Old Company Name in Catalogs and Other Documents

On April 1st, 2010, NEC Electronics Corporation merged with Renesas Technology Corporation, and Renesas Electronics Corporation took over all the business of both companies. Therefore, although the old company name remains in this document, it is a valid Renesas Electronics document. We appreciate your understanding.

Renesas Electronics website: http://www.renesas.com

April 1st, 2010 Renesas Electronics Corporation

Issued by: Renesas Electronics Corporation (http://www.renesas.com)

Send any inquiries to http://www.renesas.com/inquiry.

Notice

- 1. All information included in this document is current as of the date this document is issued. Such information, however, is subject to change without any prior notice. Before purchasing or using any Renesas Electronics products listed herein, please confirm the latest product information with a Renesas Electronics sales office. Also, please pay regular and careful attention to additional and different information to be disclosed by Renesas Electronics such as that disclosed through our website.
- Renesas Electronics does not assume any liability for infringement of patents, copyrights, or other intellectual property rights of third parties by or arising from the use of Renesas Electronics products or technical information described in this document. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
- 3. You should not alter, modify, copy, or otherwise misappropriate any Renesas Electronics product, whether in whole or in part.
- 4. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation of these circuits, software, and information in the design of your equipment. Renesas Electronics assumes no responsibility for any losses incurred by you or third parties arising from the use of these circuits, software, or information.
- 5. When exporting the products or technology described in this document, you should comply with the applicable export control laws and regulations and follow the procedures required by such laws and regulations. You should not use Renesas Electronics products or the technology described in this document for any purpose relating to military applications or use by the military, including but not limited to the development of weapons of mass destruction. Renesas Electronics products and technology may not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations.
- 6. Renesas Electronics has used reasonable care in preparing the information included in this document, but Renesas Electronics does not warrant that such information is error free. Renesas Electronics assumes no liability whatsoever for any damages incurred by you resulting from errors in or omissions from the information included herein.
- 7. Renesas Electronics products are classified according to the following three quality grades: "Standard", "High Quality", and "Specific". The recommended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below. You must check the quality grade of each Renesas Electronics product before using it in a particular application. You may not use any Renesas Electronics product for any application categorized as "Specific" without the prior written consent of Renesas Electronics. Further, you may not use any Renesas Electronics. Renesas Electronics shall not be in any way liable for any damages or losses incurred by you or third parties arising from the use of any Renesas Electronics product for an application categorized as "Specific" or for which the product is not intended where you have failed to obtain the prior written consent of Renesas Electronics. The quality grade of each Renesas Electronics product is "Standard" unless otherwise expressly specified in a Renesas Electronics data sheets or data books, etc.
 - "Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; and industrial robots.
 - "High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control systems; anti-disaster systems; anticrime systems; safety equipment; and medical equipment not specifically designed for life support.
 - "Specific": Aircraft; aerospace equipment; submersible repeaters; nuclear reactor control systems; medical equipment or systems for life support (e.g. artificial life support devices or systems), surgical implantations, or healthcare intervention (e.g. excision, etc.), and any other applications or purposes that pose a direct threat to human life.
- 8. You should use the Renesas Electronics products described in this document within the range specified by Renesas Electronics, especially with respect to the maximum rating, operating supply voltage range, movement power voltage range, heat radiation characteristics, installation and other product characteristics. Renesas Electronics shall have no liability for malfunctions or damages arising out of the use of Renesas Electronics products beyond such specified ranges.
- 9. Although Renesas Electronics endeavors to improve the quality and reliability of its products, semiconductor products have specific characteristics such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Further, Renesas Electronics products are not subject to radiation resistance design. Please be sure to implement safety measures to guard them against the possibility of physical injury, and injury or damage caused by fire in the event of the failure of a Renesas Electronics product, such as safety design for hardware and software including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult, please evaluate the safety of the final products or system manufactured by you.
- 10. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. Please use Renesas Electronics products in compliance with all applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive. Renesas Electronics assumes no liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
- 11. This document may not be reproduced or duplicated, in any form, in whole or in part, without prior written consent of Renesas Electronics.
- 12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products, or if you have any other inquiries.
- (Note 1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its majorityowned subsidiaries.
- (Note 2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.

1 VOLTAGE APPLICATION WAVEFORM AT INPUT PIN

Waveform distortion due to input noise or a reflected wave may cause malfunction. If the input of the CMOS device stays in the area between V_{IL} (MAX) and V_{IH} (MIN) due to noise, etc., the device may malfunction. Take care to prevent chattering noise from entering the device when the input level is fixed, and also in the transition period when the input level passes through the area between V_{IL} (MAX) and V_{IH} (MIN).

② HANDLING OF UNUSED INPUT PINS

Unconnected CMOS device inputs can be cause of malfunction. If an input pin is unconnected, it is possible that an internal input level may be generated due to noise, etc., causing malfunction. CMOS devices behave differently than Bipolar or NMOS devices. Input levels of CMOS devices must be fixed high or low by using pull-up or pull-down circuitry. Each unused pin should be connected to VDD or GND via a resistor if there is a possibility that it will be an output pin. All handling related to unused pins must be judged separately for each device and according to related specifications governing the device.

③ PRECAUTION AGAINST ESD

A strong electric field, when exposed to a MOS device, can cause destruction of the gate oxide and ultimately degrade the device operation. Steps must be taken to stop generation of static electricity as much as possible, and quickly dissipate it when it has occurred. Environmental control must be adequate. When it is dry, a humidifier should be used. It is recommended to avoid using insulators that easily build up static electricity. Semiconductor devices must be stored and transported in an anti-static container, static shielding bag or conductive material. All test and measurement tools including work benches and floors should be grounded. The operator should be grounded using a wrist strap. Semiconductor devices must not be touched with bare hands. Similar precautions need to be taken for PW boards with mounted semiconductor devices.

④ STATUS BEFORE INITIALIZATION

Power-on does not necessarily define the initial status of a MOS device. Immediately after the power source is turned ON, devices with reset functions have not yet been initialized. Hence, power-on does not guarantee output pin levels, I/O settings or contents of registers. A device is not initialized until the reset signal is received. A reset operation must be executed immediately after power-on for devices with reset functions.

5 POWER ON/OFF SEQUENCE

In the case of a device that uses different power supplies for the internal operation and external interface, as a rule, switch on the external power supply after switching on the internal power supply. When switching the power supply off, as a rule, switch off the external power supply and then the internal power supply. Use of the reverse power on/off sequences may result in the application of an overvoltage to the internal elements of the device, causing malfunction and degradation of internal elements due to the passage of an abnormal current.

The correct power on/off sequence must be judged separately for each device and according to related specifications governing the device.

(6) INPUT OF SIGNAL DURING POWER OFF STATE

Do not input signals or an I/O pull-up power supply while the device is not powered. The current injection that results from input of such a signal or I/O pull-up power supply may cause malfunction and the abnormal current that passes in the device at this time may cause degradation of internal elements. Input of signals during the power off state must be judged separately for each device and according to related specifications governing the device.

Caution: The μ PD70F3207H and 70F3207HY use SuperFlash[®] technology licensed from Silicon Storage Technology, Inc.

IECUBE is a registered trademark of NEC Electronics Corporation in Japan and Germany.

MINICUBE is a registered trademark of NEC Electronics Corporation in Japan and Germany or a trademark in the United States of America.

EEPROM is a trademark of NEC Electronics Corporation.

Windows and Windows NT are either registered trademarks or trademarks of Microsoft Corporation in the United States and/or other countries.

PC/AT is a trademark of International Business Machines Corporation.

SPARCstation is a trademark of SPARC International, Inc.

Solaris and SunOS are trademarks of Sun Microsystems, Inc.

SuperFlash is a registered trademark of Silicon Storage Technology, Inc. in several countries including the United States and Japan.

These commodities, technology or software, must be exported in accordance with the export administration regulations of the exporting country. Diversion contrary to the law of that country is prohibited.

- The information in this document is current as of January, 2006. The information is subject to change without notice. For actual design-in, refer to the latest publications of NEC Electronics data sheets or data books, etc., for the most up-to-date specifications of NEC Electronics products. Not all products and/or types are available in every country. Please check with an NEC Electronics sales representative for availability and additional information.
- No part of this document may be copied or reproduced in any form or by any means without the prior written consent of NEC Electronics. NEC Electronics assumes no responsibility for any errors that may appear in this document.
- NEC Electronics does not assume any liability for infringement of patents, copyrights or other intellectual property rights of third parties by or arising from the use of NEC Electronics products listed in this document or any other liability arising from the use of such products. No license, express, implied or otherwise, is granted under any patents, copyrights or other intellectual property rights of NEC Electronics or others.
- Descriptions of circuits, software and other related information in this document are provided for illustrative purposes in semiconductor product operation and application examples. The incorporation of these circuits, software and information in the design of a customer's equipment shall be done under the full responsibility of the customer. NEC Electronics assumes no responsibility for any losses incurred by customers or third parties arising from the use of these circuits, software and information.
- While NEC Electronics endeavors to enhance the quality, reliability and safety of NEC Electronics products, customers agree and acknowledge that the possibility of defects thereof cannot be eliminated entirely. To minimize risks of damage to property or injury (including death) to persons arising from defects in NEC Electronics products, customers must incorporate sufficient safety measures in their design, such as redundancy, fire-containment and anti-failure features.
- NEC Electronics products are classified into the following three quality grades: "Standard", "Special" and "Specific".

The "Specific" quality grade applies only to NEC Electronics products developed based on a customerdesignated "quality assurance program" for a specific application. The recommended applications of an NEC Electronics product depend on its quality grade, as indicated below. Customers must check the quality grade of each NEC Electronics product before using it in a particular application.

- "Standard": Computers, office equipment, communications equipment, test and measurement equipment, audio and visual equipment, home electronic appliances, machine tools, personal electronic equipment and industrial robots.
- "Special": Transportation equipment (automobiles, trains, ships, etc.), traffic control systems, anti-disaster systems, anti-crime systems, safety equipment and medical equipment (not specifically designed for life support).
- "Specific": Aircraft, aerospace equipment, submersible repeaters, nuclear reactor control systems, life support systems and medical equipment for life support, etc.

The quality grade of NEC Electronics products is "Standard" unless otherwise expressly specified in NEC Electronics data sheets or data books, etc. If customers wish to use NEC Electronics products in applications not intended by NEC Electronics, they must contact an NEC Electronics sales representative in advance to determine NEC Electronics' willingness to support a given application.

(Note)

- (1) "NEC Electronics" as used in this statement means NEC Electronics Corporation and also includes its majority-owned subsidiaries.
- (2) "NEC Electronics products" means any product developed or manufactured by or for NEC Electronics (as defined above).

PREFACE

Readers	This	manual	is	intended	for	users	who	wish	to	understand	the	functions	of	the
	V850	ES/KE1	anc	l design ap	oplic	ation sy	/stem	s using	g th	ese products				
	The t	arget pro	duo	cts are as	follo	ws.								

- μPD703207, 703207Y, 70F3207H, 70F3207HY
- Purpose
 This manual is intended to give users an understanding of the hardware functions of the V850ES/KE1 shown in the Organization below.
- Organization
 This manual is divided into two parts: Hardware (this manual) and Architecture (V850ES

 Architecture User's Manual).

Hardware

- Pin functions
- CPU function
- On-chip peripheral functions
- Flash memory programming
- Electrical specifications

- Architecture
- · Data types
- Register set
- · Instruction format and instruction set
- · Interrupts and exceptions
- Pipeline operation
- How to Read This Manual It is assumed that the readers of this manual have general knowledge in the fields of electrical engineering, logic circuits, and microcontrollers.

To find the details of a register where the name is known \rightarrow Refer to **APPENDIX C REGISTER INDEX**.

- To understand the details of an instruction function
- \rightarrow Refer to the V850ES Architecture User's Manual.
- Register format
- → The name of the bit whose number is in angle brackets (<>) in the figure of the register format of each register is defined as a reserved word in the device file.

To understand the overall functions of the V850ES/KE1

 \rightarrow Read this manual according to the **CONTENTS**.

To know the electrical specifications of the V850ES/KE1

→ Refer to CHAPTER 24 ELECTRICAL SPECIFICATIONS

The "yyy bit of the xxx register" is described as the "xxx.yyy bit" in this manual. Note with caution that even if "xxx.yyy" is described as is in a program, however, the compiler/assembler cannot recognize it correctly.

The mark <R> shows major revised points. The revised points can be easily searched by copying an "<R>" in the PDF file and specifying it in the "Find what:" field.

Conventions	Data significance: Active low representation	Higher digits on the left and lower digits on the right :: xxx (overscore over pin or signal name)
	Memory map address:	Higher addresses on the top and lower addresses on the bottom
	Note:	Footnote for item marked with Note in the text
	Caution:	Information requiring particular attention
	Remark:	Supplementary information
	Numeric representation:	Binary xxxx or xxxxB
		Decimal xxxx
		Hexadecimal xxxxH
	Prefix indicating power of	f 2 (address space, memory capacity):
		K (kilo): 2 ¹⁰ = 1,024
		M (mega): 2 ²⁰ = 1,024 ²
		G (giga): $2^{30} = 1,024^{3}$

Related DocumentsThe related documents indicated in this publication may include preliminary versions.However, preliminary versions are not marked as such.

-	ambient temperature					Т	A = −40 to	+85°C					

Notes 1. Because the POC circuit detection voltage (VPoc) is 2.1 V ±0.1 V, use the products in the voltage range of 2.2 to 5.5 V.

2. Select either of the functions of these alternate-function pins.

1.2 Features

- O Minimum instruction execution time: 50 ns (operation at main clock (fxx) = 20 MHz)
- O General-purpose registers: 32 bits × 32 registers
- O CPU features: Signed multiplication $(16 \times 16 \rightarrow 32)$: 1 to 2 clocks
 - (Instructions without creating register hazards can be continuously executed in parallel) Saturated operations (overflow and underflow detection functions are included) 32-bit shift instruction: 1 clock
 - Bit manipulation instructions
 - Load/store instructions with long/short format
- O Memory space: 64 MB of linear address space

Total: 51

- Internal memory
 - µPD703207, 703207Y (Mask ROM: 128 KB/RAM: 4 KB)
 - µPD70F3207H, 70F3207HY (Flash memory: 128 KB/RAM: 4 KB)
- O Interrupts and exceptions
 - Non-maskable interrupts: 3 sources

Maskable interrupts:	30 sources (µPD703207, 70F3207H)
	31 sources (µPD703207Y, 70F3207HY)
Software exceptions:	32 sources
Exception trap:	1 source

- O I/O lines:
- Key interrupt function
- O Timer function
- 16-bit timer/event counter P: 1 channel 16-bit timer/event counter 0: 1 channel 8-bit timer/event counter 5: 2 channels
- 8-bit timer H: 2 channels
- 8-bit interval timer BRG: 1 channel
- Watch timer/interval timer: 1 channel
- Watchdog timers
 - Watchdog timer 1 (also usable as oscillation stabilization timer): 1 channel Watchdog timer 2: 1 channel
- O Serial interface
- Asynchronous serial interface (UART):2 channels3-wire serial I/O (CSI0):2 channels
 - 1 channel (µPD703207Y, 70F3207HY)
- O A/D converter: 10-bit resolution \times 8 channels
- O Real-time output port: 6 bits \times 1 channel
- O Standby functions: HALT/IDLE/STOP modes, subclock/sub-IDLE modes
- O ROM correction: 4 correction addresses specifiable
- O Clock generator
- Main clock oscillation (fx)/subclock oscillation (fxT) CPU clock (fcPu) 7 steps (fxx, fxx/2, fxx/4, fxx/8, fxx/16, fxx/32, fxT) Clock-through mode/PLL mode selectable
- O Reset
- Reset by RESET pin

I²C bus interface (I²C):

- Reset by overflow of watchdog timer 1 (WDTRES1)
- Reset by overflow of watchdog timer 2 (WDTRES2)

- O Package: 64-pin plastic TQFP (12×12)
 - 64-pin plastic LQFP (fine pitch) (10×10)

1.3 Applications

- O Automotive
 - System control of body electrical system (power windows, keyless entry reception, etc.)
 - Submicrocontroller of control system
- O Home audio, car audio
- O AV equipment
- O PC peripheral devices (keyboards, etc.)
- O Household appliances
 - Outdoor units of air conditioners
 - Microwave ovens, rice cookers
- O Industrial devices
 - Pumps
 - Vending machines
 - FA

<R> 1.4 Ordering Information

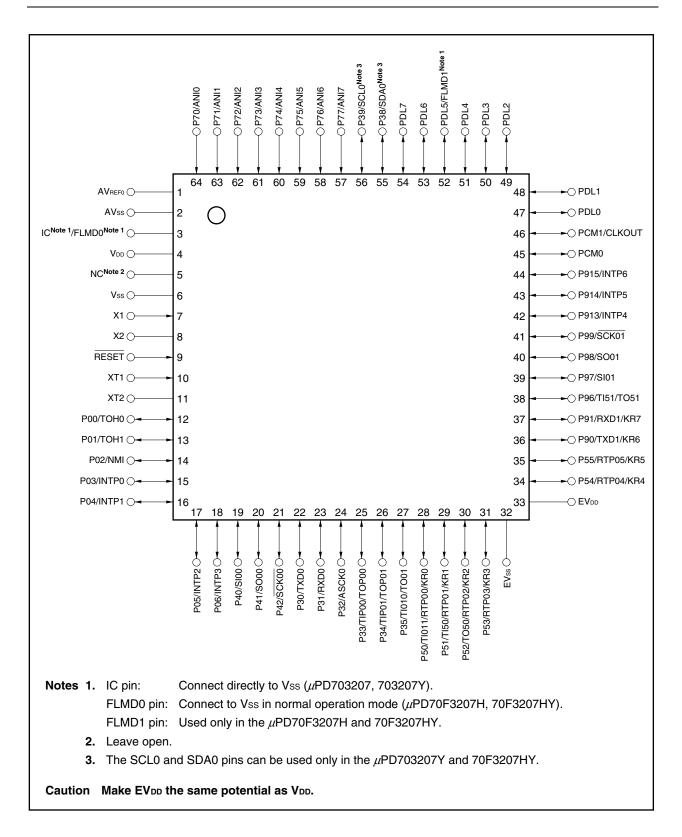

Part Number	Package	Quality Grade

Pin identification

ANI0 to ANI7:	Analog input	PDL0 to PDL7:	Port DL
ASCK0:	Asynchronous serial clock	RESET:	Reset
AVREF0:	Analog reference voltage	RTP00 to RTP05:	Real-time output port
AVss:	Ground for analog	RXD0, RXD1:	Receive data
CLKOUT:	Clock output	SCK00, SCK01:	Serial clock
EVDD:	Power supply for port	SCL0:	Serial clock
EVss:	Ground for port	SDA0:	Serial data
FLMD0, FLMD1:	Flash programming mode	SI00, SI01:	Serial input
IC:	Internally connected	SO00, SO01:	Serial output
INTP0 to INTP6:	External interrupt input	TI010, TI011,	
KR0 to KR7:	Key return	TI50, TI51,	
NC:	Non-connection	TIP00, TIP01:	Timer input
NMI:	Non-maskable interrupt request	TO01,	
P00 to P06:	Port 0	TO50, TO51,	
P30 to P35, P38, P39:	Port 3	TOH0, TOH1,	
P40 to P42:	Port 4	TOP00, TOP01:	Timer output
P50 to P55:	Port 5	TXD0, TXD1:	Transmit data
P70 to P77:	Port 7	Vdd:	Power supply
P90, P91, P96 to P99,		Vss:	Ground
P913 to P915:	Port 9	X1, X2:	Crystal for main clock
PCM0, PCM1:	Port CM	XT1, XT2:	Crystal for subclock

1.6 Function Block Configuration

(1) Internal block diagram

(2) Internal units

(a) CPU

The CPU uses five-stage pipeline control to enable single-clock execution of address calculations, arithmetic logic operations, data transfers, and almost all other types of instruction processing. Other dedicated on-chip hardware, such as a multiplier (16 bits \times 16 bits \rightarrow 32 bits) and a barrel shifter (32 bits) help accelerate complex processing.

(b) Bus control unit (BCU)

The BCU controls the internal bus.

(c) ROM

This consists of a 128 KB mask ROM or flash memory mapped to the address spaces from 0000000H to 001FFFFH.

ROM can be accessed by the CPU in one clock cycle during instruction fetch.

(d) RAM

This consists of a 4 KB RAM mapped to the address spaces from 3FFE000H to 3FFEFFFH. RAM can be accessed by the CPU in one clock cycle during data access.

(e) Interrupt controller (INTC)

This controller handles hardware interrupt requests (NMI, INTP0 to INTP6) from on-chip peripheral hardware and external hardware. Eight levels of interrupt priorities can be specified for these interrupt requests, and multiplexed servicing control can be performed.

(f) Clock generator (CG)

A main clock oscillator and subclock oscillator are provided and generate the main clock oscillation frequency (fx) and subclock frequency (fxT), respectively.

There are two modes: In the clock-through mode, fx is used as the main clock frequency (fxx) as is. In the PLL mode, fx is used multiplied by 4.

The CPU clock frequency (fcPu) can be selected from among fxx, fxx/2, fxx/4, fxx/8, fxx/16, fxx/32, and fxt.

(g) Timer/counter

One 16-bit timer/event counter 0 channel, one 16-bit timer/event counter P channel, and two 8-bit timer/event counter 5 channels are incorporated, enabling measurement of pulse intervals and frequency as well as programmable pulse output.

Two 8-bit timer/event counter 5 channels can be connected in cascade to configure a 16-bit timer.

Two 8-bit timer H channels enabling programmable pulse output are provided on chip.

(h) Watch timer

This timer counts the reference time (0.5 seconds) for counting the clock from the subclock (32.768 kHz) or f_{BRG} (32.768 kHz) from the clock generator. At the same time, the watch timer can be used as an interval timer.

(i) Watchdog timer

Two watchdog timer channels are provided on chip to detect program loops and system abnormalities. Watchdog timer 1 can be used as an interval timer. When used as a watchdog timer, it generates a non-maskable interrupt request signal (INTWDT1) or system reset signal (WDTRES1) after an overflow occurs. When used as an interval timer, it generates a maskable interrupt request signal (INTWDT1) after an overflow occurs.

Watchdog timer 2 operates by default following reset release.

It generates a non-maskable interrupt request signal (INTWDT2) or system reset signal (WDTRES2) after an overflow occurs.

(j) Serial interface (SIO)

The V850ES/KE1 includes three kinds of serial interfaces: an asynchronous serial interface (UARTn), a clocked serial interface (CSI0n), and an I²C bus interface (I²C0). The μ PD703207 and 70F3207H can simultaneously use up to four channels, and the μ PD703207Y and 70F3207HY up to five channels.

For UARTn, data is transferred via the TXDn and RXDn pins.

For CSI0n, data is transferred via the SO0n, SI0n, and SCK0n pins.

For I²C0, data is transferred via the SDA0 and SCL0 pins.

 I^2C0 is provided only in the μ PD703207Y and 70F3207HY.

Remark n = 0, 1

(k) A/D converter

This high-speed, high-resolution 10-bit A/D converter includes 8 analog input pins. Conversion is performed using the successive approximation method.

(I) ROM correction

This function is used to replace part of a program in the mask ROM with that contained in the internal RAM. Up to four correction addresses can be specified.

(m) Key interrupt function

A key interrupt request signal (INTKR) can be generated by inputting a falling edge to the eight key input pins.

(n) Real-time output function

This function transfers 6-bit data set beforehand to output latches upon occurrence of a timer compare register match signal.

A 1-channel 6-bit data real-time output function is provided on chip.

(o) Ports

As shown below, the following ports have general-purpose port functions and control pin functions.

Port	I/O	Alternate Function
P0	7-bit I/O	NMI, external interrupt, timer output
P3	8-bit I/O	Serial interface, timer I/O
P4	3-bit I/O	Serial interface
P5	6-bit I/O	Timer I/O, key interrupt function, real-time output function
P7	8-bit input	A/D converter analog input
P9	9-bit I/O	Serial interface, timer I/O, external interrupt, key interrupt function
PCM	2-bit I/O	Clock output
PDL	8-bit I/O	_

1.7 Overview of Functions

Part Number		<i>µ</i> PD703207, 703207Y	μPD70F3207H, 70F3207HY								
Internal	ROM	128 KB	128 KB (flash memory)								
memory	High-speed RAM	4 KB									
Memory s	space	64 MB									
General-p	ourpose registers	32 bits × 32 registers									
Main cloc	k	Ceramic/crystal/external clock									
(oscillatio	n frequency)	When PLL not used (2 to 10 MHz: 2.7 to 5.5 V)									
		When PLL used (2 to 5 MHz: 4.5 to 5.5 V, 2 to 2.5 MHz: 2.7 to 5.5 V)									
Subclock		Crystal/extern	nal clock								
(oscillatio	n frequency)	(32.768 kHz)									
Minimum execution	instruction time	50 ns (When main clock ope	prated at (fxx) = 20 MHz)								
DSP func	tion	32 × 32 = 64: 200 to 25	50 ns (at 20 MHz)								
		32 × 32 + 32 = 32: 300 ns (at 20 MHz)									
		16 × 16 = 32: 50 to 100 ns (at 20 MHz) 16 × 16 + 32 = 32: 150 ns (at 20 MHz)									
			U NS (AT 20 MHZ)								
I/O ports		51									
		 Input: 8 I/O: 43 (among these, N-ch open-drain output selectable: 4 	, fixed to N-ch open-drain output: 2)								
Timer		16-bit timer/event counter P: 1 channel									
		16-bit timer/event counter 0: 1 channel									
		8-bit timer/event counter 5: 2 channels									
		(16-bit timer/event counter: usable as 1 channel)									
		8-bit timer H: 2 channels									
		Watch timer: 1 channel									
		8-bit interval timer: 1 channel									
		Watchdog timer: 2 channels									
Real-time	output port	4 bits \times 1, 2 bits \times 7	1, or 6 bits \times 1								
A/D conve	erter	10-bit resolution >	× 8 channels								
Serial inte	erface	CSI: 2 channels									
		UART: 2 channels									
		I ² C bus: 1 channel ^{Note 1}									
		Dedicated baud rate generator: 2 channels									
Interrupt s	sources	External: 9 (9) ^{Note 2} , internal: 25/26 ^{Note 1}									
Power sav	ve function	STOP/IDLE/HALT/sub-IDLE mode									
Operating	supply voltage	4.5 to 5.5 V (at 20 MHz)/2.7 to 5.5 V (at 10 MHz)									
Package		64-pin plastic TQFP ($12 \times 12 \text{ mm}$)									
		64-pin plastic LQFP (fine pitch) (10 $ imes$ 10 mm)									

Notes 1. Only in the μ PD703207Y, 70F3207HY

2. The figure in parentheses indicates the number of external interrupts for which STOP mode can be released.

CHAPTER 2 PIN FUNCTIONS

The names and functions of the pins of the V850ES/KE1 are described below, divided into port pins and non-port pins.

The pin I/O buffer power supplies are divided into two systems; AVREF0 and EVDD. The relationship between these power supplies and the pins is shown below.

Power Supply	Corresponding Pins
AVREFO	Port 7
EVDD	RESET, ports 0, 3 to 5, 9, CM, DL

(1/2)

Table 2-1. Pin I/O Buffer Power Supplies

2.1 List of Pin Functions

(1) Port pins

Pin Name	Pin No.	I/O	Pull-up Resistor	Function	Alternate Function															
P00	12	I/O	Yes	Port 0	ТОН0															
P01	13			I/O port	TOH1															
P02	14			Input/output can be specified in 1-bit units.	NMI															
P03	15				INTP0															
P04	16				INTP1															
P05	17			INTP2																
P06	18		11	INTP3																
P30	22	I/O Y	Yes	Port 3	TXD0															
P31	23								I/O port	RXD0										
P32	24			Input/output can be specified in 1-bit units. P38 and P39 are fixed to N-ch open-drain	ASCK0															
P33	25																		output.	TIP00/TOP00
P34	26															TIP01/TOP01				
P35	27				TI010/TO01															
P38	55				No ^{Note 1}		SDA0 ^{Note 2}													
P39	56				SCL0 ^{Note 2}															
P40	19	I/O	Yes	Port 4 I/O port	S100															
P41	20			Input/output can be specified in 1-bit units.	SO00															
P42	2 21			P41 and P42 can be specified as N-ch open- drain output in 1-bit units.	SCK00															

Notes 1. An on-chip pull-up resistor can be provided by a mask option (only in the μ PD703207, 703207Y).

2. Only in the μPD703207Y, 70F3207HY

Pin Name	Pin No.	I/O	Pull-up Resistor	Function	Alternate Function

CHAPTER 3 CPU FUNCTIONS

The CPU of the V850ES/KE1 is based on the RISC architecture and executes most instructions in one clock cycle by using 5-stage pipeline control.

3.1 Features

<R>

- O Number of instructions:
- O Minimum instruction execution time: 50.0 ns (@ 20 MHz operation: 4.5 to 5.5 V) 100 ns (@ 10 MHz operation: 2.7 to 5.5 V)

83

O Memory space Program (physical address) space: 64 MB linear

Data (logical address) space: 4 GB linear

- $\, \odot \,$ General-purpose registers: 32 bits $\times \, 32$
- O Internal 32-bit architecture
- O 5-stage pipeline control
- O Multiply/divide instructions
- O Saturated operation instructions
- O 32-bit shift instruction: 1 clock
- O Load/store instruction with long/short format
- O Four types of bit manipulation instructions
 - SET1
 - CLR1
 - NOT1
 - TST1

3.2 CPU Register Set

The CPU registers of the V850ES/KE1 can be classified into two categories: a general-purpose program register set and a dedicated system register set. All the registers have 32-bit width.

For details, refer to the V850ES Architecture User's Manual.

(1) Program register set	(2) System register set
310	31
r0 (Zero register)	EIPC (Interrupt status saving register)
r1 (Assembler-reserved register)	EIPSW (Interrupt status saving register)
r2	
r3 (Stack pointer (SP))	FEPC (NMI status saving register)
r4 (Global pointer (GP))	FEPSW (NMI status saving register)
r5 (Text pointer (TP))	
r6	ECR (Interrupt source register)
r7	
r8	PSW (Program status word)
r9	
r10	CTPC (CALLT execution status saving register)
r11	CTPSW (CALLT execution status saving register)
r12	
r13	DBPC (Exception/debug trap status saving register
r14	DBPC (Exception/debug trap status saving register DBPSW (Exception/debug trap status saving register
r15	
r16	
r17	CTBP (CALLT base pointer)
r18	
r19	
r20	
r21	
r22	
r23	
r24	
r25	
r26	
r27	
r28	
r29	
r30 (Element pointer (EP))	
r31 (Link pointer (LP))	
31 0	
PC (Program counter)	

3.2.1 Program register set

The program register set includes general-purpose registers and a program counter.

(1) General-purpose registers (r0 to r31)

Thirty-two general-purpose registers, r0 to r31, are available. All of these registers can be used as a data variable or address variable.

However, r0 and r30 are implicitly used by instructions and care must be exercised when using these registers. r0 always holds 0 and is used for operations that use 0 and offset 0 addressing. r30 is used as a base pointer when performing memory access with the SLD and SST instructions.

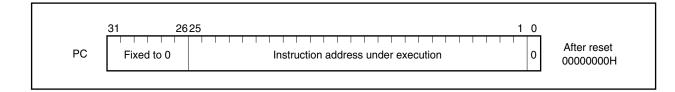

Also, r1, r3 to r5, and r31 are implicitly used by the assembler and C compiler. Therefore, before using these registers, their contents must be saved so that they are not lost, and they must be restored to the registers after the registers have been used. There are cases when r2 is used by the real-time OS. If r2 is not used by the real-time OS, r2 can be used as a variable register.

Name	Usage	Operation		
rO	Zero register Always holds 0			
r1	Assembler-reserved register	Working register for generating 32-bit immediate		
r2	Address/data variable register (w	hen r2 is not used by the real-time OS to be used)		
r3	Stack pointer	Used to generate stack frame when function is called		
r4	Global pointer Used to access global variable in data area			
r5	Text pointer	Register to indicate the start of the text area (area for placing program coc		
r6 to r29	Address/data variable register			
r30	Element pointer Base pointer when memory is accessed			
r31	Link pointer	Used by compiler when calling function		
PC	Program counter	Holds instruction address during program execution		

Table 3-1. Program Registers

(2) Program counter (PC)

This register holds the address of the instruction under execution. The lower 26 bits of this register are valid, and bits 31 to 26 are fixed to 0. If a carry occurs from bit 25 to bit 26, it is ignored. Bit 0 is fixed to 0, and branching to an odd address cannot be performed.

3.2.2 System register set

System registers control the status of the CPU and hold interrupt information.

Read from and write to system registers are performed by setting the system register numbers shown below with the system register load/store instructions (LDSR, STSR instructions).

System	System Register Name	Operand Specification Enabled	
Register No.		LDSR Instruction	STSR Instruction
0	Interrupt status saving register (EIPC) ^{Note 1}	Yes	Yes
1	Interrupt status saving register (EIPSW) ^{Note 1}	Yes	Yes
2	NMI status saving register (FEPC) ^{Note 1}	Yes	Yes
3	NMI status saving register (FEPSW) ^{Note 1}	Yes	Yes
4	Interrupt source register (ECR)	No	Yes
5	Program status word (PSW)	Yes	Yes
6 to 15	Reserved numbers for future function expansion (The operation is not guaranteed if accessed.)	No	No
16	CALLT execution status saving register (CTPC)	Yes	Yes
17	CALLT execution status saving register (CTPSW)	Yes	Yes
18	Exception/debug trap status saving register (DBPC)	Yes ^{Note 2}	Yes ^{Note 2}
19	Exception/debug trap status saving register (DBPSW)	Yes ^{Note 2}	Yes ^{Note 2}
20	CALLT base pointer (CTBP)	Yes	Yes
21 to 31	Reserved numbers for future function expansion (The operation is not guaranteed if accessed.)	No	No

Table 3-2. System Register Numbers

Notes 1. Since only one set of these registers is available, the contents of this register must be saved by the program when multiple interrupt servicing is enabled.

2. These registers can be accessed only during the interval between the execution of the DBTRAP instruction or illegal opcode and the DBRET instruction.

<R>

Caution Even if bit 0 of EIPC, FEPC, or CTPC is set (1) by the LDSR instruction, bit 0 is ignored during return with the RETI instruction following interrupt servicing (because bit 0 of PC is fixed to 0). When setting a value to EIPC, FEPC, and CTPC, set an even number (bit 0 = 0).

(1) Interrupt status saving registers (EIPC, EIPSW)

There are two interrupt status saving registers, EIPC and EIPSW.

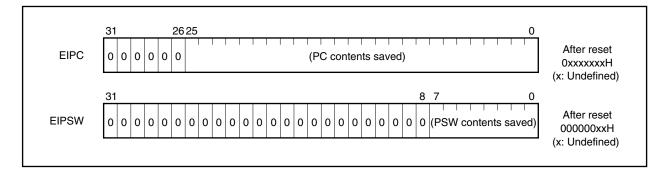

Upon occurrence of a software exception or a maskable interrupt, the contents of the program counter (PC) are saved to EIPC and the contents of the program status word (PSW) are saved to EIPSW (upon occurrence of a non-maskable interrupt (NMI), the contents are saved to the NMI status saving registers (FEPC, FEPSW)). The address of the next instruction following the instruction executed when a software exception or maskable interrupt occurs is saved to EIPC, except for some instructions (refer to **17.9 Periods in Which Interrupts Are Not Acknowledged by CPU**).

The current PSW contents are saved to EIPSW.

Since there is only one set of interrupt status saving registers, the contents of these registers must be saved by the program when multiple interrupt servicing is enabled.

Bits 31 to 26 of EIPC and bits 31 to 8 of EIPSW are reserved (fixed to 0) for future function expansion.

When the RETI instruction is executed, the values in EIPC and EIPSW are restored to the PC and PSW, respectively.

(2) NMI status saving registers (FEPC, FEPSW)

There are two NMI status saving registers, FEPC and FEPSW.

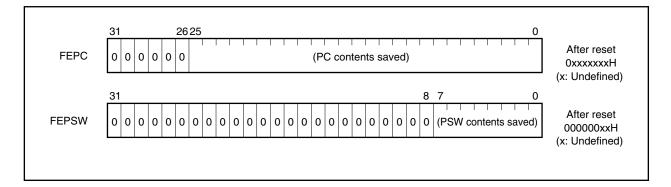

Upon occurrence of a non-maskable interrupt (NMI), the contents of the program counter (PC) are saved to FEPC and the contents of the program status word (PSW) are saved to FEPSW.

The address of the next instruction following the instruction executed when a non-maskable interrupt occurs is saved to FEPC, except for some instructions.

The current PSW contents are saved to FEPSW.

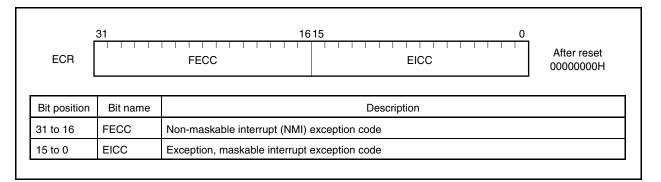

Since there is only one set of NMI status saving registers, the contents of these registers must be saved by the program when multiple interrupt servicing is performed.

Bits 31 to 26 of FEPC and bits 31 to 8 of FEPSW are reserved (fixed to 0) for future function expansion.

(3) Interrupt source register (ECR)

Upon occurrence of an interrupt or an exception, the interrupt source register (ECR) holds the source of an interrupt or an exception. The value held by ECR is the exception code coded for each interrupt source. This register is a read-only register, and thus data cannot be written to it using the LDSR instruction.

(4) Program status word (PSW)

The program status word (PSW) is a collection of flags that indicate the program status (instruction execution result) and the CPU status.

When the contents of this register are changed using the LDSR instruction, the new contents become valid immediately following completion of LDSR instruction execution. Interrupt request acknowledgment is held pending while a write to the PSW is being executed by the LDSR instruction.

(1/2)

Bits 31 to 8 are reserved (fixed to 0) for future function expansion.

PSW		RFU NP EP ID SAT CY OV S Z After reset 00000020H			
Bit position	Flag name	Description			
31 to 8	RFU	Reserved field. Fixed to 0.			
7	NP	Indicates that non-maskable interrupt (NMI) servicing is in progress. This flag is set to 1 when an NMI request is acknowledged, and disables multiple interrupts.0: NMI servicing not in progress1: NMI servicing in progress			
6	EP	Indicates that exception processing is in progress. This flag is set to 1 when an exception occurs. Moreover, interrupt requests can be acknowledged even when this bit is set.0: Exception processing not in progress1: Exception processing in progress			
5	ID	Indicates whether maskable interrupt request acknowledgment is enabled. 0: Interrupt enabled 1: Interrupt disabled			
4	SAT ^{Note}	Indicates that the result of executing a saturated operation instruction has overflowed and that the calculation result is saturated. Since this is a cumulative flag, it is set to 1 when the result of a saturated operation instruction becomes saturated, and it is not cleared to 0 even if the operation results of successive instructions do not become saturated. This flag is neither set nor cleared when arithmetic operation instructions are executed. 0: Not saturated 1: Saturated			
3	CY	Indicates whether carry or borrow occurred as the result of an operation. 0: No carry or borrow occurred 1: Carry or borrow occurred			
2	OV ^{Note}	Indicates whether overflow occurred during an operation. 0: No overflow occurred 1: Overflow occurred.			
1	S ^{Note}	Indicates whether the result of an operation is negative. 0: Operation result is positive or 0. 1: Operation result is negative.			
0	Z	Indicates whether operation result is 0. 0: Operation result is not 0. 1: Operation result is 0.			

10	(n)
12	121
14	/ _ /

Note	Note During saturated operation, the saturated operation results are determined by the contents of the O flag and S flag. The SAT flag is set (to 1) only when the OV flag is set (to 1) during saturated operation						
	Operation result status		Flag status				
		SAT	OV	S	operation result		
	Maximum positive value exceeded	1	1	0	7FFFFFFH		
	Maximum negative value exceeded	1	1	1	80000000H		
	Positive (maximum value not exceeded)	Holds value	0	0	Actual operation		
	Negative (maximum value not exceeded)	before operation		1	result		

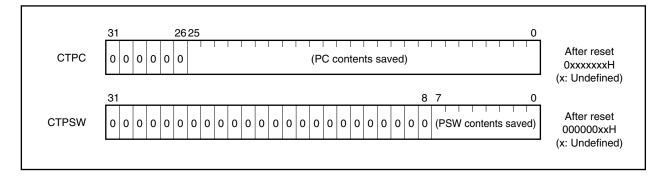

(5) CALLT execution status saving registers (CTPC, CTPSW)

There are two CALLT execution status saving registers, CTPC and CTPSW.

When the CALLT instruction is executed, the contents of the program counter (PC) are saved to CTPC, and the program status word (PSW) contents are saved to CTPSW.

The contents saved to CTPC consist of the address of the next instruction after the CALLT instruction. The current PSW contents are saved to CTPSW.

Bits 31 to 26 of CTPC and bits 31 to 8 of CTPSW are reserved (fixed to 0) for future function expansion.

(6) Exception/debug trap status saving registers (DBPC, DBPSW)

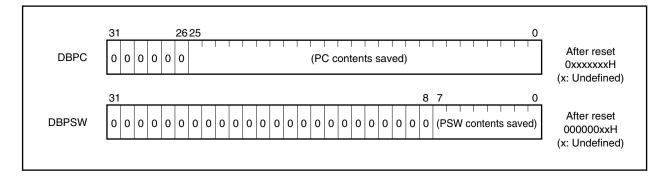

There are two exception/debug trap status saving registers, DBPC and DBPSW.

Upon occurrence of an exception trap or debug trap, the contents of the program counter (PC) are saved to DBPC, and the program status word (PSW) contents are saved to DBPSW.

The contents saved to DBPC consist of the address of the next instruction after the instruction executed when an exception trap or debug trap occurs.

The current PSW contents are saved to DBPSW.

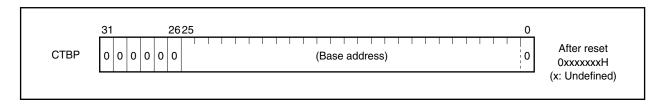

Bits 31 to 26 of DBPC and bits 31 to 8 of DBPSW are reserved (fixed to 0) for future function expansion.

(7) CALLT base pointer (CTBP)

The CALLT base pointer (CTBP) is used to specify table addresses and generate target addresses (bit 0 is fixed to 0).

Bits 31 to 26 are reserved (fixed to 0) for future function expansion.

3.3 Operating Modes

The V850ES/KE1 has the following operating modes.

(1) Normal operating mode

After the system has been released from the reset state, execution branches to the reset entry address of the internal ROM, and instruction processing is started.

(2) Flash memory programming mode

This mode is valid only in flash memory versions (μ PD70F3207H and 70F3207HY). When this mode is specified, the internal flash memory can be programmed by using a flash programmer.

(a) Specifying operating mode

The operating mode is specified according to the status (input level) of the FLMD0 and FLMD1 pins. In the normal operating mode, input a low level to the FLMD0 pin during the reset period.

A high level is input to the FLMD0 pin by the flash programmer in the flash memory programming mode if a flash programmer is connected. In the self-programming mode, input a high level to this pin from an external circuit.

Fix the specification of these pins in the application system and do not change the setting of these pins during operation.

FLMD0	FLMD1	Operating Mode	
L	×	Normal operating mode	
н	L	Flash memory programming mode	
Н	Н	Setting prohibited	

Remark H: High level

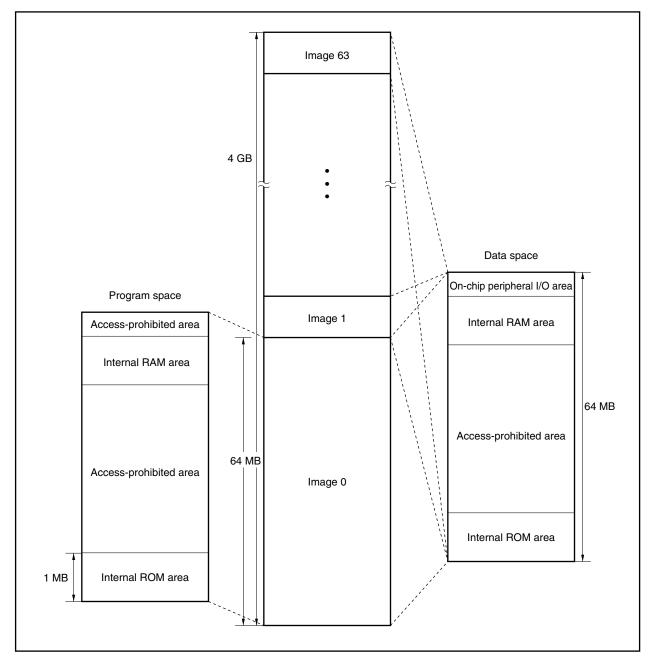

- L: Low level
- ×: don't care

3.4 Address Space

3.4.1 CPU address space

For instruction addressing, an internal ROM area of up to 1 MB, and an internal RAM area are supported in a linear address space (program space) of up to 64 MB. For operand addressing (data access), up to 4 GB of a linear address space (data space) is supported. The 4 GB address space, however, is viewed as 64 images of a 64 MB physical address space. This means that the same 64 MB physical address space is accessed regardless of the value of bits 31 to 26.

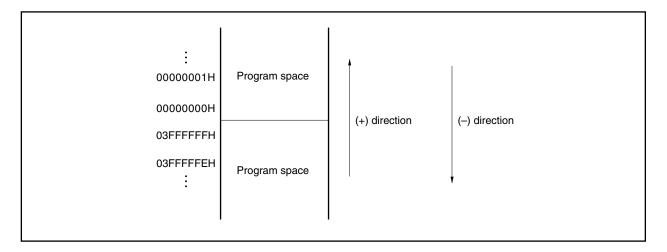

3.4.2 Wraparound of CPU address space

(1) Program space

Of the 32 bits of the program counter (PC), the higher 6 bits are fixed to 0 and only the lower 26 bits are valid. Even if a carry or borrow occurs from bit 25 to bit 26 as a result of branch address calculation, the higher 6 bits ignore this and remain 0.

Therefore, the lower-limit address of the program space, 00000000H, and the upper-limit address, 03FFFFFFH, are contiguous addresses, and the program space is wrapped around at the boundary of these addresses.

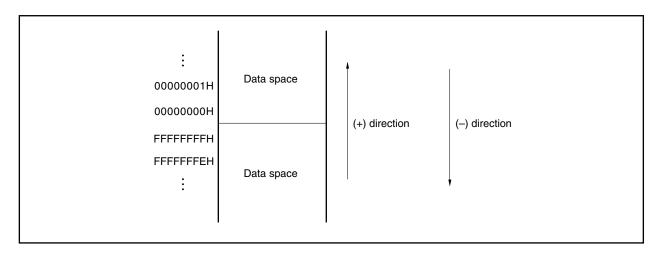

Caution No instructions can be fetched from the 4 KB area of 03FFF000H to 03FFFFFH because this area is an on-chip peripheral I/O area. Therefore, do not execute any branch operation instructions in which the destination address will reside in any part of this area.

(2) Data space

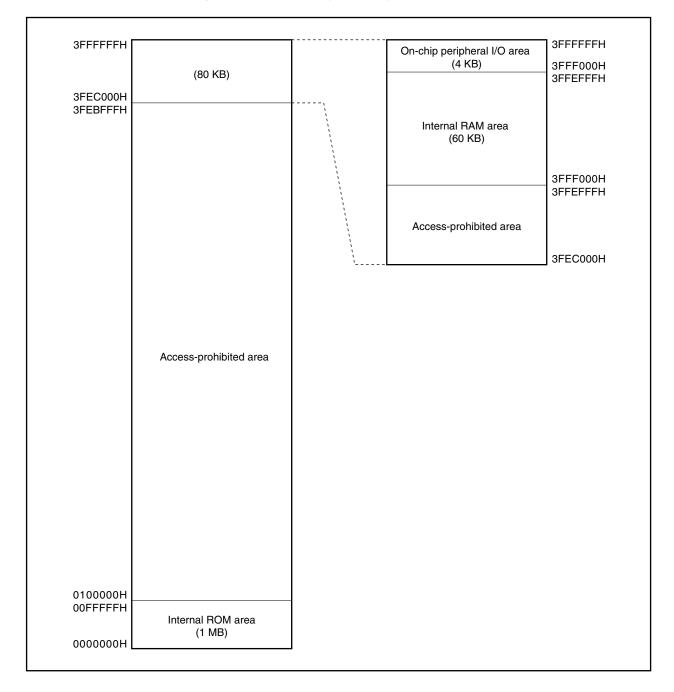

The result of an operand address calculation that exceeds 32 bits is ignored.

Therefore, the lower-limit address of the data space, address 00000000H, and the upper-limit address, FFFFFFFH, are contiguous addresses, and the data space is wrapped around at the boundary of these addresses.

3.4.3 Memory map

The V850ES/KE1 has reserved areas as shown below.

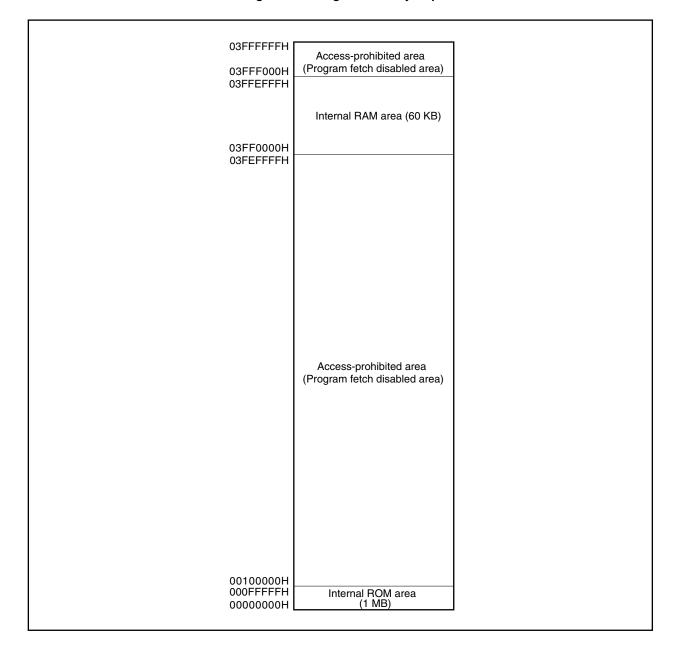

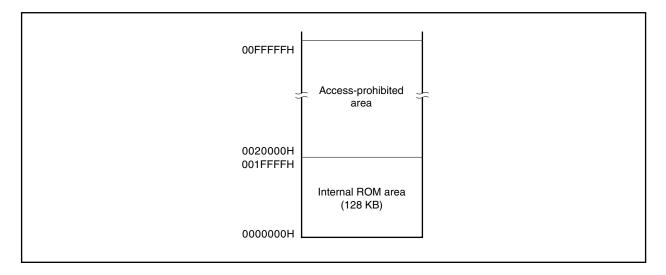

Figure 3-3. Program Memory Map

3.4.4 Areas

(1) Internal ROM area

An area of 1 MB from 0000000H to 00FFFFFH is reserved for the internal ROM area. A 128 KB area from 0000000H to 001FFFFH is provided in the V850ES/KE1. Addresses 0020000H to 00FFFFFH are an access-prohibited area.

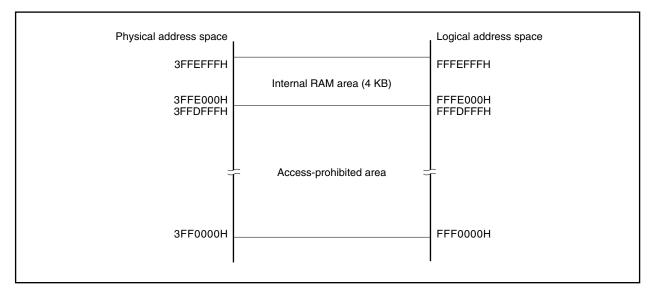

(2) Internal RAM area

An area of 60 KB maximum from 3FF0000H to 3FFEFFFH is reserved for the internal RAM area. A 4 KB area from 3FFE000H to 3FFEFFFH is provided as physical internal RAM in the V850ES/KE1. Addresses 3FF0000H to 3FFDFFFH are an access-prohibited area.

(3) On-chip peripheral I/O area

A 4 KB area from 3FFF000H to 3FFFFFH is reserved as the on-chip peripheral I/O area.

Physical address space		Logical address space
3FFFFFH		FFFFFFH
	On-chip peripheral I/O area (4 KB)	
3FFF000H		FFF000H

Figure 3-6. On-Chip Peripheral I/O Area

Peripheral I/O registers assigned with functions such as on-chip peripheral I/O operation mode specification and state monitoring are mapped to the on-chip peripheral I/O area. Program fetches are not allowed in this area.

- Cautions 1. If word access of a register is attempted, halfword access to the word area is performed twice, first for the lower bits, then for the higher bits, ignoring the lower 2 address bits.
 - 2. If a register that can be accessed in byte units is accessed in halfword units, the higher 8 bits become undefined if the access is a read operation. If a write access is performed, only the data in the lower 8 bits is written to the register.
 - 3. Addresses that are not defined as registers are reserved for future expansion. If these addresses are accessed, the operation is undefined and not guaranteed.

(4) Number of clocks for access

The following table shows the number of base clocks required for accessing each resource.

Bus Cycle Type	Area (Bus Width)	Internal ROM (32 Bits)	Internal RAM (32 Bits)	On-Chip Peripheral I/O (16 Bits)
Instruction fetch (normal access)		1	1 ^{Note 1}	-
Instruction fetch (branch)		2	2 ^{Note 1}	-
Operand data access		3	1	3 ^{Note 2}

Notes 1. If the access conflicts with a data access, the number of clock is incremented by 1.

2. This value varies depending on the setting of the VSWC register.

Remark Unit: Clocks/access

3.4.5 Recommended use of address space

The architecture of the V850ES/KE1 requires that a register that serves as a pointer be secured for address generation when operand data in the data space is accessed. The address stored in this pointer ±32 KB can be directly accessed by an instruction for operand data. Because the number of general-purpose registers that can be used as a pointer is limited, however, by keeping the performance from dropping during address calculation when a pointer value is changed, as many general-purpose registers as possible can be secured for variables, and the program size can be reduced.

(1) Program space

Of the 32 bits of the PC (program counter), the higher 6 bits are fixed to 0, and only the lower 26 bits are valid. Regarding the program space, therefore, a 64 MB space of contiguous addresses starting from 00000000H unconditionally corresponds to the memory map.

To use the internal RAM area as the program space, access the addresses 3FFE000H to 3FFEFFFH (4 KB).

(2) Data space

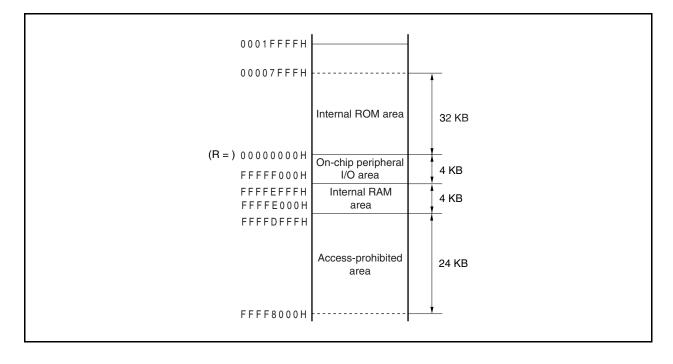

With the V850ES/KE1, it seems that there are sixty-four 64 MB address spaces on the 4 GB CPU address space. Therefore, the least significant bit (bit 25) of a 26-bit address is sign-extended to 32 bits and allocated as an address.

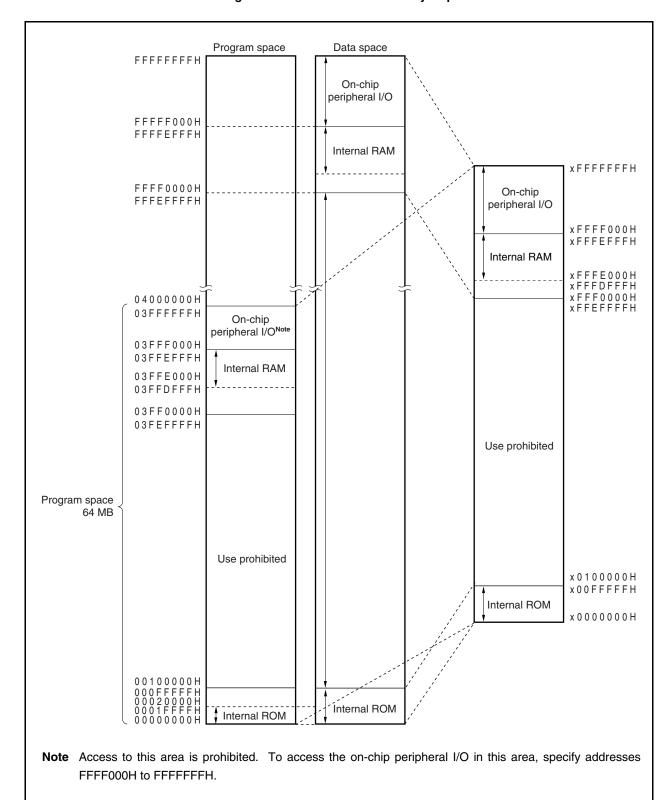

(a) Application example of wraparound

If R = r0 (zero register) is specified for the LD/ST disp16 [R] instruction, a range of addresses 00000000H ±32 KB can be addressed by sign-extended disp16. All the resources, including the internal hardware, can be addressed by one pointer.

The zero register (r0) is a register fixed to 0 by hardware, and practically eliminates the need for registers dedicated to pointers.

Example: *µ*PD703207, 703207Y

Remarks 1. ‡ indicates the recommended area.

2. This figure is the recommended memory map of the μ PD703207 and 703207Y.

3.4.6 Peripheral I/O registers

Address	Function Register Name Symbol	Symbol	R/W	/ Operable Bit Unit			After Reset

3.4.7 Special registers

Special registers are registers that prevent invalid data from being written when an inadvertent program loop occurs.

The V850ES/KE1 has the following three special registers.

- Power save control register (PSC)
- Processor clock control register (PCC)
- Watchdog timer mode register (WDTM1)

Moreover, there is also the PRCMD register, which is a protection register for write operations to the special registers that prevents the application system from unexpectedly stopping due to an inadvertent program loop. Write access to the special registers is performed with a special sequence and illegal store operations are notified to the SYS register.

(1) Setting data to special registers

Setting data to a special register is done in the following sequence.

- <1> Prepare the data to be set to the special register in a general-purpose register.
- <2> Write the data prepared in step <1> to the PRCMD register.
- <3> Write the setting data to the special register (using following instructions).
 - Store instruction (ST/SST instruction)
 - Bit manipulation instruction (SET1/CLR1/NOT1 instruction)

<4> to <8> Insert NOP instructions (5 instructions)^{Note}.

[Description Example] When using PSC register (standby mode setting)

```
ST.B r11, PSMR[r0] ; PSMR register setting (IDLE, STOP mode setting)
<1> MOV 0x02, r10
<2> ST.B r10, PRCMD[r0] ; PRCMD register write
<3> ST.B r10, PSC[r0] ; PSC register setting
<4> NOP<sup>Note</sup> ; Dummy instruction
<5> NOP<sup>Note</sup> ; Dummy instruction
<6> NOP<sup>Note</sup> ; Dummy instruction
<7> NOP<sup>Note</sup> ; Dummy instruction
<8> NOP<sup>Note</sup> ; Dummy instruction
(next instruction)
```

No special sequence is required to read special registers.

- **Note** When switching to the IDLE mode or the STOP mode (PSC.STP bit = 1), 5 NOP instructions must be inserted immediately after switching is performed.
- Cautions 1. Interrupts are not acknowledged for the store instruction for the PRCMD register. This is because continuous execution of store instructions by the program in steps <2> and <3> above is assumed. If another instruction is placed between step <2> and <3>, the above sequence may not be realized when an interrupt is acknowledged for that instruction, which may cause malfunction.
 - 2. The data written to the PRCMD register is dummy data, but use the same register as the general-purpose register used for setting data to the special register (step <3>) when writing to the PRCMD register (step <2>). The same applies to when using a general-purpose register for addressing.

(2) Command register (PRCMD)

The PRCMD register is an 8-bit register used to prevent data from being written to registers that may have a large influence on the system, possibly causing the application system to unexpectedly stop, when an inadvertent program loop occurs. Only the first write operation to the special register following the execution of a previously executed write operation to the PRCMD register, is valid.

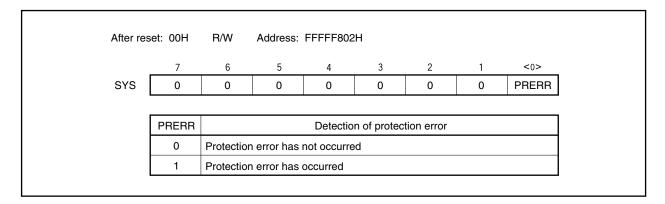

As a result, register values can be overwritten only using a preset sequence, preventing invalid write operations.

This register can only be written in 8-bit units (if it is read, an undefined value is returned).

7 6 5 4 3 2 1 0
PRCMD REG7 REG6 REG5 REG4 REG3 REG2 REG1 REG0

(3) System status register (SYS)

This register is allocated with status flags showing the operating state of the entire system. This register can be read or written in 8-bit or 1-bit units.

The operation conditions of the PRERR flag are described below.

(a) Set conditions (PRERR = 1)

- (i) When a write operation to the special register takes place without write operation being performed to the PRCMD register (when step <3> is performed without performing step <2> as described in 3.4.7
 (1) Setting data to special registers).
- (ii) When a write operation (including bit manipulation instruction) to an on-chip peripheral I/O register other than a special register is performed following write to the PRCMD register (when <3> in 3.4.7 (1) Setting data to special registers is not a special register).
- **Remark** Regarding the special registers other than the WDTM register (PCC and PSC registers), even if on-chip peripheral I/O register read (except bit manipulation instruction) (internal RAM access, etc.) is performed in between write to the PRCMD register and write to a special register, the PRERR flag is not set and setting data can be written to the special register.

(b) Clear conditions (PRERR = 0)

- (i) When 0 is written to the PRERR flag
- (ii) When system reset is performed
- Cautions 1. If 0 is written to the PRERR bit of the SYS register that is not a special register immediately following write to the PRCMD register, the PRERR bit becomes 0 (write priority).
 - 2. If data is written to the PRCMD register that is not a special register immediately following write to the PRCMD register, the PRERR bit becomes 1.

3.4.8 Cautions

(1) Wait when accessing register

Be sure to set the following register before using the V850ES/KE1.

• System wait control register (VSWC)

After setting the VSWC register, set the other registers as required.

When using an external bus, set the VSWC register and then set the various pins to the control mode by setting the port-related registers.

(a) System wait control register (VSWC)

The VSWC register controls the bus access wait time for the on-chip peripheral I/O registers.

Access to the on-chip peripheral I/O register lasts 3 clocks (during no wait), but in the V850ES/KE1, waits are required according to the internal system clock frequency. Set the values shown below to the VSWC register according to the internal system clock frequency that is used.

Operation Conditions	Internal System Clock Frequency (fcьк)	VSWC Register Setting	Number of Waits
$4.5~V \leq V_{\text{DD}} \leq 5.5~V$	32 kHz ≤ fclк < 16.6 MHz	00H	0 (no waits)
	16.6 MHz \leq fclk \leq 20 MHz	01H	1
$4.0~V \leq V_{\text{DD}} < 4.5~V$	32 kHz \leq fclk \leq 16 MHz	00H	0 (no waits)
$2.7~V \leq V_{\text{DD}} < 4.0~V$	$32 \text{ kHz} \leq \text{fclk} < 8.3 \text{ MHz}$	00H	0 (no waits)
	8.3 MHz ≤ fclk≤ 10 MHz	01H	1

This register can be read or written in 8-bit units (Address: FFFF06EH, After reset: 77H).

(b) Access to special on-chip peripheral I/O register

This product has two types of internal system buses.

One type is for the CPU bus and the other is for the peripheral bus to interface with low-speed peripheral hardware.

Since the CPU bus clock and peripheral bus clock are asynchronous, if a conflict occurs during access between the CPU and peripheral hardware, illegal data may be passed unexpectedly. Therefore, when accessing peripheral hardware that may cause a conflict, the number of access cycles is changed so that the data is received/passed correctly in the CPU. As a result, the CPU does not shift to the next instruction processing and enters the wait status. When this wait status occurs, the number of execution clocks of the instruction is increased by the number of wait clocks.

Note this with caution when performing real-time processing.

When accessing a special on-chip peripheral I/O register, additional waits may be required further to the waits set by the VSWC register.

The access conditions at that time and the method to calculate the number of waits to be inserted (number of CPU clocks) are shown below.

Number of waits to be inserted = $(2 + m) \times k$ (clocks) Number of accesses to special on-chip peripheral I/O register = $3 + m + (2 + m) \times k$ (clocks)

Peripheral Function	Register Name	Access	k
Watchdog timer 1 (WDT1)	WDTM1	Write	1 to 5
	$\begin{tabular}{lllllllllllllllllllllllllllllllllll$	} + 1	
Watchdog timer 2 (WDT2)	WDTM2	Write	3 (fixed)
16-bit timer/event counter P0 (TMP0)	TP0CCR0, TP0CCR1, TP0CNT	Read	1
	<calculation number="" of="" wa<br="">k = {(1/fxx)/((2 + m)/fcPu)}</calculation>		
	TP0CCR0, TP0CCR1	Write	0 to 2
	<pre><calculation ((2="" +="" 5="" a="" fcp="" k="{(1/fxx)" m)="" number="" occurs="" of="" per<="" pre="" wa="" wait="" when="" ×=""></calculation></pre>		ame register
16-bit timer/event counter 01 (TM01)	TMC01	Read-modify-write	1 (fixed) A wait occurs during write
I ² C0 ^{Note 2}	IICS0	Read	1 (fixed)
Asynchronous serial interfaces 0, 1 (UART0, UART1)	ASIS0, ASIS1	Read	1 (fixed)
Real-time output function 0 (RTO0)	RTBL0, RTBH0	Write (when RTPC0.RTPOE0 bit = 0)	1
A/D converter	ADM, ADS, PFM, PFT	Write	1 to 2
	ADCR, ADCRH	Read	1 to 2
	<calculation number="" of="" wa<br=""></calculation> k = ${(1/fxx) \times 2/[(2 + m)/fcpu}$		

- **Notes 1.** In the calculation of number of waits, the fractional part of its result must be multiplied by (1/fcPu) and rounded down if (1/fcPu)/(2 + m) or lower, and rounded up if (1/fcPu)/(2 + m) is exceeded.
 - 2. Only in the *µ*PD703207Y, 70F3207HY
- <R> Cautions 1. If fetched from the internal ROM or internal RAM, the number of waits is as shown above. If fetched from the external memory, the number of waits may be decreased below these. The effect of the external memory access cycles varies depending on the wait settings and the like. However, the number of waits shown above is the maximum value, so no higher value is generated.
 - 2. When the CPU operates on the subclock and no clock is input to the X1 pin, do not access a register in which a wait occurs using an access method that causes a wait. If a wait occurs, it can only be released by a reset.
 - **Remark** In the calculation for the number of waits:
 - fCPU: CPU clock frequency
 - fXX: Main clock frequency
 - m: Set value of bits 2 to 0 of the VSWC register

When the VSWC register = 00H: m = 0When the VSWC register = 01H: m = 1

(2) Restriction on conflict between sld instruction and interrupt request

(a) Description

If a conflict occurs between the decode operation of an instruction in <2> immediately before the sld instruction following an instruction in <1> and an interrupt request before the instruction in <1> is complete, the execution result of the instruction in <1> may not be stored in a register.

Instruction <1>

- Id instruction: Id.b, Id.h, Id.w, Id.bu, Id.hu
- sld instruction: sld.b, sld.h, sld.w, sld.bu, sld.hu
- Multiplication instruction: mul, mulh, mulhi, mulu

Instruction <2>

mov reg1, reg2	not reg1, reg2	satsubr reg1, reg2	satsub reg1, reg2
satadd reg1, reg2	satadd imm5, reg2	or reg1, reg2	xor reg1, reg2
and reg1, reg2	tst reg1, reg2	subr reg1, reg2	sub reg1, reg2
add reg1, reg2	add imm5, reg2	cmp reg1, reg2	cmp imm5, reg2
mulh reg1, reg2	shr imm5, reg2	sar imm5, reg2	shl imm5, reg2

<Example>

```
<i> Id.w [r11], r10
.
.
.
.
```

If the decode operation of the mov instruction <ii> immediately before the sld instruction <iii> and an interrupt request conflict before execution of the ld instruction <i> is complete, the execution result of instruction <i> may not be stored in a register.

<II> mov r10, r28 <III> sld.w 0x28, r10

(b) Countermeasure

<R>

<1> When compiler (CA850) is used

Use CA850 Ver. 2.61 or later because generation of the corresponding instruction sequence can be automatically suppressed.

<2> Countermeasure by assembler

When executing the sld instruction immediately after instruction <ii>, avoid the above operation using either of the following methods.

- · Insert a nop instruction immediately before the sld instruction.
- Do not use the same register as the sld instruction destination register in the above instruction <ii> executed immediately before the sld instruction.

CHAPTER 4 PORT FUNCTIONS

4.1 Features

- O Input-only ports: 8 pins
- O I/O ports: 43 pins
 - Fixed to N-ch open-drain output: 2
 - Switchable to N-ch open-drain output: 4
- O Input/output can be specified in 1-bit units

4.2 Basic Port Configuration

The V850ES/KE1 incorporates a total of 51 I/O port pins consisting of ports 0, 3 to 5, 7, 9, CM, and DL (including 8 input-only port pins). The port configuration is shown below.

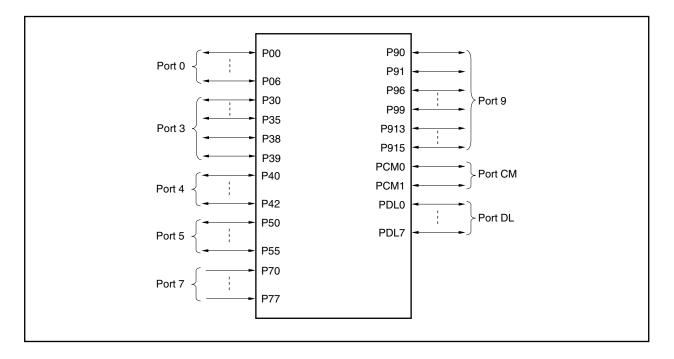

Table 4-1. Pin I/O Buffer Power Supplies

Power Supply	Corresponding Pins
AV _{REF0}	Port 7
EVDD	RESET, ports 0, 3 to 5, 9, CM, DL

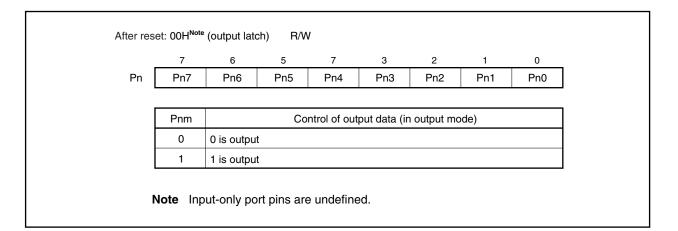

4.3 Port Configuration

Table	4-2.	Port	Configuratio	n
-------	------	------	--------------	---

Item	Configuration
Control registers	Port n register (Pn: n = 0, 3 to 5, 7, 9, CM, DL)
	Port n mode register (PMn: n = 0, 3 to 5, 9, CM, DL)
	Port n mode control register (PMCn: n = 0, 3 to 5, 9, CM)
	Port n function control register (PFCn: $n = 3, 5, 9$)
	Port 3 function control expansion register (PFCE3)
	Port n function register (PFn: $n = 3, 4, 9$)
	Pull-up resistor option register (PUn: $n = 0, 3 \text{ to } 5, 9$)
Ports	Input only: 8
	I/O: 43
Pull-up resistors	Software control: 31

(1) Port n register (Pn)

Data I/O with external devices is performed by writing to and reading from the Pn register. The Pn register is configured of a port latch that retains the output data and a circuit that reads the pin status. Each bit of the Pn register corresponds to one pin of port n and can be read or written in 1-bit units.

Writing to and reading from the Pn register is executed as follows depending on the setting of each register.

<R>

Setting of PMCn Register	Setting of PMn Register	Writing to Pn Register	Reading from Pn Register
Port mode (PMCnm bit = 0)	Output mode (PMnm bit = 0)	Write to the output latch ^{Note} . The contents of the output latch are output from the pin.	The value of the output latch is read.
	Input mode (PMnm bit = 1)	Write to the output latch ^{Note} . The status of the pin is not affected.	The pin status is read.
Alternate-function mode (PMCnm bit = 1)	Output mode (PMnm bit = 0)	Write to the output latch ^{Note} . The status of the pin is not affected. The pin operates as an alternate-function pin.	 When alternate function is output The output status of the alternate function is read. When alternate function is input The output latch value is read.
	Input mode (PMnm bit = 1)	Write to the output latch ^{Note} . The status of the pin is not affected. The pin operates as an alternate-function pin.	The pin status is read.

 Table 4-3. Writing to/Reading from Pn Register

Note The value written to the output latch is retained until a new value is written to the output latch.

(2) Port n mode register (PMn)

PMn specifies the input mode/output mode of the port.

Each bit of the PMn register corresponds to one pin of port n and can be specified in 1-bit units.

(3) Port n mode control register (PMCn)

PMCn specifies the port mode/alternate function.

Each bit of the PMCn register corresponds to one pin of port n and can be specified in 1-bit units.

After reset: 00	00H	R/W										
	7	6	5	4	3	2	1	0				
PMCn PM	PMCn7	PMCn6	PMCn5	PMCn4	PMCn3	PMCn2	PMCn1	PMCn0				
PMO	MCnm		Specification of operation mode									
(0	Port mode	ort mode									
· · ·	1	Alternate	ternate function mode									
	0		-	•	on of opera	ation mode						

(4) Port n function control register (PFCn)

PFCn is a register that specifies the alternate function to be used when one pin has two or more alternate functions.

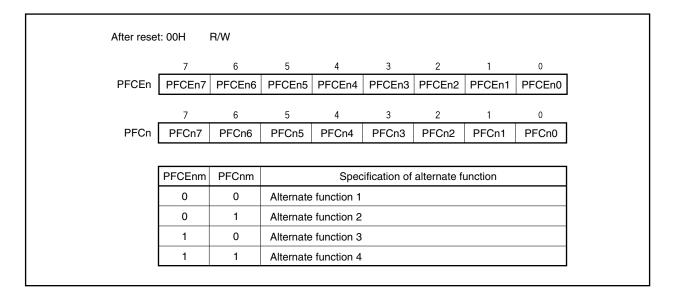

Each bit of the PFCn register corresponds to one pin of port n and can be specified in 1-bit units.

7 6 5 4 3 2 1 0 PFCn PFCn7 PFCn6 PFCn5 PFCn4 PFCn3 PFCn2 PFCn1 PFCn0	After res	set: 00H	R/W										
		7	6	5	4	3	2	1	0

PFCnm Specification of alternate function													
		PFCnm		Specification of alternate function									
0 Alternate function 1		0	Alternate f	Alternate function 1									
1 Alternate function 2		1	Alternate f	Iternate function 2									

(5) Port n function control expansion register (PFCEn)

PFCEn is a register that specifies the alternate function to be used when one pin has three or more alternate functions.

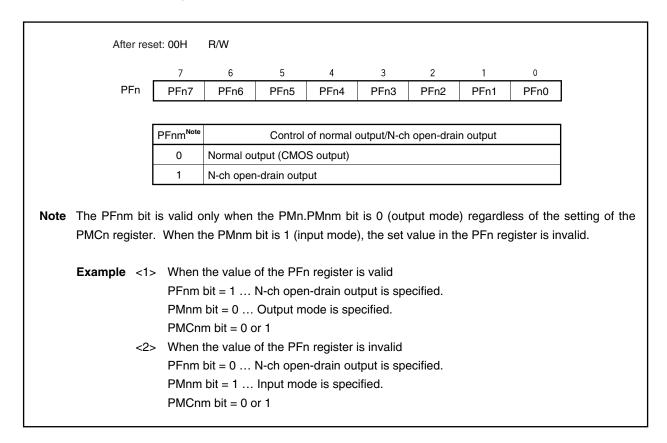

Each bit of the PFCEn register corresponds to one pin of port n and can be specified in 1-bit units.

(6) Port n function register (PFn)

PFn is a register that specifies normal output/N-ch open-drain output.

Each bit of the PFn register corresponds to one pin of port n and can be specified in 1-bit units.

(7) Pull-up resistor option register (PUn)

PUn is a register that specifies the connection of an on-chip pull-up resistor.

Each bit of the PUn register corresponds to one pin of port n and can be specified in 1-bit units.

After re	eset: 00H	R/W										
	7	6	5	4	3	2	1	0

Table 4-12. Settings When Port Pins Are Used for Alternate Functions (3/3)

4.6 Cautions

4.6.1 Cautions on bit manipulation instruction for port n register (Pn)

When a 1-bit manipulation instruction is executed on a port that provides both input and output functions, the value of the output latch of an input port that is not subject to manipulation may be written in addition to the targeted bit.

Therefore, it is recommended to rewrite the output latch when switching a port from input mode to output mode.

<Example> When PDL0 is an output port, PDL1 to PDL7 are input ports (all pin statuses are high level), and the value of the port latch is 00H, if the output of output port PDL0 is changed from low level to high level via a bit manipulation instruction, the value of the port latch is FFH. Explanation: The targets of writing to and reading from the Pn register of a port whose PMnm bit is

1 are the output latch and pin status, respectively. A bit manipulation instruction is executed in the following order in the V850ES/KE1.

<1> The Pn register is read in 8-bit units.

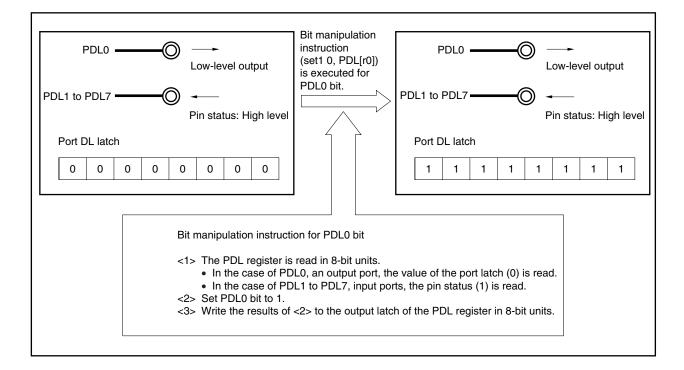

<2> The targeted one bit is manipulated.

<3> The Pn register is written in 8-bit units.

In step <1>, the value of the output latch (0) of PDL0, which is an output port, is read, while the pin statuses of PDL1 to PDL7, which are input ports, are read. If the pin statuses of PDL1 to PDL7 are high level at this time, the read value is FEH.

The value is changed to FFH by the manipulation in <2>.

FFH is written to the output latch by the manipulation in <3>.

4.6.2 Hysteresis characteristics

In port mode, the following ports do not have hysteresis characteristics.

P02 to P06 P31 to P35, P38, P39 P40, P42 P97, P99, P913 to P915

CHAPTER 5 CLOCK GENERATION FUNCTION

5.1 Overview

<R>

The following clock generation functions are available.

Main clock oscillator

<In PLL (×4) mode>

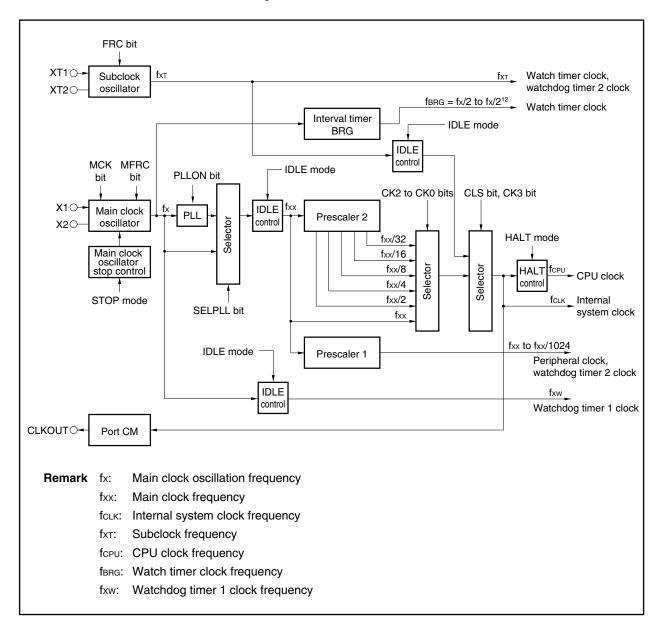

- fx = 2 to 5 MHz (fxx = 8 to 20 MHz: 4.5 V \leq V_{DD} \leq 5.5 V)
- fx = 2 to 4 MHz (fxx = 8 to 16 MHz: 4.0 V \leq V_{DD} \leq 5.5 V)
- fx = 2 to 2.5 MHz (fxx = 8 to 10 MHz: $2.7 \text{ V} \le \text{V}_{DD} \le 5.5 \text{ V}$)

<In clock through mode>

- fx = 2 to 10 MHz (fxx = 2 to 10 MHz: 2.7 V \leq VDD \leq 5.5 V)
- O Subclock oscillator
 - fxT = 32.768 kHz
- O Multiplication (×4) function by PLL (Phase Locked Loop)
 - Clock-through mode/PLL mode selectable
 - Usable voltage: VDD = 2.7 to 5.5 V
- O Internal system clock generation
 - 7 steps (fxx, fxx/2, fxx/4, fxx/8, fxx/16, fxx/32, fxt)
- O Peripheral clock generation
- O Clock output function
 - **Remark** fx: Main clock oscillation frequency
 - fxx: Main clock frequency
 - fxT: Subclock frequency

5.2 Configuration

<R> (1) Main clock oscillator

The main clock oscillator oscillates the following frequencies (fx).

- fx = 2 to 5 MHz (VDD = 4.5 to 5.5 V, in PLL mode)
- fx = 2 to 4 MHz (VDD = 4.0 to 5.5 V, in PLL mode)
- fx = 2 to 2.5 MHz (VDD = 2.7 to 5.5 V, in PLL mode)
- fx = 2 to 10 MHz (VDD = 2.7 to 5.5 V, in clock-through mode)

(2) Subclock oscillator

The subclock oscillator oscillates a frequency of 32.768 kHz (fxr).

(3) Main clock oscillator stop control

This circuit generates a control signal that stops oscillation of the main clock oscillator. Oscillation of the main clock oscillator is stopped in the STOP mode or when the PCC.MCK bit = 1 (valid only when the PCC.CLS bit = 1).

(4) Prescaler 1

This prescaler generates the clock (fxx to fxx/1024) to be supplied to the following on-chip peripheral functions: TMP0, TM01, TM50, TM51, TMH0, TMH1, CSI00, CSI01, UART0, UART1, I²C0, ADC, and WDT2

(5) Prescaler 2

This circuit divides the main clock (fxx).

The clock generated by prescaler 2 (fxx to fxx/32) is supplied to the selector that generates the CPU clock (fcPu) and internal system clock (fcLK).

fcLK is the clock supplied to the INTC, ROM correction, ROM, and RAM blocks, and can be output from the CLKOUT pin.

(6) Interval timer BRG

This circuit divides the clock (fx) generated by the main clock oscillator to a specific frequency (32.768 kHz) and supplies that clock to the watch timer block.

For details, refer to CHAPTER 10 INTERVAL TIMER, WATCH TIMER.

(7) PLL

This circuit multiplies the clock (fx) generated by the main clock oscillator.

It operates in two modes: clock-through mode in which fx is output as is, and PLL mode in which a multiplied clock is output. These modes can be selected by using the PLLCTL.SELPLL bit.

Operation of the PLL can be started or stopped by the PLLCTL.PLLON bit.

5.3 Register

(1) Processor clock control register (PCC)

The PCC register is a special register. Data can be written to this register only in combination of specific sequences (refer to **3.4.7 Special registers**).

This register can be read or written in 8-bit or 1-bit units. Reset sets PCC to 03H.

	7	<6>	5	<4>	<3>	2	1	0

	0		•					

L

СКЗ	CK2	CK1	CK0	Clock selection (fclk/fcPu)
)	0	0	0	fxx
C	0	0	1	fxx/2
0	0	1	0	fxx/4
0	0	1	1	fxx/8 (default value)
0	1	0	0	fxx/16
0	1	0	1	fxx/32
0	1	1	×	Setting prohibited
1	×	×	×	fхт

- Cautions 1. Do not change the CPU clock (by using the CK3 to CK0 bits) while CLKOUT is being output.
 - 2. Use a bit manipulation instruction to manipulate the CK3 bit. When using an 8-bit manipulation instruction, do not change the set values of the CK2 to CK0 bits.
 - 3. When the CPU operates on the subclock and no clock is input to the X1 pin, do not access a register in which a wait occurs using an access method that causes a wait (refer to 3.4.8 (1) (b) Access to special on-chip peripheral I/O register for details of the access methods). If a wait occurs, it can only be released by a reset.

Remark ×: don't care

(2/2)

- (a) Example of setting main clock operation \rightarrow subclock operation
 - <1> CK3 bit \leftarrow 1: Use of a bit manipulation instruction is recommended. Do not change the CK2 to CK0 bits.
 - <2> Subclock operation: Read the CLS bit to check if subclock operation has started. It takes the following time after the CK3 bit is set until subclock operation is started.

Max.: 1/fxT (1/subclock frequency)

<3> MCK bit \leftarrow 1: Set the MCK bit to 1 only when stopping the main clock.

Cautions 1. When stopping the main clock, stop the PLL.

2. If the following conditions are not satisfied, change the CK2 to CK0 bits so that the conditions are satisfied, then change to the subclock operation mode.

Internal system clock (fcLK) > Subclock (fxT: 32.768 kHz) × 4

Remark Internal system clock (fcLK): Clock generated from the main clock (fxx) by setting bits CK2 to CK0

[Description example]

<1>	_SET_SUB_RU	UN :	
	st.b	r0, PRCMD[r0]	
	set1	3, PCC[r0]	CK3 bit ← 1
<2>	_CHECK_CLS	:	
	tst1	4, PCC[r0]	Wait until subclock operation starts.
	bz	_CHECK_CLS	
<3>	_STOP_MAIN_	_CLOCK :	
	st.b	r0, PRCMD[r0]	
	set1	6, PCC[r0]	MCK bit \leftarrow 1, main clock is stopped

Remark The above description is an example. Note with caution that the CLS bit is read in a closed loop in <2>.

(b) Example of setting subclock operation \rightarrow main clock operation

- <1> MCK bit \leftarrow 0: Main clock starts oscillating
- <2> Insert waits by the program and wait until the oscillation stabilization time of the main clock elapses.
- <3> CK3 bit \leftarrow 0: Use of a bit manipulation instruction is recommended. Do not change the CK2 to CK0 bits.
- <4> Main clock operation: It takes the following time after the CK3 bit is set until main clock operation is started.

Max.: 1/fxT (1/subclock frequency)

Therefore, insert one NOP instruction immediately after setting the CK3 bit to 0 or read the CLS bit to check if main clock operation has started.

[Description example]

<1>	_START_MAIN	N_OSC :	
	st.b	r0, PRCMD[r0]	Release of protection of special registers
	clr1	6, PCC[r0]	Main clock starts oscillating
<2>	movea	0x55, r0, r11	Wait for oscillation stabilization time
	_WAIT_OST	:	
	nop		
	nop		
	nop		
	addi	-1, r11, r11	
	mp	r0, r11	
	bne	_PROGRAM_WAIT	
<3>	st.b	r0, PRCMD[r0]	
	clr1	3, PCC[r0]	CK3 ← 0
<4>	_CHECK_CLS	:	
	tst1	4, PCC[r0]	Wait until main clock operation starts
	bnz	_CHECK_CLS	

Remark The above description is an example. Note with caution that the CLS bit is read in a closed loop in <4>.

5.4 Operation

5.4.1 Operation of each clock

The following table shows the operation status of each clock.

Register Setting and				Р	CC Regist	er			
Operation Status	CLS bit = MCK bit =	,			CLS bit = 1, MCK bit = 0		CLS bit = 1, MCK bit = 1

WDT2 clock (sub)	0	0	0	0	0	0	0	0	0

Table 5-1.	Operation	Status of	Each Clock
------------	-----------	-----------	------------

Remark O: Operable

×: Stopped

5.4.2 Clock output function

The clock output function is used to output the internal system clock (fcLK) from the CLKOUT pin.

The internal system clock (fcLK) is selected by using the PCC.CK3 to PCC.CK0 bits.

The CLKOUT pin functions alternately as the PCM1 pin and functions as a clock output pin if so specified by the control register of port CM.

The status of the CLKOUT pin is the same as the internal system clock in Table 5-1 and the pin can output the clock when it is in the operable status. It outputs a low level in the stopped status. However, the port mode (PCM1: input mode) is selected until the CLKOUT pin output is set after reset. Consequently, the CLKOUT pin goes into a high-impedance state.

5.4.3 External clock input function

An external clock can be directly input to the oscillator. Input the clock to the X1 pin and its inverse signal to the X2 pin. Set the PCC.MFRC bit to 1 (on-chip feedback resistor not used). Note, however, that oscillation stabilization time is inserted even in the external clock mode.

5.5 PLL Function

5.5.1 Overview

The PLL function is used to output the operating clock of the CPU and on-chip peripheral function at a frequency 4 times higher than the oscillation frequency, and select the clock-through mode.

When PLL function is used:Input clock = 2 to 5 MHz (fxx: 8 to 20 MHz)Clock-through mode:Input clock = 2 to 10 MHz (fxx: 2 to 10 MHz)

5.5.2 Register

(1) PLL control register (PLLCTL)

The PLLCTL register is an 8-bit register that controls the security function of PLL and RTO. This register can be read or written in 8-bit or 1-bit units. Reset sets PLLCTL to 01H.

After res	et: 01H	R/W	Address:	FFFFF806	Н			
	7	6	5	4	3	<2>	<1>	<0>
PLLCTL	0	0	0	0	0	RTOST0 ^{Note}	SELPLL	PLLON
	PLLON			PLL o	peration	control		
	0	PLL stopp	bed					
	1	PLL oper	ating					
	SELPLL			PLL	clock slel	ection		
	0	Clock-thre	ough operat	tion				
	1	PLL oper	ation					
Note For the RTOST								

5.5.3 Usage

(1) When PLL is used

- After reset has been released, the PLL operates (PLLCTL.PLLON bit = 1), but because the default mode is the clock-through mode (PLLCTL.SELPLL bit = 0), select the PLL mode (SELPLL bit = 1).
- To set the STOP mode in which the main clock is stopped, or to set the IDLE mode, first select the clockthrough mode and then stop the PLL. To return from the IDLE or STOP mode, first enable PLL operation (PLLON bit = 1), and then select the PLL mode (SELPLL bit = 1).
- To enable the PLL operation, first set the PLLON bit to 1, wait for 200 μs, and then set the SELPLL bit to 1.
 To stop the PLL, first select the clock-through mode (SELPLL bit = 0), wait for 8 clocks or more, and then stop the PLL (PLLON bit = 0).

(2) When PLL is not used

- The clock-through mode (SELPLL bit = 0) is selected after reset has been released, but the PLL is operating (PLLON bit = 1) and must therefore be stopped (PLLON bit = 0).
- **Remark** The PLL is operable in the IDLE mode. To realize low power consumption, stop the PLL. Be sure to stop the PLL when shifting to the STOP mode.

CHAPTER 6 16-BIT TIMER/EVENT COUNTER P (TMP)

Timer P (TMP) is a 16-bit timer/event counter.

6.1 Overview

An outline of TMP0 is shown below.

- Clock selection: 8 ways
- Capture trigger input pins: 2
- External event count input pins: 1
- External trigger input pins: 1
- Timer/counters: 1
- Capture/compare registers: 2
- Capture/compare match interrupt request signals: 2
- Timer output pins: 2

6.2 Functions

TMP0 has the following functions.

- Interval timer
- External event counter
- External trigger pulse output
- One-shot pulse output
- PWM output
- Free-running timer
- Pulse width measurement

6.3 Configuration

TMP0 includes the following hardware.

Table 6-1.	Configuration of TMF	0
------------	----------------------	---

Item	Configuration
Timer register	16-bit counter
Registers	TMP0 capture/compare registers 0, 1 (TP0CCR0, TP0CCR1) TMP0 counter read buffer register (TP0CNT) CCR0, CCR1 buffer registers
Timer inputs	2 (TIP00 ^{Note} , TIP01 pins)
Timer outputs	2 (TOP00, TOP01 pins)
Control registers	TMP0 control registers 0, 1 (TP0CTL0, TP0CTL1) TMP0 I/O control registers 0 to 2 (TP0IOC0 to TP0IOC2) TMP0 option register 0 (TP0OPT0)

Note The TIP00 pin functions alternately as a capture trigger input signal, external event count input signal, and external trigger input signal.

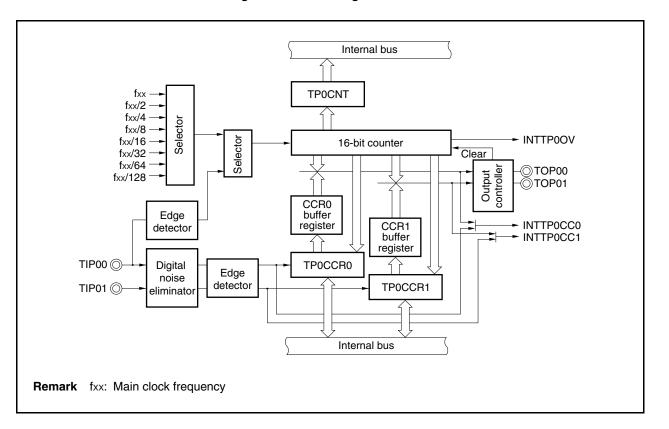

Figure 6-1. Block Diagram of TMP0

(1) 16-bit counter

This 16-bit counter can count internal clocks or external events. The count value of this counter can be read by using the TP0CNT register. When the TP0CTL0.TP0CE bit = 0, the value of the 16-bit counter is FFFFH. If the TP0CNT register is read at this time, 0000H is read.

Reset sets the TP0CE bit to 0. Therefore, the 16-bit counter is set to FFFFH.

(2) CCR0 buffer register

This is a 16-bit compare register that compares the count value of the 16-bit counter.

When the TP0CCR0 register is used as a compare register, the value written to the TP0CCR0 register is transferred to the CCR0 buffer register. When the count value of the 16-bit counter matches the value of the CCR0 buffer register, a compare match interrupt request signal (INTTP0CC0) is generated.

The CCR0 buffer register cannot be read or written directly.

The CCR0 buffer register is cleared to 0000H after reset, as the TP0CCR0 register is cleared to 0000H.

(3) CCR1 buffer register

This is a 16-bit compare register that compares the count value of the 16-bit counter.

When the TP0CCR1 register is used as a compare register, the value written to the TP0CCR1 register is transferred to the CCR1 buffer register. When the count value of the 16-bit counter matches the value of the CCR1 buffer register, a compare match interrupt request signal (INTTP0CC1) is generated.

The CCR1 buffer register cannot be read or written directly.

The CCR1 buffer register is cleared to 0000H after reset, as the TP0CCR1 register is cleared to 0000H.

(4) Edge detector

This circuit detects the valid edges input to the TIP00 and TIP01 pins. No edge, rising edge, falling edge, or both the rising and falling edges can be selected as the valid edge by using the TP0IOC1 and TP0IOC2 registers.

(5) Output controller

This circuit controls the output of the TOP00 and TOP01 pins. The output controller is controlled by the TP0IOC0 register.

(6) Selector

This selector selects the count clock for the 16-bit counter. Eight types of internal clocks or an external event can be selected as the count clock.

(7) Digital noise eliminator

This circuit is valid only when the TIP0a pin is used as a capture trigger input pin. This circuit is controlled by the TIP0a noise elimination register (PaNFC).

Remark a = 0, 1

6.4 Registers

(1) TMP0 control register 0 (TP0CTL0)

The TP0CTL0 register is an 8-bit register that controls the operation of TMP0. This register can be read or written in 8-bit or 1-bit units.

Reset sets this register to 00H.

The same value can always be written to the TP0CTL0 register by software.

		6	5	4	3	2	1	0

(3) TMP0 I/O control register 0 (TP0IOC0)

The TP0IOC0 register is an 8-bit register that controls the timer output (TOP00, TOP01 pins). This register can be read or written in 8-bit or 1-bit units. Reset sets this register to 00H.

After reset: 00H R/W Address: FFFFF5A2H 6 5 4 3 <?> <0> 1 7 TP0IOC0 0 0 0 0 TP0OL1 TP0OE1 TP0OL0 TP0OE0 TP0OL1 TOP01 pin output level settingNote 0 TOP01 pin high-level start 1 TOP01 pin low-level start TP0OE1 TOP01 pin output setting 0 Timer output disabled • When TP0OL1 bit = 0: Low level is output from the TOP01 pin • When TP0OL1 bit = 1: High level is output from the TOP01 pin 1 Timer output enabled (a square wave is output from the TOP01 pin). TP0OL0 TOP00 pin output level settingNote 0 TOP00 pin high-level start 1 TOP00 pin low-level start TP0OE0 TOP00 pin output setting 0 Timer output disabled • When TP0OL0 bit = 0: Low level is output from the TOP00 pin • When TP0OL0 bit = 1: High level is output from the TOP00 pin 1 Timer output enabled (a square wave is output from the TOP00 pin). Note The output level of the timer output pin (TOPOn) specified by the TPOOLn bit is shown below (n = 0, 1).

- Cautions 1. Rewrite the TP0OL1, TP0OE1, TP0OL0, and TP0OE0 bits when the TP0CTL0.TP0CE bit = 0. (The same value can be written when the TP0CE bit = 1.) If rewriting was mistakenly performed, clear the TP0CE bit to 0 and then set the bits again.
 - Even if the TP0OLa bit is manipulated when the TP0CE and TP0OEa bits are 0, the TOP0a pin output level varies (a = 0, 1).

(4) TMP0 I/O control register 1 (TP0IOC1)

The TP0IOC1 register is an 8-bit register that controls the valid edge of the capture trigger input signals (TIP00, TIP01 pins).

This register can be read or written in 8-bit or 1-bit units.

Reset sets this register to 00H.

	set: 00H		Address: F

(5) TMP0 I/O control register 2 (TP0IOC2)

The TP0IOC2 register is an 8-bit register that controls the valid edge of the external event count input signal (TIP00 pin) and external trigger input signal (TIP00 pin).

This register can be read or written in 8-bit or 1-bit units.

Reset sets this register to 00H.

(6) TMP0 option register 0 (TP0OPT0)

The TP0OPT0 register is an 8-bit register used to set the capture/compare operation and detect an overflow. This register can be read or written in 8-bit or 1-bit units. Reset sets this register to 00H.

After reset: 00H Address: FFFFF5A5H R/W 6 5 4 3 2 <0> 7 1 **TP0OPT0** 0 0 TP0CCS1 TP0CCS0 0 0 0 **TP00VF** TP0CCS1 TP0CCR1 register capture/compare selection 0 Compare register selected 1 Capture register selected The TP0CCS1 bit setting is valid only in the free-running timer mode. TP0CCS0 TP0CCR0 register capture/compare selection 0 Compare register selected 1 Capture register selected The TP0CCS0 bit setting is valid only in the free-running timer mode. **TP00VF** TMP0 overflow detection flag Set (1) Overflow occurred Reset (0) TP0OVF bit 0 written or TP0CTL0.TP0CE bit = 0 • The TPOOVF bit is set when the 16-bit counter count value overflows from FFFFH to 0000H in the free-running timer mode or the pulse width measurement mode. • An interrupt request signal (INTTPOOV) is generated at the same time that the TP0OVF bit is set to 1. The INTTP0OV signal is not generated in modes other than the free-running timer mode and the pulse width measurement mode. • The TP0OVF bit is not cleared even when the TP0OVF bit or the TP0OPT0 register are read when the TP0OVF bit = 1. • The TP0OVF bit can be both read and written, but the TP0OVF bit cannot be set to 1 by software. Writing 1 has no influence on the operation of TMP0. Cautions 1. Rewrite the TP0CCS1 and TP0CCS0 bits when the TP0CE bit = 0. (The same value can be written when the TP0CE bit = 1.) If rewriting was mistakenly performed, clear the TP0CE bit to 0 and then set the bits again. 2. Be sure to clear bits 1 to 3, 6, and 7 to "0".

(7) TMP0 capture/compare register 0 (TP0CCR0)

The TPOCCR0 register can be used as a capture register or a compare register depending on the mode. This register can be used as a capture register or a compare register only in the free-running timer mode, depending on the setting of the TPOOPT0.TPOCCS0 bit. In the pulse width measurement mode, the TPOCCR0 register can be used only as a capture register. In any other mode, this register can be used only as a compare register.

The TP0CCR0 register can be read or written during operation.

This register can be read or written in 16-bit units.

Reset sets this register to 0000H.

Caution Accessing the TP0CCR0 register is disabled during subclock operation with the main clock stopped. For details, refer to 3.4.8 (1) (b).

	After res	set: 0	000H	F	R/W	Ad	dress	: FFF	FF5A	A6H							
		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TPOCCR0	TP0CCR0																

(a) Function as compare register

The TP0CCR0 register can be rewritten even when the TP0CTL0.TP0CE bit = 1.

The set value of the TP0CCR0 register is transferred to the CCR0 buffer register. When the value of the 16-bit counter matches the value of the CCR0 buffer register, a compare match interrupt request signal (INTTP0CC0) is generated. If TOP00 pin output is enabled at this time, the output of the TOP00 pin is inverted.

When the TPOCCR0 register is used as a cycle register in the interval timer mode, external event count mode, external trigger pulse output mode, one-shot pulse output mode, or PWM output mode, the value of the 16-bit counter is cleared (0000H) if its count value matches the value of the CCR0 buffer register.

(b) Function as capture register

When the TP0CCR0 register is used as a capture register in the free-running timer mode, the count value of the 16-bit counter is stored in the TP0CCR0 register if the valid edge of the capture trigger input pin (TIP00 pin) is detected. In the pulse width measurement mode, the count value of the 16-bit counter is stored in the TP0CCR0 register and the 16-bit counter is cleared (0000H) if the valid edge of the capture trigger input pin (TIP00 pin) is detected.

Even if the capture operation and reading the TP0CCR0 register conflict, the correct value of the TP0CCR0 register can be read.

The following table shows the functions of the capture/compare register in each mode, and how to write data to the compare register.

Operation Mode	Capture/Compare Register	How to Write Compare Register
Interval timer	Compare register	Anytime write
External event counter	Compare register	Anytime write
External trigger pulse output	Compare register	Batch write
One-shot pulse output	Compare register	Anytime write
PWM output	Compare register	Batch write
Free-running timer	Capture/compare register	Anytime write
Pulse width measurement	Capture register	_

Table 6-2. Function of Capture/Compare Register in Each Mode and How to Write Compare Register

(8) TMP0 capture/compare register 1 (TP0CCR1)

The TP0CCR1 register can be used as a capture register or a compare register depending on the mode. This register can be used as a capture register or a compare register only in the free-running timer mode, depending on the setting of the TP0OPT0.TP0CCS1 bit. In the pulse width measurement mode, the TP0CCR1 register can be used only as a capture register. In any other mode, this register can be used only as a compare register.

The TP0CCR1 register can be read or written during operation.

This register can be read or written in 16-bit units.

Reset sets this register to 0000H.

Caution Accessing the TP0CCR1 register is disabled during subclock operation with the main clock stopped. For details, refer to 3.4.8 (1) (b).

	After res	set: 0	000H	F	₹/W	Ad	dress	: FFF	FF5A	\8H							
		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TP0CCR1	TP0CCR1																

(a) Function as compare register

The TP0CCR1 register can be rewritten even when the TP0CTL0.TP0CE bit = 1.

The set value of the TP0CCR1 register is transferred to the CCR1 buffer register. When the value of the 16-bit counter matches the value of the CCR1 buffer register, a compare match interrupt request signal (INTTP0CC1) is generated. If TOP01 pin output is enabled at this time, the output of the TOP01 pin is inverted.

(b) Function as capture register

When the TP0CCR1 register is used as a capture register in the free-running timer mode, the count value of the 16-bit counter is stored in the TP0CCR1 register if the valid edge of the capture trigger input pin (TIP01 pin) is detected. In the pulse width measurement mode, the count value of the 16-bit counter is stored in the TP0CCR1 register and the 16-bit counter is cleared (0000H) if the valid edge of the capture trigger input pin (TIP01 pin) is detected.

Even if the capture operation and reading the TP0CCR1 register conflict, the correct value of the TP0CCR1 register can be read.

The following table shows the functions of the capture/compare register in each mode, and how to write data to the compare register.

Operation Mode	Capture/Compare Register	How to Write Compare Register
Interval timer	Compare register	Anytime write
External event counter	Compare register	Anytime write
External trigger pulse output	Compare register	Batch write
One-shot pulse output	Compare register	Anytime write
PWM output	Compare register	Batch write
Free-running timer	Capture/compare register	Anytime write
Pulse width measurement	Capture register	_

Table 6-3. Function of Capture/Compare Register in Each Mode and How to Write Compare Register

(9) TMP0 counter read buffer register (TP0CNT)

The TPOCNT register is a read buffer register that can read the count value of the 16-bit counter. If this register is read when the TPOCTL0.TPOCE bit = 1, the count value of the 16-bit timer can be read. This register is read-only, in 16-bit units.

The value of the TP0CNT register is cleared to 0000H when the TP0CE bit = 0. If the TP0CNT register is read at this time, the value of the 16-bit counter (FFFFH) is not read, but 0000H is read.

The value of the TP0CNT register is cleared to 0000H after reset, as the TP0CE bit is cleared to 0.

Caution Accessing the TP0CNT register is disabled during subclock operation with the main clock stopped. For details, refer to 3.4.8 (1) (b).

15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 TPOCNT	After rea	set: 0)000H	F	، ۲	Addre	ss: F	FFFF	5AAH	4

	TP0CNT																

6.5 Operation

TMP0 can perform the following operations.

Operation	TP0CTL1.TP0EST Bit (Software Trigger Bit)	TIP00 Pin (External Trigger Input)	Capture/Compare Register Setting	Compare Register Write
Interval timer mode	Invalid	Invalid	Compare only	Anytime write
External event count mode ^{Note 1}	Invalid	Invalid	Compare only	Anytime write
External trigger pulse output mode ^{Note 2}	Valid	Valid	Compare only	Batch write
One-shot pulse output mode ^{Note 2}	Valid	Valid	Compare only	Anytime write
PWM output mode	Invalid	Invalid	Compare only	Batch write
Free-running timer mode	Invalid	Invalid	Switching enabled	Anytime write
Pulse width measurement mode ^{Note 2}	Invalid	Invalid	Capture only	Not applicable

Notes 1. To use the external event count mode, specify that the valid edge of the TIP00 pin capture trigger input is not detected (by clearing the TP0IOC1.TP0IS1 and TP0IOC1.TP0IS0 bits to "00").

2. When using the external trigger pulse output mode, one-shot pulse output mode, and pulse width measurement mode, select the internal clock as the count clock (by clearing the TP0CTL1.TP0EEE bit to 0).

6.5.1 Interval timer mode (TP0MD2 to TP0MD0 bits = 000)

In the interval timer mode, an interrupt request signal (INTTPOCC0) is generated at the specified interval if the TP0CTL0.TP0CE bit is set to 1. A square wave whose half cycle is equal to the interval can be output from the TOP00 pin.

Usually, the TP0CCR1 register is not used in the interval timer mode.

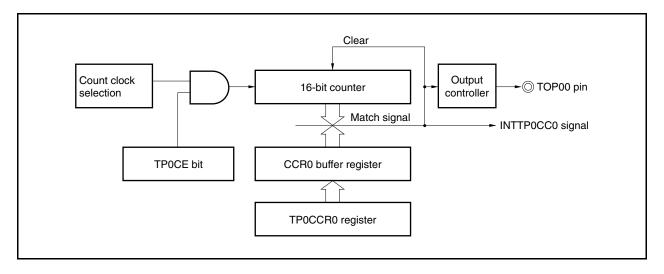

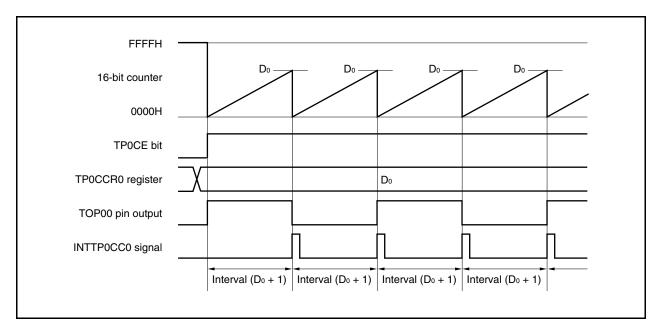

Figure 6-3. Basic Timing of Operation in Interval Timer Mode

When the TP0CE bit is set to 1, the value of the 16-bit counter is cleared from FFFFH to 0000H in synchronization with the count clock, and the counter starts counting. At this time, the output of the TOP00 pin is inverted. Additionally, the set value of the TP0CCR0 register is transferred to the CCR0 buffer register.

When the count value of the 16-bit counter matches the value of the CCR0 buffer register, the 16-bit counter is cleared to 0000H, the output of the TOP00 pin is inverted, and a compare match interrupt request signal (INTTP0CC0) is generated.

The interval can be calculated by the following expression.

Interval = (Set value of TP0CCR0 register + 1) × Count clock cycle

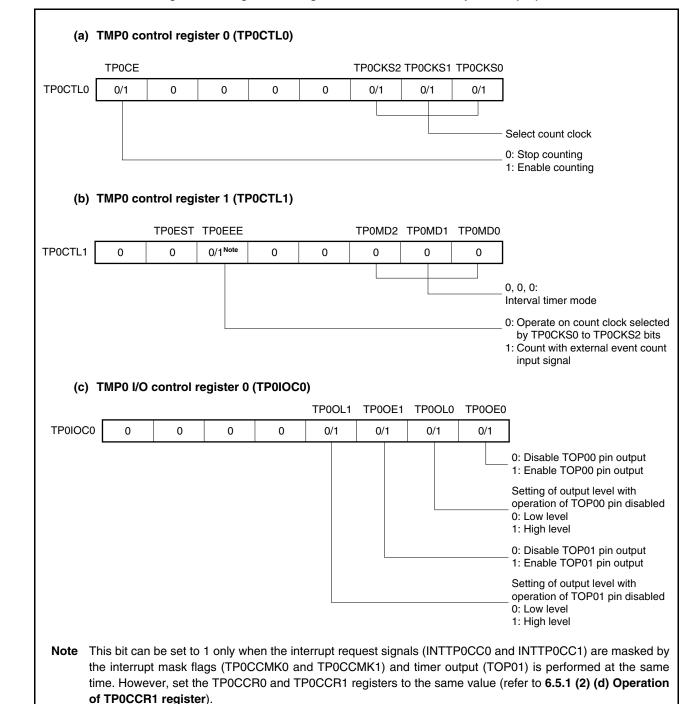

Figure 6-4. Register Setting for Interval Timer Mode Operation (1/2)

<R>

Figure 6-4. Register Setting for Interval Timer Mode Operation (2/2)

(d)		unter read buffer register (TP0CNT) g the TP0CNT register, the count value of the 16-bit counter can be read.
(e)	•	oture/compare register 0 (TP0CCR0) CCR0 register is set to D ₀ , the interval is as follows.
	Interval =	$(D_0 + 1) imes Count clock cycle$
(f)	Usually, th TP0CCR1 (INTTP0C buffer reg	bure/compare register 1 (TP0CCR1) the TP0CCR1 register is not used in the interval timer mode. However, the set value of the register is transferred to the CCR1 buffer register. A compare match interrupt request signal CC1) is generated when the count value of the 16-bit counter matches the value of the CCR1 ister. , mask the interrupt request by using the corresponding interrupt mask flag (TP0CCMK1).
	Remark	TMP0 I/O control register 1 (TP0IOC1), TMP0 I/O control register 2 (TP0IOC2), and TMP0 option register 0 (TP0OPT0) are usually not used in the interval timer mode. However, set the TP0IOC2 register to use the external event count input.

(1) Interval timer mode operation flow

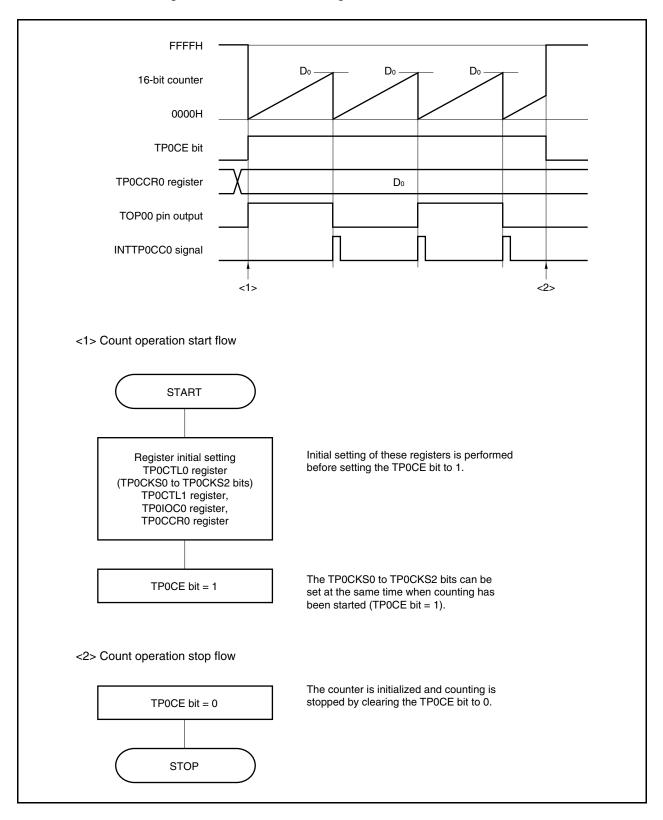

Figure 6-5. Software Processing Flow in Interval Timer Mode

(2) Interval timer mode operation timing

(a) Operation if TP0CCR0 register is cleared to 0000H

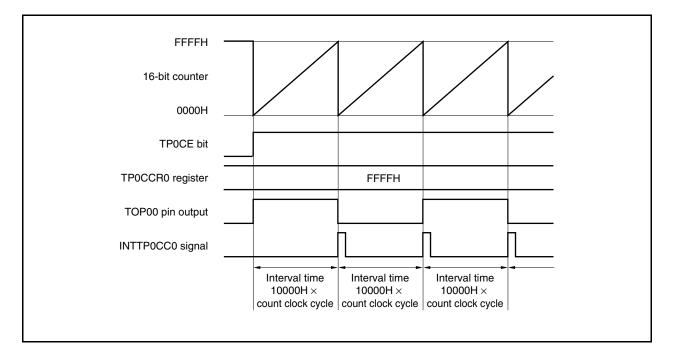

If the TP0CCR0 register is cleared to 0000H, the INTTP0CC0 signal is generated at each count clock, and the output of the TOP00 pin is inverted.

The value of the 16-bit counter is always 0000H.

Count clock					
16-bit counter	FFFFH	оооон	Оооон	Оооон	оооон
TP0CE bit					
TP0CCR0 register			0000H		
TOP00 pin output					
INTTP0CC0 signal					
		Interval time Count clock cycle	Interval time Count clock cycle	Interval time Count clock cycle	-

(b) Operation if TP0CCR0 register is set to FFFFH

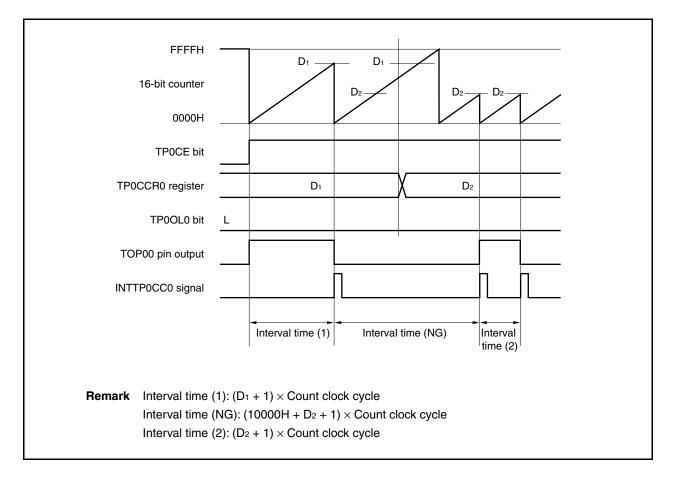

If the TPOCCR0 register is set to FFFFH, the 16-bit counter counts up to FFFFH. The counter is cleared to 0000H in synchronization with the next count-up timing. The INTTPOCC0 signal is generated and the output of the TOP00 pin is inverted. At this time, an overflow interrupt request signal (INTTPOOV) is not generated, nor is the overflow flag (TP0OPT0.TP0OVF bit) set to 1.

(c) Notes on rewriting TP0CCR0 register

To change the value of the TP0CCR0 register to a smaller value, stop counting once and then change the set value.

If the value of the TP0CCR0 register is rewritten to a smaller value during counting, the 16-bit counter may overflow.

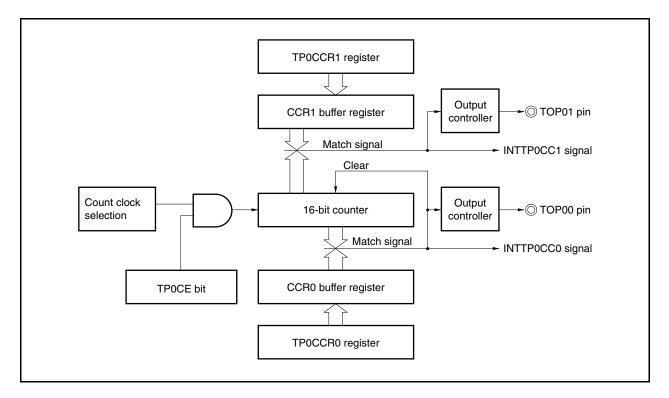

If the value of the TP0CCR0 register is changed from D_1 to D_2 while the count value is greater than D_2 but less than D_1 , the count value is transferred to the CCR0 buffer register as soon as the TP0CCR0 register has been rewritten. Consequently, the value of the 16-bit counter that is compared is D_2 .

Because the count value has already exceeded D₂, however, the 16-bit counter counts up to FFFFH, overflows, and then counts up again from 0000H. When the count value matches D₂, the INTTPOCCO signal is generated and the output of the TOP00 pin is inverted.

Therefore, the INTTP0CC0 signal may not be generated at the interval time " $(D_1 + 1) \times Count clock cycle$ " or " $(D_2 + 1) \times Count clock cycle$ " originally expected, but may be generated at an interval of " $(10000H + D_2 + 1) \times Count clock period$ ".

(d) Operation of TP0CCR1 register

If the set value of the TP0CCR1 register is less than the set value of the TP0CCR0 register, the INTTP0CC1 signal is generated once per cycle. At the same time, the output of the TOP01 pin is inverted. The TOP01 pin outputs a square wave with the same cycle as that output by the TOP00 pin.

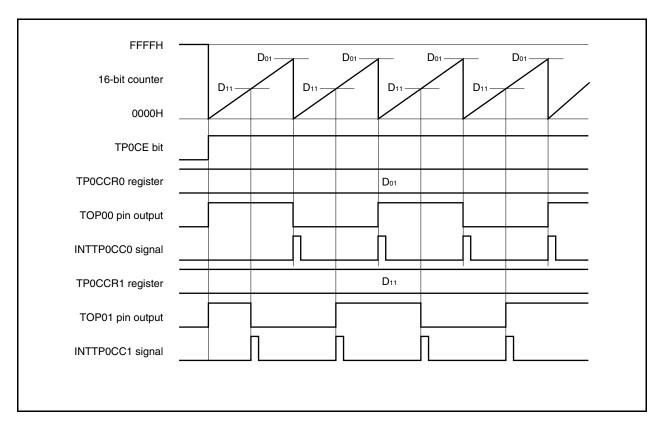

Figure 6-7. Timing Chart When $D_{01} \ge D_{11}$

If the set value of the TP0CCR1 register is greater than the set value of the TP0CCR0 register, the count value of the 16-bit counter does not match the value of the TP0CCR1 register. Consequently, the INTTP0CC1 signal is not generated, nor is the output of the TOP01 pin changed.

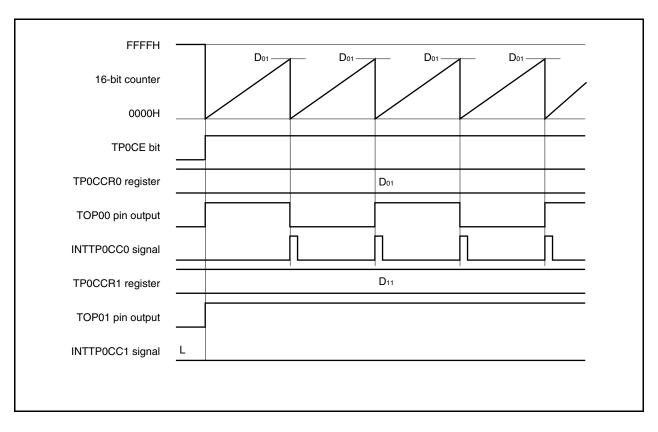

Figure 6-8. Timing Chart When Do1 < D11

6.5.2 External event count mode (TP0MD2 to TP0MD0 bits = 001)

In the external event count mode, the valid edge of the external event count input is counted when the TP0CTL0.TP0CE bit is set to 1, and an interrupt request signal (INTTP0CC0) is generated each time the specified number of edges have been counted. The timer output (TOP00, TOP01 pins) cannot be used.

Usually, the TP0CCR1 register is not used in the external event count mode.

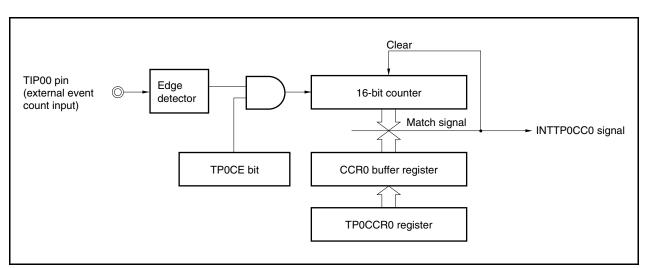

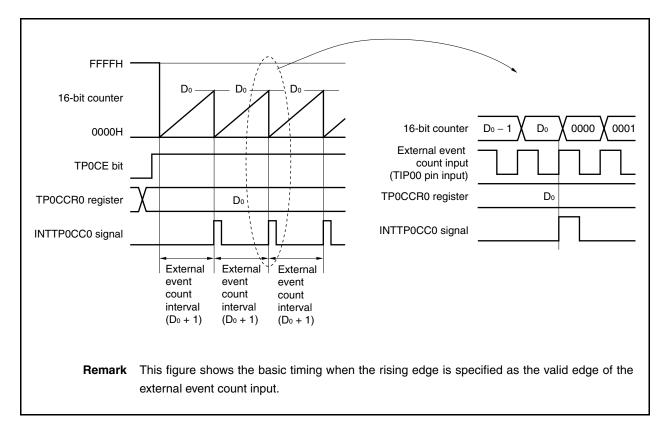

Figure 6-9. Configuration in External Event Count Mode

<R>

Figure 6-10. Basic Timing in External Event Count Mode

When the TP0CE bit is set to 1, the value of the 16-bit counter is cleared from FFFFH to 0000H. The counter counts each time the valid edge of external event count input is detected. Additionally, the set value of the TP0CCR0 register is transferred to the CCR0 buffer register.

When the count value of the 16-bit counter matches the value of the CCR0 buffer register, the 16-bit counter is cleared to 0000H, and a compare match interrupt request signal (INTTP0CC0) is generated.

The INTTP0CC0 signal is generated each time the valid edge of the external event count input has been detected (set value of TP0CCR0 register + 1) times.

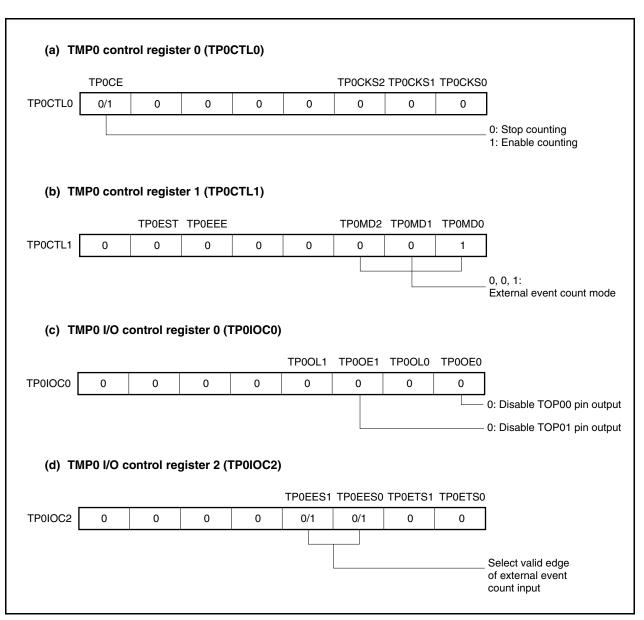

Figure 6-11. Register Setting for Operation in External Event Count Mode (2/2)

(e) TMP0 counter read buffer register (TP0CNT) The count value of the 16-bit counter can be read by reading the TP0CNT register. (f) TMP0 capture/compare register 0 (TP0CCR0) If D₀ is set to the TP0CCR0 register, the counter is cleared and a compare match interrupt request signal (INTTP0CC0) is generated when the number of external event counts reaches (D₀ + 1). (g) TMP0 capture/compare register 1 (TP0CCR1) Usually, the TP0CCR1 register is not used in the external event count mode. However, the set value of the TP0CCR1 register is transferred to the CCR1 buffer register. When the count value of the 16-bit counter matches the value of the CCR1 buffer register, a compare match interrupt request signal (INTTP0CC1) is generated. Therefore, mask the interrupt signal by using the interrupt mask flag (TP0CCMK1). Remark TMP0 I/O control register 1 (TP0IOC1) and TMP0 option register 0 (TP0OPT0) are not used in the external event count mode.

(1) External event count mode operation flow

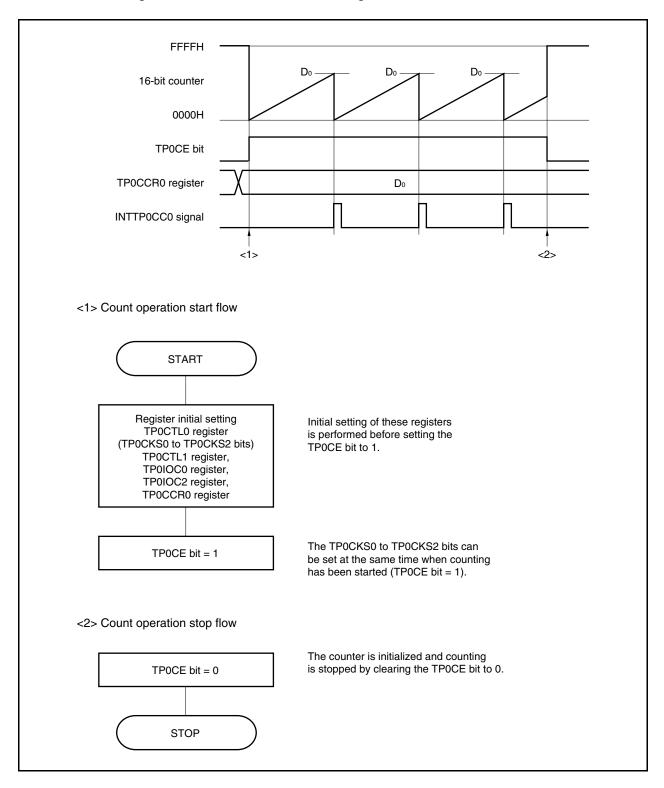

Figure 6-12. Flow of Software Processing in External Event Count Mode

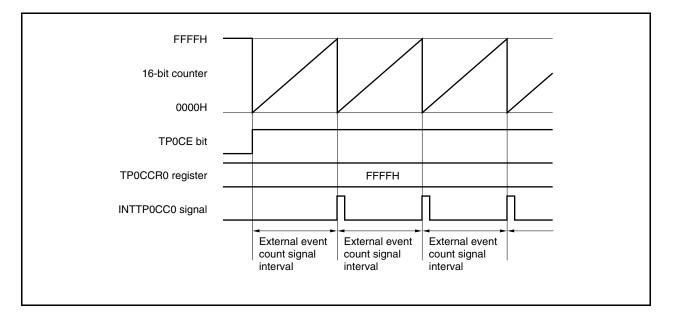

- (2) Operation timing in external event count mode
- <R> Cautions 1. In the external event count mode, do not set the TP0CCR0 and TP0CCR1 registers to 0000H.

<R>

2. In the external event count mode, use of the timer output is disabled. If performing timer output using external event count input, set the interval timer mode, and select the operation enabled by the external event count input for the count clock (TP0CTL1.TP0MD2 to TP0CTL1.TP0MD0 bits = 000, TP0CTL1.TP0EEE bit = 1).

(a) Operation if TP0CCR0 register is set to FFFFH

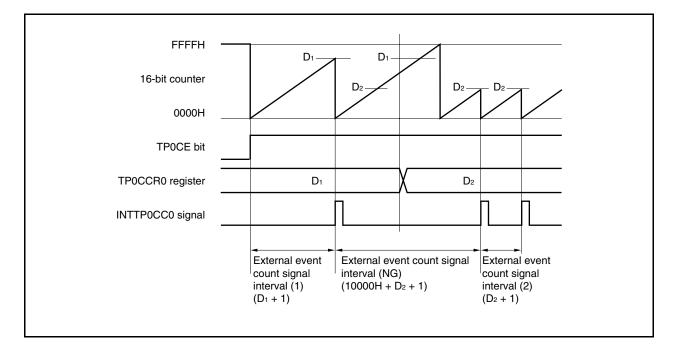

If the TP0CCR0 register is set to FFFFH, the 16-bit counter counts to FFFFH each time the valid edge of the external event count signal has been detected. The 16-bit counter is cleared to 0000H in synchronization with the next count-up timing, and the INTTP0CC0 signal is generated. At this time, the TP0OPT0.TP0OVF bit is not set.

(b) Notes on rewriting the TP0CCR0 register

To change the value of the TP0CCR0 register to a smaller value, stop counting once and then change the set value.

If the value of the TP0CCR0 register is rewritten to a smaller value during counting, the 16-bit counter may overflow.

If the value of the TP0CCR0 register is changed from D_1 to D_2 while the count value is greater than D_2 but less than D_1 , the count value is transferred to the CCR0 buffer register as soon as the TP0CCR0 register has been rewritten. Consequently, the value that is compared with the 16-bit counter is D_2 .

Because the count value has already exceeded D₂, however, the 16-bit counter counts up to FFFFH, overflows, and then counts up again from 0000H. When the count value matches D₂, the INTTPOCCO signal is generated.

Therefore, the INTTP0CC0 signal may not be generated at the valid edge count of " $(D_1 + 1)$ times" or " $(D_2 + 1)$ times" originally expected, but may be generated at the valid edge count of " $(10000H + D_2 + 1)$ times".

(c) Operation of TP0CCR1 register

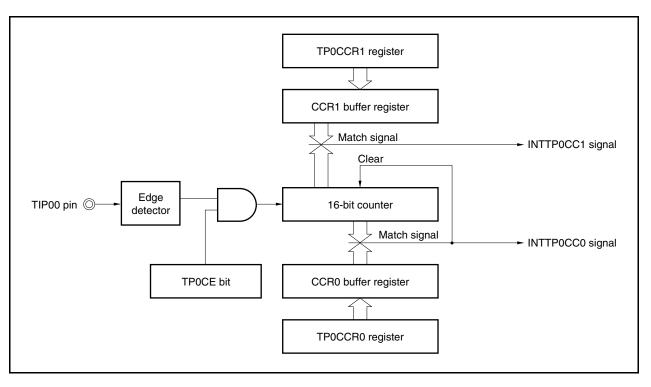

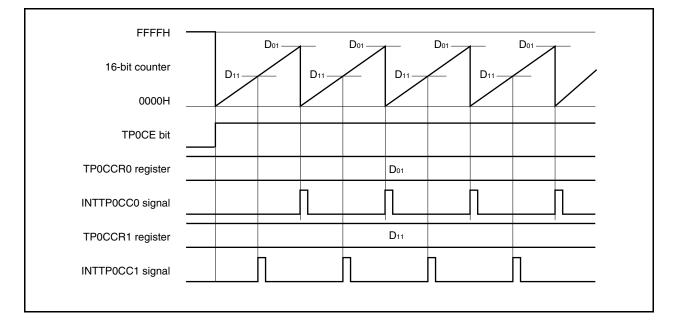

Figure 6-13. Configuration of TP0CCR1 Register

If the set value of the TP0CCR1 register is smaller than the set value of the TP0CCR0 register, the INTTP0CC1 signal is generated once per cycle.

Figure 6-14. Timing Chart When $D_{01} \ge D_{11}$

If the set value of the TP0CCR1 register is greater than the set value of the TP0CCR0 register, the INTTP0CC1 signal is not generated because the count value of the 16-bit counter and the value of the TP0CCR1 register do not match.

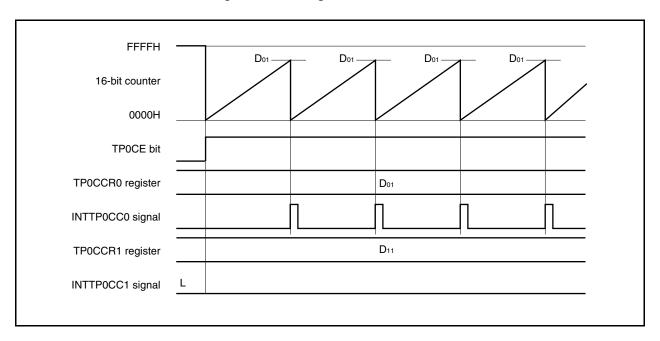

Figure 6-15. Timing Chart When Do1 < D11

6.5.3 External trigger pulse output mode (TP0MD2 to TP0MD0 bits = 010)

In the external trigger pulse output mode, 16-bit timer/event counter P waits for a trigger when the TP0CTL0.TP0CE bit is set to 1. When the valid edge of an external trigger input signal is detected, 16-bit timer/event counter P starts counting, and outputs a PWM waveform from the TOP01 pin.

Pulses can also be output by generating a software trigger instead of using the external trigger. When using a software trigger, a square wave that has one cycle of the PWM waveform as half its cycle can also be output from the TOP00 pin.

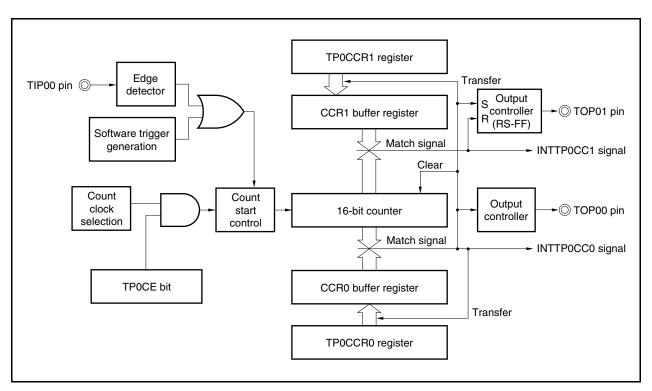

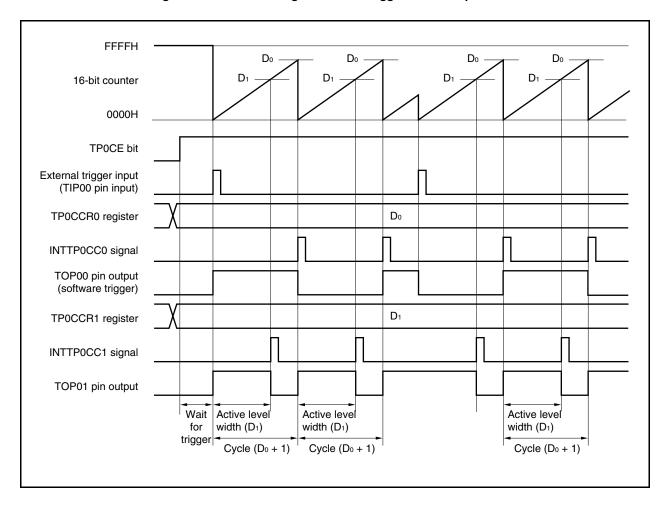

Figure 6-16. Configuration in External Trigger Pulse Output Mode

16-bit timer/event counter P waits for a trigger when the TPOCE bit is set to 1. When the trigger is generated, the 16-bit counter is cleared from FFFFH to 0000H, starts counting at the same time, and outputs a PWM waveform from the TOP01 pin. If the trigger is generated again while the counter is operating, the counter is cleared to 0000H and restarted. (The output of the TOP00 pin is inverted. The TOP01 pin outputs a high level regardless of the status (high/low) when a trigger occurs.)

<R>

The active level width, cycle, and duty factor of the PWM waveform can be calculated as follows.

Active level width = (Set value of TP0CCR1 register) × Count clock cycle Cycle = (Set value of TP0CCR0 register + 1) × Count clock cycle Duty factor = (Set value of TP0CCR1 register)/(Set value of TP0CCR0 register + 1)

The compare match interrupt request signal INTTP0CC0 is generated when the 16-bit counter counts next time after its count value matches the value of the CCR0 buffer register, and the 16-bit counter is cleared to 0000H. The compare match interrupt request signal INTTP0CC1 is generated when the count value of the 16-bit counter matches the value of the CCR1 buffer register.

The value set to the TP0CCRa register is transferred to the CCRa buffer register when the count value of the 16-bit counter matches the value of the CCRa buffer register and the 16-bit counter is cleared to 0000H.

The valid edge of an external trigger input signal, or setting the software trigger (TP0CTL1.TP0EST bit) to 1 is used as the trigger.

Remark a = 0, 1

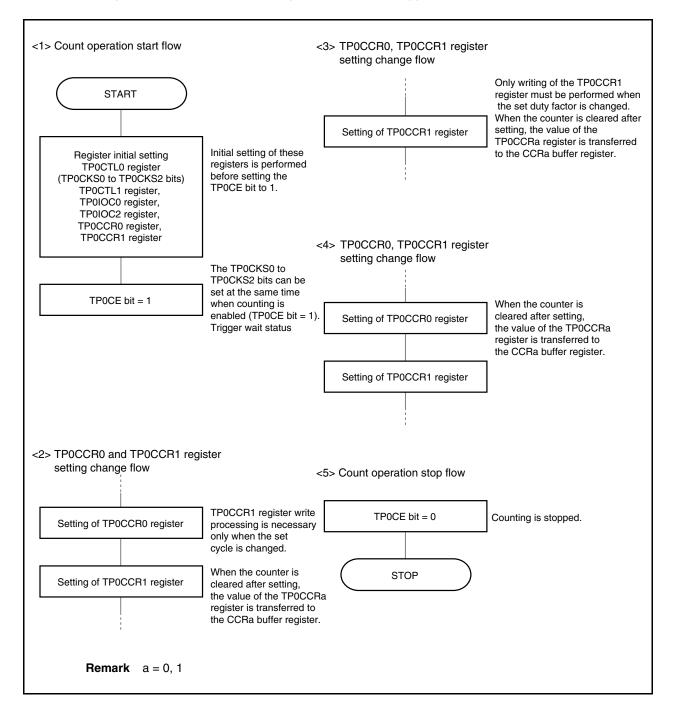

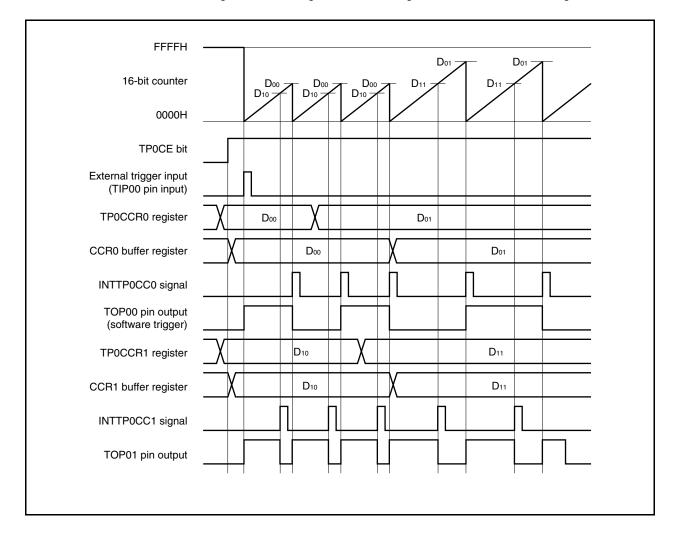

Figure 6-19. Software Processing Flow in External Trigger Pulse Output Mode (2/2)

(2) External trigger pulse output mode operation timing

(a) Note on changing pulse width during operation

To change the PWM waveform while the counter is operating, write the TP0CCR1 register last. Rewrite the TP0CCRa register after writing the TP0CCR1 register after the INTTP0CC0 signal is detected.

In order to transfer data from the TP0CCRa register to the CCRa buffer register, the TP0CCR1 register must be written.

To change both the cycle and active level width of the PWM waveform at this time, first set the cycle to the TP0CCR0 register and then set the active level width to the TP0CCR1 register.

To change only the cycle of the PWM waveform, first set the cycle to the TP0CCR0 register, and then write the same value to the TP0CCR1 register.

To change only the active level width (duty factor) of the PWM waveform, only the TP0CCR1 register has to be set.

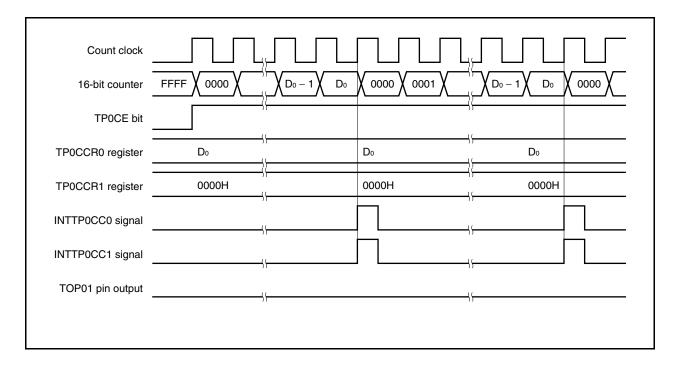

After data is written to the TP0CCR1 register, the value written to the TP0CCRa register is transferred to the CCRa buffer register in synchronization with clearing of the 16-bit counter, and is used as the value compared with the 16-bit counter.

To write the TP0CCR0 or TP0CCR1 register again after writing the TP0CCR1 register once, do so after the INTTP0CC0 signal is generated. Otherwise, the value of the CCRa buffer register may become undefined because the timing of transferring data from the TP0CCRa register to the CCRa buffer register conflicts with writing the TP0CCRa register.

Remark a = 0, 1

(b) 0%/100% output of PWM waveform

To output a 0% waveform, clear the TP0CCR1 register to 0000H. If the set value of the TP0CCR0 register is FFFFH, the INTTP0CC1 signal is generated periodically.

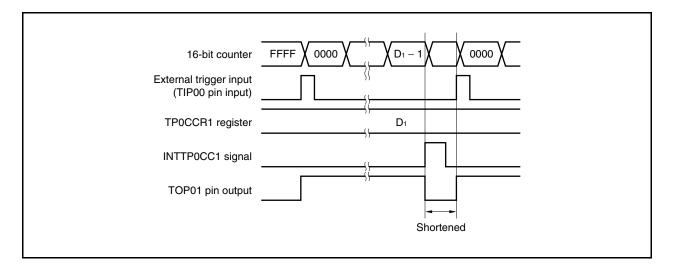

To output a 100% waveform, set a value of (set value of TP0CCR0 register + 1) to the TP0CCR1 register. If the set value of the TP0CCR0 register is FFFFH, 100% output cannot be produced.

	Count clock

	INTTP0CC1 signal		<u>}</u>		<u>}</u>	
R>	TOP01 pin output		7	,)]	

(c) Conflict between trigger detection and match with TP0CCR1 register

If the trigger is detected immediately after the INTTPOCC1 signal is generated, the 16-bit counter is immediately cleared to 0000H, the output signal of the TOP01 pin is asserted, and the counter continues counting. Consequently, the inactive period of the PWM waveform is shortened.

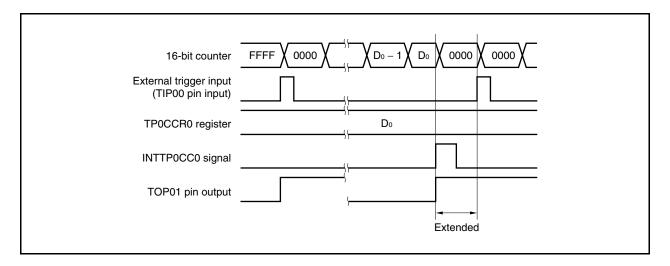

If the trigger is detected immediately before the INTTPOCC1 signal is generated, the INTTPOCC1 signal is not generated, and the 16-bit counter is cleared to 0000H and continues counting. The output signal of the TOP01 pin remains active. Consequently, the active period of the PWM waveform is extended.

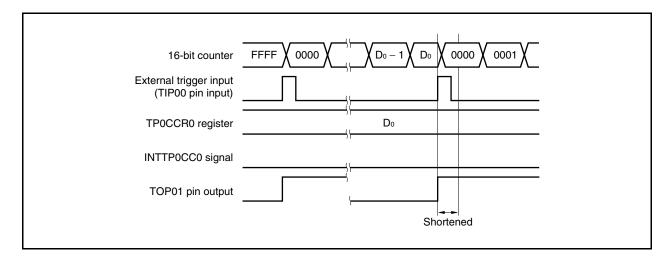

(d) Conflict between trigger detection and match with TP0CCR0 register

If the trigger is detected immediately after the INTTPOCC0 signal is generated, the 16-bit counter is cleared to 0000H and continues counting up. Therefore, the active period of the TOP01 pin is extended by time from generation of the INTTPOCC0 signal to trigger detection.

If the trigger is detected immediately before the INTTP0CC0 signal is generated, the INTTP0CC0 signal is not generated. The 16-bit counter is cleared to 0000H, the TOP01 pin is asserted, and the counter continues counting. Consequently, the inactive period of the PWM waveform is shortened.

(e) Generation timing of compare match interrupt request signal (INTTP0CC1)

The timing of generation of the INTTP0CC1 signal in the external trigger pulse output mode differs from the timing of other INTTP0CC1 signals; the INTTP0CC1 signal is generated when the count value of the 16-bit counter matches the value of the TP0CCR1 register.

Count clock		
16-bit counter	D1 - 1 D1 - 1 D1 D1 + 1 D1 + 2	
TP0CCR1 register	D1	
TOP01 pin output		
INTTP0CC1 signal		

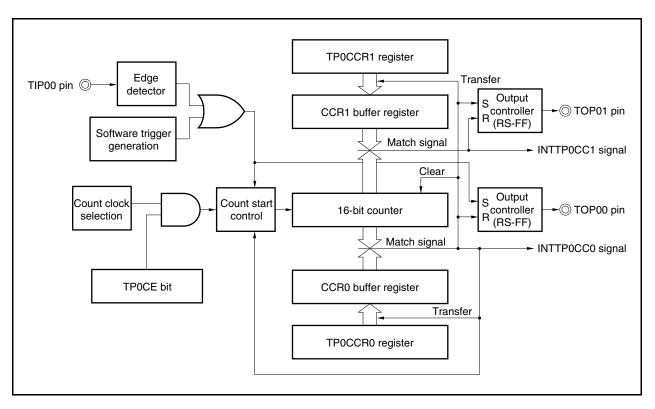

Usually, the INTTP0CC1 signal is generated in synchronization with the next count up, after the count value of the 16-bit counter matches the value of the TP0CCR1 register.

In the external trigger pulse output mode, however, it is generated one clock earlier. This is because the timing is changed to match the timing of changing the output signal of the TOP01 pin.

6.5.4 One-shot pulse output mode (TP0MD2 to TP0MD0 bits = 011)

In the one-shot pulse output mode, 16-bit timer/event counter P waits for a trigger when the TP0CTL0.TP0CE bit is set to 1. When the valid edge of an external trigger input is detected, 16-bit timer/event counter P starts counting, and outputs a one-shot pulse from the TOP01 pin.

Instead of the external trigger, a software trigger can also be generated to output the pulse. When the software trigger is used, the TOP00 pin outputs the active level while the 16-bit counter is counting, and the inactive level when the counter is stopped (waiting for a trigger).

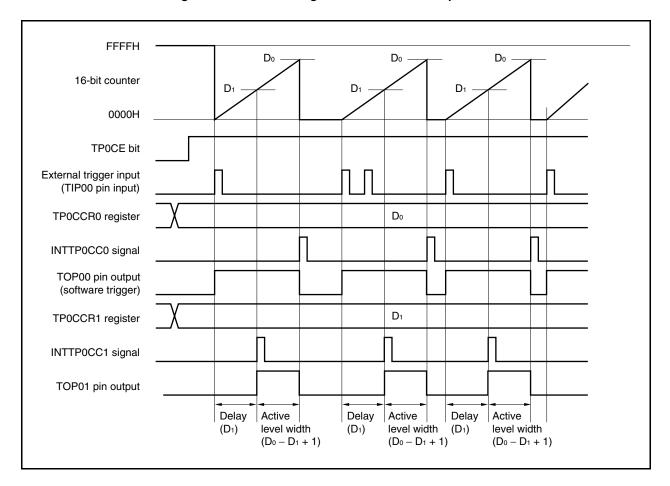

Figure 6-21. Basic Timing in One-Shot Pulse Output Mode

When the TPOCE bit is set to 1, 16-bit timer/event counter P waits for a trigger. When the trigger is generated, the 16-bit counter is cleared from FFFFH to 0000H, starts counting, and outputs a one-shot pulse from the TOP01 pin. After the one-shot pulse is output, the 16-bit counter is set to FFFFH, stops counting, and waits for a trigger. If a trigger is generated again while the one-shot pulse is being output, it is ignored.

The output delay period and active level width of the one-shot pulse can be calculated as follows.

Output delay period = (Set value of TP0CCR1 register) \times Count clock cycle Active level width = (Set value of TP0CCR0 register – Set value of TP0CCR1 register + 1) \times Count clock cycle

The compare match interrupt request signal INTTPOCC0 is generated when the 16-bit counter counts after its count value matches the value of the CCR0 buffer register. The compare match interrupt request signal INTTPOCC1 is generated when the count value of the 16-bit counter matches the value of the CCR1 buffer register.

The valid edge of an external trigger input or setting the software trigger (TP0CTL1.TP0EST bit) to 1 is used as the trigger.

(2) Operation timing in one-shot pulse output mode

(a) Note on rewriting TP0CCRa register

To change the set value of the TP0CCRa register to a smaller value, stop counting once, and then change the set value.

If the value of the TP0CCRa register is rewritten to a smaller value during counting, the 16-bit counter may overflow.

When the TP0CCR0 register is rewritten from D_{00} to D_{01} and the TP0CCR1 register from D_{10} to D_{11} where $D_{00} > D_{01}$ and $D_{10} > D_{11}$, if the TP0CCR1 register is rewritten when the count value of the 16-bit counter is greater than D_{11} and less than D_{10} and if the TP0CCR0 register is rewritten when the count value is greater than D_{01} and less than D_{00} , each set value is reflected as soon as the register has been rewritten and compared with the count value. The counter counts up to FFFFH and then counts up again from 0000H. When the count value matches D_{11} , the counter generates the INTTP0CC1 signal and asserts the TOP01 pin. When the count value matches D_{01} , the counter generates the INTTP0CC0 signal, deasserts the TOP01 pin, and stops counting.

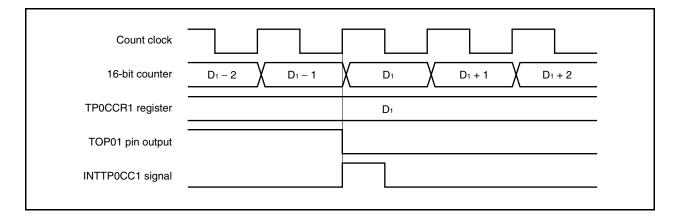

Therefore, the counter may output a pulse with a delay period or active period different from that of the one-shot pulse that is originally expected.

Remark a = 0, 1

<R>

(b) Generation timing of compare match interrupt request signal (INTTP0CC1)

The generation timing of the INTTPOCC1 signal in the one-shot pulse output mode is different from other INTTPOCC1 signals; the INTTPOCC1 signal is generated when the count value of the 16-bit counter matches the value of the TPOCCR1 register.

Usually, the INTTP0CC1 signal is generated when the 16-bit counter counts up next time after its count value matches the value of the TP0CCR1 register.

In the one-shot pulse output mode, however, it is generated one clock earlier. This is because the timing is changed to match the change timing of the TOP01 pin.

6.5.5 PWM output mode (TP0MD2 to TP0MD0 bits = 100)

In the PWM output mode, a PWM waveform is output from the TOP01 pin when the TP0CTL0.TP0CE bit is set to 1. In addition, a pulse with one cycle of the PWM waveform as half its cycle is output from the TOP00 pin.

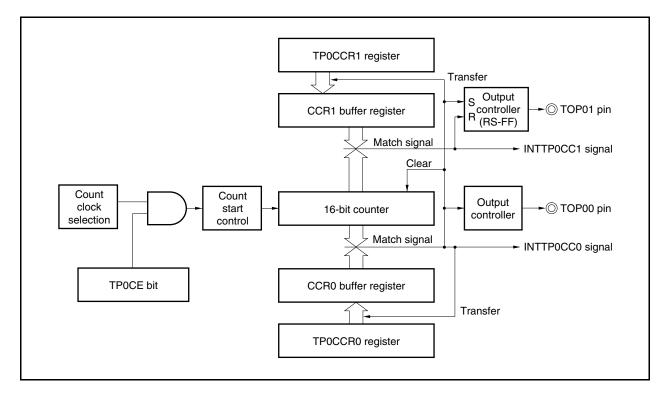

Figure 6-24. Configuration in PWM Output Mode

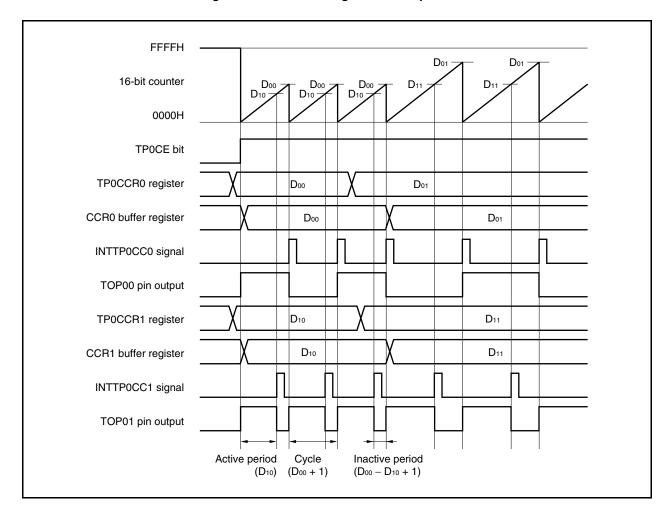

Figure 6-25. Basic Timing in PWM Output Mode

When the TP0CE bit is set to 1, the 16-bit counter is cleared from FFFFH to 0000H, starts counting, and outputs a PWM waveform from the TOP01 pin.

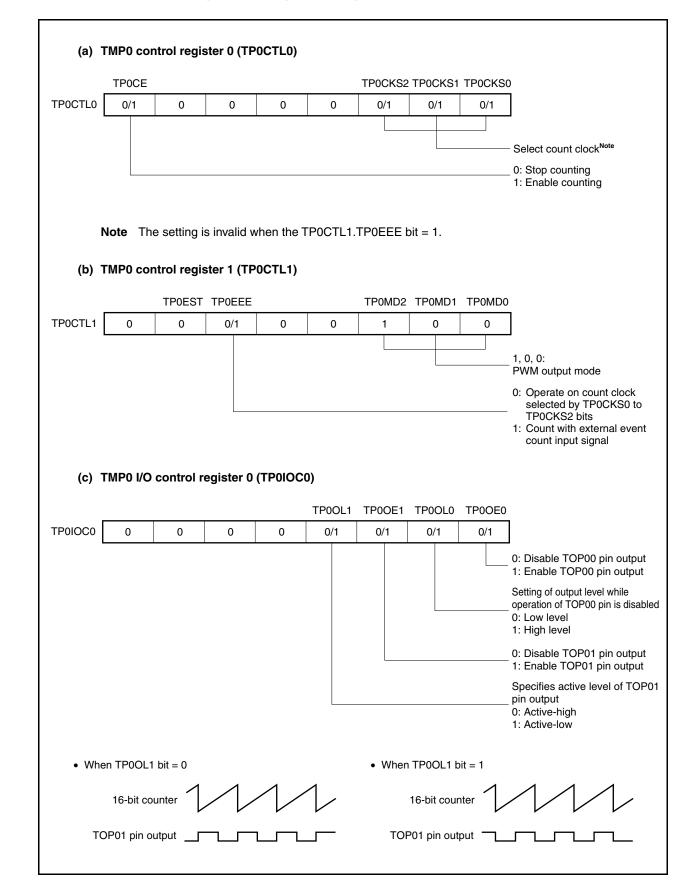

The active level width, cycle, and duty factor of the PWM waveform can be calculated as follows.

Active level width = (Set value of TP0CCR1 register) \times Count clock cycle Cycle = (Set value of TP0CCR0 register + 1) \times Count clock cycle Duty factor = (Set value of TP0CCR1 register)/(Set value of TP0CCR0 register + 1)

The PWM waveform can be changed by rewriting the TP0CCRa register while the counter is operating. The newly written value is reflected when the count value of the 16-bit counter matches the value of the CCR0 buffer register and the 16-bit counter is cleared to 0000H.

The compare match interrupt request signal INTTP0CC0 is generated when the 16-bit counter counts next time after its count value matches the value of the CCR0 buffer register, and the 16-bit counter is cleared to 0000H. The compare match interrupt request signal INTTP0CC1 is generated when the count value of the 16-bit counter matches the value of the CCR1 buffer register.

The value set to the TP0CCRa register is transferred to the CCRa buffer register when the count value of the 16-bit counter matches the value of the CCRa buffer register and the 16-bit counter is cleared to 0000H.

<R>

	(f) TMP0 capture/compare registers 0 and 1 (TP0CCR0 and TP0CCR1) If D ₀ is set to the TP0CCR0 register and D ₁ to the TP0CCR1 register, the cycle and active level of the PWM waveform are as follows.									
	Cycle = $(D_0 + 1) \times$ Count clock cycle Active level width = $D_1 \times$ Count clock cycle									
	Remark TMP0 I/O control register 1 (TP0IOC1) and TMP0 option register 0 (TP0OPT0) are not used in the PWM output mode.									

(1) Operation flow in PWM output mode

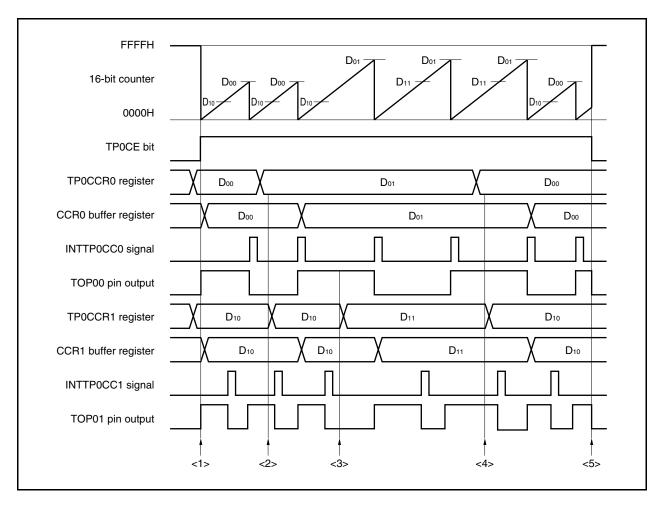

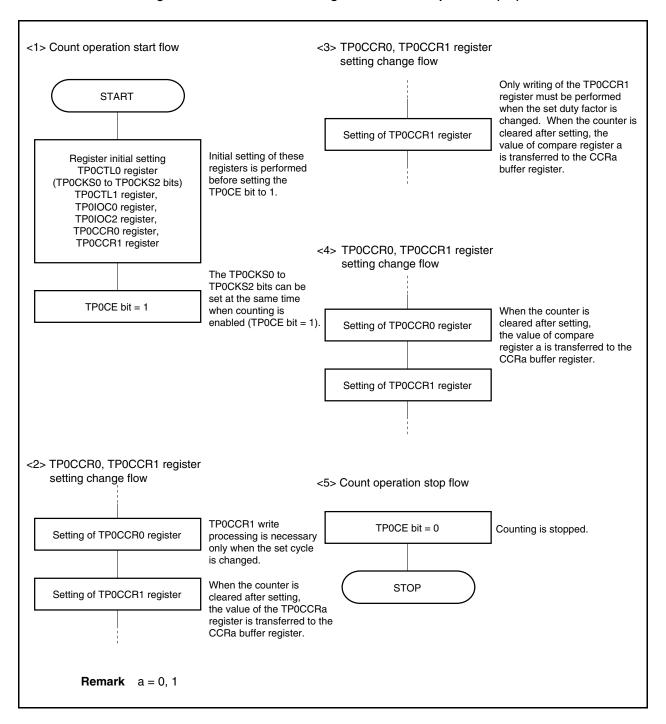

Figure 6-27. Software Processing Flow in PWM Output Mode (1/2)

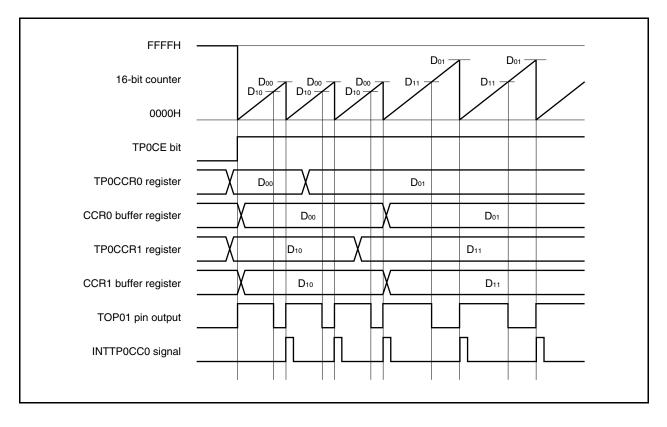

(2) PWM output mode operation timing

(a) Changing pulse width during operation

To change the PWM waveform while the counter is operating, write the TP0CCR1 register last. Rewrite the TP0CCRa register after writing the TP0CCR1 register after the INTTP0CC1 signal is detected.

To transfer data from the TP0CCRa register to the CCRa buffer register, the TP0CCR1 register must be written.

To change both the cycle and active level of the PWM waveform at this time, first set the cycle to the TP0CCR0 register and then set the active level to the TP0CCR1 register.

To change only the cycle of the PWM waveform, first set the cycle to the TP0CCR0 register, and then write the same value to the TP0CCR1 register.

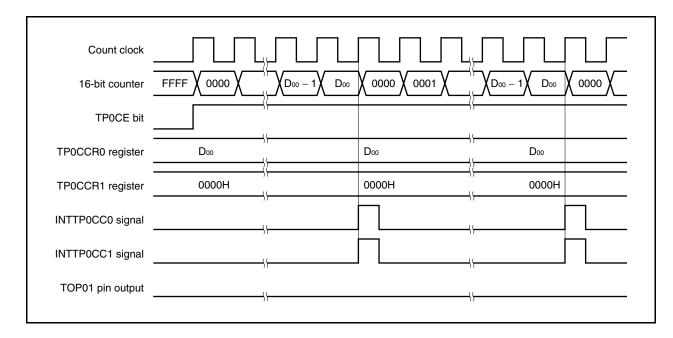

To change only the active level width (duty factor) of the PWM waveform, only the TP0CCR1 register has to be set.

After data is written to the TP0CCR1 register, the value written to the TP0CCRa register is transferred to the CCRa buffer register in synchronization with clearing of the 16-bit counter, and is used as the value compared with the 16-bit counter.

To write the TP0CCR0 or TP0CCR1 register again after writing the TP0CCR1 register once, do so after the INTTP0CC0 signal is generated. Otherwise, the value of the CCRa buffer register may become undefined because the timing of transferring data from the TP0CCRa register to the CCRa buffer register conflicts with writing the TP0CCRa register.

(b) 0%/100% output of PWM waveform

To output a 0% waveform, set the TP0CCR1 register to 0000H. If the set value of the TP0CCR0 register is FFFFH, the INTTP0CC1 signal is generated periodically.

To output a 100% waveform, set a value of (set value of TP0CCR0 register + 1) to the TP0CCR1 register. If the set value of the TP0CCR0 register is FFFFH, 100% output cannot be produced.

	Count clock		ļ

	INTTP0CC1 signal		}		<u>}</u>
>	TOP01 pin output		,	1	

<R>

(c) Generation timing of compare match interrupt request signal (INTTP0CC1)

The timing of generation of the INTTPOCC1 signal in the PWM output mode differs from the timing of other INTTPOCC1 signals; the INTTPOCC1 signal is generated when the count value of the 16-bit counter matches the value of the TPOCCR1 register.

Count clock	
16-bit counter	D1 - 2 D1 - 1 D1 D1 + 1 D1 + 2
TP0CCR1 register	D1
TOP01 pin output	
INTTP0CC1 signal	

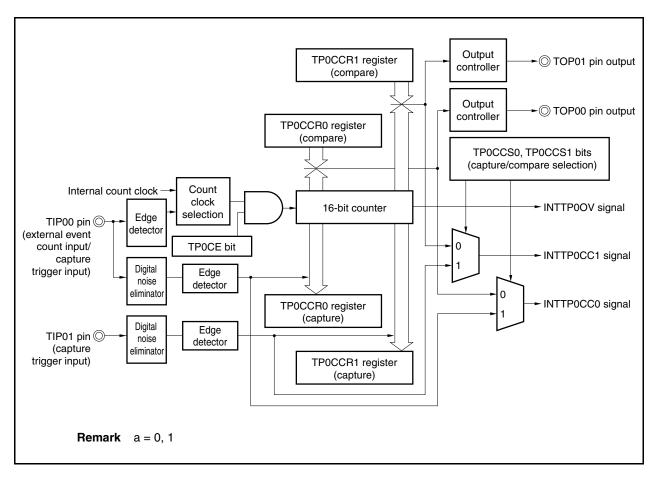

Usually, the INTTPOCC1 signal is generated in synchronization with the next counting up after the count value of the 16-bit counter matches the value of the TPOCCR1 register.

In the PWM output mode, however, it is generated one clock earlier. This is because the timing is changed to match the change timing of the output signal of the TOP01 pin.

6.5.6 Free-running timer mode (TP0MD2 to TP0MD0 bits = 101)

In the free-running timer mode, 16-bit timer/event counter P starts counting when the TP0CTL0.TP0CE bit is set to 1. At this time, the TP0CCRa register can be used as a compare register or a capture register, depending on the setting of the TP0OPT0.TP0CCS0 and TP0OPT0.TP0CCS1 bits.

When the TP0CE bit is set to 1, 16-bit timer/event counter P starts counting, and the output signals of the TOP00 and TOP01 pins are inverted. When the count value of the 16-bit counter later matches the set value of the TP0CCRa register, a compare match interrupt request signal (INTTP0CCa) is generated, and the output signal of the TOP0a pin is inverted.

The 16-bit counter continues counting in synchronization with the count clock. When it counts up to FFFH, it generates an overflow interrupt request signal (INTTPOOV) at the next clock, is cleared to 0000H, and continues counting. At this time, the overflow flag (TP0OPT0.TP0OVF bit) is also set to 1. Clear the overflow flag to 0 by executing the CLR instruction by software.

The TP0CCRa register can be rewritten while the counter is operating. If it is rewritten, the new value is reflected at that time, and compared with the count value.

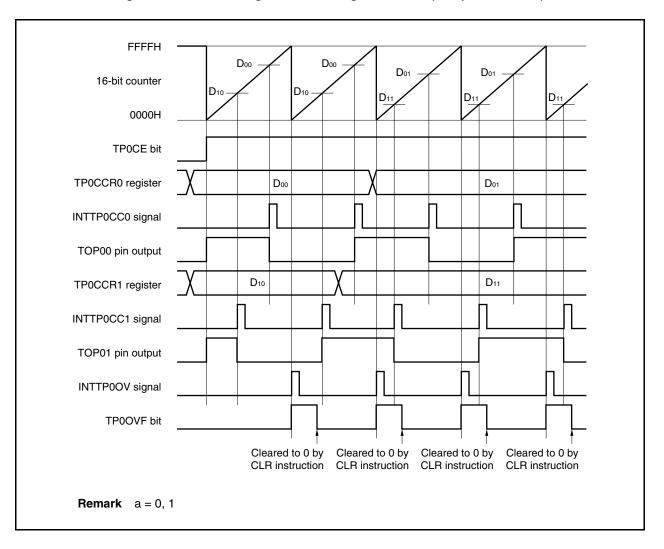

Figure 6-29. Basic Timing in Free-Running Timer Mode (Compare Function)

When the TPOCE bit is set to 1, the 16-bit counter starts counting. When the valid edge input to the TIPOa pin is detected, the count value of the 16-bit counter is stored in the TPOCCRa register, and a capture interrupt request signal (INTTPOCCa) is generated.

The 16-bit counter continues counting in synchronization with the count clock. When it counts up to FFFH, it generates an overflow interrupt request signal (INTTPOOV) at the next clock, is cleared to 0000H, and continues counting. At this time, the overflow flag (TP0OPT0.TP0OVF bit) is also set to 1. Clear the overflow flag to 0 by executing the CLR instruction by software.

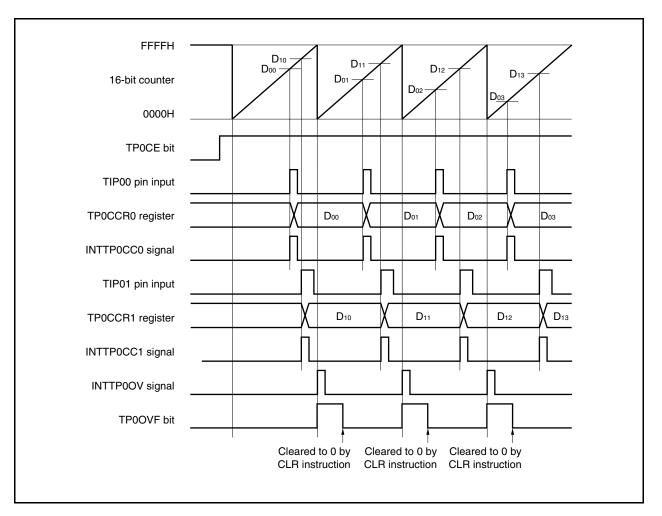

Figure 6-30. Basic Timing in Free-Running Timer Mode (Capture Function)

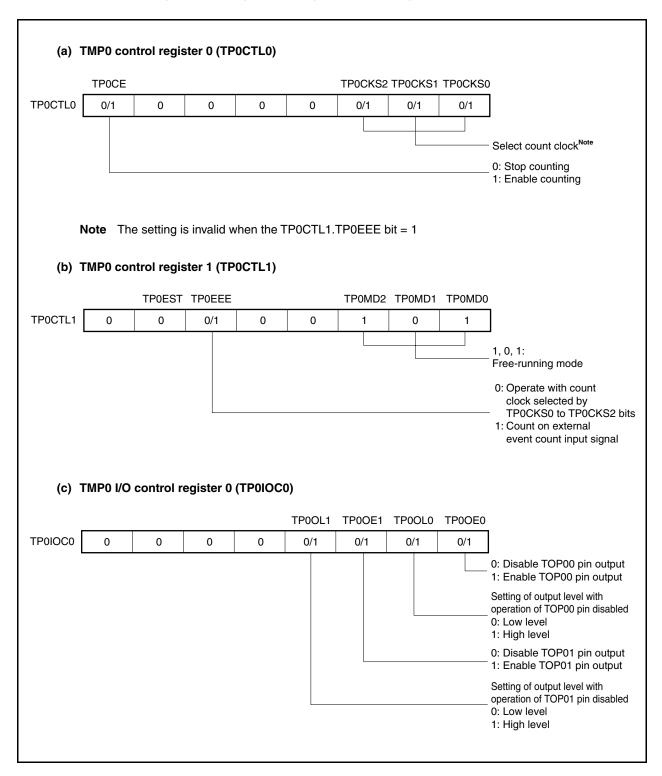

Figure 6-31. Register Setting in Free-Running Timer Mode (1/2)

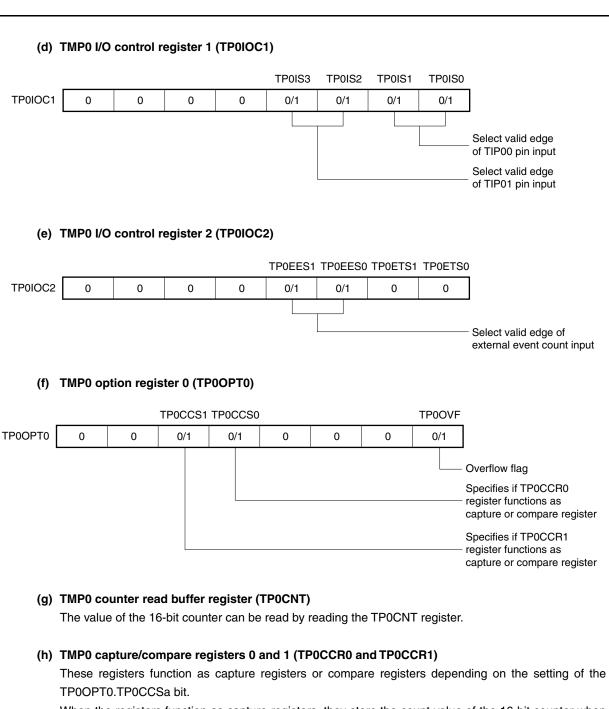

Figure 6-31. Register Setting in Free-Running Timer Mode (2/2)

When the registers function as capture registers, they store the count value of the 16-bit counter when the valid edge input to the TIP0a pin is detected.

When the registers function as compare registers and when D_a is set to the TP0CCRa register, the INTTP0CCa signal is generated when the counter reaches ($D_a + 1$), and the output signal of the TOP0a pin is inverted.

- (1) Operation flow in free-running timer mode
 - (a) When using capture/compare register as compare register

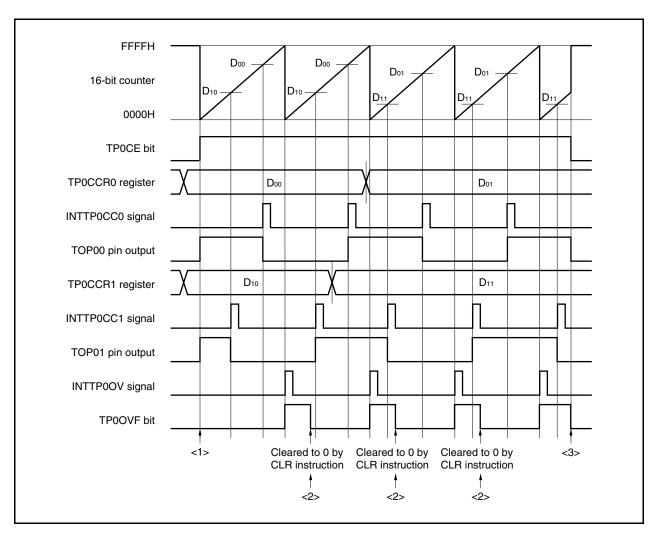

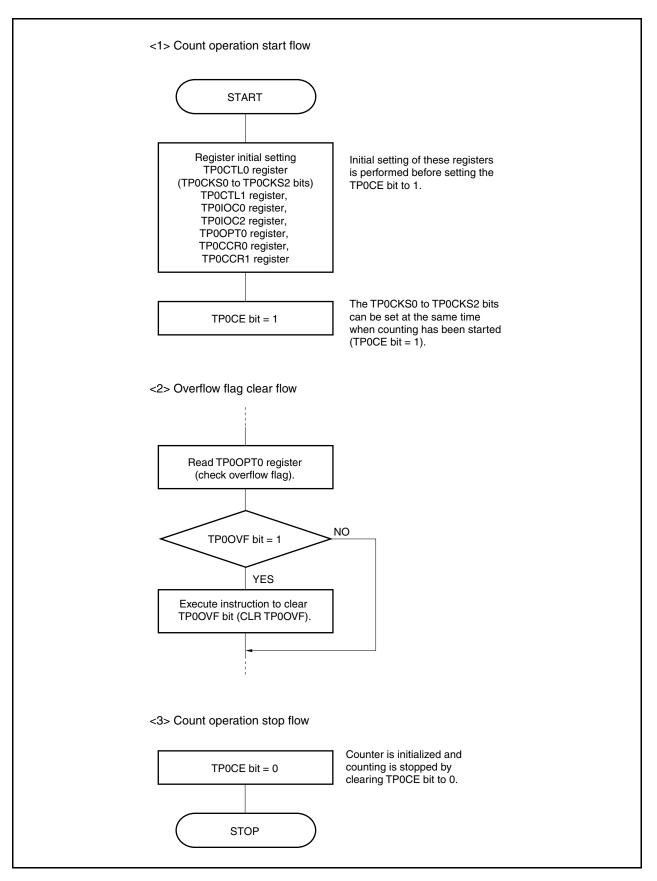

Figure 6-32. Software Processing Flow in Free-Running Timer Mode (Compare Function) (1/2)

(b) When using capture/compare register as capture register

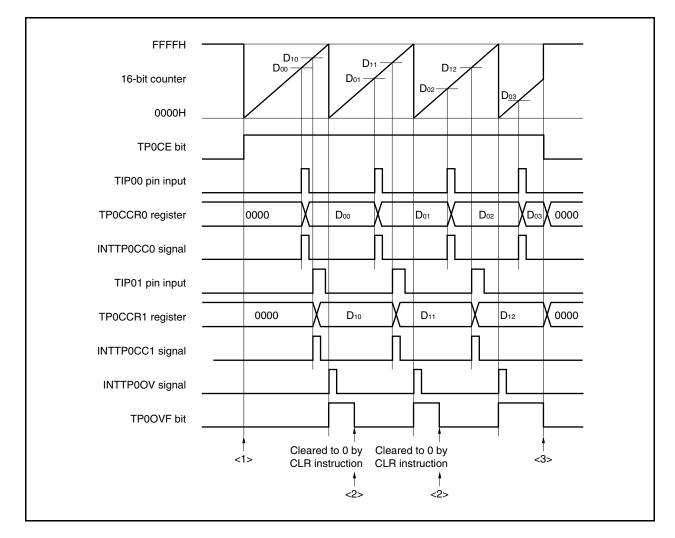

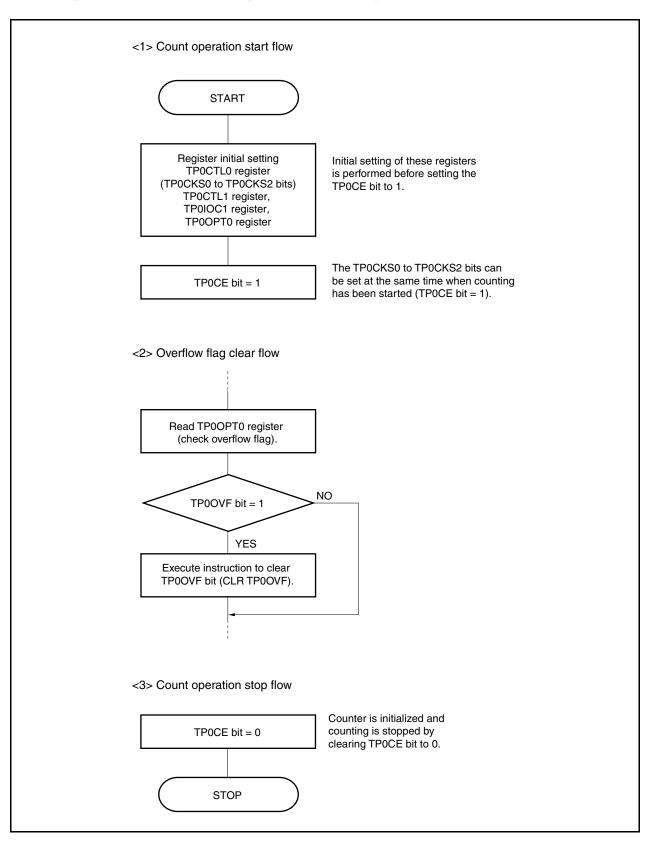

Figure 6-33. Software Processing Flow in Free-Running Timer Mode (Capture Function) (1/2)

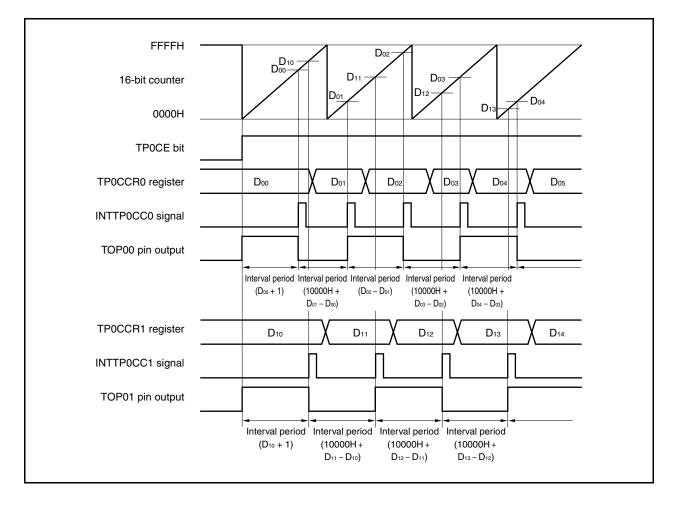

(2) Operation timing in free-running timer mode

(a) Interval operation with compare register

When 16-bit timer/event counter P is used as an interval timer with the TP0CCRa register used as a compare register, software processing is necessary for setting a comparison value to generate the next interrupt request signal each time the INTTP0CCa signal has been detected.

When performing an interval operation in the free-running timer mode, two intervals can be set with one channel.

To perform the interval operation, the value of the corresponding TP0CCRa register must be re-set in the interrupt servicing that is executed when the INTTP0CCa signal is detected.

The set value for re-setting the TP0CCRa register can be calculated by the following expression, where "Da" is the interval period.

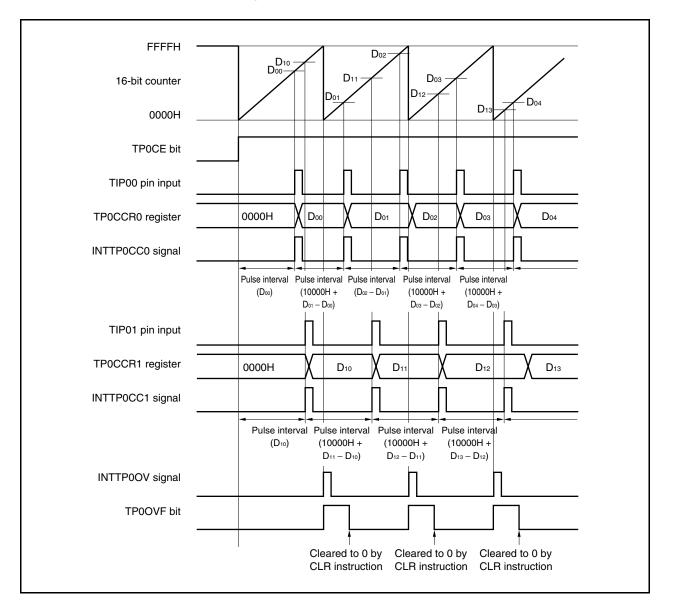

Compare register default value: Da - 1

Value set to compare register second and subsequent time: Previous set value + Da

(If the calculation result is greater than FFFFH, subtract 10000H from the result and set this value to the register.)

(b) Pulse width measurement with capture register

When pulse width measurement is performed with the TP0CCRa register used as a capture register, software processing is necessary for reading the capture register each time the INTTP0CCa signal has been detected and for calculating an interval.

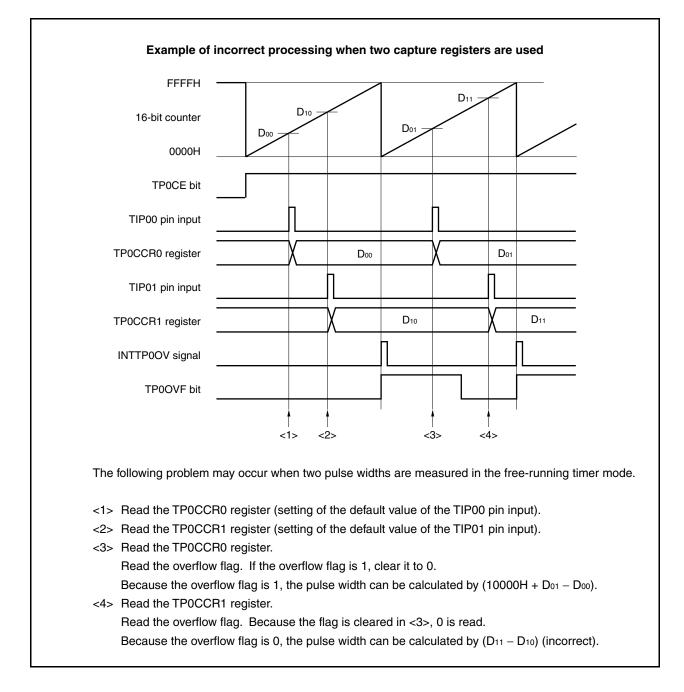

When executing pulse width measurement in the free-running timer mode, two pulse widths can be measured with one channel.

To measure a pulse width, the pulse width can be calculated by reading the value of the TP0CCRa register in synchronization with the INTTP0CCa signal, and calculating the difference between the read value and the previously read value.

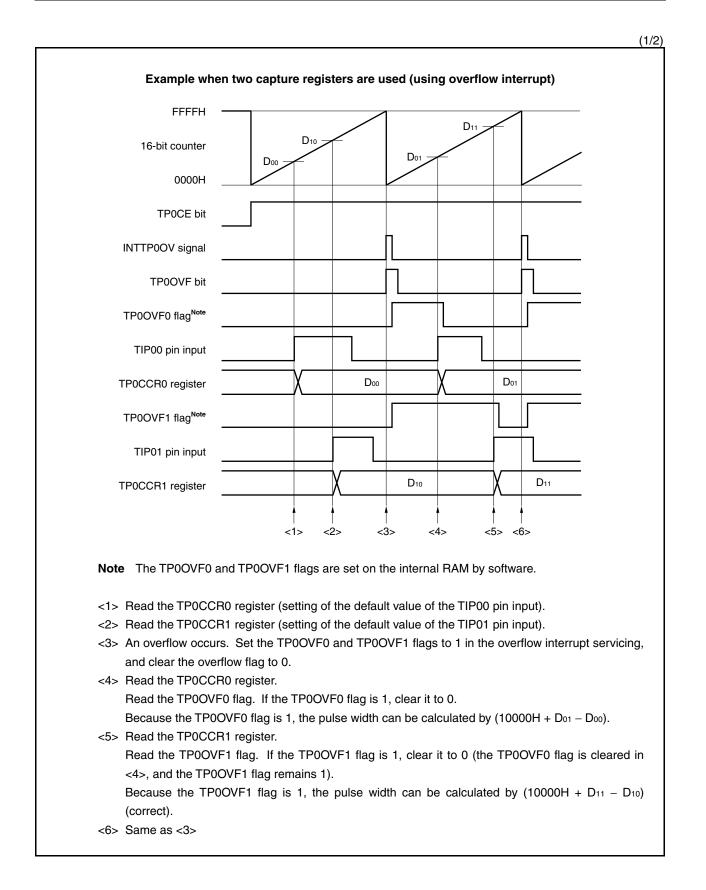

(c) Processing of overflow when two capture registers are used

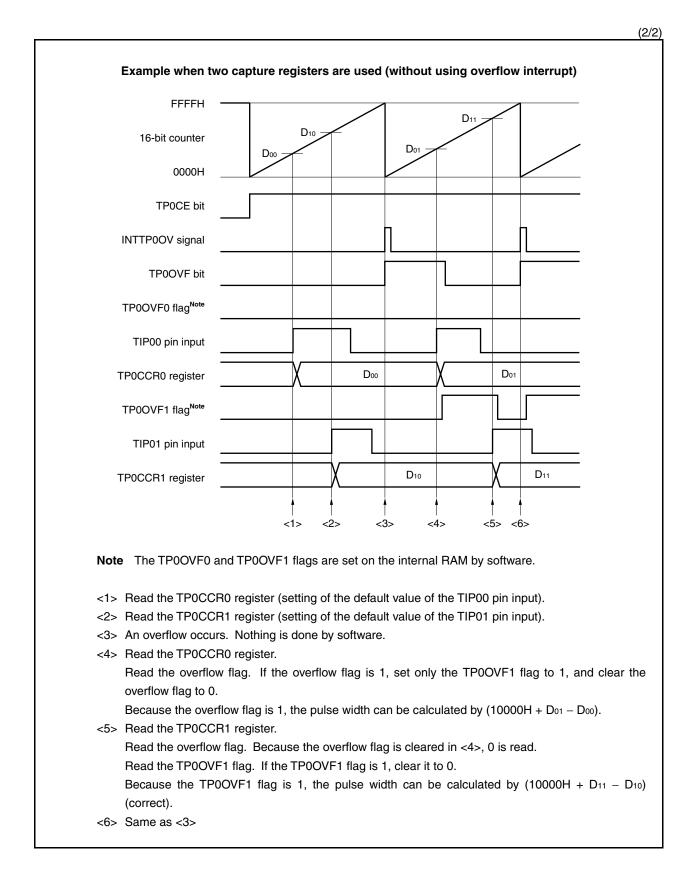

Care must be exercised in processing the overflow flag when two capture registers are used. First, an example of incorrect processing is shown below.

When two capture registers are used, and if the overflow flag is cleared to 0 by one capture register, the other capture register may not obtain the correct pulse width.

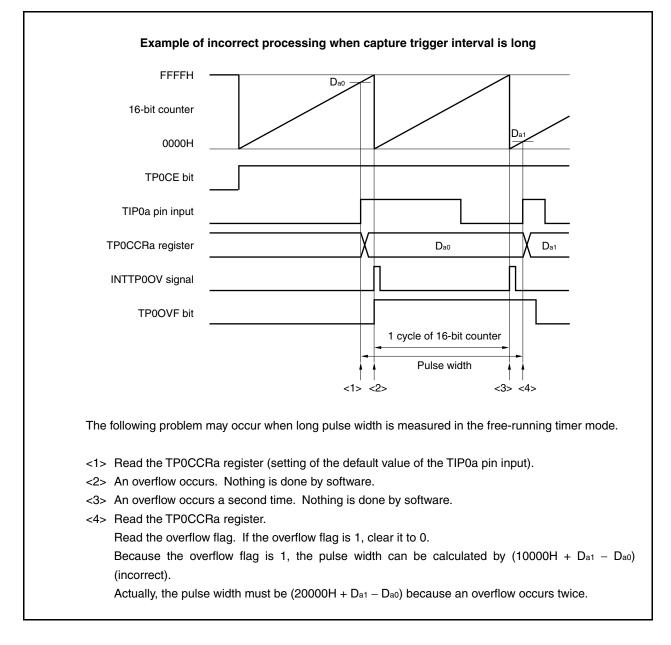

Use software when using two capture registers. An example of how to use software is shown below.

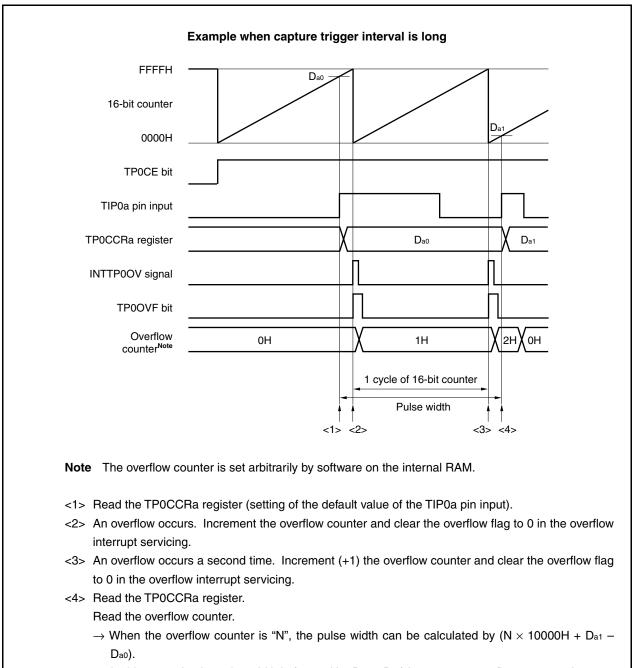

(d) Processing of overflow if capture trigger interval is long

If the pulse width is greater than one cycle of the 16-bit counter, care must be exercised because an overflow may occur more than once from the first capture trigger to the next. First, an example of incorrect processing is shown below.

If an overflow occurs twice or more when the capture trigger interval is long, the correct pulse width may not be obtained.

If the capture trigger interval is long, slow the count clock to lengthen one cycle of the 16-bit counter, or use software. An example of how to use software is shown next.

In this example, the pulse width is $(20000H + D_{a1} - D_{a0})$ because an overflow occurs twice. Clear the overflow counter (0H).

(e) Clearing overflow flag

The overflow flag can be cleared to 0 by clearing the TP0OVF bit to 0 with the CLR instruction and by writing 8-bit data (bit 0 is 0) to the TP0OPT0 register. To accurately detect an overflow, read the TP0OVF bit when it is 1, and then clear the overflow flag by using a bit manipulation instruction.

(i) Operation to write 0 (without conflict with setting)	(iii) Operation to clear to 0 (without conflict with setting)
Overflow set signal 0 write signal Overflow flag (TPOOVF bit)	Overflow set signal 0 write signal Register access signal Read Write Overflow flag (TPOOVF bit)
(ii) Operation to write 0 (conflict with setting)	(iv) Operation to clear to 0 (conflict with setting)
Overflow set signal 0 write signal Overflow flag (TP0OVF bit)	Overflow set signal

To clear the overflow flag to 0, read the overflow flag to check if it is set to 1, and clear it with the CLR instruction. If 0 is written to the overflow flag without checking if the flag is 1, the set information of overflow may be erased by writing 0 ((ii) in the above chart). Therefore, software may judge that no overflow has occurred even when an overflow actually has occurred.

If execution of the CLR instruction conflicts with occurrence of an overflow when the overflow flag is cleared to 0 with the CLR instruction, the overflow flag remains set even after execution of the clear instruction.

6.5.7 Pulse width measurement mode (TP0MD2 to TP0MD0 bits = 110)

In the pulse width measurement mode, 16-bit timer/event counter P starts counting when the TP0CTL0.TP0CE bit is set to 1. Each time the valid edge input to the TIP0a pin has been detected, the count value of the 16-bit counter is stored in the TP0CCRa register, and the 16-bit counter is cleared to 0000H.

The interval of the valid edge can be measured by reading the TP0CCRa register after a capture interrupt request signal (INTTP0CCa) occurs.

Select either the TIP00 or TIP01 pin as the capture trigger input pin. Specify "No edge detected" by using the TP0IOC1 register for the unused pins.

When an external clock is used as the count clock, measure the pulse width of the TIP01 pin because the external clock is fixed to the TIP00 pin. At this time, clear the TP0IOC1.TP0IS1 and TP0IOC1.TP0IS0 bits to 00 (capture trigger input (TIP00 pin): No edge detected).

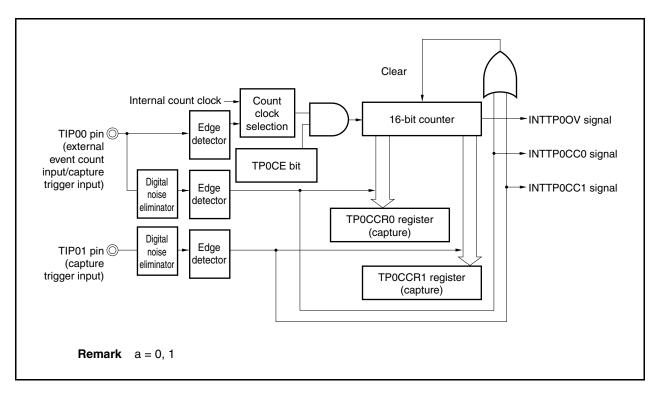

Figure 6-34. Configuration in Pulse Width Measurement Mode

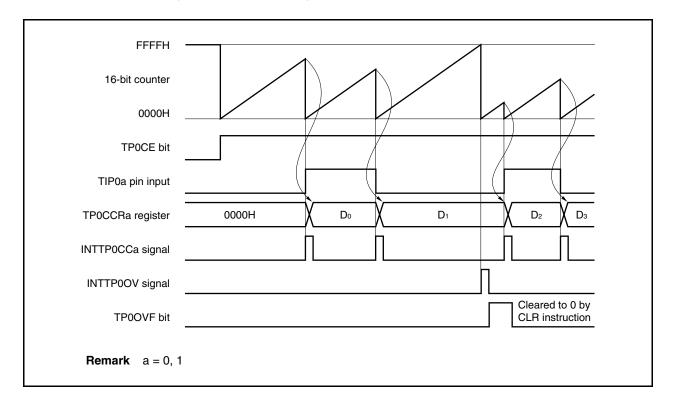

Figure 6-35. Basic Timing in Pulse Width Measurement Mode

When the TP0CE bit is set to 1, the 16-bit counter starts counting. When the valid edge input to the TIP0a pin is later detected, the count value of the 16-bit counter is stored in the TP0CCRa register, the 16-bit counter is cleared to 0000H, and a capture interrupt request signal (INTTP0CCa) is generated.

The pulse width is calculated as follows.

<R> Pulse width = Captured value × Count clock cycle

If the valid edge is not input to the TIP0a pin even when the 16-bit counter counted up to FFFFH, an overflow interrupt request signal (INTTPOOV) is generated at the next count clock, and the counter is cleared to 0000H and continues counting. At this time, the overflow flag (TP0OPT0.TP0OVF bit) is also set to 1. Clear the overflow flag to 0 by executing the CLR instruction via software.

If the overflow flag is set to 1, the pulse width can be calculated as follows.

<R> Pulse width = (10000H × TP00VF bit set (1) count + Captured value) × Count clock cycle

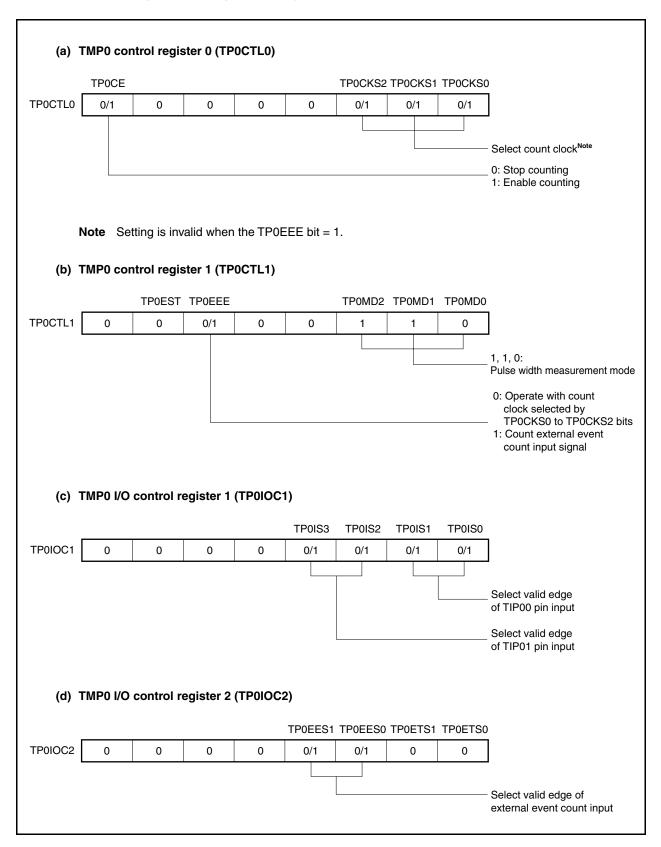

Figure 6-36. Register Setting in Pulse Width Measurement Mode (1/2)

Figure 6-36. Register Setting in Pulse Width Measurement Mode (2/2)

(1) Operation flow in pulse width measurement mode

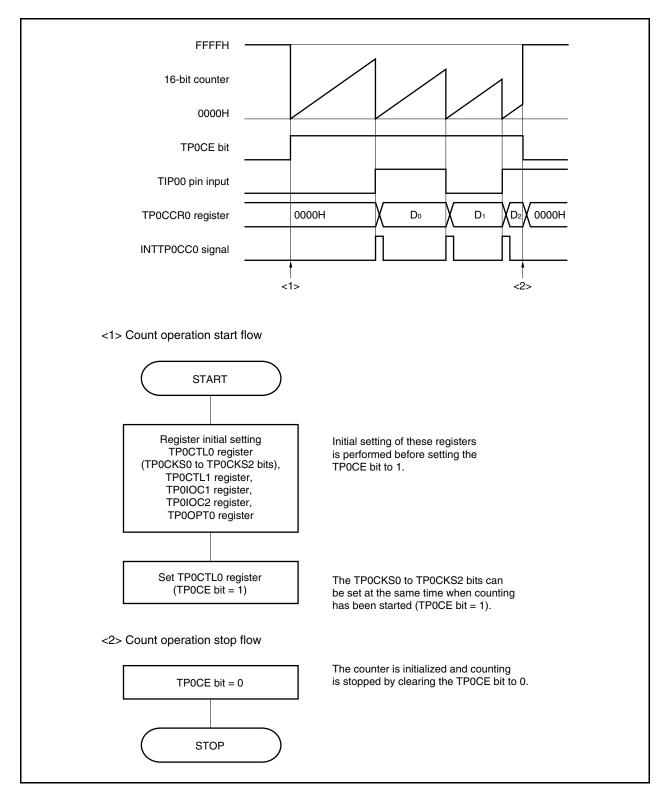

Figure 6-37. Software Processing Flow in Pulse Width Measurement Mode

(2) Operation timing in pulse width measurement mode

(a) Clearing overflow flag

The overflow flag can be cleared to 0 by clearing the TP0OVF bit to 0 with the CLR instruction and by writing 8-bit data (bit 0 is 0) to the TP0OPT0 register. To accurately detect an overflow, read the TP0OVF bit when it is 1, and then clear the overflow flag by using a bit manipulation instruction.

(i) Operation to write 0 (without conflict with setting)	(iii) Operation to clear to 0 (without conflict with setting)
Overflow set signal 0 write signal Overflow flag (TP0OVF bit)	Overflow set signal 0 write signal Register access signal Read Write Overflow flag (TP0OVF bit)
(ii) Operation to write 0 (conflict with setting)	(iv) Operation to clear to 0 (conflict with setting)
Overflow set signal 0 write signal Overflow flag (TP0OVF bit)	Overflow set signal 0 write signal Register access signal Overflow flag (TPOOVF bit)

To clear the overflow flag to 0, read the overflow flag to check if it is set to 1, and clear it with the CLR instruction. If 0 is written to the overflow flag without checking if the flag is 1, the set information of overflow may be erased by writing 0 ((ii) in the above chart). Therefore, software may judge that no overflow has occurred even when an overflow actually has occurred.

If execution of the CLR instruction conflicts with occurrence of an overflow when the overflow flag is cleared to 0 with the CLR instruction, the overflow flag remains set even after execution of the clear instruction.

6.5.8 Timer output operations

The following table shows the operations and output levels of the TOP00 and TOP01 pins.

Operation Mode	TOP01 Pin	TOP00 Pin
Interval timer mode	Square wave output	
External event count mode	Square wave output	_
External trigger pulse output mode	External trigger pulse output	Square wave output
One-shot pulse output mode	One-shot pulse output	
PWM output mode	PWM output	
Free-running timer mode	Square wave output (only when con	npare function is used)
Pulse width measurement mode		_

		1	High level immediately before counting, low level after counting is started

Remark a = 0, 1

6.6 Eliminating Noise on Capture Trigger Input Pin (TIP0a)

The TIP0a pin has a digital noise eliminator.

However, this circuit is valid only when the pin is used as a capture trigger input pin; it is invalid when the pin is used as an external event count input pin or external trigger input pin.

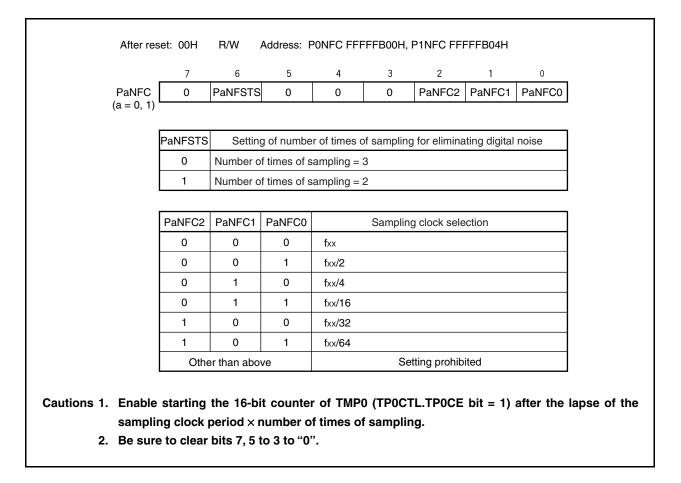

Digital noise can be eliminated by specifying the alternate function of the TIP0a pin using the PMC3, PFC3, and PFCE3 registers.

The number of times of sampling can be selected from three or two by using the PaNFC.PaNFSTS bit. The sampling clock can be selected from fxx, fxx/2, fxx/4, fxx/16, fxx/32, or fxx/64, by using the PaNFC.PaNFC2 to PaNFC.PaNFC0 bits.

(1) TIP0a noise elimination control register (PaNFC)

This register is used to select the sampling clock and the number of times of sampling for eliminating digital noise.

This register can be read or written in 8-bit or 1-bit units. Reset input clears this register to 00H.

<Setting procedure>

- <1> Select the number of times of sampling and the sampling clock by using the PaNFC register.
- <2> Select the alternate function (of the TIP0a pin) by using the PMC3, PFC3, and PFCE3 registers.
- <3> Set the operating mode of TMP0 (such as the capture mode or the valid edge of the capture trigger).
- <4> Enable the TMP0 count operation.

<Noise elimination width>

The digital noise elimination width (tw_{TIPa}) is as follows, where T is the sampling clock period and M is the number of times of sampling.

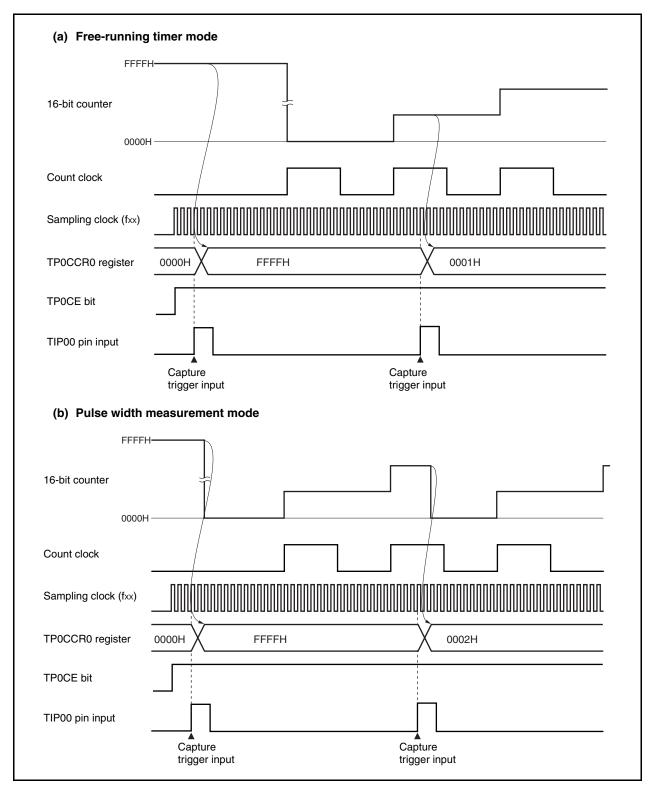

- twTIPa < (M 1)T: Accurately eliminated as noise
- $(M 1)T \le t_{WTIPa} < MT$: Eliminated as noise or detected as valid edge
- twTIPa ≥ MT: Accurately detected as valid edge

Therefore, a pulse width of MT or longer must be input so that the valid edge of the capture trigger input can be accurately detected.

6.7 Cautions

(1) Capture operation

When the capture operation is used and fxx/8, fxx/16, fxx/32, fxx/64, fxx/128, or the external event count (TP0CLT1.TP0EEE bit = 1) is selected as the count clock, FFFFH, not 0000H, may be captured in the TP0CCRn register if the capture trigger is input immediately after the TP0CE bit is set to 1.

CHAPTER 7 16-BIT TIMER/EVENT COUNTER 0

In the V850ES/KE1, one channel of 16-bit timer/event counter 0 is provided.

7.1 Functions

16-bit timer/event counter 01 has the following functions.

(1) Interval timer

16-bit timer/event counter 01 generates an interrupt request at the preset time interval.

(2) Square-wave output

16-bit timer/event counter 01 can output a square wave with any selected frequency.

(3) External event counter

16-bit timer/event counter 01 can measure the number of pulses of an externally input signal.

(4) One-shot pulse output (16-bit timer/event counters 00 and 01 only)

16-bit timer/event counter 01 can output a one-shot pulse whose output pulse width can be set freely.

(5) PPG output

16-bit timer/event counter 01 can output a rectangular wave whose frequency and output pulse width can be set freely.

(6) Pulse width measurement

16-bit timer/event counter 01 can measure the pulse width of an externally input signal.

<R>

7.2 Configuration

16-bit timer/event counter 01 includes the following hardware.

Item	Configuration
Timer/counter	16-bit timer counter 01×1 (TM01)
Register	16-bit timer capture/compare registers: 16-bit × 2 (CR010, CR011)
Timer input	2 (TI010, TI011 pins)
Timer output	1 (TO01 pin), output controller
Control registers ^{Note}	16-bit timer mode control register 01 (TMC01) Capture/compare control register 01 (CRC01)
	16-bit timer output control register 01 (TOC01)
	Prescaler mode register 01 (PRM01)

Table 7-1. Configuration of 16-bit Timer/Event Counter 01

Note To use the TI010, TI011, and TO01 pin functions, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.

The block diagram is shown below.

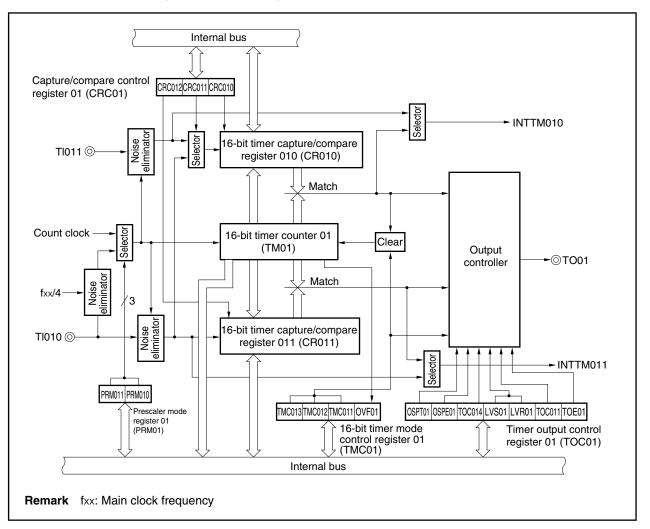

Figure 7-1. Block Diagram of 16-bit Timer/Event Counter 01

(1) 16-bit timer counter 01 (TM01)

The TM01 register is a 16-bit read-only register that counts count pulses.

The counter is incremented in synchronization with the rising edge of the count clock.

15 14 13 12 11 10 9 8 7 6 5 4		
	32	1 0
TM01		

The count value of the TM01 register can be read by reading the TM01 register when the values of the TMC01.TMC013 and TMC01.TMC012 bits are other than 00. The value of the TM01 register is 0000H if it is read when the TMC013 and TMC012 bits are 00.

The count value is reset to 0000H in the following cases.

- At reset signal generation
- If the TMC013 and TMC012 bits are cleared to 00
- If the valid edge is input to the TI010 pin in the mode in which the clear & start occurs when inputting the valid edge to the TI010 pin
- If the TM01 register and the CR010 register match in the mode in which the clear & start occurs when the TM01 register and the CR010 register match
- If the TOC01.OSPT01 bit is set to 1 in one-shot pulse output mode or if a valid edge is input to the TI010 pin.

(2) 16-bit timer capture/compare register 010 (CR010), 16-bit timer capture/compare register 011 (CR011)

The CR010 and CR011 registers are 16-bit registers that are used with a capture function or comparison function selected by using the CRC01 register.

Change of the value of the CR010 register while the timer is operating (TMC01.TMC013 and TMC01.TMC012 bits = other than 00) is prohibited.

The value of the CR011 register can be changed during operation if the value has been set in a specific way. For details, see **7.5.1 Rewriting CR011 register during TM01 operation**.

These registers can be read or written in 16-bit units.

Reset sets these registers to 0000H.

(a) 16-bit timer capture/compare register 010 (CR010)

15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 CR010 <	After res	set: 0	000H	F	R/W	Ad	dress	FFF	FF61	2H							
CR010		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CR010																

(i) When the CR010 register is used as a compare register

The value set in the CR010 register is constantly compared with the TM01 register count value, and an interrupt request signal (INTTM010) is generated if they match. The value is held until the CR010 register is rewritten.

(ii) When the CR010 register is used as a capture register

The count value of the TM01 register is captured to the CR010 register when a capture trigger is input. As the capture trigger, an edge of a phase reverse to that of the TI010 pin or the valid edge of the TI011 pin can be selected by using the CRC01 or PRM01 register.

(b) 16-bit timer capture/compare register 011 (CR011)

After res	set: 0	000H	F	R/W	Ad	dress	FFF	FF61	4H								
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
CR011																	

(i) When using the CR011 register as a compare register

The value set to the CR011 register and the count value of the TM01 register are always compared and when these values match, an interrupt request signal (INTTM011) is generated.

(ii) When using the CR011 register as a capture register

The TM01 register count value is captured to the CR011 register by inputting a capture trigger. The valid edge of the TI010 pin can be selected as the capture trigger. The valid edge of the TI010 pin is set with the PRM01 register.

- Cautions 1. When the P35 pin is used as the valid edge of TI010, it cannot be used as timer output (T001). Moreover, when the P35 pin is used as TO01, it cannot be used as the valid edge of TI010.
 - 2. If clearing of the TMC013 and TMC012 bits to 00 and input of the capture trigger conflict, then the captured data is undefined.
 - 3. To change the mode from the capture mode to the comparison mode, first clear the TMC013 and TMC012 bits to 00, and then change the setting.

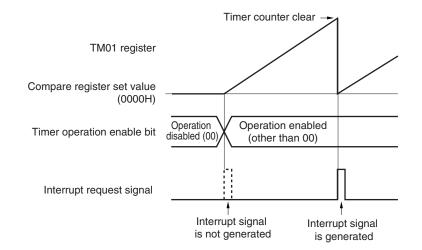

A value that has been once captured remains stored in the CR010 and CR011 registers unless the device is reset. If the mode has been changed to the comparison mode, be sure to set a comparison value.

(c) Setting range when used as compare register

When the CR010 or CR011 register is used as a compare register, set it as shown below.

Operation	CR010 Register	CR011 Register
 Operation as interval timer Operation as square-wave output Operation as external event counter 	0000H < N ≤ FFFFH	$0000H^{Note} \le M \le FFFFH$ Normally, this setting is not used. Mask the match interrupt signal (INTTM011).
 Operation in the clear & start mode entered by TI010 pin valid edge input Operation as free-running timer 	$0000H^{Note} \le N \le FFFFH$	$0000H^{Note} \le M \le FFFFH$
Operation as PPG output	$M < N \le FFFFH$	$0000 H^{\text{Note}} \leq M < N$
Operation as one-shot pulse output	$0000H^{\text{Note}} \leq N \leq \text{FFFFH} \text{ (N} \neq \text{M)}$	$0000H^{Note} \leq M \leq FFFFH \ (M \neq N)$

- **Note** When 0000H is set, a match interrupt immediately after the timer operation does not occur and timer output is not changed, and the first match timing is as follows. A match interrupt occurs at the timing when the timer counter (TM01 register) is changed from 0000H to 0001H.
 - When the timer counter is cleared due to overflow
 - When the timer counter is cleared due to TI010 pin valid edge (when clear & start mode is entered by TI010 pin valid edge input)
 - When the timer counter is cleared due to compare match (when clear & start mode is entered by match between TM01 and CR010 (CR010 = other than 0000H, CR011 = 0000H))

Remarks 1. N: CR010 register set value

- M: CR011 register set value
- 2. For details of operation enable bits (TMC01.TMC013, TMC01.TMC012 bits), refer to 7.3 (1) 16-bit timer mode control register 01 (TMC01).

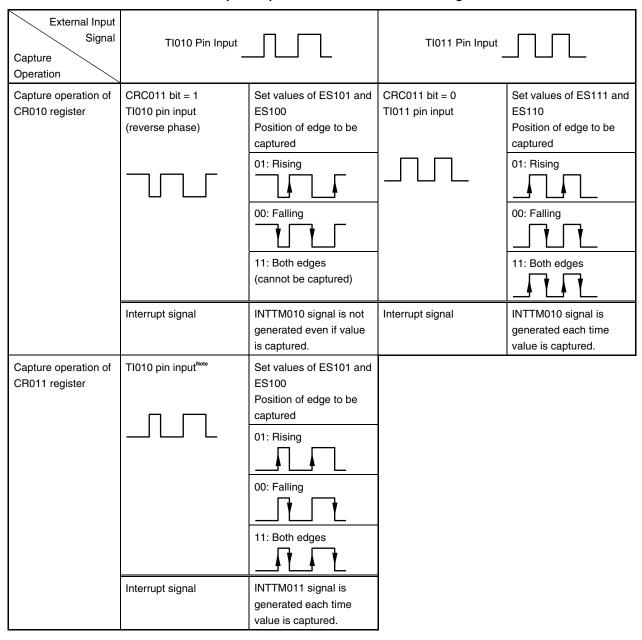

Table 7-2. Capture Operation of CR010 and CR011 Registers

Note The capture operation of the CR011 register is not affected by the setting of the CRC011 bit.

- Caution To capture the count value of the TM01 register to the CR010 register by using the phase reverse to that input to the Tl010 pin, the interrupt request signal (INTTM010) is not generated after the value has been captured. If the valid edge is detected on the Tl011 pin during this operation, the capture operation is not performed but the INTTM010 signal is generated as an external interrupt signal. To not use the external interrupt, mask the INTTM010 signal.
- Remark CRC011: See 7.3 (2) Capture/compare control register 01 (CRC01). ES111, ES110, ES101, ES100: See 7.3 (4) Prescaler mode register 01 (PRM01).

7.3 Registers

Registers used to control 16-bit timer/event counter 01 are shown below.

- 16-bit timer mode control register 01 (TMC01)
- Capture/compare control register 01 (CRC01)
- 16-bit timer output control register 01 (TOC01)
- Prescaler mode register 01 (PRM01)

Remark To use the TI010, TI011, and TO01 pin functions, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.

(1) 16-bit timer mode control register 01 (TMC01)

TMC01 is an 8-bit register that sets the 16-bit timer/event counter 01 operation mode, the TM01 register clear mode, and output timing, and detects an overflow.

Rewriting TMC01 is prohibited during operation (when the TMC013 and TMC012 bits = other than 00). However, it can be changed when the TMC013 and TMC012 bits are cleared to 00 (stopping operation) and when the OVF01 bit is cleared to 0.

This register can be read or written in 8-bit or 1-bit units.

Reset sets this register to 00H.

- Cautions 1. 16-bit timer/event counter 01 starts operation at the moment the TMC013 and TMC012 bits are set to values other than 00 (operation stop mode), respectively. Set the TMC013 and TMC012 bits to 00 to stop the operation.
 - When the main clock is stopped and the CPU is operating on the subclock, do not access the TMC01 register using an access method that causes a wait.
 For details, refer to 3.4.8 (1) (b).
 - 3. Be sure to clear bits 7 to 4 and 1 to "0".

	7	6	5	4	3	2	1	<0>

	Clear (0)	Clear (0) Clears OVF01 to 0 or TMC01.TMC013 and TMC01.TMC012 = 00													
	Set (1)	Overflow occurs.													
	OVF01 is set to 1 when the value of TM01 changes from FFFFH to 0000H in all the operation modes (free-running timer mode, clear & start mode entered by Tl010 pin valid edge input, and clear & start mode entered upon a match between TM01 and CR010). It can also be set to 1 by writing 1 to the OVF01 bit.														
ote The T		d edge is set	by the PRM	101 register											

(2) Capture/compare control register 01 (CRC01)

The CRC01 register is the register that controls the operation of the CR010 and CR011 registers. Changing the value of the CRC01 register is prohibited during operation (when the TMC01.TMC013 and TMC01.TMC012 bits = other than 00).

This register can be read or written in 8-bit or 1-bit units.

Reset sets this register to 00H.

	7	6	5	4	3	2	1	0

(3) 16-bit timer output control register 01 (TOC01)

The TOC01 register is an 8-bit register that controls the TO01 pin output.

The TOC01 register can be rewritten while only the OSPT01 bit is operating (when the TMC01.TMC013 and TMC01.TMC012 bits = other than 00). Rewriting the other bits is prohibited during operation.

However, TOC014 can be rewritten during timer operation as a means to rewrite the CR011 register (see **7.5.1 Rewriting CR011 register during TM01 operation**).

This register can be read or written in 8-bit or 1-bit units. Reset sets this register to 00H.

Cautions 1. Be sure to set the TOC01 register using the following procedure.

- <1> Set the TOC014 and TOC011 bits to 1.
- <2> Set only the TOE01 bit to 1.
- <3> Set either the LVS01 bit or LVR01 bit to 1.
- 2. Restrictions are applied to TM01 in which the timer input and output share the same pin. For details, refer to 7.6 (1) Alternate functions of TI010/TO01 pins.

	7	<6>	<5>	4	<3>	<2>	1	<0>

(2/2)

LVS01	LVR01	VR01 Setting of TO01 pin output status				
0 0		No change				
0 1		Initial value of TO01 pin output is low level (TO01 pin output is cleared to 0				
1 0		Initial value of TO01 pin output is high level (TO01 pin output is set to 1).				
1	1	Setting prohibited				
 The LVS01 and LVR01 bits can be used to set the initial value of the output level of the TO01 pin. the initial value does not have to be set, leave the LVS01 and LVR01 bits as 00. Be sure to set the LVS01 and LVR01 bits when TOE01 = 1. The LVS01, LVR01, and TOE01 bits being simultaneously set to 1 is prohibited. The LVS01 and LVR01 bits are trigger bits. By setting these bits to 1, the initial value of the output level of the TO01 pin can be set. Even if these bits are cleared to 0, output of the TO01 pin is not affected. The values of the LVS01 and LVR01 bits are always 0 when they are read. For how to set the LVS01 and LVR01 bits, see 7.5.2 Setting LVS01 and LVR01 bits. 						
TOC011	TO01 pin output control on match between CR010 and TM01 registers					
0	Disables inv	Disables inversion operation				
1	Enables inversion operation					
The interrup	t signal (INTT	M010) is generated even when the TOC011 bit = 0.				
TOE01	TO01 pin output control					
0	Disables output (TO01 pin output fixed to low level)					
	Enables output					

(4) Prescaler mode register 01 (PRM01)

The PRM01 register is the register that sets the TM01 register count clock and TI010 and TI011 pin input valid edges.

Rewriting the PRM01 register is prohibited during operation (when the TMC01.TMC013 and TMC01.TMC012 bits = other than 00).

This register can be read or written in 8-bit or 1-bit units. Reset sets this register to 00H.

- Cautions 1. Do not apply the following setting when setting the PRM011 and PRM010 bits to 11 (to specify the valid edge of the TI010 pin as a count clock).
 - Clear & start mode entered by the TI010 pin valid edge
 - Setting the TI010 pin as a capture trigger
 - 2. If the operation of the 16-bit timer/event counter 01 is enabled when the TI010 or TI011 pin is at high level and when the valid edge of the TI010 or TI011 pin is specified to be the rising edge or both edges, the high level of the TI010 or TI011 pin is detected as a rising edge. Note this when the TI010 or TI011 pin is pulled up. However, the rising edge is not detected when the timer operation has been once stopped and is then enabled again.
 - 3. When the P35 pin is used as the valid edge of TI010, it cannot be used as timer output (T001). Moreover, when the P35 pin is used as timer output (T001), it cannot be used as the valid edge of TI010.

After reset:		Addres			_			_		
	7	6	5	4	3	2	1	0		
PRM01	ES111	ES110	ES101	ES100	0	0 F	PRM011	PRM010		
	r									
	ES111	ES110	TI011 pin valid edge selection							
	0	0	Falling edge							
	0	1	Rising edge							
	1	0	Setting prohibited							
	1	1	Both falling and rising edges							
	ES101	ES100	TI010 pin valid edge selection							
	0	0	Falling edge							
	0	1	Rising edge							
	1	0	Setting prohibited							
	1	1	Both falling and rising edges							
	PRM011	PRM010	Count clock selection ^{Note 1}							
			Count Clo	ock	fxx = 20 MHz	fxx = 16 MH	Hz fx	< = 10 MHz		
	0	0	fxx		Setting prohibited	Setting prohib	oited	100 ns		
	0	1	fxx/4		200 ns	250 ns		400 ns		
	1	0	INTWT		_	_		_		
	1	1	Valid edge of T	1010 ^{Note 2}	_	_		_		

Notes 1. When the internal clock is selected, set so as to satisfy the following conditions:

 V_{DD} = 4.0 to 5.5 V: Count clock \leq 10 MHz

 V_{DD} = 2.7 to 4.0 V: Count clock $\leq 5~\text{MHz}$

2. The external clock requires a pulse longer than two cycles of the internal clock (fxx/4).

7.4 Operation

7.4.1 Interval timer operation

If the TMC01.TMC013 and TMC01.TMC012 bits are set to 11 (clear & start mode entered upon a match between the TM01 register and the CR010 register), the count operation is started in synchronization with the count clock.

When the value of the TM01 register later matches the value of the CR010 register, the TM01 register is cleared to 0000H and a match interrupt signal (INTTM010) is generated. This INTTM010 signal enables the TM01 register to operate as an interval timer.

Remarks 1. For the alternate-function pin settings, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.

2. For enabling the INTTM010 interrupt, refer to CHAPTER 17 INTERRUPT/EXCEPTION PROCESSING FUNCTION.

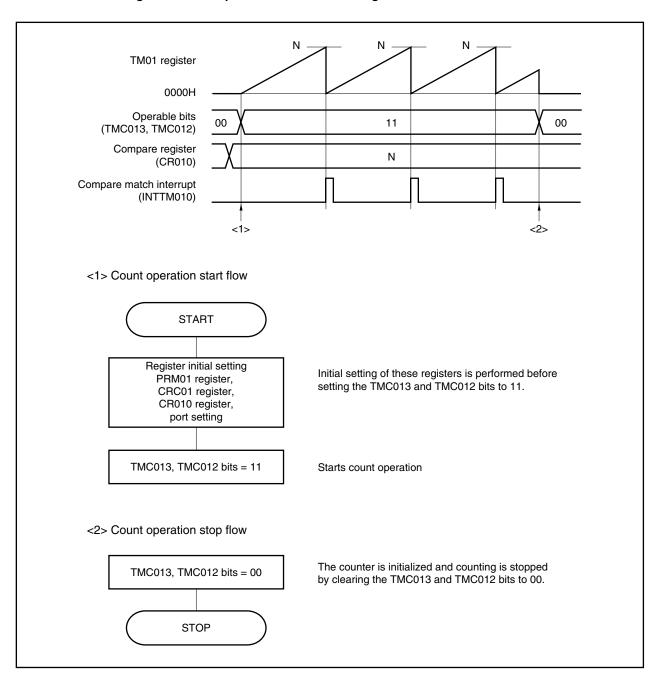

Figure 7-5. Example of Software Processing for Interval Timer Function

7.4.2 Square wave output operation

When 16-bit timer/event counter 01 operates as an interval timer (see **7.4.1**), a square wave can be output from the TO01 pin by setting the TOC01 register to 03H.

When the TMC01.TMC013 and TMC01.TMC012 bits are set to 11 (count clear & start mode entered upon a match between the TM01 register and the CR010 register), the counting operation is started in synchronization with the count clock.

When the value of the TM01 register later matches the value of the CR010 register, the TM01 register is cleared to 0000H, an interrupt signal (INTTM010) is generated, and output of the TO01 pin is inverted. This TO01 pin output that is inverted at fixed intervals enables TO01 to output a square wave.

- Remarks 1. For the alternate-function pin settings, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.
 - 2. For enabling the INTTM010 interrupt, refer to CHAPTER 17 INTERRUPT/EXCEPTION PROCESSING FUNCTION.
 - 3. Restrictions are applied to TM01. For details, refer to 7.6 (1) Alternate functions of TI010/TO01 pins.

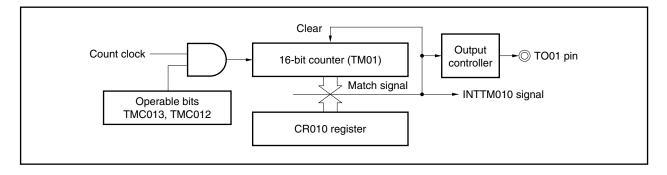

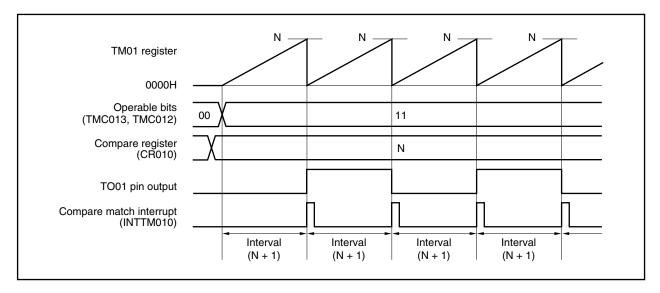

Figure 7-7. Basic Timing Example of Square Wave Output Operation

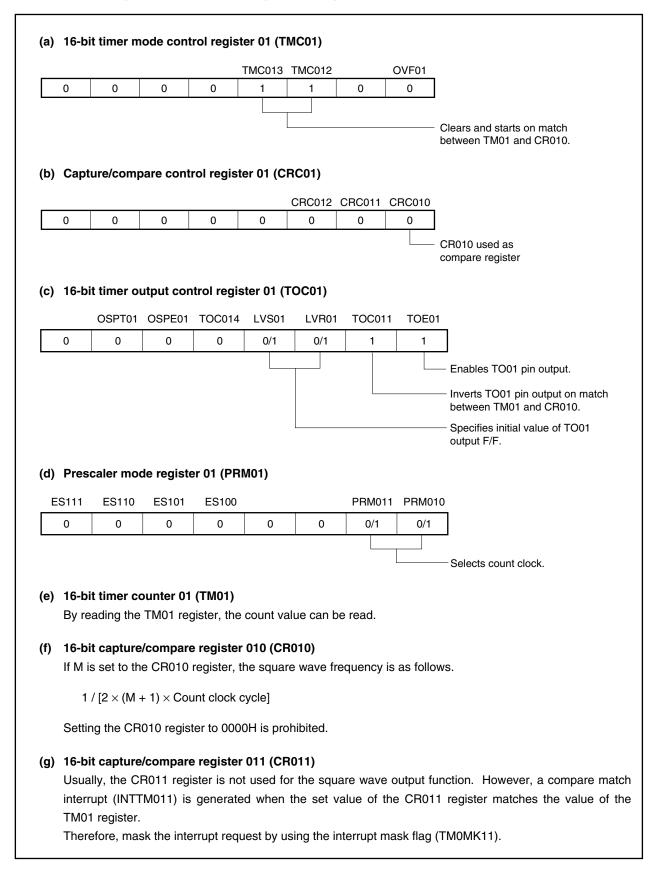

Figure 7-8. Example of Register Settings for Square Wave Output Operation

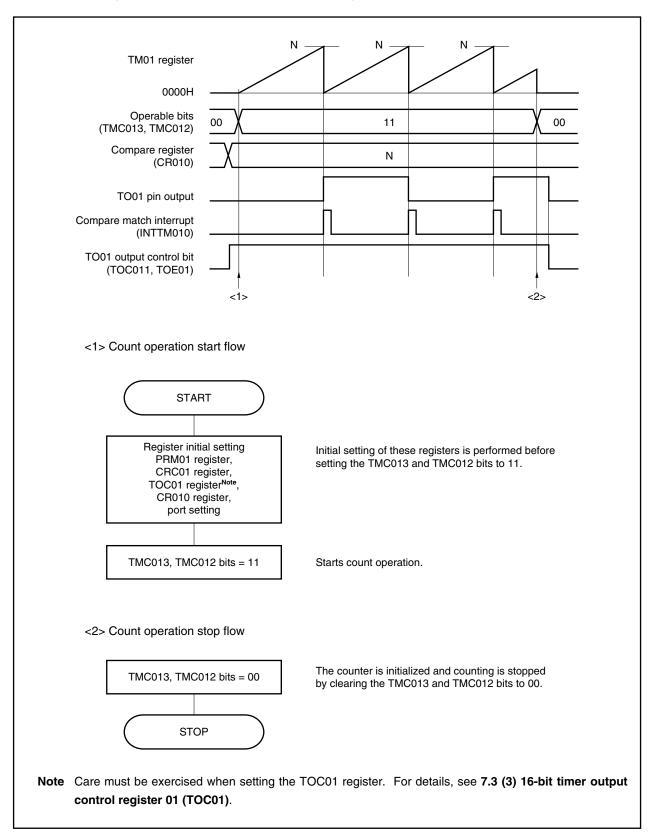

Figure 7-9. Example of Software Processing for Square Wave Output Function

7.4.3 External event counter operation

When the PRM01.PRM011 and PRM01.PRM010 bits are set to 11 (for counting up with the valid edge of the TI010 pin) and the TMC01.TMC013 and TMC01.TMC012 bits are set to 11, the valid edge of an external event input is counted, and a match interrupt signal indicating matching between the TM01 register and the CR010 register (INTTM010) is generated.

To input the external event, the TI010 pin is used. Therefore, the timer/event counter cannot be used as an external event counter in the clear & start mode entered by the TI010 pin valid edge input (when the TMC013 and TMC012 bits = 10).

The INTTM010 signal is generated with the following timing.

- Timing of generation of INTTM010 signal (second time or later)
 - = Number of times of detection of valid edge of external event input × (Set value of the CR010 register + 1)

However, the first match interrupt immediately after the timer/event counter has started operating is generated with the following timing.

• Number of times of detection of valid edge of external event input × (Set value of the CR010 register + 2)

To detect the valid edge, the signal input to the TI010 pin is sampled during the clock cycle of fxx/4. The valid edge is not detected until it is detected two times in a row. Therefore, a noise with a short pulse width can be eliminated.

- Remarks 1. For the alternate-function pin (TI010) settings, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.
 - 2. For enabling the INTTM010 interrupts, refer to CHAPTER 17 INTERRUPT/EXCEPTION PROCESSING FUNCTION.
 - 3. Restrictions are applied to TM01. For details, refer to 7.6 (1) Alternate functions of TI010/TO01 pins.

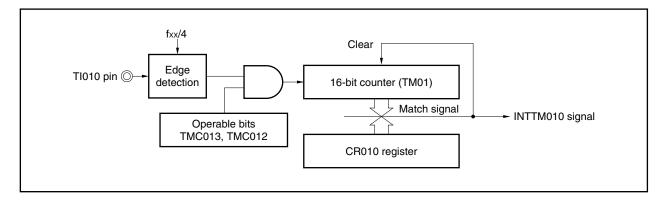

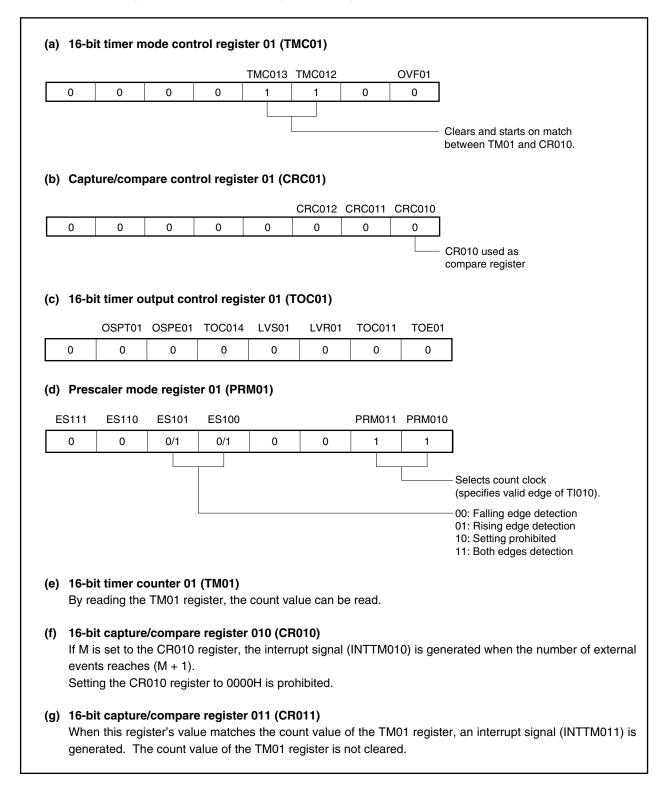

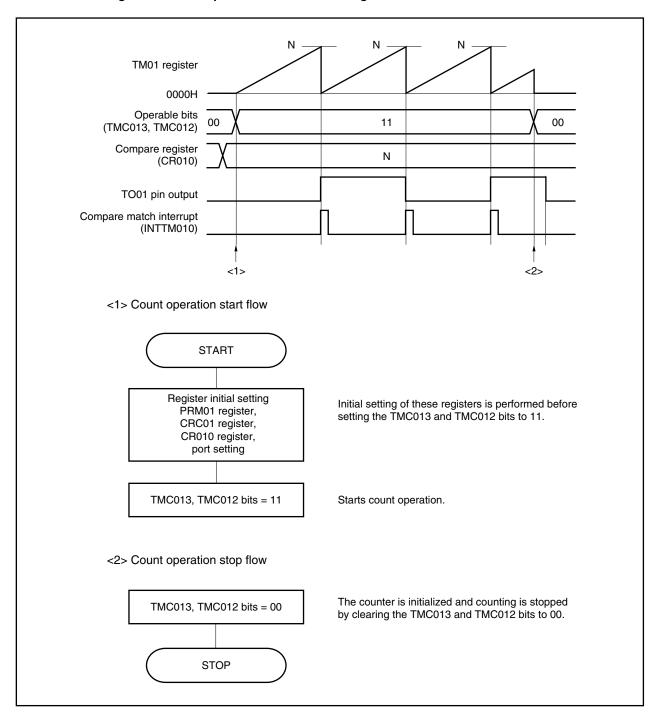

Figure 7-10. Block Diagram of External Event Counter Operation

Figure 7-11. Example of Register Settings in External Event Counter Mode

7.4.4 Operation in clear & start mode entered by TI010 pin valid edge input

When the TMC01.TMC013 and TMC01.TMC012 bits are set to 10 (clear & start mode entered by the TI010 pin valid edge input) and the count clock (set by the PRM01 register) is supplied to the timer/event counter, the TM01 register starts counting up. When the valid edge of the TI010 pin is detected during the counting operation, the TM01 register is cleared to 0000H and starts counting up again. If the valid edge of the TI010 pin is not detected, the TM01 register overflows and continues counting.

The valid edge of the TI010 pin is a cause to clear the TM01 register. Starting the counter is not controlled immediately after the start of the operation.

The CR010 and CR011 registers are used as compare registers and capture registers.

(a) When the CR010 and CR011 registers are used as compare registers

Signals INTTM010 and INTTM011 are generated when the value of the TM01 register matches the value of the CR010 and CR011 registers.

(b) When the CR010 and CR011 registers are used as capture registers

The count value of the TM01 register is captured to the CR010 register and the INTTM010 signal is generated when the valid edge is input to the TI011 pin (or when the phase reverse to that of the valid edge is input to the TI010 pin).

When the valid edge is input to the TI010 pin, the count value of the TM01 register is captured to the CR011 register and the INTTM011 signal is generated. As soon as the count value has been captured, the counter is cleared to 0000H.

- Cautions 1. Do not set the count clock as the valid edge of the TI010 pin (RPM01.PRM011 and RPM01.PRM010 bits = 11). When the PRM011 and PRM010 bits = 11, the TM01 register is cleared.
 - 2. Restrictions are applied to TM01 in which the timer input and output share the same pin. For details, refer to 7.6 (1) Alternate functions of TI010/T001 pins.
- Remarks 1. For the alternate-function pin (TI010) settings, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.
 - 2. For enabling the INTTM010 interrupt, refer to CHAPTER 17 INTERRUPT/EXCEPTION PROCESSING FUNCTION.

(1) Operation in clear & start mode entered by Tl010 pin valid edge input (CR010 register: compare register, CR011 register: compare register)

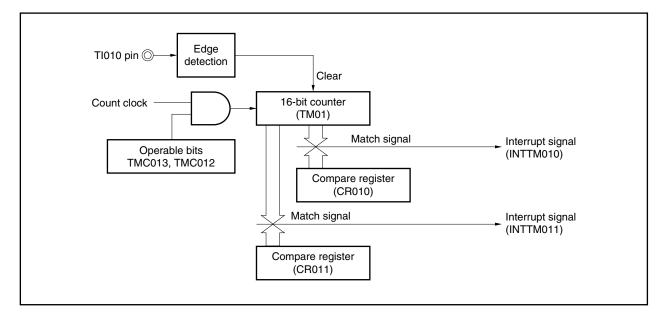

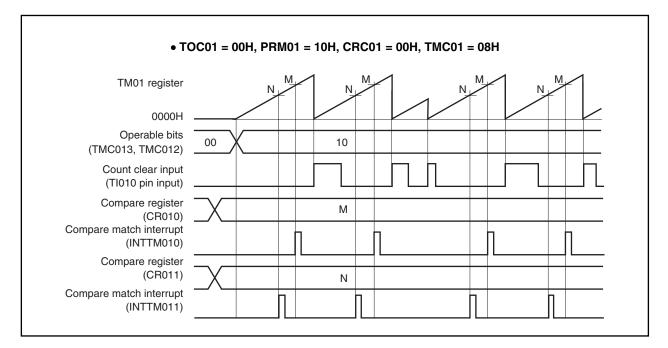

Figure 7-14. Timing Example of Clear & Start Mode Entered by TI010 Pin Valid Edge Input (CR010 Register: Compare Register, CR011 Register: Compare Register)

(2) Operation in clear & start mode entered by TI010 pin valid edge input (CR010 register: compare register, CR011 register: capture register)

> Figure 7-15. Block Diagram of Clear & Start Mode Entered by TI010 Pin Valid Edge Input (CR010 Register: Compare Register, CR011 Register: Capture Register)

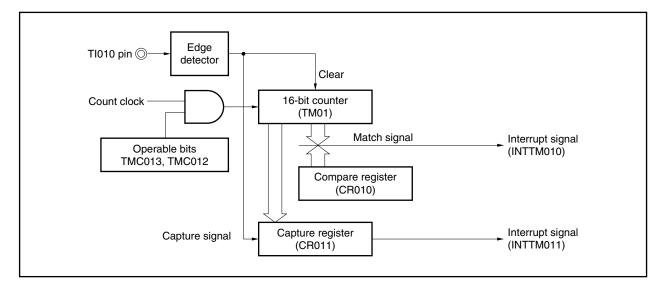

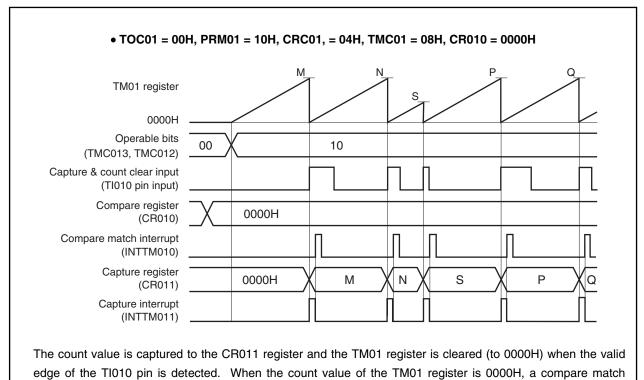

Figure 7-16. Timing Example of Clear & Start Mode Entered by TI010 Pin Valid Edge Input (CR010 Register: Compare Register, CR011 Register: Capture Register)

interrupt signal (INTTM010) is generated.

(3) Operation in clear & start mode entered by TI010 pin valid edge input (CR010 register: capture register, CR011 register: compare register)

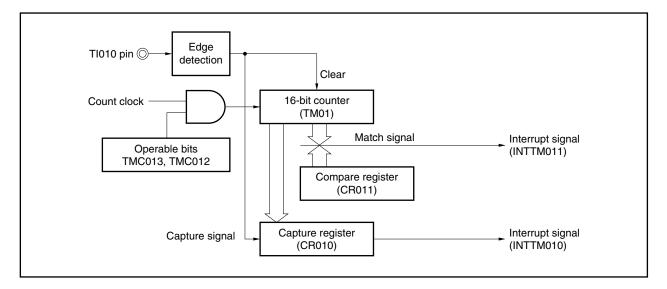

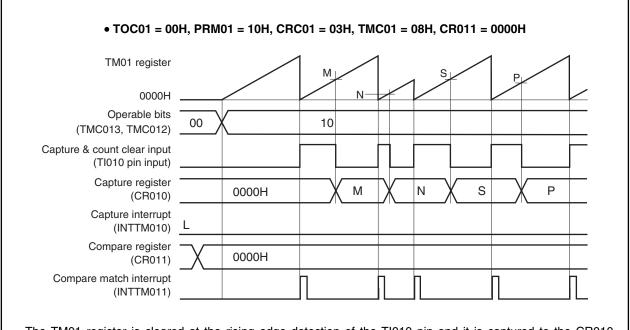

Figure 7-18. Timing Example of Clear & Start Mode Entered by TI010 Pin Valid Edge Input (CR010 Register: Capture Register, CR011 Register: Compare Register)

The TM01 register is cleared at the rising edge detection of the TI010 pin and it is captured to the CR010 register at the falling edge detection of the TI010 pin.

When the CRC01.CRC011 bit is set to 1, the count value of the TM01 register is captured to CR010 in the phase reverse to that of the signal input to the TI010 pin, but the capture interrupt signal (INTTM010) is not generated. However, the INTTM010 signal is generated when the valid edge of the TI011 pin is detected. Mask the INTTM010 signal when it is not used.

(4) Operation in clear & start mode entered by TI010 pin valid edge input (CR010 register: capture register, CR011 register: capture register)

Figure 7-19. Block Diagram of Clear & Start Mode Entered by TI010 Pin Valid Edge Input (CR010 Register: Capture Register, CR011 Register: Capture Register)

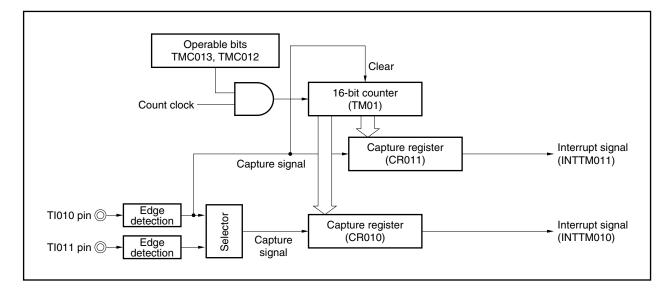

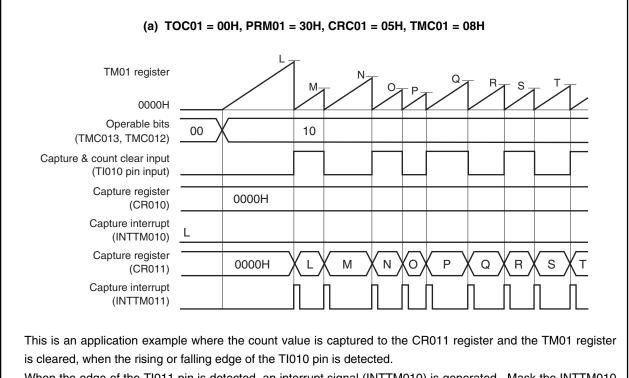

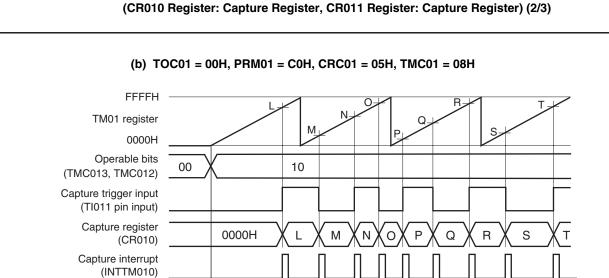

Figure 7-20. Timing Example of Clear & Start Mode Entered by TI010 Pin Valid Edge Input (CR010 Register: Capture Register, CR011 Register: Capture Register) (1/3)

When the edge of the TI011 pin is detected, an interrupt signal (INTTM010) is generated. Mask the INTTM010 signal when it is not used.

This is a timing example where an edge is not input to the TI010 pin, in an application where the count value is

Capture & count clear input

captured to the CR010 register when the rising or falling edge of the TI011 pin is detected.

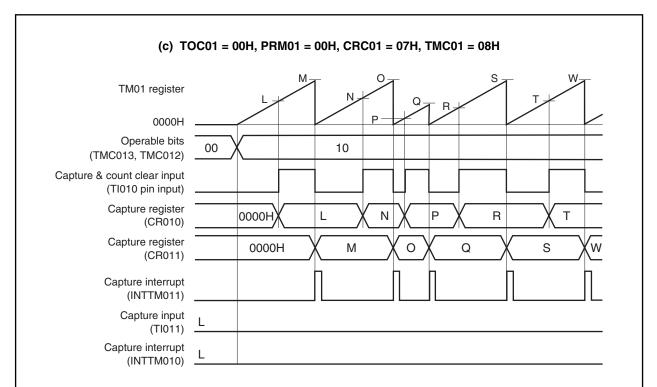

(TI010)

(CR011) Capture interrupt (INTTM011)

Capture register

Figure 7-20. Timing Example of Clear & Start Mode Entered by TI010 Pin Valid Edge Input (CR010 Register: Capture Register, CR011 Register: Capture Register) (2/3)

This is an application example where the pulse width of the signal input to the TI010 pin is measured. By setting the CRC01 register, the count value can be captured to the CR010 register in the phase reverse to the falling edge of the TI010 pin (i.e., rising edge) and to the CR011 register at the falling edge of the TI010 pin. The high- and low-level widths of the input pulse can be calculated by the following expressions.

• High-level width = [CR011 register value] – [CR010 register value] × [Count clock cycle]

• Low-level width = [CR010 register value] × [Count clock cycle]

If the reverse phase of the TI010 pin is selected as a trigger to capture the count value to the CR010 register, the INTTM010 signal is not generated. Read the values of the CR010 and CR011 registers to measure the pulse width immediately after the INTTM011 signal is generated.

However, if the valid edge specified by the PRM01.ES111 and PRM01.ES110 bits is input to the TI011 pin, the count value is not captured but the INTTM010 signal is generated. To measure the pulse width of the TI010 pin, mask the INTTM010 signal when it is not used.

(a) 16-bit timer mode control register 01 (TMC01) TMC013 TMC012 OVF01 0 0 0 0 1 0 0 0 Clears and starts at valid edge input of TI010 pin. Figure 7-21. Example of Register Settings in Clear & Start Mode Entered by TI010 Pin Valid Edge Input (1/2)

Figure 7-21. Example of Register Settings in Clear & Start Mode Entered by TI010 Pin Valid Edge Input (2/2)

(e) 16-bit timer counter 01 (TM01)

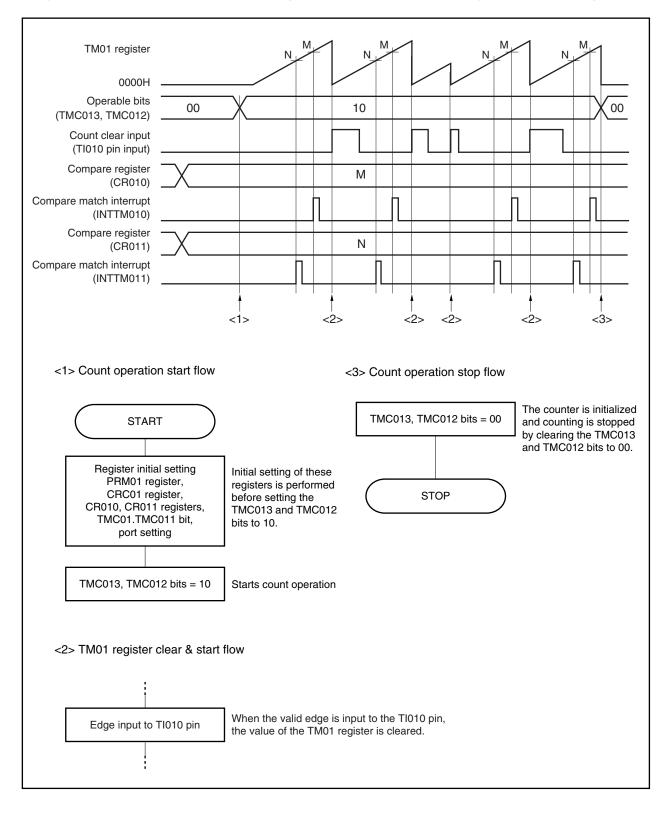

By reading the TM01 register, the count value can be read.

(f) 16-bit capture/compare register 010 (CR010)

When this register is used as a compare register and when its value matches the count value of the TM01 register, an interrupt signal (INTTM010) is generated. The count value of the TM01 register is not cleared. To use this register as a capture register, select either the TI010 or TI011 pin input as a capture trigger. When the valid edge of the capture trigger is detected, the count value of the TM01 register is stored in the CR010 register.

(g) 16-bit capture/compare register 011 (CR011)

When this register is used as a compare register and when its value matches the count value of the TM01 register, an interrupt signal (INTTM011) is generated. The count value of the TM01 register is not cleared. When this register is used as a capture register, the TI010 pin input is used as a capture trigger. When the valid edge of the capture trigger is detected, the count value of the TM01 register is stored in the CR011 register.

7.4.5 Free-running timer operation

When the TMC01.TMC013 and TMC01.TMC012 bits are set to 01 (free-running timer mode), 16-bit timer/event counter 01 continues counting up in synchronization with the count clock. When it has counted up to FFFFH, the overflow flag (TMC01.OVF01 bit) is set to 1 at the next clock, and the TM01 register is cleared (to 0000H) and continues counting. Clear the OVF01 bit to 0 by executing the CLR instruction via software.

The following three types of free-running timer operations are available.

- Both the CR010 and CR011 registers are used as compare registers.
- Either the CR010 register or CR011 register is used as a compare register and the other is used as a capture register.
- Both the CR010 and CR011 registers are used as capture registers.
- Remarks 1. For the alternate-function pin (TO01) settings, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.
 - 2. For enabling the INTTM010 and INTTM011 interrupts, refer to CHAPTER 17 INTERRUPT/EXCEPTION PROCESSING FUNCTION.
 - 3. Restrictions are applied to TM01. For details, refer to 7.6 (1) Alternate functions of TI010/TO01 pins.

(1) Free-running timer mode operation

(CR010 register: compare register, CR011 register: compare register)

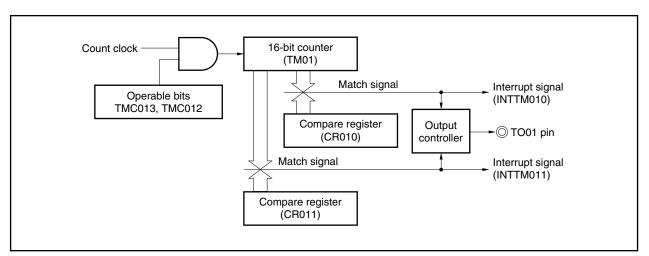

Figure 7-23. Block Diagram of Free-Running Timer Mode (CR010 Register: Compare Register, CR011 Register: Compare Register)

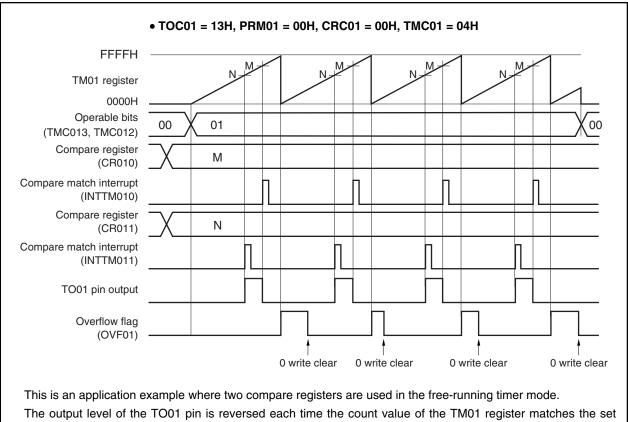

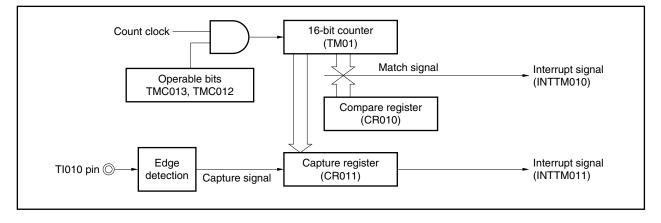

Figure 7-24. Timing Example of Free-Running Timer Mode (CR010 Register: Compare Register, CR011 Register: Compare Register)

This is an application example where two compare registers are used in the free-running timer mode. The output level of the TO01 pin is reversed each time the count value of the TM01 register matches the set values of the CR010 and CR011 registers. When the count value matches the register value, the INTTM010 or INTTM011 signal is generated.

(2) Free-running timer mode operation

(CR010 register: compare register, CR011 register: capture register)

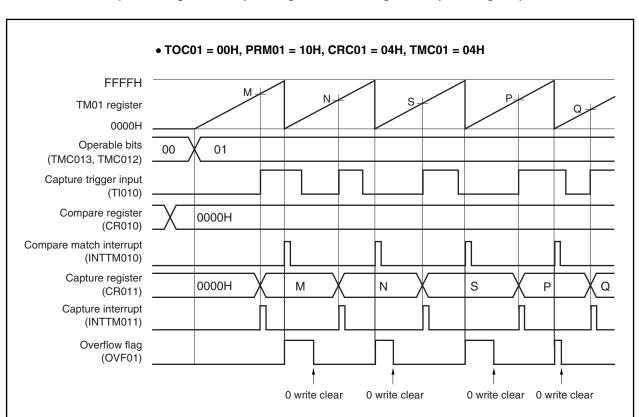

Figure 7-26. Timing Example of Free-Running Timer Mode (CR010 Register: Compare Register, CR011 Register: Capture Register)

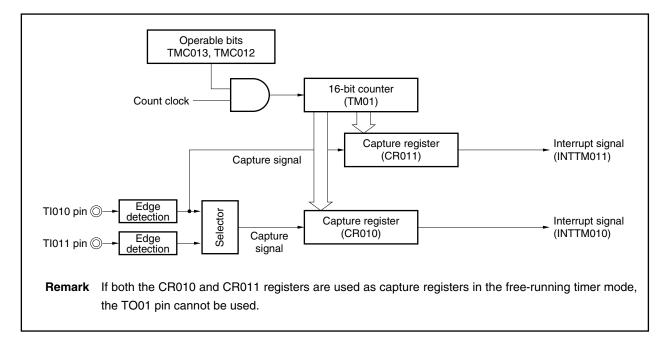

This is an application example where a compare register and a capture register are used at the same time in the free-running timer mode.

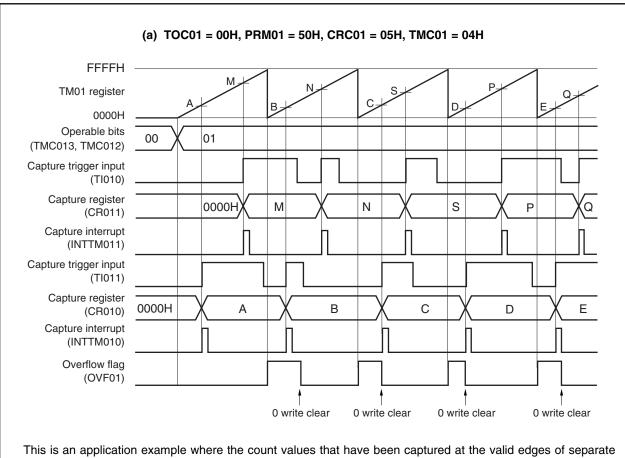

In this example, the INTTM010 signal is generated each time the count value of the TM01 register matches the set value of the CR010 register (compare register). (Because the TI010 and TO01 pins are alternate functions, the timer output (TO01) cannot be used.) In addition, the INTTM011 signal is generated and the count value of the TM01 register is captured to the CR011 register each time the valid edge of the TI010 pin is detected.

(3) Free-running timer mode operation

(CR010 register: capture register, CR011 register: capture register)

This is an application example where the count values that have been captured at the valid edges of separate capture trigger signals are stored in separate capture registers in the free-running timer mode. The count value is captured to the CR011 register when the valid edge of the TI010 pin input is detected and to the CR010 register when the valid edge of the TI011 pin input is detected.

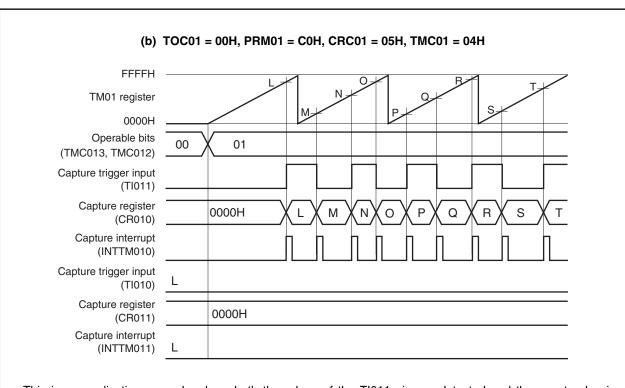

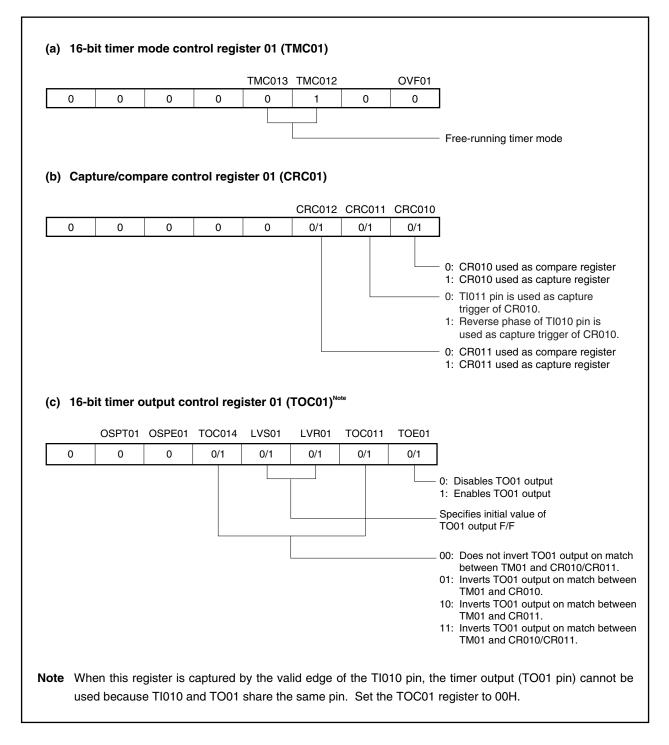

Figure 7-28. Timing Example of Free-Running Timer Mode (CR010 Register: Capture Register, CR011 Register: Capture Register) (2/2)

This is an application example where both the edges of the TI011 pin are detected and the count value is captured to the CR010 register in the free-running timer mode.

When both the CR010 and CR011 registers are used as capture registers and when the valid edge of only the TI011 pin is to be detected, the count value cannot be captured to the CR011 register.

Figure 7-29. Example of Register Settings in Free-Running Timer Mode (1/2)

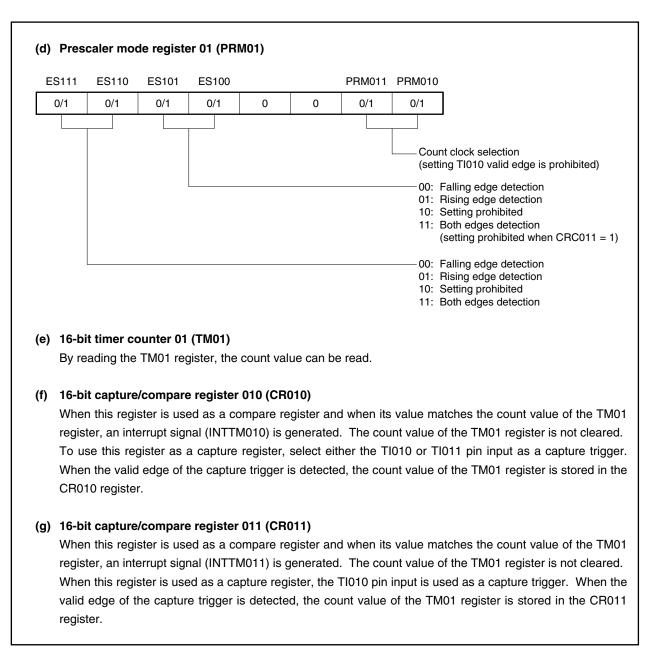

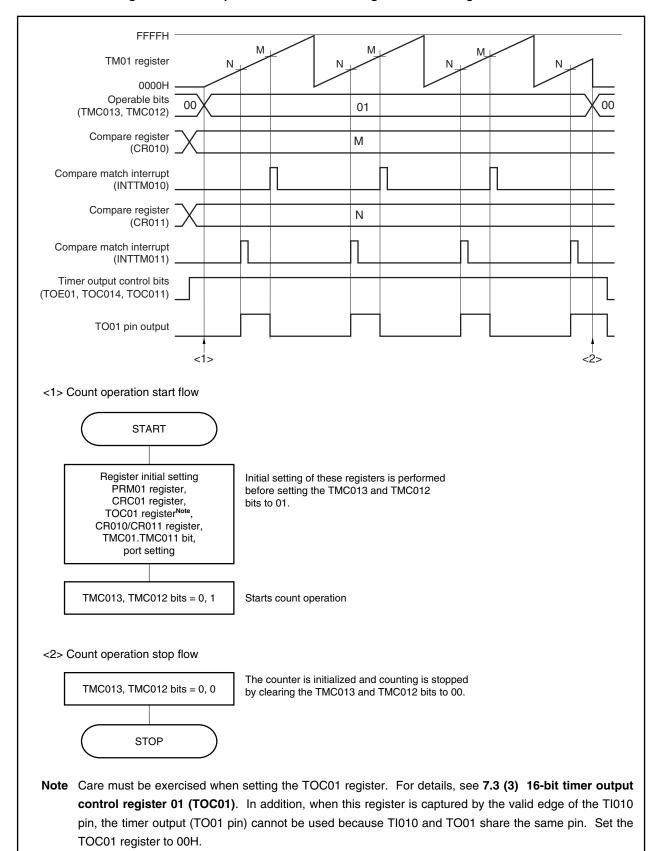

Figure 7-29. Example of Register Settings in Free-Running Timer Mode (2/2)

7.4.6 PPG output operation

A rectangular wave having a pulse width set in advance by the CR011 register is output from the TO01 pin as a PPG (Programmable Pulse Generator) signal during a cycle set by the CR010 register when the TMC01.TMC013 and TMC01.TMC012 bits are set to 11 (clear & start upon a match between the TM01 register and the CR010 register).

The pulse cycle and duty factor of the pulse generated as the PPG output are as follows.

- Pulse cycle = (Set value of the CR010 register + 1) × Count clock cycle
- Duty = (Set value of the CR011 register + 1) / (Set value of the CR010 register + 1)

Caution To change the duty factor (value of the CR011 register) during operation, see 7.5.1 Rewriting CR011 register during TM01 operation.

- Remarks 1. For the alternate-function pin (TO01) settings, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.
 - 2. For enabling the INTTM010 and INTTM011 interrupts, refer to CHAPTER 17 INTERRUPT/EXCEPTION PROCESSING FUNCTION.
 - **3.** Restrictions are applied to TM01 in which the timer input and output share the same pin. For details, refer to **7.6 (1) Alternate functions of TI010/TO01 pins.**

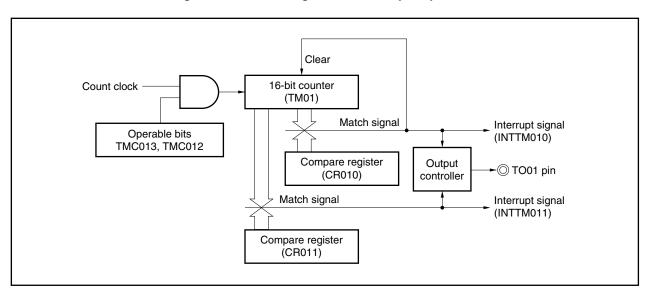

Figure 7-31. Block Diagram of PPG Output Operation

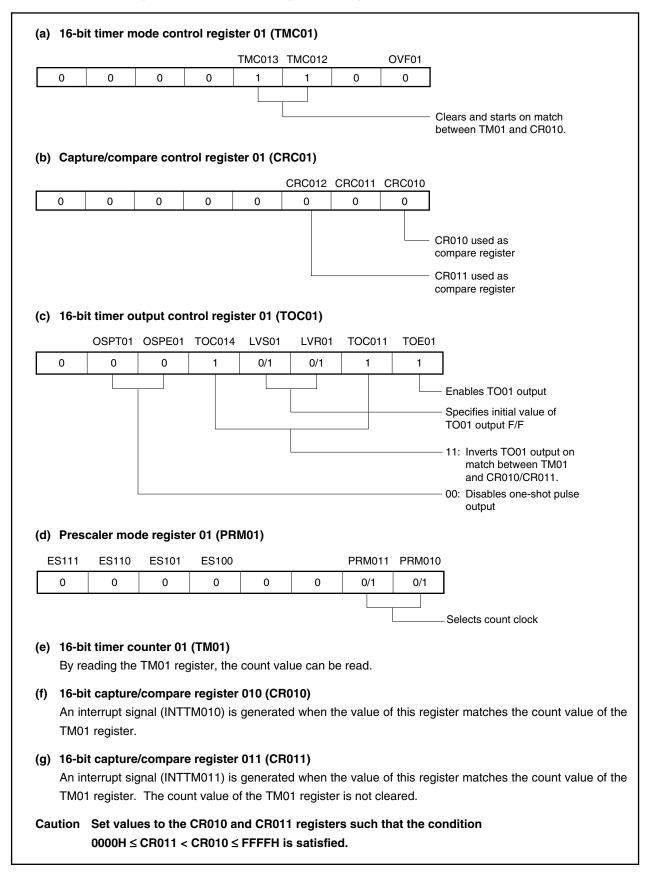

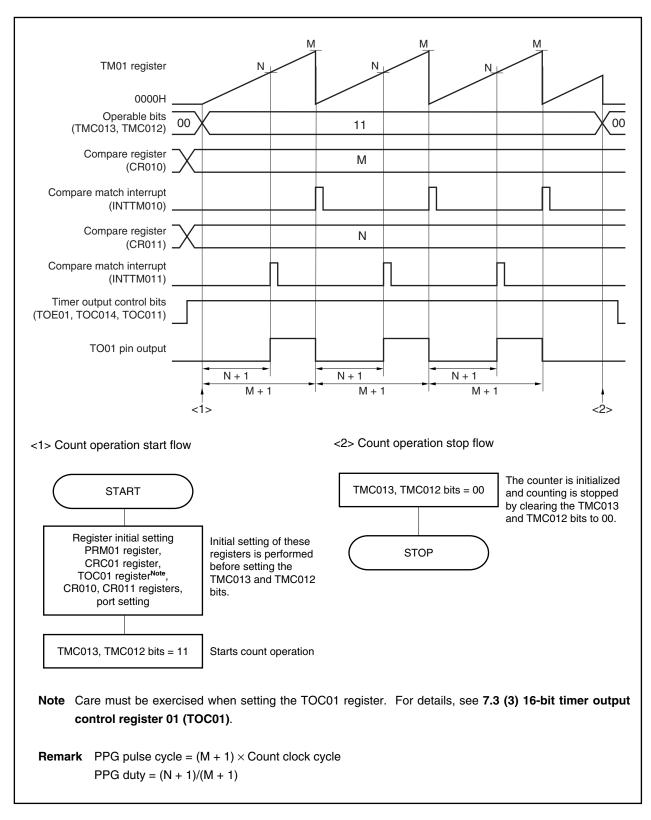

Figure 7-32. Example of Register Settings for PPG Output Operation

7.4.7 One-shot pulse output operation

A one-shot pulse can be output by setting the TMC01.TMC013 and TMC01.TMC012 bits to 01 (free-running timer mode) or to 10 (clear & start mode entered by the TI010 pin valid edge) and setting the TOC01.OSPE01 bit to 1.

When the TOC01.OSPT01 is set to 1 during timer operation, clearing & starting of the TM01 register is triggered, and a pulse of the difference between the values of the CR010 and CR011 registers is output only once from the TO01 pin.

- Cautions 1. Do not input the trigger again (setting OSPT01 to 1) while the one-shot pulse is output. To output the one-shot pulse again, generate the trigger after the current one-shot pulse output has completed.
 - 2. Restrictions are applied to TM01 in which the timer input and output share the same pin. For details, refer to 7.6 (1) Alternate functions of TI010/T001 pins.
- Remarks 1. For the alternate-function pin (TI01) settings, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.
 - 2. For enabling the INTTM010 and INTTM011 interrupts, refer to CHAPTER 17 INTERRUPT/EXCEPTION PROCESSING FUNCTION.

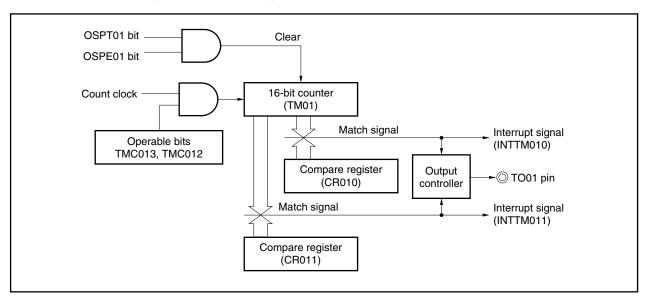

Figure 7-34. Block Diagram of One-Shot Pulse Output Operation

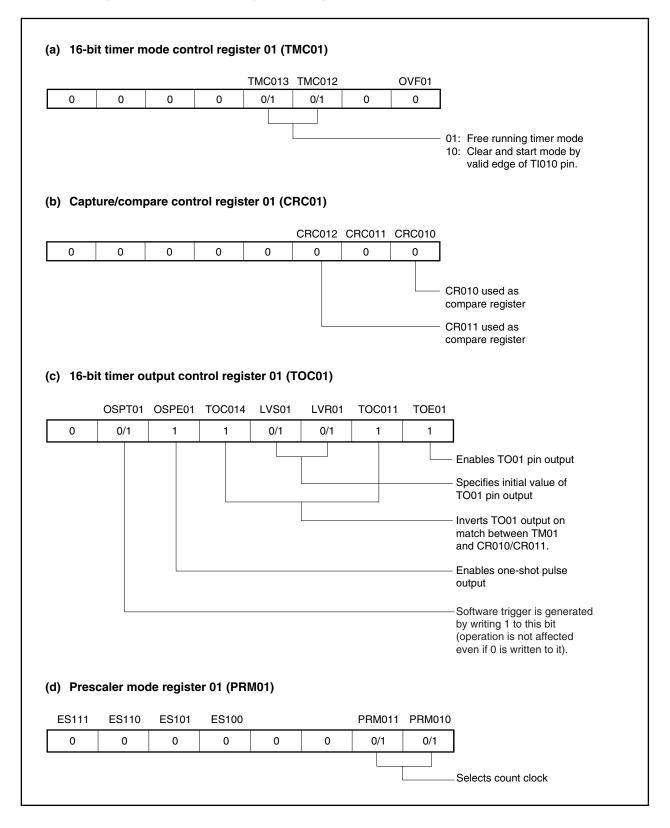

Figure 7-35. Example of Register Settings for One-Shot Pulse Output Operation (1/2)

Figure 7-35. Example of Register Settings for One-Shot Pulse Output Operation (2/2)

(e) 16-bit timer counter 01 (TM01)

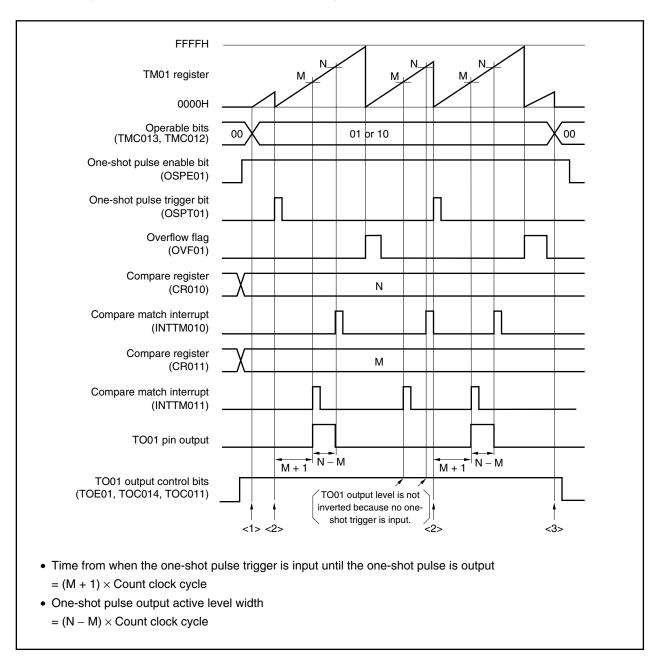

By reading the TM01 register, the count value can be read.

(f) 16-bit capture/compare register 010 (CR010)

This register is used as a compare register when a one-shot pulse is output. When the value of the TM01 register matches that of the CR010 register, an interrupt signal (INTTM010) is generated and the output level of the TO01 pin is inverted.

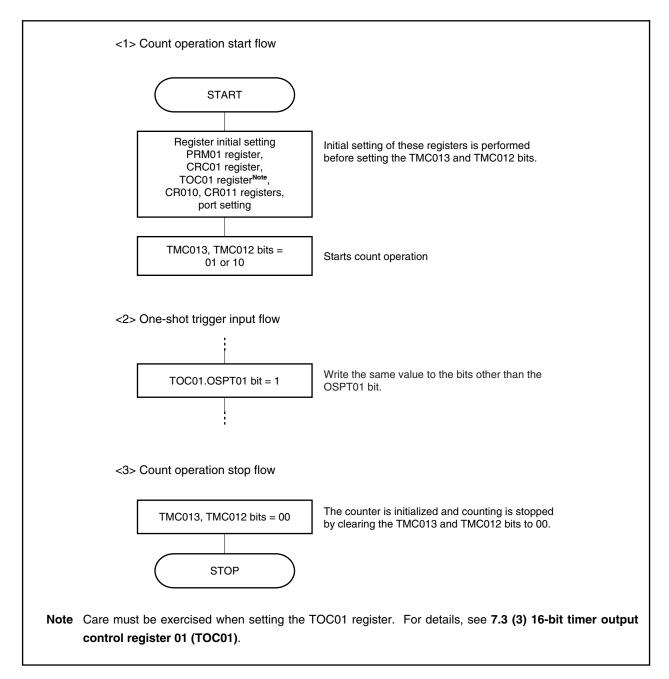

(g) 16-bit capture/compare register 011 (CR011)

This register is used as a compare register when a one-shot pulse is output. When the value of the TM01 register matches that of the CR011 register, an interrupt signal (INTTM011) is generated and the output level of the TO01 pin is inverted.

7.4.8 Pulse width measurement operation

The TM01 register can be used to measure the pulse width of the signal input to the TI010 and TI011 pins.

Measurement can be accomplished by operating the 16-bit timer/event counter 01 in the free-running timer mode or by restarting the timer in synchronization with the signal input to the TI010 pin.

When an interrupt is generated, read the value of the valid capture register and measure the pulse width. Check the TMC01.OVF01 flag. If it is set (to 1), clear it to 0 by software.

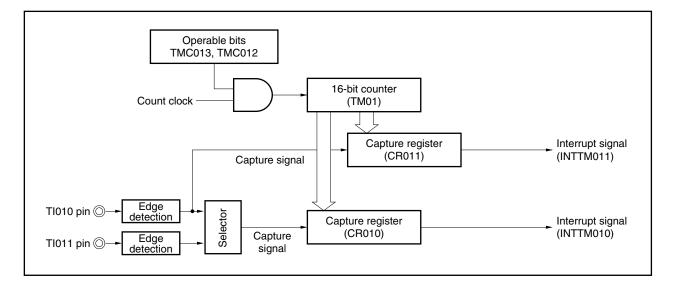

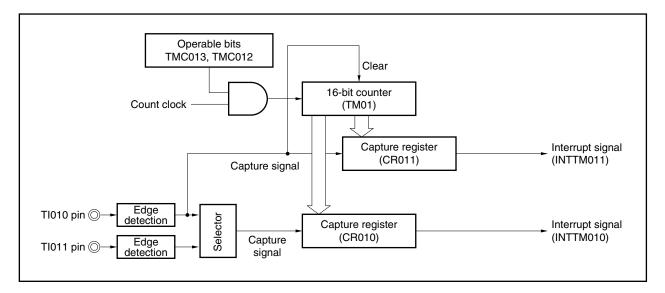

Figure 7-38. Block Diagram of Pulse Width Measurement (Clear & Start Mode Entered by TI010 Pin Valid Edge Input)

A pulse width can be measured in the following three ways.

- Measuring the pulse width by using two input signals of the TI010 and TI011 pins (free-running timer mode)
- Measuring the pulse width by using one input signal of the TI010 pin (free-running timer mode)
- Measuring the pulse width by using one input signal of the TI010 pin (clear & start mode entered by the TI010 pin valid edge input)
- Remarks 1. For the alternate-function pin (TO01) settings, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.
 - 2. For enabling the INTTM010 and INTTM011 interrupts, refer to CHAPTER 17 INTERRUPT/EXCEPTION PROCESSING FUNCTION.
 - 3. Restrictions are applied to TM01. For details, refer to 7.6 (1) Alternate functions of TI010/TO01 pins.

(1) Measuring the pulse width by using two input signals of the TI010 and TI011 pins (free-running timer mode)

Set the free-running timer mode (the TMC01.TMC013 and TMC01.TMC012 bits = 01). When the valid edge of the TI010 pin is detected, the count value of the TM01 register is captured to the CR011 register. When the valid edge of the TI011 pin is detected, the count value of the TM01 register is captured to the CR010 register. Specify detection of both the edges of the TI010 and TI011 pins.

By this measurement method, the previous count value is subtracted from the count value captured by the edge of each input signal. Therefore, save the previously captured value to a separate register in advance.

If an overflow occurs, the value becomes negative if the previously captured value is simply subtracted from the current captured value and, therefore, a borrow occurs (the PSW.CY bit is set to 1). If this happens, ignore CY and take the calculated value as the pulse width. In addition, clear the TMC01.0VF01 bit to 0.

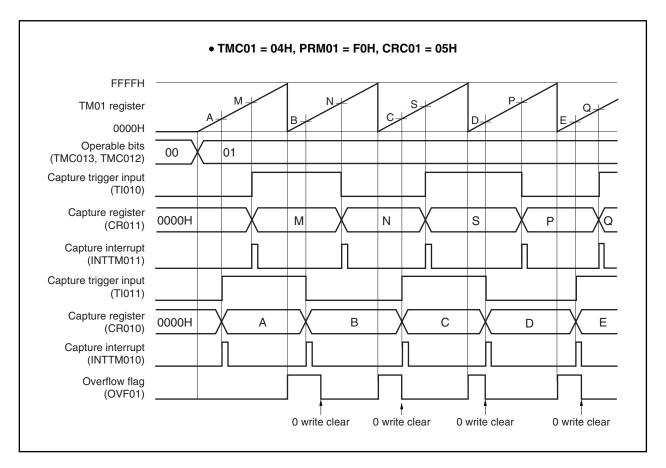

Figure 7-39. Timing Example of Pulse Width Measurement (1)

(2) Measuring the pulse width by using one input signal of the TI010 pin (free-running timer mode)

Set the free-running timer mode (the TMC01.TMC013 and TMC01.TMC012 bits = 01). The count value of the TM01 register is captured to the CR010 register in the phase reverse to the valid edge detected on the Tl010 pin. When the valid edge of the Tl010 pin is detected, the count value of the TM01 register is captured to the CR011 register.

By this measurement method, values are stored in separate capture registers when a width from one edge to another is measured. Therefore, the capture values do not have to be saved. By subtracting the value of one capture register from that of another, a high-level width, low-level width, and cycle are calculated.

If an overflow occurs, the value becomes negative if one captured value is simply subtracted from another and, therefore, a borrow occurs (the PSW.CY bit is set to 1). If this happens, ignore CY and take the calculated value as the pulse width. In addition, clear the TMC01.OVF01 bit to 0.

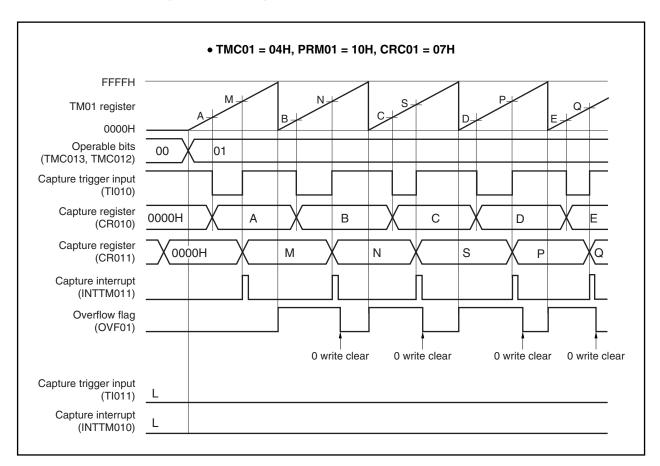

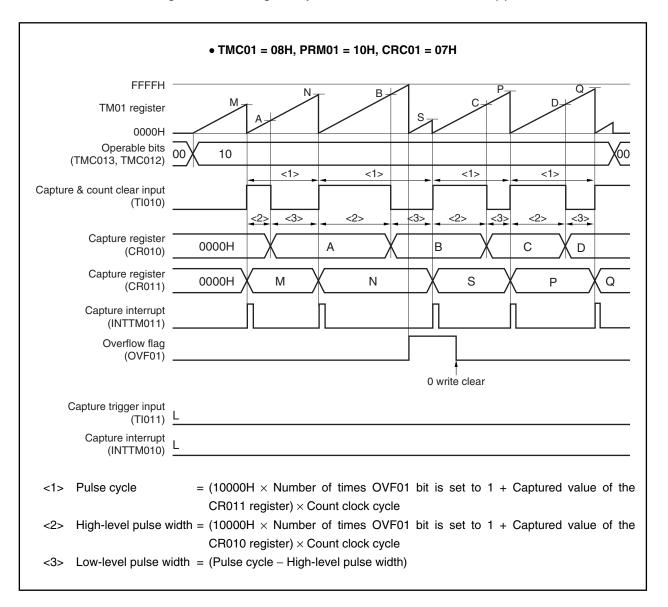

Figure 7-40. Timing Example of Pulse Width Measurement (2)

(3) Measuring the pulse width by using one input signal of the TI010 pin (clear & start mode entered by the TI010 pin valid edge input)

Set the clear & start mode entered by the TI010 pin valid edge (the TMC01.TMC013 and TMC01.TMC012 bits = 10). The count value of the TM01 register is captured to the CR010 register in the phase reverse to the valid edge of the TI010 pin, and the count value of the TM01 register is captured to the CR011 register and the TM01 register is cleared (0000H) when the valid edge of the TI010 pin is detected. Therefore, a cycle is stored in the CR011 register if the TM01 register does not overflow.

If an overflow occurs, take the value that results from adding 10000H to the value stored in the CR011 register as a cycle. Clear the TMC01.0VF01 bit to 0.

Figure 7-42. Example of Register Settings for Pulse Width Measurement Operation (1/2)

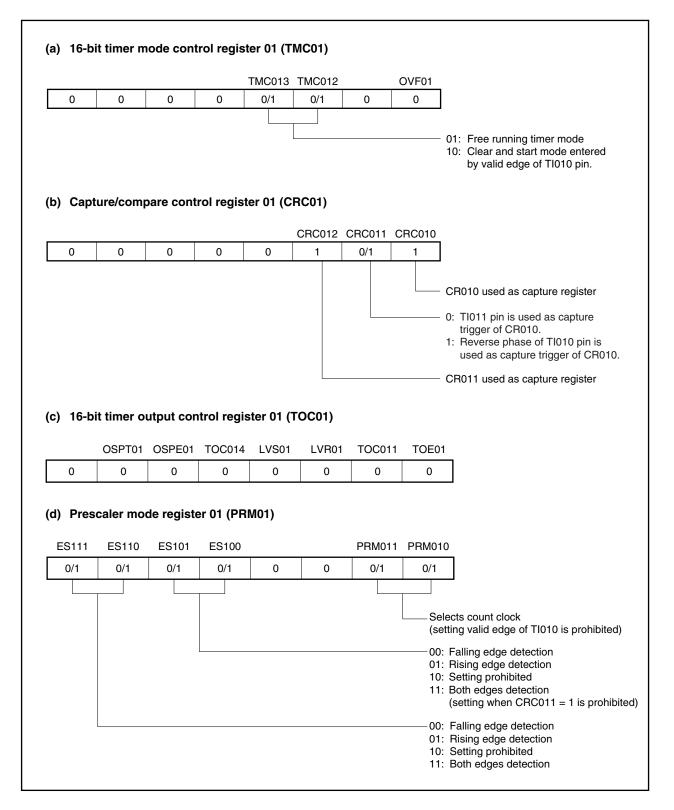

Figure 7-42. Example of Register Settings for Pulse Width Measurement Operation (2/2)

(e) 16-bit timer counter 01 (TM01)

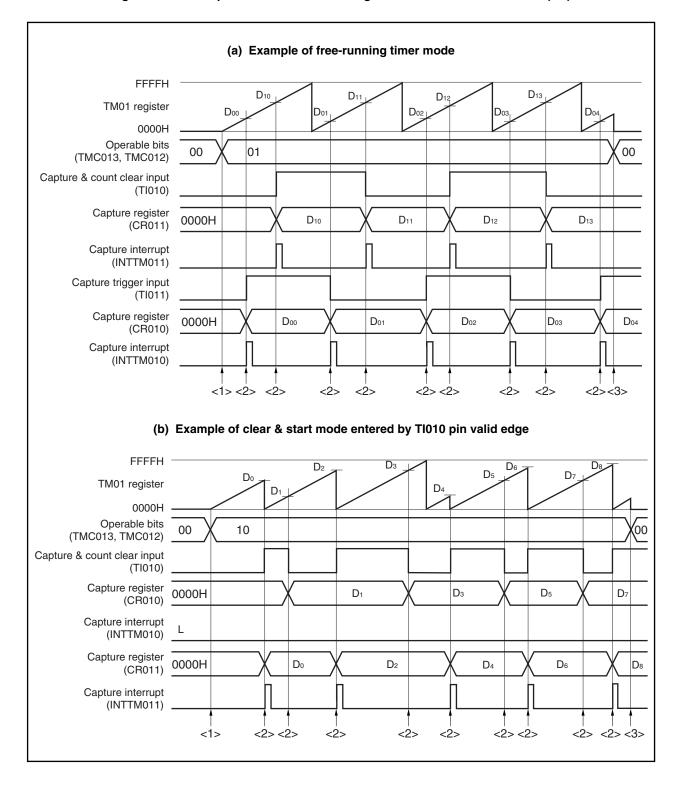

By reading the TM01 register, the count value can be read.

(f) 16-bit capture/compare register 010 (CR010)

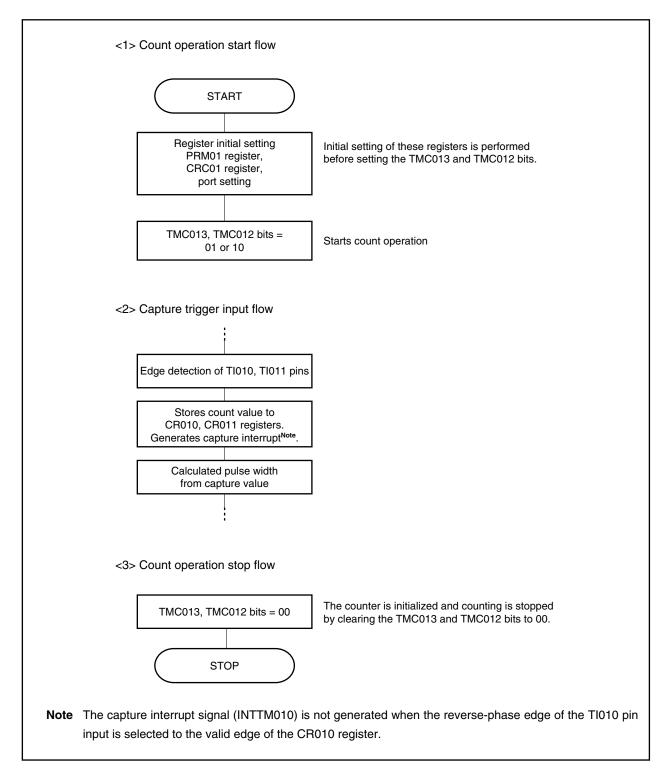

This register is used as a capture register. Either the TI010 or TI011 pin is selected as a capture trigger. When a specified edge of the capture trigger is detected, the count value of the TM01 register is stored in the CR010 register.

(g) 16-bit capture/compare register 011 (CR011)

This register is used as a capture register. The signal input to the TI010 pin is used as a capture trigger. When the capture trigger is detected, the count value of the TM01 register is stored in the CR011 register.

7.5 Special Use of TM01

7.5.1 Rewriting CR011 register during TM01 operation

In principle, rewriting the CR010 and CR011 registers of the V850ES/KE1 when they are used as compare registers is prohibited while the TM01 register is operating (TMC01.TMC013 and TMC01.TMC012 bits = other than 00).

However, the value of the CR011 register can be changed, even while the TM01 register is operating, using the following procedure if the CR011 register is used for PPG output and the duty factor is changed (change the value of the CR011 register immediately after its value matches the value of the TM01 register. If the value of the CR011 register is changed immediately before its value matches the TM01 register, an unexpected operation may be performed).

Procedure for changing value of the CR011 register

- <1> Disable interrupt INTTM011 (TM0IC10.TM0MK11 bit = 1).
- <2> Disable reversal of the timer output when the value of the TM01 register matches that of the CR011 register (TOC01.TOC014 bit = 0).
- <3> Change the value of the CR011 register.
- <4> Wait for one cycle of the count clock of the TM01 register.
- <5> Enable reversal of the timer output when the value of the TM01 register matches that of the CR011 register (TOC01.TOC014 bit = 1).
- <6> Clear the interrupt flag of INTTM011 to 0 (TM0IC10.TM0IF11 bit = 0).
- <7> Enable interrupt INTTM011 (TM0IC10.TM0MK11 bit = 0).

Remark For the TM0IC10 register, see CHAPTER 17 INTERRUPT/EXCEPTION PROCESSING FUNCTION.

7.5.2 Setting LVS01 and LVR01 bits

(1) Usage of the LVS01 and LVR01 bits

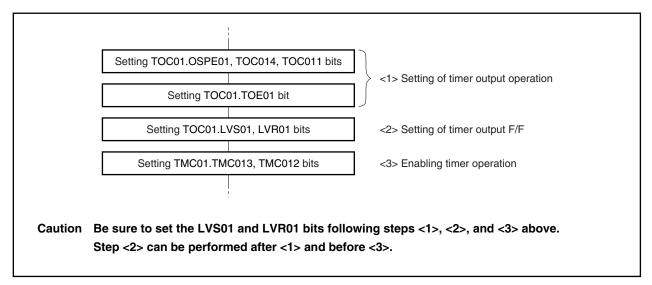

The TOC01.LVS01 and TOC01.LVR01 bits are used to set the default value of the TO01 pin output and to invert the timer output without enabling the timer operation (TMC01.TMC013 and TMC01.TMC012 bits = 00). Clear the LVS01 and LVR01 bits to 00 (default value: low-level output) when software control is unnecessary.

LVS01 Bit	LVR01 Bit	Timer Output Status
0	0	Not changed (low-level output)
0	1	Cleared (low-level output)
1	0	Set (high-level output)
1	1	Setting prohibited

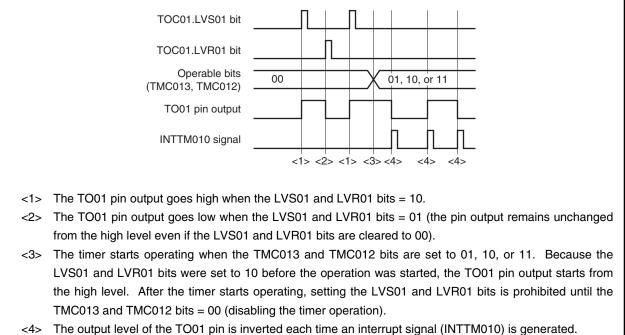

(2) Setting the LVS01 and LVR01 bits

Set the LVS01 and LVR01 bits using the following procedure.

7.6 Cautions

(1) Alternate functions of TI010/TO01 pins

In the V850ES/KE1, the timer input and output share the same pins shown in Table 7-3. Restrictions are applied to each channel, as shown in Table 7-4.

Channel	Pin	Alternate Function	Remarks
TM01	TI010	P35/TO01	Shares the pin with TO01.
	TI011	P50/KR0/RTP00	-
	TO01	P35/TI010	Shares the pin with TI010.

Table 7-3. Timer I/O Pins

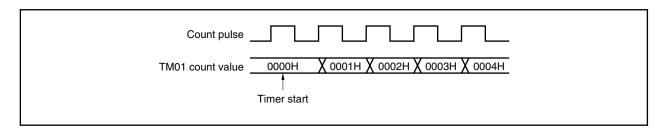

Table 7-4. Restrictions for Each Channel of 16-bit Timer/Event Counter 0

Operation	Restriction
Operation as interval timer	_
Operation as square-wave output	Setting the TI010 valid edge (PRM01.PRM011, PRM01.PRM010 bits = 11) for the count clock is prohibited since the TI010 and TO01 share the same pin (only the internal clock can be used).
Operation as external event counter	Use of the timer output (TO01) is prohibited since the TI010 and TO01 share the same pin. Set the TOC01 register to 00H.
Operation as clear & start mode by valid edge input of TI010 pin	Use of the timer output (TO01) is prohibited since the TI010 and TO01 share the same pin. Set the TOC01 register to 00H.
Operation as free-running timer	Use of the timer output (TO01) is prohibited when TI010 valid edge (PRM01.PRM011, PRM01.PRM010 bits = 11) is set for the count clock, since the TI010 and TO01 share the same pin. When the timer output (TO01) is used, setting the TI010 valid edge (PRM01.PRM011, PRM01.PRM010 bits = 11) for the count clock is prohibited (only the internal clock can be used).
Operation as PPG output	Setting the TI010 valid edge (PRM01.PRM011, PRM01.PRM010 bits = 11) for the count clock is prohibited since the TI010 and TO01 share the same pin (only the internal clock can be used).
Operation as one-shot pulse output	Use of the hardware trigger by the TI010 pin valid edge is prohibited. The software trigger (TOC01.OSPT01 bit) can be used.
Operation as pulse width measurement	Use of the timer output (TO01) is prohibited since the TI010 and TO01 share the same pin. Set the TOC01 register to 00H.

(2) Error on starting timer

An error of up to 1 clock occurs before the match signal is generated after the timer has been started. This is because the count of the TM01 register is started asynchronously to the count pulse.

(3) Setting CR010 and CR011 registers (in the mode in which clear & start occurs upon match between TM01 register and CR010 register)

Set the CR010 and CR011 registers to a value other than 0000H (when using these registers as external event counters, one-pulse count operation is not possible).

(4) Data hold timing of capture register

(a) If the valid edge of the TI011/TI010 pin is input while the CR010/CR011 register is read, the CR010/CR011 register performs capture operation, but the read value at this time is not guaranteed. However, the interrupt request signal (INTTM010/INTTM011) is generated as a result of detection of the valid edge.

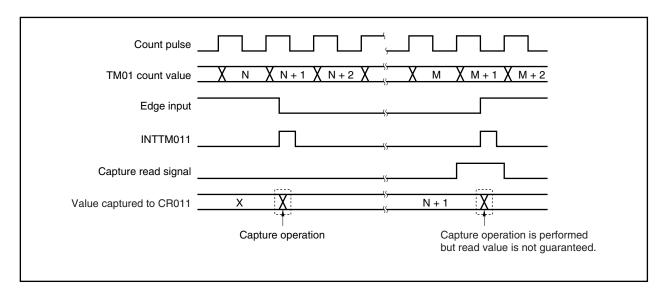

Figure 7-47. Data Hold Timing of Capture Register

(b) The values of the CR010 and CR011 registers are not guaranteed after 16-bit timer/event counter 01 has stopped.

(5) Setting valid edge

Set the valid edge of the TI010 pin while the timer operation is stopped (TMC01.TMC013 and TMC01.TMC012 bits = 00). Set the valid edge by using the PRM01.ES100 and PRM01.ES101 bits.

(6) Re-triggering one-shot pulse

Make sure that the trigger is not generated while an active level is being output in the one-shot pulse output mode. Be sure to input the next trigger after the current active level is output.

(7) Operation of OVF01 flag

(a) Setting of OVF01 flag

The TMC01.OVF01 flag is set to 1 in the following case in addition to when the TM01 register overflows.

Select the mode in which clear & start occurs upon match between the TM01 register and the CR010 register.

 $\begin{array}{c} \downarrow \\ \text{Set the CR010 register to FFFH} \\ \downarrow \end{array}$

When the TM01 register is cleared from FFFFH to 0000H upon match with the CR010 register

Figure 7-48. Operation Timing of OVF01 Flag

Count pulse	
CR010	FFFFH
TM01	герен Херен Хоооон Хооолн Х
OVF01	
INTTM010	

(b) Clearing of OVF01 flag

After the TM01 register overflows, clearing OVF01 flag is invalid and set (1) again even if the OVF01 flag is cleared (0) before the next count clock is counted (before TM01 register becomes 0001H).

(8) One-shot pulse output

One-shot pulse output operates normally in either the free-running timer mode or the mode in which clear & start occurs on the valid edge of the TI010 pin. In the mode in which clear & start occurs upon match between the TM01 register and the CR010 register, one-shot pulse output is not possible.

(9) Capture operation

(a) If valid edge of TI010 pin is specified for count clock

If the valid edge of the TI010 pin is specified for the count clock, the capture register that specified the TI010 pin as the trigger does not operate normally.

(b) To ensure that signals input from TI011 and TI010 pins are correctly captured

To accurately capture the count value, the pulse input to the TI010 and TI011 pins as a capture trigger must be wider than two count clocks selected by the PRM01 register.

(c) Interrupt signal generation

Although a capture operation is performed at the falling edge of the count clock, an interrupt request signal (INTTM010, INTTM011) is generated at the rising edge of the next count clock.

(d) Caution when CRC01.CRC011 bit is set to 1

When the count value of the TM01 register is captured to the CR010 register in the phase reverse to the signal input to the TI010 pin, the interrupt request signal (INTTM010) is not generated after the count value is captured. If the valid edge is detected on the TI011 pin during this operation, the capture operation is not performed but the INTTM010 signal is generated as an external interrupt signal. Mask the INTTM010 signal when the external interrupt is not used.

(10) Edge detection

(a) Specifying valid edge after reset

If the operation of the 16-bit timer/event counter 01 is enabled after reset and while the TI010 or TI011 pin is at high level and when the rising edge or both the edges are specified as the valid edge of the TI010 or TI011 pin, then the high level of the TI010 or TI011 pin is detected as the rising edge. Note this when the TI010 or TI011 pin is pulled up. However, the rising edge is not detected when the operation is once stopped and then enabled again.

(b) Sampling clock for noise elimination

The sampling clock for noise elimination differs depending on whether the valid edge of Tl010 is used for the count clock or as a capture trigger. In the former case, sampling is performed using fxx/4, and in the latter case, sampling is performed using the count clock selected by the PRM01 register.

When the signal input to the TI010 pin is sampled and the valid level is detected two times in a row, the valid edge is detected. Therefore, noise having a short pulse width can be eliminated.

Remark fxx: Main clock frequency

CHAPTER 8 8-BIT TIMER/EVENT COUNTER 5

In the V850ES/KE1, two channels of 8-bit timer/event counter 5 are provided.

8.1 Functions

8-bit timer/event counter 5n has the following two modes (n = 0, 1).

- Mode using 8-bit timer/event counter alone (individual mode)
- Mode using cascade connection (16-bit resolution: cascade connection mode)

These two modes are described below.

Mode using 8-bit timer/event counter alone (individual mode) 8-bit timer/event counter 5n operates as an 8-bit timer/event counter.

The following functions can be used.

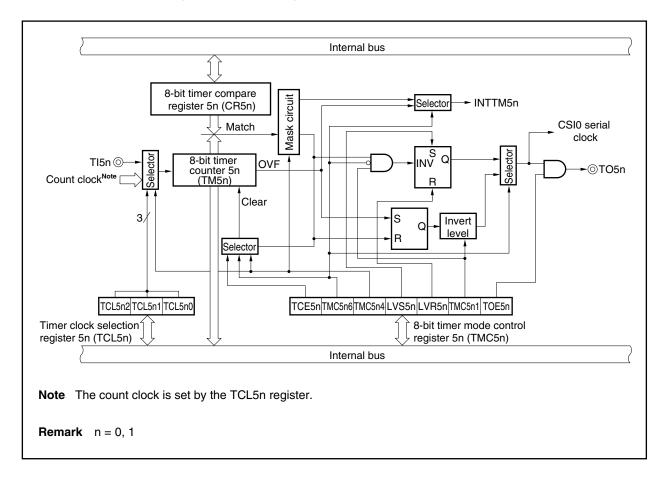

- Interval timer
- External event counter
- Square-wave output
- PWM output

(2) Mode using cascade connection (16-bit resolution: cascade connection mode)

8-bit timer/event counter 5n operates as a 16-bit timer/event counter by connecting the TM5n register in cascade. The following functions can be used.

- Interval timer with 16-bit resolution
- External event counter with 16-bit resolution
- Square-wave output with 16-bit resolution

The block diagram of 8-bit timer/event counter 5n is shown next.

8.2 Configuration

8-bit timer/event counter 5n includes the following hardware.

Item	Configuration
Timer registers	8-bit timer counter 5n (TM5n) 16-bit timer counter 5 (TM5): Only when using cascade connection
Registers	8-bit timer compare register 5n (CR5n) 16-bit timer compare register 5 (CR5): Only when using cascade connection
Timer output	1 (TO5n pin)
Control registers ^{Note}	Timer clock selection register 5n (TCL5n) 8-bit timer mode control register 5n (TMC5n) 16-bit timer mode control register 5 (TMC5): Only when using cascade connection

Note When using the functions of the TI5n and TO5n pins, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.

(1) 8-bit timer counter 5n (TM5n)

The TM5n register is an 8-bit read-only register that counts the count pulses.

The counter is incremented in synchronization with the rising edge of the count clock.

Through cascade connection, the TM5n registers can be used as a 16-bit timer.

When using the TM50 register and the TM51 register in cascade as a 16-bit timer, these registers can be read only in 16-bit units. Therefore, read these registers twice and compare the values, taking into consideration that the reading occurs during a count change.

7 6 5 4 3 2 1 0 TM5n

The count value is reset to 00H in the following cases.

- <1> Reset
- <2> When the TMC5n.TCE5n bit is cleared (0)
- <3> The TM5n register and CR5n register match in the mode in which clear & start occurs on a match between the TM5n register and the CR5n register
- Caution When connected in cascade, these registers become 0000H even when the TCE50 bit in the lowest timer (TM50) is cleared.

(2) 8-bit timer compare register 5n (CR5n)

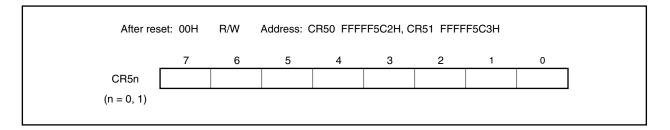

The CR5n register can be read and written in 8-bit units.

In a mode other than the PWM mode, the value set to the CR5n register is always compared to the count value of the TM5n register, and if the two values match, an interrupt request signal (INTTM5n) is generated.

In the PWM mode, TM5n register overflow causes the TO5n pin output to change to the active level, and when the values of the TM5n register and the CR5n register match, the TO5n pin output changes to the inactive level.

The value of the CR5n register can be set in the range of 00H to FFH.

When using the TM50 register and TM51 register in cascade as a 16-bit timer, the CR50 register and CR51 register operate as 16-bit timer compare register 5 (CR5). The counter value and register value are compared in 16-bit lengths, and if they match, an interrupt request signal (INTTM50) is generated.

- Cautions 1. In the mode in which clear & start occurs upon a match of the TM5n register and CR5n register (TMC5n.TMC5n6 bit = 0), do not write a different value to the CR5n register during the count operation.
 - 2. In the PWM mode, set the CR5n register rewrite interval to three or more count clocks (clock selected with the TCL5n register).
 - 3. Before changing the value of the CR5n register when using a cascade connection, be sure to stop the timer operation.

8.3 Registers

The following two registers are used to control 8-bit timer/event counter 5n.

- Timer clock selection register 5n (TCL5n)
- 8-bit timer mode control register 5n (TMC5n)
- Remark To use the functions of the TI5n and TO5n pins, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.

(1) Timer clock selection register 5n (TCL5n)

The TCL5n register sets the count clock of 8-bit timer/event counter 5n and the valid edge of the TI5n pin input. The TCL5n register can be read or written in 8-bit units. Reset sets this register to 00H.

(2) 8-bit timer mode control register 5n (TMC5n)

The TMC5n register performs the following six settings.

- Controls counting by the TM5n register
- Selects the operation mode of the TM5n register
- Selects the individual mode or cascade connection mode
- Sets the status of the timer output flip-flop
- Controls the timer output flip-flop or selects the active level in the PWM (free-running timer) mode
- Controls timer output

The TMC5n register can be read or written in 8-bit or 1-bit units. Reset sets this register to 00H.

8.4 Operation

8.4.1 Operation as interval timer

8-bit timer/event counter 5n operates as an interval timer that repeatedly generates interrupts at the interval of the count value preset in the CR5n register. If the count value in the TM5n register matches the value set in the CR5n register, the value of the TM5n register is cleared to 00H and counting is continued, and at the same time, an interrupt request signal (INTTM5n) is generated.

Setting method

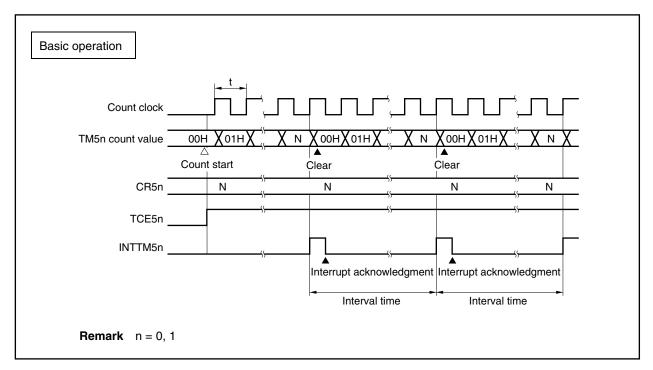

<1> Set each register.

- TCL5n register: Selects the count clock (t).
- CR5n register: Compare value (N)
- TMC5n register: Stops count operation and selects the mode in which clear & start occurs on a match between the TM5n register and CR5n register (TMC5n register = 0000xx00B, ×: don't care).
- <2> When the TMC5n.TCE5n bit is set to 1, the count operation starts.
- <3> When the values of the TM5n register and CR5n register match, the INTTM5n signal is generated (TM5n register is cleared to 00H).
- <4> Then, the INTTM5n signal is repeatedly generated at the same interval. To stop counting, set the TCE5n bit = 0.

Interval time = $(N + 1) \times t$: N = 00H to FFH

Caution During interval timer operation, do not rewrite the value of the CR5n register.

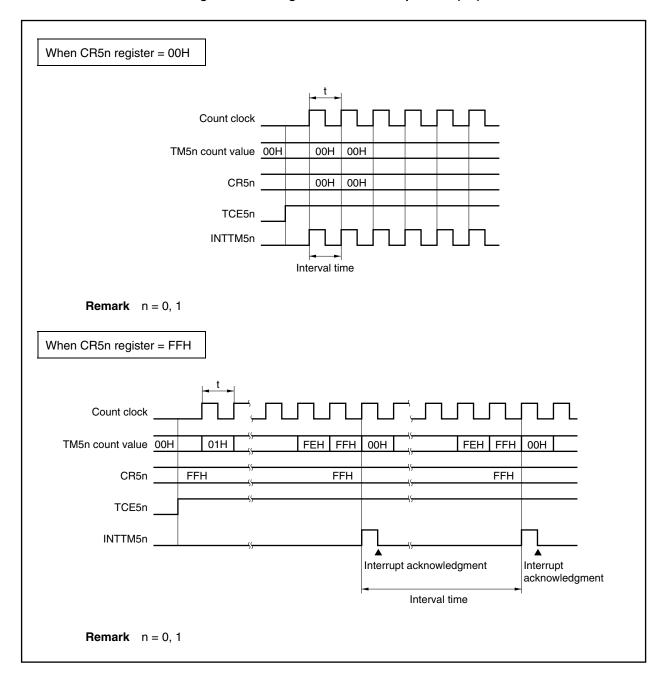

Figure 8-2. Timing of Interval Timer Operation (2/2)

8.4.2 Operation as external event counter

The external event counter counts the number of clock pulses input to the TI5n pin from an external source by using the TM5n register.

Each time the valid edge specified by the TCL5n register is input to the TI5n pin, the TM5n register is incremented. Either the rising edge or the falling edge can be specified as the valid edge.

When the count value of the TM5n register matches the value of the CR5n register, the TM5n register is cleared to 00H and an interrupt request signal (INTTM5n) is generated.

Setting method

<1> Set each register.

TCL5n register: Selects the TI5n pin input edge.

Falling edge of TI5n pin \rightarrow TLC5n register = 00H

Rising edge of TI5n pin \rightarrow TCL5n register = 01H

- CR5n register: Compare value (N)
- TMC5n register: Stops count operation, selects the mode in which clear & start occurs on a match between the TM5n register and CR5n register, disables timer output F/F inversion operation, and disables timer output.

(TMC5n register = 0000xx00B, ×: don't care)

- For the alternate-function pin settings, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.
- <2> When the TMC5n.TCE5n bit is set to 1, the counter counts the number of pulses input from the TI5n pin.
- <3> When the values of the TM5n register and CR5n register match, the INTTM5n signal is generated (TM5n register is cleared to 00H).
- <4> Then, the INTTM5n signal is generated each time the values of the TM5n register and CR5n register match.

INTTM5n signal is generated when the valid edge of TI5n pin is input N + 1 times: N = 00H to FFH

Caution During external event counter operation, do not rewrite the value of the CR5n register.

Remark n = 0, 1

Figure 8-3. Timing of External Event Counter Operation (with Rising Edge Specified)

TI5n

CR5n	N
TCE5n	
INTTM5n	
Remark n :	= 0, 1

8.4.3 Square-wave output operation

A square wave with any frequency can be output at an interval determined by the value preset in the CR5n register. By setting the TMC5n.TOE5n bit to 1, the output status of the TO5n pin is inverted at an interval determined by the count value preset in the CR5n register. In this way, a square wave of any frequency can be output (duty = 50%) (n = 0, 1).

Setting method

<1> Set each register.

- TCL5n register: Selects the count clock (t).
- CR5n register: Compare value (N)
- TMC5n register: Stops count operation, selects the mode in which clear & start occurs on a match between the TM5n register and CR5n register, sets initial value of timer output, enables timer output F/F inversion operation, and enables timer output. (TMC5n register = 00001011B or 00000111B)
- For the alternate-function pin settings, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.
- <2> When the TMC5n.TCE5n bit is set to 1, counting starts.
- <3> When the values of the TM5n register and CR5n register match, the timer output F/F is inverted. Moreover, the INTTM5n signal is generated and the TM5n register is cleared to 00H.
- <4> Then, the timer output F/F is inverted during the same interval and a square wave is output from the TO5n pin.

Frequency = 1/2t(N + 1): N = 00H to FFH

Caution Do not rewrite the value of the CR5n register during square-wave output.

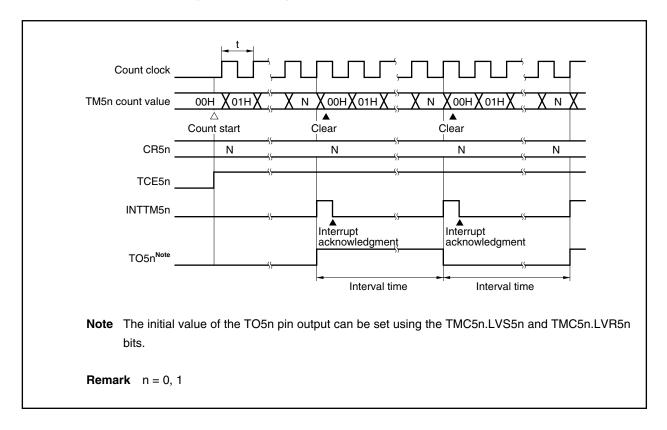

Figure 8-4. Timing of Square-Wave Output Operation

8.4.4 8-bit PWM output operation

By setting the TMC5n.TMC5n6 bit to 1, 8-bit timer/event counter 5n performs PWM output.

Pulses with a duty factor determined by the value set in the CR5n register are output from the TO5n pin.

Set the width of the active level of the PWM pulse in the CR5n register. The active level can be selected using the TMC5n.TMC5n1 bit.

The count clock can be selected using the TCL5n register.

PWM output can be enabled/disabled by the TMC5n.TOE5n bit.

Caution The CR5n register rewrite interval must be three or more operation clocks (set by the TCL5n register).

Use method

<1> Set each register.

- TCL5n register: Selects the count clock (t).
- CR5n register: Compare value (N)
- TMC5n register: Stops count operation, selects PWM mode, and leave timer output F/F unchanged, sets active level, and enables timer output. (TMC5n register = 01000001B or 01000011B)
- For the alternate-function pin settings, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.
- <2> When the TMC5n.TCE5n bit is set to 1, counting starts.

PWM output operation

- <1> When counting starts, PWM output (output from the TO5n pin) outputs the inactive level until an overflow occurs.
- <2> When an overflow occurs, the active level set by setting method <1> is output. The active level is output until the value of the CR5n register and the count value of the TM5n register match. An interrupt request signal (INTTM5n) is generated.
- <3> When the value of the CR5n register and the count value of the TM5n register match, the inactive level is output and continues to be output until an overflow occurs again.
- <4> Then, steps <2> and <3> are repeated until counting is stopped.
- <5> When counting is stopped by clearing TCE5n bit to 0, PWM output becomes inactive.

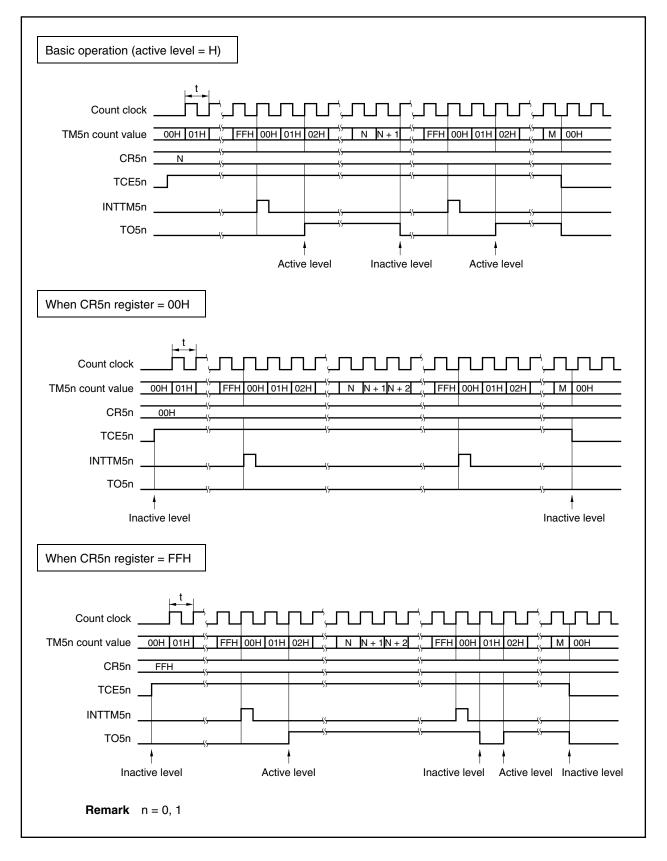

Cycle = 256t, active level width = Nt, duty = N/256: N = 00H to FFH

Remarks 1. n = 0, 1

2. For the detailed timing, refer to Figure 8-5 Timing of PWM Output Operation and Figure 8-6 Timing of Operation Based on CR5n Register Transitions.

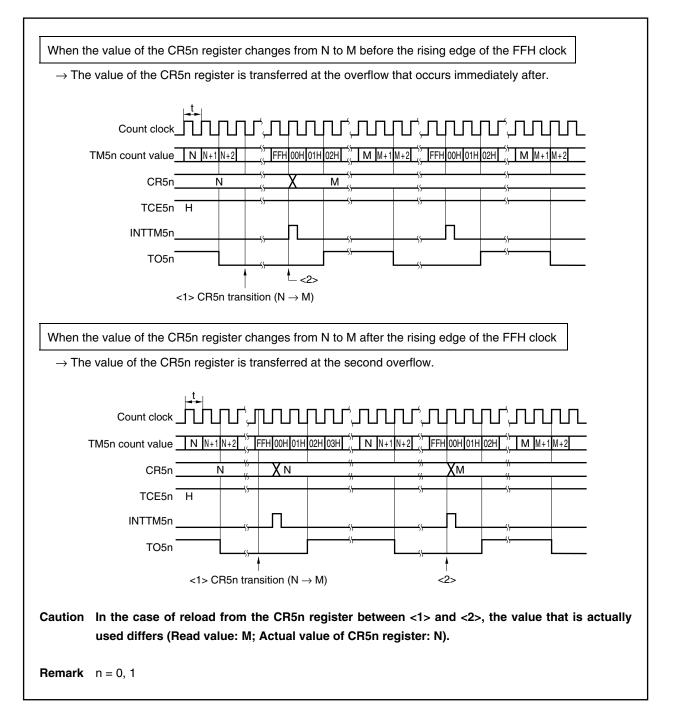

(a) Basic operation of PWM output

(b) Operation based on CR5n register transitions

8.4.5 Operation as interval timer (16 bits)

The 16-bit resolution timer/event counter mode is selected by setting the TMC51.TMC514 bit to 1.

8-bit timer/event counter 5n operates as an interval timer by repeatedly generating interrupts using the count value preset in 16-bit timer compare register 5 (CR5) as the interval.

Setting method

<1> Set each register.

 TCL50 register: 	Selects the count clock (t)

- (The TCL51 register does not need to be set in cascade connection)
- CR50 register: Compare value (N) ... Lower 8 bits (settable from 00H to FFH)
- CR51 register: Compare value (N) ... Higher 8 bits (settable from 00H to FFH)
- TMC50, TMC51 register: Selects the mode in which clear & start occurs on a match between TM5 register and CR5 register (x: don't care)
 - (TMC50 register = 0000xx00B)
 - TMC51 register = 0001xx00B
- <2> Set the TMC51.TCE51 bit to 1. Then set the TMC50.TCE50 bit to 1 to start the count operation.
- <3> When the values of the TM5 register and CR5 register connected in cascade match, the INTTM50 signal is generated (the TM5 register is cleared to 0000H).
- <4> The INTTM50 signal is then generated repeatedly at the same interval.

Interval time = $(N + 1) \times t$: N = 0000H to FFFH

- Cautions 1. To write using 8-bit access during cascade connection, set the TCE51 bit to 1 at operation start and then set the TCE50 bit to 1. When operation is stopped, clear the TCE50 bit to 0 and then clear the TCE51 bit to 0.
 - During cascade connection, TI50 input, TO50 output, and the INTTM50 signal are used. Do not use TI51 input, TO51 output, and the INTTM51 signal; mask them instead (for details, refer to CHAPTER 17 INTERRUPT/EXCEPTION PROCESSING FUNCTION). Clear the LVS51, LVR51, TMC511, and TOE51 bits to 0.
 - 3. Do not change the value of the CR5 register during timer operation.

Figure 8-7 shows a timing example of the cascade connection mode with 16-bit resolution.

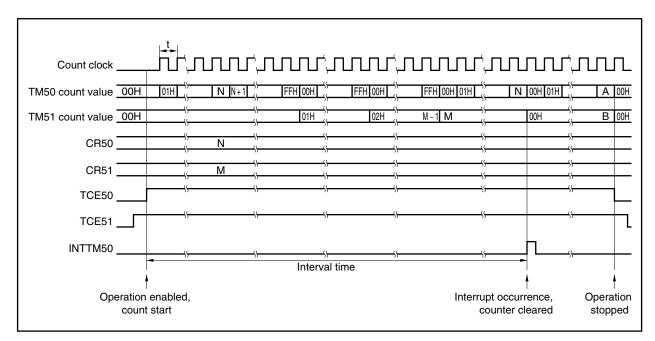

Figure 8-7. Cascade Connection Mode with 16-bit Resolution

8.4.6 Operation as external event counter (16 bits)

The 16-bit resolution timer/event counter mode is selected by setting the TMC51.TMC514 bit to 1.

The external event counter counts the number of clock pulses input to the TI50 pin from an external source using 16-bit timer counter 5 (TM5).

Setting method

<1> Set each register.

•	TCL50 register:	Selects the TI50 pin input edge.
---	-----------------	----------------------------------

(The TCL51 register does not have to be set during cascade connection.)

- Falling edge of TI50 pin \rightarrow TCL50 register = 00H
- Rising edge of TI50 pin \rightarrow TCL50 register = 01H
- CR50 register: Compare value (N) ... Lower 8 bits (settable from 00H to FFH)
- CR51 register: Compare value (N) ... Higher 8 bits (settable from 00H to FFH)
- TMC50, TMC51 registers: Stops count operation, selects the clear & stop mode entered on a match between the TM5 register and CR5 register, disables timer output F/F inversion, and disables timer output.

(×: don't care)

TMC50 register = 0000xx00B

TMC51 register = 0001xx00B

- For the alternate-function pin settings, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.
- <2> Set the TMC51.TCE51 bit to 1. Then set the TMC50.TCE50 bit to 1 and count the number of pulses input from the TI50 pin.
- <3> When the values of the TM5 register and CR5 register connected in cascade match, the INTTM50 signal is generated (the TM5 register is cleared to 0000H).
- <4> The INTTM50 signal is then generated each time the values of the TM5 register and CR5 register match.

INTTM50 signal is generated when the valid edge of TI50 pin is input N + 1 times: N = 0000H to FFFFH

- Cautions 1. During external event counter operation, do not rewrite the value of the CR5n register.
 - 2. To write using 8-bit access during cascade connection, set the TCE51 bit to 1 and then set the TCE50 bit to 1. When operation is stopped, clear the TCE50 bit to 0 and then clear the TCE51 bit to 0 (n = 0, 1).
 - 3. During cascade connection, TI50 input and the INTTM50 signal are used. Do not use TI51 input, TO51 output, and the INTTM51 signal; mask them instead (for details, refer to CHAPTER 17 INTERRUPT/EXCEPTION PROCESSING FUNCTION). Clear the LVS51, LVR51, TMC511, and TOE51 bits to 0.
 - 4. Do not change the value of the CR5 register during external event counter operation.

8.4.7 Square-wave output operation (16-bit resolution)

The 16-bit resolution timer/event counter mode is selected by setting the TMC51.TMC514 bit to 1.

8-bit timer/event counter 5n outputs a square wave of any frequency using the interval preset in 16-bit timer compare register 5 (CR5).

Setting method

<1> Set each register.

TCL50 register: Selects the count clock (t)

(The TCL51 register does not have to be set in cascade connection)

- CR50 register: Compare value (N) ... Lower 8 bits (settable from 00H to FFH)
- CR51 register: Compare value (N) ... Higher 8 bits (settable from 00H to FFH)
- TMC50, TCM51 registers: Stops count operation, selects the mode in which clear & start occurs on a match between the TM5 register and CR5 register.

LVS50	LVR50	Timer Output F/F Status Settings
1	0	High-level output
0	1	Low-level output

Enables timer output F/F inversion, and enables timer output.

- For the alternate-function pin settings, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.
- <2> Set the TMC51.TCE51 bit to 1. Then set the TMC50.TCE50 bit to 1 to start the count operation.
- <3> When the values of the TM5 register and the CR5 register connected in cascade match, the TO50 timer output F/F is inverted. Moreover, the INTTM50 signal is generated and the TM5 register is cleared to 0000H.
- <4> Then, the timer output F/F is inverted during the same interval and a square wave is output from the TO50 pin.

Frequency = 1/2t(N + 1): N = 0000H to FFFH

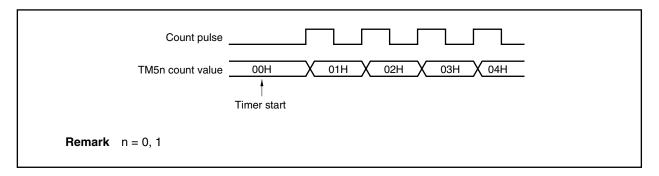

Caution Do not write a different value to the CR5 register during operation.

8.4.8 Cautions

(1) Error on starting timer

An error of up to 1 clock occurs before the match signal is generated after the timer has been started. This is because the TM5n register is started asynchronously to the count pulse.

CHAPTER 9 8-BIT TIMER H

In the V850ES/KE1, two channels of 8-bit timer H are provided.

9.1 Functions

8-bit timer Hn has the following functions (n = 0, 1).

- Interval timer
- Square wave output
- PWM output
- Carrier generator

9.2 Configuration

8-bit timer Hn includes the following hardware.

Table 9-1. Configuration of 8-bit Timer Hn

Item	Configuration
Timer registers	8-bit timer counter Hn: 1 each
Register	8-bit timer H compare register n0 (CMPn0): 1 each 8-bit timer H compare register n1 (CMPn1): 1 each
Timer outputs	TOHn, output controller
Control registers ^{Note}	8-bit timer H mode register n (TMHMDn) 8-bit timer H carrier control register n (TMCYCn)

Note To use the TOHn pin function, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.

The block diagram is shown below.

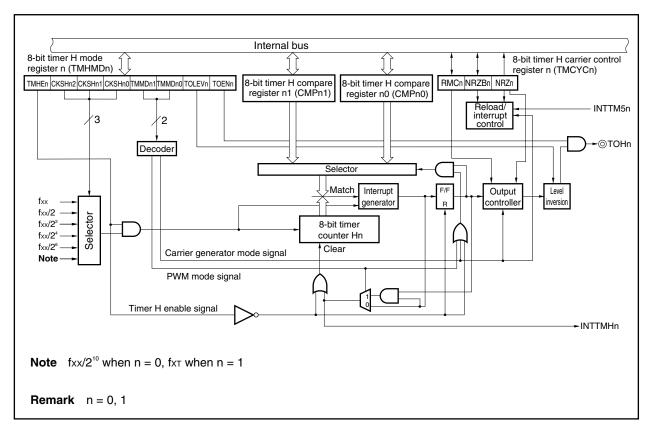

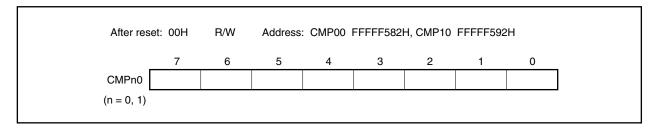

Figure 9-1. Block Diagram of 8-bit Timer Hn

(1) 8-bit timer H compare register n0 (CMPn0)

This register can be read or written in 8-bit units. This register is used in all of the timer operation modes. This register constantly compares the value set to the CMPn0 register with the count value of 8-bit timer counter Hn and, when the two values match, generates an interrupt request signal (INTTMHn) and inverts the output level of the TOHn pin.

Rewrite the value of the CMPn0 register while the timer is stopped (TMHMDn.TMHEn bit = 0). Reset sets this register to 00H.

(2) 8-bit timer H compare register n1 (CMPn1)

<R>

This register can be read or written in 8-bit units.

This register is used in the PWM output mode and carrier generator mode.

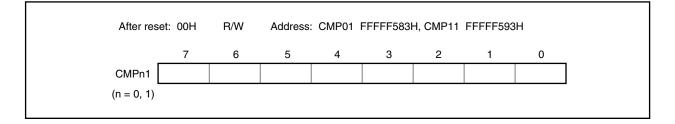

In the PWM output mode, this register constantly compares the value set to the CMPn1 register with the count value of 8-bit timer counter Hn and, when the two values match, inverts the output level of the TOHn pin. No interrupt request signal is generated.

In the carrier generator mode, the CMPn1 register always compares the value set to the CMPn1 register with the count value of 8-bit timer counter Hn and, when the two values match, generates an interrupt request signal (INTTMHn). At the same time, the count value is cleared.

The CMPn1 register can be rewritten during timer count operation.

If the value of the CMPn1 register is rewritten while the timer is operating, the new value is latched and transferred to the CMPn1 register when the count value of the timer matches the old value of the CMPn1 register, and then the value of the CMPn1 register is changed to the new value. If matching of the count value and the CMPn1 register value and writing a value to the CMPn1 register conflict, the value of the CMPn1 register is not changed.

Reset sets this register to 00H.

The CMPn1 register can be rewritten during timer count operation.

In the carrier generator mode, after the CMPn1 register is set, if the count value of 8-bit timer counter Hn and the set value of the CMPn1 register match, an interrupt request signal (INTTMHn) is generated. At the same time, the value of 8-bit timer counter Hn is cleared to 00H.

If the set value of the CMPn1 register is rewritten during timer operation, the reload timing is when the count value of 8-bit timer counter Hn and the set value of the CMPn1 register match. If the transfer timing and write to the CMPn1 register from the CPU conflict, transfer is not performed.

Caution In the PWM output mode and carrier generator mode, be sure to set the CMPn1 register when starting the timer count operation (TMHMDn.TMHEn bit = 1) after the timer count operation was stopped (TMHEn bit = 0) (be sure to set again even if setting the same value to the CMPn1 register).

User's Manual U16892EJ2V0UD

9.3 Registers

The registers that control 8-bit timer Hn are as follows.

- 8-bit timer H mode register n (TMHMDn)
- 8-bit timer H carrier control register n (TMCYCn)
- Remarks 1. To use the TOHn pin function, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.

2. n = 0, 1

(1) 8-bit timer H mode register n (TMHMDn) The TMHMDn register controls the mode of 8-bit timer Hn. TMHMDn register can be read or written in 8-bit or 1-bit units. Reset sets TMHMDn to 00H.

9.4 Operation

9.4.1 Operation as interval timer/square wave output

When the count value of 8-bit timer counter Hn and the set value of the CMPn0 register match, an interrupt request signal (INTTMHn) is generated and 8-bit timer counter Hn is cleared to 00H.

The CMPn1 register cannot be used in the interval timer mode. Even if the CMPn1 register is set, this has no effect on the timer output because matches between 8-bit timer counter Hn and the CMPn1 register are not detected.

A square wave of the desired frequency (duty = 50%) is output from the TOHn pin, by setting the TMHMDn.TOENn bit to 1.

Remarks 1. For the alternate-function pin (TOHn) settings, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.

2. For INTTMHn interrupt enable, refer to CHAPTER 17 INTERRUPT/EXCEPTION PROCESSING FUNCTION.

Setting

<1> Set each register.

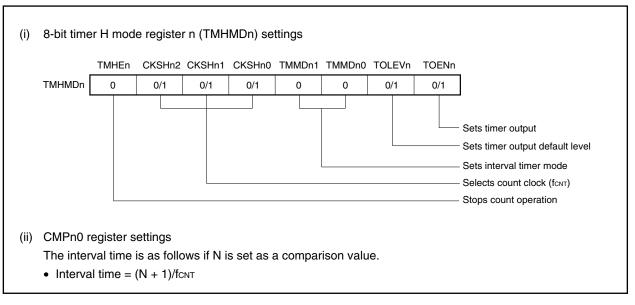

Figure 9-2. Register Settings in Interval Timer Mode

<2> When the TMHEn bit is set to 1, counting starts.

- <3> When the count value of 8-bit timer counter Hn and the set value of the CMPn0 register match, the INTTMHn signal is generated and 8-bit timer counter Hn is cleared to 00H.
- <4> Then, the INTTMHn signal is generated in the same interval. To stop the count operation, clear the TMHEn bit to 0.

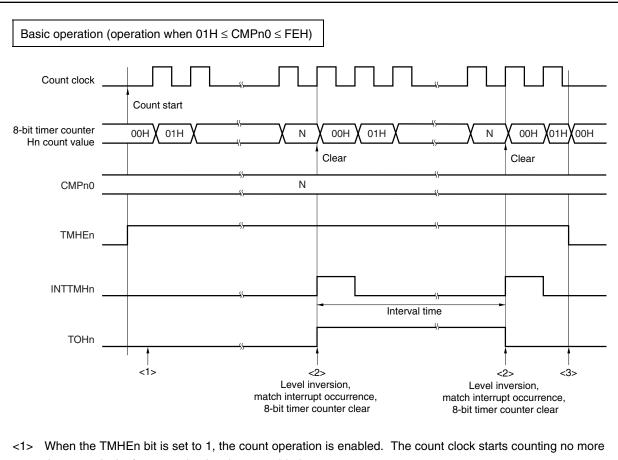

Figure 9-3. Timing of Interval Timer/Square Wave Output Operation (1/2)

than one clock after operation has been enabled.

<2> When the count value of 8-bit timer counter Hn and the set value of the CMPn0 register match, the value of 8-bit timer counter Hn is cleared, the TOHn output level is inverted, and the INTTMHn signal is output at the rising edge of the count clock.

<3> The INTTMHn signal and TOHn output are set to the default level when the TMHEn bit is cleared to 0 during 8-bit timer Hn operation. If the level is already at the default level before the TMHMDn.TMHEn bit is cleared to 0, that level is maintained.

Remarks 1. n = 0, 1 **2.** $01H \le N \le FEH$

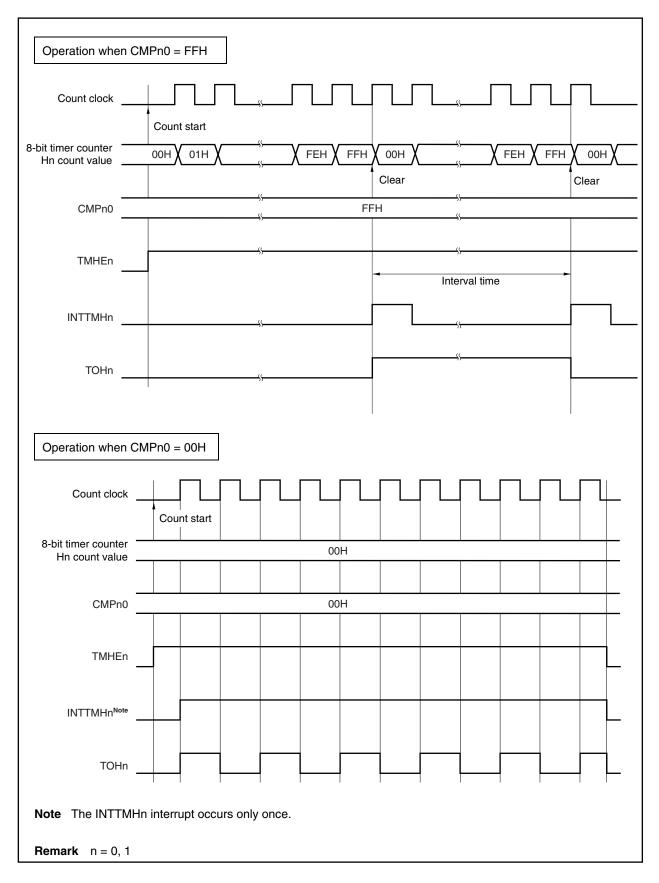

Figure 9-3. Timing of Interval Timer/Square Wave Output Operation (2/2)

<R>

9.4.2 PWM output mode operation

In the PWM output mode, a pulse of any duty and cycle can be output.

The CMPn0 register controls the timer output (TOHn) cycle. Rewriting the CMPn0 register during timer operation is prohibited.

The CMPn1 register controls the timer output (TOHn) duty. The CMPn1 register can be rewritten during timer operation.

The operation in the PWM output mode is as follows.

After timer counting starts, when the count value of 8-bit timer counter Hn and the set value of the CMPn0 register match, the TOHn output level is inverted and 8-bit timer counter Hn is cleared to 00H. When the count value of 8-bit timer counter Hn and the set value of the CMPn1 register match, the TOHn output level is inverted.

- Remarks 1. For the alternate-function pin (TOHn) settings, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.
 - 2. For INTTMHn interrupt enable, refer to CHAPTER 17 INTERRUPT/EXCEPTION PROCESSING FUNCTION.

Setting

<1> Set each register.

(i) 8-bit	timer H m	node regis	ter n (TM	HMDn) se	ettings				
	TMHEn	CKSHn2	CKSHn1	CKSHn0	TMMDn1	TMMDn0	TOLEVn	TOENn	
TMHMDn	0	0/1	0/1	0/1	1	0	0/1	1	
• Co (ii) CMP	n1 registe ompare v 1. n = 0	alue (N): S er setting alue (M): S	Sets duty		£ FFH				Enables timer output Sets timer output default level Selects PWM output mode Selects count clock (fcNT) Stops count operation

<2> When the TMHEn bit is set to 1, counting starts.

- <3> After the count operation is enabled, the first compare register to be compared is the CMPn0 register. When the count value of 8-bit timer counter Hn and the set value of the CMPn0 register match, 8-bit timer counter Hn is cleared, an interrupt request signal (INTTMHn) is generated, and the TOHn output level is inverted. At the same time, the register that is compared with 8-bit timer counter Hn changes from the CMPn0 register to the CMPn1 register.
- <4> When the count value of 8-bit timer counter Hn and the set value of the CMPn1 register match, the TOHn output level is inverted, and at the same time the register that is compared with 8-bit timer counter Hn changes from the CMPn1 register to the CMPn0 register. At this time, 8-bit timer counter Hn is not cleared and the INTTMHn signal is not generated.
- <5> A pulse of any duty can be obtained through the repetition of steps <3> and <4> above.
- <6> To stop the count operation, clear the TMHEn bit to 0.

<R>

<R>

Designating the set value of the CMPn0 register as (N), the set value of the CMPn1 register as (M), and the count clock frequency as f_{CNT}, the PWM pulse output cycle and duty are as follows.

PWM pulse output cycle = $(N + 1)/f_{CNT}$ Duty = inactive width: Active width = (M + 1) : (N + 1)

- Cautions 1. The set value of the CMPn1 register can be changed while the timer counter is operating. However, this takes a duration of at least three operating clocks (signal selected by the CKSHn2 to CKSHn0 bits of the TMHMDn register) from when the value of the CMPn1 register is changed until the value is transferred to the register.
 - Be sure to set the CMPn1 register when starting the timer count operation (TMHEn bit = 1) after the timer count operation was stopped (TMHEn bit = 0) (be sure to set again even if setting the same value to the CMPn1 register).
 - 3. Make sure that the CMPn1 register set value (M) and CMPn0 register set value (N) are within the following range.

 $00H \le CMPn1 (M) < CMPn0 (N) \le FFH$

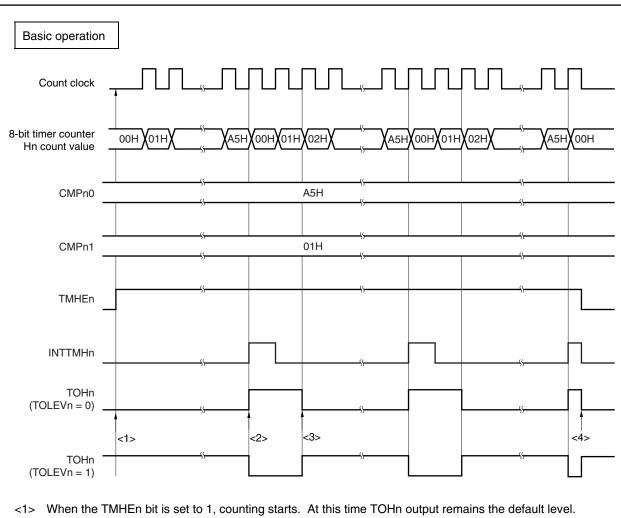

Figure 9-5. Operation Timing in PWM Output Mode (1/4)

- <2> When the count value of 8-bit timer counter Hn and the set value of the CMPn0 register match, the TOHn output level is inverted, 8-bit timer counter Hn is cleared, and the INTTMHn signal is output.
- <3> When the count value of 8-bit timer counter Hn and the set value of the CMPn1 register match, the TOHn output level is inverted. At this time, the value of 8-bit timer counter Hn is not cleared and the INTTMHn signal is not output.
- <4> When the TMHEn bit is cleared to 0 during 8-bit timer Hn operation, the INTTMHn signal and TOHn output are set to the default level.

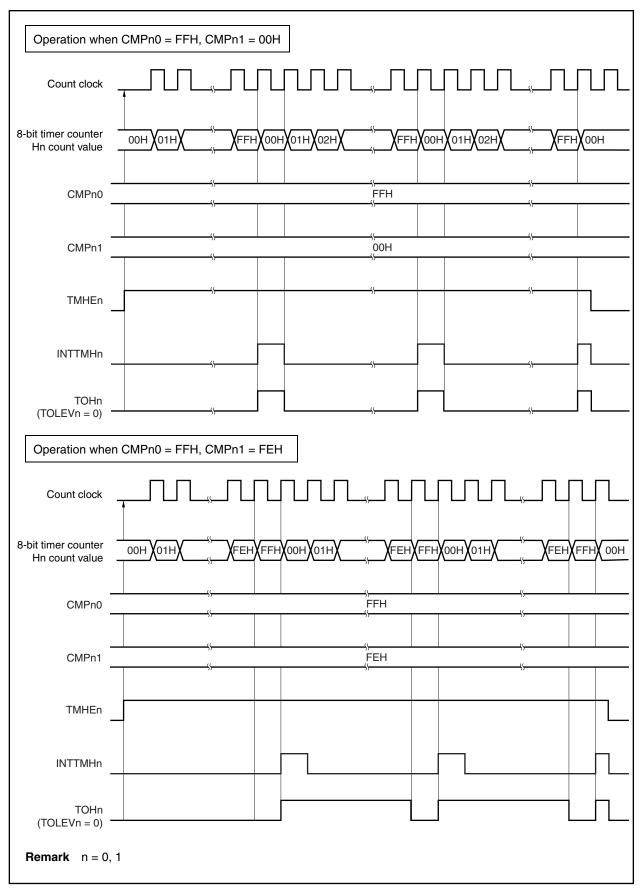

Figure 9-5. Operation Timing in PWM Output Mode (2/4)

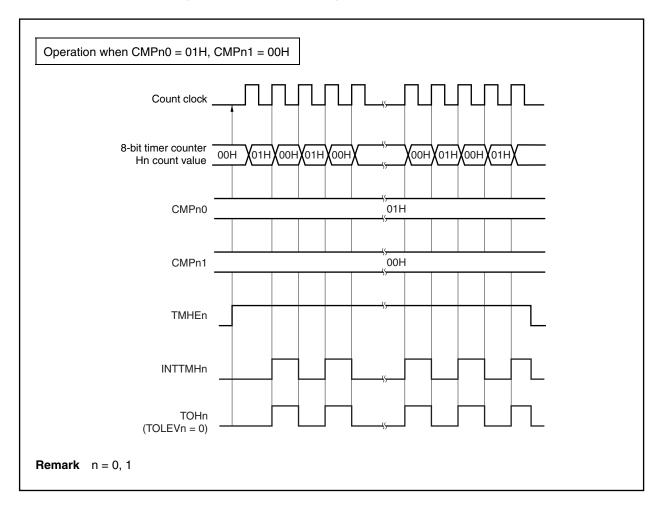

Figure 9-5. Operation Timing in PWM Output Mode (3/4)

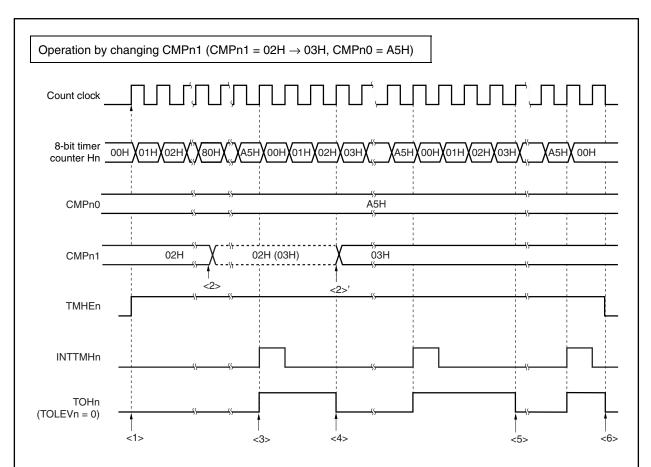

Figure 9-5. Operation Timing in PWM Output Mode (4/4)

- <1> When the TMHEn bit is set to 1, counting starts. At this time, the TOHn output remains the default level.
- <2> The set value of the CMPn1 register can be changed during count operation. This operation is asynchronous to the count clock.
- <3> When the count value of 8-bit timer counter Hn and the set value of the CMPn0 register match, 8-bit timer counter Hn is cleared, the TOHn output level is inverted, and the INTTMHn signal is generated.
- <4> Even if the value of the CMPn1 register is changed, that value is latched and not transferred to the register. When the count value of 8-bit timer counter Hn and the set value of the CMPn1 register prior to the change match, the changed value is transferred to the CMPn1 register and the value of the CMPn1 register is changed (<2>').

However, three or more count clocks are required from the time the value of the CMPn1 register is changed until it is transferred to the register. Even if a match signal is generated within three count clocks, the changed value cannot be transferred to the register.

- <5> When the count value of 8-bit timer counter Hn matches the changed set value of the CMPn1 register, the TOHn output level is inverted. 8-bit timer counter Hn is not cleared and the INTTMHn signal is not generated.
- <6> When the TMHEn bit is cleared to 0 during 8-bit timer Hn operation, the INTTMHn signal and TOHn output are set to the default level.

<R>

9.4.3 Carrier generator mode operation

The carrier clock generated by 8-bit timer Hn is output using the cycle set with 8-bit timer/event counter 5n.

In the carrier generator mode, 8-bit timer/event counter 5n is used to control the extent to which the carrier pulse of 8-bit timer Hn is output, and the carrier pulse is output from the TOHn output.

- Remarks 1. For the alternate-function pin (TOHn) settings, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.
 - 2. For INTTMHn interrupt enable, refer to CHAPTER 17 INTERRUPT/EXCEPTION PROCESSING FUNCTION.

(1) Carrier generation

In the carrier generator mode, the CMPn0 register generates a waveform with the low-level width of the carrier pulse and the CMPn1 register generates a waveform with the high-level width of the carrier pulse. During 8-bit timer Hn operation, the CMPn1 register can be rewritten, but rewriting of the CMPn0 register is prohibited.

(2) Carrier output control

Carrier output control is performed with the interrupt request signal (INTTM5n) of 8-bit timer/event counter 5n and the TMCYCn.NRZBn and TMCYCn.RMCn bits. The output relationships are as follows.

RMCn Bit	NRZBn Bit	Output				
0	0	Low level output				
0	1	High level output				
1	0	Low level output				
1	1	Carrier pulse output				

To control carrier pulse output during count operation, the TMCYCn.NRZn and TMCYCn.NRZBn bits have a master and slave bit configuration. The NRZn bit is read-only while the NRZBn bit can be read and written. The INTTM5n signal is synchronized with the 8-bit timer Hn clock and output as the INTTM5Hn signal. The INTTM5Hn signal becomes the data transfer signal of the NRZn bit and the value of the NRZBn bit is transferred to the NRZn bit. The transfer timing from the NRZBn bit to the NRZn bit is as follows.

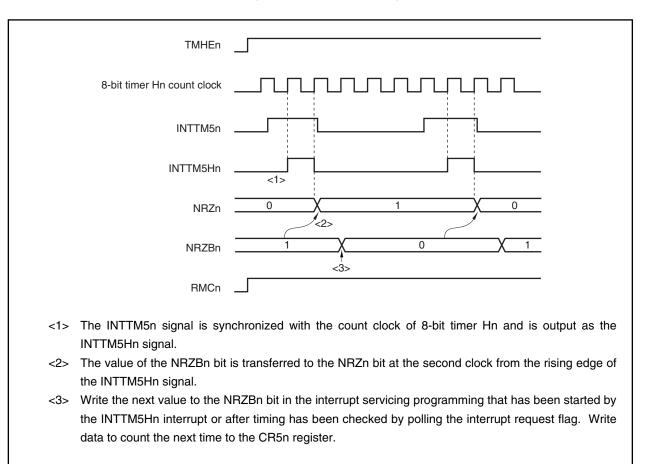

Figure 9-6. Transfer Timing

- Cautions 1. Do not rewrite the NRZBn bit again until at least the second clock after it has been rewritten, or else transfer from the NRZBn bit to the NRZn bit is not guaranteed.
 - 2. When using 8-bit timer/event counter 5n in the carrier generator mode, an interrupt occurs at the timing of <1>. An interrupt occurs at a different timing when it is used in other than the carrier generator mode.

Remark n = 0, 1

<R>

Setting

<1> Set each register.

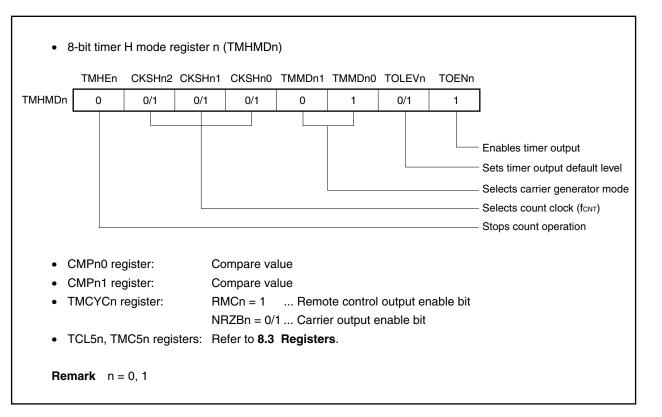

Figure 9-7. Register Settings in Carrier Generator Mode

<2> When the TMHEn bit is set to 1, 8-bit timer Hn count operation starts.

- <3> When the TMC5n.TCE5n bit is set to 1, 8-bit timer/event counter 5n count operation starts.
- <4> After the count operation is enabled, the first compare register to be compared is the CMPn0 register. When the count value of 8-bit timer counter Hn and the set value of the CMPn0 register match, the INTTMHn signal is generated, 8-bit timer counter Hn is cleared, and at the same time, the register that is compared with 8-bit timer counter Hn changes from the CMPn0 register to the CMPn1 register.
- <5> When the count value of 8-bit timer counter Hn and the set value of the CMPn1 register match, the INTTMHn signal is generated, 8-bit timer counter Hn is cleared, and at the same time, the register that is compared with 8-bit timer counter Hn changes from the CMPn1 register to the CMPn0 register.
- <6> The carrier clock is obtained through the repetition of steps <4> and <5> above.
- <7> The INTTM5n signal is synchronized with 8-bit timer Hn and output as the INTTM5Hn signal. This signal becomes the data transfer signal of the NRZBn bit and the value of the NRZBn bit is transferred to the NRZn bit.
- <8> Write the next value to the NRZBn bit in the interrupt servicing programming that has been started by the INTTM5Hn interrupt or after timing has been checked by polling the interrupt request flag. Write data to count the next time to the CR5n register.
 - <9> When the NRZn bit becomes high level, the carrier clock is output from the TOHn pin.
 - <10> Any carrier clock can be obtained through the repetition of the above steps. To stop the count operation, clear the TMHEn bit to 0.

<R>

Designating the set value of the CMPn0 register as (N), the set value of the CMPn1 register as (M), and the count clock frequency as fcNT, the carrier clock output cycle and duty are as follows.

Carrier clock output cycle = $(N + M + 2)/f_{CNT}$ Duty = High level width: Carrier clock output width = (M + 1): (N + M + 2)

- Cautions 1. Be sure to set the CMPn1 register when starting the timer count operation (TMHEn bit = 1) after the timer count operation was stopped (TMHEn bit = 0) (be sure to set again even if setting the same value to the CMPn1 register).
 - 2. Set the values of the CMPn0 and CMPn1 registers in the range of 01H to FFH.
 - 3. In the carrier generator mode, three operating clocks (signal selected by the TMHMDn.CKSHn0 to TMHMDn.CKSHn2 bits) are required for actual transfer of the new value to the register after the CMPn1 register has been rewritten.
 - 4. Be sure to perform the TMCYCn.RMCn bit setting before the start of the count operation.
 - 5. When using the carrier generator mode, set the 8-bit timer Hn count clock frequency to six times the 8-bit timer/event counter 5n count clock frequency or higher.

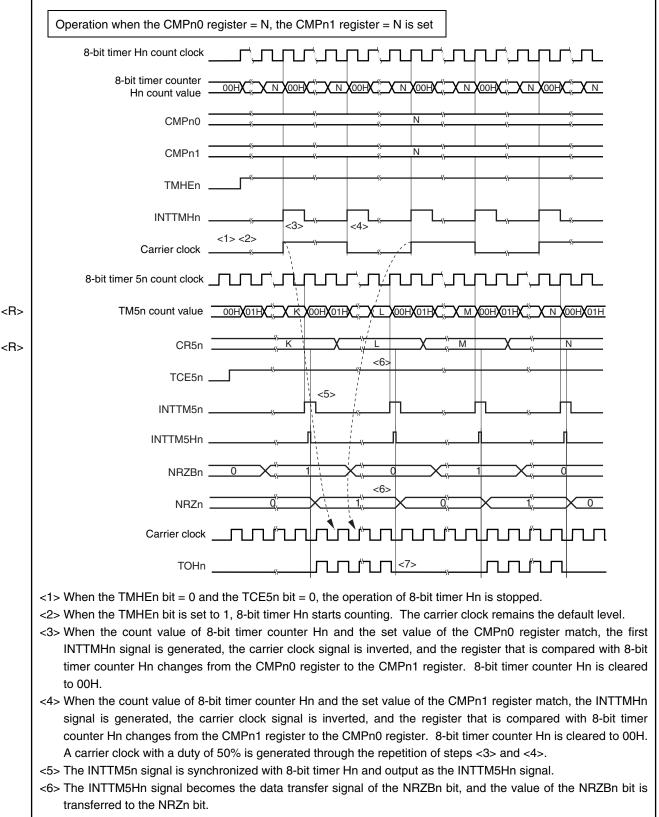

Figure 9-8. Carrier Generator Mode (1/3)

<7> The TOHn output is made low level by clearing the NRZn bit = 0.

Remark n = 0, 1

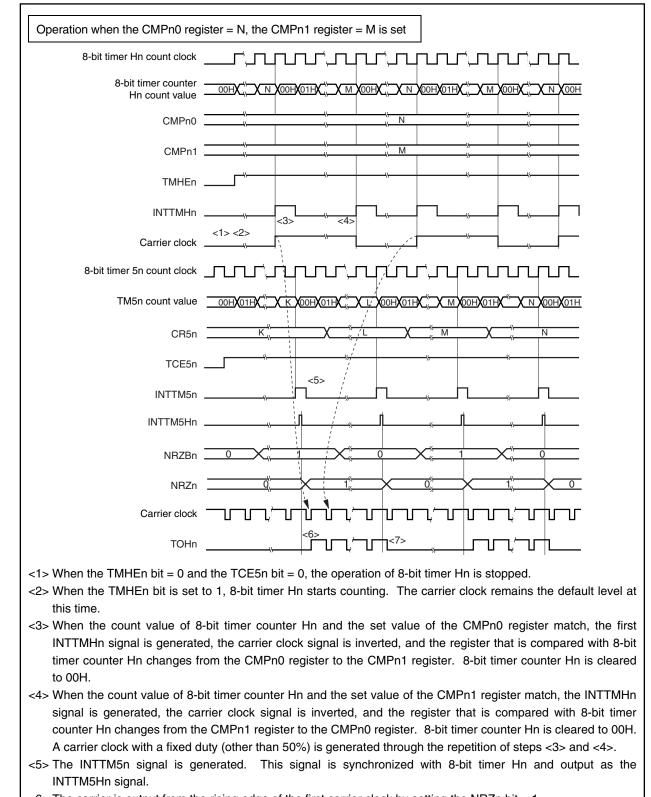

Figure 9-8. Carrier Generator Mode (2/3)

<6> The carrier is output from the rising edge of the first carrier clock by setting the NRZn bit = 1.

<7> By setting the NRZn bit = 0, the TOHn output is also maintained high level while the carrier clock is high level, and does not change to low level (the high level width of the carrier waveform is guaranteed through steps <6> and <7>).

Remark n = 0, 1

<R>

<R>

Figure 9-8. Carrier Generator Mode (3/3)

<1> When the TMHEn bit is set to 1, counting starts. The carrier clock remains the default level at this time.

- <R> <2> When the count value of the 8-bit timer counter Hn matches the value of the CMPn0 register, the INTTMHn signal is output, the carrier signal is inverted, and the 8-bit timer counter is cleared to 00H. At the same time, the compare register whose value is to be compared with that of the 8-bit timer counter Hn is changed from the CMPn0 register to the CMPn1 register.
- <R> <3> The CMPn1 register is asynchronous to the count clock, and its value can be changed while the 8-bit timer Hn is operating. The new value (L) to which the value of the register is to be changed is latched. When the count value of the 8-bit timer counter Hn matches the value (M) of the CMPn1 register before the change, the CMPn1 register is changed (<3>').

However, it takes three count clocks or more since the value of the CMPn1 register has been changed until the value is transferred to the register. Even if a match signal is generated before the duration of three count clocks elapses, the new value is not transferred to the register.

- <4> When the count value of 8-bit timer counter Hn and the value (M) of the CMPn1 register match, the INTTMHn signal is output, the carrier signal is inverted, and 8-bit timer counter Hn is cleared to 00H. At the same time, the compare register whose value is to be compared with that of the 8-bit timer counter Hn is changed from the CMPn1 register to the CMPn0 register.
- <5> The timing at which the count value of 8-bit timer counter Hn and the value of the CMPn1 register match again is the changed value (L).

Remark n = 0, 1

CHAPTER 10 INTERVAL TIMER, WATCH TIMER

The V850ES/KE1 includes interval timer BRG and a watch timer. Interval timer BRG can also be used as the source clock of the watch timer. The watch timer can also be used as interval timer WT.

Two interval timer channels and one watch timer channel can be used at the same time.

10.1 Interval Timer BRG

10.1.1 Functions

Interval timer BRG has the following functions.

- Interval timer BRG: An interrupt request signal (INTBRG) is generated at a specified interval.

 Generation of count clock for watch timer: When the main clock is used as the count clock for the watch timer, a count clock (fBRG) is generated.

10.1.2 Configuration

The following shows the block diagram of interval timer BRG.

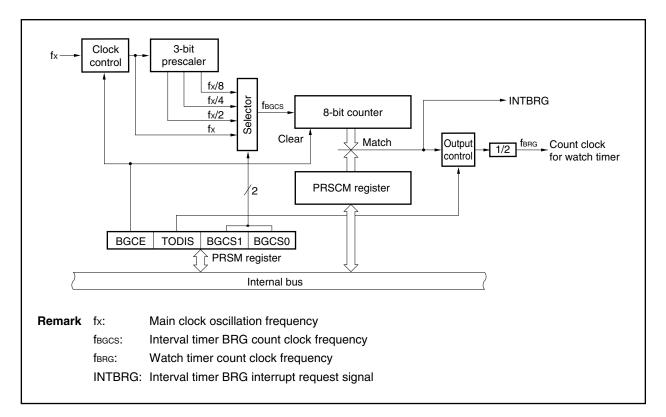

Figure 10-1. Block Diagram of Interval Timer BRG

(1) Clock control

The clock control controls supply/stop of the operation clock of interval timer BRG.

(2) 3-bit prescaler

The 3-bit prescaler divides fx to generate fx/2, fx/4, and fx/8.

(3) Selector

The selector selects the count clock (fbgcs) for interval timer BRG from fx, fx/2, fx/4, and fx/8.

(4) 8-bit counter

The 8-bit counter counts the count clock (fBGCS).

(5) Output control

The output control controls supply of the count clock (fBRG) for the watch timer.

(6) PRSCM register

The PRSCM register is an 8-bit compare register that sets the interval time.

(7) PRSM register

The PRSM register controls the operation of interval timer BRG, the selector, and clock supply to the watch timer.

10.1.3 Registers

Interval timer BRG includes the following registers.

(1) Interval timer BRG mode register (PRSM)

PRSM controls the operation of interval timer BRG, selection of count clock, and clock supply to the watch timer.

This register can be read or written in 8-bit or 1-bit units. Reset sets PRSM to 00H.

10.1.4 Operation

(1) Operation of interval timer BRG

Set the count clock by using the BGCS1 and BGCS0 bits of PRSM and the 8-bit compare value by using the PRSCM register.

When the PRSM.BGCE bit is set (1), interval timer BRG starts operating.

Each time the count value of the 8-bit counter and the set value in the PRSCM register match, an interrupt request signal (INTBRG) is generated. At the same time, the 8-bit counter is cleared to 01H and counting is continued.

The interval time can be obtained from the following equation.

Interval time = $2^m \times N/fx$

- **Remark** m: Division value (set values of BGCS1 and BGCS0^{Note} bits) = 0 to 3
 - N: Set value in PRSCM register = 1 to 256 (when the set value in the PRSCM register is 00H, N = 256)
 - fx: Main clock oscillation frequency

Note When the set value of the PRSCM register = 01H, the INTBRG interrupt occurs only once.

(2) Count clock supply for watch timer

Set the count clock by using the BGCS1 and BGCS0 bits of PRSM and the 8-bit compare value by using the PRSCM register, so that the count clock frequency (fBRG) of the watch timer is 32.768 kHz. Clear (0) the PRSM.TODIS bit at the same time.

When the PRSM.BGCE bit is set (1), fBRG is supplied to the watch timer. fBRG is obtained from the following equation.

 $f_{BRG} = f_X/(2^{m+1} \times N)$

To set fBRG to 32.768 kHz, perform the following calculation to set the BGCS1 and BGCS0 bits and the PRSCM register.

- <1> Set N = fx/65,536 (round off the decimal) to set m = 0.
- <2> If N is even, N = N/2 and m = m + 1
- <3> Repeat step <2> until N is even or m = 3
- <4> Set N to the PRSCM register and m to the BGCS1 and BGCS0 bits.

Example: When fx = 4.00 MHz

- <1> N = 4,000,000/65,536 = 61 (round off the decimal), m = 0
- <2>, <3> Since N is odd, the values remain as N = 61, m = 0
- <4> The set value in the PRSCM register: 3DH (61), the set values in the BGCS1 and BGCS0 bits: 00

Remark m: Divided value (set value in the BGCS1 and BGCS0 bits) = 0 to 3

- N: Set value in PRSCM register = 1 to 256 (when the set value in the PRSCM register is 00H, N = 256)
- fx: Main clock oscillation frequency

<R>

<R>

10.2 Watch Timer

10.2.1 Functions

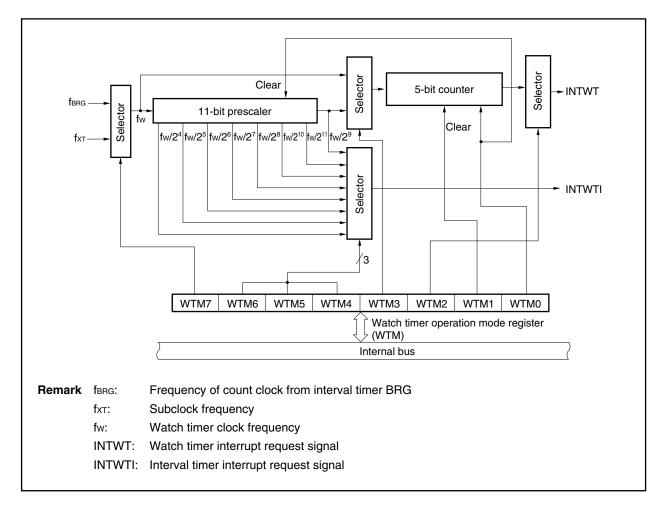

The watch timer has the following functions.

- Watch timer: An interrupt request signal (INTWT) is generated at time intervals of 0.5 or 0.25 seconds by using the main clock or subclock.
- Interval timer: An interrupt request signal (INTWTI) is generated at the preset time interval.

The watch timer and interval timer functions can be used at the same time.

10.2.2 Configuration

The following shows the block diagram of the watch timer.

(1) 11-bit prescaler

The 11-bit prescaler generates a clock of $fw/2^4$ to $fw/2^{11}$ by dividing fw.

(2) 5-bit counter

The 5-bit counter generates the watch timer interrupt request signal (INTWT) at intervals of 2^4 /fw, 2^5 /fw, 2^{13} /fw, or 2^{14} /fw by counting fw or fw/ 2^9 .

(3) Selectors

The watch timer has the following four selectors.

- Selector that selects the main clock (the clock from interval timer BRG (fBRG)) or the subclock (fxT) as the clock for the watch timer.
- Selector that selects fw or fw/2⁹ as the count clock frequency of the 5-bit counter
- Selector that selects 2⁴/fw or 2¹³/fw, or 2⁵/fw or 2¹⁴/fw as the INTWT signal generation time interval.
- Selector that selects the generation time interval of the interval timer WT interrupt request signal (INTWTI) from 2⁴/fw to 2¹¹/fw.

(4) 8-bit counter

The 8-bit counter counts the count clock (fbgcs).

(5) WTM register

The WTM register is an 8-bit register that controls the operation of the watch timer/interval timer WT and sets the interval of interrupt request signal generation.

10.2.3 Registers

The watch timer includes the following register.

(1) Watch timer operation mode register (WTM)

This register enables or disables the count clock and operation of the watch timer, sets the interval time of the 11-bit prescaler, controls the operation of the 5-bit counter, and sets the timer of watch timer interrupt request signal (INTWT) generation.

The WTM register can be read or written in 8-bit or 1-bit units. Reset sets WTM to 00H.

	0		peration					

10.2.4 Operation

(1) Operation as watch timer

The watch timer generates an interrupt request at fixed time intervals. The watch timer operates using time intervals of 0.25 or 0.5 seconds with the subclock (32.768 kHz).

The count operation starts when the WTM.WTM0 and WTM.WTM1 bits are set to 11. When these bits are cleared to 00, the 10-bit prescaler and 5-bit counter are cleared and the count operation stops.

The 5-bit counter can be cleared to synchronize the time by clearing the WTM1 bit to 0 when the watch timer and interval timer WT operate simultaneously. At this time, an error of up to 15.6 ms may occur in the watch timer, but interval timer WT is not affected.

(2) Operation as interval timer

The watch timer can also be used as an interval timer that repeatedly generates an interrupt request signal (INTWTI) at intervals specified by a count value set in advance.

The interval time can be selected by the WTM.WTM4 to WTM.WTM7 bits.

WTM7	WTM6	WTM5	WTM4		Interval Time
0	0	0	0	$2^4 \times 1/fw$	488 μ s (operating at fw = fxT = 32.768 kHz)
0	0	0	1	$2^5 imes 1/fw$	977 μ s (operating at fw = fxT = 32.768 kHz)
0	0	1	0	$2^6 imes 1/fw$	1.95 ms (operating at $f_W = f_{XT} = 32.768 \text{ kHz}$)
0	0	1	1	$2^7 \times 1/fw$	3.91 ms (operating at $f_W = f_{XT} = 32.768 \text{ kHz}$)
0	1	0	0	$2^8 \times 1/fw$	7.81 ms (operating at $f_W = f_{XT} = 32.768 \text{ kHz}$)
0	1	0	1	$2^9 imes 1/fw$	15.6 ms (operating at fw = fxT = 32.768 kHz)
0	1	1	0	$2^{10} \times 1/fw$	31.3 ms (operating at fw = fxT = 32.768 kHz)
0	1	1	1	$2^{11} \times 1/fw$	62.5 ms (operating at fw = fxT = 32.768 kHz)
1	0	0	0	$2^4 \times 1/fw$	488 μ s (operating at fw = f _{BRG} = 32.768 kHz)
1	0	0	1	$2^5 imes 1/fw$	977 μ s (operating at fw = f _{BRG} = 32.768 kHz)
1	0	1	0	$2^6 imes 1/fw$	1.95 ms (operating at fw = fBRG = 32.768 kHz)
1	0	1	1	$2^7 \times 1/fw$	3.91 ms (operating at fw = fBRG = 32.768 kHz)
1	1	0	0	$2^8 imes 1/fw$	7.81 ms (operating at fw = fBRG = 32.768 kHz)
1	1	0	1	$2^9 \times 1/fw$	15.6 ms (operating at fw = fBRG = 32.768 kHz)
1	1	1	0	$2^{10} \times 1/fw$	31.3 ms (operating at fw = fBRG = 32.768 kHz)
1	1	1	1	$2^{11} \times 1/fw$	62.5 ms (operating at fw = fBRG = 32.768 kHz)

Table 10-1. Interval Time of Interval Timer

Remark fw: Watch timer clock frequency

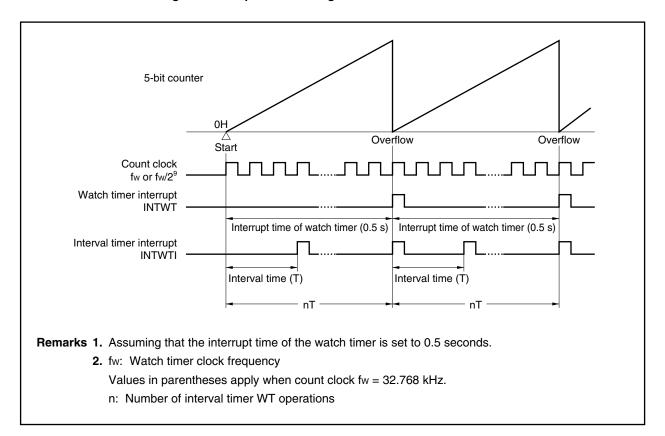

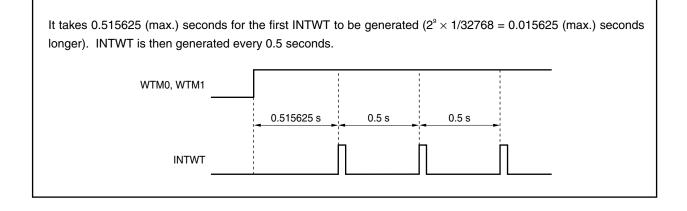

Figure 10-3. Operation Timing of Watch Timer/Interval Timer

10.3 Cautions

(1) Operation as watch timer

Some time is required before the first watch timer interrupt request (INTWT) is generated after operation is enabled (WTM.WTM1 and WTM.WTM0 bits = 11).

Figure 10-4. Example of Generation of Watch Timer Interrupt Request (INTWT) (When Interrupt Period = 0.5 s)

(2) When watch timer and interval timer BRG operate simultaneously

When using the subclock as the count clock for the watch timer, the interval time of interval timer BRG can be set to any value. Changing the interval time does not affect the watch timer (before changing the interval time, stop operation).

When using the main clock as the count clock for the watch timer, set the interval time of interval timer BRG to approximately 65.536 kHz. Do not change this value.

(3) When interval timer BRG and interval timer WT operate simultaneously

When using the subclock as the count clock for interval timer WT, the interval times of interval timers BRG and WT can be set to any values. They can also be changed later (before changing the value, stop operation). When using the main clock as the count clock for interval timer WT, the interval time of interval timer BRG can be set to any value, but cannot be changed later (it can be changed only when interval timer WT stops operation). The interval time of interval timer WT can be set to $\times 2^5$ to $\times 2^{12}$ of the set value of interval timer BRG. It can also be changed later.

(4) When watch timer and interval timer WT operate simultaneously

The interval time of interval timer WT can be set to a value between 488 μ s and 62.5 ms. It cannot be changed later.

Do not stop interval timer WT (clear (0) the WTM.WTM0 bit) while the watch timer is operating. If the WTM0 bit is set (1) after it had been cleared (0), the watch timer will have a discrepancy of up to 0.5 or 0.25 seconds.

(5) When watch timer, interval timer BRG, and interval timer WT operate simultaneously

When using the subclock as the count clock for the watch timer, the interval times of interval timers BRG and WT can be set to any values. The interval time of interval timer BRG can be changed later (before changing the value, stop operation).

When using the main clock as the count clock for the watch timer, set the interval time of interval timer BRG to approximately 65.536 kHz. It cannot be changed later. The interval time of interval timer WT can be set to a value between 488 μ s and 62.5 ms. It cannot be changed later.

Do not stop interval timer BRG (clear (0) the PRSM.BGCE bit) or interval timer WT (clear (0) the WTM.WTM0 bit) while the watch timer is operating.

CHAPTER 11 WATCHDOG TIMER FUNCTIONS

11.1 Watchdog Timer 1

11.1.1 Functions

Watchdog timer 1 has the following operation modes.

- Watchdog timer
- Interval timer

The following functions are realized from the above-listed operation modes.

- Generation of non-maskable interrupt request signal (INTWDT1) upon overflow of watchdog timer 1^{Note}
- Generation of system reset signal (WDTRES1) upon overflow of watchdog timer 1
- Generation of maskable interrupt request signal (INTWDTM1) upon overflow of interval timer
- **Note** For non-maskable interrupt servicing due to non-maskable interrupt request signal (INTWDT1, INTWDT2), refer to **17.10 Cautions**.
- **Remark** Select whether to use watchdog timer 1 in the watchdog timer 1 mode or the interval timer mode with the WDTM1 register.

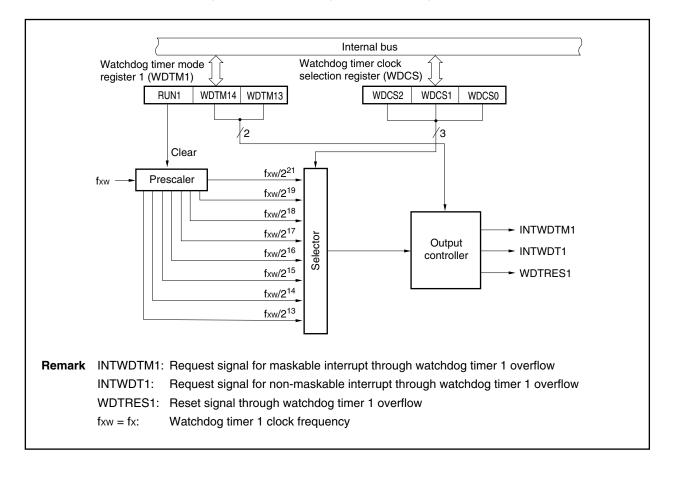

Figure 11-1. Block Diagram of Watchdog Timer 1

11.1.2 Configuration

Watchdog timer 1 includes the following hardware.

Item	Configuration
Control register	Watchdog timer clock selection register (WDCS)
	Watchdog timer mode register 1 (WDTM1)

11.1.3 Registers

The registers that control watchdog timer 1 are as follows.

- Watchdog timer clock selection register (WDCS)
- Watchdog timer mode register 1 (WDTM1)

(1) Watchdog timer clock selection register (WDCS)

This register sets the overflow time of watchdog timer 1 and the interval timer. The WDCS register can be read or written in 8-bit or 1-bit units. Reset sets WDCS to 00H.

	7	6	5	4	3	2	1	0
WDCS	0	0	0	0	0	WDCS2	WDCS1	WDCS0
	WDCS2	WDCS1	WDCS0	Overflo	w time of w	atchdog tir	mer 1/inter	val timer

	0	0	1	2 ¹⁴ /fxw	4.096	ms 3.2	77 ms	1.638 ms
	0	1	0	2 ¹⁵ /fxw	8.192	ms 6.5	54 ms	3.277 ms
	0	1	1	2 ¹⁶ /fxw	16.38	ms 13.	11 ms	6.554 ms
	1	0	0	2 ¹⁷ /fxw	32.77	ms 26.	21 ms	13.11 ms
	1	0	1	2 ¹⁸ /fxw	65.54	ms 52.	43 ms	26.2 ms
	1	1	0	2 ¹⁹ /fxw	131.1	ms 104	1.9 ms	52.43 ms
	1	1	1	2 ²¹ /fxw	524.3	ms 419	9.4 ms	209.7 ms

(2) Watchdog timer mode register 1 (WDTM1)

This register sets the watchdog timer 1 operation mode and enables/disables count operations.

This register is a special register that can be written only in a special sequence (refer to **3.4.7** Special registers).

The WDTM1 register can be read or written in 8-bit or 1-bit units. Reset sets WDTM1 to 00H.

Caution When the main clock is stopped and the CPU is operating on the subclock, do not access the WDTM1 register.

For details, refer to 3.4.8 (1) (b).

	After res	et: 00H	R/W	Address:	FFFF6C2H	ł			
		<7>	6	5	4	3	2	1	0
	WDTM1	RUN1	0	0	WDTM14	WDTM13	0	0	0

		1	0 Watchdog timer mode 1 ^{Note 3} (Upon overflow, non-maskable interrupt INTWDT1 is generated.)						
		1	1	1 Watchdog timer mode 2 (Upon overflow, reset operation WDTRES1 is started.)					
Notes 1. Once the RUN1 bit is set (to 1), it cannot be cleared (to 0) by software. Therefore, when counting is started, it cannot be stopped except reset.									
2.	Once the WDTM13 and WDTM14 bits are set (to 1), they cannot be cleared (to 0) by software and								
	can be clea	-	•		-l				-1 -:
3.	For non-married refer to 17.			servicing	aue to no	n-maskabl	e interri	upt reque	st signal (II

11.1.4 Operation

(1) Operation as watchdog timer 1

Watchdog timer 1 operation to detect a program loop is selected by setting the WDTM1.WDTM14 bit to 1. The count clock (program loop detection time interval) of watchdog timer 1 can be selected using the WDCS.WDCS0 to WDCS.WDCS2 bits. The count operation is started by setting the WDTM1.RUN1 bit to 1. When, after the count operation is started, the RUN1 bit is again set to 1 within the set program loop detection time interval, watchdog timer 1 is cleared and the count operation starts again.

If the program loop detection time is exceeded without RUN1 bit being set to 1, reset signal (WDTRES1) through the value of the WDTM1.WDTM13 bit or a non-maskable interrupt request signal (INTWDT1) is generated.

The count operation of watchdog timer 1 stops in the STOP mode and IDLE mode. Set the RUN1 bit to 1 before the STOP mode or IDLE mode is entered in order to clear watchdog timer 1.

Because watchdog timer 1 operates in the HALT mode, make sure that an overflow will not occur during HALT.

Cautions 1. When the subclock is selected for the CPU clock, the count operation of watchdog timer 1 is stopped (the value of watchdog timer 1 is maintained).

2. For non-maskable interrupt servicing due to the INTWDT1 signal, refer to 17.10 Cautions.

Clock	Program Loop Detection Time					
	fxw = 4 MHz	fxw = 5 MHz	fxw = 10 MHz			
2 ¹³ /fxw	2.048 ms	1.638 ms	0.819 ms			
2 ¹⁴ /fxw	4.096 ms	3.277 ms	1.683 ms			
2 ¹⁵ /fxw	8.192 ms	6.554 ms	3.277 ms			
2 ¹⁶ /fxw	16.38 ms	13.11 ms	6.554 ms			
2 ¹⁷ /fxw	32.77 ms	26.21 ms	13.11 ms			
2 ¹⁸ /fxw	65.54 ms	52.43 ms	26.21 ms			
2 ¹⁹ /fxw	131.1 ms	104.9 ms	52.43 ms			
2 ²¹ /fxw	524.3 ms	419.4 ms	209.7 ms			

Table 11-2. Program Loop Detection Time of Watchdog Timer 1

Remark fxw = fx: Watchdog timer 1 clock frequency

(2) Operation as interval timer

Watchdog timer 1 can be made to operate as an interval timer that repeatedly generates interrupts using the count value set in advance as the interval, by clearing the WDTM1.WDTM14 bit to 0.

When watchdog timer 1 operates as an interval timer, the interrupt mask flag (WDTMK) and priority specification flags (WDTPR0 to WDTPR2) of the WDTIC register are valid and maskable interrupt request signals (INTWDTM1) can be generated. The default priority of the INTWDTM1 signal is set to the highest level among the maskable interrupt request signals.

The interval timer continues to operate in the HALT mode, but it stops operating in the STOP mode and the IDLE mode.

- Cautions 1. Once the WDTM14 bit is set to 1 (thereby selecting the watchdog timer 1 mode), the interval timer mode is not entered as long as reset is not performed.
 - 2. When the subclock is selected for the CPU clock, the count operation of the watchdog timer 1 stops (the value of the watchdog timer is maintained).

Clock	Interval Time					
	fxw = 4 MHz	fxw = 5 MHz	fxw = 10 MHz			
2 ¹³ /fxw	2.048 ms	1.638 ms	0.819 ms			
2 ¹⁴ /fxw	4.096 ms	3.277 ms	1.638 ms			
2 ¹⁵ /fxw	8.192 ms	6.554 ms	3.277 ms			
2 ¹⁶ /fxw	16.38 ms	13.11 ms	6.554 ms			
2 ¹⁷ /fxw	32.77 ms	26.21 ms	13.11 ms			
2 ¹⁸ /fxw	65.54 ms	52.43 ms	26.21 ms			
2 ¹⁹ /fxw	131.1 ms	104.9 ms	52.43 ms			
2 ²¹ /fxw	524.3 ms	419.4 ms	209.7 ms			

Table 11-3. Interval Time of Interval Timer

Remark fxw = fx: Watchdog timer 1 clock frequency

11.2 Watchdog Timer 2

11.2.1 Functions

Watchdog timer 2 has the following functions.

- Default start watchdog timer^{Note 1}
 - \rightarrow Reset mode: Reset operation upon overflow of watchdog timer 2 (generation of WDTRES2 signal)
 - → Non-maskable interrupt request mode: NMI operation upon overflow of watchdog timer 2 (generation of INTWDT2 signal)^{Note 2}
- Input selectable from main clock and subclock as the source clock
 - Notes 1. Watchdog timer 2 automatically starts in the reset mode following reset release. When watchdog timer 2 is not used, either stop its operation before reset is executed through this function, or clear once watchdog timer 2 and stop it within the next interval time. Also, write to the WDTM2 register for verification purposes only once, even if the default settings (reset mode, interval time: fxx/2²⁵) need not be changed.
 - 2. For non-maskable interrupt servicing due to a non-maskable interrupt request signal (INTWDT2), refer to 17.10 Cautions.

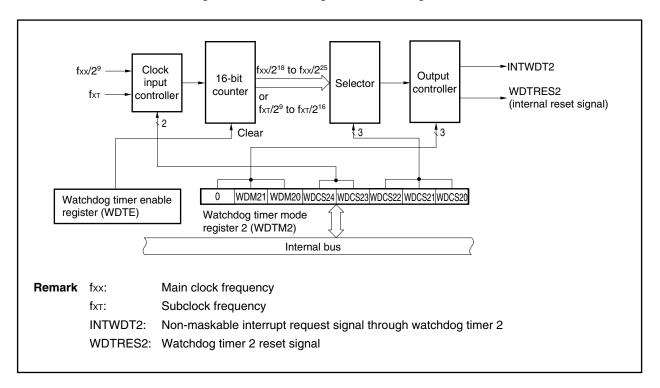

Figure 11-2. Block Diagram of Watchdog Timer 2

11.2.2 Configuration

Watchdog timer 2 includes the following hardware.

---	----------------------------

Item	Configuration
Control register	Watchdog timer mode register 2 (WDTM2)
	Watchdog timer enable register (WDTE)

11.2.3 Registers

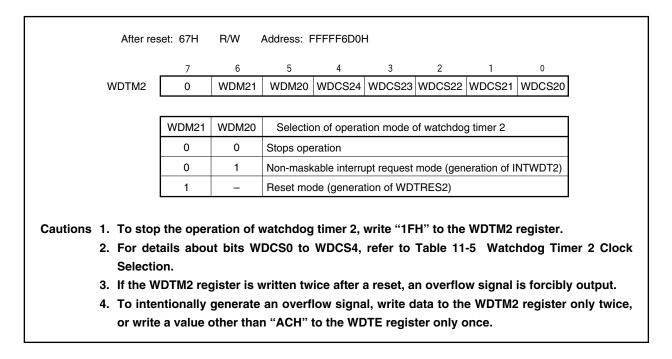

(1) Watchdog timer mode register 2 (WDTM2)

This register sets the overflow time and operation clock of watchdog timer 2.

The WDTM2 register can be read or written in 8-bit units. This register can be read any number of times, but it can be written only once following reset release. Reset sets WDTM2 to 67H.

Caution When the main clock is stopped and the CPU is operating on the subclock, do not access the WDTM2 register.

For details, refer to 3.4.8 (1) (b).

11.2.4 Operation

Watchdog timer 2 automatically starts in the reset mode following reset release.

The WDTM2 register can be written to only once following reset through byte access. To use watchdog timer 2, write the operation mode and the interval time to the WDTM2 register using 8-bit memory manipulation instructions. After this is done, the operation of watchdog timer 2 cannot be stopped.

The watchdog timer 2 program loop detection time interval can be selected by the WDTM2.WDCS24 to WDTM2.WDCS20 bits. Writing ACH to the WDTE register clears the counter of watchdog timer 2 and starts the count operation again. After the count operation starts, write ACH to the WDTE register within the set program loop detection time interval.

If the program loop detection time is exceeded without ACH being written to the WDTE register, a reset signal (WDTRES2) or non-maskable interrupt request signal (INTWDT2) is generated depending on the set value of the WDTM2.WDM21 and WDTM2.WDM20 bits.

To not use watchdog timer 2, write 1FH to the WDTM2 register.

For non-maskable interrupt servicing when the non-maskable interrupt request mode is set, refer to **17.10** Cautions.

If the main clock is selected as the source clock of watchdog timer 2, the watchdog timer stops operation in the IDLE/STOP mode. Therefore, clear watchdog timer 2 by writing ACH to the WDTE register before the IDLE/STOP mode is set.

Because watchdog timer 2 operates in the HALT mode or when the subclock is selected as its source clock in the IDLE/STOP mode, exercise care that the timer does not overflow in the HALT mode.

CHAPTER 12 REAL-TIME OUTPUT FUNCTION (RTO)

12.1 Function

The real-time output function (RTO) transfers preset data to the RTBL0 and RTBH0 registers, and then transfers this data with hardware to an external device via the real-time output latches, upon occurrence of a timer interrupt. The pins through which the data is output to an external device constitute a port called a real-time output port.

Because RTO can output signal without jitter, it is suitable for controlling a stepping motor.

In the V850ES/KE1, a 6-bit real-time output port channel is provided.

The real-time output port can be set in the port mode or real-time output port mode in 1-bit units.

The block diagram of RTO is shown below.

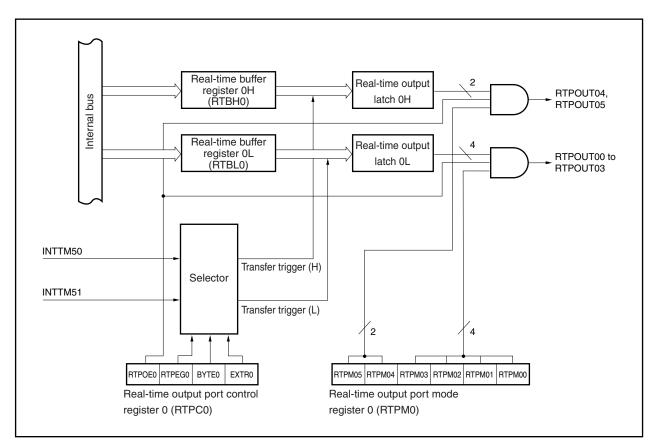

Figure 12-1. Block Diagram of RTO

12.2 Configuration

RTO includes the following hardware.

Table 12-1.	Configuration of RTO
-------------	----------------------

Item	Configuration
Registers	Real-time output buffer register 0 (RTBL0, RTBH0)
Control registers	Real-time output port mode register 0 (RTPM0) Real-time output port control register 0 (RTPC0)

(1) Real-time output buffer register 0 (RTBL0, RTBH0)

RTBL0 and RTBH0 are 4-bit registers that hold output data in advance.

These registers are mapped to independent addresses in the peripheral I/O register area.

They can be read or written in 8-bit or 1-bit units.

If an operation mode of 4 bits \times 1 channel or 2 bits \times 1 channel is specified (RTPC0.BYTE0 bit = 0), data can be individually set to the RTBL0 and RTBH0 registers. The data of both these registers can be read at once by specifying the address of either of these registers.

If an operation mode of 6 bits \times 1 channel is specified (BYTE0 bit = 1), 8-bit data can be set to both the RTBL0 and RTBH0 registers by writing the data to either of these registers. Moreover, the data of both these registers can be read at once by specifying the address of either of these registers.

Table 12-2 shows the operation when the RTBL0 and RTBH0 registers are manipulated.

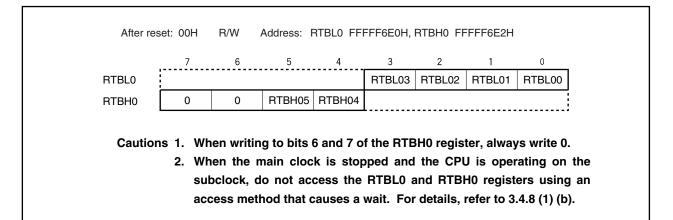

Table 12-2. Operation During Manipulation of RTBL0 and RTBH0 Registers

Operation Mode	Register to Be	Re	ad	Writ	e ^{Note}
	Manipulated	Higher 4 Bits	Lower 4 Bits	Higher 4 Bits	Lower 4 Bits
4 bits \times 1 channel, 2 bits \times	RTBL0	RTBH0	RTBL0	Invalid	RTBL0
1 channel	RTBH0	RTBH0	RTBL0	RTBH0	Invalid
6 bits \times 1 channel	RTBL0	RTBH0	RTBL0	RTBH0	RTBL0
	RTBH0	RTBH0	RTBL0	RTBH0	RTBL0

Note After setting the real-time output port, set output data to the RTBL0 and RTBH0 registers by the time a real-time output trigger is generated.

12.3 Registers

RTO is controlled using the following two types of registers.

- Real-time output port mode register 0 (RTPM0)
- Real-time output port control register 0 (RTPC0)

(1) Real-time output port mode register 0 (RTPM0)

This register selects the real-time output port mode or port mode in 1-bit units. The RTPM0 register can be read or written in 8-bit or 1-bit units. Reset sets RTPM0 to 00H.

After res	et: 00H	R/W	Address: F	FFFF6E4H	ł				
	7	6	5	4	3	2	1	0	
RTPM0	0	0	RTPM05	RTPM04	RTPM03	RTPM02	RTPM01	RTPM00

(2) Real-time output port control register 0 (RTPC0)

This register sets the operation mode and output trigger of the real-time output port.

The relationship between the operation mode and output trigger of the real-time output port is as shown in Table 12-3.

The RTPC0 register can be read or written in 8-bit or 1-bit units.

Reset sets RTPC0 to 00H.

After res	set: 00H	R/W	Address: I	FFFF6E5H					
	<7>	6	5	4	3	2	1	0	_

	1	2 bits \times 1 channel	INTTM50	No trigger
1	0	6 bits \times 1 channel	INTTM50	
	1		Setting prohibited	

12.4 Operation

If the real-time output operation is enabled by setting the RTPC0.RTPOE0 bit to 1, the data of the RTBH0 and RTBL0 registers is transferred to the real-time output latch in synchronization with the generation of the selected transfer trigger (set by the RTPC0.EXTR0 and RTPC0.BYTE0 bits). Of the transferred data, only the data of the bits specified as real-time output enabled by the RTPM0 register is output from bits RTPOUT00 to RTPOUT05. The bits specified as real-time output disabled by the RTPM0 register output 0.

If the real-time output operation is disabled by clearing the RTPOE0 bit to 0, the RTPOUT00 to RTPOUT05 signals output 0 regardless of the setting of the RTPM0 register.

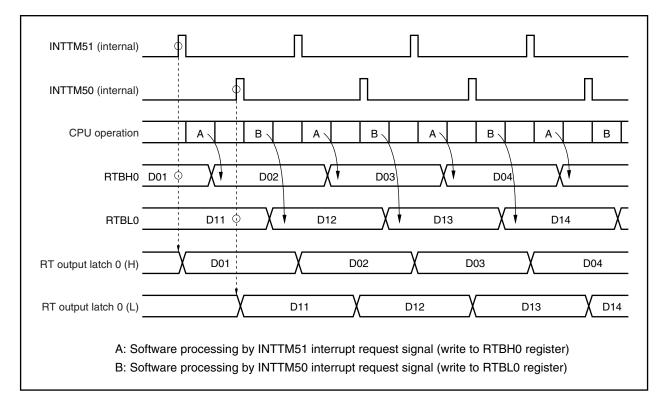

Figure 12-2. Example of Operation Timing of RTO0 (When EXTR0 and BYTE0 Bits = 00)

Remark For the operation during standby, refer to **CHAPTER 19 STANDBY FUNCTION**.

12.5 Usage

- (1) Disable real-time output. Clear the RTPC0.RTPOE0 bit to 0.
- (2) Perform initialization as follows.
 - Specify the real-time output port mode or port mode in 1-bit units. Set the RTPM0 register.
 - Channel configuration: Select the trigger and valid edge. Set the RTPC0.EXTR0, RTPC0.BYTE0, and RTPC0.RTPEG0 bits.
 - Set the initial values to the RTBH0 and RTBL0 registers^{Note 1}.
- (3) Enable real-time output. Set the RTPOE0 bit to 1.
- (4) Set the next output value to the RTBH0 and RTBL0 registers by the time the selected transfer trigger is generated^{Note 2}.
- (5) Set the next real-time output value to the RTBH0 and RTBL0 registers through interrupt servicing corresponding to the selected trigger.
- **Notes 1.** If write to the RTBH0 and RTBL0 registers is performed when the RTPOE0 bit = 0, that value is transferred to real-time output latches 0H and 0L, respectively.
 - 2. Even if write is performed to the RTBH0 and RTBL0 registers when the RTPOE0 bit = 1, data transfer to real-time output latches 0H and 0L is not performed.

Caution To reflect the real-time output signals (RTPOUT00 to RTPOUT05) to the pins, set the real-time output ports (RTP00 to RTP05) with the PMC5 and PFC5 registers.

12.6 Cautions

- (1) Prevent the following conflicts by software.
 - Conflict between real-time output disable/enable switching (RTPOE0 bit) and selected real-time output trigger
 - Conflict between write to the RTBH0 and RTBL0 registers in the real-time output enabled status and the selected real-time output trigger.
- (2) Before performing initialization, disable real-time output (RTPOE0 bit = 0).
- (3) Once real-time output has been disabled (RTPOE0 bit = 0), be sure to initialize the RTBH0 and RTBL0 registers before enabling real-time output again (RTPOE0 bit = $0 \rightarrow 1$).

12.7 Security Function

A circuit that sets the pin outputs to high impedance as a security function for when malfunctions of a stepping motor controlled by RTO occur is provided on chip. It forcibly resets the pins allocated to RTP00 to RTP05 via external interrupt INTP0 pin edge detection, placing them in the high-impedance state.

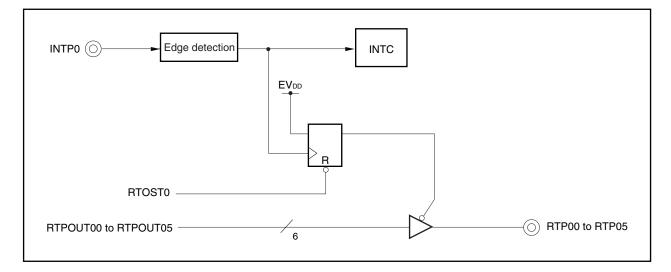

The ports (P50 to P55 pins) placed in high impedance by INTP0^{Note 1} pin are initialized^{Note 2}, so settings for these ports must be performed again.

Notes 1. Regardless of the port settings, P50 to P55 pins are all placed in high impedance via the INTP0 pin.

- 2. The bits that are initialized are all the bits corresponding to P50 to P55 pins of the following registers.
 - P5 register
 - PM5 register
 - PMC5 register
 - PU5 register
 - PFC5 register

The block diagram of the security function is shown below.

This function is set with the PLLCTL.RTOST0 bit.

(1) PLL control register (PLLCTL)

The PLLCTL register is an 8-bit register that controls the RTO security function and PLL. This register can be read or written in 8-bit or 1-bit units. Reset sets PLLCTL to 01H.

After re	set: 01H	R/W	Address: F	FFFF806H

CHAPTER 13 A/D CONVERTER

13.1 Function

The A/D converter converts analog input signals into digital values with a resolution of 10 bits and has an 8channel (ANI0 to ANI7) configuration.

The A/D converter has the following functions.

(1) 10-bit resolution A/D conversion

1 analog input channel is selected from ANI0 to ANI7, and an A/D conversion operation with resolution of 10 bits is repeatedly executed. Every time A/D conversion is completed, an interrupt request signal (INTAD) is generated.

(2) Power fail detection function

This is a function to detect low voltage in a battery. The results of A/D conversion (the value in the ADCRH register) and the PFT register are compared, and INTAD signal is generated only when the comparison conditions match.

13.2 Configuration

The A/D converter consists of the following hardware.

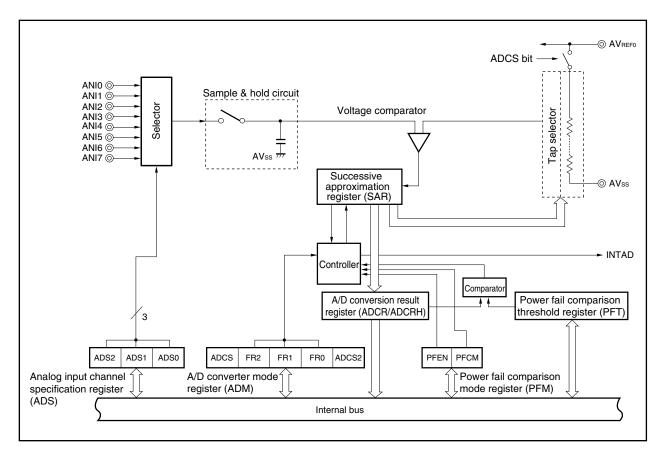

Table 13-1. Registers of A/D Converter Used by Software

Item	Configuration
Registers	 A/D conversion result register (ADCR) A/D conversion result register H (ADCRH): Only higher 8 bits can be read Power fail comparison threshold register (PFT) A/D converter mode register (ADM) Analog input channel specification register (ADS)
	Power fail comparison mode register (PFM)

(1) ANI0 to ANI7 pins

These are analog input pins for the 8 channels of the A/D converter. They are used to input analog signals to be converted into digital signals. Pins other than those selected as analog input by the ADS register can be used as input ports.

(2) Sample & hold circuit

The sample & hold circuit samples the analog input signals selected by the input circuit and sends the sampled data to the voltage comparator. This circuit holds the sampled analog input voltage during A/D conversion.

(3) Series resistor string

The series resistor string is connected between AVREFO and AVss and generates a voltage for comparison with the analog input signal.

(4) Voltage comparator

The voltage comparator compares the value that is sampled and held with the output voltage of the series resistor string.

(5) Successive approximation register (SAR)

This register compares the sampled analog voltage value with the voltage value from the series resistor string, and converts the comparison result starting from the most significant bit (MSB).

When the least significant bit (LSB) has been converted to a digital value (end of A/D conversion), the contents of the SAR register are transferred to the ADCR register.

The SAR register cannot be read or written directly.

(6) A/D conversion result register (ADCR), A/D conversion result register H (ADCRH)

Each time A/D conversion ends, the conversion results are loaded from the successive approximation register and the results of A/D conversion are held in the higher 10 bits of this register (the lower 6 bits are fixed to 0).

(7) Controller

The controller compares the A/D conversion results (the value of the ADCRH register) with the value of the PFT register when A/D conversion ends or the power fail detection function is used. It generates INTAD signal only when the comparison conditions match.

(8) AVREFO pin

This is the analog power supply pin/reference voltage input pin of the A/D converter. Always use the same potential as the V_{DD} pin even when not using the A/D converter.

The signals input to the ANI0 to ANI7 pins are converted into digital signals based on the voltage applied across AVREF0 and AVss.

(9) AVss pin

This is the ground potential pin of the A/D converter. Always use the same potential as the V_{SS} pin even when not using the A/D converter.

(10) A/D converter mode register (ADM)

This register sets the conversion time of the analog input to be converted to a digital signal and the conversion operation start/stop.

(11) Analog input channel specification register (ADS)

This register specifies the input port for the analog voltage to be converted to a digital signal.

(12) Power fail comparison mode register (PFM)

This register sets the power fail monitoring mode.

(13) Power fail comparison threshold register (PFT)

This register sets the threshold to be compared with the ADCR register.

13.3 Registers

The A/D converter is controlled by the following registers.

- A/D converter mode register (ADM)
- Analog input channel specification register (ADS)
- Power fail comparison mode register (PFM)
- Power fail comparison threshold register (PFT)
- A/D conversion result register, A/D conversion result register H (ADCR, ADCRH)

<R> (1) A/D converter mode register (ADM)

This register sets the conversion time of the analog input signal to be converted into a digital signal as well as conversion start and stop.

The ADM register can be read or written in 8-bit or 1-bit units.

Reset sets this register to 00H.

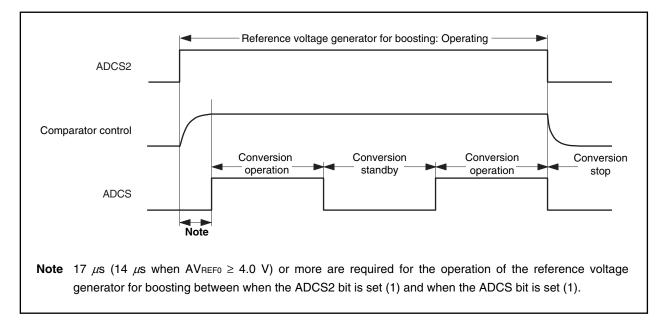

After res	set: 00H	R/W	Address: FFFFF	-200H

<R>

User's Manual U16892EJ2V0UD

(3) A/D conversion result register, A/D conversion result register H (ADCR, ADCRH)

The ADCR and ADCRH registers store the A/D conversion results.

These registers are read-only, in 16-bit or 8-bit units. However, specify the ADCR register for 16-bit access, and the ADCRH register for 8-bit access. In the ADCR register, the 10 bits of conversion results are read in the higher 10 bits and 0 is read in the lower 6 bits. In the ADCRH register, the higher 8 bits of the conversion results are read.

Reset makes these registers undefined.

After re	set: Undef	ned R	Addres	s: FFFFf2	204H				
ADCR	15 14 AD9 AD8	13 12 AD7 AD6	<u> </u>		7 6 AD1 AD0		3 2 0 0	1 0 0 0

ADCRH	AD9 Caution				••			•	ing on the
			-					registers to 3.4.8 (s using an I)(b).

The following shows the relationship between the analog input voltage input to the analog input pins (ANI0 to ANI7) and A/D conversion results (ADCR register).

$$SAR = INT \left(\frac{V_{IN}}{AV_{REF0}} \times 1024 + 0.5\right)$$
$$ADCR^{Note} = SAR \times 64$$

Or,

$$(SAR - 0.5) \times \frac{AV_{REF0}}{1024} \le V_{IN} < (SAR + 0.5) \times \frac{AV_{REF0}}{1024}$$

INT ():	Function that returns the integer part of the value in parentheses
VIN:	Analog input voltage
AVREF0:	Voltage of AVREF0 pin
ADCR:	Value in the ADCR register

Note The lower 6 bits of the ADCR register are fixed to 0.

The following shows the relationship between the analog input voltage and A/D conversion results.

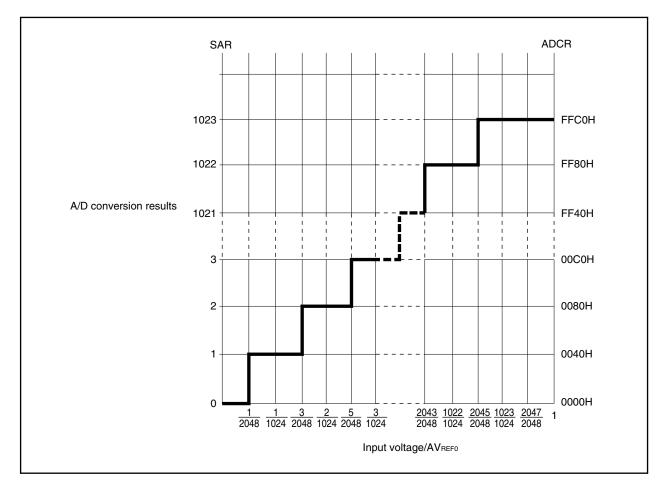

Figure 13-3. Relationship Between Analog Input Voltage and A/D Conversion Results

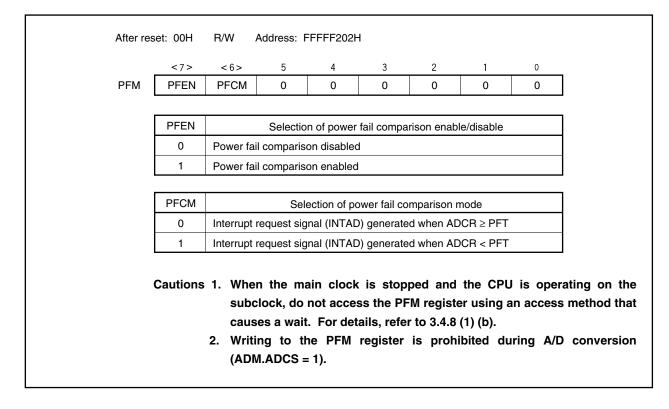

(4) Power fail comparison mode register (PFM)

This register sets the power fail monitoring mode.

The PFM register compares the value in the PFT register with the value of the ADCRH register.

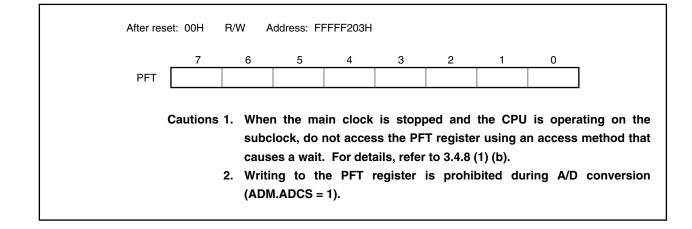

The PFM register can be read or written in 8-bit or 1-bit units.

Reset sets this register to 00H.

(5) Power fail comparison threshold register (PFT)

The PFT register sets the comparison value in the power fail comparison mode. The 8-bit data set in the PFT register is compared with the value of the ADCRH register. The PFT register can be read or written in 8-bit units. Reset sets this register to 00H.

<R>

<R>

13.4 Operation

13.4.1 Basic operation

- <1> Select the channel whose analog signal is to be converted into a digital signal using the ADS register.
- <2> Set (1) the ADM.ADCS2 bit and wait 17 μ s (14 μ s when AV_{REF0} \ge 4.0 V) or longer.
- <3> Set the ADM.ADCS bit to 1 to start A/D conversion. (Steps <4> to <10> are executed by hardware.)
- <4> The sample & hold circuit samples the voltage input to the selected analog input channel.
- <5> After sampling for a specific time, the sample & hold circuit enters the hold status and holds the input analog voltage until it has been converted into a digital signal.
- <6> Set bit 9 of the successive approximation register (SAR). The tap selector sets the voltage tap of the series resistor string to (1/2) × AV_{REF0}.
- <7> The voltage comparator compares the voltage difference between the voltage tap of the series resistor string and the analog input voltage. If the analog input voltage is greater than (1/2) × AVREF0, the MSB of the SAR register remains set. If the analog input voltage is less than (1/2) × AVREF0, the MSB is reset.
- <8> Next, bit 8 of the SAR register is automatically set and the next comparison starts. Depending on the value of bit 9 to which the result of the preceding comparison has been set, the voltage tap of the series resistor string is selected as follows.
 - Bit 9 = 1: (3/4) × AVREF0
 - Bit 9 = 0: (1/4) × AVREF0

The analog input voltage is compared with one of these voltage taps and bit 8 of the SAR register is manipulated as follows depending on the result of the comparison.

Analog input voltage \geq voltage tap: Bit 8 = 1 Analog input voltage \leq voltage tap: Bit 8 = 0

<9> The above steps are repeated until bit 0 of the SAR register has been manipulated.

- <10> When comparison of all 10 bits of the SAR register has been completed, the valid digital value remains in the SAR register, and the value of the SAR register is transferred and latched to the ADCR register. At the same time, an A/D conversion end interrupt request signal (INTAD) is generated.
- <11> Repeat steps <4> to <10> until the ADCS bit is cleared to 0.

For another A/D conversion, start at <3>. However, when operating the A/D converter with the ADCS2 bit cleared to 0, start at <2>.

13.4.2 A/D conversion operation

- Setting the ADM.ADCS bit to 1 starts conversion of the signal input to the channel specified by the ADS register. Upon completion of the conversion, the conversion result is stored in the ADCR register and a new conversion starts.
- Writing to the ADM, ADS, PFT, and PFM registers during conversion is prohibited.
- If the ADCS bit is cleared to 0 during conversion, conversion is interrupted and the conversion operation is stopped.
- For whether or not the conversion end interrupt request signal (INTAD) is generated, refer to 13.4.3.

13.4.3 Power fail monitoring function

The conversion end interrupt request signal (INTAD) can be controlled as follows using the PFM and PFT registers.

- If the PFM.PFEN bit = 0, the INTAD signal is generated each time conversion ends.
- If the PFEN bit = 1 and the PFM.PFCM bit = 0, the conversion result and the value of the PFT register are compared when conversion ends, and the INTAD signal is output only if ADCRH ≥ PFT.
- If the PFEN and PFCM bits = 1, the conversion result and the value of the PFT register are compared when conversion ends and the INTAD signal is output only if ADCRH < PFT.
- Because, when the PFEN bit = 1, the conversion result is overwritten after the INTAD signal has been output, unless the conversion result is read by the time the next conversion ends, in some cases it may appear as if the actual operation differs from the operation described above (refer to **Figure 13-4**).

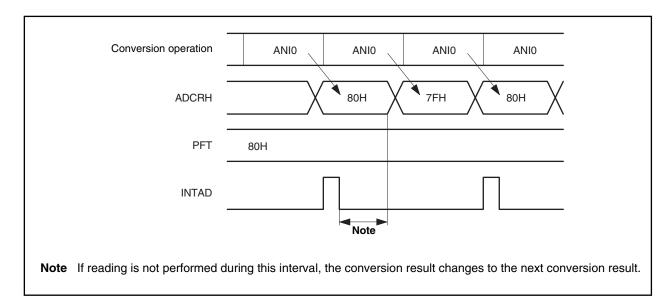

Figure 13-4. Power Fail Monitoring Function (PFCM Bit = 0)

<R>

13.4.4 Setting method

The following describes how to set registers.

- When using the A/D converter for A/D conversion
 - <1> Set (1) the ADM.ADCS2 bit.
 - <2> Select the channel and conversion time by setting the ADS.ADS2 to ADS.ADS0 bits and the ADM.FR2 to ADM.FR0 bits.
 - <3> Set (1) the ADM.ADCS bit.
 - <4> Transfer the A/D conversion data to the ADCR register.
 - <5> An interrupt request signal (INTAD) is generated.

<Changing the channel>

- <6> Change the channel by setting the ADS2 to ADS0 bits.
- <7> Transfer the A/D conversion data to the ADCR register.
- <8> An interrupt request signal (INTAD) is generated.
- <Ending A/D conversion>
 - <9> Clear (0) the ADCS bit.
 - <10> Clear (0) the ADCS2 bit.
 - Cautions 1. The time taken from <1> to <3> must be 17 μ s (14 μ s when AV_{REF0} ≥ 4.0 V) or longer.
 - 2. Steps <1> and <2> may be reversed.
 - 3. Step <1> may be omitted. However, if omitted, do not use the first conversion result after <3>.
 - 4. The time taken from <4> to <7> is different from the conversion time set by the FR2 to FR0 bits.

The time taken for <6> and <7> is the conversion time set by the FR2 to FR0 bits.

- When using the A/D converter for the power fail function
 - <1> Set (1) the PFM.PFEN bit.
 - <2> Set the power fail comparison conditions by using the PFM.PFCM bit.
 - <3> Set (1) the ADM.ADCS2 bit.
 - <4> Select the channel and conversion time by setting the ADS.ADS2 to ADS.ADS0 bits and the ADM.FR2 to ADM.FR0 bits.
 - <5> Set the threshold value in the PFT register.
 - <6> Set (1) the ADM.ADCS bit.
 - <7> Transfer the A/D conversion data to the ADCR register.
 - <8> Compare the ADCR register with the PFT register. An interrupt request signal (INTAD) is generated when the conditions match.

<Changing the channel>

- <9> Change the channel by setting the ADS2 to ADS0 bits.
- <10> Transfer the A/D conversion data to the ADCR register.
- <11> The ADCR register is compared with the PFT register. When the conditions match, an INTAD signal is generated.

<Ending A/D conversion>

- <12> Clear (0) the ADCS bit.
- <13> Clear (0) the ADCS2 bit.

13.5 Cautions

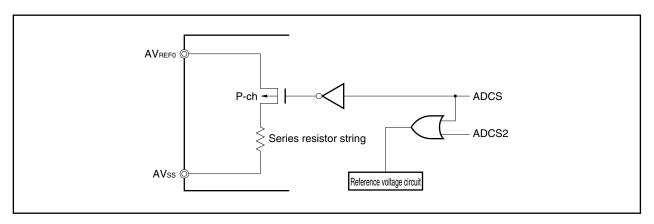

<R>

(1) Power consumption in standby mode

The operation of the A/D converter stops in the standby mode. At this time, the power consumption can be reduced by stopping the conversion operation (ADM.ADCS bit = 0) and stopping the reference voltage circuit (ADM.ADCS2 bit = 0).

Figure 13-5 shows an example of how to reduce the power consumption in the standby mode.

Figure 13-5. Example of How to Reduce Power Consumption in Standby Mode

(2) Input range of ANI0 to ANI7 pins

Use the A/D converter with the ANI0 to ANI7 pin input voltages within the specified range. If a voltage of AVREF0 or higher or AVss or lower (even if within the absolute maximum ratings) is input to these pins, the conversion value of the channel is undefined. Also, this may affect the conversion value of other channels.

(3) Conflicting operations

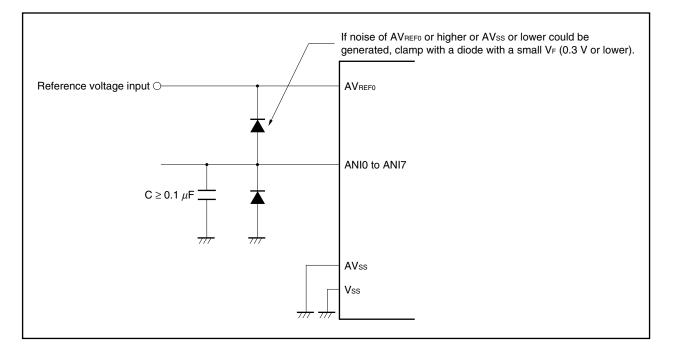

(a) Conflict between writing to the ADCR register and reading from ADCR register upon the end of conversion

Reading the ADCR register takes precedence. After the register has been read, a new conversion result is written to the ADCR register.

(b) Conflict between writing to the ADCR register and writing to the ADM register or writing to the ADS register upon the end of conversion Writing to the ADM register or ADS register takes precedence. The ADCR register is not written, and neither is the conversion end interrupt request signal (INTAD) generated.

(4) Measures against noise

To keep a resolution of 10 bits, be aware of noise on the AVREF0 and ANI0 to ANI7 pins. The higher the output impedance of the analog input source, the greater the effect of noise. Therefore, it is recommended to connect external capacitors as shown in Figure 13-6 to reduce noise.

(5) ANI0/P70 to ANI7/P77 pins

The analog input pins (ANI0 to ANI7) function alternately as input port pins (P70 to P77).

When performing A/D conversion by selecting any of the ANI0 to ANI7 pins, do not execute an input instruction to port 7 during conversion. This may decrease the conversion resolution.

If digital pulses are applied to the pin adjacent to the pin subject to A/D conversion, the value of the A/D conversion may differ from the expected value because of coupling noise. Therefore, do not apply pulses to the pin adjacent to the pin subject to A/D conversion.

(6) Input impedance of AVREFO pin

A series resistor string of tens of $k\Omega$ is connected between the AV_{REF0} pin and AV_{SS} pin.

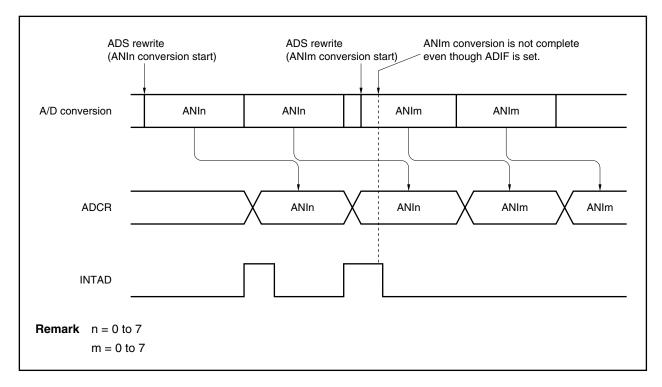

Therefore, if the output impedance of the reference voltage source is high, this will result in a series connection to the series resistor string between the AV_{REF0} pin and AV_{SS} pin, resulting in a large reference voltage error.

(7) Interrupt request flag (ADIC.ADIF bit)

Even when the ADS register is changed, the ADIF bit is not cleared (0).

Therefore, if the analog input pin is changed during A/D conversion, the ADIF bit may be set (1) because A/D conversion of the previous analog input pin ends immediately before the ADS register is rewritten. In a such case, note that if the ADIF bit is read immediately after the ADS register has been rewritten, the ADIF bit is set (1) even though A/D conversion of the analog input pin after the change has not been completed. When stopping A/D conversion once and resuming it, clear the ADIF bit (0) before resuming A/D conversion.

(8) Conversion results immediately after A/D conversion start

If the ADM.ADCS bit is set to 1 within 17 μ s (14 μ s when AVREF0 \geq 4.0 V) after the ADM.ADCS2 bit has been set to 1, or if the ADCS bit is set to 1 with the ADCS2 bit cleared to 0, the converted value immediately after the A/D conversion operation has started may not satisfy the rating. Take appropriate measures such as polling the A/D conversion end interrupt request signal (INTAD) and discarding the first conversion result.

(9) Reading A/D conversion result register (ADCR)

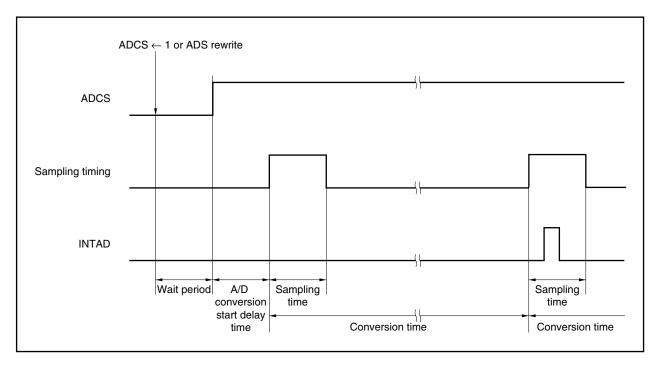

When the ADM or ADS register has been written, the contents of the ADCR register may become undefined. When the conversion operation is complete, read the conversion results before writing to the ADM or ADS register. A correct conversion result may not be able to be read at a timing other than the above. When the CPU is operating on the subclock and main clock oscillation (fx) is stopped, do not read the ADCR

register.

(10) A/D converter sampling time and A/D conversion start delay time

The A/D converter sampling time differs depending on the set value of the ADM register. A delay time exists until actual sampling is started after A/D converter operation is enabled.

When using a set in which the A/D conversion time must be strictly observed, care is required for the contents shown in Figure 13-8 and Table 13-3.

FR2	FR1	FR0	Conversion Time	Sampling Time	A/D Conversion S	Start Delay Time ^{Note}
					MIN.	MAX.
0	0	0	288/fxx	40/fxx	11/fxx	12/fxx
0	0	1	240/fxx	32/fxx	11/fxx	12/fxx
0	1	0	192/fxx	24/fxx	10/fxx	11/fxx
1	0	0	144/fxx	20/fxx	9/fxx	10/fxx
1	0	1	120/fxx	16/fxx	9/fxx	10/f×x
1	1	0	96/fxx	12/fxx	11/fxx	12/fxx
0	ther than abov	/e	Setting prohibited	_	_	_

Note The A/D conversion start delay time is the time after the wait period. For the wait function, refer to 3.4.8 (1)(b) Access to special on-chip peripheral I/O register.

Remark fxx: Main clock frequency

(11) Internal equivalent circuit

The following shows the equivalent circuit of the analog input block.

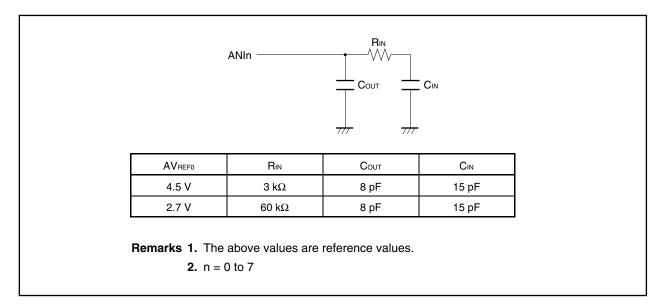

Figure 13-9. Internal Equivalent Circuit of ANIn Pin

(12) Variation of A/D conversion results

The results of the A/D conversion may vary depending on the fluctuation of the supply voltage, or may be affected by noise. To reduce the variation, take counteractive measures with the program such as averaging the A/D conversion results.

(13) A/D conversion result hysteresis characteristics

The successive approximation type A/D converter holds the analog input voltage in the internal sample & hold capacitor and then performs A/D conversion. After the A/D conversion has finished, the analog input voltage remains in the internal sample & hold capacitor. As a result, the following phenomena may occur.

- When the same channel is used for A/D conversions, if the voltage is higher or lower than the previous A/D conversion, then hysteresis characteristics may appear where the conversion result is affected by the previous value. Thus, even if the conversion is performed at the same potential, the result may vary.
- When switching the analog input channel, hysteresis characteristics may appear where the conversion result is affected by the previous channel value. This is because one A/D converter is used for the A/D conversions. Thus, even if the conversion is performed at the same potential, the result may vary.

Therefore, to obtain more accurate conversion result, perform A/D conversion twice successively for the same channel, and discard the first conversion result.

(14) Writing to register during A/D conversion

Writing to the ADM, ADS, PFT, and PFM registers during A/D conversion is prohibited.

<R>

<R>

<R>

13.6 How to Read A/D Converter Characteristics Table

Here, special terms unique to the A/D converter are explained.

(1) Resolution

This is the minimum analog input voltage that can be identified. That is, the percentage of the analog input voltage per bit of digital output is called 1 LSB (Least Significant Bit). The percentage of 1 LSB with respect to the full scale is expressed by %FSR (Full Scale Range). %FSR indicates the ratio of analog input voltage that can be converted as a percentage, and is always represented by the following formula regardless of the resolution.

- 1 %FSR = (Max. value of analog input voltage that can be converted Min. value of analog input voltage that can be converted)/100
 - $= (AV_{REF0} 0)/100$
 - = AVREF0/100

1 LSB is as follows when the resolution is 10 bits.

 $1 \text{ LSB} = 1/2^{10} = 1/1024$

= 0.098%FSR

Accuracy has no relation to resolution, but is determined by overall error.

(2) Overall error

This shows the maximum error value between the actual measured value and the theoretical value. Zero-scale error, full-scale error, linearity error and errors that are combinations of these express the overall error.

Note that the quantization error is not included in the overall error in the characteristics table.

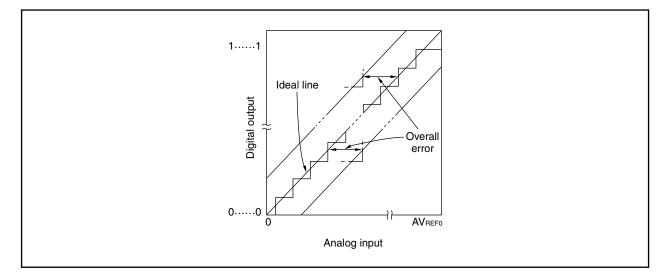

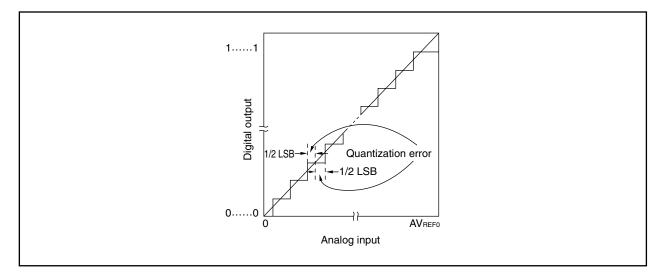

Figure 13-10. Overall Error

(3) Quantization error

When analog values are converted to digital values, a $\pm 1/2$ LSB error naturally occurs. In an A/D converter, an analog input voltage in a range of $\pm 1/2$ LSB is converted to the same digital code, so a quantization error cannot be avoided.

Note that the quantization error is not included in the overall error, zero-scale error, full-scale error, integral linearity error, and differential linearity error in the characteristics table.

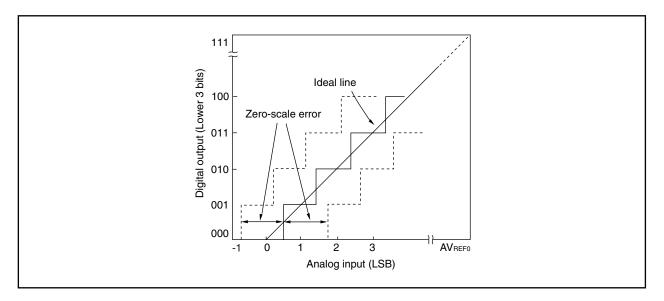

Figure 13-11. Quantization Error

(4) Zero-scale error

This shows the difference between the actual measurement value of the analog input voltage and the theoretical value (1/2 LSB) when the digital output changes from 0.....000 to 0.....001.

Figure 13-12. Zero-Scale Error

(5) Full-scale error

This shows the difference between the actual measurement value of the analog input voltage and the theoretical value (full scale -3/2 LSB) when the digital output changes from 1.....110 to 1.....111.

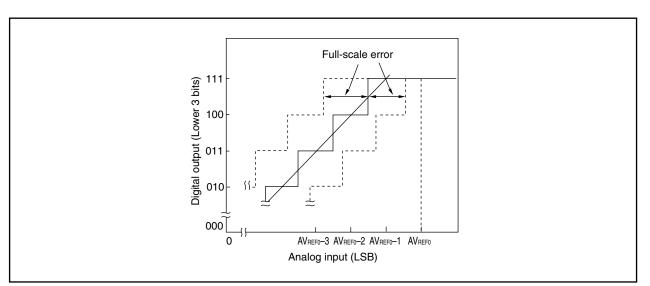

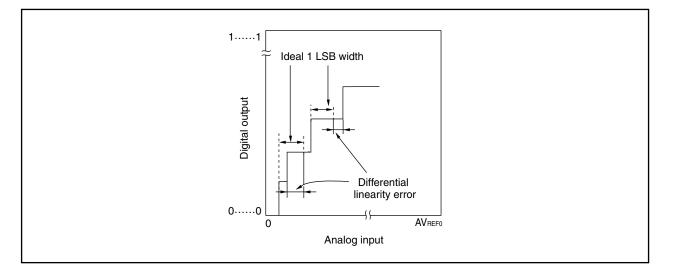

Figure 13-13. Full-Scale Error

(6) Differential linearity error

While the ideal width of code output is 1 LSB, this indicates the difference between the actual measurement value and the ideal value. This indicates the basic characteristics of the A/D conversion when the voltage applied to the analog input pins of the same channel is consistently increased bit by bit from AVss to AVREFO. When the input voltage is increased or decreased, or when two or more channels are used, refer to **13.6 (2) Overall error**.

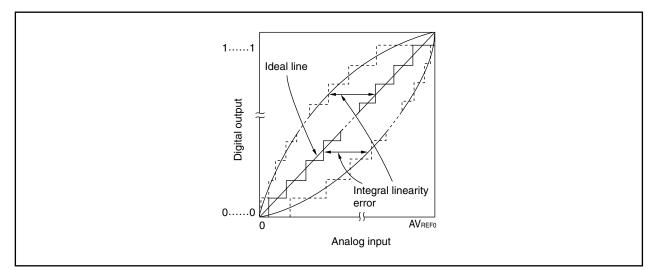

378

<R>

(7) Integral linearity error

This shows the degree to which the conversion characteristics deviate from the ideal linear relationship. It expresses the maximum value of the difference between the actual measurement value and the ideal straight line when the zero-scale error and full-scale error are 0.

(8) Conversion time

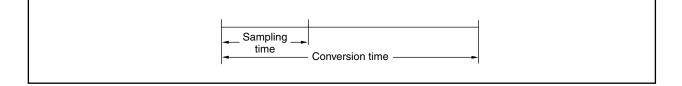

This expresses the time from when the analog input voltage was applied to the time when the digital output was obtained.

The sampling time is included in the conversion time in the characteristics table.

(9) Sampling time

This is the time the analog switch is turned on for the analog voltage to be sampled by the sample & hold circuit.

Figure 13-16. Sampling Time

CHAPTER 14 ASYNCHRONOUS SERIAL INTERFACE (UART)

In the V850ES/KE1, two channels of asynchronous serial interface (UART) are provided.

14.1 Features

- Maximum transfer speed: 312.5 kbps
- Full-duplex communications On-chip RXBn register On-chip TXBn register
- Two-pin configuration^{Note} TXDn: Transmit data output pin RXDn: Receive data input pin
- Reception error detection functions
 - Parity error
 - Framing error
 - Overrun error
- Interrupt sources: 3 types
 - Reception error interrupt request signal (INTSREn):
 - Reception completion interrupt request signal (INTSRn):
 - Transmission completion interrupt request signal (INTSTn):

Interrupt is generated according to the logical OR of the three types of reception errors Interrupt is generated when receive data is transferred from the receive shift register to the RXBn register after serial transfer is completed during a reception enabled state Interrupt is generated when the serial transmission of transmit data (8 or 7 bits) from the transmit shift register is completed

- Character length: 7 or 8 bits
- Parity functions: Odd, even, 0, or none
- Transmission stop bits: 1 or 2 bits
- On-chip dedicated baud rate generator

Note The ASCK0 pin (external clock input) is available only for UART0.

Remark n = 0, 1

14.2 Configuration

Table 14-1.	Configuration of UARTn
-------------	------------------------

Item	Configuration
Registers	Receive buffer register n (RXBn) Transmit buffer register n (TXBn) Receive shift register Transmit shift register Asynchronous serial interface mode register n (ASIMn) Asynchronous serial interface status register n (ASISn) Asynchronous serial interface transmit status register n (ASIFn)
Other	Reception control parity check Addition of transmission control parity

Remark n = 0, 1

Figure 14-1 shows the configuration of UARTn.

(1) Asynchronous serial interface mode register n (ASIMn)

The ASIMn register is an 8-bit register for specifying the operation of UARTn.

(2) Asynchronous serial interface status register n (ASISn)

The ASISn register consists of a set of flags that indicate the error contents when a reception error occurs. The various reception error flags are set (1) when a reception error occurs and are cleared (0) when the ASISn register is read.

(3) Asynchronous serial interface transmit status register n (ASIFn)

The ASIFn register is an 8-bit register that indicates the status when a transmit operation is performed. This register consists of a transmit buffer data flag, which indicates the hold status of the TXBn register data, and the transmit shift register data flag, which indicates whether transmission is in progress.

(4) Reception control parity check

The receive operation is controlled according to the contents set in the ASIMn register. A check for parity errors is also performed during a receive operation, and if an error is detected, a value corresponding to the error contents is set in the ASISn register.

(5) Receive shift register

This is a shift register that converts the serial data that was input to the RXDn pin to parallel data. One byte of data is received, and if a stop bit is detected, the receive data is transferred to the RXBn register. This register cannot be directly manipulated.

(6) Receive buffer register n (RXBn)

The RXBn register is an 8-bit buffer register for holding receive data. When 7 characters are received, 0 is stored in the MSB.

During a reception enabled state, receive data is transferred from the receive shift register to the RXBn register, synchronized with the end of the shift-in processing of one frame.

Also, the reception completion interrupt request signal (INTSRn) is generated by the transfer of data to the RXBn register.

(7) Transmit shift register

This is a shift register that converts the parallel data that was transferred from the TXBn register to serial data. When one byte of data is transferred from the TXBn register, the shift register data is output from the TXDn pin.

The transmission completion interrupt request signal (INTSTn) is generated synchronized with the completion of transmission of one frame.

This register cannot be directly manipulated.

(8) Transmit buffer register n (TXBn)

The TXBn register is an 8-bit buffer for transmit data. A transmit operation is started by writing transmit data to the TXBn register.

(9) Addition of transmission control parity

A transmit operation is controlled by adding a start bit, parity bit, or stop bit to the data that is written to the TXBn register, according to the contents that were set in the ASIMn register.

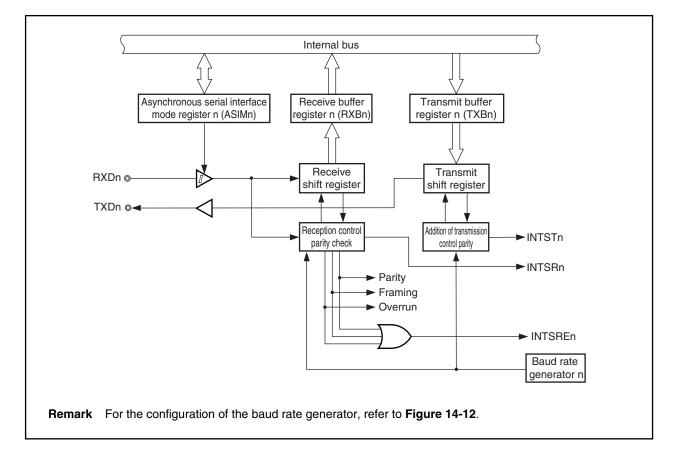

Figure 14-1. Block Diagram of UARTn

14.3 Registers

(1) Asynchronous serial interface mode register n (ASIMn)

The ASIMn register is an 8-bit register that controls the UARTn transfer operation. This register can be read or written in 8-bit or 1-bit units. Reset sets this register to 01H.

- Cautions 1. When using UARTn, be sure to set the external pins related to UARTn functions to the control made before setting the CKSRn and BRGCn registers, and then set the UARTEn bit to 1. Then set the other bits.
 - 2. Set the UARTEn and RXEn bits to 1 while a high level is input to the RXDn pin. If these bits are set to 1 while a low level is input to the RXDn pin, reception will be started.

		<7>	<6>	<5>	4	3	2	1	0	_

(2/2)

RXEn	Reception enable/disable
0	Disable reception ^{Note}
1	Enable reception
	PRXEn bit to 1 after setting the UARTEn bit to 1 at startup. Clear the UARTEn bit to 0 after clearing the pit to 0 to stop.
• To initia	alize the reception unit status, clear (0) the RXEn bit, and after letting 2 Clock cycles (base clock) elapse,

set (1) the RXEn bit again. If the RXEn bit is not set again, initialization may not be successful. (For details about the base clock, refer to **14.6.1 (1) Base clock**.)

PSn1	PSn0	Transmit operation	Receive operation
0	0	Don't output parity bit	Receive with no parity
0	1	Output 0 parity	Receive as 0 parity
1	0	Output odd parity	Judge as odd parity
1	1	Output even parity	Judge as even parity
 To over 	erwrite the	PSn1 and PSn0 bits, first clear (0) the TXEn and	RXEn bits.

If "0 parity" is selected for reception, no parity judgment is performed. Therefore, no error interrupt is generated

because the ASISn.PEn bit is not set.

CLn	Specification of character length of 1 frame of transmit/receive data
0	7 bits
1	8 bits
 To over 	erwrite the CLn bit, first clear (0) the TXEn and RXEn bits.

SLn	Specification of stop bit length of transmit data
0	1 bit
1	2 bits
• To ov	erwrite the SLn bit, first clear (0) the TXEn bit.

• Since reception is always done with a stop bit length of 1, the SLn bit setting does not affect receive operations.

ISRMn	Enable/disable of generation of reception completion interrupt request signals when an error occurs					
0	Generate a reception error interrupt request signal (INTSREn) as an interrupt when an error occurs. In this case, no reception completion interrupt request signal (INTSRn) is generated.					
1	Generate a reception completion interrupt request signal (INTSRn) as an interrupt when an error occurs. In this case, no reception error interrupt request signal (INTSREn) is generated.					
• To ove	To overwrite the ISRMn bit, first clear (0) the RXEn bit.					

Note When reception is disabled, the receive shift register does not detect a start bit. No shift-in processing or transfer processing to the RXBn register is performed, and the contents of the RXBn register are retained.

When reception is enabled, the receive shift operation starts, synchronized with the detection of the start bit, and when the reception of one frame is completed, the contents of the receive shift register are transferred to the RXBn register. A reception completion interrupt request signal (INTSRn) is also generated in synchronization with the transfer to the RXBn register.

(2) Asynchronous serial interface status register n (ASISn)

The ASISn register, which consists of 3 error flag bits (PEn, FEn and OVEn), indicates the error status when UARTn reception is complete.

The ASISn register is cleared to 00H by a read operation. When a reception error occurs, the RXBn register should be read and the error flag should be cleared after the ASISn register is read.

This register is read-only in 8-bit units.

Reset sets this register to 00H.

- Cautions 1. When the ASIMn.UARTEn bit or ASIMn.RXEn bit is cleared to 0, or when the ASISn register is read, the PEn, FEn, and OVEn bits are cleared (0).
 - 2. Operation using a bit manipulation instruction is prohibited.
 - 3. When the main clock is stopped and the CPU is operating on the subclock, do not access the ASISn register.

For details, refer to 3.4.8 (1) (b).

	_	7	6	5	4	3	2	1	0

(3) Asynchronous serial interface transmit status register n (ASIFn)

The ASIFn register, which consists of 2 status flag bits, indicates the status during transmission.

By writing the next data to the TXBn register after data is transferred from the TXBn register to the transmit shift register, transmit operations can be performed continuously without suspension even during an interrupt interval. When transmission is performed continuously, data should be written after referencing the TXBFn bit to prevent writing to the TXBn register by mistake.

This register is read-only in 8-bit or 1-bit units.

Reset sets this register to 00H.

		7	6	5	4	3	2	<1>	<0>	_

(4) Receive buffer register n (RXBn)

The RXBn register is an 8-bit buffer register for storing parallel data that had been converted by the receive shift register.

When reception is enabled (ASIMn.RXEn bit = 1), receive data is transferred from the receive shift register to the RXBn register, synchronized with the completion of the shift-in processing of one frame. Also, a reception completion interrupt request signal (INTSRn) is generated by the transfer to the RXBn register. For information about the timing for generating this interrupt request, refer to **14.5.4 Receive operation**.

If reception is disabled (ASIMn.RXEn bit = 0), the contents of the RXBn register are retained, and no processing is performed for transferring data to the RXBn register even when the shift-in processing of one frame is completed. Also, the INTSRn signal is not generated.

When 7 bits is specified for the data length, bits 6 to 0 of the RXBn register are transferred for the receive data and the MSB (bit 7) is always 0. However, if an overrun error (ASISn.OVEn bit = 1) occurs, the receive data at that time is not transferred to the RXBn register.

The RXBn register becomes FFH when a reset is input or ASIMn.UARTEn bit = 0. This register is read-only in 8-bit units.

After re	set: FFH	R A	ddress: R	XB0 FFFF	FA02H, RX	(B1 FFFF	A12H	
	7	6	5	4	3	2	1	0
RXBn	RXBn7	RXBn6	RXBn5	RXBn4	RXBn3	RXBn2	RXBn1	RXBn0
(n = 0, 1)								

(5) Transmit buffer register n (TXBn)

The TXBn register is an 8-bit buffer register for setting transmit data.

When transmission is enabled (ASIMn.TXEn bit = 1), the transmit operation is started by writing data to TXBn register.

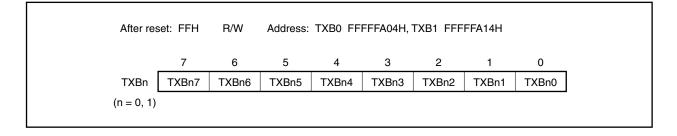

When transmission is disabled (TXEn bit = 0), even if data is written to TXBn register, the value is ignored.

The TXBn register data is transferred to the transmit shift register, and a transmission completion interrupt request signal (INTSTn) is generated, synchronized with the completion of the transmission of one frame from the transmit shift register. For information about the timing for generating this interrupt request, refer to **14.5.2 Transmit operation**.

When ASIFn.TXBFn bit = 1, writing must not be performed to TXBn register.

This register can be read or written in 8-bit units.

Reset sets this register to FFH.

14.4 Interrupt Requests

The following three types of interrupt request signals are generated from UARTn.

- Reception error interrupt request signal (INTSREn)
- Reception completion interrupt request signal (INTSRn)
- Transmission completion interrupt request signal (INTSTn)

The default priorities among these three types of interrupt request signals are, from high to low, reception error interrupt, reception completion interrupt, and transmission completion interrupt.

Table 14-2. Generated Interrupt Request Signals and Default Priorities

Interrupt Request Signal	Priority
Reception error interrupt request signal (INTSREn)	1
Reception completion interrupt request signal (INTSRn)	2
Transmission completion interrupt request signal (INTSTn)	3

(1) Reception error interrupt request signal (INTSREn)

When reception is enabled, the INTSREn signal is generated according to the logical OR of the three types of reception errors explained for the ASISn register. Whether the INTSREn signal or the INTSRn signal is generated when an error occurs can be specified according to the ASIMn.ISRMn bit. When reception is disabled, the INTSREn signal is not generated.

(2) Reception completion interrupt request signal (INTSRn)

When reception is enabled, the INTSRn signal is generated when data is shifted in to the receive shift register and transferred to the RXBn register.

The INTSRn signal can be generated in place of the INTSREn signal according to the ASIMn.ISRMn bit even when a reception error has occurred.

When reception is disabled, the INTSRn signal is not generated.

(3) Transmission completion interrupt request signal (INTSTn)

The INTSTn signal is generated when one frame of transmit data containing 7-bit or 8-bit characters is shifted out from the transmit shift register.

14.5 Operation

14.5.1 Data format

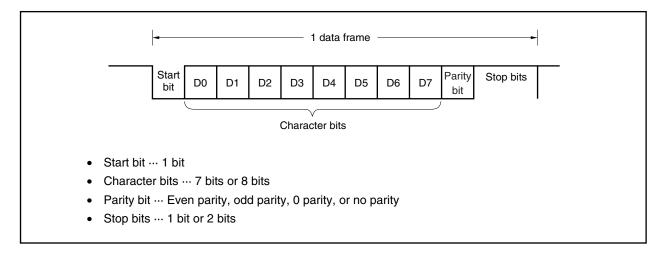

Full-duplex serial data transmission and reception can be performed.

The transmit/receive data format consists of one data frame containing a start bit, character bits, a parity bit, and stop bits as shown in Figure 14-2.

The character bit length within one data frame, the type of parity, and the stop bit length are specified according to the ASIMn register.

Also, data is transferred LSB first.

Figure 14-2. Format of UARTn Transmit/Receive Data

14.5.2 Transmit operation

When the ASIMn.UARTEn bit is set to 1, a high level is output from the TXDn pin.

Then, when the ASIMn.TXEn bit is set to 1, transmission is enabled, and the transmit operation is started by writing transmit data to the TXBn register.

(1) Transmission enabled state

This state is set by the TXEn bit.

- TXEn bit = 1: Transmission enabled state
- TXEn bit = 0: Transmission disabled state

Since UARTn does not have a CTS (transmission enabled signal) input pin, a port should be used to confirm whether the destination is in a reception enabled state.

(2) Starting a transmit operation

In the transmission enabled state, a transmit operation is started by writing transmit data to the TXBn register. When a transmit operation is started, the data in the TXBn register is transferred to the transmit shift register. Then, the transmit shift register outputs data to the TXDn pin (the transmit data is transferred sequentially starting with the start bit). The start bit, parity bit, and stop bits are added automatically.

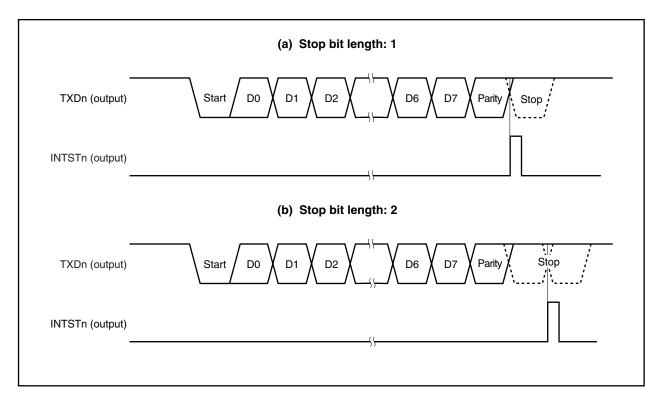

(3) Transmission interrupt

When the transmit shift register becomes empty, a transmission completion interrupt request signal (INTSTn) is generated. The timing for generating the INTSTn signal differs according to the specification of the stop bit length. The INTSTn signal is generated at the same time that the last stop bit is output.

If the data to be transmitted next has not been written to the TXBn register, the transmit operation is suspended.

Caution Normally, when the transmit shift register becomes empty, the INTSTn signal is generated. However, the INTSTn signal is not generated if the transmit shift register becomes empty due to reset.

14.5.3 Continuous transmission operation

UARTn can write the next transmit data to the TXBn register at the timing that the transmit shift register starts the shift operation. This enables an efficient transmission rate to be realized by continuously transmitting data even during the transmission completion interrupt service after the transmission of one data frame. In addition, reading the ASIFn.TXSFn bit after the occurrence of a transmission completion interrupt request signal (INTSTn) enables the TXBn register to be efficiently written twice (2 bytes) without waiting for the transmission of 1 data frame.

When continuous transmission is performed, data should be written after referencing the ASIFn register to confirm the transmission status and whether or not data can be written to the TXBn register.

Caution The values of the ASIF.TXBFn and ASIF.TXSFn bits change $10 \rightarrow 11 \rightarrow 01$ in continuous transmission.

Therefore, do not confirm the status based on the combination of the TXBFn and TXSFn bits. Read only the TXBFn bit during continuous transmission.

TXBFn	Whether or Not Writing to TXBn Register Is Enabled
0	Writing is enabled
1	Writing is not enabled

Caution When transmission is performed continuously, write the first transmit data (first byte) to the TXBn register and confirm that the TXBFn bit is 0, and then write the next transmit data (second byte) to TXBn register. If writing to the TXBn register is performed when the TXBFn bit is 1, transmit data cannot be guaranteed.

The communication status can be confirmed by referring to the TXSFn bit.

TXSFn	Transmission Status
0	Transmission is completed.
1	Under transmission.

- Cautions 1. When initializing the transmission unit when continuous transmission is completed, confirm that the TXSFn bit is 0 after the occurrence of the transmission completion interrupt, and then execute initialization. If initialization is performed when the TXSFn bit is 1, transmit data cannot be guaranteed.
 - 2. While transmission is being performed continuously, an overrun error may occur if the next transmission is completed before the INTSTn interrupt servicing following the transmission of 1 data frame is executed. An overrun error can be detected by embedding a program that can count the number of transmit data and referencing TXSFn bit.

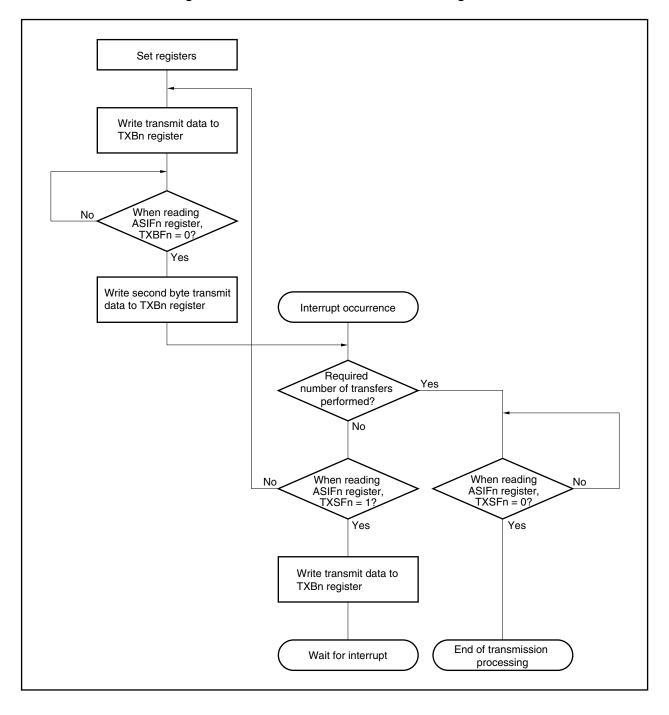

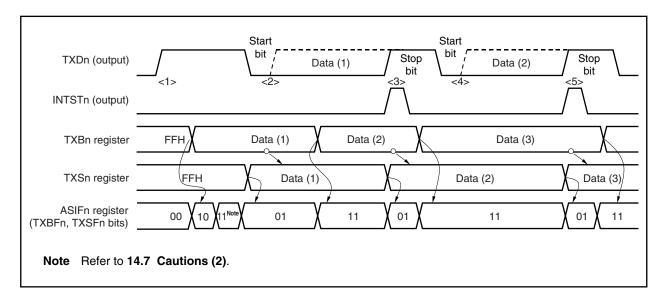

Figure 14-4. Continuous Transmission Processing Flow

(1) Starting procedure

The procedure to start continuous transmission is shown below.

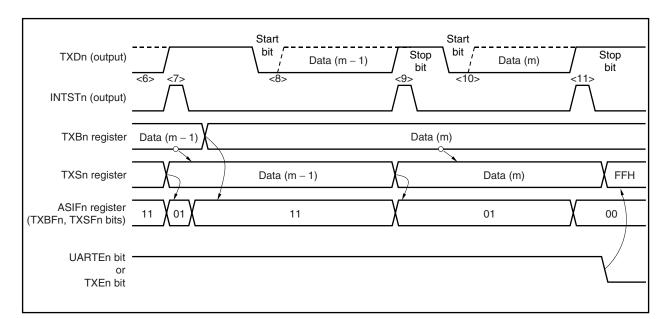

Transmission Starting Procedure	Internal Operation	ASIFn F	Register
		TXBFn	TXSFn
Set transmission mode	<1> Start transmission unit	0	0
Write data (1)		1	0
	<2> Generate start bit	1	1 ^{Note}
		0	1
	Start data (1) transmission	0	1
• Read ASIFn register (confirm that TXBFn bit = 0) ←		<u>0</u>	1
• Write data (2)	►	1	1
	< <transmission in="" progress="">></transmission>		
	<3> INTSTn interrupt occurs	0	1
 Read ASIFn register (confirm that TXBFn bit = 0)		<u>0</u>	1
• Write data (3)		1	1
	<4> Generate start bit		
	Start data (2) transmission		
	< <transmission in="" progress="">></transmission>		
	<5> INTSTn interrupt occurs	0	1
Read ASIFn register (confirm that TXBFn bit = 0)		<u>0</u>	1
• Write data (4)	<u>├</u>	1	1

Note Refer to 14.7 Cautions (2).

(2) Ending procedure

The procedure for ending continuous transmission is shown below.

Transmission End Procedure	Internal Operation	ASIFn F	Register
		TXBFn	TXSFn
	<6> Transmission of data (m – 2) is in progress	1	1
	<7> INTSTn interrupt occurs	0	1
• Read ASIFn register (confirm that TXBFn bit = 0) +		<u>0</u>	1
Write data (m)	▶	1	1
	<8> Generate start bit Start data (m – 1) transmission < <transmission in="" progress="">></transmission>

 Read ASIFn register (confirm that TXSFn bit = 1)	· · · · · · · · · · · · · · · · · · ·	0	<u>1</u>
	<10> Generate start bit Start data (m) transmission < <transmission in="" progress="">></transmission>		
	<11> Generate INTSTn interrupt	0	0
• Read ASIFn register (confirm that TXSFn bit = 0) +		0	<u>0</u>
Clear (0) the UARTEn bit or TXEn bit	Initialize internal circuits		

14.5.4 Receive operation

The awaiting reception state is set by setting the ASIMn.UARTEn bit to 1 and then setting the ASIMn.RXEn bit to 1. To start the receive operation, start sampling at the falling edge when the falling of the RXDn pin is detected. If the RXDn pin is low level at a start bit sampling point, the start bit is recognized. When the receive operation begins, serial data is stored sequentially in the receive shift register according to the baud rate that was set. A reception completion interrupt request signal (INTSRn) is generated each time the receive of one frame of data is completed. Normally, the receive data is transferred from the RXBn register to memory by this interrupt servicing.

(1) Reception enabled state

The receive operation is set to the reception enabled state by setting the RXEn bit to 1.

- RXEn bit = 1: Reception enabled state
- RXEn bit = 0: Reception disabled state

In receive disabled state, the reception hardware stands by in the initial state. At this time, the contents of the RXBn register are retained, and no reception completion interrupt or reception error interrupt is generated.

(2) Starting a receive operation

A receive operation is started by the detection of a start bit. The RXDn pin is sampled using the serial clock from baud rate generator n (BRGn).

(3) Reception completion interrupt

When the RXEn bit = 1 and the reception of one frame of data is completed (the stop bit is detected), the INTSRn signal is generated and the receive data within the receive shift register is transferred to the RXBn register at the same time.

Also, if an overrun error (ASISn.OVEn bit = 1) occurs, the receive data at that time is not transferred to the RXBn register, and either the INTSRn signal or a reception error interrupt request signal (INTSREn) is generated according to the ASIMn.ISRMn bit setting.

Even if a parity error (ASISn.PEn bit = 1) or framing error (ASISn.FEn bit = 1) occurs during a reception operation, the receive operation continues until stop bit is received, and after reception is completed, either the INTSRn signal or the INTSREn signal is generated according to the ISRMn bit setting (the receive data within the receive shift register is transferred to the RXBn register).

If the RXEn bit is cleared (0) during a receive operation, the receive operation is immediately stopped. The contents of the RXBn register and the ASISn register at this time do not change, and the INTSRn signal or the INTSREn signal is not generated.

The INTSRn signal or the INTSREn signal is not generated when the RXEn bit = 0 (reception is disabled).

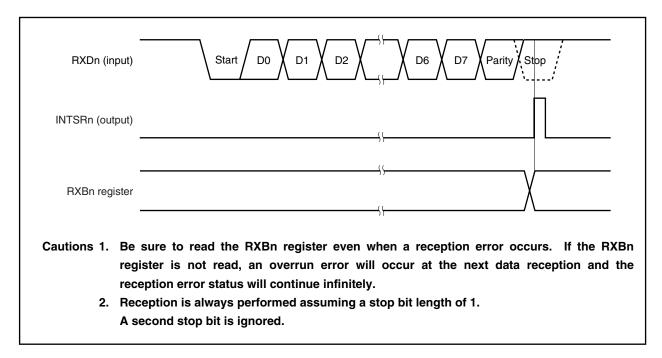

Figure 14-7. UARTn Reception Completion Interrupt Timing

14.5.5 Reception error

The three types of errors that can occur during a receive operation are a parity error, framing error, and overrun error. As a result of data reception, the various flags of the ASISn register are set (1), and a reception error interrupt request signal (INTSREn) or a reception completion interrupt request signal (INTSREn) is generated at the same time. The ASIMn.ISRMn bit specifies whether the INTSREn signal or the INTSRn signal is generated.

The type of error that occurred during reception can be detected by reading the contents of the ASISn register during the INTSREn or INTSRn interrupt servicing.

The contents of the ASISn register are cleared (0) by reading the ASISn register.

Error Flag	Reception Error	Cause
PEn	Parity error	The parity specification during transmission did not match the parity of the reception data
FEn	Framing error	No stop bit was detected
OVEn	Overrun error	The reception of the next data was completed before data was read from the RXBn register

 Table 14-3.
 Reception Error Causes

(1) Separation of reception error interrupt request signal

A reception error interrupt request signal can be separated from the INTSRn signal and generated as the INTSREn signal by clearing the ISRMn bit to 0.

Figure 14-8. When Reception Error Interrupt Request Signal Is Separated from INTSRn Signal (ISRMn Bit = 0)

(a) No error	occurs during reception	(b) An error occu	rs during reception
INTSRn signal (Reception completion interrupt)		INTSRn signal (Reception completion interrupt)	INTSRn does not occur
INTSREn signal (Reception error interrupt)		INTSREn signal (Reception error — interrupt)	

Figure 14-9. When Reception Error Interrupt Request Signal Is Included in INTSRn Signal (ISRMn Bit = 1)

(a) No error oc	curs during reception	(b) An error occu	urs during reception
INTSRn signal (Reception completion interrupt)		INTSRn signal (Reception completion _ interrupt)	
INTSREn signal (Reception error interrupt)		INTSREn signal (Reception error – interrupt)	INTSREn does not occur

14.5.6 Parity types and corresponding operation

A parity bit is used to detect a bit error in communication data. Normally, the same type of parity bit is used on the transmission and reception sides.

(1) Even parity

(i) During transmission

The parity bit is controlled so that the number of bits with the value "1" within the transmit data including the parity bit is even. The parity bit value is as follows.

- If the number of bits with the value "1" within the transmit data is odd: 1
- If the number of bits with the value "1" within the transmit data is even: 0

(ii) During reception

The number of bits with the value "1" within the receive data including the parity bit is counted, and a parity error is generated if this number is odd.

(2) Odd parity

(i) During transmission

In contrast to even parity, the parity bit is controlled so that the number of bits with the value "1" within the transmit data including the parity bit is odd. The parity bit value is as follows.

- If the number of bits with the value "1" within the transmit data is odd: 0
- If the number of bits with the value "1" within the transmit data is even: 1

(ii) During reception

The number of bits with the value "1" within the receive data including the parity bit is counted, and a parity error is generated if this number is even.

(3) 0 parity

During transmission the parity bit is set to "0" regardless of the transmit data.

During reception, no parity bit check is performed. Therefore, no parity error is generated regardless of whether the parity bit is "0" or "1".

(4) No parity

No parity bit is added to the transmit data.

During reception, the receive operation is performed as if there were no parity bit. Since there is no parity bit, no parity error is generated.

14.5.7 Receive data noise filter

The RXDn signal is sampled at the rising edge of the prescaler output base clock (fucLK). If the same sampling value is obtained twice, the match detector output changes, and this output is sampled as input data. Therefore, data not exceeding one clock width is judged to be noise and is not delivered to the internal circuit (refer to **Figure 14-11**). Refer to **14.6.1 (1) Base clock** regarding the base clock.

Also, since the circuit is configured as shown in Figure 14-10, internal processing during a receive operation is delayed by up to 2 clocks according to the external signal status.

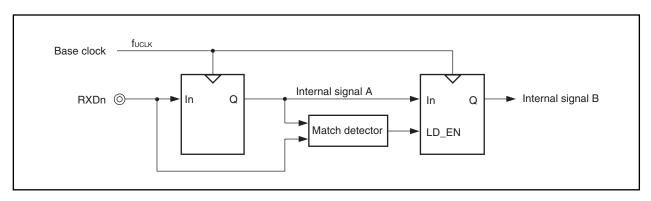

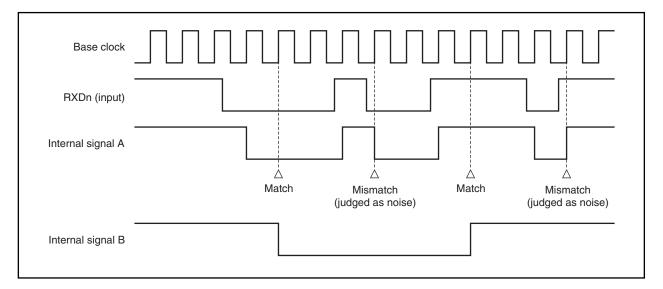

Figure 14-10. Noise Filter Circuit

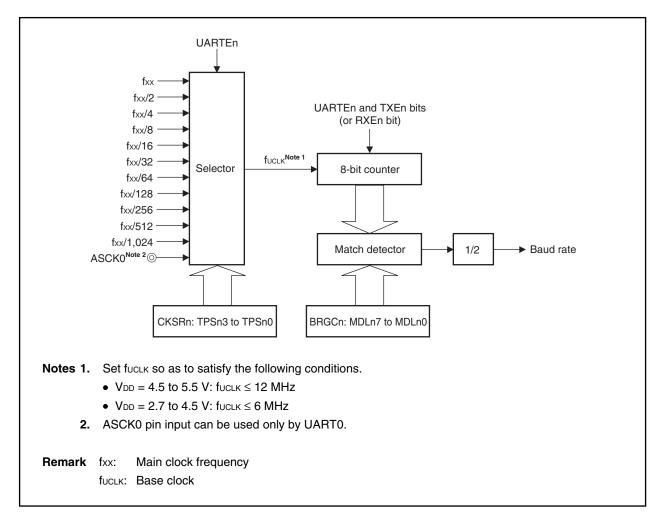

14.6 Dedicated Baud Rate Generator n (BRGn)

A dedicated baud rate generator, which consists of a source clock selector and an 8-bit programmable counter, generates serial clocks during transmission/reception by UARTn. The dedicated baud rate generator output can be selected as the serial clock for each channel.

Separate 8-bit counters exist for transmission and for reception.

14.6.1 Baud rate generator n (BRGn) configuration

(1) Base clock

When the ASIMn.UARTEn bit = 1, the clock selected according to the CKSRn.TPSn3 to CKSRn.TPSn0 bits is supplied to the transmission/reception unit. This clock is called the base clock (f_{UCLK}). When the UARTEn bit = 0, f_{UCLK} is fixed to low level.

14.6.2 Serial clock generation

A serial clock can be generated according to the settings of the CKSRn and BRGCn registers. The base clock to the 8-bit counter is selected by the CKSRn.TPSn3 to CKSRn.TPSn0 bits. The 8-bit counter divisor value can be set by the BRGCn.MDLn7 to BRGCn.MDLn0 bits.

(1) Clock select register n (CKSRn)

The CKSRn register is an 8-bit register for selecting the basic block using the TPSn3 to TPSn0 bits. The clock selected by the TPSn3 to TPSn0 bits becomes the base clock (fuclk) of the transmission/reception module.

This register can be read or written in 8-bit units.

Reset sets this register to 00H.

Caution Clear the ASIMn.UARTEn bit to 0 before rewriting the TPSn3 to TPSn0 bits.

		7	6	5	4	3	2	1	0	
	CKSRn	0	0	0	0	TPSn3	TPSn2	TPSn1	TPSn0	
	(n = 0, 1)									
TPSn3	TPSn2	TPSn1	TPSn0			Base	clock (fucu	K) ^{Note 1}

	• V _{DD} = 2	.7 to 4.5 V	: fuclк ≤ 6	MHz						
2				used only b	by UART0					
	Setting o	f UART1 is	s prohibited	l.						

(2) Baud rate generator control register n (BRGCn)

The BRGCn register is an 8-bit register that controls the baud rate (serial transfer speed) of UARTn. This register can be read or written in 8-bit units. Reset sets this register to FFH.

Caution If the MDLn7 to MDLn0 bits are to be overwritten, the ASIMn.TXEn and ASIMn.RXEn bits should be cleared to 0 first.

		7	6	5	4		3	2	1	0

Remark	2. ∤ 3. ⊺	k: Valu	e set by ud rate is	MDLn7	to MDL	_n0 bits	(k = 8,	by CKSR(9, 10,, 2 counter di	255)	to CKSR0 2.

(3) Baud rate

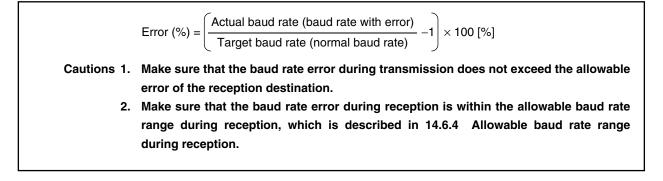

The baud rate is the value obtained by the following formula.

Baud rate [bps] =
$$\frac{f_{UCLK}}{2 \times k}$$

 f_{UCLK} = Frequency [Hz] of base clock selected by CKSRn.TPSn3 to CKSRn.TPSn0 bits. k = Value set by BRGCn.MDLn7 to BRGCn.MDLn0 bits (k = 8, 9, 10, ..., 255)

(4) Baud rate error

The baud rate error is obtained by the following formula.

Example: Base clock frequency = 10 MHz = 10,000,000 Hz Setting of BRGCn.MDLn7 to BRGCn.MDLn0 bits = 00100001B (k = 33) Target baud rate = 153,600 bps Baud rate = 10,000,000/(2 × 33) = 151,515 [bps] Error = $(151,515/153,600 - 1) \times 100$ = -1.357 [%]

14.6.3 Baud rate setting example

312500	fxx/4	08H (8)	0	fxx/2	0DH (13)	-1.54	fxx/2	08H (8)	0.00

Table 14-4. Baud Rate Generator Setting Data

Caution The allowable frequency of the base clock (fuclk) is as follows.

• VDD = 4.5 to 5.5 V: fuclk \leq 12 MHz

• VDD = 2.7 to 4.5 V: fuclk \leq 6 MHz

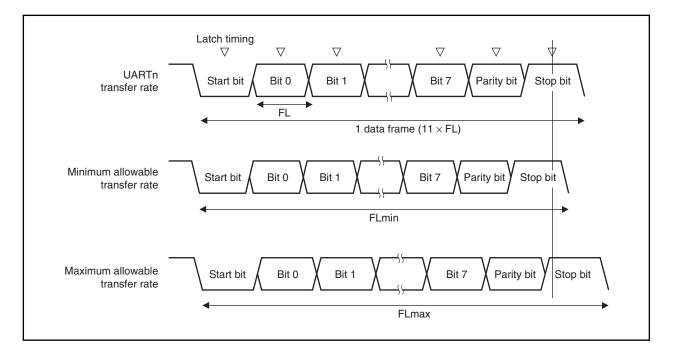

- **Remark** fxx: Main clock frequency
 - fuclk: Base clock frequency
 - k: Set values of BRGCn.MDLn7 to BRGCn.MDLn0 bits
 - ERR: Baud rate error [%]

n = 0, 1

14.6.4 Allowable baud rate range during reception

The degree to which a discrepancy from the transmission destination's baud rate is allowed during reception is shown below.

Caution The equations described below should be used to set the baud rate error during reception so that it always is within the allowable error range.

As shown in Figure 14-13, after the start bit is detected, the receive data latch timing is determined according to the counter that was set by the BRGCn register. If all data up to the final data (stop bit) is in time for this latch timing, the data can be received normally.

If this is applied to 11-bit reception, the following is theoretically true.

 $FL = (Brate)^{-1}$

Brate: UARTn baud rate

- k: BRGCn register set value
- FL: 1-bit data length

When the latch timing margin is 2 base clocks, the minimum allowable transfer rate (FLmin) is as follows.

$$FLmin = 11 \times FL - \frac{k-2}{2k} \times FL = \frac{21k+2}{2k} FL$$

Therefore, the transfer destination's maximum receivable baud rate (BRmax) is as follows.

BRmax =
$$(FLmin/11)^{-1} = \frac{22k}{21k+2}$$
 Brate

Similarly, the maximum allowable transfer rate (FLmax) can be obtained as follows.

$$\frac{10}{11} \times FLmax = 11 \times FL - \frac{k+2}{2 \times k} \times FL = \frac{21k-2}{2 \times k} FL$$
$$FLmax = \frac{21k-2}{20k} FL \times 11$$

Therefore, the transfer destination's minimum receivable baud rate (BRmin) is as follows.

BRmin =
$$(FLmax/11)^{-1} = \frac{20k}{21k-2}$$
 Brate

The allowable baud rate error of UARTn and the transfer destination can be obtained as follows from the expressions described above for computing the minimum and maximum baud rate values.

Table 14-5.	Maximum ar	nd Minimum	Allowable	Baud Rate	Error
-------------	------------	------------	-----------	------------------	-------

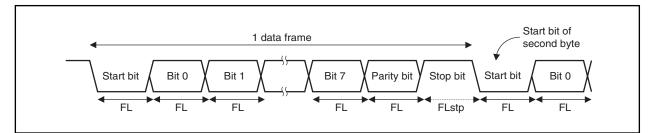

Division Ratio (k)	Maximum Allowable Baud Rate Error	Minimum Allowable Baud Rate Error
8	+3.53%	-3.61%
20	+4.26%	-4.31%
50	+4.56%	-4.58%
100	+4.66%	-4.67%
255	+4.72%	-4.73%

- Remarks 1. The reception precision depends on the number of bits in one frame, the base clock frequency, and the division ratio (k). The higher the base clock frequency and the larger the division ratio (k), the higher the precision.
 - 2. k: BRGCn register set value

14.6.5 Transfer rate during continuous transmission

During continuous transmission, the transfer rate from a stop bit to the next start bit is extended two clocks of the base clock longer than normal. However, on the reception side, the transfer result is not affected since the timing is initialized by the detection of the start bit.

Representing the 1-bit data length by FL, the stop bit length by FLstp, and the base clock frequency by fuclk yields the following equation.

FLstp = FL + 2/fuclk

Therefore, the transfer rate during continuous transmission is as follows (when the stop bit length = 1).

Transfer rate = $11 \times FL + (2/f_{UCLK})$

14.7 Cautions

Cautions to be observed when using UARTn are shown below.

- (1) When the supply of clocks to UARTn is stopped (for example, in IDLE or STOP mode), operation stops with each register retaining the value it had immediately before the supply of clocks was stopped. The TXDn pin output also holds and outputs the value it had immediately before the supply of clocks was stopped. However, operation is not guaranteed after the supply of clocks is restarted. Therefore, after the supply of clocks is restarted, the circuits should be initialized by clearing the ASIMn.UARTEn, ASIMn.RXEn, and ASIMn.TXEn bits to 000.
- (2) UARTn has a 2-stage buffer configuration consisting of the TXBn register and the transmission shift register, and has status flags (ASIFn.TXBFn and ASIFn.TXSFn bits) that indicate the status of each buffer. If the TXBFn and TXSFn bits are read in continuous transmission, the value changes 10 → 11 → 01. For the timing to write the next data to the TXBn register, read only the TXBFn bit during continuous transmission.

CHAPTER 15 CLOCKED SERIAL INTERFACE 0 (CSI0)

In the V850ES/KE1, two channels of clocked serial interface 0 (CSI0) are provided.

15.1 Features

- Maximum transfer speed: 5 Mbps
- Master mode/slave mode selectable
- Transmission data length: 8 bits or 16 bits can be set
- MSB/LSB-first selectable for transfer data
- Eight clock signals can be selected (7 master clocks and 1 slave clock)
- 3-wire type SO0n: Serial transmit data output
 - SIOn: Serial receive data input
 - SCK0n: Serial clock I/O
- Interrupt sources: 1 type
 - Transmission/reception completion interrupt request signal (INTCSI0n)
- Transmission/reception mode or reception-only mode selectable
- Two transmission buffer registers (SOTBFn/SOTBFLn, SOTBn/SOTBLn) and two reception buffer registers (SIRBn/SIRBLn, SIRBEn/SIRBELn) are provided on chip
- Single transfer mode/continuous transfer mode selectable

Remark n = 0, 1

15.2 Configuration

CSI0n is controlled via the CSIM0n register.

(1) Clocked serial interface mode register 0n (CSIM0n)

The CSIM0n register is an 8-bit register that specifies the operation of CSI0n.

(2) Clocked serial interface clock selection register n (CSICn)

The CSICn register is an 8-bit register that controls the CSI0n serial transfer operation.

(3) Serial I/O shift register 0n (SIO0n)

The SIO0n register is a 16-bit shift register that converts parallel data into serial data. The SIO0n register is used for both transmission and reception. Data is shifted in (reception) and shifted out (transmission) from the MSB or LSB side. The actual transmission/reception operations are started up by accessing the buffer register.

(4) Serial I/O shift register 0nL (SIO0nL)

The SIO0nL register is an 8-bit shift register that converts parallel data into serial data. The SIO0nL register is used for both transmission and reception. Data is shifted in (reception) and shifted out (transmission) from the MSB or LSB side. The actual transmission/reception operations are started up by access of the buffer register.

(5) Clocked serial interface receive buffer register n (SIRBn)

The SIRBn register is a 16-bit buffer register that stores receive data.

(6) Clocked serial interface receive buffer register nL (SIRBnL)

The SIRBnL register is an 8-bit buffer register that stores receive data.

(7) Clocked serial interface read-only receive buffer register n (SIRBEn)

The SIRBEn register is a 16-bit buffer register that stores receive data. The SIRBEn register is the same as the SIRBn register. It is used to read the contents of the SIRBn register.

(8) Clocked serial interface read-only receive buffer register nL (SIRBEnL)

The SIRBEnL register is an 8-bit buffer register that stores receive data. The SIRBEnL register is the same as the SIRBnL register. It is used to read the contents of the SIRBnL register.

(9) Clocked serial interface transmit buffer register n (SOTBn)

The SOTBn register is a 16-bit buffer register that stores transmit data.

(10) Clocked serial interface transmit buffer register nL (SOTBLnL)

The SOTBnL register is an 8-bit buffer register that stores transmit data.

(11) Clocked serial interface initial transmit buffer register n (SOTBFn)

The SOTBFn register is a 16-bit buffer register that stores the initial transmit data in the continuous transfer mode.

(12) Clocked serial interface initial transmit buffer register nL (SOTBFnL)

The SOTBFnL register is an 8-bit buffer register that stores initial transmit data in the continuous transfer mode.

(13) Selector

The selector selects the serial clock to be used.

(14) Serial clock controller

Controls the serial clock supply to the shift register. Also controls the clock output to the SCK0n pin when the internal clock is used.

(15) Serial clock counter

Counts the serial clock output or input during transmission/reception, and checks whether 8-bit or 16-bit data transmission/reception has been performed.

(16) Interrupt controller

Controls the interrupt request timing.

 $\textbf{Remark} \quad n=0,\ 1$

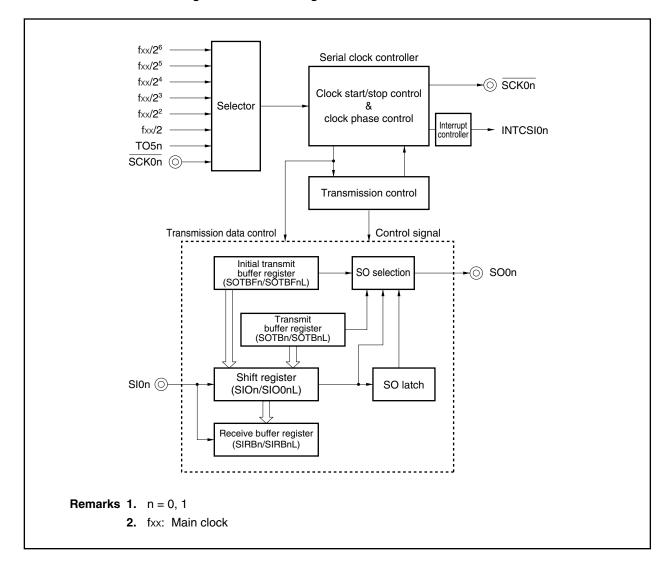

Figure 15-1. Block Diagram of Clocked Serial Interface

15.3 Registers

(1) Clocked serial interface mode register 0n (CSIM0n) The CSIM0n register controls the CSI0n operation. This register can be read or written in 8-bit or 1-bit units (however, CSOTn bit is read-only). Reset sets CSIM0n to 00H.

Caution Overwriting the CSIM0n.TRMDn, CSIM0n.CCLn, CSIM0n.DIRn, CSIM0n.CSITn, and CSIM0n.AUTOn bits can be done only when the CSOTn bit = 0. If these bits are overwritten at any other time, the operation cannot be guaranteed.

- VDD = 2.7 to 4.0 V: Serial clock \leq 2.5 MHz

Remark fxx: Main clock frequency

(3) Clocked serial interface receive buffer registers n, nL (SIRBn, SIRBnL)

The SIRBn register is a 16-bit buffer register that stores receive data.

When the receive-only mode is set (CSIM0n.TRMDn bit = 0), the reception operation is started by reading data from the SIRBn register.

This register is read-only in 16-bit units. When the lower 8 bits are used as the SIRBnL register, this register is read-only in 8-bit units.

In addition to reset input, this register can also be initialized by clearing (0) the CSIM0n.CSI0En bit.

Cautions 1. Read the SIRBn register only when a 16-bit data length has been set (CSIM0n.CCLn bit = 1).

Read the SIRBnL register only when an 8-bit data length has been set (CCLn bit = 0).

2. When the single transfer mode has been set (CSIM0n.AUTOn bit = 0), perform a read operation only in the idle state (CSIM0n.CSOTn bit = 0). If the SIRBn or SIRBnL register is read during data transfer, the data cannot be guaranteed.

) SIRBnL reg	ister	<u> </u>	R		Addres	-	IRBOL	-			-		-		1	0

(4) Clocked serial interface read-only receive buffer registers n, nL (SIRBEn, SIRBEnL)

The SIRBEn register is a 16-bit buffer register that stores receive data.

The SIRBEn register is the same as the SIRBn register. Even if the SIRBEn register is read, the next operation will not start. The SIRBEn register is used to read the contents of the SIRBn register when the serial reception is not continued.

This register is read-only in 16-bit units. However, when the lower 8 bits are used as the SIRBEnL register, the register is read-only in 8-bit units.

In addition to reset input, this register can also be initialized by clearing (0) the CSIM0n.CSI0En bit.

Cautions 1. The receive operation is not started even if data is read from the SIRBEn and SIRBEnL registers.

2. The SIRBEn register can be read only if a 16-bit data length has been set (CSIM0n.CCLn bit = 1).

The SIRBEnL register can be read only if an 8-bit data length has been set (CCLn bit = 0).

After re	eset: 0	000H	R	Ac	Idress	: SIRE	BEO F	FFFF	D06H,	SIRBI	E1 FF	FFFD1	I6H

(5) Clocked serial interface transmit buffer registers n, nL (SOTBn, SOTBnL)

The SOTBn register is a 16-bit buffer register that stores transmit data.

When the transmission/reception mode is set (CSIM0n.TRMDn bit = 1), the transmission operation is started by writing data to the SOTBn register.

This register can be read or written in 16-bit units. However, when the lower 8 bits are used as the SOTBnL register, the register is read-only in 8-bit units.

After reset, this register is initialized.

Cautions 1. Access the SOTBn register only when a 16-bit data length has been set (CSIM0n.CCLn bit = 1).

Access the SOTBnL register only when an 8-bit data length has been set (CCLn bit = 0).

 When the single transfer mode is set (CSIM0n.AUTOn bit = 0), perform access only in the idle state (CSIM0n.CSOTn bit = 0). If the SOTBn and SOTBnL registers are accessed during data transfer, the data cannot be guaranteed.

	BnL re	gister			N .		-		-	-D04H					1	0

(6) Clocked serial interface initial transmit buffer registers n, nL (SOTBFn, SOTBFnL)

The SOTBFn register is a 16-bit buffer register that stores initial transmission data in the continuous transfer mode.

The transmission operation is not started even if data is written to the SOTBFn register.

This register can be read or written in 16-bit units. However, when the lower 8 bits are used as the SOTBFnL register, the register can be read or written in 8-bit units.

After reset, this register is initialized.

Caution Access the SOTBFn register and SOTBFnL register only when a 16-bit data length has been set (CSIM0n.CCLn bit = 1), and only when an 8-bit data length has been set (CCLn bit = 0), respectively, and only in the idle state (CSIM0n.CSOTn bit = 0). If the SOTBFn and SOTBFnL registers are accessed during data transfer, the data cannot be guaranteed.

(7) Serial I/O shift registers n, nL (SIO0n, SIO0nL)

The SIO0n register is a 16-bit shift register that converts parallel data into serial data. The transfer operation is not started even if the SIO0n register is read.

This register is read-only in 16-bit units. However, when the lower 8 bits are used as the SIO0nL register, the register is read-only in 8-bit units.

In addition to reset input, this register can also be initialized by clearing (0) the CSIM0n.CSI0En bit.

Caution Read the SIO0n register and SIO0nL register only when a 16-bit data length has been set (CSIM0n.CCLn bit = 1), and only when an 8-bit data length has been set (CCLn bit = 0), respectively, and only in the idle state (CSIM0n.CSOTn bit = 0). If the SIO0n and SIO0nL registers are read during data transfer, the data cannot be guaranteed.

Table 15-1. Use of Each Buffer Register

Notes 1. It is assumed that the number of data to be transmitted is N.

2. Neither reading nor writing will start communication.

Remark In the 16-bit mode, the registers not enclosed in parentheses are used; in the 8-bit mode, the registers in parentheses are used.

15.4 Operation

15.4.1 Transmission/reception completion interrupt request signal (INTCSI0n)

The INTCSIOn signal is set (1) upon completion of data transmission/reception. Writing to the CSIMOn register clears (0) the INTCSIOn signal.

Caution The delay mode (CSIM0n.CSITn bit = 1) is valid only in the master mode (CSICn.CKS0n2 to CSICn.CKS0n0 bits are not 111B). The delay mode cannot be set when the slave mode is set (CKS0n2 to CKS0n0 bits = 111B).

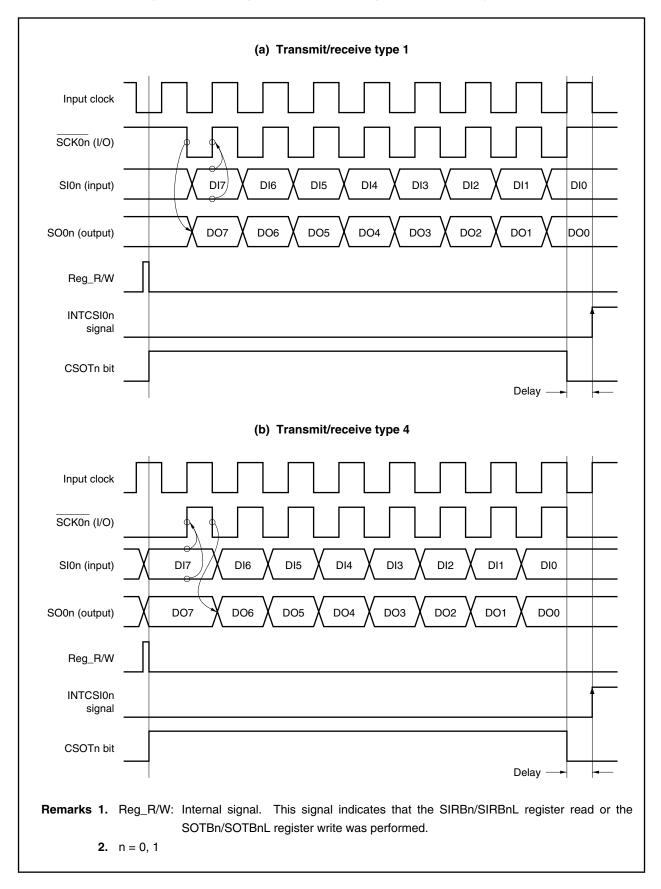

Figure 15-2. Timing Chart of INTCSI0n Signal Output in Delay Mode

15.4.2 Single transfer mode

(1) Usage

In the receive-only mode (CSIM0n.TRMDn bit = 0), communication is started by reading the SIRBn/SIRBnL register.

In the transmission/reception mode (TRMDn bit = 1), communication is started by writing to the SOTBn/SOTBnL register.

In the slave mode, the operation must be enabled beforehand (CSIM0n.CSI0En bit = 1).

When communication is started, the value of the CSIM0n.CSOTn bit becomes 1 (transmission execution status).

Upon communication completion, the transmission/reception completion interrupt request signal (INTCSI0n) is generated, and the CSOTn bit is cleared (0). The next data communication request is then waited for.

Caution When the CSOTn bit = 1, do not manipulate the CSI0n register.

Remark n = 0, 1

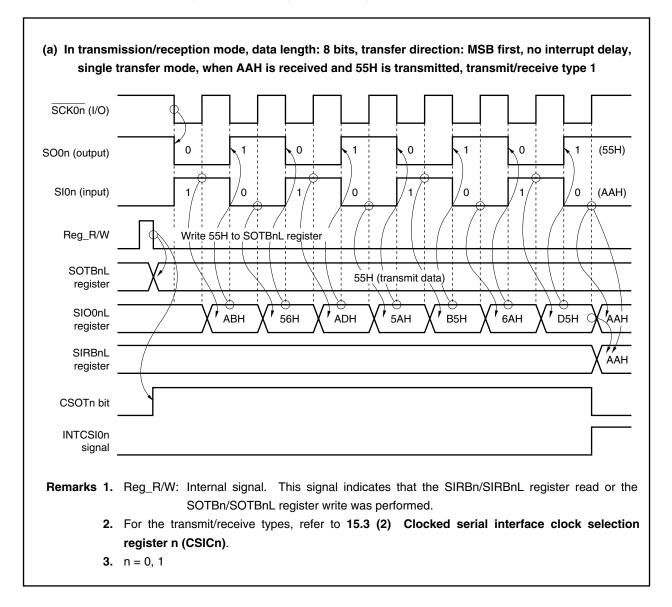

Figure 15-3. Timing Chart in Single Transfer Mode (1/2)

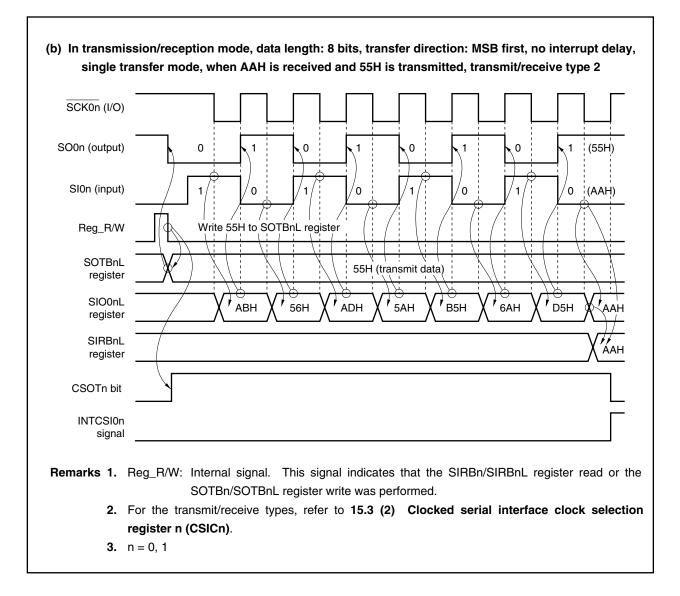

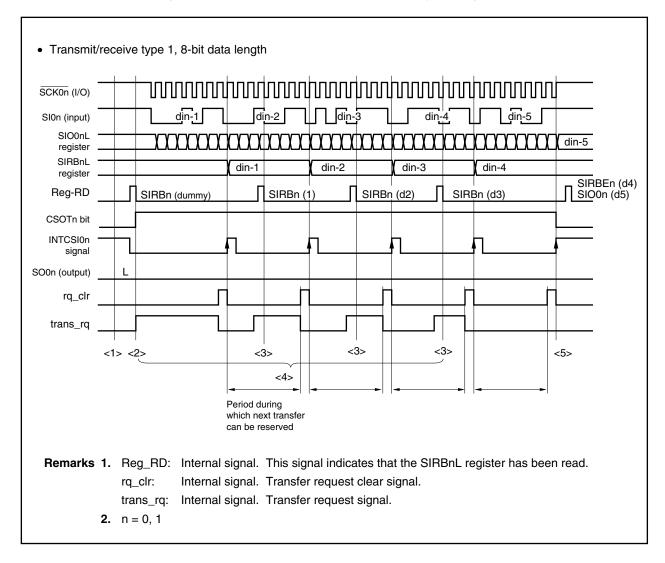

Figure 15-3. Timing Chart in Single Transfer Mode (2/2)

15.4.3 Continuous transfer mode

(1) Usage (receive-only: 8-bit data length)

- <1> Set the continuous transfer mode (CSIM0n.AUTOn bit = 1) and the receive-only mode (CSIM0n.TRMDn bit = 0).
- <2> Read the SIRBnL register (start transfer with dummy read).
- <3> When the transmission/reception completion interrupt request signal (INTCSI0n) has been generated, read the SIRBnL register^{Note} (reserve next transfer).
- <4> Repeat step <3> (N 2) times. (N: Number of transfer data) Ignore the interrupt triggered by reception of the (N – 1)th data (at this time, the SIRBEnL register can be read).
- <5> Following generation of the last INTCSI0n signal, read the SIRBEnL register and the SIO0nL register^{Note}.
- Note When transferring N number of data, receive data is loaded by reading the SIRBnL register from the first data to the (N 2)th data. The (N 1)th data is loaded by reading the SIRBEnL register, and the Nth (last) data is loaded by reading the SIO0nL register (refer to **Table 15-1 Use of Each Buffer Register**).

In the case of the continuous transfer mode, two transfer requests are set at the start of the first transfer. Following the INTCSIOn signal, transfer is continued if the SIRBnL register can be read within the next transfer reservation period. If the SIRBnL register cannot be read, transfer ends and the SIRBnL register does not receive the new value of the SIO0nL register.

The last data can be obtained by reading the SIO0nL register following completion of the transfer.

(2) Usage (transmission/reception: 8-bit data length)

- <1> Set the continuous transfer mode (CSIM0n.AUTOn bit = 1) and the transmission/reception mode (CSIM0n.TRMDn bit = 1).
- <2> Write the first data to the SOTBFnL register.
- <3> Write the 2nd data to the SOTBnL register (start transfer).
- <4> When the transmission/reception completion interrupt request signal (INTCSI0n) has been generated, write the next data to the SOTBnL register (reserve next transfer). Read the SIRBnL register to load the receive data.
- <5> Repeat step <4> as long as data to be sent remains.
- <6> When the INTCSIOn signal is generated, read the SIRBnL register to load the (N 1)th receive data (N: Number of transfer data).
- <7> Following the last INTCSIOn signal, read the SIOOnL register to load the Nth (last) receive data.

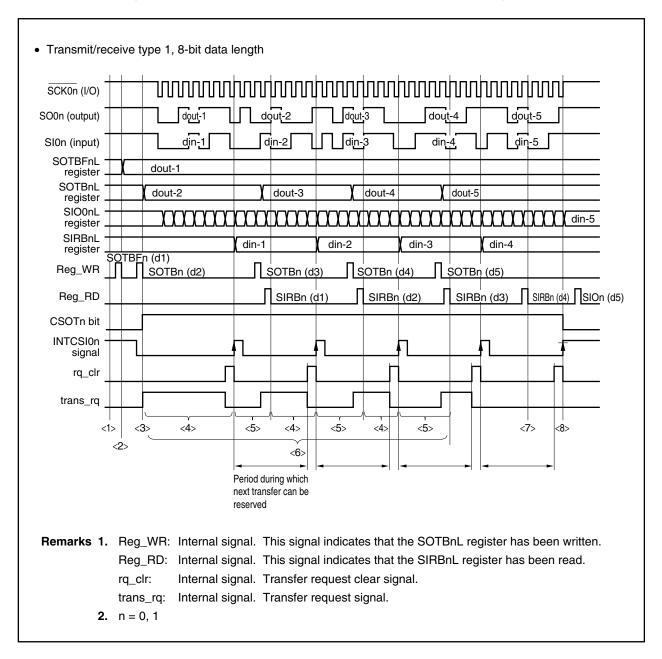

Figure 15-5. Continuous Transfer (Transmission/Reception) Timing Chart

In the case of the continuous transfer mode, two transfer requests are set at the start of the first transfer. Following the INTCSIOn signal, transfer is continued if the SOTBnL register can be written within the next transfer reservation period. If the SOTBnL register cannot be written, transfer ends and the SIRBnL register does not receive the new value of the SIO0nL register.

The last receive data can be obtained by reading the SIO0nL register following completion of the transfer.

(3) Next transfer reservation period

In the continuous transfer mode, the next transfer must be prepared with the period shown in Figure 15-6.

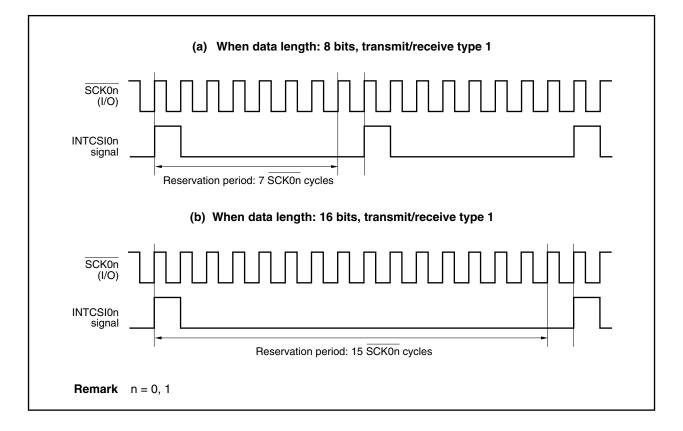

Figure 15-6. Timing Chart of Next Transfer Reservation Period (1/2)

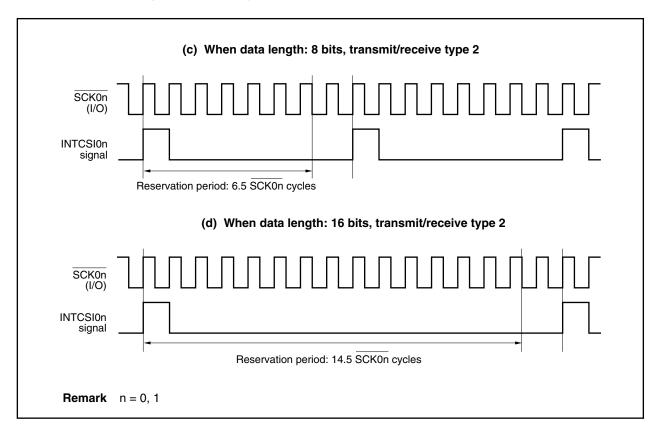

Figure 15-6. Timing Chart of Next Transfer Reservation Period (2/2)

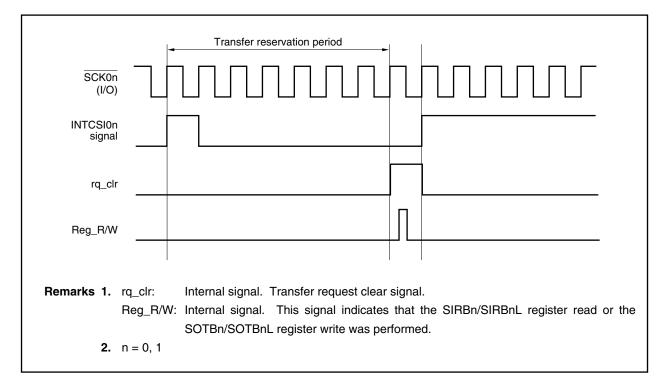

(4) Cautions

To continue continuous transfers, it is necessary to either read the SIRBn register or write to the SOTBn register during the transfer reservation period.

If access is performed to the SIRBn register or the SOTBn register when the transfer reservation period is over, the following occurs.

(i) In case of conflict between transfer request clear and register access

Since transfer request clear has higher priority, the next transfer request is ignored. Therefore, transfer is interrupted, and normal data transfer cannot be performed.

(ii) In case of conflict between transmission/reception completion interrupt request signal (INTCSI0n) generation and register access

Since continuous transfer has stopped once, executed as a new continuous transfer.

In the slave mode, a bit phase error transfer error results (refer to Figure 15-8).

In the transmission/reception mode, the value of the SOTBFn register is retransmitted, and illegal data is sent.

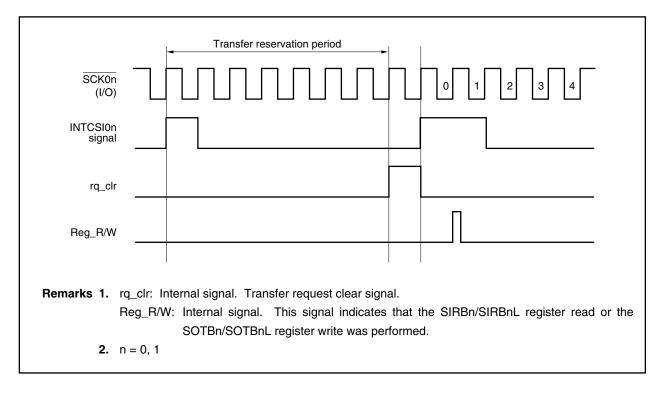

Figure 15-8. Interrupt Request and Register Access Conflict

15.5 Output Pins

The following describes the output pins. For the setting of each pin, refer to **Table 4-12 Settings When Port Pins Are Used for Alternate Functions**.

(1) SCK0n pin

When the CSI0n operation is disabled (CSIM0n.CSI0En bit = 0), the $\overline{SCK0n}$ pin output status is as follows.

CKPn	CKS0n2	CKS0n1	CKS0n0	SCK0n Pin Output
0	Don't care	Don't care	Don't care	Fixed to high level
1	1	1	1	High impedance
	Other than abo	ove		Fixed to low level

Table 15-2. SCK0n Pin Output Status

Remark n = 0, 1

(2) SO0n pin

When the CSI0n operation is disabled (CSI0En bit = 0), the SO0n pin output status is as follows.

TRMDn	DAPn	AUTOn	CCLn	DIRn	SO0n Pin Output
0	Don't care	Don't care	Don't care	Don't care	Fixed to low level
1	0	Don't care	Don't care	Don't care	SO latch value (low level)
	1	0	0	0	SOTBn7 bit value
				1	SOTBn0 bit value
			1	0	SOTBn15 bit value
				1	SOTBn0 bit value
		1	0	0	SOTBFn7 bit value
				1	SOTBFn0 bit value
			1	0	SOTBFn15 bit value
				1	SOTBFn0 bit value

Table 15-3. SO0n Pin Output Status

Remark n = 0, 1

To use the I²C bus function, use the P38/SDA0 and P39/SCL0 pins as the serial transmit/receive data I/O pin (SDA0) and the serial clock I/O pin (SCL0), respectively, and set them to N-ch open drain output.

In the V850ES/KE1, one channel of l^2 C bus is provided. The μ PD703207Y and 70F3207HY incorporate the l^2 C bus.

16.1 Features

The I²C0 has the following two modes.

- Operation stop mode
- I²C (Inter IC) bus mode (multimaster supported)

(1) Operation stop mode

This mode is used when serial transfers are not performed. It can therefore be used to reduce power consumption.

(2) I²C bus mode (multimaster supported)

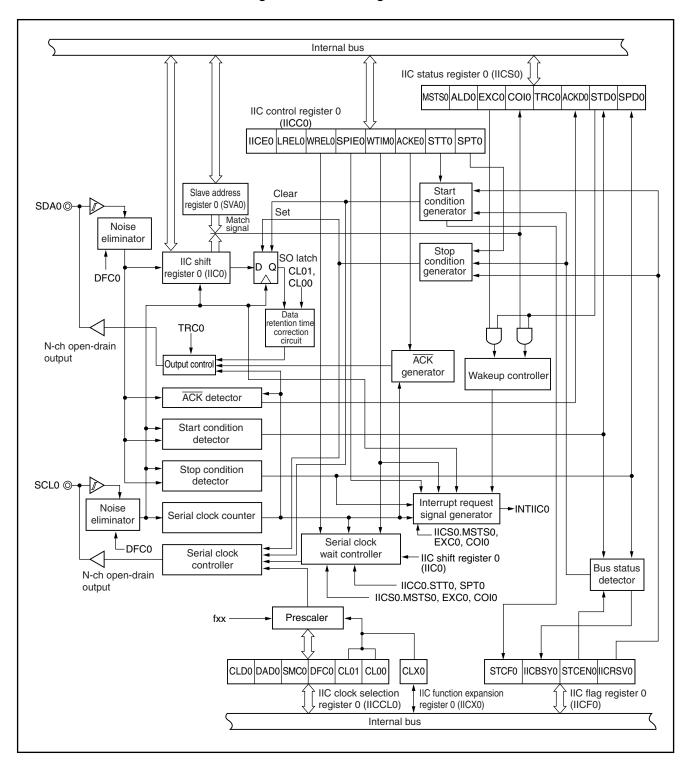

This mode is used for 8-bit data transfers with several devices via two lines: a serial clock (SCL0) line and a serial data bus (SDA0) line.

This mode complies with the I²C bus format and the master device can generate "start condition", "address", "transfer direction specification", "data", and "stop condition" data to the slave device, via the serial data bus. The slave device automatically detects these received state and data by hardware. This function can simplify the part of application program that controls the I²C bus.

Since the SCL0 and SDA0 pins are used for N-ch open drain outputs, I²C0 requires pull-up resistors for the serial clock line and the serial data bus line.

<R>

Figure 16-1. Block Diagram of I²C0

A serial bus configuration example is shown below.

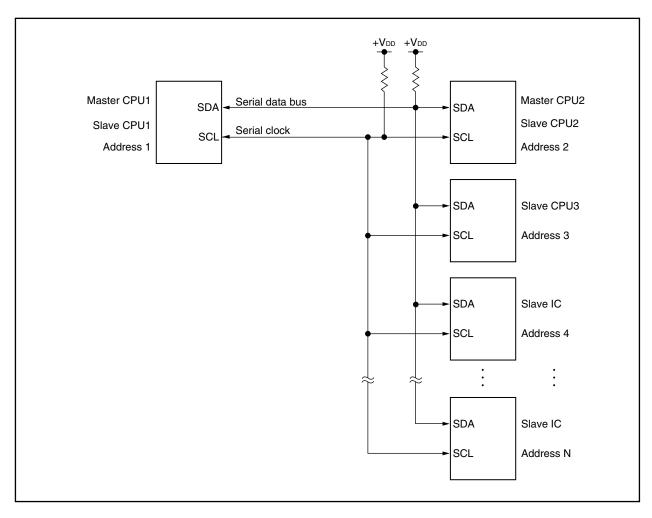

Figure 16-2. Serial Bus Configuration Example Using l^2C Bus

16.2 Configuration

I²C0 includes the following hardware.

Item	Configuration
Registers	IIC shift register 0 (IIC0) Slave address register 0 (SVA0)
Control registers	IIC control register 0 (IICC0) IIC status register 0 (IICS0) IIC flag register 0 (IICCF0) IIC clock selection register 0 (IICCL0) IIC function expansion register 0 (IICX0)

Table 16-1. Configuration of I²C0

(1) IIC shift register 0 (IIC0)

The IIC0 register is used to convert 8-bit serial data to 8-bit parallel data and to convert 8-bit parallel data to 8-bit serial data. The IIC0 register can be used for both transmission and reception.

Write and read operations to the IIC0 register are used to control the actual transmit and receive operations. The IIC0 register can be read or written in 8-bit units.

Reset sets IIC0 to 00H.

(2) Slave address register 0 (SVA0)

The SVA0 register sets local addresses when in slave mode. The SVA0 register can be read or written in 8-bit units. Reset sets SVA0 to 00H.

(3) SO latch

The SO latch is used to retain the SDA0 pin's output level.

(4) Wakeup controller

This circuit generates an interrupt request signal (INTIIC0) when the address received by this register matches the address value set to the SVA0 register or when an extension code is received.

(5) Prescaler

This selects the sampling clock to be used.

(6) Serial clock counter

This counter counts the serial clocks that are output and the serial clocks that are input during transmit/receive operations and is used to verify that 8-bit data was sent or received.

(7) Interrupt request signal generator

This circuit controls the generation of interrupt request signals (INTIIC0). An I^2C interrupt is generated following either of two triggers.

- Falling of the eighth or ninth clock of the serial clock (set by IICC0.WTIM0 bit)
- Interrupt request generated when a stop condition is detected (set by IICC0.SPIE0 bit)

(8) Serial clock controller

In master mode, this circuit generates the clock output via the SCL0 pin from a sampling clock.

(9) Serial clock wait controller

This circuit controls the wait timing.

(10) ACK generator, stop condition detector, start condition detector, and ACK detector These circuits are used to generate and detect various statuses.

(11) Data hold time correction circuit

This circuit generates the hold time for data corresponding to the falling edge of the serial clock.

(12) Start condition generator

This circuit generates a start condition when the IICC0.STT0 bit is set. However, in the communication reservation disabled status (IICF0.IICRSV0 bit = 1), when the bus is not released (IICF0.IICBSY0 bit = 1), start condition requests are ignored and the IICF0.STCF0 bit is set to 1.

(13) Stop condition generator

A stop condition is generated when the IICC0.SPT0 bit is set (1).

(14) Bus status detector

This circuit detects whether or not the bus is released by detecting start conditions and stop conditions. However, as the bus status cannot be detected immediately following operation, the initial status is set by the IICF0.STCEN0 bit.

16.3 Registers

l²C0 is controlled by the following registers.

- IIC control register 0 (IICC0)
- IIC status register 0 (IICS0)
- IIC flag register 0 (IICF0)
- IIC clock selection register 0 (IICCL0)
- IIC function expansion register 0 (IICX0)

The following registers are also used.

• IIC shift register 0 (IIC0)

<R>

• Slave address register 0 (SVA0)

Remark For the alternate-function pin settings, refer to Table 4-12 Settings When Port Pins Are Used for Alternate Functions.

(1) IIC control register 0 (IICC0)

The IICC0 register is used to enable/stop I²C0 operations, set wait timing, and set other I²C operations. The IICC0 register can be read or written in 8-bit or 1-bit units. However, set the SPIE0, WTIM0, and ACKE0 bits when the IICE0 bit is 0 or during the wait period. When setting the IICE0 bit from "0" to "1", these bits can also be set at the same time.

Reset sets this register to 00H.

Note Set the SPT0 bit to 1 only in master mode. However, the SPT0 bit must be set to 1 and a stop condition generated before the first stop condition is detected following the switch to operation enable status. For details, refer to **16.14 Cautions**.

Caution When the IICS0.TRC0 bit is set to 1, the WREL0 bit is set to 1 during the ninth clock and wait is canceled, after which the TRC0 bit is cleared to 0 and the SDA0 line is set to high impedance.

Remark The SPT0 bit is 0 if it is read after data setting.

(2) IIC status register 0 (IICS0)

The IICS0 register indicates the status of the I^2C0 bus.

The IICS0 register is read-only, in 8-bit or 1-bit units.

However, the IICS0 register can only be read when the IICC0.STT0 bit is 1 or during the wait period.

Reset sets this register to 00H.

Caution When the main clock is stopped and the CPU is operating on the subclock, do not access the IICS0 register.

For details, refer to 3.4.8 (1) (b).

(3) IIC flag register 0 (IICF0)

IICF0 is a register that set the operation mode of I^2C0 and indicate the status of the I^2C bus.

These registers can be read or written in 8-bit or 1-bit units. However, the STCF0 and IICBSY0 bits are readonly.

The IICRSV0 bit can be used to enable/disable the communication reservation function (refer to **16.13 Communication Reservation**).

The STCEN0 bit can be used to set the initial value of the IICBSY0 bit (refer to 16.14 Cautions).

The IICRSV0 and STCEN0 bits can be written only when the operation of I^2C0 is disabled (IICC0.IICE0 bit = 0). When operation is enabled, the IICF0 register can be read.

Reset sets this register to 00H.

(4) IIC clock selection register 0 (IICCL0)

The IICCL0 register is used to set the transfer clock for the l^2C0 bus.

The IICCL0 register can be read or written in 8-bit or 1-bit units. However, the CLD0 and DAD0 bits are readonly. The SMC0, CL01 and CL00 bits are set in combination with the IICX0.CLX0 bit (refer to **16.3 (6)** l^2 **C0 transfer clock setting method**).

Set the IICCL0 register when the IICC0.IICE0 bit = 0.

Reset sets this register to 00H.

(5) IIC function expansion register 0 (IICX0)

These registers set the function expansion of I²C0 (valid only in high-speed mode).

These registers can be read or written in 8-bit or 1-bit units. The CLX0 bit is set in combination with the IICCL0.SMC0, IICCL0.CL01, and IICCL0.CL00 bits (refer to **16.3 (6)** I^2 C0 transfer clock setting method). Set the IICX0 register when the IICC0.IICE0 bit = 0.

Reset sets this register to 00H.

7 6 5 4 3 2 1	
	<0>
IICX0 0 0 0 0 0 0 0 0	CLX0

(6) I²C0 transfer clock setting method

The I²C0 transfer clock frequency (fscL) is calculated using the following expression.

 $f_{SCL} = 1/(m \times T + t_R + t_F)$

m = 12, 24, 48, 54, 86, 88, 172, 198 (refer to Table 16-2 Selection Clock Setting.)

- T: 1/fxx
- tr: SCL0 rise time
- tF: SCL0 fall time

For example, the l²C0 transfer clock frequency (fscL) when fxx = 20 MHz, m = 54, $t_R = 200$ ns, and $t_F = 50$ ns is calculated using following expression.

 $f_{SCL} = 1/(54 \times 50 \text{ ns} + 200 \text{ ns} + 50 \text{ ns}) \cong 339 \text{ kHz}$

The selection clock is set using a combination of the IICCL0.SMC0, IICCL0.CL01, and IICCL0.CL00 bits and the IICX0.CLX0 bit.

<R>

1	1	1	1	Setting prohibited			

Table 16-2. Selection Clock Setting

Remark x: don't care

(7) IIC shift register 0 (IIC0)

The IIC0 register is used for serial transmission/reception (shift operations) that is synchronized with the serial clock.

The IIC0 register can be read or written in 8-bit units, but data should not be written to the IIC0 register during a data transfer.

Access (read/write) the IIC0 register only during the wait period. Accessing this register in communication states other than the wait period is prohibited. However, for the master device, the IIC0 register can be written once only after the transmission trigger bit (IICC0.STT0 bit) has been set to 1.

When the IIC0 register is written during wait, the wait is cancelled and data transfer is started. Reset sets this register to 00H.

After reset:	00H	R/W Ad	ldress: IIC0 F	FFFFD80H				
	7	6	5	4	3	2	1	0
IIC0								

(8) Slave address register 0 (SVA0)

The SVA0 register holds the I²C bus's slave addresses.

The SVA0 register can be read or written in 8-bit units, but bit 0 is fixed to 0.

However, rewriting this register is prohibited when the IICS0.STD0 bit = 1 (start condition detection). Reset sets this register to 00H.

After reset: 00)H F	R/W Ad	dress: SVA) FFFFFD83	н				
	7	6	5	4	3	2	1	0	_
SVA0								0

16.4 Functions

16.4.1 Pin configuration

The serial clock pin (SCL0) and serial data bus pin (SDA0) are configured as follows.

SCL0This pin is used for serial clock input and output. This pin is an N-ch open-drain output for both master and slave devices. Input is Schmitt input. SDA0This pin is used for serial data input and output. This pin is an N-ch open-drain output for both master and slave devices. Input is Schmitt input.

Since outputs from the serial clock line and the serial data bus line are N-ch open-drain outputs, an external pull-up resistor is required.

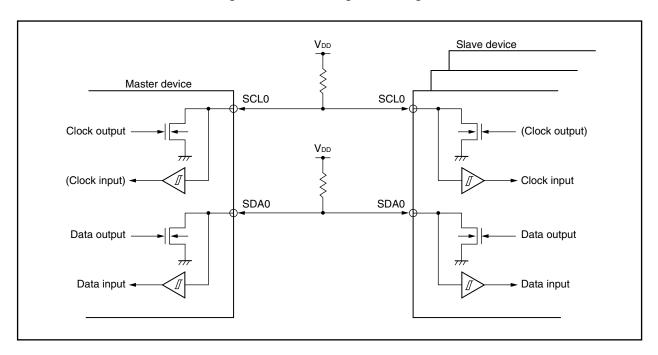

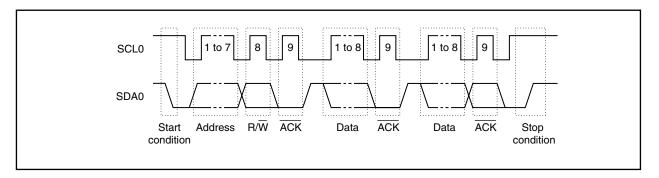

Figure 16-3. Pin Configuration Diagram

16.5 I²C Bus Definitions and Control Methods

The following section describes the l^2C bus's serial data communication format and the status generated by the l^2C bus. The transfer timing for the "start condition", "address", "transfer direction specification", "data", and "stop condition" generated via the l^2C bus's serial data bus is shown below.

The master device generates the start condition, slave address, and stop condition.

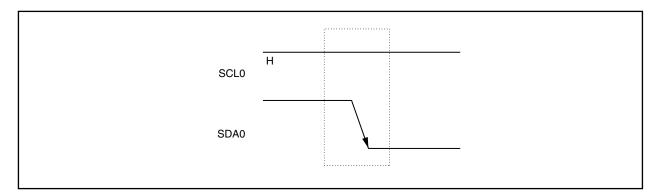

ACK can be generated by either the master or slave device (normally, it is generated by the device that receives 8bit data).

The serial clock (SCL0) is continuously output by the master device. However, in the slave device, the SCL0's lowlevel period can be extended and a wait can be inserted.

16.5.1 Start condition

A start condition is met when the SCL0 pin is at high level and the SDA0 pin changes from high level to low level. The start conditions for the SCL0 pin and SDA0 pin are generated when the master device starts a serial transfer to the slave device. Start conditions can be detected when the device is used as a slave.

A start condition is generated when the IICC0.STT0 bit is set to 1 after a stop condition has been detected (IICS0.SPD0 bit = 1). When a start condition is detected, IICS0.STD0 bit is set to 1.

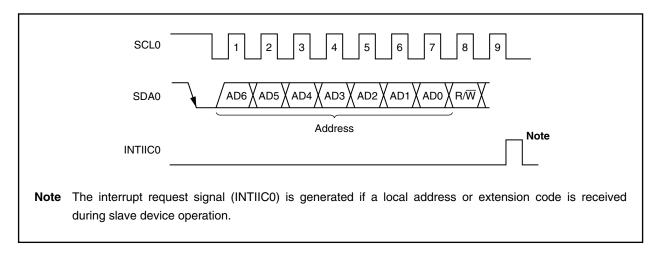

16.5.2 Addresses

The 7 bits of data that follow the start condition are defined as an address.

An address is a 7-bit data segment that is output in order to select one of the slave devices that are connected to the master device via bus lines. Therefore, each slave device connected via the bus lines must have a unique address.

The slave devices include hardware that detects the start condition and checks whether or not the 7-bit address data matches the data values stored in the SVA0 register. If the address data matches the SVA0 register values, the slave device is selected and communicates with the master device until the master device generates a start condition or stop condition.

Figure 16-6. Address

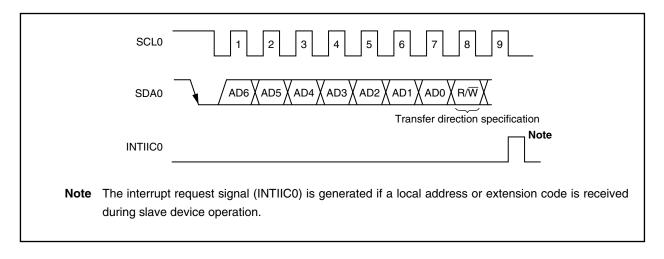

The slave address and the eighth bit, which specifies the transfer direction as described in **16.5.3** Transfer direction specification below, are together written to the IIC0 register and are then output. Received addresses are written to the IIC0 register.

The slave address is assigned to the higher 7 bits of the IIC0 register.

16.5.3 Transfer direction specification

In addition to the 7-bit address data, the master device sends 1 bit that specifies the transfer direction. When this transfer direction specification bit has a value of 0, it indicates that the master device is transmitting data to a slave device. When the transfer direction specification bit has a value of 1, it indicates that the master device is receiving data from a slave device.

<R> 16.5.4 ACK

ACK is used to confirm the serial data status of the transmitting and receiving devices.

The receiving device returns \overline{ACK} for every 8 bits of data it receives.

The transmitting device normally receives \overline{ACK} after transmitting 8 bits of data. When \overline{ACK} is returned from the receiving device, the reception is judged as normal and processing continues. The detection of \overline{ACK} is confirmed with the IICS0.ACKD0 bit.

When the master device is the receiving device, after receiving the final data, it does not return \overline{ACK} and generates the stop condition. When the slave device is the receiving device and does not return \overline{ACK} , the master device generates either a stop condition or a restart condition, and then stops the current transmission. Failure to return \overline{ACK} may be caused by the following factors.

- (a) Reception was not performed normally.
- (b) The final data was received.
- (c) The receiving device (slave) does not exist for the specified address.

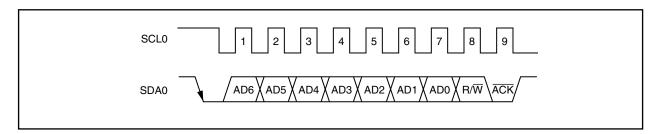

When the receiving device sets the SDA0 line to low level during the ninth clock, ACK is generated (normal reception).

When the IICC0.ACKE0 bit is set to 1, automatic \overrightarrow{ACK} generation is enabled. Transmission of the eighth bit following the 7 address data bits causes the IICS0.TRC0 bit to be set. Normally, set the ACKE0 bit to 1 for reception (TRC0 bit = 0).

When the slave device is receiving (when TRC0 bit = 0), if the slave device cannot receive data or does not need to receive any more data, clear the ACKE0 bit to 0 to indicate to the master that no more data can be received.

Similarly, when the master device is receiving (when TRC0 bit = 0) and the subsequent data is not needed, clear the ACKE0 bit to 0 to prevent \overline{ACK} from being generated. This notifies the slave device (transmitting device) of the end of the data transmission (transmission stopped).

When the local address is received, ACK is automatically generated regardless of the value of the ACKE0 bit. No ACK is generated if the received address is not a local address (NACK).

When receiving the extension code, set the ACKE0 bit to 1 in advance to generate ACK.

The ACK generation method during data reception is based on the wait timing setting, as described by the following.

• When 8-clock wait is selected (IICC0.WTIM0 bit = 0):

ACK is generated at the falling edge of the SCL0n pin's eighth clock if the ACKE0 bit is set to 1 before the wait state cancellation.

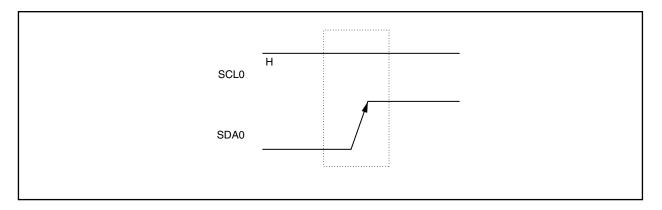

• When 9-clock wait is selected (IICC0.WTIM0 bit = 1): \overline{ACK} is generated if the ACKE0 bit is set to 1 in advance.

16.5.5 Stop condition

When the SCL0 pin is at high level, changing the SDA0 pin from low level to high level generates a stop condition.

A stop condition is generated when serial transfer from the master device to the slave device has been completed. Stop conditions can be detected when the device is used as a slave.

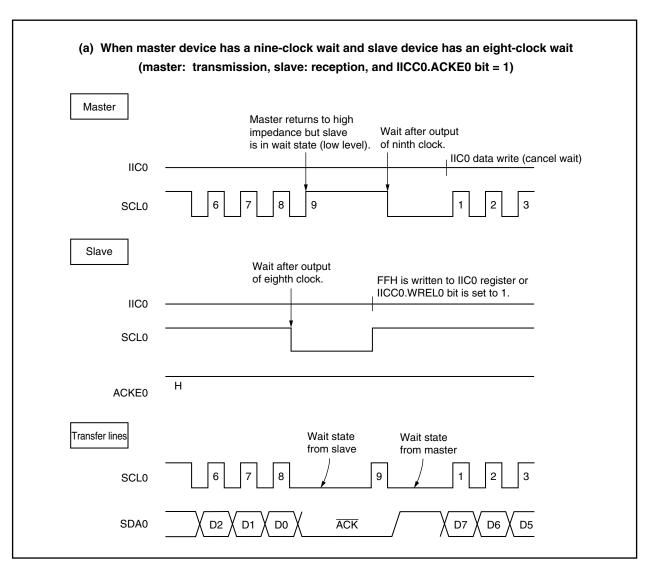

A stop condition is generated when the IICC0.SPT0 bit is set to 1. When the stop condition is detected, the IICS0.SPD0 bit is set to 1 and the interrupt request signal (INTIIC0) is generated when the IICC0.SPIE0 bit is set to 1.

16.5.6 Wait state

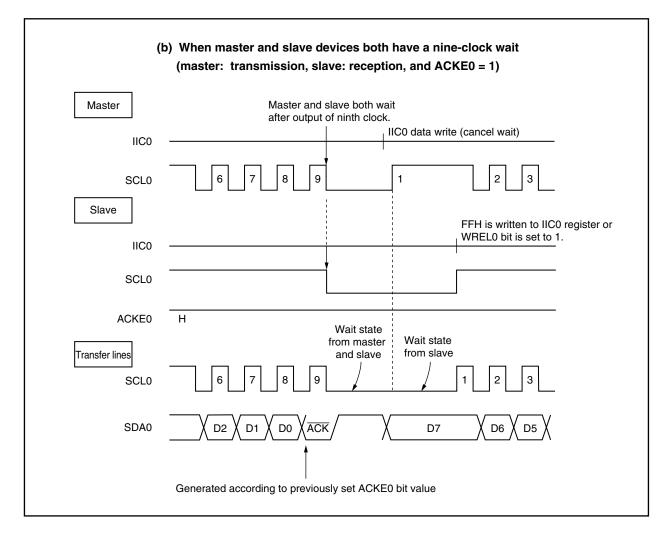

The wait state is used to notify the communication partner that a device (master or slave) is preparing to transmit or receive data (i.e., is in a wait state).

Setting the SCL0 pin to low level notifies the communication partner of the wait status. When wait status has been canceled for both the master and slave devices, the next data transfer can begin.

A wait state is automatically generated after a start condition is generated. Moreover, a wait state is automatically generated depending on the setting of the IICC0.WTIM0 bit.

Normally, when the IICC0.WREL0 bit is set to 1 or when FFH is written to the IIC0 register, the wait status is canceled and the transmitting side writes data to the IIC0 register to cancel the wait status.

The master device can also cancel the wait status via either of the following methods.

- By setting the IICC0.STT0 bit to 1
- By setting the IICC0.SPT0 bit to 1

<R> 16.5.7 Wait state cancellation method

In the case of I²C0, wait state can be canceled normally in the following ways.

- By writing data to the IIC0 register
- By setting the IICC0.WREL0 bit to 1 (wait state cancellation)
- By setting the IICC0.STT0 bit to 1 (start condition generation)^{Note}
- By setting the IICC0.SPT0 bit to 1 (stop condition generation)^{Note}

Note Master only

If any of these wait state cancellation actions is performed, I²C0 will cancel wait state and restart communication. When canceling wait state and sending data (including address), write data to the IIC0 register.

To receive data after canceling wait state, or to complete data transmission, set the WREL0 bit to 1.

To generate a restart condition after canceling wait state, set the STT0 bit to 1.

To generate a stop condition after canceling wait state, set the SPT0 bit to 1.

Execute cancellation only once for each wait state.

For example, if data is written to the IIC0 register following wait state cancellation by setting the WREL0 bit to 1, conflict between the SDA0 line change timing and IIC0 register write timing may result in the data output to the SDA0 line may be incorrect.

Even in other operations, if communication is stopped halfway, clearing the IICC0.IICE0 bit to 0 will stop communication, enabling wait state to be cancelled.

If the I²C bus dead-locks due to noise, etc., setting the IICC0.LREL0 bit to 1 causes the communication operation to be exited, enabling wait state to be cancelled.

<R> 16.6 I²C Interrupt Request Signals (INTIIC0)

16.7 Interrupt Request Signal (INTIIC0) Generation Timing and Wait Control

The setting of the IICC0.WTIM0 bit determines the timing by which the INTIIC0 signal is generated and the corresponding wait control, as shown below.

Table 16-3. INTIICO Signal Generation Timing and Wait Control

WTIM0 Bit	During	g Slave Device Ope	eration	During	g Master Device Op	eration
	Address	Data Reception	Data Transmission	Address	Data Reception	Data Transmission
0	9 ^{Notes 1, 2}	8 ^{Note 2}	8 ^{Note 2}	9	8	8
1	9 ^{Notes 1, 2}	9 ^{Note 2}	9 ^{Note 2}	9	9	9

Notes 1. The slave device's INTIIC0 signal and wait period occurs at the falling edge of the ninth clock only when there is a match with the address set to the SVA0 register.

At this point, ACK is generated regardless of the value set to the IICC0.ACKE0 bit. For a slave device that has received an extension code, the INTIIC0 signal occurs at the falling edge of the eighth clock. When the address does not match after restart, the INTIIC0 signal is generated at the falling edge of the ninth clock, but no wait occurs.

- 2. If the received address does not match the contents of the SVA0 register and extension codes have not been received, neither the INTIICO signal nor a wait occurs.
- **Remark** The numbers in the table indicate the number of the serial clock's clock signals. Interrupt requests and wait control are both synchronized with the falling edge of these clock signals.

(1) During address transmission/reception

- Slave device operation: Interrupt and wait timing are determined depending on the conditions in Notes 1 and 2 above regardless of the WTIM0 bit.
- Master device operation: Interrupt and wait timing occur at the falling edge of the ninth clock regardless of the WTIM0 bit.

(2) During data reception

• Master/slave device operation: Interrupt and wait timing are determined according to the WTIM0 bit.

(3) During data transmission

• Master/slave device operation: Interrupt and wait timing are determined according to the WTIM0 bit.

(4) Wait cancellation method

The four wait cancellation methods are as follows.

- By writing data to the IIC0 register
- By setting the IICC0.WREL0 bit (canceling wait state)
- By setting the IICC0.STT0 bit (generating start condition)^{Note}
- By setting the IICC0.SPT0 bit (generating stop condition)^{Note}

Note Master only

When an 8-clock wait has been selected (WTIM0 bit = 0), whether or not \overline{ACK} has been generated must be determined prior to wait cancellation.

(5) Stop condition detection

The INTIIC0 signal is generated when a stop condition is detected.

16.8 Address Match Detection Method

When in I²C bus mode, the master device can select a particular slave device by transmitting the corresponding slave address.

Address match detection is performed automatically by hardware. An INTIIC0 interrupt request signal occurs when a local address has been set to the SVA0 register and when the address set to the SVA0 register matches the slave address sent by the master device, or when an extension code has been received.

16.9 Error Detection

In I²C bus mode, the status of the serial data bus (SDA0) during data transmission is captured by the IIC0 register of the transmitting device, so the IIC0 register data prior to transmission can be compared with the transmitted IIC0 register data to enable detection of transmission errors. A transmission error is judged as having occurred when the compared data values do not match.

16.10 Extension Code

- (1) When the higher 4 bits of the receive address are either 0000 or 1111, the extension code flag (EXC0) is set for extension code reception and an interrupt request signal (INTIIC0) is issued at the falling edge of the eighth clock. The local address stored in the SVA0 register is not affected.
- (2) If 11110xx0 is set to the SVA0 register by a 10-bit address transfer and 11110xx0 is transferred from the master device, the results are as follows. Note that the INTIIC0 signal occurs at the falling edge of the eighth clock.
 - Higher 4 bits of data match: IICS0.EXC0 bit = 1
 - 7 bits of data match: IICS0.COI0 bit = 1
- (3) Since the processing after the INTIICO signal occurs differs according to the data that follows the extension code, such processing is performed by software. The slave that has received an extension code is always under communication, even if the addresses mismatch.

For example, when operation as a slave is not desired after the extension code is received, set the IICC0.LREL0 bit to 1 and the CPU will enter the next communication wait state.

Slave Address	R/W Bit	Description
0000 000	0	General call address
0000 000	1	Start byte
0000 001	х	CBUS address
0000 010	х	Address that is reserved for different bus format
1111 0xx	х	10-bit slave address specification

Table 16-4. Extension Code Bit Definitions

<R>

16.11 Arbitration

When several master devices simultaneously generate a start condition (when the IICC0.STT0 bit is set to 1 before the IICS0.STD0 bit is set to 1), communication among the master devices is performed as the number of clocks is adjusted until the data differs. This kind of operation is called arbitration.

When one of the master devices loses in arbitration, an arbitration loss flag (IICS0.ALD0 bit) is set (1) via the timing by which the arbitration loss occurred, and the SCL0 and SDA0 lines are both set for high impedance, which releases the bus.

The arbitration loss is detected based on the timing of the next interrupt request signal (INTIIC0) (the eighth or ninth clock, when a stop condition is detected, etc.) and the ALD0 bit = 1 setting that has been made by software.

For details of interrupt request timing, refer to 16.6 I²C Interrupt Request Signals (INTIICO).

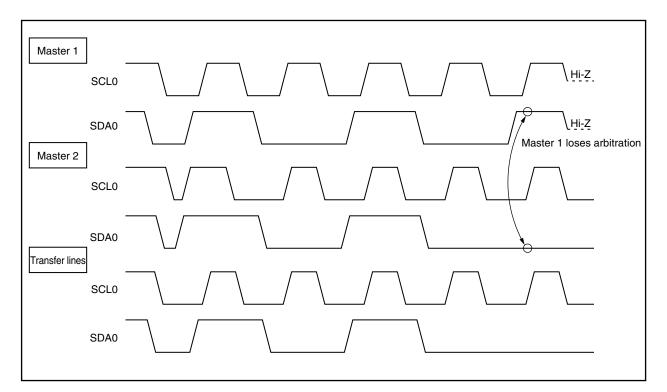

Figure 16-11. Arbitration Timing Example

Status During Arbitration	Interrupt Request Generation Timing	
During address transmission	At falling edge of eighth or ninth clock following byte transfer ^{Note 1}	
Read/write data after address transmission		
During extension code transmission		
Read/write data after extension code transmission		
During data transmission		
During ACK transfer period after data reception		
When restart condition is detected during data transfer		
When stop condition is detected during data transfer	When stop condition is generated (when IICC0.SPIE0 bit = 1) ^{Note 2}	
When the SDA0 pin is at low level while attempting to generate a restart condition	At falling edge of eighth or ninth clock following byte transfer ^{Note 1}	
When stop condition is detected while attempting to generate a restart condition	When stop condition is generated (when SPIE0 bit = 1) ^{Note 2}	
When the SDA0 pin is at low level while attempting to generate a stop condition	At falling edge of eighth or ninth clock following byte transfer ^{Note 1}	
When the SCL0 pin is at low level while attempting to generate a restart condition		

Table 16-5. Status During Arbitration and Interrupt Request Generation Timing

- **Notes 1.** When the IICC0.WTIM0 bit = 1, an interrupt request occurs at the falling edge of the ninth clock. When the WTIM0 bit = 0 and the extension code's slave address is received, an interrupt request occurs at the falling edge of the eighth clock.
 - 2. When there is a possibility that arbitration will occur, set the SPIE0 bit = 1 for master device operation.

16.12 Wakeup Function

The I²C bus slave function is a function that generates an interrupt request signal (INTIIC0) when a local address or extension code has been received.

This function makes processing more efficient by preventing unnecessary interrupt requests from occurring when addresses do not match.

When a start condition is detected, wakeup standby mode is set. This wakeup standby mode is in effect while addresses are transmitted due to the possibility that an arbitration loss may change the master device (which has generated a start condition) to a slave device.

However, when a stop condition is detected, the IICC0.SPIE0 bit is set regardless of the wake up function, and this determines whether interrupt requests are enabled or disabled.

16.13 Communication Reservation

16.13.1 When communication reservation function is enabled (IICF0.IICRSV0 bit = 0)

To start master device communications when not currently using a bus, a communication reservation can be made to enable transmission of a start condition when the bus is released. There are two modes under which the bus is not used.

- When arbitration results in neither master nor slave operation
- When an extension code is received and slave operation is disabled (ACK is not returned and the bus was released when the IICC0.LREL0 bit was set to "1").

If the IICC0.STT0 bit is set (1) while the bus is not used, a start condition is automatically generated and wait status is set after the bus is released (after a stop condition is detected).

<R>

A communication is automatically started as the master by setting the IICC0.SPIE0 bit to 1, detecting the bus release due to an interrupt request (INTIIC0) occurrence (detecting a stop condition), and then writing the address to the IIC0 register. Before detecting a stop condition, data written to the IIC0 register is set to invalid.

When the STT0 bit has been set (1), the operation mode (as start condition or as communication reservation) is determined according to the bus status.

If the bus has been releaseda start condition is generated If the bus has not been released (standby mode)communication reservation

To detect which operation mode has been determined for the STT0 bit, set the STT0 bit (1), wait for the wait period, then check the IICS0.MSTS0 bit.

Wait periods, which should be set via software, are listed in Table 16-6. These wait periods can be set via the settings for the IICX0.CLX0, IICCL0.SMC0, IICCL0.CL01, and IICCL0.CL00 bits.

<R>

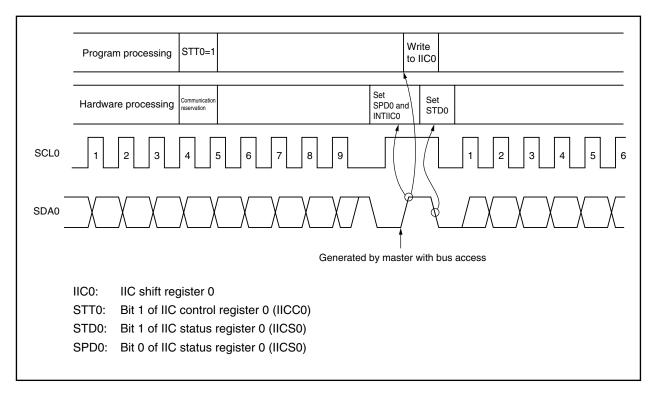

Table 16-6. Wait Periods

CLX0	SMC0	CL01	CL00	Selected Clock	Wait Period
0	0	0	0	fxx/2	46 clocks
0	0	0	1	fxx/2	86 clocks
0	0	1	0	fxx	43 clocks
0	0	1	1	fxx/3	102 clocks
0	1	0	1/0	fxx/2	30 clocks
0	1	1	0	fxx	15 clocks
0	1	1	1	fxx/3	36 clocks
1	1	0	1/0	fxx/2	18 clocks
1	1	1	0	fxx	9 clocks

The communication reservation timing is shown below.

Figure 16-12. Communication Reservation Timing

Communication reservations are accepted via the following timing. After the IICS0.STD0 bit is set to 1, a communication reservation can be made by setting the IICC0.STT0 bit to 1 before a stop condition is detected.

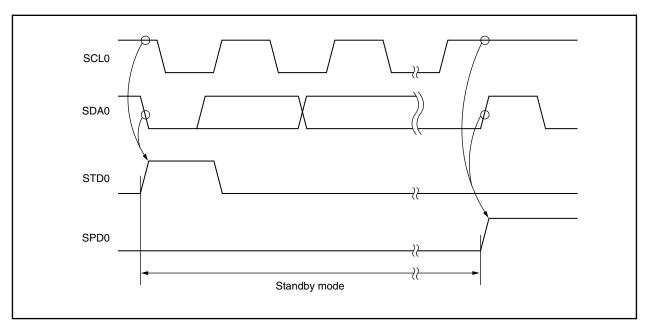

Figure 16-13. Timing for Accepting Communication Reservations

The communication reservation flowchart is illustrated below.

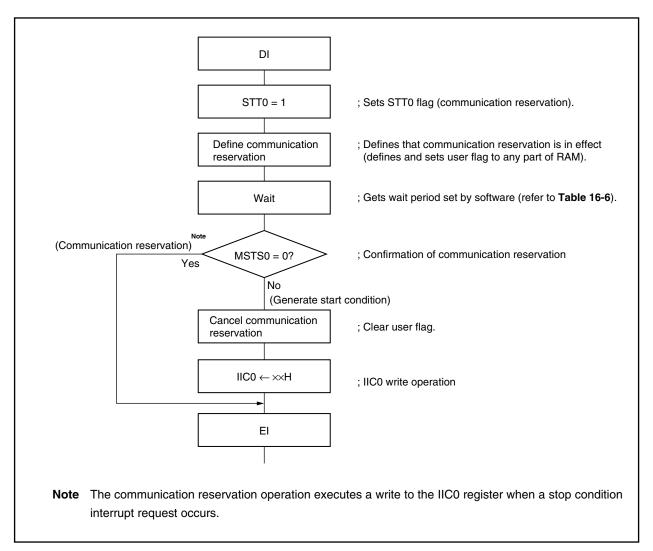

Figure 16-14. Communication Reservation Flowchart

16.13.2 When communication reservation function is disabled (IICF0.IICRSV0 bit = 1)

When the IICC0.STT0 bit is set when the bus is not used in a communication during bus communication, this request is rejected and a start condition is not generated. The following two statuses are included in the status where bus is not used.

- When arbitration results in neither master nor slave operation
- When an extension code is received and slave operation is disabled (ACK is not returned and the bus was released when the IICC0.LREL0 bit was set to 1)

To confirm whether the start condition was generated or request was rejected, check the IICF0.STCF0 flag. The time shown in Table 16-7 is required until the STCF0 flag is set after setting the STT0 bit = 1. Therefore, secure the time by software.

<R>

Table 16-7. Wait Periods

CL01	CL00	Selected Clock	Wait Period
0	0	fxx/2	6 clocks
0	1	fxx/2	6 clocks
1	0	fxx	3 clocks
1	1	fxx/3	9 clocks

16.14 Cautions

(1) When IICF0.STCEN0 bit = 0

Immediately after l^2C0 operation is enabled, the bus communication status (IICF0.IICBSY0 bit = 1) is recognized regardless of the actual bus status. To execute master communication in the status where a stop condition has not been detected, generate a stop condition and then release the bus before starting the master communication.

Use the following sequence for generating a stop condition.

<1> Set the IICCL0 register. <2> Set the IICC0.IICE0 bit. <3> Set the IICC0.SPT0 bit.

(2) When IICF0.STCEN0 bit = 1

Immediately after l^2C0 operation is enabled, the bus released status (IICBSY0 bit = 0) is recognized regardless of the actual bus status. To generate the first start condition (IICC0.STT0 bit = 1), it is necessary to confirm that the bus has been released, so as to not disturb other communications.

- <R> (3) When the IICC0.IICE0 bit of the V850ES/KE1 is set to 1 while communications with other devices are in progress, the start condition may be detected depending on the status of the communication line. Be sure to set the IICC0.IICE0 bit to 1 when the SCL0 and SDA0 lines are high level.
- <R> (4) Determine the operation clock frequency by the IICCL0 and IICX0 registers before enabling the operation (IICC0.IICE0 bit = 1). To change the operation clock frequency, clear the IICC0.IICE0 bit to 0 once.
- <R> (5) After the IICC0.STT0 and IICC0.SPT0 bits have been set to 1, they must not be re-set without being cleared to 0 first.
- <R> (6) If transmission has been reserved, set the IICC0.SPIE0 bit to 1 so that an interrupt request is generated by the detection of a stop condition. After an interrupt request has been generated, the wait state will be released by writing communication data to I²C0, then transferring will begin. If an interrupt is not generated by the detection of a stop condition, transmission will halt in the wait state because an interrupt request was not generated. However, it is not necessary to set the SPIE0 bit to 1 for the software to detect the IICS0.MSTS0 bit.

<R> 16.15 Communication Operations

The following shows three operation procedures with the flowchart.

(1) Master operation in single master system

The flowchart when using the V850ES/KE1 as the master in a single master system is shown below. This flowchart is broadly divided into the initial settings and communication processing. Execute the initial settings at startup. If communication with the slave is required, prepare the communication and then execute communication processing.

(2) Master operation in multimaster system

In the l^2C0 bus multimaster system, whether the bus is released or used cannot be judged by the l^2C bus specifications when the bus takes part in a communication. Here, when data and clock are at a high level for a certain period (1 frame), the V850ES/KE1 takes part in a communication with bus released state.

This flowchart is broadly divided into the initial settings, communication waiting, and communication processing. The processing when the V850ES/KE1 loses in arbitration and is specified as the slave is omitted here, and only the processing as the master is shown. Execute the initial settings at startup to take part in a communication. Then, wait for the communication request as the master or wait for the specification as the slave. The actual communication is performed in the communication processing, and it supports the transmission/reception with the slave and the arbitration with other masters.

(3) Slave operation

An example of when the V850ES/KE1 is used as the slave is shown below.

When used as the slave, operation is started by an interrupt. Execute the initial settings at startup, then wait for the INTIIC0 interrupt occurrence (communication waiting). When the INTIIC0 interrupt occurs, the communication status is judged and its result is passed as a flag over to the main processing. By checking the flags, necessary communication processing is performed.

16.15.1 Master operation in single master system

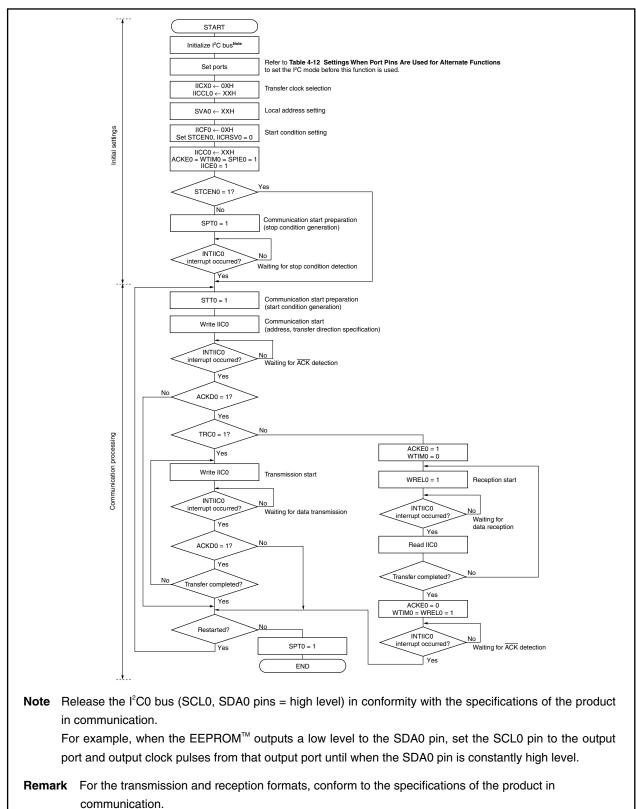

Figure 16-15. Master Operation in Single Master System

16.15.2 Master operation in multimaster system

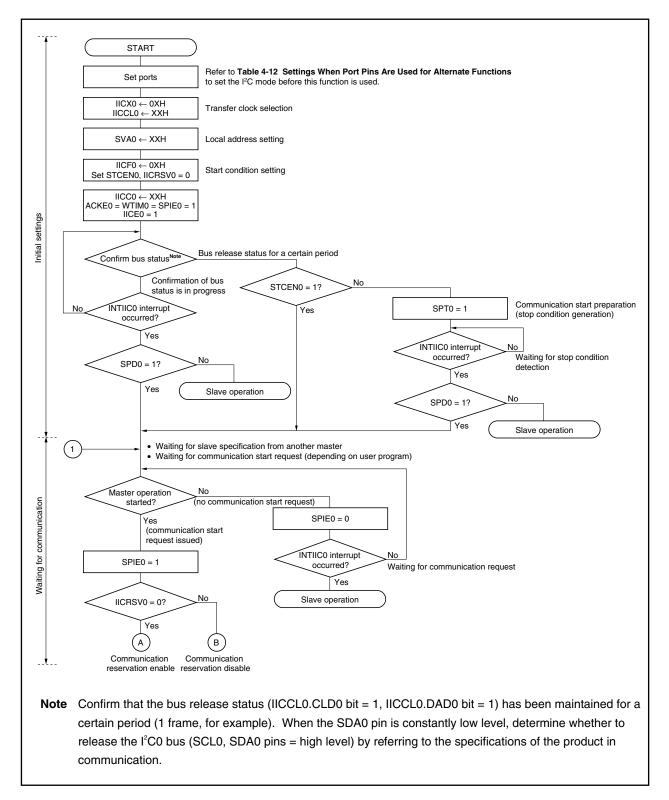

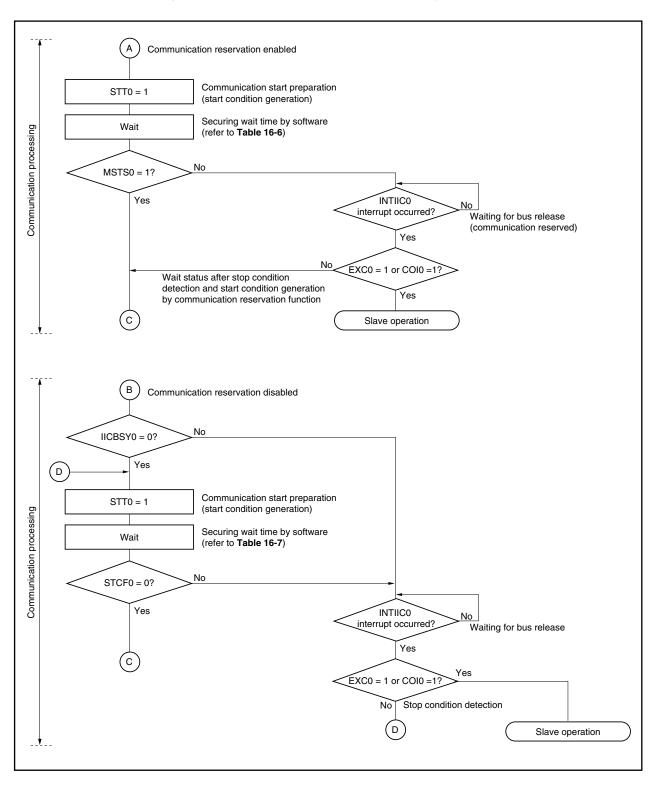

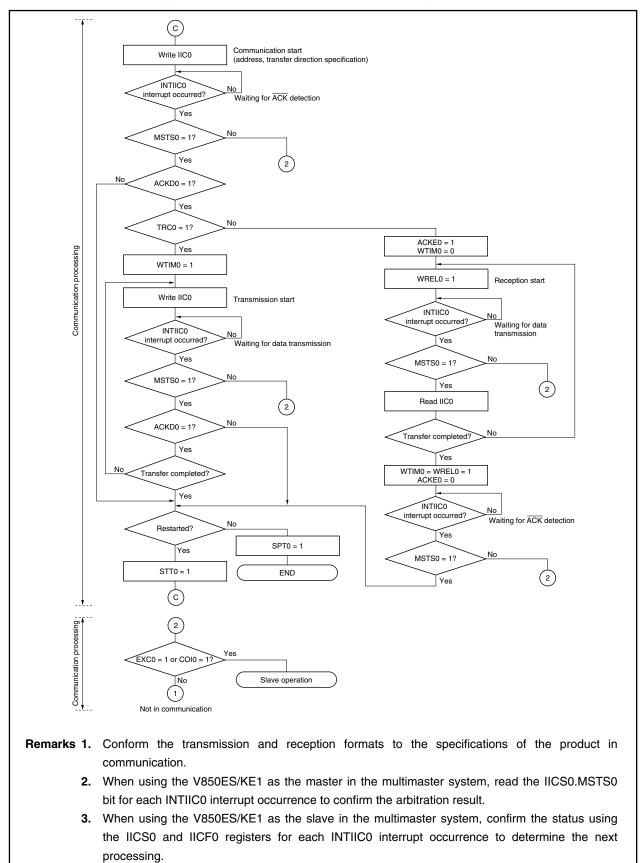

Figure 16-16. Master Operation in Multimaster System (1/3)

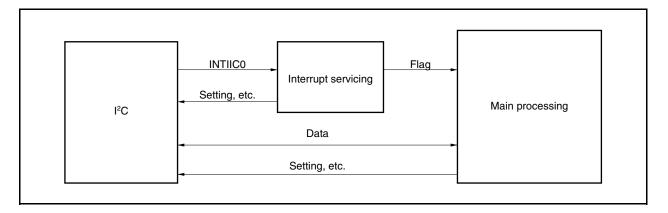

16.15.3 Slave operation

The following shows the processing procedure of the slave operation.

Basically, the operation of the slave device is event-driven. Therefore, processing by an INTIIC0 interrupt (processing requiring a significant change of the operation status, such as stop condition detection during communication) is necessary.

The following description assumes that data communication does not support extension codes. Also, it is assumed that the INTIIC0 interrupt servicing performs only status change processing and that the actual data communication is performed during the main processing.

Figure 16-17. Software Outline During Slave Operation

Therefore, the following three flags are prepared so that the data transfer processing can be performed by transmitting these flags to the main processing instead of the INTIICO signal.

(1) Communication mode flag

This flag indicates the following communication statuses.

Clear mode: Data communication not in progress

Communication mode: Data communication in progress (valid address detection stop condition detection, ACK from master not detected, address mismatch)

(2) Ready flag

This flag indicates that data communication is enabled. This is the same status as an INTIIC0 interrupt during normal data transfer. This flag is set in the interrupt processing block and cleared in the main processing block. The ready flag for the first data for transmission is not set in the interrupt processing block, so the first data is transmitted without clearance processing (the address match is regarded as a request for the next data).

(3) Communication direction flag

This flag indicates the direction of communication and is the same as the value of the IICS0.TRC0 bit.

The following shows the operation of the main processing block during slave operation.

Start I²C0 and wait for the communication enabled status. When communication is enabled, perform transfer using the communication mode flag and ready flag (the processing of the stop condition and start condition is performed by interrupts, conditions are confirmed by flags).

For transmission, repeat the transmission operation until the master device stops returning \overline{ACK} . When the master device stops returning \overline{ACK} , transfer is complete.

For reception, receive the required number of data and do not return ACK for the next data immediately after transfer is complete. After that, the master device generates the stop condition or restart condition. This causes exit from communications.

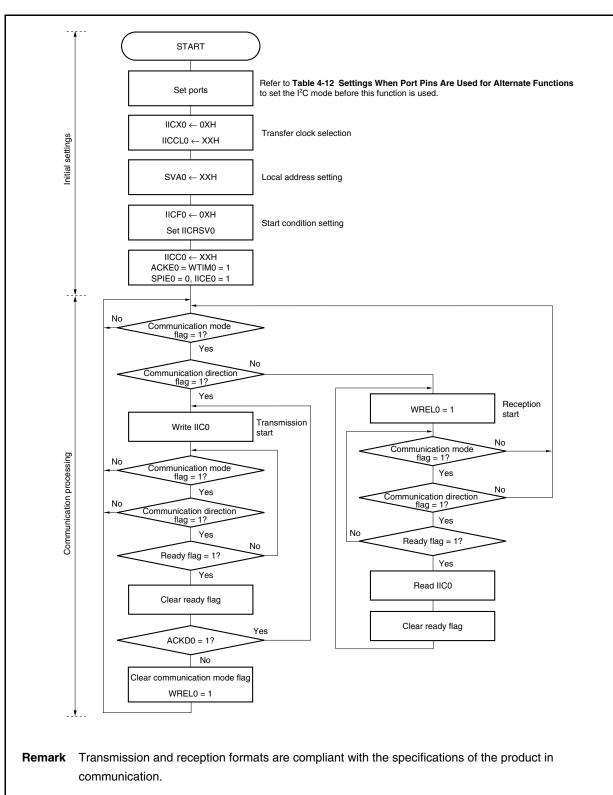

Figure 16-18. Slave Operation Flowchart (1)

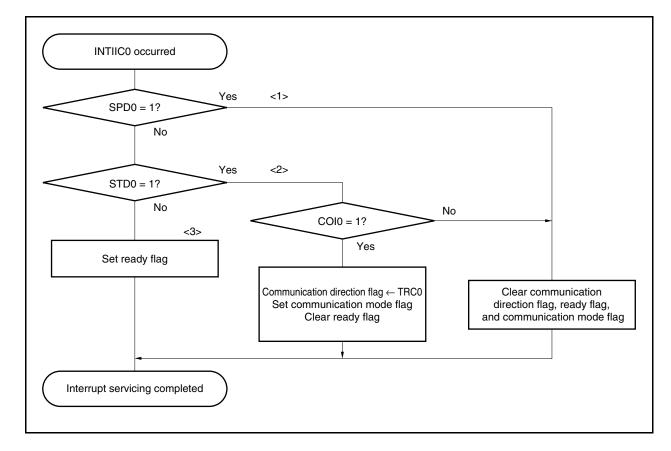

The following shows an example of the processing of the slave device by an INTIIC0 interrupt (it is assumed that no extension codes are used here). During an INTIIC0 interrupt, the status is confirmed and the following steps are executed.

- <1> When a stop condition is detected, communication is terminated.
- <2> When a start condition is detected, the address is confirmed. If the address does not match, communication is terminated. If the address matches, the communication mode is set and wait is released, and operation returns from the interrupt (the ready flag is cleared).
- <3> For data transmission/reception, when the ready flag is set, operation returns from the interrupt while the I²C0 bus remains in the wait status.

Remark <1> to <3> in the above correspond to <1> to <3> in Figure 16-19 Slave Operation Flowchart (2).

Figure 16-19	. Slave	Operation	Flowchart (2)

16.16 Timing of Data Communication

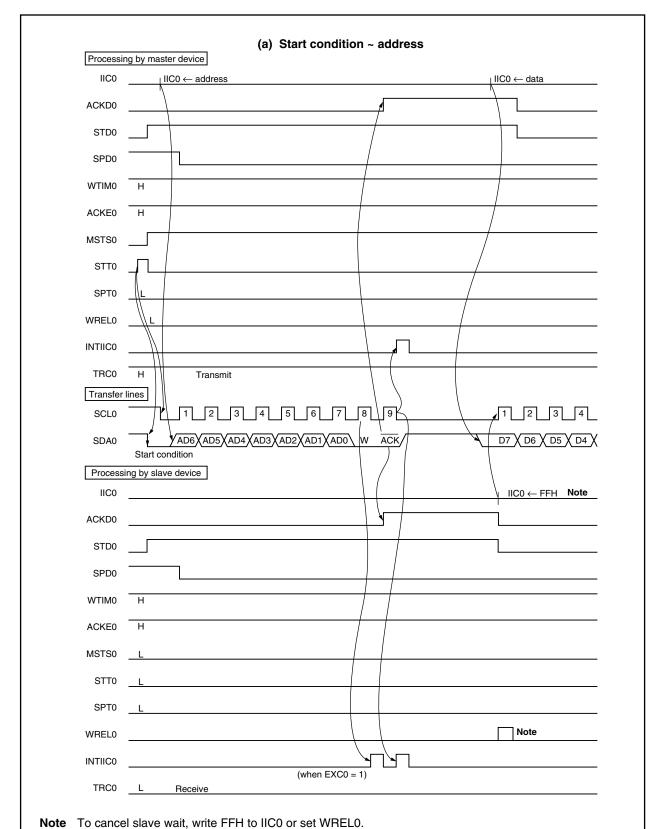

When using I²C bus mode, the master device generates an address via the serial bus to select one of several slave devices as its communication partner.

After outputting the slave address, the master device transmits the IICS0.TRC0 bit that specifies the data transfer direction and then starts serial communication with the slave device.

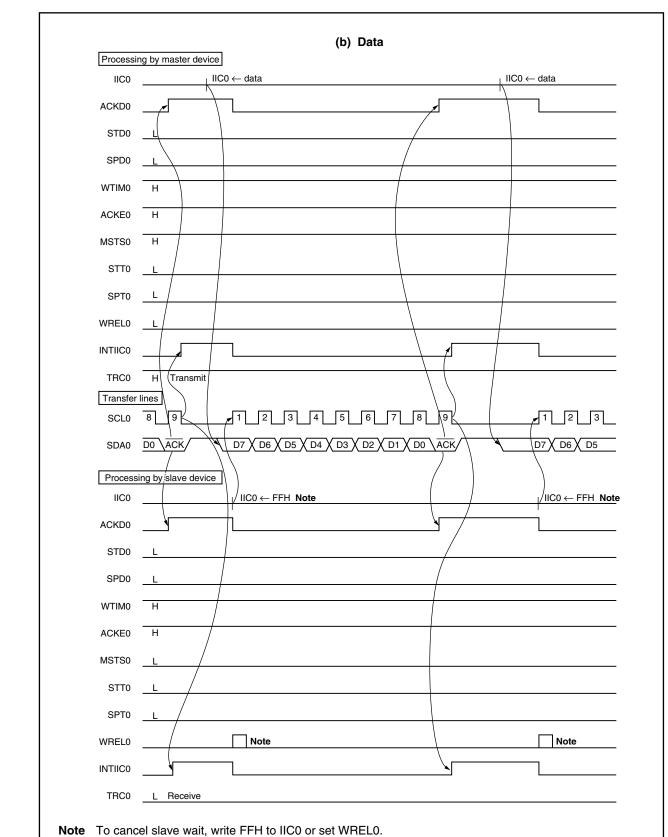

The IIC0 register's shift operation is synchronized with the falling edge of the serial clock (SCL0 pin). The transmit data is transferred to the SO latch and is output (MSB first) via the SDA0 pin.

Data input via the SDA0 pin is captured by the IIC0 register at the rising edge of the SCL0 pin.

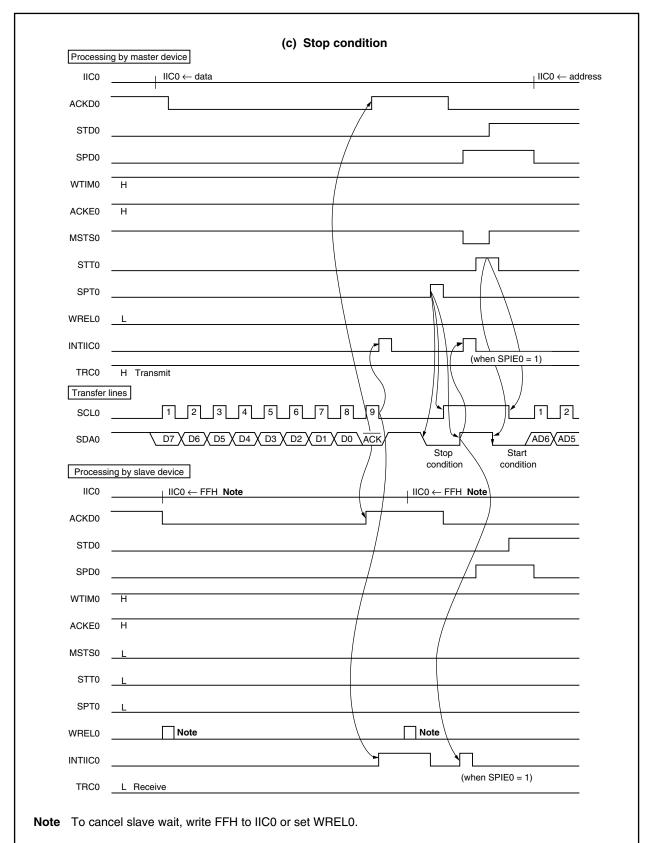

The data communication timing is shown below.

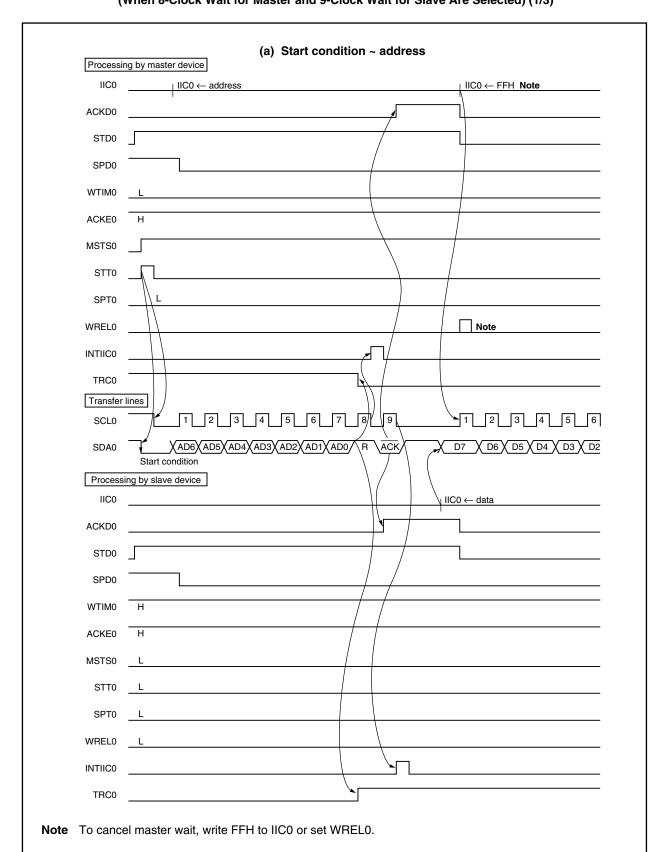

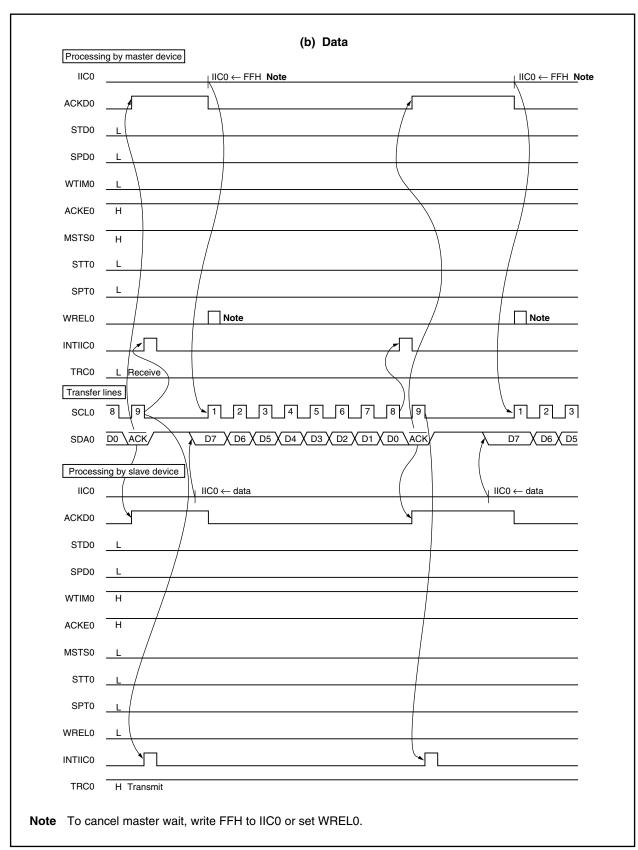

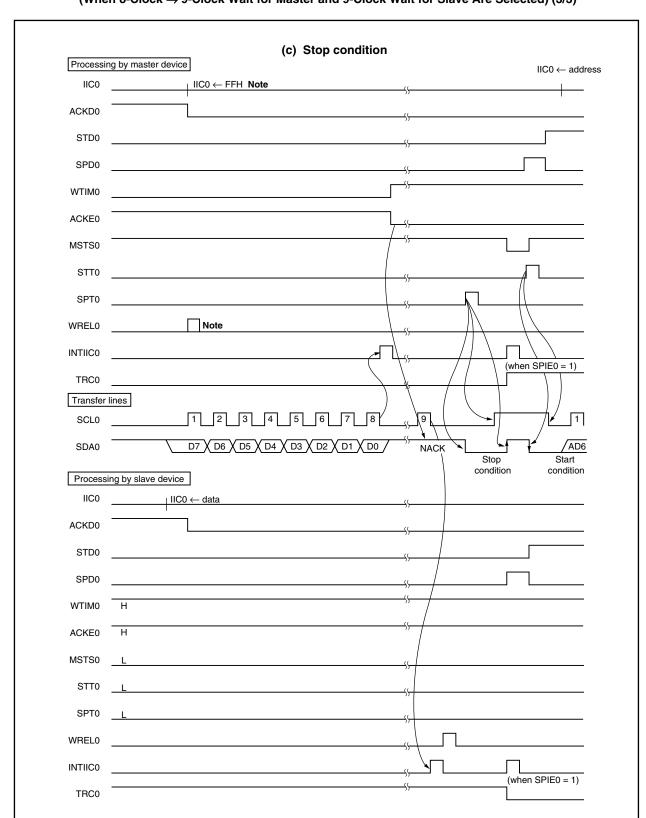

Figure 16-21. Example of Slave to Master Communication (When 8-Clock \rightarrow 9-Clock Wait for Master and 9-Clock Wait for Slave Are Selected) (3/3)

Note To cancel master wait, write FFH to IIC0 or set WREL0.

17.1 Overview

The V850ES/KE1 is provided with a dedicated interrupt controller (INTC) for interrupt servicing and realize an interrupt function that can service interrupt requests from a total of 33 or 34 sources.

An interrupt is an event that occurs independently of program execution, and an exception is an event whose occurrence is dependent on program execution.

The V850ES/KE1 can process interrupt requests from the on-chip peripheral hardware and external sources. Moreover, exception processing can be started by the TRAP instruction (software exception) or by generation of an exception event (fetching of an illegal opcode) (exception trap).

17.1.1 Features

	Interrupt Source			V850ES/KE1
Interrupt	Non-maskable	External		1 channel (NMI pin)
function	interrupt	Internal		2 channels (WDT1, WDT2)
	Maskable interrupt	External		7 channels (all edge detection interrupts)
		Internal	WDT1	1 channel
			TMP	3 channels
			тмо	2 channels
			тмн	2 channels
			TM5	2 channels
			WT	2 channels
			BRG	1 channel
			UART	6 channels
			CSI0	2 channels
			IIC ^{Note}	1 channel
			KR	1 channel
			AD	1 channel
			Total	24 channels
Exception	Software exception			16 channels (TRAP00H to TRAP0FH)
function				16 channels (TRAP10H to TRAP1FH)
	Exception trap			2 channels (ILGOP/DBG0)

Note Only in the μ PD703207Y, 70F3207HY

Table 17-1 lists the interrupt/exception sources.

Туре	Classification	Default Priority	Name	Trigger	Interrupt Source	Exception Code	Handler Address	Restored PC	Interrupt Control Register

 Table 17-1. Interrupt Source List (2/2)

Note Only in the µPD703207Y, 70F3207HY

Remarks 1. Default priority: The priority order when two or more maskable interrupt requests with the same priority level are generated at the same time. The highest priority is 0.

The priority of non-maskable interrupt request is as follows.

INTWDT2 > INTWDT1 > NMI

- Restored PC: The value of the program counter (PC) saved to EIPC, FEPC, or DBPC when interrupt/exception processing is started. The restored PC when a non-maskable or maskable interrupt is acknowledged while either of the following instructions is being executed does not become nextPC (when an interrupt is acknowledged during the execution of an instruction, the execution of that instruction is stopped and is resumed following completion of interrupt servicing).
 - Load instructions (SLD.B, SLD.BU, SLD.H, SLD.HU, SLD.W)
 - Divide instructions (DIV, DIVH, DIVU, DIVHU)
 - PREPARE, DISPOSE instructions (only when an interrupt occurs before stack pointer update)

nextPC:

- The PC value at which processing is started following interrupt/exception processing.
- The execution address of the illegal opcode when an illegal opcode exception occurs is calculated with (Restored PC – 4).

17.2 Non-Maskable Interrupts

Non-maskable interrupt request signals are acknowledged unconditionally, even when interrupts are disabled (DI state). Non-maskable interrupts (NMI) are not subject to priority control and take precedence over all other interrupt request signals.

The following three types of non-maskable interrupt request signals are available in the V850ES/KE1.

- NMI pin input (NMI)
- Non-maskable interrupt request signal (INTWDT1) due to overflow of watchdog timer 1
- Non-maskable interrupt request signal (INTWDT2) due to overflow of watchdog timer 2

There are four choices for the valid edge of an NMI pin, namely: rising edge, falling edge, both edges, and no edge detection.

The non-maskable interrupt request signal (INTWDT1) due to overflow of watchdog timer 1 functions by setting the WDTM1.WDTM14 and WDTM1.WDTM13 bits to 10.

The non-maskable interrupt request signal (INTWDT2) due to overflow of watchdog timer 2 functions by setting the WDTM2.WDM21 and WDTM2.WDM20 bits to 01.

When two or more non-maskable interrupts occur simultaneously, they are processed in a sequence determined by the following priority order (the interrupt request signals with low priority level are ignored).

INTWDT2 > INTWDT1 > NMI

If during NMI processing, an NMI, INTWDT1, or INTWDT2 request signal newly occurs, processing is performed as follows.

(1) If an NMI request signal newly occurs during NMI processing

The new NMI request signal is held pending regardless of the value of the PSW.NP bit. The NMI request signal held pending is acknowledged upon completion of processing of the NMI currently being executed (following RETI instruction execution).

(2) If an INTWDT1 request signal newly occurs during NMI processing

If the NP bit remains set (to 1) during NMI processing, the new INTWDT1 request signal is held pending. The INTWDT1 request signal held pending is acknowledged upon completion of processing of the NMI currently being executed (following RETI instruction execution).

If the NP bit is cleared (to 0) during NMI processing, a newly generated INTWDT1 request signal is executed (NMI processing is interrupted).

(3) If an INTWDT2 request signal newly occurs during NMI processing

A newly generated INTWDT2 request signal is executed regardless of the value of the NP bit (NMI processing is interrupted).

Caution For non-maskable interrupt servicing from non-maskable interrupt request signals (INTWDT1, INTWDT2), refer to 17.10 Cautions.

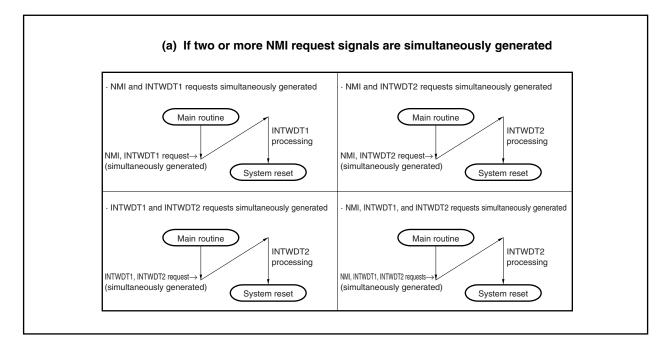

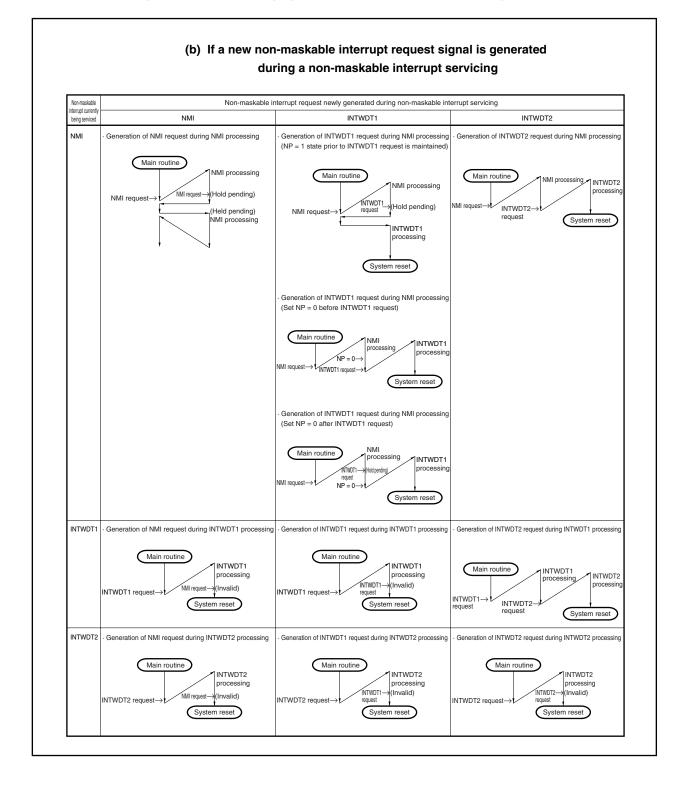

Figure 17-1. Acknowledging Non-Maskable Interrupt Request Signals (1/2)

17.2.1 Operation

Upon generation of a non-maskable interrupt request signal, the CPU performs the following processing and transfers control to a handler routine.

- <1> Saves the restored PC to FEPC.
- <2> Saves the current PSW to FEPSW.
- <3> Writes the exception code (0010H, 0020H, 0030H) to the higher halfword (FECC) of ECR.
- <4> Sets the PSW.NP and PSW.ID bits to 1 and clears the PSW.EP bit to 0.
- <5> Loads the handler address (00000010H, 00000020H, 00000030H) of the non-maskable interrupt to the PC and transfers control.

Figure 17-2 shows the servicing flow for non-maskable interrupts.

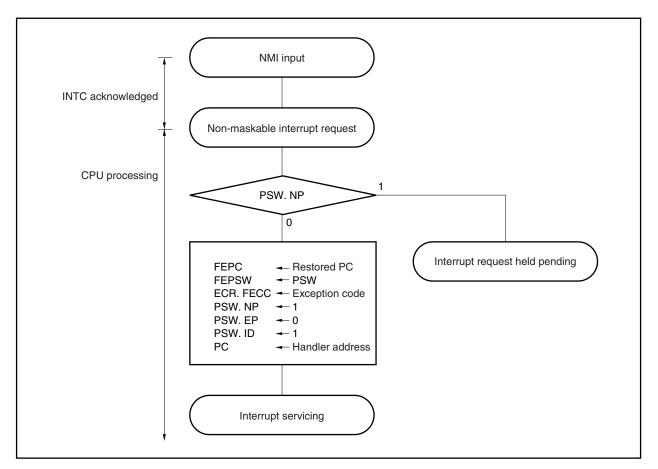

Figure 17-2. Non-Maskable Interrupt Servicing

17.2.2 Restore

Execution is restored from non-maskable interrupt servicing by the RETI instruction.

(1) In case of NMI

Restore from NMI processing is done with the RETI instruction.

When the RETI instruction is executed, the CPU performs the following processing and transfers control to the address of the restored PC.

- (i) Loads the values of the restored PC and PSW from FEPC and FEPSW, respectively, because the PSW.EP bit and the PSW.NP bit are 0 and 1, respectively.
- (ii) Transfers control back to the loaded address of the restored PC and PSW.

Figure 17-3 shows the processing flow of the RETI instruction.

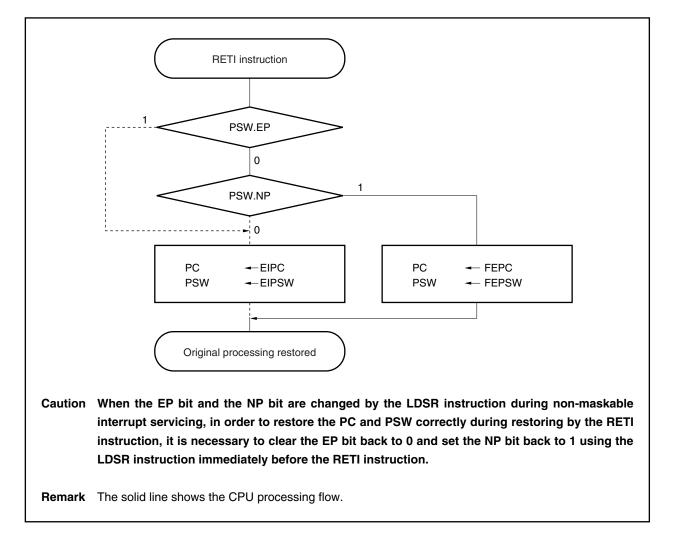

Figure 17-3. RETI Instruction Processing

(2) In case of INTWDT1, INTWDT2 signals

For non-maskable interrupt servicing by the non-maskable interrupt request signals (INTWDT1, INTWDT2), refer to **17.10 Cautions**.

17.2.3 NP flag

The NP flag is a status flag that indicates that non-maskable interrupt servicing is in progress. This flag is set when a non-maskable interrupt request has been acknowledged, and masks all non-maskable requests to prevent multiple interrupts.

		Non-maskable interrupt serving in progress								

17.3 Maskable Interrupts

Maskable interrupt request signals can be masked by interrupt control registers. The V850ES/KE1 has 30 or 31 maskable interrupt sources (refer to **17.1.1 Features**).

If two or more maskable interrupt request signals are generated at the same time, they are acknowledged according to the default priority. In addition to the default priority, eight levels of interrupt priorities can be specified by using the interrupt control registers, allowing programmable priority control.

When an interrupt request signal has been acknowledged, the interrupt disabled (DI) status is set and the acknowledgment of other maskable interrupt request signals is disabled.

When the EI instruction is executed in an interrupt servicing routine, the interrupt enabled (EI) status is set, which enables acknowledgment of interrupt request signals having a priority higher than that of the interrupt request signal currently in progress. Note that only interrupt request signals with a higher priority have this capability; interrupt request signals with the same priority level cannot be nested.

To use multiple interrupts, it is necessary to save EIPC and EIPSW to memory or a register before executing the EI instruction, and restore EIPC and EIPSW to the original values by executing the DI instruction before the RETI instruction.

When the WDTM1.WDTM14 bit is cleared to 0, the watchdog timer 1 overflow interrupt functions as a maskable interrupt (INTWDTM1).

17.3.1 Operation

If a maskable interrupt request signal is generated, the CPU performs the following processing and transfers control to a handler routine.

<1> Saves the restored PC to EIPC.

- <2> Saves the current PSW to EIPSW.
- <3> Writes an exception code to the lower halfword of ECR (EICC).
- <4> Sets the PSW.ID bit to 1 and clears the PSW.EP bit to 0.
- <5> Loads the corresponding handler address to the PC and transfers control.

The maskable interrupt request signal masked by INTC and the maskable interrupt request signal that occurs while another interrupt is being serviced (when PSW.NP bit = 1 or ID bit = 1) are held pending internally. When the interrupts are unmasked, or when the NP bit = 0 and the ID bit = 0 by using the RETI and LDSR instructions, a new maskable interrupt servicing is started in accordance with the priority of the pending maskable interrupt request signal.

Figure 17-4 shows the servicing flow for maskable interrupts.

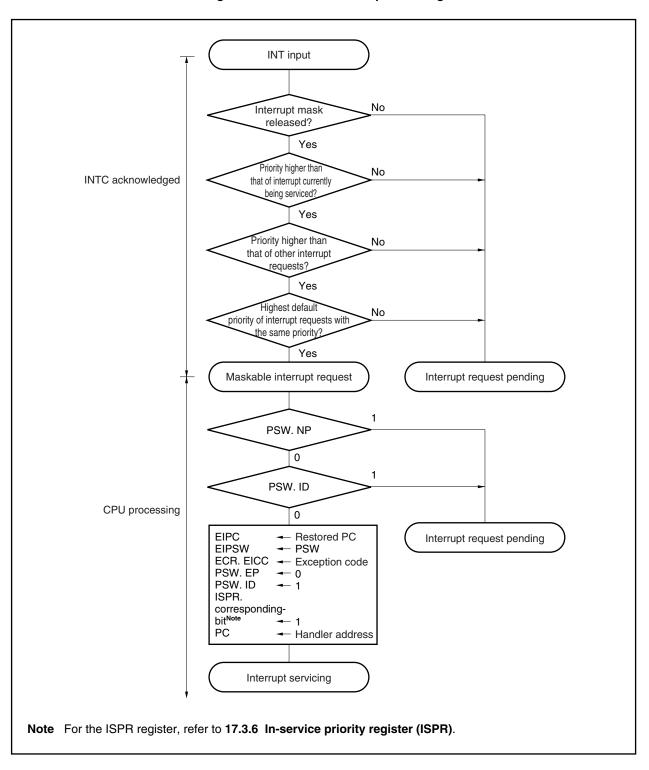

Figure 17-4. Maskable Interrupt Servicing

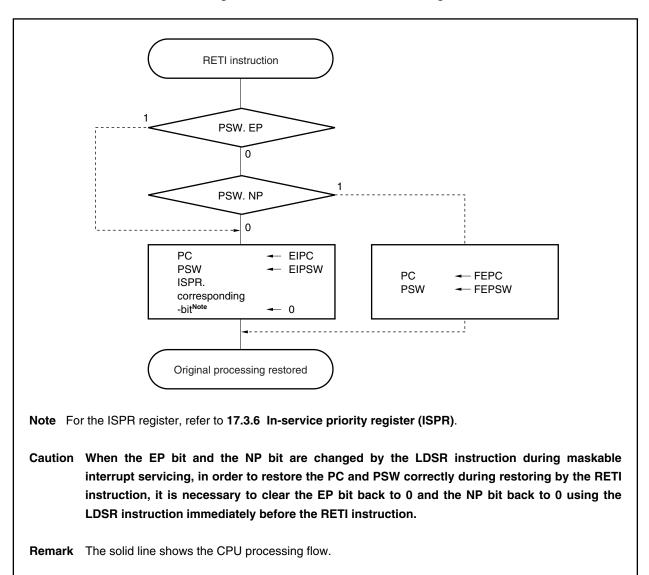

17.3.2 Restore

Execution is restored from maskable interrupt servicing by the RETI instruction.

When the RETI instruction is executed, the CPU performs the following processing and transfers control to the address of the restored PC.

- (1) Loads the values of the restored PC and PSW from EIPC and EIPSW because the PSW.EP bit and the PSW.NP bit are both 0.
- (2) Transfers control to the loaded address of the restored PC and PSW.

Figure 17-5 shows the processing flow of the RETI instruction.

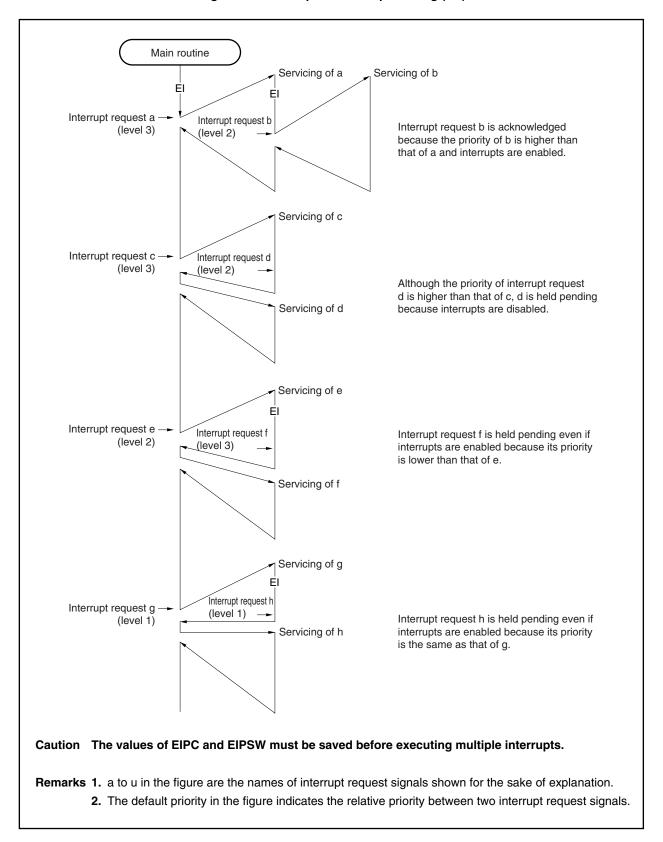

17.3.3 Priorities of maskable interrupts

INTC provides a multiple interrupt servicing in which an interrupt can be acknowledged while another interrupt is being serviced. Multiple interrupts can be controlled by priority levels.

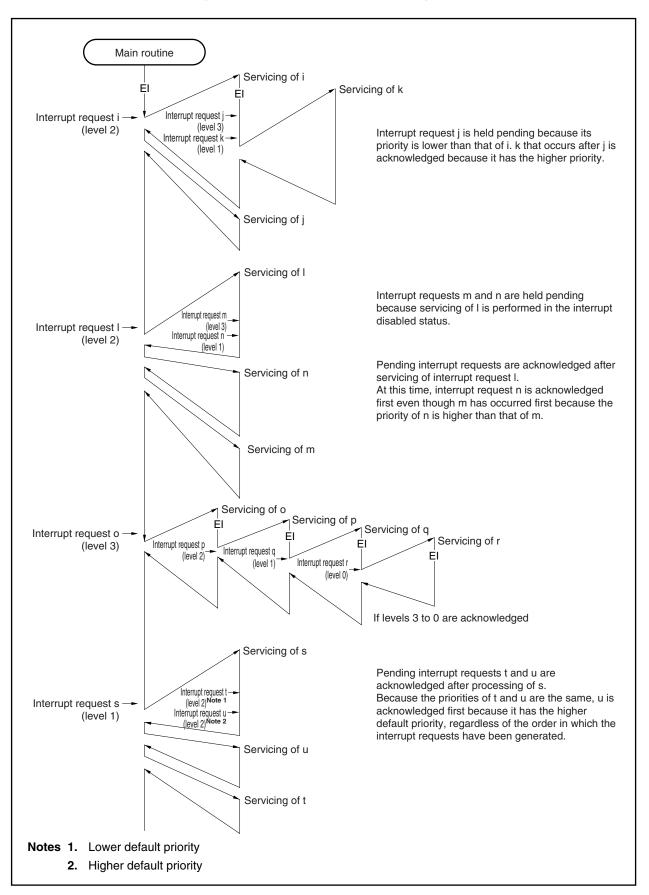

There are two types of priority level control: control based on the default priority levels, and control based on the programmable priority levels specified by the interrupt priority level specification bit (xxICn.xxPRn bit). When two or more interrupts having the same priority level specified by xxPRn are generated at the same time, interrupts are serviced in order depending on the priority level allocated to each interrupt request (default priority level) beforehand. For more information, refer to **Table 17-1 Interrupt Source List**. Programmable priority control divides interrupt requests into eight levels by setting the priority level specification flag.

Note that when an interrupt request signal is acknowledged, the PSW.ID flag is automatically set (1). Therefore, when multiple interrupts are to be used, clear (0) the ID flag beforehand (for example, by placing the EI instruction into the interrupt service program) to enable interrupts.

- Remark xx: Identifying name of each peripheral unit (refer to Table 17-2 Interrupt Control Registers (xxICn))
 - n: Peripheral unit number (refer to Table 17-2 Interrupt Control Registers (xxICn))

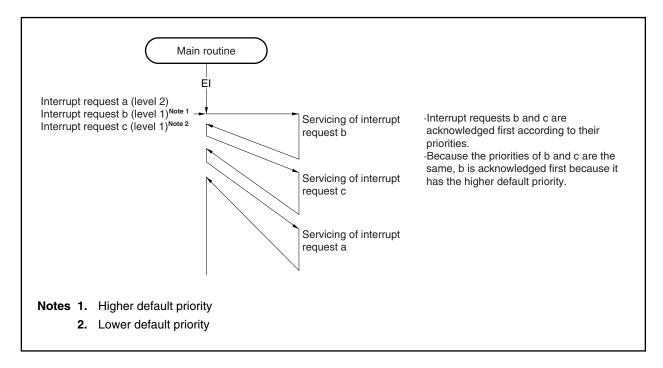

Figure 17-7. Example of Servicing Simultaneously Generated Interrupt Request Signals

17.3.4 Interrupt control register (xxlCn)

An interrupt control register is assigned to each maskable interrupt and sets the control conditions for each maskable interrupt request. The interrupt control registers can be read or written in 8-bit or 1-bit units.

Reset sets xxICn to 47H.

Caution Be sure to read the xxICn.xxIFn bit while interrupts are disabled (DI). If the xxIFn bit is read while interrupts are enabled (EI), an incorrect value may be read if there is a conflict between acknowledgment of the interrupt and reading of the bit.

Note Only in the μ PD703207Y, 70F3207HY

17.3.5 Interrupt mask registers 0, 1, 3 (IMR0, IMR1, IMR3)

These registers set the interrupt mask status for maskable interrupts. The xxMKn bit of the IMR0, IMR1, and IMR3 registers and the xxMKn bit of the xxICn register are respectively linked.

The IMRm register can be read or written in 16-bit units (m = 0, 1, 3).

When the higher 8 bits of the IMRk register are treated as the IMRkH register and the lower 8 bits of the IMRk register as the IMRkL register, they can be read or written in 8-bit or 1-bit units (k = 0, 1).

Caution In the device file, the xxMKn bit of the xxICn register is defined as a reserved word. Therefore, if bit manipulation is performed using the name xxMKn, the xxICn register, not the IMRm register, is rewritten (as a result, the IMRm register is also rewritten).

17.3.6 In-service priority register (ISPR)

This register holds the priority level of the maskable interrupt currently being acknowledged. When the interrupt request signal is acknowledged, the bit of this register corresponding to the priority level of that interrupt request signal is set (1) and remains set while the interrupt is being serviced.

When the RETI instruction is executed, the bit among those that are set (1) in the ISPR register that corresponds to the interrupt request signal having the highest priority is automatically cleared (0) by hardware. However, it is not cleared (0) when execution is returned from non-maskable interrupt servicing or exception processing.

This register is read-only in 8-bit or 1-bit units.

Reset sets ISPR to 00H.

Caution If an interrupt is acknowledged while the ISPR register is being read in the interrupt enabled (EI) status, the value of the ISPR register after the bits of the register have been set to 1 by acknowledging the interrupt may be read. To accurately read the value of the ISPR register before an interrupt is acknowledged, read the register while interrupts are disabled (DI status).

Rema	Remark n = 0 to 7 (priority level)										

17.3.7 ID flag

The interrupt disable flag (ID) is allocated to the PSW and controls the maskable interrupt's operating state, and stores control information regarding enabling/disabling reception of interrupt request signals.

Reset sets this flag to 0000020H.

17.4 External Interrupt Request Input Pins (NMI, INTP0 to INTP6)

17.4.1 Noise elimination

(1) Noise elimination for NMI pin

The NMI pin includes a noise eliminator that operates using analog delay. Therefore, a signal input to the NMI pin is not detected as an edge unless it maintains its input level for a certain period. The edge is detected only after a certain period has elapsed.

The NMI pin is used for releasing the STOP mode. In the STOP mode, noise elimination using the system clock is not performed because the internal system clock is stopped.

(2) Noise elimination for INTP0 to INTP6 pins

The INTP0 to INTP6 pins include a noise eliminator that operates using analog delay. Therefore, a signal input to each pin is not detected as an edge unless it maintains its input level for a certain period. The edge is detected only after a certain period has elapsed.

17.4.2 Edge detection

The valid edges of the NMI and INTP0 to INTP6 pins can be selected from the following four types for each pin.

- Rising edge
- Falling edge
- Both edges
- No edge detection

After reset, the edge detection for the NMI pin is set to "no edge detection". Therefore, interrupt requests cannot be acknowledged (the NMI pin functions as a normal port) unless a valid edge is specified by the INTRO, INTFO, INTR9H, and INTF9H registers.

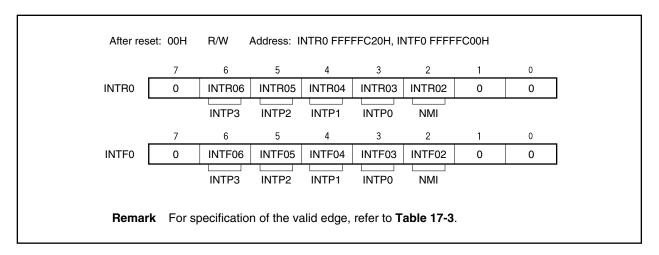

When using the P02/NMI pin as an output port, set the NMI pin valid edge to "no edge detection".

(1) External interrupt rising and falling edge specification registers 0 (INTR0, INTF0)

These are 8-bit registers that specify detection of the rising and falling edges of the NMI and INTP0 to INTP3 pins.

These registers can be read or written in 8-bit or 1-bit units. Reset sets these registers to 00H.

Caution When switching to the port function from the external interrupt function (alternate function), edge detection may be performed. Therefore, set the port mode after setting the INTF0n and INTR0n bits = 00.

INTF0n	INTR0n	Valid edge specification (n = 2 to 6)			
0	0	No edge detection			
0	1	Rising edge			
1	0	Falling edge			
1	1	Both edges			

Remark n = 2: Control of NMI pin

n = 3 to 6: Control of INTP0 to INTP3 pins

- (2) External interrupt rising and falling edge specification registers 9H (INTR9H, INTF9H) These are 8-bit registers that specify detection of the rising edge of the INTP4 to INTP6 pins. These registers can be read or written in 8-bit or 1-bit units. Reset sets these registers to 00H.
 - Caution When switching to the port function from the external interrupt function (alternate function), edge detection may be performed. Therefore, set the port mode after setting the INTF9n and INTR9n bits = 00.

0	1	Rising edge			
1	0	Falling edge			
1	1	Both edges			

Remark n = 13 to 15: Control of INTP4 to INTP6 pins

17.5 Software Exceptions

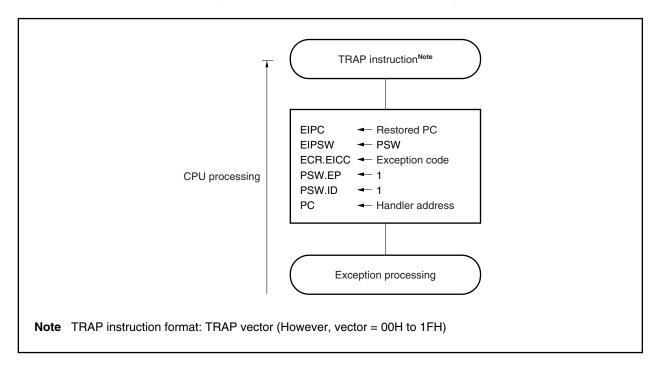

A software exception is generated when the CPU executes the TRAP instruction. Software exceptions can always be acknowledged.

17.5.1 Operation

If a software exception occurs, the CPU performs the following processing and transfers control to a handler routine.

- <1> Saves the restored PC to EIPC.
- <2> Saves the current PSW to EIPSW.
- <3> Writes an exception code to the lower 16 bits (EICC) of ECR (interrupt source).
- <4> Sets the PSW.EP and PSW.ID bits to 1.
- <5> Loads the handler address (00000040H or 00000050H) for the software exception routine to the PC and transfers control.

Figure 17-8 shows the software exception processing flow.

The handler address is determined by the operand (vector) of the TRAP instruction. If the vector is 00H to 1FH, the handler address is 00000040H, and if the vector is 10H to 1FH, the handler address is 00000050H.

17.5.2 Restore

Execution is restored from software exception processing by the RETI instruction.

When the RETI instruction is executed, the CPU performs the following processing and transfers control to the address of the restored PC.

<1> Loads the restored PC and PSW from EIPC and EIPSW because the PSW.EP bit is 1.

<2> Transfers control to the address of the restored PC and PSW.

Figure 17-9 shows the processing flow of the RETI instruction.

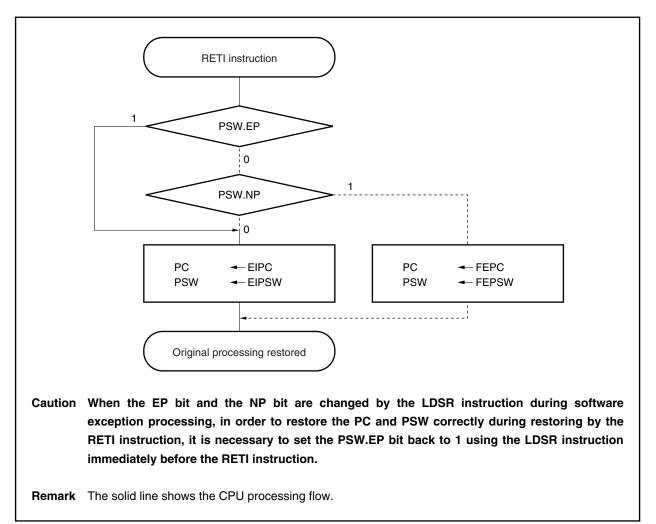

Figure 17-9. RETI Instruction Processing

17.5.3 EP flag

The EP flag, which is bit 6 of the PSW, is a status flag that indicates that exception processing is in progress. It is set when an exception occurs.

	et: 00000020										
	31		8	7	6	5	4	3	2	1	0
PSW		0		NP	ΕP	ID	SAT	CY	OV	S	Z
	EP	Exc	Exception processing status								
	0	Exception processing not in progress									
		Exception processing in progress									

17.6 Exception Trap

The exception trap is an interrupt that is requested when the illegal execution of an instruction takes place. In the V850ES/KE1, an illegal opcode trap (ILGOP) is considered as an exception trap.

17.6.1 Illegal opcode

An illegal opcode is defined as an instruction with instruction opcode (bits 10 to 5) = 111111B, sub-opcode (bits 26 to 23) = 0111B to 1111B, and sub-opcode (bit 16) = 0B. When such an instruction is executed, an exception trap is generated.

Caution It is recommended not to use illegal opcode because instructions may newly be assigned in the future.

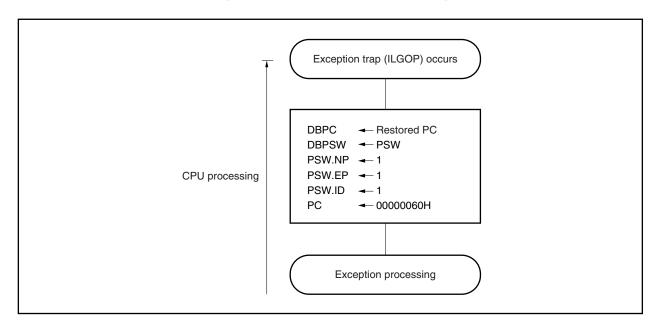

(1) Operation

Upon generation of an exception trap, the CPU performs the following processing and transfers control to a handler routine.

- <1> Saves the restored PC to DBPC.
- <2> Saves the current PSW to DBPSW.
- <3> Sets the PSW.NP, PSW.EP, and PSW.ID bits.
- <4> Loads the handler address (0000060H) for the exception trap routine to the PC and transfers control.

Figure 17-10 shows the exception trap processing flow.

Figure 17-10. Exception Trap Processing

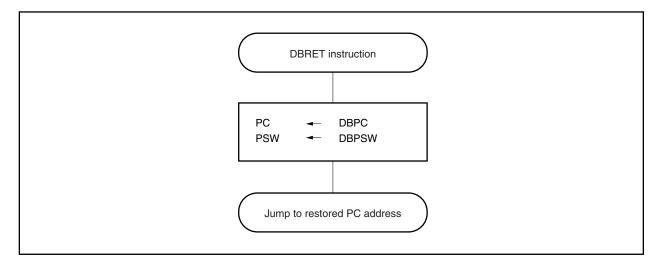

(2) Restore

Execution is restored from exception trap processing by the DBRET instruction. When the DBRET instruction is executed, the CPU performs the following processing and transfers control to the address of the restored PC.

- <1> Loads the restored PC and PSW from DBPC and DBPSW.
- <2> Transfers control to the loaded address of the restored PC and PSW.

Figure 17-11 shows the processing flow for restore from exception trap processing.

17.6.2 Debug trap

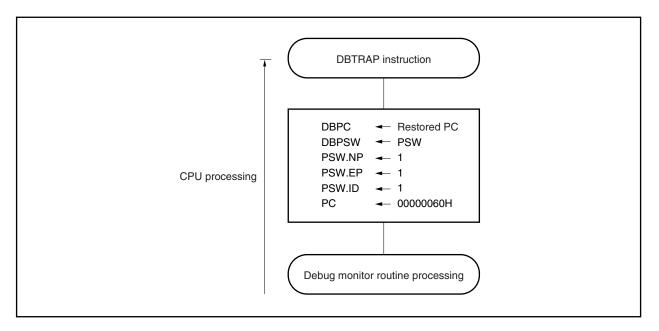

A debug trap is an exception that occurs upon execution of the DBTRAP instruction and that can be acknowledged at all times.

When a debug trap occurs, the CPU performs the following processing.

(1) Operation

- <1> Saves the restored PC to DBPC.
- <2> Saves the current PSW to DBPSW.
- <3> Sets the PSW.NP, PSW.EP, and PSW.ID bits to 1.
- <4> Sets the handler address (0000060H) for the debug trap routine to the PC and transfers control.

Figure 17-12 shows the debug trap processing flow.

(2) Restore

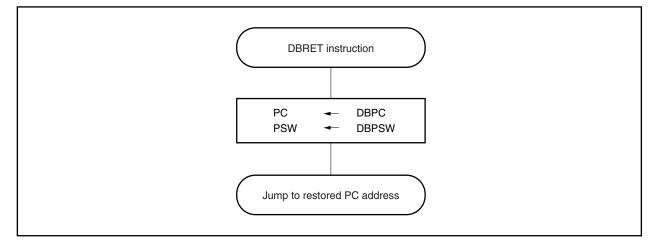

Execution is restored from debug trap processing by the DBRET instruction. When the DBRET instruction is executed, the CPU performs the following processing and transfers control to the address of the restored PC.

<1> Loads the restored PC and PSW from DBPC and DBPSW.

<2> Transfers control to the loaded address of the restored PC and PSW.

Figure 17-13 shows the processing flow for restore from debug trap processing.

17.7 Multiple Interrupt Servicing Control

Multiple interrupt servicing control is a function that stops an interrupt service routine currently in progress if a higher priority interrupt request signal is generated, and processes the acknowledgment operation of the higher priority interrupt request signal.

If an interrupt request signal with a lower or equal priority is generated and a service routine is currently in progress, the later interrupt request signal will be held pending.

Multiple interrupt servicing control is performed when interrupts are enabled (PSW.ID bit = 0). Even in an interrupt servicing routine, multiple interrupt control must be performed while interrupts are enabled (ID bit = 0).

If a maskable interrupt or software exception is generated in a maskable interrupt or software exception service program, EIPC and EIPSW must be saved.

The following example illustrates the procedure.

(1) To acknowledge maskable interrupt request signals in service program

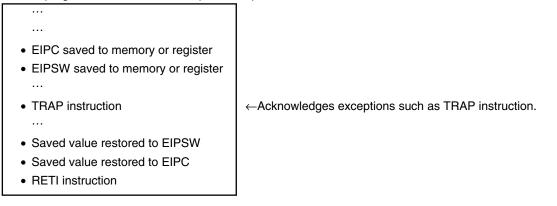

Service program for maskable interrupt or exception

 EIPC saved to memory or register 	
 EIPSW saved to memory or register 	
 El instruction (enables interrupt acknowledgment) 	
	←Ackno
 DI instruction (disables interrupt acknowledgment) 	
 Saved value restored to EIPSW 	
 Saved value restored to EIPC 	
RETI instruction	

Acknowledges maskable interrupt

(2) To generate exception in service program

Service program for maskable interrupt or exception

Priorities 0 to 7 (0 is the highest) can be set for each maskable interrupt request in multiple interrupt servicing control by software. To set a priority level, write values to the xxICn.xxPRn0 to xxICn.xxPRn2 bits corresponding to each maskable interrupt request. After reset, interrupt requests are masked by the xxICn.xxMKn bit, and the priority is set to level 7 by the xxPRn0 to xxPRn2 bits.

Priorities of maskable interrupts are as follows.

(High) Level 0 > Level 1 > Level 2 > Level 3 > Level 4 > Level 5 > Level 6 > Level 7 (Low)

Interrupt servicing that has been suspended as a result of multiple interrupt servicing control is resumed after the interrupt servicing of the higher priority has been completed and the RETI instruction has been executed. A pending interrupt request signal is acknowledged after the current interrupt servicing has been completed and the RETI instruction has been executed.

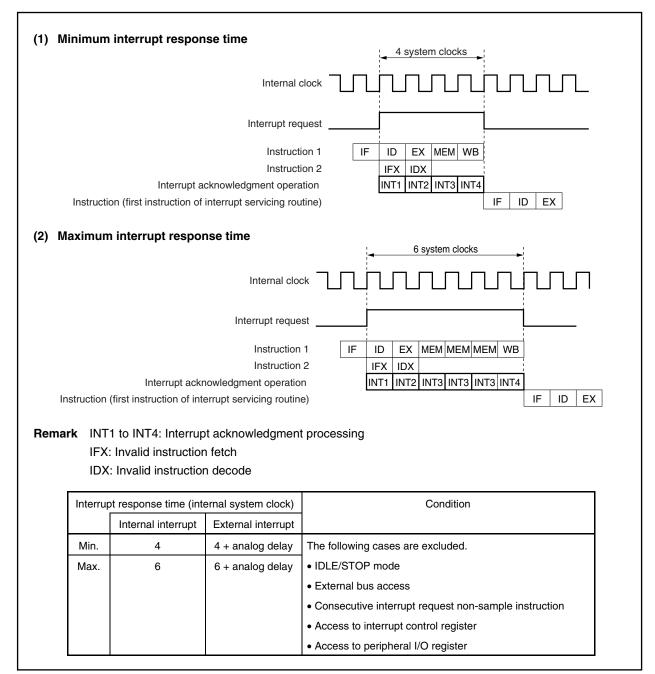

Caution In a non-maskable interrupt servicing routine (in the time until the RETI instruction is executed), maskable interrupts are not acknowledged and held pending.

17.8 Interrupt Response Time

Except in the following cases, the CPU interrupt response time is a minimum of 4 clocks. If inputting consecutive interrupt request signals, at least 4 clocks must be placed between each interrupt request signal.

- IDLE/STOP mode
- · External bus access
- Consecutive interrupt request non-sample instruction (refer to 17.9 Periods in Which Interrupts Are Not Acknowledged by CPU)
- · Access to interrupt control register
- Access to peripheral I/O register

Figure 17-14. Pipeline Operation During Interrupt Request Signal Acknowledgment (Outline)

17.9 Periods in Which Interrupts Are Not Acknowledged by CPU

Interrupts are acknowledged by the CPU while an instruction is being executed. However, no interrupt is acknowledged between an interrupt request non-sample instruction and the next instruction (interrupts are held pending).

The following instructions are interrupt request non-sample instructions.

- El instruction
- DI instruction
- LDSR reg2, 0x5 instructions (vs. PSW)
- Store instruction for the PRCMD register
- Store instruction and SET1, NOT1, and CLR1 instructions for the following registers
 - Interrupt-related registers: Interrupt control register (xxICn), interrupt mask registers 0, 1, 3 (IMR0, IMR1, IMR3)
 - Power save control register (PSC)

17.10 Cautions

Design the system so that restoring by the RETI instruction is as follows after a non-maskable interrupt triggered by a non-maskable interrupt request signal (INTWDT1/INTWDT2) is serviced.

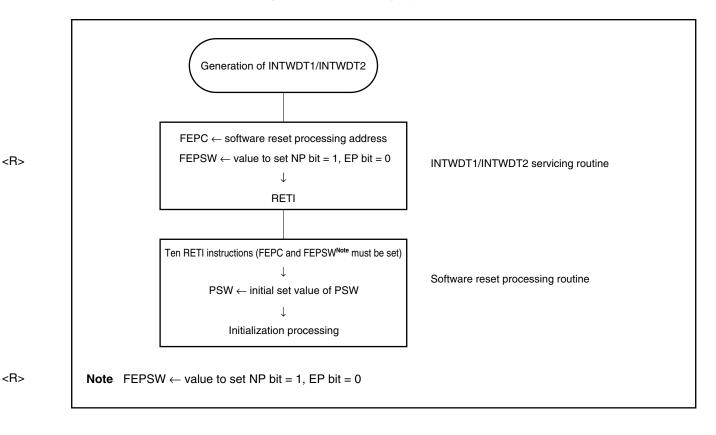

Figure 17-15. Restoring by RETI Instruction

CHAPTER 18 KEY INTERRUPT FUNCTION

18.1 Function

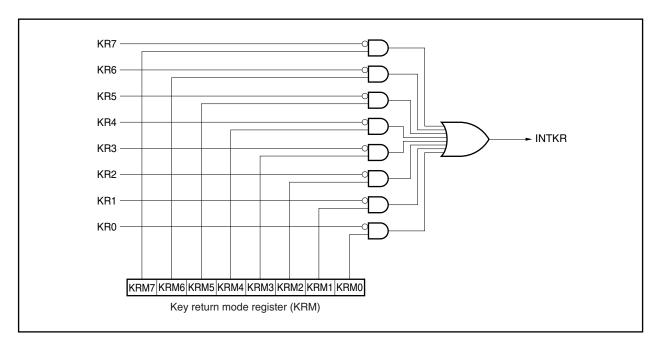

A key interrupt request signal (INTKR) can be generated by inputting a falling edge to the eight key input pins (KR0 to KR7) by setting the KRM register.

Caution If any of the KR0 to KR7 pins is at low level, the INTKR signal is not generated even if a falling edge is input to another pin.

Flag	Pin Description
KRM0	Controls KR0 signal in 1-bit units
KRM1	Controls KR1 signal in 1-bit units
KRM2	Controls KR2 signal in 1-bit units
KRM3	Controls KR3 signal in 1-bit units
KRM4	Controls KR4 signal in 1-bit units
KRM5	Controls KR5 signal in 1-bit units
KRM6	Controls KR6 signal in 1-bit units
KRM7	Controls KR7 signal in 1-bit units

Table 18-1. Assignment of Key Return Detection Pins

Figure 18-1. Key Return Block Diagram

18.2 Register

(1) Key return mode register (KRM)

The KRM register controls the KRM0 to KRM7 bits using the KR0 to KR7 signals. This register can be read or written in 8-bit or 1-bit units. Reset sets KRM to 00H.

CHAPTER 19 STANDBY FUNCTION

19.1 Overview

The power consumption of the system can be effectively reduced by using the standby modes in combination and selecting the appropriate mode for the application.

The available standby modes are listed in Table 19-1.

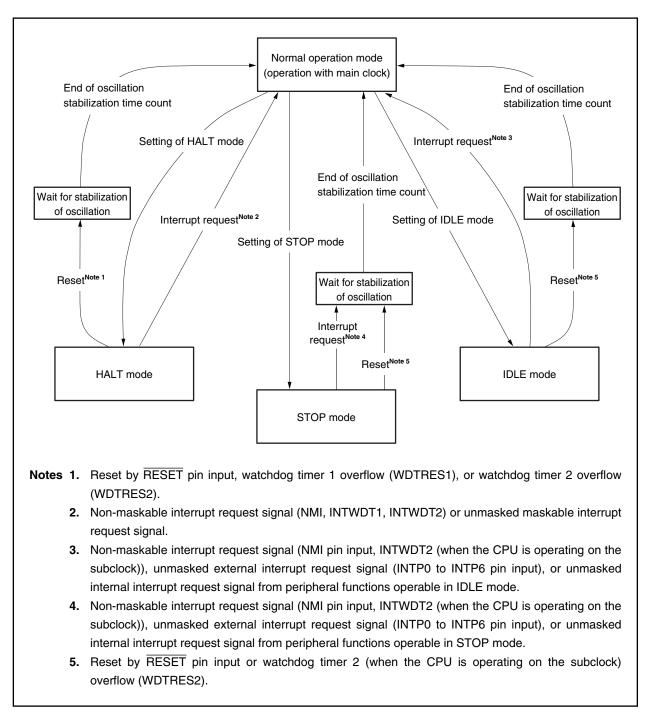

Mode	Functional Outline
HALT mode	Mode to stop only the operating clock of the CPU
IDLE mode	Mode to stop all the operations of the internal circuits except the oscillator ^{Note 1}
STOP mode	Mode to stop all the operations of the internal circuits except the subclock oscillator.Note 2
Subclock operation mode	Mode to use the subclock as the internal system clock
Sub-IDLE mode	Mode to stop all the operations of the internal circuits, except the oscillator, in the subclock operation mode

Table 19-1. Standby Modes

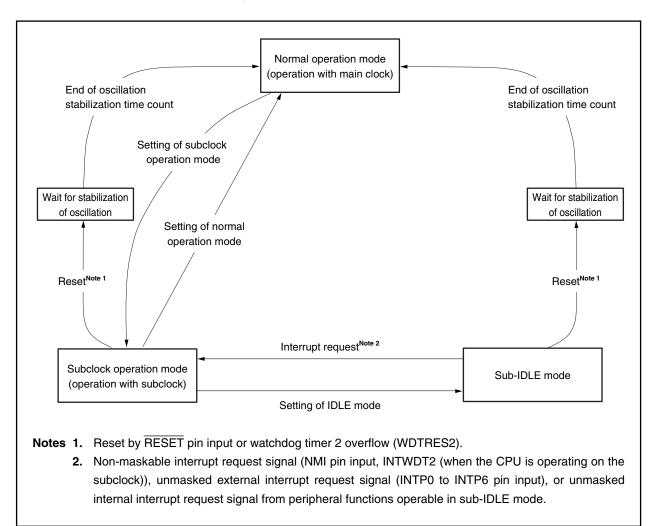

Notes 1. The PLL does not stop. To realize low power consumption, stop the PLL and then shift to the IDLE mode.

2. Change to the clock-through mode, stop the PLL, then shift to the STOP mode. For details, refer to CHAPTER 5 CLOCK GENERATION FUNCTION.

19.2 Registers

(1) Power save control register (PSC)

the STP bit to 1.

This is an 8-bit register that controls the standby function. The STP bit of this register is used to specify the standby mode. The PSC register is a special register that can be written to only in a special sequence (refer to **3.4.7 Special registers**).

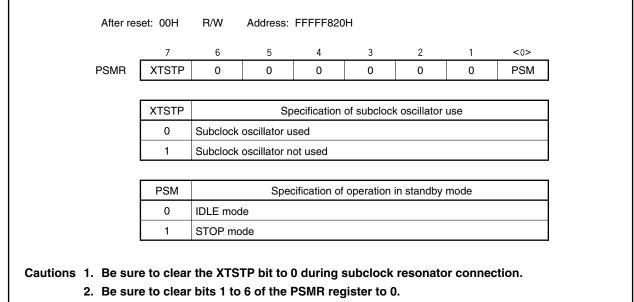

This register can be read or written in 8-bit or 1-bit units. Reset sets PSC to 00H.

	<7>	6	<5>	<4>	3	2	<1>	0
PSC	NMI2M	0	NMIOM	INTM	0	0	STP	0
	NMI2M		Control of re	-	-	-	-	nal

te In this case, st	,				,			
•	g of NM	2M, NM	0M, and I being he	INTM bit Id pendir	s becon ng when	nes inva the IDLE	lid. If ti	at the same here is an node is set,

2. When the IDLE/STOP mode is set, set the PSMR.PSM bit and then set the STP bit.

(2) Power save mode register (PSMR)

This is an 8-bit register that controls the operation status in the standby mode and the clock operation. This register can be read or written in 8-bit or 1-bit units. Reset sets PSMR to 00H.

3. The PSM bit is valid only when the PSC.STP bit is 1.

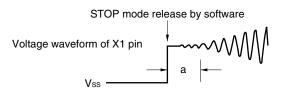

(3) Oscillation stabilization time selection register (OSTS)

The wait time until the oscillation stabilizes after the STOP mode is released is controlled by the OSTS register. The OSTS register can be read or written in 8-bit units.

Reset sets OSTS to 01H.

After re	set: 01H	R/W	Address: F	FFFF6C0	Н			
	7	6	5	4	3	2	1	0
OSTS	0	0	0	0	0	OSTS2	OSTS1	OSTS0
	OSTS2	OSTS1	OSTS0	Se	lection of os	cillation st	abilizatior	n time
					fx			
					4 MHz	5 N	/Hz	10 MHz
	0	0	0	2 ¹³ /fx	2.048 ms	1.63	38 ms	0.819 ms
	0	0	1	2 ¹⁵ /fx	8.192 ms	6.55	54 ms	3.277 ms
	0	1	0	2 ¹⁶ /fx	16.38 ms	13.1	11 ms	6.554 ms
	0	1	1	2 ¹⁷ /fx	32.77 ms	26.2	21 ms	13.11 ms
	1	0	0	2 ¹⁸ /fx	65.54 ms	52.4	43 ms	26.21 ms
	1	0	1	2 ¹⁹ /fx	131.1 ms	104	.9 ms	52.43 ms
	1	1	0	2 ²⁰ /fx	262.1 ms	209	.7 ms	104.9 ms
	1	1	1	2 ²¹ /fx	524.3 ms	419	.4 ms	209.7 ms

Cautions 1. The wait time following release of the STOP mode does not include the time until the clock oscillation starts ("a" in the figure below) following release of the STOP mode, regardless of whether the STOP mode is released by reset or the occurrence of an interrupt request signal.

- 2. Be sure to clear bits 3 to 7 to "0".
- The oscillation stabilization time following reset release is 2¹⁵/fx (because the initial value of the OSTS register = 01H).
- 4. The oscillation stabilization time is also inserted during external clock input.

Remark fx: Main clock oscillation frequency

19.3 HALT Mode

19.3.1 Setting and operation status

The HALT mode is set when a dedicated instruction (HALT) is executed in the normal operation mode.

In the HALT mode, the clock oscillator continues operating. Only clock supply to the CPU is stopped; clock supply to the other on-chip peripheral functions continues.

As a result, program execution is stopped, and the internal RAM retains the contents before the HALT mode was set. The on-chip peripheral functions that are independent of instruction processing by the CPU continue operating. Table 19-3 shows the operation status in the HALT mode.

The average power consumption of the system can be reduced by using the HALT mode in combination with the normal operation mode for intermittent operation.

Cautions 1. Insert five or more NOP instructions after the HALT instruction.

2. If the HALT instruction is executed with an unmasked interrupt request signal held pending, the system shifts to the HALT mode, but the HALT mode is immediately released by the pending interrupt request signal.

19.3.2 Releasing HALT mode

The HALT mode is released by a non-maskable interrupt request signal (NMI pin input, INTWDT1, INTWDT2 signal), an unmasked maskable interrupt request signal, and reset signal (RESET pin input, WDTRES1, WDTRES2 signal).

After the HALT mode has been released, the normal operation mode is restored.

(1) Releasing HALT mode by non-maskable interrupt request signal or unmasked maskable interrupt request signal

The HALT mode is released by a non-maskable interrupt request signal or an unmasked maskable interrupt request signal, regardless of the priority of the interrupt request. If the HALT mode is set in an interrupt servicing routine, however, an interrupt request that is issued later is serviced as follows.

- (a) If an interrupt request signal with a priority lower than that of the interrupt request currently being serviced is issued, only the HALT mode is released, and that interrupt request signal is not acknowledged. The interrupt request signal itself is retained.
- (b) If an interrupt request signal with a priority higher than that of the interrupt request currently being serviced is issued (including a non-maskable interrupt request signal), the HALT mode is released and that interrupt request signal is acknowledged.

Release Source	Interrupt Enabled (EI) Status	Interrupt Disabled (DI) Status		
Non-maskable interrupt request signal	Execution branches to the handler address			
Maskable interrupt request signal	Execution branches to the handler address or the next instruction is executed	The next instruction is executed		

Table 19-2. Operation After Releasing HALT Mode by Interrupt Request Signal

(2) Releasing HALT mode by reset

The same operation as the normal reset operation is performed.

Setting of HALT Mode		When CPU Is Operating with Main Clock					
Item		When Subclock Is Not Used	When Subclock Is Used

Table 19-3. Operation Status in HALT Mode

Note Only in the μ PD703207Y, 70F3207HY

19.4 IDLE Mode

19.4.1 Setting and operation status

The IDLE mode is set by clearing the PSMR.PSM bit to 0 and setting the PSC.STP bit to 1 in the normal operation mode.

In the IDLE mode, the clock oscillator continues operation but clock supply to the CPU and other on-chip peripheral functions stops.

As a result, program execution stops and the contents of the internal RAM before the IDLE mode was set are retained. The CPU and other on-chip peripheral functions stop operating. However, the on-chip peripheral functions that can operate with the subclock or an external clock continue operating.

Table 19-5 shows the operation status in the IDLE mode.

The IDLE mode can reduce the power consumption more than the HALT mode because it stops the operation of the on-chip peripheral functions. The main clock oscillator does not stop, so the normal operation mode can be restored without waiting for the oscillation stabilization time after the IDLE mode has been released, in the same manner as when the HALT mode is released.

Caution Insert five or more NOP instructions after the instruction that stores data in the PSC register to set the IDLE mode.

19.4.2 Releasing IDLE mode

The IDLE mode is released by a non-maskable interrupt request signal (NMI pin input, INTWDT2 signal (when the CPU is operating on the subclock)), unmasked external interrupt request signal (INTP0 to INTP6 pin input), unmasked internal interrupt request signal from the peripheral functions operable in the IDLE mode, or reset (RESET pin input, WDTRES2 signal (when the CPU is operating on the subclock)).

After the IDLE mode has been released, the normal operation mode is restored.

(1) Releasing IDLE mode by non-maskable interrupt request signal or unmasked maskable interrupt request signal

The IDLE mode is released by a non-maskable interrupt request signal or an unmasked maskable interrupt request signal, regardless of the priority of the interrupt request. If the IDLE mode is set in an interrupt servicing routine, however, an interrupt request that is issued later is serviced as follows.

- (a) If an interrupt request signal with a priority lower than that of the interrupt request currently being serviced is issued, only the IDLE mode is released, and that interrupt request signal is not acknowledged. The interrupt request signal itself is retained.
- (b) If an interrupt request signal with a priority higher than that of the interrupt request currently being serviced is issued (including a non-maskable interrupt request signal), the IDLE mode is released and that interrupt request signal is acknowledged.

Release Source	Interrupt Enabled (EI) Status	Interrupt Disabled (DI) Status			
Non-maskable interrupt request signal	Execution branches to the handler address				
Maskable interrupt request signal	Execution branches to the handler address or the next instruction is executed	The next instruction is executed			

Table 19-4. Operation After Releasing IDLE Mode by Interrupt Request Signal

Caution The interrupt request signal that is disabled by setting the PSC.NMI2M, PSC.NMI0M, and PSC.INTM bits to 1 (interrupt disabled) becomes invalid and the IDLE mode is not released.

(2) Releasing IDLE mode by reset

The same operation as the normal reset operation is performed.

	Setting of IDLE Mode	When CPU Is Opera	ting with Main Clock				
Item		When Subclock Is Not Used	When Subclock Is Used				
CPU		Stops operation					
ROM correction		Stops operation

<R>

2. Set the ADM.ADCS and ADM.ADCS2 bits to 00B.

Remark n = 0, 1

19.5 STOP Mode

19.5.1 Setting and operation status

The STOP mode is set when the PSMR.PSM bit is set to 1 and the PSC.STP bit is set to 1 in the normal operation mode.

In the STOP mode, the subclock oscillator continues operating but the main clock oscillator stops. Clock supply to the CPU and the on-chip peripheral functions is stopped.

As a result, program execution is stopped, and the contents of the internal RAM before the STOP mode was set are retained. The CPU and other on-chip peripheral functions stop operating. However, the on-chip peripheral functions that can operate with the subclock oscillator or an external clock continue operating.

Table 19-7 shows the operation status in the STOP mode.

Because the STOP mode stops operation of the main clock oscillator, it reduces the power consumption to a level lower than the IDLE mode. If the subclock oscillator and external clock are not used, the power consumption can be minimized with only leakage current flowing.

Caution Insert five or more NOP instructions after the instruction that stores data in the PSC register to set the STOP mode.

19.5.2 Releasing STOP mode

The STOP mode is released by a non-maskable interrupt request signal (NMI pin input, INTWDT2 signal (when the CPU is operating on the subclock)), unmasked external interrupt request signal (INTP0 to INTP6 pin input), unmasked internal interrupt request signal from the peripheral functions operable in the STOP mode, or reset (RESET pin input, WDTRES2 signal (when the CPU is operating on the subclock)).

After the STOP mode has been released, the normal operation mode is restored after the oscillation stabilization time has been secured.

(1) Releasing STOP mode by non-maskable interrupt request signal or unmasked maskable interrupt request signal

The STOP mode is released by a non-maskable interrupt request signal or an unmasked maskable interrupt request signal, regardless of the priority of the interrupt request. If the STOP mode is set in an interrupt servicing routine, however, an interrupt request that is issued later is serviced as follows.

- (a) If an interrupt request signal with a priority lower than that of the interrupt request currently being serviced is issued, only the STOP mode is released, and that interrupt request signal is not acknowledged. The interrupt request signal itself is retained.
- (b) If an interrupt request signal with a priority higher than that of the interrupt request currently being serviced is issued (including a non-maskable interrupt request signal), the STOP mode is released and that interrupt request signal is acknowledged.

Release Source	Interrupt Enabled (EI) Status	Interrupt Disabled (DI) Status
Non-maskable interrupt request signal	Execution branches to the handler address	
Maskable interrupt request signal	Execution branches to the handler address or the next instruction is executed	The next instruction is executed

Table 19-6. Operation After Releasing STOP Mode by Interrupt Request Signal

Caution The interrupt request signal that is disabled by setting the PSC.NMI2M, PSC.NMI0M, and PSC.INTM bits to 1 (interrupt disabled) becomes invalid and the STOP mode is not released.

(2) Releasing STOP mode by reset

The same operation as the normal reset operation is performed.

Se	etting of STOP Mode	When CPU Is Operating with Main Clock	
Item		When Subclock Is Not Used	When Subclock Is Used

<R>

<R>

2. Set the ADM.ADCS and ADM.ADCS2 bits to 00B.

Remark n = 0, 1

19.5.3 Securing oscillation stabilization time when STOP mode is released

When the STOP mode is released, only the oscillation stabilization time set by the OSTS register elapses. If the STOP mode has been released by reset, however, the reset value of the OSTS register, 2^{15} /fx (8.192 ms at fx = 4 MHz) elapses.

The operation performed when the STOP mode is released by an interrupt request signal is shown below.

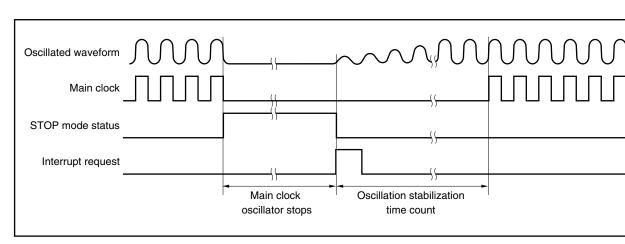

Figure 19-2. Oscillation Stabilization Time

Caution For details of the OSTS register, refer to 19.2 (3) Oscillation stabilization time selection register (OSTS).

19.6 Subclock Operation Mode

19.6.1 Setting and operation status

The subclock operation mode is set when the PCC.CK3 bit is set to 1 in the normal operation mode.

When the subclock operation mode is set, the internal system clock is changed from the main clock to the subclock. When the PCC.MCK bit is set to 1, the operation of the main clock oscillator is stopped. As a result, the system operates only with the subclock.

Table 19-8 shows the operation status in subclock operation mode.

In the subclock operation mode, the power consumption can be reduced to a level lower than in the normal operation mode because the subclock is used as the internal system clock. In addition, the power consumption can be further reduced to the level of the STOP mode by stopping the operation of the main clock oscillator.

- Cautions 1. When manipulating the CK3 bit, do not change the set values of the PCC.CK2 to PCC.CK0 bits (using a bit manipulation instruction to manipulate the bit is recommended). For details, refer to 5.3 (1) Processor clock control register (PCC).
 - If the following conditions are not satisfied, change the CK2 to CK0 bits so that the conditions are satisfied and set the subclock operation mode. Internal system clock (fcLk) > Subclock (fxT: 32.768 kHz) × 4

Remark Internal system clock (fcLK): Clock generated from the main clock (fxx) by setting the CK2 to CK0 bits

19.6.2 Releasing subclock operation mode

The subclock operation mode is released when the CK3 bit is cleared to 0 or by reset ($\overline{\text{RESET}}$ pin input, WDTRES1, WDTRES2 signal). If the main clock is stopped (MCK bit = 1), set the MCK bit to 1, secure the oscillation stabilization time of the main clock by software, and clear the CK3 bit to 0.

The normal operation mode is restored when the subclock operation mode is released.

Caution When manipulating the CK3 bit, do not change the set values of the CK2 to CK0 bits (using a bit manipulation instruction to manipulate the bit is recommended). For details, refer to 5.3 (1) Processor clock control register (PCC).

Setting of Subclock Operation Item Mode		Operation Status	
		When Main Clock Is Oscillating	When Main Clock Is Stopped
CPU		Operable	
ROM correction		Operable	
Subclock oscillate	or	Oscillation enabled

Remark n = 0, 1

<R>

19.7 Sub-IDLE Mode

19.7.1 Setting and operation status

The sub-IDLE mode is set when the PSMR.PSM bit is cleared to 0 and the PSC.STP bit is set to 1 in the subclock operation mode.

In this mode, the clock oscillator continues operation but clock supply to the CPU and the other on-chip peripheral functions is stopped.

As a result, program execution is stopped and the contents of the internal RAM before the sub-IDLE mode was set are retained. The CPU and the other on-chip peripheral functions are stopped. However, the on-chip peripheral functions that can operate with the subclock or an external clock continue operating.

Table 19-10 shows the operation status in the sub-IDLE mode.

Because the sub-IDLE mode stops operation of the CPU and other on-chip peripheral functions, it can reduce the power consumption more than the subclock operation mode. If the sub-IDLE mode is set after the main clock has been stopped, the power consumption can be reduced to a level as low as that in the STOP mode.

Caution Following the store instruction to set the PSC register to the sub-IDLE mode, insert the five or more NOP instructions.

19.7.2 Releasing sub-IDLE mode

The sub-IDLE mode is released by a non-maskable interrupt request signal (NMI pin input, INTWDT2 signal (when the CPU is operating on the subclock)), unmasked external interrupt request signal (INTP0 to INTP6 pin input), unmasked internal interrupt request signal from the peripheral functions operable in the sub-IDLE mode, or reset (RESET pin input, WDTRES2 signal (when the CPU is operating on the subclock)).

When the sub-IDLE mode is released by an interrupt request signal, the subclock operation mode is set. If it is released by reset, the normal operation mode is restored.

(1) Releasing sub-IDLE mode by non-maskable interrupt request signal or unmasked maskable interrupt request signal

The sub-IDLE mode is released by a non-maskable interrupt request signal or an unmasked maskable interrupt request signal, regardless of the priority of the interrupt request. If the sub-IDLE mode is set in an interrupt servicing routine, however, an interrupt request signal that is issued later is serviced as follows.

- (a) If an interrupt request signal with a priority lower than that of the interrupt request currently being serviced is issued, only the sub-IDLE mode is released, and that interrupt request signal is not acknowledged. The interrupt request signal itself is retained.
- (b) If an interrupt request signal with a priority higher than that of the interrupt request currently being serviced is issued (including a non-maskable interrupt request signal), the sub-IDLE mode is released and that interrupt request signal is acknowledged.

Release Source	Interrupt Enabled (EI) Status	Interrupt Disabled (DI) Status
Non-maskable interrupt request signal	Execution branches to the handler address	
Maskable interrupt request signal	Execution branches to the handler address or the next instruction is executed	The next instruction is executed

Table 19-9. Operation After Releasing Sub-IDLE Mode by Interrupt Request Signal

Caution The interrupt request signal that is disabled by setting the PSC.NMI2M, PSC.NMI0M, and PSC.INTM bits to 1 (interrupt disabled) becomes invalid and the sub-IDLE mode is not released.

(2) Releasing sub-IDLE mode by reset

The same operation as the normal reset operation is performed.

	Setting of Sub-IDLE	Operation Status	
Item	Mode	When Main Clock Is Oscillating	When Main Clock Is Stopped
CPU		Stops operation	
ROM correction		Stops operation	
Subclock oscillator		Oscillation enabled	
Interrupt controller		Stops operation

CHAPTER 20 RESET FUNCTION

20.1 Overview

The following reset functions are available.

- Reset function by RESET pin input
- Reset function by overflow of watchdog timer 1 (WDTRES1)
- Reset function by overflow of watchdog timer 2 (WDTRES2)

If the RESET pin goes high, the reset status is released, and the CPU starts executing the program. Initialize the contents of each register in the program as necessary.

The RESET pin has a noise eliminator that operates by analog delay to prevent malfunction caused by noise.

20.2 Configuration

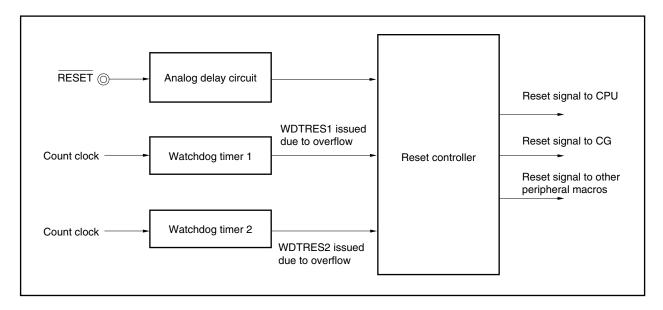

Figure 20-1. Reset Block Diagram

20.3 Operation

The system is reset, initializing each hardware unit, when a low level is input to the **RESET** pin or if watchdog timer 1 or watchdog timer 2 overflows (WDTRES1 or WDTRES2).

While a low level is being input to the RESET pin, the main clock oscillator stops. Therefore, the overall power consumption of the system can be reduced.

If the RESET pin goes high or if the WDTRES1 or WDTRES2 signal is received, the reset status is released.

If the reset status is released by $\overline{\text{RESET}}$ pin input or the WDTRES2 signal, the oscillation stabilization time elapses (reset value of OSTS register: 2¹⁵/fxx) and then the CPU starts program execution.

If the reset status is released by the WDTRES1 signal, the oscillation stabilization time is not inserted because the main clock oscillator does not stop.

<R>

Table 20-1. Hardware Status on RESET Pin Input or Occurrence of WDTRES2 Signal

ltem	During Reset	After Reset	
Main clock oscillator (fx)	Oscillation stops	Oscillation starts	
Subclock oscillator (fxT)	Oscillation continues	Oscillation continues	
Peripheral clock (fxx to fxx/1024)	Operation stops	Operation starts after securing oscillation stabilization time	
Internal system clock (fclk)	Operation stops	Operation starts after securing oscillation stabilization time (initialized to fxx/8)	
CPU clock (fcpu)	Operation stops	Operation starts after securing oscillation stabilization time (initialized to fxx/8)	
Watchdog timer 1 clock (fxw)	Operation stops	Operation starts	
CPU	Initialized	Program execution starts after securing oscillation stabilization time	
Internal RAM	Undefined if power-on reset or writing data to RAM (by CPU) and reset input conflict (data is damaged). Otherwise value immediately before reset input is retained.		
I/O lines	High impedance		
On-chip peripheral I/O registers	Initialized to specified status		
Watchdog timer 2	Operation stops	Operation starts after securing oscillation stabilization time	
Other on-chip peripheral functions	Operation stops	Operation can be started after securing oscillation stabilization time	

<R>

Table 20-2. Hardware Status on Occurrence of WDTRES1 Signal

Item	During Reset	After Reset	
Main clock oscillator (fx)	Oscillation continues	Oscillation continues	
Subclock oscillator (fxt)	Oscillation continues	Oscillation continues	
Peripheral clock (fxx to fxx/1024)	Operation stops Operation starts		
Internal system clock (fclk)	Oscillation continues (initialized to fxx/8)		
CPU clock (fcpu)	Oscillation continues (initialized to fxx/8)		
Watchdog timer 1 clock (fxw)	Operation continues		
Internal RAM	Undefined if writing data to RAM (by CPU) and reset input conflict (data is damaged). Otherwise value immediately before reset input is retained.		
I/O lines	High impedance		
On-chip peripheral I/O registers	Initialized to specified status

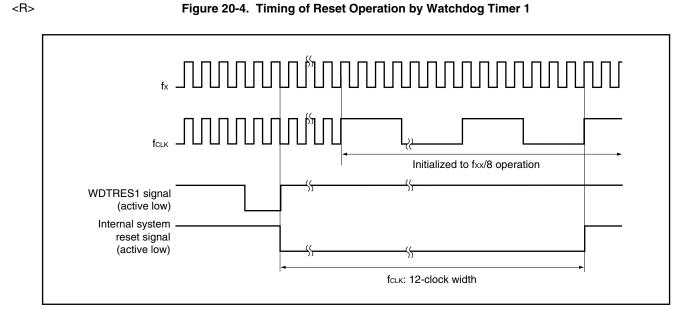

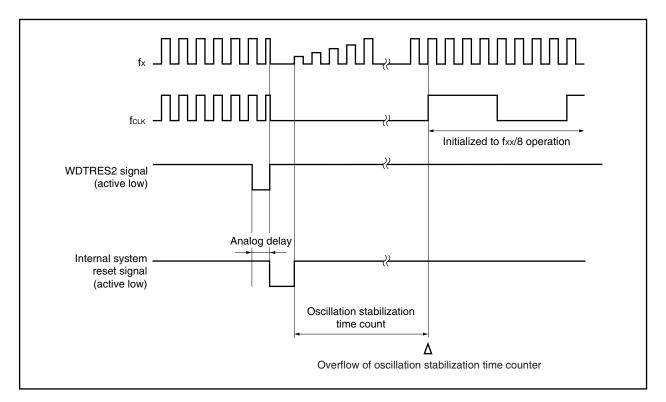

Figure 20-5. Timing of Reset Operation by Watchdog Timer 2

CHAPTER 21 ROM CORRECTION FUNCTION

21.1 Overview

The ROM correction function is used to replace part of the program in the internal ROM with the program of an external memory or the internal RAM.

By using this function, program bugs found in the internal ROM can be corrected.

Up to four addresses can be specified for correction.

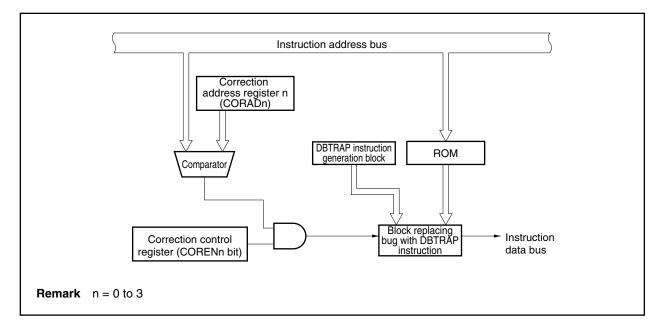

Figure 21-1. Block Diagram of ROM Correction

21.2 Registers

(1) Correction address registers 0 to 3 (CORAD0 to CORAD3)

These registers are used to set the first address of the program to be corrected.

The program can be corrected at up to four places because four CORADn registers are provided.

The CORADn register can be read or written in 32-bit units.

If the higher 16 bits of the CORADn register are used as the CORADnH register, and the lower 16 bits as the CORADnL register, these registers can be read or written in 16-bit units.

Reset sets CORADn to 0000000H.

Set correction addresses in the range of 0000000H to 001FFFEH in the V850ES/KE1. Bits 0 and 20 to 31 are fixed to 0.

After reset: 0000000H R/W Address: CORAD0 FFFFF840H, CORADOL FFFFF840H, CORADOH FFFFF842H, CORAD1 FFFFF844H, CORAD1L FFFFF844H, CORAD1H FFFFF846H, CORAD2 FFFFF848H, CORAD2L FFFFF848H, CORAD2H FFFFF84AH, CORAD3 FFFFF84CH, CORAD3L FFFFF84CH, CORAD3H FFFFF84EH 20 19 17 16 31 1 0 CORADn Fixed to 0 Note Correction address 0 (n = 0 to 3)Note Be sure to clear these bits to 0.

(2) Correction control register (CORCN)

This register disables or enables the correction operation at the address specified by the CORADn register. Each channel can be enabled or disabled by this register. This register can be read or written in 8-bit or 1-bit units.

Reset sets CORCN to 00H.

After res	et: 00H	R/W	Address:	FFFFF880	Н				
	7	6	5	4	<3>	<2>	<1>	<0>	
CORCN	0	0	0	0	COREN3	COREN2	COREN1	COREN0	
	CORENn		(Correction c	peration er	nable/disab	le		
	0	Disabled							
	1	Enabled							
	Remark	n = 0 to 3	3						

Table 21-1. Correspondence Between CORCN Register Bits and CORADn Registers

CORCN Register Bit	Corresponding CORADn Register
COREN3	CORAD3
COREN2	CORAD2
COREN1	CORAD1
COREN0	CORAD0

21.3 ROM Correction Operation and Program Flow

- <1> If the address to be corrected and the fetch address of the internal ROM match, the fetch code is replaced by the DBTRAP instruction.
- <2> When the DBTRAP instruction is executed, execution branches to address 00000060H.
- <3> Software processing after branching causes the result of ROM correction to be judged (the fetch address and ROM correction operation are confirmed) and execution to branch to the correction software.
- <4> After the correction software has been executed, the return address is set, and return processing is started by the DBRET instruction.
- Cautions 1. The software that performs <3> and <4> must be executed in the external memory or internal RAM.
 - 2. When setting an address to be corrected to the CORADn register, clear the higher bits to 0 in accordance with the capacity of the internal ROM.
 - 3. The ROM correction function cannot be used to correct the data of the internal ROM. It can only be used to correct instruction codes. If ROM correction is used to correct data, that data is replaced with the DBTRAP instruction code.

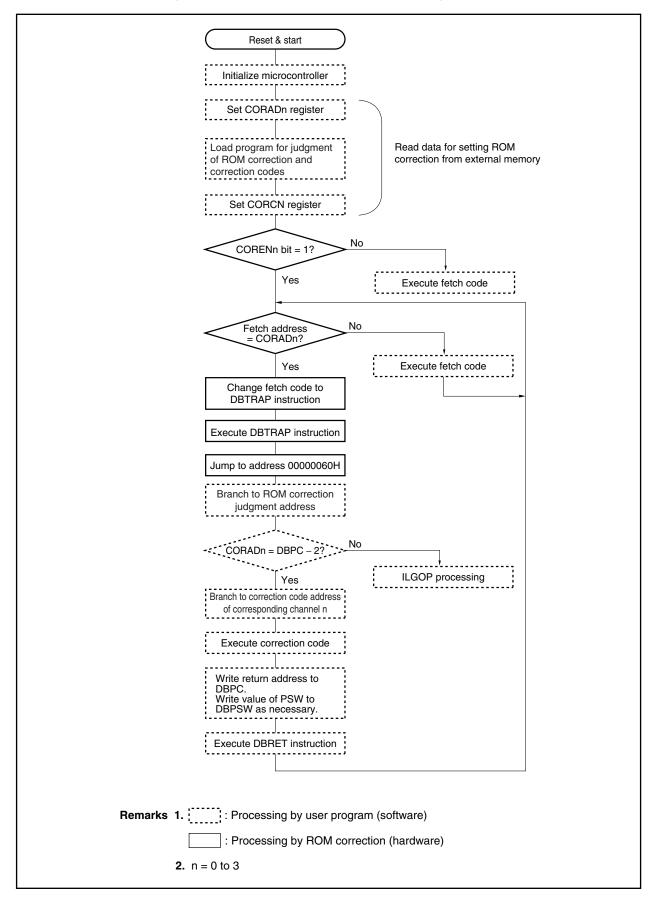

Figure 21-2. ROM Correction Operation and Program Flow

CHAPTER 22 FLASH MEMORY

The following products are the flash memory versions (single power supply) of the V850ES/KE1.

- Caution There are differences in noise immunity and noise radiation between the flash memory and mask ROM versions. When pre-producing and application set with the flash memory version and then mass-producing it with the mask ROM version, be sure to conduct sufficient evaluation for the commercial samples (not engineering samples) of the mask ROM version. For the electrical specifications related to the flash memory rewriting, refer to CHAPTER 24 ELECTRICAL SPECIFICATIONS.
- μPD70F3207H, 70F3207HY: On-chip 128 KB flash memory

Flash memory versions are commonly used in the following development environments and mass production applications.

- O For altering software after the V850ES/KE1 is soldered onto the target system.
- O For data adjustment when starting mass production.
- O For differentiating software according to the specification in small scale production of various models.
- O For facilitating inventory management.
- O For updating software after shipment.

22.1 Features

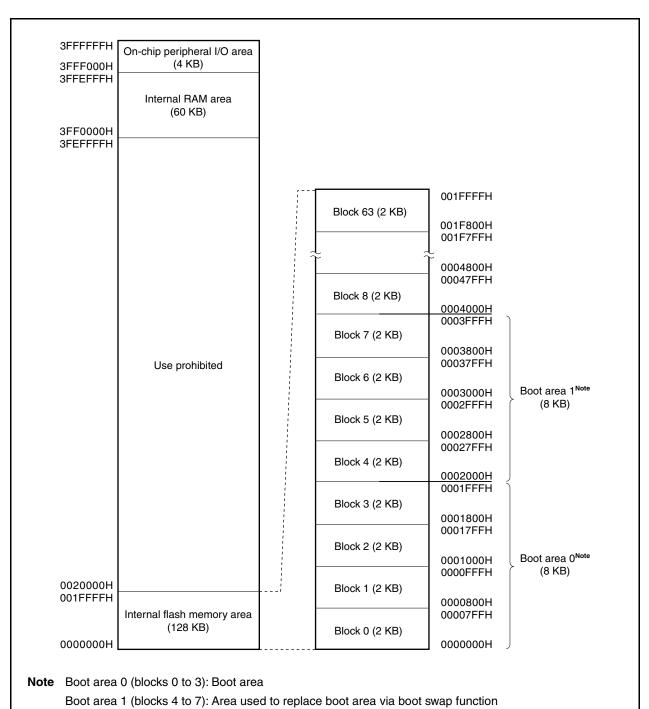

- O 4-byte/1-clock access (when instruction is fetched)
- O Capacity: 128 KB
- O Write voltage: Erase/write with a single power supply
- O Rewriting method
 - Rewriting by communication with dedicated flash programmer via serial interface (on-board/off-board programming)
 - Rewriting flash memory by user program (self programming)
- O Flash memory write prohibit function supported (security function)
- O Safe rewriting of entire flash memory area by self programming using boot swap function
- O Interrupts can be acknowledged during self programming.

Caution TM50 and TM51 (including interrupts INTTM50 and INTTM51) cannot be used during self programming. For details, refer to 22.5.6 Internal resources used.

22.2 Memory Configuration

The 128 KB internal flash memory area is divided into 64 blocks and can be programmed/erased in block units. All the blocks can also be erased at once.

When the boot swap function is used, the physical memory (blocks 0 to 3) located at the addresses of boot area 0 is replaced by the physical memory (blocks 4 to 7) located at the addresses of boot area 1. For details of the boot swap function, refer to **22.5 Rewriting by Self Programming**.

22.3 Functional Outline

The internal flash memory of the V850ES/KE1 can be rewritten by using the rewrite function of the dedicated flash programmer, regardless of whether the V850ES/KE1 has already been mounted on the target system or not (on-board/off-board programming).

In addition, a security function that prohibits rewriting the user program written to the internal flash memory is also supported, so that the program cannot be changed by an unauthorized person.

The rewrite function using the user program (self programming) is ideal for an application where it is assumed that the program is changed after production/shipment of the target system. A boot swap function that rewrites the entire flash memory area safely is also supported. In addition, interrupt servicing is supported during self programming, so that the flash memory can be rewritten under various conditions, such as while communicating with an external device.

Rewrite Method	Functional Outline	Operation Mode
On-board programming	Flash memory can be rewritten after the device is mounted on the target system, by using a dedicated flash programmer.	Flash memory programming mode
Off-board programming	Flash memory can be rewritten before the device is mounted on the target system, by using a dedicated flash programmer and a dedicated program adapter board (FA series).	
Self programming	Flash memory can be rewritten by executing a user program that has been written to the flash memory in advance by means of on-board/off- board programming. (During self-programming, instructions cannot be fetched from or data access cannot be made to the internal flash memory area. Therefore, the rewrite program must be transferred to the internal RAM or external memory in advance).	Normal operation mode

Table 22-1. Rewrite Method

Remark The FA series is a product of Naito Densei Machida Mfg. Co., Ltd.

	Function	Functional Outline	Support (O: Support	ed, \times : Not supported)
			On-Board/Off-Board Programming	Self Programming
	Block erasure	The contents of specified memory blocks are erased.	0	0
	Chip erasure	The contents of the entire memory area are erased all at once.	0	×
	Write	Writing to specified addresses, and a verify check to see if write level is secured are performed.	0	0
	Verify/checksum	Data read from the flash memory is compared with data transferred from the flash programmer.	0	× (Can be read by user program)
	Blank check	The erasure status of the entire memory is checked.	0	0
<r></r>	Security setting	Use of the block erase command, chip erase command, program command, and read command can be prohibited, and rewriting boot area can be prohibited.	0	× (Supported only when setting is changed from enable to disable)

Table 22-2. Basic Functions

The following table lists the security functions. The block erase command prohibit, chip erase command prohibit, and program command prohibit functions are enabled by default after shipment, and security can be set by rewriting via on-board/off-board programming. Each security function can be used in combination with the others at the same time.

<R>

Table 22-3. Security Functions

Function	Functional Outline
Block erase command prohibit	Execution of a block erase command on all blocks is prohibited. Setting of prohibition can be initialized by execution of a chip erase command.
Chip erase command prohibit	Execution of block erase and chip erase commands on all the blocks is prohibited. Once prohibition is set, setting of prohibition cannot be initialized because the chip erase command cannot be executed.
Program command prohibit	Execution of program and block erase commands on all the blocks is prohibited. Setting of prohibition can be initialized by execution of the chip erase command.
Read command prohibit	Executing of a read command on all blocks is prohibited. Setting of prohibition can be initialized by execution of the chip erase command.
Boot area rewrite prohibit	Boot areas from block 0 to the specified last block can be protected. The protected boot area cannot be rewritten (erased and written). Setting of prohibition cannot be initialized by execution of the chip erase command.

<R>

Table 22-4. Security Setting

Function		ations When Each Security Is Set Executable, –: Not Supported)	Notes on Se	curity Setting
	On-Board/ Off-Board Programming	Self Programming	On-Board/ Off-Board Programming	Self Programming
Block erase command prohibit	Block erase command: × Chip erase command: √ Program command: √ Read command: √	Block erasure (FlashBlockErase): √ Chip erasure: – Write (FlashWordWrite): √ Read (FlashWordRead): √	Setting of prohibition can be initialized by chip erase command.	Supported only when setting is changed from enable to prohibit
Chip erase command prohibit	Block erase command: \times Chip erase command: \times Program command: \checkmark Read command: \checkmark	Block erasure (FlashBlockErase): √ Chip erasure: – Write (FlashWordWrite): √ Read (FlashWordRead): √	Setting of prohibition cannot be initialized.	
Program command prohibit	Block erase command: × Chip erase command: √ ^{Note 1} Program command: × Read command: √	Block erasure (FlashBlockErase): √ Chip erasure: – Write (FlashWordWrite): √ Read (FlashWordRead): √	Setting of prohibition can be initialized by chip erase command.	
Read command prohibit	Block erase command: √ Chip erase command: √ Program command: √ Read command: ×	Block erasure (FlashBlockErase): √ Chip erasure: – Write (FlashWordWrite): √ Read (FlashWordRead): √	Setting of prohibition can be initialized by chip erase command.	
Boot area rewrite prohibit	Block erase command: $\sqrt{Note 2}$ Chip erase command: \times Program command: $\sqrt{Note 2}$ Read command: $$	Block erasure (FlashBlockErase): √ Chip erasure: – Write (FlashWordWrite): √ Read (FlashWordRead): √	Setting of prohibition cannot be initialized.	

Notes 1. In this case, since the erase command is invalid, data different from the data already written in the flash memory cannot be written.

2. The boot area for which rewriting is prohibited is invalid.

<R> (1) Security setting by PG-FP4 (Security flag settings)

When disabling the read command (Disable Read), to raise the security level, it is recommended to also disable the block erase command (Disable Block Erase) and program command (Disable Program). Furthermore, similar to the mask ROM products, when program rewriting is not necessary, additionally disable the chip erase command (Disable Chip Erase).

reprogramming" in "Security flag settings" and select the last block of the boot area for which rewriting is to be disabled.

22.4 Rewriting by Dedicated Flash Programmer

The flash memory can be rewritten by using a dedicated flash programmer after the V850ES/KE1 is mounted on the target system (on-board programming). The flash memory can also be rewritten before the device is mounted on the target system (off-board programming) by using a dedicated program adapter (FA series).

22.4.1 Programming environment

The following shows the environment required for writing programs to the flash memory of the V850ES/KE1.

A host machine is required for controlling the dedicated flash programmer.

UART0 or CSI00 is used for the interface between the dedicated flash programmer and the V850ES/KE1 to perform writing, erasing, etc. A dedicated program adapter (FA series) is required for off-board writing.

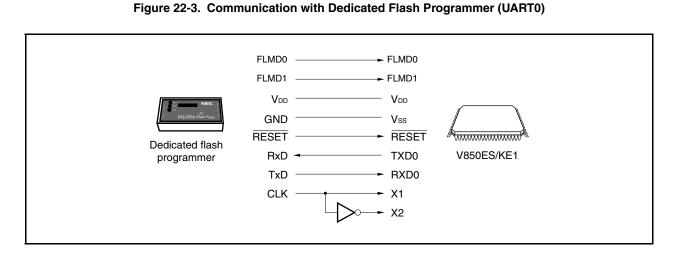

Remark The FA series is a product of Naito Densei Machida Mfg. Co., Ltd.

22.4.2 Communication mode

Communication between the dedicated flash programmer and the V850ES/KE1 is performed by serial communication using the UART0 or CSI00 interfaces of the V850ES/KE1.

(1) UART0

Transfer rate: 9,600 to 153,600 bps

(2) CSI00

Serial clock: 2.4 kHz to 2.5 MHz (MSB first)

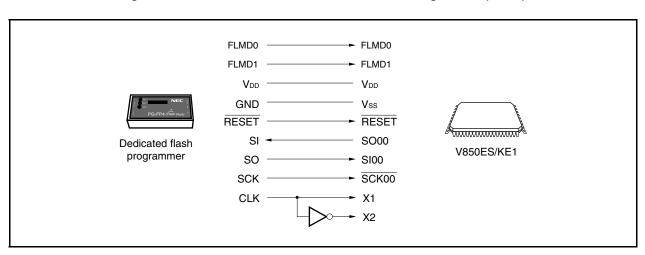

Figure 22-4. Communication with Dedicated Flash Programmer (CSI00)

(3) CSI00 + HS

Serial clock: 2.4 kHz to 2.5 MHz (MSB first)

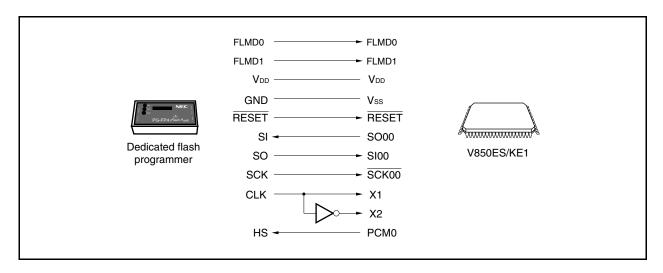

Figure 22-5. Communication with Dedicated Flash Programmer (CSI00 + HS)

The dedicated flash programmer outputs the transfer clock, and the V850ES/KE1 operates as a slave.

When the PG-FP4 is used as the dedicated flash programmer, it generates the following signals to the V850ES/KE1. For details, refer to the **PG-FP4 User's Manual (U15260E)**.

	PG-FP4			Proces	ssing for Conr	nection
Signal Name	I/O	Pin Function	Pin Name	UART0	CSI00	CSI00 + HS
FLMD0	Output	Write enable/disable	FLMD0	0	O	0

Table 22-6. Wiring Between μ PD70F3207H, 70F3207HY and PG-FP4

Note When using the clock out of the flash programmer, connect CLK of the programmer to X1, and connect its inverse signal to X2.

Figure 22-6. Wiring Example of V850ES/KE1 Flash Writing Adapter (FA-64GK-9ET-A, FA-64GB-8EU-A) (1/2)

<R>

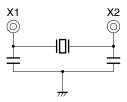

<R> Figure 22-6. Wiring Example of V850ES/KE1 Flash Writing Adapter (FA-64GK-9ET-A, FA-64GB-8EU-A) (2/2)

Notes 1. Wire the FLMD1 pin as shown in the figure, or connect it to GND on board via a pull-down resistor.

- 2. The above figure shows an example of wiring when the clock is supplied from the PG-FP4. Be sure to set and connect as follows when the clock is supplied from the PG-FP4.
 - Set J1 of the flash adapter (FA) to the VDD side.
 - Connect CLKOUT of FA to CLKIN of FA.
 - Connect X1 of FA to X1 of the device.
 - Connect X2 of FA to X2 of the device.

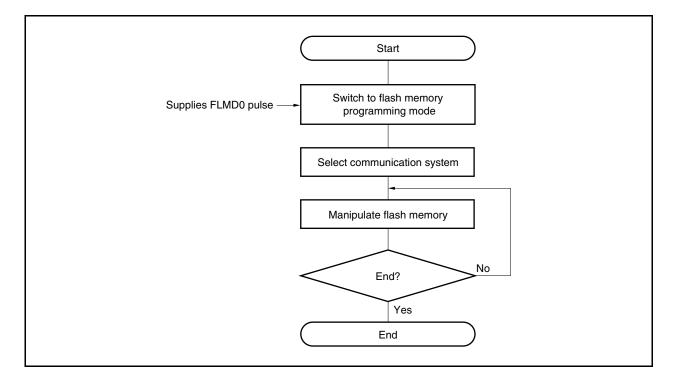

If an oscillator is created on the flash adapter and a clock is supplied, the above setting and connections will not necessary. The following shows a circuit example.

- 3. Corresponding pin when using UART0
- **Remarks 1.** Handle the pins not described above in accordance with the specified handling of unused pins (refer to **2.2 Pin I/O Circuits and Recommended Connection of Unused Pins).** When connecting to VDD via a resistor, use of a resistor of 1 k Ω to 10 k Ω is recommended.
 - **2.** This adapter is for a 64-pin plastic TQFP or 64-pin plastic LQFP (fine pitch) package.
 - 3. This diagram shows the wiring when using a handshake-supporting CSI.

22.4.3 Flash memory control

The following shows the procedure for manipulating the flash memory.

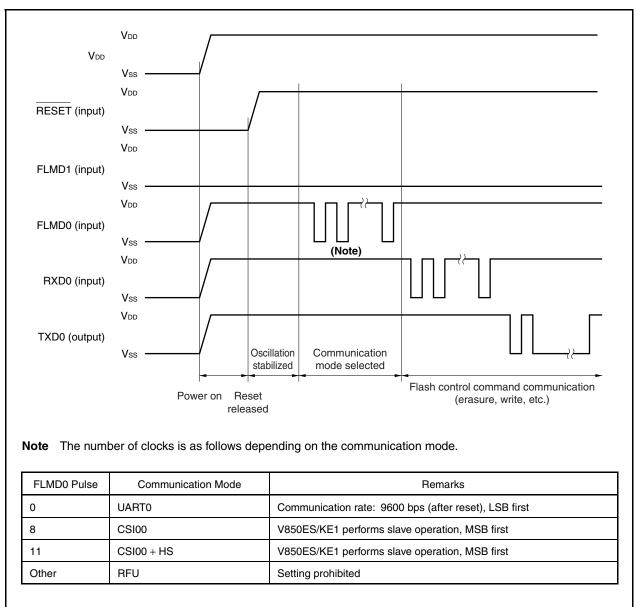

22.4.4 Selection of communication mode

In the V850ES/KE1, the communication mode is selected by inputting pulses (12 pulses max.) to the FLMD0 pin after switching to the flash memory programming mode. The FLMD0 pulse is generated by the dedicated flash programmer.

The following shows the relationship between the number of pulses and the communication mode.

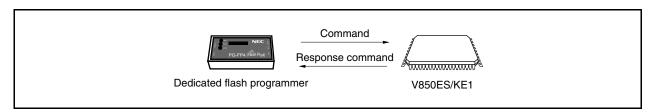

Caution When UART0 is selected, the receive clock is calculated based on the reset command sent from the dedicated flash programmer after receiving the FLMD0 pulse.

22.4.5 Communication commands

The V850ES/KE1 communicates with the dedicated flash programmer by means of commands. The signals sent from the dedicated flash programmer to the V850ES/KE1 are called "commands". The response signals sent from the V850ES/KE1 to the dedicated flash programmer are called "response commands".

Figure 22-9. Communication Commands

The following shows the commands for flash memory control in the V850ES/KE1. All of these commands are issued from the dedicated flash programmer, and the V850ES/KE1 performs the processing corresponding to the commands.

Classification	Command Name		Support		Function
		CSI00	CSI00 + HS	UART0	
Blank check	Block blank check command	0	0	0	Checks if the contents of the memory in the specified block have been correctly erased.
Erase	Chip erase command	0	0	0	Erases the contents of the entire memory.
	Block erase command	0	0	0	Erases the contents of the memory of the specified block.
Write	Program command	0	0	0	Writes the specified address range, and executes a contents verify check.
Verify	Verify command	0	0	0	Compares the contents of memory in the specified address range with data transferred from the flash programmer.
	Checksum command	0	0	0	Reads the checksum in the specified address range.
System setting, control	Silicon signature command	0	0	0	Reads silicon signature information.
	Security setting command	0	0	0	Disables chip erase, block erase, program, and read commands and disables rewriting the boot area.

Table 22-7. Flash Memory Control Commands

22.4.6 Pin connection

When performing on-board writing, mount a connector on the target system to connect to the dedicated flash programmer. Also, incorporate a function on-board to switch from the normal operation mode to the flash memory programming mode.

In the flash memory programming mode, all the pins not used for flash memory programming become the same status as that immediately after reset. Therefore, pin handling is required when the external device does not acknowledge the status immediately after a reset.

(1) FLMD0 pin

In the normal operation mode, input a voltage of Vss level to the FLMD0 pin. In the flash memory programming mode, supply a write voltage of Vbb level to the FLMD0 pin.

Because the FLMD0 pin serves as a write protection pin in the self programming mode, a voltage of V_{DD} level must be supplied to the FLMD0 pin via port control, etc., before writing to the flash memory. For details, refer to **22.5.5 (1)** FLMD0 pin.

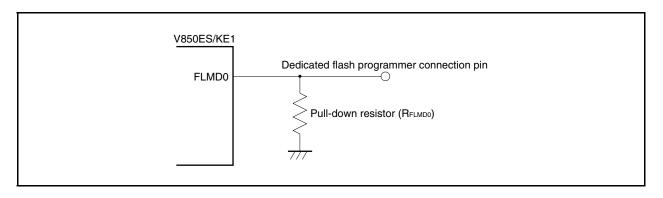

Figure 22-10. FLMD0 Pin Connection Example

(2) FLMD1 pin

When 0 V is input to the FLMD0 pin, the FLMD1 pin does not function. When V_{DD} is supplied to the FLMD0 pin, the flash memory programming mode is entered, so 0 V must be input to the FLMD1 pin. The following shows an example of the connection of the FLMD1 pin.

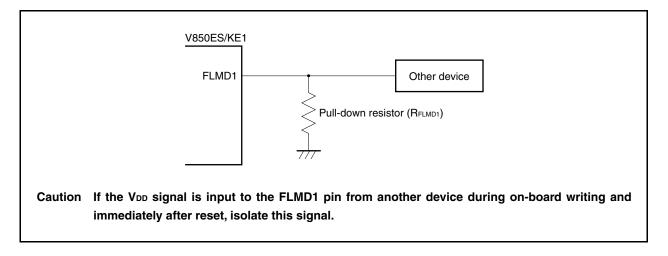

Table 22-8. Relationship Between FLMD0 and FLMD1 Pins and Operation Mode When Reset Is Released

FLMD0	FLMD1	Operation Mode
0	don't care	Normal operation mode
V _{DD}	0	Flash memory programming mode
VDD	Vdd	Setting prohibited

(3) Serial interface pin

The following shows the pins used by each serial interface.

Serial Interface	Pins Used
UART0	TXD0, RXD0
CSI00	SO00, SI00, SCK00
CSI00 + HS	SO00, SI00, SCK00, PCM0

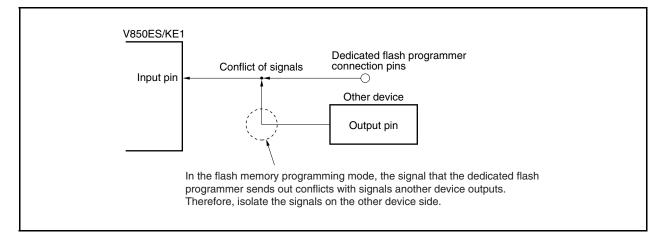

Table 22-9. Pins Used by Serial Interfaces

When connecting a dedicated flash programmer to a serial interface pin that is connected to another device on-board, care should be taken to avoid conflict of signals and malfunction of the other device.

(a) Conflict of signals

When the dedicated flash programmer (output) is connected to a serial interface pin (input) that is connected to another device (output), a conflict of signals occurs. To avoid the conflict of signals, isolate the connection to the other device or set the other device to the output high-impedance status.

(b) Malfunction of other device

When the dedicated flash programmer (output or input) is connected to a serial interface pin (input or output) that is connected to another device (input), the signal is output to the other device, causing the device to malfunction. To avoid this, isolate the connection to the other device.

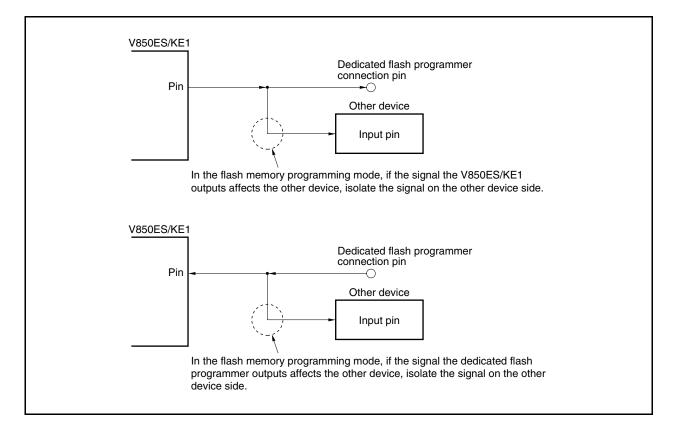

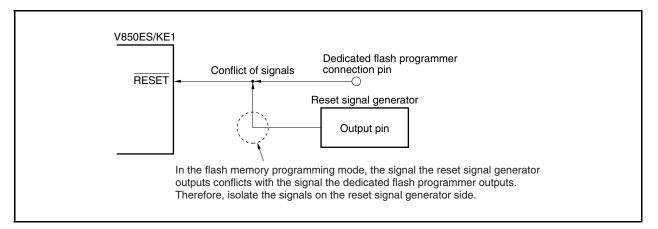

Figure 22-13. Malfunction of Other Device

(4) RESET pin

When the reset signals of the dedicated flash programmer are connected to the RESET pin that is connected to the reset signal generator on-board, a conflict of signals occurs. To avoid the conflict of signals, isolate the connection to the reset signal generator.

When a reset signal is input from the user system in the flash memory programming mode, the programming operation will not be performed correctly. Therefore, do not input signals other than the reset signals from the dedicated flash programmer.

(5) Port pins (including NMI)

When the system shifts to the flash memory programming mode, all the pins that are not used for flash memory programming are in the same status as that immediately after reset. If the external device connected to each port does not recognize the status of the port immediately after reset, pins require appropriate processing, such as connecting to V_{DD} via a resistor or connecting to V_{SS} via a resistor.

(6) Other signal pins

Connect X1, X2, XT1, and XT2 in the same status as that in the normal operation mode.

(7) Power supply

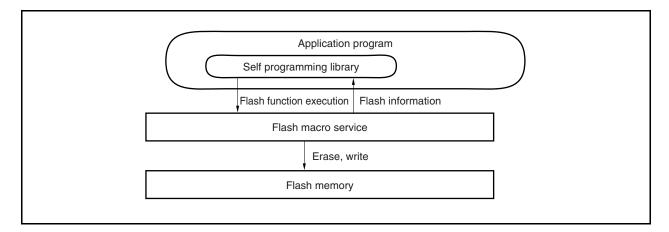

Supply the same power (VDD, VSS, EVDD, EVSS, AVSS, AVREFO) as in normal operation mode.

22.5 Rewriting by Self Programming

22.5.1 Overview

The V850ES/KE1 supports a flash macro service that allows the user program to rewrite the internal flash memory by itself. By using this interface and a self programming library that is used to rewrite the flash memory with a user application program, the flash memory can be rewritten by a user application transferred in advance to the internal RAM or external memory. Consequently, the user program can be upgraded and constant data can be rewritten in the field.

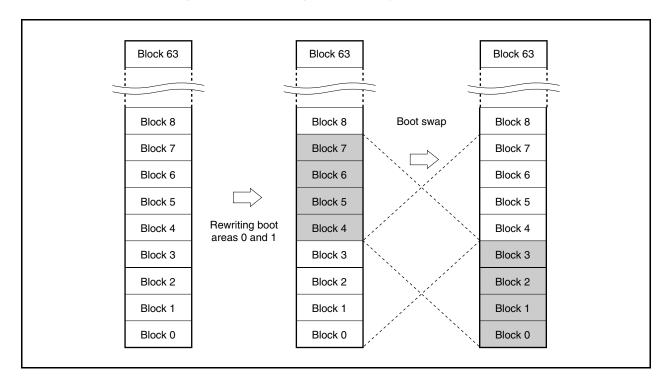

22.5.2 Features

(1) Secure self programming (boot swap function)

The V850ES/KE1 supports a boot swap function that can exchange the physical memory (blocks 0 to 3) of boot area 0 with the physical memory (blocks 4 to 7) of boot area 1. By writing the start program to be rewritten to boot area 1 in advance and then swapping the physical memory, the entire area can be safely rewritten even if a power failure occurs during rewriting because the correct user program always exists in boot area 0.

<R> (2) Interrupt support

Instructions cannot be fetched from the flash memory during self programming. Conventionally, therefore, a user handler written to the flash memory could not be used even if an interrupt occurred. Therefore, in the V850ES/KE1, to use an interrupt during self programming, processing transits to the specific address^{Note} in the internal RAM. Allocate the jump instruction that transits processing to the user interrupt servicing at the specific address^{Note} in the internal RAM.

 Note
 NMI interrupt:
 Start address of internal RAM

 Maskable interrupt:
 Start address of internal RAM + 4 addresses

22.5.3 Standard self programming flow

The entire processing to rewrite the flash memory by flash self programming is illustrated below.

22.5.4 Flash functions

Function Name	Outline	Support
FlashEnv	Initialization of flash control macro	V
FlashBlockErase	Erasure of only specified one block	V
FlashWordWrite	Writing from specified address	V
FlashBlockIVerify	Internal verification of specified block	V
FlashBlockBlankCheck	Blank check of specified block	V
FlashFLMDCheck	Check of FLMD pin	V
FlashGetInfo	Reading of flash information	V
FlashSetInfo	Setting of flash information	V
FlashBootSwap	Swapping of boot area	V
FlashWordRead	Reading data from specified address	V

Table 22-10. Main Flash Function List

Remark For details, refer to the V850 Series Flash Memory Self Programming (Single Power Supply Flash Memory) User's Manual.

Contact an NEC Electronics sales representative for the above manual.

22.5.5 Pin processing

(1) FLMD0 pin

The FLMD0 pin is used to set the operation mode when reset is released and to protect the flash memory from being written during self rewriting. It is therefore necessary to keep the voltage applied to the FLMD0 pin at 0 V when reset is released and a normal operation is executed. It is also necessary to apply a voltage of V_{DD} level to the FLMD0 pin during the self programming mode period via port control before the memory is rewritten.

When self programming has been completed, the voltage on the FLMD0 pin must be returned to 0 V.

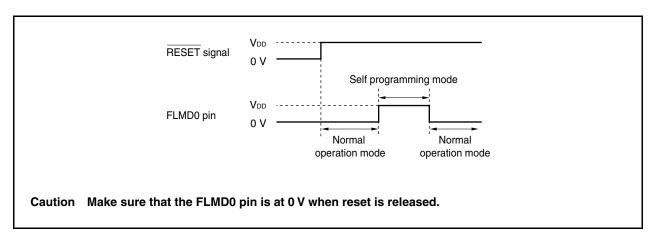

Figure 22-18. Mode Change Timing

22.5.6 Internal resources used

The following table lists the internal resources used for self programming. These internal resources can also be used freely for purposes other than self programming.

Table 22-11. Internal Resources Used

Resource Name	Description
Entry RAM area (internal RAM/external RAM size: 136 bytes)	Routines and parameters used for the flash macro service are located in this area. The entry program and default parameters are copied by calling a library initialization function.
Stack area (stack size: 600 bytes)	An extension of the stack used by the user is used by the library (can be used in both the internal RAM and external RAM).
Library code (code size: Approx. 1600 bytes)	Program entity of library (can be used anywhere other than the flash memory block to be manipulated).
Application program	Executed as user application. Calls flash functions.
Maskable interrupt	Can be used in user application execution status or self programming status. To use this interrupt in the self-programming status, since the processing transits to the address of the internal RAM start address + 4 addresses (3FFE004H), allocate the jump instruction that transits the processing to the user interrupt servicing at the address of the internal RAM start address + 4 addresses (3FFE004H) in advance.
NMI interrupt	Can be used in user application execution status or self programming status. To use this interrupt in the self-programming status, since the processing transits to the address of the internal RAM start address (3FFE000H), allocate the jump instruction that transits the processing to the user interrupt servicing at the internal RAM start address (3FFE000H) in advance.
TM50, TM51	Because TM50 and TM51 are used in the flash macro service, do not use them in the self programming status. When using TM50 and TM51 after self programming, set them again.

Remark For details, refer to the V850 Series Flash Memory Self Programming (Single Power Supply Flash Memory) User's Manual. Contact an NEC Electronics sales representative for the above manual.

CHAPTER 23 ON-CHIP DEBUG FUNCTION

The V850ES/KE1 is not provided with an on-chip debug function. However, a pseudo on-chip debug function can be realized by using the on-chip debug emulator (MINICUBE[®]) and debug adapter (QB-V850ESKX1-DA). For connection examples, refer to **A.4.2 When using MINICUBE QB-V850MINI**.

23.1 ROM Security Function

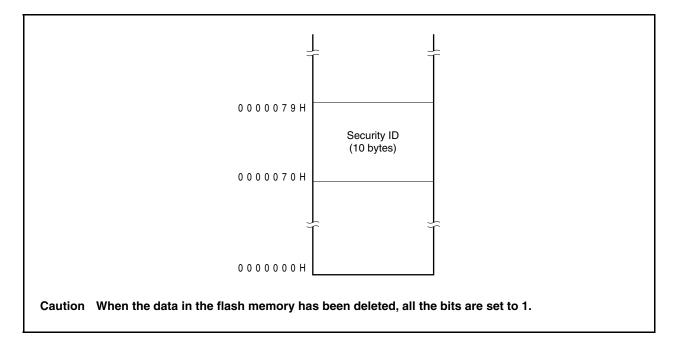

23.1.1 Security ID

The flash memory versions of the V850ES/KE1 perform authentication using a 10-byte ID code to prevent the contents of the flash memory from being read by an unauthorized person during on-chip debugging by the on-chip debug emulator.

Set the ID code in the 10-byte on-chip flash memory area from 0000070H to 0000079H to allow the debugger perform ID authentication.

If the IDs match, the security is released and reading flash memory and using the on-chip debug emulator are enabled.

- Set the 10-byte ID code to 0000070H to 0000079H.
- Bit 7 of 0000079H is the on-chip debug emulator enable flag.
 (0: Disable, 1: Enable)
- When the on-chip debug emulator is started, the debugger requests ID input. When the ID code input on the debugger and the ID code set in 0000070H to 0000079H match, the debugger starts.
- Debugging cannot be performed if the on-chip debug emulator enable flag is 0, even if the ID codes match.

<R>

23.1.2 Setting

The following shows how to set the ID code as shown in Table 23-1.

When the ID code is set as shown in Table 23-1, the ID code input in the configuration dialog box of the ID850QB is "123456789ABCDEF123D4" (not case sensitive).

Address	Value
0x70	0x12
0x71	0x34
0x72	0x56
0x73	0x78
0x74	0x9A
0x75	0xBC
0x76	0xDE
0x77	0XF1
0x78	0x23
0x79	0xD4

The ID code can be specified for the device file that supports the CA850 Ver. 2.60 or later and the security ID by the PM+ linker option setting.

Compiler Common (×

[Program example (when using CA850 Ver. 2.60 or later)]

23.2 Cautions

- If a reset signal is input (from the target system or a reset signal from an internal reset source) during RUN (program execution), the break function may malfunction.
- (2) Even if the reset signal is masked by the mask function, the I/O buffer (port pin) may be reset if a reset signal is input from a pin.
- (3) Because a software breakpoint set in the internal flash memory is realized by the ROM correction function, it is made temporarily invalid by target reset or internal reset generated by watchdog timer 2. The breakpoint becomes valid again when a hardware break or forced break occurs, but a software break does not occur until then.
- (4) Pin reset during a break is masked and the CPU and peripheral I/O are not reset. If pin reset or internal reset is generated as soon as the flash memory is read by the RAM monitor function while the user program is being executed, the CPU and peripheral I/O may not be correctly reset.
- (5) Emulation of ROM correction cannot be executed.

CHAPTER 24 ELECTRICAL SPECIFICATIONS

Parameter	Symbol	Conditions		Ratings	Unit
Supply voltage	VDD	$V_{DD} = EV_{DD} = AV_{REF0}$		–0.3 to +6.5	V
	EVDD	VDD = EVDD = AVREFO		–0.3 to +6.5	V

Analog input voltage Output current, low Output current, high Operating ambient temperature		Flash memory version		-40 to +125	°C

Absolute Maximum Ratings (T_A = 25°C)

Notes 1. Be sure not to exceed the absolute maximum ratings (MAX. value) of each supply voltage.

- P00 to P06, P30 to P35, P40 to P42, P50 to P55, P90, P91, P96 to P99, P913 to P915, PCM0, PCM1, PDL0 to PDL7
- Cautions 1. Do not directly connect the output (or I/O) pins of IC products to each other, or to VDD, VCC, and GND. Open-drain pins or open-collector pins, however, can be directly connected to each other. Direct connection of the output pins between an IC product and an external circuit is possible, if the output pins can be set to the high-impedance state and the output timing of the external circuit is designed to avoid output conflict.
 - 2. Product quality may suffer if the absolute maximum rating is exceeded even momentarily for any parameter. That is, the absolute maximum ratings are rated values at which the product is on the verge of suffering physical damage, and therefore the product must be used under conditions that ensure that the absolute maximum ratings are not exceeded. The ratings and conditions indicated for DC characteristics and AC characteristics represent the quality assurance range during normal operation.

Parameter	Symbol	Conditions		MIN.	TYP.	MAX.	Unit
Input capacitance	Cı	fx = 1 MHz	P70 to P77			15	pF
I/O capacitance	Сю	Unmeasured pins	Note			15	pF

		V _{DD} = 2.7 to 5.5 V	0.0625		6	MHz	
		Operating with subclock ^{Note}	V _{DD} = 2.7 to 5.5 V		32.768		kHz

Note Do not stop the main clock.

Internal System Clock Frequency vs. Supply Voltage

Main Clock Oscillator Characteristics

Recommended Circuit	Parameter	Conditions		MIN.	TYP.	MAX.	Unit
	Oscillation	In PLL mode	V _{DD} = 4.5 to 5.5 V	2		5	MHz
X1 X2	frequency		V _{DD} = 4.0 to 5.5 V	2		4	MHz
(fx) ^{Note 1}	(fx)		V _{DD} = 2.7 to 5.5 V	2		2.5	MHz
		In clock through mode	V _{DD} = 2.7 to 5.5 V	2		10	MHz
	Oscillation	After reset is released			2 ¹⁵ /fx		s
-	stabilization time ^{Note 2}	After STOP mode is rele	eased		Note 3		S

(1) Crystal resonator, ceramic resonator (T_A = -40 to $+85^{\circ}$ C, V_{DD} = 2.7 to 5.5 V, V_{SS} = 0 V)

Notes 1. Indicates only oscillator characteristics.

- 2. Time required to stabilize the resonator after reset or STOP mode is released.
- **3.** The value differs depending on the OSTS register settings.

(2) External clock ($T_A = -40$ to $+85^{\circ}C$, $V_{DD} = 2.7$ to 5.5 V, $V_{SS} = 0$ V)

Recommended Circuit	Parameter	Conditions		MIN.	TYP.	MAX.	Unit
X1 X2	X1, X2 input	In PLL mode	V _{DD} = 4.5 to 5.5 V	2		5	MHz
	frequency		V _{DD} = 4.0 to 5.5 V	2		4	MHz
Å	(fx) ^{Note}		V _{DD} = 2.7 to 5.5 V	2		2.5	MHz
External clock		In clock through mode	$V_{DD} = 2.7 \text{ to } 5.5 \text{ V}$	2		10	MHz

Note The duty ratio of the input waveform must be within $50\% \pm 5\%$.

Cautions 1. When using the main clock oscillator, wire as follows in the area enclosed by the broken lines in the above figures to avoid an adverse effect from wiring capacitance.

- Keep the wiring length as short as possible.
- Do not cross the wiring with the other signal lines.
- Do not route the wiring near a signal line through which a high fluctuating current flows.
- Always make the ground point of the oscillator capacitor the same potential as Vss.
- Do not ground the capacitor to a ground pattern through which a high current flows.
- Do not fetch signals from the oscillator.
- 2. When the main clock is stopped and the device is operating on the subclock, wait until the oscillation stabilization time has been secured by the program before switching back to the main clock.

Subclock Oscillator Characteristics

Recommended Circuit	Parameter	Conditions	MIN.	TYP.	MAX.	Unit
	Oscillation frequency (fxT) ^{Note 1}		32	32.768	35	kHz
	Oscillation stabilization time ^{Note 2}			10		S

(1) Crystal resonator ($T_A = -40$ to $+85^{\circ}C$, $V_{DD} = 2.7$ to 5.5 V, $V_{SS} =$	0 V)
---	------

Notes 1. Indicates only oscillator characteristics.

2. Time required from when V_{DD} reaches oscillation voltage range (2.7 V (MIN.)) to when the crystal resonator stabilizes.

(2) External clock (T_A = -40 to +85°C, V_{DD} = 2.7 to 5.5 V, V_{SS} = 0 V)

Recommended Circuit	Parameter	Conditions	MIN.	TYP.	MAX.	Unit
XT1 XT2	Input frequency (f _{XT}) ^{Note}		32		35	kHz

Note The duty ratio of the input waveform must be within $50\% \pm 5\%$.

Cautions 1. When using the subclock oscillator, wire as follows in the area enclosed by the broken lines in the above figures to avoid an adverse effect from wiring capacitance.

- Keep the wiring length as short as possible.
- Do not cross the wiring with the other signal lines.
- Do not route the wiring near a signal line through which a high fluctuating current flows.
- Always make the ground point of the oscillator capacitor the same potential as Vss.
- Do not ground the capacitor to a ground pattern through which a high current flows.
- Do not fetch signals from the oscillator.
- 2. The subclock oscillator is designed as a low-amplitude circuit for reducing power consumption, and is more prone to malfunction due to noise than the main clock oscillator. Particular care is therefore required with the wiring method when the subclock is used.

Parameter	Symbol	Conditions	MIN.	TYP.	MAX.	Unit

Clock Timing

Basic Operation

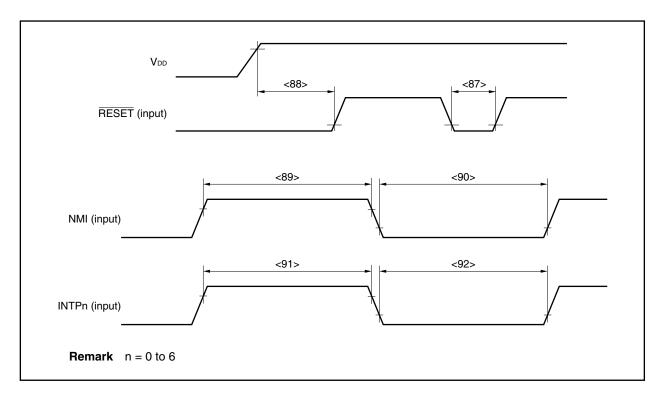

(1) Reset/external interrupt timing

(TA = -40 to +85°C, VDD = EVDD = AVREF0 = 2.7 to 5.5 V, Vss = EVss = AVss = 0 V, CL = 50 pF)

Parameter	Sym	nbol	Conditions	MIN.	MAX.	Unit
RESET low-level width	twrsL1	<87>	Reset in power-on status	2		μs
	twrsl2	<88>	Power-on-reset	2		μs
NMI high-level width	twniн	<89>	Analog noise elimination	1		μs
NMI low-level width	twnil	<90>	Analog noise elimination	1		μs
INTPn high-level width	twiтн	<91>	n = 0 to 6 (analog noise elimination)	600		ns
INTPn low-level width	twi⊤∟	<92>	n = 0 to 6 (analog noise elimination)	600		ns

Remark The above specification shows the pulse width that is accurately detected as a valid edge. If a pulse narrower than the above specification is input, therefore, it may also be detected as a valid edge.

Reset/Interrupt

	, ,			,	, I,

				V _{DD} = 2.7 to 5.5 V	2T _{smp0} + 200 ^{Note 1}		ns
<r></r>	TI01n low-level width	t⊤ıo∟	<94>	V _{DD} = 4.5 to 5.5 V	2T _{smp0} + 100 ^{Note 1}		ns
				$V_{DD} = 2.7$ to 5.5 V	2T _{smp0} + 200 ^{Note 1}		ns
<r></r>	TI5n high-level width	tтіsн	<95>	$V_{DD} = 4.5$ to 5.5 V	50		ns
				$V_{DD} = 2.7$ to 5.5 V	100		ns
<r></r>	TI5n low-level width	t⊤i5L	<96>	$V_{DD} = 4.5$ to 5.5 V	50		ns
				$V_{DD} = 2.7$ to 5.5 V	100		ns
<r></r>	TIP0n high-level width	tтірн	<97>	V _{DD} = 4.5 to 5.5 V	$np \times T_{\text{smpp}} + 100^{\text{Note 2}}$		ns
				$V_{DD} = 2.7$ to 5.5 V	$np \times T_{smpp} + 200^{\text{Note 2}}$		ns
<r></r>	TIP0n low-level width	t tipl	<98>	V _{DD} = 4.5 to 5.5 V	$np \times T_{\text{smpp}} + 100^{\text{Note 2}}$		ns
				V _{DD} = 2.7 to 5.5 V	$np \times T_{\text{smpp}} + 200^{\text{Note 2}}$		ns

Timer Timing (TA = -40 to $+85^{\circ}$ C, VDD = EVDD = AVREF0 = 2.7 to 5.5 V, Vss = EVss = AVss = 0 V, CL = 50 pF)

Notes 1. Tsmp0: Timer 0 count clock cycle

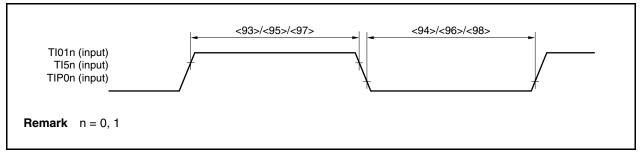

However, $T_{smp0} = 4/f_{XX}$ when TI010 is used as an external clock.

2. np: Number of sampling clocks set by the PnNFC.PnNFSTS bit
 T_{smpp}: Digital noise elimination sampling clock cycle of TIP0n pin
 If TIP00 is used as an external event count input or an external trigger input, however, T_{smpp} = 0 (digital noise is not eliminated).

Remarks 1. n = 0, 1

2. The above specification shows the pulse width that is accurately detected as a valid edge. If a pulse narrower than the above specification is input, therefore, it may also be detected as a valid edge.

Timer Input Timing

UART Timing

$(T_A = -40 \text{ to } +85^{\circ}\text{C}, V_{DD} = \text{EV}_{DD} = \text{AV}_{REF0} = 2.7 \text{ to } 5.5 \text{ V}, V_{SS} = \text{EV}_{SS} = \text{AV}_{SS} = 0 \text{ V}, C_L = 50 \text{ pF})$

SDA0 and SCL0 signal fall time		t⊧	<112>	-	300	20 + 0.1Cb ^{Note 5}	300	ns
Stop condition setup time		tsu:sto	<113>	4.0	-	0.6	-	μs
Pulse width of spike suppressed by input filter		tsp	<114>	-	_	0	50	ns
Capacitance lo	ad of each bus line	Cb		_	400	-	400	pF

Notes 1. At the start condition, the first clock pulse is generated after the hold time.

- 2. The system requires a minimum of 300 ns hold time internally for the SDA0 signal (at VIHmin. of SCL0 signal) in order to occupy the undefined area at the falling edge of SCL0.
- **3.** If the system does not extend the SCL0 signal low hold time (tLow), only the maximum data hold time (tHD:DAT) needs to be satisfied.
- **4.** The high-speed mode l²C bus can be used in the normal-mode l²C bus system. In this case, set the high-speed mode l²C bus so that it meets the following conditions.
 - If the system does not extend the SCL0 signal's low state hold time: tsu:DAT ≥ 250 ns
 - If the system extends the SCL0 signal's low state hold time: Transmit the following data bit to the SDA0 line prior to the SCL0 line release (t_{Rmax.} + t_{SU:DAT} = 1000 + 250 = 1250 ns: Normal mode l²C bus specification).
- 5. Cb: Total capacitance of one bus line (unit: pF)

I²C Bus Mode (µPD703207Y, 70F3207HY Only)

_

Remark The external dimensions and materials of the ES version are the same as those of the mass-produced version.

CHAPTER 26 RECOMMENDED SOLDERING CONDITIONS

The V850ES/KE1 should be soldered and mounted under the following recommended conditions.

For soldering methods and conditions other than those recommended below, contact an NEC Electronics sales representative.

For technical information, see the following website.

Semiconductor Device Mount Manual (http://www.necel.com/pkg/en/mount/index.html)

Table 26-1. Surface Mounting Type Soldering Conditions (1/2)

```
    (1) μPD703207GK-xxx-9ET-A:
    64-pin plastic TQFP (12 × 12)
    μPD703207YGK-9ET-A:
    64-pin plastic TQFP (12 × 12)
    μPD70F3207GK-9ET-A:
    64-pin plastic TQFP (12 × 12)
    μPD70F3207YGK-9ET-A:
    64-pin plastic TQFP (12 × 12)
```

Soldering Method	Soldering Conditions	Recommended Condition Symbol
Infrared reflow	Package peak temperature: 260°C, Time: 60 seconds max. (at 220°C or higher), Count: Three times or less, Exposure limit: 7 days ^{Note} (after that, prebake at 125°C for 20 to 72 hours)	IR60-207-3
Wave soldering	Can be supported. For details, consult an NEC Electronics sales representative.	-
Partial heating	Pin temperature: 350°C max., Time: 3 seconds max. (per pin row)	_

Note After opening the dry pack, store it at 25°C or less and 65% RH or less for the allowable storage period.

Caution Do not use different soldering methods together (except for partial heating).

Remarks 1. Products with -A at the end of the part number are lead-free products.

2. For soldering methods and conditions other than those recommended above, consult an NEC Electronics sales representative.

APPENDIX A DEVELOPMENT TOOLS

The following development tools are available for the development of systems that employ the V850ES/KE1. Figure A-1 shows the development tool configuration.

• Support for PC98-NX series

Unless otherwise specified, products supported by IBM PC/AT[™] compatibles are compatible with PC98-NX series computers. When using PC98-NX series computers, refer to the explanation for IBM PC/AT compatibles.

Windows[™]

Unless otherwise specified, "Windows" means the following OSs.

- Windows 98, 2000
- Windows Me
- Windows XP
- Windows NT[™] Ver. 4.0

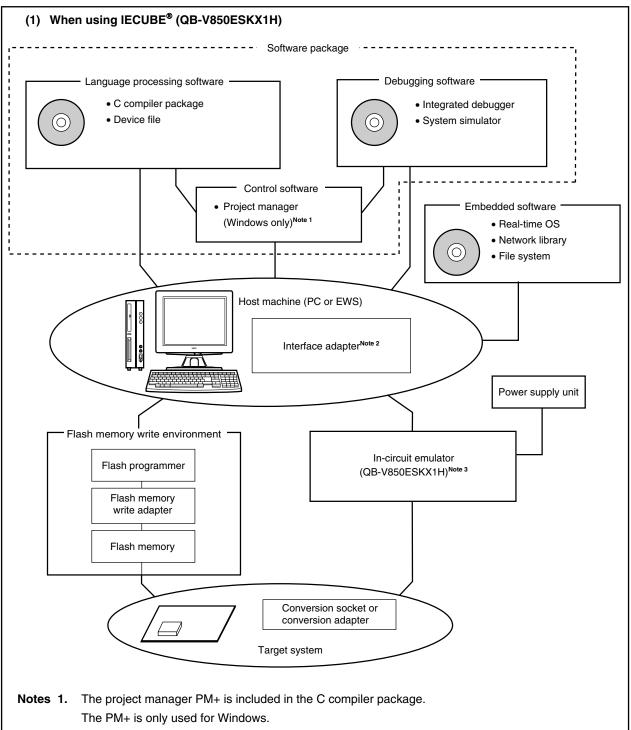

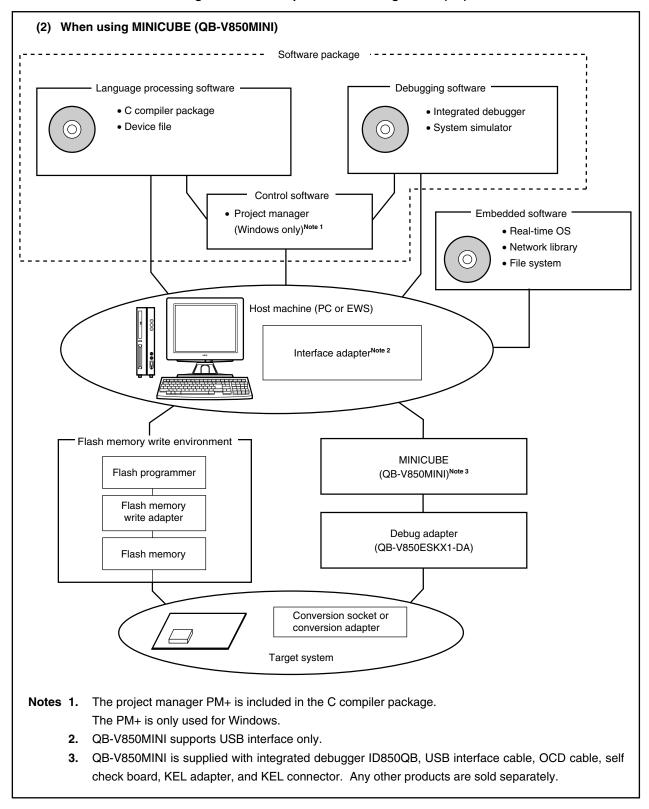

Figure A-1. Development Tool Configuration (1/2)

- **2.** QB-V850ESKX1H supports USB only.
- **3.** QB-V850ESKX1H is supplied with ID850QB, a flash memory programmer (PG-FPL), power supply unit, and a USB interface adapter. Any other products are sold separately.

Figure A-1. Development Tool Configuration (2/2)

A.1 Software Package

SP850	Development tools (software) common to the V850 Series are combined in this package.
V850 Series software package	Part number: µSxxxxSP850

Remark ×××× in the part number differs depending on the host machine and OS used.

μS<u>××××</u>SP850

××××	Host Machine	OS	Supply Medium
AB17	PC-9800 series,	Windows (Japanese version)	CD-ROM
BB17 IBM PC/AT compatibles		Windows (English version)	

A.2 Language Processing Software

	CA850This compiler converts programs written in C language into object codes executa a microcontroller. This compiler is started from project manager PM+.	
		Part number: µSxxxxCA703000
<r> DF703218 This file contains information peculiar to the device.</r>		·
Device file This device file should be used in combination with a tool (CA850 and		This device file should be used in combination with a tool (CA850 and ID850QB).
	The corresponding OS and host machine differ depending on the tool to be	

Remark ×××× in the part number differs depending on the host machine and OS used.

AB17	PC-9800 series,	Windows (Japanese version)	CD-ROM
BB17	IBM PC/AT compatibles	Windows (English version)	
3K17	SPARCstation [™]	SunOS [™] (Rel. 4.1.4), Solaris [™] (Rel. 2.5.1)	

A.3 Control Software

PM+ Project manager	This is control software designed to enable efficient user program development in the Windows environment. All operations used in development of a user program, such as starting the editor, building, and starting the debugger, can be performed from the PM+. cautionscore.com
	The PM+ is included in the C compiler package CA850. It can only be used in Windows.

<R> A.4 Debugging Tools (Hardware)

A.4.1 When using IECUBE QB-V850ESKX1H

The system configuration when connecting the QB-V850ESKX1H to the host machine (PC-9821 series, PC/AT compatible) is shown below. They can still be connected without the optional products.

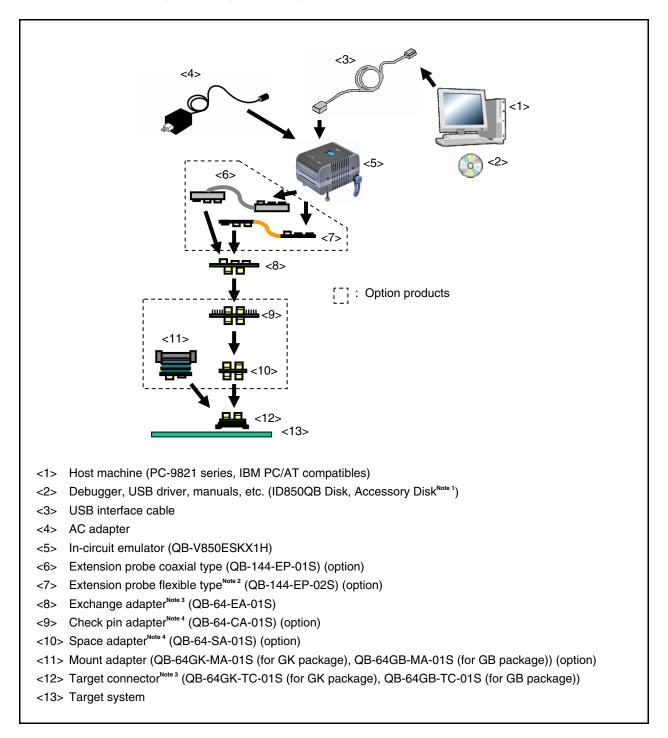

Figure A-2. System Configuration (QB-V850ESKX1H Used) (2/2)

- **Notes 1.** Obtain the device file from the NEC Electronics website. http://www.necel.com/micro/ods/eng/index.html
 - 2. Under development
 - **3.** Depending on the ordering number, supplied with the device.
 - When QB-V850ESKX1H-ZZZ is ordered The exchange adapter and the target connector are not supplied.
 - When QB-V850ESKX1H-S64GK is ordered The QB-64-EA-01S and QB-64GK-TC-01S are supplied.
 - When QB-V850ESKX1H-S64GB is ordered
 - The QB-64-EA-01S and QB-64GB-TC-01S are supplied.
 - 4. When using both <9> and <10>, the order between <9> and <10> is not cared.

<5>	QB-V850ESKX1H ^{№™} In-circuit emulator	The in-circuit emulator serves to debug hardware and software when developing application systems using a V850ES/KE1 product. It corresponds to the integrated debugger ID850QB. This emulator should be used in combination with a power supply unit and emulation probe. Use USB to connect this emulator to the host machine.
<3>	USB interface cable	Cable to connect the host machine and the QB-V850ESKX1H.
<4>	AC adapter	100 to 240 V can be supported by replacing the AC plug.
<8>	QB-64-EA-01S Exchange adapter	Adapter to perform pin conversion.
<9>	QB-64-CA-01S Check pin adapter	Adapter used in waveform monitoring using the oscilloscope, etc.
<10>	QB-64-SA-01S Space adapter	Adapter to adjust the height.
<11>	QB-64GK-MA-01S, QB-64GB-MA-01S Mount adapter	Adapter to mount the V850ES/KE1 with socket. • QB-64GK-MA-01S: For 64-pin plastic TQFP (GK-9ET type) • QB-64GB-MA-01S: For 64-pin plastic LQFP (GB-8EU type)
<12> QB-64GK-TC-01S, QB-64GB-TC-01S Target connector		Connector to solder on the target system. • QB-64GK-TC-01S: For 64-pin plastic TQFP (GK-9ET type) • QB-64GB-TC-01S: For 64-pin plastic LQFP (GB-8EU type)

Note QB-V850ESKX1H is supplied with a power supply unit, USB interface cable, and flash memory programmer (PG-FPL). It is also supplied with integrated debugger ID850QB as control software.

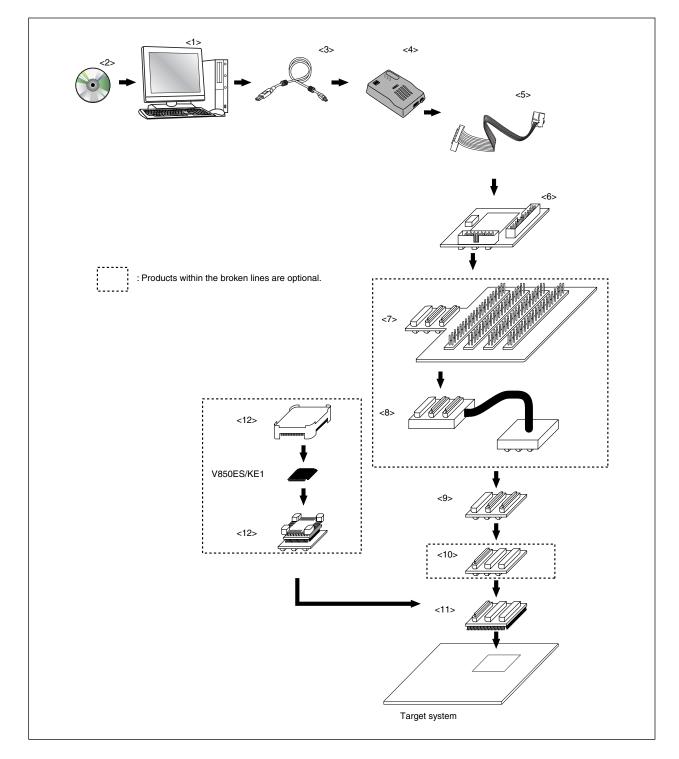

Remark The numbers in the square brackets correspond to the numbers in Figure A-2.

A.4.2 When using MINICUBE QB-V850MINI

(1) Debug emulation using MINICUBE and QB-V850ESKX1-DA

The following shows the system configuration when using MINICUBE, debug adapter QB-V850ESKX1-DA, and the host machine (PC-9821 series, PC/AT compatibles) connected together. They can still be connected without the optional products.

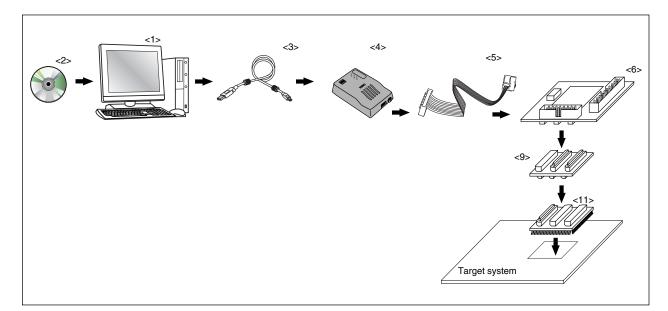

Figure A-4. Example of System Configuration Using QB-V850ESKX1-DA (Not Using Optional Products)

<1> Host machine	PC with USB ports	
<2> CD-ROM ^{Note}	This CD-ROM is provided with MINICUBE and includes an ID850QB integrated debugger, N-Wire checker, a device driver, and documents.	
<3> USB interface cable	This cable, supporting USB, is provided with MINICUBE and used to connect the host machine to MINICUBE. The length of this cable is approximately 2 m.	
<4> MINICUBE On-chip debug emulator	This on-chip emulator is used to debug hardware and software when developing the application systems using the V850ES/KE1. This supports the ID850QB integrated debugger.	
<5> OCD cable	This cable is used to connect MINICUBE to the target system. This is provided with MINICUBE. The length of this cable is approximately 20 cm.	
<6> QB-V850ESKX1-DA Debug adapter	This operates as an in-circuit emulator by using in combination with MINICUBE. This is provided with MINICUBE.	
<7> QB-144-CA-01S (optional) Check pin adapter	Adapter used when monitoring waveforms on an oscilloscope.	
<8> QB-144-EP-01S (optional) Extension probe coaxial type	This probe is used to connect the QB-V850ESKX1-DA to the exchange adapter. The length of this cable is approximately 40 cm.	
<9> QB-64-EA-01S Exchange adapter	Adapter that performs pin conversion	
<10> QB-64-SA-01S (optional) Space adapter	Adapter for height regulation	
<11> QB-64GK-TC-01S, QB-64GB-TC-01S Target connector	Connector soldered to target system • QB-64GK-TC-01S: For 64-pin plastic TQFP (GK-9ET type) • QB-64GB-TC-01S: For 64-pin plastic LQFP (GB-8EU type)	
<12> QB-64GK-MA-01S (optional), QB-64GB-MA-01S (optional) Mount adapter	Adapter for socket mounting of the V850ES/KE1 • QB-64GK-MA-01S: For 64-pin plastic TQFP (GK-9ET type) • QB-64GB-MA-01S: For 64-pin plastic LQFP (GB-8EU type)	

Note Obtain device files from the NEC Electronics website. http://www.necel.com/micro/ods/eng/index_e.html

Remark The numbers shown in the above table correspond to the numbers in Figures A-3 and A-4.

A.5 Debugging Tools (Software)

ID850QB	This debugger supports the in-circuit emulators for the V850 Series. The ID850QB is
Integrated debugger Windows-based software.	
	It has improved C-compatible debugging functions and can display the results of tracing
	with the source program using an integrating window function that associates the source
program, disassemble display, and memory display with the trace result.	
	It should be used in combination with the device file.
	Part number: µSxxxxID703000-QB

Remark ×××× in the part number differs depending on the host machine and OS used.

*μ*S<u>××××</u>ID703000-QB

 XXXX	Host Machine	OS	Supply Medium
AB17	PC-9800 series,	Windows (Japanese version)	CD-ROM
BB17	IBM PC/AT compatibles	Windows (English version)	

A.6 Embedded Software

RX850, RX850 Pro Real-time OS	The RX850 and RX850 Pro are real-time OSs conforming to μ ITRON 3.0 specifications. A tool (configurator) for generating multiple information tables is supplied. RX850 Pro has more functions than RX850.
	Part number: μSxxxxRX703000-ΔΔΔΔ (RX850) μSxxxxRX703100-ΔΔΔΔ (RX850 Pro)
V850mini-NET (provisional name) (Network library)	This is a network library conforming to RFC. It is a lightweight TCP/IP of compact design, requiring only a small memory. In addition to the TCP/IP standard set, an HTTP server, SMTP client, and POP client are also supported.
RX-FS850 (File system)	This is a FAT file system function. It is a file system that supports the CD-ROM file system function. This file system is used with the real-time OS RX850 Pro.

Caution To purchase the RX850 or RX850 Pro, first fill in the purchase application form and sign the user agreement.

Remark xxxx and $\Delta\Delta\Delta\Delta$ in the part number differ depending on the host machine and OS used.

μ S××××RX703000- $\Delta\Delta\Delta\Delta$

 $\mu S \times \times \times RX703100 - \Delta \Delta \Delta \Delta$

ΔΔΔΔ	Product Outline	Maximum Number for Use in Mass Production
001	Evaluation object	Do not use for mass-produced product.
00K	Mass-production object	0.1 million units
001M		1 million units
010M		10 million units
S01	Source program	Object source program for mass production

 XXXX	Host Machine	OS	Supply Medium
AB17	PC-9800 series,	Windows (Japanese version)	CD-ROM
BB17	IBM PC/AT compatibles	Windows (English version)	
3K17	SPARCstation	Solaris (Rel. 2.5.1)	

A.7 Flash Memory Writing Tools

Flashpro IV (part number: PG-FP4) Flash programmer	Flash programmer dedicated to microcontrollers with on-chip flash memory.
FA-64GK-9ET-A Flash memory writing adapter	Flash memory writing adapter used connected to the Flashpro IV. • FA-64GK-9ET-A: For 64-pin plastic TQFP (GK-9ET type)
FA-64GB-8EU-A Flash memory writing adapter	Flash memory writing adapter used connected to the Flashpro IV.FA-64GB-8EU-A: For 64-pin plastic LQFP (fine pitch) (GB-8EU type)

Remark FA-64GK-9ET-A and FA-64GB-8EU-A are products of Naito Densei Machida Mfg. Co., Ltd.

TEL: +81-45-475-4191 Naito Densei Machida Mfg. Co., Ltd.

APPENDIX B INSTRUCTION SET LIST

B.1 Conventions

(1) Register symbols used to describe operands

Register Symbol	Explanation
reg1	General-purpose registers: Used as source registers.
reg2	General-purpose registers: Used mainly as destination registers. Also used as source register in some instructions.
reg3	General-purpose registers: Used mainly to store the remainders of division results and the higher 32 bits of multiplication results.
bit#3	3-bit data for specifying the bit number
immX	X bit immediate data
dispX	X bit displacement data
regID	System register number
vector	5-bit data that specifies the trap vector (00H to 1FH)
сссс	4-bit data that shows the condition codes
sp	Stack pointer (r3)
ер	Element pointer (r30)
listX	X item register list

(2) Register symbols used to describe opcodes

Register Symbol	Explanation
R	1-bit data of a code that specifies reg1 or regID
r	1-bit data of the code that specifies reg2
w	1-bit data of the code that specifies reg3
d	1-bit displacement data
1	1-bit immediate data (indicates the higher bits of immediate data)
i	1-bit immediate data
сссс	4-bit data that shows the condition codes
CCCC	4-bit data that shows the condition codes of Bcond instruction
bbb	3-bit data for specifying the bit number
L	1-bit data that specifies a program register in the register list

(3) Register symbols used in operations

Register Symbol	Explanation
\leftarrow	Input for
GR[]	General-purpose register
SR[]	System register
zero-extend (n)	Expand n with zeros until word length.
sign-extend (n)	Expand n with signs until word length.
load-memory (a, b)	Read size b data from address a.
store-memory (a, b, c)	Write data b into address a in size c.
load-memory-bit (a, b)	Read bit b of address a.
store-memory-bit (a, b, c)	Write c to bit b of address a.
saturated (n)	Execute saturated processing of n (n is a 2's complement). If, as a result of calculations, $n \ge 7FFFFFFFH$, let it be 7FFFFFFH. $n \le 80000000H$, let it be 80000000H.
result	Reflects the results in a flag.
Byte	Byte (8 bits)
Halfword	Halfword (16 bits)
Word	Word (32 bits)
+	Addition
-	Subtraction
П	Bit concatenation
x	Multiplication
÷	Division
%	Remainder from division results
AND	Logical product
OR	Logical sum
XOR	Exclusive OR
NOT	Logical negation
logically shift left by	Logical shift left
logically shift right by	Logical shift right
arithmetically shift right by	Arithmetic shift right

(4) Register symbols used in execution clock

Register Symbol	Explanation
i	If executing another instruction immediately after executing the first instruction (issue).
r	If repeating execution of the same instruction immediately after executing the first instruction (repeat).
I	If using the results of instruction execution in the instruction immediately after the execution (latency).

(5) Register symbols used in flag operations

Identifier	Explanation
(Blank)	No change
0	Clear to 0
х	Set or cleared in accordance with the results.
R	Previously saved values are restored.

(6) Condition codes

Condition Code (cccc)	Condition Formula	Explanation
0 0 0 0	OV = 1	Overflow
1000	OV = 0	No overflow
0001	CY = 1	Carry Lower (Less than)
1001	CY = 0	No carry Not lower (Greater than or equal)
0010	Z = 1	Zero
1010	Z = 0	Not zero
0011	(CY or Z) = 1	Not higher (Less than or equal)
1011	(CY or Z) = 0	Higher (Greater than)
0100	S = 1	Negative
1 1 0 0	S = 0	Positive
0101	-	Always (Unconditional)
1 1 0 1	SAT = 1	Saturated
0110	(S xor OV) = 1	Less than signed
1 1 1 0	(S xor OV) = 0	Greater than or equal signed
0 1 1 1	((S xor OV) or Z) = 1	Less than or equal signed
1 1 1 1	((S xor OV) or Z) = 0	Greater than signed

Notes 1. dddddddd: Higher 8 bits of disp9.

- 2. 3 if there is an instruction that rewrites the contents of the PSW immediately before.
- **3.** If there is no wait state (3 + the number of read access wait states).
- **4.** n is the total number of list12 load registers. (According to the number of wait states. Also, if there are no wait states, n is the total number of list12 registers. If n = 0, same operation as when n = 1)
- 5. RRRRR: other than 00000.
- 6. The lower halfword data only are valid.
- 7. ddddddddddddddddd: The higher 21 bits of disp22.
- 8. ddddddddddddd: The higher 15 bits of disp16.
- 9. According to the number of wait states (1 if there are no wait states).
- **10.** b: bit 0 of disp16.
- 11. According to the number of wait states (2 if there are no wait states).

- **Notes 12.** In this instruction, for convenience of mnemonic description, the source register is made reg2, but the reg1 field is used in the opcode. Therefore, the meaning of register specification in the mnemonic description and in the opcode differs from other instructions.
 - rrrrr = regID specification
 - RRRRR = reg2 specification
 - 13. iiiii: Lower 5 bits of imm9.
 - IIII: Higher 4 bits of imm9.
 - 14. Do not specify the same register for general-purpose registers reg1 and reg3.
 - 15. sp/imm: specified by bits 19 and 20 of the sub-opcode.
 - **16.** ff = 00: Load sp in ep.
 - 01: Load sign expanded 16-bit immediate data (bits 47 to 32) in ep.
 - 10: Load 16-bit logically left shifted 16-bit immediate data (bits 47 to 32) in ep.
 - 11: Load 32-bit immediate data (bits 63 to 32) in ep.
 - **17.** If imm = imm32, n + 3 clocks.
 - **18.** rrrrr: Other than 00000.
 - **19.** ddddddd: Higher 7 bits of disp8.
 - 20. dddd: Higher 4 bits of disp5.
 - 21. dddddd: Higher 6 bits of disp8.

TM01	16-bit timer counter 01	Timer	223
TM0IC10	Interrupt control register	INTC	528
TM0IC11	Interrupt control register	INTC	528
TM5	16-bit timer counter 5	Timer	288
TM50	8-bit timer counter 50	Timer	288
TM51	8-bit timer counter 51	Timer	288
TM5IC0	Interrupt control register	INTC	528
TM5IC1	Interrupt control register	INTC	528
TMC01	16-bit timer mode control register 01	Timer	228
TMC50	8-bit timer mode control register 50	Timer	291
TMC51	8-bit timer mode control register 51	Timer	291
TMCYC0	8-bit timer H carrier control register 0	Timer	312
TMCYC1	8-bit timer H carrier control register 1	Timer	312
TMHIC0	Interrupt control register	INTC	528
TMHIC1	Interrupt control register	INTC	528
TMHMD0	8-bit timer H mode register 0	Timer	310
TMHMD1	8-bit timer H mode register 1	Timer	311
TOC01	16-bit timer output control register 01	Timer	231
TP0CCIC0	Interrupt control register	INTC	528
TP0CCIC1	Interrupt control register	INTC	528

			(5/5
Symbol	Name	Unit	Page
TP0CCR0	TMP0 capture/compare register 0	Timer	142
TP0CCR1	TMP0 capture/compare register 1	Timer	144
TP0CNT	TMP0 counter read buffer register	Timer	146
TP0CTL0	TMP0 control register 0	Timer	136
TP0CTL1	TMP0 control register 1	Timer	137
TP0IOC0	TMP0 I/O control register 0	Timer	138
TP0IOC1	TMP0 I/O control register 1	Timer	139
TP0IOC2	TMP0 I/O control register 2	Timer	140
TP0OPT0	TMP0 option register 0	Timer	141
TP00VIC	Interrupt control register	INTC	528
TXB0	Transmit buffer register 0	UART	388
TXB1	Transmit buffer register 1	UART	388
VSWC	System wait control register	CPU	67
WDCS	Watchdog timer clock selection register	WDT	342
WDT1IC	Interrupt control register	INTC	528
WDTE	Watchdog timer enable register	WDT	348
WDTM1	Watchdog timer mode register 1	WDT	343, 533
WDTM2	Watchdog timer mode register 2	WDT	347
WTIC	Interrupt control register	INTC	528
WTIIC	Interrupt control register	INTC	528
WTM	Watch timer operation mode register	WT	335

D.1 Major Revisions in This Edition

,,	(1/3)
Page	Description
Throughout	Modification of oscillation frequency
p. 23	Modification of 1.4 Ordering Information
p. 36	Modification of 2.2 Pin I/O Circuits and Recommended Connection of Unused Pins
p. 39	Addition of Type 13-AD to 2.3 Pin I/O Circuits
p. 40	Modification of 3.1 Features
p. 43	Modification of Table 3-2 System Register Numbers
p. 67	Modification of 3.4.8 (1) (a) System wait control register (VSWC)
p. 68	Modification of 3.4.8 (1) (b) Access to special on-chip peripheral I/O register
p. 69	Modification of 3.4.8 (2) (b) Countermeasure
p. 72	Modification of Table 4-3 Writing to/Reading from Pn Register
p. 140	Addition of Caution 3 to 6.4 (5) TMP0 I/O control register 2 (TP0IOC2)
p. 149	Modification of Figure 6-4 Register Setting for Interval Timer Mode Operation
p. 158	Modification of Figure 6-10 Basic Timing in External Event Count Mode
p. 162	Addition of Cautions to 6.5.2 (2) Operation timing in external event count mode
p. 167	Modification of Figure 6-17 Basic Timing in External Trigger Pulse Output Mode
p. 167	Addition of description to 6.5.3 External trigger pulse output mode (TP0MD2 to TP0MD0 bits = 010)
p. 174	Modification of 6.5.3 (2) (b) 0%/100% output of PWM waveform
p. 182	Modification of Figure 6-23 Software Processing Flow in One-Shot Pulse Output Mode
p. 183	Modification of 6.5.4 (2) (a) Note on rewriting TP0CCRa register
p. 187	Modification of Figure 6-26 Register Setting in PWM Output Mode
p. 192	Modification of 6.5.5 (2) (b) 0%/100% output of PWM waveform
p. 212	Modification of 6.5.7 Pulse width measurement mode (TP0MD2 to TP0MD0 bits = 110)
pp. 221 to 285	Modification of description in CHAPTER 7 16-BIT TIMER/EVENT COUNTER 0
p. 307	Addition of description to 9.2 (1) 8-bit timer H compare register n0 (CMPn0)
p. 308	Addition of description to 9.2 (2) 8-bit timer H compare register n1 (CMPn1)
p. 315	Addition of Note to Figure 9-3 Timing of Interval Timer/Square Wave Output Operation
p. 317	Modification of Caution 1 and addition of Caution 3 to 9.4.2 PWM output mode operation
p. 321	Modification of Figure 9-5 Operation Timing in PWM Output Mode
p. 323	Addition of <3> to Figure 9-6 Transfer Timing
p. 324	Addition of <8> to 9.4.3 Carrier generator mode operation
pp. 326 to 328	Modification of Figure 9-8 Carrier Generator Mode
р. 333	Modification of 10.1.4 (1) Operation of interval timer BRG
p. 347	Addition of Caution 4 to 11.2.3 (1) Watchdog timer mode register 2 (WDTM2)
p. 348	Addition of Caution 4 to 11.2.3 (2) Watchdog timer enable register (WDTE)
p. 362	Modification of 13.3 (1) A/D converter mode register (ADM)
p. 364	Addition of Caution 3 to 13.4 (2) Analog input channel specification register (ADS)

Page	Description
p. 367	Addition of Caution to 13.4 (4) Power fail comparison mode register (PFM)
p. 367	Addition of Caution to 13.4 (5) Power fail comparison threshold register (PFT)
p. 369	Modification of 13.4.2 A/D conversion operation
p. 371	Modification of Figure 13-5 Example of How to Reduce Power Consumption in Standby Mode
p. 375	Addition of 13.5 (12) Variation of A/D conversion results, (13) A/D conversion result hysteresis characteristics, and (14) Writing to register during A/D conversion
p. 378	Addition of description to 13.6 (6) Differential linearity error
p. 438	Modification of Figure 16-1 Block Diagram of I ² C0
p. 441	Addition of 16.2 (13) Stop condition generator
pp. 442, 443	Modification of 16.3 (1) IIC control register 0 (IICC0)
pp. 447, 448	Modification of 16.3 (2) IIC status register 0 (IICS0)
p. 451	Addition of description to 16.3 (3) IIC flag register 0 (IICF0)
p. 452	Addition of description to 16.3 (4) IIC clock selection register 0 (IICCL0)
p. 453	Addition of description to 16.3 (5) IIC function expansion register 0 (IICX0)
p. 455	Addition of description to 16.3 (7) IIC shift register 0 (IIC0)
p. 455	Addition of description to 16.3 (8) Slave address register 0 (SVA0)
p. 460	Modification of 16.5.4 ACK
p. 464	Addition of 16.5.7 Wait state cancellation method
pp. 465 to 486	Modification of 16.6 I ² C Interrupt Request Signals (INTIIC0)
p. 489	Addition of description to 16.10 Extension Code
p. 492	Modification of 16.13.1 When communication reservation function is enabled (IICF0.IICRSV0 bit = 0)
p. 492	Modification of Table 16-6 Wait Periods
p. 493	Modification of Figure 16-12 Communication Reservation Timing
p. 495	Modification of Table 16-7 Wait Periods
p. 496	Addition of 16.14 Cautions (3) to (6)
pp. 497 to 501	Modification of 16.15 Communication Operations
p. 503	Modification of Figure 16-18 Slave Operation Flowchart (1)
p. 504	Modification of Figure 16-19 Slave Operation Flowchart (2)
pp. 506 to 508	Modification of Figure 16-20 Example of Master to Slave Communication (When 9-Clock Wait Is Selected for Both Master and Slave)
pp. 509 to 511	Modification of Figure 16-21 Example of Slave to Master Communication
p. 547	Modification of Figure 17-15 Restoring by RETI Instruction
p. 560	Modification of Table 19-5 Operation Status in IDLE Mode
p. 563	Modification of Table 19-7 Operation Status in STOP Mode
p. 566	Modification of Table 19-8 Operation Status in Subclock Operation Mode
p. 567	Addition of Caution to 19.7.1 Setting and operation status
p. 569	Modification of Table 19-10 Operation Status in Sub-IDLE Mode
p. 572	Modification of Table 20-1 Hardware Status on RESET Pin Input or Occurrence of WDTRES2 Signal
p. 572	Modification of Table 20-2 Hardware Status on Occurrence of WDTRES1 Signal

	(3/3
Page	Description
p. 574	Addition of Figure 20-4 Timing of Reset Operation by Watchdog Timer 1
p. 574	Addition of Figure 20-5 Timing of Reset Operation by Watchdog Timer 2
p. 582	Modification of Table 22-2 Basic Functions
p. 582	Modification of Table 22-3 Security Functions
p. 583	Addition of Table 22-4 Security Setting
p. 584	Addition of 22.3 (1) Security setting by PG-FP4 (Security flag settings)
pp. 589, 590	Modification of Figure 22-6 Wiring Example of V850ES/KE1 Flash Writing Adapter (FA-64GK-9ET-A, FA- 64GB-8EU-A)
p. 593	Modification of Table 22-7 Flash Memory Control Commands
p. 600	Modification of 22.5.2 (2) Interrupt support
p. 601	Modification of Figure 22-17 Standard Self Programming Flow
p. 603	Modification of Table 22-11 Internal Resources Used
pp. 604 to 606	Addition of CHAPTER 23 ON-CHIP DEBUG FUNCTION
pp. 607 to 609, 612, 614, 615, 620, 622, 625, 626	Modification of CHAPTER 24 ELECTRICAL SPECIFICATIONS
pp. 629, 630	Addition of CHAPTER 26 RECOMMENDED SOLDERING CONDITIONS
p. 633	Addition of (2) to Figure A-1 Development Tool Configuration
p. 634	Modification of A.2 Language Processing Software
p. 635 to 638	Modification of A.4 Debugging Tools
p. 656	Addition of APPENDIX D REVISION HISTORY
