To our customers,

Old Company Name in Catalogs and Other Documents

On April 1\textsuperscript{st}, 2010, NEC Electronics Corporation merged with Renesas Technology Corporation, and Renesas Electronics Corporation took over all the business of both companies. Therefore, although the old company name remains in this document, it is a valid Renesas Electronics document. We appreciate your understanding.

Renesas Electronics website: http://www.renesas.com

April 1\textsuperscript{st}, 2010
Renesas Electronics Corporation

Issued by: Renesas Electronics Corporation (http://www.renesas.com)
Send any inquiries to http://www.renesas.com/inquiry.
Notice

1. All information included in this document is current as of the date this document is issued. Such information, however, is subject to change without any prior notice. Before purchasing or using any Renesas Electronics products listed herein, please confirm the latest product information with a Renesas Electronics sales office. Also, please pay regular and careful attention to additional and different information to be disclosed by Renesas Electronics such as that disclosed through our website.

2. Renesas Electronics does not assume any liability for infringement of patents, copyrights, or other intellectual property rights of third parties by or arising from the use of Renesas Electronics products or technical information described in this document. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.

3. You should not alter, modify, copy, or otherwise misappropriate any Renesas Electronics product, whether in whole or in part.

4. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation of these circuits, software, and information in the design of your equipment. Renesas Electronics assumes no responsibility for any losses incurred by you or third parties arising from the use of these circuits, software, or information.

5. When exporting the products or technology described in this document, you should comply with the applicable export control laws and regulations and follow the procedures required by such laws and regulations. You should not use Renesas Electronics products or the technology described in this document for any purpose relating to military applications or use by the military, including but not limited to the development of weapons of mass destruction. Renesas Electronics products and technology may not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations.

6. Renesas Electronics has used reasonable care in preparing the information included in this document, but Renesas Electronics does not warrant that such information is error free. Renesas Electronics assumes no liability whatsoever for any damages incurred by you resulting from errors or omissions from the information included herein.

7. Renesas Electronics products are classified according to the following three quality grades: “Standard”, “High Quality”, and “Specific”. The recommended applications for each Renesas Electronics product depends on the product’s quality grade, as indicated below. You must check the quality grade of each Renesas Electronics product before using it in a particular application. You may not use any Renesas Electronics product for any application categorized as “Specific” without the prior written consent of Renesas Electronics. Further, you may not use any Renesas Electronics product for any application for which it is not intended without the prior written consent of Renesas Electronics. Renesas Electronics shall not be in any way liable for any damages or losses incurred by you or third parties arising from the use of any Renesas Electronics product for an application categorized as “Specific” or for which the product is not intended where you have failed to obtain the prior written consent of Renesas Electronics. The quality grade of each Renesas Electronics product is “Standard” unless otherwise expressly specified in a Renesas Electronics data sheets or data books, etc.

   “Standard”: Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; and industrial robots.

   “High Quality”: Transportation equipment (automobiles, trains, ships, etc.); traffic control systems; anti-disaster systems; anti-crime systems; safety equipment; and medical equipment not specifically designed for life support.

   “Specific”: Aircraft; aerospace equipment; submersible repeaters; nuclear reactor control systems; medical equipment or systems for life support (e.g. artificial life support devices or systems), surgical implantations, or healthcare intervention (e.g. excision, etc.), and any other applications or purposes that pose a direct threat to human life.

8. You should use the Renesas Electronics products described in this document within the range specified by Renesas Electronics, especially with respect to the maximum rating, operating supply voltage range, movement power voltage range, heat radiation characteristics, installation and other product characteristics. Renesas Electronics shall have no liability for malfunctions or damages arising out of the use of Renesas Electronics products beyond such specified ranges.

9. Although Renesas Electronics endeavors to improve the quality and reliability of its products, semiconductor products have specific characteristics such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Further, Renesas Electronics products are not subject to radiation resistance design. Please be sure to implement safety measures to guard them against the possibility of physical injury, and injury or damage caused by fire in the event of the failure of a Renesas Electronics product, such as safety design for hardware and software including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult, please evaluate the safety of the final products or system manufactured by you.

10. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. Please use Renesas Electronics products in compliance with all applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive. Renesas Electronics assumes no liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.

11. This document may not be reproduced or duplicated, in any form, in whole or in part, without prior written consent of Renesas Electronics.

12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products, or if you have any other inquiries.

(Note 1) “Renesas Electronics” as used in this document means Renesas Electronics Corporation and also includes its majority-owned subsidiaries.

(Note 2) “Renesas Electronics product(s)” means any product developed or manufactured by or for Renesas Electronics.

Software Manual

Renesas 32-Bit RISC
Microcomputer
SuperH™ RISC engine Family
1. These materials are intended as a reference to assist our customers in the selection of the Renesas Technology Corp. product best suited to the customer's application; they do not convey any license under any intellectual property rights, or any other rights, belonging to Renesas Technology Corp. or a third party.

2. Renesas Technology Corp. assumes no responsibility for any damage, or infringement of any third-party's rights, originating in the use of any product data, diagrams, charts, programs, algorithms, or circuit application examples contained in these materials.

3. All information contained in these materials, including product data, diagrams, charts, programs and algorithms represents information on products at the time of publication of these materials, and are subject to change by Renesas Technology Corp. without notice due to product improvements or other reasons. It is therefore recommended that customers contact Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor for the latest product information before purchasing a product listed herein.

The information described here may contain technical inaccuracies or typographical errors. Renesas Technology Corp. assumes no responsibility for any damage, liability, or other loss rising from these inaccuracies or errors.

Please also pay attention to information published by Renesas Technology Corp. by various means, including the Renesas Technology Corp. Semiconductor home page (http://www.renesas.com).

4. When using any or all of the information contained in these materials, including product data, diagrams, charts, programs, and algorithms, please be sure to evaluate all information as a total system before making a final decision on the applicability of the information and products. Renesas Technology Corp. assumes no responsibility for any damage, liability or other loss resulting from the information contained herein.

5. Renesas Technology Corp. semiconductors are not designed or manufactured for use in a device or system that is used under circumstances in which human life is potentially at stake. Please contact Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor when considering the use of a product contained herein for any specific purposes, such as apparatus or systems for transportation, vehicular, medical, aerospace, nuclear, or undersea repeater use.

6. The prior written approval of Renesas Technology Corp. is necessary to reprint or reproduce in whole or in part these materials.

7. If these products or technologies are subject to the Japanese export control restrictions, they must be exported under a license from the Japanese government and cannot be imported into a country other than the approved destination.

Any diversion or reexport contrary to the export control laws and regulations of Japan and/or the country of destination is prohibited.

8. Please contact Renesas Technology Corp. for further details on these materials or the products contained therein.

---

Keep safety first in your circuit designs!

1. Renesas Technology Corp. puts the maximum effort into making semiconductor products better and more reliable, but there is always the possibility that trouble may occur with them. Trouble with semiconductors may lead to personal injury, fire or property damage. Remember to give due consideration to safety when making your circuit designs, with appropriate measures such as (i) placement of substitutive, auxiliary circuits, (ii) use of nonflammable material or (iii) prevention against any malfunction or mishap.
Preface

The SH-4 has been developed as the top-end model in the SuperH™* RISC engine family, featuring a 128-bit graphic engine for multimedia applications and 360 MIPS performance.

The SH-4 CPU has a RISC type instruction set, and features upward-compatibility at the instruction set level with SH-1, SH-2, SH-3 microcomputers.

In addition to single- and double-precision floating-point operation capability, the on-chip FPU has a 128-bit graphic engine that enables 32-bit floating-point data to be processed 128 bits at a time. It also supports $4 \times 4$ array operations and inner product operations.

A superscalar architecture is employed that enables simultaneous execution of two instructions (including FPU instructions), providing performance of up to twice that of conventional architectures at the same frequency.

This software manual gives details of the SH-4 instructions. For hardware details, refer to the relevant hardware manual.

Related Manual:
SH7750, SH7750S, SH7750R Group Hardware Manual
SH7751, SH7751R Group Hardware Manual

3.2 Register Descriptions

26 Description added

1. Page table entry high register (PTEH):

After updating the ASID field of PTEH register, a branch instruction to the P0, P3, or U0 area, where the new ASID value will be used, should be located at least 6 instructions after the PTEH update instruction.

Description amended

3. Page table entry assistance register (PTEA):

In the SH7750 Series, except the SH7750, ...

In the SH7750 series access to ...

3.3.1 Physical Memory Space

29 Description amended

In the SH7750S, SH7750R, SH7751, and SH7751R, ...

3.3.7 Address Space Identifier (ASID)

35 Note added

Notes: 1. In single virtual memory mode of the SH7751 Series, entries with the same virtual page number (VPN) but different ASIDs cannot be set in the TLB simultaneously.

2. In single virtual memory mode of the SH7751, if the UTLB contains address translation information including an ITLB miss address with a different ASID and unshared state (SH bit is 0), SH7751 may hang up or an instruction TLB multiple hit exception may occur during hardware ITLB miss handling (see section 3.5.4, Hardware ITLB Miss Handling). To avoid this, when switching the ASID values (PTEH and ASID) of the current processing, purge the UTLB, or manage the changes of the program instruction addresses in user mode so that no instruction is executed in an address area (including overrun prefetch of instruction) that is registered in the UTLB with a different ASID and unshared address translation information. Note that this restriction does not apply to the SH7750, SH7750S, SH7750R, SH7751R, and SH7760.

4.1.1 Features

59 Description amended

... The features of these caches are summarized in table 4.1 and 4.2.

After a power-on reset or manual reset, the initial value of the EMODE bit is 0. The SH-4 supports two 32-byte store queues (SQs) for performing high-speed writes to external memory. SQ features are shown in table 4.3.

(1) Cache Control Register (CCR): CCR contains the following bits:

- **EMODE**: Double-sized cache mode (Available for SH7750R, SH7751R, and SH7760; reserved bit for SH7750, SH7750S, and SH7751)
- **IIX**: IC index enable
- **ICI**: IC invalidation
- **ICE**: IC enable
- **OIX**: OC index enable
- **ORA**: OC RAM enable
- **OCI**: OC invalidation
- **CB**: Copy-back enable
- **WT**: Write-through enable
- **OCE**: OC enable

Longword access to CCR can be performed from H'FF00 001C in the P4 area and H'1F00 001C in area 7. The CCR bits are used for the cache settings described below. Consequently, CCR modifications must only be made by a program in the non-cached P2 area. After CCR is updated, an instruction that performs data access to the P0, P1, P3, or U0 area should be located at least four instructions after the CCR update instruction. Also, a branch instruction to the P0, P1, P3, or U0 area should be located at least eight instructions after the CCR update instruction.
### 4.2 Register Descriptions

#### Figure 4.1 Cache and Store Queue Control Registers

- **EMODE**: Double-sized cache mode bit
  
  In the SH7750R, SH7751R, and SH7760, this bit indicates whether the double-sized cache mode is used or not. This bit is reserved in the SH7750, SH7750S, and SH7751. The EMODE bit must not be written to while the cache is being used.

  0: SH7750/SH7750S/SH7751-compatible mode *(initial value)*
  1: Double-sized cache mode

  **Note:** *No compatibility for RAM mode in OC index mode and address assignment in RAM mode.

- **IIX**: IC index enable bit
  
  0: Address bits [12:5] used for IC entry selection
  1: Address bits [25] and [11:5] used for IC entry selection

- **ICI**: IC invalidation bit
  
  When 1 is written to this bit, the V bits of all IC entries are cleared to 0. This bit always returns 0 when read.

- **ICE**: IC enable bit
  
  Indicates whether or not the IC is to be used. When address translation is performed, the IC cannot be used unless the C bit in the page management information is also 1.

  0: IC not used
  1: IC used

- **OIX**: OC index enable bit
  
  0: Address bits [13:5] used for OC entry selection
  1: Address bits [25] and [12:5] used for OC entry selection

  **Note:** *When the ORA bit is 1 in the SH7750R, the OIX bit should be cleared to 0.*

- **ORA**: OC RAM enable bit
  
  When the OC is enabled (OCE = 1), the ORA bit specifies whether the 8 kbytes from entry 128 to entry 255 and from entry 384 to entry 511 of the OC are to be used as RAM. When the OC is not enabled (OCE = 0), the ORA bit should be cleared to 0.

  0: 16 kbytes used as cache
  1: 8 kbytes used as cache, and 8 kbytes as RAM

  **Note:** *When the OIX bit in the SH7750R is 1, the ORA bit should be cleared to 0.*
Hereafter, this section explains the SH7750, SH7750S and SH7751. For other SH-4 products, refer to the corresponding products’ hardware manual.

In the SH7750 and SH7750S, ...

INTEVT (SH7750/SH7750S/SH7750R)

Description amended

6. The exception code is written to bits 11–0 of the exception event register (EXPEVT): SH7750, SH7750S, SH7750R, bits 13–0 of the exception event register (EXPEVT): SH7751, SH7751R, SH7760 or interrupt event register (INTEVT).

Module/source: Example of the SH7751/SH7751R. For details, refer to the corresponding products’ hardware manual.

Note 3 deleted

In the SH7750, SH7750S and SH7750R, if the SCK2 pin is ...

In the SH7751, SH7750R and SH7760, if the RESET pin is ...

5.6.3 Interrupts 115 Description amended

(3) Peripheral Module Interrupts [Example of SH7751/SH7751R]

For details, refer to the corresponding products' hardware manual.

- Source: The interrupt mask bit setting in SR is smaller than the peripheral module (H-UDI, GPIO, DMAC, PCIC, TMU, RTC, SCI, SCIF, WDT, or REF) interrupt level, and the BL bit in SR is 0 (accepted at instruction boundary).

6.6.1 Geometric Operation Instructions 129 Description amended

In future version of SuperH™ RISC engine family, the above error is guaranteed, but the same result as SH-4 is not guaranteed.

6.7 Usage Notes 131, 132 Newly added

6.7.1 Notice about FPU Instructions Issues

6.7.2 Notice about the 132 Overflow Flag by FIPR and FTRV Instruction Command

6.7.3 Notice about the 133 Sign of the Operation Result by FIPR and FTRV Instruction Command

6.7.4 Notice about Double Precision FADD and FSUB Instructions for SH-4 133, 134

Section 1  Overview

1.1  SH-4 Features

The SH-4 is a 32-bit RISC (reduced instruction set computer) microprocessor, featuring instruction set upward-compatibility with SH-1, SH-2, and SH-3 microcomputers. Its 16-bit fixed-length instruction set enables program code size to be reduced by almost 50% compared with 32-bit instructions.

The features of the SH-4 are summarized in table 1.1.

**Figure 2.1 Data Formats**
2.2 Register Configuration

2.2.1 Privileged Mode and Banks

Processor Modes: The SH-4 has two processor modes, user mode and privileged mode. The SH-4 normally operates in user mode, and switches to privileged mode when an exception occurs or an interrupt is accepted. There are four kinds of registers—general registers, system registers, control registers, and floating-point registers—and the registers that can be accessed differ in the two processor modes.

General Registers: There are 16 general registers, designated R0 to R15. General registers R0 to R7 are banked registers which are switched by a processor mode change.

In privileged mode, the register bank bit (RB) in the status register (SR) defines which banked register set is accessed as general registers, and which set is accessed only through the load control register (LDC) and store control register (STC) instructions.

When the RB bit is 1 (that is, when bank 1 is selected), the 16 registers comprising bank 1 general registers R0_BANK1 to R7_BANK1 and non-banked general registers R8 to R15 can be accessed as general registers R0 to R15. In this case, the eight registers comprising bank 0 general registers R0_BANK0 to R7_BANK0 are accessed by the LDC/STC instructions. When the RB bit is 0 (that is, when bank 0 is selected), the 16 registers comprising bank 0 general registers R0_BANK0 to R7_BANK0 and non-banked general registers R8 to R15 can be accessed as general registers R0 to R15. In this case, the eight registers comprising bank 1 general registers R0_BANK1 to R7_BANK1 are accessed by the LDC/STC instructions.

In user mode, the 16 registers comprising bank 0 general registers R0_BANK0 to R7_BANK0 and non-banked general registers R8 to R15 can be accessed as general registers R0 to R15. The eight registers comprising bank 1 general registers R0_BANK1 to R7_BANK1 cannot be accessed.

Control Registers: Control registers comprise the global base register (GBR) and status register (SR), which can be accessed in both processor modes, and the saved status register (SSR), saved program counter (SPC), vector base register (VBR), saved general register 15 (SGR), and debug base register (DBR), which can only be accessed in privileged mode. Some bits of the status register (such as the RB bit) can only be accessed in privileged mode.

System Registers: System registers comprise the multiply-and-accumulate registers (MACH/MACL), the procedure register (PR), the program counter (PC), the floating-point status/control register (FPSCR), and the floating-point communication register (FPUL). Access to these registers does not depend on the processor mode.
Floating-Point Registers: There are thirty-two floating-point registers, FR0–FR15 and XF0–XF15. FR0–FR15 and XF0–XF15 can be assigned to either of two banks (FPR0_BANK0–FPR15_BANK0 or FPR0_BANK1–FPR15_BANK1).

FR0–FR15 can be used as the eight registers DR0/2/4/6/8/10/12/14 (double-precision floating-point registers, or pair registers) or the four registers FV0/4/8/12 (register vectors), while XF0–XF15 can be used as the eight registers XD0/2/4/6/8/10/12/14 (register pairs) or register matrix XMTRX.

Register values after a reset are shown in table 2.1.

**Rev. 6.00  Sep 13, 2006  page 8 of 424**

REJ09B0318-0600
2.2.2 General Registers

Figure 2.3 shows the relationship between the processor modes and general registers. The SH-4 has twenty-four 32-bit general registers (R0_BANK0–R7_BANK0, R0_BANK1–R7_BANK1, and R8–R15). However, only 16 of these can be accessed as general registers R0–R15 in one processor mode. The SH-4 has two processor modes, user mode and privileged mode, in which R0–R7 are assigned as shown below.

- R0_BANK0–R7_BANK0
  In user mode (SR.MD = 0), R0–R7 are always assigned to R0_BANK0–R7_BANK0.
  In privileged mode (SR.MD = 1), R0–R7 are assigned to R0_BANK0–R7_BANK0 only when SR.RB = 0.

- R0_BANK1–R7_BANK1
  In user mode, R0_BANK1–R7_BANK1 cannot be accessed.
  In privileged mode, R0–R7 are assigned to R0_BANK1–R7_BANK1 only when SR.RB = 1.
### Figure 2.3  General Registers

**Programming Note:** As the user’s R0–R7 are assigned to R0_BANK0–R7_BANK0, and after an exception or interrupt R0–R7 are assigned to R0_BANK1–R7_BANK1, it is not necessary for the interrupt handler to save and restore the user’s R0–R7 (R0_BANK0–R7_BANK0).

After a reset, the values of R0_BANK0–R7_BANK0, R0_BANK1–R7_BANK1, and R8–R15 are undefined.
### 2.2.3 Floating-Point Registers

Figure 2.4 shows the floating-point registers. There are thirty-two 32-bit floating-point registers, divided into two banks (FPR0_BANK0–FPR15_BANK0 and FPR0_BANK1–FPR15_BANK1). These 32 registers are referenced as FR0–FR15, DR0/2/4/6/8/10/12/14, FV0/4/8/12, XF0–XF15, XD0/2/4/6/8/10/12/14, or XMTRX. The correspondence between FPRn_BANKi and the reference name is determined by the FR bit in FPSCR (see figure 2.4).

- Floating-point registers, FPRn_BANKi (32 registers)
  - FPR0_BANK0, FPR1_BANK0, FPR2_BANK0, FPR3_BANK0, FPR4_BANK0, FPR5_BANK0, FPR6_BANK0, FPR7_BANK0, FPR8_BANK0, FPR9_BANK0, FPR10_BANK0, FPR11_BANK0, FPR12_BANK0, FPR13_BANK0, FPR14_BANK0, FPR15_BANK0
  - FPR0_BANK1, FPR1_BANK1, FPR2_BANK1, FPR3_BANK1, FPR4_BANK1, FPR5_BANK1, FPR6_BANK1, FPR7_BANK1, FPR8_BANK1, FPR9_BANK1, FPR10_BANK1, FPR11_BANK1, FPR12_BANK1, FPR13_BANK1, FPR14_BANK1, FPR15_BANK1

- Single-precision floating-point registers, FRi (16 registers)
  - When FPSCR.FR = 0, FR0–FR15 are assigned to FPR0_BANK0–FPR15_BANK0.
  - When FPSCR.FR = 1, FR0–FR15 are assigned to FPR0_BANK1–FPR15_BANK1.

- Double-precision floating-point registers or single-precision floating-point register pairs, DRi (8 registers): A DR register comprises two FR registers.
  - DR0 = \{FR0, FR1\}, DR2 = \{FR2, FR3\}, DR4 = \{FR4, FR5\}, DR6 = \{FR6, FR7\}, DR8 = \{FR8, FR9\}, DR10 = \{FR10, FR11\}, DR12 = \{FR12, FR13\}, DR14 = \{FR14, FR15\}

- Single-precision floating-point vector registers, FVi (4 registers): An FV register comprises four FR registers
  - FV0 = \{FR0, FR1, FR2, FR3\}, FV4 = \{FR4, FR5, FR6, FR7\}, FV8 = \{FR8, FR9, FR10, FR11\}, FV12 = \{FR12, FR13, FR14, FR15\}

- Single-precision floating-point extended registers, XFi (16 registers)
  - When FPSCR.FR = 0, XF0–XF15 are assigned to FPR0_BANK1–FPR15_BANK1.
  - When FPSCR.FR = 1, XF0–XF15 are assigned to FPR0_BANK0–FPR15_BANK0.

- Single-precision floating-point extended register pairs, XDi (8 registers): An XD register comprises two XF registers
  - XD0 = \{XF0, XF1\}, XD2 = \{XF2, XF3\}, XD4 = \{XF4, XF5\}, XD6 = \{XF6, XF7\}, XD8 = \{XF8, XF9\}, XD10 = \{XF10, XF11\}, XD12 = \{XF12, XF13\}, XD14 = \{XF14, XF15\}
• Single-precision floating-point extended register matrix, XMTRX: XMTRX comprises all 16 XF registers

\[
XMTRX = \begin{bmatrix}
    XF0 & XF4 & XF8 & XF12 \\
    XF1 & XF5 & XF9 & XF13 \\
    XF2 & XF6 & XF10 & XF14 \\
    XF3 & XF7 & XF11 & XF15 \\
\end{bmatrix}
\]

<td>T</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note: —: Reserved. These bits are always read as 0, and should only be written with 0.

- **MD:** Processor mode
  - MD = 0: User mode (some instructions cannot be executed, and some resources cannot be accessed)
  - MD = 1: Privileged mode

- **RB:** General register bank specifier in privileged mode (set to 1 by a reset, exception, or interrupt)
  - RB = 0: R0_BANK0–R7_BANK0 are accessed as general registers R0–R7. (R0_BANK1–R7_BANK1 can be accessed using LDC/STC R0_BANK–R7_BANK instructions.)
  - RB = 1: R0_BANK1–R7_BANK1 are accessed as general registers R0–R7. (R0_BANK0–R7_BANK0 can be accessed using LDC/STC R0_BANK–R7_BANK instructions.)

- **BL:** Exception/interrupt block bit (set to 1 by a reset, exception, or interrupt)
  - BL = 1: Interrupt requests are masked. If a general exception other than a user break occurs while BL = 1, the processor switches to the reset state.

- **FD:** FPU disable bit (cleared to 0 by a reset)
  - FD = 1: An FPU instruction causes a general FPU disable exception, and if the FPU instruction is in a delay slot, a slot FPU disable exception is generated. (FPU instructions: H'F*** instructions, LDC(L)/STS(L) instructions for FPUL/FPSR)

- **M, Q:** Used by the DIV0S, DIV0U, and DIV1 instructions.

- **IMASK:** Interrupt mask level
  - External interrupts of a same level or a lower level than IMASK are masked.

- **S:** Specifies a saturation operation for a MAC instruction.

- **T:** True/false condition or carry/borrow bit
Saved status register, SSR (32 bits, privilege protection, initial value undefined): The current contents of SR are saved to SSR in the event of an exception or interrupt.

Saved program counter, SPC (32 bits, privilege protection, initial value undefined): The address of an instruction at which an interrupt or exception occurs is saved to SPC.

Global base register, GBR (32 bits, initial value undefined): GBR is referenced as the base address in a GBR-referencing MOV instruction.

Vector base register, VBR (32 bits, privilege protection, initial value = H'0000 0000): VBR is referenced as the branch destination base address in the event of an exception or interrupt. For details, see section 5, Exceptions.

Saved general register 15, SGR (32 bits, privilege protection, initial value undefined): The contents of R15 are saved to SGR in the event of an exception or interrupt.

Debug base register, DBR (32 bits, privilege protection, initial value undefined): When the user break debug function is enabled (BRCR.UBDE = 1), DBR is referenced as the user break handler branch destination address instead of VBR.

2.2.5 System Registers

Multiply-and-accumulate register high, MACH (32 bits, initial value undefined)
Multiply-and-accumulate register low, MACL (32 bits, initial value undefined)
MACH/MACL is used for the added value in a MAC instruction, and to store a MAC instruction or MUL operation result.

Procedure register, PR (32 bits, initial value undefined): The return address is stored in PR in a subroutine call using a BSR, BSRF, or JSR instruction, and PR is referenced by the subroutine return instruction (RTS).

Program counter, PC (32 bits, initial value = H'A000 0000): PC indicates the instruction fetch address.

Floating-point status/control register, FPSCR (32 bits, initial value = H'0004 0001)

<table>
<thead>
<tr>
<th>31</th>

<td>FR</td>
<td>SZ</td>
<td>PR</td>
<td>DN</td>
<td>Cause</td>
<td>Enable</td>
<td>Flag</td>
<td>RM</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note: —: Reserved. These bits are always read as 0, and should only be written with 0.
• FR: Floating-point register bank
  FR = 0: FPR0_BANK0–FPR15_BANK0 are assigned to FR0–FR15; FPR0_BANK1–FPR15_BANK1 are assigned to XF0–XF15.
  FR = 1: FPR0_BANK0–FPR15_BANK0 are assigned to XF0–XF15; FPR0_BANK1–FPR15_BANK1 are assigned to FR0–FR15.

• SZ: Transfer size mode
  SZ = 0: The data size of the FMOV instruction is 32 bits.
  SZ = 1: The data size of the FMOV instruction is a 32-bit register pair (64 bits).

• PR: Precision mode
  PR = 0: Floating-point instructions are executed as single-precision operations.
  PR = 1: Floating-point instructions are executed as double-precision operations (the result of instructions for which double-precision is not supported is undefined).
  Do not set SZ and PR to 1 simultaneously; this setting is reserved.
  [SZ, PR = 11]: Reserved (FPU operation instruction is undefined.)

• DN: Denormalization mode
  DN = 0: A denormalized number is treated as such.
  DN = 1: A denormalized number is treated as zero.

• Cause: FPU exception cause field
• Enable: FPU exception enable field
• Flag: FPU exception flag field

When an FPU operation instruction is executed, the FPU exception cause field is cleared to zero first. When the next FPU exception is occurred, the corresponding bits in the FPU exception cause field and FPU exception flag field are set to 1. The FPU exception flag field holds the status of the exception generated after the field was last cleared.
• RM: Rounding mode
  RM = 00: Round to Nearest
  RM = 01: Round to Zero
  RM = 10: Reserved
  RM = 11: Reserved

• Bits 22 to 31: Reserved

Floating-point communication register, FPUL (32 bits, initial value undefined): Data transfer between FPU registers and CPU registers is carried out via the FPUL register.

Programming Note: When $SZ = 1$ and big endian mode is selected, FMOV can be used for double-precision floating-point load or store operations. In little endian mode, two 32-bit data size moves must be executed, with $SZ = 0$, to load or store a double-precision floating-point number.

### 2.3 Memory-Mapped Registers

The control registers are double-mapped to the following two memory areas. All registers have two addresses.

H'1C00 0000–H'1FFF FFFF
H'FC00 0000–H'FFFF FFFF

These two areas are used as follows.

• H'1C00 0000–H'1FFF FFFF
  This area must be accessed using the MMU's address translation function. A memory-mapped register can be accessed by setting the page number of this area in the corresponding field of the TLB. Operation is not guaranteed if this area is accessed without using the MMU's address translation function.

• H'FC00 0000–H'FFFF FFFF
  Access to area H'FC00 0000–H'FFFF FFFF in user mode will cause an address error. Memory-mapped registers can be referenced in user mode by means of access that involves address translation.

Note: Do not access undefined locations in either area. The operation of an access to an undefined location is undefined. Also, memory-mapped registers must be accessed using a fixed data size. The operation of an access using an invalid data size is undefined.
2.4 Data Format in Registers

Register operands are always longwords (32 bits). When a memory operand is only a byte (8 bits) or a word (16 bits), it is sign-extended into a longword when loaded into a register.

![Register Format Diagram]

2.5 Data Formats in Memory

Memory data formats are classified into bytes, words, and longwords. Memory can be accessed in 8-bit byte, 16-bit word, or 32-bit longword form. A memory operand less than 32 bits in length is sign-extended before being loaded into a register.

A word operand must be accessed starting from a word boundary (even address of a 2-byte unit: address 2n), and a longword operand starting from a longword boundary (even address of a 4-byte unit: address 4n). An address error will result if this rule is not observed. A byte operand can be accessed from any address.

Big endian or little endian byte order can be selected for the data format. The endian should be set with the MD5 external pin in a power-on reset. Big endian is selected when the MD5 pin is low, and little endian when high. The endian cannot be changed dynamically. Bit positions are numbered left to right from most-significant to least-significant. Thus, in a 32-bit longword, the leftmost bit, bit 31, is the most significant bit and the rightmost bit, bit 0, is the least significant bit.

The data format in memory is shown in figure 2.5.

![Memory Format Diagram]
Note: The SH-4 does not support endian conversion for the 64-bit data format. Therefore, if double-precision floating-point format (64-bit) access is performed in little endian mode, the upper and lower 32 bits will be reversed.

### 2.6 Processor States

The SH-4 has five processor states: the reset state, exception-handling state, bus-released state, program execution state, and power-down state.

**Reset State:** In this state the CPU is reset. There are two kinds of reset state, power-on reset and manual reset, defined as shown in table 2.6 according to the relevant external pin states.

<table>
<thead>
<tr>
<th></th>
<th>Power-On Reset State</th>
<th>Manual Reset State</th>
</tr>
</thead>
<tbody>
<tr>
<td>SH7750/SH7750S/SH7750R</td>
<td>RESET = 0 and MRESET = 1</td>
<td>RESET = 0 and MRESET = 0</td>
</tr>
<tr>
<td>SH7751/SH7751R, SH7760</td>
<td>RESET = 0</td>
<td>RESET = 1 and MRESET = 0</td>
</tr>
</tbody>
</table>

For more information on resets, see section 5, Exceptions.

In the power-on reset state, the internal state of the CPU and the on-chip peripheral module registers are initialized. In the manual reset state, the internal state of the CPU and registers of on-chip peripheral modules other than the bus state controller (BSC) are initialized. Since the bus state controller (BSC) is not initialized in the manual reset state, refreshing operations continue. Refer to the register configurations in the relevant sections for further details.

**Exception-Handling State:** This is a transient state during which the CPU’s processor state flow is altered by a reset, general exception, or interrupt exception handling source.

In the case of a reset, the CPU branches to address H’A000 0000 and starts executing the user-coded exception handling program.

In the case of a general exception or interrupt, the program counter (PC) contents are saved in the saved program counter (SPC), the status register (SR) contents are saved in the saved status register (SSR), and the R15 contents are saved in saved general register 15 (SGR). The CPU branches to the start address of the user-coded exception service routine found from the sum of the contents of the vector base address and the vector offset. See section 5, Exceptions, for more information on resets, general exceptions, and interrupts.

**Program Execution State:** In this state the CPU executes program instructions in sequence.
**Power-Down State:** In the power-down state, CPU operation halts and power consumption is reduced. The power-down state is entered by executing a SLEEP instruction. There are two modes in the power-down state: sleep mode and standby mode. For details, see hardware manual, Power-Down Modes.

**Bus-Released State:** In this state the CPU has released the bus to a device that requested it.

SH7750, SH7750S, and SH7750R state transitions are shown in figure 2.6, and SH7751, SH7751R, and SH7760 state transitions in figure 2.7.

![Figure 2.6 Processor State Transitions (SH7750/SH7750S/SH7750R)](image-url)
2.7 Processor Modes

There are two processor modes: user mode and privileged mode. The processor mode is determined by the processor mode bit (MD) in the status register (SR). User mode is selected when the MD bit is cleared to 0, and privileged mode when the MD bit is set to 1. When the reset state or exception state is entered, the MD bit is set to 1. When exception handling ends, the MD bit is cleared to 0 and user mode is entered. There are certain registers and bits which can only be accessed in privileged mode.
3.1 Overview

3.1.1 Features

The SH-4 can handle 29-bit external memory space from an 8-bit address space identifier and 32-bit logical (virtual) address space. Address translation from virtual address to physical address is performed using the memory management unit (MMU) built into the SH-4. The MMU performs high-speed address translation by caching user-created address translation table information in an address translation buffer (translation lookaside buffer; TLB). The SH-4 has four instruction TLB (ITLB) entries and 64 unified TLB (UTLB) entries. UTLB copies are stored in the ITLB by hardware. A paging system is used for address translation, with support for four page sizes (1, 4, and 64 Kbytes, and 1 Mbyte). It is possible to set the virtual address space access right and implement storage protection independently for privileged mode and user mode.

3.1.2 Role of the MMU

The MMU was conceived as a means of making efficient use of physical memory. As shown in figure 3.1, when a process is smaller in size than the physical memory, the entire process can be mapped onto physical memory, but if the process increases in size to the point where it does not fit into physical memory, it becomes necessary to divide the process into smaller parts, and map the parts requiring execution onto physical memory on an ad hoc basis ((1)). Having this mapping onto physical memory executed consciously by the process itself imposes a heavy burden on the process. The virtual memory system was devised as a means of handling all physical memory mapping to reduce this burden ((2)). With a virtual memory system, the size of the available virtual memory is much larger than the actual physical memory, and processes are mapped onto this virtual memory. Thus processes only have to consider their operation in virtual memory, and mapping from virtual memory to physical memory is handled by the MMU. The MMU is normally managed by the OS, and physical memory switching is carried out so as to enable the virtual memory required by a task to be mapped smoothly onto physical memory. Physical memory switching is performed via secondary storage, etc.

The virtual memory system that came into being in this way works to best effect in a time sharing system (TSS) that allows a number of processes to run simultaneously ((3)). Running a number of processes in a TSS did not increase efficiency since each process had to take account of physical memory mapping. Efficiency is improved and the load on each process reduced by the use of a virtual memory system ((4)). In this system, virtual memory is allocated to each process. The task of the MMU is to map a number of virtual memory areas onto physical memory in an efficient
manner. It is also provided with memory protection functions to prevent a process from inadvertently accessing another process’s physical memory.

When address translation from virtual memory to physical memory is performed using the MMU, it may happen that the translation information has not been recorded in the MMU, or the virtual memory of a different process is accessed by mistake. In such cases, the MMU will generate an exception, change the physical memory mapping, and record the new address translation information.

Although the functions of the MMU could be implemented by software alone, having address translation performed by software each time a process accessed physical memory would be very inefficient. For this reason, a buffer for address translation (the translation lookaside buffer: TLB) is provided in hardware, and frequently used address translation information is placed here. The TLB can be described as a cache for address translation information. However, unlike a cache, if address translation fails—that is, if an exception occurs—switching of the address translation information is normally performed by software. Thus memory management can be performed in a flexible manner by software.

There are two methods by which the MMU can perform mapping from virtual memory to physical memory: the paging method, using fixed-length address translation, and the segment method, using variable-length address translation. With the paging method, the unit of translation is a fixed-size address space called a page (usually from 1 to 64 kbytes in size).

In the following descriptions, the address space in virtual memory in the SH-4 is referred to as virtual address space, and the address space in physical memory as physical address space.
Figure 3.1 Role of the MMU
3.1.3 Register Configuration

The MMU registers are shown in table 3.1.

Table 3.1 MMU Registers

</table>

Notes: 1. The initial value is the value after a power-on reset or manual reset.
2. This is the address when using the virtual/physical address space P4 area. The area 7 address is the address used when making an access from physical address space area 7 using the TLB.

3.1.4 Caution

Operation is not guaranteed if an area designated as a reserved area in this manual is accessed.
### 3.2 Register Descriptions

There are six MMU-related registers.

<table>
<thead>
<tr>
<th>Register</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>1. PTEH</strong></td>
<td>Page table entry high register (PTEH): Longword access to PTEH can be performed from H’FF00 0000 in the P4 area and H’1F00 0000 in area 7. PTEH consists of the virtual page number (VPN) and address space identifier (ASID). When an MMU exception or address error exception occurs, the VPN of the virtual address at which the exception occurred is set in the VPN field by hardware. VPN varies according to the page size, but the VPN set by hardware when an exception occurs consists of the upper 22 bits of the virtual address which caused the exception. VPN setting</td>
</tr>
<tr>
<td><strong>2. PTEL</strong></td>
<td></td>
</tr>
<tr>
<td><strong>3. PTEA</strong></td>
<td></td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td><strong>5. TEA</strong></td>
<td>Virtual address at which MMU exception or address error occurred</td>
</tr>
<tr>
<td><strong>6. MMUCR</strong></td>
<td></td>
</tr>
</tbody>
</table>

Note: — indicates a reserved bit: the write value must be 0, and a read will return an undefined value.
can also be carried out by software. The number of the currently executing process is set in the ASID field by software. ASID is not updated by hardware. VPN and ASID are recorded in the UTLB by means of the LDLTB instruction.

After updating the ASID field of PTEH register, a branch instruction to the P0, P3, or U0 area, where the new ASID value will be used, should be located at least 6 instructions after the PTEH update instruction.

2. **Page table entry low register (PTEL):** Longword access to PTEL can be performed from H'FF00 0004 in the P4 area and H'1F00 0004 in area 7. PTEL is used to hold the physical page number and page management information to be recorded in the UTLB by means of the LDTLB instruction. The contents of this register are not changed unless a software directive is issued.

3. **Page table entry assistance register (PTEA):** Longword access to PTEA can be performed from H'FF00 0034 in the P4 area and H'1F00 0034 in area 7. PTEL is used to store assistance bits for PCMCIA access to the UTLB by means of the LDTLB instruction.

In the SH7750 Series, except the SH7750, when access to a PCMCIA interface area is performed from the CPU with MMUCR.AT = 0, access is always performed using the values of the SA bit and TC bit in this register. In the SH7750, it is not possible to access a PCMCIA interface area with MMUCR.AT = 0.

In the SH7750 series access to a PCMCIA interface area by the DMAC is always performed using the DMAC’s CHCRn.SSAN, CHCRn.DSAN, CHCRn.STC, and CHCRn.DTC values. See the DMAC section in hardware manual for details.

The contents of this register are not changed unless a software directive is issued.

4. **Translation table base register (TTB):** Longword access to TTB can be performed from H'FF00 0008 in the P4 area and H'1F00 0008 in area 7. TTB is used, for example, to hold the base address of the currently used page table. The contents of TTB are not changed unless a software directive is issued. This register can be freely used by software.

5. **TLB exception address register (TEA):** Longword access to TEA can be performed from H'FF00 000C in the P4 area and H'1F00 000C in area 7. After an MMU exception or address error exception occurs, the virtual address at which the exception occurred is set in TEA by hardware. The contents of this register can be changed by software.

6. **MMU control register (MMUCR):** MMUCR contains the following bits:

   - LRUI: Least recently used ITLB
   - URB: UTLB replace boundary
   - URC: UTLB replace counter
SQMD: Store queue mode bit
SV: Single virtual mode bit
TI: TLB invalidate
AT: Address translation bit

Longword access to MMUCR can be performed from H'FF00 0010 in the P4 area and H'1F00 0010 in area 7. The individual bits perform MMU settings as shown below. Therefore, MMUCR rewriting should be performed by a program in the P1 or P2 area. After MMUCR is updated, an instruction that performs data access to the P0, P3, U0, or store queue area should be located at least four instructions after the MMUCR update instruction. Also, a branch instruction to the P0, P3, or U0 area should be located at least eight instructions after the MMUCR update instruction. MMUCR contents can be changed by software. The LRUI bits and URC bits may also be updated by hardware.

- LRUI: The LRU (least recently used) method is used to decide the ITLB entry to be replaced in the event of an ITLB miss. The entry to be purged from the ITLB can be confirmed using the LRUI bits. LRUI is updated by means of the algorithm shown below. A dash in this table means that updating is not performed.

<table>
<thead>
<tr>
<th>LRUI</th>
<th>[5]</th>
<th>[4]</th>
<th>[3]</th>
<th>[2]</th>
<th>[1]</th>
<th>[0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>When ITLB entry 0 is used</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>—</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>When ITLB entry 1 is used</td>
<td>1</td>
<td>—</td>
<td>—</td>
<td>0</td>
<td>0</td>
<td>—</td>
</tr>
<tr>
<td>When ITLB entry 2 is used</td>
<td>—</td>
<td>1</td>
<td>—</td>
<td>1</td>
<td>—</td>
<td>0</td>
</tr>
<tr>

<td>*</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Other than the above</td>
<td>Setting prohibited</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Ensure that values for which “Setting prohibited” is indicated in the above table are not set at the discretion of software. After a power-on or manual reset the LRUI bits are initialized to 0, and therefore a prohibited setting is never made by a hardware update.

- **URB:** Bits that indicate the UTLB entry boundary at which replacement is to be performed. Valid only when URB > 0.

- **URC:** Random counter for indicating the UTLB entry for which replacement is to be performed with an LDTLB instruction. URC is incremented each time the UTLB is accessed. When URB > 0, URC is reset to 0 when the condition URC = URB occurs. Also note that, if a value is written to URC by software which results in the condition URC > URB, incrementing is first performed in excess of URB until URC = H'3F. URC is not incremented by an LDTLB instruction.

- **SQMD:** Store queue mode bit. Specifies the right of access to the store queues.
  0: User/privileged access possible
  1: Privileged access possible (address error exception in case of user access)

- **SV:** Bit that switches between single virtual memory mode and multiple virtual memory mode.
  0: Multiple virtual memory mode
  1: Single virtual memory mode
  When this bit is changed, ensure that 1 is also written to the TI bit.

- **TI:** Writing 1 to this bit invalidates (clears to 0) all valid UTLB/ITLB bits. This bit always returns 0 when read.

- **AT:** Specifies MMU enabling or disabling.
  0: MMU disabled
  1: MMU enabled
  MMU exceptions are not generated when the AT bit is 0. In the case of software that does not use the MMU, therefore, the AT bit should be cleared to 0.

### 3.3 Memory Space

#### 3.3.1 Physical Memory Space

The SH-4 supports a 32-bit physical memory space, and can access a 4-Gbyte address space. When the MMUCR.AT bit is cleared to 0 and the MMU is disabled, the address space is this physical memory space. The physical memory space is divided into a number of areas, as shown in figure 3.3. The physical memory space is permanently mapped onto 29-bit external memory.
space; this correspondence can be implemented by ignoring the upper 3 bits of the physical memory space addresses. In privileged mode, the 4-Gbyte space from the P0 area to the P4 area can be accessed. In user mode, a 2-Gbyte space in the U0 area can be accessed. Accessing the P1 to P4 areas (except the store queue area) in user mode will cause an address error.

Figure 3.3 Physical Memory Space (MMUCR.AT = 0)

In the SH7750, it is not possible to access a PCMCIA interface area from the CPU.

In the SH7750S, SH7750R, SH7751, and SH7751R, when access to a PCMCIA interface area is performed from the CPU, the SA and TC values set in the PTEA register are always used for the access.

Access to a PCMCIA interface area by the DMAC is always performed using the DMAC’s CHCRn.SSAn and CHCRn.STCn values. See the DMAC section for details.

P0, P1, P3, U0 Areas: The P0, P1, P3, and U0 areas can be accessed using the cache. Whether or not the cache is used is determined by the cache control register (CCR). When the cache is used, with the exception of the P1 area, switching between the copy-back method and the write-through method for write accesses is specified by the CCR.WT bit. For the P1 area, switching is specified by the CCR.CB bit. Zeroizing the upper 3 bits of an address in these areas gives the corresponding
external memory space address. However, since area 7 in the external memory space is a reserved area, a reserved area also appears in these areas.

**P2 Area:** The P2 area cannot be accessed using the cache. In the P2 area, zeroizing the upper 3 bits of an address gives the corresponding external memory space address. However, since area 7 in the external memory space is a reserved area, a reserved area also appears in this area.

**P4 Area:** The P4 area is mapped onto SH-4 on-chip I/O channels. This area cannot be accessed using the cache. The P4 area is shown in detail in figure 3.4.

![Diagram of P4 Area](image)

**Figure 3.4 P4 Area**

The area from H'E000 0000 to H'E3FF FFFF comprises addresses for accessing the store queues (SQs). When the MMU is disabled (MMUCR.AT = 0), the SQ access right is specified by the MMUCR.SQMD bit. For details, see section 4.6, Store Queues.
The area from H'F000 0000 to H'F0FF FFFF is used for direct access to the instruction cache address array. For details, see section 4.5.1, IC Address Array.

The area from H'F100 0000 to H'F1FF FFFF is used for direct access to the instruction cache data array. For details, see section 4.5.2, IC Data Array.

The area from H'F200 0000 to H'F2FF FFFF is used for direct access to the instruction TLB address array. For details, see section 3.7.1, ITLB Address Array.

The area from H'F300 0000 to H'F3FF FFFF is used for direct access to instruction TLB data arrays 1 and 2. For details, see sections 3.7.2, ITLB Data Array 1, and 3.7.3, ITLB Data Array 2.

The area from H'F400 0000 to H'F4FF FFFF is used for direct access to the operand cache address array. For details, see section 4.5.3, OC Address Array.

The area from H'F500 0000 to H'F5FF FFFF is used for direct access to the operand cache data array. For details, see section 4.5.4, OC Data Array.

The area from H'F600 0000 to H'F6FF FFFF is used for direct access to the unified TLB address array. For details, see section 3.7.4, UTLB Address Array.

The area from H'F700 0000 to H'F7FF FFFF is used for direct access to unified TLB data arrays 1 and 2. For details, see sections 3.7.5, UTLB Data Array 1, and 3.7.6, UTLB Data Array 2.

The area from H'FC00 0000 to H'FFFF FFFF is the control register area.

### 3.3.2 External Memory Space

The SH-4 supports a 29-bit external memory space. The external memory space is divided into eight areas as shown in figure 3.5. Areas 0 to 6 relate to memory, such as SRAM, synchronous DRAM, DRAM, and PCMCIA. Area 7 is a reserved area. For details, see section 13, Bus State Controller (BSC), in the Hardware Manual.
3.3.3 Virtual Memory Space

Setting the MMUCR.AT bit to 1 enables the P0, P3, and U0 areas of the physical memory space in the SH-4 to be mapped onto any external memory space in 1-, 4-, or 64-kbyte, or 1-Mbyte, page units. By using an 8-bit address space identifier, the P0, U0, P3, and store queue areas can be increased to a maximum of 256. This is called the virtual memory space. Mapping from virtual memory space to 29-bit external memory space is carried out using the TLB. Only when area 7 in external memory space is accessed using virtual memory space, addresses H'1C00 0000 to H'1FFF FFFF of area 7 are not designated as a reserved area, but are equivalent to the P4 area control register area in the physical memory space. Virtual memory space is illustrated in figure 3.6.
When areas P0, P3, and U0 are mapped onto PCMCIA interface areas by the TLB in the cache-enabled state, it is necessary to specify 1 for the WT bit of that page, or to clear the C bit to 0. Access is performed using the SA and TC values set for individual TLB pages.

It is not possible to access a PCMCIA interface area from the CPU by access to area P1, P2, or P4. Access to a PCMCIA interface area by the DMAC is always performed using the DMAC’s CHCRn.SSan and CHCRn.STCn values. See the DMAC section for details.

**P0, P3, U0 Areas:** The P0 area (excluding addresses H'7C00 0000 to H'7FFF FFFF), P3 area, and U0 area allow access using the cache and address translation using the TLB. These areas can be mapped onto any external memory space in 1-, 4-, or 64-kbyte, or 1-Mbyte, page units. When CCR is in the cache-enabled state and the TLB enable bit (C bit) is 1, accesses can be performed using the cache. In write accesses to the cache, switching between the copy-back method and the write-through method is indicated by the TLB write-through bit (WT bit), and is specified in page units.
Only when the P0, P3, and U0 areas are mapped onto external memory space by means of the TLB, addresses H'1C00 0000 to H'1FFF FFFF of area 7 in external memory space are allocated to the control register area. This enables control registers to be accessed from the U0 area in user mode. In this case, the C bit for the corresponding page must be cleared to 0.

**P1, P2, P4 Areas:** Address translation using the TLB cannot be performed for the P1, P2, or P4 area (except for the store queue area). Accesses to these areas are the same as for physical memory space. The store queue area can be mapped onto any external memory space by the MMU. However, operation in the case of an exception differs from that for normal P0, U0, and P3 spaces. For details, see section 4.6, Store Queues.

### 3.3.4 On-Chip RAM Space

In the SH-4, half (8 kbytes) of the instruction cache (16 kbytes) can be used as on-chip RAM. This can be done by changing the CCR settings.

When the operand cache is used as on-chip RAM (CCR.ORA = 1), P0 area addresses H'7C00 0000 to H'7FFF FFFF are an on-chip RAM area. Data accesses (byte/word/longword/quadword) can be used in this area. This area can only be used in RAM mode.

### 3.3.5 Address Translation

When the MMU is used, the virtual address space is divided into units called pages, and translation to physical addresses is carried out in these page units. The address translation table in external memory contains the physical addresses corresponding to virtual addresses and additional information such as memory protection codes. Fast address translation is achieved by caching the contents of the address translation table located in external memory into the TLB. In the SH-4, basically, the ITLB is used for instruction accesses and the UTLB for data accesses. In the event of an access to an area other than the P4 area, the accessed virtual address is translated to a physical address. If the virtual address belongs to the P1 or P2 area, the physical address is uniquely determined without accessing the TLB. If the virtual address belongs to the P0, U0, or P3 area, the TLB is searched using the virtual address, and if the virtual address is recorded in the TLB, a TLB hit is made and the corresponding physical address is read from the TLB. If the accessed virtual address is not recorded in the TLB, a TLB miss exception is generated and processing switches to the TLB miss exception routine. In the TLB miss exception routine, the address translation table in external memory is searched, and the corresponding physical address and page management information are recorded in the TLB. After the return from the exception handling routine, the instruction which caused the TLB miss exception is re-executed.
3.3.6 Single Virtual Memory Mode and Multiple Virtual Memory Mode

There are two virtual memory systems, single virtual memory and multiple virtual memory, either of which can be selected with the MMUCR.SV bit. In the single virtual memory system, a number of processes run simultaneously, using virtual address space on an exclusive basis, and the physical address corresponding to a particular virtual address is uniquely determined. In the multiple virtual memory system, a number of processes run while sharing the virtual address space, and a particular virtual address may be translated into different physical addresses depending on the process. The only difference between the single virtual memory and multiple virtual memory systems in terms of operation is in the TLB address comparison method (see section 3.4.3, Address Translation Method).

3.3.7 Address Space Identifier (ASID)

In multiple virtual memory mode, the 8-bit address space identifier (ASID) is used to distinguish between processes running simultaneously while sharing the virtual address space. Software can set the ASID of the currently executing process in PTEH in the MMU. The TLB does not have to be purged when processes are switched by means of ASID.

In single virtual memory mode, ASID is used to provide memory protection for processes running simultaneously while using the virtual memory space on an exclusive basis.

Notes:
1. In single virtual memory mode of the SH7751 Series, entries with the same virtual page number (VPN) but different ASIDs cannot be set in the TLB simultaneously.
2. In single virtual memory mode of the SH7751, if the UTLB contains address translation information including an ITLB miss address with a different ASID and unshared state (SH bit is 0), SH7751 may hang up or an instruction TLB multiple hit exception may occur during hardware ITLB miss handling (see section 3.5.4, Hardware ITLB Miss Handling). To avoid this, when switching the ASID values (PTEH and ASID) of the current processing, purge the UTLB, or manage the changes of the program instruction addresses in user mode so that no instruction is executed in an address area (including overrun prefetch of instruction) that is registered in the UTLB with a different ASID and unshared address translation information. Note that this restriction does not apply to the SH7750, SH7750S, SH7750R, SH7751R, and SH7760.
3.4 TLB Functions

3.4.1 Unified TLB (UTLB) Configuration

The unified TLB (UTLB) is so called because of its use for the following two purposes:

1. To translate a virtual address to a physical address in a data access
2. As a table of address translation information to be recorded in the instruction TLB in the event of an ITLB miss

Information in the address translation table located in external memory is cached into the UTLB. The address translation table contains virtual page numbers and address space identifiers, and corresponding physical page numbers and page management information. Figure 3.7 shows the overall configuration of the UTLB. The UTLB consists of 64 fully-associative type entries. Figure 3.8 shows the relationship between the address format and page size.

![UTLB Configuration](image)

**Figure 3.7 UTLB Configuration**
### Relationship between Page Size and Address Format

- **VPN**: Virtual page number
  - For 1-Kbyte page: upper 22 bits of virtual address
  - For 4-Kbyte page: upper 20 bits of virtual address
  - For 64-Kbyte page: upper 16 bits of virtual address
  - For 1-Mbyte page: upper 12 bits of virtual address

- **ASID**: Address space identifier
  - Indicates the process that can access a virtual page.
  - In single virtual memory mode and user mode, or in multiple virtual memory mode, if the SH bit is 0, this identifier is compared with the ASID in PTEH when address comparison is performed.
• **SH**: Share status bit
  - When 0, pages are not shared by processes.
  - When 1, pages are shared by processes.

• **SZ**: Page size bits
  - Specify the page size.
  - 00: 1-Kbyte page
  - 01: 4-Kbyte page
  - 10: 64-Kbyte page
  - 11: 1-Mbyte page

• **V**: Validity bit
  - Indicates whether the entry is valid.
  - 0: Invalid
  - 1: Valid
  - Cleared to 0 by a power-on reset.
  - Not affected by a manual reset.

• **PPN**: Physical page number
  - Upper 22 bits of the physical address.
  - With a 1-Kbyte page, PPN bits [28:10] are valid.
  - With a 4-Kbyte page, PPN bits [28:12] are valid.
  - With a 64-Kbyte page, PPN bits [28:16] are valid.
  - With a 1-Mbyte page, PPN bits [28:20] are valid.
  - The synonym problem must be taken into account when setting the PPN (see section 3.5.5, Avoiding Synonym Problems).

• **PR**: Protection key data
  - 2-bit data expressing the page access right as a code.
  - 00: Can be read only, in privileged mode
  - 01: Can be read and written in privileged mode
  - 10: Can be read only, in privileged or user mode
  - 11: Can be read and written in privileged mode or user mode
• C: Cacheability bit
  Indicates whether a page is cacheable.
  0: Not cacheable
  1: Cacheable
  When control register space is mapped, this bit must be cleared to 0.
  When performing PCMCIA space mapping in the cache enabled state, either clear this bit to 0
  or set the WT bit to 1.

• D: Dirty bit
  Indicates whether a write has been performed to a page.
  0: Write has not been performed
  1: Write has been performed

• WT: Write-through bit
  Specifies the cache write mode.
  0: Copy-back mode
  1: Write-through mode
  When performing PCMCIA space mapping in the cache enabled state, either set this bit to 1 or
  clear the C bit to 0.

• SA: Space attribute bits
  Valid only when the page is mapped onto PCMCIA connected to area 5 or 6.
  000: Undefined
  001: Variable-size I/O space (base size according to $IOIS16$ signal)
  010: 8-bit I/O space
  011: 16-bit I/O space
  100: 8-bit common memory space
  101: 16-bit common memory space
  110: 8-bit attribute memory space
  111: 16-bit attribute memory space

• TC: Timing control bit
  Used to select wait control register bits in the bus control unit for areas 5 and 6.
  0: WCR2 (A5W2–A5W0) and PCR (A5PCW1–A5PCW0, A5TED2–A5TED0, A5TEH2–
   A5TEH0) are used
  1: WCR2 (A6W2–A6W0) and PCR (A6PCW1–A6PCW0, A6TED2–A6TED0, A6TEH2–
   A6TEH0) are used
3.4.2  Instruction TLB (ITLB) Configuration

The ITLB is used to translate a virtual address to a physical address in an instruction access. Information in the address translation table located in the UTLB is cached into the ITLB. Figure 3.9 shows the overall configuration of the ITLB. The ITLB consists of 4 fully-associative type entries.

```
```

Notes:
1. D and WT bits are not supported.
2. There is only one PR bit, corresponding to the upper of the PR bits in the UTLB.

Figure 3.9  ITLB Configuration

3.4.3  Address Translation Method

Figures 3.10 and 3.11 show flowcharts of memory accesses using the UTLB and ITLB.
Data access to virtual address (VA)

1. **On-chip I/O access**
   - VA is in P4 area

2. **Data TLB miss exception**
   - CCR.OCE?
     - 0
     - 1

3. **Data TLB protection violation exception**
   - CCR.CB?
     - 0
     - 1

4. **Initial page write exception**
   - V = 1
     - Only one entry matches
     - SR.MD?
       - 0
       - 1
     - PR?
       - 0
       - 1

5. **Cache access in copy-back mode**
   - C = 1
     - and CCR.OCE = 1

6. **Cache access in write-through mode**
   - WT?
     - 0
     - 1

**Figure 3.10 Flowchart of Memory Access Using UTLB**
Figure 3.11 Flowchart of Memory Access Using ITLB
3.5 MMU Functions

3.5.1 MMU Hardware Management

The SH-4 supports the following MMU functions.

1. The MMU decodes the virtual address to be accessed by software, and performs address translation by controlling the UTLB/ITLB in accordance with the MMUCR settings.
2. The MMU determines the cache access status on the basis of the page management information read during address translation (C, WT, SA, and TC bits).
3. If address translation cannot be performed normally in a data access or instruction access, the MMU notifies software by means of an MMU exception.
4. If address translation information is not recorded in the ITLB in an instruction access, the MMU searches the UTLB, and if the necessary address translation information is recorded in the UTLB, the MMU copies this information into the ITLB in accordance with MMUCR.LRUI.

3.5.2 MMU Software Management

Software processing for the MMU consists of the following:

1. Setting of MMU-related registers. Some registers are also partially updated by hardware automatically.
2. Recording, deletion, and reading of TLB entries. There are two methods of recording UTLB entries: by using the LDTLB instruction, or by writing directly to the memory-mapped UTLB. ITLB entries can only be recorded by writing directly to the memory-mapped ITLB. For deleting or reading UTLB/ITLB entries, it is possible to access the memory-mapped UTLB/ITLB.
3. MMU exception handling. When an MMU exception occurs, processing is performed based on information set by hardware.

3.5.3 MMU Instruction (LDTLB)

A TLB load instruction (LDTLB) is provided for recording UTLB entries. When an LDTLB instruction is issued, the SH-4 copies the contents of PTEH, PTEL, and PTEA to the UTLB entry indicated by MMUCR.URC. ITLB entries are not updated by the LDTLB instruction, and therefore address translation information purged from the UTLB entry may still remain in the ITLB entry. As the LDTLB instruction changes address translation information, ensure that it is
issued by a program in the P1 or P2 area. The operation of the LDTLB instruction is shown in figure 3.12.

![Figure 3.12 Operation of LDTLB Instruction](image)

### 3.5.4 Hardware ITLB Miss Handling

In an instruction access, the SH-4 searches the ITLB. If it cannot find the necessary address translation information (i.e. in the event of an ITLB miss), the UTLB is searched by hardware, and if the necessary address translation information is present, it is recorded in the ITLB. This procedure is known as hardware ITLB miss handling. If the necessary address translation
information is not found in the UTLB search, an instruction TLB miss exception is generated and processing passes to software.

3.5.5 Avoiding Synonym Problems

When 1- or 4-Kbyte pages are recorded in TLB entries, a synonym problem may arise. The problem is that, when a number of virtual addresses are mapped onto a single physical address, the same physical address data is recorded in a number of cache entries, and it becomes impossible to guarantee data integrity. This problem does not occur with the instruction TLB or instruction cache. In the SH-4, entry specification is performed using bits [13:5] of the virtual address in order to achieve fast operand cache operation. However, bits [13:10] of the virtual address in the case of a 1-Kbyte page, and bits [13:12] of the virtual address in the case of a 4-Kbyte page, are subject to address translation. As a result, bits [13:10] of the physical address after translation may differ from bits [13:10] of the virtual address.

Consequently, the following restrictions apply to the recording of address translation information in UTLB entries.

1. When address translation information whereby a number of 1-Kbyte page UTLB entries are translated into the same physical address is recorded in the UTLB, ensure that the VPN [13:10] values are the same.
2. When address translation information whereby a number of 4-Kbyte page UTLB entries are translated into the same physical address is recorded in the UTLB, ensure that the VPN [13:12] values are the same.
3. Do not use 1-Kbyte page UTLB entry physical addresses with UTLB entries of a different page size.
4. Do not use 4-Kbyte page UTLB entry physical addresses with UTLB entries of a different page size.

The above restrictions apply only when performing accesses using the cache. When cache index mode is used, VPN [25] is used for the entry address instead of VPN [13], and therefore the above restrictions apply to VPN [25].

Note: When multiple items of address translation information use the same physical memory to provide for future SuperH RISC engine family expansion, ensure that the VPN [20:10] values are the same. Also, do not use the same physical address for address translation information of different page sizes.
3.6 MMU Exceptions

There are seven MMU exceptions: the instruction TLB multiple hit exception, instruction TLB miss exception, instruction TLB protection violation exception, data TLB multiple hit exception, data TLB miss exception, data TLB protection violation exception, and initial page write exception. Refer to figures 3.10 and 3.11 for the conditions under which each of these exceptions occurs.

3.6.1 Instruction TLB Multiple Hit Exception

An instruction TLB multiple hit exception occurs when more than one ITLB entry matches the virtual address to which an instruction access has been made. If multiple hits occur when the UTLB is searched by hardware in hardware ITLB miss handling, a data TLB multiple hit exception will result.

When an instruction TLB multiple hit exception occurs a reset is executed, and cache coherency is not guaranteed.

Hardware Processing: In the event of an instruction TLB multiple hit exception, hardware carries out the following processing:

1. Sets the virtual address at which the exception occurred in TEA.
2. Sets exception code H'140 in EXPEVT.
3. Branches to the reset handling routine (H'A000 0000).

Software Processing (Reset Routine): The ITLB entries which caused the multiple hit exception are checked in the reset handling routine. This exception is intended for use in program debugging, and should not normally be generated.

3.6.2 Instruction TLB Miss Exception

An instruction TLB miss exception occurs when address translation information for the virtual address to which an instruction access is made is not found in the UTLB entries by the hardware ITLB miss handling procedure. The instruction TLB miss exception processing carried out by hardware and software is shown below. This is the same as the processing for a data TLB miss exception.
**Hardware Processing:** In the event of an instruction TLB miss exception, hardware carries out the following processing:

1. Sets the VPN of the virtual address at which the exception occurred in PTEH.
2. Sets the virtual address at which the exception occurred in TEA.
3. Sets exception code H'040 in EXPEVT.
4. Sets the PC value indicating the address of the instruction at which the exception occurred in SPC. If the exception occurred at a delay slot, sets the PC value indicating the address of the delayed branch instruction in SPC.
5. Sets the SR contents at the time of the exception in SSR. The R15 contents at this time are saved in SGR.
6. Sets the MD bit in SR to 1, and switches to privileged mode.
7. Sets the BL bit in SR to 1, and masks subsequent exception requests.
8. Sets the RB bit in SR to 1.
9. Branches to the address obtained by adding offset H'0000 0400 to the contents of VBR, and starts the instruction TLB miss exception handling routine.

**Software Processing (Instruction TLB Miss Exception Handling Routine):** Software is responsible for searching the external memory page table and assigning the necessary page table entry. Software should carry out the following processing in order to find and assign the necessary page table entry.

1. Write to PTEL the values of the PPN, PR, SZ, C, D, SH, V, and WT bits in the page table entry recorded in the external memory address translation table. If necessary, the values of the SA and TC bits should be written to PTEA.
2. When the entry to be replaced in entry replacement is specified by software, write that value to URC in the MMUCR register. If URC is greater than URB at this time, the value should be changed to an appropriate value after issuing an LDTLB instruction.
3. Execute the LDTLB instruction and write the contents of PTEH, PTEL, and PTEA to the TLB.
4. Finally, execute the exception handling return instruction (RTE), terminate the exception handling routine, and return control to the normal flow. The RTE instruction should be issued at least one instruction after the LDTLB instruction.
3.6.3 Instruction TLB Protection Violation Exception

An instruction TLB protection violation exception occurs when, even though an ITLB entry contains address translation information matching the virtual address to which an instruction access is made, the actual access type is not permitted by the access right specified by the PR bit. The instruction TLB protection violation exception processing carried out by hardware and software is shown below.

**Hardware Processing:** In the event of an instruction TLB protection violation exception, hardware carries out the following processing:

1. Sets the VPN of the virtual address at which the exception occurred in PTEH.
2. Sets the virtual address at which the exception occurred in TEA.
3. Sets exception code H'0A0 in EXPEVT.
4. Sets the PC value indicating the address of the instruction at which the exception occurred in SPC. If the exception occurred at a delay slot, sets the PC value indicating the address of the delayed branch instruction in SPC.
5. Sets the SR contents at the time of the exception in SSR. The R15 contents at this time are saved in SGR.
6. Sets the MD bit in SR to 1, and switches to privileged mode.
7. Sets the BL bit in SR to 1, and masks subsequent exception requests.
8. Sets the RB bit in SR to 1.
9. Branches to the address obtained by adding offset H'0000 0100 to the contents of VBR, and starts the instruction TLB protection violation exception handling routine.

**Software Processing (Instruction TLB Protection Violation Exception Handling Routine):** Resolve the instruction TLB protection violation, execute the exception handling return instruction (RTE), terminate the exception handling routine, and return control to the normal flow. The RTE instruction should be issued at least one instruction after the LDTLB instruction.

3.6.4 Data TLB Multiple Hit Exception

A data TLB multiple hit exception occurs when more than one UTLB entry matches the virtual address to which a data access has been made. A data TLB multiple hit exception is also generated if multiple hits occur when the UTLB is searched in hardware ITLB miss handling.

When a data TLB multiple hit exception occurs a reset is executed, and cache coherency is not guaranteed. The contents of PPN in the UTLB prior to the exception may also be corrupted.
Hardware Processing: In the event of a data TLB multiple hit exception, hardware carries out the following processing:

1. Sets the virtual address at which the exception occurred in TEA.
2. Sets exception code H'140 in EXPEVT.
3. Branches to the reset handling routine (H'A000 0000).

Software Processing (Reset Routine): The UTLB entries which caused the multiple hit exception are checked in the reset handling routine. This exception is intended for use in program debugging, and should not normally be generated.

3.6.5 Data TLB Miss Exception

A data TLB miss exception occurs when address translation information for the virtual address to which a data access is made is not found in the UTLB entries. The data TLB miss exception processing carried out by hardware and software is shown below.

Hardware Processing: In the event of a data TLB miss exception, hardware carries out the following processing:

1. Sets the VPN of the virtual address at which the exception occurred in PTEH.
2. Sets the virtual address at which the exception occurred in TEA.
3. Sets exception code H'040 in the case of a read, or H'060 in the case of a write, in EXPEVT (OCBP, OCBWB: read; OCBI, MOVCA.L: write).
4. Sets the PC value indicating the address of the instruction at which the exception occurred in SPC. If the exception occurred at a delay slot, sets the PC value indicating the address of the delayed branch instruction in SPC.
5. Sets the SR contents at the time of the exception in SSR. The R15 contents at this time are saved in SGR.
6. Sets the MD bit in SR to 1, and switches to privileged mode.
7. Sets the BL bit in SR to 1, and masks subsequent exception requests.
8. Sets the RB bit in SR to 1.
9. Branches to the address obtained by adding offset H'0000 0400 to the contents of VBR, and starts the data TLB miss exception handling routine.

Software Processing (Data TLB Miss Exception Handling Routine): Software is responsible for searching the external memory page table and assigning the necessary page table entry. Software should carry out the following processing in order to find and assign the necessary page table entry.
1. Write to PTEL the values of the PPN, PR, SZ, C, D, SH, V, and WT bits in the page table entry recorded in the external memory address translation table. If necessary, the values of the SA and TC bits should be written to PTEA.

2. When the entry to be replaced in entry replacement is specified by software, write that value to URC in the MMUCR register. If URC is greater than URB at this time, the value should be changed to an appropriate value after issuing an LDTLB instruction.

3. Execute the LDTLB instruction and write the contents of PTEH, PTEL, and PTEA to the UTLB.

4. Finally, execute the exception handling return instruction (RTE), terminate the exception handling routine, and return control to the normal flow. The RTE instruction should be issued at least one instruction after the LDTLB instruction.

3.6.6 Data TLB Protection Violation Exception

A data TLB protection violation exception occurs when, even though a UTLB entry contains address translation information matching the virtual address to which a data access is made, the actual access type is not permitted by the access right specified by the PR bit. The data TLB protection violation exception processing carried out by hardware and software is shown below.

**Hardware Processing:** In the event of a data TLB protection violation exception, hardware carries out the following processing:

1. Sets the VPN of the virtual address at which the exception occurred in PTEH.
2. Sets the virtual address at which the exception occurred in TEA.
3. Sets exception code H'0A0 in the case of a read, or H'0C0 in the case of a write, in EXPEVT (OCBP, OCBWB: read; OCBI, MOVCA.L: write).
4. Sets the PC value indicating the address of the instruction at which the exception occurred in SPC. If the exception occurred at a delay slot, sets the PC value indicating the address of the delayed branch instruction in SPC.
5. Sets the SR contents at the time of the exception in SSR. The R15 contents at this time are saved in SGR.
6. Sets the MD bit in SR to 1, and switches to privileged mode.
7. Sets the BL bit in SR to 1, and masks subsequent exception requests.
8. Sets the RB bit in SR to 1.
9. Branches to the address obtained by adding offset H'0000 0100 to the contents of VBR, and starts the data TLB protection violation exception handling routine.
Software Processing (Data TLB Protection Violation Exception Handling Routine): Resolve the data TLB protection violation, execute the exception handling return instruction (RTE), terminate the exception handling routine, and return control to the normal flow. The RTE instruction should be issued at least one instruction after the LDTLB instruction.

3.6.7 Initial Page Write Exception

An initial page write exception occurs when the D bit is 0 even though a UTLB entry contains address translation information matching the virtual address to which a data access (write) is made, and the access is permitted. The initial page write exception processing carried out by hardware and software is shown below.

**Hardware Processing:** In the event of an initial page write exception, hardware carries out the following processing:

1. Sets the VPN of the virtual address at which the exception occurred in PTEH.
2. Sets the virtual address at which the exception occurred in TEA.
3. Sets exception code H'080 in EXPEVT.
4. Sets the PC value indicating the address of the instruction at which the exception occurred in SPC. If the exception occurred at a delay slot, sets the PC value indicating the address of the delayed branch instruction in SPC.
5. Sets the SR contents at the time of the exception in SSR. The R15 contents at this time are saved in SGR.
6. Sets the MD bit in SR to 1, and switches to privileged mode.
7. Sets the BL bit in SR to 1, and masks subsequent exception requests.
8. Sets the RB bit in SR to 1.
9. Branches to the address obtained by adding offset H'0000 0100 to the contents of VBR, and starts the initial page write exception handling routine.
Software Processing (Initial Page Write Exception Handling Routine): The following processing should be carried out as the responsibility of software:

1. Retrieve the necessary page table entry from external memory.
2. Write 1 to the D bit in the external memory page table entry.
3. Write to PTEL the values of the PPN, PR, SZ, C, D, WT, SH, and V bits in the page table entry recorded in external memory. If necessary, the values of the SA and TC bits should be written to PTEA.
4. When the entry to be replaced in entry replacement is specified by software, write that value to URC in the MMUCR register. If URC is greater than URB at this time, the value should be changed to an appropriate value after issuing an LDTLB instruction.
5. Execute the LDTLB instruction and write the contents of PTEH, PTEL, and PTEA to the UTLB.
6. Finally, execute the exception handling return instruction (RTE), terminate the exception handling routine, and return control to the normal flow. The RTE instruction should be issued at least one instruction after the LDTLB instruction.

3.7 Memory-Mapped TLB Configuration

To enable the ITLB and UTLB to be managed by software, their contents can be read and written by a P2 area program with a MOV instruction in privileged mode. Operation is not guaranteed if access is made from a program in another area. A branch to an area other than the P2 area should be made at least 8 instructions after this MOV instruction. The ITLB and UTLB are allocated to the P4 area in physical memory space. VPN, V, and ASID in the ITLB can be accessed as an address array, PPN, V, SZ, PR, C, and SH as data array 1, and SA and TC as data array 2. VPN, D, V, and ASID in the UTLB can be accessed as an address array, PPN, V, SZ, PR, C, D, WT, and SH as data array 1, and SA and TC as data array 2. V and D can be accessed from both the address array side and the data array side. Only longword access is possible. Instruction fetches cannot be performed in these areas. For reserved bits, a write value of 0 should be specified; their read value is undefined.
3.7.1 ITLB Address Array

The ITLB address array is allocated to addresses H’F200 0000 to H’F2FF FFFF in the P4 area. An address array access requires a 32-bit address field specification (when reading or writing) and a 32-bit data field specification (when writing). Information for selecting the entry to be accessed is specified in the address field, and VPN, V, and ASID to be written to the address array are specified in the data field.

In the address field, bits [31:24] have the value H’F2 indicating the ITLB address array, and the entry is selected by bits [9:8]. As longword access is used, 0 should be specified for address field bits [1:0].

In the data field, VPN is indicated by bits [31:10], V by bit [8], and ASID by bits [7:0].

The following two kinds of operation can be used on the ITLB address array:

1. ITLB address array read
   VPN, V, and ASID are read into the data field from the ITLB entry corresponding to the entry set in the address field.

2. ITLB address array write
   VPN, V, and ASID specified in the data field are written to the ITLB entry corresponding to the entry set in the address field.

![Figure 3.13 Memory-Mapped ITLB Address Array](image-url)
3.7.2 ITLB Data Array 1

ITLB data array 1 is allocated to addresses H'F300 0000 to H'F37F FFFF in the P4 area. A data array access requires a 32-bit address field specification (when reading or writing) and a 32-bit data field specification (when writing). Information for selecting the entry to be accessed is specified in the address field, and PPN, V, SZ, PR, C, and SH to be written to the data array are specified in the data field.

In the address field, bits [31:23] have the value H'F30 indicating ITLB data array 1, and the entry is selected by bits [9:8].

In the data field, PPN is indicated by bits [28:10], V by bit [8], SZ by bits [7] and [4], PR by bit [6], C by bit [3], and SH by bit [1].

The following two kinds of operation can be used on ITLB data array 1:

1. ITLB data array 1 read
   PPN, V, SZ, PR, C, and SH are read into the data field from the ITLB entry corresponding to the entry set in the address field.

2. ITLB data array 1 write
   PPN, V, SZ, PR, C, and SH specified in the data field are written to the ITLB entry corresponding to the entry set in the address field.

![Figure 3.14 Memory-Mapped ITLB Data Array 1](image-url)
### 3.7.3 ITLB Data Array 2

ITLB data array 2 is allocated to addresses H'F380 0000 to H'F3FF FFFF in the P4 area. A data array access requires a 32-bit address field specification (when reading or writing) and a 32-bit data field specification (when writing). Information for selecting the entry to be accessed is specified in the address field, and SA and TC to be written to data array 2 are specified in the data field.

In the address field, bits [31:23] have the value H'F38 indicating ITLB data array 2, and the entry is selected by bits [9:8].

In the data field, SA is indicated by bits [2:0], and TC by bit [3].

The following two kinds of operation can be used on ITLB data array 2:

1. **ITLB data array 2 read**
   SA and TC are read into the data field from the ITLB entry corresponding to the entry set in the address field.

2. **ITLB data array 2 write**
   SA and TC specified in the data field are written to the ITLB entry corresponding to the entry set in the address field.

![Figure 3.15 Memory-Mapped ITLB Data Array 2](image)

### 3.7.4 UTLB Address Array

The UTLB address array is allocated to addresses H'F600 0000 to H'F6FF FFFF in the P4 area. An address array access requires a 32-bit address field specification (when reading or writing) and a 32-bit data field specification (when writing). Information for selecting the entry to be accessed is specified in the address field, and VPN, D, V, and ASID to be written to the address array are specified in the data field.
In the address field, bits [31:24] have the value H'F6 indicating the UTLB address array, and the entry is selected by bits [13:8]. The address array bit [7] association bit (A bit) specifies whether or not address comparison is performed when writing to the UTLB address array.

In the data field, VPN is indicated by bits [31:10], D by bit [9], V by bit [8], and ASID by bits [7:0].

The following three kinds of operation can be used on the UTLB address array:

1. UTLB address array read
   VPN, D, V, and ASID are read into the data field from the UTLB entry corresponding to the entry set in the address field. In a read, associative operation is not performed regardless of whether the association bit specified in the address field is 1 or 0.

2. UTLB address array write (non-associative)
   VPN, D, V, and ASID specified in the data field are written to the UTLB entry corresponding to the entry set in the address field. The A bit in the address field should be cleared to 0.

3. UTLB address array write (associative)
   When a write is performed with the A bit in the address field set to 1, comparison of all the UTLB entries is carried out using the VPN specified in the data field and PTEH.ASID. The usual address comparison rules are followed, but if a UTLB miss occurs, the result is no operation, and an exception is not generated. If the comparison identifies a UTLB entry corresponding to the VPN specified in the data field, D and V specified in the data field are written to that entry. If there is more than one matching entry, a data TLB multiple hit exception results. This associative operation is simultaneously carried out on the ITLB, and if a matching entry is found in the ITLB, V is written to that entry. Even if the UTLB comparison results in no operation, a write to the ITLB side only is performed as long as there is an ITLB match. If there is a match in both the UTLB and ITLB, the UTLB information is also written to the ITLB.

3.7.5 UTLB Data Array 1

UTLB data array 1 is allocated to addresses H’F700 0000 to H’F77F FFFF in the P4 area. A data array access requires a 32-bit address field specification (when reading or writing) and a 32-bit data field specification (when writing). Information for selecting the entry to be accessed is specified in the address field, and PPN, V, SZ, PR, C, D, SH, and WT to be written to the data array are specified in the data field.

In the address field, bits [31:23] have the value H’F70 indicating UTLB data array 1, and the entry is selected by bits [13:8].

In the data field, PPN is indicated by bits [28:10], V by bit [8], SZ by bits [7] and [4], PR by bits [6:5], C by bit [3], D by bit [2], SH by bit [1], and WT by bit [0].

The following two kinds of operation can be used on UTLB data array 1:

1. UTLB data array 1 read
   PPN, V, SZ, PR, C, D, SH, and WT are read into the data field from the UTLB entry corresponding to the entry set in the address field.

2. UTLB data array 1 write
   PPN, V, SZ, PR, C, D, SH, and WT specified in the data field are written to the UTLB entry corresponding to the entry set in the address field.

3.7.6 UTLB Data Array 2

UTLB data array 2 is allocated to addresses H'F780 0000 to H'F7FF FFFF in the P4 area. A data array access requires a 32-bit address field specification (when reading or writing) and a 32-bit data field specification (when writing). Information for selecting the entry to be accessed is specified in the address field, and SA and TC to be written to data array 2 are specified in the data field.

In the address field, bits [31:23] have the value H'F78 indicating UTLB data array 2, and the entry is selected by bits [13:8].

In the data field, TC is indicated by bit [3], and SA by bits [2:0].

The following two kinds of operation can be used on UTLB data array 2:

1. UTLB data array 2 read
   SA and TC are read into the data field from the UTLB entry corresponding to the entry set in the address field.

2. UTLB data array 2 write
   SA and TC specified in the data field are written to the UTLB entry corresponding to the entry set in the address field.

4.1 Overview

4.1.1 Features

The SH-4 has an on-chip 8-Kbyte instruction cache (IC) for instructions and 16-Kbyte operand cache (OC) for data. Half of the memory of the operand cache (8 kbytes) can also be used as on-chip RAM. The features of these caches are summarized in table 4.1 and 4.2.

After a power-on reset or manual reset, the initial value of the EMODE bit is 0. The SH-4 supports two 32-byte store queues (SQs) for performing high-speed writes to external memory. SQ features are shown in table 4.3.

</table>

Notes:
1. The initial value is the value after a power-on or manual reset.
2. This is the address when using the virtual/physical address space P4 area. When making an access from physical address space area 7 using the TLB, the upper 3 bits of the address are ignored.
4.2 Register Descriptions

There are three cache and store queue related control registers, as shown in figure 4.1.

![Figure 4.1 Cache and Store Queue Control Registers](image)

(1) **Cache Control Register (CCR):** CCR contains the following bits:

- **EMODE:** Double-sized cache mode (Available for SH7750R, SH7751R, and SH7760; reserved bit for SH7750, SH7750S, and SH7751)
- **IIX:** IC index enable
- **ICI:** IC invalidation
- **ICE:** IC enable
- **OIX:** OC index enable
- **ORA:** OC RAM enable
- **OCI:** OC invalidation
- **CB:** Copy-back enable
- **WT:** Write-through enable
- **OCE:** OC enable

Longword access to CCR can be performed from H'FF00 001C in the P4 area and H'1F00 001C in area 7. The CCR bits are used for the cache settings described below. Consequently, CCR modifications must only be made by a program in the non-cached P2 area. After CCR is updated,
an instruction that performs data access to the P0, P1, P3, or U0 area should be located at least four instructions after the CCR update instruction. Also, a branch instruction to the P0, P1, P3, or U0 area should be located at least eight instructions after the CCR update instruction.

- **EMODE**: Double-sized cache mode bit
  In the SH7750R, SH7751R, and SH7760, this bit indicates whether the double-sized cache mode is used or not. This bit is reserved in the SH7750, SH7750S, and SH7751. The EMODE bit must not be written to while the cache is being used.
  0: SH7750/SH7750S/SH7751-compatible mode* (initial value)
  1: Double-sized cache mode
  Note: * No compatibility for RAM mode in OC index mode and address assignment in RAM mode.

- **IIX**: IC index enable bit
  0: Address bits [12:5] used for IC entry selection
  1: Address bits [25] and [11:5] used for IC entry selection

- **ICI**: IC invalidation bit
  When 1 is written to this bit, the V bits of all IC entries are cleared to 0. This bit always returns 0 when read.

- **ICE**: IC enable bit
  Indicates whether or not the IC is to be used. When address translation is performed, the IC cannot be used unless the C bit in the page management information is also 1.
  0: IC not used
  1: IC used

- **OIX**: OC index enable bit*
  0: Address bits [13:5] used for OC entry selection
  1: Address bits [25] and [12:5] used for OC entry selection
  Note: * When the ORA bit is 1 in the SH7750R, the OIX bit should be cleared to 0.

- **ORA**: OC RAM enable bit*
  When the OC is enabled (OCE = 1), the ORA bit specifies whether the 8 kbytes from entry 128 to entry 255 and from entry 384 to entry 511 of the OC are to be used as RAM. When the OC is not enabled (OCE = 0), the ORA bit should be cleared to 0.
  0: 16 kbytes used as cache
  1: 8 kbytes used as cache, and 8 kbytes as RAM
  Note: * When the OIX bit in the SH7750R is 1, the ORA bit should be cleared to 0.
• OCI: OC invalidation bit
  When 1 is written to this bit, the V and U bits of all OC entries are cleared to 0. This bit always returns 0 when read.

• CB: Copy-back bit
  Indicates the P1 area cache write mode.
  0: Write-through mode
  1: Copy-back mode

• WT: Write-through bit
  Indicates the P0, U0, and P3 area cache write mode. When address translation is performed, the value of the WT bit in the page management information has priority.
  0: Copy-back mode
  1: Write-through mode

• OCE: OC enable bit
  Indicates whether or not the OC is to be used. When address translation is performed, the OC cannot be used unless the C bit in the page management information is also 1.
  0: OC not used
  1: OC used

(2) Queue Address Control Register 0 (QACR0): Longword access to QACR0 can be performed from H'FF00 0038 in the P4 area and H'1F00 0038 in area 7. QACR0 specifies the area onto which store queue 0 (SQ0) is mapped when the MMU is off.

(3) Queue Address Control Register 1 (QACR1): Longword access to QACR1 can be performed from H'FF00 003C in the P4 area and H'1F00 003C in area 7. QACR1 specifies the area onto which store queue 1 (SQ1) is mapped when the MMU is off.
Hereafter, this section explains the SH7750, SH7750S and SH7751. For other SH-4 products, refer to the corresponding products’ hardware manual.

### 4.3 Operand Cache (OC)

#### 4.3.1 Configuration

Figure 4.2 shows the configuration of the operand cache.

![Figure 4.2 Configuration of Operand Cache](image)
The operand cache consists of 512 cache lines, each composed of a 19-bit tag, V bit, U bit, and 32-byte data.

- **Tag**
  Stores the upper 19 bits of the 29-bit external memory address of the data line to be cached. The tag is not initialized by a power-on or manual reset.

- **V bit (validity bit)**
  Indicates that valid data is stored in the cache line. When this bit is 1, the cache line data is valid. The V bit is initialized to 0 by a power-on reset, but retains its value in a manual reset.

- **U bit (dirty bit)**
  The U bit is set to 1 if data is written to the cache line while the cache is being used in copy-back mode. That is, the U bit indicates a mismatch between the data in the cache line and the data in external memory. The U bit is never set to 1 while the cache is being used in write-through mode, unless it is modified by accessing the memory-mapped cache (see section 4.5, Memory-Mapped Cache Configuration). The U bit is initialized to 0 by a power-on reset, but retains its value in a manual reset.

- **Data field**
  The data field holds 32 bytes (256 bits) of data per cache line. The data array is not initialized by a power-on or manual reset.

### 4.3.2 Read Operation

When the OC is enabled (CCR.OCE = 1) and data is read by means of an effective address from a cacheable area, the cache operates as follows:

1. The tag, V bit, and U bit are read from the cache line indexed by effective address bits [13:5].
2. The tag is compared with bits [28:10] of the address resulting from effective address translation by the MMU:
   - If the tag matches and the V bit is 1 → (3a)
   - If the tag matches and the V bit is 0 → (3b)
   - If the tag does not match and the V bit is 0 → (3b)
   - If the tag does not match, the V bit is 1, and the U bit is 0 → (3b)
   - If the tag does not match, the V bit is 1, and the U bit is 1 → (3c)
3a. Cache hit

The data indexed by effective address bits [4:0] is read from the data field of the cache line indexed by effective address bits [13:5] in accordance with the access size (quadword/longword/word/byte).

3b. Cache miss (no write-back)

Data is read into the cache line from the external memory space corresponding to the effective address. Data reading is performed, using the wraparound method, in order from the longword data corresponding to the effective address, and when the corresponding data arrives in the cache, the read data is returned to the CPU. While the remaining one cache line of data is being read, the CPU can execute the next processing. When reading of one line of data is completed, the tag corresponding to the effective address is recorded in the cache, and 1 is written to the V bit.

3c. Cache miss (with write-back)

The tag and data field of the cache line indexed by effective address bits [13:5] are saved in the write-back buffer. Then data is read into the cache line from the external memory space corresponding to the effective address. Data reading is performed, using the wraparound method, in order from the longword data corresponding to the effective address, and when the corresponding data arrives in the cache, the read data is returned to the CPU. While the remaining one cache line of data is being read, the CPU can execute the next processing. When reading of one line of data is completed, the tag corresponding to the effective address is recorded in the cache, 1 is written to the V bit, and 0 to the U bit. The data in the write-back buffer is then written back to external memory.

4.3.3 Write Operation

When the OC is enabled (CCR.OCE = 1) and data is written by means of an effective address to a cacheable area, the cache operates as follows:

1. The tag, V bit, and U bit are read from the cache line indexed by effective address bits [13:5].
2. The tag is compared with bits [28:10] of the address resulting from effective address translation by the MMU:

   - If the tag matches and the V bit is 1 → (3a) → (3b)
   - If the tag matches and the V bit is 0 → (3c) → (3d)
   - If the tag does not match and the V bit is 0 → (3c) → (3d)
   - If the tag does not match, the V bit is 1, and the U bit is 0 → (3c) → (3d)
   - If the tag does not match, the V bit is 1, and the U bit is 1 → (3e) → (3d)
3a. Cache hit (copy-back)

A data write in accordance with the access size (quadword/longword/word/byte) is performed for the data indexed by bits [4:0] of the effective address of the data field of the cache line indexed by effective address bits [13:5]. Then 1 is set in the U bit.

3b. Cache hit (write-through)

A data write in accordance with the access size (quadword/longword/word/byte) is performed for the data indexed by bits [4:0] of the effective address of the data field of the cache line indexed by effective address bits [13:5]. A write is also performed to the corresponding external memory using the specified access size.

3c. Cache miss (no copy-back/write-back)

A data write in accordance with the access size (quadword/longword/word/byte) is performed for the data indexed by bits [4:0] of the effective address of the data field of the cache line indexed by effective address bits [13:5]. Then, data is read into the cache line from the external memory space corresponding to the effective address. Data reading is performed, using the wraparound method, in order from the longword data corresponding to the effective address, and one cache line of data is read excluding the written data. During this time, the CPU can execute the next processing. When reading of one line of data is completed, the tag corresponding to the effective address is recorded in the cache, and 1 is written to the V bit and U bit.

3d. Cache miss (write-through)

A write of the specified access size is performed to the external memory corresponding to the effective address. In this case, a write to cache is not performed.

3e. Cache miss (with copy-back/write-back)

The tag and data field of the cache line indexed by effective address bits [13:5] are first saved in the write-back buffer, and then a data write in accordance with the access size (quadword/longword/word/byte) is performed for the data indexed by bits [4:0] of the effective address of the data field of the cache line indexed by effective address bits [13:5]. Then, data is read into the cache line from the external memory space corresponding to the effective address. Data reading is performed, using the wraparound method, in order from the longword data corresponding to the effective address, and one cache line of data is read excluding the written data. During this time, the CPU can execute the next processing. When reading of one line of data is completed, the tag corresponding to the effective address is recorded in the cache, and 1 is written to the V bit and U bit. The data in the write-back buffer is then written back to external memory.
4.3.4 Write-Back Buffer

In order to give priority to data reads to the cache and improve performance, the SH-4 has a write-back buffer which holds the relevant cache entry when it becomes necessary to purge a dirty cache entry into external memory as the result of a cache miss. The write-back buffer contains one cache line of data and the physical address of the purge destination.

<table>
<thead>
<tr>

</tr>
</thead>
</table>

Figure 4.3 Configuration of Write-Back Buffer

4.3.5 Write-Through Buffer

The SH-4 has a 64-bit buffer for holding write data when writing data in write-through mode or writing to a non-cacheable area. This allows the CPU to proceed to the next operation as soon as the write to the write-through buffer is completed, without waiting for completion of the write to external memory.

<table>
<thead>
<tr>
<th>Physical address bits [28:0]</th>
<th>LW0</th>
<th>LW1</th>
</tr>
</thead>
</table>

Figure 4.4 Configuration of Write-Through Buffer

4.3.6 RAM Mode

Setting CCR.ORA to 1 enables 8 kbytes of the operand cache to be used as RAM. The operand cache entries used as RAM are entries 128 to 255 and 384 to 511. Other entries can still be used as cache. RAM can be accessed using addresses H'7C00 0000 to H'7FFF FFFF. Byte-, word-, longword-, and quadword-size data reads and writes can be performed in the operand cache RAM area. Instruction fetches cannot be performed in this area.

An example of RAM use is shown below. Here, the 4 kbytes comprising OC entries 128 to 256 are designated as RAM area 1, and the 4 kbytes comprising OC entries 384 to 511 as RAM area 2.
• When OC index mode is off (CCR.OIX = 0)
  H'7C00 0000 to H'7C00 0FFF (4 kB): Corresponds to RAM area 1
  H'7C00 1000 to H'7C00 1FFF (4 kB): Corresponds to RAM area 1
  H'7C00 2000 to H'7C00 2FFF (4 kB): Corresponds to RAM area 2
  H'7C00 3000 to H'7C00 3FFF (4 kB): Corresponds to RAM area 2
  : : :
  RAM areas 1 and 2 then repeat every 8 kbytes up to H'7FFF FFFF.
  Thus, to secure a continuous 8-Kbyte RAM area, the area from H'7C00 1000 to H'7C00 2FFF
  can be used, for example.

• When OC index mode is on (CCR.OIX = 1)
  H'7C00 0000 to H'7C00 0FFF (4 kB): Corresponds to RAM area 1
  H'7C00 1000 to H'7C00 1FFF (4 kB): Corresponds to RAM area 1
  H'7C00 2000 to H'7C00 2FFF (4 kB): Corresponds to RAM area 1
  : : :
  H'7DFF F000 to H'7DFF FFFF (4 kB): Corresponds to RAM area 1
  H'7E00 0000 to H'7E00 0FFF (4 kB): Corresponds to RAM area 2
  H'7E00 1000 to H'7E00 1FFF (4 kB): Corresponds to RAM area 2
  : : :
  H'7FFF F000 to H'7FFF FFFF (4 kB): Corresponds to RAM area 2

  As the distinction between RAM areas 1 and 2 is indicated by address bit [25], the area from
  H'7DFF F000 to H'7E00 0FFF should be used to secure a continuous 8-Kbyte RAM area.

4.3.7 OC Index Mode

Setting CCR.OIX to 1 enables OC indexing to be performed using bit [25] of the effective address.
This is called OC index mode. In normal mode, with CCR.OIX cleared to 0, OC indexing is
performed using bits [13:5] of the effective address; therefore, when 16 kbytes or more of
consecutive data is handled, the OC is fully used by this data. This results in frequent cache
misses. Using index mode allows the OC to be handled as two 8-Kbyte areas by means of
effective address bit [25], providing efficient use of the cache.
4.3.8 Coherency between Cache and External Memory

Coherency between cache and external memory should be assured by software. In the SH-4, the following four new instructions are supported for cache operations. For details of these instructions, see section 9, Instruction Descriptions.

- Invalidate instruction: OCBI @Rn  Cache invalidation (no write-back)
- Purge instruction: OCBP @Rn  Cache invalidation (with write-back)
- Write-back instruction: OCBWB @Rn  Cache write-back
- Allocate instruction: MOVCA.L R0,@Rn  Cache allocation

4.3.9 Prefetch Operation

The SH-4 supports a prefetch instruction to reduce the cache fill penalty incurred as the result of a cache miss. If it is known that a cache miss will result from a read or write operation, it is possible to fill the cache with data beforehand by means of the prefetch instruction to prevent a cache miss due to the read or write operation, and so improve software performance. If a prefetch instruction is executed for data already held in the cache, or if the prefetch address results in a UTLB miss or a protection violation, the result is no operation, and an exception is not generated. For details of the prefetch instruction, see section 9.74, PREF.

Prefetch instruction: PREF @Rn
4.4 Instruction Cache (IC)

4.4.1 Configuration

Figure 4.5 shows the configuration of the instruction cache.

![Diagram of Instruction Cache Configuration]

Figure 4.5 Configuration of Instruction Cache
The instruction cache consists of 256 cache lines, each composed of a 19-bit tag, V bit, and 32-byte data (16 instructions).

- **Tag**
  Stores the upper 19 bits of the 29-bit external address of the data line to be cached. The tag is not initialized by a power-on or manual reset.

- **V bit (validity bit)**
  Indicates that valid data is stored in the cache line. When this bit is 1, the cache line data is valid. The V bit is initialized to 0 by a power-on reset, but retains its value in a manual reset.

- **Data array**
  The data field holds 32 bytes (256 bits) of data per cache line. The data array is not initialized by a power-on or manual reset.

### 4.4.2 Read Operation

When the IC is enabled (CCR.ICE = 1) and instruction fetches are performed by means of an effective address from a cacheable area, the instruction cache operates as follows:

1. The tag and V bit are read from the cache line indexed by effective address bits [12:5].
2. The tag is compared with bits [28:10] of the address resulting from effective address translation by the MMU:
   - If the tag matches and the V bit is 1 → (3a)
   - If the tag matches and the V bit is 0 → (3b)
   - If the tag does not match and the V bit is 0 → (3b)
   - If the tag does not match and the V bit is 1 → (3b)

3a. Cache hit
   The data indexed by effective address bits [4:2] is read as an instruction from the data field of the cache line indexed by effective address bits [12:5].

3b. Cache miss
   Data is read into the cache line from the external memory space corresponding to the effective address. Data reading is performed, using the wraparound method, in order from the longword data corresponding to the effective address, and when the corresponding data arrives in the cache, the read data is returned to the CPU as an instruction. When reading of one line of data is completed, the tag corresponding to the effective address is recorded in the cache, and 1 is written to the V bit.
4.4.3 IC Index Mode

Setting CCR.IIX to 1 enables IC indexing to be performed using bit [25] of the effective address. This is called IC index mode. In normal mode, with CCR.IIX cleared to 0, IC indexing is performed using bits [12:5] of the effective address; therefore, when 8 kbytes or more of consecutive program instructions are handled, the IC is fully used by this program. This results in frequent cache misses. Using index mode allows the IC to be handled as two 4-Kbyte areas by means of effective address bit [25], providing efficient use of the cache.

4.5 Memory-Mapped Cache Configuration

In the SH7750 and SH7750S, to enable the IC and OC to be managed by software, their contents can be read and written by a P2 area program with a MOV instruction in privileged mode.

In privileged mode in the SH7751, the contents of OC can be read and written by a P1 or P2 area program with a MOV instruction, and the contents of IC can be read and written by a P2 area program with a MOV instruction.

Operation is not guaranteed if access is made from a program in another area. In this case, a branch to the other area should be made at least 8 instructions after this MOV instruction. The IC and OC are allocated to the P4 area in physical memory space. Only data accesses can be used on both the IC address array and data array and the OC address array and data array, and accesses are always longword-size. Instruction fetches cannot be performed in these areas. For reserved bits, a write value of 0 should be specified; their read value is undefined.

4.5.1 IC Address Array

The IC address array is allocated to addresses H'F000 0000 to H'F0FF FFFF in the P4 area. An address array access requires a 32-bit address field specification (when reading or writing) and a 32-bit data field specification. The entry to be accessed is specified in the address field, and the write tag and V bit are specified in the data field.

In the address field, bits [31:24] have the value H'F0 indicating the IC address array, and the entry is specified by bits [12:5]. CCR.IIX has no effect on this entry specification. The address array bit [3] association bit (A bit) specifies whether or not association is performed when writing to the IC address array. As only longword access is used, 0 should be specified for address field bits [1:0].

In the data field, the tag is indicated by bits [31:10], and the V bit by bit [0]. As the IC address array tag is 19 bits in length, data field bits [31:29] are not used in the case of a write in which association is not performed. Data field bits [31:29] are used for the virtual address specification only in the case of a write in which association is performed.
The following three kinds of operation can be used on the IC address array:

1. IC address array read
   The tag and V bit are read into the data field from the IC entry corresponding to the entry set in the address field. In a read, associative operation is not performed regardless of whether the association bit specified in the address field is 1 or 0.

2. IC address array write (non-associative)
   The tag and V bit specified in the data field are written to the IC entry corresponding to the entry set in the address field. The A bit in the address field should be cleared to 0.

3. IC address array write (associative)
   When a write is performed with the A bit in the address field set to 1, the tag stored in the entry specified in the address field is compared with the tag specified in the data field. If the MMU is enabled at this time, comparison is performed after the virtual address specified by data field bits [31:10] has been translated to a physical address using the ITLB. If the addresses match and the V bit is 1, the V bit specified in the data field is written into the IC entry. This operation is used to invalidate a specific IC entry. If an ITLB miss occurs during address translation, or the comparison shows a mismatch, no operation results and the write is not performed. If an instruction TLB multiple hit exception occurs during address translation, processing switches to the instruction TLB multiple hit exception handling routine.

**Figure 4.6 Memory-Mapped IC Address Array**

### 4.5.2 IC Data Array

The IC data array is allocated to addresses H'F100 0000 to H'F1FF FFFF in the P4 area. A data array access requires a 32-bit address field specification (when reading or writing) and a 32-bit data field specification. The entry to be accessed is specified in the address field, and the longword data to be written is specified in the data field.
In the address field, bits [31:24] have the value H'F1 indicating the IC data array, and the entry is specified by bits [12:5]. CCR.IIX has no effect on this entry specification. Address field bits [4:2] are used for the longword data specification in the entry. As only longword access is used, 0 should be specified for address field bits [1:0].

The data field is used for the longword data specification.

The following two kinds of operation can be used on the IC data array:

1. IC data array read
   Longword data is read into the data field from the data specified by the longword specification bits in the address field in the IC entry corresponding to the entry set in the address field.

2. IC data array write
   The longword data specified in the data field is written for the data specified by the longword specification bits in the address field in the IC entry corresponding to the entry set in the address field.

**Figure 4.7 Memory-Mapped IC Data Array**

### 4.5.3 OC Address Array

The OC address array is allocated to addresses H'F400 0000 to H'F4FF FFFF in the P4 area. An address array access requires a 32-bit address field specification (when reading or writing) and a 32-bit data field specification. The entry to be accessed is specified in the address field, and the write tag, U bit, and V bit are specified in the data field.

In the address field, bits [31:24] have the value H'F4 indicating the OC address array, and the entry is specified by bits [13:5]. CCR.OIX and CCR.ORA have no effect on this entry specification. The address array bit [3] association bit (A bit) specifies whether or not association is performed when writing to the OC address array. As only longword access is used, 0 should be specified for address field bits [1:0].
In the data field, the tag is indicated by bits [31:10], the U bit by bit [1], and the V bit by bit [0].
As the OC address array tag is 19 bits in length, data field bits [31:29] are not used in the case of a write in which association is not performed. Data field bits [31:29] are used for the virtual address specification only in the case of a write in which association is performed.

The following three kinds of operation can be used on the OC address array:

1. OC address array read
   The tag, U bit, and V bit are read into the data field from the OC entry corresponding to the entry set in the address field. In a read, associative operation is not performed regardless of whether the association bit specified in the address field is 1 or 0.

2. OC address array write (non-associative)
   The tag, U bit, and V bit specified in the data field are written to the OC entry corresponding to the entry set in the address field. The A bit in the address field should be cleared to 0.
   When a write is performed to a cache line for which the U bit and V bit are both 1, after write-back of that cache line, the tag, U bit, and V bit specified in the data field are written.

3. OC address array write (associative)
   When a write is performed with the A bit in the address field set to 1, the tag stored in the entry specified in the address field is compared with the tag specified in the data field. If the MMU is enabled at this time, comparison is performed after the virtual address specified by data field bits [31:10] has been translated to a physical address using the UTLB. If the addresses match and the V bit is 1, the U bit and V bit specified in the data field are written into the OC entry.
   If the OC entry U bit is 1, and 0 is written to the V bit or to the U bit, write-back is performed. If an UTLB miss occurs during address translation, or the comparison shows a mismatch, no operation results and the write is not performed. If a data TLB multiple hit exception occurs during address translation, processing switches to the data TLB multiple hit exception handling routine.

Figure 4.8 Memory-Mapped OC Address Array
### 4.5.4 OC Data Array

The OC data array is allocated to addresses H'F500 0000 to H'F5FF FFFF in the P4 area. A data array access requires a 32-bit address field specification (when reading or writing) and a 32-bit data field specification. The entry to be accessed is specified in the address field, and the longword data to be written is specified in the data field.

In the address field, bits [31:24] have the value H'F5 indicating the OC data array, and the entry is specified by bits [13:5]. CCR.OIX and CCR.ORA have no effect on this entry specification. Address field bits [4:2] are used for the longword data specification in the entry. As only longword access is used, 0 should be specified for address field bits [1:0].

The data field is used for the longword data specification.

The following two kinds of operation can be used on the OC data array:

1. **OC data array read**
   
   Longword data is read into the data field from the data specified by the longword specification bits in the address field in the OC entry corresponding to the entry set in the address field.

2. **OC data array write**
   
   The longword data specified in the data field is written for the data specified by the longword specification bits in the address field in the OC entry corresponding to the entry set in the address field. This write does not set the U bit to 1 on the address array side.

```
Address field

... : Reserved bits (0 write value, undefined read value)
```

**Figure 4.9 Memory-Mapped OC Data Array**
4.6  Store Queues

Two 32-byte store queues (SQs) are supported to perform high-speed writes to external memory. In the SH7750S and SH7751, when not using the SQs, the low power dissipation power-down modes, in which SQ functions are stopped, can be used. The queue address control registers (QACR0 and QACR1) cannot be accessed while SQ functions are stopped. See section 9, Power-Down Modes, for the procedure for stopping SQ functions.

4.6.1  SQ Configuration

There are two 32-byte store queues, SQ0 and SQ1, as shown in figure 4.10. These two store queues can be set independently.

![Store Queue Configuration](image)

4.6.2  SQ Writes

A write to the SQs can be performed using a store instruction on P4 area H'E000 0000 to H'E3FF FFFC. A longword or quadword access size can be used. The meaning of the address bits is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>[1:0]</td>
<td>00</td>
<td>Fixed at 0</td>
</tr>
</tbody>
</table>
4.6.3 Transfer to External Memory

Transfer from the SQs to external memory can be performed with a prefetch instruction (PREF). Issuing a PREF instruction for P4 area H'E000 0000 to H'E3FF FFFC starts a transfer from the SQs to external memory. The transfer length is fixed at 32 bytes, and the start address is always at a 32-byte boundary. While the contents of one SQ are being transferred to external memory, the other SQ can be written to without a penalty cycle, but writing to the SQ involved in the transfer to external memory is deferred until the transfer is completed.

The SQ transfer destination external memory address bit [28:0] specification is as shown below, according to whether the MMU is on or off.

- When MMU is on (MMUCR.AT = 1)
  The SQ area (H'E000 0000 to H'E3FF FFFF) is set in VPN of the UTLB, and the transfer destination external memory address in PPN. The ASID, V, SZ, SH, PR, and D bits have the same meaning as for normal address translation, but the C and WT bits have no meaning with regard to this page. It is not possible to perform data transfer to a PCMCIA interface area using the SQs.
  When a prefetch instruction is issued for the SQ area, address translation is performed and external memory address bits [28:10] are generated in accordance with the SZ bit specification. For external memory address bits [9:5], the address prior to address translation is generated in the same way as when the MMU is off. External memory address bits [4:0] are fixed at 0. Transfer from the SQs to external memory is performed to this address.

- When MMU is off (MMUCR.AT = 0)
  The SQ area (H'E000 0000 to H'E3FF FFFF) is specified as the address at which a prefetch is performed. The meaning of address bits [31:0] is as follows:

  [31:26]: 111000 Store queue specification
  [25:6]: Address External memory address bits [25:6]
  [5]: 0/1 0: SQ0 specification
       1: SQ1 specification and external memory address bit [5]
  [4:2]: Don’t care No meaning in a prefetch
  [1:0] 00 Fixed at 0

  External memory address bits [28:26], which cannot be generated from the above address, are generated from the QACR0/1 registers.

  QACR0 [4:2]: External memory address bits [28:26] corresponding to SQ0
  QACR1 [4:2]: External memory address bits [28:26] corresponding to SQ1
External memory address bits [4:0] are always fixed at 0 since burst transfer starts at a 32-byte boundary.

In the SH7750, it is not possible to perform data transfer to a PCMCIA interface area using the SQs.

In the SH7750S and SH7751, data transfer to a PCMCIA interface area is always performed using the values of the SA bit and TC bit in PTEA.

### 4.6.4 SQ Protection

It is possible to set protection against SQ writes and transfers to external memory. If an SQ write violates the protection setting, an exception will be generated but the SQ contents will be corrupted. If a transfer from the SQs to external memory (prefetch instruction) violates the protection setting, the transfer to external memory will be inhibited and an exception will be generated.

- **When MMU is on**
  
  Operation is in accordance with the address translation information recorded in the UTLB, and MMUCR.SQMD. Write type exception judgment is performed for writes to the SQs, and read type for transfer from the SQs to external memory (PREF instruction), and a TLB miss exception, protection violation exception, or initial page write exception is generated. However, if SQ access is enabled, in privileged mode only, by MMUCR.SQMD, an address error will be flagged in user mode even if address translation is successful.

- **When MMU is off**
  
  Operation is in accordance with MMUCR.SQMD.

  0: Privileged/user access possible

  1: Privileged access possible

  If the SQ area is accessed in user mode when MMUCR.SQMD is set to 1, an address error will be flagged.
4.6.5   SQ Usage Notes

If an exception occurs within the three instructions preceding an instruction that writes to an SQ
in the SH7750 and SH7750S, a branch may be made to the exception handling routine after
execution of the SQ write that should be suppressed when exception occurs.

This may be due to the bug described in 1 or 2 below.

1. When SQ data is transferred to external memory within a normal program
   If a PREF instruction for transfer from an SQ to external memory is included in the three
   instructions preceding an SQ store instruction, the SQ is updated because the SQ write that
   should be suppressed when a branch is made to the exception handling routine is executed, and
   after returning from the exception handling routine the execution order of the PREF instruction
   and SQ store instruction is reversed, so that erroneous data may be transferred to external
   memory.

2. When SQ data is transferred to external memory in an exception handling routine
   If store queue contents are transferred to external memory within an exception handling
   routine, erroneous data may be transferred to external memory.

Example 1: When a SQ store instruction is executed after a PREF instruction for transfer from
that same SQ to external memory

PREF instruction; PREF instruction for transfer from SQ to external memory
   ; Address of this saved to SPC when exception occurs.
   ; Instruction 1, instruction 2, or instruction 3 may be executed on return from
   ; exception handling routine.
Instruction 1; May be executed if a SQ store instruction.
Instruction 2; May be executed if a SQ store instruction.
Instruction 3; May be executed if a SQ store instruction.
Instruction 4; Note executed even if a SQ store instruction.

Example 2: When an instruction that generates an exception branches using a branch instruction

Instruction 1 (branch instruction); Address of this instruction is saved to SPC when exception
occurs.
Instruction 2; May be executed if instruction 1 is a delay slot instruction and an instruction to store
data to SQ.
Instruction 3
Instruction 4
Instruction 5
Instruction 6
Instruction 7 (branch destination of instruction 1); May be executed if a SQ access instruction. Instruction 8; May be executed if a SQ store instruction.

**Example 3:** When an instruction that generates an exception does not branch using a branch instruction

Instruction 1 (branch instruction); Address of this instruction is saved to SPC when exception occurs. Instruction 2; May be executed if a SQ store instruction. Instruction 3; May be executed if a SQ store instruction. Instruction 4; May be executed if a SQ store instruction. Instruction 5

To recover from this problem it is necessary that conditions 1 and 2 be satisfied.

1. After the PREF instruction to transfer data from the store queue (SQ0, SQ1) to external memory, a store instruction for the same store queue must be executed, and conditions a and b below must be satisfied.
   a. Three NOP instructions*1 must be inserted between the above two instructions.
   b. There must not be a PREF instruction to transfer data from the store queue to external memory in the delay slot of the branch instruction.

2. There must be no PREF instruction to transfer data from the store queue to external memory executed in the exception handling routine.
   If such an instruction is executed, and if there is a store to the store queue instruction among the four instructions*2 at the address referred to by SPC, the data transferred to external memory by the PREF instruction may indicate that execution of the store instruction has completed.

Notes: 1. If there are other instructions between the above two instructions, the problem can be avoided if the other instructions and NOP instructions together total three or more instructions.
   2. If the instruction at the address referred to by SPC is a branch instruction the two instructions at the branch destination may be affected.
Section 5 Exceptions

5.1 Overview

5.1.1 Features

Exception handling is processing handled by a special routine, separate from normal program processing, that is executed by the CPU in case of abnormal events. For example, if the executing instruction ends abnormally, appropriate action must be taken in order to return to the original program sequence, or report the abnormality before terminating the processing. The process of generating an exception handling request in response to abnormal termination, and passing control to a user-written exception handling routine, in order to support such functions, is given the generic name of exception handling.

SH-4 exception handling is of three kinds: for resets, general exceptions, and interrupts.

5.1.2 Register Configuration

The registers used in exception handling are shown in table 5.1.

Table 5.1 Exception-Related Registers

<table>
<thead>
<tr>
<th>Name</th>
<th>Abbreviation</th>
<th>R/W</th>
<th>Initial Value</th>
<th>P4 Address</th>
<th>Area 7 Address</th>
<th>Access Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRAPA exception</td>
<td>TRA</td>

<tr>
<td>register</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Notes: 1. H'0000 0000 is set in a power-on reset, and H'0000 0020 in a manual reset.
2. This is the address when using the virtual/physical address space P4 area. When making an access from physical address space area 7 using the TLB, the upper 3 bits of the address are ignored.
5.2 Register Descriptions

There are three registers related to exception handling. These are allocated to memory, and can be accessed by specifying the P4 address or area 7 address.

1. The exception event register (EXPEVT) resides at P4 address H'FF00 0024, and contains a 12-bit exception code. The exception code set in EXPEVT is that for a reset or general exception event. The exception code is set automatically by hardware when an exception occurs. EXPEVT can also be modified by software.

2. The interrupt event register (INTEVT) resides at P4 address H'FF00 0028, and contains a 12-bit (SH7750, SH750S, SH7750R) or 14-bit (SH7751, SH7751R) exception code. The exception code set in INTEVT is that for an interrupt request. The exception code is set automatically by hardware when an exception occurs. INTEVT can also be modified by software.

3. The TRAPA exception register (TRA) resides at P4 address H'FF00 0020, and contains 8-bit immediate data (imm) for the TRAPA instruction. TRA is set automatically by hardware when a TRAPA instruction is executed. TRA can also be modified by software.

The bit configurations of EXPEVT, INTEVT, and TRA are shown in figure 5.1.

<table>
<thead>
<tr>
<th>EXPEVT (SH7750/SH7750S/SH7750R, SH7751/SH7751R, SH7760), INTEVT (SH7750/SH7750S/SH7750R)</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>-----</td>
</tr>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

Legend:
- 0: Reserved bits. These bits are always read as 0, and should only be written with 0.
- imm: 8-bit immediate data of the TRAPA instruction
5.3 Exception Handling Functions

5.3.1 Exception Handling Flow

In exception handling, the contents of the program counter (PC), status register (SR), and R15 are saved in the saved program counter (SPC), saved status register (SSR), and saved general register 15 (SGR), and the CPU starts execution of the appropriate exception handling routine according to the vector address. An exception handling routine is a program written by the user to handle a specific exception. The exception handling routine is terminated and control returned to the original program by executing a return-from-exception instruction (RTE). This instruction restores the PC and SR contents and returns control to the normal processing routine at the point at which the exception occurred.

The SGR contents are not written back to R15 by an RTE instruction.

The basic processing flow is as follows. See section 2, Programming Model, for the meaning of the individual SR bits.

1. The PC, SR, and R15 contents are saved in SPC, SSR, and SGR.
2. The block bit (BL) in SR is set to 1.
3. The mode bit (MD) in SR is set to 1.
4. The register bank bit (RB) in SR is set to 1.
5. In a reset, the FPU disable bit (FD) in SR is cleared to 0.
6. The exception code is written to bits 11–0 of the exception event register (EXPEVT): SH7750, SH7750S, SH7750R, bits 13–0 of the exception event register (EXPEVT): SH7751, SH7751R, SH7760 or interrupt event register (INTEVT).
7. The CPU branches to the determined exception handling vector address, and the exception handling routine begins.

5.3.2 Exception Handling Vector Addresses

The reset vector address is fixed at H'A000 0000. Exception and interrupt vector addresses are determined by adding the offset for the specific event to the vector base address, which is set by software in the vector base register (VBR). In the case of the TLB miss exception, for example, the offset is H'0000 0400, so if H'9C08 0000 is set in VBR, the exception handling vector address will be H'9C08 0400. If a further exception occurs at the exception handling vector address, a duplicate exception will result, and recovery will be difficult; therefore, fixed physical addresses (P1, P2) should be specified for vector addresses.
### 5.4 Exception Types and Priorities

Table 5.2 shows the types of exceptions, with their relative priorities, vector addresses, and exception/interrupt codes.

**Priority:** Priority is first assigned by priority level, then by priority order within each level (the lowest number represents the highest priority).

**Exception transition destination:** Control passes to H'A000 0000 in a reset, and to [VBR + offset] in other cases.

**Exception code:** Stored in EXPEVT for a reset or general exception, and in INTEVT for an interrupt.

**IRL:** Interrupt request level (pins IRL3–IRL0).

**Module/source:** Example of the SH7751/SH7751R. For details, refer to the corresponding products’ hardware manual.

**Notes:**
1. When BRCR.UBDE = 1, PC = DBR. In other cases, PC = VBR + H’100.
2. The priority order of external interrupts and peripheral module interrupts can be set by software.
5.5 Exception Flow

5.5.1 Exception Flow

Figure 5.2 shows an outline flowchart of the basic operations in instruction execution and exception handling. For the sake of clarity, the following description assumes that instructions are executed sequentially, one by one. Figure 5.2 shows the relative priority order of the different kinds of exceptions (reset/general exception/interrupt). Register settings in the event of an exception are shown only for SSR, SPC, SGR, EXPEVT/INTEVT, SR, and PC, but other registers may be set automatically by hardware, depending on the exception. For details, see section 5.6, Description of Exceptions. Also, see section 5.6.4, Priority Order with Multiple Exceptions, for exception handling during execution of a delayed branch instruction and a delay slot instruction, and in the case of instructions in which two data accesses are performed.

![Figure 5.2 Instruction Execution and Exception Handling](image-url)
5.5.2 Exception Source Acceptance

A priority ranking is provided for all exceptions for use in determining which of two or more simultaneously generated exceptions should be accepted. Five of the general exceptions—the general illegal instruction exception, slot illegal instruction exception, general FPU disable exception, slot FPU disable exception, and unconditional trap exception—are detected in the process of instruction decoding, and do not occur simultaneously in the instruction pipeline. These exceptions therefore all have the same priority. General exceptions are detected in the order of instruction execution. However, exception handling is performed in the order of instruction flow (program order). Thus, an exception for an earlier instruction is accepted before that for a later instruction. An example of the order of acceptance for general exceptions is shown in figure 5.3.
Figure 5.3  Example of General Exception Acceptance Order
5.5.3 Exception Requests and BL Bit

When the BL bit in SR is 0, exceptions and interrupts are accepted.

When the BL bit in SR is 1 and an exception other than a user break is generated, the CPU’s internal registers and the registers of the other modules are set to their states following a manual reset, and the CPU branches to the same address as in a reset (H'A000 0000). For the operation in the event of a user break, see User Break Controller in the hardware manual. If an ordinary interrupt occurs, the interrupt request is held pending and is accepted after the BL bit has been cleared to 0 by software. If a nonmaskable interrupt (NMI) occurs, it can be held pending or accepted according to the setting made by software.

Thus, normally, SPC and SSR are saved and then the BL bit in SR is cleared to 0, to enable multiple exception state acceptance.

5.5.4 Return from Exception Handling

The RTE instruction is used to return from exception handling. When the RTE instruction is executed, the SPC contents are restored to PC and the SSR contents to SR, and the CPU returns from the exception handling routine by branching to the SPC address. If SPC and SSR were saved to external memory, set the BL bit in SR to 1 before restoring the SPC and SSR contents and issuing the RTE instruction.

5.6 Description of Exceptions

The various exception handling operations are described here, covering exception sources, transition addresses, and processor operation when a transition is made.

5.6.1 Resets

(1) Power-On Reset

- Sources:
  - SCK2 pin high level and RESET pin low level (SH7750/SH7750S/SH7750R)/RESET pin low level (SH7751/SH7751R)
  - When the watchdog timer overflows while the WT/IT bit is set to 1 and the RSTS bit is cleared to 0 in WTCSR. For details, see Clock Oscillation Circuits in hardware manual.
- Transition address: H'A000 0000
Transition operations:
Exception code H'000 is set in EXPEVT, initialization of VBR and SR is performed, and a branch is made to PC = H'A000 0000.
In the initialization processing, the VBR register is set to H'0000 0000, and in SR, the MD, RB, and BL bits are set to 1, the FD bit is cleared to 0, and the interrupt mask bits (I3–I0) are set to B'1111.
CPU and on-chip peripheral module initialization is performed. For details, see the register descriptions in the relevant sections. For some CPU functions, the TRST pin and RESET pin must be driven low. It is therefore essential to execute a power-on reset and drive the TRST pin low when powering on.
If the SCK2 pin is changed to the low level while the RESET pin is low, a manual reset may occur after the power-on reset operation. Do not drive the SCK2 pin low during this interval (see Electrical Characteristics in the hardware manual).
In the SH7750, SH7750S and SH7750R, if the SCK2 pin is changed to the low level while the RESET pin is low, a manual reset may occur after the power-on reset operation. Do not drive the SCK2 pin low during this interval. For details, see Electrical Characteristics in the hardware manual.
In the SH7751, SH7750R and SH7760, if the RESET pin is driven high before the MRESET pin while both these pins are low, a manual reset may occur after the power-on reset operation. The RESET pin must be driven high at the same time as, or after, the MRESET pin.

```
Power_on_reset() {
    EXPEVT = H'00000000;
    VBR = H'00000000;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    SR.(I0-I3) = B'1111;
    SR.FD=0;
    Initialize_CPU();
    Initialize_Module(PowerOn);
    PC = H'A0000000;
}
```
(2) Manual Reset

- Sources:
  - SCK2 pin low level and RESET pin low level (SH7750/SH7750S/SH7750R)/MRESET pin low level and RESET pin high level (SH7751/SH7751R, SH7760)
  - When a general exception other than a user break occurs while the BL bit is set to 1 in SR
  - When the watchdog timer overflows while the WT/IT bit is set to 1 and the RSTS bit is set to 1 in WTCSR. For details, see Clock Oscillation Circuits in the hardware manual.

- Transition address: H'A000 0000

- Transition operations:
  Exception code H'020 is set in EXPEVT, initialization of VBR and SR is performed, and a branch is made to PC = H'A000 0000.
  In the initialization processing, the VBR register is set to H'0000 0000, and in SR, the MD, RB, and BL bits are set to 1, the FD bit is cleared to 0, and the interrupt mask bits (I3–I0) are set to B'1111.
  CPU and on-chip peripheral module initialization is performed. For details, see the register descriptions in the relevant sections.

```c
Manual_reset()
{
    EXPEVT = H'00000020;
    VBR = H'00000000;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    SR.(I0-I3) = B'1111;
    SR.FD = 0;
    Initialize_CPU();
    Initialize_Module(Manual);
    PC = H'A0000000;
}
```

(3) H-UDI Reset

- Source: SDIR.TI3–T10 = B'0110 (negation) or B'0111 (assertion)
- Transition address: H'A000 0000
- Transition operations:
  Exception code H'000 is set in EXPEVT, initialization of VBR and SR is performed, and a branch is made to PC = H'A000 0000.

In the initialization processing, the VBR register is set to H'0000 0000, and in SR, the MD, RB, and BL bits are set to 1, the FD bit is cleared to 0, and the interrupt mask bits (I3–I0) are set to B'1111.

CPU and on-chip peripheral module initialization is performed. For details, see the register descriptions in the relevant sections.

```c
H-UDI_reset()
{
    EXPEVT = H'00000000;
    VBR = H'00000000;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    SR.(I0-I3) = B'1111;
    SR.FD = 0;
    Initialize_CPU();
    Initialize_Module(PowerOn);
    PC = H'A0000000;
}
```
(4) **Instruction TLB Multiple-Hit Exception**

- Source: Multiple ITLB address matches
- Transition address: H'A000 0000
- Transition operations:
  - The virtual address (32 bits) at which this exception occurred is set in TEA, and the corresponding virtual page number (22 bits) is set in PTEH [31:10]. ASID in PTEH indicates the ASID when this exception occurred.
  - Exception code H'140 is set in EXPEVT, initialization of VBR and SR is performed, and a branch is made to PC = H'A000 0000.
  - In the initialization processing, the VBR register is set to H'0000 0000, and in SR, the MD, RB, and BL bits are set to 1, the FD bit is cleared to 0, and the interrupt mask bits (I3–I0) are set to B'1111.
  - CPU and on-chip peripheral module initialization is performed in the same way as in a manual reset. For details, see the register descriptions in the relevant sections.

```c
TLB_multi_hit()
{
    TEA = EXCEPTION_ADDRESS;
    PTEH.VPN = PAGE_NUMBER;
    EXPEVT = H'00000140;
    VBR = H'00000000;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    SR.(I0-I3) = B'1111;
    SR.FD = 0;
    Initialize_CPU();
    Initialize_Module(Manual);
    PC = H'A0000000;
}
```
Section 5 Exceptions

(5) Operand TLB Multiple-Hit Exception

- Source: Multiple UTLB address matches
- Transition address: H'A000 0000
- Transition operations:
  The virtual address (32 bits) at which this exception occurred is set in TEA, and the corresponding virtual page number (22 bits) is set in PTEH [31:10]. ASID in PTEH indicates the ASID when this exception occurred.
  Exception code H'140 is set in EXPEVT, initialization of VBR and SR is performed, and a branch is made to PC = H'A000 0000.
  In the initialization processing, the VBR register is set to H'0000 0000, and in SR, the MD, RB, and BL bits are set to 1, the FD bit is cleared to 0, and the interrupt mask bits (I3–I0) are set to B'1111.
  CPU and on-chip peripheral module initialization is performed in the same way as in a manual reset. For details, see the register descriptions in the relevant sections.

TLB_multi_hit()
{
    TEA = EXCEPTION_ADDRESS;
    PTEH.VPN = PAGE_NUMBER;
    EXPEVT = H'00000140;
    VBR = H'00000000;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    SR.(I0-I3) = B'1111;
    SR.FD = 0;
    Initialize_CPU();
    Initialize_Module(Manual);
    PC = H'A0000000;
}
5.6.2 General Exceptions

(1) Data TLB Miss Exception

- Source: Address mismatch in UTLB address comparison
- Transition address: VBR + H'0000 0400
- Transition operations:
  The virtual address (32 bits) at which this exception occurred is set in TEA, and the corresponding virtual page number (22 bits) is set in PTEH [31:10]. ASID in PTEH indicates the ASID when this exception occurred.
  The PC and SR contents for the instruction at which this exception occurred are saved in SPC and SSR, and the contents of R15 are saved in SGR.
  Exception code H'040 (for a read access) or H'060 (for a write access) is set in EXPEVT. The BL, MD, and RB bits are set to 1 in SR, and a branch is made to PC = VBR + H'0400.
  To speed up TLB miss processing, the offset is separate from that of other exceptions.

```c
Data_TLB_miss_exception()
{
    TEA = EXCEPTION_ADDRESS;
    PTEH.VPN = PAGE_NUMBER;
    SPC = PC;
    SSR = SR;
    SGR = R15;
    EXPEVT = read_access ? H'00000040 : H'00000060;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    PC = VBR + H'00000400;
}
```
(2) Instruction TLB Miss Exception

- Source: Address mismatch in ITLB address comparison
- Transition address: VBR + H'0000 0400
- Transition operations:
  The virtual address (32 bits) at which this exception occurred is set in TEA, and the corresponding virtual page number (22 bits) is set in PTEH[31:10]. ASID in PTEH indicates the ASID when this exception occurred.

  The PC and SR contents for the instruction at which this exception occurred are saved in SPC and SSR, and the contents of R15 are saved in SGR.

  Exception code H'040 is set in EXPEVT. The BL, MD, and RB bits are set to 1 in SR, and a branch is made to PC = VBR + H'0400.

  To speed up TLB miss processing, the offset is separate from that of other exceptions.

ITLB_miss_exception()
{
    TEA = EXCEPTION_ADDRESS;
    PTEH.VPN = PAGE_NUMBER;
    SPC = PC;
    SSR = SR;
    SGR = R15;
    EXPEVT = H'00000040;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    PC = VBR + H'00000400;
}
### (3) Initial Page Write Exception

- **Source:** TLB is hit in a store access, but dirty bit D = 0
- **Transition address:** VBR + H'0000 0100
- **Transition operations:**
  
  The virtual address (32 bits) at which this exception occurred is set in TEA, and the corresponding virtual page number (22 bits) is set in PTEH [31:10]. ASID in PTEH indicates the ASID when this exception occurred.

  The PC and SR contents for the instruction at which this exception occurred are saved in SPC and SSR, and the contents of R15 are saved in SGR.

  Exception code H'080 is set in EXPEVT. The BL, MD, and RB bits are set to 1 in SR, and a branch is made to PC = VBR + H'0100.

```
Initial_write_exception()
{
    TEA = EXCEPTION_ADDRESS;
    PTEH.VPN = PAGE_NUMBER;
    SPC = PC;
    SSR = SR;
    SGR = R15;
    EXPEVT = H'00000080;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    PC = VBR + H'00000100;
}
```
(4) Data TLB Protection Violation Exception

- Source: The access does not accord with the UTLB protection information (PR bits) shown below.

<table>
<thead>
<tr>
<th>PR</th>
<th>Privileged Mode</th>
<th>User Mode</th>
</tr>
</thead>
<tbody>
<tr>

<td>Read/write access possible</td>
<td>Read/write access possible</td>
</tr>
</tbody>
</table>

- Transition address: VBR + H'0000 0100

- Transition operations:
  The virtual address (32 bits) at which this exception occurred is set in TEA, and the corresponding virtual page number (22 bits) is set in PTEH [31:10]. ASID in PTEH indicates the ASID when this exception occurred.
  The PC and SR contents for the instruction at which this exception occurred are saved in SPC and SSR, and the contents of R15 are saved in SGR.
  Exception code H'0A0 (for a read access) or H'0C0 (for a write access) is set in EXPEVT. The BL, MD, and RB bits are set to 1 in SR, and a branch is made to PC = VBR + H'0100.

Data_TLB_protection_violation_exception()
{
    TEA = EXCEPTION_ADDRESS;
    PTEH.VPN = PAGE_NUMBER;
    SPC = PC;
    SSR = SR;
    SGR = R15;
    EXPEVT = read_access ? H'000000A0 : H'000000C0;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    PC = VBR + H'00000100;
}
(5) Instruction TLB Protection Violation Exception

- Source: The access does not accord with the ITLB protection information (PR bits) shown below.

<table>
<thead>
<tr>
<th>PR</th>
<th>Privileged Mode</th>
<th>User Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Access possible</td>
<td>Access not possible</td>
</tr>
<tr>
<td>1</td>
<td>Access possible</td>
<td>Access possible</td>
</tr>
</tbody>
</table>

- Transition address: VBR + H'0000 0100

- Transition operations:
  
The virtual address (32 bits) at which this exception occurred is set in TEA, and the corresponding virtual page number (22 bits) is set in PTEH [31:10]. ASID in PTEH indicates the ASID when this exception occurred.

  The PC and SR contents for the instruction at which this exception occurred are saved in SPC and SSR, and the contents of R15 are saved in SGR.

  Exception code H'0A0 is set in EXPEVT. The BL, MD, and RB bits are set to 1 in SR, and a branch is made to PC = VBR + H'0100.

  ```c
  ITLB_protection_violation_exception()
  {
      TEA = EXCEPTION_ADDRESS;
      PTEH.VPN = PAGE_NUMBER;
      SPC = PC;
      SSR = SR;
      SGR = R15;
      EXPEVT = H'000000A0;
      SR.MD = 1;
      SR.RB = 1;
      SR.BL = 1;
      PC = VBR + H'00000100;
  }
  ```

(6) Data Address Error

- Sources:
  - Word data access from other than a word boundary (2n + 1)
  - Longword data access from other than a longword data boundary (4n + 1, 4n + 2, or 4n + 3)
  - Quadword data access from other than a quadword data boundary (8n + 1, 8n + 2, 8n + 3, 8n + 4, 8n + 5, 8n + 6, or 8n + 7)
  - Access to area H'8000 0000–H'FFFF FFFF in user mode

- Transition address: VBR + H'0000 0100

- Transition operations:
The virtual address (32 bits) at which this exception occurred is set in TEA, and the corresponding virtual page number (22 bits) is set in PTEH [31:10]. ASID in PTEH indicates the ASID when this exception occurred.
The PC and SR contents for the instruction at which this exception occurred are saved in SPC and SSR, and the contents of R15 are saved in SGR.
Exception code H'0E0 (for a read access) or H'100 (for a write access) is set in EXPEVT. The BL, MD, and RB bits are set to 1 in SR, and a branch is made to PC = VBR + H'0100. For details, see section 3, Memory Management Unit (MMU).

```c
Data_address_error()
{
    TEA = EXCEPTION_ADDRESS;
    PTEN.VPN = PAGE_NUMBER;
    SPC = PC;
    SSR = SR;
    SGR = R15;
    EXPEVT = read_access? H'000000E0: H'00000100;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    PC = VBR + H'00000100;
}
```
(7) **Instruction Address Error**

- **Sources:**
  - Instruction fetch from other than a word boundary (2n +1)
  - Instruction fetch from area H'8000 0000–H'FFFF FFFF in user mode
- **Transition address:** VBR + H'0000 0100
- **Transition operations:**
  The virtual address (32 bits) at which this exception occurred is set in TEA, and the corresponding virtual page number (22 bits) is set in PTEH [31:10]. ASID in PTEH indicates the ASID when this exception occurred.
  The PC and SR contents for the instruction at which this exception occurred are saved in SPC and SSR, and the contents of R15 are saved in SGR.
  Exception code H'0E0 is set in EXPEVT. The BL, MD, and RB bits are set to 1 in SR, and a branch is made to PC = VBR + H'0100. For details, see section 3, Memory Management Unit (MMU).

```c
Instruction_address_error()
{
  TEA = EXCEPTION_ADDRESS;
  PTEN.VPN = PAGE_NUMBER;
  SPC = PC;
  SSR = SR;
  SGR = R15;
  EXPEVT = H'000000E0;
  SR.MD = 1;
  SR.RB = 1;
  SR.BL = 1;
  PC = VBR + H'00000100;
}
```
(8) Unconditional Trap

- Source: Execution of TRAPA instruction
- Transition address: VBR + H'0000 0100
- Transition operations:
  As this is a processing-completion-type exception, the PC contents for the instruction following the TRAPA instruction are saved in SPC. The values of SR and R15 when the TRAPA instruction is executed are saved in SSR and SGR. The 8-bit immediate value in the TRAPA instruction is multiplied by 4, and the result is set in TRA [9:0]. Exception code H'160 is set in EXPEVT. The BL, MD, and RB bits are set to 1 in SR, and a branch is made to PC = VBR + H'0100.

```
TRAPA_exception()
{
    SPC = PC + 2;
    SSR = SR;
    SGR = R15;
    TRA = imm << 2;
    EXPEVT = H'00000160;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    PC = VBR + H'00000100;
}
```
(9) General Illegal Instruction Exception

- **Sources:**
  - Decoding of an undefined instruction not in a delay slot
    - Delayed branch instructions: JMP, JSR, BRA, BRAF, BSR, BSRF, RTS, RTE, BT/S, BF/S
    - Undefined instruction: H'FFFD
  - Decoding in user mode of a privileged instruction not in a delay slot
    - Privileged instructions: LDC, STC, RTE, LDTLB, SLEEP, but excluding LDC/STC
      instructions that access GBR

- **Transition address:** VBR + H'0000 0100
- **Transition operations:**
  - The PC and SR contents for the instruction at which this exception occurred are saved in SPC
    and SSR, and the contents of R15 are saved in SGR.
  - Exception code H'180 is set in EXPEVT. The BL, MD, and RB bits are set to 1 in SR, and a
    branch is made to PC = VBR + H'0100. Operation is not guaranteed if an undefined code other
    than H'FFFD is decoded.

```c
General_illegal_instruction_exception()
{
    SPC = PC;
    SSR = SR;
    SGR = R15;
    EXPEVT = H'00000180;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    PC = VBR + H'00000100;
}
```
(10) Slot Illegal Instruction Exception

- **Sources:**
  - Decoding of an undefined instruction in a delay slot
    - Delayed branch instructions: JMP, JSR, BRA, BRAF, BSR, BSRF, RTS, RTE, BT/S, BF/S
    - Undefined instruction: H'FFFD
  - Decoding of an instruction that modifies PC in a delay slot
    - Instructions that modify PC: JMP, JSR, BRA, BRAF, BSR, BSRF, RTS, RTE, BT, BF, BT/S, BF/S, TRAPA, LDC Rm, SR, LDC.L @Rm+,SR
  - Decoding in user mode of a privileged instruction in a delay slot
    - Privileged instructions: LDC, STC, RTE, LDTLB, SLEEP, but excluding LDC/STC instructions that access GBR
  - Decoding of a PC-relative MOV instruction or MOVA instruction in a delay slot

- **Transition address:** VBR + H'0000 0100

- **Transition operations:**
  - The PC contents for the preceding delayed branch instruction are saved in SPC. The SR and R15 contents when this exception occurred are saved in SSR and SGR.
  - Exception code H'1A0 is set in EXPEVT. The BL, MD, and RB bits are set to 1 in SR, and a branch is made to PC = VBR + H'0100. Operation is not guaranteed if an undefined code other than H'FFFD is decoded.

```c
Slot_illegal_instruction_exception()
{
    SPC = PC - 2;
    SSR = SR;
    SGR = R15;
    EXPEVT = H'000001A0;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    PC = VBR + H'00000100;
}
```
(11) General FPU Disable Exception

- Source: Decoding of an FPU instruction* not in a delay slot with SR.FD = 1
- Transition address: VBR + H'0000 0100
- Transition operations:
  The PC and SR contents for the instruction at which this exception occurred are saved in SPC and SSR, and the contents of R15 are saved in SGR.
  Exception code H'800 is set in EXPEVT. The BL, MD, and RB bits are set to 1 in SR, and a branch is made to PC = VBR + H'0100.

Note: * FPU instructions are instructions in which the first 4 bits of the instruction code are F (but excluding undefined instruction H'FFFD), and the LDS, STS, LDS.L, and STS.L instructions corresponding to FPUL and FPSCR.

```c
General_fpu_disable_exception()
{
    SPC = PC;
    SSR = SR;
    SGR = R15;
    EXPEVT = H'00000800;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    PC = VBR + H'00000100;
}
```
(12) Slot FPU Disable Exception

- Source: Decoding of an FPU instruction in a delay slot with SR.FD = 1
- Transition address: VBR + H'0000 0100
- Transition operations:
  The PC contents for the preceding delayed branch instruction are saved in SPC. The SR and R15 contents when this exception occurred are saved in SSR and SGR.
  Exception code H'820 is set in EXPEVT. The BL, MD, and RB bits are set to 1 in SR, and a branch is made to PC = VBR + H'0100.

```c
Slot_fpu_disable_exception()
{
    SPC = PC - 2;
    SSR = SR;
    SGR = R15;
    EXPEVT = H'00000820;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    PC = VBR + H'00000100;
}
```
(13) User Breakpoint Trap

- Source: Fulfilling of a break condition set in the user break controller
- Transition address: VBR + H'0000 0100, or DBR
- Transition operations:
  In the case of a post-execution break, the PC contents for the instruction following the instruction at which the breakpoint is set are set in SPC. In the case of a pre-execution break, the PC contents for the instruction at which the breakpoint is set are set in SPC.
  The SR and R15 contents when the break occurred are saved in SSR and SGR. Exception code H'1E0 is set in EXPEVT.
  The BL, MD, and RB bits are set to 1 in SR, and a branch is made to PC = VBR + H'0100. It is also possible to branch to PC = DBR.
  For details of PC, etc., when a data break is set, see User Break Controller in the hardware manual.

```c
User_break_exception()
{
    SPC = (pre_execution break? PC : PC + 2);
    SSR = SR;
    SGR = R15;
    EXPEVT = H'000001E0;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    PC = (BRCR.UBDE==1 ? DBR : VBR + H'00000100);
}
```
(14) FPU Exception

- Source: Exception due to execution of a floating-point operation
- Transition address: VBR + H'0000 0100
- Transition operations:
  The PC and SR contents for the instruction at which this exception occurred are saved in SPC and SSR, and the contents of R15 are saved in SGR. Exception code H'120 is set in EXPEVT. The BL, MD, and RB bits are set to 1 in SR, and a branch is made to PC = VBR + H'0100.

\[
\text{FPU\_exception()}
\]
\[
\begin{align*}
\text{SPC} &= \text{PC}; \\
\text{SSR} &= \text{SR}; \\
\text{SGR} &= \text{R15}; \\
\text{EXPEVT} &= \text{H'00000120}; \\
\text{SR.MD} &= 1; \\
\text{SR.RB} &= 1; \\
\text{SR.BL} &= 1; \\
\text{PC} &= \text{VBR + H'00000100};
\end{align*}
\]
5.6.3 Interrupts

(1) NMI

- Source: NMI pin edge detection
- Transition address: VBR + H'0000 0600
- Transition operations:
  The contents of PC and SR immediately after the instruction at which this interrupt was accepted are saved in SPC and SSR, and the contents of R15 are saved in SGR.
  Exception code H'1C0 is set in INTEVT. The BL, MD, and RB bits are set to 1 in SR, and a branch is made to PC = VBR + H'0600. When the BL bit in SR is 0, this interrupt is not masked by the interrupt mask bits in SR, and is accepted at the highest priority level. When the BL bit in SR is 1, a software setting can specify whether this interrupt is to be masked or accepted. For details, see Interrupt Controller in the hardware manual.

```c
NMI()
{
    SPC = PC;
    SSR = SR;
    SGR = R15;
    INTEVT = H'000001C0;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    PC = VBR + H'00000600;
}
```
Section 5  Exceptions

(2) IRL Interrupts

- Source: The interrupt mask bit setting in SR is smaller than the IRL (3–0) level, and the BL bit in SR is 0 (accepted at instruction boundary).

- Transition address: VBR + H'0000 0600

- Transition operations:
  The PC contents immediately after the instruction at which the interrupt is accepted are set in SPC. The SR and R15 contents at the time of acceptance are set in SSR and SGR.
  The code corresponding to the IRL (3–0) level is set in INTEVT. See Table 19.5, Interrupt Exception Handling Sources and Priority Order, for the corresponding codes. The BL, MD, and RB bits are set to 1 in SR, and a branch is made to VBR + H'0600. The acceptance level is not set in the interrupt mask bits in SR. When the BL bit in SR is 1, the interrupt is masked. For details, see Interrupt Controller in the hardware manual.

IRL()
{
    SPC = PC;
    SSR = SR;
    SGR = R15;
    INTEVT = H'00000200 ~ H'000003C0;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    PC = VBR + H'00000600;
}

(3) Peripheral Module Interrupts (Example of SH7751/SH7751R)

For details, refer to the corresponding products' hardware manual.

- Source: The interrupt mask bit setting in SR is smaller than the peripheral module (H-UDI, GPIO, DMAC, PCIC, TMU, RTC, SCI, SCIF, WDT, or REF) interrupt level, and the BL bit in SR is 0 (accepted at instruction boundary).

- Transition address: VBR + H'0000 0600

- Transition operations:
  The PC contents immediately after the instruction at which the interrupt is accepted are set in SPC. The SR and R15 contents at the time of acceptance are set in SSR and SGR.
  The code corresponding to the interrupt source is set in INTEVT. The BL, MD, and RB bits are set to 1 in SR, and a branch is made to VBR + H'0600. The module interrupt levels should be set as values between B'0000 and B'1111 in the interrupt priority registers (IPRA–IPRC) in the interrupt controller. For details, see Interrupt Controller in the hardware manual.

```c
Module_interruption()
{
    SPC = PC;
    SSR = SR;
    SGR = R15;
    INTEVT = H'00000400 ~ H'00000760;
    SR.MD = 1;
    SR.RB = 1;
    SR.BL = 1;
    PC = VBR + H'00000600;
}
```
5.6.4 Priority Order with Multiple Exceptions

With some instructions, such as instructions that make two accesses to memory, and the indivisible pair comprising a delayed branch instruction and delay slot instruction, multiple exceptions occur. Care is required in these cases, as the exception priority order differs from the normal order.

1. Instructions that make two accesses to memory
   
   With MAC instructions, memory-to-memory arithmetic/logic instructions, and TAS instructions, two data transfers are performed by a single instruction, and an exception will be detected for each of these data transfers. In these cases, therefore, the following order is used to determine priority.
   
   a. Data address error in first data transfer
   b. TLB miss in first data transfer
   c. TLB protection violation in first data transfer
   d. Initial page write exception in first data transfer
   e. Data address error in second data transfer
   f. TLB miss in second data transfer
   g. TLB protection violation in second data transfer
   h. Initial page write exception in second data transfer

2. Indivisible delayed branch instruction and delay slot instruction
   
   As a delayed branch instruction and its associated delay slot instruction are indivisible, they are treated as a single instruction. Consequently, the priority order for exceptions that occur in these instructions differs from the usual priority order. The priority order shown below is for the case where the delay slot instruction has only one data transfer.
   
   a. The delayed branch instruction is checked for priority level 1 and 2 abort type and re-execution type exceptions.
   b. The delay slot instruction is checked for priority level 1 and 2 abort type and re-execution type exceptions.
   c. The delayed branch instruction is checked for a priority level 2 completion type exception.
   d. The delay slot instruction is checked for a priority level 2 completion type exception.
   e. A check is performed for priority level 3 in the delayed branch instruction and priority level 3 in the delay slot instruction. (There is no priority ranking between these two.)
   f. A check is performed for priority level 4 in the delayed branch instruction and priority level 4 in the delay slot instruction. (There is no priority ranking between these two.)

   If the delay slot instruction has a second data transfer, two checks are performed in step b, as in 1 above.
If the accepted exception (the highest-priority exception) is a delay slot instruction re-execution type exception, the branch instruction PR register write operation (PC → PR operation performed in BSR, BSRF, JSR) is inhibited.

### 5.7 Usage Notes

1. Return from exception handling
   a. Check the BL bit in SR with software. If SPC and SSR have been saved to external memory, set the BL bit in SR to 1 before restoring them.
   b. Issue an RTE instruction. When RTE is executed, the SPC contents are set in PC, the SSR contents are set in SR, and branch is made to the SPC address to return from the exception handling routine.

2. If an exception or interrupt occurs when SR.BL = 1
   a. Exception
      When an exception other than a user break occurs, a manual reset is executed. The value in EXPEVT at this time is H'0000 0020; the value of the SPC and SSR registers is undefined.
   b. Interrupt
      If an ordinary interrupt occurs, the interrupt request is held pending and is accepted after the BL bit in SR has been cleared to 0 by software. If a nonmaskable interrupt (NMI) occurs, it can be held pending or accepted according to the setting made by software. In the sleep or standby state, however, an interrupt is accepted even if the BL bit in SR is set to 1.

3. SPC when an exception occurs
   a. Re-execution type exception
      The PC value for the instruction in which the exception occurred is set in SPC, and the instruction is re-executed after returning from exception handling. If an exception occurs in a delay slot instruction, however, the PC value for the delay slot instruction is saved in SPC regardless of whether or not the preceding delay slot instruction condition is satisfied.
   b. Completion type exception or interrupt
      The PC value for the instruction following that in which the exception occurred is set in SPC. If an exception occurs in a branch instruction with delay slot, however, the PC value for the branch destination is saved in SPC.

4. An exception must not be generated in an RTE instruction delay slot, as the operation will be undefined in this case.
5.8 Restrictions

Restrictions on first instruction of exception handling routine

- Do not locate a BT, BF, BT/S, BF/S, BRA, or BSR instruction at address VBR + H'100, VBR + H'400, or VBR + H'600.

- When the UBDE bit in the BRCR register is set to 1 and the user break debug support function* is used, do not locate a BT, BF, BT/S, BF/S, BRA, or BSR instruction at the address indicated by the DBR register.

Note: * See User Break Debug Support Function in the hardware manual.
6.1 Overview

The floating-point unit (FPU) has the following features:

- Conforms to IEEE754 standard
- 32 single-precision floating-point registers (can also be referenced as 16 double-precision registers)
- Two rounding modes: Round to Nearest and Round to Zero
- Two denormalization modes: Flush to Zero and Treat Denormalized Number
- Six exception sources: FPU Error, Invalid Operation, Divide By Zero, Overflow, Underflow, and Inexact
- Comprehensive instructions: Single-precision, double-precision, graphics support, system control

When the FD bit in SR is set to 1, the FPU cannot be used, and an attempt to execute an FPU instruction will cause an FPU disable exception.

6.2 Data Formats

6.2.1 Floating-Point Format

A floating-point number consists of the following three fields:

- Sign (s)
- Exponent (e)
- Fraction (f)

The SH-4 can handle single-precision and double-precision floating-point numbers, using the formats shown in figures 6.1 and 6.2.

\[
\begin{array}{cccccc}
31 & 30 & 29 & 28 & 27 & 0 \\
\hline
s & e & f \\
\end{array}
\]

Figure 6.1 Format of Single-Precision Floating-Point Number
The exponent is expressed in biased form, as follows:

\[ e = E + \text{bias} \]

The range of unbiased exponent \( E \) is \( E_{\text{min}} - 1 \) to \( E_{\text{max}} + 1 \). The two values \( E_{\text{min}} - 1 \) and \( E_{\text{max}} + 1 \) are distinguished as follows. \( E_{\text{min}} - 1 \) indicates zero (both positive and negative sign) and a denormalized number, and \( E_{\text{max}} + 1 \) indicates positive or negative infinity or a non-number (NaN). Table 6.1 shows bias, \( E_{\text{min}} \), and \( E_{\text{max}} \) values.

Table 6.1 Floating-Point Number Formats and Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Single-Precision</th>
<th>Double-Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total bit width</td>
<td>32 bits</td>
<td>64 bits</td>
</tr>
<tr>
<td>Sign bit</td>
<td>1 bit</td>
<td>1 bit</td>
</tr>
<tr>
<td>Exponent field</td>
<td>8 bits</td>
<td>11 bits</td>
</tr>
<tr>
<td>Fraction field</td>
<td>23 bits</td>
<td>52 bits</td>
</tr>
<tr>
<td>Precision</td>
<td>24 bits</td>
<td>53 bits</td>
</tr>
<tr>
<td>Bias</td>
<td>+127</td>
<td>+1023</td>
</tr>
<tr>
<td>( E_{\text{max}} )</td>
<td>+127</td>
<td>+1023</td>
</tr>
<tr>
<td>( E_{\text{min}} )</td>
<td>–126</td>
<td>–1022</td>
</tr>
</tbody>
</table>

Floating-point number value \( v \) is determined as follows:

- If \( E = E_{\text{max}} + 1 \) and \( f \neq 0 \), \( v \) is a non-number (NaN) irrespective of sign \( s \)
- If \( E = E_{\text{max}} + 1 \) and \( f = 0 \), \( v = (-1)^s \times \infty \) (positive or negative infinity)
- If \( E_{\text{min}} \leq E \leq E_{\text{max}} \), \( v = (-1)^s \times 2^E \times (1.f) \) [normalized number]
- If \( E = E_{\text{min}} - 1 \) and \( f \neq 0 \), \( v = (-1)^s \times 2^{E_{\text{min}}} \times (0.f) \) [denormalized number]
- If \( E = E_{\text{min}} - 1 \) and \( f = 0 \), \( v = (-1)^s \times 0 \) [positive or negative zero]

Table 6.2 shows the ranges of the various numbers in hexadecimal notation.

<td>H'FF800000  00000000 to H'FFFFFFF  FFFFFFFF</td>
</tr>
</tbody>
</table>

### 6.2.2 Non-Numbers (NaN)

Figure 6.3 shows the bit pattern of a non-number (NaN). A value is NaN in the following case:

- Sign bit: Don’t care
- Exponent field: All bits are 1
- Fraction field: At least one bit is 1

The NaN is a signaling NaN (sNaN) if the MSB of the fraction field is 1, and a quiet NaN (qNaN) if the MSB is 0.
An sNaN is input in an operation, except copy, FABS, and FNEG, that generates a floating-point value.

- When the EN.V bit in the FPSCR register is 0, the operation result (output) is a qNaN.
- When the EN.V bit in the FPSCR register is 1, an invalid operation exception will be generated. In this case, the contents of the operation destination register are unchanged.

If a qNaN is input in an operation that generates a floating-point value, and an sNaN has not been input in that operation, the output will always be a qNaN irrespective of the setting of the EN.V bit in the FPSCR register. An exception will not be generated in this case.

The qNaN values generated by the SH-4 as operation results are as follows:

- Single-precision qNaN: H'7FBFFFFF
- Double-precision qNaN: H'7FF7FFFF FFFFFFFF

See section 9, Instruction Descriptions, for details of floating-point operations when a non-number (NaN) is input.

### Denormalized Numbers

For a denormalized number floating-point value, the exponent field is expressed as 0, and the fraction field as a non-zero value.

When the DN bit in the FPU’s status register FPSCR is 1, a denormalized number (source operand or operation result) is always flushed to 0 in a floating-point operation that generates a value (an operation other than copy, FNEG, or FABS).

When the DN bit in FPSCR is 0, a denormalized number (source operand or operation result) is processed as it is. See section 9, Description of Instructions, for details of floating-point operations when a denormalized number is input.
6.3 Registers

6.3.1 Floating-Point Registers

Figure 6.4 shows the floating-point register configuration. There are thirty-two 32-bit floating-point registers, referenced by specifying FR0–FR15, DR0/2/4/6/8/10/12/14, FV0/4/8/12, XF0–XF15, XD0/2/4/6/8/10/12/14, or XMTRX.

1. Floating-point registers, FPRi_BANKj (32 registers)
   
   FPR0_BANK0–FPR15_BANK0
   FPR0_BANK1–FPR15_BANK1

2. Single-precision floating-point registers, FRi (16 registers)
   
   When FPSCR.FR = 0, FR0–FR15 indicate FPR0_BANK0–FPR15_BANK0;
   when FPSCR.FR = 1, FR0–FR15 indicate FPR0_BANK1–FPR15_BANK1.

3. Double-precision floating-point registers, DRi (8 registers): A DR register comprises two FR registers
   
   DR0 = {FR0, FR1}, DR2 = {FR2, FR3}, DR4 = {FR4, FR5}, DR6 = {FR6, FR7},
   DR8 = {FR8, FR9}, DR10 = {FR10, FR11}, DR12 = {FR12, FR13}, DR14 = {FR14, FR15}

4. Single-precision floating-point vector registers, FVi (4 registers): An FV register comprises four FR registers
   
   FV0 = {FR0, FR1, FR2, FR3}, FV4 = {FR4, FR5, FR6, FR7},
   FV8 = {FR8, FR9, FR10, FR11}, FV12 = {FR12, FR13, FR14, FR15}

5. Single-precision floating-point extended registers, XFi (16 registers)
   
   When FPSCR.FR = 0, XF0–XF15 indicate FPR0_BANK1–FPR15_BANK1;
   when FPSCR.FR = 1, XF0–XF15 indicate FPR0_BANK0–FPR15_BANK0.

6. Double-precision floating-point extended registers, XDi (8 registers): An XD register comprises two XF registers
   
   XD0 = {XF0, XF1}, XD2 = {XF2, XF3}, XD4 = {XF4, XF5}, XD6 = {XF6, XF7},
   XD8 = {XF8, XF9}, XD10 = {XF10, XF11}, XD12 = {XF12, XF13}, XD14 = {XF14, XF15}
7. Single-precision floating-point extended register matrix, XMTRX: XMTRX comprises all 16 XF registers

\[
\begin{bmatrix}
    XF0 & XF4 & XF8 & XF12 \\
    XF1 & XF5 & XF9 & XF13 \\
    XF2 & XF6 & XF10 & XF14 \\
    XF3 & XF7 & XF11 & XF15 \\
\end{bmatrix}
\]

<td></td>
<td></td>
</tr>
</tbody>
</table>

Note: —: Reserved. These bits are always read as 0, and should only be written with 0.

- **FR**: Floating-point register bank
  - FR = 0: FPR0_BANK0–FPR15_BANK0 are assigned to FR0–FR15; FPR0_BANK1–FPR15_BANK1 are assigned to XF0–XF15.
  - FR = 1: FPR0_BANK0–FPR15_BANK0 are assigned to XF0–XF15; FPR0_BANK1–FPR15_BANK1 are assigned to FR0–FR15.

- **SZ**: Transfer size mode
  - SZ = 0: The data size of the FMOV instruction is 32 bits.
  - SZ = 1: The data size of the FMOV instruction is a 32-bit register pair (64 bits).

- **PR**: Precision mode
  - PR = 0: Floating-point instructions are executed as single-precision operations.
  - PR = 1: Floating-point instructions are executed as double-precision operations (graphics support instructions are undefined).

  Do not set SZ and PR to 1 simultaneously; this setting is reserved.

  [SZ, PR = 11]: Reserved (FPU operation instruction is undefined.)

- **DN**: Denormalization mode
  - DN = 0: A denormalized number is treated as such.
  - DN = 1: A denormalized number is treated as zero.

- **Cause**: FPU exception cause field
- **Enable**: FPU exception enable field
- **Flag**: FPU exception flag field

<table>
<thead>
<tr>
<th>FPU Error (E)</th>
<th>Invalid Operation (V)</th>
<th>Division by Zero (Z)</th>

<tr>
<td>Flag</td>
<td>FPU exception flag field</td>
<td>None</td>
<td>Bit 6</td>
<td>Bit 5</td>
<td>Bit 4</td>
</tr>
</tbody>
</table>
When an FPU operation instruction is executed, the FPU exception cause field is cleared to zero first. When the next FPU exception is occurred, the corresponding bits in the FPU exception cause field and FPU exception flag field are set to 1. The FPU exception flag field holds the status of the exception generated after the field was last cleared.

- **RM**: Rounding mode
  - RM = 00: Round to Nearest
  - RM = 01: Round to Zero
  - RM = 10: Reserved
  - RM = 11: Reserved

- **Bits 22 to 31**: Reserved
  These bits are always read as 0, and should only be written with 0.

Notes: The following functions have been added to the FPU of the SH-4 (not provided in the FPU of the SH7718):
1. The FR, SZ, and PR bits have been added.
2. Exception O (overflow), U (underflow), and I (inexact) bits have been added to the cause, enable, and flag fields.
3. An exception E (FPU error) bit has been added to the cause field.

### 6.3.3 Floating-Point Communication Register (FPUL)

Information is transferred between the FPU and CPU via the FPUL register. The 32-bit FPUL register is a system register, and is accessed from the CPU side by means of LDS and STS instructions. For example, to convert the integer stored in general register R1 to a single-precision floating-point number, the processing flow is as follows:

\[ R1 \rightarrow \text{(LDS instruction)} \rightarrow \text{FPUL} \rightarrow \text{(single-precision FLOAT instruction)} \rightarrow FR1 \]

### 6.4 Rounding

In a floating-point instruction, rounding is performed when generating the final operation result from the intermediate result. Therefore, the result of combination instructions such as FMAC, FTRV, and FIPR will differ from the result when using a basic instruction such as FADD, FSUB, or FMUL. Rounding is performed once in FMAC, but twice in FADD, FSUB, and FMUL.

There are two rounding methods, the method to be used being determined by the RM field in FPSCR.
• RM = 00: Round to Nearest
• RM = 01: Round to Zero

**Round to Nearest:** The value is rounded to the nearest expressible value. If there are two nearest expressible values, the one with an LSB of 0 is selected.

If the unrounded value is $2^{E_{\text{max}}} (2 - 2^{-P})$ or more, the result will be infinity with the same sign as the unrounded value. The values of $E_{\text{max}}$ and $P$, respectively, are 127 and 24 for single-precision, and 1023 and 53 for double-precision.

**Round to Zero:** The digits below the round bit of the unrounded value are discarded.

If the unrounded value is larger than the maximum expressible absolute value, the value will be the maximum expressible absolute value.

### 6.5 Floating-Point Exceptions

FPU-related exceptions are as follows:

- General illegal instruction/slot illegal instruction exception
  The exception occurs if an FPU instruction is executed when SR.FD = 1.

- FPU exceptions
  The exception sources are as follows:
  — FPU error (E): When FPSCR.DN = 0 and a denormalized number is input
  — Invalid operation (V): In case of an invalid operation, such as NaN input
  — Division by zero (Z): Division with a zero divisor
  — Overflow (O): When the operation result overflows
  — Underflow (U): When the operation result underflows
  — Inexact exception (I): When overflow, underflow, or rounding occurs

The FPSCR cause field contains bits corresponding to all of above sources E, V, Z, O, U, and I, and the FPSCR flag and enable fields contain bits corresponding to sources V, Z, O, U, and I, but not E. Thus, FPU errors cannot be disabled.

When an exception source occurs, the corresponding bit in the cause field is set to 1, and 1 is added to the corresponding bit in the flag field. When an exception source does not occur, the corresponding bit in the cause field is cleared to 0, but the corresponding bit in the flag field remains unchanged.
FPU exception handling

FPU exception occurs in the following cases:

- FPU error (E): FPSCR.DN = 0 and a denormalized number is input
- Invalid operation (V): FPSCR.EN.V = 1 and (instruction = FTRV or invalid operation)
- Division by zero (Z): FPSCR.EN.Z = 1 and division with a zero divisor
- Overflow (O): FPSCR.EN.O = 1 and instruction with possibility of operation result overflow
- Underflow (U): FPSCR.EN.U = 1 and instruction with possibility of operation result underflow
- Inexact exception (I): FPSCR.EN.I = 1 and instruction with possibility of inexact operation result

These possibilities are shown in the individual instruction descriptions. All exception events that originate in the FPU are assigned as the same exception event. The meaning of an exception is determined by software by reading system register FPSCR and interpreting the information it contains. If no bits are set in the cause field of FPSCR when one or more of bits O, U, I, and V (in case of FTRV only) are set in the enable field, this indicates that an actual FPU exception is not generated. Also, the destination register is not changed by any FPU exception handling operation.

Except for the above, the bit corresponding to source V, Z, O, U, or I is set to 1, and a default value is generated as the operation result.

- Invalid operation (V): qNAN is generated as the result.
- Division by zero (Z): Infinity with the same sign as the unrounded value is generated.
- Overflow (O):
  - When rounding mode = RZ, the maximum normalized number, with the same sign as the unrounded value, is generated.
  - When rounding mode = RN, infinity with the same sign as the unrounded value is generated.
- Underflow (U):
  - When FPSCR.DN = 0, a denormalized number with the same sign as the unrounded value, or zero with the same sign as the unrounded value, is generated.
  - When FPSCR.DN = 1, zero with the same sign as the unrounded value, is generated.
- Inexact exception (I): An inexact result is generated.

6.6 Graphics Support Functions

The supports two kinds of graphics functions: new instructions for geometric operations, and pair single-precision transfer instructions that enable high-speed data transfer.
6.6.1 Geometric Operation Instructions

Geometric operation instructions perform approximate-value computations. To enable high-speed computation with a minimum of hardware, the SH-4 ignores comparatively small values in the partial computation results of four multiplications. Consequently, the error shown below is produced in the result of the computation:

$$\text{Maximum error} = \text{MAX} (\text{individual multiplication result} \times 2^{-\text{MIN (number of multiplier significant digits–1, number of multiplicand significant digits–1)}}) + \text{MAX} (\text{result value} \times 2^{-23}, 2^{-149})$$

The number of significant digits is 24 for a normalized number and 23 for a denormalized number (number of leading zeros in the fractional part).

In future version of SuperH™ RISC engine family, the above error is guaranteed, but the same result as SH-4 is not guaranteed.

**FIPR FVm, FVn (m, n: 0, 4, 8, 12):** Examples of the use of this instruction are shown below.

- Inner product (m ≠ n):
  This operation is generally used for surface/rear surface determination for polygon surfaces.
- Sum of square of elements (m = n):
  This operation is generally used to find the length of a vector.

Since approximate-value computations are performed to enable high-speed computation, the inexact exception (I) bit in the cause field and flag field is always set to 1 when an FIPR instruction is executed. Therefore, if the corresponding bit is set in the enable field, enable exception handling will be executed.

**FTRV XMTRX, FVn (n: 0, 4, 8, 12):** Examples of the use of this instruction are shown below.

- Matrix (4 × 4) · vector (4):
  This operation is generally used for viewpoint changes, angle changes, or movements called vector transformations (4-dimensional). Since affine transformation processing for angle + parallel movement basically requires a 4 × 4 matrix, the SH-4 supports 4-dimensional operations.
- Matrix (4 × 4) × matrix (4 × 4):
  This operation requires the execution of four FTRV instructions.

Since approximate-value computations are performed to enable high-speed computation, the inexact exception (I) bit in the cause field and flag field is always set to 1 when an FTRV instruction is executed. Therefore, if the corresponding bit is set in the enable field, FPU exception...
handling will be executed. For the same reason, it is not possible to check all data types in the registers beforehand when executing an FTRV instruction. If the V bit is set in the enable field, FPU exception handling will be executed.

**FRCHG:** This instruction modifies banked registers. For example, when the FTRV instruction is executed, matrix elements must be set in an array in the background bank. However, to create the actual elements of a translation matrix, it is easier to use registers in the foreground bank. When the LDC instruction is used on FPSCR, this instruction expends 4 to 5 cycles in order to maintain the FPU state. With the FRCHG instruction, an FPSCR.FR bit modification can be performed in one cycle.

### 6.6.2 Pair Single-Precision Data Transfer

In addition to the powerful geometric operation instructions, the SH-4 also supports high-speed data transfer instructions.

When FPSCR.SZ = 1, the SH-4 can perform data transfer by means of pair single-precision data transfer instructions.

- **FMOV DRm/XDm, DRn/XDRn (m, n: 0, 2, 4, 6, 8, 10, 12, 14)**
- **FMOV DRm/XDm, @Rn (m: 0, 2, 4, 6, 8, 10, 12, 14; n: 0 to 15)**

These instructions enable two single-precision (2 × 32-bit) data items to be transferred; that is, the transfer performance of these instructions is doubled.

- **FSCHG**
  
  This instruction changes the value of the SZ bit in FPSCR, enabling fast switching between use and non-use of pair single-precision data transfer.

**Programming Note**

When FPSCR.SZ = 1 and big-endian mode is used, FMOV can be used for a double-precision floating-point load or store. In little-endian mode, a double-precision floating-point load or store requires execution of two 32-bit data size operations with FPSCR.SZ = 0.
6.7 Usage Notes

6.7.1 Notice about FPU Instructions Issues

When a rounding mode of Round to Nearest is used, underflow flag is not set even if the result is in the range to cause underflow defined in IEEE754.

Phenomenon: When a rounding mode of Round to Nearest is used, result of infinity precision $x$ satisfies 1 or 2 (single precision), or result of infinity precision $x$ satisfies 3 or 4 (double precision), there is a case that the result after rounding become a normalized number but underflow flag is set in IEEE754.

The FPU does not set underflow flag in the above case, correct results are written to FRn.

Once more underflow flag is not set but inexact flag is set in this case. So FPU exceptions occurs when enable field is set.

1. $H'007F FFFF < x < H'0080 0000$
2. $H'807F FFFF > x > H'8080 0000$
3. $H'000F FFFF FFFF FFFF < x < H'0010 0000 0000 0000$
4. $H'800F FFFF FFFF FFFF > x > H'8010 0000 0000 0000$

Examples:

Case of single precision
FPSCR.RM = 00 (Round to Nearest), FPSCR.PR = 0 (single precision),
FMUL instruction ($H'00FF F000 * H'3F00 0800$) is executed.

- IEEE754
  Result: $H'0080 0000$
  FPSCR: $H'0004 300C$
- SH-4 FPU
  Result: $H'0080 0000$
  FPSCR: $H'0004 1004$

Case of double precision
FPSCR.RM = 00 (Round to Nearest), FPSCR.PR = 1 (double precision),
FDIV instruction ($H'001F FFFF FFFF FFFF/H'4000 0000 0000 0000$) is executed.
IEEE754
Result : H'0010 0000 0000 0000
FPSCR : H'000C 300C

SH-4 FPU
Result : H'0010 0000 0000 0000
FPSCR : H'000C 1004

**Effect:** The main purpose of underflow is to indicate the result of arithmetic is a denormalized number or zero, but the result of arithmetic is a normalized number in this case. So this case-underflow flag is not set—does not violate this main purpose of detecting an underflow. The effect of this debug is limited to users who need all underflow case exactly.

**Workaround**

1. Use FPSCR.RM = 01 (Round to Zero)
2. When using FPSCR.RM = 00 (Round to Nearest), in order to detect the precise underflow condition, set enable field of inexact, and analyze the underflow condition in the exception handler.

### 6.7.2 Notice about the Overflow Flag by FIPR and FTRV Instruction Command

When the maximum error produced in the result of the computation of FIPR or FTRV is larger than the maximum normalized number (H'7F7F FFFF), the overflow flag may be set to 1, even if the operation result is a positive or negative zero (H'0000 0000 or H'8000 0000).

**Workaround:** FIPR and FTRV instruction command is not used, but it is operated by FADD and FMUL and FMAC instruction command.

**Example:** The operation result after "FIPR FV4, FV0" which considers the following register value as an input, and FV0 command execution (FR7) is H'0000 0000 (positive zero). It is not concerned but an overflow flag is set. When input the following register value, an operation results after "FIPR FV4, FV0" instruction command (FR7) execution is "H'0000 0000 (positive zero).

Regardless of H'0000 0000 (positive zero) which is the result (FR7) after execution of "FIPR FV4, F0" instruction command, the overflow flag may be set.

FPSCR = H'00040001
FR0 = H'FF7EF631, FR1 = H80000000, FR2 = H'8087F451, FR3 = H'7F7EF631
FR4 = H'7F7EF631, FR5 = H'0087F451, FR6 = H'7F7EF631, FR7 = H'7F7EF631
6.7.3 Notice about the Sign of the Operation Result by FIPR and FTRV Instruction Command

When two or more of the data which are operated by FIPR and FTRV instruction command are infinity, and all of the infinities in the result of multiplication in FIPR or FTRV instruction operation have the same sign, there is a possibility to mistake the sign of operation result.

Workaround

1. Do not use an infinity. When all of the following a–c conditions consist, an infinity isn’t treated.
   a. Rounding to Zero (FPSCR.RM = 01) is used as a rounding mode.
   b. It is not divided by Zero.
   c. A positive or negative infinity is not loaded to FR0–FR15 or XF0–XF15.
2. Neither FIPR nor the FTRV instruction commands are used, and it operates it by FADD, FMUL, and FMAC instruction command.

6.7.4 Notice about Double Precision FADD and FSUB Instructions for SH-4

This document reports the analysis on problem about double precision FADD and FSUB instruction for SH-4. All SH-4 products and SH-4 core has the same problem. This document explains the problem.

Condition in which the Problem Occurs: When all the following conditions are satisfied, the Problem may occur.

1. Double precision FADD instruction or Double precision FSUB instruction is executed.
2. Difference of exponents of two inputs (DRm,DRn) is 43 to 50.
3. Bit 24 to 31 of the input with the smaller absolute value of DRn and DRm is NOT all 0.
4. Bit 0 to 23 of the input with the smaller absolute value of DRn and DRm is all 0.
5. Bit 32 to 40 of the input with the smaller absolute value of DRn and DRm is all 0.

What happens by the Problem is

The operation is inexact but FPSCR.Flag.I or FPSCR.Cause.I may not be set to 1. The operation has incorrect rounding.

In detail, SH-4 selects the smallest expressible value of larger side of the pre-rounding one instead of the largest expressible value of smaller side of the pre-rounding one, or vice versa.
Examples: The result of double precision FSUB DR0,DR2 is H’C4B250D2 0CC1F974 as against the expected value H’C4B250D2 0CC1F973, and FPSCR.Flag.I or FPSCR.Cause.I is not set to 1, though the operation is inexact.

(input data) FPSCR = H’ 000C0001
DR0 = H’ C1F00000 80000000, DR2 = H’ C4B250D2 0CC1FB74
(correct result) DR2 = H’C4B250D2 0CC1F973
(result of FPU) DR2 = H’C4B250D2 0CC1F974

Effect of the problem: In addition to the above explanation, the effect of the numeric value of this problem can be limited within the boundary that can be described by the small arithmetic error, 1/256 of LSB in the significant, and the rounding mechanism. Strictly speaking, it is explained as follows.

a: The computing result of infinite accuracy
b: The largest expressible value of smaller side of a
c: The smallest expressible value of larger side of a
d: The right rounded value of a
e: FPU’s rounded value of a

1. Round to Nearest
   When the rounding is correctly performed, the value of the rounding error is
   \[0 <= |d - a| <= (1/2) * (c - b)\]
   But the result of FPU is
   \[0 <= |e - a| < (129/256) * (c - b)\]
   The range of the rounding error is 1/256 * (c – b) larger than that of correct error.

2. Round to Zero
   When the rounding is correctly performed, the value of the rounding error is
   \[-(1) * (c - b) < |d| - |a| <= 0\]
   But the result of FPU is
   \[-(1) * (c - b) < |e| - |a| < (1/256) * (c - b)\]
   The range of the rounding error is 1/256 * (c – b) larger than that of correct error.
6.7.5 FPU Double Precision

Double precision denormalized numbers in the FDIV, FADD, FSUB, and FMUL instructions give wrong results.

**Target User:** Software designers who develop software in scientific and engineering field are the target.

Especially, those designers who use double precision floating point instructions and treat the denormalized number as it is. But this concerning target is not for those designers who use double precision floating point instructions and treat zero-flushed denormalized number and also not for those designers who use single precision floating point instruction as well.

**Phenomena:** These are two phenomena. First, when the inputs are denormalized numbers as described in (a) and (b), then wrong results are generated. And second one, when the inputs are denormalized numbers and qNaN as described in (c), then wrong results are generated:

(a) In double-precision FDIV, there are cases that are wrong results generates as 0 or infinity when inputs include denormalized number.

(b) In double-precision FMUL, there are cases that the wrong result generates as infinity when inputs include denormalized number.

(c) In double-precision FDIV, FADD, FSUB, or FMUL, there are cases that exception occurs by mistake and the wrong result generates as infinity when inputs are denormalized number and qNaN.

**Effect:** The worst case is, when double precision FDIV or FMUL instruction with denormalized number’s input is used the wrong result is written in register. Particularly, denormalized number/denormalized number = 0, denormalized number/0 = 0 is not appropriate in mathematical sense.

**Workaround:** 1 is recommended. 2 is desirable when there are needs to calculate denormalized numbers in scientific and engineering fields.

1. Double precision instruction is only used at the mode “FPSCR.DN = B’1’” which means denormalized number is treated as zero. The performance does not decrease in this workaround.
2. The case that wrong results are generated when inputs are denormalized numbers (a, b) should be modified by software. Please refer to section 4, *Software modification* in detail.
   — Source and destination register (DRn) should be saved.
   — When the result is 0 or infinity in double-precision FDIV, the function that calculate denormalized numbers is called. The function should be prepared by software designer.
The case that wrong results are generated when inputs are denormalized numbers and qNaN (c) should be modified by TRAP routine. Please refer to section 5, *TRAP routine modification* in detail.

— When one of the input is denormalized numbers and the other is qNaN in double-precision FDIV, FADD, FSUB, or FMUL, qNaN (H'7FF7FFFF_FFFFFFFF) is written in destination register by the TRAP routine.

### Details

**Definition:** Data pattern that cause wrong results is defined. The data patterns from (A) to (D) in tables correspond to the following patterns.

(A) Double precision denormalized number

H'00000000_XXXXXXXX or H'80000000_XXXXXXXX (X: 0 or 1)

Condition: H'XXXXXXXX! = H'00000000

(B) Double precision denormalized number

H'000YYYYY_XXXXXXXX or H'800YYYYY_XXXXXXXX (X: 0 or 1)

Condition: H'YYYYY! = H'00000

(C) Double precision qNaN

H'7FF00000_XXXXXXXX or H'FFF00000_XXXXXXXX (X: 0 or 1)

Condition: H'XXXXXXXX! = H'00000000

(D) Double precision qNaN *unlimited qNaN

H'7FFXXXXX_XXXXXXXX or H'FFFXXXXX_XXXXXXXX (X: 0 or 1)

Condition: H'XXXXX_XXXXXXXX! = H'00000_00000000

### Wrong results list

Table 6.3 shows the combination of instruction and data that generate wrong results in case of FPSCR.DN = B'0 (denormalized numbers is treated as it is).

The inputs (A), (B), and (C) are the data patterns as the above definition.

The NG types from (1) to (7) is classified from the wrong results category and these NG types is used in tables 6.4 to 6.6.

In NG types (1), (2), (3), and (7), the output 0 or infinity is the wrong result.

In NG types (4), (5), and (6), if exception TRAP (FPU Error) occurs then qNaN is not written. The relations among the items of Phenomena and table 6.3 are as follows:

— Phenomena (a) corresponds to the NG types (1), (2), and (3) in the table 6.3.

— Phenomena (b) corresponds to the NG type (7).

— Phenomena (c) corresponds to the NG types (4), (5), and (6).

- SH-4 outputs correct results in dotted box.
- SH-4 outputs wrong results in white box.

Software Modification

- NG type: (1), (2), or (3)

In NG types (1), (2), or (3), software should be modified according to the following flows. Source operand is adjusted by multiplying $2^{1536}$, and should be calculated as normalized number.

If NG type is (1) and Divide by Zero exception is enabled, divide by zero exception occurs and the destination register is not modified.

If NG type is (1) and Divide by Zero exception is disabled, the destination register is set to infinity with sign based on source operands.
• NG type: (7)
  If NG type is (7), FPU Error exception does not occur. But results is correct, and thus modification by software is not needed.

**Trap Routine Modification:** In NG types (4), (5), or (6), instruction and input data should be checked and qNaN should be written in destination register as table 6.7 in TRAP routine.

qNaN is always H'7FF7FFFF_FFFFFFF.

Section 7 Instruction Set

7.1 Execution Environment

PC: At the start of instruction execution, PC indicates the address of the instruction itself.

Data sizes and data types: The SH-4’s instruction set is implemented with 16-bit fixed-length instructions. The SH-4 can use byte (8-bit), word (16-bit), longword (32-bit), and quadword (64-bit) data sizes for memory access. Single-precision floating-point data (32 bits) can be moved to and from memory using longword or quadword size. Double-precision floating-point data (64 bits) can be moved to and from memory using longword size. When a double-precision floating-point operation is specified (FPSCR.PR = 1), the result of an operation using quadword access will be undefined. When the SH-4 moves byte-size or word-size data from memory to a register, the data is sign-extended.

Load-Store Architecture: The SH-4 features a load-store architecture in which operations are basically executed using registers. Except for bit-manipulation operations such as logical AND that are executed directly in memory, operands in an operation that requires memory access are loaded into registers and the operation is executed between the registers.

Delayed Branches: Except for the two branch instructions BF and BT, the SH-4’s branch instructions and RTE are delayed branches. In a delayed branch, the instruction following the branch is executed before the branch destination instruction. This execution slot following a delayed branch is called a delay slot. For example, the BRA execution sequence is as follows:

<table>
<thead>
<tr>
<th>Static Sequence</th>
<th>Dynamic Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>BRA R1, R0</td>
<td>BRA R1, R0</td>
</tr>
<tr>
<td>next_2</td>
<td>target_instr</td>
</tr>
</tbody>
</table>

Delay Slot: An illegal instruction exception may occur when a specific instruction is executed in a delay slot. See section 5, Exceptions. The instruction following BF/S or BT/S for which the branch is not taken is also a delay slot instruction.
T Bit: The T bit in the status register (SR) is used to show the result of a compare operation, and is referenced by a conditional branch instruction. An example of the use of a conditional branch instruction is shown below.

ADD #1, R0 ; T bit is not changed by ADD operation
CMP/EQ R1, R0 ; If R0 = R1, T bit is set to 1
BT TARGET ; Branches to TARGET if T bit = 1 (R0 = R1)

In an RTE delay slot, status register (SR) bits are referenced as follows. In instruction access, the MD bit is used before modification, and in data access, the MD bit is accessed after modification. The other bits—S, T, M, Q, FD, BL, and RB—after modification are used for delay slot instruction execution. The STC and STC.L SR instructions access all SR bits after modification.

Constant Values: An 8-bit constant value can be specified by the instruction code and an immediate value. 16-bit and 32-bit constant values can be defined as literal constant values in memory, and can be referenced by a PC-relative load instruction.

MOV.W @(disp, PC), Rn
MOV.L @(disp, PC), Rn

There are no PC-relative load instructions for floating-point operations. However, it is possible to set 0.0 or 1.0 by using the FLDI0 or FLDI1 instruction on a single-precision floating-point register.

7.2 Addressing Modes

Addressing modes and effective address calculation methods are shown in table 7.1. When a location in virtual memory space is accessed (MMUCR.AT = 1), the effective address is translated into a physical memory address. If multiple virtual memory space systems are selected (MMUCR.SV = 0), the least significant bit of PTEH is also referenced as the access ASID. See section 3, Memory Management Unit (MMU).

</tr>
</tbody>
</table>
### Effective Address Calculation Method

#### Register indirect with displacement

**Instruction Format:** @(disp:4, Rn)

**Effective Address Calculation Method:** Effective address is register Rn contents with 4-bit displacement disp added. After disp is zero-extended, it is multiplied by 1 (byte), 2 (word), or 4 (longword), according to the operand size.

**Calculation Formula:**
- Byte: Rn + disp → EA
- Word: Rn + disp × 2 → EA
- Longword: Rn + disp × 4 → EA

#### Indexed register indirect

**Instruction Format:** @(R0, Rn)

**Effective Address Calculation Method:** Effective address is sum of register Rn and R0 contents.

**Calculation Formula:** Rn + R0 → EA

#### GBR indirect with displacement

**Instruction Format:** @(disp:8, GBR)

**Effective Address Calculation Method:** Effective address is register GBR contents with 8-bit displacement disp added. After disp is zero-extended, it is multiplied by 1 (byte), 2 (word), or 4 (longword), according to the operand size.

**Calculation Formula:**
- Byte: GBR + disp → EA
- Word: GBR + disp × 2 → EA
- Longword: GBR + disp × 4 → EA

#### Indexed GBR indirect

**Instruction Format:** @(R0, GBR)

**Effective Address Calculation Method:** Effective address is sum of register GBR and R0 contents.

**Calculation Formula:** GBR + R0 → EA
<table>

**Note:** For the addressing modes below that use a displacement (disp), the assembler descriptions in this manual show the value before scaling (\( \times 1, \times 2, \text{or} \times 4 \)) is performed according to the operand size. This is done to clarify the operation of the chip. Refer to the relevant assembler notation rules for the actual assembler descriptions.

- @ (disp:4, Rn)  ; Register indirect with displacement
- @ (disp:8, GBR) ; GBR indirect with displacement
- @ (disp:8, PC)  ; PC-relative with displacement
- disp:8, disp:12 ; PC-relative

#### 7.4 Notes on Use of TRAPA Instruction/SLEEP Instruction/Undefined Instruction (H’FFFD)

- There is a possibility of writing the erroneous data in cache when TRAPA instruction or Undefined instruction code H’FFFD is executed.
- When TRAPA instruction or Undefined instruction code H’FFFD is executed, the ITLB hit judgment may be mistaken. Then, after re-registration, there is a possibility to generate the ITLB multi-hit exception.
- There is a possibility of writing the erroneous data in the FPU registers or MACH and MACL registers, when TRAPA instruction or SLEEP instruction or Undefined instruction code H’FFFD is executed.
Generated Condition

1. There is a possibility of writing a wrong instruction to Instruction cache when three following conditions consist at the same time.
   a. Instruction cache is ON. (CCR.ICE = 1)
   b. TRAPA instruction or Undefined instruction code H'FFFD in a Cache On Space (U0/P0/P1/P3 space) is executed.
   c. The code interpreted as the instruction (both read and write) accessed to the address (H'F0000000–H'F7FFFFFF) exists in following 4 words of TRAPA instruction or Undefined instruction code H'FFFD of above-mentioned b.

2. There is a possibility of writing the erroneous data in Operand cache when three following conditions consist at the same time.
   a. Operand cache is ON. (CCR.OCE = 1)
   b. Undefined instruction code H'FFFD is executed.
   c. The code interpreted as the OCBI/OCBP/OCBWB/TAS.B instruction accessed to the built-in store queues address (H'E0000000–H'E3FFFFFF) exists in following 4 words of Undefined instruction code H'FFFD of above-mentioned b.

3. There is a possibility to which the ITLB hit judgment is mistaken when three conditions of the following conditions consist at the same time. When the ITLB hit is mistaken and it is judged that it makes a mistake, re-registration to ITLB is done. After that, there is a possibility to generate the ITLB multi-hit exception.
   a. MMU is ON. (MMUCR.AT = 1)
   b. TRAPA instruction or Undefined instruction code H'FFFD in the TLB conversion space (U0/P0/P3 space) is executed.
   c. The code interpreted as the instruction (both read and write) accessed to the address (H'F0000000–H'F7FFFFFF) exists in following 4 words of TRAPA instruction or Undefined instruction code H'FFFD of above-mentioned b.

4. There is a possibility of writing a wrong value to register (FR0–FR15, XF0–XF15, FPSCR, and FPUL) related to FPU, MACH, and MACL when two following conditions consist at the same time.
   a. TRAPA or SLEEP instruction or Undefined instruction code H'FFFD is executed.
   b. The code interpreted in combining FPSCR and PR at that time in following 8 words of TRAPA or SLEEP instruction or Undefined instruction code H'FFFD of above-mentioned a, excluding H'FFFD in H'Fxxx (the instruction whose initial 4 bits are H'F) as an Undefined instruction exists.

Example: Instruction H'FxxE (x: arbitrary hexadecimal number) is defined here as an Undefined instruction in FPSCR.PR = 1.
Note: For the number of following instructions, internally, there is a possibility that this trouble occurs in case of 1 to 3 is following 2xI clock, and in case of 4 is the case of it is executable within following 4xI clock. Therefore, the number of instructions which can be executed in 2xI clock or 4xI clock is maximum 4 instructions or maximum 8 instructions respectively.

Workaround: Take measures of either following 1 or 2.

1. Put the NOP instruction on eight following words of TRAPA instruction, SLEEP instruction, and Undefined instruction code H'FFFD.

2. Put “OR R0, R0” instruction on five following words of TRAPA instruction, SLEEP instruction, and Undefined instruction code H'FFFD. The OR instruction is not executed simultaneously. Therefore, because it requires more than 5xI clock for execution, “In case of H'Fxxx exists in eight following words” of the generation condition of 4-b can be evaded.
Section 8 Pipelining

The SH-4 is a 2-ILP (instruction-level-parallelism) superscalar pipelining microprocessor. Instruction execution is pipelined, and two instructions can be executed in parallel. The execution cycles depend on the implementation of a processor. For details, refer to the corresponding products' hardware manual.

8.1 Pipelines

Figure 8.1 shows the basic pipelines. Normally, a pipeline consists of five or six stages: instruction fetch (I), decode and register read (D), execution (EX/SX/F0/F1/F2/F3), data access (NA/MA), and write-back (S/FS). An instruction is executed as a combination of basic pipelines. Figure 8.2 shows the instruction execution patterns.
1. General Pipeline

<table>
<thead>
<tr>
<th>I</th>
<th>D</th>
<th>EX</th>
<th>NA</th>
<th>S</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Instruction fetch
- Instruction decode
- Issue
- Register read
- Destination address calculation for PC-relative branch
- Operation
- Non-memory data access
- Write-back

2. General Load/Store Pipeline

<table>
<thead>
<tr>
<th>I</th>
<th>D</th>
<th>EX</th>
<th>MA</th>
<th>S</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Instruction fetch
- Instruction decode
- Issue
- Register read
- Address calculation
- Memory data access
- Write-back

3. Special Pipeline

<table>
<thead>
<tr>
<th>I</th>
<th>D</th>
<th>SX</th>
<th>NA</th>
<th>S</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>

<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Instruction fetch
- Instruction decode
- Issue
- Register read
- Address calculation
- Memory data access
- Write-back

5. Floating-Point Pipeline

<table>
<thead>
<tr>
<th>I</th>
<th>D</th>
<th>F1</th>
<th>F2</th>
<th>FS</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Instruction fetch
- Instruction decode
- Issue
- Register read
- Computation 1
- Computation 2
- Computation 3
- Write-back

6. Floating-Point Extended Pipeline

<table>
<thead>
<tr>
<th>I</th>
<th>D</th>
<th>F0</th>
<th>F1</th>
<th>F2</th>
<th>FS</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Instruction fetch
- Instruction decode
- Issue
- Register read
- Computation 0
- Computation 1
- Computation 2
- Computation 3
- Write-back

7. FDIV/FSQRT Pipeline

Figure 8.2 Instruction Execution Patterns (cont)
Figure 8.2 Instruction Execution Patterns (cont)
8.2 Parallel-Executability

Instructions are categorized into six groups according to the internal function blocks used, as shown in table 8.1. Table 8.2 shows the parallel-executability of pairs of instructions in terms of groups. For example, ADD in the EX group and BRA in the BR group can be executed in parallel.

Table 8.1 Instruction Groups

8.3 Execution Cycles and Pipeline Stalling

There are three basic clocks in this processor: the I-clock, B-clock, and P-clock. Each hardware unit operates on one of these clocks, as follows:

- I-clock: CPU, FPU, MMU, caches
- B-clock: External bus controller
- P-clock: Peripheral units

The frequency ratios of the three clocks are determined with the frequency control register (FRQCR). In this section, machine cycles are based on the I-clock unless otherwise specified. For details of FRQCR, see Clock Oscillation Circuits in the hardware manual.

Instruction execution cycles are summarized in table 8.3. Penalty cycles due to a pipeline stall or freeze are not considered in this table.

- Issue rate: Interval between the issue of an instruction and that of the next instruction
- Latency: Interval between the issue of an instruction and the generation of its result (completion)
- Instruction execution pattern (see figure 8.2)
- Locked pipeline stages
- Interval between the issue of an instruction and the start of locking
- Lock time: Period of locking in machine cycle units
The instruction execution sequence is expressed as a combination of the execution patterns shown in figure 8.2. One instruction is separated from the next by the number of machine cycles for its issue rate. Normally, execution, data access, and write-back stages cannot be overlapped onto the same stages of another instruction; the only exception is when two instructions are executed in parallel under parallel-executability conditions. Refer to (a) through (d) in figure 8.3 for some simple examples.

Latency is the interval between issue and completion of an instruction, and is also the interval between the execution of two instructions with an interdependent relationship. When there is interdependency between two instructions fetched simultaneously, the latter of the two is stalled for the following number of cycles:

- (Latency) cycles when there is flow dependency (read-after-write)
- (Latency – 1) or (latency – 2) cycles when there is output dependency (write-after-write)
  - Single/double-precision FDIV, FSQRT is the preceding instruction (latency – 1) cycles
  - The other FE group is the preceding instruction (latency – 2) cycles
- 5 or 2 cycles when there is anti-flow dependency (write-after-read), as in the following cases:
  - FTRV is the preceding instruction (5 cycle)
  - A double-precision FADD, FSUB, or FMUL is the preceding instruction (2 cycles)

In the case of flow dependency, latency may be exceptionally increased or decreased, depending on the combination of sequential instructions (figure 8.3 (e)).

- When a floating-point (FPU) computation is followed by an FPU register store, the latency of the floating-point computation may be decreased by 1 cycle.
- If there is a load of the shift amount immediately before an SHAD/SHLD instruction, the latency of the load is increased by 1 cycle.
- If an instruction with a latency of less than 2 cycles, including write-back to an FPU register, is followed by a double-precision FPU instruction, FIPR, or FTRV, the latency of the first instruction is increased to 2 cycles.

The number of cycles in a pipeline stall due to flow dependency will vary depending on the combination of interdependent instructions or the fetch timing (see figure 8.3 (e)).

Output dependency occurs when the destination operands are the same in a preceding FE group instruction and a following LS group instruction.

For the stall cycles of an instruction with output dependency, the longest latency to the last write-back among all the destination operands must be applied instead of “latency” (see figure 8.3 (f)). A stall due to output dependency with respect to FPSCR, which reflects the result of a floating-point operation, never occurs. For example, when FADD follows FDIV with no dependency
between FPU registers, FADD is not stalled even if both instructions update the cause field of FPSCR.

Anti-flow dependency can occur only between a preceding double-precision FADD, FMUL, FSUB, or FTRV and a following FMOV, FLDI0, FLDI1, FABS, FNEG, or FSTS. See figure 8.3 (g).

If an executing instruction locks any resource—i.e. a function block that performs a basic operation—a following instruction that attempts to use the locked resource must be stalled (figure 8.3 (h)). This kind of stall can be compensated by inserting one or more instructions independent of the locked resource to separate the interfering instructions. For example, when a load instruction and an ADD instruction that references the loaded value are consecutive, the 2-cycle stall of the ADD is eliminated by inserting three instructions without dependency. Software performance can be improved by such instruction scheduling.

Other penalties arise in the event of exceptions or external data accesses, as follows.

- Instruction TLB miss
- Instruction access to external memory (instruction cache miss, etc.)
- Data access to external memory (operand cache miss, etc.)
- Data access to a memory-mapped control register

During the penalty cycles of an instruction TLB miss or external instruction access, no instruction is issued, but execution of instructions that have already been issued continues. The penalty for a data access is a pipeline freeze: that is, the execution of uncompleted instructions is interrupted until the arrival of the requested data. The number of penalty cycles for instruction and data accesses is largely dependent on the user’s memory subsystems.

There is the possibility that idle cycles are added to the number of cycles which is set by Bus State Controller (BSC) for the external memory, because of the data transmission between different clock frequency internal Buses.
(a) Serial execution: non-parallel-executable instructions

<table>
<thead>
<tr>
<th>Instruction</th>
<th>I</th>
<th>D</th>
<th>EX</th>
<th>NA</th>
<th>S</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHAD R0,R1</td>
<td></td>
<td></td>
<td>EX</td>
<td>NA</td>
<td>S</td>
</tr>
<tr>
<td>ADD R2,R3</td>
<td></td>
<td></td>
<td>EX</td>
<td>NA</td>
<td>S</td>
</tr>
<tr>
<td>next</td>
<td></td>
<td></td>
<td>EX</td>
<td>NA</td>
<td>S</td>
</tr>
</tbody>
</table>

EX-group SHAD and EX-group ADD cannot be executed in parallel. Therefore, SHAD is issued first, and the following ADD is recombined with the next instruction.

(b) Parallel execution: parallel-executable and no dependency

<table>
<thead>
<tr>
<th>Instruction</th>
<th>I</th>
<th>D</th>
<th>EX</th>
<th>NA</th>
<th>S</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD R2,R1</td>
<td></td>
<td></td>
<td>EX</td>
<td>NA</td>
<td>S</td>
</tr>
<tr>
<td>MOV.L @R4,R5</td>
<td></td>
<td></td>
<td>EX</td>
<td>MA</td>
<td>S</td>
</tr>
</tbody>
</table>

EX-group ADD and LS-group MOV.L can be executed in parallel. Overlapping of stages in the 2nd instruction is possible.

(c) Issue rate: multi-step instruction

<table>
<thead>
<tr>
<th>Instruction</th>
<th>I</th>
<th>D</th>
<th>SX</th>
<th>MA</th>
<th>S</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND.B#1,@(R0,GBR)</td>
<td></td>
<td></td>
<td>SX</td>
<td>MA</td>
<td>S</td>
</tr>
<tr>
<td>MOV R1,R2</td>
<td></td>
<td></td>
<td>SX</td>
<td>MA</td>
<td>S</td>
</tr>
<tr>
<td>next</td>
<td></td>
<td></td>
<td>SX</td>
<td>NA</td>
<td>S</td>
</tr>
</tbody>
</table>

AND.B and MOV are fetched simultaneously, but MOV is stalled due to resource locking. After the lock is released, MOV is refetched together with the next instruction.

(d) Branch

<table>
<thead>
<tr>
<th>Instruction</th>
<th>I</th>
<th>D</th>
<th>EX</th>
<th>NA</th>
<th>S</th>
</tr>
</thead>
<tbody>
<tr>
<td>BT/S L_far</td>
<td></td>
<td></td>
<td>EX</td>
<td>NA</td>
<td>S</td>
</tr>
<tr>
<td>ADD R0,R1</td>
<td></td>
<td></td>
<td>EX</td>
<td>NA</td>
<td>S</td>
</tr>
<tr>
<td>SUB R2,R3</td>
<td></td>
<td></td>
<td>EX</td>
<td>NA</td>
<td>S</td>
</tr>
</tbody>
</table>

No stall occurs if the branch is not taken.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>I</th>
<th>D</th>
<th>EX</th>
<th>NA</th>
<th>S</th>
</tr>
</thead>
<tbody>
<tr>
<td>BT/S L_far</td>
<td></td>
<td></td>
<td>EX</td>
<td>NA</td>
<td>S</td>
</tr>
<tr>
<td>ADD R0,R1</td>
<td></td>
<td></td>
<td>EX</td>
<td>NA</td>
<td>S</td>
</tr>
<tr>
<td>L_far</td>
<td></td>
<td></td>
<td>EX</td>
<td>NA</td>
<td>S</td>
</tr>
</tbody>
</table>

If the branch is taken, the I-stage of the branch destination is stalled for the period of latency. This stall can be covered with a delay slot instruction which is not parallel-executable with the branch instruction.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>I</th>
<th>D</th>
<th>EX</th>
<th>NA</th>
<th>S</th>
</tr>
</thead>
<tbody>
<tr>
<td>BT L_skip</td>
<td></td>
<td></td>
<td>EX</td>
<td>NA</td>
<td>S</td>
</tr>
<tr>
<td>ADD #1,R0</td>
<td></td>
<td></td>
<td>EX</td>
<td>NA</td>
<td>S</td>
</tr>
<tr>
<td>L_skip:</td>
<td></td>
<td></td>
<td>EX</td>
<td>NA</td>
<td>S</td>
</tr>
</tbody>
</table>

Even if the BT/BF branch is taken, the I-stage of the branch destination is not stalled if the displacement is zero.

#### Figure 8.3 Examples of Pipelined Execution (cont)

- **Zero-cycle latency**: The following instruction, ADD, is not stalled when executed after an instruction with zero-cycle latency, even if there is dependency.
- **1-cycle latency**: ADD and MOV.L are not executed in parallel, since MOV.L references the result of ADD as its destination address.
- **2-cycle latency**: Because MOV.L and ADD are not fetched simultaneously in this example, ADD is stalled for only 1 cycle even though the latency of MOV.L is 2 cycles.
- **4-cycle latency for FPSCR**: Due to the flow dependency between the load and the SHAD/SHLD shift amount, the latency of the load is increased to 3 cycles.
- **7-cycle latency for lower FR**: 8-cycle latency for upper FR
- **3-cycle latency for upper/lower FR**: FR1 write
- **3-cycle latency**: FADD DR0,DR2
- **3-cycle increase**: FIPR FV0,FV4
- **2-cycle latency**: FMOM @R1,XD14
- **1-cycle increase**: FTRV XMTRX,FV0

</tbody>
</table>

**Notes:**
1. See table 8.1 for the instruction groups.
2. Latency “L1/L2...”: Latency corresponding to a write to each register, including MACH/MACL/FPSCR. Example: MOV.B @Rm+, Rn “1/2”: The latency for Rm is 1 cycle, and the latency for Rn is 2 cycles.
3. Branch latency: Interval until the branch destination instruction is fetched
4. Conditional branch latency “2 (or 1)”: The latency is 2 for a nonzero displacement, and 1 for a zero displacement.

Rev. 6.00 Sep 13, 2006 page 190 of 424
REJ09B0318-0600

RENESAS
5. Double-precision floating-point instruction latency \((L1, L2)/L3\): L1 is the latency for FR \(n+1\), L2 that for FR \(n\), and L3 that for FPSCR.

6. FTRV latency \((L1, L2, L3, L4)/L5\): L1 is the latency for FR \(n\), L2 that for FR \(n+1\), L3 that for FR \(n+2\), L4 that for FR \(n+3\), and L5 that for FPSCR.

7. Latency \(L1/L2/L3/L4\) of MAC.L and MAC.W instructions: L1 is the latency for Rm, L2 that for Rn, L3 that for MACH, and L4 that for MACL.

8. Latency \(L1/L2\) of MUL.L, MULS.W, MULU.W, DMULS.L, and DMULU.L instructions: L1 is the latency for MACH, and L2 that for MACL.

9. Execution pattern: The instruction execution pattern number (see figure 8.2)

10. Lock/stage: Stage locked by the instruction

11. Lock/start: Locking start cycle; 1 is the first D-stage of the instruction.

12. Lock/cycles: Number of cycles locked

Exceptions:

1. When a floating-point computation instruction is followed by an FMOV store, an STS FPUL, Rn instruction, or an STS.L FPUL, @-Rn instruction, the latency of the floating-point computation is decreased by 1 cycle.

2. When the preceding instruction loads the shift amount of the following SHAD/SHLD, the latency of the load is increased by 1 cycle.

3. When an LS group instruction with a latency of less than 3 cycles is followed by a double-precision floating-point instruction, FIPR, or FTRV, the latency of the first instruction is increased to 3 cycles.

   Example: In the case of FMOV FR4,FR0 and FIPR FV0,FV4, FIPR is stalled for 2 cycles.

4. When MAC*/MUL*/DMUL* is followed by an STS.L MAC*, @-Rn instruction, the latency of MAC*/MUL*/DMUL* is 5 cycles.

5. In the case of consecutive executions of MAC*/MUL*/DMUL*, the latency is decreased to 2 cycles.

6. When an LDS to MAC* is followed by an STS.L MAC*, @-Rn instruction, the latency of the LDS to MAC* is 4 cycles.

7. When an LDS to MAC* is followed by MAC*/MUL*/DMUL*, the latency of the LDS to MAC* is 1 cycle.

8. When an FSCHG or FRCHG instruction is followed by an LS group instruction that reads or writes to a floating-point register, the aforementioned LS group instruction[s] cannot be executed in parallel.

9. When a single-precision FTRC instruction is followed by an STS FPUL, Rn instruction, the latency of the single-precision FTRC instruction is 1 cycle.
Section 9  Instruction Descriptions

Instructions are listed in this section in alphabetical order. The following format is used for the instruction descriptions.

<table>
<thead>
<tr>
<th>Instruction Name</th>
<th>Full Name</th>
<th>Instruction Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function</td>
<td></td>
<td>(Indication of delayed branch instruction or interrupt-disabling instruction)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>The assembler input format is shown. imm and disp are numeric values, expressions, or symbols.</td>
<td>Summarizes the operation of the instruction.</td>
<td>Shown in MSB $\leftrightarrow$ LSB order.</td>
<td>The no-wait value is shown.</td>
<td>Shows the T bit value after execution of the instruction.</td>
</tr>
</tbody>
</table>

Description

Describes the operation of the instruction.

Notes

Identifies points to be noted when using the instruction.

Operation

Shows the operation in C. This is given as reference material to help understand the operation of the instruction. Use of the following resources is assumed.

- char 8-bit integer
- short 16-bit integer
- int 32-bit integer
- long 64-bit integer
- float single-precision floating point number (32 bits)
- double double-precision floating point number (64 bits)

These are data types.
unsigned char Read_Byte(unsigned long Addr);
unsigned short Read_Word(unsigned long Addr);
unsigned long Read_Long(unsigned long Addr);
These reflect the respective sizes of address Addr. A word read from other than a 2n address, or a longword read from other than a 4n address, will be detected as an address error.

unsigned char Write_Byte(unsigned long Addr, unsigned long Data);
unsigned short Write_Word(unsigned long Addr, unsigned long Data);
unsigned long Write_Long(unsigned long Addr, unsigned long Data);
These write data Data to address Addr, using the respective sizes. A word write to other than a 2n address, or a longword write to other than a 4n address, will be detected as an address error.

Delay_Slot(unsigned long Addr);
Shifts to execution of the slot instruction at address (Addr).

unsigned long R[16];
unsigned long SR,GBR,VBR;
unsigned long MACH,MACL,PR;
unsigned long PC;
Registers

}
Example

An example is shown using assembler mnemonics, indicating the states before and after execution of the instruction.

Italics (e.g., `.align`) indicate an assembler control instruction. The meaning of the assembler control instructions is given below. For details, refer to the Cross-Assembler User’s Manual.

- `.org` Location counter setting
- `.data.w` Word integer data allocation
- `.data.l` Longword integer data allocation
- `.sdata` String data allocation
- `.align 2` 2-byte boundary alignment
- `.align 4` 4-byte boundary alignment
- `.align 32` 32-byte boundary alignment
- `.arepeat 16` 16-times repeat expansion
- `.arepeat 32` 32-times repeat expansion
- `.aendr` Count-specification repeat expansion end

Note: SuperH™ RISC engine family cross-assembler version 1.0 does not support conditional assembler functions.
9.1 ADD Binary Addition

**Format**

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD Rm,Rn</td>
<td>Rn+Rm → Rn</td>
<td>0011nnnnnnmmn1100</td>
<td>1</td>
<td>—</td>
</tr>
<tr>
<td>ADD #imm,Rn</td>
<td>Rn+imm → Rn</td>
<td>0111nnnnnnnnnn1111111</td>
<td>1</td>
<td>—</td>
</tr>
</tbody>
</table>

**Description**

This instruction adds together the contents of general registers Rn and Rm and stores the result in Rn.

8-bit immediate data can also be added to the contents of general register Rn.

8-bit immediate data is sign-extended to 32 bits, allowing use in decrement operations.

**Operation**

```c
ADD(long m, long n) /* ADD Rm,Rn */
{
    R[n]+=R[m];
    PC+=2;
}

ADDI(long i, long n)  /* ADD #imm,Rn */
{
    if ((i&0x80)==0)
        R[n]+=(0x000000FF & (long)i);
    else R[n]+=(0xFFFFFF00 | (long)i);
    PC+=2;
}
```
Example

ADD R0, R1
; Before execution R0 = H’7FFFFFFF, R1 = H’00000001
; After execution R1 = H’80000000

ADD #H’01, R2
; Before execution R2 = H’00000000
; After execution R2 = H’00000001

ADD #H’FE, R3
; Before execution R3 = H’00000001
; After execution R3 = H’FFFFFFF
### 9.2 ADDC ADD with Carry

#### Description

This instruction adds together the contents of general registers Rn and Rm and the T bit, and stores the result in Rn. A carry resulting from the operation is reflected in the T bit. This instruction is used for additions exceeding 32 bits.

#### Operation

```c
ADDC(long m, long n)    /* ADDC Rm,Rn */
{
    unsigned long tmp0,tmp1;

    tmp1=R[n]+R[m];
    tmp0=R[n];
    R[n]=tmp1+T;
    if (tmp0>tmp1) T=1;
    else T=0;
    if (tmp1>R[n]) T=1;
    PC+=2;
}
```

#### Example

- **CLRT** ; R0:R1(64 bits) + R2:R3(64 bits) = R0:R1(64 bits)
- **ADDC R3,R1** ; Before execution T = 0, R1 = H'00000000, R3 = H'FFFFFFFF
  After execution T = 1, R1 = H'00000000
- **ADDC R2,R0** ; Before execution T = 1, R0 = H'0000000000, R2 = H'00000000
  After execution T = 0, R0 = H'00000000
9.3 ADDV ADD with (V flag) overflow check Arithmetic Instruction

Binary Addition with Overflow Check

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADDV</td>
<td>Rm,Rn</td>
<td>Rn+Rm → Rn, overflow → T</td>
<td>0011nnnnnnnnnnnn</td>
<td>1</td>
<td>Overflow</td>
</tr>
</tbody>
</table>

Description

This instruction adds together the contents of general registers Rn and Rm and stores the result in Rn. If overflow occurs, the T bit is set.

Operation

ADDV(long m, long n) /* ADDV Rm,Rn */
{
  long dest, src, ans;

  if ((long)R[n] >= 0) dest = 0;
  else dest = 1;
  if ((long)R[m] >= 0) src = 0;
  else src = 1;
  src += dest;
  R[n] += R[m];
  if ((long)R[n] >= 0) ans = 0;
  else ans = 1;
  ans += dest;
  if (src == 0 || src == 2) {
    if (ans == 1) T = 1;
    else T = 0;
  }
  else T = 0;
  PC += 2;
}
Example

ADDV R0, R1  ; Before execution  R0 = H'00000001, R1 = H'7FFFFFFE, T=0
              ; After execution  R1 = H'7FFFFFFF, T=0

ADDV R0, R1  ; Before execution  R0 = H'00000002, R1 = H'7FFFFFFE, T=0
              ; After execution  R1 = H'80000000, T=1
### 9.4 AND Logical AND

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND Rm,Rn</td>
<td>Rm &amp; Rm → Rn</td>
<td>0010nnnnnnnnnnnnn1001</td>
<td>1</td>
<td>—</td>
</tr>
<tr>
<td>AND #imm,R0</td>
<td>R0 &amp; imm → R0</td>
<td>11001000iiiiiiiiiiii</td>
<td>1</td>
<td>—</td>
</tr>
<tr>
<td>AND.B #imm,@(R0,GBR)</td>
<td>(R0+GBR) &amp; imm → (R0+GBR)</td>
<td>11001101iiiiiiiiiiiiii</td>
<td>4</td>
<td>—</td>
</tr>
</tbody>
</table>

**Description**

This instruction ANDs the contents of general registers Rn and Rm and stores the result in Rn.

This instruction can be used to AND general register R0 contents with zero-extended 8-bit immediate data, or, in indexed GBR indirect addressing mode, to AND 8-bit memory with 8-bit immediate data.

**Notes**

With AND #imm,R0, the upper 24 bits of R0 are always cleared as a result of the operation.

**Operation**

```c
AND(long m, long n)    /* AND Rm,Rn */
{
    R[n]&=R[m];
    PC+=2;
}

ANDI(long i)    /* AND #imm,R0 */
{
    R[0]&=(0x000000FF & (long)i);
    PC+=2;
}

ANDM(long i)    /* AND.B #imm,@(R0,GBR) */
{
```
```c
long temp;

temp=(long)Read_BGRA(R[0]);
temp&=(0x000000FF & (long)i);
Write_BGRA(R[0],temp);
PC+=2;
}

Example

AND    R0,R1 ; Before execution  R0 = H'AAAAAAAAA, R1 = H'555555555
       ; After execution        R1 = H'00000000
AND    #H'0F,R0 ; Before execution  R0 = H'FFFFFFFF
       ; After execution        R0 = H'00000000F
AND.B  #H'80, @(R0,GBR) ; Before execution  (R0,GBR) = H'A5
       ; After execution        (R0,GBR) = H'80
```
### 9.5 BF Branch if False Branch Instruction

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>BF label</td>
<td>If $T = 0$&lt;br&gt;$PC + 4 + \text{disp} \times 2 \rightarrow PC$&lt;br&gt; If $T = 1$, nop</td>
<td>10001011dddddddd</td>
<td>1</td>
<td>—</td>
</tr>
</tbody>
</table>

**Description**

This is a conditional branch instruction that references the $T$ bit. The branch is taken if $T = 0$, and not taken if $T = 1$. The branch destination is address ($PC + 4 + \text{displacement} \times 2$). The PC source value is the BF instruction address. As the 8-bit displacement is multiplied by two after sign-extension, the branch destination can be located in the range from $-256$ to $+254$ bytes from the BF instruction.

**Notes**

If the branch destination cannot be reached, the branch must be handled by using BF in combination with a BRA or JMP instruction, for example.

**Operation**

```
BF(int d) /* BF disp */
{
    int disp;

    if ({(d&0x80)==0)
        disp=(0x000000FF & d);
    else    disp=(0xFFFFFF00 | d);
    if (T==0)
        PC=PC+4+(disp<<1);
    else    PC+=2;
}
```
Example

CLRT ; Normally T = 0
BT  TRGET_T ; T = 0, so branch is not taken.
BF  TRGET_F ; T = 0, so branch to TRGET_F.
NOP ;
NOP ;

TRGET_F: ; ← BF instruction branch destination
### 9.6 BF/S Branch if False with delay Slot

#### Conditional Branch with Delay

#### Branch Instruction

Delayed Branch Instruction

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>BF/S label</td>
<td>If $T = 0$</td>
<td>10001111ddudddd</td>
<td>1</td>
<td>—</td>
</tr>
<tr>
<td></td>
<td>$PC + 4 + \text{disp} \times 2 \rightarrow PC$</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If $T = 1$, nop</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Description

This is a delayed conditional branch instruction that references the $T$ bit. If $T = 1$, the next instruction is executed and the branch is not taken. If $T = 0$, the branch is taken after execution of the next instruction.

The branch destination is address $(PC + 4 + \text{displacement} \times 2)$. The PC source value is the BF/S instruction address. As the 8-bit displacement is multiplied by two after sign-extension, the branch destination can be located in the range from $-256$ to $+254$ bytes from the BF/S instruction.

#### Notes

As this is a delayed branch instruction, when the branch condition is satisfied, the instruction following this instruction is executed before the branch destination instruction.

Interrupts are not accepted between this instruction and the following instruction.

If the following instruction is a branch instruction, it is identified as a slot illegal instruction.

If this instruction is located in the delay slot immediately following a delayed branch instruction, it is identified as a slot illegal instruction.

If the branch destination cannot be reached, the branch must be handled by using BF/S in combination with a BF, BRA, or JMP instruction, for example.
**Operation**

```c
BFS(int d)  /* BFS disp */
{
    int disp;
    unsigned int temp;

    temp=PC;
    if ((d&0x80)==0)
        disp=(0x000000FF & d);
    else    disp=(0xFFFFFF00 | d);
    if (T==0)
        PC=PC+4+(disp<<1);  // PC updated for branch taken
    else PC+=4;
    Delay_Slot(temp+2);
}
```

**Example**

```
CLRT     ; Normally T = 0
BT/S TRGET_T ; T = 0, so branch is not taken.
NOP      ;
BF/S TRGET_F  ; T = 0, so branch to TRGET.
ADD R0,R1   ; Executed before branch.
NOP      ;
TRGET_F:     ; ← BF/S instruction branch destination
```
9.7 BRA BRAnch Branch Instruction

Unconditional Branch

Delayed Branch Instruction

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>BRA label</td>
<td>PC + 4 + disp × 2 → PC</td>
<td>1010dddddddddddd</td>
<td>1</td>
<td>—</td>
</tr>
</tbody>
</table>

**Description**

This is an unconditional branch instruction. The branch destination is address (PC + 4 + displacement × 2). The PC source value is the BRA instruction address. As the 12-bit displacement is multiplied by two after sign-extension, the branch destination can be located in the range from −4096 to +4094 bytes from the BRA instruction. If the branch destination cannot be reached, this branch can be performed with a JMP instruction.

**Notes**

As this is a delayed branch instruction, the instruction following this instruction is executed before the branch destination instruction.

Interrupts are not accepted between this instruction and the following instruction. If the following instruction is a branch instruction, it is identified as a slot illegal instruction.

**Operation**

```c
BRA(int d)    /* BRA disp */
{
    int disp;
    unsigned int temp;

    temp=PC;
    if ((d&0x800)==0)
        disp=(0x00000FFF & d);
    else   disp=(0xFFFFF000 | d);
    PC=PC+4+(disp<<1);
    Delay_Slot(temp+2);
}
```
Example

BRA TRGET ; Branch to TRGET.
ADD R0, R1 ; ADD executed before branch.
NOP ;
TRGET: ; ← BRA instruction branch destination
9.8 BRAF BRAnch Far
Unconditional Branch

<tbody>
<tr>
<td>BRAF Rn</td>
<td>PC + 4 + Rn → PC</td>
<td>0000nnnn00100011</td>
<td>2</td>
<td>—</td>
</tr>
</tbody>
</table>

### Description

This is an unconditional branch instruction. The branch destination is address (PC + 4 + Rn). The branch destination address is the result of adding 4 plus the 32-bit contents of general register Rn to PC.

### Notes

As this is a delayed branch instruction, the instruction following this instruction is executed before the branch destination instruction.

Interrupts are not accepted between this instruction and the following instruction. If the following instruction is a branch instruction, it is identified as a slot illegal instruction.

### Operation

BRAF(int n) /* BRAF Rn */
{
    unsigned int temp;

    temp=PC;
    PC=PC+4+R[n];
    Delay_Slot(temp+2);
}

### 9.9 BSR Branch to SubRoutine

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>BSR label</td>
<td>PC + 4 → PR, PC + 4 + disp × 2 → PC</td>
<td>1011dddddddddddd</td>
<td>1</td>
<td>—</td>
</tr>
</tbody>
</table>

**Description**

This instruction branches to address (PC + 4 + displacement × 2), and stores address (PC + 4) in PR. The PC source value is the BSR instruction address. As the 12-bit displacement is multiplied by two after sign-extension, the branch destination can be located in the range from –4096 to +4094 bytes from the BSR instruction. If the branch destination cannot be reached, this branch can be performed with a JSR instruction.

**Notes**

As this is a delayed branch instruction, the instruction following this instruction is executed before the branch destination instruction.

Interrupts are not accepted between this instruction and the following instruction. If the following instruction is a branch instruction, it is identified as a slot illegal instruction.

**Operation**

```c
BSR(int d) /* BSR disp */
{
    int disp;
    unsigned int temp;

    temp=PC;
    if ((d&0x800)==0)
        disp=(0x00000FFF & d);
    else disp=(0xFFFFF000 | d);
    PR=PC+4;
    PC=PC+4+(disp<<1);
    Delay_Slot(temp+2);
}
```
Example

    BSR TRGET ; Branch to TRGET.
    MOV R3, R4 ; MOV executed before branch.
    ADD R0, R1 ; Subroutine procedure return destination (contents of PR)

    

    TRGET: ; ← Entry to procedure
    MOV R2, R3 ;
    RTS ; Return to above ADD instruction.
    MOV #1, R0 ; MOV executed before branch.
9.10 BSRF Branch to SubRoutine Far
Branch to Subroutine Procedure

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>

<td>2</td>
<td>—</td>
</tr>
<tr>
<td></td>
<td>PC + 4 + Rn → PC</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Description**

This instruction branches to address (PC + 4 + Rn), and stores address (PC + 4) in PR. The PC source value is the BSRF instruction address. The branch destination address is the result of adding the 32-bit contents of general register Rn to PC + 4.

**Notes**

As this is a delayed branch instruction, the instruction following this instruction is executed before the branch destination instruction.

Interrupts are not accepted between this instruction and the following instruction. If the following instruction is a branch instruction, it is identified as a slot illegal instruction.

**Operation**

```c
BSRF(int n) /* BSRF Rn */
{
    unsigned int temp;

    temp=PC;
    PR=PC+4;
    PC=PC+4+R[n];
    Delay_Slot(temp+2);
}
```
Example

```
MOV.L  #(TRGET-BSRF_PC), R0  ; Set displacement.
BSRF   R0                   ; Branch to TRGET.
MOV    R3, R4               ; MOV executed before branch.
BSRF_PC:
    ;
    ADD R0, R1               ;
    ....
TRGET:                        ; ← Entry to procedure
    MOV R2, R3               ;
    RTS                      ; Return to above ADD instruction.
    MOV #1, R0               ; MOV executed before branch.
```
### 9.11 BT Branch if True

#### Conditional Branch

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
</table>
| BT label | If $T = 1$  
PC + 4 + disp $\times$ 2 $\rightarrow$ PC  
If $T = 0$, nop | 10001001dddddddd | 1 | — |

#### Description

This is a conditional branch instruction that references the T bit. The branch is taken if $T = 1$, and not taken if $T = 0$.

The branch destination is address ($PC + 4 +$ displacement $\times 2$). The PC source value is the BT instruction address. As the 8-bit displacement is multiplied by two after sign-extension, the branch destination can be located in the range from $-256$ to $+254$ bytes from the BT instruction.

#### Notes

If the branch destination cannot be reached, the branch must be handled by using BT in combination with a BRA or JMP instruction, for example.

#### Operation

```
BT(int d)    /* BT disp */
{
    int disp;

    if ((d&0x80)==0)
        disp=(0x000000FF & d);
    else disp=(0xFFFFFF00 | d);
    if (T==1)
        PC=PC+4+(disp<<1);
    else PC+=2;
}
```
Example

```
SETT ; Normally T = 1
BF TRGET_F ; T = 1, so branch is not taken.
BT TRGET_T ; T = 1, so branch to TRGET_T.
NOP ;
NOP ;
TRGET_T: ; ← BT instruction branch destination
```
9.12 BT/S Branch if True with delay Slot
Conditional Branch with Delay

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>BT/S label</td>
<td>If $T = 1$</td>
<td>1000 1101 dddddddd</td>
<td>1</td>
<td>—</td>
</tr>
<tr>
<td></td>
<td>$PC + 4 + \text{disp} \times 2 \rightarrow PC$</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If $T = 0$, nop</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Description**

This is a conditional branch instruction that references the T bit. The branch is taken if $T = 1$, and not taken if $T = 0$.

The PC source value is the BT/S instruction address. As the 8-bit displacement is multiplied by two after sign-extension, the branch destination can be located in the range from $-256$ to $+254$ bytes from the BT/S instruction. If the branch destination cannot be reached, the branch must be handled by using BT/S in combination with a BRA or JMP instruction, for example.

**Notes**

As this is a delayed branch instruction, when the branch condition is satisfied, the instruction following this instruction is executed before the branch destination instruction.

Interrupts are not accepted between this instruction and the following instruction.

If the following instruction is a branch instruction, it is identified as a slot illegal instruction.
Operation

BTS(int d) /* BTS disp */
{
    int disp;
    unsigned temp;

    temp=PC;
    if ((d&0x80)==0)
        disp=(0x000000FF & d);
    else disp=(0xFFFFFF00 | d);
    if (T==1)
        PC=PC+4+(disp<<1);
    else PC+=4;
    Delay_Slot(temp+2);
}

Example

SETT ; Normally T = 1
BF/S TRGET_F ; T = 1, so branch is not taken.
NOP ;
BT/S TRGET_T ; T = 1, so branch to TRGET_T.
ADD R0,R1 ; Executed before branch.

<td>Result of comparison</td>
</tr>
</tbody>
</table>

### Description

This instruction compares general registers Rn and Rm, and sets the T bit if the specified condition (cond) is true. If the condition is false, the T bit is cleared. The contents of Rn are not changed. Nine conditions can be specified. For the two conditions PZ and PL, Rn is compared with 0.

With the EQ condition, sign-extended 8-bit immediate data can be compared with R0. The contents of R0 are not changed.

<td></td>
</tr>
</tbody>
</table>

**Description**

This instruction performs initial settings for signed division. This instruction is followed by a DIV1 instruction that executes 1-digit division, for example, and repeated divisions are executed to find the quotient. See the description of the DIV1 instruction for details.

**Operation**

```c
DIV0S(long m, long n)    /* DIV0S Rm,Rn */
{
    if ((R[n] & 0x80000000)==0) Q=0;
    else Q=1;
    if ((R[m] & 0x80000000)==0) M=0;
    else M=1;
    T=! (M==Q);
    PC+=2;
}
```

**Example**

<td>DIV1 Rm,Rn</td>
<td>1-step division (Rn ÷ Rm)</td>
<td>0011nnnnnnnn0100 1</td>
<td>Result of calculation</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

This instruction performs 1-digit division (1-step division) of the 32-bit contents of general register Rn (dividend) by the contents of Rm (divisor). The quotient is obtained by repeated execution of this instruction alone or in combination with other instructions. The specified registers and the M, Q, and T bits must not be modified during these repeated executions.

In 1-step division, the dividend is shifted 1 bit to the left, the divisor is subtracted from this, and the quotient bit is reflected in the Q bit according to whether the result is positive or negative.

The remainder can be found as follows after first finding the quotient using the DIV1 instruction:

\[(\text{Remainder}) = (\text{dividend}) - (\text{divisor}) \times (\text{quotient})\]

Detection of division by zero or overflow is not provided. Check for division by zero and overflow division before executing the division. A remainder operation is not provided. Find the remainder by finding the product of the divisor and the obtained quotient, and subtracting this value from the dividend.

Initial settings should first be made with the DIV0S or DIV0U instruction. DIV1 is executed once for each bit of the divisor. If a quotient of more than 17 bits is required, place an ROTCL instruction before the DIV1 instruction. See the examples for details of the division sequence.

Operation

```c
DIV1(long m, long n) /* DIV1 Rm,Rn */
{
    unsigned long tmp0, tmp2;
    unsigned char old_q, tmp1;
    old_q=Q;
    Q=(unsigned char)((0x80000000 & R[n])!=0);
    tmp2= R[m];
```
R[n] <<= 1;
R[n] |= (unsigned long)T;

switch(old_q) {
    case 0: switch(M) {
        case 0: tmp0 = R[n];
            R[n] -= tmp2;
            tmp1 = (R[n] > tmp0);
            switch(Q) {
                case 0: Q = tmp1;
                    break;
                case 1: Q = (unsigned char)(tmp1 == 0);
                    break;
            }
            break;
        case 1: tmp0 = R[n];
            R[n] += tmp2;
            tmp1 = (R[n] < tmp0);
            switch(Q) {
                case 0: Q = (unsigned char)(tmp1 == 0);
                    break;
                case 1: Q = tmp1;
                    break;
            }
            break;
    }
    break;
    case 1: switch(M) {
        case 0: tmp0 = R[n];
            R[n] += tmp2;
            tmp1 = (R[n] < tmp0);
            switch(Q) {
                case 0: Q = tmp1;
                    break;

<tr>
<td>DT Rn</td>
<td>Rn – 1 → Rn; if Rn = 0, 1 → T; if Rn ≠ 0, 0 → T</td>
<td>0100nnnn00010000</td>
<td>1</td>
<td>Test result</td>
</tr>
</tbody>
</table>

**Description**

This instruction decrements the contents of general register Rn by 1 and compares the result with zero. If the result is zero, the T bit is set to 1. If the result is nonzero, the T bit is cleared to 0.

**Operation**

```c
DT(long n) /* DT Rn */
{
    R[n]--;
    if (R[n]==0) T=1;
    else T=0;
    PC+=2;
}
```

**Example**

```assembly
MOV  #4, R5    ; Set loop count
LOOP:
    ADD  R0, R1  ;
    DT  R5      ; Decrement R5 value and check for 0.
    BF  LOOP    ; If T = 0, branch to LOOP (in this example, 4 loops are executed).
```
9.23 EXTS EXTend as Signed Arithmetic Instruction

<table>
<thead>
<tr>

</tr>
<tr>
<td>EXTS.W Rm,Rn</td>
<td>Rm sign-extended from word → Rn</td>
<td>0110nnnnnnnnnnn1</td>
<td>1</td>
<td>—</td>
</tr>
</tbody>
</table>

Description

This instruction sign-extends the contents of general register Rm and stores the result in Rn.

For a byte specification, the value of Rm bit 7 is transferred to Rn bits 8 to 31. For a word specification, the value of Rm bit 15 is transferred to Rn bits 16 to 31.

Operation

```
EXTSB(long m, long n) /* EXTS.B Rm,Rn */
{
    R[n]=R[m];
    if ((R[m]&0x00000080)==0) R[n]|=0x000000FF;
    else R[n]|=0xFFFFFF00;
    PC+=2;
}

EXTSW(long m, long n) /* EXTS.W Rm,Rn */
{
    R[n]=R[m];
    if ((R[m]&0x00008000)==0) R[n]|=0x0000FFFF;
    else R[n]|=0xFFFF0000;
    PC+=2;
}
```
Example

EXTS.B R0,R1 ; Before execution R0 = H'00000080
              ; After execution R1 = H'FFFFFF80

EXTS.W R0,R1 ; Before execution R0 = H'00008000
              ; After execution R1 = H'FFFF8000
9.24 EXTU EXTend as Unsigned Arithmetic Instruction

</tr>
<tr>
<td>EXTU.W</td>
<td>Rm zero-extended from word → Rn</td>
<td>0110nnnnmmmm1101</td>
<td>1</td>
<td>—</td>
</tr>
</tbody>
</table>

Description

This instruction zero-extends the contents of general register Rm and stores the result in Rn.

For a byte specification, 0 is transferred to Rn bits 8 to 31. For a word specification, 0 is transferred to Rn bits 16 to 31.

Operation

```c
EXTUB(long m, long n) /* EXTU.B Rm,Rn */
{
    R[n]=R[m];
    R[n]&=0x000000FF;
    PC+=2;
}

EXTUW(long m, long n) /* EXTU.W Rm,Rn */
{
    R[n]=R[m];
    R[n]&=0x0000FFFF;
    PC+=2;
}
```
Example

EXTU.B  R0, R1  ; Before execution  R0 = H'FFFFFF80
              ; After execution  R1 = H'00000080

EXTU.W  R0, R1  ; Before execution  R0 = H'FFFF8000

<td>FABS</td>
<td></td>
<td>DRn</td>
<td>→ DRn</td>
<td>1111nnnn001011101</td>
</tr>
</tbody>
</table>

Description

This instruction clears the most significant bit of the contents of floating-point register FRn/DRn to 0, and stores the result in FRn/DRn.

The cause and flag fields in FPSCR are not updated.

Operation

```c
void FABS (int n){
    FR[n] = FR[n] & 0x7fffffff;
    pc += 2;
}
/* Same operation is performed regardless of precision. */
```

Possible Exceptions:
None
9.26 FADD Floating-point ADD Floating-Point Instruction

<table>
<thead>
<tr>
<th>PR</th>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>

<td>FADD</td>
<td>FRm,FRn FRn + FRm → FRn</td>
<td>1111nnnnnn00000</td>
<td>1</td>
<td>—</td>
</tr>
<tr>
<td>1</td>
<td>FADD</td>
<td>DRm,DRn DRn + DRm → DRn</td>
<td>1111nn00nn00000</td>
<td>6</td>
<td>—</td>
</tr>
</tbody>
</table>

Description

When FPSCR.PR = 0: Arithmetically adds the two single-precision floating-point numbers in FRn and FRm, and stores the result in FRn.

When FPSCR.PR = 1: Arithmetically adds the two double-precision floating-point numbers in DRn and DRm, and stores the result in DRn.

When FPSCR.enable.O/U/I is set, an FPU exception trap is generated regardless of whether or not an exception has occurred. When an exception occurs, correct exception information is reflected in FPSCR.cause and FPSCR.flag, and FRn or DRn is not updated. Appropriate processing should therefore be performed by software.

Operation

```c
void FADD (int m,n)
{
    pc += 2;
    clear_cause();
    if((data_type_of(m) == sNaN) ||
       (data_type_of(n) == sNaN)) invalid(n);
    else if((data_type_of(m) == qNaN) ||

**Description**

1. When FPSCR.PR = 0: Arithmetically compares the two single-precision floating-point numbers in FRn and FRm, and stores 1 in the T bit if they are equal, or 0 otherwise.
2. When FPSCR.PR = 1: Arithmetically compares the two double-precision floating-point numbers in DRn and DRm, and stores 1 in the T bit if they are equal, or 0 otherwise.
3. When FPSCR.PR = 0: Arithmetically compares the two single-precision floating-point numbers in FRn and FRm, and stores 1 in the T bit if FRn > FRm, or 0 otherwise.
4. When FPSCR.PR = 1: Arithmetically compares the two double-precision floating-point numbers in DRn and DRm, and stores 1 in the T bit if DRn > DRm, or 0 otherwise.

**Operation**

<td>FVm,FVn</td>
<td>FVm ⋅ FVm → FR[n + 3]</td>
<td>1111nnmm11101101</td>
<td>1</td>
</tr>
</tbody>
</table>

**Notes:**

- FV0 = {FR0, FR1, FR2, FR3}
- FV4 = {FR4, FR5, FR6, FR7}
- FV8 = {FR8, FR9, FR10, FR11}
- FV12 = {FR12, FR13, FR14, FR15}

### Description

When FPSCR.PR = 0: This instruction calculates the inner products of the 4-dimensional single-precision floating-point vector indicated by FVn and FVm, and stores the results in FR[n + 3].

The FIPR instruction is intended for speed rather than accuracy, and therefore the results will differ from those obtained by using a combination of FADD and FMUL instructions. The FIPR execution sequence is as follows:

1. Multiplies all terms. The results are 28 bits long.
2. Aligns these results, rounding them to fit within 30 bits.
3. Adds the aligned values.
4. Performs normalization and rounding.

Special processing is performed in the following cases:

1. If an input value is an sNaN, an invalid exception is generated.
2. If the input values to be multiplied include a combination of 0 and infinity, an invalid exception is generated.
3. In cases other than the above, if the input values include a qNaN, the result will be a qNaN.
4. In cases other than the above, if the input values include infinity:
   a. If multiplication results in two or more infinities and the signs are different, an invalid exception will be generated.
   b. Otherwise, correct infinities will be stored.
5. If the input values do not include an sNaN, qNaN, or infinity, processing is performed in the normal way.

When FPSCR.enable.O/U/I is set, an FPU exception trap is generated regardless of whether or not an exception has occurred. When an exception occurs, correct exception information is reflected in FPSCR.cause and FPSCR.flag, and FRn or DRn is not updated. Appropriate processing should therefore be performed by software.

**Operation**

```c
void FIPR(int m,n) /* FIPR FVm,FVn */
{
    if(FPSCR_PR == 0) {
        pc += 2;
        clear_cause();
        fipr(m,n);
    }
    else undefined_operation();
}
```

**Possible Exceptions:**
- Invalid operation
- Overflow

</tbody>
</table>

**Description**

When FPSCR.PR = 0, this instruction loads floating-point 0.0 (0x00000000) into FRn.

**Operation**

```c
void FLDI0(int n)
{
    FR[n] = 0x00000000;
    pc += 2;
}
```

**Possible Exceptions:**

None

<td>—</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

Description

When FPSCR.PR = 0, this instruction loads floating-point 1.0 (0x3F800000) into FRn.

Operation

void FLDI1(int n)
{
    FR[n] = 0x3F800000;
    pc += 2;
}

Possible Exceptions:
None
9.34 FLDS Floating-point Load to System register Floating-Point Instruction
Transfer to System Register

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>FLDS FRm,FPUL</td>
<td>FRm → FPUL</td>
<td>1111mmmm00011101</td>
<td>1</td>
<td>—</td>
</tr>
</tbody>
</table>

Description

This instruction loads the contents of floating-point register FRm into system register FPUL.

Operation

```c
void FLDS(int m, float *FPUL) {
    *FPUL = FR[m];
    pc += 2;
}
```

Possible Exceptions:
None
9.35 FLOAT Floating-point convert from integer Floating-Point Instruction

Integer to Floating-Point Conversion

<table>
<thead>
<tr>
<th>PR</th>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>FLOAT</td>
<td>(float)FPUL → FRn</td>
<td>1111nnn00101101</td>
<td>1</td>
<td>—</td>
</tr>
<tr>
<td>1</td>
<td>FLOAT</td>
<td>(double)FPUL → DRn</td>
<td>1111nnn00101101</td>
<td>2</td>
<td>—</td>
</tr>
</tbody>
</table>

Description

When FPSCR.PR = 0: Taking the contents of FPUL as a 32-bit integer, converts this integer to a single-precision floating-point number and stores the result in FRn.

When FPSCR.PR = 1: Taking the contents of FPUL as a 32-bit integer, converts this integer to a double-precision floating-point number and stores the result in DRn.

When FPSCR.enable.I = 1, an FPU exception trap is generated regardless of whether or not an exception has occurred. When an exception occurs, correct exception information is reflected in FPSCR.cause and FPSCR.flag, and FRn or DRn is not updated. Appropriate processing should therefore be performed by software.
Operation

```c
void FLOAT(int n, float *FPUL)
{
 union {
     double d;
     int l[2];
 } tmp;
 pc += 2;
 clear_cause();
 if(FPSCR.PR==0){
     FR[n] = *FPUL; /* convert from integer to float */
     tmp.d = *FPUL;
     if(tmp.l[1] & 0xffffffff) inexact();
 } else {
     DR[n>>1] = *FPUL; /* convert from integer to double */
 }
}
```

Possible Exceptions:
Inexact: Not generated when FPSCR.PR = 1.
9.36 **FMAC** Floating-point Multiply and **AC**cumulate Floating-Point Instruction

### Floating-Point Multiply and Accumulate

#### PR Format Summary of Operation Instruction Code  Execution States  T Bit

<table>
<thead>
<tr>
<th>PR</th>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>FMAC FR0,FRm,FRn</td>
<td>FR0*FRm + FRn → FRn</td>
<td>1111nnnnnnnn1110</td>
<td>1</td>
<td>—</td>
</tr>
<tr>
<td>1</td>
<td>—</td>
<td>—</td>
<td>—</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

### Description

When FPSCR.PR = 0: This instruction arithmetically multiplies the two single-precision floating-point numbers in FR0 and FRm, arithmetically adds the contents of FRn, and stores the result in FRn.

When FPSCR.enable.O/U/I is set, an FPU exception trap is generated regardless of whether or not an exception has occurred. When an exception occurs, correct exception information is reflected in FPSCR.cause and FPSCR.flag, and FRn or DRn is not updated. Appropriate processing should therefore be performed by software.

### Operation

```c
void FMAC(int m,n) {
    pc += 2;
    clear_cause();
    if(FPSCR_PR == 1) undefined_operation();

### Description

1. This instruction transfers FRm contents to FRn.
2. This instruction transfers DRm contents to DRn.
3. This instruction transfers FRm contents to memory at address indicated by Rn.
4. This instruction transfers DRm contents to memory at address indicated by Rn.
5. This instruction transfers contents of memory at address indicated by Rm to FRn.
6. This instruction transfers contents of memory at address indicated by Rm to DRn.
7. This instruction transfers contents of memory at address indicated by Rm to FRn, and adds 4 to Rm.
8. This instruction transfers contents of memory at address indicated by Rm to DRn, and adds 8 to Rm.
9. This instruction subtracts 4 from Rn, and transfers FRm contents to memory at address indicated by resulting Rn value.

10. This instruction subtracts 8 from Rn, and transfers DRm contents to memory at address indicated by resulting Rn value.

11. This instruction transfers contents of memory at address indicated by (R0 + Rm) to FRn.

12. This instruction transfers contents of memory at address indicated by (R0 + Rm) to DRn.

13. This instruction transfers FRm contents to memory at address indicated by (R0 + Rn).

14. This instruction transfers DRm contents to memory at address indicated by (R0 + Rn).

**Operation**

```c

**Description**

1. This instruction transfers XDm contents to memory at address indicated by Rn.
2. This instruction transfers contents of memory at address indicated by Rm to XDn.
3. This instruction transfers contents of memory at address indicated by Rm to XDn, and adds 8 to Rm.
4. This instruction subtracts 8 from Rn, and transfers XDm contents to memory at address indicated by resulting Rn value.
5. This instruction transfers contents of memory at address indicated by (R0 + Rm) to XDn.
6. This instruction transfers XDm contents to memory at address indicated by (R0 + Rn).
7. This instruction transfers XDm contents to XDn.
8. This instruction transfers XDm contents to DRn.
9. This instruction transfers DRm contents to XDn.
Operation

```c
void FMOV_STORE_XD(int m, n) /* FMOV XDm,@Rn */
{
    store_quad(XD[(m>>1)], R[n]);
    pc += 2;
}

void FMOV_LOAD_XD(int m, n) /* FMOV @Rm,XDn */
{
    load_quad(R[m], XD[(n>>1)]);
    pc += 2;
}

void FMOV_RESTORE_XD(int m, n) /* FMOV @Rm+,DBn */
{
    load_quad(R[m], XD[(n>>1)]);
    R[m] += 8;
    pc += 2;
}

void FMOV_SAVE_XD(int m, n) /* FMOV XDm,@Rn */
{
    store_quad(XD[(m>>1)], R[n]-8);
    R[n] -= 8;
    pc += 2;
}

void FMOV_INDEX_LOAD_XD(int m, n) /* FMOV @(R0,Rm),XDn */
{
    load_quad(R[0] + R[m], XD[(n>>1)]);
    pc += 2;
}

void FMOV_INDEX_STORE_XD(int m, n) /* FMOV XDm,@(R0,Rn) */
{
    store_quad(XD[(m>>1)], R[0] + R[n]);
    pc += 2;
}

void FMOV_XDXD(int m, n) /* FMOV XDm,XDn */
{
}
```
void FMOV_XDDR(int m,n)  /* FMOV XDm,DRn */
{
    XD[n>>1] = XD[m>>1];
    pc += 2;
}

void FMOV_DRXD(int m,n)  /* FMOV DRm,XDn */
{
    DR[n>>1] = XD[m>>1];
    pc += 2;
}

Possible Exceptions:
- Data TLB miss exception
- Data protection violation exception
- Initial write exception
- Address error

<td>FMUL DRm,DRn</td>
<td>DRn*DRm → DRn</td>
<td>111nnn0mm00010</td>
<td>6</td>
<td>—</td>
</tr>
</tbody>
</table>

Description

When FPSCR.PR = 0: Arithmetically multiplies the two single-precision floating-point numbers in FRn and FRm, and stores the result in FRn.

When FPSCR.PR = 1: Arithmetically multiplies the two double-precision floating-point numbers in DRn and DRm, and stores the result in DRn.

When FPSCR.enable.O/U/I is set, an FPU exception trap is generated regardless of whether or not an exception has occurred. When an exception occurs, correct exception information is reflected in FPSCR.cause and FPSCR.flag, and FRn or DRn is not updated. Appropriate processing should therefore be performed by software.

Operation

```c
void FMUL(int m,n)
{
    pc += 2;
    clear_cause();
    if((data_type_of(m) == sNaN) ||
       (data_type_of(n) == sNaN)) invalid(n);
    else if((data_type_of(m) == qNaN) ||
             (data_type_of(n) == qNaN)) qnan(n);
    else if((data_type_of(m) == DENORM) ||
             (data_type_of(n) == DENORM)) set_E();
    else switch (data_type_of(m)){
        case NORM: switch (data_type_of(n)){
            case PZERO:
            case NZERO: zero(n,sign_of(m)^sign_of(n)); break;
        }
    }
```
case PINF:
  case NINF:   inf(n,sign_of(m)^sign_of(n));  break;
  default:     normal_fmul(m,n);  break;
}      break;
case PZERO:
  case NZERO: switch (data_type_of(n)){
    case PINF:
      case NINF: invalid(n); break;
      default:    zero(n,sign_of(m)^sign_of(n));break;
    }      break;
    case PINF :
      case NINF : switch (data_type_of(n)){
        case PZERO:
          case NZERO: invalid(n);  break;
          default:    inf(n,sign_of(m)^sign_of(n));break
        }       break;
    }
}

</tbody>
</table>

Description

This instruction inverts the most significant bit (sign bit) of the contents of floating-point register FRn/DRn, and stores the result in FRn/DRn.

The cause and flag fields in FPSCR are not updated.

Operation

```c
void FNEG (int n){
    FR[n] = -FR[n];
    pc += 2;
}
```

/* Same operation is performed regardless of precision. */

Possible Exceptions:

None
9.41  **FRCHG**  FR-bit **CHanGe**  Floating-Point Instruction

<table>
<thead>
<tr>
<th>PR</th>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>

<tr>
<td>1</td>
<td>—</td>
<td>—</td>
<td>—</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

**Description**

This instruction inverts the FR bit in floating-point register FPSCR. When the FR bit in FPSCR is changed, FR0 to FR15 in FPR0_BANK0 to FPR15_BANK0 and FPR0_BANK1 to FPR15_BANK1 become XR0 to XR15, and XR0 to XR15 become FR0 to FR15. When FPSCR.FR = 0, FPR0_BANK0 to FPR15_BANK0 correspond to FR0 to FR15, and FPR0_BANK1 to FPR15_BANK1 correspond to XR0 to XR15. When FPSCR.FR = 1, FPR0_BANK1 to FPR15_BANK1 correspond to FR0 to FR15, and FPR0_BANK0 to FPR15_BANK0 correspond to XR0 to XR15.

**Operation**

```c
void FRCHG() /* FRCHG */
{
  if(FPSCR.PR == 0){
    FPSCR ^= 0x00200000; /* bit 21 */
    PC += 2;
  }
  else undefined_operation();
}
```

**Possible Exceptions:**

None
### Description

This instruction inverts the SZ bit in floating-point register FPSCR. Changing the SZ bit in FPSCR switches FMOV instruction data transfer between one single-precision data unit and a data pair. When FPSCR.SZ = 0, the FMOV instruction transfers one single-precision data unit. When FPSCR.SZ = 1, the FMOV instruction transfers two single-precision data units as a pair.

### Operation

```c
void FSCHG() /* FSCHG */
{
    if(FPSCR_PR == 0){
        FPSCR ^= 0x00100000; /* bit 20 */
        PC += 2;
    }
    else undefined_operation();
}
```

### Possible Exceptions:

None

<td>4</td>
</tr>
<tr>
<td>1</td>
<td>—</td>
<td>—</td>
<td>—</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

**Description**

When FPSCR.PR = 0: This instruction takes the contents of floating-point registers XF0 to XF15 indicated by XMTRX as a 4-row × 4-column matrix, takes the contents of floating-point registers FR[n] to FR[n + 3] indicated by FVn as a 4-dimensional vector, multiplies the array by the vector, and stores the results in FV[n].

\[
\begin{bmatrix}
\end{bmatrix}
\times
\begin{bmatrix}
FR[n] \\
FR[n+1] \\
FR[n+2] \\
FR[n+3]
\end{bmatrix}
\rightarrow
\begin{bmatrix}
FR[n] \\
FR[n+1] \\
FR[n+2] \\
FR[n+3]
\end{bmatrix}
\]

The FTRV instruction is intended for speed rather than accuracy, and therefore the results will differ from those obtained by using a combination of FADD and FMUL instructions. The FTRV execution sequence is as follows:

1. Multiplies all terms. The results are 28 bits long.
2. Aligns these results, rounding them to fit within 30 bits.
3. Adds the aligned values.
4. Performs normalization and rounding.

Special processing is performed in the following cases:

1. If an input value is an sNaN, an invalid exception is generated.
2. If the input values to be multiplied include a combination of 0 and infinity, an invalid operation exception is generated.
3. In cases other than the above, if the input values include a qNaN, the result will be a qNaN.
4. In cases other than the above, if the input values include infinity:
   a. If multiplication results in two or more infinities and the signs are different, an invalid
      exception will be generated.
   b. Otherwise, correct infinities will be stored.
5. If the input values do not include an sNaN, qNaN, or infinity, processing is performed in the
   normal way.

When FPSCR.enable.V/O/U/I is set, an FPU exception trap is generated regardless of whether or
not an exception has occurred. When an exception occurs, correct exception information is
reflected in FPSCR.cause and FPSCR.flag, and FRn or DRn is not updated. Appropriate
processing should therefore be performed by software.

**Operation**

```c
void FTRV (int n) /* FTRV FVn */
{
    float saved_vec[4], result_vec[4];
    int saved_fpscr;
    int dst, i;
    if(FPSCR_PR == 0) {
        PC += 2;
        clear_cause();
        saved_fpscr = FPSCR;
        FPSCR &= ~ENABLE_VOUI; /* mask VOUI enable */
        dst = 12 - n;          /* select other vector than FVn */
        for(i=0;i<4;i++) saved_vec[i] = FR[dst+i];
        for(i=0;i<4;i++){
            for(j=0;j<4;j++) FR[dst+j] = XF[i+4j];
            fipr(n,dst);
            saved_fpscr |= FPSCR & (CAUSE|FLAG) ;
            result_vec[i] = FR[dst+3];
        }
        for(i=0;i<4;i++) FR[dst+i] = saved_vec[i];
        FPSCR = saved_fpscr;
        if(FPSCR & ENABLE_VOUI) fpu_exception_trap();
        else    for(i=0;i<4;i++)   FR[n+i] = result_vec [i];
    }
}```
else undefined_operation();
}

Possible Exceptions:
• Invalid operation
• Overflow
• Underflow
• Inexact
9.48 JMP JuMP Branch Instruction

Unconditional Branch Delayed Branch Instruction

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>JMP @Rn</td>
<td>Rn → PC</td>
<td>0100nnnn00101011</td>
<td>2</td>
<td>—</td>
</tr>
</tbody>
</table>

Description

Unconditionally makes a delayed branch to the address specified by Rn.

Notes

As this is a delayed branch instruction, the instruction following this instruction is executed before the branch destination instruction.

Interrupts are not accepted between this instruction and the following instruction. If the following instruction is a branch instruction, it is identified as a slot illegal instruction.

Operation

```c
JMP(int n)/* JMP @Rn */
{
    unsigned int temp;

    temp=PC;
    PC=R[n];
    Delay_Slot(temp+2);
}
```

Example

```assembly
MOV.L JMP_TABLE,R0 ; R0 = TRGET address
JMP @R0 ; Branch to TRGET.
MOV R0,R1 ; MOV executed before branch.
.align 4
JMP_TABLE: .data.l TRGET ; Jump table
...........
TRGET: ADD #1,R1 ; ← Branch destination
```
9.49 JSR  Jump to SubRoutine Branch Instruction
Branch to Subroutine Procedure Delayed Branch Instruction

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>JSR @Rn</td>
<td>PC + 4 → PR, Rn → PC</td>
<td>0100nnnn00001011</td>
<td>2</td>
<td>—</td>
</tr>
</tbody>
</table>

**Description**

This instruction makes a delayed branch to the subroutine procedure at the specified address after execution of the following instruction. Return address (PC + 4) is saved in PR, and a branch is made to the address indicated by general register Rn. JSR is used in combination with RTS for subroutine procedure calls.

**Notes**

As this is a delayed branch instruction, the instruction following this instruction is executed before the branch destination instruction.

Interrupts are not accepted between this instruction and the following instruction. If the following instruction is a branch instruction, it is identified as a slot illegal instruction.

**Operation**

```c
JSR(int n) /* JSR @Rn */
{
    unsigned int temp;

    temp=PC;
    PR=PC+4;
    PC=R[n];
    Delay_Slot(temp+2);
}
```
Example

```assembly
MOV.L  JSR_TABLE,R0  ;R0 = TRGET address
JSR    @R0        ;Branch to TRGET.
XOR    R1,R1      ;XOR executed before branch.
ADD    R0,R1      ;← Procedure return destination (PR contents)
........
.align  4
JSR_TABLE:  .data.l TRGET       ;Jump table
TRGET:      NOP            ;← Entry to procedure
           MOV    R2,R3      ;
           RTS            ;Return to above ADD instruction.
           MOV    #70,R1    ;MOV executed before RTS.
```

REJ09B0318-0600

Renesas
Description

These instructions store the source operand in the control register SR, GBR, VBR, SSR, SPC, DBR, or R0_BANK to R7_BANK.

Notes

With the exception of LDC Rm,GBR and LDC.L @Rm+,GBR, the LDC/LDC.L instructions are privileged instructions and can only be used in privileged mode. Use in user mode will cause an illegal instruction exception. However, LDC Rm,GBR and LDC.L @Rm+,GBR can also be used in user mode.

With the LDC Rm, Rn_BANK and LDC.L @Rm, Rn_BANK instructions, Rn_BANK0 is accessed when the RB bit in the SR register is 1, and Rn_BANK1 is accessed when this bit is 0.

Operation

```c
LDCSR(int m)      /* LDC Rm,SR : Privileged */
{               
    SR=R[m]&0x700083F3;
    PC+=2;           
}

LDCGBR(int m)     /* LDC Rm,GBR */
{               
    GBR=R[m];         
    PC+=2;           
}

LDCVBR(int m)      /* LDC Rm,VBR : Privileged */

         ; After execution     PR = H'12345678
LDS.L   @R15+,MACL  ; Before execution  R15 = H'100000000
        ; After execution     R15 = H'100000004, MACL = (H'10000000)
9.53 LDTLB Load PTEH/PTEL/PTEA to TLB System Control Instruction (Privileged Instruction)

Load to TLB

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDTLB</td>
<td>PTEH/PTEL/PTEA → TLB</td>
<td>0000000000111000</td>
<td>1</td>
<td>—</td>
</tr>
</tbody>
</table>

Description

This instruction loads the contents of the PTEH/PTEL/PTEA registers into the TLB (translation lookaside buffer) specified by MMUCR.URC (random counter field in the MMC control register).

LDTLB is a privileged instruction, and can only be used in privileged mode. Use of this instruction in user mode will cause an illegal instruction exception.

Notes

As this instruction loads the contents of the PTEH/PTEL/PTEA registers into a TLB, it should be used either with the MMU disabled, or in the P1 or P2 virtual space with the MMU enabled (see section 3, Memory Management Unit, for details). After this instruction is issued, there must be at least one instruction between the LDTLB instruction and issuance of an instruction relating to address to areas P0, U0, and P3 (i.e. BRAF, BSRF, JMP, JSR, RTS, or RTE).
Operation

LDTLB( ) /*LDTLB */
{
    TLB[MMUCR. URC] .ASID=PTEH & 0x000000FF;
    TLB[MMUCR. URC] .VPN=(PTEH & 0xFFFFFC00)>>10;
    TLB[MMUCR. URC] .PPN=(PTEH & 0x1FFFFFC00)>>10;
    TLB[MMUCR. URC] .SZ=(PTEL & 0x00000080)>>6 |
                   (PTEL & 0x00000010)>>4;
    TLB[MMUCR. URC] .SH=(PTEH & 0x00000002)>>1;
    TLB[MMUCR. URC] .PR=(PTEH & 0x00000060)>>5;
    TLB[MMUCR. URC] .WT=(PTEH & 0x00000001);
    TLB[MMUCR. URC] .C=(PTEH & 0x00000008)>>3;
    TLB[MMUCR. URC] .D=(PTEH & 0x00000004)>>2;
    TLB[MMUCR. URC] .V=(PTEH & 0x00000010)>>8;
    TLB[MMUCR. URC] .SA=(PTEA & 0x00000007);
    TLB[MMUCR. URC] .TC=(PTEA & 0x00000008)>>3;

    PC+=2;
}

Example

MOV @R0,R1 ; Load page table entry (upper) into R1
MOV R1,@R2 ; Load R1 into PTEH; R2 is PTEH address (H'FF000000)
LDTLB     ; Load PTEH, PTEL, PTEA registers into TLB
9.54 MAC.L Multiply and ACcumulate

Long Arithmetic Instruction

Double-Precision Multiply-and-Accumulate Operation

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAC.L @Rm+,@Rn+</td>
<td>Signed, (Rn) × (Rm) + MAC → MAC</td>
<td>0000nnnnmm1111</td>
<td>2–5</td>
<td>—</td>
</tr>
<tr>
<td>Rn + 4 → Rn, Rm + 4 → Rm</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

This instruction performs signed multiplication of the 32-bit operands whose addresses are the contents of general registers Rm and Rn, adds the 64-bit result to the MAC register contents, and stores the result in the MAC register. Operands Rm and Rn are each incremented by 4 each time they are read.

If the S bit is 0, the 64-bit result is stored in the linked MACH and MACL registers.

If the S bit is 1, the addition to the MAC register contents is a saturation operation at the 48th bit from the LSB. In a saturation operation, only the lower 48 bits of the MAC register are valid, and the result range is limited to H'FFFF800000000000 (minimum value) to H'00007FFFFFFF (maximum value).

Operation

```c
MACL(long m, long n) /* MAC.L @Rm+,@Rn+ */
{
    unsigned long RnL,RnH,RmL,RmH,Res0,Res1,Res2;
    unsigned long temp0,temp1,temp2,temp3;
    long tempm,tempn,fnLmL;

    tempn=(long)Read_Long(R[n]);
    R[n]+=4;
    tempm=(long)Read_Long(R[m]);
    R[m]+=4;
```
if (tempn < 0) tempn = 0 - tempn;
if (tempm < 0) tempm = 0 - tempm;

temp1 = (unsigned long)tempn;
temp2 = (unsigned long)tempm;

RnL = temp1 & 0x0000FFFF;
RnH = (temp1 >> 16) & 0x0000FFFF;
RmL = temp2 & 0x0000FFFF;
RmH = (temp2 >> 16) & 0x0000FFFF;
temp0 = RmL * RnL;
temp1 = RmH * RnL;
temp2 = RmL * RnH;
temp3 = RmH * RnH;

Res2 = 0;

Res1 = temp1 + temp2;
if (Res1 < temp1) Res2 += 0x00010000;

temp1 = (Res1 << 16) & 0xFFFF0000;
Res0 = temp0 + temp1;
if (Res0 < temp0) Res2 ++;

Res2 = Res2 + ((Res1 >> 16) & 0x0000FFFF) + temp3;

if (fnLmL < 0) {
    Res2 = Res2;
    if (Res0 == 0) Res2 ++;
    else Res0 = (Res0) + 1;
}
if (S == 1) {
    Res0 = MACL + Res0;
if (MACL>Res0) Res2++;

</tr>
</tbody>
</table>

Description

This instruction performs signed multiplication of the 16-bit operands whose addresses are the contents of general registers Rm and Rn, adds the 32-bit result to the MAC register contents, and stores the result in the MAC register. Operands Rm and Rn are each incremented by 2 each time they are read.

If the S bit is 0, a 16 × 16 + 64 → 64-bit multiply-and-accumulate operation is performed, and the 64-bit result is stored in the linked MACH and MACL registers.

If the S bit is 1, a 16 × 16 + 32 → 32-bit multiply-and-accumulate operation is performed, and the addition to the MAC register contents is a saturation operation. In a saturation operation, only the MACL register is valid, and the result range is limited to H'80000000 (minimum value) to H'7FFFFFFF (maximum value). If overflow occurs, the LSB of the MACH register is set to 1. H'80000000 (minimum value) is stored in the MACL register if the result overflows in the negative direction, and H'7FFFFFFF (maximum value) is stored if the result overflows in the positive direction.

Notes

If the S bit is 0, a 16 × 16 + 64 → 64-bit multiply-and-accumulate operation is performed.
Operation

MACW(long m, long n) /* MAC.W @Rm+,@Rn+ */
{
    long tempm, tempn, dest, src, ans;
    unsigned long templ;

## Description

This instruction stores immediate data, sign-extended to longword, in general register Rn. In the case of word or longword data, the data is stored from memory address (PC + 4 + displacement × 2) or (PC + 4 + displacement × 4).

With word data, the 8-bit displacement is multiplied by two after zero-extension, and so the relative distance from the table is in the range up to PC + 4 + 510 bytes. The PC value is the address of this instruction.

With longword data, the 8-bit displacement is multiplied by four after zero-extension, and so the relative distance from the operand is in the range up to PC + 4 + 1020 bytes. The PC value is the address of this instruction. A value with the lower 2 bits adjusted to B'00 is used in address calculation.

## Notes

If a PC-relative load instruction is executed in a delay slot, an illegal slot instruction exception will be generated.
Operation

MOVI(int i, int n) /* MOV #imm,Rn */
{
    if ((i&0x80)==0) R[n]=(0x000000FF & i);
    else R[n]=(0xFFFFFF00 | i);

Description

This instruction transfers the source operand to the destination. Byte, word, or longword can be specified as the data size, but the register is always R0. If the transfer data is byte-size, the 8-bit displacement is only zero-extended, so a range up to +255 bytes can be specified. If the transfer data is word-size, the 8-bit displacement is multiplied by two after zero-extension, enabling a range up to +510 bytes to be specified. With longword transfer data, the 8-bit displacement is multiplied by four after zero-extension, enabling a range up to +1020 bytes to be specified.

When the source operand is memory, the loaded data is sign-extended to longword before being stored in the register.

Notes

When loading, the destination register is always R0.
Operation

MOVBLG(int d) /* MOV.B @(disp,GBR),R0 */
{

### Description

This instruction transfers the source operand to the destination. It is ideal for accessing data inside a structure or stack. Byte, word, or longword can be specified as the data size, but with byte or word data the register is always R0.

If the data is byte-size, the 4-bit displacement is only zero-extended, so a range up to +15 bytes can be specified. If the data is word-size, the 4-bit displacement is multiplied by two after zero-extension, enabling a range up to +30 bytes to be specified. With longword data, the 4-bit displacement is multiplied by four after zero-extension, enabling a range up to +60 bytes to be specified. If a memory operand cannot be reached, the previously described @(R0,Rn) mode must be used.

When the source operand is memory, the loaded data is sign-extended to longword before being stored in the register.

### Notes

When loading byte or word data, the destination register is always R0. Therefore, if the following instruction attempts to reference R0, it is kept waiting until completion of the load instruction. This allows optimization by changing the order of instructions.
Operation

MOVBS4(long d, long n) /* MOV.B R0, @(disp,Rn) */
{
    long disp;
    disp=(0x0000000F & (long)d);
    Write_Bit(R[n]+disp,R[0]);

    disp=(0x0000000F & (long)d);
    R[0]=Read_Bit(R[m]+disp);
    if ((R[0]&0x80)==0) R[0]&=0x000000FF;
    else R[0]|=0xFFFFFF00;
MOVWL4(long m, long d) /* MOV.W @(disp,Rm),R0 */
{
    long disp;

    disp=(0x0000000F & (long)d);
    R[0]=Read_Word(R[m]+(disp<<1));
    if ((R[0]&0x8000)==0) R[0]&=0x0000FFFF;
    else R[0]|=0xFFFF0000;
    PC+=2;
}

MOVLL4(long m, long d, long n) /* MOV.L @(disp,Rm),Rn */
{
    long disp;

    disp=(0x0000000F & (long)d);
    R[n]=Read_Long(R[m]+(disp<<2));
    PC+=2;
}

Example

MOV.L @(2,R0),R1  ; Before execution (R0+8) = H'12345670
; After execution  R1 = (H'12345670)
MOV.L R0,@(H'F,R1)  ; Before execution R0 = H'FFFF7F80
; After execution  (R1+60) = H'FFFF7F80
9.60 MOVA MOVe effective Address Data Transfer Instruction

Effective Address Transfer

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOVA @(disp,PC),R0</td>
<td>disp × 4 + PC + 4 → R0</td>
<td>11000111dddddddd</td>
<td>1</td>
<td>—</td>
</tr>
</tbody>
</table>

Description

This instruction stores the source operand effective address in general register R0. The 8-bit displacement is multiplied by four after zero-extension. The PC value is the address of this instruction, but a value with the lower 2 bits adjusted to B'00 is used in address calculation.

Notes

If this instruction is executed in a delay slot, an illegal slot instruction exception will be generated.

Operation

```
MOVA(int d) /* MOVA @(disp,PC),R0 */
{
    unsigned int disp;

    disp=(unsigned int)(0x000000FF & d);
    R[0]=(PC&0xFFFFFFFC)+4+(disp<<2);
    PC+=2;
}
```

Example

```
Address .org H'1006
1006 MOVA STR,R0 ; STR address → R0
1008 MOV.B @R0,R1 ; R1 = “X” ← Position after adjustment of lower 2 bits of PC
100A ADD R4,R5 ; ← Original PC position in MOVA instruction address calculation
    .align 4
100C STR:.sdata "XYZP12"
```
9.61 MOVCA.L MOVE with Cache block Allocation Data Transfer Instruction

Cache Block Allocation

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOVCA.L R0,@Rn</td>
<td>R0 → (Rn)</td>
<td>0000nnnn11000011</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

This instruction stores the contents of general register R0 in the memory location indicated by effective address Rn. This instruction differs from other store instructions as follows.

If write-back is selected for the accessed memory, and a cache miss occurs, the cache block will be allocated but an R0 data write will be performed to that cache block without performing a block read. Other cache block contents are undefined.

Operation

```c
MOVCAL(int n) /*MOVCA.L R0,@Rn */
{
    if ((is_write_back_memory(R[n]))
        && (look_up_in_operand_cache(R[n]) == MISS))
        allocate_operand_cache_block(R[n]);
    Write_Long(R[n], R[0]);
    PC+=2;
}
```

Possible Exceptions:
- Data TLB miss exception
- Data TLB protection violation exception
- Initial page write exception
- Address error
### 9.62 MOVT MOVe T bit Data Transfer Instruction

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOVT Rn</td>
<td>T → Rn</td>
<td>0000nnnn00101001</td>
<td>1</td>
<td>—</td>
</tr>
</tbody>
</table>

#### Description

This instruction stores the T bit in general register Rn. When T = 1, Rn = 1; when T = 0, Rn = 0.

#### Operation

```c
MOVT(long n)               /* MOVT Rn */
{
    R[n]=(0x00000001 & SR);
    PC+=2;
}
```

#### Example

```
XOR    R2,R2  ; R2 = 0
CMP/PZ   R2   ; T = 1
MOVT   R0   ; R0 = 1
CLRT      ; T = 0
MOVT   R1   ; R1 = 0
```
9.63 MUL.L  Multiply Long (Double-Precision)

### Arithmetic Instruction

**Format**

<table>
<thead>
<tr>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>MUL.L Rm,Rn</td>
<td>Rn × Rm → MACL</td>
<td>2–5</td>
</tr>
</tbody>
</table>

**Summary of Operation**

MUL.L Rm,Rn

**Instruction Code**

<table>
<thead>
<tr>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000nnnnnnnnnnn0111</td>
<td>2–5</td>
<td>—</td>
</tr>
</tbody>
</table>

**Description**

This instruction performs 32-bit multiplication of the contents of general registers Rn and Rm, and stores the lower 32 bits of the result in the MACL register. The contents of MACH are not changed.

**Operation**

```c
MULL(long m, long n) /* MUL.L Rm,Rn */
{
    MACL = R[n] × R[m];
    PC += 2;
}
```

**Example**

MUL.L R0, R1

Before execution: R0 = H'FFFFFFFE, R1 = H'00005555

After execution: MACL = H'FFFF5556

STS MACL, R0

; Get operation result
9.64 MULS.W MULtiply as Signed Word Arithmetic Instruction

Signed Multiplication

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>MULS.W</td>
<td>Rm,Rn</td>
<td>Signed, Rn × Rm → MACL</td>
<td>0010nnnnnnnn1111</td>
<td>2–5</td>
</tr>
<tr>
<td>MULS</td>
<td>Rm,Rn</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

This instruction performs 16-bit multiplication of the contents of general registers Rn and Rm, and stores the 32-bit result in the MACL register. The multiplication is performed as a signed arithmetic operation. The contents of MACH are not changed.

Operation

```
MULS(long m, long n) /* MULS Rm,Rn */
{
    MACL=((long)(short)R[n]*(long)(short)R[m]);
    PC+=2;
}
```

Example

```
MULS.W   R0,R 1   ; Before execution  R0 = H'FFFFFFFE, R1 = H'00005555
          ; After execution  MACL = H'FFFF5556
STS    MACL,R0  ; Get operation result
```
9.65  MULU.W  MULtiply as Unsigned Word  Arithmetic Instruction

Unsigned Multiplication

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>MULU.W</td>
<td>Unsigned, Rn × Rm → MACL</td>
<td>0010nnnnnnnn1110</td>
<td>2–5</td>
<td>—</td>
</tr>
<tr>
<td>MULU</td>
<td>Rm,Rn</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

This instruction performs 16-bit multiplication of the contents of general registers Rn and Rm, and stores the 32-bit result in the MACL register. The multiplication is performed as an unsigned arithmetic operation. The contents of MACH are not changed.

Operation

```c
MULU(long m, long n) /* MULU Rm,Rn */
{
    MACL=((unsigned long)(unsigned short)R[n]∗
         (unsigned long)(unsigned short)R[m];
    PC+=2;
}
```

Example

```c
MULU.W R0,R1; Before execution R0 = H'00000002, R1 = H'FFFF AAAA
               ; After execution MACL = H'00015554
STS MACL,R0; Get operation result
```
9.66 NEG NEGate Arithmetic Instruction

Sign Inversion

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>NEG Rm,Rn</td>
<td>0 – Rm → Rn</td>
<td>0110nnnnmmmm1011</td>
<td>1</td>
<td>—</td>
</tr>
</tbody>
</table>

**Description**

This instruction finds the two’s complement of the contents of general register Rm and stores the result in Rn. That is, it subtracts Rm from 0 and stores the result in Rn.

**Operation**

```c
NEG(long m, long n) /* NEG Rm,Rn */
{
    R[n]=0-R[m];
    PC+=2;
}
```

**Example**

```c
NEG R0,R1    ; Before execution  R0 = H'00000001
             ; After execution  R1 = H'FFFFFFFF
```
9.67 NEGC NEGate with Carry  
Sign Inversion with Borrow

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>NEGC Rm,Rn</td>
<td>0 – Rm – T → Rn, borrow → T</td>
<td>0110nnnnnnnn1010</td>
<td>1</td>
<td>Borrow</td>
</tr>
</tbody>
</table>

**Description**

This instruction subtracts the contents of general register and the T bit from 0 and stores the result in Rn. A borrow resulting from the operation is reflected in the T bit. The NEGC instruction is used for sign inversion of a value exceeding 32 bits.

**Operation**

```c
NEGC(long m, long n) /* NEGC Rm,Rn */
{
    unsigned long temp;

    temp=0-R[m];
    R[n]=temp-T;
    if (0<temp) T=1;
    else T=0;
    if (temp<R[n]) T=1;
    PC+=2;
}
```

**Example**

```
CLRT          ; Sign inversion of R0:R1 (64 bits)
NEGC R1,R1    ; Before execution R1 = H'00000001, T = 0
               ; After execution R1 = H'FFFFFFFF, T = 1
NEGC R0,R0    ; Before execution R0 = H'00000000, T = 1
               ; After execution R0 = H'FFFFFFFF, T = 1
```

<tbody>
<tr>
<td>NOT</td>
<td>Rm, Rn</td>
<td>( \sim Rm \rightarrow Rn )</td>
<td>0110nnnnnnnnnn0111</td>
<td>1</td>
</tr>
</tbody>
</table>

**Description**

This instruction finds the one’s complement of the contents of general register Rm and stores the result in Rn. That is, it inverts the Rm bits and stores the result in Rn.

**Operation**

```c
NOT(long m, long n) /* NOT Rm,Rn */
{
    R[n]=\sim R[m];
    PC+=2;
}
```

**Example**

```assembly
NOT R0, R1 ; Before execution R0 = H'AAAAAAAA
           ; After execution R1 = H'55555555
```
### 9.70 OCBI Operand Cache Block Invalidate

#### Data Transfer Instruction

Cache Block Invalidation

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>OCBI @Rn</td>
<td>Operand cache block invalidation</td>
<td>0000nnnn10010011</td>
<td>1</td>
<td>—</td>
</tr>
</tbody>
</table>

#### Description

This instruction accesses data using the contents indicated by effective address Rn. In the case of a hit in the cache, the corresponding cache block is invalidated (the V bit is cleared to 0). If there is unwritten information (U bit = 1), write-back is not performed even if write-back mode is selected. No operation is performed in the case of a cache miss or an access to a non-cache area.

#### Operation

```c
OCBI(int n) /* OCBI @Rn */
{
    invalidate_operand_cache_block(R[n]);
    PC+=2;
}
```

#### Possible Exceptions:

- Data TLB miss exception
- Data TLB protection violation exception
- Initial page write exception
- Address error

Note that the above exceptions are generated even if OCBI does not operate.
9.71 OCBP Operand Cache Block Purge Data Transfer Instruction

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>OCBP @Rn</td>
<td>Operand cache block purge</td>
<td>0000nnnn10100011</td>
<td>1</td>
<td>—</td>
</tr>
</tbody>
</table>

Description

This instruction accesses data using the contents indicated by effective address Rn. If the cache is hit and there is unwritten information (U bit = 1), the corresponding cache block is written back to external memory and that block is invalidated (the V bit is cleared to 0). If there is no unwritten information (U bit = 0), the block is simply invalidated. No operation is performed in the case of a cache miss or an access to a non-cache area.

Operation

```c
OCBP(int n) /* OCBP @Rn */
{
    if(is_dirty_block(R[n])) write_back(R[n])
    invalidate_operand_cache_block(R[n]);
    PC+=2;
}
```

Possible Exceptions:

- Data TLB miss exception
- Data TLB protection violation exception
- Address error

Note that the above exceptions are generated even if OCBP does not operate.
**Description**

This instruction accesses data using the contents indicated by effective address Rn. If the cache is hit and there is unwritten information (U bit = 1), the corresponding cache block is written back to external memory and that block is cleaned (the U bit is cleared to 0). In other cases (i.e. in the case of a cache miss or an access to a non-cache area, or if the block is already clean), no operation is performed.

**Operation**

```c
OCBWB(int n) /* OCBWB @Rn */
{
    if(is_dirty_block(R[n])) write_back(R[n]);
    PC+=2;
}
```

**Possible Exceptions:**
- Data TLB miss exception
- Data TLB protection violation exception
- Address error

Note that the above exceptions are generated even if OCBWB does not operate.
### Logical OR

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>OR Rm,Rn</td>
<td>Rn</td>
<td>Rm → Rn</td>
<td>0010nnnnnnmm1011</td>
<td>1</td>
</tr>
<tr>
<td>OR #imm,R0</td>
<td>R0</td>
<td>imm → R0</td>
<td>11001011iiiiiiii</td>
<td>1</td>
</tr>
<tr>
<td>OR.B #imm,@(R0,GBR)</td>
<td>(R0 + GBR)</td>
<td>imm → (R0 + GBR)</td>
<td>11001111iiiiiiii</td>
<td>4</td>
</tr>
</tbody>
</table>

**Description**

This instruction ORs the contents of general registers Rn and Rm and stores the result in Rn.

This instruction can be used to OR general register R0 contents with zero-extended 8-bit immediate data, or, in indexed GBR indirect addressing mode, to OR 8-bit memory with 8-bit immediate data.
Operation

```c
OR(long m, long n) /* OR Rm,Rn */
{
    R[n]|=R[m];
    PC+=2;
}

ORI(long i)  /* OR #imm,R0 */
{
    R[0]|=(0x000000FF & (long)i);
    PC+=2;
}

ORM(long i) /* OR.B #imm,@(R0,GBR) */
{
    long temp;

    temp=(long)Read_Byte(GBR+R[0]);
    temp|=(0x000000FF & (long)i);
    Write_Byte(GBR+R[0],temp);
    PC+=2;
}
```

Example

```plaintext
OR  R0,R1     ; Before execution  R0 = H'AAAA5555, R1 = H'55550000
     ; After execution  R1 = H'FFFF5555

OR  #H'F0,R0  ; Before execution  R0 = H'00000008
     ; After execution  R0 = H'000000F8

OR.B #H'50,@(R0,GBR) ; Before execution  (R0,GBR) = H'A5
                        ; After execution  (R0,GBR) = H'F5
```
9.74  **PREF**  **PREFetch data to cache**  **Data Transfer Instruction**

Prefetch to Data Cache

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>PREF @Rn</td>
<td>Prefetch cache block</td>
<td>0000nnnn10000011</td>
<td>1</td>
<td>—</td>
</tr>
</tbody>
</table>

**Description**

This instruction reads a 32-byte data block starting at a 32-byte boundary into the operand cache. The lower 5 bits of the address specified by Rn are masked to zero.

This instruction does not generate address-related errors. In the event of an error, the PREF instruction is treated as an NOP (no operation) instruction.

**Operation**

```
PREF(int n) /* PREF */
{
    PC+=2;
}
```

**Example**

```
MOV.L   #SOFT_PF,R1 ; R1 address is SOFT_PF
PREF   @R1 ; Load SOFT_PF data into on-chip cache

.align 32
SOFT_PF:  .data.l  H'12345678
          .data.l  H'9ABCDEF0
          .data.l  H'AAAA5555
          .data.l  H'5555AAAA
          .data.l  H'11111111
          .data.l  H'22222222
          .data.l  H'33333333
          .data.l  H'44444444
```

9.79 RTE ReTurn from Exception System Control Instruction
Return from Exception Handling
(Privileged Instruction)
Delayed Branch Instruction

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>RTE</td>
<td>SSR → SR, SPC → PC</td>
<td>0000000001010111</td>
<td>5</td>
<td>—</td>
</tr>
</tbody>
</table>

**Description**

This instruction returns from an exception or interrupt handling routine by restoring the PC and SR values from SPC and SSR. Program execution continues from the address specified by the restored PC value.

RTE is a privileged instruction, and can only be used in privileged mode. Use of this instruction in user mode will cause an illegal instruction exception.

**Notes**

As this is a delayed branch instruction, the instruction following the RTE instruction is executed before the branch destination instruction.

Interrupts are not accepted between this instruction and the following instruction. An exception must not be generated by the instruction in this instruction’s delay slot. If the following instruction is a branch instruction, it is identified as a slot illegal instruction.

If this instruction is located in the delay slot immediately following a delayed branch instruction, it is identified as a slot illegal instruction.

The SR value accessed by the instruction in the RTE delay slot is the value restored from SSR by the RTE instruction. The SR and MD values defined prior to RTE execution are used to fetch the instruction in the RTE delay slot.
Operation

```c
RTE() /* RTE */
{
    unsigned int temp;
    temp=PC;
    SR=SSR;
    PC=SPC;
    Delay_Slot(temp+2);
}
```

Example

```
RTE ; Return to original routine.
ADD #8,R14 ; Executed before branch.
```

Note: In a delayed branch, the actual branch operation occurs after execution of the slot instruction, but instruction execution (register updating, etc.) is in fact performed in delayed branch instruction → delay slot instruction order. For example, even if the register holding the branch destination address is modified in the delay slot, the branch destination address will still be the register contents prior to the modification.
9.80 RTS ReTurn from Subroutine Branch Instruction

Return from Subroutine Procedure Delayed Branch Instruction

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>RTS</td>
<td>PR → PC</td>
<td>0000000000001011</td>
<td>2</td>
<td>—</td>
</tr>
</tbody>
</table>

Description

This instruction returns from a subroutine procedure by restoring the PC from PR. Processing continues from the address indicated by the restored PC value. This instruction can be used to return from a subroutine procedure called by a BSR or JSR instruction to the source of the call.

Notes

As this is a delayed branch instruction, the instruction following this instruction is executed before the branch destination instruction.

Interrupts are not accepted between this instruction and the following instruction. If the following instruction is a branch instruction, it is identified as a slot illegal instruction.

The instruction that restores PR must be executed before the RTS instruction. This restore instruction cannot be in the RTS delay slot.

Operation

```c
RTS(); /* RTS */
{
    unsigned int temp;

    temp=PC;
    PC=PR;
    Delay_Slot(temp+2);
}
```
Example

```assembly
MOV.L TABLE, R3 ; R3 = TRGET address
JSR @R3 ; Branch to TRGET.
NOP ; NOP executed before branch.
ADD R0, R1 ; ← Subroutine procedure return destination (PR contents)
........
TABLE: .data.l TRGET ; Jump table
........
TRGET: MOV R1, R0 ; ← Entry to procedure
RTS ; PR contents → PC
MOV #12, R0 ; MOV executed before branch.
```
9.81 SETS SET S bit System Control Instruction

<td></td>
<td>When Rm &lt; 0,</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Rn &gt;&gt; Rm → [MSB → Rn]</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

This instruction arithmetically shifts the contents of general register Rn. General register Rm specifies the shift direction and the number of bits to be shifted.

Rn register contents are shifted to the left if the Rm register value is positive, and to the right if negative. In a shift to the right, the MSB is added at the upper end.

The number of bits to be shifted is specified by the lower 5 bits (bits 4 to 0) of the Rm register. If the value is negative (MSB = 1), the Rm register is represented as a two’s complement. The left shift range is 0 to 31, and the right shift range, 1 to 32.
Operation

```
SHAD(int m,n) /*SHAD Rm,Rn */
{
    int sgn=R[m] & 0x80000000;
    if (sgn==0)
        R[n] <<= (R[m] & 0x1F);
    else if ((R[m] & 0x1F) == 0) {
        if ((R[n] & 0x80000000) == 0)
            R[n] = 0;
        else
            R[n] = 0xFFFFFFFF;
    }
    else
        R[n]=(long)R[n] >> (~(R[m] & 0x1F)+1);
    PC+=2;
}
```

Example

```
SHAD R1,R2  ; Before execution   R1 = H'FFFFFFEC, R2 = H'80180000
            ; After execution   R1 = H'FFFFFFEC, R2 = H'FFFFF801

SHAD R3,R4  ; Before execution   R3 = H'00000014, R4 = H'FFFFF801
            ; After execution   R3 = H'00000014, R4 = H'80100000
```

    if (temp==1) R[n]|=0x80000000;
    else R[n]&=0x7FFFFFFF;
    PC+=2;
}
```

Example

```
SHAR R0   ; Before execution  R0 = H'80000001, T = 0
 ; After execution  R0 = H'C0000000, T = 1
```
Section 9   Instruction Descriptions

9.86   SHLD   SHift Logical Dynamically   Shift Instruction

SHLD Rm, Rn

When Rm ≥ 0,
Rn << Rm → Rn

When Rm < 0,
Rn >> Rm → [0 → Rn]

Description

This instruction logically shifts the contents of general register Rn. General register Rm specifies the shift direction and the number of bits to be shifted.

Rn register contents are shifted to the left if the Rm register value is positive, and to the right if negative. In a shift to the right, 0s are added at the upper end.

The number of bits to be shifted is specified by the lower 5 bits (bits 4 to 0) of the Rm register. If the value is negative (MSB = 1), the Rm register is represented as a two’s complement. The left shift range is 0 to 31, and the right shift range, 1 to 32.
Operation

```
SHLD(int m,n)/*SHLD Rm,Rn */
{
    int sgn = R[m] & 0x80000000;
    if (sgn == 0)
        R[n] <<= (R[m] & 0x1F);
    else if ((R[m] & 0x1F) == 0)
        R[n] = 0;
    else
        R[n]=(unsigned)R[n] >> ((~R[m] & 0x1F)+1);
    PC+=2;
}
```

Example

```
SHLD R1, R2 ; Before execution R1 = H'FFFFFFEC, R2 = H'80180000
; After execution R1 = H'FFFFFFEC, R2 = H'00000801
SHLD R3, R4 ; Before execution R3 = H'00000014, R4 = H'FFFFF801
; After execution R3 = H'00000014, R4 = H'80100000
```

9.91 SLEEP

System Control Instruction
(Privileged Instruction)

Format:  

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>SLEEP</td>
<td>Sleep</td>
<td>0000000000011011</td>
<td>4</td>
<td>—</td>
</tr>
</tbody>
</table>

Description

This instruction places the CPU in the power-down state.

In power-down mode, the CPU retains its internal state, but immediately stops executing instructions and waits for an interrupt request. When it receives an interrupt request, the CPU exits the power-down state.

SLEEP is a privileged instruction, and can only be used in privileged mode. Use of this instruction in user mode will cause an illegal instruction exception.

Notes

SLEEP performance depends on the standby control register (STBCR). See Power-Down Modes in hardware manual, for details.

Operation

```c
SLEEP( )    /* SLEEP */
{
    Sleep_standby();
}
```

Example

```c
SLEEP               ; Transition to power-down mode
```

</tbody>
</table>
Description

This instruction stores control register SR, GBR, VBR, SSR, SPC, SGR, DBR or Rm_BANK (m = 0–7) in the destination.

Rm_BANK operands are specified by the RB bit of the SR register:
when the RB bit is 1 Rm_BANK0 is accessed,
when the RB bit is 0 Rm_BANK1 is accessed.

Notes

STC/STC.L can only be used in privileged mode excepting STC GBR, Rn/STC.L GBR, @-Rn.
Use of these instructions in user mode will cause illegal instruction exceptions.

Operation

```
STCSR(int n)      /* STC SR,Rn : Privileged */
{
    R[n]=SR;
    PC+=2;
}

STCGBR(int n)     /* STC GBR,Rn */

    PC+=2;
}
STS_RESTORE(int n) /* STS.L FPSCR,@-Rn */
{
    R[n] -= 4;
    Write_Long(R[n],FPSCR & 0x003FFFFF)
    PC+=2;
}

Possible Exceptions:
• Data TLB miss exception
• Data TLB protection violation exception
• Address error
Examples

- **STS**
  
  Example 1:
  
  ```
  MOV.L #H'12ABCDEF, R12
  LDS R12, FPUL
  STS FPUL, R13
  
  ; After executing the STS instruction:
  ; R13 = 12ABCDEF
  ```
  
  Example 2:
  
  ```
  STS FPSCR, R2
  
  ; After executing the STS instruction:
  ; The current content of FPSCR is stored in register R2
  ```

- **STS.L**
  
  Example 1:
  
  ```
  MOV.L #H'0C700148, R7
  STS.L FPUL, @-R7
  
  ; Before executing the STS.L instruction:
  ; R7 = 0C700148
  ; After executing the STS.L instruction:
  ; R7 = 0C700144, and the content of FPUL is saved at memory location 0C700144.
  ```
  
  Example 2:
  
  ```
  MOV.L #H'0C700154, R8
  STS.L FPSCR, @-R8
  
  ; After executing the STS.L instruction:
  ; The content of FPSCR is saved at memory location 0C700150.
  ```
9.95 SUB SUBtract binary Arithmetic Instruction

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>

<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUB Rm,Rn</td>
<td>Rn – Rm → Rn</td>
<td>0011nnnnmmmm1000</td>
<td>1</td>
<td>—</td>
</tr>
</tbody>
</table>

Description

This instruction subtracts the contents of general register Rm from the contents of general register Rn and stores the result in Rn. For immediate data subtraction, ADD #imm,Rn should be used.

Operation

```
SUB(long m, long n) /* SUB Rm,Rn */
{
    R[n]=R[m];
    PC+=2;
}
```

Example

```
SUB R0,R1 ; Before execution  R0 = H'00000001, R1 = H'80000000
            ; After execution  R1 = H'7FFFFFFFF
```
9.96 **SUBC**  **SUBtract with Carry**

**Arithmetic Instruction**

Binary Subtraction with Borrow

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>

<tbody>
<tr>
<td>SUBC</td>
<td>Rm,Rn</td>
<td>Rn – Rm – T → Rn, borrow → T0011nnnnnnnn1010</td>
<td>1</td>
<td>Borrow</td>
</tr>
</tbody>
</table>

**Description**

This instruction subtracts the contents of general register Rm and the T bit from the contents of general register Rn, and stores the result in Rn. A borrow resulting from the operation is reflected in the T bit. This instruction is used for subtractions exceeding 32 bits.

**Operation**

```
SUBC(long m, long n) /* SUBC Rm,Rn */
{
    unsigned long tmp0,tmp1;
    
    tmp1=R[n]-R[m];
    tmp0=R[n];
    R[n]=tmp1-T;
    if (tmp0<tmp1) T=1;
    else T=0;
    if (tmp1<R[n]) T=1;
    PC+=2;
}
```

**Example**

```
CLRT     ; R0:R1(64 bits) – R2:R3(64 bits) = R0:R1(64 bits)
SUBC     R3,R1     ; Before execution T = 0, R1 = H'00000000, R3 = H'00000001
          ; After execution T = 1, R1 = H'FFFFFFFF
SUBC     R2,R0     ; Before execution T = 1, R0 = H'00000000, R2 = H'00000000
          ; After execution T = 1, R0 = H'FFFFFFFF
```
9.97 SUBV SUBtract with (V flag) underflow check
Binary Subtraction with Underflow Check

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>

<tbody>
<tr>
<td>SUBV Rm,Rn</td>
<td>Rn – Rm → Rn, underflow → T</td>
<td>0011nnnnnnnn1011</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

Description

This instruction subtracts the contents of general register Rm from the contents of general register Rn, and stores the result in Rn. If underflow occurs, the T bit is set.

Operation

```c
SUBV(long m, long n) /* SUBV Rm,Rn */
{
    long dest, src, ans;

    if ((long)R[n]>=0) dest=0;
    else dest=1;
    if ((long)R[m]>=0) src=0;
    else src=1;
    src+=dest;
    R[n]-=R[m];
    if ((long)R[n]>=0) ans=0;
    else ans=1;
    ans+=dest;
    if (src==1) {
        if (ans==1) T=1;
        else T=0;
    }
    else T=0;
    PC+=2;
}
```
Example

```
SUBV R0, R1 ; Before execution R0 = H'00000002, R1 = H'80000001
           ; After execution R1 = H'7FFFFFFF, T = 1
SUBV R2, R3 ; Before execution R2 = H'FFFFFFFE, R3 = H'7FFFFFFE
           ; After execution R3 = H'80000000, T = 1

</tr>
<tr>
<td>SWAP.W Rm,Rn</td>
<td>Rm (\rightarrow) upper-/lower-word swap (\rightarrow) Rn</td>
<td>0110nnnnnnnn1001</td>
<td>1</td>
<td>—</td>
</tr>
</tbody>
</table>

### Description

This instruction swaps the upper and lower parts of the contents of general register Rm, and stores the result in Rn.

In the case of a byte specification, the 8 bits from bit 15 to bit 8 of Rm are swapped with the 8 bits from bit 7 to bit 0. The upper 16 bits of Rm are transferred directly to the upper 16 bits of Rn.

In the case of a word specification, the 16 bits from bit 31 to bit 16 of Rm are swapped with the 16 bits from bit 15 to bit 0.

### Operation

```c
SWAPB(long m, long n) /* SWAP.B Rm,Rn */
{
    unsigned long temp0,temp1;

    temp0=R[m]&0xFFFF0000;
    temp1=(R[m]&0x000000FF)<<8;
    R[n]=(R[m]&0x0000FF00)>>8;
    R[n]=R[n]|temp1|temp0;
    PC+=2;
}

SWAPW(long m, long n) /* SWAP.W Rm,Rn */
{
    unsigned long temp;
```

9.99 TAS Test And Set Logical Instruction

Memory Test and Bit Setting

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>
<th>Execution States</th>
<th>T Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>TAS.B  @Rn</td>
<td>If (Rn) = 0, 1 → T, else 0 → T</td>
<td>0100nnnn00011011</td>
<td>5</td>
<td>Test result</td>
</tr>
<tr>
<td>1 → MSB of (Rn)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

This instruction purges the cache block corresponding to the memory area specified by the contents of general register Rn, reads the byte data indicated by that address, and sets the T bit to 1 if that data is zero, or clears the T bit to 0 if the data is nonzero. The instruction then sets bit 7 to 1 and writes to the same address. The bus is not released during this period.

The purge operation is executed as follows.

In a purge operation, data is accessed using the contents of general register Rn as the effective address. If there is a cache hit and the corresponding cache block is dirty (U bit = 1), the contents of that cache block are written back to external memory, and the cache block is then invalidated (by clearing the V bit to 0). If there is a cache hit and the corresponding cache block is clean (U bit = 0), the cache block is simply invalidated (by clearing the V bit to 0). A purge is not executed in the event of a cache miss, or if the accessed memory location is non-cacheable.

The two TAS.B memory accesses are executed automatically. Another memory access is not executed between the two TAS.B accesses.
Operation

TAS(int n) /* TAS.B @Rn */
{
    int temp;

    temp=(int)Read_Byte(R[n]); /* Bus Lock */
    if (temp==0) T=1;
    else T=0;
    temp|=0x00000080;
    Write_Byte(R[n],temp);    /* Bus unlock */
    PC+=2;
}

Possible Exceptions:
• Data TLB miss exception
• Data TLB protection violation exception
• Initial page write exception
• Address error

Exceptions are checked taking a data access by this instruction as a byte store.
9.100 TRAPA TRAP Always System Control Instruction

Description

This instruction starts trap exception handling. The values of (PC + 2), SR, and R15 are saved to SPC and SSR, and 8-bit immediate data is stored in the TRA register (bits 9 to 2). The processor mode is switched to privileged mode (the MD bit in SR is set to 1), and the BL bit and RB bit in SR are set to 1. As a result, exception and interrupt requests are masked (not accepted), and the BANK1 registers (R0_BANK1 to R7_BANK1) are selected. Exception code 0x160 is written to the EXPEVT register (bits 11 to 0). The program branches to address (VBR + H'00000100), indicated by the sum of the VBR register contents and offset H'00000100.
Operation

TRAPA(int i) /* TRAPA #imm */
{
    int imm;

    imm=(0x000000FF & i);
    TRA=imm<<2;
    SSR=SR;
    SPC=PC+2;
    SGR=R15;
    SR.MD=1;
    SR.BL=1;
    SR.RB=1;
    EXPEVT=0x00000160;
    PC=VBR+H'000000100;
}

9.101 TST  TeST logical  Logical Instruction

AND Operation  T Bit Setting

<table>
<thead>
<tr>
<th>Format</th>
<th>Summary of Operation</th>
<th>Instruction Code</th>

<td>11001100iiiiiiiiii</td>
<td>3</td>
<td>Test result</td>
</tr>
</tbody>
</table>

Description

This instruction ANDs the contents of general registers Rn and Rm, and sets the T bit if the result is zero. If the result is nonzero, the T bit is cleared. The contents of Rn are not changed.

This instruction can be used to AND general register R0 contents with zero-extended 8-bit immediate data, or, in indexed GBR indirect addressing mode, to AND 8-bit memory with 8-bit immediate data. The contents of R0 or the memory are not changed.

Operation

```c
TST(long m, long n) /* TST Rm,Rn */
{
    if ((R[n]&R[m])==0) T=1;
    else T=0;
    PC+=2;
}

TSTI(long i) /* TST #imm,R0 */
{
    long temp;

    temp=R[0]&(0x00000000FF & (long)i);
    if (temp==0) T=1;
    else T=0;
}
```

Rev. 6.00  Sep 13, 2006  page 404 of 424

<td>XOR.B #imm,@(R0,GBR)</td>
<td>(R0 + GBR) ^ imm →</td>
<td>11001110iiiiiiiiii</td>
<td>4</td>
<td>—</td>
</tr>
</tbody>
</table>

**Description**

This instruction exclusively ORs the contents of general registers Rn and Rm, and stores the result in Rn.

This instruction can be used to exclusively OR register R0 contents with zero-extended 8-bit immediate data, or, in indexed GBR indirect addressing mode, to exclusively OR 8-bit memory with 8-bit immediate data.

**Operation**

```c
XOR(long m, long n) /* XOR Rm,Rn */
{
    R[n]^=R[m];
    PC+=2;
}
```

```c
XORI(long i) /* XOR #imm,R0 */
{
    R[0]^=(0x000000FF & (long)i);
    PC+=2;
}
```

```c
XORM(long i) /* XOR.B #imm,@(R0,GBR) */
{
    int temp;
    ```
temp=(long)Read_Byte(GBR+R[0]);
temp^=(0x000000FF & (long)i);
Write_Byte(GBR+R[0],temp);
PC+=2;
}

Example

</tbody>
</table>
Appendix B  Instruction Prefetch Side Effects

The SH-4 is provided with an internal buffer for holding pre-read instructions, and always performs pre-reading. Therefore, program code must not be located in the last 20-byte area of any memory space. If program code is located in these areas, the memory area will be exceeded and a bus access for instruction pre-reading may be initiated. A case in which this is a problem is shown below.

<table>
<thead>
<tr>
<th>Address</th>
<th>Instruction</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>H'03FFFFF8</td>
<td>ADD R1,R4</td>
<td></td>

</tr>
<tr>
<td>H'04000000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>H'04000002</td>
<td>Instruction prefetch address</td>
<td></td>
</tr>
</tbody>
</table>

Figure B.1  Instruction Prefetch

Figure B.1 presupposes a case in which the instruction (ADD) indicated by the program counter (PC) and the address H'04000002 instruction prefetch are executed simultaneously. It is also assumed that the program branches to an area outside area 1 after executing the following JMP instruction and delay slot instruction.

In this case, the program flow is unpredictable, and a bus access (instruction prefetch) to area 1 may be initiated.

Instruction Prefetch Side Effects
1. It is possible that an external bus access caused by an instruction prefetch may result in misoperation of an external device, such as a FIFO, connected to the area concerned.
2. If there is no device to reply to an external bus request caused by an instruction prefetch, hangup will occur.

Remedies
1. These illegal instruction fetches can be avoided by using the MMU.
2. The problem can be avoided by not locating program code in the last 20 bytes of any area.

Renesas Technology America, Inc.
450 Holger Way, San Jose, CA 95134-1368, U.S.A
