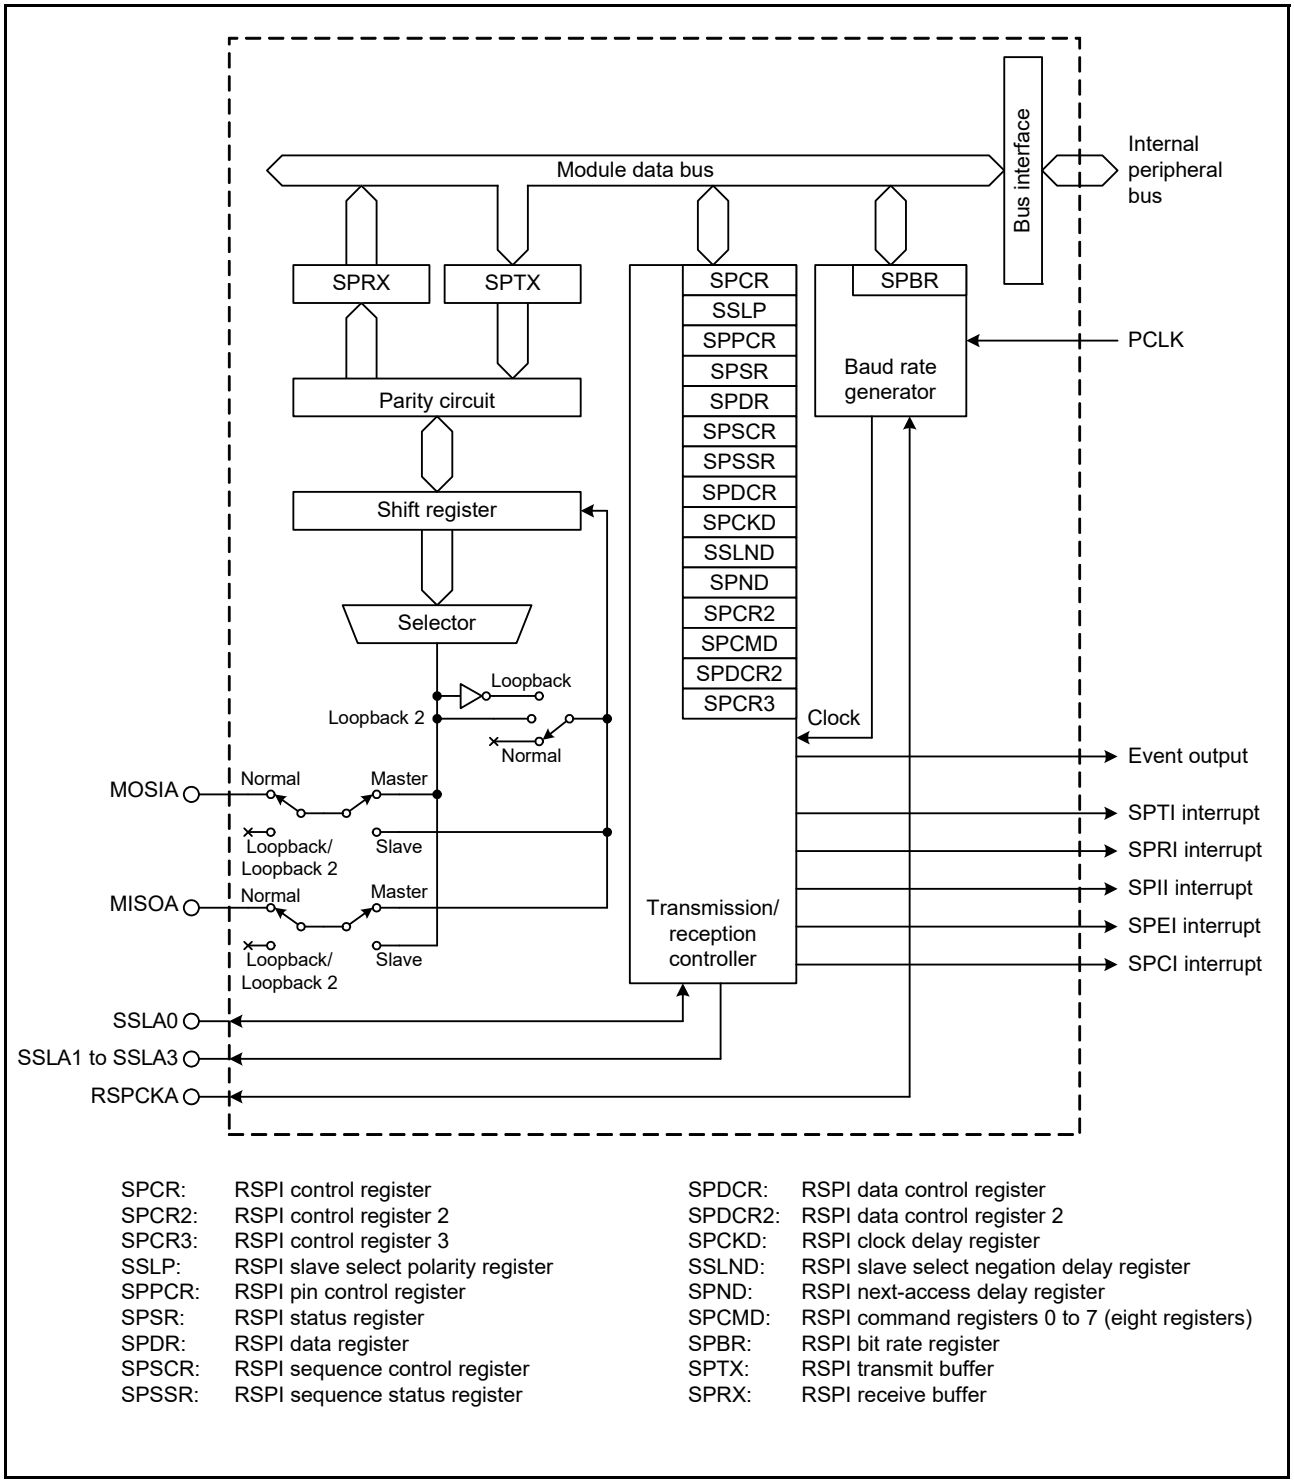
Table 37.1 RSPI Specifications (1/2)

Item	Description
Number of channels	One channel
RSPI transfer functions	• Use of MOSI (master out/slave in), MISO (master in/slave out), SSL (slave select), and RSPCK (RSPI clock) signals allows serial communications through SPI operation (4-wire method) or clock synchronous operation (3-wire method). • Communication mode: Full-duplex or simplex (transmit-only or receive-only (in slave mode)) can be selected. • Switching of the polarity of RSPCK • Switching of the phase of RSPCK
Data format	• MSB first/LSB first selectable • Transfer bit length is selectable as 8, 9, 10, 11, 12, 13, 14, 15, 16, 20, 24, or 32 bits. • 128-bit transmit/receive buffers • Up to four frames can be transferred in one round of transmission/reception (each frame consisting of up to 32 bits). • Byte swapping of transmit and receive data is selectable. • Logic level of transmit and receive data can be inverted.
Bit rate	• In master mode, the on-chip baud rate generator generates RSPCK by frequency-dividing PCLK (the division ratio ranges from divided by 2 to divided by 4096). • In slave mode, the minimum PCLK clock divided by 4 can be input as RSPCK (the maximum frequency of RSPCK is that of PCLK divided by 4). Width at high level: 2 cycles of PCLK; width at low level: 2 cycles of PCLK
Buffer configuration	• Double buffer configuration for the transmit/receive buffers • 128 bits for the transmit/receive buffers
Error detection	• Mode fault error detection • Overrun error detection*1 • Parity error detection • Underrun error detection
SSL control function	• Four SSL pins (SSLA0 to SSLA3) for each channel • In single-master mode, SSLA0 to SSLA3 pins are output. • In multi-master mode: SSLA0 pin for input, and SSLA1 to SSLA3 pins for either output or unused. • In slave mode: SSLA0 pin for input, and SSLA1 to SSLA3 pins for unused. • Controllable delay from SSL output assertion to RSPCK operation (RSPCK delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable delay from RSPCK stop to SSL output negation (SSL negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Function for changing SSL polarity
Control in master transfer	• A transfer of up to eight commands can be executed sequentially in looped execution. • For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity/phase, transfer data length, MSB/LSB first, burst, RSPCK delay, SSL negation delay, and next-access delay • A transfer can be initiated by writing to the transmit buffer. • MOSI signal value specifiable in SSL negation • RSPCK auto-stop function • Delay between data bytes under burst transfer can be reduced.

Table 37.1 RSPI Specifications (2/2)

Item	Description
Interrupt sources	• Interrupt sources Receive buffer full interrupt Transmit buffer empty interrupt Error interrupt (mode fault, overrun, underrun, or parity error) Idle interrupt Communication end interrupt
Event link function (output)	• The following events can be output to the event link controller. (RSPI0) Receive buffer full event Transmit buffer empty event Error event (mode fault, overrun, underrun, or parity error) Idle event Communication end event
Others	• Function for initializing the RSPI • Loopback mode
Low power consumption function	Module stop state can be set.

Note 1. In master reception and when the RSPCK auto-stop function is enabled, an overrun error does not occur because the transfer clock is stopped at the timing of overrun error detection.



SPCR:	RSPI control register	SPDCR:	RSPI data control register
SPCR2:	RSPI control register 2	SPDCR2:	RSPI data control register 2
SPCR3:	RSPI control register 3	SPCKD:	RSPI clock delay register
SSLP:	RSPI slave select polarity register	SSLND:	RSPI slave select negation delay register
SPPCR:	RSPI pin control register	SPND:	RSPI next-access delay register
SPSR:	RSPI status register	SPCMD:	RSPI command registers 0 to 7 (eight registers)
SPDR:	RSPI data register	SPBR:	RSPI bit rate register
SPSCR:	RSPI sequence control register	SPTX:	RSPI transmit buffer
SPSSR:	RSPI sequence status register	SPRX:	RSPI receive buffer

Figure 37.1 RSPI Block Diagram

Table 37.2 lists the I/O pins used in the RSPI.
The RSPI automatically switches the I/O direction of the SSLA0 pin. SSLA0 is set as an output when the RSPI is a single master and as an input when the RSPI is a multi-master or a slave. Pins RSPCKA, MOSIA, and MISOA are automatically set as inputs or outputs according to the setting of master or slave and the level input on the SSLA0 pin. Refer to section 37.3.2, Controlling RSPI Pins for details.

Table 37.2 RSPI Pin Configuration

Channel	Pin Name	I/O	Function
RSPI0	RSPCKA	I/O	Clock I/O
	MOSIA	I/O	Master transmit data I/O
	MISOA	I/O	Slave transmit data I/O
	SSLA0	I/O	Slave selection I/O
	SSLA1	Output	Slave selection output
	SSLA2	Output	Slave selection output
	SSLA3	Output	Slave selection output

37.2 Register Descriptions

37.2.1 RSPI Control Register (SPCR)

Address(es): RSPI0.SPCR 000D 0100h

	b7	b6	b5	b4	b3	b2	b1	b0
	SPRIE	SPE	SPTIE	SPEIE	MSTR	MODFEN	TXMD	SPMS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SPMS	RSPI Mode Select*1	0: SPI operation (4-wire method) 1: Clock synchronous operation (3-wire method)	R/W
b1	TXMD	Communications Operating Mode Select*1	0: Full-duplex communications (enables the receiver) 1: Transmit-only simplex communications (disables the receiver)	R/W
b2	MODFEN	Mode Fault Error Detection Enable *1	0: Disables the detection of mode fault error 1: Enables the detection of mode fault error	R/W
b3	MSTR	RSPI Master/Slave Mode Select*1	0: Slave mode 1: Master mode	R/W
b4	SPEIE	Error Interrupt Enable	0: Disables the generation of error interrupt requests 1: Enables the generation of error interrupt requests	R/W
b5	SPTIE	Transmit Buffer Empty Interrupt Enable	0: Disables the generation of transmit buffer empty interrupt requests 1: Enables the generation of transmit buffer empty interrupt requests	R/W
b6	SPE	RSPI Function Enable	0: Disables the RSPI function 1: Enables the RSPI function	R/W
b7	SPRIE	Receive Buffer Full Interrupt Enable	0: Disables the generation of receive buffer full interrupt requests 1: Enables the generation of receive buffer full interrupt requests	R/W

Note 1. Do not change the values of the MSTR, MODFEN, TXMD, and SPMS bits while the SPE bit is 1.

SPMS Bit (RSPI Mode Select)

The SPMS bit selects SPI operation (4-wire method) or clock synchronous operation (3-wire method).
The SSLA0 to SSLA3 pins are not used in clock synchronous operation. The RSPCKA, MOSIA, and MISOA pins handle communications. If clock synchronous operation is to proceed in master mode (SPCR.MSTR = 1), the SPCMDm.CPHA bit can be set to either 0 or 1. Set the CPHA bit to 1 if clock synchronous operation is to proceed in slave mode (SPCR.MSTR = 0). Do not set the CPHA bit to 0 when clock synchronous operation is to proceed in slave mode (SPCR.MSTR = 0).

TXMD Bit (Communications Operating Mode Select)

The TXMD bit selects full-duplex communications or transmit-only simplex communications.
When performing communications with the TXMD bit set to 1, the RSPI performs only transmit operations and not receive operations (refer to section 37.3.6, Communications Operating Mode).
When the TXMD bit is set to 1, receive buffer full interrupt requests cannot be used.
When the SPCR3.RXMD bit is set to 1 (receive-only simplex communications), the setting of this bit is ignored.

MODFEN Bit (Mode Fault Error Detection Enable)

The MODFEN bit enables or disables the detection of mode fault error (refer to section 37.3.10, Error Detection). In addition, the RSPI determines the I/O direction of the SSLA0 to SSLA3 pins based on combinations of the MODFEN and MSTR bits (refer to section 37.3.2, Controlling RSPI Pins).

MSTR Bit (RSPI Master/Slave Mode Select)

The MSTR bit selects master/slave mode of the RSPI. According to MSTR bit settings, the RSPI determines the direction of pins RSPCKA, MOSIA, MISOA, and SSLA0 to SSLA3.

SPEIE Bit (Error Interrupt Enable)

The SPEIE bit enables or disables the generation of error interrupt requests when the RSPI detects a mode fault error or underrun error and sets the SPSR.MODF flag to 1, when the RSPI detects an overrun error and sets the SPSR.OVRF flag to 1, or when the RSPI detects a parity error and sets the SPSR.PERF flag to 1 (refer to section 37.3.10, Error Detection).

SPTIE Bit (Transmit Buffer Empty Interrupt Enable)

The SPTIE bit enables or disables the generation of transmit buffer empty interrupt requests when the RSPI detects when the transmit buffer is empty.

A transmit buffer empty interrupt request when transmission starts is generated by setting the SPE and SPTIE bits to 1 at the same time or by setting the SPE bit to 1 after setting the SPTIE bit to 1.

Note that a transmit buffer interrupt is generated when the SPTIE bit is 1 even if the RSPI function is disabled (the SPTIE bit is changed to 0).

SPE Bit (RSPI Function Enable)

The SPE bit enables or disables the RSPI function.

When the SPSR.MODF flag is 1, the SPE bit cannot be set to 1. For details, refer to section 37.3.10, Error Detection.

Setting the SPE bit to 0 disables the RSPI function, and initializes a part of the module function. For details, refer to section 37.3.11, Initializing RSPI. Furthermore, a transmit buffer empty interrupt request is generated by the state of the SPE bit changing from 0 to 1 or from 1 to 0.

SPRIE Bit (Receive Buffer Full Interrupt Enable)

If the RSPI has detected a receive buffer full write after completion of a serial transfer, the SPRIE bit enables or disables the generation of a receive buffer full interrupt request.

37.2.2 RSPI Slave Select Polarity Register (SSLP)

Address(es): RSPI0.SSLP 000D 0101h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	SSL3P	SSL2P	SSL1P	SSL0P
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SSL0P	SSL0 Signal Polarity Setting	0: SSL0 signal is active low 1: SSL0 signal is active high	R/W
b1	SSL1P	SSL1 Signal Polarity Setting	0: SSL1 signal is active low 1: SSL1 signal is active high	R/W
b2	SSL2P	SSL2 Signal Polarity Setting	0: SSL2 signal is active low 1: SSL2 signal is active high	R/W
b3	SSL3P	SSL3 Signal Polarity Setting	0: SSL3 signal is active low 1: SSL3 signal is active high	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Do not change the SSLP register while the SPCR.SPE bit is 1.

37.2.3 RSPI Pin Control Register (SPPCR)

Address(es): RSPI0.SPPCR 000D 0102h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	MOIFE	MOIFV	—	—	SPLP2	SPLP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SPLP	RSPI Loopback	0: Normal mode 1: Loopback mode (data is inverted for transmission)	R/W
b1	SPLP2	RSPI Loopback 2	0: Normal mode 1: Loopback mode (data is not inverted for transmission)	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	MOIFV	MOSI Idle Fixed Value	0: The level output on the MOSIA pin during MOSI idling corresponds to low 1: The level output on the MOSIA pin during MOSI idling corresponds to high	R/W
b5	MOIFE	MOSI Idle Value Fixing Enable	0: MOSI output value equals final data from previous transfer 1: MOSI output value equals the value set in the MOIFV bit	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Do not change the SPPCR register while the SPCR.SPE bit is 1.

SPLP Bit (RSPI Loopback)

The SPLP bit selects the mode of the RSPI pins.

When the SPLP bit is set to 1, the RSPI shuts off the path between the MISOA pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIA pin and the shift register if the SPCR.MSTR bit is 0, and connects (inverts) the input path and output path for the shift register (loopback mode).

SPLP2 Bit (RSPI Loopback 2)

The SPLP2 bit selects the mode of the RSPI pins.

When the SPLP2 bit is set to 1, the RSPI shuts off the path between the MISOA pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIA pin and the shift register if the SPCR.MSTR bit is 0, and connects the input path and output path for the shift register (loopback mode).

MOIFV Bit (MOSI Idle Fixed Value)

If the MOIFE bit is 1 in master mode, the MOIFV bit determines the MOSIA pin output value during the SSL negation period (including the SSL retention period during a burst transfer).

MOIFE Bit (MOSI Idle Value Fixing Enable)

The MOIFE bit fixes the MOSIA output value when the RSPI in master mode is in an SSL negation period (including the SSL retention period during a burst transfer). When the MOIFE bit is 0, the RSPI outputs the last data from the previous serial transfer during the SSL negation period to the MOSIA pin. When the MOIFE bit is 1, the RSPI outputs the fixed value set in the MOIFV bit to the MOSIA pin.

37.2.4 RSPI Status Register (SPSR)

Address(es): RSPI0.SPSR 000D 0103h

	b7	b6	b5	b4	b3	b2	b1	b0
	SPRF	SPCF	SPTEF	UDRF	PERF	MODF	IDLNF	OVRF
Value after reset:	0	0	1	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	OVRF	Overrun Error Flag	0: No overrun error occurs 1: An overrun error occurs	R/(W) *1
b1	IDLNF	Idle Flag	0: RSPI is in the idle state 1: RSPI is in the transfer state	R
b2	MODF	Mode Fault Error Flag	0: Neither a mode fault error nor an underrun error occurs 1: A mode fault error or an underrun error occurs	R/(W) *1
b3	PERF	Parity Error Flag	0: No parity error occurs 1: A parity error occurs	R/(W) *1
b4	UDRF	Underrun Error Flag	This flag is used with the MODF flag to check the state in terms of mode fault errors and underrun errors. b4 b2 0 0: Neither a mode fault error nor an underrun error occurs 0 1: A mode fault error occurs 1 1: An underrun error occurs	R/(W) *1, *2
b5	SPTEF	Transmit Buffer Empty Flag	0: Transmit buffer has valid data 1: Transmit buffer has no valid data	R*3
b6	SPCF	Communication End Flag	0: Communication does not start or communication is in progress 1: Communication has ended	R/(W) *1
b7	SPRF	Receive Buffer Full Flag	0: Receive buffer has no valid data 1: Receive buffer has valid data	R*3

Note 1. Only 0 can be written to clear the flag after reading 1.
Note 2. Clear the MODF and UDRF flags at the same time.
Note 3. The write value should be 1.

OVRF Flag (Overrun Error Flag)

The OVRF flag indicates the occurrence of an overrun error. In master mode (when the SPCR.MSTR bit is 1) and when the RSPCK clock auto-stop function is enabled (the SPCR2.SCKASE bit is 1), an overrun error does not occur; accordingly this flag does not become 1. For details, refer to section 37.3.10.1, Overrun Error.

[Setting condition]

- When the next data reception ends while the SPCR.TXMD bit is 0 and the receive buffer is full.
- When the next data reception ends while the SPCR.MSTR bit is 0, the SPCR3.RXMD bit is 1, and the receive buffer is full.

[Clearing condition]

- When the SPSR register is read while the OVRF flag is 1, and then 0 is written to the OVRF flag.

IDLNF Flag (Idle Flag)

The IDLNF flag indicates the transfer status of the RSPI.

[Setting condition]

Master mode

- When both of the conditions in master mode under the [Clearing condition] below are not satisfied.

Slave mode

- When the SPCR.SPE bit is set to 1 (enables the RSPI function).

[Clearing condition]

Master mode

- When the SPCR.SPE bit is set to 0 (disables the RSPI function)
- When all of the following conditions are satisfied.
  1. The transmit buffer is empty (the SPTEF flag is 1)
  2. The SPSSR.SPCP[2:0] bits are 000b
  3. The transmission of the last bit has been completed and the time specified by the SSLND.SLNDL[2:0] and SPND.SPNDL[2:0] bits has elapsed

Slave mode

- When the SPCR.SPE bit is set to 0 (disables the RSPI function).

MODF Flag (Mode Fault Error Flag)

Indicates the occurrence of a mode fault error or an underrun error. The UDRF flag indicates whether the error is a mode fault error or an underrun error.

[Setting condition]

Multi-master mode

- When the input level of the SSLAi pin changes to the active level while the SPCR.MSTR bit is 1 (master mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), the RSPI detects a mode fault error.

Slave mode

- When the SSLAi pin is negated before the RSPCK cycle necessary for data transfer ends while the SPCR.MSTR bit is 0 (slave mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), the RSPI detects a mode fault error.
- When the serial transfer starts while the SPCR.SPE bit is 1 (enables the RSPI function) and the transmit data are not ready for output, the RSPI detects an underrun error.

The active level of the SSLAi signal is determined by the SSLP.SSLiP bit (SSLi signal polarity setting bit).

[Clearing condition]

- When the SPSR register is read while the MODF flag is 1, and then 0 is written to the MODF flag.

PERF Flag (Parity Error Flag)

Indicates the occurrence of a parity error.

[Setting condition]

- When a data reception ends while the SPCR.TXMD bit is 0 and the SPCR2.SPPE bit is 1, the RSPI detects a parity error.
- When a data reception ends while the SPCR.MSTR bit is 0, the SPCR3.RXMD bit is 1, and the SPCR2.SPPE bit is 1, the RSPI detects a parity error.

[Clearing condition]

- When the SPSR register is read while the PERF flag is 1, and then 0 is written to the PERF flag.

UDRF Flag (Underrun Error Flag)

Indicates the occurrence of an underrun error. When this flag becomes 1, the MODF flag becomes 1 too. When the MODF flag is 1 and this flag is 0, the error is a mode fault error.

[Setting condition]

- When the serial transfer starts while the SPCR.MSTR bit is 0 (slave mode), the SPCR3.RXMD bit is 0, the SPCR.SPE bit is 1 (enables the RSPI function), and the transmit data are not ready for output, the RSPI detects an underrun error

[Clearing condition]

- When 0 is written to the UDRF flag after reading the SPSR register while the UDRF flag is 1

SPTEF Flag (Transmit Buffer Empty Flag)

Indicates whether the transmit buffer (SPTX) in the RSPI data register has valid data.

[Setting condition]

- When the SPCR.SPE bit is set to 0 (disables the RSPI function).
- When the number of frames of transmit data specified by the SPDCR.SPFC[1:0] bits have been transferred from the transmit buffer to the shift register.

[Clearing condition]

- When the number of frames of transmit data specified by the SPDCR.SPFC[1:0] bits is written to the SPDR register.

The SPDR register can be set only when the SPTEF flag is 1. The data in the transmit buffer is not updated when the SPDR register is set while the SPTEF flag is 0.

SPCF Flag (Communication End Flag)

This flag indicates a completion of the RSPI communication.

[Setting condition]

Master mode

- When all of the following conditions are satisfied.
  1. The transmit buffer is empty (the SPTEF flag is 1)
  2. The SPSSR.SPCP[2:0] bits are 000b
  3. The transmission of the last bit has been completed and the time specified by the SSLND.SLNDL[2:0] and SPND.SPNDL[2:0] bits has elapsed

Full-duplex or transmit-only simplex communications in slave mode (SPI operation)

- When all of the following conditions are satisfied.
  1. The transmit buffer is empty (the SPTEF flag is 1)
  2. The transmit shift register is empty
  3. The SSLA0 signal has been negated

Full-duplex or transmit-only simplex communications in slave mode (clock synchronous operation)

- When all of the following conditions are satisfied.
  1. The transmit buffer is empty (the SPTEF flag is 1)
  2. The transmit shift register is empty
  3. The last bit of the last data has been received (the last even edge of the RSPCK)

Receive-only simplex communications in slave mode (SPI operation)

- When the SSLA0 signal is negated after the number of frames set in the SPDCR.SPFC[1:0] bits have been received.

Receive-only simplex communications in slave mode (clock synchronous operation)

- When the number of frames set in the SPDCR.SPFC[1:0] bits have been received (the last even edge of the

RSPCK).

[Clearing condition]

Full-duplex or transmit-only simplex communications

- When the next transmit data is written to the transmit buffer
- When 0 is written to the SPCF flag after reading the SPSR register while the SPCF flag is 1

Receive-only simplex communications in SPI operation

- When the assertion of the SSLA0 signal for the next data has been detected
- When 0 is written to the SPCF flag after reading the SPSR register while the SPCF flag is 1

Receive-only simplex communications in slave mode (clock synchronous operation)

- When the first edge of the RSPCK signal for the next data has been detected
- When 0 is written to the SPCF flag after reading the SPSR register while the SPCF flag is 1

SPRF Flag (Receive Buffer Full Flag)

Indicates whether the receive buffer (SPRX) in the RSPI data register has valid data.

[Setting condition]

- When the number of frames of receive data specified by the SPDCR.SPFC[1:0] bits is transferred from shift register to the receive buffer (SPRX) while the SPCR.TXMD bit is 0 (full duplex) and the SPRF flag is 0.
  Note that the SPRF flag does not become 1 when the OVRF flag is 1.
- When the number of frames of receive data specified by the SPDCR.SPFC[1:0] bits is transferred from shift register to the receive buffer (SPRX) while the SPCR.MSTR bit is 0, the SPCR3.RXMD bit is 1, and the SPRF flag is 0.
  Note that the SPRF flag does not become 1 when the OVRF flag is 1.

[Clearing condition]

- When all of the received data are read from the SPDR register.

37.2.5 RSPI Data Register (SPDR)

- When accessing in longword size

Address(es): RSPI0.SPDR 000D 0104h

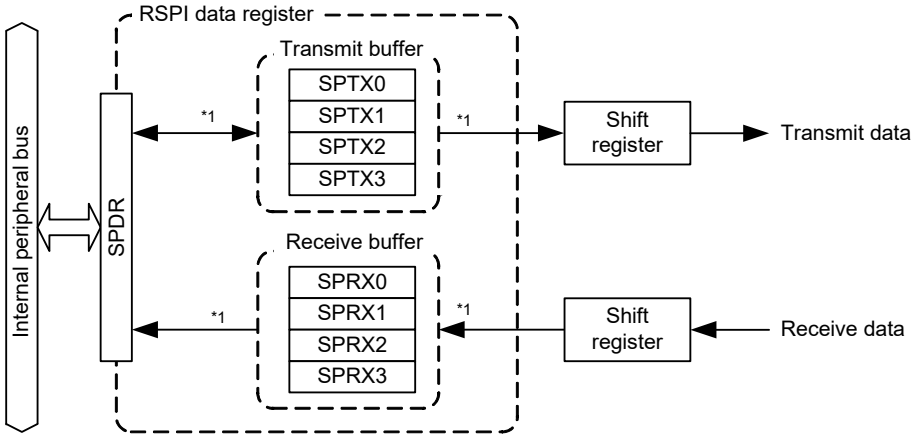
- When accessing in byte size

Address(es): RSPI0.SPDR.HH 000D 0104h

	b7	b6	b5	b4	b3	b2	b1	b0
	HH							
Value after reset:	0	0	0	0	0	0	0	0

The SPDR register is the interface with the buffers that hold data for transmission and reception by the RSPI.
When accessing in longwords (the SPLW bit is 1 and the SPBYT bit is 0), access the SPDR register in 32-bit units.
When accessing in words (the SPLW bit is 0 and the SPBYT bit is 0), access the SPDR.H register in 16-bit units.
When accessing in bytes (the SPBYT bit is 1), access the SPDR.HH register in 8-bit units.
The transmit buffer (SPTX) and receive buffer (SPRX) are independent but are both mapped to the SPDR register.
Figure 37.2 shows the Configuration of the SPDR Register.



Note 1. The destination buffer and stage for access is automatically switched by hardware.

Figure 37.2 Configuration of the SPDR Register

The transmit and receive buffers each have four stages. The number of stages to be used is selectable by the number of frames specification bits in the RSPI data control register (SPDCR.SPFC[1:0]). The eight stages of the buffer are all mapped to the single address of the SPDR register.

Data written to the SPDR register are written to a transmit-buffer stage (SPTXn) (n = 0 to 3) and then transmitted from the buffer. The receive buffer holds received data on completion of reception. The receive buffer is not updated if an overrun is generated.

Furthermore, if the data length is other than 32 bits, bits not referred to in SPTXn (n = 0 to 3) are stored in the corresponding bits in SPRXn. For example, if the data length is 9 bits, received data are stored in the SPRXn[8:0] bits and the SPTXn[31:9] bits are stored in the SPRXn[31:9] bits.

(1) Bus Interface

The SPDR register is the interface with 32-bit wide transmit and receive buffers, each of which has four stages, for a total of 32 bytes. In other words, the 32 bytes are mapped to the 4-byte address space for the SPDR register. Furthermore, the unit of access for the SPDR register is selected by the SPDCR.SPLW bit and the SPDCR.SPBYT bit.
Data for transmission should be flush with the LSB end of the register. Received data are stored flush with the LSB end.
Operations involved in writing to and reading from the SPDR register are described below.

(a) Writing

Data written to the SPDR register are written to a transmit buffer (SPTXn). This is not influenced by the value of the SPDCR.SPRDTD bit unlike when reading from the SPDR register.
The transmit buffer includes a transmit buffer write pointer which is automatically updated to indicate the next stage each time data are written to the SPDR register.
Figure 37.3 shows the configuration of the bus interface with the transmit buffer in the case of writing to the SPDR register.

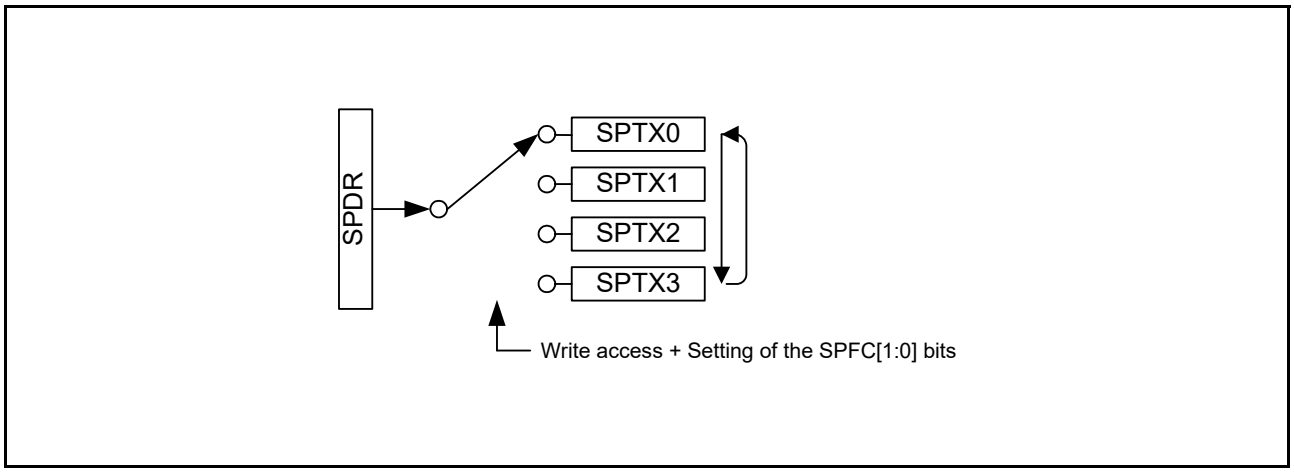


Figure 37.3 Configuration of the SPDR Register (Writing)

The sequence for switching the transmit buffer write pointer differs with the setting of the number of frames specification bits in the RSPI data control register (SPDCR.SPFC[1:0]).

- Settings of the SPFC[1:0] bits and sequence of switching the pointer among SPTX0 to SPTX3.
  When the SPFC[1:0] bits are 00b: SPTX0 → SPTX0 → SPTX0 → …
  When the SPFC[1:0] bits are 01b: SPTX0 → SPTX1 → SPTX0 → SPTX1 → …
  When the SPFC[1:0] bits are 10b: SPTX0 → SPTX1 → SPTX2 → SPTX0 → SPTX1 → …
  When the SPFC[1:0] bits are 11b: SPTX0 → SPTX1 → SPTX2 → SPTX3 → SPTX0 → SPTX1 → …

When 1 is written to the RSPI function enable bit in the RSPI control register (SPCR.SPE) while the bit's current value is 0, SPTX0 will be the destination the next time writing proceeds.
When writing to the transmit buffer (SPTXn) after generation of the transmit buffer empty interrupt (after the SPSR.SPTEF flag becomes 1), write the number of frames set by the number of frames specification bits (SPFC[1:0]) in the RSPI data control register (SPDCR). Even if the number of frames is written to the transmit buffer (SPTXn), the value of the buffer is not updated after completion of the writing and before generation of the next transmit buffer empty interrupt (while the SPSR.SPTEF flag is 0).

(b) Reading

The SPDR register can be read to read the value of a receive buffer (SPRXn) or a transmit buffer (SPTXn). The setting of the RSPI receive/transmit data select bit in the RSPI data control register (SPDCR.SPRDTD) selects whether reading is of the receive or transmit buffer.

The sequence of reading the SPDR register is controlled by independent pointers, receive buffer read pointer and transmit buffer read pointer.

Figure 37.4 shows the configuration of the bus interface with the receive and transmit buffers in the case of reading from the SPDR register.

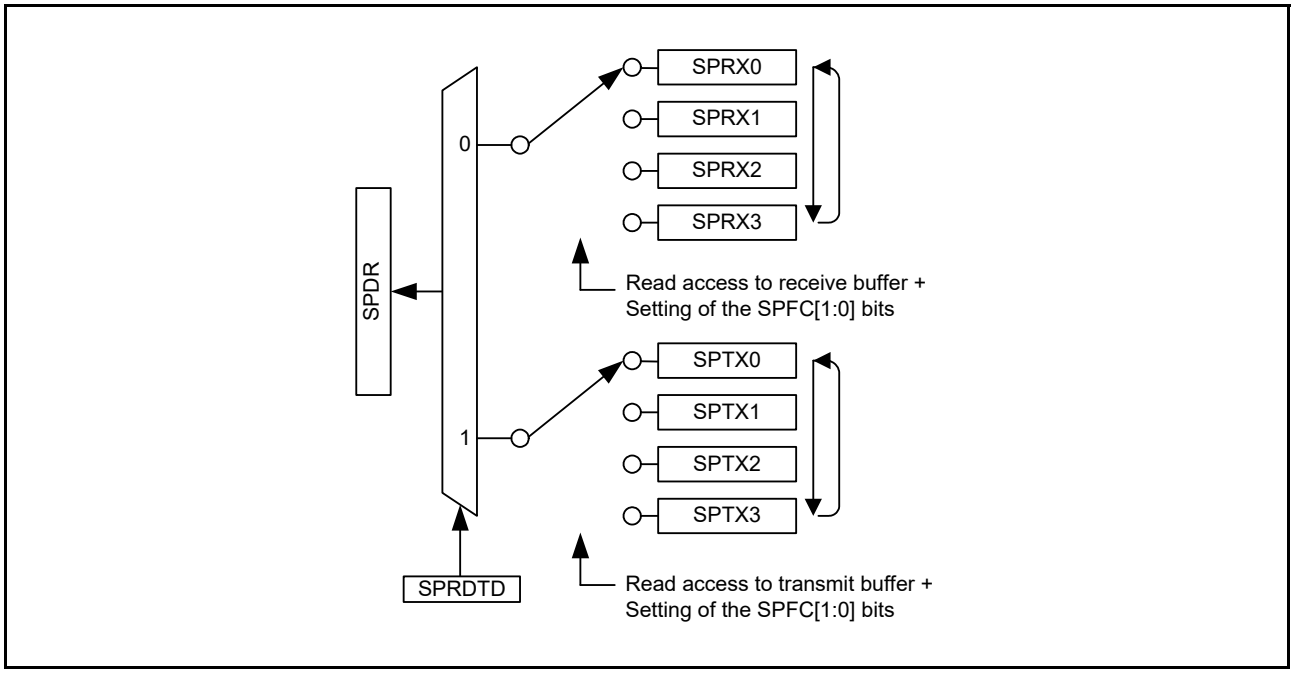

Figure 37.4 Configuration of the SPDR Register (Reading)

Reading the receive buffer switches the receive buffer read pointer to the next buffer automatically.

The sequence of switching the receive buffer read pointer is the same as that for the transmit buffer write pointer. However, when 1 is written to the RSPI function enable bit in the RSPI control register (SPCR.SPE) while the bit's current value is 0, SPRX0 will be indicated by the buffer read pointer the next time reading proceeds.

The transmit buffer read pointer is updated when writing to the SPDR register, and not updated when reading from the transmit buffer. When reading from the transmit buffer, the value most recently written to the SPDR register is read. However, after generation of the transmit buffer empty interrupt, the values read from the transmit buffer are all 0 in the interval after completion of writing the number of frames of data specified in the number of frames specification bits (SPDCR.SPFC[1:0]) and before generation of the next buffer empty interrupt (while the SPSR.SPTEF flag is 0).

37.2.6 RSPI Sequence Control Register (SPSCR)

Address(es): RSPI0.SPSCR 000D 0108h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SPSLN[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SPSLN[2:0]	RSPI Sequence Length Specification	b2 b0 Sequence Length — Referenced SPCMD0 to SPCMD7 registers (No.) 0 0 0: 1 — 0→0→… 0 0 1: 2 — 0→1→0→… 0 1 0: 3 — 0→1→2→0→… 0 1 1: 4 — 0→1→2→3→0→… 1 0 0: 5 — 0→1→2→3→4→0→… 1 0 1: 6 — 0→1→2→3→4→5→0→… 1 1 0: 7 — 0→1→2→3→4→5→6→0→… 1 1 1: 8 — 0→1→2→3→4→5→6→7→0→… The order in which the SPCMD0 to SPCMD7 registers are to be referenced is changed according to the sequence length that is set in these bits. The relationship among the setting of these bits, sequence length, and the SPCMD0 to SPCMD7 registers referenced by the RSPI is shown above. However, the RSPI in slave mode references the SPCMD0 register.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SPSCR register sets the sequence length when the RSPI operates in master mode. When changing the SPSCR.SPSLN[2:0] bits while both the SPCR.MSTR and SPCR.SPE bits are 1, the bits should be changed while the SPSR.IDLNF flag is 0.

SPSLN[2:0] Bits (RSPI Sequence Length Specification)

The SPSLN[2:0] bits specify a sequence length when the RSPI in master mode performs sequential operations. The RSPI in master mode changes the SPCMD0 to SPCMD7 registers to be referenced and the order in which they are referenced according to the sequence length that is set in the SPSLN[2:0] bits.
In slave mode, the SPCMD0 register is referred.

37.2.7 RSPI Sequence Status Register (SPSSR)

Address(es): RSPI0.SPSSR 000D 0109h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	SPECM[2:0]			—	SPCP[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SPCP[2:0]	RSPI Command Pointer	b2 b0 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
b3	—	Reserved	This bit is read as 0.	R
b6 to b4	SPECM[2:0]	RSPI Error Command	b6 b4 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
b7	—	Reserved	This bit is read as 0.	R

The SPSSR register indicates the sequence control status when the RSPI operates in master mode.
Any writing to the SPSSR register is ignored.

SPCP[2:0] Bits (RSPI Command Pointer)

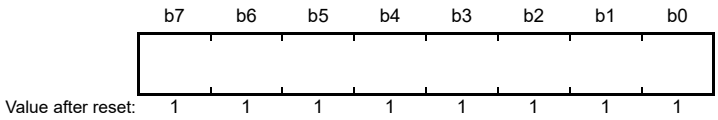
The SPCP[2:0] bits indicate the SPCMDm register that is currently pointed to by the pointer during sequence control by the RSPI.
For the RSPI's sequence control, refer to section 37.3.12.1, Master Mode Operation.

SPECM[2:0] Bits (RSPI Error Command)

The SPECM[2:0] bits indicate the SPCMDm register that is specified by the SPCP[2:0] bits when an error is detected during sequence control by the RSPI. The RSPI updates the SPECM[2:0] bits only when an error is detected. If both the SPSR.OVRF and SPSR.MODF flags are 0 and there is no error, the values of the SPECM[2:0] bits have no meaning.
For the RSPI's error detection function, refer to section 37.3.10, Error Detection. For the RSPI's sequence control, refer to section 37.3.12.1, Master Mode Operation.

37.2.8 RSPI Bit Rate Register (SPBR)

Address(es): RSPI0.SPBR 000D 010Ah



The SPBR register sets the bit rate in master mode. Do not change the SPBR register while both the SPCR.MSTR and SPCR.SPE bits are 1.

When the RSPI is used in slave mode, the bit rate depends on the bit rate of the input clock (bit rate satisfying the electrical characteristics should be used) regardless of the settings of the SPBR register and the SPCMDm.BRDV[1:0] bits (bit rate division setting bits).
The bit rate is determined by combinations of the SPBR register setting and the SPCMDm.BRDV[1:0] bit setting. The equation for calculating the bit rate is given below. In the equation, n denotes the SPBR register setting (0, 1, 2, …, 255), and N denotes the BRDV[1:0] bit setting (0, 1, 2, 3).

$$\text{Bit rate} = \frac{f(PCLK)}{2 \times (n+1) \times 2^{N}}$$

Table 37.3 lists examples of the relationship among the SPBR register settings, the BRDV[1:0] bit settings, and bit rates.
Use the bit rate that meets electrical characteristics based on the AC specifications of the target device.

Table 37.3 Relationship among SPBR Settings, BRDV[1:0] Settings, and Bit Rates

SPBR (n)	BRDV[1:0] Bits (N)	Division Ratio	Bit Rate							
			PCLK = 32 MHz	PCLK = 36 MHz	PCLK = 40 MHz	PCLK = 50 MHz	PCLK = 60 MHz	PCLK = 80 MHz	PCLK = 100 MHz	PCLK = 120 MHz
0	0	2	16.0 Mbps	18.0 Mbps	20.0 Mbps	25.0 Mbps	30.0 Mbps	40.0 Mbps	—	—

37.2.9 RSPI Data Control Register (SPDCR)

Address(es): RSPI0.SPDCR 000D 010Bh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	SPBYT	SPLW	SPRDTD	—	—	SPFC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	SPFC[1:0]	Number of Frames Specification	b1 b0 0 0: 1 frame 0 1: 2 frames 1 0: 3 frames 1 1: 4 frames	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	SPRDTD	RSPI Receive/Transmit Data Select	0: The SPDR values are read from the receive buffer 1: The SPDR values are read from the transmit buffer (but only if the transmit buffer is empty)	R/W
b5	SPLW	RSPI Longword Access/ Word Access Specification*1	0: The SPDR register is accessed in words 1: The SPDR register is accessed in longwords	R/W
b6	SPBYT	RSPI Byte Access Specification	0: The SPDR register is accessed in words or longwords (the SPLW bit is enabled) 1: The SPDR register is accessed in bytes (the SPLW bit is disabled)	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. Set the SPBYT bit to 0, when accessing the SPDR register in words or longwords.

Up to four frames can be transmitted or received in one round of transmission or reception activation. The amount of data in each transfer is controlled by the combination of the SPCMDm.SPB[3:0] bits, the SPSCR.SPSLN[2:0] bits, and the SPDCR.SPFC[1:0] bits.
When changing the SPDCR.SPFC[1:0] bits while the SPCR.SPE bit is 1, the bits should be changed while the SPSR.IDLNF flag is 0.

SPFC[1:0] Bits (Number of Frames Specification)

The SPFC[1:0] bits specify the number of frames that can be stored in the SPDR register (per transfer activation). Up to four frames can be transmitted or received in one round of transmission or reception, and the amount of data is determined by the combination of the SPSCR.SPSLN[2:0] bits, and the SPDCR.SPFC[1:0] bits. Furthermore, the setting of the SPFC[1:0] bits adjusts the number of frames for generation of receive buffer full interrupt, and start of transmission or generation of transmit buffer empty interrupts.
When the number of frames of transmit data specified by SPFC[1:0] bits is written to the SPDR register, the SPSR.SPTEF flag becomes 0 and transmission starts. Then, when the specified number of frames of transmit data has been transferred to the shift register, the SPTEF flag becomes 1 and the RSPI transmit buffer empty interrupt is generated.
When the number of frames specified by the SPFC[1:0] bits are received, the SPSR.SPRF flag becomes 1 and the receive buffer full interrupt is generated.
Table 37.4 lists the frame configurations that can be stored in the SPDR register and examples of combinations of settings for transmission and reception. Do not select the combinations of settings other than those shown in the examples.

Table 37.4 Settable Combinations of SPSLN[2:0] Bits and SPFC[1:0] Bits

Setting	SPSLN[2:0]	SPFC[1:0]	Number of Frames in a Single Sequence	Number of Frames at which Transmit Buffer or Receive Buffer Status Becomes “Has Valid Data”
1-1	000b	00b	1	1
1-2	000b	01b	2	2
1-3	000b	10b	3	3
1-4	000b	11b	4	4
2-1	001b	01b	2	2
2-2	001b	11b	4	4
3	010b	10b	3	3
4	011b	11b	4	4
5	100b	00b	5	1
6	101b	00b	6	1
7	110b	00b	7	1
8	111b	00b	8	1

SPRDTD Bit (RSPI Receive/Transmit Data Select)

The SPRDTD bit selects whether the SPDR register reads values from the receive buffer or from the transmit buffer.
If reading is from the transmit buffer, the value written to the SPDR register immediately beforehand is read.
When reading the transmit buffer, do so before writing of the number of frames set in the SPFC[1:0] bits is finished and after generation of the transmit buffer empty interrupt (While the SPSR.SPTEF flag is 1).
For details, refer to section 37.2.5, RSPI Data Register (SPDR).

SPLW Bit (RSPI Longword Access/Word Access Specification)

The SPLW bit specifies the access width for the SPDR register. This bit setting is enabled when the SPBYT bit is 0.
Access to the SPDR register in words when the SPLW bit is 0 and in longwords when the SPLW bit is 1.
Also, when the SPLW bit is 0, set the SPCMDm.SPB[3:0] bits (RSPI data length setting bits) to 8 to 16 bits. Do not select 20, 24, or 32 bits.

SPBYT Bit (RSPI Byte Access Specification)

The SPBYT bit specifies the access width for the SPDR register. Access to the SPDR register according to the SPLW bit setting when the SPBYT bit is 0. Access to the SPDR register in bytes when the SPBYT bit is 1.
When the SPBYT bit is 1, set the SPCMDm.SPB[3:0] bits (RSPI data length setting bits) to 8 bits. Do not select 9 to 16, 20,24, or 32 bits.

37.2.10 RSPI Clock Delay Register (SPCKD)

Address(es): RSPI0.SPCKD 000D 010Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SCKDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SCKDL[2:0]	RSPCK Delay Setting	b2 b0 0 0 0: 1 RSPCK 0 0 1: 2 RSPCK 0 1 0: 3 RSPCK 0 1 1: 4 RSPCK 1 0 0: 5 RSPCK 1 0 1: 6 RSPCK 1 1 0: 7 RSPCK 1 1 1: 8 RSPCK	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SPCKD register sets a period from the beginning of SSLAi signal assertion to RSPCK oscillation (RSPCK delay) when the SPCMDm.SCKDEN bit is 1. Do not change the SPCKD register while both the SPCR.MSTR and SPCR.SPE bits are 1.

SCKDL[2:0] Bits (RSPCK Delay Setting)

The SCKDL[2:0] bits set an RSPCK delay value when the SPCMDm.SCKDEN bit is 1.
When using the RSPI in slave mode, set the SCKDL[2:0] bits to 000b.

37.2.11 RSPI Slave Select Negation Delay Register (SSLND)

Address(es): RSPI0.SSLND 000D 010Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SLNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SLNDL[2:0]	SSL Negation Delay Setting	b2 b0 0 0 0: 1 RSPCK 0 0 1: 2 RSPCK 0 1 0: 3 RSPCK 0 1 1: 4 RSPCK 1 0 0: 5 RSPCK 1 0 1: 6 RSPCK 1 1 0: 7 RSPCK 1 1 1: 8 RSPCK	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SSLND register sets a period (SSL negation delay) from the transmission of a final RSPCK edge to the negation of the SSLAi signal during a serial transfer by the RSPI in master mode. Do not change the SSLND register while both the SPCR.MSTR and SPCR.SPE bits are 1.

SLNDL[2:0] Bits (SSL Negation Delay Setting)

The SLNDL[2:0] bits set an SSL negation delay value when the SPCMDm.SLNDEN bit is 1.
When using the RSPI in slave mode, set the SLNDL[2:0] bits to 000b.

37.2.12 RSPI Next-Access Delay Register (SPND)

Address(es): RSPI0.SPND 000D 010Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SPNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SPNDL[2:0]	RSPI Next-Access Delay Setting	b2 b0 0 0 0: 1 RSPCK + 2 PCLK 0 0 1: 2 RSPCK + 2 PCLK 0 1 0: 3 RSPCK + 2 PCLK 0 1 1: 4 RSPCK + 2 PCLK 1 0 0: 5 RSPCK + 2 PCLK 1 0 1: 6 RSPCK + 2 PCLK 1 1 0: 7 RSPCK + 2 PCLK 1 1 1: 8 RSPCK + 2 PCLK	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SPND sets a non-active period (next-access delay) of the SSLAi signal after termination of a serial transfer when the SPCMDm.SPNDEN bit is 1. Do not change the SPND register while both the SPCR.MSTR and SPCR.SPE bits are 1.

SPNDL[2:0] Bits (RSPI Next-Access Delay Setting)

The SPNDL[2:0] bits set a next-access delay when the SPCMDm.SPNDEN bit is 1.
When using the RSPI in slave mode, set the SPNDL[2:0] bits to 000b.

37.2.13 RSPI Control Register 2 (SPCR2)

Address(es): RSPI0.SPCR2 000D 010Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	SCKASE	PTE	SPIIE	SPOE	SPPE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SPPE	Parity Enable*1	0: Does not add the parity bit to transmit data and does not check the parity bit of receive data 1: Adds the parity bit to transmit data and checks the parity bit of receive data	R/W
b1	SPOE	Parity Mode*1	0: Selects even parity for use in transmission and reception 1: Selects odd parity for use in transmission and reception	R/W
b2	SPIIE	Idle Interrupt Enable	0: Disables the generation of idle interrupt requests 1: Enables the generation of idle interrupt requests	R/W
b3	PTE	Parity Self-Diagnosis	0: Disables the self-diagnosis function of the parity circuit 1: Enables the self-diagnosis function of the parity circuit	R/W
b4	SCKASE	RSPCK Auto-Stop Function Enable*1	0: Disables the RSPCK auto-stop function 1: Enables the RSPCK auto-stop function	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Do not change the SPPE, SPOE, and SCKASE bits while the SPCR.SPE bit is 1.

SPPE Bit (Parity Enable)

The SPPE bit enables or disables the parity function.

SPOE Bit (Parity Mode)

The SPOE bit specifies odd or even parity.

When even parity is set, parity bit addition is performed so that the total number of 1-bits in the transmit/receive character plus the parity bit is even. Similarly, when odd parity is set, parity bit addition is performed so that the total number of 1-bits in the transmit/receive character plus the parity bit is odd.

The SPOE bit is valid only when the SPPE bit is 1.

SPIIE Bit (Idle Interrupt Enable)

The SPIIE bit enables or disables the generation of idle interrupt requests when the RSPI being in the idle state is detected and the SPSR.IDLNF flag is set to 0.

PTE Bit (Parity Self-Diagnosis)

The PTE bit enables the self-diagnosis function of the parity circuit in order to check whether the parity function is operating correctly.

SCKASE Bit (RSPCK Auto-Stop Function Enable)

The SCKASE bit enables or disables the RSPCK auto-stop function. When this function is enabled, the RSPCK clock is stopped before an overrun error occurs when data is received in master mode. For details, refer to section 37.3.10.1, Overrun Error.

37.2.14 RSPI Command Register m (SPCMDm) (m = 0 to 7)

Address(es): RSPI0.SPCMD0 000D 0110h, RSPI0.SPCMD1 000D 0112h, RSPI0.SPCMD2 000D 0114h, RSPI0.SPCMD3 000D 0116h, RSPI0.SPCMD4 000D 0118h, RSPI0.SPCMD5 000D 011Ah, RSPI0.SPCMD6 000D 011Ch, RSPI0.SPCMD7 000D 011Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b12	LSBF	RSPI LSB First	0: MSB first 1: LSB first	R/W
b13	SPNDEN	RSPI Next-Access Delay Enable	0: A next-access delay of 1 RSPCK + 2 PCLK 1: A next-access delay is equal to the setting of the RSPI next-access delay register (SPND)	R/W
b14	SLNDEN	SSL Negation Delay Setting Enable	0: An SSL negation delay of 1 RSPCK 1: An SSL negation delay is equal to the setting of the RSPI slave select negation delay register (SSLND)	R/W
b15	SCKDEN	RSPCK Delay Setting Enable	0: An RSPCK delay of 1 RSPCK 1: An RSPCK delay is equal to the setting of the RSPI clock delay register (SPCKD)	R/W

x: Don’t care

The SPCMDm register is used to set a transfer format for the RSPI in master mode. Each channel has eight RSPI command registers (SPCMD0 to SPCMD7). Some of the bits in the SPCMD0 register is used to set a transfer mode for the RSPI in slave mode. The RSPI in master mode sequentially references the SPCMDm register according to the settings in the SPSCR.SPSLN[2:0] bits, and executes the serial transfer that is set in the referenced SPCMDm register. SPCMDm register should be set while the transmit buffer is empty (data for the next transfer is not set) and before setting of the data that is to be transmitted when that SPCMDm register is referenced.
An SPCMDm register that is referenced by the RSPI in master mode can be checked by means of the SPSSR.SPCP[2:0] bits. Do not change the SPCMDm register while the SPCR.MSTR bit is 0 and the SPCR.SPE bit is 1.

CPHA Bit (RSPCK Phase Setting)

The CPHA bit sets an RSPCK phase of the RSPI in master mode or slave mode. Data communications between RSPI modules require the same RSPCK phase setting between the modules.

CPOL Bit (RSPCK Polarity Setting)

The CPOL bit sets an RSPCK polarity of the RSPI in master mode or slave mode. Data communications between RSPI modules require the same RSPCK polarity setting between the modules.

BRDV[1:0] Bits (Bit Rate Division Setting)

The BRDV[1:0] bits are used to determine the bit rate. A bit rate is determined by combinations of the settings in the BRDV[1:0] bits and the SPBR register (refer to section 37.2.8, RSPI Bit Rate Register (SPBR)). The settings in the SPBR register determine the base bit rate. The settings in the BRDV[1:0] bits are used to select a bit rate which is obtained by dividing the base bit rate by 1, 2, 4, or 8. In the SPCMDm register, different BRDV[1:0] bit settings can be specified. This enables execution of serial transfers at a different bit rate for each command.

SSLA[2:0] Bits (SSL Signal Assertion Setting)

The SSLA[2:0] bits control the SSLAi signal assertion when the RSPI performs serial transfers in master mode.
Setting the SSLA[2:0] bits controls the assertion for the SSLAi signal. When an SSLAi signal is asserted, its polarity is determined by the set value in the corresponding SSLP. When the SSLA[2:0] bits are set to 000b in multi-master mode, serial transfers are performed with all the SSL signals in the negated state (as the SSLA0 pin acts as input).
When using the RSPI in slave mode, set the SSLA[2:0] bits to 000b.

SSLKP Bit (SSL Signal Level Keeping)

When the RSPI in master mode performs a serial transfer, the SSLKP bit specifies whether the SSLAi signal level for the current command is to be kept or negated between the SSL negation timing associated with the current command and the SSL assertion timing associated with the next command.
Setting the SSLKP bit to 1 enables a burst transfer. For details, refer to section 37.3.12.1, Master Mode Operation (4) Burst Transfer.
When using the RSPI in slave mode, the SSLKP bit should be set to 0.

SPB[3:0] Bits (RSPI Data Length Setting)

The SPB[3:0] bits set a transfer data length for the RSPI in master mode or slave mode. When the SPDCR.SPBYT is 1, set the SPB[3:0] bits to 0100b (8 bits). When the SPBYT bit is 0 and the SPDCR.SPLW bit is 0, set the SPB[3:0] bits to 0100b (8 bits) to 1111b (16 bits).

LSBF Bit (RSPI LSB First)

The LSBF bit sets the data format of the RSPI in master mode or slave mode to MSB first or LSB first.

SPNDEN Bit (RSPI Next-Access Delay Enable)

The SPNDEN bit sets the period from the time the RSPI in master mode terminates a serial transfer and sets the SSLAi signal inactive until the RSPI enables the SSLAi signal assertion for the next access (next-access delay). If the SPNDEN bit is 0, the RSPI sets the next-access delay to 1 RSPCK + 2 PCLK. If the SPNDEN bit is 1, the RSPI inserts a next-access delay in compliance with the SPND setting.

When using the RSPI in slave mode, the SPNDEN bit should be set to 0.

SLNDEN Bit (SSL Negation Delay Setting Enable)

The SLNDEN bit sets the period from the time the RSPI in master mode stops RSPCK oscillation until the RSPI sets the SSLAi signal inactive (SSL negation delay). If the SLNDEN bit is 0, the RSPI sets the SSL negation delay to 1 RSPCK. If the SLNDEN bit is 1, the RSPI negates the SSL signal at an SSL negation delay in compliance with the SSLND setting.

When using the RSPI in slave mode, the SLNDEN bit should be set to 0.

SCKDEN Bit (RSPCK Delay Setting Enable)

The SCKDEN bit sets the period from the point when the RSPI in master mode activates the SSLAi signal until the RSPCK starts oscillation (RSPI clock delay). If the SCKDEN bit is 0, the RSPI sets the RSPCK delay to 1 RSPCK. If the SCKDEN bit is 1, the RSPI starts the oscillation of RSPCK at an RSPCK delay in compliance with the SPCKD setting.

When using the RSPI in slave mode, the SCKDEN bit should be set to 0.

37.2.15 RSPI Data Control Register 2 (SPDCR2)

Address(es): RSPI0.SPDCR2 000D 0120h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	DINV	BYSW
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BYSW	Byte Swap	0: Byte swapping of SPDR data disabled 1: Byte swapping of SPDR data enabled	R/W
b1	DINV	Transfer Data Invert	0: Data bits in the transmit buffer are transferred to the shift register as they are. Data bits in the shift register are transferred to the receive buffer as they are. 1: Data bits in the transmit buffer are transferred to the shift register with inverting. Data bits in the shift register are transferred to the receive buffer with inverting.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to enable or disable byte swapping and logic inverting of transmit and receive data.
The SPCR.SPE bit should be 0 when rewriting this register.

BYSW Bit (Byte Swap)

On transmit, this bit specifies that data bytes written in the SPDR register will be swapped before being transmitted. On receive, this bit specifies that received bytes will be swapped before the data is transferred to the SPDR register. This bit setting is enabled when the SPDCR.SPBYT bit is 0.
When using byte swap, set the SPCMD.SPB[3:0] bits to 1111b (16 bits), 0010b (32 bits), or 0011b (32 bits). Also, set the SPCR2.SPPE bit to 0 (parity bit not added). For details, refer to sections 37.3.4.3 Byte Swap Transmission and 37.3.4.4 Byte Swap Reception.

DINV Bit (Transfer Data Invert)

This bit is used to invert the logic levels of the data bits when the data is transferred from the transmit buffer to the shift register and from the shift register to the receive buffer.
The parity bit is added for the data in the transmit shift register and the parity is checked for the data in the receive shift register.

37.2.16 RSPI Control Register 3 (SPCR3)

Address(es): RSPI0.SPCR3 000D 0121h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	SPCIE	—	—	SCKDDIS	RXMD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RXMD	Receive Operating Mode Setting	0: Full-duplex or transmit-only simplex communications (enables the transmitter) 1: Receive-only simplex communications (disables the transmitter)	R/W
b1	SCKDDIS	RSPCK Delay Between Data Byte Disable	0: Inserts delays between data bytes during burst transfer 1: Does not insert delays between data bytes during burst transfer	R/W
b3 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b4	SPCIE	Communication End Interrupt Enable	0: Disables the generation of communication end interrupt requests 1: Enables the generation of communication end interrupt requests	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Do not change the RXMD and SCKDDIS bits while the SPCR.SPE bit is 1.

This register is used to set the operating mode of the RSPI.

RXMD Bit (Receive Operating Mode Setting)

This bit is used to stop the transmitter and operate only the receiver. This bit is valid only in slave mode.
When this bit is 1, the setting of the SPCR.TXMD bit is ignored.

SCKDDIS Bit (RSPCK Delay Between Data Byte Disable)

This bit is used to select whether the RSPCK delay between data bytes is to be inserted or not during burst transfer. This bit is valid only when the SPCR.MSTR bit is 1 (master mode) and the SPCMDm.SSLKP bit is 1. Set this bit to 0 in slave mode.

SPCIE Bit (Communication End Interrupt Enable)

This bit is used to enable or disable the generation of the communication end interrupt request.

37.3 Operation

In this section, the serial transfer period means a period from the beginning of driving valid data to the fetching of the final valid data.

37.3.1 Overview of RSPI Operations

The RSPI is capable of synchronous serial transfers in slave mode (SPI operation), single-master mode (SPI operation), multi-master mode (SPI operation), slave mode (clock synchronous operation), and master mode (clock synchronous operation). A particular mode of the RSPI can be selected by using the MSTR, MODFEN, and SPMS bits in SPCR. Table 37.5 lists the relationship between RSPI modes and SPCR settings, and a description of each mode.

Table 37.5 Relationship between RSPI Modes and SPCR Settings and Description of Each Mode

	SPI Operation			Clock Synchronous Operation	
Mode	**Slave**	**Single-Master**	**Multi-Master**	**Slave**	**Master**
MSTR bit setting	0	1	1	0	1
MODFEN bit setting	0 or 1	0	1	0	0
SPMS bit setting	0	0	0	1	1
RSPCKA signal	Input	Output	Output/Hi-Z*1	Input	Output
MOSIA signal	Input	Output	Output/Hi-Z*1	Input	Output
MISOA signal	Output/Hi-Z*2	Input	Input	Output	Input
SSLA0 signal	Input	Output	Input	Hi-Z*3	Hi-Z*3
SSLA1 to SSLA3 signals	Hi-Z*3	Output	Output/Hi-Z*1	Hi-Z*3	Hi-Z*3
SSL polarity change function	Supported	Supported	Supported	—	—
Transfer rate	Up to PCLK/4	Up to PCLK/2	Up to PCLK/2	Up to PCLK/4	Up to PCLK/2
Clock source	RSPCK input	On-chip baud rate generator	On-chip baud rate generator	RSPCK input	On-chip baud rate generator
Clock polarity	Two				
Clock phase	Two	Two	Two	One (CPHA = 1)	Two
First transfer bit	MSB/LSB				
Transfer data length	8 to 16, 20, 24, 32 bits				
Burst transfer	Possible (CPHA = 1)	Possible (CPHA = 0,1)	Possible (CPHA = 0,1)	—	—
RSPCK delay control	Not supported	Supported	Supported	Not supported	Supported
SSL negation delay control	Not supported	Supported	Supported	Not supported	Supported
Next-access delay control	Not supported	Supported	Supported	Not supported	Supported
Transfer activation method	SSL input active or RSPCK oscillation	Transmit buffer is written to when a transmit buffer empty interrupt request is generated or the SPTEF flag is 1	Transmit buffer is written to when a transmit buffer empty interrupt request is generated or the SPTEF flag is 1	RSPCK oscillation	Transmit buffer is written to when a transmit buffer empty interrupt request is generated or the SPTEF flag is 1
Sequence control	Not supported	Supported	Supported	Not supported	Supported
Transmit buffer empty detection	Supported*7	Supported	Supported	Supported*7	Supported
Receive buffer full detection	Supported*4				
Overrun error detection	Supported*4	Supported*4, *6	Supported*4, *6	Supported*4	Supported*4, *6
Underrun error detection	Supported*7	Not supported	Not supported	Supported*7	Not supported
Parity error detection	Supported*4, *5				
Mode fault error detection	Supported (MODFEN = 1)	Not supported	Supported	Not supported	Not supported

Note 1. When SSLA0 is asserted by another master device, the pin becomes Hi-Z.
Note 2. When SSLA0 is negated or the SPCR.SPE bit is 0, the pin becomes Hi-Z.
Note 3. This function is not supported in this mode.
Note 4. When the SPCR.TXMD bit is 1, the detections of receiver buffer full, overrun error, and parity error are not performed.
Note 5. When the SPCR2.SPPE bit is 0, the detection of parity error is not performed.

Note 6. When the SPCR2.SCKASE bit is 1, the detection of overrun error is not performed.
Note 7. When the SPCR3.RXMD bit is 1, the detections of transmit buffer empty and underrun error are not performed.

37.3.2 Controlling RSPI Pins

The RSPI in single-master mode (SPI operation) or multi-master mode (SPI operation) determines MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) according to MOIFE and MOIFV bit settings in SPPCR, as listed in Table 37.6.

Table 37.6 MOSI Signal Value Determination during SSL Negation Period

MOIFE Bit	MOIFV Bit	MOSIA Signal Value during SSL Negation Period
0	0, 1	Final data from previous transfer
1	0	Low
1	1	High

37.3.3 RSPI System Configuration Examples

37.3.3.1 Single Master/Single Slave (with This MCU Acting as Master)

Figure 37.5 shows a single-master/single-slave RSPI system configuration example when this MCU is used as a master. In the single-master/single-slave configuration, the SSLA0 to SSLA3 output of this MCU (master) are not used. The SSL input of the SPI slave is fixed to the low level, and the SPI slave is maintained in a select state.*1
This MCU (master) drives the RSPCKA and MOSIA. The SPI slave drives the MISO.

Note 1. In the transfer format corresponding to the case where the SPCMDm.CPHA bit is 0, there are slave devices for which the SSL signal cannot be fixed to the active level. In situations where the SSL signal cannot be fixed, the SSLAi output of this MCU should be connected to the SSL input of the slave device.

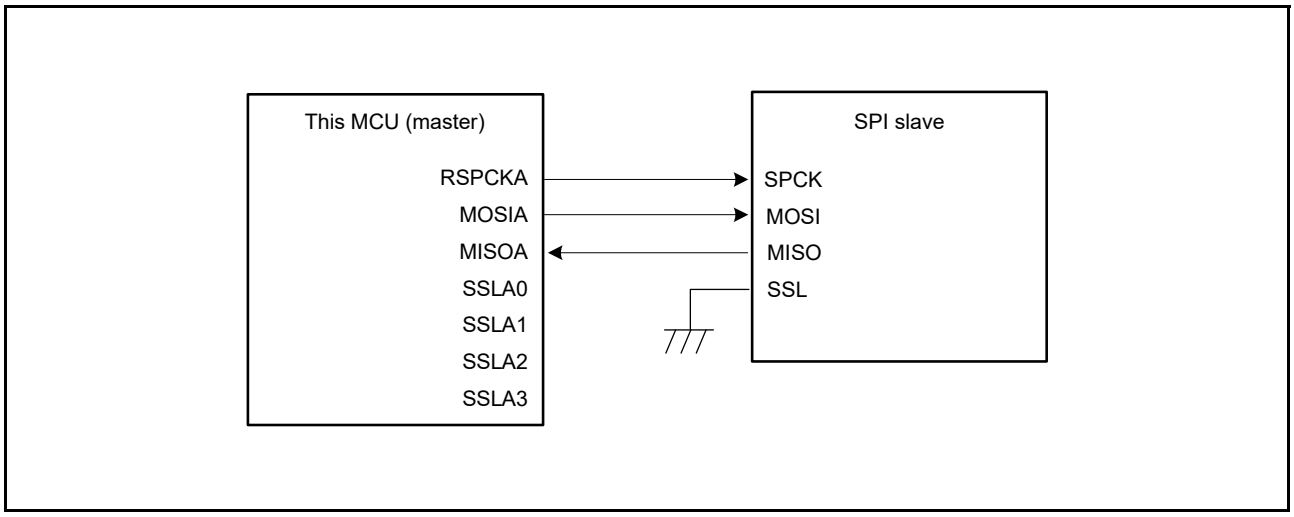

Figure 37.5 Single-Master/Single-Slave Configuration Example (This MCU = Master)

37.3.3.2 Single Master/Single Slave (with This MCU Acting as Slave)

Figure 37.6 shows a single-master/single-slave RSPI system configuration example when this MCU is used as a slave. When this MCU is to operate as a slave, the SSLA0 pin is used as SSL input. The SPI master drives the RSPCK and MOSI. This MCU (slave) drives the MISOA.*1

In the single-slave configuration in which the SPCMDm.CPHA bit is set to 1, the SSLA0 input of this MCU (slave) is fixed to the low level, this MCU (slave) is maintained in a select state, and in this manner it is possible to execute serial transfer (Figure 37.7). In this configuration, the communication end interrupt and the communication end event are not generated.

Note 1. When SSLA0 is at the non-active level, the pin state is Hi-Z.

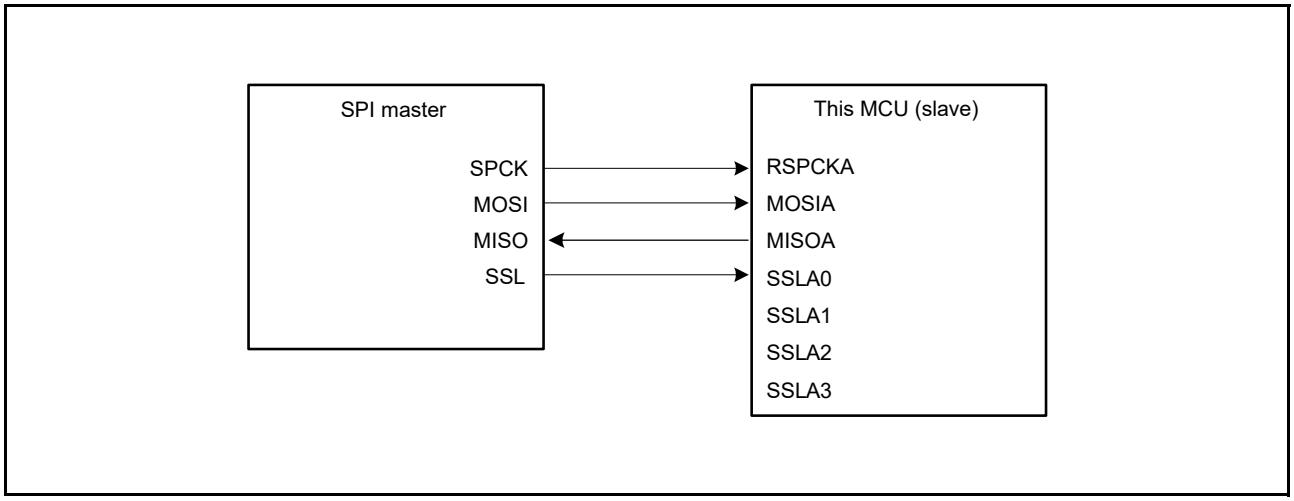

Figure 37.6 Single-Master/Single-Slave Configuration Example (This MCU = Slave, CPHA = 0)

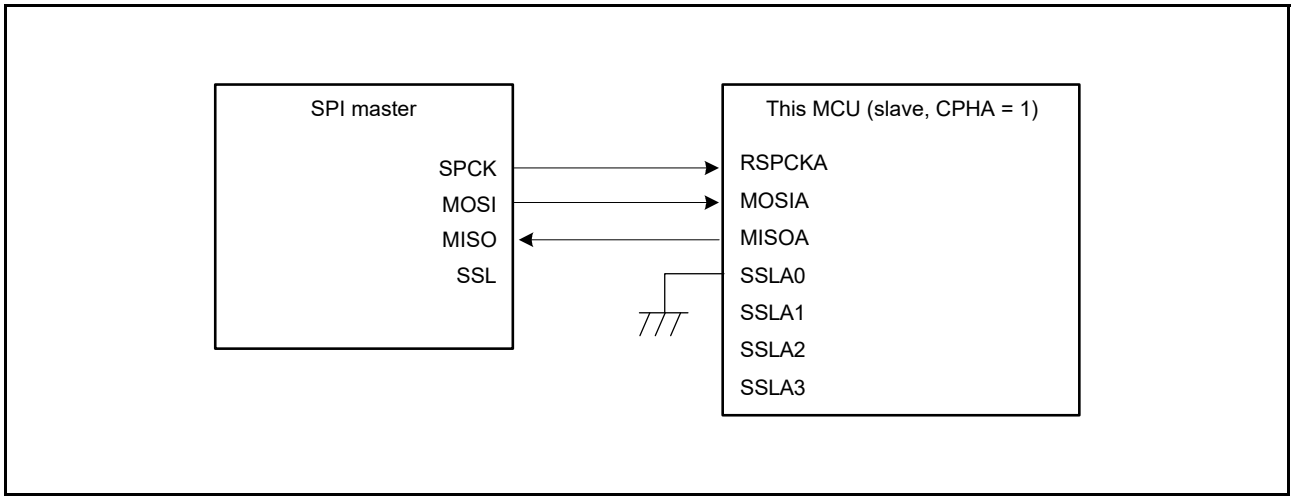

Figure 37.7 Single-Master/Single-Slave Configuration Example (This MCU = Slave, CPHA = 1)

37.3.3.3 Single Master/Multi-Slave (with This MCU Acting as Master)

Figure 37.8 shows a single-master/multi-slave RSPI system configuration example when this MCU is used as a master. In the example of Figure 37.8, the RSPI system is comprised of this MCU (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCKA and MOSIA outputs of this MCU (master) are connected to the RSPCK and MOSI inputs of SPI slave 0 to SPI slave 3. The MISO outputs of SPI slave 0 to SPI slave 3 are all connected to the MISOA input of this MCU (master). SSLA0 to SSLA3 outputs of this MCU (master) are connected to the SSL inputs of SPI slave 0 to SPI slave 3, respectively.

This MCU (master) drives RSPCKA, MOSIA, and SSLA0 to SSLA3. Of the SPI slave 0 to SPI slave 3, the slave that receives low-level input into the SSL input drives MISO.

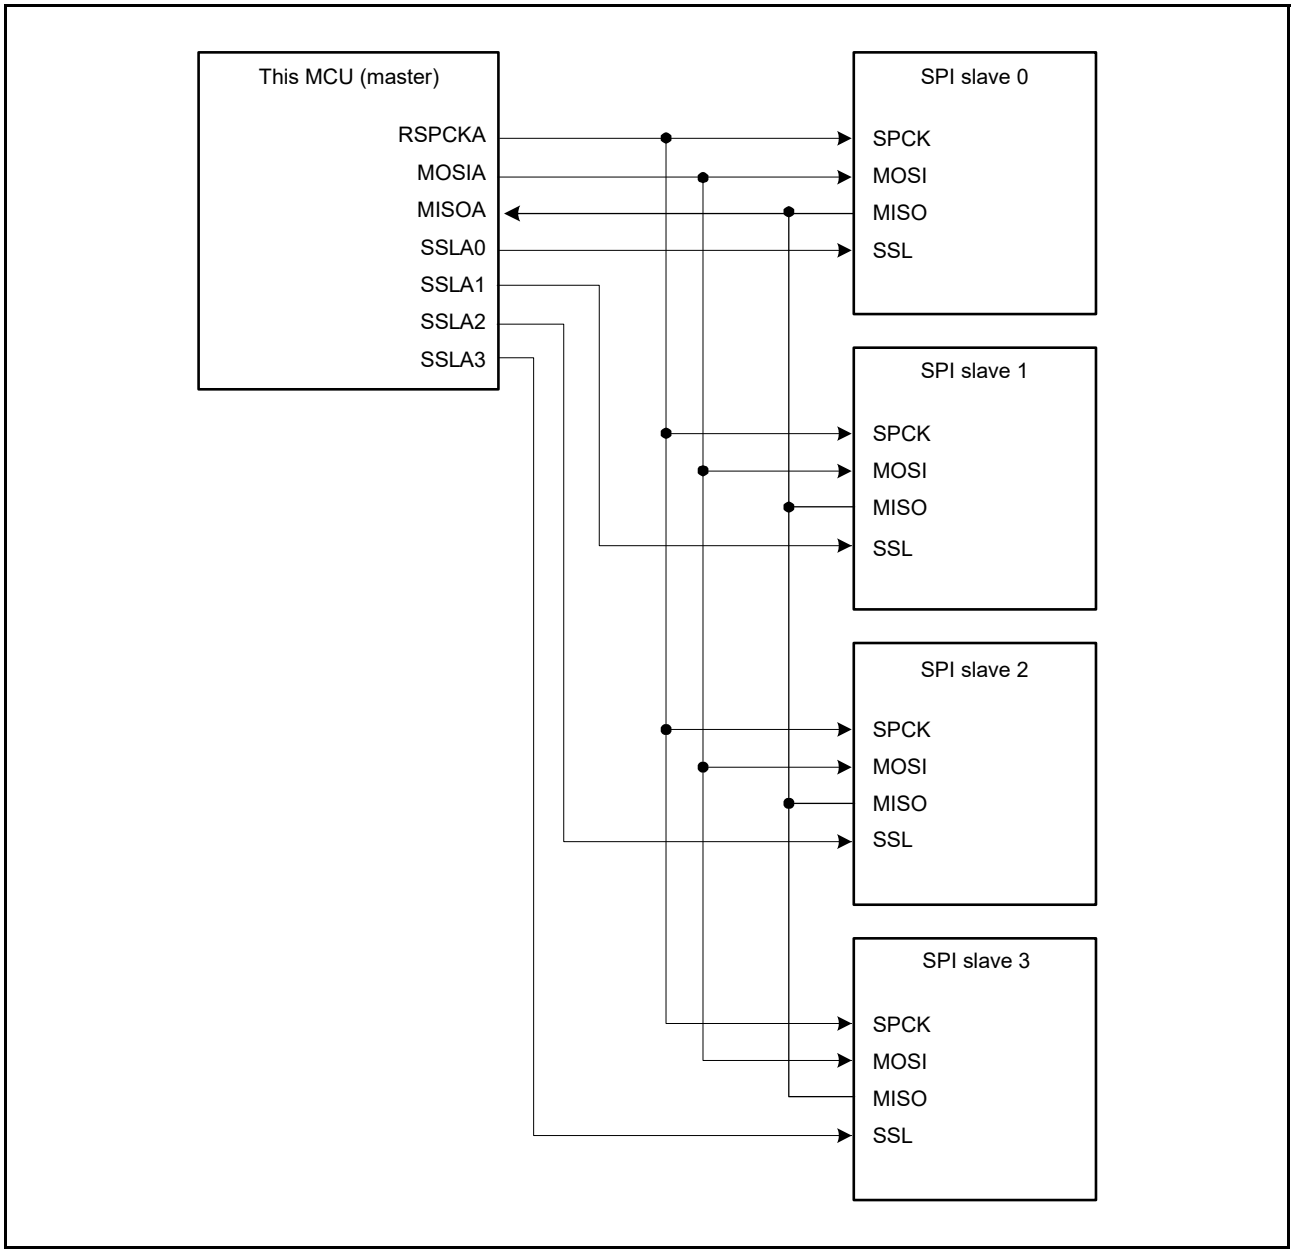

Figure 37.8 Single-Master/Multi-Slave Configuration Example (This MCU = Master)

37.3.3.4 Single Master/Multi-Slave (with This MCU Acting as Slave)

Figure 37.9 shows a single-master/multi-slave RSPI system configuration example when this MCU is used as a slave. In the example of Figure 37.9, the RSPI system is comprised of an SPI master and two MCUs (slave X and slave Y).
The SPCK and MOSI outputs of the SPI master are connected to the RSPCKA and MOSIA inputs of the MCUs (slave X and slave Y). The MISOA outputs of the MCUs (slave X and slave Y) are all connected to the MISO input of the SPI master. SSLX and SSLY outputs of the SPI master are connected to the SSLA0 inputs of the MCUs (slave X and slave Y), respectively.
The SPI master drives SPCK, MOSI, SSLX, and SSLY. Of the MCUs (slave X and slave Y), the slave that receives low-level input into the SSLA0 input drives MISOA.

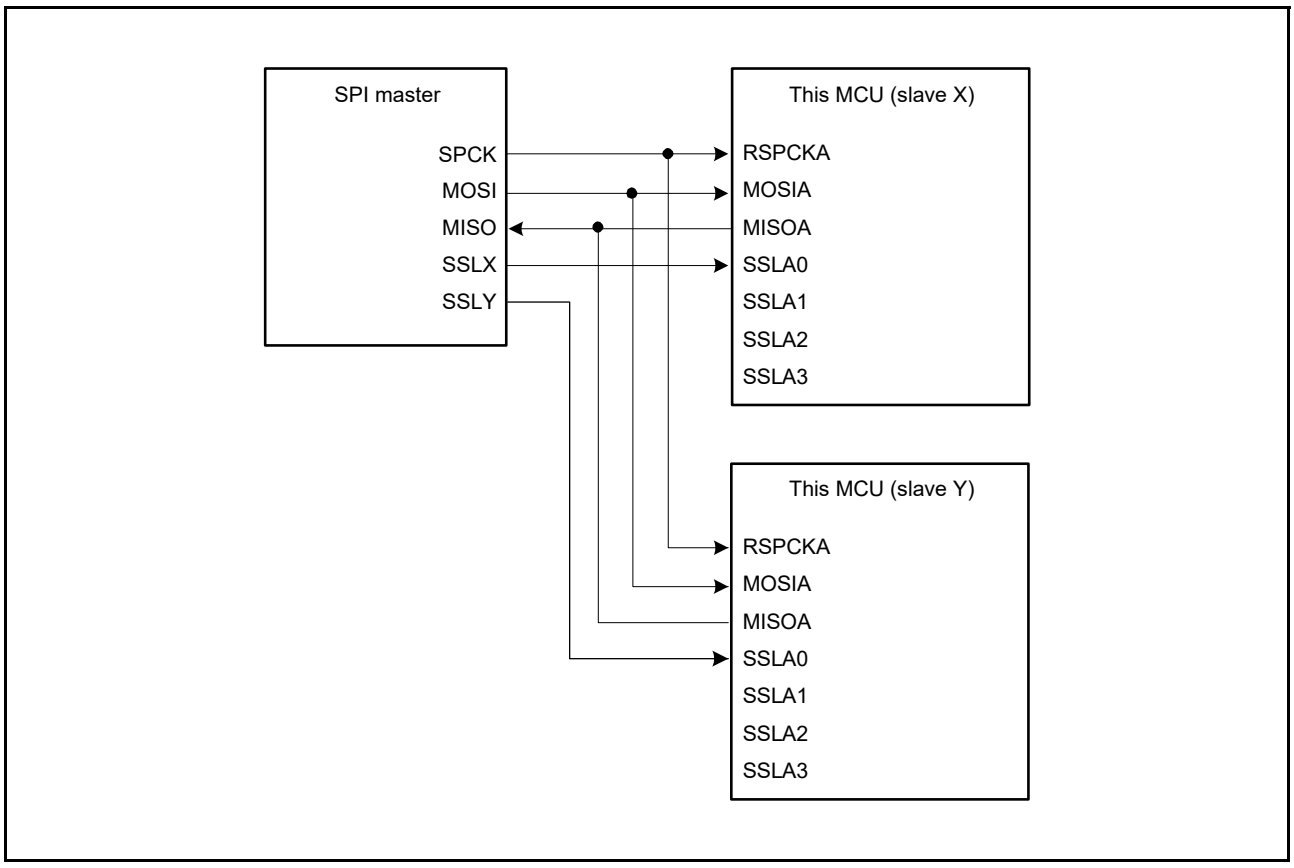

Figure 37.9 Single-Master/Multi-Slave Configuration Example (This MCU = Slave)

37.3.3.5 Multi-Master/Multi-Slave (with This MCU Acting as Master)

Figure 37.10 shows a multi-master/multi-slave RSPI system configuration example when this MCU is used as a master. In the example of Figure 37.10, the RSPI system is comprised of two MCUs (master X and master Y) and two SPI slaves (SPI slave 1 and SPI slave 2).

The RSPCKA and MOSIA outputs of the MCUs (master X and master Y) are connected to the RSPCK and MOSI inputs of SPI slaves 1 and 2. The MISO outputs of SPI slaves 1 and 2 are connected to the MISOA inputs of the MCUs (master X and master Y). Any generic port Y output from this MCU (master X) is connected to the SSLA0 input of this MCU (master Y). Any generic port X output of this MCU (master Y) is connected to the SSLA0 input of this MCU (master X). The SSLA1 and SSLA2 outputs of the MCUs (master X and master Y) are connected to the SSL inputs of the SPI slaves 1 and 2. In this configuration example, since the system can be comprised solely of SSLA0 input, and SSLA1 and SSLA2 outputs for slave connections, the SSLA3 output of this MCU is not required.

This MCU drives RSPCKA, MOSIA, SSLA1, and SSLA2 when the SSLA0 input level is high. When the SSLA0 input level is low, this MCU detects a mode fault error, sets RSPCKA, MOSIA, SSLA1, and SSLA2 to Hi-Z, and releases the RSPI bus right to the other master. Of the SPI slaves 1 and 2, the slave that receives low-level input into the SSL input drives MISO.

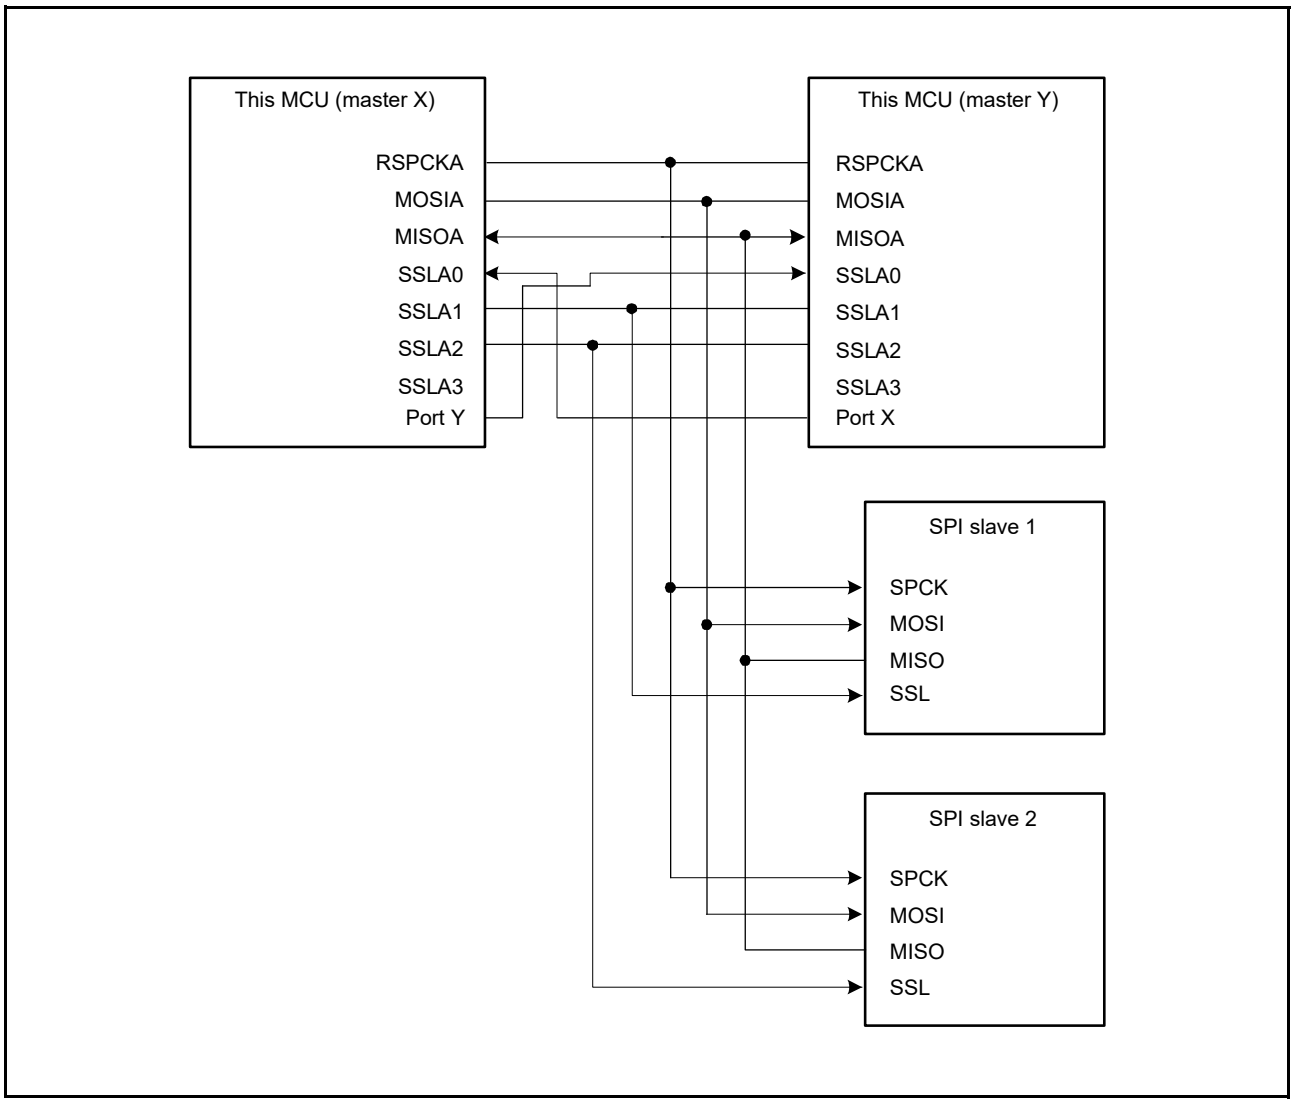

Figure 37.10 Multi-Master/Multi-Slave Configuration Example (This MCU = Master)

37.3.3.6 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (with This MCU Acting as Master)

Figure 37.11 shows a master (clock synchronous operation)/slave (clock synchronous operation) RSPI system configuration example when this MCU is used as a master. In the master (clock synchronous operation)/slave (clock synchronous operation) configuration, SSLA0 to SSLA3 of this MCU (master) are not used.
This MCU (master) drives the RSPCKA and MOSIA. The SPI slave drives the MISO.

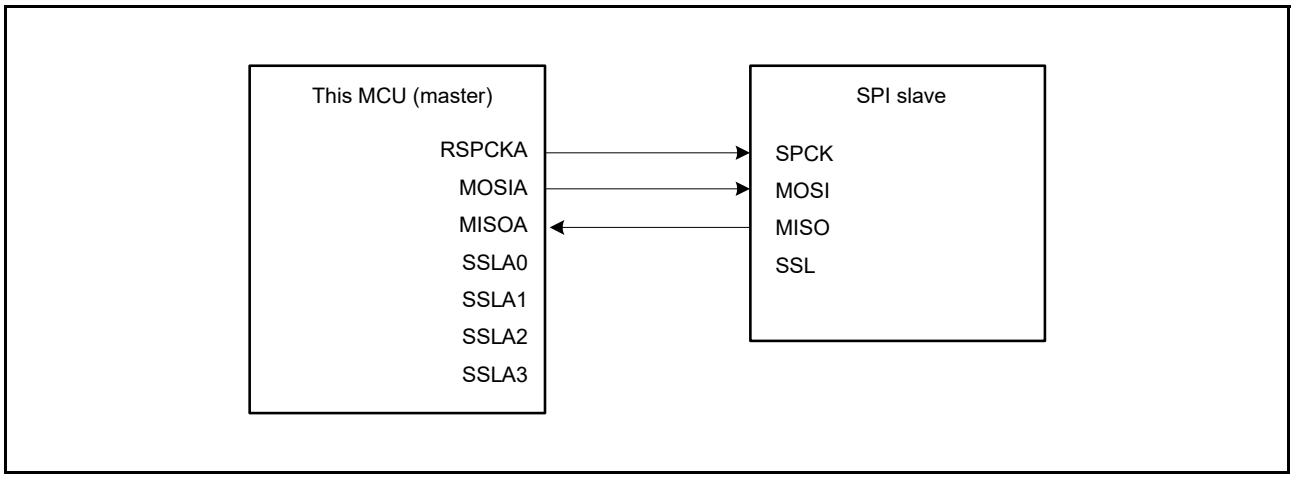

Figure 37.11 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This MCU = Master)

37.3.3.7 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (with This MCU Acting as Slave)

Figure 37.12 shows a master (clock synchronous operation)/slave (clock synchronous operation) RSPI system configuration example when this MCU is used as a slave. When this MCU is to operate as a slave (clock synchronous operation), this MCU (slave) drives the MISOA and the SPI master drives the SPCK and MOSI. In addition, SSLA0 to SSLA3 of this MCU (slave) are not used.
Only in the single-slave configuration in which the SPCMDm.CPHA bit is set to 1, this MCU (slave) can execute serial transfer.

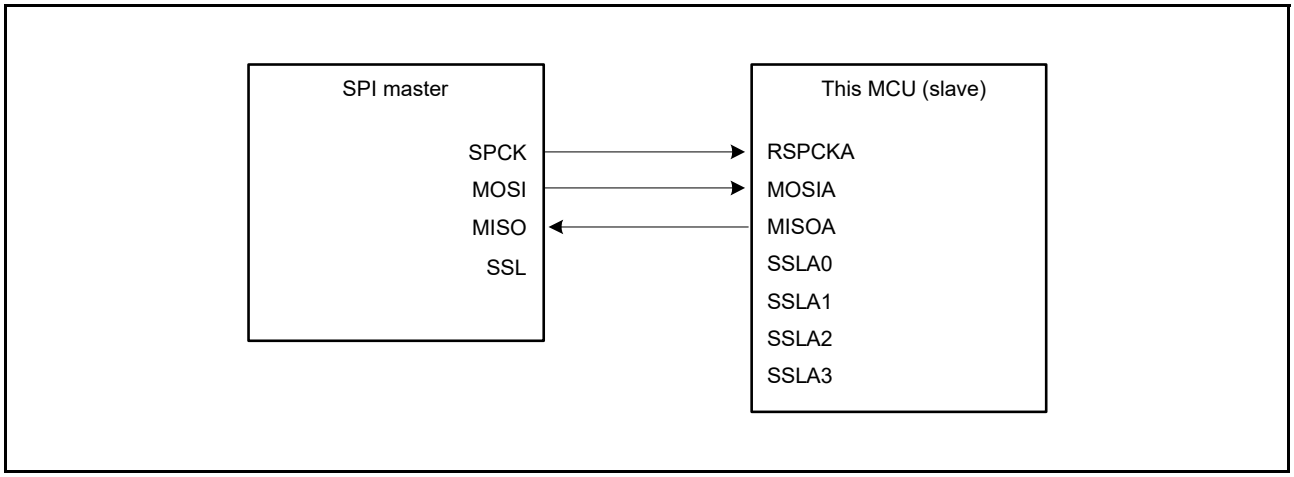

Figure 37.12 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This MCU = Slave, CPHA = 1)

37.3.4 Data Format

The RSPI's data format depends on the settings in RSPI command register m (SPCMDm) (m = 0 to 7) and the parity enable bit in RSPI control register 2 (SPCR2.SPPE) and RSPI data control register 2 (SPDCR2). Regardless of whether the MSB or LSB is first, the RSPI treats the range from the LSB bit in the RSPI data register (SPDR) to the selected data length as transfer data.
The format of one frame of data before or after transfer is shown below.

(a) With Parity Disabled

When parity is disabled, transmission or reception of data proceeds with the length in bits selected in the RSPI data length setting bits in RSPI command register m (SPCMDm.SPB[3:0]).

(b) With Parity Enabled

When parity is enabled, transmission or reception of data proceeds with the length in bits selected in the RSPI data length setting bits in RSPI command register m (SPCMDm.SPB[3:0]). In this case, however, the last bit is a parity bit.

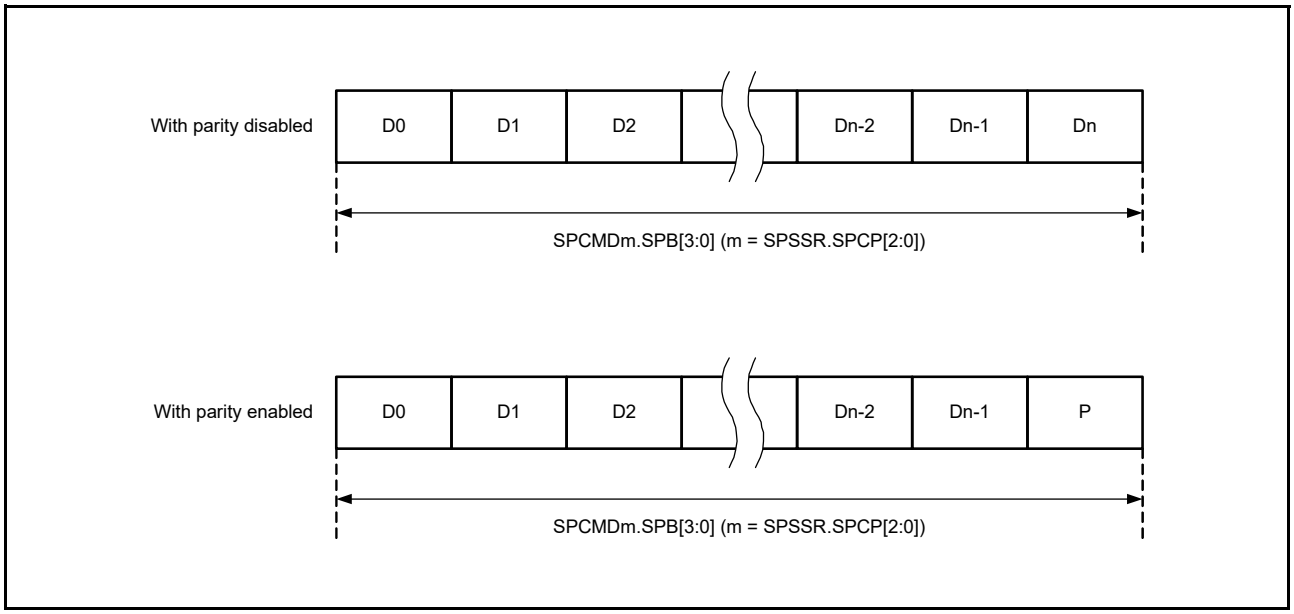

Figure 37.13 Outline of the Data Format (with Parity Disabled/Enabled)

37.3.4.1 When Parity is Disabled (SPCR2.SPPE = 0)

When parity is disabled, data for transmission are copied to the shift register with no prior processing. A description of the connection between the RSPI data register (SPDR) and the shift register in terms of the combination of MSB or LSB first and data length is given below.

(1) MSB First Transfer (32-Bit Data)

Figure 37.14 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, an RSPI data length of 32 bits, and MSB first selected.
In transmission, bits T31 to T00 from the current stage of the transmit buffer are copied to the shift register. Data for transmission are shifted out from the shift register in order from T31, through T30, and so on to T00.
In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R31 to R00 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer.

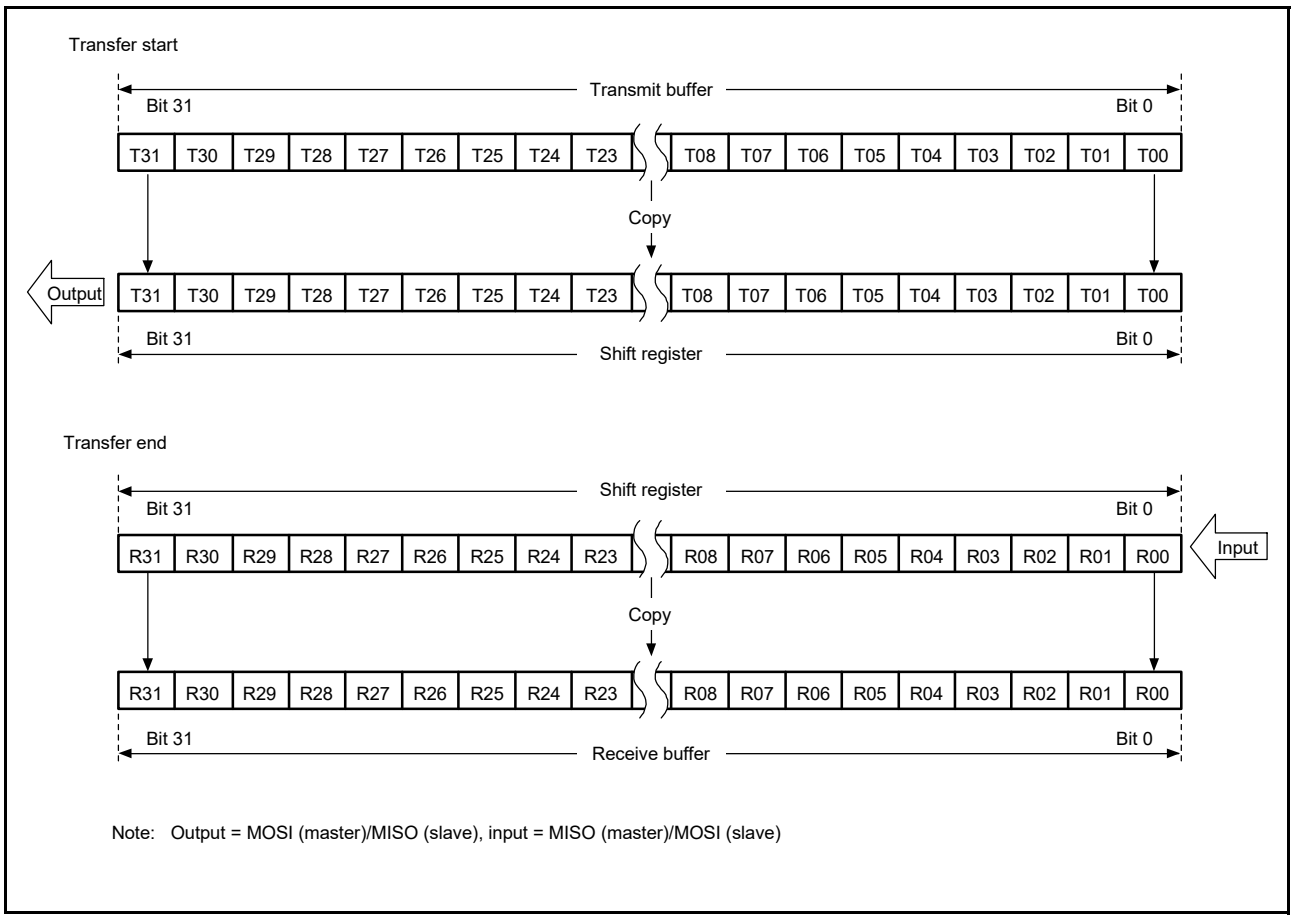

Figure 37.14 MSB First Transfer (32-Bit Data, Parity Disabled)

(2) MSB First Transfer (24-Bit Data)

Figure 37.15 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, 24 bits as the RSPI data length for an example that is not 32 bits, and MSB first selected.
In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are copied to the shift register. Data for transmission are shifted out from the shift register in order from T23, through T22, and so on to T00.
In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R23 to R00 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. At this time, if the SPCR3.RXMD bit is 0, the upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being set in the upper 8 bits of the receive buffer. If the SPCR3.RXMD bit is 1, 00h is stored in the upper 8 bits of the receive buffer.

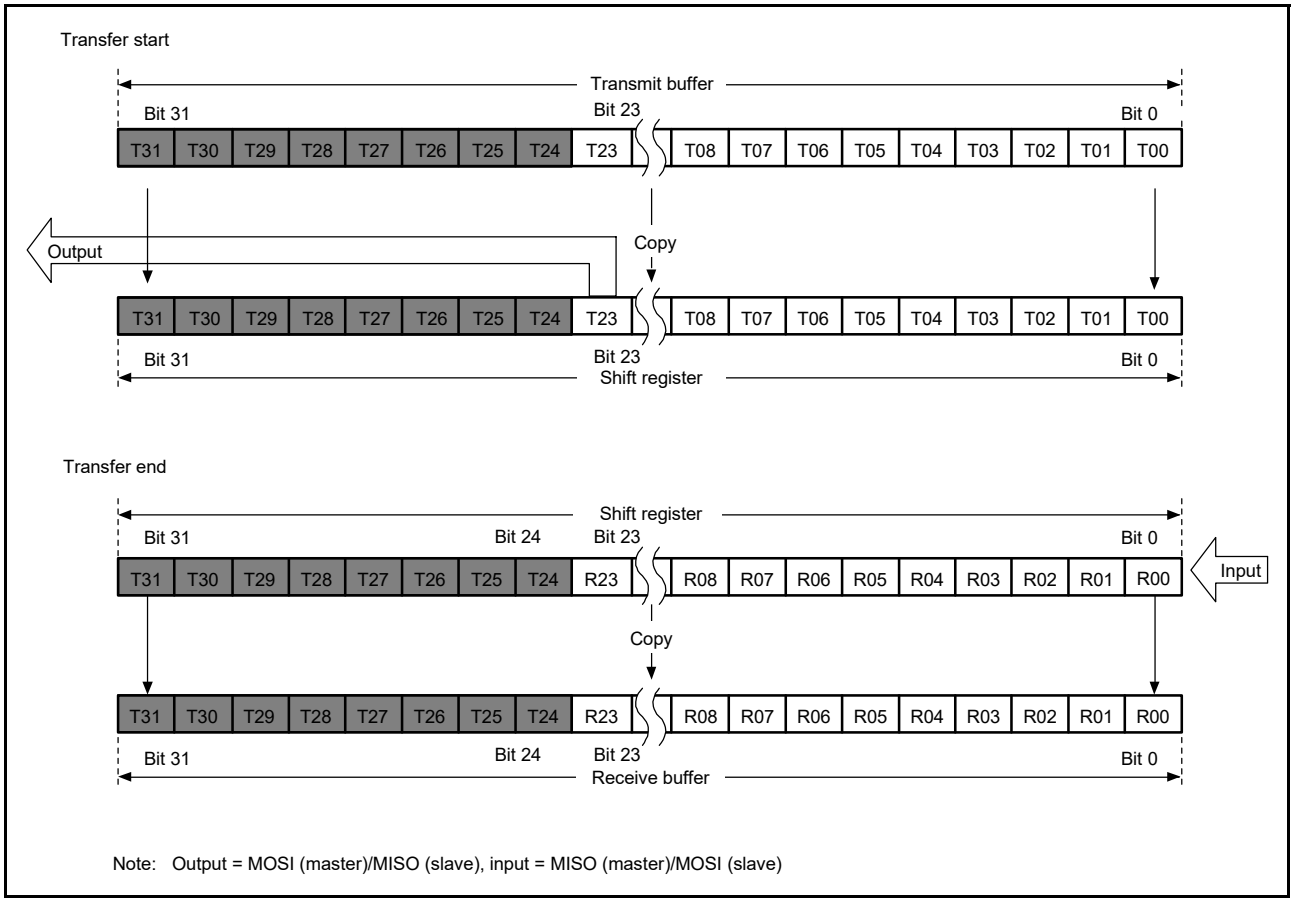

Figure 37.15 MSB First Transfer (24-Bit Data, Parity Disabled)

(3) LSB First Transfer (32-Bit Data)

Figure 37.16 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, an RSPI data length of 32 bits, and LSB first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are reordered bit by bit to obtain the order T00 to T31 for copying to the shift register. Data for transmission are shifted out from the shift register in order from T00, through T01, and so on to T31.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R00 to R31 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer.

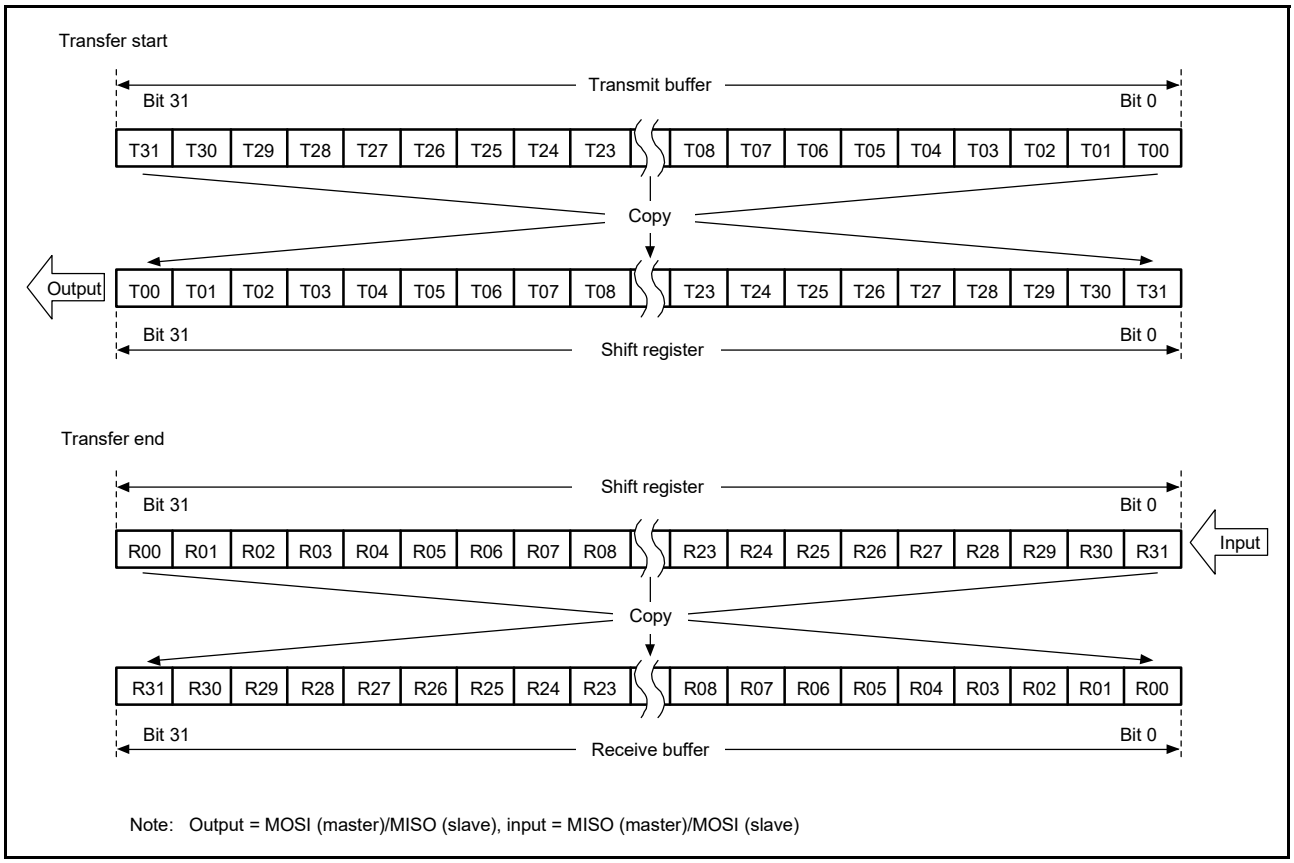

Figure 37.16 LSB First Transfer (32-Bit Data, Parity Disabled)

(4) LSB First Transfer (24-Bit Data)

Figure 37.17 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, 24 bits as the RSPI data length for an example that is not 32 bits, and LSB first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are reordered bit by bit to obtain the order T00 to T23 for copying to the shift register. Data for transmission are shifted out from the shift register in order from T00, through T01, and so on to T23.

In reception, received data are shifted in bit by bit through bit 8 of the shift register. When bits R00 to R23 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. At this time, if the SPCR3.RXMD bit is 0, the upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being set in the upper 8 bits of the receive buffer. If the SPCR3.RXMD bit is 1, 00h is stored in the upper 8 bits of the receive buffer.

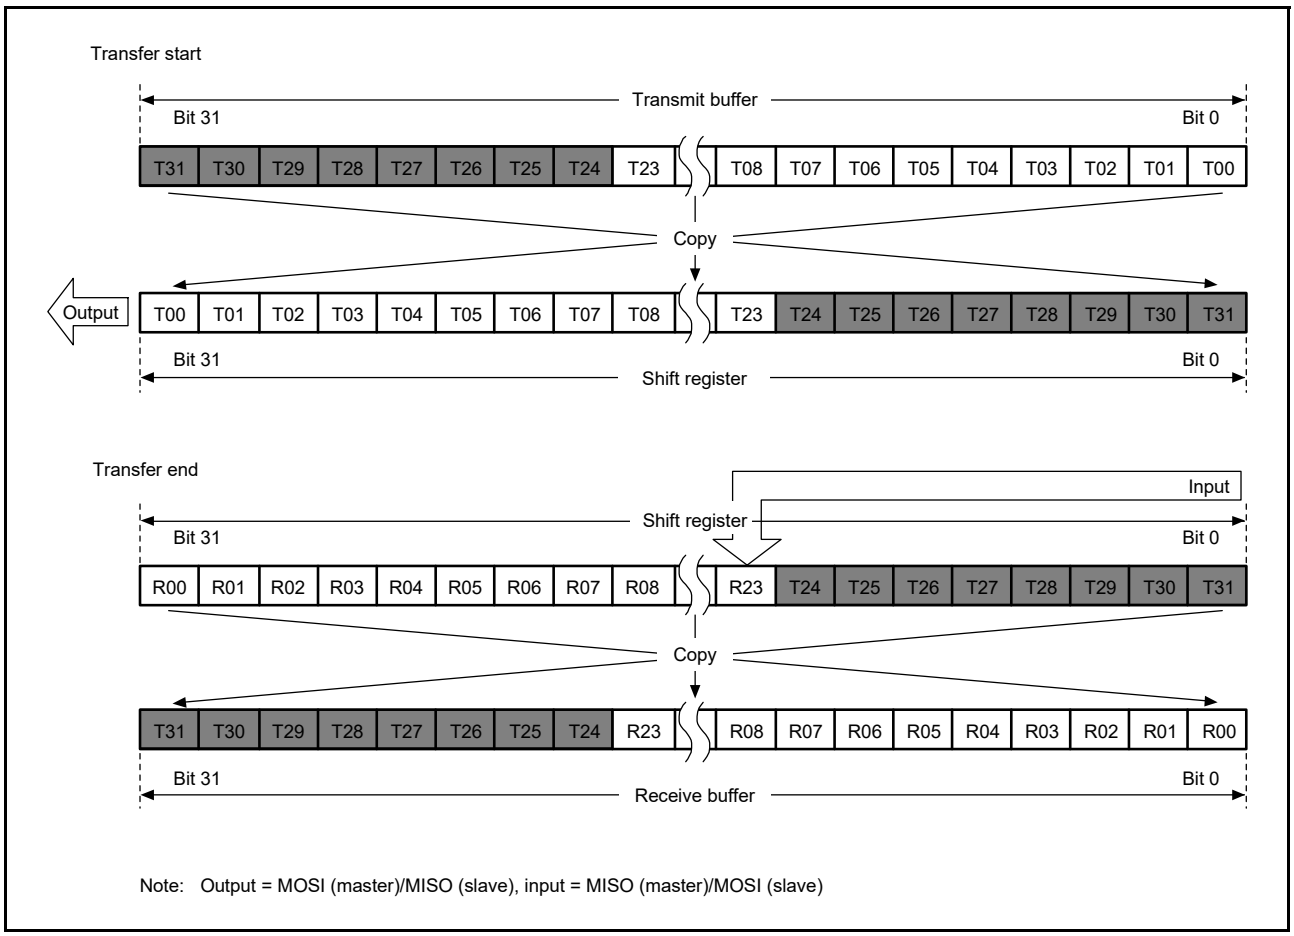

Figure 37.17 LSB First Transfer (24-Bit Data, Parity Disabled)

37.3.4.2 When Parity is Enabled (SPCR2.SPPE = 1)

When parity is enabled, the lowest-order bit of the data for transmission becomes a parity bit. Hardware calculates the value of the parity bit.

(1) MSB First Transfer (32-Bit Data)

Figure 37.18 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, an RSPI data length of 32 bits, and MSB first selected.
In transmission, the value of the parity bit (P) is calculated from bits T31 to T01. This replaces the final bit, T00, and the whole is copied to the shift register. Data are transmitted in the order T31, T30, …, T01, and P.
In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R31 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R31 to P are checked by judging the parity.

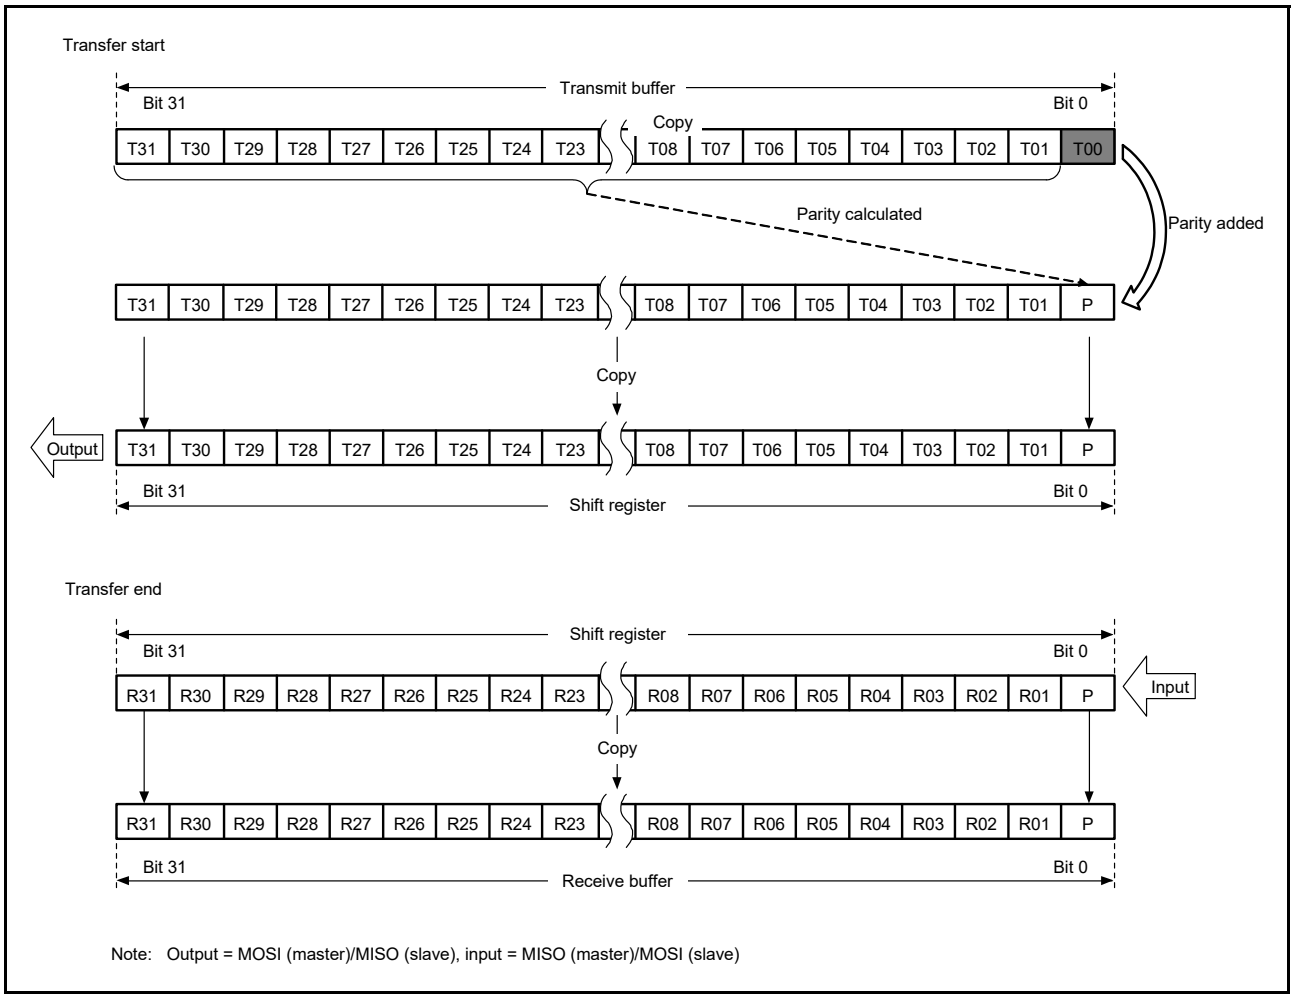

Figure 37.18 MSB First Transfer (32-Bit Data, Parity Enabled)

(2) MSB First Transfer (24-Bit Data)

Figure 37.19 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, 24 bits as the RSPI data length for an example that is not 32 bits, and MSB first selected.
In transmission, the value of the parity bit (P) is calculated from bits T23 to T01. This replaces the final bit, T00, and the whole is copied to the shift register. Data are transmitted in the order T23, T22, …, T01, and P.
In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R23 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R23 to P are checked by judging the parity. At this time, if the SPCR3.RXMD bit is 0, the upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being set in the upper 8 bits of the receive buffer. If the SPCR3.RXMD bit is 1, 00h is stored in the upper 8 bits of the receive buffer.

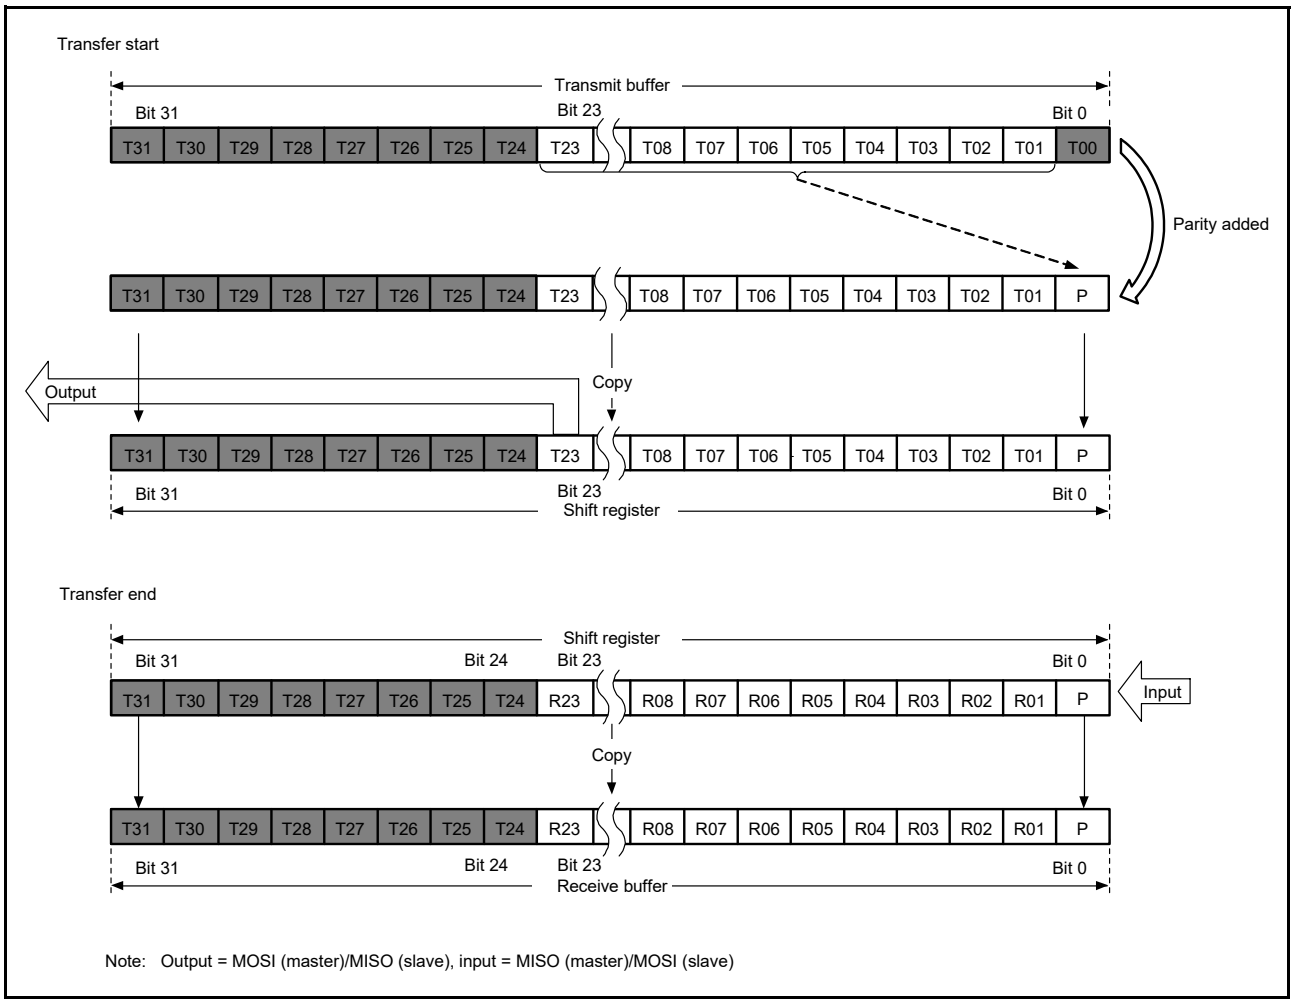

Figure 37.19 MSB First Transfer (24-Bit Data, Parity Enabled)

(3) LSB First Transfer (32-Bit Data)

Figure 37.20 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, an RSPI data length of 32 bits, and LSB first selected.

In transmission, the value of the parity bit (P) is calculated from bits T30 to T00. This replaces the final bit, T31, and the whole is copied to the shift register. Data are transmitted in the order T00, T01, …, T30, and P.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R00 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P are checked by judging the parity.

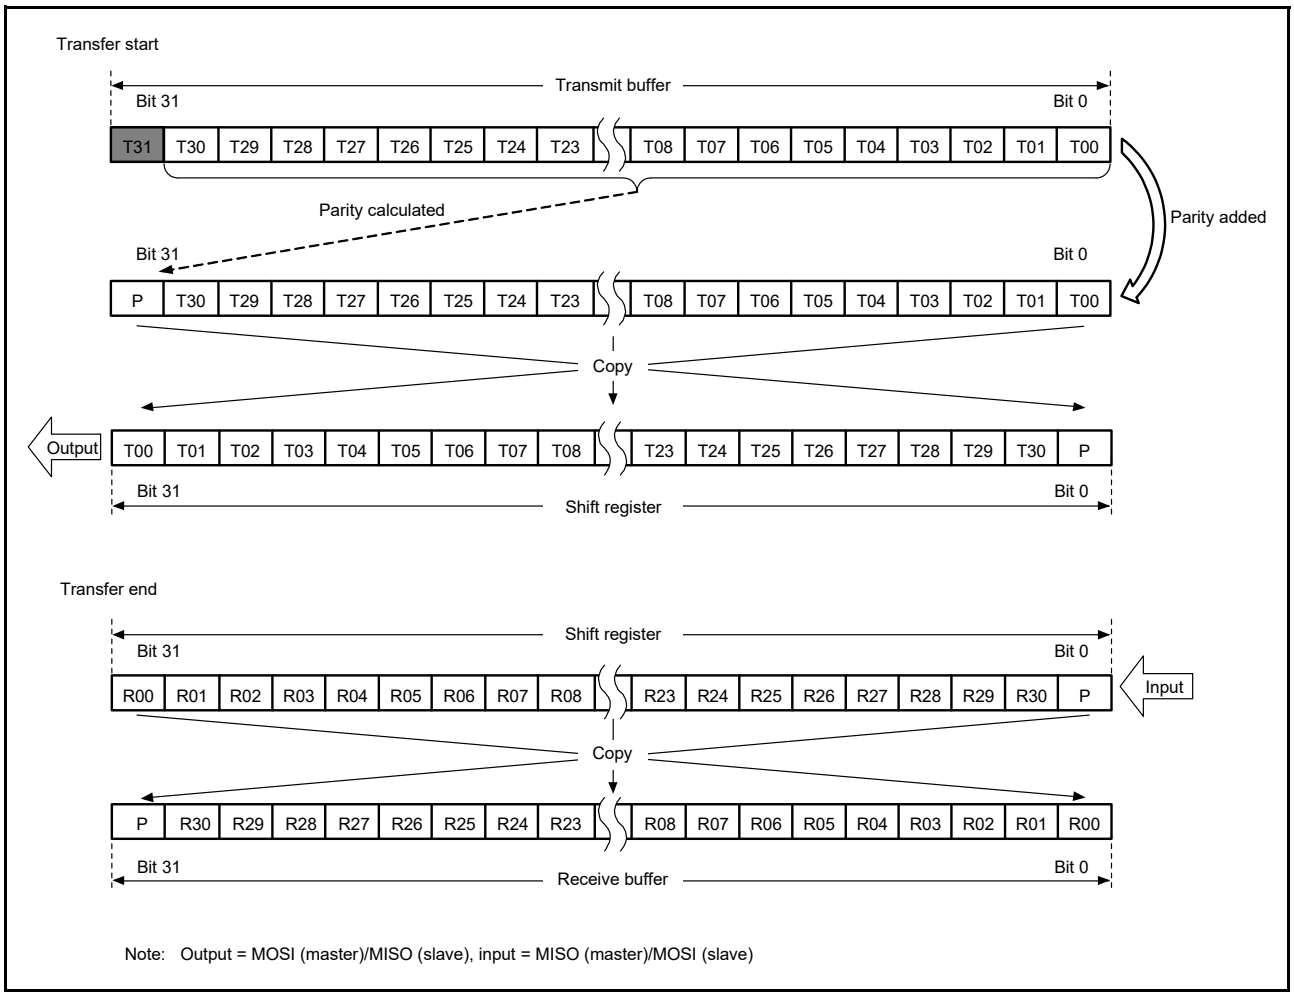

Figure 37.20 LSB First Transfer (32-Bit Data, Parity Enabled)

(4) LSB First Transfer (24-Bit Data)

Figure 37.21 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, 24 bits as the RSPI data length for an example that is not 32 bits, and LSB first selected.
In transmission, the value of the parity bit (P) is calculated from bits T22 to T00. This replaces the final bit, T23, and the whole is copied to the shift register. Data are transmitted in the order T00, T01, …, T22, and P.
In reception, received data are shifted in bit by bit through bit 8 of the shift register. When bits R00 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P are checked by judging the parity. At this time, if the SPCR3.RXMD bit is 0, the upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being set in the upper 8 bits of the receive buffer. If the SPCR3.RXMD bit is 1, 00h is stored in the upper 8 bits of the receive buffer.

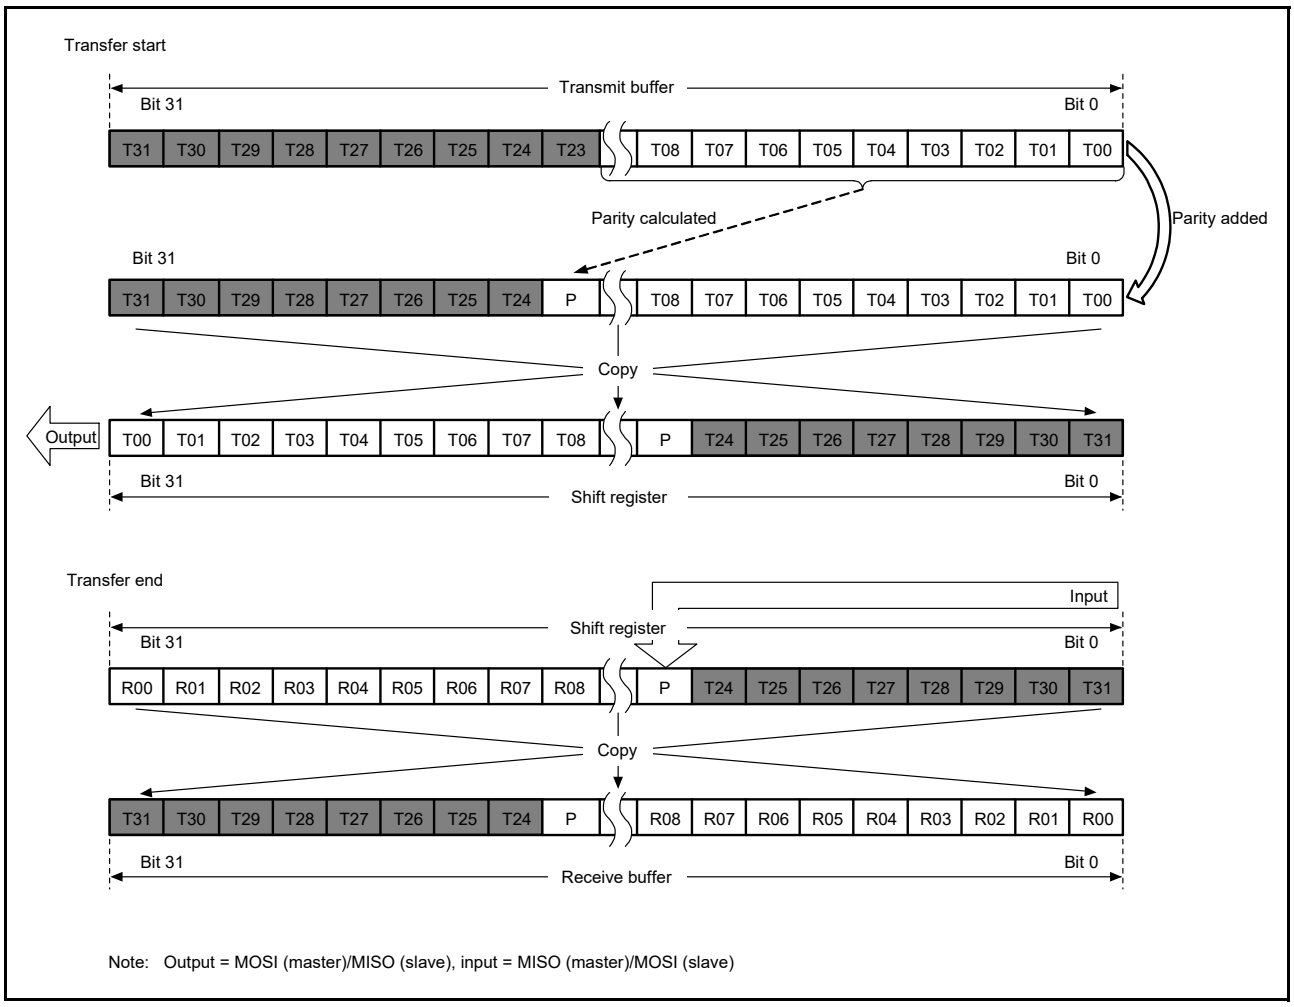

Figure 37.21 LSB First Transfer (24-Bit Data, Parity Enabled)

37.3.4.3 Byte Swap Transmission

When the SPDCR2.BYSW bit is 1 (byte swapping of SPDR data enabled), data bytes written in the transmit buffer (SPDR) will be swapped (in 8 bit units) when the data is transferred to the shift register. Figure 37.22 shows data transfer between the SPDR register and the shift register when data length is 32 bits.

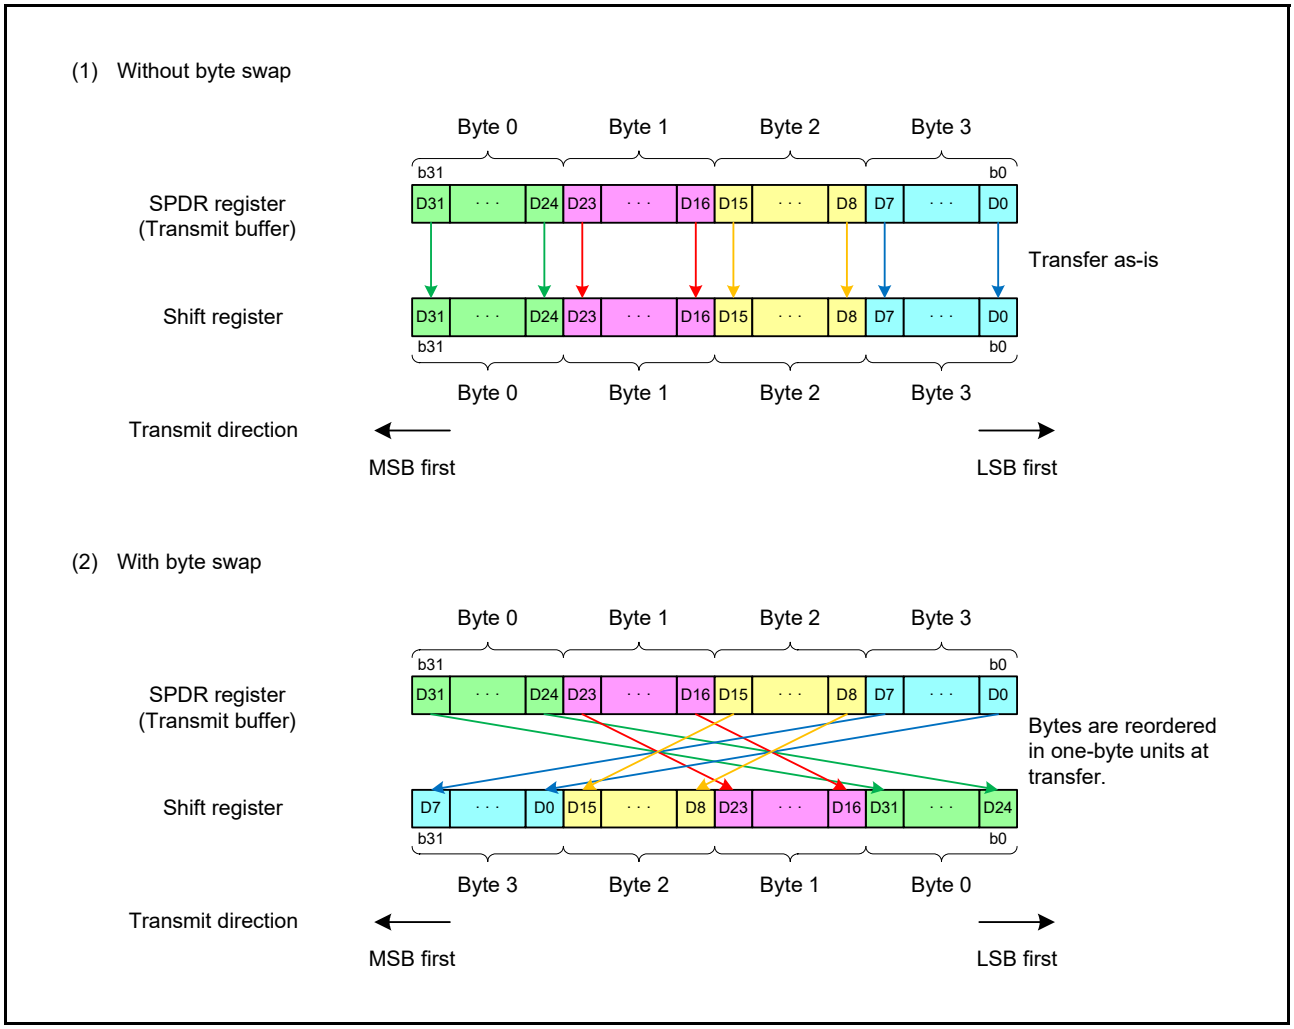

Figure 37.22 Transmit Data Handling in MSB/LSB First with Byte Swapping Enabled/Disabled

37.3.4.4 Byte Swap Reception

When the SPDCR2.BYSW bit is 1 (byte swapping of SPDR data enabled), data bytes in the shift register will be swapped (in 8 bit units) when the data is transferred to the receive buffer (SPDR). Figure 37.23 shows data transfer between the shift register and the SPDR register when data length is 32 bits.

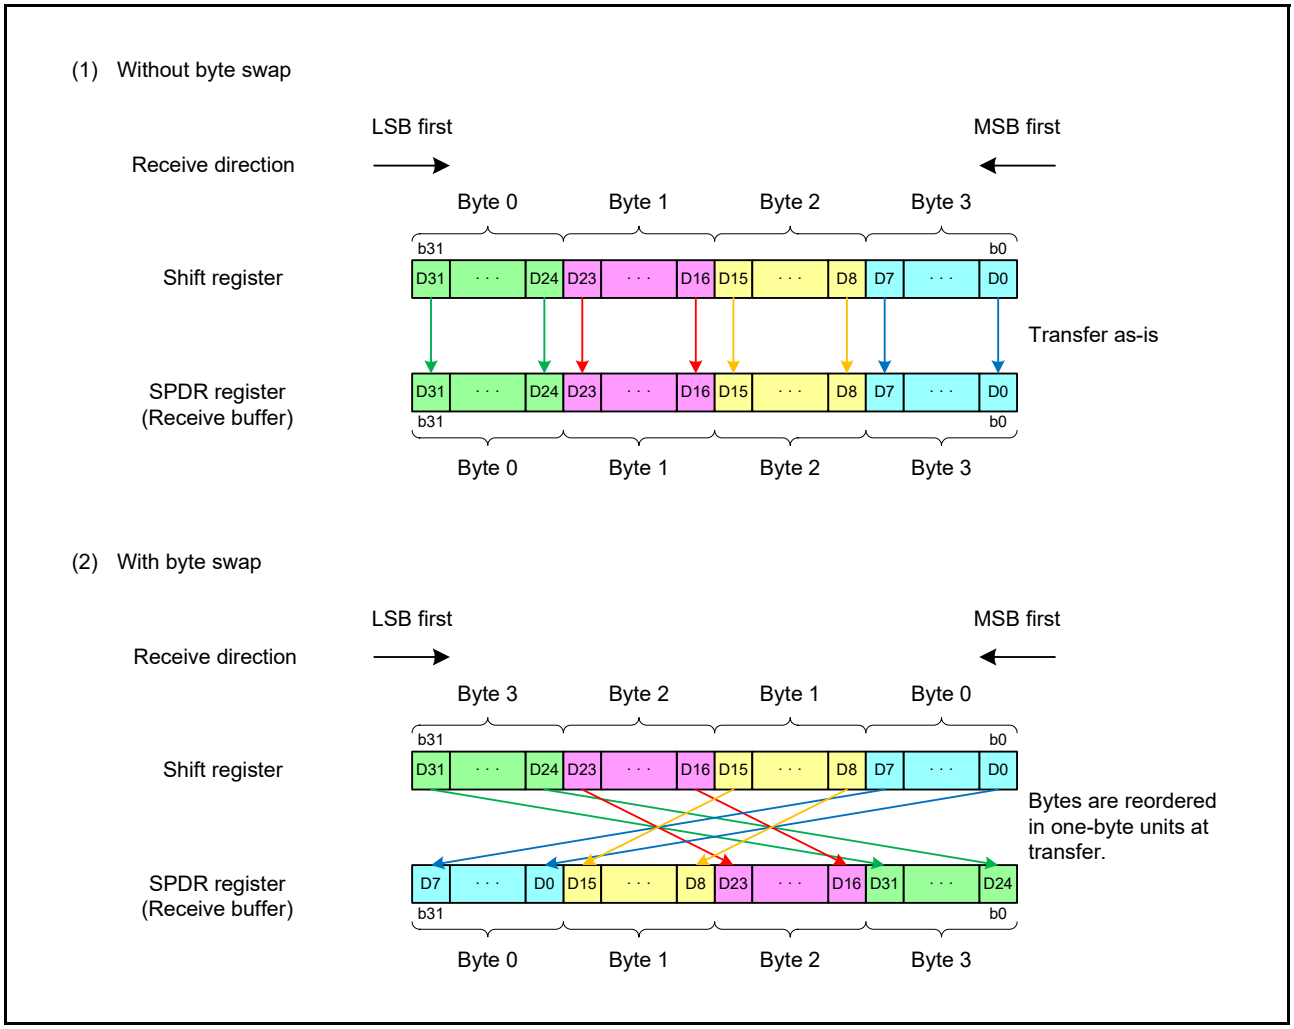

Figure 37.23 Receive Data Handling in MSB/LSB First with Byte Swapping Enabled/Disabled

37.3.5 Transfer Format

37.3.5.1 CPHA = 0

Figure 37.24 shows a sample transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 0. Note that clock synchronous operation (the SPCR.SPMS bit is 1) should not performed when the RSPI operates in slave mode (SPCR.MSTR = 0) and the CPHA bit is 0. In Figure 37.24, RSPCKA (CPOL = 0) indicates the RSPCKA signal waveform when the SPCMDm.CPOL bit is 0; RSPCKA (CPOL = 1) indicates the RSPCKA signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the RSPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the RSPI settings. For details, refer to section 37.3.2, Controlling RSPI Pins.

When the SPCMDm.CPHA bit is 0, the driving of valid data to the MOSIA and MISOA signals commences at an SSLAi signal assertion timing. The first RSPCKA signal change timing that occurs after the SSLAi signal assertion becomes the first transfer data fetch timing. After this timing, data is sampled at every 1 RSPCK cycle. The change timing for MOSIA and MISOA signals is 1/2 RSPCK cycles after the transfer data fetch timing. The CPOL bit setting does not affect the RSPCKA signal operation timing; it only affects the signal polarity.

t1 denotes a period from an SSLAi signal assertion to RSPCKA oscillation (RSPCK delay). t2 denotes a period from the termination of RSPCKA oscillation to an SSLAi signal negation (SSL negation delay). t3 denotes a period in which SSLAi signal assertion is suppressed for the next transfer after the end of serial transfer (next-access delay). t1, t2, and t3 are controlled by a master device running on the RSPI system. For a description of t1, t2, and t3 when the RSPI of this MCU is in master mode, refer to section 37.3.12.1, Master Mode Operation.

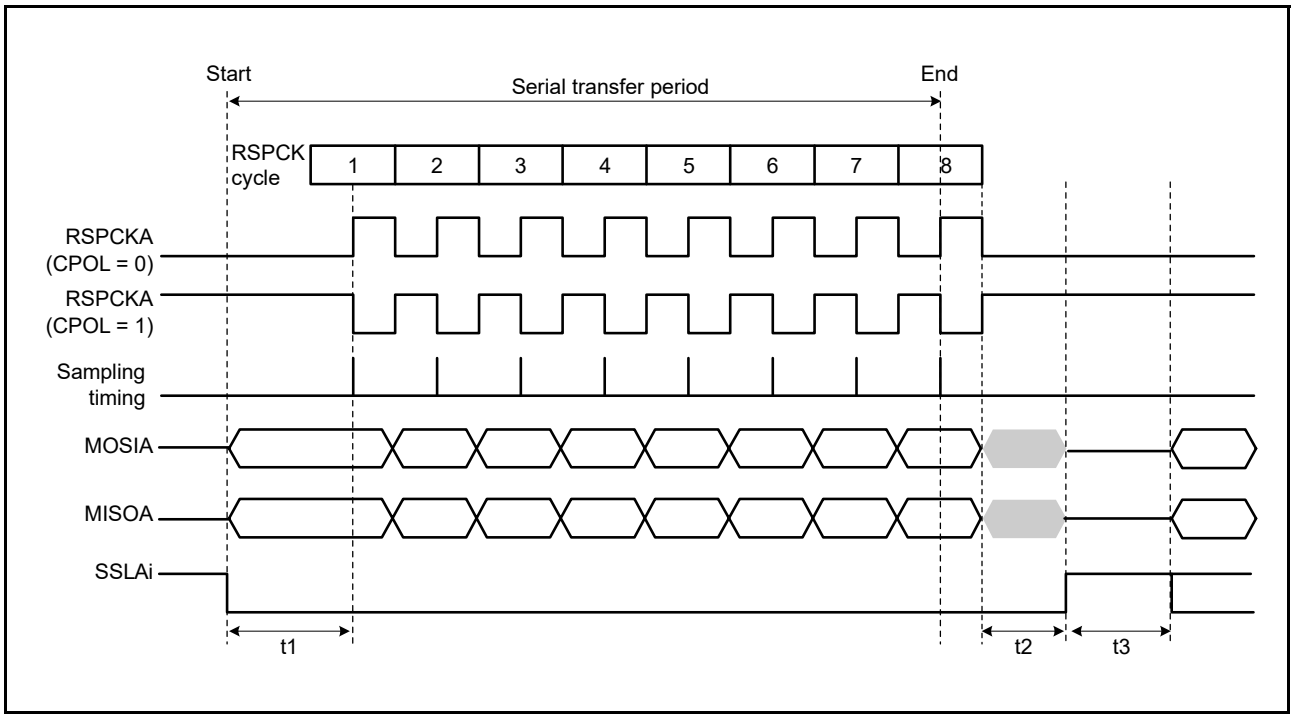

Figure 37.24 RSPI Transfer Format (CPHA = 0)

37.3.5.2 CPHA = 1

Figure 37.25 shows a sample transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 1. However, when the SPCR.SPMS bit is 1, the SSLAi signals are not used, and only the three signals RSPCKA, MOSIA, and MISOA handle communications. In Figure 37.25, RSPCK (CPOL = 0) indicates the RSPCKA signal waveform when the SPCMDm.CPOL bit is 0; RSPCKA (CPOL = 1) indicates the RSPCKA signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the RSPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the RSPI mode (master or slave). For details, refer to section 37.3.2, Controlling RSPI Pins.

When the SPCMDm.CPHA bit is 1, the driving of invalid data to the MISOA signal commences at an SSLAi signal assertion timing. The output of valid data to the MOSIA and MISOA signals commences at the first RSPCKA signal change timing that occurs after the SSLAi signal assertion. After this timing, data is updated at every 1 RSPCK cycle. The transfer data fetch timing is 1/2 RSPCK cycles after the data update timing. The SPCMDm.CPOL bit setting does not affect the RSPCKA signal operation timing; it only affects the signal polarity.

t1, t2, and t3 are the same as those in the case of CPHA = 0. For a description of t1, t2, and t3 when the RSPI of this MCU is in master mode, refer to section 37.3.12.1, Master Mode Operation.

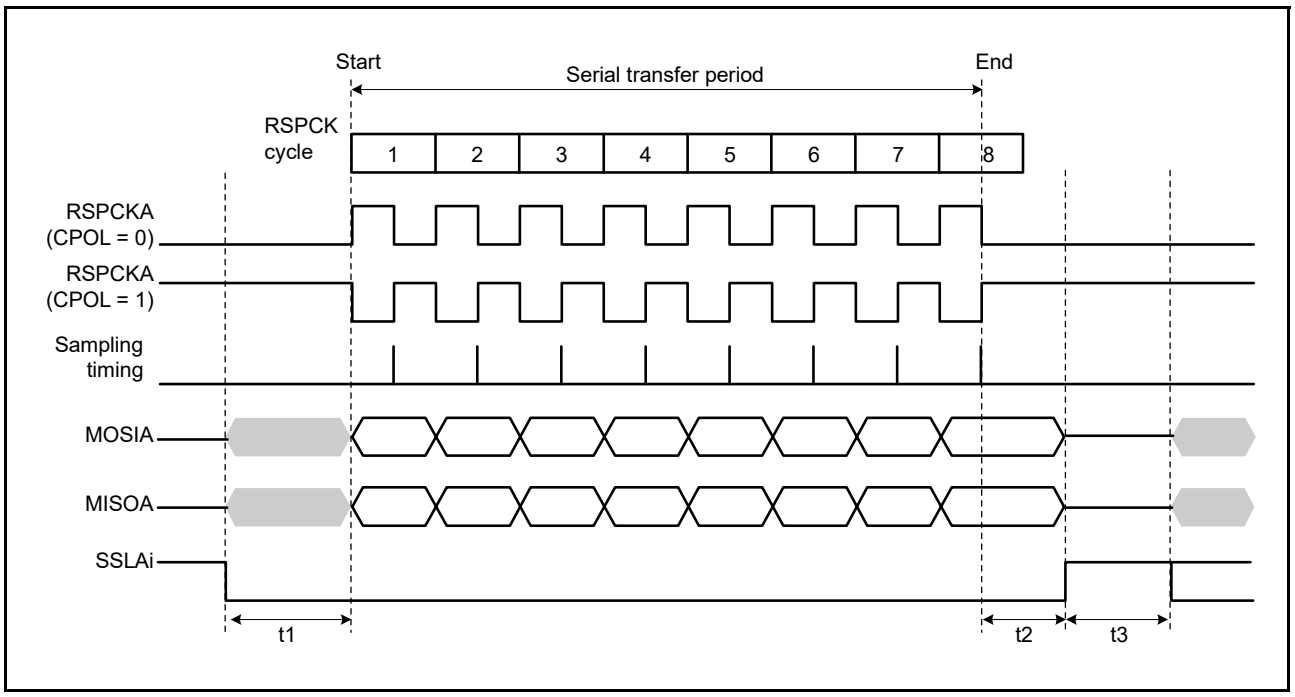

Figure 37.25 RSPI Transfer Format (CPHA = 1)

37.3.6 Communications Operating Mode

Full-duplex communications, transmit-only simplex communications, or receive-only simplex communications can be selected by the SPCR.TXMD and SPCR3.RXMD bits.
'SPDR access' shown in Figure 37.26 and Figure 37.27 indicate the condition of access to the SPDR register, where 'W' denotes a write cycle.

37.3.6.1 Full-Duplex Communications (SPCR.TXMD = 0, SPCR3.RXMD = 0)

Figure 37.26 shows an example of operation when the SPCR.TXMD bit is set to 0 and the SPCR3.RXMD bit is set to 0. In the example in Figure 37.26, the RSPI performs an 8-bit serial transfer in which the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKA waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

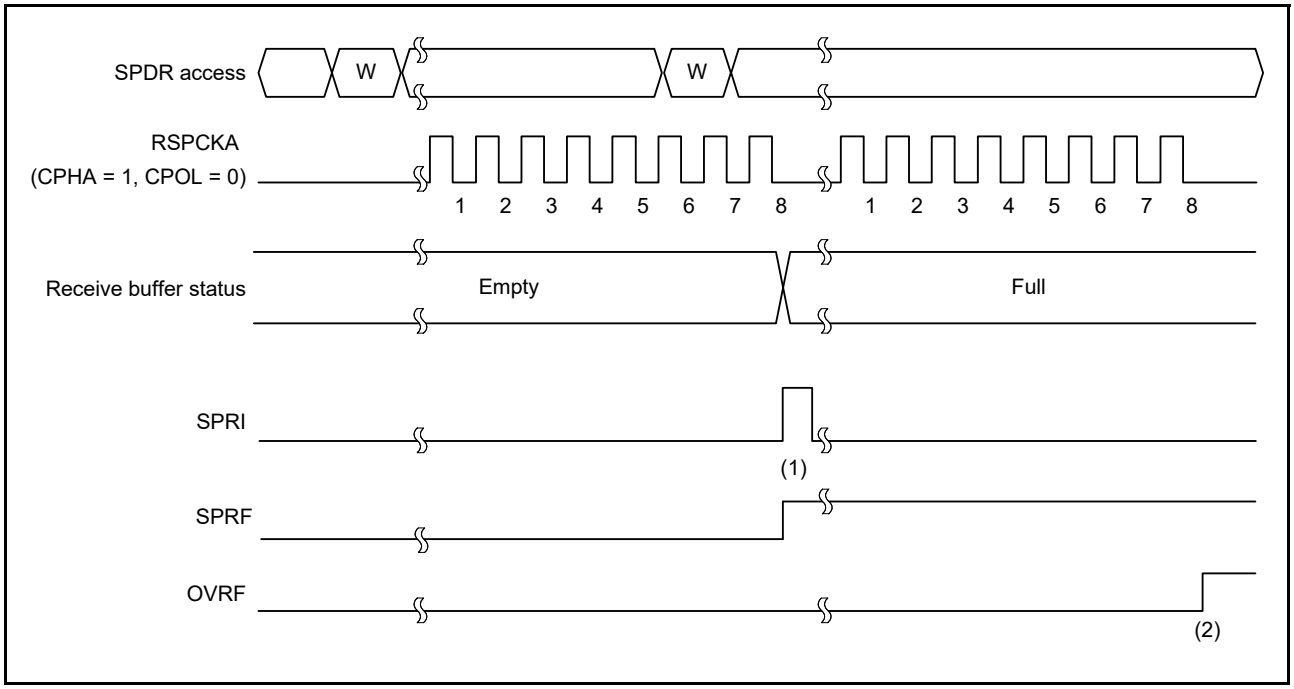

Figure 37.26 Operation Example of SPCR.TXMD = 0 and SPCR3.RXMD = 0

The operation of the flags at timings shown in steps (1) and (2) in the figure is described below.

(1) When a serial transfer ends with the receive buffer of the SPDR register empty, the RSPI generates a receive buffer full interrupt request (SPRI) (sets the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer.

(2) When a serial transfer ends with the receive buffer of the SPDR register holding data that was received in the previous serial transfer, the RSPI sets the SPSR.OVRF flag to 1 and discards the received data in the shift register.

When full-duplex communications (SPCR.TXMD = 0, SPCR3.RXMD = 0) is selected, reception occurs simultaneously with transmit operations. As such, the SPRF and OVRF flags in the SPSR register become 1 at the timing described in (1) and (2), respectively, according to the state of the receive buffer.

37.3.6.2 Transmit-only Simplex Communications (SPCR.TXMD = 1, SPCR3.RXMD = 0)

Figure 37.27 shows an example of operation when the SPCR.TXMD bit is set to 1 and the SPCR3.RXMD bit is set to 0. In the example in Figure 37.27, the RSPI performs an 8-bit serial transfer in which the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKA waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

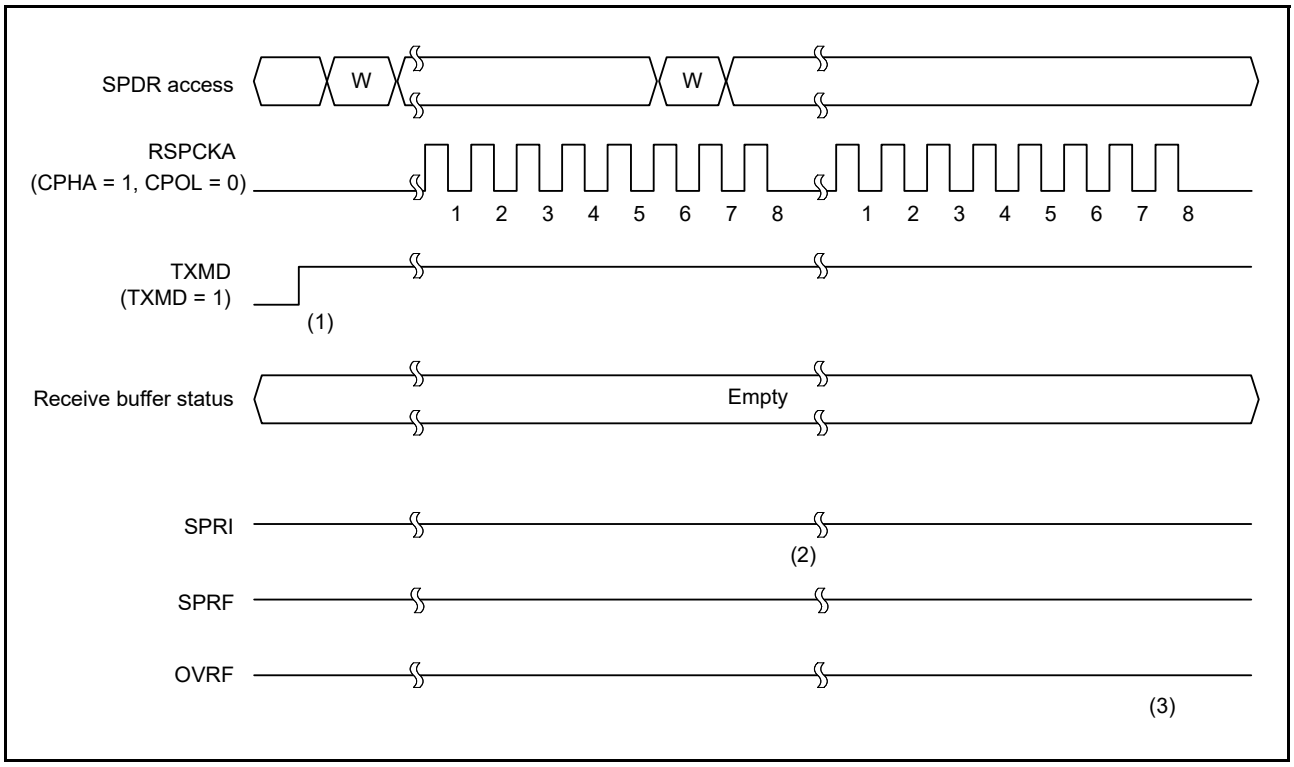

Figure 37.27 Operation Example of SPCR.TXMD = 1 and SPCR3.RXMD = 0

The operation of the flags at timings shown in steps (1) to (3) in the figure is described below.

(1) Make sure there is no data left in the receive buffer and the SPSR.SPRF, OVRF flags are 0 before entering the mode of transmit-only simplex communications (SPCR.TXMD = 1, SPCR3.RXMD = 0).

(2) When a serial transfer ends with the receive buffer of the SPDR register empty, if the mode of transmit-only simplex communications is selected (SPCR.TXMD = 1, SPCR3.RXMD = 0), the SPRF flag remains 0 and the RSPI does not copy the data from the shift register to the receive buffer.

(3) Since the receive buffer of the SPDR register does not hold data that was received in the previous serial transfer, even when a serial transfer ends, the SPSR.OVRF flag retains the value of 0, and the data in the shift register is not copied to the receive buffer.

When performing transmit-only simplex communications (SPCR.TXMD = 1, SPCR3.RXMD = 0), the RSPI transmits data but does not receive data. Therefore, the SPSR.SPRF, OVRF flags remain 0 at the timings of (1) to (3).

37.3.6.3 Receive-only Simplex Communications (SPCR3.RXMD = 0)

The receive-only simplex communications are valid only when the SPCR.MSTR bit is 0 (slave mode).
Figure 37.28 shows an example of operation when the SPCR3.RXMD bit is set to 1. In the example in Figure 37.28, the RSPI performs an 8-bit serial transfer in which the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKA waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

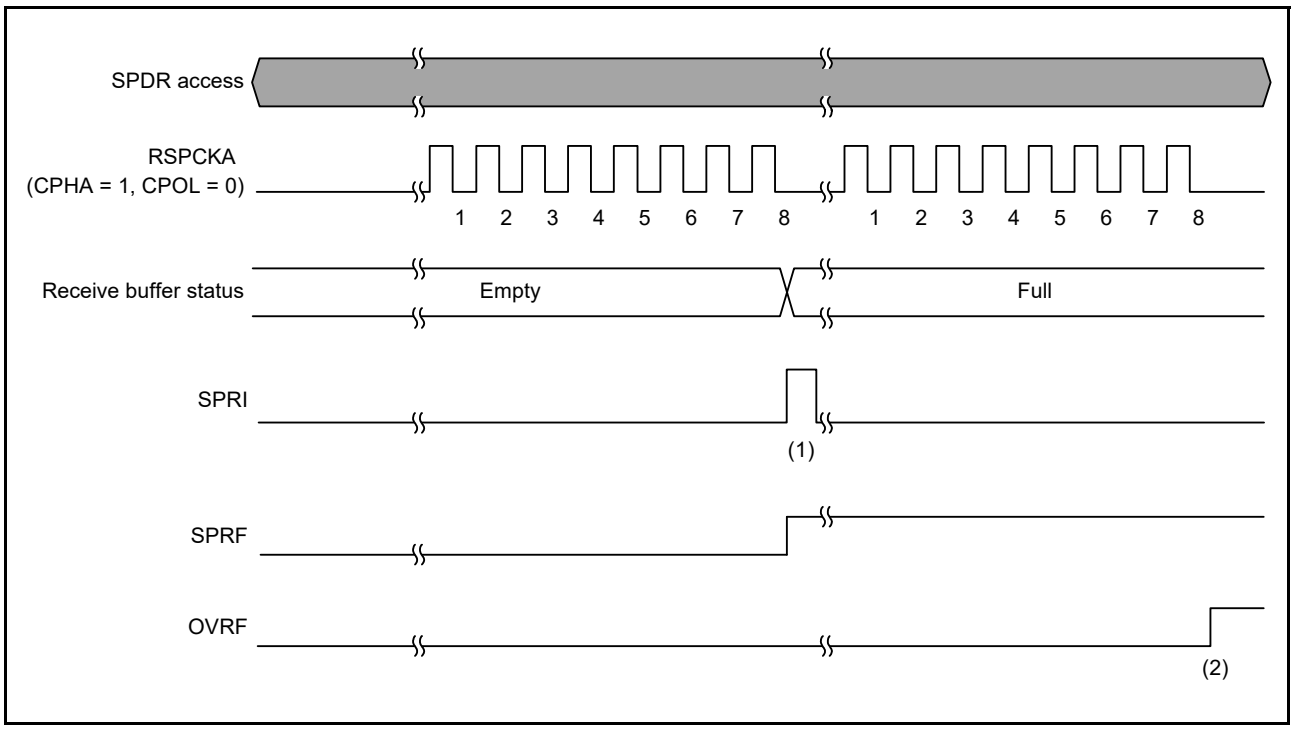

Figure 37.28 Operation Example of SPCR3.RXMD = 1

The operation of the flags at timings shown in steps (1) and (2) in the figure is described below.

(1) When a serial transfer ends with the receive buffer of the SPDR register empty, the RSPI generates a receive buffer full interrupt request (SPRI) (sets the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer.

(2) When a serial transfer ends with the receive buffer of the SPDR register holding data that was received in the previous serial transfer, the RSPI sets the SPSR.OVRF flag to 1 and discards the received data in the shift register.

37.3.7 Transmit Buffer Empty/Receive Buffer Full Interrupts

Figure 37.29 shows an example of operation of the transmit buffer empty interrupt (SPTI) and the receive buffer full interrupt (SPRI). 'SPDR access' shown in Figure 37.29 indicates the condition of access to the SPDR register, where 'W' denotes a write cycle, and 'R' a read cycle. In the example in Figure 37.29, the RSPI performs an 8-bit serial transfer in which the SPCR.TXMD bit is 0, the SPCR3.RXMD bit is 0, the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKA waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

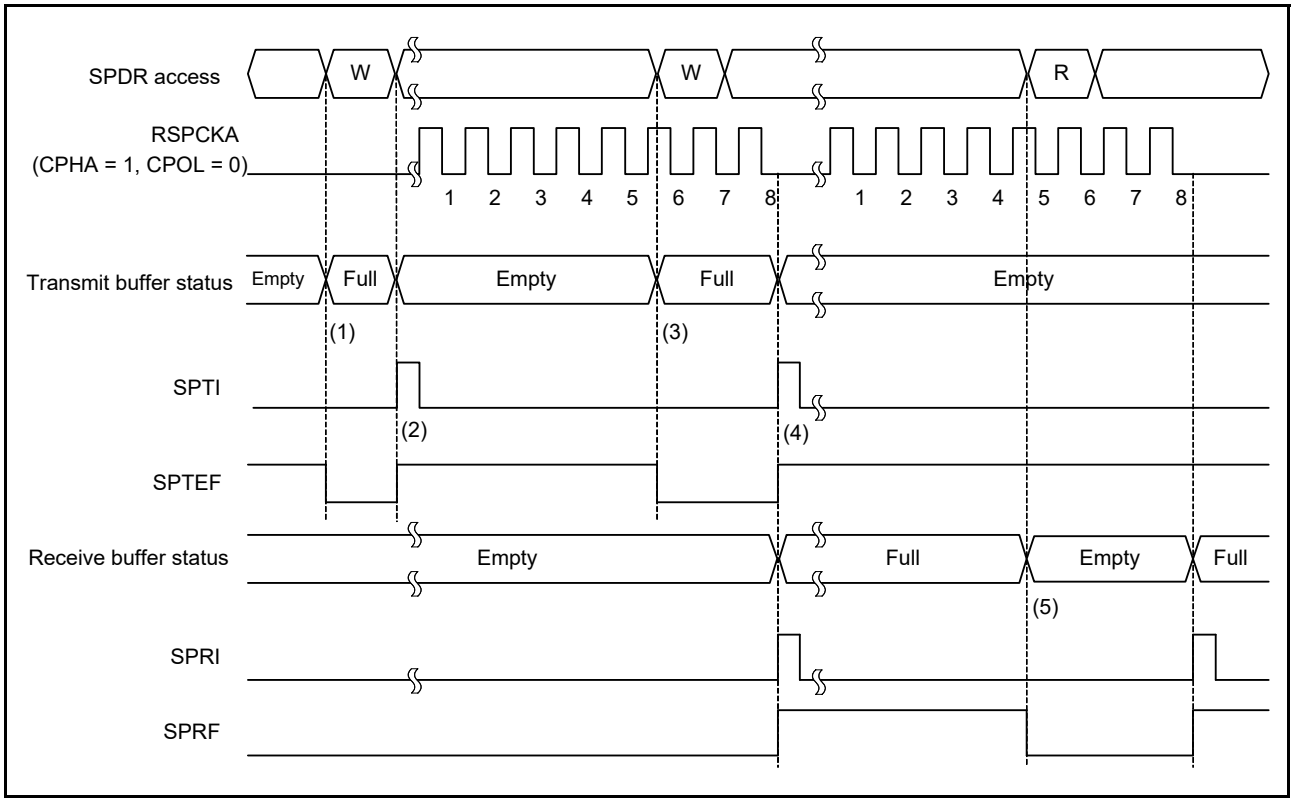

Figure 37.29 Operation Example of SPTI and SPRI Interrupts

The operation of the interrupts at timings shown in steps (1) to (5) in the figure is described below.

(1) When transmit data is written to the SPDR register when the transmit buffer of the SPDR register is empty (data for the next transfer is not set), the RSPI writes data to the transmit buffer and sets the SPSR.SPTEF flag to 0.

(2) If the shift register is empty, the RSPI copies the data from the transmit buffer to the shift register and generates a transmit buffer empty interrupt request (SPTI) and sets the SPSR.SPTEF flag to 1. How a serial transfer is started depends on the mode of the RSPI. For details, refer to section 37.3.12, SPI Operation, and section 37.3.13, Clock Synchronous Operation.

(3) When transmit data is written to the SPDR register in the transmit buffer empty interrupt routine or in the transmit buffer empty detecting process by polling the SPTEF flag, the data is transferred to the transmit buffer and the SPSR.SPTEF flag becomes 0. Because the data being transmitted is stored in the shift register, the RSPI does not copy the data from the transmit buffer to the shift register.

(4) When the serial transfer ends with the receive buffer of the SPDR register being empty, the RSPI copies the receive data from the shift register to the receive buffer, generates a receive buffer full interrupt request (SPRI), and sets the SPSR.SPRF flag to 1. Since the shift register becomes empty upon completion of serial transfer, when the transmit buffer had been full before the serial transfer ended, the RSPI sets the SPSR.SPTEF flag to 1 and copies the data from the transmit buffer to the shift register. Even when received data is not copied from the shift register to the receive buffer in an overrun error status, upon completion of the serial transfer, the RSPI determines that the shift register is empty, thus data transfer from the transmit buffer to the shift register is enabled.

(5) When the SPDR register is read in the receive buffer full interrupt routine or in the receive buffer full detecting process by polling the SPRF flag, the receive data can be read. When the receive data is read, the SPRF flag becomes 0.

If transmit data is written to the SPDR register while the transmit buffer holds data that has not yet been transmitted (the SPTEF flag is 0), the RSPI does not update the data in the transmit buffer. Transmit data should be written to the SPDR register in the transmit buffer empty interrupt request routine or in the transmit buffer empty detecting process by polling the SPTEF flag. To use a transmit buffer empty interrupt, set the SPTIE bit in SPCR to 1.
When setting the SPCR.SPE bit to 0 (RSPI disabled), the SPCR.SPTIE bit should also be set to 0. Otherwise (if the SPCR.SPE bit is 0 and the SPCR.SPTIE is 1), a transmit buffer empty interrupt request will occur.
When serial transfer ends with the receive buffer being full (the SPRF flag is 1), the RSPI does not copy data from the shift register to the receive buffer, and detects an overrun error (refer to section 37.3.10, Error Detection). To prevent a receive data overrun error, read the received data using a receive buffer full interrupt request before the next serial transfer ends. To use an receive buffer full interrupt, set the SPCR.SPRIE bit to 1.
Transmit and receive interrupts or the corresponding IRn.IR flags (where n is the interrupt vector number) in the ICU can be used to confirm the states of the transmit and receive buffers. Refer to section 14, Interrupt Controller (ICUG), for the interrupt vector numbers. The status of the transmit and receive buffers can be also confirmed by the SPTEF and SPRF flags.

37.3.8 Idle Interrupt

When the SPSR.IDLNF flag becomes 0 while the SPCR2.SPIIE bit is 1, an idle interrupt request (SPII) is generated.
In master mode, the IDLNF flag is 0 before transmission. Therefore, write data in the transmit buffer and set the SPIIE bit to 1 after the IDLNF flag becomes 1 so that an idle interrupt is not generated at this time. When the SSLA0 signal is negated after the transmission is completed and the next data is not supplied until next-access delay time (t3) elapses, the IDLNF flag becomes 0.

37.3.9 Communication End Interrupt

When the SPSR.SPCF flag becomes 1 while the SPCR3.SPCIE bit is 1 or when the SPCIE bit is set to 1 while the SPCR.SPE bit is 1 and SPCF flag is 1, a communication end interrupt request (SPCI) is generated.
The conditions for setting the SPCF flag to 1 differ depending on the operating mode of the RSPI. For details, refer to section 37.2.4, RSPI Status Register (SPSR).

37.3.9.1 In Master Mode

In master mode, the conditions for setting the SPCF flag to 1 are the same in any combination of SPI operation or clock synchronous operation and full-duplex or transmit-only simplex communications.
When the SPSSR.SPCP[2:0] bits becomes 000b and there is no next transmit data, the SPSR.IDLNF flag becomes 0 and the SPCF flag becomes 1.
The SPCF flag is cleared when 0 is written to the SPCF flag after confirming the flag is 1 or when the next data is written to the transmit buffer.

37.3.9.2 Full-duplex or transmit-only simplex communications in slave mode under SPI operation

When the SSLA0 signal is negated while the transmit buffer and the transmit shift register are empty, the SPSR.SPCF flag becomes 1.
The SPCF flag is cleared when 0 is written to the SPCF flag after confirming the flag is 1 or when the next data is written

to the transmit buffer.

37.3.9.3 Receive-only simplex communications in slave mode under SPI operation

When the SSLA0 signal is negated after the number of frames set in the SPDCR.SPFC[1:0] bits have been received, the SPSR.SPCF flag becomes 1.
The SPCF flag is cleared when 0 is written to the SPCF flag after confirming the flag is 1 or when the SSLA0 signal is asserted when the next communication is started.

37.3.9.4 Full-duplex or transmit-only simplex communications in slave mode under clock synchronous operation

When the transmit buffer and the transmit shift register are empty, the SPSR.SPCF flag becomes 1 at the sampling timing of the last bit (the last even edge of the RSPCK).
The SPCF flag is cleared when 0 is written to the SPCF flag after confirming the flag is 1 or when the next data is written to the transmit buffer.

37.3.9.5 Receive-only simplex communications in slave mode under clock synchronous operation

When the number of frames set in the SPDCR.SPFC[1:0] bits have been received (the last even edge of the RSPCK), the SPSR.SPCF flag becomes 1.
The SPCF flag is cleared when 0 is written to the SPCF flag after confirming the flag is 1 or when the RSPCK signal changes when next communication is started.

37.3.10 Error Detection

In the normal RSPI serial transfer, the data written to the transmit buffer of the SPDR register is transmitted, and the received data can be read from the receive buffer of the SPDR register. If access is made to the SPDR register, depending on the status of the transmit/receive buffer or the status of the RSPI at the beginning or end of serial transfer, in some cases non-normal transfers can be executed.

If a non-normal transfer operation occurs, the RSPI detects the event as an underrun error, overrun error, parity error, or mode fault error. Table 37.7 lists the relationship between non-normal transfer operations and the RSPI's error detection function.

Table 37.7 Relationship between Non-Normal Transfer Operations and RSPI Error Detection Function

	Occurrence Condition	RSPI Operation	Error Detection
1	The SPDR register is written when the transmit buffer is full.	• The contents of the transmit buffer are kept. • Missing write data.	None
2	The SPDR register is read when the receive buffer is empty.	If reception has completed, then the received data is output to the bus. Otherwise, data received previously is output instead.	None
3	Serial transfer is started when transmit data is still not loaded on the shift register while the RSPI is set to perform full-duplex or transmit-only simplex communications in slave mode.	• Serial transfer is suspended • Transmit/receive data is missing • The MISO signal output is disabled • RSPI function is disabled	Underrun error
4	Serial transfer terminates when the receive buffer is full.	• The contents of the receive buffer are kept. • Missing receive data.	Overrun error
5	An incorrect parity bit is received when performing full-duplex or receive-only simplex communications with the parity function enabled.	The parity error flag is set.	Parity error
6	The SSLA0 input signal is asserted when the serial transfer is idle in multi-master mode.	• Driving of the RSPCKA, MOSIA, SSLA1 to SSLA3 output signals is stopped. • RSPI function is disabled.	Mode fault error
7	The SSLA0 input signal is asserted during serial transfer in multi-master mode.	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the RSPCKA, MOSIA, SSLA1 to SSLA3 output signals is stopped. • RSPI function is disabled.	Mode fault error
8	The SSLA0 input signal is negated during serial transfer in slave mode.	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the MISOA output signal is stopped. • RSPI function is disabled.	Mode fault error

On operation 1 described in Table 37.7, the RSPI does not detect an error. To prevent data omission during the writing to the SPDR register, the SPDR register should be written when a transmit buffer empty interrupt request occurs or while the SPSR.SPTEF flag is 1.

Likewise, the RSPI does not detect an error on operation 2. To prevent extraneous data from being read, the SPDR register should be read when a receive buffer full interrupt request occurs or while the SPSR.SPRF flag is 1.

An underrun error shown in 3 is described in section 37.3.10.4, Underrun Error. An overrun error shown in 4 is described in section 37.3.10.1, Overrun Error. A parity error shown in 5 is described in section 37.3.10.2, Parity Error. A mode fault error shown in 6 to 8 is described in section 37.3.10.3, Mode Fault Error.

For the transmit and receive interrupts, refer to section 37.3.7, Transmit Buffer Empty/Receive Buffer Full Interrupts.

37.3.10.1 Overrun Error

If a serial transfer ends when the receive buffer of the SPDR register is full, the RSPI detects an overrun error, and sets the SPSR.OVRF flag to 1. When the OVRF flag is 1, the RSPI does not copy data from the shift register to the receive buffer so that the data prior to the occurrence of the error is retained in the receive buffer. To set the OVRF flag to 0, write 0 to the OVRF flag after the CPU has read the SPSR register with the OVRF flag set to 1.
Figure 37.30 shows an example of operations of the SPRF and OVRF flags. 'SPSR access' and 'SPDR access' shown in Figure 37.30 indicate the condition of accesses to the SPSR and SPDR registers, respectively, where 'W' denotes a write cycle, and 'R' a read cycle. In the example in Figure 37.30, the RSPI performs an 8-bit serial transfer in which the SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKA waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

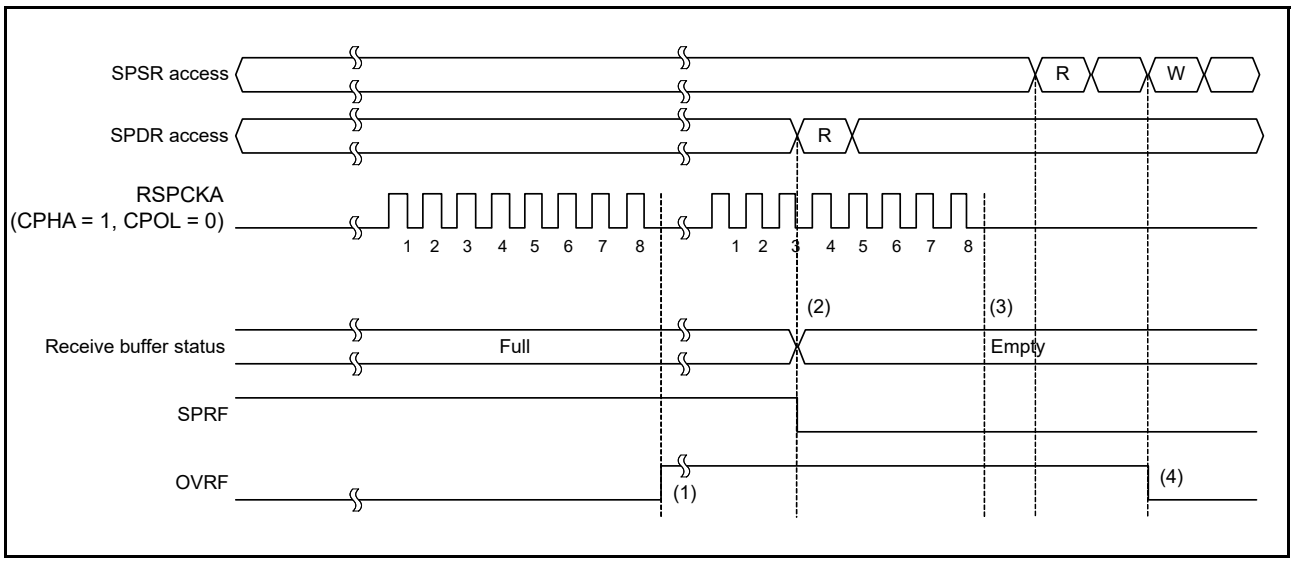

Figure 37.30 Operation Example of the SPRF and OVRF Flags

The operation of the flags at the timing shown in steps (1) to (4) in the figure is described below.

(1) If a serial transfer terminates with the receive buffer full (the SPRF flag is 1), the RSPI detects an overrun error, and sets the OVRF flag to 1. The RSPI does not copy the data in the shift register to the receive buffer. Even if the SPPE bit is 1, parity errors are not detected. In master mode, the RSPI copies the pointer value to the SPCMDm register to the SPSSR.SPECM[2:0] bits.

(2) When the SPDR register is read, the RSPI outputs the data in the receive buffer. At this time the SPRF flag becomes 0. Even if the receive buffer becomes empty, the OVRF flag does not become 0.

(3) If the serial transfer ends with the OVRF flag being 1 (an overrun error occurs), the RSPI does not copy the data in the shift register to the receive buffer (the SPRF flag remains 0). A receive buffer full interrupt is not generated. Even if the SPPE bit is 1, parity errors are not detected. When in master mode, the RSPI does not update the SPSSR.SPECM[2:0] bits. When in an overrun error state and the RSPI does not copy the received data from the shift register to the receive buffer, upon termination of the serial transfer, the RSPI determines that the shift register is empty; in this manner, data transfer from the transmit buffer to the shift register is enabled.

(4) If 0 is written to the OVRF flag after the SPSR register is read when the OVRF flag is 1, the OVRF flag is set to 0.

The occurrence of an overrun can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. When executing a serial transfer, measures should be taken to ensure the early detection of overrun errors, such as reading the SPSR register immediately after the SPDR register is read. When the RSPI is used in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.
If an overrun error occurs and the OVRF flag is set to 1, normal reception operations cannot be performed until the OVRF flag is set to 0.

When the RSPCK auto-stop function is enabled in master mode, an overrun error does not occur. Figure 37.31 and Figure 37.32 show the clock stop waveform when a serial transfer continues while the receive buffer is full in master mode.

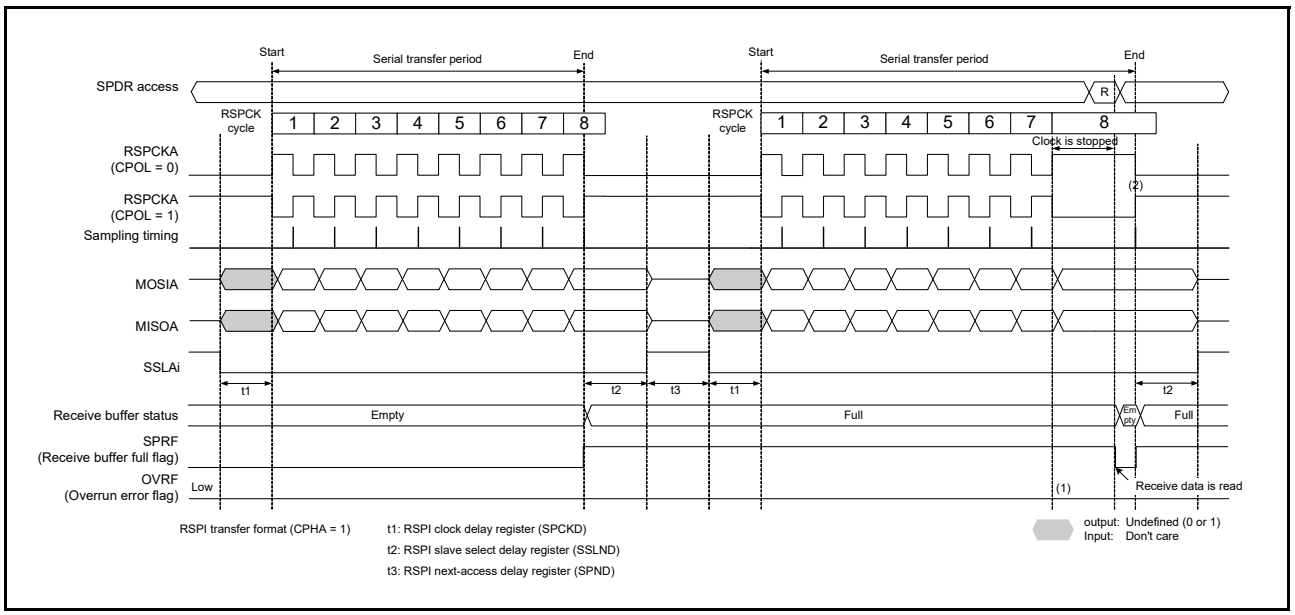

Figure 37.31 Clock Stop Waveform When a Serial Transfer Continues While the Receive Buffer is Full in Master Mode (CPHA = 1)

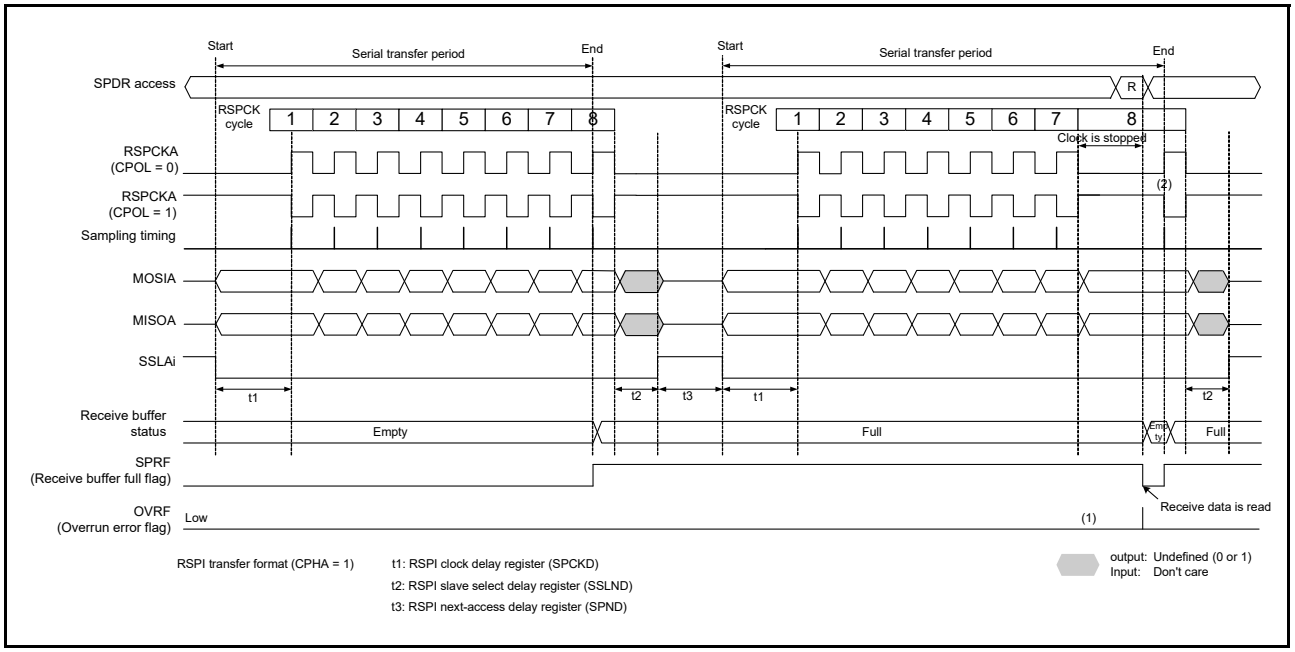

Figure 37.32 Clock Stop Waveform When a Serial Transfer Continues While the Receive Buffer is Full in Master Mode (CPHA = 0)

The operation of the flags at the timings shown in steps (1) and (2) in the figure is described below.

(1) When the receive buffer is full, an overrun error does not occur because the RSPCK clock is stopped.

(2) If the SPDR register is read while the clock is stopped, data in the receive buffer can be read. The RSPCK clock restarts after reading the receive buffer (after the SPRF flag becomes 0).

37.3.10.2 Parity Error

If full-duplex communication or receive-only simplex communication is performed with the SPCR.TXMD bit set to 0 and the SPCR2.SPPE bit set to 1, when serial transfer ends, the RSPI checks whether there are parity errors. Upon detecting a parity error in the received data, the RSPI sets the SPSR.PERF flag to 1. Since the RSPI does not copy the data in the shift register to the receive buffer when the SPSR.OVRF flag is set to 1, parity error detection is not performed for the received data. To set the PERF flag to 0, write 0 to the PERF flag after the SPSR register is read with the PERF flag set to 1.

Figure 37.33 shows an example of operation of the OVRF and PERF flags. 'SPSR access' shown in Figure 37.33 indicates the condition of access to the SPSR register, where 'W' denotes a write cycle, and 'R' a read cycle. In the example of Figure 37.33, full-duplex communication or receive-only simplex communication is performed while the SPCR.TXMD bit is 0 and the SPCR2.SPPE bit is 1. The RSPI performs an 8-bit serial transfer in which the SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKA waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

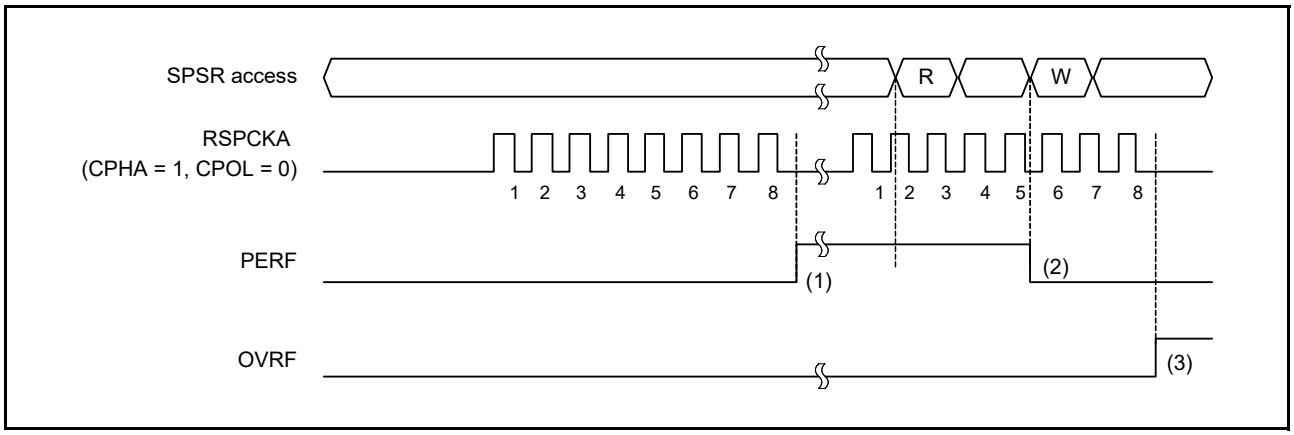

Figure 37.33 Operation Example of PERF Flag

The operation of the flags at the timing shown in steps (1) to (3) in the figure is described below.

(1) If a serial transfer terminates with the RSPI not detecting an overrun error, the RSPI copies the data in the shift register to the receive buffer. The RSPI judges the received data at this timing, and sets the PERF flag to 1 if a parity error is detected. In master mode, the RSPI copies the pointer value to the SPCMDm register to the SPSSR.SPECM[2:0] bits.

(2) If 0 is written to the PERF flag after the SPSR register is read when the PERF flag is 1, the PERF flag is set to 0.

(3) When the RSPI detects an overrun error and serial transfer is terminated, the data in the shift register is not copied to the receive buffer. The RSPI does not perform parity error detection at this timing.

The occurrence of a parity error can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. When executing a serial transfer, measures should be taken to ensure the early detection of parity errors, such as reading the SPSR register. When the RSPI is used in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.

37.3.10.3 Mode Fault Error

The RSPI operates in multi-master mode when the SPCR.MSTR bit is 1, the SPCR.SPMS bit is 0, and the SPCR.MODFEN bit is 1. If the active level is input with respect to the SSLA0 input signal of the RSPI in multi-master mode, the RSPI detects a mode fault error irrespective of the status of the serial transfer, and sets the SPSR.MODF flag to 1. Upon detecting the mode fault error, the RSPI copies the value of the pointer to the SPCMDm register to the SPSSR.SPECM[2:0] bits. The active level of the SSLA0 signal is determined by the SSLP.SSL0P bit.
When the MSTR bit is 0, the RSPI operates in slave mode. The RSPI detects a mode fault error if the MODFEN bit of the RSPI in slave mode is 1, and the SPMS bit is 0, and if the SSLA0 input signal is negated during the serial transfer period (from the time the driving of valid data is started to the time the final valid data is fetched).
Upon detecting a mode fault error, the RSPI stops driving of the output signals and clears the SPCR.SPE bit to 0 (refer to section 37.3.11, Initializing RSPI). In the case of multi-master configuration, detection of a mode fault error is used to stop driving of the output signals and the RSPI function, which allows the master right to be released.
The occurrence of a mode fault error can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. Detecting mode fault errors without utilizing the error interrupt requires polling of the SPSR register. When using the RSPI in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.
When the MODF flag is 1, writing of the value 1 to the SPE bit is ignored by the RSPI. To enable the RSPI function after the detection of a mode fault error, set the MODF flag to 0. When setting the MODF flag to 0, the SPE bit becomes 1.

37.3.10.4 Underrun Error

If a serial transfer is started when the SPCR.SPE bit is 1 (RSPI function is enabled) and transmit data is still not loaded on the shift register while RSPI operates in slave mode (the SPCR.MSTR bit is 0) and transmitter is enabled (the SPCR3.RXMD bit is 0), the RSPI detects an underrun error, and sets the SPSR.MODF and SPSR.UDRF flags to 1. Upon detecting an underrun error, the RSPI stops driving of the output signals and clears the SPCR.SPE bit to 0. Clearing of the SPE bit disables the RSPI function. (Refer to section 37.3.11, Initializing RSPI). The occurrence of an underrun error can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. Detecting underrun errors without utilizing the error interrupt requires polling of the SPSR register. When the MODF flag is 1, writing of the value 1 to the SPE bit is ignored by the RSPI. To enable the RSPI function after the detection of an underrun error, set the MODF flag to 0. When setting the MODF flag to 0, the SPE bit becomes 1.

37.3.11 Initializing RSPI

If 0 is written to the SPCR.SPE bit or the RSPI sets the SPE bit to 0 because of the detection of a mode fault error or an underrun error, the RSPI disables the RSPI function, and initializes some of the module functions. When a system reset is generated, the RSPI initializes all of the module functions. The following describes initialization by the clearing of the SPCR.SPE bit and initialization by a system reset.

37.3.11.1 Initialization by Clearing the SPE Bit

When the SPCR.SPE bit is set to 0, the RSPI performs the following initialization:

- Aborting the transmission and reception that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state of the RSPI
- Initializing the transmit buffer of the RSPI (Set the SPTEF flag to 1)

Initialization by the clearing of the SPE bit does not initialize the control bits of the RSPI. For this reason, the RSPI can be started in the same transfer mode as prior to the initialization if the SPE bit is set to 1 again.
The SPSR.SPRF, SPCF, UDRF, PERF, MODF, and OVRF flags are not initialized, nor is the value of the RSPI sequence status register (SPSSR) initialized. For this reason, even after the RSPI is initialized, data from the receive buffer can be read and the communication status that was being executed before the initialization and the status of error occurrence during the RSPI transfer can be checked.
The transmit buffer is initialized to an empty state (the SPTEF flag is 1). Therefore, if the SPCR.SPTIE bit is set to 1 after RSPI initialization, a transmit buffer empty interrupt is generated. When the RSPI is initialized, in order to disable any transmit buffer empty interrupt, 0 should be written to the SPTIE bit simultaneously with the writing of 0 to the SPE bit.

37.3.11.2 System Reset

The initialization by a system reset completely initializes the RSPI through the initialization of all bits for controlling the RSPI, initialization of the status bits, and initialization of data registers, in addition to the requirements described in section 37.3.11.1, Initialization by Clearing the SPE Bit.

37.3.12 SPI Operation

37.3.12.1 Master Mode Operation

The only difference between single-master mode operation and multi-master mode operation lies in mode fault error detection (refer to section 37.3.10, Error Detection). When operating in single-master mode, the RSPI does not detect mode fault errors whereas the RSPI running in multi-master mode does detect mode fault errors. This section explains operations that are common to single-master mode and multi-master mode.

(1) Starting a Serial Transfer

The RSPI updates the data in the transmit buffer (SPTX) when data is written to the RSPI data register (SPDR) with the RSPI transmit buffer being empty (the SPTEF flag is 1 and data for the next transfer is not set). When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR register, the RSPI copies data from the transmit buffer to the shift register and starts serial transfer. Upon copying transmit data to the shift register, the RSPI changes the status of the shift register to “full”, and upon termination of serial transfer, it changes the status of the shift register to “empty”. The status of the shift register cannot be referenced.
For details on the RSPI transfer format, refer to section 37.3.5, Transfer Format. The polarity of the SSLAi output pins depends on the SSLP register settings.

(2) Terminating a Serial Transfer

Irrespective of the SPCMDm.CPHA bit, the RSPI terminates the serial transfer after transmitting an RSPCKA edge corresponding to the final sampling timing. If free space is available in the receive buffer (SPRX) (the SPRF flag is 0), upon termination of serial transfer, the RSPI copies data from the shift register to the receive buffer of the SPDR register. It should be noted that the final sampling timing varies depending on the bit length of transfer data. In master mode, the RSPI data length depends on the SPCMDm.SPB[3:0] bit setting. The polarity of the SSLAi output pin depends on the SSLP register settings.
For details on the RSPI transfer format, refer to section 37.3.5, Transfer Format.

(3) Sequence Control

The transfer format that is employed in master mode is determined by the SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers.

The SPSCR register is a register used to determine the sequence configuration for serial transfers that are executed by the RSPI in master mode. The following items are set in the SPCMDm register: SSLAi pin output signal value, MSB/LSB first, data length, some of the bit rate settings, RSPCK polarity/phase, whether the SPCKD register is to be referenced, whether the SSLND register is to be referenced, and whether the SPND register is to be referenced. The SPBR register holds some of the bit rate settings; the SPCKD register, an RSPI clock delay value; the SSLND register, an SSL negation delay; and the SPND register, a next-access delay value.

According to the sequence length that is assigned to the SPSCR register, the RSPI makes up a sequence comprised of a part or all of the SPCMDm register. The RSPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the RSPI function is enabled, the RSPI loads the pointer to the commands in the SPCMD0 register, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The RSPI increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, the RSPI sets the pointer in the SPCMD0 register, and in this manner the sequence is executed repeatedly.

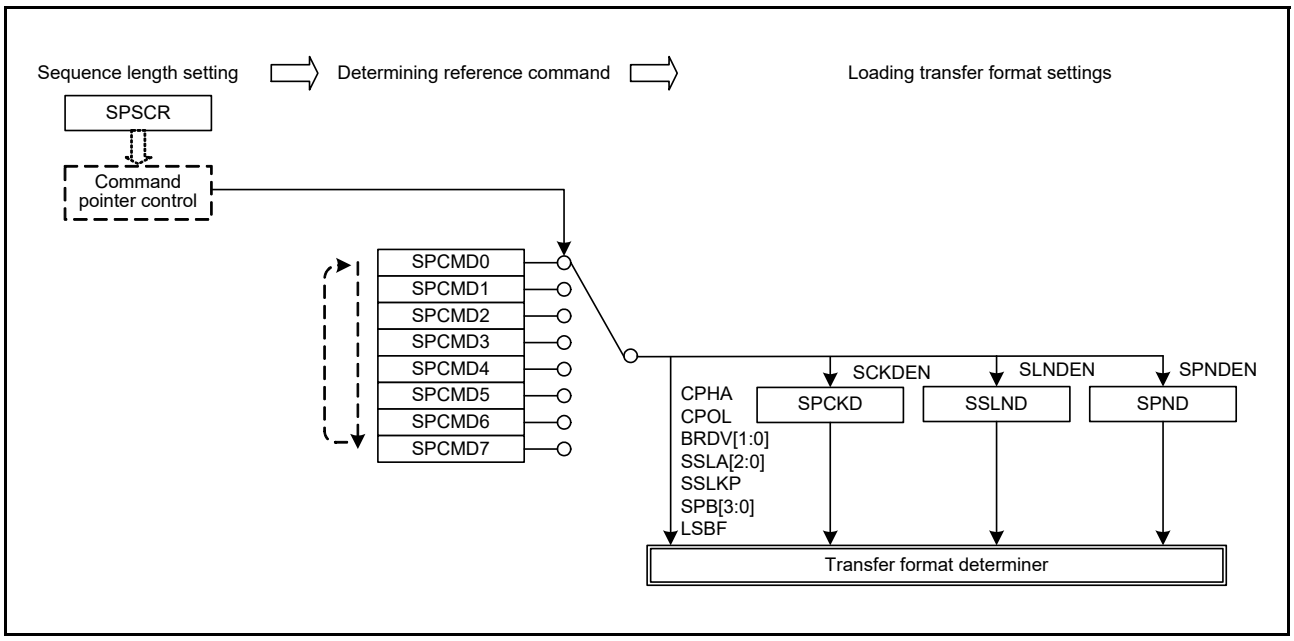

Figure 37.34 Procedure for Determining the Form of Serial Transfer in Master Mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

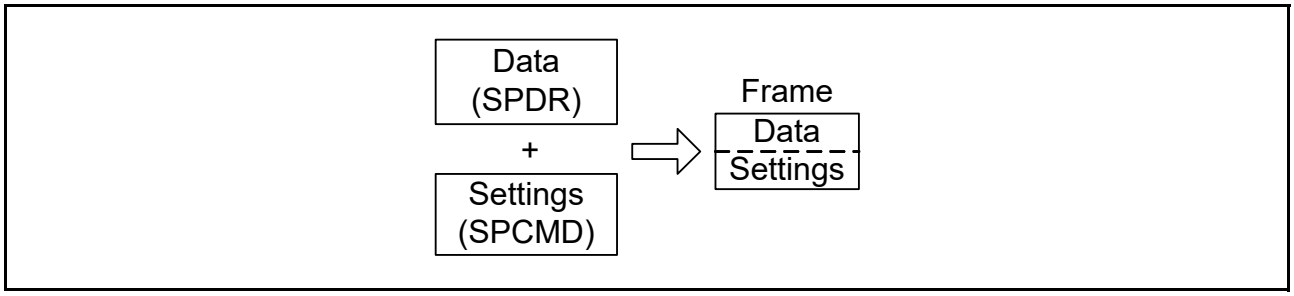

Figure 37.35 Concept of a Frame

Figure 37.36 shows the relationship between the command and the transmit and receive buffers in the sequence of operations specified by the settings in Table 37.4.

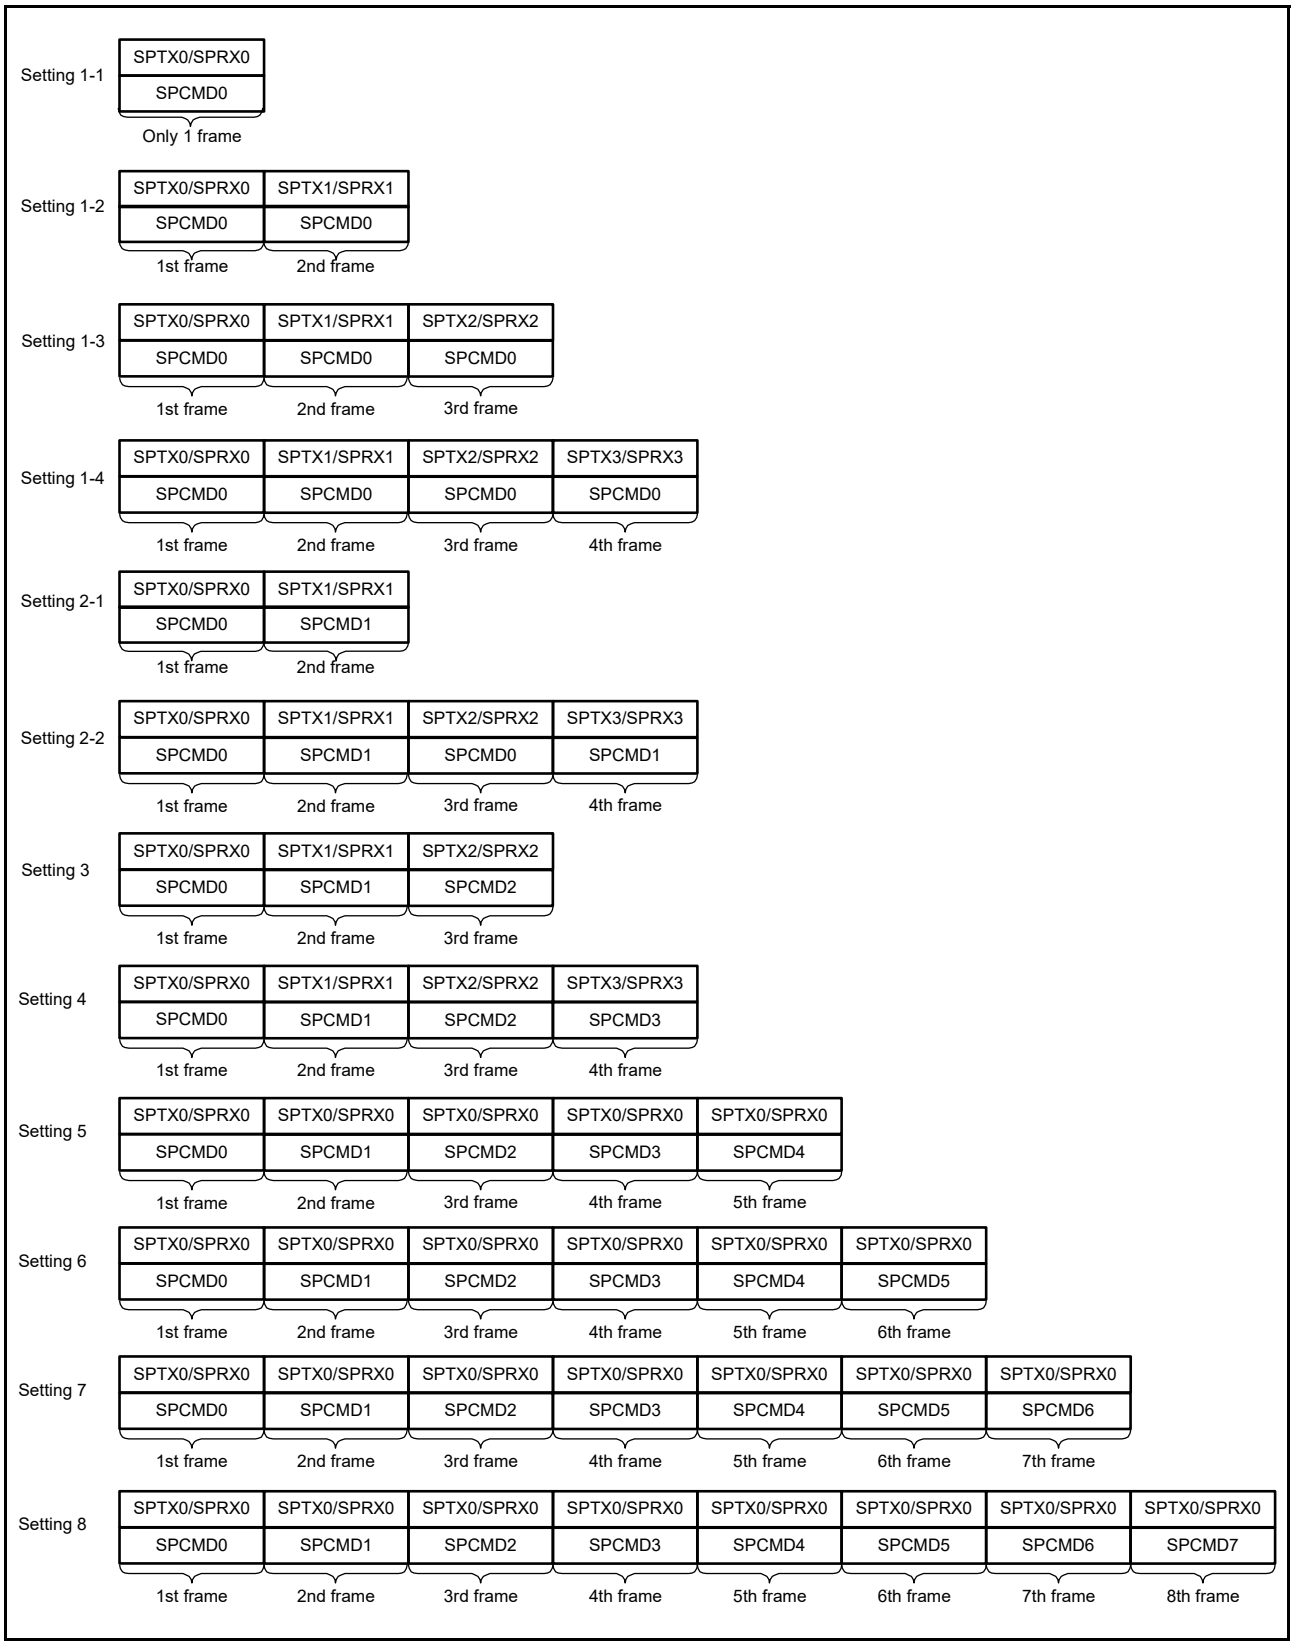

Figure 37.36 Correspondence between the RSPI Command Register and Transmit/Receive Buffers in Sequence Operations

(4) Burst Transfer

If the SPCMDm.SSLKP bit that the RSPI references during the current serial transfer is 1, the RSPI keeps the SSLAi signal level during the serial transfer until the beginning of the SSLAi signal assertion for the next serial transfer. If the SSLAi signal level for the next serial transfer is the same as the SSLAi signal level for the current serial transfer, the RSPI can execute continuous serial transfers while keeping the SSLAi signal assertion status (burst transfer).
Figure 37.37 shows an example of an SSLAi signal operation for the case where a burst transfer is implemented using SPCMD0 and SPCMD1 register settings. The text below explains the RSPI operations (1) to (7) as shown in Figure 37.37. It should be noted that the polarity of the SSLAi output signal depends on the SSLP register settings.

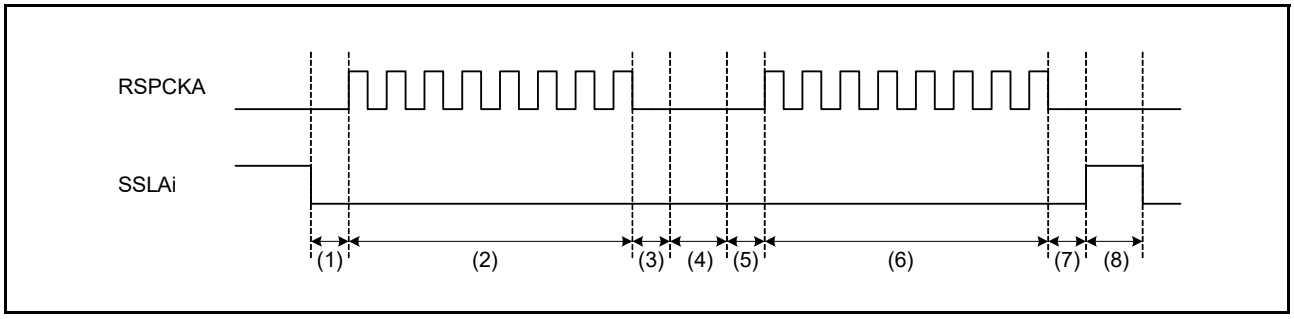

Figure 37.37 Example of Burst Transfer Operation Using SSLKP Bit (CPHA = 1, CPOL = 0)

(1) Based on the SPCMD0 register, the RSPI asserts the SSLAi signal and inserts RSPCK delays.
(2) The RSPI executes serial transfers according to the SPCMD0 register.
(3) The RSPI inserts SSL negation delays.
(4) Since the SPCMD0.SSLKP bit is 1, the RSPI keeps the SSLAi signal value on the SPCMD0 register. This period is sustained, at the shortest, for a period equal to the next-access delay of the SPCMD0 register. If the shift register is empty after the passage of a minimum period, this period is sustained until the transmit data is stored in the shift register for the next transfer.
(5) Based on the SPCMD1 register, the RSPI inserts RSPCK delays.
(6) The RSPI executes serial transfers according to the SPCMD1 register.
(7) The RSPI inserts SSL negation delays.
(8) Because the SPCMD1.SSLKP bit is 0, the RSPI negates the SSLAi signal. In addition, a next-access delay is inserted according to the SPCMD1 register.

If the SSLAi signal output settings in the SPCMDm register in which 1 is assigned to the SSLKP bit are different from the SSLAi signal output settings in the SPCMDm register to be used in the next transfer, the RSPI switches the SSLAi signal status to SSLAi signal assertion ((5) in Figure 37.37) corresponding to the command for the next transfer. Note that if such an SSLAi signal switching occurs, the slaves that drive the MISOA signal compete, and collision of signal levels may occur.
The RSPI in master mode references the SSLAi signal operation within the module for the case where the SSLKP bit is not used. Even when the SPCMDm.CPHA bit is 0, the RSPI can accurately start serial transfers by using the SSLAi signal assertion for the next transfer that is detected internally.
When the SPCR3.SCKDDIS bit is set to 1 (Does not insert delays between data bytes during burst transfer), the delays described in (3) to (5) above are not inserted and only delay of 0.5 cycles of RSPCK is inserted.

(5) RSPCK Delay (t1)

The RSPCK delay value in master mode depends on the SPCMDm.SCKDEN bit setting and the SPCKD register setting. The RSPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines an RSPCK delay value during serial transfer by using the SPCMDm.SCKDEN bit and the SPCKD register, as listed in Table 37.8. For a definition of RSPCK delay, refer to section 37.3.5, Transfer Format.
When the SPCMDm.SSLKP bit is set to 1 (burst transfer) and the SPCR3.SCKDDIS bit is set to 1 (Does not insert delays between data bytes during burst transfer), the RSPCK delay is inserted only in the first frame.

Table 37.8 Relationship among SCKDEN Bit, SPCKD, and RSPCK Delay Value

SPCMDm.SCKDEN Bit	SPCKD.SCKDL[2:0] Bits	RSPCK Delay Value
0	000b to 111b	1 RSPCK
1	000b	1 RSPCK
	001b	2 RSPCK
	010b	3 RSPCK
	011b	4 RSPCK
	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(6) SSL Negation Delay (t2)

The SSL negation delay value in master mode depends on the SPCMDm.SLNDEN bit setting and the SSLND register setting. The RSPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines an SSL negation delay value during serial transfer by using the SPCMDm.SLNDEN bit and the SSLND register, as listed in Table 37.9. For a definition of SSL negation delay, refer to section 37.3.5, Transfer Format.
When the SPCMDm.SSLKP bit is set to 1 (burst transfer) and the SPCR3.SCKDDIS bit is set to 1 (Does not insert delays between data bytes during burst transfer), the SSL negation delay is inserted only in the last frame.

Table 37.9 Relationship among SLNDEN Bit, SSLND, and SSL Negation Delay Value

SPCMDm.SLNDEN Bit	SSLND.SLNDL[2:0] Bits	SSL Negation Delay Value
0	000b to 111b	1 RSPCK
1	000b	1 RSPCK
	001b	2 RSPCK
	010b	3 RSPCK
	011b	4 RSPCK
	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(7) Next-Access Delay (t3)

The next-access delay value in master mode depends on the SPCMDm.SPNDEN bit setting and the SPND setting. The RSPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines a next-access delay value during serial transfer by using the SPCMDm.SPNDEN bit and SPND, as listed in Table 37.10. For a definition of next-access delay, refer to section 37.3.5, Transfer Format.

When the SPCMDm.SSLKP bit is set to 1 (burst transfer) and the SPCR3.SCKDDIS bit is set to 1 (Does not insert delays between data bytes during burst transfer), the next-access delay is inserted only in the last frame.

Table 37.10 Relationship among SPNDEN Bit, SPND, and Next-Access Delay Value

SPCMDm.SPNDEN Bit	SPND.SPNDL[2:0] Bits	Next-Access Delay Value
0	000b to 111b	1 RSPCK + 2 PCLK
1	000b	1 RSPCK + 2 PCLK
	001b	2 RSPCK + 2 PCLK
	010b	3 RSPCK + 2 PCLK
	011b	4 RSPCK + 2 PCLK
	100b	5 RSPCK + 2 PCLK
	101b	6 RSPCK + 2 PCLK
	110b	7 RSPCK + 2 PCLK
	111b	8 RSPCK + 2 PCLK

(8) Initialization Flowchart

Figure 37.38 is a flowchart illustrating an example of initialization in SPI operation when the RSPI is used in master mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

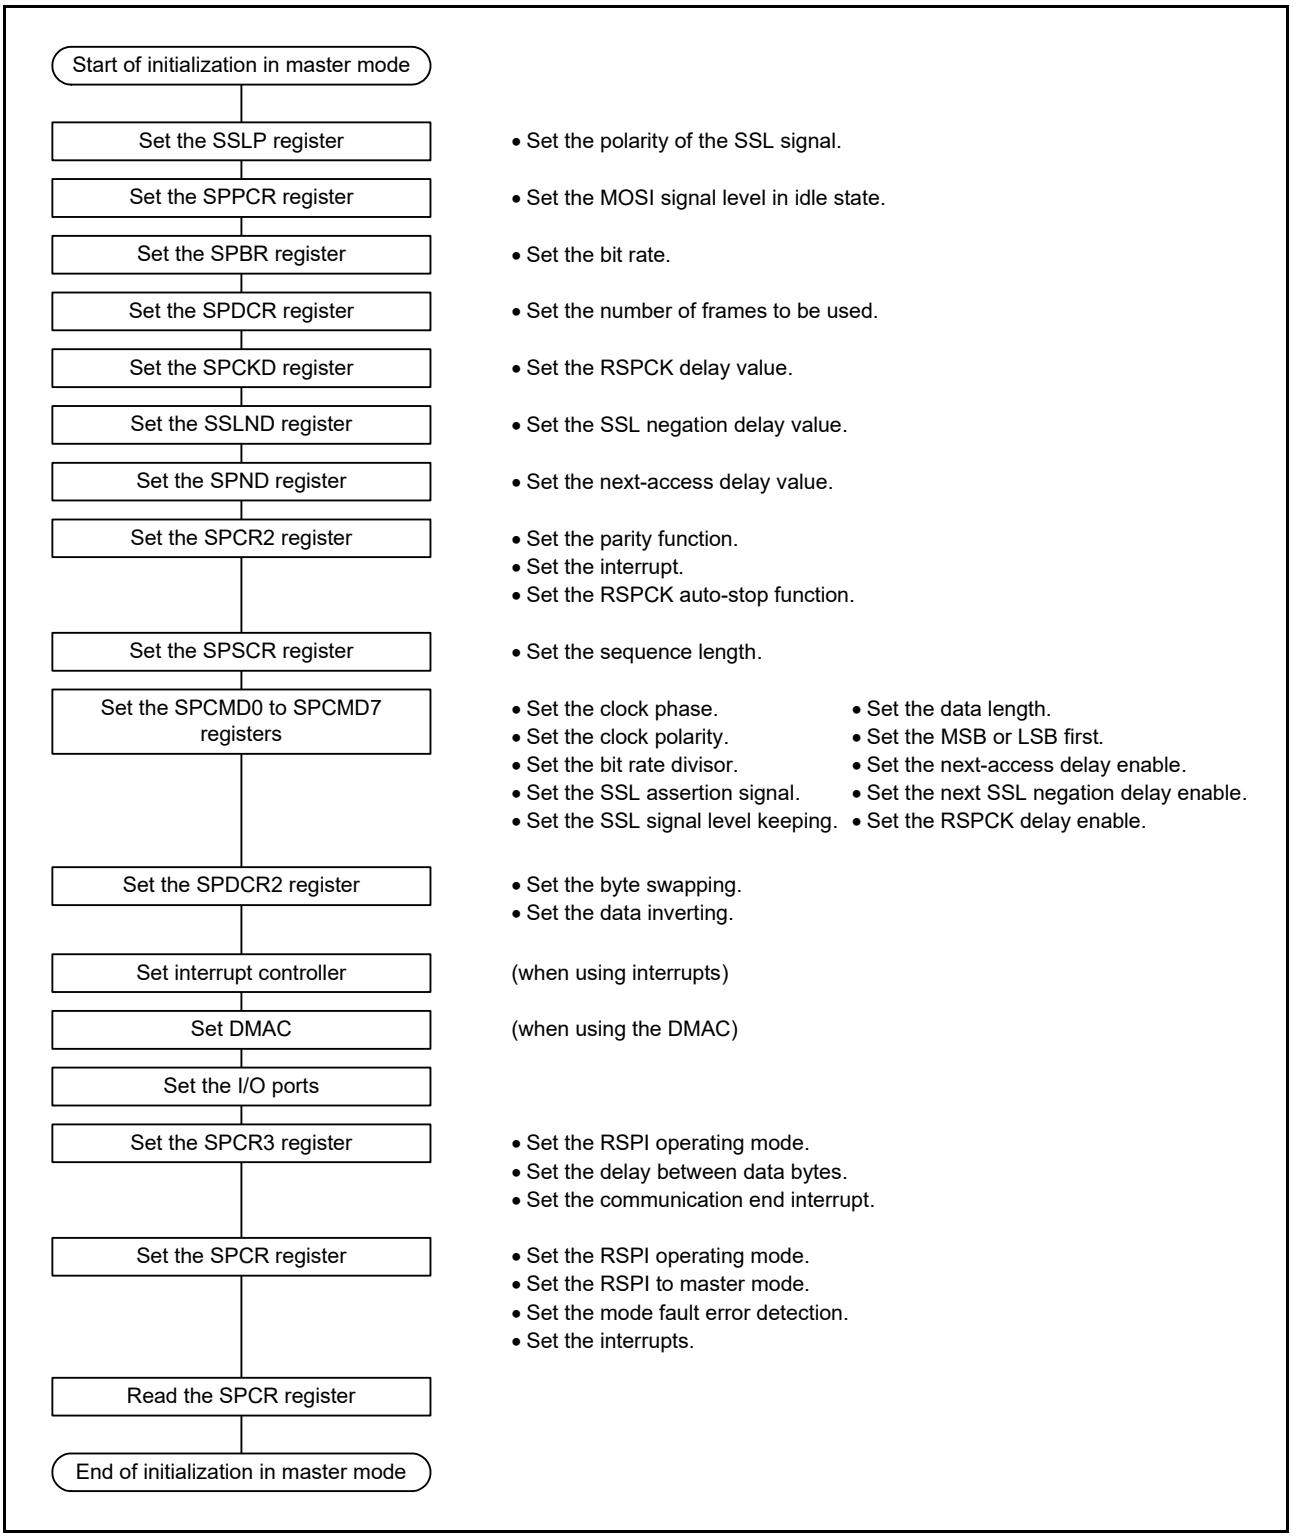

Figure 37.38 Example of Initialization Flowchart in Master Mode (SPI Operation)

(9) Software Processing Flow

Figure 37.40 to Figure 37.42 show examples of the flow of software processing.

(a) Communication Preprocessing Flow

Before starting communications, clear the error flags and disable the idle interrupt and communication end interrupt. Then enable the RSPI function and the required interrupts at the same time.

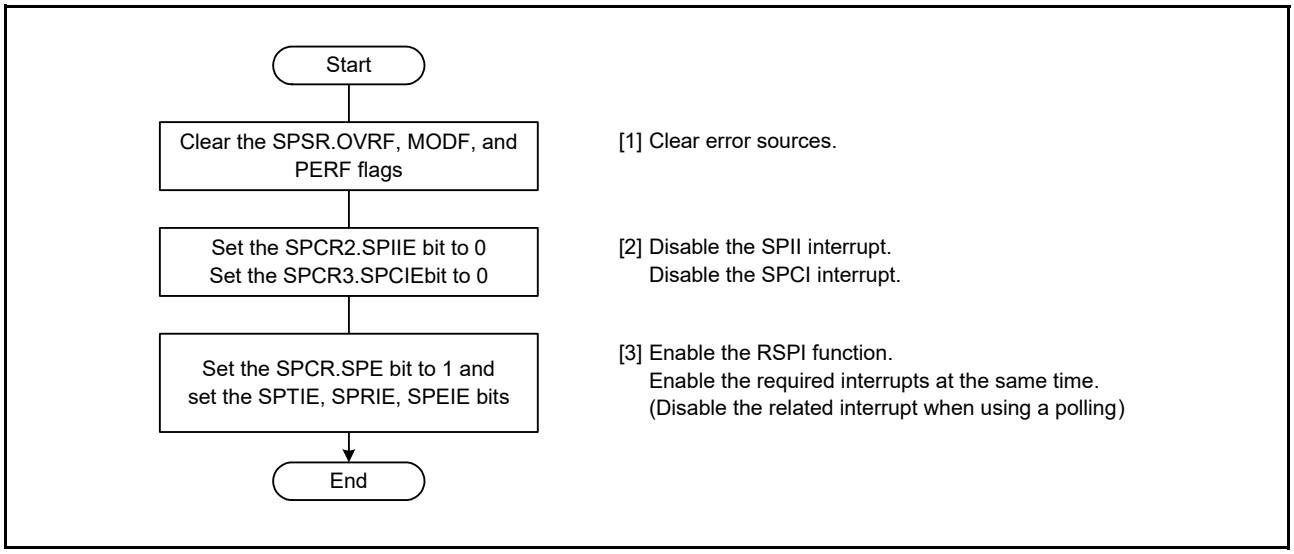

Figure 37.39 Flowchart in Master Mode (Communication Preprocess)

(b) Transmit Processing Flow

When transmitting data, the CPU will be notified of the completion of data transmission by enabling the SPII or SPCI interrupt after the last writing of data for transmission.

The completion of data transmission can also be checked by polling to see if the SPSR.IDLNF flag has become 0 or the SPCF flag has become 1, instead of using the SPII or SPCI interrupt. However, one cycle of PCLK is required for the time from when data for transmission is written in the SPDR register to when the IDLNF flag becomes 1 and the SPCF flag becomes 0. After the last data is written in the SPDR register, discard the value of the SPSR register once not to judge the condition with the IDLNF flag which has not yet become 1 or the SPCF flag which has not yet become 0, and read and use the value of the IDLNF or SPCF flag to confirm the completion of data transmission.

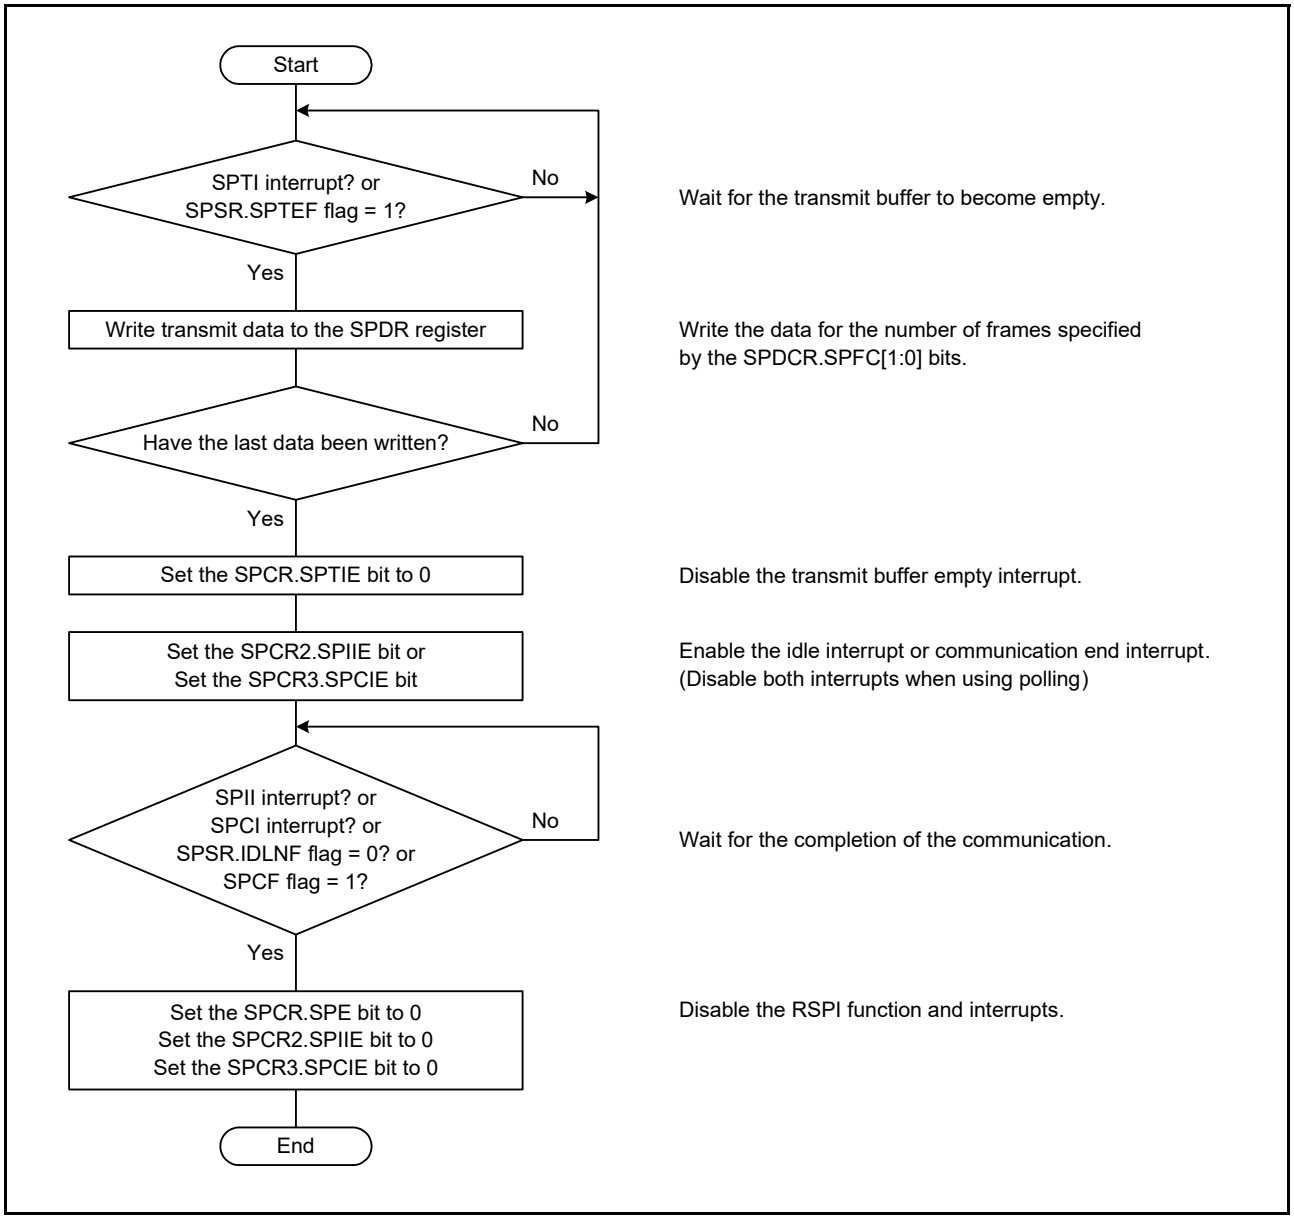

Figure 37.40 Flowchart in Master Mode (Transmission)

(c) Receive Processing Flow

The RSPI does not support receive-only simplex communications in master mode, so processing for transmission is required.

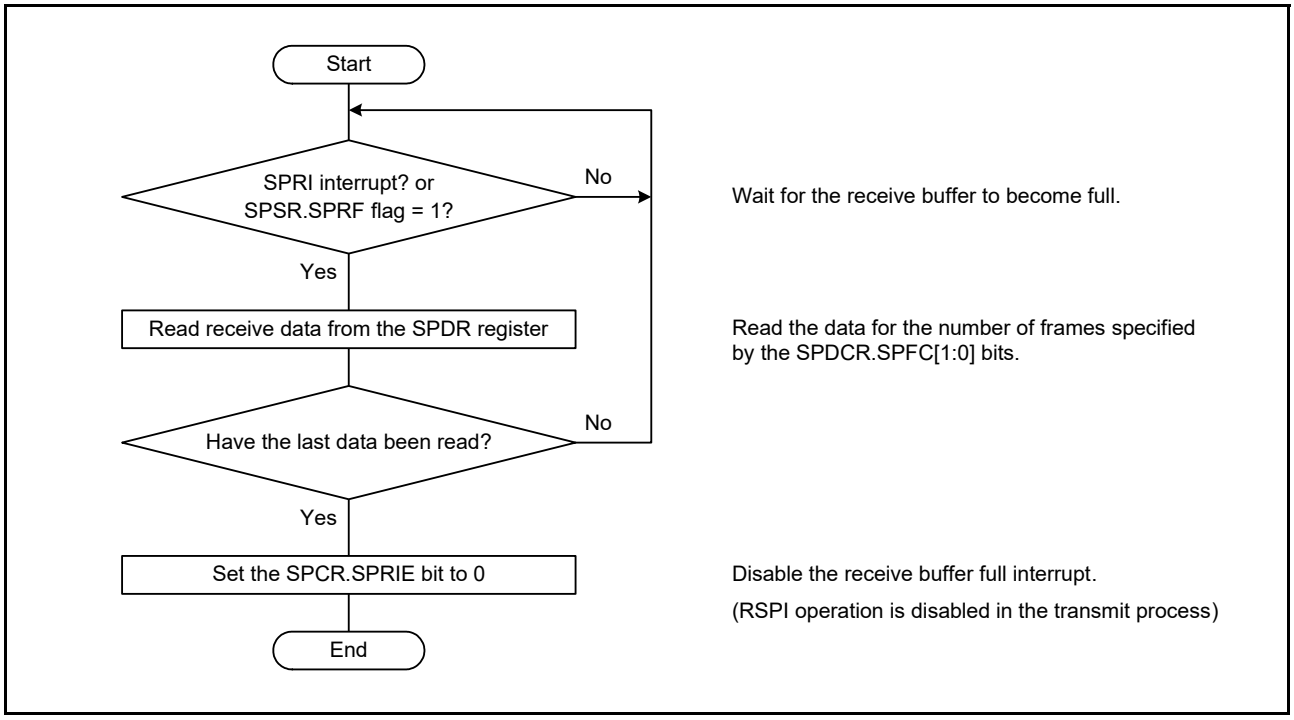

Figure 37.41 Flowchart in Master Mode (Reception)

(d) Flow of Error Processing

When a mode fault error is generated, the SPCR.SPE bit is automatically cleared, stopping operations for transmission and reception. For errors from other sources, however, the SPCR.SPE bit is not cleared and operations for transmission and reception continue; accordingly, we recommend clearing of the SPCR.SPE bit to stop operations in the case of errors other than mode fault errors. Not doing so will lead to updating of the SPSSR.SPECM[2:0] bits.
When interrupts are used and an error occurs, if the ICU.IRn.IR flag for the SPTI or SPRI interrupt request is set to 1, clear the ICU.IRn.IR flag in the error processing routine. If the SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the RSPI.

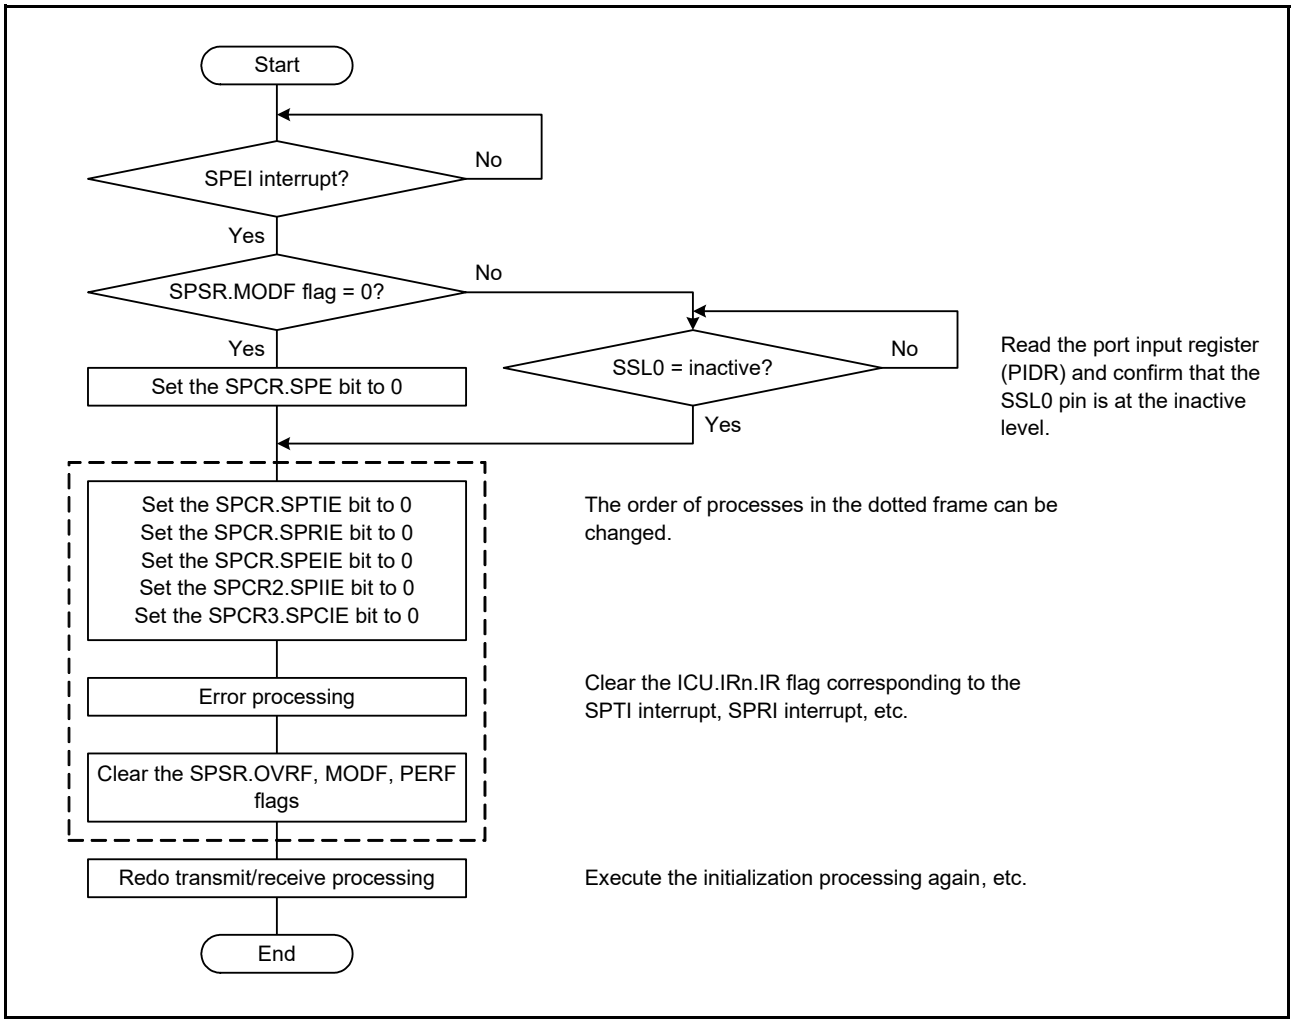

Figure 37.42 Flowchart for Master Mode (Error Processing)

37.3.12.2 Slave Mode Operation

(1) Starting a Serial Transfer

If the SPCMD0.CPHA bit is 0, when detecting an SSLA0 input signal assertion, the RSPI needs to start driving valid data to the MISOA output signal. For this reason, when the CPHA bit is 0, the assertion of the SSLA0 input signal triggers the start of a serial transfer.
If the CPHA bit is 1, when detecting the first RSPCKA edge in an SSLA0 signal asserted condition, the RSPI needs to start driving valid data to the MISOA output signal. For this reason, when the CPHA bit is 1, the first RSPCKA edge in an SSLA0 signal asserted condition triggers the start of a serial transfer.
Irrespective of the CPHA bit setting, the timing at which the RSPI starts driving of the MISOA output signal is the SSLA0 signal assertion timing. The data which is output by the RSPI is either valid or invalid, depending on the CPHA bit setting.
For details on the RSPI transfer format, refer to section 37.3.5, Transfer Format. The polarity of the SSLA0 input signal depends on the setting of the SSLP.SSL0P bit.

(2) Terminating a Serial Transfer

Irrespective of the SPCMD0.CPHA bit, the RSPI terminates the serial transfer after detecting an RSPCKA edge corresponding to the final sampling timing. When free space is available in the receive buffer (the SPRF flag is 0), upon termination of serial transfer the RSPI copies received data from the shift register to the receive buffer of the SPDR register. Upon termination of a serial transfer the RSPI changes the status of the shift register to “empty”, regardless of the receive buffer state. A mode fault error occurs if the RSPI detects an SSLA0 input signal negation from the beginning of serial transfer to the end of serial transfer (refer to section 37.3.10, Error Detection).
The final sampling timing changes depending on the bit length of transfer data. In slave mode, the RSPI data length depends on the SPCMD0.SPB[3:0] bit setting. The polarity of the SSLA0 input signal depends on the SSLP.SSL0P bit setting.
For details on the RSPI transfer format, refer to section 37.3.5, Transfer Format.

(3) Notes on Single-Slave Operations

If the SPCMD0.CPHA bit is 0, the RSPI starts serial transfers when it detects the assertion edge for an SSLA0 input signal. In the type of configuration shown in Figure 37.7 as an example, if the RSPI is used in single-slave mode, the SSLA0 signal is fixed at the active state. Therefore, when the CPHA bit is set to 0, the RSPI cannot correctly start a serial transfer. To correctly execute transmit/receive operations by the RSPI in slave mode in a configuration in which the SSLA0 input signal is fixed at the active state, the CPHA bit should be set to 1. If there is a need for setting the CPHA bit to 0, the SSLA0 input signal should not be fixed.

(4) Burst Transfer

If the SPCMD0.CPHA bit is 1, continuous serial transfer (burst transfer) can be executed while retaining the assertion state for the SSLA0 input signal. If the CPHA bit is 1, the period from the first RSPCKA edge to the sampling timing for the reception of the final bit in an SSLA0 signal active state corresponds to a serial transfer period. Even when the SSLA0 input signal remains at the active level, the RSPI can accommodate burst transfers because it can detect the start of an access.
If the CPHA bit is 0, the second and subsequent serial transfers during burst transfer cannot be executed correctly.

(5) Initialization Flowchart

Figure 37.43 is a flowchart illustrating an example of initialization in SPI operation when the RSPI is used in slave mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

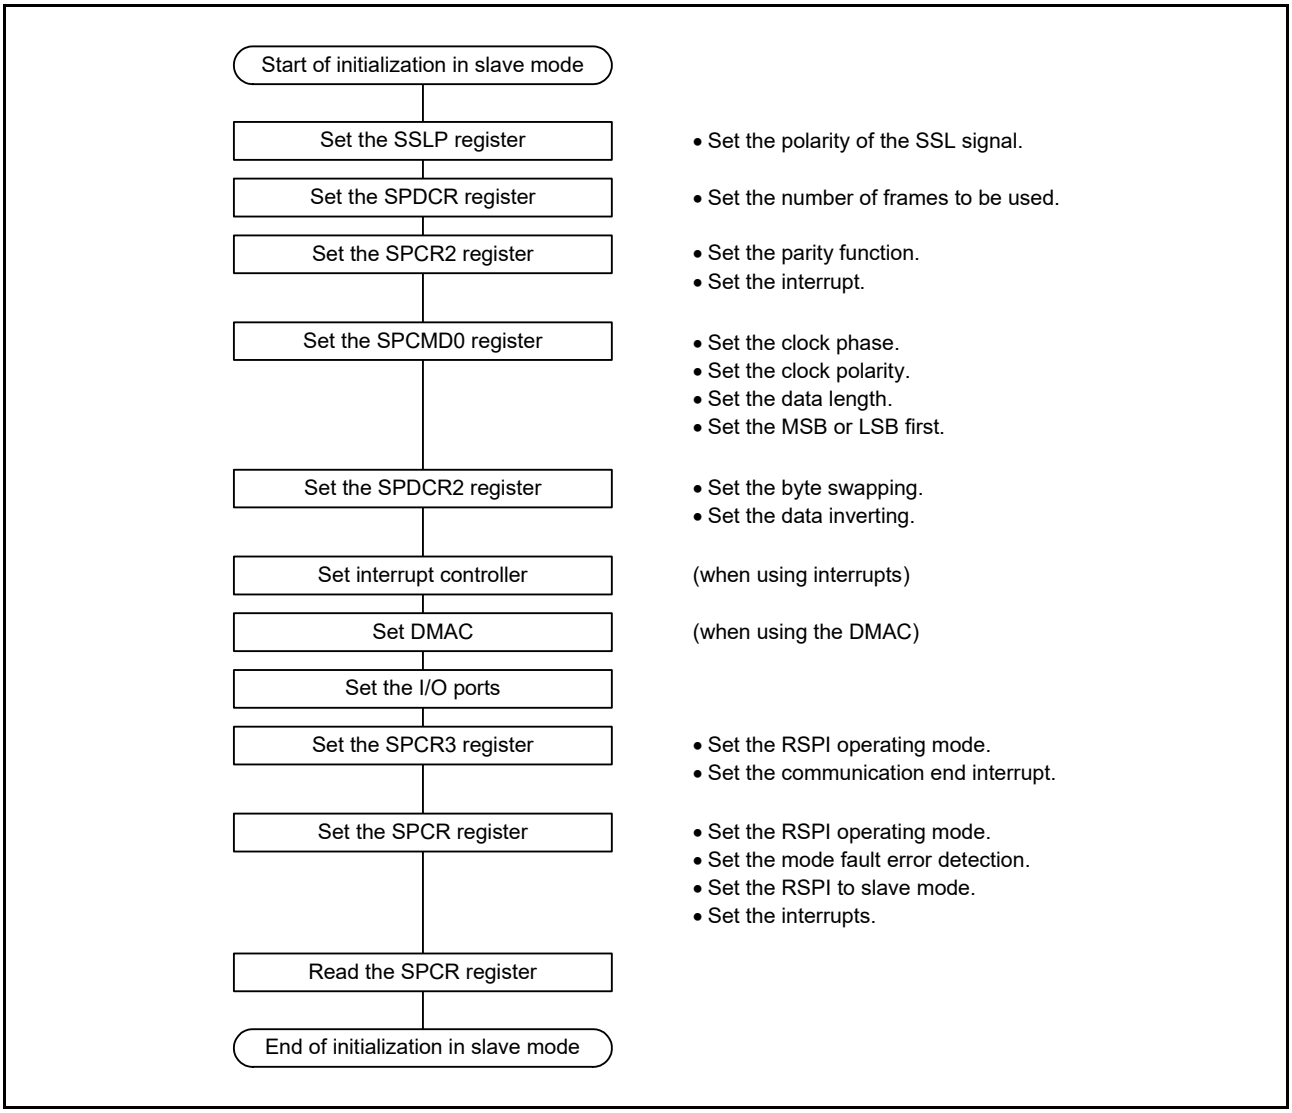

Figure 37.43 Example of Initialization Flowchart in Slave Mode (SPI Operation)

(6) Software Processing Flow

Figure 37.45 to Figure 37.47 show examples of the flow of software processing.

(a) Communication Preprocessing Flow

Before starting communications, clear the error flags and disable the idle interrupt and communication end interrupt. Then enable the RSPI function and the required interrupts at the same time.

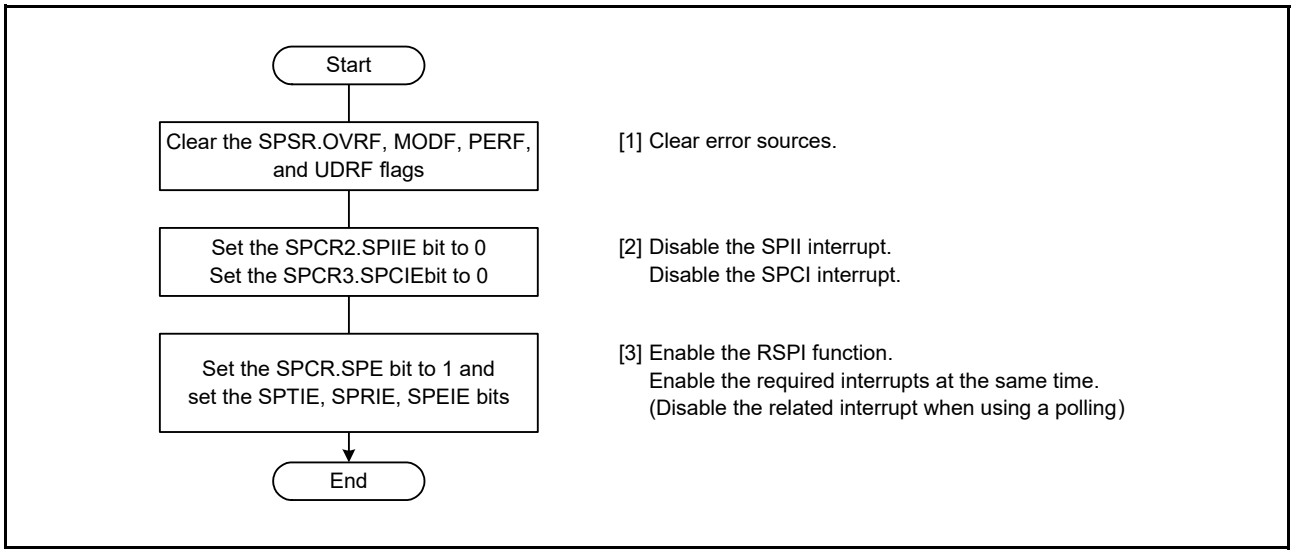

Figure 37.44 Flowchart in Slave Mode (Communication Preprocess)

(b) Transmit Processing Flow

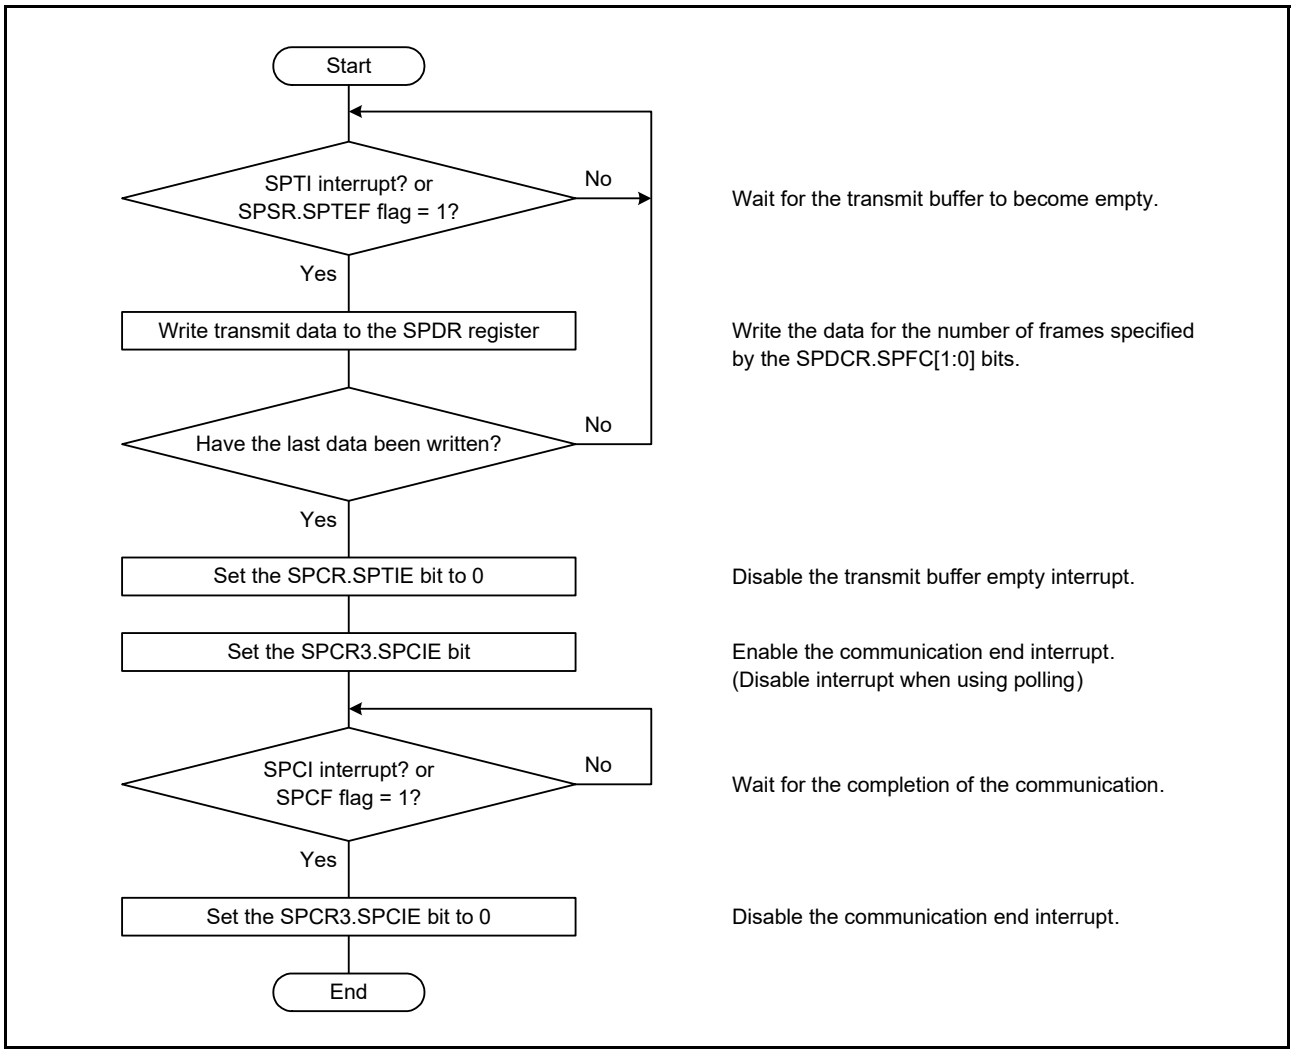

Figure 37.45 Flowchart in Slave Mode (Transmission)

(c) Receive Processing Flow

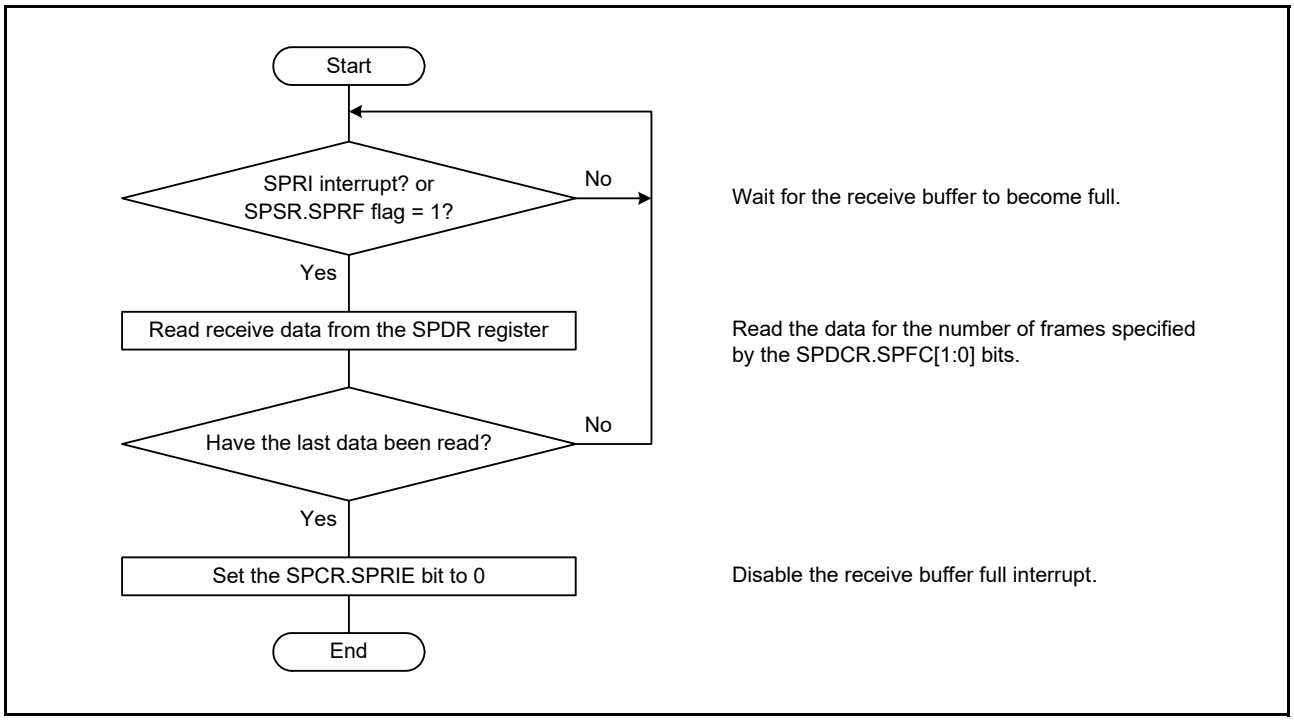

Figure 37.46 Flowchart in Slave Mode (Reception)

(d) Flow of Error Processing

In slave mode, even when a mode fault error is generated, the SPSR.MODF flag can be cleared regardless of the status of the SSLA0 pin.

When interrupts are used and an error occurs, if the ICU.IRn.IR flag for the SPTI or SPRI interrupt request is set to 1, clear the ICU.IRn.IR flag in the error processing routine. If the SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the RSPI.

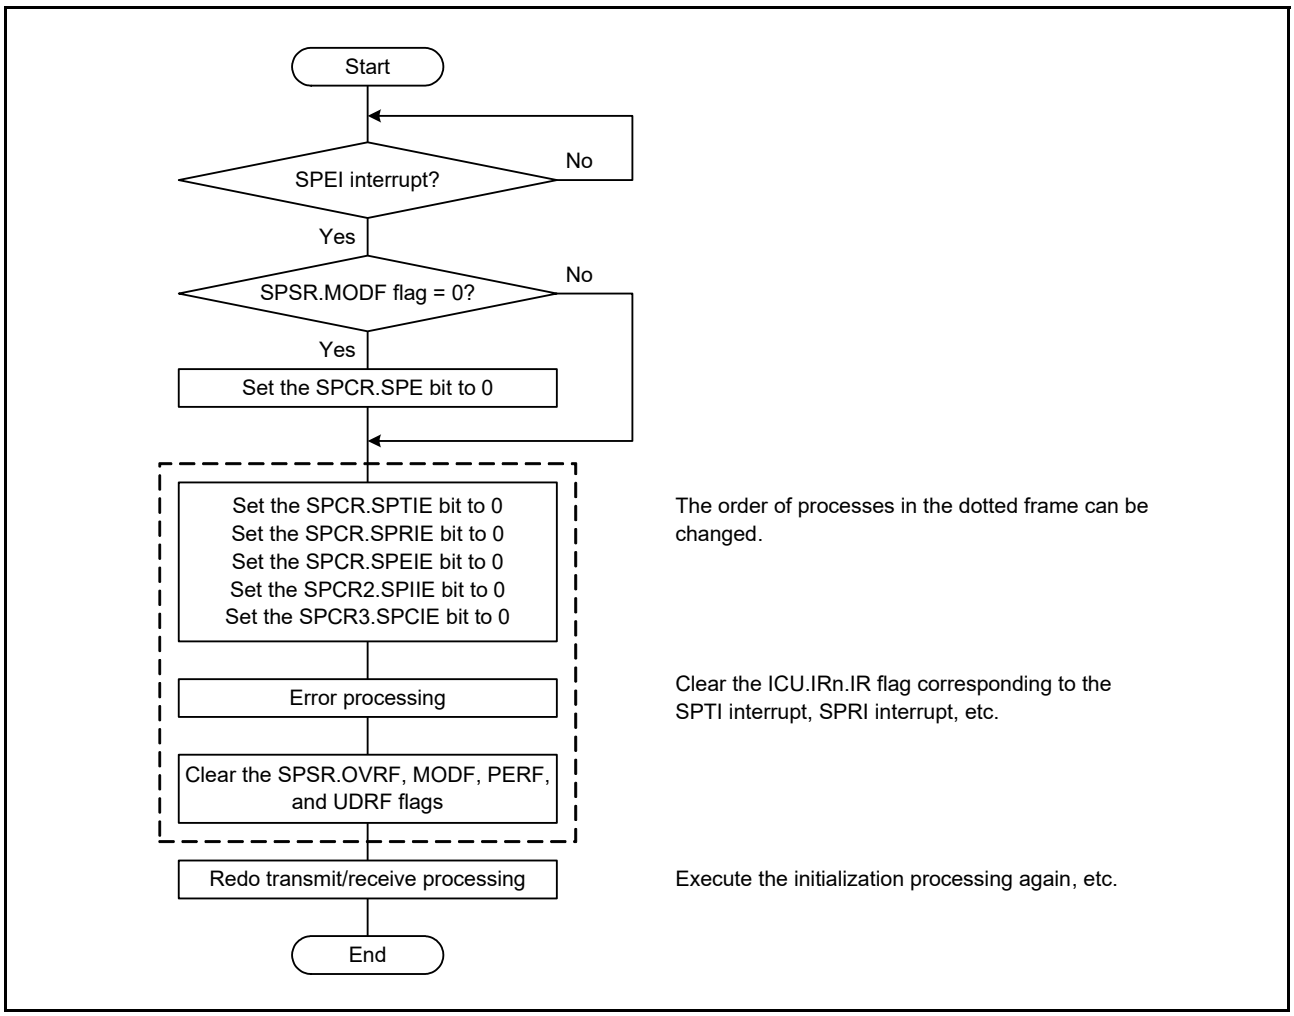

Figure 37.47 Flowchart for Slave Mode (Error Processing)

37.3.13 Clock Synchronous Operation

Setting the SPCR.SPMS bit to 1 selects clock synchronous operation of the RSPI. In clock synchronous operation, the SSLAi pin is not used, and the three pins of RSPCKA, MOSIA, and MISOA handle communications. The SSLAi pin is available as I/O port pins.
Although clock synchronous operation does not require use of the SSLAi pin, operation of the module is the same as in SPI operation. That is, in both master and slave mode operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected because the SSLAi pin is not used.
Furthermore, do not set the SPCMDm.CPHA bit to 0 if clock synchronous operation is to proceed in slave mode (SPCR.MSTR = 0).

37.3.13.1 Master Mode Operation

(1) Starting a Serial Transfer

The RSPI updates the data in the transmit buffer (SPTX) of the SPDR register when data is written to the SPDR register with the transmit buffer being empty (the SPTEF flag is 1 and data for the next transfer is not set). When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR register, the RSPI copies data from the transmit buffer to the shift register and starts serial transmission. Upon copying transmit data to the shift register, the RSPI changes the status of the shift register to “full”, and upon termination of serial transfer, it changes the status of the shift register to “empty”. The status of the shift register cannot be referenced.
For details on the RSPI transfer format, refer to section 37.3.5, Transfer Format.
However, transfer in clock synchronous operation is conducted without the SSLA0 output signal.

(2) Terminating a Serial Transfer

The RSPI terminates the serial transfer after transmitting an RSPCKA edge corresponding to the sampling timing. If free space is available in the receive buffer (SPRX) (the SPRF flag is 0), upon termination of serial transfer, the RSPI copies data from the shift register to the receive buffer of the RSPI data register (SPDR).
It should be noted that the final sampling timing varies depending on the bit length of transfer data. In master mode, the RSPI data length depends on the SPCMDm.SPB[3:0] bit setting.
For details on the RSPI transfer format, refer to section 37.3.5, Transfer Format.
However, transfer in clock synchronous operation is conducted without the SSLA0 output signal.

(3) Sequence Control

The transfer format employed in master mode is determined by SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers. Although the SSLAi signals are not output in clock synchronous operation, these settings are valid.
The SPSCR register is a register used to determine the sequence configuration for serial transfers that are executed by the RSPI in master mode. The following items are set in the SPCMDm register: SSLAi output signal value, MSB/LSB first, data length, some of the bit rate settings, RSPCKA polarity/phase, whether the SPCKD register is to be referenced, whether the SSLND register is to be referenced, and whether the SPND register is to be referenced. The SPBR register holds some of the bit rate settings; the SPCKD register, an RSPI clock delay value; the SSLND register, an SSL negation delay; and the SPND register, a next-access delay value.
According to the sequence length that is assigned to the SPSCR register, the RSPI makes up a sequence comprised of a part or all of the SPCMDm register. The RSPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the RSPI function is enabled, the RSPI loads the pointer to the commands in the SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The RSPI increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, the RSPI sets the pointer in the SPCMD0 register, and in this manner the sequence is executed repeatedly.

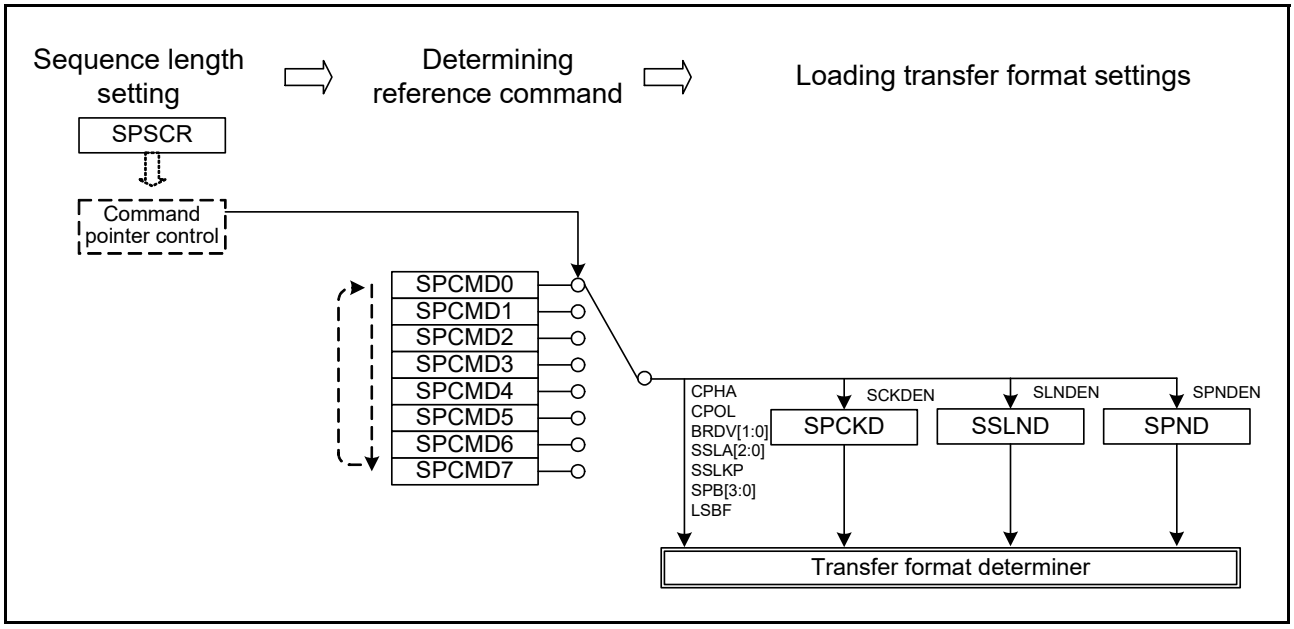

Figure 37.48 Procedure for Determining the Form of Serial Transmission in Master Mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

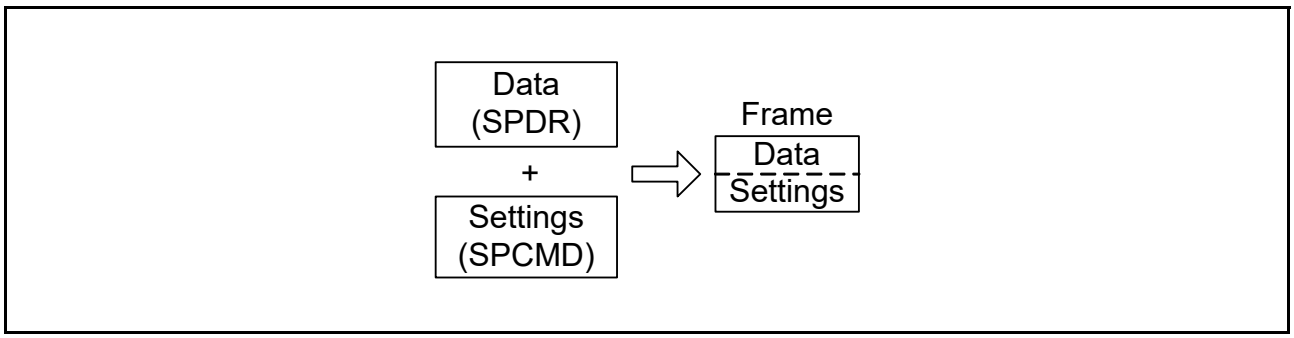

Figure 37.49 Concept of a Frame

Figure 37.50 shows the relationship between the command and the transmit and receive buffers in the sequence of operations specified by the settings in Table 37.4.

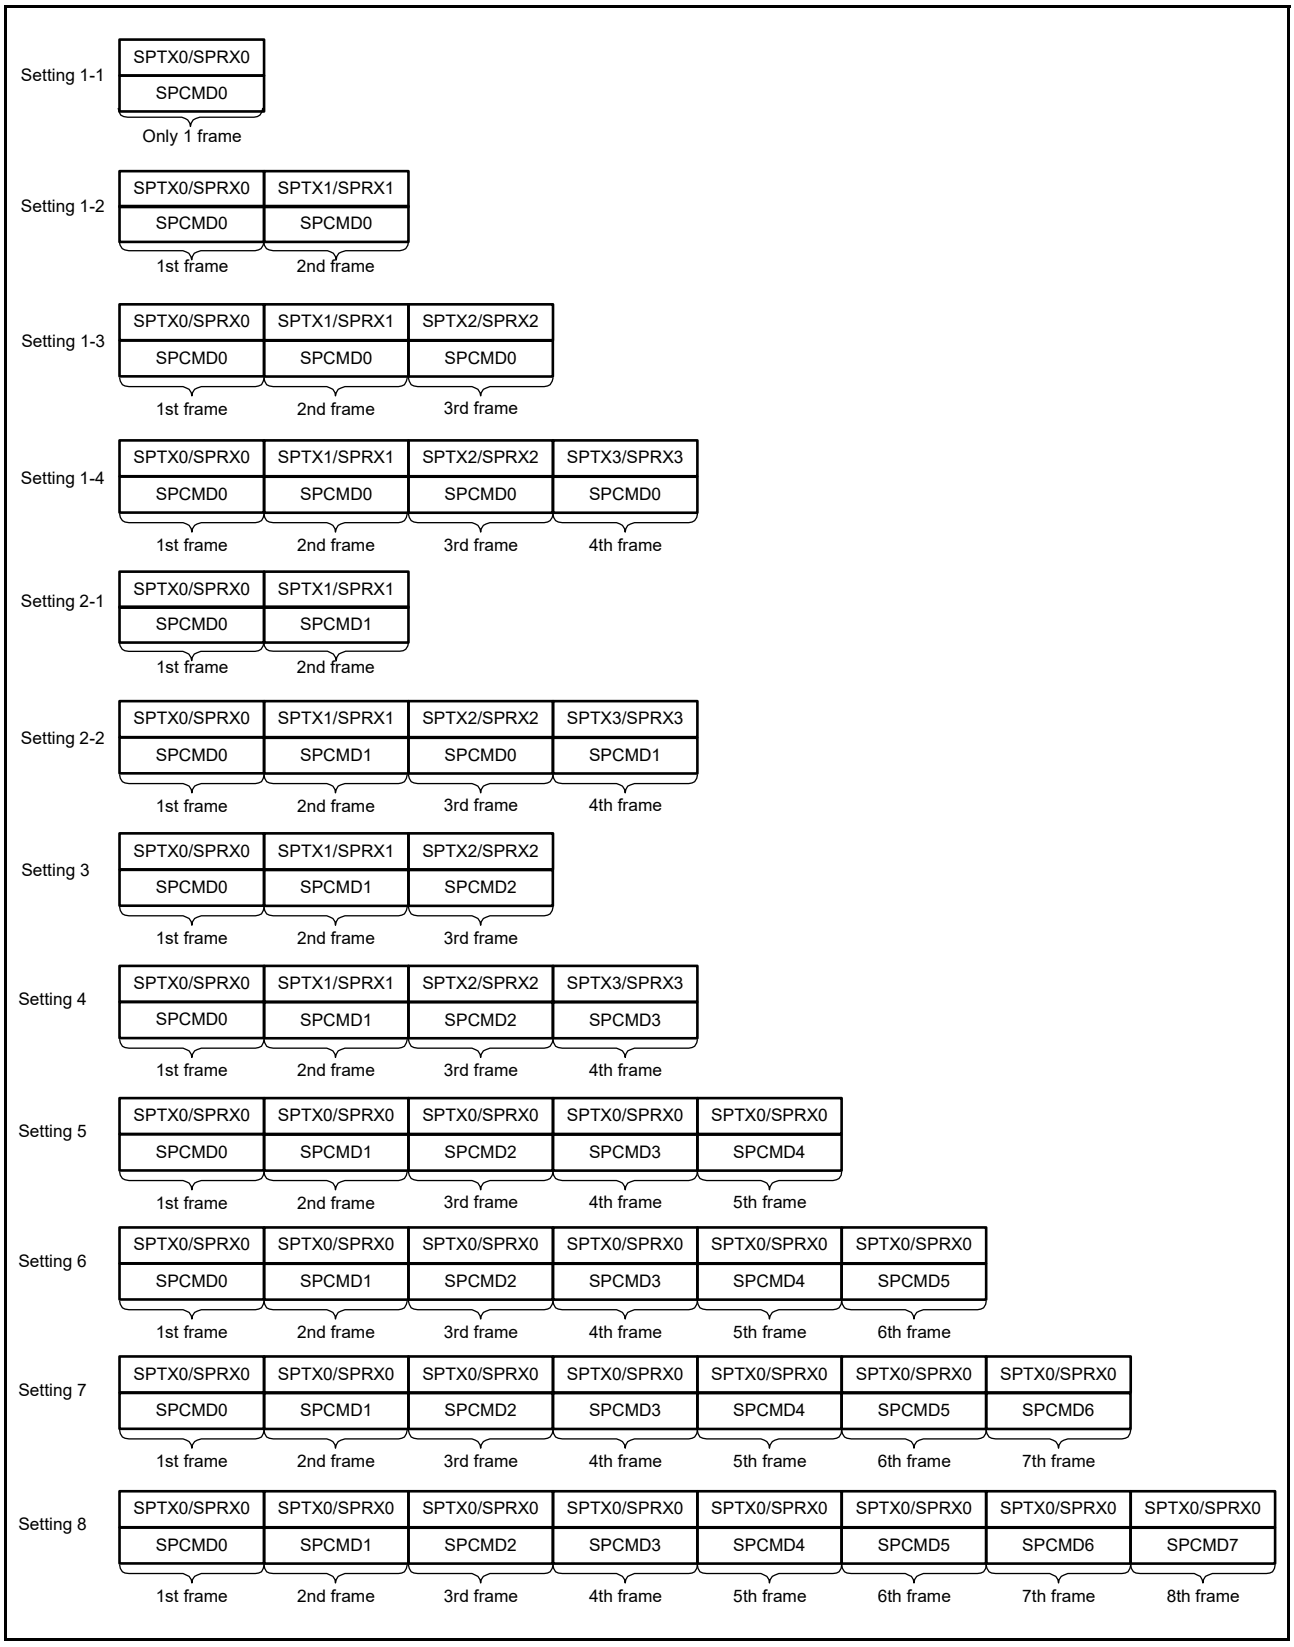

Figure 37.50 Correspondence between the RSPI Command Register and Transmit/Receive Buffers in Sequence Operations

(4) Initialization Flowchart

Figure 37.51 is a flowchart illustrating an example of initialization in clock synchronous operation when the RSPI is used in master mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

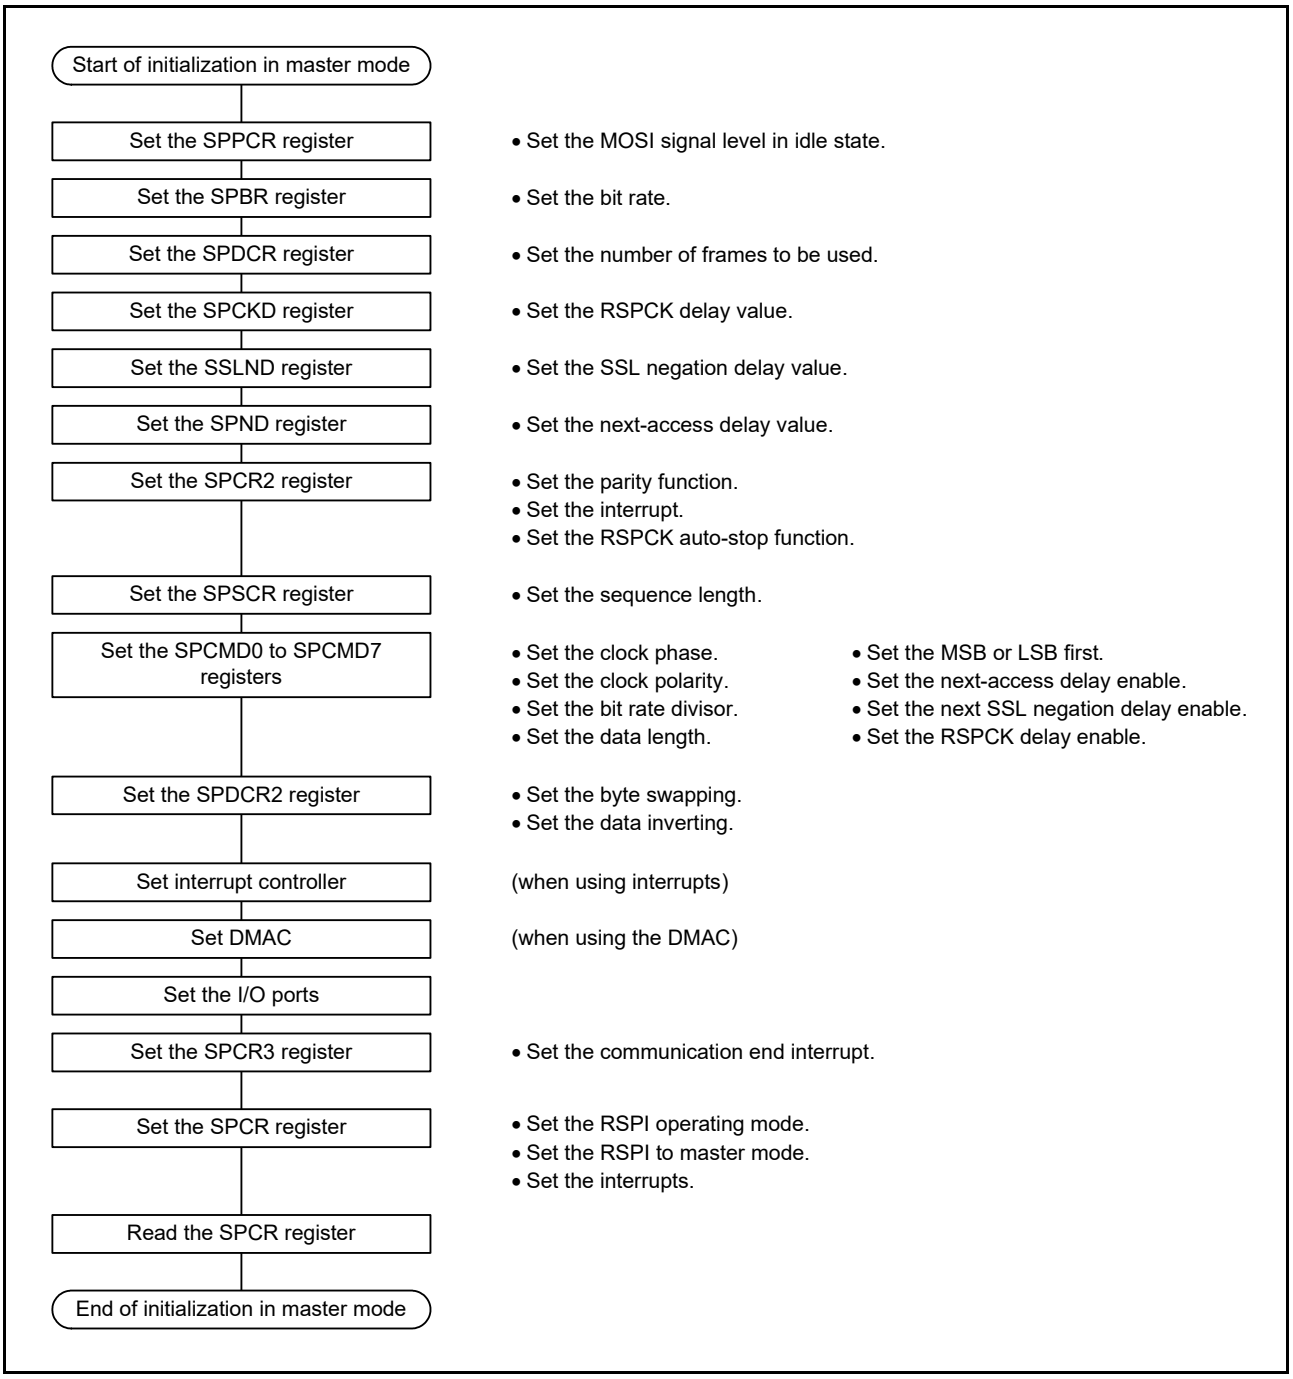

Figure 37.51 Example of Initialization Flowchart in Master Mode (Clock Synchronous Operation)

(5) Flow of Software Processing

Software processing during clock-synchronous operation when the RSPI is used in master mode is the same as that for SPI master mode operation. For details, refer to section 37.3.12.1, (9) Software Processing Flow. Note that mode fault errors will not occur.

37.3.13.2 Slave Mode Operation

(1) Starting a Serial Transfer

When the SPCR.SPMS bit is 1, the first RSPCKA edge triggers the start of a serial transfer in the RSPI.
When the SPMS bit is 1, the RSPI drives the MISOA output signal.
For details on the RSPI transfer format, refer to section 37.3.5, Transfer Format.
It should be noted that the SSLA0 input signal is not used in clock synchronous operation.

(2) Terminating a Serial Transfer

The RSPI terminates the serial transfer after detecting an RSPCKA edge corresponding to the final sampling timing. When free space is available in the receive buffer (the SPRF flag is 0), upon termination of serial transfer the RSPI copies received data from the shift register to the receive buffer of the SPDR register. Upon termination of a serial transfer the RSPI changes the status of the shift register to “empty” regardless of the receive buffer status. The final sampling timing changes depending on the bit length of transfer data. In slave mode, the RSPI data length depends on the SPCMD0.SPB[3:0] bit setting.
For details on the RSPI transfer format, refer to section 37.3.5, Transfer Format.

(3) Initialization Flowchart

Figure 37.52 is a flowchart illustrating an example of initialization in clock synchronous operation when the RSPI is used in slave mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

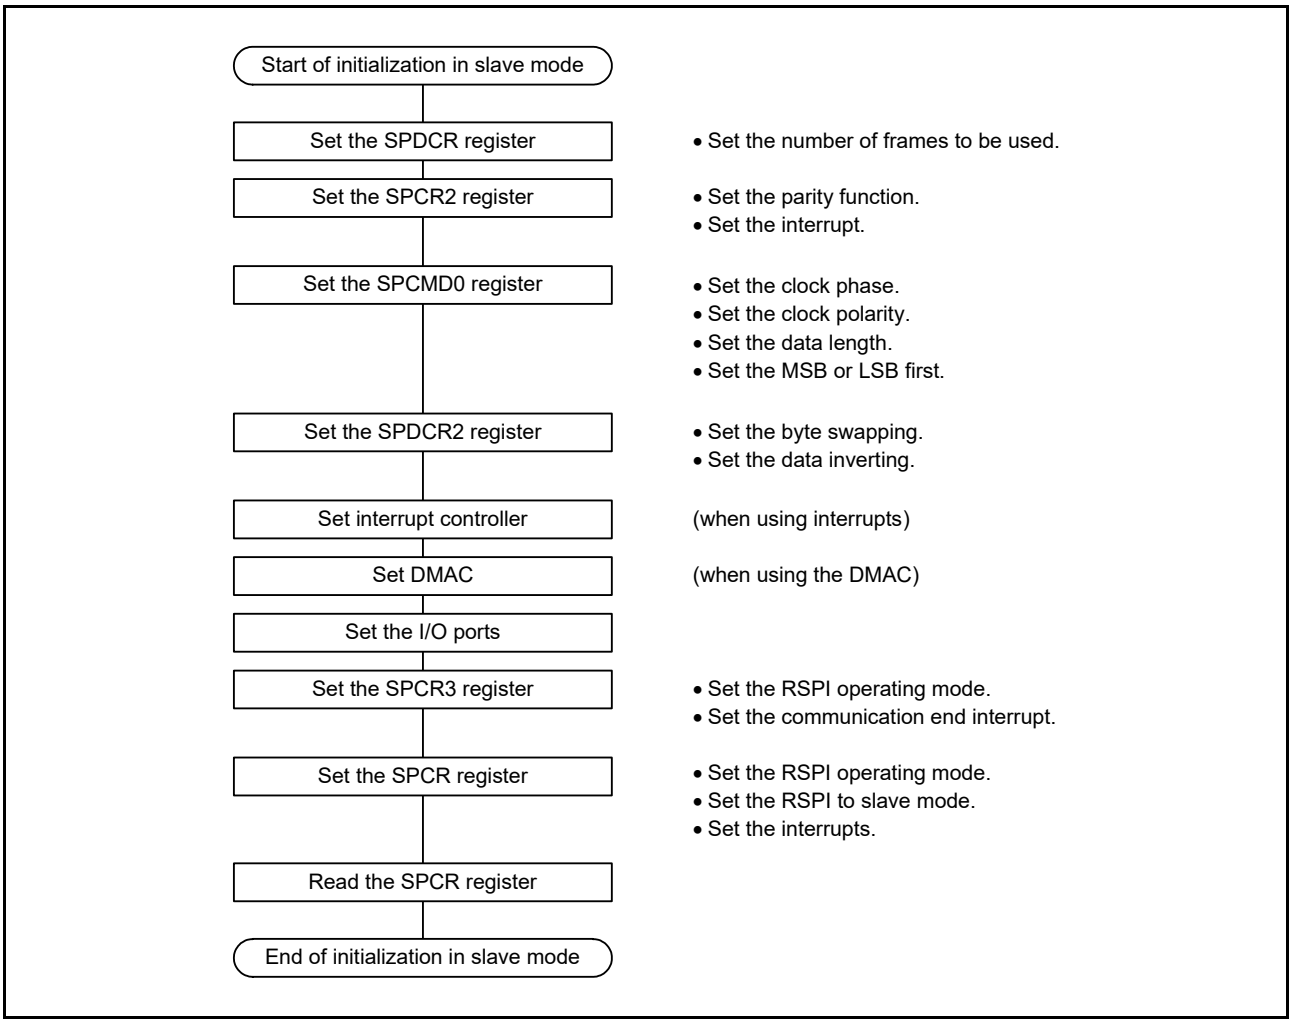

Figure 37.52 Example of Initialization Flowchart in Slave Mode (Clock Synchronous Operation)

(4) Flow of Software Processing

Software processing during clock-synchronous operation when the RSPI is used in slave mode is the same as that for SPI slave mode operation. For details, refer to section 37.3.12.2, (6) Software Processing Flow. Note that mode fault errors will not occur.

37.3.14 Loopback Mode

When 1 is written to the SPPCR.SPLP2 bit or SPPCR.SPLP bit, the RSPI shuts off the path between the MISOA pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIA pin and the shift register if the SPCR.MSTR bit is 0, and connects the input path and output path of the shift register. The RSPI does not shut off the path between the MOSIA pin and the shift register if the SPCR.MSTR bit is 1, and between the MISOA pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data for the RSPI or the reversed transmit data becomes the received data for the RSPI.
Table 37.11 lists the relationship among the SPLP2 and SPLP bits and the received data. Figure 37.53 shows the configuration of the shift register I/O paths for the case where the RSPI in master mode is set in loopback mode (SPPCR.SPLP2 = 0, SPPCR.SPLP = 1).

Table 37.11 SPLP2 and SPLP Bit Settings and Received Data

SPPCR.SPLP2 Bit	SPPCR.SPLP Bit	Received Data
0	0	Input data from the MOSIA pin or MISOA pin
0	1	Inverted transmit data
1	0	Transmit data
1	1	Transmit data

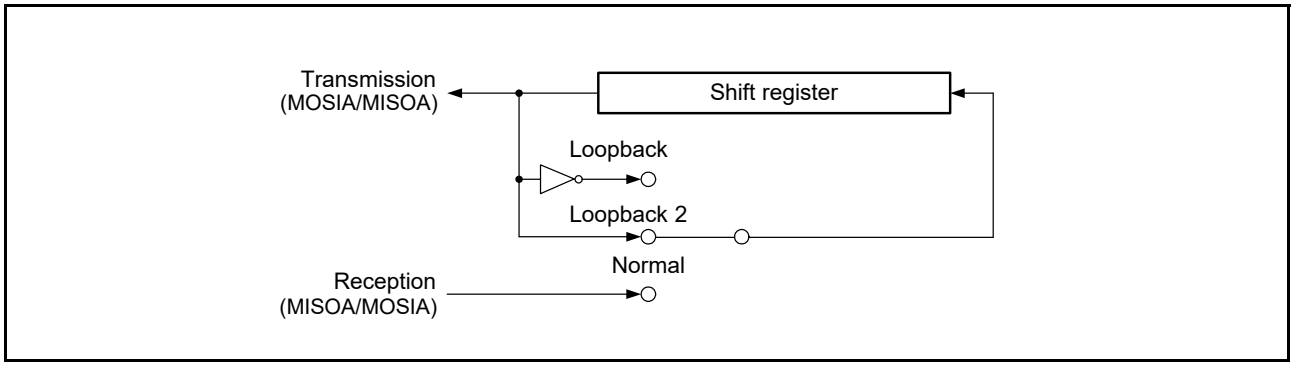

Figure 37.53 Configuration of Shift Register I/O Paths in Loopback Mode (Master Mode)

37.3.15 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. In order to detect defects in the parity bit adding unit and error detecting unit of the parity circuit, self-diagnosis is executed for the parity circuit following the flowchart shown in Figure 37.54.

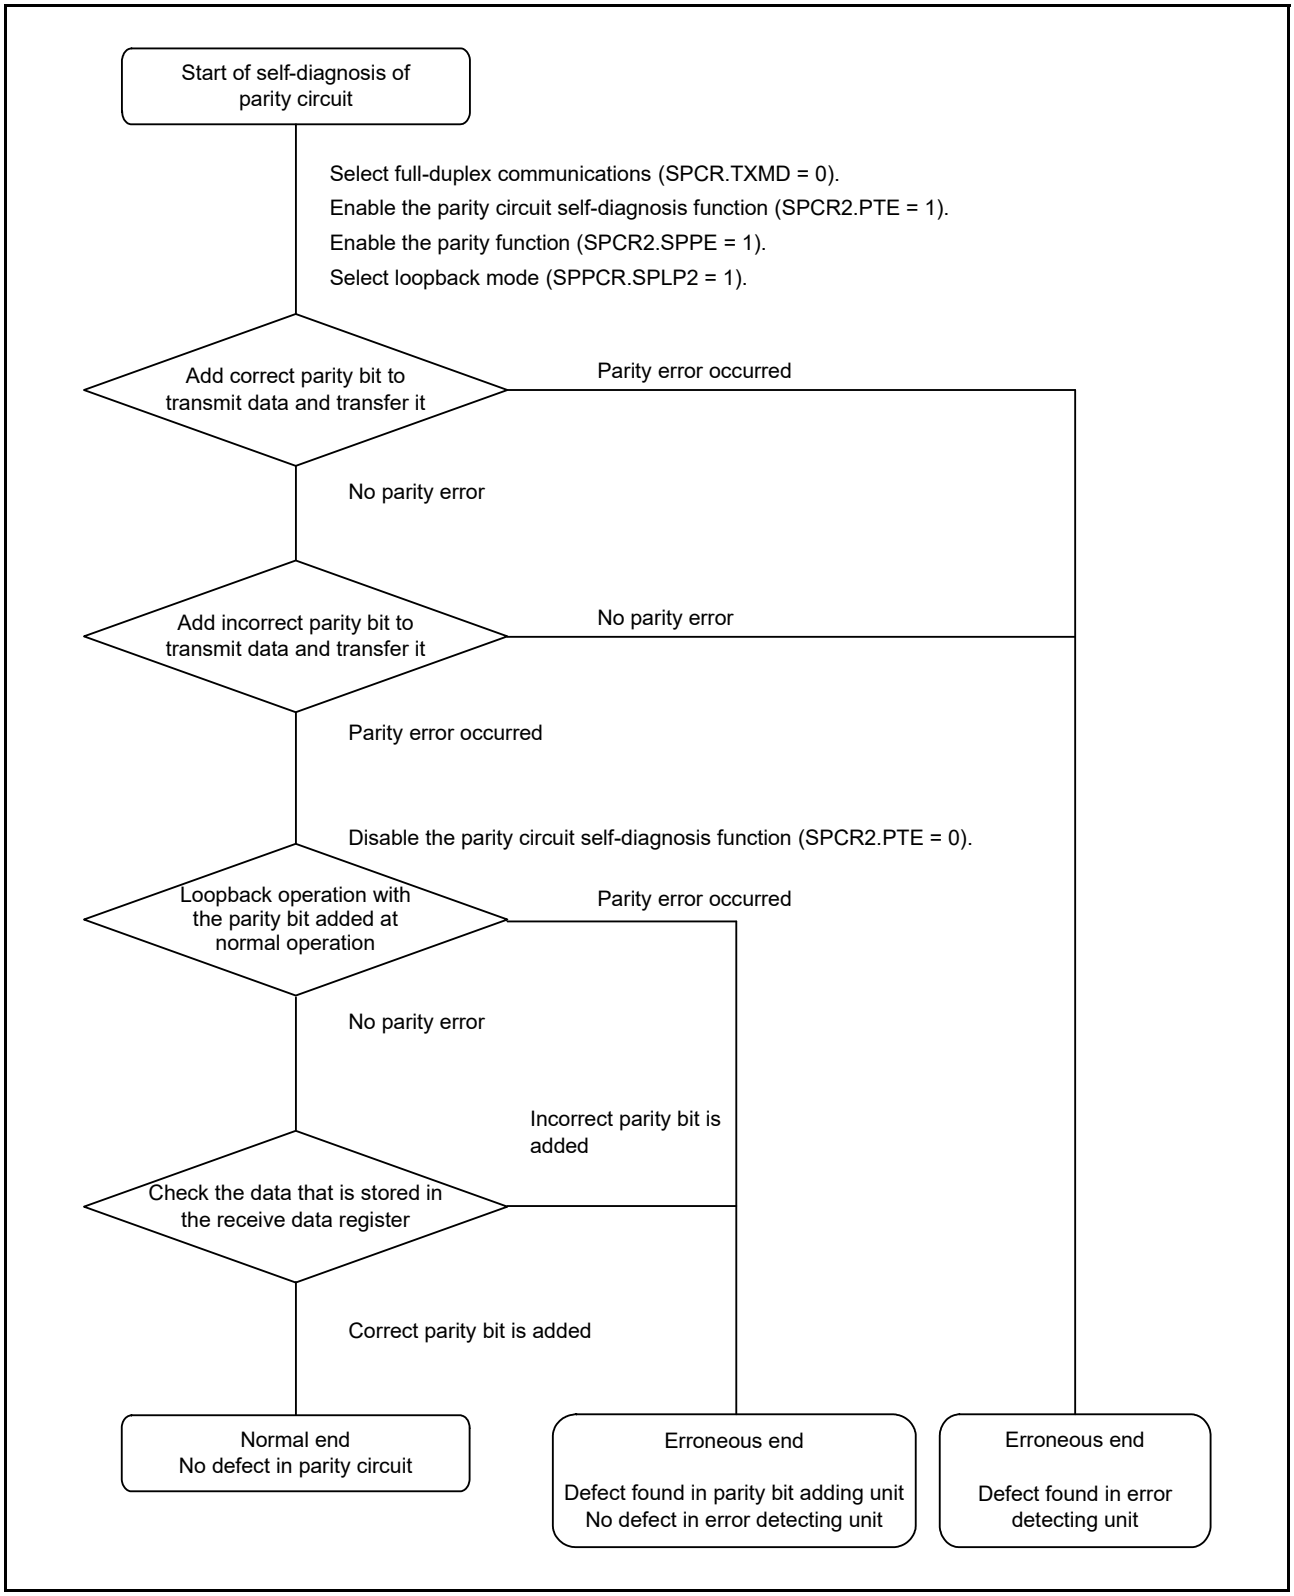

Figure 37.54 Flowchart for Self-Diagnosis of Parity Circuit

37.3.16 Interrupt Sources

The RSPI has interrupt sources of receive buffer full, transmit buffer empty, error (mode fault, underrun, overrun, and parity error), idle, and communication end. In addition, the DTC or DMAC can be activated by the receive buffer full or transmit buffer empty interrupt to perform data transfer.

Since the vector address for SPEI is allocated to interrupt requests due to mode fault, underrun, overrun, and parity errors, the actual interrupt source must be determined from the flags. Interrupt sources for the RSPI are listed in Table 37.12. An interrupt is generated on satisfaction of an interrupt condition in Table 37.12. Clear the receive buffer full and transmit buffer empty sources through data transfer.

When using the DTC or DMAC to perform data transmission/reception, the DTC or DMAC must be set up first to be in a status in which transfer is enabled before making the RSPI settings. For the method for setting the DTC or DMAC, refer to section 17, DMA Controller (DMACAa), or section 18, Data Transfer Controller (DTCb).

If the conditions for generating a transmit buffer empty or receive buffer full interrupt are generated while the ICU.IRn.IR flag is 1, the interrupt is not output as a request for ICU but is retained internally (the capacity for retention is one request per source). A retained interrupt request is output when the ICU.IRn.IR flag becomes 0. A retained interrupt request is automatically discarded once it is output as an actual interrupt request. The interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) for an internally retained interrupt request can also be cleared to 0.

Table 37.12 Interrupt Sources of RSPI

Interrupt Source	Symbol	Interrupt Condition	DMAC/DTC Activation
Receive buffer full	SPRI	The receive buffer becomes full (the SPRF flag becomes 1) while the SPCR.SPRIE bit is 1.	Possible
Transmit buffer empty	SPTI	The transmit buffer becomes empty (the SPTEF flag becomes 1) while the SPCR.SPTIE bit is 1.	Possible
Errors (mode fault, underrun, overrun, and parity error)	SPEI	The SPSR.MODF, UDRF, OVRF, or PERF flag is set to 1 while the SPCR.SPEIE bit is 1.	Impossible
Idle	SPII	The SPSR.IDLNF flag is set to 0 while the SPCR2.SPIIE bit is 1.	Impossible
Communication end	SPCI	The SPSR.SPCF flag is set to 1 while the SPCR3.SPCIE bit is 1.	Impossible

37.4 Link Operation by Event Linking

The RSPI0 supports the following event output for the event link controller (ELC). The event link output signal is output regardless of the interrupt enable bit setting.

37.4.1 Receive Buffer Full Event Output

This event signal is output when received data have been transferred from the shift register to the SPDR register on completion of serial transfer.

37.4.2 Transmit Buffer Empty Event Output

This event signal is output when data for transmission have been transferred from the transmit buffer to the shift register and when the value of the SPE bit has changed from 0 to 1.

37.4.3 Mode Fault, Underrun, Overrun, or Parity Error Event Output

(1) Mode Fault

Table 37.13 lists the occurrence conditions of a mode fault event.

Table 37.13 Occurrence Conditions of Mode Fault Event

	SPCR.MODFEN Bit	SSLA0 Pin	Remarks
Master (SPCR.MSTR bit = 1)	1	Active	Under the condition (the SPCR.MSTR bit is 1 and the MODFEN bit is 1), if the SPCR.SPMS bit is 0, mode fault error, overrun error, and parity error event output cannot be used. Do not set the ELSRn register to 52h.
Slave (SPCR.MSTR bit = 0)	1	Not active	Event is output only when the pin is deactivated during transmission.

(2) Underrun

The condition for this event signal being output in response to an underrun is the start of serial transfer with the transmit buffer containing no transmit data while the value of the SPCR.MSTR bit is 0 and the value of the SPCR.SPE bit is 1, in which case the UDRF and MODF flags are set to 1.

(3) Overrun

The condition for this event signal being output in response to an overrun is completion of serial transfer while the receive buffer contains data that have not been read and the value of the SPCR.TXMD bit is 0, in which case the OVRF flag is set to 1.

(4) Parity Error

The condition for this event signal being output in response to a parity error is detection of a parity error on completion of serial transfer while the value of the TXMD bit in SPCR is 0 and the value of the SPPE bit in SPCR2 is 1.

37.4.4 Idle Event Output

(1) In Master Mode

In master mode, an event is output when the condition for setting the IDLNF flag (idle flag) to 0 is satisfied.

(2) In Slave Mode

In slave mode, an event is output when the SPCR.SPE bit is set to 0 (RSPI is initialized).

37.4.5 Communication End Event Output

During both SPI operation and clock synchronous operation in master mode, an event is output under the condition for setting the IDLNF flag (idle flag) from 1 to 0. In slave mode, an event is output under the conditions listed in Table 37.14 and Table 37.14.

Table 37.14 Generating Conditions of Communication End Event (Slave mode, full-duplex or transmit-only simplex communications)

RSPI Mode	Transmit Buffer State	Shift Register State	Others
SPI operation (SPMS = 0)	Empty	Empty	Negation of the SSLA0 input
Clock synchronous operation (SPMS = 1)	Empty	Empty	Even edge detection of the last RSPCKA for the last data

Table 37.15 Generating Conditions of Communication End Event (Slave mode, receive-only simplex communications)

RSPI Mode	Condition
SPI operation (SPMS = 0)	Negation of the SSLA0 input after the last data was received
Clock synchronous operation (SPMS = 1)	Even edge detection of the last RSPCKA for the last data

Whether the operation is in master mode or slave mode, an event is not output if 0 is written to the SPCR.SPE bit during communication or the SPCR.SPE bit is cleared by the mode fault error.

37.5 Usage Notes

37.5.1 Setting Module Stop Function

Module stop control register B (MSTPCRB) can be used to enable or disable the RSPI. Immediately after a reset, operation of the RSPI is disabled. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

37.5.2 Note on Low Power Consumption Functions

When using the module stop function and entering a low power consumption mode other than sleep mode, set the SPCR.SPE bit to 0 before completing communication.

37.5.3 Notes on Starting Transfer

If the ICU.IRn.IR flag is 1 at the time transfer is to be started, an interrupt request is internally retained after transfer starts, and this can lead to unanticipated behavior of the ICU.IRn.IR flag.
When the ICU.IRn.IR flag is 1 at the time transfer is to start, follow the procedure below to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1).

1. Confirm that transfer has stopped (i.e. that the SPCR.SPE bit is 0).
2. Set the relevant interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) to 0.
3. Read the relevant interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) and confirm that its value is 0.
4. Set the ICU.IRn.IR flag to 0.

37.5.4 Notes on the SPRF and SPTEF flags

When polling the SPSR.SPRF flag and/or SPSR.SPTEF flag, set the SPCR.SPRIE bit and/or SPCR.SPTIE bit to 0.

38. Serial Peripheral Interface (RSPIA)

38.1 Overview

The serial peripheral interface (RSPIA) supports high-speed, full-duplex or simplex synchronous serial communications with multiple processors and peripheral devices.

38.1.1 Features

The RSPIA has the following features.

Table 38.1 RSPIA Specifications (1/2)

Item	Description
Transfer functions	• Use of MOSI (master out/slave in), MISO (master in/slave out), SSL (slave select), and RSPCK (RSPI clock) signals allows serial communications through SPI operation (4-wire method) or clock synchronous operation (3-wire method). • Full-duplex or simplex (transmit-only or receive-only) communications can be selected. • Serial communication is possible in master mode and slave mode. • Variable serial transfer clock polarity • Variable serial transfer clock phase
Data format	• MSB first/LSB first selectable • Transfer bit length can be changed to 4 through 32 bits. • Transmit buffer size/receive buffer size: 32 bits × 4 stages FIFO • Up to four frames can be transferred in one round of transmission/reception (each frame consisting of up to 32 bits). • Byte swapping of transmit and receive data is selectable. • Logic level of transmit and receive data can be inverted.
Bit rate	• In master mode, the on-chip baud rate generator generates RSPCK by frequency-dividing PCLKA. The division ratio ranges from divided by 2 to divided by 4096. • In slave mode, an external input clock is used as a serial clock. The maximum frequency of RSPCK is that of PCLKA divided by 2 (width at high level: 1 cycle of PCLKA; width at low level: 1 cycle of PCLKA).
Buffer configuration	• Transmit buffer and receive buffer are configured independently.
Error detection	• Mode fault error detection • Underrun error detection • Overrun error detection • Parity error detection • Receive data ready detection
SSL control function	[Motorola SPI mode] • Four SSL signals per RSPIA channel (SSL00 to SSL03) • In single-master mode, the SSL00 to SSL03 signals are output. • In multi-master mode: The SSL00 signal is input and the SSL01 to SSL03 signals are output or Hi-Z. • In slave mode: The SSL00 signal is input and the SSL01 to SSL03 signals are Hi-Z (not used). • Controllable delay from SSL output assertion to RSPCK operation (RSPCK delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable delay from RSPCK stop to SSL output negation (SSL negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Function for changing SSL polarity

Table 38.1 RSPIA Specifications (2/2)

Item	Description
SSL control function	[TI SSP mode] • Four SSL signals per RSPIA channel (SSL00 to SSL03) • In single-master mode, the SSL00 to SSL03 signals are output. • In multi-master mode: The SSL00 signal is input and the SSL01 to SSL03 signals are output or Hi-Z. • In slave mode: The SSL00 signal is input and the SSL01 to SSL03 signals are Hi-Z (not used). • Controllable delay from SSL output assertion to RSPCK operation (RSPCK delay) Range: 0 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable delay from RSPCK stop to OE output negation (OE negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Function for changing SSL polarity
Communication Protocol	• Motorola SPI • TI SSP (synchronous serial protocol)
Control in master transfer	[Motorola SPI mode] • A transfer of up to eight commands can be executed sequentially in looped execution. • For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity/phase, transmit data length, MSB/LSB first, burst, RSPCK delay, SSL negation delay, and next-access delay • A transfer can be initiated by writing to the transmit buffer. • MOSI signal value specifiable in SSL negation • RSPCK auto-stop function (enabled or disabled by setting) • Delay between data bytes under burst transfer can be reduced. [TI SSP mode] • A transfer of up to eight commands can be executed sequentially in looped execution. • For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity/phase, transmit data length, MSB/LSB first, burst, RSPCK delay, SSL negation delay (OE negation delay), and next-access delay • A transfer can be initiated by writing to the transmit buffer. • MOSI signal value specifiable in SSL negation • RSPCK auto-stop function (enabled or disabled by setting) • Delay between data bytes under burst transfer can be reduced.
Interrupt sources	Five interrupt sources • Receive buffer full/receive data ready interrupt • Transmit buffer empty interrupt • Communication end interrupt • Error interrupt (mode fault error, underrun error, overrun error, parity error, or receive data ready) • Idle interrupt
Event link function	Five event types can be output to the event link controller. • Receive buffer full/receive data ready event signal • Transmit buffer empty event signal • Mode fault error, underrun error, overrun error, parity error, or receive data ready event signal • Idle event signal • Communication end event signal
Others	• Function for disabling (initializing) the RSPI • Loopback mode • SPE bit status polling function
Low power consumption function	Module stop state can be set.

Figure 38.1 RSPIA Block Diagram

38.1.3 Pin Configuration

The RSPIA has serial pins listed in Table 38.2 for each channel. The RSPIA automatically switches the I/O direction of the SSL00 pin. SSL00 is set as an output when the RSPIA is a single master and as an input when the RSPIA is a multi-master or a slave. Pins RSPCK0, MOSI0, and MISO0 are automatically set as inputs or outputs according to the setting of master or slave, and the SPI operation (4-wire method) or clock synchronous operation (3-wire method) level input on the SSL00 pin. Refer to section 38.3.2, Controlling RSPI Pins for details.

Table 38.2 RSPIA Pin Configuration

Pin Name	Abbreviation	I/O	Function
RSPI clock	RSPCK0	I/O	Clock I/O
Master transmit data	MOSI0	I/O	Master transmit data I/O
Slave transmit data	MISO0	I/O	Slave transmit data I/O
Slave select 0	SSL00	I/O	Slave selection I/O
Slave select 1	SSL01	Output	Slave selection output
Slave select 2	SSL02	Output	Slave selection output
Slave select 3	SSL03	Output	Slave selection output

38.2 Register Descriptions

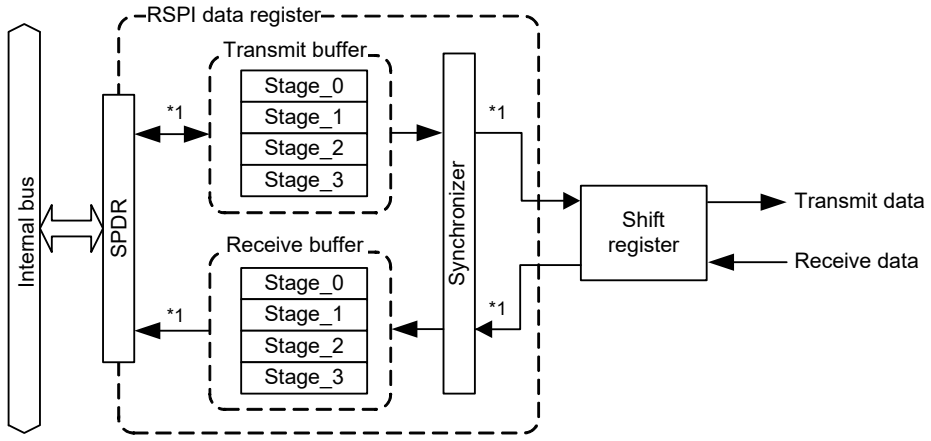
38.2.1 RSPI Data Register (SPDR)

Address(es): RSPIA0.SPDR 000E 2800h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The SPDR register is the interface with the buffers that hold data for transmission and reception by the RSPI. The transmit buffer and receive buffer are independent. Figure 38.2 shows the configuration of the SPDR register.



Note 1. The destination buffer and stage for access is automatically switched by hardware.

Figure 38.2 Configuration of SPDR Register

The transmit and receive buffers each have 32 bits × 4 stages of FIFO. The eight stages of FIFO are all mapped to the single address of the SPDR register. Data written to the SPDR register are written to a transmit-buffer stage (SPTXn, n = 0 to 3) and then transmitted from the buffer. The receive buffer (SPRXn, n = 0 to 3) holds received data on completion of reception. The receive buffer is not updated if an overrun is generated.

(1) Bus Interface

The SPDR register is the interface with 32-bit wide transmit buffer (SPTXn, n = 0 to 3) and receive buffer (SPRXn, n = 0 to 3), each of which has four stages, for a total of 32 bytes. In other words, the 32 bytes are mapped to the 4-byte address space for the SPDR register.
Data for transmission should be flush with the LSB end of the register. Received data are stored flush with the LSB end.
Operations involved in writing to and reading from the SPDR register are described below.

(a) Writing

The transmit buffer includes a transmit buffer write pointer which is automatically updated to indicate the next stage each time data are written to the SPDR register. Figure 38.3 shows the configuration of the bus interface with the transmit buffer in the case of writing to the SPDR register.

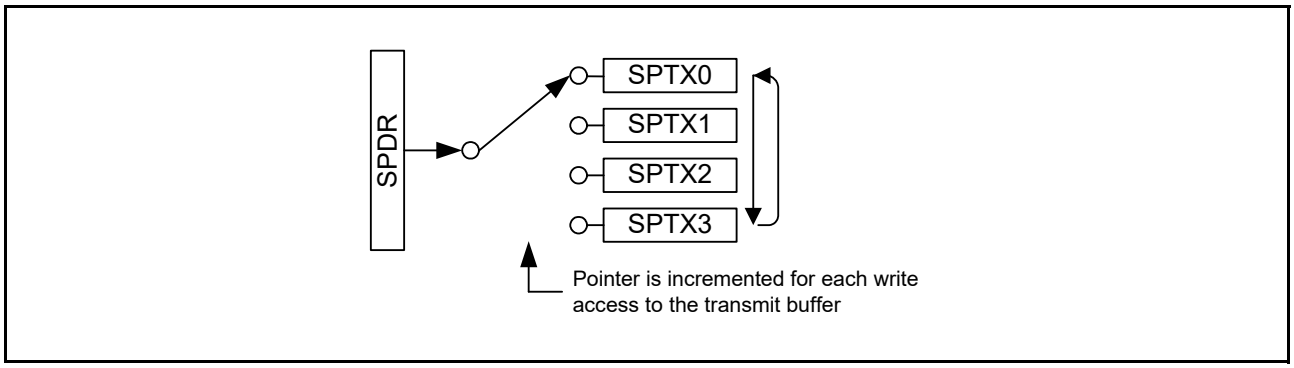


Figure 38.3 Configuration of SPDR Register (Writing)

Sequence of switching the pointer among SPTX0 to SPTX3:
SPTX0 → SPTX1 → SPTX2 → SPTX3 → SPTX0 → SPTX1 → …

When writing to the transmit buffer (SPTXn) after generation of the transmit buffer empty interrupt (after the SPSR.SPTEF flag becomes 1), write the number of frames + 1 set by the transmission FIFO threshold setting bits of RSPI FIFO control register (SPFCR.TTRG[1:0]). Writing to the transmit buffer (SPTXn, n = 0 to 3) in the state where there is no empty stages in the transmit FIFO does not update the buffer value.

(b) Reading

The SPDR register can be read to read the value of a receive buffer (SPRXn, n = 0 to 3) or a transmit buffer (SPTXn, n = 0 to 3). The setting of the RSPI receive/transmit data select bit in the RSPI data control register (SPDCR.SPRDTD) selects whether reading is of the receive or transmit buffer.
The sequence of reading the SPDR register is controlled by independent pointers, receive buffer read pointer and transmit buffer read pointer.
Figure 38.4 shows the configuration of the bus interface with the receive and transmit buffers in the case of reading from the SPDR register.

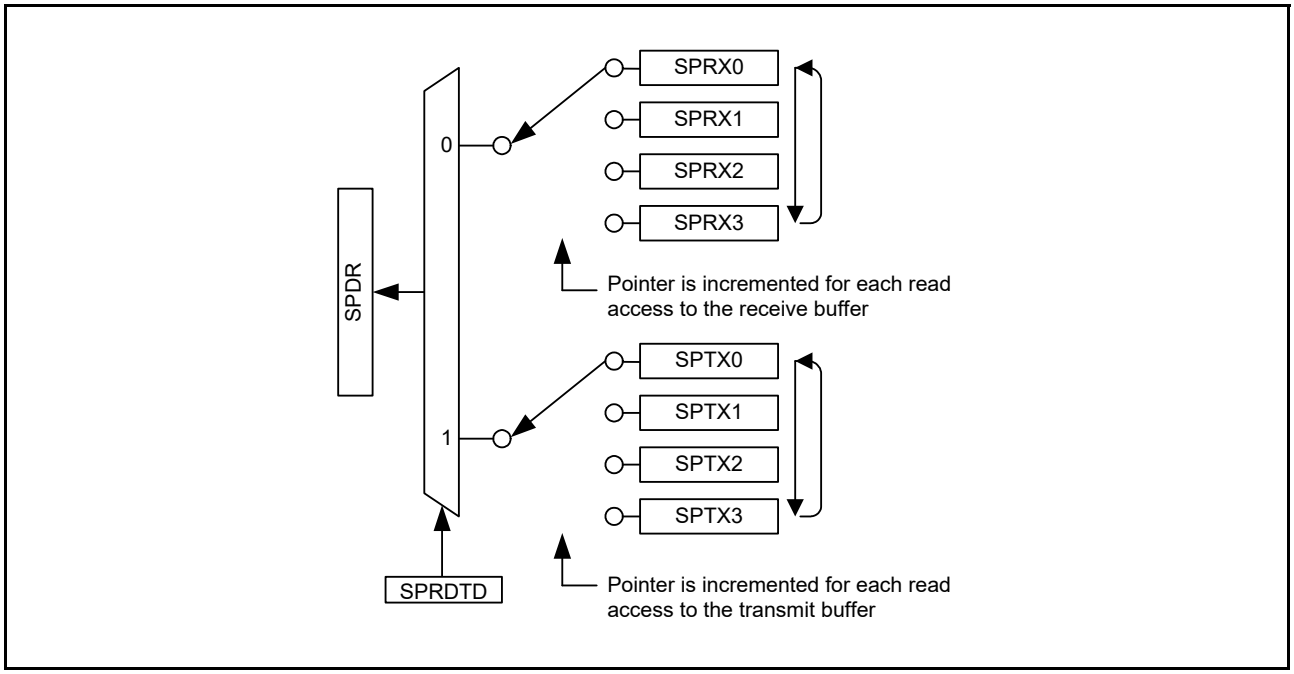

Figure 38.4 Configuration of SPDR (Reading)

Reading the receive buffer switches the receive buffer read pointer to the next buffer automatically.
The sequence of switching the receive buffer read pointer is the same as that for the transmit buffer write pointer.
The transmit buffer read pointer is updated when writing to the SPDR register, and not updated when reading from the transmit buffer. When reading from the transmit buffer, the value most recently written to the SPDR register is read.

38.2.2 RSPI Clock Delay Register (SPCKD)

Address(es): RSPIA0.SPCKD 000E 2804h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SCKDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SCKDL[2:0]	RSPCK Delay Setting	b2 b0 0 0 0: 1 RSPCK 0 0 1: 2 RSPCK 0 1 0: 3 RSPCK 0 1 1: 4 RSPCK 1 0 0: 5 RSPCK 1 0 1: 6 RSPCK 1 1 0: 7 RSPCK 1 1 1: 8 RSPCK	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R

[Motorola SPI]
The SPCKD register sets a period from the beginning of SSL0n signal assertion to RSPCK oscillation (RSPCK delay) when the SPCMDm.SCKDEN bit is 1. If the value of the SPCKD register is changed while both the SPCR.MSTR and SPCR.SPE bits are 1, the operation after the change is not guaranteed.

[TI SSP]
The SPCKD register sets a period from the beginning of SSL0n signal assertion to RSPCK oscillation (RSPCK delay) when the SPCMDm.SCKDEN bit is 1, and also sets a period until the SSL0n signal is negated. If the value of the SPCKD register is changed while both the SPCR.MSTR and SPCR.SPE bits are 1, the operation after the change is not guaranteed.

SCKDL[2:0] Bits (RSPCK Delay Setting)
The SCKDL[2:0] bits set an RSPCK delay value when the SPCMDm.SCKDEN bit is 1.
When using the RSPIA in slave mode, set the SCKDL[2:0] bits to 000b.

38.2.3 RSPI Slave Select Negation Delay Register (SSLND)

Address(es): RSPIA0.SSLND 000E 2805h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SLNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SLNDL[2:0]	SSL Negation Delay Setting	[In master mode] b2 b0 0 0 0: 1 RSPCK 0 0 1: 2 RSPCK 0 1 0: 3 RSPCK 0 1 1: 4 RSPCK 1 0 0: 5 RSPCK 1 0 1: 6 RSPCK 1 1 0: 7 RSPCK 1 1 1: 8 RSPCK [In slave mode, TI SSP] b2 b0 0 0 0: 1 PCLKA 0 0 1: 2 PCLKA 0 1 0: 3 PCLKA 0 1 1: 4 PCLKA 1 0 0: 5 PCLKA 1 0 1: 6 PCLKA 1 1 0: 7 PCLKA 1 1 1: 8 PCLKA	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R

[Motorola SPI]
The SSLND register sets a period (SSL negation delay) from the transmission of a final RSPCK edge to the negation of the SSL0n signal during a serial transfer by the RSPIA in master mode when the SPCMDm.SLNDEN bit is 1. If the value of the SSLND register is changed while both the SPCR.MSTR and SPCR.SPE bits are 1, the operation after the change is not guaranteed.

[TI SSP]
The SSLND register sets a period (SSL negation delay) from the transmission of a final RSPCK edge to the negation of the OE signal during a serial transfer by the RSPIA in master mode, or from the detection of a final RSPCK edge to the negation of the OE signal during a serial transfer by the RSPIA in slave mode. If the value of the SSLND register is changed while the SPCR.SPE bit is 1, the operation after the change is not guaranteed.

SLNDL[2:0] Bits (SSL Negation Delay Setting)

[Motorola SPI]
The SLNDL[2:0] bits set an SSL negation delay value when the SPCMDm.SLNDEN bit is 1.
When using the RSPIA in slave mode, set the SLNDL[2:0] bits to 000b.

[TI SSP]
The SLNDL[2:0] bits set an OE negation delay value when the SPCMDm.SLNDEN bit is 1.

[Clock synchronous]
When using the RSPIA in slave mode, set the SLNDL[2:0] bits to 000b.

38.2.4 RSPI Next-Access Delay Register (SPND)

Address(es): RSPIA0.SPND 000E 2806h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SPNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SPNDL[2:0]	RSPI Next-Access Delay Setting	b2 b0 0 0 0: 1 RSPCK + 5 PCLKA 0 0 1: 2 RSPCK + 5 PCLKA 0 1 0: 3 RSPCK + 5 PCLKA 0 1 1: 4 RSPCK + 5 PCLKA 1 0 0: 5 RSPCK + 5 PCLKA 1 0 1: 6 RSPCK + 5 PCLKA 1 1 0: 7 RSPCK + 5 PCLKA 1 1 1: 8 RSPCK + 5 PCLKA	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SPND register sets a non-active period (next-access delay) of the SSL0n signal after termination of a serial transfer when the SPCMDm.SPNDEN bit is 1. If the value of the SPND register is changed while both the SPCR.MSTR and SPCR.SPE bits are 1, the operation after the change is not guaranteed.

SPNDL[2:0] Bits (RSPI Next-Access Delay Setting)

The SPNDL[2:0] bits set a next-access delay when the SPCMDm.SPNDEN bit is 1.
When using the RSPIA in slave mode, set the SPNDL[2:0] bits to 000b.

38.2.5 RSPI Control Register (SPCR)

Address(es): RSPIA0.SPCR 000E 2808h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	SYNDIS	MSTR	CMMD[1:0]		—	—	FRFS	SPMS	—	—	SPCIE	SPTIE	RDRIS	SPIIE	SPRIE	SPEIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	MODFEN	SCKDDIS	SCKASE	PTE	—	SPOE	SPPE	MRCKS	—	—	—	—	—	—	SPE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SPE	RSPI Function Enable	0: Disables the RSPI function 1: Enables the RSPI function	R/W
b6 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b7	MRCKS	Master Receive Clock Select	Set this bit to 1.	R/W
b8	SPPE	Parity Enable	0: A parity bit is not added to transmit data. Received-data parity check is not performed. 1: A parity bit is added to transmit data. Received-data parity check is performed.	R/W
b9	SPOE	Parity Mode	0: Even parity is used for transmission and reception. 1: Odd parity is used for transmission and reception.	R/W
b10	—	Reserved	This bit is read as 0. The write value should be 0.	R
b11	PTE	Parity Self-Diagnosis	0: Disables the self-diagnosis function of the parity circuit 1: Enables the self-diagnosis function of the parity circuit	R/W
b12	SCKASE	RSPCK Auto-Stop Function Enable	0: Disables the RSPCK auto-stop function 1: Enables the RSPCK auto-stop function	R/W
b13	SCKDDIS	RSPCK Delay Between Data Bytes Disable	0: Delay between frames is inserted in burst transfer 1: Delay between frames is not inserted in burst transfer.	R/W
b14	MODFEN	Mode Fault Error Detection Enable	0: Disables the detection of mode fault error 1: Enables the detection of mode fault error	R/W
b15	—	Reserved	This bit is read as 0. The write value should be 0.	R
b16	SPEIE	Error Interrupt Enable	0: Disables the error interrupt 1: Enables the error interrupt	R/W
b17	SPRIE	Receive Buffer Full Interrupt Enable	0: Disables the receive buffer full interrupt 1: Enables the receive buffer full interrupt	R/W
b18	SPIIE	Idle Interrupt Enable	0: Disables the idle interrupt 1: Enables the idle interrupt	R/W
b19	RDRIS	Receive Data Ready Interrupt Select	0: Receive data full interrupt 1: Error interrupt	R/W
b20	SPTIE	Transmit Buffer Empty Interrupt Enable	0: Disables the transmit buffer empty interrupt 1: Enables the transmit buffer empty interrupt	R/W
b21	SPCIE	Communication End Interrupt Enable	0: Disables the communication end interrupt 1: Enables the communication end interrupt	R/W
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R
b24	SPMS	RSPI Mode Select	0: SPI operation (4-wire method) 1: Clock synchronous operation (3-wire method)	R/W
b25	FRFS	Frame Format Select	0: Motorola SPI 1: TI SSP When the SPMS bit is 1 (clock synchronous operation (3-wire method)), the setting of this bit is disabled.	R/W
b27, b26	—	Reserved	These bits are read as 0. The write value should be 0.	R

Bit	Symbol	Bit Name	Description	R/W
b29, b28	CMMD[1:0]	Communication Mode Select	b29 b28 0 0: Transmit-receive mode (full-duplex) 0 1: Transmit-only mode (simplex, receiver disabled) 1 0: Receive-only mode (simplex, transmitter disabled) 1 1: Setting prohibited	R/W
b30	MSTR	RSPI Master/Slave Mode Select	0: Slave mode 1: Master mode	R/W
b31	SYNDIS	Synchronizer Disable	Set this bit to 1.	R/W

The SPCR register is used to specify the operating modes. If the value of the MRCKS, SPPE, SPOE, PTE, SCKASE, SCKDDIS, MODFEN, SPMS, FRFS, CMMD[1:0], MSTR, or SYNDIS bit is changed while the SPCR.SPE bit is 1, the operation after the change is not guaranteed.

SPE Bit (RSPI Function Enable)

This bit enables or disables the RSPI function. Setting this bit to 1 enables the RSPI function. When the SPSR.MODF flag is 1, this bit is set to 0. This bit cannot be set to 1 until the MODF flag is cleared. For details, refer to section 38.3.10, Error Detection.

Setting this bit to 0 disables the RSPI function, and initializes a part of the module function. For details, refer to section 38.3.12, Initializing RSPIA.

MRCKS Bit (Master Receive Clock Select)

This bit selects the clock used to sample the received data in master mode. Set this bit to 1 for this MCU. This bit setting is effective only when the loopback function is not used (when SPPCR.SPLP = 0 and SPPCR.SPLP2 = 0) and in master mode.

SPPE Bit (Parity Enable)

This bit is used to enable or disable the parity function.

SPOE Bit (Parity Mode)

This bit is used to specify even parity or odd parity.

In even parity mode, the parity bit is determined so that the sum of 1 (parity bit + transmit characters or receive characters) becomes an even number. In the same way, in odd parity mode, a parity bit is determined so that the sum of 1 (parity bit + transmit characters or receive characters) becomes an odd number. The SPOE bit is effective only when the SPCR.SPPE bit is set to 1.

PTE Bit (Parity Self-Diagnosis)

This bit is used to enable or disable self-diagnosis of the parity circuit to confirm that the parity function is normal.

SCKASE Bit (RSPCK Auto-Stop Function Enable)

This bit is used to enable or disable the RSPCK auto-stop function. When this function is enabled, the RSPCK stops immediately before an overrun error occurs during data reception in master mode. For details, refer to section 38.3.10.1, Overrun Error.

SCKDDIS Bit (RSPCK Delay Between Data Bytes Disable)

This bit controls whether insert the delay time between the burst transfer frames.

Valid in the master mode (SPCR.MSTR = 1) for frames with the SPCMDm.SSLKP bit set to 1.

This bit should be set to 0 in slave mode (SPCR.MSTR = 0). Table 38.3 shows the usage of SSL delay control between transfer frames. For details, refer to (4) Burst Transfer in section 38.3.13.1, Master Mode Operation.

Table 38.3 Usage of SSL Delay Control between Transfer Frames (Master mode)

Conditions		SPCMDm.SSLKP bit	SPCR.SCKDDIS bit	SSL delay control register *1 (RSPCK delay, SSL negation delay, next access delay)
Non-burst transfers		0	0	It is possible to control each delay of RSPCK delay, SSL negation delay and next access delay
Burst transfer with delay between frames	From the 1st frame to the last previous frame	1	0	
	The last frame	0	0	
Burst transfer with no delay between frames	From the 1st frame to the last previous frame	1	1	• RSPCK delay of the 1st frame • SSL negation delay and next access delay of the last frame
	The last frame	0	1	

Note 1. RSPCK delay is controlled by the SPCKD.SCKDL[2:0] bits and SPCMDm.SCKDEN bit.
SSL negation delay is controlled by the SSLND.SLNDL[2:0] bits and SPCMDm.SLNDEN bit.
Next access delay is controlled by the SPND.SPNDL[2:0] bits and SPCMDm.SPNDEN bit.

Setting	Operation example (Motorola SPI, SCKDDIS = 1)
SPCMD0.SSLKP = 1	Burst transfer/no interframe delay between 0 and 1 (SSL0n keep active)
SPCMD1.SSLKP = 1	Burst transfer/no interframe delay between 1 and 2 (SSL0n keep active)
SPCMD2.SSLKP = 1	Burst transfer/no interframe delay between 2 and 3 (SSL0n keep active)
SPCMD3.SSLKP = 1	Burst transfer/no interframe delay between 3 and 4 (SSL0n keep active)
SPCMD4.SSLKP = 0	Does not perform burst transfer, and once in-activate SSL0n.*1
SPCMD5.SSLKP = 1	Burst transfer/no interframe delay between 5 and 6 (SSL0n keep active)
SPCMD6.SSLKP = 1	Burst transfer/no interframe delay between 6 and 7 (SSL0n keep active)
SPCMD7.SSLKP = 0	Does not perform burst transfer, and once in-activate SSL0n.*1

Note 1. SCKDDIS setting is invalid because it does not perform burst transfer.

MODFEN Bit (Mode Fault Error Detection Enable)

This bit is used to enable or disable detection of a mode fault error. (Refer to section 38.3.10, Error Detection.) The RSPIA determines SSL00 pin input or output direction according to the combination of the MODFEN and MSTR bits (refer to section 38.3.2, Controlling RSPI Pins).

SPEIE Bit (Error Interrupt Enable)

This bit is used to enable or disable an error interrupt request.
When the SPSR.MODF, OVRF, or PERF flag is set to 1 while this bit is 1, an error interrupt request is generated (refer to section 38.3.10, Error Detection).

SPRIE Bit (Receive Buffer Full Interrupt Enable)

This bit is used to enable or disable a receive buffer full interrupt request.

SPIIE Bit (Idle Interrupt Enable)

This bit is used to enable or disable an idle interrupt requests.
When the SPSR.IDLNF flag changes from 1 to 0 while this bit is 1, an idle interrupt request is generated.

RDRIS Bit (Receive Data Ready Interrupt Select)

This bit is used to select the SPRI interrupt request or SPEI interrupt request to be generated when the receive data ready is detected (SPSR.RRDYF = 1).

SPTIE Bit (Transmit Buffer Empty Interrupt Enable)

This bit is used to enable or disable a transmit buffer empty interrupt request.

SPCIE Bit (Communication End Interrupt Enable)

This bit controls generation of a communication end interrupt request.

SPMS Bit (RSPI Mode Select)

This bit is used to select SPI operation (4-wire method) or clock synchronous operation (3-wire method).
For clock synchronous operation, the SSL0n pin is not used but three pins RSPCK0, MOSI0, and MISO0 are used for communication. When SPMS = 1 (clock synchronous operation (3-wire)), the setting of the FRFS bit is invalid.
To perform clock synchronous operation in master mode (SPCR.MSTR = 1), the SPCMDm.CPHA bit can be set to 0 or 1. To perform clock synchronous operation in slave mode (SPCR.MSTR = 0), set the CPHA bit to 1. If this bit is set to 0 for clock synchronous operation in slave mode (SPCR.MSTR = 0), subsequent operation is not guaranteed.
Table 38.4 lists the communication status according to the settings of the MSTR bit, CMMD[1:0] bits, FRFS bit, and SPMS bit of the RSPI control register (SPCR) as follows.

Table 38.4 RSPI Communication Status

SPCR. MSTR	SPCR. CMMD[1:0]	SPCR. FRFS	SPCR. SPMS	Communication Status	Communi-cation Status No.
1	00b	0	0	Transmit-Receive Master mode/Motorola SPI/SPI operation (4-wire)	1-1
1	00b	1	0	Transmit-Receive Master mode/TI SSP/SPI operation (4-wire)	1-2
1	00b	—	1	Transmit-Receive Master mode/Clock synchronous operation (3-wire)	1-3
1	01b	0	0	Transmit-only Master mode/Motorola SPI/SPI operation (4-wire)	1-4
1	01b	1	0	Transmit-only Master mode/TI SSP/SPI operation (4-wire)	1-5
1	01b	—	1	Transmit-only Master mode/Clock synchronous operation (3-wire)	1-6
1	10b	0	0	Receive-only Master mode/Motorola SPI/SPI operation (4-wire)	1-7
1	10b	1	0	Receive-only Master mode/TI SSP/SPI operation (4-wire)	1-8
1	10b	—	1	Receive-only Master mode/Clock synchronous operation (3-wire)	1-9
0	00b	0	0	Transmit-Receive Slave mode/Motorola SPI/SPI operation (4-wire) (default)	0-1
0	00b	1	0	Transmit-Receive Slave mode/TI SSP/SPI operation (4-wire)	0-2
0	00b	—	1	Transmit-Receive Slave mode/Clock synchronous operation (3-wire)	0-3
0	01b	0	0	Transmit-only Slave mode/Motorola SPI/SPI operation (4-wire)	0-4
0	01b	1	0	Transmit-only Slave mode/TI SSP/SPI operation (4-wire)	0-5
0	01b	—	1	Transmit-only Slave mode/Clock synchronous operation (3-wire)	0-6
0	10b	0	0	Receive-only Slave mode/Motorola SPI/SPI operation (4-wire)	0-7
0	10b	1	0	Receive-only Slave mode/TI SSP/SPI operation (4-wire)	0-8
0	10b	—	1	Receive-only Slave mode/Clock synchronous operation (3-wire)	0-9

—: don't care

FRFS Bit (Frame Format Select)

This bit selects the communication protocol. The format of the RSPI terminal (RSPCK0, SSL0n (n = 0 to 3) can be set according to the set communication protocol.
When the SPMS bit is 1 (clock synchronous operation (3-wire method)), this bit is invalid because SSL0n pin is not used.

CMMD[1:0] Bits (Communication Mode Select)

This bit is used to select the transmit-receive, transmit-only, and receive-only serial communication.
When CMMD[1:0] is set to 01b for communication, transmit-only is performed without reception.
When CMMD[1:0] is set to 10b for communication, receive-only is performed without transmission.

When CMMD[1:0] is set to 01b for communication, a receive buffer full interrupt request cannot be used.
When CMMD[1:0] is set to 10b for communication, a transmit buffer empty interrupt request cannot be used.
Refer to section 38.3.6, Communication Mode.

MSTR Bit (RSPI Master/Slave Mode Select)

This bit is used to select master mode or slave mode of the RSPIA. The RSPIA determines input/output directions of pins RSPCK0, MOSI0, MISO0, and SSL01 to SSL03 according to the MSTR bit setting.

SYNDIS Bit (Synchronizer Disable)

Set this bit to 1 for this MCU.

38.2.6 RSPI Receive-Only Mode Control Register (SPRMCR)

Address(es): RSPIA0.SPRMCR 000E 280Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	START	TERM	—	RFC[4:0]				
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	RFC[4:0]	Receive Frame Count Select	The number of received frames can be adjusted in receive-only master mode. b4 b0 0 0 0 0 0: This function is not used. 0 0 0 0 1: Automatically stop communication after processing 1 received frame : 1 1 1 1 1: Automatically stop communication after processing 31 received frames Settings are not effective except in receive-only master mode.	R/W
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R
b6	TERM	Reception Terminate	1: Receive End (Writable only in receive-only master mode) The read value is always 0.	W
b7	START	Reception Start	1: Receive Start (Writable only in receive-only master mode) The read value is always 0.	W

The SPRMCR register is used to control the start and completion of communication for receive-only master mode. If the RFC[4:0] bits are changed while the SPCR.SPE bit is 1, the operation after the change is not guaranteed.

RFC[4:0] Bits (Receive Frame Count Select)

The number of received frames can be adjusted when operating in receive-only master mode. Valid only when the master mode (SPCR.MSTR = 1) and the communication mode select bits (SPCR.CMMD[1:0]) are 10b. After reception is started by the START bit, the communication is automatically stopped after processing frames according to the value set in these bits.

TERM Bit (Reception Terminate)

This bit is used to end reception in receive-only master mode. Valid only when the master mode (SPCR.MSTR = 1) and the communication mode select bits (SPCR.CMMD[1:0]) are 10b.

START Bit (Reception Start)

This bit is used to start reception in receive-only master mode. Valid only when the master mode (SPCR.MSTR = 1) and the communication mode select bits (SPCR.CMMD[1:0]) are 10b.
Writing 1 to this bit during reception is not accepted. Write again after reception is completed.

38.2.7 RSPI Receive Data Ready Detect Condition Setting Register (SPDRCSR)

Address(es): RSPIA0.SPDRCSR 000E 280Dh

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	—	0h: Disables receive data ready detection function 1h: Performs receive data ready detection after 1 PCLKA : FFh: Performs receive data ready detection after 255 PCLKA	R/W

The SPDRCSR register is used to set the RSPI receive data ready detection function. If the setting value is changed while the SPCR.SPE bit is 1, the operation after the change is not guaranteed.
The receive data ready detection function can be disabled or, if used, the period until detection can be set from 1 to 255 PCLKA. The value set in the SPDRCSR register is used to 1 set the RRDYF flag. For details, see the description of the RRDYF flag in section 38.2.16, RSPI Status Register (SPSR).

38.2.8 RSPI Pin Control Register (SPPCR)

Address(es): RSPIA0.SPPCR 000E 280Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	MOIFE	MOIFV	—	—	SPLP2	SPLP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SPLP	RSPI Loopback	0: Normal mode 1: Loopback mode (data is inverted for transmission)	R/W
b1	SPLP2	RSPI Loopback 2	0: Normal mode 1: Loopback mode (data is not inverted for transmission)	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b4	MOIFV	MOSI Idle Fixed Value	0: The fixed value during MOSI idling corresponds to low 1: The fixed value during MOSI idling corresponds to high	R/W
b5	MOIFE	MOSI Idle Value Fixing Enable	0: MOSI output value equals final data from previous transfer 1: MOSI output value equals the value set in the MOIFV bit	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SPPCR register is used to set pin mode of the RSPIA. If this register is changed while the SPCR.SPE bit is 1, the operation after the change is not guaranteed.

SPLP Bit (RSPI Loopback)

When the SPLP bit is set to 1, the RSPIA shuts off the path between the MISO0 pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSI0 pin and the shift register if the SPCR.MSTR bit is 0, and connects (inverts) the input path and output path for the shift register (loopback mode).

SPLP2 Bit (RSPI Loopback 2)

When the SPLP2 bit is set to 1, the RSPIA shuts off the path between the MISO0 pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSI0 pin and the shift register if the SPCR.MSTR bit is 0, and connects the input path and output path for the shift register (loopback mode).
If this bit is set to 1 together with the SPLP bit, setting this bit takes precedence.

MOIFV Bit (MOSI Idle Fixed Value)

If the MOIFE bit is 1 in master mode, the MOIFV bit determines the MOSI0 pin output value during the SSL negation period (including the SSL retention period during a burst transfer).

MOIFE Bit (MOSI Idle Value Fixing Enable)

The MOIFE bit fixes the MOSI0 output value when the RSPIA in master mode is in an SSL negation period (including the SSL retention period during a burst transfer). When the MOIFE bit is 0, the RSPIA outputs the last data from the previous serial transfer during the SSL negation period to the MOSI0 pin. When the MOIFE bit is 1, the RSPIA outputs the fixed value set in the MOIFV bit to the MOSI0 pin.

38.2.9 RSPI Slave Select Polarity Register (SSLP)

Address(es): RSPIA0.SSLP 000E 2810h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	SSL3P	SSL2P	SSL1P	SSL0P
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SSL0P	SSL00 Signal Polarity Setting	[Motorola SPI] 0: The SSL00 signal is active low. 1: The SSL00 signal is active high. [TI SSP] 0: The SSL00 signal is active high. 1: The SSL00 signal is active low.	R/W
b1	SSL1P	SSL01 Signal Polarity Setting	[Motorola SPI] 0: The SSL01 signal is active low. 1: The SSL01 signal is active high. [TI SSP] 0: The SSL01 signal is active high. 1: The SSL01 signal is active low.	R/W
b2	SSL2P	SSL02 Signal Polarity Setting	[Motorola SPI] 0: The SSL02 signal is active low. 1: The SSL02 signal is active high. [TI SSP] 0: The SSL02 signal is active high. 1: The SSL02 signal is active low.	R/W
b3	SSL3P	SSL03 Signal Polarity Setting	[Motorola SPI] 0: The SSL03 signal is active low. 1: The SSL03 signal is active high. [TI SSP] 0: The SSL03 signal is active high. 1: The SSL03 signal is active low.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SSLP register is used to set the polarity of SSL0n signals (n = 0 to 3) of the RSPIA. If this register is changed while the SPCR.SPE bit is 1, the operation after the change is not guaranteed.

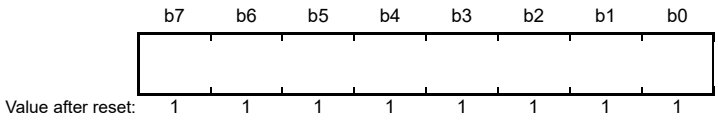
SSLnP Bits (SSL0n Signal Polarity Setting) (n = 0 to 3)

These bits are used to specify the polarity of SSL0n signals. The values of the SSLnP bit indicate the active polarity of SSL0n signals.

Note: SSL00 is different from SSL01 to SSL03. When slave or multi-master, it functions as an input.
For details, refer to section 38.3.3.2, Single Master/Single Slave (with This MCU Acting as Slave), and section 38.3.3.5, Multi-Master/Multi-Slave (with This MCU Acting as Master).

38.2.10 RSPI Bit Rate Register (SPBR)

Address(es): RSPIA0.SPBR 000E 2811h



The SPBR register is used to set the bit rate in master mode. If the value of the SPBR register is changed while both the SPCR.MSTR and SPCR.SPE bits are 1, the operation after the change is not guaranteed.
The bit rate is determined by combinations of the SPBR register setting and the SPCMDm.BRDV[1:0] bit setting.
When the RSPIA is used in slave mode, the bit rate depends on the frequency of the input clock (bit rate satisfying the electrical characteristics should be used) regardless of the settings of the SPBR register and the SPCMDm.BRDV[1:0] bits.
The equation for calculating the bit rate is given below. In the equation, n denotes the SPBR register setting (0, 1, 2, …, 255), and N denotes the BRDV[1:0] bit setting (0, 1, 2, 3).

$$\text{Bit rate} = \frac{f(PCLKA)}{2 \times (n+1) \times 2^{N}}$$

Table 38.5 lists examples of the relationship among the SPBR register settings, the BRDV[1:0] bit settings, and bit rates.

Table 38.5 Relationship among SPBR Register Settings, BRDV[1:0] Bit Settings, and Bit Rates

SPBR (n)	BRDV[1:0] Bits (N)	Division Ratio	Bit Rate				
			PCLKA = 32 MHz	PCLKA = 36 MHz	PCLKA = 40 MHz	PCLKA = 50 MHz	PCLKA = 120 MHz
0	0	2	16.0 Mbps	18.0 Mbps	20.0 Mbps	25.0 Mbps	60.0 Mbps
1	0	4	8.00 Mbps	9.00 Mbps	10.0 Mbps	12.5 Mbps	30.0 Mbps
2	0	6	5.33 Mbps	6.00 Mbps	6.67 Mbps	8.33 Mbps	20.0 Mbps
3	0	8	4.00 Mbps	4.50 Mbps	5.00 Mbps	6.25 Mbps	15.0 Mbps
4	0	10	3.20 Mbps	3.60 Mbps	4.00 Mbps	5.00 Mbps	12.0 Mbps
5	0	12	2.67 Mbps	3.00 Mbps	3.33 Mbps	4.16 Mbps	10.0 Mbps
5	1	24	1.33 Mbps	1.50 Mbps	1.67 Mbps	2.08 Mbps	5.00 Mbps
5	2	48	677 kbps	750 kbps	833 kbps	1.04 Mbps	2.50 Mbps
5	3	96	333 kbps	375 kbps	417 kbps	521 kbps	1.25 Mbps
255	3	4096	7.81 kbps	8.80 kbps	9.78 kbps	12.2 kbps	29.3 kbps

38.2.11 RSPI Sequence Control Register (SPSCR)

Address(es): RSPIA0.SPSCR 000E 2813h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SPSLN[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SPSLN[2:0]	RSPI Sequence Length Setting	b2 b0 Sequence Length — Referenced SPCMD0 to SPCMD7 (No.) 0 0 0: 1 — 0→0→… 0 0 1: 2 — 0→1→0→… 0 1 0: 3 — 0→1→2→0→… 0 1 1: 4 — 0→1→2→3→0→… 1 0 0: 5 — 0→1→2→3→4→0→… 1 0 1: 6 — 0→1→2→3→4→5→0→… 1 1 0: 7 — 0→1→2→3→4→5→6→0→… 1 1 1: 8 — 0→1→2→3→4→5→6→7→0→… The order in which the SPCMD0 to SPCMD7 registers are to be referenced is changed according to the sequence length that is set in these bits. The relationship among the setting of these bits, sequence length, and SPCMD0 to SPCMD7 registers referenced by the RSPIA is shown above. However, the RSPIA in slave mode references SPCMD0.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SPSCR register is used to set the sequence length when the RSPIA operates in master mode. When changing the SPSCR.SPSLN[2:0] bits while both the SPCR.MSTR and SPCR.SPE bits are 1, the bits should be changed while the SPSR.IDLNF flag is 0.

SPSLN[2:0] Bits (RSPI Sequence Length Setting)

The SPSLN[2:0] bits specify a sequence length when the RSPIA in master mode performs sequential operations. The RSPIA in master mode changes SPCMD0 to SPCMD7 registers to be referenced and the order in which they are referenced according to the sequence length that is set in the SPSLN[2:0] bits. For details, refer to (3) Sequence Control in section 38.3.13.1, Master Mode Operation.

In slave mode, SPCMD0 is referred.

38.2.12 RSPI Command Register m (SPCMDm) (m = 0 to 7)

Address(es): RSPIA0.SPCMD0 000E 2814h, RSPIA0.SPCMD1 000E 2818h, RSPIA0.SPCMD2 000E 281Ch, RSPIA0.SPCMD3 000E 2820h, RSPIA0.SPCMD4 000E 2824h, RSPIA0.SPCMD5 000E 2828h, RSPIA0.SPCMD6 000E 282Ch, RSPIA0.SPCMD7 000E 2830h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	SSLA[2:0]			—	—	—	SPB[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CPHA	RSPCK Phase Setting	0: Data sampling on odd edge, data variation on even edge 1: Data variation on odd edge, data sampling on even edge	R/W
b1	CPOL	RSPCK Polarity Setting	0: RSPCK is low when idle 1: RSPCK is high when idle	R/W
b3, b2	BRDV[1:0]	Bit Rate Division Setting	b3 b2 0 0: These bits select the base bit rate 0 1: These bits select the base bit rate divided by 2 1 0: These bits select the base bit rate divided by 4 1 1: These bits select the base bit rate divided by 8	R/W
b6 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R
b7	SSLKP	SSL Signal Level Keeping	0: Negates all SSL signals upon completion of transfer 1: Keeps the SSL signal level from the end of transfer until the beginning of the next access	R/W
b11 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R
b12	LSBF	RSPI LSB First	0: MSB first 1: LSB first	R/W
b13	SPNDEN	RSPI Next-Access Delay Enable	0: A next-access delay of 1 RSPCK + 5 PCLKA 1: A next-access delay is equal to the setting of the RSPI next-access delay register (SPND)	R/W
b14	SLNDEN	SSL Negation Delay Setting Enable	0: In master mode, an SSL negation delay of 1 RSPCK In slave and TI SSP mode, an SSL negation delay of 1 PCLKA 1: An SSL negation delay is equal to the setting of the RSPI slave select negation delay register (SSLND)	R/W
b15	SCKDEN	RSPCK Delay Setting Enable	0: In Motorola SPI mode, an RSPCK delay of 1 RSPCK In TI SSP mode, an RSPCK delay of 0 RSPCK 1: An RSPCK delay is equal to the setting of the RSPI clock delay register (SPCKD)	R/W
b20 to b16	SPB[4:0]	RSPI Data Length Setting	b20 b16 00000 to 00010: Setting prohibited 0 0 0 1 1: 4 bits 0 0 1 0 0: 5 bits 0 0 1 0 1: 6 bits : : 1 1 1 1 0: 31 bits 1 1 1 1 1: 32 bits	R/W
b23 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R
b26 to b24	SSLA[2:0]	SSL Signal Assertion Setting	b26 b24 0 0 0: SSL00 0 0 1: SSL01 0 1 0: SSL02 0 1 1: SSL03 100 to 111: Setting prohibited	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SPCMDm register is used to set a transfer format for the RSPIA in master mode. Each channel has eight RSPI command registers (SPCMD0 to SPCMD7). Some of the bits in SPCMD0 register is used to set a transfer mode for the RSPIA in slave mode. The RSPIA in master mode sequentially references SPCMDm register according to the settings in the SPSCR.SPSLN[2:0] bits, and executes the serial transfer that is set in the referenced SPCMDm register.
The SPCMDm register should be set while the transmit buffer is empty (data for the next transfer is not set) and before setting of the data that is to be transmitted when that SPCMDm register is referenced.
SPCMDm that is referenced by the RSPIA in master mode can be checked by means of the SPSSR.SPCP[2:0] bits. If this register is changed while the SPCR.SPE bit is 1, the operation after the change is not guaranteed.

CPHA Bit (RSPCK Phase Setting)

The CPHA bit is used to set an RSPCK phase of the RSPIA in master mode or slave mode. Data communications between RSPIA modules require the same RSPCK phase setting between the modules.
When the SPCR.SPMS is 0 and the SPCR.FRFS bit is 1 in TI SSP mode, setting the CPHA bit to 0 is not effective.

CPOL Bit (RSPCK Polarity Setting)

The CPOL bit is used to set an RSPCK polarity of the RSPIA in master mode or slave mode. Data communications between RSPIA modules require the same RSPCK polarity setting between the modules.

BRDV[1:0] Bits (Bit Rate Division Setting)

The BRDV[1:0] bits are used to determine the bit rate. A bit rate is determined by combinations of the settings in the BRDV[1:0] bits and the SPBR register (refer to section 38.2.10, RSPI Bit Rate Register (SPBR)). The settings in the SPBR register determine the base bit rate. The settings in the BRDV[1:0] bits are used to select a bit rate which is obtained by dividing the base bit rate by 1, 2, 4, or 8. In the SPCMDm register, different BRDV[1:0] bit settings can be specified. This enables execution of serial transfers at a different bit rate for each command.

SSLKP Bit (SSL Signal Level Keeping)

When the RSPIA in master mode performs a serial transfer, the SSLKP bit specifies whether the SSL0n (n = 0 to 3) signal level for the current command is to be kept or negated between the SSL0n negation timing associated with the current command and the SSL0n assertion timing associated with the next command.
Setting the SSLKP bit to 1 enables a burst transfer. For details, refer to section 38.3.13.1, Master Mode Operation (4) Burst Transfer.
When using the RSPIA in slave mode, the SSLKP bit should be set to 0.

LSBF Bit (RSPI LSB First)

The LSBF bit is used to set the data format of the RSPIA in master mode or slave mode to MSB first or LSB first.

SPNDEN Bit (RSPI Next-Access Delay Enable)

The SPNDEN bit is used to set the period from the time the RSPIA in master mode terminates a serial transfer and sets the SSL0n signal inactive until the RSPIA enables the SSL0n signal assertion for the next access (next-access delay). If the SPNDEN bit is 0, the RSPIA sets the next-access delay to 1 RSPCK + 5 PCLKA. If the SPNDEN bit is 1, the RSPIA inserts a next-access delay in compliance with the SPND setting.
When using the RSPIA in slave mode, the SPNDEN bit should be set to 0.

SLNDEN Bit (SSL Negation Delay Setting Enable)

[Motorola SPI]
The SLNDEN bit is used to set the period from the time the RSPIA in master mode stops RSPCK oscillation until the RSPIA sets the SSL signal inactive (SSL negation delay). If the SLNDEN bit is 0, the RSPIA sets the SSL negation delay to 1 RSPCK. If the SLNDEN bit is 1, the RSPIA negates the SSL signal at an SSL negation delay in compliance

with the SSLND setting.
When using the RSPIA in slave mode, set the SLNDL[2:0] bits to 000b.

[TI SSP]
The SLNDEN bit is used to set the period from the time the RSPIA in master mode stops RSPCK oscillation until the RSPIA sets the OE signal inactive, or from the detection of a final RSPCK edge to the negation of the OE signal by the RSPIA in slave mode. If the SLNDEN bit is 0, the SSL negation delay is 1 RSPCK in master mode and 1 PCLKA in slave mode. If the SLNDEN bit is 1, the RSPIA negates the SSL signal at an SSL negation delay in compliance with the SSLND setting.

[Clock synchronous]
When using the RSPIA in slave mode, set this bit to 0.

SCKDEN Bit (RSPCK Delay Setting Enable)

[Motorola SPI]
The SCKDEN bit is used to set the period from the point when the RSPIA in master mode activates the SSL signal until the RSPCK starts oscillation (RSPCK delay). If the SCKDEN bit is 0, the RSPIA sets the RSPCK delay to 1 RSPCK. If the SCKDEN bit is 1, the RSPIA starts the oscillation of RSPCK at an RSPCK delay in compliance with the SPCKD setting.

[TI SSP]
The SCKDEN bit is used to set the period from the point when the RSPIA in master mode activates the SSL signal until the RSPCK starts oscillation (RSPCK delay) and to the negation of the SSL0n signal. If the SCKDEN bit is 0, the RSPIA does not set the RSPCK delay. If the SCKDEN bit is 1, the RSPIA starts the oscillation of RSPCK at an RSPCK delay in compliance with the SPCKD setting.
When using the RSPIA in slave mode, the SCKDEN bit should be set to 0.

SPB[4:0] Bits (RSPI Data Length Setting)

The SPB[4:0] bits are used to set a transmit data length for the RSPIA in master mode or slave mode.

SSLA[2:0] Bits (SSL Signal Assertion Setting)

The SSLA[2:0] bits control the SSL0n signal assertion when the RSPIA performs serial transfers in master mode. Setting the SSLA[2:0] bits controls the assertion for the SSL0n signal. When an SSL0n (n = 0 to 3) signal is asserted, its polarity is determined by the set value in the corresponding SSLP. When the SSLA[2:0] bits are set to 000b in multi-master mode, serial transfers are performed with all the SSL signals in the negated state (as the SSL00 pin acts as input).
When using the RSPIA in slave mode, set the SSLA[2:0] bits to 000b.

38.2.13 RSPI Data Control Register (SPDCR)

Address(es): RSPIA0.SPDCR 000E 2840h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	SPFC[1:0]		—	—	—	DINV	SPRDTD	—	—	BYSW
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BYSW	Byte Swap	0: Byte swapping of SPDR data disabled 1: Byte swapping of SPDR data enabled	R/W
b2, b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b3	SPRDTD	RSPI Receive/Transmit Data Select	0: SPDR values are read from the receive buffer 1: SPDR values are read from the transmit buffer	R/W
b4	DINV	Transfer Data Invert	0: Not invert serial data 1: Invert serial data	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R
b9, b8	SPFC[1:0]	Number of Frames Setting	b9 b8 0 0: 1 frame 0 1: 2 frames 1 0: 3 frames 1 1: 4 frames	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SPDCR register is used to control the data format of the RSPIA. If this register is changed while the SPCR.SPE bit is 1, the operation after the change is not guaranteed.

BYSW Bit (Byte Swap)

The BYSW bit is used to swap a transmit/receive data in byte units. A data alignment after byte swap is different by a data length (setting of SPCMDm.SPB[4:0]).

When using byte swap, set the data length (setting of SPCMDm.SPB[4:0]) to 32 bits or 16 bits. Other case of data length (i.e. 4 to 15, 17 to 31-bit length), byte swap is not guaranteed. For the arrangement of data before and after swapping data lengths of 32 bits and 16 bits, refer to section 38.3.4.4, Byte Swap Transmission and section 38.3.4.5, Byte Swap Reception.

If this bit is changed while the SPCR.SPPE bit is 1, the operation is not guaranteed.

SPRDTD Bit (RSPI Receive/Transmit Data Select)

The SPRDTD bit is used to whether the SPDR register reads values from the receive buffer or from the transmit buffer. If reading is from the transmit buffer, the value written to the SPDR register immediately beforehand is read.

DINV Bit (Transfer Data Invert)

The DINV bit is used to invert transmit data and receive data.

When the DINV bit is set to 1, transmit buffer (SPTX) data is inverted to invert transmit data and receive data, and then the inverted data is stored in the receive buffer (SPRX). The parity bit is the value corresponding to the inverted transmission/reception data.

SPFC[1:0] Bits (Number of Frames Setting)

The SPFC[1:0] bits are used for the condition to set the SPSR.SPCF flag in slave receive-only mode.

For details on the SPCF flag setting conditions, refer to [Setting condition] of the SPCF flag in section 38.2.16.

Note that these bits are not effective except in the slave receive-only mode.

38.2.14 RSPI FIFO Control Register (SPFCR)

Address(es): RSPIA0.SPFCR 000E 2844h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	TTRG[1:0]		—	—	—	—	—	—	RTRG[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	RTRG[1:0]	Receive FIFO Threshold Setting	b1 b0 0 0: When the receive FIFO fill level is 0. 0 1: When the receive FIFO fill level is 1. 1 0: When the receive FIFO fill level is 2. 1 1: When the receive FIFO fill level is 3.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b9, b8	TTRG[1:0]	Transmit FIFO Threshold Setting	b9 b8 0 0: When the transmit FIFO free level is 0. 0 1: When the transmit FIFO free level is 1. 1 0: When the transmit FIFO free level is 2. 1 1: When the transmit FIFO free level is 3.	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SPFCR register is used to control the FIFO threshold. If this register is changed while the SPCR.SPE bit is 1, the operation after the change is not guaranteed.

RTRG[1:0] Bits (Receive FIFO Threshold Setting)

The RTRG[1:0] bits are used to select receive FIFO threshold. When the number of data stored in the receive FIFO is greater than the threshold value set by RTRG[1:0], the receive buffer full flag is set.

TTRG[1:0] Bits (Transmit FIFO Threshold Setting)

The TTRG[1:0] bits are used to select transmit FIFO threshold. When the number of empty stages in the transmit FIFO is greater than the threshold value set in TTRG[1:0], the transmit buffer empty flag is set.

38.2.15 RSPI Sequence Status Register (SPSSR)

Address(es): RSPIA0.SPSSR 000E 2851h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	SPECM[2:0]			—	SPCP[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SPCP[2:0]	RSPI Command Pointer	b2 b0 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
b3	—	Reserved	This bit is read as 0.	R
b6 to b4	SPECM[2:0]	RSPI Error Command	b6 b4 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
b7	—	Reserved	This bit is read as 0.	R

The SPSSR register indicates the sequence control status when the RSPIA operates in master mode.
Any writing to the SPSSR register is ignored.

SPCP[2:0] Bits (RSPI Command Pointer)

The SPCP[2:0] bits indicate the SPCMDm register that is currently pointed to by the pointer during sequence control by the RSPIA.
For the RSPIA's sequence control, refer to section 38.3.13.1, Master Mode Operation.

SPECM[2:0] Bits (RSPI Error Command)

The SPECM[2:0] bits indicate the SPCMDm register that is specified by the SPCP[2:0] bits when an error is detected during sequence control by the RSPIA. The RSPIA updates the SPECM[2:0] bits only when an error is detected. If the SPSR.OVRF, MODF, and PERF flags are 0 and there is no error, the values of the SPECM[2:0] bits have no meaning.
For the RSPIA's error detection function, refer to section 38.3.10, Error Detection. For the RSPIA's sequence control, refer to section 38.3.13.1, Master Mode Operation.

38.2.16 RSPI Status Register (SPSR)

Address(es): RSPIA0.SPSR 000E 2852h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SPRF	SPCF	SPTEF	UDRF	PERF	MODF	IDLNF	OVRF	RRDYF	—	—	—	—	—	—	—
Value after reset:	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0.	R
b7	RRDYF	Receive Data Ready Flag	0: Receive data ready is not detected 1: Receive data ready is detected	R
b8	OVRF	Overrun Error Flag	0: No overrun error occurs 1: An overrun error occurs	R
b9	IDLNF	Idle Flag	0: RSPIA is in the idle state 1: RSPIA is in the transfer state	R
b10	MODF	Mode Fault Error Flag	0: Neither a mode fault error nor an underrun error occurs 1: A mode fault error or an underrun error occurs	R
b11	PERF	Parity Error Flag	0: No parity error occurs 1: A parity error occurs	R
b12	UDRF	Underrun Error Flag	This flag is used with the MODF flag to check the state in terms of mode fault errors and underrun errors. MODF UDRF 0 x: Neither a mode fault error nor an underrun error occurs 1 0: A mode fault error occurs 1 1: An underrun error occurs	R
b13	SPTEF	Transmit Buffer Empty Flag	0: The number of empty stages in the transmit FIFO ≤ the value set by the SPFCR.TTRG[1:0] bits 1: The number of empty stages in the transmit FIFO > the value set by the SPFCR.TTRG[1:0] bits	R
b14	SPCF	Communication End Flag	0: RSPIA is not communicating or communicating 1: RSPIA communication is completed	R
b15	SPRF	Receive Buffer Full Flag	0: The number of data stored in the receive FIFO ≤ number of frames set by the SPFCR.RTRG[1:0] bits 1: The number of data stored in the receive FIFO > number of frames set by the SPFCR.RTRG[1:0] bits	R

x: don't care

The SPSR register is used to store flags that indicate RSPIA's operating status.

RRDYF Flag (Receive Data Ready Flag)

The RRDYF flag indicates a certain period of time has elapsed while the number of data stored in the receive FIFO during communication (SPCR.SPE = 1) is equal to or less than the receive FIFO threshold value.
This flag is set to 0 when the receive operation is not performed (SPCR.CMMD[1:0] = 01b).

[Setting condition]

When all the following conditions are satisfied.

- SPDRCSR register ≠ 00h.
- After the receive FIFO has been written, when the number of data stored in the receive FIFO is equal to or less than the receive FIFO threshold value and the value set by the SPDRCSR register has elapsed

[Clearing condition]

When 1 is written to the SPSCLR.RRDYFC bit.

OVRF Flag (Overrun Error Flag)

The OVRF flag indicates the occurrence of an overrun error. In master mode (when the SPCR.MSTR bit is 1) and when the RSPCK auto-stop function is enabled (the SPCR.SCKASE bit is 1), an overrun error does not occur; accordingly this flag does not become 1. For details, refer to section 38.3.10.1, Overrun Error.

[Setting condition]

When serial transfer is completed with no free space in the receive FIFO under any of the following conditions.

- The SPCR.CMMD[1:0] bits are 00b (transmit-receive master mode or transmit-receive slave mode).
- The SPCR.CMMD[1:0] bits are 10b (receive-only master mode or receive-only slave mode).

[Clearing condition]

When 1 is written to the SPSCLR.OVRFC bit

IDLNF Flag (Idle Flag)

The IDLNF flag indicates the transfer status of the RSPIA.

[Setting condition]

(1) Transmit-receive master mode or transmit-only master mode

- When none of the conditions are satisfied in transmit-receive master mode or transmit-only master mode under the [Clearing condition] below.

(2) Transmit-only master mode

- When 1 is written to the SPRMCR.START bit.

(3) Slave mode

- The SPCR.SPE bit is 1 (enables the RSPI function)

[Clearing condition]

(1) Transmit-receive master mode or transmit-only master mode

Communication status: No. 1-1 to 1-6 (for details, refer to Table 38.4 RSPI Communication Status)

- When the SPCR.SPE bit is set to 0 (disables the RSPI function)
- When all of the following conditions are satisfied.
  (a) The the next transmit data is not set in the transmit buffer (SPTX)
  (b) The SPSSR.SPCP[2:0] bits are 000b (beginning of sequence control)
  (c) The operations up to the next-access delay have finished (the master main state machine has entered the idle state)

(2) Transmit-only master mode

Communication status: No. 1-7 to 1-9 (for details, refer to Table 38.4 RSPI Communication Status)

- When the SPCR.SPE bit is set to 0 (disables the RSPI function)
- When any of the following conditions is satisfied.
  (a) When the SPRMCR.RFC[4:0] bits are 00000b, after 1 is written to the SPRMCR.TERM bit, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)
  (b) When the SPRMCR.RFC[4:0] bits are other than 00000b, after 1 is written to the SPRMCR.TERM bit, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)
  (c) When the SPRMCR.RFC[4:0] bits are other than 00000b, after the operation is completed for the number of received frames set by the SPRMCR.RFC[4:0] bits, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)

(3) Slave mode

Communication status: No. 0-1 to 0-9 (for details, refer to Table 38.4 RSPI Communication Status)

- When the SPCR.SPE bit is set to 0 (disables the RSPI function)

MODF Flag (Mode Fault Error Flag)

Indicates the occurrence of a mode fault error or an underrun error. The UDRF flag indicates whether the error is a mode fault error or an underrun error.

[Setting condition]

(1) Multi-master mode

- When the input level of the SSL0n pin changes to the active level while the SPCR.MSTR bit is 1 (master mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), the RSPIA detects a mode fault error

(2) Slave mode (SPI operation, Motorola SPI)

When any of the following conditions are satisfied.

- When the SSL00 pin is negated before the RSPCK cycle necessary for data transfer ends while the SPCR.MSTR bit is 0 (slave mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), the RSPIA detects a mode fault error
- When the serial transfer starts while the SPCR.SPE bit is 1 (enables the RSPI function) and the transmit data are not ready for output, the RSPIA detects an underrun error

(3) Slave mode (SPI operation, TI SSP)

When any of the following conditions are satisfied.

- When the SSL00 pin is asserted before the RSPCK cycle necessary for data transfer ends while the SPCR.MSTR bit is 0 (slave mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), the RSPIA detects a mode fault error
- When the serial transfer starts while the SPCR.SPE bit is 1 (enables the RSPI function) and the transmit data are not ready for output, the RSPIA detects an underrun error

The active level of the SSL0n signal is determined by the SSLP.SSLnP bit (SSL signal polarity setting bit).

[Clearing condition]

When 1 is written to the SPSCLR.MODFC bit

PERF Flag (Parity Error Flag)

Indicates the occurrence of a parity error.

[Setting condition]

When the serial transfer ends and a parity error is detected while the SPCR.SPPE bit is 1 under any of the following conditions.

- The SPCR.CMMD[1:0] bits are 00b (transmit-receive master mode or transmit-receive slave mode)
- The SPCR.CMMD[1:0] bits are 10b (receive-only master mode or receive-only slave mode)

[Clearing condition]

When 1 is written to the SPSCLR.PERFC bit

UDRF Flag (Underrun Error Flag)

When a mode fault error or an underrun error has occurred, the UDRF flag indicates whether the error is a mode fault error or an underrun error.

[Setting condition]

When the serial transfer starts while the SPCR.MSTR bit is 0, the SPCR.CMMD[1:0] bits are 00b or 01b (transmit-receive slave mode or transmit-only slave mode), the SPCR.SPE bit is 1 (enables the RSPI function) and the transmit data are not ready for output, the RSPIA detects an underrun error

[Clearing condition]

When 1 is written to the SPSCLR.UDRFC bit

SPTEF Flag (Transmit Buffer Empty Flag)

Indicates whether the transmit buffer (SPTXn, n = 0 to 3) in the RSPI data register (SPDR) has valid data.

[Setting condition]

When any of the following conditions are satisfied.

- When the SPCR.SPE bit is 0 (disables the RSPI function)
- When the number of empty transmission FIFO stages is greater than the threshold value set in SPFCR.TTRG[1:0]
- When 1 is written to the SPFCLR.FCLR bit

[Clearing condition]

When any of the following conditions are satisfied.

- At the final access when transmit data is written to SPDR (SPTXn) in one processing routine using DTC/DMAC
- When 1 is written to the SPSCLR.SPTEFC bit

The SPDR register can be set only when the SPSR.SPTEF flag is 1. The data in the transmit buffer (SPTXn) is not updated when the SPDR register is set while the SPSR.SPTEF flag is 0.

SPCF Flag (Communication End Flag)

Indicates communication end status of RSPI. It turns 1 at communication end and turns 0 at starting next communication.

[Setting condition]

(1) Transmit-receive master mode or transmit-only master mode

Communication status: No. 1-1 to 1-6 (for details, refer to Table 38.4 RSPI Communication Status)

When all of the following conditions are satisfied.

- The next transmit data is not set in the transmission buffer (SPTXn)
- The SPSSR.SPCP[2:0] bits are 000b (beginning of sequence control)
- The operations up to the next-access delay have finished (the master main state machine has entered the idle state)

(2) Transmit-only master mode

Communication status: No. 1-7 to 1-9 (for details, refer to Table 38.4 RSPI Communication Status)

When any of the following conditions are satisfied.

- When the SPRMCR.RFC[4:0] bits are 00000b, after 1 is written to the SPRMCR.TERM bit, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)
- When the SPRMCR.RFC[4:0] bits are other than 00000b, after 1 is written to the SPRMCR.TERM bit, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)

- When the SPRMCR.RFC[4:0] bits are other than 00000b, after the operation is completed for the number of received frames set by the SPRMCR.RFC[4:0] bits, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)

(3) Transmit-receive slave mode or transmit-only slave mode (SPI operation, Motorola SPI)
Communication status: No. 0-1, 0-4 (for details, refer to Table 38.4 RSPI Communication Status)
When all of the following conditions are satisfied.

- The next transmit data is not set in the transmission buffer (SPTXn)
- The transmission shift register is empty (RSPIA does not perform serial transfer)
- The SSL00 input is negated

(4) Transmit-receive slave mode or transmit-only slave mode (SPI operation, TI SSP)
Communication status: No. 0-2, 0-5 (for details, refer to Table 38.4 RSPI Communication Status)
When all of the following conditions are satisfied.

- The next transmit data is not set in the transmission buffer (SPTXn)
- The transmission shift register is empty (RSPIA does not perform serial transfer)
- When the SSL negation delay is completed

(5) Transmit-receive slave mode or transmit-only slave mode (clock synchronous operation)
Communication status: No. 0-3, 0-6 (for details, refer to Table 38.4 RSPI Communication Status)
When all of the following conditions are satisfied.

- The next transmit data is not set in the transmission buffer (SPTXn)
- The transmission shift register is empty (RSPIA does not perform serial transfer)
- The last even edge of RSPCK of the frame was detected (SPCMDm.CPHA = 1)

(6) Receive-only slave mode (SPI operation, Motorola SPI)
Communication status: No. 0-7 (for details, refer to Table 38.4 RSPI Communication Status)

- SSL00 input was negated after getting frames for SPDCR.SPFC[1:0] set value in the receive buffer (SPRX)

(7) Receive-only slave mode (SPI operation, TI SSP)
Communication status: No. 0-8 (for details, refer to Table 38.4 RSPI Communication Status)

- SSL negation delay is completed after getting frames for SPDCR.SPFC[1:0] set value in the receive buffer (SPRX).

(8) Receive-only slave mode (clock synchronous operation)
Communication status: No. 0-9 (for details, refer to Table 38.4 RSPI Communication Status)

- The last even edge of RSPCK of the last frame received for SPFC[1:0] set value was detected (SPCMDm.CPHA = 1)

[Clearing condition]
(1) Transmit-receive master mode or transmit-only master mode
Communication status: No. 1-1 to 1-6 (for details, refer to Table 38.4 RSPI Communication Status)
When any of the following conditions are satisfied.

- The next transmit data is set in the transmission buffer (SPTXn)
- When 1 is written to the SPSCLR.SPCFC bit

(2) Transmit-only master mode

Communication status: No. 1-7 to 1-9 (for details, refer to Table 38.4 RSPI Communication Status)
When any of the following conditions are satisfied.

- When 1 is written to the SPRMCR.START bit while the SPCR.SPE bit is 1
- When 1 is written to the SPSCLR.SPCFC bit

(3) Transmit-receive slave mode or transmit-only slave mode

Communication status: No. 0-1 to 0-6 (for details, refer to Table 38.4 RSPI Communication Status)
When any of the following conditions are satisfied.

- The next transmit data is set in the transmission buffer (SPTXn)
- When 1 is written to the SPSCLR.SPCFC bit

(4) Receive-only slave mode (SPI operation)

Communication status: No. 0-7, 0-8 (for details, refer to Table 38.4 RSPI Communication Status)
When any of the following conditions are satisfied.

- The SSL00 input assertion of next data is detected
- When 1 is written to the SPSCLR.SPCFC bit

(5) Receive-only slave mode (clock synchronous operation)

Communication status: No. 0-9 (for details, refer to Table 38.4 RSPI Communication Status)
When any of the following conditions are satisfied.

- The first edge of RSPCK of the next data was detected
- When 1 is written to the SPSCLR.SPCFC bit

SPRF Flag (Receive Buffer Full Flag)

Indicates whether the receive buffer (SPRX) in the RSPI data register has valid data.

[Setting condition]

When the number of data stored in the receive FIFO is greater than the number of frames set in the SPFCR.RTRG[1:0] bits in transmit-receive mode or receive-only mode.
Note that the SPRF flag does not become 1 when the OVRF flag is 1 (Refer to section 38.3.10, Error Detection, for details).

[Clearing condition]

When any of the following conditions are satisfied.

- At the final access when receive data is read from SPDR register (SPRXn, n = 0 to 3) in one processing routine using DTC/DMAC
- When 1 is written to the SPSCLR.SPRFC bit
- When 1 is written to the SPFCLR.FCLR bit

38.2.17 RSPI Transmit FIFO Status Register (SPTFSR)

Address(es): RSPIA0.SPTFSR 000E 2858h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	FREE[2:0]		
Value after reset:	0	0	0	0	0	1	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	FREE[2:0]	Transmit FIFO Free Level	b2 b0 0 0 0: Number of empty stages 0 0 0 1: Number of empty stages 1 0 1 0: Number of empty stages 2 0 1 1: Number of empty stages 3 1 0 0: Number of empty stages 4	R
b7 to b3	—	Reserved	These bits are read as 0.	R

FREE[2:0] Bits (Transmit FIFO Free Level)

Indicate the number of empty transmit FIFO stages. By setting the SPCR.SPE bit to 0, the FREE[2:0] bits will be 100b.

38.2.18 RSPI Receive FIFO Status Register (SPRFSR)

Address(es): RSPIA0.SPRFSR 000E 285Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	FILL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	FILL[2:0]	Receive FIFO Fill Level	b2 b0 0 0 0: Number of stored stages 0 0 0 1: Number of stored stages 1 0 1 0: Number of stored stages 2 0 1 1: Number of stored stages 3 1 0 0: Number of stored stages 4	R
b7 to b3	—	Reserved	These bits are read as 0.	R

FILL[2:0] Bits (Receive FIFO Fill Level)

Indicate the number of stored receive FIFO stages. By setting the SPCR.SPE bit to 0, the FILL[2:0] bits will be 000b.

38.2.19 RSPI Status Clear Register (SPSCLR)

Address(es): RSPIA0.SPSCLR 000E 286Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SPRFC	SPCFC	SPTEFC	UDRFC	PERFC	MODFC	—	OVRFC	RRDYFC	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b7	RRDYFC	RSPI Receive Data Ready Flag Clear	By writing 1, the RSPI receive data ready flag can be cleared. The read value is always 0.	W
b8	OVRFC	Overrun Error Flag Clear	By writing 1, the overrun error flag can be cleared. The read value is always 0.	W
b9	—	Reserved	This bit is read as 0. The write value should be 0.	R
b10	MODFC	Mode Fault Error Flag Clear	By writing 1, the mode fault error flag can be cleared. The read value is always 0.	W*1
b11	PERFC	Parity Error Flag Clear	By writing 1, the parity error flag can be cleared. The read value is always 0.	W
b12	UDRFC	Underrun Error Flag Clear	By writing 1, the underrun error flag can be cleared. The read value is always 0.	W*1, *2
b13	SPTEFC	Transmit Buffer Empty Flag Clear	By writing 1, the transmit buffer empty flag can be cleared. The read value is always 0.	W
b14	SPCFC	Communication End Flag Clear	By writing 1, the communication end flag can be cleared. The read value is always 0.	W
b15	SPRFC	Receive Buffer Full Flag Clear	By writing 1, the receive buffer full flag can be cleared. The read value is always 0.	W

Note 1. Before setting the MODFC and UDRFC, make sure that the SPSR.MODF and UDRF flags are set to 1.
Note 2. When the UDRF flag is cleared, the MODF flag is cleared at the same time (MODFC = 1).

The SPSCLR register is used to clear the status flags in the SPSR register that indicates the operating status of RSPIA.

38.2.20 RSPI FIFO Clear Register (SPFCLR)

Address(es): RSPIA0.SPFCLR 000E 286Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	FCLR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	FCLR	FIFO Clear	By writing 1, the pointer in the FIFO and the stored data are initialized. The read value is always 0.	W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SPFCLR register is used to clear the FIFO. If the value of the SPFCLR register is changed while the SPCR.SPE bit is 1, the operation after the change is not guaranteed.

FCLR Bit (FIFO Clear)

Writing 1 to this bit initializes the pointer and stored data in the transmit/receive FIFO.

38.3 Operation

In this section, the serial transfer period means a period from the beginning of driving valid data to the fetching of the final valid data.

38.3.1 Overview of RSPI Operations

The RSPIA is capable of serial transfers in the following five modes.

(1) Slave mode (SPI operation)
(2) Single-master mode (SPI operation)
(3) Multi-master mode (SPI operation)
(4) Slave mode (clock synchronous operation)
(5) Master mode (clock synchronous operation).

A particular mode of the RSPIA can be selected by using the MSTR, MODFEN, SPMS, and FRFS bits in SPCR. Table 38.6 lists the relationship between RSPI modes and SPCR settings, and a description of each mode.

Table 38.6 Relationship between RSPI Modes and SPCR Settings and Description of Each Mode

	SPI Operation			Clock Synchronous Operation	
Mode	**Slave**	**Single-Master**	**Multi-Master**	**Slave**	**Master**
MSTR bit setting	0	1	1	0	1
MODFEN bit setting	0 or 1	0	1	0	0
SPMS bit setting	0	0	0	1	1
FRFS bit setting	Enabled	Enabled	Enabled	Disabled	Disabled
RSPCK0 signal	Input	Output	Output/Hi-Z*1	Input	Output
MOSI0 signal	Input	Output	Output/Hi-Z*1	Input	Output
MISO0 signal	Output/Hi-Z*2	Input	Input	Output	Input
SSL00 signal	Input	Output	Input	Hi-Z (not used)	Hi-Z (not used)
SSL01 to SSL03 signals	Hi-Z (not used)	Output	Output/Hi-Z*1	Hi-Z (not used)	Hi-Z (not used)
Output pin mode	CMOS/open-drain				
SSL polarity change function	Supported	Supported	Supported	—	—
Transfer rate	Up to PCLKA/2				
Clock source	RSPCK input	On-chip baud rate generator	On-chip baud rate generator	RSPCK input	On-chip baud rate generator
Clock polarity	Two				
Clock phase	Two*3	Two*3	Two*3	One (CPHA = 1)	Two
First transfer bit	MSB/LSB				
Transmit data length	4 to 32 bits				
Burst transfer	Possible (CPHA = 1)	Possible (CPHA = 0,1)	Possible (CPHA = 0,1)	—	—
RSPCK delay control	Not supported	Supported	Supported	Not supported	Supported
SSL negation delay control	Not supported*4	Supported	Supported	Not supported	Supported
Next-access delay control	Not supported	Supported	Supported	Not supported	Supported
Transfer activation method	SSL input active or RSPCK oscillation	Transmit buffer is written to when a transmit buffer empty interrupt request is generated or the SPTEF flag is 1	Transmit buffer is written to when a transmit buffer empty interrupt request is generated or the SPTEF flag is 1	RSPCK oscillation	Transmit buffer is written to when a transmit buffer empty interrupt request is generated or the SPTEF flag is 1
Sequence control	Not supported	Supported	Supported	Not supported	Supported
Transmit buffer empty detection	Supported*5	Supported	Supported	Supported*5	Supported
Receive buffer full detection	Supported*6				
Overrun error detection	Supported*6	Supported*6, *7	Supported*6, *7	Supported*6	Supported*6, *7
Parity error detection	Supported*6, *8				
Mode fault error detection	Supported (MODFEN = 1)	Not supported	Supported	Not supported	Not supported
Underrun error detection	Supported*5	Not supported	Not supported	Supported*5	Not supported

Note 1. Motorola SPI: When SSL00 is asserted by another master device, the pin becomes Hi-Z.
TI SSP: When the SPCR.SPE bit is 1, the pin becomes Hi-Z from the time SSL00 is asserted by another master device until the end of communication.

Note 2. Motorola SPI: When SSL00 is negated or the SPCR.SPE bit is 0, the pin becomes Hi-Z.
TI SSP: The pin becomes Hi-Z when the RSPIA is not communicating (from the end of communication to the next assertion of SSL00) or when the SPCR.SPE bit is 0.

Note 3. In TI SSP mode, setting the SPCMDm.CPHA bit to 0 is not effective.

Note 4. Available only in TI SSP mode.

Note 5. When RSPIA is receive-only slave mode (refer to Table 38.4 RSPI Communication Status), transmit buffer empty error detection and underrun error detection are not performed.

Note 6. When RSPIA is transmit-only master mode or transmit-only slave mode (refer to Table 38.4 RSPI Communication Status), receiver buffer full detection, overrun error detection, and parity error detection are not performed.

Note 7. When the SPCR.SCKASE bit is 1, overrun error detection does not proceed.

Note 8. When the SPCR.SPPE bit is 0, parity error detection is not performed.

38.3.2 Controlling RSPI Pins

The RSPIA in single-master mode (SPI operation) or multi-master mode (SPI operation) determines MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) according to MOIFE and MOIFV bit settings in SPPCR, as listed in Table 38.7.

Table 38.7 MOSI Signal Value Determination during SSL Negation Period

MOIFE Bit	MOIFV Bit	MOSI Signal Value during SSL Negation Period
0	0, 1	Final data from previous transfer
1	0	Low
1	1	High

38.3.3 RSPI System Configuration Examples

This configuration example describes that the low level of SSL0n signals is the active level.
When connecting and using in a multi-slave or multi-master mode, the transfer format of the connected device should be unified to either Motorola SPI or TI SSP.

38.3.3.1 Single Master/Single Slave (with This MCU Acting as Master)

Figure 38.5 shows a single-master/single-slave RSPI system configuration example when this MCU is used as a master. In the single-master/single-slave configuration, the SSL00 to SSL03 output of this MCU (master) are not used. The SSL input of the SPI slave is fixed to the low level, and the SPI slave is maintained in a select state. In the transfer format corresponding to the case where the SPCMDm.CPHA bit is 0, there are slave devices for which the SSL signal cannot be fixed to the active level. In situations where the SSL signal cannot be fixed, the SSL0n output of this MCU should be connected to the SSL input of the slave device.
This MCU (master) drives the RSPCK0 and MOSI0. The SPI slave drives the MISO.

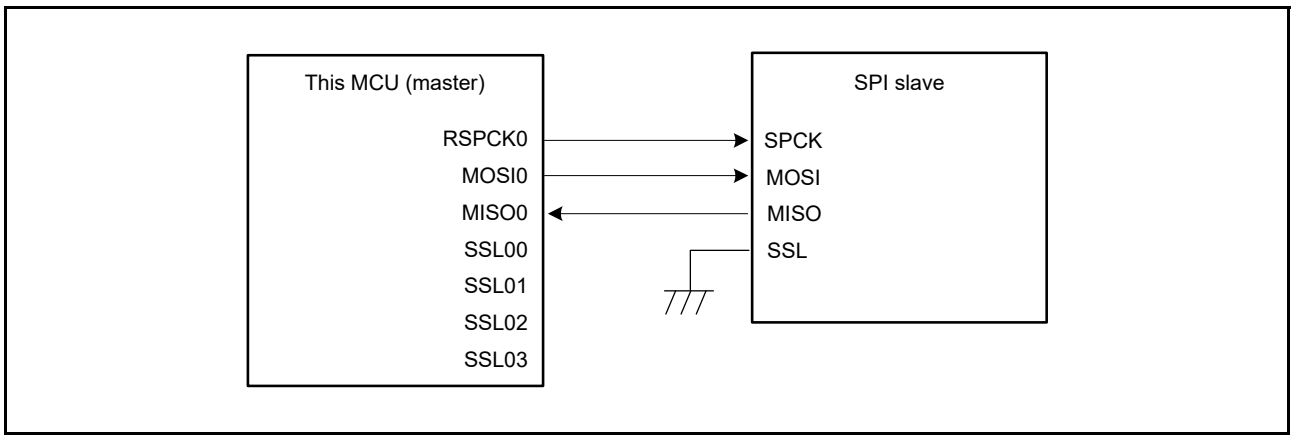

Figure 38.5 Single-Master/Single-Slave Configuration Example (This MCU = Master)

38.3.3.2 Single Master/Single Slave (with This MCU Acting as Slave)

Figure 38.6 shows a single-master/single-slave RSPI system configuration example when this MCU is used as a slave. When this MCU is to operate as a slave, the SSL00 pin is used as SSL input. The SPI master drives the SPCK and MOSI. This MCU (slave) drives the MISO0. When SSL00 is at the non-active level, the pin state is Hi-Z.
In the single-slave configuration in which the SPCMDm.CPHA bit is set to 1, set the SPCR.FRFS bit to 0, and set the SPCR.SPMS bit to 0, the SSL00 input of this MCU (slave) is fixed to the low level, this MCU (slave) is maintained in a select state, and in this manner it is possible to execute serial transfer (Figure 38.7). Note that the communication end event and the communication end interrupt do not output when SSL00 input was fixed as Figure 38.7.

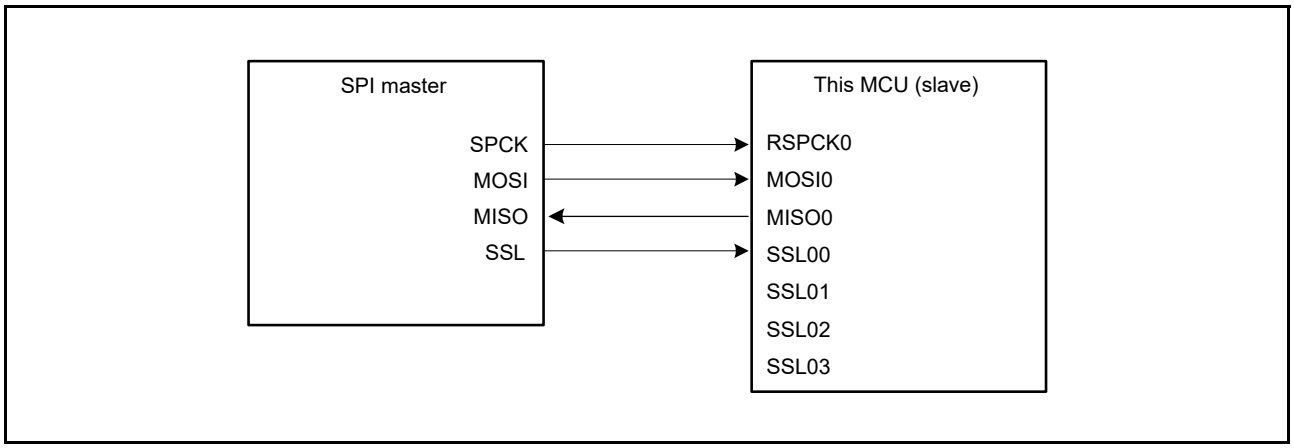

Figure 38.6 Single-Master/Single-Slave Configuration Example (This MCU = Slave, CPHA = 0)

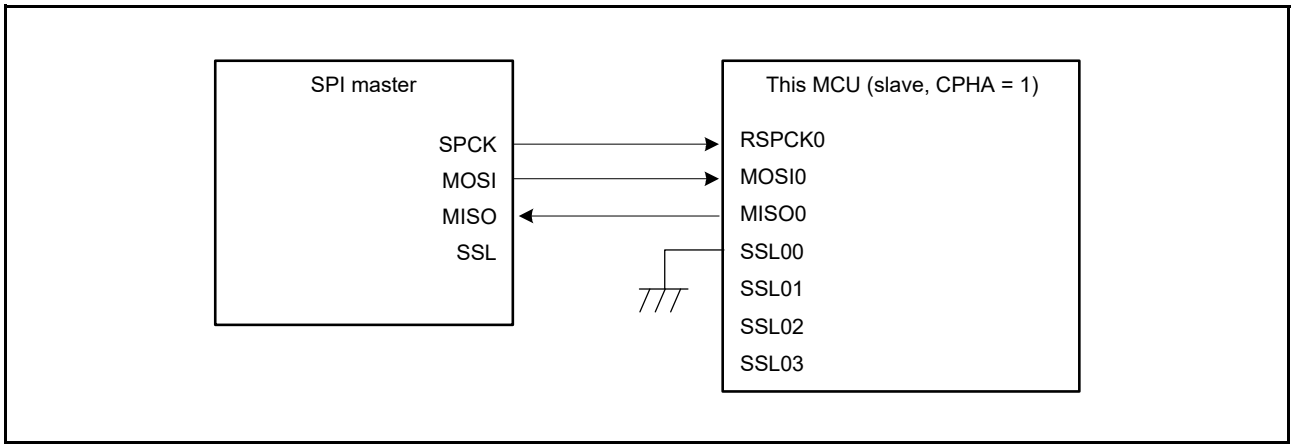

Figure 38.7 Single-Master/Single-Slave Configuration Example (This MCU = Slave, CPHA = 1)

38.3.3.3 Single Master/Multi-Slave (with This MCU Acting as Master)

Figure 38.8 shows a single-master/multi-slave RSPI system configuration example when this MCU is used as a master. In the example of Figure 38.8, the RSPI system is comprised of this MCU (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCK0 and MOSI0 outputs of this MCU (master) are connected to the SPCK and MOSI inputs of SPI slave 0 to SPI slave 3. The MISO outputs of SPI slave 0 to SPI slave 3 are all connected to the MISO0 input of this MCU (master). SSL00 to SSL03 outputs of this MCU (master) are connected to the SSL inputs of SPI slave 0 to SPI slave 3, respectively.

This MCU (master) drives RSPCK0, MOSI0, and SSL00 to SSL03. Of the SPI slave 0 to SPI slave 3, the slave that receives low-level input into the SSL input drives MISO.

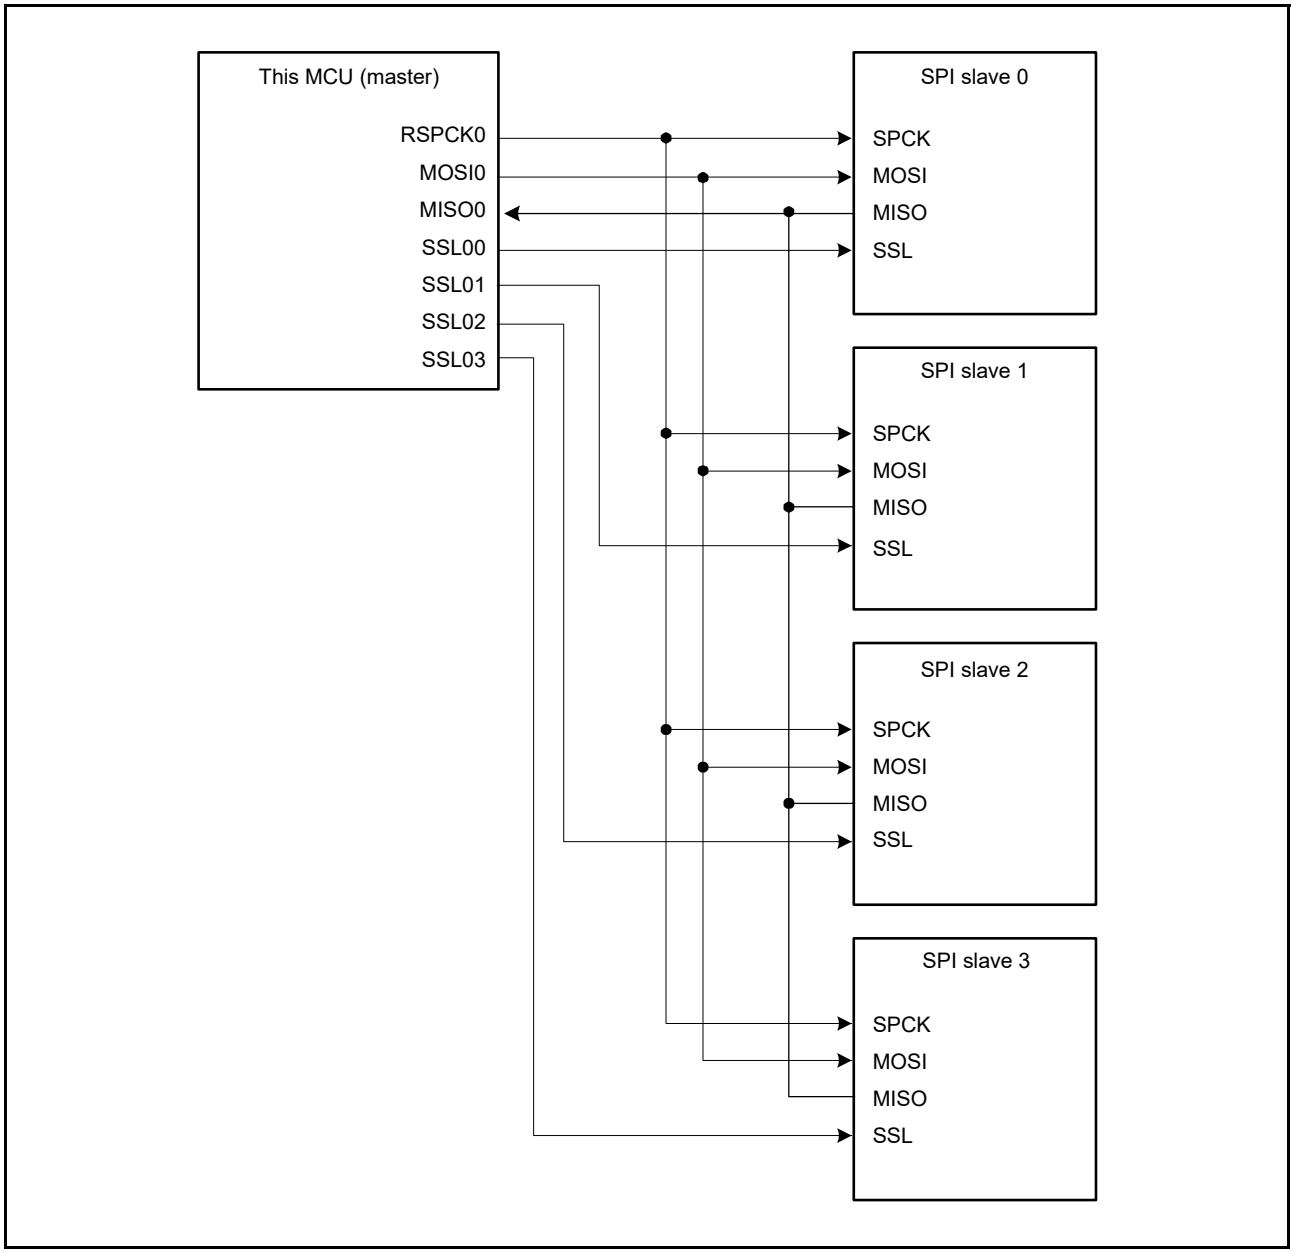

Figure 38.8 Single-Master/Multi-Slave Configuration Example (This MCU = Master)

38.3.3.4 Single Master/Multi-Slave (with This MCU Acting as Slave)

Figure 38.9 shows a single-master/multi-slave RSPI system configuration example when this MCU is used as a slave. In the example of Figure 38.9, the RSPI system is comprised of an SPI master and two MCUs (slave X and slave Y). The SPCK and MOSI outputs of the SPI master are connected to the RSPCK0 and MOSI0 inputs of the MCUs (slave X and slave Y). The MISO0 outputs of the MCUs (slave X and slave Y) are all connected to the MISO input of the SPI master. SSLX and SSLY outputs of the SPI master are connected to the SSL00 inputs of the MCUs (slave X and slave Y), respectively.
The SPI master always drives SPCK, MOSI, SSLX, and SSLY. Of the MCUs (slave X and slave Y), the slave that receives low-level input into the SSL00 input drives MISO0.

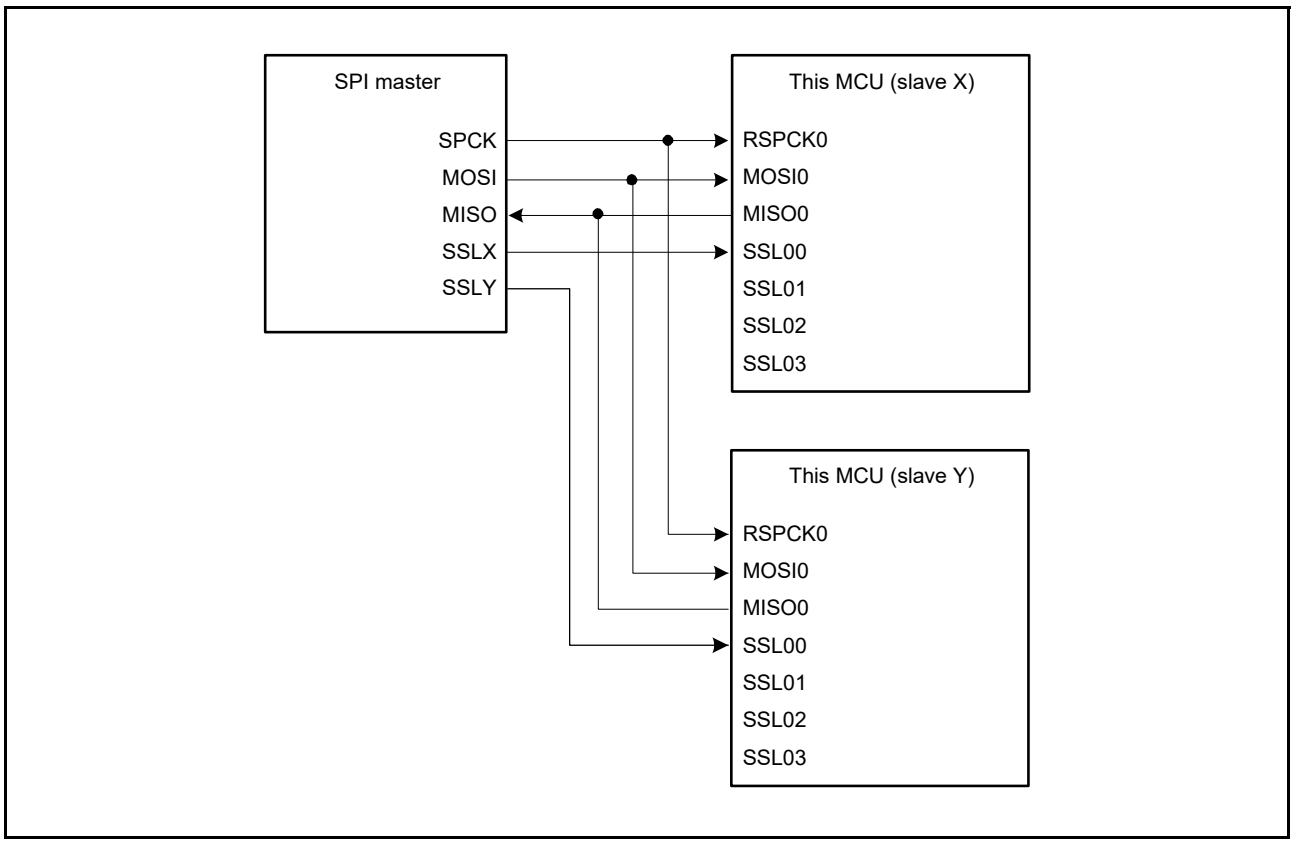

Figure 38.9 Single-Master/Multi-Slave Configuration Example (This MCU = Slave)

38.3.3.5 Multi-Master/Multi-Slave (with This MCU Acting as Master)

Figure 38.10 shows a multi-master/multi-slave RSPI system configuration example when this MCU is used as a master. In the example of Figure 38.10, the RSPI system is comprised of two MCUs (master X and master Y) and two SPI slaves (SPI slave 1 and SPI slave 2).

The RSPCK0 and MOSI0 outputs of the MCUs (master X and master Y) are connected to the SPCK and MOSI inputs of SPI slaves 1 and 2. The MISO outputs of SPI slaves 1 and 2 are connected to the MISO0 inputs of the MCUs (master X and master Y). Any generic port Y output from this MCU (master X) is connected to the SSL00 input of this MCU (master Y). Any generic port X output of this MCU (master Y) is connected to the SSL00 input of this MCU (master X). The SSL01 and SSL02 outputs of the MCUs (master X and master Y) are connected to the SSL inputs of the SPI slaves 1 and 2. In this configuration example, since the system can be comprised solely of SSL00 input, and SSL01 and SSL02 outputs for slave connections, the SSL03 output of this MCU is not required.

This MCU drives RSPCK0, MOSI0, SSL01, and SSL02 when the SSL00 input level is high. When the SSL00 input level is low, this MCU detects a mode fault error, sets RSPCK0, MOSI0, SSL01, and SSL02 to Hi-Z, and releases the RSPI bus right to the other master. Of the SPI slaves 1 and 2, the slave that receives low-level input into the SSL input drives MISO.

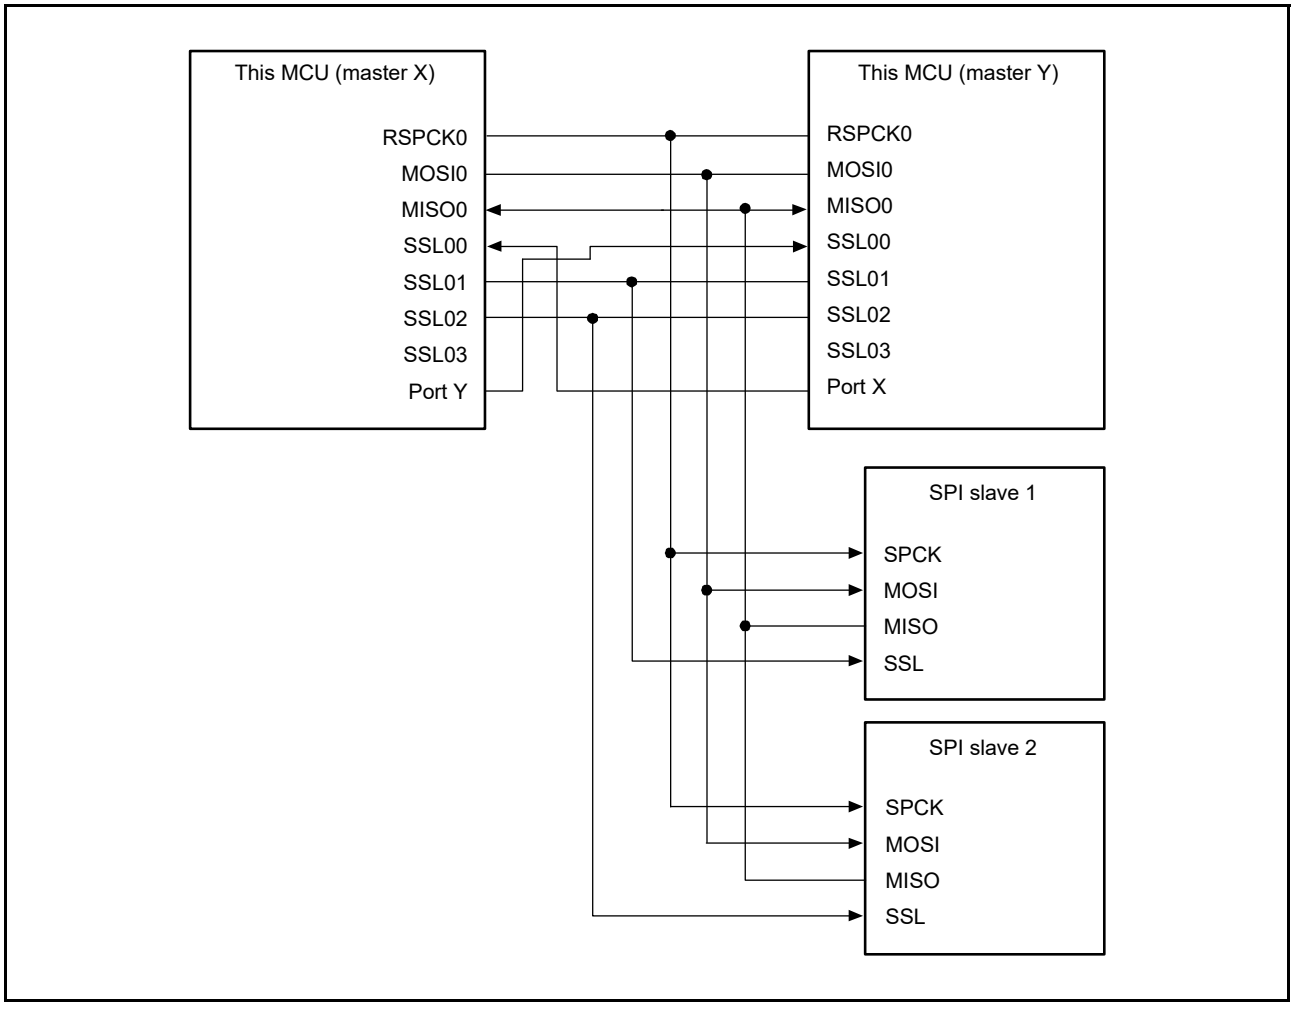

Figure 38.10 Multi-Master/Multi-Slave Configuration Example (This MCU = Master)

When setting TI SSP, enter the following levels for port X and port Y.

- Start of communication: the value of SSLP.SSL0P of the other master
- End of communication: the inverted value of SSLP.SSL0P of the other master

38.3.3.6 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (with This MCU Acting as Master)

Figure 38.11 shows a master (clock synchronous operation)/slave (clock synchronous operation) RSPI system configuration example when this MCU is used as a master. In the master (clock synchronous operation)/slave (clock synchronous operation) configuration, SSL00 to SSL03 of this MCU (master) are not used.
This MCU (master) drives the RSPCK0 and MOSI0. The SPI slave drives the MISO.

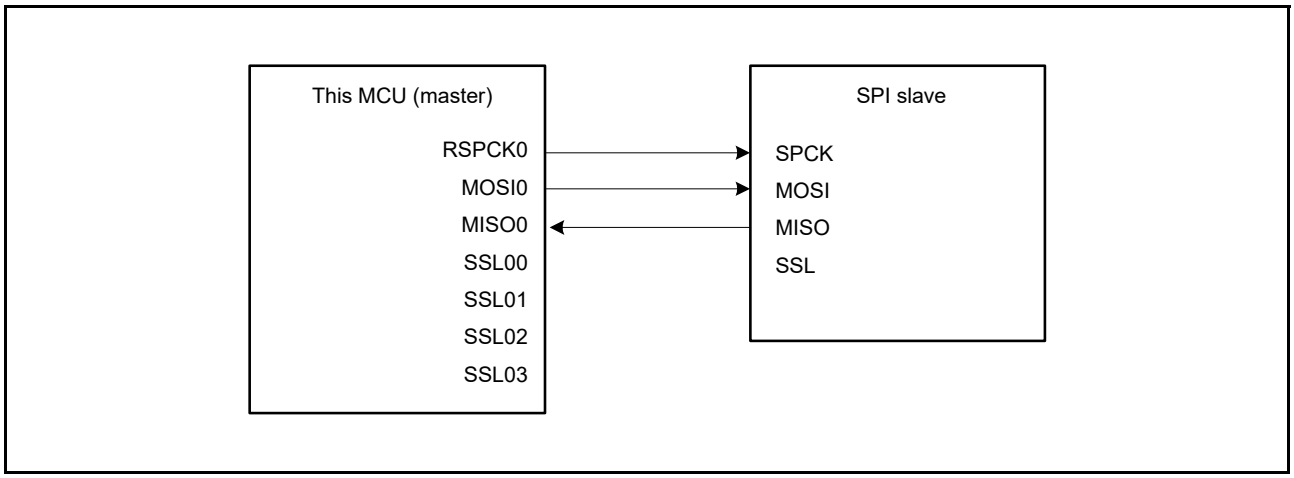

Figure 38.11 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This MCU = Master)

38.3.3.7 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (with This MCU Acting as Slave)

Figure 38.12 shows a master (clock synchronous operation)/slave (clock synchronous operation) RSPI system configuration example when this MCU is used as a slave. When this MCU is to operate as a slave (clock synchronous operation), this MCU (slave) drives the MISO0 and the SPI master drives the SPCK and MOSI. In addition, SSL00 to SSL03 of this MCU (slave) are not used.
Only in the single-slave configuration in which the SPCMDm.CPHA bit is set to 1, this MCU (slave) can execute serial transfer.

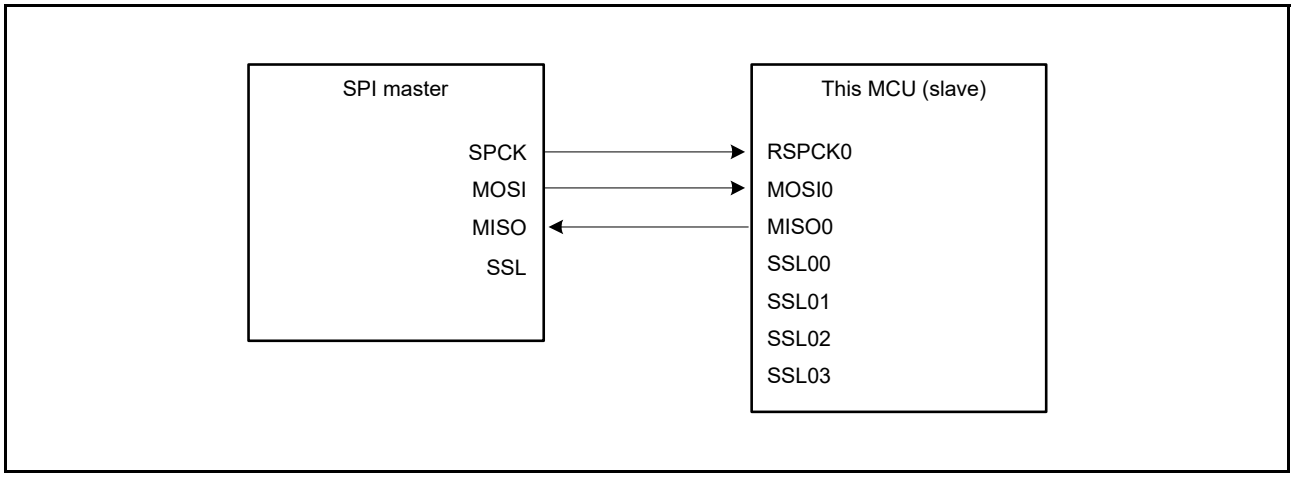

Figure 38.12 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This MCU = Slave, CPHA = 1)

38.3.4 Data Format

The RSPIA's data format depends on the settings in RSPI command register m (SPCMDm) (m = 0 to 7) and the parity enable bit in RSPI control register (SPCR.SPPE). Regardless of whether the MSB or LSB is first, the RSPIA treats the range from the LSB bit in the RSPI data register (SPDR) to the selected data length as transmit data.

38.3.4.1 Data Format of One Frame

The format of one frame of data before or after transfer is shown below.

(a) With Parity Disabled

When parity is disabled, transmission or reception of data proceeds with the length in bits selected in the RSPI data length setting bits in RSPI command register m (SPCMDm.SPB[4:0]).

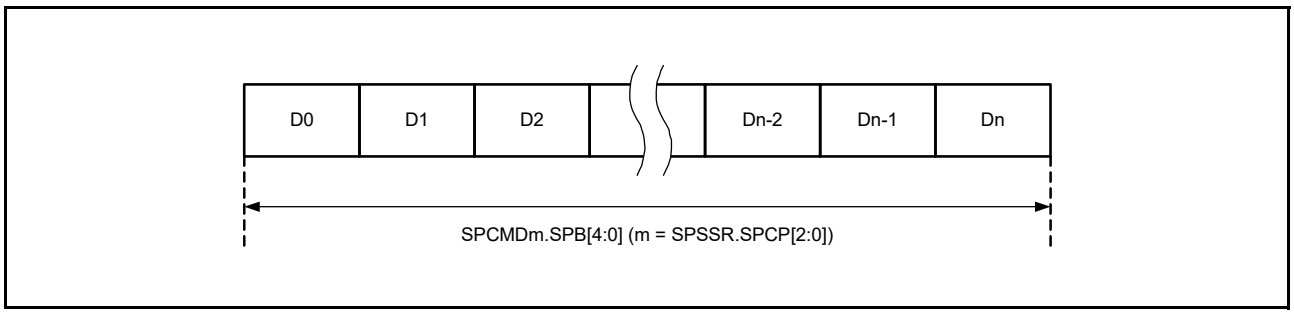

Figure 38.13 Outline of the Data Format (with Parity Disabled)

(b) With Parity Enabled

When parity is enabled, transmission or reception of data proceeds with the length in bits selected in the RSPI data length setting bits in RSPI command register m (SPCMDm.SPB[4:0]). In this case, however, the last bit is a parity bit.

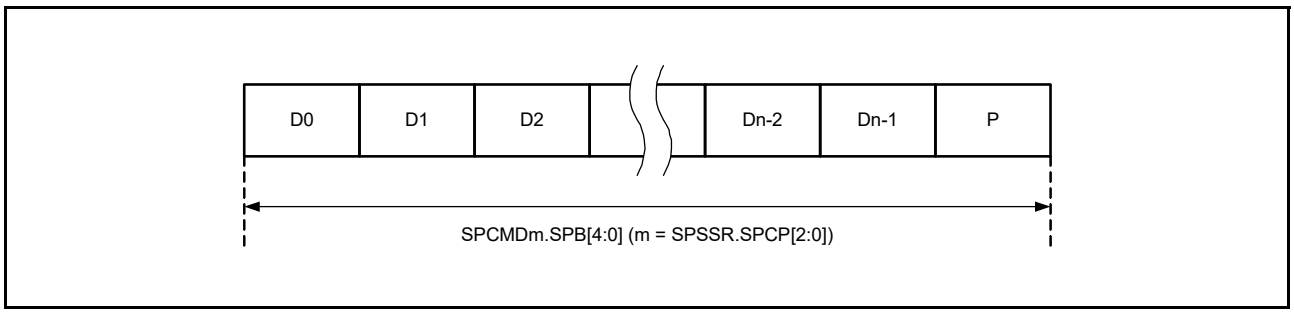

Figure 38.14 Outline of the Data Format (with Parity Enabled)

38.3.4.2 When Parity is Disabled (SPCR.SPPE = 0)

When parity is disabled, data for transmission are copied to the shift register with no prior processing. A description of the connection between the RSPI data register (SPDR) and the shift register in terms of the combination of MSB or LSB first and data length is given below.

(1) MSB First Transfer (32-Bit Data)

Figure 38.15 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, an RSPI data length of 32 bits, and MSB first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are copied to the shift register. Data for transmission are shifted out from the shift register in order from T31, through T30, and so on to T00.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R31 to R00 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer.

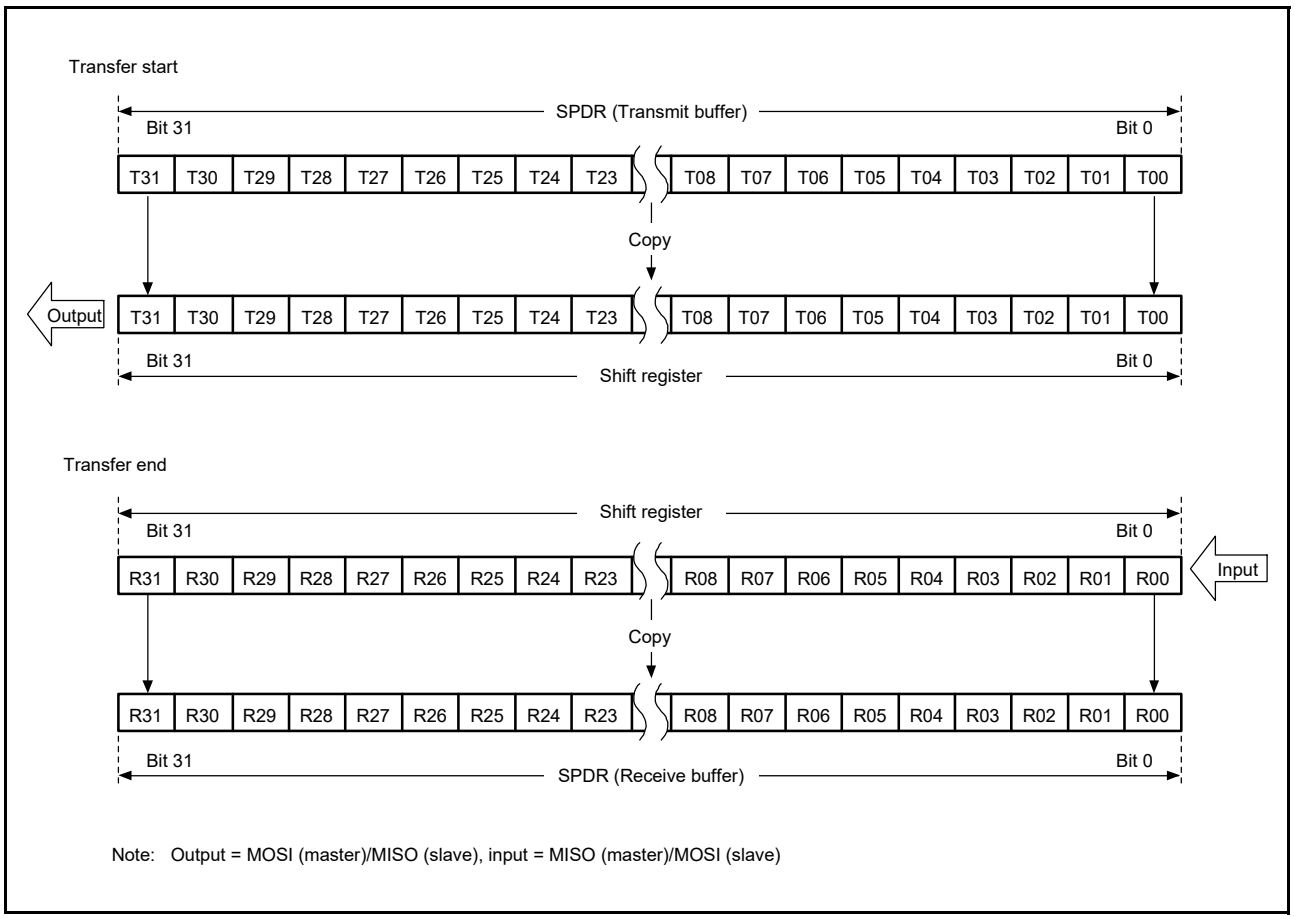

Figure 38.15 MSB First Transfer (32-Bit Data, Parity Disabled)

(2) MSB First Transfer (24-Bit Data)

Figure 38.16 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, 24 bits as the RSPI data length for an example that is not 32 bits, and MSB first selected.
In transmission, the lower-order 24 bits (T23 to T00) from the current stage of the transmit buffer are copied to the shift register. Data for transmission are shifted out from the shift register in order from T23, through T22, and so on to T00.
In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R23 to R00 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer.

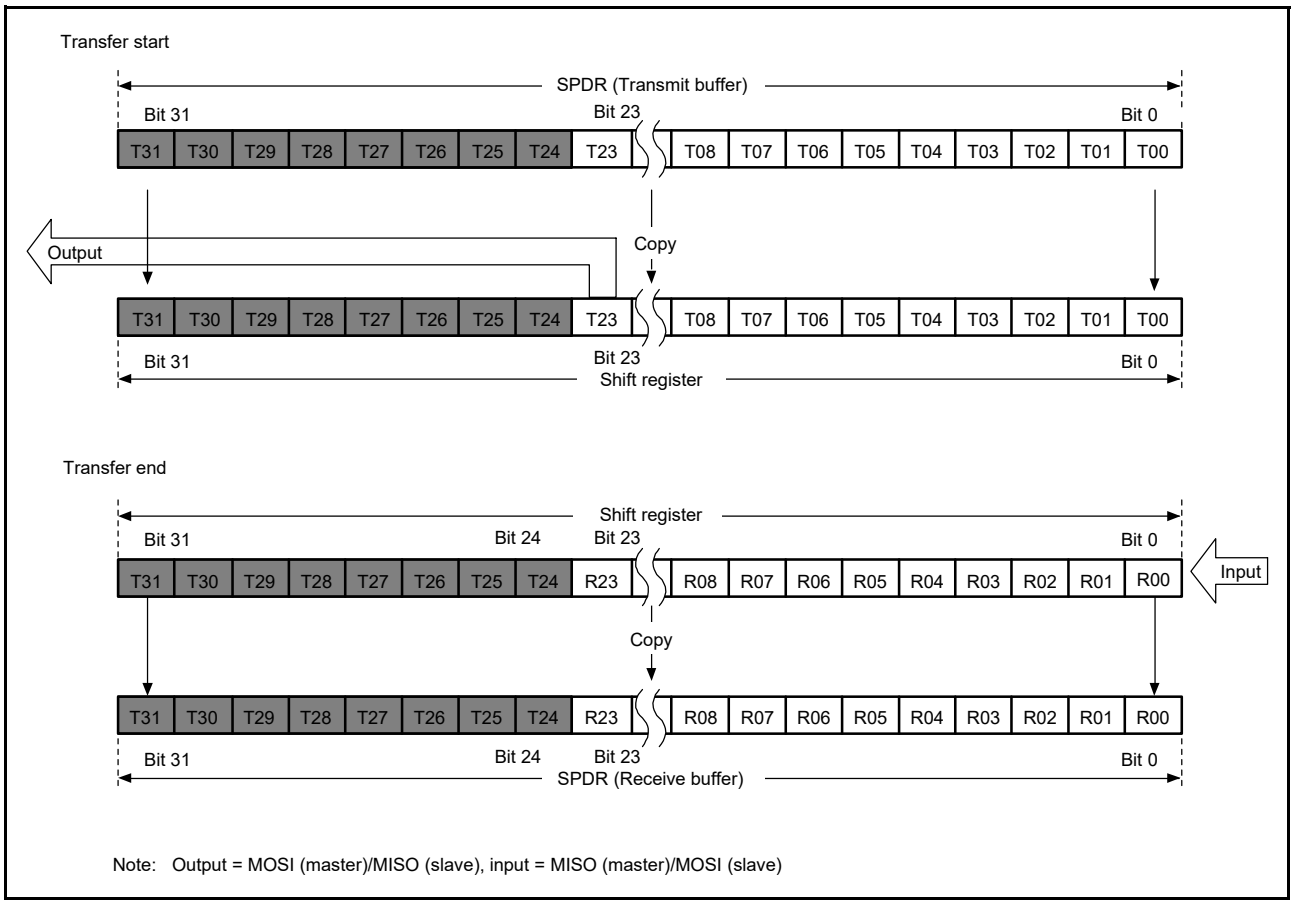

Figure 38.16 MSB First Transfer (24-Bit Data, Parity Disabled)

(3) LSB First Transfer (32-Bit Data)

Figure 38.17 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, an RSPI data length of 32 bits, and LSB first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are reordered bit by bit to obtain the order T00 to T31 for copying to the shift register. Data for transmission are shifted out from the shift register in order from T00, through T01, and so on to T31.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R00 to R31 have been collected after input of the required number of cycles of RSPCK, the values in the shift register are reordered bit by bit to obtain the order R31 to R00 for copying to the receive buffer.

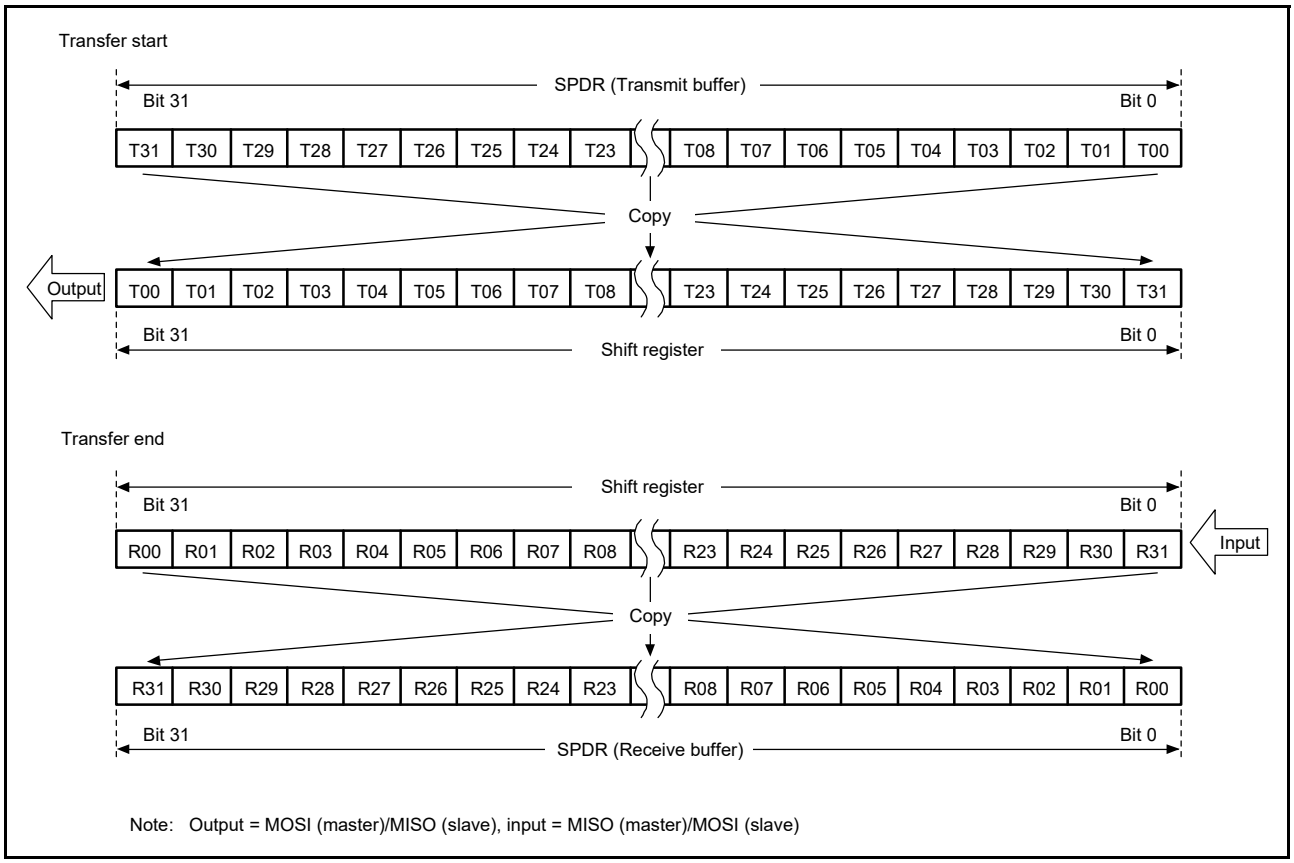

Figure 38.17 LSB First Transfer (32-Bit Data, Parity Disabled)

(4) LSB First Transfer (24-Bit Data)

Figure 38.18 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, 24 bits as the RSPI data length for an example that is not 32 bits, and LSB first selected.

In transmission, the lower-order 24 bits (T23 to T00) from the current stage of the transmit buffer are reordered bit by bit to obtain the order T00 to T23 for copying to the shift register. Data for transmission are shifted out from the shift register in order from T00, through T01, and so on to T23.

In reception, received data are shifted in bit by bit through bit 8 of the shift register. When bits R00 to R23 have been collected after input of the required number of cycles of RSPCK, the values in the shift register are reordered bit by bit to obtain the order R23 to R00 for copying to the receive buffer.

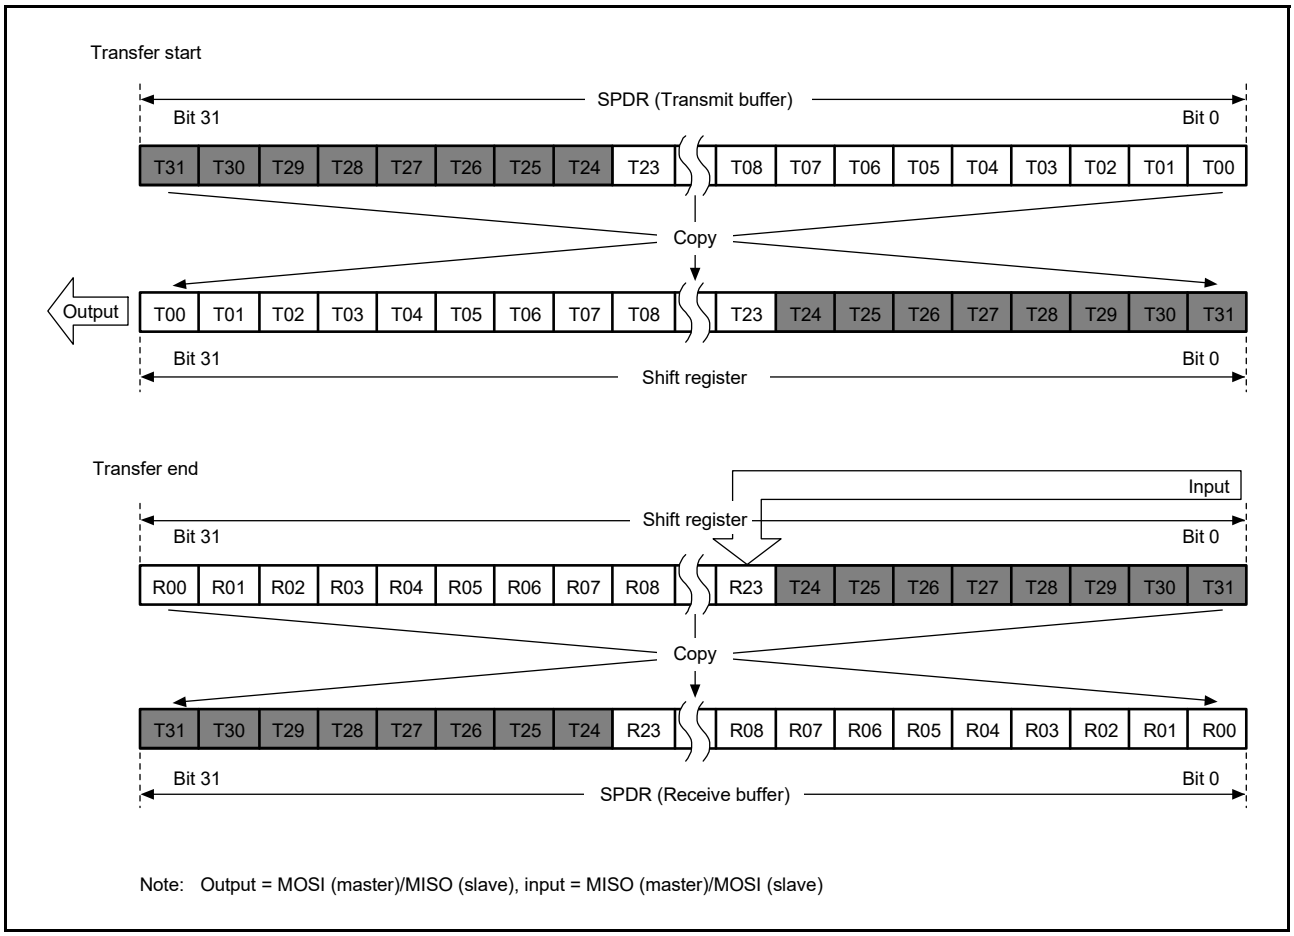

Figure 38.18 LSB First Transfer (24-Bit Data, Parity Disabled)

38.3.4.3 When Parity is Enabled (SPCR.SPPE = 1)

When parity is enabled, the lowest-order bit of the data for transmission becomes a parity bit. Hardware calculates the value of the parity bit.

(1) MSB First Transfer (32-Bit Data)

Figure 38.19 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, an RSPI data length of 32 bits, and MSB first selected.

In transmission, the value of the parity bit (P) is calculated from bits T31 to T01. This replaces the final bit, T00, and the whole is copied to the shift register. Data are transmitted in the order T31, T30, …, T01, and P.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R31 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the receive buffer, the data from R31 to P are checked to judge the parity error.

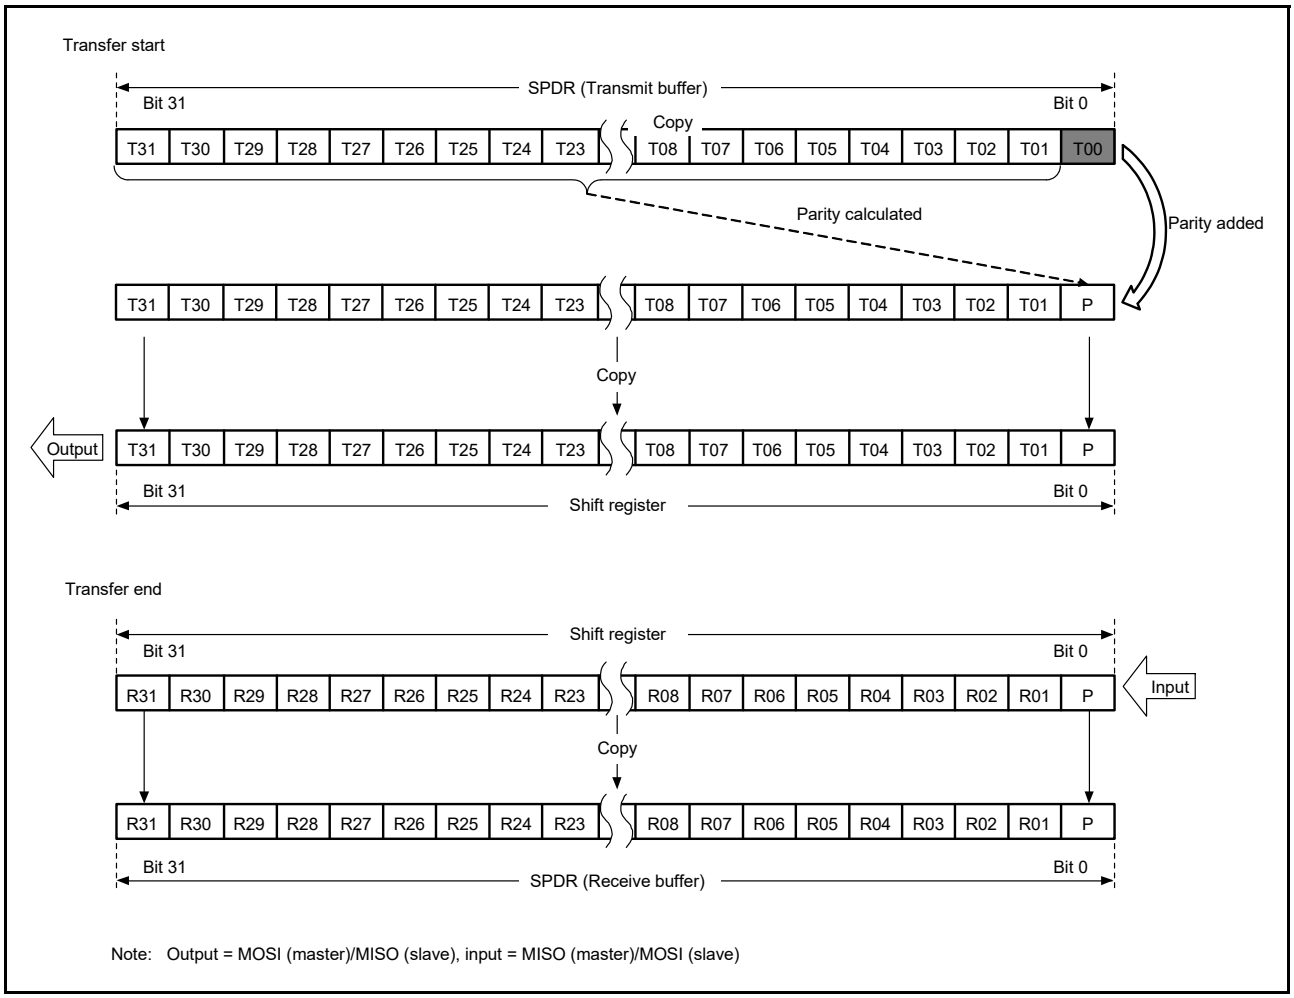

Figure 38.19 MSB First Transfer (32-Bit Data, Parity Enabled)

(2) MSB First Transfer (24-Bit Data)

Figure 38.20 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, 24 bits as the RSPI data length for an example that is not 32 bits, and MSB first selected.
In transmission, the value of the parity bit (P) is calculated from bits T23 to T01. This replaces the final bit, T00, and the whole is copied to the shift register. Data are transmitted in the order T23, T22, …, T01, and P.
In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R23 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the receive buffer, the data from R23 to P are checked to judge the parity error.

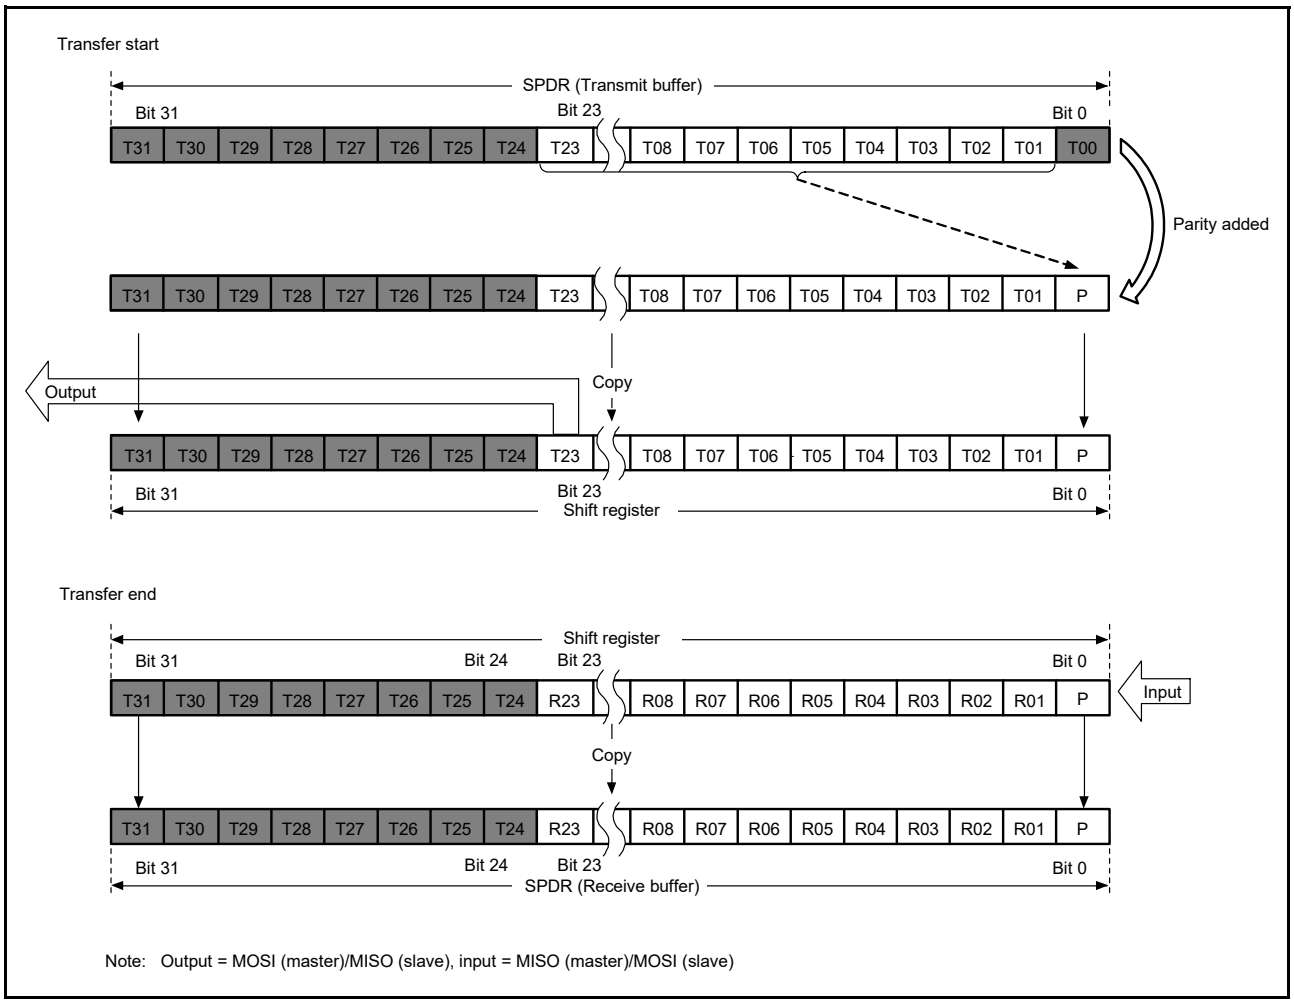

Figure 38.20 MSB First Transfer (24-Bit Data, Parity Enabled)

(3) LSB First Transfer (32-Bit Data)

Figure 38.21 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, an RSPI data length of 32 bits, and LSB first selected.

In transmission, the value of the parity bit (P) is calculated from bits T30 to T00. This replaces the final bit, T31, and the whole is copied to the shift register. Data are transmitted in the order T00, T01, …, T30, and P.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R00 to P have been collected after input of the required number of cycles of RSPCK, the values in the shift register are reordered bit by bit to obtain the order P to R00 for copying to the receive buffer. On copying of data to the receive buffer, the data from R00 to P are checked to judge the parity error.

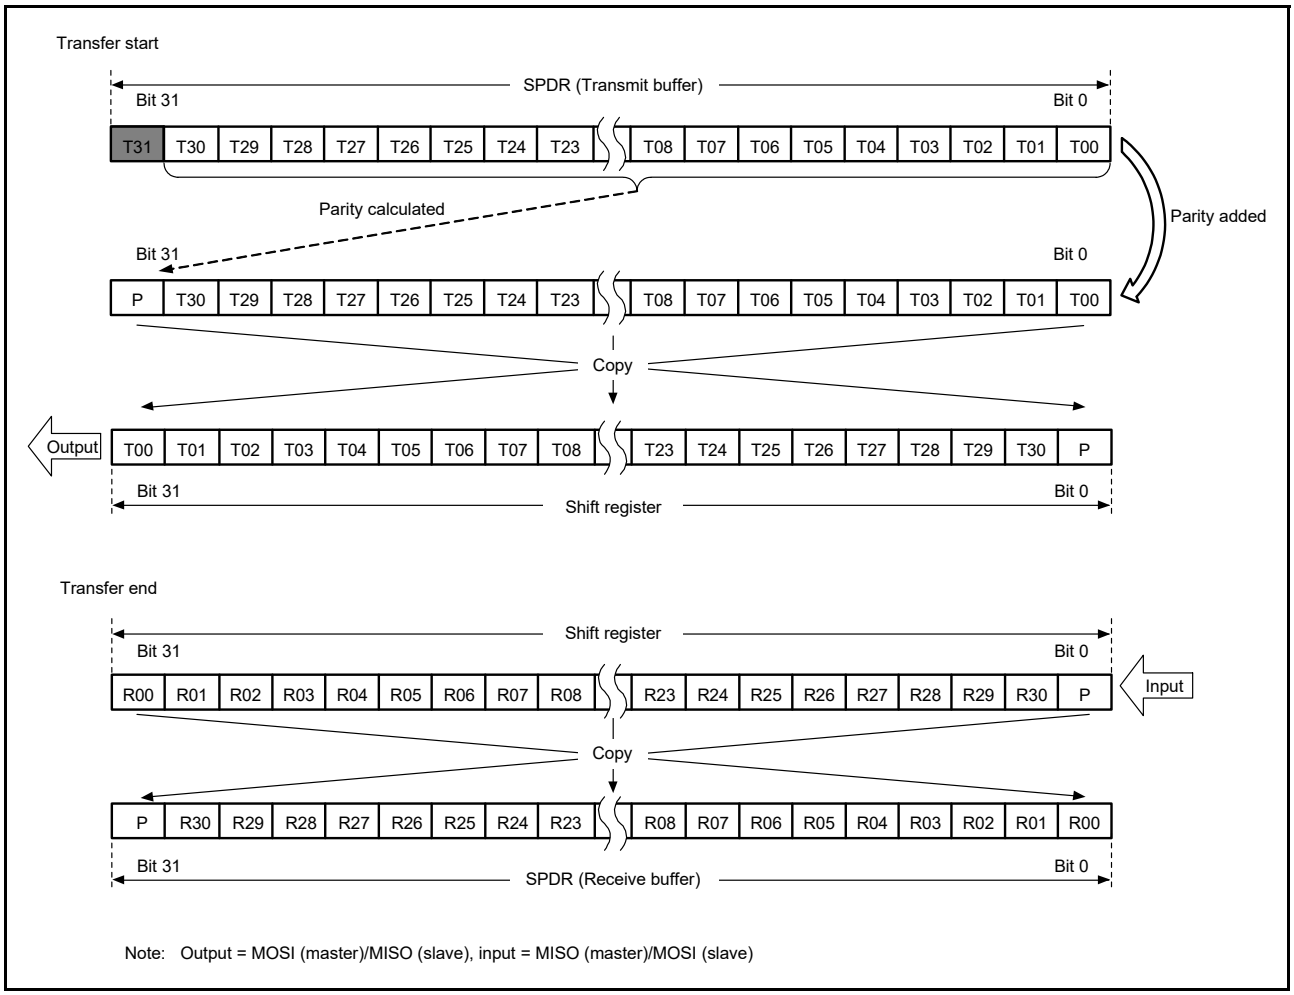

Figure 38.21 LSB First Transfer (32-Bit Data, Parity Enabled)

(4) LSB First Transfer (24-Bit Data)

Figure 38.22 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, 24 bits as the RSPI data length for an example that is not 32 bits, and LSB first selected.
In transmission, the value of the parity bit (P) is calculated from bits T22 to T00. This replaces the final bit, T23, and the whole is copied to the shift register. Data are transmitted in the order T00, T01, …, T22, and P.
In reception, received data are shifted in bit by bit through bit 8 of the shift register. When bits R00 to P have been collected after input of the required number of cycles of RSPCK, the values in the shift register are reordered bit by bit to obtain the order P (bit 23) to R00 (bit 0) for copying to the receive buffer. On copying of data to the receive buffer, the data from R00 to P are checked to judge the parity error.

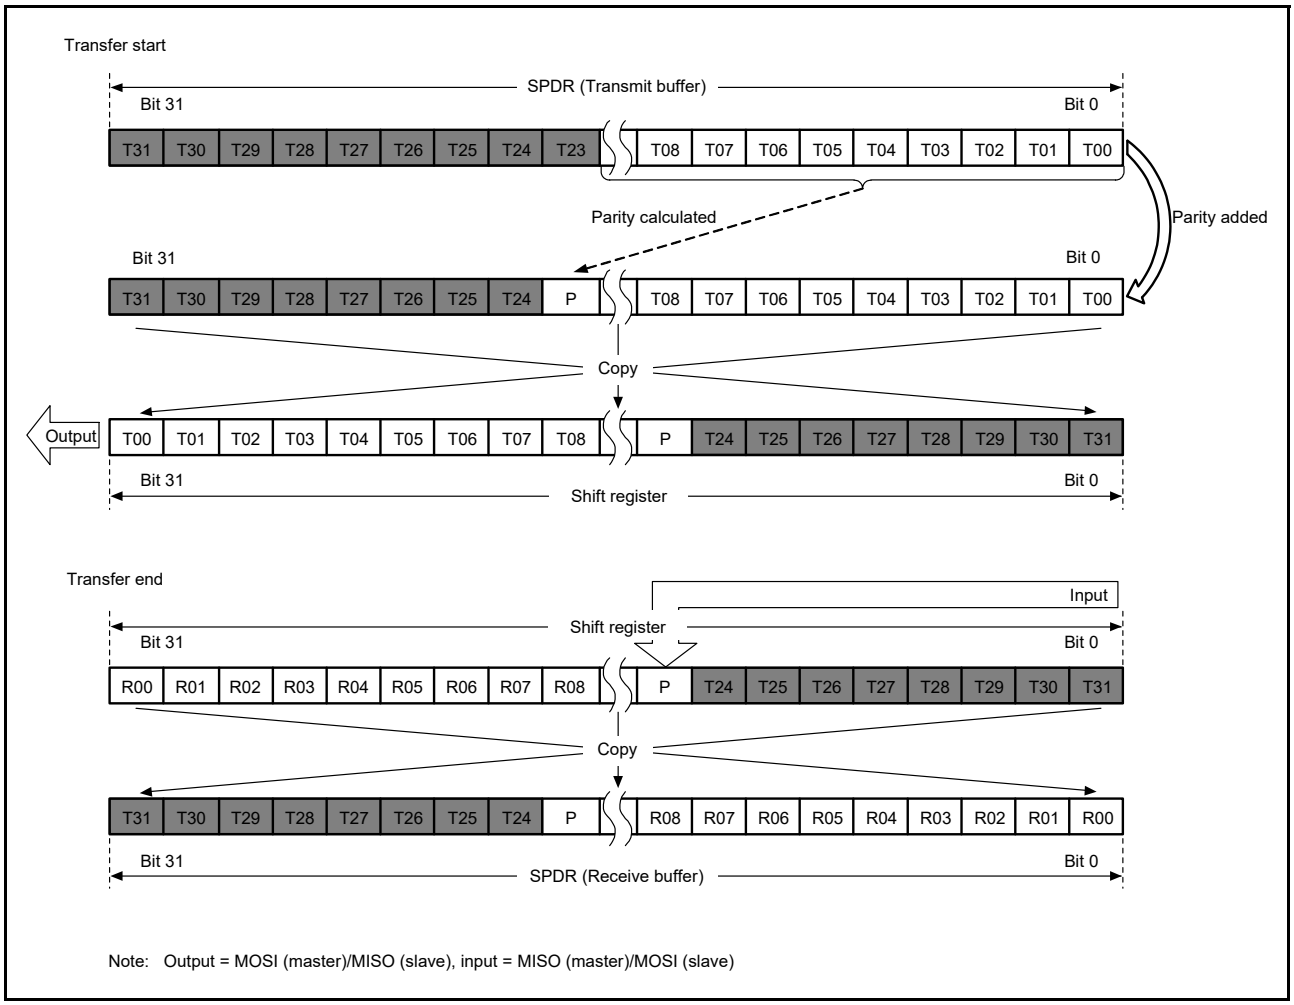

Figure 38.22 LSB First Transfer (24-Bit Data, Parity Enabled)

38.3.4.4 Byte Swap Transmission

When the SPDCR.BYSW bit is 1 (byte swapping of SPDR data enabled), data bytes written in the transmit buffer (SPDR) will be swapped (in 8 bit units) when the data is transferred to the shift register. Figure 38.23 shows data transfer between the SPDR register and the shift register when data length is 32 bits in combination of MSB/LSB first with byte swapping enabled/disabled.

(1) MSB first transfer (when the byte swap is disabled)
Data (Byte 3 [T31 to T24] to Byte 0 [T07 to T00]) in the transmit buffer are copied to the shift register. Bit values in the shift register are shifted and transmitted in the order of T31, T30, …, and T00 as transmit data.

(2) MSB first transfer (when the byte swap is enabled)
Byte values of the transmit buffer (Byte 3 [T31 to T24] to Byte 0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte 0 [T07 to T00] to Byte 3 [T31 to T24].
Bit values in the shift register are shifted and transmitted in the order of T07, T06, …, T00, T15, T14, …, T08, T23, T22, …, T16, T31, T30, …, and T24 as transmit data.

(3) LSB first transfer (when the byte swap is disabled)
Bit values of the transmit buffer (Byte 3 [T31 to T24] to Byte 0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte 0 [T00 to T07] to Byte 3 [T24 to T31].
Bit values in the shift register are shifted and transmitted in the order of T00, T01, …, and T31 as transmit data.

(4) LSB first transfer (when the byte swap is enabled)
Bit values of each byte of the transmit buffer (Byte 3 [T31 to T24] to Byte 0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte 3 [T24 to T31] to Byte 0 [T00 to T07].
Bit values in the shift register are shifted and transmitted in the order of T24, T25, …, T31, T16, T17, …, T23, T08, T09, …, T15, T00, T01, …, and T07 as transmit data.

32-bit Byte Swap Specifications	Byte Swap is Disabled (BYSW = 0)	Byte Swap is Enabled (BYSW = 1)
MSB-first (LSBF = 0)		LSB-first (LSBF = 1)		
Figure 38.23 Transmit Data Handling in MSB/LSB First with Byte Swapping Enabled/Disabled (Data Length = 32 bits)

Figure 38.24 shows data transfer between the SPDR register and the shift register when data length is 16 bits in combination of MSB/LSB first with byte swapping enabled/disabled.

(1) MSB first transfer (when the byte swap is disabled)
Data (Byte 1 [T15 to T08] to Byte 0 [T07 to T00]) in the transmit buffer are copied to the shift register in the order of Byte 1 [T15 to T08] to Byte 0 [T07 to T00]. Bit values in the shift register are shifted and transmitted in the order of T15, T14, …, and T00 as transmit data.

(2) MSB first transfer (when the byte swap is enabled)
Byte values of the transmit buffer (Byte 1 [T15 to T08] to Byte 0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte 0 [T07 to T00] to Byte 1 [T15 to T08]. Bit values in the shift register are shifted and transmitted in the order of T07, T06, …, T00, T15, T14, …, T08 as transmit data.

(3) LSB first transfer (when the byte swap is disabled)
Bit values of the transmit buffer (Byte 1 [T15 to T08] to Byte 0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte 0 [T00 to T07] to Byte 1 [T15 to T08]. Bit values in the shift register are shifted and transmitted in the order of T00, T01, …, and T15 as transmit data.

(4) LSB first transfer (when the byte swap is enabled)
Bit values of each byte of the transmit buffer (Byte 1 [T15 to T08] to Byte 0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte 1 [T08 to T15] to Byte 0 [T00 to T07].
Bit values in the shift register are shifted and transmitted in the order of T08, T09, …, T15, T00, T01, …, and T07 as transmit data.

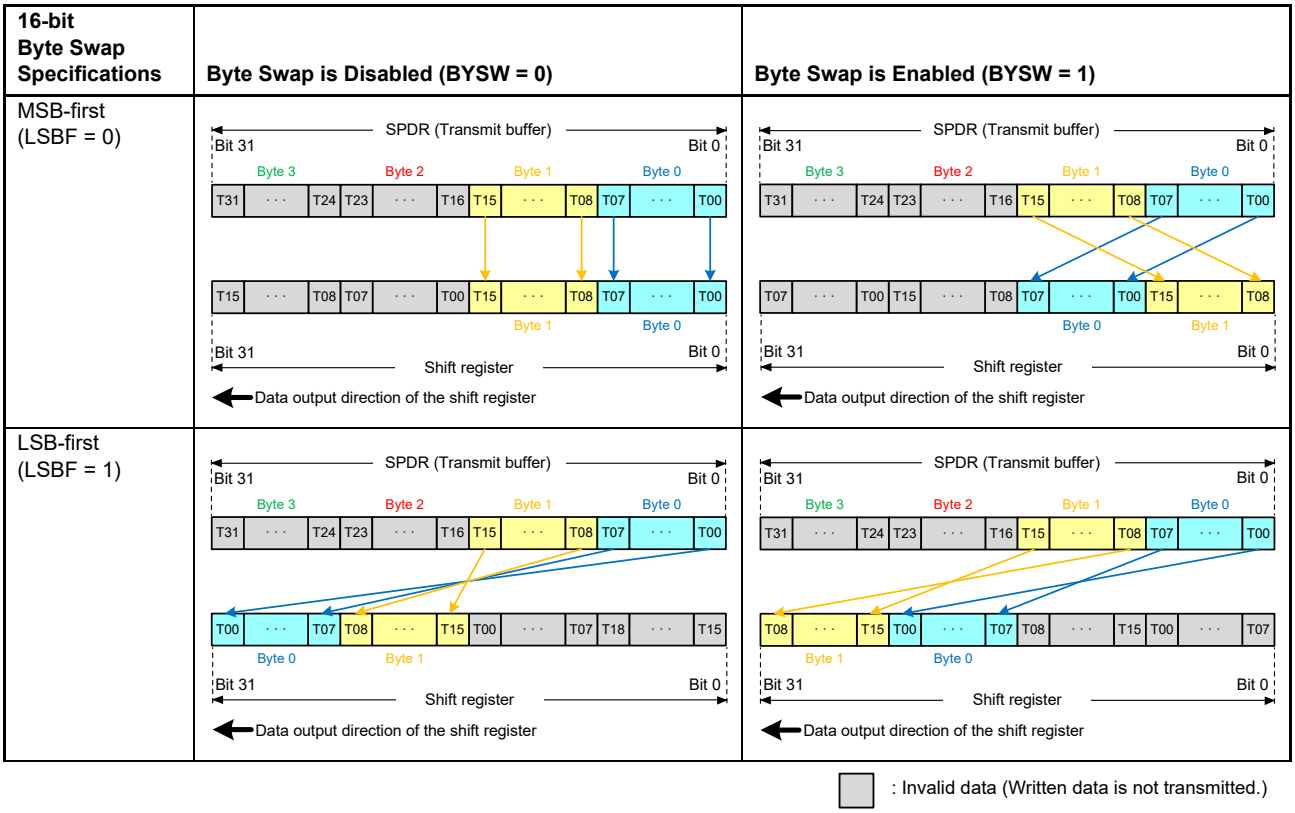

Figure 38.24 Transmit Data Handling in MSB/LSB First with Byte Swapping Enabled/Disabled (Data Length = 16 bits)

Note 1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMDm.SPB[4:0] setting). If setting the other length (4 to 15 or 17 to 31 bits), the operation is not guaranteed.

Note 2. When the byte swap is enabled, disable the parity function (SPCR.SPPE = 0). If the parity function is enabled (SPCR.SPPE = 1), the operation after the change is not guaranteed.
Note 3. Set the SPDCR.BYSW bit, while the SPCR.SPE bit is 0. If the value of the SPDCR.BYSW bit is changed while the SPCR.SPE bit is 1, the operation after the change is not guaranteed.

38.3.4.5 Byte Swap Reception

When the SPDCR.BYSW bit is 1 (byte swapping of SPDR data enabled), data bytes in the shift register will be swapped (in 8 bit units) when the data is transferred to the receive buffer (SPDR). Figure 38.25 shows data transfer between the shift register and the SPDR register when data length is 32 bits in combination of MSB/LSB first with byte swapping enabled/disabled.

(1) MSB first transfer (when the byte swap is disabled)
The first received data (R31) is stored in bit 0 of the shift register, and received data is shifted in the order of R31, R30, …, and R00. When necessary RSPCK cycles are input and data is stored from Byte 3 [R31 to R24] to Byte 0 [R07 to R00], the shift register value is copied to the receive buffer.

(2) MSB first transfer (when the byte swap is enabled)
The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07, R06, …, R00, R15, R14, …, R08, R23, R22, …, R16, R31, R30, …, and R24. When necessary RSPCK cycles are input and data is stored from Byte 0 [R07 to R00] to Byte 3 [R31 to R24], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].

(3) LSB first transfer (when the byte swap is disabled)
The first received data (R00) is stored in bit 0 of the shift register, and received data is shifted in the order of R00, R01, …, and R31. When necessary RSPCK cycles are input and data is stored from Byte 0 [R00 to R07] to Byte 3 [R24 to R31], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].

(4) LSB first transfer (when the byte swap is enabled)
The first received data (R24) is stored in bit 0 of the shift register, and received data is shifted in the order of R24, R25, …, R31, R16, R17, …, R23, R08, R09, …, R15, R00, R01, …, and R07. When necessary RSPCK cycles are input and data is stored from Byte 3 [R24 to R31] to Byte 0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].

32-bit Byte Swap Specifications	Byte Swap is Disabled (BYSW = 0)	Byte Swap is Enabled (BYSW = 1)
MSB-first (LSBF = 0)		LSB-first (LSBF = 1)		
Figure 38.25 Receive Data Handling in MSB/LSB First with Byte Swapping Enabled/Disabled (Data Length = 32 bits)

Figure 38.26 shows data transfer between the shift register and the SPDR register when data length is 16 bits in combination of MSB/LSB first with byte swapping enabled/disabled.

(1) MSB first transfer (when the byte swap is disabled)
The first received data (R15) is stored in bit 0 of the shift register, and received data is shifted in the order of R15, R14, …, and R00. When necessary RSPCK cycles are input and data is stored from Byte 3 [R31 to R24] to Byte 0 [R07 to R00], the shift register value is copied to the receive buffer.

(2) MSB first transfer (when the byte swap is enabled)
The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07, R06, …, R00, R15, R14, …, and R08. When necessary RSPCK cycles are input and data is stored from Byte 0 [R07 to R00] to Byte 1 [R15 to R08], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].

(3) LSB first transfer (when the byte swap is disabled)
The first received data (R00) is stored in bit 15 of the shift register, and received data is shifted in the order of R00, R01, …, R07, R08, R09, …, and R15. When necessary RSPCK cycles are input and data is stored from Byte 0 [R00 to R07] to Byte 1 [R08 to R15], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].

(4) LSB first transfer (when the byte swap is enabled)
The first received data (R08) is stored in bit 15 of the shift register, and received data is shifted in the order of R08, R09, …, R15, R00, R01, …, and R15. When necessary RSPCK cycles are input and data is stored from Byte 1 [R08 to R15] to Byte 0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].

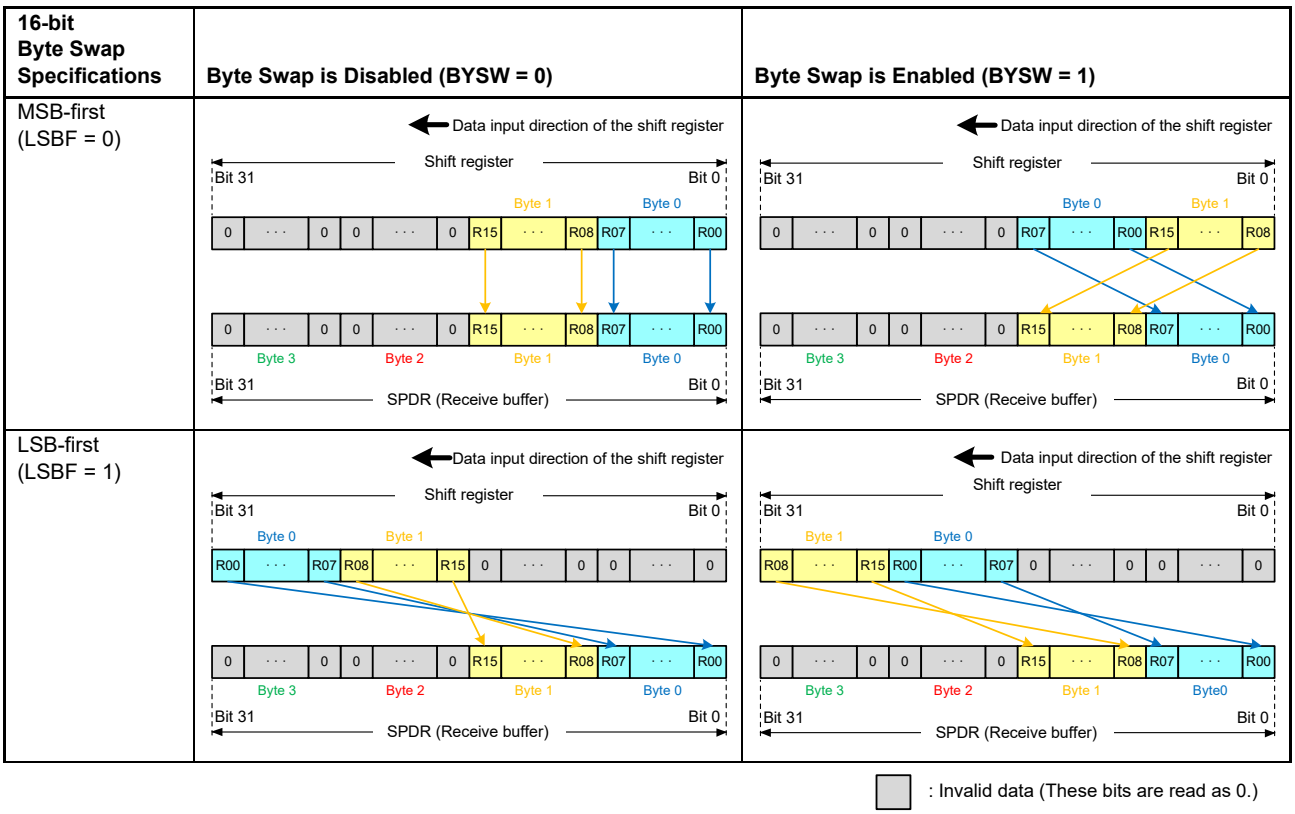

Figure 38.26 Receive Data Handling in MSB/LSB First with Byte Swapping Enabled/Disabled (Data Length = 16 bits)

Note 1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMDm.SPB[4:0] setting). If setting the other length (4 to 15 or 17 to 31 bits), the operation is not guaranteed.
Note 2. When the byte swap is enabled, disable the parity function (SPCR.SPPE = 0). If the parity function is enabled (SPCR.SPPE = 1), the operation after the change is not guaranteed.
Note 3. Set the SPDCR.BYSW bit, while the SPCR.SPE bit is 0. If the value of the SPDCR.BYSW bit is changed while the SPCR.SPE bit is 1, the operation after the change is not guaranteed.

38.3.5 Transfer Format (Frame Format)

38.3.5.1 CPHA = 0

Figure 38.27 shows a sample transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 0. Note that clock synchronous operation (the SPCR.SPMS bit is 1) should not performed when the RSPIA operates in slave mode (SPCR.MSTR = 0) and the CPHA bit is 0. In Figure 38.27, RSPCK0 (CPOL = 0) indicates the RSPCK0 signal waveform when the SPCMDm.CPOL bit is 0; RSPCK0 (CPOL = 1) indicates the RSPCK0 signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the RSPIA fetches serial transfer data into the shift register. The I/O directions of the signals depend on the RSPIA settings. For details, refer to section 38.3.2, Controlling RSPI Pins.

When the SPCMDm.CPHA bit is 0, the driving of valid data to the MOSI0 and MISO0 signals commences at an SSL0n signal assertion timing. The first RSPCK0 signal change timing that occurs after the SSL0n signal assertion becomes the first transfer data fetch timing. After this timing, data is sampled at every 1 RSPCK cycle. The change timing for MOSI0 and MISO0 signals is 1/2 RSPCK cycles after the transfer data fetch timing. The CPOL bit setting does not affect the RSPCK0 signal operation timing; it only affects the signal polarity.

t1 denotes a period from an SSL0n signal assertion to RSPCK0 oscillation (RSPCK delay). t2 denotes a period from the termination of RSPCK0 oscillation to an SSL0n signal negation (SSL negation delay). t3 denotes a period in which SSL0n signal assertion is suppressed for the next transfer after the end of serial transfer (next-access delay). t1, t2, and t3 are controlled by a master device running on the RSPI system. For a description of t1, t2, and t3 when the RSPIA of this MCU is in master mode, refer to section 38.3.13.1, Master Mode Operation.

[Motorola SPI]

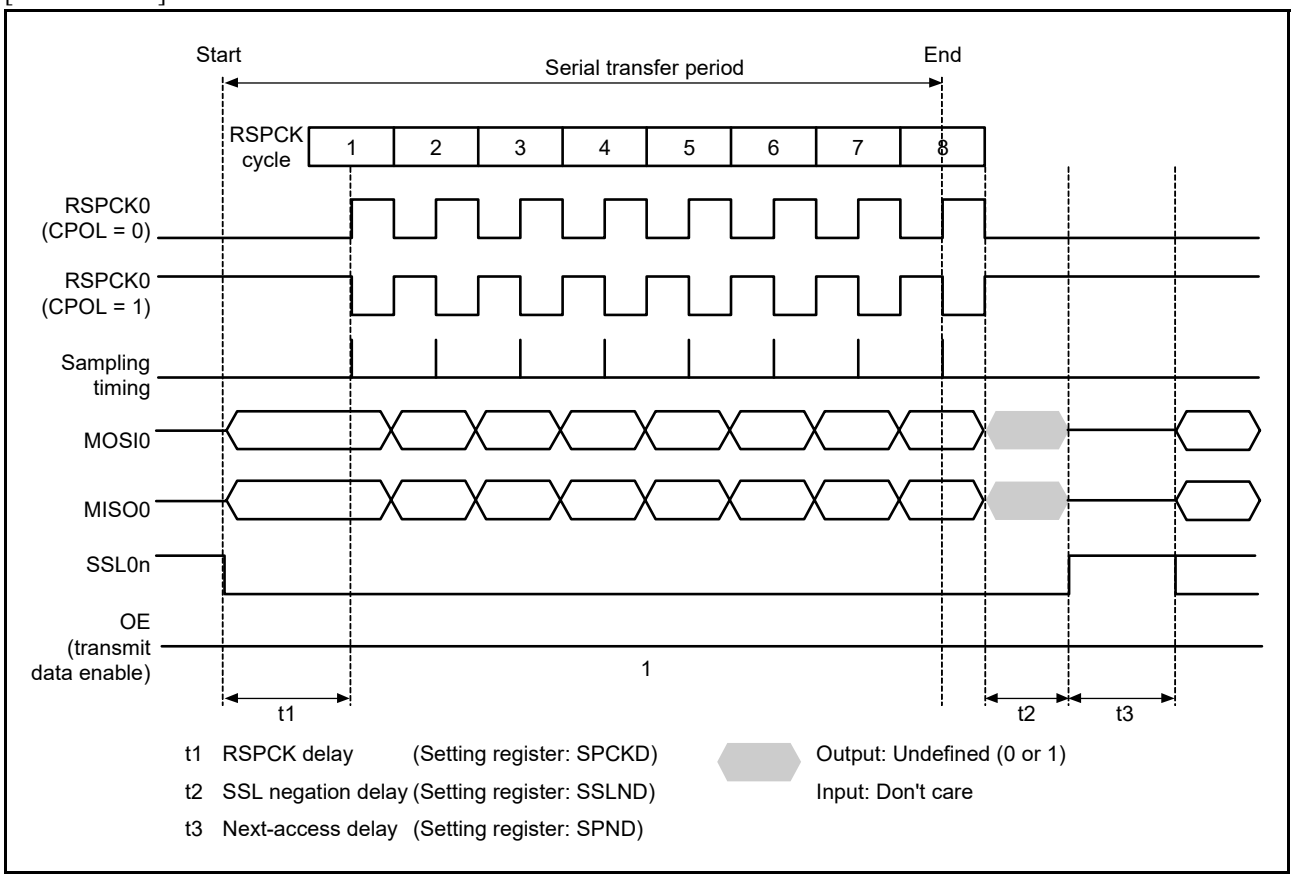

Figure 38.27 RSPI Transfer Format (CPHA = 0, FRFS = 0)

[TI SSP]

In TI SSP mode, setting the CPHA bit to 0 is not effective.

38.3.5.2 CPHA = 1

Figure 38.28 and Figure 38.29 show sample transfer formats for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 1. However, when the SPCR.SPMS bit is 1, the SSL0n signals are not used, and only the three signals RSPCK0, MOSI0, and MISO0 handle communications. In Figure 38.28, RSPCK0 (CPOL = 0) indicates the RSPCK0 signal waveform when the SPCMDm.CPOL bit is 0; RSPCK0 (CPOL = 1) indicates the RSPCK0 signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the RSPIA fetches serial transfer data into the shift register. The I/O directions of the signals depend on the RSPI mode (master or slave). For details, refer to section 38.3.2, Controlling RSPI Pins.

When the SPCMDm.CPHA bit is 1, the driving of invalid data to the MISO0 signal commences at an SSL0n signal assertion timing. The output of valid data to the MOSI0 and MISO0 signals commences at the first RSPCK0 signal change timing that occurs after the SSL0n signal assertion. After this timing, data is updated at every 1 RSPCK cycle. The transfer data fetch timing is 1/2 RSPCK cycles after the data update timing. The SPCMDm.CPOL bit setting does not affect the RSPCK0 signal operation timing; it only affects the signal polarity.

t1, t2, and t3 are the same as those in the case of CPHA = 0. For a description of t1, t2, and t3 when the RSPIA of this MCU is in master mode, refer to section 38.3.13.1, Master Mode Operation.

[Motorola SPI]

[TI SSP]

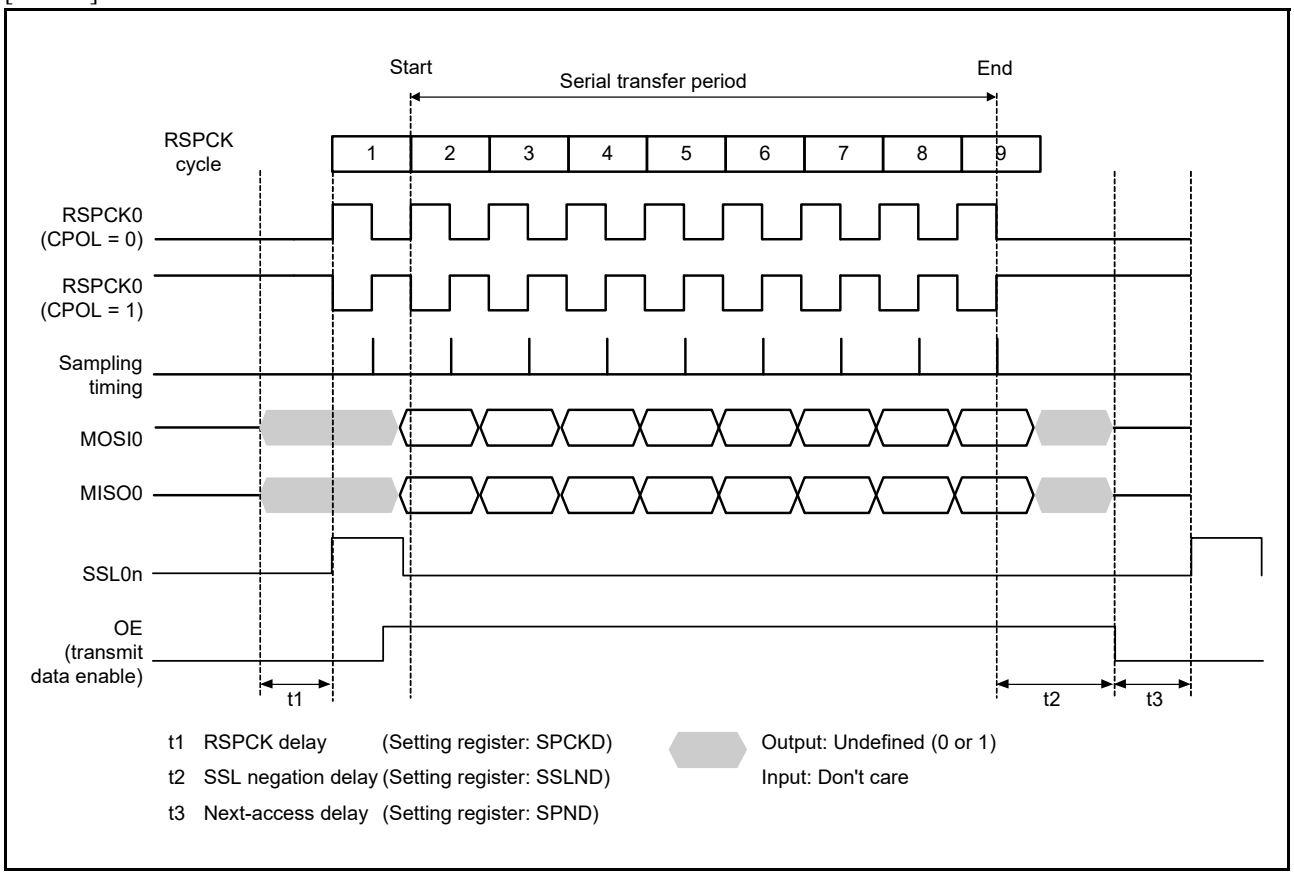

Figure 38.29 RSPI Transfer Format (CPHA = 1, FRFS = 1)

38.3.6 Communication Mode

Transmit-receive mode, transmit-only mode, and receive-only mode can be selected by the communication mode select bit (SPCR.CMMD[1:0]).

The SPDR access shown in Figure 38.30, Figure 38.31 and Figure 38.32 indicate the condition of access to the SPDR register, where W denotes a write cycle.

38.3.6.1 Transmit-Receive Mode (SPCR.CMMD[1:0] = 00b)

Figure 38.30 shows an example of operation when the communication mode select bits (SPCR.CMMD[1:0]) are set to 00b. In the example in Figure 38.30, the RSPIA performs an 8-bit serial transfer in which SPFCR.TTRG[1:0] = 00b, SPFCR.RTRG[1:0] = FIFO stage – 1, SPCMDm.CPHA = 1, and SPCMDm.CPOL = 0. The numbers given under the RSPCK0 waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

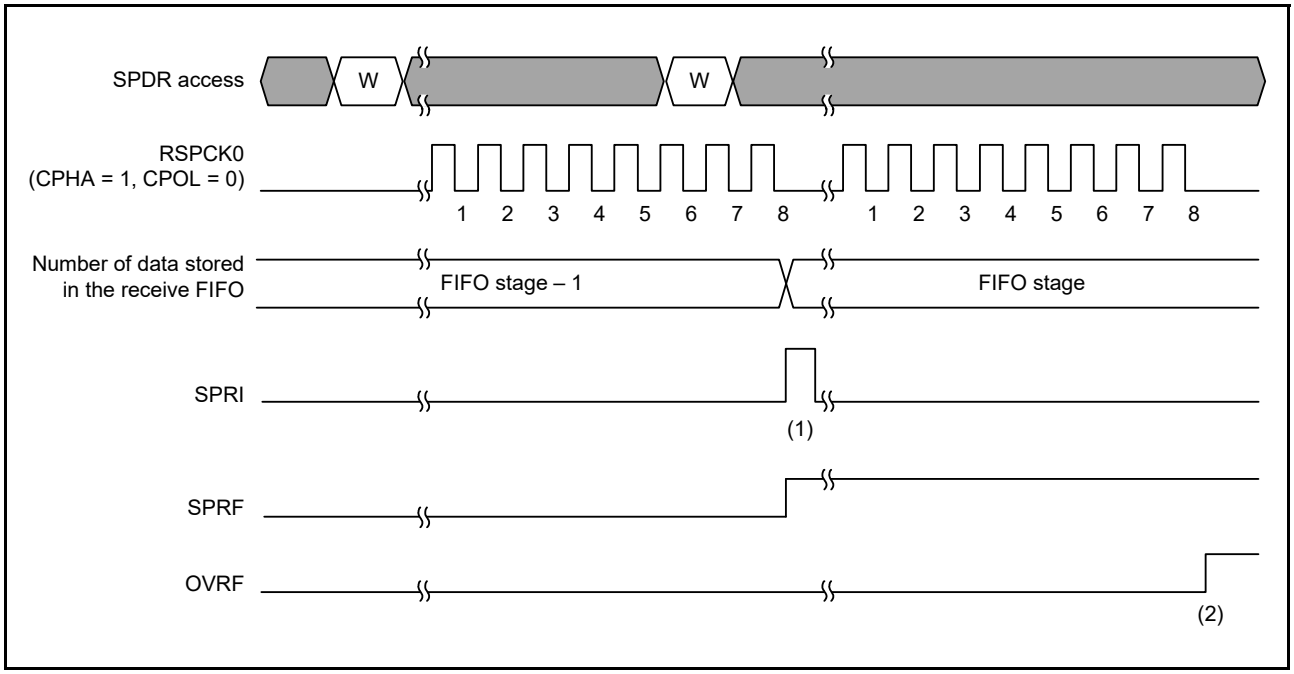

Figure 38.30 Operation Example of SPCR.CMMD[1:0] = 00b

The operation of the flags at timings shown in steps (1) and (2) in the figure is described below.

(1) When a serial transfer ends while the number of data stored in the SPDR receive buffer matches the number of frames set in SPFCR.RTRG[1:0] bits, the RSPIA generates a receive buffer full interrupt request (SPRI) (sets the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer.

(2) When a serial transfer ends with data for the number of FIFO stages is stored in the SPDR receive buffer, the RSPIA sets the SPSR.OVRF flag to 1 and discards the received data in the shift register.

When transmit-receive mode (CMMD[1:0] = 00b) is selected, reception occurs simultaneously with transmit operations. As such, the SPRF and OVRF flags in the SPSR register become 1 at the timing described in (1) and (2), respectively, according to the state of the receive buffer.

38.3.6.2 Transmit-Only Mode (SPCR.CMMD[1:0] = 01b)

Figure 38.31 shows an example of operation when the communication mode select bits (SPCR.CMMD[1:0]) are set to 01b. In the example in Figure 38.31, the RSPIA performs an 8-bit serial transfer in which SPFCR.TTRG[1:0] = 00b, SPFCR.RTRG[1:0] = 00b, SPCMDm.CPHA = 1, and SPCMDm.CPOL = 0. The numbers given under the RSPCK0 waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

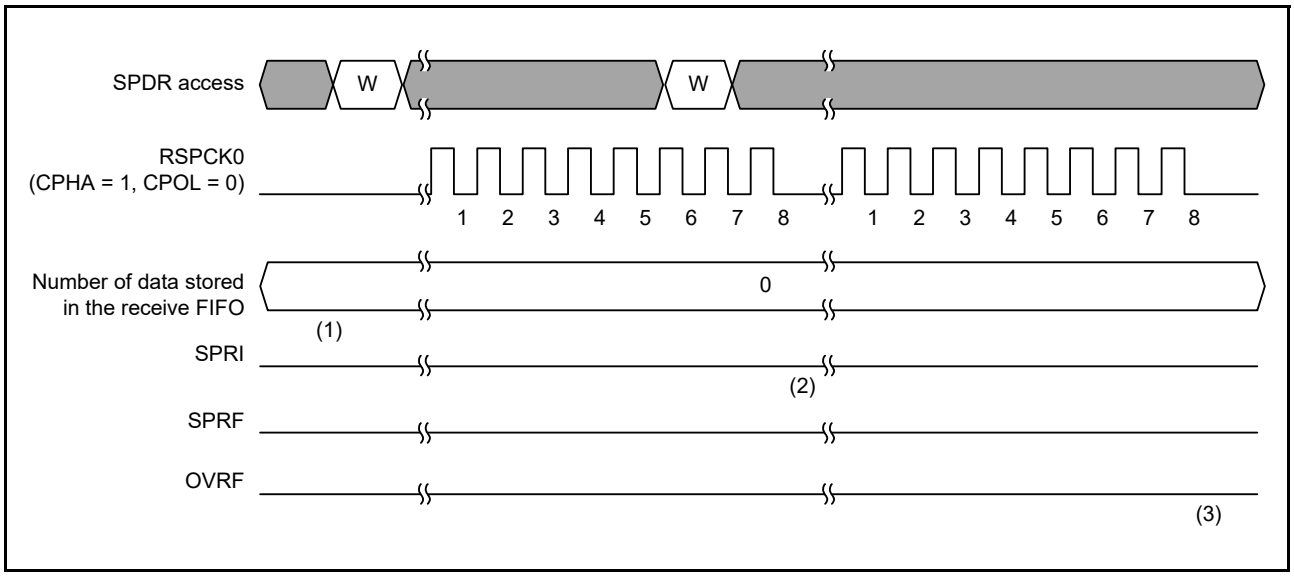

Figure 38.31 Operation Example of SPCR.CMMD[1:0] = 01b

The operation of the flags at timings shown in steps (1) to (3) in the figure is described below.

(1) Make sure there is no data left in the receive buffer and the SPSR.SPRF, OVRF flags are 0 before entering the mode of transmit operations only (SPCR.CMMD[1:0] = 01b).

(2) When a serial transfer ends without received data in the receive FIFO of SPDR, if transmit-only mode is selected (SPCR.CMMD[1:0] = 01b), the SPRF flag remains 0 and the RSPIA does not copy the data from the shift register to the receive buffer.

(3) Since the receive buffer of SPDR does not hold data that was received in the previous serial transfer, even when a serial transfer ends, the SPSR.OVRF flag retains the value of 0, and the data in the shift register is not copied to the receive buffer.

When transmit-only mode (SPCR.CMMD[1:0] = 01b) is selected, the RSPIA transmits data but does not receive data. Therefore, the SPSR.SPRF, OVRF flags remain 0 at the timings of (1) to (3).

38.3.6.3 Receive-Only Mode (SPCR.CMMD[1:0] = 10b)

Figure 38.32 shows an example of operation when the communication mode select bits (SPCR.CMMD[1:0]) are set to 10b. In the example in Figure 38.32, the RSPIA performs an 8-bit serial transfer in which SPFCR.TTRG[1:0] = 00b, SPFCR.RTRG[1:0] = FIFO stage – 1, SPCMDm.CPHA = 1, and SPCMDm.CPOL = 0. The numbers given under the RSPCK0 waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

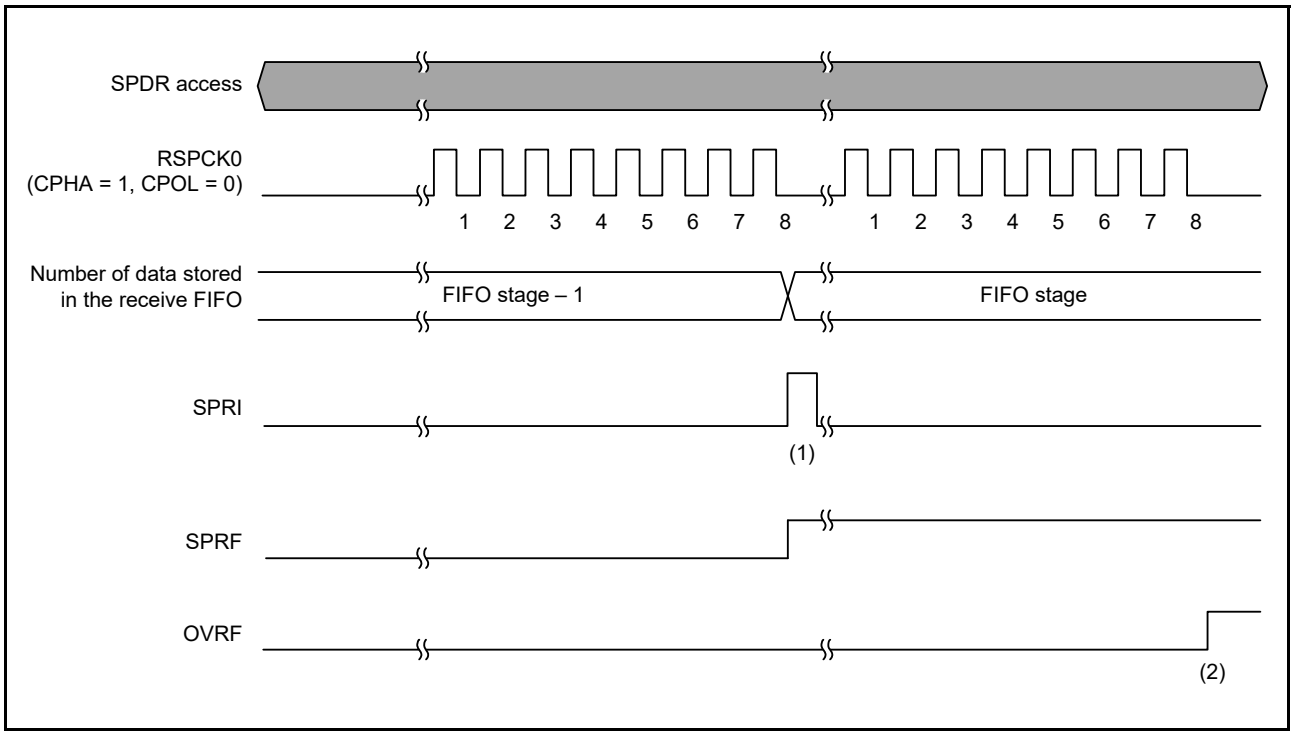

Figure 38.32 Operation Example of SPCR.CMMD[1:0] = 10b

The operation of the flags at timings shown in steps (1) to (2) in the figure is described below.

(1) When a serial transfer ends while the number of data stored in the SPDR receive buffer matches the number of frames set in SPFCR.RTRG[1:0] bits, the RSPIA generates a receive buffer full interrupt request (SPRI) (sets the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer.

(2) When a serial transfer ends with data for the number of FIFO stages is stored in the SPDR receive buffer, the RSPIA sets the SPSR.OVRF flag to 1 and discards the received data in the shift register.

38.3.7 Transmit Buffer Empty/Receive Buffer Full Interrupts

Figure 38.33 shows an example of operation of the transmit buffer empty interrupt (SPTI) and the receive buffer full interrupt (SPRI). The SPDR register access shown in Figure 38.33 indicate the conditions of access to the SPDR register, where W denotes a write cycle, and R a read cycle. In the examples in Figure 38.33, the RSPIA performs an 8-bit serial transfer in which the SPCR.CMMD[1:0] bits are 00b, SPFCR.TTRG[1:0] bits are 00b, the SPFCR.RTRG[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCK0 waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

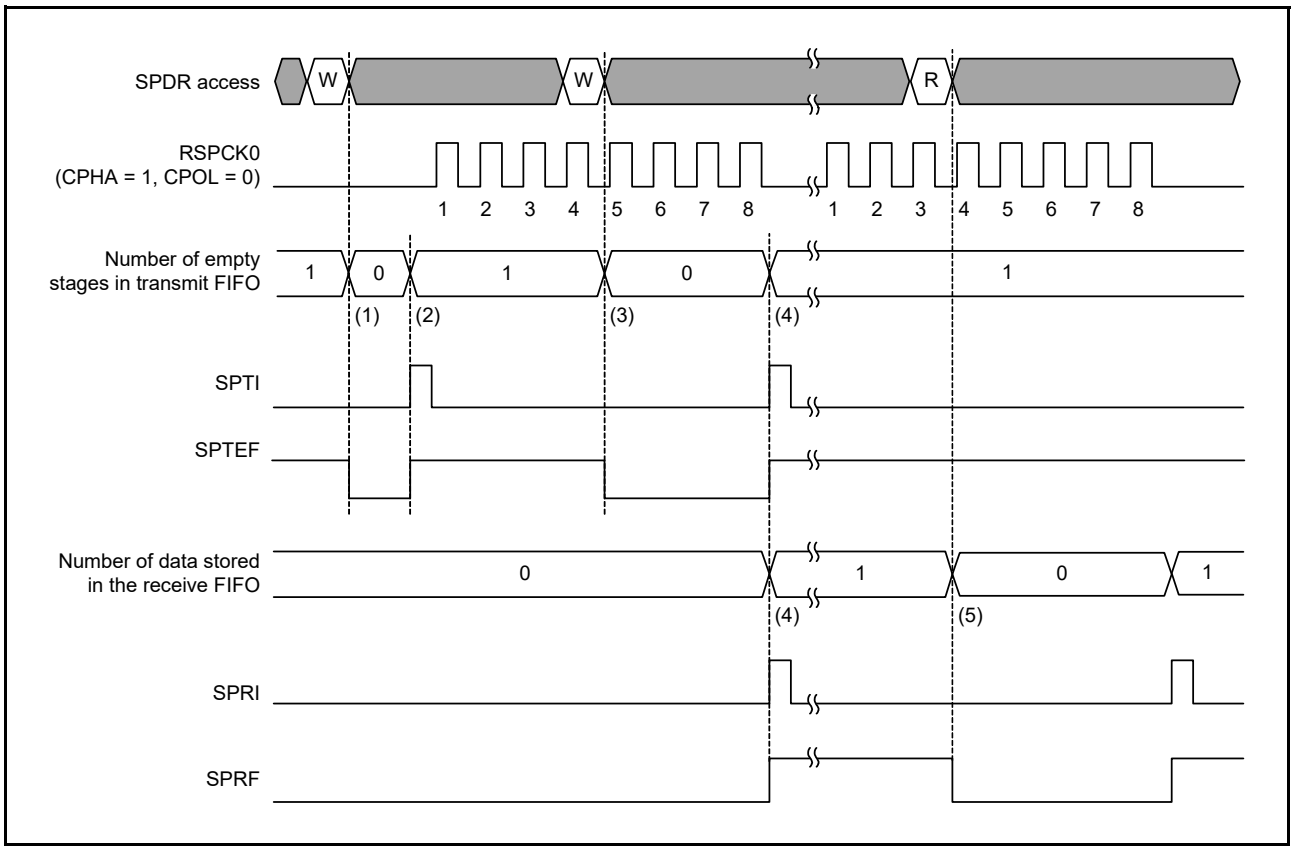

Figure 38.33 Operation Example of SPTI and SPRI Interrupts

The operation of the interrupts at timings shown in steps (1) to (5) in the figure is described below.

(1) If transmit data is written to SPDR when the next transmit data is not set in the transmit FIFO, the RSPIA writes data to the transmit buffer. When transmit data is written to SPDR in one processing routine using DTC/DMAC, the SPSR.SPTEF flag becomes 0 at the last access.

(2) If the shift register is empty, the RSPIA copies the data from the transmit buffer to the shift register. If the number of empty stage of the transmit FIFO is greater than the threshold value, the RSPIA generates a transmit buffer empty interrupt request (SPTI) and sets the SPSR.SPTEF flag to 1. How a serial transfer is started depends on the mode of the RSPIA. For details, refer to section 38.3.13, SPI Operation, and section 38.3.14, Clock Synchronous Operation.

(3) When transmit data is written to SPDR in the transmit buffer empty interrupt routine or in the transmit buffer empty detecting process by polling the SPTEF flag, the data is transferred to the transmit buffer. When transmit data is written to SPDR in one processing routine using DTC/DMAC, the SPSR.SPTEF flag becomes 0 at the last access. Because the data being transmitted is stored in the shift register, the RSPIA does not copy the data from the transmit buffer to the shift register.

(4) If the serial transfer ends (data sampling clock edge in the final bit is detected) when the data stored in the receive FIFO of SPDR < the number of FIFO stages, the RSPIA copies the receive data from the shift register to the receive buffer. At this time, if the data stored in the receive FIFO is greater than the threshold value, the RSPIA generates a

receive buffer full interrupt request (SPRI), and sets the SPSR.SPRF flag to 1. Since the shift register becomes empty upon completion of the serial transfer, when the next transmit data had been set in the transmit FIFO before the serial transfer ended, the RSPIA sets the SPSR.SPTEF flag to 1 and copies the data from the transmit buffer to the shift register. Even when received data is not copied from the shift register to the receive buffer in an overrun error status, upon completion of the serial transfer, the RSPIA determines that the shift register is empty, thus data transfer from the transmit buffer to the shift register is enabled.

(5) When SPDR is read in the receive buffer full interrupt (SPRI) routine or in the receive buffer full detecting process by polling the SPRF flag, the receive data can be read. If the received data is read from SPDR in one processing routine using DTC/DMAC, the SPRF flag becomes 0 at the last access.

If transmit data is written to SPDR while no empty stages in the transmit FIFO, the RSPIA does not update the data in the transmit buffer. Transmit data should be written to SPDR in the transmit buffer empty interrupt request routine or in the transmit buffer empty detecting process by polling the SPTEF flag.

When setting the SPCR.SPE bit to 0 (RSPI function disabled), if the SPCR.SPTIE is 1, a transmit buffer empty interrupt request will occur. However, transmit buffer empty interrupt is inhibited by disabling transmit buffer empty interrupt (the SPTIE bit is 0) at the same time as SPE bit setting.

When serial transfer ends while data is stored in the receive FIFO for the number of FIFO stages, the RSPIA does not copy data from the shift register to the receive buffer, and detects an overrun error (refer to section 38.3.10, Error Detection). To prevent a receive data overrun error, read the received data before the next serial transfer ends.

Transmit buffer empty interrupt and receive buffer full interrupt or the corresponding IRn.IR flags (where n is the interrupt vector number) in the ICU can be used to confirm the states of the transmit and receive buffers. The status of the transmit and receive buffers can be also confirmed by the SPTEF and SPRF flags.

38.3.8 Idle Interrupts

When the SPSSR.SPCP[2:0] bits becomes 000b, if the next transmit data is not set, the SPSR.IDLNF flag is set to 0 and an idle interrupt request is generated. An interrupt request is also made by setting the SPCR.SPE bit to 0.

[Motorola SPI]

Figure 38.34 shows an example of idle interrupt operation during normal operation.

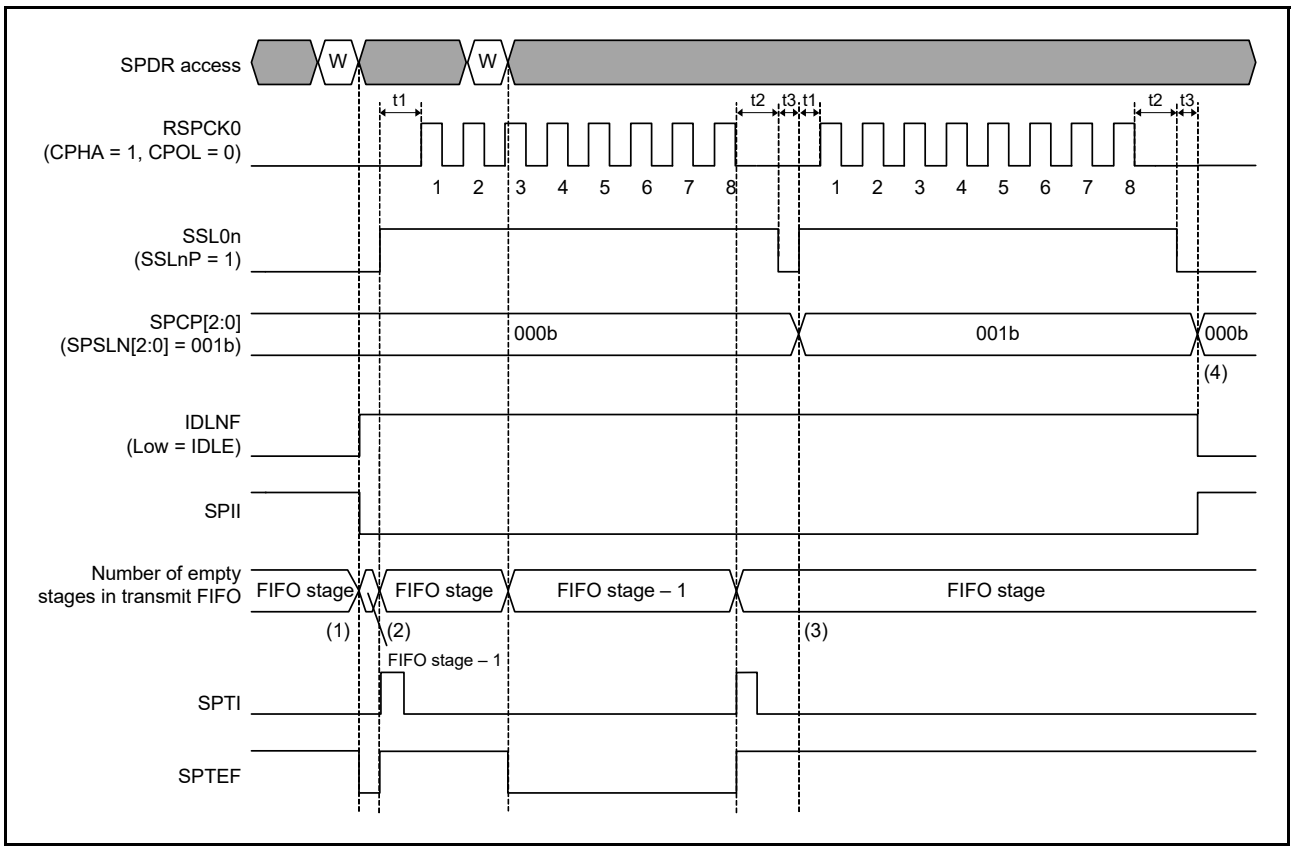

Figure 38.34 Operation Example of Idle Interrupts (Master Mode, Motorola SPI)

(1) At the start of transmission, if the next transmit data is not set in the transmission buffer, the SPSR.IDLNF flag becomes 0 (IDLE). Writing transmit data sets the SPSR.IDLNF flag to 1 (BUSY). When the SPCR.SPIIE bit is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPCR.SPIIE bit to 0 before starting transmission.

(2) After transmission has started, the SPSR.IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.

(3) The SPSSR.SPCP[2:0] bits change the command to the next one at the end of t3 cycle. When the next command is not 000b, the SPSR.IDLNF flag remains unchanged even when the next transmit data has not been written.

(4) The SPSR.IDLNF flag becomes 0 (IDLE) at the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPCR.SPIIE bit is 1, an SPII interrupt is output.

[TI SSP]

Figure 38.35 shows an example of idle interrupt operation during normal operation.

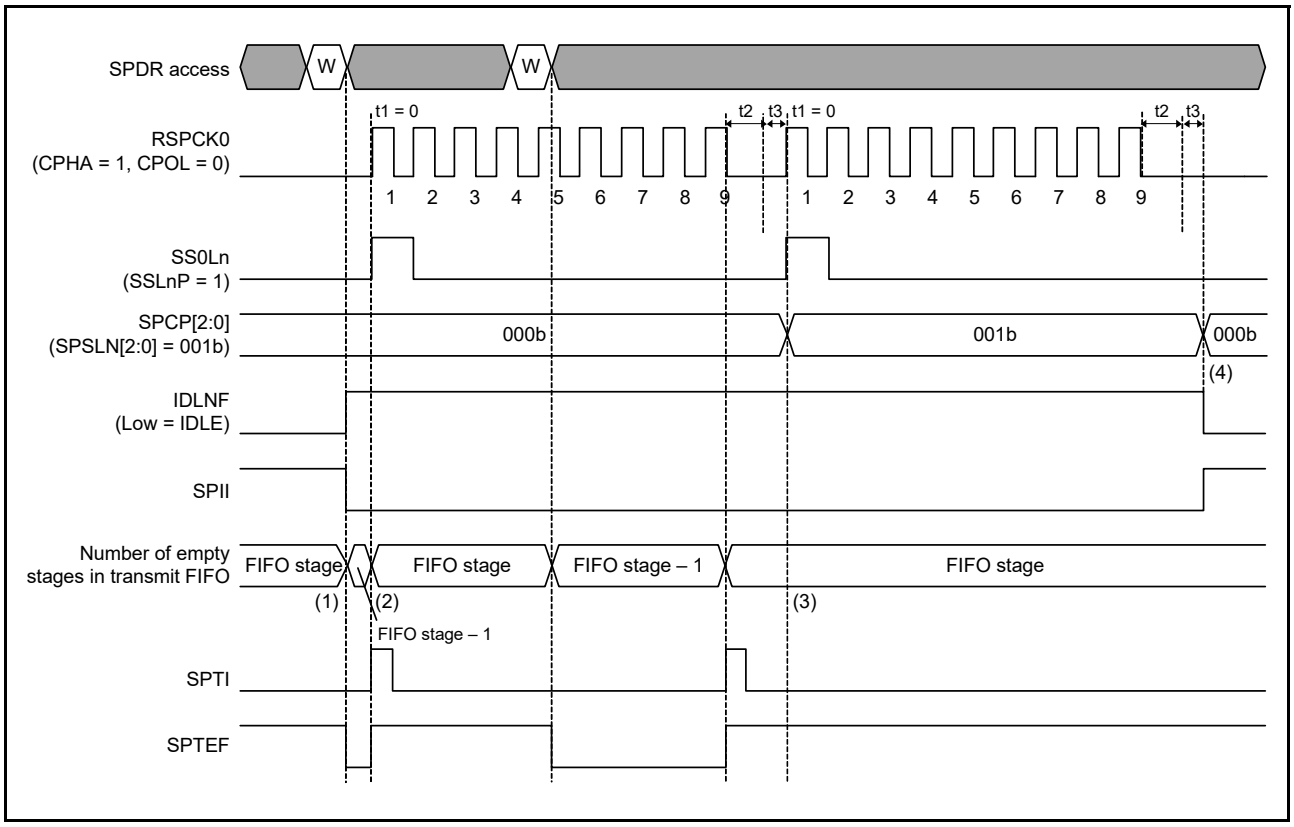

Figure 38.35 Operation Example of Idle Interrupts (Master Mode, TI SSP)

(1) At the start of transmission, if the next transmit data is not set in the transmission buffer, the SPSR.IDLNF flag becomes 0 (IDLE). Writing transmit data sets the SPSR.IDLNF flag to 1 (BUSY). When the SPCR.SPIIE bit is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPCR.SPIIE bit to 0 before starting transmission.

(2) After transmission has started, the SPSR.IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.

(3) The SPSSR.SPCP[2:0] bits change the command to the next one at the end of t3 cycle. When the next command is not 000b, the SPSR.IDLNF flag remains unchanged even when the next transmit data has not been written.

(4) The SPSR.IDLNF flag becomes 0 (IDLE) the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPCR.SPIIE bit is 1, an SPII interrupt is output.

An idle interrupt during slave mode operation depends only on the value of the SPCR.SPE bit.

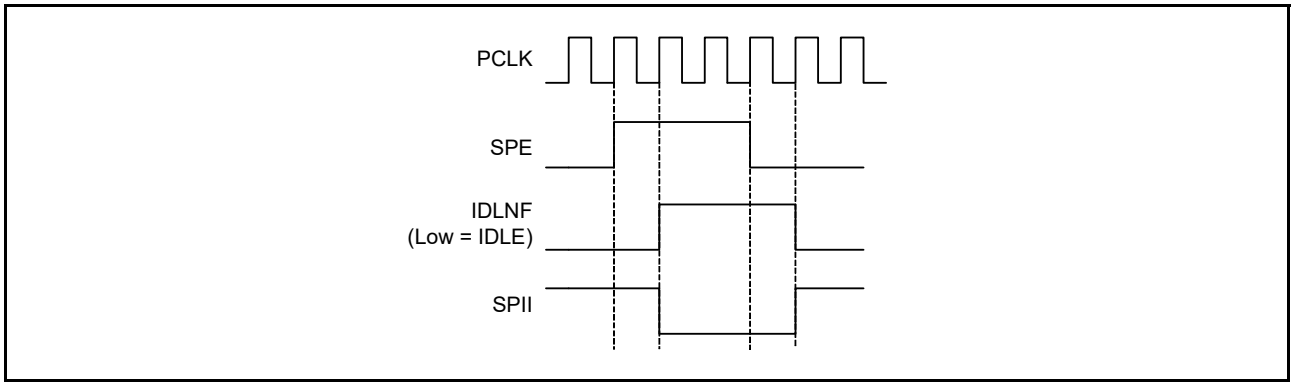

Figure 38.36 Operation Example of Idle Interrupts (Slave Mode)

38.3.9 Communication End Interrupts

38.3.9.1 Transmit-Receive Master Mode or Transmit-Only Master Mode

Refer to the description of the SPCF Flag (Communication End Flag) in section 38.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during transmit-receive master mode or transmit-only master mode.

[Motorola SPI]

Figure 38.37 shows an example of the SPCI interrupt operation during transmit-receive master mode/transmit-only master mode.

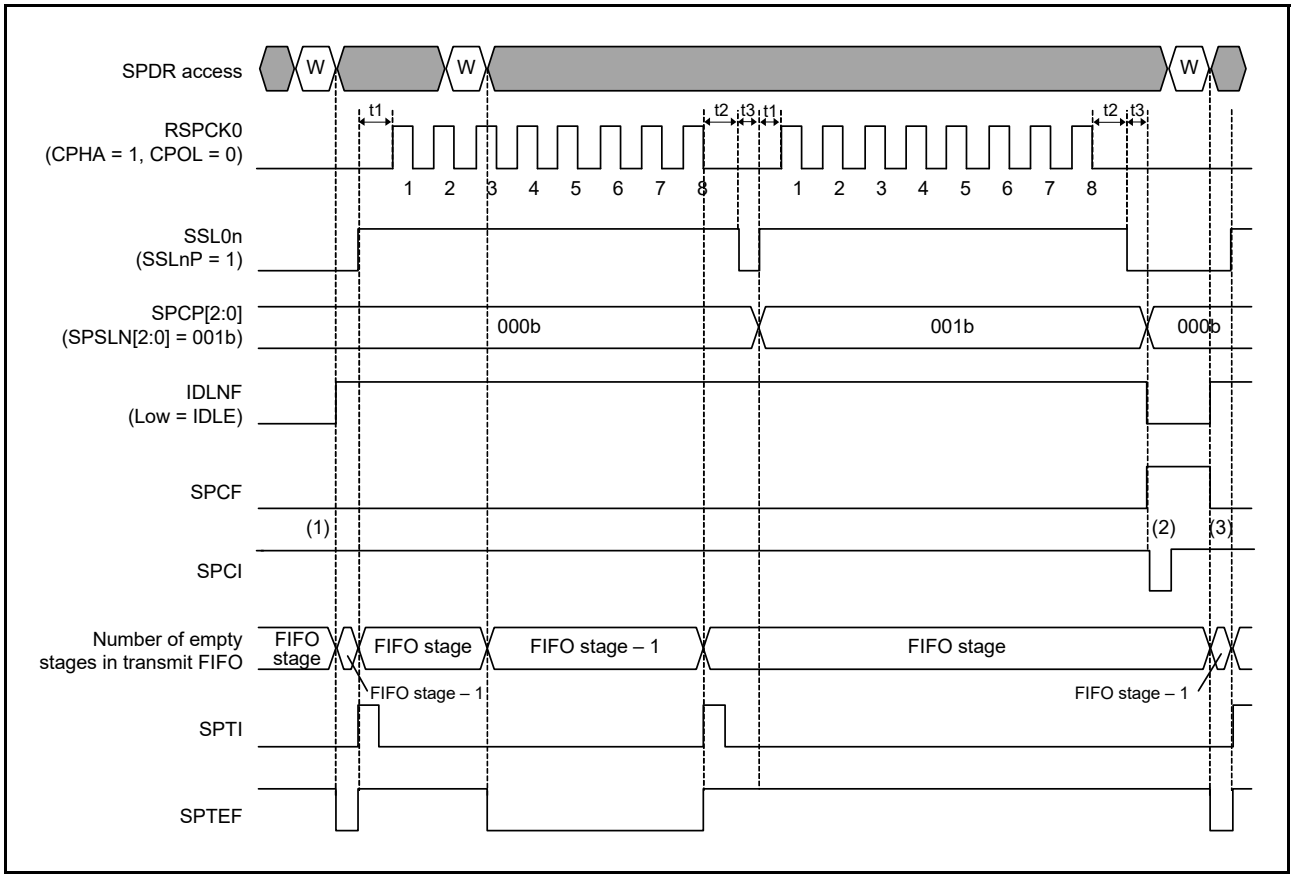

Figure 38.37 Operation Example of SPCI Interrupts (Transmit-Receive Master Mode/Transmit-Only Master Mode, Motorola SPI)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) at the end of t3 cycle, because the next command is 000b and there is no next transmit data. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when the next transmit data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

[TI SSP]

Figure 38.38 shows an example of the SPCI interrupt operation during transmit-receive master mode/transmit-only master mode.

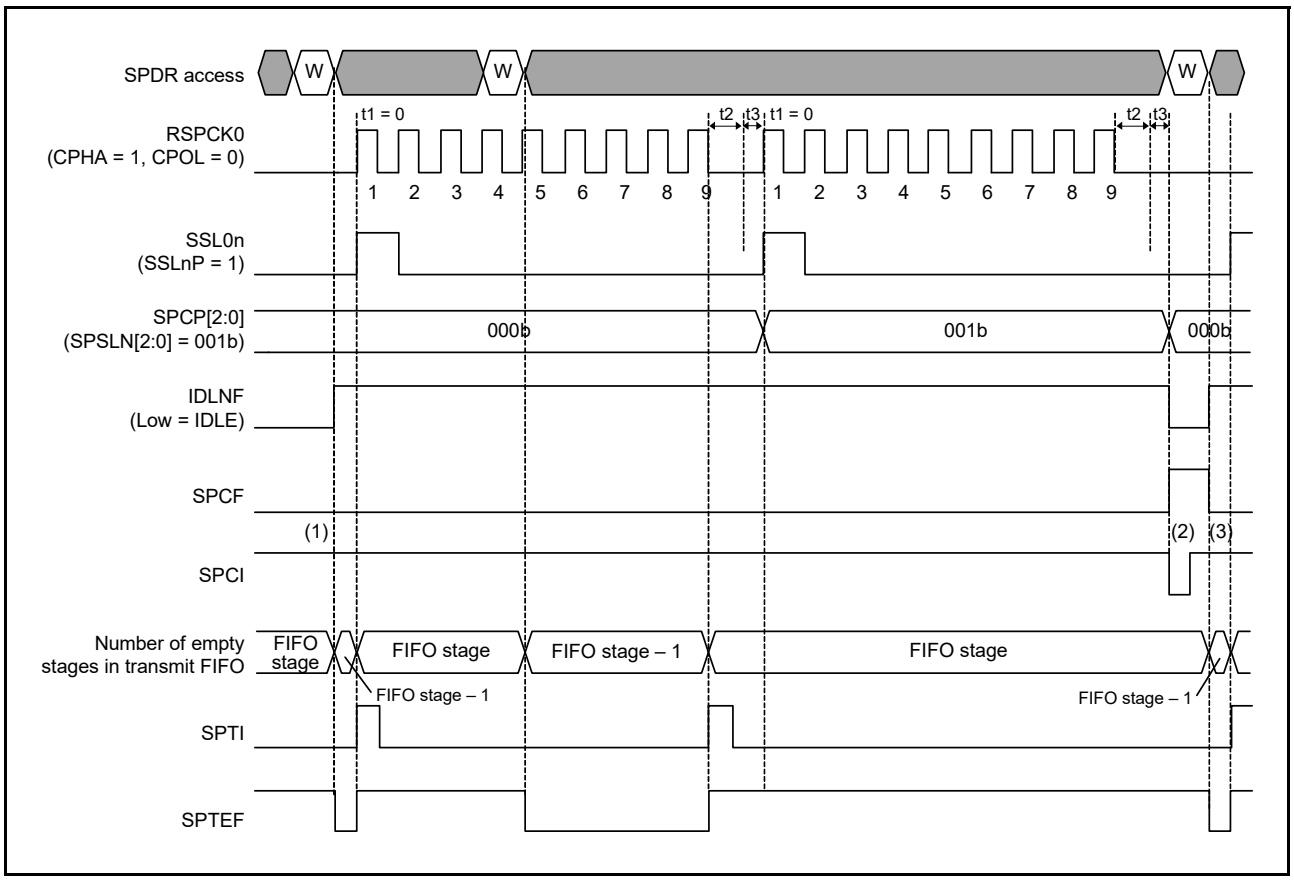

Figure 38.38 Operation Example of SPCI Interrupts (Transmit-Receive Master Mode/Transmit-Only Master Mode, TI SSP)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) at the end of t3 cycle, because the next command is 000b and there is no next transmit data. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when the next transmit data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

38.3.9.2 Receive-Only Master Mode

Refer to the description of the SPCF Flag (Communication End Flag) in section 38.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during receive-only master mode.

Figure 38.39 shows an example of the SPCI interrupt operation during receive-only master mode when the SPRMCR.RFC[4:0] bits are 00000b.

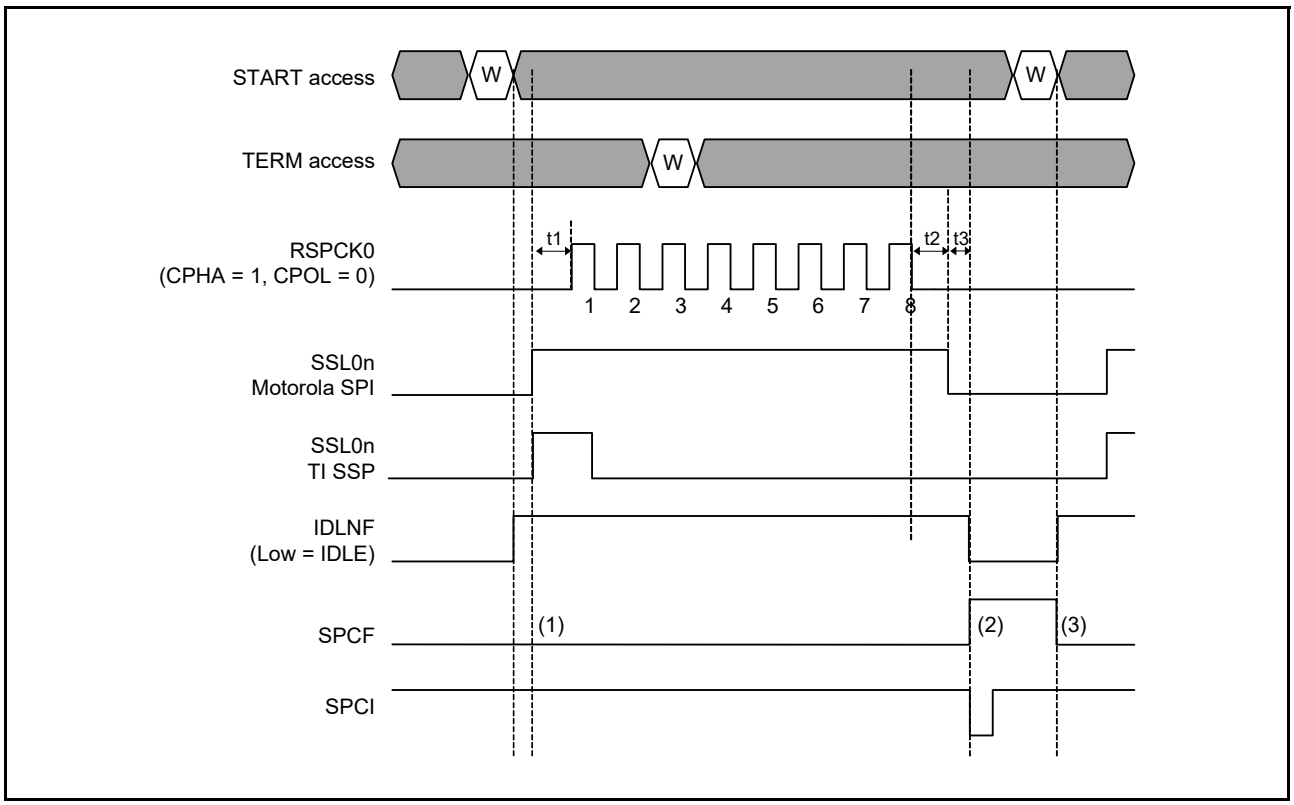

Figure 38.39 Operation Example of SPCI Interrupts (RFC[4:0] = 00000b) (Receive-Only Master Mode)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) When the SPRMCR.TERM bit is set to 1 during communication, the SPCF flag becomes 1 (communication end) at the end of t3 cycle. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when 1 is written to the SPRMCR.START bit. Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

Figure 38.40 shows an example of the SPCI interrupt operation during receive-only master mode when the SPRMCR.RFC[4:0] bits are not 00000b.

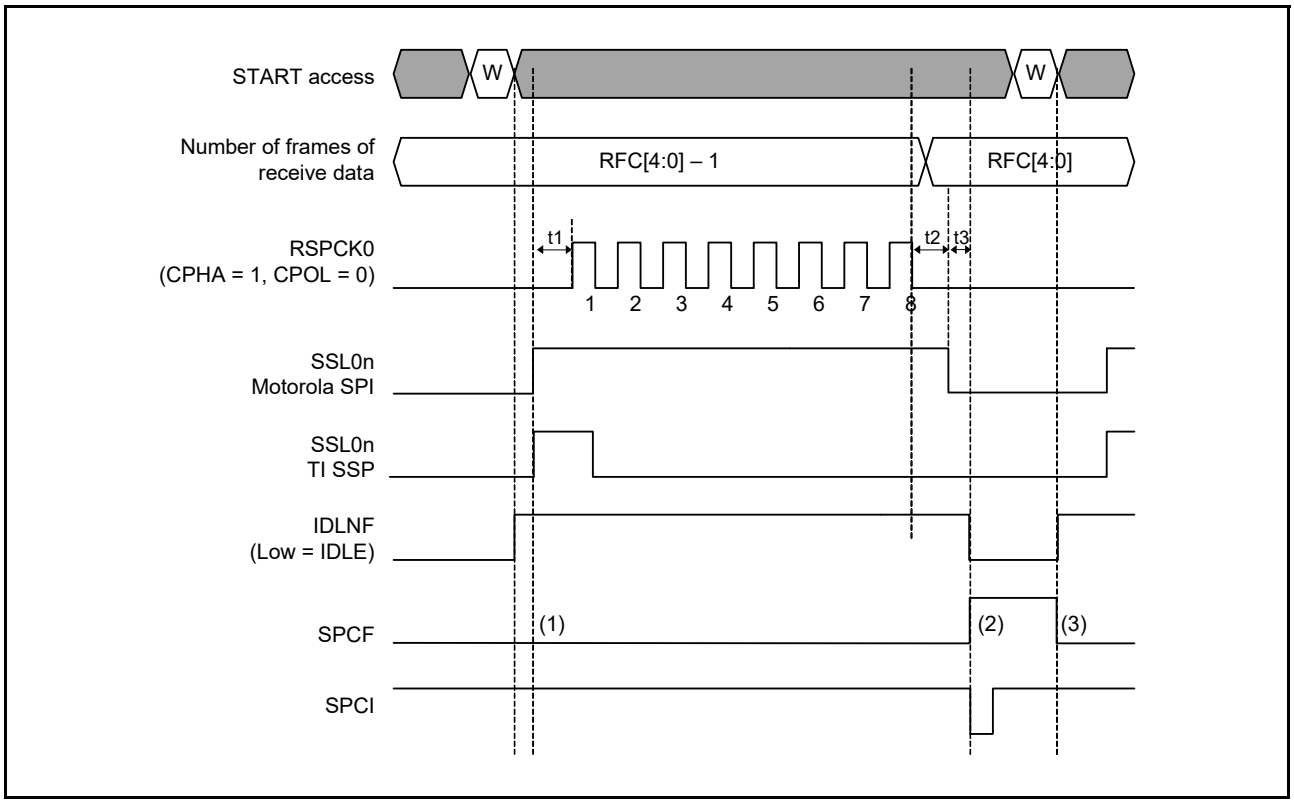

Figure 38.40 Operation Example of SPCI Interrupts (RFC[4:0] ≠ 00000b) (Receive-Only Master Mode)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.
(2) The SPCF flag becomes 1 (communication end) at the end of t3 cycle after receiving the number of frames set by the SPRMCR.RFC[4:0] bits. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCR.SPCIE bit is 1.
(3) The SPCF flag becomes 0 when 1 is written to the SPRMCR.START bit. Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

In slave mode operation, the output timing of the SPCI interrupt is deferent due to the value of the SPCR.SPMS bit (RSPI mode select bit). And the clear timing of the communication end interrupt is deferent due to the communication mode (transmit-receive, transmit-only, or receive-only).

38.3.9.3 Transmit-Receive Slave Mode or Transmit-Only Slave Mode on SPI Operation (4-Wire Method)

Refer to the description of the SPCF Flag (Communication End Flag) in section 38.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during transmit-receive slave mode or transmit-only slave mode on SPI operation (4-wire method).

[Motorola SPI]

Figure 38.41 shows an example of the SPCI interrupt operation during transmit-receive slave mode/transmit-only slave mode on SPI operation.

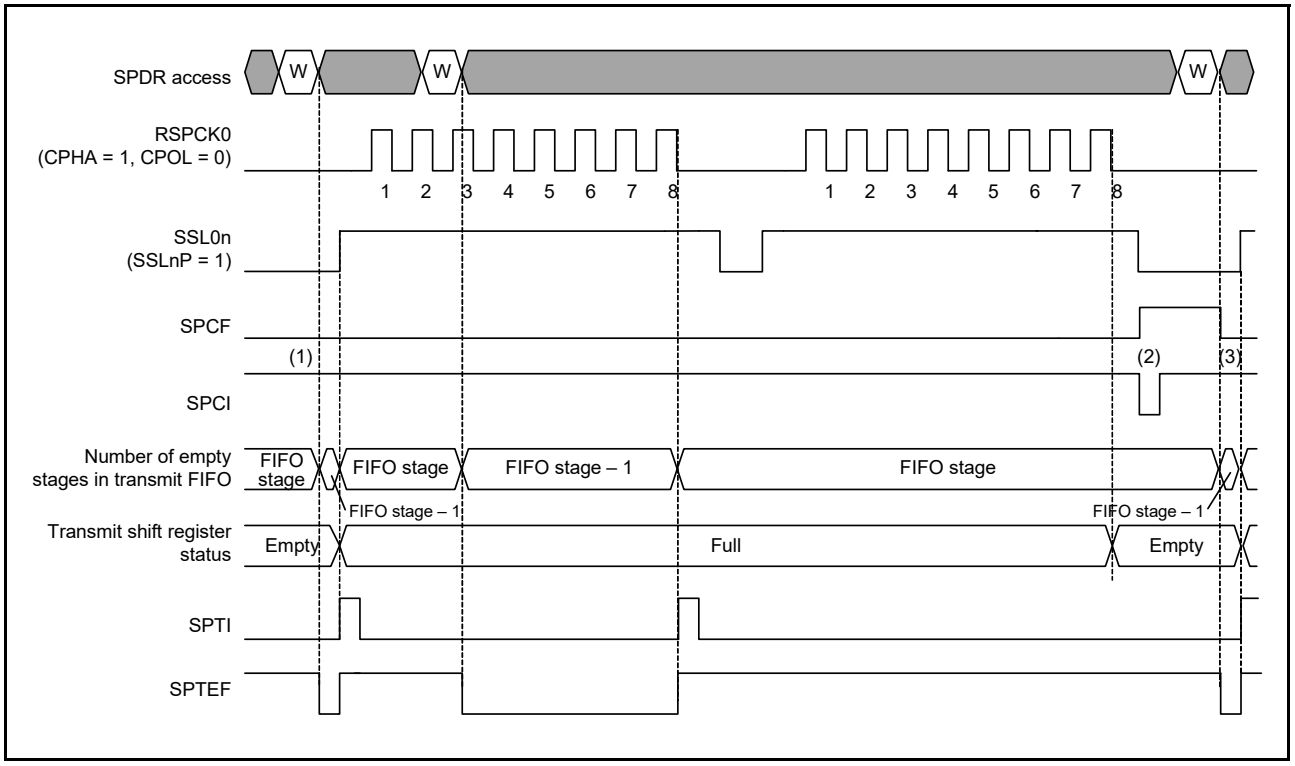

Figure 38.41 Operation Example of SPCI Interrupts (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, Motorola SPI)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) at the timing of SSL0n negation, when the next transmit data is not set in the transmit FIFO and the transmit shift register is empty. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when the next transmit data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

[TI SSP]

Figure 38.42 shows an example of the SPCI interrupt operation during transmit-receive slave mode/transmit-only slave mode on SPI operation.

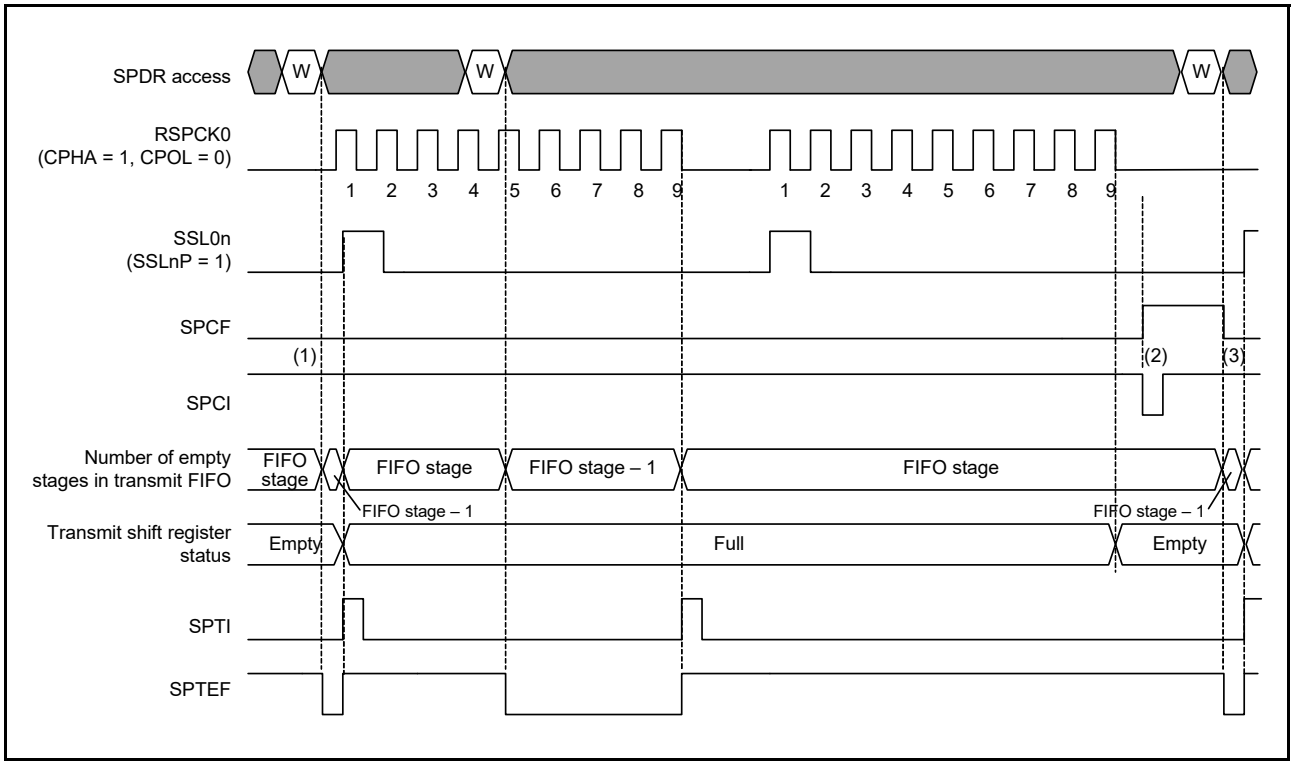

Figure 38.42 Operation Example of SPCI Interrupts (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, TI SSP)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) when the next transmit data is not set in the transmit FIFO, the transmit shift register is empty, and SSL negation delay is completed. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when the next transmit data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

38.3.9.4 Receive-Only Slave Mode on SPI Operation (4-Wire Method)

Refer to the description of the SPCF Flag (Communication End Flag) in section 38.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during receive-only slave mode on SPI operation (4-wire method).

[Motorola SPI]

Figure 38.43 shows an example of the SPCI interrupt operation during receive-only slave mode on SPI operation.

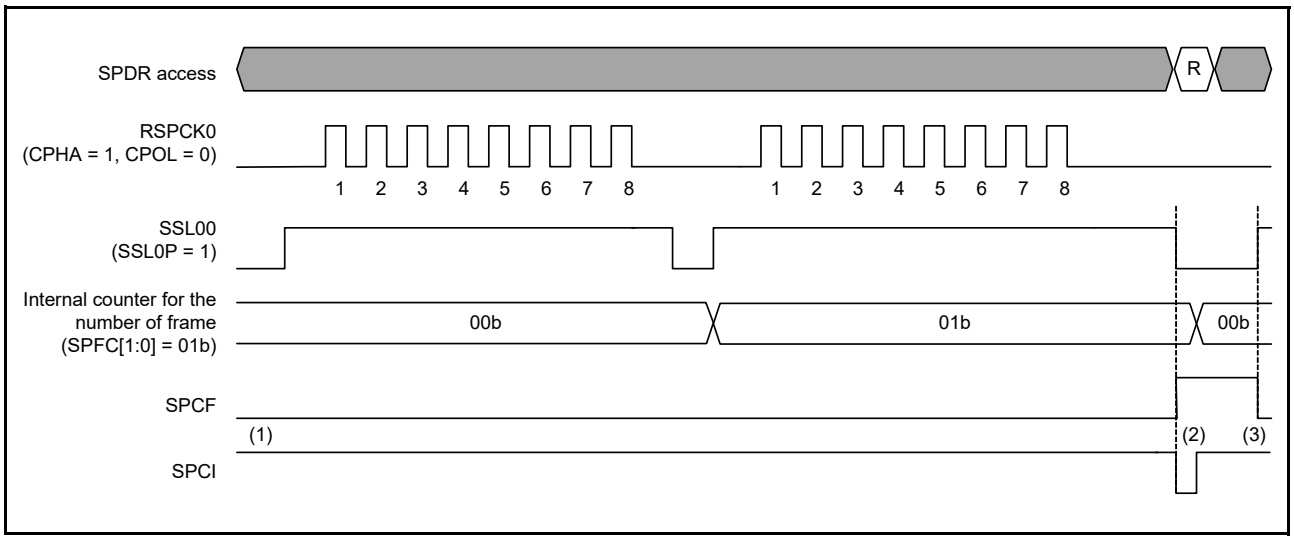

Figure 38.43 Operation Example of SPCI Interrupts (Receive-Only Slave Mode, Motorola SPI)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) After the frames of the value set in the SPDCR.SPFC[1:0] bits are stored in the receive buffer, the SPCF flag becomes 1 (communication end) at the timing of SSL00 negation. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCIE bit is 1.

(3) The SPCF flag becomes 0 at the SSL00 assertion when the next transmission start. Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

[TI SSP]

Figure 38.44 shows an example of the SPCI interrupt operation during receive-only slave mode on SPI operation.

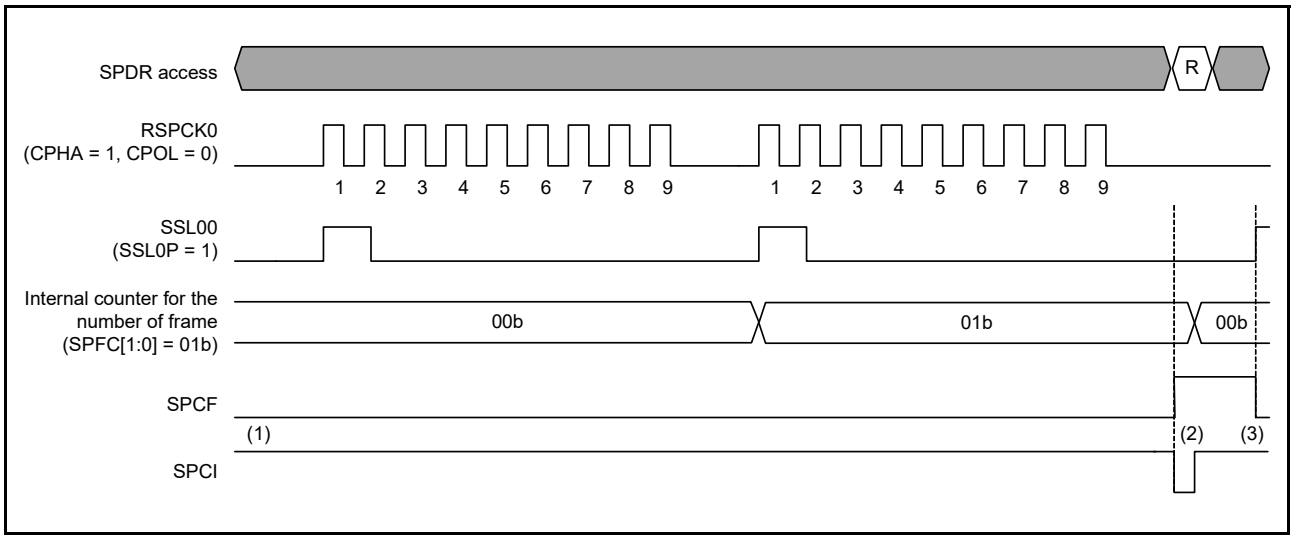

Figure 38.44 Operation Example of SPCI Interrupts (Receive-Only Slave Mode, TI SSP)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) After the frames of the value set in the SPDCR.SPFC[1:0] bits are stored in the receive buffer, the SPCF flag becomes 1 (communication end) at the timing when SSL00 negation delay is completed. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCIE bit is 1.

(3) The SPCF flag becomes 0 at the SSL00 assertion when the next transmission start. Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

38.3.9.5 Transmit-Receive Slave Mode or Transmit-Only Slave Mode on Clock Synchronous Operation (3-Wire Method)

Refer to the description of the SPCF Flag (Communication End Flag) in section 38.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during transmit-receive slave mode or transmit-only slave mode on clock synchronous operation (3-wire method).

Figure 38.45 shows an example of the SPCI interrupt operation during transmit-receive slave mode/transmit-only slave mode on clock synchronous operation.

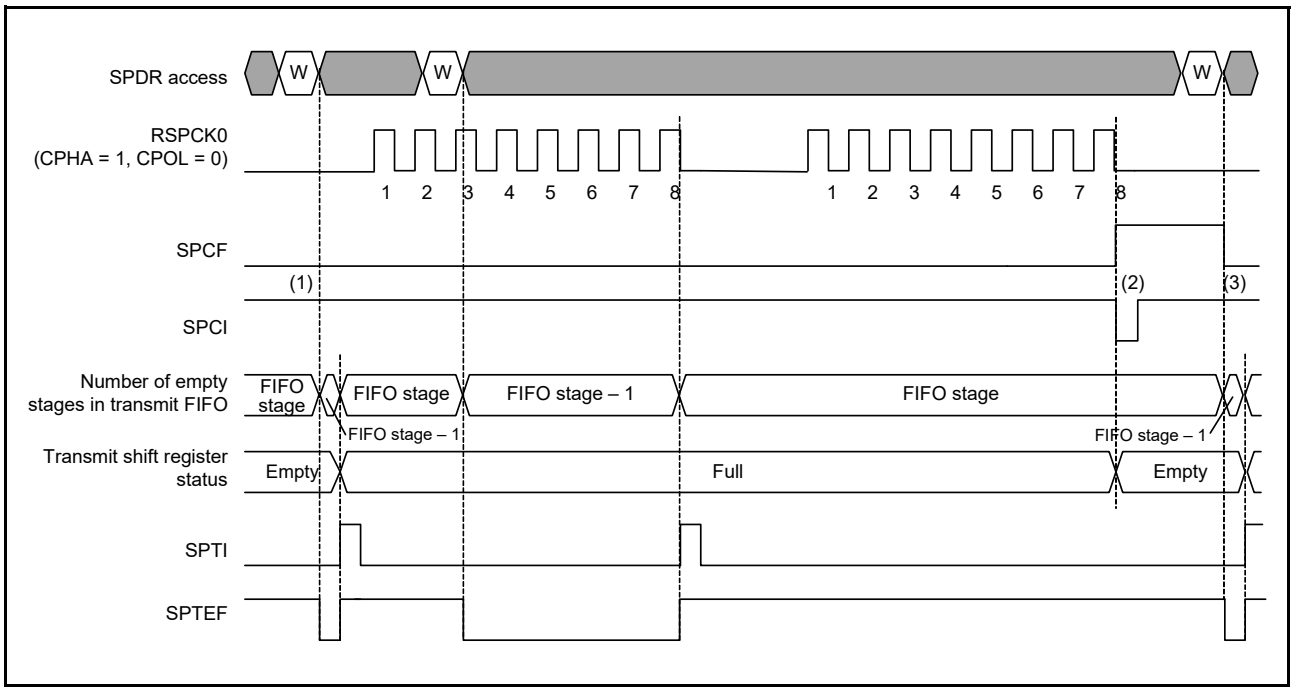

Figure 38.45 Operation Example of SPCI Interrupts (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, Clock Synchronous Operation)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) at the sampling timing of the final data bit of RSPCK0, when the next transmit data is not set in the transmit buffer and the transmit shift register is empty. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when the next transmit data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

38.3.9.6 Receive-Only Slave Mode on Clock Synchronous Operation (3-Wire Method)

Refer to the description of the SPCF Flag (Communication End Flag) in section 38.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during receive-only slave mode on clock synchronous operation (3-wire method).

Figure 38.46 shows an example of the SPCI interrupt operation during receive-only slave mode on clock synchronous operation.

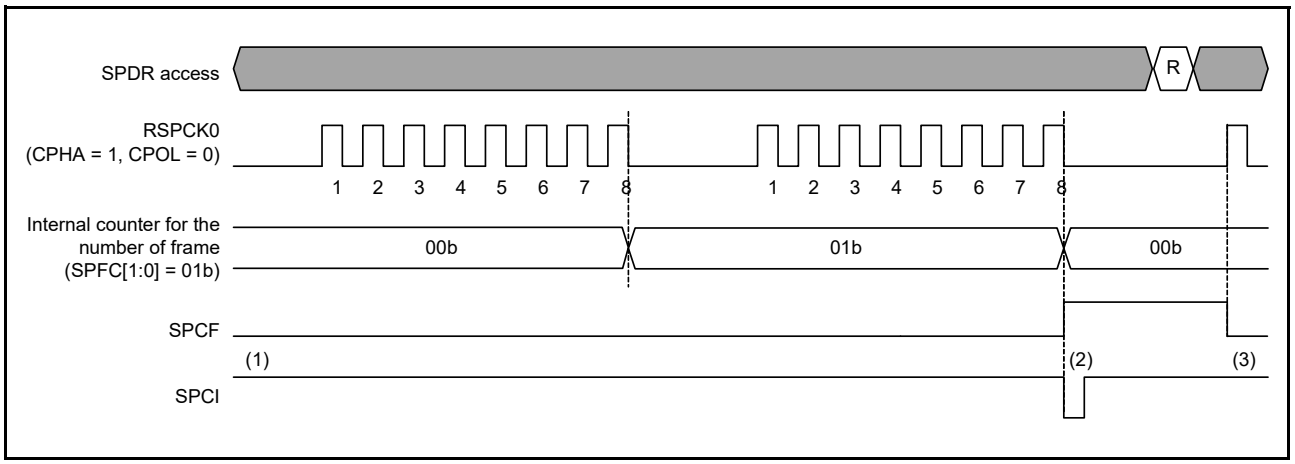

Figure 38.46 Operation Example of SPCI Interrupts (Receive-Only Slave Mode, Clock Synchronous Operation)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) at the sampling timing of the final data bit of RSPCK0, when the final frame of the value set in the SPDCR.SPFC[1:0] bits is received. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 at the first edge of RSPCK0 for the next transmission. Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

38.3.10 Error Detection

In the normal serial transfer of the RSPIA, the data written to the transmit buffer of SPDR is transmitted, and the received data can be read from the receive buffer of SPDR. If access is made to SPDR, depending on the status of the transmit/receive buffer or the status of the RSPIA at the beginning or end of serial transfer, in some cases non-normal transfers can be executed.

If a non-normal transfer operation occurs, the RSPIA detects the event as an underrun error, overrun error, parity error, or mode fault error. Table 38.8 lists the relationship between non-normal transfer operations and the RSPIA's error detection function.

Table 38.8 Relationship between Non-Normal Transfer Operations and Error Detection Function of RSPIA

	Occurrence Condition	RSPI Operation	Error Detection
1	The SPDR register is written while no empty stages in the transmit FIFO.	• The contents of the transmit buffer are kept. • Missing write data.	None
2	The SPDR register is read while no empty stages in the receive FIFO.	If reception has completed, then the received data is output to the bus. Otherwise, data received previously is output instead.	None
3	Serial transfer is started in transmit-receive slave mode or transmit-only slave mode when transmit data is not ready to output.	• Serial transfer is suspended • Transmit/receive data is missing • The MISO0 output signal is disabled • RSPI function is disabled	Underrun error Refer to section 38.3.10.4, Underrun Error for underrun error.
4	Serial transfer terminates when data is stored in the receive FIFO with no empty FIFO stage.	• The contents of the receive FIFO are kept • Missing receive data	Overrun error Refer to section 38.3.10.1, Overrun Error for overrun error.
5	An incorrect parity bit is received with the parity function enabled in the transmit-receive mode or receive-only mode	The parity error flag is asserted.	Parity error Refer to section 38.3.10.2, Parity Error for parity error.
6	The SSL00 input signal is asserted when the serial transfer is idle in multi-master mode.	• Driving of the RSPCK0, MOSI0, SSL01 to SSL03 output signals is stopped. • RSPI function is disabled.	Mode fault error Refer to section 38.3.10.3, Mode Fault Error for mode fault error.
7	The SSL00 input signal is asserted during serial transfer in multi-master mode.	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the RSPCK0, MOSI0, SSL01 to SSL03 output signals is stopped. • RSPI function is disabled.	
8	The SSL00 input signal is negated during serial transfer in slave mode. [Motorola SPI]	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the MISO0 output signal is stopped. • RSPI function is disabled.	
9	The SSL00 input signal is asserted during serial transfer in slave mode. [TI SSP]	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the MISO0 output signal is stopped. • RSPI function is disabled.	
10	After data is stored in the receive FIFO with RDRIS = 1, the number of stored data is less than the threshold value and no receive data is written for the set value of the SPDRCSR register.	• The receive data ready flag is asserted.	Receive data ready Refer to section 38.3.11, Received Data Ready Detection for receive data ready

On operation 1 in Table 38.8, the RSPIA does not detect an error. To prevent data omission during the writing to SPDR, the SPDR register should be written when a transmit buffer empty interrupt request occurs or while the SPSR.SPTEF flag is 1.

Likewise, the RSPIA does not detect an error on operation 2. To prevent extraneous data from being read, the SPDR register should be read when a receive buffer full interrupt request occurs or while the SPSR.SPRF flag is 1.

For the transmit and receive interrupts, refer to section 38.3.7, Transmit Buffer Empty/Receive Buffer Full Interrupts.

38.3.10.1 Overrun Error

If a serial transfer ends while no empty stages in the receive FIFO, the RSPIA detects an overrun error, and sets the SPSR.OVRF flag to 1. When the OVRF flag is 1, the RSPIA does not copy data from the shift register to the receive buffer so that the data prior to the occurrence of the error is retained in the receive buffer. To set the SPSR.OVRF flag to 0, issue a system reset or write 1 to the SPSRC.OVRFC bit.

Figure 38.47 shows an example of operations of the SPSR.SPRF and OVRF flags. The SPSCLR and SPDR accesses shown in Figure 38.47 indicate the condition of accesses to SPSCLR and SPDR, respectively, where W denotes a write cycle, and R a read cycle. In the example in Figure 38.47, the RSPIA performs an 8-bit serial transfer in which the SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCK0 waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

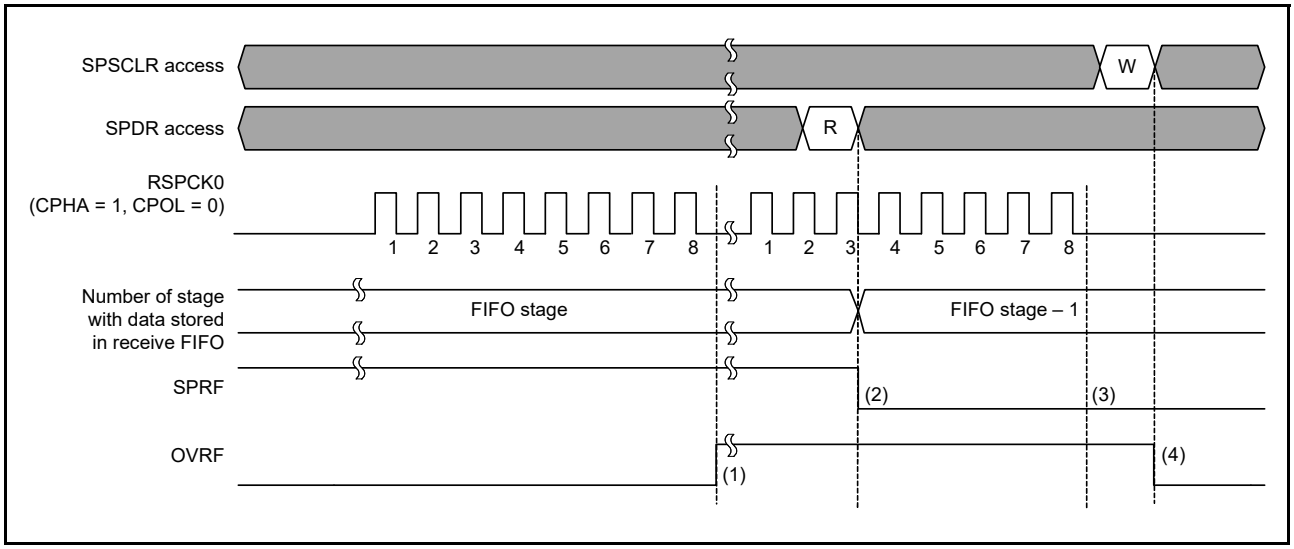

Figure 38.47 Operation Example of SPRF and OVRF Flags

The operation of the flags at the timing shown in steps (1) to (4) in the figure is described below.

(1) If a serial transfer terminates while no empty stages in the receive FIFO, the RSPIA detects an overrun error, and sets the OVRF flag to 1. The RSPIA does not copy the data in the shift register to the receive buffer. Even if the SPPE bit is 1, parity errors are not detected. In master mode, the RSPIA copies the pointer value to SPCMDm register to the SPSSR.SPECM[2:0] bits.

(2) When SPDR is read, the RSPIA outputs the data in the receive buffer. At this time the SPRF flag becomes 0 at the last access when the received data is read from the SPDR register in one processing routine using DTC/DMAC. Even if the receive buffer becomes empty, the OVRF flag does not become 0.

(3) If the serial transfer ends with the OVRF flag being 1 (an overrun error occurs), the RSPIA does not copy the data in the shift register to the receive buffer (the SPRF flag remains 0). A receive buffer full interrupt is not generated. Even if the SPPE bit is 1, parity errors are not detected. When in master mode, the RSPIA does not update the SPSSR.SPECM[2:0] bits. When in an overrun error state and the RSPIA does not copy the received data from the shift register to the receive buffer, upon termination of the serial transfer, the RSPIA determines that the shift register is empty; in this manner, data transfer from the transmit buffer to the shift register is enabled.

(4) When 1 is written to the SPSCLR.OVRFC bit, the OVRF flag is set to 0.

The occurrence of an overrun can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. When executing a serial transfer without using an error interrupt, measures should be taken to ensure the early detection of overrun errors, such as reading the SPSR register immediately after SPDR is read. When the RSPIA is used in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits. If an overrun error occurs and the OVRF flag is set to 1, normal reception operations cannot be performed until the OVRF flag is set to 0.

When the RSPCK auto-stop function is enabled in master mode, an overrun error does not occur. Figure 38.48 and Figure 38.49 show the clock stop waveform when a serial transfer continues while no empty stages in the receive FIFO in master mode.

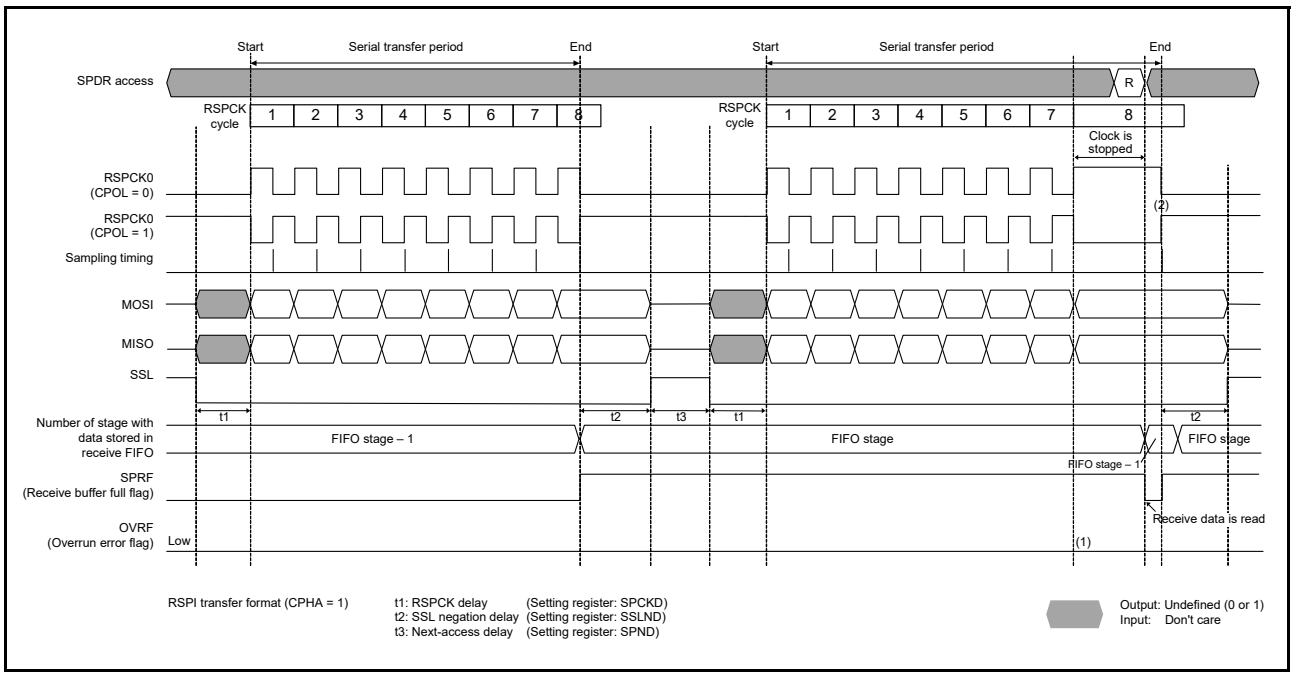

Figure 38.48 Clock Stop Waveform When a Serial Transfer Continues While No Empty Stages in the Receive FIFO in Master Mode (CPHA = 1)

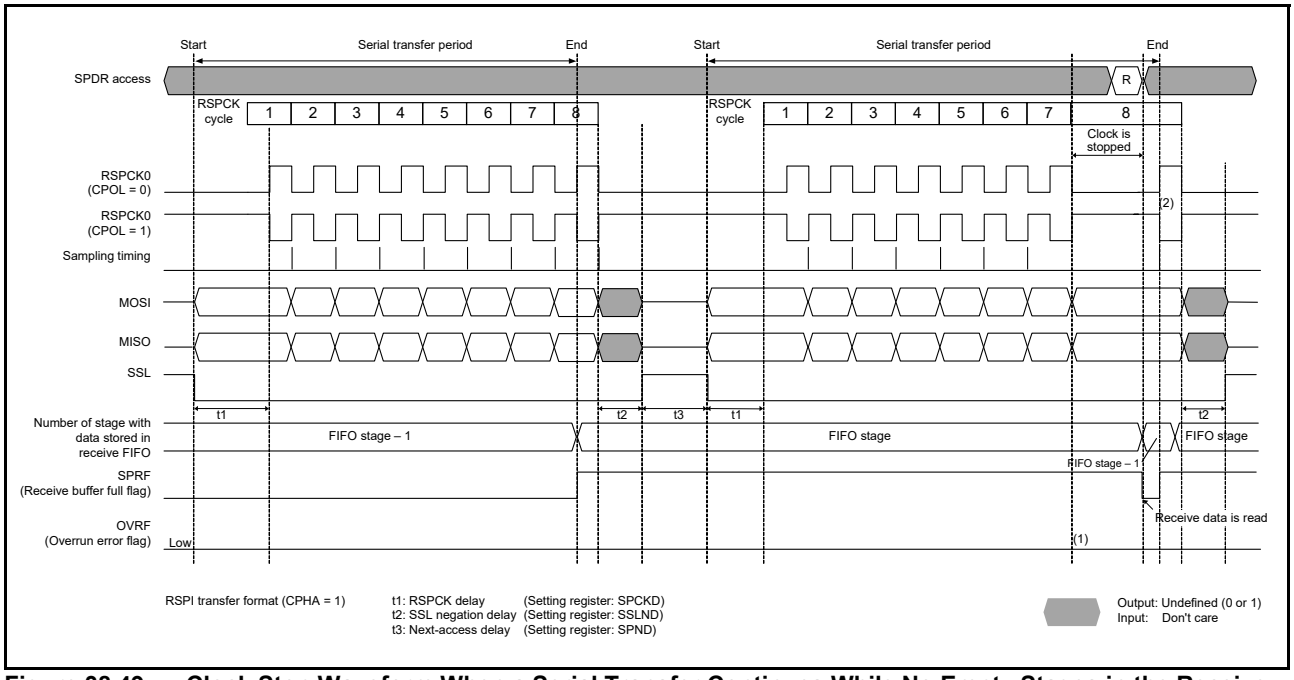

Figure 38.49 Clock Stop Waveform When a Serial Transfer Continues While No Empty Stages in the Receive FIFO in Master Mode (CPHA = 0)

The operation of the flags at the timings shown in steps (1) and (2) in the figure is described below.

(1) When no empty stages in the receive FIFO, an overrun error does not occur because the RSPCK0 is stopped.

(2) If SPDR is read while the clock is stopped, data in the receive buffer can be read. The RSPCK0 restarts after reading the receive buffer.

When the RSPCK auto-stop function is enabled for transfer with no delay of between frames during burst transfer in master mode, an overrun error does not occur. Figure 38.50 and Figure 38.51 show the clock stop waveform when there is no delay between frames during burst transfer and a serial transfer continues while no empty stages in the receive FIFO in master mode.

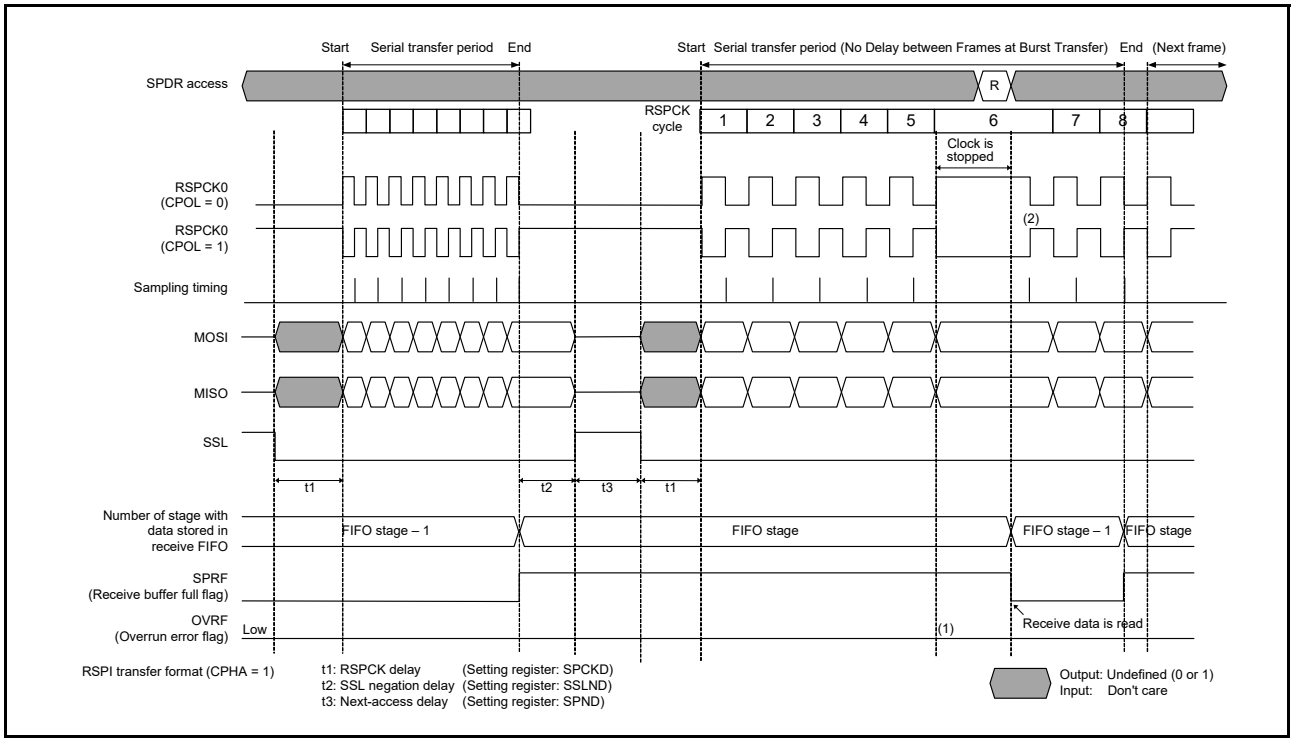

Figure 38.50 Clock Stop Waveform When a Serial Transfer Continues While No Empty Stages in the Receive FIFO in Master Mode (No Delay between Frames at Burst Transfer, CPHA = 1)

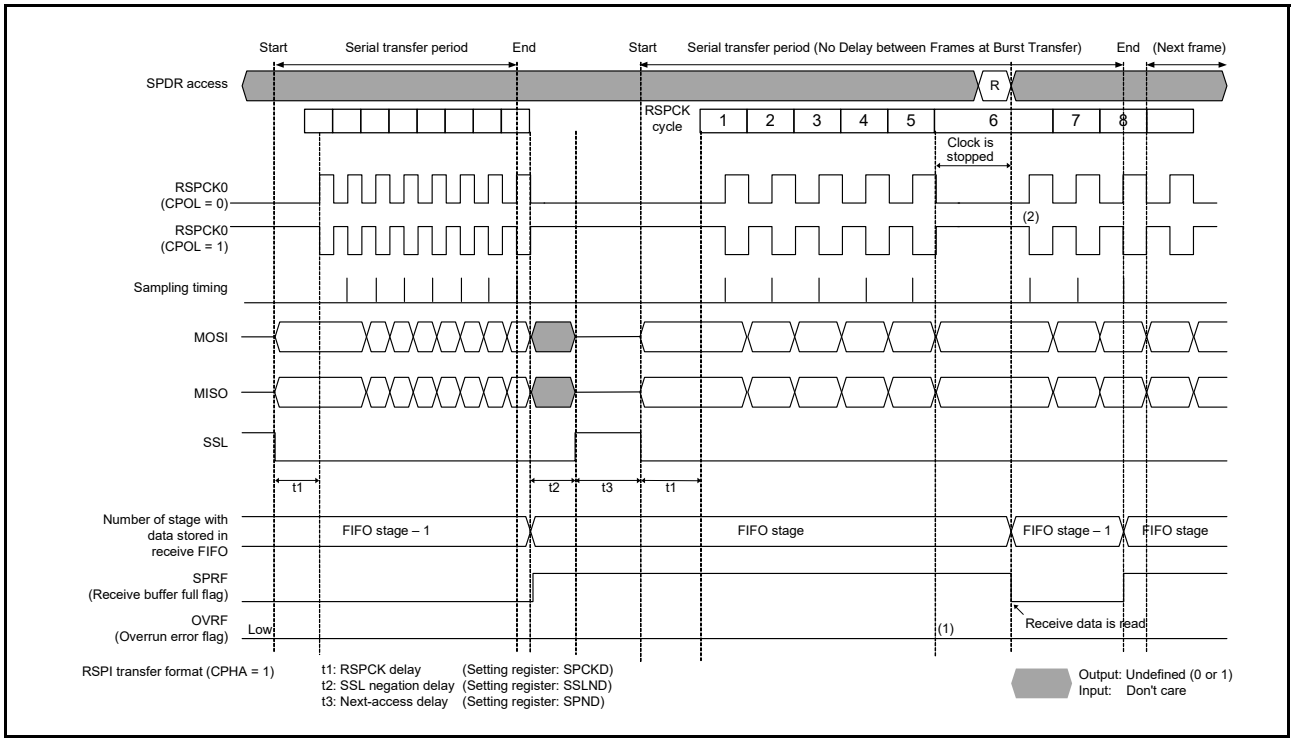

Figure 38.51 Clock Stop Waveform When a Serial Transfer Continues While No Empty Stages in the Receive FIFO in Master Mode (No Delay between Frames at Burst Transfer, CPHA = 0)

The operation of the flags at the timings shown in steps (1) and (2) in the figure is described below.

(1) When no empty stages in the receive FIFO, an overrun error does not occur because the RSPCK0 is stopped.

(2) If SPDR is read while the clock is stopped, data in the receive buffer can be read. The RSPCK0 restarts after reading the receive buffer.

38.3.10.2 Parity Error

If the SPCR.SPPE bit set to 1, when serial transfer in transmit-receive mode or receive-only mode terminates, the RSPIA checks whether there are parity errors. Upon detecting a parity error in the received data, the RSPIA sets the SPSR.PERF flag to 1. Since the RSPIA does not copy the data in the shift register to the receive buffer when the SPSR.OVRF flag is set to 1, parity error detection is not performed for the received data. To set the PERF flag to 0, issue a system reset or write 1 to the SPSCLR.PERFC bit.

Figure 38.52 shows an example of operation of the OVRF and PERF flags. The SPSR access shown in Figure 38.52 indicates the condition of access to SPSR register, where W denotes a write cycle, and R a read cycle. In the example of Figure 38.52, serial communications is performed while the SPCR.SPPE bit is 1. The RSPIA performs an 8-bit serial transfer in which the SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCK0 waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

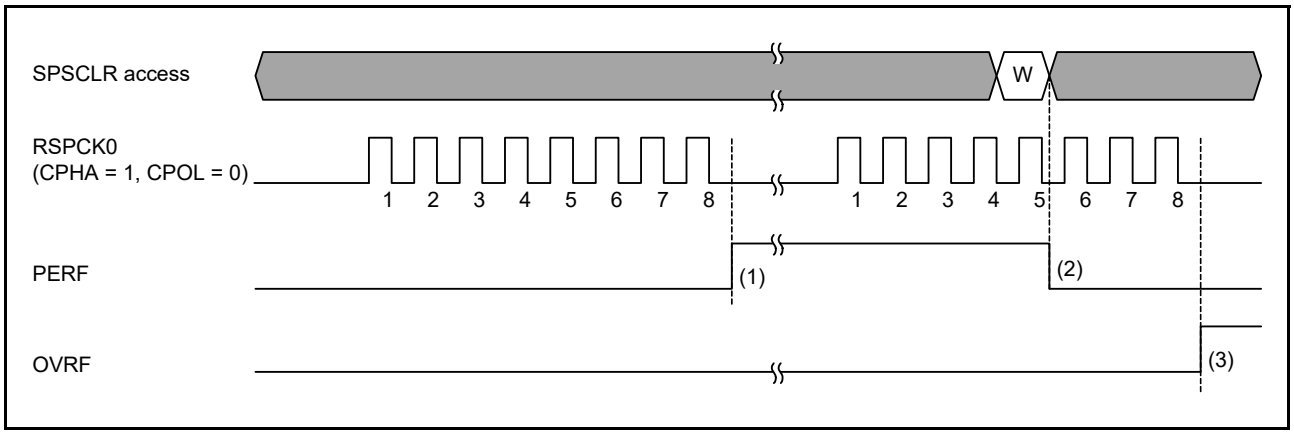

Figure 38.52 Operation Example of PERF Flag

The operation of the flags at the timing shown in steps (1) to (3) in the figure is described below.

(1) If a serial transfer terminates with the RSPIA not detecting an overrun error, the RSPIA copies the data in the shift register to the receive buffer. The RSPIA judges the received data at this timing, and sets the PERF flag to 1 if a parity error is detected. In master mode, the RSPIA copies the pointer value to SPCMDm register to the SPSSR.SPECM[2:0] bits.

(2) When 1 is written to the SPSCLR.PERFC bit, the PERF flag is set to 0.

(3) When the RSPIA detects an overrun error and serial transfer is terminated, the data in the shift register is not copied to the receive buffer. The RSPIA does not perform parity error detection at this timing.

The occurrence of a parity error can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. To use an error interrupt, set the SPCR.SPEIE bit to 1. When executing a serial transfer without using an error interrupt, measures should be taken to ensure the early detection of parity errors, such as reading the SPSR register. When the RSPIA is used in master mode, the pointer value to SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.

38.3.10.3 Mode Fault Error

The RSPIA operates in multi-master mode when the SPCR.MSTR bit is 1, the SPCR.SPMS bit is 0, and the SPCR.MODFEN bit is 1. If the active level is input with respect to the SSL00 input signal of the RSPIA in multi-master mode, the RSPIA detects a mode fault error irrespective of the status of the serial transfer, and sets the SPSR.MODF flag to 1. Upon detecting the mode fault error, the RSPIA copies the value of the pointer to SPCMDm to the SPSSR.SPECM[2:0] bits. The active level of the SSL00 signal is determined by the SSLP.SSL0P bit.
When the MSTR bit is 0, the RSPIA operates in slave mode. The RSPIA detects a mode fault error if the MODFEN bit of the RSPIA in slave mode is 1, and the SPMS bit is 0, and the following conditions are satisfied during the serial transfer period (from the time the driving of valid data is started to the time the final valid data is fetched).

- In the Motorola SPI mode, when the SSL00 input signal is negated during the serial transfer period
- In the TI SSP mode, when the SSL00 input signal is asserted during the serial transfer period
  However, during a burst transfer, no error is detected even if the SSL00 input signal is asserted during the last bit of frame.

Upon detecting a mode fault error, the RSPIA stops driving of the output signals and sets the SPCR.SPE bit to 0. When the SPE bit is cleared, the RSPI function is disabled (refer to section 38.3.12, Initializing RSPIA). In the case of multi-master configuration, detection of a mode fault error is used to stop driving of the output signals and the RSPI function, which allows the master right to be released.
The occurrence of a mode fault error can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. Detecting mode fault errors without utilizing the error interrupt requires polling of the SPSR register. When using the RSPIA in master mode, the pointer value to SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.
When the MODF flag is 1, writing of the value 1 to the SPE bit is ignored by the RSPIA. To enable the RSPI function after the detection of a mode fault error, set the MODF flag to 0.

38.3.10.4 Underrun Error

If RSPIA operates in slave mode (the SPCR.MSTR bit is 0) and the communication mode select bits (CMMD[1:0]) in the RSPI control register (SPCR) is set to 00b or 01b, when serial transfer is started before transmit data output is ready with the SPCR.SPE bit is 1 (RSPI function is enabled), the RSPIA detects an underrun error, and sets the SPSR.MODF and SPSR.UDRF flags to 1.
Upon detecting an underrun error, the RSPIA stops driving of the output signals and sets the SPCR.SPE bit to 0. Clearing of the SPE bit disables the RSPI function. (Refer to section 38.3.12, Initializing RSPIA).
The occurrence of an underrun error can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. Detecting underrun errors without utilizing the error interrupt requires polling of the SPSR register.
When the MODF flag is 1, writing of the value 1 to the SPE bit is ignored by the RSPIA. To enable the RSPI function after the detection of an underrun error, set the MODF flag to 0.

38.3.11 Received Data Ready Detection

When the SPCR.CMMD[1:0] bits are 00b, 01b or 11b, and the value of the SPDRCSR register is not 00h, after receiving data in the receive FIFO during communication (SPE = 1), the SPSR.RRDYF flag is set to 1 when the received data is not stored even after the number of received FIFOs is equal to or less than the threshold value and the value set in the SPDRCSR register has elapsed.

When the receive data ready is detected, the interrupt and event link output can be selected as SPRI or SPEI with the SPCR.RDRIS bit.

Figure 38.53 shows an example of received data ready detection operation.

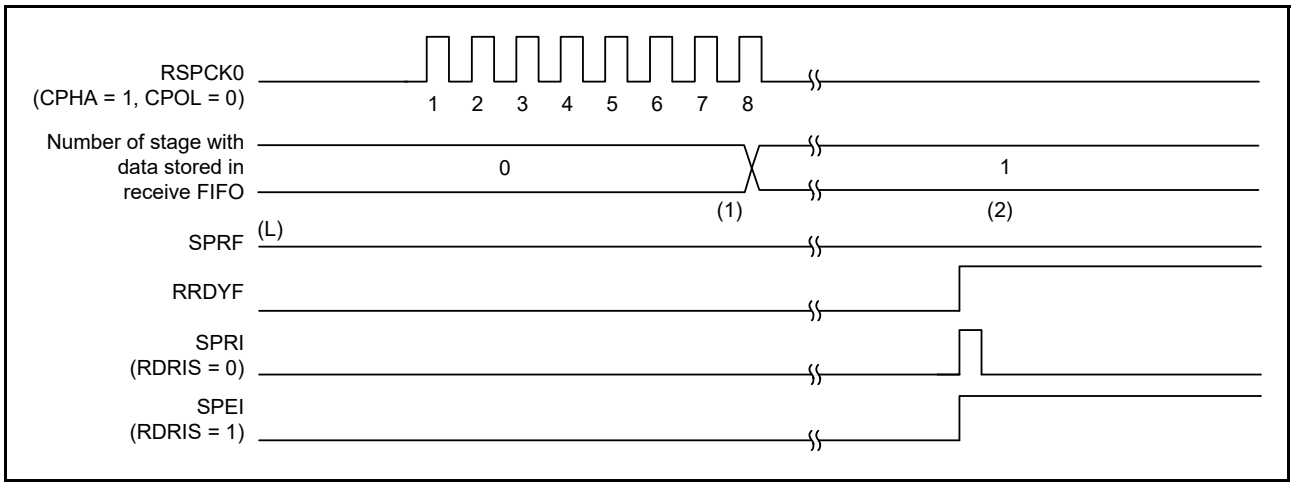

Figure 38.53 Received Data Ready Detection

The operation at the timing shown in steps (1) and (2) in the figure is described below.

(1) Store the received data to the receive FIFO. The SPSR.SPRF flag is 0, because the number of data stored in the receive FIFO is equal to or less than the value of the SPFCR.RTRG[1:0] bits.

(2) Set the RRDYF flag and assert SPRI or SPEI because data is not written to the receive FIFO for the value of the SPDRCSR register from (1).

38.3.12 Initializing RSPIA

If 0 is written to the SPCR.SPE bit or the RSPIA sets the SPE bit to 0 because of the detection of a mode fault error or an underrun error, the RSPIA disables the RSPI function, and initializes some of the module functions. When a system reset is generated, the RSPIA initializes all of the module functions. The following describes initialization by the clearing of the SPCR.SPE bit and initialization by a system reset.

38.3.12.1 Initialization by Clearing the SPE Bit

When the SPCR.SPE bit is set to 0, the RSPIA performs the following initialization:

- Suspending any serial transfer that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state of the RSPIA
- Set the SPSR.SPTEF flag to 1

Initialization by the clearing of the SPE bit does not initialize the control bits of the RSPIA. For this reason, the RSPIA can be started in the same transfer mode as prior to the initialization if the SPE bit is set to 1 again.
The SPSR.SPCF, SPRF, OVRF, MODF, PERF, and UDRF flags are not initialized, nor is the value of the RSPI sequence status register (SPSSR) initialized. For this reason, even after the RSPIA is initialized, data from the receive buffer, the communication end status, and the error status during RSPI transfer can be read to check them.
The SPSR.SPTEF flag is initialized to 1. Therefore, if the SPCR.SPTIE bit is set to 1 after RSPIA initialization, a transmit buffer empty interrupt is generated. When the CPU initializes the RSPIA, in order to disable any transmit buffer empty interrupt, 0 should be written to the SPTIE bit simultaneously with the writing of 0 to the SPE bit.

38.3.12.2 System Reset

The initialization by a system reset completely initializes the RSPIA through the initialization of all bits for controlling the RSPIA, initialization of the status bits, and initialization of data registers, in addition to the requirements described in section 38.3.12.1, Initialization by Clearing the SPE Bit.

38.3.13 SPI Operation

38.3.13.1 Master Mode Operation

The only difference between single-master mode operation and multi-master mode operation lies in mode fault error detection (refer to section 38.3.10, Error Detection). When operating in single-master mode, the RSPIA does not detect mode fault errors whereas the RSPIA running in multi-master mode does detect mode fault errors. This section explains operations that are common to single-master mode and multi-master mode.

(1) Starting a Serial Transfer

The RSPIA updates the data in the transmit buffer (SPTXn, n = 0 to 3) when data is written to the RSPI data register (SPDR) with the transmit buffer being empty (data for the next transfer is not set). When the shift register is empty the RSPIA copies data from the transmit buffer to the shift register and starts serial transfer. Upon copying transmit data to the shift register, the RSPIA changes the status of the shift register to “full”, and upon termination of serial transfer, it changes the status of the shift register to “empty”. The status of the shift register cannot be referenced.
For details on the RSPI transfer format, refer to section 38.3.5, Transfer Format (Frame Format). The polarity of the SSL0n output pins depends on the SSLP register settings.

(2) Terminating a Serial Transfer

[Except receive-only operation in master mode]
Irrespective of the SPCMDm.CPHA bit, the RSPIA terminates the serial transfer after transmitting an RSPCK0 edge corresponding to the final sampling timing. If the number of data stored in the receive FIFO is less than the number of FIFO stages, after the termination of serial transfer, the RSPIA copies data from the shift register to the receive buffer of the SPDR register.
It should be noted that the final sampling timing varies depending on the bit length of transmit data. In master mode, the RSPI data length depends on the SPCMDm.SPB[4:0] bits setting. The polarity of the SSL0n output pin depends on the SSLP register settings.
For details on the RSPI transfer format, refer to section 38.3.5, Transfer Format (Frame Format).

[Receive-only operation in master mode]
The RSPIA terminates the serial transfer when any of the following conditions is satisfied.

- After the RSPIA detects the RSPCK0 edge corresponding to the final sampling timing irrespective of the SPCMDm.CPHA bit
- When writing 1 to the SPRMCR.TERM bit during the serial transfer period

If the number of data stored in the receive FIFO is less the number of FIFO stages, after termination of serial transfer, the RSPIA copies data from the shift register to the receive buffer of the SPDR register.
It should be noted that the final sampling timing varies depending on the bit length of transmit data. In master mode, the RSPI data length depends on the SPCMDm.SPB[4:0] bits setting. The polarity of the SSL0n output pin depends on the SSLP register settings.
For details on the RSPI transfer format, refer to section 38.3.5, Transfer Format (Frame Format).

(3) Sequence Control

The transfer format that is employed in master mode is determined by the following registers.

- RSPI sequence control register (SPSCR)
- RSPI command register m (SPCMDm) (m = 0 to 7)
- RSPI bit rate register (SPBR)
- RSPI clock delay register (SPCKD)
- RSPI slave select negation delay register (SSLND)
- RSPI next-access delay register (SPND)

SPSCR is a register used to determine the sequence configuration for serial transfers that are executed by the RSPIA in master mode. The following items are set in the SPCMDm register: SSL0n pin output signal value, MSB/LSB first, data length, some of the bit rate settings, RSPCK polarity/phase, whether SPCKD is to be referenced, whether SSLND is to be referenced, and whether SPND is to be referenced. The SPBR register holds some of the bit rate settings; the SPCKD register, an RSPI clock delay value; the SSLND register, an SSL negation delay; and the SPND register, a next-access delay value.

According to the sequence length that is assigned to the SPSCR register, the RSPIA makes up a sequence comprised of a part or all of the SPCMDm register. The RSPIA contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the RSPI function is enabled, the RSPIA loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The RSPIA increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, the RSPIA sets the pointer in SPCMD0, and in this manner the sequence is executed repeatedly.

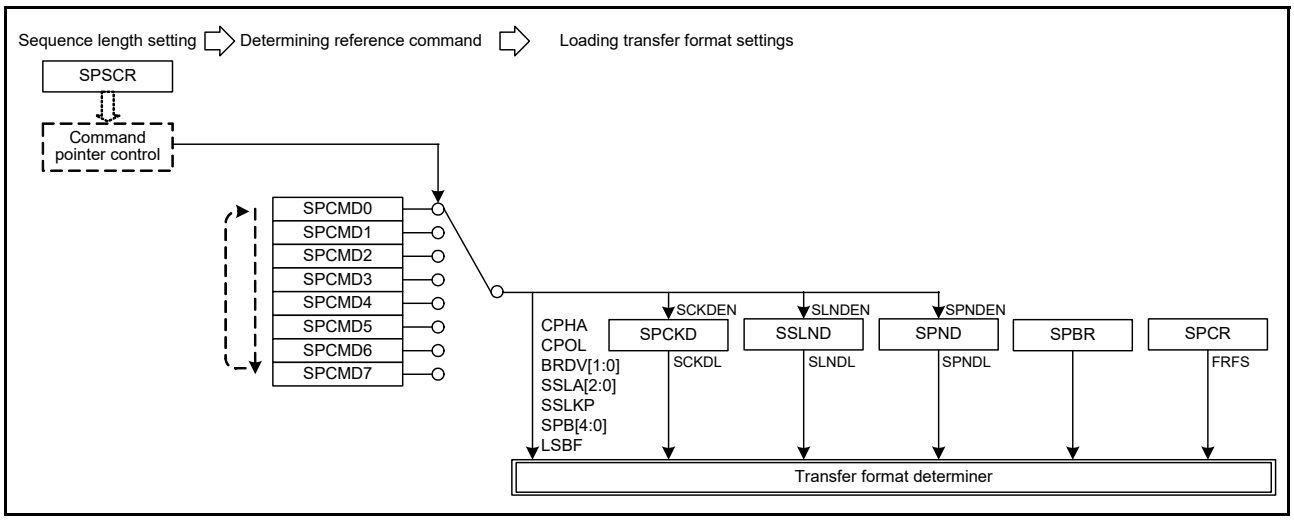

Figure 38.54 Procedure for Determining the Form of Serial Transfer in Master Mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

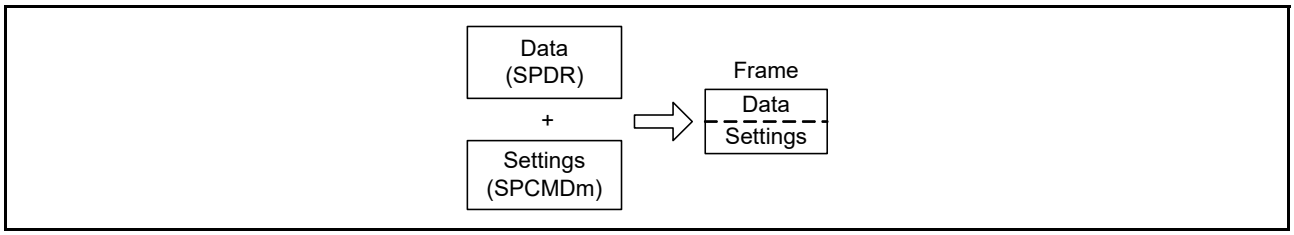

Figure 38.55 Concept of a Frame

Figure 38.56 shows the relationship between the command and the transmit buffer (SPTXn, n = 0 to 3) and receive buffer (SPRXn, n = 0 to 3) in sequence operations.

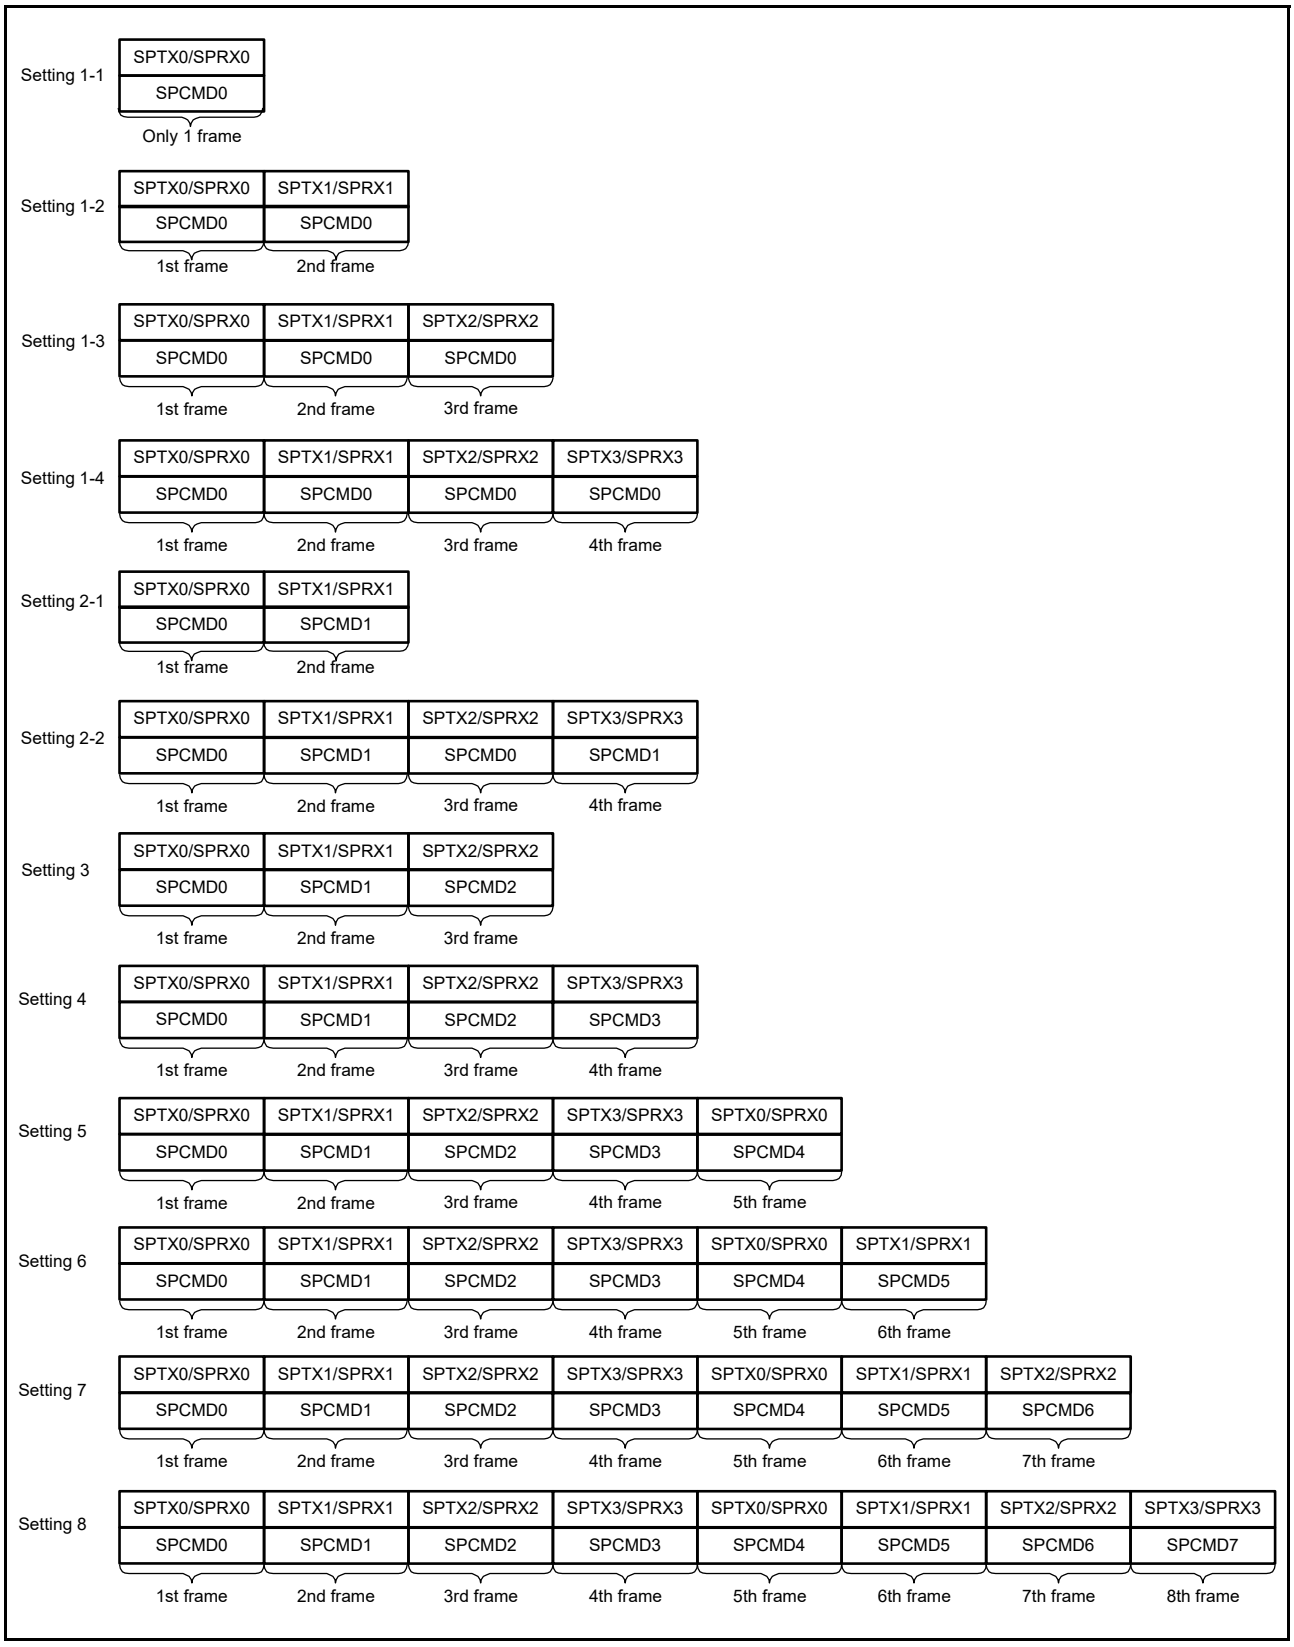

Figure 38.56 Correspondence between the RSPI Command Register m and Transmit/Receive Buffers in Sequence Operations

(4) Burst Transfer

[Motorola SPI]

If the SPCMDm.SSLKP bit that the RSPIA references during the current serial transfer is 1, the RSPIA keeps the SSL0n signal level during the serial transfer until the beginning of the SSL0n signal assertion for the next serial transfer. If the SSL0n signal level for the next serial transfer is the same as the SSL0n signal level for the current serial transfer, the RSPIA can execute continuous serial transfers while keeping the SSL0n signal assertion status (burst transfer).

- When the SPCR.SCKDDIS bit (RSPCK delay between data bytes disable bit) is 0

Figure 38.57 shows an example of an SSL0n signal operation for the case where a burst transfer is implemented using SPCMD0 and SPCMD1 register settings. The text below explains the RSPI operations (1) to (8) as shown in Figure 38.57. It should be noted that the polarity of the SSL0n output signal depends on the SSLP register settings.

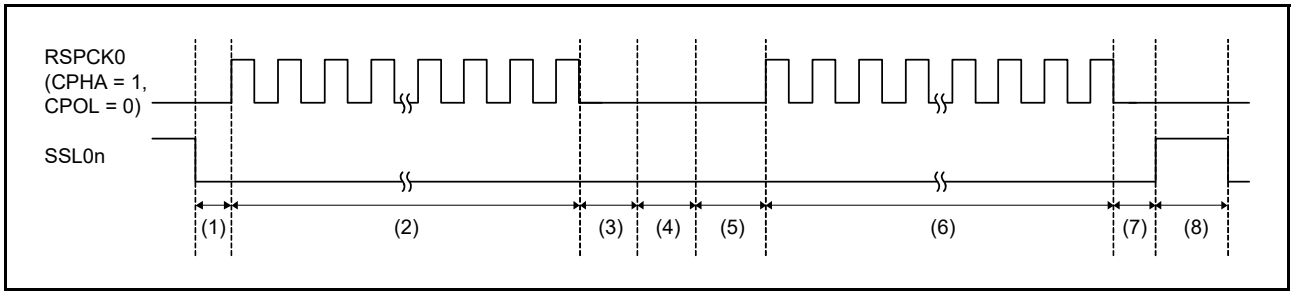

Figure 38.57 Example of Burst Transfer Operation Using SSLKP Bit (SCKDDIS = 0, FRFS = 0)

(1) Based on SPCMD0, the RSPIA asserts the SSL0n signal and inserts RSPCK delays.
(2) The RSPIA executes serial transfers according to SPCMD0.
(3) The RSPIA inserts SSL negation delays.
(4) In transmit-receive mode or transmit-only mode, since the SPCMD0.SSLKP bit is 1, the RSPIA keeps the SSL0n signal value on SPCMD0. This period is sustained, at the shortest, for a period equal to the next-access delay of SPCMD0 and additional 5 PCLKA cycles. If the shift register is empty after the passage of a minimum period, this period is sustained until the transmit data is stored in the shift register for the next transfer.
In receive-only mode, since the SPCMD0.SSLKP bit is 1, the RSPIA keeps the SSL0n signal value on SPCMD0. This period is sustained for a period equal to the next-access delay of SPCMD0 and additional 5 PCLKA cycles.
(5) Based on SPCMD1, the RSPIA asserts the SSL0n signal and inserts RSPCK delays.
(6) The RSPIA executes serial transfers according to SPCMD1.
(7) The RSPIA inserts SSL negation delays.
(8) Since the SPCMD1.SSLKP bit is 0, the RSPIA negates the SSL0n signal. In addition, a next-access delay is inserted according to SPCMD1.

Note: If the SSL0n signal output settings in the SPCMDm register in which 1 is assigned to the SSLKP bit (to use for burst transfer) are different from the SSL0n signal output settings in the SPCMDm register to be used in the next transfer, the RSPIA switches the SSL0n signal status to SSL0n signal assertion ((5) in Figure 38.57) corresponding to the command for the next transfer. Note that if such an SSL0n signal switching occurs, the slaves that drive the MISO0 signal compete, and collision of signal levels may occur.

The RSPIA in master mode references the SSL0n signal operation within the module for the case where the SSLKP bit is not used. Even when the SPCMDm.CPHA bit is 0, the RSPIA can accurately start serial transfers by using the SSL0n signal assertion for the next transfer that is detected internally. For this reason, burst transfer in master mode is enabled regardless of the CPHA bit setting. (Refer to section 38.3.13, SPI Operation.)

- When the SPCR.SCKDDIS bit (RSPCK delay between data bytes disable bit) is 1

Figure 38.58 shows an example of an SSL0n signal operation for the case where a burst transfer is implemented using SPCMD0 and SPCMD1 register settings. The text below explains the RSPI operations (1) to (6) as shown in Figure 38.58. It should be noted that the polarity of the SSL0n output signal depends on the SSLP register settings.

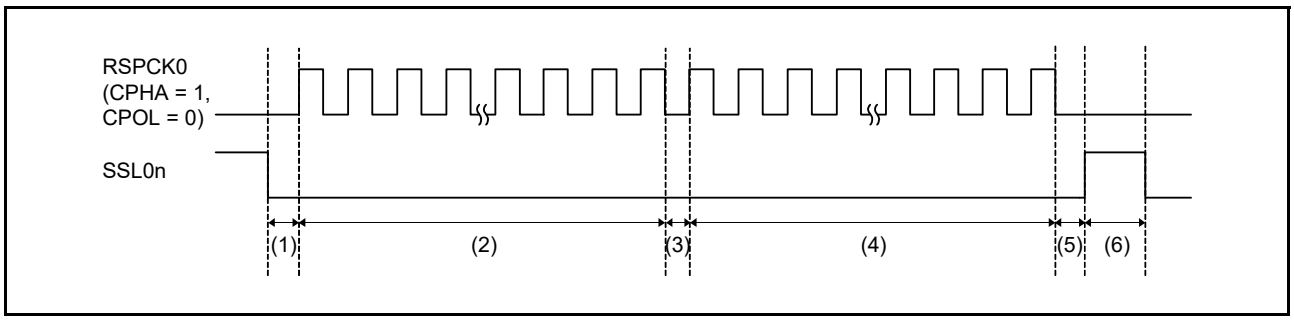

Figure 38.58 Example of Burst Transfer Operation Using SSLKP Bit (SCKDDIS = 1, FRFS = 0)

(1) Based on the SPCMD0 register, the RSPIA asserts the SSL0n signal and inserts RSPCK delays.
The RSPCK delay is inserted only the first frame of burst transfer.

(2) In transmit-receive mode or transmit-only mode, the RSPIA executes serial transfers according to the SPCMD0 register. The RSPIA waits for the last clock output until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.
In receive-only mode, the RSPIA executes serial transfers according to the SPCMD0 register.

(3) In transmit-receive mode or transmit-only mode, since the SPCMD0.SSLKP bit is 1, the RSPIA keeps the SSL0n signal value on the SPCMD0 register. If the shift register is not empty, RSPCK negate period between frames is 0.5 RSPCK.
In receive-only mode, since it is not the last frame*1, the RSPIA keeps the SSL0n signal value on the SPCMD0 register. RSPCK negate period between frames is 0.5 RSPCK.

(4) The RSPIA executes serial transfers according to the SPCMD1 register.

(5) The RSPIA inserts SSL negation delays.

(6) In transmit-receive mode or transmit-only mode, since the SPCMD1.SSLKP bit is 0, the RSPIA negates the SSL0n signal. In addition, a next-access delay is inserted according to the SPCMD1 register.
In receive-only mode, the RSPIA negates the SSL0n signal. In addition, a next-access delay is inserted according to the SPCMD1 register.

Note 1. In receive-only mode, the last frame is a frame set by the SPRMCR.RFC[4:0] bits when SPRMCR.RFC[4:0] ≠ 00000b or a frame in which SPRMCR.TERM = 1 has been accepted.

[TI SSP]
The RSPIA asserts the SSL0n signal for one cycle at the start of serial transfer.
The RSPIA can execute continuous serial transfers by asserting the SSL0n signal for one cycle at the start of serial transfer (burst transfer).

- When the SPCMDm.SSLKP bit (SSL signal level keeping bit) is 1, and the SPCR.SCKDDIS bit (RSPCK delay between data bytes disable bit) is 1

Figure 38.59 shows an example of an SSL0n signal operation and the serial data MISO0/MOSI0 for the case where a burst transfer is implemented using the SPCMD0 and SPCMD1 register settings. The text below explains the RSPI operations (1) to (6) as shown in Figure 38.59. It should be noted that the polarity of the SSL0n output signal depends on the SSLP register settings.

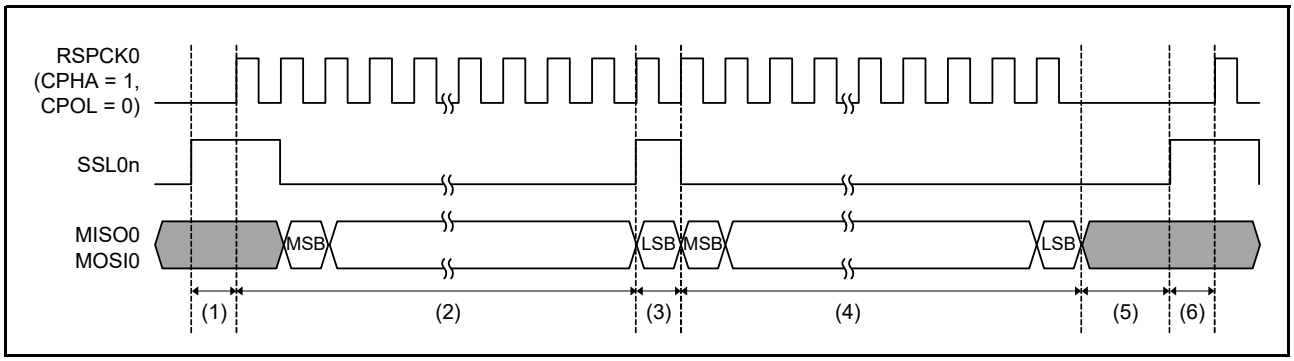

Figure 38.59 Example of Burst Transfer Operation (FRFS = 1)

(1) Based on the SPCMD0 register, the RSPIA asserts the SSL0n signal and inserts RSPCK delays.
The RSPCK delay is inserted only the first frame of burst transfer.
(2) The RSPIA executes serial transfers according to the SPCMD0 register.
(3) Final data transfer and the SSL0n assertion are performed simultaneously.
During transmit-receive/transmit-only operation, the RSPIA waits for the last clock output until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.
(4) The RSPIA executes serial transfers according to the SPCMD1 register.
(5) The RSPIA inserts SSL0n negation delays at the last frame*1.
(6) A next-access delay is inserted according to the SPCMD1 register.

Note 1. In receive-only mode, the last frame is a frame set by the SPRMCR.RFC[4:0] bits when SPRMCR.RFC[4:0] ≠ 00000b or a frame in which SPRMCR.TERM = 1 has been accepted.
Note: If the SSL0n signal output settings in the SPCMDm register in which 1 is assigned to the SSLKP bit are different from the SSL0n signal output settings in the SPCMDm register to be used in the next transfer, the RSPIA switches the SSL0n signal status to SSL0n signal assertion ((5) in Figure 38.59) corresponding to the command for the next transfer. Note that if such an SSL0n signal switching occurs, the slaves that drive the MISO0 signal compete, and collision of signal levels may occur.

(5) RSPCK Delay (t1)

The RSPCK delay value of the RSPIA in master mode depends on the SPCMDm.SCKDEN bit setting and the SPCKD register setting. The RSPIA determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines an RSPCK delay value during serial transfer by using the SPCMDm.SCKDEN bit and the SPCKD.SCKDL[2:0] bits, as listed in Table 38.9. For a definition of RSPCK delay, refer to section 38.3.5, Transfer Format (Frame Format).

The RSPCK delay is inserted only the first frame of burst transfer when data transfer is performed without delay between frames in burst transfer (SPCMDm.SSLKP = 1, SPCR.SCKDDIS = 1).

Table 38.9 Relationship among SCKDEN Bit, SCKDL[2:0] Bits, and RSPCK Delay Value

SPCMDm.SCKDEN Bit	SPCKD.SCKDL[2:0] Bits	RSPCK Delay Value	
		Motorola SPI	TI SSP
0	000b to 111b	1 RSPCK	0 RSPCK
1	000b	1 RSPCK	1 RSPCK
	001b	2 RSPCK	2 RSPCK
	010b	3 RSPCK	3 RSPCK
	011b	4 RSPCK	4 RSPCK
	100b	5 RSPCK	5 RSPCK
	101b	6 RSPCK	6 RSPCK
	110b	7 RSPCK	7 RSPCK
	111b	8 RSPCK	8 RSPCK

(6) SSL Negation Delay (t2)

The SSL negation delay value of the RSPIA in master mode depends on the SPCMDm.SLNDEN bit setting and the SSLND register setting. The RSPIA determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines an SSL negation delay value during serial transfer by using the SPCMDm.SLNDEN bit and SSLND.SLNDL[2:0] bits, as listed in Table 38.10. For a definition of SSL negation delay, refer to section 38.3.5, Transfer Format (Frame Format).

The SSL negation delay is inserted only the last frame of burst transfer when data transfer is performed without delay between frames in burst transfer (SPCMDm.SSLKP = 1, SPCR.SCKDDIS = 1).

Table 38.10 Relationship among SLNDEN Bit, SLNDL[2:0] Bits, and SSL Negation Delay Value

SPCMDm.SLNDEN Bit	SSLND.SLNDL[2:0] Bits	SSL Negation Delay Value
0	000b to 111b	1 RSPCK
1	000b	1 RSPCK
	001b	2 RSPCK
	010b	3 RSPCK
	011b	4 RSPCK
	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(7) Next-Access Delay (t3)

The next-access delay value of the RSPIA in master mode depends on the SPCMDm.SPNDEN bit setting and the SPND setting. The RSPIA determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines a next-access delay value during serial transfer by using the SPCMDm.SPNDEN bit and the SPND.SPNDL[2:0] bits, as listed in Table 38.11. For a definition of next-access delay, refer to section 38.3.5, Transfer Format (Frame Format).

The next-access delay is inserted only the last frame of burst transfer when data transfer is performed without delay between frames in burst transfer (SPCMDm.SSLKP = 1, SPCR.SCKDDIS = 1).

Table 38.11 Relationship among SPNDEN Bit, SPNDL[2:0], and Next-Access Delay Value

SPCMDm.SPNDEN Bit	SPND.SPNDL[2:0] Bits	Next-Access Delay Value
0	000b to 111b	1 RSPCK + 5 PCLKA
1	000b	1 RSPCK + 5 PCLKA
	001b	2 RSPCK + 5 PCLKA
	010b	3 RSPCK + 5 PCLKA
	011b	4 RSPCK + 5 PCLKA
	100b	5 RSPCK + 5 PCLKA
	101b	6 RSPCK + 5 PCLKA
	110b	7 RSPCK + 5 PCLKA
	111b	8 RSPCK + 5 PCLKA

(8) Initialization Flowchart

Figure 38.60 is a flowchart illustrating an example of initialization in SPI operation when the RSPIA is used in master mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

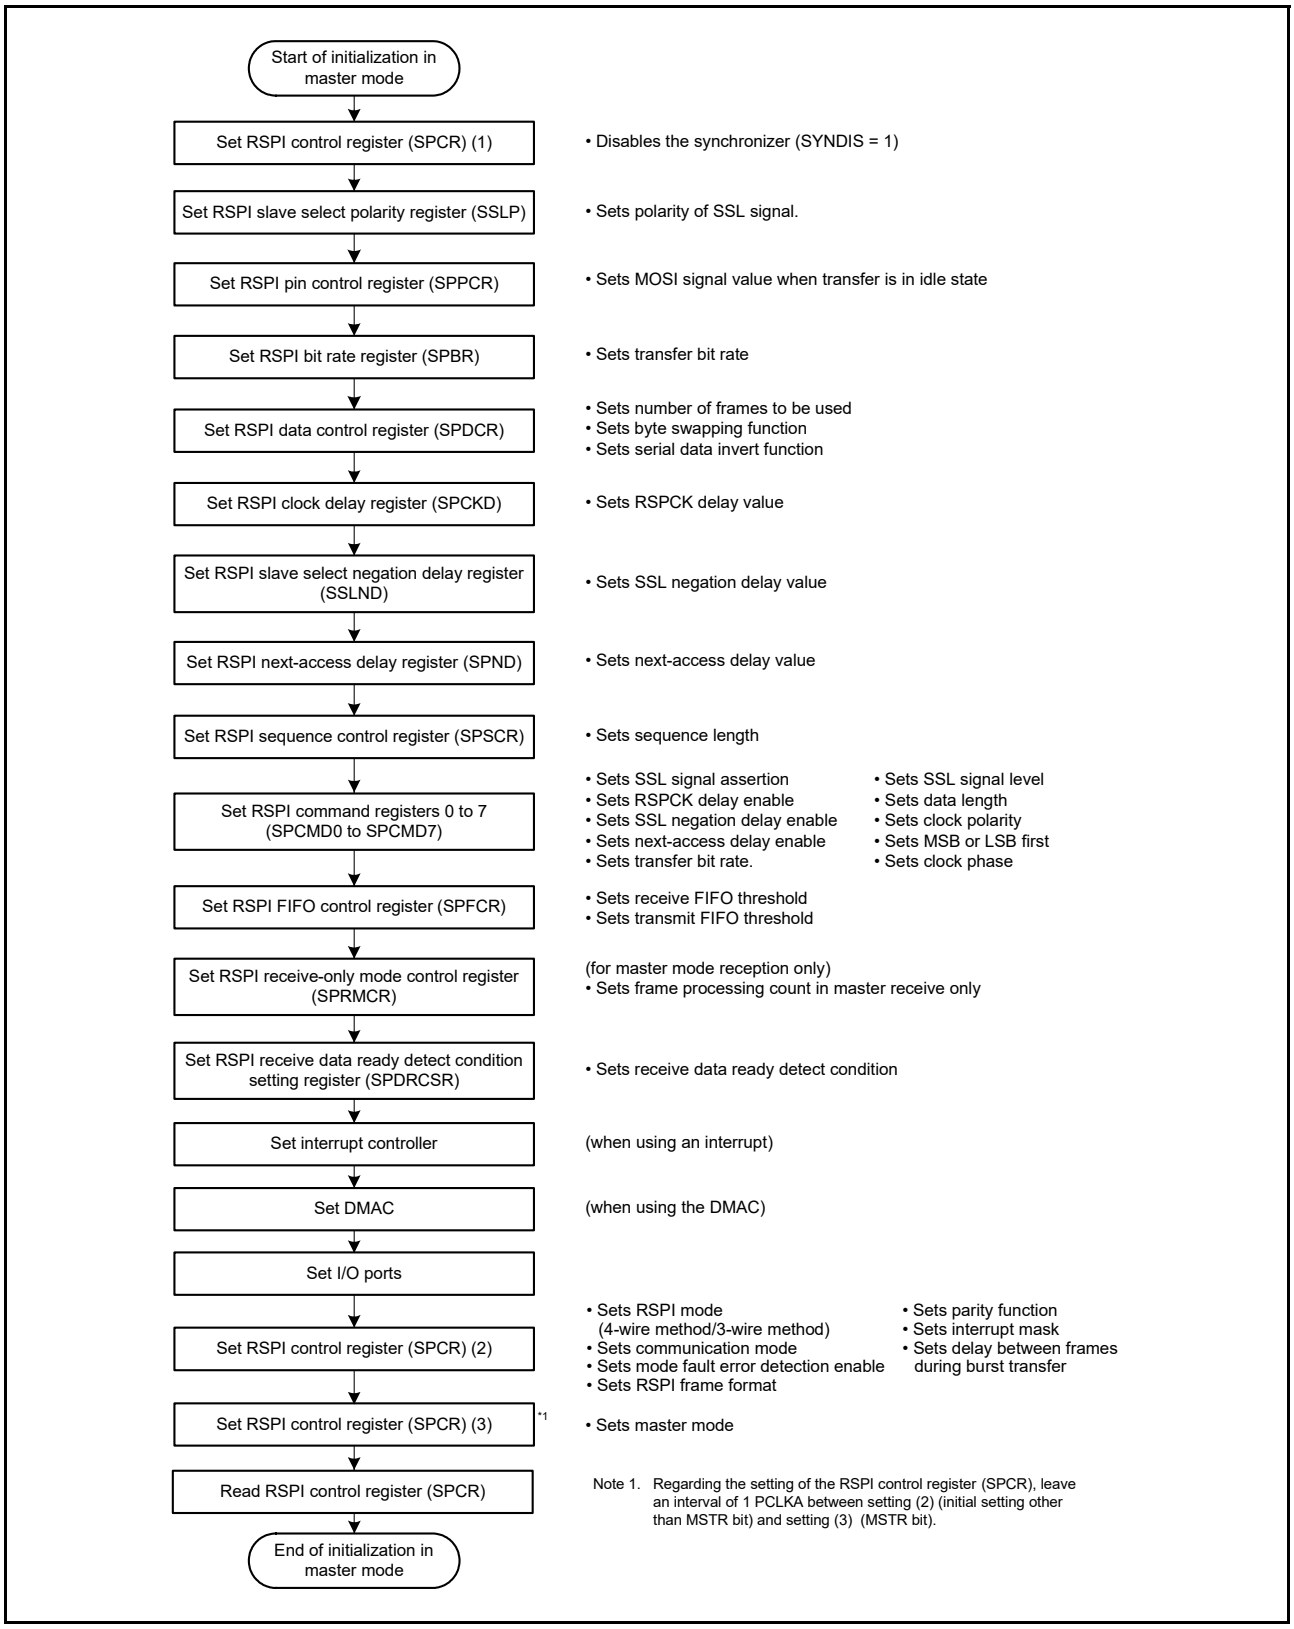

Figure 38.60 Example of Initialization Flowchart in Master Mode (SPI Operation)

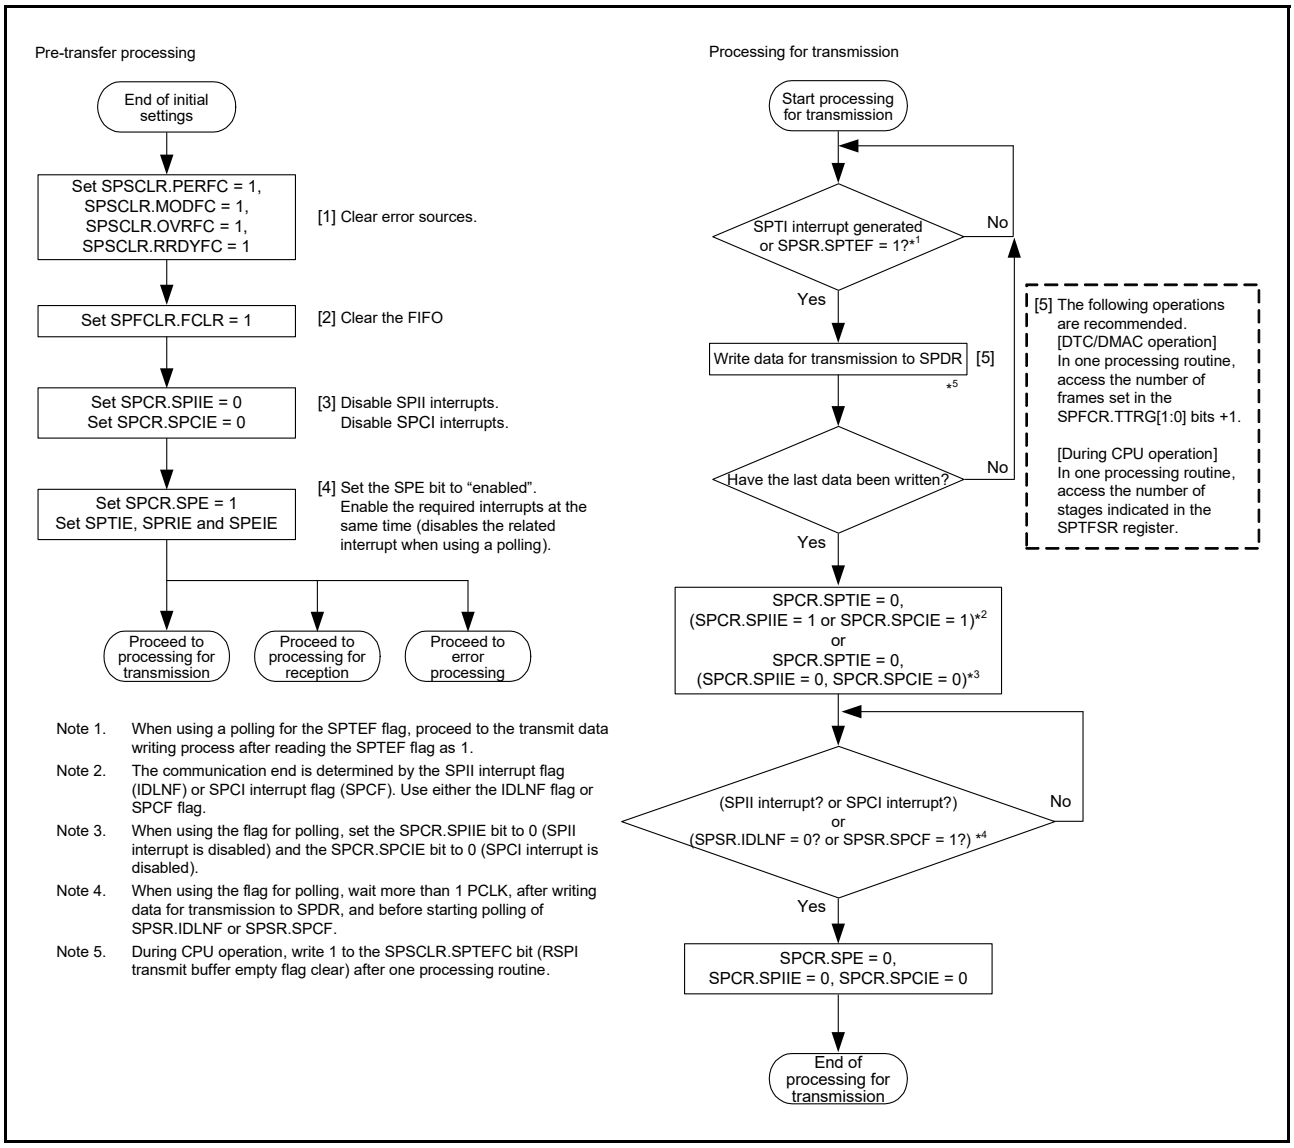
(9) Software Processing Flow

Figure 38.61 to Figure 38.63 show examples of the flow of software processing.

(a) Transmit Processing Flow

Enabling SPII or SPCI interrupt after final transmit data is written makes it possible to notify the CPU that transmission of all data has been completed.



Note 1. When using a polling for the SPTEF flag, proceed to the transmit data writing process after reading the SPTEF flag as 1.

Note 2. The communication end is determined by the SPII interrupt flag (IDLNF) or SPCI interrupt flag (SPCF). Use either the IDLNF flag or SPCF flag.

Note 3. When using the flag for polling, set the SPCR.SPIIE bit to 0 (SPII interrupt is disabled) and the SPCR.SPCIE bit to 0 (SPCI interrupt is disabled).

Note 4. When using the flag for polling, wait more than 1 PCLK, after writing data for transmission to SPDR, and before starting polling of SPSR.IDLNF or SPSR.SPCF.

Note 5. During CPU operation, write 1 to the SPSCLR.SPTEFC bit (RSPI transmit buffer empty flag clear) after one processing routine.

Figure 38.61 Flowchart in Master Mode (Transmission)

(b) Receive Processing Flow

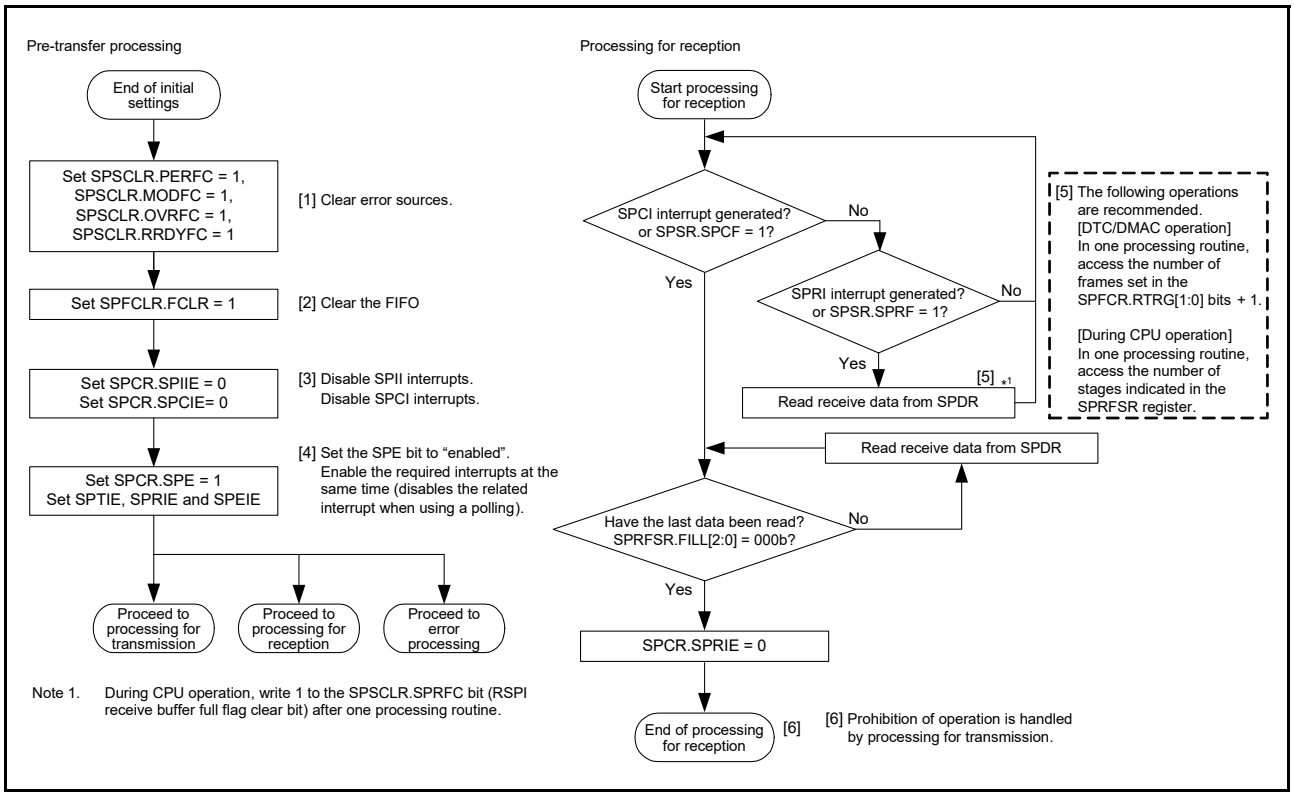


Figure 38.62 Flowchart in Master Mode (Reception)

(c) Receive-Only Processing Flow

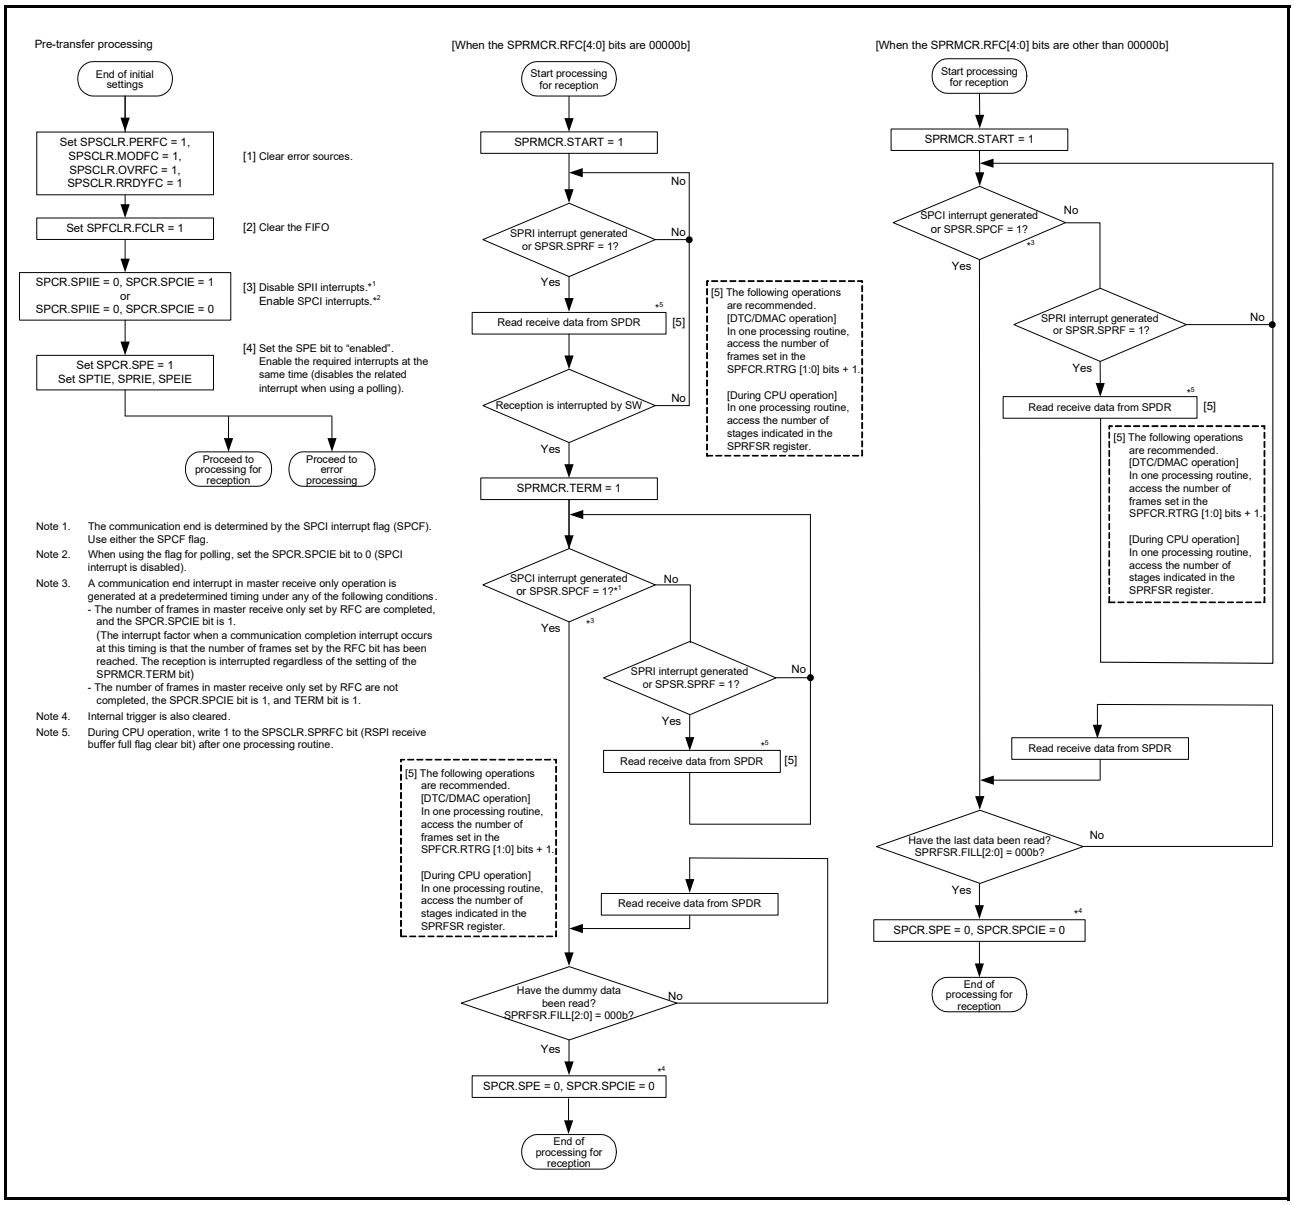

Figure 38.63 Flowchart in Master Mode (Receive-Only)

(d) Flow of Error Processing

When a mode fault error is generated, the SPCR.SPE bit is automatically cleared, stopping operations for transmission and reception. For errors from other sources, however, the SPCR.SPE bit is not cleared and operations for transmission and reception continue; accordingly, we recommend clearing of the SPCR.SPE bit to stop operations in the case of errors other than mode fault errors. Not doing so will lead to updating of the SPSSR.SPECM[2:0] bits.

When interrupts are used and an error occurs, if the ICU.IRn.IR flag for the SPTI or SPRI interrupt request is set to 1, clear the ICU.IRn.IR flag in the error processing routine. If the SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the RSPIA.

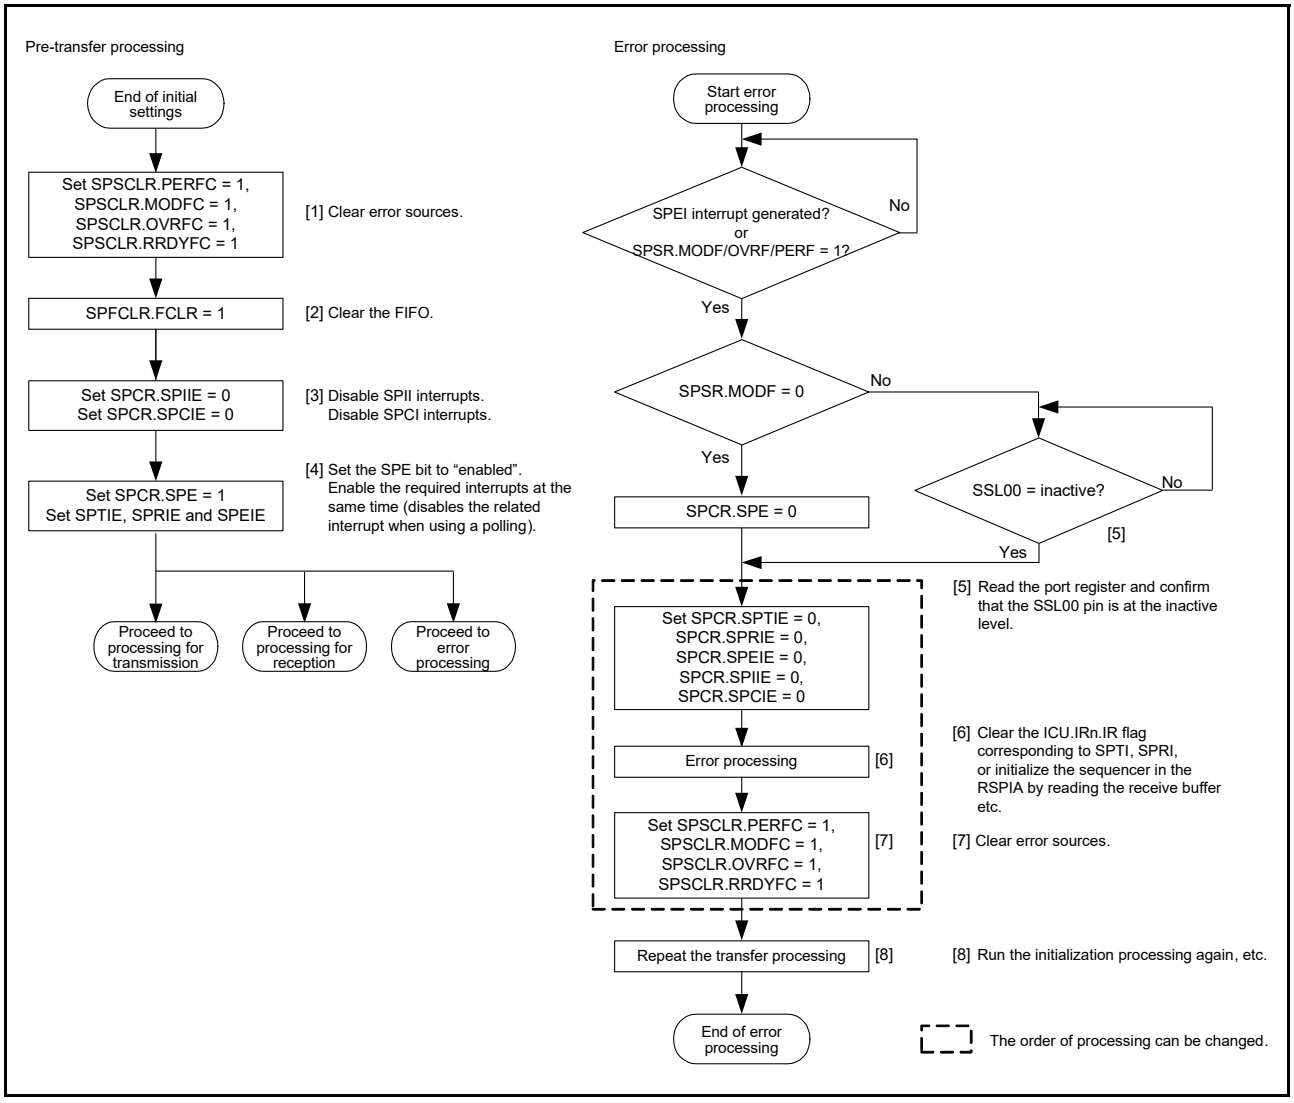

Figure 38.64 Flowchart for Master Mode (Error Processing)

38.3.13.2 Slave Mode Operation

(1) Starting a Serial Transfer

If the SPCMD0.CPHA bit is 0, when detecting an SSL00 input signal assertion, the RSPIA needs to start driving valid data to the MISO0 output signal. For this reason, when the CPHA bit is 0, the assertion of the SSL00 input signal triggers the start of a serial transfer.
If the CPHA bit is 1, when detecting the first RSPCK0 edge in an SSL00 signal asserted condition, the RSPIA needs to start driving valid data to the MISO0 output signal. For this reason, when the CPHA bit is 1, the first RSPCK0 edge in an SSL00 signal asserted condition triggers the start of a serial transfer.
Irrespective of the CPHA bit setting, the timing at which the RSPIA starts driving of the MISO0 output signal is the SSL00 signal assertion timing. The data which is output by the RSPIA is either valid or invalid, depending on the CPHA bit setting.
For details on the RSPI transfer format, refer to section 38.3.5, Transfer Format (Frame Format). The polarity of the SSL00 input signal depends on the setting of the SSLP.SSL0P bit.

(2) Terminating a Serial Transfer

Irrespective of the SPCMD0.CPHA bit, the RSPIA terminates the serial transfer after detecting an RSPCK0 edge corresponding to the final sampling timing. When the number of data stored in the receive FIFO is less than the number of FIFO stages, upon termination of serial transfer the RSPIA copies received data from the shift register to the receive buffer of the SPDR register. Upon termination of a serial transfer the RSPIA changes the status of the shift register to “empty”, regardless of the receive buffer state. A mode fault error occurs if the RSPIA detects an SSL00 input signal negation from the beginning of serial transfer to the end of serial transfer (refer to section 38.3.10, Error Detection).
The final sampling timing changes depending on the bit length of transmit data. In slave mode, the RSPI data length depends on the SPCMD0.SPB[4:0] bit setting. The polarity of the SSL00 input signal depends on the SSLP.SSL0P bit setting. For details on the RSPI transfer format, refer to section 38.3.5, Transfer Format (Frame Format).

(3) Notes on Single-Slave Operation

[Motorola SPI]
If the SPCMD0.CPHA bit is 0, when detecting an SSL00 input signal assertion edge, the RSPIA starts a serial transfer. Upon the SSL00 input signal is fixed to the active level when using the RSPIA in single slave mode in a configuration as shown in Figure 38.7, the RSPIA cannot start a serial transfer correctly while the CPHA bit is 0. To correctly perform transmission and reception of the RSPIA in slave mode in a configuration where the SSL00 input signal is fixed to the active level, set the CPHA bit to 1. If the CPHA bit must be set to 0, do not fix the SSL00 input signal to active level.

[TI SSP]
In the TI SSP mode, upon the SSL00 input signal is fixed to the inactive level when using the RSPIA in single slave mode in a configuration as shown in Figure 38.7, the RSPIA cannot start a serial transfer correctly.
When using the RSPIA in single slave mode, operate in a configuration as shown in Figure 38.6.

(4) Burst Transfer

[Motorola SPI]
When the SPCMD0.CPHA bit is 1, continuous serial transfer (burst transfer) is available while maintaining the SSL00 input signal assertion state. When the CPHA bit is 1, the period (from the first RSPCK0 edge in the SSL00 input signal active state until the sampling timing for receiving the final bit) corresponds to the serial transfer period. Even if the SSL00 input signal is always at the active level, start of an access can be detected, which allows burst transfer.
When the CPHA bit is 0, the second and subsequent serial burst transfers cannot be performed correctly for the same reason as (3).

[TI SSP]
In serial transfer, data transfer starts after the SSL0n input signal is asserted for RSPCK 1 cycle. Since frame transfer starts from the SSL0n input signal, SSL must be asserted between frames.

(5) Initialization Flowchart

Figure 38.65 shows an example of initialization flow when using the RSPIA in slave-mode SPI operation. For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.

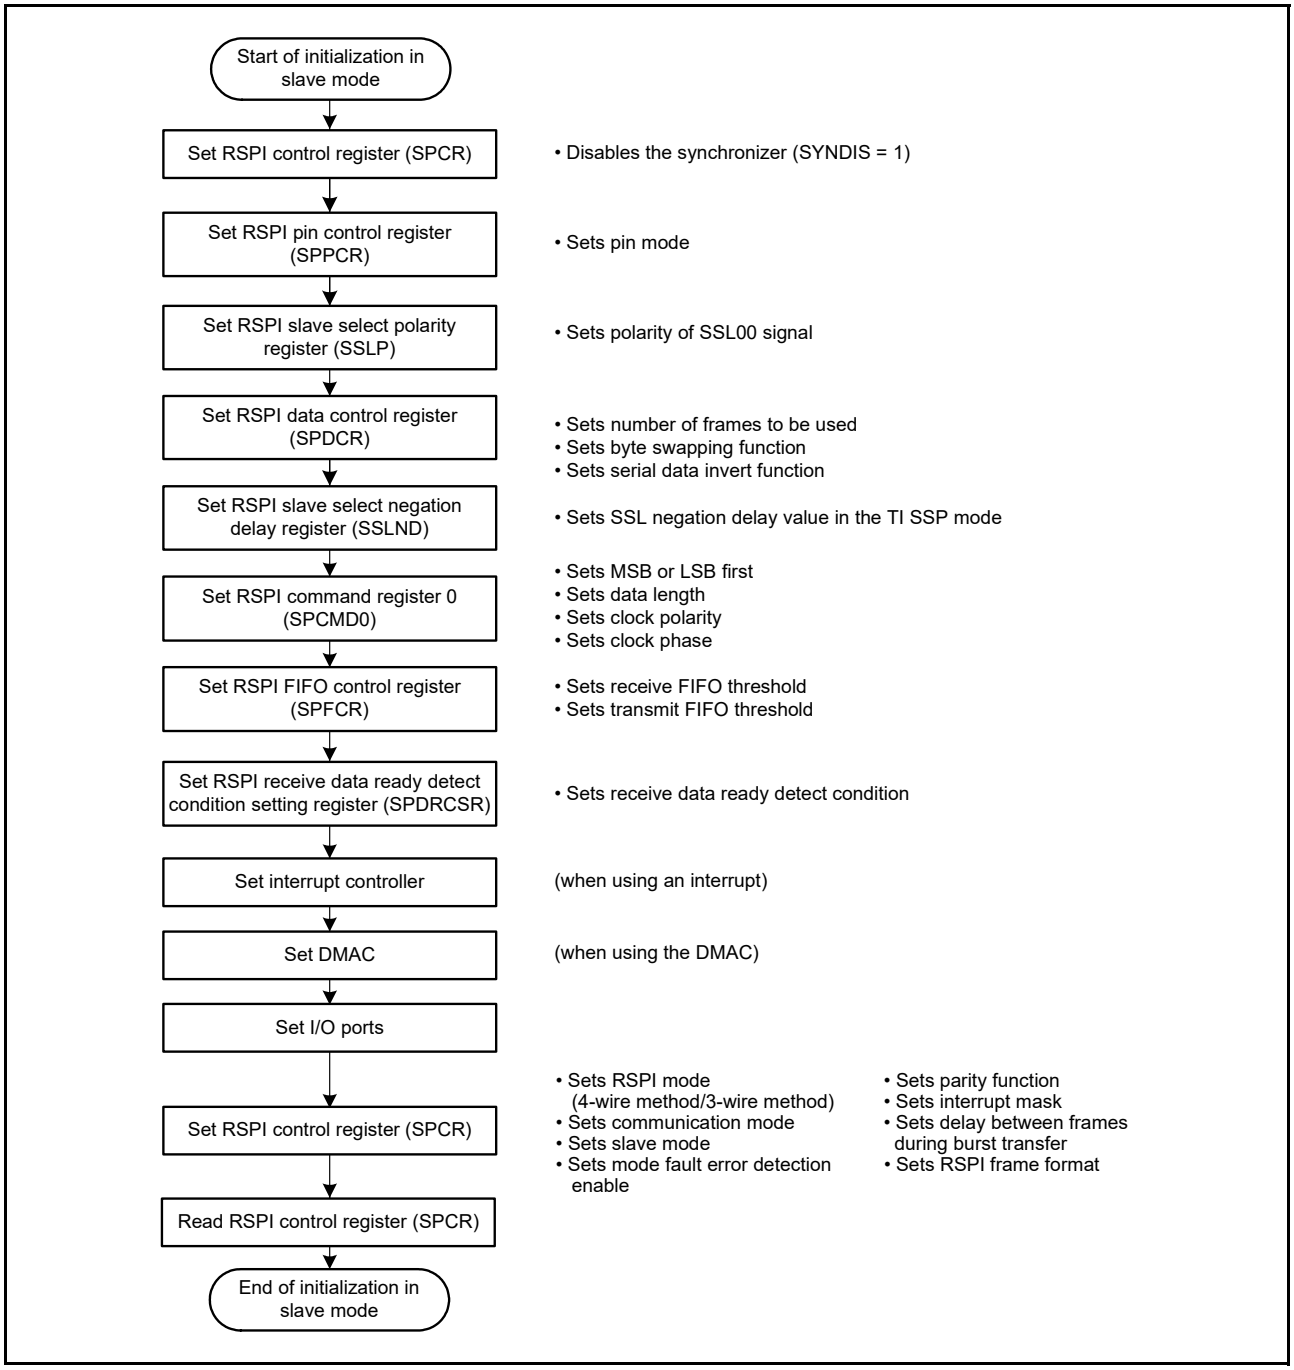

Figure 38.65 Example of Initialization Flow in Slave Mode

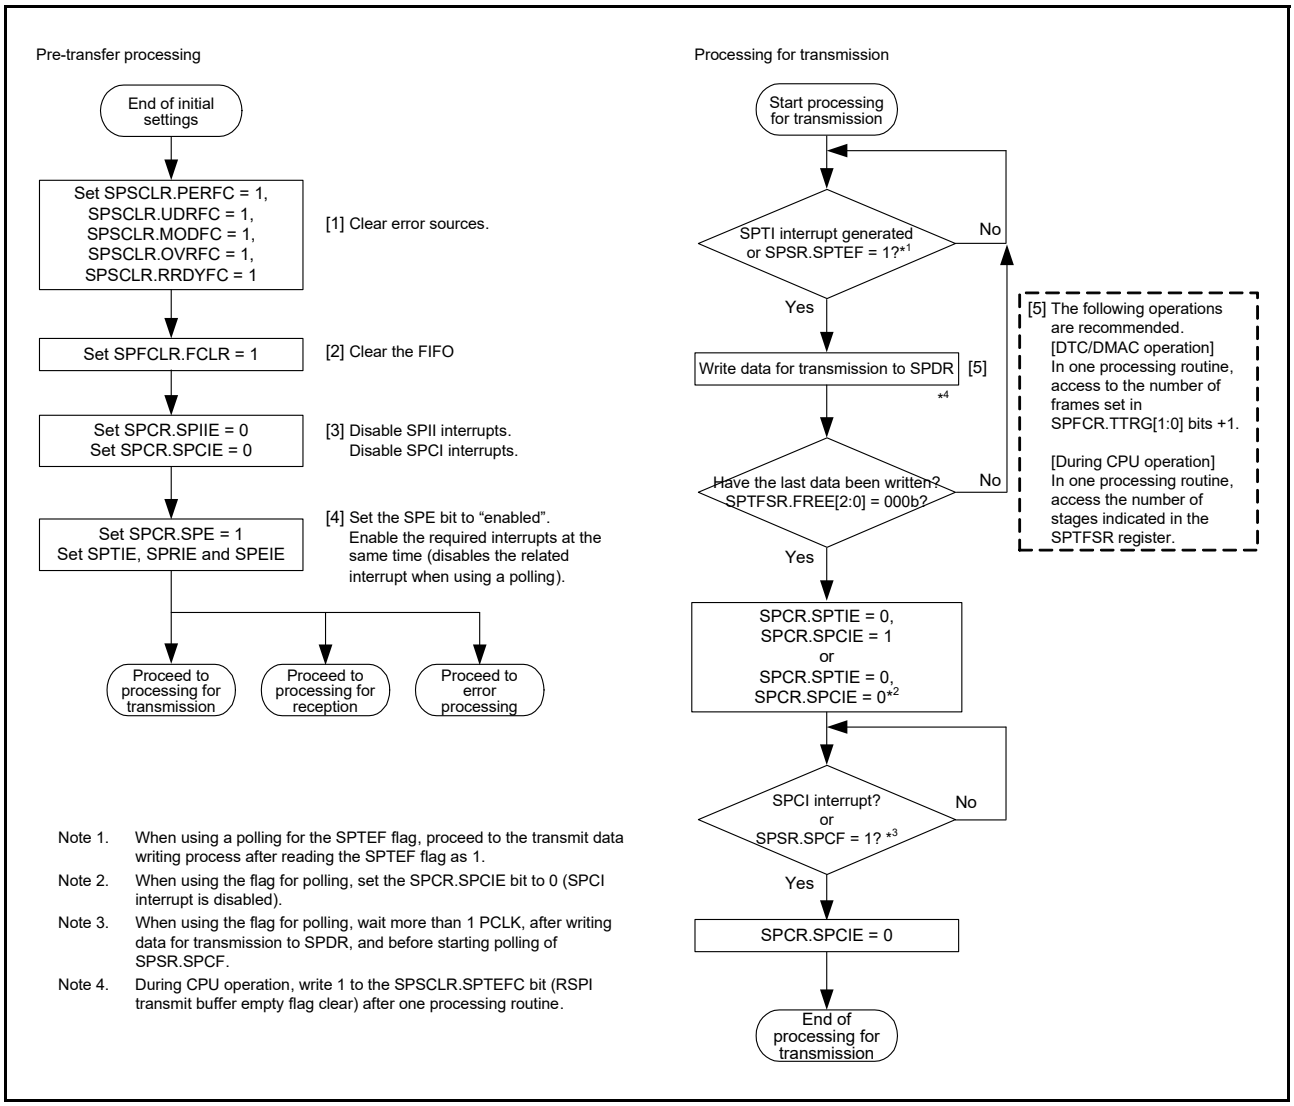
(6) Software Processing Flow

Figure 38.66 to Figure 38.69 show examples of the flow of software processing.

(a) Transmit Processing Flow



Note 1. When using a polling for the SPTEF flag, proceed to the transmit data writing process after reading the SPTEF flag as 1.

Note 2. When using the flag for polling, set the SPCR.SPCIE bit to 0 (SPCI interrupt is disabled).

Note 3. When using the flag for polling, wait more than 1 PCLK, after writing data for transmission to SPDR, and before starting polling of SPSR.SPCF.

Note 4. During CPU operation, write 1 to the SPSCLR.SPTEFC bit (RSPI transmit buffer empty flag clear) after one processing routine.

Figure 38.66 Flowchart in Slave Mode (Transmission)

(b) Receive Processing Flow

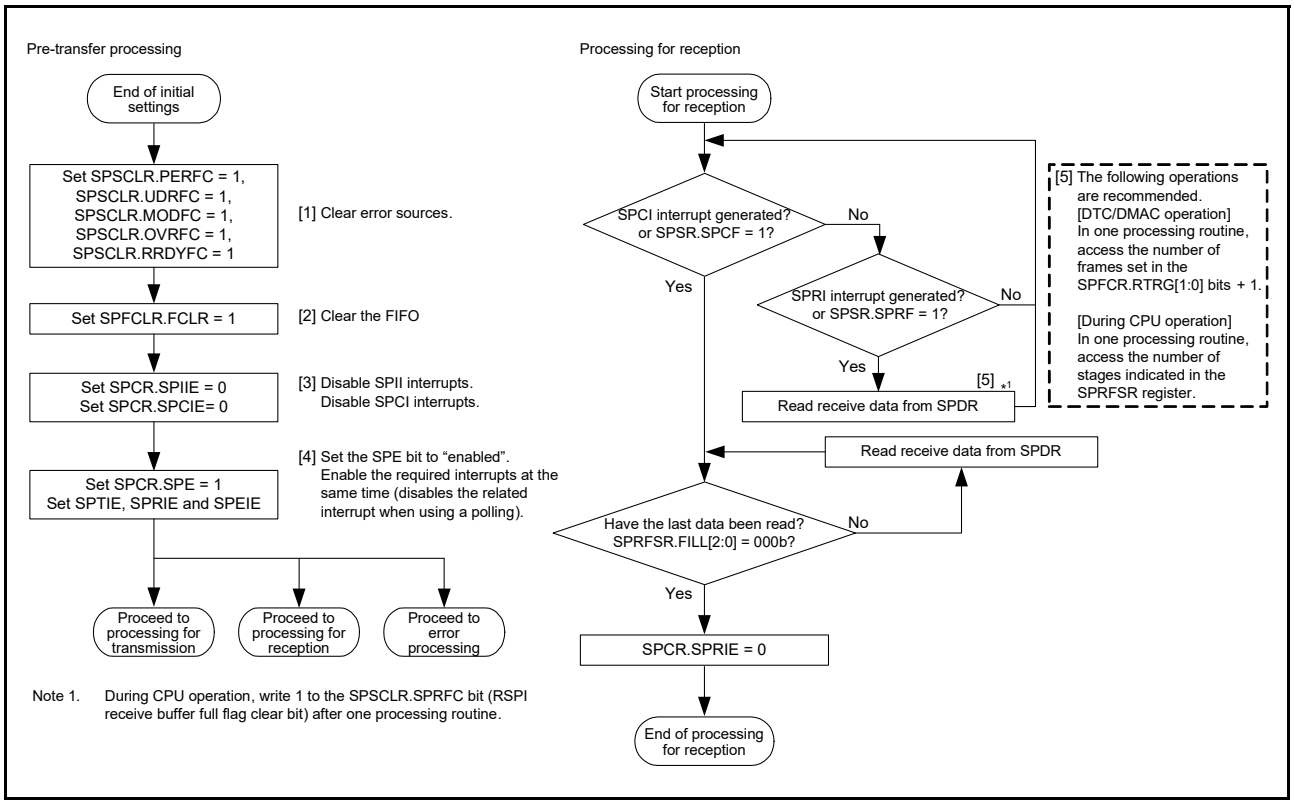


Figure 38.67 Flowchart in Slave Mode (Reception)

(c) Receive-Only Processing Flow

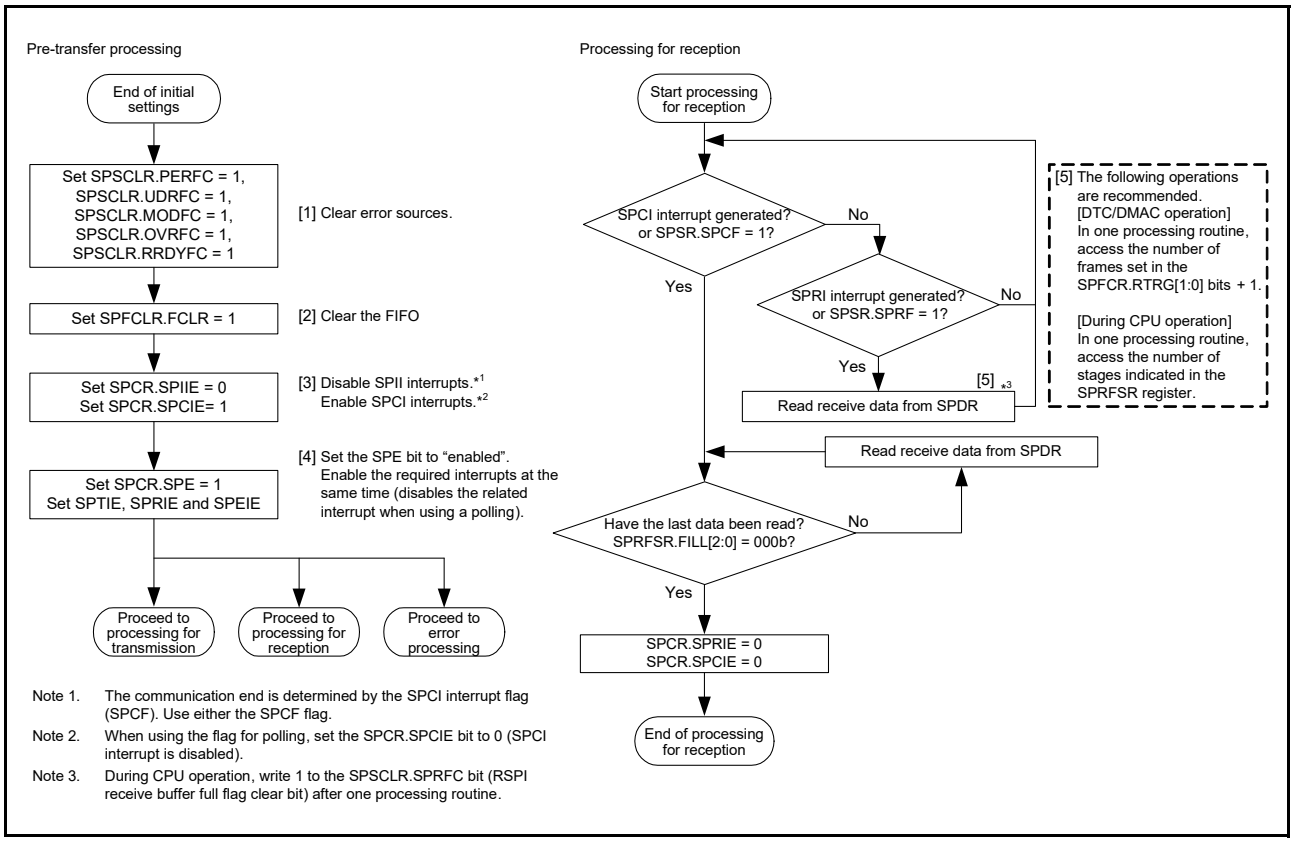

Figure 38.68 Flowchart in Slave Mode (Receive-Only)

(d) Flow of Error Processing

In slave mode operation, the MODF flag can be cleared regardless of the SSL00 pin status even when a mode fault error is generated.

When interrupts are used and an error occurs, if the ICU.IRn.IR flag for the SPTI or SPRI interrupt request is set to 1, clear the ICU.IRn.IR flag in the error processing routine. If the SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the RSPIA.

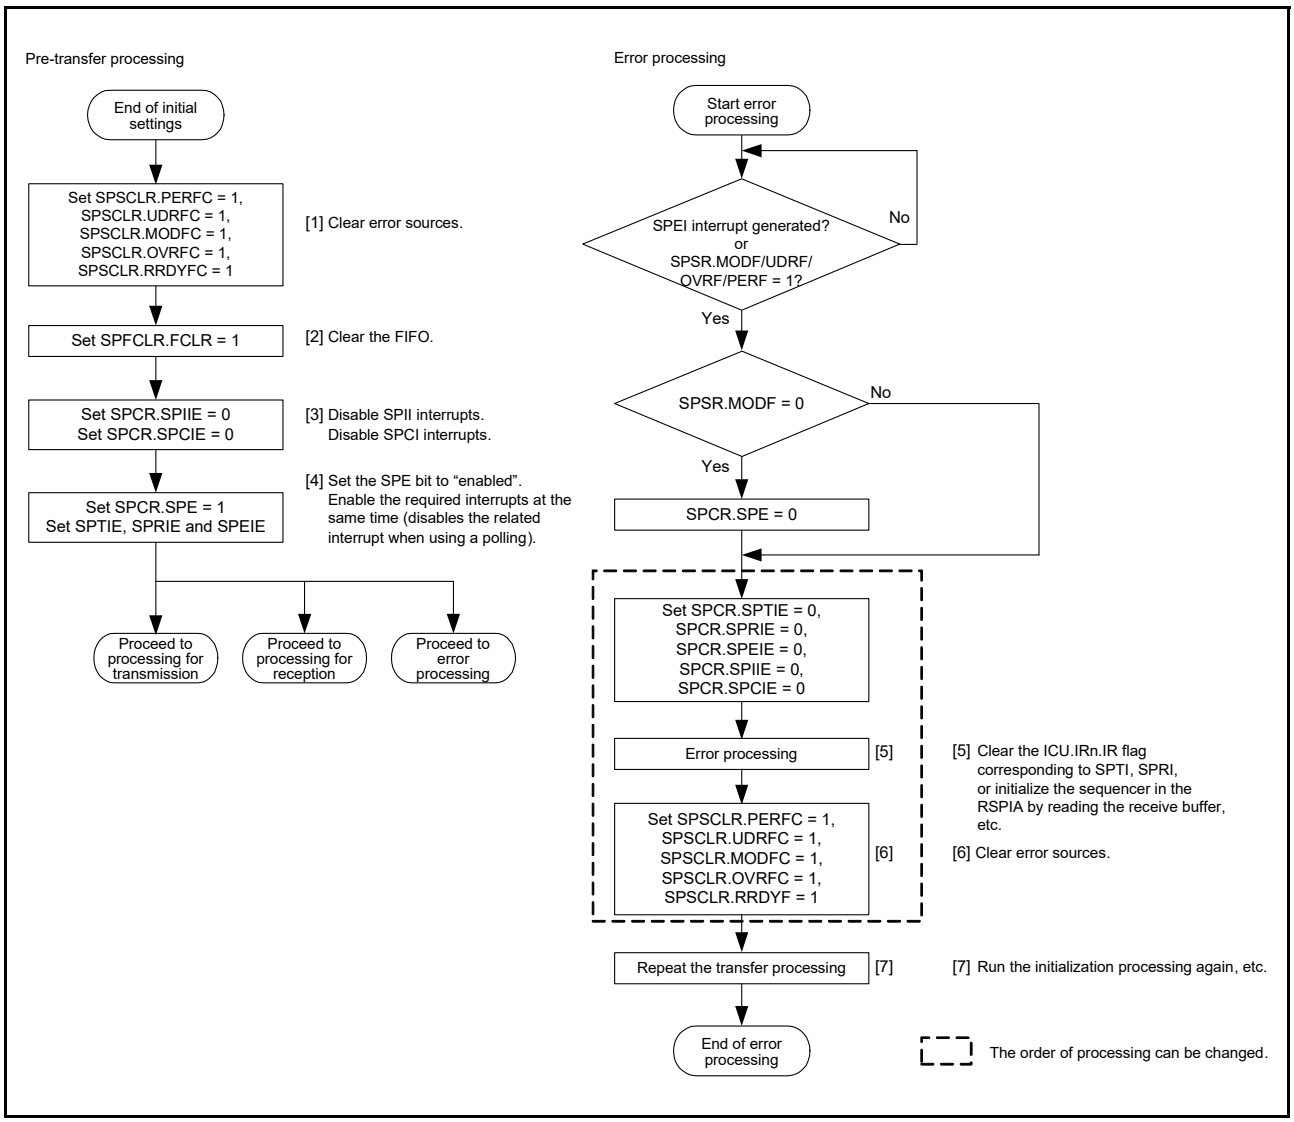

Figure 38.69 Flowchart in Slave Mode (Error Processing)

38.3.14 Clock Synchronous Operation

Setting the SPCR.SPMS bit to 1 selects clock synchronous operation of the RSPIA. In clock synchronous operation, the SSL0n pin is not used, and the three pins of RSPCK0, MOSI0, and MISO0 handle communications. The SSL0n pin is available as I/O port pins.
Although clock synchronous operation does not require use of the SSL0n pin, operation of the module is the same as in SPI operation. That is, in both master and slave mode operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected because the SSL0n pin is not used.
Furthermore, do not set the SPCMDm.CPHA bit to 0 if clock synchronous operation is to proceed in slave mode (SPCR.MSTR = 0).

38.3.14.1 Master Mode Operation

(1) Starting a Serial Transfer

The RSPIA updates the data in the transmit buffer (SPTXn, n = 0 to 3) of the SPDR register when data is written to the SPDR register with the transmit buffer being empty (data for the next transfer is not set). When the shift register is empty, the RSPIA copies data from the transmit buffer to the shift register and starts serial transmission. Upon copying transmit data to the shift register, the RSPIA changes the status of the shift register to “full”, and upon termination of serial transfer, it changes the status of the shift register to “empty”. The status of the shift register cannot be referenced.
For details on the RSPI transfer format, refer to section 38.3.5, Transfer Format (Frame Format).
However, transfer in clock synchronous operation is conducted without the SSL0n output signal.

(2) Terminating a Serial Transfer

The RSPIA terminates the serial transfer after transmitting an RSPCK0 edge corresponding to the final sampling timing. If the number of data stored in the receive FIFO is less than the number of FIFO stages, upon termination of serial transfer, the RSPIA copies data from the shift register to the receive buffer of the RSPI data register (SPDR).
It should be noted that the final sampling timing varies depending on the bit length of transmit data. In master mode, the RSPI data length depends on the SPCMDm.SPB[4:0] bit setting. For details on the RSPI transfer format, refer to section 38.3.5, Transfer Format (Frame Format).
However, transfer in clock synchronous operation is conducted without the SSL0n output signal.

(3) Sequence Control

The transfer format employed in master mode is determined by the following registers:

- RSPI sequence control register (SPSCR)
- RSPI command register m (SPCMDm) (m = 0 to 7)
- RSPI bit rate register (SPBR)
- RSPI clock delay register (SPCKD)
- RSPI slave select negation delay register (SSLND)
- RSPI next-access delay register (SPND)

Although the SSL0n signals are not output in clock synchronous operation, these settings are valid.

The SPSCR register is a register used to determine the sequence configuration for serial transfers that are executed by the RSPIA in master mode. The following items are set in the SPCMDm register: MSB/LSB first, data length, some of the bit rate settings, RSPCK polarity/phase, whether the SPCKD register is to be referenced, whether the SSLND register is to be referenced, and whether the SPND register is to be referenced. The SPBR register holds some of the bit rate settings; the SPCKD register, an RSPI clock delay value; the SSLND register, an SSL negation delay; and the SPND register, a next-access delay value.
According to the sequence length that is assigned to the SPSCR register, the RSPIA makes up a sequence comprised of a part or all of the SPCMDm register. The RSPIA contains a pointer to the SPCMDm register that makes up the sequence.

The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the RSPI function is enabled, the RSPIA loads the pointer to the commands in the SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The RSPIA increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, the RSPIA sets the pointer in the SPCMD0 register, and in this manner the sequence is executed repeatedly.

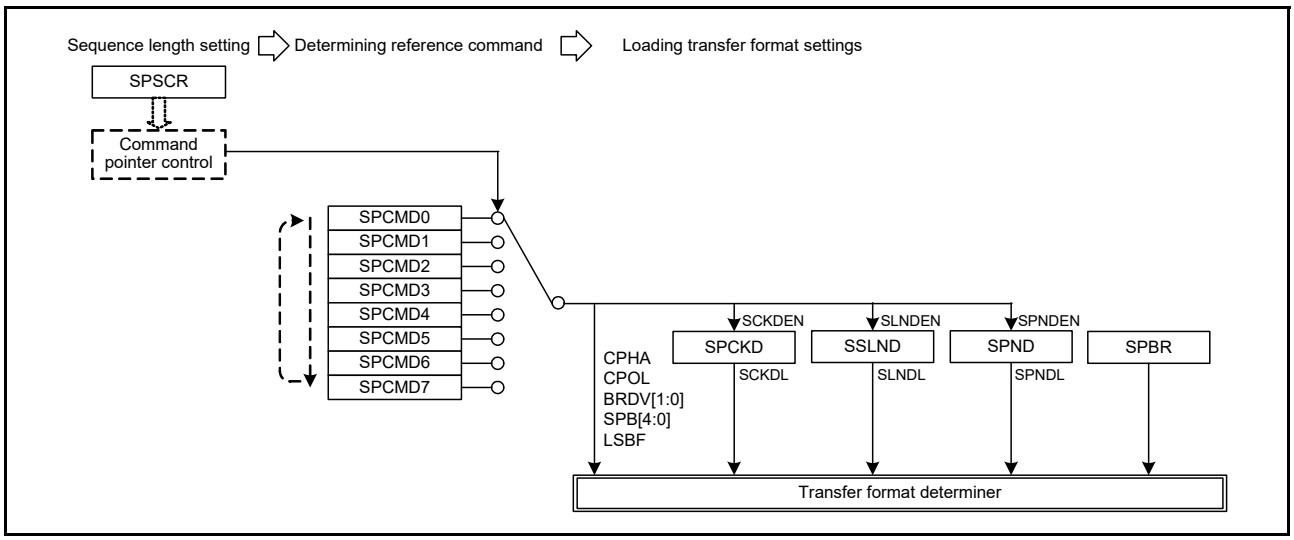

Figure 38.70 Procedure for Determining the Form of Serial Transfer in Master Mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

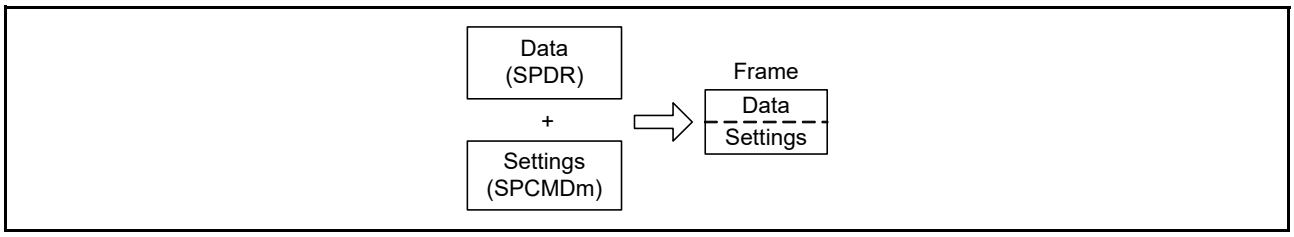

Figure 38.71 Concept of a Frame

Figure 38.72 shows the relationship between the command and the transmit buffer (SPTXn, n = 0 to 3) and receive buffer (SPRXn, n = 0 to 3) in the sequence of operations.

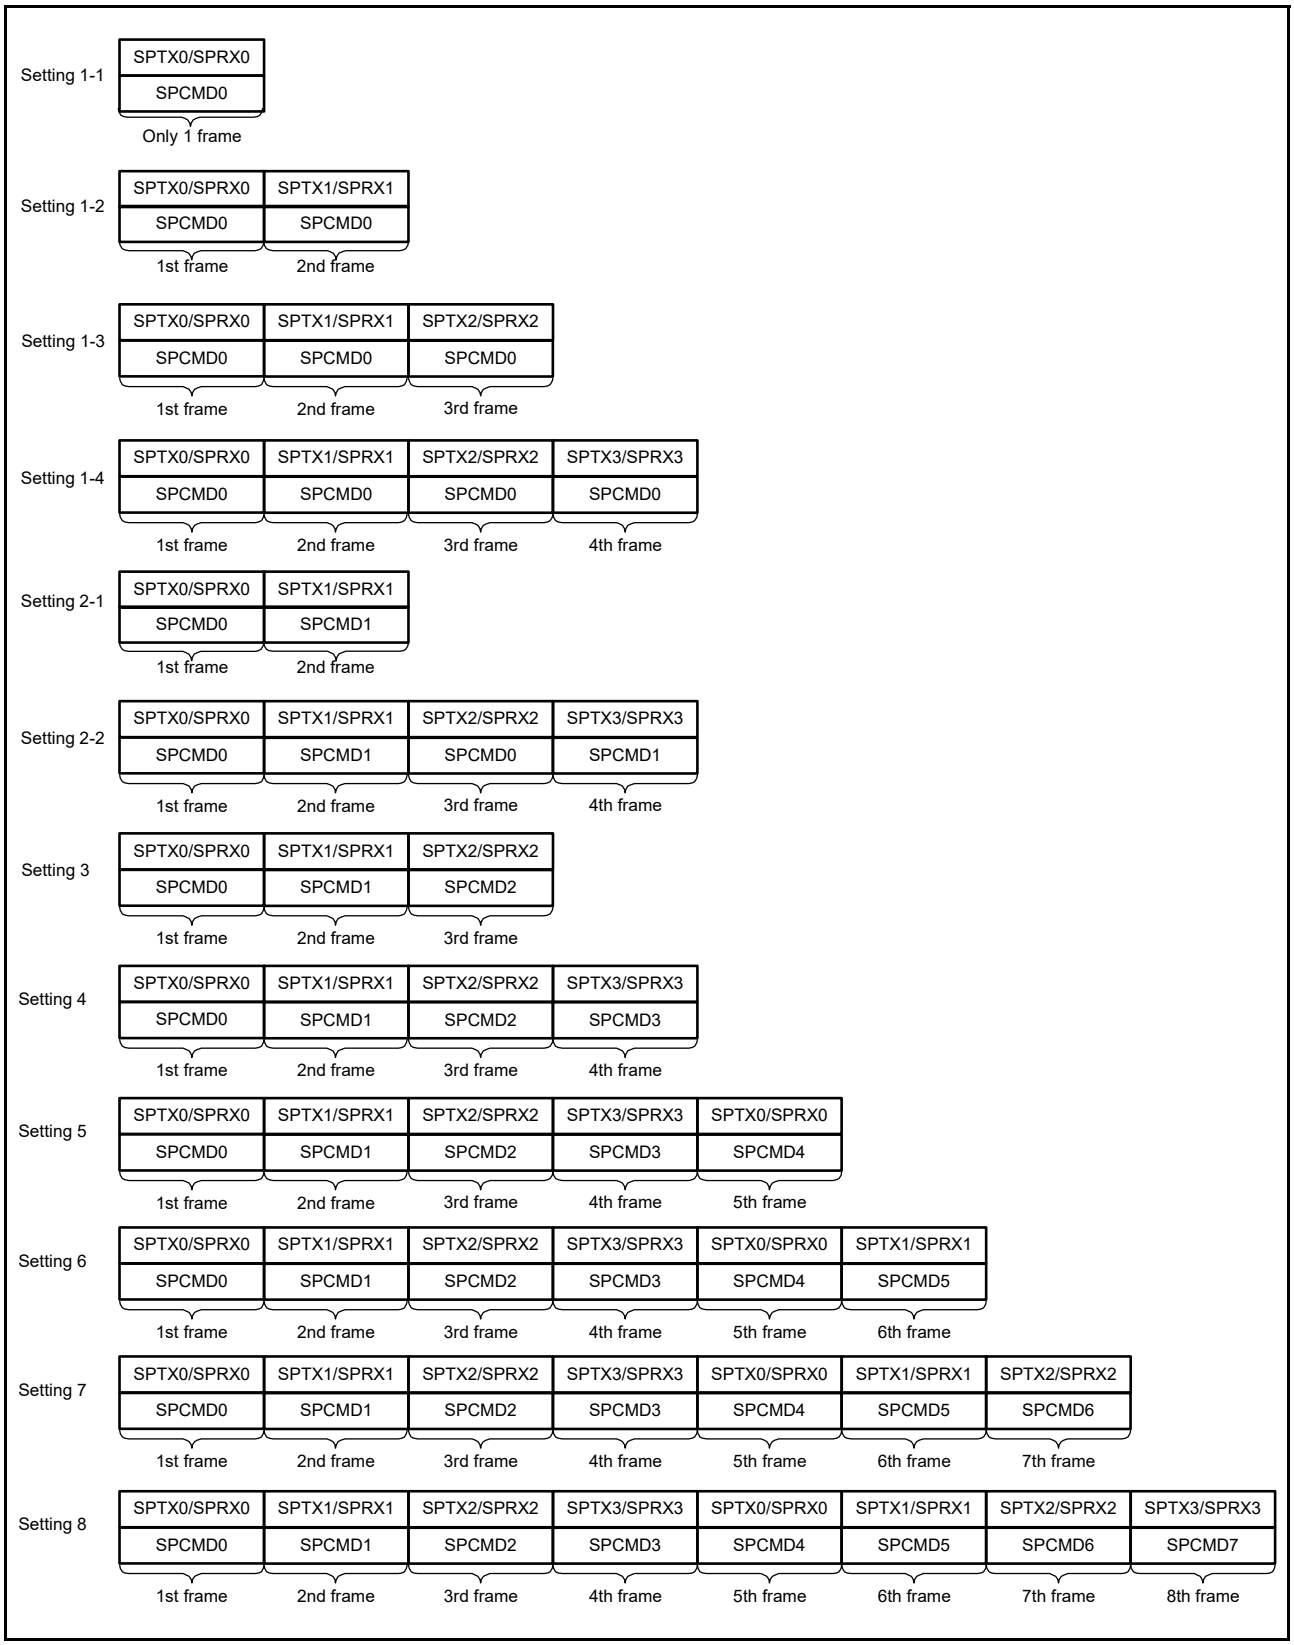

Figure 38.72 Correspondence between the RSPI Command Register m and Transmit/Receive Buffers in Sequence Operations

(4) Initialization Flowchart

Figure 38.73 is a flowchart illustrating an example of initialization in clock synchronous operation when the RSPIA is used in master mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

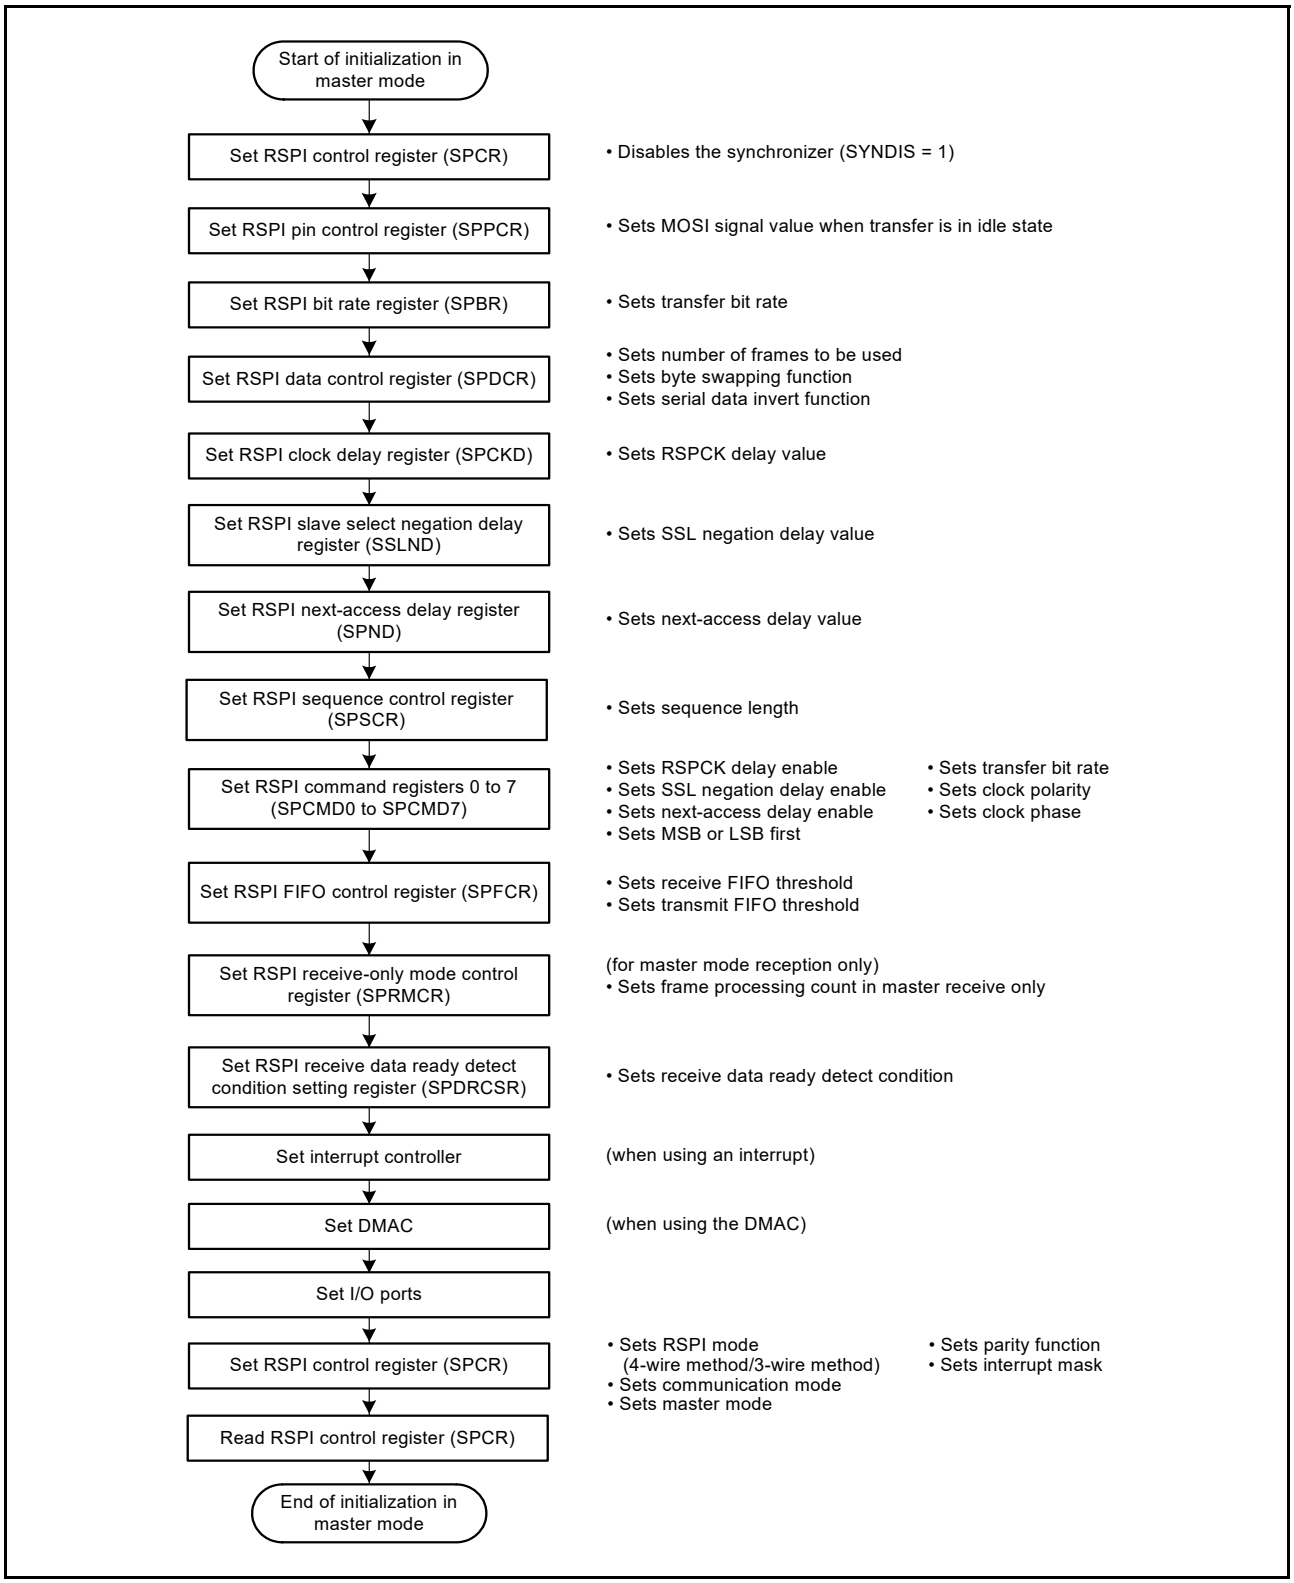

Figure 38.73 Example of Initialization Flowchart in Master Mode (Clock Synchronous Operation)

(5) Flow of Software Processing

Software processing during clock-synchronous operation when the RSPIA is used in master mode is the same as that for SPI master mode operation. For details, refer to section 38.3.13.1, (9) Software Processing Flow. Note that mode fault errors will not occur.

38.3.14.2 Slave Mode Operation

(1) Starting a Serial Transfer

When the SPCR.SPMS bit is 1, the first RSPCK0 edge triggers the start of a serial transfer in the RSPIA.
When the SPMS bit is 1, the RSPIA drives the MISO0 output signal.
For details on the RSPI transfer format, refer to section 38.3.5, Transfer Format (Frame Format).
It should be noted that the SSL00 input signal is not used in clock synchronous operation.

(2) Terminating a Serial Transfer

The RSPIA terminates the serial transfer after detecting an RSPCK0 edge corresponding to the final sampling timing. When the number of data stored in the receive FIFO is less than the number of FIFO stages, upon termination of serial transfer the RSPIA copies received data from the shift register to the receive buffer of the SPDR register. Upon termination of a serial transfer the RSPIA changes the status of the shift register to “empty” regardless of the receive buffer status. The final sampling timing changes depending on the bit length of transmit data. In slave mode, the RSPI data length depends on the SPCMD0.SPB[4:0] bit setting.
For details on the RSPI transfer format, refer to section 38.3.5, Transfer Format (Frame Format).

(3) Initialization Flowchart

Figure 38.74 is a flowchart illustrating an example of initialization in clock synchronous operation when the RSPIA is used in slave mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

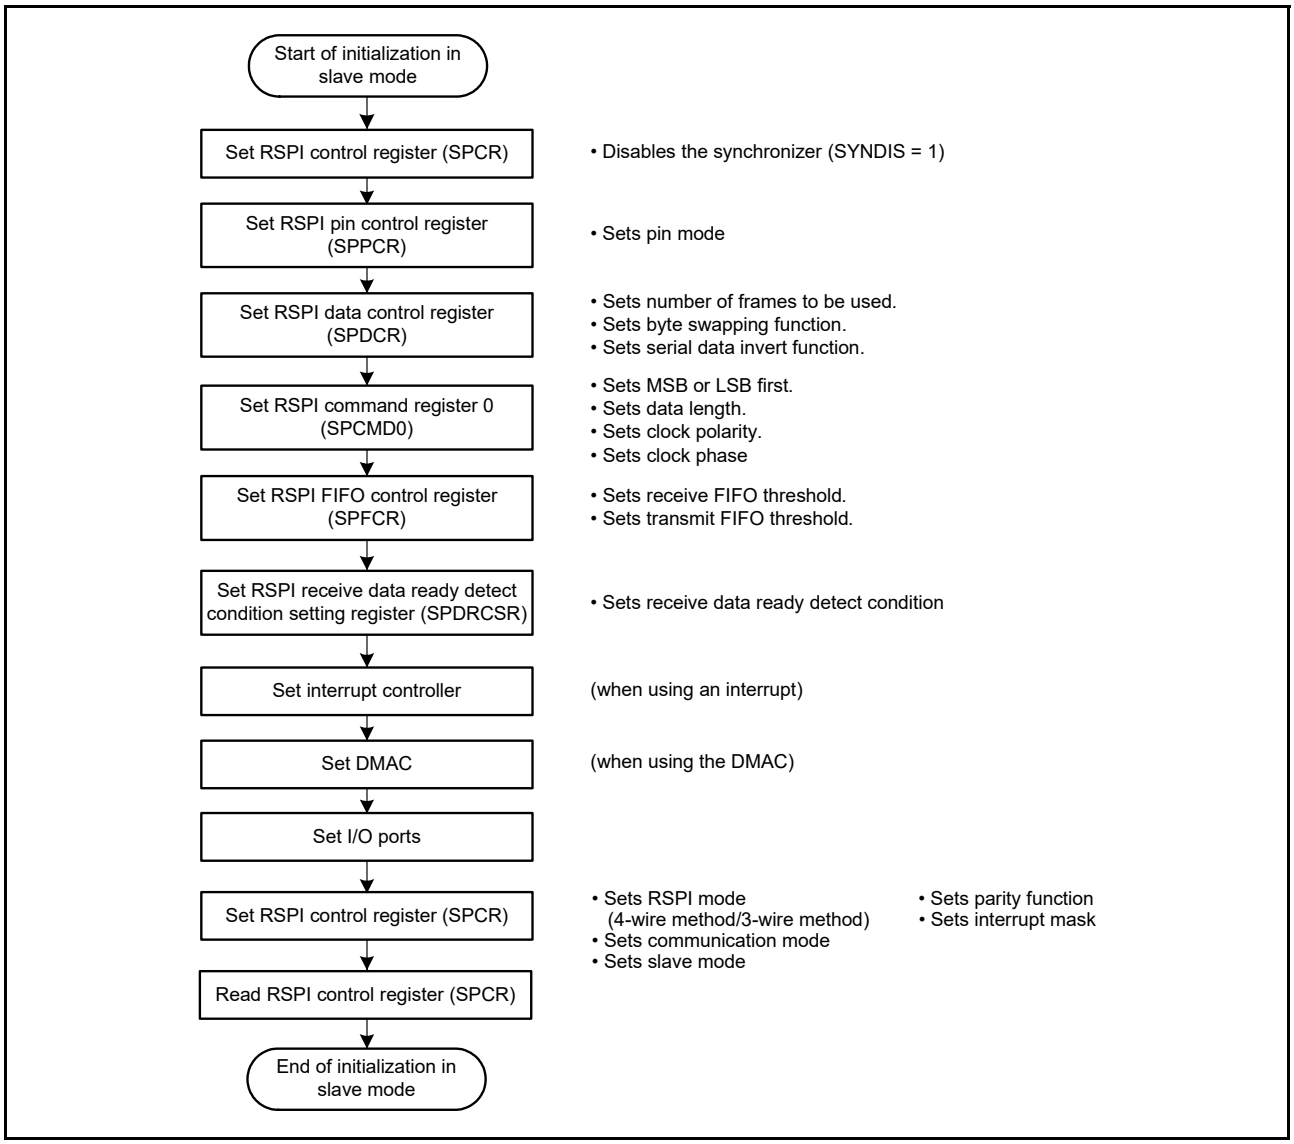

Figure 38.74 Example of Initialization Flowchart in Slave Mode (Clock Synchronous Operation)

(4) Flow of Software Processing

Software processing during clock-synchronous operation when the RSPIA is used in slave mode is the same as that for SPI slave mode operation. For details, refer to section 38.3.13.2, (6) Software Processing Flow. Note that mode fault errors will not occur.

38.3.15 Loopback Mode

When 1 is written to the SPPCR.SPLP2 bit or SPPCR.SPLP bit, the RSPIA shuts off the path between the MISO0 pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSI0 pin and the shift register if the SPCR.MSTR bit is 0, and connects the input path and output path of the shift register. The RSPIA does not shut off the path between the MOSI0 pin and the shift register if the SPCR.MSTR bit is 1, and between the MISO0 pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode.
When a serial transfer is executed in loopback mode, the transmit data for the RSPIA or the reversed transmit data becomes the received data for the RSPIA.
Table 38.12 lists the relationship among the SPLP2 and SPLP bits and the received data.

Table 38.12 SPLP2 and SPLP Bit Settings and Received Data

SPPCR.SPLP2 Bit	SPPCR.SPLP Bit	Received Data
0	0	Input data from the MOSI0 pin or MISO0 pin
0	1	Inverted transmit data
1	x	Transmit data

x: Don’t care.

Figure 38.75 shows the configuration of the shift register I/O paths in loopback mode.

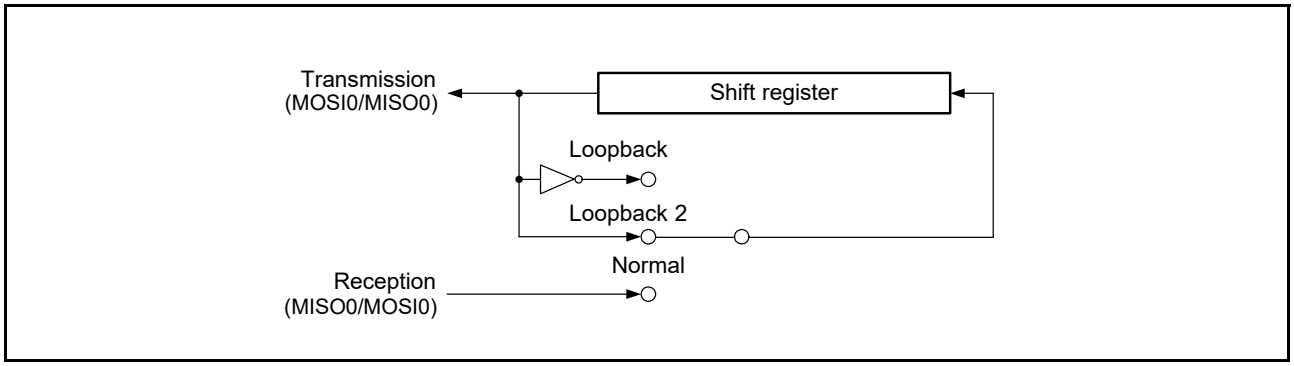

Figure 38.75 Configuration of Shift Register I/O Paths in Loopback Mode

38.3.16 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. In order to detect defects in the parity bit adding unit and error detecting unit of the parity circuit, self-diagnosis is executed for the parity circuit following the flowchart shown in Figure 38.76.

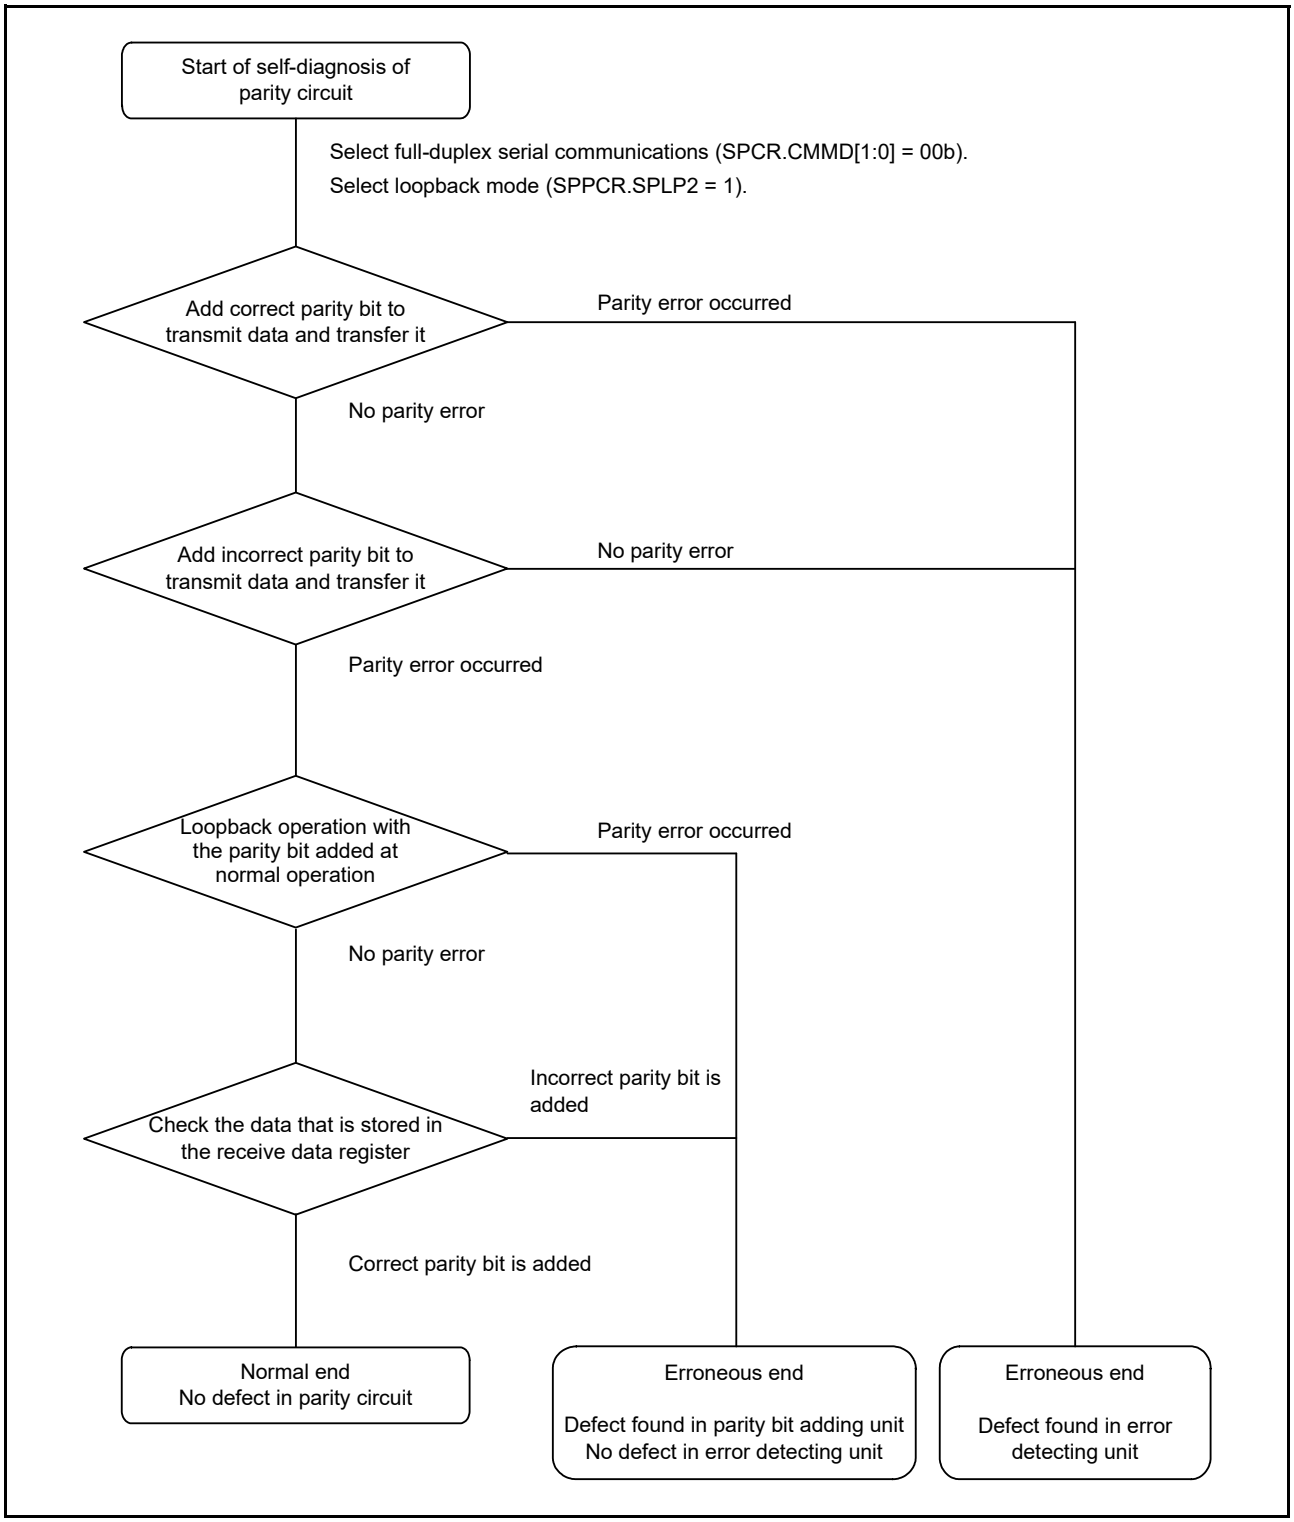

Figure 38.76 Flowchart for Self-Diagnosis of Parity Circuit

38.3.17 Interrupt Sources

The RSPIA has interrupt sources of receive buffer full, transmit buffer empty, error (mode fault, underrun, overrun, and parity error), idle, communication end, and receive data ready. In addition, the DTC or DMAC can be activated by the receive buffer full or transmit buffer empty interrupt to perform data transfer.

Since the vector address for SPEI is allocated to interrupt requests due to mode fault, underrun, overrun, parity errors, and receive data ready (only when the RDRIS bit is 1), the actual interrupt source must be determined from the flags.

Interrupt sources for the RSPIA are listed in Table 38.13. An interrupt is generated on satisfaction of an interrupt condition in Table 38.13. Clear the receive buffer full and transmit buffer empty sources through data transfer.

When using the DTC or DMAC to perform data transmission/reception, the DTC or DMAC must be set up first to be in a status in which transfer is enabled before making the RSPIA settings. For the method for setting the DTC or DMAC, refer to section 17, DMA Controller (DMACAa), or section 18, Data Transfer Controller (DTCb).

If the conditions for generating a transmit buffer empty or receive buffer full interrupt are generated while the ICU.IRn.IR flag is 1, the interrupt is not output as a request for ICU but is retained internally (the capacity for retention is one request per source). A retained interrupt request is output when the ICU.IRn.IR flag becomes 0. A retained interrupt request is automatically discarded once it is output as an actual interrupt request. The interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) for an internally retained interrupt request can also be cleared to 0.

Table 38.13 Interrupt Sources of RSPIA

Interrupt Source	Symbol	Interrupt Condition	DMAC/DTC Activation
Receive buffer full Receive data ready	SPRI	The SPSR.SPRF flag is set to 1 while the SPCR.SPRIE bit is 1, or the RRDYF flag is set to 1 while the SPEIE is 1 and RDRIS bit is 0.	Possible
Transmit buffer empty	SPTI	The SPSR.SPTEF flag is set to 1 while the SPCR.SPTIE bit is 1.	Possible
Mode fault error Underrun error Overrun error Parity error Receive data ready	SPEI	The SPSR.MODF, OVRF, or PERF flag is set to 1 while the SPCR.SPEIE bit is 1, or the RRDYF flag is set to 1 while the SPEIE and RDRIS bits are 1.	Impossible
Idle	SPII	The SPSR.IDLNF flag is set to 0 while the SPCR.SPIIE bit is 1.	Impossible
Communication end	SPCI	The SPSR.SPCF flag is set to 1 while the SPCR.SPCIE bit is 1.	Impossible

38.3.18 Link Operation by Event Linking

The RSPIA supports the following event output for the event link controller (ELC). The event link output signal is output regardless of the interrupt enable bit setting.

38.3.18.1 Receive Buffer Full Event Output

This event signal is output when the number of data stored in the receive FIFO is greater than the threshold value, or when the SPCR.RDRIS bit = 0 and after writing to the receive FIFO, and the number of data stored in the receive FIFO is equal to or less than the threshold value, the value set in the SPDRCSR register has elapsed.
A receive buffer full event is output at the timing shown in Figure 38.77.

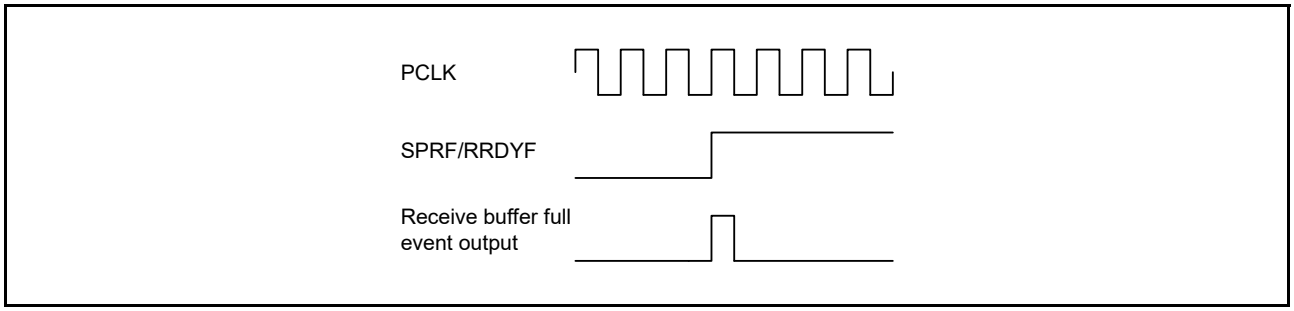

Figure 38.77 Event Output Timing of the Receive Buffer Full

38.3.18.2 Transmit Buffer Empty Event Output

This event signal is output when the number of empty stages in the transmit FIFO is greater than the threshold value or when the value of the SPCR.SPE bit has changed from 0 to 1.
A transmit buffer empty event is output at the timing shown in Figure 38.78.

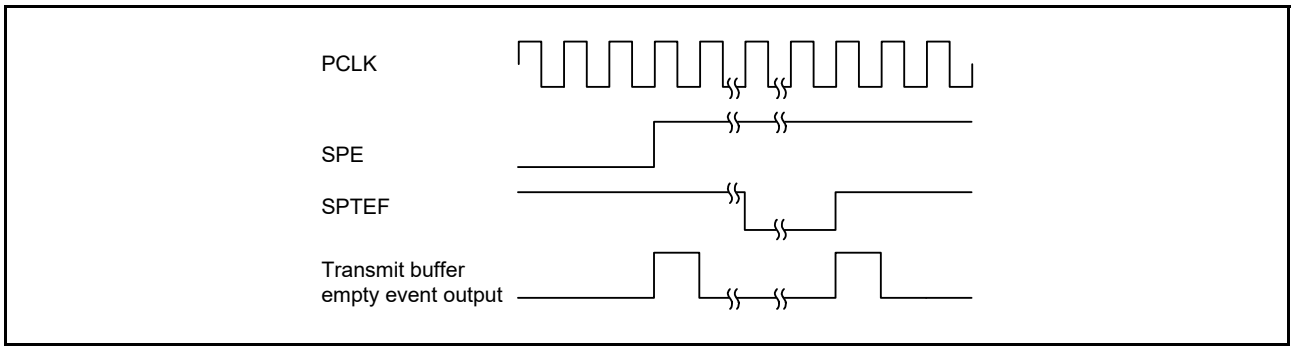

Figure 38.78 Event Output Timing of the Transmit Buffer Empty

38.3.18.3 Error Event Output

The error event signal is output due to five sources (mode fault, underrun, overrun, parity error, and receive data ready). For notes on error event output, see section 38.4.2, Note on Error Events Output.

(1) Mode Fault

A mode fault event occurs when all the following conditions are satisfied:

- SPI operation (SPCR.SPMS = 0)
- Slave mode (SPCR.MSTR = 0)
- The detection of mode fault error is enabled (SPCR.MODFEN = 1)
- Any of the following conditions are satisfied
  1. In the Motorola SPI mode, the SSL00 pin is deactivated during data transfer.
  2. In the TI SSP mode, the SSL00 pin is activated during data transfer.

(2) Underrun

The condition for this event signal being output in response to an underrun is the start of serial transfer while the value of the SPCR.MSTR bit is 0 (slave mode), the value of the SPCR.SPE bit is 1 (enables the RSPI function), and the transmit data are not ready for output.

(3) Overrun

The condition for this event signal being output in response to an overrun is completion of the serial transfer while the value of the SPCR.CMMD[1:0] bits are 00b or 10b, and the data is stored in the receive FIFO for the number of FIFO stages, in which case the SPSR.OVRF flag is set to 1.

(4) Parity Error

The condition for this event signal being output in response to a parity error is detection of a parity error on completion of the serial transfer while the value of the SPCR.CMMD[1:0] bits are 00b or 10b, and the value of the SPCR.SPE bit is 1.

(5) Receive Data Ready

The condition for this event signal being output in response to a receive data ready is elapsing of the value set by the SPDRSCR register when the number of data stored in the receive FIFO is less than or equal to the receive FIFO threshold value after the data has stored in the receive FIFO, while the value of the SPCR.CMMD[1:0] bits are 00b or 10b, the value of the SPCR.RDRIS bit is 1.

(6) Output Timing

Each error event signal is output at the timing shown in Figure 38.79.
Error event is output each time an error occurs.

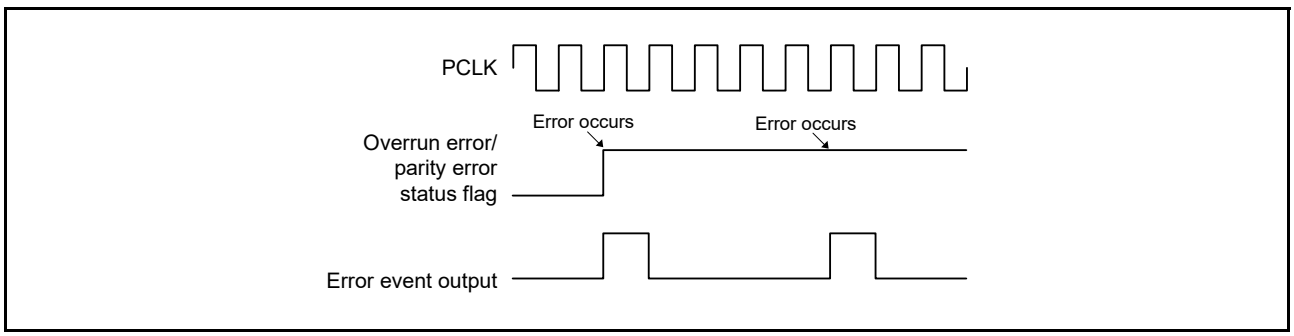

Figure 38.79 Error Event Output Timing

38.3.18.4 Idle Event Output

(1) In Master Mode

[Transmit-receive mode/transmit-only mode]

In transmit-receive master mode or transmit-only master mode, an event is output when the SPSR.IDLNF flag (idle flag) changes from 1 to 0.

The SPSR.IDLNF flag changes from 1 to 0 only when any of the following conditions are satisfied.

(a) The SPCR.SPE bit becomes 0 (RSPI is initialized) during transmission

(b) All the following conditions are satisfied:

- The next transmit data is not set in the transmission buffer (SPTXn, n = 0 to 3)
- The SPSSR.SPCP[2:0] bits are 000b (beginning of sequence control)
- The operations up to the next-access delay have finished (the master main state machine has entered the idle state)

[Receive-only mode]

In receive-only master mode, an event is output when any of the following conditions are satisfied.

(a) The SPCR.SPE bit is set to 0 (RSPI is initialized).

(b) Any the following conditions are satisfied:

- When the SPRMCR.RFC[4:0] bits are 00000b, after 1 is written to the SPRMCR.TERM bit, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)
- When the SPRMCR.RFC[4:0] bits are other than 00000b, after 1 is written to the SPRMCR.TERM bit, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)
- When the SPRMCR.RFC[4:0] bits are other than 00000b, after the operation is completed for the number of received frames set by the SPRMCR.RFC[4:0] bits, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)

(2) In Slave Mode

In slave mode, an event is output when the SPCR.SPE bit is set to 0 (RSPI is initialized).

(3) Output Timing

An idle event is output at the timing shown in Figure 38.80.

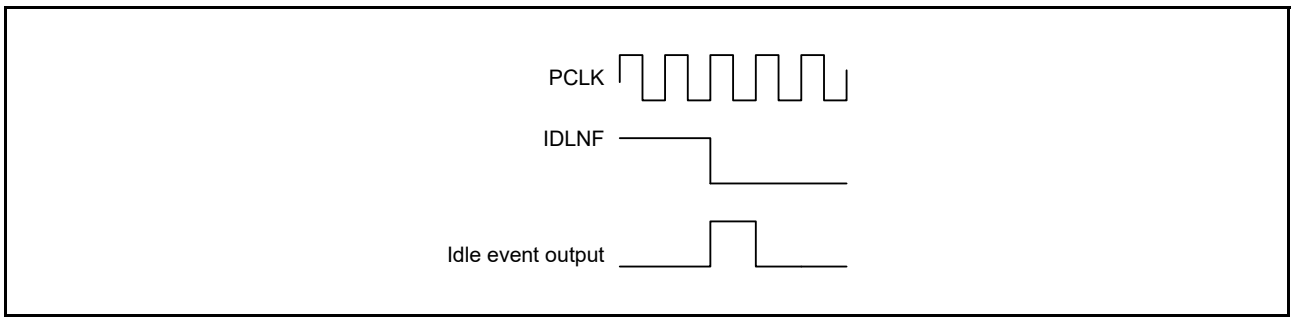

Figure 38.80 Idle Event Output Timing

38.3.18.5 Communication End Event Output

In master mode, an event is output under the condition for setting the SPSR.IDLNF flag (idle flag) from 1 to 0. In slave mode, an event is output under the conditions listed in Table 38.14 and Table 38.15.

Table 38.14 Generating Conditions of Communication End Event (Transmit-Receive Slave Mode/Transmit-Only Slave Mode)

RSPI Mode	Transmit Buffer State	Shift Register State	Others
SPI operation (SPMS = 0, FRFS = 0)	Empty	Empty	Negation of the SSL00 input
SPI operation (SPMS = 0, FRFS = 1)	Empty	Empty	Completion of the SSL negation delay
Clock synchronous operation (SPMS = 1)	Empty	Empty	Even edge detection of the last RSPCK0 for the last data

Table 38.15 Generating Conditions of Communication End Event (Receive-Only Slave Mode)

RSPI Mode	Condition
SPI operation (SPMS = 0, FRFS = 0)	Negation of the SSL00 input after storing the number of frames set by the SPDCR.SPFC[1:0] bits in the receive buffer
SPI operation (SPMS = 0, FRFS = 1)	Completion of the SSL negation delay after storing the number of frames set by the SPDCR.SPFC[1:0] bits in the receive buffer
Clock synchronous operation (SPMS = 1)	Even edge detection of the last RSPCK0 for the last frame set by the SPDCR.SPFC[1:0] bits

Whether the operation is in master mode or slave mode, an event is not output if 0 is written to the SPCR.SPE bit during communication or the SPCR.SPE bit is cleared by the mode fault error or underrun error.
A communication end event is output at timings shown in Figure 38.81 to Figure 38.86. The communication end event output timing in master operation is omitted because it is output at the same timing as an idle event.

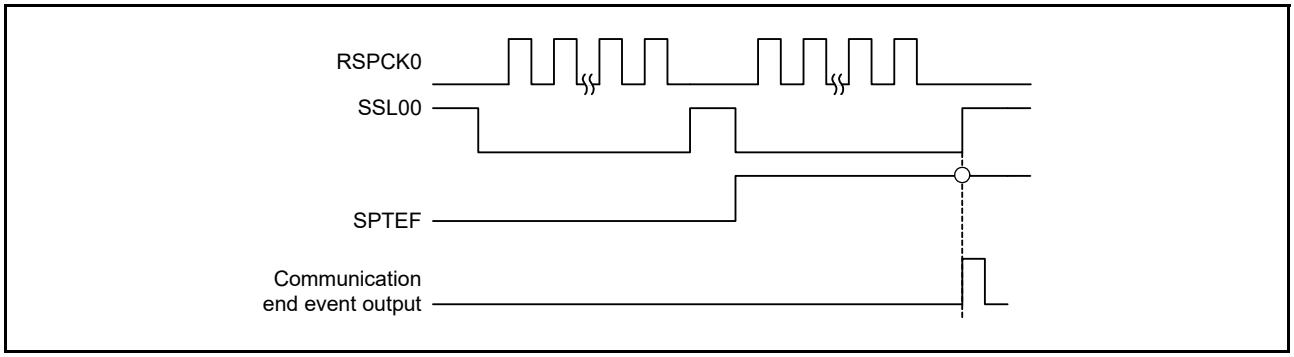

Figure 38.81 Communication End Event Output Timing (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, Motorola SPI Operation)

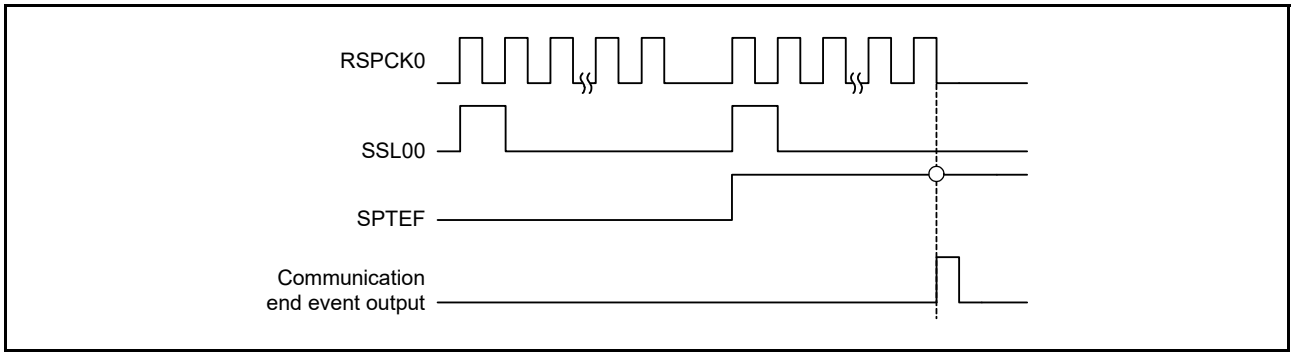

Figure 38.82 Communication End Event Output Timing (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, TI SSP Operation)

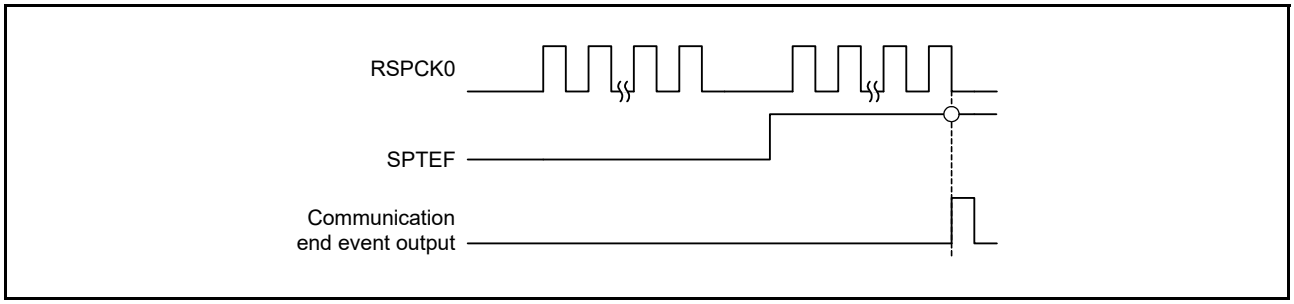

Figure 38.83 Communication End Event Output Timing (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, Clock Synchronous Operation)

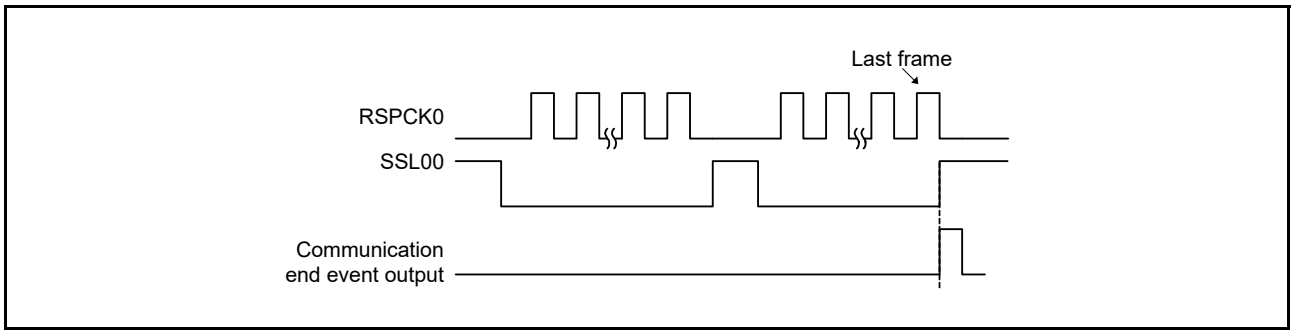

Figure 38.84 Communication End Event Output Timing (Receive-Only Slave Mode, Motorola SPI Operation)

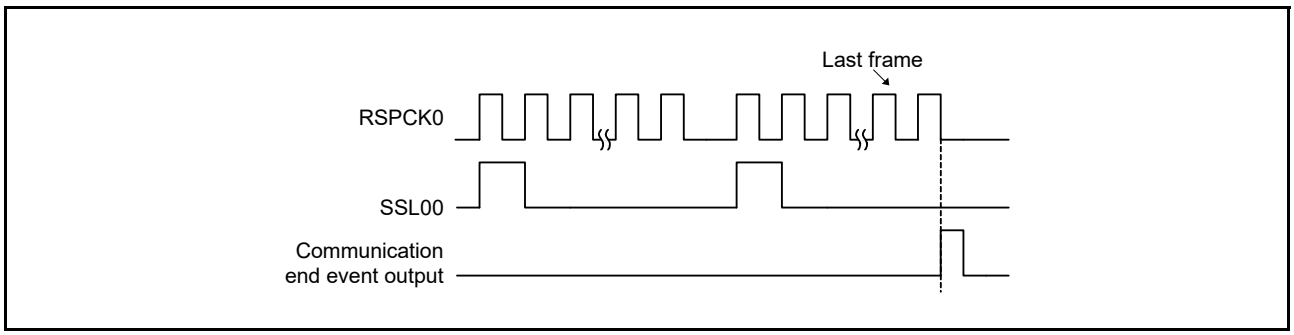

Figure 38.85 Communication End Event Output Timing (Receive-Only Slave Mode, TI SSP Operation)

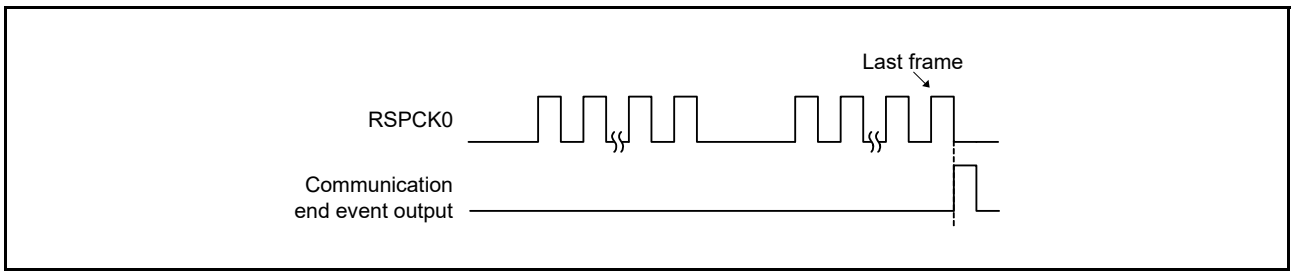

Figure 38.86 Communication End Event Output Timing (Receive-only slave mode, Clock Synchronous Operation)

38.4 Usage Notes

38.4.1 Notes on Starting Transfer

When the ICU.IRn.IR flag is 1 at the time transfer is to start, follow the procedure below to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1).

1. Confirm that transfer has stopped (i.e. that the SPCR.SPE bit is 0).
2. Set the relevant interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) to 0.
3. Read the relevant interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) and confirm that its value is 0.
4. Set the ICU.IRn.IR flag to 0.

38.4.2 Note on Error Events Output

To enable SPI operation of the RSPIA in master mode in the multi-master environment (SPCR.SPMS bit = 0, SPCR.MSTR bit = 1, and SPCR.MODFEN bit = 1), do not use any output of error events.

38.4.3 Note on Low Power Consumption Functions

To reduce power consumption of this module by using the low power consumption functions, set the SPCR.SPE bit to 0 to terminate communication, and then use the low power consumption functions.

38.4.4 Note on the SPRF and SPTEF flags

When polling the SPSR.SPRF flag and/or SPSR.SPTEF flag, set the SPCR.SPRIE bit and/or SPCR.SPTIE bit to 0.

38.4.5 Notes on Burst Transfer in Master Mode

During burst transfer, changing the following settings between the SPCMDm register with the SSLKP bit set to 1 and the SPCMDm register used in the next transfer is prohibited.

- SSL Signal Assertion setting (SSLA[2:0] bits)
- RSPCK output setting (CPHA, CPOL, BRDV[1:0] bits)

38.4.6 Notes on Operating in Slave, TI SSP Mode

In the slave TI SSP mode, the delay between frames must observe the following intervals. Secure the following intervals on the master side.

[Master side: interval from the RSPCK edge of last bit to the RSPCK edge of next SSL] > [Slave side: OE delay time = PCLKA * (1 to 2) + SLNDL[2:0] setting value]

38.4.7 Notes on the Data Length

Table 38.16 shows the relationship between the data length and operation of the RSPIA.

Table 38.16 Relationship between the Data Length and Operation of the RSPIA

Data Length										
4 bit	**5 bit**	**6 bit**	**7 bit**	**8 bit**	**9 bit**	**10 bit**	**11 bit**	**12 bit**	**13 bit**	**14 bit**
Conditionally possible	Conditionally possible	Conditionally possible	Possible	Possible	Possible	Possible	Possible	Possible	Possible	Possible

Possible: Operating possible
Conditionally possible: Operating possible when the SPCR.SCKASE or SCKDDIS bit is 0.

38.4.8 Notes when SPCR.SPE = 1

If the value of the registers listed below are changed while the SPCR.SPE bit is 1, the operation after the change is not guaranteed.

Table 38.17 List of Registers that Cannot Be Rewritten When SPCR.SPE = 1 (1/2)

Register	Bit
SPCKD	SCKDL[2:0]

Note 1. Rewriting prohibited in slave mode. In master mode, rewriting is available only when there is no next transmit data in the transmit FIFO.

39. CRC Calculator (CRCA)

The CRC (Cyclic Redundancy Check) calculator generates CRC codes.

39.1 Overview

Table 39.1 lists the specifications of the CRC calculator, and Figure 39.1 shows a block diagram of the CRC calculator.

Table 39.1 CRC Specifications

Item	Description	
Data size	8 bits	32 bits
Data for CRC calculation*1	CRC codes are generated for any desired data in 8n-bit units (where n is a whole number)	CRC codes are generated for any desired data in 32n-bit units (where n is a whole number)
CRC processor unit	8-bit parallel processing	32-bit parallel processing
CRC generating polynomial	One of three generating polynomials is selectable • 8-bit CRC $X^8 + X^2 + X + 1$ • 16-bit CRC $X^{16} + X^{15} + X^2 + 1$ $X^{16} + X^{12} + X^5 + 1$	One of two generating polynomials is selectable • 32-bit CRC $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$ $X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$
CRC calculation switching	The order of the bits produced by CRC calculation can be switched for LSB first or MSB first communication	
Low power consumption	Module stop state can be set.	

Note 1. The circuit does not have a function to divide data for calculation into CRC calculation units. Write data in 8-bit or 32-bit units.

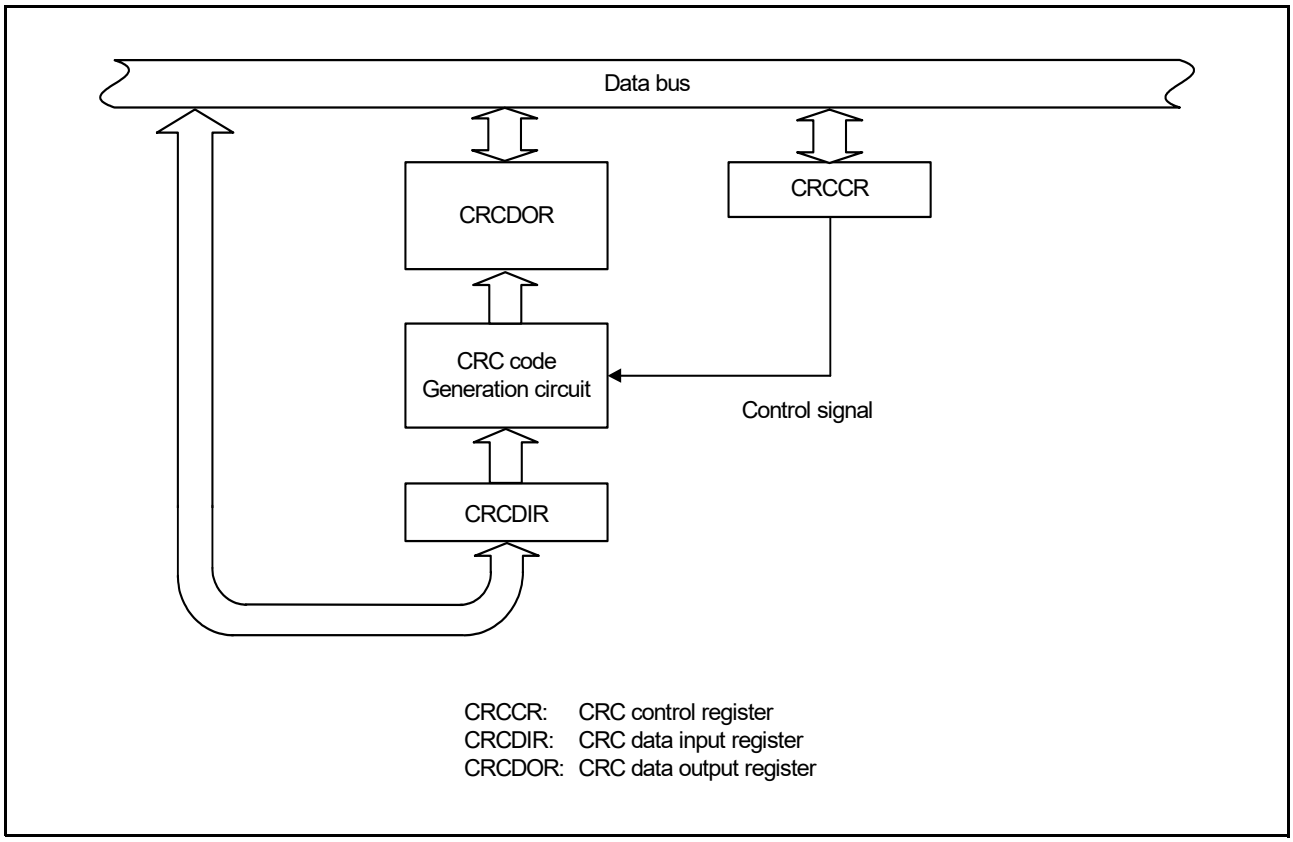

Figure 39.1 CRC Block Diagram

39.2 Register Descriptions

39.2.1 CRC Control Register (CRCCR)

Address(es): CRC.CRCCR 0008 8280h

	b7	b6	b5	b4	b3	b2	b1	b0
	DORCLR	LMS	—	—	—	GPS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	GPS[2:0]	CRC Generating Polynomial Switching	b2 b1 b0 0 0 0: No calculation is executed. 0 0 1: 8-bit CRC ($X^8 + X^2 + X + 1$) 0 1 0: 16-bit CRC ($X^{16} + X^{15} + X^2 + 1$) 0 1 1: 16-bit CRC ($X^{16} + X^{12} + X^5 + 1$) 1 0 0: 32-bit CRC ($X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$) 1 0 1: 32-bit CRC ($X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$) 1 1 0: No calculation is executed. 1 1 1: No calculation is executed.	R/W
b5 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	LMS	CRC Calculation Switching	0: Generates CRC for LSB first communication. 1: Generates CRC for MSB first communication.	R/W
b7	DORCLR	CRCDOR Register Clear	1: Clears the CRCDOR register. This bit is read as 0.	W*1

Note 1. Only 1 can be written.

LMS Bit (CRC Calculation Switching)

The setting this bit selects the order of the bits of generated CRC codes. The bit selects transmission of the lower-order byte of the CRC code first for LSB first communication, or the higher-order byte first for MSB first communication. For details on the transmission and reception of CRC codes, refer to section 39.3, Operation.

DORCLR Bit (CRCDOR Register Clear)

Write 1 to this bit so that the CRCDOR register is set to 0000 0000h.
This bit is read as 0. Writing 0 to this bit has no effect.

39.2.2 CRC Data Input Register (CRCDIR)

- When 32-bit CRC is selected

Address(es): CRC.CRCDIR 0008 8284h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- When 16-bit or 8-bit CRC is selected

Address(es): CRC.CRCDIR 0008 8284h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

The CRCDIR register is a readable and writable register. Write data for CRC calculation to this register.
When generating a 32-bit CRC, the CRCDIR register should be accessed in longword units. When generating a 8-bit or 16-bit CRC, the CRCDIR register should be accessed in byte units.

39.2.3 CRC Data Output Register (CRCDOR)

- When 32-bit CRC is selected

Address(es): CRC.CRCDOR 0008 8288h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- When 16-bit CRC is selected

Address(es): CRC.CRCDOR 0008 8288h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- When 8-bit CRC is selected

Address(es): CRC.CRCDOR 0008 8288h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

The CRCDOR register is a readable and writable register.
The value after a reset is 0000 0000h. When calculating with the initial value set to a value other than 0000 0000h, rewrite the CRCDOR register.
Writing data to the CRCDIR register stores result of calculation in the CRCDOR register. In addition, following communication data, when a CRC code is written to the CRCDIR register and if the calculation result is 0000 0000h, there is no error in the communication data.
When a 32-bit CRC is selected, the CRCDOR register should be accessed in longword units. When a 16-bit CRC is selected, the CRCDOR register should be accessed in word units. When an 8-bit CRC is selected, the CRCDOR register should be accessed in byte units.

39.3 Operation

The CRC calculator generates CRC codes for use in LSB first or MSB first communication.
The following shows examples of generating the CRC code for input data (F0h) using the 16-bit CRC generating polynomial ($X^{16} + X^{12} + X^5 + 1$). In these examples, the value of the CRC data output register (CRCDOR) is cleared by setting the DORCLR bit to 1 to set the initial value for CRC calculation to 0000 0000h.

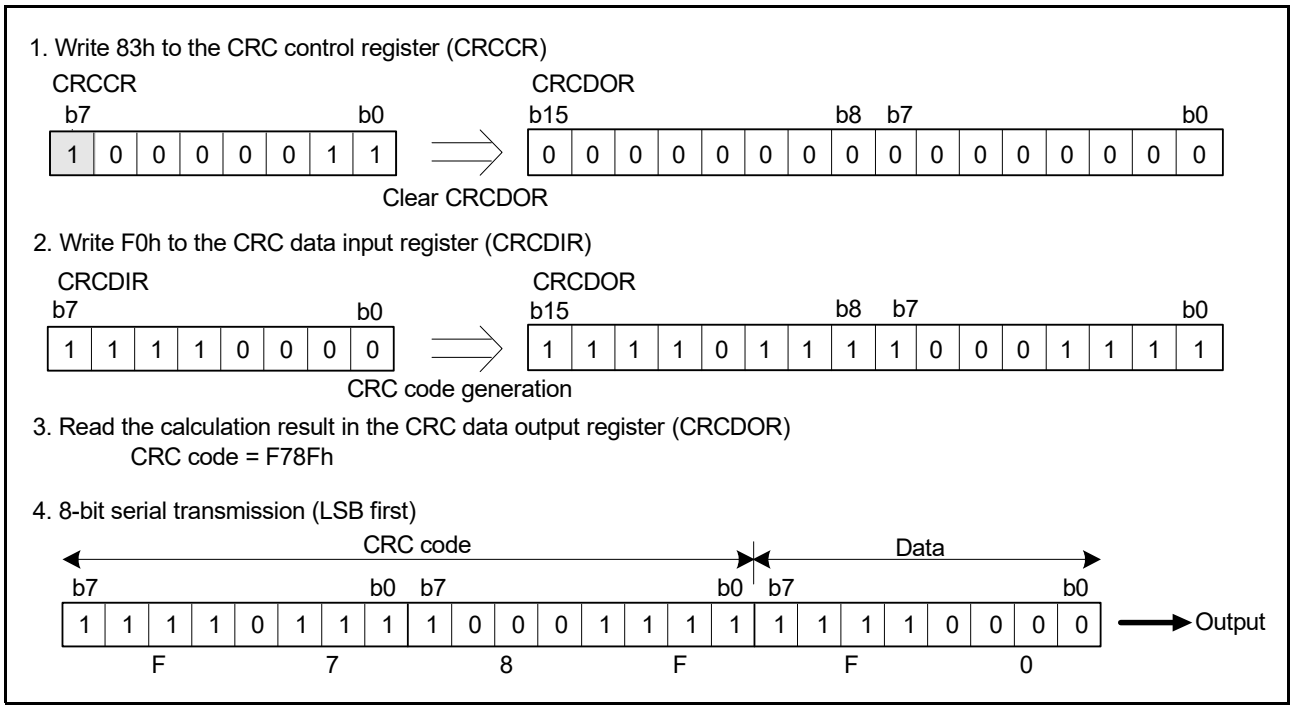

Figure 39.2 LSB First Data Transmission

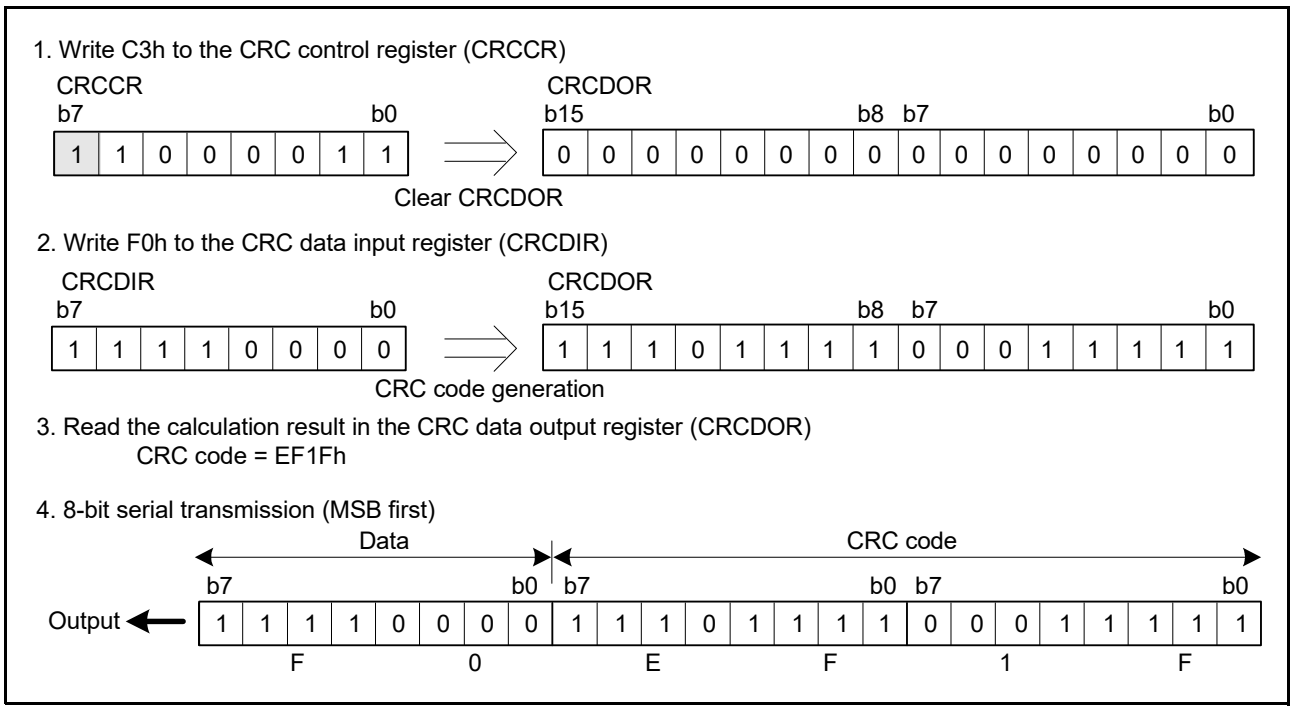

Figure 39.3 MSB First Data Transmission

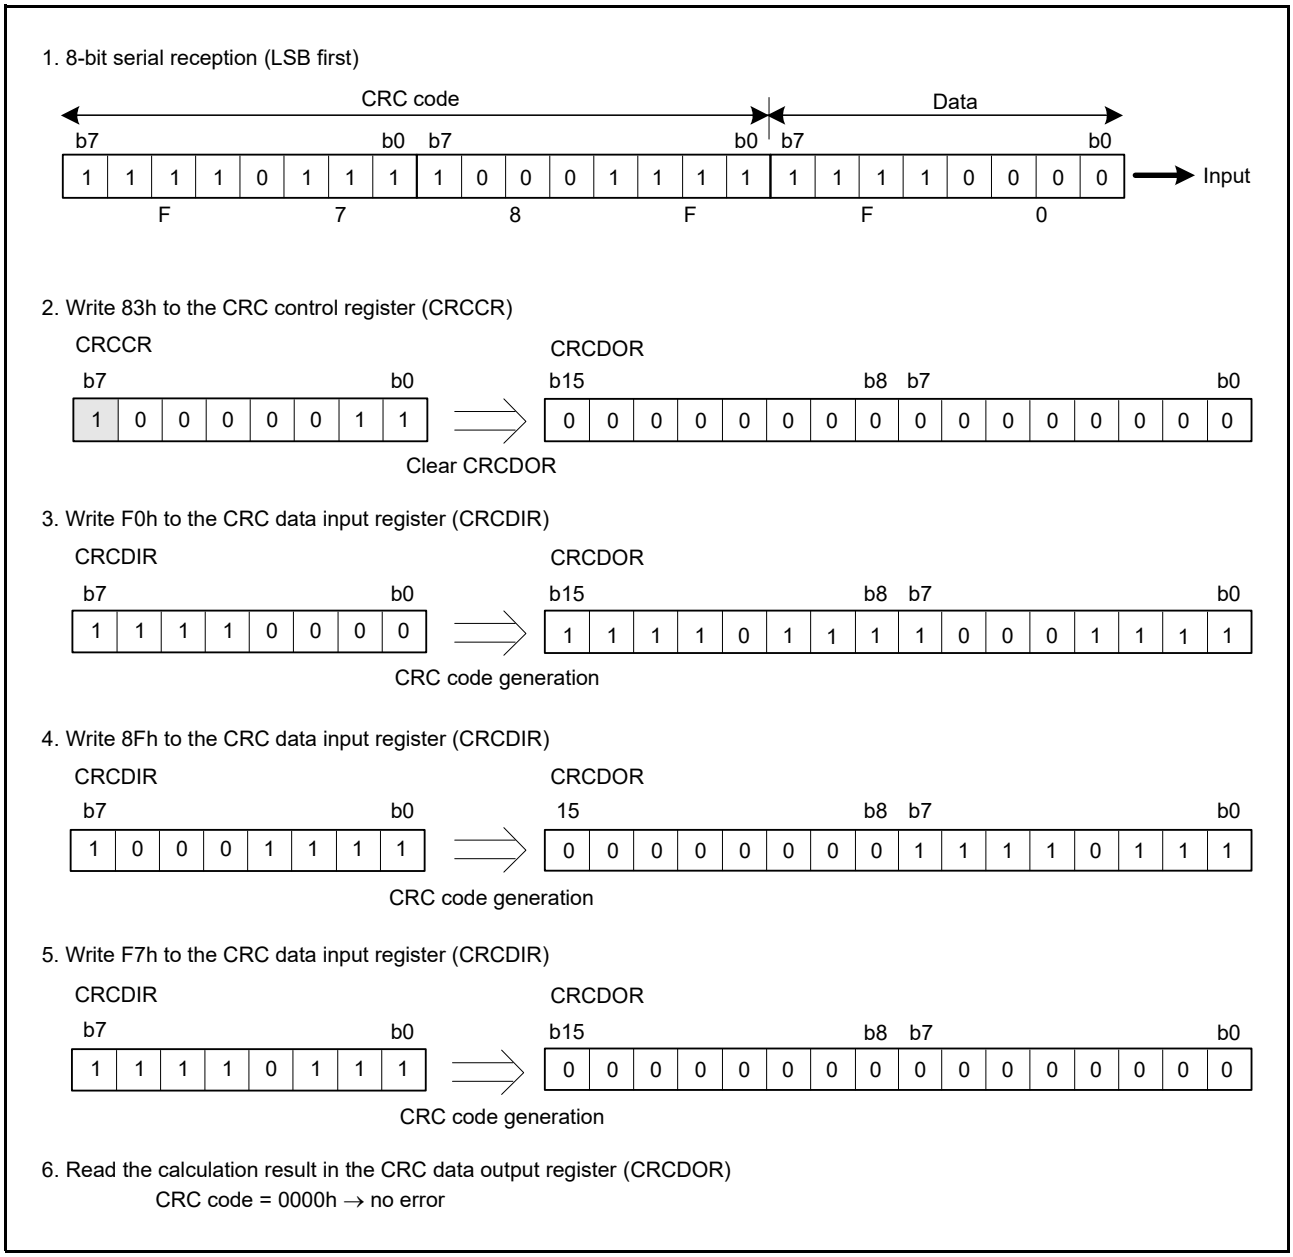

Figure 39.4 LSB First Data Reception

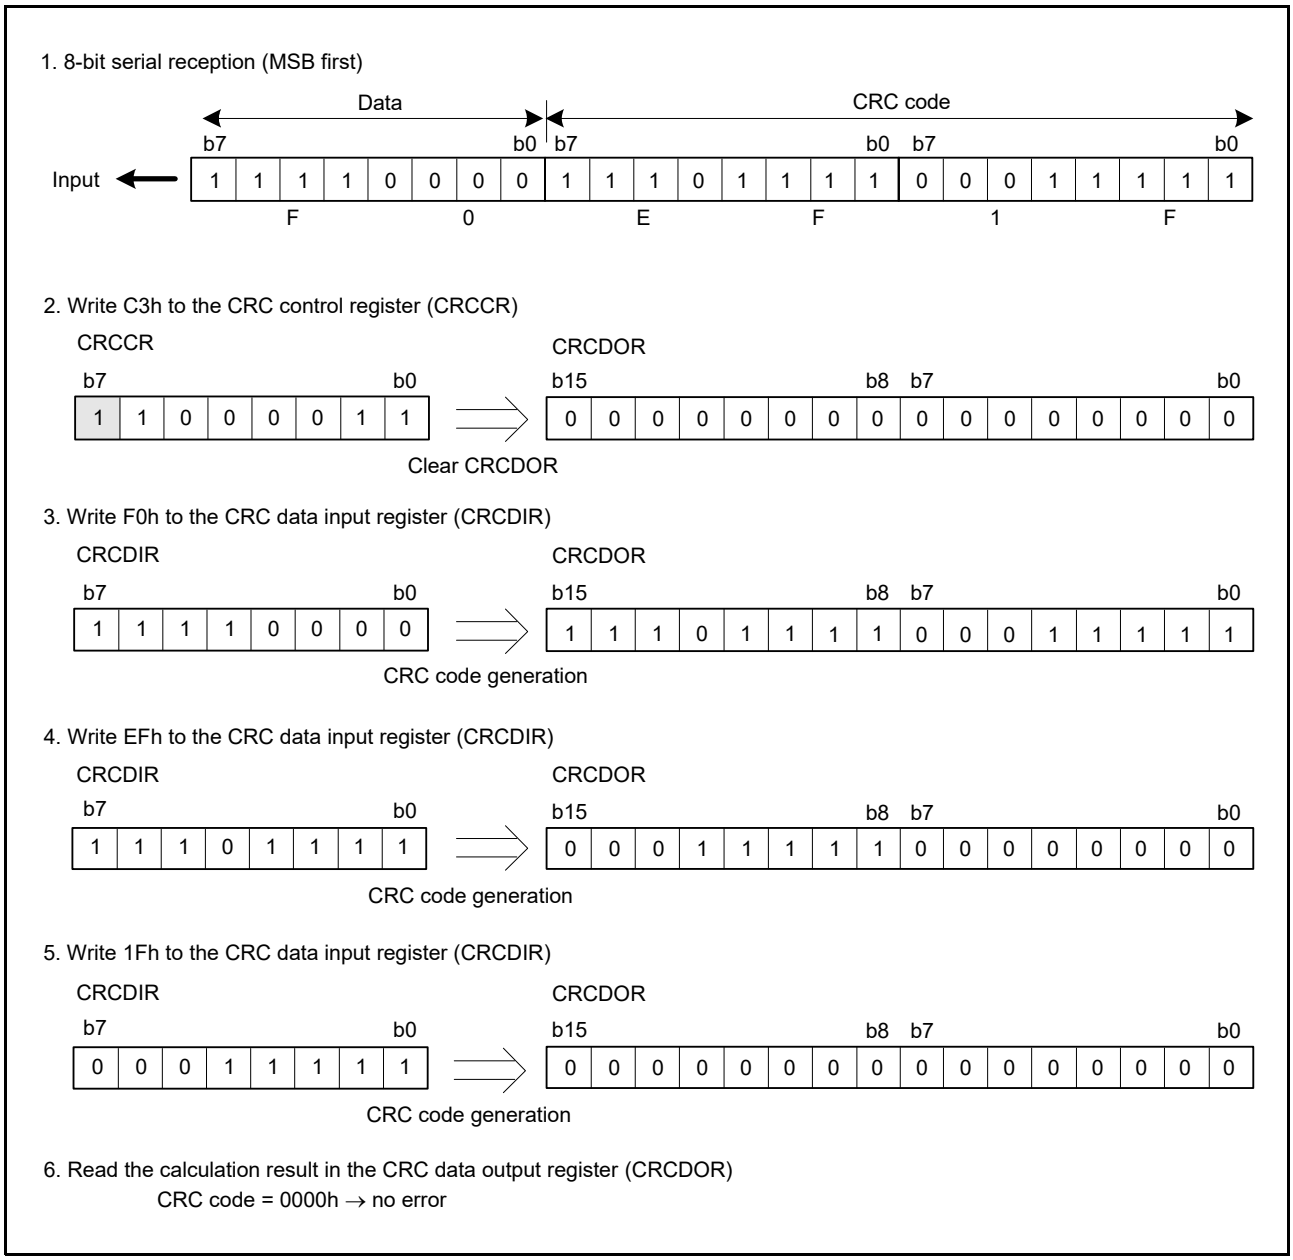

Figure 39.5 MSB First Data Reception

39.4 Usage Notes

39.4.1 Module Stop Function Setting

Operation of the CRC calculator can be disabled or enabled using the module stop control register B (MSTPCRB). After a reset, the CRC is in the module stop state. Register access is enabled by releasing the module stop state.
For details, refer to section 11, Low Power Consumption.

39.4.2 Note on Transmission

Note that the sequence of transmission for the CRC code differs according to whether transmission is LSB first or MSB first.

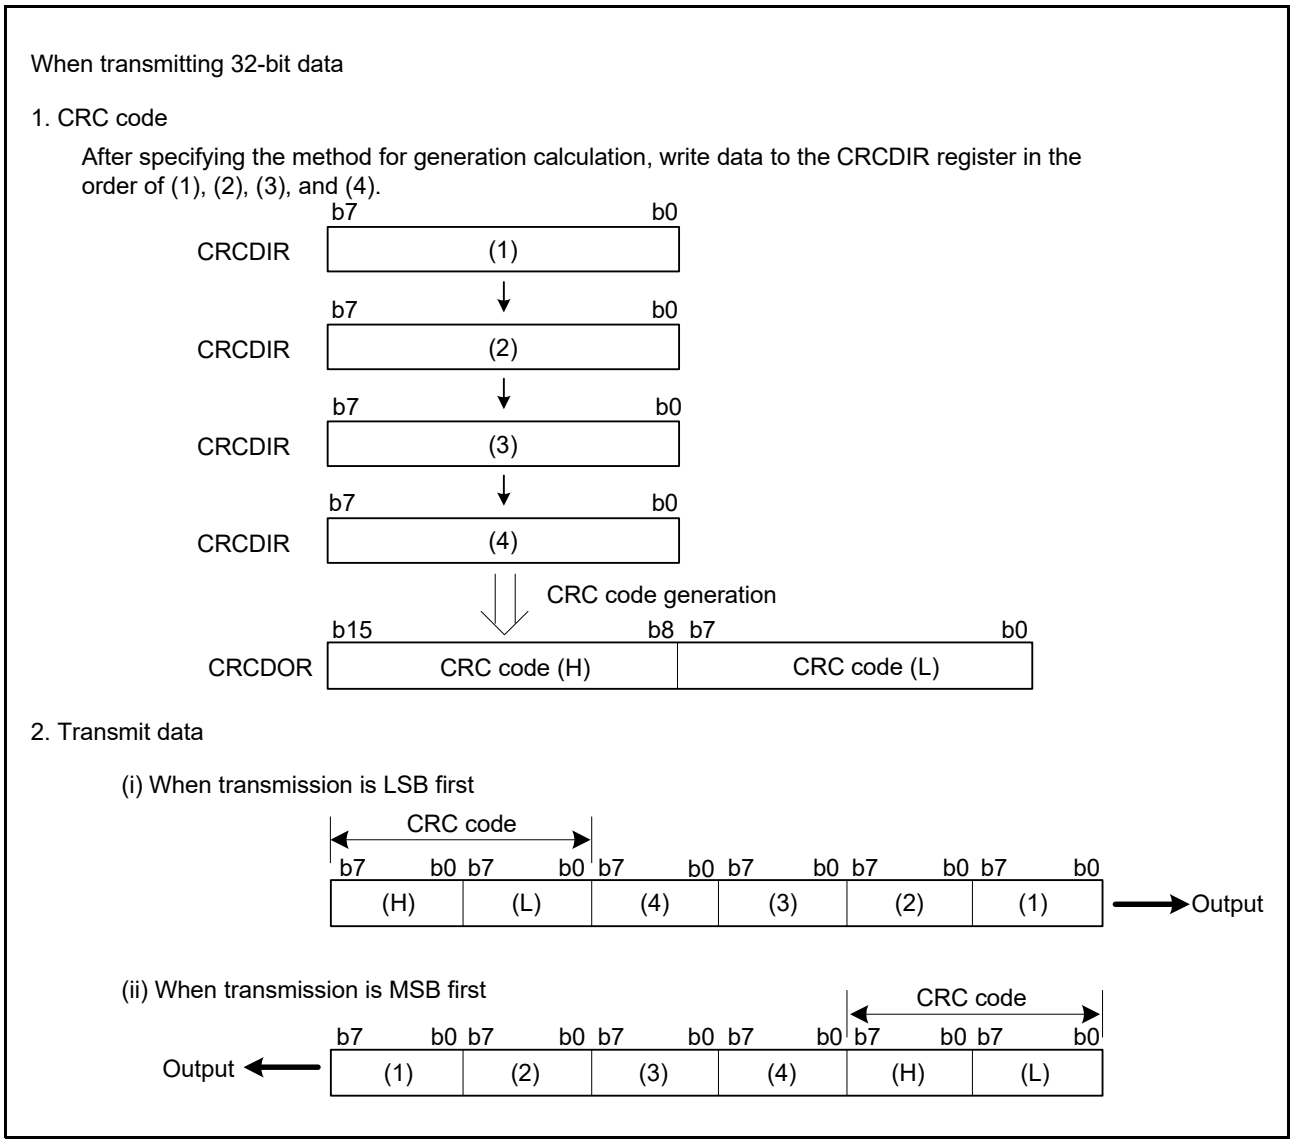

Figure 39.6 LSB First and MSB First Data Transmission

40. Arithmetic Unit for Trigonometric Functions (TFUv2)

This MCU has an arithmetic unit for trigonometric functions (TFUv2). TFUv2 has an upward compatible architecture with TFUv1 and supports fixed-point numbers as well as floating-point numbers.

The TFU has hardware processing functionality for sin, cos, atan, and hypot_k calculations that provide sinθ, cosθ, atan(y/x), and $\sqrt{x^2+y^2}/k$, respectively. For the value of k, see section 40.3.1, Arithmetic Processing.

40.1 Overview

Table 40.1 lists the specifications of the TFU.

Table 40.1 TFU specifications

Item	Description				
Arithmetic Processing	Calculation of sine, cosine, arctangent, and hypotenuse • A sine and cosine can be simultaneously calculated. • An arctangent and hypotenuse can be simultaneously calculated.

		Output	$\sqrt{x^2+y^2}/k$	0 ≤ $\sqrt{x^2+y^2}/k$ ≤ $\sqrt{2}/k$	—
Data Type for Processing	Single-precision floating-point, fixed-point two's-complement				
Number of cycles for calculation	Sine: 5 Cosine: 5 Arctangent: 14 Hypotenuse: 14				

Note 1. float_max is the maximum value that can be expressed as single-precision floating-point: $(2 - 2^{-23}) \times 2^{127}$.

40.2 Register Descriptions

40.2.1 Fixed-Point Sincos Input and Output Setting Register (FXSCIOC)

Address(es): TFU.FXSCIOC 0008 1404h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	OF[1:0]		—	—	—	IUF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IUF	Input Unit and Format Setting	0: Unit of turns, Q1.31 format 1: Unit of radians, Q3.29 format	R/W
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5, b4	OF[1:0]	Output Format Setting	b5 b4 0 0: Q1.31 0 1: Q2.30 1 0: Q3.29 1 1: Setting prohibited	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Set this register before starting a calculation. Operation cannot be guaranteed if writing to this register is attempted during a calculation.

IUF Bit (Input Unit and Format Setting)

The IUF bit is used to set the unit and format of the input values in fixed-point sincos operations.

OF[1:0] Bits (Output Format Setting)

The OF[1:0] bits are used to set the format of the output values in fixed-point sincos operations. Exactly expressing the value +1.0 is not possible in Q1.31 format. When the exact value of $\sin\theta$ or $\cos\theta$ should be +1.0 in Q1.31 format, the value read from the FXSCDT0 or FXSCDT1 register is $+1.0 - 2^{-31}$ instead.

40.2.2 Fixed-Point Atanhypot_k Input and Output Setting Register (FXATIOC)

Address(es): TFU.FXATIOC 0008 1405h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	OUF	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	OUF	Output Unit and Format Setting	0: Unit of turns, Q1.31 format 1: Unit of radians, Q3.29 format	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Set this register before starting a calculation. Operation cannot be guaranteed if writing to this register is attempted during a calculation.

OUF Bit (Output Unit and Format Setting)

The OUF bit is used to set the unit and format of the output values of atan calculations in fixed-point atanhypot_k operations. Note that the format of the output value of every hypot_k calculation simultaneous with an atan calculation is Q3.29 regardless of the value of this bit.

40.2.3 Trigonometric Status Register (TRGSTS)

Address(es): TFU.TRGSTS 0008 1408h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	ERRF	BSYF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BSYF	Calculation in Progress Flag	0: No calculating 1: Calculating	R/W *1
b1	ERRF	Input Error Flag	0: No input error occurred 1: Input error occurred	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing to this flag is invalid.

BSYF Flag (Calculation in Progress Flag)

The BSYF flag indicates whether a calculation is in progress. Writing to this flag is ignored.

[Setting condition]

- When calculation started

[Clearing condition]

- When calculation completed

ERRF Flag (Input Error Flag)

The ERRF flag indicates whether an input error occurred during a calculation. Follow the procedure for restoring the error flag described in section 40.4.2, How to Use Interrupts, to write to this register.

[Setting condition]

- When input error occurred*1 or this flag is set to 1

[Clearing condition]

- When the next calculation started or this flag is set to 0

Note 1. For details on input error, see section 40.3.5, Relationship Between Input and Output Values for Atan Operation.

40.2.4 Floating-Point Sincos Data Register 0 (FPSCDT0)

Address(es): TFU.FPSCDT0 0008 1410h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FPSCDT0 register is used to read the output value of cosθ in a floating-point sincos operation. For details, see Table 40.2. For how to use this register, see section 40.4.1, Procedures for Using the TFU.
Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.
Only write to or read from this register in a floating-point sincos operation. Writing to any other data register 0, that is, to the FPATDT0, FXSCDT0, or FXATDT0 register, makes the value of this register undefined. Writing to data saving and restoring register 0 (DTSR0) makes the value of this register the same as that written to the DTSR0 register.

40.2.5 Floating-Point Sincos Data Register 1 (FPSCDT1)

Address(es): TFU.FPSCDT1 0008 1414h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FPSCDT1 register is used to input an angle value θ and to read the output value of sinθ in a floating-point sincos operation. For details, see Table 40.2. Writing to this register starts a floating-point sincos operation. For how to use this register, see section 40.4.1, Procedures for Using the TFU.
Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.
Only write to or read from this register in a floating-point sincos operation. Writing to any other data register 1, that is, to the FPATDT1, FXSCDT1, or FXATDT1 register, makes the value of this register undefined. Writing to data saving and restoring register 1 (DTSR1) makes the value of this register the same as that written to the DTSR1 register.

Table 40.2 Input/Output value of FPSCDT0 and FPSCDT1

Register	Input value	Output value
FPSCDT0	Not used	cosθ
FPSCDT1	Angleθ	sinθ

40.2.6 Floating-Point Atanhypot_k Data Register 0 (FPATDT0)

Address(es): TFU.FPATDT0 0008 1418h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FPATDT0 register is used to input a coordinate value x and to read the output value of $\sqrt{x^2+y^2}/k$ in a floating-point atanhypot_k operation. For details, see Table 40.3. For how to use this register, see section 40.4.1, Procedures for Using the TFU.

Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

Only write to or read from this register in a floating-point atanhypot_k operation. Writing to any other data register 0, that is, to the FPSCDT0, FXSCDT0, or FXATDT0 register, makes the value of this register undefined. Writing to data saving and restoring register 0 (DTSR0) makes the value of this register the same as that written to the DTSR0 register.

40.2.7 Floating-Point Atanhypot_k Data Register 1 (FPATDT1)

Address(es): TFU.FPATDT1 0008 141Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FPATDT1 register is used to input a coordinate value y and to read the output value of atan(y/x) in a floating-point atanhypot_k operation. For details, see Table 40.3. Writing to this register starts a floating-point atanhypot_k operation. For how to use this register, see section 40.4.1, Procedures for Using the TFU.

Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

Only write to or read from this register in a floating-point atanhypot_k operation. Writing to any other data register 1, that is, to the FPSCDT1, FXSCDT1, or FXATDT1 register, makes the value of this register undefined. Writing to data saving and restoring register 1 (DTSR1) makes the value of this register the same as that written to the DTSR1 register.

Table 40.3 Input/Output value of FPATDT0 and FPATDT1

Register	Input value	Output value
FPATDT0	Input coordinates x	$\sqrt{x^2+y^2}/k$
FPATDT1	Input coordinates y	atan(y/x)

40.2.8 Fixed-Point Sincos Data Register 0 (FXSCDT0)

Address(es): TFU.FXSCDT0 0008 1420h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FXSCDT0 register is used to read the output value of cosθ in a fixed-point sincos operation. For details, see Table 40.4. For how to use this register, see section 40.4.1, Procedures for Using the TFU.
Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.
Only write to or read from this register in a fixed-point sincos operation. Writing to any other data register 0, that is, to the FPSCDT0, FPATDT0, or FXATDT0 register, makes the value of this register undefined. Writing to data saving and restoring register 0 (DTSR0) makes the value of this register the same as that written to the DTSR0 register.

40.2.9 Fixed-Point Sincos Data Register 1 (FXSCDT1)

Address(es): TFU.FXSCDT1 0008 1424h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FXSCDT1 register is used to input an angle value θ and to read the output value of sinθ in a fixed-point sincos operation. For details, see Table 40.4. Writing to this register starts a fixed-point sincos operation. For how to use this register, see section 40.4.1, Procedures for Using the TFU.
Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.
Only write to or read from this register in a fixed-point sincos operation. Writing to any other data register 1, that is, to the FPSCDT1, FPATDT1, or FXATDT1 register, makes the value of this register undefined. Writing to data saving and restoring register 1 (DTSR1) makes the value of this register the same as that written to the DTSR1 register.

Table 40.4 Input/Output value of FXSCDT0 and FXSCDT1

Register	Input value	Unit and format of the input values	Output value	Output value formats
FXSCDT0	Not used	—	cosθ	Q1.31, Q2.30, or Q3.29 in accordance with the value of FXSCIOC.OF[1:0] bits
FXSCDT1	Angleθ	FXSCIOC.IUF = 0: turns, Q1.31 FXSCIOC.IUF = 1: radians, Q3.29	sinθ	

Exactly expressing the value +1.0 is not possible when the output value format is Q1.31. When the exact value of sinθ or cosθ should be +1.0 in Q1.31 format, the value read from the FXSCDT0 or FXSCDT1 register is $+1.0 - 2^{-31}$ instead.

40.2.10 Fixed-Point Atanhypot_k Data Register 0 (FXATDT0)

Address(es): TFU.FXATDT0 0008 1428h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FXATDT0 register is used to input a coordinate value x and to read the output value of $\sqrt{x^2+y^2}/k$ in a fixed-point atanhypot_k operation. For details, see Table 40.5. For how to use this register, see section 40.4.1, Procedures for Using the TFU.

Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

Only write to or read from this register in a fixed-point atanhypot_k operation. Writing to any other data register 0, that is, to the FPSCDT0, FPATDT0, or FXSCDT0 register, makes the value of this register undefined. Writing to data saving and restoring register 0 (DTSR0) makes the value of this register the same as that written to the DTSR0 register.

40.2.11 Fixed-Point Atanhypot_k Data Register 1 (FXATDT1)

Address(es): TFU.FXATDT1 0008 142Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FXATDT1 register is used to input a coordinate value y and to read the output value of atan(y/x) in a fixed-point atanhypot_k operation. For details, see Table 40.5. Writing to this register starts a fixed-point atanhypot_k operation. For how to use this register, see section 40.4.1, Procedures for Using the TFU.

Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

Only write to or read from this register in a fixed-point atanhypot_k operation. Writing to any other data register 1, that is, to the FPSCDT1, FPATDT1, or FXSCDT1 register, makes the value of this register undefined. Writing to data saving and restoring register 1 (DTSR1) makes the value of this register the same as that written to the DTSR1 register.

Table 40.5 Input/Output value of FXATDT0 and FXATDT1

Register	Input value	Input value formats	Output value	Unit and format of the output values
FXATDT0	Input coordinates x	Q1.31	$\sqrt{x^2 + y^2}/k$	—, Q3.29
FXATDT1	Input coordinates y	Q1.31	atan(y/x)	FXATIOC.OUF = 0: turns, Q1.31 FXATIOC.OUF = 1: radians, Q3.29

40.2.12 Data Saving and Restoring Register 0 (DTSR0)

Address(es): TFU.DTSR0 0008 1430h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DTSR0 register is used to save and restore the data in data registers 0 that are FPSCDT0, FPATDT0, FXSCDT0, or FXATDT0 registers. The value read from this register is either that most recently written to any of data registers 0 or the latest result of arithmetic processing in any of data registers 0. Writing to this register makes the values of all data registers 0 the same as that written to this register.

Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

For how to use this register, see section 40.4.2, How to Use Interrupts.

40.2.13 Data Saving and Restoring Register 1 (DTSR1)

Address(es): TFU.DTSR1 0008 1434h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DTSR1 register is used to save and restore the data in data registers 1 that are FPSCDT1, FPATDT1, FXSCDT1, or FXATDT1 registers. The value read from this register is either that most recently written to any of data registers 1 or the latest result of arithmetic processing in any of data registers 1. Writing to this register makes the values of all data registers 1 the same as that written to this register.

Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

For how to use this register, see section 40.4.2, How to Use Interrupts.

40.3 Operation

40.3.1 Arithmetic Processing

The trigonometric function unit has two arithmetic operations, the sincos operation and the atanhypot_k operation. Here, “sincos operation” means simultaneous sin and cos calculations and “atanhypot_k operation” means simultaneous atan and hypot_k calculations. For details, see Table 40.6.

Table 40.6 Arithmetic Processing

Operation	Input value	Output value
sincos	Angle value θ	cosθ and sinθ
atanhypot_k	Coordinates x and y	atan(y/x) and $\sqrt{x^2+y^2}/k$

Note: The value of scaling factor *k* is:

$$k = \prod_{i=0}^{\infty} \frac{1}{\sqrt{1+2^{-2i}}} \fallingdotseq 0.607252935008881256169 4$$

Multiplying the output value of the TFU $\sqrt{x^2+y^2}/k$ by k provides $\sqrt{x^2+y^2}$.

40.3.2 Input and Output Value Formats

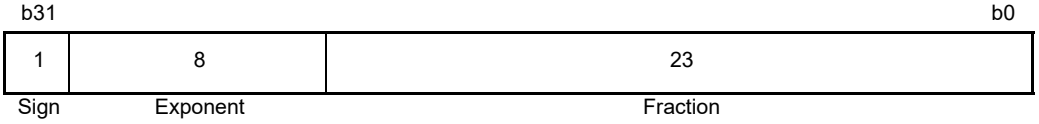
The TFU supports single-precision floating-point numbers and fixed-point numbers as its input and output values. For details on single-precision floating-point numbers and fixed-point numbers, see section 40.3.2.1, Single-Precision Floating-Point Numbers, and section 40.3.2.2, Fixed-Point Numbers, respectively. Note that the precision of fixed-point calculations is lower than 32 bits, although the input and output values are fixed-point numbers in 32-bit format.

40.3.2.1 Single-Precision Floating-Point Numbers

Floating-Point Number

The TFU supports the format for single-precision floating-point numbers specified in the IEEE754 standard.

- Single-Precision Floating-Point Number



Sign: sign field (1-bit)
Exponent: exponent field (8-bit)
Fraction: significand field (23-bit)

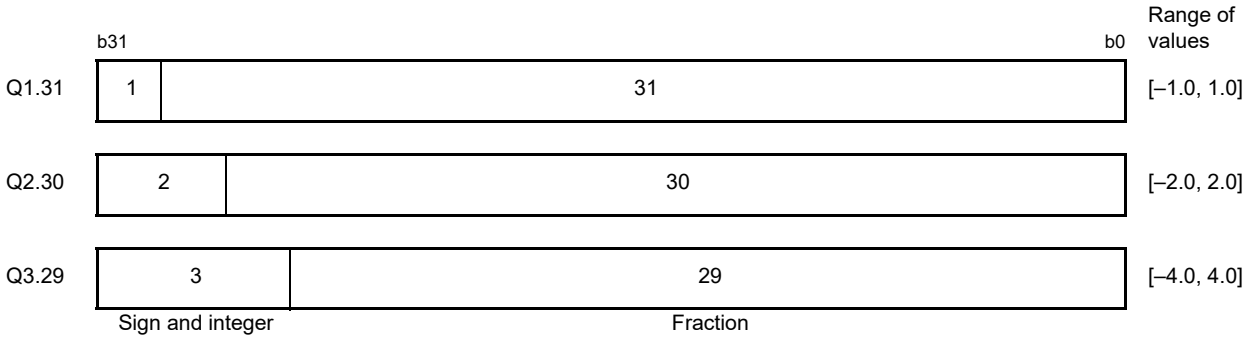
Numerical = $(-1)^S \times (1 + F \times 2^{-23}) \times 2^{(E-127)}$ (normalized value)
Numerical = $(-1)^S \times (0 + F \times 2^{-23}) \times 2^{-126}$ (denormalized value)

The TFU supports the numerical formats of single-precision floating-point numbers listed below.

S	E	F	Numerical
Any value	0 < E < 255	Any value	$(-1)^S \times 1.F \times 2^{(E-127)}$ (Normal Numbers)
Any value	E = 0	F > 0	$(-1)^S \times 0.F \times 2^{-126)}$ (Subnormal Numbers)
S = 0	E = 0	F = 0	$(-1)^0 \times 0.0$ (Positive zero: +0)
S = 1	E = 0	F = 0	$(-1)^{-1} \times 0.0$ (Negative zero: –0)
S = 0	E = 255	F = 0	Positive infinity: +∞
S = 1	E = 255	F = 0	Negative infinity: –∞
Any value	E = 255	400000h > F > 0	SNaN (Signaling Not a Number)
Any value	E = 255	F ≥ 400000h	QNaN (Quiet Not a Number)

40.3.2.2 Fixed-Point Numbers

The TFU supports the two’s-complement formats shown below.



40.3.3 Units of Angles

The TFU supports radians and turns as the units for angles. 0 to 2π radians and 0 to 1 turns respectively represent 0- to 360-degree rotations.

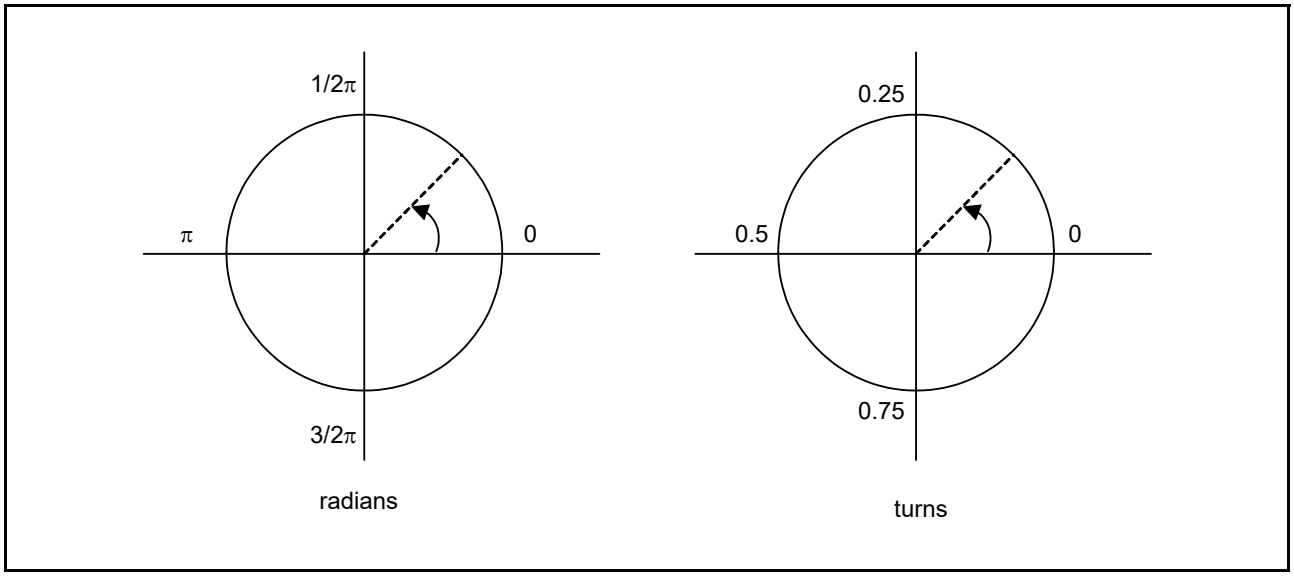


Figure 40.1 Units of Angles

40.3.4 Relationship Between Input and Output Values for Sincos Operation

The output value of a floating-point sin or cos calculation is specified as listed in Table 40.7 when the input value is ±0, ±∞, SNaN (Signaling Not a Number), or QNaN (Quiet Not a Number).

Table 40.7 Relationship Between Special Input Value and Its Output Value (for Sincos Operation)

Input (*θ*)	Output (cos)	Output (sin)
–∞	QNaN	QNaN
–0	+1	–0
+0	+1	+0
+∞	QNaN	QNaN
SNaN/QNaN	QNaN	QNaN

Note: The output value of QNaN is FFC0 0000h.

40.3.5 Relationship Between Input and Output Values for Atan Operation

The output value of a floating-point atan calculation is specified as listed in Table 40.8 when either of the input values x or y is ±0, ±∞, SNaN (Signaling Not a Number), or QNaN (Quiet Not a Number). An input error is detected when both of the input values x and y are ±0.

Table 40.8 Relationship Between Special Input Value and Its Output Value (for Floating-Point Atan Operation)

y \ x	−∞	Negative value	−0	+0	Positive value	+∞	SNaN/QNaN
−∞	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN
Negative value	QNaN	—	−π/2	−π/2	—	QNaN	QNaN
−0	QNaN	−π	QNaN*1	QNaN*1	−0	QNaN	QNaN
+0	QNaN	+π	QNaN*1	QNaN*1	+0	QNaN	QNaN
Positive value	QNaN	—	+π/2	+π/2	—	QNaN	QNaN
+∞	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN
SNaN/QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN

Note 1. An input error occurs for the special input value, and the input error flag (TRGSTS.ERRF) is set.

An input error is detected when both of the input values x and y of a fixed-point atan calculation are 0, even for the values other than 0 in 32-bit fixed-point format that are handled as 0 by the TFU. The output value of an atan calculation is 0 when an input error has occurred.

40.3.6 Relationship Between Input and Output Values for hypot_k Operation

The output value of a floating-point hypot_k calculation is specified as listed in Table 40.9 in either of the following cases: when either of the input values x or y is ±∞, SNaN (Signaling Not a Number), or QNaN (Quiet Not a Number), or when both of the input values x and y are ±0. An input error is detected when both of the input values x and y are ±0. The reason is that such values cause errors in atan calculations although hypot_k calculations are possible.

Table 40.9 Relationship Between Special Input Value and Its Output Value (for hypot_k Operation)

y \ x	−∞	Negative value	−0	+0	Positive value	+∞	SNaN/QNaN
−∞	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN
Negative value	QNaN	—	—	—	—	QNaN	QNaN
−0	QNaN	—	+0*1	+0*1	—	QNaN	QNaN
+0	QNaN	—	+0*1	+0*1	—	QNaN	QNaN
Positive value	QNaN	—	—	—	—	QNaN	QNaN
+∞	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN
SNaN/QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN

Note 1. An input error occurs for the special input value, and the input error flag (TRGSTS.ERRF) is set.

An input error is detected when both of the input values x and y of a fixed-point hypot_k calculation are 0, even for the values other than 0 in 32-bit fixed-point format that are handled as 0 by the TFU. The reason is that such values cause errors in atan calculations although hypot_k calculations are possible. The output value of a hypot_k calculation is 0 when an input error has occurred.

40.4 Usage Procedures

40.4.1 Procedures for Using the TFU

There are two procedures for reading the result of an operation: reading the data register after the operation is completed (Procedure 1) and reading the data register without waiting for the operation to be completed (Procedure 2). Table 40.10 shows the advantages and disadvantages of each procedure. Figure 40.2 shows the procedures for sincos operations and Figure 40.3 shows the procedures for atanhypot_k operations. Read SCDTn (n = 0, 1) in Figure 40.2 as FPSCDTn and FXSCDTn in the case of floating-point sincos operations and fixed-point sincos operations, respectively. Read ATDTn in Figure 40.3 as FPATDTn and FXATDTn in the case of floating-point atanhypot_k operations and fixed-point atanhypot_k operations, respectively.

Table 40.10 Advantages and Disadvantages of Procedures for Sincos and Atanhypot_k Operations

Method	Advantages	Disadvantages
Procedure 1: reading the data register after the operation is completed	The bus is not occupied.	Detecting completion of a calculation by checking the TRGSTS.BSYF flag is required.
Procedure 2: reading the data register without waiting for the operation to be completed	Detecting completion of a calculation by checking the TRGSTS.BSYF flag is not required, resulting in fewer cycles being required for execution.	The bus is occupied until completion of the calculation.

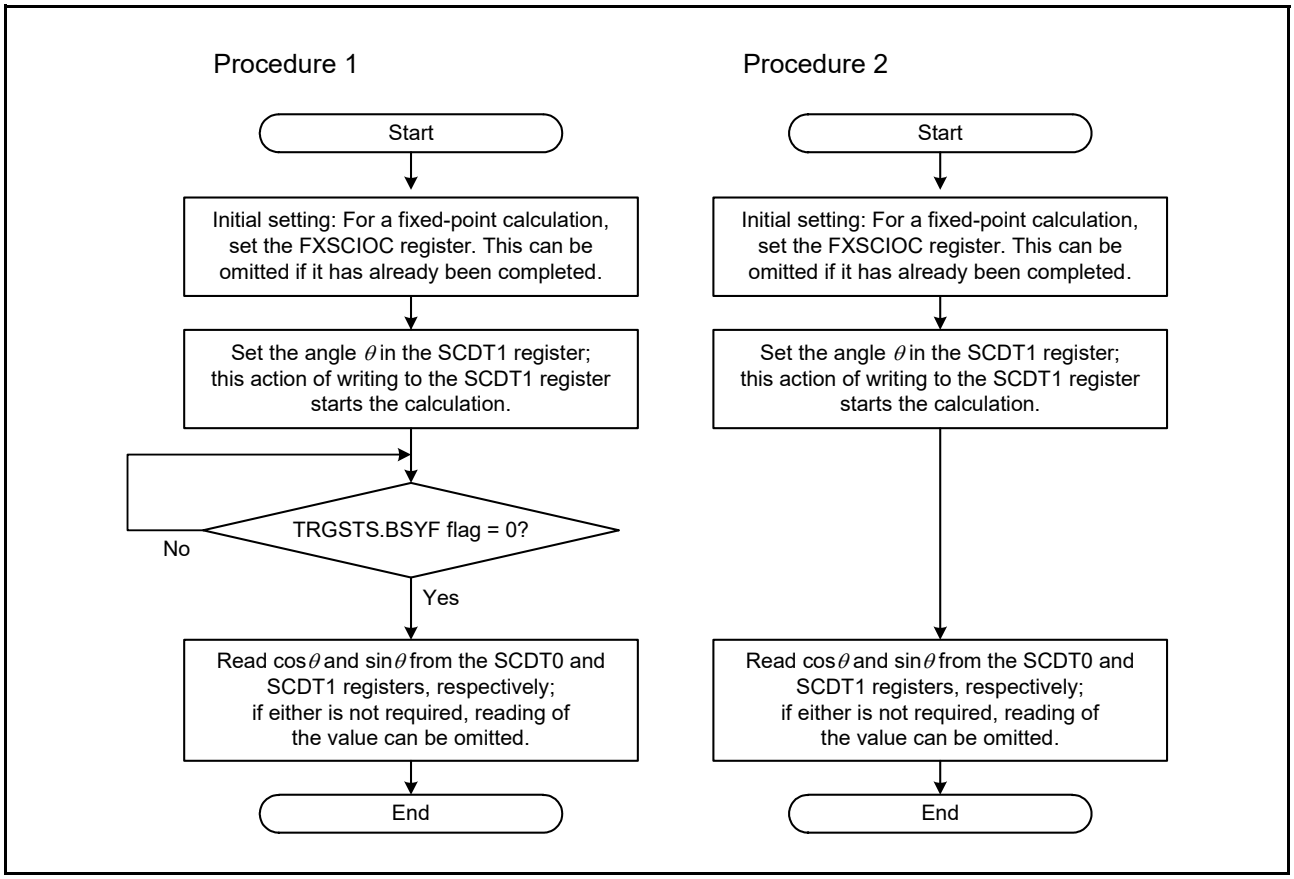

Figure 40.2 Procedure for Using TFU (Sincos Operation)

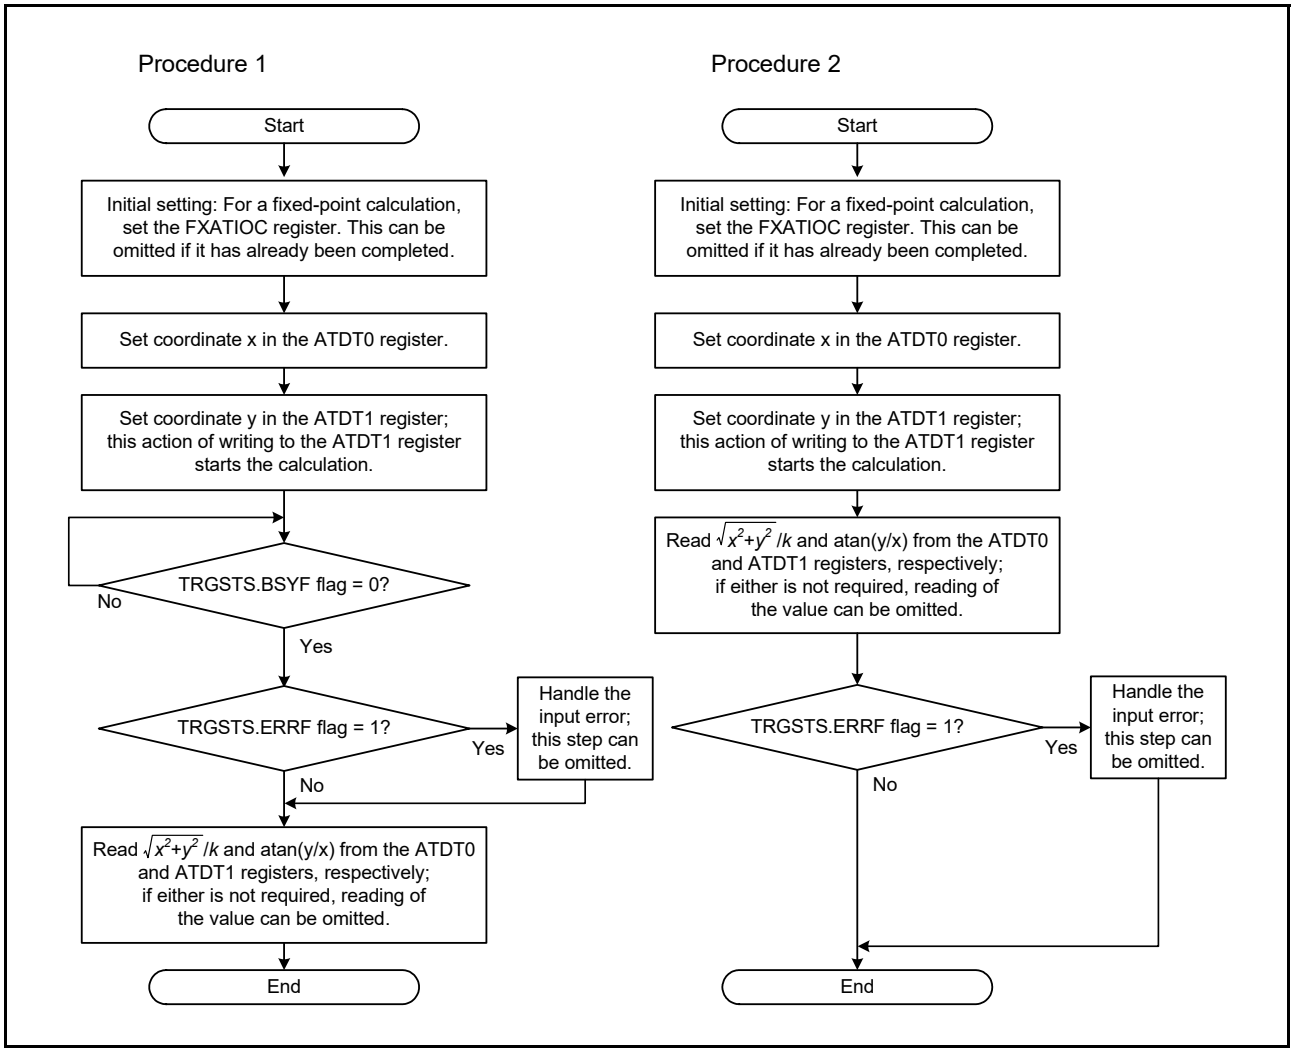

Figure 40.3 Procedure for Using TFU (Atanhypot_k Operation)

40.4.2 How to Use Interrupts

If an interrupt is accepted in the following order, the values stored in the data registers and the error flag prior to the acceptance of the interrupt may become incorrect in terms of the software after execution is returned from the interrupt handler.

1. The interrupt is accepted between writing to the data registers and reading of the data registers and the error flag during any of the procedures described in section 40.4.1, Procedures for Using the TFU.
2. The TFU is used to execute any calculation in the handler.

Accordingly, avoid such incorrect operation when, for example, using the TFU with multiple interrupts and their handlers by taking either of the following measures.

(1) Disabling interrupts that otherwise may disrupt processing between writing to the data registers and reading of the data registers and the error flag

(2) Saving and restoring data registers and the error flag in interrupt handlers that may disrupt processing*1, *2

Note 1. Regardless of the type of operation executed in the interrupt handler or the type of operation executed before accepting an interrupt, use the DTSR0, DTSR1, and TRGSTS registers to save and restore data registers and error flags. Figure 40.4 shows the save/restore procedure in an interrupt handler. By following this procedure, after returning from the interrupt handler, the processing that was being performed before accepting the interrupt can be continued without malfunctioning.

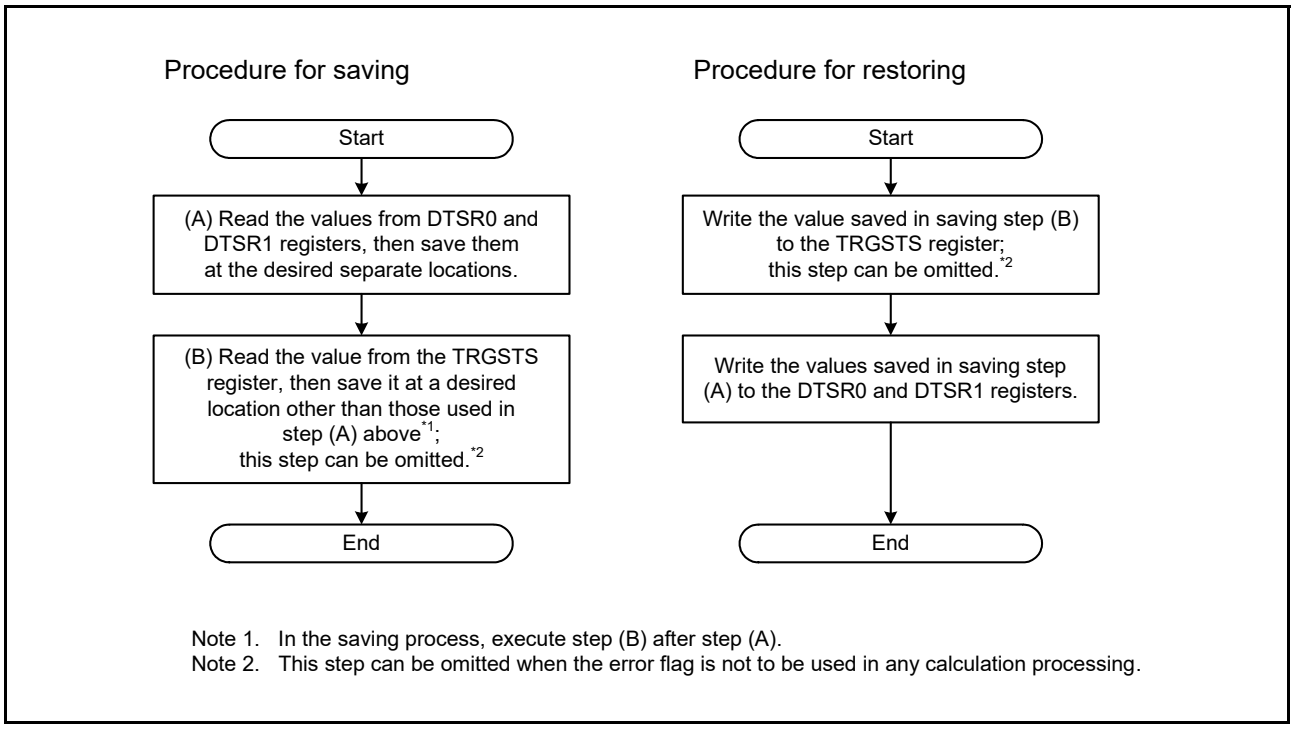

Figure 40.4 Procedures for Saving and Restoring in Interrupt Handlers

Note 2. As well as the data registers and the error flag, interrupt handlers that may change the values of the setting registers (FXSCIOC and FXATIOC) also require saving and restoring of the setting register values. Accordingly, save and restore the values of the setting registers as required. Saving of the setting registers must be executed after step (A) of the saving process in Figure 40.4.

41. Trusted Secure IP (TSIP-Lite)

This MCU incorporates a Trusted Secure IP Lite (TSIP-Lite) module to provide security functions. The module consists of an access management circuit, encryption engine, and random number generator. In combination with the TSIP-Lite library, the TSIP-Lite can prevent eavesdropping (confidentiality), falsification of information (integrity), and impersonation (authenticity).
Key information to be used in encrypting and decrypting data is only stored within the TSIP-Lite, and any external access can be shut out to obtain a system with strong security.

41.1 Overview

Table 41.1 summarizes the specifications of the TSIP-Lite. Figure 41.1 shows a block diagram of the TSIP-Lite.

Table 41.1 Specifications of TSIP-Lite

Item	Description
Access control	Access management circuit • In case of irregular access to the TSIP-Lite due to a falsified program or runaway execution of a program, this circuit blocks all subsequent access and stops the output of data from the TSIP-Lite.
Encryption engine	AES: Compliant with NIST FIPS PUB 197 algorithm • Key sizes: 128 or 256 bits • Block sizes: 128 bits • Block cipher mode of operation ECB, CBC, CTR: Compliant with NIST SP 800-38A CMAC: Compliant with NIST SP 800-38B CCM: Compliant with NIST SP 800-38C GCM: Compliant with NIST SP 800-38D XTS: Compliant with NIST SP 800-38E GCTR • Number of cycles for execution*1 ECB, CBC, CTR, CMAC, GCTR, XTS: 44 cycles of PCLKB for 128-bit keys, 61 cycles of PCLKB for 256-bit keys CCM: 88 cycles of PCLKB for 128-bit keys AES-GCM • AES-GCM is realized by combining AES-GCTR and GHASH. Key management • Keys are only valid within the TSIP-Lite. • Only key generation information is output from the TSIP-Lite. • Keys can be regenerated by the input of key generation information to the TSIP-Lite. Endian • Big or little
Generation of random numbers	32-bit true random number generator • The TSIP-Lite library can assemble 32-bit true random numbers to generate 128- or 256-bit true random numbers. • The generated 128-bit and 256-bit true random numbers are used as keys in encrypting and decrypting data.
Protection against illicit key copying	• An ID unique to the MCU (unique ID) is accessible from the access management circuit through the dedicated bus. • Combining the unique ID with the key generation information prevents the illicit copying of the key to another MCU.
Supervisor mode	• The supervisor mode signal is connected to the access management circuit and is used to limit control of the TSIP-Lite module to supervisor mode only.
Interrupt sources	Three These can be used as triggers for data transfer by the DMAC or DTC.
Low power consumption	Setting of the module stop state is possible.

Note 1. This does not include the overhead for calling functions of the TSIP-Lite library.

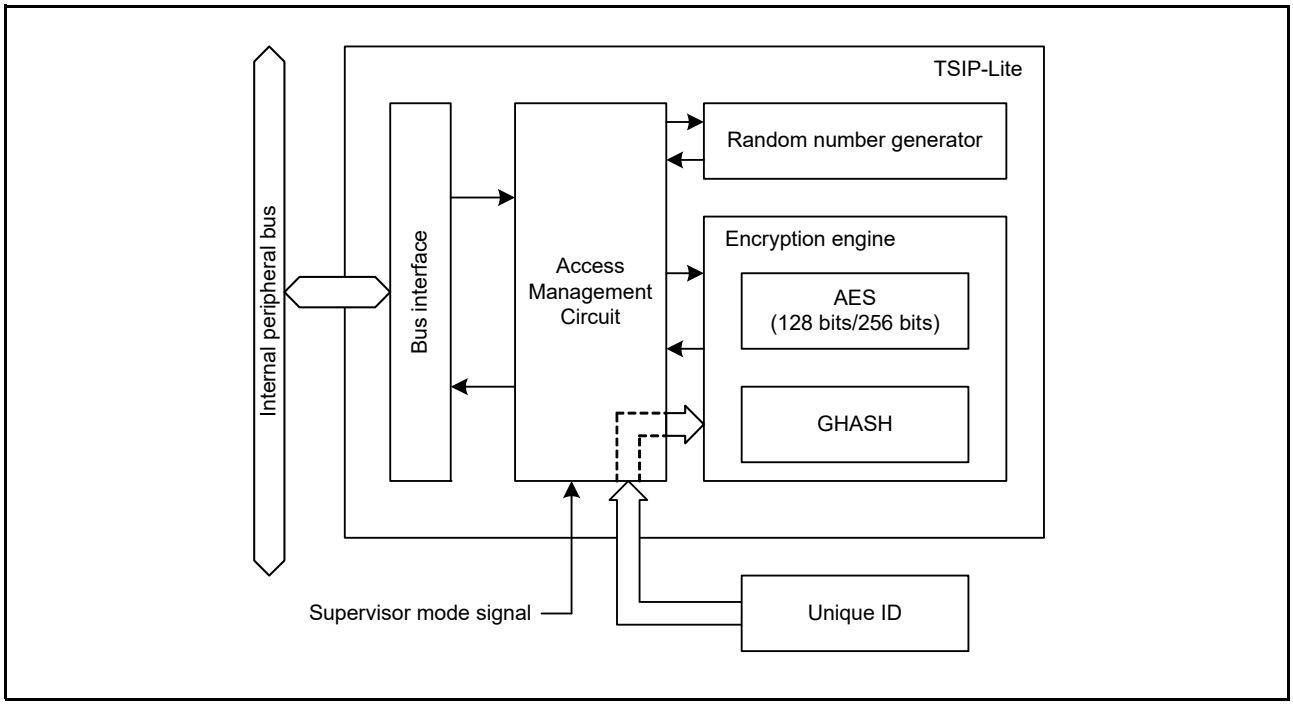

Figure 41.1 TSIP-Lite Block Diagram

41.2 Operation

41.2.1 Operating Modes and State Transitions

Figure 41.2 shows the state transitions of the TSIP-Lite.
Use of the TSIP-Lite security functions is only possible through use of the TSIP-Lite library provided by Renesas Electronics, in accordance with the state transitions as shown in the figure below.
When irregular access to the TSIP-Lite (access that violates the defined procedure) due to a falsified program or a program entering runaway execution, etc. is attempted, the access management circuit does not accept any subsequent access and stops the output of any data from the TSIP-Lite.

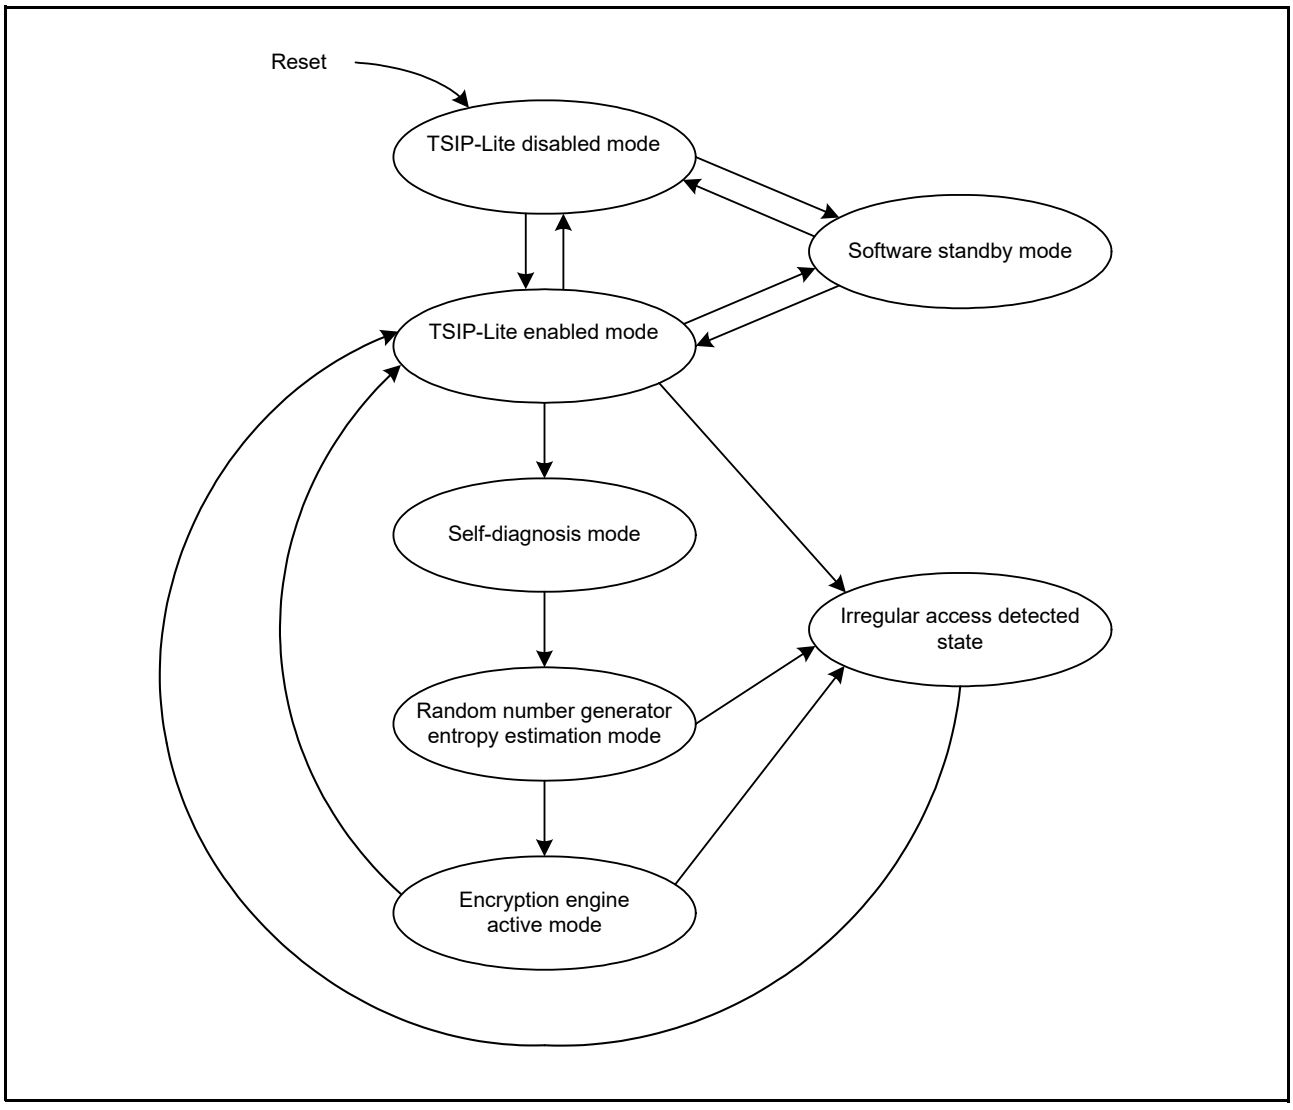

Figure 41.2 TSIP-Lite Operating Modes and State Transitions

Many of the security functions that the TSIP-Lite offers are applicable only in the encryption engine active mode. The operations that can be performed in this mode are given below.

(1) Key Installation
(2) Encryption and decryption
(3) Key generation
(4) Random number generation

41.2.2 Encryption Engine

Figure 41.3 shows processes of the encryption engine integrated in the TSIP-Lite.
The encryption engine, using the key generation information, performs plaintext to ciphertext encryption and ciphertext to plaintext decryption by hardware.
In no part of the encryption or decryption process, is key data or intermediate data ever exposed outside of the TSIP-Lite.

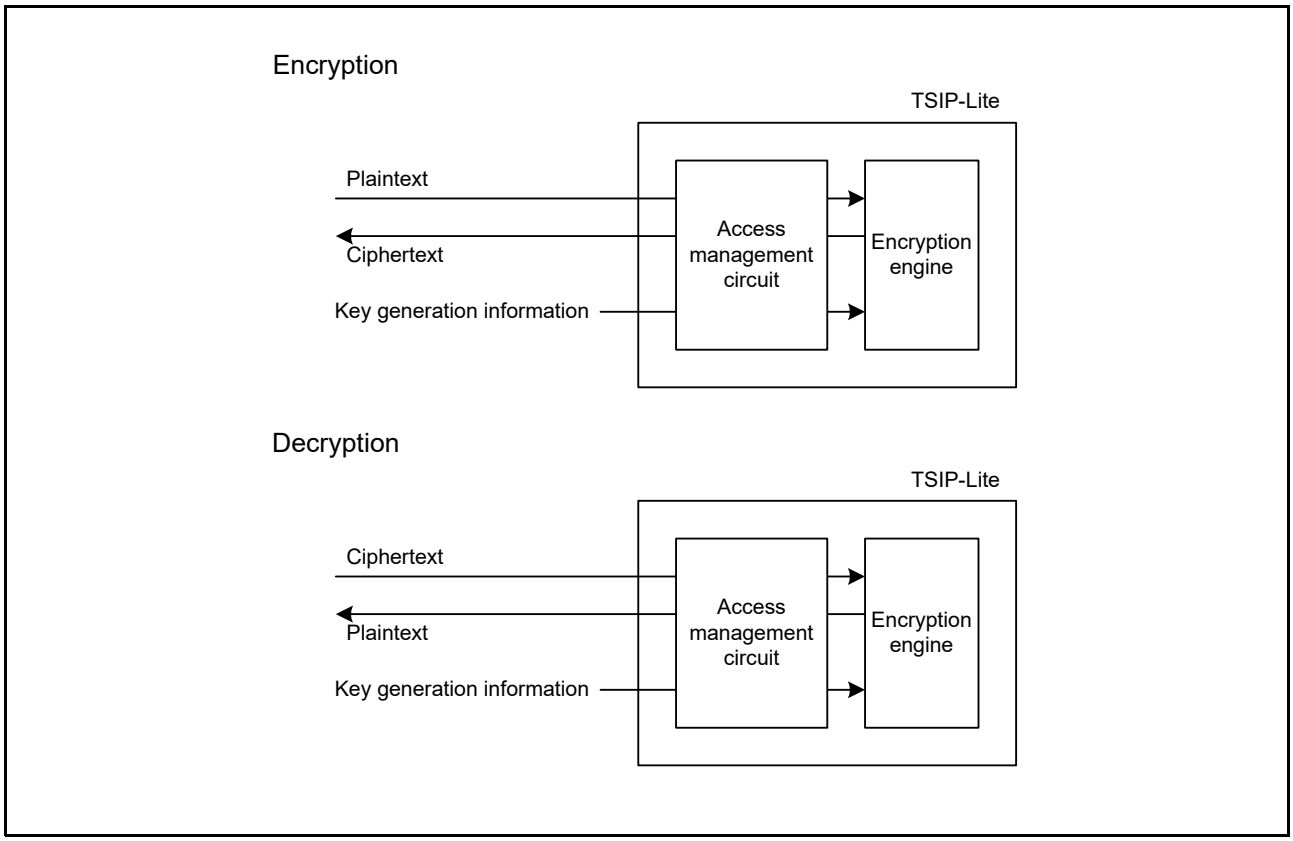

Figure 41.3 Encryption and Decryption processes by Encryption Engine

41.2.3 Key Installation

The key installation is the operation that safely converts the user key to the key generation information and stores it in flash memory. The procedure for installing the key data are given below.

(1) The user uses the key (Key-2) used for encrypting the user key to encrypt the user key (Key-1) producing eKey-1.
(2) The user sends the encrypted user key (eKey-1) to the TSIP-Lite over the serial interface.
(3) The key generation information of the Key-2 (Index-2) contained in the TSIP-Lite library is used to recover the Key-2, which is then used to decrypt the user key.
(4) The user key is converted to user key generation information (Index-1) using the unique ID and a random number, and stored in flash memory.

The installation process and flow chart are given in Figure 41.4 and Figure 41.5, respectively.
Once the key data is installed, the user key generation information (Index-1) can then be used to perform encryption or decryption.

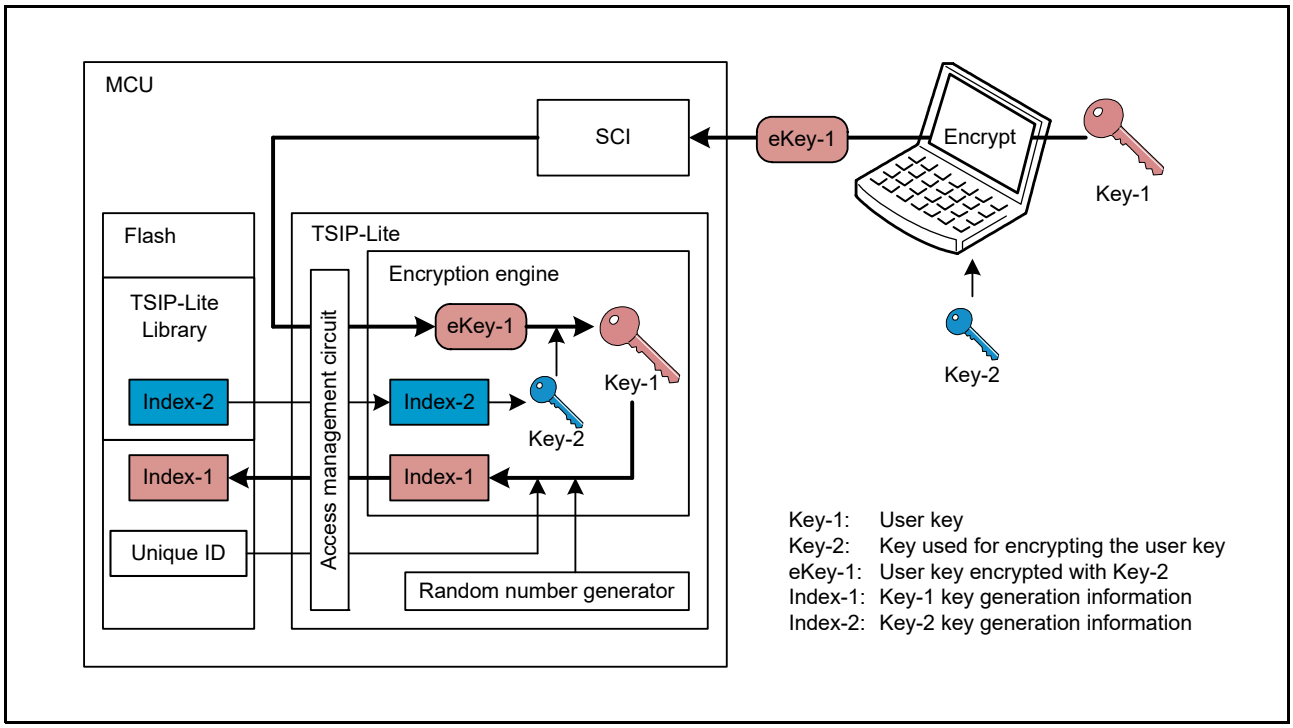

Figure 41.4 Key Installation Process

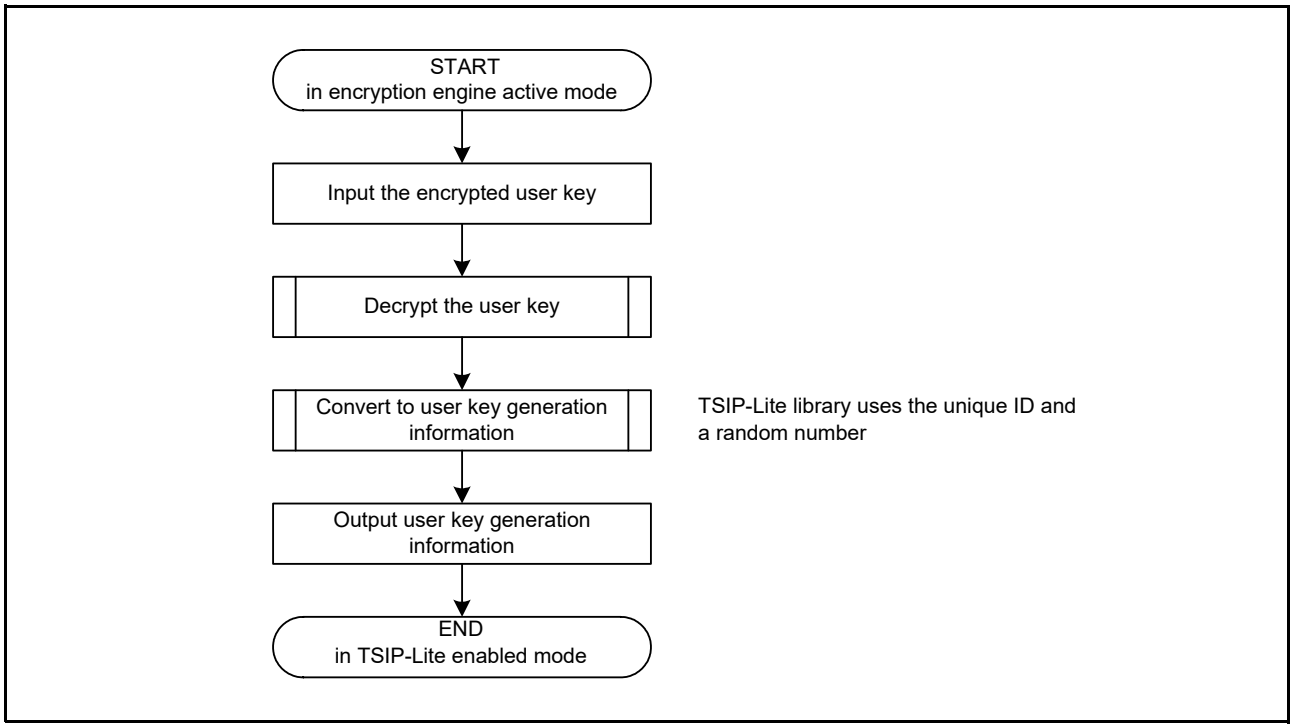

Figure 41.5 Key Installation Flow Chart

41.2.4 Encryption and Decryption

The procedures for encrypting and decrypting data are given below.

(1) Input the key generation information into the TSIP-Lite, and recover the key data.
(2) Input the data to encrypt or decrypt into the TSIP-Lite. This converts plaintext into ciphertext, and ciphertext into plaintext.
(3) Read the converted data.

The encryption engine has an input buffer and an output buffer, enabling encryption/decryption to proceed in parallel with data input/output.
Figure 41.6, Figure 41.7, and Figure 41.8 show the timing diagram, encryption flow, and decryption flow, respectively.

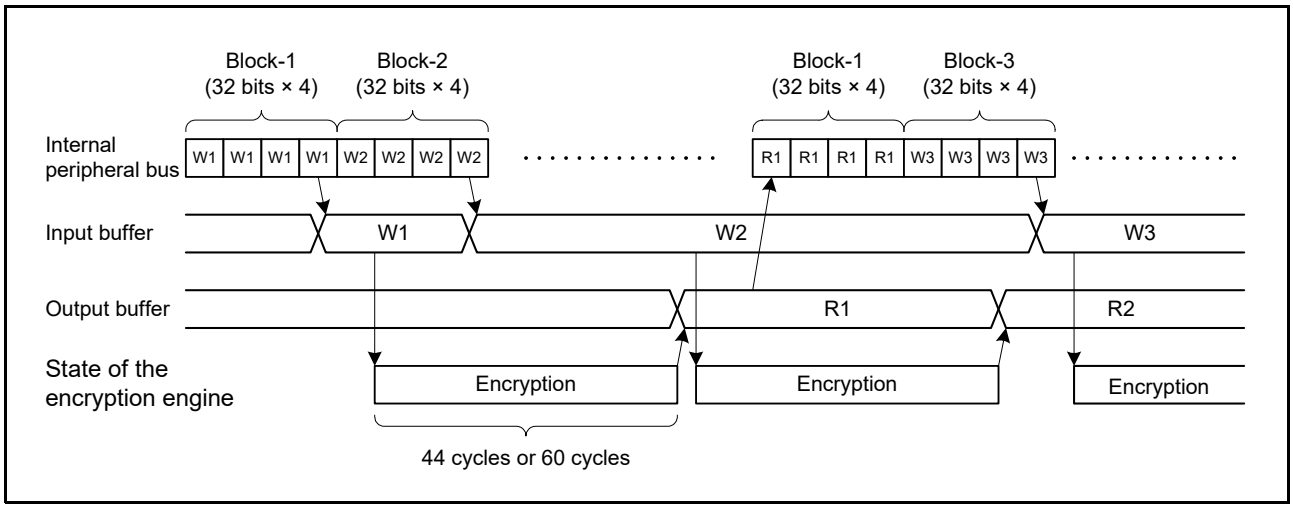

Figure 41.6 Encryption and Decryption Timing Diagram

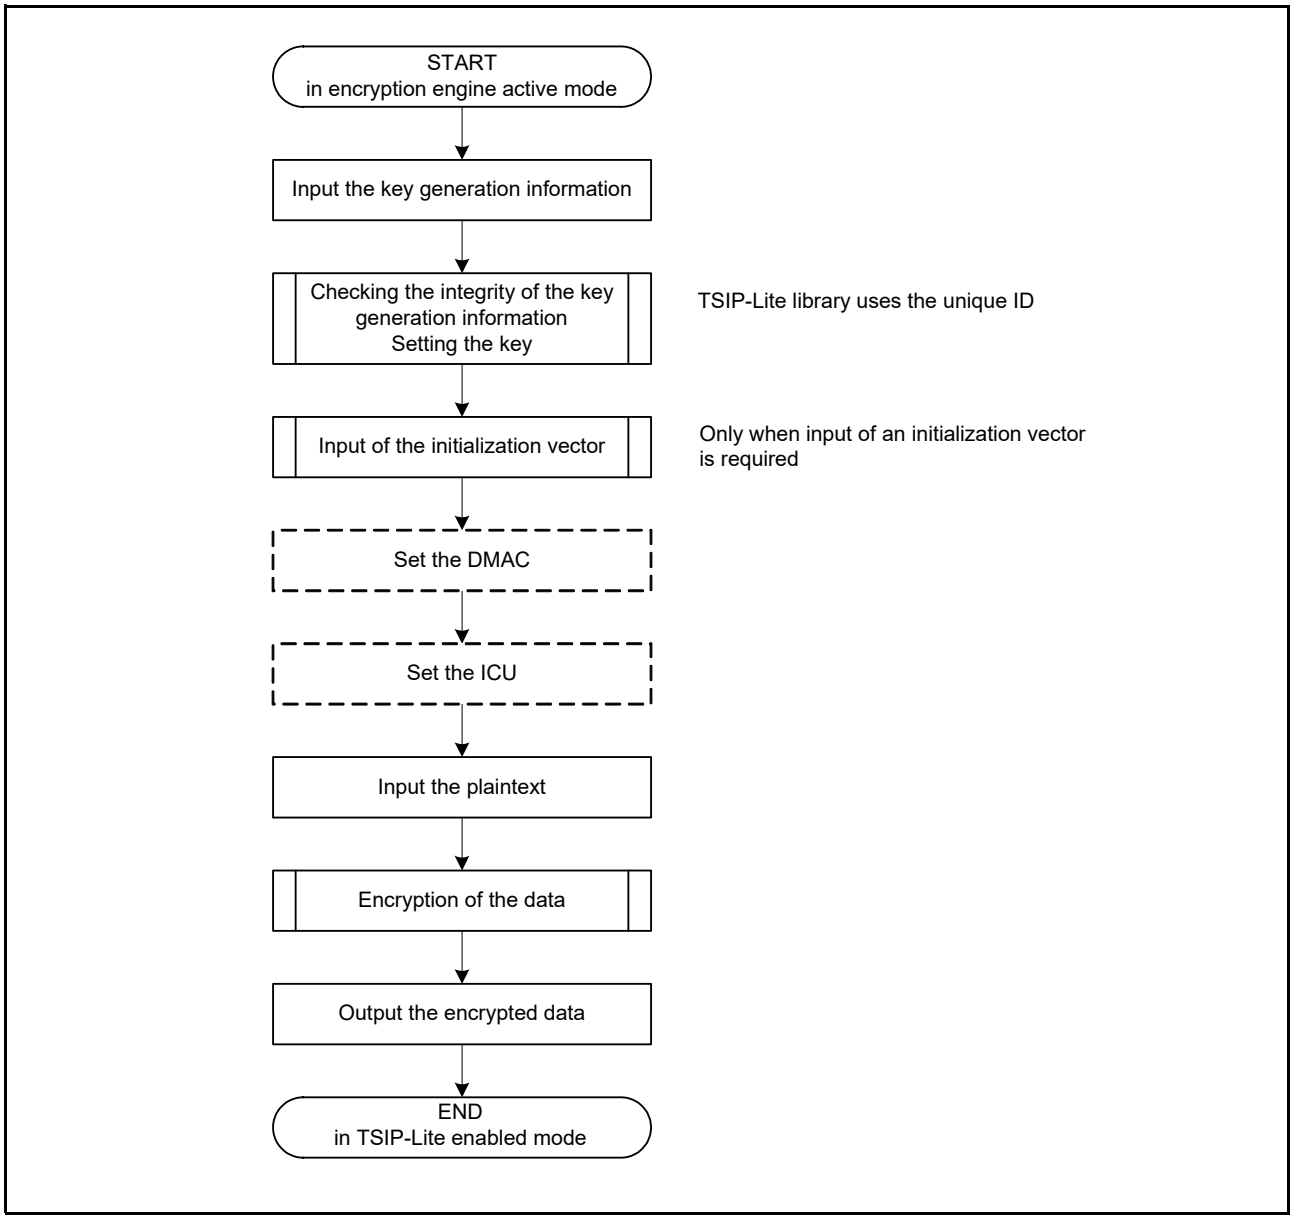

Figure 41.7 Encryption Flow Chart

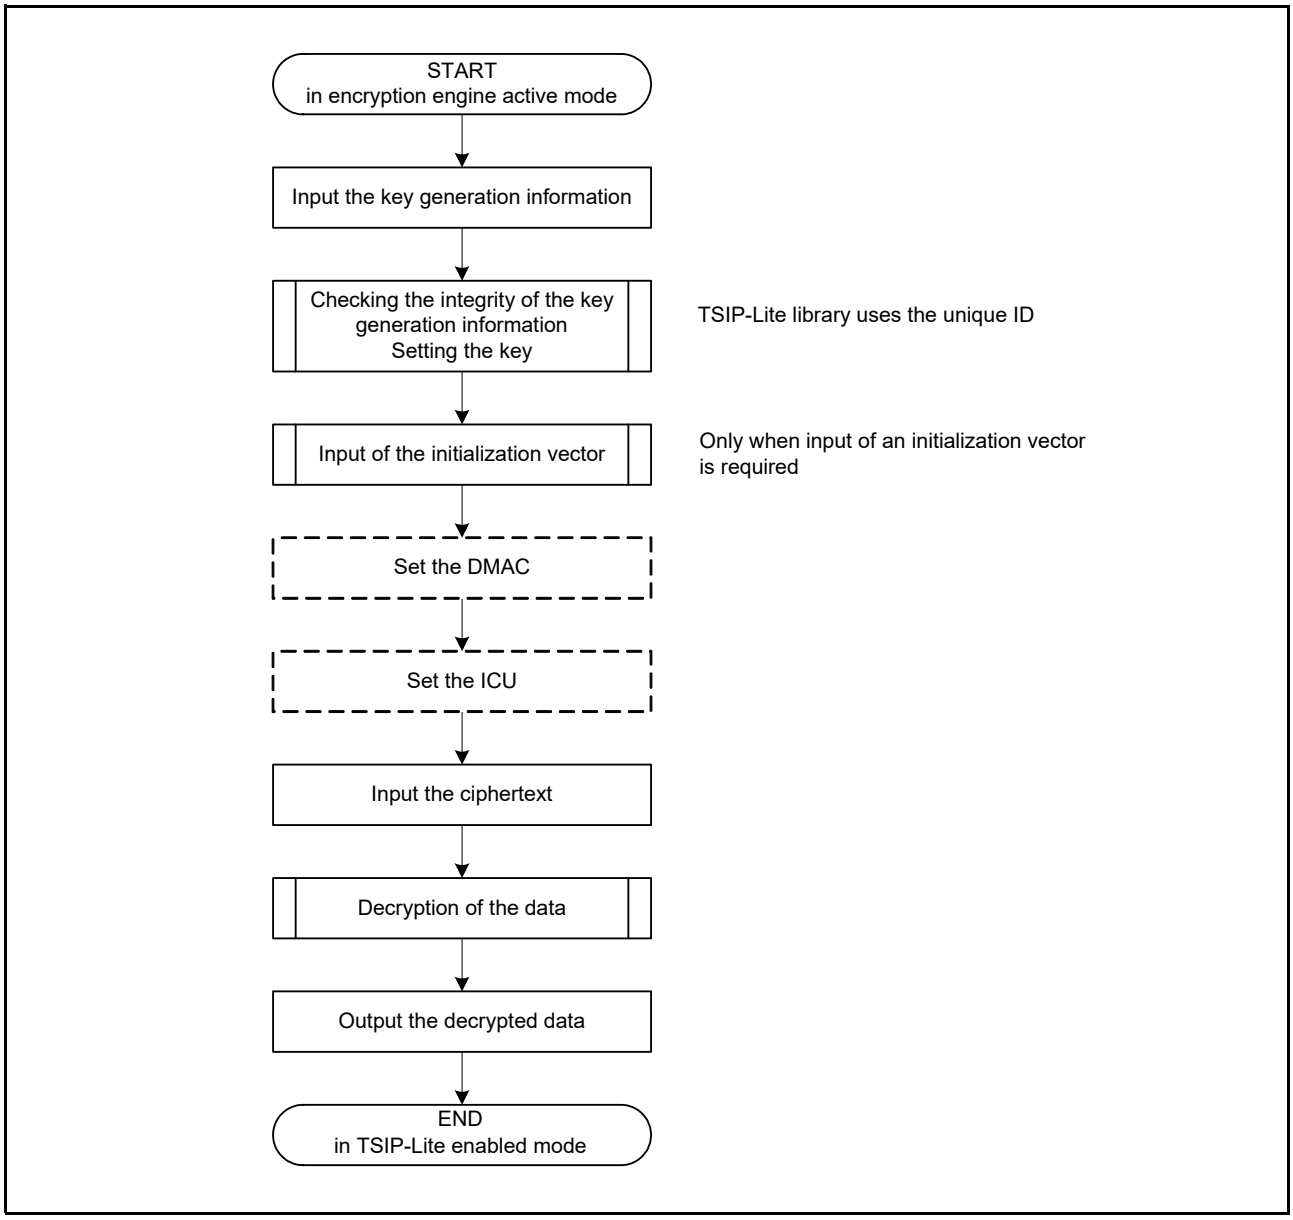

Figure 41.8 Decryption Flow Chart

41.2.5 Generating Key Generation Information (by Using Random Numbers)

Figure 41.9 shows the generating flow for the key generation information by using random numbers.

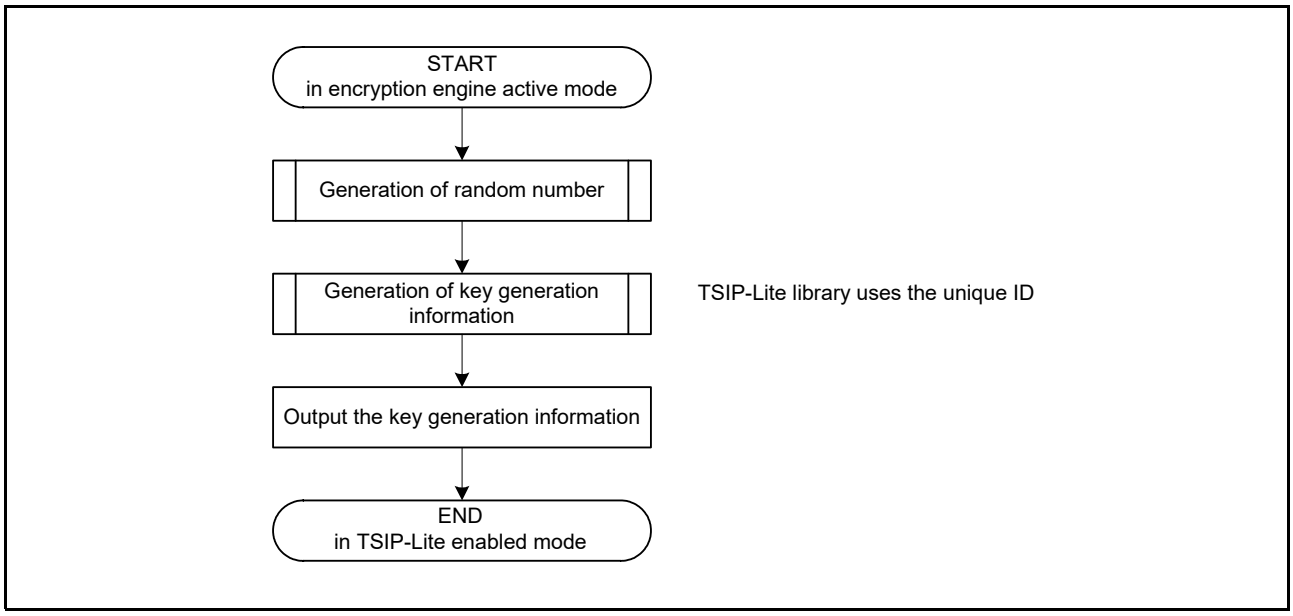

Figure 41.9 Key Generation Information Generating Flow Chart (Using Random Numbers)

41.2.6 Random Number Generation

Figure 41.10 shows the random number generation flow.

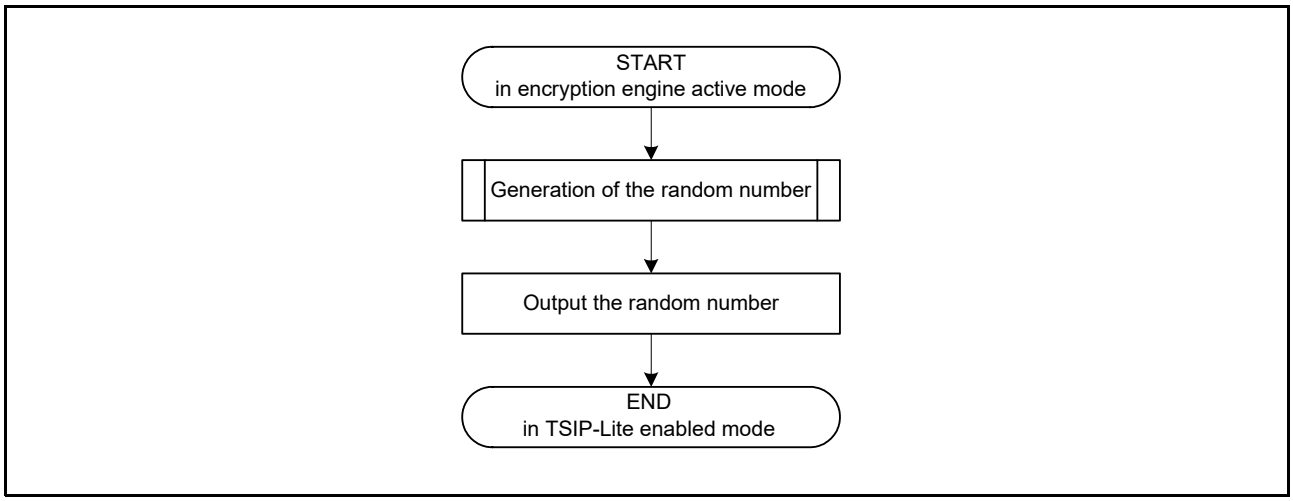

Figure 41.10 Random Number Generation Flow Chart

41.3 Interrupt

Table 41.2 lists the interrupt sources.
TSIP-Lite library uses interrupts caused by these interrupt sources. Do not set the ICU.IERm.IENj bits corresponding to these interrupt sources to 0.

Table 41.2 TSIP-Lite Interrupt Sources

Name	Interrupt Source	DTC Triggerable	DMAC Triggerable
RD	Data read ready	Yes	Yes
WR	Data write ready	Yes	Yes
Error	Illegal access detected	No	No

41.4 Usage Notes

41.4.1 Standby Mode

When standby mode is entered while the encryption engine is in processing, proper processing cannot be resumed after standby mode is exited. Standby mode should therefore be entered only after first entering TSIP-Lite disabled mode or TSIP-Lite enabled mode.

41.4.2 Setting the Module Stop Function

The module stop control register D (MSTPCRD) enables or disables operation of the TSIP-Lite. After a reset, the TSIP-Lite is stopped. After exiting the module stop state, the TSIP-Lite can be accessed. Refer to section 11, Low Power Consumption for details.

41.4.3 TSIP-Lite Library

Use of the TSIP-Lite requires the TSIP-Lite library provided by Renesas Electronics. Please contact our sales office for information regarding the TSIP-Lite library.

42. 12-Bit A/D Converter (S12ADHa)

42.1 Overview

This MCU has up to three units of 12-bit successive approximation A/D converters (S12AD, S12AD1, S12AD2).
The 12-bit A/D converter converts analog input of the selected channels, temperature sensor output, or internal reference voltage into a 12-bit digital value through successive approximation.
The A/D converter has three operating modes: single scan mode in which the arbitrarily selected analog inputs are converted in ascending channel order; continuous scan mode in which the arbitrarily selected analog inputs are continuously converted in ascending channel order; and group scan mode in which the arbitrarily selected analog inputs are arbitrarily divided into two groups (groups A and B) or three groups (groups A, B, and C) and converted in ascending channel order in each group.
In group scan mode, either two groups (groups A and B) or three groups (groups A, B, and C) is selected.
The conditions for scanning start of each group (A, B, and C) (synchronous trigger) can be independently selected, thus allowing A/D conversion of each group to be started independently.
During group priority operation, in addition to the above-mentioned operation, a trigger to start scanning for the priority group is accepted during scan for the low-priority group, and scan for the priority group is started after scan for the low-priority group was interrupted. The priority order is group A > group B > group C. Accordingly, as priority operation, when a trigger to start scanning for group B is accepted during scan for group C, group C scan is interrupted, and scan for group B is started. Likewise, when a trigger to start scanning for group A is accepted during scan for group C, group C scan is interrupted and scan for group A is started. In the same way, when a trigger to start scanning for group A is accepted during scan for group B, group B scan is interrupted and scan for group A is started.
The interrupted scan operation can be restarted after the scanning of the priority group is completed.
In double trigger mode, one analog input channel arbitrarily selected is converted in single scan mode or group scan mode (group A), and the resulting data of A/D conversion started by the first and second synchronous triggers are stored into different registers (duplication of A/D conversion data).
Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages internally generated in the 12-bit A/D converter is converted.
The temperature sensor output or internal reference voltage can be selected in single scan mode and group scan mode. A/D conversion is performed on the temperature sensor output prior to internal reference voltage when both the temperature sensor output and internal reference voltage are selected.
The temperature sensor output or internal reference voltage cannot be selected in continuous scan mode.
The MCU incorporates the comparison function (with windows A and B). In addition, the value of A/D conversion and the reference value of the low side can be compared by a comparator.
Table 42.1 lists the specifications of the 12-bit A/D converter and Table 42.2 lists the functions of the 12-bit A/D converter. Figure 42.1 to Figure 42.4 show block diagrams of the 12-bit A/D converter.

Table 42.1 Specifications of 12-Bit A/D Converter (1/2)

Item	Description
Number of units	Three units (S12AD, S12AD1, and S12AD2) (products with 64 Kbytes of RAM) Two units (S12AD and S12AD2) (products with 48 Kbytes of RAM)
Input channels	Four channels for S12AD, four channels for S12AD1, and 14 channels for S12AD2 (products with 64 Kbytes of RAM) Seven channels for S12AD and eight channeld for S12AD2 (products with 48 Kbytes of RAM)
Extended analog function	Temperature sensor output, internal reference voltage (S12AD2 only)
A/D conversion method	Successive approximation method
Resolution	12 bits
Conversion time	0.9 µs per channel (when A/D conversion clock ADCLK = 60 MHz)
A/D conversion clock	Peripheral module clock PCLKB*1 and A/D conversion clock ADCLK*1 can be set so that the frequency ratio should be one of the following. PCLKB to ADCLK frequency ratio = 1:1, 2:1, 4:1, 1:2 ADCLK is set using the clock generation circuit. A/D conversion clock (ADCLK) can operate between 8 MHz at a minimum and 60 MHz at a maximum.
Data registers	• One register per channel for analog input, one register per unit for A/D-converted data duplication in double trigger mode, and two registers per unit for A/D-converted data duplication during extended operation in double trigger mode. • One register for temperature sensor (S12AD2) • One register for internal reference (S12AD2) • One register per unit for self-diagnosis • The results of A/D conversion are stored in 12-bit A/D data registers. • The value obtained by adding up A/D-converted results is stored as a value in the number of bit for conversion accuracy + 2 bits/4 bits*2 in the A/D data registers in A/D-converted value addition mode. • Double trigger mode (selectable in single scan and group scan modes): The first piece of A/D-converted analog-input data on one selected channel is stored in the data register for the channel, and the second piece is stored in the duplication register. • Extended operation in double trigger mode (available for specific triggers): A/D-converted analog-input data on one selected channel is stored in the duplication register that is prepared for each type of trigger.
Operating modes	Operating modes can be set individually for each unit. • Single scan mode: A/D conversion is performed only once on the analog inputs arbitrarily selected. A/D conversion is performed only once on the temperature sensor output (S12AD2). A/D conversion is performed only once on the internal reference voltage (S12AD2). • Continuous scan mode: A/D conversion is performed repeatedly on the analog inputs arbitrarily selected. • Group scan mode: Two (groups A and B) or three (groups A, B, and C) can be selected as the number of the groups to be used. (Only the combination of groups A and B can be selected when the number of the groups is two.) Analog inputs, temperature sensor output (S12AD2), and internal reference voltage (S12AD2) that are arbitrarily selected are divided into two groups (group A and B) or three groups (group A, B, and C), and A/D conversion of the analog input selected on a group basis is performed only once. The conditions for scanning start of groups A, B, and C (synchronous trigger) can be independently selected, thus allowing A/D conversion of each group to be started independently. • Group scan mode (when group priority control selected): If a priority-group trigger is input during scanning of the low-priority group, scan of the low-priority group is stopped and scan of the priority group is started. The priority order is group A (highest) > group B > group C (lowest). Whether or not to restart scanning of the low-priority group after processing for the high-priority group completes, is selectable. Rescan can also be set to start either from the beginning of the selected channel or the channel on which A/D conversion is not completed.
Conditions for A/D conversion start	• Software trigger • Synchronous trigger Trigger by the multi-function timer pulse unit (MTU), general PWM timer (GPTW), 8-bit timer (TMR), or event link controller (ELC). • Asynchronous trigger A/D conversion can be triggered by the external trigger ADTRG0# (S12AD), ADTRG1# (S12AD1), or ADTRG2# (S12AD2) pin (individually for each unit).

Table 42.1 Specifications of 12-Bit A/D Converter (2/2)

Item	Description
Functions	• Channel-dedicated sample-and-hold function (three channels each for S12AD and S12AD1) (Constant sampling can be set) • Variable sampling time (can be set per channel) • Self-diagnosis of 12-bit A/D converter • Selectable A/D-converted value addition mode or average mode • Analog input disconnection detection assist function (discharge function/precharge function) • Double trigger mode (duplication of A/D conversion data) • Automatic clear function of A/D data registers • Comparison function (windows A and B) • Order of channel conversion in each unit can be set. • Input signal amplification function by programmable gain amplifier (three channels each for S12AD and S12AD1) (only for products with 64 Kbytes of RAM)
Interrupt sources	• In the modes except double trigger mode and group scan mode, a scan end interrupt request (S12ADI, S12ADI1, or S12ADI2) can be generated on completion of single scan (individually for each unit). • In double trigger mode, a scan end interrupt request (S12ADI, S12ADI1, or S12ADI2) can be generated on completion of double scan (individually for each unit). • In group scan mode, a scan end interrupt request (S12ADI, S12ADI1, or S12ADI2) can be generated on completion of group A scan, whereas a group B scan end interrupt request (S12GBADI, S12GBADI1, or S12GBADI2) can be generated on completion of group B scan, and a group C scan end interrupt request (S12GCADI, S12GCADI1, or S12GCADI2) can be generated on completion of group C scan. • When double trigger mode is selected in group scan mode, an A/D scan end interrupt request (S12ADI, S12ADI1, or S12ADI2) can be generated on completion of double scan of group A, and the corresponding scan end interrupt request (S12GBADI/S12GCADI, S12GBADI1/S12GCADI1, or S12GBADI2/S12GCADI2) can be generated on completion of group B and group C scan. • A compare interrupt request (S12CMPAI, S12CMPAI1, S12CMPAI2, S12CMPBI, S12CMPBI1, or S12CMPBI2) can be generated upon a match with the comparison condition for the digital compare function. • The S12ADI/S12ADI1/S12ADI2, S12GBADI/S12GBADI1/S12GBADI2, and S12GCADI/S12GCADI1/S12GCADI2 interrupts can trigger the DMA controller (DMAC) and data transfer controller (DTC).
Event link	• The event signal is generated when all scans are finished. • The event signal is generated depending on conditions for comparison function window in single scan mode. • Able to start scanning by a trigger from the ELC
Low power consumption function	• Module stop state can be set.*3, *4

Note 1. The peripheral module clock PCLKB frequency is set according to the setting of the SCKCR.PCKB[3:0] bits and the A/D conversion clock ADCLK frequency is set according to the setting of the SCKCR.PCKD[3:0] bits.
Note 2. The number of extended bits during addition differs depending on the addition count.
2-bit extension: 1-time to 4-time conversion (add zero to three times)
4-bit extension: 16-time conversion (add 15 times)
Note 3. Refer to section 11, Low Power Consumption for details.
Note 4. Wait for 1 µs or longer to start A/D conversion after release from the module stop state.

Table 42.2 Functions of 12-Bit A/D Converter (1/3)

Item			Pin Name, Abbreviation

Channel-dedicated sample-and-hold function		Target channels	AN000 to AN002	AN100 to AN102	—
Interrupts			S12ADI, S12GBADI, S12GCADI, S12CMPAI, S12CMPBI interrupt	S12ADI1, S12GBADI1, S12GCADI1, S12CMPAI1, S12CMPBI1 interrupt	S12ADI2, S12GBADI2, S12GCADI2, S12CMPAI2, S12CMPBI2 interrupt
Setting of module stop function*1, *2			MSTPCRA.MSTPA17 bit	MSTPCRA.MSTPA16 bit	MSTPCRA.MSTPA23 bit

Note: When setting an A/D conversion start trigger to ADTRG0#, ADTRG1#, or ADTRG2#, set the pin mode control bit in the port mode register for the corresponding pin to 1 (peripheral functions), and set the pin function select bit in the pin function control register to ADTRG0#, ADTRG1#, or ADTRG2#. Refer to section 20, I/O Ports and section 21, Multi-Function Pin Controller (MPC) for details.

Note 1. Refer to section 11, Low Power Consumption for details.

Note 2. Wait for 1 µs or longer to start A/D conversion after release from the module stop state.

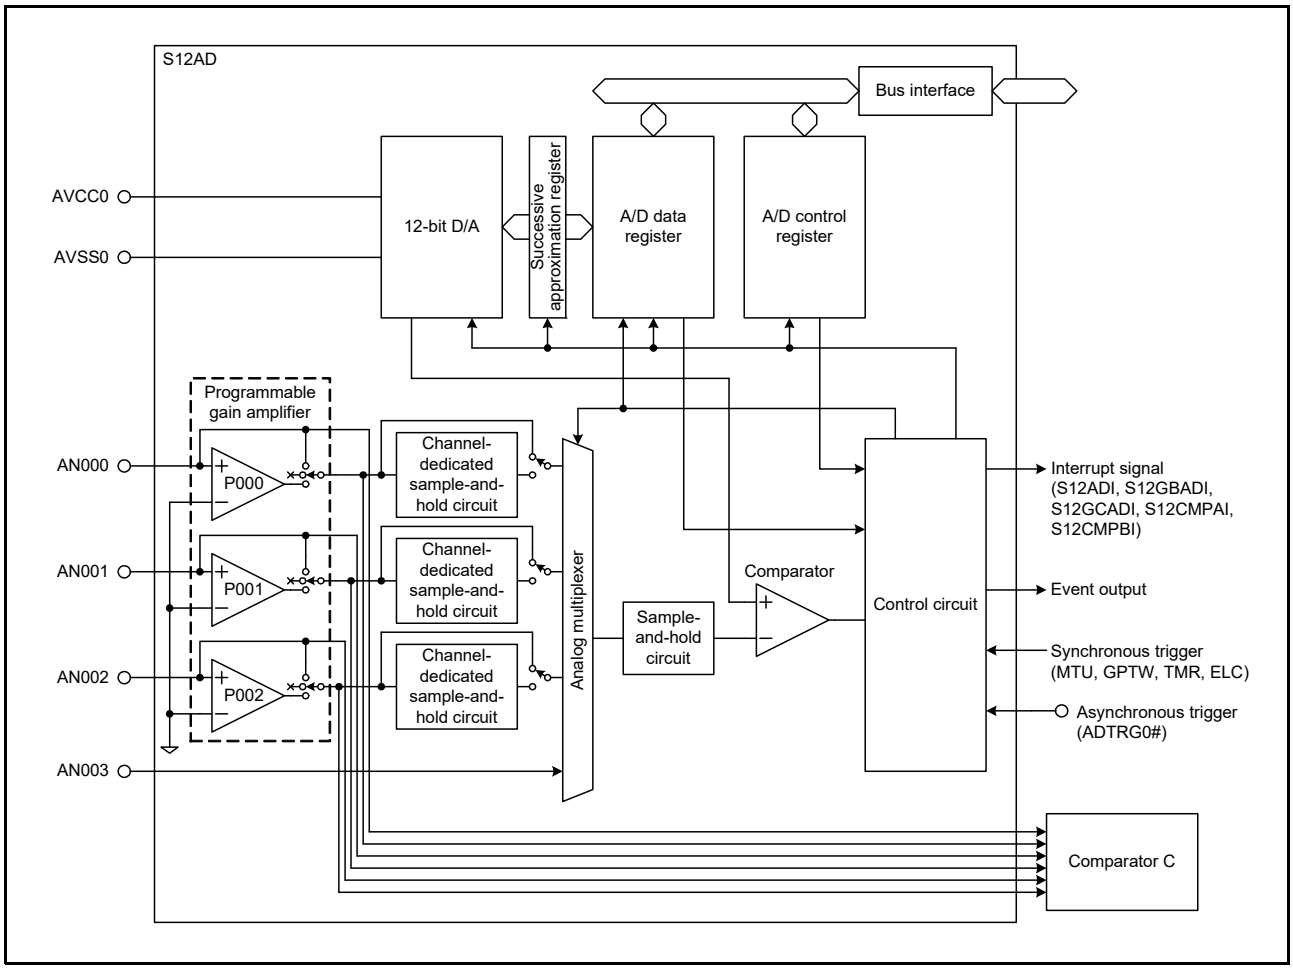

Figure 42.1 Block Diagram of 12-Bit A/D Converter (Products with 64 Kbytes of RAM, Unit 0)

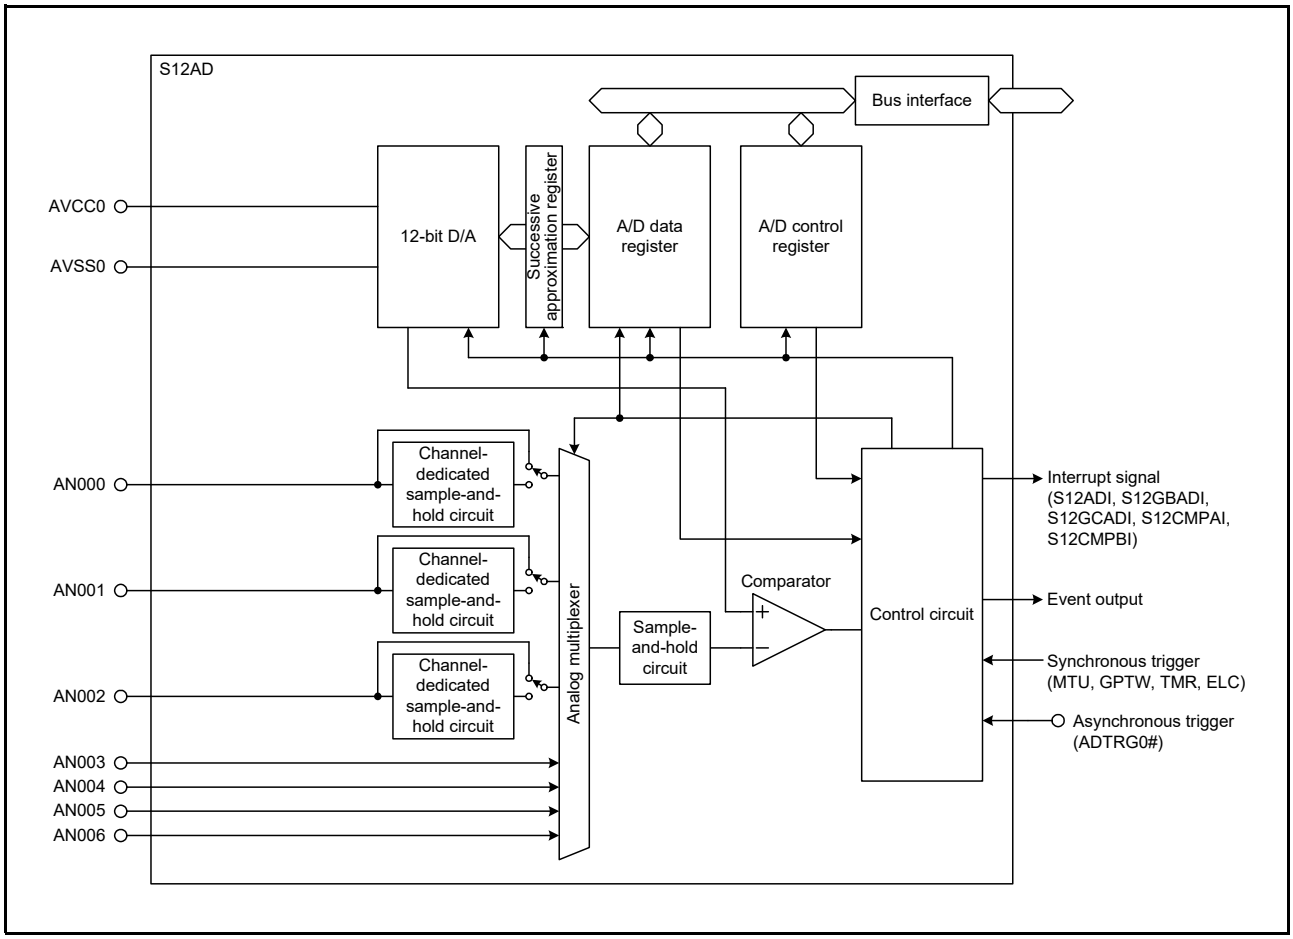

Figure 42.2 Block Diagram of 12-Bit A/D Converter (Products with 48 Kbytes of RAM, Unit 0)

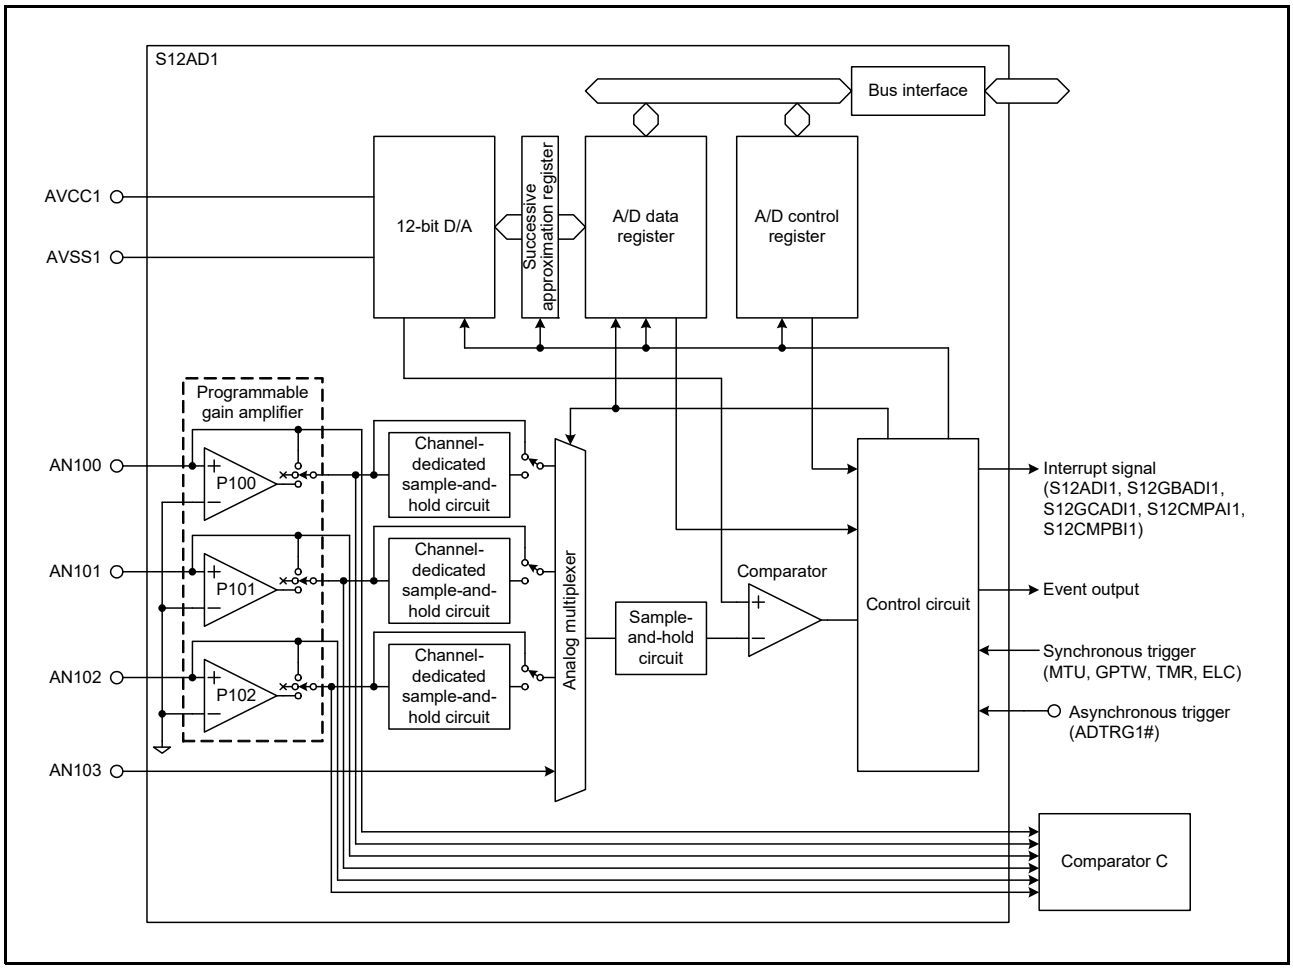

Figure 42.3 Block Diagram of 12-Bit A/D Converter (Products with 64 Kbytes of RAM, Unit 1)

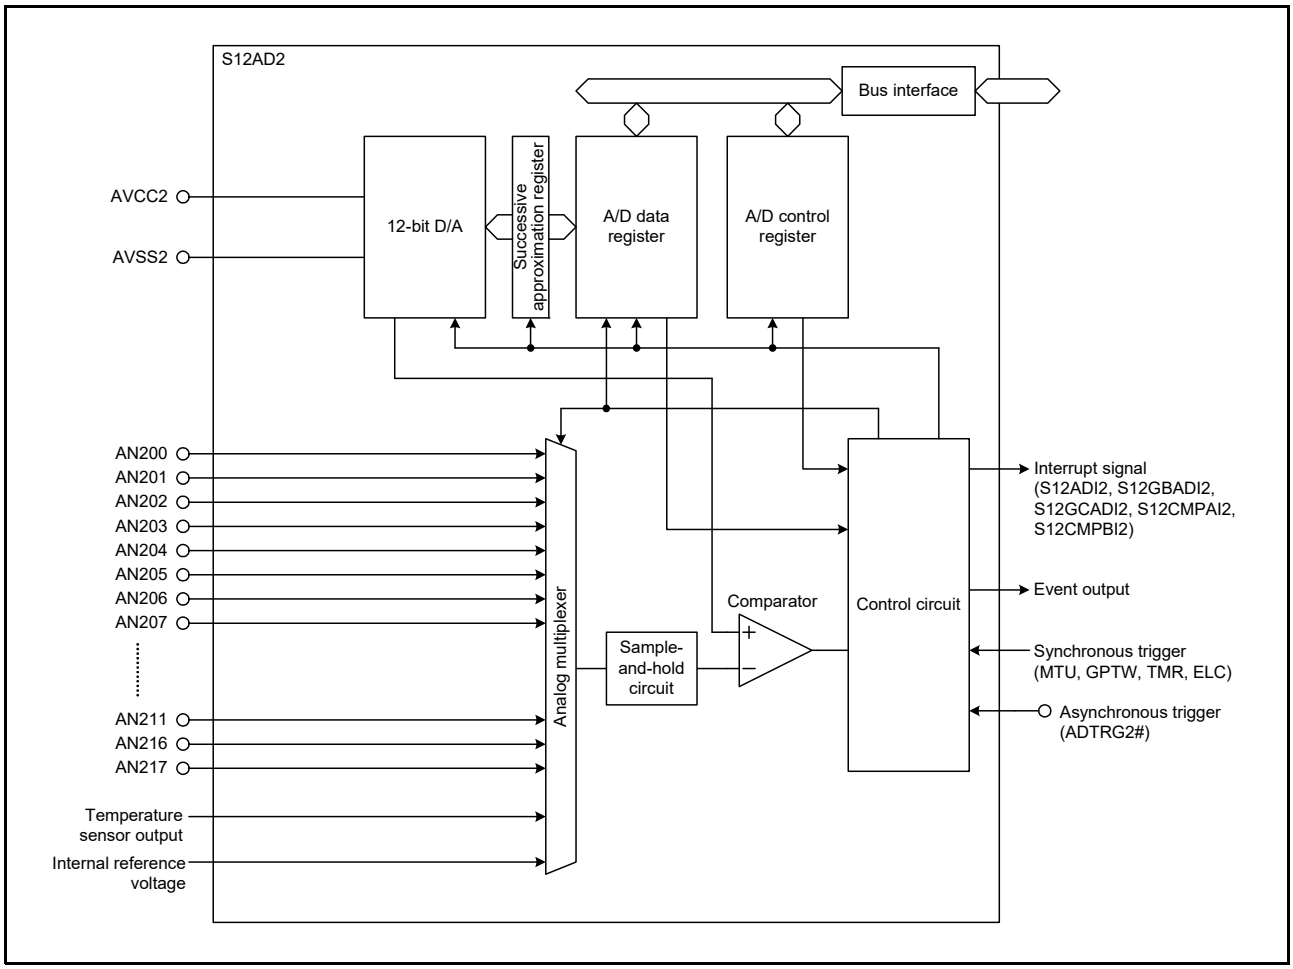

Figure 42.4 Block Diagram of 12-Bit A/D Converter (Unit 2)

Table 42.3 lists the input/output pins of the 12-bit A/D converter.

There are three 12-bit A/D converter units, unit 0 (S12AD), unit 1 (S12AD1), and unit 2 (S12AD2), with operation independent of each other. The input channels of S12AD, S12AD1, and S12AD2 can be divided into three groups for operation.

Table 42.3 Input/Output Pins of 12-Bit A/D Converter

Unit	Pin Name	I/O	Function
Unit 0 (S12AD)	AVCC0	—	Analog power supply pin
	AVSS0	—	Analog ground pin
	AN000 to AN006	Input	Analog input pins
	ADTRG0#	Input	External trigger input pin for starting A/D conversion
	ADST0	Output	Output pin for state of the ADST bit
Unit 1 (S12AD1)	AVCC1	—	Analog power supply pin
	AVSS1	—	Analog ground pin
	AN100 to AN103	Input	Analog input pins
	ADTRG1#	Input	External trigger input pin for starting A/D conversion
	ADST1	Output	Output pin for state of the ADST bit
Unit 2 (S12AD2)	AVCC2	—	Analog power supply pin
	AVSS2	—	Analog ground pin
	AN200 to AN211, AN216, AN217	Input	Analog input pins
	ADTRG2#	Input	External trigger input pin for starting A/D conversion
	ADST2	Output	Output pin for state of the ADST bit

42.2 Register Descriptions

Products with 48 Kbytes of RAM do not have unit 1 (S12AD1). Do not access the registers in unit 1.

42.2.1 A/D Data Registers y (ADDRy) (y = 0 to 11, 16, 17), A/D Data Duplication Register (ADDBLDR), A/D Data Duplication Register A (ADDBLDRA), A/D Data Duplication Register B (ADDBLDRB), A/D Temperature Sensor Data Register (ADTSDR), A/D Internal Reference Voltage Data Register (ADOCDR)

Address(es): S12AD.ADDR0 0008 9020h, S12AD.ADDR1 0008 9022h, S12AD.ADDR2 0008 9024h, S12AD.ADDR3 0008 9026h, S12AD.ADDR4 0008 9028h, S12AD.ADDR5 0008 902Ah, S12AD.ADDR6 0008 902Ch, S12AD.ADDBLDR 0008 9018h, S12AD.ADDBLDRA 0008 9084h, S12AD.ADDBLDRB 0008 9086h, S12AD1.ADDR0 0008 9220h, S12AD1.ADDR1 0008 9222h, S12AD1.ADDR2 0008 9224h, S12AD1.ADDR3 0008 9226h, S12AD1.ADDBLDR 0008 9218h, S12AD1.ADDBLDRA 0008 9284h, S12AD1.ADDBLDRB 0008 9286h, S12AD2.ADDR0 0008 9420h, S12AD2.ADDR1 0008 9422h, S12AD2.ADDR2 0008 9424h, S12AD2.ADDR3 0008 9426h, S12AD2.ADDR4 0008 9428h, S12AD2.ADDR5 0008 942Ah, S12AD2.ADDR6 0008 942Ch, S12AD2.ADDR7 0008 942Eh, S12AD2.ADDR8 0008 9430h, S12AD2.ADDR9 0008 9432h, S12AD2.ADDR10 0008 9434h, S12AD2.ADDR11 0008 9436h, S12AD2.ADDR16 0008 9440h, S12AD2.ADDR17 0008 9442h, S12AD2.ADDBLDR 0008 9418h, S12AD2.ADDBLDRA 0008 9484h, S12AD2.ADDBLDRB 0008 9486h, S12AD2.ADTSDR 0008 941Ah, S12AD2.ADOCDR 0008 941Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ADDRy registers (y = 0 to 6: S12AD, y = 0 to 3: S12AD1, y = 0 to 11, 16, 17: S12AD2) are 16-bit read-only registers which store the A/D conversion results.
The ADDBLDR register is a 16-bit read-only register used in double trigger mode. The ADDBLDR register stores the results of A/D conversion when the conversion is started by the second trigger.
The ADDBLDRA and ADDBLDRB registers are 16-bit read-only registers that store the A/D conversion results in response to the respective triggers during extended operation in double trigger mode.
The ADTSDR register is a 16-bit read-only register that stores the A/D-converted value of the temperature sensor output.
The ADOCDR register is a 16-bit read-only register that stores the A/D conversion results of the internal reference voltage.
The format of each register differs depending on the conditions below.

- Settings of the A/D data register format select bit (ADCER.ADRFMT) (right-justified or left-justified)
- Settings of the addition count select bits (ADADC.ADC[2:0]) (2-, 3-, 4-, or 16-time conversion)
- Settings of the average mode enable bit (ADADC.AVEE) (add or average)

The data formats for each given condition are shown below.

(1) When A/D-Converted Value Addition/Average Mode is Disabled

- Right-justified format
  The A/D-converted value is stored in bits 11 to 0. Bits 15 to 12 are read as 0.
- Left-justified format
  The A/D-converted value is stored in bits 15 to 4. Bits 3 to 0 are read as 0.

(2) When A/D-Converted Average Mode is Selected

A/D-converted value average mode can be set only when 2- or 4-time conversion is selected in A/D-converted value addition mode.

- Right-justified format
  The mean value of the A/D-converted results of the same channel is stored in bits 11 to 0.
  Bits 15 to 12 are read as 0.

- Left-justified format
  The mean value of the A/D-converted results of the same channel is stored in bits 15 to 4.
  Bits 3 to 0 are read as 0.

(3) When A/D-Converted Value Addition Mode is Selected

When A/D-converted addition mode is selected, the value added by the A/D-converted value of the same channel is indicated. The number of A/D conversions can be set to 1, 2, 3, 4, or 16 times. If A/D-converted addition mode is selected, when the conversion count is set to 1 to 4 times, the value added by the A/D conversion result is retained in the A/D data register as 2-bit extended data of the conversion accuracy bits; when the conversion count is set to 16 times, the value added by the A/D conversion result is retained in the A/D data register as 4-bit extended data of the conversion accuracy bits. Even if A/D-converted value addition mode is selected, the value is stored in the A/D data register according to the settings of the A/D data register format select bits.

- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)
  The value added by the A/D-converted value of the same channel is stored in bits 13 to 0.
  Bits 15 and 14 are read as 0.
- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)
  The value added by the A/D-converted value of the same channel is stored in bits 15 to 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)
  The value added by the A/D-converted value of the same channel is stored in bits 15 to 2.
  Bits 1 and 0 are read as 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)
  The value added by the A/D-converted value of the same channel is stored in bits 15 to 0.

42.2.2 A/D Self-Diagnosis Data Register (ADRD)

Address(es): S12AD.ADRD 0008 901Eh, S12AD1.ADRD 0008 921Eh, S12AD2.ADRD 0008 941Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ADRD register is a 16-bit read-only register that stores the A/D conversion results based on the 12-bit A/D converter's self-diagnosis. In addition to the A/D-converted value, the self-diagnosis status is included in. In the ADRD register, the different formats are used depending on the conditions below.

- Settings of the A/D data register format select bit (ADCER.ADRFMT) (right-justified or left-justified)

The A/D-converted value addition mode and A/D-converted value average mode cannot be applied to the A/D self-diagnosis function. If temperature sensor output or internal reference voltage is selected, self-diagnosis function cannot be selected. For details of self-diagnosis, refer to section 42.2.14, A/D Control Extended Register (ADCER).

The data formats for each given condition are shown below.

- Right-justified format
  The A/D-converted value is stored in bits 11 to 0. The self-diagnosis status is stored in bits 15 and 14.
  Bits 13 and 12 are read as 0.
- Left-justified format
  The A/D-converted value is stored in bits 15 to 4. The self-diagnosis status is stored in bits 1 and 0.
  Bits 3 and 2 are read as 0.

Table 42.4 Self-Diagnosis Status Description

Bits 15 and 14 for Right-Justified Format Setting Bits 1 and 0 for Left-Justified Format Setting	Self-Diagnosis Status
00b	Self-diagnosis has never been executed since power-on.
01b	Self-diagnosis using the voltage of 0 V has been executed.
10b	Self-diagnosis using the voltage of 1/2 × AVCC has been executed.
11b	Self-diagnosis using the voltage of AVCC has been executed.

Note: For details of self-diagnosis, refer to section 42.2.14, A/D Control Extended Register (ADCER).

42.2.3 A/D Control Register (ADCSR)

Address(es): S12AD.ADCSR 0008 9000h, S12AD1.ADCSR 0008 9200h, S12AD2.ADCSR 0008 9400h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ADST	ADCS[1:0]		ADIE	—	—	TRGE	EXTRG	DBLE	GBADIE	—	DBLANS[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	DBLANS[4:0]	Double Trigger Channel Select	These bits select one analog input channel for double triggered operation. The setting is only effective while double trigger mode is selected.	R/W
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6	GBADIE	Group B Scan End Interrupt Enable	0: Group B scan end interrupt is disabled. 1: Group B scan end interrupt is enabled.	R/W
b7	DBLE	Double Trigger Mode Select	0: Deselects double trigger mode. 1: Selects double trigger mode.	R/W
b8	EXTRG	Trigger Select	0: A/D conversion is started by synchronous trigger. 1: A/D conversion is started by asynchronous trigger.	R/W
b9	TRGE	Trigger Start Enable	0: Disables A/D conversion to be started by synchronous or asynchronous trigger. 1: Enables A/D conversion to be started by synchronous or asynchronous trigger.	R/W
b11, b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12	ADIE	Scan End Interrupt Enable	0: Scan end interrupt is disabled. 1: Scan end interrupt is enabled.	R/W
b14, b13	ADCS[1:0]	Scan Mode Select	b14 b13 0 0: Single scan mode 0 1: Group scan mode 1 0: Continuous scan mode 1 1: Setting prohibited	R/W
b15	ADST	A/D Conversion Start	0: Stops A/D conversion process. 1: Starts A/D conversion process.	R/W

The ADCSR register sets double trigger mode, A/D conversion start trigger; enables/disables scan end interrupt; selects the scan mode; and starts or stops A/D conversion.

DBLANS[4:0] Bits (Double Trigger Channel Select)

The DBLANS[4:0] bits select one of the channels for A/D conversion data duplication in double trigger mode. The A/D conversion results of the analog input of the channel selected by the DBLANS[4:0] bits are stored into the A/D data register y when conversion is started by the first trigger, and into the A/D data duplication register when started by the second trigger. Table 42.5 shows selection of the channel for double triggered operation.

When double trigger mode is selected, the channels selected by the ADANSA0 and ADANSA1 registers are invalid, and the channel selected by the DBLANS[4:0] bits is subjected to A/D conversion instead.

When double trigger mode is selected in group scan mode, double trigger mode operation is performed for group A only and not performed for group B or C. Also, in double trigger mode, the analog inputs of multiple channels, temperature sensor outputs, or internal reference voltage cannot be selected for group A, but can be selected for groups B and C.

The DBLANS[4:0] bits should be set while the ADST bit is 0. They should not be set simultaneously when 1 is written to the ADST bit.

Table 42.5 Relationship Between DBLANS[4:0] Bits Settings and Double Trigger Enabled Channels

	Duplication Channel		
DBLANS[4:0]	S12AD (Unit 0)	S12AD1 (Unit 1)	S12AD2 (Unit 2)
00000b	AN000	AN100	AN200
00001b	AN001	AN101	AN201
00010b	AN002	AN102	AN202
00011b	AN003	AN103	AN203
00100b	AN004	—	AN204
00101b	AN005	—	AN205
00110b	AN006	—	AN206
00111b	—	—	AN207
01000b	—	—	AN208
01001b	—	—	AN209
01010b	—	—	AN210
01011b	—	—	AN211
10000b	—	—	AN216
10001b	—	—	AN217

—: Do not specify this value.

Note: Duplication cannot be selected for the A/D conversion data of self-diagnosis, temperature sensor output, and internal reference voltage.

GBADIE Bit (Group B Scan End Interrupt Enable)

The GBADIE bit enables or disables group B scan end interrupt in group scan mode.

A group B scan end interrupt is provided individually for each unit. Table 42.6 shows the relationship between each unit and the scan end interrupt for group B.

Table 42.6 Relationship Between Each Unit and Group B Scan End Interrupt

Unit	Group B Scan End Interrupt
S12AD	S12GBADI
S12AD1	S12GBADI1
S12AD2	S12GBADI2

DBLE Bit (Double Trigger Mode Select)

Double trigger mode has a function to store the resulting data of A/D conversion started by the first and second synchronous triggers into separate registers.

When double trigger mode is selected, the channels specified in the ADANSA0 and ADANSA1 registers are invalid and the channel selected by the DBLANS[4:0] bits is effective instead. Double trigger mode can be only operated by the synchronous trigger selected by the ADSTRGR.TRSA[6:0] bits. Do not generate an asynchronous or software trigger.

The A/D conversion results started by the first trigger are stored into the A/D data register y and those started by the second trigger are stored into the A/D data duplication register. In this case, when the ADIE bit is set to 1, the interrupt request is generated upon completion of the second conversion instead of upon completion of the first conversion.

In continuous scan mode, double trigger mode should not be selected. In addition, double trigger mode should not be used for self-diagnosis, or conversion of the temperature sensor output and internal reference voltage. When using double trigger mode in group scan mode, A/D conversion of the temperature sensor output or internal reference voltage should not be selected for group A.

The DBLE bit should be set after the ADST bit has been set to 0.

EXTRG Bit (Trigger Select)

The EXTRG bit selects the synchronous trigger or the asynchronous trigger as the trigger for starting A/D conversion. To use an external pin (asynchronous trigger) to start A/D conversion, set the ADCSR.TRGE and ADCSR.EXTRG bits to 1 while the external trigger pin (ADTRG0#, ADTRG1#, or ADTRG2#) is being driven high. Then, if the ADTRG0#, ADTRG1#, or ADTRG2# signal is changed to low, the falling edge is detected and the scan process is started. In this case, the pulse width of the low-level input must be at least 1.5 clock cycles of PCLKB.
Table 42.7 lists the units and the corresponding external pins (asynchronous triggers).

Table 42.7 Relationship Between Each Unit and External Pin (Asynchronous Trigger)

Unit	External Pin (Asynchronous Trigger)
S12AD	ADTRG0#
S12AD1	ADTRG1#
S12AD2	ADTRG2#

TRGE Bit (Trigger Start Enable)

The TRGE bit enables or disables A/D conversion by the synchronous trigger and the asynchronous trigger.
This bit should be set to 1 in group scan mode.

ADIE Bit (Scan End Interrupt Enable)

The ADIE bit enables or disables the A/D scan end interrupt in scans except for groups B and C scan in group scan mode.
With double trigger mode deselected, the A/D scan conversion end interrupt is generated after the first scan is completed if the ADIE bit is set to 1.
With double trigger mode selected, the A/D scan conversion end interrupt is generated after the second scan is completed if the ADIE bit is set to 1 as long as the scan is started by the synchronous trigger selected by the ADSTRGR.TRSA[6:0] bits.
When scan is started by a software trigger, even with double trigger mode selected, the A/D scan conversion end interrupt is generated if the ADIE bit is set to 1 when the scan is completed. The A/D scan conversion end interrupt is provided individually for each unit. Table 42.8 shows the relationship between each unit and the A/D scan conversion end interrupt.

Table 42.8 Relationship Between Each Unit and A/D Scan Conversion End Interrupt

Unit	A/D Scan Conversion End Interrupt
S12AD	S12ADI
S12AD1	S12ADI1
S12AD2	S12ADI2

ADCS[1:0] Bits (Scan Mode Select)

The ADCS[1:0] bits selects the scan mode.
In single scan mode, A/D conversion is performed for the analog inputs for up to seven channels for A/D converter unit 0, four channels for unit 1, and 14 channels for unit 2 selected with the ADANSA0 and ADANSA1 registers in the ascending order of arbitrary channel number, and the A/D conversion is stopped when one cycle of the A/D scan conversion is completed for all the selected channels.
The temperature sensor output or internal reference voltage can be selected; however, it cannot be selected with a channel input. Conversion of the temperature sensor output takes priority over that of internal reference voltage when both the temperature sensor output and internal reference voltage are selected.
In continuous scan mode, A/D conversion is performed for the analog inputs for up to seven channels for A/D converter unit 0, four channels for unit 1, and 14 channels for unit 2 selected with the ADANSA0 and ADANSA1 registers in the ascending order of arbitrary channel number, and the A/D conversion is repeated from the first channel when one cycle

of the A/D scan conversion is completed for all the selected channels.
In continuous scan mode, selecting the temperature sensor output and internal reference voltage is prohibited.
In group scan mode, A/D conversion is performed for the analog inputs (group A) for up to seven channels for A/D converter unit 0, four channels for unit 1, and 14 channels for unit 2 selected with the ADANSA0 and ADANSA1 registers in the ascending order of arbitrary channel number after scanning is started by the synchronous trigger selected by the ADSTRGR.TRSA[6:0] bits, and the A/D conversion is stopped when one cycle of the A/D scan conversion is completed for all the selected channels.
A/D conversion is also performed for the analog inputs (group B or C) for up to seven channels for A/D converter unit 0, four channels for unit 1, and 14 channels for unit 2 selected with the ADANSB0 and ADANSB1 registers and the ADANSC0 and ADANSC1 registers in the ascending order of arbitrary channel number after A/D conversion is started by the synchronous trigger selected by the ADSTRGR.TRSB[6:0] bits and the ADGCTRGR2.TRSC6 and ADGCTRGR.TRSC[5:0] bits, and when A/D conversion is completed for all the selected channels, A/D conversion is stopped.
The temperature sensor output or internal reference voltage can be selected; however, it cannot be selected with a channel input in the same group. Conversion of the temperature sensor output takes priority over that of internal reference voltage when both the temperature sensor output and internal reference voltage are selected.
When selecting group scan mode, different channels and triggers should be selected for groups A, B, and C.
When using two groups while group scan mode is set, use groups A and B (ADGCTRGR.GRCE bit = 0). When using three groups, use groups A, B, and C (ADGCTRGR.GRCE bit = 1).
The ADCS[1:0] bits should be set while the ADST bit is 0. They should not be set simultaneously when 1 is written to the ADST bit.

Table 42.9 Selection of Scan Mode, Double Trigger Mode, and Targets for A/D Conversion

Scan Mode Setup	Double Trigger Mode Setting	Targets for A/D Conversion				
		Self-Diagnosis	Analog Input (Including Group A)	Analog Input (Group B and Group C)	Temperature Sensor Output	Internal Reference Voltage
Single scan	DBLE = 0	✓	✓	×	✓	✓
	DBLE = 1	×	✓ (1 channel only)	×	×	×
Continuous scan	DBLE = 0	✓	✓	×	×	×
	DBLE = 1	×	×	×	×	×
Group scan	DBLE = 0	✓	✓	✓	✓	✓
	DBLE = 1	×	✓ (1 channel only)	✓	✓ (Group B and Group C)	✓ (Group B and Group C)

✓: Selectable, ×: Not selectable

ADST Bit (A/D Conversion Start)

The ADST bit starts or stops A/D conversion process.
Before the ADST bit is set to 1, set the A/D conversion clock, the conversion mode, and conversion target analog input.
[Setting conditions]

- 1 is written by software.
- The synchronous trigger selected by the ADSTRGR.TRSA[6:0] bits is detected with the ADCSR.EXTRG and ADCSR.TRGE bits being set to 0 and 1, respectively.
- The synchronous trigger selected by the ADSTRGR.TRSB[6:0] bits is detected with the ADCSR.TRGE bit being set to 1 in group scan mode.
- The asynchronous trigger is detected with the ADCSR.TRGE and ADCSR.EXTRG bits being set to 1 and the ADSTRGR.TRSA[6:0] bits being set to 0000000b.
- With group priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1),

a group B or C trigger is detected and A/D conversion of group B or C is started.

- With group priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADGSPCR.GBRP bit is set to 1 and A/D conversion of the lowest-priority group is started.

[Clearing conditions]

- 0 is written by software.
- The A/D conversion of all the selected channels, temperature sensor output, or the internal reference voltage (for unit 2 only) is completed in single scan mode.
- Group A scan is completed in group scan mode.
- Group B scan is completed in group scan mode.
- Group C scan is completed in group scan mode.
- With group priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADGSPCR.GBRSCN bit is set to 1 and the scanning of the low-priority group started by a trigger is stopped.

Note: When group priority control operation mode has been enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), do not set the ADST bit to 1.

Note: When group priority control operation mode has been enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1) and the ADGSPCR.GBRP bit = 1, do not set the ADST bit to 0. When forcibly terminating A/D conversion, follow the procedure for clearing the ADST bit.

Note: When the single-scan continuous function is used (ADGSPCR.GBRP bit = 1) with group priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADST bit remains as 1.

42.2.4 A/D Channel Select Register A0 (ADANSA0)

(1) S12AD.ADANSA0

Address(es): S12AD.ADANSA0 0008 9004h

b5	ANSA005			R/W
b6	ANSA006			R/W
b15 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD.ADANSA0 register selects analog input channels for A/D conversion from among AN000 to AN006. In group scan mode, this register selects group A channels.

ANSA0n Bit (A/D Conversion Channel Select) (n = 00 to 06)

The ANSA0n bit selects analog input channels for A/D conversion from among AN000 to AN006. The channels to be selected and the number of channels can be arbitrarily set. The ANSA000 bit corresponds to AN000 and the ANSA006 bit corresponds to AN006.

When double trigger mode is selected, the channel selected by the S12AD.ADCSR.DBLANS[4:0] bits is selected in group A, and the ANSA0n bit setting is invalid.

The ANSA0n bit should be set while the S12AD.ADCSR.ADST bit is 0.

(2) S12AD1.ADANSA0

Address(es): S12AD1.ADANSA0 0008 9204h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Bit	Symbol	Bit Name	Description	R/W
b0	ANSA000	A/D Conversion Channel Select	Select whether the voltages on AN100 to AN103 are to be converted or not. 0: Not selected for conversion 1: Selected for conversion	R/W
b1	ANSA001			R/W
b2	ANSA002			R/W
b3	ANSA003			R/W
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD1.ADANSA0 register selects analog input channels for A/D conversion from among AN100 to AN103. In group scan mode, this register selects group A channels.

ANSA0n Bit (A/D Conversion Channel Select) (n = 00 to 03)

The ANSA0n bit selects analog input channels for A/D conversion from among AN100 to AN103. The channels to be selected and the number of channels can be arbitrarily set. The ANSA000 bit corresponds to AN100 and the ANSA003 bit corresponds to AN103.

When double trigger mode is selected, the channel selected by the S12AD1.ADCSR.DBLANS[4:0] bits is selected in group A, and the ANSA0n bit setting is invalid.

The ANSA0n bit should be set while the S12AD1.ADST bit is 0.

(3) S12AD2.ADANSA0

Address(es): S12AD2.ADANSA0 0008 9404h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b10	ANSA010			R/W
b11	ANSA011			R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD2.ADANSA0 register selects analog input channels for A/D conversion from among AN200 to AN211. In group scan mode, this register selects group A channels.

ANSA0n Bit (A/D Conversion Channel Select) (n = 00 to 11)

The ANSA0n bit selects analog input channels for A/D conversion from among AN200 to AN211. The channels to be selected and the number of channels can be arbitrarily set. The ANSA000 bit corresponds to AN200 and the ANSA011 bit corresponds to AN211.

When performing A/D conversion of the temperature sensor output or internal reference voltage in single scan mode or for group A in group scan mode, do not select analog input channels (set this register to 0000h).

When double trigger mode is selected, the channel selected by the S12AD2.ADCSR.DBLANS[4:0] bits is selected in group A, and the ANSA0n bit setting is invalid.

The ANSA0n bit should be set while the S12AD2.ADCSR.ADST bit is 0.

42.2.5 A/D Channel Select Register A1 (ADANSA1)

Address(es): S12AD2.ADANSA1 0008 9406h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Bit	Symbol	Bit Name	Description	R/W
b0	ANSA100	A/D Conversion Channel Select	Select whether the voltages on AN216 to AN217 are to be converted or not. 0: Not selected for conversion 1: Selected for conversion	R/W
b1	ANSA101			R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD2.ADANSA1 register selects analog input channels for A/D conversion from among AN216 to AN217. In group scan mode, this register selects group A channels.

ANSA1n Bit (A/D Conversion Channel Select) (n = 00, 01)

The ANSA1n bit selects analog input channels for A/D conversion from among AN216 to AN217. The channels to be selected and the number of channels can be arbitrarily set. The ANSA100 bit corresponds to AN216 and the ANSA101 bit corresponds to AN217.

When performing A/D conversion of the temperature sensor output or internal reference voltage in single scan mode or for group A in group scan mode, do not select analog input channels (set this register to 0000h).

When double trigger mode is selected, the channel selected by the S12AD2.ADCSR.DBLANS[4:0] bits is selected in group A, and the ANSA1n bit setting is invalid.

The ANSA1n bit should be set while the S12AD2.ADCSR.ADST bit is 0.

42.2.6 A/D Channel Select Register B0 (ADANSB0)

(1) S12AD.ADANSB0

Address(es): S12AD.ADANSB0 0008 9014h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	ANSB006	ANSB005	ANSB004	ANSB003	ANSB002	ANSB001	ANSB000
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ANSB000	A/D Conversion Channel Select	Select whether the voltages on AN000 to AN006 are to be converted or not. 0: Not selected for conversion 1: Selected for conversion	R/W
b1	ANSB001			R/W
b2	ANSB002			R/W
b3	ANSB003			R/W
b4	ANSB004			R/W
b5	ANSB005			R/W
b6	ANSB006			R/W
b15 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD.ADANSB0 register selects analog input channels for A/D conversion from among AN000 to AN006 in group B when group scan mode is selected. The S12AD.ADANSB0 register is not used in any scan mode other than group scan mode.

ANSB0n Bit (A/D Conversion Channel Select) (n = 00 to 06)

The ANSB0n bit selects analog input channels for A/D conversion from among AN000 to AN006 in group B when group scan mode is selected. The S12AD.ADANSB0 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the S12AD.ADANSA0 register), the channels specified in group C (the S12AD.ADANSC0 register), and the channels corresponding to group A, selected with the S12AD.ADCSR.DBLANS[4:0] bits in double trigger mode should be excluded as the channels to be selected and the number of channels to be set.

The ANSB000 bit corresponds to AN000 and the ANSB006 bit corresponds to AN006.

The ANSB0n bit should be set while the S12AD.ADCSR.ADST bit is 0.

(2) S12AD1.ADANSB0

Address(es): S12AD1.ADANSB0 0008 9214h

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ANSB000	A/D Conversion Channel Select	Select whether the voltages on AN100 to AN103 are to be converted or not. 0: Not selected for conversion 1: Selected for conversion	R/W
b1	ANSB001			R/W
b2	ANSB002			R/W
b3	ANSB003			R/W
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD1.ADANSB0 register selects analog input channels for A/D conversion from among AN100 to AN103 in group B when group scan mode is selected. The S12AD1.ADANSB0 register is not used in any scan mode other than group scan mode.

ANSB0n Bit (A/D Conversion Channel Select) (n = 00 to 03)

The ANSB0n bit selects analog input channels for A/D conversion from among AN100 to AN103 in group B when group scan mode is selected. The S12AD1.ADANSB0 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the S12AD1.ADANSA0 register), the channels specified in group C (the S12AD1.ADANSC0 register), and the channels corresponding to group A, selected with the S12AD1.ADCSR.DBLANS[4:0] bits in double trigger mode should be excluded as the channels to be selected and the number of channels to be set.

The ANSB000 bit corresponds to AN100 and the ANSB003 bit corresponds to AN103.

The ANSB0n bit should be set while the S12AD1.ADCSR.ADST bit is 0.

(3) S12AD2.ADANSB0

Address(es): S12AD2.ADANSB0 0008 9414h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b10	ANSB010			R/W
b11	ANSB011			R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD2.ADANSB0 register selects analog input channels for A/D conversion from among AN200 to AN211 in group B when group scan mode is selected. The S12AD2.ADANSB0 register is not used in any scan mode other than group scan mode.

ANSB0n Bit (A/D Conversion Channel Select) (n = 00 to 11)

The ANSB0n bit selects analog input channels for A/D conversion from among AN200 to AN211 in group B when group scan mode is selected. The S12AD2.ADANSB0 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the S12AD2.ADANSA0 and S12AD2.ADANSA1 registers), the channels specified in group C (the S12AD2.ADANSC0 and S12AD2.ADANSC1 registers), and the channels corresponding to group A, selected with the S12AD2.ADCSR.DBLANS[4:0] bits in double trigger mode should be excluded as the channels to be selected and the number of channels to be set.

When performing A/D conversion of the temperature sensor output or internal reference voltage for group B in group scan mode, do not select analog input channels (set this register to 0000h).

The ANSB000 bit corresponds to AN200 and the ANSB011 bit corresponds to AN211.

The ANSB0n bit should be set while the S12AD2.ADCSR.ADST bit is 0.

42.2.7 A/D Channel Select Register B1 (ADANSB1)

Address(es): S12AD2.ADANSB1 0008 9416h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ANSB101	ANSB100
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ANSB100	A/D Conversion Channel Select	Select whether the voltages on AN216 to AN217 are to be converted or not. 0: Not selected for conversion 1: Selected for conversion	R/W
b1	ANSB101			R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD2.ADANSB1 register selects analog input channels for A/D conversion from among AN216 to AN217 in group B when group scan mode is selected. The S12AD2.ADANSB1 register is not used in any scan mode other than group scan mode.

ANSB1n Bit (A/D Conversion Channel Select) (n = 00, 01)

The ANSB1n bit selects analog input channels for A/D conversion from among AN216 to AN217 in group B when group scan mode is selected. The S12AD2.ADANSB1 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the S12AD2.ADANSA0 and S12AD2.ADANSA1 registers), the channels specified in group C (the S12AD2.ADANSC0 and S12AD2.ADANSC1 registers), and the channels corresponding to group A, selected with the S12AD2.ADCSR.DBLANS[4:0] bits in double trigger mode should be excluded as the channels to be selected and the number of channels to be set.

When performing A/D conversion of the temperature sensor output or internal reference voltage for group B in group scan mode, do not select analog input channels (set this register to 0000h).

The ANSB100 bit corresponds to AN216 and the ANSB101 bit corresponds to AN217.

The ANSB1n bit should be set while the S12AD2.ADCSR.ADST bit is 0.

42.2.8 A/D Channel Select Register C0 (ADANSC0)

(1) S12AD.ADANSC0

Address(es): S12AD.ADANSC0 0008 90D4h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	ANSC006	ANSC005	ANSC004	ANSC003	ANSC002	ANSC001	ANSC000
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ANSC000	A/D Conversion Channel Select	Select whether the voltages on AN000 to AN006 are to be converted or not. 0: Not selected for conversion 1: Selected for conversion	R/W
b1	ANSC001			R/W
b2	ANSC002			R/W
b3	ANSC003			R/W
b4	ANSC004			R/W
b5	ANSC005			R/W
b6	ANSC006			R/W
b15 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD.ADANSC0 register selects analog input channels for A/D conversion from among AN000 to AN006 in group C when group scan mode is selected. The S12AD.ADANSC0 register is not used in any scan mode other than group scan mode.

ANSC0n Bit (A/D Conversion Channel Select) (n = 00 to 06)

The ANSC0n bit selects analog input channels for A/D conversion from among AN000 to AN006 in group C when group scan mode is selected. The S12AD.ADANSC0 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the S12AD.ADANSA0 register), the channels specified in group B (the S12AD.ADANSB0 register), and the channels corresponding to group A, selected with the S12AD.ADCSR.DBLANS[4:0] bits in double trigger mode should be excluded as the channels to be selected and the number of channels to be set.

The ANSC000 bit corresponds to AN000 and the ANSC006 bit corresponds to AN006.

The ANSC0n bit should be set while the S12AD.ADCSR.ADST bit is 0.

(2) S12AD1.ADANSC0

Address(es): S12AD1.ADANSC0 0008 92D4h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ANSC000	A/D Conversion Channel Select	Select whether the voltages on AN100 to AN103 are to be converted or not. 0: Not selected for conversion 1: Selected for conversion	R/W
b1	ANSC001			R/W
b2	ANSC002			R/W
b3	ANSC003			R/W
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD1.ADANSC0 register selects analog input channels for A/D conversion from among AN100 to AN103 in group C when group scan mode is selected. The S12AD1.ADANSC0 register is not used in any scan mode other than group scan mode.

ANSC0n Bit (A/D Conversion Channel Select) (n = 00 to 03)

The ANSC0n bit selects analog input channels for A/D conversion from among AN100 to AN103 in group C when group scan mode is selected. The S12AD1.ADANSC0 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the S12AD1.ADANSA0 register), the channels specified in group B (the S12AD1.ADANSB0 register), and the channels corresponding to group A, selected with the S12AD1.ADCSR.DBLANS[4:0] bits in double trigger mode should be excluded as the channels to be selected and the number of channels to be set.

The ANSC000 bit corresponds to AN100 and the ANSC003 bit corresponds to AN103.

The ANSC0n bit should be set while the S12AD1.ADCSR.ADST bit is 0.

(3) S12AD2.ADANSC0

Address(es): S12AD2.ADANSC0 0008 94D4h

b9	ANSC009			R/W
b10	ANSC010			R/W
b11	ANSC011			R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD2.ADANSC0 register selects analog input channels for A/D conversion from among AN200 to AN211 in group C when group scan mode is selected. The S12AD2.ADANSC0 register is not used in any scan mode other than group scan mode.

ANSC0n Bit (A/D Conversion Channel Select) (n = 00 to 11)

The ANSC0n bit selects analog input channels for A/D conversion from among AN200 to AN211 in group C when group scan mode is selected. The S12AD2.ADANSC0 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the S12AD2.ADANSA0 and S12AD2.ADANSA1 registers), the channels specified in group B (the S12AD2.ADANSB0 and S12AD2.ADANSB1 registers), and the channels corresponding to group A, selected with the S12AD2.ADCSR.DBLANS[4:0] bits in double trigger mode should be excluded as the channels to be selected and the number of channels to be set.

When performing A/D conversion of the temperature sensor output or internal reference voltage or for group C in group scan mode, do not select analog input channels (set this register to 0000h).

The ANSC000 bit corresponds to AN200 and the ANSC011 bit corresponds to AN211.

The ANSC0n bit should be set while the S12AD2.ADCSR.ADST bit is 0.

42.2.9 A/D Channel Select Register C1 (ADANSC1)

Address(es): S12AD2.ADANSC1 0008 94D6h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ANSC101	ANSC100
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ANSC100	A/D Conversion Channel Select	Select whether the voltages on AN216 to AN217 are to be converted or not. 0: Not selected for conversion 1: Selected for conversion	R/W
b1	ANSC101			R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD2.ADANSC1 register selects analog input channels for A/D conversion from among AN216 to AN217 in group C when group scan mode is selected. The S12AD2.ADANSC1 register is not used in any scan mode other than group scan mode.

ANSC1n Bit (A/D Conversion Channel Select) (n = 00, 01)

The ANSC1n bit selects analog input channels for A/D conversion from among AN216 to AN217 in group C when group scan mode is selected. The S12AD2.ADANSC1 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the S12AD2.ADANSA0 and S12AD2.ADANSA1 registers), the channels specified in group B (the S12AD2.ADANSB0 and S12AD2.ADANSB1 registers), and the channels corresponding to group A, selected with the S12AD2.ADCSR.DBLANS[4:0] bits in double trigger mode should be excluded as the channels to be selected and the number of channels to be set.

When performing A/D conversion of the temperature sensor output or internal reference voltage or for group C in group scan mode, do not select analog input channels (set this register to 0000h).

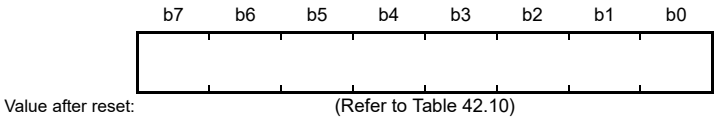
The ANSC100 bit corresponds to AN216 and the ANSC101 bit corresponds to AN217.

The ANSC1n bit should be set while the S12AD2.ADCSR.ADST bit is 0.

42.2.10 A/D Channel Conversion Order Setting Register n (ADSCSn) (n = 0 to 13)

(1) S12AD.ADSCSn (n = 0 to 6)

Address(es): S12AD.ADSCS0 0008 91C0h, S12AD.ADSCS1 0008 91C1h, S12AD.ADSCS2 0008 91C2h, S12AD.ADSCS3 0008 91C3h, S12AD.ADSCS4 0008 91C4h, S12AD.ADSCS5 0008 91C5h, S12AD.ADSCS6 0008 91C6h



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	—	Specify the order of channels for conversion by the 12-bit A/D converter. The channel with the number set in an ADSCSn register is the (n+1)th to be converted (refer to Table 42.10).	R/W

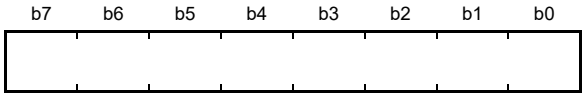
The ADSCSn register specifies the order of channels for conversion by the 12-bit A/D converter unit 0.
The order of conversion is set in the order AN000, AN001, ..., AN006 after a reset.
To change the order, change the values in the ADSCSn registers.
To use the channel-dedicated sample-and-hold circuit for AN000 to AN002, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register. When setting them to the ADSCS3 register, the results of conversion for the channels are not guaranteed.
If a specified channel is not selected for conversion in the channel selection registers (ADANSA0, ADANSB0, and ADANSC0), A/D conversion of the corresponding channel does not proceed. Set the channels for conversion in order starting from the ADSCS0 register, and set all the channels other than those above in the rest of the registers. Do not set the same value to plural registers.

Table 42.10 Relationship Between the Value After Reset of the A/D Channel Conversion Order Setting Register n (ADSCSn) and Conversion Order

Register Symbol	Order of Conversion	Value After Reset	Channel Numbers that Can be Set:
ADSCS0	First	00h	00h to 06h (for AN000 to AN006)
ADSCS1	Second	01h	
ADSCS2	Third	02h	
ADSCS3	Fourth	03h	
ADSCS4	Fifth	04h	
ADSCS5	Sixth	05h	
ADSCS6	Seventh	06h	

(2) S12AD1.ADSCSn (n = 0 to 3)

Address(es): S12AD1.ADSCS0 0008 93C0h, S12AD1.ADSCS1 0008 93C1h, S12AD1.ADSCS2 0008 93C2h, S12AD1.ADSCS3 0008 93C3h



Value after reset: (Refer to Table 42.11)

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	—	Specify the order of channels for conversion by the 12-bit A/D converter. The channel with the number set in an ADSCSn register is the (n+1)th to be converted (refer to Table 42.11).	R/W

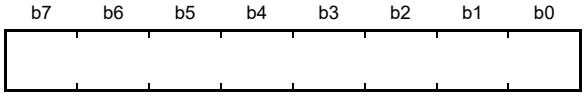
The ADSCSn register specifies the order of channels for conversion by the 12-bit A/D converter unit 1.
The order of conversion is set in the order AN100, AN101, ..., AN103 after a reset.
To change the order, change the values in the ADSCSn registers.
To use the channel-dedicated sample-and-hold circuit for AN100 to AN102, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register. When setting them to the ADSCS3 register, the results of conversion for the channels are not guaranteed.
If a specified channel is not selected for conversion in the channel selection registers (ADANSA0, ADANSB0, and ADANSC0), A/D conversion of the corresponding channel does not proceed. Set the channels for conversion in order starting from the ADSCS0 register, and set all the channels other than those above in the rest of the registers. Do not set the same value to plural registers.

Table 42.11 Relationship Between the Value After Reset of the A/D Channel Conversion Order Setting Register n (ADSCSn) and Conversion Order

Register Symbol	Order of Conversion	Value After Reset	Channel Numbers that Can be Set:
ADSCS0	First	00h	00h to 03h (for AN100 to AN103)
ADSCS1	Second	01h	
ADSCS2	Third	02h	
ADSCS3	Fourth	03h	

(3) S12AD2.ADSCSn (n = 0 to 13)

Address(es): S12AD2.ADSCS0 0008 95C0h, S12AD2.ADSCS1 0008 95C1h, S12AD2.ADSCS2 0008 95C2h, S12AD2.ADSCS3 0008 95C3h, S12AD2.ADSCS4 0008 95C4h, S12AD2.ADSCS5 0008 95C5h, S12AD2.ADSCS6 0008 95C6h, S12AD2.ADSCS7 0008 95C7h, S12AD2.ADSCS8 0008 95C8h, S12AD2.ADSCS9 0008 95C9h, S12AD2.ADSCS10 0008 95CAh, S12AD2.ADSCS11 0008 95CBh, S12AD2.ADSCS12 0008 95D0h, S12AD2.ADSCS13 0008 95D1h



Value after reset: (Refer to Table 42.12)

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	—	Specify the order of channels for conversion by the 12-bit A/D converter. The channel with the number set in an ADSCSn register is the (n+1)th to be converted (refer to Table 42.12).	R/W

The ADSCSn register specifies the order of channels for conversion by the 12-bit A/D converter unit 2.
The order of conversion is set in the order AN200, AN201, ..., AN211, AN216, and AN217 after a reset.
To change the order, change the values in the ADSCSn registers.
If a specified channel is not selected for conversion in the channel selection registers (ADANSA0/1, ADANSB0/1, and ADANSC0/1), A/D conversion of the corresponding channel does not proceed. Set the channels for conversion in order starting from the ADSCS0 register, and set all the channels other than those above in the rest of the registers. Do not set the same value to plural registers.
Furthermore, the places of the temperature sensor output and internal reference voltage in the order of conversion are fixed.

Table 42.12 Relationship Between the Value After Reset of the A/D Channel Conversion Order Setting Register n (ADSCSn) and Conversion Order

Register Symbol	Order of Conversion	Value After Reset	Channel Numbers that Can be Set:
ADSCS0	First	00h	00h to 0Bh, 10h, and 11h (for AN200 to AN211, AN216, AN217)

ADSCS13	Fourteenth	11h	

42.2.11 A/D-Converted Value Addition/Average Function Channel Select Register 0 (ADADS0)

(1) S12AD.ADADS0

Address(es): S12AD.ADADS0 0008 9008h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	ADS006	ADS005	ADS004	ADS003	ADS002	ADS001	ADS000
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ADS000	A/D-Converted Value Addition/Average Channel Select	Set an A/D-converted value addition/average mode for AN000 to AN006. 0: A/D-converted value addition/average mode is disabled 1: A/D-converted value addition/average mode is enabled	R/W
b1	ADS001			R/W
b2	ADS002			R/W
b3	ADS003			R/W
b4	ADS004			R/W
b5	ADS005			R/W
b6	ADS006			R/W
b15 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD.ADADS0 register selects channels AN000 to AN006 on which A/D conversion is performed successively 2, 3, 4, or 16 times and then converted values are added (integrated) or averaged.

ADS0n Bit (A/D-Converted Value Addition/Average Channel Select) (n = 00 to 06)

When the ADS0n bit of the number that is the same as that of A/D-converted channel selected by the S12AD.ADANSA0.ANSA0n bit or the S12AD.ADCSR.DBLANS[4:0] bits and the S12AD.ADANSB0.ANSB0n bit and the S12AD.ADANSC0.ANSC0n bit is set to 1, A/D conversion of analog input of the selected channels is performed successively 2, 3, 4, or 16 times that is set with the S12AD.ADADC.ADC[2:0] bits.

When the S12AD.ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D data register.

When the S12AD.ADADC.AVEE bit is 1, the mean value of the results obtained by addition (integration) is stored in the A/D data register.

An A/D conversion channel with addition/average mode disabled executes a regular one-time conversion and stores the value in the A/D data register.

The ADS0n bit should be set while the S12AD.ADCSR.ADST bit is 0.

(2) S12AD1.ADADS0

Address(es): S12AD1.ADADS0 0008 9208h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	ADS003	ADS002	ADS001	ADS000
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ADS000	A/D-Converted Value Addition/Average Channel Select	Set an A/D-converted value addition/average mode for AN100 to AN103. 0: A/D-converted value addition/average mode is disabled 1: A/D-converted value addition/average mode is enabled	R/W
b1	ADS001			R/W
b2	ADS002			R/W
b3	ADS003			R/W
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD1.ADADS0 register selects channels AN100 to AN103 on which A/D conversion is performed successively 2, 3, 4, or 16 times and then converted values are added (integrated) or averaged.

ADS0n Bit (A/D-Converted Value Addition/Average Channel Select) (n = 00 to 03)

When the ADS0n bit of the number that is the same as that of A/D-converted channel selected by the S12AD1.ADANSA0.ANSA0n bit or the S12AD1.ADCSR.DBLANS[4:0] bits and the S12AD1.ADANSB0.ANSB0n bit and the S12AD1.ADANSC0.ANSC0n bit is set to 1, A/D conversion of analog input of the selected channels is performed successively 2, 3, 4, or 16 times that is set with the S12AD1.ADADC.ADC[2:0] bits.

When the S12AD1.ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D data register.

When the S12AD1.ADADC.AVEE bit is 1, the mean value of the results obtained by addition (integration) is stored in the A/D data register.

An A/D conversion channel with addition/average mode disabled executes a regular one-time conversion and stores the value in the A/D data register.

The ADS0n bit should be set while the S12AD1.ADCSR.ADST bit is 0.

(3) S12AD2.ADADS0

Address(es): S12AD2.ADADS0 0008 9408h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Bit	Symbol	Bit Name	Description	R/W
b0	ADS000	A/D-Converted Value Addition/Average Channel Select	Set an A/D-converted value addition/average mode for AN200 to AN211. 0: A/D-converted value addition/average mode is disabled 1: A/D-converted value addition/average mode is enabled	R/W
b1	ADS001			R/W
b2	ADS002			R/W
b3	ADS003			R/W
b4	ADS004			R/W
b5	ADS005			R/W
b6	ADS006			R/W
b7	ADS007			R/W
b8	ADS008			R/W
b9	ADS009			R/W
b10	ADS010			R/W
b11	ADS011			R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD2.ADADS0 register selects channels AN200 to AN211 on which A/D conversion is performed successively 2, 3, 4, or 16 times and then converted values are added (integrated) or averaged.

ADS0n Bit (A/D-Converted Value Addition/Average Channel Select) (n = 00 to 11)

When the ADS0n bit of the number that is the same as that of A/D-converted channel selected by the S12AD2.ADANSA0.ANSA0n bit or the S12AD2.ADCSR.DBLANS[4:0] bits and the S12AD2.ADANSB0.ANSB0n bit and the S12AD2.ADANSC0.ANSC0n bit is set to 1, A/D conversion of analog input of the selected channels is performed successively 2, 3, 4, or 16 times that is set with the S12AD2.ADADC.ADC[2:0] bits.

When the S12AD2.ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D data register.

When the S12AD2.ADADC.AVEE bit is 1, the mean value of the results obtained by addition (integration) is stored in the A/D data register.

An A/D conversion channel with addition/average mode disabled executes a regular one-time conversion and stores the value in the A/D data register.

The ADS0n bit should be set while the S12AD2.ADCSR.ADST bit is 0.

Figure 42.5 shows a scanning operation sequence in which both the S12AD2.ADADS0.ADS002 and S12AD2.ADADS0.ADS006 bits are set to 1.
It is assumed that addition mode is selected (S12AD2.ADADC.AVEE bit = 0) in continuous scan mode (S12AD2.ADCSR.ADCS[1:0] bits = 10b), the addition count is set to three times (S12AD2.ADADC.ADC[2:0] bits = 011b), and channels AN200 to AN207 are selected (S12AD2.ADANSA0 register = 00FFh). The conversion process begins with AN200. The AN202 conversion is performed successively four times (add three times), and the added (integrated) value is stored in A/D data register 2. After that the AN203 conversion is started. The AN206 conversion is performed successively four times and the added (integrated) value is stored in A/D data register 6. After conversion of AN207, the conversion operation is once again performed in the same sequence from AN200.

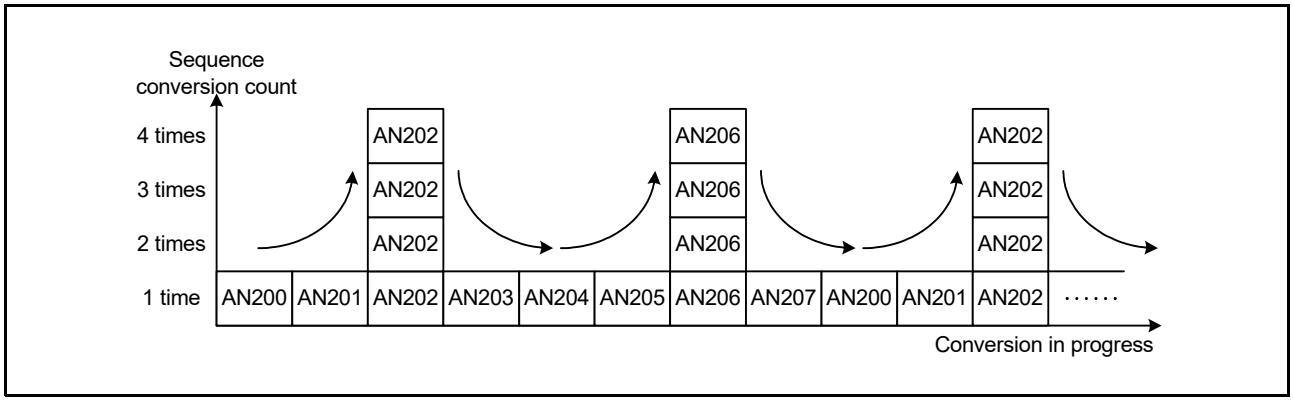

Figure 42.5 Scan Conversion Sequence with S12AD2.ADADC.ADC[2:0] = 011b, S12AD2.ADADC.AVEE = 0, S12AD2.ADADS0.ADS002 = 1, and S12AD2.ADADS0.ADS006 = 1

42.2.12 A/D-Converted Value Addition/Average Function Channel Select Register 1 (ADADS1)

Address(es): S12AD2.ADADS1 0008 940Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ADS101	ADS100
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ADS100	A/D-Converted Value Addition/Average Channel Select	Set an A/D-converted value addition/average mode for AN216 to AN217. 0: A/D-converted value addition/average mode is disabled 1: A/D-converted value addition/average mode is enabled	R/W
b1	ADS101			R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD2.ADADS1 register selects channels AN216 to AN217 on which A/D conversion is performed successively 2, 3, 4, or 16 times and then converted values are added (integrated) or averaged.

ADS1n Bit (A/D-Converted Value Addition/Average Channel Select) (n = 00, 01)

When the ADS1n bit of the number that is the same as that of A/D-converted channel selected by the S12AD2.ADANSA1.ANSA1n bit or the S12AD2.ADCSR.DBLANS[4:0] bits, the S12AD2.ADANSB1.ANSB1n bit, and the S12AD2.ADANSC1.ANSC1n bit is set to 1, A/D conversion of analog input of the selected channels is performed successively 2, 3, 4, or 16 times that is set with the S12AD2.ADADC.ADC[2:0] bits. When the S12AD2.ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D data register. When the S12AD2.ADADC.AVEE bit is 1, the mean value of the results obtained by addition (integration) is stored in the A/D data register.

An A/D conversion channel with addition/average mode disabled executes a regular one-time conversion and stores the value in the A/D data register.

The ADS1n bit should be set while the S12AD2.ADCSR.ADST bit is 0.

42.2.13 A/D-Converted Value Addition/Average Count Select Register (ADADC)

Address(es): S12AD.ADADC 0008 900Ch, S12AD1.ADADC 0008 920Ch, S12AD2.ADADC 0008 940Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	AVEE	—	—	—	—	ADC[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	ADC[2:0]	Addition Count Select	b2 b0 0 0 0: 1-time conversion (no addition; same as normal conversion) 0 0 1: 2-time conversion (addition once) 0 1 0: 3-time conversion (addition twice)*1 0 1 1: 4-time conversion (addition three times) 1 0 1: 16-time conversion (addition 15 times)*1 Settings other than above are prohibited.	R/W
b6 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	AVEE	Average Mode Enable	0: Addition mode is selected. 1: Average mode is selected.	R/W

Note 1. The AVEE bit is enabled only when 2-time or 4-time conversion is selected. When average mode is selected (ADADC.AVEE bit = 1), do not set 3-time conversion (ADADC.ADC[2:0] bits = 010b) nor 16-time conversion (ADADC.ADC[2:0] bits = 101b).

When the A/D-converted value addition/average modes are enabled for A/D conversion of the channels, temperature sensor output, or internal reference voltage, the number of addition and whether they are to be added or averaged is specified in the ADADC register.

ADC[2:0] Bits (Addition Count Select)

The number of addition from channels including those channels selected in double-trigger mode (by the ADCSR.DBLANS[4:0] bits), temperature sensor output, or internal reference voltage for which A/D conversion and addition or averaging is enabled, is selected by the setting of the ADC[2:0] bits.
The ADC[2:0] bits should be set while the ADCSR.ADST bit is 0.

AVEE Bit (Average Mode Enable)

The AVEE bit selects whether the results of A/D conversion from channels, including those selected in double-trigger mode (by the DBLANS[4:0] bits), temperature sensor output, or internal reference voltage are to be averaged or added when A/D conversion and addition/average modes are enabled.
When average mode is selected by setting the AVEE bit to 1, do not set the addition count to one time (ADC[2:0] bits = 000b), three times (ADC[2:0] bits = 010b), or 16 times (ADC[2:0] bits = 101b). The mean value of 1-time, 3-time, and 16-time conversion cannot be obtained.
The AVEE bit should be set while the ADCSR.ADST bit is 0.

42.2.14 A/D Control Extended Register (ADCER)

Address(es): S12AD.ADCER 0008 900Eh, S12AD1.ADCER 0008 920Eh, S12AD2.ADCER 0008 940Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ADRFMT	—	—	—	DIAGM	DIAGLD	DIAGVAL[1:0]		—	ASE	ACE	—	—	—	—	—

b4 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	ACE	A/D Data Register Automatic Clearing Enable	0: Disables automatic clearing. 1: Enables automatic clearing.	R/W
b6	ASE	A/D Data Register Automatic Setting Enable	0: Disables automatic setting. 1: Enables automatic setting.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b9, b8	DIAGVAL[1:0]	Self-Diagnosis Conversion Voltage Select	b9 b8 0 0: Setting prohibited in self-diagnosis voltage fixed mode 0 1: Uses the voltage of 0 V for self-diagnosis. 1 0: Uses the voltage of 1/2 × AVCC for self-diagnosis. 1 1: Uses the voltage of AVCC for self-diagnosis.	R/W
b10	DIAGLD	Self-Diagnosis Mode Select	0: Rotation mode for self-diagnosis voltage 1: Fixed mode for self-diagnosis voltage	R/W
b11	DIAGM	Self-Diagnosis Enable	0: Disables self-diagnosis of 12-bit A/D converter. 1: Enables self-diagnosis of 12-bit A/D converter.	R/W
b14 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	ADRFMT	A/D Data Register Format Select	0: Right-justified is selected for the A/D data register format. 1: Left-justified is selected for the A/D data register format.	R/W

Note 1. If both the ACE and the ASE bits are set to 1, neither automatic clearing nor automatic setting is performed.

The ADCER register sets self-diagnosis mode, format of A/D data registers y (ADDRy), and automatic clearing of A/D data registers.

ACE Bit (A/D Data Register Automatic Clearing Enable)

The ACE bit enables or disables automatic clearing (all 0) of the ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, or ADOCDR register after any of these registers have been read by the CPU, DTC, or DMAC. Automatic clearing of the A/D data register is enabled to detect a failure which has not been updated in the A/D data register.

ASE Bit (A/D Data Register Automatic Setting Enable)

The ACE bit enables or disables automatic setting (all 1) of the ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, or ADOCDR register after any of these registers have been read by the CPU, DTC, or DMAC. Automatic setting of the A/D data register is enabled to detect a failure which has not been updated in the A/D data register.

DIAGVAL[1:0] Bits (Self-Diagnosis Conversion Voltage Select)

The DIAGVAL[1:0] bits select the voltage value used in self-diagnosis voltage fixed mode. For details, refer to the descriptions of the DIAGLD bit.
Self-diagnosis should not be executed by setting the DIAGLD bit to 1 when the DIAGVAL[1:0] bits are set to 00b.

DIAGLD Bit (Self-Diagnosis Mode Select)

The DIAGLD bit selects whether the three voltage values are rotated or the fixed voltage is used in self-diagnosis.

Setting this bit (DIAGLD) to 0 allows conversion of the voltages in rotation mode where 0 V, 1/2 × AVCC, and AVCC are converted in that order. When self-diagnosis rotation mode is selected after a reset, self-diagnosis is performed from 0 V. When self-diagnosis voltage fixed mode is selected, the fixed voltage specified by the DIAGVAL[1:0] bits is converted. In self-diagnosis voltage rotation mode, the self-diagnosis voltage value does not return to 0 when scan conversion is completed. When scan conversion is restarted, therefore, rotation starts at the voltage value following the previous value. If fixed mode is switched to rotation mode, rotation starts at the fixed voltage value.
The DIAGLD bit should be set while the ADCSR.ADST bit is 0.

DIAGM Bit (Self-Diagnosis Enable)

The DIAGM bit enables or disables self-diagnosis.
Self-diagnosis is used to detect a failure of the 12-bit A/D converter. Specifically, one from among the internally generated voltages 0, 1/2 × AVCC, or AVCC is selected for conversion. When conversion is completed, information on the converted voltage and the conversion result is stored into the self-diagnosis data register (ADRD). The ADRD register can then be read out by software to determine whether the conversion result falls within the normal range (normal) or not (abnormal). Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages is converted. When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed in groups A, B, and C.
The DIAGM bit should be set while the ADCSR.ADST bit is 0.
When performing the self-diagnosis, A/D conversion of the temperature sensor output and internal reference voltage is prohibited regardless of scanning groups.

ADRFMT Bit (A/D Data Register Format Select)

The ADRFMT bit specifies right-justified or left-justified for the data to be stored in the ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADRD, ADCMPDR0, ADCMPDR1, ADWINLLB, or ADWINULB register.
The ADRFMT bit should be set while the ADCSR.ADST bit is 0.

For details on the format of each data register, refer to section 42.2.1, A/D Data Registers y (ADDRy) (y = 0 to 11, 16, 17), A/D Data Duplication Register (ADDBLDR), A/D Data Duplication Register A (ADDBLDRA), A/D Data Duplication Register B (ADDBLDRB), A/D Temperature Sensor Data Register (ADTSDR), A/D Internal Reference Voltage Data Register (ADOCDR), section 42.2.2, A/D Self-Diagnosis Data Register (ADRD), section 42.2.33, A/D Comparison Function Window A Lower Level Setting Register (ADCMPDR0), section 42.2.34, A/D Comparison Function Window A Upper Level Setting Register (ADCMPDR1), section 42.2.40, A/D Comparison Function Window B Lower Level Setting Register (ADWINLLB), and section 42.2.41, A/D Comparison Function Window B Upper Level Setting Register (ADWINULB).

42.2.15 A/D Conversion Start Trigger Select Register (ADSTRGR)

Address(es): S12AD.ADSTRGR 0008 9010h, S12AD1.ADSTRGR 0008 9210h, S12AD2.ADSTRGR 0008 9410h

	—	TRSA[6:0]							—	TRSB[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	TRSB[6:0]	Group B A/D Conversion Start Trigger Select	Select the A/D conversion start trigger for group B in group scan mode.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b14 to b8	TRSA[6:0]	A/D Conversion Start Trigger Select	Select the A/D conversion start trigger in single scan mode and continuous mode. In group scan mode, the A/D conversion start trigger for group A is selected.	R/W
b15	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

The ADSTRGR register selects the A/D conversion start trigger.

TRSB[6:0] Bits (Group B A/D Conversion Start Trigger Select)

The TRSB[6:0] bits select the trigger to start scanning of the analog input selected in group B. The TRSB[6:0] bits require to be set only in group scan mode and are not used in any other scan mode. For the scan conversion start trigger for group B, setting a software trigger or an asynchronous trigger is prohibited. Therefore, the TRSB[6:0] bits should be set to the value other than 00h and the ADCSR.TRGE bit should be set to 1 in group scan mode.

When two groups are selected (ADGCTRGR.GRCE bit = 0) during group priority operation in group scan mode, setting the ADGSPCR.GBRP bit to 1 allows group B to continuously operate in single scan mode. When setting the GBRP bit to 1, set the TRSB[6:0] bits to 3Fh or 7Fh. Note that the issuance period of trigger for A/D conversion must be more than or equal to the actual scan conversion time (t_{SCAN}). If the issuance period is less than t_{SCAN}, A/D conversion by the trigger may have no effect.

When selecting a trigger from the MTU operated on a PCLKC cycle as an A/D conversion start trigger, a delay of the period for synchronization processing occurs. Refer to section 42.3.7, Analog Input Sampling Time and Scan Conversion Time for details.

Table 42.13 lists the A/D conversion startup sources selected by the TRSB[6:0] bits.

TRSA[6:0] Bits (A/D Conversion Start Trigger Select)

The TRSA[6:0] bits select the trigger to start A/D conversion in single scan mode and continuous scan mode. In group scan mode, the trigger to start scanning of the analog input selected in group A is selected. When performing scanning in group scan mode or double trigger mode, set the ADCSR.TRGE bit to 1 and set the ADCSR.EXTRG bit to 0.

- When using the A/D conversion startup source of a synchronous trigger, set the ADCSR.TRGE bit to 1 and set the ADCSR.EXTRG bit to 0.
- When using the asynchronous trigger, set the ADCSR.TRGE bit to 1 and set the ADCSR.EXTRG bit to 1.
- Software trigger (ADCSR.ADST) is enabled regardless of the settings of the ADCSR.TRGE bit, the ADCSR.EXTRG bit, and the TRSA[6:0] bits.

Note that the issuance period of trigger for A/D conversion must be more than or equal to the actual scan conversion time (t_{SCAN}). If the issuance period is less than t_{SCAN}, A/D conversion by a trigger may have no effect. When selecting a trigger from the MTU operated on a PCLKC cycle as an A/D conversion start trigger, a delay of the period for synchronization processing occurs. Refer to section 42.3.7, Analog Input Sampling Time and Scan Conversion

Time for details.

Table 42.14 lists the selection of A/D conversion start sources selected by the TRSA[6:0] bits.

b10	TSSB	Group B Temperature Sensor Output A/D Conversion Select	0: Temperature sensor output is not A/D-converted 1: Temperature sensor output is A/D-converted	R/W
b11	OCSB	Group B Internal Reference Voltage A/D Conversion Select	0: Internal reference voltage is not A/D-converted 1: Internal reference voltage is A/D-converted	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADEXICR register specifies the settings of A/D conversion of the temperature sensor output, internal reference voltage.

TSSAD Bit (Temperature Sensor Output A/D-Converted Value Addition/Average Mode Select)

When A/D conversion of the temperature sensor output is selected and the TSSAD bit is set to 1, A/D conversion of the temperature sensor output is performed in sequence for the count set in the ADADC.ADC[2:0] bits (2, 3, 4, or 16 times). The added (accumulated) total value is returned to the A/D temperature sensor data register (ADTSDR) when the ADADC.AVEE bit is 0 and the average is returned to the ADTSDR register when the ADADC.AVEE bit is 1. The TSSAD bit should be set while the ADCSR.ADST bit is 0.

OCSAD Bit (Internal Reference Voltage A/D-Converted Value Addition/Average Mode Select)

When A/D conversion of the internal reference voltage is selected and the OCSAD bit is set to 1, A/D conversion of the internal reference voltage is performed in sequence for the count set in the ADADC.ADC[2:0] bits (2, 3, 4, or 16 times). When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D internal reference voltage data register (ADOCDR). When the ADADC.AVEE bit is 1, the mean value is stored in the ADOCDR register. The OCSAD bit should be set while the ADCSR.ADST bit is 0.

TSSA Bit (Temperature Sensor Output A/D Conversion Select)

The TSSA bit selects A/D conversion of the temperature sensor output for group A in single scan mode or group scan mode. When A/D conversion of the temperature sensor output is performed, set the ADCSR.DBLE bit to 0.
The TSSA bit should be set while the ADCSR.ADST bit is 0. When setting the TSSB or ADGCEXCR.TSSC bit to 1, set this bit to 0.

The temperature sensor output can be selected in single scan mode and group scan mode. Set the sampling time to at least 4 µs when A/D-converting the temperature sensor output. When setting the TSSA bit to 1, the temperature sensor is automatically activated. After activation, only start A/D conversion after waiting 200 µs for the sensor output to become stable. When A/D conversion is started, auto-discharging for 15 cycles of ADCLK proceeds before sampling.
A/D conversion of the temperature sensor outputs in groups B and C should be handled in the same way.

OCSA Bit (Internal Reference Voltage A/D Conversion Select)

The OCSA bit selects A/D conversion of the internal reference voltage for group A in single scan mode or group scan mode. When A/D conversion of the internal reference voltage is performed, set the ADCSR.DBLE bit to 0.
The OCSA bit should be set while the ADCSR.ADST bit is 0. When setting the OCSB or ADGCEXCR.OCSC bit to 1, set this bit to 0.
To perform A/D conversion of the internal reference voltage, set the OCSA bit to 1, wait for at least 400 ns, and then start A/D conversion. When A/D conversion is started, auto-discharging for 15 cycles of ADCLK proceeds before sampling.
When the disconnection detection assist function is also in use, the setting of the ADNDIS[4:0] bits is ignored.
A/D conversion of the internal reference voltages in groups B and C should be handled in the same way.

TSSB Bit (Group B Temperature Sensor Output A/D Conversion Select)

The TSSB bit selects A/D conversion of the temperature sensor output for group B in group scan mode.
This bit should be set while the ADCSR.ADST bit is 0. When setting the TSSA or ADGCEXCR.TSSC bit to 1, set this bit to 0.
Refer to description of the TSSA bit for A/D-converting the temperature sensor output.

OCSB Bit (Group B Internal Reference Voltage A/D Conversion Select)

The OCSB bit selects A/D conversion of the internal reference voltage for group B in group scan mode.
This bit should be set while the ADCSR.ADST bit is 0. When setting the OCSA or ADGCEXCR.OCSC bit to 1, set this bit to 0.
Refer to description of the OCSA bit for A/D-converting the internal reference voltage.

42.2.17 A/D Group C Extended Input Control Register (ADGCEXCR)

Address(es): S12AD2.ADGCEXCR 0008 94D8h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	OCSC	TSSC
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TSSC	Group C Temperature Sensor Output A/D Conversion Select	0: Temperature sensor output is not A/D-converted 1: Temperature sensor output is A/D-converted	R/W
b1	OCSC	Group C Internal Reference Voltage A/D Conversion Select	0: Internal reference voltage is not A/D-converted 1: Internal reference voltage is A/D-converted	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADGCEXCR register specifies extended input for group C.

TSSC Bit (Group C Temperature Sensor Output A/D Conversion Select)

The TSSC bit selects A/D conversion of the temperature sensor output for group C in group scan mode.
The TSSC bit should be set while the ADCSR.ADST bit is 0. When setting the ADEXICR.TSSA or ADEXICR.TSSB bit to 1, set this bit to 0.
Refer to description of the ADEXICR.TSSA bit for A/D-converting the temperature sensor output.

OCSC Bit (Group C Internal Reference Voltage A/D Conversion Select)

The OCSC bit selects A/D conversion of the internal reference voltage for group C in group scan mode.
The OCSC bit should be set while the ADCSR.ADST bit is 0. When setting the ADEXICR.OCSA or ADEXICR.OCSB bit to 1, set this bit to 0.
Refer to description of the ADEXICR.OCSA bit for A/D-converting the internal reference voltage.

42.2.18 A/D Group C Trigger Select Register (ADGCTRGR)

Address(es): S12AD.ADGCTRGR 0008 90D9h, S12AD1.ADGCTRGR 0008 92D9h, S12AD2.ADGCTRGR 0008 94D9h

	b7	b6	b5	b4	b3	b2	b1	b0
	GRCE	GCADIE	TRSC[5:0]					
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	TRSC[5:0]	Group C A/D Conversion Start Trigger Select	In combination with the ADGCTRGR2.TRSC6 bit, these bits select the A/D conversion start trigger for group C in group scan mode.	R/W
b6	GCADIE	Group C Scan End Interrupt Enable	0: Group C scan end interrupt is disabled. 1: Group C scan end interrupt is enabled.	R/W
b7	GRCE	Group C A/D Conversion Operation Enable	Enables A/D conversion operation for group C. 0: Group C is not used 1: Group C is used	R/W

The ADGCTRGR register enables operation for group C and selects the A/D conversion start trigger. For details on group priority operation, refer to Table 42.21 and Table 42.22.

TRSC[5:0] Bits (Group C A/D Conversion Start Trigger Select)

In combination with the ADGCTRGR2.TRSC6 bit, the TRSC[5:0] bits select the trigger to start scanning of the analog input selected in group C. These bits are used for group scan mode only; not used for any other modes. Software trigger or asynchronous trigger cannot be set as the scan conversion trigger for group C. When using group C in group scan mode, set the TRSC6:TRSC[5:0] bits to a value other than 00h, set the ADCSR.TRGE bit to 1, and set the GRCE bit to 1. When group C is used during group priority control in group scan mode and the ADGSPCR.GBRP bit is set to 1, group C can be continuously operated in single scan mode. When continuously operating group C in single scan mode, set the TRSC[5:0] bits to 3Fh to disable trigger selection.

Note that the issuance period of trigger for A/D conversion must be more than or equal to the actual scan conversion time (t_{SCAN}). If the issuance period is less than t_{SCAN}, A/D conversion by a trigger may have no effect.

When selecting a trigger from the MTU operated on a PCLKC cycle as an A/D conversion start trigger, a delay of the period for synchronization processing occurs. Refer to section 42.3.7, Analog Input Sampling Time and Scan Conversion Time for details.

Table 42.15 lists the selection of A/D conversion start sources selected by the TRSC6 and TRSC[5:0] bits for group C.

Note 1. Unit 0
Note 2. Unit 1
Note 3. Unit 2

GCADIE Bit (Group C Scan End Interrupt Enable)

The GCADIE bit enables or disables scan end interrupt generation for group C. A scan end interrupt for group C is provided individually for each unit. Table 42.16 shows the relationship between each unit and the scan end interrupt for group C.

Table 42.16 Relationship Between Each Unit and Group C Scan End Interrupt

Unit	Group C Scan End Interrupt
S12AD	S12GCADI
S12AD1	S12GCADI1
S12AD2	S12GCADI2

GRCE Bit (Group C A/D Conversion Operation Enable)

When using group C in group scan mode, set the GRCE bit to 1.
When the GRCE bit is 0, trigger input for group C is disabled.
During group priority operation (the ADGSPCR.PGS bit is 1) with group C used, when the ADGSPCR.GBRP bit is set to 1, single scan for group C is continuously operated. When the GRCE bit is set to 1, single scan for group B is not continuously operated.
The GRCE bit should be set while the ADCSR.ADST bit is 0.

42.2.19 A/D Group C Trigger Select Register 2 (ADGCTRGR2)

Address(es): S12AD.ADGCTRGR2 0008 90DCh, S12AD1.ADGCTRGR2 0008 92DCh, S12AD2.ADGCTRGR2 0008 94DCh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	TRSC6
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TRSC6	Group C A/D Conversion Start Trigger Select	In combination with the ADGCTRGR.TRSC[5:0] bits, this bit selects the A/D conversion start trigger for group C in group scan mode.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADGCTRGR2 register is used in combination with the ADGCTRGR register to select the A/D conversion start trigger for group C. For details, refer to section 42.2.18, A/D Group C Trigger Select Register (ADGCTRGR).

42.2.20 A/D Sampling State Register n (ADSSTRn) (n = 0 to 11, L, T, O)

Address(es): S12AD.ADSSTR0 0008 90E0h, S12AD.ADSSTR1 0008 90E1h, S12AD.ADSSTR2 0008 90E2h, S12AD.ADSSTR3 0008 90E3h, S12AD.ADSSTR4 0008 90E4h, S12AD.ADSSTR5 0008 90E5h, S12AD.ADSSTR6 0008 90E6h, S12AD1.ADSSTR0 0008 92E0h, S12AD1.ADSSTR1 0008 92E1h, S12AD1.ADSSTR2 0008 92E2h, S12AD1.ADSSTR3 0008 92E3h, S12AD2.ADSSTR0 0008 94E0h, S12AD2.ADSSTR1 0008 94E1h, S12AD2.ADSSTR2 0008 94E2h, S12AD2.ADSSTR3 0008 94E3h, S12AD2.ADSSTR4 0008 94E4h, S12AD2.ADSSTR5 0008 94E5h, S12AD2.ADSSTR6 0008 94E6h, S12AD2.ADSSTR7 0008 94E7h, S12AD2.ADSSTR8 0008 94E8h, S12AD2.ADSSTR9 0008 94E9h, S12AD2.ADSSTR10 0008 94EAh, S12AD2.ADSSTR11 0008 94EBh, S12AD2.ADSSTRL 0008 94DDh, S12AD2.ADSSTRT 0008 94DEh, S12AD2.ADSSTRO 0008 94DFh

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	1	1	0	1	1

The ADSSTRn register sets the sampling time for analog input.
Set the sampling time based on the number of clock cycles for ADCLK (A/D conversion clock). The initial value is 27 clock cycles. If the impedance of analog input signal source is too high to secure sufficient sampling time or if the ADCLK is slow, the sampling time can be adjusted. The ADSSTRn register should be set while the ADCSR.ADST bit is 0.
Specify the value for the register as a multiples of 3 in the range from 12 to 252 (clock cycles).
A sampling time can be determined by the following formula:

$$\text{Sampling time} = \text{ADSSTR} \times t_C(\text{ADCLK})$$

Table 42.17 shows the relationship between the A/D sampling state register and the relevant channels.
For details, refer to section 42.3.7, Analog Input Sampling Time and Scan Conversion Time.

Table 42.17 Relationship Between A/D Sampling State Register and Relevant Channels

Unit	Register Name	Relevant Channels
S12AD	ADSSTR0 register	AN000, Self-Diagnosis
	ADSSTR1 register	AN001
	ADSSTR2 register	AN002
	ADSSTR3 register	AN003
	ADSSTR4 register	AN004
	ADSSTR5 register	AN005
	ADSSTR6 register	AN006
S12AD1	ADSSTR0 register	AN100, Self-Diagnosis
	ADSSTR1 register	AN101
	ADSSTR2 register	AN102
	ADSSTR3 register	AN103
S12AD2	ADSSTR0 register	AN200, Self-Diagnosis
	ADSSTR1 register	AN201
	ADSSTR2 register	AN202
	ADSSTR3 register	AN203
	ADSSTR4 register	AN204
	ADSSTR5 register	AN205
	ADSSTR6 register	AN206
	ADSSTR7 register	AN207
	ADSSTR8 register	AN208
	ADSSTR9 register	AN209
	ADSSTR10 register	AN210
	ADSSTR11 register	AN211
	ADSSTRL register	AN216, AN217
	ADSSTRT register	Temperature sensor output*1
	ADSSTRO register	Internal reference voltage*2

Note 1. When performing A/D conversion of the temperature sensor output, it is necessary to set the sampling time that meets the specification described in section 49, Electrical Characteristics.
Note 2. When performing A/D conversion of the internal reference voltage, the sampling time should be 4 µs or longer.

42.2.21 A/D Sample-and-Hold Circuit Control Register (ADSHCR)

Address(es): S12AD.ADSHCR 0008 9066h, S12AD1.ADSHCR 0008 9266h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SHANS[2:0]			SSTSH[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	SSTSH[7:0]	Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting	Set a sampling time between 12 and 252 clock cycles.	R/W
b8	SHANS[0]	Channel-Dedicated Sample-and-Hold Circuit Bypass Select	Select whether to use or not use (bypass) the channel-dedicated sample-and-hold circuits either for AN000 or AN100. 0: Channel-dedicated sample-and-hold circuit is disabled. 1: Channel-dedicated sample-and-hold circuit is enabled.	R/W
b9	SHANS[1]		Select whether to use or not use (bypass) the channel-dedicated sample-and-hold circuits either for AN001 or AN101. 0: Channel-dedicated sample-and-hold circuit is disabled. 1: Channel-dedicated sample-and-hold circuit is enabled.	R/W
b10	SHANS[2]		Select whether to use or not use (bypass) the channel-dedicated sample-and-hold circuits either for AN002 or AN102. 0: Channel-dedicated sample-and-hold circuit is disabled. 1: Channel-dedicated sample-and-hold circuit is enabled.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADSHCR register sets the parameters related to channel-dedicated sample-and-hold circuits.

SSTSH[7:0] Bits (Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting)

The SSTSH[7:0] bits set the sampling time for the channel-dedicated sample-and-hold circuits when the ADSHMSR.SHMD bit is 0. Set the sampling time in clock cycles of ADCLK (A/D conversion clock). The initial value is 27 clock cycles. If the impedance of analog input signal source is too high to secure sufficient sampling time or if ADCLK is slow, the sampling time can be adjusted. Set the SSTSH[7:0] bits while the ADCSR.ADST bit is 0. Set a value between 12 and 252 clock cycles as the setting for sampling time.
Also, set a value such that the sampling time will be no less than 0.4 µs.

SHANS[2:0] Bits (Channel-Dedicated Sample-and-Hold Circuit Bypass Select)

The SHANS[2:0] bits select whether to use or bypass the channel-dedicated sample-and-hold circuits of AN000 to AN002 of unit 0 or AN100 to AN102 of unit 1. Set the SHANS[2:0] bits while both the ADCSR.ADST and ADSHMSR.SHMD bits are 0. If any of channels AN000 to AN002 of unit 0 or AN100 to AN102 of unit 1 is selected for group B or group C while operation is under group A priority control in group scan mode, the channel-dedicated sample-and-hold circuit should be disabled.
No channels of unit 2 have channel-dedicated sample-and-hold circuits.

42.2.22 A/D Sample-and-Hold Operating Mode Select Register (ADSHMSR)

Address(es): S12AD.ADSHMSR 0008 907Ch, S12AD1.ADSHMSR 0008 927Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SHMD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SHMD	Channel-Dedicated Sample-and-Hold Circuit Operating Mode Setting	0: Constant sampling of the channel-dedicated sample-and-hold circuits is disabled. 1: Constant sampling of the channel-dedicated sample-and-hold circuits is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADSHMSR register enables or disables constant sampling of the sample-and-hold circuit dedicated for channels.

SHMD Bit (Channel-Dedicated Sample-and-Hold Circuit Operating Mode Setting)

When the SHMD bit is set to 1, constant sampling of the sample-and-hold circuit for the channels selected by the ADSHCR.SHANS[2:0] bits is enabled. The SHMD bit should be set while the ADCSR.ADST bit is 0.

When the constant sampling function is enabled, constant sampling is performed while the 12-bit A/D converter is in the wait state and holding is performed when the A/D conversion is in progress.

Enable use of the channel-dedicated sample-and-hold circuit (ADSHCR.SHANS[2:0] ≠ 000b), enable normal sampling by the channel-dedicated sample-and-hold circuit (ADSHMSR.SHMD = 1), and wait for 6 cycles of ADCLK to pass before input of a trigger signal.

42.2.23 A/D Disconnection Detection Control Register (ADDISCR)

Address(es): S12AD.ADDISCR 0008 907Ah, S12AD1.ADDISCR 0008 927Ah, S12AD2.ADDISCR 0008 947Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	ADNDIS[4:0]				
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	ADNDIS[3:0]	A/D Disconnection Detection Assist Setting	Specify the period for discharging or precharging as a number of ADCLK cycles. b3 b0 0 0 0 0: No charging (disconnection detection assist function is disabled.) 0 0 1 1: Charging period of 3 clock cycles 0 1 1 0: Charging period of 6 clock cycles 1 0 0 1: Charging period of 9 clock cycles 1 1 0 0: Charging period of 12 clock cycles 1 1 1 1: Charging period of 15 clock cycles Settings other than above are prohibited.	R/W
b4	ADNDIS[4]		0: Discharge 1: Precharge	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADDISCR register sets the disconnection detection assist function.

ADNDIS[4:0] Bits (A/D Disconnection Detection Assist Setting)

The ADNDIS[4:0] bits select either precharge or discharge and the period of precharge/discharge for the A/D disconnection detection assist function. Setting the ADNDIS[4] bit = 1 allows to select precharge and setting the ADNDIS[4] bit = 0 allows to select discharge. The period of precharge/discharge can be set with the ADNDIS[3:0] bits. When ADNDIS[3:0] bits = 0000b, the disconnection detection assist function is disabled. Set the ADNDIS[3:0] bits to 0000b or a multiple of 3. A value other than those above cannot be set. The value set in the ADNDIS[3:0] bits is used to set the number of clock cycles that determines the precharging or discharging period.

The ADNDIS[4:0] bits should be set when the ADCSR.ADST bit is 0.

The disconnection detection assist function cannot be used when the PGA output, temperature sensor output, or internal reference voltage is converted, or when the self-diagnosis function is used. Set the ADNDIS[3:0] bits to 0000b.

When A/D conversion of a temperature sensor output or internal reference voltage proceeds, auto-discharging is also executed beforehand. Therefore, the ADNDIS[4:0] bits are automatically fixed to 0Fh during conversion for a scan group that includes a temperature sensor output or internal reference voltage, and the corresponding analog input paths in the A/D converter are discharged. Sampling starts after discharging is completed.

After the A/D conversion of a temperature sensor output or internal reference voltage is finished, the ADNDIS[4:0] bits automatically return to the setting before the conversion.

42.2.24 A/D Event Link Control Register (ADELCCR)

Address(es): S12AD.ADELCCR 0008 907Dh, S12AD1.ADELCCR 0008 927Dh, S12AD2.ADELCCR 0008 947Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	ELCC[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	ELCC[2:0]	Event Link Control	b2 b0 0 0 0: An event signal is generated when scanning for group A is completed. 0 0 1: An event signal is generated when scanning for group B is completed. 0 1 0: An event signal is generated when scanning for group A, group B, or group C is completed. 1 0 0: An event signal is generated when scanning for group C is completed. Settings other than above are prohibited.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADELCCR register is used to set an event signal generation condition at completion of scanning.

ELCC[2:0] Bits (Event Link Control)

The ELCC[2:0] bits are used to select an event signal generation condition at completion of scanning.

42.2.25 A/D Group Scan Priority Control Register (ADGSPCR)

Address(es): S12AD.ADGSPCR 0008 9080h, S12AD1.ADGSPCR 0008 9280h, S12AD2.ADGSPCR 0008 9480h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	GBRP	LGRRS	—	—	—	—	—	—	—	—	—	—	—	—	GBRSCN	PGS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PGS	Group Priority Control Setting *1	0: Operation is without group priority control 1: Operation is with group priority control	R/W
b1	GBRSCN	Low-Priority Group Restart Setting	(Enabled only when PGS = 1. Reserved when PGS = 0.) 0: Scanning for the group is not restarted after having been interrupted due to group priority control. 1: Scanning for the group is restarted after having been interrupted due to group priority control.	R/W
b13 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	LGRRS	Restart Channel Select	(Enabled when PGS = 1 and GBRSCN = 1. Reserved when PGS = 0 or GBRSCN = 0.) 0: Scanning is restarted from the scan start channel. 1: Scanning is restarted from the channel on which A/D conversion is not completed.	R/W
b15	GBRP	Single Scan Continuous Start *2	(Enabled only when PGS = 1. Reserved when PGS = 0.) 0: Single scan is not continuously started. 1: Single scan for the lowest-priority group is continuously started.	R/W

Note 1. When the PGS bit is to be set to 1, the ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode). If the bits are set to any other values, proper operation is not guaranteed.
Note 2. When the GBRP bit has been set to 1, single scan is performed continuously for the lowest-priority group regardless of the setting of the GBRSCN bit.

The ADGSPCR register is used to interrupted scanning of the low-priority group and make settings for priority control of scanning for the priority group in group scan mode.
For the settings on group priority operation, refer to Table 42.21 and Table 42.22.

PGS Bit (Group Priority Control Setting)

The PGS bit sets the priority of operation in group scan mode. Set this bit to 1 when giving priority to operation on the group.
When the PGS bit is to be set to 1, the ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode).
During group priority operation, a trigger to start scanning for the priority group is accepted during scan for the low-priority group, and scan for the priority group is started after scan for the low-priority group was interrupted. The priority order is group A > group B > group C.
When a trigger to start scanning for group B is accepted during scan for group C, group C scan is interrupted, and scan for group B is started. When a trigger to start scanning for group A is accepted during scan for group C, group C scan is interrupted, and scan for group A is started.
Likewise, when a trigger to start scanning for group A is accepted during scan for group B, group B scan is interrupted and scan for group A is started.
When setting the PGS bit to 0, clearing should be performed by software according to section 42.6.2, Notes on Stopping A/D Conversion. When setting the PGS bit to 1, follow the procedure described in section 42.3.5.3, Operation under Group Priority Control.

GBRSCN Bit (Low-Priority Group Restart Setting)

The GBRSCN bit controls the restarting of scan operation during group priority control.
If a scan operation on the low-priority group has been stopped by a priority group trigger input with the GBRSCN bit set to 1, the scan operation is restarted after the scanning of the priority group is completed. Also, if a low-priority trigger is input during scan for the priority group, the scan operation on the low-priority group is restarted after the scan for the priority group is completed.
If the GBRSCN bit has been set to 0, triggers that are input during A/D conversion are ignored. Also, the ADCSR.ADST bit must be 0 when the GBRSCN bit is to be set.
The setting of the GBRSCN bit is enabled when the PGS bit is set to 1.

LGRRS Bit (Restart Channel Select)

The LGRRS bit sets the channel on which scan is restarted during group priority control. The setting of the LGRRS bit is enabled when the PGS and GBRSCN bits are set to 1.
If a scan operation on the low-priority group has been stopped due to group priority operation with the LGRRS bit set to 0, the scan operation is restarted from the start channel after the scan for the priority group is completed.
If a scan operation on the low-priority group has been stopped due to group priority operation with the LGRRS bit set to 1, the scan operation is restarted*1 on the channel on which A/D conversion is not competed after the scan for the priority group is completed.
The LGRRS bit should be set while the ADCSR.ADST bit is 0.

Note 1. If A/D conversion on the addition set channel is not completed for the set number of times when scanning is stopped, A/D conversion on the channel is restarted for the set number of times when scanning is restarted.

GBRP Bit (Single Scan Continuous Start)

The GBRP bit is set when the lowest-priority group is continuously operated in single scan mode while group priority operation is set. The lowest-priority group is group C when groups A, B, and C are used; group B when groups A and B are used.
Setting the GBRP bit to 1 starts a single scan on the lowest-priority group. On completion of the scan, another single scan on the lowest-priority group is automatically started.
If scanning has been stopped due to group priority operation, single scan on the lowest-priority group is automatically restarted on completion of the A/D conversion on the priority group.
Disable the trigger input for the lowest-priority group before setting the GBRP bit to 1. When the GBRP bit is set to 1, only the lowest-priority group is scanned again even if the GBRSCN bit is 0.
The ADCSR.ADST bit must be 0 when the GBRP bit is to be set.
The setting of the GBRP bit is enabled when the PGS bit is 1.

42.2.26 A/D Comparison Function Control Register (ADCMPCR)

Address(es): S12AD.ADCMPCR 0008 9090h, S12AD1.ADCMPCR 0008 9290h, S12AD2.ADCMPCR 0008 9490h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CMPAIE	WCMPE	CMPBIE	—	CMPAE	—	CMPBE	—	—	—	—	—	—	—	CMPAB[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CMPAB[1:0]	Window A/B Complex Conditions Setting	b1 b0 0 0: Window A comparison condition matched OR window B comparison condition matched 0 1: Window A comparison condition matched XOR window B comparison condition matched 1 0: Window A comparison condition matched AND window B comparison condition matched 1 1: Setting is prohibited	R/W
b8 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9	CMPBE	Comparison Window B Enable	0: Comparison window B disabled 1: Comparison window B enabled	R/W
b10	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b11	CMPAE	Comparison Window A Enable	0: Comparison window A disabled 1: Comparison window A enabled	R/W
b12	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b13	CMPBIE	Comparison B Interrupt Enable	0: Comparison interrupt by a match with the comparison condition (window B) is disabled 1: Comparison interrupt by a match with the comparison condition (window B) is enabled	R/W
b14	WCMPE	Window Function Setting	0: The window function is disabled Window A or B operates as a comparator for comparing between one value on the low side and the A/D-converted value 1: The window function is enabled Window A or B operates as a window comparator for comparing between two values on the high and low sides and the A/D-converted value	R/W
b15	CMPAIE	Comparison A Interrupt Enable	0: Comparison interrupt by a match with the comparison condition (window A) is disabled 1: Comparison interrupt by a match with the comparison condition (window A) is enabled	R/W

The ADCMPCR register is used to set the settings for the comparison window function (windows A and B).

CMPAB[1:0] Bits (Window A/B Complex Conditions Setting)

The CMPAB[1:0] bits are enabled when single scan mode and window A/B are both enabled (CMPAE bit = 1 and CMPBE bit = 1). These bits specify the monitor conditions of the ADWINMON.MONCOMB flag. The CMPAB[1:0] bits should be set when the ADCSR.ADST bit is 0.

CMPBE Bit (Comparison Window B Enable)

The CMPBE bit is used to disable or enable comparison window B. The CMPBE bit should be set when the ADCSR.ADST bit is 0.

To set the following registers, set this bit to 0.

- A/D channel select registers A0/A1/B0/B1/C0/C1 (ADANSA0, ADANSA1, ADANSB0, ADANSB1, ADANSC0, and ADANSC1)
- Bits OCSB, TSSB, OCSA, and TSSA in the A/D conversion extended input control register (ADEXICR.OCSB,

TSSB, OCSA, and TSSA)

- Bits OCSC and TSSC in the A/D group C extended input control register (ADGCEXCR.OCSC and TSSC)
- The CMPCHB[5:0] bits in the window B channel select register (ADCMPBNSR.CMPCHB[5:0])

CMPAE Bit (Comparison Window A Enable)

The CMPAE bit is used to disable or enable comparison window A. The CMPAE bit should be set when the ADCSR.ADST bit is 0.

To set the following registers, set this bit to 0.

- A/D channel select registers A0/A1/B0/B1/C0/C1 (ADANSA0, ADANSA1, ADANSB0, ADANSB1, ADANSC0, and ADANSC1)
- Bits OCSB, TSSB, OCSA, and TSSA in the A/D conversion extended input control register (ADEXICR.OCSB, TSSB, OCSA, and TSSA)
- Bits OCSC and TSSC in the A/D group C extended input control register (ADGCEXCR.OCSC and TSSC)
- Window A channel select registers 0 and 1 (ADCMPANSR0 and ADCMPANSR1)
- Window A extended input select register (ADCMPANSER)

CMPBIE Bit (Comparison B Interrupt Enable)

Enables or disables comparison interrupts by a window B comparison condition match. A single comparison interrupt exists for each unit. Table 42.18 lists the relationship between each unit and its comparison interrupt.

WCMPE Bit (Window Function Setting)

The WCMPE bit is used to disable or enable the window function. The WCMPE bit should be set when the ADCSR.ADST bit is 0.

CMPAIE Bit (Comparison A Interrupt Enable)

Enables or disables comparison interrupts by a window A comparison condition match. A single comparison interrupt exists for each unit. Table 42.18 lists the relationship between each unit and its comparison interrupt.

Table 42.18 Relationship Between Each Unit and Its Comparison Interrupt Unit

Unit	Comparison Interrupt	
	When Window A Comparison Condition is Met	When Window B Comparison Condition is Met
S12AD	S12CMPAI	S12CMPBI
S12AD1	S12CMPAI1	S12CMPBI1
S12AD2	S12CMPAI2	S12CMPBI2

42.2.27 A/D Comparison Function Window A Channel Select Register 0 (ADCMPANSR0)

(1) S12AD.ADCMPANSR0

Address(es): S12AD.ADCMPANSR0 0008 9094h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	CMPCHA006	CMPCHA005	CMPCHA004	CMPCHA003	CMPCHA002	CMPCHA001	CMPCHA000
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPCHA000	Comparison Window A Channel Select	These bits determine whether to include pins AN000 to AN006 as the targets for comparison window A. 0: Exclude from the targets for comparison window A. 1: Include as the targets for comparison window A.	R/W
b1	CMPCHA001			R/W
b2	CMPCHA002			R/W
b3	CMPCHA003			R/W
b4	CMPCHA004			R/W
b5	CMPCHA005			R/W
b6	CMPCHA006			R/W
b15 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD.ADCMPANSR0 register selects analog inputs AN000 to AN006 of the channels that perform comparison with the conditions of comparison window A.

CMPCHA0n Bit (Comparison Window A Channel Select) (n = 00 to 06)

The comparison function is enabled when the CMPCHA0n bit with the same index number as the A/D conversion channel selected by the ADANSA0.ANSA0n bit, the ADANSB0.ANSB0n bit, and the ADANSC0.ANSC0n bit is set to 1.

The CMPCHA0n bit should be set while the ADCSR.ADST bit is 0.

(2) S12AD1.ADCMPANSR0

Address(es): S12AD1.ADCMPANSR0 0008 9294h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	CMPCHA003	CMPCHA002	CMPCHA001	CMPCHA000
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPCHA000	Comparison Window A Channel Select	These bits determine whether to include pins AN100 to AN103 as the targets for comparison window A. 0: Exclude from the targets for comparison window A. 1: Include as the targets for comparison window A.	R/W
b1	CMPCHA001			R/W
b2	CMPCHA002			R/W
b3	CMPCHA003			R/W
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD1.ADCMPANSR0 register selects analog inputs AN100 to AN103 of the channels that perform comparison with the conditions of comparison window A.

CMPCHA0n Bit (Comparison Window A Channel Select) (n = 00 to 03)

The comparison function is enabled when the CMPCHA0n bit with the same index number as the A/D conversion channel selected by the ADANSA0.ANSA0n bit, the ADANSB0.ANSB0n bit, and the ADANSC0.ANSC0n bit is set to 1.

The CMPCHA0n bit should be set while the ADCSR.ADST bit is 0.

(3) S12AD2.ADCMPANSR0

Address(es): S12AD2.ADCMPANSR0 0008 9494h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b10	CMPCHA010			R/W
b11	CMPCHA011			R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD2.ADCMPANSR0 register selects analog inputs AN200 to AN211 of the channels that perform comparison with the conditions of comparison window A.

CMPCHA0n Bit (Comparison Window A Channel Select) (n = 00 to 11)

The comparison function is enabled when the CMPCHA0n bit with the same index number as the A/D conversion channel selected by the ADANSA0.ANSA0n bit, the ADANSB0.ANSB0n bit, and the ADANSC0.ANSC0n bit is set to 1.

The CMPCHA0n bit should be set while the ADCSR.ADST bit is 0.

42.2.28 A/D Comparison Function Window A Channel Select Register 1 (ADCMPANSR1)

Address(es): S12AD2.ADCMPANSR1 0008 9496h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CMPCHA101	CMPCHA100
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPCHA100	Comparison Window A Channel Select	These bits determine whether to include pins AN216 to AN217 as the targets for comparison window A. 0: Exclude from the targets for comparison window A. 1: Include as the targets for comparison window A.	R/W
b1	CMPCHA101			R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADCMPANSR1 register selects analog inputs AN216 to AN217 of the channels that perform comparison with the conditions of comparison window A.

CMPCHA1n Bit (Comparison Window A Channel Select) (n = 00, 01)

The comparison function is enabled when the CMPCHA1n bit with the same index number as the A/D conversion channel selected by the ADANSA1.ANSA1n bit, the ADANSB1.ANSB1n bit, and the ADANSC1.ANSC1n bit is set to 1.

The CMPCHA1n bit should be set while the ADCSR.ADST bit is 0.

42.2.29 A/D Comparison Function Window A Extended Input Select Register (ADCMPANSER)

Address(es): S12AD2.ADCMPANSER 0008 9492h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	CMPSOC	CMPSTS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPSTS	Temperature Sensor Output Comparison Select	0: Temperature sensor output is excluded from the targets for comparison window A 1: Temperature sensor output is included as the targets for comparison window A	R/W
b1	CMPSOC	Internal Reference Voltage Compare Select	0: Internal reference voltage is excluded from the targets for comparison window A 1: Internal reference voltage is included as the targets for comparison window A	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADCMPANSER register selects whether the temperature sensor output or internal reference voltage is compared under the conditions of comparison window A.

CMPSTS Bit (Temperature Sensor Output Comparison Select)

The comparison window A is enabled when the CMPSTS bit is set to 1 while the ADEXICR.TSSA, ADEXICR.TSSB, or the ADGCEXCR.TSSC bit is 1. The CMPSTS bit should be set while the ADCSR.ADST bit is 0.

CMPSOC Bit (Internal Reference Voltage Compare Select)

The comparison window A is enabled when the CMPSOC bit is set to 1 while the ADEXICR.OCSA, ADEXICR.OCSB, or ADGCEXCR.OCSC bit is 1. The CMPSOC bit should be set while the ADCSR.ADST bit is 0.

42.2.30 A/D Comparison Function Window A Comparison Condition Setting Register 0 (ADCMPLR0)

(1) S12AD.ADCMPLR0

Address(es): S12AD.ADCMPLR0 0008 9098h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b5	CMPLCHA005			R/W
b6	CMPLCHA006			R/W
b15 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD.ADCMPLR0 register specifies the conditions for comparison of the values in the S12AD.ADCMPDR0/ADCMPDR1 register and the value of A/D conversion. The S12AD.ADCMPLR0 register should be set while the S12AD.ADCSR.ADST bit is 0.

CMPLCHA0n Bit (Comparison Window A Comparison Condition Select) (n = 00 to 06)

The CMPLCHA0n bit specifies the comparison conditions of the channels (AN000 to AN006) targeted for the window A comparison conditions. The condition can be specified for each analog input for comparison. The CMPLCHA000 bit corresponds to AN000 and the CMPLCHA006 bit corresponds to AN006.

b3	CMPLCHA003			R/W
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD1.ADCMPLR0 register specifies the conditions for comparison of the values in the S12AD1.ADCMPDR0/ADCMPDR1 register and the value of A/D conversion. The S12AD1.ADCMPLR0 register should be set while the S12AD1.ADCSR.ADST bit is 0.

CMPLCHA0n Bit (Comparison Window A Comparison Condition Select) (n = 00 to 03)

The CMPLCHA0n bit specifies the comparison conditions of the channels (AN100 to AN103) targeted for the window A comparison conditions. The condition can be specified for each analog input for comparison. The CMPLCHA000 bit corresponds to AN100 and the CMPLCHA003 bit corresponds to AN103.

(3) S12AD2.ADCMPLR0

Address(es): S12AD2.ADCMPLR0 0008 9498h

b11	CMPLCHA011			R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The S12AD2.ADCMPLR0 register specifies the conditions for comparison of the values in the S12AD2.ADCMPDR0/ADCMPDR1 register and the value of A/D conversion. The S12AD2.ADCMPLR0 register should be set while the S12AD2.ADCSR.ADST bit is 0.

CMPLCHA0n Bit (Comparison Window A Comparison Condition Select) (n = 00 to 11)

The CMPLCHA0n bit specifies the comparison conditions of the channels (AN200 to AN211) targeted for the window A comparison conditions. The condition can be specified for each analog input for comparison. The CMPLCHA000 bit corresponds to AN200 and the CMPLCHA011 bit corresponds to AN211.

When the result of comparison of each analog input matches with the pre-set condition, the ADCMPSR0.CMPSTCHA0n flag (n = 00 to 11) becomes 1 and a comparison interrupt (S12CMPAI, S12CMPAI1, S12CMPAI2) is generated. The conditions for comparison are shown in Figure 42.6.

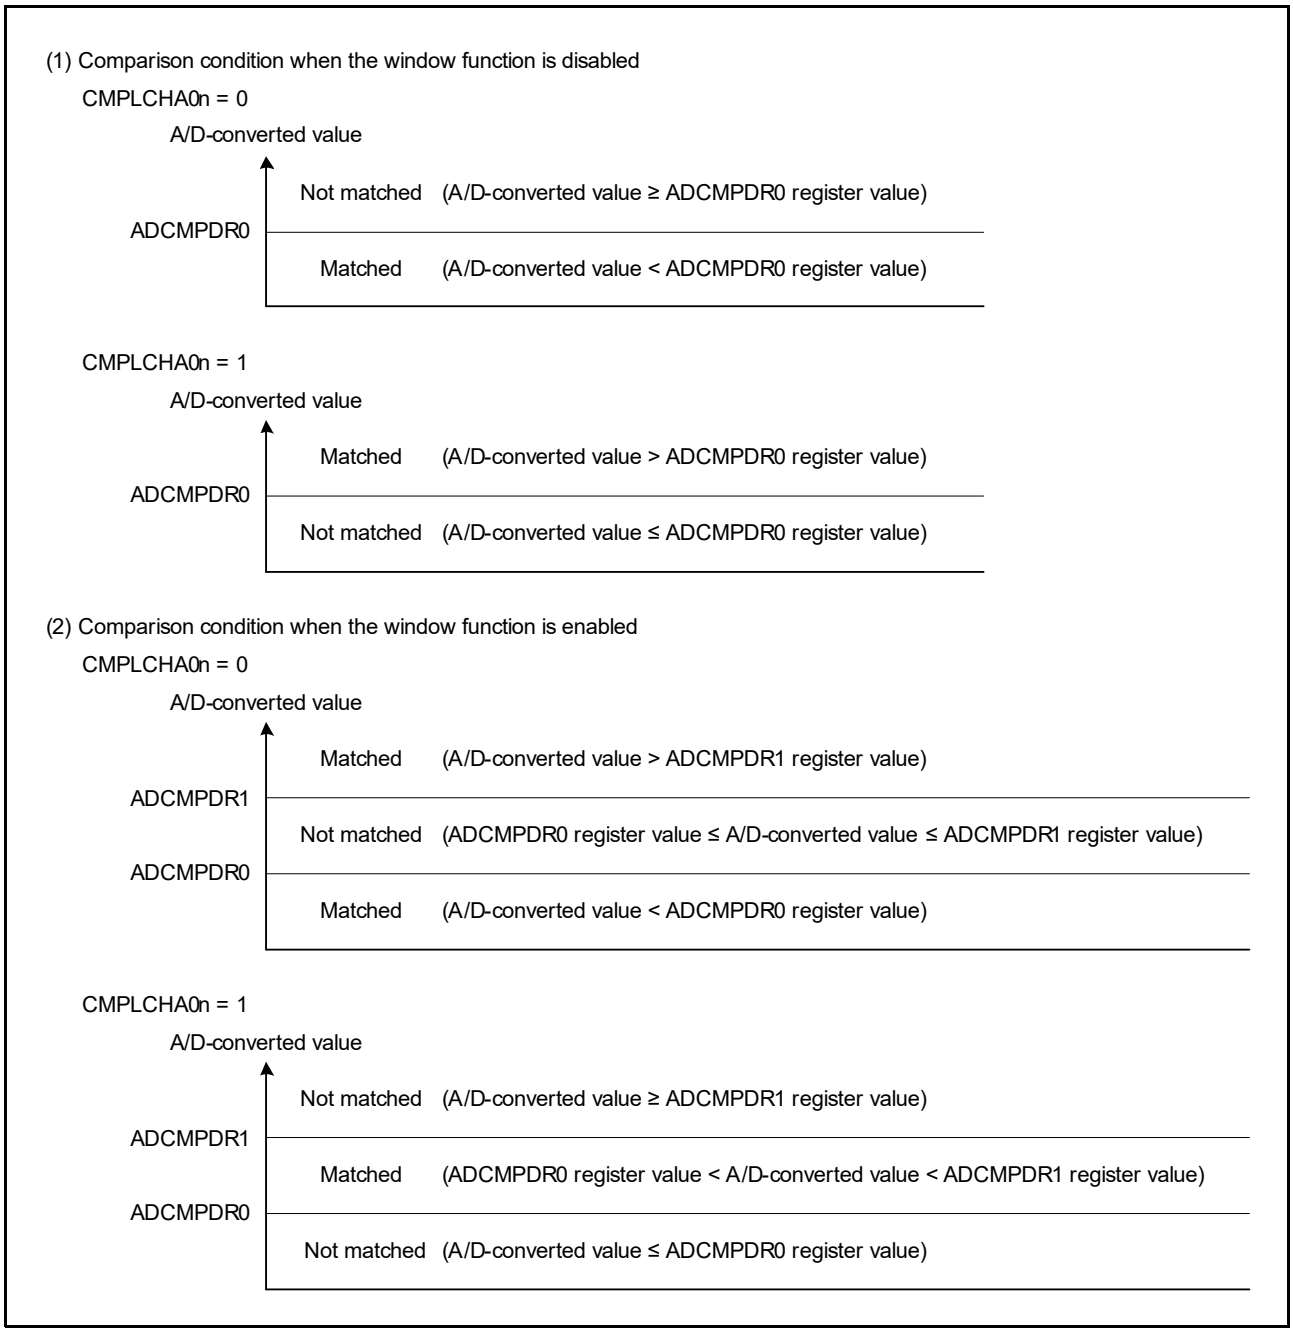

Figure 42.6 Details of Comparison Condition: Comparison Function Window A

42.2.31 A/D Comparison Function Window A Comparison Condition Setting Register 1 (ADCMPLR1)

Address(es): S12AD2.ADCMPLR1 0008 949Ah

Bit	Symbol	Bit Name	Description	R/W
b0	CMPLCHA100	Comparison Window A Comparison Condition Select	When the window function is disabled (the ADCMPCR.WCMPE bit is 0) 0: ADCMPDR0 register value > A/D-converted value 1: ADCMPDR0 register value < A/D-converted value When the window function is enabled (the ADCMPCR.WCMPE bit is 1) 0: A/D-converted value < ADCMPDR0 register value or ADCMPDR1 register value < A/D-converted value 1: ADCMPDR0 register value < A/D-converted value < ADCMPDR1 register value	R/W
b1	CMPLCHA101			R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADCMPLR1 register specifies the conditions for comparison of the values in the ADCMPDR0/ADCMPDR1 register and the value of A/D conversion. The ADCMPLR1 register should be set while the ADCSR.ADST bit is 0.

CMPLCHA1n Bit (Comparison Window A Comparison Condition Select) (n = 00, 01)

The CMPLCHA1n bit specifies the comparison conditions of the channels (AN216 to AN217) targeted for the window A comparison conditions. The condition can be specified for each analog input for comparison. The CMPLCHA100 bit corresponds to AN216 and the CMPLCHA101 bit corresponds to AN217.

When the result of comparison of each analog input matches with the pre-set condition, the S12AD2.ADCMPSR1.CMPSTCHA1n flag becomes 1 and a comparison interrupt (S12CMPAI2) is generated. The conditions for comparison are shown in Figure 42.6.

42.2.32 A/D Comparison Function Window A Extended Input Comparison Condition Setting Register (ADCMPLER)

Address(es): S12AD2.ADCMPLER 0008 9493h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	CMPLOC	CMPLTS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPLTS	Comparison Window A Temperature Sensor Output Comparison Condition Select	When the window A function is disabled (the ADCMPCR.WCMPE bit is 0) 0: ADCMPDR0 register value > A/D-converted value 1: ADCMPDR0 register value < A/D-converted value When the window A function is enabled (the ADCMPCR.WCMPE bit is 1) 0: A/D-converted value < ADCMPDR0 register value or ADCMPDR1 register value < A/D-converted value 1: ADCMPDR0 register value < A/D-converted value < ADCMPDR1 register value	R/W
b1	CMPLOC	Comparison Window A Internal Reference Voltage Comparison Condition Select	When the window A function is disabled (the ADCMPCR.WCMPE bit is 0) 0: ADCMPDR0 register value > A/D-converted value 1: ADCMPDR0 register value < A/D-converted value When the window A function is enabled (the ADCMPCR.WCMPE bit is 1) 0: A/D-converted value < ADCMPDR0 register value or ADCMPDR1 register value < A/D-converted value 1: ADCMPDR0 register value < A/D-converted value < ADCMPDR1 register value	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADCMPLER register specifies the conditions for comparison of the values in the ADCMPDR0/ADCMPDR1 register and the value of A/D conversion. The ADCMPLER register should be set while the ADCSR.ADST bit is 0.

CMPLTS Bit (Comparison Window A Temperature Sensor Output Comparison Condition Select)

The CMPLTS bit selects the comparison conditions of temperature sensor output targeted for window A.
When the result of comparison of temperature sensor output matches with the pre-set condition, the ADCMPSER.CMPFTS flag becomes 1. A comparison interrupt (S12CMPAI2) is generated.
Figure 42.6 shows the conditions for comparison.

CMPLOC Bit (Comparison Window A Internal Reference Voltage Comparison Condition Select)

The CMPLOC bit selects the comparison conditions of the internal reference voltage targeted for window A.
When the result of comparison of the internal reference voltage matches with the pre-set condition, the ADCMPSER.CMPFOC flag becomes 1. A comparison interrupt (S12CMPAI2) is generated.
Figure 42.6 shows the conditions for comparison.

42.2.33 A/D Comparison Function Window A Lower Level Setting Register (ADCMPDR0)

Address(es): S12AD.ADCMPDR0 0008 909Ch, S12AD1.ADCMPDR0 0008 929Ch, S12AD2.ADCMPDR0 0008 949Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ADCMPDR0 register is a readable and writable register that specifies the reference data when the comparison window A function is used. The ADCMPDR0 register specifies the lower level of window A.
Writing to the ADCMPDR0 register is enabled even when A/D conversion is in progress. Rewriting the register value during the A/D conversion dynamically changes the reference data.
Satisfy the condition of [Upper limit level ≥ Lower limit level (ADCMPDR1 setting value ≥ ADCMPDR0 setting value)] when setting.

The data formats of the register for each given condition are shown below.

- Setting of the A/D data register format select bit (right-justified or left-justified format)
- Setting of the A/D-converted value addition/averaging function channel select register (A/D-converted value addition/averaging mode is enabled or disabled)
- Setting of the A/D-converted value addition/average count select register (addition/averaging mode is selected and addition count is selected)

Note: When the comparison values are set in a different format from that of the A/D data register y (ADDRy), correct result of comparison cannot be obtained.

(1) When A/D-Converted Value Addition/Average Mode is Disabled

- Right-justified format
  The comparison level (lower) to be compared is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Left-justified format
  The comparison level (lower) to be compared is set in bits 15 to 4. Write 0 to bits 3 to 0.

(2) When A/D-Converted Average Mode is Selected

A/D-converted value average mode can be set only when 2- or 4-time conversion is selected in A/D-converted value addition mode.

- Right-justified format
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Left-justified format
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 15 to 4. Write 0 to bits 3 to 0.

(3) When A/D-Converted Value Addition Mode is Selected

When A/D-converted value addition mode is selected, the value for comparison with the result of cumulative A/D-converted value of the same channel is specified. Conversion 1, 2, 3, 4, or 16 times is selectable. When A/D-converted value addition mode is selected and if conversion 1 to 4 is selected, the resolution of the results of conversion will be extended by 2 bits and so set a value for comparison with the results in the ADCMPDR0 register. When conversion 16 times is selected, the resolution of the results of conversion will be extended by 4 bits and so set a value for

comparison with the results in the ADCMPDR0 register.
Even when A/D-converted value addition mode is selected, set the value for reference based on the setting of the A/D data register format select bit.

- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 13 to 0. Write 0 to bits 15 and 14.
- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 15 to 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)
  The comparison level (lower) to be compared with the A/D-converted value of the same channel is set in bits 15 to 2. Write 0 to bits 1 and 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 15 to 0.

42.2.34 A/D Comparison Function Window A Upper Level Setting Register (ADCMPDR1)

Address(es): S12AD.ADCMPDR1 0008 909Eh, S12AD1.ADCMPDR1 0008 929Eh, S12AD2.ADCMPDR1 0008 949Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ADCMPDR1 register is a readable and writable register that specifies the data for reference when the comparison window A function is used. The register specifies the upper level of window A.
A write operation to the ADCMPDR1 register is enabled even during A/D conversion. Rewriting the value of the register during A/D conversion dynamically changes the reference data.
Satisfy the condition of [upper limit level ≥ lower limit level (ADCMPDR1 setting value ≥ ADCMPDR0 setting value)] when setting.
The ADCMPDR1 register is not used when the window function is disabled.

The data formats of the register for each given condition are shown below.

- Setting of the A/D data register format select bit (right-justified or left-justified format)
- Setting of the A/D-converted value addition/averaging function channel select register (A/D-converted value addition/averaging mode is enabled or disabled)
- Setting of the A/D-converted value addition/averaging time select register (addition/averaging mode is selected and addition count is selected)

Note: When the comparison values are set in a different format from that of the A/D data register y (ADDRy), correct result of comparison cannot be obtained.

(1) When A/D-Converted Value Addition/Average Mode is Disabled

- Right-justified format
  The comparison level (upper) is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Left-justified format
  The comparison level (upper) is set in bits 15 to 4. Write 0 to bits 3 to 0.

(2) When A/D-Converted Average Mode is Selected

A/D-converted value average mode can be set only when 2- or 4-time conversion is selected in A/D-converted value addition mode.

- Right-justified format
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Left-justified format
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 15 to 4. Write 0 to bits 3 to 0.

(3) When A/D-Converted Value Addition Mode is Selected

When A/D-converted value addition mode is selected, the value for comparison with the result of cumulative A/D-converted value of the same channel is specified. Conversion 1, 2, 3, 4, or 16 times is selectable. When A/D-converted value addition mode is selected and if conversion 1 to 4 is selected, the resolution of the results of conversion will be extended by 2 bits and so set a value for comparison with the results in the ADCMPDR1 register. When conversion 16

times is selected, the resolution of the results of conversion will be extended by 4 bits and so set a value for comparison with the results in the ADCMPDR1 register.
Even when A/D-converted value addition mode is selected, set the value for reference based on the setting of the A/D data register format select bit.

- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)
  The comparison level (upper) to be compared with the A/D-converted value of the same channel is set bits 13 to 0. Write 0 to bits 15 and 14.
- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)
  The comparison level (upper) to be compared with the A/D-converted value of the same channel is set bits 15 to 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)
  The comparison level (upper) to be compared with the A/D-converted value of the same channel is set in bits 15 to 2. Write 0 to bits 1 and 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)
  The comparison level (upper) to be compared with the A/D-converted value of the same channel is set bits 15 to 0.

42.2.35 A/D Comparison Function Window A Channel Status Register 0 (ADCMPSR0)

(1) S12AD.ADCMPSR0

Address(es): S12AD.ADCMPSR0 0008 90A0h

	—	—	—	—	—	—	—	—	—	CMPSTCHA006	CMPSTCHA005	CMPSTCHA004	CMPSTCHA003	CMPSTCHA002	CMPSTCHA001	CMPSTCHA000
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPSTCHA000	Comparison Window A Flag	When window A operation is enabled (ADCMPCR.CMPAE = 1) These bits indicate the comparison result of the channels (AN000 to AN006) for the window A comparison condition 0: The comparison condition is not satisfied. 1: The comparison condition is satisfied.	R/(W) *1
b1	CMPSTCHA001			R/(W) *1
b2	CMPSTCHA002			R/(W) *1
b3	CMPSTCHA003			R/(W) *1
b4	CMPSTCHA004			R/(W) *1
b5	CMPSTCHA005			R/(W) *1
b6	CMPSTCHA006			R/(W) *1
b15 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 0 can be written to clear the flag after reading 1.

The S12AD.ADCMPSR0 register is a register that stores the result of comparison by the comparison window A function.

CMPSTCHA0n Flag (Comparison Window A Flag) (n = 00 to 06)

The CMPSTCHA0n flag is a status flag that indicate the result of comparison of the channels (AN000 to AN006) of the comparison condition for window A. When the conversion result matches with the comparison condition specified in the ADCMPLR0.CMPLCHA0n bit on completion of A/D conversion, this flag becomes 1.

When the ADCMPCR.CMPAIE bit is 1, a comparison interrupt request (S12CMPAI) is generated at the setting of the flag. The CMPSTCHA000 flag corresponds to AN000 and the CMPSTCHA006 flag corresponds to AN006.

1 cannot be written to the CMPSTCHA0n flag.

[Setting condition]

- When ADCMPCR.CMPAE bit = 1 and the condition set in the ADCMPLR0.CMPLCHA0n bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

(2) S12AD1.ADCMPSR0

Address(es): S12AD1.ADCMPSR0 0008 92A0h

Bit	Symbol	Bit Name	Description	R/W
b0	CMPFTS	Comparison Window A Temperature Sensor Output Comparison Flag	When window A operation is enabled (ADCMPCR.CMPAE = 1) This bit indicates the comparison result of the temperature sensor output 0: The comparison condition is not satisfied. 1: The comparison condition is satisfied.	R/(W) *1
b1	CMPFOC	Comparison Window A Internal Reference Voltage Comparison Flag	When window A operation is enabled (ADCMPCR.CMPAE = 1) This bit indicates the comparison result of the internal reference voltage 0: The comparison condition is not satisfied. 1: The comparison condition is satisfied.	R/(W) *1
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 0 can be written to clear the flag after reading 1.

The ADCMPSER register is a register that stores the result of comparison by the comparison window A function.

CMPFTS Flag (Comparison Window A Temperature Sensor Output Comparison Flag)

The CMPFTS flag is a status flag that indicates the result of comparison of the temperature sensor output. When the conversion result matches with the comparison condition specified in the ADCMPLER.CMPLTS bit upon completion of A/D conversion, this flag becomes 1. When the ADCMPCR.CMPAIE bit is 1, a comparison interrupt request (S12CMPAI2) is generated upon the setting of the flag.
1 cannot be written to the CMPFTS flag.
[Setting condition]

- When ADCMPCR.CMPAE bit = 1 and the condition set in the ADCMPLER.CMPLTS bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

CMPFOC Flag (Comparison Window A Internal Reference Voltage Comparison Flag)

The CMPFOC flag is a status flag that indicates the result of comparison of the internal reference voltage. When the conversion result matches with the comparison condition specified in the ADCMPLER.CMPLOC bit upon completion of A/D conversion, this flag becomes 1. When the ADCMPCR.CMPAIE bit is 1, a comparison interrupt request (S12CMPAI2) is generated upon the setting of the flag.
1 cannot be written to the CMPFOC flag.
[Setting condition]

- When ADCMPCR.CMPAE bit = 1 and the condition set in the ADCMPLER.CMPLOC bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

42.2.38 A/D Comparison Function Window A/B Status Monitoring Register (ADWINMON)

Address(es): S12AD.ADWINMON 0008 908Ch, S12AD1.ADWINMON 0008 928Ch, S12AD2.ADWINMON 0008 948Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	MONCMPB	MONCMPA	—	—	—	MONCOMB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MONCOMB	Combination Result Monitoring Flag	This flag indicates the combination result. This flag is valid when both window A operation and window B operation are enabled. 0: The complex condition for window A/B is not satisfied. 1: The complex condition for window A/B is satisfied.	R
b3 to b1	—	Reserved	These bits are read as 0.	R
b4	MONCMPA	Comparison Result Monitor A Flag	0: The comparison condition for window A is not satisfied. 1: The comparison condition for window A is satisfied.	R
b5	MONCMPB	Comparison Result Monitor B Flag	0: The comparison condition for window B is not satisfied. 1: The comparison condition for window B is satisfied.	R
b7, b6	—	Reserved	These bits are read as 0.	R

The ADWINMON register can monitor the results of comparison and the combined result.

MONCOMB Flag (Combination Result Monitoring Flag)

The MONCOMB bit is a dedicated bit for reading the combined result of comparison condition A and B that were set in the ADCMPCR.CMPAB[1:0] bits as a combined condition.

[Setting condition]

- When ADCMPCR.CMPAE bit = 1 and ADCMPCR.CMPBE bit = 1, the condition set in the ADCMPCR.CMPAB[1:0] bits is satisfied.

[Clearing condition]

- No match with the combined condition set in the ADCMPCR.CMPAB[1:0] bits
- When ADCMPCR.CMPAE bit = 0 or ADCMPCR.CMPBE bit = 0

MONCMPA Flag (Comparison Result Monitor A Flag)

The MONCMPA bit is a dedicated bit for reading 1 when the condition set in the ADCMPLR0, ADCMPLR1, or ADCMPLER register matches with the A/D-converted value of the channel targeted for window A and for reading 0 when such condition is not satisfied.

[Setting condition]

- When ADCMPCR.CMPAE bit = 1, the condition set in the ADCMPLR0.CMPLCHA0n bit is satisfied.

[Clearing condition]

- When ADCMPCR.CMPAE bit = 1, the condition set in the ADCMPLR0.CMPLCHA0n bit is not satisfied.
- When ADCMPCR.CMPAE bit = 0 (the ADCMPCR.CMPAE bit is automatically cleared to 0).

MONCMPB Flag (Comparison Result Monitor B Flag)

The MONCMPB bit is a dedicated bit for reading 1 when the condition set in the ADCMPBNSR.CMPLB bit matches with the A/D-converted value of the channel targeted for window B and for reading 0 when such condition is not satisfied.

[Setting condition]

- When ADCMPCR.CMPBE bit = 1, the condition set in the ADCMPBNSR.CMPLB bit is satisfied.

[Clearing condition]

- When ADCMPCR.CMPBE bit = 1, the condition set in the ADCMPBNSR.CMPLB bit is not satisfied.
- When ADCMPCR.CMPBE bit = 0 (the ADCMPCR.CMPBE bit is automatically cleared to 0).

42.2.39 A/D Comparison Function Window B Channel Select Register (ADCMPBNSR)

(1) S12AD.ADCMPBNSR

Address(es): S12AD.ADCMPBNSR 0008 90A6h

	b7	b6	b5	b4	b3	b2	b1	b0
	CMPLB	—	CMPCHB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	CMPCHB[5:0]	Comparison Window B Channel Select	Select the channel that compares with the condition of comparison window B b5 b0 0 0 0 0 0 0: AN000 0 0 0 0 0 1: AN001 0 0 0 0 1 0: AN002 : : 0 0 0 1 0 1: AN005 0 0 0 1 1 0: AN006 Settings other than above are prohibited.	R/W
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	CMPLB	Comparison Window B Comparison Condition Setting	When the window function is disabled (the ADCMPCR.WCMPE bit is 0) 0: ADWINLLB register value > A/D-converted value 1: ADWINLLB register value < A/D-converted value When the window function is enabled (the ADCMPCR.WCMPE bit is 1) 0: A/D-converted value < ADWINLLB register value or ADWINULB register value < A/D-converted value 1: ADWINLLB register value < A/D-converted value < ADWINULB register value	R/W

The S12AD.ADCMPBNSR register is used to specify the comparison window B function.

CMPCHB[5:0] Bits (Comparison Window B Channel Select)

The CMPCHB[5:0] bits select the channel to be compared with the comparison window B from AN000 to AN006. When the number of the A/D conversion channel selected in the ADANSAy.ANSAyn bit (y = 0 to 1, n = 00 to 06) and the ADANSBy.ANSByn bit is specified, the comparison window B function is enabled.
The CMPCHB[5:0] bits should be set while the ADCSR.ADST bit is 0.

CMPLB Bit (Comparison Window B Comparison Condition Setting)

The CMPLB bit specifies the condition for comparison of the channels for window B. When the result of comparison of each analog input matches with the pre-set condition, the ADCMPBSR.CMPSTB flag becomes 1 and a comparison interrupt (S12CMPBI) is generated. The conditions for comparison are shown in Figure 42.7.

(2) S12AD1.ADCMPBNSR

Address(es): S12AD1.ADCMPBNSR 0008 92A6h

	b7	b6	b5	b4	b3	b2	b1	b0
	CMPLB	—	CMPCHB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	CMPCHB[5:0]	Comparison Window B Channel Select	Select the channel that compares with the condition of comparison window B b5 b0 0 0 0 0 0 0: AN100 0 0 0 0 0 1: AN101 0 0 0 0 1 0: AN102 0 0 0 0 1 1: AN103 Settings other than above are prohibited.	R/W
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	CMPLB	Comparison Window B Comparison Condition Setting	When the window function is disabled (the ADCMPCR.WCMPE bit is 0) 0: ADWINLLB register value > A/D-converted value 1: ADWINLLB register value < A/D-converted value When the window function is enabled (the ADCMPCR.WCMPE bit is 1) 0: A/D-converted value < ADWINLLB register value or ADWINULB register value < A/D-converted value 1: ADWINLLB register value < A/D-converted value < ADWINULB register value	R/W

The S12AD1.ADCMPBNSR register is used to specify the comparison window B function.

CMPCHB[5:0] Bits (Comparison Window B Channel Select)

The CMPCHB[5:0] bits select the channel to be compared with the comparison window B from AN100 to AN103.
When the number of the A/D conversion channel selected in the ADANSAy.ANSAyn bit (y = 0 to 1, n = 00 to 03) and the ADANSBy.ANSByn bit is specified, the comparison window B function is enabled.
The CMPCHB[5:0] bits should be set while the ADCSR.ADST bit is 0.

CMPLB Bit (Comparison Window B Comparison Condition Setting)

The CMPLB bit specifies the condition for comparison of the channels for window B. When the result of comparison of each analog input matches with the pre-set condition, the ADCMPBSR.CMPSTB flag becomes 1 and a comparison interrupt (S12CMPBI1) is generated. The conditions for comparison are shown in Figure 42.7.

(3) S12AD2.ADCMPBNSR

Address(es): S12AD2.ADCMPBNSR 0008 94A6h

	b7	b6	b5	b4	b3	b2	b1	b0
	CMPLB	—	CMPCHB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	CMPCHB[5:0]	Comparison Window B Channel Select	Select the channel that compares with the condition of comparison window B b5 b0 0 0 0 0 0 0: AN200 0 0 0 0 0 1: AN201 0 0 0 0 1 0: AN202 : : 0 0 0 1 1 0: AN206 0 0 0 1 1 1: AN207 : : 0 0 1 0 1 0: AN210 0 0 1 0 1 1: AN211 0 1 0 0 0 0: AN216 0 1 0 0 0 1: AN217 1 0 0 0 0 0: Temperature sensor 1 0 0 0 0 1: Internal reference voltage Settings other than above are prohibited.	R/W
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	CMPLB	Comparison Window B Comparison Condition Setting	When the window function is disabled (the ADCMPCR.WCMPE bit is 0) 0: ADWINLLB register value > A/D-converted value 1: ADWINLLB register value < A/D-converted value When the window function is enabled (the ADCMPCR.WCMPE bit is 1) 0: A/D-converted value < ADWINLLB register value or ADWINULB register value < A/D-converted value 1: ADWINLLB register value < A/D-converted value < ADWINULB register value	R/W

The S12AD2.ADCMPBNSR register is used to specify the comparison window B function.

CMPCHB[5:0] Bits (Comparison Window B Channel Select)

The CMPCHB[5:0] bits select the channel to be compared under the comparison window B condition from AN200 to AN211, AN216, AN217, temperature sensor, and internal reference voltage.

When the number of the A/D conversion channel selected in the ADANSAy.ANSAyn bit (y = 0, 1, n = 00 to 11) and the ADANSBy.ANSByn bit is specified, the comparison window B function is enabled.

The CMPCHB[5:0] bits should be set while the ADCSR.ADST bit is 0.

CMPLB Bit (Comparison Window B Comparison Condition Setting)

The CMPLB bit specifies the condition for comparison of the channels for window B. When the result of comparison of each analog input matches with the pre-set condition, the ADCMPBSR.CMPSTB flag becomes 1 and a comparison interrupt (S12CMPBI2) is generated. The conditions for comparison are shown in Figure 42.7.

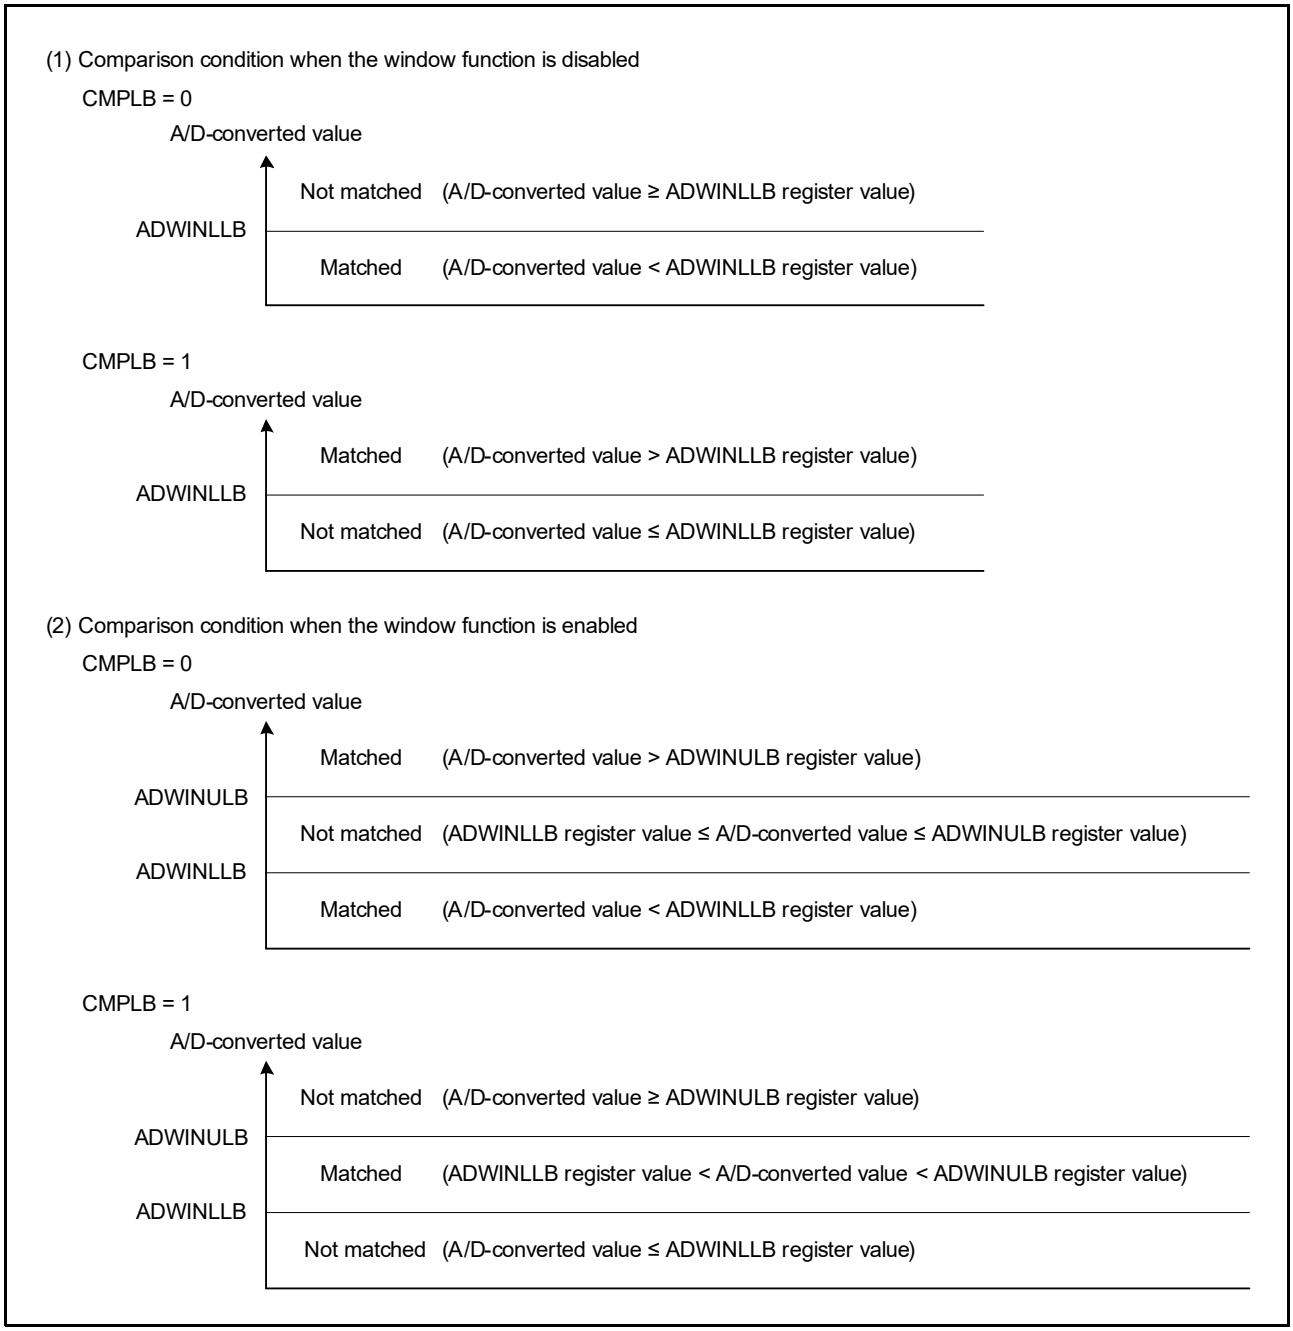

Figure 42.7 Details of Comparison Condition: Comparison Function Window B

42.2.40 A/D Comparison Function Window B Lower Level Setting Register (ADWINLLB)

Address(es): S12AD.ADWINLLB 0008 90A8h, S12AD1.ADWINLLB 0008 92A8h, S12AD2.ADWINLLB 0008 94A8h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ADWINLLB register is a readable and writable register that specifies reference data when comparison window B is in use. The register specifies the lower level of window B.
A write operation to the ADWINLLB register is enabled even during A/D conversion. Rewriting the value of the register during A/D conversion dynamically changes the reference data.
Satisfy the condition of [upper limit level ≥ lower limit level (ADWINULB register setting value ≥ ADWINLLB register setting value)] when setting.

The data formats of the register for each given condition are shown below.

- Setting of the A/D data register format select bit (right-justified or left-justified format)
- Setting of the A/D-converted value addition/averaging function channel select register (A/D-converted value addition/averaging mode is enabled or disabled)
- Setting of the A/D-converted value addition/averaging count select register (addition/averaging mode is selected and addition count is selected)

Note: When the comparison values are set in a different format from that of the A/D data register y (ADDRy), correct result of comparison cannot be obtained.

(1) When A/D-Converted Value Addition/Average Mode is Disabled

- Right-justified format
  The comparison level (lower) to be compared is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Left-justified format
  The comparison level (lower) to be compared is set in bits 15 to 4. Write 0 to bits 3 to 0.

(2) When A/D-Converted Average Mode is Selected

A/D-converted value average mode can be set only when 2- or 4-time conversion is selected in A/D-converted value addition mode.

- Right-justified format
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Left-justified format
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 15 to 4. Write 0 to bits 3 to 0.

(3) When A/D-Converted Value Addition Mode is Selected

When A/D-converted value addition mode is selected, the value for comparison with the result of cumulative A/D-converted value of the same channel is specified. Conversion 1, 2, 3, 4, or 16 times is selectable. When A/D-converted value addition mode is selected and if conversion 1 to 4 is selected, the resolution of the results of conversion will be extended by 2 bits and so set a value for comparison with the results in the ADWINLLB register. When conversion 16 times is selected, the resolution of the results of conversion will be extended by 4 bits and so set a value for comparison with the results in the ADWINLLB register.

Even when A/D-converted value addition mode is selected, set the value for reference based on the setting of the A/D data register format select bit.

- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 13 to 0. Write 0 to bits 15 and 14.
- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 15 to 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)
  The comparison level (lower) to be compared with the A/D-converted value of the same channel is set in bits 15 to 2. Write 0 to bits 1 and 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 15 to 0.

42.2.41 A/D Comparison Function Window B Upper Level Setting Register (ADWINULB)

Address(es): S12AD.ADWINULB 0008 90AAh, S12AD1.ADWINULB 0008 92AAh, S12AD2.ADWINULB 0008 94AAh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ADWINULB register is a readable and writable register that specifies the data for reference when the comparison window B function is used. The register specifies the upper level of window B.
A write operation to the register is enabled even during A/D conversion. Rewriting the value of the register during A/D conversion dynamically changes the reference data.
Satisfy the condition of [upper limit level ≥ lower limit level (ADWINULB register setting value ≥ ADWINLLB register setting value)] when setting.
The register is not used when the window function is disabled.

The data formats of the register for each given condition are shown below.

- Setting of the A/D data register format select bit (right-justified or left-justified format)
- Setting of the A/D-converted value addition/averaging function channel select register (A/D-converted value addition/averaging mode is enabled or disabled)
- Setting of the A/D-converted value addition/averaging count select register (addition/averaging mode is selected and addition count is selected)

Note: When the comparison values are set in a different format from that of the A/D data register y (ADDRy), correct result of comparison cannot be obtained.

(1) When A/D-Converted Value Addition/Average Mode is Disabled

- Right-justified format
  The comparison level (upper) is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Left-justified format
  The comparison level (upper) is set in bits 15 to 4. Write 0 to bits 3 to 0.

(2) When A/D-Converted Average Mode is Selected

A/D-converted value average mode can be set only when 2- or 4-time conversion is selected in A/D-converted value addition mode.

- Right-justified format
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Left-justified format
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 15 to 4. Write 0 to bits 3 to 0.

(3) When A/D-Converted Value Addition Mode is Selected

When A/D-converted value addition mode is selected, the value for comparison with the result of cumulative A/D-converted value of the same channel is specified. Conversion 1, 2, 3, 4, or 16 times is selectable. When A/D-converted value addition mode is selected and if conversion 1 to 4 is selected, the resolution of the results of conversion will be extended by 2 bits and so set a value for comparison with the results in the ADWINULB register. When conversion 16

times is selected, the resolution of the results of conversion will be extended by 4 bits and so set a value for comparison with the results in the ADWINULB register.
Even when A/D-converted value addition mode is selected, set the value for reference based on the setting of the A/D data register format select bit.

- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)
  The comparison level (upper) to be compared with the A/D-converted value of the same channel is set bits 13 to 0. Write 0 to bits 15 and 14.
- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)
  The comparison level (upper) to be compared with the A/D-converted value of the same channel is set bits 15 to 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)
  The comparison level (upper) to be compared with the A/D-converted value of the same channel is set in bits 15 to 2. Write 0 to bits 1 and 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)
  The comparison level (upper) to be compared with the A/D-converted value of the same channel is set bits 15 to 0.

42.2.42 A/D Comparison Function Window B Channel Status Register (ADCMPBSR)

(1) S12AD.ADCMPBSR

Address(es): S12AD.ADCMPBSR 0008 90ACh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CMPSTB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPSTB	Comparison Window B Flag	0: The comparison condition is not satisfied. 1: The comparison condition is satisfied.	R/(W) *1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 0 can be written to clear the flag after reading 1.

The S12AD.ADCMPBSR register is used to store results of comparison of the comparison window B function.

CMPSTB Flag (Comparison Window B Flag)

The CMPSTB flag is a status flag that indicates the result of comparison of the channels for window B comparison conditions (AN000 to AN006).

When the conversion result matches with the comparison condition that is set in the ADCMPBNSR.CMPLB bit upon completion of A/D conversion, this flag becomes 1. When the ADCMPCR.CMPBIE bit is 1, a comparison interrupt request (S12CMPBI) is generated upon the setting of the flag.

1 cannot be written to the CMPSTB flag.

[Setting condition]

- When ADCMPCR.CMPBE bit = 1 and the condition set in the ADCMPBNSR.CMPLB bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

(2) S12AD1.ADCMPBSR

Address(es): S12AD1.ADCMPBSR 0008 92ACh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CMPSTB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPSTB	Comparison Window B Flag	0: The comparison condition is not satisfied. 1: The comparison condition is satisfied.	R/(W) *1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 0 can be written to clear the flag after reading 1.

The S12AD1.ADCMPBSR register is used to store results of comparison of the comparison window B function.

CMPSTB Flag (Comparison Window B Flag)

The CMPSTB flag is a status flag that indicates the result of comparison of the channels for window B comparison conditions (AN100 to AN103).
When the conversion result matches with the comparison condition that is set in the ADCMPBNSR.CMPLB bit upon completion of A/D conversion, this flag becomes 1. When the ADCMPCR.CMPBIE bit is 1, a comparison interrupt request (S12CMPBI1) is generated upon the setting of the flag.
1 cannot be written to the CMPSTB flag.
[Setting condition]

- When ADCMPCR.CMPBE bit = 1 and the condition set in the ADCMPBNSR.CMPLB bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

(3) S12AD2.ADCMPBSR

Address(es): S12AD2.ADCMPBSR 0008 94ACh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CMPSTB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPSTB	Comparison Window B Flag	0: The comparison condition is not satisfied. 1: The comparison condition is satisfied.	R/(W) *1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 0 can be written to clear the flag after reading 1.

The S12AD2.ADCMPBSR register is used to store results of comparison of the comparison window B function.

CMPSTB Flag (Comparison Window B Flag)

The CMPSTB flag is a status flag that indicates the result of comparison of the channels for window B comparison conditions (AN200 to AN211, AN216, AN217, temperature sensor, internal reference voltage).
When the conversion result matches with the comparison condition that is set in the ADCMPBNSR.CMPLB bit upon completion of A/D conversion, this flag becomes 1. When the ADCMPCR.CMPBIE bit is 1, a comparison interrupt request (S12CMPBI2) is generated upon the setting of the flag.
1 cannot be written to the CMPSTB flag.
[Setting condition]

- When ADCMPCR.CMPBE bit = 1 and the condition set in the ADCMPBNSR.CMPLB bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

42.2.43 A/D Programmable Gain Amplifier Control Register (ADPGACR)

(1) S12AD.ADPGACR

Address(es): S12AD.ADPGACR 0008 91A0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

42.2.45 A/D Internal Reference Voltage Monitoring Circuit Enable Register (ADVMONCR)

Address(es): S12AD2.ADVMONCR 0008 95E2h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	VDE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	VDE	Voltage Monitoring Circuit Enable	0: Disables internal reference voltage monitoring circuit operation. 1: Enables internal reference voltage monitoring circuit operation.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADVMONCR register is used to enable the voltage monitoring circuit operation for the internal reference voltage.
Set the register while the ADCSR.ADST bit is 0.

42.2.46 A/D Internal Reference Voltage Monitoring Circuit Output Enable Register (ADVMONO)

Address(es): S12AD2.ADVMONO 0008 95E4h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	VDO
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	VDO	Voltage Monitoring Circuit Voltage Output Enable	0: Disables voltage output of internal reference voltage monitoring circuit. 1: Enables voltage output of internal reference voltage monitoring circuit.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADVMONO register is used to enable the voltage output of the voltage monitoring circuit for the internal reference voltage.
Set the register while the ADCSR.ADST bit is 0.

42.3 Operation

42.3.1 A/D Converter Initialization Flowchart

Initialize the A/D converter following the example of flowchart shown in Figure 42.8.

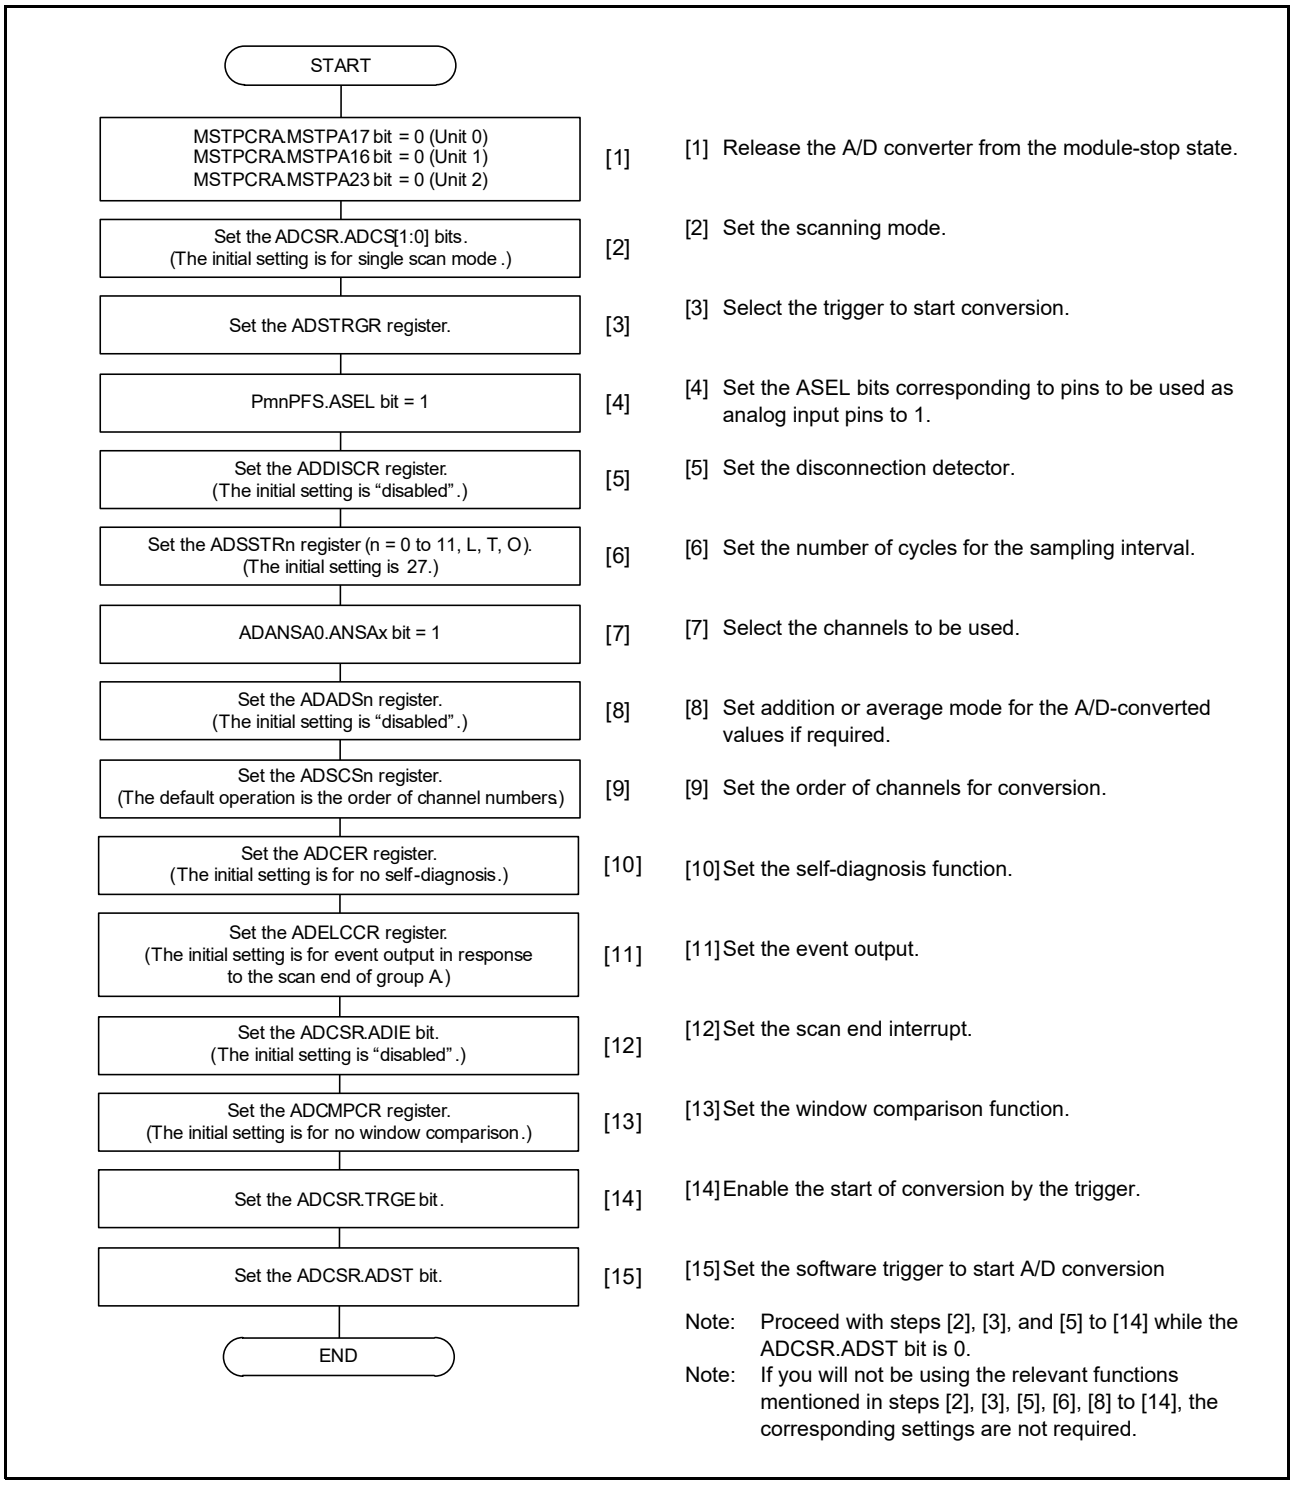

Figure 42.8 A/D Converter Initialization Flowchart

42.3.2 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.
A scan conversion is performed in three operating modes: single scan mode, continuous scan mode, and group scan mode. In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until the ADCSR.ADST bit is cleared to 0 from 1 by software. In group scan mode, the selected channels of groups A, B, and C are scanned once after starting to be scanned according to the respective synchronous trigger.
In single scan mode and continuous scan mode, A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
In group scan mode, A/D conversion is performed for analog channels of groups A, B, and C selected by the ADANSA0 and ADANSA1 registers, the ADANSB0 and ADANSB1 registers, and the ADANSC0 and ADANSC1 registers, respectively, according to the order of conversion specified in the ADSCSn register.
When self-diagnosis is selected, it is executed once at the beginning of each scan and one of the three voltages internally generated in the 12-bit A/D converter is converted.
The temperature sensor output and the internal reference voltage can be selected; however, they cannot be selected in combination with an analog input of the channels in the same group.
Conversion of the temperature sensor output takes priority when the temperature sensor output and internal reference voltage are selected simultaneously.
When converting the temperature sensor output or the internal reference voltage, an auto-discharging is automatically performed.
Double trigger mode is to be used with single scan mode or group scan mode. With double trigger mode being enabled, A/D conversion data of a channel selected by the ADCSR.DBLANS[4:0] bits is duplicated only if the conversion is started by the synchronous trigger selected by the ADSTRGR.TRSA[6:0] bits. In group scan mode, the double trigger function can be used only for group A.
Extended double trigger mode indicates a state when the following synchronous trigger (two synchronous trigger sources enabled) is selected by the TRSA[6:0] bits in the A/D conversion start trigger select register (ADSTRGR) in double trigger mode.

- TRG4AN or TRG4BN (the ADSTRGR.TRSA[6:0] bits are set to 0001011b)
- TRG7AN or TRG7BN (the ADSTRGR.TRSA[6:0] bits are set to 0001111b)
- TRGA0N or TRG0N (the ADSTRGR.TRSA[6:0] bits are set to 0011001b)
- TRGA9N or TRG9N (the ADSTRGR.TRSA[6:0] bits are set to 0011010b)
- TRGA0N or TRGA9N (the ADSTRGR.TRSA[6:0] bits are set to 0011011b)
- TRG0N or TRG9N (the ADSTRGR.TRSA[6:0] bits are set to 0011100b)
- GTADTRA0N or GTADTRB0N (the ADSTRGR.TRSA[6:0] bits are set to 1001000b)
- GTADTRA1N or GTADTRB1N (the ADSTRGR.TRSA[6:0] bits are set to 1001001b)
- GTADTRA2N or GTADTRB2N (the ADSTRGR.TRSA[6:0] bits are set to 1001010b)
- GTADTRA3N or GTADTRB3N (the ADSTRGR.TRSA[6:0] bits are set to 1001011b)
- GTADTRA4N or GTADTRB4N (the ADSTRGR.TRSA[6:0] bits are set to 1010100b)
- GTADTRA5N or GTADTRB5N (the ADSTRGR.TRSA[6:0] bits are set to 1010101b)
- GTADTRA6N or GTADTRB6N (the ADSTRGR.TRSA[6:0] bits are set to 1010110b)
- GTADTRA7N or GTADTRB7N (the ADSTRGR.TRSA[6:0] bits are set to 1010111b)
- ELCTRG00N or ELCTRG01N, ELCTRG10N or ELCTRG11N, or ELCTRG20N or ELCTRG21N (the ADSTRGR.TRSA[6:0] bits are set to 0111010b)

In extended double trigger mode, in addition to normal operations in double trigger mode, A/D conversion data is stored in A/D data duplication register A (ADDBLDRA) or A/D data duplication register B (ADDBLDRB) depending on the trigger type. If two types of triggers have occurred simultaneously in this mode, A/D conversion data is not sorted by the trigger sources and is stored in data duplication register B (ADDBLDRB).

Note that if a new trigger is input during A/D conversion caused by another trigger, the new trigger is ignored.
When any of AN000 to AN002 or AN100 to AN102 channels is set as a channel-dedicated sample-and-hold circuit by the ADSHCR.SHANS[2:0] bits, the target analog input is sampled and held before the first A/D conversion of each scan.

42.3.3 Single Scan Mode

42.3.3.1 Basic Operation (Without Channel-Dedicated Sample-and-Hold Circuits)

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as below.

(1) When the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input, A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
(Specified conversion order in Figure 42.9: AN000 → AN001 → AN002)

(2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).

(3) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).

(4) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a wait state.

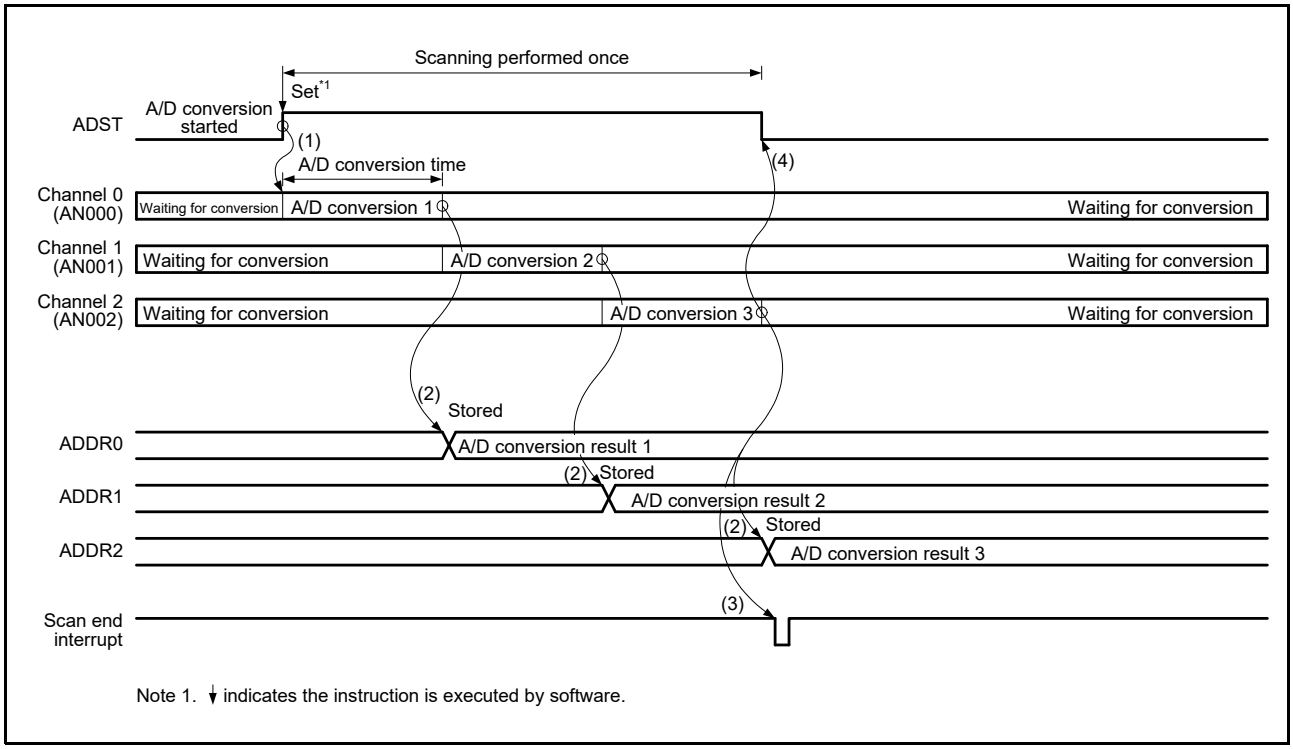

Figure 42.9 Example of Operation in Single Scan Mode (Basic Operation: AN000, AN001, AN002 Selected)

42.3.3.2 Basic Operation (with Channel-Dedicated Sample-and-Hold Circuits, with Constant Sampling Disabled)

When a channel-dedicated sample-and-hold circuit is used, sample-and-hold operations are performed first, and this is followed by A/D conversion once of the analog inputs on all selected channels. The ADSHCR.SHANS[2:0] bits are used to select the channels for which the channel-dedicated sample-and-hold circuits are to be used.

(1) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input.
(2) After sample-and-hold operation, A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register.
(3) Each time A/D conversion of a single channel is completed, the result of A/D conversion is stored in the corresponding A/D data register (ADDRy).
(4) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
(5) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a wait state.

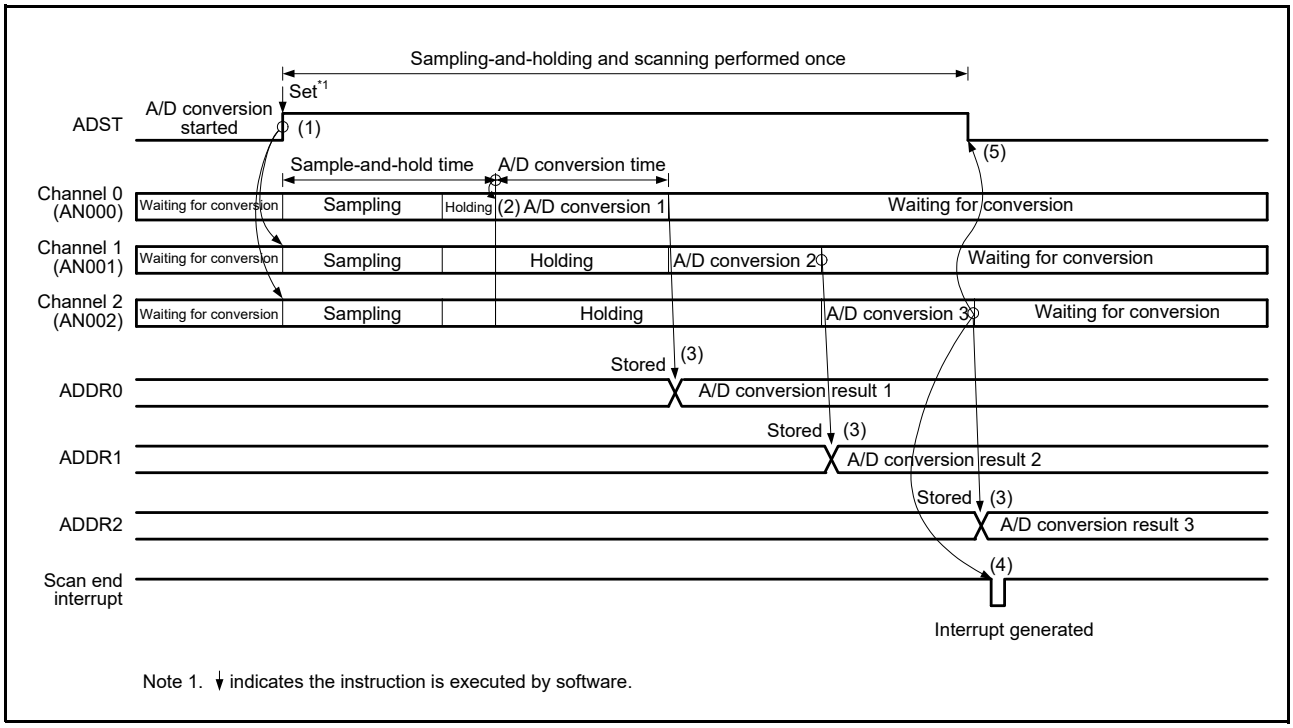

Figure 42.10 Example of Operation in Single Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used; AN000, AN001, AN002 Selected, with Constant Sampling Disabled)

42.3.3.3 Basic Operation (with Channel-Dedicated Sample-and-Hold Circuits, with Constant Sampling Enabled)

When constant sampling is enabled and the channel sample-and-hold circuit is used, a single A/D conversion is performed for analog input of all channels selected after sampling and holding is executed.
The channels for channel sample-and-hold circuit can be selected in the ADSHCR.SHANS[2:0] bits.

(1) When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuit selected in the ADSHCR.SHANS[2:0] bits starts constant sampling.
(2) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input. After setting the ADSHMSR.SHMD bit to 1 and 750 ns minimum are elapsed, set the ADCSR.ADST bit to 1.
(3) When the stabilizing time for the sample-and-hold circuit is elapsed, A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register.
(4) Each time A/D conversion of a single channels is completed, the A/D-converted value is stored in the corresponding A/D data register (ADDRy), the sample-and-hold circuit resumes constant sampling.
(5) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
(6) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a wait state. When a single scan is performed in sequence, set the time of constant sampling of the sample-and-hold circuit to 400 ns or longer (when allowable impedance of the source of the enabling signal is 1 kΩ).
(7) When the ADSHMSR.SHMD bit is cleared to 0, the sample-and-hold circuit stops.

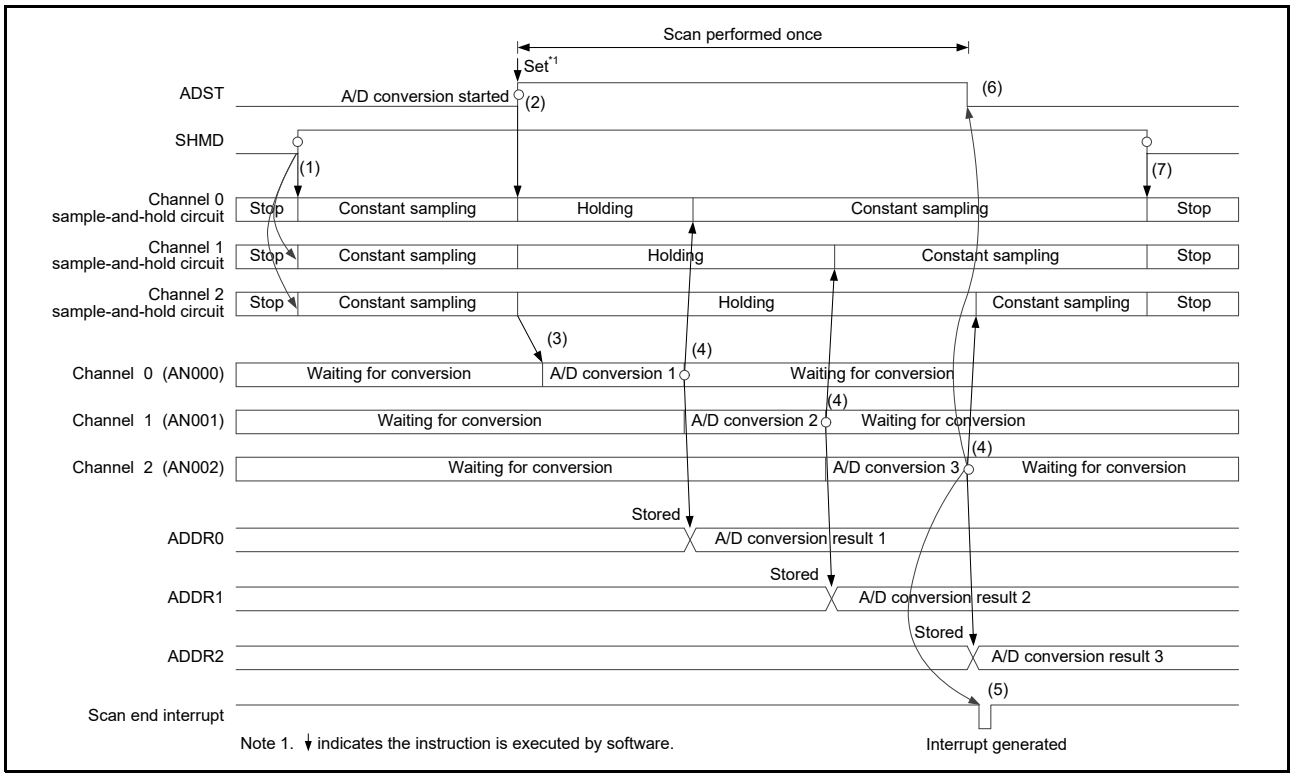

Figure 42.11 Example of Operation in Single Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used; AN000 to AN002 Selected, with Constant Sampling Enabled)

42.3.3.4 Channel Selection and Self-Diagnosis (Without Channel-Dedicated Sample-and-Hold Circuits)

When channels and self-diagnosis are selected, A/D conversion is performed once for the reference voltage supplied to the 12-bit A/D converter as below. After that, A/D conversion is performed only once on the analog input of the selected channels.

(1) A/D conversion for self-diagnosis is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input.
(2) When A/D conversion for self-diagnosis is completed, A/D conversion result is stored into the A/D self-diagnosis data register (ADRD), A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
(3) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(4) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
(5) The ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a wait state.

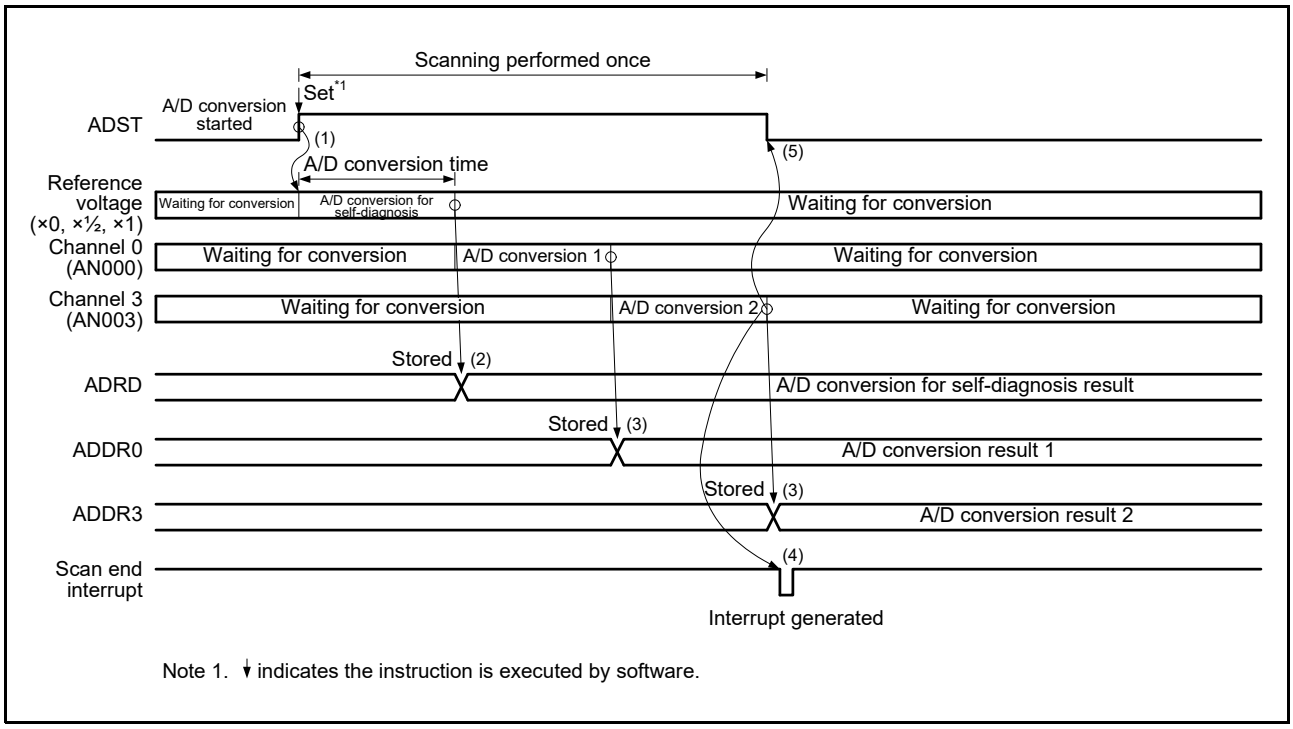

Figure 42.12 Example of Operation in Single Scan Mode (Basic Operation: AN000, AN003 Selected + Self-Diagnosis)

42.3.3.5 Channel Selection and Self-Diagnosis (with Channel-Dedicated Sample-and-Hold Circuits, with Constant Sampling Disabled)

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used, sample-and-hold operations are performed first, and A/D conversion is performed once for the reference voltage supplied to the 12-bit A/D converter as below. After that, A/D conversion is performed only once on the analog input of the selected channels. The self-diagnosis cannot be used with the temperature sensor output or with the internal reference voltage.

(1) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input.
(2) A/D conversion for self-diagnosis is started after completion of sampling and holding.
(3) When A/D conversion for self-diagnosis is completed, A/D conversion result is stored into the A/D self-diagnosis data register (ADRD), A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register.
(4) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(5) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
(6) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a wait state.

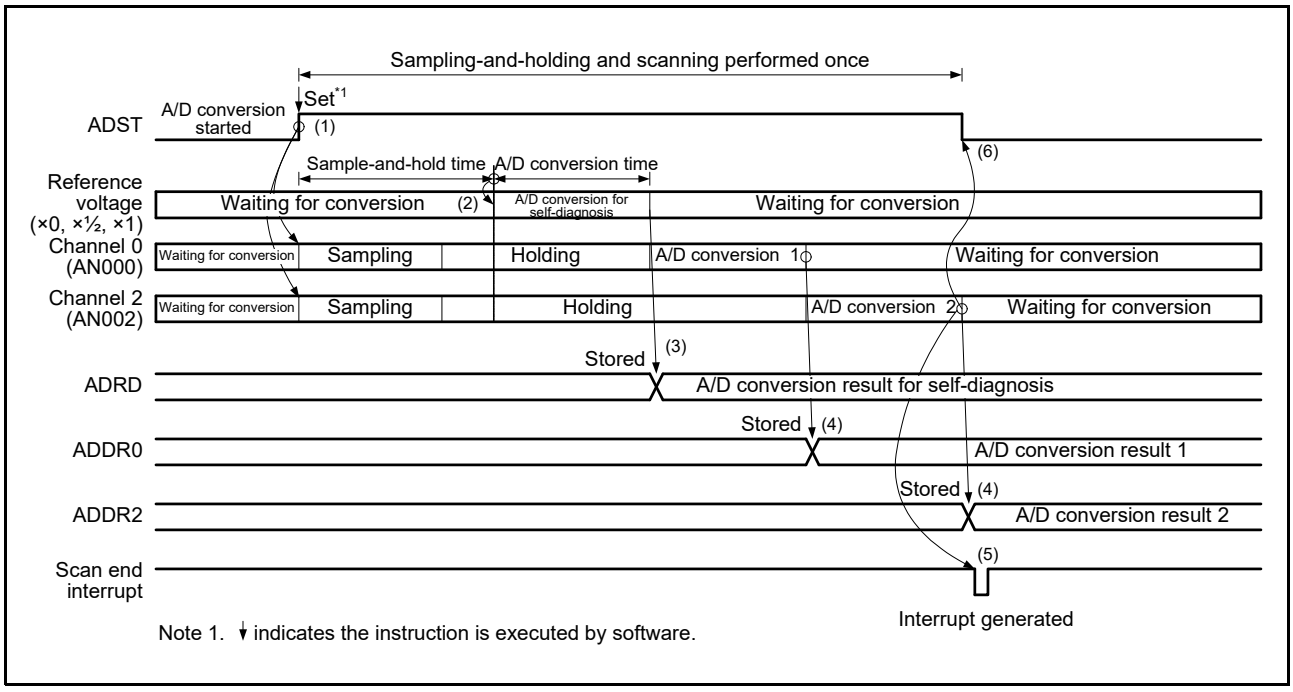

Figure 42.13 Example of Operation in Single Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used: AN000, AN002 Selected + Self-Diagnosis, with Constant Sampling Disabled)

42.3.3.6 Channel Selection and Self-Diagnosis (with Channel-Dedicated Sample-and-Hold Circuits, with Constant Sampling Enabled)

When self-diagnosis is selected with channels and a channel-dedicated sample-and-hold circuit is used with constant sampling enabled, sample-and-hold operations are performed first, and A/D conversion is performed on the reference voltage supplied to the 12-bit A/D converter as described below. After that, A/D conversion is performed only once on the analog input of the selected channels. The self-diagnosis cannot be used with the temperature sensor output or with the internal reference voltage.

(1) When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuit selected in the ADSHCR.SHANS[2:0] bits starts constant sampling.
(2) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input. After setting the ADSHMSR.SHMD bit to 1 and 750 ns minimum are elapsed, set the ADCSR.ADST bit to 1.
(3) When the stabilizing time for the sample-and-hold circuit is elapsed, A/D conversion by self-diagnosis is started.
(4) When A/D conversion for self-diagnosis is completed, A/D conversion result is stored into the A/D self-diagnosis data register (ADRD), A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register.
(5) Each time A/D conversion of a single channel is completed, the A/D-converted value is stored in the corresponding A/D data register (ADDRy), the sample-and-hold circuit resumes constant sampling.
(6) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
(7) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a wait state. When a single scan is performed in sequence, set the time of constant sampling of the sample-and-hold circuit to 400 ns or longer (when allowable impedance of the source of the enabling signal is 1 kΩ).
(8) When the ADSHMSR.SHMD bit is cleared to 0, the sample-and-hold circuit stops.

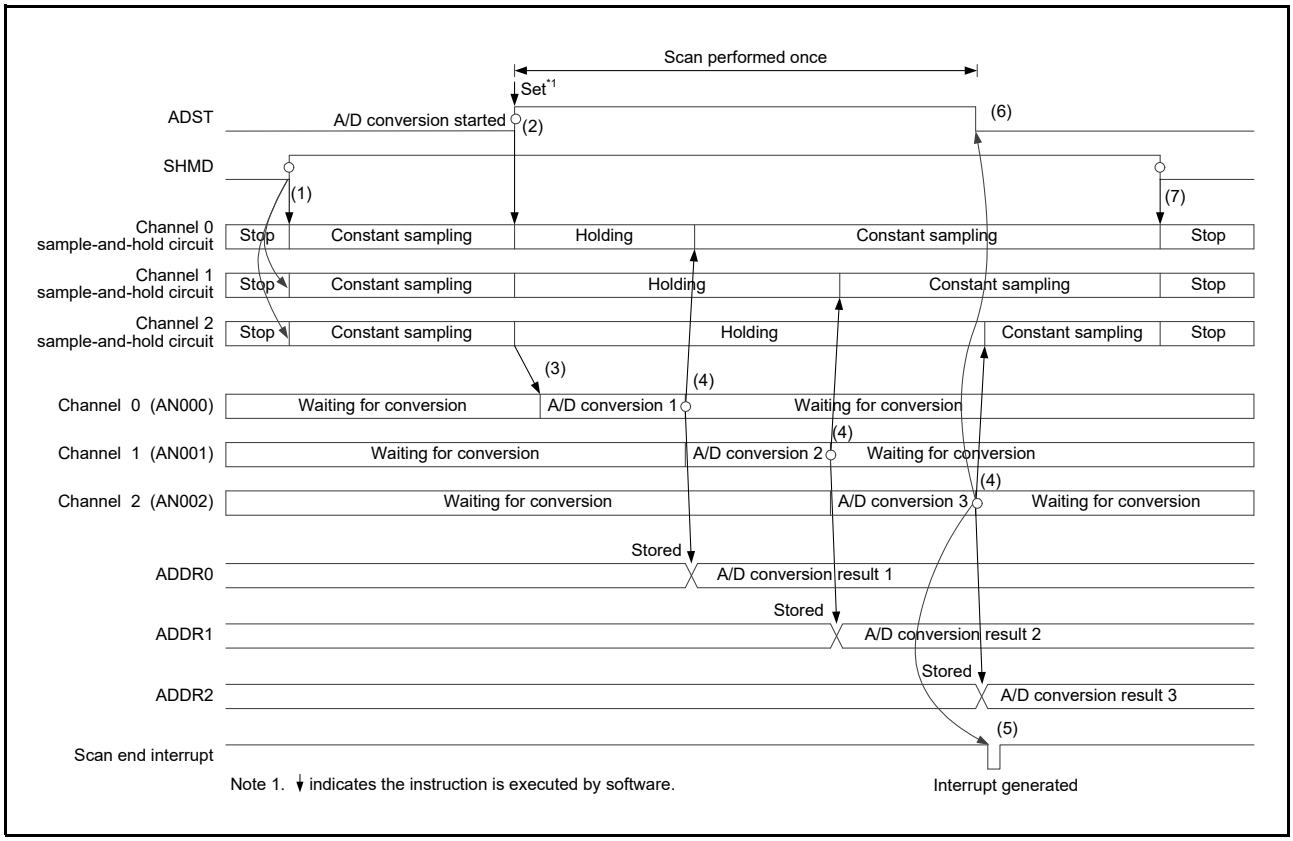

Figure 42.14 Example of Operation in Single Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used; AN000, AN002 Selected + Self-Diagnosis, with Constant Sampling Enabled)

42.3.3.7 A/D Conversion with Temperature Sensor Output/Internal Reference Voltage Selected

When temperature sensor output or internal reference voltage is selected with channels, A/D conversion is performed only once for the temperature sensor output or for internal reference voltage as described below.
When the temperature sensor output and internal reference voltage are both selected, A/D conversion is performed for the temperature sensor output first and then for internal reference voltage.
Selecting the temperature sensor output and internal reference voltage simultaneously for analog input is prohibited.

(1) When the ADCSR.ADST bit becomes 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input, auto-discharging and A/D conversion is performed in this order for the temperature sensor output.
(2) When A/D conversion of the temperature sensor output is completed, the A/D-converted value is stored in the corresponding A/D temperature sensor data register (ADTSDR), and then, auto-discharging and A/D conversion is performed in this order for the internal reference voltage.
(3) After completion of A/D conversion of the internal reference voltage, the A/D-converted value is stored in the corresponding A/D internal reference voltage data register (ADOCDR), a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
(4) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a wait state.

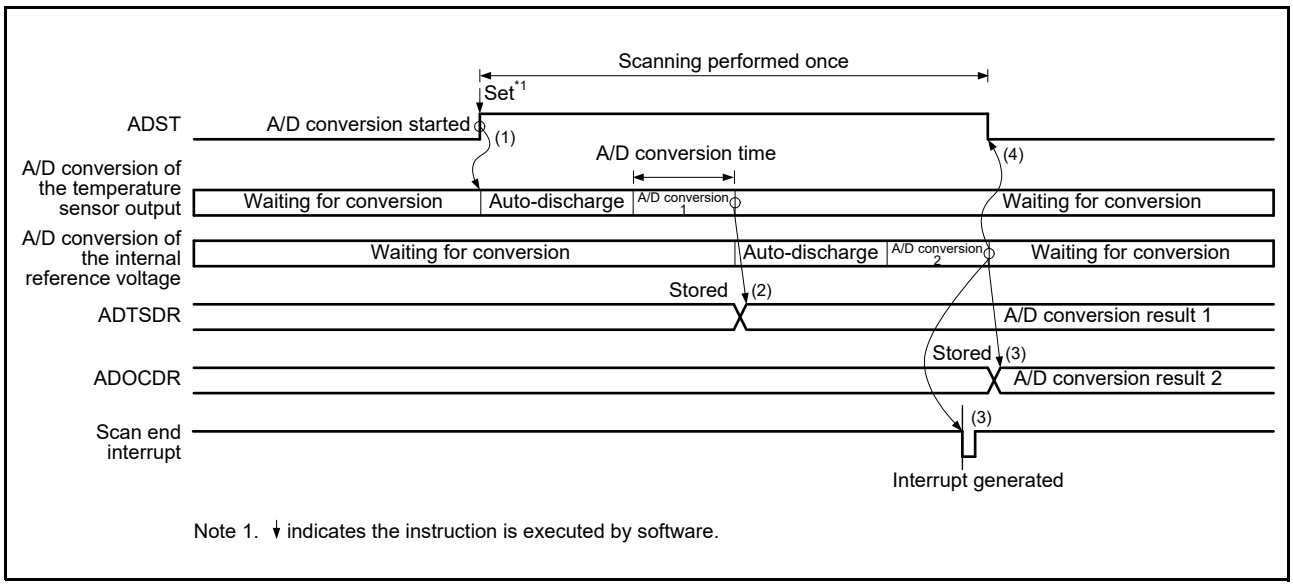

Figure 42.15 Example of Operation in Single Scan Mode (Basic Operation: Temperature Sensor Output and Internal Reference Voltage Selected)

42.3.3.8 A/D Conversion in Double Trigger Mode

In single scan mode with double trigger mode, single scan operation started by synchronous trigger is performed twice as below.

Deselect self-diagnosis and set the temperature sensor A/D conversion select bit (ADEXICR.TSSA, ADEXICR.TSSB, ADGCEXCR.TSSC) and internal reference voltage A/D conversion select bit (ADEXICR.OCSA, ADEXICR.OCSB, ADGCEXCR.OCSC) to 0.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid. In double trigger mode, synchronous triggers should be selected using the ADSTRGR.TRSA[6:0] bits, the ADCSR.EXTRG bit should be set to 0, and the ADCSR.TRGE bit should be set to 1. Software trigger should not be used.

(1) When the ADCSR.ADST bit becomes 1 (starting A/D conversion) by synchronous trigger input, A/D conversion is started on the single channel selected by the ADCSR.DBLANS[4:0] bits.
(2) When A/D conversion is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(3) The ADCSR.ADST bit is automatically cleared to 0 and the 12-bit A/D converter enters a wait state. Here, a scan end interrupt request is not generated irrespective of the ADCSR.ADIE bit setting (scan end interrupt is enabled).
(4) When the ADCSR.ADST bit is set to 1 (starting A/D conversion) by the second trigger input, A/D conversion is started on the single channel selected by the ADCSR.DBLANS[4:0] bits.
(5) When A/D conversion is completed, the A/D conversion result is stored into the A/D data duplication register (ADDBLDR).
(6) A scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
(7) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion is completed. Then the 12-bit A/D converter enters a wait state.

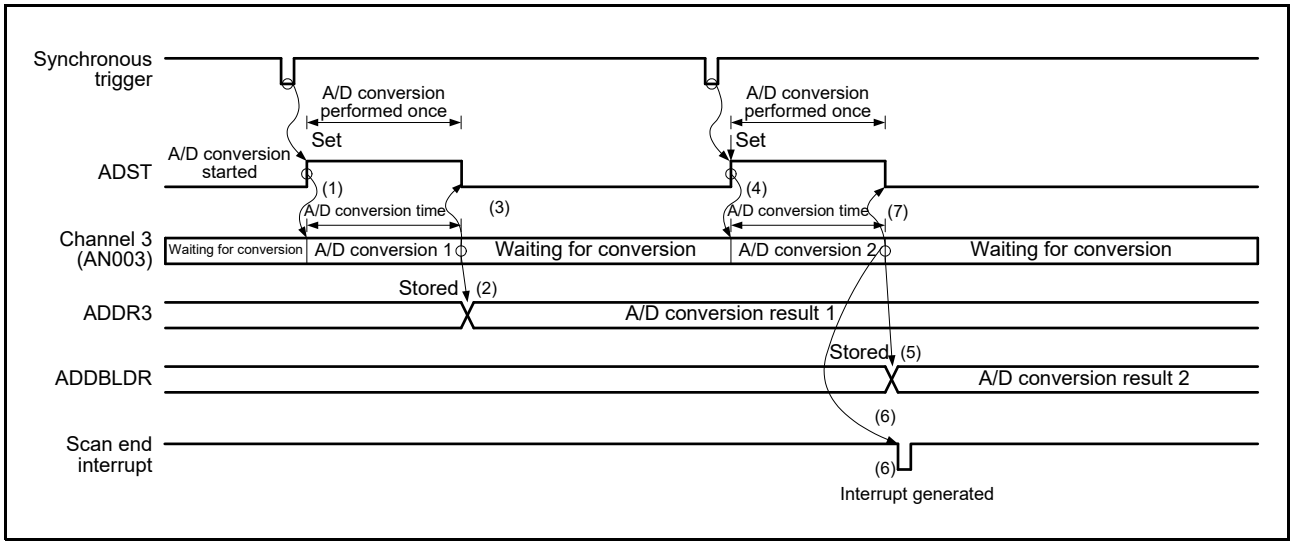

Figure 42.16 Example of Operation in Single Scan Mode (Double Trigger Mode Selected; AN003 Duplicated)

42.3.3.9 A/D Conversion in Extended Double Trigger Mode

When selecting the double-trigger mode in single-scanning mode, with TRG4AN or TRG4BN, TRG7AN or TRG7BN, TRGA0N or TRG0N, TRGA9N or TRG9N, TRGA0N or TRGA9N, TRG0N or TRG9N, GTADTRA0N or GTADTRB0N, GTADTRA1N or GTADTRB1N, GTADTRA2N or GTADTRB2N, GTADTRA3N or GTADTRB3N, GTADTRA4N or GTADTRB4N, GTADTRA5N or GTADTRB5N, GTADTRA6N or GTADTRB6N, GTADTRA7N or GTADTRB7N, or ELCTRG00N or ELCTRG01N/ELCTRG10N or ELCTRG11N/ELCTRG20N or ELCTRG21N selected in the TRSA[6:0] bits of the A/D conversion start trigger select register (ADSTRGR), proceed with single scanning mode twice as follows.
Deselect self-diagnosis and set the temperature sensor A/D conversion select bit (ADEXICR.TSSA, ADEXICR.TSSB, ADGCEXCR.TSSC) and internal reference voltage A/D conversion select bit (ADEXICR.OCSA, ADEXICR.OCSB, ADGCEXCR.OCSC) to 0.
Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid. In extended double trigger mode, the ADCSR.EXTRG bit should be set to 0, and the ADCSR.TRGE bit should be set to 1. Software trigger should not be used.

(1) When the ADCSR.ADST bit is set to 1 (starting A/D conversion) by TRG4AN input, A/D conversion is started on the single channel selected by the ADCSR.DBLANS[4:0] bits.
(2) When A/D conversion is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy) and A/D data duplication register A (ADDBLDRA).
(3) The ADCSR.ADST bit is automatically cleared to 0 and the 12-bit A/D converter enters a wait state. Here, a scan end interrupt request is not generated irrespective of the ADCSR.ADIE bit setting (scan end interrupt is enabled).
(4) When the ADCSR.ADST bit is set to 1 (starting A/D conversion) by TRG4BN input, A/D conversion is started on the single channel selected by the ADCSR.DBLANS[4:0] bits.
(5) When A/D conversion is completed, the A/D conversion result is stored into A/D data duplication register (ADDBLDR) and A/D data duplication register B (ADDBLDRB).
(6) A scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
(7) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion is completed. Then the 12-bit A/D converter enters a wait state.

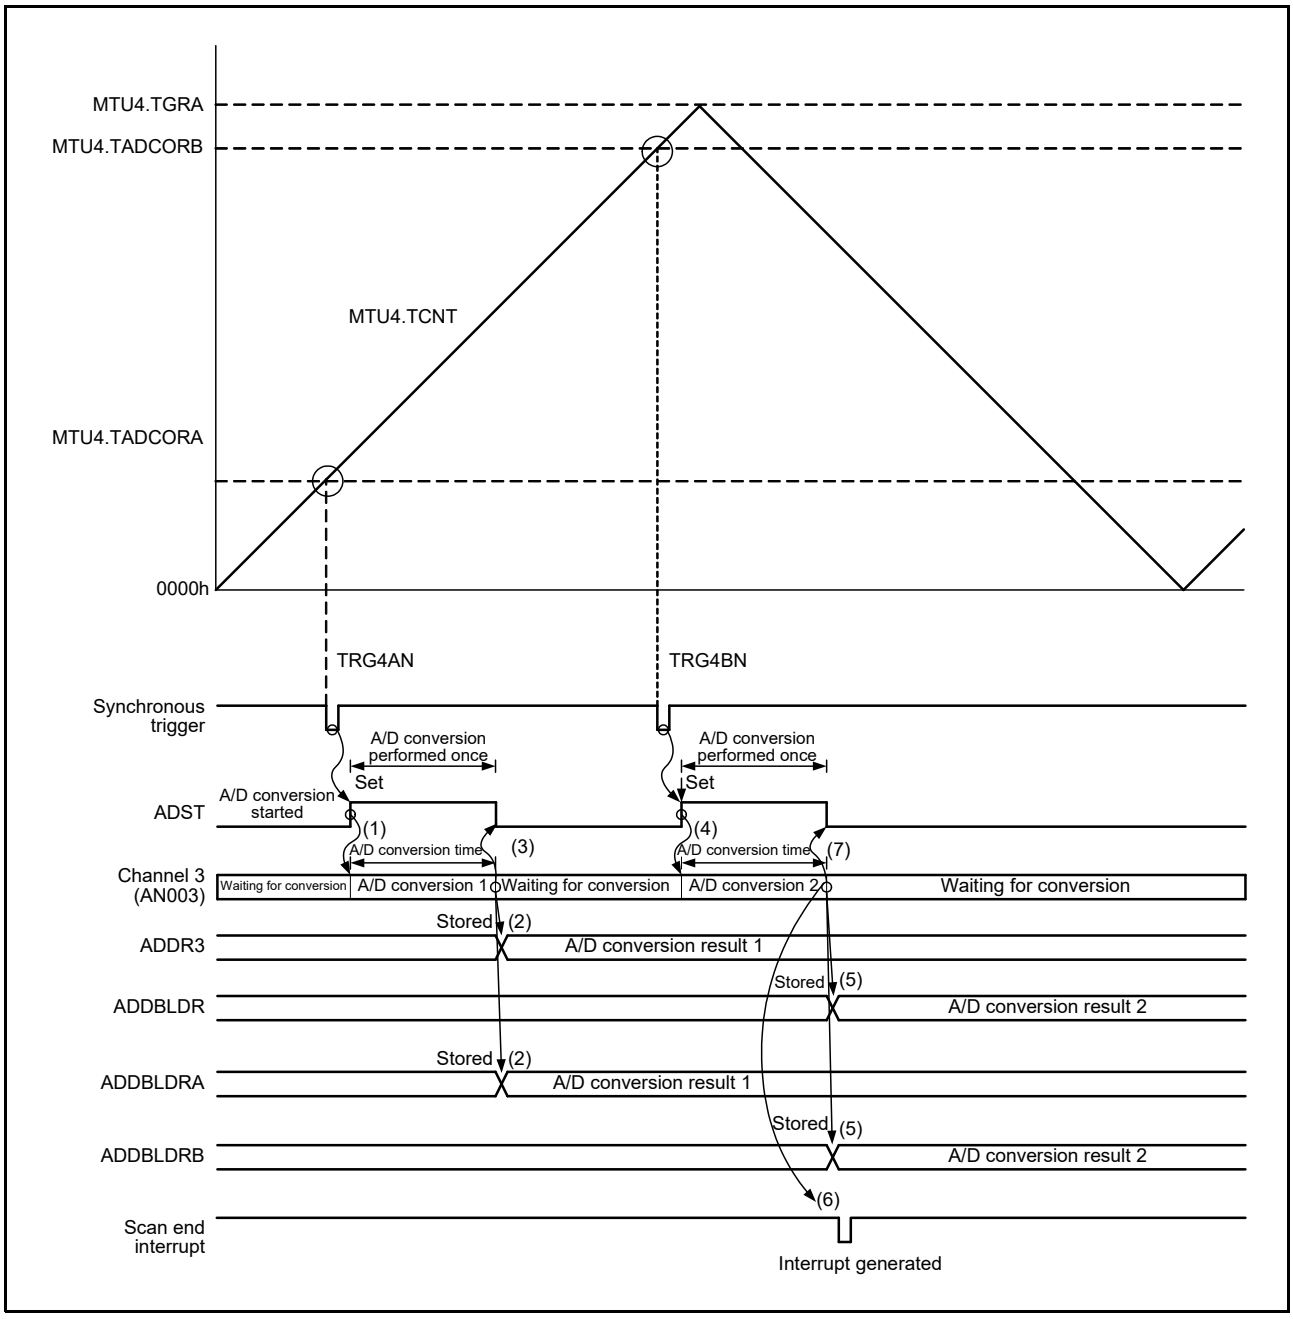

Figure 42.17 Example of Extended Operation in Double Trigger Mode (1)
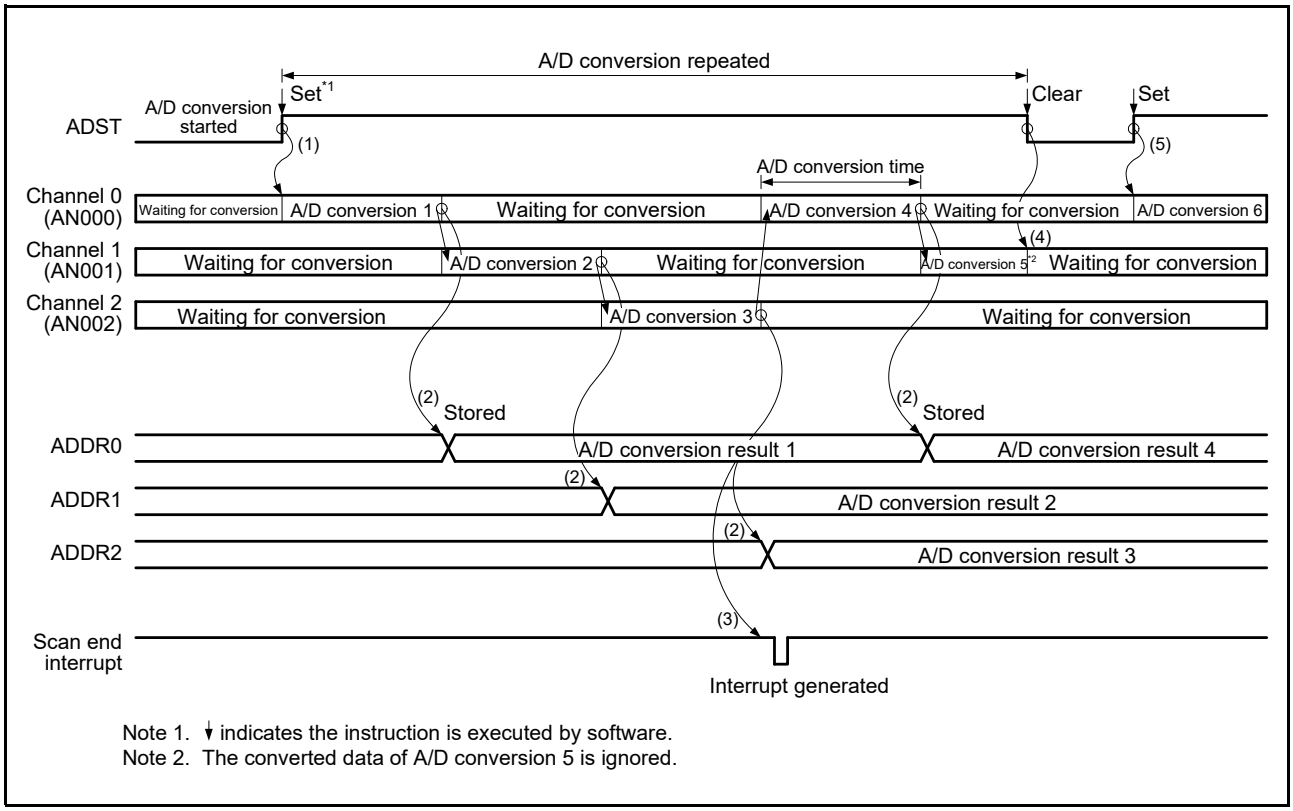
(Duplication Selected for AN003, TRG4AN or TRG4BN Selected, First Trigger is TRG4AN)

42.3.4 Continuous Scan Mode

42.3.4.1 Basic Operation (Without Channel-Dedicated Sample and-Hold Circuits)

In basic operation of continuous scan mode, A/D conversion is performed repeatedly on the analog input of the specified channels as below.
In continuous scan mode, specify A/D conversion select bits for the temperature sensor and for the internal reference voltage to deselect respectively.

(1) When the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input, A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. (Specified conversion order in Figure 42.18: AN000 → AN001 → AN002)
(2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(3) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
The 12-bit A/D converter sequentially starts A/D conversion for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
(4) The ADCSR.ADST bit is not automatically cleared and steps (2) and (3) are repeated as long as the bit remains 1 (starting A/D conversion). When the ADCSR.ADST bit is set to 0 (stopping A/D conversion), A/D conversion stops and the 12-bit A/D converter enters a wait state.
(5) When the ADCSR.ADST bit is later set to 1 (starting A/D conversion), A/D conversion starts again for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.



Note 1. ↓ indicates the instruction is executed by software.
Note 2. The converted data of A/D conversion 5 is ignored.

Figure 42.18 Example of Operation in Continuous Scan Mode (Basic Operation: AN000 to AN002 Selected)

42.3.4.2 Basic Operation (with Channel-Dedicated Sample-and-Hold Circuits, with Constant Sampling Disabled)

When a channel-dedicated sample-and-hold circuit is used, sample-and-hold operations are performed first and A/D conversion is repeated for analog input of all selected channels as described below. The ADSHCR.SHANS[2:0] bits are used to select the channels for which the channel-dedicated sample-and-hold circuits are to be used.
In continuous scan mode, specify A/D conversion select bits for the temperature sensor and for the internal reference voltage to deselect respectively.

(1) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, synchronous trigger input, or asynchronous trigger input.
(2) After sample-and-hold operation, A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register.
(3) Each time A/D conversion of a single channel is completed, the result of A/D conversion is stored in the corresponding A/D data register (ADDRy).
(4) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled). At the same time, analog input sampling is started for all the channels for which the channel-dedicated sample-and-hold circuits are to be used.
(5) The ADCSR.ADST bit is not automatically cleared and steps (2) to (4) are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (stopping A/D conversion), A/D conversion stops and the 12-bit A/D converter enters a wait state.
(6) When the ADCSR.ADST bit is then set to 1 (starting A/D conversion), analog input sampling is started again for all the channels for which the channel-dedicated sample-and-hold circuits are to be used.

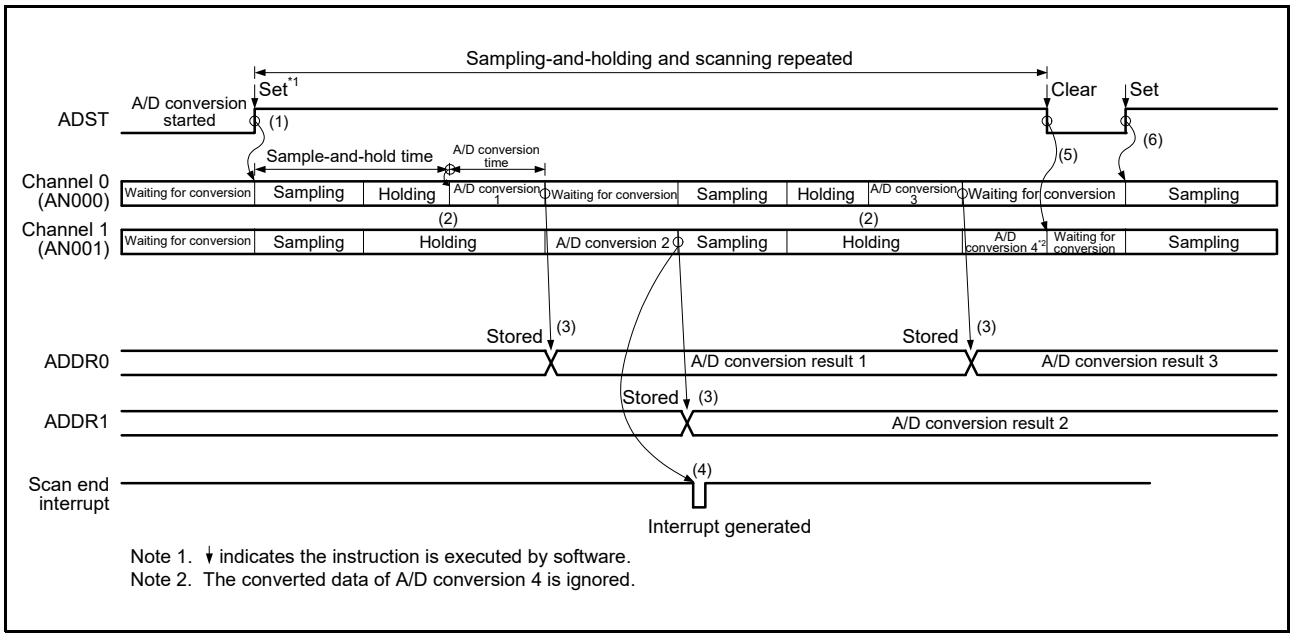


Figure 42.19 Example of Operation in Continuous Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used, AN000/AN001 Selected, with Constant Sampling Disabled)

42.3.4.3 Basic Operation (with Channel Sample-and-Hold Circuits, with Constant Sampling Enabled)

When constant sampling is enabled and a channel sample-and-hold circuit is used, sample-and-hold operations are performed first and A/D conversion is repeated for analog input of all selected channels as described below.
The ADSHCR.SHANS[2:0] bits are used to select the channels for which the channel-dedicated sample-and-hold circuits are to be used.
In continuous scan mode, specify A/D conversion select bits for the temperature sensor and for the internal reference voltage to deselect respectively.

(1) When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuit selected in the ADSHCR.SHANS[2:0] bits starts constant sampling.
(2) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input. After setting the ADSHMSR.SHMD bit to 1 and 750 ns minimum are elapsed, set the ADCSR.ADST bit to 1.
(3) When the stabilizing time for the sample-and-hold circuit is elapsed, A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register.
(4) Each time A/D conversion of a single channels is completed, the A/D-converted value is stored in the corresponding A/D data register (ADDRy), the sample-and-hold circuit resumes constant sampling.
(5) After completion of A/D conversion of all selected channels, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled). In addition, all channels that use channel sample-and-hold circuit start holding of analog inputs.
(6) The ADCSR.ADST bit is not automatically cleared and steps (3) to (5) are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (stopping A/D conversion), A/D conversion is stopped and the 12-bit A/D converter enters into a wait state.
(7) When the ADSHMSR.SHMD bit is cleared to 0, the sample-and-hold circuit stops.
(8) After that, when the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuit selected in the ADSHCR.SHANS[2:0] bits starts constant sampling.
(9) When the ADCSR.ADST bit is set to 1 (starting A/D conversion), all channels that uses sample-and-hold circuit starts holding analog inputs.

Note: If only a channel with a channel-dedicated sample-and-hold circuit is selected and continuous scanning is performed, securing a period for normal sampling will not be possible in the second and subsequent rounds of continuous scanning. To proceed with scanning continuously while the sample-and-hold circuit is enabled, select AN003 and set the period for constant sampling of the sample-and-hold circuit to at least 400 ns.

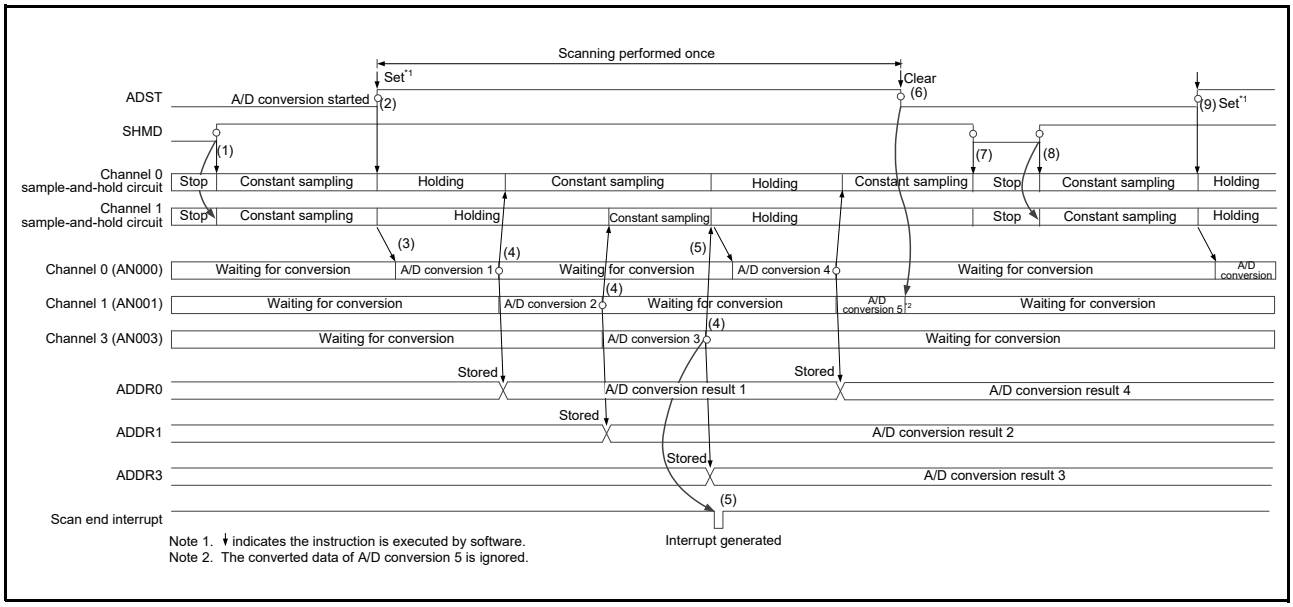

Figure 42.20 Example of Operation in Continuous Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used: AN000, AN001, and AN003 Selected, with Constant Sampling Enabled)

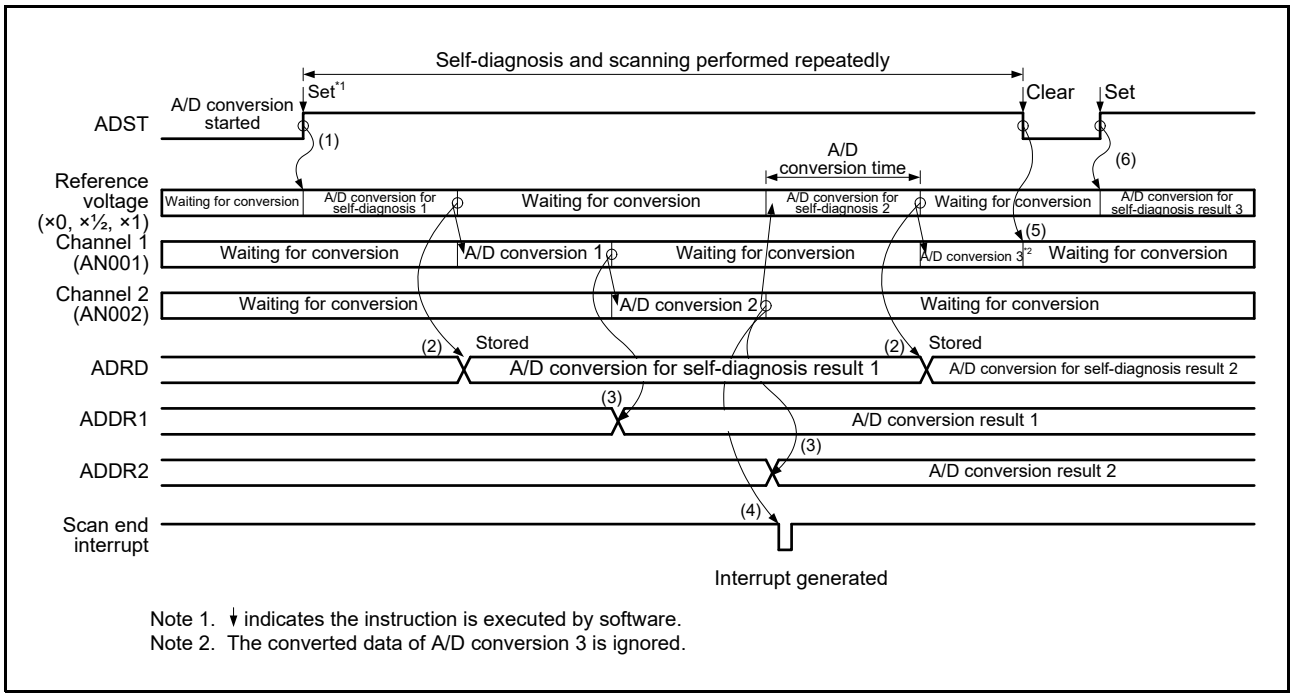
42.3.4.4 Channel Selection and Self-Diagnosis (Without Channel-Dedicated Sample-and-Hold Circuits)

When channels and self-diagnosis are selected at the same time, A/D conversion is first performed for the reference voltage supplied to the 12-bit A/D converter, and then A/D conversion is performed on the analog input of the selected channels, which sequence is repeated as below.

(1) When the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input, A/D conversion for self-diagnosis is started first.
(2) When A/D conversion for self-diagnosis is completed, A/D conversion result is stored into the A/D self-diagnosis data register (ADRD), A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
(3) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(4) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled). At the same time, the 12-bit A/D converter starts A/D conversion for self-diagnosis, and, upon its completion, starts A/D conversion for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
(5) The ADCSR.ADST bit is not automatically cleared and steps (2) to (4) are repeated as long as the bit remains 1. When the ADST bit is set to 0 (stopping A/D conversion), A/D conversion stops and the 12-bit A/D converter enters a wait state.
(6) When the ADCSR.ADST bit is later becomes 1 (starting A/D conversion), the A/D conversion for self-diagnosis is started again.



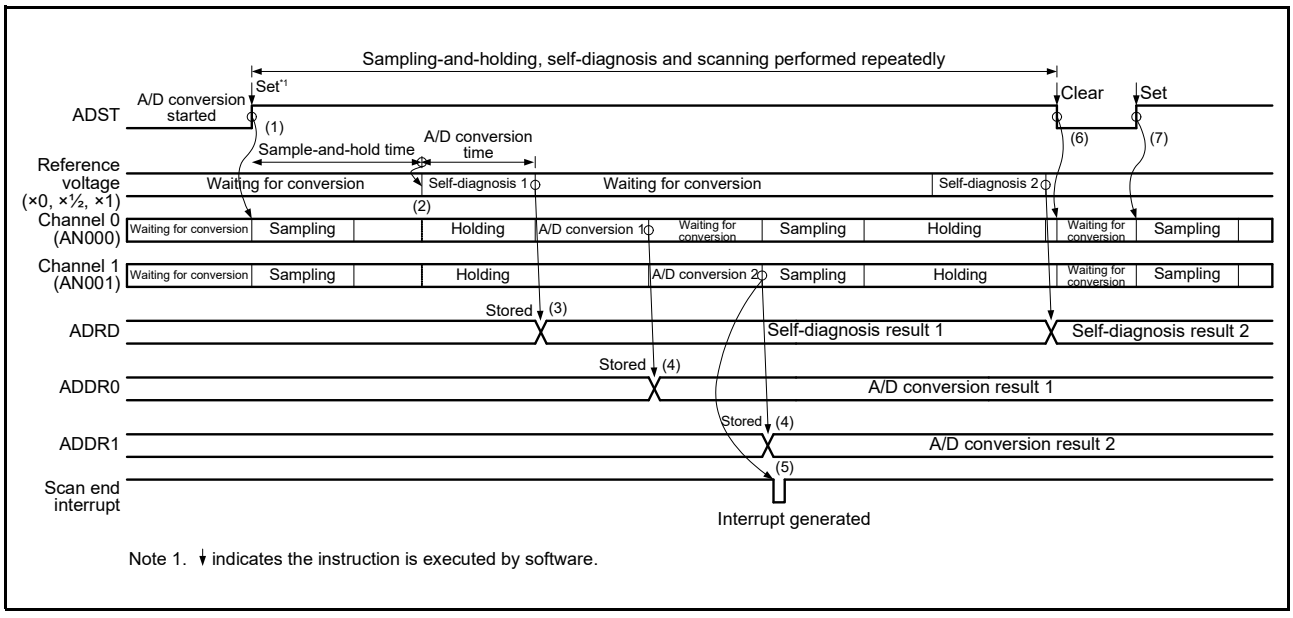
Note 1. ↓ indicates the instruction is executed by software.
Note 2. The converted data of A/D conversion 3 is ignored.

Figure 42.21 Example of Operation in Continuous Scan Mode (Basic Operation; AN001 and AN002 Selected + Self-Diagnosis)

42.3.4.5 Channel Selection and Self-Diagnosis (with Channel-Dedicated Sample-and-Hold Circuits, with Constant Sampling Disabled)

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used, sample-and-hold operations are performed first, and A/D conversion is performed for the reference voltage supplied to the 12-bit A/D converter as below. After that, A/D conversion is performed repeatedly on the analog input of the selected channels. In continuous scan mode, specify A/D conversion select bits for the temperature sensor and for the internal reference voltage to deselect respectively.

(1) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input.
(2) A/D conversion for self-diagnosis is started after completion of sampling and holding.
(3) When A/D conversion for self-diagnosis is completed, A/D conversion result is stored into the A/D self-diagnosis data register (ADRD), A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register.
(4) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(5) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled). At the same time, analog input sampling is started for all the channels for which the channel-dedicated sample-and-hold circuits are to be used.
(6) The ADCSR.ADST bit is not automatically cleared and steps (2) to (5) are repeated as long as the ADCSR.ADST bit as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (stopping A/D conversion), A/D conversion stops and the 12-bit A/D converter enters a wait state.
(7) When the ADCSR.ADST bit is later becomes 1 (starting A/D conversion), the A/D conversion for self-diagnosis is started again.



Note 1. ↓ indicates the instruction is executed by software.

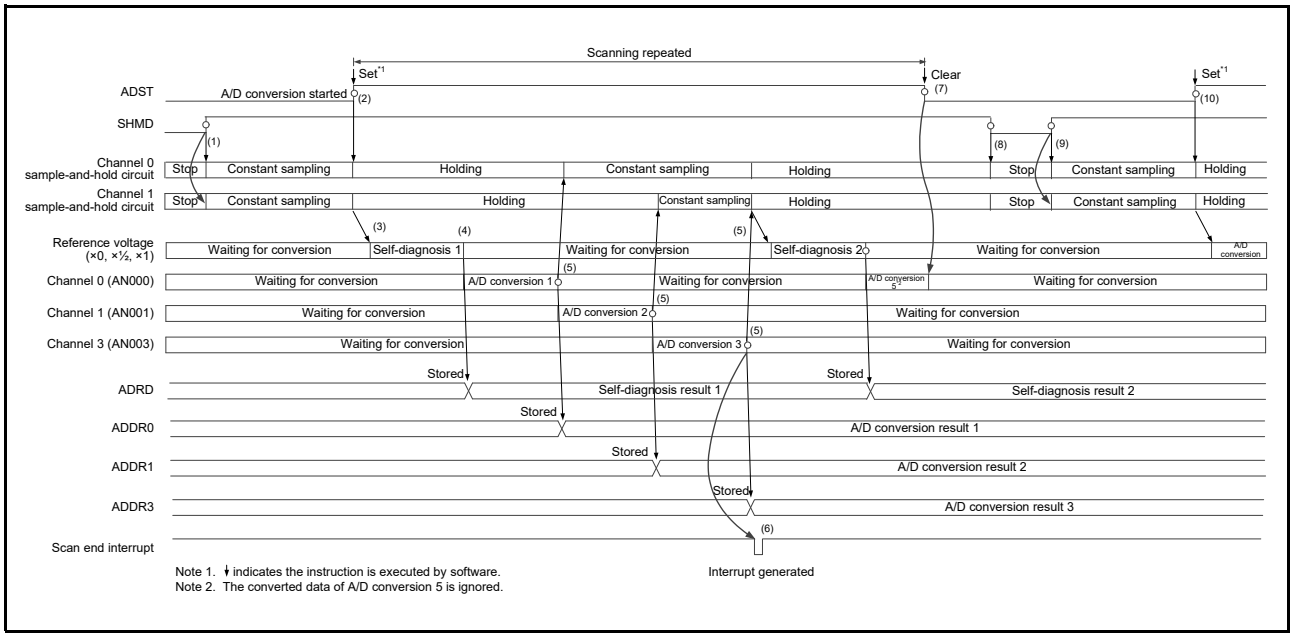
Figure 42.22 Example of Operation in Continuous Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used: AN000 and AN001 Selected + Self-Diagnosis)

42.3.4.6 Channel Selection and Self-Diagnosis (with Channel-Dedicated Sample-and-Hold Circuits, with Constant Sampling Enabled)

When self-diagnosis is selected with channels and a channel-dedicated sample-and-hold circuit is used with constant sampling enabled, sample-and-hold operations are performed first and A/D conversion is performed for the reference voltage to be supplied to the 12-bit A/D converter as described below. After that, A/D conversion is performed repeatedly on the analog input of the selected channels.

(1) When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuit selected in the ADSHCR.SHANS[2:0] bits starts constant sampling.
(2) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input. After setting the ADSHMSR.SHMD bit to 1 and 750 ns minimum are elapsed, set the ADCSR.ADST bit to 1.
(3) When the stabilizing time for the sample-and-hold circuit is elapsed, A/D conversion by self-diagnosis is started.
(4) When A/D conversion for self-diagnosis is completed, A/D conversion result is stored into the A/D self-diagnosis data register (ADRD), A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register.
(5) Each time A/D conversion of a single channels is completed, the A/D-converted value is stored in the corresponding A/D data register (ADDRy), the sample-and-hold circuit resumes constant sampling.
(6) After completion of A/D conversion of all selected channels, if the ADCSR.ADIE bit is set to 1 (scan end interrupt is enabled), a scan end interrupt request is generated. In addition, all channels that use channel sample-and-hold circuit start holding of analog inputs.
(7) The ADCSR.ADST bit is not automatically cleared and steps (3) to (6) are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (stopping A/D conversion), A/D conversion is stopped and the 12-bit A/D converter enters into a wait state.
(8) When the ADSHMSR.SHMD bit is cleared to 0, the sample-and-hold circuit stops.
(9) After that, when the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuit selected in the ADSHCR.SHANS[2:0] bits starts constant sampling.
(10) When the ADCSR.ADST bit is set to 1 (starting A/D conversion), all channels that uses sample-and-hold circuit starts holding analog inputs.

Note: If only a channel with a channel-dedicated sample-and-hold circuit is selected and continuous scanning is performed, securing a period for normal sampling will not be possible in the second and subsequent rounds of continuous scanning. To proceed with scanning continuously while the sample-and-hold circuit is enabled, select AN003 and set the period for constant sampling of the sample-and-hold circuit to at least 400 ns.



Note 1. ↓ indicates the instruction is executed by software.
Note 2. The converted data of A/D conversion 5 is ignored.

Figure 42.23 Example of Operation in Continuous Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used: AN000, AN001, and AN003 Selected + Self-Diagnosis, with Constant Sampling Enabled)

42.3.5 Group Scan Mode

42.3.5.1 Basic Operation

Either two (groups A and B) or three (groups A, B, and C) can be selected as the number of the groups to be used in group scan mode.

In basic operation of group scan mode, A/D conversion is performed once on the analog inputs of all the specified channels in groups A and B, or groups A, B, and C after scan is started by a synchronous trigger as below. Scan operation of each group is similar to the scan operation in single scan mode.

The synchronous triggers of groups A, B, and C can be selected using the TRSA[6:0] and TRSB[6:0] bits in the ADSTRGR register, and the ADGCTRGR2.TRSC6 and ADGCTRGR.TRSC[5:0] bits, respectively. Different triggers should be used for each group A, B, and C so that scanning of groups A, B, and C does not occur simultaneously. Software trigger should not be used.

The channels to be scanned are selected using registers ADANSA0 and ADANSA1 and bits TSSA and OCSA in register ADEXICR for group A, registers ADANSB0 and ADANSB1 and bits TSSB and OCSB in register ADEXICR for group B, and registers ADANSC0 and ADANSC1 and bits TSSC and OCSC in register ADGCEXCR for group C.

When the temperature sensor output is to be scanned, set only one from among the TSSA, TSSB, and TSSC bits to 1. In the same way, when the internal reference voltage is to be scanned, set only one from among the OCSA, OCSB, and OCSC bits to 1. Discharging for a period of 15 ADCLK is performed for all the conversion channels in a scan group where the temperature sensor output or the internal reference voltage is set.

When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed for groups A and B, or groups A, B, and C.

The following describes operation in group scan mode using a trigger from the MTU. The TRG4AN, TRG4BN, and TRG4ABN triggers from the MTU are assumed to be used to start conversion of groups A, B and C, respectively.

(1) Scanning of group A is started by the TRG4AN trigger from the MTU.
(2) When group A scanning is completed, a scan end interrupt is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
(3) Scanning of group B is started by the TRG4BN trigger from the MTU.
(4) When group B scanning is completed, a group B scan end interrupt is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).
(5) Scanning of group C is started by the TRG4ABN trigger from the MTU.
(6) When group C scanning is completed, a group C scan end interrupt is generated if the ADGCTRGR.GCADIE bit is 1 (group C scan end interrupt is enabled).

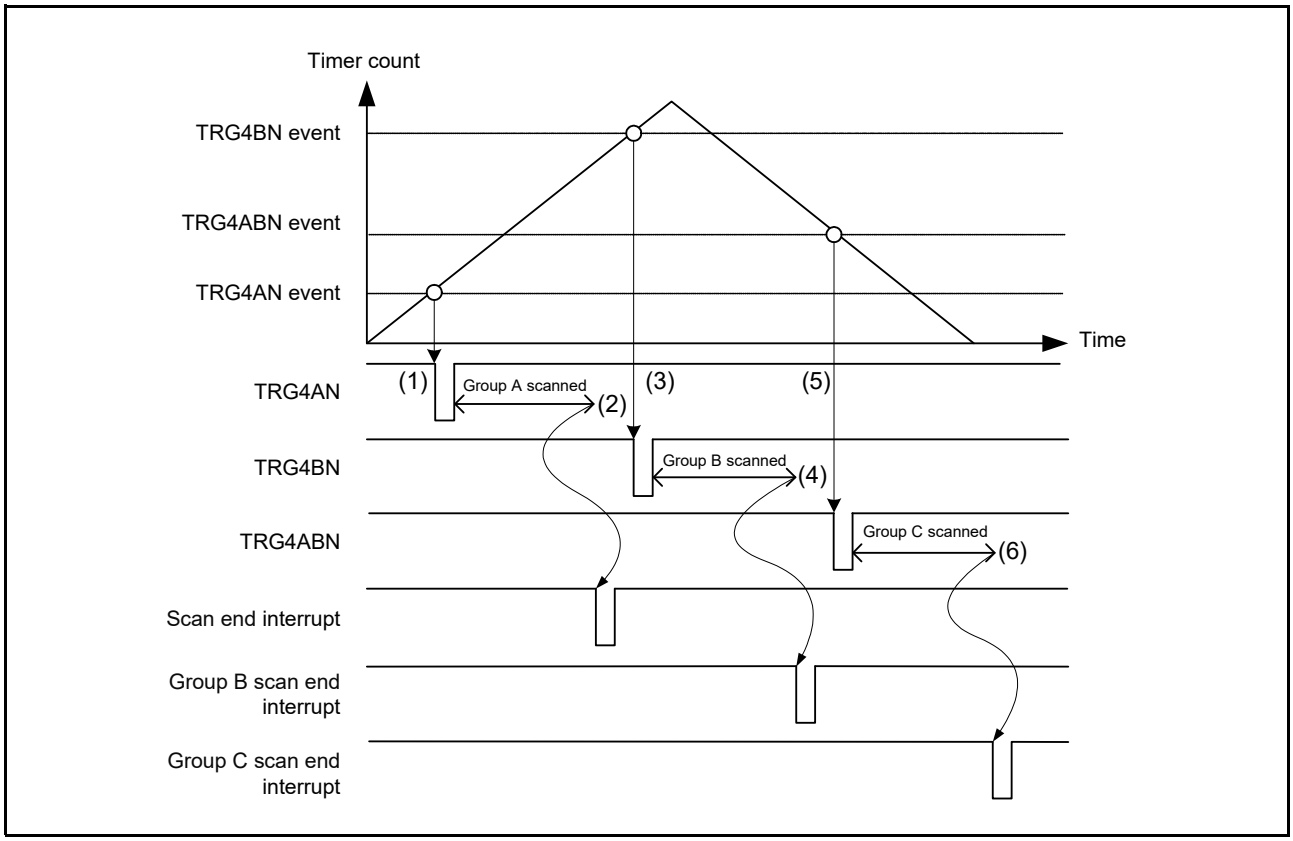


Figure 42.24 Example of Operation in Group Scan Mode (Basic Operation: Synchronous Triggers from MTU Used)

The following describes operation using the temperature sensor output or the internal reference voltage (in group scan mode and not in group priority operation).

The operation is based on a setting: channel 0 to be A/D-converted for group A, the temperature sensor output and internal reference voltage to be A/D-converted for group B, and channel 1 to be A/D-converted for group C.

(1) When input of the group A trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), scan for group A starts.

(2) Start A/D conversion for channel 0, and on its completion, the A/D-converted value is stored in the corresponding A/D data register (ADDR0).

(3) A scan end interrupt is generated if the ADCSR.ADIE bit is set to 1 (scan end interrupt is enabled).

(4) The ADCSR.ADST bit is automatically cleared to 0 when scan for group A is completed, and the 12-bit A/D converter enters a wait state.

(5) When input of the group B trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), scan for group B starts.

(6) Before A/D-converting the temperature sensor output, 15 ADCLK is inserted as a discharging period. After a completion of the discharging period, A/D conversion for the temperature sensor output starts, and the A/D-converted value is stored in the corresponding A/D data register (ADTSDR) upon completion of A/D conversion. Next, before A/D-converting the internal reference voltage, 15 ADCLK is inserted as a discharging period. After a completion of the discharging period, A/D conversion for the internal reference voltage starts, and the A/D-converted value is stored in the corresponding A/D data register (ADOCDR) upon completion of A/D conversion.

(7) Group B scan end interrupt is output if the ADCSR.GBADIE bit is set to1 (group B scan end interrupt is enabled).

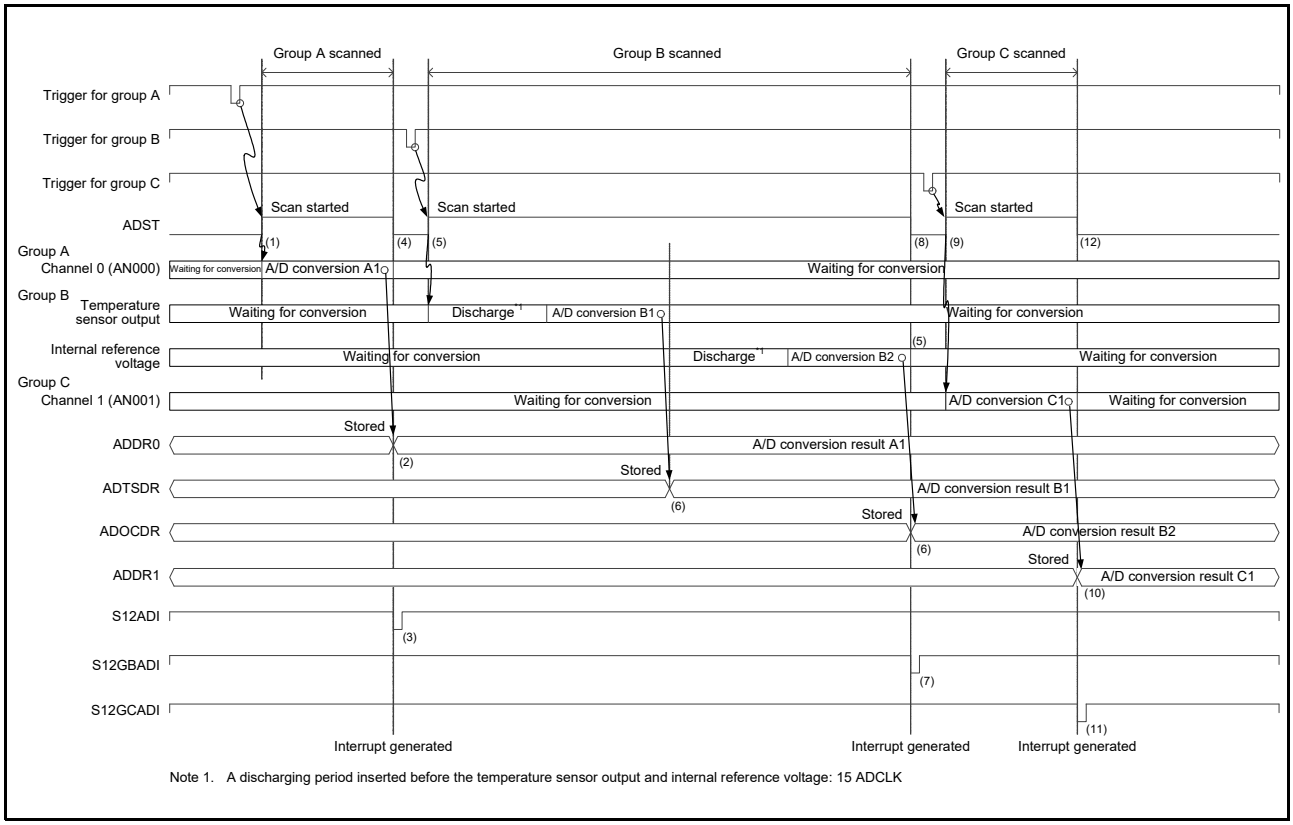
(8) The ADCSR.ADST bit is automatically cleared to 0 when scan for group B is completed, and the 12-bit A/D converter enters a wait state.

(9) When input of the group C trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), scan for group C starts.

(10) Start A/D conversion for channel 1, and on its completion, the A/D-converted value is stored in the corresponding A/D data register (ADDR1).

(11) Group C scan end interrupt is output if the ADGCTRGR.GCADIE bit is set to1 (group C scan end interrupt is enabled).

(12) The ADCSR.ADST bit is automatically cleared to 0 when scan for group C is completed, and the 12-bit A/D converter enters a wait state.



Note 1. A discharging period inserted before the temperature sensor output and internal reference voltage: 15 ADCLK

Figure 42.25 Operation When Using the Temperature Sensor Output and the Internal Reference Voltage (in Group Scan Mode and Not in Group Priority Operation)

42.3.5.2 A/D Conversion in Double Trigger Mode

When double trigger mode is selected in group scan mode, two rounds of single scan operation started by a synchronous trigger are performed as a sequence for group A. For groups B and C, single scan operation started by a synchronous trigger is performed once.
In group scan mode, the synchronous triggers of groups A, B, and C can be selected using the TRSA[6:0] and TRSB[6:0] bits in the ADSTRGR register, and the ADGCTRGR2.TRSC6 and ADGCTRGR.TRSC[5:0] bits, respectively. Different triggers should be used for each group A, B, and C so that scanning of groups A, B, and C does not occur simultaneously. Software trigger and asynchronous trigger should not be used. When TRG4AN or TRG4BN, TRG7AN or TRG7BN, TRGA0N or TRG0N, TRGA9N or TRG9N, TRGA0N or TRGA9N, TRG0N or TRG9N, GTADTRA0N or GTADTRB0N, GTADTRA1N or GTADTRB1N, GTADTRA2N or GTADTRB2N, GTADTRA3N or GTADTRB3N, GTADTRA4N or GTADTRB4N, GTADTRA5N or GTADTRB5N, GTADTRA6N or GTADTRB6N, GTADTRA7N or GTADTRB7N, or ELCTRG00N or ELCTRG01N/ELCTRG10N or ELCTRG11N/ELCTRG20N or ELCTRG21N is selected as the synchronous trigger of group A by the ADSTRGR.TRSA[6:0] bits, operation is performed in extended double trigger mode.
The channels to be scanned are selected using bits ADCSR.DBLANS[4:0] for group A, registers ADANSB0 and ADANSB1 for group B, and registers ADANSC0 and ADANSC1 for group C.
When double trigger mode is selected in group scan mode, the temperature sensor A/D conversion select bit (ADEXICR.TSSA) and internal reference voltage A/D conversion select bit (ADEXICR.OCSA) are set to 0 (not selected).
When double trigger mode is selected in group scan mode, self-diagnosis cannot be selected.
Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1.
The following describes operation in group scan mode with double trigger mode using a synchronous trigger from the MTU. The TRG4ABN, TRGA0N, and TRGA1N triggers from the MTU are assumed to be used to start conversion of groups A, B, and C, respectively.

(1) Scanning of group C is started by the TRGA1N trigger from the MTU.
(2) When group C scanning is completed, a group C scan interrupt is generated if the ADGCTRGR.GCADIE bit is 1 (group C scan end interrupt is enabled).
(3) Scanning of group B is started by the TRGA0N trigger from the MTU.
(4) When group B scanning is completed, a group B scan end interrupt is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).
(5) The first scanning of group A is started by the first TRG4ABN trigger from the MTU.
(6) When the first scanning of group A is completed, the conversion result is stored into the corresponding A/D data register (ADDRy); a scan end interrupt request is not generated irrespective of the ADCSR.ADIE bit setting.
(7) The second scanning of group A is started by the second TRG4ABN trigger from the MTU.
(8) When the second scanning of group A is completed, the conversion result is stored into the ADDBLDR register a scan end interrupt is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
(9) The second scanning of group B is started by the second TRGA0N trigger from the MTU.
(10) When the second scanning of group B is completed, a group B scan end interrupt is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).
(11) The second scanning of group C is started by the second TRGA1N trigger from the MTU.
(12) When the second scanning of group C is completed, a group C scan end interrupt is generated if the ADGCTRGR.GCADIE bit is 1 (group C scan end interrupt is enabled).

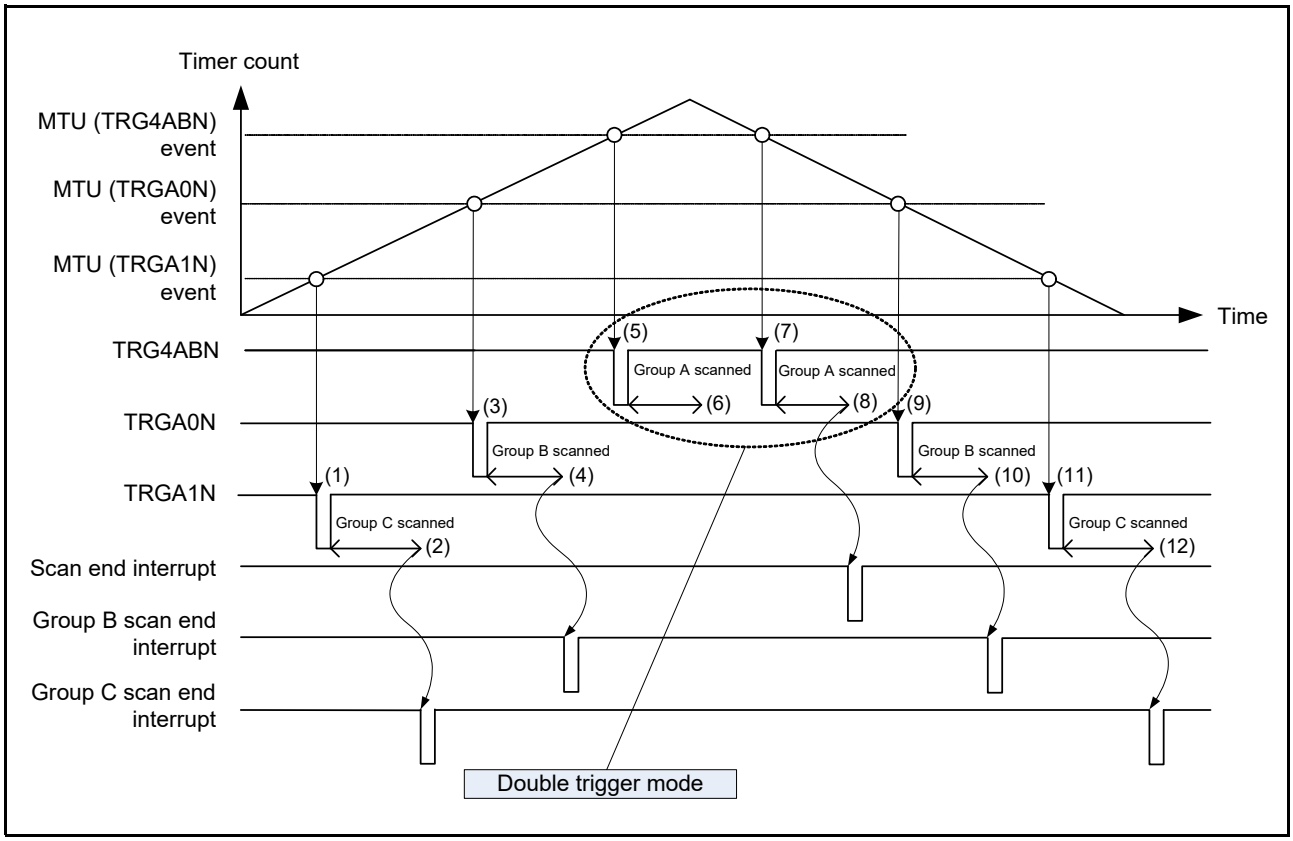


Figure 42.26 Example of Operation in Group Scan Mode with Double Trigger Mode (Basic Operation: Synchronous Triggers from MTU Used)

42.3.5.3 Operation under Group Priority Control

Setting the ADGSPCR.PGS bit to 1 in group scan mode makes operation proceed under group priority control. The group priority order is group A > group B > group C. Either two (groups A and B) or three (groups A, B, and C) can be selected as the number of the groups to be used in group scan mode. When setting the ADGSPCR.PGS bit to 1, follow the procedure described in Figure 42.27. If the procedure is not followed, proper scanning operation and data storage are not guaranteed.

In basic operation of group scan mode, if group A, B, or C is scanning, all other trigger inputs are ignored. Under group priority control, if a priority group trigger is input during A/D conversion for the low-priority group, A/D conversion for the low-priority group is interrupted and A/D conversion for the priority group proceeds.

If the ADGSPCR.GBRSCN bit is 0, the converter enters a wait state for the low-priority group on completion of the A/D conversion for the priority group.

The trigger input for the low-priority group during scanning is ignored.

If the ADGSPCR.GBRSCN bit is 1, the converter automatically restarts scanning for the low-priority group from the head of the group after A/D conversion for the priority group.

Also, the trigger input for the low-priority group generated during scanning for the priority group is enabled, and the converter automatically restarts scanning for the low-priority group after scanning for the priority group.

When the ADGSPCR.LGRRS bit is 0 while the ADGSPCR.GBRSCN bit is 1, the converter restarts scanning for the low-priority group from the head of the group. When the ADGSPCR.LGRRS bit is 1, the converter restarts scanning for the low-priority group from the channel on which scanning is interrupted.

However, when self-diagnosis is used, the converter restarts scanning from the channel on which scanning is interrupted after self-diagnosis is completed.

Table 42.20 summarizes operations in response to the input of a trigger during scanning with the settings of the ADGSPCR.GBRSCN bit.

When the ADGSPCR.GBRP bit is set to 1, scanning operations for the group of the lowest priority are continuously performed in single scan mode.

For the trigger settings in group scan mode, select a synchronous trigger for group A using the ADSTRGR.TRSA[6:0] bits, select a synchronous trigger different from that of group A for group B using the ADSTRGR.TRSB[6:0] bits, and select a synchronous trigger different from those of groups A and B for group C using the ADGCTRGR2.TRSC6 and ADGCTRGR.TRSC[5:0] bits.

Set the ADSTRGR.TRSB[6:0] bits to 3Fh or 7Fh when setting group scan mode for two groups (the ADGCTRGR.GRCE bit to 0) and setting the ADGSPCR.GBRP bit to 1.

Set the ADGCTRGR.TRSC[5:0] bits to 3Fh when setting group scan mode for three groups (the ADGCTRGR.GRCE bit to 1) and setting the ADGSPCR.GBRP bit to 1.

Furthermore, as targets for scanning, select channels for group A by using the ADANSA0 and ADANSA1 registers, and the ADEXICR.TSSA and ADEXICR.OCSA bits; select the group B channels by using the ADANSB0 and ADANSB1 registers, and the ADEXICR.TSSB and ADEXICR.OCSB bits; and select the group C by using the ADANSC0 and ADANSC1 registers, and the ADGCEXCR.TSSC and ADGCEXCR.OCSC bits respectively.

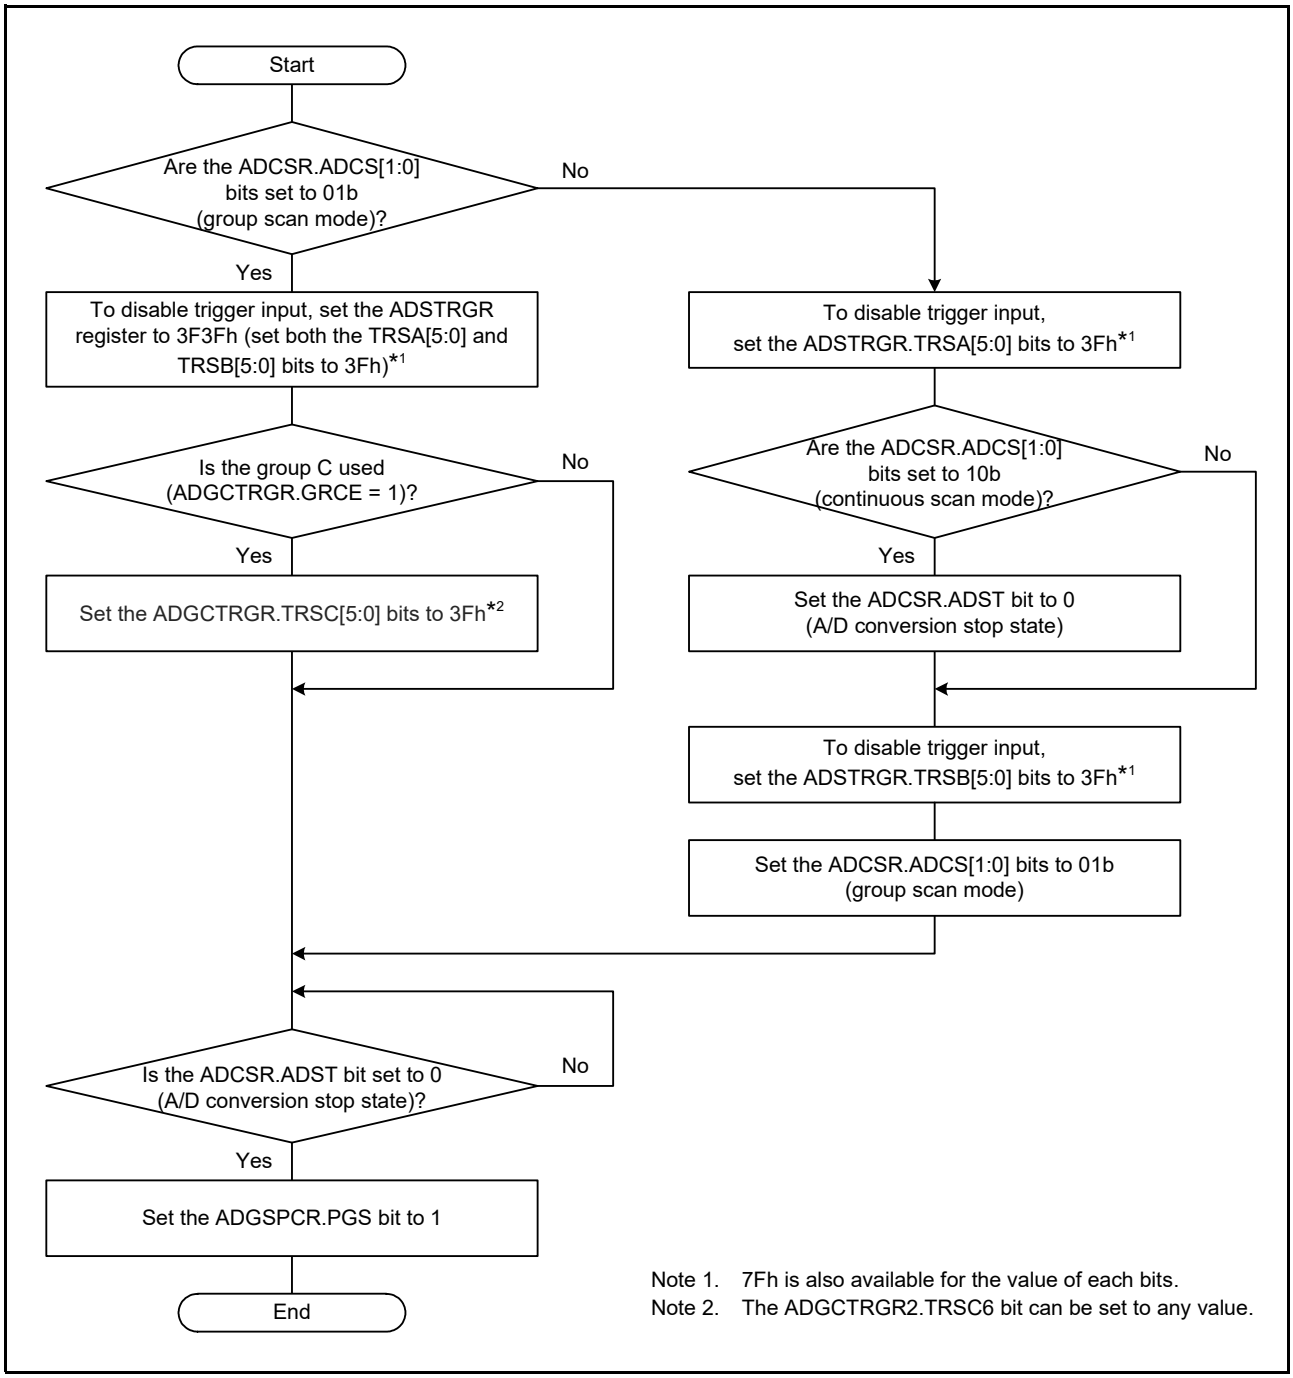

Figure 42.27 Flow of Setting the ADGSPCR.PGS Bit

Table 42.20 Control of Scanning Operations According to the Settings of the ADGSPCR.GBRSCN Bit

Scanning Operation	Trigger Input	ADGSPCR.GBRSCN = 0	ADGSPCR.GBRSCN = 1
When A/D conversion for group A is in progress	Input of trigger for group A	Trigger input is ineffective.	Trigger input is ineffective.
	Input of trigger for group B	Trigger input is ineffective.	A/D conversion is performed on group B after A/D conversion on group A is completed.
	Input of trigger for group C	Trigger input is ineffective.	A/D conversion is performed on group C after A/D conversion on group A is completed.
When A/D conversion for group B is in progress	Input of trigger for group A	A/D conversion in progress for group B interrupted and conversion for group A starts.	• A/D conversion in progress for group B is interrupted and conversion for group A starts. • A/D conversion for group B starts after conversion for group A is completed.
	Input of trigger for group B	Trigger input is ineffective.	Trigger input is ineffective.
	Input of trigger for group C	Trigger input is ineffective.	A/D conversion is performed on group C after A/D conversion on group B is completed.
When A/D conversion for group C is in progress	Input of trigger for group A	A/D conversion in progress for group C interrupted and conversion for group A starts.	• A/D conversion in progress for group C is interrupted and conversion for group A starts. • A/D conversion for group C starts after conversion for group A is completed.
	Input of trigger for group B	A/D conversion in progress for group C is interrupted and conversion for group B starts.	• A/D conversion in progress for group C is interrupted and conversion for group B starts. • A/D conversion for group C starts after conversion for group B is completed.
	Input of trigger for group C	Trigger input is ineffective.	Trigger input is ineffective.

When using group priority operation mode, refer to the following tables to select the desirable operating mode and set the registers.

Table 42.21 Group Priority Operation Setting and Operating Mode for Two Groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 0)

ADGSPCR			
GBRSCN	LGRRS	GBRP	Operation
0	x	0	Group priority operation for two groups (groups A and B) • When a group A trigger is input, group B scan is completed (not restarted)
1	0	0	Group priority operation for two groups (groups A and B) • After a scan for group B is interrupted, upon completion of a scan for group A, a scan for group B starts again from the beginning according to the order specified in the ADANSB0 register.
1	1	0	Group priority operation for two groups (groups A and B) • After group B scan is interrupted, group B scan is restarted from the channel on which scan was interrupted*1, among the channels selected with the ADANSB0 register after group A scan is completed.
x	0	1	Group priority operation for two groups (groups A and B) • Single scan for group B is started continuously without start trigger input. After group B scan is interrupted, single scan is restarted from the head of the channel selected with the ADANSB0 register after scan for group A is completed.
1	1	1	Group priority operation for two groups (groups A and B) • Single scan for group B is started continuously without start trigger input. After group B scan was interrupted, single scan is restarted from the channel on which scan was interrupted*1, among the channels selected with the ADANSB0 register after group A scan is completed.

x = Don't care

Note 1. When self-diagnosis is used (ADCER.DIAGM = 1), A/D conversion of the interrupted channel is started after self-diagnosis.

Table 42.22 Group Priority Operation Setting and Operating Mode for Three Groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 1)

ADGSPCR			
GBRSCN	**LGRRS**	**GBRP**	**Operation**
0	x	0	Group priority operation for three groups (groups A, B, and C) • When a group A trigger is input, group B scan is completed (not restarted) • When a trigger for group A or B is input, group C scan is completed (not restarted).
0	x	1	Group priority operation for three groups (groups A, B, and C) • When a group A trigger is input, group B scan is completed (not restarted) • Single scan for group C is started continuously without start trigger input. After group C scan is interrupted, scan is restarted from the head of the channel selected with the ADANSC0 and ADANSC1 registers after scan for groups A and B is completed.
1	0	0	Group priority operation for three groups (groups A, B, and C) • After group B scan is interrupted, scan is restarted from the head of the channel selected with the ADANSB0 and ADANSB1 registers after group A scan is completed. • After group C scan is interrupted, scan is restarted from the head of the channel selected with the ADANSC0 and ADANSC1 registers after scan for groups A and B is completed.
1	1	0	Group priority operation for three groups (groups A, B, and C) • After group B scan is interrupted, scan is restarted from the channel on which scan was interrupted*1, among the channels selected with the ADANSB0 and ADANSB1 registers after scan for group A is completed. • After group C scan is interrupted, scan is restarted from the channel on which scan was interrupted*1, among the channels selected with the ADANSC0 and ADANSC1 registers after scan for groups A and B is completed.
1	0	1	Group priority operation for three groups (groups A, B, and C) • After group B scan is interrupted, scan is restarted from the head of the channel selected with the ADANSB0 and ADANSB1 registers after group A scan is completed. • Single scan for group C is started continuously without start trigger input. After group C scan is interrupted, single scan is restarted from the head of the channel selected with the ADANSC0 and ADANSC1 registers after scan for groups A and B is completed.
1	1	1	Group priority operation for three groups (groups A, B, and C) • After scanning for group B is interrupted, once scanning for group A completes, scanning is resumed starting from the channel on which scanning was interrupted*1, among those channels selected with the ADANSB0 and ADANSB1 registers. • Single scan for group C is started continuously without start trigger input. After group C scan is interrupted, single scan is restarted from the channel on which scan was interrupted*1, among the channels selected with the ADANSC0 and ADANSC1 registers after scan for groups A and B is completed.

x = Don’t care

Note 1. When self-diagnosis is used (ADCER.DIAGM = 1), A/D conversion of the interrupted channel is started after self-diagnosis.

(1) Group Priority Operation for Two Groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 0)

The following examples 1 to 5 show group priority operation in group scan mode (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0) when channel 0 is selected for group A and channels 1 to 3 are selected for group B.

Operation example 1: Input of the group A trigger signal during a group B scan, with the rescan setting

(1) When input of the group B trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion starts for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register. (Specified conversion order in Figure 42.28: AN000 → AN001 → AN002 → AN003)

(2) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).

(3) When a group A trigger is input during the group B scanning, the ADCSR.ADST bit retains the value as 1, and the group B scan is interrupted, and the group A scan starts for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.

(4) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).

(5) A scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).

(6) When the ADGSPCR.GBRSCN bit is set to 1 (restarting a group scan which was interrupted due to group priority in scanning), the ADCSR.ADST bit retains the value as 1, and the group B scan for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register is restarted.

(7) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).

(8) A group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).

(9) The ADCSR.ADST bit is automatically cleared to 0 when scan of all selected channels is completed, and the 12-bit A/D converter enters a wait state.

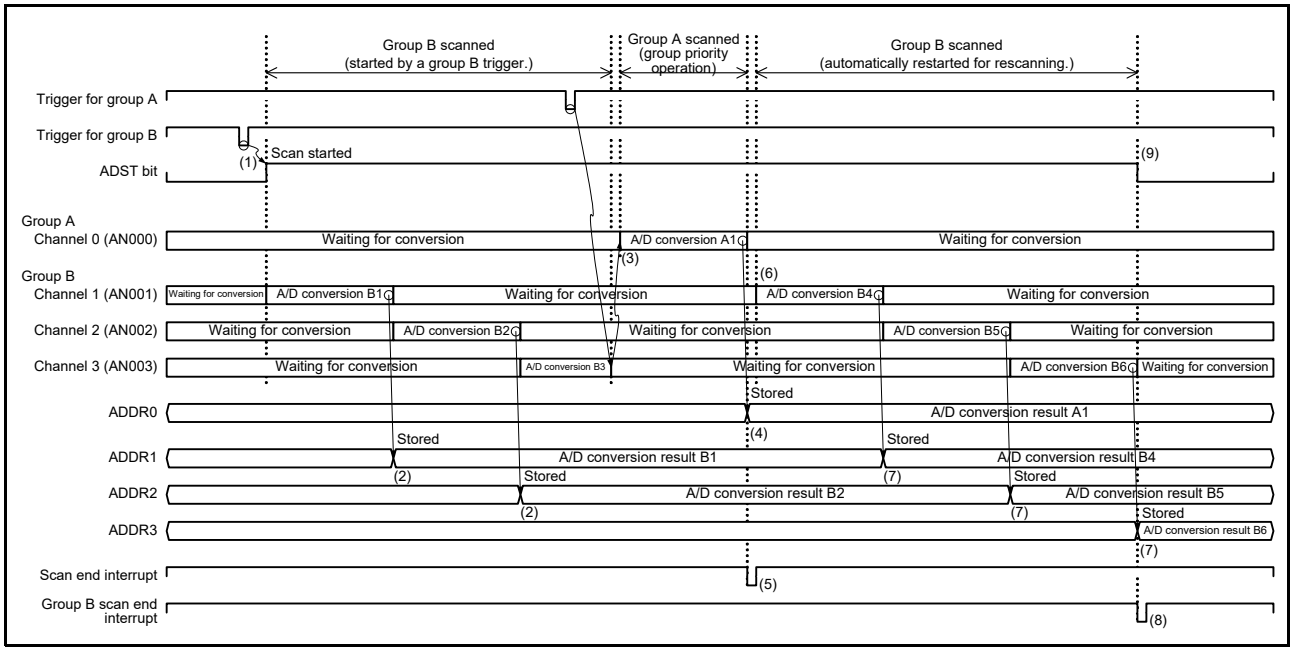

Figure 42.28 Example 1 of Group Priority Operation: Input of Group A Trigger Signal During Group B Scan, with the Rescan Setting (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0)

Operation example 2: Input of the group A trigger signal during a group B rescan, with the rescan setting

Figure 42.29 shows an example when a group A trigger is input during rescan operation on group B.

If a group A trigger is input, scan for group A starts even while rescan operation is in progress. Scan for group B starts after scan for group A is completed.

Operations of the ADCSR.ADST bit, storing to the A/D conversion result in the A/D data register (ADDRy), and interrupt requests are the same as example 1.

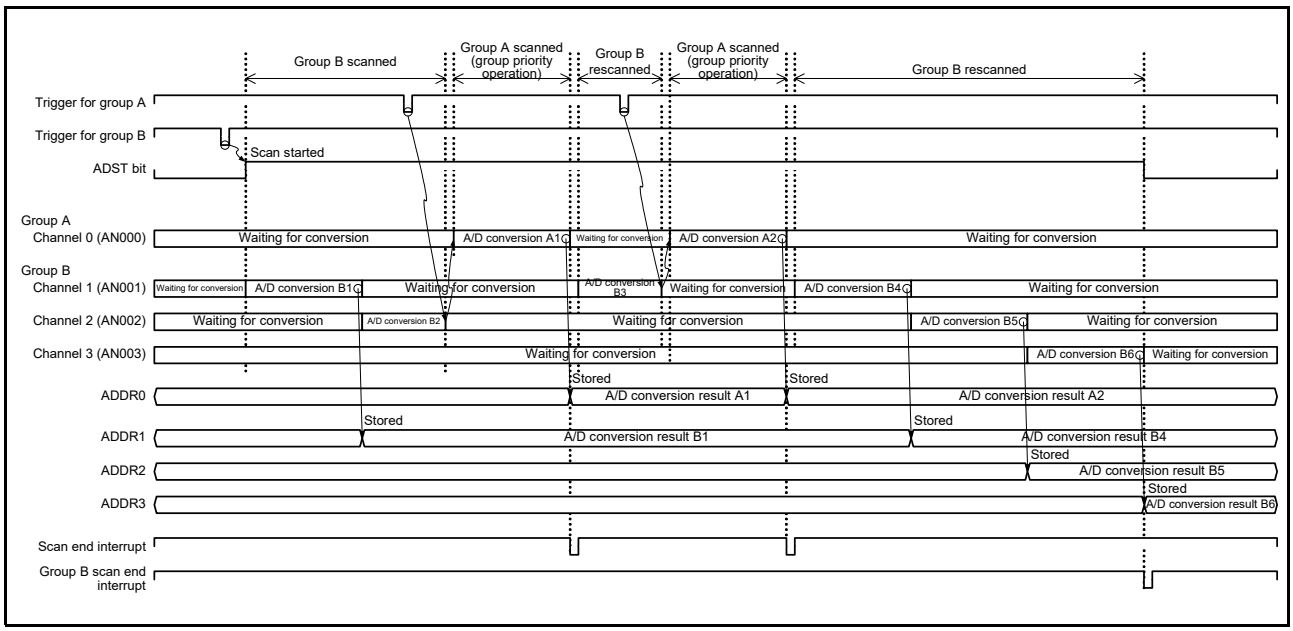

Figure 42.29 Example 2 of Group Priority Operation: Input of Group A Trigger Signal During Group B Rescan, with the Rescan Setting (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0)

Operation example 3: Input of the group B trigger signal during a group A scan, with the rescan setting

The following describes an example when a group B trigger is input during scan operation on group A when the ADGPSCR.GBRSCN bit is 1 (scan for the group is restarted after having been interrupted due to group priority operation).
If the ADGPSCR.GBRSCN bit is 0, all group B triggers that are input during scan operation on group A are disabled.

(1) When input of the group A trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), a group A scan starts for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
(2) When a group B trigger is input during a group A scanning, a group B becomes ready for a scan.
(3) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(4) After scan for group A is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
(5) After the group A scan ends, the ADCSR.ADST bit retains the value as 1, and the group B scan is started for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register.
(When a group A trigger is input during the group B scanning, the group A scan is started in the same way as in the example 1, and the group B scan is restarted after the group A scan ends.)
(6) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(7) After scan for group B is completed, a group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).
(8) The ADCSR.ADST bit is automatically cleared to 0 when scan of all selected channels is completed, and the 12-bit A/D converter enters a wait state.

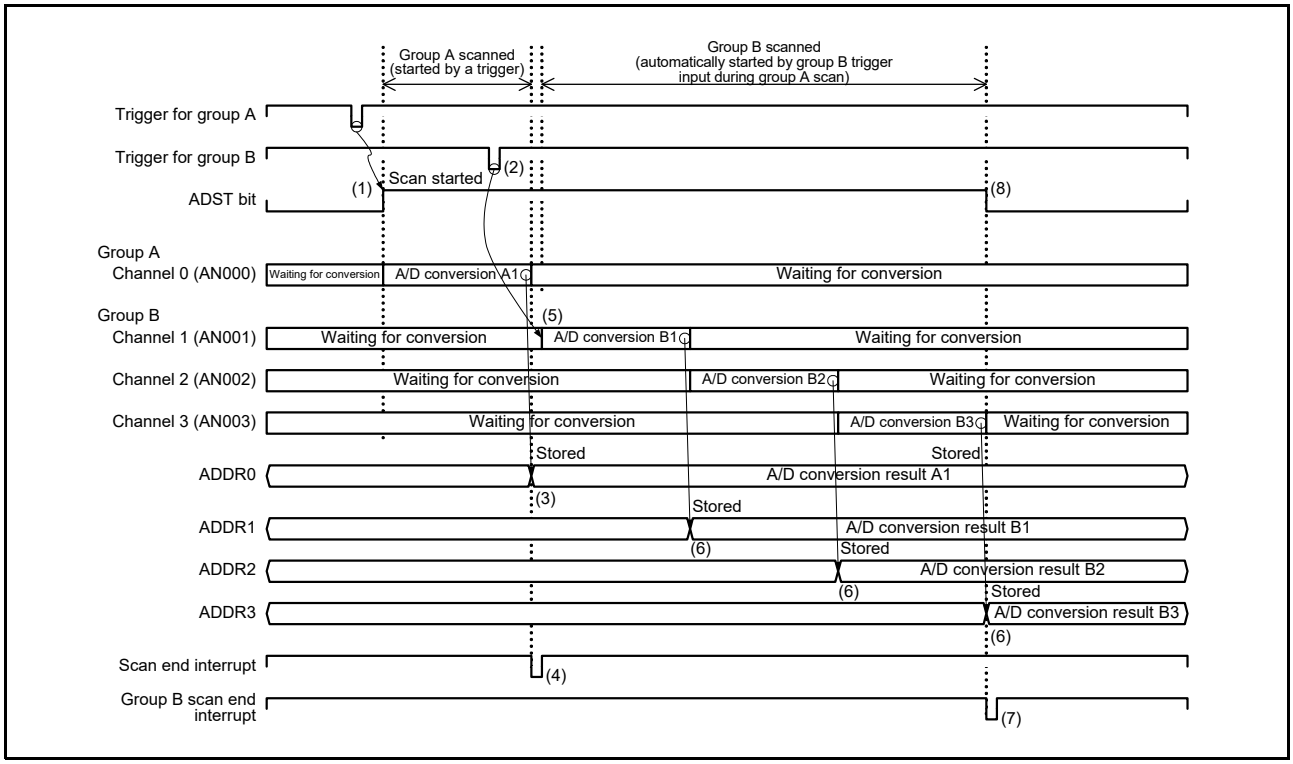

Figure 42.30 Example 3 of Group Priority Operation: Input of Group B Trigger Signal During Group A Scan, with the Rescan Setting (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0)

Operation example 4 shows group priority operation in group scan mode (ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0) when channel 0 is selected for group A and channels 1 to 3 are selected for group B.

Operation Example 4 Input of the group A trigger signal during a group B scan, without the rescan setting

(1) When input of the group B trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), a group B scan starts for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register.

(2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).

(3) When a group A trigger is input during the group B scanning, the ADCSR.ADST bit retains the value as 1, and the group B scan is interrupted, and the group A scan starts for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.

(4) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).

(5) After scan for group A is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).

(6) The ADCSR.ADST bit is automatically cleared to 0 when scan for group A is completed, and the 12-bit A/D converter enters a wait state. Scan for group B is not started until the next group B trigger is input.

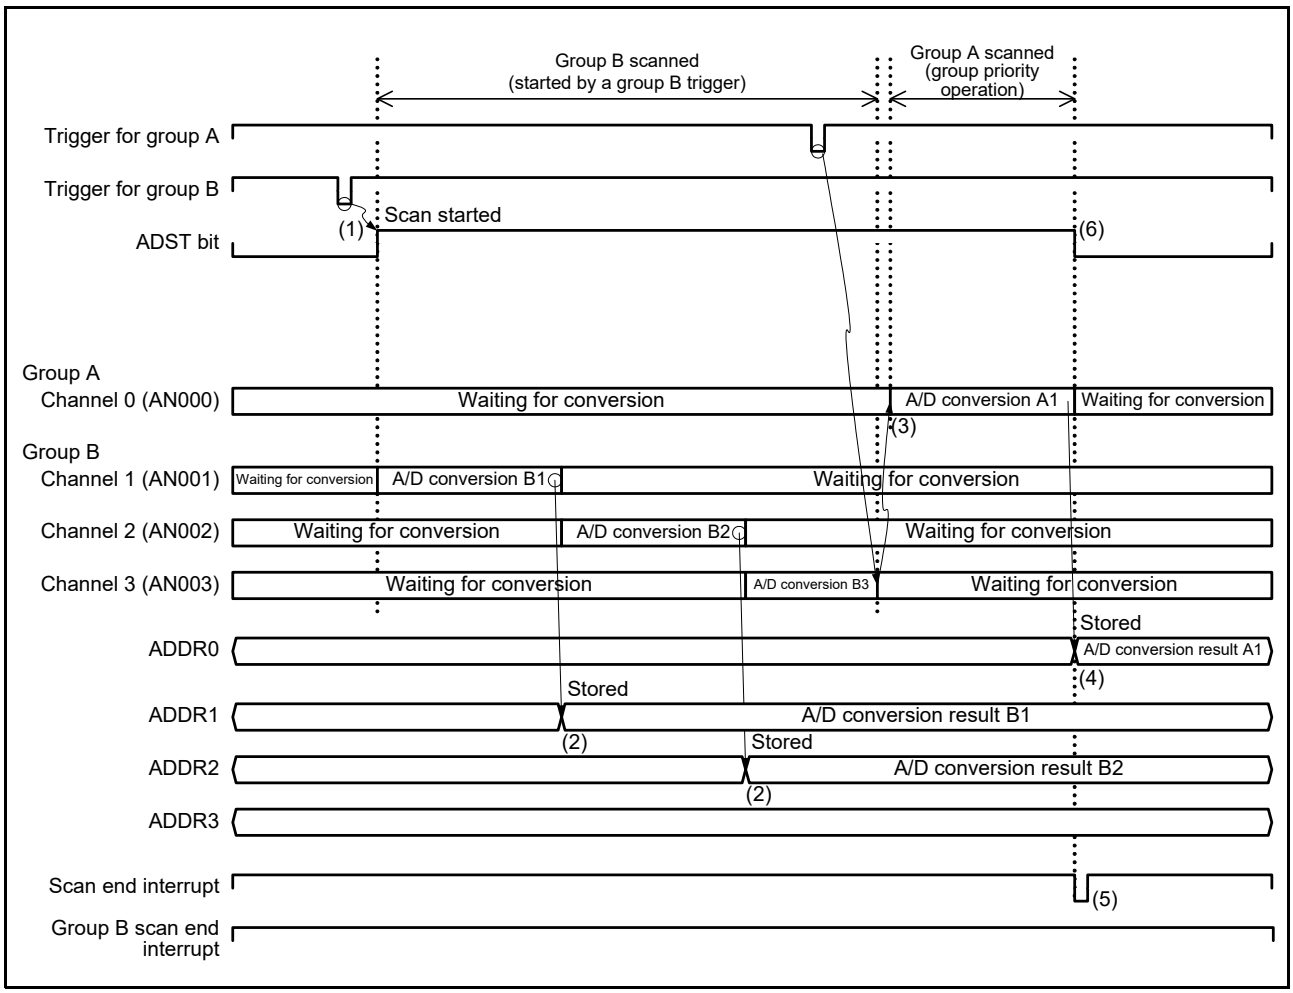

Figure 42.31 Example 4 of Group Priority Operation: Input of Group A Trigger Signal During Group B Scan, Without the Rescan Setting (ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0)

Operation example 5 shows group priority operation in group scan mode (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 0) when channel 0 is selected for group A and channels 1 and 2 are selected for group B. When the ADGCTRGR.GRCE bit is set to 1, single scan mode is continuously operated on group C and scan for group B is started by trigger input.

Operation example 5: Continuous single scan operation on group B

(1) When the ADGSPCR.GBRP bit is set to 1, the ADCSR.ADST bit is set to 1 (starting A/D conversion), and a group B scan is started for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register.
(2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(3) When a group A trigger is input during the group B scanning, the ADCSR.ADST bit retains the value as 1, and the group B scan is interrupted, and the group A scan starts for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
(4) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(5) After scan for group A is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
(6) When the ADGSPCR.GBRP bit is set to 1 (selecting continuous single scanning), the ADCSR.ADST bit retains the value as 1, and the group B scan for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register is restarted.
(7) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(8) A group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).
(9) When the ADGSPCR.GBRP bit is set to 1 (selecting continuous single scanning), the ADCSR.ADST bit retains the value as 1, and the group B scan for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register is restarted.

To continuously operate single scan for group B, disable trigger input for group B.
Steps (6) to (9) are repeated as long as the ADGSPCR.GBRP bit remains 1. Clearing of the ADCSR.ADST bit to 0 is prohibited while the ADGSPCR.GBRP bit is set to 1. To forcibly stop scanning when ADGSPCR.GBRP = 1, follow the procedures for clear operation by software through the ADCSR.ADST bit shown in section 42.6.2, Notes on Stopping A/D Conversion.

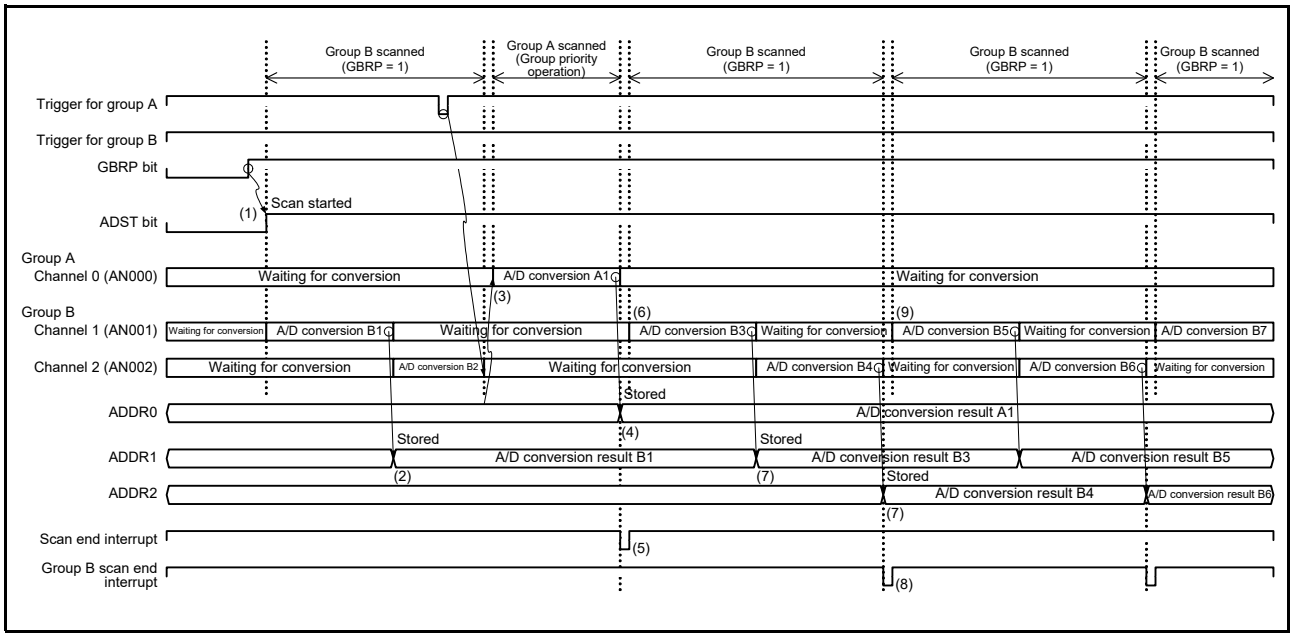

Figure 42.32 Example 5 for Group Priority Operation: Continuous Single Scan Operation on Group B (ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 1, ADGCTRGR.GRCE = 0)

(2) Group Priority Operation for Three Groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 1)

The following examples 1 to 5 show group priority operation in group scan mode (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1) when channel 0 is selected for group A, channels 1 and 2 are selected for group B, and channels 3 and 4 are selected for group C.
The priority groups mean groups A and B for group C and group A for group B.

Operation example 1: Priority group trigger input during low-priority group scan, with the rescan setting

(1) When input of the group C trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), the group C scan starts for the analog channels selected in the ADANSC0 and ADANSC1 registers according to the order of conversion specified in the ADSCSn register.
(2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(3) When a group B trigger is input during the group C scanning, the ADCSR.ADST bit retains the value as 1, the group C scan is interrupted, and the group B scan starts for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register. The A/D conversion result is not stored into the corresponding data register (ADDRy) if A/D conversion is not completed when the scan is interrupted.
(4) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(5) When a group A trigger is input during the group B scanning, the ADCSR.ADST bit retains the value as 1, and the group B scan is interrupted, and the group A scan starts for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. The A/D conversion result is not stored into the corresponding data register (ADDRy) if A/D conversion is not completed when the scan is interrupted.
(6) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(7) A scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
(8) When the ADGSPCR.GBRSCN bit is set to 1 (restarting a group scan which was interrupted due to group priority in scanning), the ADCSR.ADST bit retains the value as 1, and the group B scan for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register is restarted. At this time, the group B scan is restarted from the channel that the A/D conversion was interrupted if the ADGSPCR.LGRRS bit is set to 1.
(9) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(10) A group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).
(11) When the ADGSPCR.GBRSCN bit is set to 1, the ADCSR.ADST bit retains the value as 1, the group C scan for the analog channels selected in the ADANSC0 and ADANSC1 registers according to the order of conversion specified in the ADSCSn register is restarted. At this time, the group C scan is restarted from the channel that the A/D conversion was interrupted if the ADGSPCR.LGRRS bit is set to 1.
(12) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(13) A group C scan end interrupt is generated if the ADGCTRGR.GCADIE bit is 1 (group C scan end interrupt is enabled).
(14) The ADCSR.ADST bit is automatically cleared to 0 when scan of all selected channels is completed, and the 12-bit A/D converter enters a wait state.

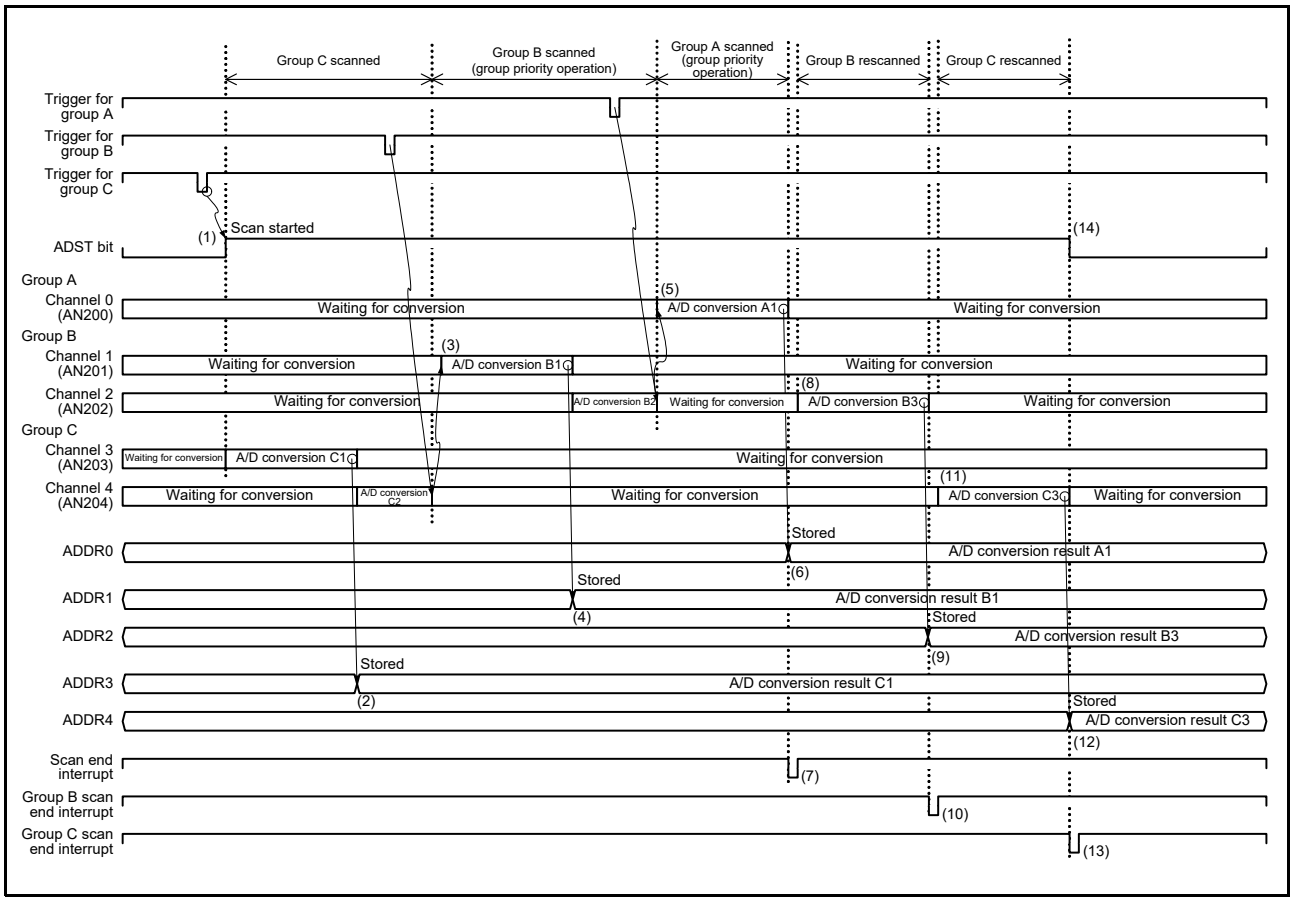

Figure 42.33 Example 1 of Group Priority Operation: Priority Group Trigger Input During Low-Priority Group Scan, with the Rescan Setting (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1)

Operation example 2: Priority group trigger input during low-priority group rescan, with the rescan setting

Figure 42.34 shows an example when a group A trigger is input during rescan operation on group B.
If a trigger for the priority groups (groups A and B for group C and group A for group B) is input, scan for the priority group starts even while rescan operation on the low-priority group is in progress. After scan for the priority group is completed, scan for the low-priority group is restarted after having been interrupted.
Operations of the ADCSR.ADST bit, storing to the A/D conversion result in the A/D data register (ADDRy), and interrupt requests are the same as example 1.

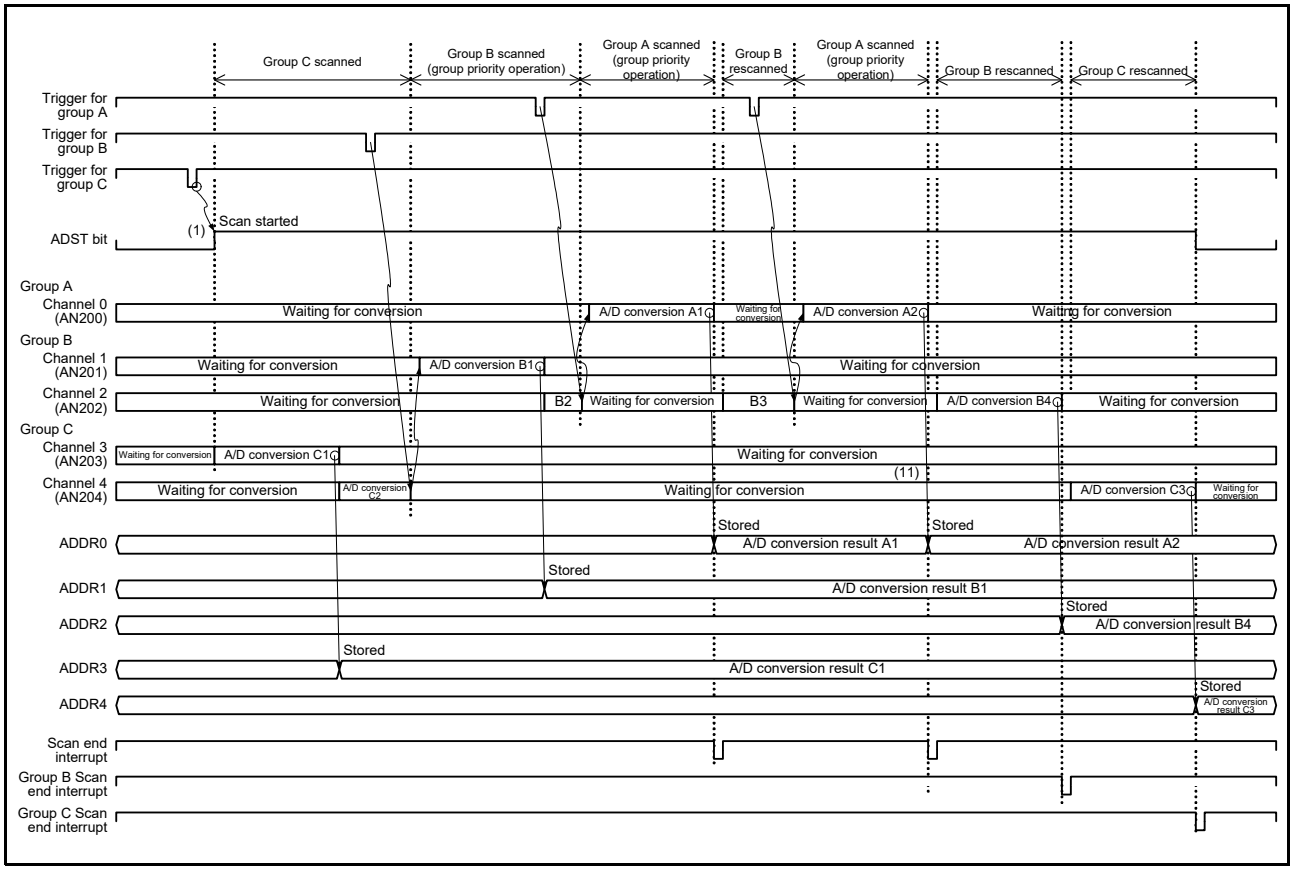

Figure 42.34 Example 2 of Group Priority Operation: Priority Group Trigger Input During Low-Priority Group Rescan, with the Rescan Setting (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1)

Operation example 3: Low-priority group trigger input during priority group scan, with the rescan setting

The following describes an example when a trigger for the low-priority group is input during scan operation on the priority group when the ADGPSCR.GBRSCN bit is 1 (scan for the group is restarted after having been interrupted due to group priority operation). If the ADGPSCR.GBRSCN bit is 0, all triggers for the low-priority group that are input during scan operation on the priority group are disabled.

(1) When input of the group A trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), a group A scan starts for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
(2) If a group B trigger is input during scan for group A, scan for group B can be started.
(3) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(4) After scan for group A is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
(5) After the group A scan ends, the ADCSR.ADST bit retains the value as 1, and the group B scan is started for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register. At this time, the group B scan is restarted from the channel that the A/D conversion was suspended if the ADGSPCR.LGRRS bit is set to 1.
(When a group A trigger is input during the group B scanning, the group A scan is started in the same way as in the example 1, and the group B scan is restarted after the group A scan ends.)
(6) If a group C trigger is input during scan for group B, scan for group C can be started.
(7) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(8) After scan for group B is completed, a group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).
(9) After scan for group B is completed, scan for the ANx channels of group C selected in the ADANSC0 and ADANSC1 registers, starts from the channel with the smallest number x while the ADCSR.ADST bit remains 1. If the ADGSPCR.LGRRS bit is set to 1 at this time, scan for group C starts from the channel on which A/D conversion was interrupted.
(When a group A or B trigger is input during scan for group C, group A or B scan starts as in example 1, and group C scan starts after group A or B scan is completed.)
(10) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(11) After scan for group C is completed, a group C scan end interrupt request is generated if the ADGCTRGR.GCADIE bit is 1 (group C scan end interrupt is enabled).
(12) The ADCSR.ADST bit is automatically cleared to 0 when scan of all selected channels is completed, and the 12-bit A/D converter enters a wait state.

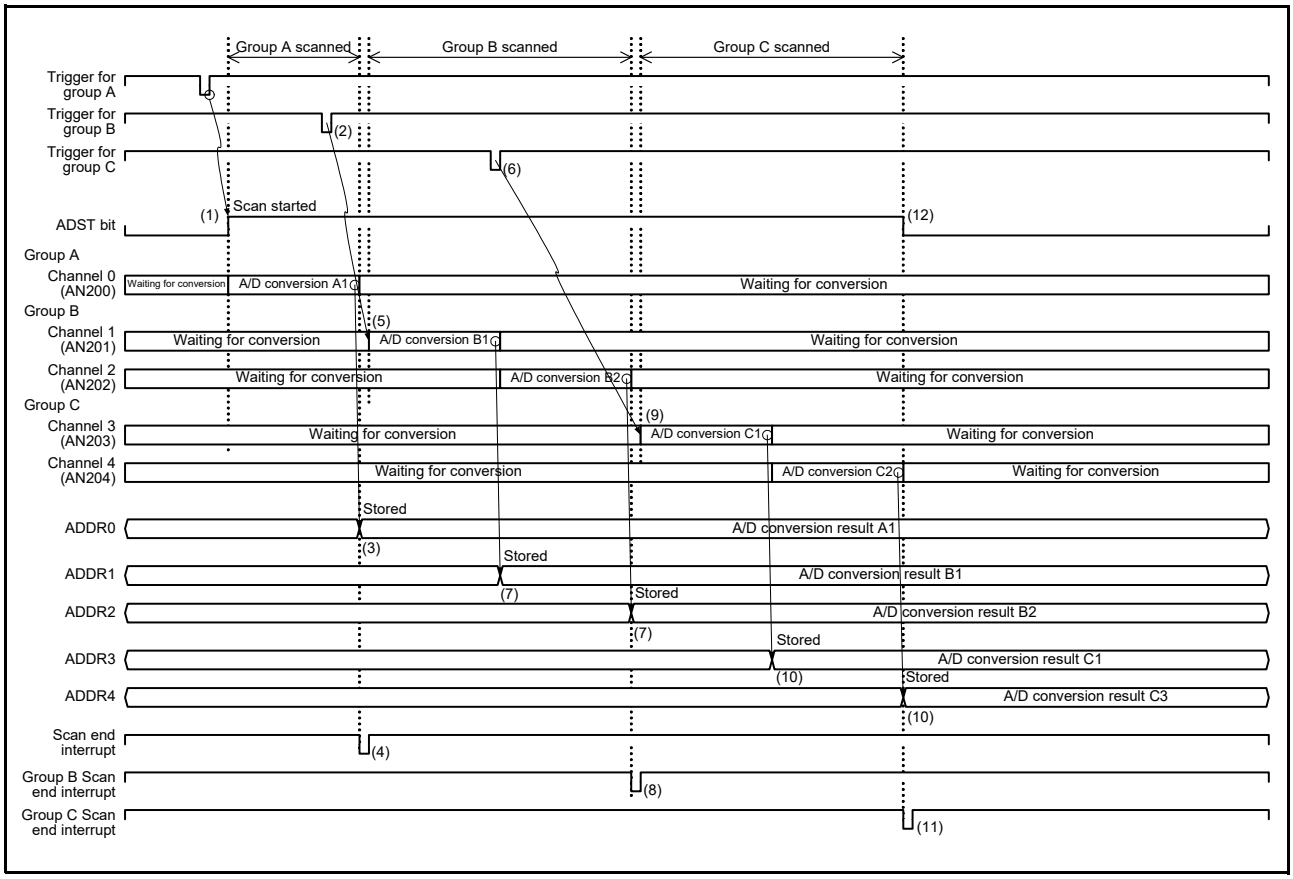

Figure 42.35 Example 3 of Group Priority Operation: Low-Priority Group Trigger Input During Priority Group Scan, with the Rescan Setting (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1, ADGCTRGR.GRCE = 1)

Operation example 4 shows group priority operation in group scan mode (ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0) when channel 0 is selected for group A, channels 1 and 2 are selected for group B, and channels 3 and 4 are selected for group C.

Operation example 4: Priority group trigger input during low-priority group scan, without the rescan setting

(1) When input of the group C trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), the group C scan starts for the analog channels selected in the ADANSC0 and ADANSC1 registers according to the order of conversion specified in the ADSCSn register.

(2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).

(3) When a group B trigger is input during the group C scanning, the ADCSR.ADST bit retains the value as 1, the group C scan is interrupted, and the group B scan starts for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register. The A/D conversion result is not stored into the corresponding data register (ADDRy) if A/D conversion is not completed when the scan is interrupted.

(4) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).

(5) When a group A trigger is input during the group B scanning, the ADCSR.ADST bit retains the value as 1, and the group B scan is interrupted, and the group A scan starts for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. The A/D conversion

result is not stored into the corresponding data register (ADDRy) if A/D conversion is not completed when the scan is interrupted.

(6) After scan for group A is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).

(7) The ADCSR.ADST bit is automatically cleared to 0 when scan for group A is completed, and the 12-bit A/D converter enters a wait state. Scan for groups C and B is not started until the next trigger corresponding to the group is input.

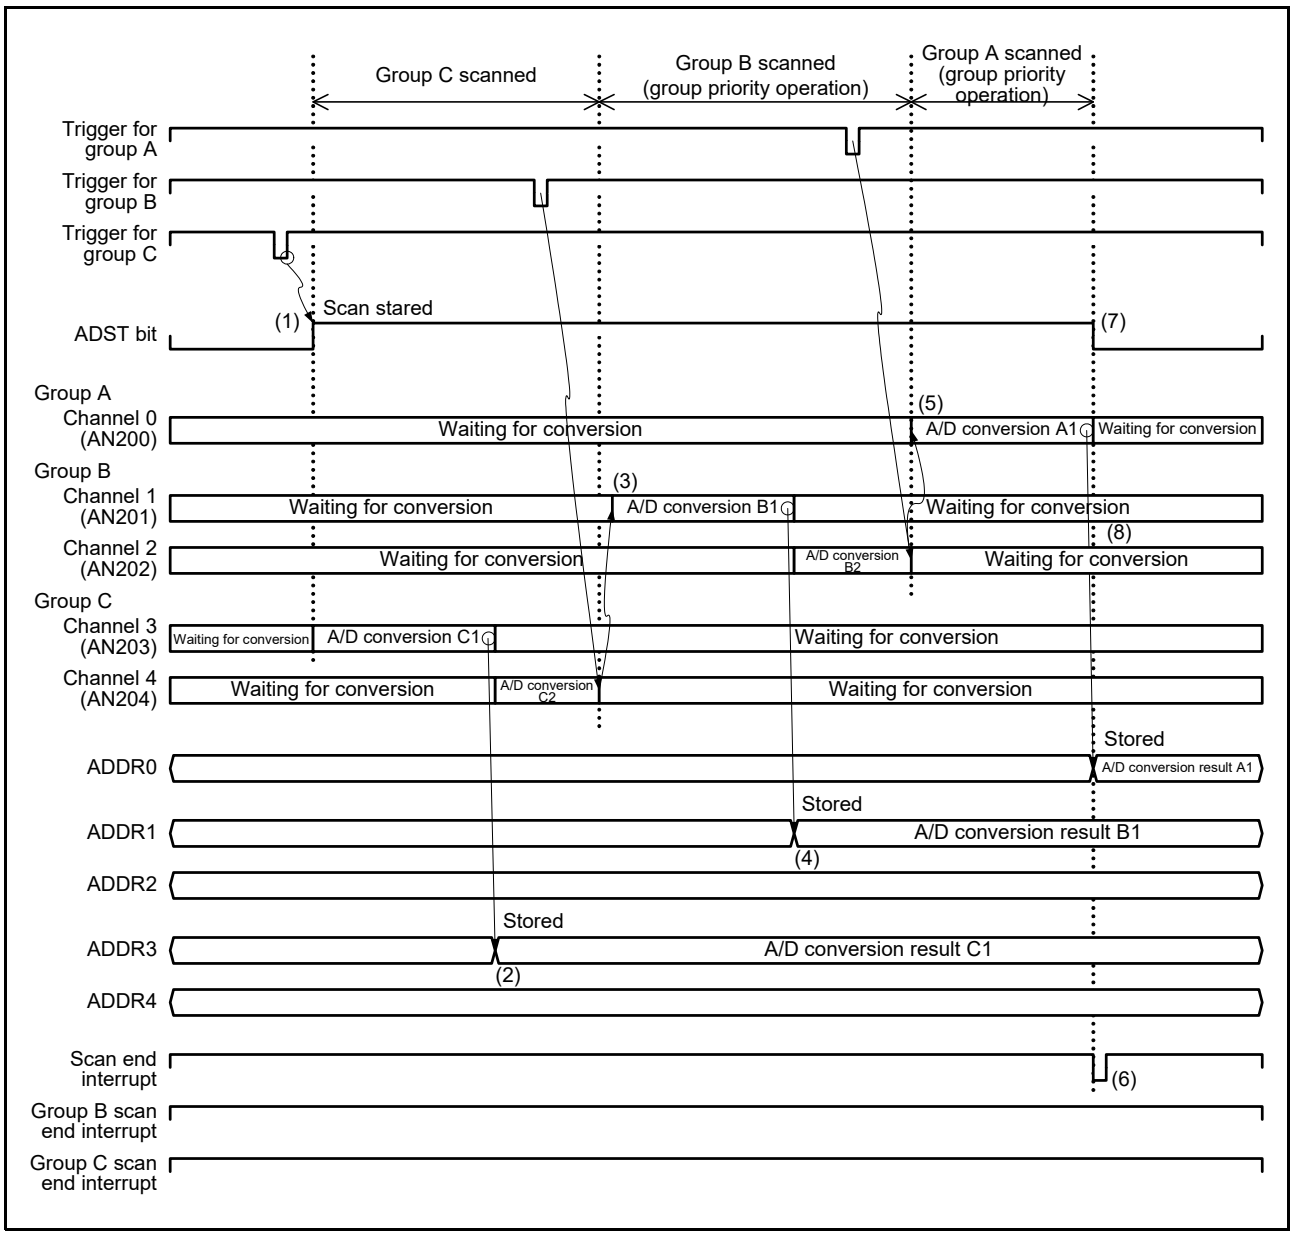

Figure 42.36 Example 4 of Group Priority Operation: Priority Group Trigger Input During Low-Priority Group Scan, Without the Rescan Setting (ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1)

Operation example 5 shows group priority operation in group scan mode (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 1) when channel 0 is selected for group A, channel 1 is selected for group B, and channels 2 and 3 are selected for group C.

When the ADGCTRGR.GRCE bit is set to 0, single scan mode is continuously operated on group B and trigger input for group C is disabled.

Operation example 5: Continuous single scan operation on group C

(1) When the ADGSPCR.GBRP bit is set to 1, the ADCSR.ADST bit is set to 1 (starting A/D conversion), and a group C scan is started for the analog channels selected in the ADANSC0 and ADANSC1 registers according to the order of conversion specified in the ADSCSn register.
(2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(3) When a group B trigger is input during the group C scanning, the ADCSR.ADST bit retains the value as 1, the group C scan is interrupted, and the group B scan starts for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register. The A/D conversion result is not stored into the corresponding data register (ADDRy) if A/D conversion is not completed when the scan is interrupted.
(4) When a group A trigger is input during the group B scanning, the ADCSR.ADST bit retains the value as 1, and the group B scan is interrupted, and the group A scan starts for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. The A/D conversion result is not stored into the corresponding data register (ADDRy) if A/D conversion is not completed when the scan is interrupted.
(5) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(6) A scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
(7) When the ADGSPCR.GBRSCN bit is set to 1 (restarting a group scan which was interrupted due to group priority in scanning), the ADCSR.ADST bit retains the value as 1, and the group B scan for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register is restarted. At this time, the group B scan is restarted from the channel that the A/D conversion was interrupted if the ADGSPCR.LGRRS bit is set to 1.
(8) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(9) A group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).
(10) When the ADGSPCR.GBRSCN bit is set to 1 (restarting a group scan which was interrupted due to group priority in scanning), the ADCSR.ADST bit retains the value as 1, and the group C scan for the analog channels selected in the ADANSC0 and ADANSC1 registers according to the order of conversion specified in the ADSCSn register is restarted. At this time, the group C scan is restarted from the channel that the A/D conversion was interrupted if the ADGSPCR.LGRRS bit is set to 1.
(11) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(12) A group C scan end interrupt is generated if the ADGCTRGR.GCADIE bit is 1 (group C scan end interrupt is enabled).
(13) When the ADGSPCR.GBRP bit is set to 1 (selecting continuous single scanning), the ADCSR.ADST bit retains the value as 1, and the group C scan for the analog channels selected in the ADANSC0 and ADANSC1 registers according to the order of conversion specified in the ADSCSn register is restarted.

To continuously operate single scan for group C, disable trigger input for group B.
Steps (13), (11), (12), and then (13) are repeated as long as the ADGSPCR.GBRP bit remains 1.
Clearing of the ADCSR.ADST bit to 0 is prohibited while the ADGSPCR.GBRP bit is set to 1.
To forcibly stop scanning when ADGSPCR.GBRP = 1, follow the procedures for clear operation by software through the ADCSR.ADST bit shown in section 42.6.2, Notes on Stopping A/D Conversion.

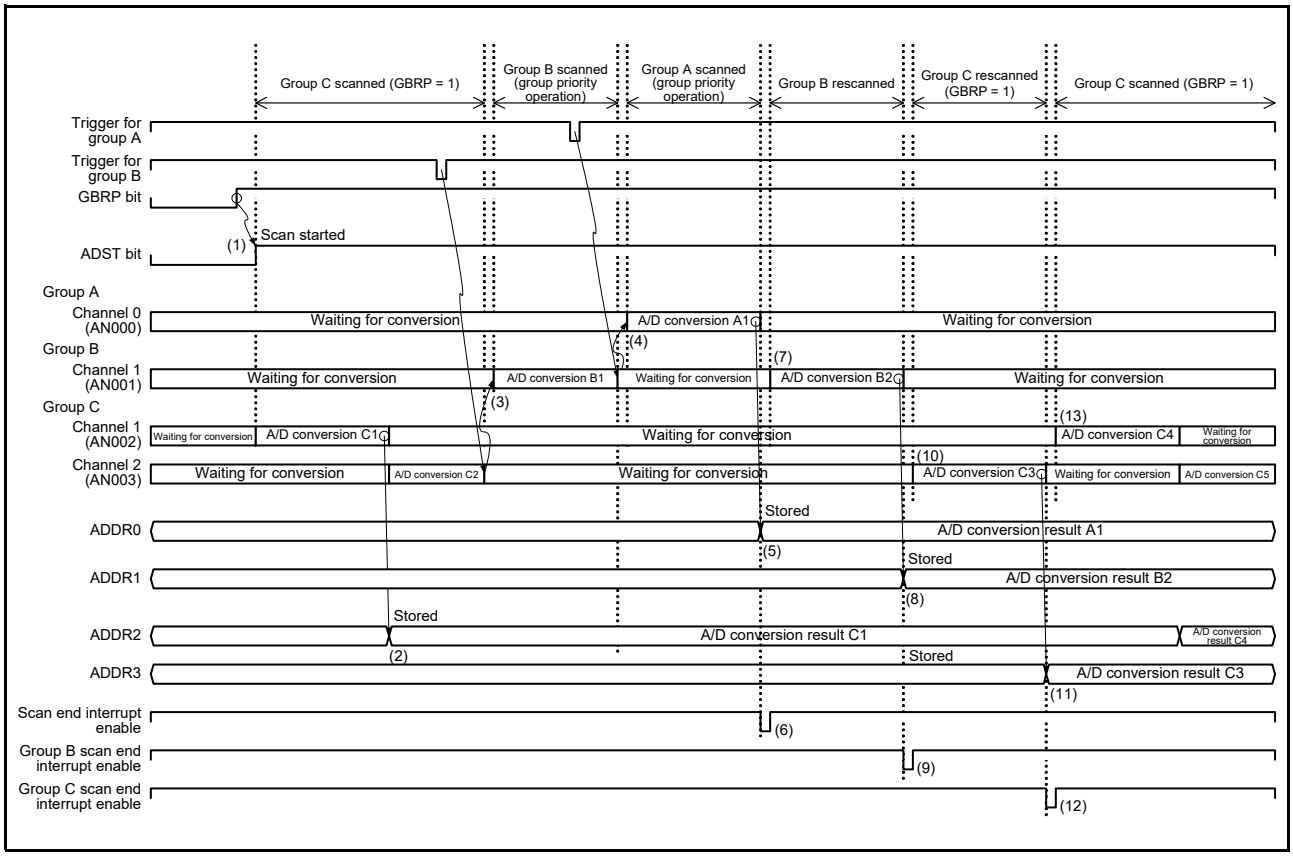

Figure 42.37 Example 5 for Group Priority Operation: Continuous Single Scan Operation on Group C (ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 1)

42.3.6 Comparison Function (Window A and Window B)

42.3.6.1 Comparison Function Windows A/B

The comparison function compares the reference values set in registers ADCMPDR0, ADCMPDR1, ADWINLLB, and ADWINULB with the A/D conversion results. When this function is used, self-diagnosis or double trigger mode cannot be used. A window comparison function can also be used (when ADCMPCR.WCMPE = 1), enabling comparison of two values. Two sets of voltage level ranges can be set in the window comparison function, one for window A and one for window B.

Operation when window comparison is enabled (ADCMPCR.WCMPE = 1) in combination with continuous scan mode is described below.

(1) When the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input, A/D conversion is performed for selected channels, temperature sensor output, and internal reference voltage in this order.

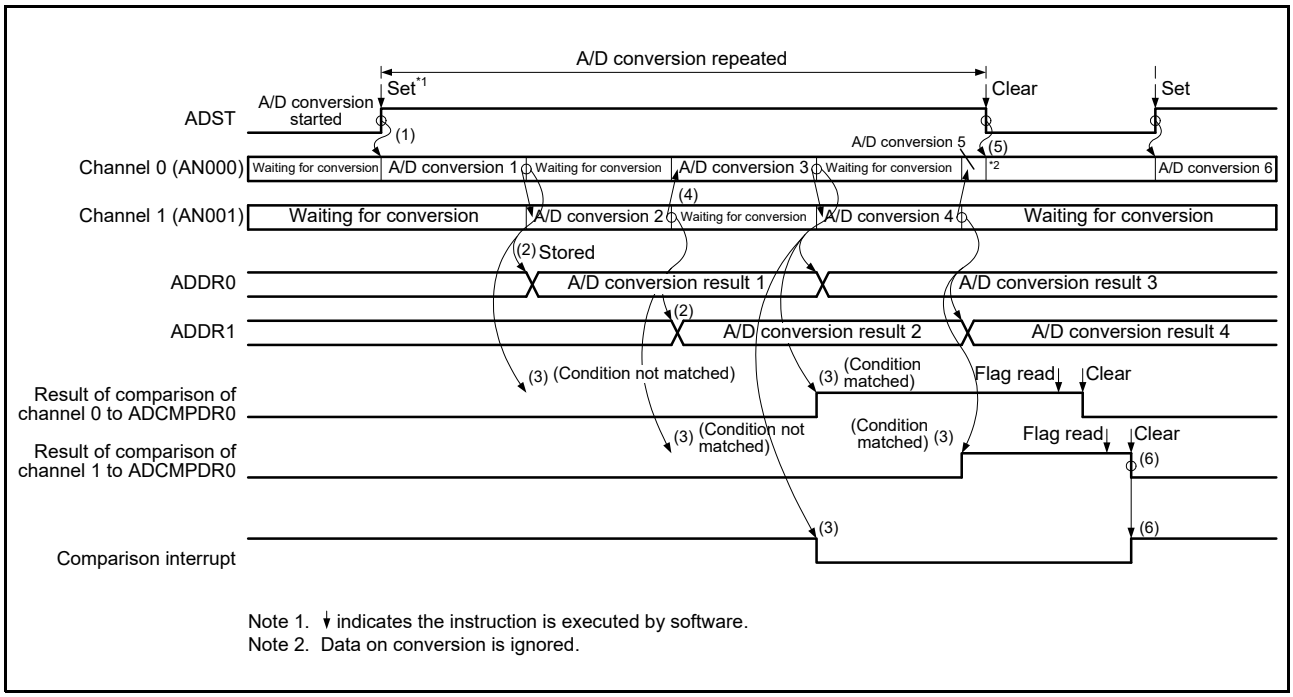
(2) Each time A/D conversion of a single channels is completed, the A/D-converted value is stored in the corresponding A/D data register (ADDRy, ADTSDR, or ADOCDR). When the ADCMPCR.CMPAE bit = 1 and window A is selected in the ADCMPANSRy and ADCMPANSER registers, the A/D-converted value is compared with the setting values of the ADCMPDR0 and ADCMPDR1 registers.
When the ADCMPCR.CMPBE bit = 1 and window B is selected in the ADCMPBNSR register, the A/D-converted value is compare with the setting values of the ADWINULB and ADWINLLB registers.

(3) For window A, upon a comparison match with the conditions specified in the ADCMPLR0, ADCMPLR1, and ADCMPLER registers, the flags of comparison window A (ADCMPSR0.CMPSTCHA0n, ADCMPSR1.CMPSTCHA1n, ADCMPSER.CMPFTS, and ADCMPSER.CMPFOC) become 1.
In this case, if the ADCMPCR.CMPAIE bit is set to 1, an interrupt request S12CMPAI is generated.
Similarly, for window B, upon a match with the conditions set in the ADCMPBNSR.CMPLB register, the comparison window B flag (ADCMPBSR.CMPSTB) becomes 1. In this case, if the ADCMPCR.CMPBIE bit is set to 1, an interrupt request S12CMPBI is generated.

(4) When all selected A/D conversion and comparison are completed, scanning is performed again.

(5) Set the ADCSR.ADST bit to 0 (stopping A/D conversion) and execute the processing for the channels in which the comparison flag is 1.

(6) After the processing above, clear all comparison flags. When comparison is re-executed, start A/D conversion again.



Note 1. ↓ indicates the instruction is executed by software.
Note 2. Data on conversion is ignored.

Figure 42.38 Example of Operation of Comparison (AN000 and AN001 for Targets for Comparison)

42.3.6.2 Restrictions on Comparison Function

The Comparison function has the following restrictions.

1. Use of self-diagnosis and double trigger mode is prohibited.
   (ADRD, ADDBLDR, ADDBLDRA, and ADDBLDRB are not targeted for the comparison function)
2. When using a matching or unmatching event, set to single scan mode.
3. When temperature sensor or internal reference voltage is selected for window A, operation of window B is prohibited.
4. When temperature sensor or internal reference voltage is selected for window B, operation of window A is prohibited.
5. The same channel cannot be set for window A and window B.
6. Satisfy the condition of [reference value (high side) ≥ reference value (low side)].

42.3.7 Analog Input Sampling Time and Scan Conversion Time

Figure 42.39 shows the scan conversion timing in single scan mode, in which scan conversion is started by software or a synchronous trigger. Figure 42.40 shows the scan conversion timing in single scan mode, in which scan conversion is started by an asynchronous trigger. The scan conversion time (t_{SCAN}) includes the start-of-scanning-delay time (t_D), channel-dedicated sample-and-hold circuit processing time (t_{SPLSH})*1, disconnection detection assistance processing time (t_{DIS})*2, auto-discharging processing time when A/D converting the temperature sensor output and the internal reference voltage (t_{ADIS}), self-diagnosis A/D conversion processing time (t_{DIAG})*3, A/D conversion processing time (t_{CONV}), channel-dedicated sample-and-hold circuit end time (t_{SHED})*4, and end-of-scanning-delay time (t_{ED}).
The A/D conversion processing time (t_{CONV}) consists of sampling time (t_{SPL}) and time for conversion by successive approximation (t_{SAM}). The sampling time (t_{SPL}) is used to charge sample-and-hold circuits in the A/D converter. If there is not sufficient sampling time due to the high impedance of an analog input signal source, or if the A/D conversion clock (ADCLK) is slow, sampling time can be adjusted using the ADSSTR register.
The time for conversion by successive approximation (t_{SAM}) is at 24 clock cycles of ADCLK. Table 42.23 shows the scan conversion time.

The scan conversion time (t_{SCAN}) in single scan mode for which the number of selected channels is n can be determined as follows:

$t_{SCAN} = t_D + t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + (t_{CONV} \times n)$*5 $+ t_{ED}$

t_{SCAN} (when converting temperature sensor output and internal reference voltage) $= t_D + (t_{ADIS} \times m) + (t_{CONV} \times m) + t_{ED}$*6, *7, *8

The scan conversion time for the first cycle in continuous scan mode is t_{SCAN} for single scan minus t_{ED} plus t_{SHED}.
The scan conversion time for the second and subsequent cycles in continuous scan mode is fixed to $t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + t_{DSD} + (t_{CONV} \times n)$*5 $+ t_{SHED}$.

Note 1. When no channel-dedicated sample-and-hold circuits are used, $t_{SPLSH} = 0$.
Note 2. When disconnection detection assistance is not selected, $t_{DIS} = 0$. When A/D-converting the temperature sensor output and the internal reference voltage, the value is fixed to 0Fh indicating 15 ADCLK.
Note 3. When the self-diagnosis function is not used, $t_{DIAG} = 0$, $t_{DSD} = 0$.
Note 4. When no channel-dedicated sample-and-hold circuits are used, $t_{SHED} = 0$. Here, continuous scan mode is assumed. In single scan mode and group scan mode, t_{SHED} is included in the end-of-scanning-delay time (t_{ED}).
Note 5. Although the total t_{CONV} can be expressed as $t_{CONV} \times n$ when the sampling times (t_{SPL}) of the selected channels are the same, it is basically expressed as the sum of the sampling times (t_{SPL}) for each of the channels and times for conversion by successive approximation (t_{SAM}) for each of the channels.
Note 6. Set m to 2 to perform A/D conversion both the temperature sensor output and internal reference voltage, or set m to 1 to perform A/D conversion either of them.
Note 7. When performing A/D conversion of the temperature sensor output or internal reference voltage, both the t_{SPLSH} and t_{DIAG} are 0, since A/D conversion of the self-diagnosis and analog channels cannot be selected in these cases.
Note 8. If the self-diagnosis and analog channels are in one group and the temperature sensor output and internal reference are in another, A/D conversion for all of them can be performed for a group scan.

Table 42.23 Times for Conversion During Scanning (in Numbers of Cycles of ADCLK and PCLKB)

Item			Symbol		Type/Conditions: Synchronous Trigger*3	Asynchronous Trigger	Software Trigger	Unit
Scan start processing time*1, *2	A/D conversion on group under group priority control.	The low-priority group is to be stopped. (The priority group is started after low-priority group B is stopped due to an A/D conversion start trigger of the priority group.)	t_D		2 PCLKB + 6 ADCLK (5 PCLKB + 3 ADCLK)*4	—	—	Cycle
		The low-priority group is not to be stopped. (Started by an A/D conversion start trigger of the priority group.)			2 PCLKB + 4 ADCLK	—	—	
	A/D conversion when self-diagnosis is enabled	A/D conversion for self-diagnosis is to be started.			2 PCLKB + 6 ADCLK	4 PCLKB + 6 ADCLK	6 ADCLK	
	Other than above				2 PCLKB + 4 ADCLK	4 PCLKB + 4 ADCLK	4 ADCLK	
Channel-dedicated sample-and-hold processing time*1	Sampling time		t_{SPLSH}	t_{SH}	When constant sampling is disabled: Setting values of the ADSHCR.SSTSH[7:0] bits (initial value:1Bh) × ADCLK When constant sampling is enabled: 0			
	Wait time between sampling and A/D conversion			t_W	12 ADCLK			
Disconnection detection assistance processing time			t_{DIS}		The setting of ADNDIS[3:0] (initial value = 00h) × ADCLK*5			
Auto-discharging processing time (Time required at the conversion of the temperature sensor output and the internal reference voltage)			t_{ADIS}		15 ADCLK			
Self-diagnosis conversion processing time*1	Sampling time		t_{DIAG}	t_{SPL}	The setting of ADSSTR0 (initial value = 1Bh) × ADCLK			
	Time for conversion by successive approximation			t_{SAM}	24 ADCLK			
	Normal A/D conversion is to be started after completion of self-diagnosis conversion.		t_{DED}		2 ADCLK			
	A/D conversion for self-diagnosis is to be started after completion of conversion for continuous scan on the last channel specified.		t_{DED}		2 ADCLK			
A/D conversion processing time*1	Sampling time		t_{CONV}	t_{SPL}	The setting of ADSSTRn (n = 0 to 11, L, T, O) (initial value = 1Bh) × ADCLK			
	Time for conversion by successive approximation			t_{SAM}	24 ADCLK			
Channel-dedicated sample-and-hold end processing time			t_{SHED}		2 ADCLK			
Scan end processing time*1			t_{ED}		1 PCLKB + 3 ADCLK (2 PCLKB + 2 ADCLK)*4			

Note 1. For t_D, t_{SPLSH}, t_{DIAG}, t_{CONV}, and t_{ED}, refer to Figure 42.39 and Figure 42.40.
Note 2. This is the maximum time required from software writing or trigger input to start A/D conversion.
Note 3. Time consumed on the paths from timer output to trigger input is not included.
Note 4. Maximum time for when ADCLK is faster than PCLKB (PCLKB to ADCLK frequency ratio = 1:2)
Note 5. When A/D-converting the temperature sensor output and the internal reference voltage, the value is fixed to 0Fh indicating 15 ADCLK.

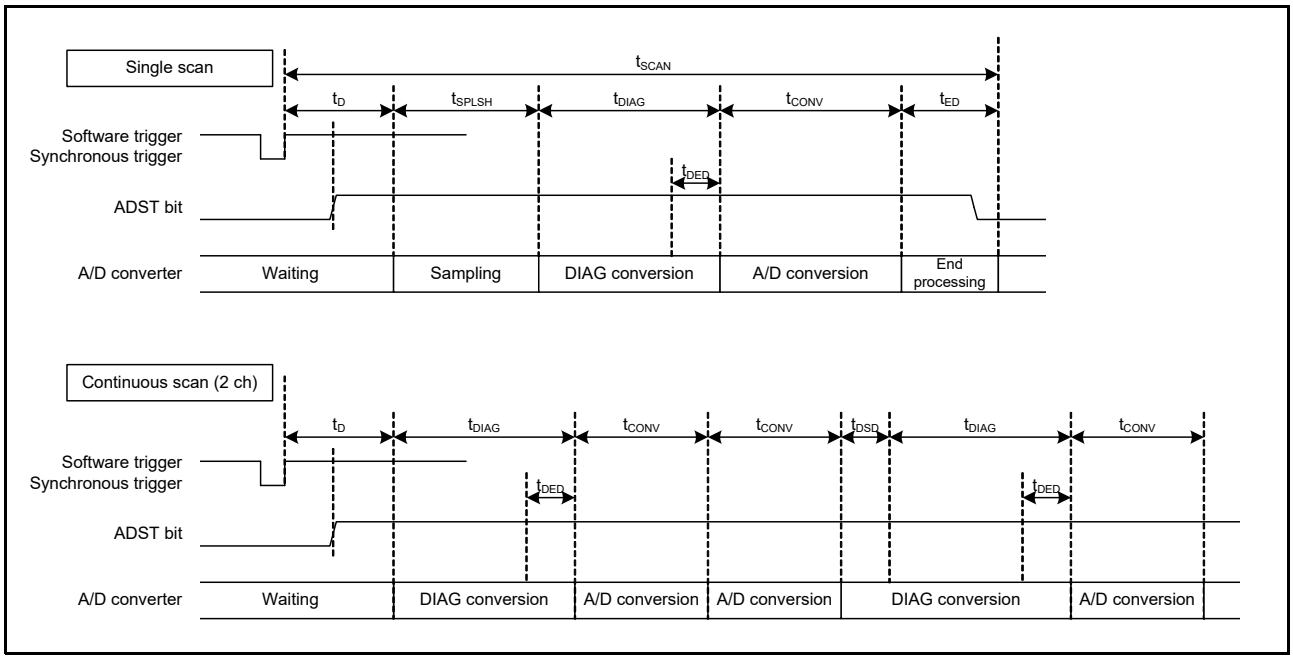


Figure 42.39 Scan Conversion Timing (Started by Software or Synchronous Trigger)

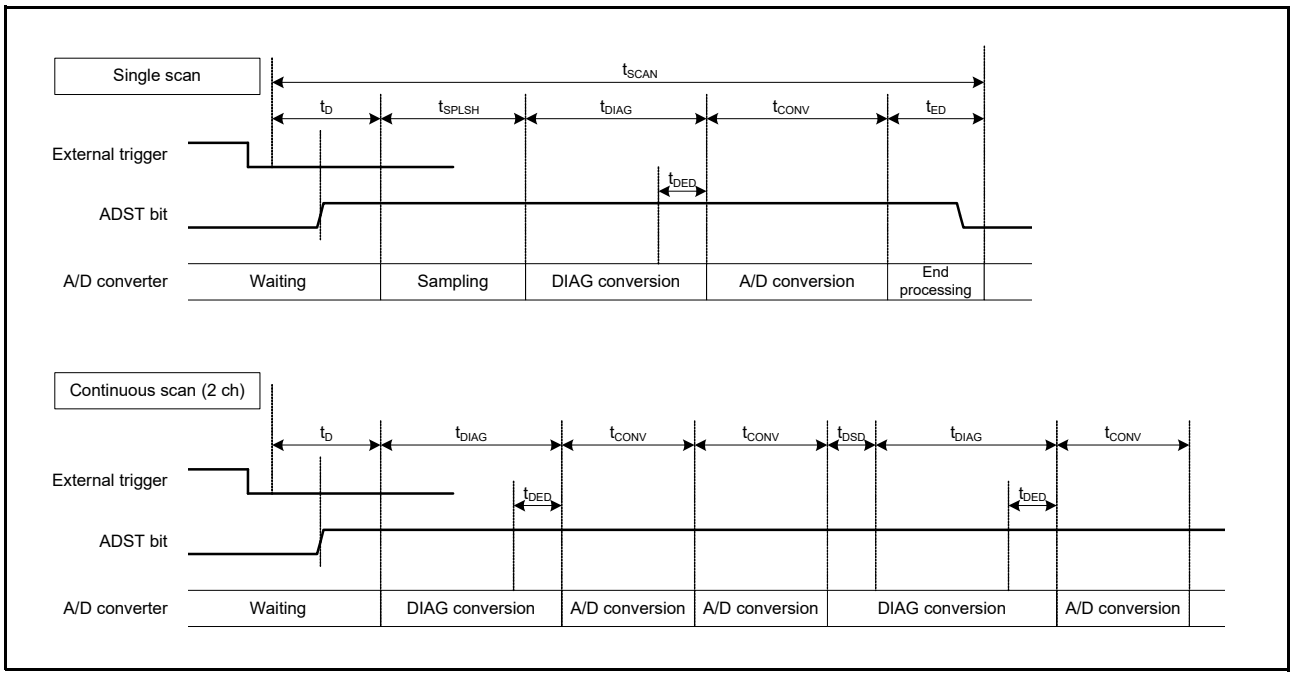

Figure 42.40 Scan Conversion Timing (Started by Software or Asynchronous Trigger)

42.3.7.1 Timing of Suspension and Starting of Scanning in Operation under Group Priority Control

The timings for suspension and starting of scanning in operation under group priority control that must considered are listed below.

1. The timing for suspending a scan of a group with a lower-priority and the timing for starting a scan of a group with a higher-priority.
2. The time at which scanning by the group with a lower-priority is resumed on completion of scanning by the higher-priority group when the trigger for scanning by the lower-priority group is accepted during scanning by the higher-priority group.
3. The timing for performing sequential single scans by a lower-priority group.

Figure 42.41 shows the timing diagram of each of the above cases.
The times at which scanning by group A is completed and scanning by group C resumes or scanning by group B is completed and scanning by group C resumes are the same as those for group A and group B in Figure 42.41.
The timing for consecutive single scans is the same for group B and group C.

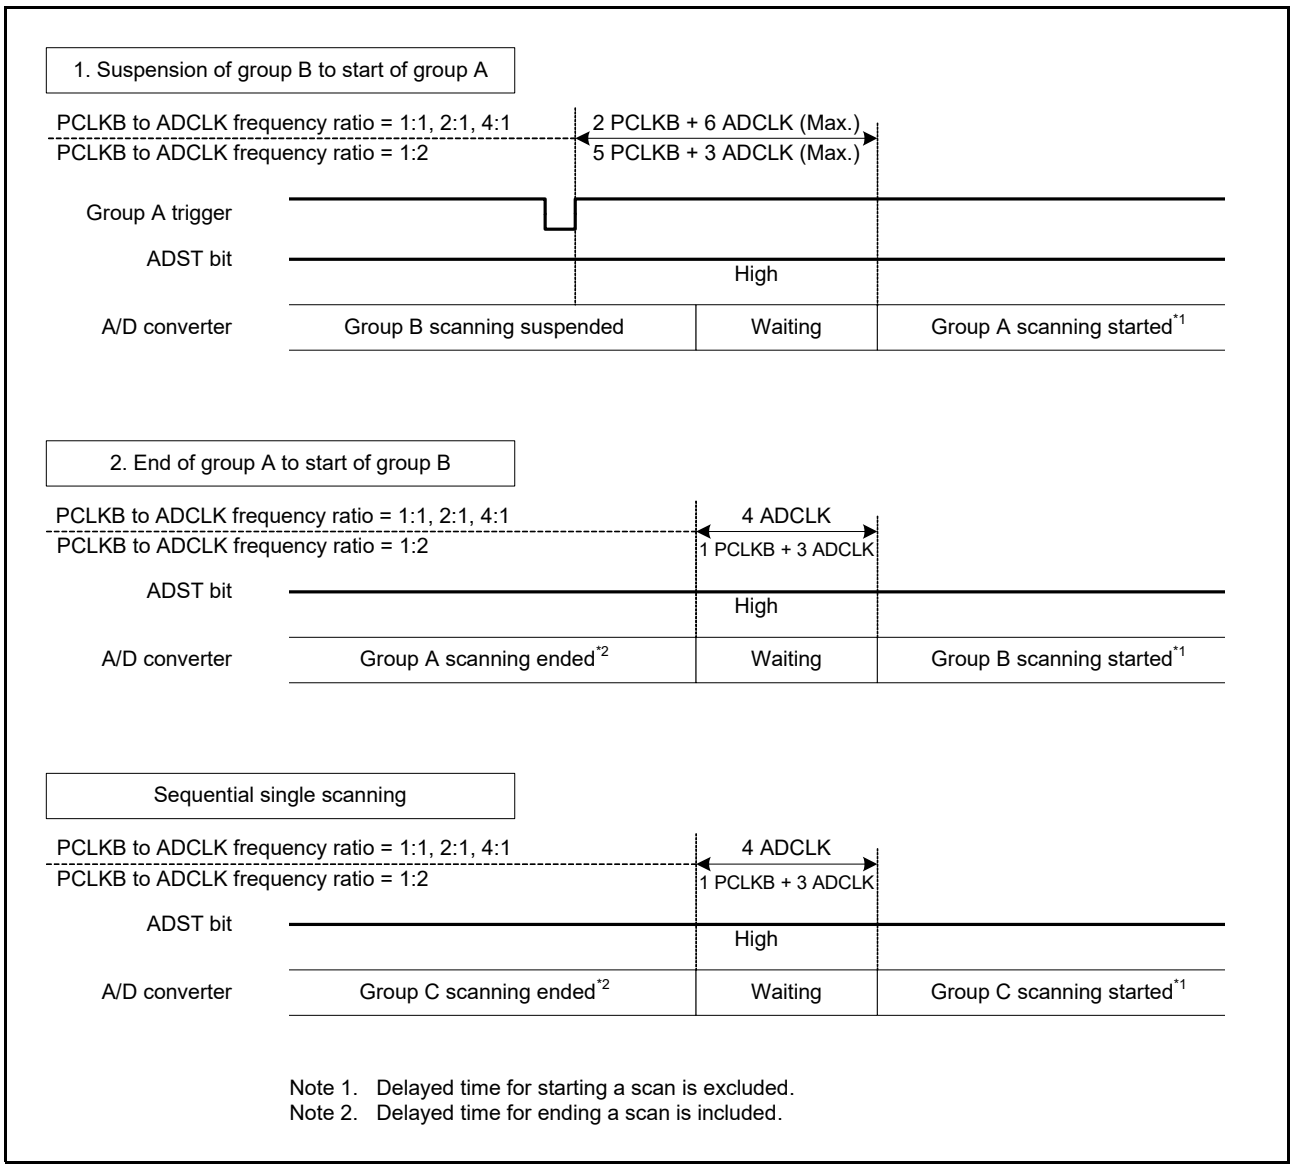

Figure 42.41 Timing of Stop/Start of Scanning in Group Priority Mode

42.3.8 Usage Example of A/D Data Register Automatic Clearing Function

Setting the ADCER.ACE bit to 1 automatically clears the A/D data registers (ADDRy, ADRD, ADTSDR, ADOCDR, ADDBLDR, ADDBLDRA, and ADDBLDRB) to 0000h when the A/D data registers (ADDRy, ADRD, ADTSDR, ADOCDR, ADDBLDR, ADDBLDRA, and ADDBLDRB) are read by the CPU, DTC, or DMAC.
This function enables detection of update failures of the A/D data registers (ADDRy, ADRD, ADTSDR, ADOCDR, ADDBLDR, ADDBLDRA, and ADDBLDRB). The following describes the examples in which the function to automatically clear the ADDRy register is enabled and disabled.
In a case where the ADCER.ACE bit is 0 (automatic clearing disabled), if the A/D conversion result (0222h) is not written to the ADDRy register for some reason, the old data (0111h) will be the ADDRy register value. Furthermore, if this ADDRy register value is read into a general register using an A/D scan end interrupt, the old data (0111h) can be saved in the general register. When checking whether there is an update failure, it is necessary to frequently save the old data in the RAM or a general register.
In a case where the ADCER.ACE bit is 1 (automatic clearing enabled), when ADDRy = 0111h is read by the CPU, DTC, or DMAC, the ADDRy register is automatically cleared to 0000h. After that, if the A/D conversion result (0222h) cannot be transferred to the ADDRy register for some reason, the cleared data (0000h) remains as the ADDRy register value. If this ADDRy register value is read into a general register using an A/D scan end interrupt at this point, 0000h will be saved in the general register.
Occurrence of an ADDRy register update failure can be determined by simply checking that the read data value is 0000h.

42.3.9 A/D-Converted Value Addition/Average Mode

In A/D-converted value addition mode, the same channel is A/D-converted 2, 3, 4, or 16 consecutive times and the sum of the converted values is stored in the data register. In A/D-converted value average mode, the same channel is A/D-converted two or four consecutive times and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that are present. This function, however, cannot always guarantee an improvement in A/D conversion accuracy.
The A/D-converted value addition/average mode can be used when A/D conversion of the channel select analog input, temperature sensor output (for unit 2 only), or internal reference voltage (for unit 2 only) is selected.

42.3.10 Disconnection Detection Assist Function

This converter incorporates the function to fix the charge for sampling capacitance to the specified state before start of A/D conversion. This function enables disconnection detection in wiring of analog inputs.
Figure 42.42 illustrates the A/D conversion operation when the disconnection detection assist function is used. Figure 42.43 shows an example of disconnection detection when precharge is selected. Figure 42.44 shows an example of disconnection detection when discharge is selected.

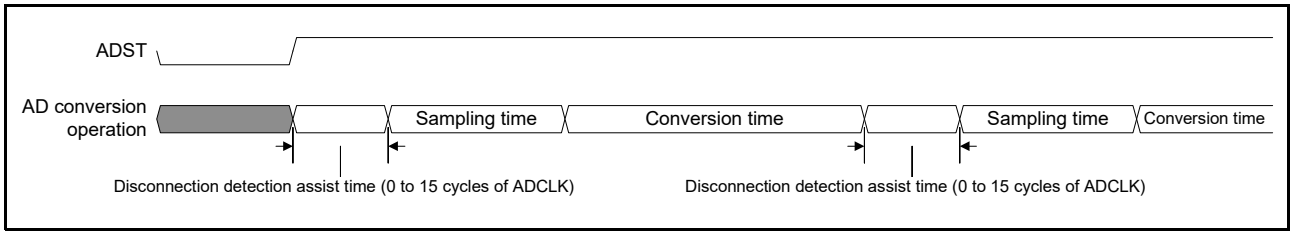

Figure 42.42 Operation of A/D Conversion When the Disconnection Detection Assist Function is Used

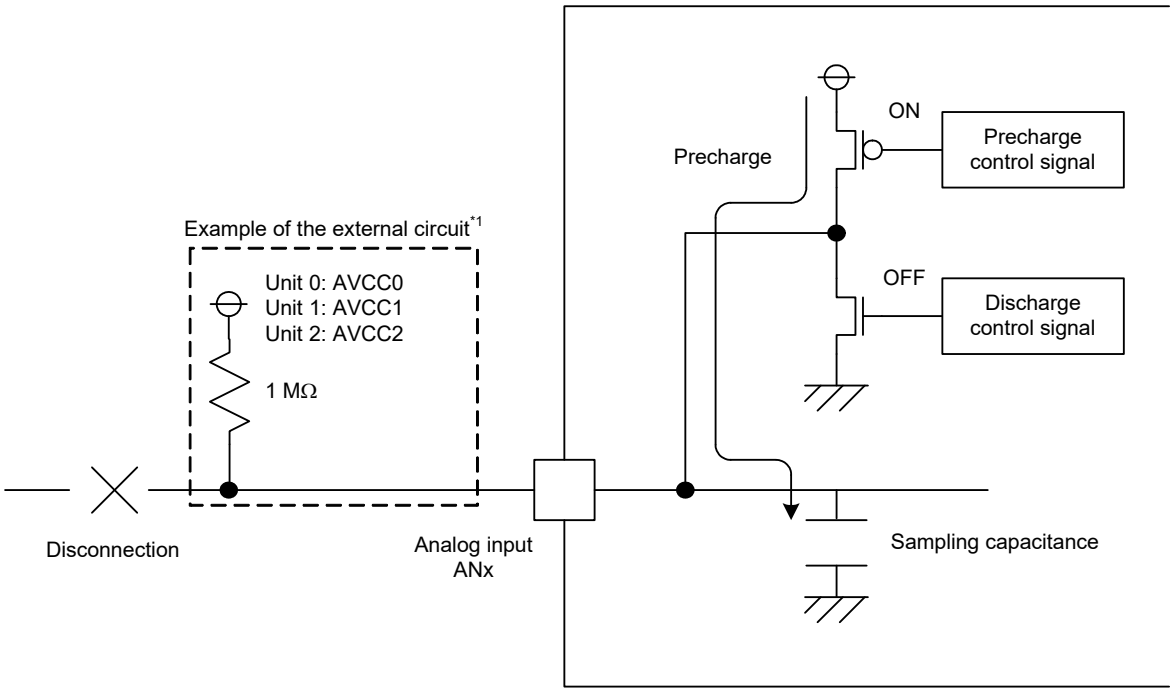
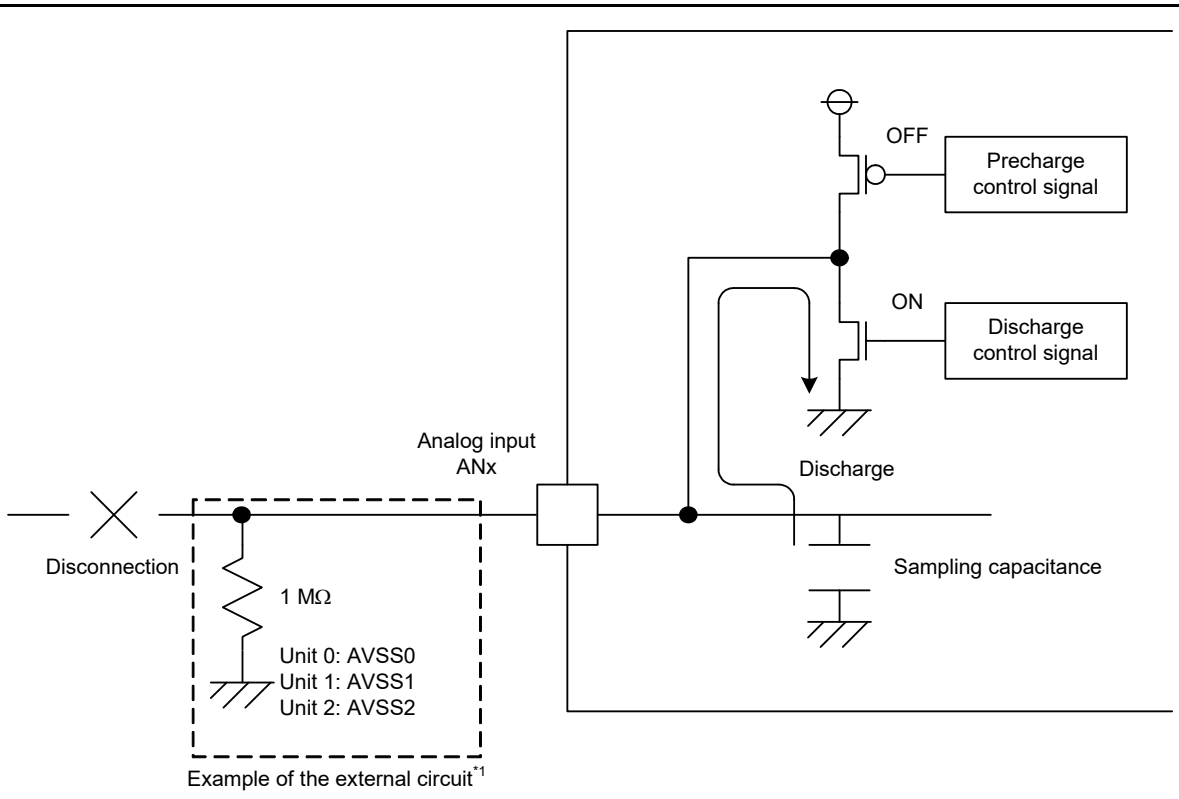


Note 1. Use the results of conversion after fully evaluating them because the resulting values when disconnection occurs depend on the external circuits.

Figure 42.43 Example of Disconnection Detection When Precharge is Selected



Note 1. Use the results of conversion after fully evaluating them because the resulting values when disconnection occurs depend on the external circuits.

Figure 42.44 Example of Disconnection Detection When Discharge is Selected

42.3.11 Starting A/D Conversion with Asynchronous Trigger

The A/D conversion can be started by the input of an asynchronous trigger. To start up the A/D converter by an asynchronous trigger, the A/D conversion start trigger select bits (ADSTRGR.TRSA[6:0]) should be set to 0000000b, and a high-level signal should be input to the asynchronous trigger (ADTRG0# pin). Then, the ADCSR.TRGE and ADCSR.EXTRG bits should be set to 1. Figure 42.45 shows a timing of the asynchronous trigger input.
For the time from when the ADST bit is set to 1 until conversion starts, refer to section 42.6.3, A/D Conversion Restarting Timing and Termination Timing. An asynchronous trigger cannot be selected for group B or group C in group scan mode.

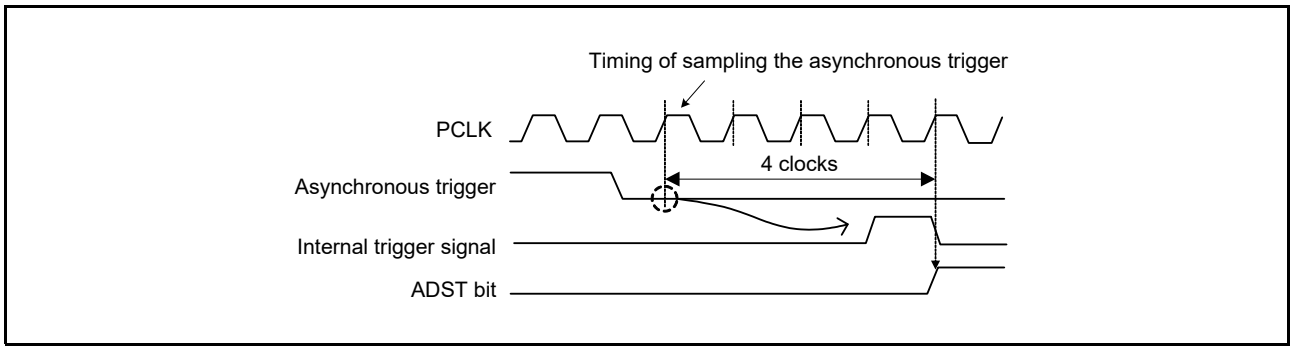


Figure 42.45 Timing of the Asynchronous Trigger Input

42.3.12 Starting A/D Conversion with Synchronous Trigger from Peripheral Module

The A/D conversion can be started by a synchronous trigger. To start the A/D conversion by a synchronous trigger, the ADCSR.TRGE bit should be set to 1, the ADCSR.EXTRG bit should be cleared to 0, and the relevant sources should be selected by the ADSTRGR.TRSA[6:0] bits, the ADSTRGR.TRSB[6:0] bits, and the ADGCTRGR2.TRSC6 and ADGCTRGR.TRSC[5:0 bits.

42.3.13 Conversion Function in the Order of Arbitrary Channel Number

Conversion function in the order of arbitrary channel number is used to convert analog channels of each unit in the 12-bit A/D converter in the order set by the ADSCSn register.

Setting the same channel in the ADSCSn register is prohibited. Channels whose order can be set with this function are analog channels only.

The conversion order for the self-diagnosis, temperature sensor, and internal reference voltage cannot be changed.

Table 42.24 Example of Conversion Order When the ADSCSn Register (n = 0 to 4) is Set to the Initial Value in the Scan Group A

ADSCSn Setting Value		A/D Conversion Order			ADANSA0 Setting Value
Symbol	Initial Value	Physical Channel	Priority	Conversion Order	Channel Select Bit
ADSCS0	00h	AN000	High	1	ANSA0[0] =1
ADSCS1	01h	AN001	↓	2	ANSA0[1] =1
ADSCS2	02h	AN002		3	ANSA0[2] =1
ADSCS3	03h	AN003		4	ANSA0[3] =1
ADSCS4	04h	AN004	Low	5	ANSA0[4] =1

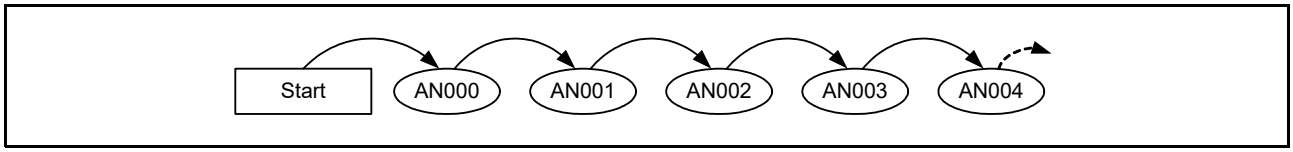

Figure 42.46 Example of Conversion Order (Setting Based on Table 42.24)

Table 42.25 Example of Conversion Order When a Setting Value of the ADSCSn Register (n = 0 to 4) is Modified in the Scan Group A

ADSCSn Setting Value		A/D Conversion Order			ADANSA0 Setting Value
Symbol	Value Set by User	Physical Channel	Priority	Conversion Order	Channel Select Bit
ADSCS0	04h	AN004	High	1	ANSA0[4] =1
ADSCS1	02h	AN002	↓	2	ANSA0[2] =1
ADSCS2	00h	AN000		3	ANSA0[0] =1
ADSCS3	01h	AN001		4	ANSA0[1] =1
ADSCS4	03h	AN003	Low	5	ANSA0[3] =1

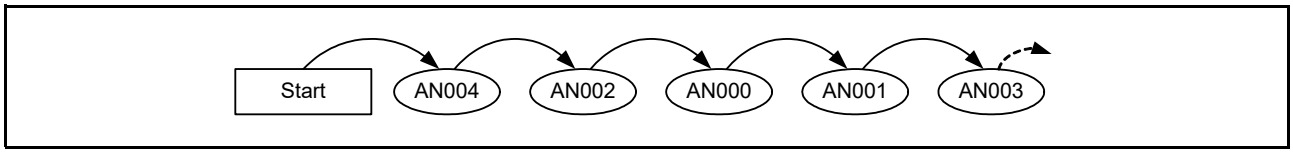

Figure 42.47 Example of Conversion Order (Setting Based on Table 42.25)

Table 42.26 Example of Conversion Order When a Setting Value of the ADSCSn Register (n = 0 to 4) is Modified in the Scan Group A (When the ANSA0[1] Bit is Set to Deselect.)

ADSCSn Setting Value		A/D Conversion Order			ADANSA0 Setting Value
Symbol	Value Set by User	Physical Channel	Priority	Conversion Order	Channel Select Bit
ADSCS0	04h	AN004	High	1	ANSA0[4] =1
ADSCS1	02h	AN002	↓	2	ANSA0[2] =1
ADSCS2	00h	AN000		3	ANSA0[0] =1
ADSCS3	01h	AN001		4	ANSA0[1] =0
ADSCS4	03h	AN003	Low	5	ANSA0[3] =1

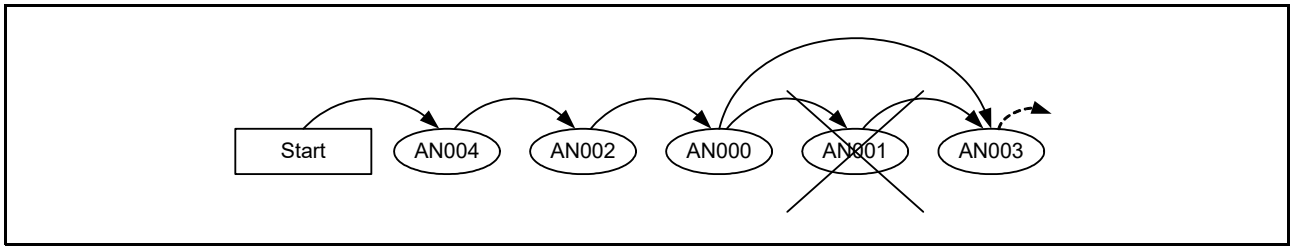

Figure 42.48 Example of Conversion Order (Setting Based on Table 42.26)

42.3.14 Internal Reference Voltage Monitoring Function

The internal reference voltage monitoring function is used to output the internal reference voltage to the A/D converter. Set the A/D internal reference voltage monitoring circuit enable register (ADVMONCR) and the A/D internal reference voltage monitoring circuit output enable register (ADVMONO), and enable the internal reference voltage A/D select bit (OCSA/B/C) to perform A/D conversion of the internal reference voltage.

Example of the operation is shown below.

(1) Set the VDE bit in the A/D internal reference voltage monitoring circuit enable register (ADVMONCR) to 1.
(2) Set the VDO bit in the A/D internal reference voltage monitoring circuit output enable register (ADVMONO) to 1.
(3) Select the internal reference voltage either by the internal reference voltage A/D conversion select bit (OCSA) in the A/D conversion extended input control register, the group B internal reference voltage A/D conversion select bit (OCSB), or the group C internal reference voltage A/D conversion select bit (OCSC) in the A/D group C extended input control register (ADGCEXCR).
(4) After inserting the waiting period of 500 ns, the ADCSR.ADST bit becomes 1 (starting A/D conversion) either by software, synchronous trigger (MTU, TMR, and ELC), or asynchronous trigger, and then, auto-discharging of the internal reference voltage is performed and A/D conversion of the internal reference voltage starts.
(5) When A/D conversion of the internal reference voltage is completed, A/D conversion result is stored to the corresponding A/D internal reference voltage data register (ADOCDR).
(6) S12ADI2 interrupt request is generated (pulse output and level output) if the ADCSR.ADST bit is set to 1 (scan end interrupt is enabled).
(7) The ADCSR.ADST bit is automatically cleared upon completion of A/D conversion, and the 12-bit A/D converter enters a wait state.
(8) Set the VDO bit in the A/D internal reference voltage monitoring circuit output enable register (ADVMONO) to 0.
(9) Set the VDE bit in the A/D internal reference voltage monitoring circuit enable register (ADVMONCR) to 0.

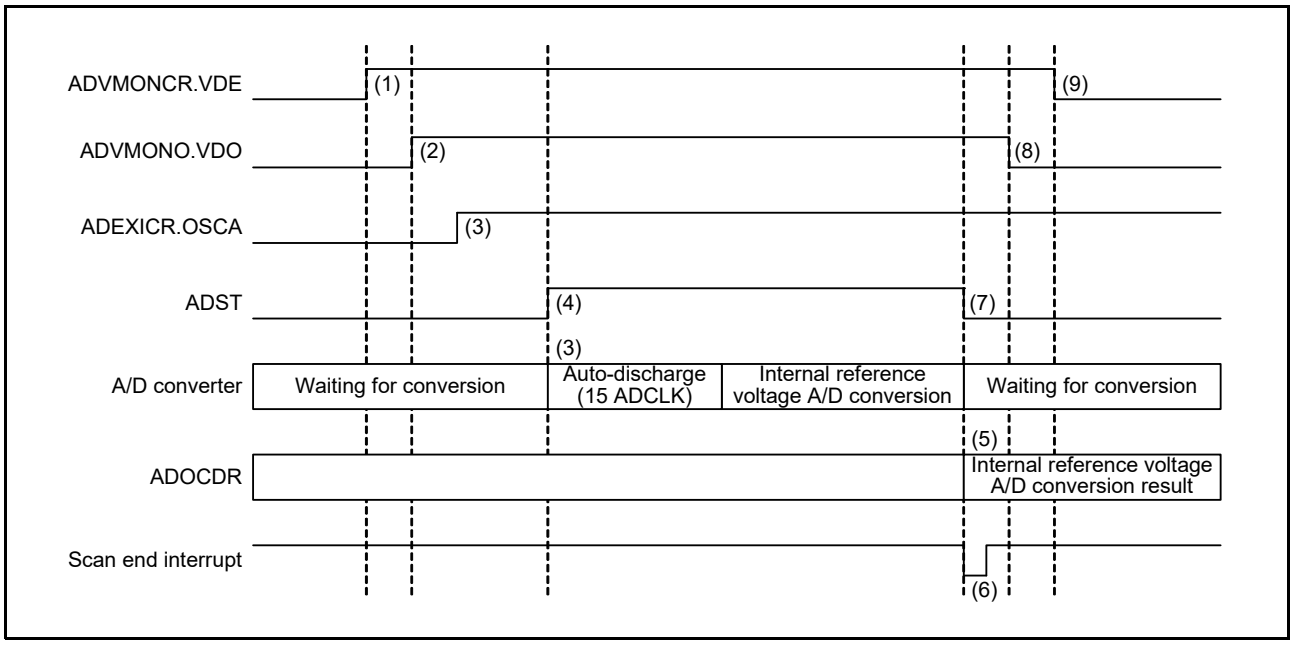

Figure 42.49 Example of Internal Reference Voltage Monitor Output A/D Conversion

42.4 Interrupt Sources and DTC/DMA Transfer Requests

42.4.1 Interrupt Requests

The 12-bit A/D converter can generate scan end interrupt requests S12ADI/S12ADI1/S12ADI2, S12GBADI/S12GBADI1/S12GBADI2, and S12GCADI/S12GCADI1/S12GCADI2 to the CPU.
The module also can generate the S12CMPAI or S12CMPBI interrupt which is the request of interrupting to the CPU in response to matches with a condition for comparison.
Setting the ADCSR.ADIE bit to 1 and 0 enables and disables an S12ADI/S12ADI1/S12ADI2 interrupt, respectively; similarly, setting the ADCSR.GBADIE bit to 1 and 0 enables and disables a S12GBADI/S12GBADI1/S12GBADI2 interrupt, respectively.
Setting the ADCMPCR.CMPAIE bit to 1 enables an S12CMPAI interrupt and setting the ADCMPCR.CMPAIE bit to 0 disables an S12CMPAI interrupt.
Setting the ADCMPCR.CMPBIE bit to 1 enables an S12CMPBI interrupt and setting the ADCMPCR.CMPBIE bit to 0 disables an S12CMPBI interrupt.
In addition, the DTC/DMA transfer can be triggered when an S12ADI/S12ADI1/S12ADI2, S12GBADI/S12GBADI1/S12GBADI2, or S12GCADI/S12GCADI1/S12GCADI2 interrupt is generated. Using an S12ADI/S12ADI1/S12ADI2, S12GBADI/S12GBADI1/S12GBADI2, or S12GCADI/S12GCADI1/S12GCADI2 interrupt to allow the DTC or DMAC to read the converted data enables sequence conversion without burden on software.
For details on DTC and DMAC settings, refer to section 18, Data Transfer Controller (DTCb) and section 17, DMA Controller (DMACAa).

42.4.2 Scan Complete Event Output to ELC

The ELC can set up linked operation of a module specified in advance by using the S12ADI, S12ADI1, or S12ADI2 interrupt request signal as an event signal.
The S12GBADI, S12GBADI1, or S12GBADI2 interrupt, S12CMPAI, S12CMPAI1, or S12CMPAI2 interrupt, and S12CMPBI, S12CMPBI1, or S12CMPBI2 interrupt request signals cannot be used as event signals. An event signal is output regardless of the setting of the corresponding interrupt request enable bit. The 12-bit A/D converter outputs the A/D conversion completed signals as event signals.

42.5 Allowable Impedance of Signal Source

Figure 42.50 shows an equivalent circuit of an analog input pin and an external sensor.
To perform A/D conversion accurately, the internal capacitor (Cs) must be fully charged within the sampling time. If the impedance (R0) of the signal source is high and it takes time to charge Cs, extend the sampling time with the ADSSTRn register. Conversely, if R0 is small, the sampling time can be shortened. Refer to the electrical characteristics for the permissible signal source impedance under various operating conditions.
When converting only a single pin input in single scan mode, the influence of R0 can be ignored because the input load becomes practically only the internal input resistor (Rs) by connecting an external high-capacity capacitor (C). However, because a low-pass filter is formed by R0 and C, it may not possible to follow the analog signal that changes at high speed. Insert a low-impedance buffer when converting high speed analog signals or when converting multiple pins in scan mode.

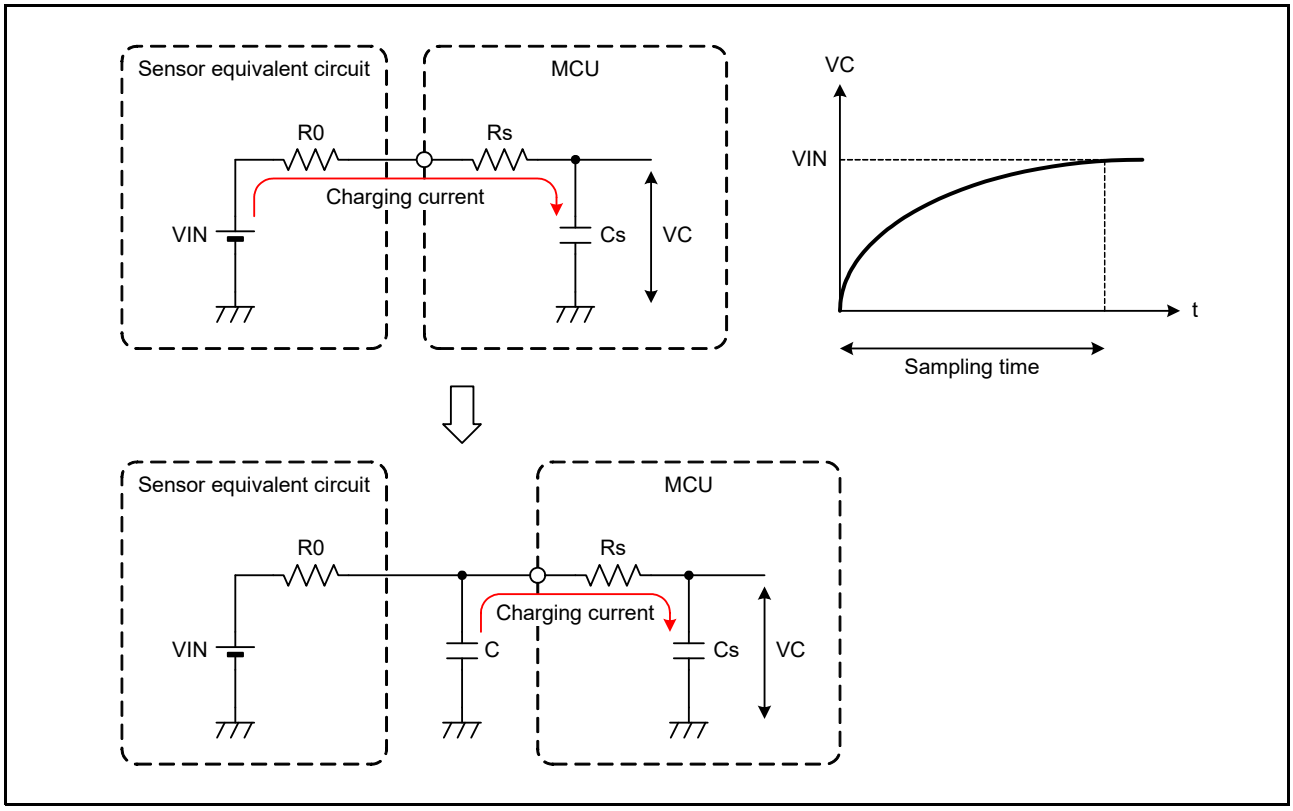

Figure 42.50 Equivalent Circuit of Analog Input Pin and External Sensor

42.6 Usage Notes

42.6.1 Notes on Reading Data Registers

The A/D data registers, A/D data duplication registers, A/D data duplication register A, A/D data duplication register B, A/D temperature sensor data register, A/D internal reference voltage data register, and A/D self-diagnosis data register should be read in 16-bit units. If a register is read twice in 8-bit units, that is, the higher-order byte and lower-order byte are separately read, the A/D-converted value having been read first may disagree with the A/D-converted value having been read for the second time. To prevent this, the data registers should never be read in 8-bit units.

42.6.2 Notes on Stopping A/D Conversion

42.6.2.1 Procedure of Stopping A/D Conversion

To stop A/D conversion when an asynchronous trigger or a synchronous trigger has been selected as the condition for starting A/D conversion, follow the procedure in Figure 42.51.

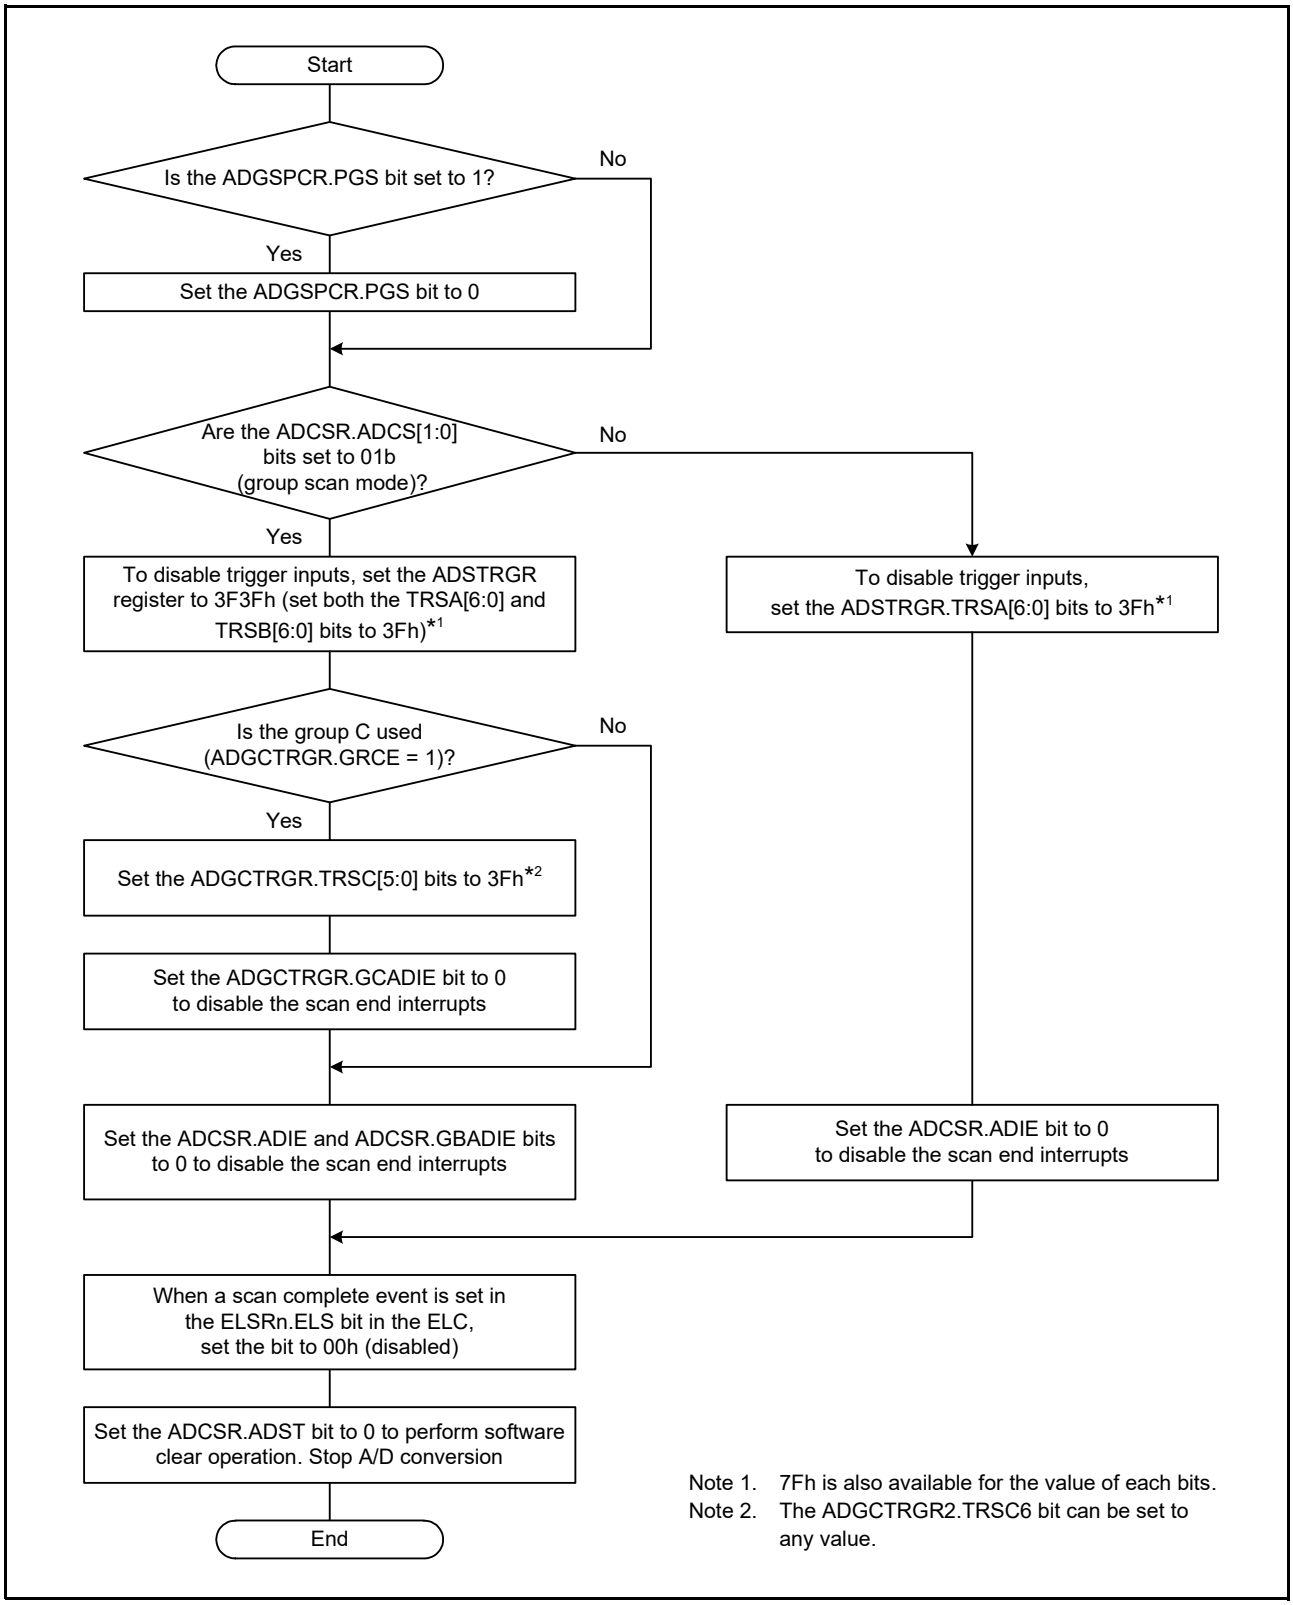

Figure 42.51 Procedure for Clear Operation by Software Through the ADCSR.ADST Bit

42.6.2.2 Notes on Modes and Status Flags

The following values should be initialized or reset as described below: the voltage status used in self-diagnosis, the odd-even determination for the double-trigger mode, the monitor flags for the comparison function.

- Re-set the voltage for use in self-diagnosis by setting the ADCER.DIAGLD bit to 1 and setting the ADCER.DIAGVAL[1:0] bits.
- Make double-trigger mode effective starting from the first scan by changing the ADCSR.DBLE bit from 0 to 1.
- Set the ADCMPCR.CMPAE and ADCMPCR.CMPBE bits to 0, which clears the monitor flags for the comparison function (MONCMPA, MONCMPB, MONCOMB).
- Initialize the constant sampling function (enabled by setting the ADSHMSR.SHMD bit to 1) by setting the ADSHMSR.SHMD bit to 0. After this, when using constant sampling function again, wait for at least 1 cycle of ADCLK and then set the ADSHMSR.SHMD bit to 1.

42.6.3 A/D Conversion Restarting Timing and Termination Timing

Starting operation of the analog blocks of the 12-bit A/D converter after setting the ADCSR.ADST bit to 1 takes up to six cycles of ADCLK. Stopping operation of the analog blocks of the 12-bit A/D converter by setting the ADCSR.ADST bit to 0 for a forced stop of the converter takes up to two cycles of ADCLK.
A period from forcible termination to idling of analog blocks takes a maximum of 1 PCLKB + 1 ADCLK cycles when PCLKB to ADCLK frequency ratio is 1:2 (ADCLK is faster).

42.6.4 Notes on Scan End Interrupt Handling

When scanning the same analog input twice using any trigger, the first A/D-converted data is overwritten with the second A/D-converted data in the case that the CPU does not complete reading the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated.

42.6.5 Module Stop Function Setting

Operation of the 12-bit A/D converter can be disabled or enabled by setting module stop control register. The 12-bit A/D converter is stopped after released from the reset state. Register access is enabled by releasing the module stop state.
After the module stop state is released, wait for 1 µs to start A/D conversion. To stop the operation of the 12-bit A/D converter using module stop function, set the ADVMONCR.VDE and ADVMONO.VDO bits to 0.
For details, refer to section 11, Low Power Consumption.

42.6.6 Notes on Entering Low Power Consumption States

Before entering the module stop state or software standby mode, make sure to stop A/D conversion. Here, set the ADCSR.ADST bit to 0, and secure certain period of time until the analog unit of the 12-bit A/D converter is stopped. Follow the procedure given below to secure this time.
Set the ADCSR.ADST bit to 0 by following the procedure in Figure 42.51 procedure for clear operation by software through the ADCSR.ADST bit. Then wait for two clock cycles of ADCLK before entering the module stop mode or software standby mode.

42.6.7 Notes on Canceling Software Standby Mode

After releasing the A/D converter from software standby, wait for the oscillation stabilization flag for the main clock or PLL clock to become 1, wait for at least a further 1 µs after that, and then start A/D conversion.
For details, refer to section 11, Low Power Consumption.

42.6.8 Error in Absolute Accuracy When Disconnection Detection Assistance is in Use

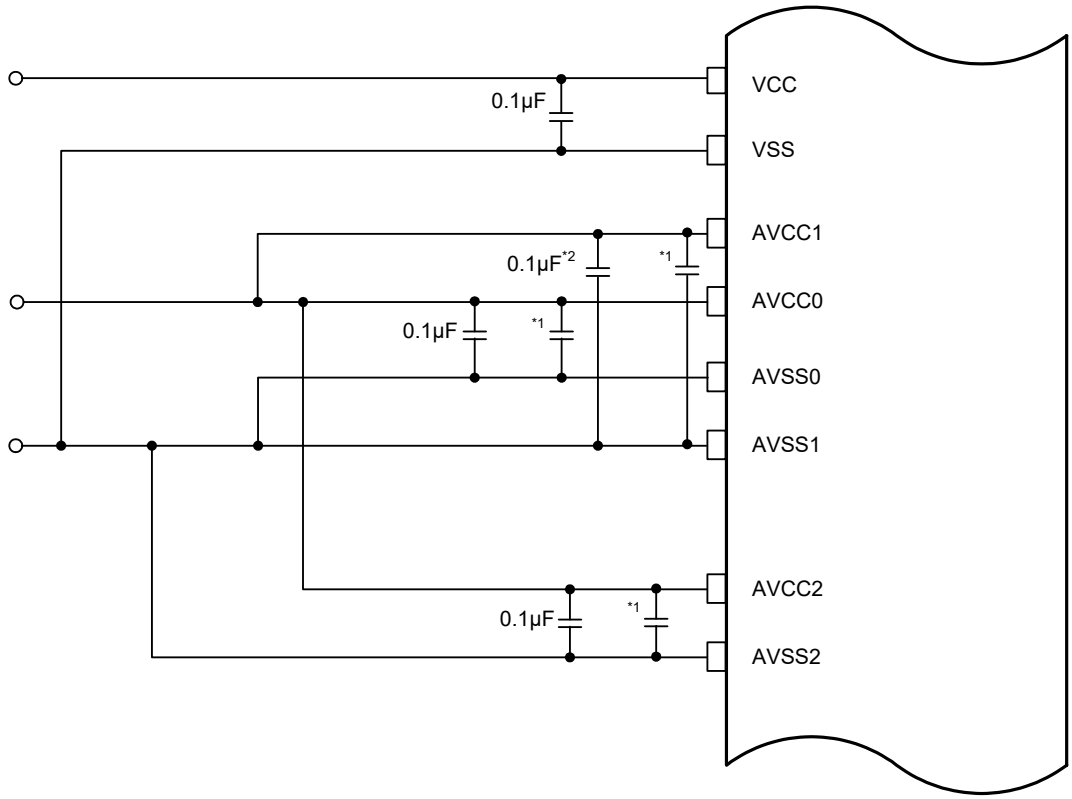
Using disconnection detection assistance leads to an error in absolute accuracy of the A/D converter. This is because an error voltage is input to the analog input pins due to the resistive voltage division between the pull-up or pull-down resistor (Rp) and the resistance of the signal source (Rs).
This error in absolute accuracy is calculated from the following formula. Only use disconnection detection assistance after thorough evaluation.

Maximum error in absolute accuracy (LSB) = 4095 × Rs/Rp

42.6.9 Voltage Range of Analog Power Supply Pins

If this MCU is used with the voltages outside the following ranges, the reliability of the MCU may be affected.

- Analog input voltage range
  Set the voltage within the range from AVSSn to AVCCn (n = 0 to 2) when applying voltages to analog pins AN000 to AN006, AN100 to AN103, AN200 to AN211, AN216, and AN217.
- Relationship between power supply pin pairs (AVCCn–AVSSn, VCC–VSS)
  The following condition should be satisfied: AVSSn = VSS (n = 0 to 2). When performing A/D conversion of analog input pins AN216 and AN217, the following condition should be satisfied: AVCCn = VCC.
  A 0.1-µF capacitor should be connected between each pair of power supply pins to create a closed loop with the shortest route possible as shown in Figure 42.52, and connection should be made so that the following condition is satisfied at the supply side: AVSSn = VSS
  When the 12-bit A/D converter is not used, the following conditions should be satisfied:
  AVCCn = VCC and AVSSn = VSS



Note1. When using the A/D converter with the A/D conversion clock at a frequency above 40 MHz, add a 0.01-µF capacitor between each 0.1-µF capacitor and power-supply pin.
Note2. Place the capacitors between AVCC1 and AVSS1 closer to the MCU than those for AVCC0 and AVSS0.

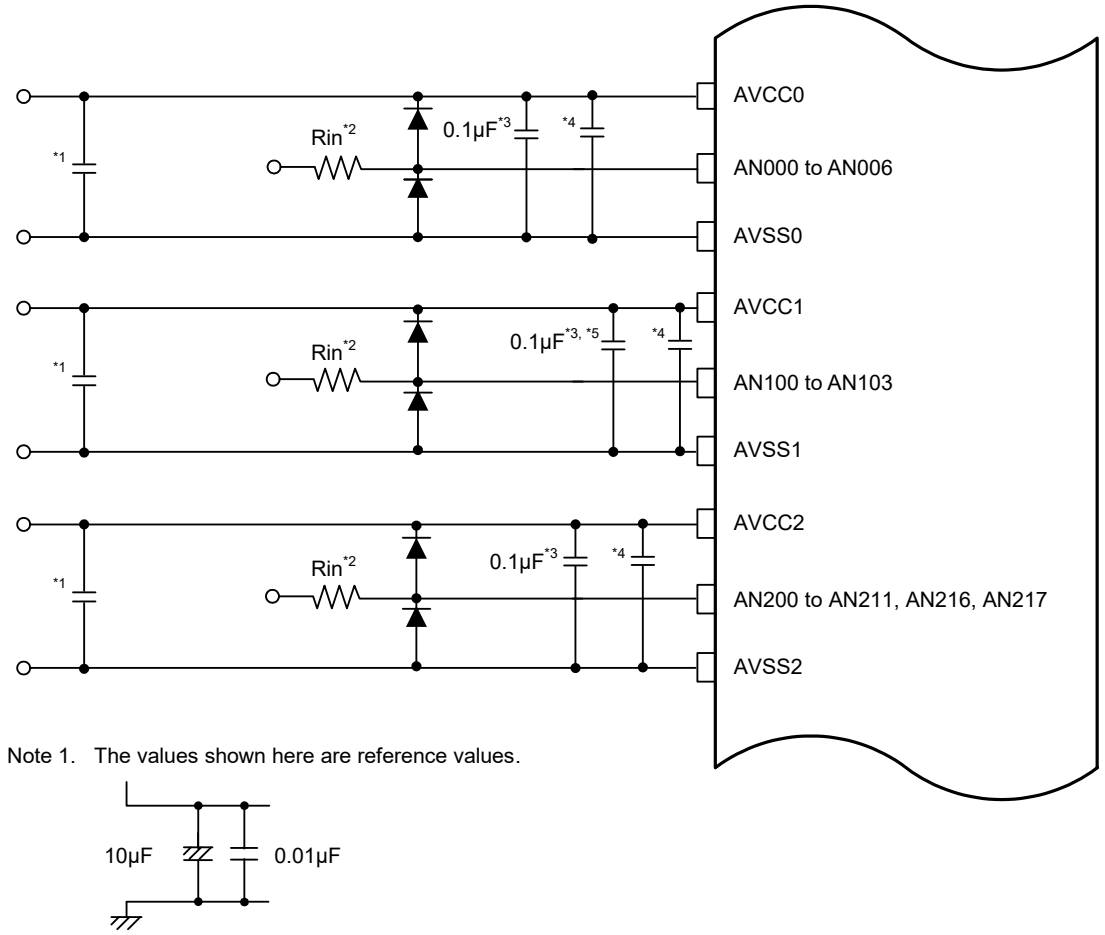
Figure 42.52 Example for Connecting Power Supply Pins

42.6.10 Notes on Board Design

The board should be designed so that digital circuits and analog circuits are separated from each other as far as possible. In addition, digital circuit signal lines and analog circuit signal lines should not intersect or placed near each other. If these rules are not followed, noise will be produced on analog signals and A/D conversion accuracy will be affected. The analog input pins (AN000 to AN006, AN100 to AN103, AN200 to AN211, AN216, and AN217) and analog power supply (AVCCn) should be separated from digital circuits using the analog ground (AVSSn). The analog ground (AVSSn) should be connected to a stable digital ground (VSS) on the board (single-point ground plane connection).

42.6.11 Notes on Noise Prevention

To prevent the analog input pins (AN000 to AN006, AN100 to AN103, AN200 to AN211, AN216, and AN217) from being destroyed by abnormal voltage such as excessive surge, capacitors should be inserted between AVCCn and AVSSn, and protection circuits should be connected to protect the above analog input pins as shown Figure 42.53.



Note 1. The values shown here are reference values.

Note2. Rin: Signal source impedance
Note3. Place the capacitors to be placed between the power supply pins AVCC0 and AVSS0, AVCC1 and AVSS1, and AVCC2 and AVSS2 as close to the pins as possible to improve the precision of A/D conversion.
Note4. When using the A/D converter with the A/D conversion clock at a frequency above 40 MHz, add a 0.01-µF capacitor between each 0.1-µF capacitor and power-supply pin.
Note5. Place the capacitors between AVCC1 and AVSS1 closer to the MCU than those for AVCC0 and AVSS0.

Figure 42.53 Sample Protection Circuit for Analog Inputs

42.6.12 Notes on Using Channel-Dedicated Sample-and-Hold Circuit

Enable use of the channel-dedicated sample-and-hold circuit (ADSHCR.SHANS[2:0] ≠ 000b), enable normal sampling by the channel-dedicated sample-and-hold circuit (ADSHMSR.SHMD = 1), and wait for 6 cycles of ADCLK to pass before input of a trigger signal.

To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register.

43. 12-Bit D/A Converter (R12DAb)

43.1 Overview

This MCU includes two channels of 12-bit D/A converter.
Table 43.1 lists the specifications of the 12-bit D/A converter and Figure 43.1 shows a block diagram of the 12-bit D/A converter.

Table 43.1 Specifications of 12-Bit D/A Converter

Item	Specifications
Resolution	12 bits
Output channels	Two channels
Measure against mutual interference between analog modules	Measure against interference between D/A and A/D conversion D/A converted data update timing is controlled by the 12-bit A/D converter synchronous D/A conversion enable signal from the 12-bit A/D converter (unit 2). Therefore, the degradation of A/D conversion accuracy due to interference is reduced by controlling the timing in which the 12-bit D/A converter inrush current occurs, with the enable signal.
Low power consumption function	Module stop state can be set.
Event link function (input)	DA0 conversion can be started when an event signal is input.
Destination Selection	Outputs to the external pin and to the comparator C are separately controllable.

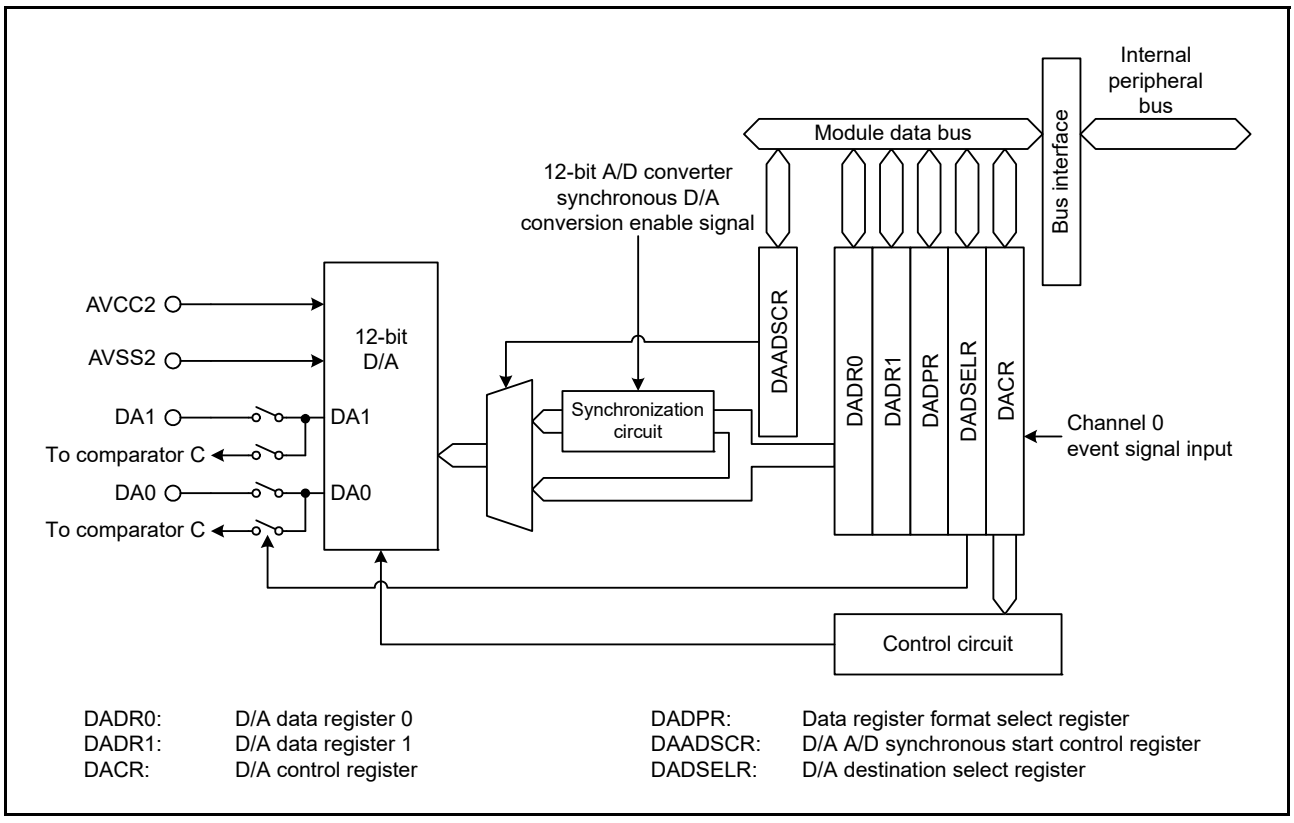


Figure 43.1 Block Diagram of 12-Bit D/A Converter

Table 43.2 lists the pin configuration of the 12-bit D/A converter.

Table 43.2 Pin Configuration of 12-Bit D/A Converter

Pin Name	I/O	Function
AVCC2	Input	Analog power supply pin
AVSS2	Input	Analog ground pin
DA0	Output	Channel 0 analog output pin
DA1	Output	Channel 1 analog output pin

43.2 Register Descriptions

43.2.1 D/A Data Register m (DADRm) (m = 0, 1)

Address(es): DA.DADR0 0008 8040h, DA.DADR1 0008 8042h

• DADPR.DPSEL bit = 0 (data is right-justified)

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

• DADPR.DPSEL bit = 1 (data is left-justified)

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
													—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DADRm register is a 16-bit readable/writable register, which stores data to which D/A conversion is to be performed. Whenever an analog output is enabled, the values in DADRm are converted and output from the D/A converter.

12-bit data can be relocated by setting the DADPR.DPSEL bit.

Bits "—" are read as 0. The write value should be 0.

43.2.2 D/A Control Register (DACR)

Address(es): DA.DACR 0008 8044h

	b7	b6	b5	b4	b3	b2	b1	b0
	DAOE1	DAOE0	DAE	—	—	—	—	—
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b5	DAE	D/A Enable*1	0: D/A conversion of channels 0 and 1 is controlled individually. 1: D/A conversion of channels 0 and 1 is enabled collectively.	R/W
b6	DAOE0	D/A Output Enable 0	0: Analog output of channel 0 (DA0) is disabled. 1: D/A conversion of channel 0 is enabled. Analog output of channel 0 (DA0) is enabled.	R/W
b7	DAOE1	D/A Output Enable 1	0: Analog output of channel 1 (DA1) is disabled. 1: D/A conversion of channel 1 is enabled. Analog output of channel 1 (DA1) is enabled.	R/W

Note 1. This bit controls D/A conversion in combination with the DAOEm bit (m = 0, 1). The DAOEm bit controls output of the results of conversion. For details, see Table 43.3.

Table 43.3 Controls of D/A Conversion

b5	b7	b6	
DAE	DAOE1	DAOE0	Description
0	0	0	D/A conversion and analog output pins (DA0, DA1) are disabled.*1
		1	D/A conversion of channel 0 is enabled. D/A conversion of channel 1 is disabled. Analog output of channel 0 (DA0) is enabled. Analog output of channel 1 (DA1) is disabled.*1
	1	0	D/A conversion of channel 0 is disabled. D/A conversion of channel 1 is enabled. Analog output of channel 0 (DA0) is disabled.*1 Analog output of channel 1 (DA1) is enabled.
		1	D/A conversion of channels 0 and 1 is enabled. Analog output of channels 0 and 1 (DA0, DA1) is enabled.
1	x	x	D/A conversion of channels 0 and 1 is enabled. Analog output of channels 0 and 1 (DA0, DA1) is enabled collectively.

x: Don't care

Note 1. When analog output is disabled, the analog output signal is placed in the Hi-Z state.

This register should be set when the DAADSCR.DAADST bit is 1 (measure against interference between D/A and A/D conversion is enabled) while the 12-bit A/D converter (unit 2) is halted (the ADCSR.ADST bit is 0). At that time, the software trigger should be selected for the 12-bit A/D converter (unit 2) trigger to securely stop the 12-bit A/D converter (unit 2).
Select the destination for each channel by using the DADSELR register before setting this register.

DAE Bit (D/A Enable)

The DAE bit controls D/A conversion and analog output in combination with the DAOEm bit (m = 0, 1).
When the measure against an interference between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the DAE bit while the ADCSR.ADST bit in the 12-bit A/D converter (unit 2) is 0. At that time, the software trigger should be selected for the 12-bit A/D converter (unit 2) trigger to securely stop the 12-bit A/D converter (unit 2).

DAOEm Bit (D/A Output Enable m) (m = 0, 1)

The DAOEm bit controls D/A conversion and analog output in combination with the DAE bit.

When both the DAOEm bit and DAE bit are 0, D/A conversion of channel m is not done and no conversion result is output.

When the measure against an interference between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the DAOEi bit while the ADCSR.ADST bit in the 12-bit A/D converter (unit 2) is 0. At that time, the software trigger should be selected for the 12-bit A/D converter (unit 2) trigger to securely stop the 12-bit A/D converter (unit 2).

The event link function can be used to set the DAOE0 bit to 1. The DAOE0 bit becomes 1 when the event specified by setting the ELSR16 register of the ELC occurs, and output of the D/A conversion results starts.

43.2.3 Data Register Format Select Register (DADPR)

Address(es): DA.DADPR 0008 8045h

	b7	b6	b5	b4	b3	b2	b1	b0
	DPSEL	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	DPSEL	Format Select	0: Data is right-justified. 1: Data is left-justified.	R/W

43.2.4 D/A A/D Synchronous Start Control Register (DAADSCR)

Address(es): DA.DAADSCR 0008 8046h

	b7	b6	b5	b4	b3	b2	b1	b0
	DAADST	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	DAADST	D/A A/D Synchronous Conversion	0: 12-bit D/A converter operation does not synchronize with 12-bit A/D converter (unit 2) operation. (measure against interference between D/A and A/D conversion is disabled) 1: 12-bit D/A converter operation synchronizes with 12-bit A/D converter (unit 2) operation. (measure against interference between D/A and A/D conversion is enabled)	R/W

As a measure against interference between D/A and A/D conversion, the DAADSCR register selects whether or not the timing for starting 12-bit D/A conversion is synchronized with the 12-bit A/D converter synchronous D/A conversion enable signal from the 12-bit A/D converter (unit 2).
This register should be set while the 12-bit A/D converter (unit 2) is halted (while the ADCSR.ADST bit is 0 after selecting software trigger as the 12-bit A/D converter (unit 2) trigger).

DAADST Bit (D/A A/D Synchronous Conversion)

Setting the DAADST bit to 0 allows the DADRm register value (m = 0, 1) to be converted into analog data at any time.
Setting the DAADST bit to 1 allows synchronous D/A conversion with the 12-bit A/D converter synchronous D/A conversion enable signal from the 12-bit A/D converter (unit 2). Therefore, even if the DADRm register value is modified, D/A conversion does not start until the 12-bit A/D converter (unit 2) completes A/D conversion.
Set this bit while the ADCSR.ADST bit is set to 0. At this time, the software trigger should be selected for the 12-bit A/D converter trigger to securely stop the 12-bit A/D converter (unit 2).
The event link function cannot be used when the DAADST bit is set to 1. Stop the event link function by setting the ELSR16 register of the ELC. The setting of the DAADST bit is common to channels 0 and 1 of the 12-bit D/A converter.

43.2.5 D/A Destination Select Register (DADSELR)

Address(es): DA.DADSELR 0008 8049h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	OUTREF1	OUTREF0	OUTDA1	OUTDA0
Value after reset:	0	0	0	0	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	OUTDA0	DA0 pin output enable	0: Does not output the channel 0 analog voltage from the DA0 pin 1: Output the channel 0 analog voltage from the DA0 pin	R/W
b1	OUTDA1	DA1 pin output enable	0: Does not output the channel 1 analog voltage from the DA1 pin 1: Output the channel 1 analog voltage from the DA1 pin	R/W
b2	OUTREF0	Reference voltage 0 output enable	0: Does not use the channel 0 analog voltage as a reference voltage for the comparator C 1: Use the channel 0 analog voltage as a reference voltage for the comparator C	R/W
b3	OUTREF1	Reference voltage 1 output enable	0: Does not use the channel 1 analog voltage as a reference voltage for the comparator C 1: Use the channel 1 analog voltage as a reference voltage for the comparator C	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R

The DADSELER register is used to set the destinations of the analog voltage generated by the D/A converter. Select such destinations with this register before the output is enabled with the DACR register.

43.3 Operation

The 12-bit D/A converter includes D/A conversion circuits for two channels, each of which can operate independently. When the DACR.DAOEm bit (m = 0, 1) is set to 1, D/A converter is enabled and the conversion result is output. An operation example of D/A conversion on channel 0 is shown below. Figure 43.2 shows the timing of this operation.

(1) Set the data for D/A conversion in the DADPR.DPSEL bit and the DADR0 register.
(2) Select the destination of the D/A converter analog voltage by using the DADSELR register.
(3) Set the DACR.DAOE0 bit to 1 to start D/A conversion. The DA0 output settles to the voltage corresponding to the setting value after the conversion time tDCONV has elapsed. The DA0 output voltage is held at this level until the DADR0 register is updated or the DAOE0 bit is set to 0. The output voltage (reference) is expressed by the following formula:

$$\frac{\text{Value of DADRm register}}{4096} \times \text{AVCC2}$$

(4) When the DADR0 register is updated, the conversion starts. The DA0 output settles at the new output voltage after the conversion time tDCONV has elapsed.
When the DAADSCR.DAADST bit is 1 (measure against interference between D/A and A/D conversion is enabled), it takes a maximum of one A/D conversion time for D/A conversion to start. When ADCLK is faster than the peripheral module clock, it may take longer than one A/D conversion time.
(5) When the DAOE0 bit is set to 0, analog output is disabled.

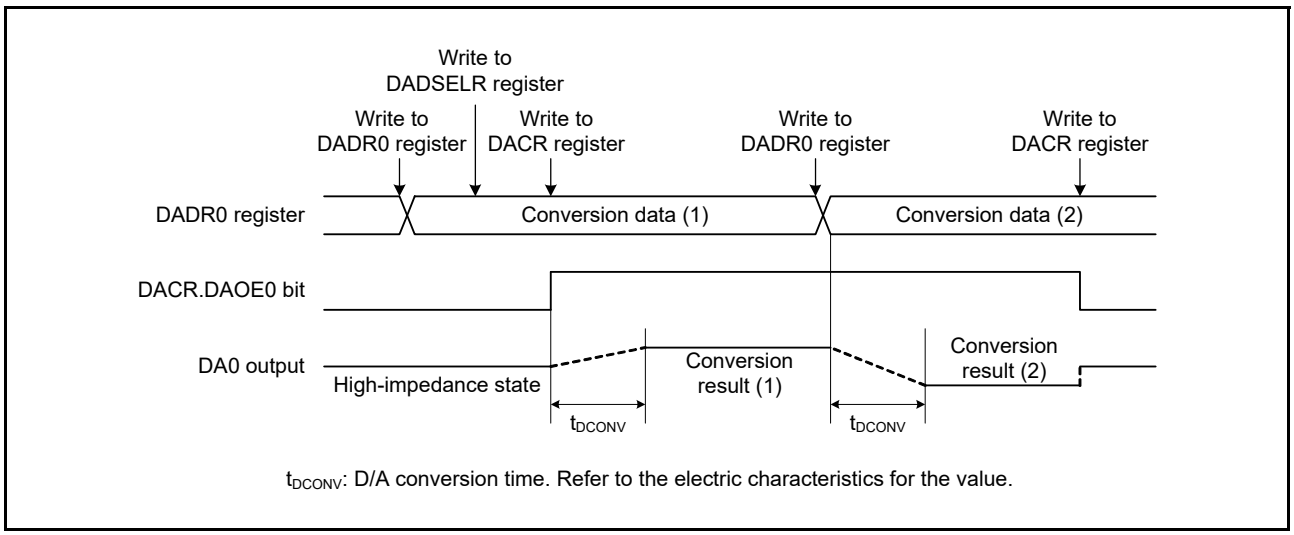

Figure 43.2 Example of 12-Bit D/A Converter Operation

43.3.1 Measure against Interference between D/A and A/D Conversion

When D/A conversion starts, an inrush current occurs to the 12-bit D/A converter. Since the same analog power supply is shared by the 12-bit D/A converter and 12-bit A/D converter (unit 2), the inrush current may interfere with the proper operation of the 12-bit A/D converter (unit 2).

With the DAADSCR.DAADST bit being 1, even if the DADRm register data (m = 0, 1) is modified during 12-bit A/D converter (unit 2) operation, D/A conversion does not start immediately but starts synchronously with A/D conversion completion. It takes a maximum of one A/D conversion time for the DADRm register data update to be reflected as the D/A conversion circuit input. Before reflection, the DADRm register value does not correspond to the analog output value.

When this function is enabled, it is impossible to check by any software means whether the DADRm register value has been D/A converted or not.

Even with the DAADSCR.DAADST bit being 1, when the DADRm register data is modified while the 12-bit A/D converter (unit 2) is halted, D/A conversion starts in one PCLKB cycle.

Figure 43.3 shows an example of channel 0 D/A conversion, in which the 12-bit D/A converter operates synchronously with the 12-bit A/D converter (unit 2).

(1) Confirm that the 12-bit A/D converter (unit 2) is halted. Set the DAADSCR.DAADST bit to 1.
(2) Confirm that the 12-bit A/D converter (unit 2) is halted. Set the DACR.DAOE0 bit to 1.
(3) Set the DADR0 register. When ADCLK is faster than the peripheral module clock, it may take longer than one A/D conversion time.

- If the 12-bit A/D conversion is halted (ADCSR.ADST bit = 0) when the DADR0 register is modified, D/A conversion starts in one PCLKB cycle.
- If the 12-bit A/D conversion is in progress (ADCSR.ADST bit = 1) when the DADR0 register is modified, D/A conversion starts upon A/D conversion completion. If the DADR0 register is modified twice during A/D conversion, the first update may not be converted.

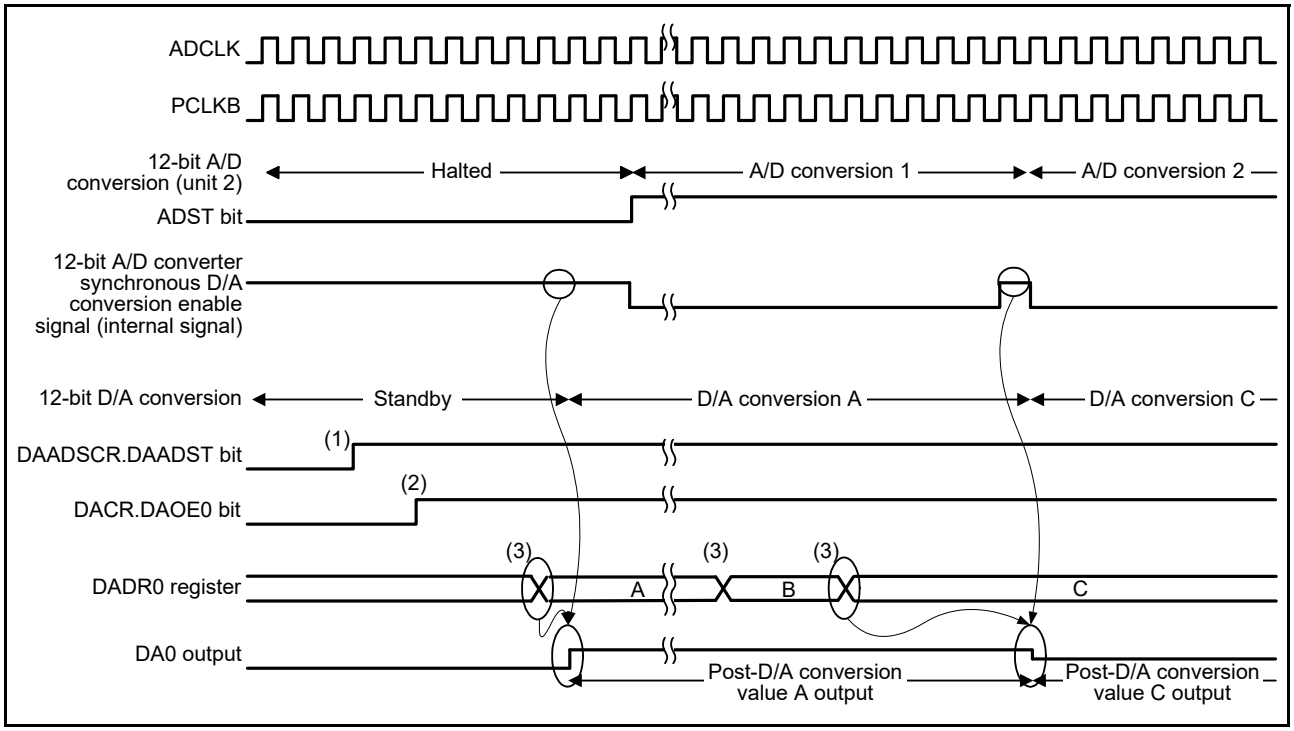

Figure 43.3 Example of Conversion When the 12-Bit D/A Converter is Synchronized with the 12-Bit A/D Converter (Unit 2)

When ADCLK is faster than PCLKB, the 12-bit D/A converter may not be able to capture a 12-bit A/D converter synchronous D/A conversion enable signal for one ADCLK cycle which is output between A/D conversion 1 and A/D conversion 2. Figure 43.4 shows example when the 12-bit D/A converter cannot capture the 12-bit A/D converter synchronous D/A conversion enable signal. In this case, the DA0 output is held at the level of the post-D/A conversion value A.

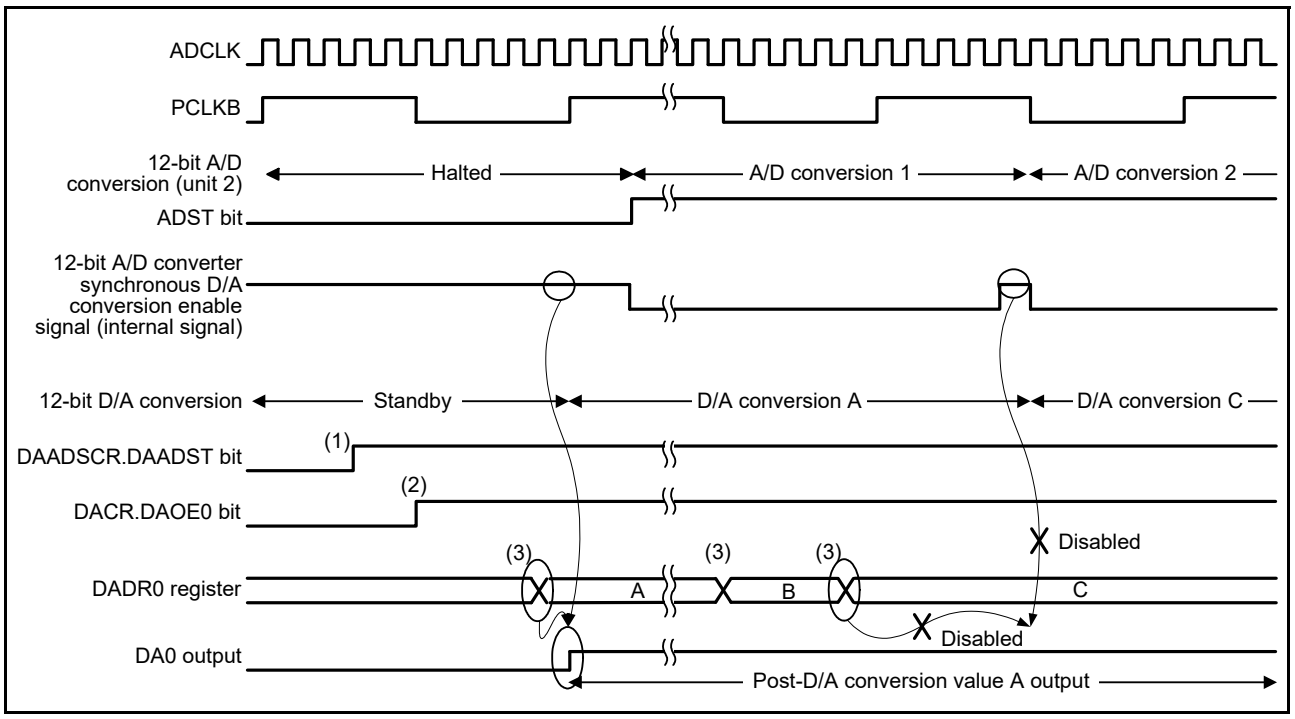

Figure 43.4 Example When the 12-Bit D/A Converter Cannot Capture the 12-Bit A/D Converter Synchronous D/A Conversion Enable Signal

43.4 Event Link Operation Setting Procedure

The event link operation procedure is described below.

(1) Set the DADPR.DPSEL bit and set the data for D/A conversion in the DADR0 register.
(2) Select the destination of the D/A converter analog voltage by using the DADSELR register.
(3) Set the bit value of the ELSR16 setting event signal to link the ELSR16 register of the ELC.
(4) Set the ELCR.ELCON bit to 1. This procedure enables event link operation for all modules with the event link function selected.
(5) Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE0 bit becomes 1, and D/A conversion on channel 0 starts.
(6) Set the ELSR16.ELS[7:0] bits to 0000 0000b to stop event link operation of 12-bit D/A converter channel 0. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

43.5 Usage Notes on Event Link Operation

(1) When the event link function is used, set the DACR.DAE bit to 0.
(2) When the event specified by the ELSR16 register is generated while the write cycle is performed to the DACR.DAOE0 bit, the write cycle is stopped, and the setting to 1 by the generated event takes precedence.
(3) Use of the event link function is prohibited when the DAADSCR.DAADST bit is set to 1 as the measure against an interfere between D/A and A/D conversions.

43.6 Usage Notes

43.6.1 Module Stop Function Setting

Operation of the 12-bit D/A converter can be disabled or enabled using the module stop control register. The initial setting is for operation of the 12-bit D/A converter to be stopped. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

43.6.2 Operation of the D/A Converter in Module Stop State

When the MCU enters the module stop state with D/A conversion enabled, the D/A converter outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current has to be reduced in the module stop state, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

43.6.3 Operation of the D/A Converter in Software Standby Mode

When the MCU enters software standby mode with D/A conversion enabled, the D/A converter outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current has to be reduced in software standby mode, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

43.6.4 Note on Usage When Measure against Interference between D/A and A/D Conversion is Enabled

When the DAADSCR.DAADST bit is 1 (measure against interference between D/A and A/D conversion is enabled), do not place the 12-bit A/D converter (unit 2) in the module stop state. It may halt D/A conversion in addition to A/D conversion.

43.6.5 Note on Using the D/A Converter Analog Voltage as a Reference Voltage for the Comparator C

When setting the DADSELR.OUTREFn bit (n = 0, 1) to 1, refer to section 45.4.5, Setting the D/A Converter.

43.6.6 Note on Enabling the Outputs Both to the DAn pin (n = 0, 1) and Comparator C

When the DADSELR.OUTDAn and OUTREFn bits are set to 1 simultaneously, the characteristics specified in section 49.8, D/A Conversion Characteristics may not be satisfied due to the influence of the load connected to the DAn pin. A full evaluation is recommended before use when both outputs are to be enabled.

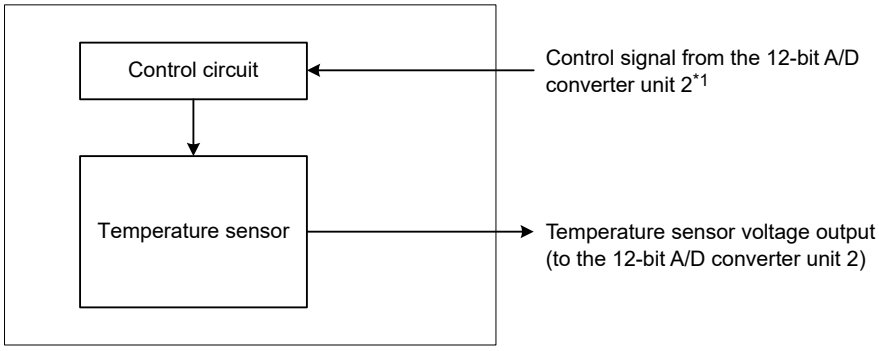
44. Temperature Sensor (TEMPS)

44.1 Overview

This MCU has a built-in temperature sensor. The temperature sensor outputs a voltage proportional to temperature. By converting the output voltage of the temperature sensor into a digital value with a 12-bit A/D converter unit 2 and converting it into temperature, the internal temperature of the MCU can be obtained.
Table 44.1 lists the specifications of the temperature sensor, and Figure 44.1 shows a block diagram of the temperature sensor.

Table 44.1 Specifications of Temperature Sensor

Item	Description
Temperature sensor voltage output	Temperature sensor outputs a voltage to the 12-bit A/D converter unit 2.
Temperature Sensor Calibration Data	Reference data measured for each chip at factory shipment is stored.



Note 1. When any of TSSA or TSSB bit in the ADEXICR register, or ADGCEXCR.TSSC bit for 12-bit A/D converter is set to 1, the temperature sensor is activated.

Figure 44.1 Block Diagram of Temperature Sensor

44.2 Register Descriptions

44.2.1 Temperature Sensor Calibration Data Register (TSCDR)

Address(es): TEMPS.TSCDR 007F B17Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—												
Value after reset:	0	0	0	0	Unique value for each chip											

The TSCDR register stores temperature sensor calibration data measured for each chip at factory shipment. The TSCDR register is a 32-bit read-only register and should be read in 32-bit units.
Temperature sensor calibration data is a digital value obtained using the 12-bit A/D converter unit 2 to convert the voltage output by the temperature sensor under the condition of Tj = 125°C and AVCC2 = 5 V.
The voltage V1 output by the temperature sensor under the condition of Tj = 125°C can be calculated from the value of the TSCDR register according to the formula below.

V1 = 5 × value of the TSCDR register/4096 [V]

Note that the AVCC2 voltage does not affect voltage V1.

44.3 Using the Temperature Sensor

The temperature sensor outputs a voltage proportional to temperature. By converting this voltage into a digital value with a 12-bit A/D converter unit 2 and converting it into temperature, the internal temperature of the MCU can be obtained.

44.3.1 Preparation for Using the Temperature Sensor

Perform a calibration of the temperature sensor as shown below. The voltage output by the temperature sensor is proportional to temperature, which can be calculated according to the following formula.

Formula for the temperature characteristic:
T = (Vs – V1)/Slope + T1

T: Measured temperature (°C)
Vs: Voltage output by the temperature sensor when the temperature is measured (V)
T1: Sample temperature measurement at first point (°C)
V1: Voltage output by the temperature sensor when T1 is measured (V)
T2: Sample temperature measurement at second point (°C)
V2: Voltage output by the temperature sensor when T2 is measured (V)
Slope: Temperature slope of the temperature sensor (V/°C); Slope = (V2 – V1)/(T2 – T1)

Since there are individual differences in temperature sensors, it is recommended to prepare a temperature slope by performing trial measurements at two different temperatures as shown below.
Use the 12-bit A/D converter unit 2 to measure the voltage V1 output by the temperature sensor at temperature T1. Again, using the 12-bit A/D converter unit 2, measure the voltage V2 output by the temperature sensor at a different temperature T2. Obtain the temperature slope (Slope = (V2 – V1)/(T2 – T1)) from these results.
Subsequently, obtain temperatures by substituting the slope into the formula for the temperature characteristic (T = (Vs – V1)/Slope + T1).

If you are using the temperature slope given in Table 49.50 of section 49, Electrical Characteristics, use the 12-bit A/D converter unit 2 to measure the voltage V1 output by the temperature sensor at temperature T1, and then calculate the temperature characteristic by using the formula below.
However, this calibration gives less accurate temperatures than two-point calibration.

T = (Vs – V1)/Slope + T1

T: Measured temperature (°C)
Vs: Voltage output by the temperature sensor when the temperature is measured (V)
T1: Sample temperature measurement at first point (°C)
V1: Voltage output by the temperature sensor when T1 is measured (V)
Slope: Temperature slope given in Table 49.50 ÷ 1000 (V/°C)

In this MCU, the TSCDR register stores the temperature value (CAL_{125}) of the temperature sensor measured under the condition of Tj = 125°C and AVCC2 = 5 V. By using this value as the sample measurement result at the first point, preparation before using the temperature sensor can be omitted.
If V1 is calculated from CAL_{125},

$V1 = 5 \times CAL_{125}/4096$ [V]
Using this, the measured temperature can be calculated according to the formula below.

T = (Vs – V1)/Slope + 125 [°C]

T: Measured temperature (internal temperature of the MCU) (°C)
Vs: Voltage output by the temperature sensor when the temperature is measured (V)
V1: Voltage output by the temperature sensor when Tj = 125°C and AVCC2 = 5 V (V)
Slope: Temperature slope given in Table 49.50 ÷ 1000 (V/°C)

Error in the measured temperature (the range of variation is 3σ) is shown in Figure 44.2.

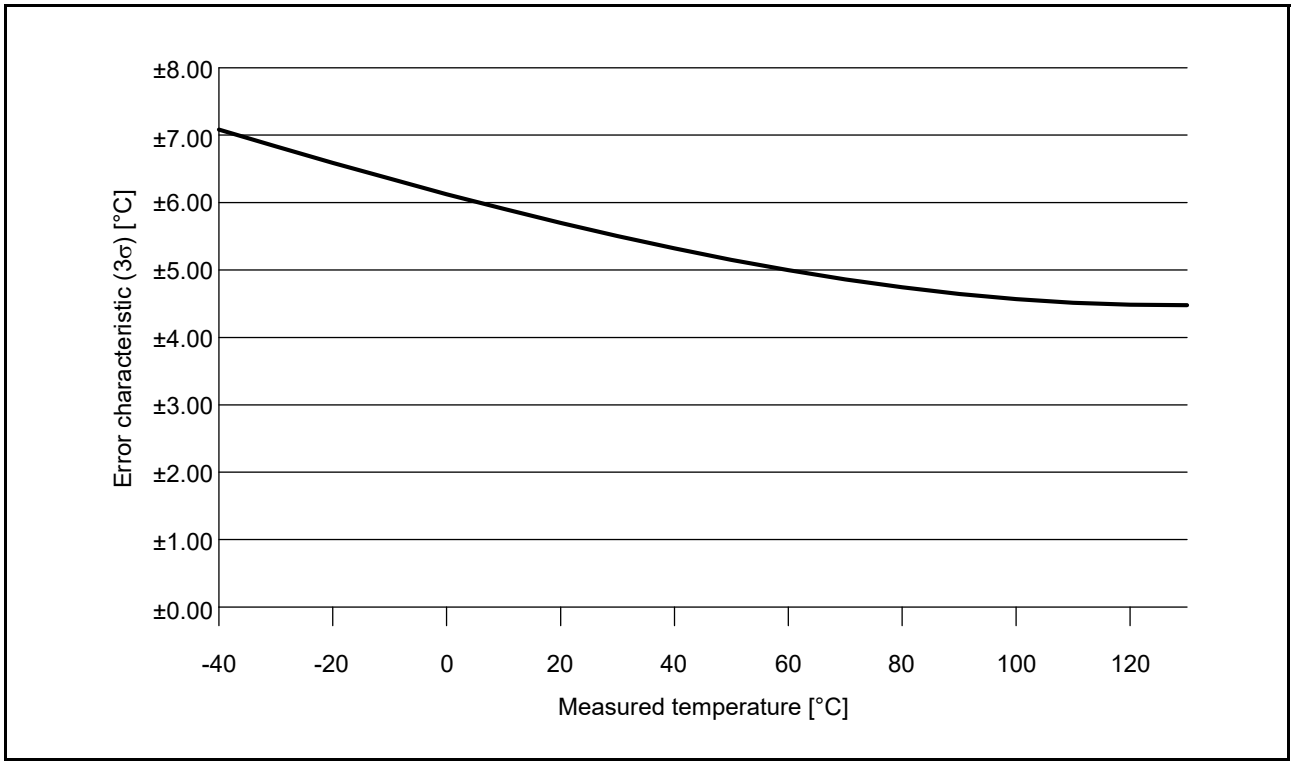


Figure 44.2 Error in the Measured Temperature

44.3.2 Setting of 12-Bit A/D Converter Unit 2

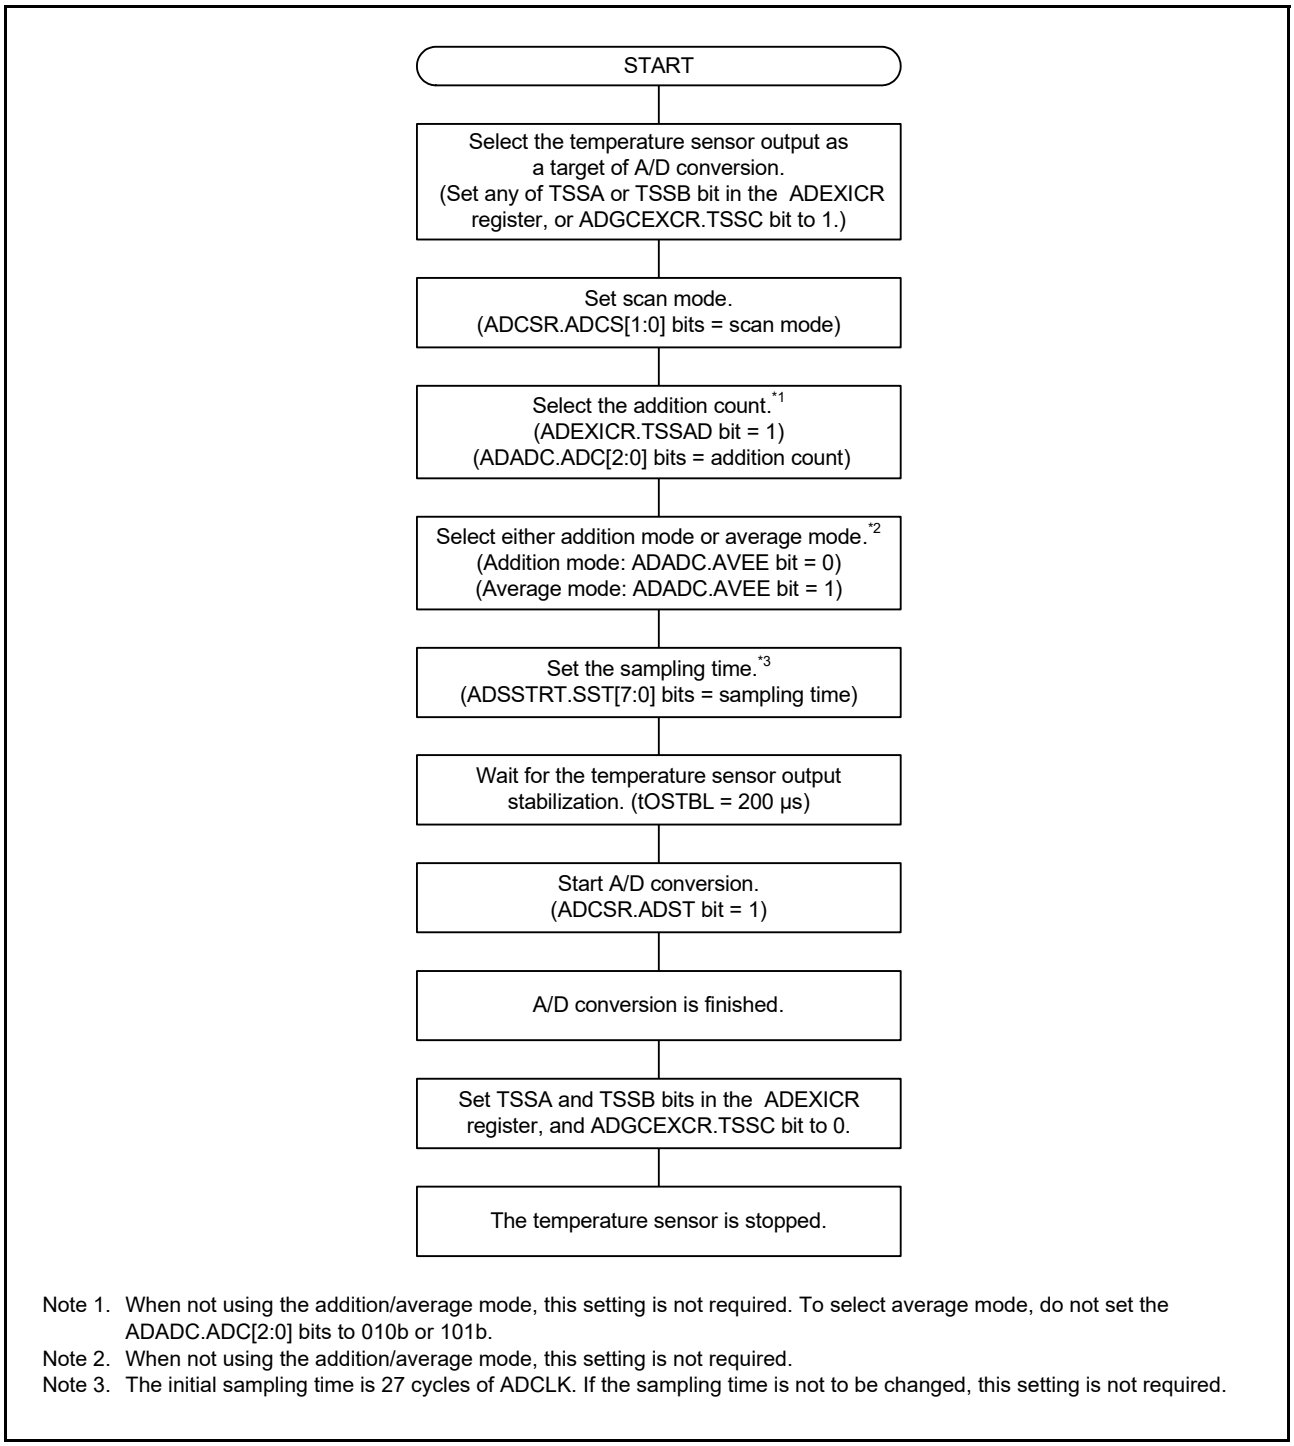
For A/D conversion of temperature sensor output voltages, 12-bit A/D converter unit 2 registers should be set as follows.

- Selecting the Temperature Sensor Voltage as a Source for A/D Conversion
  Select the temperature sensor voltage as a source for A/D conversion by setting the temperature sensor output A/D conversion select bit in the A/D conversion extended input control register (TSSA or TSSB in the ADEXICR register, or ADGCEXCR.TSSC) to 1.
- Setting Scan Mode
  Select scan mode by setting the scan mode select bits in the A/D control register (ADCSR.ADCS[1:0]).
  Set the bits to the single scan mode or the group scan mode.
- Setting Addition/Average Mode
  For A/D conversion of the temperature sensor output, additional or average mode is selectable. To use either additional or average mode, set the temperature sensor output A/D converted value addition mode select bit in the A/D conversion extended input control register (ADEXICR.TSSAD) to 1, and the addition count select bits in the A/D converted value addition count select register (ADADC.ADC[2:0]) to the desired number of addition. Furthermore, clear the AVEE bit in ADADC to 0 to select addition mode; set the AVEE bit in ADADC to 1 to select average mode. In average mode, however, the ADC[2:0] bits in ADADC should not be set to 010b or 101b.
- Setting the Sampling Time of the 12-bit A/D converter Unit 2
  The sampling time of the 12-bit A/D converter can be changed at converting the output from the temperature sensor. The initial sampling time is 27 cycles of ADCLK. To change the setting of sampling time from 27 cycles of ADCLK, set the A/D sampling state register T (ADSSTRT) while the ADCSR.ADST bit is 0. Refer to section 42.2.20, A/D Sampling State Register n (ADSSTRn) (n = 0 to 11, L, T, O) for the setting range of the sampling time. Set the sampling time to satisfy the specifications described in section 49, Electrical Characteristics.

Setting the A/D conversion start bit in the A/D control register (ADCSR.ADST) to 1 starts A/D conversion, and the result is stored in the A/D temperature sensor data register (ADTSDR). If you will be using A/D conversion of the output from the temperature sensor, do so in accord with section 44.3.3, Procedure for Using the Temperature Sensor.

44.3.3 Procedure for Using the Temperature Sensor

Figure 44.3 shows the procedure for using the temperature sensor.



Note 1. When not using the addition/average mode, this setting is not required. To select average mode, do not set the ADADC.ADC[2:0] bits to 010b or 101b.
Note 2. When not using the addition/average mode, this setting is not required.
Note 3. The initial sampling time is 27 cycles of ADCLK. If the sampling time is not to be changed, this setting is not required.

Figure 44.3 Procedure for Using the Temperature Sensor

44.3.4 Timing of A/D Conversion of Temperature Sensor Output

Figure 44.4 shows the timing from the start of temperature-sensor operation until the completion of A/D conversion when only the output from the temperature sensor is to be A/D converted and conversion is in single-scan mode. The times shown in the figure are described in Table 44.2.
When setting the ADST bit to 1 to perform the A/D conversion of the temperature sensor, auto-discharge is performed before sampling. The A/D conversion time of the temperature sensor includes the time for the auto discharge.

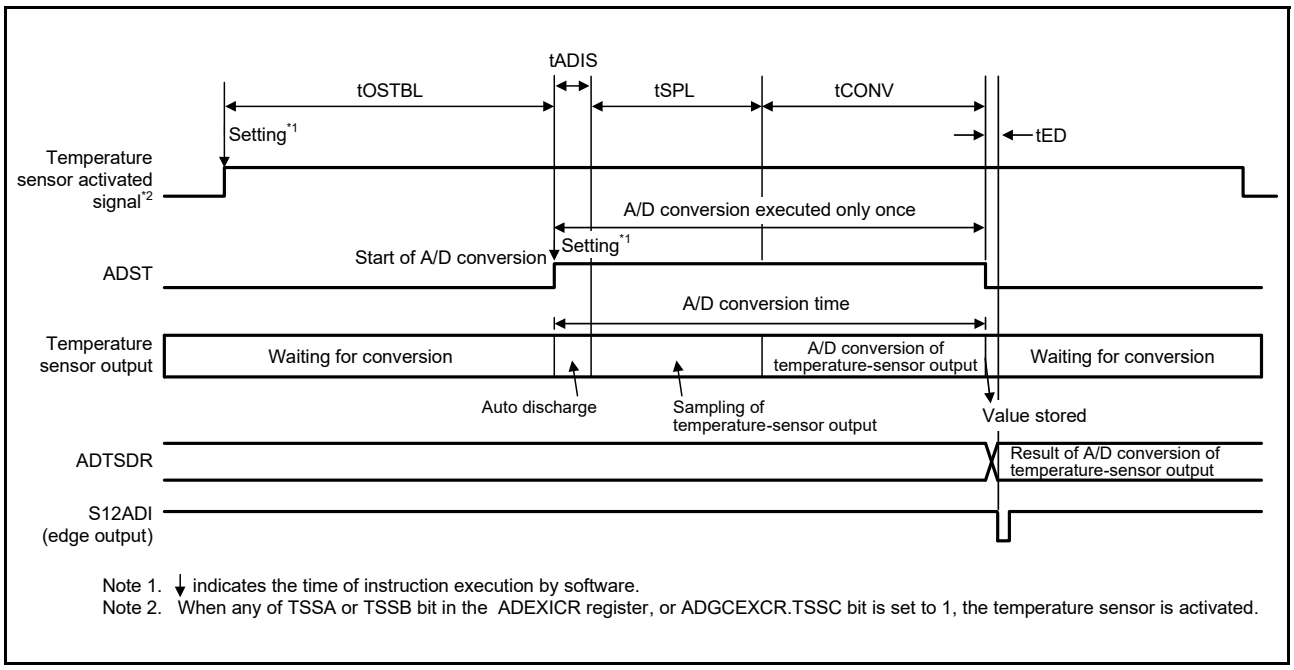


Figure 44.4 Timing from the Start of Temperature-Sensor Operation until Completion of A/D Conversion

Table 44.2 Time until Completion of A/D Conversion after the Start of Temperature-Sensor Operation

Item	Symbol	Time
Temperature-sensor output stabilization wait time	tOSTBL	200 µs (min)
Auto discharge time	tADIS	15 × tC(ADCLK)
12-bit A/D converter unit 2 input sampling time	tSPL	ADSSTRT setting × tC(ADCLK)
A/D conversion time	tCONV	Refer to Table 42.23, Times for Conversion During Scanning (in Numbers of Cycles of ADCLK and PCLKB) in section 42.3.7, Analog Input Sampling Time and Scan Conversion Time.
Scan conversion end delay time	tED	Refer to Table 42.23, Times for Conversion During Scanning (in Numbers of Cycles of ADCLK and PCLKB) in section 42.3.7, Analog Input Sampling Time and Scan Conversion Time.

44.4 Usage Note

44.4.1 Activating the Temperature Sensor

The temperature sensor is controlled by the registers in the 12-bit A/D converter unit 2 (S12AD2). To activate the temperature sensor, set any of TSSA or TSSB bit in the ADEXICR register, or ADGCEXCR.TSSC bit to 1 after releasing the S12AD2 from the module stop state. For details, refer to section 42, 12-Bit A/D Converter (S12ADHa).

45. Comparator C (CMPCa)

45.1 Overview

Comparator C compares a reference input voltage to an analog input voltage.
The comparison result can be read by software and output externally, and an interrupt request can be generated upon any changes to the comparison result.
The reference input voltage of comparator C can be selected from the input from the CVREFC0 or CVREFC1 pin, or the output from the on-chip D/A converter 0 or the on-chip D/A converter 1.
There are four analog inputs, one of which is to be selected.
Table 45.1 lists the specification of comparator C, Figure 45.1 shows a block diagram of comparator C, Table 45.2 shows a comparator C pin configuration, and Table 45.3 shows the analog input pin connections for comparator C.
In this section, “PCLK” is used to refer to PCLKB.

Table 45.1 Comparator C Specifications

Item	Specification
Number of channels	Six (comparator C0 to comparator C5)
Analog input voltages	Input voltage from the CMPCnm pin (n = channel number; m = 0 to 3)
Reference input voltage	Input voltage from the CVREFC0 or CVREFC1 pin, or output voltage from on-chip D/A converter 0 or on-chip D/A converter 1
Comparison result	The comparison result can be output externally.
Digital filter function	• One of three sampling periods can be selected. • The filter function can also be disabled. • A noise-filtered signal can be used to generate the interrupt request output, event output to the ELC, and POE source output*1, and the signal can be used to read the comparison result via registers.
Interrupt request	• An interrupt request is generated upon detecting a valid edge of the comparison result. • A valid edge can be selected from a rising or a falling edge or both edges.
Low power consumption function	Module stop state can be set.

Note 1. The POE only uses the level detection signal, and the POEG uses the level detection and edge detection signals.

45.2 Register Descriptions

45.2.1 Comparator Control Register (CMPCTL)

Address(es): CMPC0.CMPCTL 000A 0C80h, CMPC1.CMPCTL 000A 0CA0h, CMPC2.CMPCTL 000A 0CC0h, CMPC3.CMPCTL 000A 0CE0h, CMPC4.CMPCTL 000A 0D00h, CMPC5.CMPCTL 000A 0D20h

	b7	b6	b5	b4	b3	b2	b1	b0
	HCMPON	CDFS[1:0]		CEG[1:0]		—	COE	CINV
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CINV	Comparator Output Polarity Select*1, *4	0: Comparator output not inverted 1: Comparator output inverted	R/W
b1	COE	Comparator Output Enable	0: Comparator output disabled (the output signal is fixed to 0) 1: Comparator output enabled	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4, b3	CEG[1:0]	Comparator Edge Interrupt Detection Select	b4 b3 0 0: Interrupt request is not generated. 0 1: Rising edge 1 0: Falling edge 1 1: Both edges	R/W
b6, b5	CDFS[1:0]	Noise Filter Sampling Select*1, *2, *4	b6 b5 0 0: Noise filter not used 0 1: Sampling frequency is PCLK/8. 1 0: Sampling frequency is PCLK/16. 1 1: Sampling frequency is PCLK/32.	R/W
b7	HCMPON	Comparator Operation Enable*3	0: Operation stopped (the output signal is fixed to 0) 1: Operation enabled (input to the comparator pins is enabled)	R/W

Note: Set this register before setting registers in the ELC when using event output.
Note: Set this register before setting registers in the POE when using comparator output as a POE source.
Note 1. Rewrite the CDFS[1:0] and CINV bits only after disabling the comparator output (COE bit = 0).
Note 2. If the CDFS[1:0] bits are changed from 00b (noise filter not used) to a value other than 00b (noise filter used), allow four sampling times to elapse until the filter output is updated, and then use the CMPCn interrupt request output, an event output, and a POE source output.
Note 3. The operation stabilization wait time is required after enabling comparator operation (HCMPON bit = 1). As for the value, refer to section 49, Electrical Characteristics.
Note 4. Rewriting the CINV bit or CDFS[1:0] bits may generate a CMPCn interrupt request, event output, and POE source. Before changing these bits, set the registers in the ELC so that the comparator output is not linked and set the registers in the POE/POEG so that comparator output is not used for output disabling control. After changing these bits, also set the corresponding interrupt status flag (IR) in the interrupt request register, the POE comparator channel n output detection flag (n = 0 to 5), and the GPTW or CMPC output stop request detection flag in the POEG to 0.

CEG[1:0] Bits (Comparator Edge Interrupt Detection Select)

These bits select which edge of comparator output signal is used to generate an interrupt request.

The valid edge is set for the signal after the comparator polarity is selected by the CINV bit and the filter is selected by CDFS[1:0] bits.

45.2.2 Comparator Input Select Register (CMPSEL0)

Address(es): CMPC0.CMPSEL0 000A 0C84h, CMPC1.CMPSEL0 000A 0CA4h, CMPC2.CMPSEL0 000A 0CC4h, CMPC3.CMPSEL0 000A 0CE4h, CMPC4.CMPSEL0 000A 0D04h, CMPC5.CMPSEL0 000A 0D24h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	CMPSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	CMPSEL[3:0]	Comparator Input Select*1, *2, *3	• Comparator C0 b3 b0 0 0 0 0: No input 0 0 0 1: CMPC00 selected 0 0 1 0: CMPC01 selected 0 1 0 0: CMPC02 selected 1 0 0 0: CMPC03 selected Settings other than above are prohibited. • Comparator C1 b3 b0 0 0 0 0: No input 0 0 0 1: CMPC10 selected 0 0 1 0: CMPC11 selected 0 1 0 0: CMPC12 selected 1 0 0 0: CMPC13 selected Settings other than above are prohibited. • Comparator C2 b3 b0 0 0 0 0: No input 0 0 0 1: CMPC20 selected 0 0 1 0: CMPC21 selected 0 1 0 0: CMPC22 selected 1 0 0 0: CMPC23 selected Settings other than above are prohibited. • Comparator C3 b3 b0 0 0 0 0: No input 0 0 0 1: CMPC30 selected 0 0 1 0: CMPC31 selected 0 1 0 0: CMPC32 selected 1 0 0 0: CMPC33 selected Settings other than above are prohibited. • Comparator C4 b3 b0 0 0 0 0: No input 0 0 0 1: CMPC40 selected 0 0 1 0: CMPC41 selected 0 1 0 0: CMPC42 selected 1 0 0 0: CMPC43 selected Settings other than above are prohibited. • Comparator C5 b3 b0 0 0 0 0: No input 0 0 0 1: CMPC50 selected 0 0 1 0: CMPC51 selected 0 1 0 0: CMPC52 selected 1 0 0 0: CMPC53 selected Settings other than above are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Rewrite the CMPSEL[3:0] bits in the following procedure. Writing a value other than 0000b while the value of these bits is not

0000b is invalid. Writing 1 to two or more bits is also invalid. In both cases, the previous value is retained.
(1) Set the CMPCTL.COE bit to 0.
(2) Set the CMPSEL[3:0] bits to 0000b.
(3) Set a new value to the CMPSEL[3:0] bits (with 1 set in only one of the bits).
(4) Wait for the stabilization time for input selection. As for the value, refer to section 49, Electrical Characteristics.
(5) Set the CMPCTL.COE bit to 1.
(6) Set the corresponding interrupt status flag (IR) in the interrupt request register to 0.
(7) Set the GPTW or CMPC output stop request detection flag (POEGGj.IOCF (j = A to D)) in the corresponding POEG to 0.

Note 2. When using the event output, note that writing to these bits after the corresponding register in the ELC is set may trigger the output of an event signal.

Note 3. If COMPn level detection signal is used as a POE source, note that write access to these bits after the setting of any register in the POE may generate a POE source.

45.2.3 Comparator Reference Voltage Select Register (CMPSEL1)

Address(es): CMPC0.CMPSEL1 000A 0C88h, CMPC1.CMPSEL1 000A 0CA8h, CMPC2.CMPSEL1 000A 0CC8h, CMPC3.CMPSEL1 000A 0CE8h, CMPC4.CMPSEL1 000A 0D08h, CMPC5.CMPSEL1 000A 0D28h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	CVRS[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	CVRS[3:0]	Reference Input Voltage Select*1, *2, *3, *4	b3 b0 0 0 0 0: No input 0 0 0 1: On-chip D/A converter 1 output voltage selected as reference input voltage 0 0 1 0: On-chip D/A converter 0 output voltage selected as reference input voltage 0 1 0 0: Input voltage to the CVREFC1 pin selected as reference input voltage 1 0 0 0: Input voltage to the CVREFC0 pin selected as reference input voltage Settings other than above are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. When the on-chip D/A converter output voltage is used, set the D/A converter for generating comparator C reference voltage before enabling comparator operation (CMPCTL.HCMPON bit = 1). For details on setting the D/A converter, refer to section 43, 12-Bit D/A Converter (R12DAb).

Note 2. Rewrite the CVRS[3:0] bits in the following procedure. Be sure to set the CVRS[3:0] bits to 0000b before changing the set value. Direct rewriting from 0001b to 0010b or 0010b to 0001b, for example, will be ignored even if it is tried.
(1) Set the CMPCTL.COE bit to 0.
(2) Set the CVRS[3:0] bits to 0000b.
(3) Set a new value to the CVRS[3:0] bits (with 1 set in only one of the bits).
(4) Wait for the stabilization time for input selection. As for the value, refer to section 49, Electrical Characteristics.
(5) Set the CMPCTL.COE bit to 1.
(6) Set the corresponding interrupt status flag (IR) in the interrupt request register to 0.
(7) Set the GPTW or CMPC output stop request detection flag (POEGGj.IOCF (j = A to D)) in the corresponding POEG to 0.

Note 3. When using the event output, note that writing to these bits after the corresponding register in the ELC is set may trigger the output of an event signal.

Note 4. If COMPn level detection signal is used as a POE source, note that write access to these bits after the setting of any register in the POE may generate a POE source.

45.2.4 Comparator Output Monitor Register (CMPMON)

Address(es): CMPC0.CMPMON 000A 0C8Ch, CMPC1.CMPMON 000A 0CACh, CMPC2.CMPMON 000A 0CCCh, CMPC3.CMPMON 000A 0CECh, CMPC4.CMPMON 000A 0D0Ch, CMPC5.CMPMON 000A 0D2Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CMPMON0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPMON0	Comparator Output Monitor Flag *1	0: Comparator output is 0. 1: Comparator output is 1.	R
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. When comparator operation is enabled (CMPCTL.HCMPON and COE bits are 1) while the noise filter is disabled (CMPCTL.CDFS[1:0] bits are 00b), read the CMPMON0 bit twice and use the value only when the results match.

45.2.5 Comparator External Output Enable Register (CMPIOC)

Address(es): CMPC0.CMPIOC 000A 0C90h, CMPC1.CMPIOC 000A 0CB0h, CMPC2.CMPIOC 000A 0CD0h, CMPC3.CMPIOC 000A 0CF0h, CMPC4.CMPIOC 000A 0D10h, CMPC5.CMPIOC 000A 0D30h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CPOE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CPOE	External Pin Output Enable	Comparison result by the comparator is output to an external pin. 0: Output to the comparator external pin is disabled (the output signal is fixed to low) 1: Output to the comparator external pin is enabled	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

45.2.6 Comparator Control Register 2 (CMPCTL2)

Address(es): CMPC0.CMPCTL2 000A 0C98h, CMPC1.CMPCTL2 000A 0CB8h, CMPC2.CMPCTL2 000A 0CD8h, CMPC3.CMPCTL2 000A 0CF8h, CMPC4.CMPCTL2 000A 0D18h, CMPC5.CMPCTL2 000A 0D38h

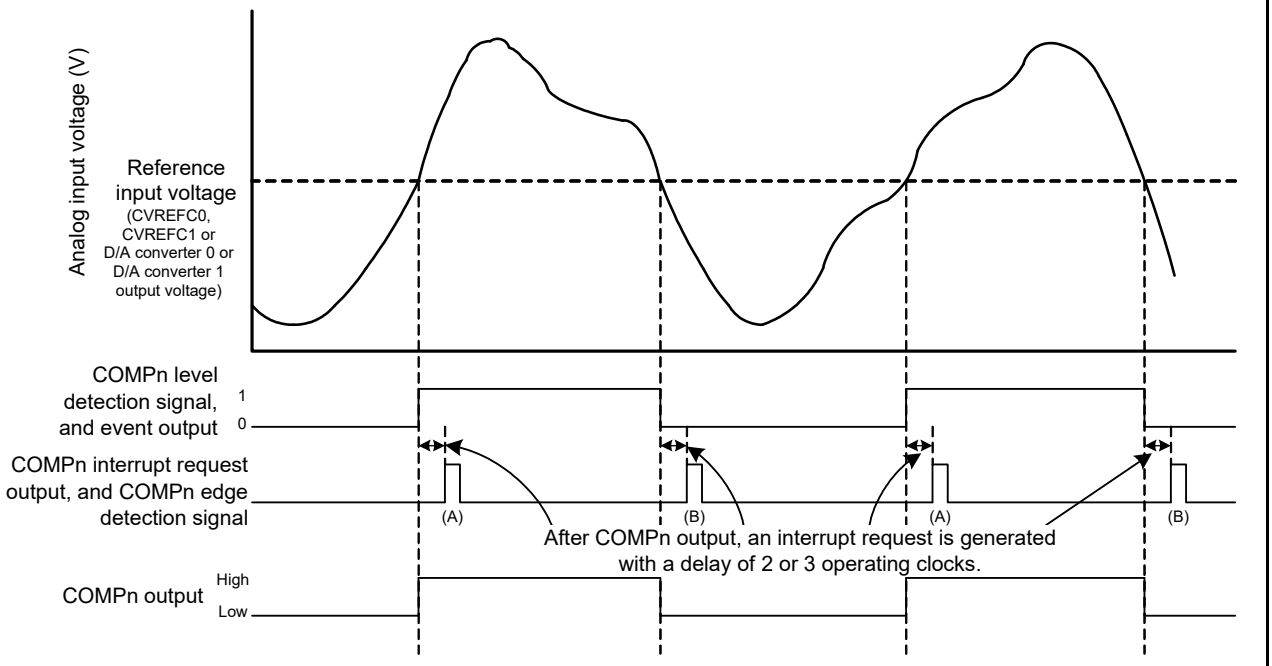
	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CNFS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CNFS	Noise Filter Judgment Standard Setting	0: Output changes when the same value is sampled 3 times. 1: Output changes when the same value is sampled 4 times.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

45.3 Operation

45.3.1 Comparator Operation Example

Figure 45.2 shows an operation example of the comparator. The COMPn level detection signal (n = 0 to 5) becomes high when the analog input voltage is higher than the reference input voltage, and the COMPn level detection signal becomes low when the analog input voltage is lower than the reference input voltage (when the CMPCTL.CINV bit is 0). The COMPn level detection signal can also be used as event output signal. When the CPOE bit in the corresponding CMPIOC register is 1, the signal is output from the COMPn pin. Interrupt request and COMPn edge detection signal are output in response to changes in the comparator output.



Note: The above diagram applies when the CMPIOC.CPOE bit is 1 (pin output enabled), the CMPCTL.CDFS[1:0] bits are 00b (filter not used), the CMPCTL.CEG[1:0] bits are 11b (both edges selected), and the CMPCTL.CINV bit is 0 (comparator output not inverted).

Figure 45.2 Comparator Operation Example (n = 0 to 5)

45.3.2 Noise Filter

Comparator C contains a noise filter. The sampling clock can be selected by the CMPCTL.CDFS[1:0] bits and the number of matches can be selected by the CMPCTL2.CNFS bit.

The comparator output signal is sampled every sampling clock, and if the same value is sampled three or four times, that value is determined as the noise filter output at the next sampling clock.

Figure 45.3 shows the configuration of the noise filter and edge detector and Figure 45.4 shows an example of the comparator noise filter and interrupt operation.

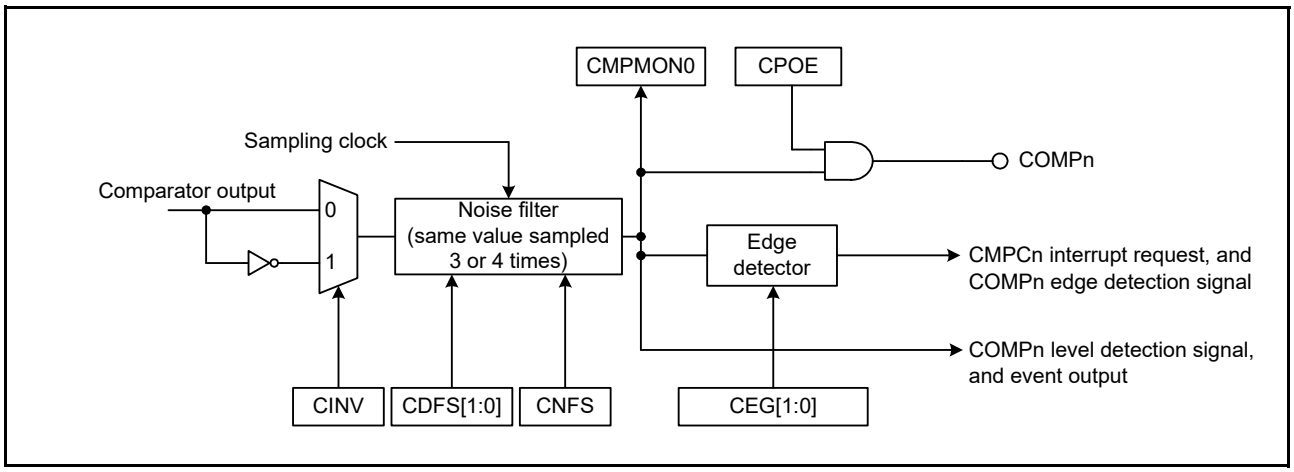


Figure 45.3 Noise Filter and Edge Detector Configuration (n = 0 to 5)

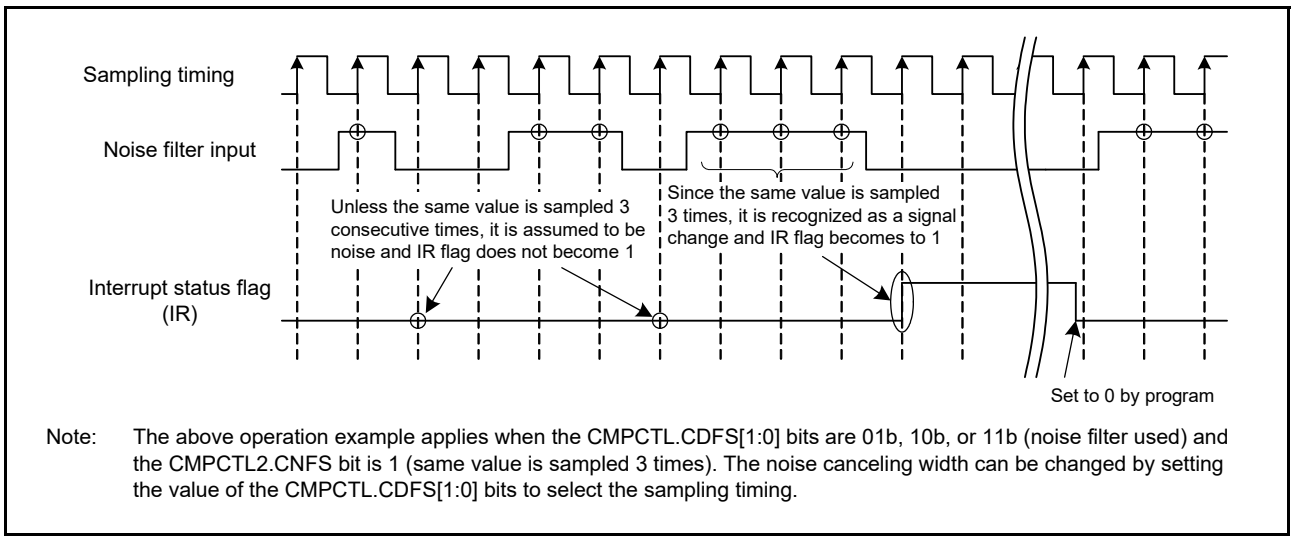


Note: The above operation example applies when the CMPCTL.CDFS[1:0] bits are 01b, 10b, or 11b (noise filter used) and the CMPCTL2.CNFS bit is 1 (same value is sampled 3 times). The noise canceling width can be changed by setting the value of the CMPCTL.CDFS[1:0] bits to select the sampling timing.

Figure 45.4 Noise Filter and Interrupt Operation Example

45.3.3 Interrupts

Comparator C generates an interrupt request upon detecting any changes in the comparison result.
When using the CMPCn interrupt, set at least one of bits CMPCTL.CEG[1:0] to 1 (to a value other than 00b (interrupt request is not generated)).
To use the CMPCn interrupt, use the following setting procedure. Note that steps (1), (2), and (3) can be set in any order.

(1) When using the on-chip D/A converter output voltage as the reference input voltage, set the D/A converter for generating comparator C reference voltage and enable operation.
(2) Set the CMPSEL0 or CMPSEL1 register to set the input of the comparator.
(3) Set the CMPCTL.CINV and CDFS[1:0] bits and the CMPCTL2.CNFS bit to select inversion or non-inversion processing and the sampling timing and number of matches of the noise filter.
(4) Enable the edge for interrupt detection (set the CMPCTL.CEG[1:0] bits to a value other than 00b).
(5) Enable input of the comparator (set the CMPCTL.HCMPON bit to 1) and wait for the time until the comparator operation is stabilized. As for the value, refer to section 49, Electrical Characteristics.
(6) Enable output of the comparator (set the CMPCTL.COE bit to 1).

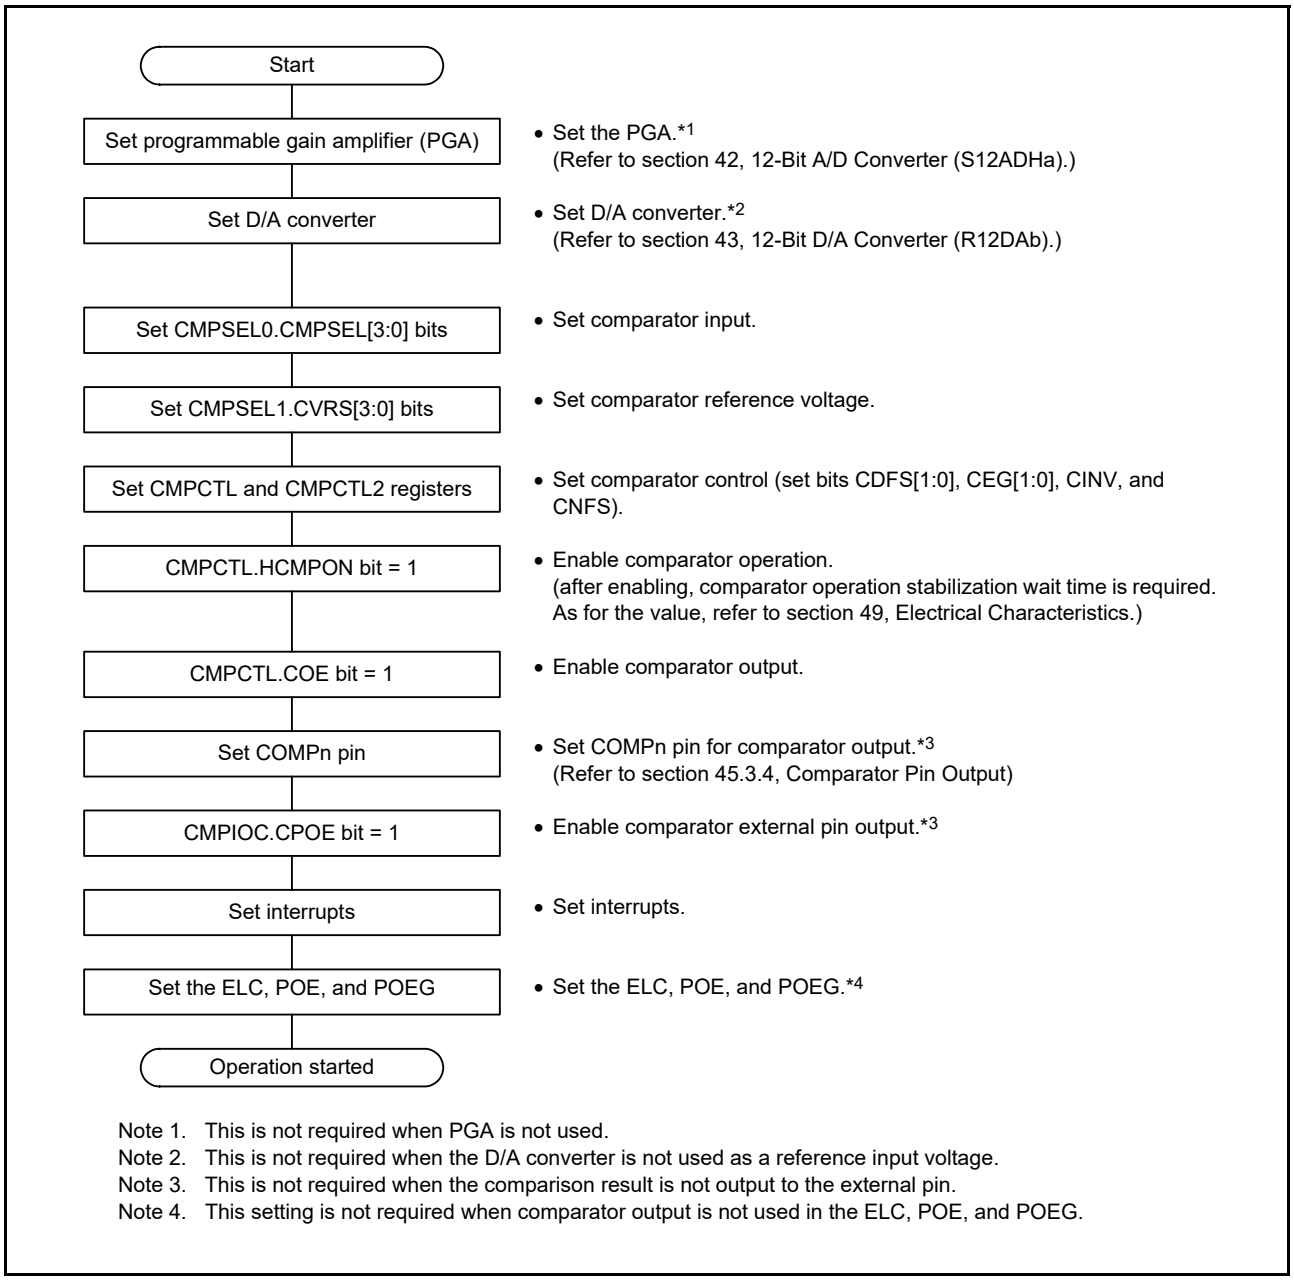
45.3.4 Comparator Pin Output

The comparison results can be output to the COMPn pins (n = 0 to 5). The CMPCTL.CINV bit can be used to set the output polarity (non-inverted output or inverted output), and the CMPIOC.CPOE bit can be used to enable or disable the output.
To output the comparison result to the external pin COMPn, use the following setting procedure. Note that the ports are set to input after reset.

(1) Execute steps (1) to (3) and steps (5) and (6) shown in section 45.3.3, Interrupts.
(2) Output the comparison result by the comparator to an external pin (set the CMPIOC.CPOE bit to 1).
(3) Set the port mode register and the pin function control register corresponding to each comparator output pin.

45.3.5 Comparator Setting Flowchart

Figure 45.5 shows the flowchart for setting the comparator-related registers.



Note 1. This is not required when PGA is not used.
Note 2. This is not required when the D/A converter is not used as a reference input voltage.
Note 3. This is not required when the comparison result is not output to the external pin.
Note 4. This setting is not required when comparator output is not used in the ELC, POE, and POEG.

Figure 45.5 Comparator Operation Setting Flowchart (n = 0 to 5)

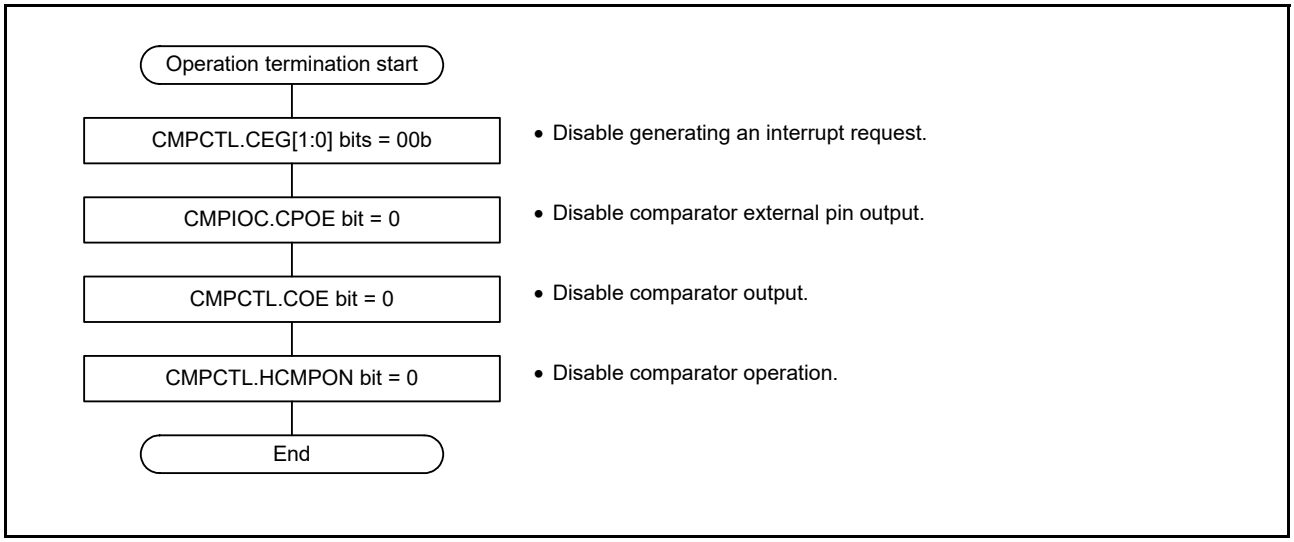


Figure 45.6 Comparator Operation Termination Flowchart

45.4 Usage Notes

45.4.1 Module Stop Function Setting

Operation of comparator C can be disabled or enabled using module stop control register B (MSTPCRB). After the reset, comparator C is halted. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

45.4.2 Comparator C Operation in Module Stop State

When the module stop state is entered while comparator C is operating, analog circuits in the comparator C is not stopped and the analog power supply current is the same as that when comparator C is being used. If the analog power supply current needs to be reduced in the module stop state, set the CMPCTL.HCMPON bit to 0 to stop comparator C.

45.4.3 Comparator C Operation in Software Standby Mode

When software standby mode is entered while comparator C is operating, analog circuits in the comparator C is not stopped and the analog power supply current is the same as that when comparator C is being used. If the analog power supply current needs to be reduced in software standby mode, set the CMPCTL.HCMPON bit to 0 to stop comparator C.

45.4.4 Comparator Operation while the 12-Bit A/D Converter is in the Module-Stop State

The same module stop signal controls the programmable gain amplifiers (PGAs) and the 12-bit A/D converter. The comparison of PGA output for the following pins is not possible while the 12-bit A/D converter is in the module stop state.

- PGA output for AN000 pin
- PGA output for AN001 pin
- PGA output for AN002 pin
- PGA output for AN100 pin
- PGA output for AN101 pin
- PGA output for AN102 pin

The comparison for the following analog input pins is not possible when the 12-bit A/D converter is in the module-stop state.

- AN000 pin
- AN001 pin
- AN002 pin
- AN100 pin
- AN101 pin
- AN102 pin

45.4.5 Setting the D/A Converter

Set the D/A converter, set the output to the comparator C using the D/A destination select register (DADSELR), and wait for the D/A converter output settling time. Similarly, before making any changes to the settings of the D/A converter stop the comparator temporarily, and after the changes are made, wait for the D/A converter output settling time before enabling the comparator.

46. Data Operation Circuit (DOCA)

46.1 Overview

The data operation circuit (DOC) is used to compare, add, or subtract 16- or 32-bit values.

Table 46.1 lists the specifications of the DOC and Figure 46.1 is a block diagram of the DOC.

An interrupt can be generated if the result of 16- or 32-bit comparison meets one of the set interrupt conditions or if the result of the addition or subtraction result of 16- or 32-bit values is an overflow or underflow.

Table 46.1 DOC Specifications

Item	Description
Data operation function	• Comparison of 16- or 32-bit values (equal or not equal, greater or less than, or within or beyond a range) • Addition or subtraction of 16- or 32-bit values
Lower power consumption function	The DOC can be placed in a module-stop state.
Interrupts	• The result of data comparison meets the detection condition. • The result of data addition is greater than FFFFh (DOCR.DOPSZ = 0) or FFFF FFFFh (DOCR.DOPSZ = 1), which is an overflow. • The result of data subtraction is less than 0000h (DOCR.DOPSZ = 0) or 0000 0000h (DOCR.DOPSZ = 1), which is an underflow.
Event link function (output)	• The result of data comparison meets the detection condition. • The result of data addition is greater than FFFFh (DOCR.DOPSZ = 0) or FFFF FFFFh (DOCR.DOPSZ = 1), which is an overflow. • The result of data subtraction is less than 0000h (DOCR.DOPSZ = 0) or 0000 0000h (DOCR.DOPSZ = 1), which is an underflow.

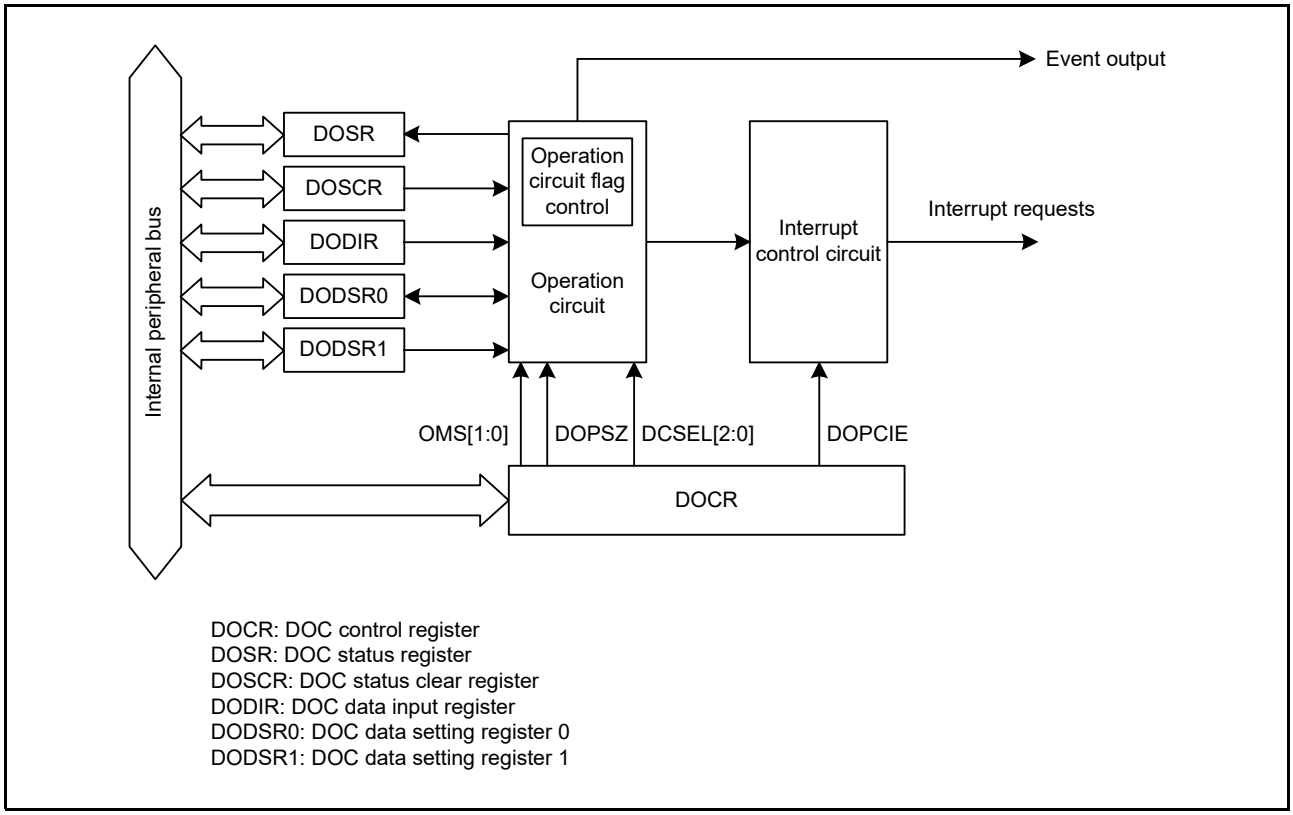

Figure 46.1 DOC Block Diagram

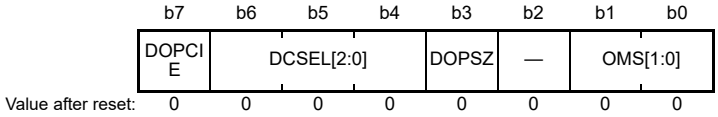
46.2 Register Descriptions

46.2.1 DOC Control Register (DOCR)

Address(es): DOC.DOCR 000A 0580h



Bit	Symbol	Bit Name	Description	R/W
b1, b0	OMS[1:0]	Operating Mode Select	b1 b0 0 0: Data comparison mode 0 1: Data addition mode 1 0: Data subtraction mode 1 1: Setting prohibited	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	DOPSZ	Data Operation Size Select	0: 16-bit width 1: 32-bit width	R/W
b6-b4	DCSEL[2:0]	Detection Condition Select*1	b6 b4 0 0 0: Not equal to (DODIR ≠ DODSR0) 0 0 1: Equal to (DODIR = DODSR0) 0 1 0: Less than (DODIR < DODSR0) 0 1 1: Greater than (DODIR > DODSR0) 1 0 0: Within the range (DODSR0 < DODIR < DODSR1) 1 0 1: Beyond the range (DODIR < DODSR0, DODSR1 < DODIR) Settings other than above are prohibited.	R/W
b7	DOPCIE	Data Operation Circuit Interrupt Enable	0: Interrupt disabled 1: Interrupt enabled	R/W

Note 1. Valid only when data comparison mode is selected.

The DOCR register specifies the operation of DOC, or enabling or disabling of the interrupt.

OMS[1:0] Bits (Operating Mode Select)

These bits select the operating mode of the DOC.

DOPSZ Bit (Data Operation Size Select)

This bit selects the size of the data operation.

DCSEL[2:0] Bits (Detection Condition Select)

This bit is valid only when data comparison mode is selected.

This bit selects the condition for detection in data comparison mode.

DOPCIE Bit (Data Operation Circuit Interrupt Enable)

Setting this bit to 1 enables interrupts from the DOC.

46.2.2 DOC Status Register (DOSR)

Address(es): DOC.DOSR 000A 0584h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	DOPCF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DOPCF	Data Operation Result Flag	Indicates the result of an operation.	R
b7-b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

The DOSR register indicates the results of data operation.

DOPCF Flag (Data Operation Result Flag)

[Setting conditions]

- The setting of the DOCR.OMS[1:0] bits is 00b (data comparison mode) and the result of data comparison meets the condition selected by the DOCR.DCSEL[2:0] bits.
- The setting of the DOCR.OMS[1:0] bits is 01b (data addition mode) and the result of addition was greater than FFFFh (DOCR.DOPSZ = 0) or FFFF FFFFh (DOCR.DOPSZ = 1).
- The setting of the DOCR.OMS[1:0] bits is 10b (data subtraction mode) and the result of subtraction is below 0000h (DOCR.DOPSZ = 0) or 0000 0000h (DOCR.DOPSZ = 1).

[Clearing condition]

- Writing 1 to the DOSCR.DOPCFCL bit

46.2.3 DOC Status Clear Register (DOSCR)

Address(es): DOC.DOSCR 000A 0588h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	DOPCFCL
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DOPCFCL	Data Operation Result Clear	0: Retain the value of the DOPCF flag. 1: Clears the DOPCF flag.	W
b7-b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

The DOSCR register is for clearing the DOPCF flag. It is always read as 00h.

DOPCFCL Bit (Data Operation Result Clear)

Writing 1 to this bit clears the DOSR.DOPCF flag.

46.2.4 DOC Data Input Register (DODIR)

Address(es): DOC.DODIR 000A 058Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DODIR register is a readable and writable register that holds values for use in operations.
Access the DODIR register with the data operation size selected by the DOCR.DOPSZ bit.

46.2.5 DOC Data Setting Register 0 (DODSR0)

Address(es): DOC.DODSR0 000A 0590h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DODSR0 register is a readable and writable register that holds values for use in comparison or the results of other operations.
Access the DODSR0 register with the data operation size selected by the DOCR.DOPSZ bit.
In data comparison mode, store the standard value for use in comparison in this register. When either ‘within the range’ (DOCR.DCSEL[2:0] = 100b) or ‘beyond the range’ (DOCR.DCSEL[2:0] = 101b) is selected, specify the lower boundary of the range.
In data addition or data subtraction mode, this register holds the results of operations.

46.2.6 DOC Data Setting Register 1 (DODSR1)

Address(es): DOC.DODSR1 000A 0594h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DODSR1 register is a readable and writable register that holds a value for use in range comparison.
Access the DODSR1 register with the data operation size selected by the DOCR.DOPSZ bit.
When either ‘within the range’ (DOCR.DCSEL[2:0] = 100b) or ‘beyond the range’ (DOCR.DCSEL[2:0] = 101b) is selected in data comparison mode, specify the upper boundary of the range.
This register is only used when either ‘within the range’ or ‘beyond the range’ is selected.

46.3 Operation

46.3.1 Data Comparison Mode

Figure 46.2 to Figure 46.7 show an example of the steps involved in data comparison mode operation by the DOC*1. An example of operation with the operation size of 32 bits is shown below.

(1) Writing 00b to the DOCR.OMS[1:0] bits places the DOC in the data comparison mode. At the same time, write to the DOCR.DCSEL[2:0] bits to select the condition to be detected.
(2) Specify the standard values for comparison in the DODSR0 and DODSR1 registers.*2
(3) Write the value for comparison in the DODIR register.
(4) If the value written to the DODIR register satisfies the condition set in the DOCR.DCSEL[2:0] bits, the DOSR.DOPCF flag becomes 1, and an ELC event is generated. If the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also issued.

Note 1. Comparison is made to proceed at the same time a value is written to the DODIR register. Writing values to the DODSR0 and DODSR1 registers does not make comparison proceed.
Note 2. Setting of the DODSR1 register is only required when either 'within the range' or 'beyond the range' is selected. Set a greater value for the DODSR1 register than that of the DODSR0 register.

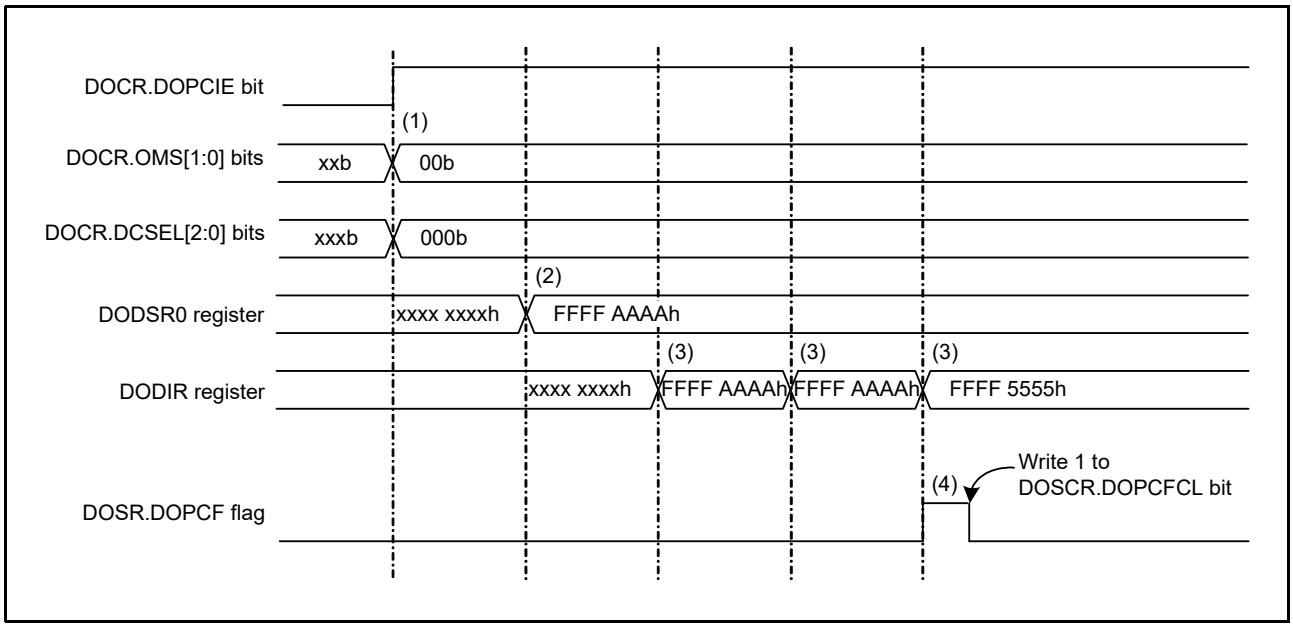


Figure 46.2 Example of the Operation of 'Not Equal to' as the Detection Condition in Data Comparison Mode

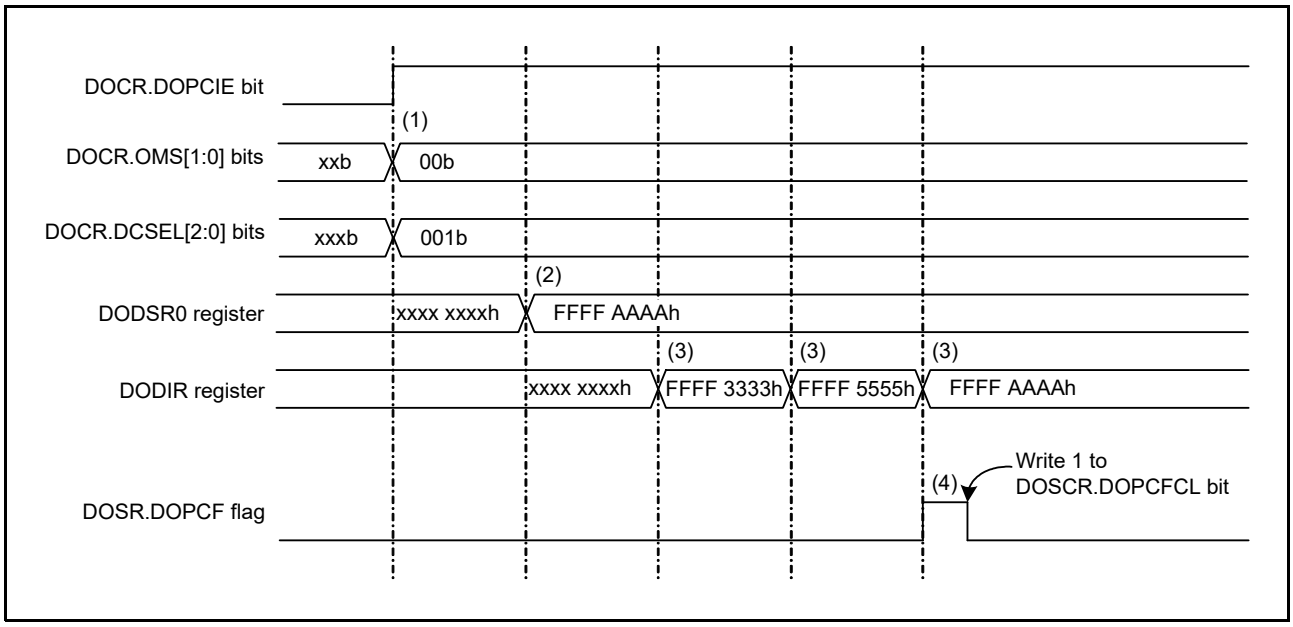

Figure 46.3 Example of the Operation of 'Equal to' as the Detection Condition in Data Comparison Mode

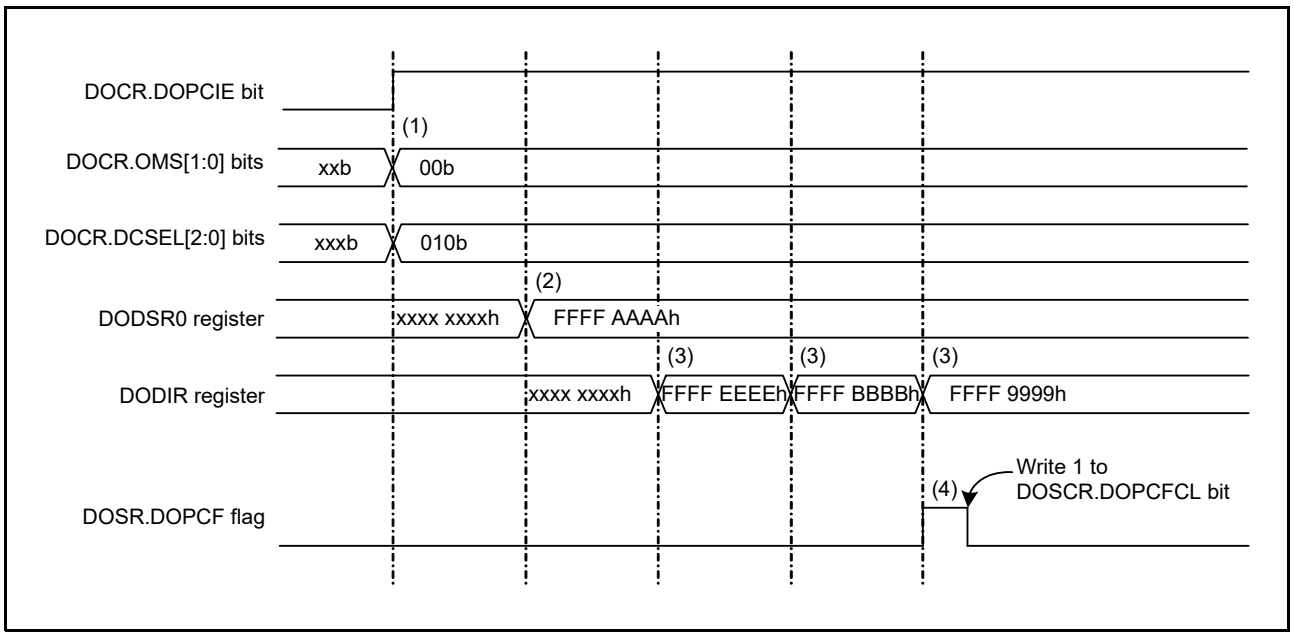

Figure 46.4 Example of the Operation of 'Less Than' as the Detection Condition in Data Comparison Mode

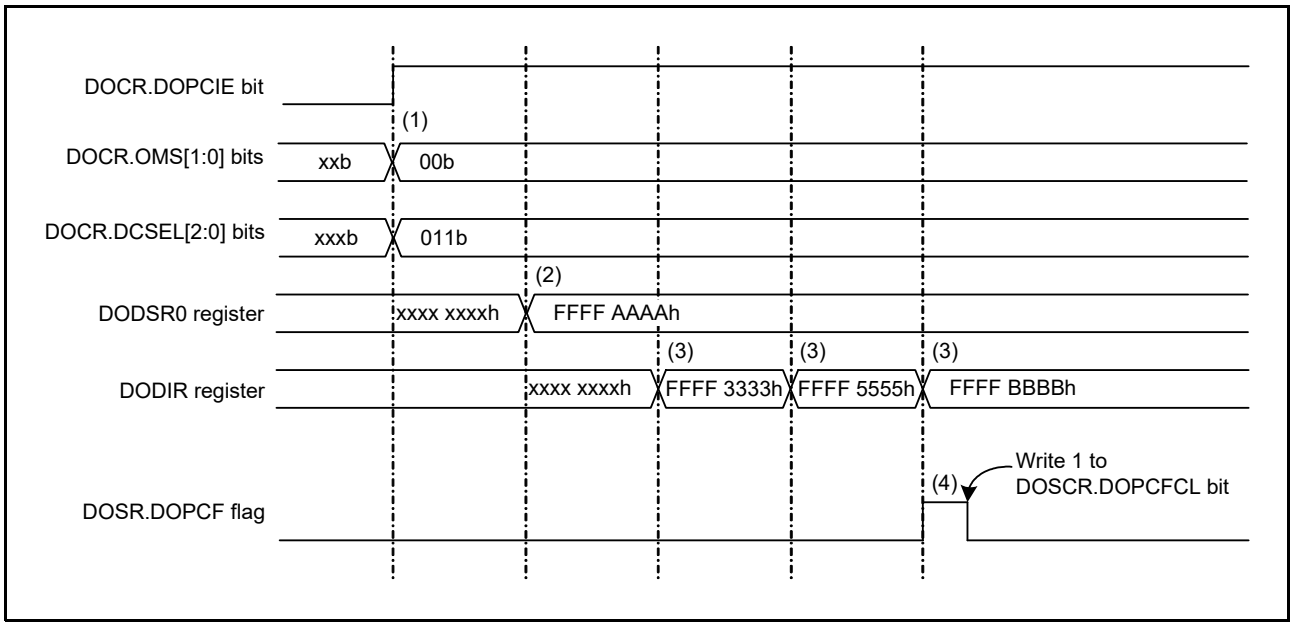

Figure 46.5 Example of the Operation of 'Greater Than' as the Detection Condition in Data Comparison Mode

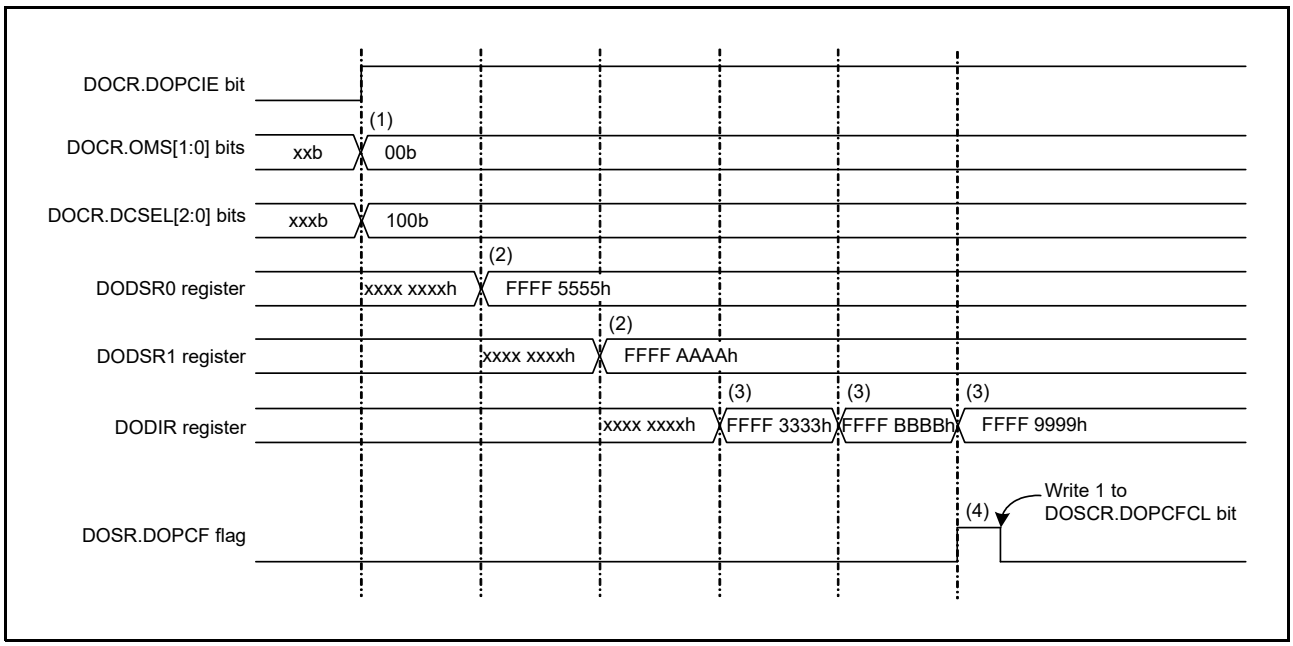

Figure 46.6 Example of the Operation of 'Within the Range' as the Detection Condition in Data Comparison Mode

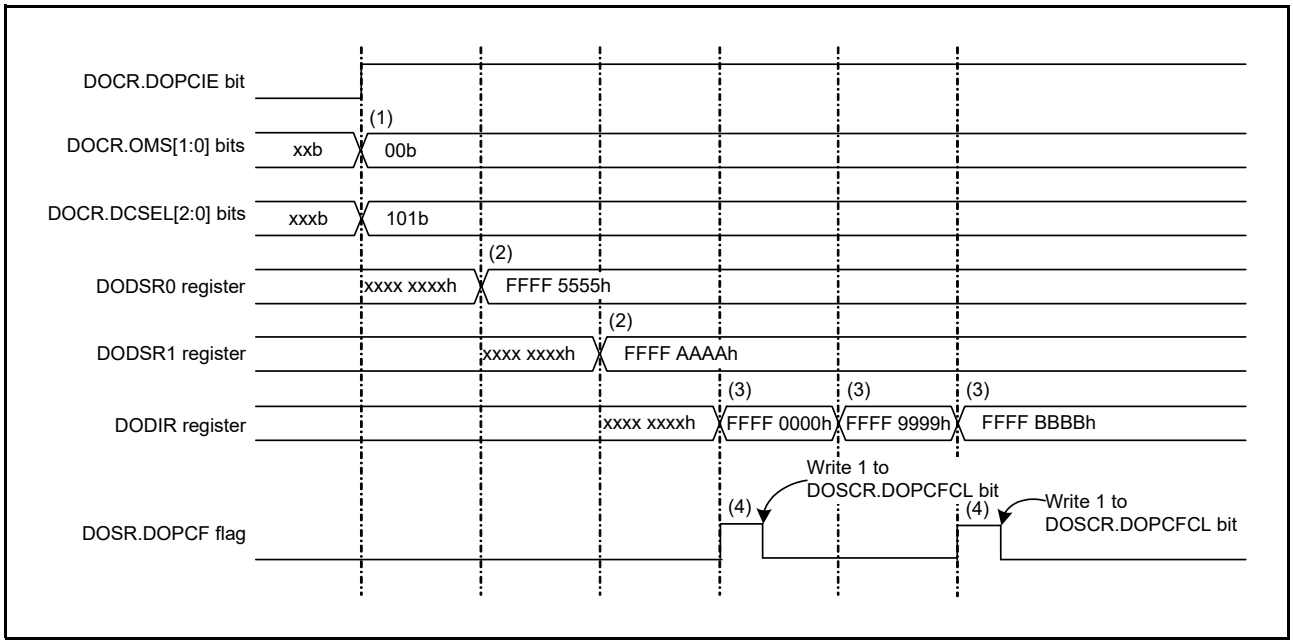

Figure 46.7 Example of the Operation of 'Beyond the Range' as the Detection Condition in Data Comparison Mode

46.3.2 Data Addition Mode

Figure 46.8 shows an example of the steps involved in data addition mode operation*1 by the DOC.
An example of operation when the data operation size is 32 bits is shown below.

(1) Writing 01b to the DOCR.OMS[1:0] bits selects data addition mode.
(2) Set the initial value in the DODSR0 register.
(3) Write the value for addition in the DODIR register. The result of the operation is stored in DODSR0.
(4) Write all values for use in addition to the DODIR register.
(5) If the result of the operation is greater than FFFF FFFFh, the DOSR.DOPCF flag becomes 1, and an ELC event is generated. If the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also issued.

Note 1. Addition is made to proceed at the same time as a value is written to the DODIR register. Writing a value to the DODSR0 register does not make addition proceed.

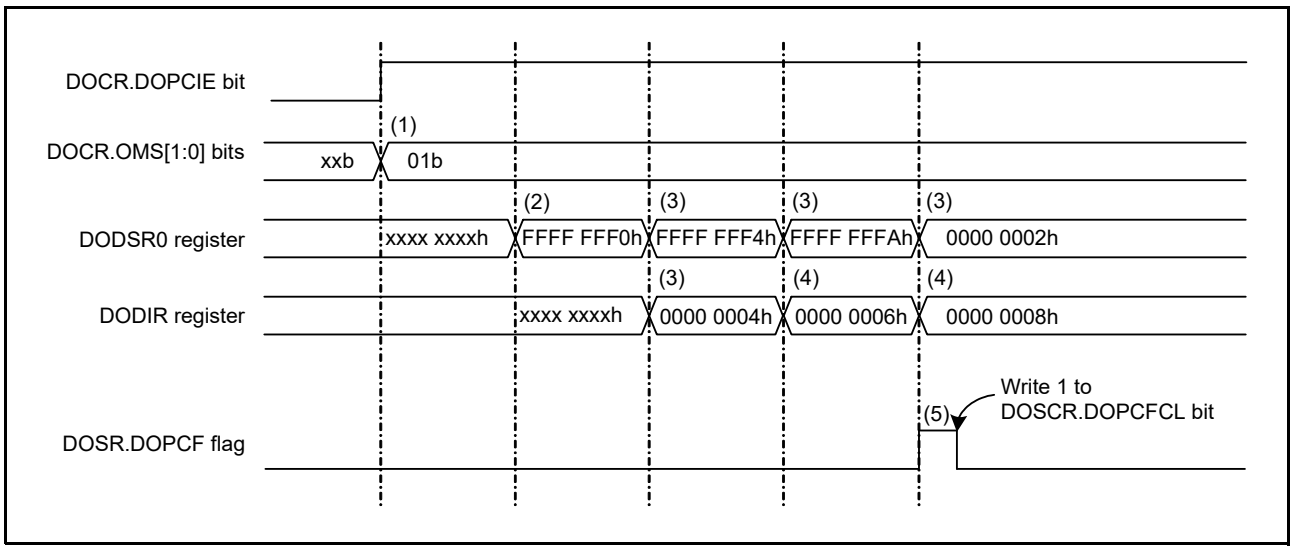

Figure 46.8 Example of Operation in Data Addition Mode

46.3.3 Data Subtraction Mode

Figure 46.9 shows an example of the steps involved in data subtraction mode operation*1 by the DOC.
An example of operation when the data operation size is 32 bits is shown below.

(1) Writing 10b to the DOCR.OMS[1:0] bits selects data subtraction mode.
(2) Set the initial value in the DODSR0 register.
(3) Write the value for subtraction in the DODIR register. The result of the operation is stored in DODSR0.
(4) Write all values for use in subtraction to the DODIR register.
(5) If the result of the operation is less than 0000 0000h, the DOSR.DOPCF flag becomes 1, and an ELC event is generated. If the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also issued.

Note 1. Subtraction is made to proceed at the same time a value is written to the DODIR register. Writing a value to the DODSR0 register does not make subtraction proceed.

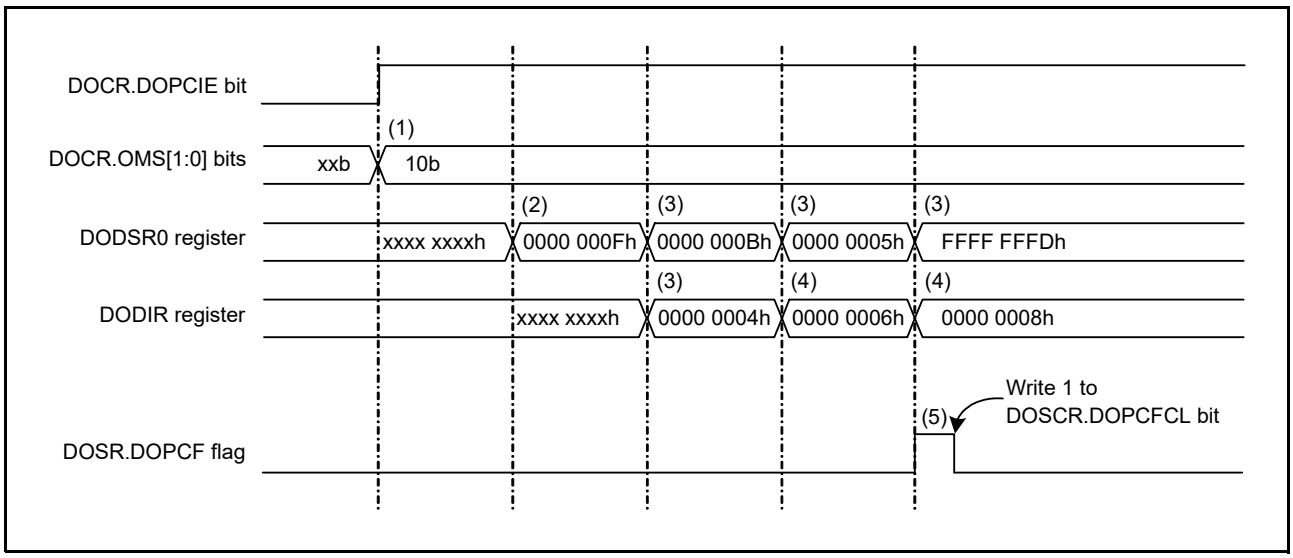

Figure 46.9 Example of Operation in Data Subtraction Mode

46.4 Interrupt Requests

The data operation circuit interrupt (DOPCI) is the interrupt request generated by the DOC. The DOSR.DOPCF flag becomes 1 when the interrupt source condition is satisfied, and an interrupt request is also issued if the DOCR.DOPCIE bit is 1.
Table 46.2 lists the details of the interrupt request.

Table 46.2 Interrupt Request from DOC

Interrupt Request	Data Operation Result Flag	Interrupt Generation Timing
Data operation circuit interrupt (DOPCI)	DOPCF	• The result of data comparison meets the detection condition. • The result of data addition is greater than FFFFh (DOCR.DOPSZ = 0) or FFFF FFFFh (DOCR.DOPSZ = 1). • The result of data subtraction is less than 0000h (DOCR.DOPSZ = 0) or 0000 0000h (DOCR.DOPSZ = 1).

46.5 Event Link Output

The DOC outputs event signals for the event link controller (ELC) under the following conditions, and these can be used to initiate operations by other modules selected in advance.

- The result of data comparison meets the detection condition.
- The result of data addition is greater than FFFFh (DOCR.DOPSZ = 0) or FFFF FFFFh (DOCR.DOPSZ = 1).
- The result of data subtraction is less than 0000h (DOCR.DOPSZ = 0) or 0000 0000h (DOCR.DOPSZ = 1).

46.5.1 Interrupt Handling and Event Linking

The DOC has a bit to enable or disable interrupts. When an interrupt source condition is satisfied while the interrupt is enabled, the interrupt request signal is issued to the CPU.
In contrast, an event link output signal is sent to other modules as an event signal via the ELC when an interrupt source is generated, regardless of the setting of the corresponding interrupt enable bit.

46.6 Usage Note

46.6.1 Module Stop Function Setting

Operation of the DOC can be enabled or disabled by setting the MSTPB6 bit in module stop control register B (MSTPCRB). The DOC is initially disabled after a reset. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

47. RAM

This MCU has a 64-Kbyte high-speed static RAM (RAM), which runs at the frequency of 120 MHz in the no-wait state.

47.1 Overview

Table 47.1 lists the specifications of the RAM.

Table 47.1 Specifications of RAM

Item	RAM
Capacity	64 Kbytes, 48 Kbytes
Address	• Products with 64 Kbytes of RAM 0000 0000h to 0000 FFFFh • Products with 48 Kbytes of RAM 0000 0000h to 0000 BFFFh
Memory bus	Memory bus 1
Access	• Single-cycle access is possible for both reading and writing.*1 • Enabling or disabling of the RAM is selectable.*2
Low power consumption function	Transitions to the module stop state are possible.
Error checking	• Parity check: Detection of 1-bit errors • A non-maskable interrupt or interrupt is generated in response to an error.

Note 1. When accessing across the 8-byte boundary, the number of cycles is doubled.
Note 2. Selectable by the RAME bit in SYSCR1. For details on SYSCR1, see section 3.2.2, System Control Register 1 (SYSCR1).

47.2 Register Descriptions

47.2.1 RAM Operating Mode Control Register (RAMMODE)

Address(es): RAM.RAMMODE 0008 1200h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	RAMMODE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	RAMMODE[1:0]	RAM Operating Mode Select	b1 b0 0 0: Parity checking is disabled. 0 1: Parity checking is enabled. Settings other than above are prohibited.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R

The RAMMODE register is write-protected by the RAM protection register (RAMPRCR). Before writing to the RAMMODE register, set the RAMPRCR.RAMPRCR bit to 1 to enable writing to it. Set the RAMMODE register before starting access to the RAM. If this register is modified after accessing to the RAM, RAM operation is not guaranteed.

47.2.2 RAM Error Status Register (RAMSTS)

Address(es): RAM.RAMSTS 0008 1201h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	RAMERR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RAMERR	RAM Error Status Flag	0: A parity check error has not occurred. 1: A parity check error has occurred.	R/(W)*1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Only 0 can be written to clear the flag.

When parity checking is enabled, the RAMERR flag is set to 1 if a parity check error is detected. The RAM error interrupt request is also generated at this time.
When parity checking is disabled, the RAMERR flag is not set to 1 because no parity check error is detected.
Writing 0 to the RAMERR flag clears the RAM error interrupt request corresponding to the parity check error.

47.2.3 RAM Error Address Capture Register (RAMECAD)

Address(es): RAM.RAMECAD 0008 1208h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	READ		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	READ													—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	—	Reserved	These bits are read as 0.	R
b18 to b3	READ	Error Address	The address where an error is found is read.	R
b31 to b19	—	Reserved	These bits are read as 0.	R

When parity checking is enabled, this register will hold the address where a parity check error was found.
The address of the 8-byte boundary below the location where the error was found is stored in this register at the same time the RAMSTS.RAMERR flag is set to 1.
The error address is not updated when the RAMERR flag is 1 (error has occurred). Its value does not change when parity checking is disabled because no parity check error is detected.
The RAMECAD register is initialized only by a reset.

47.2.4 RAM Protection Register (RAMPRCR)

Address(es): RAM.RAMPRCR 0008 1204h

	b7	b6	b5	b4	b3	b2	b1	b0
	KW[6:0]							RAMPRCR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RAMPRCR	RAMMODE Register Write Control	0: Disables writing to the RAMMODE register. 1: Enables writing to the RAMMODE register.	R/W
b7 to b1	KW[6:0]	Write Key Word	Enables or disables the rewriting of the RAMPRCR register. When rewriting the RAMPRCR register, write 1111000b to the KW[6:0] bits.	R/W

Writing 1 to the RAMPRCR bit is possible when KW[6:0] = 1111000b. Otherwise writing to RAMPRCR clears the bit to 0. The value of KW[6:0] is read as 0000000b.
The targets for write protection by the RAMPRCR register is the RAM operating mode control register (RAMMODE). Once the RAMPRCR bit is set to 1, writing to RAMMODE register is enabled until the RAMPRCR bit is cleared to 0. Clear the RAMPRCR bit to 0 after writing to RAMMODE register.

47.3 Operation

47.3.1 Parity Checking

Enabling and disabling of parity checking can be selected through the RAMMODE register setting. In the initial state, parity checking is disabled. Even parity checking is used in this device.
1-bit parity check code is added to each 1-byte data for writing, and the parity is checked for reading.
If a 1-bit error is detected in the 1 byte when the parity is checked for reading, a RAM error interrupt can be generated. If a 2-bit error or more is detected in the 1 byte, errors cannot be correctly detected.
After power-on, parity check code is undefined until data is written. To use parity checking, write the initial value to all areas while parity checking is enabled before accessing to the RAM immediately after a reset.
Operation cannot be guaranteed if access is made to an area where the initial value is not written.

47.3.2 RAM Error Interrupt Function

A RAM error interrupt is generated when the RAMSTS.RAMERR bit that indicates a parity check error has been changed to 1 while parity checking is enabled.
Writing 0 to the bit clears the RAM interrupt.

47.3.3 Interrupt Source

Of the RAM interrupt sources, that due to the detection of an error through parity checking can be used as either a non-maskable interrupt or a maskable interrupt. For details, see section 14, Interrupt Controller (ICUG).

Table 47.2 RAM Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
RAMERR	RAM error	Not possible	Not possible

47.4 Usage Notes

47.4.1 Low Power Consumption Function

Power consumption can be reduced by setting module stop control register C (MSTPCRC) to stop supply of the clock signal to the RAM.
Setting the MSTPCRC.MSTPC0 bit to 1 stops supply of the clock signal to the RAM.
Stopping supply of the clock signal places the RAM in the module stop state.
The RAM operates after a reset.
The RAM is not accessible in the module stop state.
Do not allow transitions to the module stop state while accessing to the RAM.
Access to the RAM in the module stop state is prohibited. If access is attempted, correct operation is not guaranteed.
For details on the MSTPCRC register, refer to section 11, Low Power Consumption.

47.4.2 Notes on Using Error Checking of RAM

Data in RAM are undefined when the power is turned on. Therefore, parity check errors occur if the data are read before initialization. The RAM is read in 8-byte (64-bit) units. Initialize it on 8-byte boundaries.
When a program is executed in the RAM with the parity check enabled, initialize the RAM in consideration of possible instruction prefetching by the CPU. Instruction prefetching can be performed up to 32 bytes. The initialization must thus cover extra 24 to 31 bytes from the last address of the program.

47.4.3 Notes on Self-Diagnosis of the RAM

A write buffer is mounted for the RAM. When the same address is read after a write operation, data in the write buffer, rather than in the memory cell of the RAM may be read. When the RAM is self-diagnosed, confirm that the data have been written by following the procedure below so that data will not be read from the write buffer.

(1) Write data to the address targeted for diagnosis.
(2) Write data to an address which is at least 4 addresses away from the that in (1).
(3) Read the data from the address in (1).

48. Flash Memory (FLASH)

This MCU incorporates code flash memory, data flash memory, and option-setting memory.
The code flash memory stores instructions and operands, and the data flash memory stores only data. For option-setting memory, refer to section 7, Option-Setting Memory (OFSM).

48.1 Overview

Table 48.1 lists the specifications of the code flash memory/data flash memory, and Figure 48.1 is a block diagram of the flash memory related modules.
The I/O pins used in boot mode, refer to Table 48.18.
The flash sequencer controls the program and erase operation of the flash memory. The FACI (flash application command interface) controls the flash sequencer according to the specified FACI commands.
Regarding the configuration of the code flash memory, refer to Figure 48.2, and for the configuration of the data flash memory, refer to Figure 48.4.

Table 48.1 Specifications of Code Flash Memory and Data Flash Memory

Item	Code Flash Memory	Data Flash Memory
Memory capacity	Up to 512 Kbytes	16 Kbytes
Read cycle	One cycle	A read operation takes eight cycles of FCLK in 16- or 8-bit access
Value after erase	FFh	Undefined
Program/erase method	• Code flash memory and data flash memory can be programmed or erased with the FACI commands set in the FACI command issuing area (007E 0000h). • Program/erase via a serial interface transfer by a flash-memory programmer (serial programming) • Program/erase of flash memory by user program (self-programming)	
Security function	Protects against illicit tampering with or reading out of data in flash memory	
Protection function	Protects against erroneous rewriting of the flash memory	
Dual bank function	The dual-bank structure makes a safe update possible in cases where program operation is suspended. • Linear mode: the code flash memory is used as one area • Dual mode: the code flash memory is divided into two areas	Not available
Trusted memory (TM) function	Protects against illicit reading of the code flash memory • Linear mode: blocks 8 and 9 • Dual mode: blocks 8, 9, 30, and 31	Not available
Background operations (BGOs)*1	• The code flash memory can be read while the code flash memory is being programmed or erased.*2 • The data flash memory can be read while the code flash memory is being programmed or erased. • The code flash memory can be read while the data flash memory is being programmed or erased.	
Program/erase unit	• Program unit: 128 bytes • Erase unit: per block	• Program unit: 4 bytes • Erase unit: per block
Other functions	Interrupts can be accepted during self-programming.	
On-board programming (serial programming/ self-programming)	Program/erase in boot mode (SCI interface) • The asynchronous serial interface (SCI1) is used. • The transfer rate is adjusted automatically. Program/erase in boot mode (FINE interface) • FINE is used. Program/erase in single-chip mode • Code flash memory and data flash memory can be programmed or erased by the rewrite routine in the user program.	
Unique ID	A 12-byte ID code provided for each MCU	

Note 1. The BGO function cannot be used to rewrite the configuration setting area.
Note 2. Limitations apply to the combinations of the address ranges for program/erase process and reading process. Refer to Table 48.24.

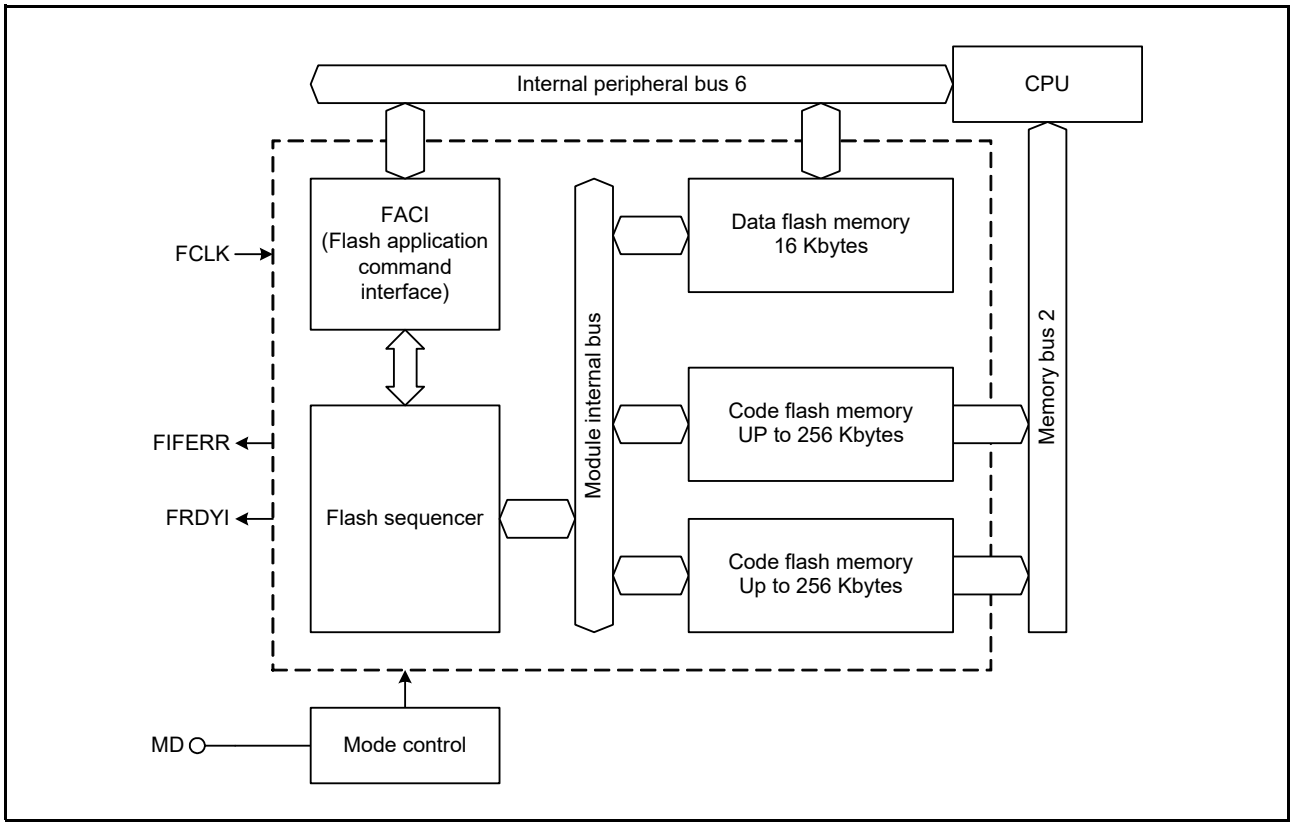

Figure 48.1 Block Diagram of Flash Memory Related Modules

48.2 Hardware Interface Area

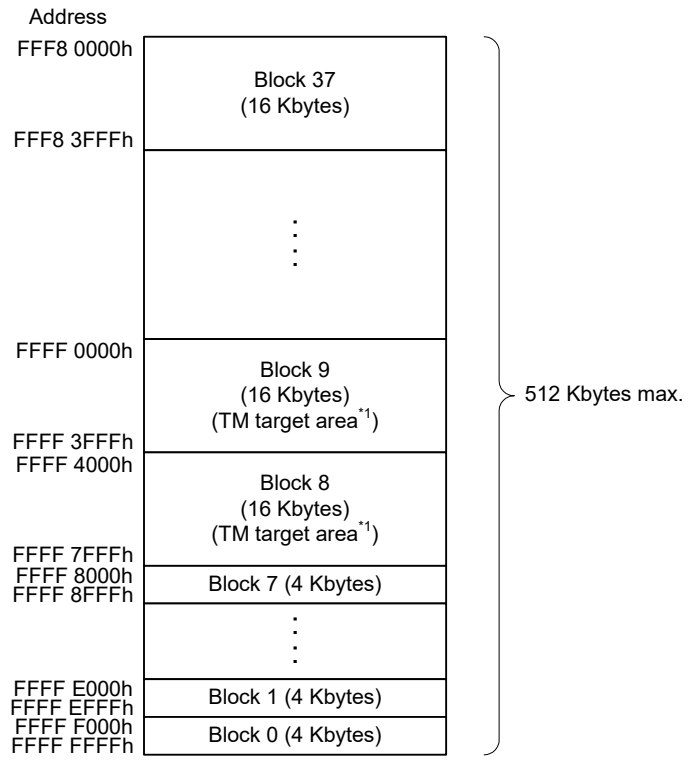
Using the hardware interface with the flash memory requires accessing to the area containing registers of the hardware, that for the issuing of FACI commands. Table 48.2 summarizes information on all of these areas.

Table 48.2 Information on the Hardware Interface Area

Area	Address	Capacity
Area containing the various registers of the hardware	Refer to section 48.4, Register Descriptions.	Refer to section 48.4, Register Descriptions.
FACI command-issuing area	007E 0000h	4 bytes
Configuration setting area	0012 0040h to 0012 00FFh	192 bytes

48.3 Structure of Memory

Figure 48.2 shows the mapping of the code flash memory in linear mode. Figure 48.3 show the memory map of code flash memory in dual mode. The code flash memory can be used as 2 bank areas by using the dual bank function. This dual-bank structure allows a safe update of a program while a user program is running.
The code flash memory in this MCU is divided into 4- and 16-Kbyte blocks, which are used as erase units. The code flash memory is available as an area for storing the user program.
When the TM function is enabled in linear mode, blocks 8 and 9 are the TM target areas.

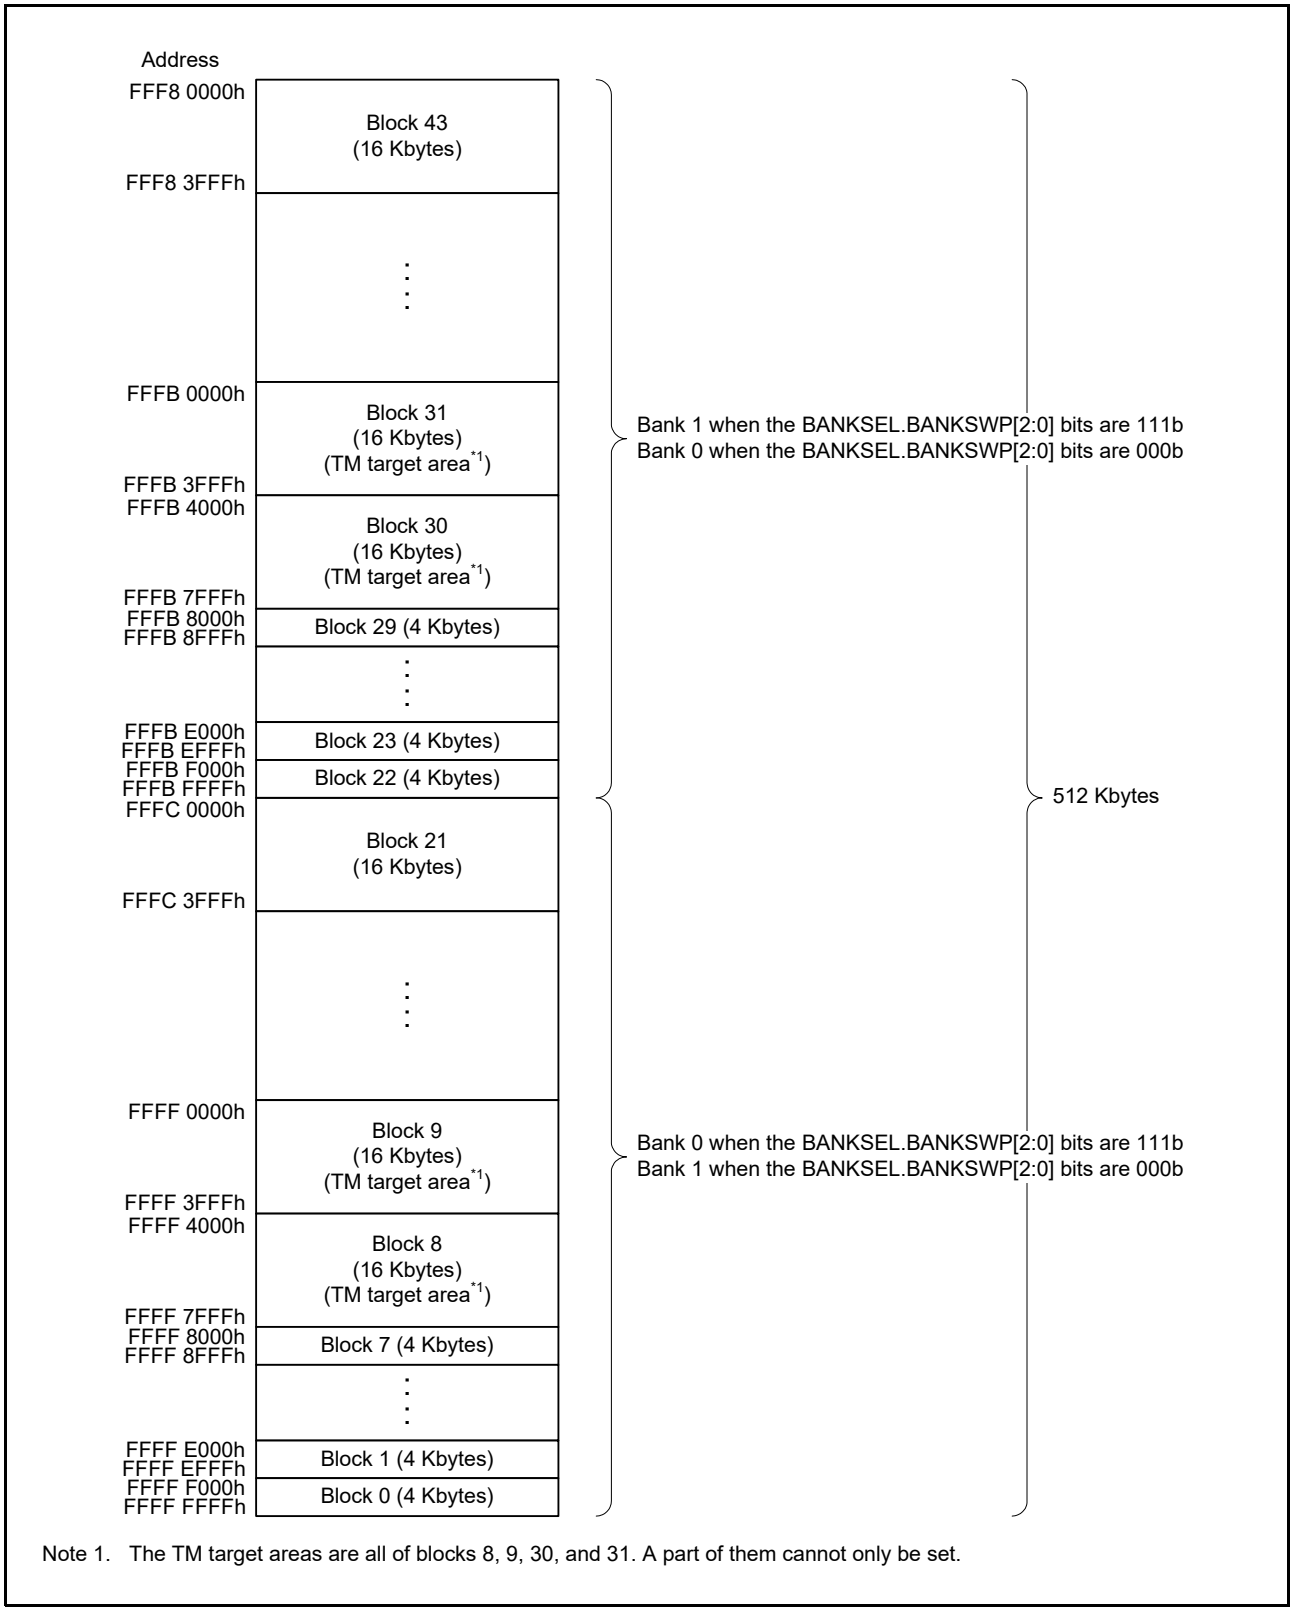


Code Flash Memory Capacity	Address	Number of Blocks
512 Kbyte	FFF8 0000h to FFFF FFFFh	0 to 37
256 Kbytes	FFFC 0000h to FFFF FFFFh	0 to 21
128 Kbytes	FFFE 0000h to FFFF FFFFh	0 to 13

Note 1. Both blocks 8 and 9 are the target areas for handling as TM. Setting only block 8 or only block 9 is not allowed.

Figure 48.2 Mapping of the Code Flash Memory in Linear Mode

When the TM function is enabled in dual mode, blocks 8 and 9, and blocks 30 and 31 are the TM target areas.



Note 1. The TM target areas are all of blocks 8, 9, 30, and 31. A part of them cannot only be set.

Figure 48.3 Mapping of the Code Flash Memory in Dual Mode (Products with 512 Kbytes of code flash memory)

The data flash memory in this MCU is divided into 64-byte blocks, each of which is an erase unit. Figure 48.4 shows the mapping of the data flash memory.

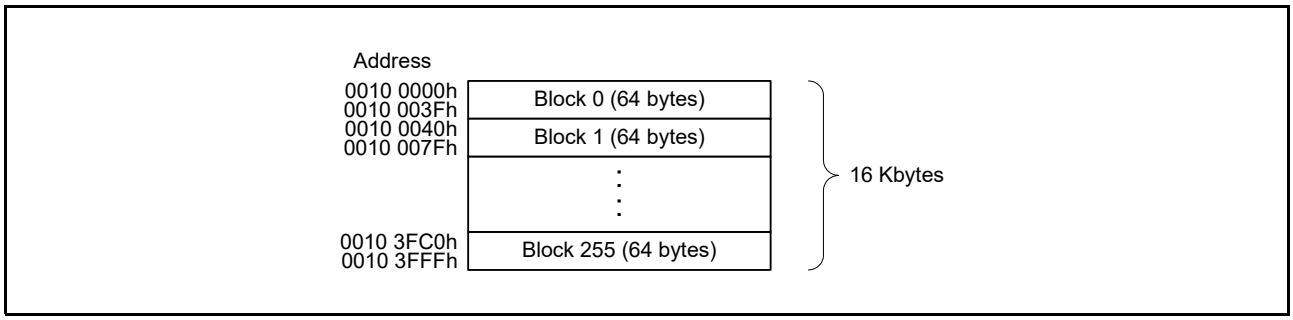


Figure 48.4 Mapping of the Data Flash Memory

48.4 Register Descriptions

48.4.1 Flash P/E Protect Register (FWEPROR)

Address(es): FLASH.FWEPROR 0008 C296h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	FLWE[1:0]	
Value after reset:	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	FLWE[1:0]	Flash Program/Erase Enable	b1 b0 0 0: Program, block erase, and blank check are disabled. 0 1: Program, block erase, and blank check are enabled. 1 0: Program, block erase, and blank check are disabled. 1 1: Program, block erase, and blank check are disabled.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register enables or disables the following three FACI commands for flash memory: program, block erase, and blank check.
This register is initialized not only by a reset but also by a transition to software standby mode.

48.4.2 Flash Access Status Register (FASTAT)

Address(es): FLASH.FASTAT 007F E010h

	b7	b6	b5	b4	b3	b2	b1	b0
	CFAE	—	—	CMDLK	DFAE	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b3	DFAE	Data Flash Memory Access Violation Flag	0: No data flash memory access violation has occurred. 1: A data flash memory access violation has occurred.	R/W*1
b4	CMDLK	Command Lock Flag	0: The flash sequencer is not in the command-locked state. 1: The flash sequencer is in the command-locked state.	R
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	CFAE	Code Flash Memory Access Violation Flag	0: No code flash memory access violation has occurred. 1: A code flash memory access violation has occurred.	R/W*1

Note 1. Only 0 can be written to clear the flag after 1 is read.

This register indicates whether a code flash memory or data flash memory access violation has occurred. If either of the CFAE, and DFAE flags is 1, the CMDLK flag is set to 1 and the flash sequencer enters the command-locked state (refer to section 48.5.3.2, Error Protection). To release it from the command-locked state, a status clear command or forced stop command must be issued by the FACI after clearing the CFAE and DFAE flags in the FASTAT register to 0.

DFAE Flag (Data Flash Memory Access Violation Flag)

This flag indicates whether a data flash memory access violation has occurred. If this flag is set to 1, the FSTATR.ILGLERR flag is set to 1, placing the flash sequencer in the command-locked state.

[Setting Condition]

- Refer to Table 48.10, Error Protection Type

[Clearing Condition]

- When 0 is written after reading of 1

CMDLK Flag (Command Lock Flag)

This flag indicates that the flash sequencer is in the command-locked state.

[Setting Condition]

- When the flash sequencer detects any of errors listed in Table 48.10, Error Protection Type and transitions to the command-locked state

[Clearing Condition]

- When the flash sequencer starting to process a status clear or forced stop command while the CFAE or DFAE flag in the FASTAT register is 0

CFAE Flag (Code Flash Memory Access Violation Flag)

This flag indicates whether a code flash memory access violation has occurred. If this flag is set to 1, the FSTATR.ILGLERR flag is set to 1, placing the flash sequencer in the command-locked state.

[Setting Conditions]

- Refer to Table 48.10, Error Protection Type

[Clearing Condition]

- When 0 is written after reading of 1

48.4.3 Flash Access Error Interrupt Enable Register (FAEINT)

Address(es): FLASH.FAEINT 007F E014h

	b7	b6	b5	b4	b3	b2	b1	b0
	CFAEIE	—	—	CMDLKIE	DFAEIE	—	—	—
Value after reset:	1	0	0	1	1	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	After a reset is released, write 0 to this bit.	R/W
b2, b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b3	DFAEIE	Data Flash Memory Access Violation Interrupt Enable	0: Generation of an FIFERR interrupt request is disabled when FASTAT.DFAE is set to 1. 1: Generation of an FIFERR interrupt request is enabled when FASTAT.DFAE is set to 1.	R/W
b4	CMDLKIE	Command Lock Interrupt Enable	0: Generation of an FIFERR interrupt request is disabled when FASTAT.CMDLK is set to 1. 1: Generation of an FIFERR interrupt request is enabled when FASTAT.CMDLK is set to 1.	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	CFAEIE	Code Flash Memory Access Violation Interrupt Enable	0: Generation of an FIFERR interrupt request is disabled when FASTAT.CFAE is set to 1. 1: Generation of an FIFERR interrupt request is enabled when FASTAT.CFAE is set to 1.	R/W

This register enables or disables generation of a flash access error (FIFERR) interrupt request.

DFAEIE Bit (Data Flash Memory Access Violation Interrupt Enable)

This bit enables or disables generation of an FIFERR interrupt request when a data flash memory access violation occurs and the FASTAT.DFAE flag is set to 1.

CMDLKIE Bit (Command Lock Interrupt Enable)

This bit enables or disables generation of an FIFERR interrupt request when the flash sequencer enters the command-locked state and the FASTAT.CMDLK flag is set to 1.

CFAEIE Bit (Code Flash Memory Access Violation Interrupt Enable)

This bit enables or disables generation of an FIFERR interrupt request when a code flash memory access violation occurs and the FASTAT.CFAE flag is set to 1.

48.4.4 Flash Ready Interrupt Enable Register (FRDYIE)

Address(es): FLASH.FRDYIE 007F E018h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	FRDYIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	FRDYIE	Flash Ready Interrupt Enable	0: Generation of an FRDY interrupt request is disabled. 1: Generation of an FRDY interrupt request is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

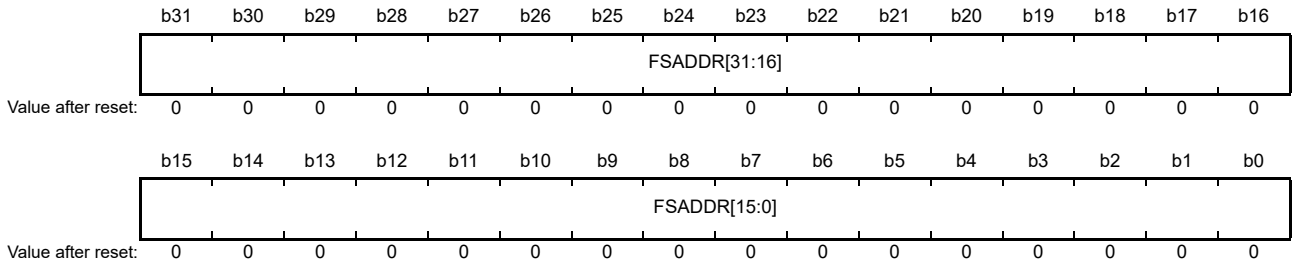
This register enables or disables generation of a flash ready (FRDY) interrupt request.

FRDYIE Bit (Flash Ready Interrupt Enable)

This bit is used to enable or disable generation of an FRDY interrupt request when the FASTAT.FRDY flag is changed from 0 to 1 upon completion of processing by the flash sequencer of program, block erase, and blank check command.

48.4.5 FACI Command Processing Start Address Register (FSADDR)

Address(es): FLASH.FSADDR 007F E030h



Bit	Symbol	Bit Name	Description	R/W
b31 to b0	FSADDR[31:0]	FACI Command Processing Start Address	Start Address for FACI Command Processing	R/W*1

Note 1. Writing to these bits is possible only when the FSTATR.FRDY flag is 1. Writing to these bits while the FSTATR.FRDY flag = 0 is ignored. The value of the lower 2 bits (b1 and b0) is fixed to 00b.

This register specifies the address where the target area for command processing starts when the FACI command for program, block erase, blank check, or configuration set is issued.
The FSADDR register is initialized when the FSUINITR.SUINIT bit is set to 1. It is also initialized by a reset.

FSADDR[31:0] Bits (FACI Command Processing Start Address)

These bits specify the start address for FACI command processing. Bits 31 to 24 are ignored in FACI command processing for the code flash memory. Bits 31 to 19 are ignored in FACI command processing for the data flash memory. Bits that do not reach the address boundaries are also ignored. Table 48.3 shows the address boundary for each command.

Table 48.3 Address Boundary for Each of the Commands

Command	Address Boundary
Program (code flash memory)	128-byte
Program (data flash memory)	4-byte
Block erase (code flash memory)	4-Kbyte or 16-Kbyte
Block erase (data flash memory)	64-byte
Blank check	4-byte
Configuration set	16-byte

Refer to Table 48.17, Address Used by Configuration Set Command for the start address of the configuration setting area.

48.4.6 FACI Command Processing End Address Register (FEADDR)

Address(es): FLASH.FEADDR 007F E034h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	FEADDR[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	FEADDR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	FEADDR[31:0]	FACI Command Processing End Address	The end address for FACI command processing	R/W*1

Note 1. Writing to these bits is possible only when the FSTATR.FRDY flag is 1. Writing to these bits while the FSTATR.FRDY flag = 0 is ignored. The value of the lower 2 bits (b1 and b0) is fixed to 00b.

This register is used to specify the end address of the area targeted for the blank check command handling. When the FBCCNT.BCDIR bit is 0, the setting value of the FSADDR register must be the setting of the FEADDR register or lower. When the FBCCNT.BCDIR bit is 1, the value of the FSADDR register must be at least that of the FEADDR register. If the settings of the FBCCNT.BCDIR bit and the FSADDR and FEADDR registers are inconsistent with the above rules, the flash sequencer enters the command-locked state (refer to section 48.5.3.2, Error Protection).
The FEADDR register is initialized when the FSUINITR.SUINIT bit is set to 1. It is also initialized by a reset.

FEADDR[31:0] Bits (FACI Command Processing End Address)

These bits are used to specify the end address for handling of the blank check command. In command processing, bits 31 to 19, 1, and 0 are ignored.

48.4.7 Flash Status Register (FSTATR)

Address(es): FLASH.FSTATR 007F E080h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	FRDY	ILGLERR	ERSERR	PRGERR	SUSRDY	DBFULL	ERSSPD	PRGSPD	—	FLWEERR	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	FLWEERR	Flash P/E Protection Error Flag	0: An error has not occurred. 1: An error has occurred.	R
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b8	PRGSPD	Program Suspend Status Flag	0: The flash sequencer is in a state other than those corresponding to the value 1. 1: The flash sequencer is in the program suspend processing state or the program-suspended state.	R
b9	ERSSPD	Erase Suspend Status Flag	0: The flash sequencer is in a state other than those corresponding to the value 1. 1: The flash sequencer is in the erase suspend processing state or the erase-suspended state.	R
b10	DBFULL	Data Buffer Full Flag	0: The data buffer is empty. 1: The data buffer is full.	R
b11	SUSRDY	Suspend Ready Flag	0: The flash sequencer cannot receive P/E suspend commands. 1: The flash sequencer can receive P/E suspend commands.	R
b12	PRGERR	Program Error Flag	0: Program operation has been completed successfully. 1: An error has occurred during program operation.	R
b13	ERSERR	Erase Error Flag	0: Erase operation has been completed successfully. 1: An error has occurred during erase operation.	R
b14	ILGLERR	Illegal Command Error Flag	0: The flash sequencer has not detected an illegal FACI command or illegal flash memory access. 1: The flash sequencer has detected an illegal FACI command or illegal flash memory access.	R
b15	FRDY	Flash Ready Flag	0: Programming, block erase, P/E suspend, P/E resume, forced stop, blank check, or configuration set command processing is in progress. 1: None of the above is in progress.	R
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register indicates the state of the flash sequencer.

FLWEERR Flag (Flash P/E Protection Error Flag)

This flag indicates a violation of the flash memory program/erase protection setting in the FWEPROR register. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting Condition]

- Refer to Table 48.10, Error Protection Type

[Clearing Condition]

- When the flash sequencer starts processing of a forced stop command

PRGSPD Flag (Program Suspend Status Flag)

This flag indicates that the flash sequencer is in the processing of program suspend or has transitioned to the program-suspended state.

[Setting Condition]

- When the flash sequencer starts processing in response to a program suspend command

[Clearing Conditions]

- When the flash sequencer has received a P/E resume command
  (after write access to the FACI command-issuing area is completed)
- When the flash sequencer starts processing of a forced stop command

ERSSPD Flag (Erase Suspend Status Flag)

This flag indicates that the flash sequencer is the processing of erase suspend or has transitioned to the erase-suspended state.

[Setting Condition]

- When the flash sequencer starts processing in response to an erase suspend command

[Clearing Conditions]

- Reception of the P/E resume command by the flash sequencer
  (after write access to the FACI command-issuing area is completed)
- When the flash sequencer starts processing of a forced stop command

DBFULL Flag (Data Buffer Full Flag)

This flag indicates the state of the data buffer when a program command is issued. The FACI incorporates a buffer for write data (data buffer). When data for writing to the flash memory are issued to the FACI command-issuing area while the data buffer is full, the FACI inserts a wait cycle in the peripheral bus 6.

[Setting Condition]

- When the data buffer becomes full while a program command is being issued

[Clearing Condition]

- When the data buffer becomes empty

SUSRDY Flag (Suspend Ready Flag)

This flag indicates whether the flash sequencer can receive a P/E suspend command.

[Setting Condition]

- When the flash sequencer is ready to accept the P/E suspend command after the program or erase sequence has started

[Clearing Conditions]

- When the flash sequencer has accepted the P/E suspend command or forced stop command (after write access to the FACI command-issuing area is completed)
- When the flash sequencer enters the command-locked state during program or erase operation
- When program or erase operation has been completed

PRGERR Flag (Program Error Flag)

This flag indicates the result of programming the flash memory. If this flag is 1, the flash sequencer is in the command-locked state.

[Setting Condition]

- Refer to Table 48.10, Error Protection Type

[Clearing Condition]

- When the flash sequencer starts processing of a status clear or forced stop command

ERSERR Flag (Erase Error Flag)

This flag indicates the result of erasing the flash memory. If this flag is 1, the flash sequencer is in the command-locked state.

[Setting Condition]

- Refer to Table 48.10, Error Protection Type

[Clearing Condition]

- When the flash sequencer starts processing of a status clear or forced stop command

ILGLERR Flag (Illegal Command Error Flag)

This flag indicates that the flash sequencer has detected an illegal FACI command or flash memory access. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting Condition]

- Refer to Table 48.10, Error Protection Type

[Clearing Condition]

- When the flash sequencer starts processing of a status clear or forced stop command while the DFAE and CFAE flag in the FASTAT register is 0

If the flash sequencer completes processing of a status clear or forced stop command while the CFAE or DFAE flag in the FASTAT register is 1, this flag is set to 1. This flag is temporarily set to 0 during processing of a forced stop command, and is re-set to 1 when the CFAE or DFAE flag is detected as 1 upon completion of command processing.

FRDY Flag (Flash Ready Flag)

This flag indicates the command processing state of the flash sequencer.

[Setting Conditions]

- When the flash sequencer completes command processing
- When the flash sequencer receives a P/E suspend command and suspends program or erase sequence to the flash memory
- When the flash sequencer has received a forced stop command and ended command processing

[Clearing Conditions]

- When the flash sequencer receives the FACI command of the setting of the program and configuration and after the first write access is made to the FACI command-issuing area
- When the flash sequencer receives any FACI command other than of the setting of the program and configuration and after the last write access is made to the FACI command issuing area

48.4.8 Flash P/E Mode Entry Register (FENTRYR)

Address(es): FLASH.FENTRYR 007F E084h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								FENTRYD	—	—	—	—	—	—	FENTRYC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	FENTRYC	Code Flash Memory P/E Mode Entry	0: Code flash memory is in read mode. 1: Code flash memory is in P/E mode.	R/W*1, *2
b6 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	FENTRYD	Data Flash Memory P/E Mode Entry	0: Data flash memory is in read mode. 1: Data flash memory is in P/E mode.	R/W*1, *2
b15 to b8	KEY[7:0]	Key Code	Key code	R/W*3

Note 1. Writing to these bits is possible only when the FSTATR.FRDY flag is 1. Writing to these bits while the FSTATR.FRDY flag = 0 is ignored.
Note 2. Writing to this bit is enabled only when this register is written in 16-bit units with the KEY[7:0] bits set to AAh.
Note 3. Written values are not retained by these bits. These bits are read as 0.

This register is used to specify code flash memory P/E mode and data flash memory P/E mode. To specify code flash memory P/E mode or data flash memory P/E mode so that the flash sequencer can receive FACI commands, set either the FENTRYD or FENTRYC bit to 1 to place the flash sequencer in P/E mode.
Note that writing AA81h in this register causes the FSTATR.ILGLERR flag to be set to 1, and the flash sequencer to enter the command-locked state.
The FENTRYR register is initialized when the FSUINITR.SUINIT bit is set to 1. It is also initialized by a reset.

FENTRYC Bit (Code Flash Memory P/E Mode Entry)

This bit specifies the P/E mode for code flash memory.
[Setting Condition]

- When AA01h is written to the FENTRYR register while the FSTATR.FRDY flag is 1 and the FENTRYR register is 0000h

[Clearing Conditions]

- When the FENTRYR register is written in 8-bit units while the FSTATR.FRDY flag is 1
- When the FENTRYR register is written in 16-bit units with the KEY[7:0] bits set to a value other than AAh while the FSTATR.FRDY flag is 1
- When AA00h is written to the FENTRYR register while the FSTATR.FRDY flag is 1
- When the FENTRYR register is written while the FSTATR.FRDY flag is 1 and the FENTRYR register is not 0000h

FENTRYD Bit (Data Flash Memory P/E Mode Entry)

This bit specifies the P/E mode for data flash memory.
[Setting Condition]

- When AA80h is written to the FENTRYR register while the FSTATR.FRDY flag is 1 and the FENTRYR register is 0000h

[Clearing Conditions]

- When the FENTRYR register is written in 8-bit units while the FSTATR.FRDY flag is 1
- When the FENTRYR register is written in 16-bit units with the KEY[7:0] bits set to a value other than AAh while the FSTATR.FRDY flag is 1

- When AA00h is written to the FENTRYR register while the FSTATR.FRDY flag is 1
- When the FENTRYR register is written while the FSTATR.FRDY flag is 1 and the FENTRYR register is not 0000h

KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the FENTRYD and FENTRYC bits.

48.4.9 Flash Sequencer Set-Up Initialization Register (FSUINITR)

Address(es): FLASH.FSUINITR 007F E08Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	SUINIT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SUINIT	Set-Up Initialization	0: The FEADDR, FCPSR, FSADDR, FENTRYR, and FBCCNT flash sequencer set-up registers keep their current values. 1: The FEADDR, FCPSR, FSADDR, FENTRYR, and FBCCNT flash sequencer set-up registers are initialized.	R/W*1, *2
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	Key code	R/W*3

Note 1. Writing to these bits is possible only when the FSTATR.FRDY flag is 1. Writing to these bits while the FSTATR.FRDY flag = 0 is ignored.
Note 2. Writing to these bits is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to 2Dh.
Note 3. Written values are not retained by these bits. These bits are read as 0.

This register is used for initialization of the flash sequencer set-up.

SUINIT Bit (Set-Up Initialization)

This bit initializes the following flash sequencer set-up registers.

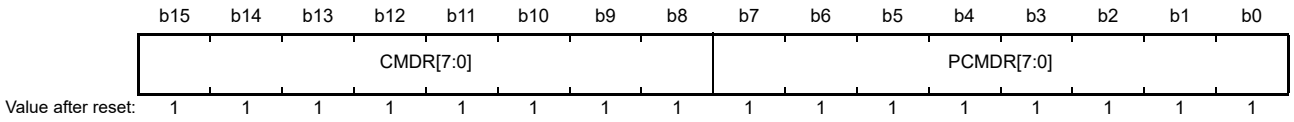
- FEADDR
- FCPSR
- FSADDR
- FENTRYR
- FBCCNT

KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the SUINIT bit.

48.4.10 FACI Command Register (FCMDR)

Address(es): FLASH.FCMDR 007F E0A0h



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	PCMDR[7:0]	Precommand Flag	The command immediately before the latest command is stored.	R
b15 to b8	CMDR[7:0]	Command Flag	The latest command is stored.	R

This register records the two most recent commands accepted by the FACI.

PCMDR[7:0] Flags (Precommand Flag)

These flags indicate the command received immediately before the last command received by the FACI.

CMDR[7:0] Flags (Command Flag)

These flags indicate the latest command received by the FACI.

Table 48.4 States of FCMDR after Receiving Commands

Command	CMDR	PCMDR
Program	E8h	Previous command
Block erase	D0h	20h
P/E suspend	B0h	Previous command
P/E resume	D0h	Previous command
Status clear	50h	Previous command
Forced stop	B3h	Previous command
Blank check	D0h	71h
Configuration set	40h	Previous command

48.4.11 Flash P/E Status Register (FPESTAT)

Address(es): FLASH.FPESTAT 007F E0C0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	PEERRST[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	PEERRST[7:0]	P/E Error Status Flag	00h: No error 02h: Program error 12h: Erase error	R
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register indicates the result of programming or erasing the flash memory.

PEERRST[7:0] Flags (P/E Error Status Flag)

These flags indicate the source of an error that occurred during a program or erase operation to the code flash memory or data flash memory. The value of these flags is only valid if the ERSERR or PRGERR flag in the FSTATR register is 1 when the FSTATR.FRDY flag becomes 1. When the ERSERR and PRGERR flags are 0, these flags retain their value to indicate the source of the last error to have occurred.

48.4.12 Data Flash Blank Check Control Register (FBCCNT)

Address(es): FLASH.FBCCNT 007F E0D0h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	BCDIR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BCDIR	Blank Check Direction	0: Blank checking is executed from lower addresses to higher addresses (incremental mode). 1: Blank checking is executed from higher addresses to lower addresses (decremental mode).	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register specifies the addressing mode in processing of a blank check command.
The register is initialized when the FSUINITR.SUINIT bit is set to 1. It is also initialized by a reset.

BCDIR Bit (Blank Check Direction)

This bit specifies the addressing mode for blank checking.

48.4.13 Data Flash Blank Check Status Register (FBCSTAT)

Address(es): FLASH.FBCSTAT 007F E0D4h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	BCST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BCST	Blank Check Status Flag	0: The target area is in the non-programmed state (i.e. is blank; the area has been erased but has not yet been re-programmed). 1: The target area has been programmed with 0s or 1s.	R
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register stores the results of checking in response to a blank check command.

BCST Flag (Blank Check Status Flag)

This flag indicates the results of checking in response to a blank check command.
At the point where the FSTATR.FRDY flag is set to 1, the valid data is stored in the BCST flag.

48.4.14 Data Flash Programming Start Address Register (FPSADDR)

Address(es): FLASH.FPSADDR 007F E0D8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	PSADR[18:16]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PSADR[15:0]															
Value after reset:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b18 to b0	PSADR[18:0]	Programmed Area Start Address	The address of the first programmed area	R
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register indicates the address of the first programmed area to be found in processing of a blank check command.

PSADR[18:0] Bits (Programmed Area Start Address)

These bits indicate the address of the first programmed area to be found in processing of a blank check command. The address is an offset from the address where the data flash memory starts. The setting of these bits is valid only while the FBCSTAT.BCST flag is 1 and when the FSTATR.FRDY flag becomes 1. When the FBCSTAT.BCST flag is 0, the PSADR[18:0] bits holds the address detected by the previous check.

48.4.15 Flash Access Window Monitor Register (FAWMON)

Address(es): FLASH.FAWMON 007F E0DCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	BTFLG	—	—	FAWE[12:0]												
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	FSPR	—	—	FAWS[12:0]												
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b12 to b0	FAWS[12:0]	Flash Access Window Start Address	Flash access window start address	R
b14, b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	FSPR	Access Window Protection Flag	0: With protection (P/E disabled) 1: Without protection (P/E enabled)	R
b28 to b16	FAWE[12:0]	Flash Access Window End Address	Flash access window end address	R
b30, b29	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31	BTFLG	Start-Up Area Select Flag*2	0: Startup area 0 is in the range from FFFF 8000h to FFFF BFFFh, startup area 1 is in the range from FFFF C000h to FFFF FFFFh. 1: Startup area 1 is in the range from FFFF 8000h to FFFF BFFFh, startup area 0 is in the range from FFFF C000h to FFFF FFFFh.	R

Note 1. The value of the blank product is FFFF FFFFh. This register is set to a specified value after programming of the flash memory with the user program.
Note 2. When the FSUACR.SAS[1:0] bits are changed to 1xb, the startup area is dependent on the setting of the FSUACR.SAS[1:0] bits regardless of the setting of the FAW.BTFLG bit.

This register indicates the values of the write protection flag and start-up area select flag for setting the flash access window start/end address, and the access window. When a reset or configuration set command is executed, the FACI transfers data from the option-setting memory to this register and the setting of the option-setting memory is enabled.

FAWS[12:0] Bits (Flash Access Window Start Address)

These bits are used to verify the access window start address setting value.

FSPR Flag (Access Window Protection Flag)

This flag indicates whether or not protection for a configuration set command for the access window setting or for writing to the FSUACR register is available.

FAWE[12:0] Bits (Flash Access Window End Address)

These bits are used to verify the access window end address setting value. The value of these bits indicates the first address of the next P/E-enabled block as configured in the access window.

BTFLG Flag (Start-Up Area Select Flag)

This flag indicates whether the start-up area is switched by using start-up program protection.

48.4.16 Flash Sequencer Processing Switching Register (FCPSR)

Address(es): FLASH.FCPSR 007F E0E0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ESUSPMD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ESUSPMD	Erase Suspend Mode	0: Suspend priority mode 1: Erase priority mode	R/W
b15 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is for selecting the erase suspend mode.
The register is initialized when the FSUINITR.SUINIT bit is set to 1. It is also initialized by a reset.

ESUSPMD Bit (Erase Suspend Mode)

This bit is for selecting the erase suspend mode when a P/E suspend command is issued while the flash sequencer is executing erase sequence (refer to section 48.6.7.5, P/E Suspend Command). This bit should be set before issuing a block erase command.

48.4.17 Flash Sequencer Processing Clock Frequency Notification Register (FPCKAR)

Address(es): FLASH.FPCKAR 007F E0E4h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								PCKA[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	PCKA[7:0]	Flash Sequencer Processing Clock Frequency Notification	These bits are used to set the frequency of the FlashIF clock (FCLK) and notify the flash sequencer of the frequency used	R/W*1, *2
b15 to b8	KEY[7:0]	Key Code	Key code	R/W*3

Note 1. Writing to these bits is possible only when the FSTATR.FRDY flag is 1. Writing to these bits while the FSTATR.FRDY flag = 0 is ignored.
Note 2. Writing to these bits is enabled only when this register is written in 16-bit units with the KEY[7:0] bits set to 1Eh.
Note 3. Written values are not retained by these bits. These bits are read as 0.

This register specifies the frequency of the FlashIF clock (FCLK) generated in the clock generator and notifies the flash sequencer of the frequency used. The flash sequencer determines the FACI command processing time based on the frequency notified by the FPCKAR register. The initial value is set to the maximum operating frequency of the FCLK.

PCKA[7:0] Bits (Flash Sequencer Processing Clock Frequency Notification)

These bits are used to specify the frequency of the FCLK generated in the clock generator and to notify the flash sequencer of the frequency used. Set the desired frequency in these bits before issuing an FACI command. Specifically, convert the frequency represented in MHz into a binary number and set it in these bits.

Example: When frequency is 35.9 MHz (PCKA[7:0] = 24h)
Round up the first decimal place of 35.9 MHz to a whole number (= 36) and convert it into a binary number.

If the value set in these bits is smaller than the frequency of the FCLK, the rewriting characteristics of the flash memory cannot be guaranteed. Conversely, if the value set in these bits is greater than the frequency of the FCLK, the rewriting characteristics of the flash memory can be guaranteed although the FACI command processing time such as time for rewriting will increase (the FACI command processing time becomes the shortest when the frequency of the FCLK is the same as the value set in the bits).

KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the PCKA[7:0] bits.

48.4.18 Start-Up Area Control Register (FSUACR)

Address(es): FLASH.FSUACR 007F E0E8h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	SAS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	SAS[1:0]	Start-Up Area Select	b1 b0 0 x: A start-up area is selected based on the setting of the FAW.BTFLG bit. 1 0: The area from FFFF C000h to FFFF FFFFh is selected as the address range for startup area 0, and the area from FFFF 8000h to FFFF BFFFh is selected as the address range for startup area 1, regardless of the setting of the FAW.BTFLG bit. 1 1: The area from FFFF C000h to FFFF FFFFh is selected as the address range for startup area 1, and the area from FFFF 8000h to FFFF BFFFh is selected as the address range for startup area 0, regardless of the setting of the FAW.BTFLG bit.	R/W*1, *2
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	Key codes	R/W*3

x: Don't care

Note 1. Writable only when the FAW.FSPR bit is 1. When the FAW.FSPR bit is 0, writing to these bits are ignored.
Note 2. Writing to these bits is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to 66h.
Note 3. Written values are not retained by these bits. These bits are read as 0.

This register is used to switch startup areas 0 and 1 by startup program protection.
Do not use this register in dual mode (the MDE.BANKMD[2:0] bits are 000b). In dual mode, starting up proceeds from startup area 0.

SAS[1:0]Bits (Start-Up Area Select)

These bits are used to switch startup areas 0 and 1.

KEY[7:0] Bits (Key Code)

These bits enables or disable overwriting to the SAS[1:0] bits.

48.4.19 Unique ID Register n (UIDRn) (n = 0 to 2)

Address(es): FLASH.UIDR0 007F B174h, FLASH.UIDR1 007F B1E4h, FLASH.UIDR2 007F B1E8h

b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset: Unique value for each chip

b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset: Unique value for each chip

The UIDRn is a read-only register that stores a 12-byte ID code (unique ID) for identifying the individual MCU. The UIDRn register should be read in 32-bit units.

48.5 Overview of Functions

48.5.1 Program and Erase Methods

By using a flash-memory programmer to program the flash memory of this MCU, the device can be rewritten regardless of whether this is before or after it is mounted on the target system.
Furthermore, security functions to prohibit rewriting or reading of the user program written to the flash memory are incorporated, and this can prevent falsification and illicit reading of the programs by third parties. Blocks 8 and 9 (blocks 8, 9, 30, and 31 in dual mode) of the code flash memory can also be protected against reading by using the TM function.
Programming by the user program (self-programming) is available to suit applications where the application on the target system may require updating after manufacturing or shipment. Protection features for the safe rewriting of the flash memory are also incorporated. Furthermore, interrupt processing during self-programming is supported, so programming can proceed at the same time as processing for external communications, etc., and this is the case in various situations.
Table 48.5 lists the overview of the methods of programming and the corresponding operating modes.

Table 48.5 Methods of Programming

Method of Programming	Functional Overview	Operating Mode
Programming by a flash-memory programmer	A serial programmer is capable of on-board programming of the flash memory after the device is mounted on the target system. The TM function can be in enabled or disabled at this time.	Boot mode
Self-programming	The execution of the user program that is written to code flash memory in advance by serial programming executing is also capable of programming the flash memory. The TM function can be in the enabled state at this time. The background operation capability makes it possible to fetch instructions or otherwise read data from code flash memory while the data flash memory is being programmed. Therefore, the data flash memory can be rewritten by executing a program for writing contained by the code flash memory. Furthermore, background operation can also be used for reading and writing to code flash memory alone, but only when the address range of code flash memory that is the target for programming and the address range of code flash memory that is the target for reading satisfy particular conditions (refer to Table 48.24). When this is the case, at the time of self-programming, a program for programming that is in the code flash memory can be executed to rewrite the code flash memory. In cases where background operation is not possible, instructions in the code flash memory cannot be fetched and data cannot be accessed while code flash memory is being re-written by self-programming. In such cases, a program for programming must be transferred to the internal RAM in advance and executed.	Single-chip mode

The programmable/erasable area of the flash memory and the boot program after a reset are different according to each mode. The differences between modes are listed in Table 48.6.

Table 48.6 Differences between Modes

Item	Single-chip Mode	Boot Mode (SCI or FINE Interface)
Programmable and erasable area	• Code flash memory • Data flash memory • Option-setting memory (programming only)	• Code flash memory • Data flash memory • Option-setting memory
Boot program at a reset	Program on the code flash memory	Boot program

Table 48.7 lists the functions of the flash memory. Serial programmer commands realize each function of serial programming, while reading of the flash memory by an FACI command or the user program realizes each function of self-programming.
For security function settings, refer to section 7.2.1, Serial Programmer Command Control Register (SPCC), in section 7, Option-Setting Memory (OFSM).

Table 48.7 List of Basic Functions

Function	Functional Overview	Support Status	
		Serial Programming	Self-programming
Blank check	This is used to check a specified block to ensure that writing to it has not already proceeded. Results of reading from data flash memory to which nothing has been written after erasure are not guaranteed, so use blank checking to confirm that programming to memory has not proceeded after erasure.	Supported	Supported
Block erase	Erases the memory contents in the specified block.	Supported	Supported
Program	Write to the specified address.	Supported	Supported
Verify/Checksum	Compares the data read from flash memory and the data transferred from a flash memory programmer.	Supported	Not supported (read by user program is possible)
Read	Read data programmed to flash memory.	Supported	Supported
Setting of control or ID codes	Sets the OSIS register.	Supported	Supported
Setting the security functions	Sets the SPCC register and enables the following functions. • Prohibition of on-chip debugger connection • Serial programmer ID code protection • Prohibition of serial programmer connection	Supported	Supported with conditions (Only switching the configuration from disabled to enabled is possible)
Area protection and start-up program protection functions	Configures the area protection and start-up program protection functions.	Supported	Supported
Configuration clear	Erases the configuration setting area. Disables the TM function.	Supported	Not supported
Dual bank function	Switches different modes (linear or dual).	Supported	Supported
Setting the TM function	Sets the TM function.	Supported	Supported with conditions (Only switching the configuration from disabled to enabled is possible)

48.5.2 Security Functions

The flash memory supports various security functions.
The security function includes on-chip debugger ID code protection, prohibition of on-chip debugger connection, serial programmer ID code protection, and prohibition of serial programmer connection.
In serial programming, serial programmer ID code protection and prohibition of serial programmer connection can be used. On-chip debugger ID code protection and prohibition of on-chip debugger connection can be used when using the on-chip debugger.
Table 48.8 lists the security functions supported by the flash memory, and Table 48.9 lists the operations with security settings.

Table 48.8 Lists of Security Functions

Function	Description
On-chip debugger ID code protection	Connection to the on-chip debugger can be controlled by judging the ID code.
Prohibition of on-chip debugger connection	Connection to the on-chip debugger is prohibited regardless of the ID code setting.
Serial programmer ID code protection	Connection of a serial programmer can be controlled by judging the control code or ID code.
Prohibition of serial programmer connection	Connection of a serial programmer for serial programming is prohibited. Since execution of the configuration clear command is also prohibited when the connection of a serial programmer is prohibited, changing a security setting from “disabled” to “enabled” is not possible.

Table 48.9 Operations with Security Settings

	Programming/Erasing/Reading with Respective Security Settings		Notes for Security Setting	
Function	Serial Programming	Self-Programming	Serial Programming	Self-Programming
Prohibition of on-chip debugger connection	Block erase commands: Supported Program commands: Supported Read commands: Supported	Block erase commands: Supported Program commands: Supported Read commands: Supported	The configuration clear command can initialize the setting for prohibition.	Since the configuration clear command is not supported, initialization of the setting for prohibition is not possible.
Serial programmer ID code protection	(When the ID codes do not match) Block erase commands: Not supported Program commands: Not supported Read commands: Not supported (When the ID codes match) Block erase commands: Supported Program commands: Supported Read commands: Supported	(Judgment of the ID codes is not performed.) Block erase commands: Supported Program commands: Supported Read commands: Supported	The configuration clear command can initialize the setting for prohibition.	(Judgment of the ID codes is not performed.)
Prohibition of serial programmer connection	Block erase commands: Not supported Program commands: Not supported Read commands: Not supported	Block erase commands: Supported Program commands: Supported Read commands: Supported	Since execution of the configuration clear command is prohibited, initialization of the setting for prohibition is not possible.	Since the configuration clear command is not supported, initialization of the setting for prohibition is not possible.

48.5.2.1 On-Chip Debugger ID Code Protection

This function is used to prohibit connection to the on-chip debugger (OCD).
The code sent from the emulator is compared with the ID code set in the OCD/serial programmer ID setting register (OSIS) to determine whether they match. If they match, connection to the OCD is allowed. If they do not match, connection to the OCD is prohibited.
For details on the OSIS register, refer to section 7.2.2, OCD/Serial Programmer ID Setting Register (OSIS).

48.5.2.2 Serial Programmer ID Code Protection

This function is used to prohibit connection with the serial programmer.
The code sent from the serial programmer is compared with the ID code set in the OCD/serial programmer ID setting register (OSIS) to determine whether they match. If they match, connection with the serial programmer is allowed. If they do not match, the serial programmer cannot be connected. If the control code is 45h and the codes do not match three times in a row, all data in the flash memory are erased. However, if the FAW.FSPR bit is 0, the flash memory is not erased.
For details on the OSIS register, refer to section 7.2.2, OCD/Serial Programmer ID Setting Register (OSIS). For details on the FAW register, refer to section 7.2.9, Flash Access Window Setting Register (FAW).

48.5.3 Protection Function

48.5.3.1 Software Protection

Software protection disables programming and erasing of the code flash memory through the settings of control registers. If an attempt is made to issue an FACI command against software protection, the flash sequencer enters the command-locked state.

(1) Protection through FWEPROR Register

Programming cannot proceed in any mode unless the FWEPROR.FLWE[1:0] bits are set to 01b.

(2) Protection through FENTRYR Register

When the FENTRYR register is set to 0000h, the flash sequencer enters read mode. In read mode, FACI commands cannot be accepted. If an attempt is made to issue an FACI command in read mode, the flash sequencer enters the command-locked state.

48.5.3.2 Error Protection

Error protection detects erroneous issuance of FACI commands, unauthorized access, and flash sequencer malfunction. FACI command acceptance is disabled (command-locked state) in response to the detection of these errors. The flash memory cannot be programmed or erased while the flash sequencer is in the command-locked state. For release from the command-locked state, issue a status clear or forced stop command while the CFAE and DFAE flags in the FASTAT register are 0. The status clear command can only be used while the FSTATR.FRDY flag is 1. The forced stop command can be used regardless of the value of the FRDY flag.
Generation of a flash access error (FIFERR) interrupt detects malfunction. An FIFERR interrupt is generated under any of the following conditions.

- When violation in access to the data flash memory occurred (the FASTAT.DFAE flag is 1) while the FAEINT.DFAEIE bit is 1
- When the flash sequencer enters the command lock state (when the FASTAT.CMDLK flag is 1) while the FAEINT.CMDLKIE bit is 1
- When violation in access to the code flash memory occurred (when the FASTAT.CFAE flag is 1) while the FAEINT.CFAEIE bit is 1

When the flash sequencer enters the command-locked state in response to a command other than the P/E suspend command during program or erase operation, the flash sequencer continues the program or erase operation. In this state, the P/E suspend command cannot be used to suspend the program or erase operation. If a command is issued in the command-locked state, the FSTATR.ILGLERR flag becomes 1 and the other flags retain the values set due to previous error detection.
Table 48.10 shows error protection types and status bit values after error detection.

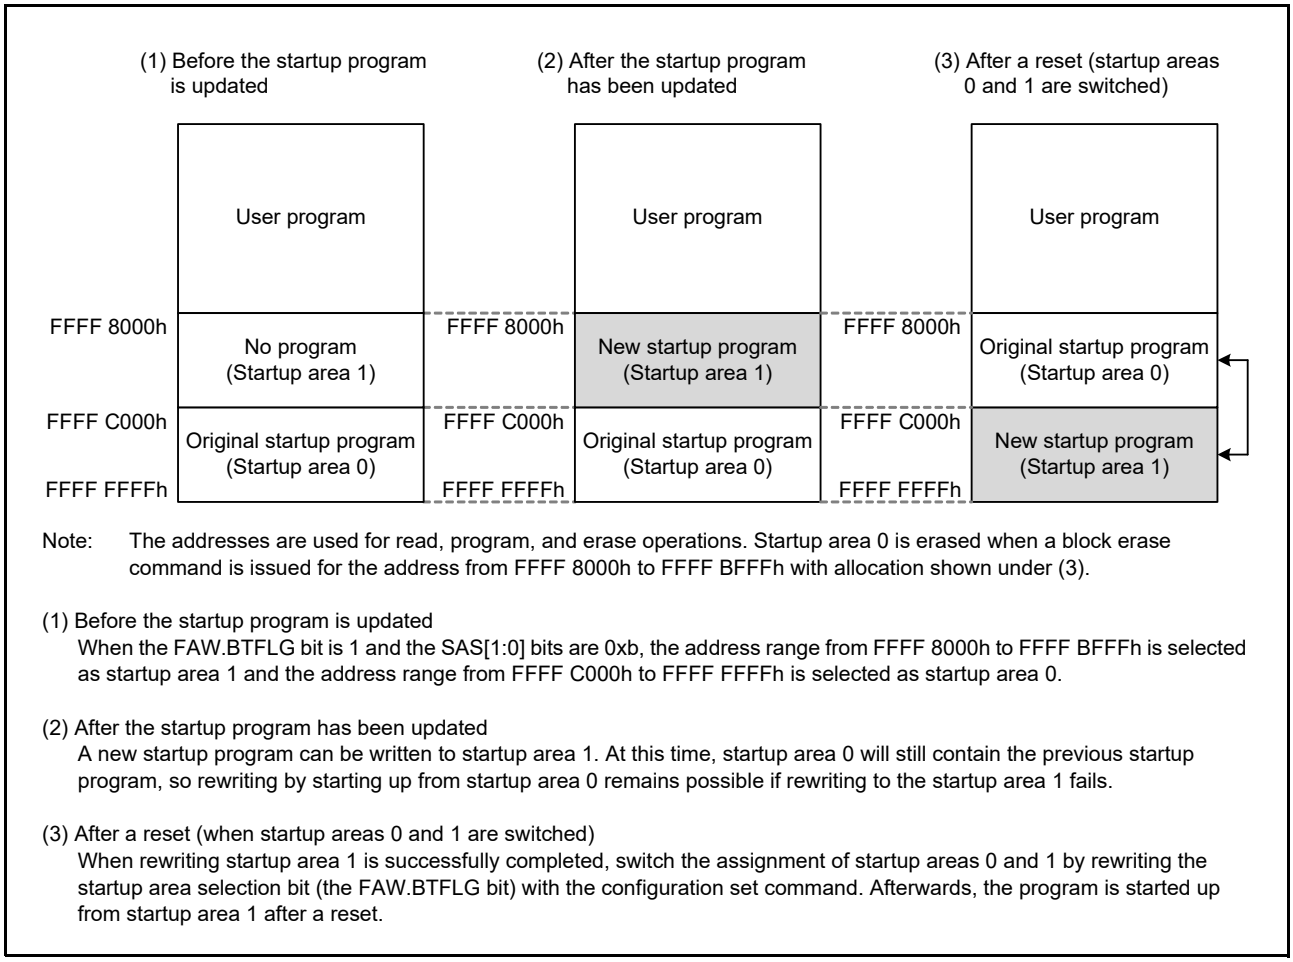
Table 48.10 Error Protection Type

Error Type	Description	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE
FENTRYR setting error	AA81h was written to the FENTRYR register.	1	0	0	0	0	0
	The FENTRYR register value at suspension disagrees with that at resumption.	1	0	0	0	0	0
Illegal command error	An undefined code was written on the first access of an FACI command.	1	0	0	0	0	0
	A value other than D0h was written on the last access of an FACI command with multiple access cycles.	1	0	0	0	0	0
	The value “N” (refer to Table 48.16) specified in the second access of the FACI command in the program or configuration set command is illegal.	1	0	0	0	0	0
	A blank check command was issued with one of the following settings. • The FBCCNT.BCDIR bit is 0, and the value in the FSADDR register > that in the FEADDR register • The FBCCNT.BCDIR bit is 1, and the value in the FEADDR register > that in the FSADDR register • The value of bits b18 to b0 of the FEADDR register is set in the range from 0 4000h to 7 FFFFh	1	0	0	0	0	0
	An FACI command not acceptable in each mode was issued (refer to Table 48.13).	1	0	0	0	0	0
	A program or block erase command was issued to an area protected by area protection.	1	0	0	0	0	0
	An FACI command was issued when command acceptance conditions are not satisfied (refer to Table 48.14)	1	0/1	0/1	0/1	0/1	0/1
Erase error	An error occurs during erase operation.	0	1	0	0	0	0
Program error	An error occurs during program operation.	0	0	1	0	0	0
Code flash memory access violation	A program command or block erase command was issued under the following settings in code flash memory P/E mode. • The value of bits b23 to b0 of the FSADDR register is set in the range from 00 0000h to F7 FFFFh*1 or from 00 0000h to FB FFFFh*2	1	0	0	0	1	0
Data flash memory access violation	A program command or block erase command was issued under the following settings in data flash memory P/E mode. • The value of bits b18 to b0 of the FSADDR register is set in the range from 0 4000h to 7 FFFFh	1	0	0	0	0	1
	A configuration set command was issued under the following settings in data flash memory P/E mode • The value of bits b18 to b0 of the FSADDR register is set in the range from 0 0000h to 0 003Fh or from 0 0100h to 7 FFFFh	1	0	0	0	0	1
Security error	A configuration set command was issued to the FAW register while the FAW.FSPR bit was 0.	1	0	0	0	0	0
Others	The FACI command-issuing area was accessed in read mode	1	0	0	0	0	0
	The FACI command-issuing area was read in code flash memory P/E mode or data flash memory P/E mode	1	0	0	0	0	0
Flash P/E protection error	A flash memory program/erase protection error for the setting of the FWEPROR register was detected during command processing by the flash sequencer.	0	0/1	0/1	1	0	0

Note 1. For products with 64 Kbytes of RAM
Note 2. For products with 48 Kbytes of RAM

48.5.4 Start-Up Program Protection

Protection of the startup program is for protection of the program to be started after a reset (the startup program). This function provides a way to safely update the startup program when rewriting is suspended during a reset.
The startup area is 8 Kbytes in size and is assigned to the code flash memory. This function uses the values of the FAW.BTFLG bit and the FSUACR.SAS[1:0] bits to change the area where the startup program is stored in block units (see Figure 48.5 to Figure 48.8).
In protection of the startup program, the state of the selection of the startup area can be fixed by the access window protection bit (FAW.FSPR). However, the FAW.FSPR bit never be restored to 1 once the flag is set to 0. Exercise extra caution when handling the FAW.FSPR bit.
In addition, this protection cannot be used when dual mode is selected by the bank mode switching function (when the MDE.BANKMD[2:0] bits are 000b).



Note: The addresses are used for read, program, and erase operations. Startup area 0 is erased when a block erase command is issued for the address from FFFF 8000h to FFFF BFFFh with allocation shown under (3).

(1) Before the startup program is updated
When the FAW.BTFLG bit is 1 and the SAS[1:0] bits are 0xb, the address range from FFFF 8000h to FFFF BFFFh is selected as startup area 1 and the address range from FFFF C000h to FFFF FFFFh is selected as startup area 0.

(2) After the startup program has been updated
A new startup program can be written to startup area 1. At this time, startup area 0 will still contain the previous startup program, so rewriting by starting up from startup area 0 remains possible if rewriting to the startup area 1 fails.

(3) After a reset (when startup areas 0 and 1 are switched)
When rewriting startup area 1 is successfully completed, switch the assignment of startup areas 0 and 1 by rewriting the startup area selection bit (the FAW.BTFLG bit) with the configuration set command. Afterwards, the program is started up from startup area 1 after a reset.

Figure 48.5 Concept of Protection of the Startup Program

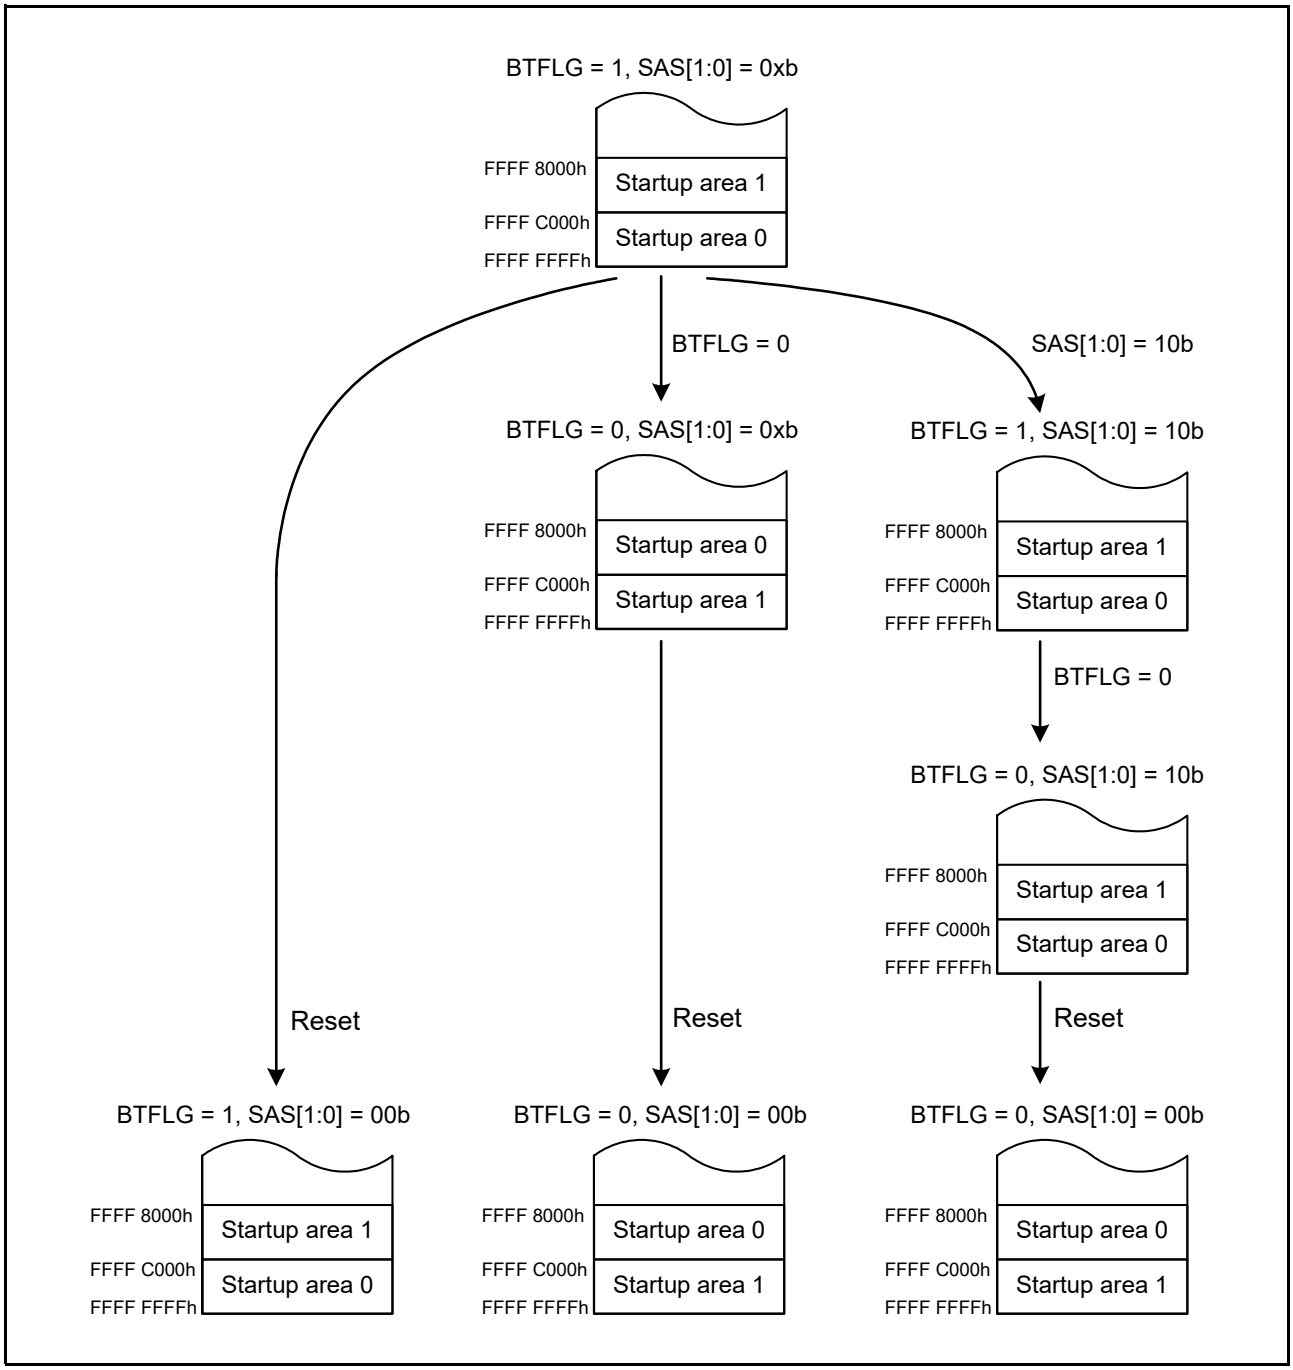


Figure 48.6 Example 1 of Transitions for Startup Program Protection Settings

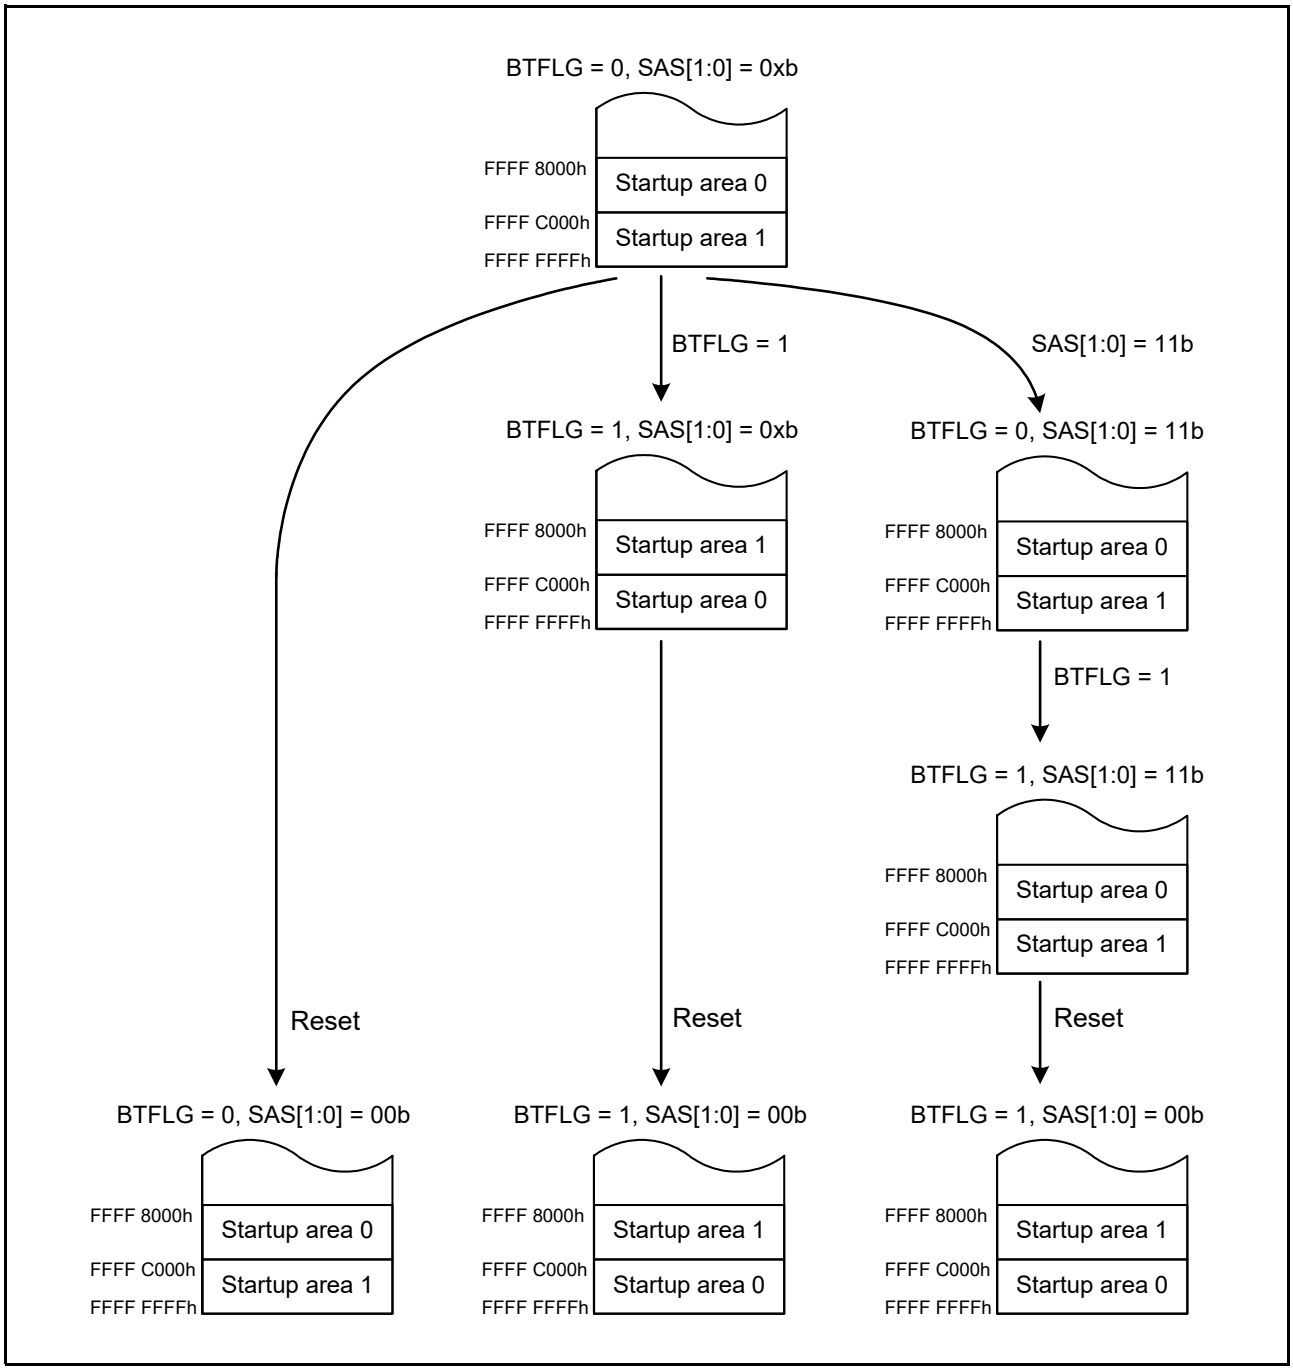

Figure 48.7 Example 2 of Transitions for Startup Program Protection Settings

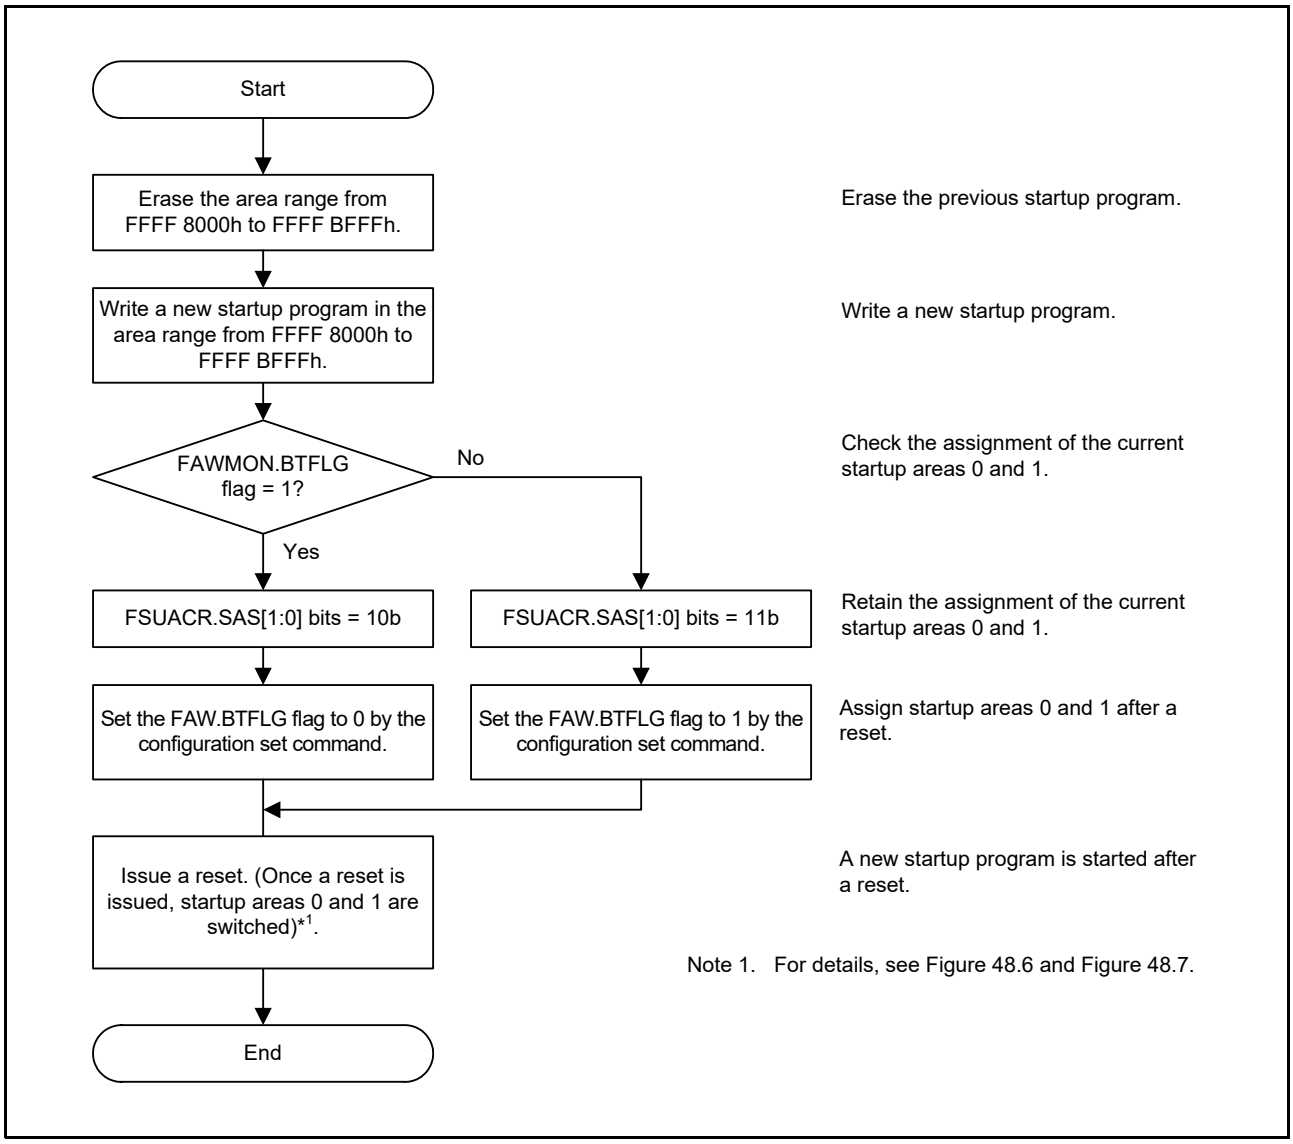

Figure 48.8 Example of Flowchart for Selecting Startup Area

48.5.5 Protection by Area Protection

Issuing an FACI command that programs or erases the area set outside the access window leads to the command-locked state. The access window is valid only in the code flash memory. The access window is valid in self-programming mode or serial programming mode.

The access window can be set in block units.

Figure 48.9 shows the Area Protection Overview.

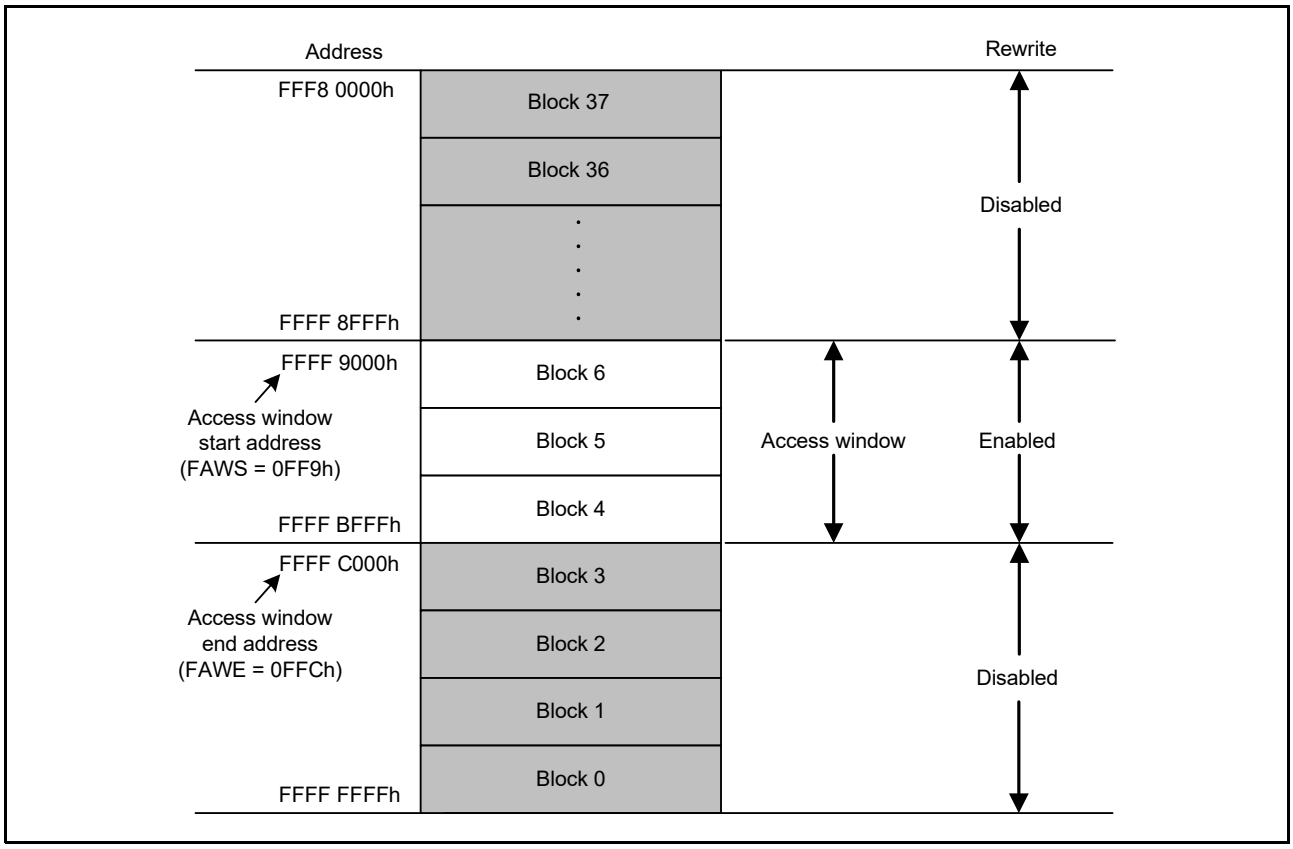

Figure 48.9 Area Protection Overview (When Blocks 4 to 6 are Set as the Access Window in Products with 512 Kbytes of Code Flash Memory)

48.5.6 Dual Bank Function

This protection uses the functions of bank mode switching and startup bank selection to update a program while a user program is running and to provide a safe method of updating in cases where program operation is suspended during a reset.

48.5.6.1 Switching Bank Modes

The bank mode switching function selects either linear mode in which the code flash memory is used as one area, or dual mode in which the code flash memory is divided into two bank areas. Figure 48.10 shows an example of flow of switching bank modes. A reset after setting the MDE.BANKMD[2:0] bits in the option setting memory determines the mode of the bank mode switching function. Selecting dual mode enables the startup bank selection function.
When dual mode is selected by bank mode switching function (the MDE.BANKMD[2:0] bits are 000b), start-up program protection function cannot be used.

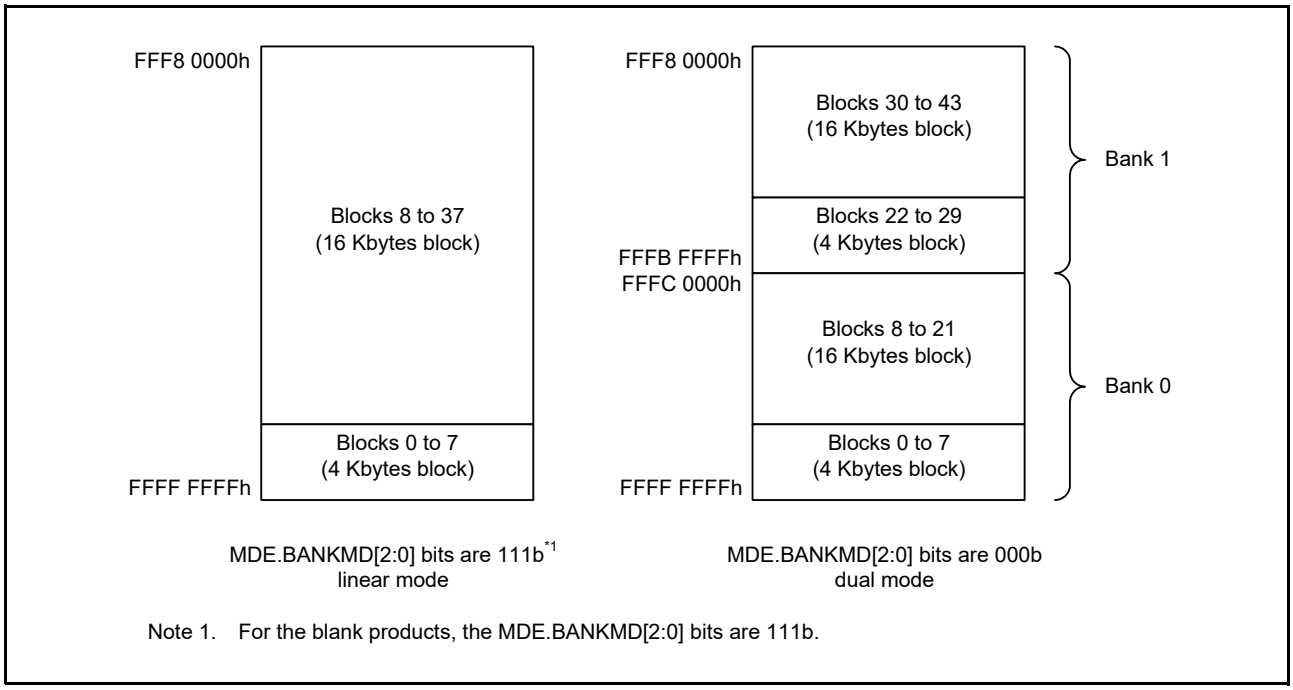

Figure 48.10 Example of Bank Mode Switching (For Products with 512 Kbytes of Code Flash Memory)

48.5.6.2 Selecting the Startup Bank

Startup bank selection provides a way to safely update the program by selecting a bank area to be started in dual mode (when the MDE.BANKMD[2:0] bits are 000b) when program operation is suspended during a reset. Figure 48.11 is a schematic view of startup bank selection and Figure 48.12 shows an example of the flow of startup bank selection. A reset after setting the value of the BANKSEL.BANKSWP[2:0] bits in the option-setting memory changes the addresses of banks 0 and 1 and booting up a program proceeds from the updated area. When the address is switched by using startup bank selection, the P/E target for the FACI commands is also switched. This function is invalid in linear mode.

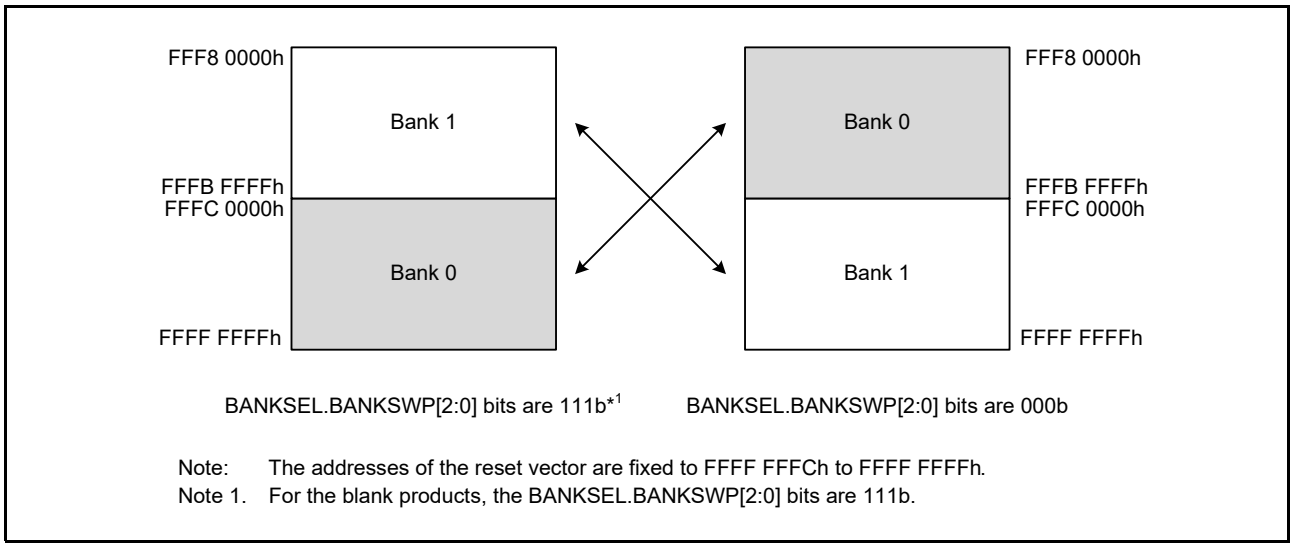

Figure 48.11 Example of Startup Bank Selection (For Products with 512 Kbytes of Code Flash Memory)

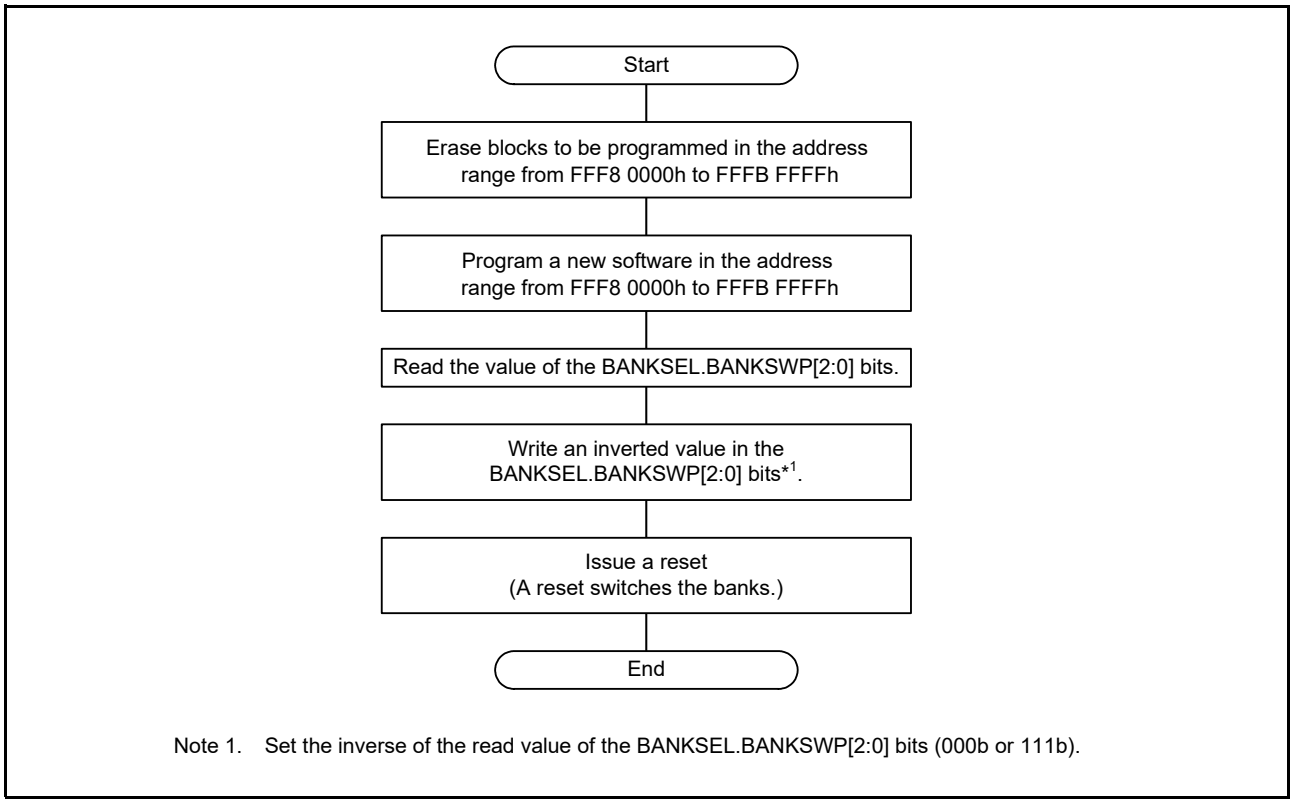

Figure 48.12 Example of Startup Bank Selection Flow (For Products with 512 Kbytes of Code Flash Memory)

48.5.7 Suspend Function

Reading from the flash memory without using the BGO function is not possible during program or erase operation. When a P/E suspend command is issued to suspend the program or erase operation to the flash memory, reading from the flash memory is enabled. Regarding P/E suspend commands, there are one program suspend mode and two erase suspend modes (suspend priority mode and erase priority mode). To resume suspended program or erase operation, the P/E resume command is available.

48.5.8 Trusted Memory

This MCU has a trusted memory (hereafter referred to as TM) function to prevent reading of blocks 8 and 9 (blocks 8, 9, 30, and 31 in dual mode) in the code flash memory by outsider software. When set as trusted memory, these areas are suitable for storing software that handles processing for encryption algorithms, device control software that is associated with proprietary or confidential know-how, purchased middleware, and so on.
Table 48.11 lists the specifications of the TM function, Table 48.12 lists access restrictions within the TM target area when the TM function is enabled, and Figure 48.13 shows the cases where the CPU is able to operate in relation to the TM target area.

Table 48.11 TM Specifications

Item	Description
TM target area	Linear mode: Blocks 8 and 9 in the code flash memory (32 Kbytes in total) Dual mode: Blocks 8 and 9 in the code flash memory (32 Kbytes in total) and blocks 30 and 31 (32 Kbytes in total)

Table 48.11 TM Specifications

Item	Description
Access restrictions when TM is enabled	Refer to Table 48.12, Restrictions on Access to the TM Target Area while the TM Function is Enabled.
How to run program code when the TM function is enabled	When the TM function is enabled, starting to run program code in an area being handled as TM is only possible with a branch instruction from program code outside the areas being handled as TM.
Interrupt processing during the execution of program code in an area being handled as TM while the TM function is enabled	Both the acceptance of requests for interrupt processing and return from interrupt processing are possible.
Security function	Enabling the TM function restricts access to program code in the areas for handling as TM to instruction fetching only
Protection functions	• Restrictions on data access to the TM target area when the TM function is enabled*1 • Once enabled, the TM function prevents its own disabling until the areas being handled as TM target area are erased. • Once enabled, the TM function prevents further writing to the areas being handled as TM target area

Note 1. Access to data in operations that include the borders of the TM target areas is also not allowed.

Table 48.12 Restrictions on Access to the TM Target Area while the TM Function is Enabled

Type of Access	CPU	DMAC/DTC
Instruction fetching	Yes	—
Access to data*1	No	No

Note: When using the on-chip debugger (OCD), the same restrictions apply as for the DMAC in the table above. For the OCD operation to the TM target area, refer to the manual of the emulator to be used.
Note 1. Place data outside the TM target areas.

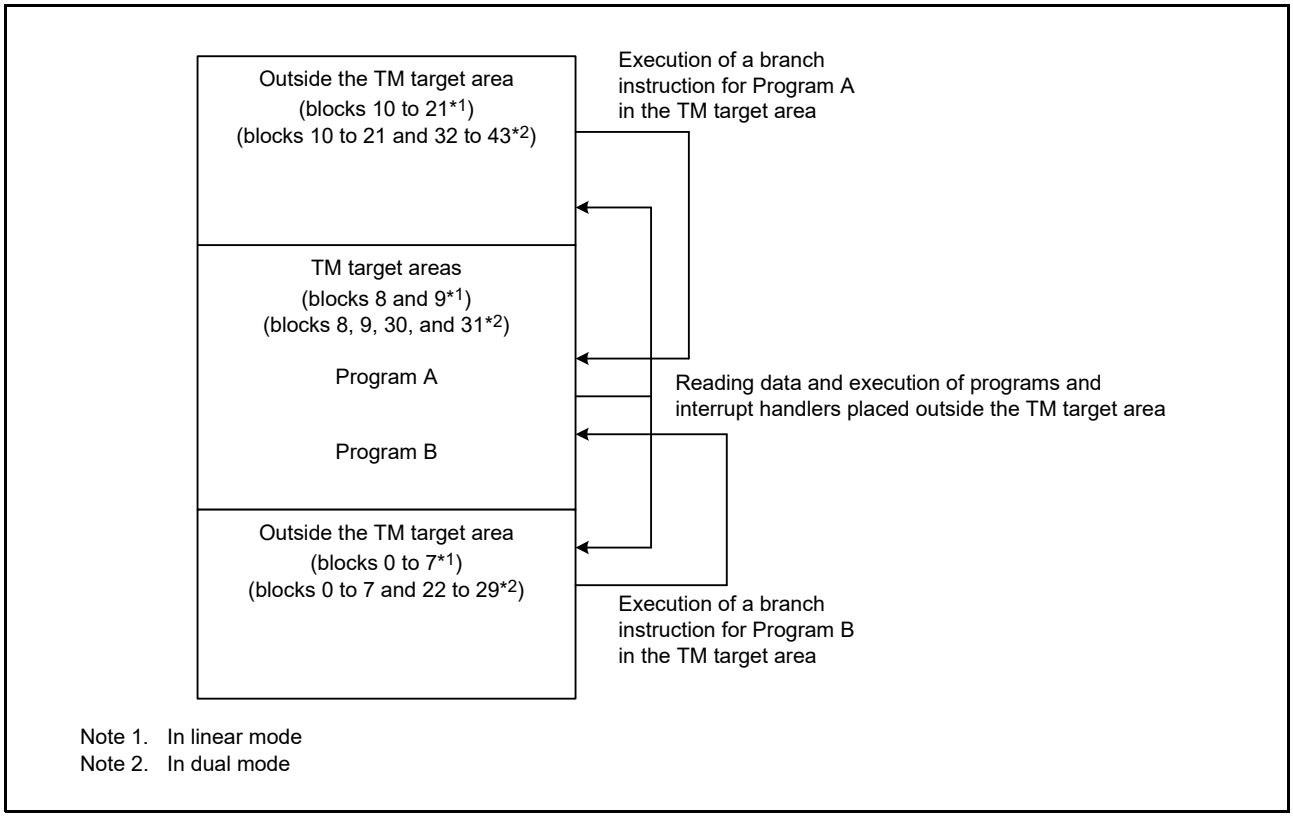

Figure 48.13 Cases where CPU is Allowed to Operate in Relation to the TM Target Area when the TM Function is Enabled

48.5.8.1 Allocating Program Code to the TM Target Area

When the TM function is enabled, implement countermeasures in the form of software for the TM target area as required as further measures to prevent the running of programs for access to consecutive addresses in the TM target areas from areas outside the TM target areas.

48.5.8.2 How to Enable the TM Function

(1) By Self-Programming

After programming to blocks 8 and 9 (blocks 8, 9, 30, and 31 in dual mode) of the code flash memory, i.e. the target areas for TM, use the configuration set command of the FACI to enable the TM function.
Figure 48.14 is a flowchart of the procedure for enabling the TM function by self-programming.

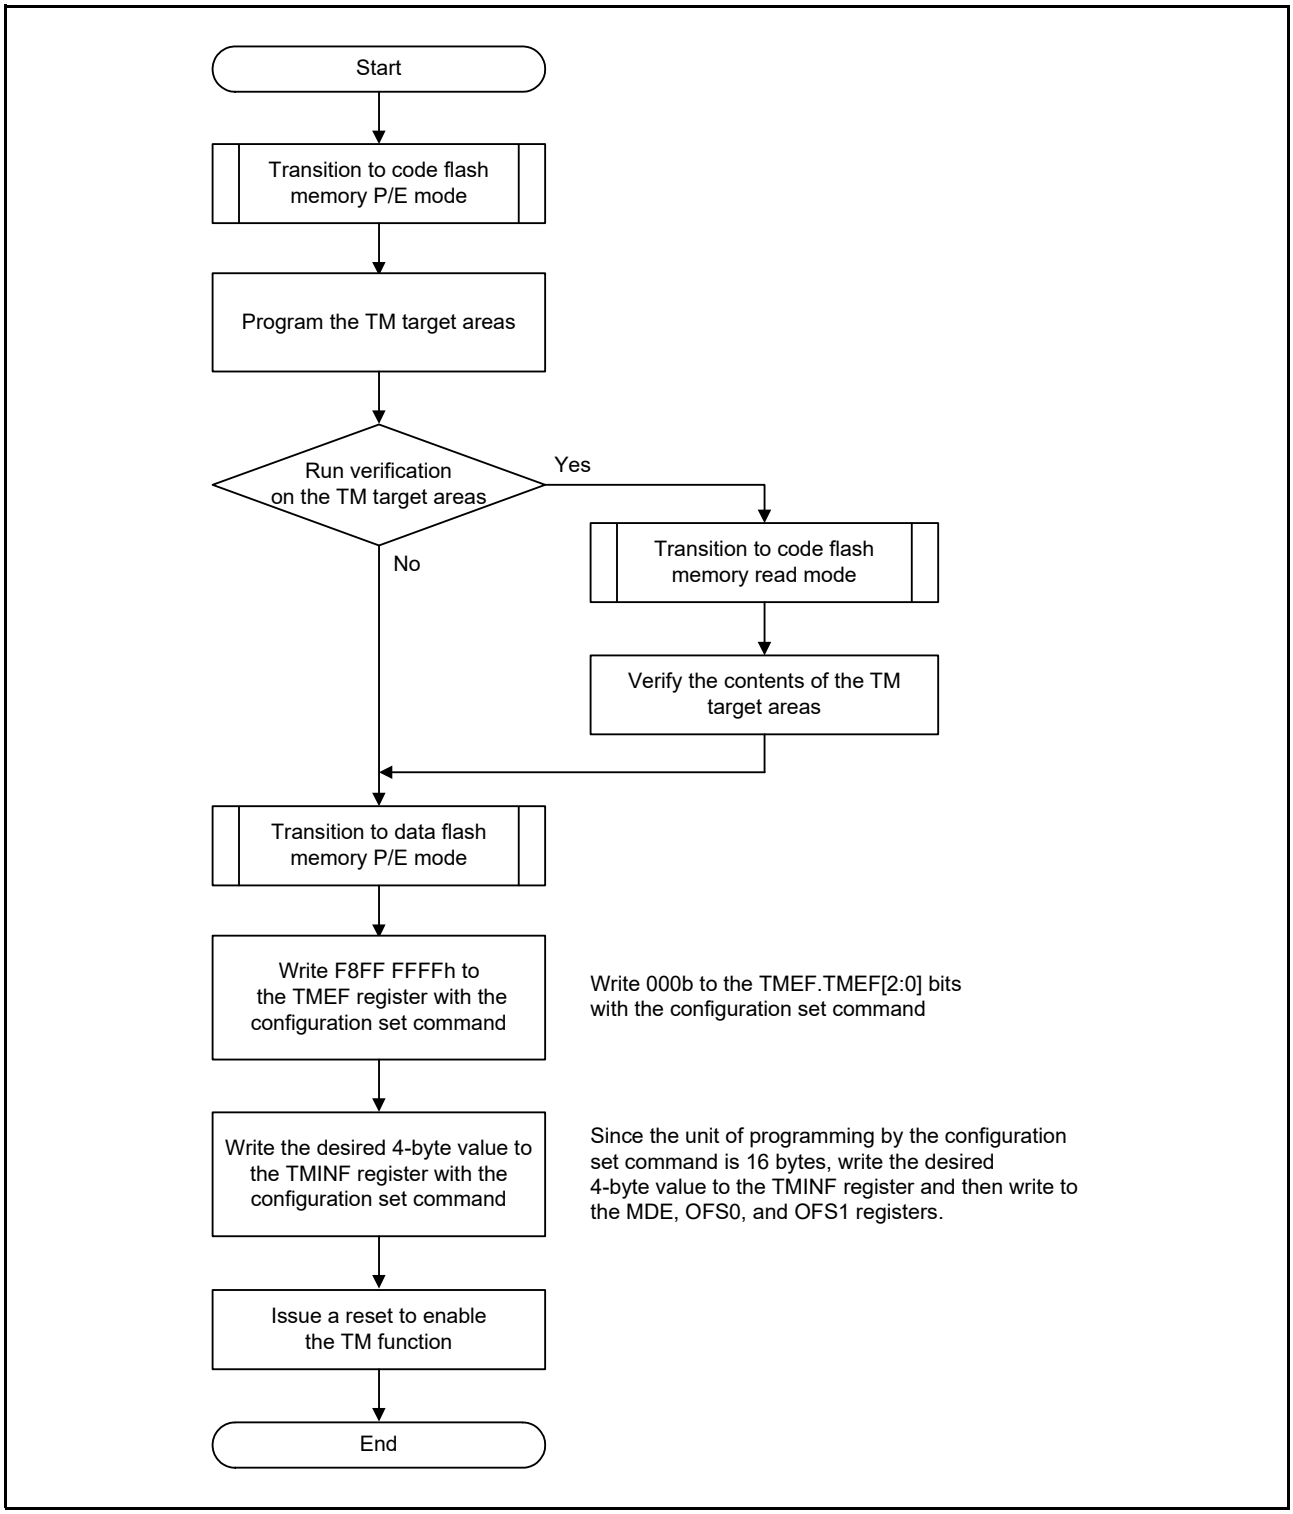

Figure 48.14 Flowchart for Enabling the TM Function by Self-Programming

(2) By Using Boot Mode

In boot mode, use the configuration program command among the boot commands to enable the TM function after programming to blocks 8 and 9 (blocks 8, 9, 30, and 31 in dual mode) of the code flash memory.
For the configuration program command among the boot commands, refer to section 48.8.22, Configuration Program Command.
Figure 48.15 is a flowchart of enabling the TM function in boot mode.

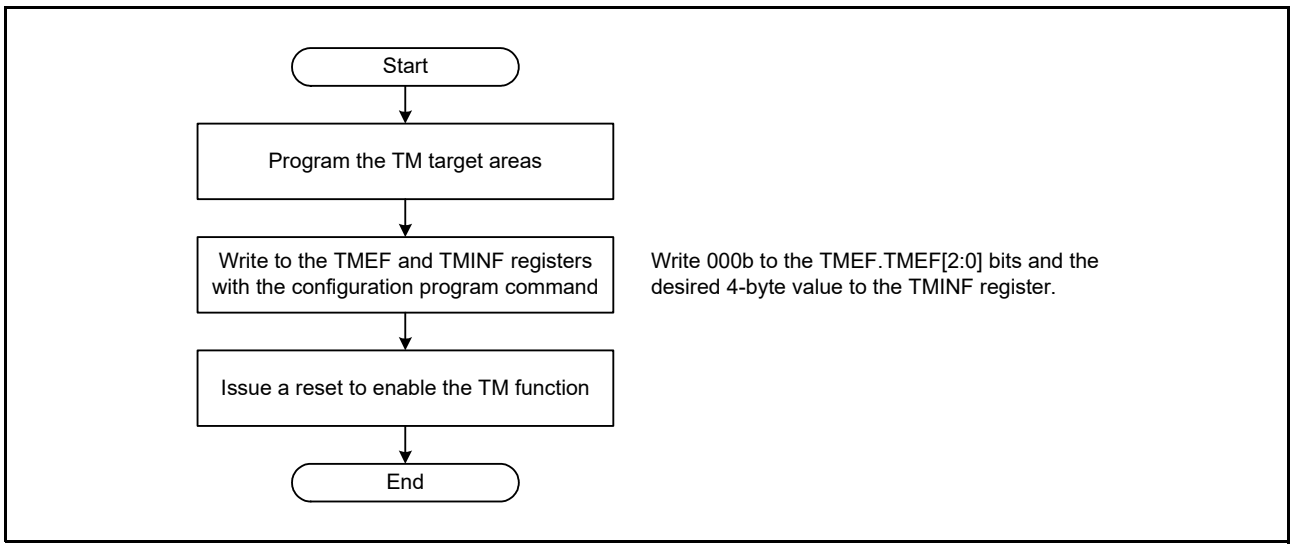

Figure 48.15 Flowchart for Enabling the TM Function by Using Boot Mode

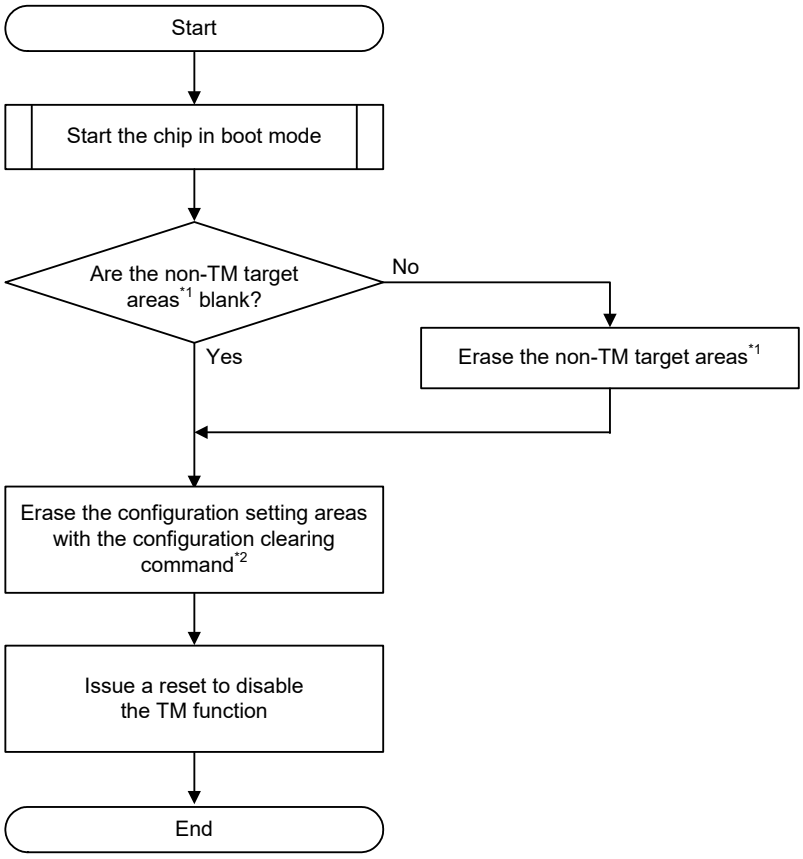
48.5.8.3 How to Disable the TM Function

The TM function cannot be disabled unless the TM target areas are first erased with the configuration clear command. Do not use the configuration clear command for this purpose unless the TM function is to be disabled.
Figure 48.16 is a flowchart of disabling the TM function in boot mode.



Note 1. Non-TM target areas are the areas other than blocks 8 and 9 (blocks 8, 9, 30, and 31 in dual mode) of the code flash memory and data flash memory.
Note 2. The configuration clear command erases the configuration setting area including the TMEF and TMINF registers and the TM target areas.

Figure 48.16 Flowchart for Disabling the TM Function in Boot Mode

48.5.8.4 Notes on Enabling the TM Function

(1) Protection against Access to the TM Target Areas

While the TM function is enabled, the only type of access to the TM target areas is instruction fetching by the CPU, so do not allocate data to the TM target areas.
If the CPU, DMAC, DTC, or OCD attempt access to data in the TM target areas while the TM function is enabled, values are always read as 0 instead of the actual values.

(2) Further Programming to the TM Target Areas

Further programming to the TM target areas is not allowed as long as the TM function is enabled.
If you need to program further data, follow the procedure described in section 48.5.8.3, How to Disable the TM Function; and follow the procedure described in section 48.5.8.2, How to Enable the TM Function, to program blocks 8 and 9 (blocks 8, 9, 30, and 31 in dual mode) of the code flash memory and to re-enable the TM function.

(3) Executing the Configuration Clear Command

Follow the procedure in section 48.5.8.3, How to Disable the TM Function, before issuing the configuration clear command.

(4) When the MPU Setting is for Access to the TM Target Areas

When the TM function is enabled, even if the MPU is set to allow access to the TM target areas, the TM function takes priority.

(5) FACI Block Erase Command for the TM Target Areas

There are no special restrictions on block erase of the TM target areas with the FACI block erase command. Accordingly, since each area corresponds to an erase block, the areas can be erased by issuing the block erase command.

(6) Conditions for Correct Operation of the TM Function

The TM function operates normally under the conditions prescribed in section 49, Electrical Characteristics.

48.6 Flash Sequencer

48.6.1 Operating Modes of the Flash Sequencer

The flash sequencer has three operating modes as shown in Figure 48.17. Transitions between modes are initiated by changing the value of the FENTRYR register.
When the value of the FENTRYR register is 0000h, the flash sequencer is in read mode. In this mode, it does not receive FACI commands. Code flash memory and data flash memory are readable.
When the value of the FENTRYR register is 0001h, the flash sequencer is in code flash memory P/E mode where the code flash memory can be programmed or erased by FACI commands. Data flash memory is readable. Under the conditions where BGO is allowed, code flash memory is readable.
When the value of the FENTRYR register is 0080h, the flash sequencer is in data flash memory P/E mode where the data flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is not readable. However, the code flash memory is readable.

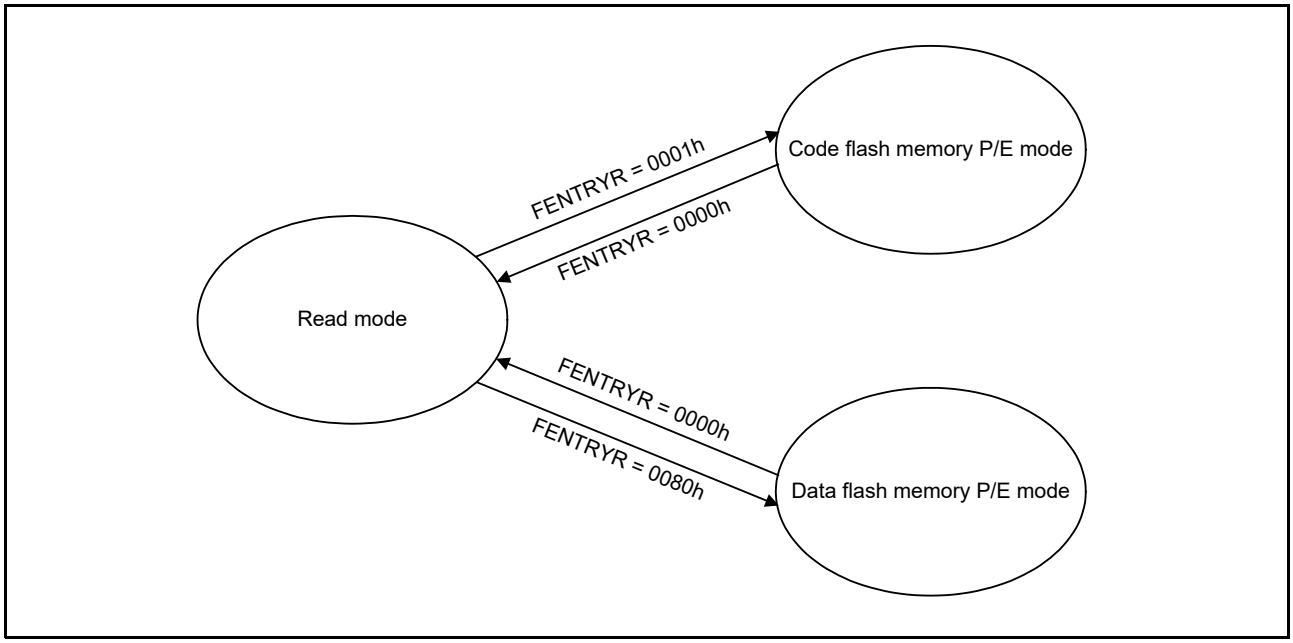


Figure 48.17 Modes of the Flash Sequencer

48.6.2 Read Mode

Read mode is for high-speed reading of the code flash memory or data flash memory.

(1) Code Flash Memory

Special settings are not required to read code flash memory in single-chip mode. Data can simply be read out through access to addresses in the code flash memory.

When reading code flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state), all bits are read as 1.

(2) Data Flash Memory

Special settings are not required to read data flash memory in single-chip mode. Data can simply be read out through access to addresses in the data flash memory.

Values read from data flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state) are undefined. Use a blank check command when you need to confirm that an area is in the non-programmed state.

48.6.3 Code Flash Memory P/E Mode

In this mode, the code flash memory is in P/E mode, and the data flash memory is in read mode. The sequencer enters this mode when setting the FENTRYR.FENTRYD bit to 0 and the FENTRYR.FENTRYC bit to 1.

48.6.4 Data Flash Memory P/E Mode

In this mode, the code flash memory is in read mode, and the data flash memory is in P/E mode. The sequencer enters this mode when setting the FENTRYR.FENTRYD bit to 1 and the FENTRYR.FENTRYC bit to 0.

48.6.5 Transitions of Operating Modes

Each FACI command can be accepted in a specific mode or state of the flash sequencer. FACI commands should be issued after the transition of the flash sequencer to the code flash memory P/E mode or data flash memory P/E mode and checking of the state of the flash sequencer. Use the FSTATR and FASTAT registers to check the state of the flash sequencer. The value of the FASTAT.CMDLK flag is the logical OR of values of the ILGLERR, ERSERR, PRGERR, and FLWEERR flags in the FSTATR register, and the CFAE and DFAE flags in the FASTAT register. Therefore, the occurrence of errors can be checked by reading the value of the FASTAT.CMDLK flag.
Table 48.13 lists the available commands in each operating mode.

Table 48.13 Operating Mode and Available Commands

Operating Mode	FENTRYR Register Value	Available Commands
Read mode	0000h	None
Code flash memory P/E mode	0001h	Program Block erase P/E suspend P/E resume Status clear Forced stop
Data flash memory P/E mode	0080h	Program Block erase P/E suspend P/E resume Status clear Forced stop Blank check Configuration set

Table 48.14 shows the state of the flash sequencer and acceptable FACI commands. An appropriate mode is assumed to be set before the commands are executed.

Table 48.14 Acceptable FACI Commands and the State of the Flash Sequencer

	Processing of Program or Erase*1	Processing of Configuration Set	Suspending Program or Erase	Blank checking	During Program Suspend	During Erase Suspend	Program during Erase Suspend	Command-Locked State (FRDY = 1)	Command-Locked State (FRDY = 0)	Processing of Forced Stop Command	Other State
FRDY flag	0	0	0	0	1	1	0	1	0	0	1
SUSRDY flag	1	0	0	0	0	0	0	0	0	0	0
ERSSPD flag	0	0	0/1	0/1	0	1	1	0/1	0/1	0	0
PRGSPD flag	0	0	0/1	0/1	1	0	0	0/1	0/1	0	0
CMDLK flag	0	0	0	0	0	0	0	1	1	0	0
Program	×	×	×	×	×	✓*2	×	×	×	×	✓
Block erase	×	×	×	×	×	×	×	×	×	×	✓
P/E suspend	✓	×	×	×	×	×	×	—	×	×	—
P/E resume	×	×	×	×	✓	✓	×	×	×	×	×
Status clear	×	×	×	×	✓	✓	×	✓	×	×	✓
Forced stop	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
Blank check	×	×	×	×	✓*3	✓*3	×	×	×	×	✓*3
Configuration set	×	×	×	×	×	×	×	×	×	×	✓*3

✓: Acceptable
×: Not acceptable (the sequencer in the command-locked state)
—: Ignored
Note 1. Cases that the program or erase operation is completed before the P/E suspend command is accepted are also included.
Note 2. Program command can be issued to a block other than the erase-suspended block.
Note 3. Acceptable only in data flash memory P/E mode

48.6.5.1 Transition to Code Flash Memory P/E Mode

To use the FACI commands for the code flash memory, a transition to code flash memory P/E mode is required. To enter code flash memory P/E mode, set the FENTRYR.FENTRYC bit to 1.

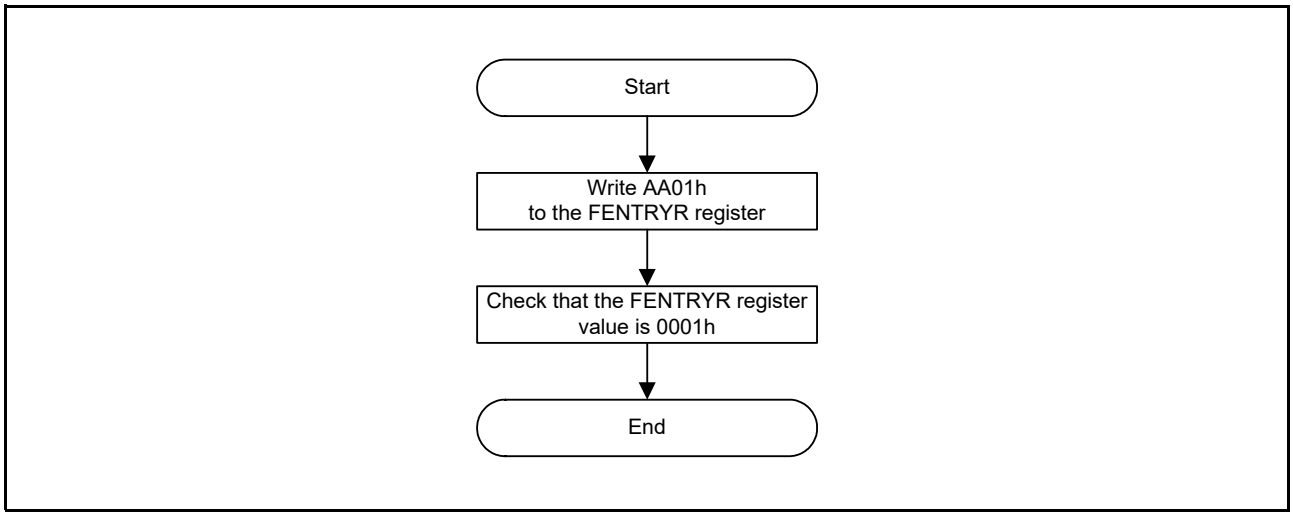

Figure 48.18 Procedure for Transition to Code Flash Memory P/E Mode

48.6.5.2 Transition to Data Flash Memory P/E Mode

To use the FACI commands for the data flash memory, a transition to data flash memory P/E mode is required. To enter data flash memory P/E mode, set the FENTRYR.FENTRYD bit to 1.

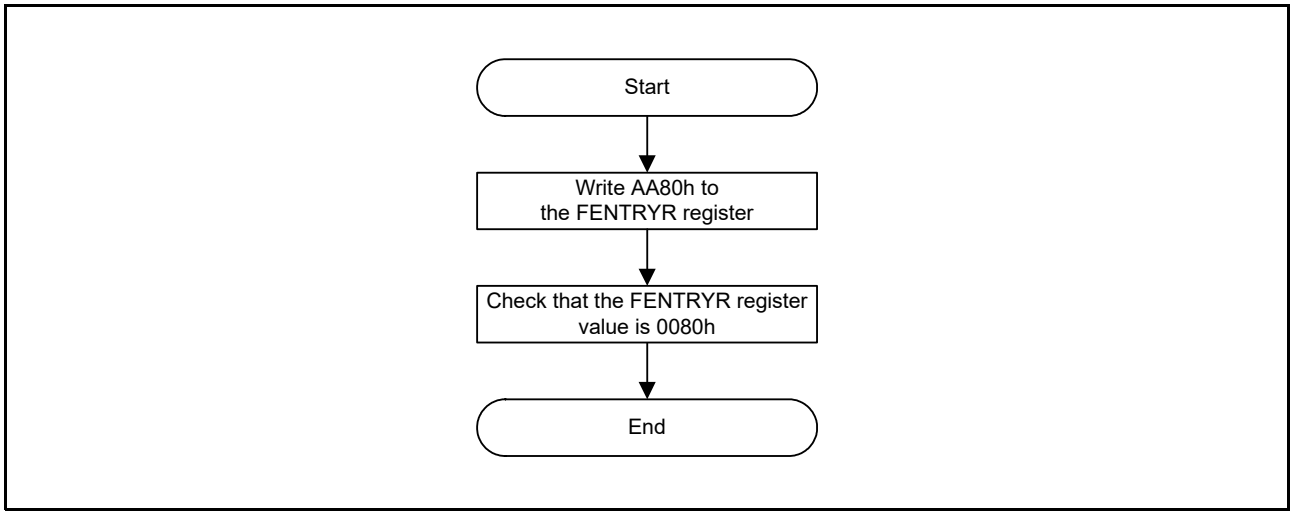

Figure 48.19 Procedure for Transition to Data Flash Memory P/E Mode

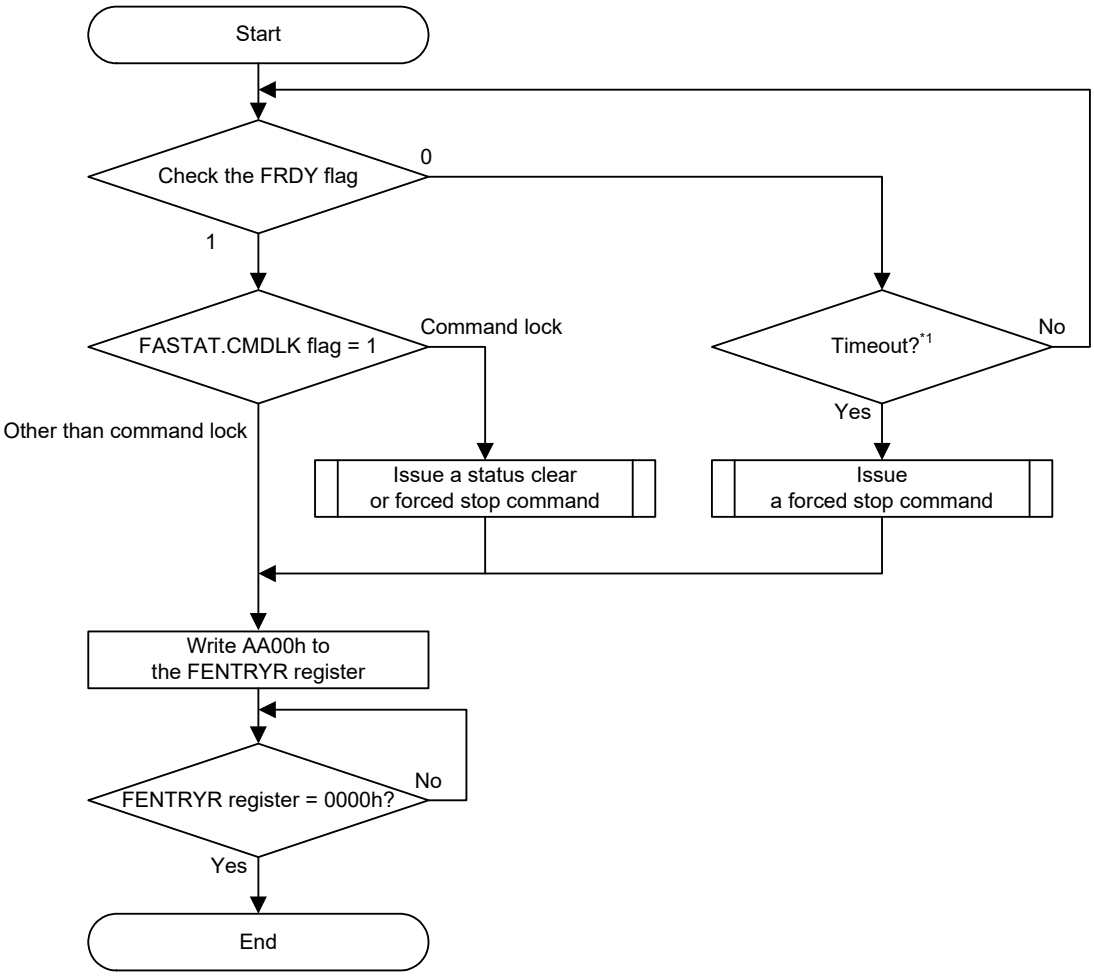
48.6.5.3 Transition to Read Mode

To read the flash memory without using the BGO function, a transition to read mode is required. To return to read mode, set the FENTRYR register to 0000h. The transition to read mode should be made after processing by the flash sequencer is completed and while operation is in other than in the command-locked state. In addition, operation is started in read mode after release from the reset state.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for processing of the FACI command that is in progress (refer to section 49, Electrical Characteristics).

Figure 48.20 Procedure for Transition to Read Mode

48.6.6 List of FACI Commands

Table 48.15 List of FACI Commands

FACI Command	Description
Program	This is used to program the code flash memory and data flash memory. The program unit is 128 bytes for the code flash memory and 4 bytes for the data flash memory.
Block erase	This is used to erase the code flash memory and data flash memory. The erase unit is one block. (code flash memory: 4 K or 16 Kbytes, data flash memory: 64 bytes)
P/E suspend	This suspends program or erase operation.
P/E resume	This resumes suspended program or erase operation.
Status clear	This initializes the ILGLERR, ERSERR, and PRGERR flags in the FSTATR register, and the CMDLK flag in the FASTAT register and releases the flash sequencer from the command-locked state.
Forced stop	This forcibly stops processing of FACI commands and initializes the FSTATR register.
Blank check	This is used to check if data flash memory is blank. Units of blank checking: 4 bytes to 16 Kbytes (specified in 4-byte units).
Configuration set	This is used to set the configuration setting area. Units of setting: 16 bytes.

The FACI commands are issued by writing to the FACI command-issuing area (refer to Table 48.2). When write access as shown in Table 48.16 proceeds in the specified state, the flash sequencer executes the processing corresponding to the given command (refer to section 48.6.5, Transitions of Operating Modes).

Table 48.16 FACI Command Formats

FACI Commands	Number of Write Access	Data to be Written to the FACI Command-Issuing Area			
		1st Access	2nd Access	3rd to (N+2)th Access	(N+3)th Access
Program (code flash memory) 128-byte programming, N = 64	67	E8h	40h (= N)	WD_1 to WD_{64}	D0h
Program (data flash memory) 4-byte programming: N = 2	5	E8h	02h (= N)	WD_1 and WD_2	D0h
Block erase	2	20h	D0h	—	—
P/E suspend	1	B0h	—	—	—
P/E resume	1	D0h	—	—	—
Status clear	1	50h	—	—	—
Forced stop	1	B3h	—	—	—
Blank check	2	71h	D0h	—	—
Configuration set N = 8	11	40h	08h (= N)	WD_1 to WD_8	D0h

Note: WD_N (N = 1, 2,…): Nth 16-bit data to be programmed.

The flash sequencer clears the FSTATR.FRDY flag to 0 at the start of processing of a command other than the status clear command and sets this bit to 1 upon completion of command processing.
When the setting of the FRDYIE.FRDYIE bit is 1 and when the FSTATR.FRDY flag is set to 1, a flash ready (FRDY) interrupt is generated.

48.6.7 Usage of FACI Commands

This section gives an overview of the usage of FACI commands.

48.6.7.1 Overview Flow when FACI Command is Used

Figure 48.21 shows an overview flow when the FACI command is used.
When using the BGO function, the jump to the internal RAM (other than code flash memory) is not required because an FACI command can be issued for the code or data flash memory by using the rewriting program in the code flash memory.
When the FCLK is changed, changing the FPCKAR register shortens time for processing the FACI command. For details, refer to section 48.4.17, Flash Sequencer Processing Clock Frequency Notification Register (FPCKAR).

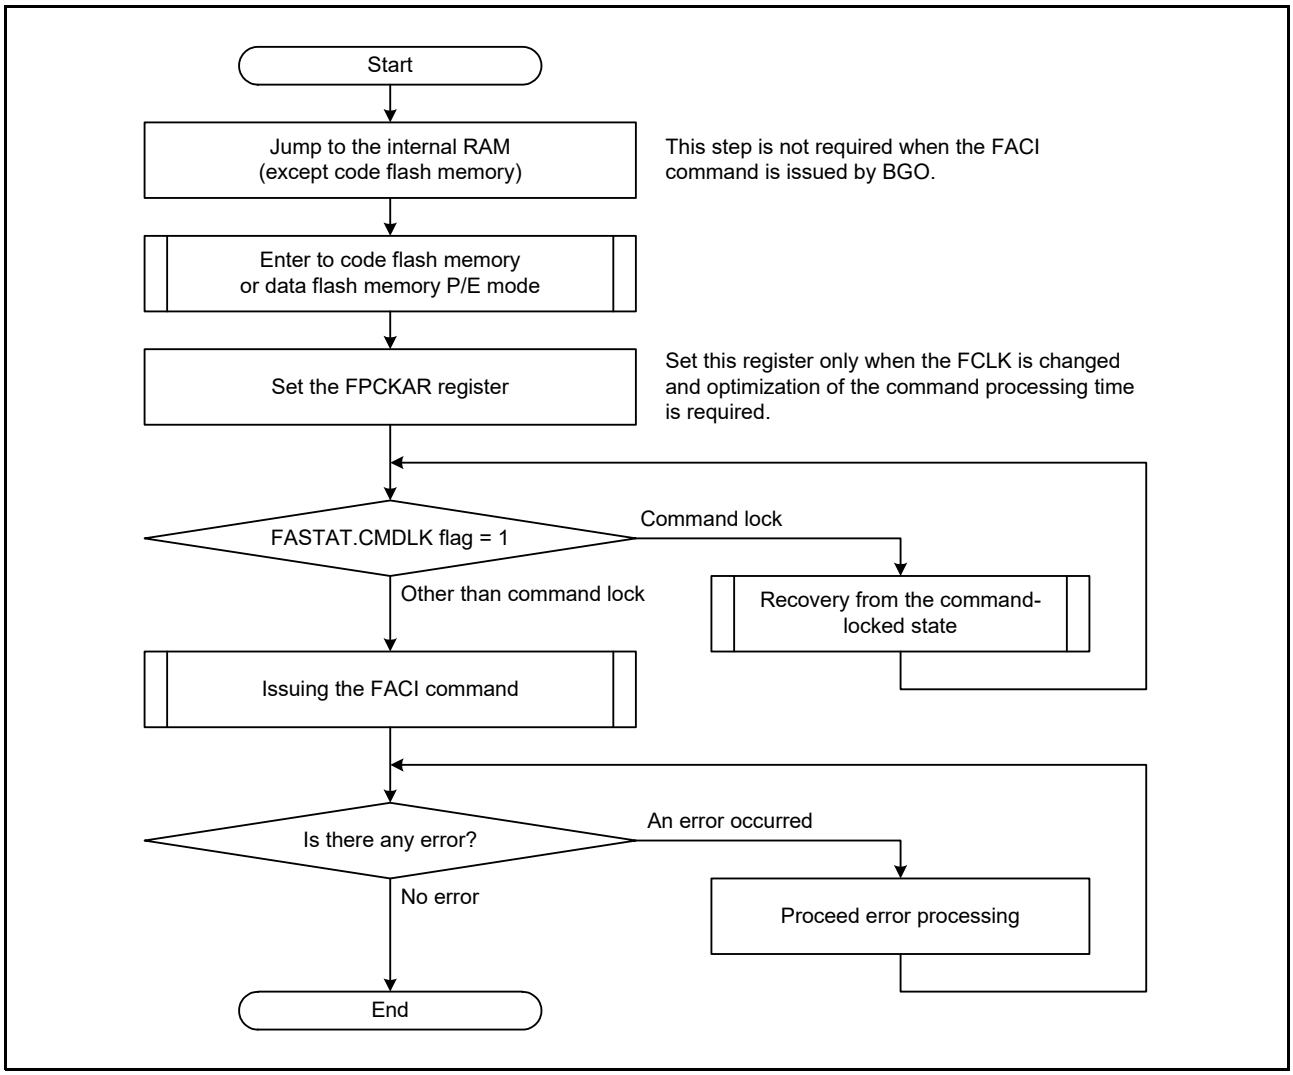


Figure 48.21 Overview Flow when FACI Command is Used

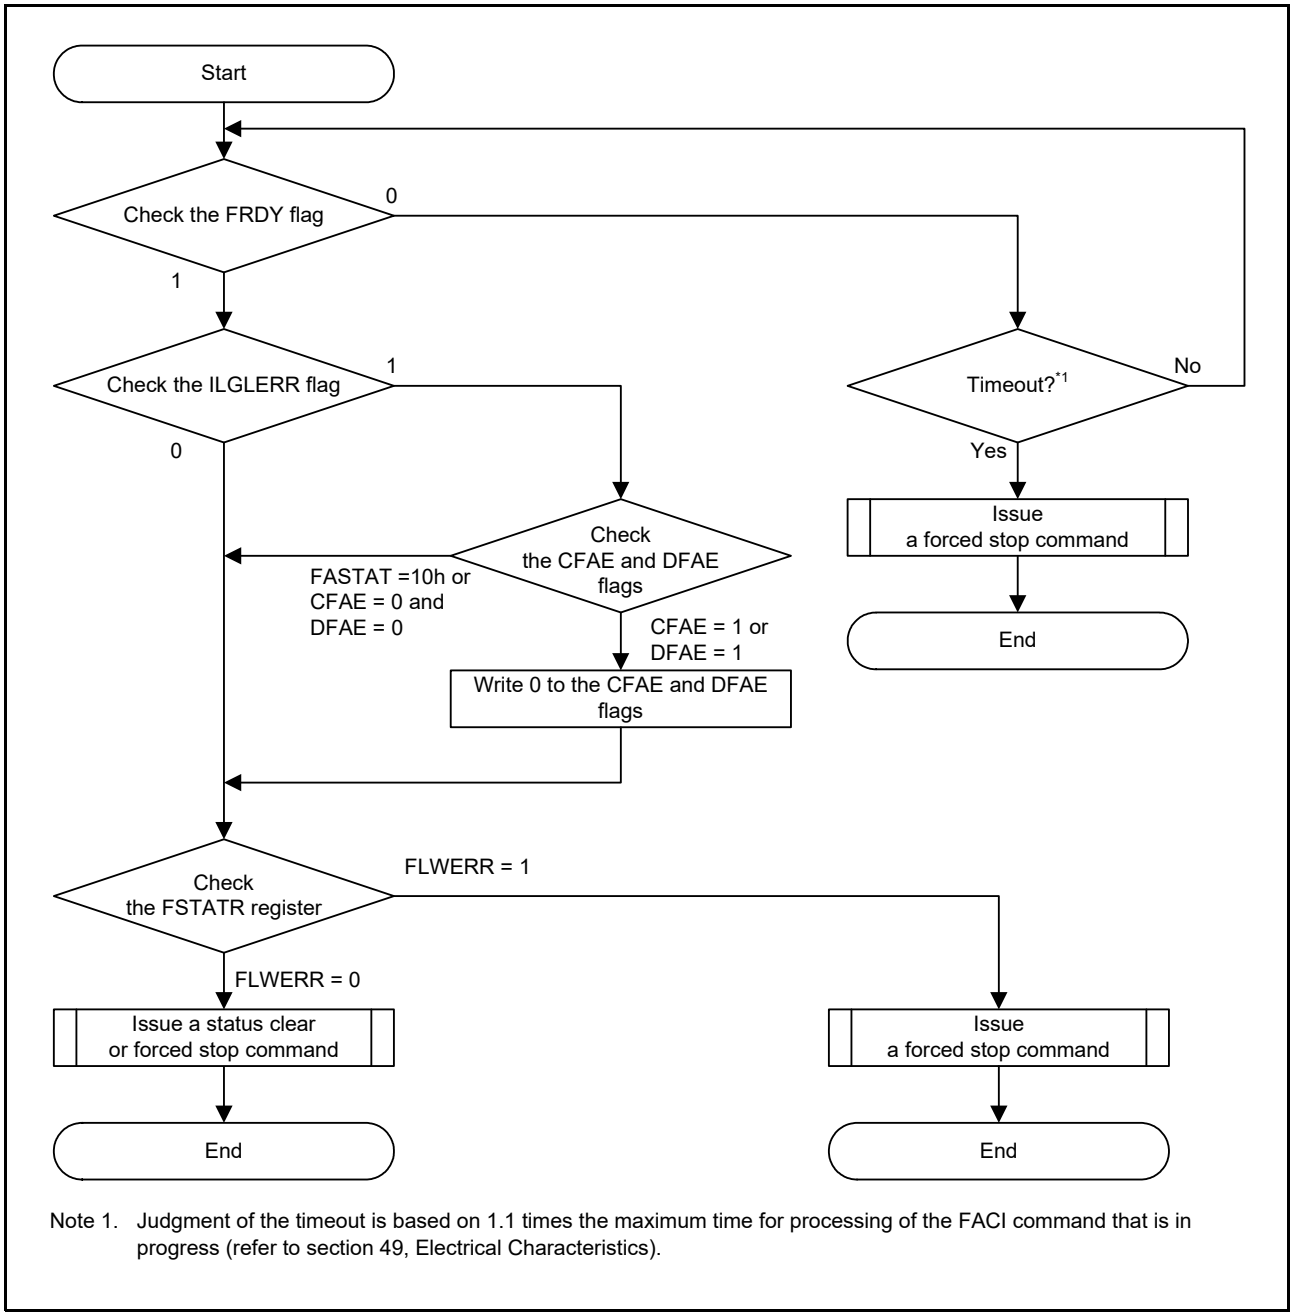
48.6.7.2 Recovery from the Command-Locked State

When the flash sequencer enters the command-locked state, FACI commands cannot be accepted. To release the sequencer from the command-locked state, use the status clear command, or forced stop command, or FASTAT register. When the command-locked state is detected by checking for an error before issuing the P/E suspend command, the FSTATR.FRDY flag may hold 0 as the command processing has not been completed. If processing is not completed within the maximum program/erase time specified in section 49, Electrical Characteristics, this can be considered a timeout, and the flash sequencer should be stopped by the forced stop command.
When the FSTATR.ILGLERR flag is 1, check the FASTAT value. If the CFAE or DFAE flag in the FASTAT register is 1, set the CFAE or DFAE flag in the FASTAT register to 0 and then issue the status clear and forced stop commands.
The FSTATR.FLWEERR flag is not changed from 1 to 0 by the status clear command. When this flag is set to 1, use the forced stop command for release from the command-locked state. The other bits that indicate the command-locked state can be changed from 1 to 0 by the status clear or forced stop command.

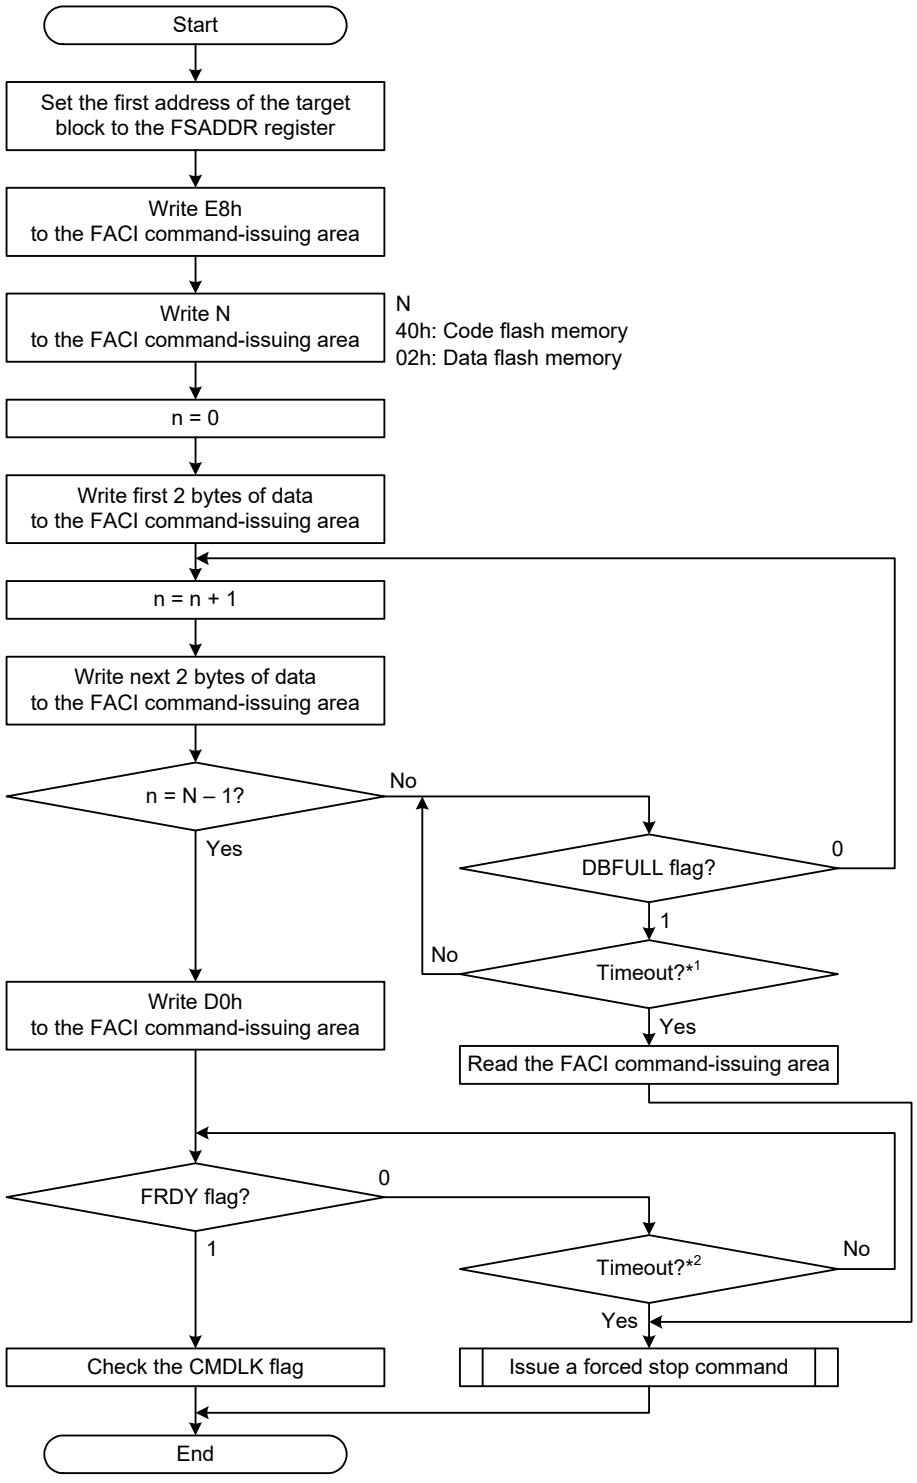


Note 1. Judgment of the timeout is based on 1.1 times the maximum time for processing of the FACI command that is in progress (refer to section 49, Electrical Characteristics).

Figure 48.22 Recovery from the Command-Locked State

48.6.7.3 Program Command

A program command is used for writing to the code flash memory and data flash memory.
Before issuing a program command, set the first address of the target block in the FSADDR register.
Writing D0h to the FACI command-issuing area at the final access of the FACI command-issuing starts the program command processing. Completion of command processing can be checked by reading the FSTATR.FRDY flag. If the target area of program command processing contains the area not for writing, write FFFFh to the corresponding area.
Issuing a program command consecutively while the FACI internal data buffer is full leads to a wait on the peripheral bus 6 and this may affect on the bus accesses of the other peripheral IP modules. To avoid the generation of such a wait, issue an FACI command while the FSTATR.DBFULL flag is 0.
Writing to the data flash memory will not lead to the data buffer becoming full.

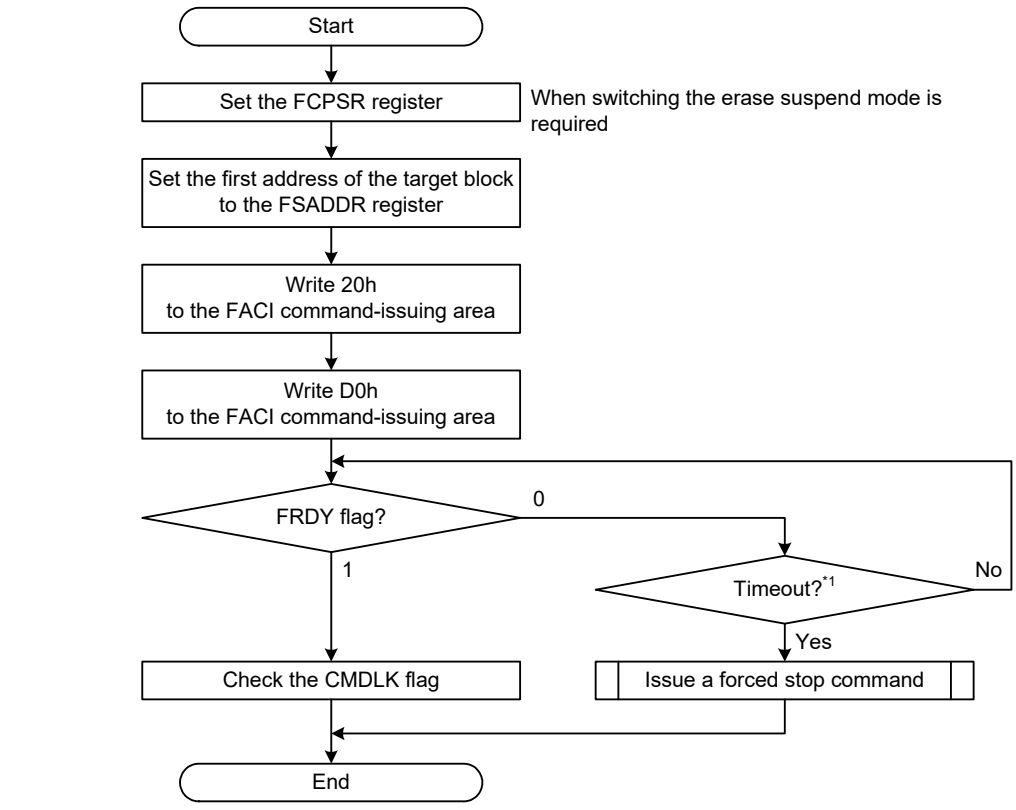


Note 1. Judgment of the timeout is based on 1.4 µs elapsing (when FCLK ≥ 20 MHz)
Note 2. Judgment of the timeout is based on 1.1 times 128-byte programming time (max) for code flash memory.
For data flash memory, judgment is based on 1.1 times 4-byte programming time (max).
For the 128-byte programming time and 4-byte programming time, refer to section 49, Electrical Characteristics.

Figure 48.23 Usage of the Program Command

48.6.7.4 Block Erase Command

A block erase command is used to erase the code flash memory, lock bit, and data flash memory in single-block units. Before issuing a block erase command, set the first address of the target block in the FSADDR register. Writing 20h and D0h to the FACI command-issuing area starts processing of a block erase command. Completion of command processing can be checked by reading the FSTATR.FRDY flag.
The FCPSR register must be set before issuing the block erase command. The setting of the FCPSR register must be changed to switch the suspending method (suspend priority mode/erase priority mode) by the P/E suspend command.



Note 1. Judgment of the timeout is based on 1.1 times 16-Kbyte erase time (max) for code flash memory. For data flash memory, judgment is based on 1.1 times 64-byte erase time (max). For the 16-Kbyte erase time and 64-byte erase time, refer to section 49, Electrical Characteristics.

Figure 48.24 Usage of the Block Erase Command

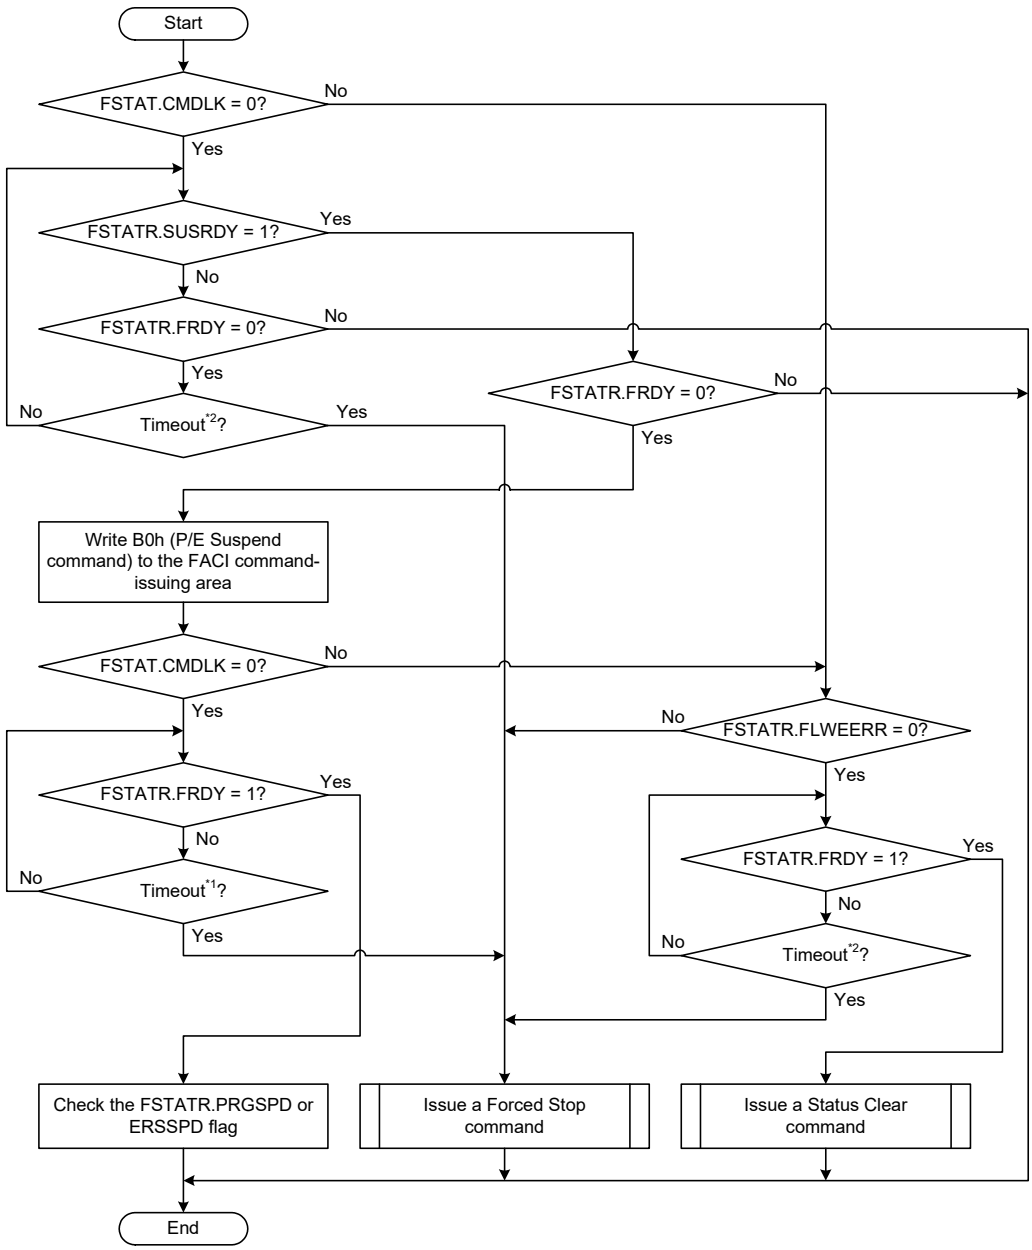
48.6.7.5 P/E Suspend Command

The P/E suspend command is used to suspend an in-progress program or erase operation. Before issuing a P/E suspend command, check that the FASTAT.CMDLK flag is 0, and the execution of program/erase is normally performed. To confirm that the P/E suspend command can be received, also check that the FSTATR.SUSRDY flag is 1. After issuing a P/E suspend command, read the FASTAT.CMDLK flag to confirm that its value is not 1 (the flash sequencer is not in the command-locked state).

If an error occurs during program or erase processing, the FASTAT.CMDLK flag is set to 1. When P/E processing is completed between the FSTATR.SUSRDY flag having been confirmed to be 1 and acceptance of the P/E suspend command, the P/E suspend command is ignored and the flash sequencer does not enter the suspended state (the FSTATR.FRDY flag is 1 and the ERSSPD and PRGSPD flags in the FSTATR register are 0).

When a P/E suspend command is received and then the program/erase suspend processing finishes normally, the flash sequencer enters the suspended state, the FSTATR.FRDY flag is set to 1, and the ERSSPD or PRGSPD flag in the FSTATR register is 1. After issuing a P/E suspend command, check that the ERSSPD or PRGSPD flag in the FSTATR register is 1 and the suspended state is entered, and then decide the subsequent flow. If a P/E resume command is issued in the subsequent flow although the suspended state is not entered, an illegal command error occurs and the flash sequencer moves to the command-locked state (refer to section 48.5.3.2, Error Protection).

If the erase-suspended state is entered, program to blocks other than the one currently suspended can be performed. In addition, the program- and erase-suspended states can move to read mode by clearing the FENTRYR register.



Note 1. For both the code flash and data flash memory, judgment of the timeout is based on 1.1 times the maximum value of the erase suspend latency.

Note 2. For both the code flash and data flash memory, judgment of the timeout is based on 1.1 times the maximum value of the erase time.

For the erase suspend latency and the erase time, refer to section 49, Electrical Characteristics.

Figure 48.25 Usage of the P/E Suspend Command

(1) Suspension during Program Operation

When a P/E suspend command is issued during program operation to flash memory, the flash sequencer suspends the program operation. Figure 48.26 shows the program suspend operation.

When the flash sequencer accepts a program or P/E resume command, it sets the FSTATR.FRDY flag to 0 and starts program sequence. When the flash sequencer is ready to accept the P/E suspend command after the program sequence has started, it sets the FSTATR.SUSRDY flag to 1. When a P/E suspend command is issued, the flash sequencer accepts the command and sets the FSTATR.SUSRDY flag to 0. When the flash sequencer receives a P/E suspend command while a program pulse is being applied, it continues to apply the pulse. After the specified pulse application time, the flash sequencer finishes applying program pulse, starts the suspend processing, and sets the FSTATR.PRGSPD flag to 1. When the suspend processing is completed, the flash sequencer sets the FSTATR.FRDY flag to 1 and enters the program-suspended state. When the flash sequencer receives a P/E resume command in the program-suspended state, it sets the FSTATR.FRDY and PRGSPD flags to 0 and resumes the program sequence.

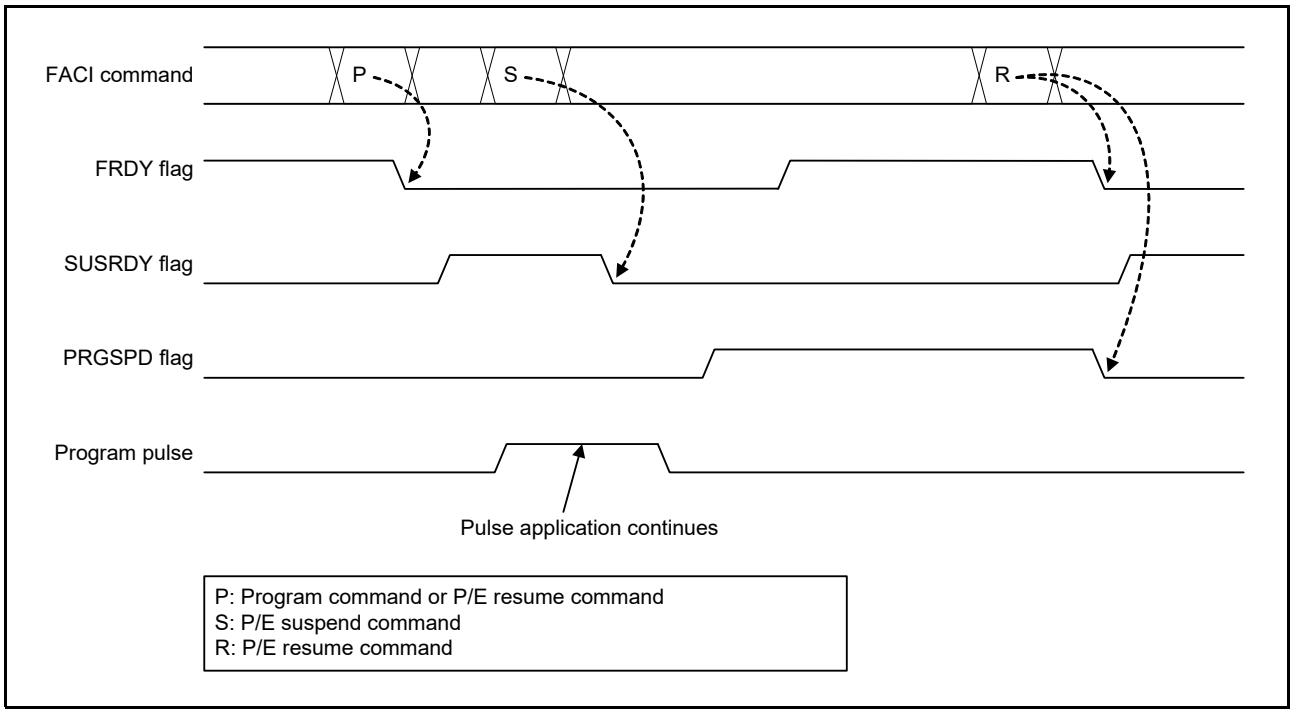


Figure 48.26 Program Suspend Operation

(2) Suspension during Erase Operation (Suspend Priority Mode)

This MCU supports the suspend priority mode as a suspend method during erase operation. Figure 48.27 shows the erase suspend operation in suspend priority mode (the FCPSR.ESUSPMD bit is set to 0).

When the flash sequencer accepts a block erase or P/E resume command, it sets the FSTATR.FRDY flag to 0 and starts erase sequence. When the flash sequencer is ready to accept the P/E suspend command after the erase sequence has started, it sets the FSTATR.SUSRDY flag to 1. When a P/E suspend command is issued, the flash sequencer accepts the command and sets the FSTATR.SUSRDY flag to 0. When the flash sequencer receives a P/E suspend command during erase sequence, the flash sequencer starts the suspend processing even while an erase pulse is being applied and sets the FSTATR.ERSSPD flag to 1. When the suspend processing is completed, the flash sequencer sets the FSTATR.FRDY flag to 1 and enters the erase-suspended state. When the flash sequencer receives a P/E resume command in the erase-suspended state, it sets the FSTATR.FRDY and ERSSPD flags to 0 and resumes the erase sequence. The behavior of the FSTATR.FRDY, SUSRDY, and ERSSPD flags when the erase sequence is suspended or resumed is the same regardless of the erase suspend mode.

The setting of the erase suspend mode affects the control method of erase pulses. In suspend priority mode, when a P/E suspend command is received while an erase pulse A, which has never been interrupted, is being applied, the flash sequencer stops applying erase pulse A and enters the erase-suspended state. When the flash sequencer receives a P/E suspend command again while the erase sequence is resumed by a P/E resume command and erase pulse A is being re-applied, it continues to apply erase pulse A. After the specified pulse application time, the flash sequencer finishes applying erase pulse A and enters the erase-suspended state. When the flash sequencer accepts a P/E resume command again and starts applying a new erase pulse B, and then accepts a P/E suspend command again, it stops applying erase pulse B.

In suspend priority mode, the application of an erase pulse is interrupted once per pulse to give priority to the suspend processing, thus reducing the suspend latency.

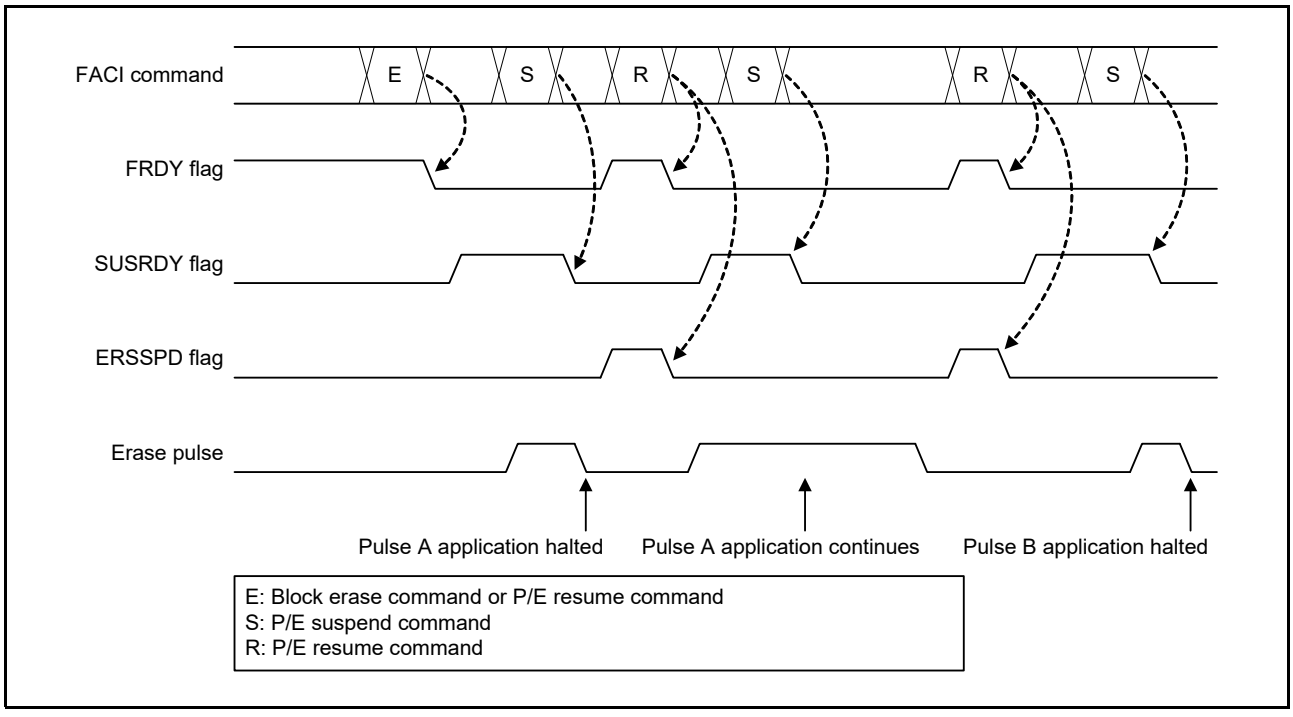

Figure 48.27 Erase Suspend Operation (Suspend Priority Mode)

(3) Suspension during Erase Operation (Erase Priority Mode)

This MCU supports the erase priority mode as a suspend method during erase operation.

Figure 48.28 shows the erase suspend operation in erase priority mode (the FCPSR.ESUSPMD bit is set to 1). The control method of erase pulses in erase priority mode is the same as that of program pulses for the program suspend processing.

When the flash sequencer receives a P/E suspend command while an erase pulse is being applied, the flash sequencer continues to apply the pulse. In this mode, the erase pulse is not re-applied when a P/E resume command is issued, thus reducing the overall time required for the erase operation compared to the suspend priority mode.

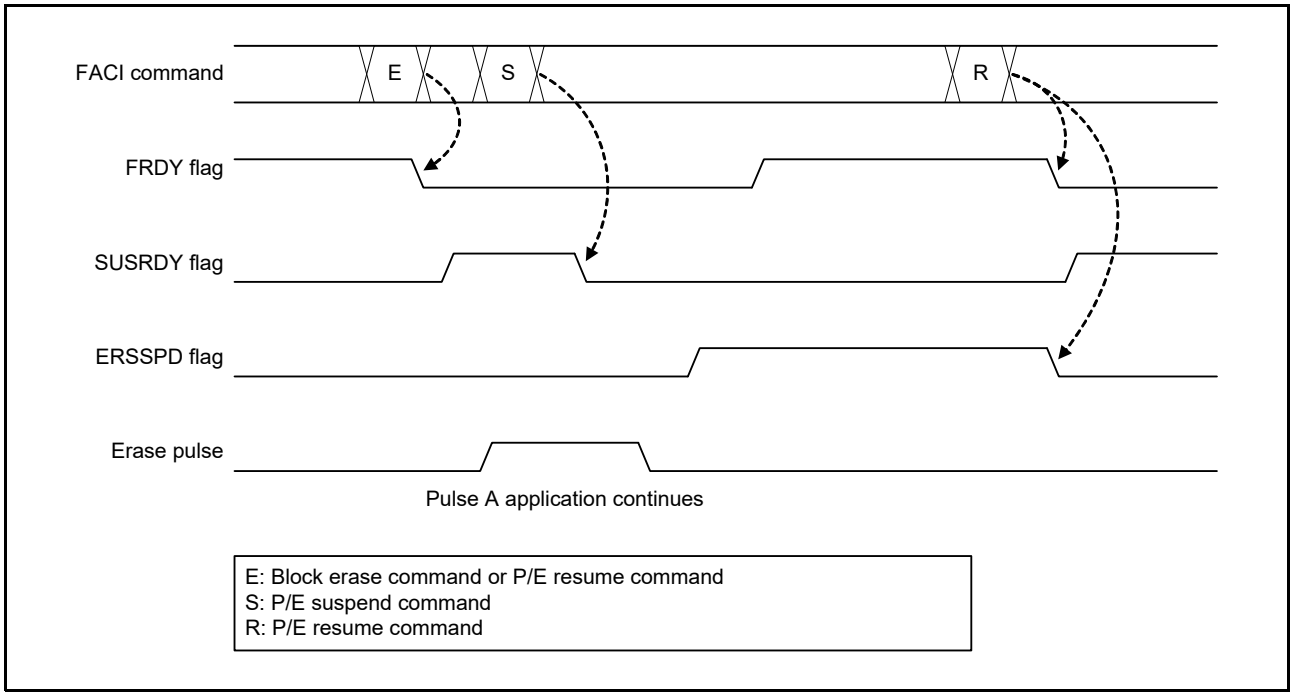

Figure 48.28 Erase Suspend Operation (Erase Priority Mode)

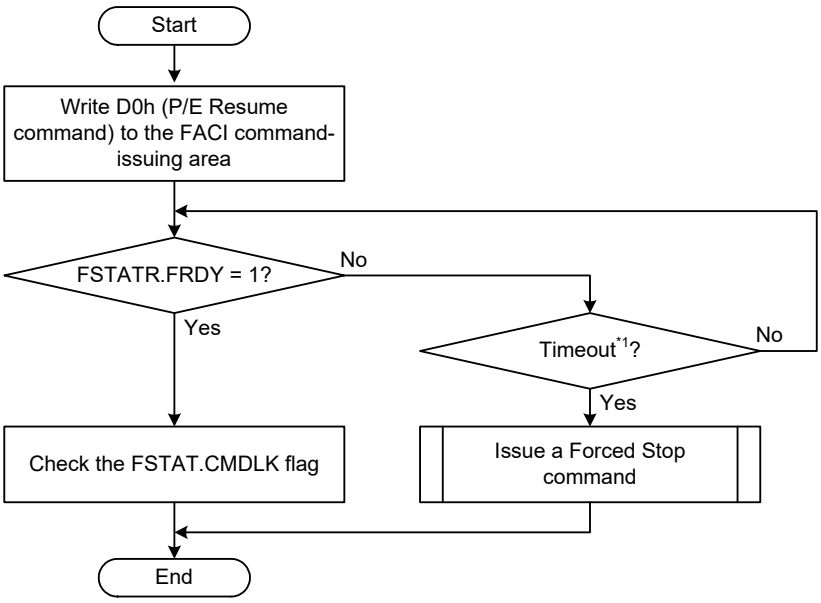
48.6.7.6 P/E Resume Command

To resume the suspended program or erase operation, use the P/E resume command. If the FENTRYR register setting is changed during suspend, reset the FENTRYR register value to the value immediately before the P/E suspend command was issued, and then issue a P/E resume command. Completion of processing of the resumed command can be confirmed by the FSTATR.FRDY flag.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for halted processing of the FACI command (refer to section 49, Electrical Characteristics).

Figure 48.29 Usage of the P/E Resume Command

48.6.7.7 Status Clear Command

When one of the ILGLERR, ERSERR, PRGERR, and FLWEERR flag bits in the FSTATR register is set to 1, the flash sequencer enters the command-locked state. When one of the CFAE and DFAE flags in the FASTAT register is set to 1, the flash sequencer also enters the command lock state. In the command-locked state, the flash sequencer can accept only status clearing command or forced end command.

The status clear command is used to clear the command-locked state (refer to section 48.6.7.2, Recovery from the Command-Locked State). To clear the CMDLK flags in the FASTAT register, and the ILGLERR, ERSERR, and PRGERR flags in the FSTATR register in the command-locked state, the status clear command is available.

The FSTATR.FLWEERR flag cannot only be cleared by the status clearing command, but can only be cleared by the forced end command.

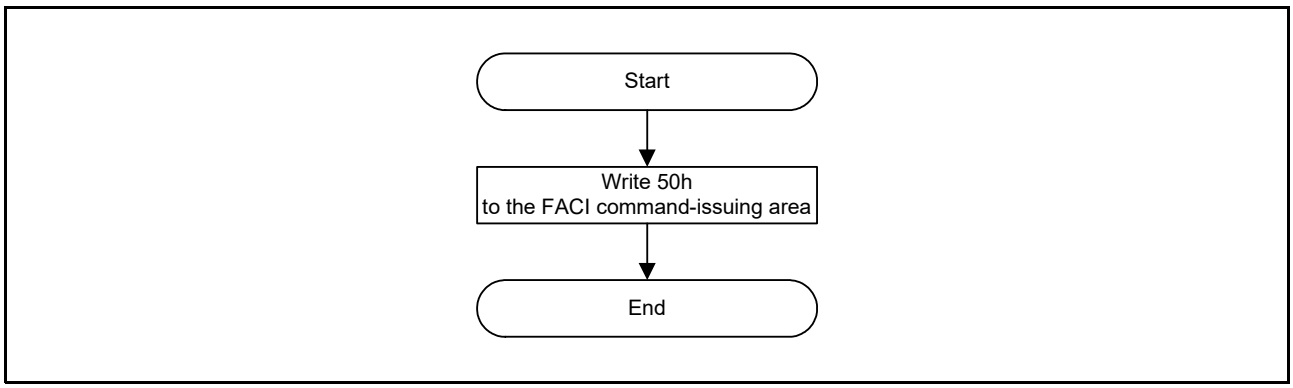


Figure 48.30 Usage of the Status Clear Command

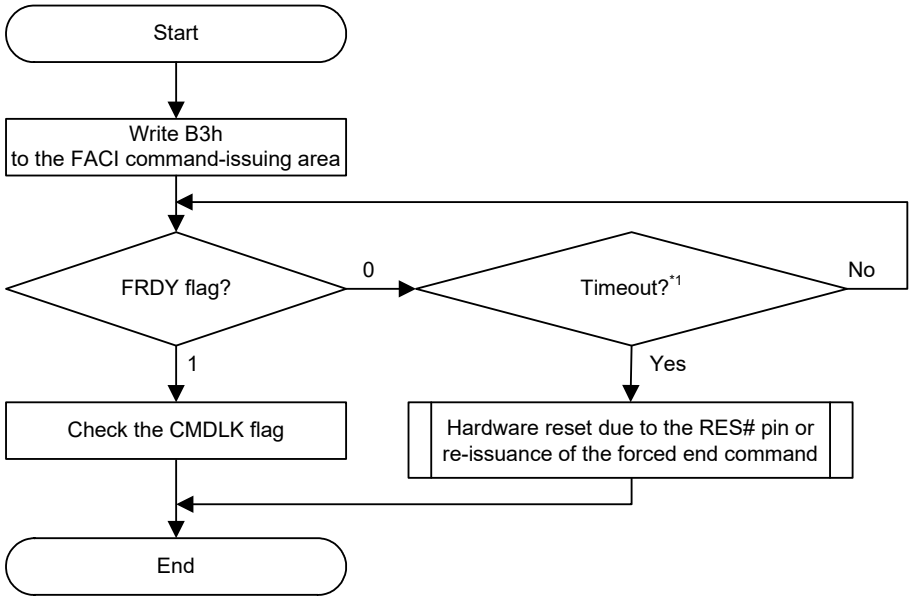
48.6.7.8 Forced Stop Command

The forced stop command forcibly terminates command processing by the flash sequencer. This command can interrupt the command processing faster than the P/E suspend command, but the values of the area being programmed or erased are not guaranteed. Also, the interrupted operation cannot be resumed. A program or erase operation terminated by a forced stop command is also defined as one program/erase cycle.
Executing the forced stop command initializes the entire flash sequencer and part of the FACI. It also initializes the FASTAT.CMDLK flag and the FSTATR register. Therefore, this command can also be used in the recovery procedure from the command-locked state and the time-out process of the flash sequencer (refer to section 48.6.7.2, Recovery from the Command-Locked State).



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for the forced stop command (refer to section 49, Electrical Characteristics).

Figure 48.31 Usage of the Forced Stop Command

How to Use the Forced Stop Command when a Command is being issued

When processing is terminated by the forced stop command while a timeout is generated based on the DBFULL bit judgment of the program command, writing to the FACI command issuing area may be handled as the data written by the program command. In this case, read the FACI command issuing area and generate a command lock intentionally, then issue the forced stop command according to the method of returning from the command lock state. A command lock can be generated although the access size for reading the FACI command issuing area is in 8-, 16-, or 32-bit units.

48.6.7.9 Blank Check Command

Values read from data flash memory that has been erased but not yet been programming again (i.e. that is in the nonprogrammed state) are undefined. Use the blank check command when you need to confirm that an area is in the nonprogrammed state.

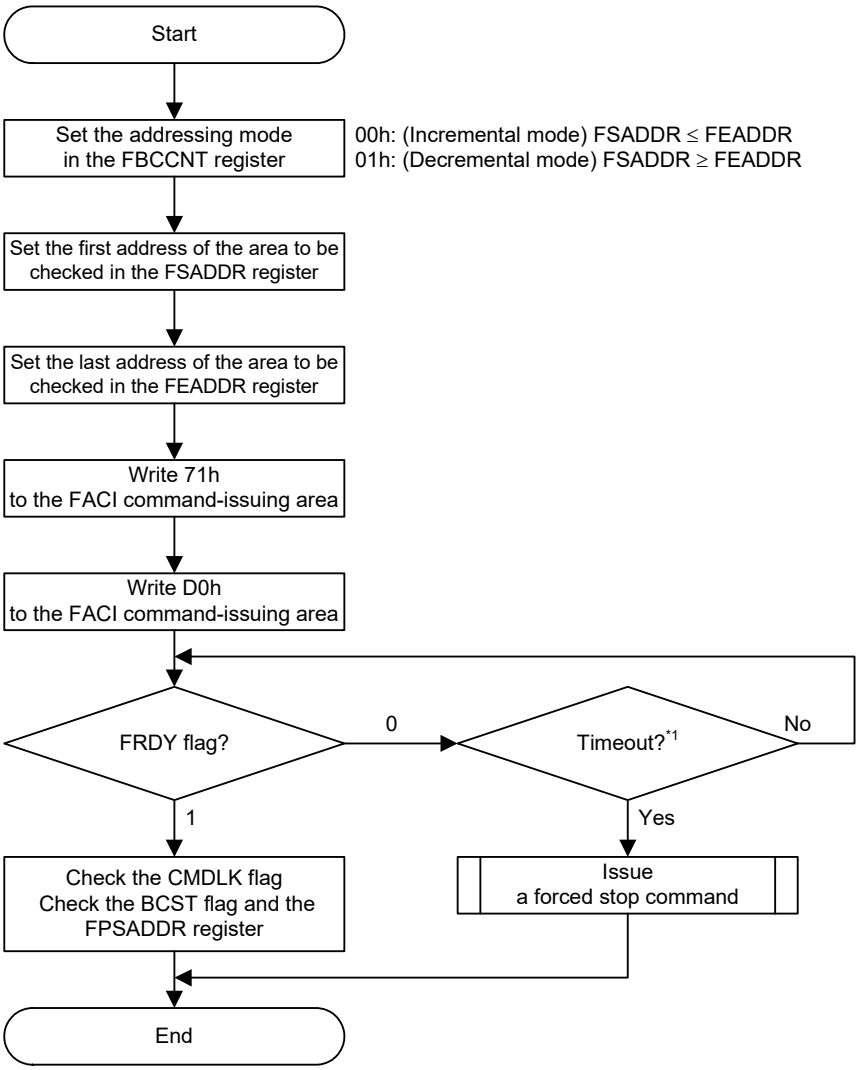
Before issuing a blank check command, set addressing mode, start and end addresses of the target area for blank checking to the FBCCNT, FSADDR, and FEADDR registers.

When the FBCCNT.BCDIR bit is 1, the value specified in the FSADDR register must be set at least the value specified in the FEADDR register.

When the FBCCNT.BCDIR bit is 0, the value specified in the FSADDR register must be the value specified in the FEADDR register or less.

When the settings of the FBCCNT.BCDIR bit, FSADDR register, and FEADDR register are inconsistent, the flash sequencer enters the command-locked state. The size of the target area for blank checking is in the range from 4 bytes to 16 Kbytes and is set in units of 4 bytes.

Write 71h and D0h to the FACI command-issuing area to start blank checking. Completion of processing can be confirmed by the FSTATR.FRDY flag. At the end of processing, the result of blank checking is stored in the FBCSTAT.BCST flag. If the target area for blank checking includes areas where programming has been completed, the flash sequencer stores the address of the programmed data that it first detected in the FPSADDR register.

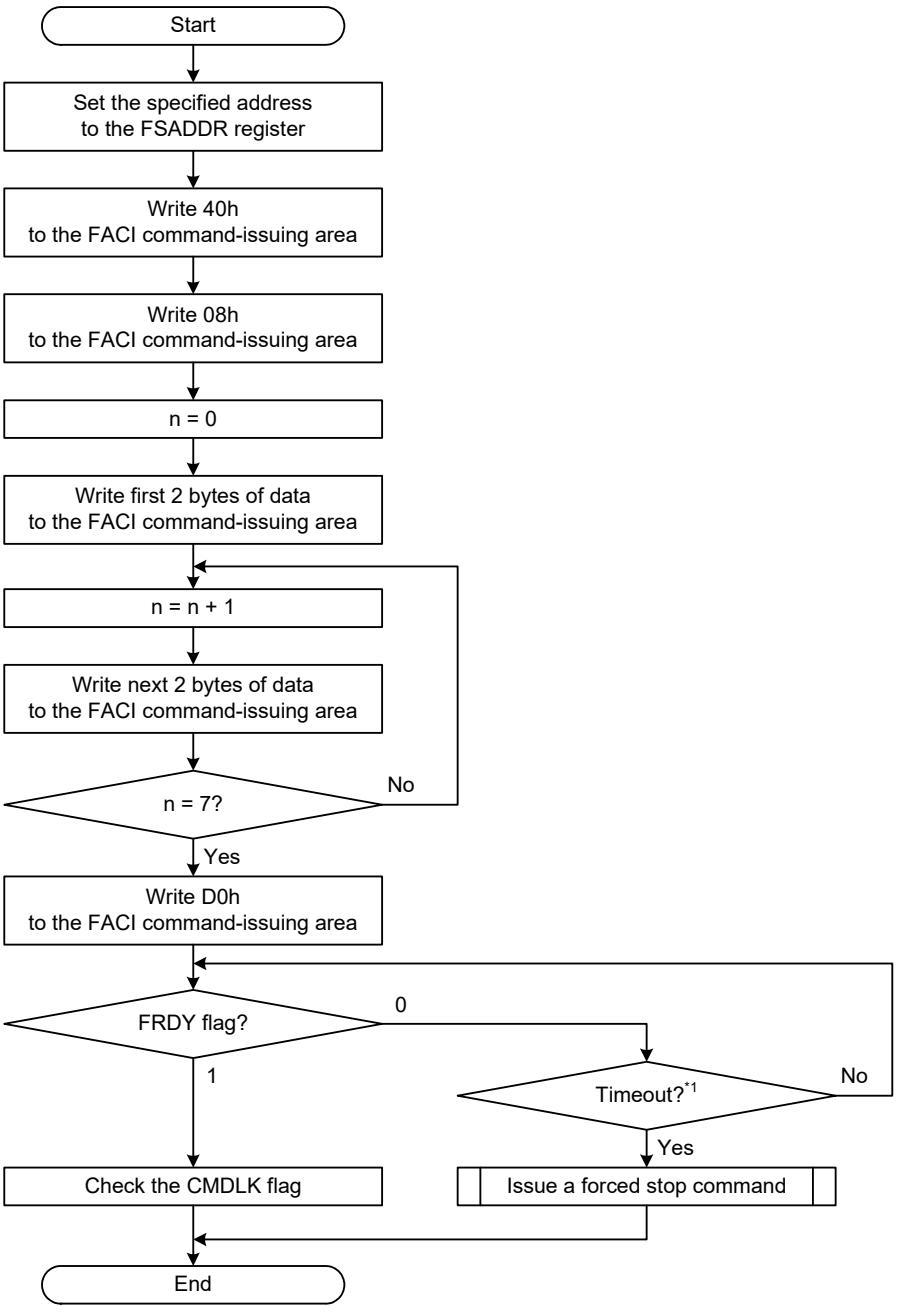


Note 1. Judgment of the timeout is based on 1.1 times the blank checking time (max.) for the entire target area. For the blank checking time, refer to section 49, Electrical Characteristics.

Figure 48.32 Usage of the Blank Check Command

48.6.7.10 Configuration Set Command

The configuration set command is used to set the configuration setting area.
Before issuing a configuration set command, set the specified address (shown in Table 48.17) in the FSADDR register.
Writing D0h to the FACI command-issuing area in the final access for issuing the FACI command starts processing of the configuration set command.



Note 1. Timeout is judged to be after 70ms (when 20 MHz ≤ FCLK ≤ 60 MHz), or 140 ms (when FCLK = 4 MHz).

Figure 48.33 Usage of the Configuration Set Command

The correspondence between the possible target data for configuration setting and the address value set in the FSADDR register is shown in Table 48.17.

Table 48.17 Address Used by Configuration Set Command

Address	FSADDR Register Value	Setting Data	Operation of additional writing		Timing when the Setting is Enabled
			FAW.FSPR bit is 1	FAW.FSPR bit is 0	
0012 0040h	0000 0040h	• Serial programmer command control register (SPCC) • TM enable flag register (TMEF)	Writable*1 (from 1 to 0 only)	Writable*1 (from 1 to 0 only)	After a reset or when command is executed*2
0012 0050h	0000 0050h	• OCD/serial programmer ID setting register (OSIS)	Writable	Writable	After a reset
0012 0060h	0000 0060h	• TM identification data register (TMINF) • Endian select register (MDE) • Option function select register 0 (OFS0) • Option function select register 1 (OFS1)	Writable	Writable	After a reset
0012 0090h	0000 0090h	• Bank select register (BANKSEL)	Writable	Writable	After a reset
0012 00A0h	0000 00A0h	• Flash access window setting register (FAW)*3	Writable	Not writable*3	After a reset or when command is executed

Note 1. Once these bits are set to 0, the bits cannot be restored to 1 by using the configuration setting command.
Note 2. The setting in the serial programmer command control register (SPCC) is enabled after a reset. The setting of the TM enable flag register (TMEF) is enabled after a reset or when command is executed.
Note 3. The FAW.FSPR bit cannot be restored to 1 once it is set to 0. Therefore, setting the access window and start-up area select bits again becomes impossible. (when the configuration setting command is issued to the address of 0012 00A0h, the flash sequencer enters the command-locked state.) Exercise extra caution when handling the FAW.FSPR bit.

48.7 Boot Mode

There are two serial programming modes; the boot mode (SCI interface) with SCI and the boot mode (FINE interface) with FINE. Table 48.18 lists the I/O pins used in boot mode.
I/O pins that are not used in boot mode are in the same state as that after a reset.

Table 48.18 I/O Pins Used in Boot Mode

Pin Name	I/O	Mode to be Used	Use
PN6/MD	Input	Boot mode (SCI interface)	Selection of operating mode
PD5/RXD1	Input		For host communication (to receive data through SCI)
PD3/TXD1	Output		For host communication (to transmit data through SCI)
PN6/MD/FINED	I/O	Boot mode (FINE interface)	Selection of operating mode, FINE data I/O

48.7.1 Boot Mode (SCI Interface)

In boot mode (SCI interface), the host sends control commands and data for programming, and the code flash memory and data flash memory can be programmed or erased. An on-chip SCI handles transfer between the host and this MCU in asynchronous mode. Tools for transmission of control commands and the data for programming must be prepared in the host.
When this MCU is activated in boot mode (SCI interface), the program (boot program) in a dedicated area within the MCU is executed. The boot program automatically adjusts the bit rate of the SCI and controls program/erase operation by receiving control commands from the host.
Figure 48.34 shows the system configuration for operations in boot mode (SCI interface).

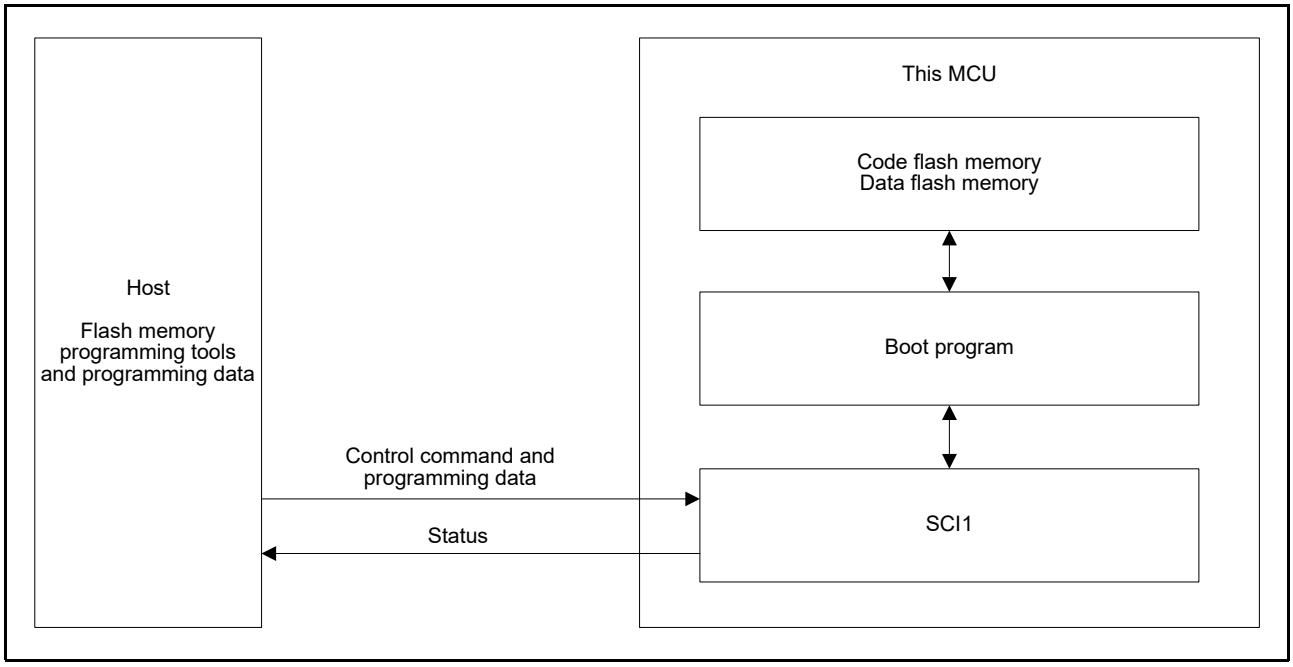


Figure 48.34 System Configuration for Operations in Boot Mode (SCI Interface)

48.7.2 Boot Mode (FINE Interface)

The flash memory can be programmed and erased using the FINE in boot mode (FINE interface). The code flash memory and data flash memory can be rewritten.

48.7.2.1 Operating Conditions in Boot Mode (FINE Interface)

FINE is used to communicate with the serial programmer in boot mode (FINE Interface).
Figure 48.35 shows an Example of Pin Connections in Boot Mode (FINE Interface). Table 48.19 lists Pin Handling in Boot Mode (FINE Interface).
The example of pin connections shown in Figure 48.35 is a simplified circuit. Operations are not guaranteed in all systems.

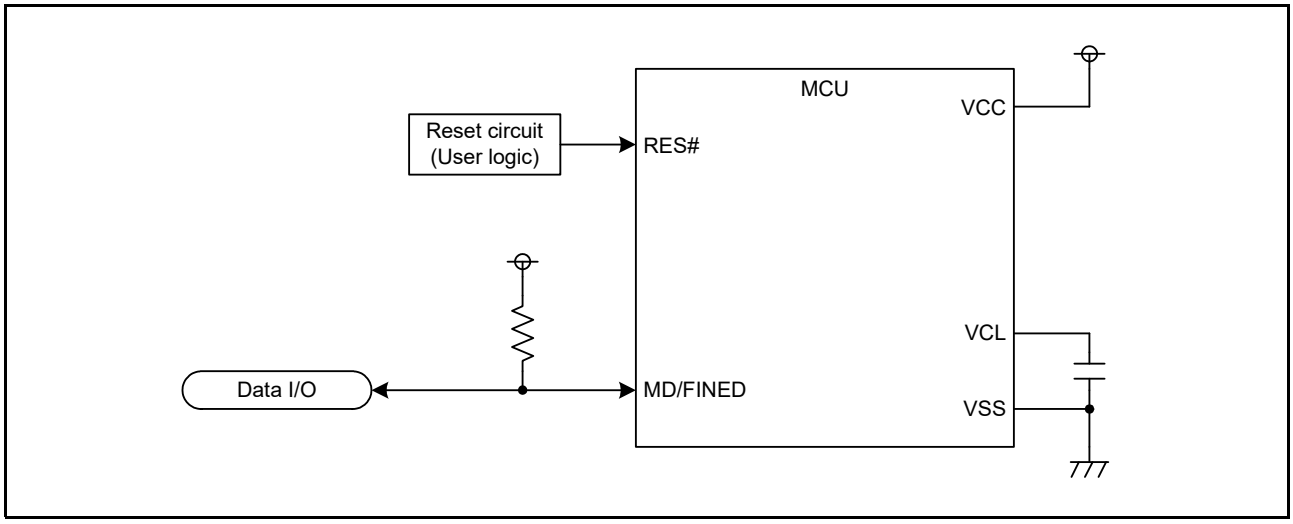

Figure 48.35 Example of Pin Connections in Boot Mode (FINE Interface)

Table 48.19 Pin Handling in Boot Mode (FINE Interface)

Pin Name	Name	I/O	Function
VCC, VSS	Power supply input	Input	Input 2.7 V or higher to the VCC pin. Input 0 V to the VSS pin.
VCL	Decoupling capacitor connect pin	—	Connect to the VSS pin via a 0.47-μF multilayer ceramic capacitor for stabilizing the internal voltage.
MD/FINED	Operating mode control/data I/O	I/O	Connect the VCC pin via a resistor (pull up).
RES#	Reset input	Input	Reset pin. Connect to the reset circuit.

48.8 Boot Mode Communications Protocol

This section describes the communications protocol for use in boot mode. When developing a serial programmer, use this communications protocol to control it.

48.8.1 How to Start the Chip Up in Boot Mode

(1) How to Start the Chip Up in Boot Mode (SCI Interface)

The chip starts up in boot mode (SCI interface) if the MD pin is at the low level on release from the reset state (i.e. when the level on the RES# pin changes from low to high). A waiting time of at least 400 ms is required while the RES# pin is held at the high level after the chip starts up in boot mode (SCI interface) until communications with the MCU can proceed.

Figure 48.36 shows the states of pins up to communications in boot mode (SCI interface) becoming possible.

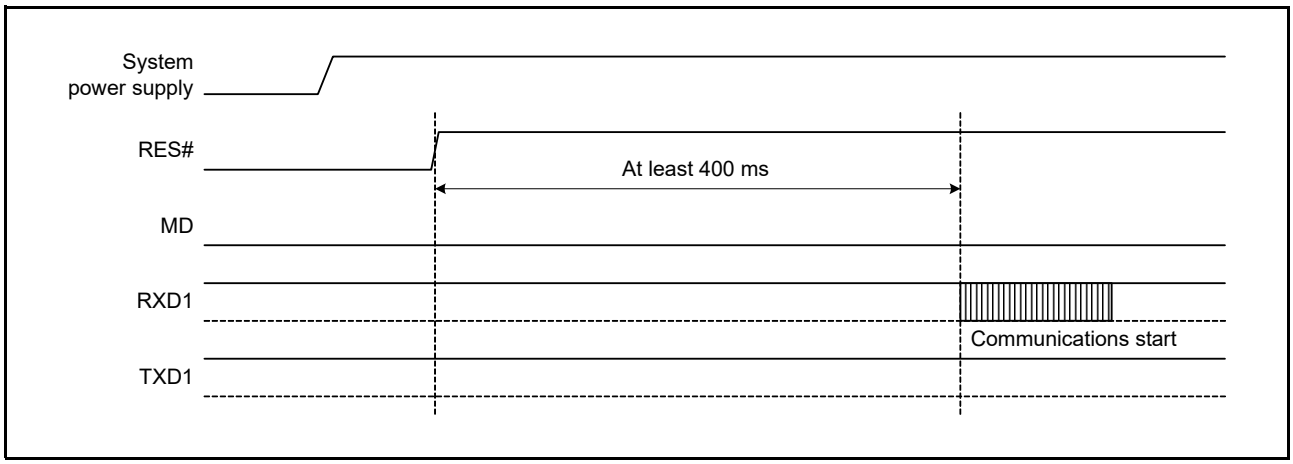

Figure 48.36 States of Pins Up to Communications in Boot Mode (SCI Interface) Becoming Possible

48.8.2 State Transitions in Boot Mode

48.8.2.1 State Transitions in Boot Mode (SCI Interface)

Figure 48.37 shows a flowchart for transition to boot mode (SCI interface).

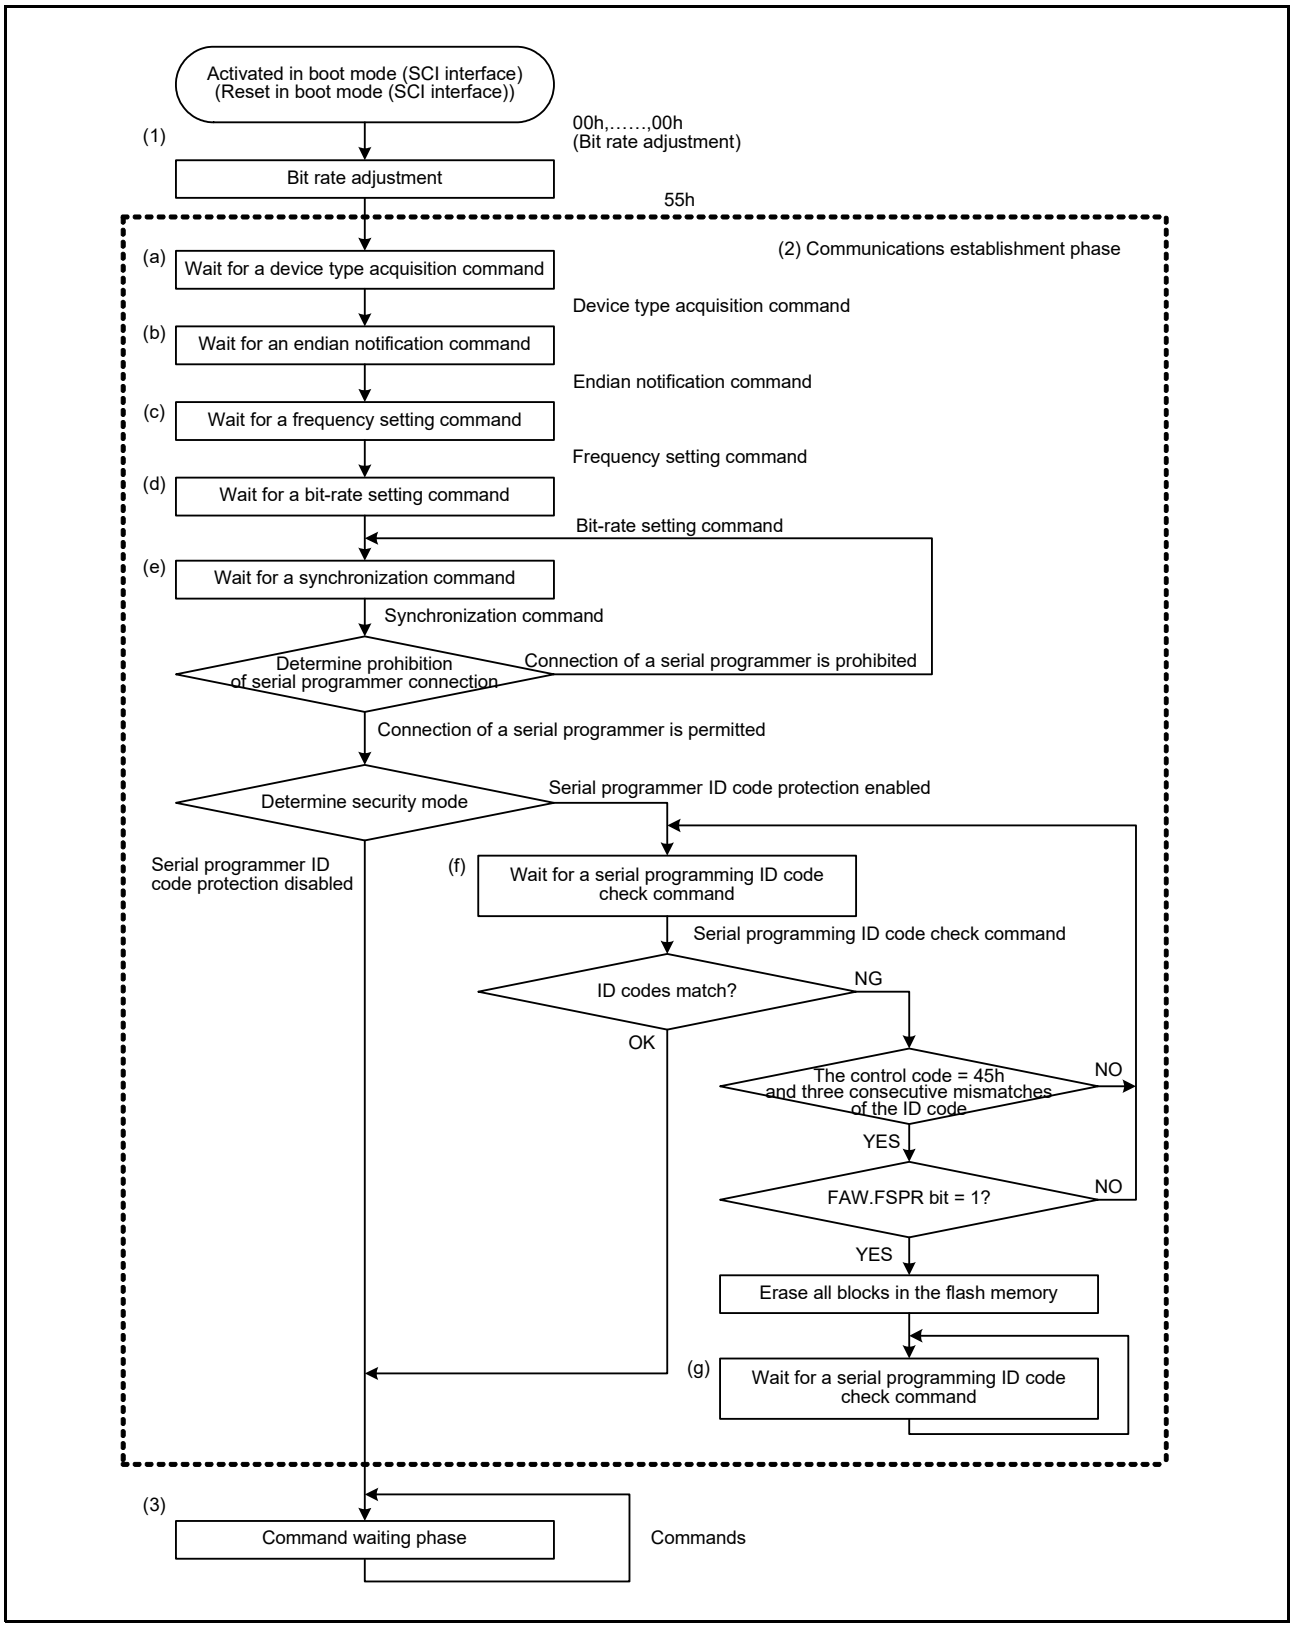

Figure 48.37 Flowchart for Transition to Boot Mode (SCI Interface)

(1) Matching the bit rates

When this MCU is activated in boot mode, the bit rate of the SCI is automatically adjusted to match that of the host. On completion of this automatic bit rate adjustment, this MCU transmits the value 00h to the host. On subsequent correct reception of the value 55h sent from the host, this MCU enters the communications establishment phase. For details on matching of the bit rates, refer to section 48.8.3, Automatic Adjustment of the Bit Rate.

(2) Communications establishment phase

The device, endian, frequency, and bit rate are selected in this phase. If serial programmer ID code protection is enabled, ID code authentication is performed. For the commands to use in the communications establishment phase, refer to section 48.8.5, Communications Establishment Phase.

(a) Waiting for a device type acquisition command

In this state, the MCU is waiting for a device type acquisition command to be sent from the host. When it receives a device type acquisition command, the state moves to waiting for an endian notification command. For details of the device type acquisition command, refer to section 48.8.9, Device Type Acquisition Command.

(b) Waiting for an endian notification command

In this state, the MCU is waiting for an endian notification command to be sent from the host. When it receives an endian notification command, the state moves to waiting for a frequency setting command. For details of the endian notification command, refer to section 48.8.10, Endian Notification Command.

(c) Waiting for a frequency setting command

In this state, the MCU is waiting for a frequency setting command to be sent from the host. When it receives a frequency setting command, the state moves to waiting for a bit-rate setting command. For details of the frequency setting command, refer to section 48.8.11, Frequency Setting Command.

(d) Waiting for a bit-rate setting command

In this state, the MCU is waiting for a bit-rate setting command to be sent from the host. When it receives a bit-rate setting command, the state moves to waiting for a synchronization command. For details of the bit-rate setting command, refer to section 48.8.12, Bit-Rate Setting Command.

(e) Waiting for a synchronization command

In this state, the MCU is waiting for a synchronization command to be sent from the host. When it receives a synchronization command, it determines whether the serial programmer ID code protection is enabled or disabled. When the ID code protection is disabled, the MCU enters the command waiting phase. When the ID code protection is enabled, it enters the state of waiting for a serial programming ID code check command. If the MCU has been set to prohibit the connection of a serial programmer, this MCU transmits an error code to indicate that connecting a serial programmer is prohibited and remains in the state of waiting for a synchronization command. For details of the synchronization command, refer to section 48.8.13, Synchronization Command.

(f) Waiting for a serial programming ID code check command

In this state, the MCU is waiting for a serial programming ID code check command to be sent from the host. The control code and ID codes sent are compared with the control code and ID codes in the OSIS register, and the command waiting phase is entered if they match. If they do not match, the next transition is back to the state of waiting for a serial programming ID code check command. If the control code is 45h and the codes do not match three times in a row, all data in the flash memory are erased*1.
For details of the ID code check command, refer to section 48.8.15, Serial Programming ID Code Check Command.

Note 1. When the FAW.FSPR bit is 0, the data in the flash memory are not erased.

(g) Waiting for a serial programming ID code check command (after erase)

After all blocks in the flash memory are erased, reboot the MCU in boot mode.

(3) Phase of waiting for commands

In this state, program and erase operations proceed according to commands from the host. For details of the commands that can be issued in the command waiting phase, refer to section 48.8.6, Command Waiting Phase.

48.8.3 Automatic Adjustment of the Bit Rate

When this MCU is booted up in boot mode (SCI interface), asynchronous transfer by the SCI is used to measure the periods at low level of consecutive bytes with value 00h that are sent from the host. While the period at low level is being measured, set the host's SCI transfer format to 8-bit data, one stop bit, no parity, and a transfer rate of 9,600 bps. This MCU measures the periods at low level in the signal from the host, adjusts the bit rate of its SCI, and then sends the value 00h to the host.

If reception of the value 00h by the host is successful, the host responds by sending the value 55h to this MCU. If successful reception of 00h by the host is not possible, reboot this MCU in boot mode, and then repeat the process of automatically adjusting the bit rate. If reception of the value 55h by this MCU is successful, it responds by sending C2h to the host, and if successful reception of 55h by this MCU is not possible, it responds by sending FFh to the host.

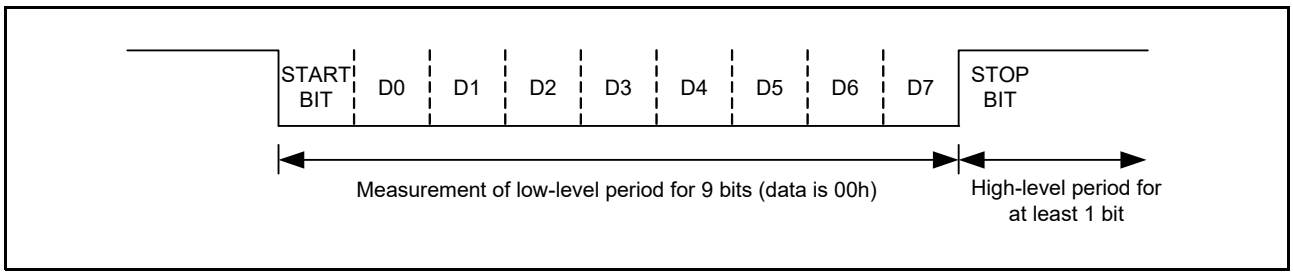

Figure 48.38 Transfer Format Used by SCI in Automatic Adjustment of Bit Rate

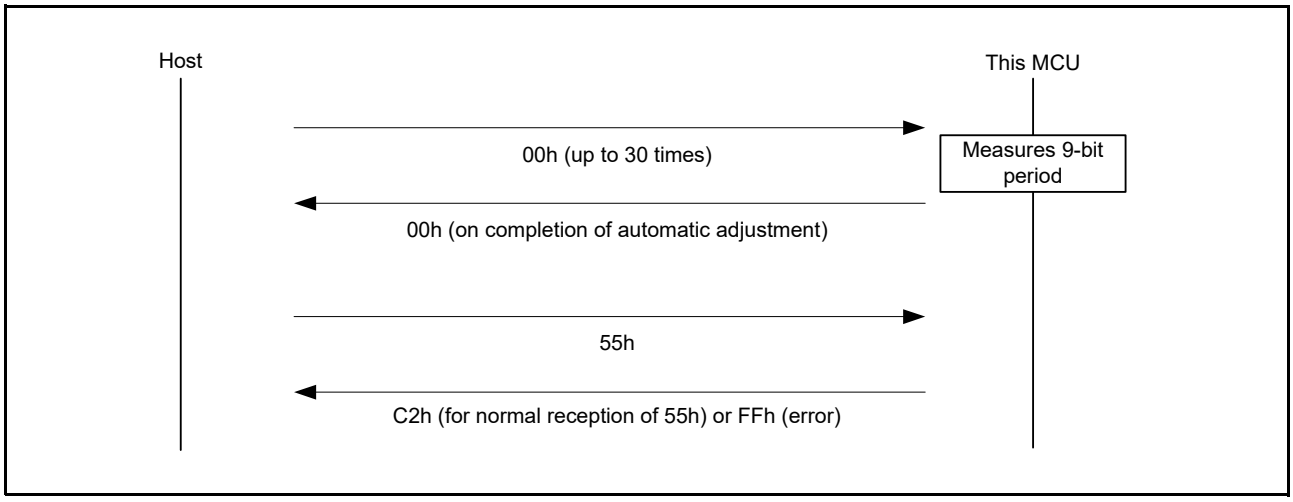

Figure 48.39 Sequence of Transfer between Host and This MCU

For the host's SCI bit rate, ensure that SCI communications proceed under the conditions given in Table 48.20.

Table 48.20 Conditions for Automatic Bit-Rate Adjustment

Bit Rate of SCI in Host
9,600 bps

48.8.4 Packet Format

(1) Command packet

The host sends commands to this MCU in the format below.

SOH	LNH	LNL	COM	Command information (variable length) (up to 255 bytes)	SUM	ETX

Symbol	Code	Description
SOH	01h	Start of a packet (1 byte)
LNH	—	Upper byte of packet length (length of COM and the command information) (1 byte)
LNL	—	Lower byte of packet length (length of COM and the command information) (1 byte)
COM	—	Command code (1 byte)
Command information	—	Command information (up to 255 bytes)
SUM*1	—	Two's complement of the sum of values of LNH, LNL, COM, and the command information (1 byte)
ETX	03h	End of a packet (1 byte)

Note 1. SUM indicates the 1 byte of data that produces 00h as the result of adding LNH, LNL, COM, the command information, and SUM itself.

(2) Status packet and data packet

Data transmission proceeds between the host and this MCU in the format below.

SOD	LNH	LNL	RES	Data (variable length) (up to 1024 bytes)	SUM	ETB	or	ETX

Symbol	Code	Description
SOD	81h	Start of a packet (1 byte)
LNH	—	Upper byte of packet length (length of RES and the data) (1 byte)
LNL	—	Lower byte of packet length (length of RES and the data) (1 byte)
RES	—	Response code (1 byte)
Data	—	Data (up to 1024 bytes)
SUM*1	—	Two's complement of the sum of values of LNH, LNL, RES, and the data (1 byte)
ETB	17h	End of a packet (1 byte)
ETX	03h	End of the last packet (1 byte)

Note 1. SUM indicates the 1 byte of data that produces 00h as the result of adding LNH, LNL, RES, the data, and SUM itself.

48.8.5 Communications Establishment Phase

Table 48.21 lists the commands available in the commands establishment phase.
The synchronization command and ID authentication mode acquisition command can also be used in the command waiting phase.

Table 48.21 Commands Available in the Communications Establishment Phase

Command Name	Function
Device type acquisition	Transmits the oscillation frequency and CPU operating frequency (in Hz) supported by boot mode to the host.
Endian notification	Indicates whether big-endian or little-endian is to be used.
Frequency setting	Sets the values of the oscillation frequency and CPU operating frequency (in Hz).
Bit-rate setting	Changes the bit rate.
Synchronization	This command is used in processing for communications synchronization. It is also used when confirming whether the MCU can accept commands.
ID authentication mode acquisition	This command sends the enabled/disabled state of the serial programmer ID code protection to the host.
Serial programming ID code check	Determines whether the control code and ID code written in the option-setting memory matches the control code and ID code sent by the host.

In the communications establishment phase, send commands from the host in the order of the device type acquisition, endian notification, frequency setting, bit-rate setting, and synchronization commands according to the responses to commands. When serial programmer ID code protection is enabled, send the ID authentication mode acquisition or serial programming ID code check command following the synchronization command.
If commands are issued in an incorrect order or other commands are issued, this MCU returns a response indicating a flow error.

48.8.6 Command Waiting Phase

Table 48.22 lists the commands available in the command waiting phase.
The synchronization command and ID authentication mode acquisition command can also be used in the communications establishment phase.

Table 48.22 Commands Available in the Command Waiting Phase

Command Name	Function
Synchronization	Refer to Table 48.21.
Blank check	Check that a selected area is blank.
Block erase	Erases a selected single block.
Area erase	Erases the specified area.
Program	Programs the selected area.
Read	Reads data from a selected area.
ID authentication mode acquisition	Refer to Table 48.21.
Configuration clear	Erases the configuration setting area and the TM target areas.
Configuration program	Set values to the configuration setting area.
Configuration read	Read values set in the configuration setting area.
Simple addition checksum	Calculates the sum of values in a selected area.
Acquisition of the number of the area information	Obtains the number of area information of the flash memory.
Acquisition of the area information	Obtains the area information of the flash memory.

If the host has sent an undefined command, this MCU returns a response indicating an error in the form of a unsupported command.

48.8.7 Command Transfer Sequence

Though the sequence of transfer differs from command to command, common transfer sequences are used for the commands that only make settings for this MCU and for the commands that obtain information on the settings in this MCU. However, as the contents of the command packet, status packet, and data packet differ for each command, refer to the sections on the individual commands for details.

(1) Common transfer sequence for the commands that only make settings

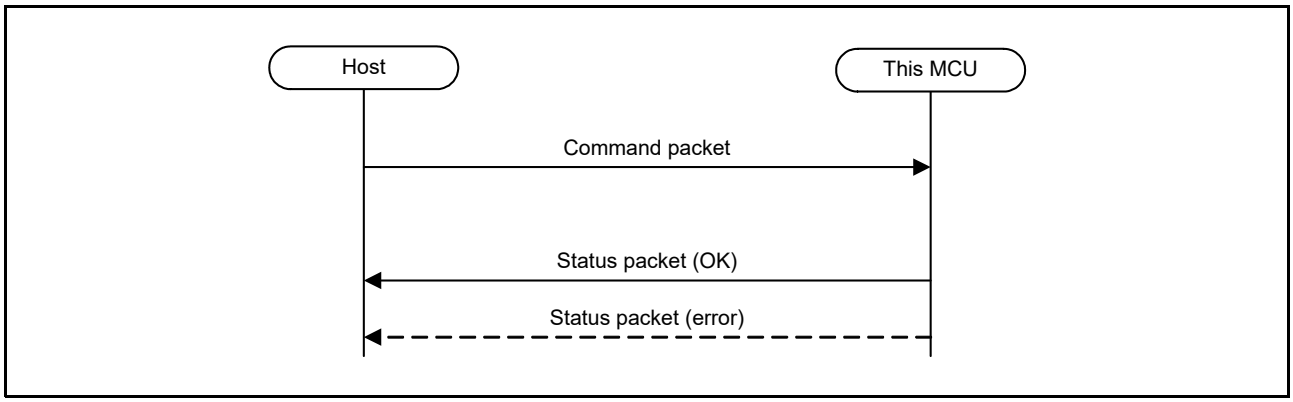

Figure 48.40 Common Transfer Sequence for the Commands that Only Make Settings

(2) Common transfer sequence for the commands that obtain information on settings

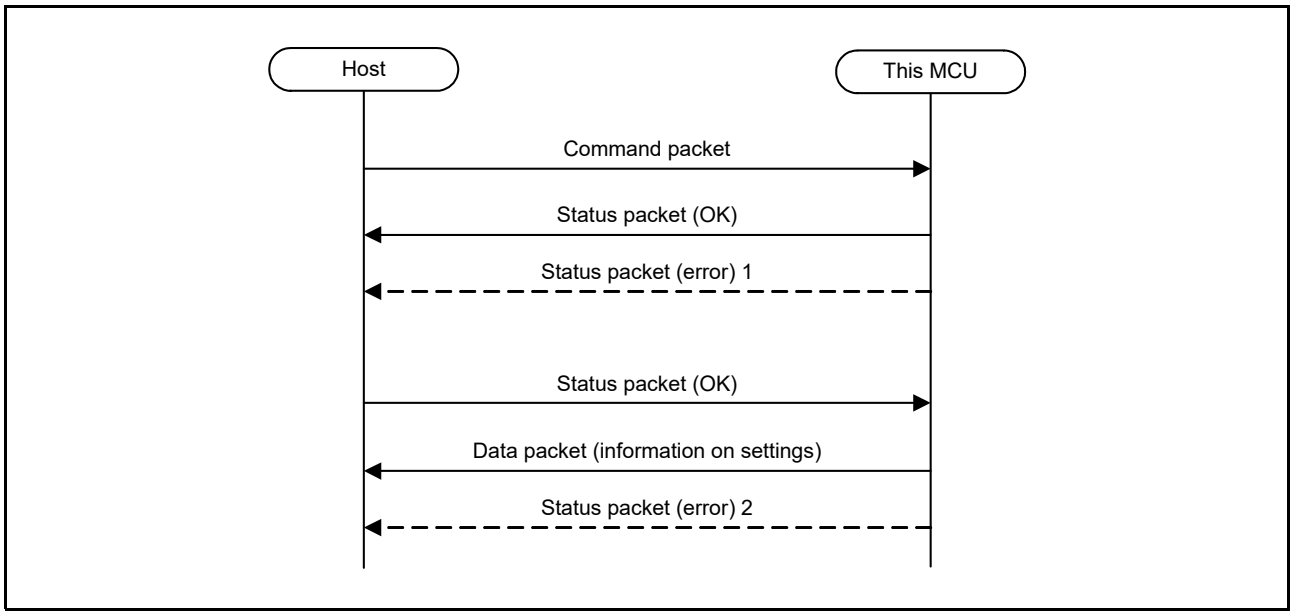

Figure 48.41 Common Transfer Sequence for the Commands that Obtain Information on Settings

Table 48.23 Common Transfer Sequence

Command Name	Common Transfer Sequence Type
Device type acquisition	Command that obtains information on settings
Endian notification	Command that only makes a setting
Frequency setting	Command that obtains information on settings
Bit rate setting	Not in a common transfer sequence
Synchronization	Command that only makes a setting
ID authentication mode acquisition	Command that obtains information on settings
Serial programming ID code check	Command that only makes a setting
Blank check	Command that only makes a setting
Block erase	Command that only makes a setting
Area erase	Command that only makes a setting
Program	Not in a common transfer sequence
Read	Not in a common transfer sequence
Configuration clear	Command that only makes a setting
Configuration program	Not in a common transfer sequence
Configuration read	Command that obtains information on settings
Simple addition checksum	Command that obtains information on settings
Acquisition of the number of the area information	Command that obtains information on settings
Acquisition of the area information	Command that obtains information on settings

For the command transfer sequences that are not in a common transfer sequence, refer to the sections on the individual commands.

48.8.8 Unsupported Commands

When this MCU receives an undefined command packet, it returns an unsupported error (C0h) and enters the command waiting state.

(1) Command packet structure

SOH	LNH	LNL	COM		SUM	ETX

SOH: 01h
LNH: Upper byte of packet length
LNL: Lower byte of packet length
COM: Command code*1
SUM: Sum of values
ETX: 03h

Note 1. Command code other than those specified in Table 48.22.

(2) Status packet structure

SOD	LNH	LNL	RES	ERR	SUM	ETX

SOD: 81h
LNH: 00h
LNL: 02h
RES: 80h | COM (command code)
ERR: Error code
C0h (“unsupported” error)
C1h (packet error)
C2h (checksum error)
C3h (flow error)
SUM: Sum of values
ETX: 03h

48.8.9 Device Type Acquisition Command

This command is used to make the MCU send the input frequency and system clock frequency (in Hz) supported by boot mode (SCI interface).
This command can only be accepted in the communications establishment phase.

(1) Command packet structure

SOH	LNH	LNL	COM	SUM	ETX

SOH: 01h
LNH: 00h
LNL: 01h
COM: 38h
SUM: C7h
ETX: 03h

(2) Data packet structure

SOD	LNH	LNL	RES	TYP	OSA	OSI	CPA	CPI	SUM	ETX

The values sent is given below.

Maximum input frequency = 16,000,000 Hz
- OSA (1st byte): 00h
- OSA (2nd byte): F4h
- OSA (3rd byte): 24h
- OSA (4th byte): 00h

Minimum input frequency = 16,000,000 Hz
- OSI (1st byte): 00h
- OSI (2nd byte): F4h
- OSI (3rd byte): 24h
- OSI (4th byte): 00h

Maximum system clock (ICLK) = 120,000,000 Hz
- CPA (1st byte): 07h
- CPA (2nd byte): 27h
- CPA (3rd byte): 0Eh
- CPA (4th byte): 00h

Minimum system clock: (ICLK) = 120,000,000 Hz
- CPI (1st byte): 07h
- CPI (2nd byte): 27h
- CPI (3rd byte): 0Eh
- CPI (4th byte): 00h

SOD: 81h
LNH: 00h
LNL: 19h
RES: 38h (OK)
TYP: Type code (8 bytes)*1
OSA: Maximum input frequency (4 bytes)
OSI: Minimum input frequency (4 bytes)
CPA: Maximum system clock frequency (4 bytes)
CPI: Minimum system clock frequency (4 bytes)
SUM: Sum of values
ETX: 03h

Note 1. Reserved data

(3) Status packet structure, normal termination

SOD	LNH	LNL	RES	SUM	ETX

SOD: 81h
LNH: 00h
LNL: 01h
RES: 38h (OK)
SUM: C7h
ETX: 03h

(4) Status packet structure, error occurrence 1

SOD	LNH	LNL	RES	ERR	SUM	ETX

SOD: 81h
LNH: 00h
LNL: 02h
RES: B8h (error)
ERR: Error code
C1h (packet error)
C2h (checksum error)
C3h (flow error)
SUM: Sum of values
ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

(5) Status packet structure, error occurrence 2

SOD	LNH	LNL	RES	ERR	SUM	ETX

SOD: 81h
LNH: 00h
LNL: 02h
RES: B8h (error)
ERR: Error code
C1h (packet error)
C2h (checksum error)
SUM: Sum of values
ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

48.8.10 Endian Notification Command

This command is used to inform the MCU of the endian (big or little).
Specify either endian as the endian information according to the data to be programmed.
This command can only be accepted in the communications establishment phase.

(1) Command packet structure

SOH	LNH	LNL	COM	END	SUM	ETX

SOH: 01h
LNH: 00h
LNL: 02h
COM: 36h
END: Endian information
00h (big-endian)

(2) Status packet structure, normal termination

SOD	LNH	LNL	RES	SUM	ETX

SOD: 81h
LNH: 00h
LNL: 01h
RES: 36h (OK)
SUM: C9h
ETX: 03h

(3) Status packet structure, error occurrence

SOD	LNH	LNL	RES	ERR	SUM	ETX

SOD: 81h
LNH: 00h
LNL: 02h
RES: B6h (error)
ERR: Error code
C1h (packet error)
C2h (checksum error)
C3h (flow error)
D7h (endian error)
SUM: Sum of values
ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

48.8.11 Frequency Setting Command

This command is used to set the values of oscillation frequency and CPU operating frequency (in Hz).
In boot mode (SCI interface) or boot mode (FINE interface), the HOCO runs at 16 MHz and the ICLK runs at 120 MHz, so set the input frequency to 16 MHz and the system clock frequency to 120 MHz. Furthermore, in boot mode (SCI interface) or boot mode (FINE interface), the FCLK and PCLKB run at 60 MHz, so the MCU sends that the frequency of the peripheral module clock is 60 MHz.
This command can only be accepted in the communications establishment phase.

(1) Command packet structure

SOH	LNH	LNL	COM	OC1	OC2	OC3	OC4	CC1	CC2	CC3	CC4	SUM	ETX

When the input frequency is 16,000,000 Hz and the system clock frequency is 120,000,000 Hz, send the values as below.

OC1: 00h CC1: 07h
OC2: F4h CC2: 27h
OC3: 24h CC3: 0Eh
OC4: 00h CC4: 00h

SOH: 01h

ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

48.8.12 Bit-Rate Setting Command

This command is used to change the bit rate after receiving bit rate data (in bps).
If an error occurs, the bit rate is not changed.
This command can only be accepted in the communications establishment phase.
In boot mode (FINE interface), switching of the bit rate does not proceed. Set the desired value for the bit rate.

(1) Procedure

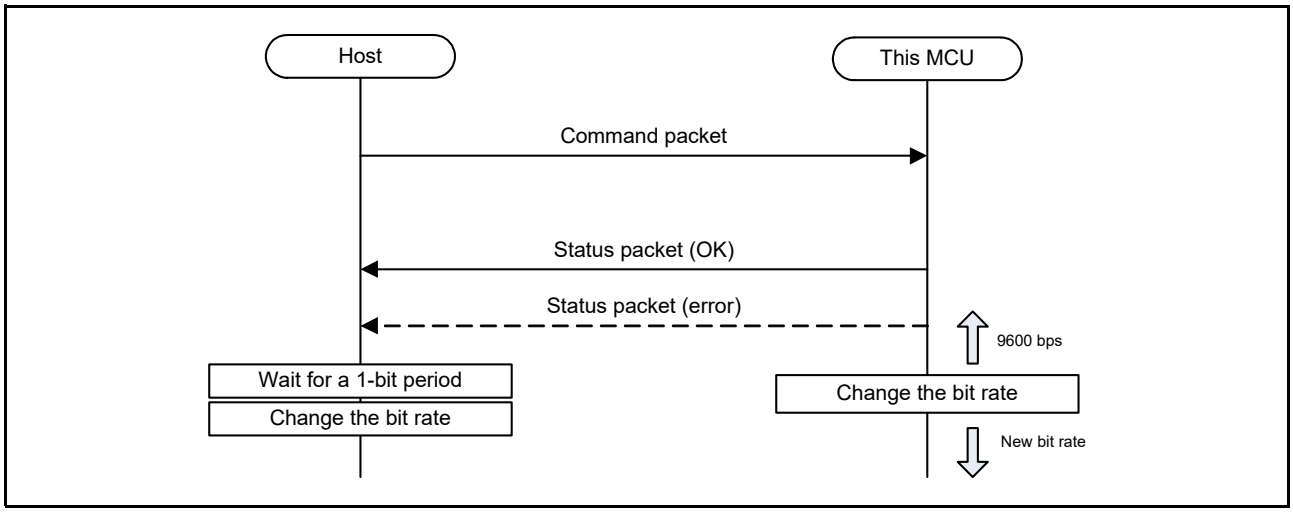

Figure 48.42 Bit-Rate Setting Command Transfer Sequence

(2) Command packet structure

SOH	LNH	LNL	COM	BR1	BR2	BR3	BR4	SUM	ETX

After the error code is returned, the chip returns to the command waiting state.

48.8.13 Synchronization Command

This command is used in processing to synchronize communications.
It is also used when checking whether the MCU is ready to accept commands. If a serial programmer connection is prohibited, a serial programmer connection prohibition error is returned.
This command can be accepted in both the communications establishment and command waiting phases.

(1) Command packet structure

ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

48.8.15 Serial Programming ID Code Check Command

This command determines whether the control code and ID codes set in the OSIS register match the control code and ID codes sent by the host, and sends the result to the host.
This command can be accepted in the communications establishment phase. When the serial programmer ID code protection is enabled, the MCU does not enter the command waiting phase unless processing in response to this command ends normally.
If the control code is 45h and the codes do not match three times in a row, all data in the flash memory are erased*1.

Note 1. When the FAW.FSPR bit is 0, data in the flash memory are not erased.

After the error code is returned, the chip returns to the command waiting state.

48.8.16 Blank Check Command

This command checks whether the specified area is blank.
Specify a range in the code flash memory with addresses on 128-byte boundaries or in the data flash memory with addresses on 4-byte boundaries. When the TM function is enabled, attempting a blank check for the area containing the TM target area will result in an error.
This command can only be accepted in the command waiting phase.

After the error code is returned, the chip returns to the command waiting state.

48.8.17 Block Erase Command

This command is used to erase a specified single block.
Specify the block to erase by the first address of the block.
When the TM function is enabled, the TM target area cannot be erased. To erase the TM target area when the TM function is enabled, use the configuration clear command.
This command can only be accepted in the command waiting phase.

(1) Command packet structure

ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

48.8.18 Area Erase Command

The area erase command erases the specified area successively, block by block, in ascending order of addresses.
The target area can be selected from the code flash memory or data flash memory.
When the TM function is enabled, only blocks other than the TM target area are erased.
This command can only be accepted in the command waiting phase.

After the error code is returned, the chip returns to the command waiting state.

48.8.19 Program Command

This command sets up the MCU for data to be programmed to its flash memory and specifies the area where the data are to be programmed.
Specify addresses for a data length that is a multiple of 128 bytes for the code flash memory or a multiple of 4 bytes for the data flash memory. Furthermore, as the address where programming is to start, specify an address on a 128-byte boundary for the code flash memory or on a 4-byte boundary for the data flash memory.
When the TM function is enabled, the TM target area cannot be programmed.
This command can only be accepted in the command waiting phase.

48.8.21 Configuration Clear Command

This command is used to erase the option-setting memory (configuration setting area) and the TM target area.
This command cannot be issued when the code flash memory and data flash memory are not blank. If an access window has been set, set the TM target area to be located within the access window before sending this command.
When the serial programmer ID code protection is enabled, a reset is required to disable it.
This command can only be accepted in the command waiting phase.

After the error code is returned, the chip returns to the command waiting state.

48.8.22 Configuration Program Command

This command is used to receive data to be written to the option-setting memory and to program the data in the specified area.
Programming must be specified in the unit acquired by using the area information acquisition command.
This command can only be accepted in the command waiting phase.
Once the FAW.FSPR bit has been enabled, the bit cannot be disabled.
For details of the FAW.FSPR bit, refer to section 7.2.9, Flash Access Window Setting Register (FAW) in section 7, Option-Setting Memory (OFSM).
Rewriting the SPCC.SPE bit while the connection of serial programmer is prohibited leads to normal termination, but programming does not proceed.
In addition, this MCU cannot be connected to a serial programmer at a reset while connection to a serial programmer is disabled.
Writing to the TMEF.TMEF[2:0] bits, TMINF register, and MDE.BANKMD[2:0] bits while the TMEF.TMEF[2:0] bits are 000b in linear mode leads to normal termination, but programming does not proceed.
Writing to the TMEF.TMEF[2:0] bits, TMINF register, and MDE.BANKMD[2:0] bits while the TMEF.TMEF[2:0] bits or the TMEF.TMEFDB[2:0] bits are 000b in dual mode leads to normal termination, but programming does not proceed.

After the error code is returned, the chip returns to the command waiting state.

48.8.24 Simple Addition Checksum Command

This command is used to calculate the sum of values in the specified area and send the result to the host. While the TM function is enabled, however, the values in the TM target areas are not included in the calculation.
The target area of this command can be selected from the code flash memory and data flash memory. Calculation is by simple addition. The initial value is 0 and the sum of values in the specified area is obtained by adding the values of all bytes.
When code flash memory is specified as the target area, all 512 Kbytes, which is the maximum capacity of this MCU group, is added.
When data flash memory is specified as the target area, the result becomes undefined if an erased area exists. When a simple addition checksum is to be executed for the data flash memory, make sure that data have been written throughout the area.
This command can only be accepted in the command waiting phase.

48.8.27 Usage Example

Figure 48.46 shows an example of the procedure for reprogramming.

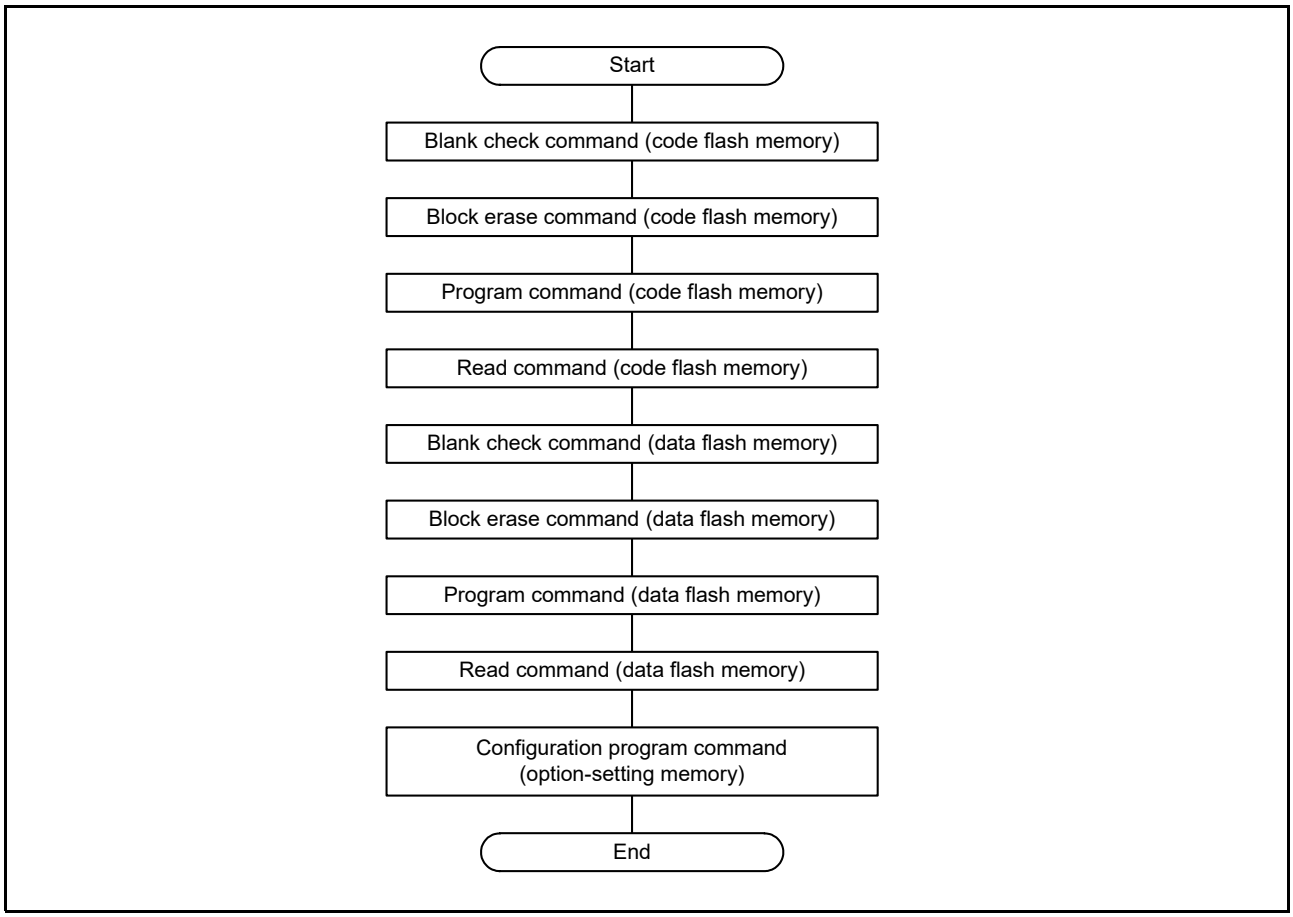

Figure 48.46 Example of Reprogramming Procedure

48.8.28 Rewriting Flash Memory When Using Dual Mode

The flash memory is erased (blank) as shipped by Renesas, so the setting of the MDE.BANKMD[2:0] bits is 111b (linear mode). To use the flash memory in dual mode, set the MDE.BANKMD[2:0] bits to 000b (dual mode).

(1) Rewriting in Dual Mode

Figure 48.47 shows an example of rewriting flash memory after switching to dual mode. The user program can be written to bank 0, bank 1, or both.

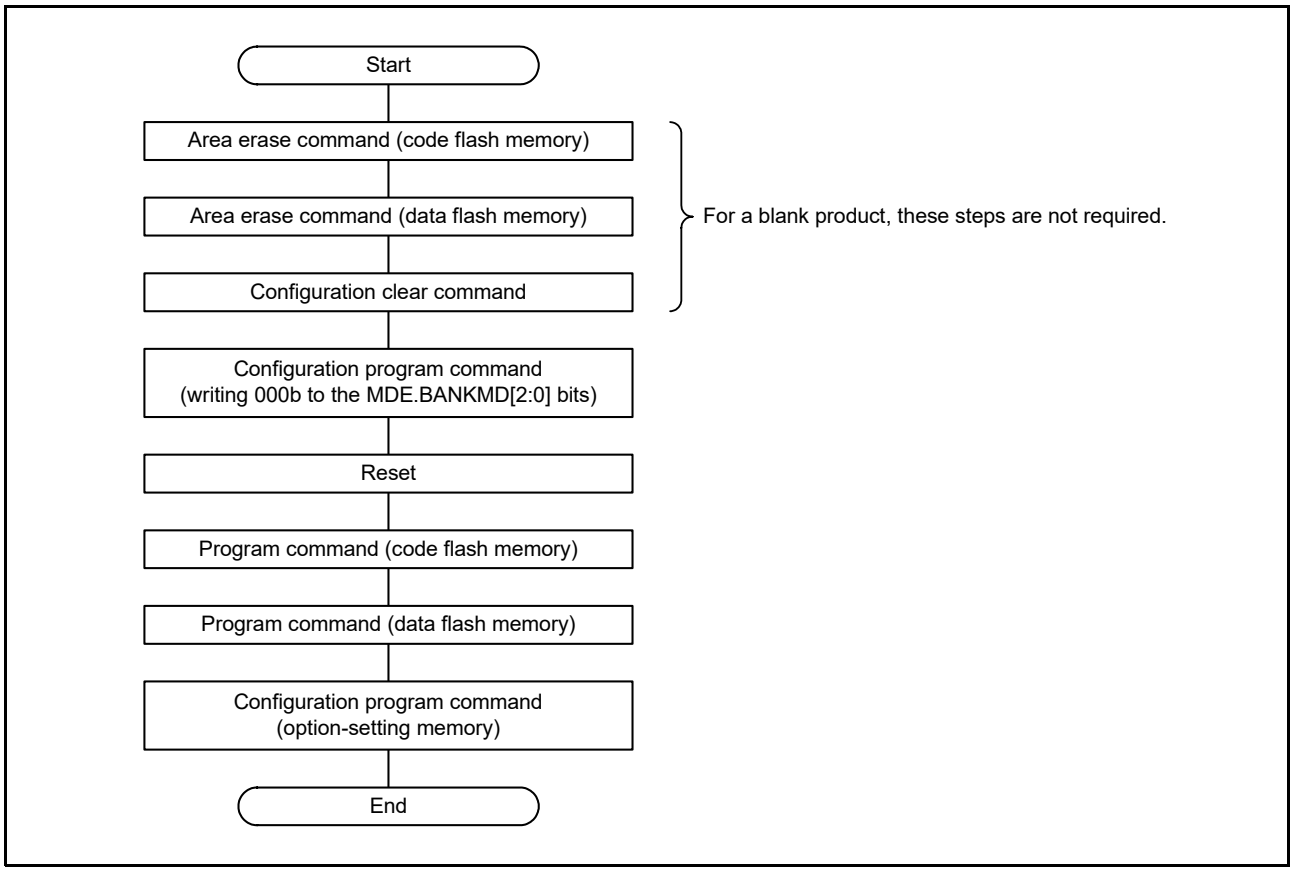

Figure 48.47 Example of Rewriting Flash Memory after Switching to Dual Mode

(2) Rewriting in Linear Mode

Figure 48.48 shows an example of rewriting flash memory in linear mode. Figure 48.49 shows the memory map before and after a reset.

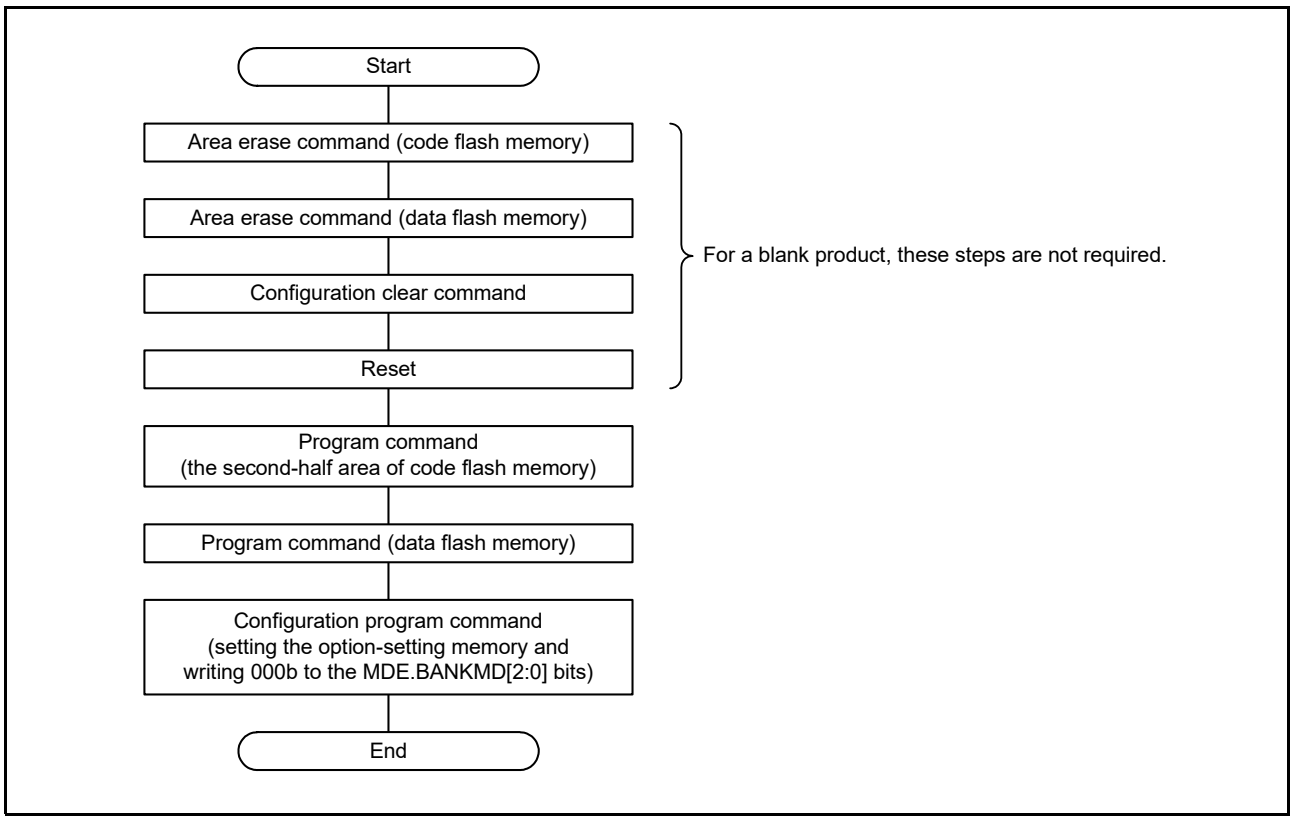

Figure 48.48 Example of Rewriting Flash Memory in Linear Mode

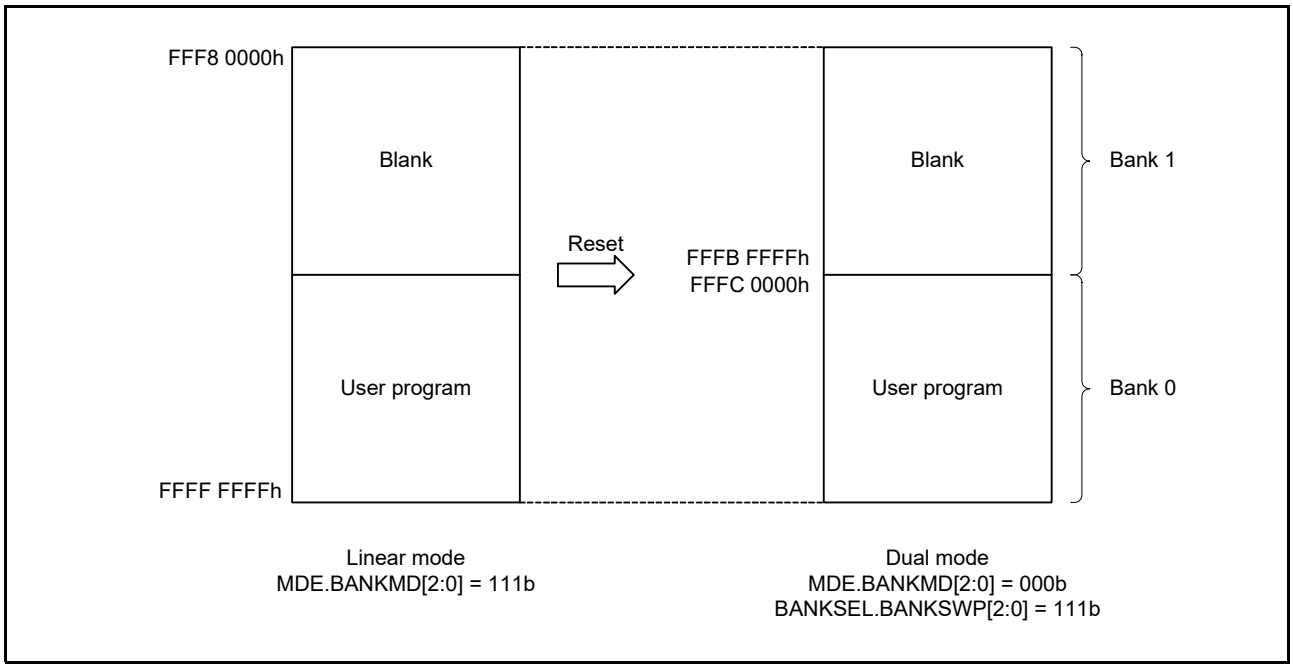

Figure 48.49 Memory Map before and after a Reset

48.9 Using the Serial Programmer for Rewriting (Serial Programming)

By providing a connector on the board, it is possible to program the MCU with a serial programmer while the MCU is mounted on the board.

48.9.1 Environments for Serial Programming

The recommended environments for rewriting the flash memory of the MCU are described below.

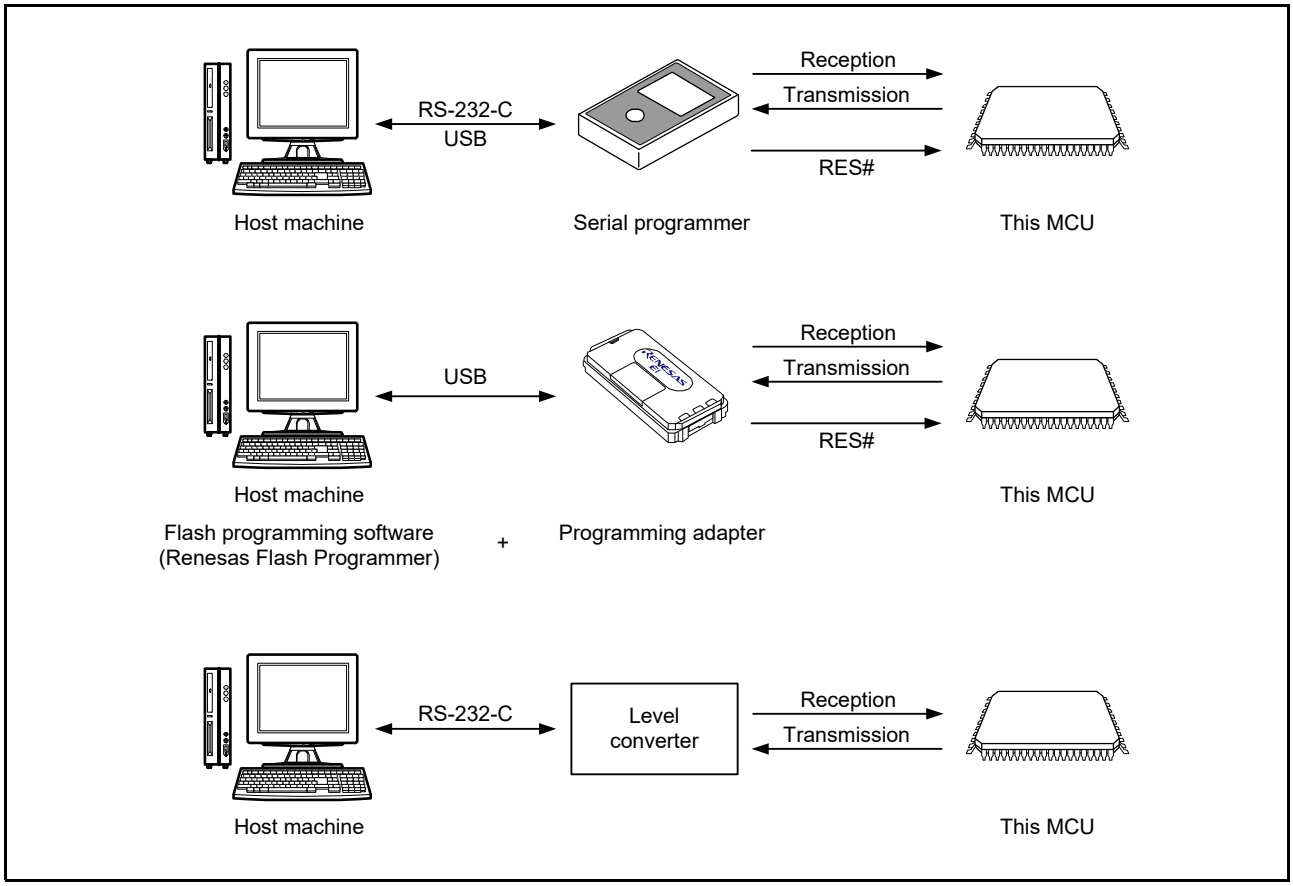

Figure 48.50 Environments for Rewriting the Flash Memory

Note: For details of the serial programmers, refer to the manual of each serial programmer; for details of the Renesas Flash Programmer flash programming software, refer to the Renesas Flash Programmer Flash Programming Software User's Manual.

48.10 Programming through Self-Programming

48.10.1 Overview

This MCU supports programming of the flash memory by the user program itself. The FACI commands can be used with user programs for writing to the flash memory. This allows upgrading of user programs and rewriting of constant data fields.

When the data flash memory is programmed, the background operation facility makes it possible to execute a programming program from the code flash memory to program the data flash memory. Furthermore, the programming program can be copied to internal RAM in advance of the program operation, and executed from the given destination to program the data flash memory.

Background operation is also available for use when the address ranges of the area of code flash memory to be programmed and the area of code flash memory to be read satisfy particular conditions (see Table 48.24). At the time of self-programming in this case, a programming program in code flash memory can be used to program the code flash memory. Also, the programming program can be copied to internal RAM in advance of the program operation, and executed from the given destination to program the code flash memory. This is useful when the address ranges do not satisfy the conditions for background operation.

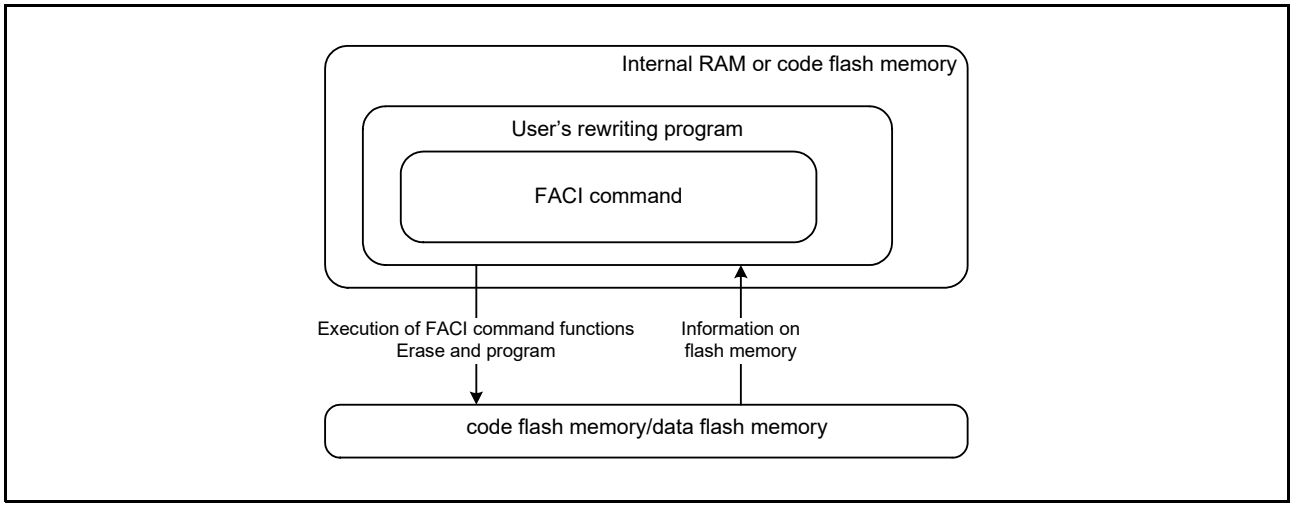

Figure 48.51 Schematic View of Self-Programming

48.10.2 Background Operation

The BGO is can be used to execute the flash rewrite routine on the code flash memory when the data flash memory or other area of code flash memory is rewritten.
Background operations can be used when the combination of the flash memory for rewriting and the flash memory for reading is any of those listed below.

Table 48.24 Conditions under which Background Operation is Usable

		Range for Rewriting	Range for Reading
Common to linear and dual modes		• Data flash memory	• Code flash memory
Linear mode	Products with 512 Kbytes of code flash memory	• First half (256-Kbyte area) of the code flash memory (addresses FFF8 0000h to FFFB FFFFh)	• Second half (256-Kbyte area) of the code flash memory (addresses FFFC 0000h to FFFF FFFFh) • Data flash memory
		• Second half (256-Kbyte area) of the code flash memory (addresses FFFC 0000h to FFFF FFFFh)	• First half (256-Kbyte area) of the code flash memory (addresses FFF8 0000h to FFFB FFFFh) • Data flash memory
Dual mode	When the BANKSEL.BANKSWP[2:0] bits are 111b:	• Bank 1 area of the code flash memory	• Bank 0 area of the code flash memory • Data flash memory
	When the BANKSEL.BANKSWP[2:0] bits are 000b:	• Bank 0 area of the code flash memory	• Bank 1 area of the code flash memory • Data flash memory

48.11 Usage Notes

(1) Reading Area Where Program or Erase Operation was Aborted or Suspended

The data stored in the area where program or erase operation has been aborted or suspended are undefined. To avoid malfunctions caused by reading undefined data, take care not to fetch instructions or read data from the area where program or erase operation was aborted or suspended.

(2) Suspension During Program/Erase Operation

When program or erase operation is interrupted by issuing the P/E suspend command, the program or erase operation can be resumed by issuing the P/E resume command. After the suspend processing is successfully completed and the ERSSPD or PRGSPD flag is set to 1, if the flash sequencer enters the command-locked state for some reason and a forced stop command is issued, the suspended operation cannot be resumed. Also, since the values in the area where the operation was suspended are not guaranteed, erase that area.

(3) Prohibition of Additional Programming

Programming to the code flash memory or data flash memory twice is not possible. To program code flash memory or data flash memory which has already been programmed, erase the relevant area.

(4) Resets During Program, Erase, or Blank Check Operation

In the case of a reset due to the signal on the RES# pin during program, erase, or blank check operation, wait for at least t_{RESWF} (refer to section 49, Electrical Characteristics) of the reset input period once the operating voltage is within the range stipulated in the electrical characteristics after assertion of the reset signal, and then release the device from the reset state.

(5) Allocation of Vectors for Interrupts and Other Exceptions During Program/Erase Operation

Generation of an interrupt or other exception during program or erase operation may lead to fetching of the vector from the code flash memory. If the conditions for using the background operation (BGO) are not satisfied, set the address for vector to an address that is not in the code flash memory or disable interrupts.

(6) Abnormal Termination During Program, Erase, or Blank Check Operation

Even if program or erase operation ends abnormally due to the generation of a reset by the RES# pin, the program or erase state of the flash memory with undefined data cannot be verified or checked. For the area where program or erase operation ends abnormally, the blank check function cannot judge whether the area is erased successfully or not. Erase the area again and confirm that the corresponding area is completely erased before using.

(7) Items Prohibited During Program, Erase, or Blank Check Operation

High voltage is applied to the flash memory during program, erase, or blank check operation. To prevent damage to the flash memory, do not perform the following operations.

- Have the operating voltage from the power supply go beyond the permitted range.
- Change the FWEPROR.FLWE[1:0] bits.
- Change the SCKCR.FCK[3:0] and PCLKB[3:0] bits.
- Change the SCKCR3.CKSEL[2:0] bits.
- Change the RSTCKCR.RSTCKEN bit.
- Transition to the all module clock stop mode or software standby mode.

49. Electrical Characteristics

49.1 Absolute Maximum Ratings

Table 49.1 Absolute Maximum Rating

Conditions: VSS = AVSS0 = AVSS1 = AVSS2 = 0V

Item		Symbol	Value	Unit
Power supply voltage*1		VCC	–0.3 to +6.5	V
Analog power supply voltage*1		AVCC0, AVCC1, AVCC2	–0.3 to +6.5	V
Input voltage	PB1 and PB2	V_{in}	–0.3 to +6.5	V
	P40 to P47, P50 to P55, and P60 to P65		–0.3 to AVCC2 + 0.3 (up to 6.5)	
	Other than above		–0.3 to VCC + 0.3 (up to 6.5)	
Junction temperature		T_j	–40 to +125	°C
Storage temperature		T_{stg}	–55 to +125	°C

Caution: Permanent damage to the LSI may result if absolute maximum ratings are exceeded.

Note 1. Insert capacitors with good frequency characteristics between each power supply pin and the ground. Specifically, place capacitors with a value around 0.1 µF as close as possible to every power supply pin, and use the shortest and thickest possible traces.

49.2 Recommended operating conditions

Table 49.2 Recommended operating conditions (1)

Item		Symbol	Min.	Typ.	Max.	Unit
Power supply voltage		VCC*1	2.7	—	5.5	V
		VSS	—	0	—	
Analog power supply voltage*2		AVCC0, AVCC1, AVCC2*1	3.0	—	5.5	V
		AVSS0, AVSS1, AVSS2	—	0	—	
Input voltage	PB1, PB2	V_{in}	–0.3	—	5.8	V
	P40 to P47, P50 to P55, and P60 to P65		–0.3	—	AVCC2 + 0.3	
	Other than above		–0.3	—	VCC + 0.3	
Operating temperature	D version	T_{opr}	–40	—	85	°C
	G version		–40	—	105	
Junction temperature	D version	T_j	–40	—	105	°C
	G version		–40	—	125	

Note 1. Comply with the following voltage condition: VCC ≤ AVCC0 = AVCC1 = AVCC2

Note 2. When not using any of the12-bit A/D converter (unit 0 to 2), 12-bit D/A converter, comparator C, or temperature sensor, connect AVCC0, AVCC1, and AVCC2 to VCC, and AVSS0, AVSS1, and AVSS2 to VSS, respectively. For details, refer to section 42.6.9, Voltage Range of Analog Power Supply Pins.

Table 49.3 Recommended operating conditions (2)

Item	Symbol	Value
Decoupling capacitance to stabilize the internal voltage	C_{VCL}	0.47 µF ± 30%*1

Note 1. Use a multilayer ceramic capacitor whose nominal capacitance is 0.47 µF and a capacitance tolerance is ±30% or better.

49.3 DC Characteristics

Table 49.4 DC Characteristics (1)

	Pins other than those above and PE2			10	—	100		VCC = 2.7 to 5.5 V V_{in} = 0 V
Input pull-down resistors	EMLE		R_{PD}	10	—	100	kΩ	V_{in} = VCC = AVCC
Input capacitance	RIIC pins		C_{in}	—	—	16	pF	V_{bias} = 0 V V_{amp} = 20 mV f = 1 MHz T_a = 25°C
	Other than above			—	—	8		
Output voltage of the VCL pin			V_{CL}	—	1.25	—	V	

Note 1. The input leakage current value at the EMLE pin is only when V_{in} = 0 V.

Table 49.6 DC Characteristics (3) (Products with 64 Kbytes of RAM)

Conditions: VCC = 2.7 to 5.5 V, AVCC0 = AVCC1 = AVCC2 = 3.0 to 5.5 V, VSS = AVSS0 = AVSS1 = AVSS2 = 0 V,
$T_a = T_{opr}$

Item				Symbol	D version		G version		Unit	Test Conditions
					Typ.	Max.	Typ.	Max.		
Supply current*1	Normal operating mode	Full operation*2		I_{CC}*3	—	66	—	74	mA	ICLK = 120 MHz PCLKA = 120 MHz PCLKB = 60 MHz PCLKC = 120 MHz PCLKD = 60 MHz FCLK = 60 MHz
		Normal operation	Peripheral module clocks are supplied*4		22	—	22	—		
			Peripheral module clocks are stopped*4, *5		11	—	11	—		
		CoreMark	Peripheral module clocks are stopped*4, *5		18	—	18	—		
		Sleep mode: Peripheral module clocks are supplied*4			18	36	18	44		
		All module clock stop mode (reference value)			8.1	22	8.1	29		
		Increase current by BGO operation*6			16	—	16	—		
		Increase current by operating Trusted Secure IP			4.3	5.2	4.3	5.2		
	Software standby mode				0.9	8	0.9	13		

Note 1. Supply current values are measured when all output pins are unloaded and all input pull-up resistors are disabled.
Note 2. Peripheral module clocks are supplied. This does not include operations as BGO (background operations).
Note 3. I_{CC} depends on f (ICLK) as follows.
• D version product
I_{CC} Max. = 0.417 × f + 16 (full operation in normal operating mode)
I_{CC} Typ. = 0.144 × f + 5 (normal operation in normal operating mode)
I_{CC} Max. = 0.167 × f + 16 (sleep mode)
• G version product
I_{CC} Max. = 0.433 × f + 22 (full operation in normal operating mode)
I_{CC} Typ. = 0.144 × f + 5 (normal operation in normal operating mode)
I_{CC} Max. = 0.183 × f + 22 (sleep mode)
Note 4. This does not include operations as BGO (background operations). Whether the peripheral module clocks are supplied or stopped is controlled only by the bit settings in the module stop control registers A to D.
Note 5. When peripheral module clocks are stopped, each clock frequency is set for division by 64, and the frequencies of FCLK, PCLKA, PCLKB, PCLKC, and PCLKD are the same.
Note 6. This is an increase caused by program/erase operation to the code flash memory or data flash memory during executing the user program.

Table 49.7 DC Characteristics (3) (Products with 48 Kbytes of RAM)

Conditions: VCC = 2.7 to 5.5 V, AVCC0 = AVCC1 = AVCC2 = 3.0 to 5.5 V, VSS = AVSS0 = AVSS1 = AVSS2 = 0 V,
$T_a = T_{opr}$

Item				Symbol	D version		G version		Unit	Test Conditions
					Typ.	Max.	Typ.	Max.		
Supply current*1	Normal operating mode	Full operation*2		I_{CC}*3	—	47	—	52	mA	ICLK = 120 MHz PCLKA = 120 MHz PCLKB = 60 MHz PCLKC = 120 MHz PCLKD = 60 MHz FCLK = 60 MHz
		Normal operation	Peripheral module clocks are supplied*4		17	—	17	—		
			Peripheral module clocks are stopped*4, *5		10	—	10	—		
		CoreMark	Peripheral module clocks are stopped*4, *5		16	—	16	—		
		Sleep mode: Peripheral module clocks are supplied*4			13	25	13	29		
		All module clock stop mode (reference value)			7.4	16	7.4	20		
		Increase current by BGO operation*6			12	—	12	—		
	Software standby mode				0.9	5	0.9	8		

Note 1. Supply current values are measured when all output pins are unloaded and all input pull-up resistors are disabled.
Note 2. Peripheral module clocks are supplied. This does not include operations as BGO (background operations).
Note 3. I_{CC} depends on f (ICLK) as follows.
• D version product
I_{CC} Max. = 0.283 × f + 13 (full operation in normal operating mode)
I_{CC} Typ. = 0.107 × f + 4.3 (normal operation in normal operating mode)
I_{CC} Max. = 0.100 × f + 13 (sleep mode)
• G version product
I_{CC} Max. = 0.285 × f + 17.8 (full operation in normal operating mode)
I_{CC} Typ. = 0.107 × f + 4.3 (normal operation in normal operating mode)
I_{CC} Max. = 0.093 × f + 17.8 (sleep mode)
Note 4. This does not include operations as BGO (background operations). Whether the peripheral module clocks are supplied or stopped is controlled only by the bit settings in the module stop control registers A to D.
Note 5. When peripheral module clocks are stopped, each clock frequency is set for division by 64, and the frequencies of FCLK, PCLKA, PCLKB, PCLKC, and PCLKD are the same.
Note 6. This is an increase caused by program/erase operation to the code flash memory or data flash memory during executing the user program.

		Large current output*3, *5		—	—	–15.0	
	P40 to P47, P50 to P55, and P60 to P65			—	—	–4.0	
Permissible high-level output current (total)	Total of all output pins		ΣI_{OH}	—	—	–35	mA

Caution: To protect the LSI's reliability, the output current values should not exceed the values in this table.

Note 1. The listed value applies when normal driving ability is set with a pin for which normal driving ability is selectable.

Note 2. The listed value applies when high driving ability is set with a pin for which normal driving ability is selectable, or when the pin to which high driving ability is fixed is in use.

Note 3. The listed value applies when large current output is set with a pin for which large current output ability is selectable.

Note 4. The listed value applies when VCC is at least 4.5 V.

Note 5. The listed value applies when VCC is at least 4.0 V.

Table 49.11 Standard Output Characteristics (1)

Conditions: VCC = AVCC0 = AVCC1 = AVCC2 = 5.0 V,

49.4.3 Timing of Recovery from Low Power Consumption Modes

Table 49.21 Timing of Recovery from Low Power Consumption Modes (1)

Conditions: VCC = 2.7 to 5.5 V, AVCC0 = AVCC1 = AVCC2 = 3.0 to 5.5 V,
VSS = AVSS0 = AVSS1 = AVSS2 = 0 V,
$T_a = T_{opr}$

Item			Symbol	Min.	Typ.	Max.		Unit	Test Conditions
						$t_{SBYOSCWT}$*2	t_{SBYSEQ}*3		
Recovery time after cancellation of software standby mode*1	Crystal resonator connected to main clock oscillator	Main clock oscillator operating	t_{SBYMC}	—	—	{(MSTS[7:0] bits × 32) + 76} / 0.216	100 + 7 / f_{ICLK} + 2n / f_{MAIN}	µs	Figure 49.11
		Main clock oscillator and PLL circuit operating	t_{SBYPC}	—	—	{(MSTS[7:0] bits × 32) + 138} / 0.216	100 + 7 / f_{ICLK} + 2n / f_{PLL}		
	External clock input to main clock oscillator	Main clock oscillator operating	t_{SBYEX}	—	—	352	100 + 7 / f_{ICLK} + 2n / f_{EXMAIN}	µs	
		Main clock oscillator and PLL circuit operating	t_{SBYPE}	—	—	639	100 + 7 / f_{ICLK} + 2n / f_{PLL}		
	High-speed on-chip oscillator operating	High-speed on-chip oscillator operating	t_{SBYHO}	—	—	454	100 + 7 / f_{ICLK} + 2n / f_{HOCO}	µs	
		High-speed on-chip oscillator operating and PLL circuit operating	t_{SBYPH}	—	—	741	100 + 7 / f_{ICLK} + 2n / f_{PLL}		
	Low-speed on-chip oscillator operating*4		t_{SBYLO}	—	—	338	100 + 7 / f_{ICLK} + 2n / f_{LOCO}	µs	

Note 1. The time for return after release from software standby is determined by the value obtained by adding the oscillation stabilization waiting time ($t_{SBYOSCWT}$) and the time required for operations by the software standby release sequencer (t_{SBYSEQ}).
Note 2. When several oscillators were running before the transition to software standby, the greatest value of the oscillation stabilization waiting time $t_{SBYOSCWT}$ is selected.
Note 3. For n, the greatest value is selected from among the internal clock division settings.
Note 4. This condition applies when $f_{ICLK} : f_{FCLK}$ = 1 : 1, 2 : 1, or 4 : 1.

Conditions: VCC = 2.7 to 5.5 V, AVCC0 = AVCC1 = AVCC2 = 3.0 to 5.5 V,
VSS = AVSS0 = AVSS1 = AVSS2 = 0 V, $T_a = T_{opr}$,
PCLKA = 8 to 120 MHz, PCLKB = 8 to 60 MHz,
High-drive output is selected by the driving ability control register.

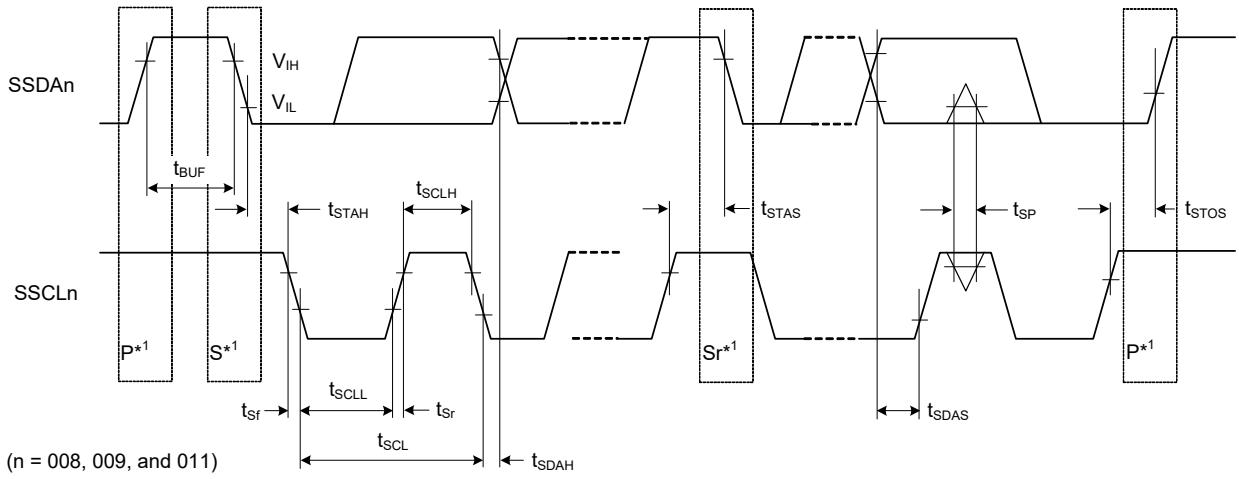
Item		Symbol	Min.	Max.	Unit	Test Conditions
Simple IIC (Standard-mode)	SSCL, SSDA input rise time	t_{Sr}	—	1000	ns	Figure 49.46
	SSCL, SSDA input fall time	t_{Sf}	—	300	ns	
	SSCL, SSDA input spike pulse removal time	t_{SP}	0	4 × t_{Pcyc}	ns	
	Data input setup time	t_{SDAS}	250	—	ns	
	Data input hold time	t_{SDAH}	0	—	ns	
	SSCL, SSDA capacitive load	C_b*1	—	400	pF	
Simple IIC (Fast-mode)	SSCL, SSDA input rise time	t_{Sr}	—	300	ns	
	SSCL, SSDA input fall time	t_{Sf}	—	300	ns	
	SSCL, SSDA input spike pulse removal time	t_{SP}	0	4 × t_{Pcyc}	ns	
	Data input setup time	t_{SDAS}	100	—	ns	
	Data input hold time	t_{SDAH}	0	—	ns	
	SSCL, SSDA capacitive load	C_b*1	—	400	pF	

Note: t_{Pcyc} refers to the period of PCLKB in RSCI8 and RSCI9, and of PCLKA in RSCI11.
Note 1. C_b is the total capacitance of the bus lines.



Note 1. S, P, and Sr indicate the following conditions.
S: Start condition
P: Stop condition
Sr: Restart condition

Test conditions
V_{IH} = 0.7 × VCC, V_{IL} = 0.3 × VCC
V_{OL} = 0.6 V, I_{OL} = 6 mA

	Restart condition input setup time	t_{STAS}	300	—		
	Stop condition input setup time	t_{STOS}	300	—		
	Data input setup time	t_{SDAS}	t_{IICcyc} + 50	—		
	Data input hold time	t_{SDAH}	0	—		
	SCL, SDA capacitive load	C_b*2	—	400	pF	

Note: t_{IICcyc}: RIIC internal reference clock (IICφ) cycle
Note 1. The value within parentheses is applicable when the value of the ICMR3.NF[1:0] bits is 11b while the digital filter is enabled by the setting ICFER.NFE = 1.
Note 2. C_b is the total capacitance of the bus lines.
Note 3. When VCC ≥ 4.5 V, VOLSR.RICVLS = 0
When VCC < 4.5 V, VOLSR.RICVLS = 1

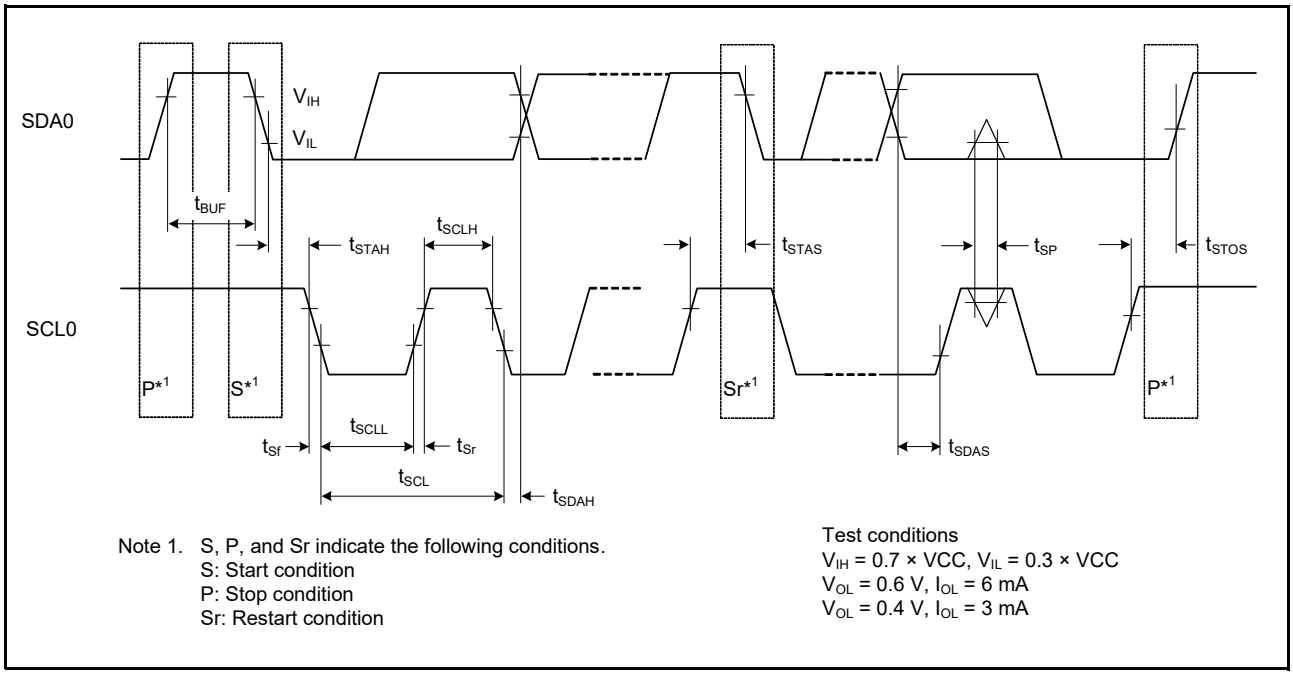

Figure 49.67 RIIC Bus Interface Input/Output Timing

49.4.5.14 RI3C

Table 49.40 RI3C Timing (Open Drain Timing Parameters)

Conditions: VCC = AVCC0 = AVCC1 = AVCC2 = 3.0 to 3.6 V,
VSS = AVSS0 = AVSS1 = AVSS2 = 0 V, $T_a = T_{opr}$,
PCLKA = 8 to 120 MHz, PCLKB = 8 to 60 MHz

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
SCL clock low period	t_{LOW_OD}	200*1, *2	—	—	ns	Figure 49.68
	$t_{DIG\_OD\_L}$	t_{LOW_ODmin} + t_{fDA_ODmin}	—	—		
SDA signal fall time	t_{fDA_OD}	t_{CF}	—	33	ns	Figure 49.68
SDA data setup time open drain mode	t_{SU_OD}	3*1	—	—	ns	Figure 49.68, Figure 49.69
Clock after START (S) condition	t_{CAS}	38.4 ns*3	—	For ENTAS0: 1 µs	—	Figure 49.68
			—	For ENTAS1: 100 µs		
			—	For ENTAS2: 2 ms		
			—	For ENTAS3: 50 ms*4		
Clock before STOP (P) condition	t_{CBP}	$t_{CASmin}/2$	—	—	sec	Figure 49.70
Current controller to secondary controller overlap time during handoff	$t_{CRHPOverlap}$	$t_{DIG\_OD\_Lmin}$	—	—	ns	Figure 49.71
Bus available condition	t_{AVAL}	1*5	—	—	µs	
Bus idle condition	t_{IDLE}	1	—	—	ms	
Time internal where new controller not driving SDA low	$t_{NEWCRLock}$	$t_{AVALmin}$	—	—	µs	Figure 49.71

Note 1. This is approximately equal to $t_{LOWmin} + t_{DS\_ODmin} + t_{rDA\_ODtyp} + t_{SU\_ODmin}$.
Note 2. The controller may use a shorter low period if it knows that this is safe, i.e., that SDA is already above V_{IH}.
Note 3. On a legacy bus where I^2C devices need to see start, the t_{CAS} Min value is further constrained.
Note 4. Targets that do not support the optional ENTASx CCCs shall use the t_{CAS} Max value shown for ENTAS3
Note 5. On a mixed bus with Fm legacy I^2C devices, t_{AVAL} is 300 ns shorter than the Fm bus free condition time (t_{BUF})

Erase suspend latency in erase priority mode		t_{SEED}	—	—	1.7	—	—	1.7	ms	
Forced stop command		t_{FD}	—	—	32	—	—	20	µs	
Data retention*3, *4		t_{DRP}	20	—	—	20	—	—	Year	T_a ≤ 85°C
			10	—	—	10	—	—		T_a ≤ 105°C

Note 1. Definition of program/erase cycle:
The program/erase cycle is the number of erasing for each block. When the number of program/erase cycles is n, each block can be erased n times. For instance, when 256-byte program is performed 32 times for different addresses in 8-Kbyte block and then the block is erased, the program/erase cycle is counted as one. However, the same address cannot be programmed more than once before the next erase cycle (overwriting is prohibited).

Note 2. Characteristics are degraded as the number of program/erase increases. This is the minimum value of program/erase cycles to guarantee all characteristics listed in this table.

Note 3. This shows the characteristic when the flash memory writer or self-programming library from Renesas Electronics is in use, and the number of times programming and erasure proceed does not exceed the specified value.

Note 4. These values are based on the results of reliability testing.

Table 49.54 Data Flash Memory Characteristics

Conditions: VCC = 2.7 to 5.5 V, AVCC0 = AVCC1 = AVCC2 = 3.0 to 5.5 V,
VSS = AVSS0 = AVSS1 = AVSS2 = 0 V,
Temperature range for program/erase: $T_a = T_{opr}$

Item		Symbol	FCLK = 4 MHz			20 MHz ≤ FCLK ≤ 60 MHz			Unit	Test Conditions
			Min.	Typ.	Max.	Min.	Typ.	Max.		
Program time	4 bytes	t_{DP4}	—	0.36	3.8	—	0.16	1.7	ms

			10	—	—	10	—	—		$T_a \leq 105°C$

Note 1. Definition of program/erase cycle:
The program/erase cycle is the number of erasing for each block. When the number of program/erase cycles is n, each block can be erased n times. For instance, when 4-byte program is performed 512 times for different addresses in 2-Kbyte block and then the block is erased, the program/erase cycle is counted as one. However, the same address cannot be programmed more than once before the next erase cycle (overwriting is prohibited).

Note 2. Characteristics are degraded as the number of program/erase increases. This is the minimum value of program/erase cycles to guarantee all characteristics listed in this table.

Note 3. This shows the characteristic when the flash memory writer or self-programming library from Renesas Electronics is in use, and the number of times programming and erasure proceed does not exceed the specified value.

Note 4. These values are based on the results of reliability testing.

P81	Single-chip mode		Hi-Z	Keep-O
P82/IRQ3	Single-chip mode		Hi-Z	Keep-O*1

Table 1.1 Port States in Each Processing State (2 / 2)

Port Name Pin Name	Operating Mode According to Registers Setting	Reset	Software Standby Mode
P90, P91, P92	Single-chip mode	Hi-Z	Keep-O
P93/IRQ14	Single-chip mode	Hi-Z	Keep-O*1
P94	Single-chip mode	Hi-Z	Keep-O
P95/IRQ1, P96/IRQ4	Single-chip mode	Hi-Z	Keep-O*1
PA0	Single-chip mode	Hi-Z	Keep-O
PA1/IRQ14	Single-chip mode	Hi-Z	Keep-O*1
PA2, PA3, PA4	Single-chip mode	Hi-Z	Keep-O
PA5/IRQ1	Single-chip mode	Hi-Z	Keep-O*1
PB0/IRQ8, PB1/IRQ4	Single-chip mode	Hi-Z	Keep-O*1
PB2	Single-chip mode	Hi-Z	Keep-O
PB3/IRQ9, PB4/IRQ3	Single-chip mode	Hi-Z	Keep-O*1
PB5	Single-chip mode	Hi-Z	Keep-O
PB6/IRQ2	Single-chip mode	Hi-Z	Keep-O*1
PB7	Single-chip mode	Hi-Z	Keep-O
PD0, PD1, PD2, PD3	Single-chip mode	Hi-Z	Keep-O
PD4/IRQ2, PD5/IRQ6, PD6/IRQ5, PD7/IRQ8	Single-chip mode	Hi-Z	Keep-O*1
PE0/IRQ7, PE1/IRQ15	Single-chip mode	Hi-Z	Keep-O*1
PE2/NMI/ IRQ0	Single-chip mode	Hi-Z	Keep-O*1
PE3/IRQ2, PE4/IRQ1, PE5/IRQ0	Single-chip mode	Hi-Z	Keep-O*1
PN6	Single-chip mode	Pull up*2	Keep-O
PN7/IRQ5	Single-chip mode	Pull down*3	Keep-O*1

Keep-O: Output pins retain their previous values, and input pins become high-impedance. Note that the input pull-up resistor remains enabled when it is enabled by the pull-up resistor control register.

Hi-Z: High-impedance

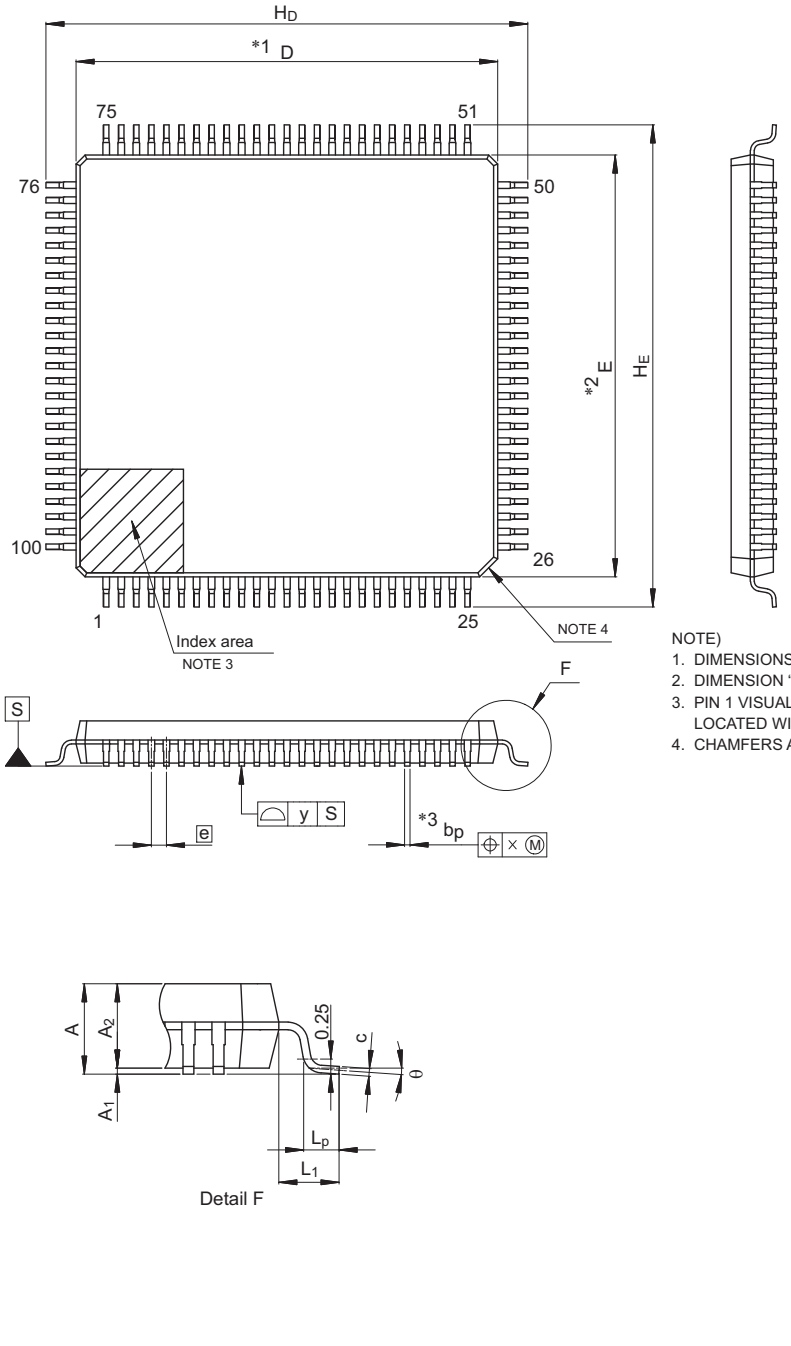
Note 1. Input is enabled if the pin is specified as the software standby cancelling source while it is used as an external interrupt pin.
Note 2. This pin functions as MD after release from the reset state, and the pull-up resistor connected to the MD pin is enabled.
Note 3. This pin functions as EMLE after release from the reset state, and the pull-down resistor connected to the EMLE pin is enabled.

Appendix 2. Package Dimensions

Information on the latest version of the package dimensions or mountings has been displayed in “Packages” on Renesas Electronics Corporation website.

JEITA Package Code	RENESAS Code	Previous Code	MASS (Typ) [g]
P-LFQFP100-14x14-0.50	PLQP0100KB-B	—	0.6

Unit: mm



NOTE)
1. DIMENSIONS “*1” AND “*2” DO NOT INCLUDE MOLD FLASH.
2. DIMENSION “*3” DOES NOT INCLUDE TRIM OFFSET.
3. PIN 1 VISUAL INDEX FEATURE MAY VARY, BUT MUST BE LOCATED WITHIN THE HATCHED AREA.
4. CHAMFERS AT CORNERS ARE OPTIONAL, SIZE MAY VARY.

REVISION HISTORY	RX26T Group User's Manual: Hardware

Classifications

- Items with Technical Update document number: Changes according to the corresponding issued Technical Update
- Items without Technical Update document number: Minor changes that do not require Technical Update to be issued

Rev.	Date	Description		Classification
		Page	Summary	
1.00	Jan 16, 2023	—	First edition, issued	
1.01	Mar 01, 2023	Features		
		62	Package, changed	
		1. Overview		
		74 to 76	Table 1.3 List of Products, changed	
		7. Option-Setting Memory (OFSM)		
		230	7.2.9 Flash Access Window Setting Register (FAW), changed	
		16. Memory-Protection Unit (MPU)		
		423	16.4.4 Processing in Response to Memory-Protection Errors (2) When an instruction memory-protection error is generated, changed	
		24. General PWM Timer (GPTWa)		
		1001	Table 24.2 GPTW Functions (n = 0 to 7), changed	
		44. Temperature Sensor (TEMPS)		
		2674	44.3.2 Setting of 12-Bit A/D Converter Unit 2, changed	
		2675	Figure 44.3 Procedure for Using the Temperature Sensor, changed	
		45. Comparator C (CMPCa)		
		2688	Figure 45.6 Comparator Operation Termination Flowchart, changed	
		49. Electrical Characteristics		
		2832	Table 49.10 Permissible Output Currents, changed	
		2835	Table 49.13 Thermal Resistance Value (Reference), changed	
1.10	Aug 10, 2023	1. Overview		
		71	Table 1.1 Outline of Specifications (9/9), changed	
		74 to 76	Table 1.3 List of Products, changed	
		77	Figure 1.1 How to Read the Product Part Number, changed	
		8. Voltage Detection Circuit (LVDA)		
		236	Table 8.1 Voltage Detection Circuit Specifications, changed	
		19. Event Link Controller (ELC)		
		514	Table 19.2 Correspondence between the ELSRn Register and the Peripheral Modules, changed	
		—	19.4.1 Setting ELSRn Register (2) Setting ELSR24, ELSR25, ELSR26, and ELSR27 Registers, deleted	
		22. Multi-Function Timer Pulse Unit 3 (MTU3d)		
		735	Figure 22.47 Example of Complementary PWM Mode Setting Procedure, changed	
		24. General PWM Timer (GPTWa)		
		1017 to 1020	24.2.7 General PWM Timer Clear Source Select Register (GTCSR), changed	TN-RX*-A0268A/E
		1033 to 1038	24.2.12 General PWM Timer Control Register (GTCR), changed	
		1085, 1086	24.2.37 General PWM Timer Inter Channel Logical Operation Function Setting Register (GTICLF), changed	
		1094 to 1096	24.2.42 General PWM Timer Operation Enable Bit Simultaneous Control Register (GTSECR), changed	TN-RX*-A0268A/E
		1105 to 1107	24.2.46 Output Phase Switching Control Register (OPSCR), changed	
		1124	Table 24.11 The GTPR Buffer Transfer Timing in Complementary PWM Mode, changed	TN-RX*-A0268A/E
		1184	Table 24.17 Immediate Single Buffer Transfer from the GTCCRD Register in Complementary PWM Mode 4 (1), changed	
		1225	Table 24.23 Settings of the Registers Used to Set Sources for Synchronous Clearing, added	

Rev.	Date	Description		Classification
		Page	Summary	
1.10	Aug 10, 2023	1303	24.10.3 Range of Settings for the GTPBR and GTPDBR Registers in the Complementary PWM Mode, added	TN-RX*-A0268A/E
		1305	24.10.7 Note on Counter Clearing in the Complementary PWM Mode, added	
			24.10.8 Note on Disabling PWM Initial Output After Synchronous Clearing in the Complementary PWM Mode, added	
		25. High Resolution PWM Waveform Generation Circuit (HRPWM)		
		1318	25.4.3 Notes on Delay Settings for HRPWM, changed	
		26. GPTW Port Output Enable (POEG)		
		1321	Figure 26.2 POEG Block Diagram, changed	
		1328	26.3.1 Request to Stop Output in Response to Detection of Active Level or Edge Input on the Corresponding GTETRGn Pin (n = A to D), changed	
		1332	26.3.7 Requests to Stop Output in Response to Detected Signals and Canceling the Requests, changed	
		32. Serial Communications Interface (SCIk, SCIh)		
		1470	Table 32.16 Maximum Bit Rate for Each Operating Frequency (Asynchronous Mode) (for SCI1, SCI5, and SCI6), added	
		33. Serial Communications Interface (RSCI)		
		1603	Table 33.1 RSCI Specifications (3/3), changed	TN-RX*-A0268A/E
		1628	Table 33.18 Examples of BRR[7:0] Bits Settings for Various Bit Rates (Clock Synchronous Mode, Simple SPI Mode), changed	
		1650	33.2.13 DE Signal Control Register (DECR), changed	
		1807	33.14 RS-485 Driver Control Function, changed	
		1816	Table 33.49 RSCI Event Link Signal List, changed	TN-RX*-A0268A/E
		—	33.18 Event Linking (5) Receive Data Match Event Output, deleted	
		—	(6) Receive Data Unmatch Event Output, deleted	
		—	(7) Active Edge Detection Event Output, deleted	
		35. I3C Bus Interface (RI3C)		
		1981, 1982	35.3.1.4 Combo Transfer Command, changed	
		1985	35.3.2 Response Descriptor (1) I3C Controller Mode, changed	
		1996	Figure 35.11 Bus Conditions, changed	
		1997	Figure 35.12 Example of RI3C Initialization Flowchart, changed	
		1998	Figure 35.13 I3C Communication Flow, changed	
		2008	Figure 35.28 I3C Controller CRR Processing Flow, changed	
		2019	Figure 35.46 I3C Target CRR Processing Flow, changed	
		2021	Figure 35.48 I3C Target Receives GET CCC Command while Data Exists by Writing from the ICDR Register to the Transmit Buffer, changed	TN-RX*-A0268A/E
		2035	Figure 35.63 Controller Role Request: ACK, changed	
			Figure 35.64 Controller Role Request: NACK (Not Match the DADR[7:0] Bits) and RCRRN = 1, changed	
		2036	Figure 35.65 Controller Role Request: NACK (ROLE[1:0] = 00b (I3C Target)) and RCRRN = 0, changed	
			Figure 35.66 Controller Role Request: NACK (CRRRJ = 1) and RCRRN = 1 (1/2), changed	
		2037	Figure 35.67 Controller Role Request: NACK (CRRRJ = 1) and RCRRN = 1 (2/2), changed	
		36. CAN FD Module (CANFD)		
		2055 to 2058	36.2.2 Channel Control Register (CHCR), changed	
		2241	Figure 36.58 Global Interrupt Block Diagram, changed	
		2242	Figure 36.59 Channel Interrupt Block Diagram, changed	
		40. Arithmetic Unit for Trigonometric Functions (TFUv2)		
		2468	Table 40.1 TFU specifications, changed	
		2469	40.2.1 Fixed-Point Sincos Input and Output Setting Register (FXSCIOC), changed	
		2470	40.2.2 Fixed-Point Atanhypot_k Input and Output Setting Register (FXATIOC), changed	
		2475	Table 40.4 Input/Output value of FXSCDT0 and FXSCDT1, changed	
		2477	Table 40.5 Input/Output value of FXATDT0 and FXATDT1, changed	

Rev.	Date	Description		Classification
		Page	Summary	
1.10	Aug 10, 2023	2479, 2480	40.3.2.1 Single-Precision Floating-Point Numbers, changed	
		2481	40.3.3 Units of Angles, changed	
		42. 12-Bit A/D Converter (S12ADHa)		
		2604	42.3.3.4 Channel Selection and Self-Diagnosis (Without Channel-Dedicated Sample-and-Hold Circuits), changed	
		48. Flash Memory (FLASH)		
		2713	48.1 Overview, changed	
		2714	Figure 48.1 Block Diagram of Flash Memory Related Modules, changed	
		2723	48.4.5 FACI Command Processing Start Address Register (FSADDR), changed	
		2724	48.4.6 FACI Command Processing End Address Register (FEADDR), changed	
		2781	Table 48.17 Address Used by Configuration Set Command, changed	
		2826, 2827	48.8.28 Rewriting Flash Memory When Using Dual Mode, added	TN-RX*-A0267A/E
		2830	Table 48.24 Conditions under which Background Operation is Usable, changed	
		49. Electrical Characteristics		
		2835	Table 49.6 DC Characteristics (3) (Products with 64 Kbytes of RAM), changed	
		2836	Table 49.7 DC Characteristics (3) (Products with 48 Kbytes of RAM), changed
